In the IR spectrum of **1**, the crystal water stretching mode appears at 3506 cm^{-1}. The absorption bands in the frequency range 3400–3163 cm^{-1} are attributed to ν(NH) vibrations of the amine group of the HOr and en ligands. The bands with medium intensities at 3400 and 3315 cm^{-1}correspond to the NH_2 and NH_3 stretching vibration of the protonated en ligand. The $N_{(3)}$–H stretching bands at 3147 cm^{-1} of orotic acid [56] disappeared with complex **1** formation. This indicates the deprotonation of the N(3) atom and coordination to the cadmium(II) ion. Stretching of the carbonyl groups of polycrystalline H_3Or give rise to three strong and overlapped bands, at 1729 ($66\%\nu_{C=O(carboxylic)} + 17\%\nu_{C5=O4,in\text{-}phase}$), 1719 ($56\%\nu_{C5=O4} + 19\%\nu_{C=O(carboxylic),out\text{-}of\text{-}phase}$) and 1700 cm^{-1} ($73\%\nu_{C4=O3} + 11\%\nu_{ring}$) [56]. In the infrared spectrum of [CuHOr(H$_2$O)-en]$\cdot$ H$_2$O [19], a complex band at 1655 cm^{-1} appears. Three carbonyl bands were observed on the bis(deprotonation) of HOr, with a red-shift of all three bands. The carbonyl stretchings are overlapped with the water bending band and give two very strong broadened absorptions at 1635 and 1618 cm^{-1}. From the IR spectrum of **1**, it can be assumed that the orotate residues, HOr^{2-}, are coordinated as bidentate ligands to the metal through the carboxylic oxygen and N(3) from the pyrimidine ring. The medium-intense band at 1492 cm^{-1} is assigned to the C–N stretching of the uracilate ring.

3.2. Thermal studies

The endothermic peak ($DTG_{max} = 188$ °C) in the temperature range 149–217 °C corresponds to the loss of two crystal water molecules. In the second and third stages, in the temperature range 218–324 °C, the Cd(II) complex is involved in the decomposition of the two enH ligand molecules, giving an endothermic effect ($DTG_{max} = 232$ and 296 °C). In the following stages CO_2/CO is released from the orotate and the residual organic matter burns. The

Symmetry codes (**2**): (i) $-x+3/2, y+1/2, -z-1/2$, (ii) $-x+3/2, -y+1/2, -z$, (iii) $-x+2, y, -z-1/2$, (iv) $-x+2, -y, -z$ (v) $x, -y, z-1/2$.

3.3. Crystallographic analysis

3.3.1. trans-$[Cd(HOr)_2(enH)_2]\cdot 2H_2O$

The molecular structure of **1** with the atom labelling is shown in Fig. 1. Selected bond lengths and angles and hydrogen bonding geometries are given in Tables 2 and 3, respectively. The compound crystallizes in the triclinic space group $P\bar{1}$. Each orotic acid molecule has donated one H atom to the ethylenediamine N atom of a ethylenediammonium molecule, forming the bis(ethylenediammonium)bis(orotate)cadmium(II) dihydrate complex. The Cd(II) ion in *trans*-$[Cd(HOr)_2(enH)_2]\cdot 2H_2O$ is in a distorted octahedral configuration, coordinated by two molecules of orotato and two molecules of enH ligands. The bis(deprotonated) orotato ligands coordinate to the cadmium atom through both the heterocyclic N2 atom and the adjacent carboxylate group O1 atom, creating a chelate ring, while the protonated en ligands behave as a unusual monodentate ligand through the N3 atom. As there is just one HOr ligand in the other bidentate orotate complexes [6–25], the en ligands in the $[Co(HOr)(en)_2]H_2Or\cdot 5H_2O$, $[Cu(HOr)(en)(H_2O)]\cdot H_2O$ [19] and $[Pd(HOr)(en)]\cdot 0.5H_2O$ [10] complexes bond in a bidentate manner. The two N atoms of HOr and two O atoms of the carboxylate group of HOr form the equatorial plane, whereas the N atoms of the enH ligands are in the apical positions. The Cd1–N3 bond distance of 2.344(2) Å is similar to that found in $\{[Cd(barb)_2(\mu\text{-en})]\cdot 2H_2O\}_n$ (2.281(1) Å) [50] and $[Cd_2(en)_5](ClO_4)_4$ (2.324(5) Å) [47]. The Cd–N2 and

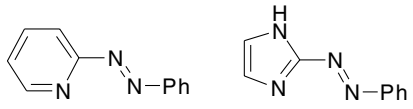
Cd–O1 bond distances of 2.284(2) and 2.385(2) Å, respectively, are significantly longer than that found in $[Co(HOr)(en)_2]H_2Or \cdot 5H_2O$ (1.974(4) and 1.914(4) Å), $[Cu(HOr)(en)(H_2O)] \cdot H_2O$ (1.986(3) and 1.990(2) Å) [19], $[Pd(HOr)(en)] \cdot 0.5H_2O$ (2.011(4) and 2.012(3) Å) [10], $[Cu(HOr)(NH_3)_2]$ (2.005(3) and 1.962(3) Å) [11] and $[Cu(HOr)(tea)] \cdot H_2O$ (2.007(2) and 1.944(2) Å) [20]. The HOr ligand is essentially planar with a r.m.s. deviation of 0.0361 Å, and the largest deviation from the mean plane is −0.0787 (13) Å for the O1 atom. The carboxylate C–O distances in the orotate anion also display some variability, depending on their environment. The C–O distances are practically equal in the H_2Or^- anion acting as a counter ion [37]. In **1**, the oxygen atoms of the orotate ligand have different environments; while the carboxylate O1 atom coordinates to the Cd atom, O2 acts as an acceptor for two hydrogen bonds, O5–H25···O2 and N4–H34···O2, the O3 and O4 atoms of the orotate ligand making hydrogen bonds via O5–H15, C7–H7A, N4–H24 and N4–H14, N3–H23, N3–H13, respectively. Therefore, the C–O bond lengths are in the range 1.238(2)–1.261(2) Å [C1–O3 = 1.238(2), C2–O4 = 1.252(2), C5–O1 = 1.261(2) and C5–O2 = 1.243(2) Å], which are comparable with those in similar Co(II), Ni(II) and Cu(II) complexes [19,24].

The crystal packing was formed by intermolecular hydrogen bonding. The hydrogen bonds observed are: (i) hydrogen bonding among water molecule O5 and carboxylate oxygen O2 (O5···O2 = 2.972(3) Å, at $x-1, y, z$), carbonyl oxygen O3 (O5···O3 = 2.851(3) Å, $x, y-1, z$) and pyrimidine nitrogen N1 (N1···O5 = 2.903(3) Å, $-x-1, -y, -z+1$) (Fig. 2), (ii) hydrogen bonding of the amine group of the protonated en ligand and orotate oxygens $O1^{iv}$, $O2^{vii}$, $O3^{v}$ and $O4^{ii}$ atoms [N4···O1 = 2.941(3) Å, (iv) $x-1, y, z$, N4···O2 = 2.799(3) Å, (vii) $-x, -y-1, -z$, N4···O3 = 3.407(3) Å, (v) $-x-1, -y, -z$, N4···O4 = 2.831(3) Å, (ii) $x, y, z-1$] (Fig. 2). There are also hydrogen bonds between the NH_2 group of the enH ligand which is coordinated to a Cd atom and the carbonyl oxygen O4 of orotate and also the orotate C7 atom and the carbonyl oxygen O3 and the carboxylate oxygen O1. The details for hydrogen bond geometries are given in Table 3.

3.3.2. *cis*-$[Cd(H_2O)_2(phen)_2](H_2Or)_2 \cdot 2H_2O$

A view of the molecule and its atom numbering scheme are shown in Fig. 3 and selected bond lengths and bond angles are given in Table 2. In the *cis*-$[Cd(H_2O)_2(phen)_2](H_2Or)_2 \cdot 2H_2O$ complex, the Cd atom exhibits a distorted octahedral coordination geometry defined by four nitrogen atoms from two chelating phen ligands together with two aqua ligands. The coordinated water molecule [Cd1–O1 = 2.305(3) Å] and two phen N atoms [Cd1–N1 = 2.313(3), Cd1–N2 = 2.327(3) Å] and the symmetry related N atom (symmetry codes: $2-x, y, 1/2-z$) form the equatorial plane with bond angles of $O1–Cd–N2^{i} = 159.95(9)°$ and $N1–Cd–N1^{i} = 175.03(9)°$, whereas the symmetry related fourth phen N atom and the second water molecule are in apical positions with an $O1–Cd1–N1^{i}$ angle of 160.1(1)°. These values are in agreement with those previously reported for other phen containing metal orotate complexes [23,38]. The equatorial plane and the phen ligand are approximately planar. The carboxylate C–O distances are practically equal when the orotate ligand acts as a counter ion [C13–O2 = 1.229(4), C13–O3 = 1.244(4), C15–O4 = 1.219(3), C16–O5 = 1.238(4) Å].

The complex **2** exhibits intramolecular and intermolecular hydrogen bonds as listed in Table 3. The coordinated water molecules link the orotate ions to the metal complex via $O1–H1A···O3^{ii}$ and $O1–H1B···O5^{iv}$ hydrogen bonds ((ii) $-x+3/2, -y+1/2, -z$ and (iv) $-x+2, -y, -z$). Each uncoordinated water molecule (O6) is hydrogen bonded to orotate ions through $O6–H6B···O4^{v}$ and O6–H6A···O2 hydrogen bonds. Furthermore, the symmetry related orotate ions are linked by $N3–H3N···O4^{iii}$ and $N4–H4···O5^{iv}$ hydrogen bonds to form chains (see Table 2 for symmetry codes).



Appendix A. Supplementary material

CCDC 630739 and 630738 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.03.060.

I II

Recently, there has been an increasing interest in azomethine ligands, due to the photochromatic, redox active, pH responsive and photo-redox activity of this functional moiety [10,11]. Excellent examples of such predesigned molecular materials are 1-arylimino-l-arylhydrazono-propan-2-one (**III**) [12]. The arylamidrazones (**III**) are new class of bidentate ligands having a low-lying π^*(CN) MOs conjugated with π^*(N=N) MOs.

III

The conjugation shown in the structure of (**III**) is expected to create an extremely strong electron acceptor situation when they are bound to Ru(II). In this study, we extend our synthesis of azomethine ligands to include several new bidentate ligands and their Ru(II) complexes. Changing the substituents (X, Y and R) is expected to vary the π-acceptor ligands properties on these new bidentate ligands and thus "tune" the electronic properties of the ruthenium and consecutively the energy of MLCT bands. The spectral studies, redox properties and single crystal X-ray structures (for two representative examples) of these new families are described in this work.

2. Experimental

2.1. Materials

The reagents, aniline derivatives, α-chloroacetylacetone, α-chloroacetoacetate, ruthenium trichloride, 2,2′-bipyridine (bpy), lithium chloride and solvents (reagent grade), were purchased from Aldrich and were used as received. Tetrabutylammonium hexafluorophosphate (TBAH), purchased from Aldrich, was recrystallized twice from 1:1 ethanol/water solution and then vacuum dried at 110 °C. Hydrazonyl chlorides were prepared according to reported procedures [13]. The synthesis and the physical characterization of the ligand, 1-(4-chlorophenylimino)-l-(phenylhydrazono)-propan-2-one (**6c**) and the complex *trans*-[Ru(bpy)-(**6c**)Cl_2] (**11**) have been described previously [12]. Elemental analysis was performed by Canadian Microanalytical Services Ltd. (Canada).

2.2. General procedure for syntheses of arylamidrazones (*L*)

A solution of arylamine (20 mmol) and triethylamine (2.4 g, 24 mmol) in 5.0 mL ethanol was added to a 10 mL solution of the appropriate hydrazonyl chloride (20 mmol). The resulted reaction mixture was refluxed for 2 h. Condensing the solution followed by cooling produce a yellow solid which was collected by filtration, washing with water and recrystallizing from 2-propanol.

2.2.1. 1-(Phenylimino)-1-(phenylhydrazono)-propan-2-one (*6a*)

Yield: 2.6 g (52%). *Anal.* Calc. for $C_{15}H_{13}N_3O$: C, 71.7; H, 5.21; N, 16.7. Found. C, 72.3; H, 5.10; N, 16.9%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 352 (8.83×10^4), 294 (5.24×10^4), 214 (6.90×10^4). IR: ν(N=N) 1496, ν(C=N) 1601, ν(C=O) 1668. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.64 (2H, d, H3), 6.92 (2H, t, H4), 7.05 (2H, d, H2), 7.31 (4H, m, H1, HX, HY), 2.63 (3H, s, HR). M.p. is 132–134 °C.

2.2.2. 1-(4-Methylphenylimino)-1-(phenylhydrazono)-propan-2-one (*6b*)

Yield: 3.0 g (57%). *Anal.* Calc. for $C_{16}H_{15}N_3O$: C, 72.4; H, 5.70; N, 15.8. Found: C, 72.1; H, 5.21; N, 15.5%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 353 (8.09×10^4), 294 (4.69×10^4), 240 (6.24×10^4). IR: ν(N=N) 1478, ν(C=N) 1599, ν(C=O) 1664. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.58 (2H, d, H2), 6.97 (1H, t, HX), 7.07 (2H, d, H1), 7.09 (2H, d, H4), 7.27 (2H, d, H3) 2.31 (3H, s, HR), 2.63 (3H, s, HY). M.p. is 132–134 °C.

2.2.3. 1-(4-Bromophenylimino)-1-(phenylhydrazono)-propan-2-one (*6d*)

Yield: 4.0 g (60%). *Anal.* Calc. for $C_{15}H_{12}BrN_3O$: C, 54.6; H, 3.66; N, 12.7. Found: C, 54.2; H, 3.88; N, 12.5%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 351 (8.92×10^4), 294 (5.32×10^4), 243 (6.98×10^4). IR: ν(N=N) 1478, ν(C=N) 1596, ν(C=O) 1675. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.51 (2H, d, H2), 6.987 (1H, t, HX), 7.1 (2H, d, H3), 7.31 (2H, t, H4), 7.35 (2H, d, H1), 2.6 (3H, s, HR). M.p. is 144–146 °C.

2.2.4. 1-(Naphthylimino)-1-(phenylhydrazono)-propan-2-one (*6e*)

Yield: 3.8 g (63%). *Anal.* Calc. for $C_{19}H_{15}N_3O$: 75.7; H, 5.02; N, 13.9. Found: C, 75.6; H, 5.21; N, 13.7%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 358 (8.80×10^4), 294 (5.20×10^4), 210 (6.86×10^4). IR: ν(N=N) 1504, ν(C=N) 1600, ν(C=O) 1673. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.34 (1H, d, H (naphthyl proton)), 6.91 (1H, t, HX), 7.04 (2H, d, H (naphthyl proton)), 7.31 (3H, m, H4, H (naphthyl proton)), 7.6 (3H, m, H3), 7.9 (1H, d, H (naphthyl proton)), 8.1 (1H, d, H (naphthyl proton)), 2.71 (3H, s, HR). M.p. is 148–150 °C.

2.2.5. 1-(4-Methyloxyphenylimino)-1-(phenylhydrazono)-propan-2-one (*6f*)

Yield: 3.1 g (55%). *Anal.* Calc. for $C_{16}H_{15}N_3O_2$: C, 68.3; H, 5.37; N, 14.9. Found: C, 68.1; H, 5.21; N, 15.1%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 357 (8.75×104), 297 (5.0×104), 240 (6.78×10^4). IR: ν(N=N) 1504, ν(C=N)

1618, ν(C=O) 1660. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.62 (2H, d, H1), 6.80 (2H, d, H2), 6.92 (1H, t, HX), 7.03 (2H, t, H4), 7.25 (2H, d, H3), 3.75 (3H, s, HY), 2.75 (3H, s, HR). M.p. is 98–100 °C.

2.2.6. 1-(4-Nitrophenylimino)-1-(phenylhydrazono)-propan-2-one (**6g**)

Yield: 3.1 g (51%). *Anal.* Calc. for $C_{15}H_{14}N_4O_3$: C, 60.4; H, 4.73; N, 18.8. Found: C, 60.1; H, 4.51; N, 18.5%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 338 (8.81×10^4), 297 (5.20×10^4), 231 (6.85×10^4). IR: ν(N=N) 1505, ν(C=N) 1602, ν(C=O) 1667. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.34 (2H, d, H2), 7.02 (1H, t, HX), 7.13 (2H, d, H3), 7.31 (2H, t, H4) 8.16 (2H, d, H1), 2.60 (3H, s, HR). M.p. is 174–176 °C.

2.2.7. Methyl-1-(phenylimino)-1-(phenylhydrazono)-acetate (**7a**)

Yield: 3.2 g (59%). *Anal.* Calc. for $C_{15}H_{13}N_3O_2$: C, 67.4; H, 4.90; N, 15.7. Found: C, 67.1; H, 5.21; N, 15.5%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 335 (8.85×10^4), 291 (5.23×10^4), 234 (6.91×10^4). IR: ν(N=N) 1504, ν(C=N) 1600, ν(C=O) 1696. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.66 (2H, d, H1), 6.9 (2H, t, H2), 7.09 (2H, t, H4), 7.25 (4H, m, H3, HX, HY), 3.9 (3H, s, HR). M.p. is 134–136 °C.

2.2.8. Methyl-1-(4-chlorophenylimino)-1-(phenylhydrazono)-acetate (**7c**)

Yield: 3.1 g (51%). *Anal.* Calc. for $C_{15}H_{12}N_3O_2Cl$: C, 59.7; H, 4.01; N, 13.9. Found: C, 59.5; H, 4.21; N, 13.5%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 345 (8.79×10^4), 294 (5.18×10^4), 240 (6.89×10^4). IR: ν(N=N), 1489 ν(C=N), 1593, ν(C=O) 1705. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.54 (2H, d, H1), 6.9 (1H, t, HX), 7.09 (2H, t, H4), 7.18 (2H, d, H2), 7.27 (2H, d, H3), 3.9 (3H, s, HR). M.p. is 87–89 °C.

2.2.9. Methyl-1-(phenylimino)-1-(4-chlorophenylhydrazono)-acetate (**8a**)

Yield: 3.6 g (60%). *Anal.* Calc. for $C_{15}H_{12}N_3O_2Cl$: C, 59.7; H, 4.01; N, 11.8. Found: C, 59.6; H, 4.20; N, 11.6%. UV–Vis in acetonitrile λ_{max} (ε_{max}): 340 (8.7×10^4), 275 (5.17×10^4), 211 (6.89×10^4). IR: ν(N=N), 1490 ν(C=N), 1598, ν(C=O) 1705. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.65 (1H, t, HX), 6.9 (2H, d, H4), 7.0 (2H, d, H2), 7.2 (2H, t, H1), 7.3 (2H, d, H3), 3.8 (3H, s, HR). m.p. is 104–106 °C.

2.2.10. Methyl-1-(4-chlorophenylimino)-1-(4-chlorophenylhydrazono)-acetate (**8c**)

Yield: 3.7 g (55%). *Anal.* Calc. for $C_{15}H_{11}N_3O_2Cl_2$: C, 53.6; H, 3.30; N, 12.5. Found: C, 53.9; H, 3.50; N, 12.2%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 342 (8.89×10^4), 300 (5.29×10^4), 246 (6.94×10^4). IR: ν(N=N) 1488, ν(C=N) 1588, ν(C=O) 1706. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.55 (2H, d, H2), 7.03(2H, d, H4), 7.25 (2H, d, H1), 7.38 (2H, d, H3), 3.87(3H, s, HR). M.p. is 84–86 °C.

2.2.11. Methyl-1-(4-bromophenylimino)-1-(4-chlorophenylhydrazono)-acetate (**8d**)

Yield: 4.7g (62%). *Anal.* Calc. for $C_{15}H_{11}N_3O_2ClBr$: C, 47.3; H, 2.91; N, 11.0. Found: C, 47.5; H, 3.20; N, 10.9%. UV–Vis in acetonitrile: λ_{max} (ε_{max}): 340 (8.81×10^4), 305 (5.22×10^4), 246 (6.88×10^4). IR: ν(N=N) 1484, ν(C=N) 1599, ν(C=O) 1712. ^{1}H NMR (in $CDCl_3$, δ ppm): 6.51 (2H, d, H1), 7.02 (2H, d, H4), 7.21 (2H, d, H2), 7.39 (2H, d, H3), 3.93 (3H, s, HR). M.p. is 97–99 °C.

2.3. General procedure for the syntheses of trans-[Ru(bpy)(**L**)Cl_2]

Ruthenium trichloride trihydrate (261 mg, 1.0 mmol) and (1.0 mmol) of (**L**) were dissolved in 100 mL of absolute ethanol. After refluxing for 1 h, 1.0 mmol of bpy was added to the solution. The reaction was heated for an additional 2 h then an excess amount of LiCl (500 mg, 11.8 mmol) was added. After allowing the reaction mixture to reflux for an additional 1 h, the solvent was then removed by rotary evaporator. The crude product was dissolved in dichloromethane, filtered and washed with water to remove the unreacted ruthenium trichloride and lithium chloride. The filtrate was reduced to 20 mL and purified by chromatography (50×3 cm) column containing 250 g alumina grade (III). The first pale yellow band, thought to be the azomethine ligand (**L**) was eluted with hexane. Acetone was used to elute the second dark-red band of the product.

2.3.1. trans-[Ru(bpy)(**6a**)Cl_2] · 0.5H_2O (**9**)

Yield: 301 mg (52%). *Anal.* Calc. for $RuC_{25}H_{21}N_5OCl_2\cdot0.5H_2O$: C, 51.0; H, 3.77; N, 11.9. Found: C, 51.0; H, 3.65; N, 11.9.%. UV–Vis in DMF: λ_{max} (ε_{max}): 509 (13.1×10^3). ^{1}H NMR (in $CDCl_3$, δ ppm): 6.98 (1H, t, H8′), 7.03 (1H, t, H8), 7.10 (1H, d, H9), 7.51 (6H, m, H2, H4, H7′, HX), 7.74 (1H, t, HY), 7.79 (3H, m, H3, H7), 7.83 (1H, d, H9′), 7.93 (1H, d, H6), 7.97 (1H, d, H6′), 8.06 (2H, d, H1), 2.79 (3H, s, HR).

2.3.2. trans-[Ru(bpy)(**6b**)Cl_2] (**10**)

Yield. 231 mg (39%). *Anal.* Calc. for $RuC_{26}H_{23}N_5OCl_2$: C, 52.6; H, 3.91; N, 11.8. Found: C, 51.3; H, 3.19; N, 11.4%. UV–Vis in DMF: λ_{max} (ε_{max}): 513 (10.5×10^3). ^{1}H NMR (in $CDCl_3$, δ ppm): 7.01 (1H, t, H8), 7.05 (1H, t, H8′), 7.23 (1H, d, H9), 7.3 (2H, d, H1), 7.4 (2H, d, H2), 7.5 (2H, t, H4), 7.72 (1H, t, HX), 7.82 (3H, m, H9, H6, H6′), 7.93 (1H, d, H7′), 7.97 (1H, d, H7), 8.06 (2H, d, H3), 2.49 (3H, s, HY), 2.78 (3H, s, HR).

2.3.3. trans-[Ru(bpy)(**6d**)Cl_2] · CH_2Cl_2 (**12**)

Yield: 311 mg (47%). *Anal.* Calc. for $RuC_{25}H_{20}N_5OCl_2Br\cdot CH_2Cl_2$: C, 42.0; H, 2.98; N, 9.42. Found: C, 42.4; H, 2.69; N, 9.25%. 2.4. Instrumentation

Cyclic voltammetry studies were performed in 99.8% anhydrous acetonitrile (Aldrich, HPLC grade) using a BAS CV-27W voltammetric analyzer and plotted on a BAS XY recorder. Three electrodes were utilized in this system, two platinum-disk working and counter (auxiliary) electrodes (BAS, 1.6-mm diameter), and a silver wire pseudo-reference electrode with ferrocene (0.665 V versus NHE) as an internal reference [14]. To control the temperature, a Haake D8-G refrigerated bath and circulator was used to maintain the cell temperature at 25.0 ± 0.1 °C. Tetrabutylammonium hexafluorophosphate (0.1 M) was twice recrystallized and vacuum dried at 110 °C, and used as the supporting electrolyte. Spectroscopic data were obtained using the following instruments Cary 5 spectrophotometer; IR spectra (KBr disk, 4000–200 cm), FT-IR JASCO model 420; H NMR spectra (Bruker (AC) 300 MHz FT NMR spectrometer). Spectroelectrochemistry for complex **18** was performed using an optically transparent thin layer electrochemistry (OTTLE) cell [15]. The cell had interior dimensions of roughly 1×2 cm with a path length of 0.2 cm and was fitted with an Ag/AgCl reference electrode. ITO (indium-tin oxide) coated glass served as working and counters electrodes and was purchased from Delta-Technologies. Spectra were obtained on Cary 5 spectrophotometer versus appropriate background of solvent and electrolyte at scan rate of 1800 nm/min. The potential was controlled by the same BAS CV-27 which was used for cyclic voltammetry. At any given potential, the system was allowed to come to equilibrium ($i \approx 0$ μA) before the spectrum was taken.

2.5. Computational methods

The crystallographic geometry of Ru(II) complex **18** was used as a representative example for our calculations. All calculations were carried out with GAUSSIAN-03 program package [16]. The Becke three parameters hybrid exchange [17] and the Lee–Yang–Parr correlation functionals [18] (B3LYP) were used. Time-dependent density functional theory (TD-DFT) [19,20] was used for the calculation of the lowest 10 singlet to singlet excitation energy.

2.6. Crystallography

Crystallographic data of crystals of compound **13** or **18** were collected at 298(2) K using a Bruker/Siemens SMART APEX instrument (Mo Kα radiation, $\lambda = 0.71073$ Å). Data were measured using phi and omega scans of 0.5° per frame for 20 {10} s, and a full sphere of data were collected. A total of 1282 {1464} frames were collected with a final resolution of 0.83 Å. Cell parameters were retrieved using APEX2 [21] software and refined using SAINTPlus on all observed reflections [22]. Data reduction and correction for Lp and decay were performed using the SAINTPlus software. Absorption corrections were applied using SADABS [23]. The structure was solved by direct methods and refined by least squares method on F^2 using the SHELXTL program package [24]. The structure was solved in the space group $P\bar{1}$ for **13** and $\{P2_1/c\}$ for **18** by analysis of systematic absences. In **13** the disordered toluene solvent (50% occupied, modeled as a rigid group from coordinates from the Cambridge Database) was held isotropic. In complex **17**, the disordered methyl ester group (50%) and the acetone solvent (50%) were held isotropic. All other non-hydrogen atoms were refined anisotropically. No decomposition was observed during data collection for both structures. Details of the data collection and refinement of **13** and **18** are given in Table 1. Selected bond lengths and angles for **13** and **18** are given in Table 2.

3. Results and discussion

3.1. Synthesis

The new ligands (**6**–**8**) used in this study were prepared in a two-step sequence starting with commercially

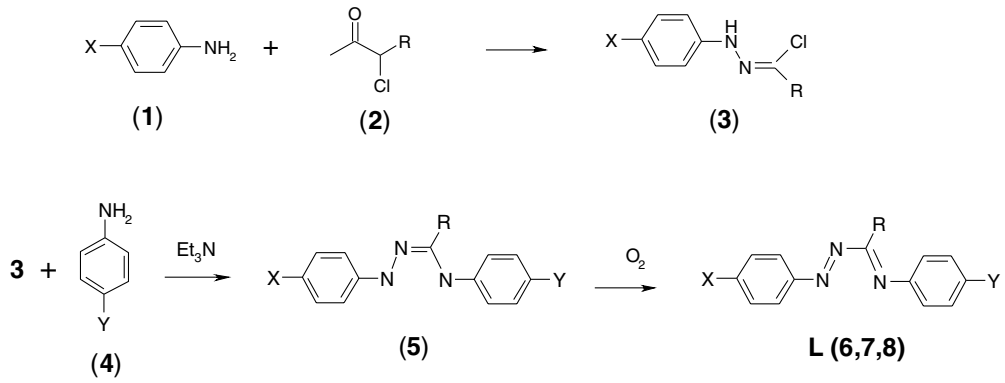
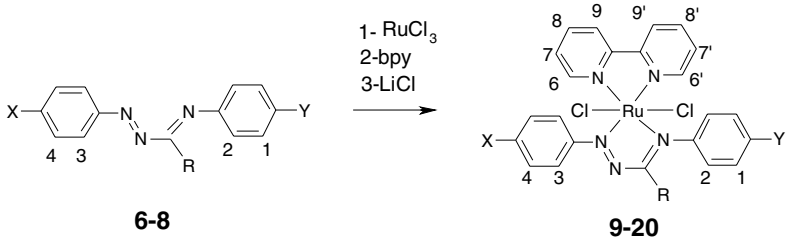
available aniline derivatives (**1**) and β-diketone or β-diketoester (**2**) as shown in Scheme 1. Reaction of the hydrazonyl chloride **3** with the appropriate aniline derivatives (**4**), followed by air oxidation for the intermediate (**5**) in refluxing ethanol gave the azomethine ligands (**6**–**8**) (Scheme 1). The structures of these ligands were conformed by ^{1}H NMR, mass spectra and elemental analysis.



The synthesis of *trans*-[Ru(bpy)LCl_2] was achieved by the stepwise equimolar addition of ruthenium trichloride hydrate, azoimine ligands, bpy and then an excess of lithium chloride (Scheme 2).

These neutral complexes are air stable, soluble in several organic solvents and were recrystallized easily as dark red platelets from slowly evaporating solutions of a mixture of dichloromethane/toluene or acetone. The structures of the diamagnetic complexes were confirmed by ^{1}H NMR spectra and crystallography. The chemical shifts (see Section 2) were assigned on the basis of the literature values and spin–spin interactions. Electron donating or withdrawing substituents on **L** had a respective shielding or deshielding effect on chemical shifts.

The IR spectra of the ligands (see Section 2) exhibit a sharp band at 1660–1712 cm^{-1} corresponds to C=O stretching frequency of the acetyl or the ester group. The formation of the azoimine ligand was confirmed by the intense bands at 1580–1600 and 1470–1490 cm^{-1} which correspond to C=N and N=N stretching bands, respectively. In all complexes, ν(N=N) is red-shifted by 25–30 cm^{-1} compared to that of the ligands, which is a good indication of N-coordination [25].



3.2. Crystal structures

Crystallographic data for complexes **13** and **18** are compiled in Table 1 and ORTEP figures of **13** and **18** are shown in Figs. 1 and 2, respectively. In addition, selected inner coordination sphere bond parameters of **13** and **18** are listed in Tables 2. Complex **13** crystallizes in two conformations with some minor differences in bond lengths and angles (see Table 2). The presence of two conformers is suggested to be due the crystallization of toluene in the lattice and to crystal packing forces. The Ru–N [N(azo): N(19) and N(54)] bond distances (average, 1.946 Å) are shorter than the Ru–N [N(methine): N(25) and N(60)] (average, 2.017 Å) bond distance by 0.07 Å and shorter than those of Ru–N(azo) (1.971, 2.014 Å) in other azo-pyridines complexes [25,26]. This shortening may be due to greater π-back donation from Ru-d orbital to the empty π* orbital of the azoimine ligand, and this comes as an indication that the M–L π interaction is localized in the M–azo fragment [9,27]. For complex (**18**), Ru–N(azo) bond distance is 1.959 Å and is shorter than Ru–N(methine) bond distance of 2.024 Å with both slightly longer than the average bond distance of Ru–N(azo) (1.946 Å) and Ru–N(methine) (2.017 Å) of complex (**13**). This is probably due to the electron withdrawing ester group which is attached to azomethine moiety in complex (**18**). As shown in Figs. 1 and 2, the Ru(II) ion of complex **13** and **18** occupies a distorted octahedral coordination sphere in which the chloride ligands are trans to each other and the azomethine and bipyridine nitrogen donor atoms are

Scheme 2.

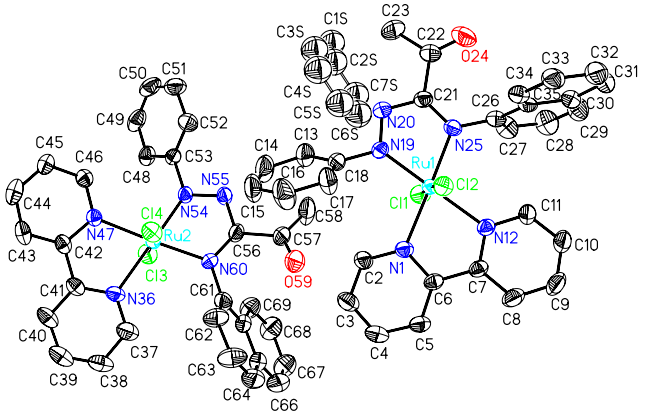

Fig. 1. Thermal ellipsoid drawing (30%) of complex **13** showing the two independent conformations of the Ru complex and the solvent toluene molecule (0.5 occupancy). Hydrogen atoms have been omitted for clarity.

equatorially coordinated. In the equatorial plane, the five-membered rings described by the coordination of an azomethine ligand and of bpy to ruthenium have approximately equivalent coordination bite-angles (Table 2) and deviate considerably from ideal octahedral geometry.

For complexes **13** and **18**, the Ru–N(azo) and Ru–N(methine) distances are shorter than corresponding lengths in similar reported ruthenium azo-imine complexes $(tcc\text{-}Ru(papm)_2Cl_2$ [26] and $tcc\text{-}Ru(aai\text{-}Bz)_2Cl_2$ [25]). This is due to the greater π-back bonding of d(Ru)–π*(azo) and this suggests that the new azomethine bidentate ligands are stronger π-acceptor ligands compared to reported azo-imine ligands [25,26]. The strong π-acidity for these new bidentate ligands are supported by the large positive shift of the Ru(III/II) couple (Table 3) as discussed below.

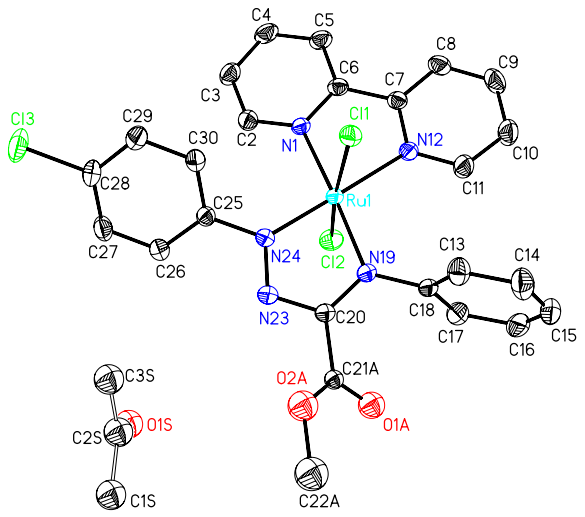

Fig. 2. Thermal ellipsoid plot (30%) of complex **18**. Hydrogen atoms omitted for clarity. The ester group is shown in only one of the disordered conformations (acetone 0.5 occupancy).

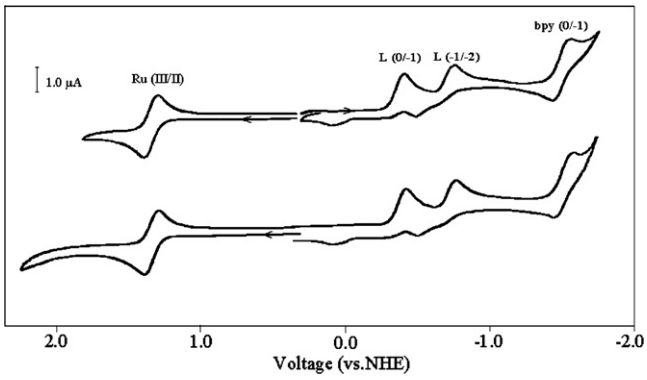
3.3. Electrochemistry

The electrochemical behavior of the complexes in acetonitrile was examined by cyclic voltammetry. The results are summarized in Table 3. As a representative example, the cyclic voltammogram for complex **18** is shown in Fig. 3. At positive potentials, the single wave between 1.0 and 1.30 V is assigned to a reversible Ru(III/II) couple. These couples were determined from the average of the anodic and cathodic peak potentials ($E_{1/2}$), where $E_{1/2} = (E_{pa} + E_{pc})/2$ at scan rate of 100 mV. This couple occurs at more positive potentials compared to many dihalide ruthenium(II) complexes [27]. At negative potentials, three one-electron ligand reduction waves were observed between −0.4 and −2.0 V. The two irreversible waves between −0.56 and −0.88 V versus NHE (cathodic wave peak maxima) are assigned to the two electron reduction of the azo group analogous to the azopyridine systems. The LUMO of **L** can accommodate up to two electrons and the reduction may be represented by the following equation [26]:



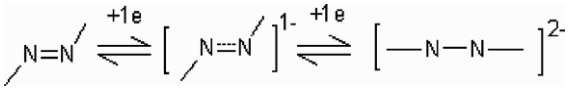


Fig. 3. Cyclic voltammogram for **18** in acetonitrile 0.1 M TBAH at 25 °C, data reported in V vs. NHE with scan rate of 0.1 V/s.

(1)

The wave at the most negative potential scanned (less than −1.60 versus NHE) is assigned to the reduction of bpy. The difference in the ligand reduction potentials can be explained by the greater stability of azo group orbitals compared to that of bpy (see theoretical calculations below). Both Ru(III/II) and the reduction potential for the auxiliary ligand were shifted to more positive potentials upon replacing the acetyl group attached to azomethine moieties with the more withdrawing ester group.

Lever [29] has developed an electrochemical parameterization method to calculate ruthenium(III/II) couples of complexes with octahedral geometry as shown in the following equation:

$$E_{Ru(III/II)} = 0.97\left[\sum E_L\right] + 0.04 \quad \text{in V versus NHE} \qquad (2)$$

where $\sum E_L$ is the sum of electrochemical parameters for each ligand in the complex. The parameter E_L is a measure of the stabilizing effect a ligand has on the Ru(II) state and so the greater the magnitude of positive E_L the more positive the Ru(III/II) couple. For *trans*-[Ru(bpy)LCl$_2$], the E_L of **L** was calculated and listed in Table 3. It is observed that the magnitude of E_L increases as the number of electron withdrawing substituents attached to the azoimine moiety increases. These parameters are approximately the same as those reported for phenylazopyridine ($E_L = 0.40$) and tolylazopyridine ($E_L = 0.41$) but significantly higher than that for the weaker π-acid bpy ($E_L = 0.259$) or for the π-donor chloride ($E_L = -0.24$) [29].

3.4. Electronic structure

Theoretical calculations were performed on **18** using GAUSSIAN-03 program package [16]. Relative percentages of atomic contributions to the lowest unoccupied and highest occupied molecular orbitals have been placed in Table 4. Moreover, the isodensity plots for the HOMOs and LUMOs orbitals of **18** are shown in Fig. 4. Results indicate that the LUMO is constructed mainly from the

Table 4
Relative percentages of atomic contributions to the lowest unoccupied and highest occupied molecular orbitals (LUMO and HOMO) of **18**

MO	Energy (eV)	Ru	bpy	Azo-imine ring	Cl	Others[a]
LUMO − 4	−6.50	5	4	9	57	26

LUMO + 4	−0.66	14	3	24	5	54

[a] Group attached to azo-imine ring (Cl-Ph, Ph, CO_2CH_3).

π^* orbital of azoimine together with a small contribution from π^* orbital of bpy. In addition, the LUMO has 21% metal d-orbital character which suggests significant back donation [30]. The LUMO + 1, LUMO + 2 and LUMO + 3 are mainly bpy in character. For the HOMOs, the three highest energy orbitals (HOMO, HOMO − 1 and HOMO − 2) have a significant contributions of Ru(dπ) orbitals.

The lowest 10 singlet-to-singlet spin-allowed excitation states were taken into account for the calculation of the electronic absorption spectrum by using TD-DFT method. The calculated energy of excitation states and transition oscillator strength (f) (only $f > 0.005$ is listed) of **18** are shown in Table 5. The absorption spectrum of **18** was simulated using GAUSSSUM software [31] based on the obtained TD-DFT results. Each excited state was interpolated by a Gaussian convolution with the full-width at half-maximum (FWHM) of 3000 cm^{-1}. In good agreement, both simulated absorption spectrum of **18**, Fig. 5, and experimental spectrum, in Fig. 7, show two visible region absorptions. The computed spectrum is for gas phase complexes and shows a moderate red-shift to lower energy transitions because of the absence of solvation effects. For the lower energy band ($\lambda_{max} = 499$ (experimental) and 563 (calculated) nm), the initial states are HOMO − 1 and HOMO − 2 orbitals (Table 5), which have sizable contributions of Ru(dπ) orbitals. The LUMO possesses a significant contribution from the π^* orbital of azomethine and because of this, the lower energy band is assigned to MLCT (Ru(dπ) → π^* azomethine). The shoulder centered at 390 (experimental) and 447 (calculated) nm is assigned to overlapping MLCT and ligand–ligand transitions. The MLCT transition results from Ru(dπ) → bpy(π^*) (or HOMO → LUMO + 2), while the ligand–ligand transition result mainly from the HOMO − 3 and HOMO − 4 which is mainly chloride in character to the azomethine π^* orbital (LUMO).

3.5. Spectroelectrochemistry

The MLCT bands of the complexes exhibit relatively little solvatochromism with a shift to higher values in the hydroxylic solvents compared with nonhydroxylic solvents. This can be attributed to significant metal–ligand orbital mixing [30] while the small shift for MLCT to higher energy can be attributed to more solvation of the dipolar ground state relative to less dipolar excited state by the polar solvent [32].

Spectroelectrochemistry of **11** and **18** in DMF solution (Figs. 6 and 7, respectively) was performed in order to obtain the visible electronic absorption spectra of the Ru(III) oxidation state. Reversibility was indicated by the maintenance of the isosbestic points in the absorption spectrum for both forward (oxidation) and reverse (reduction)

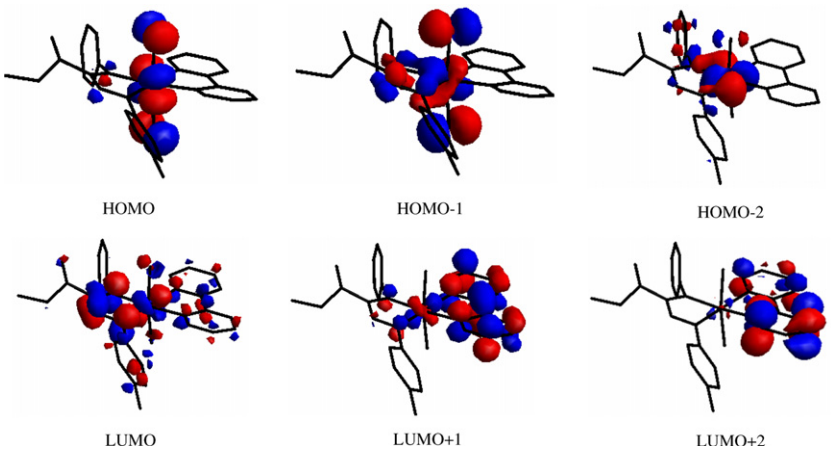

Fig. 4. Isodensity plots (isodensity contour = 0.04) of the HOMO and LUMO orbitals of complex **18**.

processes and the greater than 95% recovery of the Ru(II) complex spectrum. As shown in Figs. 6 and 7, oxidation of these complexes results in a decrease in the intensity of the lower energy band that we have assigned to a MLCT transition. The concomitant growth of absorbance at $\lambda > 550$ nm is assigned to chloride-to-Ru(III) ($p\pi \rightarrow d\pi^*$) ligand-to-metal charge transfer LMCT transitions. The higher energy band at 368 nm ($\varepsilon = 9810\ M^{-1}\ cm^{-1}$) in the absorption spectrum of $\mathbf{11}^+$ (Fig. 6), is only a shoulder in the spectrum of $\mathbf{18}^+$ (Fig. 7), suggesting that the acetyl group of the ligand **6c** participates in the state descriptions responsible for this absorption.

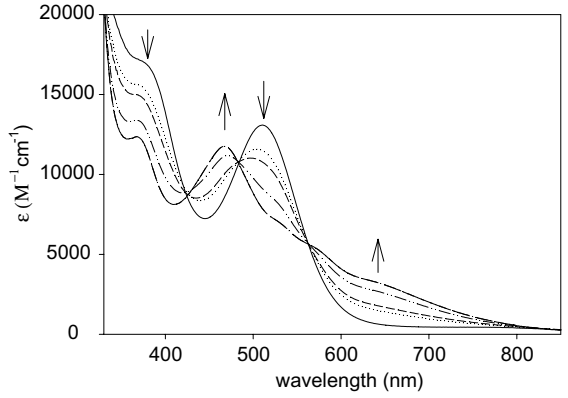

Fig. 6. Spectroelectrochemical oxidation of complex **11** in DMF, 0.1 M TBAH, 25 °C.

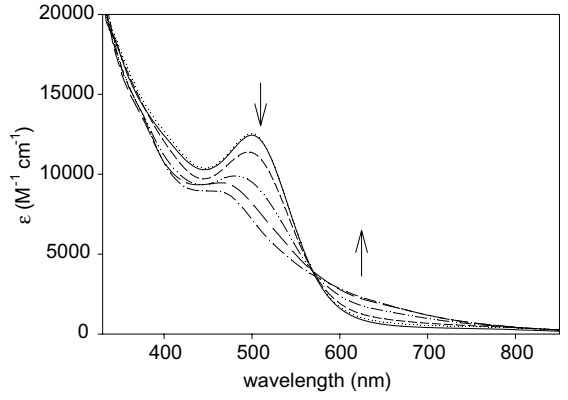

Fig. 7. Spectroelectrochemical oxidation of complex **18** in DMF, 0.1 M TBAH, 25 °C.

The MLCT band of a Ru(II) mononuclear complex and its electrochemistry provide information about the relative energies of the complex's metal and ligand-based orbitals. The change in dπ-orbital energy can be measured experimentally by measuring the potential of the Ru(III/II) couple. For the complexes of this study, acetate azomethine ligands shift the Ru(III/II) couple approximately 100 mV positive relative to their propanone analogues. This can be explained by the enhanced π-acceptor properties of acetate azomethine ligands which originate from the inductive effect of the carboxy methyl ester group. The relationship between MLCT band energy and the ligand electrochemical parameter, E_L(L), for the azomethine ligands (Table 3) is revealed by Fig. 8. The linear correlation that is observed strongly suggests that substitution of the azomethine ligand provides researchers with a useful tool for the fabrication of novel ruthenium(II)–polypyridine complexes that have specific electronic and structural properties.

4. Conclusions

Ten ruthenium(II) complexes, *trans*-[Ru(bpy)LCl_2], where bpy is 2,2′-bipyridine and **L** is a substituted azomethine ligand, were synthesized and characterized by crystallography and spectroscopic and electrochemical methods. Crystallographic studies of **13** and **18** show that bidentate azomethine ligands are strong π-acceptors that coordinate via imine and azo nitrogens. Cyclic voltammetric studies of *trans*-[Ru(bpy)LCl_2] complexes show reversible ruthenium-based oxidation–reduction processes and irreversible ligand-based redox reactions. The electronic effect of the azomethine substituents was seen in the ruthenium and ligand couples, which shifted to more positive values when stronger electron-withdrawing substituents were introduced. The high degree of metal-to-azomethine back dona-

tion is evident from the diminished solvatochromism of the MLCT band which suggests considerable mixing of metal and ligands orbitals [28]. The electronic absorption spectra of these complexes show a strong band in the visible region which is assigned to a $d\pi$-to-$p\pi^*$ (Ru(II)-to-azomethine) MLCT transition based on TD-DFT calculations and spectroelectrochemical correlations. Azomethine ligands are a useful tool for the fabrication of novel ruthenium(II)–polypyridine complexes with specific electronic and structural properties.

5. Supplementary material

CCDC 638037 and 638038 contain the supplementary crystallographic data for **13** and **18**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

with quinoline-2-carboxylic acid. Quinoline-2-carboxylic acid is the biological compound involved in the metabolism of tryptophan. It is a strong chelator providing the donor set similar to that responsible for binding metal ion in PQQ (pyrroloquinilnequinone) cofactor of quinoprotein family [9].

Here, we present synthesis and spectroscopic data for $[ReOCl_2(quin\text{-}2\text{-}c)(PPh_3)]$ (**1**), $[ReOBr_2(quin\text{-}2\text{-}c)(PPh_3)]$ (**2**), $[ReOCl_2(quin\text{-}2\text{-}c)(AsPh_3)]$ (**3**) and $[ReOBr_2(quin\text{-}2\text{-}c)(AsPh_3)]$ (**4**) complexes. X-ray studies have been performed for **1** and **4**, and electronic structure of **1** has been calculated with the density functional theory (DFT). The singlet–singlet electronic transitions of **1** have been calculated with the time-dependent DFT method (TD-DFT method), and the UV–Vis spectra of these complexes have been discussed on this basis.

Currently, density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [10]. Recent calculations with TD-DFT method for open- and closed-shell of 5d-metal complexes (including rhenium complexes) have also supported the TD-DFT method to be applicable for such systems giving good assignment of experimental spectra [11,12].

Some theoretical investigations have been carried out on rhenium compounds. The electronic structures of nitrido, oxo, carbonyl, nitrosyl and nitrile rhenium complexes, as well as their spectroscopic properties, bonding and reactivity have been theoretically studied at the HF, MP2, EHT and DFT levels of theory using various basis sets [13–22]. Gancheff and co-workers [15] have performed extended tests of the ability of the B3LYP method in LANL2DZ basis set for rhenium compounds in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has shown to be sufficient for the geometry optimization and calculation of spectral properties. It gives good agreement with the experimental data and its use is justified in the case of large molecules.

2. Experimental

2.1. General procedure

The reagents used to the synthesis were commercially available and were used without further purification. The $[ReOX_3(AsPh_3)_2]$ and $[ReOX_3(PPh_3)_2]$ complexes were prepared according to the literature methods [23].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 1000–180 nm in chloroform solution. Elemental analyses (C,H,N) were performed on a Perkin-Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOCl_2(quin\text{-}2\text{-}c)(PPh_3)]$ (**1**)

A mixture of $[ReOCl_3(PPh_3)_2]$ (0.50 g, 0.6 mmol), quinoline-2-carboxylic acid (0.12 g, 0.69 mmol) and acetone (50 ml) was stirred at room temperature for 3 h. Half of the solvent was removed and diethyl ether (50 ml) was added to precipitate the product as a green solid, which was filtered off and dried. Yield: 85%. Crystals suitable for X-ray investigation were obtained by recrystallization from acetonitrile.

Anal. Calc. for $C_{28}H_{21}Cl_2NO_3PRe$: C, 47.53; H, 2.99; N, 1.98. Found: C, 47.70; H, 3.06; N, 2.05%.

2.3. Preparation of $[ReOBr_2(quin\text{-}2\text{-}c)(PPh_3)]$ (**2**)

A procedure similar to that for $[ReOCl_2(quin\text{-}2\text{-}c)(PPh_3)]$ was used with $[ReOBr_3(PPh_3)_2]$ (0.50 g, 0.52 mmol and quinoline-2-carboxylic acid (0.10 g, 0.58 mmol). Crystalline precipitate of $[ReOBr_2(quin\text{-}2\text{-}c)(PPh_3)]$ was collected in 80% yield.

Anal. Calc. for $C_{28}H_{21}Br_2NO_3PRe$: C, 42.22; H, 2.66; N, 1.76. Found: C, 42.35; H, 2.72; N, 1.84%.

2.4. Preparation of $[ReOCl_2(quin\text{-}2\text{-}c)(AsPh_3)]$ (**3**)

A procedure similar to that for $[ReOCl_2(quin\text{-}2\text{-}c)(PPh_3)]$ was used with $[ReOCl_3(AsPh_3)_2]$ (0.50 g, 0.54 mmol) and quinoline-2-carboxylic acid (0.11 g, 0.64 mmol). Crystalline precipitate of $[ReOCl_2(quin\text{-}2\text{-}c)(AsPh_3)]$ was collected in 80% yield.

Anal. Calc. for $C_{28}H_{21}Cl_2NO_3AsRe$: C, 44.75; H, 2.82; N, 1.86. Found: C, 44.68; H, 2.92; N, 1.85%.

2.5. Preparation of $[ReOBr_2(quin\text{-}2\text{-}c)(AsPh_3)]$ (**4**)

A procedure similar to that for $[ReOCl_2(quin\text{-}2\text{-}c)(PPh_3)]$ was used with $[ReOBr_3(AsPh_3)_2]$ (0.50 g, 0.47 mmol) and quinoline-2-carboxylic acid (0.10 g, 0.58 mmol). Yield: 85%. Crystals suitable for X-ray investigation were obtained by recrystallization from acetonitrile.

Anal. Calc. for $C_{28}H_{21}Br_2NO_3AsRe$: C, 40.02; H, 2.52; N, 1.67. Found: C, 40.22; H, 2.63; N, 1.69%.

2.6. Crystal structures determination and refinement

The X-ray intensity data of **1** and **4** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and absorption correction [24] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal

1.2 times the value of equivalent temperature factor of the parent atom. SHELXS 97 [25], SHELXL 97 [26] and SHELXTL [27] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Computational details

GAUSSIAN 03 program [28] was used in the calculations. The geometry of **1** was optimized in singlet state with the DFT method with the use of B3LYP functional [29,30]. The electronic spectrum of **1** was calculated with the TDDFT method [31]. The calculations were performed by using ECP basis set on the rhenium atom, and the standard 6-31G basis set for others. For chloride, oxygen, phosphorous and nitrogen atoms, diffuse and polarization functions were added [32,33]. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [34] was used for the valence electrons. Additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ on the rhenium atom were added [35].

Natural bond orbital (NBO) calculations were performed with the NBO code [36] included in GAUSSIAN 03.

4. Results and discussion

4.1. Preparation and infrared data

The $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ (X = Cl, Br; E = As, P) complexes were prepared in good yields by ligand exchange reactions starting from $[ReOX_3(EPh_3)_2]$ complexes and quinoline-2-carboxylic acid in acetone:

$$[ReOX_3(EPh_3)_2] + \text{quin-2-cH} \rightarrow [ReOX_2(\text{quin-2-c})(EPh_3)] + HX + EPh_3, \quad X = Cl, Br; E = As, P$$

They were isolated as green microcrystalline solids, soluble in common organic solvents.

The selected frequencies observed in the IR spectra of $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ complexes are collected in Table 2. The values of $\Delta\nu(CO_2) = \nu_{as}(CO_2) - \nu_s(CO_2)$ are equal to ≈370 cm^{-1} for $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ compounds, and indicate that the carboxylate group binds in a monodentate fashion [37].

The strong ν(Re=O) stretching bands of $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ compounds are in the higher end of the range observed for $\{ReO\}^{3+}$ core complexes. This suggests that the Re-carboxylate bond *trans* to the oxo ligand does not compete effectively for the d_{Re} orbitals and the bond is relatively weak. Moreover, the narrow range in which the ν(Re=O) bands appear is very similar to those observed for Re(V)-oxo complexes with an monoanionic oxygen (RO^- and $R\text{–}COO^-$,) *trans* to the oxo group [38].

Table 2
Selected IR frequencies (cm^{-1}) values of $[ReOX_2(qiun\text{-}2\text{-}c)(EPh_3)]$ complexes

Complex	ν(Re=O)	ν_{as}(COO)	ν_s(COO)
1	996	1689	1318
2	990	1693	1320
3	987	1691	1319
4	988	1692	1320

Table 3
Analysis of short contacts between the quinoline rings and triphenyl phospine ring (distances in Å and angles in °)

R(I)	R(J)	Cg···Cg	α	β	d_p
1					
Cg(1)	Cg(3)	3.7306	11.61	23.38	3.183
Cg(2)	Cg(3)	5.2775	3.32	53.90	3.034

Cg(2)	Cg(4)	5.1335	24.82	41.08	2.249

R_1, R_2, R_3, R_4 indicates the centroids of aromatic rings containing N(1), C(24), C(13), C(1) atoms, respectively, α is a dihedral angle between planes I and J, β is an angle between Cg(I)–Cg(J) vector and normal to plane I and d_p is a perpendicular distance of Cg(I) on ring J plane.

4.2. Crystal structures

Both complexes crystallise in the monoclinic space group $P2_1/c$. Although the crystal packing motives are different in compounds **1** and **4**, both molecules are isomorphic in solid state.

The classical hydrogen bonds cannot be found in the structures **1** and **4**, only some C–H···O weak inter- and intramolecular hydrogen bonds exist [39]. Additionally in

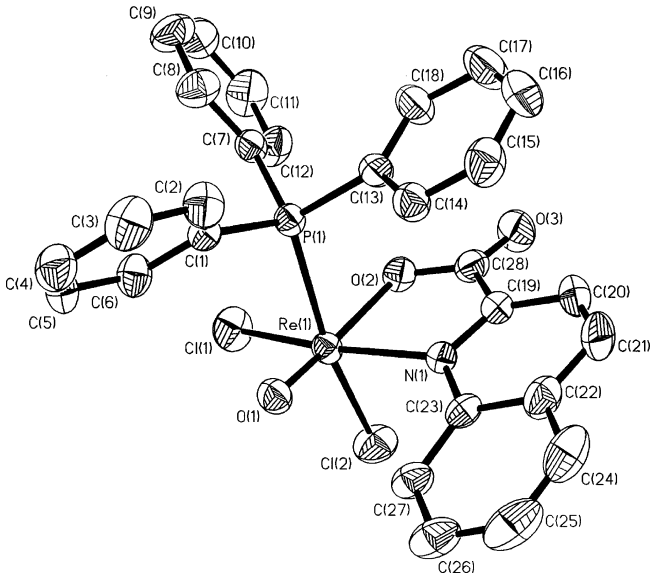

Fig. 1. The molecular structure of **1**. Displacement ellipsoids are drawn at 50% probability.

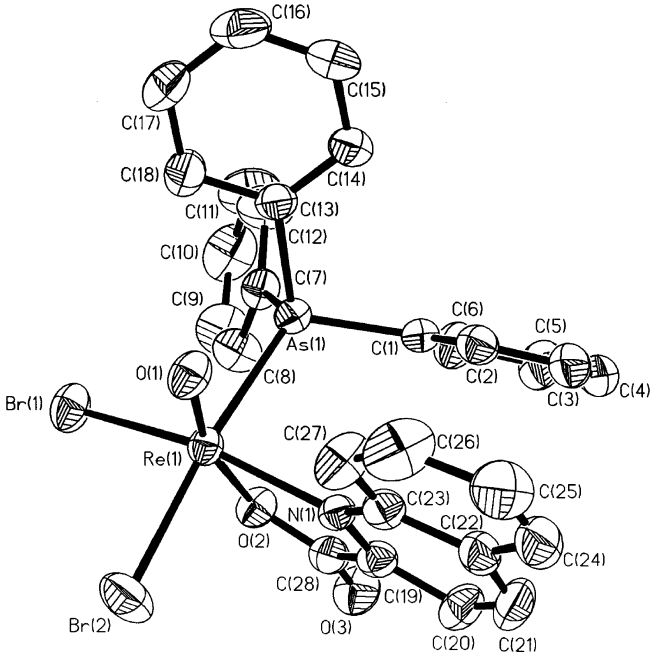

Fig. 2. The molecular structure of **4**. Displacement ellipsoids are drawn at 50% probability.

Cl(2)	−0.400
P(1)	1.399

the structures **1** and **4** exist π···π stacking interactions between the quinoline rings and one of the triphenyl phospine rings. (Table 3) [40].

The molecular structures of **1** and **4** are presented in Figs. 1 and 2, and the selected bond distances and angles are collected in Tables 4 and 5, respectively.

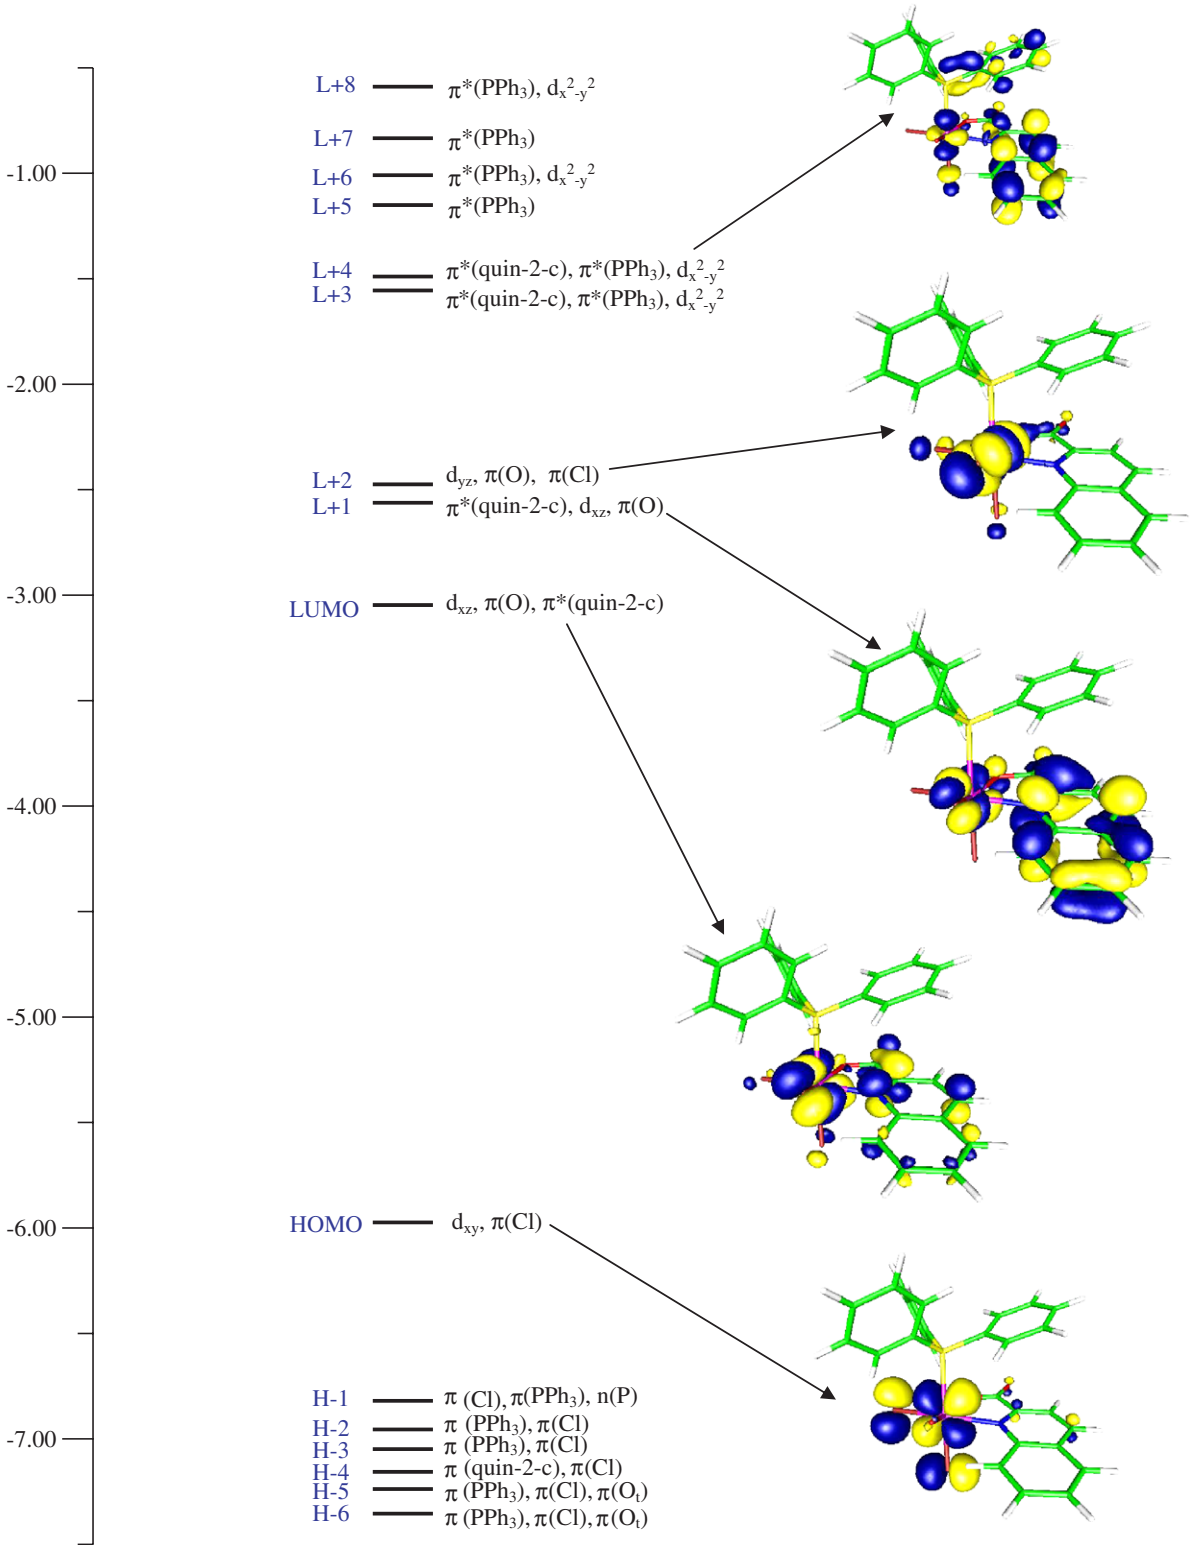

Fig. 3. The energy (eV), character and some contours of the unoccupied molecular orbitals of **1**. Positive values of the orbital contour are represented in blue (0.04 au) and negative values – in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Table 7
The occupancy of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligand for **1**

BD	Occupancy	BD	BD*	Occupancy
Re–O_t	1.989	$0.558(d)_{Re} + 0.830(p)_O$	$0.830(d)_{Re} - 0.558(p)_O$	0.271
Re–O_t	1.982	$0.573(d)_{Re} + 0.820(p)_O$	$0.820(d)_{Re} - 0.573(p)_O$	0.272

BD denotes 2-center bond.
* Denotes antibond NBO.

The geometry of $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ compounds reveals typical features of quasi-octahedral oxorhenium(V)complexes with oxygenated bidentate ligands. For complex **1**, the rhenium atom is displaced 0.2234(7) Å from the plane formed by the two chloride, one nitrogen and one phosphorous atoms (plane A) and 0.0919(8) and 0.0654(10) Å from the planes formed respectively by the two oxygen, one chloride and one phosphorous atoms (plane B) and two oxygen, one chloride and one nitrogen atoms (plane C). Least squares plane A is inclined at 87.52(5)° to plane B and at 88.29(4)° to plane C. Planes B and C are inclined at 89.41(23)°. These values in **4** are respectively, 0.2869(7), 0.0748(9), and 0.0751(12) Å, 87.95(6)°, 88.68(6)° and 89.14(4)°. The deformation of the octahedron is caused by the presence multiple bonding ligand (terminal oxo) and narrow bite angle of the chelating ligand. The high concentration of electronic density along the Re—O_t axis strongly influences the positions of the adjacent halogen atoms, which are pushed away. In each complex, the rhenium atom is coordinated by a terminal oxygen atom (O_t), two halide ions in *cis* arrangement, the phosphorus or arsine atom from EPh_3 molecule, and the bidentate *N*,*O* donors of the carboxylate ligand. The oxygen atom of *quin-2-c* ligand lies in *trans* position to the terminal oxo ion.

The Re–O_t bond lengths of $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ complexes fall in the range 1.639–1.76 Å, typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicate the presence of a triple bond Re≡O [41]. The interatomic distances between the rhenium atom and the oxygen atom of carboxylate ligand are almost equal to an ideal single Re–O bond length. The last one, predicted by the use of Pauling's covalent radius for oxygen and Cotton and Lippard's value for the octahedral covalent radius of rhenium(V), should be ca. 2.04 Å [42].

Table 8
Band position [nm] and molar absorption coefficient [$dm^3\,mol^{-1}\,cm^{-1}$] (in brackets) of $[ReOX_2(qiun\text{-}2\text{-}c)(EPh_3)]$ complexes

1	2	3	4
856.3 (55)	827.1 (80)	847.1 (75)	898.8 (60)

429.6 (3520)	430.7 (4320)	430.4 (2770)	420.4 (2880)
376.7 (4060)	370.3 (5680)	370.0 (3060)	369.9 (3220)
274.8 (20550)	285.2 (16900)	314.8 (13515)	286.0 (13200)
238.5 (175200)	241.5 (128320)	239.9 (14130)	239.9 (117380)
207.9 (180750)	210.7 (176670)	207.4 (190225)	210.8 (165650)

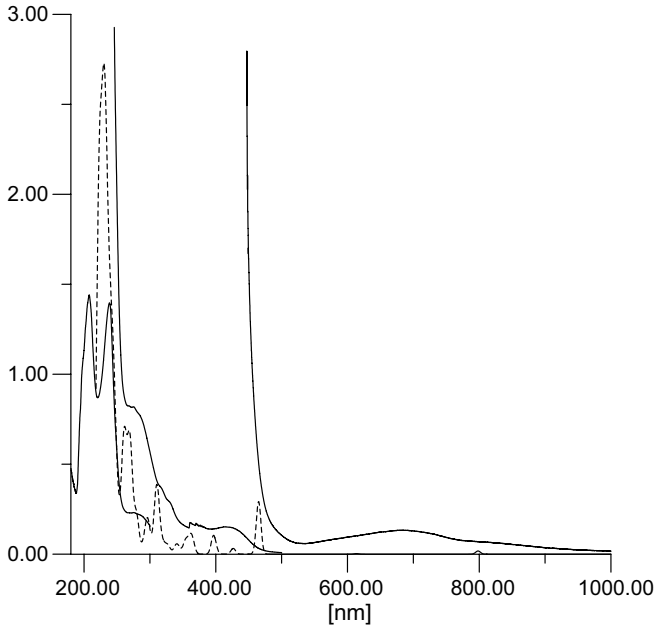

Fig. 4. The experimental (——) and calculated (----) electronic absorption spectra of **1**.

The Re(1)–X(1) distances *trans* to the phosphorus or arsine atom of EPh_3 molecule are slightly longer than the Re(1)–X(2) bonds *trans* to the nitrogen atom of the *quin-2-c* ligand. It indicates *structural trans* effect of the EPh_3 ligands.

4.3. Geometry optimisation, charge distribution, electronic structure and NBO analysis

The geometry of **1** was optimised in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters of **1** are gathered in Table 4. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data (discussed above) are well reproduced in the calculations. The plane A is inclined at 87.96° to plane B and at 89.00° to plane C. Planes B and C are inclined at 87.23°.

Table 6 presents the atomic charges from the Natural Population Analysis (NPA) for **1**. The calculated charge on the rhenium atom in **1** is considerable lower than the formal charge +5, corresponding d^2 configuration of the central ion. The populations of the d_{xy}, d_{xz}, d_{yz}, $d_{x^2-y^2}$ and d_{z^2} rhenium orbitals equal to 1.071, 0.842, 0.824,

1.898 and 0.883 also significantly differ from the formal d^2 configuration of the rhenium atom in **1**. It results from charge donation from the oxo ligands, halide ions and phosphine molecule. ligands. The P atom is positively charged, and the charges on the terminal oxo, halide and oxygen atom of *quin-2-c* are significantly smaller than −2, −1 and −1, respectively. The terminal oxo ions are less negative in comparison with the oxygen atoms of *quin-2-c* ligand. It indicates the higher electron density delocalization from the terminal ligand towards the rhenium center and corresponds to differences in the Re–O(1) and Re–O(2) bond lengths.

The $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ complexes are closed-shell structures. The molecular orbital diagram of **1** with several occupied and unoccupied molecular orbital contours is presented in Fig. 3. The local symmetry of the rhenium centre has been considered in the discussion: *z*-axis goes along the O–Re–O linkage, and *x*-axis – through the P–Re–Cl bonds. The HOMO–LUMO gap equals to 2.93 eV. The highest occupied MO is of d_{xy} type with some contributions from p_π chloride orbitals. The remaining four d-type orbitals of rhenium are found among unoccupied MOs. It confirms d^2 configuration of the rhenium atoms in $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ complexes.

The rhenium–terminal oxygen interaction in **1** is described as a triple bond. Assuming that rhenium uses its six valence orbitals, $5d_{x^2-y^2}$, $5d_{z^2}$, 6s, $6p_x$, $6p_y$ and $6p_z$ to form σ-bonds with the six ligands, empty $5d_{xz}$ and $5d_{yz}$ orbitals are available to overlap with $2p_x$ and $2p_y$ orbitals on the terminal oxygen to form an effective triple bond. The LUMO and LUMO + 2 (Fig. 3) are ascribed as π-antibonding rhenium–oxygen molecular orbitals.

Additional information about nature rhenium-terminal oxygen bonding has been obtained by NBO analysis. The occupancy and composition of the calculated $Re–O_t$ natural bond orbitals (NBOs) are given in Table 7.

Table 9

ε, molar absorption coefficient ($dm^3\ mol^{-1}\ cm^{-1}$); *f*, oscillator strength; H, highest occupied molecular orbital; L, lowest unoccupied molecular orbital.

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [36].

Two detected natural Re–O_t bond orbitals of **1** are π orbitals – the p_x and p_y oxygen orbitals and d_{xz} and d_{yz} rhenium orbitals are involved in their formation. Not detected $\sigma_{Re–Ot}$ bond has character of predominant Coulomb-type interactions between the central ion and ligands [43]. The terminal oxo ligand of **1** has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital. Accordingly, NBO analysis confirms a triple bond between the rhenium and the terminal oxygen ligand.

4.4. Electronic spectra

The electronic spectra of $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ complexes are very similar in terms of the position, intensity and shape of the bands in the whole region 1000–180 nm. The positions and molar absorption coefficients of electronic bands for $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)]$ complexes are given in Table 8.

The experimental and calculated electronic spectra of **1** are presented in Fig. 4. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. Table 9 presents the calculated singlet–singlet electronic transitions of **1** and their assignments to the experimental bands. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.015 are listed in Table 9.

The longest wavelength experimental bands at 856.3 and 692.7 nm can be attributed to the transitions of d → d character. However, due to some participation of π^* orbitals of the *quin-2-c* ligand in the LUMO orbital, character of the H → L electronic transition is ascribed as d → d/π^*(quin-2-c). The metal-ligand charge transfer (d → π^*quin-2-c) makes the largest contribution into the experimental band at 429.6 nm. The absorption band at 376.7 nm is assigned to ligand-metal charge transfer ($\pi_{quin\text{-}2\text{-}c}/\pi_{EPh3}/\pi_{Cl}/\pi_O$ → d) transitions, whereas the experimental bands at 274.8 and 239.9 nm result mainly from the ligand–ligand charge transfer and interligand (IL) transitions.

5. Supplementary material

CCDC 639645 and 639646 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgement

The GAUSSIAN 03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland.

was prepared as previously reported [3]. Elemental analyses (C, H, N, S) were performed on a LECO CHNS-932 analyzer. Molybdenum was determined by titration with lead(II) nitrate [9]. IR spectra (KBr dispersion, 4000–400 cm^{-1} range) were recorded on a Nicolet Impact 410 (Software Omnic for Windows) spectrometer. NMR spectra were recorded on a Varian Mercury-plus 300 spectrometer (300 MHz for ^1H) at 20 °C, and Varian Unity Inova 400 spectrometer (400 MHz for ^1H and 161.92 MHz for ^{31}P) for variable temperature experiments. Chemical shifts are relative to TMS (^1H), or external 85% H_3PO_4 (^{31}P), with downfield values reported as positive. Coupling constants *J* are given in Hertz.

2.2. Preparation of compounds $Mo_2O_5(acac)_2L_2$

2.2.1. Preparation of $Mo_2O_5(acac)_2(H_2O)_2$

$MoO_2(acac)_2$ (0.326 g, 1 mmol) was dissolved in 96% ethanol (15 ml). The resulting solution was stirred for 45 min at r.t. and concentrated under vacuum nearly to dryness. Then diethyl ether (20 ml) was added and the mixture was stirred for 10 min. The white precipitate that formed was collected by filtration, washed with diethyl ether (3 × 3 ml) and dried under vacuum. Yield: 0.223 g (88%). IR (cm^{-1}): *ν*(Mo=O) 903(s), 949(s), *ν*(Mo–O–Mo) 766(s). ^1H NMR (methanol-d_4, 300 MHz, *δ*, ppm): 5.85 (s, 2H, CH), 4.90 (s, 4H, H_2O), 2.11 (br, 12H, CH_3). *Anal.* Calc. for $C_{10}H_{18}Mo_2O_{11}$: C, 23.73; H, 3.58; Mo, 37.91. 2.2.2. Preparation of $Mo_2O_5(acac)_2(D_2O)_2$

$MoO_2(acac)_2$ (0.065 g, 0.2 mmol) was dissolved in 96% EtOD (EtOD/D_2O, 96/4, v/v, 5 ml). The resulting solution was stirred for 15 min at r.t. and concentrated under vacuum nearly to dryness. Then diethyl ether (8 ml) was added and the mixture was stirred for 5 min. The white precipitate that formed was collected by filtration, washed with diethyl ether (3 × 3 ml) and dried under vacuum. Yield: 0.035 g (68%). IR (cm^{-1}): *ν*(O–D) 2427(s), *ν*(Mo=O) 904(s), 949(s), *ν*(Mo–O–Mo) 768(s). ^1H NMR (methanol-d_4, 300 MHz, *δ*, ppm): 5.85 (s, 2H, CH), 2.11 (br, 12H, CH_3). *Anal.* Calc. for $C_{10}H_{14}D_4Mo_2O_{11}$: C, 23.54; H, 2.77; Mo, 37.61. Found: C, 23.41; H, 2.05; Mo, 37.74%.

2.2.3. Preparation of $Mo_2O_5(acac)_2L_2$ [L = DMSO, p-Tol_2 SO, DMF, DMA, DMBA, TMU, $OPPh_3$, HMPA]

A mixture of $MoO_2(acac)_2$ (0.326 g, 1 mmol) and L (1.1 mmol) in 96% ethanol (15 ml) was stirred for 45 min at r.t. The resulting solution was concentrated under vacuum to approximately 2 ml. Then diethyl ether (20 ml) was added and the precipitate that formed was filtered, washed with diethyl ether (3 × 3 ml) and dried under vacuum.

$Mo_2O_5(acac)_2(DMSO)_2$: Yield: 0.304 g (97%). M.p. (dec.) 142–144 °C. IR (cm^{-1}): *ν*(Mo=O) 902(s), 928(s), *ν*(Mo–O–Mo) 780(s). ^1H NMR (methanol-d_4, 300 MHz, *δ*, ppm): 5.85 (s, 2H, CH), 2.66 (s, 12H, S–CH_3), 2.11 (br, 12H, CH_3). *Anal.* Calc. for $C_{14}H_{26}Mo_2O_{11}S_2$: C, 26.85; H, 4.18; S, 10.24. Found: C, 26.89; H, 4.21; S, 10.47%.

$Mo_2O_5(acac)_2$(*p*-$Tol_2SO)_2$: Yield: 0.442 g (95%). IR (cm^{-1}): *ν*(Mo=O) 907(s), 938(s), *ν*(Mo–O–Mo) 771(s). ^1H NMR (methanol-d_4, 300 MHz, *δ*, ppm): 7.56–7.50 (m, 8H, Ph), 7.37–7.31 (m, 8H, Ph), 5.84 (s, 2H, CH), 2.37 (s, 12H, *Ph*–CH_3), 2.11 (br, 12H, CH_3). *Anal.* Calc. for $C_{38}H_{42}Mo_2O_{11}S_2$: C, 49.04; H, 4.55; S, 6.89. 2.2.4. Preparation of $Mo_2O_5(acac)_2L_2$ [L = Bu_2SO, $OPBu_3$]

A mixture of $MoO_2(acac)_2$ (0.326 g, 1 mmol) and L (1.1 mmol) in 96% ethanol (15 ml) was stirred for 45 min at r.t. The resulting solution was concentrated under vacuum near to dryness, *ca.* 1 ml, then a mixture of diethyl

ether:hexane (1:1, v/v, 20 ml) was added. The precipitate that formed was collected by filtration, washed with diethyl ether:hexane (1:1, 3 × 3 ml) and dried under vacuum.

$Mo_2O_5(acac)_2(Bu_2SO)_2$: Yield: 0.344 g (87%). IR (cm^{-1}): ν(Mo=O) 904(s), 934(s), ν(Mo–O–Mo) 755(s). ^1H NMR (methanol-d_4, 300 MHz, δ, ppm): 5.85 (s, 2H, CH), 2.88–2.69 (m, 8H, $CH_{2\alpha}$), 2.11 (br, 12H, CH_3), 1.80–1.78 (m, 8H, $CH_{2\beta}$), 1.60–1.41 (m, 8H, $CH_{2\gamma}$), 0.99 (t, $^3J_{H-H} = 7.3$ Hz, 12H, CH_2–CH_3). *Anal.* Calc. for $C_{26}H_{50}Mo_2O_{11}S_2$: C, 39.30; H, 6.34; S, 8.07. Found: C, 39.52; H, 6.74; S, 8.49%.

$Mo_2O_5(acac)_2(OPBu_3)_2$: Yield: 0.377 g (83%). IR (cm^{-1}): ν(Mo=O) 903(s), 938(s), ν(Mo–O–Mo) 753(s). ^1H NMR ($CDCl_3$, 300 MHz, δ, ppm): 5.83 (s, 2H, CH), 2.21 (s, 6H, CH_3), 2.14 (s, 6H, CH_3), 1.76–1.34 (m, 36H, CH_2), 0.93 (t, $^3J_{H-H} = 7.3$ Hz, 18H, CH_2–CH_3). *Anal.* Calc. for $C_{34}H_{68}Mo_2O_{11}P_2$: C, 45.04; H, 7.56; Mo, 21.16. Found: C, 45.24; H, 7.68; Mo, 19.99%.

2.3. Crystal-structure determinations

Suitable single crystals of $Mo_2O_5(acac)_2(D_2O)_2$ were grown by cooling an acetone-d_6 solution of this compound in a freezer. Single crystals of $Mo_2O_5(acac)_2(DMF)_2$ were grown by slow evaporation of a solution of the complex in 96% ethanol. Crystal data for the compounds were collected using a Bruker SMART CCD area-detector diffractometer with Mo Kα radiation. Intensities were integrated [10] from several series of exposures, each exposure covering 0.3° in ω, and the total data set being a sphere. All non-hydrogen atoms were assigned anisotropic displacement parameters and refined without positional constraints. For $Mo_2O_5(acac)_2(D_2O)_2$ deuterium atoms D(4A) and D(4B) were located in the electron density difference map, assigned isotropic displacement parameters and refined without positional constraints. All other hydrogen atoms were constrained to ideal geometries and refined with fixed isotropic displacement parameters. Table 1 provides the crystallographic details for these compounds.

2.4. Catalytic activity

The measurement of the catalytic activity of $Mo_2O_5(acac)_2(DMSO)_2$ in the oxidation of PPh_3 with DMSO was monitored by ^{31}P NMR (161.92 MHz) spectroscopy as previously reported [11], and compared with that of $MoO_2(acac)_2$ under the same conditions. We carried out experiments at 25 and 75 °C, for $[Mo]_0 = 0.02$ mol dm^{-3} and $[PPh_3]_0/[Mo] = 20$.

3. Results and discussion

3.1. Synthesis and characterization of the complexes

It is well known that $MoO_2(acac)_2$ can be easily prepared by treating acidic solutions of molybdates with acetylacetone [3]. However, it is somewhat difficult to purify it by re-crystallization from common solvents because of its propensity to hydrolyze with any adventitious water. This hydrolysis should lead to the final product $MoO_3 \cdot nH_2O$, but it is not always immediately formed.

While we were carrying out studies on the reactivity of $MoO_2(acac)_2$ with a variety of chiral acids it was soon evident that the diketonate was hydrolyzed in solution very quickly. This process seemed to proceed in two consecutive well differentiated steps. Indeed, we were able to obtain the hydrate $Mo_2O_5(acac)_2(H_2O)_2$ without significant difficulty, which strongly supports the idea that the hydrolytic removal of acetylacetonate from $MoO_2(acac)_2$ takes place in this way, the second step occurring very slowly at room temperature (Scheme 1).

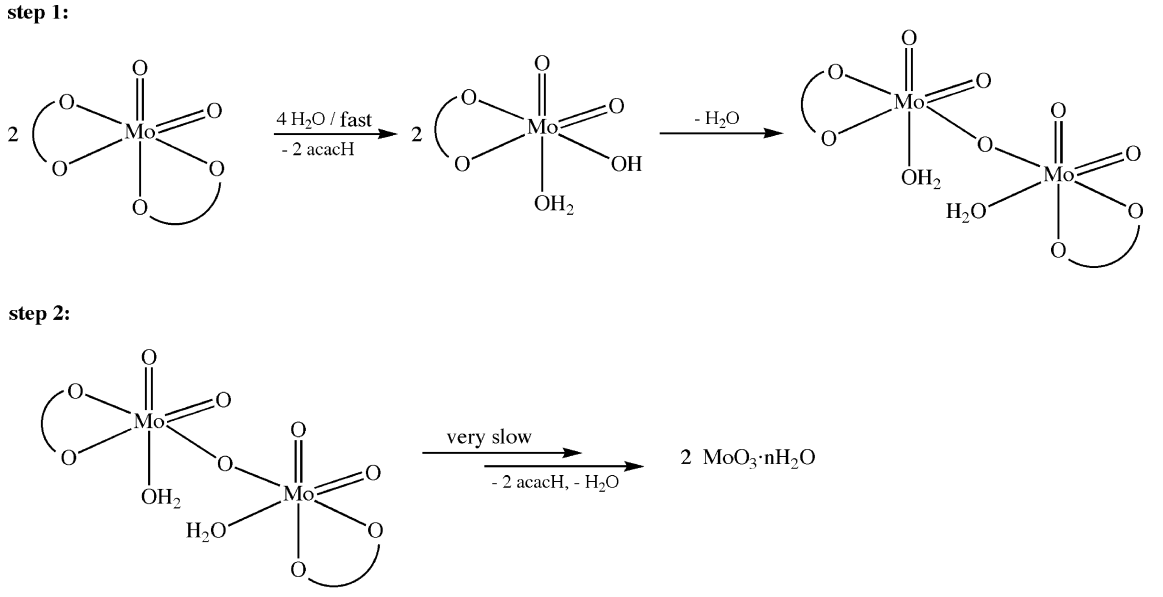
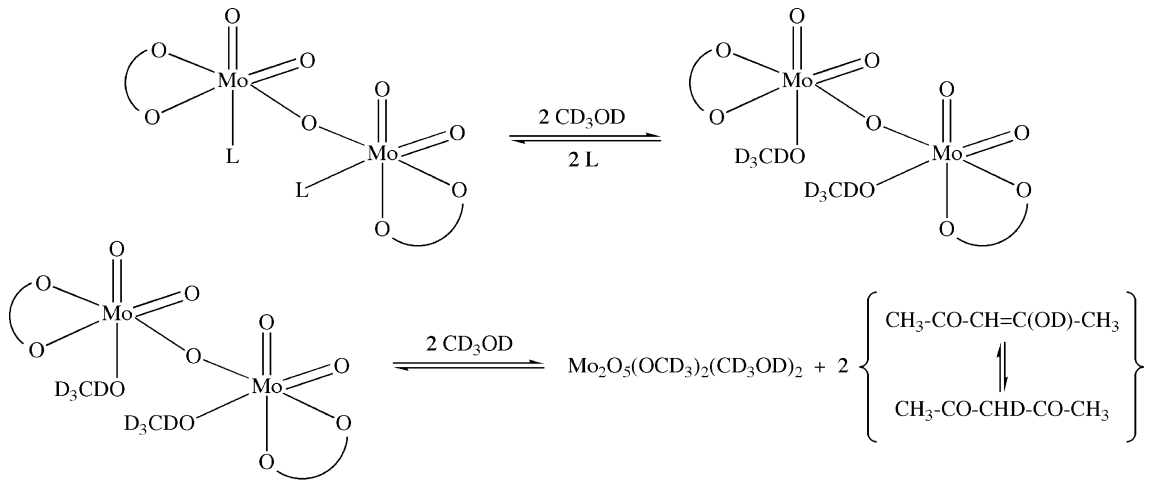
This assumption is in accordance with the behavior observed for $MoO_2(acac)_2$ in 96% ethanol. Thus, when the ^1H NMR of $MoO_2(acac)_2$ is recorded in 96% ethanol-d_6, from the outset the spectrum shows the same amount of acacH and coordinated acac. This indicates that the hydrolysis of the first acetylacetonate takes place quickly, and that the dinuclear dioxomolybdenum species are present in solution from the beginning. However, the hydrolysis of the second acetylacetonate is a slow process.

Thus, $Mo_2O_5(acac)_2(H_2O)_2$, and the closely related $Mo_2O_5(acac)_2(D_2O)_2$, could be obtained by treating $MoO_2(acac)_2$ with mixtures of ethanol–water close to the azeotropic composition, as described in the experimental part. Then we attempted to prepare the anhydrous parent compound $Mo_2O_5(acac)_2$ by warming up $Mo_2O_5(acac)_2(H_2O)_2$ smoothly under vacuum, and by treating it with 2,2-dimethoxypropane, although without success. We also failed to obtain satisfactory results by reacting MoO_3 with $MoO_2(acac)_2$ in several solvents, including the molten diketonate.



As previously reported [11–13], a wide number of dioxomolybdenum(VI) compounds could be readily prepared from $MoO_2X_2(H_2O)_2$ (X = Cl, Br) *via* substitution of water with ligands able to displace it from the coordination sphere of molybdenum. Based on these results we treated $Mo_2O_5(acac)_2(H_2O)_2$ with representative monodentate tertiary amines, amides, sulfoxides and phosphine oxides and could prepare the above mentioned $Mo_2O_5(acac)_2L_2$ compounds. Higher yields were obtained in a simpler manner by carrying out the reactions of $MoO_2(acac)_2$ with the corresponding ligand in 96% ethanol, as an one-pot synthesis. It is likely that other compounds with common amides, sulfoxides and phosphine oxides might be similarly prepared. However, we were unable to isolate the related compounds with N-donor ligands such as tributylamine and 4-methylpyridine. With these bases we always obtained ill-defined products without characteristic IR bands attributable to *cis*-dioxomolybdenum and acetylacetonate groups. This result was not surprising at all since we had observed in other dioxomolybdenum(VI) complexes that amines, in presence of water, induce complete hydrolysis leading to alkylammonium molybdates.

The analytical data (C, H, N, S, Mo) for these compounds were in good agreement with those expected for products with the formulation $Mo_2O_5(acac)_2L_2$. All the compounds are colorless or white, though they slowly develop a blue coloration when left in air. They are insoluble in diethyl ether and hydrocarbons, somewhat soluble in tetrahydrofuran and acetone, and soluble in lighter alcohols, solvents from which they could be re-crystallized.



The derivatives of DMSO, DMA and $OPPh_3$ melt with decomposition in the range 122–144 °C while all the other products decompose before melting. However they can be stored for months, in a dry atmosphere in the dark and at room temperature, without noticeable decomposition.

We have found that these dioxomolybdenum complexes react with common organophosphines and phosphites (PPh_3, PBu_3, $P(OBu)_3$, $P(OPh)_3$) leading to brown solutions. It is likely that, at least in part, new dinuclear complexes with a $[Mo_2O_4]^{2+}$ core might be formed in this process, though we do not have confident analytical data to support this assumption.

The IR spectra of the compounds are characterized by two strong bands in the region 880–950 cm^{-1} which indicate that, as usual for dioxomolybdenum(VI) species, the *cis*-MoO_2 moiety is present in all products [14]. We find it difficult to establish correlations between the position of these bands and the nature of the ligands. The com-

Scheme 1.

Scheme 2.

pounds also show a band in the range 735–780 cm^{-1}, characteristic of ν(Mo–O–Mo) [15]; this band is not easy to assign in the $OPPh_3$ complex, since the ligand also absorbs in this region.

The ^1H NMR spectra for $Mo_2O_5(acac)_2(OPBu_3)_2$ has been recorded using $CDCl_3$ as solvent, and is characterized by two singlets of equal intensity for the methyl groups and another singlet for the CH group from the acac ligand. The signals characteristic for the free neutral ligand are shifted, as usual, to lower fields due to coordination. The ^1H NMR spectra for all the others complexes have been recorded in methanol-d_4 because of their low solubility in other common deuterated solvents. These NMR spectra show the signals corresponding to the neutral ligands in the same positions as the free ligands. The signals for the acac group are similar to those found for the coordinated acac in the above mentioned $MoO_2(acac)_2$. At room temperature there is only one broad signal for the methyl groups from the acac ligand, solved as two singlets (2.16 and 2.06 ppm) at low temperature (−40 °C), which is consistent with a dynamic equilibrium in solution. The intensity of the singlet at 5.85 ppm assigned to the CH group decreases slowly with time, supporting the idea of exchange between hydrogen and deuterium atoms. Taking into account both facts, a possible explanation is an exchange between the deuterium of methanol-d_4 and the methynic hydrogen of acetylacetonate *via* coordination and de-coordination to the molybdenum center as shown in Scheme 2.

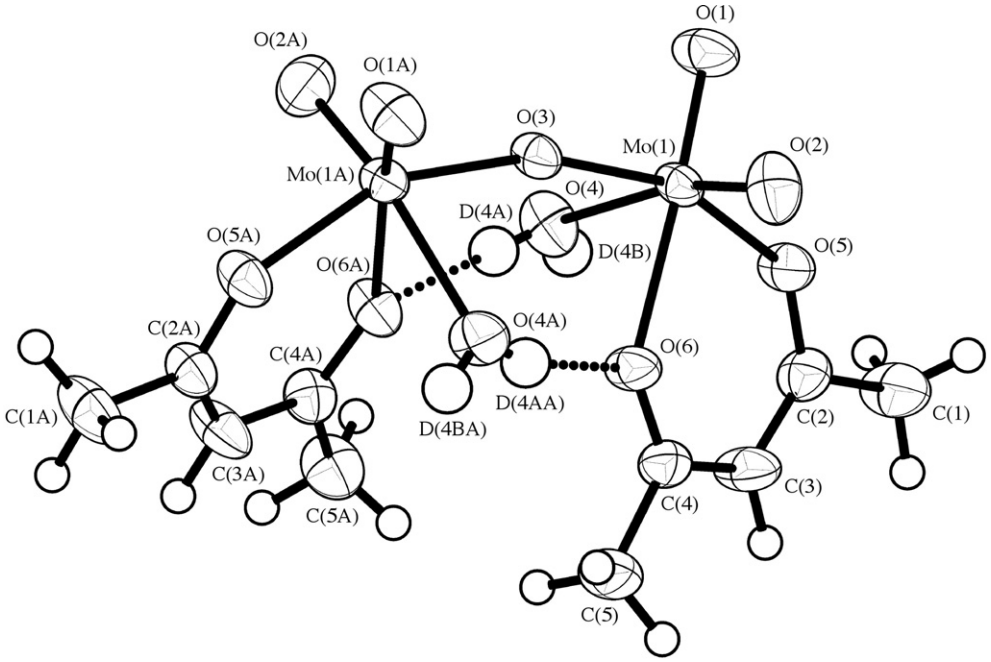


Fig. 1. Molecular structure and atom-labelling scheme for $Mo_2O_5(acac)_2(D_2O)_2$ with thermal ellipsoids at the 50% probability level, showing hydrogen bonds involving deuterium.

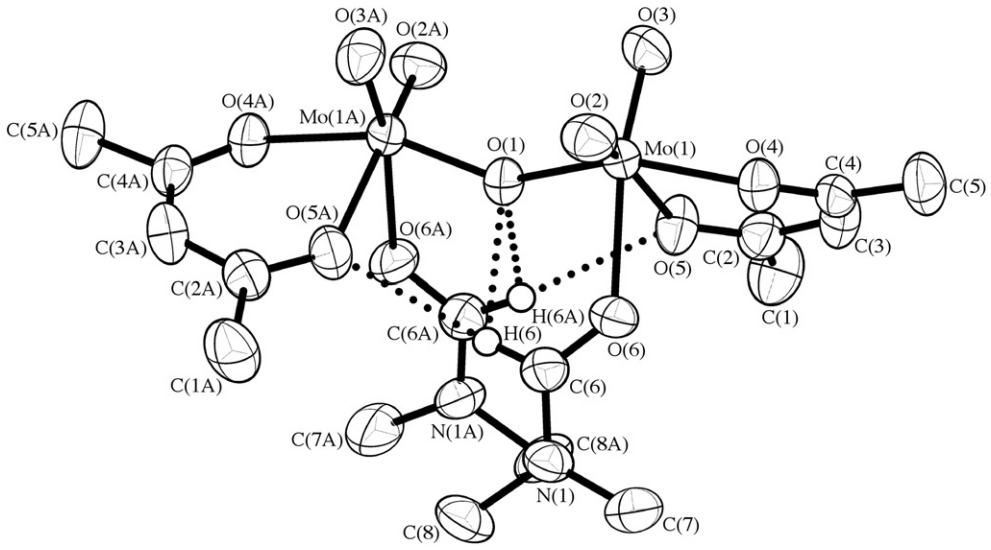

Fig. 2. Molecular structure and atom-labelling scheme for $Mo_2O_5(acac)_2(DMF)_2$ with thermal ellipsoids at the 50% probability level, showing hydrogen bonds; hydrogen atoms are omitted for clarity.

3.2. Molecular structures

Dinuclear compounds with a $[Mo_2O_5]^{2+}$ core have been known for a long time. They can have a single, double or triple bridge, the former being the most common [16]. To the best of our knowledge, the compounds presented here are the first examples of complexes with this core and the acetylacetonate ligand. The molecular structures for $Mo_2O_5(acac)_2(L)_2$ (L = D_2O, DMF) were determined by single-crystal X-ray diffraction analysis. Views of $Mo_2O_5(acac)_2(D_2O)_2$ and $Mo_2O_5(acac)_2(DMF)_2$ are shown in Figs. 1 and 2. Selected bond lengths and angles are listed in Table 2, and hydrogen contacts for $Mo_2O_5(acac)_2(D_2O)_2$ and $Mo_2O_5(acac)_2(DMF)_2$ in Tables 3 and 4, respectively.

In both complexes the molybdenum atom is coordinated in a pseudo-octahedral fashion, as expected, with distortions from the ideal geometry mainly arising from the different nature of the O-donor atom set and the bite of the acac ligand. The two terminal oxo ligands on molybdenum are mutually *cis*, and *cis* to the bridging oxo. One acetylacetonate and one water-d_2 (or dimethylformamide) ligand complete the six-coordination sphere of molybdenum.

The Mo–Ot distances, ranging from 1.678 to 1.703 Å, are within the range usually found in dioxomolybdenum(VI) compounds (1.65–1.75 Å) [17]. The Mo–Ob distances are practically equivalent in both compounds, 1.888 Å. The two sets of Mo–O distances to the acetylacetonate ligands, 2.040 and 2.058 Å (*trans* to Ob), and 2.202 and 2.207 Å (*trans* to Ot), indicate that Ot has a larger *trans*-weakening effect than Ob. The long Mo–OD_2 and Mo–$OCHNMe_2$ (*trans* to Ot), distances of 2.284 and 2.270 Å illustrate the large structural *trans* effect of the Ot ligand.

The angles subtended by the atoms coordinated to molybdenum are also in the range of those found for similar complexes [18]. The largest *cis* O–Mo–O bond angles correspond to the shortest Mo–O bond distances, in agreement with the idea that interligand or interbond repulsions determine such coordination spheres.

With regard to the Mo–O–Mo angles, 160° and 149° for $Mo_2O_5(acac)_2(D_2O)_2$ and $Mo_2O_5(acac)_2(DMF)_2$ respectively, the values are very likely determined by the nature of the neutral ligands. Indeed, in complexes with a $[Mo_2O_5]^{2+}$ core and a single bridging oxo ligand, the

Symmetry transformations used to generate equivalent atoms: #1 $-x+2$, y, $-z+3/2$.

Mo–O–Mo angle varies from 136° to 180° [16]; the fact that in the compound $Mo_2O_5(SCN)_2L_2$ (L = 4,4′-di-*tert*-butyl-2,2′-bipyridine) [19] molecules with linear and angular (156°) Mo–O–Mo arrangements coexist in the crystal, suggest that, in the absence of steric hindrance, the value of this angle plays a minor role in the stability of the compound. Thus in the D_2O complex the moderate intramolecular hydrogen bonds (Table 3 and Fig. 1) involving coordinated water-d_2 might be responsible for the bending of the Mo–O–Mo unit. Similarly, the intramolecular hydrogen contacts of the methynic hydrogen from the coordinated dimethylformamide and oxygen atoms in acetylacetonate (Table 4 and Fig. 2) might be of sufficient relevance to determine the Mo–O–Mo angle in $Mo_2O_5(acac)_2(DMF)_2$.

It should be noted that in these compounds the unit cell contains both enantiomers. The crystal is racemic, with opposite enantiomers related by a crystallographic inversion center.

The crystal packing in both compounds can be described as stacking of alternate planes, each of them formed by one of the enantiomers, linked only by Van der Waals forces. Hydrogen bonds also play a significant role in the packing for $Mo_2O_5(acac)_2(D_2O)_2$; in a given plane each molecule is linked to four others by hydrogen bonds as shown in Fig. 3.

Based on the nature of the ligands and the structures found for the D_2O and DMF derivatives it is probable that

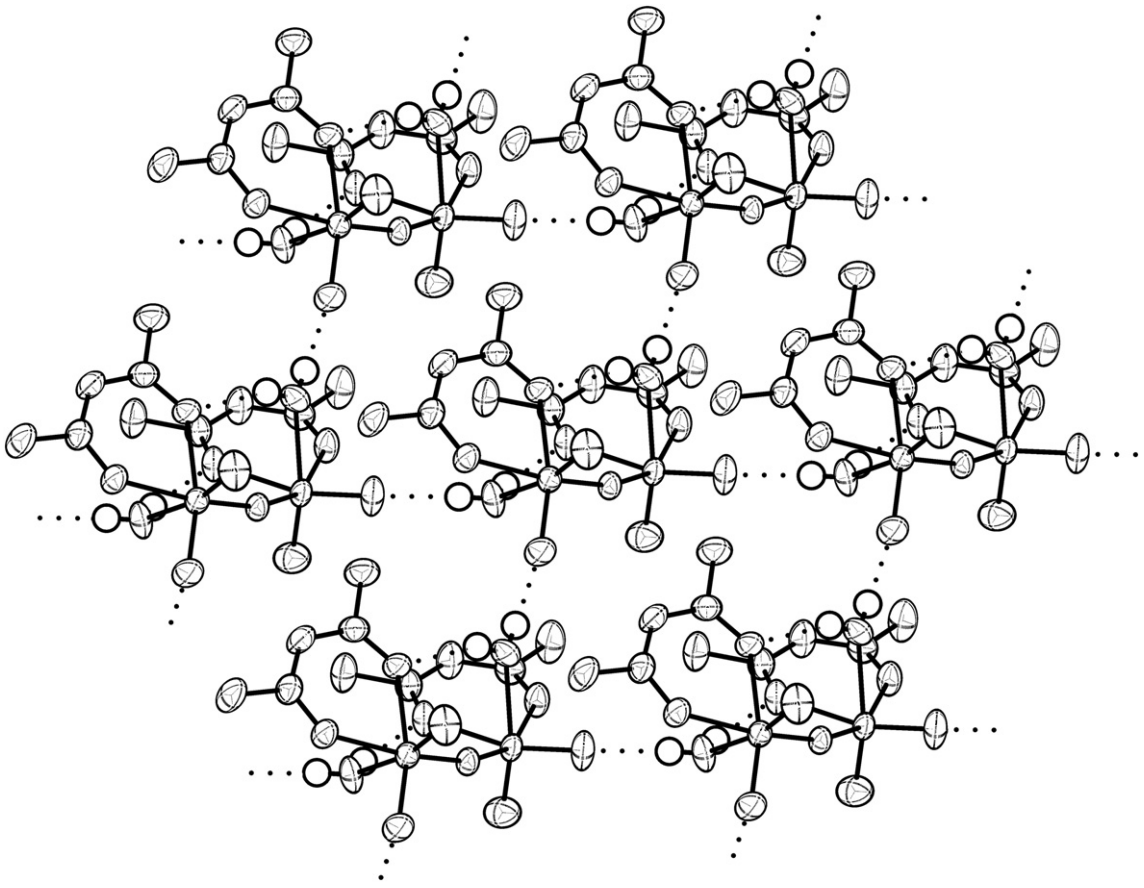

Fig. 3. Crystal structure for $Mo_2O_5(acac)_2(D_2O)_2$ with thermal ellipsoids at the 50% probability level, showing hydrogen bonds; hydrogen atoms are omitted for clarity.

all the compounds possess similar related structures. However, it is also probable that some of them, especially those containing large neutral ligands, might be formed by centrosymmetric molecules to minimize repulsions.

3.3. Catalytic tests in oxotransfer reactions

The behavior of these compounds toward phosphines and phosphites is indicative of oxotransfer processes from the dioxomolybdenum center to the P oxoacceptor. The slow discoloration of the resulting products when DMSO was added and the evolution of the foul-smelling dimethyl sulfide after several hours are indicative of oxo-transference from DMSO to the reduction products. These observations suggest that the compounds possess a low ability to work as oxotransfer catalysts at temperatures near to room temperature. In view that $MoO_2(acac)_2$ has been recently used to catalyze a few relevant oxotransfer processes [6–8], we have measured the rate of oxidation of PPh_3 to $OPPh_3$ by DMSO in presence of $Mo_2O_5(acac)_2(DMSO)_2$ and $MoO_2(acac)_2$, and confirmed that the transformation goes very slowly at room temperature in both cases (24 h, 3% conversion). However the activity increases significantly with temperature. The behavior of the compounds is very similar and *ca.* 24 h are required at 75 °C to get 95% conversion.

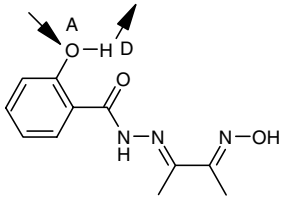
largely uninvestigated. As a ligand, the oxime moiety is potentially ambidentate [15] and can coordinate either through the nitrogen or oxygen atom. The vast literature on structural studies of oxime complexes reveals some interesting features of its coordination behavior. It may coordinate to one metal ion through the nitrogen atom and another metal ion through the oxygen atom. Thus it can form a $\mu_{1,2}(N,O)$ oximato-bridged extended network [16]. In the majority of complexes only the nitrogen atom coordinates to the metal center, and the oxygen atom does not take part in coordination [17]. The hydrogen atom of the oxime –OH group can form potentially strong intra- or intermolecular hydrogen bonds [18] with other donor atoms or groups. Thus metal complexes bearing non-deprotonated oximes may be considered as supramolecular synthons, capable of forming extended supramolecular networks via intermolecular hydrogen bonds. The orientation of the oxime group in these molecules plays a major role in determining the dimensionality of the extended network. Keeping this in mind, we have synthesized Schiff bases of diacetyl monooxime with benzoyl hydrazide, salicyloyl hydrazide, anthraniloyl hydrazide and isonicotinoyl hydrazide, to study the supramolecule forming abilities of these Schiff bases. These aroyl hydrazones have been chosen in such a way that the aroyl moiety varies from being a H-bond donor as well as acceptor (salicyloyl), only a H-bond donor (anthraniloyl) and only a H-bond acceptor (isonicotinoyl). We shall show below that such a systematic variation of the H-bond forming ability has a profound effect on the supramolecular structures of these molecules (see Scheme 1).



dmoBH : *The aroyl moiety has no H bond forming capability*

dmoAH :*The aroyl moiety is a H-bond donor only*

dmoInH :*The aroyl moiety is a H-bond acceptor only*

dmoSH :*The aroyl moiety is both a H-bond donor and H-bond acceptor*

2. Experimental

2.1. Materials

Diacetyl monooxime and methyl/ethyl esters of benzoic, salicylic, anthranilic and isonicotinic acids were obtained from Aldrich and were used without further purification. Organic solvents were purified following published procedures [19]. TEAP was prepared following the literature procedure [20].

2.2. Physical measurements

Elemental analyses were performed on a Perkin–Elmer 2400 C,H,N analyzer. UV–Vis spectra were recorded using a JASCO 7850 spectrophotometer. ^{1}H NMR spectra were recorded on a Bruker 500 MHz spectrometer using $Si(CH_3)_4$ as an internal standard. Cyclic voltammetry was carried out using a PAR Versastat instrument driven by E-chem software. A three-electrode configuration with Pt working and auxiliary electrodes, Ag/AgCl reference electrode and tetraethylammonium perchlorate (TEAP) as the supporting electrolyte was used. The potentials were calibrated against the ferrocene/ferrocenium couple.

2.3. Synthesis of the ligands

All the four aroyl hydrazides were prepared by known methods [21]. The four Schiff base ligands used in this study were prepared by refluxing an equimolar mixture of diacetyl monooxime and the respective hydrazide in methanolic medium. A typical synthesis is described below.

2.3.1. Benzoyl hydrazone of diacetyl monooxime (dmoBH)

To a 30 ml methanolic solution of diacetyl monooxime (1.01 g, 10 mmol), benzoyl hydrazide (1.36 g, 10 mmol) dissolved in 50 ml methanol was added and refluxed for 2.5 h. On reducing the volume to ~30 ml, a white solid appeared. The solid was filtered and thoroughly washed with ethanol (2×5 ml) followed by diethyl ether (2×5 ml). Yield: 1.58 g, 72%. The solid was recrystallised from hot ethanol. *Anal.* Calc. for $C_{11}H_{13}N_3O_2$: C, 60.27; H, 5.94; N, 19.18. Found: C, 60.71, H, 5.85; N, 18.98%. M.p. 190 °C. 2.4. Syntheses of the complexes

All the complexes were prepared following a similar method of reacting a methanolic solution of the metal salt, ligand and Et_3N in a 1:2:2 ratio. Preparation of one of the nickel complexes is described below.

*2.4.1. $Ni^{II}(dmoS)_2$ (**1**) · 2DMF*

To a 50 ml methanolic solution of the ligand dmoSH (0.235 g, 1 mmol) Et_3N (0.101 g, 1 mmol) was added with stirring when the initially colorless solution turned yellow. Addition of $Ni(ClO_4)_2.6H_2O$ (0.183 g, 0.5 mmol) to the yellow solution produced a light brown colored solution. After 5 h of stirring the volume of the solution was reduced to ~20 ml and filtered. A light brown colored solid was obtained. The residue was thoroughly washed with methanol (3 × 3 ml), followed by diethyl ether (2 × 5 ml). The crude product was recrystallised from a solution in a DMF–diethyl ether mixture. Yield 0.229 g, 68%. *Anal.* Calc. for $C_{28}H_{38}N_8NiO_8$: C, 49.89; H, 5.64; N, 16.63. Found: C, 50.02; H, 5.67; N, 16.71%. 2.5. X-ray crystallographic studies

X-ray quality single crystals were obtained by diffusion of a DMF (for **1** and **2**)/DMSO (for **5** and **8**) solution of the compound into liquid diethyl ether. Data were collected

on a Bruker Smart CCD area detector diffractometer at 93(2) K, using graphite monochromated Mo Kα radiation for **1**, **2** and **5** and using Cu Kα radiation at 293(2) K for **8**. The use of Cu Kα radiation for **8** was not for any scientific necessity but because of the limitations of the facility available at that point in time. The data were solved by direct methods and refined by the full matrix least squares method using SHELX-97 [22]. The non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were placed at calculated positions and refined as riding atoms using isotropic displacement parameters. Corrections for Lorentz polarization effects and a semi empirical absorption were applied. The refinements converged with residuals summarized in Table 1.

2.6. Computational studies

All calculations were performed using the HYPERCHEM 7.01 program [23], using the default parameters of the program. The structure of the ligands were optimized first with MM^+, followed by the PM3 method [24]. Single point calculations on the hydrazone ligands in their coordination conformation were performed using the PM3 method, which includes configuration interaction arising from singly excited states arising from the 20 highest occupied and 20 lowest unoccupied molecular orbitals.

3. Results and discussion

3.1. Syntheses

The Schiff base ligands dmoBH, dmoSH, dmoAH and dmoInH were prepared according to the method described above. All the ligands were obtained in good yield and high purity, as confirmed by the spectroscopic data (IR and ^{1}H NMR spectra). All the complexes were obtained easily by stirring the reactants at room temperature in methanol. Use of one equivalent of base for each equivalent of ligand

left the oxime –OH unaffected. So this hydrogen can play an important role in determining the supramolecular architecture through hydrogen bonding.

3.2. Structures of Ni(dmoS)$_2$ (**1**) · 2DMF and Ni(dmoA)$_2$ (**2**) · 2DMF

The molecular structures of **1** and **2** are shown in Figs. 1 and 2, respectively. Selected bond distances and angles of the two molecules are collected in Table 2. The Ni(II) centers in both molecules are in a distorted octahedral geometry with a N_4O_2 donor environment. Each ligand is coordinated through the oxime nitrogen, the imine nitrogen and the enolate oxygen. The oxime oxygen does not participate in coordination. All the six bonds formed by the Ni(II) center are different and they vary in the following order for both molecules: Ni–N_{imine}(hydrazone) < Ni–O < Ni–N_{oxime}. This order is in agreement with earlier reports [25], where, for a tridentate ligand, the metal ligand bonds involving the terminal donors were found to be longer than that involving the central donor. The main reason behind this observation is probably the relatively small bite angles of the chelates which results in a bending away of the terminal donors from the metal d_σ and p_σ orbitals. The average Ni–N_{oxime} and Ni–O bond lengths for the two molecules are very close to each other, while the average Ni–N_{imine} bond length for **2** is larger than that of **1**. A plot of the lone pair energy of the donor atom (L), obtained by PM3 calculation on the deprotonated ligands, versus Ni–L distance was found to be linear (Fig. 3;

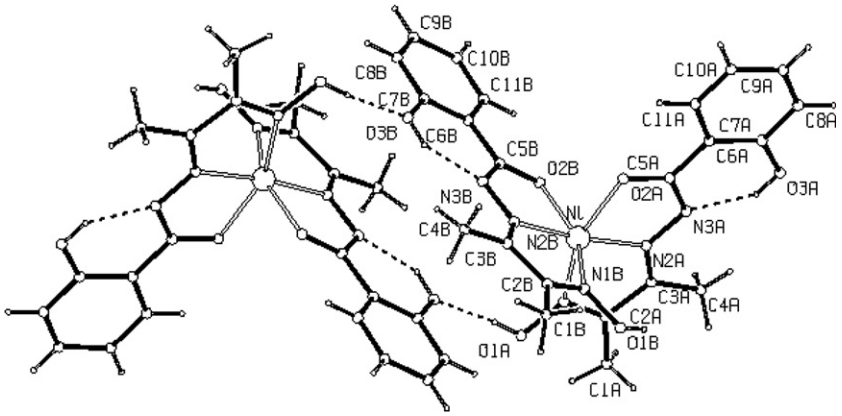

Fig. 4. H-bonded dimer formation for **1**.

|R| = 0.92). Each ligand forms two planar chelate rings and the dihedral angle between these two rings is between 0.90° and 1.34°, suggesting overall planarity of the tridentate ligands which favors substantial electron delocalization over the ligand backbone.

The chelate rings formed by the second ligand are almost orthogonal to those formed by the first. For both **1** and **2** there are two intramolecular hydrogen bonds, formed between N3A and N3B and the phenolic hydrogens H3AA and H3BA for **1** and between N3A and N3B and the aniline hydrogens H4AE and H4BE for **2**.

Though the molecular structures of **1** and **2** are very similar, the three-dimensional supramolecular structures of **1** and **2** are radically different, because of the different H-bonding abilities of the pendant phenolic –OH (for **1**) and anilinic $-NH_2$ (for **2**). Both the compounds contain two co-crystallized DMF molecules in the asymmetric unit, and these co-crystallized solvent molecules play vital roles in linking the close packed individual residues in the crystal into a supramolecular network.

In **1** there are a pair of hydrogen bonds between the oxime hydrogen H1AD and the phenolic oxygen O3B of an adjacent molecule and the oxime hydrogen H1AD of the second molecule with the phenolic oxygen O3B of the first molecule, resulting in formation of self assembled complementary hydrogen bonded dimers (Fig. 4). There are two sets of DMF molecules in the lattice. One set of DMF molecules, whose oxygen and nitrogen atoms are designated as O2S and N2S, respectively (residue 3), are involved in connecting the dimers along the '*b*' axis via O(1B)–H(1BD)···O(2S) and C(12S)–H(12A)···O(1B)[a] hydrogen bonds (Fig. 5, Table 3), resulting in a zig-zag pattern along this axis (symmetry code for a is $1-2x$, $1-2y$, $1-2z$). The other set of DMF molecules, whose oxygen and nitrogen atoms are designated as O1S and N1S (residue 2), connect the dimeric units along the '*a*' axis through C–H···O hydrogen bonds. The C4B–H4BB of one molecule of a dimer is hydrogen bonded to O1S, while the hydrogen of C(22S)–H(22C) bond of the same DMF is weakly hydrogen bonded to the oxime oxygen O1B of an adjacent dimer. Thus each dimer unit is connected to its adjacent two dimer units via a pair of H-bonding DMF molecules, resulting in a one dimensional chain (along the '*a*' axis) of dimers (Fig. 6). Apart from hydrogen bond-

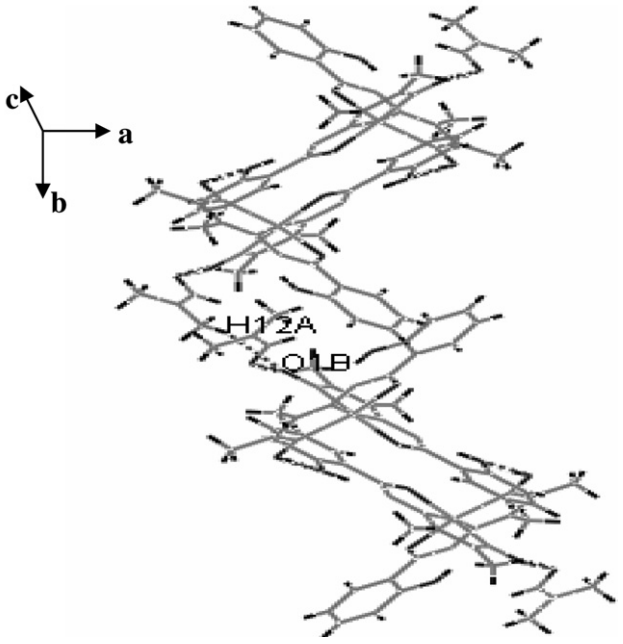

Fig. 5. Propagation of H-bonded dimers of **1** along the '*b*' axis'' view along c^* (perpendicular to the *ab* plane).

Symmetry transformations: #1 = $-x+1$, $-y+1$, $-z+1$; a = $1-2x$, $1-2y$, $1-2z$; b = $-1+x$, y, z.

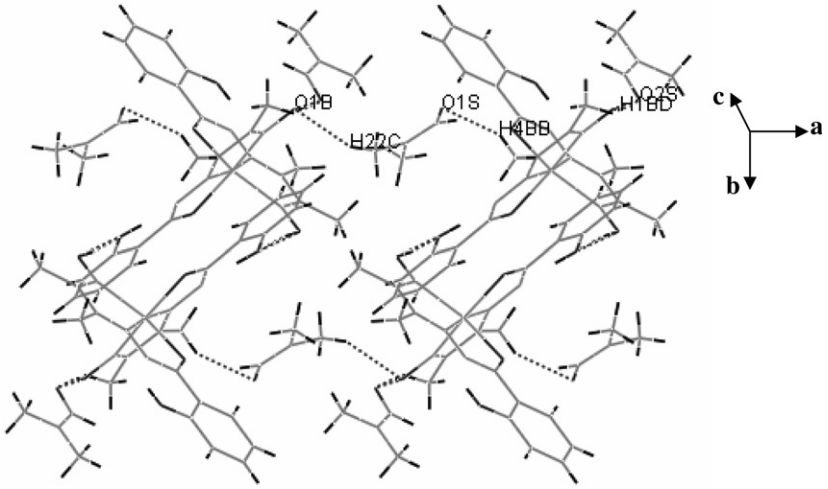

Fig. 6. Propagation of the dimers units of **1** along the '*a*' axis (view along c^*).

ing DMF molecules described above, that bind pairs of adjacent dimers along the '*a*' axis, the adjacent dimers are also connected to each other via complementary C–H···O hydrogen bonds involving the C–H protons H4AB and H1AC of the CH_3 fragments of one dimeric unit and the oxime and amide oxygens O1A and O2B respectively of the other dimeric unit (Supplementary Figure, SF 1). Different parallel one dimensional chains (along the '*a*' axis) are interconnected along the '*c*' axis through C(13S)–H(13C)···O(1S)^b hydrogen bonds (symmetry code for b is $1 + x$, y, $1 + z$) (Supplementary Figure, SF 2).

Unlike **1** · 2DMF, where there are discrete hydrogen bonded dimers in the solid state, there is no such dimer formation in the crystal structure of **2** · 2DMF. Moreover, the oxime oxygens or hydrogens of a given Ni(II) complex moiety (residue 1) do not participate in hydrogen bonding with the adjacent Ni(II) complex moieties, rather they only form hydrogen bonds with nearby solvent molecules.

There are two pendant anilinic $-NH_2$ moieties in a given asymmetric unit. As mentioned earlier each one of these $-NH_2$ groups forms one intramolecular hydrogen bond with the corresponding amide nitrogen. The two intramolecular hydrogen bonds are N(4A)–H(4AE)···N(3A) and N(4B)–H(4BD)···N(3B). Apart from these intramolecular hydrogen bonds, each anilinic $-NH_2$ moiety is also involved in one intermolecular hydrogen bond formation using its own hydrogen atom and the amide oxygen of a neighboring unit (Fig. 7). Thus N4A is connected to O2B

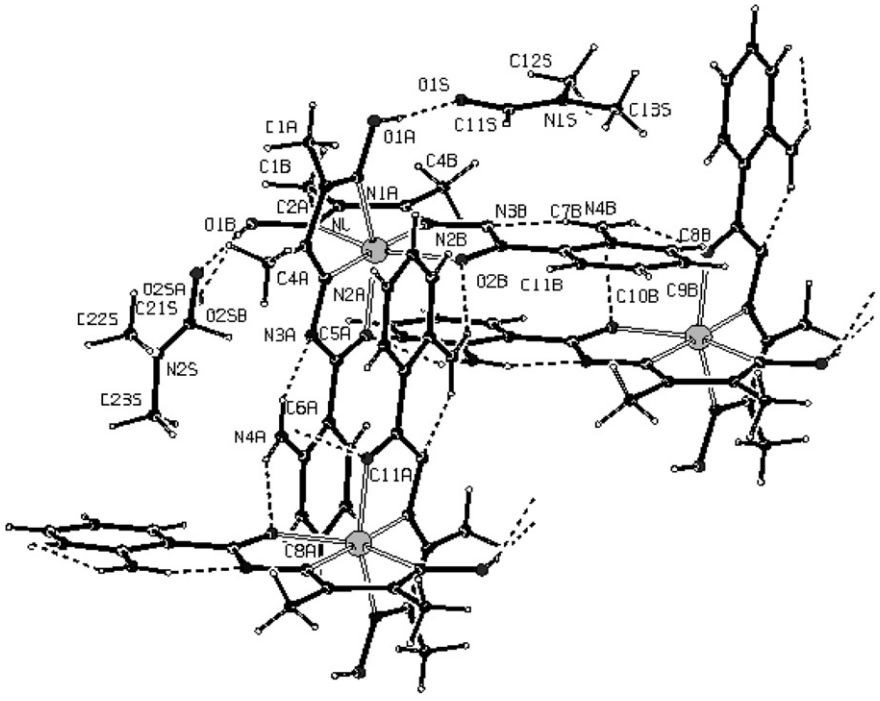

Fig. 7. Complementary hydrogen bonds with the adjacent units in a three-dimensional supramolecular assembly of **2** · 2DMF.

Table 4
Hydrogen bonds for Ni(dmoA)$_2$ (**2**) · 2 DMF (Å and °)

D–H···A	*d*(D–H)	*d*(H···A)	*d*(D···A)	∠(DHA)
O(1A)–H(1AD)···O(1S)	0.84	1.79	2.612(4)	164.1
O(1B)–H(1BD)···O(2SA)	0.84	1.78	2.595(5)	162.0
O(1B)–H(1BD)···O(2SB)	0.84	1.86	2.488(13)	130.3
N(4A)–H(4AD)···O(2B)^{c}	0.88	2.18	2.976(3)	150.9
N(4A)–H(4AE)···N(3A)	0.88	2.06	2.709(4)	129.4
N(4B)–H(4BE)···O(2A)^{d}	0.88	2.11	2.919(4)	153.1

C(8A)–H(8AA)···O(2B)	0.95	2.59	3.337(4)	136.0
C(9A)–H9AA···O(1A)^{e}	0.95	2.43	3.358(5)	165.0

Symmetry transformations: c = 1 − *x*, 1 − *y*, −*z*; d = 1 − *x*, 1 − *y*, −1 − *z*; e = −1 + *x*, −1 + *y*, *z*.

of a neighboring unit via N(4A)–H(4AD)···O(2B)^{c} while N4B is connected to O2A of another neighboring unit via N(4B)–H(4BE)···O(2A)^{d} hydrogen bonds (symmetry code for c is 1 − *x*, 1 − *y*, −*z*; and that for d is 1 − *x*, 1 − *y*, −1 − *z*; Table 4). An identical pair of hydrogen bonds connects O2A and O2B of the first unit with the N4B^{d} and N4A^{c} of the other two units, respectively. N4A^{d}, O2B^{d} and N4B^{c} and O2A^{c} are then involved in similar hydrogen bonding interactions with their adjacent units resulting in the propagation of a complementary hydrogen bonded self assembled infinite zig-zag chain along the '*c*' axis (Supplementary Figure SF4). Apart from the N–H···O bonds described above, which are responsible for the propagation of the infinite chain, there are also complementary C–H···O contacts lending additional stability to the chain. The major such contacts are: C(8A)–H(8AA)···O(2B)^{c} and C(8A)–H(8AA)^{c}···O(2B); C(8B)–H(8BA)···O(2A)^{d} and C(8B)–H(8BA)^{d}···O(2A). Two neighboring chains are connected by C(9A)–H(9AA)···O(1A)^{e} hydrogen bonds (symmetry code for e is −1 + *x*, −1 + *y*, *z*). The co-crystallized DMF molecules are hydrogen bonded to their parent Ni(II) complex unit via O(1A)–H(1AD) ···O(1S) and O(1B)–H(1BD)···O(2SA) interactions.

3.3. Structures of Zn(dmoS)$_2$ (5) and Zn(dmoIn)$_2$ (8)

The Zn(II) complexes **5** and **8** crystallize without incorporating any solvent molecules in their lattice. The molecular structures of both the Zn(II) complexes possess a C_2 symmetry which makes the two ligands coordinated to a given metal ion equivalent (Figs. 8 and 9). Zn(II) is in a highly distorted octahedral environment in both molecules, however in **8** the distortion of the Zn(II) coordination polyhedron is much more severe than that in **5**. Thus in **5** the *cis*-angles vary between 73.47(8)° and 119.10(8)°, while the *trans*-angles are in the range 148.31(7)–162.81(12)° (Table 5). In **8**, the *cis*-angles are in the range 68.19(17)–129.17(18)°, while the *trans*-angles are in the range 142.2(3)–146.17(15)°. The Zn–N(2) and Zn–O(2) distances are shorter in **8** compared to those in **5**, however the Zn–N(1) distance is considerably shorter in **5** than that in **8**. In **5** the five-membered chelate rings involving the oxime nitrogen and imine nitrogen constitute good least square planes (planes containing the atoms Zn, N(1), C(2), C(3) and N(2) and their symmetry related counterparts, $\chi^2 = 53.2$), while the planarity of the chelate rings involving the hydrazone fragments only (i.e. planes containing Zn,

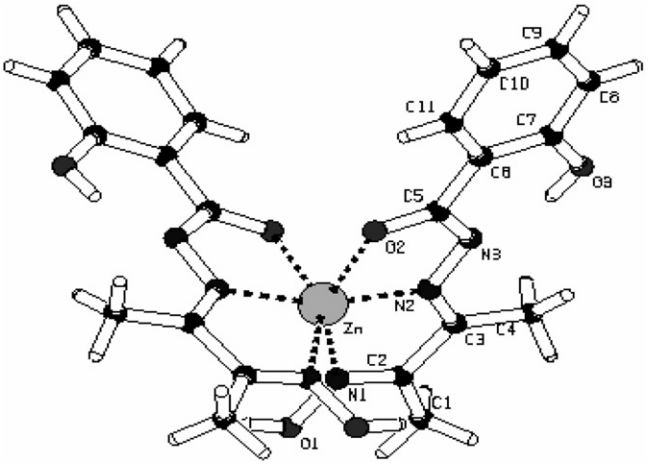

Fig. 8. PLUTON diagram of Zn^{II}(dmoS)$_2$ (**5**) with the atom numbering scheme.

O(2)–Zn–O(2)#1	93.81(11)	95..9(2)
N(2)–Zn–N(1)#1	119.10(8)	83.49(17)
O(2)–Zn–N(1)#1	94.11(8)	99.88(17)
O(2)–Zn–N(1)	148.31(7)	146.17(15)
N(2)–Zn–N(1)	73.47(8)	68.19(17)

Symmetry transformation to get the equivalent position #1: for **5** is −*x*, −*y*, *z*; for **8** is −*x*, *y*, −*z* + 3/2.

N(2), N(3), C(5) and O(2) and their symmetry related counterparts, $\chi^2 = 3108.0$), are relatively poor. The dihedral angle between the two chelate planes formed by a given ligand is ~5°, which may be compared with the value of ~1° found in the corresponding Ni(II) complex **1** · 2DMF, containing the same ligand, indicating the ligand is more puckered in the Zn(II) complex. The metal ligand distances in the Ni(II) complex are also much shorter than the corresponding Zn(II) complex, probably because of the crystal field stabilization energy of Ni(II) as well as due to its more regular geometry. In contrast to **5**, no reasonably good least square plane can be described which includes the oxime nitrogen N(1) or its symmetric equivalent N(1A) for compound **8**, though the hydrazone fragment consisting of N(2), N(3), C(5), O(2) or its symmetrically equivalent counterpart along with Zn form a least square plane with $\chi^2 = 432.0$. The dihedral angle between the chelate planes involving the hydrazone fragment of the two ligands is only 68.5(2)° in **8**, compared to the near ideal value of 88.10(10)° for **5**.

Whereas the Ni(II) complex (**1**) of the salicyloyl hydrazone ligand of DAMO (dmoSH) forms self assembled complementary H-bonded dimers in the solid state, the corresponding Zn(II) complex (**5**) of the same ligand is connected to four similar neighboring units through H-bonds (Table 6). The two pendant phenolic oxygens O3 and O3#1 of each complex unit are H-bonded to the oxime oxygens $O1^f$ and $O1^g$ of two neighboring units via O(1)–$H(1D)^f\cdots O(3)$ and O(1)–$H(1D)^g\cdots O(3\#1)$ ($f = 1/2 + x$, $-y$, $-1/2 + z$, $g = -1/2 - x$, y, $-1/2 + z$). Again the two pendant oxime hydrogens O(1)–H(1D) and O(1#1)–H(1D#1) connect the first unit with two other neighboring units via O(1)–H(1D)···$O(3)^h$ and O(1#1)–H(1D#1)···$O(3)^i$ ($h = -1/2 + x$, $-y$, $1/2 + z$; $i = 1/2 - x$, y, $1/2 + z$). The phenolic oxygens of the complex units f and g and the oxime hydrogens of complex units h and i then participate in further hydrogen bonding to form a layer structure (Figs. 10 and 11). Several such layers are then arranged along the *b* axis to produce a three-dimensional array.

The molecules of **8** self organize into two interpenetrating one-dimensional zig-zag chains through complementary pairs of hydrogen bonding (Fig. 12, Table 7). Each complex moiety is connected to two adjacent moieties (of symmetry $j = x + 1/2$, $-y + 1/2$, $z + 1/2$ and $\mathbf{k} = -x$, y, $-z + 3/2$) via O(1)–H(1D)···$N(4)^j$ and O(1)–$H(1D)^k\cdots$N(4) hydrogen bonds, where any given complex unit acts as an acceptor of two hydrogen bonds (from one oxime hydrogen of each of the two adjacent units) using its two isonicotinic nitrogens N4 and N4#1, and using two of its own oxime hydrogens H1D and H1D#1 to act as donors

Table 6
Hydrogen bonds for $Zn(dmoS)_2$ (**5**) (Å and °)

O(1)–H(1D)···$O(3)^h$	0.84	1.74	2.580(3)	172.8
O(3)–H(3O)···N(3)	0.84	1.69	2.443(3)	148.7

Symmetry transformations: $h = -1/2 + x$, $-y$, $1/2 + z$.

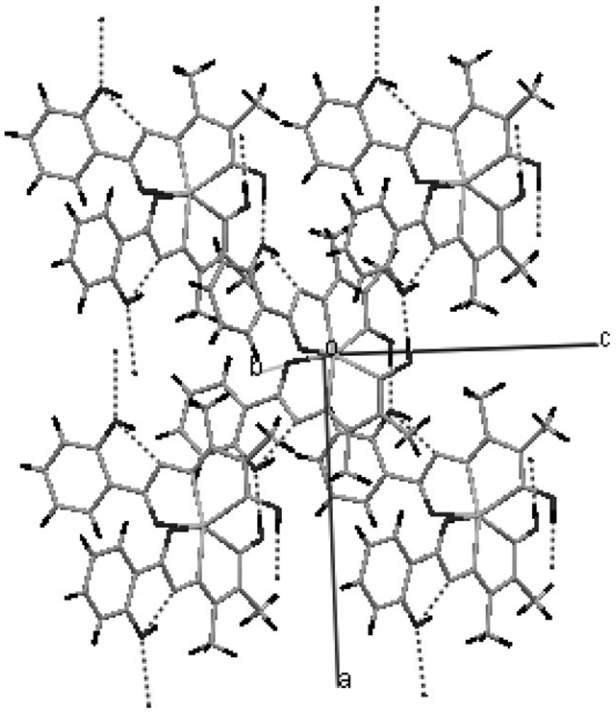

Fig. 10. Layer structure of **5**.

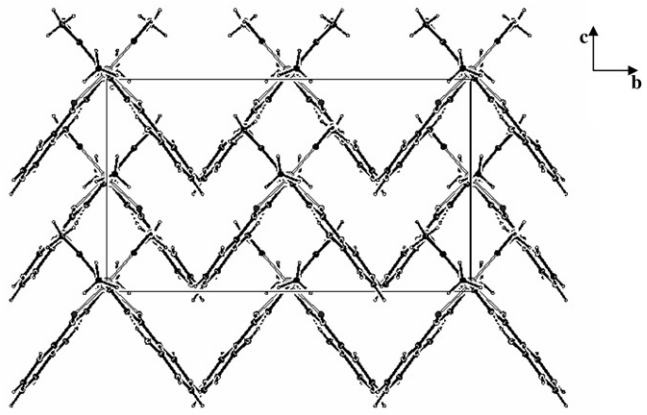

Fig. 11. Packing diagram of **5**.

of two hydrogen bonds, one each to two of its adjacent units described above. As a result of the formation of these hydrogen bonded zig-zag chains, the isonicotinic rings of two adjacent moieties become parallel to each other. These two rings have a C_g–C_g distance of 3.843(4) Å (C_g is the centroid of the ring [26]), resulting in appreciable π–π interactions between them.

3.4. IR spectra

In all the ligands and the corresponding complexes, a broad band in the region 3100–3300 cm^{-1} indicates the presence of hydrogen bonded –OH groups. The ν_{N-H} band for the amide functionality (in the free ligand) and that of the $-NH_2$ group (for anthraniloyl hydrazone) is buried under the broad band of –OH. In all the ligands a strong

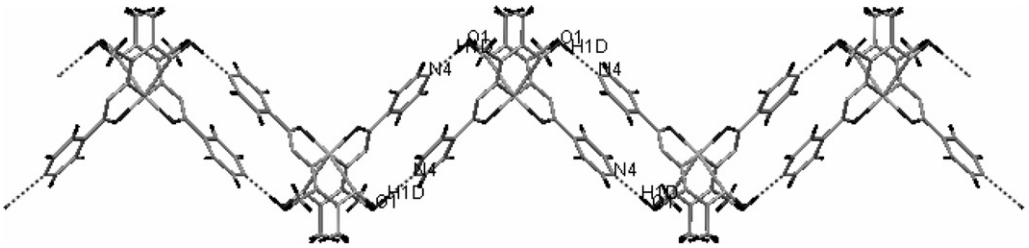

Fig. 12. Two interpenetrating one-dimensional zig-zag chains through complementary pairs of hydrogen bonding in **8** (view along the '*c*' axis).

Table 7
Hydrogen bonds for $Zn(dmoIn)_2$ (**8**) (Å and °)

D–H···A	*d*(D–H)	*d*(H···A)	*d*(D···A)	∠(DHA)
O(1)–H(1D)···N(4)^{j}	0.82	1.87	2.686(7)	171.5

Symmetry transformations: j = $x + 1/2$, $-y + 1/2$, $z + 1/2$.

sharp band is observed spanning the region 1648–1675 cm^{-1}, due to C=O stretching. This band disappears in the complexes and a new band develops around 1050 cm^{-1}. This is a clear evidence of enolization of the ligands during complexation. A moderately strong band in the ligands between 1580 and 1608 cm^{-1} due to $\nu_{C=N}$ shifts to lower energy in the complexes, indicating the participation of the imine nitrogen in coordination. All the ligands and the complexes show one or more weak bands in the region 1050–900 cm^{-1} due to oxime N–O stretching.

3.5. Electronic spectra

Electronic spectra of the nickel complexes in DMSO solution show a broad band of very low intensity ($\varepsilon \sim 30\ M^{-1}\ cm^{-1}$) around ~850 nm. This band seems to be an overlapping of the spin allowed transition $^3A_2 \rightarrow {}^3T_1$ (ν_2) with the spin forbidden transition $^3A_2 \rightarrow {}^1E$ [27]. The ν_3 band is masked by a high intensity charge transfer band around ~380 nm, while the ν_1 band is probably located above 1000 nm, which is beyond the detection range of our instrument. Additionally, there are charge transfer bands and intraligand transitions present in the UV region for all the complexes (Supplementary Figure SF6 and SF7) .

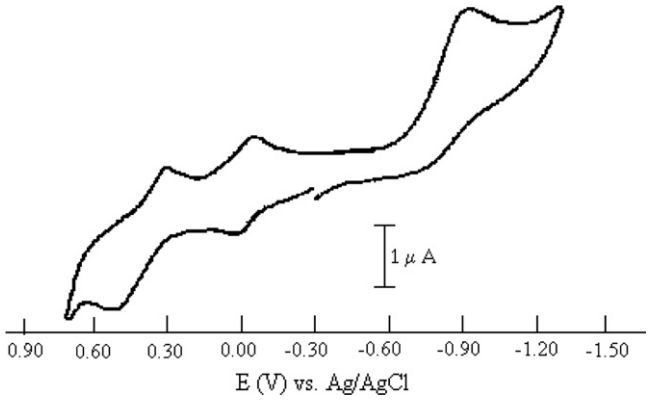

Fig. 13. Cyclic voltammogram (scan rate 10 mV s^{-1}) of $Ni(dmoA)_2$ (**2**) · 2DMF in DMSO solution at a platinum electrode at 298 K.

3.5.1. Electrochemical properties

Anodic scans of all the Ni(II) and Zn(II) complexes show an irreversible or quasi-reversible oxidation in the region 0.40–0.70 V (Table 8). So this oxidation is definitely a ligand based oxidation. The Ni(II) complexes **2** and **3** show a reversible oxidative Ni^{II}/Ni^{III} couple with $E_{1/2}$ values of 0.14 and 0.07 V respectively (Fig. 13). An irreversible reduction peak in the region −0.8 to 1.0 V is obtained for most of the complexes on a cathodic scan. This peak has been assigned to reduction of the ligand.

4. Conclusions

We have designed four ligands in such a way that they can have different types of hydrogen bonding ability. All the ligands contain the oxime moiety, which can be a

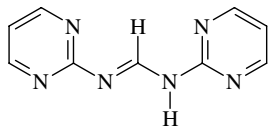
hydrogen bond donor as well as an acceptor. In the salicyloyl hydrazide Schiff bases, the salicyl –OH group can also function as a hydrogen bond donor as well as acceptor. The aromatic $–NH_2$ group in anthraniloyl hydrazone has two hydrogen atoms for donation but it cannot act as a hydrogen bond acceptor. On the other hand, the isonicotinoyl nitrogen can only act as an H-bond acceptor. In $Ni(dmoS)_2$ (**1**) · 2DMF and $Zn(dmoS)_2$ (**5**) the salicyloyl hydrazone moiety forms two different types of hydrogen bonding pattern; in $Ni(dmoS)_2$ (**1**) · 2DMF it forms a linear chain of dimers, whereas in $Zn(dmoS)_2$ (**5**) it forms a hydrogen bonded layer structure. Thus the metal ions can be used to control the stereochemical orientation of the ligands which in turn determine the nature of the hydrogen bonded supramolecular network. In $Ni(dmoA)_2$ (**2**) · 2DMF each $–NH_2$ group in anthraniloyl hydrazone acts as one intramolecular and one intermolecular hydrogen bond donor, leading to the formation of a one dimensional zig-zag chain. A zig-zag chain is also formed in $Zn(dmoIn)_2$ (**8**). In $Ni(dmoS)_2$ (**1**) · 2DMF, $Ni(dmoA)_2$ (**2**) · 2DMF and $Zn(dmoIn)_2$ (**8**) the supramolecular network is obtained via self assembly through complementary hydrogen bonding, however such complementary hydrogen bonding is absent in $Zn(dmoS)_2$ (**5**). As the compounds are soluble only in DMF or DMSO and **1** and **2** only crystallize from DMF while for **5** and **8** crystals were obtained only from a DMSO solution, we cannot investigate the role of the solvent in determining the supramolecular structure, particularly for **1** and **2**.

Acknowledgments

This work has been supported by grants from AICTE and UGC, Government of India, New Delhi. S.N. acknowledges UGC, Government of India, for financial support. We also acknowledge the use of IR and UV–Vis spectrophotometers of our department purchased from a DST (India)-FIST grant.



Appendix A. Supplementary material

CCDC 287946, 287947, 287948 and 287945 contain the supplementary crystallographic data for **1** · 2DMF, **2** · 2DMF, **5** and **8**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.03.063.

HL2

2. Experimental

2.1. General procedures

All manipulations were carried out under dry, oxygen-free nitrogen by using Schlenk techniques, unless otherwise noted. Diethyl ether, hexanes and tetrahydrofuran were purified by distillation from sodium/benzophenone. NMR spectra were measured on a Bruker Avance 300 MHz spectrometer. UV–Vis spectra were obtained from a Shimadzu UV-2450 spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer or Perkin–Elmer CHN-2400.

2.2. Materials

Molybdenum carbonyl was purchased from Strem Chemical Co. and used as received. $Mo_2(O_2CCH_3)_4$ [9], *N*,*N*′-bis(pyrimidine-2-yl)formamidine (H**L1**) [10] and *N*-(2-pyrimidinyl)formamide (H**L2**) [11] were prepared according to the previously reported procedures.

2.3. Preparations of $Mo_2(O_2CCH_3)$(**L1**) $_2$(**L2**) (**1**)

H**L1** (0.40 g, 2.0 mmol) and H**L2** (0.12 g, 1.0 mmol) were placed in a flask containing $Mo_2(O_2CCH_3)_4$ (0.44 g, 1.0 mmol) in 15 mL THF. The mixture was then stirred at room temperature for 1 h to yield a red solution. The solvent was reduced and ether added to induce precipitation. The solid was filtered, washed with ether and then dried under reduced pressure. Yield: 0.23 g (23%). *Anal.* Calc. for $C_{33}H_{34}Mo_2N_{15}O_5$ (MW = 912.61): C, 43.43; H, 3.76; N, 23.02. Found: C, 43.02; H, 3.57; N, 23.42%. ^{1}H NMR (300 MHz, DMSO-d_6): δ 2.53 (s, 3H, CH_3), 6.77 (t, 1H, H^{para}, $^3J_{H-H} = 4.41$ Hz), 7.03 (t, 2H, H^{para}, $^3J_{H-H} = 4.70$ Hz), 7.06 (t, 2H, H^{para}, $^3J_{H-H} = 4.70$ Hz), 8.20 (dd, 1H, H^{meta}, $^3J_{H-H} = 2.35$ Hz), 8.32 (d, 1H, H^{meta}, $^3J_{H-H} = 4.70$ Hz), 8.42 (d, 4H, H^{meta}, $^3J_{H-H} = 4.70$ Hz), 8.48 (d, 4H, H^{meta}, $^3J_{H-H} = 5.00$ Hz), 9.99 (s, 1H, CH), 10.41 (s, 2H, CH). IR (cm^{-1}, KBr disk): 1698(m), 1637(m), 1560(m), 1521(m), 1387(s), 1307(m), 1285(m), 1243(w), 1098(w), 965(w), 882(w), 811(m), 677(w), 641(w), 482(w), 459(w), 442(w). UV–Vis (λ_{max}, nm (ε, M^{-1} cm^{-1})): 453 (3802). Crystals suitable for X-ray crystallography were obtained by layering a THF solution of **1** with hexanes.

2.4. Preparation of trans-Mo_2(**L1**)$_2$ (**L2**)$_2$ (**2**)

H**L1** (0.40 g, 2.0 mmol) and H**L2** (0.24 g, 2.0 mmol) were placed in a flask containing $Mo_2(O_2CCH_3)_4$ (0.44 g, 1.0 mmol) in 15 mL CH_3CN. The mixture was then stirred at room temperature for 1 h to yield a red solution. The solvent was reduced and ether added to induce precipitation. The red solid was filtered, washed with ether and then dried under reduced pressure. The ^{1}H NMR spectrum shows that only one complex form was obtained, which was characterized as *trans*-Mo_2 (**L1**)$_2$(**L2**)$_2$ by X-ray crystallography. Plate red crystals were obtained by layering the red solution of *trans*-Mo_2(**L1**)$_2$(**L2**)$_2$ in CH_3CN with ether. 0.30 g (31%). *Anal.* Calc. for $C_{28}H_{22}Mo_2N_{18}O_3$ (MW = 834.52): C, 44.14; H, 4.01; N, 25.73. Found: C, 44.17; H, 3.72; N, 26.12%. ^{1}H NMR (300 MHz, DMSO-d_6): δ 6.86 (t, 2H, H^{para}, $^3J_{H-H} = 4.41$ Hz), 7.03 (t, 4H, H^{para}, $^3J_{H-H} = 4.70$ Hz), 8.45 (d, 10H, H^{meta}, $^3J_{H-H} = 4.70$ Hz), 8.75 (dd, 2H, H^{meta}, $^3J_{H-H} = 2.35$ Hz), 10.01 (s, 2H, CH), 10.36 (s, 2H, CH). IR (cm^{-1}, KBr disk): 1660(m), 1581(m), 1560(m), 1534(m), 1516(s), 1426(s), 1385(s), 1351(s), 1301(w), 1288(s), 1258(m), 1205(w), 1185(w), 1100(w), 1016(w), 991(w), 976(m), 939(m), 882(m), 817(m), 790(m), 735(w), 705(w), 652(w), 640(w), 606(w), 531(w), 440(w). UV–Vis (λ_{max}, nm (ε, M^{-1} cm^{-1})): 538 (1419).

2.5. Preparation of cis-Mo_2(**L1**)$_2$ (**L2**)$_2$ (**3**)

When the reaction described for the preparation of **2** was carried out in 15 mL MeOH, a red solid was obtained. The ^{1}H NMR spectrum shows that two complexes were formed in about equal amounts. By layering the solution of the red solid in THF with ether, both plate and hexagonal crystals were formed and were separated manually. The plate crystals were characterized as **2**, while the hexagonal ones as **3** by X-ray crystallography. Yield for **3**: 0.12 g (14%). *Anal.* Calc. for $C_{28}H_{22}Mo_2N_{18}O_3$ (MW = 834.52): C, 44.14; H, 4.01; N, 25.73. Found: C, 44.22; H, 3.82; N, 26.01%. ^{1}H NMR (300 MHz, DMSO-d_6): δ 6.81 (t, 2H, H^{para}, $^3J_{H-H} = 4.70$ Hz), 6.97 (t, 2 H, H^{para}, $^3J_{H-H} = 4.41$ Hz), 7.00 (t, 2H, H^{para}, $^3J_{H-H} = 4.70$ Hz), 8.11 (d, 4H, H^{meta}, $^3J_{H-H} = 4.70$ Hz), 8.45 (d, 4H, H^{meta}, $^3J_{H-H} = 4.70$ Hz), 8.53 (dd, 2H, H^{meta}, $^3J_{H-H} = 2.35$ Hz), 8.65 (dd, 2H, H^{meta}, $^3J_{H-H} = 2.35$ Hz), 10.08 (s, 2H, CH), 10.37 (s, 2 H, CH). IR (cm^{-1}, KBr disk): 1650(m), 1519(m), 1427(m), 1388(s), 1288(m), 1245(w), 1188(w), 995(s), 875(s), 767(m), 640(w), 601(w). UV–Vis (λ_{max}, nm (ε, M^{-1} cm^{-1})): 533 (1790).

2.6. Preparations of Mo_2(**L2**)$_4$ (**4**)

A solution of Na**L2** was prepared by stirring $NaNH_2$ (0.078 g, 2.0 mmol) and H**L2** (0.25 g, 2.0 mmol) in THF (20 mL) at room temperature for 1 h. The resulting solution was then transferred to a flask containing a solution of $Mo_2(O_2CCH_3)_4$ (0.22 g, 0.5 mmol) in 20 mL THF. A

Crystals suitable for X-ray crystallography were obtained by slow diffusion of ether into a THF solution of **4**.

3. X-ray crystallography

The diffraction data of complexes **1**–**4** were collected at 22 °C on a Siemens P4 diffractometer or Siemens SMART CCD diffractometer, which was equipped with graphite-monochromated Mo Kα ($K_\alpha = 0.71073$ Å) radiation. The crystals suitable for X-ray crystallography were sealed inside the capillary. Data reduction was carried by standard methods with use of well-established computational procedures [12]. The structure factors were obtained after Lorentz and polarization correction. The structure of complex **1** was solved by a direct method and refined by using least-squares refinements [13]. The final agreement factors were $R_1 = 0.0699$, w$R_2 = 0.1177$. The crystallographic procedures for complexes **2**–**4** were similar to those for **1**. Disordered solvent molecules, presumabled to be THF, are presented in complexes **1**, **3** and **4,** and the PLATON/

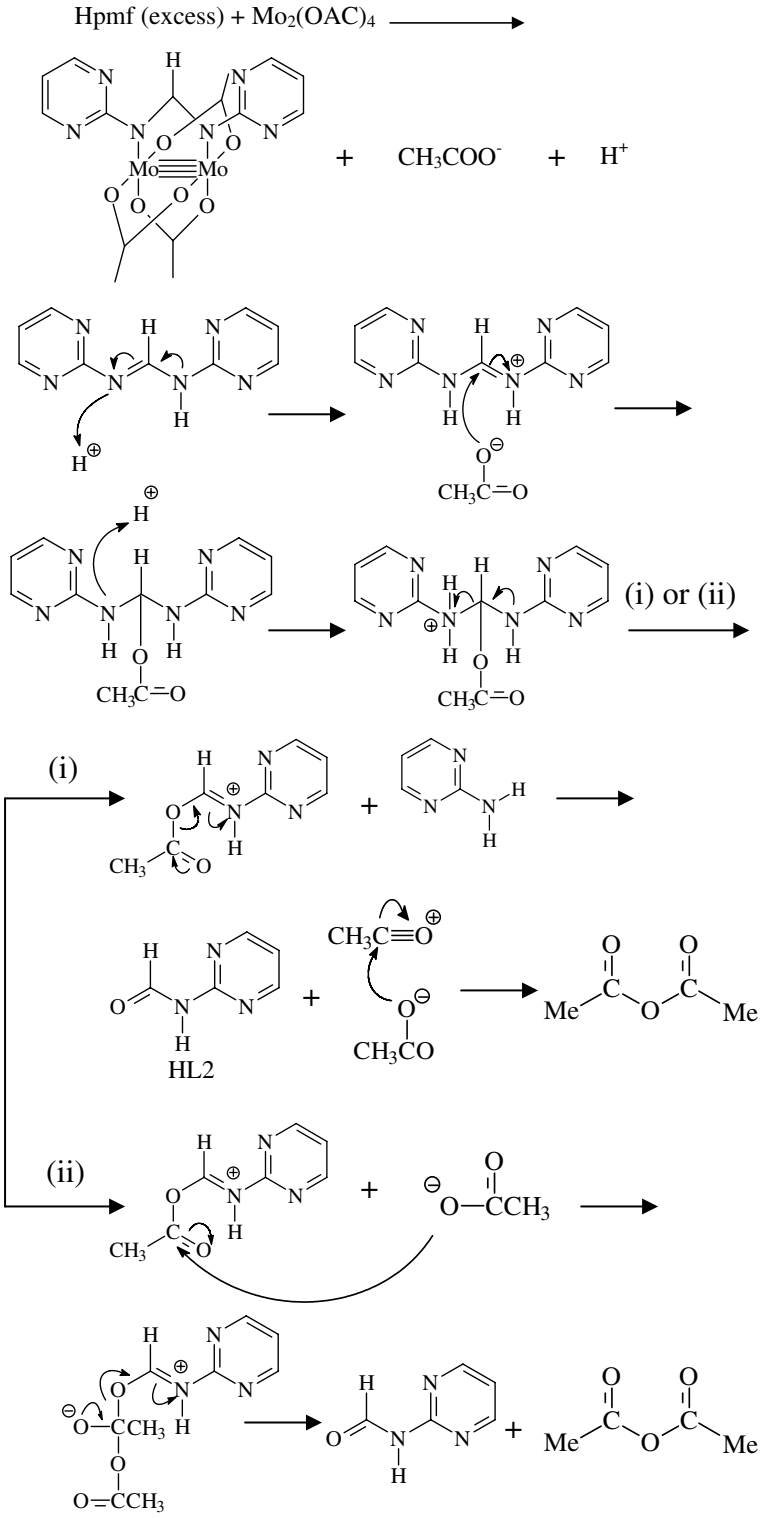
SQUEEZE tool was applied [14]. Large solvent void volumes were observed for these structures. The relative percentages per unit cell are 40.4% for **1** (1730.8 out of 4281.2 $Å^3$), 32.4% for **3** (1386.8 out of 4275.9 $Å^3$) and 20.4% for **4** (2029.7 out of 9960 $Å^3$). Where relevant, data cited are given without disordered solvent contributions. Basic information pertaining to the crystal parameters and structure refinement is summarized in Table 1. Selected bond distances and angles for **1**–**4** are given in Tables 2–5.

4. Results and discussion

4.1. Syntheses and spectroscopic studies



By the reaction of 2 equiv. of *N*,*N*′-bis(pyrimidyl-2-yl)formamidine (H**L1**) and 1 equiv. of *N*-(2-pyrimidinyl)formamide (H**L2**) with 1 equiv. of $Mo_2(O_2CCH_3)_4$ in THF, the complex $Mo_2(O_2CCH_3)(\mathbf{L1})_2(\mathbf{L2})$ (**1**) was obtained. When the reaction was carried out in a 2:2:1 ratio in CH_3CN, the complex *trans*-$Mo_2(\mathbf{L1})_2(\mathbf{L2})_2$ (**2**) was isolated. Both complexes **2** and *cis*-$Mo_2(\mathbf{L1})_2(\mathbf{L2})_2$ (**3**) can be prepared if the reaction in a 2:2:1 ratio was carried out in CH_3OH. The plate and hexagonal crystals which were obtained for **2** and **3**, respectively, were separated manually. To our best knowledge, it is the first time that both *cis* and *trans* forms of dimolybdenum complexes containing formamidinate ligands are able to be separated by using different solvents. The complex $Mo_2(\mathbf{L2})_4$ (**4**) was prepared by reacting the sodium salt of *N*-(2-pyrimidinyl)formamide (H**L2**) with $Mo_2(O_2CCH_3)_4$ in THF. These complexes were characterized by spectroscopic methods and their structures determined by X-ray crystallography. There were distinct color changes from yellow to red in these reactions. These complexes are air-sensitive and decompose in air after several days. In the UV–Vis spectra, complexes **1**–**4** show the lowest energy bands at 453, 538, 533 and 530 nm, respectively, which can be assigned to the $\delta \rightarrow \delta^*$ excitations of the Mo–Mo quadruple bonds. For the two isomers **2** and **3**, the *trans* form is red-shifted by 5 nm from the *cis* form. Complexes **1**–**3** were first obtained unexpectedly with low yields in the reactions of $Mo_2(O_2CCH_3)_4$with excess H**L1** in different solvents, presumably due to the decomposition of H**L1** to H**L2**. Two possible decomposition pathways

Scheme 1. Two possible decomposition pathways for the formation of H**L2**.

are proposed, Scheme 1, involving the attack of the hydroxyl oxygen atom of the CH_3COO^- anion obtained from the reaction of $Mo_2(O_2CCH_3)_4$ with excess H**L1** to the methine carbon atom of the protonated H**L1** ligand, followed by breaking of the N–C bond to give H**L2**, 2-aminopyrimidine and acetic anhydride. The acetic anhydride was characterized by its IR spectrum. The acetyl cation, CH_3CO^+, has been used in the acetylation of benzene [15] and the formation of acetic anhydride by decomposition of acetic acid adsorbed on Ni(111) has been reported [16].

4.2. Structure of *1*

Red crystals of **1** conform to the space group *Pnma* with eight molecules in a unit cell. Fig. 1a shows the ORTEP diagram for **1**. The molecular structure of **1** consists of two molybdenum atoms [Mo–Mo = 2.0951(17) Å] which are spanned by one bridging acetate, two **L1** and one **L2** ligand. The **L1** ligands are coordinated to the molybdenum centers through the two central nitrogen atoms, leaving the pyrimidyl nitrogen atoms uncoordinated and resulting in Mo···N intra-molecular interactions of 3.067 and 3.114 Å to the pyrimidyl nitrogen atoms. The **L2** ligand is coordinated to the metal centers through one of the pyrimidyl nitrogen atoms and the amine nitrogen atom, resulting in a Mo···O distance of 3.174 Å to the uncoordinated oxygen atom. The observed Mo–N distances fall in a wide range from 2.140 to 2.159 Å in **1**. The molecules of **1** are interlinked through extensive C–H···N (H···N = 2.536 Å, ∠C–H···

N = 162.9°) and C–H···O (H···O = 2.346 Å, ∠C–H ···O = 174.2°) interactions to form a 3-D structure, Fig. 1b. Intermolecular π–π interactions through the pyrimidyl rings with interplanar distances of 3.598 Å between the pyrimidyl rings are also found.

4.3. Structures of *2* and *3*

Red crystals of **2** and **3** conform to the space group $P2_1/c$ with two and four molecules in a unit cell, respectively. Figs. 2 and 3 show the ORTEP diagrams for **2** and **3**, respec-

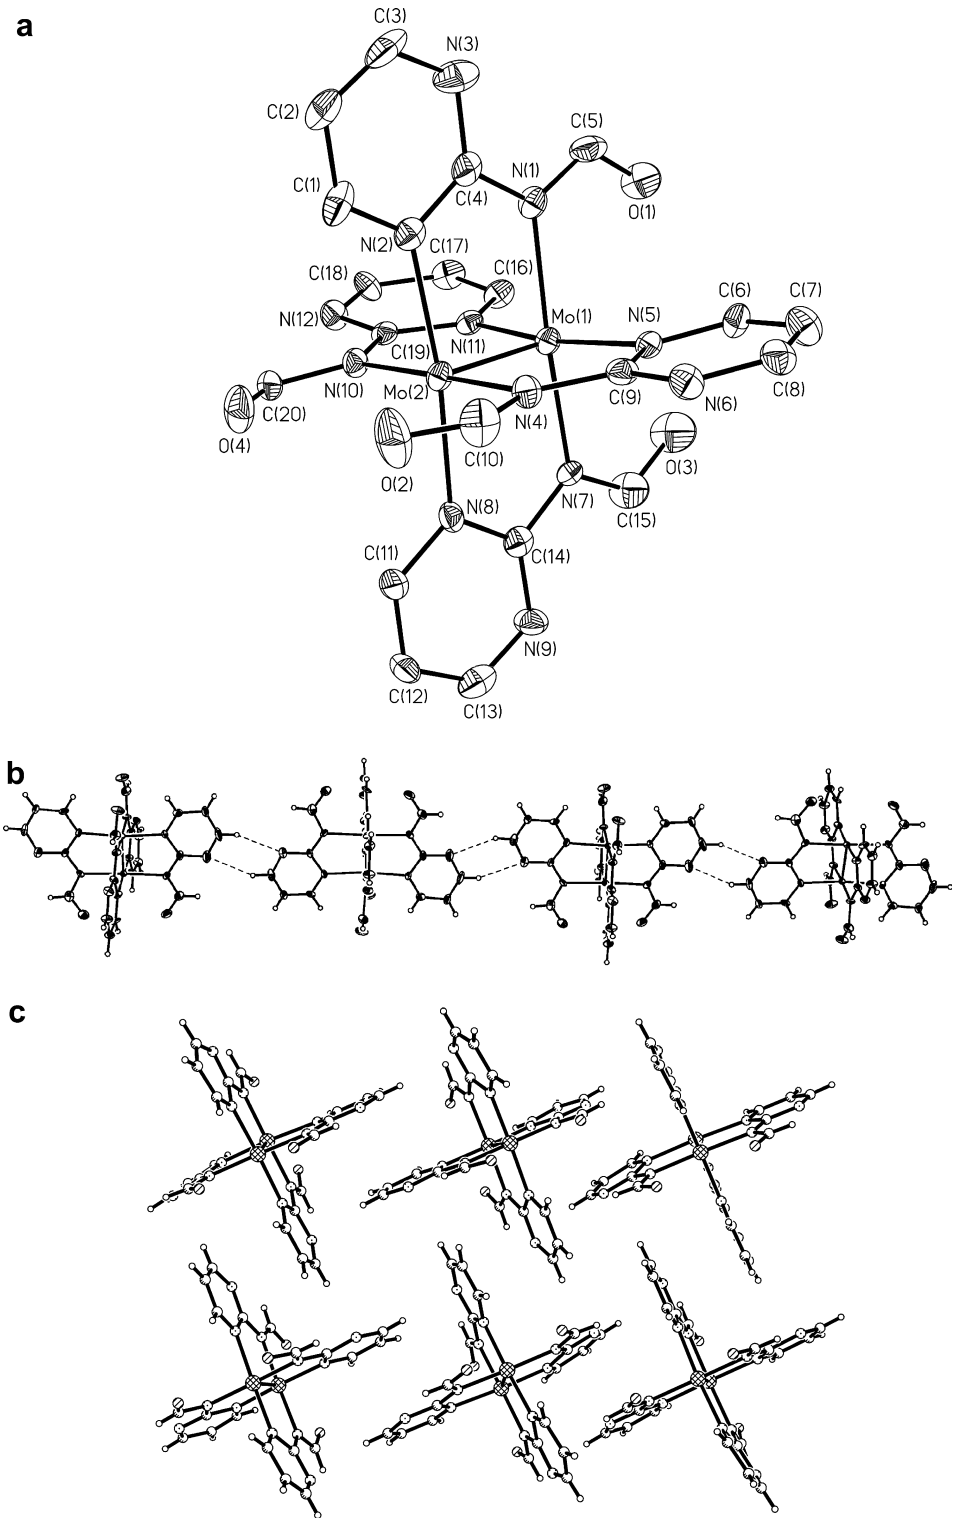

Fig. 4. (a) An ORTEP diagram showing one of the three independent molecules of **4**, which contains Mo(1) and Mo(2) atoms. Thermal ellipsoids are shown at the 30% probability level for the molecular structure. (b) A diagram showing the linear chain of the molecules linked by the self-complementary double C–H···N hydrogen bonds. (c) A diagram showing the intermolecular π–π and C–H···π interactions of **4**.

tively. The molecular structure of **2** consists of two molybdenum atoms [Mo–Mo = 2.103(1) Å] which are spanned by two *trans* **L1** and two *trans* **L2** ligands, while the two molybdenum atoms [Mo–Mo = 2.1017(3) Å] of **3** are spanned by two *cis* **L1** and two *cis* **L2** ligands. The **L1** and **L2** ligands in **2** and **3** are coordinated to the molybdenum centers with bridging modes similar to those in **1**, resulting in Mo···N and Mo···O intra-molecular interactions in the range of 3.118–3.220 and 3.096–3.191 Å, respectively. The Mo–N bond distances fall in the range from 2.146 to 2.200 Å in **2** and 2.142 to 2.197 Å in **3**. The cis–trans isomerism does not lead to significant differences in the Mo–Mo and Mo–N distances. While the molecules of **2** are interlinked through π–π interactions with interplanar distances of 3.672 Å between the pyrimidyl rings, those of **3** are interlinked through both C–H···O (H···O = 2.415, 2.388 Å, ∠C–H···O = 158.5°, 163.1°) and intermolecular π–π interactions with interplanar distances of 3.682 Å.

Complexes **2** and **3** establish the first pair of *trans* and *cis* forms of dimolybdenum complexes containing formamidinate ligands. For comparison it is noted that a pair of dimolybdenum complexes containing benzanidinate and acetate ligands, *trans*- and *cis*-$Mo_2(O_2CCH_3)_2$[PhC(NSi$(CH_3)_3)_2]_2$, have been reported, where the benzamidinates adopt bridging and chelating bonding modes, respectively [17].

4.4. Structure of 4

Red crystals of **4** conform to the space group $P\bar{4}c2$ with 14 molecules in a unit cell. Each asymmetric unit contains one and three quarters of the dinuclear molecules, including a full molecule [Mo(1)–Mo(2)], a half molecule [Mo(3)–Mo(4)] and a quarter of the molecule [Mo(5)–Mo(5A)]. Fig. 4a shows the ORTEP diagram of one of the three independent molecules containing the Mo(1) and Mo(2) atoms. The molecular structure of **4** consist of two molybdenum atoms which are spanned by four **L2** ligands. The Mo–Mo separations are 2.0866 (10), 2.0826 (12) and 2.084 (2) Å, and the observed Mo–N distances fall in a wide range from 2.138(7) to 2.183(8) Å. The **L2** ligands are coordinated to the metal centers through the two nitrogen atoms, resulting in Mo···O intra-molecular interactions in the range from 3.039–3.116 Å. Noticeably, the molecules of **4** are interlinked though self-complementary double C–H···N (H···N = 2.519 Å, ∠C–H···N = 154.7°) hydrogen bonds to form linear chains, Fig. 4b, which are linked through C–H···O (H···O = 2.513 Å, ∠C–H···O = 98.7°) hydrogen bonds. These molecules are also linked through intermolecular π–π and C–H···π interactions through the pyrimidyl rings and the pyrimidyl hydrogen atoms. The interplanar distances between the pyrimidyl rings are 3.716 and 3.891 Å, while the C–H···π distances are 2.898 and 3.280 Å, Fig. 4c.

Complex **4** invites comparisons with Mo_2[pyNC(O)$CH_3]_4$ [18] and Mo_2[pyNC(O)$CH_2CH_3]_4$ [Mo–Mo = 2.0806(4), 2.0826(6) and 2.0869(4) Å] [19]. The structure of the complex Mo_2[pyNC(O)$CH_3]_4$ was solved in the space group $I4/m$ by using a disordered model and thus its ligand arrangements cannot be certain [18]. While the amido oxygen atoms in the ligands of the three forms of Mo_2[pyNC(O)$CH_2CH_3]_4$ are either toward the axial position of the Mo_2 unit or away from that position [19], all the amido oxygen atoms in the three independent molecules of **4** are toward the axial positions. Since the ligands in Mo_2[pyNC(O)$CH_2CH_3]_4$ and **4** are similar in nature, no significant difference in their Mo–Mo distances are observed.

4.5. Structural comparisons

The pmf^- ligands in complexes **1**–**3** are not flat but are twisted about the C–N bonds, with dihedral angles of 17.2 for **1**, 10.7 for **2** and 19.8 and 26.0° for **3** between the two pyrimidyl rings of the pmf^- ligands, presumably due to the formation of Mo···N and Mo···O axial interactions. It is noted that complex **3** shows the largest dihedral angle, which can be ascribed to the fact that the*cis* form adopts the more sterically crowded environment for the

Table 6
Structural comparisons for complexes **1**–**4**, units in Å

Compound	Mo–Mo	Mo–N	Mo···N	Mo–O	Mo···O	π–π interaction	C–H···π interaction
1	2.0951(17)	2.140–2.159	3.067 3.114	2.124 2.154	3.174	3.598	
2	2.103(1)	2.146–2.200	3.118 3.220		3.163	3.672	
3	2.1017(3)	2.142–2.197	3.120 3.126 3.173 3.173		3.096 3.191	3.682	
4	2.0866(10) 2.0826(12) 2.084(2)	2.138–2.183			3.039–3.116	3.716, 3.891	2.898, 3.280

pairs of **L1** and **L2** ligands. However, no significant relationship between the dihedral angles and the Mo···N distances is observed, indicating that the nature of the weak interactions such as C–H···O, C–H···N hydrogen bonds and π–π interactions, which appear frequently in these complexes to self-assemble their molecules, play an important role in determining these angles and distances.

A comparison of then structural parameters for complexes **1**–**4** is listed in Table 6. The Mo–Mo distances are typical for complexes containing a quadruple bond and fall into the 'normal' range of 2.06–2.17 Å for the quadruply bonded dimolybdenum complexes [18]. It is also seen that complexes **1**–**3**, which contain both Mo···N and Mo···O axial interactions, show significantly longer Mo–Mo distances than complex **4** which has only Mo···O interactions.

[16,17], Burns and Hill [18] and Mereiter [19]. Mereiter [19] studied the crystal structure of natural and synthetic curite. Dissolution experiments on crystals of synthetic curite were recently described by Schindler et al. [20]. Infrared spectrum of curite was described without any details by Gevork'yan et al. (together with curite thermal decomposition) [21,22]. Thermal analysis and infrared spectra of curite were published by Čejka et al. [23] and reviewed in detail by Čejka [24]. Kubatko et al. [25,26] recently described the thermodynamics of curite formation.

The sheet structure of curite crystals has orthorhombic symmetry, space group *Pnam*, and unit-cell parameters: *a*, 12.53–12.58; *b*, 13.01–13.03; *c*, 8.39–8.40 Å, $Z = 2$ [3,16,17]. Compositional variability has been observed in curite [14,16,17]. The structure of curite contains three symmetrically unique uranium atoms in form of the $(UO_2)^{2+}$ units, forming $UO_2\Phi_4$ and $UO_2\Phi_5$ polyhedra ($\Phi = O^{2-}$ or OH^-). One uranium cation $U^{6+}(1)$ is coordinated by three atoms of O^{2-} and one OH^-units at the equatorial position of a tetragonal bipyramid, while the other two uranium cations $U^{6+}(2)$ and $U^{6+}(3)$ are both coordinated by three O^{2-} and two OH^- units thus forming uranyl pentagonal bipyramids. There are two structurally distinct Pb^{2+} in the curite structure, both coordinated by six uranyl oxygens, one equatorial O^{2-} of uranyl polyhedra and two water molecules. One symmetrically distinct H_2O site is present [3,16,17].

According to Li and Burns, the geometries of the Pb polyhedra are distorted owing to the electron lone pair stereo activity of Pb^{2+} [16,17]. Because of Pb content variability in the interlayer (some Pb sites are not fully occupied), the charge-balancing mechanism $O^{2-} \Longleftrightarrow OH^-$ was assumed in the uranyl anion sheets in the crystal structure of curite. Li and Burns studied 14 crystals of natural curite and one crystal of synthetic curite and concluded that the structural formula of curite may be written as $Pb_{3+x}(H_2O)[(UO_2)_4O_{4+x}(OH)_{3-x}]_2$. From the bond-valence parameters point of view, some O^{2-} ions may be under bonded. The structure of curite contains water molecules and hydroxyl ions. An appropriate arrangement of hydrogen-bonding network present in the curite structure is therefore expected.

Raman spectroscopy has proven very useful for the study of minerals [27–34]. Indeed Raman spectroscopy has proven most suitable for the study of diagentically related minerals as often occurs with uranyl minerals [29–31,33,35]. Some previous studies have been undertaken by the authors using Raman spectroscopy to study complex secondary minerals formed by crystallisation from concentrated sulphate solutions [36]. The significance of this work rests with the use of Raman spectroscopy to analyse complex mixtures of diagenetically related minerals. Often when studying secondary minerals of uranium, complex mixtures occur. Raman spectroscopy can focus on individual crystals and analyse these individual crystals. This paper forms a part of our Raman and infrared spectroscopy research of secondary minerals including uranyl minerals.

2. Experiments

2.1. Minerals

The curite samples used in this work were obtained from the Mineralogical Research Company and originated from Shinkolobwe Mine and The Ranger Uranium Mine, Northern Territory, Australia. The minerals were analysed by X-ray diffraction for phase purity and for chemical composition by energy dispersive X-ray analysis (EDX).

2.2. Raman spectroscopy

Crystals of curite were placed on the stage of an Olympus BHSM microscope, equipped with 10× and 50× objectives and part of a Renishaw 1000 Raman microscope system, which also includes a monochromator, a filter system and a charge coupled device (CCD). Raman spectra were excited by a HeNe laser (633 nm) at a resolution of 2 cm^{-1} in the range between 100 and 4000 cm^{-1}. Repeated acquisition using the highest magnification was accumulated to improve the signal to noise ratio. Spectra were calibrated using the 520.5 cm^{-1} line of a silicon wafer. In

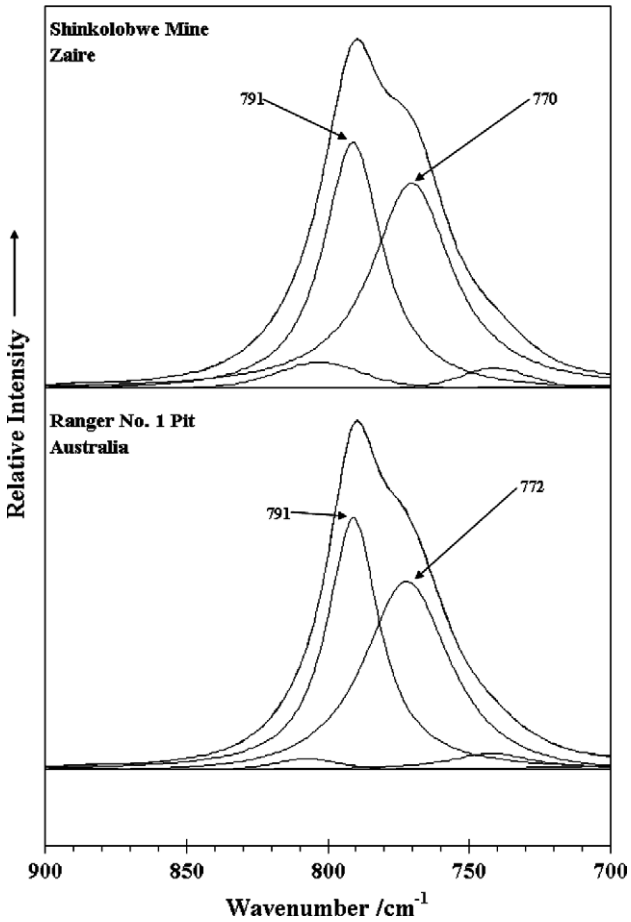

Fig. 1. Raman spectra of curite in the 700–900 cm^{-1} region from The Ranger Uranium Mine and Shinkolobwe Mine.

order to ensure that the correct spectra are obtained, the incident excitation radiation was scrambled. Previous studies by the authors provide more details of the experimental technique [37–41].

Spectral manipulation such as baseline adjustment, smoothing and normalisation were performed using the Spectracalc software package GRAMS (Galactic Industries Corporation, NH, USA). Band component analysis was undertaken using the Jandel 'PEAKFIT' software package which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done using a Lorentz–Gauss cross-product function with the minimum number of component bands used for the fitting process. The Gauss–Lorentz ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations of $r^2 > 0.995$.

2.3. Infrared spectroscopy

Infrared spectra were obtained using a Nicolet Nexus 870 FTIR spectrometer with a smart endurance single bounce diamond ATR cell. Spectra over the 4000–525 cm^{-1} range were obtained by the co-addition of 64

scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectral manipulation such as baseline adjustment, smoothing and normalisation was performed using the GRAMS® software package (Galactic Industries Corporation, Salem, NH, USA).

3. Results and discussion

As mentioned above, the space group of curite is $D_{2h}{}^{16}$–*Pnam*: $C_1(8)$, $2C_i(4)$, $C_s(4)$, $Z = Z_p = 2$. In the unit cell, there are three different types of uranium: U(1) in $C_s(4)$ position forms one kind of tetrahedral bipyramidal polyhedra [$(UO_2)O_3(OH)$], while U(2) and U(3) in $C_s(4)$ and $C_1(8)$ positions thus form two kinds of pentagonal bipyramidal polyhedra [$(UO_2)O_3(OH)_2$] [14–16,19,42]. Factor group analysis of the nonsymmorphic space group, in which curite crystallizes, is isomorphous with point group D_{2h}. The symmetry lowering is accompanied with infrared activation of the ν_1 $(UO_2)^{2+}$ symmetric stretching vibration and splitting of the ν_2 (δ) $(UO_2)^{2+}$ bending vibration [14,23,24]. Thus, all (UO_2) vibrations are both Raman and infrared active.

3.1. Raman spectrum of curite

The Raman spectra of curite from The Ranger Uranium Mine and Shinkolobwe Mine in the 700–900 cm^{-1} region are shown in Fig. 1. Fig. 2 displays the infrared spectra of curite in the 500–1200 cm^{-1}. Results of the Raman spectral analysis are reported in Table 1. Bands at 885 cm^{-1} (1.795 Å) and 886.2 (1.795 Å) cm^{-1}, respectively, are attributed to the ν_3 $(UO_2)^{2+}$ antisymmetric stretching vibrations (Fig. 1). Bands at 803 (1.808 Å) and 791.1 (1.82 Å) cm^{-1} and 807.2 (1.803 Å) and 791 (1.82 Å) cm^{-1}, respectively, are assigned to the ν_1 $(UO_2)^{2+}$ symmetric stretching vibrations. As in the case of corresponding infra-

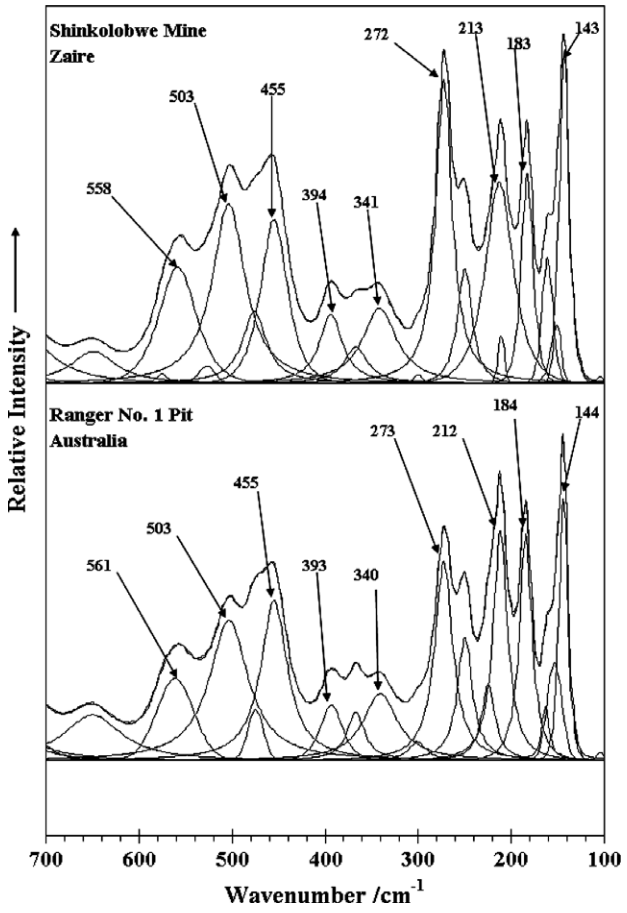

Fig. 3. Raman spectra of curite in the 100–700 cm^{-1} region from The Ranger Uranium Mine and Shinkolobwe Mine.

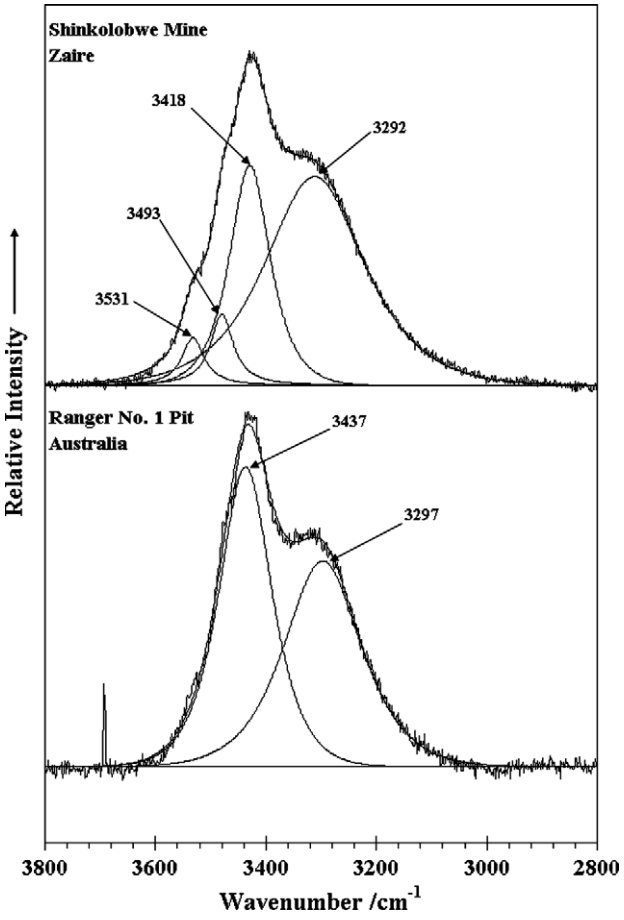

Fig. 4. Raman spectra of curite in the 2800–3800 cm^{-1} region from The Ranger Uranium Mine and Shinkolobwe Mine.

red bands, U–O bond lengths in uranyls were calculated with two empirical relations by Bartlett and Cooney [43]. Obtained values are in agreement with the data from single crystal structure analyses of curite [15,17,19].

Bands in the range 772–649 cm^{-1} may be connected with the molecular water librations modes and/or out-of-plane γ U–OH bending vibrations (Fig. 3). Bands in the range 454–575 cm^{-1} are related to the ν (U_3O) bridge elongation, 340–394 cm^{-1} to the ν $U_3(OH)_3$ elongation, 249–301 cm^{-1} to the γ (U_3O) out-of-plane bending and/or ν_2 (δ) $(UO_2)^{2+}$ bending vibrations, 161–210 cm^{-1} to the (UO_2) translations, and 143–154 cm^{-1} to the $(UO_2)^{2+}$ rotations [14,23,44–46].

3.2. Infrared spectrum of curite

U–O bond lengths for uranyls (Å) calculated with the empirical relation by Bartlett and Cooney [43] are given in parentheses. Bands at 912.3 (1.776 Å) and 876.1 (1.802 Å) cm^{-1} (Shinkolobwe sample), and 911.0 (1.777 Å) and 872.9 (1.805 Å) cm^{-1} (Ranger sample) are attributed to the ν_3 $(UO_2)^{2+}$ antisymmetric stretching vibrations. Bands at 959.8 (1.743 Å) and 937.7 (1.758 Å) cm^{-1} and 958.9 (1.744 Å) and 937.2 (1.758 Å) cm^{-1} may be also attributed to the ν_3 $(UO_2)^{2+}$ vibrations, however, calculated U–O bond lengths are much lower than those inferred from the X-ray single crystal structure analysis of natural and synthetic curite (average values 1.84 Å (see for example, Mereiter [19]); 1.79 Å, Taylor et al. [15]; 1.844 Å, Li and Burns [17]). These bands are connected with the δ U–OH bending vibrations. The ν_1 $(UO_2)^{2+}$ symmetric stretching vibration may be infrared active. According to empirical relations ν_1 $(UO_2)^{2+} = 0.94\nu_3$ $(UO_2)^{2+}$ Å and $\nu_1 = 0.89\nu_3$ $(UO_2)^{2+} + 21$ Å [for details see Čejka 1999 and references therein], this vibration should be located in the region 860–820 cm^{-1} and 833–798 cm^{-1}, respectively. Bands at 847.8 (1.764 Å) and 795 (1.816 Å) cm^{-1} and 845.2 (1.766 Å) cm^{-1}, respectively, are therefore attributed to the ν_1 $(UO_2)^{2+}$ vibrations. Bands in the range 1576–1003 cm^{-1} are assigned to the δ U–OH bending vibrations, while those in the range 783–688 cm^{-1} with the γ U–OH vibrations and/or libration modes of water molecules. According to Dothée [44,45], bands in the range 600–530 are assigned to the ν U_3O bridge elongation.

Fig. 4 displays the Raman spectra in the 2400–3800 cm^{-1} region of curite. Figs. 5 and 6 display the Infra-

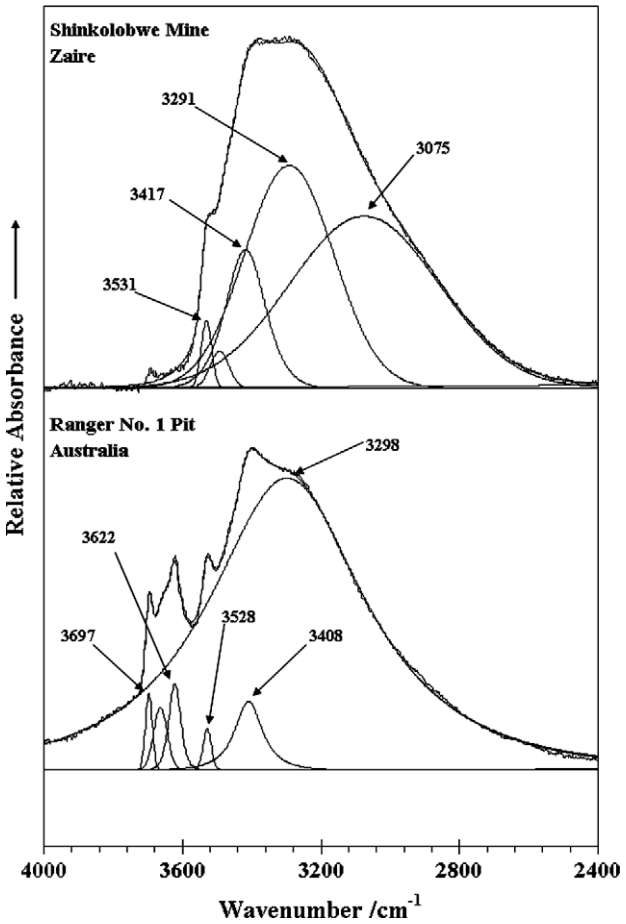

Fig. 5. Infrared spectra of curite in the 2400–4000 cm^{-1} region from The Ranger Uranium Mine and Shinkolobwe Mine.

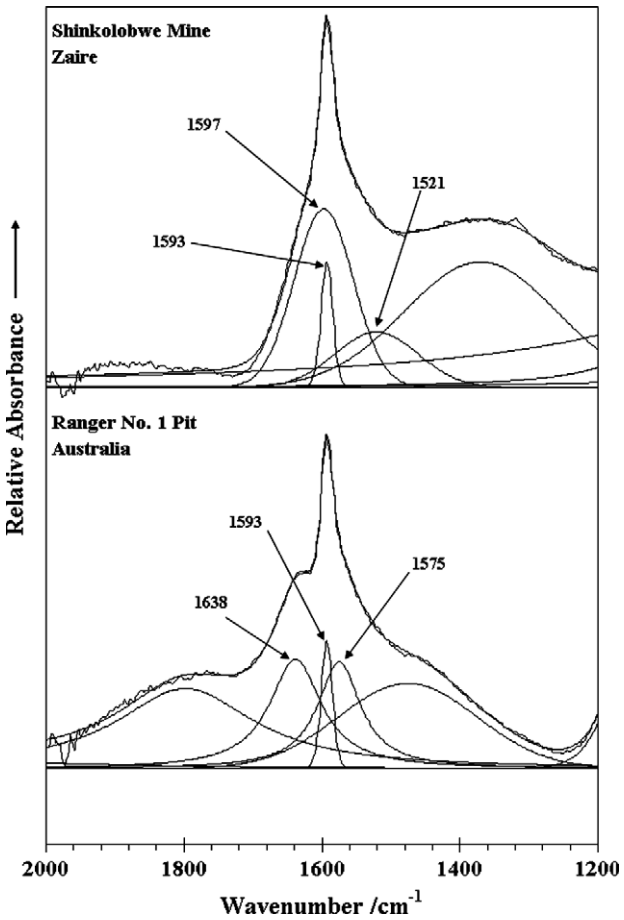

Fig. 6. Infrared spectra of curite in the 1200–2000 cm^{-1} region from The Ranger Uranium Mine and Shinkolobwe Mine.

red spectra of curite in the 2400–4000 cm^{-1} and 1200–2000 cm^{-1} regions from The Ranger Uranium Mine and Shinkolobwe Mine. Bands in the range 3531–3074 cm^{-1} (Shinkolobwe sample) are connected to the νOH stretching vibrations of water molecules and hydroxyls. It may be inferred that the wavenumbers correspond to weak to strong hydrogen bonds in the crystal structure of curite from Shinkolobwe [47]. A somewhat different arrangement of water molecules was observed in the infrared spectrum of the curite sample from Ranger Mine (3696.9–3297.7 cm^{-1}). It may be inferred that in the crystal structure of this sample practically free hydroxyls and weakly hydrogen bonded hydroxyls and water molecules are present [47]. This is in agreement with two bands observed close to 1595 cm^{-1} (Shinkolobwe sample) and bands at 1638.3 and 1593 cm^{-1} (Ranger sample) attributed to the δ H_2O bending vibrations. Bands at 2102.1 cm^{-1} and 1798.0 cm^{-1}, respectively, may be assigned to overtones and/or combination bands. Bands in the range 3297–3532 cm^{-1} are assigned to the ν OH stretching vibrations of water molecules and hydroxyl ions (Figs. 4 and 5). The wavenumbers prove the presence of relatively strong to weak hydrogen bonds in the crystal structure of curite. This does not fully agree with the observed infrared bands. Only a band at 1597.2 cm^{-1} (Shinkolobwe sample) was observed (Fig. 6). It may be assigned to the δ H_2O bending vibration. This band corresponds to water molecules relatively weakly bonded in the structure of curite. Bands in the range 1519–1552 cm^{-1} are connected with the δ U–OH bending vibration.

4. Conclusions

(a) Raman and infrared spectra of two curite samples were studied.
(b) Bands connected with the $(UO_2)^{2+}$ and $(OH)^-$ stretching and bending vibrations were attributed respecting their number as a result of FGA-correlation.
(c) Coincidence of some of the bands of the $(UO_2)^{2+}$ stretching vibrations with the bands assigned to U–OH bending vibrations was examined.
(d) U–O bond lengths in uranyls were calculated and compared with the X-ray single crystal structure data. Both data are in good agreement.
(e) The presence of free or weakly hydrogen bonded symmetrically distinct hydroxyls located in the sheets were inferred from the infrared spectrum of curite sample from Ranger Mine. This is in agreement with the crystal structure of curite.
(f) Water molecules of the interlayer together with hydroxyls from the uranyl anion sheet participate in a set of hydrogen bonds forming thus a complex hydrogen-bonding network which influences the origin, formation and stability of the mineral. This is supported by the fact that infrared and Raman spectra of the both curite samples somewhat differ in the regions of OH stretching and H_2O bending vibrations.

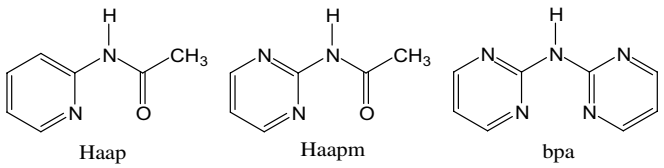
$M(Haap)_2(H_2O)_2](NO_3)_2$ (with $M = Co^{2+}$, Ni^{2+}, Zn^{2+}) and for $Pd(aap)_2$ [5].

The ligand Haap might have biological interest, while as a free ligand it was tested as an inducer for the Friend Leukemia cells [6]. Very recently the pair wise arrangement of a donor and acceptor H-bond group was realized and the molecule was used as a highly effective co-crystallising agent for carboxylate acids [7].



This paper focuses on amides monofunctionalized at the N site to form a chelating ligand, like in the ligand *N*-(pyridin-2-yl)acetamide [4]. With one of the N–H groups now available at the backside of the ligand, lattice stabilisation and even lattice engineering becomes possible with the counter anions, or other H-bond acceptors outside the coordination sphere. The phenomenon is well known for lattice stabilisation of coordination compounds. However, to use more than one function at the backside of the ligand is relatively rare.

In fact, the ligand bis(pyrimidyl)amine (bpa), see Scheme 1, has recently been introduced by us [8,9] and we have shown several cases of special lattice stabilisations by this type of hydrogen bonding [10–13]. This bpa ligand, however, has the structure A–D–A (where A is H-bond acceptor, and D stands for H-bond donor), allowing only asymmetric self-association yielding pairs A–**D**–**A**/**A**–**D**–A, where bold means involved in H-bond interaction.

We now have used the substituted amine, to generate the pair of ligands *N*-(pyridin-2-yl)acetamide (Haap) and the newly designed *N*-(pyrimidin-2-yl)acetamide (Haapm), as shown in Scheme 1. In the second case, a matching pair **A**–**D**/**A**–**D** would be available. The normal pyridine ligand (Haap) has been used as a reference, where only the amide H-bond donor is available.

To select a proper metal, we have chosen Cu(II), due to its plasticity in the coordination sphere and its preference for a trans geometry of weakly coordinating anions. This paper describes 10 new Cu(II) coordination compounds with the above ligand pair Haap and Haapm; we have chosen the anions: chloride, nitrate, tetrafluoridoborate, perchlorate, and triflate, to simultaneously study the effect of the decreasing capacity of the anions to coordinate. Characterisation of the new compounds has been performed by Infrared, ligand field and EPR spectroscopy. In addition 3D structures for five different compounds have been determined, which all proved the coordination mode of the ligand to be bis-bidentate (N,O).

It turned out that in all cases the N–H group of the ligand takes part in lattice stabilisation via extensive intermolecular hydrogen bonding. However, most surprisingly, the second N atom in the heterocyclic ring of Haapm does not take part in any hydrogen bond acceptance, contrary to the earlier reported, related bpa ligand.

Scheme 1. The ligands Haap, Haapm and for comparison bpa.

2. Experimental

2.1. Syntheses

The ligand Haap was synthesized according to the literature [4], by refluxing equimolar amounts of 2-aminopyridine and acetic anhydride for 2 h. Purification of the ligand was performed by distillation [4].

The new ligand Haapm was synthesized according to the same procedure as for Haap, but now using 2-aminopyrimidine in stead of 2-aminopyridine. The remaining brown solid was purified first by drying in an oven at 120 °C and then by recrystallisation from a mixture of toluene/hexane (1:1). Yield: 85%. *Anal.* Calc. for $C_6H_7N_3O$: C, 52.5; H, 5.2; N, 30.6. Found: C, 52.4; H, 5.2; N, 30.6%. NMR: 8.6 (doublet, phenyl) 7.0 (triplet, phenyl); 2.49 (methyl); 8.8 (NH).

Synthesis of the Cu(II) coordination compounds: 0.1 mmol of the Cu(II) salt and 0.2 mmol of the ligand were each dissolved in methanol. The solutions were slowly put together and filtered to remove any non-dissolved precipitate. After a few days the blue crystalline, or microcrystalline product separated. Yields are 50% or higher. The same compounds were obtained when using ethanol in stead of methanol. All new compounds show satisfactory elemental analyses as seen in Table 1.

2.2. Physical measurements

C, H, N determinations were performed on a Perkin–Elmer 2400 Series II analyzer. UV–Vis–NIR spectra were obtained on a Perkin–Elmer Lambda900 spectrophotometer using the diffuse reflectance technique, with MgO as a reference.

X-band powder EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer at RT and at 77 K, using DPPH ($g = 2.0036$) as a standard.

FTIR spectra were obtained on a Perkin–Elmer Paragon 1000 FTIR spectrophotometer equipped with a Golden Gate ATR device, using the reflectance technique (4000–300 cm^{-1}, res. 4 cm^{-1}).

2.3. Crystal structure determination and refinement of the structures

A suitable crystal of each of the five compounds was selected from their mother liquids and mounted to a glass fibre using the oil-drop method [14]; data were collected on a Nonius Kappa CCD diffractometer (graphite-monochromated Mo Kα radiation). The intensity data were corrected for Lorentz and polarisation effects, for absorption and extinction. The structures were solved by direct methods.

The programs COLLECT [15], SHELXS-97 [16], SHELXL-97 [17] were used for data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was done against all reflections. All non-hydrogen atoms were refined anisotropically. All H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. Selected bond distances and angles are given in Table 2. Crystallographic data of the compounds are summarized in Table 3.

3. Results and discussion

3.1. General structure and stoichiometry, and molecular structure

For all the five different counter ions, in all cases a similar stoichiometry was obtained, i.e. $Cu(LL)_2(anion)_2$, with similar colours and spectra properties. Table 1 lists some major properties of all 10 compounds, and explains the used code. A listing of major IR amide bands is given in Supplementary Table S1. No solvent molecules were found to be present in the lattice, irrespective of the used synthesis in all 10 compounds. In several cases crystals suitable for single-crystal structure determination were obtained, and five of these with high-quality crystals are included in this paper, including each of the five different anions.

A thermal ellipsoid plot, together with the used numbering scheme is shown in Fig. 1, for compound $Cu(Haap)_2(ClO_4)_2$ (**2**), whereas Fig. 2 shows the structure of $Cu(Haapm)_2(CF_3SO_3)_2$ (**6**). Projections of the structures for compounds **5**, **8** and **9**, respectively, are given in Supplementary figures S1–S3. Selected bond lengths and bond angles for all five compounds are given in Table 2.

The Cu(II) ion has a distorted octahedral geometry with the basal plane formed by two nitrogen atoms and two oxygen atoms of two bischelating ligands with Cu–N distances which vary from 2.005(2) to 2.042(2) Å and Cu–O distances which vary from 1.930(2) to 1.960(2) Å. All five compounds have basically the same overall structure, compounds **2**, **5**, **6** and **9** also have a centre of symmetry locating through the Cu(II) ion, while compound **8** has no

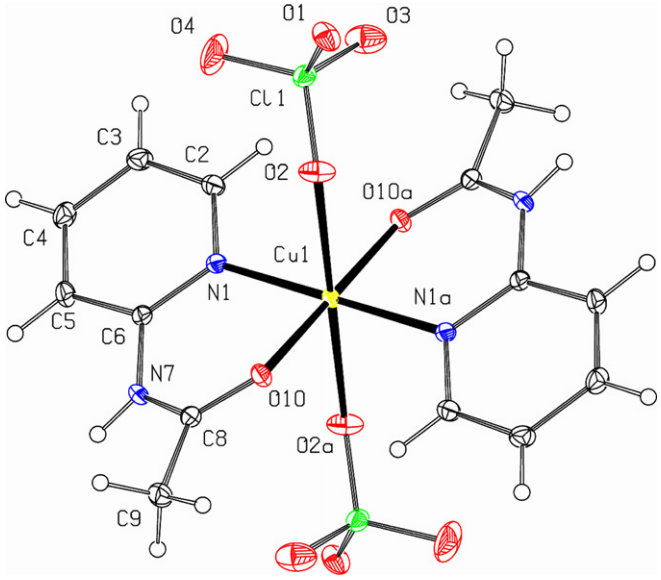


Fig. 1. Thermal ellipsoid plot (50% probability) of compound **2** with the used atom-labelling scheme.

[a] Bifurcated H atom.

centre of symmetry. Therefore, in compounds **2**, **5**, **6** and **9** the basal trans angles are 180°, while in compound **8** the basal trans angles are 174.84(7)° and 174.00(7)°.

The axial positions are occupied by an atom of an anion with semi-coordination distances of 2.476(2) Å ($Cu–O_{ClO_4}$), 2.815(1) Å (Cu–Cl), 2.417(2) Å ($Cu–O_{CF_3SO_3}$), 2.421(2) and 2.463(2) Å ($Cu–O_{NO_3}$) and 2.476(2) Å ($Cu–F_{BF_4}$).

3.2. Lattice structures and hydrogen bonding

A point of special interest is the intermolecular H-bond pattern for these compounds, as five of them have just the N–H donor group, whereas the other five have the imine-N as a possible N–H acceptor in the lattice, in analogy to the bis(pyrimidin-2-yl)amine complexes. In fact all five compounds do show only a clear N–H··· anion hydrogen bond, which is quite strong given the geometries (see Table 2). In compounds **2**, **6** and **9** which have the ClO_4^-, $CF_3SO_3^-$ and BF_4^- as an anion the H-bonds are formed by the amine N–H donor and one atom of the anion with distances of 2.954(3), 2.832(2) and 2.881(3) Å, respectively, providing a 1D polymeric double-chain type array. In Fig. 3 an example is shown for one of these compounds. The nitrate compound **8** also gives a quite similar polymeric array, but in this case the H-bond between the N–H and the nitrate oxygen atoms are alternating with distances of 2.776(3) Å and (bifurcated H-bonds of) 3.003(3) and 3.046(3) Å with the other nitrate oxygen (see figure S4 for details). Compound **5** differs from the other ones, as the H-bond between the amine N–H and the Cl^- ion provides an zigzag 2D-based polymeric array with N–H···. Cl contact distance of 3.156(3) Å, as shown in Fig. 4. Most surprisingly, and in fact not predicted, the other N atom of the pyrimidine ring, in compounds **6**, **8** and **9**, which has a lone pair, and which is know to take part in H bonding in the ligand bpa (see Scheme 1), does not take part in any hydrogen bonding in these compounds. The shortest contacts with any intermolecular atom are all over 4 Å. The reasons for this are not understood at the moment, but future studies are planned to use counter anions, like hydrogencarbonate and hydrogensulfate, that would provide a N–H donor, while at the same time using one O atom to bind to the metal.

3.3. Electronic and infrared spectroscopy

The diffuse reflectance spectra of the powdered solids are summarized in Table 1. All compounds (**1**–**10**) show a ligand field spectrum with a strong broad tail-shaped band with a centre around $14.3–16.0 \times 10^3$ cm^{-1}, values which are consistent with a (distorted) octahedral geometry [18]. No attempts were undertaken to a detailed analysis on the very small different peaks in the LF spectra.

In Table S1, selected infrared bands are given. The amide I band consists mainly of $\nu_{(C=O)}$ and the amide II bands arise mainly of $\nu_{(C=N)}$ [4]. When an amide group coordinates through the oxygen atom, the amide I band will shift to lower frequency and the amide II band to

higher frequency [4]. As can be seen in Table S1 the amide bands shift indeed to lower, respectively. higher frequency, which confirms that the coordination in all compounds is through the oxygen and the nitrogen atom. The anion bands are observed at the normal frequencies for mono-coordinated anions [19]. The $\nu_{as(S=O)}$ stretching bands in the triflate compounds (compounds **1** and **6**) are observed at 1275, 1249 cm^{-1} and 1276, 1244 cm^{-1}, respectively. All these bands are in agreement with the literature for mono-dentate and/or H-bonded triflate absorptions [20,21].

The N–H stretch vibrations of the amide groups nicely correlate with the known basicity of the anions and the bands vary from 3340 cm^{-1} (for BF_4^-, the weakest acceptor) to 2700 cm^{-1} (for Cl^-, the strongest acceptor), see Table S1. As can be seen from the infrared spectra of the NH/CH regions of the compounds (figure S5 for compounds **1**–**5** and figure S6 for compounds **6**–**10**) the strength of the H

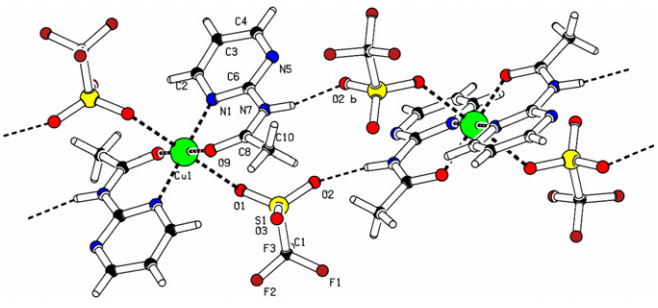

Fig. 3. 1D polymeric antiparallel chain array formed by intermolecular hydrogen bonds via Cu, triflate and NH groups (compound **6**).

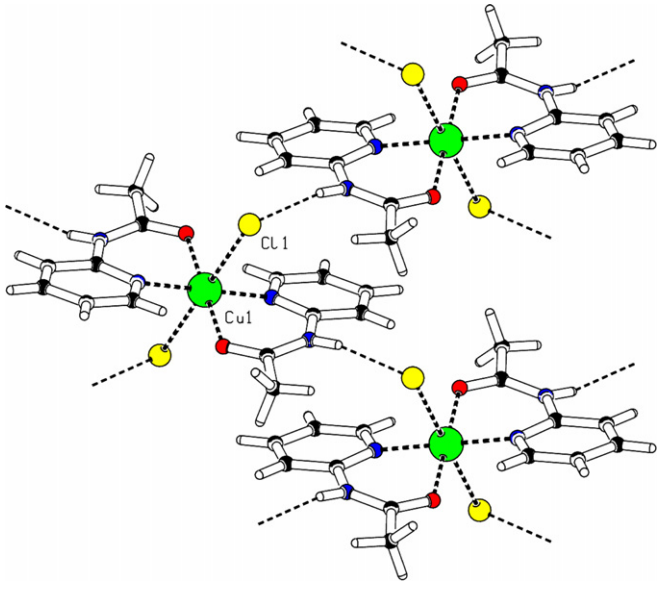

Fig. 4. Zigzag polymeric 2D array formed by lattice hydrogen bonding via Cu–Cl–NH groups (compound **5**).

bonds, as measured by the N–H centre of gravity, nicely follows the order of: $BF_4 < ClO_4 < CF_3SO_3 < NO_3 < Cl$.

3.4. Magnetic properties

X-band EPR spectra of polycrystalline powders of the complexes (**1**–**10**) were recorded at room temperature. As shown in Table 1 the compounds **2**, **7**, **9** and **10** show an axial $S = 1/2$ signal with a $g_\perp$ at 2.06–2.08 and with an unresolved (often weak to very weak) $g_\parallel$ values of 2.23–2.31. Compounds **1** and **8** show resolved hyperfine splitting on $g_\parallel$ with a value of 2.28 and an $A_\parallel$ of 15.6 mT and 16.2 mT, respectively. These g values are in the usual range for copper in a (distorted) elongated octahedral environment [18]. The other compounds do not show this hyperfine splitting, which is ascribed to exchange narrowing by too close intermolecular contacts.

4. Concluding remarks

All above, new mononuclear-based Cu(II) compounds with the known ligand Haap and with the newly designed ligand Haapm appeared to be easy to synthesize and have been characterized by standard methods, as well as by X-ray structure determinations. Different anions have been used and in all cases, irrespective of solvent and ratio M:L the same stoichiometry, i.e. $M(LL)_2(anion)_2$, was found, suggesting a stable lattice energy. All compounds have an elongated octahedral geometry.

As predicted with the design of the ligands and the complexes, the rear side of the ligand with the N–H group, plays a key role in the formation of the 3D structure and the formation of chains of the type –**Cu**–**anion**–**NH-(ligand)**–**Cu**– . Only in the case of the small chloride anion, a different packing (2D), but also based on the N–H groups at the rear side of the ligand is found. The strength of the hydrogen bonding, as measured by the lowering of the N–H stretch, runs parallel with the basic properties of the anions. Surprisingly, the second ring nitrogen in the ligand Haapm does not appear to play a role at all in the hydrogen bonding, despite the availability and exposure of its lone pair to the lattice. Further studies with different anions, i.e. those that contain a NH donor, should shed further light on this interesting lattice engineering problem.

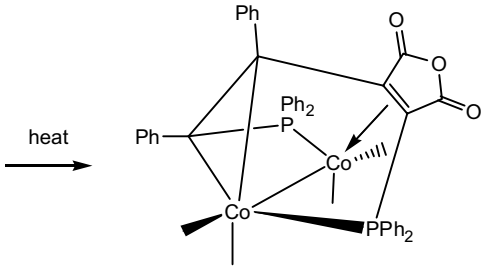
anhydride ligand. These reactions are depicted in Eqs. (1) and (2), respectively.



(1)

(2)

Wishing to further explore the chemistry of our zwitterionic hydrocarbyl complexes, we have investigated the substitution reactivity of $Co_2(CO)_4$[μ-PhC=C(H)PPh_2C=C(PPh_2)C(O)OC(O)] (**1**) with PMe_3 [5]. The addition of PMe_3 to **1** is shown to trigger the insertion of a CO group into one of the Co–C(hydrocarbyl) bonds to give the acyl species $Co_2(CO)_3(PMe_3)$[μ-PhC(CO)=C(H)PPh_2C= C(PPh_2)C(O)OC(O)] (**2**). Compound **2** undergoes a formal CO deinsertion upon thermolysis to afford the simple PMe_3-substituted derivative $Co_2(CO)_3$(P-Me_3)[μ-PhC=C(H)PPh_2C=C(PPh_2)C(O)OC (O)] (**3**). The course of these substitution reactions has been established through NMR spectroscopy and X-ray crystallographic analyses of compounds **2** and **3**.

2. Experimental

2.1. General

The starting dicobalt compound $Co_2(CO)_4$[μ-PhC=C(H)PPh_2C=C(PPh_2)C(O)OC(O)] was prepared from $Co_2(CO)_6$(μ-PhCCH) and bma accordingly to the published procedure [2]. The alkyne compound $Co_2(CO)_6$-(μ-PhCCH) was synthesized from $Co_2(CO)_8$ and phenylacetylene [6], while the diphosphine ligand bma was synthesized from 2,3-dichloromaleic anhydride and Ph_2PSiMe_3 [7]. PMe_3 was prepared from $P(OPh)_3$ and MeMgI [8]. The chemicals phenylacetylene, $P(OPh)_3$, and MeI were purchased from Aldrich Chemical Co. and used as received. $Co_2(CO)_8$ was purchased from Strem Chemicals and stored under CO and in the refrigerator when not in use. The ^{13}CO (99%) used in the preparation of the ^{13}C-enriched sample of $Co_2(CO)_6$(μ-PhCCH) was obtained from Isotec. All reaction and NMR solvents were distilled from an appropriate drying agent using Schlenk techniques and stored under argon in storage vessels equipped with high-vacuum Teflon stopcocks [9]. The combustion analyses were performed by Atlantic Microlab, Norcross, GA.

The IR spectral data were recorded on a Nicolet 20 SXB FT-IR spectrometer in sealed 0.1 mm NaCl cells, while the ^{13}C spectral data were recorded at 50 MHz on a Varian Gemini-200 spectrometer. The ^{31}P NMR spectra were collected in the proton-decoupled mode on a Varian 300-VXR spectrometer at 121 MHz, with the reported chemical shifts referenced to external H_3PO_4 (85%), taken to have $\delta = 0$.

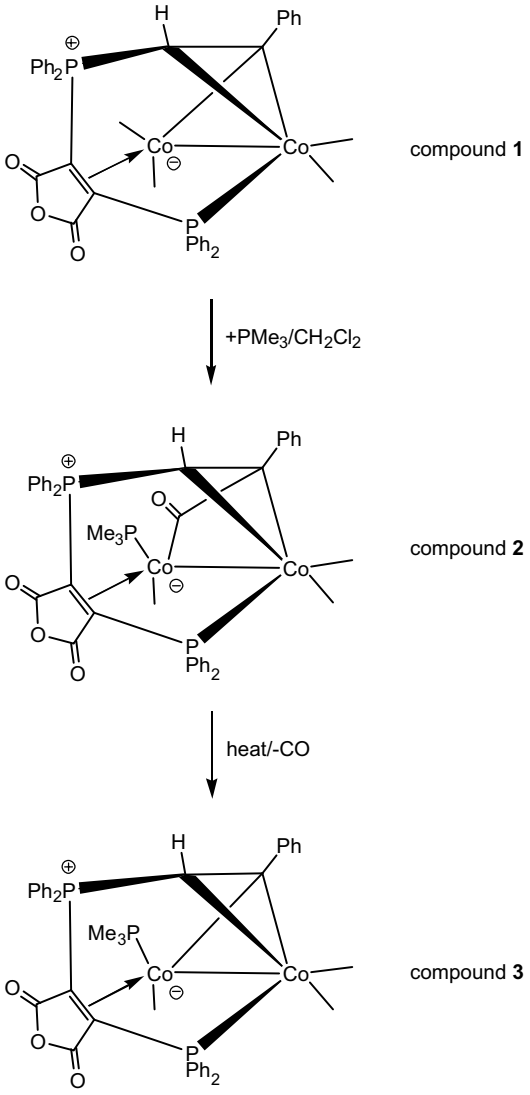
2.2. Synthesis of $Co_2(CO)_3(PMe_3)$[μ-PhC(CO)=C(H)PPh_2C=C(PPh_2)C(O)OC(O)] (2)

To a small Schlenk tube containing 0.20 g (0.20 mmol) of **1** in 15 mL of CH_2Cl_2 at room temperature was added 1.05 equiv. of PMe_3 (0.42 mL of a 0.5 M solution of PMe_3 in CH_2Cl_2). The reaction was instantaneous based on TLC and IR analyses of the reaction solution, which revealed the complete consumption of **1** and the formation of **2**. The solvent was removed under vacuum and the residue was passed across a short column of silica gel using CH_2Cl_2/acetone (95:5) as the eluent. Recrystallization of crude **2** from CH_2Cl_2/heptane afforded the analytical sample and single crystals of **2** suitable for X-ray diffraction analysis. Yield of black-green **2**: 0.18 g (85%). IR (CH_2Cl_2): ν(CO) 2022 (vs), 1985 (vs), 1777 (m, symm anhydride), 1719 (m, antisymm anhydride), 1590 (bw, acyl) cm^{-1}. ^{13}C NMR (THF, 178 K): δ 197.83 (d, 1C, $J_{P-C} = 23$ Hz), 206.65 (s, 2C), 234.50 (d, 1C, $J_{P-C} = 15$ Hz). ^{31}P NMR (THF, 178 K): δ 14.90 (overlapping resonances, 2P), 19.21 (d, 1P, $J_{P-P} = 61$ Hz, phosphonium moiety). *Anal.* Calc. for $C_{43}H_{35}Co_2O_7P_3$: C, 59.06; H, 4.03. Found: C, 59.36; H, 4.38%.

2.3. Thermolysis of $Co_2(CO)_3(PMe_3)[\mu\text{-}PhC(CO)=C(H)PPh_2C=C(PPh_2)C(O)OC(O)]$ and formation of $Co_2(CO)_3(PMe_3)[\mu\text{-}PhC=C(H)PPh_2C=C(PPh_2)C(O)OC(O)]$ (3)

To a Schlenk tube under argon was charged 0.20 g (0.23 mmol) of **2**, followed by the addition of 20 mL of 1,2-dichloroethane (DCE) via syringe. The vessel was sealed and then heated at 60 °C for 1 h, at which time TLC analysis confirmed the presence of compounds **1**, **2**, and **3**. Heating was continued for another hour and the solution examined again by TLC. At this point, only compounds **1** (minor) and **3** (major) were observed ($R_f = 0.80$ for **1** and $R_f = 0.65$ for **3** using CH_2Cl_2 as the eluent). The desired compound **3** was isolated after solvent removal and purification by column chromatography over silica gel using CH_2Cl_2 as the mobile phase. Crude **3** was subsequently recrystallized from CH_2Cl_2/hexane to furnish the combustion sample and the single crystals of **3** suitable for X-ray crystallography. Yield of **3**: 82% (0.16 g). IR (CH_2Cl_2): ν(CO) 2001 (s), 1958 (s), 1777 (m, symm anhydride), 1721 (m, antisymm anhydride) cm^{-1}. ^{13}C NMR (THF, 178 K): δ 202.07 (d, 1C, $J_{P-C} = 20$ Hz), 207.37 (d, 1C, $J_{P-C} = 21$ Hz), 211.89 (s, 1C). ^{31}P NMR (THF, 178 K): δ 10.80 (overlapping resonances, 2P), 33.78 (d, 1P, $J_{P-P} = 67$ Hz, phosphonium moiety). *Anal.* Calc. for for $C_{42}H_{35}Co_2O_6P_3$: C, 59.59; H, 4.13. Found: C, 59.29; H, 4.26%.

2.4. X-ray diffraction data



Tables 1 and 2 contain the X-ray data and processing parameters and selected bond distances and angles, respectively, for compounds **2** and **3**. A suitable crystal was selected and sealed inside a Lindemann capillary, followed by mounting on an Enraf-Nonius CAD-4 diffractometer. After the cell constants were obtained, intensity data in the range of $2° \leqslant 2\theta \leqslant 44°$ (**2**) and $2° \leqslant 2\theta \leqslant 40°$ (**3**) were collected at 298 K and were corrected for Lorentz, polarization, and absorption (DIFABS). The structures of compounds **2** and **3** were solved using SHELX-86. All non-hydrogen atoms were located with difference Fourier maps and full-matrix least-squares refinement in both compounds. In the case of **2**, the cobalt, phosphorus, oxygen, and the carbonyl carbon atoms were refined anisotropically, with the phenyl, hydrocarbyl, and maleic anhydride ring carbon atoms refined isotropically. Due to the poor scattering displayed by the crystal of **3**, only the Co and P atoms were refined anisotropically. All hydrogen atoms were assigned calculated positions and allowed to ride on the attached heavy atom. Refinement on **2** converged at $R = 0.0427$ and $R_w = 0.0460$ for 2127 unique reflections

Table 1

with $I > 3\sigma(I)$, while **3** afforded convergence values of $R = 0.0620$ and $R_w = 0.0715$ for 1375 unique reflections with $I > 3\sigma(I)$.

3. Results and discussion

3.1. Synthesis, spectroscopic data, and X-ray diffraction structure of 2

Treatment of **1** with a slight excess of PMe_3 at room temperature leads to a rapid reaction based on the brown to black-green color change exhibited by the reaction solution. TLC examination confirmed the complete consumption of brown **1** and the presence of a slower moving black-green spot corresponding to **2** at $R_f = 0.50$ using CH_2Cl_2/acetone (95:5) as the eluent. No reaction between **1** and PMe_3 was observed at 0 °C, while the reaction between **1** and PPh_3 conducted at room temperature showed no sign for the formation of any product. This latter observation suggests that the CO insertion reaction that affords **2** is sensitive to the nucleophilicity of incoming ligand and does not proceed via a pre-equilibrium involving the unsaturated acyl species $Co_2(CO)_3$[μ-PhC(CO)=C(H)PPh_2C=C(PPh_2)C(O)OC(O)], as added phosphine would be captured without complications under these circumstances. Compound **2** was subsequently isolated in high yield as a mildly air-sensitive solid after chromatographic separation over silica using the aforementioned eluent. Scheme 1 depicts the transformation of **1** to **2**.

Compound **2** was characterized by IR and NMR spectroscopies, elemental analysis, and X-ray crystallography. The IR spectrum displays terminal Co–CO bands 2022 (vs) and 1985 (vs) cm^{-1} and two ν(CO) bands for the kinematically coupled carbonyl groups associated with the anhydride ring at 1777 (m) and 1719 (m) cm^{-1} [10]. The shift to lower energy by both sets of carbonyl groups in **2** relative to **1** is consistent with the addition of an electron-rich PMe_3 ligand to **1**. The acyl band in **2** appears as a broad, weak band at 1590 cm^{-1}, in agreement with the reported frequencies in other such acyl derivatives [11]. The low-temperature ^{13}C NMR spectrum of a ^{13}CO-enriched sample of **2** exhibits two terminal Co–CO resonances at δ 197.83 (1C) and 206.65 (2C) and an acyl CO resonance at δ 234.50 [12], while the ^{31}P NMR spectrum reveals an overlapping singlet and doublet at δ 14.90 for the cobalt-bound phosphine groups and a down-field doublet at δ 19.21 belonging to the phosphonium moiety. The ^{31}P NMR data recorded for **2** parallel those data reported by us for compound **1**, which displays ^{31}P chemical shifts at δ 4.70 and 31.30 for the phosphine and phosphonium groups, respectively [2].

The solid-state structure of **2** was determined by single-crystal X-ray diffraction analysis [13].[1] Single crystals of **2** exist as discrete molecules in the unit cell with no unusually short inter- or intramolecular contacts. The ORTEP diagram of **1**, shown in Fig. 1, confirms the regiospecific addition of the PMe_3 ligand to the Co(2) atom and the insertion of the C(4)O(4) carbonyl group into the Co(2)–C(17) bond of **1**. The Co(1)–Co(2) bond distance of 2.650(2) Å is 0.101 Å longer than the cobalt–cobalt bond length reported for compound **1**. This lengthening is attributed to the presence of the ancillary PMe_3 ligand. The Co(1)–P(1) and Co(2)–P(3) distances of 2.187(3) Å and 2.239(3) Å, respectively, fall within acceptable ranges for such linkages [14]. The Co(2)–C(4) and C(4)–C(17) distances of 1.944(9) Å and 1.48(1) Å, respectively, and the angles associated with the Co(2)–C(4)–C(17) [114.7(6)°] and Co(2)–C(4)–O(4) [123.7(7)°] linkages exhibit values consistent with other acyl-substituted cobalt compounds

[1] The chiral space group $P2_12_12_1$ exhibited by compound **2** presumably reflects a spontaneous separation of one of the enantiomers from the bulk sample whose composition consists of a racemic mixture of **2**. Unfortunately, the absolute chirality associated with the two stereocenters in the X-ray structure **2** cannot be definitively ascertained based on the available X-ray data.

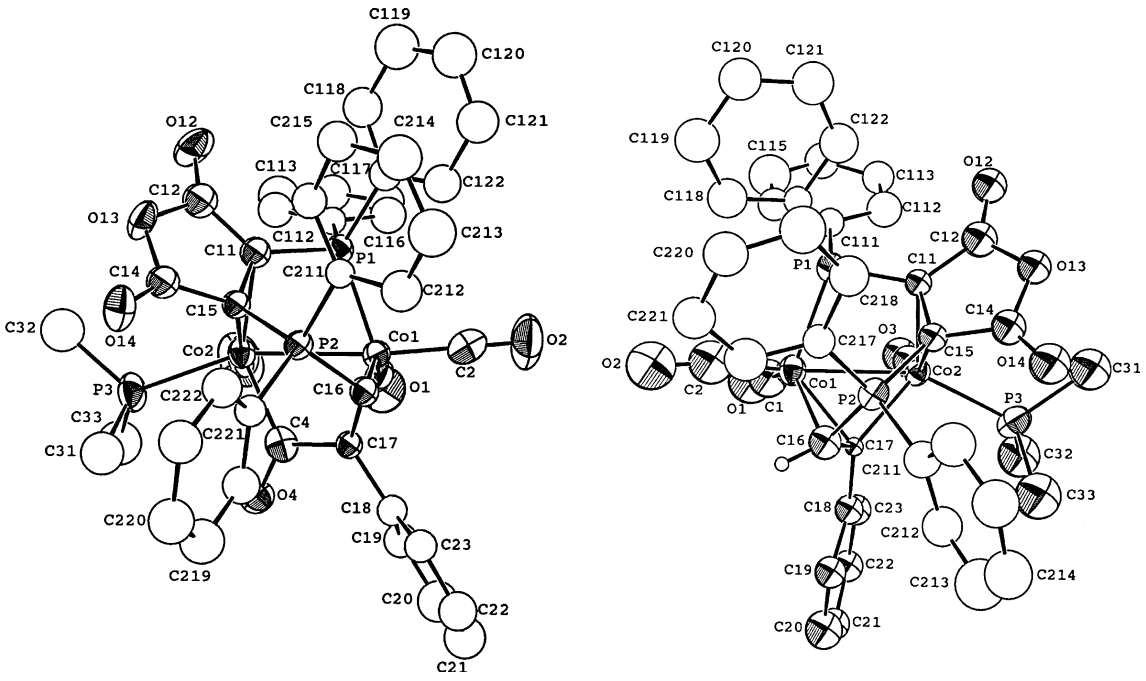

Fig. 1. ORTEP diagrams of compounds **2** (left) and **3** (right) showing the thermal ellipsoids at the 30% probability level.

[15]. The three terminal CO groups display distances and angles consistent with such groups. The remaining bond distances and angles are unremarkable and require no comment.

3.2. Synthesis, spectroscopic data, and X-ray diffraction structure of 3

The temperature sensitivity of **2** was subsequently verified during a routine thermolysis study. Heating **2** in either DCE or toluene solution over the temperature range of 50–75 °C leads to the consumption of **2** and concurrent formation of the simple phosphine-substituted compound **3** as the major product, as assessed by TLC and IR analyses. TLC examination also revealed the presence of a small amount of compound **1** and some decomposed material that remained irreversibly bound to the TLC plate irrespective of the mobile phase employed. The observation of **1** during the thermolysis reaction raises an interesting aspect concerning the route leading to **3**. It is possible that **1** serves as the principal product from the acyl-deinsertion reaction, which in turn requires the expulsion of the PMe_3 ligand from **2**. Once regenerated **1** could again react with the liberated PMe_3 to furnish **2** and then ultimately produce **3** through a slower secondary event(s). The observation of both **1** and **3** from **2** is also consistent with a dual reaction manifold, where the amount of each product (**1** and **3**) reflects a kinetic preference associated with the acyl-deinsertion step [16]. Of these two general paths, we favor the latter one based on the results obtained from the thermolysis of a toluene solution of **2** that was purged with argon in order to remove the liberated CO and PMe_3. Under such conditions, the back reaction between **1** and PMe_3 would be eliminated. Accordingly, **1** would be observed as the dominant product, provided that the expulsion of PMe_3 from **2** is favored over CO dissociation. The significant amount of **3** that accompanies this particular experiment (TLC monitoring) indicates that the conversion of **2** to **3** proceeds primarily through the liberation of CO and not PMe_3. The bottom portion of Scheme 1 shows the conversion of **2** to **3**.

Compound **3** was isolated by column chromatography in 82% yield and characterized by traditional spectroscopic methods, combustion analysis, and X-ray crystallography. The IR spectrum of **3** showed two strong carbonyl stretching bands at 2001 and 1958 cm^{-1} belonging to the terminal Co–CO groups and two anhydride carbonyl bands at 1777 (m) and 1721 (m) cm^{-1} that represent the vibrationally coupled symmetric and antisymmetric anhydride stretches, respectively. The presence of three terminal Co–CO groups in **3** was verified by ^{13}C NMR spectroscopy of a ^{13}CO-enriched sample of **3**. Here, ^{13}C resonances recorded at δ 202.07, 207.37, and 211.89 support the formulated structure of **3** and the loss of the acyl moiety. The ^{31}P NMR spectrum of **3** exhibits a high-field resonance at δ 10.80 for the overlapping cobalt-bound phosphine moieties and the hydrocarbyl-bound phosphonium ligand at δ 33.78. These data are similar to those chemical shifts recorded for compound **2**.

The molecular composition of **3** was established by X-ray diffraction analysis. The ORTEP diagram of **3** depicted in the right-hand portion of Fig. 1 confirms the loss of the acyl moiety in the conversion of **2** to **3**. With the exception of the ancillary PMe_3 group at Co(2), the overall structure of **3** is comparable to the published structure of **1** [2]. The 2.553(4) Å bond distance for the Co(1)–Co(2) vector is in

keeping with its single-bond designation and consistent with those Co–Co bond lengths found in other dinuclear cobalt compounds [17]. The cobalt-bound alkene moieties defined by the atoms C(11)–C(15) and C(16)–C(17) exhibit bond distances of 1.39(3) and 1.40(3) Å, respectively, that are slightly shorter than those distances found in **2**. The remaining bond distances and angles are unexceptional and require no comment.

4. Conclusions

The addition of PMe_3 to $Co_2(CO)_4$[μ-PhC= C(H)PPh_2 C=C(PPh_2)C(O)OC(O)] (**1**) promotes the regiospecific CO insertion into one of the Co-C(hydrocarbyl) bonds and production of the acyl compound $Co_2(CO)_3$-(PMe_3)[μ-PhC(CO)=C(H)PPh_2C=C(PPh_2)C(O)OC(O)] (**2**). This represents the first example of a phosphine-induced CO-insertion reaction in a zwitterionic hydrocarbyl compound of this genre. Compound **2** is thermally unstable and undergoes decarbonylation to furnish the PMe_3-substituted compound $Co_2(CO)_3(PMe_3)$[μ-PhC=C(H)PPh_2C= C(PPh_2)C(O)OC(O)] (**3**) and **1**, as the major and minor products, respectively. Our future endeavors will explore the generality of this reaction with isonitrile ligands and different phosphines, and the kinetics for the CO insertion reaction will be investigated using low-temperature spectroscopic techniques.

Scheme 1. The structures of pyridylmethylthiobenzoic acid **1** and **2**.

2. Results and discussion

2.1. Reaction of 2-(2-pyridylmethylthio)benzoic acid (*1*) with R_2SnO (R = Et or ^nBu)

Upon treatment of 2-(2-pyridylmethylthio)benzoic acid with R_2SnO (R = Et or ^nBu) in a 1:1 molar ratio in anhydrous benzene, dimeric compounds $\{[(2\text{-}PyCH_2SC_6H_4CO_2)SnR_2]_2O\}_2$ [R = Et (**3**) and ^nBu (**4**)] were yielded, which have been characterized by elemental analyses, IR as well as NMR spectra. The NMR spectra of these two compounds are consistent with their structures as dimeric distannoxanes. For instance, the ^{119}Sn spectra of these compounds verify the presence of *endo*- and *exo*-cyclic tin atoms. A pair of resonances of equal intensities is observed at −207.92 and −209.58 ppm for **3** as well as at −194.13 and −193.13 ppm for **4**. These values are comparable with those reported for other dimeric distannoxanes with cyclic Sn_2O_2 units [13,21–23], and correspond to a five-coordinated or weakly six-coordinated tin atom. In addition, the ^1H and ^{13}C NMR spectra of these two compounds also support the suggested structures, and exhibit two sets of ethyl signals for **3** and butyl signals for **4**.

In order to prove the role of these heteroatoms in the carboxylate ligands, the structure of **4** has also been confirmed further by X-ray crystallography, and presented in Fig. 1. Selected bond distances and angles are listed in Table 1. As seen in Fig. 1, the pyridyl nitrogen atoms do not coordinate to the tin atoms. The crystallographically unique carboxylic ligands display different coordination

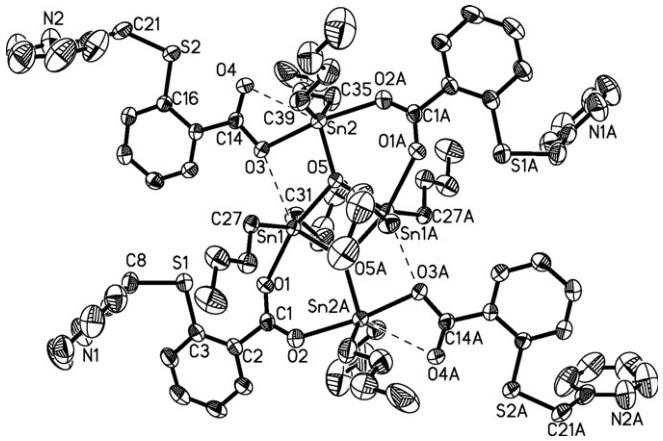

Fig. 1. The molecular structure of **4** with the thermal ellipsoids at the 30% probability level. Hydrogen atoms are omitted for clarity. Symmetric operation of "A" is 1 − *x*, 2 − *y*, 1 − *z*.

modes. One acts as a monodentate ligand by the carboxylate oxygen, while the other is a bridging bidentate ligand by two oxygen atoms of the carboxyl group. Each tin atom adopts a five-coordinate distorted trigonal bipyramidal geometry with two oxygen atoms (O1 and O5 for Sn1 as well as O3 and O2A for Sn2) occupying the axial positions. The axial O–Sn–O angles (O1–Sn1–O5 165.1(1)° and O3–Sn2–O2A 170.4(1)°) significantly derivate from 180°. Some weak intramolecular Sn···O interactions are also observed. The Sn···O distances (Sn1···O3 2.83(1) Å, Sn2···O4 2.77(1) Å) are significantly shorter than the sum of the van der Waal's radii for the Sn and O atom of 3.57 Å [9], but are markedly longer than the covalent Sn–O distance, such as Sn1–O1 (2.257(3) Å) and Sn1–O5 (2.166(3) Å).

2.2. Reaction of 2-(4-pyridylmethylthio)benzoic acid (*2*) with R_2SnO (R = Et or ^nBu)

The reaction of 2-(4-pyridylmethylthio)benzoic acid with Et_2SnO in a 1:1 molar ratio in anhydrous benzene also gives a dimeric compound, $\{[(4\text{-}PyCH_2SC_6H_4CO_2)SnEt_2]_2O\}_2$ (**5**). Although its ^{119}Sn NMR spectrum only shows a broad single resonance peak at −193.17 ppm (possibly owing to coincidental overlapping), the ^{13}C NMR spectrum clearly shows two sets of signals for the ethyl

carbons, consistent with the structure of a dimeric distannoxane, like in **4**. However, treatment of 2-(4-pyridylmethylthio)benzoic acid with $^{n}Bu_2SnO$ in a 1:1 molar ratio under similar reaction conditions only yields the diorganotin dicarboxylate $(4\text{-}PyCH_2SC_6H_4CO_2)_2Sn(^{n}Bu)_2$ (**6**). Its ^{1}H and ^{13}C NMR spectra exhibit only one set of butyl signals. In addition, the ^{119}Sn NMR spectrum of **6** displays one resonance at −155.56 ppm, markedly different from those of **3**–**5**, but comparable with those reported for related diorganotin dicarboxylates [10,22,23]. Although the tin atom in this compound is seven-coordinate in the solid state (see Fig. 3), this ^{119}Sn NMR chemical shift is not consistent with that of a seven-coordinate tin centre [8,16], suggesting that the seven-coordinate structure of tin is not retained, and extensive dissociation may occur in solution. It is known that the steric hindrance of the carboxylic acid or alkyl groups of tin significantly affects the coordinate environment of the tin atom in organotin carboxylates [8,9,24]. So the greater bulkiness of the butyl group compared to that of the ethyl group possibly plays a key role in the formation of **6** in this reaction.

The distannoxane structure for **5** and dicarboxylate structure for **6** are also supported by their X-ray diffraction analyses. The molecular structure of **5** is presented in Fig. 2, and selected bond distances and angles are listed in Table 1. To a first approximation, the molecular structure of **5** is similar to that of **4**. For instance, they both have tetranuclear distannoxane structures, and the pyridyl nitrogen atoms do not participate in coordination to the tin atoms in either of these two compounds. On the other hand, some noticeable differences exist between **4** and **5**. In **5**, one tin atom (Sn1) adopts a five-coordinate distorted trigonal bipyramidal geometry, while the other tin (Sn2) is in a six-coordinate distorted octahedral geometry. The coordination modes of the carboxylic ligands are also different in these two compounds. One carboxylic ligand in **5** acts as a bidentate bridging ligand, while the other is a bidentate chelating ligand. In addition, the Sn1···O2 distance (3.045(4) Å) in **5** is longer than the corresponding Sn1···O3 distance (2.83(1) Å) in **4**, implying weaker nonbonded Sn···O interactions in **5**. Additionally, it is noteworthy pointing out these two compounds have short Sn1···Sn1A separations (3.302(4) Å in **4** and 3.300(1) Å in **5**) [12,25].

The molecular structure of **6** is presented in Fig. 3, and selected bond distances and angles are listed in Table 2. The tin atom has a seven-coordinate distorted pentagonal-bipyramidal geometry, with four oxygen atoms of two chelating carboxylate ligands and the pyridyl nitrogen atom occupying the equatorial plane and two butyl groups lying in axial positions with an axial angle C27–Sn1–C31of 167.0(1)°. The Sn1 atom lies in the plane formed by the Sn1

[a] Symmetry code of "A" is $0.5-x, 0.5+y, 0.5-z$.
[b] Symmetry code of "A" is $-0.5+x, 0.5-y, 0.5+z$.

O1, O2, O3, O4 and N2A atoms, and only deviates from the plane by 0.0101 Å. Furthermore, this compound forms a linkage coordination polymer through the interactions of the pyridyl nitrogen atoms with the adjacent tin atoms. The Sn1–N2A bond distance is 2.510(4) Å, comparable with those reported in other related seven-coordinate organotin dicarboxylates [8,12,16].

2.3. Reaction of 1 and 2 with $(Ph_3Sn)_2O$

Reaction of pyridylmethylthiobenzoic acids **1** and **2** with $(Ph_3Sn)_2O$ in a 2:1 molar ratio gives triphenyltin carboxylates (2-$PyCH_2SC_6H_4CO_2$)$SnPh_3$ (**7**) and (4-$PyCH_2SC_6H_4CO_2$)$SnPh_3$ (**8**), which have also been characterized by elemental analyses, IR, NMR spectra and X-ray crystallography. The molecular structure of **7** is presented in Fig. 4, and indicates that the tin is in a distorted tetrahedral geometry. The carboxylate group acts as unidentate ligand. Like **4** and **5**, the pyridyl nitrogen atom in **7** does not participate in coordination to the tin atom. Additionally, other weak non-bonded interactions, such as intramolecular Sn···O (Sn1···O2 2.737(3) Å) and intermolecular S···S (S1···$S1^i$ 3.617(4) Å, symmetry code: i = 1 − *x*, 2 − *y*, 2 − *z*) interactions, have also been observed in this compound.

Like compound **6**, **8** forms a linkage coordination polymer through the interactions of the pyridyl nitrogen atoms with the adjacent tin atoms, as shown in Fig. 5. In **8**, however, the tin atom adopts a five-coordinate distorted trigonal bipyramidal geometry with one oxygen atom and the pyridyl nitrogen atom occupying the axial positions with an axial angle O2–Sn1–N1A of 175.27(9)° (see Table 2). The non-bonded Sn···O distance (Sn1···O1 3.040(3) Å) is significantly longer than the corresponding Sn···O distances in **4** and **7** (Sn1···O3 2.83(1) Å in **4** and Sn1···O2 2.737(3) Å in **7**), but is similar to that in **5** (Sn1···O2 3.045(4) Å). The Sn–N distance is 2.524(2) Å, also similar with that in **6** (2.510(4) Å) and other related polymeric triphenyltin derivatives containing pyridyl carboxylate ligands, such as 4-$PyCO_2SnPh_3$ (2.512(6) Å) [26,27].

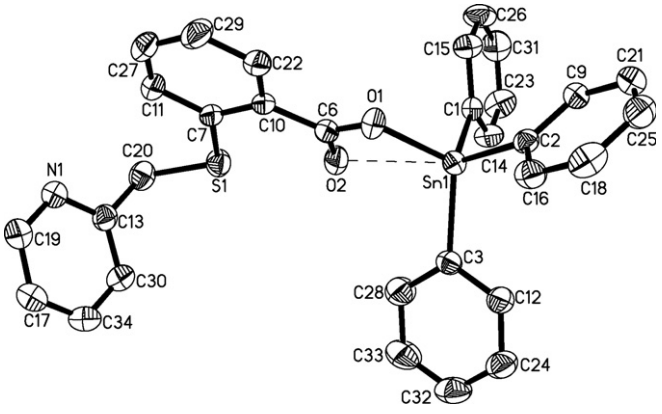

Fig. 4. The molecular structure of **7** with the thermal ellipsoids at the 30% probability level. Hydrogen atoms are omitted for clarity. Selected bond distances [Å] and angles [°]: Sn1–O1 = 2.058(2), Sn1···O2 = 2.737(3), Sn1–C1 = 2.120(3), Sn1–C2 = 2.127(3), Sn1–C3 = 2.126(3), C6–O1 = 1.304(4), C6–O2 = 1.237(4), C20–S1 = 1.819(4), S1···$S1^i$ = 3.617(4) Å; C1–Sn1–C3 = 119.4(1), C2–Sn1–O1 = 98.6(1), C1–Sn1–O1 = 106.4(1), O1–C6–O2 = 120.2(3), C7–S1–C20 = 104.3(1)° (symmetry code: i = 1 − *x*, 2 − *y*, 2 − *z*).

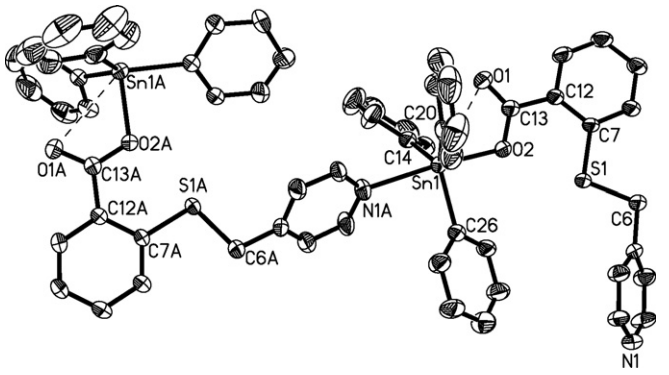

Fig. 5. The molecular structure of **8** with the thermal ellipsoids at the 30% probability level. Hydrogen atoms are omitted for clarity. Symmetric operation of "A" is −0.5 + *x*, 0.5 − *y*, 0.5 + *z*.

The IR and NMR spectra of compounds **7** and **8** are also consistent with their structures. For instance, the considerable differences between the asymmetric and symmetric stretching vibrations of the carboxylate groups (292 cm^{-1} in **7** and 301 cm^{-1} in **8**) indicate that they act as unidentate ligands [27,28]. The ^{119}Sn NMR spectrum of **7** displays one resonance at −103.44 ppm, very close to the values reported for the corresponding four-coordinated triphenyltin carboxylates, such as 105.97 ppm in $Ph_3SnO_2CCH_2CH_2COC_6H_4C_6H_5$ [29]. Although the tin atom in **8** is five-coordinate in the solid state (see Fig. 5), its ^{119}Sn NMR chemical shift (−107.52 ppm) is similar to that of **7**, indicating that the polymeric five-coordinate organotin structure is lost in solution. This result has also been observed in **6** and other polymeric or oligomeric organotin derivatives [30].

2.4. Biological activity

Preliminary *in vitro* tests for fungicidal activity of compounds **3**–**8** have been carried out by the fungi growth inhibition method [31]. These compounds are dissolved in DMF at a concentration of 50 ppm. The data are summarized in Table 3, and show that all compounds display certain activity to *Physolospora piricola* at a low concentration. Moreover, the triphenyltin carb-

Table 3
The fungicidal activities of compounds **3**–**8**

Compound	Inhibition ratio (%) (50 ppm)					
	3	**4**	**5**	**6**	**7**	**8**
Gibbereila zeae	0	0	0	0	60.8	47.8
Alternaria solani	0	0	0	23.5	70.0	23.5
Cercospora arachidicola	0	0	0	0	50.0	56.3
Physolospora piricola	45.6	39.7	39.7	51.4	70.6	85.2
Fusarium oxysporum	0	0	0	0	64.0	64.0

oxylates **7** and **8** are more active than the other diorganotin derivatives, similar to the results reported previously by Alt [32]. In addition, compound **8** shows the highest inhibition percentage for *Physolospora piricola* (85.2%) *in vitro*.

3. Experimental

Multinuclear NMR spectra were obtained with a Bruker AV300 or Mercury 300BB spectrometer using $CDCl_3$ as solvent unless otherwise noted, and the chemical shifts were reported in ppm with respect to reference standards (internal $SiMe_4$ for ^1H NMR and ^{13}C NMR spectra, external $SnMe_4$ for ^{119}Sn NMR). IR spectra were obtained on a Bio-Rad FTS 6000 spectrometer using KBr discs. Elemental analyses were carried out on a Perkin–Elmer 2400C analyzer. Melting points were measured with an X-4 digital micro melting-point apparatus and were uncorrected.

3.1. Preparation of pyridylmethylthiobenzoic acids

These acids were prepared by a slight modification of the method in the literature [20]. To a solution of KOH (0.241 mol) in 50 ml of EtOH and 10 ml of water, thiosalicylic acid (73.1 mmol) and chloromethylpyridine–HCl (73.2 mmol) were added. The reaction mixture was stirred at room temperature for 2 h, and then water (100 ml) was added. The water solution was extracted with diethyl ether (3×50 ml), and the organic phase was discarded to remove unreacted starting materials. The water phase was acidified to a pH value of 4 with 2 M HCl to give a white precipitate, which was filtered off, washed by water, and dried in air to yield pyridylmethylthiobenzoic acid, which could be crystallized with a large amount of alcohol.

3.1.1. Preparation of 2-(2-pyridylmethylthio)benzoic acid (*1*)

This acid was obtained by the reaction of thiosalicylic acid with 2-chloromethylpyridine–HCl. Yield: 72%; mp 173 °C (dec.). ^1H NMR (DMSO): $\delta = 8.53$ (d, 1H, C_5H_4N), 7.89 (d, 1H, C_5H_4N), 7.77–7.48, 7.28–7.20 (m, m, 4H, 2H, C_5H_4N and C_6H_4), 4.31 (s, 2H, CH_2) ppm. ^{13}C NMR (DMSO): $\delta = 167.3$ (CO_2H), 157.1, 149.0, 140.8, 136.9, 132.3, 130.9, 127.8, 125.8, 124.0, 123.3, 122.3 (C_5H_5N and C_6H_4), 37.8 (CH_2) ppm. IR (cm^{-1}): ν(C=O) 1688.8 s.

3.1.2. Preparation of 2-(4-pyridylmethylthio)benzoic acid (*2*)

This acid was obtained similarly to **1** using thiosalicylic acid and 4-chloromethylpyridine–HCl. Yield: 70%; mp 180 °C (dec.). ^1H NMR (DMSO): $\delta = 8.48$ (d, 2H, C_5H_4N), 7.87 (d, 2H, C_5H_4N), 7.48–7.39, 7.21–7.17 (m, m, 3H, 1H, C_6H_4), 4.23 (s, 2H, CH_2) ppm. ^{13}C NMR (DMSO): $\delta = 167.3$ (CO_2H), 149.6, 146.3, 140.0, 132.3, 130.9, 128.1, 125.9, 124.3, 124.1 (C_5H_5N and C_6H_4), 34.3 (CH_2) ppm. IR (cm^{-1}): ν(C=O) 1690.1 s.

3.2. Reaction of pyridylmethylthiobenzoic acid with R_2SnO ($R = {}^nBu$ or Et)

A mixture of pyridylmethylthiobenzoic acid **1** or **2** (1 mmol) and R_2SnO (1 mmol) in anhydrous benzene (40 ml) was stirred and heated at reflux for 8 h to yield a clear solution. After removing the benzene *in vacuo*, the crude product was recrystallized from a suitable solvent.

3.2.1. Preparation of $\{[(RCO_2)SnEt_2]_2O\}_2$ (R = 2-(2-pyridylmethylthio)phenyl) (*3*)

This compound was obtained by the reaction of **1** with Et_2SnO. The reaction time was 15 h. The crude product was recrystallized from benzene/hexane to afford white crystals of **3**. Yield: 65%; mp 167–169 °C. ^1H NMR: $\delta = 8.54$ (d, 2H, C_5H_4N), 7.90, 7.60–7.52, 7.36–7.14 (d, m, m, 2H, 4H, 8H, C_5H_4N and C_6H_4), 4.30 (s, 4H, CH_2), 1.67–1.61, 1.41–1.33 (m, m, 8H, 12H, $SnCH_2CH_3$) ppm. ^{13}C NMR: $\delta = 173.13$ (COO), 157.96, 153.17, 151.99, 149.29, 137.01, 131.82, 131.59, 126.16, 124.18, 123.18, 122.26 (C_5H_4N and C_6H_4), 39.24 (CH_2), 23.17, 21.28, 10.31, 10.06 (ethyl carbons) ppm. ^{119}Sn NMR: $\delta = -207.92$, -209.58 ppm. IR (cm^{-1}): ν_{as} (COO) 1591, 1572, ν_s (COO) 1399, 1346. *Anal.* Calc. for $C_{34}H_{40}N_2O_5S_2Sn_2$: C, 47.58; H, 4.70; N, 3.26. Found: C, 47.26; H, 4.25; N, 3.15%.

3.2.2. Preparation of $\{[(RCO_2)Sn({}^nBu)_2]_2O\}_2$ (R = 2-(2-pyridylmethylthio)phenyl) (*4*)

This compound was obtained by the reaction of **1** with $^nBu_2SnO$, and was recrystallized from ether to afford white crystals of **4**. Yield: 62%; mp 92–94 °C. ^1H NMR: $\delta = 8.55$ (d, 2H, C_5H_4N), 7.85–7.10 (m, 14H, C_5H_4N and C_6H_4), 4.30 (s, 4H, CH_2), 1.77–1.55, 1.34–1.21 (m, m, 16H, 8H, $SnCH_2CH_2CH_2$), 0.85–0.73 (m, 12H, CH_3) ppm. ^{13}C NMR: $\delta = 172.98$ (COO), 157.81, 157.51, 149.09, 139.91, 136.68, 131.27, 131.03, 126.21, 124.05, 122.97, 121.98 (C_5H_4N and C_6H_4), 39.14 (CH_2), 30.08, 28.47, 27.64, 27.37, 26.87, 26.82, 13.59, 13.53 (butyl carbons) ppm. ^{119}Sn NMR: $\delta = -194.13$, -195.13 ppm. IR (cm^{-1}): ν_{as} (COO) 1591, 1575, ν_s (COO) 1406, 1346. *Anal.* Calc. for $C_{42}H_{56}N_2O_5S_2Sn_2$: C, 51.98; H, 5.82; N, 2.89. Found: C, 51.67; H, 5.89; N, 2.70%.

3.2.3. Preparation of $\{[(RCO_2)SnEt_2]_2O\}_2$ (R = 2-(4-pyridylmethylthio)phenyl) (*5*)

This compound was obtained by the reaction of **2** (1 mmol) with Et_2SnO (1 mmol), and was recrystallized from benzene/hexane to afford white crystals of **5**. Yield: 64%; mp 174–177 °C. ^1H NMR: $\delta = 8.46$ (d, 4H, C_5H_4N), 7.81 (d, 2H, C_6H_4), 7.29–7.19, 7.09–7.03 (m, m, 6H, 4H, C_5H_4N and C_6H_4), 4.03 (s, 4H, CH_2), 1.59–1.46, 1.33–1.25 (m, m, 8H, 12H, $SnCH_2CH_3$) ppm. ^{13}C NMR: $\delta = 172.90$ (COO), 150.21, 148.61, 136.37, 132.67, 131.48, 128.33, 126.32, 124.49, 123.42 (C_5H_4N and C_6H_4), 34.67 (CH_2), 22.92, 20.97, 10.03, 9.76 (ethyl carbons) ppm. ^{119}Sn NMR: $\delta = -193.17$ (br) ppm. IR (cm^{-1}): ν_{as} (COO) 1592, 1573, ν_s (COO) 1459, 1398. *Anal.* Calc. for

$C_{34}H_{40}N_2O_5S_2Sn_2$: C, 47.58; H, 4.70; N, 3.26. Found: C, 47.62; H, 4.57; N, 3.23%.

3.2.4. Preparation of $(RCO_2)_2Sn(^nBu)_2$ (R = 2-(4-pyridylmethylthio)phenyl) (6)

This compound was obtained by the reaction of **2** (1 mmol) with $^nBu_2SnO$ (1 mmol), and was recrystallized from ethyl acetate/hexane to afford white crystals of **6**. Yield: 68%; mp 174–176 °C. ^{1}H NMR: $\delta = 8.58$ (d, 4H, C_5H_4N), 8.17 (d, 2H, C_6H_4), 7.44–7.38, 7.24–7.19 (m, m, 6H, 4H, C_5H_4N and C_6H_4), 4.15 (s, 4H, CH_2), 1.90–1.84, 1.80–1.73, 1.44–1.37 (m, m, m, 4H, 4H, 4H, $SnCH_2CH_2CH_2$), 0.88 (t, 6H, CH_3) ppm. ^{13}C NMR: $\delta = 175.58$ (*C*OO), 149.89, 146.11, 140.30, 132.60, 132.52, 128.62, 125.92, 124.62, 124.03 (C_5H_4N and C_6H_4), 36.23 (CH_2), 26.73, 26.26, 26.19, 13.57 (butyl carbons) ppm. ^{119}Sn NMR: $\delta = -155.56$ ppm. IR (cm^{-1}): ν_{as} (COO) 1615, ν_s (COO) 1401. *Anal.* Calc. for $C_{34}H_{38}N_2O_4S_2Sn$: C, 56.60; H, 5.31; N, 3.88. Found: C, 56.39; H, 5.20; N, 3.64%.

3.3. Reaction of pyridylmethylthiobenzoic acid with $(Ph_3Sn)_2O$

A mixture of pyridylmethylthiobenzoic acid **1** or **2** (2 mmol) and $(Ph_3Sn)_2O$ (1 mmol) in anhydrous benzene (40 ml) was stirred and heated at reflux for 6 h to yield a clear solution. After removing the benzene *in vacuo*, the crude product was recrystallized from a suitable solvent.

3.3.1. Preparation of RCO_2SnPh_3 (R = 2-(2-pyridylmethylthio)phenyl) (7)

This compound was obtained by the reaction of **1** with $(Ph_3Sn)_2O$, and recrystallized from ether/hexane to afford white crystals of **7**. Yield: 78%; mp 103–105 °C. ^{1}H NMR: $\delta = 8.57$, 8.15 (d, d, 1H, 1H, C_5H_4N), 7.97–7.76 (m, 6H, C_6H_5), 7.61, 7.52–7.33, 7.19–7.12 (t, m, m, 1H, 12H, 2H, C_6H_5, C_5H_4N and C_6H_4), 4.34 (s, 2H, CH_2) ppm. ^{13}C NMR: $\delta = 172.87$ (*C*OO), 157.62, 149.10, 141.11, 138.48, 137.43, 137.04, 136.91, 132.93, 132.38, 130.15, 128.93, 126.08, 124.17, 122.98, 122.14 (C_6H_5, C_5H_4N and C_6H_4), 38.97 (CH_2) ppm. ^{119}Sn NMR: $\delta = -103.44$ ppm. IR (cm^{-1}): ν_{as} (COO) 1622, ν_s (COO) 1330. *Anal.* Calc. for $C_{31}H_{25}NO_2SSn$: C, 62.65; H, 4.24; N, 2.36. Found: C, 62.38; H, 4.55; N, 2.43%.

3.3.2. Preparation of RCO_2SnPh_3 (R = 2-(4-pyridylmethylthio)phenyl) (8)

This compound was obtained by the reaction of **2** with $(Ph_3Sn)_2O$, and recrystallized from benzene/hexane to afford slight yellow crystals of **8**. Yield: 80%; mp 186–188 °C. ^{1}H NMR: $\delta = 8.49$, 7.18 (d, d, 2H, 2H, C_5H_4N), 8.11 (d, 1H, C_6H_4), 7.95–7.74 (m, 6H, C_6H_5), 7.47–7.29 (m, 12H, C_6H_5 and C_6H_4), 4.08 (s, 2H, CH_2) ppm. ^{13}C NMR: $\delta = 172.38$ (*C*OO), 149.88, 146.24, 139.88, 138.43, 137.00, 132.61, 132.03, 130.16, 128.92, 128.35, 126.38, 124.72, 124.02 (C_6H_5, C_5H_4N and C_6H_4), 36.49 (CH_2) ppm. ^{119}Sn NMR: $\delta = -107.52$ ppm. IR (cm^{-1}): ν_{as} (COO) 1632, ν_s (COO) 1331. *Anal.* Calc. for $C_{31}H_{25}NO_2SSn$: C, 62.65; H, 4.24; N, 2.36. Found: C, 62.58; H, 4.47; N, 2.24%.

4. Crystal structure determinations

Crystals of **4** and **7** suitable for X-ray analyses were obtained by slowly cooling their hot ether/hexane solutions. Crystals of **6** suitable for X-ray analysis were

obtained by slow diffusion of hexane into its CH_2Cl_2 solution at room temperature. Crystals of **5** and **8** suitable for X-ray analyses were obtained by slowly cooling their hot benzene/hexane solutions. Intensity data were collected on a Rigaku Saturn CCD detector for **4** and **5**, and a Bruker SMART CCD diffractometer for **6**–**8**. One carbon (C4) of an ethyl group at the tin atom in **5** is disordered and was refined over two sites with occupancies of 0.41 for C4 and 0.59 for C4′. The pyridyl carbons (C1–C4) and the phenyl carbons (C27, C28, C30 and C31) in **8** are also disordered. The site occupation factors of these disordered atoms were adjusted (0.63 for C1–C4 atoms and 0.59 for C27, C28, C30 and C31 atoms) to give reasonable thermal parameters. The structures were solved by direct methods and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined anisotropically. A summary of the fundamental crystal data for **4**–**8** is listed in Table 4.

undergo significant changes in coordination geometry during the redox process. The ability to deliberately control the microstructure of a coordination polymer by using macroscopic principles, through dissociation/binding of ligands from/to metal centres by an applied potential can have numerous material applications [15]. Copper(I) polypyridine complexes also display interesting photoluminescent properties. There has been considerable interest to harness the photophysical properties of copper(I) polypyridines for many practical applications, such as light harvesters, molecular sensors and switches [16]. The excellent photophysical properties of copper(I) polypyridines have opened a new area of study involving their intercalation with biological systems, in particular DNA intercalation and cleavage [17].

Phenanthroline based ligands, such as dipyrido[3,2-*f*:2′,3′-*h*]-quinoxaline (dpq), dipyridophenazine (dppz) and 7,8-dimethylpyridophenazine (dppx) with an extended planar quinoxaline moiety, can act as good bidentate ligands as well as good binders to DNA. Several ruthenium(II) complexes, such as $[RuL_2(dpq)]^{2+}$ (L = bpy or phen), have been synthesized because they bind to DNA strongly by intercalating the aromatic dpq ligand between the base pair. Moreover, on binding to DNA they strongly luminesce, acting as "light switches" [18]. More recently, the synthesis, structure and DNA binding of a copper(I) complex of dpq has been reported [19]. It has also been shown that copper(II) complexes having photoactive and DNA binding ligands cleave DNA on irradiation with red light [20]. Ternary copper(II) complexes derived from tridentate ONO and ONS ligands and the DNA binding ligand dpq cleaves DNA on exposure to red light [21]. In view of the growing interest in the use of the ligand dpq, which besides the studies made above has not been used extensively, we have been interested to explore the coordination chemistry of the dpq transition metal complexes in greater detail. Herein we report the synthesis, X-ray crystal structures, spectroscopic properties and redox activities of zinc(II), copper(I), copper(II), nickel(II), cobalt(II), cobalt(III), iron(II) and manganese(II) complexes of dpq.

dpq

2. Experimental

2.1. Materials

All chemicals were obtained from commercial sources and were used as received. Solvents were dried and purified according to standard methods [22]. 1,2-Diaminoethane was dried over potassium hydroxide before vacuum distillation. 1,10-Phenanthroline-5,6-dione was prepared according to the reported method [23].

Caution: The perchlorate salts reported here are potentially explosive and, therefore, should be handled with care.

2.2. Preparation of dipyrido[3,2-f:2′,3′-h]-quinoxaline (dpq)

The ligand was prepared by the condensation of 1,10-phenanthroline-5,6-dione and 1,2-diaminoethane in a modified method [24]. To an acetonitrile solution (20 mL) of 1,10-phenanthroline-5,6-dione (1.05 g, 5 mmol), an acetonitrile solution (10 mL) of 1,2-diaminoethane (0.30 g, 5 mmol) was added. The mixture was refluxed for 3 h after which it was cooled to room temperature. A black resinous precipitate was removed by filtration and the filtrate was dried on a rotary evaporator. The crude product thus obtained was recrystallized from acetonitrile to get the white crystalline pure compound. Yield: 2.5 g (70%). *Anal.* Calc. for $C_{14}H_8N_4$: C, 72.40; H, 3.47; N, 24.12. Found: C, 72.40; H, 3.48; N, 24.08%. IR (KBr): 3446br, 1635w, 1577m, 1519w, 1467m, 1392s, 1207w, 1116w, 1080m, 870w, 1212m, 808s, 740s, 686w, 621m. ^{1}H NMR ($CDCl_3$, 300 MHz): δ 9.45 (d, 2H), 9.23 (d, 2H), 8.93 (s, 2H), 7.74 (m, 2H).

2.3. Preparation of the metal complexes

2.3.1. $[Cu^I(dpq)_2](ClO_4)$ (1)

To a solution of dpq (0.46 g, 2 mmol) in dry methanol (10 mL) was added a solution of $[Cu(CH_3CN)_4](ClO_4)$ (0.33 g, 1 mmol) in dry methanol (10 mL) under a nitrogen atmosphere. The resulting dark red solution was refluxed for 0.5 h, during which time a dark maroon microcrystalline compound was deposited. The product was collected by filtration and washed with methanol. Yield: 0.50 g (80%). *Anal.* Calc. for $C_{28}H_{16}N_8O_4ClCu$: C, 53.59; H, 2.57; N, 17.86. Found: C, 53.50; H, 2.60; N, 17.78%. ESI-MS (positive, in acetonitrile): $m/z = 527.08$ (100%) $[Cu(dpq)_2]^+$. IR (KBr): 3434br, 3085w, 1627w, 1576m, 1470m, 1434w, 1420s, 1384s, 1275w, 1085s, 839w, 734m, 630m cm^{-1}. ^{1}H NMR (DMSO-d_6, 300 MHz): δ 9.65 (d, 2H), 9.31 (s, 2H), 9.14 (d, 2H), 8.18 (dd, 2H). UV–Vis–NIR (λ_{max}/nm (ε/M^{-1} cm^{-1})): 215 (62000), 255 (100000), 300 (34000), 445 (4700).

2.3.2. $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (2)

To a solution of dpq (0.46 g, 2 mmol) in methanol (15 mL) was added a methanol solution (10 mL) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1.0 mmol). The resulting blue solution was stirred at room temperature for 0.5 h. On concentration of the solution to ca. 10 mL on a hot plate, a crystalline product was deposited. This was filtered and recrystallized from 1:1 acetonitrile–ethanol to obtain single crystals of a bluish-green colour. Yield: 0.60 g (75%). *Anal.*

Calc. for $C_{28}H_{20}N_8O_{10}Cl_2Cu$: C, 44.08; H, 2.64; N, 14.69. Found: C, 44.18; H, 2.62; N, 14.65%. ESI-MS (positive, in acetonitrile): $m/z = 626.03$ (15%) $[Cu(dpq)_2(ClO_4)]^+$; 264.55 (100%) $[Cu(dpq)_2]^{2+}$. IR (KBr): 3403br, 3085w, 1626w, 1582m, 1532m, 1488s, 1428s, 1388s, 1282w, 1087s, 818m, 731s, 622m cm^{-1}. UV–Vis–NIR (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$)): 215 (63000), 260 (100000), 295 (35000), 700 (100), 900 (115).

2.3.3. $[Cu^{II}(dpq)_2](ClO_4)_2$ (3)

A dry acetonitrile solution (15 mL) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1.0 mmol) and a solution of dpq (0.46 g, 2 mmol) in the same solvent were mixed together. The resulting solution was refluxed for 0.5 h, during which period a clear blue solution was obtained. The solution was filtered and the filtrate was concentrated on a water bath to ca. 5 mL. On slow evaporation of the solvent at room temperature, a blue crystalline product was deposited. This was filtered and washed with 1:1 acetonitrile–diethyl ether. Yield: 0.58 g (80%). *Anal.* Calc. for $C_{28}H_{16}N_8O_8Cl_2Cu$: C, 46.26; H, 2.22; N, 15.41. Found: C, 46.18; H, 2.20; N, 15.36%. ESI-MS (positive, in acetonitrile): $m/z = 626.03$ (20%) $[Cu(dpq)_2(ClO_4)]^+$; 264.55 (100%) $[Cu(dpq)_2]^{2+}$. IR (KBr): 3078w, 1619w, 1582m, 1531w, 1485m, 1407s, 1387m, 1308m, 1213w, 1088s, 818m, 731s, 625m cm^{-1}. UV–Vis–NIR (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$)): 215 (63000), 260 (100000), 295 (35000), 700 (50), 900 (55).

2.3.4. $[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (4)

To a dry acetonitrile solution (15 mL) of compound 1,10-phenanthroline-5,6-dione (0.42 g, 2 mmol) was added an acetonitrile solution (10 mL) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1.0 mmol) and the resulting green solution was set to reflux. A solution of 1,2-diaminoethane (0.12 g, 2 mmol) in 10 mL of dry acetonitrile was gradually added to the reaction mixture under refluxing conditions. The solution became reddish-brown and the reflux was continued for 2 h during which time a dark maroon microcrystalline compound was deposited. The product was collected by filtration and was identified to be copper(I) compound **1**. The green filtrate on standing at room temperature produced bright green single crystals of compound **4**. These were filtered and washed with 1:1 acetonitrile–diethyl ether. Yield: 0.45 g (60%). *Anal.* Calc. for $C_{56}H_{34}N_{16}O_{17}Cl_4Cu_2$: C, 45.70; H, 2.33; N, 15.23. Found: C, 45.65; H, 2.30; N, 15.17%. ESI-MS (positive, in acetonitrile): $m/z = 626.03$ (15%) $[Cu(dpq)_2(ClO_4)]^+$; 264.55 (100%) $[Cu(dpq)_2]^{2+}$. IR (KBr): 3407br, 3081w, 1615w, 1581m, 1531w, 1486m, 1407s, 1388m, 1308w, 1214w, 1088s, 818m, 732m, 625m cm^{-1}. UV–Vis–NIR (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$)): 215 (63000), 260 (100000), 295 (35000), 700 (190), 900 (200).

2.3.5. $[Zn^{II}(dpq)_2(ClO_4)_2]$ (5)

A solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (0.34 g, 1 mmol) in 10 mL of dry acetonitrile was added to a solution of dpq (0.46 g, 2 mmol) in acetonitrile (10 mL) and the mixture was refluxed for 1 h. The solution was filtered and the filtrate was concentrated to ca. 5 mL on a hot plate. On slow evaporation of the solvent at the room temperature, light yellow crystals deposited. The product was filtered and washed with 1:1 acetonitrile–diethyl ether. Yield: 0.55 g (75%). *Anal.* Calc. for $C_{28}H_{16}N_8O_8Cl_2Zn$: C, 46.14; H, 2.21; N, 15.38. Found: C, 46.11; H, 2.19; N, 15.41%. ESI-MS (positive, in acetonitrile): $m/z = 627.03$ (20%) $[Zn(dpq)_2(ClO_4)]^+$; 265.05 (100%) $[Zn(dpq)_2]^{2+}$. IR (KBr): 3423br, 3052w, 1613w, 1582m, 1529w, 1481m, 1446w, 1403s, 1388s, 1338w, 1262w, 1212w, 1084s, 925w, 873w, 827m, 737m, 630s cm^{-1}. ^1H NMR (DMSO-d_6, 300 MHz): δ 9.74 (d, 2H), 9.17 (s, 2H), 8.38 (d, 2H), 7.95 (dd, 2H). UV–Vis–NIR (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$)): 225 (46600), 255 (92000), 300 (28600).

2.3.6. $[Ni^{II}(dpq)_3](ClO_4)_2$ (6)

To a methanol solution of dpq (0.35 g, 1.5 mmol) was added a solution (10 mL) of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.16 g, 0.5 mmol) in methanol. The pink coloured solution was refluxed for 0.5 h and the microcrystalline product that deposited was filtered and recrystallized from 1:1 acetonitrile–ethanol. Yield: 0.38 g (85%). *Anal.* Calc. for $C_{42}H_{24}N_{12}O_8Cl_2Ni$: C, 52.86; H, 2.53; N, 17.70. Found: C, 52.76; H, 2.50; N, 17.61%. ESI-MS (positive, in acetonitrile): $m/z = 378.09$ (100%) $[Ni(dpq)_3]^{2+}$. IR (KBr): 3419br, 3091w, 1613w, 1581m, 1530w, 1481m, 1446w, 1388s, 1338w, 1304w, 1262w, 1212m, 1084s, 925w, 873w, 827m, 737m, 630m cm^{-1}. ^1H NMR (DMSO-d_6, 300 MHz): δ 50.30 (2H), 17.93 (2H), 10.14 (2H). UV–Vis–NIR (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$)): 215 (60000), 260 (110000), 300 (4000), 785 (11), 855 (9).

2.3.7. $[Co^{II}(dpq)_3](ClO_4)_2$ (7)

This compound was prepared in the same way as described for **6**, using $Co(ClO_4)_2 \cdot 6H_2O$ instead of $Ni(ClO_4)_2 \cdot 6H_2O$. Yield: 85%. *Anal.* Calc. for $C_{42}H_{24}N_{12}O_8Cl_2Co$: C, 52.85; H, 2.53; N, 17.61. Found: C, 52.79; H, 2.51; N, 17.55%. ESI-MS (positive, in acetonitrile): $m/z = 378.59$ (100%) $[Co(dpq)_3]^{2+}$. IR (KBr): 3415br, 3083w, 1611w, 1581m, 1530m, 1481m, 1404s, 1389s, 1314w, 1282w, 1213m, 1088s, 816m, 735m, 623m cm^{-1}. ^1H NMR (DMSO-d_6, 300 MHz): δ 99.88 (2H), 49.84 (2H), 18.14 (2H), 13.63 (2H). UV–Vis–NIR (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$)): 210 (58000), 250 (107000), 290 (52000), 910 (10).

2.3.8. $[Co^{III}(dpq)_3](ClO_4)_3$ (8)

Compound **7** (0.48 g, 0.5 mmol) was dissolved in 15 mL of dry methanol and a mixture of $(C_4H_9)_4NBr$ (0.16 g, 0.5 mmol) and Br_2 (80 mg, 0.5 mmol) in methanol (2 mL) was added to it over a period of 0.5 h. A pink coloured compound of the composition $[Co^{III}(dpq)_3]Br_3$ that deposited was collected by filtration and washed thoroughly with methanol. The product was suspended in methanol (20 mL) and a methanol (5 mL) solution of $AgClO_4$ (3 mmol) was added to it. The mixture was stirred for 1 h

and the precipitated AgBr was removed by filtration. The filtrate on concentration produced bright pink crystals. Yield: 85%. *Anal*. Calc. for $C_{42}H_{24}N_{12}O_{12}Cl_3Co$: C, 47.86; H, 2.29; N, 15.95. Found: C, 47.78; H, 2.25; N, 15.89%. ESI-MS (positive, in acetonitrile): $m/z = 426.06$ (80%) $[Co(dpq)_3(ClO_4)]^{2+}$; 252.73 (100%) $[Co(dpq)_3]^{3+}$. IR (KBr): 3415br, 3078br, 1619w, 1582m, 1531w, 1485m, 1407s, 1387m, 1213w, 1088s, 818m, 731s, 625m cm^{-1}. ^1H NMR (DMSO-d_6, 300 MHz): δ 9.86 (d, 2H), 9.50 (s, 2H), 8.14 (dd, 2H), 7.88 (d, 2H). UV–Vis–NIR (λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)): 210 (66000), 250 (95000), 290 (sh, 34000), 460 (210).

2.3.9. $[Fe(dpq)_3](ClO_4)_2$ (**9**)

To a methanol solution of dpq (0.35 g, 1.5 mmol) was added solid $Fe(ClO_4)_2 \cdot 6H_2O$ (0.16 g, 0.5 mmol) under nitrogen. The solution was heated under reflux for 0.5 h, during which time a deep red crystalline compound was deposited. This was collected by filtration and recrystallized from 1:1 ethanol–acetonitrile. Yield: 0.35 g, 85%. *Anal*. Calc. for $C_{42}H_{24}N_{12}O_8Cl_2Fe$: C, 53.02; H, 2.54; N, 17.66. Found: C, 52.97; H, 2.48; N, 17.60%. ESI-MS (positive, in acetonitrile): $m/z = 378.59$ (100%) $[Fe(dpq)_3]^{2+}$. IR (KBr): 3415br, 3083w, 1632m, 1580w, 1483m, 1406s, 1385s, 1260w, 1210w, 1107s, 1088s, 813m, 733m, 627m cm^{-1}. ^1H NMR (DMSO-d_6, 300 MHz): δ 9.55 (d, 2H), 9.37 (s, 2H), 7.94 (d, 2H), 7.88 (dd, 2H). UV–Vis–NIR (λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)): 255 (144000), 295 (54000), 440 (7100), 520 (10600), 850 (5).

2.3.10. $[Mn^{II}(dpq)_3](ClO_4)_2$ (**10**)

This compound was prepared in the same way as described for **6**, using $Mn(ClO_4)_2 \cdot 6H_2O$ instead of $Ni(ClO_4)_2 \cdot 6H_2O$. Yield: 0.38 g (80%). *Anal*. Calc. for $C_{42}H_{24}N_{12}O_8Cl_2Mn$: C, 53.07; H, 2.54; N, 17.68. Found: C, 53.00; H, 2.50; N, 17.68%. ESI-MS (positive, in acetonitrile): $m/z = 376.59$ (100%) $[Mn(dpq)_3]^{2+}$. IR (KBr): 3421br, 3098w, 1646w, 1581m, 1529w, 1478m, 1436w, 1389s, 1307w, 1213w, 1085s, 878w, 737m, 627m cm^{-1}. UV–Vis–NIR (λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)): 225 (58300), 255 (115000), 295 (35000).

2.4. Physical measurements

The C, H and N analyses were performed on a Perkin–Elmer 2400 II elemental analyzer. IR spectra were recorded using KBr disks on a Shimadzu FTIR 8400S spectrometer. The electronic absorption spectra were obtained with a Perkin–Elmer 950 UV/Vis/NIR spectrophotometer. The electrospray ionization mass spectra (ESI-MS) were measured on a Micromass Qtof YA 263 mass spectrometer. The electrochemical measurements were carried out with a BAS 100 B electrochemistry system using a three-electrode assembly comprising a glassy carbon working electrode, Pt auxiliary electrode and an aqueous Ag/AgCl reference electrode. The cyclic voltammetric (CV) and square wave voltammetric (SWV) measurements were carried out at 25 °C under a nitrogen atmosphere at room temperature. The solutions were 1 mmol dm^{-3} in complexes and 0.1 mol dm^{-3} in tetraethylammonium perchlorate (TEAP) as the supporting electrolyte. The reference electrode was separated from the bulk electrolyte by a salt bridge containing the supporting electrolyte in nitromethane solutions. IR compensation was made automatically during each run. Under the experimental conditions the $E_{1/2}$ values of the ferrocene/ferrocenium couple were observed at 435 and 410 mV in acetonitrile and nitromethane, respectively.

2.5. Crystallography

Crystals suitable for structure determinations of $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (**2**), $[Cu^{II}(dpq)_2](ClO_4)_2$ (**3**), $[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**) and $[Zn^{II}(dpq)_2(ClO_4)_2]$ (**5**) were obtained by slow evaporation of their acetonitrile–ethanol solutions. The crystals were mounted on glass fibres using perfluoropolyether oil. Intensity data were collected on a Bruker AXS SMART APEX diffractometer at 153(2) K for **2**, **4** and **5** and at 223(2) K for **3** using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The data were processed with SAINT [25] and absorption corrections were made with SADABS [25] The structures were solved by direct and Fourier methods and refined by full-matrix least-squares methods based on F^2 using SHELX-97 [26]. For the structure solutions and refinements the SHELX-TL software package [27] was used. The non-hydrogen atoms were refined anisotropically, while the hydrogen atoms were placed at geometrically calculated positions with fixed thermal parameters. Crystal data and details of data collection are listed in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

The ligand dipyrido[3,2-*f*:2′,3′-*h*] quinoxaline, abbreviated as dpq, has been obtained by [1+1] cyclocondensation between 1,10-phenanthroline-5,6-dione and 1,2-diaminoethane. The ligand dpq readily reacts with $[Cu(CH_3CN)_4](ClO_4)$ in acetonitrile under nitrogen to produce the copper(I) complex $[Cu^{I}(dpq)_2](ClO_4)$ (**1**). The reaction with $Cu(ClO_4)_2 \cdot 6H_2O$ under slightly different conditions, however, gives rise to three different products **2**–**4**, all of which have been structurally characterized. For example, the reaction between the ligand and the metal salt in methanol produces the bluish-green compound $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (**2**), while the reaction carried out in dry acetonitrile produces blue crystals of composition $[Cu^{II}(dpq)_2](ClO_4)_2$ (**3**). In contrast, if the condensation reaction between 1,10-phenanthroline-5,6-dione and 1,2-diaminoethane is carried out in acetonitrile in the presence of $Cu(ClO_4)_2 \cdot 6H_2O$, initially the copper(I) complex **1** is deposited and from the filtrate a green coloured co-crystal-

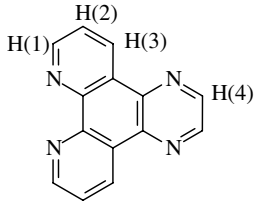
lized compound of composition $[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**) is isolated. The reaction between dpq and $Zn(ClO_4)_2 \cdot 6H_2O$ in a 2:1 ratio in methanol leads to the formation of $[Zn^{II}(dpq)_2(ClO_4)_2]$ (**5**). The tris-dpq complexes $[M^{II}(dpq)_3](ClO_4)_2$ (M = Ni (**6**), Co (**7**), Fe (**9**) and Mn (**10**)) are obtained by the direct reaction between the ligand and the metal salt in a 1:3 ratio. The cobalt(II) complex on oxidation with bromine produces the corresponding cobalt(III) complex as the bromide salt, which on treatment with a stoichiometric amount of silver perchlorate affords the cobalt(III) compound $[Co^{III}(dpq)_3](ClO_4)_3$ (**8**).



In all the perchlorate compounds, characteristic ClO_4^- vibrations for ionic perchlorate are observed at about 1085–1090 and 625–630 cm^{-1}.

Compounds **1**–**10** have been characterized by their ESI (positive) mass spectra measurements in acetonitrile. Complex $[Cu^{I}(dpq)_2](ClO_4)$ (**1**) exhibits a single peak at 527.08 due to the unipositive cation $[Cu^{I}(dpq)_2]^+$. For complexes **2**–**5**, similar spectral features have been observed. They are characterized by the observation of both unipositively charged $[M^{II}(dpq)_2(ClO_4)]^+$ and doubly-positively charged $[M^{II}(dpq)_2]^{2+}$ (M = Cu and Zn) species. For the tris-dpq compounds **6**, **7**, **9** and **10** only one peak is observed due to the dication $[M^{II}(dpq)_3]^{2+}$ (M = Ni, Co, Fe and Mn). The mass spectra of the cobalt(III) complex $[Co(dpq)_3](ClO_4)_3$ (**8**) exhibits the features expected for the doubly-positively charged $[Co(dpq)_3(ClO_4)]^{2+}$ and triply-positively charged $[Co(dpq)_3]^{3+}$ species. As examples, the observed and the simulated spectra of compounds **8** and **10** are shown in Fig. S1a and b.

3.2. ^1H NMR spectra

^{1}H NMR spectroscopic studies were carried out for complexes **1**, **5**, **6**, **7**, **8** and **9** in $(CD_3)_2SO$. The observed chemical shifts along with the spectral assignments are given in Section 2.

For the diamagnetic complexes **1**, **5**, **8** and **9** the ligand resonances are expected to be observed as a doublet H(1), doublet of doublet H(2), doublet H(3) and a singlet H(4) (the numbering scheme for the protons is shown in Scheme 1). For complex **1**, the two doublets are observed at 9.65 ($J = 8.3$ Hz) and 9.14 ($J = 5.2$ Hz) ppm for H(1) and H(3), respectively, while the singlet and the doublet of doublet appear at 9.31 and 8.18 ($J = 5.1$, 2.9 Hz) ppm. The spectral features exhibited by **5** and **9** are quite similar. The H(4) proton is observed as a sharp singlet at $\delta = 9.17$ ppm for **5** and at 9.37 ppm for **9**. Complex **5** exhibits two doublets for H(1) and H(3) at $\delta = 9.73$ ($J = 8.8$ Hz) and 8.37 ($J = 4.8$ Hz) ppm, respectively; however, for **9** these two peaks are observed at $\delta = 9.55$ ($J = 8.2$ Hz) and 7.95 ($J = 5.2$ Hz) ppm. The H(2) proton

Scheme 1.

appears as a doublet of doublet at $\delta = 7.94$ ppm ($J = 4.9$, 3.3 Hz) in **5** and at 7.87 ppm ($J = 5.2$,2.8 Hz) in **9**. The spectrum of **9** is shown in Fig. S2a. Finally, $[Co^{III}(dpq)_3](ClO_4)_3$ (**8**) exhibits a doublet at 9.88 ppm ($J = 8.2$ Hz), the singlet at 9.49 ppm, the doublet of doublet at 8.13 ppm ($J = 5.8$, 2.4 Hz) and a doublet at 7.87 ppm ($J = 5.6$ Hz), which are due to the H(1), H(4), H(2) and H(3) protons, respectively (Fig. S2b).

Studies on the paramagnetic ^{1}H NMR spectroscopic behaviour of the two complexes **6** and **7** have been carried out in $(CD_3)_2SO$ solution. In paramagnetic compounds, hyperfine-shifted resonances are observed due to interactions between nuclear spin and unpaired electron spins, in addition to the normal diamagnetic nuclear spin interactions. Electron and nuclear spin interactions occurring through bonds give rise to the Fermi contact shift, while those interactions occurring through space give rise to a dipolar or pseudocontact shift. The dipolar shift depends on the magnetic anisotropy of the system and the position in space of a given proton. The contribution of contact shift decreases rapidly with the increase of the number of bonds connecting the proton with the paramagnetic centre, and vanishes after three or four bond separations. However, when the unpaired electron spin is delocalized the interaction remains significant for protons many bonds away from the metal centre. For assignment of signals in paramagnetic compounds, measurement of longitudinal relaxation times (T_1) and transverse relaxation times (T_2) are particularly important. T_1 correlates with the proximity of proton to paramagnetic centre, while $T_2 = 1/\tau(\text{fwh})$, where fwh is the full width of a signal at its half-height, correlates the line width to the proximity of a proton to the paramagnetic site. Closer proximity of a proton to the metal centre gives rise to a shorter T_1 and broader line width.

Fig. S2c shows the spectrum observed for the high-spin cobalt(II) complex **7**. Of the four observed resonances, the three signals that are observed at 49.84, 18.14 and 13.63 ppm are sharp, while the one observed at 99.90 ppm is broader. The assignments made for these signals from T_1 values, line widths and integration of protons are given in Table 2. The spectrum of the high-spin nickel(II) complex (**6**), however, exhibits (Fig. S2d) only three signals at 50.30 H(2), 17.90 H(3) and 10.15 H(4) ppm, all having the same areas of integration. The assignment of the signals of structurally related nickel(II) compound **6** has been made straightforward by comparison with **7**. As may be noted, the broadening of the resonances increases as they are shifted to lower fields. It seems that the missing resonance H(1) is lost due to line broadening and its shift to a considerably lower field.

Table 2
Chemical shifts, T_1 values, line widths and spectral assignments for $[Co^{II}(dpq)_3](ClO_4)_2$ (**7**) in DMSO-d_6

δ (ppm)	Relative area	T_1 (ms)	$\Delta_{1/2}$ (Hz)[a]	Assignment[b]
99.89	1	<1	305	H(1)
49.84	1	29.77	45	H(2)
18.14	1	51.64	25	H(3)
13.77	1	359.17	20	H(4)

[a] Full width at half-height.
[b] Proton sites are illustrated in Scheme 1.

3.3. Crystal structures

3.3.1. $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (2)

The ORTEP representation of the cation $[Cu(dpq)_2(H_2O)]^{2+}$ in **2** is shown in Fig. 1a and the relevant bond distances and angles are given in Table 3. The five-coordinated copper(II) centre $[CuN_4O]$ adopts a distorted trigonal bipyramidal geometry. The atoms N(1), N(2) and O(WA1) form an exact trigonal plane on which the copper atom lies. The nitrogen atoms N(2) and N(4) are *trans*-axially disposed. The distances of the copper centre from the donor atoms in the trigonal plane are unequal; the Cu–N(1) [2.105(2) Å] and Cu–O(WA1) [2.142(2) Å] distances are considerably longer than the Cu–N(3) distance [2.029(2) Å]. The two axial distances Cu–N(2) [1.966(2) Å] and Cu–N(4) [1.972(2) Å], however, are very close and are shorter than the equatorial bond lengths. Considerable departure of the relevant angles in the equatorial plane [N(1)–Cu–N(3) = 125.55(8)°, N(1)–Cu–O(WA1) = 95.24(7)° and N(3)–Cu–O(WA1) = 139.21(7)°] from the desired angle of 120° are indicative of distortion from ideal tbp geometry. The *trans*-axial N(2)–Cu–N(4) angle is 172.21(8)°. The indicator of a five-coordinated geometry τ in this case is 0.55 ($\tau = 0$ for sp and 1 for tbp) [28].

An interesting array of intra and intermolecular hydrogen bonds is observed in compound **2** (Fig. 1b and Table S1). The two hydrogen atoms of the coordinated water (WA1) are bridged with a perchlorate oxygen O(23) and the oxygen atom of the solvated water (WA2), whose hydrogen atoms in turn are bridged with a perchlorate oxygen O(11) and a quinoxaline nitrogen atom N(6) of a symmetry related adjacent molecule. In effect, the two adjacent complex molecules form a dimeric unit by involving the ionic perchlorates and the solvated water in the hydrogen bonding network.

It should be mentioned that after determination of the structures of the copper(II) compounds **2**–**4**, we found that the X-ray structure of **2** has been reported by another group [20]. While the structure determination of **2** by us has been made at 153 K, the reported one was made at 293 K. Accordingly, the unit cell parameters found in the present case are relatively shorter as compared to the earlier reported values [20]. The influence of temperature can be appreciated by comparing the unit cell volume, which is 1443.81(2) Å^3 at 153 K as against 1481.7(8) Å^3 at 293 K. In terms of Cu–N distances, the difference observed in the two sets of studies are insignificant, albeit the Cu–O(W) distance reported here [2.1236(18) Å] is somewhat shorter compared to the reported value [2.145(3) Å]. As

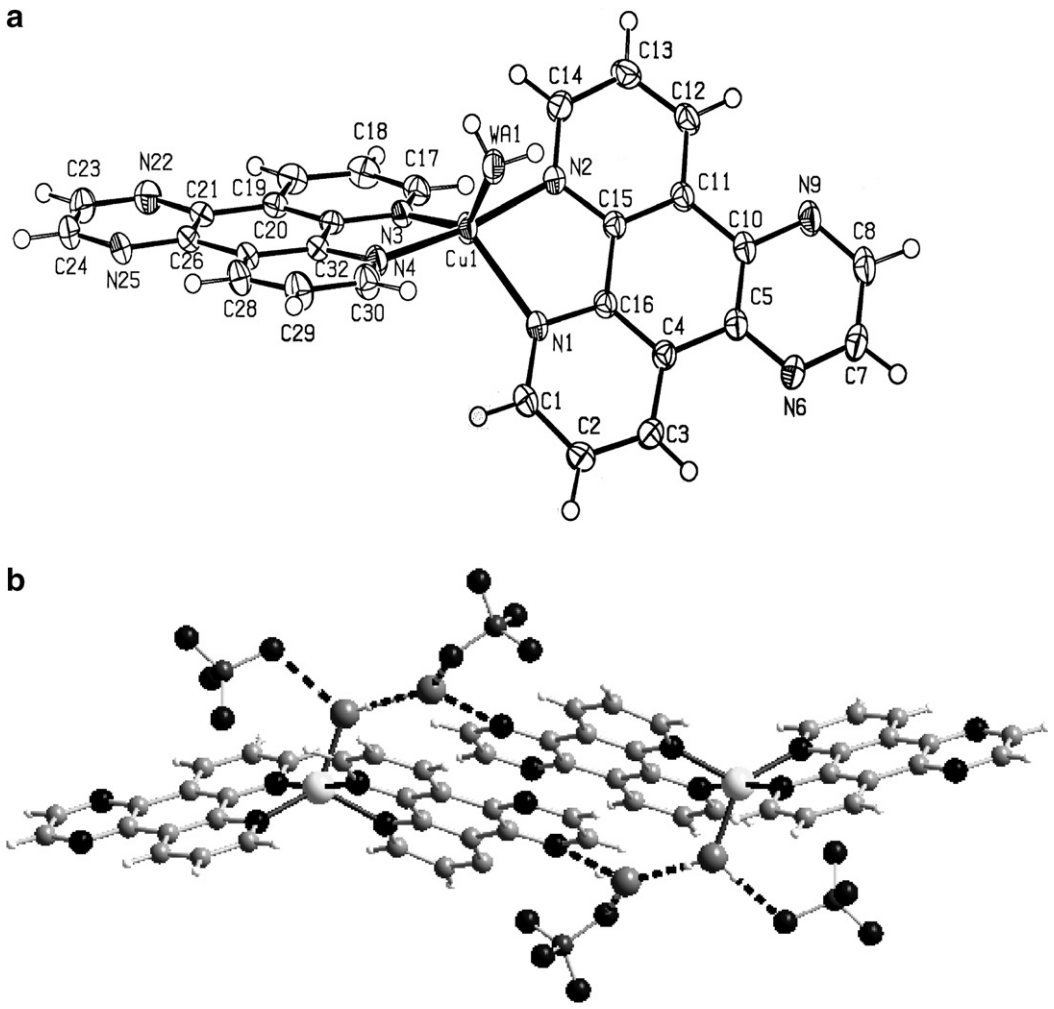


Fig. 1. (a). An ORTEP representation of the molecule $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (**2**) showing 50% probability displacement ellipsoids. (b) Dimeric structures formed by the intermolecular hydrogen bonding network involving the perchlorate ion and solvated water molecule in complex $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (**2**).

expected, the influence of temperature becomes more conspicuous in the relatively weaker hydrogen bridged distances. Since with the lowering of temperature the thermal vibration gets reduced, accordingly O···O and O···N distances at 153 K are found to be shorter by 0.03–0.09 Å relative to those reported at 293 K.

3.3.2. *[Cu(dpq)$_2$](ClO$_4$)$_2$ (**3**)*

In complex **3**, one of the perchlorate anions is disordered, whose three oxygen atoms O(22), O(23) and O(24) have double occupancy (0.55:0.55), while O(21) and Cl(2) have unique occupancy. The ORTEP projection of the cation $[Cu(dpq)_2]^{2+}$ is shown in Fig. 2. The four-coordinated CuN_4 core, in terms of a square planar description, does not turn out to be satisfactory because the donor atoms involved are alternatively displaced above and below the least-squares plane by 0.40 Å, albeit the copper centre is lying exactly on the mean plane. The alternative description in terms of a tetrahedral configuration is also unsatisfactory because the dihedral angle θ between the opposing CuN_2 planes is 37.9° ($\theta = 0°$ for square planar and 90° for tetrahedral). In **3**, the distances Cu–N(1) [2.022(2) Å] and Cu–N(2) [1.992(2) Å] are nearly equal, as are the complimentary distances Cu–N(3) [2.026(2) Å] and Cu–N(4) [1.987(2) Å]. The *transoid* angles N(1)–Cu–N(3) [146.40(7)°] and N(2)–Cu–N(4) [167.54(8)°] deviate considerably from the values expected for a square planar geometry. The *cisoid* angles N(1)–Cu–N(2) and N(3)–Cu–N(4) are equal [82.20(7)°], while the two other opposing angles N(1)–Cu–N(4) and N(2)–Cu–N(3) are 100.14(7)° and 102.70(7)°, respectively. Clearly, the tetrahedral description is worse relative to the square planar description.

A consideration of the proximities of the oxygen atoms of one of the perchlorate anions to the copper centre reveals that the disordered oxygen O(22) is 2.427(4) Å away from the metal atom. If this distance is reckoned as a bond, Fig. S3 provides another ORTEP representation of the $[Cu(dpq)_2(ClO_4)]^+$ cation. In the five-coordinated environment $[CuN_4O]$, the geometry of the copper centre may be either trigonal bipyramidal (tbp) or square pyramidal

[a] For **5** 'A' indicates: $-x, y, -z + 1/2$.

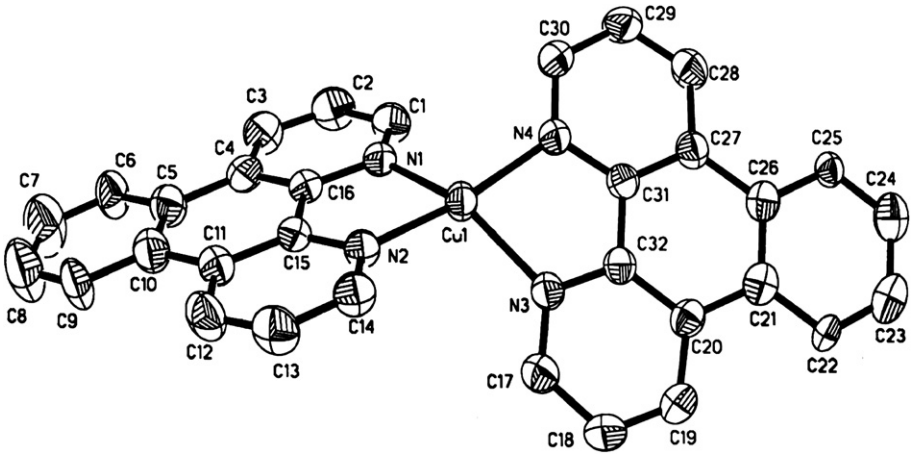

Fig. 2. A four-coordinated ORTEP projection of the molecule $[Cu^{II}(dpq)_2](ClO_4)_2$ (**3**) showing 50% probability displacement ellipsoids.

(sp). To consider the tbp geometry, the atoms N(1), N(3) and O(221) form the trigonal plane and the atoms N(2) and N(4) are *trans*-axially disposed. However, the angles N(1)–Cu–N(3) [146.40(7)°], N(1)–Cu–O(221) [95.34(16)°] and N(3)–Cu–O(221) [117.56(16)°] all deviate from the ideal angle of 120°. The *trans* angles N(2)–Cu–N(4) [167.54(8)°] also deviates from 180°. Moreover, the value of $\tau = 0.35$ falls short of that to be a tbp candidate. In favor or against the alternative sp geometry with a Cu–O(221) apical distance of 2.427(4) Å, the same arguments made for the square planar geometry apply.

3.3.3. $[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**)

Complex **4** is a co-crystallized compound in which the asymmetric unit contains two cationic species viz.

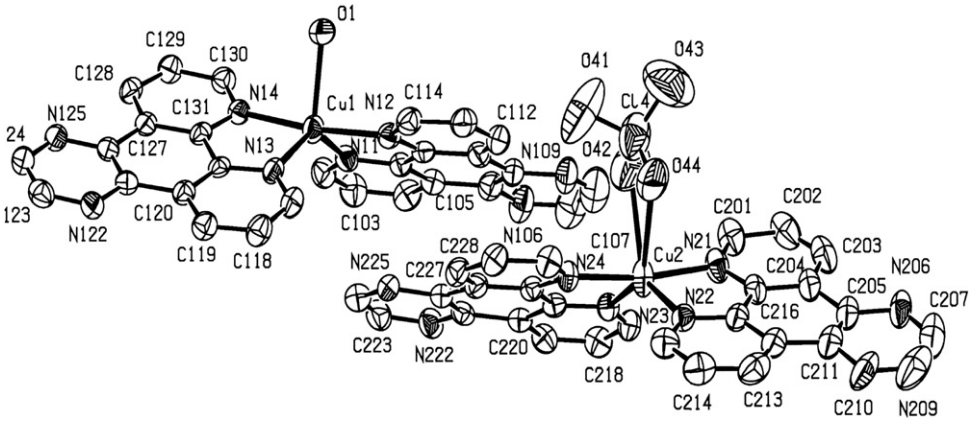

Fig. 3. An ORTEP representation of the cation of the complex $[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**) showing 50% probability displacement ellipsoids.

$\{Cu(dpq)_2(H_2O)\}^{2+}$ and $\{Cu(dpq)_2(ClO_4)\}^{+}$, and three perchlorate anions. An ORTEP projection of the cations in **4** is shown in Fig. 3. It may be noted that **4** can be considered as the 1:1 co-crystals of **2** and **3**. However, it will be evident that notwithstanding the same composition, the cationic species of **4** have subtle structural differences from **2** and **3**.

In **4**, the five-coordinated copper(II) centre in $[Cu(dpq)_2(H_2O)]^{2+}$ cation obtains a tbp geometry with N(11), N(13) and O(1) forming the trigonal plane and N(12) and N(14) occupying the axial positions. Unlike **3**, in which the two equatorial Cu–N distances are significantly different, in **6** the two equatorial Cu–N(11) and Cu–N(13) distances are equal [2.043(4) Å]. The third equatorial Cu–O(1) bond length, however, is long [2.144(3) Å]. The *trans* axially disposed Cu–N(12) and Cu–N(14) bond distances are also equal [1.982(4) Å]. The N–Cu–N and N–Cu–O bond angles in the trigonal plane lie in the range 109–136°. The *trans* N(12)–Cu–N(14) angle is 173.32(14)°. The value of τ in this case (0.63) is greater than that of **3** (0.55), indicating lesser distortion in the present case.

The ORTEP projection of the cation $[Cu(dpq)_2(ClO_4)]^{+}$ in **4** (Fig. 4) shows that the two perchlorate oxygens O(42) and O(44) are bound to the copper(II) centre in a bidentate fashion. For a better view of the six-coordinated metal core $[CuN_4O_2]$ another ORTEP projection is shown in Fig. S4. It may be noted that in terms of an octahedral description, the metal centre is located in the basal plane formed by the atoms N(22), N(23), O(44) and O(42). However, these atoms are displaced from the least-squares plane by ±0.215(5) Å for the oxygen atoms and ±0.123(4) Å for the nitrogen atoms. Since the Cu–N(22)/N(23) distances [2.046(4) and 2.041(4) Å] are much shorter as compared to the Cu–O(42)/O(44) distances [2.540(4) and 2.510(5) Å], the metal atom in the N_2O_2 plane is located closer to the nitrogen atoms. The *trans*-axial Cu–N(21)/N(24) distances are 1.982(4) and 1.977(4) Å, and are even shorter than the equatorial distances, indicating a distorted compressed geometry.

3.3.4. *[Zn(dpq)$_2$(ClO$_4$)$_2$] (**5**)*

The molecular structure of the zinc(II) complex $[Zn(dpq)_2(ClO_4)_2]$ (**5**) is shown in Fig. 4. A twofold axis passes mid-way through the metal-bound perchlorate oxygens O(14) and O(14A). The coordination environment around the six-coordinated metal centre $[ZnN_4O_2]$ may be considered as distorted octahedral. The atoms N(2), N(2A), O(14A) and O(14) form the best plane, although the atoms N(2)/N(2A) are displaced from the mean plane by ±0.214(2) Å and O(14)/O(14A) by ±0.265(2) Å. The metal atom lies exactly on the mean plane. The nitrogen atoms N(1) and N(1A) are *trans*-axially disposed to the metal centre. The equatorial and axial Zn–N distances [2.120(2) and 2.127(2) Å] are almost equal, while the equatorial Zn–O distances [2.190(2) Å] are slightly longer. The *trans*-axial N(1)–Zn–N(1A) angle is 169.57(11)°, while the *trans*-equatorial N(2)–Zn–O(14A) angle is 161.42(8)°. The trigonal planes N(1)O(14A)N(2A) and N(1A)O(14)-N(2) are inclined to each other by 50.0°, again indicating a distorted octahedral geometry. The relevant bond distances and bond angles are listed in Table 3.

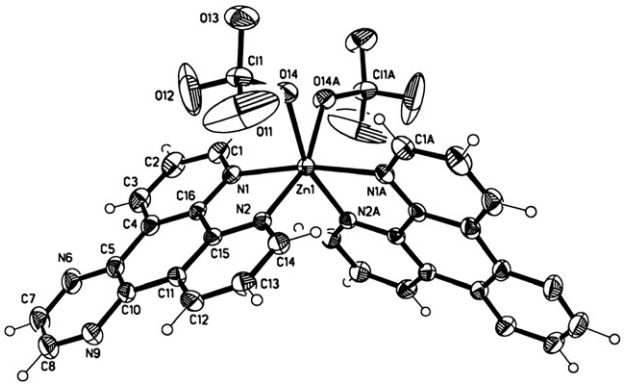

Fig. 4. An ORTEP projection of the complex $[Zn^{II}(dpq)_2(ClO_4)_2]$ (**5**) showing 50% probability displacement ellipsoids. 'A' indicates the symmetry operation $(1-x, y, -z+1/2)$.

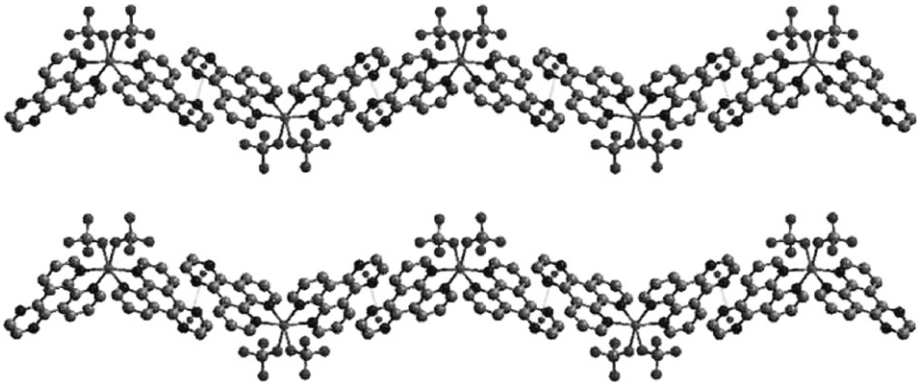

Fig. 5. An 1-D growth of the molecule $[Zn^{II}(dpq)_2(ClO_4)_2]$ (**5**) through π–π stacking interactions.

Another interesting structural feature of this compound is the presence of a π–π interaction between the pyrazine ring C(5)N(6)C(7)C(8)C(9)C(10) of the adjacent molecule, forming a sinusoidal pattern, as shown in Fig. 5. The distance between the centroid of the pyrazine rings is 3.542 Å.

3.4. Electronic spectra

The absorption spectroscopic behaviour of compounds **1**–**10** have been studied in acetonitrile. In addition, the spectra of compounds **2**–**4** have been obtained in nitromethane. The UV–Vis–NIR spectral data for theses compounds in acetonitrile are given in Section 2.

All of the complexes exhibit three very strong absorption bands at 215–225 nm, 250–260 nm and 290–300 nm, due to the ligand centred π–π* transitions. In the case of the copper(I) complex **1**, a strong band observed at 415 nm ($\varepsilon = 4700\ M^{-1}\ cm^{-1}$) is due to a metal-to-ligand charge transfer (MLCT) transition. This charge transfer transition occurs from the filled metal orbital (d^{10}) to the empty π* antibonding orbital of the bipyridine ligand. Although the solid state structures of the three copper(II) complexes $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2$ (**2**), $[Cu^{II}(dpq)_2](ClO_4)_2$ (**3**) and $[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**) are different, in acetonitrile solution they exhibit similar spectral features in the visible and near IR region. Two broad absorption bands are observed at 700 and 900 nm. It is documented, especially for copper(II) complexes, that a single d–d band with a high energy shoulder is indicative of a trigonal bipyramidal stereochemistry around the metal centre, while an absorption envelop with a low energy shoulder is characteristic of a square pyramidal geometry. Some penta-coordinated copper(II) complexes with two d–d bands of equal intensity appear to possess an intermediate distorted geometry [29]. The broadness of these bands are indicative of the presence of more than two transitions at lower energies as expected for copper(II) in a distorted trigonal bipyramidal environment. Indeed, deconvolution of the absorption spectrum of **2** in acetonitrile by Gaussian line-shape analysis gives rise to three peaks (shown in Fig. S5), which are due to the $d_{x^2-y^2} \rightarrow d_{z^2}$, $d_{xy} \rightarrow d_{z^2}$ and d_{xz}, $d_{yz} \rightarrow d_{z^2}$ transitions in ascending order of energies. It appears that the identical spectra observed for complexes **2**–**4** in acetonitrile is due the presence of the same penta-coordinated species, $[Cu^{II}(dpq)_2(CH_3CN)]^{2+}$, in all three cases. However, in nitromethane, which is a non-coordinating solvent, some variation in positions and intensities of these bands in the three cases becomes evident. This is illustrated in Fig. S6a–c by deconvoluting the absorption spectra observed for **2**–**4** in nitromethane. The spectral data and the deconvoluted peak positions of **2**–**4** in nitromethane are listed in Table 4.

The absorption spectrum of the nickel(II) complex $[Ni(dpq)_3](ClO_4)_2$ (**6**) shows the presence of bands at 215 ($\varepsilon = 60\,000\ M^{-1}\ cm^{-1}$), 260 ($\varepsilon = 110\,000\ M^{-1}\ cm^{-1}$), 300 nm ($\varepsilon = 40\,000\ M^{-1}\ cm^{-1}$), 785 ($\varepsilon = 11\ M^{-1}\ cm^{-1}$) and 855 nm ($\varepsilon = 9\ M^{-1}\ cm^{-1}$). In octahedral nickel(II) complexes three spin-allowed transitions $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3T_{1g}$, $^3T_{1g}(P)$ are normally observed. Because the separation of the energy between the $^3A_{2g} \rightarrow {}^3T_{2g}$ and $^3A_{2g} \rightarrow {}^3T_{1g}$ transitions in a wide variety of octahedral nickel(II) complexes lies in the range 5000–8000 cm^{-1}, it is highly unlikely that the two absorption peaks observed as a doublet at 855 nm (11 700 cm^{-1}) and 785 nm (12 750 cm^{-1}), which differ only by 1000 cm^{-1}, could be assigned due to these transitions. On the other hand, when Dq/B approaches unity the ^1E_g state lies close to $^3T_{1g}$, and due to their extensive mixing the spin forbidden $^3A_{2g} \rightarrow {}^1E_g$ transitions steals intensity from the spin-allowed $^3A_{2g} \rightarrow {}^3T_{1g}$ transition, being observed as a doublet.

Table 4
UV–Vis and deconvoluted absorption peaks for complexes **2**–**4** in nitromethane

Compound	λ_{max}/nm (ε/$M^{-1}\ cm^{-1}$)	Deconvoluted peaks (nm)
$[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (**2**)	740 (140), 870 (115)	695, 865, 935
$[Cu^{II}(dpq)_2](ClO_4)_2$ (**3**)	710 (150), 840 (120)	685, 835, 940
$[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**)	725 (150), 870 (115)	695, 880, 950

The tris-dpq cobalt(II) complex **7** exhibits a lone d–d band at 910 nm ($\varepsilon = 10\ M^{-1}\ cm^{-1}$) in addition to the internal ligand transitions observed at 210 ($\varepsilon = 58\,000\ M^{-1}\ cm^{-1}$), 250 ($\varepsilon = 107\,000\ M^{-1}\ cm^{-1}$) and 290 nm ($\varepsilon = 52\,000\ M^{-1}\ cm^{-1}$). The observed d–d band is due to the $^4T_{1g} \rightarrow {}^4T_{2g}$ transition. A second band, which is expected to be observed at ca. 500 nm in octahedral cobalt(II) complexes due to the $^4T_{1g} \rightarrow {}^4T_{1g}$ (P) transition, is not seen in the present case. In the cobalt(III) complex $[Co(dpq)_3]^{3+}$ ($\mathbf{9}^{3+}$), aside from the bands observed at 210 ($\varepsilon = 66\,000\ M^{-1}\ cm^{-1}$), 250 ($\varepsilon = 95\,000\ M^{-1}\ cm^{-1}$) and 290 nm ($\varepsilon = 34\,000\ M^{-1}\ cm^{-1}$), a band due to the $^1A_{1g} \rightarrow {}^1T_{1g}$ transition is observed at 460 nm ($\varepsilon = 210\ M^{-1}\ cm^{-1}$). The higher energy $^1A_{1g} \rightarrow {}^1T_{2g}$ transition is apparently masked by the intense band observed at 290 nm. Since the energy of the $^1T_{1g}$ state is $10Dq - C$ ($C \approx 4B \approx 2000\ cm^{-1}$) [9], the value of $10Dq$ is estimated to be $24\,200\ cm^{-1}$.

The low-spin iron(II) complex **10** exhibits MLCT absorptions at 440 and 520 nm and a d–d transition at 850 nm.

3.5. Electrochemistry

The electrochemical characteristics of complexes **1, 2**, **3**, **4**, **7** and **8** have been examined by CV and SWV and the observed redox potentials are given in Table 5.

The copper(I) complex $[Cu(dpq)_2](ClO_4)$ (**1**) undergoes a one electron quasireversible ($\Delta E_p = 120$ mV) oxidation at $E_{1/2} = 110$ mV in acetonitrile. As mentioned earlier, the absorption spectra of the copper(II) complexes (**2**–**4**) have been examined in acetonitrile and nitromethane, hence, the electrochemical behaviour of these compounds have also been studied in those two solvents. In acetonitrile, similar to the absorption spectral behaviour, all the three compounds (**2**–**4**) exhibit identical electrochemical responses with $E_{1/2} = 120$ mV and $\Delta E_p = 150$ mV. Cyclic voltammograms of these compounds, however, differ significantly in nitromethane, as observed in their electronic spectra. In nitromethane, the $E_{1/2}$ value of $[Cu(dpq)_2(H_2O)](ClO_4)_2 \cdot H_2O$ (**2**) is 325 mV ($\Delta E_p = 70$ mV) (Fig. S7a), that of $[Cu(dpq)_2](ClO_4)_2$ (**3**) is 355 mV ($\Delta E_p = 70$ mV) (Fig. S7b) and finally for $[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**) (Fig. S7c) the $E_{1/2}$ and ΔE_p values are 350 mV and 70 mV. As expected, the redox behaviour of the cobalt(II) complex **7** in the oxidative mode and the cobalt(III) complex **8** in the reductive mode are identical. The $E_{1/2}$ value of the fully reversible ($\Delta E_p = 70$ mV) Co^{II}/Co^{III} couple is 540 mV (shown in Fig. S8).

Table 5
Electrochemical data[a] for complexes **1**–**4**, **7** and **8**

Compound	Acetonitrile		Nitromethane	
	$E^b_{1/2}$ (mV)	ΔE^c_p	$E_{1/2}$ (mV)	ΔE_p
$[Cu^I(dpq)_2](ClO_4)$ (**1**)	110	120	330	70
$[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2$ (**2**)	110	130	325	70
$[Cu^{II}(dpq)_2](ClO_4)_2$ (**3**)	105	120	355	70
$[\{Cu^{II}(dpq)_2(H_2O)\}\{Cu^{II}(dpq)_2(ClO_4)\}](ClO_4)_3$ (**4**)	100	120	350	70
$[Co^{II}(dpq)_3](ClO_4)_2$ (**7**)	535	70		
$[Co^{III}(dpq)_3](ClO_4)_3$ (**8**)	540	70		

[a] All the potentials are against Ag/AgCl reference electrode.
[b] $E_{1/2}$ values are the average of those obtained from cyclic voltammetric and square wave voltammetric measurements, which are within ±5 mV.
[c] ΔE_p refers to the peak to peak separation at a scan rate of 100 mV s^{-1}.

4. Conclusion

Copper(I), copper(II), zinc(II), nickel(II), cobalt(II), cobalt(III), manganese(II) and iron(II) complexes (**1**–**10**) of dipyrido[3,2-*f*:2′,3′-*h*]-quinoxaline (dpq) have been synthesized and structurally characterized. Various spectroscopic and electrochemical properties of these compounds have been studied.

The most significant aspect of the study is the isolation and structural characterization of three copper(II) complexes of dpq. The compound of composition $[Cu^{II}(dpq)_2(H_2O)](ClO_4)_2$ (**1**) has been obtained by reacting $Cu(ClO_4)_2 \cdot 6H_2O$ with dpq in methanol. The structure determination of this bluish-green compound has revealed that copper(II) has a highly deformed penta-coordinated geometry and can be best described as a distorted trigonal bipyramid with a τ value of 0.55. When the reaction between $Cu(ClO_4)_2 \cdot 6H_2O$ and dpq is carried out in dry acetonitrile, the blue coloured product isolated has the composition $[Cu(dpq)_2](ClO_4)_2$ (**3**). This compound has an irregular geometry. As such, the $[Cu(dpq)_2]^{2+}$ cation deviates from a square planar configuration to a tetrahedral geometry, although the extent of tetrahedral distortion is rather less (dihedral angle $\theta = 38°$). The close proximity of an oxygen atom of a distorted perchlorate (Cu–$OClO_3 = 2.43$ Å) confers a five-coordinate geometry, which again is neither square planar nor trigonal bipyramidal. In the third method of preparation, the condensation reaction between 1,10-phenanthroline-5,6-dione and 1,2-diaminoethane has been carried out in the presence of $Cu(ClO_4)_2 \cdot 6H_2O$ in methanol. Initially, a dark coloured copper(I) complex of composition $[Cu(dpq)_2](ClO_4)$ (**1**) gets deposited and from the solution a second green coloured complex of copper(II) having the composition $[\{Cu(dpq)_2(H_2O)\}\{Cu(dpq)_2(OClO_3)\}](ClO_4)_3$ (**4**) has been isolated. The structure determination of this compound has established the presence of the two different complex cations in the asymmetric unit. It may therefore be considered as a co-crystal. The structure of the $[Cu(dpq)_2(H_2O)]^{2+}$ cation is not exactly the same as the earlier described compound. The tbp geometry is more regular ($\tau = 0.63$) in this case. In the cation $[Cu(dpq)_2(ClO_4)]^+$, the perchlorate is bound to the metal centre in a bidentate fashion [Cu–O = 2.51 and 2.54 Å], thus conferring a six-coordinate geometry to the copper. Similar to the other structures, in this case the metal centre also obtains a highly irregular geometry which is intermediate between octahedral and trigonal prismatic (the angle between the two trigonal faces is 32°).

The zinc compound $[Zn(dpq)_2(OClO_3)_2]$ (**5**) also shows an interesting structure. Because the two perchlorates are unidentately coordinated to the metal centre, the zinc(II) centre obtains a distorted octahedral geometry. In the crystal lattice, the quinoxaline ring of the complex unit is involved in an intermolecular π–π interaction which leads to the generation of a sinusoidal chain.

The proton NMR spectra of the complexes, including those of the paramagnetic complexes $[Ni^{II}(dpq)_3](ClO_4)_2$ (**6**) and $[Co^{II}(dpq)_3](ClO_4)_2$ (**7**) have been studied. The assignment of protons for complex **7** has been made on the basis of their T_1 and T_2 values. The redox behaviour of copper(II) complexes **2**–**4** in acetonitrile is identical but in nitromethane they exhibit different behaviour from each other. The cobalt(II) and cobalt(III) complexes **7** and **8** undergo a reversible electron transfer reaction and the $E_{1/2}$ values of the Co^{II}/Co^{III} couple in acetonitrile is 540 mV.

Acknowledgements

We gratefully acknowledge Prof. K. Nag for his invaluable help and suggestions during the course of this work and in the preparation of the manuscript. M.G. and P.B. are also thankful to CSIR, India for the award of a research fellowship.

Appendix A. Supplementary material

CCDC 637011, 637012, 637013 and 637014 contain the supplementary crystallographic data for **2**, **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. ESI-MS (positive) for complexes **8** and **10** (Fig. S1a and b), ^1H NMR spectra of **6**, **7**, **8**, **9** (Fig. S2a–d), ORTEP representation of cation $[Cu(dpq)_2(ClO_4)]^+$ in complex **3** (Fig. S3), six-coordinated metal core $[CuN_4O_2]$ in one of the units of the complex **4** (Fig. S4), UV–Vis–NIR spectra of **2** in acetonitrile (Fig. S5) and **2**–**4** in nitromethane (Fig. S6a–c) with deconvolution, cyclic voltammogram of complexes **2**–**4** and ferrocene in nitromethane (Fig. S7a–c) and cyclic voltammogram of complexes **7** and **8** (Fig. S8). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.04.014.

Herein, we report on the synthesis and characterization of **L2**, as well as on its thiol-protected precursor **L1**. Protonation constants of **L2** and its stability constants with Cu^{2+}, Zn^{2+} and Cd^{2+} will also be reported. An analysis of the protonation scheme of **L2** is discussed, as well as the structural environment in solution of Cu(II) and Zn(II) in the complexes with **L2**.

2. Experimental

2.1. Reagents

Chemicals and solvents were of reagent grade and were used without further purification, unless stated otherwise. 1,4,7,10-tetraazacyclododecane (cyclen) was purchased from Strem (New-Buryport, MA, USA). Sodium hydride, triphenylmethane-thiol, tetrahydrofuran, dibromoethane, toluene, sodium hydroxide, methanol, dichloromethane, ammonium, hydrochloride acid, deuterated water and chloroform were obtained from Aldrich Chemical Co. Silica gel 60 (70–230 mesh, pH range = 6.5–7.5) was obtained from Merck.

2.2. Analytical methods

^{1}H (300 MHz) and ^{13}C (75.5 MHz) NMR spectra were recorded in a Varian Unit Inova-300 spectrometer at a probe temperature of about 20°C. The spectra were performed in $CDCl_3$ (δ/ppm: ^{1}H: 7.24; ^{13}C: 77.00) or D_2O versus an external reference of 1,4-dioxane (δ/ppm: ^{1}H: 3.75; ^{13}C: 69.20). Positive-ion mass spectra were obtained in a Finnigan FT/MS 2001-DT FTICR mass spectrometer by laser desorption ionization. pH measurements were performed in a ORION SA 720. UV–Vis spectra were done in a Cary 500. EPR spectroscopic measurements of the copper complex were recorded with a Bruker ESP 380 spectrometer equipped with continuous-flow cryostats for liquid nitrogen, operating at X-band.

2.3. Synthesis of 2-[1,4,7,10-tetraazacyclododecan-1-yl]-ethanetritylthiol (*L1*)

To a solution of cyclen (285 mg, 1.5 mmol) in hot toluene (50 cm^3) was slowly added bromoethyl tritylthiol [7] (210 mg; 0.5 mmol) dissolved in toluene (50 cm^3). The reaction mixture was refluxed overnight and then a solution of NaOH (20%) added. The organic phase was separated and the solvent evaporated under vacuo. The solid obtained was purified by silica-gel chromatography using as eluent a mixture of $CHCl_3$/MeOH/aq. NH_3 (gradient 100:0:0 → 0:100:0 → 0:80:20, $R_f = 0.2$ in 80:20 MeOH/ aq. NH_3 solution) **L1** (100 mg, 43%); δ_H/(300 MHz, $CDCl_3$): 7.37 (6 H, d, aromatic protons), 7.26–7.14 (9 H, m, aromatic protons), 2.89–2.84 (4 H, m), 2.52–2.48 (8 H, m), 2.36–2.32 (8 H, m); δ_C(75.5 MHz, $CDCl_3$): 144.9 (Ph), 129.6 (Ph), 127.8 (Ph), 126.5 (Ph), 66.8 ($SCPh_3$), 53.5 ($CH_2CH_2SCPh_3$), 50.80 (C_{ring}), 46.9 (C_{ring}), 46.1 (C_{ring}), 44.9 (C_{ring}), 29.4 ($CH_2CH_2SCPh_3$).

2.4. Synthesis of 2-[1,4,7,10-tetraazacyclododecan-1-yl]-ethanethiol (*L2*)

Compound **L1** was refluxed in 20% HCl, for 2 h. After cooling to room temperature, the resulting solution was washed with dichloromethane, the aqueous extracts separated and vacuum dried yielding a white solid **L2** (75 mg, 80%). δ_H (300 MHz, D_2O, pD 1.05): 2.54 (2 H, t, C(1)H); 2.70 (2 H, t, C(2)H); 2.84 (4 H, t, C(3)H); 2.97 (4 H, br m, C(6)H); 3.07 (8 H, br m, C(4)H + C(5)H); δ_C (75.5 MHz, D_2O/ 1,4-dioxane, pD 1.05): 56.8 (*C2*); 50.3 (*C3*); 45.6 (*C4*); 44.4 (*C6*); 43.9 (*C5*); 22.0 (*C1*); *m/z* (LDI): calc. for $[^{12}C_{10}{}^1H_{25}{}^{14}N_4{}^{32}S]^+$: 233.179, $[^{12}C_{10}{}^1H_{24}{}^{14}N_4{}^{32}S^{23}Na]^+$: 255.161, $[^{12}C_{10}{}^1H_{25}{}^{14}N_4{}^{32}S^{39}K]^+$: 271.135; found: $[M+H]^+$: 233.191, $[M+Na]^+$: 255.156, $[M+K]^+$: 271.118.

2.5. X-ray crystal analyses

Crystal data for **L1**: $C_{29}H_{52}N_4O_{10}S_2$, $M_r = 680.87$, triclinic, space group $P\bar{1}$, $a = 8.1242(1)$, $b = 8.8600(1)$, $c = 27.0151(4)$ Å, $\alpha = 81.8670(10)$, $\beta = 82.1130(10)$, $\gamma = 63.9020(10)°$, $U = 1722.57(4)$ Å^3, $Z = 2$, $D_c = 1.313$ g cm^{-3}, μ (Mo Kα) = 1.260 mm^{-1}. Suitable colourless prismatic crystals (0.40 × 0.32 × 0.06 mm) were mounted in air on a goniometer head. X-ray diffraction experiments were performed with a Bruker AXS APEX CCD detector diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0{:}71073$ Å), at 150 K in the ϕ and ω scans mode. A semi empirical absorption correction was carried out using SADABS [8].

Data collection, cell refinement and data reduction were done with the SMART and SAINT programs [9]. The structures were solved by direct methods using SIR97 [10] and refined by fullmatrix least-squares methods using the program SHELXL97 [11] using the winGX software package [12]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The H atoms of the CH and CH_2 were placed at calculated positions using a riding model, with distances C–H = 0.95 Å (aromatic) and C–H = 0.99 Å (CH_2) and with Uiso(H) = 1.2Ueq(C) of the parent atom. The H atoms in the water, NH_2 and NH were located in difference Fourier maps and its coordinates and isotropic thermal parameters were refined.

The residual electronic density ranging from 0.393 to −0.392 e Å^{-3} was within expected values. The final refinement of 472 parameters converged to final R and R_W indices $R_1 = 0.0408$ and $wR_2 = 0.0972$ for 7020 reflections with $I > 2\sigma(I)$. Molecular graphics were prepared using ORTEP 3 [13].

2.6. Potentiometric studies

2.6.1. Reagents and solutions

Metal ion solutions were prepared at about 2.5×10^{-3} mol dm^{-3} from the nitrate salts of the metals and were titrated using standard methods [14]. Deionized

(Millipore/Milli-Q System) distilled water was used. Carbonate-free solutions of the KOH titrant were obtained, maintained and discarded when the percentage of carbonate was about 0.5% of the total amount of base [15].

2.6.2. Equipment and work conditions

The equipment was used as described before [16]. The temperature was kept at 25.0 ± 0.1 °C, atmospheric CO_2 was excluded from the cell during the titrations by passing purified nitrogen across the top of the experimental solution in the reaction cell. The ionic strength of the solutions was kept at 0.10 mol dm^{-3} with KNO_3.

2.6.3. Measurements

The $[H^+]$ of the solutions was determined by the measurement of the electromotive force (emf) of the cell, $E = E^{\circ\prime} + Q\log[H^+] + E_j$. $E^{\circ\prime}$, Q, E_j and $K_w = ([H^+][OH^-])$ were obtained as described previously [17]. The value of K_w was found equal to $10^{-13.80}$ (mol dm^{-3})^2. The potentiometric equilibrium measurements were made on 25.00 cm^3 of $\approx 2.00 \times 10^{-3}$ mol dm^{-3} ligand solutions diluted to a final volume of 30.00 cm^3, in the absence of metal ions and in the presence of each metal ion for which the C_M:C_L ratio was 1:1. A minimum of two replicate measurements was taken.

The emf data were taken after additions of 0.050 cm^3 increments of standard KOH solution, and after stabilization in this direction, equilibrium was then approached from the other direction adding standard nitric acid.

For determination of the stability constants, out-of-cell titrations were performed in the pH region from which the direct and back titrations were not superimposed. In such regions, independent vials each one at different pH were prepared and left to equilibrate in a water bath at 25.0 °C and the corresponding pH values checked every week till stabilization of the pH, which occurred generally within 2–4 weeks.

2.6.4. Calculation of equilibrium constants

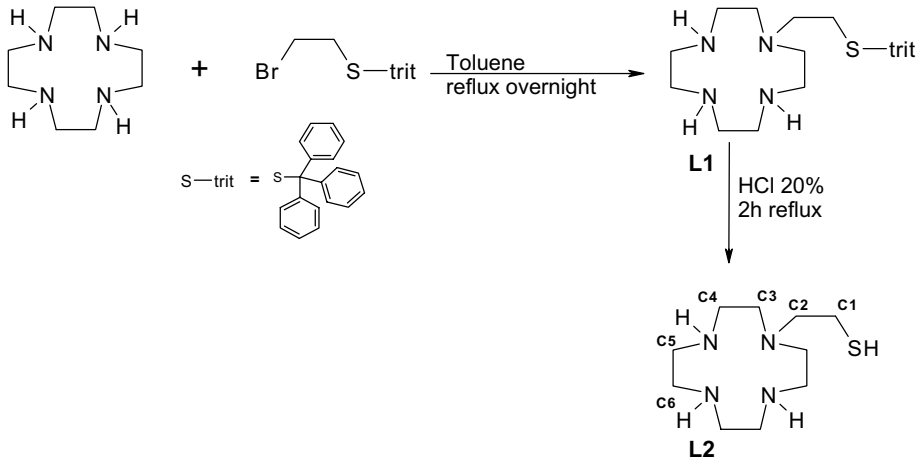
Overall protonation constants, β_i^H were calculated by fitting the potentiometric data obtained for the free ligand with HYPERQUAD program [18]. Stability constants of the various species formed in solution were obtained from the experimental data corresponding to the titration of solutions of the different metal ions, each of them with different metal to ligand ratios, also using the HYPERQUAD program. The initial computations were obtained in the form of overall stability constants, $\beta_{M_mH_hL_l}$ values, $\beta_{M_mH_hL_l} = [M_mH_hL_l]/([M]_m \times [H]_h \times [L]_l)$. Differences, in log units, between the values $\beta_{M(HL)}$ (or $\beta_{MLH_{-1}}$) and β_{ML} provide the stepwise reaction constants. The species considered in a particular model were those that could be justified by the principles of co-ordination chemistry. The errors quoted are the standard deviations of the overall stability constants given directly by the program for the input data, which include all the experimental points of all titration curves. The hydrolysis constants of the metal ions were taken from the literature and kept constant for the calculations [19].

2.7. NMR studies

2.7.1. ^{13}C NMR titration

The electrode was calibrated with standard buffer solutions and the final pD was calculated according to the equation $pD = pH^* + (0.40 \pm 0.02)$ [20], where pH^* corresponds to the reading of the pH meter. The solutions ($\approx 2 \times 10^{-3}$ M) used for the NMR titration measurements were made up in D_2O and the pD value was adjusted by adding DCl or CO_2-free KOD. The solutions were allowed to stabilize and the pD values were measured directly in the NMR-tube with a combination microelectrode Mettler-Toledo U402-M3-S7/200.

2.7.2. EPR studies



The Cu^{2+}/**L2** complexes ($\approx 1.6 \times 10^{-3}$ mol dm^{-3} in 40% DMSO/H_2O solution) were prepared at pH 5, 8 and 12 and were recorded at 104 K. The EPR spectra of Cu^{2+}/cyclen complexes were also recorded at the same pH values and conditions for comparison.

3. Results and discussion

3.1. Synthesis and characterization

Different synthetic procedures have been described to prepare mono-substitued tetraazamacrocycles, namely the introduction of the side chain on the amine before cyclization [21–23], pH controlled reactions [24], protection/deprotection methods [25] or alkylation of the macrocycle using an excess of the ligand versus the desired alkylating agent [26]. It has also been reported that it was possible to introduce one oxygen or sulphur pendant arm in the cyclen backbone by reacting cyclen with stoichiometric amounts of trimethylene oxide or ethylene sulphide, respectively [27,4,5a,5b,5c]. Following our previous work on tetraazamacrocycles, we have tried the synthesis of the mono-*N*-(2-ethanethiol) cyclen derivative (**L2**) following the described methodology [4]. In our hands, such synthetic procedure has never worked properly and compound **L2** could never be isolated. **L2** was synthesized in 40% overall yield, by slow addition of bromoethyl tritylthiol [7] to cyclen, in a 1:3 molar ratio, followed by acidic deprotection of the thiol group (Scheme 1).

Compound **L1** was also isolated and characterized by ^1H and ^{13}C NMR spectroscopy and by X-ray crystallography, upon purification by column chromatography using MeOH/NH_3 as eluent. Slow concentration of the fractions containing **L1** led to crystals suitable for X-ray crystallography. Compound **L1** crystallizes on the triclinic system, $P\bar{1}$ space group, with cell parameters $a = 8.1242(1)$ Å, $b = 8.8600(1)$ Å, $c = 27.0151(4)$ Å, $\alpha = 81.867(1)°$ $\beta = 82.113(1)°$ $\gamma = 63.902(1)°$ and $V = 1722.57(4)$ Å^3. The asymmetric unit contains one molecule of diprotonated

Scheme 1. Syntheses of **L1** and **L2**.

L1 ($C_{29}H_{40}N_4S$), one sulphate dianion $(SO_4)^{2-}$ and six water molecules, given the molecular formula $[C_{29}H_{40}N_4S]\cdot SO_4\cdot 6H_2O$. In Fig. 1 is presented an ORTEP diagram showing the numbering scheme of the asymmetric unit.

Some selected bond lengths (Å) and angles (°) for the dication $[C_{29}H_{40}N_4S]^{2+}$ are listed in Table 1.

The macrocycle was found to be protonated in the amines N2 and N4. The average $C–N_{protonated}$ bond distances (1.490 Å) are slightly longer than the average $C–N_{unprotonated}$ ones (1.467 Å). These differences compare well with the values previously reported for other protonated macrocyclic ligands [28]. The four nitrogen atoms of the macrocycle are coplanar with an rms of 0.0306, the CH_2 groups of the backbone are below this plane, while the sulphur arm is above the plane, pointing in the opposite direction. The calculated torsion angle N1–C2–C1–S1 of 178.1° shows the relative position of the pendant arm towards the macrocycle cavity.

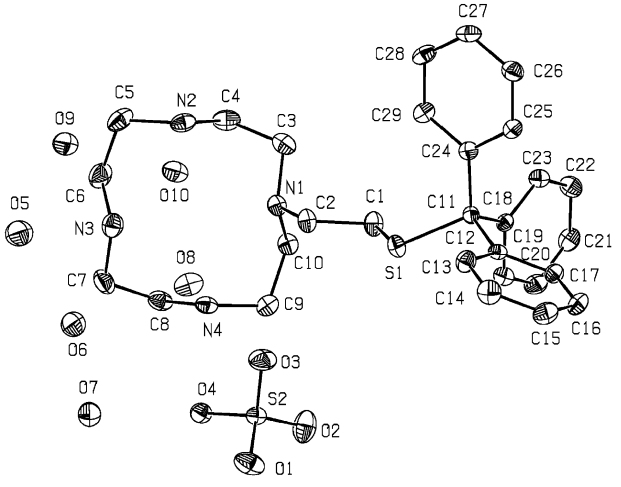


Fig. 1. ORTEP diagram with atomic numbering scheme of asymmetric unit with thermal ellipsoids at 50% probability level. Hydrogen atoms are omitted for clarity.

The crystal packing of compound **L1** is characterized (Fig. 2) by the formation of a bidimensional layer parallel to the bc plane due to several hydrogen bonds between the water molecules and due to intermolecular short N···O and C···O contacts between SO_4^{2-} units and the macrocycle (Table 2).

Compound **L2** is quite soluble in water and stable under aerobic conditions. The formulation of **L2** was mainly based on multinuclear NMR spectroscopy (^1H, ^{13}C, $^1H,^1H$ COSY, $^1H,^{13}C$ HSQC) at different pD values (range 1–14) and also on mass spectrometry. In the LDI-positive mass spectrum three main peaks were found at $m/z =$ 233.191, 255.156 and 271.118 corresponding to $[M+H]^+$, $[M+Na]^+$ and $[M+K]^+$, respectively.

In the pD range studied, the ^{13}C NMR spectra recorded exhibit six resonances, a pattern consistent with the two-fold symmetry expected for **L2**: four resonances were assigned to the carbon atoms of the backbone and the other two to the carbon atoms of the pendant arm. The ^1H NMR spectra at pD 1.05 presented five resonances with different multiplicities at 2.54, 2.70, 2.84, 2.97, 3.07 ppm in an intensity ratio of 2:2:4:4:8. At higher pD values, the ^1H NMR spectra became less clear due to the overlapping of some resonances. 2D NMR studies ($^1H,^1H$ and $^1H,^{13}C$ correlations) were performed at pD 1.05. In Fig. 3 is shown

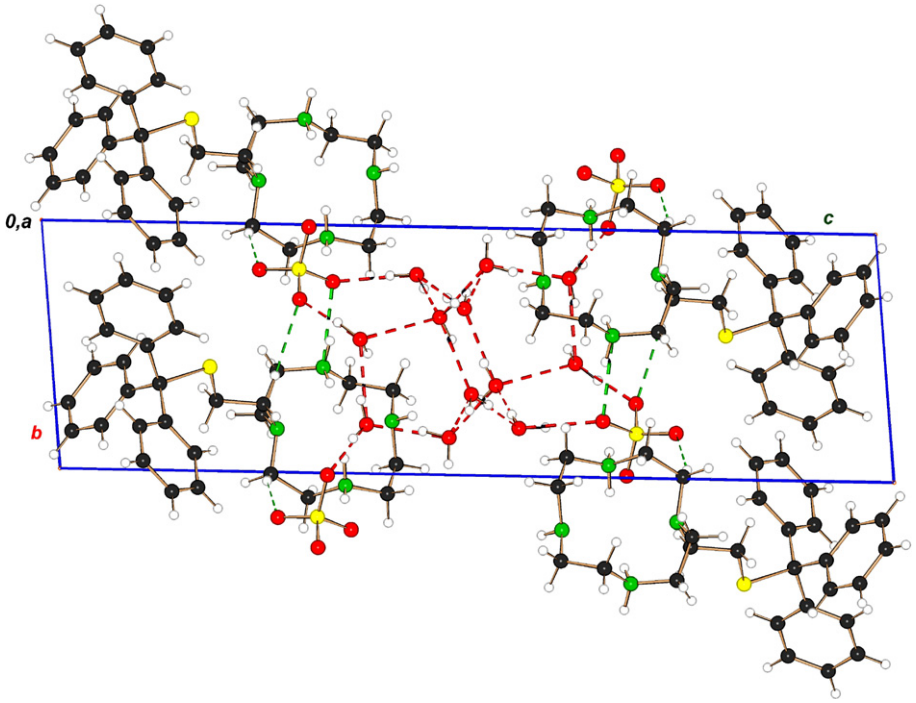

Fig. 2. Crystal structure of **L1** viewed along *a*.

Table 2
Selected hydrogen bonds and short contacts in the crystal structure of compound **L1**

	Distance (Å)
$O_{sulphate}\cdots N$

the g-COSY $^{1}H,^{1}H$ and the g-HSQC $^{1}H,^{13}C$ 2D correlations. From these studies it was possible to conclude that the triplets centered at 2.54 and 2.70 ppm correlate with the carbons at 22.03 and 56.81 ppm, respectively. Based on the carbon and proton NMR data of the free arm and on literature data, the resonances at 22.03 and 56.81 ppm were assigned to the α (C1) and β (C2) carbon atoms of the pendant arm, respectively (Scheme 1). The triplet centred at 2.84 ppm (4 H) correlates with the carbon atoms at 50.26 ppm, assigned to C3. The multiplet at 2.97 ppm (4 H) correlates with the carbon atom at 44.39 ppm and correlates with the multiplet at 3.07 ppm (8 H). Based on these data the resonance at 44.39 ppm was assigned to the C6 carbon atoms and the multiplet at 3.07 ppm (8 H) was assigned to the protons bound to the C4 and C5 atoms which appear at 45.64 and 43.92 ppm, respectively. In Table 3 are presented the chemical shifts and the corresponding assignment of the resonances of **L2** at pD 1.05.

3.2. Acid–base behaviour

The protonation constants of **L2** were determined by potentiometry at 25.0 °C and 0.10 mol dm^{-3} KNO_3 ionic strength. The values found are summarized in Table 4. Compound **L2** has five protonation constants, from which four could be determined by potentiometry, but the remaining one is too low to be determined by this technique. Just for comparison, in Table 4 are also shown the protonation constants for cyclen, 2-hydroxyethyl cyclen (**L3**) and 3-hydroxypropyl cyclen (**L4**) (Fig. 4) [27,29].

Based on the values of Table 4 it is difficult to ascribe the protonation sequence of **L2**. In order to understand this sequence a ^{13}C NMR titration was performed. These studies were carried out at 20 °C without controlling the ionic strength [30]. In Fig. 5 are shown the ^{13}C NMR titration curves.

The ^{13}C NMR spectra recorded for **L2** exhibit six resonances in the entire pD range. For each magnetically equivalent carbon atom, single resonances have been observed, indicating a rapid exchange between protonated species. For the interpretation of these data, the pK_H values determined for **L2** (Table 4) were converted in terms of pK_D, using the correlation $pK_D = 0.11 + 1.10\,pK_H$, determined for polyaza and polyoxa–polyaza macrocyclic compounds by Delgado et al. [31]: $pK_{D1} = 12.19$, $pK_{D2} = 11.09$, $pK_{D3} = 9.08$ and $pK_{D4} = 2.62$. From the analysis of the

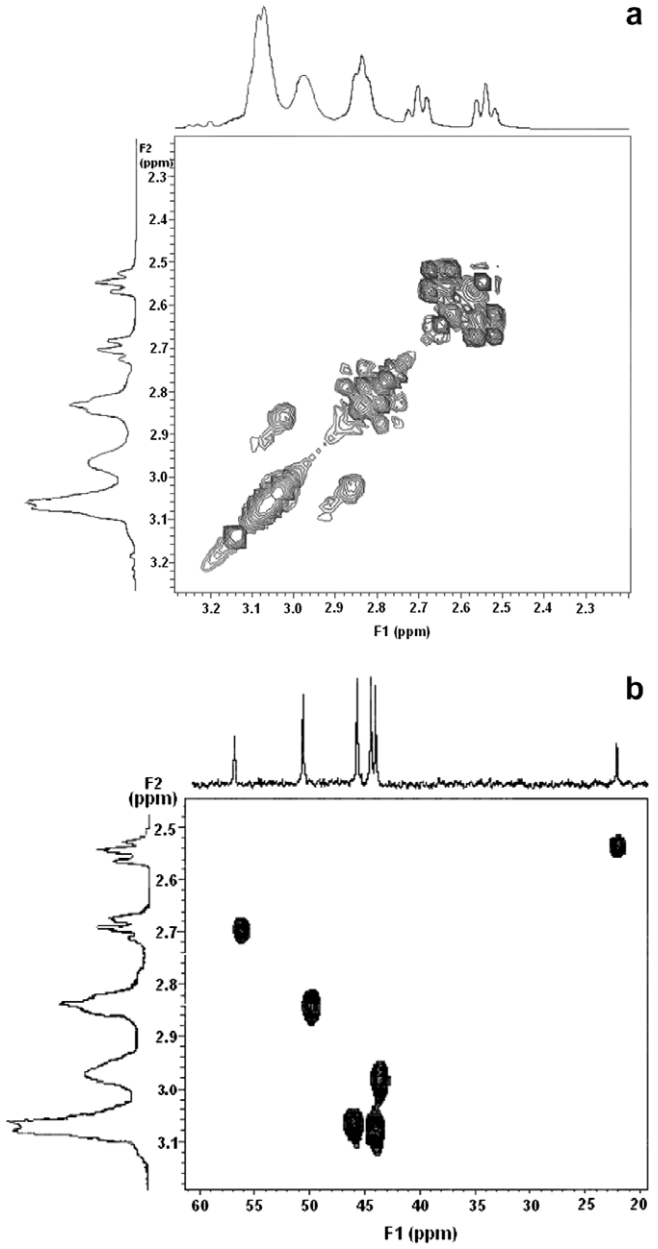

Fig. 3. g-Cosy $^{1}H,^{1}H$ (a) and g-HSQC $^{1}H,^{13}C$ (b) 2D correlations for **L2** at pD 1.05.

Table 3
^{1}H and ^{13}C NMR data for **L2** at pD 1.05

Assignment	Chemical shift (ppm)	
	^{1}H	^{13}C
C1	2.54 (t, 2 H)	22.03
C2	2.70 (t, 2 H)	56.81
C3	2.84 (t, 4 H)	50.26
C4	3.07 (m, 8 H)	45.64

C6	2.97 (m, 4 H)	44.39

NMR titration curves, three pD regions were defined, one comprising two protonation constants ($13.0 \geqslant pD \geqslant 10.5$), and the other two comprising one protonation constant each ($10.5 \geqslant pD \geqslant 8.0$ and $pD \leqslant 3.0$). The high symmetry of **L2** makes difficult to predict the protonation sequence, but an attempt has been made taking into account that when a protonation occurs at a given site the β-carbons are upfield shifted [32]. In the $13.0 \geqslant pD \geqslant 10.5$ region two protonations occur, and their constant values differ only by one log unit, which makes difficult to distinguish the effect of each one. However, taking into account that in this range the resonances ***C2***, ***C4*** and ***C5*** are upfield shifted, while ***C1*** shifts downfield, it seems that the thiolate group is protonated and a second proton may be shared by the $\mathbf{N}_{I}$ and $\mathbf{N}_{III}$ amines. In the region $10.5 \geqslant pD \geqslant 8.0$ a third protonation occurs on one amine of the macrocyclic ring, and this proton together with the one already existing in the macrocycle backbone will be shared by the $\mathbf{N}_{I}/\mathbf{N}_{II}/\mathbf{N}_{II}$ amines centres. This is supported by the upfield shift of the resonances ***C1***, ***C3***, and ***C6***. In the pD range 8.0–3.0 no significant changes were observed, but for $pD \leqslant 3.0$ the ***C1***, ***C4*** and ***C5*** carbon atoms are upfield shifted, being ***C1*** the most significantly shifted (ca. 1 ppm), which may indicate the protonation of the $\mathbf{N}_{I}$ centre.

3.3. Stability constants

The complexation of **L2** with Cu^{2+}, Zn^{2+} and Cd^{2+} was followed by potentiometry, at 25.0 °C and 0.1 mol dm^{-3}

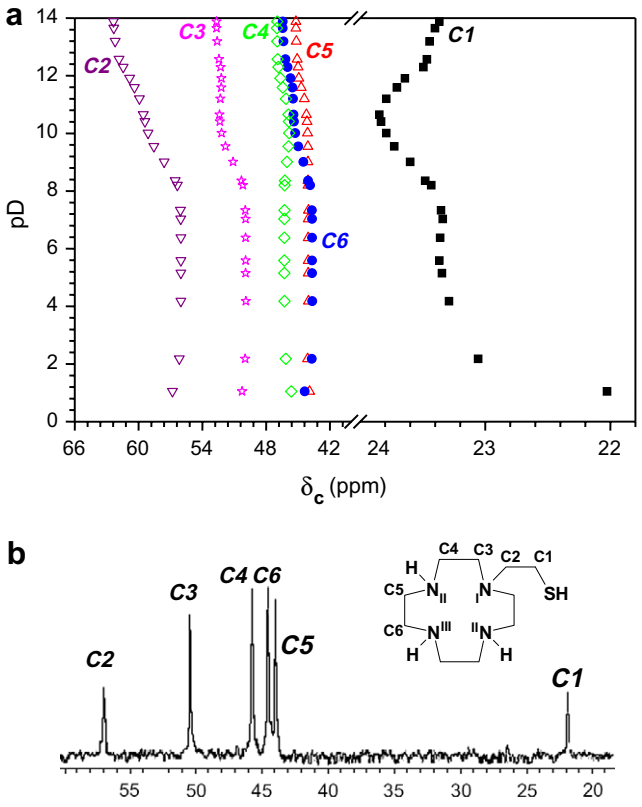

Fig. 5. (a) ^{13}C NMR titration curves for **L2** (chemical shift (δ_C) in function of pD): ■, *C1*; ▽, *C2*; ☆, *C3*; ♦, *C4*; △, *C5* and ●, *C6*. (b) ^{13}C NMR spectrum of **L2** (D_2O, pD 1.05).

KNO_3, and the corresponding stability constants were determined. The kinetics of formation of the complexes of **L2** with the transition metal ions studied is relatively slow. The stability constants were determined by the use of a batch method in the pH regions where complexation equilibrium was not attained during in-cell titrations, leading to stability constants with relatively high standard deviations. In Table 5 are listed the stability constants of the complexes of **L2** with Cu^{2+}, Zn^{2+} and Cd^{2+}, together with the constants for the corresponding complexes with related tetraazmacrocycles. Cyclam was included due to its very high affinity for copper(II) [33].

Only mononuclear species were formed with the studied metal ions, namely [ML], [M(HL)], [M(H_2L)], [M(L(OH))] and [M(L(OH)$_2$)]. The latter species is only formed for Cd^{2+}, while [M(H_2L)] only exists when $M = Cu^{2+}$. At physiological pH, the [ML] complex is formed at about 100% for Cu^{2+}, while for Cd^{2+} and for Zn^{2+} only above pH 8 this is the main species (Fig. 6).

The trend found for the stability of the complexes studied, [CuL] > [ZnL] ≈ [CdL], follows the usual order for cyclen derivatives. However the $\log K_{CuL}/\log K_{ZnL}$ and $\log K_{CuL}/\log K_{CdL}$ ratios are smaller than usually found for ligands having only amine donor atoms, such as cyclen and cyclam. This feature, together with the larger values of K_{ML} observed for **L2**, when compared to cyclen, strongly suggests the involvement of the arm in the coordination sphere of the metal centre. For all the metal ions, completely different direct and backtitration potentiometric curves were obtained, suggesting structural rearrangements, may be related with the formation and break of the M–S bond.

A direct comparison of stability constants of **L2** and those reported for cyclen, **L3**, **L4** and cyclam can only be made using the pM ($-\log[M^{2+}]$) values (Table 6) [35], due to the different basicity of the ligands.

These data indicate that compound **L2** has higher affinity for the transition metal ions studied than the tetraaza-

Table 6
pM values[a] calculated for **L2** and other related ligands (pH 7.4)

Ion	L2	Cyclen	L4	Cyclam
Cu^{2+}	14.24	9.27, 10.02	11.59	10.19, 10.54
Cd^{2+}	11.91	4.73	7.29	2.57
Zn^{2+}	11.77	5.68	7.99	2.42

[a] The values were calculated for 100% excess of free ligand, using the program HySS [35], $C_L = 2C_M = 1 \times 10^{-5}$ mol dm^{-3} and the stability constants given in Table 5.

macrocycles considered for comparison. For the same cavity size, the presence of a coordinating pendant arm increases significantly the stability of the complexes. A decrease of the pM values is found when the cavity size increases. However, **L2** shows a low selectivity for Cu over Zn and Cd.

3.4. Structural studies in solution

3.4.1. NMR studies of zinc(II) complexes

To assess the nature of the inner sphere of the zinc, the ^{13}C NMR spectra of solutions containing Zn^{2+} and **L2** (1:1 molar ratio) have been recorded at different pD values. Based on the species distribution diagram (Fig. 6), we have chosen the 5.6, 7.6 and 11.6 pH values, which correspond to the [Zn(HL)], [ZnL] and [Zn(L(OH))] species, respectively. In Table 7 are collected the chemical shifts of the carbon atoms of the Zn^{2+}/**L2** species formed as well as those for the free **L2**, recorded in the same experimental conditions.

Table 7
Chemical shift (δ/ppm) of the carbon atoms of **L2** and of the species Zn/**L2** at pD 6, 8 and 12

	pD ≈ 6		pD ≈ 8		pD ≈ 12	
	L2	**Zn/L2**	**L2**	**Zn/L2**	**L2**	**Zn/L2**
C1	23.36	26.37	23.43	26.02	23.64	25.97
C2	56.02	55.07	56.36	57.22	60.84	57.18
C3	49.93	51.66	50.20	52.22	52.22	52.18
C4	46.30	46.54	46.26	47.22	46.66	47.19
C5	44.04	45.64	44.05	46.18	44.93	44.45
C6	43.69	44.40	43.87	44.49	45.71	46.14

Most of the carbon atoms of **L2** are significantly downfield shifted upon coordination to the Zn^{2+}. These results are consistent with the formation of a Zn^{2+}/**L2** complex and seem to indicate that all the donor atoms are coordinated to the metal. The significant downfield shift observed for ***C2***, when pD increases from 6 to 8, may be correlated to the deprotonation followed by coordination of the thiol group, in agreement with the potentiometric studies (Table 5).

3.4.2. UV–Vis and EPR spectroscopic studies of copper(II) complexes

The UV–Vis–NIR and the EPR spectra of Cu^{2+}/**L2** and Cu^{2+}/cyclen complexes were recorded at pH 5, 8 and 12, which for Cu^{2+}/**L2** corresponds to about 100% of the [Cu(HL)], [CuL] and [Cu(L(OH))] species, respectively (Fig. 6). As can be seen in Table 8, the electronic spectra of the Cu^{2+} complexes with **L2** and cyclen exhibit two well defined bands, one in the UV–Vis range and another in the charge transfer region. A red-shift of the band in the UV–Vis is expected when the geometry of a Cu^{2+} complex changes from a square planar to a penta-coordinated one. For Cu^{2+}/cyclam [36] and Cu^{2+}/1,4,8-trimethyl-11-(2-thioethyl)-1,4,8,11-tetraazacyclotetradecane [5a], which have been considered to be four and five-coordinated, the maximum absorption of the bands has been reported to be at $\lambda_{max} = 513$ nm and 622 nm, respectively. Our data for Cu^{2+}/**L2** and Cu^{2+}/cyclen seem to indicate that in the complexes studied in this work the copper centre is five-coordinated. In the pH range studied, both complexes present the same pattern for the UV–Vis spectra and the maximum of absorption does not change significantly with the pH. These results may suggest that the environment around the Cu is the same, independently of the protonation of the corresponding ligand. However, the molar absorptivity of the complex Cu^{2+}/**L2** increases with pH, indicating a highest distortion for the complex, most probably due to the deprotonation of the sulphur atom and formation of a strong apical Cu–S bond.

In Fig. 7 are shown the X-band EPR spectra of Cu^{2+}/**L2** and Cu^{2+}/cyclen complexes and their simulated spectra, at different pH values. All the spectra indicated the presence

[c] Ref. [36].
[d] Ref. [38].

of only one species, except for Cu^{2+}/**L2** at pH 5, which revealed the presence of two species. All the spectra showed the expected four well-resolved lines at low field, due to the interaction of the unpaired electron spin with the copper nucleus. The hyperfine coupling constants (A) and g values obtained by the simulation of the spectra [37] are shown in Table 8, together with those of other copper(II) complexes taken from literature, for comparison [36,38]. The simulation of the spectra revealed three different g values with $g_z > (g_x + g_y)/2$ and the lowest $g \geqslant 2.04$, which is characteristic of mononuclear copper(II) complexes having rhombic-octahedral with elongation of the axial bonds or distorted square-based pyramidal symmetries, and $d_{x^2-y^2}$ ground state.

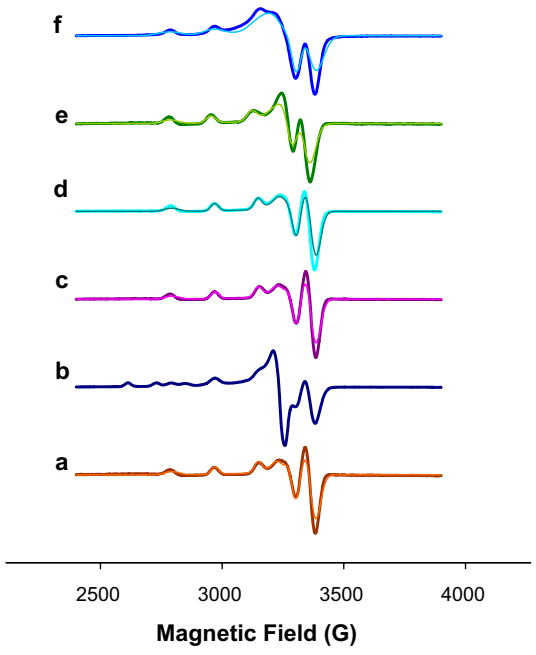

Fig. 7. X-band EPR spectra of copper complexes of **L2** and cyclen in $\approx 1.5\times10^{-3}$ mol dm^{-3} and 40% DMSO/H$_2$O solutions (strong lines) and the simulated spectra (smooth lines) at different pH values: (a) Cu^{2+}/Cyclen, pH 5, at 114.5 K; (b) Cu^{2+}/**L2**, pH 5, at 111.6 K; (c) Cu^{2+}/Cyclen, pH 8, at 105.9 K; (d) Cu^{2+}/**L2**, pH 8, at 112.2 K; (e) Cu^{2+}/Cyclen, pH 12, at 119.4 K and (f) Cu^{2+}/**L2**, pH 12, at 107.6 K. All spectra were recorded with microwave power of 2.0 mW, modulation amplitude of 1 mT, and frequency of 9.41 GHz.

The two species present, at pH 5, in the EPR spectrum of Cu^{2+}/**L2** are in about the same proportion, based on the intensity of the bands. The simulation of this spectrum could not be obtained and so is not presented. Nevertheless, the direct analysis of the spectrum and the estimated g_z and A_z parameters suggest that one species (species A) corresponds to the aqua-complex [Cu(H$_2$O)$_6$]$^{2+}$, and the other to the species found at pH 8 (species B).

The EPR parameters of the Cu^{2+}/**L2** and Cu^{2+}/cyclen complexes (at pH $\geqslant$ 5) are similar, pointing to identical coordination environments. The g_i and A_i values are related to the electronic transitions by the factors derived from the ligand field theory [39]: the g_i values increase and the A_i values decrease as the equatorial ligand field becomes weaker or the axial ligand field stronger and this occurs with the simultaneous red-shift of the d–d absorption bands in the electronic spectra [39,40].

Additionally the EPR data obtained in this work for the copper(II) complexes of **L2** and cyclen are quite different from those for Cu^{2+}/cyclam also collected in Table 8. In the latter complex the copper has a square planar geometry, with the equatorial plane formed by the four nitrogen atoms of the macrocycle and the metal centre included into the cavity [41]. Indeed, the 12-membered cavity of **L2** and cyclen is too small for the copper centre, and therefore the macrocycle take a folded arrangement with the metal out of the cavity. In the cyclen complex a water molecule or other solution ion completes a five-coordination geometry, while in the Cu^{2+}/**L2** the sulphur of the arm certainly do the same effect. A square-pyramidal geometry is expected for **L2** complexes since in the case of a trigonal-bipyramidal a $g_\perp > g_\parallel$ and a UV–Vis band in the region 800–850 nm would be observed [42]. Thus, considering the UV–Vis and the EPR data, a square pyramidal geometry

is expected for all the complexes studied in this work, and the small changes observed for Cu^{2+}/**L2** versus Cu^{2+}/cyclen can be most probably only assigned to distortions in the structure, promoted by a stronger coordination of the thiol group at higher pH.

4. Concluding remarks

A mono-N-substituted cyclen derivative with a 2-ethanethiol pendant arm, 2-[1,4,7,10-tetraazacyclododecan-1-yl]-ethanethiol (**L2**), has been successfully synthesized, being its thiol-protected precursor (**L1**) also characterized in solution and in the solid state. Compound **L2** was characterized by 2D NMR studies and its protonation constants were determined by potentiometry. An analysis of the protonation scheme of **L2** was discussed based on ^{13}C NMR titration. The stability constants of **L2** with Cu^{2+}, Zn^{2+} and Cd^{2+} were determined by potentiometry, and their values follow the usual trend found for cyclen derivatives: [Cu**L2**] > [Zn**L2**] ≈ [Cd**L2**]. At physiological pH, the pM values calculated for the metal complexes of **L2** have shown that this ligand is less selective for Cu^{2+} over Zn^{2+} and Cd^{2+}, compared to cyclen and cyclam. Spectroscopic data indicate that **L2** forms penta-coordinated complexes with Cu^{2+} and Zn^{2+}.

In summary, the introduction of a thiol pendant arm in the cyclen backbone has improved the affinity for Cu^{2+} but its selectivity has decreased. Radioactive studies with copper are underway to evaluate the possible use of this ligand for biological applications.

5. Supplementary material

CCDC 636011 contains the supplementary crystallographic data (excluding structure factors) for **L1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

electronic configuration Cu(I) ions do not have an energetically preferred geometry and their coordination is therefore mainly governed by steric repulsions. Aside from the two donor species P and S the remaining space around the copper ion is usually occupied by a fourth ligand, usually a halide. In our experiments we have decided to verify if the absence of other soft species can influence the coordination and in particular if in these conditions the imino nitrogen becomes a suitable donor for coordination. In this paper, the complexes of 4-fluorobenzaldehyde thiosemicarbazones (Hfbt and Me-Hfbt, Scheme 2) with Cu(I) nitrate, sulphate and acetate in the presence of triphenylphosphine (Ph_3P) are reported. The choice of these oxoanions was envisaged to stabilize the ligand in the *Z* conformation thank to their capability to form concerted hydrogen bonds while the *N*-methylated derivative was used for comparison to verify if the terminal amino hydrogen, not involved in the aforementioned hydrogen bonds, can influence the crystal packing. All of these compounds have been characterized by elemental analysis, IR, ^{1}H NMR spectroscopy and compounds **1**, **5** and **6** also by X-ray crystallography Scheme 3.

2. Experimental

2.1. Materials and techniques

$[Cu(PPh_3)_2NO_3]$, $[Cu_2(PPh_3)_4SO_4]$ and $[Cu(PPh_3)_2(CH_3COO)]$ were prepared by reduction of the corresponding Cu(II) salt using a fourfold excess of PPh_3 in CH_3OH at reflux temperature for 1, 2 and 3 h, respectively. The white powder formed in the reaction flask was filtered to separate the product from Ph_3PO and washed first with EtOH and then with diethyl ether. $Cu(NO_3)_2 \cdot 3H_2O$, $CuSO_4 \cdot 5H_2O$, $Cu(CH_3CCO)_2 \cdot H_2O$ were procured from Carlo Erba while PPh_3 was purchased from Aldrich. C, H, N, S analyses were obtained with a Carbo-Erba 1108 instrument. IR spectra were recorded using KBr pellets on a Nicolet 5PC FTIR spectrophotometer in the 4000–400 cm^{-1} range. ^{1}H NMR spectra were recorded on a Bruker AC300 spectrometer at 300 MHz in DMSO with TMS as the internal reference.

2.2. Preparation of the ligands and of their complexes

4-Fluorobenzaldehyde thiosemicarbazone was prepared by condensation of 4-fluorobenzaldehyde with thiosemicarbazide or N^1-methylthiosemicarbazide in a 1:1 molar ratio in ethanol using the procedure reported in the literature [18].

2.2.1. Synthesis of $[Cu(PPh_3)_2(Hfbt)]NO_3$ (1)

To a stirred solution of $[Cu(PPh_3)_2NO_3]$ (1.650 g, 2.54 mmol) in methanol (30 mL) was added an equimolar amount of the ligand (0.502 g, 2.54 mmol) dissolved in methanol (30 mL). The contents were stirred for 2 h at room temperature. The clear solution was allowed to evaporate at room temperature and a yellow colored crystalline product was formed. The isolated powder was recrystallized from EtOH 95% and crystals apt for X-ray diffraction were obtained (yield: 1.400 g, 65%; m.p.: 184 °C). The complex is soluble in DMSO, $CHCl_3$ and CH_2Cl_2. *Anal.* Calc. for $C_{44}H_{38}CuFN_4O_3P_2S$: C, 62.37; H, 4.52; N, 6.61; S, 3.78. Found: C, 62.45; H, 4.17; N, 6.64; S, 3.81%. Main IR peaks (KBr, cm^{-1}): $\nu_{as}(NH_2)$ 3442 m; $\nu_s(NH_2)$ 3118 m; ν(N–H) 3284 w, $\nu(C–H_{aromatic})$ 3054 w, $\nu(C–C_{aromatic})$ 1627 s, 1506 s and 1480 s; ν(C=N) 1602 s; ν(C–P) 1433 vs; $\nu(NO_3)$ 1384 vs and 1293 s; ν(C–F) 1234 s; $\delta(C–H_{aromatic})$ 1156 m and 1093 m; ν(C=S) 827 m; $\gamma(C–H_{aromatic})$ 745 vs and 695 vs. ^{1}H NMR data (δ, ppm; DMSO-d_6): 7.25 (t, b, 8H, overlapped ligand H_m and PPh_3H_p); 7.37 (t, 12H, PPh_3H_m); 7.87 (dd, 2H, ligand H_o); 7.99 (s, 1H, C*H*=N); 8.29 and 8.39 (2 s, 1H each, NH_2); 11.61 (s, 1H, C(S)N*H*).

2.2.2. Synthesis of $[Cu(PPh_3)_2(Hfbt)]_2SO_4 \cdot CH_3OH$ (2)

To a stirred solution of $[Cu_2(PPh_3)_4SO_4]$ (0.662 g, 0.52 mmol) in methanol (20 mL) was added a twofold molar amount of the ligand (0.205 g, 1.04 mmol) dissolved in methanol (20 mL). The contents were stirred for 2 h at room temperature. A yellow powder was formed and the product was filtered (yield: 0.600 g, 68%; m.p.: 132 °C). The complex is soluble in DMSO, $CHCl_3$ and CH_2Cl_2. *Anal.* Calc. for $C_{89}H_{80}Cu_2F_2N_6O_5P_4S_3$: C, 62.93; H, 4.75; N, 4.95; S, 5.66. Found: C, 62.51; H, 4.49; N, 4.83; S, 5.50%. Main IR peaks (KBr, cm^{-1}): $\nu_{as}(NH_2)$ 3377 s; $\nu_s(NH_2)$ 3143 m; ν(N–H) 3289 m, $\nu(C–H_{aromatic})$ 3052 m, $\nu(C–C_{aromatic})$ and overlapped ν(C=N) 1602 vs, $\nu(C–C_{aromatic})$

1507 vs and 1480 s; ν(C–P) 1434 vs; ν(C–F) 1234 s; δ(C–$H_{aromatic}$) 1155 s and 1094 s; $\nu(SO_4)$ 1121 s; ν(C=S) 833 m; γ(C–$H_{aromatic}$) 745 vs and 696 vs. ^{1}H NMR data (δ, ppm; DMSO-d_6): 7.24 (t, b, 8H, overlapped ligand H_m and PPh_3H_p); 7.36 (t, 12H, PPh_3H_m); 7.45 (t, 12H, PPh_3H_o); 7.86 (bs, 2H, ligand H_o); 7.99 (s, 1H, C*H*=N); 8.29 and 8.39 (2s, 1H each, NH_2); 11.58 (s, 1H, C(S)N*H*).

2.2.3. Synthesis of $[Cu(PPh_3)_2(Hfbt)]CH_3COO$ (3)

To a stirred solution of $[Cu(PPh_3)_2(CH_3COO)]$ (0.672 g, 1.04 mmol) in methanol (25 mL) was added an equimolar amount of the ligand (0.205 g, 1.04 mmol) dissolved in methanol (25 mL). The contents were stirred for 2 h at room temperature. The clear solution was allowed to evaporate and a yellow product was afforded (yield: 0.650 g, 76%; dec.: 178 °C). The complex is soluble in DMSO, $CHCl_3$ and CH_2Cl_2. *Anal.* Calc. for $C_{46}H_{41}CuFN_3O_2P_2S$: C, 65.43; H, 4.89; N, 4.98; S, 3.80. Found: C, 65.84; H, 4.78; N, 5.01; S, 3.69%. Main IR peaks (KBr, cm^{-1}): $\nu(NH_2)$ 3481 m, 3382 m, 3141 w; ν(NH) 3293 m, 3238 w; ν(C–$H_{aromatic}$) 3052 m; ν_{as}(COO) 1580 s; ν(C–$C_{aromatic}$) 1596 s and 1478 s; ν(C–P) 1434 vs; ν(C–F) 1229 s; δ(C–$H_{aromatic}$) 1156 m and 1094 m; ν(C=S) 834 m; γ(C–$H_{aromatic}$) 746 vs and 696 vs. ^{1}H NMR data (δ, ppm; DMSO-d_6): 2.10 (bs, 3H, CH_3COO); 7.26 (t, b, 8H, overlapped ligand H_m and PPh_3H_p); 7.40 (t, 12H, PPh_3H_m); 7.52 (t, 12H PPh_3H_o); 7.95 (dd, 2 H, ligand H_o); 8.06 (s, 1H, C*H*=N); 8.30 and 8.41 (2s, 1H each, NH_2); 11.54 (s, 1H, C(S)N*H*).

2.2.4. Synthesis of $[Cu(PPh_3)_2(Me\text{-}Hfbt)]NO_3 \cdot CH_3OH$ (4)

To a stirred solution of $[Cu(PPh_3)_2NO_3]$ (1.134 g, 1.75 mmol) in methanol (25 mL) was added an equimolar amount of the ligand (0.368 g, 1.74 mmol) dissolved in methanol (20 mL). The contents were stirred for 2 h at room temperature. The clear solution was allowed to evaporate at room temperature and a yellow colored powder was obtained (yield: 1.078 g, 69%; m.p.: 100 °C). The complex is soluble in DMSO, $CHCl_3$ and CH_2Cl_2. *Anal.* Calc. for $C_{46}H_{44}CuFN_4O_4P_2S$: C, 61.84; H, 4.96; N, 6.27; S, 3.59. Found: C, 61.72; H, 4.65; N, 6.31; S, 3.53%. Main IR peaks (KBr, cm^{-1}): ν(N–H) 3382 m, 3239 m, ν(C–$H_{aromatic}$) 3052 w; ν(C–$H_{aliphatic}$) 2998 m; ν(C–$C_{aromatic}$) 1601 s, 1507 s and 1480 s; ν(C=N) 1566 s; ν(C–P) 1434 vs; $\nu(NO_3)$ 1384 vs and 1292 s; ν(C–F) 1234 s; δ(C–$H_{aromatic}$) 1156 m and 1093 m; ν(C=S) 834 w; γ(C–$H_{aromatic}$) 746 vs and 696 vs. ^{1}H NMR data (δ, ppm; DMSO-d_6): 2.99 (d, 3H, NCH_3); 7.24 (t, b, 8H, overlapped ligand H_m and PPh_3 H_p); 7.37 (t, 12H, PPh_3H_m); 7.47 (t, 12H PPh_3H_o); 7.86 (dd, 2H, ligand H_o); 7.99 (s, 1H, C*H*=N); 8.56 (s, 1H, N*H*CH_3); 11.44 (s, 1H, C(S)N*H*).

2.2.5. Synthesis of $[Cu(PPh_3)_2(Me\text{-}Hfbt)]_2SO_4$ (5)

To a stirred solution of $[Cu_2(PPh_3)_4SO_4]$, (0.631 g, 0.50 mmol) in methanol (35 mL) was added a twofold molar amount of the ligand (0.209 g, 1.00 mmol) dissolved in methanol (15 mL). The contents were stirred for 2 h at room temperature. The clear solution was allowed to evaporate at room temperature and a yellow colored crystalline product was formed. The isolated powder was dissolved in warm EtOH 95% and crystals apt for X-ray diffraction were obtained (yield: 1.050 g, 62%; m.p.: 143 °C). The complex is soluble in DMSO, $CHCl_3$ and CH_2Cl_2. *Anal.* Calc. for $C_{90}H_{80}Cu_2F_2N_6O_4P_4S_3$: C, 63.78; H, 4.76; N, 4.96; S, 5.68. Found: C, 63.55; H, 4.68; N, 4.91; S, 5.51%. Main IR peaks (KBr, cm^{-1}): ν(NH) 3446 w, 3378 w, 3226 w; ν(C–$H_{aromatic}$) 3051 m; ν(C–$H_{aliphatic}$) 2934 m; ν(C–$C_{aromatic}$) 1602 s, 1508 vs and 1480 s; ν(C=N) 1567 m; ν(C–P) 1435 vs; ν(C–N) 1329 m; ν(C–F) 1233 s; δ(C–$H_{aromatic}$) 1156 m and 1093 m; $\nu(SO_4)$ 1118 s; ν(C=S) 831 m; γ(C–$H_{aromatic}$) 746 vs and 697 vs. ^{1}H NMR data (δ, ppm; DMSO-d_6): 2.08 (s, 3H, NCH_3); 7.25 (t, b, 8H, overlapped ligand H_m and PPh_3 H_p); 7.37 (t, 12H, PPh_3H_m); 7.44 (t, 12H PPh_3H_o); 7.86 (dd, 2H, ligand H_o); 8.00 (s, 1H, C*H*=N); 8.27 (s, 1H, N*H*CH_3); 11.54 (s, 1H, C(S)N*H*).

2.2.6. Synthesis of $\{[Cu(PPh_3)_2(Me\text{-}Hfbt)]CH_3COO\}_2 \cdot 2EtOH \cdot H_2O$ (6)

To a stirred solution of $[Cu(PPh_3)_2(CH_3COO)]$ (0.619 g, 0.96 mmol) in ethanol 95% (25 mL) was added an equimolar amount of the ligand (0.202 g, 0.96 mmol) dissolved in ethanol (15 mL). The contents were stirred for 2 h at reflux temperature. The clear solution was allowed to evaporate at room temperature and yellow-brown crystals suitable for X-ray diffraction were afforded (yield: 1.280 g, 74%; m.p.: 144 °C). The complex is soluble in DMSO, $CHCl_3$ and CH_2Cl_2. *Anal.* Calc. for $C_{98}H_{100}Cu_2F_2N_6O_7P_4S_2$: C, 64.42; H, 5.52; N, 4.60; S, 3.51. Found: C, 64.45; H, 5.55; N, 4.62; S, 3.53%. Main IR peaks (KBr, cm^{-1}): ν(NH) 3378 w, 3238 w; ν(C–$H_{aromatic}$) 3053 m; ν(C–$H_{aliphatic}$) 2970 m; ν_{as}(COO) 1619 vs; ν_s(COO) 1396 s; ν(C–$C_{aromatic}$) 1599 vs, 1507 vs and 1480 vs; ν(C–P) 1434 vs; ν(C–F) 1232 s; δ(C–$H_{aromatic}$) 1156 m and 1093 m; ν(C=S) 832 m; γ(C–$H_{aromatic}$) 746 vs and 697 vs. ^{1}H NMR data (δ, ppm; DMSO-d_6): 1.18 (t, 3H, CH_3CH_2OH), 2.10 (bs, 6H, NCH_3 + CH_3COO); 3.72 (q, 2H, CH$_3$CH_2OH), 7.28 (t, b, 8H, overlapped ligand H_m and PPh_3 H_p); 7.39 (t, 12H, PPh_3H_m); 7.48 (t, 12H PPh_3H_o); 7.91 (dd, 2H, ligand H_o); 8.04 (s, 1H, C*H*=N); 8.34 (s, 1H, N*H*CH_3); 11.58 (s, 1H, C(S)N*H*).

2.3. Crystallography

Relevant data concerning data collection and details of structure refinement are summarized in Table 1. Intensity data were collected on a Philips PW1100 (compounds **1** and **6**) and on a SMART 1000 Bruker AXS diffractometer (compound **5**) with Mo Kα radiation. Data from crystals of compounds **1** and **6** collected on the Philips diffractometer were non corrected for absorption while for compound **5** an absorption correction was carried out using the SADABS [19] procedure. The WINGX [20] package was used all through the refinement and completion of the structure. The structures were solved using direct methods (SIR-97 [21]). Refinements were carried out by full matrix least-

squares cycles SHELXL97 [22] for all compounds. The hydrogen atoms were calculated with standard geometry and refined in riding position. Atomic scattering factors were taken from the International Tables for Crystallography [23]. The program PARST [24] was employed for the geometrical description and ORTEP [25] and MERCURY [26] for the drawings.

3. Results and discussion

3.1. Synthesis and spectroscopy

Compounds (**1**), (**5**) and (**6**) afforded crystals suitable for X-ray diffraction studies and structural data allow for a correlation between structures and spectroscopic data. As for complexes obtained from NO_3^- is concerned, the IR spectral behaviour of (**1**) and (**4**) is very similar in all the observed range. This allows to suppose that the Me-Hfbt ligand of complex (**4**) is in the same environment of complex (**1**). It is useful to note that the same differences found between complex (**1**) and its free ligand are also found between (**4**) and its free ligand. The IR absorptions of the C=S groups are shifted at lower frequencies with respect to the free ligand (827 cm^{-1} for (**1**) versus 836 cm^{-1} and 834 cm^{-1} for (**4**) versus 837) indicating the weakening of the C=S bond after coordination. Changes in the spectral ranges between 1500 and 1600 cm^{-1} (νC=N) and between 1130 and 1340 cm^{-1} (NC(=S)N absorptions) indicate the C=N involvement in coordination. It can also be generally observed a broadening of the ν(NH) absorptions, showing a different behaviour of the hydrogen bonding network in the complexes with respect to the free ligands. This can be due to the fact that also in the free ligands at the solid state N–H bonds are involved in strong hydrogen bonds. For this reason it is not always observed in the IR spectra of complexes a shift to lower frequencies with respect to the free ligand. The absorption at *ca.* 1394 and 1293 cm^{-1} are assigned to the absorptions of the non coordinated inorganic ligand. NMR data suggest that also in solution ligands are in their neutral form as can be observed from the presence at 11.61 ppm for (**1**) and 11.44 ppm for (**4**). With respect of NMR data of the free ligands, a slight shift to low field of N–H protons is observed (up to 0.20 ppm).

Similar considerations can be also drawn for complexes (**2**) and (**5**) obtained from SO_4^{2-} and (**3**) and (**6**) from CH_3COO^- anions. In particular for (**2**) and (**5**) can be observed the presence at 1120 cm^{-1} strong absorption of ionic SO_4^{2-}. The IR spectra of complexes (**3**) and (**6**) result more complicated because of the presence of CH_3COO^- asymmetric and symmetric stretchings.

In this way for all complexes a tetrahedral coordination by means of S,N, P, P can be assumed.

3.2. Crystal structures of the complexes

The syntheses allowed to isolate in crystalline form complexes (**1**), (**5**) and (**6**) and in order to establish their structural features, single crystal X-ray crystallography experiments were carried out (Table 2).

In Fig. 1 is reported the ORTEP view of complex $Cu(PPh_3)_2(Hfbt)]NO_3$ (**1**). The structure can be described as formed by a cationic complex molecule with a nitrate as a counterion and the copper(I) ion coordinates two triphenylphosphines and a parafluorobenzaldehyde thiosemicarbazone molecule in its neutral form. The thiosemicarbazone binds to the metal through the sulfur and the iminic nitrogen and forms a five-term chelation ring with an angle N–Cu–S of 85.13(5)°. The P–Cu–P angle is rather

wide (125.07(5)°) and the copper tetrahedral coordination is therefore strongly distorted. The coordination bonds have distances that range from 2.136(2) Å for the Cu1–N3 bond to 2.3482(8) Å for the Cu1–S1 bond. The nitrate ion forms a strong charge assisted H-bonding with the thiosemicarbazone NH groups through two of its oxygens (see Table 3). The thiosemicarbazone moiety, that should be expected to be planar because of the extended conjugated system of double bonds, is significantly distorted: the angle between the average plane of the 4-fluorobenzaldehyde ring and that of the thiosemicarbazide moiety is 23.63(7)°. This distortion can be interpreted as a double interaction of the fluorophenyl moiety with two phenyls belonging to two different triphenylphosphines.

The main feature that characterizes the packing of these molecules is a so-called sixfold phenyl embrace (6PE) [27a,27b,27c,27d] (P1...P1^{I} $I = (1 - x, -y, -z)$ distance 6.979 Å) (see Fig. 2) between two centrosymmetrically related molecules. The phenyls of the triphenylphosphines involved in this interaction present what the aforementioned paper calls a "good rotor" conformation with torsion angles (defined by the copper, the phosphorus, the ipso carbon and the next carbon atom of the phenyl group which gives the torsion angle in the range 90°, −90°) of 43.53°, 45.69° and 49.21° while the other triphenylphosphine has a more irregular conformation (torsion angles of 23.90°, 37.31°, 78.23°) due to an edge-to-face interaction between the fluorobenzene group with a tpp phenyl group.

	O6(ethanol)…O4 (acetate)	2.792(9)	O6–H…O4	154.6(6)

To complete the description of the packing it is noteworthy to observe the presence of two longer P…P distances due to the presence of two pairs of phenyls belonging to two centrosymmetrically related molecules that interact edge-to-face (see Fig. 2). The other N terminal hydrogen atom seem to play no role in the packing.

The structure of compound **5**, $[Cu(PPh_3)_2(Me\text{-}Hfbt)]_2SO_4$, is reported in Fig. 3. The asymmetric unit is formed by two complex $[Cu(PPh_3)_2(Me\text{-}Hfbt)]^+$ cations bridged by a sulfate anion. The two cationic moieties differ significantly in their geometrical features. One of the thiosemicarbazone ligand (molecule A) presents a marked dihedral angle (43.6(3)°) between the average plane of the thiosemicarbazide moiety and that of the fluorobenzyl ring, while in the other (molecule B) is almost planar (the same dihedral angle is 2.91(3)°). The sulfate ion forms two

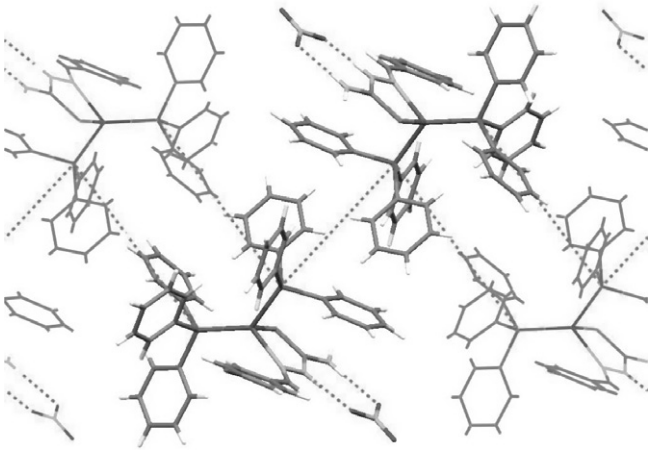

Fig. 2. MERCURY drawing of the packing of compound (**1**) showing the two molecules (capped sticks) involved in the six phenyl embrace and the looser pheny–phenyl interactions between adjacent molecules (in wireframe).

charge assisted H-bonds connecting the two complex molecules A and B (see Table 3).

Also this packing is determined by a very tight six-atom phenyl embrace characterized by a P4…$P4^I$ ($I = -x$, $1-x$, $-z$) interaction with a distance of 6.645 Å (see Fig. 4), much shorter than that observed in the previous one. A looser sixfold phenyl embrace is observed between P2 and $P3^I$ ($I = -x$, $-1/2+y$, $1/2-z$) (distance 7.66 Å) and this interaction together with the previously described contact form a bidimensional layer of molecules that lie on the *yz* plane. These layers are connected by a third interaction between two tpp that is characterized by a longer P…P distance of 7.785 Å [P1…$P3^I$ $I = 1+x$, y, z].

The crystal structure of compound **6** $\{[Cu(PPh_3)_2(Me\text{-}Hfbt)]CH_3COO\}_2 \cdot 2EtOH \cdot H_2O$ is reported in Fig. 5. In the asymmetric unit are present two independent complex cations, two acetate ions, two ethanol molecules and a water. The carboxyl group of the acetate forms two hydrogen bonds (see Table 3) with the NH groups of the thiosemicarbazide moiety in a way analogous to that observed in the nitrate derivative previously discussed (**1**). Moreover one of the two carboxylic oxygens (different in molecule A and in molecule B, see Fig. 6) in both acetates is also involved in a bifurcated but strong hydrogen bond with the ethanols (see Table 3). As in the previous case in the two complex molecules the thiosemicarbazone ligands have different planarities and precisely a dihedral angle between the thiourea moiety and the aromatic ring of 8.5(2)° in molecule A and 37.0(2)° in molecule B. Noteworthy the P–Cu–P angles [121.20(5)° and 123.15(5)°] that are by far smaller than those found in the other two complexes [126.83(3)° in compound **1** and 135.39(8)° and 128.52(9)° in compound **5**].

A series of considerations must be done on the hydrogen bonding system found in these compounds. A common feature is the strong charge assisted hydrogen bondings that stabilize the ligand in its neutral form. In particular some

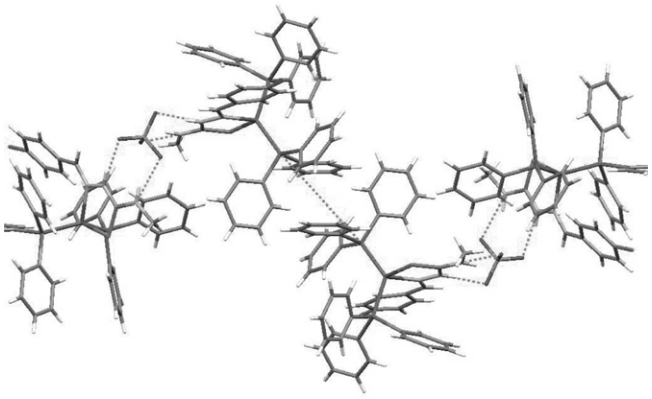

Fig. 4. MERCURY drawing of the packing of compound (**5**) showing two sulphate bridged dimeric molecules involved in the P4...P4 six phenyl embrace.

of these hydrogen bonds formed with the acidic hydrazinic nitrogen are among the shortest observed in the literature. Using a thiourea moiety as a reference we have found in the CSD [28a,28b] that the average N–H...O distance is 2.918(8) Å for the nitrate ion, 2.872(12) Å for the sulfate ion and 2.882(9) Å for the acetate that are comparable with the distances observed for the aminic NH in compound **1** (2.906(3) Å) while those found in complex **5** (2.751(33) and 2.757(10) Å) and in compound **6** (2.701(7) and 2.805(6) Å) are remarkably shorter. The hydrogen bonds that involve the hydrazinic nitrogen are very strong with distances of 2.717(2) Å for **1**, 2.740(9) Å in **5** and 2.746(6) Å and 2.720(6) Å in **6**. The only exception is the hydrazinic N of molecule B of compound **5** (2.902(9) Å) in which the distance is larger than the average and this distortion is probably due to the packing.

4. Conclusions

As hypothesized in the introduction the main features presented by these copper(I) complex molecules are determined by three factors: (a) the absence of soft donor atoms, besides P and S, that force the imino nitrogen to coordinate to the metal center; (b) the overall flatness of the thiosemicabazone moiety that allows its insertion in the cleft formed by the bulky blob of the two triphenylphosphines and, (c) the presence of the charged assisted hydrogen bonds formed by the anions that contribute to the *Z* configuration of the ligand. A contribution that is not predictable in the detail but that is decisive in understanding the overall packing and some distortions in the planarity of the thiosemicarbazone ligand in the crystal is the extended system of weak interactions among the aromatic rings.

Appendix A. Supplementary material

CCDC 640078, 640079 and 640080 contain the supplementary crystallographic data for **1**, **5** and **6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.04.026.

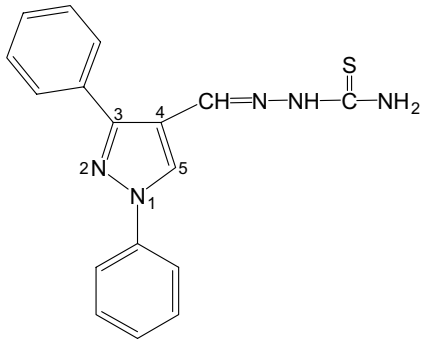

Fig. 1. Chemical structure of Ph_2PzTSC.

structural variation on the heterocyclic ring might bring out significant enhancement in their biological effects, especially in corresponding metal complexes, often with novel structural information. Synthesis and spectroscopic characterization of nickel(II) complexes with some pyrazolyl thiosemicarbazones, such as 5-methyl-3-formylpyrazole-3-substituted thiosemicarbazones have been reported by other authors [14–16]. As a part of our investigation toward synthesis and structural characterization of new compounds containing biorelevant pyrazolyl thiosemicarbazones, the present paper reports the synthesis, spectroscopic, and structural properties of 1,3-diphenylpyrazole-4-carboxaldehyde thiosemicarbazone ligand (Ph_2PzTSC, Fig. 1) and its nickel(II) complex.

2. Experimental

2.1. Reagents and starting materials

Solvents and reagents were obtained from commercial sources. The solvents were purified using the established method [17]. Thiosemicarbazide and nickel(II) acetate tetrahydrate were purchased from Aldrich Chemicals, USA. 1,3-Diphenylpyrazole-4-carboxaldehyde was synthesized according to Rathelot et al. procedure [18].

2.2. Preparation of Ph_2PzTSC

The Ph_2PzTSC ligand was prepared by refluxing the mixture of the 1,3-diphenylpyrazole-4-carboxaldehyde (1.24 g, 5 mmol) and thiosemicarbazide (0.45 g, 5 mmol) in ethanol (20 cm^3) for 4 h. One drop of glacial acetic acid was previously added into the mixture. After cooling, the white precipitate was filtered, washed with cold chloroform in order to remove the traces of unchanged aldehyde, and dried over anhydrous calcium chloride. Yield: 1.25 g, 78%. The suitable crystals for X-ray analysis were obtained by recrystallization of the ligand from the mixture of acetone and methanol (1:1 v/v).

Anal. Calc. for $C_{17}H_{15}N_5S$: C, 63.53; H, 4.70; N, 21.79. Found: C, 63.75; H, 4.62; N, 21.55%. UV–Vis spectra (cm^{-1}/log ε): 31950 (4.0); ~30 000 (4.0).

^1H NMR (200 MHz, DMSO-d_6): 7.38–7.70, m (8H, Ar); 7.80, br s (1H, NH_2); 7.90, d (2H, Ar, $J = 7.86$ Hz, *ortho*-H, N-substituted phenyl); 8.22, s (1H, Pz); 8.27, br s (1H, NH_2); 9.19, s (1H, CH=N); 11.34, br s (1H, NH).

^{13}C NMR (200 MHz, DMSO-d_6): 117.43; 118.66; 127.15; 127.85; 128.30; 128.75; 128.91; 129.85; 132.28; 135.10; 139.20; 151.52; 177.72.

2.3. Preparation of $[Ni(Ph_2PzTSC\text{-}H)_2]$

$Ni(CH_3COO)_2 \cdot 4H_2O$ (0.25 g, 1 mmol) was dissolved in methanol (10 cm^3) under heating and the solution was mixed with a warm solution of Ph_2PzTSC (0.32 g, 1 mmol) in acetone (20 cm^3). The heating was continuated for several minutes. After 10 h of standing, the brown crystals were filtered and washed with acetone and dried over anhydrous calcium chloride Yield: 0.16 g, 46%.

Anal. Calc. for $C_{34}H_{28}N_{10}NiS_2$: C, 58.38; H, 4.03; N, 20.02; Ni, 8.39. Found: C, 58.42; H, 3.98; N, 20.12; Ni, 8.42%. $\lambda_M(DMF) = 3.3$ S cm^2 mol^{-1}. UV–Vis: (cm^{-1}/log ε): ~33 300 (4.0); 30 210 (4.3); 25 500 sh (3.7); 19 300 sh (2.1). sh (shoulder).

^1H NMR (200 MHz, DMSO-d_6): 6.97–7.19, m (7H; 5H, phenyl and 2H, NH_2); 7.49, s (1H, Pz); 7.50, d (1H, Ar, $J = 7.36$Hz, *para*-H, N-substituted phenyl); 7.65, t, (2H, Ar, $J = 7.66$Hz, *meta*-H, N-substituted phenyl); 8.03, d, (2H, $J = 7.77$Hz, *ortho*-H, N-substituted phenyl); 9.84, s (1H, CH=N, azomethine).

^{13}C NMR (200 MHz, DMSO-d_6): 114.29; 119.89; 127.62; 127.86; 128.44; 128.83; 129.88; 130.10; 130.89; 139.23; 150.17; 152.68; 173.46.

IR (KBr pellets): 3466, 3284, 3067, 1626, 1596, 1526, 1513, 1504, 1219, 956, 705, 672 cm^{-1}.

2.4. Physical measurements

Elemental (C, H, N) analysis of the samples was carried out by standard micromethods in the Center for Instrumental Analysis, Faculty of Chemistry, Belgrade. Nickel content was determined by the complexometric titration with EDTA method, upon the destruction of complex with the mixture of concentrated H_2SO_4 and HNO_3. Molar conductivity of freshly prepared 1×10^{-3} mol dm^{-3} solution was measured on a Jenway 4010 conductivity meter. IR spectra were recorded on a Perkin Elmer Spectrum One FT-IR spectrometer with a KBr disc. ^1H and ^{13}C NMR spectra were obtained using a Varian Gemini 200 spectrometer. Electronic spectra were recorded on a Secomam (Anthelie 2, Advanced, for the range 270–900 nm) and on a Thermo Nicolet instrument (NEXUS 670 FT-IR, for the range 900–1400 nm) in $(1–2) \times 10^{-3}$ mol dm^{-3} DMF solutions of the ligand and complex. Thermal analysis in argon and air gas carriers with a 15 dm^3/min flowing rate and a heating rate of 10 K/min were carried out using a DuPont 1090 TA system. For thermogravimetric

measurements platinum crucible was employed. DSC curves were recorded in open aluminum sample pans. As a reference an empty pan was used. The sample masses were about 5 mg.

2.5. X-ray data collection and structure refinement

The diffraction data for both compounds were collected on an Enraf-Nonius CAD4 diffractometer [19] by using graphite-monochromated Mo Kα (0.71073 Å) radiation at 293(2) K. The data were corrected for Lorentz and polarization effects [20]. Cell constants and the orientation matrix for data collection, obtained from 25 centered reflections in the θ range of 13.17–15.81° for the ligand, corresponded to an orthorhombic cell. In the case off the complex, the 25 centered reflections in the θ range 13.97–17.25° led to a triclinic cell. Both structures were solved by direct methods and difference Fourier methods and refined on the F^2 by full-matrix least-square method [21]. In both cases the all H atoms were determined from ΔF maps but at the final stage of the refinement they were placed at geometrically calculated positions (in purpose to decrease the number of refined parameters). The calculated C–H and N–H distances were 0.93 and of 0.86 Å respectively, and the isotropic displacement parameters are equal to 1.5 and 1.2 times of the equivalent isotropic displacement parameters of the C and N atoms. The software used for the publication are: PLATON [22], WinGX [23], PARST [24] and ORTEPIII [25]. Crystal and structure refinement data for Ph_2PzTSC and $[Ni(Ph_2PzTSC\text{-}H)_2]$ are summarized in Table 1.

3. Results and discussion

3.1. Syntheses and general properties of ligand and complex

The title ligand, 1,3-diphenylpyrazole-4-carboxaldehyde thiosemicarbazone (Ph_2PzTSC) was synthesized in good yield (78%) by condensation from warm ethanolic solutions of the corresponding aldehyde and thiosemicarbazide in an 1:1 mole ratio, in the presence of a small quantity of the glacial acetic acid. The white crystals of the ligand are stable at room temperature. The ligand is very soluble in Me_2CO and DMF, soluble in MeOH, less soluble in aqueous EtOH, and practically insoluble in Et_2O and water.

The brown single crystals of the *cis*-square-planar $[Ni(Ph_2PzTSC\text{-}H)_2]$ complex were obtained by reaction of the warm methanolic solution of $Ni(CH_3COO)_2 \cdot 4H_2O$ with acetone solution of the ligand in mole ratio of 1:1. The complex is soluble in DMF, less soluble in Me_2CO, and insoluble in Et_2O, MeOH, EtOH, and water.

The ligand participates in coordination with nickel(II) ion in its monoanionic form after deprotonation of the hydrazine nitrogen, due to the presence of acetate ion as a Brönsted base, resulting in complex of non-electrolyte type. This is in the agreement with its low molar conductivity. The diamagnetism of the complex is in the accordance with its square-planar structure confirmed by X-ray analysis. The diamagnetic property of the complex is also retained in DMF solution.

3.2. IR spectral studies

A comparative study of the IR spectral data of the complex with that of the ligand gives valuable information regarding bonding sites of the ligand molecule.

The IR spectra of compounds with C=S group attached to a nitrogen show an absorption band due to ν(C=S) stretching in the region between 1020 and 1250 cm^{-1}. In principle, the ligand can exhibit thione/thiol tautomerism, since it contains a thioamide NH–C=S functional group [26]. The missing ν(S–H) band between 2600 and 2800 cm^{-1} indicates that the ligand remains in its thione form. The ligand exhibits a strong band at 1098 and a medium one at 1064 cm^{-1} due to ν(C=S) stretches [27]. Also, two bands at 831 and 807 cm^{-1} in the spectrum of the free ligand can be attributed to vibrations involving interaction between ν(C=S) stretching and ν(C–N) stretchings [28]. The appearance of these bands indicates the existence of ligand in its thione form in the solid state. The disappear-

ance of the ν(C=S) band in this region and the appearance of a medium intensity band at 672 cm^{-1} in the spectrum of the complex suggests the thioenolization of the C=S group and coordination of the thiolate sulfur to nickel [29].

In the spectrum of the ligand three bands appear in the frequency range 3000–4000 cm^{-1}. Two of them, at 3327 and 3257 cm^{-1}, belong to are due to asymmetrical and symmetrical $\nu(NH_2)$ stretching, respectively, and one to the hydrazine ν(NH) at 3159 cm^{-1} [30]. The spectral ν(N–H) band of thiosemicarbazone disappears in the complex indicating the deprotonation of the NH group and coordination via the thiolate sulfur. On the other hand, the bands in the region attributed to symmetrical and asymmetrical stretching modes $\nu(NH_2)$ in the spectrum of the ligand, undergo a change in the spectrum of the complex. This is explained by the coordination of sulfur from C=S(NH_2) group as reported earlier [31,32].

In the ligand spectrum, the strong band observed at 1618 cm^{-1} is assigned to ν(C=N) stretching vibrations [33]. This band shifts to higher wavenumbers at 1626 cm^{-1} in the spectrum of the complex, indicating the coordination of nitrogen of the azomethine group to the central metal ion [31,34].

According to the literature data [15,16], IR bands assigned to $\nu(C{=}N_{pz})$ (pyrazole ring) have been found to shift to the higher frequency region in the nickel complexes referring to the participation of the ring nitrogen atom as a potential bonding site. The negative shift of the very strong $\nu(C{=}N_{pz})$ frequencies from 1543 cm^{-1} in the spectrum of the free Ph_2PzTSC to 1526 cm^{-1} after complexation with nickel(II) ion does not indicate the involvement of pyrazole nitrogen in bonding. This band shifting to lower wavenumbers could be explained by resonance effects through the all conjugated system after the deprotonation and complexation with nickel(II) ion.

3.3. NMR spectral studies

The assignment of all reported signals (^{1}H and ^{13}C) was carried out by means of 1D and 2D homo- and heteronuclear correlated NMR spectroscopy.

3.3.1. ^{13}C NMR spectra

The carbon C=S signal appears at higher field in the spectrum of the complex compared to that in the ligand. This behavior suggests thione-to-thiol evolution in the ligand, an increase in the thiocarbonyl-deprotonated nitrogen bond order [35] and possible coordination of the nickel ion to the thiolic sulfur atom.

^{13}C NMR spectrum shows an unexpectedly low positive $\Delta\delta = \delta$(complex) − δ(free ligand) shift of only 2.0 ppm for the azomethine carbon. In the earlier reports, the complexation through azomethine nitrogen causes a great positive chemical shift of the azomethine carbon in the ^{13}C NMR spectra of complexes [35,36]. On the other side, the C-5 pyrazole carbon exhibits a great positive shift of 15.0 ppm, while the C-4 carbon is shifted to higher field for 3.1 ppm. This behavior of the C-5 pyrazole carbon is probably caused by the positive resonance effect of the phenyl-substituted pyrazole nitrogen, due to the delocalization of π-electrons through C-5, C-4, azomethine carbon, and thiosemicarbazone part of the molecule after the deprotonation of hydrazine nitrogen and complexation. Thus, the reduced electron density of the azomethine carbon after coordination is compensated by resonance effect which results in low difference in the chemical shift of the azomethine carbon in the spectrum of the free ligand compared to that in the complex. In this way the electron density of the azomethine nitrogen is significantly increased as well as its nucleophility facilitating its coordination to nickel(II). The practically same δ-value for C-3 pyrazole carbon (139.2 ppm) in the ^{13}C NMR spectrum of the free ligand compared to the corresponding shift in the complex confirms this hypothesis. The chemical shifts of the other carbon atoms undergo no significant changes upon complexation.

3.3.2. ^{1}H NMR spectra

The ^{1}H NMR spectrum of Ph_2PzTSC ligand show a broad singlet at 11.34 ppm relative to the NH next to C=S, while the signal of the azomethine proton appears at 9.19 ppm. The sharp singlet of the pyrazole proton appears at 8.22 ppm while the aromatic protons occur in 7.38–7.92 ppm range. It is interesting to notice the presence of two broad singlets for two NH_2 protons, at 8.27 and 7.80 ppm respectively. These two protons are different which means that the free rotation around C–N bond is hindered because of its partial double bond character [37].

The coordinating mode of the ligand was confirmed by comparing ^{1}H NMR spectral data of the ligand with the corresponding ones in the complex. The absence of the NH proton signal in the spectrum of the complex suggests the thioenolization and subsequently, the replacement of a proton by the metal ion. This replacement with nickel(II) induces the shift of NH_2 protons to lower δ-values in the spectrum of the complex (overlapped with the aromatic protons shifts in 6.97–7.19 ppm region).

A significant downfield shift of the azomethine proton signal in the complex ($\Delta\delta = 0.65$ ppm) with respect to the corresponding free ligand confirms the coordination of azomethine nitrogen [15,27].

It is interesting to emphasize that C-5 pyrazole proton shifts to lower δ-value from 8.22 ppm in the spectrum of the ligand to 7.49 ppm in the spectrum of the complex. On the other hand, the doublet assigned to *ortho*-N-substituted phenyl protons at 7.90 ppm (center of doublet) is shifted to lower field in the spectrum of the complex at 8.03 ppm, together with *meta* and *para* protons. These shifts are induced by positive resonance effect of phenyl-substituted pyrazole nitrogen and the participation of its electron pair in the delocalization of π-electrons after coordination, which is in the accordance with ^{13}C NMR spectral data for the free ligand and its nickel complex. The

other aromatic proton shifts of the ligand and those in the complex appear in the expected region.

3.4. Electronic spectra

Similarly to the ligand, the red-brownish DMF solution of the Ni(II) complex absorbs in the UV range in several unresolved bands belonging to intraligand transitions. A shoulder appearing at about 25 500 cm^{-1} is probably CT band.

The only one d–d band at about 19 000 cm^{-1} appearing as a shoulder of this CT band is consistent with the assumption of a preserved square-planar geometry in DMF solution. In the near IR region, under 10 000 cm^{-1} no bands were observed, as is usual in complexes with this geometry [38].

3.5. Crystal structures

3.5.1. Crystal structure of Ph_2PzTSC

Fig. 2. shows an ORTEP plot of Ph_2PzTSC ligand with the atomic numbering scheme. Relevant bond distances and angles are listed in Table 2. The thiosemicarbazone moiety of the ligand shows E configuration around the C2–N1 and C1–N2 bond as found in most of the thiosemicarbazones. As confirmed by the C=S bond distance of 1.692(5) Å, the ligand is present in its thione form. The partial double bond characters in formally single bonds of thiosemicarbazone moiety suggest the extensive electron delocalization. Consequently, this part of molecule exhibits considerable planarity. The moiety comprising C2, N1, N2, C1, S1, and N3 atoms has a mean plane deviation of 0.036 Å with the N1 showing the greatest displacement of 0.082 Å. The formally single C2–C3 bond (1.453(7) Å) which connects the thiosemicarbazone fragment to the rest of the molecule allows its free rotation, thus the dihedral angle formed between the best planes of the thiosemicarbazone fragment and the central pyrazole ring achieves 48.3°.

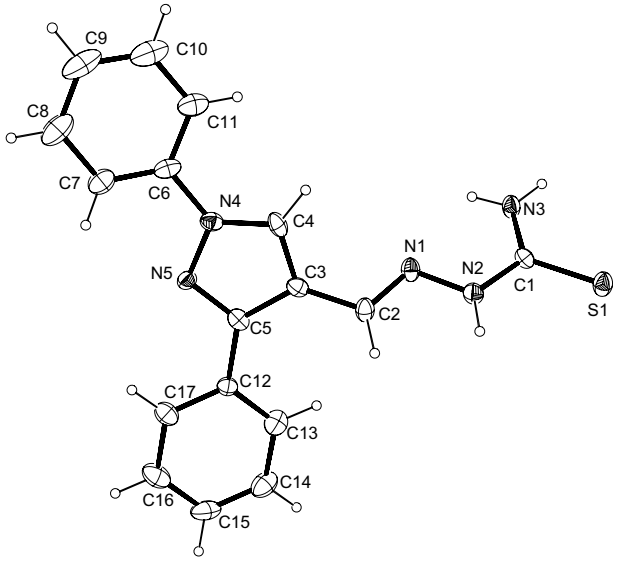

Fig. 2. Crystal structure of Ph_2PzTSC with the atomic numbering scheme. Ellipsoids are drawn at the 50% probability level.

N2–C1–N3	117.4(4)	119.4(4)	118.3(3)
N5–N4–C6	119.5(5)	120.5(3)	120.2(3)
N5–C5–C12	118.4(5)	119.4(4)	121.3(3)

The bond lengths within the aromatic parts of the molecule are normal [39]. The phenyl rings are titled in the same direction relative to the central pyrazole moiety. The dihedral angles formed between the best planes of the pyrazole and the two phenyl rings are similar, 18.1° and 19.1° with the C6–C11 and C12–C17 rings respectively. The dihedral angle between the titled phenyls is 6.0°.

The three intramolecular hydrogen bonds of the very bent character (D–H···A ≈ 100°) stabilize the geometry of Ph_2PzTSC (Table 3). The strongest intermolecular N3–H3···N5 hydrogen bond connects the centrosymmetrically related molecules into the cyclic dimers. Since this interaction is formed between the thiosemicarbazone and pyrazole moieties it probably causes the above mentioned twisting of the thiosemicarbazone fragment. The two interactions of the N–H···S type (Table 3) further connect the molecules of the ligand into the 2D structures parallel to the *ac* crystallographic plane. The segment of this 2D hydrogen bonded pattern is shown in Fig. 3.

3.5.2. Crystal structure of $[Ni(Ph_2PzTSC\text{-}H)_2]$

In $[Ni(Ph_2PzTSC\text{-}H)_2]$ complex the Ni(II) ion lies in an approximately square-planar coordination environment formed by two hydrazine N1 and two thiol S1 atoms from

N3b–H3b···N2b^{vii}	0.86	2.12	2.968(2)	168.9(3)

Symmetry codes: (i) x, y, z; (ii) $-x+2$, $-y$, $-z+2$; (iii) $x+1.5$, y, $-z+2.5$; (iv) $x+0.5$, y, $-z+2.5$; (v) x, y, z; (vi) $-x$, $-y$, $-z+2$; (vii) $-x+1$, $-y$, $-z+1$.

the deprotonated thiosemicarbazone ligands (Fig. 4). The molecules of L have the *cis* mutual arrangement. The four donor atoms are significantly displaced from the mean coordination plane with the maximum deviation of atom N1a (0.471 Å).

The deviation from the regular square-planar geometry is also indicated by the coordination angles (Table 2). The N1a–Ni–N1b angle of 102.5(2)° shows significant disagreement with the theoretical value (90°) probably due to the steric effects between the bulky fragments attached to N1 atoms. The S1a–Ni–S1b angle shows almost ideal value of 90.1(1)°. The coordination bond distances Ni–N and Ni–S are comparable to those found in similar neutral square-planar complexes of Ni(II). Comparison of the remaining bonds in [Ni(Ph_2PzTSC-H)$_2$] to those of the uncoordinated ligand Ph_2PzTSC shows marked differences probably originated by the ligand's deprotonation and coordination. The most significant difference is found in the C–S bond which increases its length upon the ligand complexation for an average value of 0.048 Å. On the contrary, C1–N2 bond decreases its length for the similar average value.

Five membered chelate rings assume envelope conformation (the puckering parameters are: $q_2 = 0.324(3)$ Å, $\phi_2 = 181.0(7)°$, $q_2 = 0.320(2)$ Å, $\phi_2 = 182.5(7)°$ for the branches A and B respectively) and form the dihedral angle of 20.4°. The thiosemicarbazide moiety upon complexation retains its planarity, however it is worth mentioning that the dihedral angle between its best plane and central pyrazole ring decrease from the value of 48.3° to the values of 19.2° and 16.9° in the A and B branch respectively. This change in the ligand geometry is probably caused by the

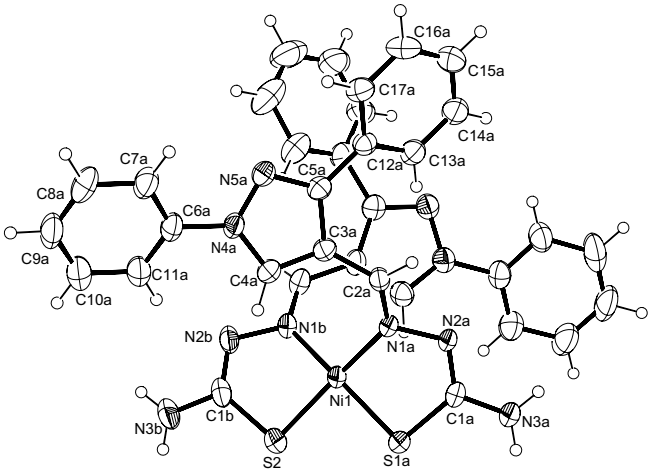

Fig. 4. Crystal structure of [Ni(Ph_2PzTSC-H)$_2$] with the atomic numbering scheme (the atomic numbering in the branch B is equivalent to A and is partly excluded for the sake of clarity). Ellipsoids are drawn at the 50% probability level.

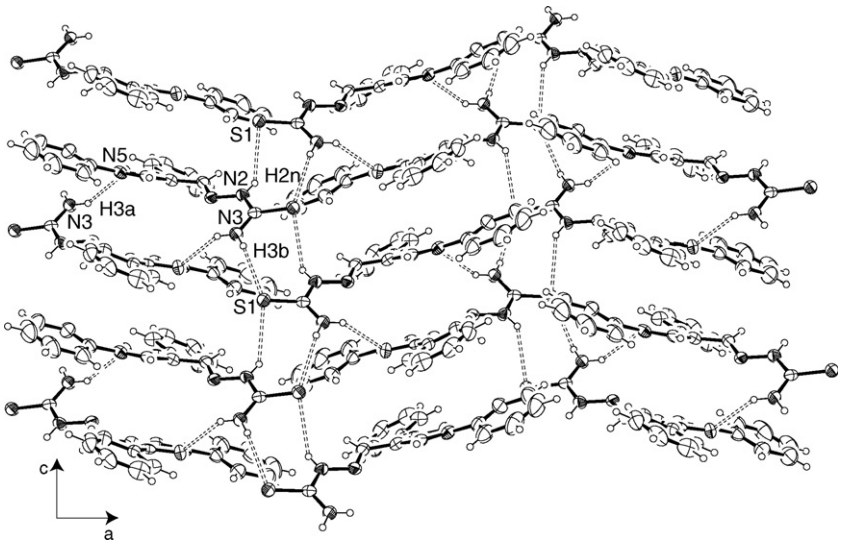

Fig. 3. View of the 2D hydrogen bonding linkage in Ph_2PzTSC.

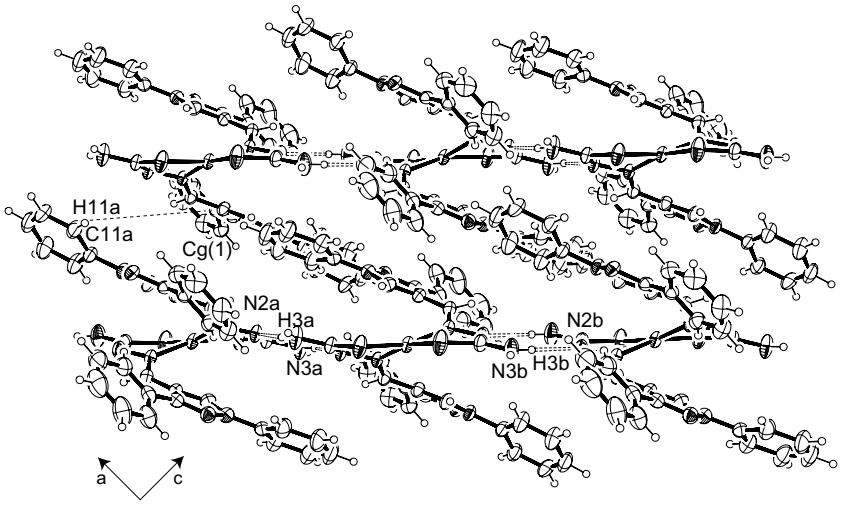

Fig. 5. Segment of the 2D molecular arrangement in [Ni(Ph_2PzTSC-H)$_2$].

braking of the N3–H3···N5 hydrogen bond, which plays a key role in the ligand's crystal arrangement. In the molecule of complex, the atom N5 remains only as an acceptor in the two intramolecular C–H···N bonds also present in the molecule of the free ligand (Table 3).

The molecules of complex are interconnected by the two pairs of N–H···N hydrogen bonds acting on each side of the molecule and connecting the [Ni(Ph_2PzTSC-H)$_2$] into the chains parallel to the diagonal of the *ac* plane. There is no further hydrogen bonding in this crystal structure; however the arrangement of the bulky carbonyl fragments provides the additional stabilizing contacts of the C–H···π type (C13a–H13a···Cg(1)^{i}: H13a···Cg = 2.92 Å, C13a–H13a···Cg = 140.1°; C11a–H11a···Cg(2)^{ii}: H11a···Cg = 2.88 Å, C11a–H11a···Cg = 137.1°; C17b–H17b···Cg(1)^{iii}: H17b···Cg = 2.99 Å, C17b–H17b···Cg = 102.3°. Cg(1) and Cg(2) are the centers of the rings N4b–C5b and C12a–C17a respectively. Symmetry codes: (i) x, y, z; (ii): $-x+1$, $-y$, $-z+2$; (iii) $-x$, $-y-1$, $-z+1$). It is interesting to notice that the dihedral angles formed between the central pyrazole moiety and the phenyl rings increase, compared to the corresponding angles in the ligand molecule (from 18.1° and 19.0° in HL to 27.0° and 27.2° (branch A) and 26.2° and 27.2° (B branch) of [Ni(Ph_2PzTSC-H)$_2$] respectively). However, in contrast to the branch B where the phenyl rings are as in the case of the ligand titled in the same direction regarding the pyrazole ring (the dihedral angle between the phenyls is 16.7°), in the A branch the phenyl rings are titled in the mutually opposite directions regarding the pyrazole (the dihedral angle between the phenyls is 49.3°). Namely, the C6a–C11a phenyl has the orientation which is different from those present in the free ligand and the branch B. It appears that in the absence of the other intermolecular interactions the C11a–H···π interaction in which this phenyl is involved has the decisive role in its final orientation. The segment of the 2D molecular arrangement is given in Fig. 5.

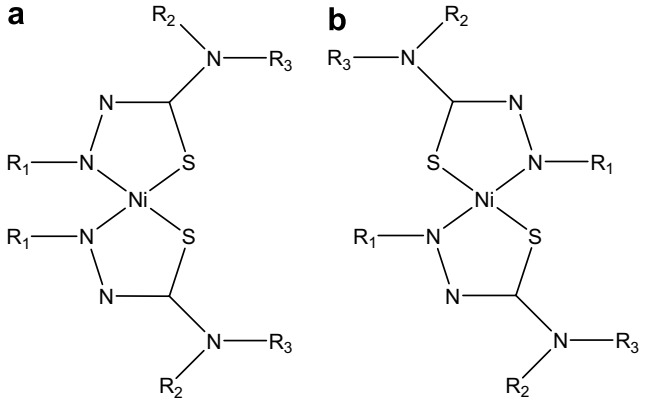

Fig. 6. Bis (bidentate) *cis*- and *trans*-Ni(II) complexes with thiosemicarbazide-based ligands.

3.5.3. Comparative database study of the similar bis(bidentate) Ni(II) complexes with the thiosemicarbazide-based ligands

As the X-ray analysis of [Ni(Ph_2PzTSC-H)$_2$] has shown, the square-planar geometry of this complex is rather tetrahedrally deformed (NNSS donor atoms deviate for 0.27 Å in average from the mean plane defined with these atoms). To compare its structural parameters and the coordination geometry to those of the similar bis(bidentate) Ni(II) complexes with the thiosemicarbazide-based ligands (Fig. 6) the CSD [40] search has been included. There are 37 crystal structures with the coordination number four extracted from the CSD and their refcodes are listed in Table 4.[1] The fact that only one (NIEPZF) of these structures shows the tetrahedral arrangement of the ligands can be explained by known preference of the Ni(II) ions to form square-planar complexes. From the remaining crystal structures, only

[1] List of references for all crystal structures extracted from CSD is given in the Supplementary material.

The complexes with the *cis*-positioned voluminous ligands are labeled by asterisk (*).

[a] List of references for all crystal structures extracted from CSD is given in the Supplementary material.

eight show the *cis* mutual arrangement (Fig. 6a) of the bidentate ligands, suggesting that this configuration is generally less favorable than *trans* (Fig. 6b). As expected, due to the steric hindrance the interligand N–Ni–N angle is larger in the *cis*-complexes with bulky carbonyl moieties attached to N donor atoms and it is ranging from 99.7° to 103.8°. Corresponding geometrical parameters calculated for [Ni(Ph_2PzTSC-H)$_2$] correlate very well with these values.

To compare the extent of the tetrahedral distortion on the same level (from the ideal square-planar geometry) in each of the listed complexes, we have analyzed the values of the dihedral angles formed between two N–Ni–S best planes. In Table 4. this angle is assigned as P1/P2. Because the N–Ni–S planes contain the central metal ion and a whole set of the donor atoms, the angle between them is sufficient to define the degree of the deformation of the coordination geometry from the ideal square-planar (P1/P2 = 0°) toward the tetrahedral one (P1/P2 = 90°). The structures in Table 4 are sorted with the reference to P1/P2 parameter. According to it the greatest deformations from the regular square-planar geometry are found in the complexes with the *cis*-positioned voluminous ligands as it is the case in the novel [Ni(Ph_2PzTSC-H)$_2$] which is the second most deformed. Interesting is the case of QEBDAC structure which exhibits somewhat less deformed square-planar geometry (P1/P2 parameter) but the most deformed chelate rings (based on parameters Ni_P3 and Ni_P4 which represent the displacement of the Ni atom from the best planes of the rest of the chelate rings). These observations suggest that there are two ways in which the geometry of the *cis*-Ni(II) square-planar complexes adopts to the requirements of the voluminous ligands: (1) through the distortion of the coordination geometry around the metal ion; (2) through the deformation of the preferentially planar five membered chelate rings.

It is evident that the *trans*-complexes have more regular square-planar geometry which is reflected in very low values of the P1/P2 parameter (Table 4) with NNSS donor atoms being practically in coplanar position. If voluminous substituents in these complexes exist they are also in *trans* position and from that reason they are not able to form intramolecular steric interactions. It seems however that in some cases (KOMGAU and FACKIE) they still affect the chelate rings conformation.

3.6. Thermal analysis

The decomposition curves of Ph_2PzTSC refer to the melting of the compound which is accompanied by its decomposition with an onset temperature of 490 K (217 °C). The fragmentation steps are superposed avoiding thus the determination of the decomposition mechanism. Some coke residue is observed in argon above 1000 K.

The decomposition of [Ni(Ph_2PzTSC-H)$_2$] begins at the same temperature (490 K) as that of the ligand with a low mass loss of about 2% (repeated measurements with samples from different synthesis). This means that the complex formation does not raise the thermal stability of the compound as is usual. On the basis of the mass loss, taking into account the short range interactions in the crystal, the leaving fragment is most probable an ammonia molecule (Calc. 2.4%). In IR spectrum of the intermediate the band of the original complex, assigned to $\nu(NH_2)$ vibration, has almost completely vanished, supporting the proposition of the departure of an ammonia molecule during the thermal decomposition up to 520 K. The deep purple color of the complex has also changed to dark brown.

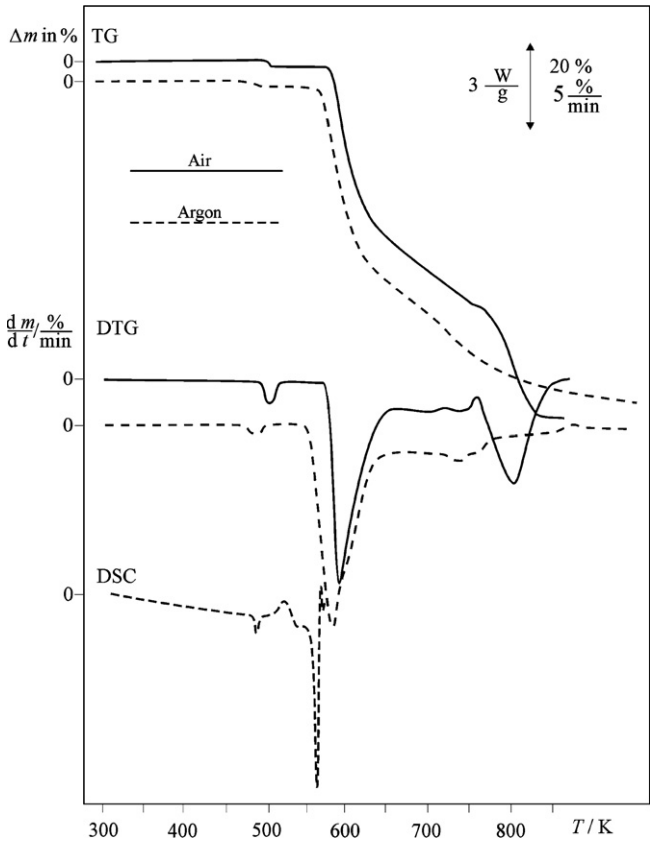

Fig. 7. Thermal decomposition curves of [Ni(Ph_2PzTSC-H)$_2$].

The mass loss is accompanied with an endothermic DSC peak which is followed by an exothermic one in a temperature range of 510–530 K. For this DSC peak no corresponding DTG peak is observed (see Fig. 7). Namely, in 510–560 K temperature range DTG curve falls to zero referring to formation of a stable intermediate. The exothermic process may be the consequence of a spontaneous intra- or intermolecular rearrangement [41], due to the loss of NH_3 molecule. According to the observation with a hot-stage microscope, there is no melting of the intermediate up to 550 K. The melting with an onset temperature at 550 K is immediately followed by an exothermic decomposition.

The decomposition of the complex begins at somewhat higher temperature in air, being continuous above 560 K in both atmospheres (Fig. 7). There is no possibility thus to determine the decomposition mechanism. As in sulfur containing complexes in air, in a platinum crucible, uncontrollable oxidation processes are taking place [42,43], it is meaningless to analyze the composition of the residue. In argon the decomposition is not finished up to 1000 K.

a small amount of $(PMe_3)_2B_{12}H_{10}$ [6]. These compounds were characterized by elemental analysis only. The possibility of isomers of $(PMe_3)_2B_{12}H_{10}$ was not addressed.

During our studies of the syntheses of pallada-diarsaboranes, we obtained some products having charge-compensating Lewis base ligands bonded to cage boron atoms [8]. Many other transition metal-mediated substitution reactions of phosphines (PR_3) onto boron atoms of polyhedral cage molecules have been reported. For example, reaction of $PdI_2(PPh_3)_2$ with $Cs[TeB_{10}H_{11}]$ in refluxing toluene formed 2-I-2-PPh_3-*closo*-2,1-$PdTeB_{10}H_9(PPh_3)$ in good yield [9]. Another example is the conversion of 8,8-$(PMe_2Ph)_2$-*nido*-8,7-$PtCB_9H_{11}$ in refluxing toluene to 6-PMe_2Ph-*closo*-1-CB_9H_8 in good yield [10]. These results lead us to study more generally some palladium-assisted substitution reactions of $B_{10}H_{10}(-2)$ and $B_{12}H_{12}(-2)$ ions, including a brief mention of 1,7-$(PMe_2Ph)_2B_{12}H_{10}$ [11]. Recently, the synthesis and crystal structure determination of $N(n\text{-}Bu)_4[PPh_3\text{-}B_{12}H_{11}]$ was reported [12]. This derivative was prepared by reaction of $[N(n\text{-}Bu)_4]_2[B_{12}H_{11}I]$ with $Pd(Ph_3)_4$.

In this report, we describe in detail the reaction of $(PMe_2Ph)_2PdCl_2$ with $Na_2[B_{12}H_{12}]$ and also with K[7,8-$C_2B_9H_{12}$] to give several charge-compensated products in moderate yields.

2. Experimental

2.1. Physical measurements

Boron (^{11}B) NMR spectra were obtained at 115.85 MHz (21 °C) with a Nicolet NT-360 spectrometer and were externally referenced to $BF_3(OEt_2)$. Phosphorus (^{31}P) NMR spectra were obtained at 146.2 MHz (21 °C) and externally referenced to 85% H_3PO_4. Proton (^1H) NMR spectra were obtained at 361.1 MHz (21 °C) and internally referenced to trace protonated solvent. In all NMR spectra, positive chemical shifts were downfield. Melting points were obtained in sealed, evacuated capillaries and are uncorrected.

2.2. Materials

All reactions were performed under an atmosphere of prepurified nitrogen. Tetrahydrofuran (THF) was freshly distilled from sodium benzophenone ketyl. Dichloromethane (CH_2Cl_2) was distilled from P_2O_5. Potassium dodecahydro-7,8-dicarba-*nido*-undecaborate(1−), K[7,8-$C_2B_9H_{12}$], was prepared by a literature method [13]. Bis(dimethylphenylphosphine) palladium(II) chloride was prepared by the method of Wild et al. [14].

2.3. $(PMe_2Ph)_2$-*closo*-$B_{12}H_{10}$ isomers and $Na[(PMe_2Ph)$-*closo*-$B_{12}H_{11}]$

In a typical reaction scheme, $Na_2B_{12}H_{12}$ (1.81 g, 9.6 mmol) was placed in a 500 mL round-bottom flask equipped with a magnetic stir bar and dissolved in 40 mL dry THF. In a separate flask, $(PMe_2Ph)_2PdCl_2$ (4.35 g, 9.6 mmol) was dissolved in 240 mL of dry THF and then transferred slowly via cannula to the stirred solution of $Na_2B_{12}H_{12}$. The mixture was stirred at room temperature for 1 day during which time the color changed from orange to brown. The mixture was vacuum filtered to remove solid material. To the clear THF solution was added an excess of $NaBH_4$ to reduce all remaining palladium species to Pd^0. Vigorous gas evolution occurred as the mixture was brought to reflux, which was continued for 6 h. The mixture was left at room temperature over night to complete the reduction. The mixture was filtered through a coarse-fritted filter under nitrogen to remove the reduced metal solids (*Caution:* The filtered solids may spontaneously ignite if exposed to air). The THF was removed from the filtrate by rotary evaporation leaving a thick white oil. This crude mixture was dissolved in CH_2Cl_2 and mixed with 3 g of silica gel (Merck grade 60, 230–400 mesh, 60 Å). The CH_2Cl_2 was removed in vacuo and the solids were packed on a 35 cm × 2.4 cm silica gel chromatography column, and eluted initially with 1:1 (v/v) toluene:CH_2Cl_2. There were four bands. Band I, $R_f = 0.96$ by TLC (CH_2Cl_2 mobile phase, I_2 development) was determined by ^{11}B NMR to be $(PMe_2Ph)BH_3$, $^{11}B\{^1H\}$, −38 ppm, $J_{B-P} = 61$ Hz [15] Band II, $R_f = 0.85$ was a white solid (353 mg, 8.82% yield) and $R_f = 0.6$ was determined to be 1,12-$(PMe_2Ph)_2$-$B_{12}H_{10}$ by ^{11}B NMR (see Table 1). Band III, 1,7-$(PMe_2Ph)_2$-$B_{12}H_{10}$, a white solid, m.p. 202–206 °C (1.201 g, 30.14% yield). And band IV was eluted with 1:1 CH_2Cl_2:CH_3CN and was found to be a relatively insoluble compound, whose ^{11}B NMR spectrum was consistent with Na-[(PMe_2Ph)-$B_{12}H_{11}$] (see Table 2–6).

2.4. PMe_2Ph-*nido*-7,8-$C_2B_9H_{11}$ isomers

In a two-neck, round-bottom flask equipped with a septum and nitrogen inlet were placed K[*nido*-7,8-$C_2B_9H_{12}$] (172 mg, 0.998 mmol) and $(PMe_2Ph_2PdCl_2$ (226 mg, 0.498 mmol), and 25 mL dry distilled CH_2Cl_2. The dicarbollide salt did not fully dissolve. The solution gradually darkened from yellow to orange to brown while stirring overnight. The reaction mixture was filtered on a coarse-fritted funnel, to leave behind some gray solids. The brown filtrate was rotary evaporated, and the remaining solids extracted with benzene. An excess of $NaBH_4$ was added to the benzene solution to reduce all remaining palladium species to Pd^0. The solution was brought to reflux for 4 h. The mixture was filtered through a coarse-fritted funnel to remove fluffy grayish solids, resulting in a nearly colorless filtrate. The benzene was rotary evaporated to a yellow oil (221 mg, 81.9% crude yield). ^{11}B NMR indicated that the oil consisted of a mixture of 9-PMe_2Ph-*nido*-7,8-$C_2B_9H_{11}$ (major product) and 10-PMe_2Ph-*nido*-7,8-$C_2B_9H_{11}$ (minor product). Subsequent crystallization from CH_2Cl_2/pentane at 5 °C yielded pale yellow needles of 9-PMe_2Ph-*nido*-7,8-$C_2B_9H_{11}$.

2.5. Crystal structure determinations – general

The diffractometer utilized for data collection was designed and constructed locally. The apparatus comprised a Picker X-ray generator and Picker four-circle goniostat equipped with a Furnas Monochromater (HOG crystal) was modified by addition of stepping motors (Slo-Syn) on each of the four axes, and a fifth motor drives a 20-position filter/attenuator wheel. The latter allows top/bottom-left/right alignment of reflections. All motors are driven by a locally designed ISA board in an IBM-PC compatible computer. The computer also has a timer/scaler board which is used to accumulate the counts from the scintillation counter

used with the goniostat. The control software, PCPS.EXE, is the Picker software written by W. E. Streib of the Indiana University Molecular Structure Center (IUMSC). The software for structure solution and refinement include SHELXTL-PC and other versions of SHELX, as well as the XTEL program library.

2.6. Crystal structure determination of 1,7-$(PMe_2Ph)_2B_{12}H_{10}$

A typical crystal of 1,7-$(PMe_2Ph)_2$-$B_{12}H_{10}$ was grown by slow evaporation from a 1:1 solution of toluene and CH_2Cl_2. The crystal was affixed to the end of a glass fiber using silicone grease and transferred to the goniostat where it was cooled to −174 °C for characterization and data collection.

A systematic search of a limited hemisphere of reciprocal space located a set of diffraction maxima with no symmetry or systematic absences, corresponding to a triclinic space group. Subsequent solution and refinement of the structure confirmed the centrosymmetric choice, $P\bar{1}$.

All hydrogen atoms were clearly visible in a difference Fourier phased on the nonhydrogen atoms, and were refined isotropically in the final cycles of refinement. A final difference Fourier was essentially featureless, the largest peak being 0.34 e/Å^3.

2.7. Crystal structure determination of 9-(PMe_2Ph)-7,8-$C_2B_9H_{11}$

Pale yellow crystals of a 9-$PPhMe_2$-7,8-$C_2B_9H_{11}$ were grown from a solution of CH_2Cl_2/pentane held at 5 °C. A small, well-formed fragment of a larger crystal was affixed to the end of a glass fiber using silicone grease and transferred to the goniostat where it was cooled to −174 °C for characterization and data collection.

A systematic search of a limited hemisphere of reciprocal space located a set of diffraction maxima with monoclinic symmetry and systematic absences corresponding to one of the centered space groups $C2/c$ or Cc. Subsequent solution and refinement confirmed the centrosymmetric choice, $C2/c$.

Data were collected using a continuous θ, 2θ scan technique with fixed backgrounds at each extreme of the scan. Data were corrected for Lorentz and polarization effects. The structure was solved by direct methods (MULTAN 78) and standard Fourier techniques. All hydrogen atoms were clearly visible in a difference Fourier phased on the nonhydrogen atoms, and were included in the least squares refinement.

A final difference Fourier was essentially featureless, the largest peak being 0.32 e/Å^3. It was observed that this peak was near the bridging hydride in the B_9C_2 cage, and in fact would appear to bridge the two carbon atoms. Attempts to model this as a partial occupancy bridging hydrogen (with the occupancy of the located bridge allowed to vary also) did not lead to a successful convergence. In all probability, the hydrogen may "float" on the face of the carborane, but the crystallographic evidence is lacking.

The structure is essentially the same as that reported for 9-PPh_3-*nido*-7,8-$C_2B_9H_{11}$ [22] and 9-$PMePh_2$-*nido*-7,8-$C_2B_9H_{11}$ [20,21]. The diphenylmethyl phosphine structure reported by Zakharkin et al. is remarkably similar, and is nearly isostructural [20,21].

3. Results and discussion

3.1. PMe_2Ph derivatives of the $B_{12}H_{12}^{-2}$ ion

Reaction of $Na_2[B_{12}H_{12}]$ with $(PMe_2Ph)_2PdCl_2$ at ambient temperature gave three phosphine-substituted products, each in low yield, namely $Na[(PMe_2Ph)B_{12}H_{11}]$, 1,7-$(PMe_2Ph)_2B_{12}H_{10}$ (30% yield, approx.) and 1,12-$(PMe_2Ph)_2B_{12}H_{10}$ (8% yield, approx.). The crude reaction mixture was subsequently treated with excess sodium borohydride to reduce all palladium-containing intermediates, "L_nPdX_m" to palladium metal. The first band to be eluted during column chromatography on silica gel, 1:1 (v/v) toluene:CH_2Cl_2 was $(PMe_2Ph)BH_3$ identified by ^{11}B NMR, $\delta_{^{11}B} = -38$ ppm, $J_{B-P} = 61$ Hz [15]. The boron in this compound originated from $NaBH_4$, added to the reaction mixture during workup and was not due to degradation of the $B_{12}H_{12}(-2)$ ion.

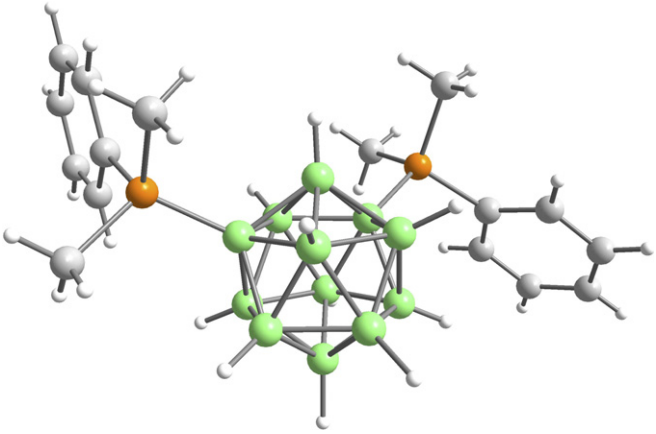

Fig. 1. X-ray structure of 1,7-$(PMe_2Ph)_2$-*closo*-$B_{12}H_{10}$.

The 1,12-$(PMe_2Ph)_2B_{12}H_{10}$ isomer was identified by its ^{11}B NMR spectrum (see Table 1), which indicates a high symmetry (D_{5h}) and excludes the 1,2- or 1,7-isomer configuration for this product.

An X-ray structural determination (Fig. 1) has been undertaken on the other bis-phosphine isomer which was isolated and it conclusively proves it to be the 1,7-isomer.

The 1,7-$(PMe_2Ph)_2B_{12}H_{10}$ product was obtained in the higher yield and is statistically the most favored bis-phosphine derivative. Note that steric factors may be important in this substitution process since to-date no 1,2-bis-phosphine product has been observed.

The X-ray structure (Fig. 1) shows no anomalous distances or angles. The B–P distances, 1.9055 and 1.9113 Å are quite usual, as are the B–B distances, which all are in the range 1.760–1.804 Å. This compares favorably with the B–P distance of 1.928 Å found for $[N(n\text{-}Bu)_4][(PPh_3)\text{-}B_{12}H_{11}]$ [12].

The B–P coupling constant for the 1,7-disubstituted product as determined by ^{31}P NMR was 150 Hz. This is within the range of values observed for similar phosphine-borane compounds (118–200 Hz) [16,17]. The value could not be corroborated by ^{11}B NMR, however, because the doublet was not well-enough resolved for accurate measurement. The B–P coupling constant observed for $Na[(PMe_2Ph)\text{-}B_{12}H_{11}]$ in the ^{11}B NMR spectrum was 141 Hz. This agreed well with the B–P value reported previously for $N(n\text{-}Bu)_4\text{-}[PPh_3\text{-}B_{12}H_{11}]$ of 134 Hz [12].

3.2. PMe_2Ph-*nido*-7,8-$C_2B_9H_{11}$ isomers

Reaction of *nido*-7,8-$C_2B_9H_{12}(-1)$ ion with $(PMe_2Ph)_2\text{-}PdCl_2$ at ambient temperature yielded two isomers of (PMe_2Ph)-*nido*-7,8-$C_2B_9H_{11}$. The combined crude yield of both the asymmetric 9-isomer and symmetric 10-isomer was 82%. The ^{11}B NMR spectrum of the mixture suggested that the 9-isomer predominated by approximately 2:1. Preference for reaction at the 9 position has been observed in electrophilic substitution reaction of *nido*-7,8-$C_2B_9H_{12}(-1)$ ion by I_2 [18], by $(C_5H_5)Fe(CO)_2$(alkene)(+1) ion [19] and by Ph_2PCl [20,21]. The ^{11}B NMR spectra of 9- and 10-PMe_2Ph-*nido*-7,8-$C_2B_9H_{11}$ agree with those of the two isomers of the previously-reported (PPh_3)-*nido*-7,8-$C_2B_9H_{11}$ [20–23] and $(PMePh_2)$-*nido*-7,8-$C_2B_9H_{11}$ [20,21] (see Table 1). The asymmetric 9-isomer has nine distinct resonances in its spectrum, whereas the C_s symmetric 10-isomer has six resonances in a 2:2:2:1:1:1 area ratio. In each of the 9-isomer derivatives, the resonance at approximately −12.6 to −15.6 ppm displayed $^{11}B\text{–}^{31}P$ spin–spin coupling of 149–164 Hz. For the 10-isomer derivatives, the resonance at −32.1 to −34.5 ppm displayed $^{11}B\text{–}^{31}P$ coupling of 145–150 Hz.

The X-ray structure (Fig. 2) shows no anomalous distances or angles. The B–P distance of 1.905 Å is typical of

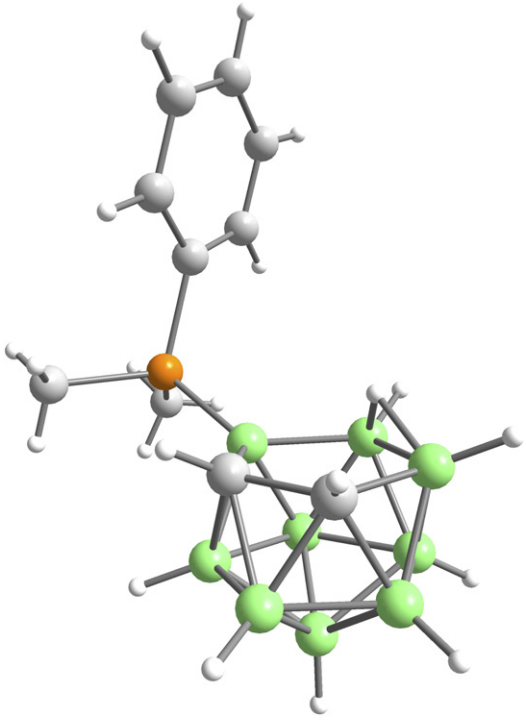

Fig. 2. X-ray structure of 9-(PMe_2Ph)-*nido*-7,8-$C_2B_9H_{11}$.

phosphine boranes; the B–B distances are all in the range 1.745–1.870 Å, and the B–C distances are slightly shorter at 1.589–1.738 Å which is typical of carborane species.

Appendix A. Supplementary material

CCDC 634413 and 634414 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.04.025.

may be assumed that, although the dissociation of [Gd(DTPA-BMA)(H_2O)] is fast and a complexation equilibrium exists in body fluids, the high selectivity of the DTPA-BMA ensures sufficient *in vivo* safety of the injected CA [5–7]. More recently, however, it was found that the kinetic stability of [Gd(DTPA-BMA)(H_2O)] and related [Gd(DTPA-bis(amide))(H_2O)] complexes is high enough to be compared with that of $[Gd(DTPA)(H_2O)]^{2-}$ [8,9]. This finding also implies that stability constants and selectivities play a minor role in determining the non-toxicity of a CA; the crucial factor is undoubtedly the high kinetic stability. In other words, toxicity of the Gd(III) complexes is an intrinsic property and cannot be directly related to the thermodynamic or kinetic stabilities. The knowledge of the thermodynamic stability, conditional stability, and selectivity helps to understand the *in vivo* stability of the complexes [10,11].

There are now known a variety of DTPA-bis(amide) ligands, many of which carry aromatic or large aliphatic substituents, thus resulting in poor solubility in water upon complexation with Gd [12–18]. High solubility in water along with non-toxicity is an essential criterion for practical application as MRI CA. Despite the availability of such a great number of DTPA-bis(amides), little synthetic attempt has been made for the modification of the terminal bis(amide) groups with additional alkyl carboxylate sidearms such as seen in Chart 1.

Intrigued by these observations and motivated by our continued search for novel DTPA-bis(amide) ligands, [19] we have designed and synthesized a new class of DTPA-bis(amide) ligands (**1a**–**1l**) and their Gd(III) complexes of the type [Gd(**1**)(H_2O)] · xH_2O (**2a**–**2l**). In addition, with a potential application for as MRI CA in mind, some relevant physicochemical properties were measured. They are (i) the protonation constants of **1a**–**1l**, (ii) thermodynamic and conditional stability constants of **2a**–**2l**, (iii) the selectivity of **1a**–**1l** for the Gd(III) ion over the endogenous metal ions such as Zn(II), Ca(II), and Cu(II), and (iv) relaxivities (R_1 and R_2) of **2a**–**2l** both in aqueous and hydroxypropyl-β-cyclodextrin (HP-β-CD) solutions. These and comparative results will be presented in this paper.

2. Experimental

2.1. General remarks

All reactions were carried out under an atmosphere of dinitrogen using the standard Schlenk techniques. Solvents were purified and dried using standard procedures. All commercial reagents were purchased from Aldrich and used as received unless otherwise stated. Deionized water was used for all experiments. Hydroxypropyl-β-cyclodextrin (HP-β-CD) was obtained from TCI and used without further purification. The ^1H and ^{13}C NMR experiments were performed on a Bruker Advance 400 or 500 Spectrometer by Korea Basic Science Institute (KBSI). Chemical shifts were given as δ values with reference to tetramethylsilane (TMS) as an internal standard. Coupling constants are in Hz. FAB-mass spectra were obtained by using a JMS-700 model (Jeol, Japan) mass spectrophotometer. IR spectra were run on a Mattson FT-IR Galaxy 6030E spectrophotometer by KBSI. Elemental analyses were performed by Center for Instrumental Analysis, KNU. T_1 measurements were carried out using an inversion recovery method with a variable inversion time (TI) at 1.5 T (64 MHz). The magnetic resonance (MR) images were acquired at 35 different TI values ranging from 50 to 1750 ms. T_1 relaxation times were obtained from the non-linear least square fit of the signal intensity measured at each TI value. For T_2 measurements the CPMG (Carr–Purcell–Meiboon–Gill) pulse sequence was adapted for multiple spin-echo measurements. Thirty four images were acquired with 34 different echo time (TE) values ranging from 10 to 1900 ms. T_2 relaxation times were obtained from the non-linear least squares fit of the mean pixel values for the multiple spin-echo measurements at each echo time. Relaxivities (R_1 and R_2) were then calculated as an inverse of relaxation time per mM.

2.2. Potentiometric measurements

Potentiometric titrations were performed with an automatic titrator to determine the protonation constants of the DTPA-bis(amide) ligands and the stability constants of corresponding metal complexes. The autotitrating system consists of a 798 MPT Titroprocessor, a 728 stirrer and a PT-100 combination pH electrode (Metrohm). The pH electrode was calibrated using standard buffer solutions. All calibrations and titrations were carried out under a CO_2-free nitrogen atmosphere in a sealed glass vessel (50 cm^3) thermostatted at 25 ± 0.1 °C at an ionic strength of 0.10 mol/dm^3 KCl. The concentrations of metal ion

and amide solutions were maintained at approximately 0.6 mmol/dm^3. A CO_2-free KOH solution (0.100 mol/dm^3) was used as a titrant to minimize the changes in ionic strength during the titration. Dioxygen and carbon dioxide were excluded from the reaction mixtures by maintaining a positive pressure of purified nitrogen in the titration cell. The electromotive force of the cell is given by $E = E^{0} + Q\log[H^+] + E_j$, and both E^{0} and Q were determined by titrating a solution with a known hydrogen-ion concentration at the same ionic strength, using the acid range of the titration. The liquid-junction potential (E_j) was found to be negligible under the experimental conditions employed.

2.3. Computational method

The protonation constants of the ligands and the overall stability constants of various metal complexes formed in aqueous solutions were determined from the titration data using the computer program HYPERQUAD [20]. The accuracy of this method was verified by measuring the protonation and the stability constants for Ca(II), Zn(II), Cu(II), and Gd(III) complexes of [DTPA-BMA]$^{3-}$. The results were compared with the literature values [7].

2.4. Syntheses

2.4.1. Diethylenetriamine-N,N′,N″-triacetic-N,N′-dianhydride

The title compound was prepared according to the literature method with a slight modification [21]. The product was obtained as a white solid. Yield 33.2 g (93%). ^{1}H NMR [DMSO-d_6, 400 MHz], δ 3.70 (s, 8H, terminal NCH_2CO$_2$), 3.30 (s, 2H, central NCH_2CO$_2$), 2.75 (t, $J = 7.6$, 4H, NCH_2) and 2.59 (t, $J = 7.6$, 4H, NCH_2).

2.4.2. Syntheses of methyl and ethyl esters of the amino acids

2.4.2.1. Methyl-3-aminopropionate hydrochloride. To a stirred suspension of 3-aminopropionic acid (2.23 g, 25 mmol) in methanol (50 mL) was added thionyl chloride (3.57 g, 30 mmol) for 10 min at 0 °C. The reaction mixture was then left under reflux for 2 h, after which the mixture was cooled to RT. The solvent was removed under a reduced pressure, and the residue triturated thrice with hexane (30 mL). The resulting solid was dried under vacuo for 6 h. Yield 3.32 g (95%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.36$ (br s, 3H, NH_2HCl), 3.69 (s, 3H, OCH_3), 3.05 (m, 2H, H3), 2.80 (t, $J = 7.04$, 2H, H2). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 171.04$ (C1), 52.09 (*C*H$_3$), 34.87 (C3), 31.52 (C2). *Anal.* Calc. for $C_4H_{10}ClNO_2$: C, 34.42; H, 7.22; N, 10.03. Found: C, 34.47; H, 7.28; N, 10.17%.

2.4.2.2. Methyl-4-aminobutanoate hydrochloride. The title compound was obtained by following the same procedure for methyl-3-aminopropionate hydrochloride by replacing 3-aminopropionic acid with 4-aminobutanoic acid. Yield 3.69 g (96%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.23$ (br s, 3H, NH_2HCl), 3.59 (s, 3H, OCH_3), 2.77 (m, 2H, H4), 2.44 (t, $J = 7.52$, 2H, H2), 1.81 (m, 2H, H3). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 173.00$ (C1), 51.75 (*C*H$_3$), 38.29 (C4), 30.53 (C2), 22.67 (C3). *Anal.* Calc. for $C_5H_{12}ClNO_2$: C, 39.10; H, 7.87; N, 9.12. Found: C, 38.70; H, 8.05; N, 9.00%.

2.4.2.3. Methyl-5-aminopentanoate hydrochloride. The title compound was obtained by following the same procedure for methyl-3-aminopropionate hydrochloride by replacing 3-aminopropionic acid with 5-aminopentanoic acid. Yield 3.94 g (94%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.17$ (br s, 3H, NH_2HCl), 3.57 (s, 3H, OCH_3), 2.73 (m, 2H, H5), 2.32 (t, $J = 6.54$, 2H, H2), 1.56 (m, 4H, H3, H4). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 173.42$ (C1), 51.62 (*C*H$_3$), 38.60 (C5), 33.00 (C2), 26.34 (C4), 21.72 (C3). *Anal.* Calc. for $C_6H_{14}ClNO_2$: C, 42.99; H, 8.42; N, 8.36. Found: C, 42.63; H, 8.55; N, 8.28%.

2.4.2.4. Methyl-6-aminohexanoate hydrochloride. The title compound was obtained by following the same procedure for methyl-3-aminopropionate hydrochloride by replacing 3-aminopropionic acid with 6-aminohexanoic acid. Yield 4.32 g (95%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.14$ (br s, 3H, NH_2HCl), 3.57 (s, 3H, OCH_3), 2.71 (t, $J = 7.52$, 2H, H6), 2.29 (t, $J = 7.28$, 2H, H2), 1.53 (m, 4H, H3, H5), 1.29 (m, 2H, H4). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 173.56$ (C1), 51.58 (*C*H$_3$), 38.77 (C6), 33.35 (C2), 26.88 (C5), 25.63 (C3), 24.22 (C4). *Anal.* Calc. for $C_7H_{16}ClNO_2$: C, 46.28; H, 8.88; N, 7.71. Found: C, 45.89; H, 9.15; N, 7.69%.

2.4.2.5. Ethyl-3-aminopropionate hydrochloride. The title compound was obtained by following the same procedure for methyl-3-aminopropionate hydrochloride by replacing methanol with ethanol. Yield 3.57 g (93%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.29$ (br s, 3H, NH_2HCl), 4.07 (q, $J = 7.00$ 2H, OCH_2), 2.97 (t, $J = 7.04$, 2H, H3), 2.71 (t, $J = 7.04$, 2H, H2), 1.18 (t, $J = 7.00$, 3H, CH_3). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 170.57$ (C1), 60.75 (*C*H$_2$), 34.85 (C3), 31.65 (C2), 14.32 (*C*H$_3$). *Anal.* Calc. for $C_5H_{12}ClNO_2$: C, 39.10; H, 7.87; N, 9.12. Found: C, 38.79; H, 8.03; N, 9.00%.

2.4.2.6. Ethyl-4-aminobutanoate hydrochloride. The title compound was obtained by following the same procedure for methyl-3-aminopropionate hydrochloride by replacing 3-aminopropionic acid with 4-aminobutanoic acid and methanol with ethanol. Yield 3.94 g (94%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.24$ (br s, 3H, NH_2HCl), 4.04 (q, $J = 7.04$, 2H, OCH_2), 2.77 (m, 2H, H4), 2.41 (t, $J = 7.54$, 2H, H2), 1.81 (qn, $J = 7.52$, 2H, H3), 1.16 (t, $J = 7.04$, 3H, CH_3). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 172.52$ (C1), 60.29 (*C*H$_2$), 38.29 (C4), 30.75 (C2), 22.68 (C3), 14.43 (*C*H$_3$). *Anal.* Calc. for $C_6H_{14}ClNO_2$: C, 42.99; H, 8.42; N, 8.36. Found: C, 42.72; H, 8.62; N, 8.28%.

2.4.2.7. Ethyl-5-aminopentanoate hydrochloride. The title compound was obtained by following the same procedure for methyl-3-aminopropionate hydrochloride by replacing 3-aminopropionic acid with 5-aminopentanoic acid and methanol with ethanol. Yield 4.22 g (93%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.18$ (br s, 3H, NH_2HCl), 4.03 (q, $J = 7.00$, 2H, OCH_2), 2.73 (m, 2H, H5), 2.29 (t, $J = 6.52$, 2H, H2), 1.56 (m, 4H, H3, H4), 1.16 (t, $J = 7.00$, 3H, CH_3). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 172.93$ (C1), 60.12 (CH_2), 38.62 (C5), 33.23 (C2), 26.62 (C4), 21.75 (C3), 14.44 (CH_3). *Anal.* Calc. for $C_7H_{16}ClNO_2$: C, 46.28; H, 8.88; N, 7.71. Found: C, 45.82; H, 9.12; N, 7.61%.

2.4.2.8. Ethyl-6-aminohexanoate hydrochloride. The title compound was obtained by following the same procedure for methyl-3-aminopropionate hydrochloride by replacing 3-aminopropionic acid with 6-aminohexanoic acid and methanol with ethanol. Yield 4.65 g (95%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 8.16$ (br s, 3H, NH_2HCl), 4.03 (q, $J = 7.00$, 2H, OCH_2), 2.71 (m, 2H, H6), 2.26 (t, $J = 7.28$, 2H, H2), 1.53 (m, 4H, H3, H5), 1.29 (m, 2H, H4), 1.16 (t, $J = 7.00$, 3H, CH_3). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 173.09$ (C1), 60.05 (CH_2), 38.77 (C6), 33.56 (C2), 26.85 (C5), 25.61 (C3), 24.23 (C4), 14.44 (CH_3). *Anal.* Calc. for $C_8H_{18}ClNO_2$: C, 49.10; H, 9.27; N, 7.16. Found: C, 48.89; H, 9.54; N, 7.12%.

2.4.3. Syntheses of the DTPA-bis(amide) ligands

*2.4.3.1. Compound **1a** · 3.5H$_2$O.* To a suspension of DTPA-bis(anhydride) (1.79 g, 5 mmol) in dry DMF (15 mL) was added 3-aminopropionic acid (0.891 g, 10 mmol). The mixture was stirred at 65 °C for 4 h. The solvent was removed from the reaction mixture under reduced pressure, and the residue dissolved in methanol (10 mL). The solution was passed through a short column of silica gel (60 mesh) with methanol as an eluent. The residue obtained after removal of the solvent from the eluate was triturated with a mixture of acetone and diethylether (30:70 v/v, 150 mL). The solid product was isolated by filtration, washed with acetone (3×30 mL) and dried under vacuo at 70 °C for 8 h. Yield 2.21 g (74%). ^{1}H [DMSO-d_6, 400 MHz], $\delta = 7.97$ (s, 2H, CH_2CONH), 3.34 (s, 2H, H7), 3.18 (s, 4H, H5), 3.12 (m, 4H, H1′), 3.08 (s, 4H, H3), 2.87 (s, 4H, H2), 2.70 (s, 4H, H1), 2.24 (t, $J = 6.56$ 4H, H2′). ^{13}C [DMSO-d_6, 100 MHz], $\delta = 171.92$ (C3′), 171.70 (C8/C6), 169.04 (C6/C8), 168.83 (C4), 56.32 (C7), 54.00 (C5), 51.05 (C3), 49.15 (C2), 33.60 (C1), 32.85 (C2′), 30.97 (C1′). *Anal.* Calc. for $C_{20}H_{33}N_5O_{12} \cdot 3.5H_2O$: C, 40.13; H, 6.74; N, 11.70. 2.4.4. Syntheses of the Gd(III) complexes

2.4.4.1. Compound ***2a*** $\cdot$ *7H_2O.* To a solution of **1a** (1.20 g, 2 mmol) in deionized water (10 mL) was added Gd_2O_3 (0.36 g 1 mmol). The suspension was stirred for 6 h at 100 °C during which time a pale yellow solution resulted. The reaction mixture was cooled to RT and passed through a Celite column to remove any solid impurities. The solvent was removed and the residue taken up in methanol (3 mL). The methanolic solution was added drop wise into acetone at 0 °C with stirring to precipitate the product as a white solid. The product was isolated by filtration, washed with acetone, dried under vacuo at 80 °C for 6 h. Yield 1.37 g (82%). *Anal.* Calc. for $C_{20}H_{32}GdN_5O_{13}\cdot 7H_2O$: C, 28.81; H, 5.56; N, 8.40. Found: C, 28.73; H, 5.38; N, 8.45%. FABMS (*m*/*z*): Calc. for $C_{20}H_{31}GdN_5O_{12}$: 691.12 $[MH-(H_2O)]^+$. Found: 691.18 $[MH-(H_2O)]^+$.

2.4.4.2. Compound ***2b*** $\cdot$ *5H_2O.* This compound was obtained essentially by following the same procedure as that for **2a** by replacing **1a** with **1b**. Yield 1.50 g (91%). *Anal.* Calc. for $C_{22}H_{36}GdN_5O_{13}\cdot 5H_2O$: C, 31.99; H, 5.61; N, 8.48. Found: C, 32.03; H, 5.50; N, 8.47%. 3. Results and discussion

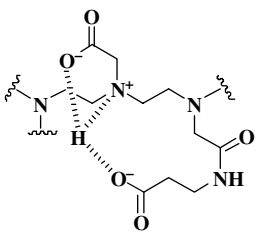
3.1. Synthesis and characterization

Chart 1 shows a list of new Gd(III) complexes of DTPA-bis-amides derivatized by alkyl carboxylic acids (or esters) on the amide side-arms. The new series of ligands are obtainable from the simple condensation of DTPA-bis(anhydride) with corresponding aminocarboxylic acid (or esters) in an 1:2 molar ratio in DMF. The complex formation can be carried out by the reaction with Gd_2O_3 ([Gd]/[L] = 1/2) under reflux in deionized water. The complexes are obtained as white solids, yet isolated as hydrated forms due to their highly hygroscopic nature. Naturally they are soluble almost indefinitely in water and some organic solvents such as alcohol, DMF, and DMSO.



The complex formation can be confirmed straightforwardly by analytical and various spectroscopic techniques (^1H and ^{13}C NMR, FAB-mass). As stated above, it is quite common for these complexes to exist as hydrated solids thus to be formulated as $[Gd(\mathbf{1})(H_2O)]\cdot xH_2O$. Although attempted crystallization for further structural confirmation has so far been futile, the coordination of one water molecule can be deduced from the X-ray crystal structure of a related Gd-complex reported earlier by us [19].

3.2. Protonation constants

The protonation constants of **1a**–**1l** were determined by potentiometric titration in the pH range 2–11. The protonation constants (K_i^H) are defined in Eq. (1), where $i = 1,2,\ldots$

$$K_i^H = [H_iL]/[H_{i-1}L][H^+] \quad (1)$$

The calculated protonation constants are presented in Table 1 along with those for DTPA-BMA and DTPA for comparative purposes. It is known that for the DTPA-bis(amide) ligands the first protonation takes place at the central nitrogen atom, while the second and the third at the terminal amine nitrogen atoms [22]. Table 1 shows that all but **1i** exhibit higher first protonation constants ($\log K_1^H$) than DTPA-BMA. Some of the ligands such as **1a**–**1c** show even higher values than the parent DTPA. When the comparison is made within the present series, those carrying carboxylic acids in the amide side-arms (**1a**–**1d**) reveal higher protonation constants than those carrying carboxylic esters (**1e**–**1l**). It seems quite obvious then that the presence of the carboxylic acid in the amide side-arm renders the protonation of the central amine nitrogen facile by some co-operative interaction, possibly by hydrogen bonding between the carboxylic acid in the amide side-arm and the acetate arm on the central amine nitrogen as proposed in the structure **A** (*vide infra*). Yet, such a co-operative interaction seems to be less conspicuous or even negligible in the case of those carrying alkyl carboxylate side-arms as observed with **1e**–**1l** exhibiting relatively lower $\log K_1^H$ values.

(A)

The length of alkyl chain in the amide side-arm also seems to play a role, as evidenced by a little lower $\log K_1^H$ value for **1d** as compared with those for **1a**–**1c**. These

[a] Data obtained from Ref. [7].
[b] Ref. [36].

observations may be attributed to the long distance between the central amine nitrogen and the carboxylic acid in the side-arm.

A drastic decrease in the second protonation constant ($\log K_2^H$) is found with DTPA-BMA as well as the present series although the decrease is relatively small with DTPA. These observations indicate that the second protonation becomes much more difficult with DTPA-bis(amides) than with DTPA. This is because the terminal amine nitrogen of DTPA-BMA, for example, is strongly involved in the hydrogen bonding interaction with the acetate as well as the amide proton on the same terminal nitrogen, thus making the terminal nitrogen less basic [22–25]. However, such an interaction seems to be less pronounced in the present series than that in DTPA-BMA, as demonstrated in Table 1. A little higher affinity for the second protonation with the present series may be explained in terms of the structure **B**, where the terminal nitrogen becomes more prone towards protonation because of the hydrogen bonding interaction taking place within the amide side-arm. Yet, the basicity of the terminal amine nitrogen can be decreased by the presence of the vicinal electron-withdrawing amide functionality in the DTPA-bis(amide) series [18]. With DTPA, however, such an induction effect is absent.

In the same vein, the hydrogen bonding interaction proposed here may also account for higher third protonation constants ($\log K_3^H$) for the present series than that for DTPA-BMA (Table 1). Here again, the inductive effect of the vicinal amide group may by operative.

(**B**)

3.3. Thermodynamic stability constants

The thermodynamic stability constants ($K_{ML(therm)}$) are described by Eq. (2), where M is the free unhydrolyzed aqua metal ion, L the totally deprotonated free ligand, and ML the nonprotonated and nonhydrolyzed complex.

$$K_{ML(therm)} = [ML]/[M][L] \quad (2)$$

The direct potentiometric titration method cannot be applied for the measurement of the stability constants of Gd(III) complexes of bis(amides) since they are formed at low pH. Instead, they were determined by employing the method of ligand–ligand competition potentiometric titration between EDTA and bis(amide) ligands (L) for Gd(III) ion [26–28]. Yet, the stability constants of Cu(II), Zn(II), and Ca(II) complexes were measured by direct titration of the ligands.

In Table 2 are listed the thermodynamic stability constants for the complexes of **1a**–**1l** along with DTPA-BMA and DTPA for comparison. Quite obviously and expectedly, the stability constants of not only DTPA-BMA but also **1a**–**1l**are significantly lower than that of DTPA. The DTPA-bis(amide) type ligands are in general a weaker base than DTPA due to the presence of amide oxygens, a weaker donor than carboxylate oxygens of DTPA towards coordination with the Gd(III) ion [19]. When the comparison is made between DTPA-BMA and **1a**–**1l**, the former exhibits somewhat lower or comparable $\log K_{GdL(therm)}$ values than the latter except for **1e**, **1f**, and **1h**. Of the twelve ligands in the present series, the first three (**1a**–**1c**) show the highest stability than any of the rest in the series, the observation being consistent with the order of ligand basicity as shown in Table 1. Here again, as is the case with protonation constants, not only carboxylic acid groups but also the length of alkyl chain in the amide side-arms seem to be essential. For instance, it is those carrying carboxylic acids on the amide side-arm (**1a**–**1d**) that demonstrate the highest thermodynamic stability in the series. The exact role of the carboxylic acids has yet to be clarified although some sort of coordinative interaction with the central Gd(III) ion may be taken into consideration as a partial explanation for the increased stability. Therefore, relatively lower stability constants found with **1e**–**1l** are naturally the consequences of ester formation. As for the influence of the alkyl chain in the amide side-arm, it is best illustrated by the lowest stability constant of **1d** possessing the longest alkyl chain among the four carboxylic acid derivatives (**1a**–**1d**).

3.4. Conditional stability constants and selectivity constants

The conditional stability constants reveal the extent of complexation at the given pH. To understand the stability of the complexes at the physiological pH, the stability constants of the complexes have been evaluated at pH 7.4 using Eq. (3), [7,29] where K_n^H ($n = 1, 2, 3, \ldots$) are the stepwise protonation constants of the ligands.

$$K_{ML(cond)} = K_{ML(therm)}(1 + K_1^H[H] + K_1^H K_2^H[H]^2 + K_1^H K_2^H K_3^H[H]^3 + \cdots)^{-1} \quad (3)$$

In Table 2 are also listed conditional stability constants of Gd(III), Zn(II), Ca(II), and Cu(II) complexes of **1a**–**1l**. Here again, the most obvious observation is that DTPA exhibits the highest conditional stability constants than any of DTPA-bis(amides) regardless of metals. All but **1f** and **1h** among the DTPAbis(amide) ligands described here, form Gd(III) complexes with slightly higher or comparable conditional stability than DTPA-BMA at pH 7.4 (Table 2).

The logarithmic selectivity constant (log K_{sel}) of a ligand for Gd(III) over Ca(II), Zn(II), or Cu(II) is defined as the difference between $K_{GdL(therm)}$ and $K_{ML(therm)}$ (M = Ca(II), Zn(II) and Cu(II)). In other words, these constants are a measure of affinity of the ligands towards Gd(III) over other metal ions. Table 2 shows that all ligands demonstrate favorable selectivity towards Gd(III) over Zn(II) and Cu(II), and even greater selectivity than DTPA-BMA and DTPA except for **1f** and **1h**. In the case of Ca(II), DTPA shows the highest affinity towards Gd(III) than other ligands.

The modified selectivity constants (K'_{sel}) are better employed to have a deeper insight into the stability of Gd(III) complexes as compared with other endogenous metal complexes of Ca(II), Zn(II), Cu(II), and proton at the physiological pH. They can be calculated using the following Eqs. (4)–(8) and $K_{ML(therm)}$ values in Eq. (4). Here α's are the side reaction coefficients.

$$K'_{sel} = K_{ML(therm)}(\alpha_{H^{-1}} + \alpha_{CaL^{-1}} + \alpha_{CuL^{-1}} + \alpha_{ZnL^{-1}})^{-1} \quad (4)$$

$$\alpha_{H^{-1}} = 1 + K_1^H[H] + K_1^H K_2^H[H]^2 + K_1^H K_2^H K_3^H[H]^3 + \cdots \quad (5)$$

$$\alpha_{CaL^{-1}} = 1 + K_{CaL}[Ca^{2+}] \quad (6)$$

$$\alpha_{CuL^{-1}} = 1 + K_{CuL}[Cu^{2+}] \quad (7)$$

$$\alpha_{ZnL^{-1}} = 1 + K_{ZnL}[Zn^{2+}] \quad (8)$$

The log K'_{sel} values at pH 7.4 for the Gd(III) complexes of **1a**–**1l** were calculated using the in vivo concentrations of $[Cu(II)] = 1.0 \times 10^{-3}$ mM, $[Ca(II)] = 2.5$ mM, and $[Zn(II)] = 5.0 \times 10^{-2}$ mM, [7] and are collected in Table 2. The table shows all DTPA-bis(amides) reveal greater selectivity (higher log K'_{sel} values) towards Gd(III) than DTPA. Yet, further significant observations other than the one stated above can hardly be made, although those amides carrying ethyl carboxylates in the amide side-arm seem to impart some extra in vivo stability for the Gd(III) complexes (Table 2).

In Table 3 are shown the pM values, total metal ion sequestering ability of a ligand, for the complexes of Gd(III), Zn(II), Ca(II), and Cu(II) incorporating **1a**–**1l**, DTPA-BMA, and DTPA as ligands. The larger pM values reflect a higher affinity of the ligand for the metal ion under the specified conditions [30]. The table indicates that most of the ligands of the present series are much stronger Gd(III) chelating agent than DTPA-BMA. The higher pGd values compared to the corresponding pCa, pZn and pCu values reflect the Gd(III) complexes are stable enough to avoid interference by other endogenously available metal ions. Different pGd values among **1a**–**1l** seem to indicate that here again the presence of carboxylic acid

Table 3
The pM[a] values of the complexes of Gd(III), Zn(II), Ca(II) and Cu(II) at pH 7.4

Ligands	pGd	pCa	pZn	pCu
1a	17.71	7.05	11.36	11.86
1b	16.65	7.88	12.12	12.65
1c	16.52	8.68	11.87	12.35
1d	16.18	6.90	10.50	10.95
1e	15.87	6.04	10.50	10.95
1f	13.49	6.76	10.40	10.98
1g	16.66	6.73	12.06	12.57
1h	13.72	6.58	10.12	10.90
1i	15.46	6.64	9.72	10.23
1j	16.44	6.08	10.21	10.90
1k	15.95	6.33	10.55	10.81
1l	15.18	6.35	9.42	9.83
DTPA-BMA	13.88	4.19	9.06	10.05
DTPA	17.14	5.45	13.39	16.06

[a] $pM = -\log[M]_{free}$ at pH 7.4; $[\text{metal ion}]_{total} = 1\ \mu mol/dm^3$; $[ligand]_{total} = 1.1\ \mu mol/dm^3$.

groups as well as the length of alkyl chains in the amide side-arms play certain roles.

3.5. Relaxometric studies

The relaxivities R_1 and R_2 of **2a**–**2l** in aqueous and aqueous HP-β-CD solutions are collected in Table 4. In aqueous solutions, the complexes show significantly lower relaxivities than analogous Gd(III) complexes of DTPA-BMA and DTPA. Yet, it is known that a significant increase in relaxivity is established when "host–guest" inclusion complexes are formed between the hydrophobic β-cyclodextrin cavity of hydroxypropyl-β-cyclodextrin (HP-β-CD) and Gd(III) complexes [10,31,32]. Such inclusion becomes possible through non-covalent interactions between β-cyclodextrin cavities and the substituents of ligands coordinated to the Gd(III) ion. Thus, hydrophobicity of the substituents in the ligand determines the stability of the inclusion complex [33]. In addition, HP-β-CD is biocompatible and has been used in the preparation of aqueous solution of water-insoluble drugs [34–36]. In this regard, the aliphatic amide side-arms in **2a**–**2l** are expected to interact with the hydrophobic cavities of the β-CD moieties of HP-β-CD thus leading to the formation of "host–guest" complexes. Indeed, dramatic increases in R_1 and R_2 values are to be noted. These observations demonstrate that the inclusion has truly taken place between **2** and HP-β-CD.

Table 4
Relaxivity data of **2a**–**2l** in aqueous and aqueous HP-β-CD solutions

Complexes	R_1 ($mM^{-1}\ s^{-1}$)	R_2 ($mM^{-1}\ s^{-1}$)	R_1^a in HP-β-CD ($mM^{-1}\ s^{-1}$)	R_2^a in HP-β-CD ($mM^{-1}\ s^{-1}$)
2a	1.58	1.50	9.4	9.7
2b	1.43	1.23	10.4	11.0
2c	1.31	1.00	8.6	8.7
2d	1.44	1.23	11.6	12.1
2e	1.59	1.71	8.7	8.8
2f	1.54	1.35	8.8	8.9
2g	1.47	1.31	9.1	9.2
2h	1.65	1.52	12.6	13.0
2i	1.95	1.94	10.1	10.4
2j	1.71	1.63.	12.2	12.5
2k	1.68	1.65	10.4	10.5
2l	1.54	1.40	10.5	10.8
Gd(DTPA-BMA)	4.58	4.76		
$[Gd(DTPA)]^{2-}$[b]	3.40	3.80		

[a] [HP-β-CD] = 50 mM.
[b] $[Gd(DTPA)]^{2-}$, R_1 and R_2 measured at $B_0 = 1.0$ T.

nal residual solvent peaks. Elemental analyses were performed by the Analytical Chemistry Division of Bhabha Atomic Research Centre, Mumbai. The TG/DTA for **7** and **8** were recorded on a Mettler TGA-851E instrument under the flow of an air.

2.2. Synthesis of (3,5-dimethyl,N,N-dibutyl, carbamoyl methyl pyrazole (*L₁*)

3,5-Dimethyl pyrazole (4.6 g, 0.048 mol), $ClCH_2CONBu_2$ (10.0 g, 0.048 mol) and triethylamine (10 ml) were refluxed in 1,2-dichloroethane for 80 h and the resulting solution was treated with 100 ml of 20% HCl solution. The organic layer was separated, dried over anhydrous Na_2SO_4, filtered and dried. The resulting colorless solid was recrystallized from hot hexane as a white solid. Yield: 12.0 g (94%). Elemental *Anal*. Calc. for $C_{15}H_{27}N_3O$: C, 67.9; H, 10.2; N, 15.8. Found: C, 67.8; H, 10.0; N, 15.6%. IR (KBr, Nujol): ν/cm^{-1} 1653 (CO). ^1H NMR (25 °C, $CDCl_3$): δ 0.92 (t, 6 Hz, CH_3, Bu), 0.95 (t, 6 Hz, CH_3, Bu), 1.32–1.40 (m, CH_2, Bu), 1.47–1.52 (m, CH_2, Bu), 2.18 (s, CH_3, dmPz), 2.19 (s, CH_3, dmPz), 3.28 (m, NCH_2, Bu), 4.81 (s, NCH_2CO), 5.83 (s, dmPz). (25 °C, CD_3OD): δ 0.92 (t, 6 Hz, CH_3, Bu), 0.99 (t, 6 Hz, CH_3, Bu), 1.32 (m, CH_2, Bu), 1.42 (m, CH_2, Bu), 1.52 (m, CH_2, Bu), 1.62 (m, CH_2, Bu), 2.18 (s, CH_3, dmPz), 2.19 (s, CH_3, dmPz), 3.35 (m, NCH_2, Bu), 4.97 (s, NCH_2CO), 5.94 (s, dmPz).

2.3. Synthesis of (3,5-dimethyl,N,N-di-isobutyl carbamoyl methyl pyrazole (*L₂*)

This was prepared similarly to $\mathbf{L_1}$ by taking 3,5-dimethyl pyrazole (3.7 g, 0.039 mol), $ClCH_2CON^iBu_2$ (8.0 g, 0.039 mol) and triethylamine (10 ml). The final product was obtained as white needles. Yield: 9.7 g (94%). Elemental *Anal*. Calc. for $C_{15}H_{27}N_3O$: C, 67.9; H, 10.2; N, 15.8. Found: C, 67.7; H, 10.1; N, 15.5%. IR (KBr, Nujol): ν/cm^{-1} 1655 (CO); ^1H NMR (25 °C, $CDCl_3$): δ 0.85 (d, 7 Hz, CH_3, ^{i}Bu), 0.95 (d, 7 Hz, CH_3, ^{i}Bu), 1.99 (m, CH, ^{i}Bu), 2.18 (s, CH_3, dmPz), 2.19 (s, CH_3, dmPz), 3.16 (d, 7.5 Hz, NCH_2, ^{i}Bu), 3.28 (d, 7.5 Hz, NCH_2, ^{i}Bu), 4.83 (s, NCH_2CO), 5.82 (s, dmPz).

2.4. Synthesis of (N,N-dibutyl, carbamoyl methyl pyrazole (*L₃*)

This was prepared similarly to $\mathbf{L_1}$ by taking pyrazole (3.3 g, 0.049 mol), $ClCH_2CONBu_2$ (10.0 g, 0.049 mol) and triethylamine (10 ml). The final product was obtained as a semi-solid. Yield: 10.0 g (90%). Elemental *Anal*. Calc. for $C_{13}H_{23}N_3O$: C, 65.8; H, 9.7; N, 17.7. Found: C, 65.4; H, 10.0; N, 17.4%. IR (KBr, Nujol): ν/cm^{-1} 1655 (CO). ^1H NMR (25 °C, $CDCl_3$): δ 0.88 (t, 6 Hz, CH_3, Bu), 0.94 (t, 6 Hz, CH_3, Bu), 1.3 (m, CH_2, Bu), 1.52 (m, CH_2, Bu), 3.28 (m, NCH_2, Bu), 4.96 (s, NCH_2CO), 6.28 (t, 2 Hz, Pz), 7.50 (d, 2 Hz, Pz), 7.52 (d, 2 Hz, Pz).

2.5. Synthesis of N,N-diisobutyl, carbamoyl methyl pyrazole (*L₄*)

This was prepared similarly to $\mathbf{L_1}$ by taking pyrazole (3.0 g, 0.044 mol), $ClCH_2CON^iBu_2$ (9.2 g, 0.044 mol) and triethylamine (10 ml). The final product was obtained as a semi-solid. Yield: 9.6 g (91%). Elemental *Anal*. Calc. for $C_{15}H_{27}N_3O$: C, 65.8; H, 9.7; N, 17.7. Found: C, 65.7; H, 10.1; N, 17.5%. IR (KBr, Nujol): ν/cm^{-1} 1654 (CO). ^1H NMR (25 °C, $CDCl_3$): δ 0.82 (d, 7 Hz, CH_3, ^{i}Bu), 0.94 (d, 7 Hz, CH_3, ^{i}Bu), 1.99 (m, CH, ^{i}Bu), 3.13 (d, 7 Hz, NCH_2, ^{i}Bu), 3.18 (d, 7 Hz, NCH_2, ^{i}Bu), 4.98 (s, NCH_2CO), 6.28 (t, 2 Hz, Pz), 7.49 (d, 2 Hz, Pz), 7.52 (d, 2 Hz, Pz).

2.6. Synthesis of 3,5-dimethyl,N,N-dioctyl, carbamoyl methyl pyrazole (*L₅*)

This was prepared similarly to $\mathbf{L_1}$ by taking 3,5-dimethyl pyrazole (3.0 g, 0.031 mol), $ClCH_2CON(C_8H_{17})_2$ (10.0 g, 0.031 mol) and triethylamine (10 ml). The final product was obtained as a pasty liquid. Yield: 11.0 g (93%). Elemental *Anal*. Calc. for $C_{23}H_{43}N_3O$: C, 73.2; H, 11.4; N, 11.1. Found: C, 72.7; H, 10.4; N, 10.5%. IR (KBr, Nujol): ν/cm^{-1} 1654 (CO). ^1H NMR (25 °C, $CDCl_3$): δ 0.84 (m, CH_3, C_8H_{17}), 1.2–1.3 (br, CH_2, C_8H_{17}), 2.16 (s, CH_3, dmPz), 2.18 (s, CH_3, dmPz), 3.25 (m, NCH_2, C_8H_{17}), 3.77 (m, NCH_2, C_8H_{17}), 4.78 (s, NCH_2CO), 5.83 (s, dmPz).

2.7. Synthesis of [$UO_2(NO_3)_2$*L₁*] (*6*)

To a solution of $\mathbf{L_1}$ (550 mg, 2.08 mmol) in $CHCl_3$, solid $[UO_2(NO_3)_2 \cdot 6H_2O]$ (502 mg, 1.0 mmol) was added and stirred for few minutes until all $[UO_2(NO_3)_2 \cdot 6H_2O]$ dissolves to give clear solution. This solution was filtered and allowed to stand for over night in a closed vial. This process deposited yellow crystalline solid, which was filtered, washed with $CHCl_3$ and dried. Yield: 600 mg (91%). Elemental *Anal*. Calc. for $[UO_2(NO_3)_2C_5H_7N_2CH_2CON(C_4H_9)_2]$, $C_{15}H_{27}N_5O_9U$: C, 27.3; H, 4.1; N, 10.6. Found: C, 27.0; H, 4.0; N, 10.1%. IR (KBr, Nujol): ν/cm^{-1} 1614 (CO), 930 (O=U=O). ^1H NMR (25 °C, CD_3COCD_3): δ 0.97 (t, 7 Hz, CH_3, Bu), 1.07 (t, 7 Hz, CH_3, Bu), 1.47 (m, CH_2, Bu), 1.60 (m, CH_2, Bu), 1.88 (m, CH_2, Bu), 2.48 (s, CH_3, dmPz), 2.72 (s, CH_3, dmPz), 3.97 (br, NCH_2, Bu), 4.13 (br, NCH_2, Bu), 5.47 (s, NCH_2CO), 6.51 (s, dmPz).

2.8. Synthesis of [$UO_2(NO_3)_2$*L₂*] (*7*)

It was prepared similarly to **6** by taking $\mathbf{L_2}$ (500 mg, 1.89 mmol) and $[UO_2(NO_3)_2 \cdot 6H_2O]$ (450 mg, 0.89 mmol). Yield: 550 mg (93%). Elemental *Anal*. Calc. for $[UO_2(NO_3)_2C_5H_7N_2CH_2CON(^iC_4H_9)_2]$, $C_{15}H_{27}N_5O_9U$: C, 27.3; H, 4.1; N, 10.6. Found: C, 27.1; H, 3.9; N, 10.3%. IR (KBr, Nujol mull): ν/cm^{-1} 1600 (CO), 939 (O=U=O). ^1H NMR (25 °C, CD_3COCD_3): δ 0.93 (d, 7 Hz, CH_3, ^{i}Bu), 1.08 (d, 7 Hz, CH_3, ^{i}Bu), 2.21 (m, CH,

^{i}Bu), 2.45 (s, CH_3, dmPz), 2.70 (s, CH_3, dmPz), 3.84 (br, NCH_2, ^{i}Bu), 4.06 (br, NCH_2, ^{i}Bu), 5.52 (s, NCH_2CO), 6.49 (s, dmPz).

2.9. Synthesis of $[UO_2(NO_3)_2\mathbf{L_3}]$ (**8**)

It was prepared similarly to **6** by taking $\mathbf{L_3}$ (500 mg, 2.11 mmol) and $[UO_2(NO_3)_2 \cdot 6H_2O]$ (502 mg, 1.0 mmol). Yield: 600 mg (95%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2C_3H_3N_2CH_2CON(C_4H_9)_2]$, $C_{13}H_{23}N_5O_9U$: C, 24.7; H, 3.6; N, 11.1. Found: C, 24.5; H, 3.3; N, 10.7%. IR (KBr, Nujol): ν/cm^{-1} 1612 (CO), 929 (O=U=O). ^{1}H NMR (25 °C, CD_3COCD_3): δ 0.98 (t, 7 Hz, CH_3, Bu), 0.99 (t, 6 Hz, CH_3, Bu), 1.48 (m, CH_2, Bu), 1.62 (m, CH_2, Bu), 1.89 (m, CH_2, Bu), 3.98 (br, NCH_2, Bu), 4.20 (br, NCH_2, Bu), 5.62 (s, NCH_2CO), 6.40 (br, Pz), 7.71 (br, Pz), 7.83 (br, Pz).

2.10. Synthesis of $[UO_2(NO_3)_2\mathbf{L_4}]$ (**9**)

It was prepared similarly to **6** by taking $\mathbf{L_4}$ (500 mg, 2.11 mmol) and $[UO_2(NO_3)_2 \cdot 6H_2O]$ (400 mg, 0.79 mmol). Yield: 502 mg (93%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2C_3H_3N_2CH_2CON(^{i}C_4H_9)_2]$, $C_{13}H_{23}N_5O_9U$: C, 24.7; H, 3.6; N, 11.1. Found: C, 24.4; H, 3.5; N, 10.9%. IR (KBr, Nujol): ν/cm^{-1} 1595 (CO), 941 (O=U=O). ^{1}H NMR (25 °C, CD_3COCD_3): δ 0.93 (d, 7 Hz, CH_3, ^{i}Bu), 1.01 (d, 7 Hz, CH_3, ^{i}Bu), 2.24 (m, CH, ^{i}Bu), 3.87 (br, NCH_2, ^{i}Bu), 4.08 (br, NCH_2, ^{i}Bu), 5.63 (s, NCH_2CO), 6.42 (br, Pz), 7.67 (br, Pz), 7.82 (br, Pz).

2.11. Synthesis of $[La(NO_3)_3(\mathbf{L_4})_2]$ (**10**)

To a solution of $\mathbf{L_4}$ (700 mg, 2.97 mmol) in ethyl acetate, solid $[La(NO_3)_3 \cdot 6H_2O]$ (400 mg, 0.92 mmol) was added and refluxed for 2 h. The resulting white solid was filtered, washed with ethyl acetate, hexane and dried. Yield: 680 mg (92%). Elemental *Anal.* Calc. for $[La(NO_3)_3\{C_3H_3N_2CH_2CON(^{i}C_4H_9)_2\}_2]$, $C_{26}H_{46}N_9O_{11}La$: C, 39.1; H, 5.8; N, 15.8. Found: C, 38.7; H, 5.4; N, 15.2%. IR (KBr, Nujol): ν/cm^{-1} 1615, 1603 (CO). ^{1}H NMR (25 °C, CD_3COCD_3): δ 0.84 (d, 7 Hz, CH_3, ^{i}Bu), 0.99 (d, 7 Hz, CH_3, ^{i}Bu), 2.12 (m, CH, ^{i}Bu), 3.32 (d, NCH_2, ^{i}Bu), 3.50 (d, NCH_2, ^{i}Bu), 5.37 (s, NCH_2CO), 6.34 (t, Pz), 7.68 (d, Pz), 7.84 (d, Pz).

2.12. Synthesis of $[Ce(NO_3)_3(\mathbf{L_4})_2]$ (**11**)

To a solution of $\mathbf{L_4}$ (650 mg, 2.75 mmol) in ethyl acetate, solid $[Ce(NO_3)_3 \cdot 6H_2O]$ (400 mg, 0.92 mmol) was added and refluxed for 2 h. The resulting white solid was filtered, washed with ethyl acetate, hexane and dried. Yield: 650 mg (88%). Elemental *Anal.* Calc. for $[Ce(NO_3)_3\{C_3H_3N_2CH_2CON(^{i}C_4H_9)_2\}_2]$, $C_{26}H_{46}N_9O_{11}Ce$: C, 39.0; H, 5.7; N, 15.7. Found: C, 38.6; H, 5.5; N, 15.4%. IR (KBr, Nujol): ν/cm^{-1} 1613, 1603 (CO). ^{1}H NMR (25 °C, CD_3COCD_3): δ 0.85 (d, CH_3, ^{i}Bu), 1.00 (d, CH_3, ^{i}Bu), 2.12 (m, CH, ^{i}Bu), 3.31 (d, NCH_2, ^{i}Bu), 3.49 (d, NCH_2, ^{i}Bu), 5.34 (m, NCH_2CO), 6.32 (m, Pz), 7.66 (br, Pz), 7.82 (m, Pz).

2.13. Solvent extraction studies

Distribution studies were performed by using a solution of $\mathbf{L_5}$ in toluene (as such, without any pre-equilibration for the acidity variation experiments and pre-equilibrated with 3 M HNO_3 for the slope measurements) with the required aqueous phase spiked with ^{233}U, ^{239}Pu or ^{241}Am tracers in a thermostated water bath for 1 h at 25 ± 0.1 °C. Assay of organic and aqueous phases were done in duplicate by alpha counting using a dioxane based liquid scintillator for ^{233}U and ^{239}Pu and direct γ counting for ^{241}Am. The distribution ratio (D) is defined as the ratio of the concentration of uranium in the organic phase to that of the aqueous phase.

2.14. X-ray diffraction studies of **6**, **7** and **11**

Data for the crystals **6**, **7** and **11** were measured with the Mo Kα radiation ($\lambda = 0.71073$ Å) using the MARresearch Image Plate System. The crystals were positioned at 70 mm from the Image Plate. Ninety-five frames were measured at 2° intervals with a counting time of 2 min. Data analysis was carried out with the XDS program [36a]. The structures were solved using direct methods with the SHELXS program [36b]. In **11** one of the alkyl chains was disordered with three of the carbon atoms refined over two sites. Apart from these disordered atoms, all non-hydrogen atoms in all these structures were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon atoms were included in the geometric positions and given thermal parameters equivalent to 1.2 times those of the atoms to which they attached. Empirical absorption corrections were carried out using the DIFABS program [36c]. The struc-

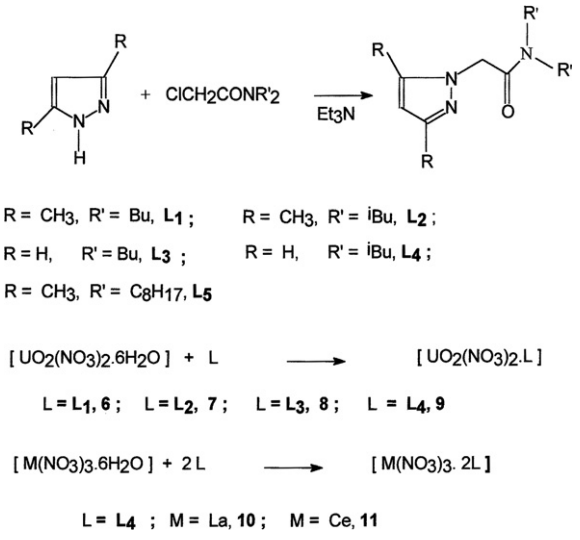
$w = 1/[\sigma^2(F_o^2) + (0.0122P)^2 + 18.3632P]$ for **7**, $w = 1/[\sigma^2(F_o^2) + (0.0253P)^2 + 19.30227P]$ for **11**. where $P = (F_o^2 + 2F_c^2)/3$ for **7** and **11**.

tures were refined to convergence on F^2 using SHELXL [36d]. Selected crystallographic data for **7** and **11** are summarized in Table 1 and for **6** given as Supplementary material (Table 2).

3. Results and discussion

3.1. Synthesis and characterization of CMPz ligands

The reaction of pyrazole or dimethyl pyrazole with various monochloroacetyl amides yielded the corresponding carbamoyl methyl pyrazoles [37] $\mathbf{L_1}$ to $\mathbf{L_5}$ (Scheme 1). The IR spectra of $\mathbf{L_1}$ to $\mathbf{L_5}$ showed the presence of a carbamoyl group in all these ligands. The ^{1}H NMR spectra of $\mathbf{L_1}$ to $\mathbf{L_5}$ showed the expected peaks and multiplicities. The –NCH_2CO– protons of all these ligands showed a single resonance around 4.8–4.9 ppm and are deshielded about 0.8–0.9 ppm with respect to the starting chloroacetyl amides.



3.2. Complexation study of L_1, L_2, L_3 and L_4 with uranyl nitrate

The complexing ability of $\mathbf{L_1}$, $\mathbf{L_2}$, $\mathbf{L_3}$ and $\mathbf{L_4}$ with uranyl nitrate was studied by using elemental analysis, IR and NMR spectroscopic techniques. The reaction of $[UO_2(NO_3)_2 \cdot 6H_2O]$ with $\mathbf{L_1}$, $\mathbf{L_2}$, $\mathbf{L_3}$ or $\mathbf{L_4}$, yielded the compounds **6–9** (Scheme 1). The C, H and N analysis revealed that the ratio of ligand to uranyl nitrate is 1:1 in all these compounds. The IR spectra of **6–9** show that the water molecules from the starting compound $[UO_2(NO_3)_2 \cdot 6H_2O]$ are completely replaced by the ligand and that the ligand is bonded through the carbamoyl oxygen atom to the uranyl group.

The observed frequency differences for a carbamoyl ($\Delta\nu_{CO} = 35–50\ cm^{-1}$, where $\Delta\nu_{CO} = \nu_{CO(free\ ligand)} - \nu_{CO(coordinated)}$) [14–28] group are consistent with the supposition that the carbamoyl group is bonded to the uranyl group directly in the reported compounds. Similar differences are also observed in the compounds of CMP, CMPO or CMSO with uranyl nitrate such as, $[UO_2(NO_3)_2(^iC_3H_7O)_2POCH_2CONEt_2]$ [14], $[UO_2(NO_3)_2(C_6H_5)_2POCH_2CONEt_2]$ [17] or $[UO_2(NO_3)_2\ C_6H_5SOH_2CONBu_2]$ [28]. The ^{1}H NMR spectra of **6–9** show that both the NCH_2CO (ca. 0.5–0.6 ppm) and pyrazole (ca. 0.3–0.7 ppm) protons are deshielded with respect to the free ligand, indicating that the ligand is bonded to the uranyl group in solution. It is apparent from the elemental analysis and IR spectral results that ligands $\mathbf{L_1}$–$\mathbf{L_4}$ are acting as bidentate chelating ligand in compounds **6–9** in the solid state to give similar structures to those observed in the compounds of CMPO, CMP or CMSO with uranyl nitrate. Structures of compounds **6** and **7** have been determined by single crystal X-ray diffraction methods and show the bidentate chelating mode of bonding for the ligand in the solid state.

3.3. Molecular structures of 6 and 7

The molecular structure of **6** is shown in Supplementary material (Fig. 1) and that of **7** is shown in Fig. 2. The selected interatomic bond distances and angles for **7** are given in Table 3 and those of **6** Supplementary material (Table 4). The structures of **6** and **7** are similar and show that the uranium atom is surrounded by seven oxygen atoms and one nitrogen atom in a hexagonal bi-pyramidal geometry. Four oxygen atoms of the two nitrate groups, together with one oxygen and one nitrogen atoms of the CMPz ligand form the equatorial hexagonal plane. The five oxygen and one nitrogen atoms (O5N) are coplanar to within 0.14 Å in **6** and 0.13 Å in **7**. The two uranyl oxygen atoms occupy the axial positions. Two nitrate groups act as bidentate chelating ligands and bonded through the oxygen atoms to the uranyl group. The CMPz ligand acts as a

Scheme 1.

Ce1–O11	2.477(4)	O11–Ce1–O41	72.08(16)
Ce1–N18	2.732(5)	O42–N43–O41	116.1(5)

bidentate chelating ligand and is bonded through both the pyrazolyl nitrogen and carbamoyl oxygen atoms to the uranyl group.

This is a similar type of co-ordination to that observed in the compounds of the bi-functional ligands, CMP, CMPO, *β*-Sulfoxo phosphine oxide, malonamide and CMSO with uranyl nitrate such as, $[UO_2(NO_3)_2Ph\{EtO\}POCH_2CONEt_2]$, $[UO_2(NO_3)_2Ph_2POCH_2CONEt_2]$ [17], $[UO_2(NO_3)_2(^iC_3H_7O)_2\ POCH_2SO(p\text{-}CH_3C_6H_4)]$ [20],$[UO_2(NO_3)_2(^iC_3H_7)_2NCO)_2CH_2]$ [27] and $[UO_2(NO_3)_2C_6H_5SOH_2CONBu_2]$ [28]. The observed U–N(pyrazolyl) bond distances (2.551(19) Å) in **6** and (2.554(9) Å) in **7** are very close to the values observed in $[UO_2(NO_3)_2(C_{12}H_8N_2)]$ ($C_{12}H_8N_2$ = phenanthroline) (2.556(2) Å) [31,32] and $[UO_2(C_{15}H_{11}N_3)_2(OTf)_2]$ ($C_{15}H_{11}N_3$ = terpyridine) (2.567(6), 2.592(6) Å) [33,34]. The U–O(amide) distances (2.377(9) Å) in **6** and (2.364(7) Å) in **7** are slightly shorter than the values observed in $[UO_2(NO_3)_2Ph\{EtO\}POCH_2CONEt_2]$ (2.426(8) Å), $[UO_2(NO_3)_2Ph_2POCH_2CONEt_2]$ (2.404(5) Å) [17], $[UO_2(NO_3)_2(^iC_3H_7)_2NCOCH_2CON(^iC_3H_7)_2]$ (2.41(2) Å) [27] and $[UO_2(NO_3)_2C_6H_5SOH_2CONBu_2]$ (2.442(9) Å) [28]. The observed average U–O(NO_3) bond distance 2.524(8) Å is normal [17,20,27,28]. The angles subtended at the metal atom show that the uranium atom has a slightly distorted hexagonal bi-pyramidal geometry.

3.4. Complexation study of L_4 with lanthanum(III) and cerium(III) Nitrates

The reaction of L_4 with $La(NO_3)_3 \cdot 6H_2O$ or $Ce(NO_3)_3 \cdot 6H_2O$ yielded **10** or **11** (Scheme 1). The C, H, N analysis revealed that the ratio of ligand to metal is 2:1 in both the compounds. The IR spectra of **11** and **12** show that the water molecules from the starting compounds $[M(NO_3)_3 \cdot 6H_2O]$ are replaced completely by the ligands. The spectra show further that the ligands are bonded through the carbamoyl oxygen atoms to the metal ion. ($\Delta\nu_{CO} = 41$–$53\ cm^{-1}$, where $\Delta\nu_{CO} = \nu_{CO\ (free\ ligand)} - \nu_{CO(coordinated)}$). This arrangement is similar to that observed in the compounds of CMPO, CMP, CMSO or malonamide with lanthanide(III) nitrate compounds such as: $[Gd(NO_3)_3\{(^iC_3H_7O)_2POCH_2SO(p\text{-}CH_3C_6H_4)\}_2]$ [19], $[Ce(NO_3)_3(TMSA)_2]$, $[Ce(NO_3)_3(TMSA)_2]_\alpha$ [25] and $[Ce(NO_3)_3\{C_6H_5SOH_2CONBu_2\}_2]$ [28]. The ^1H NMR of the compounds show that both the NCH_2CO (ca. 0.4 ppm) and pyrazole (ca. 0.2–0.3 ppm) protons of the CMPz ligand are deshielded with respect to the free ligand, indicating that the ligand is bonded to the lanthanide ion in solution. The structure of compound **11** has been determined by single crystal X-ray diffraction methods and showing the bidentate chelating mode of bonding for the carbamoyl methyl pyrazole ligand.

3.5. Molecular structure of 11

The molecular structure of **11**, which contains a crystallographic twofold axis is shown in Fig. 3 together with the numbering scheme and selected interatomic bond distances and angles are given in Table 3. The structure shows that the cerium(III) ion is bonded to two CMPz ligands and three nitrate groups to give a coordination number of ten. Both CMPz ligands are bidentate being bonded through both the pyrazolyl nitrogen and carbamoyl oxygen atoms to the cerium(III) nitrate. Six oxygen atoms from three nitrate groups, two oxygen and two nitrogen atoms from two CMPz ligands form a bi-capped square anti-prismatic geometry around the cerium ion. Similar structures are also observed in the compounds of CMP, CMPO, CMSO or bis(diphenylphosphino methane) dioxide with lanthanide (III) nitrates, viz., $[Sm(NO_3)_3\{(^iPrO)_2POCH_2CONEt_2\}_2]$ [15][$Nd(NO_3)_3\{Ph_2POCH_2CONEt_2\}_2$] [16][$Ce(NO_3)_3(C_6H_5SOCH_2CONBu_2)_2$] [28] and $[M(NO_3)_3(DPPMO)_2]$ (M = La or Ce) [38]. The observed metal to oxygen and metal to nitrogen bond distances are in the range of (2.650(4)–2.660(5) Å) for Ce–O(nitrate) [28,38], 2.477(4) Å for Ce–O(amide) [15,28,39] and 2.732(5) Å for

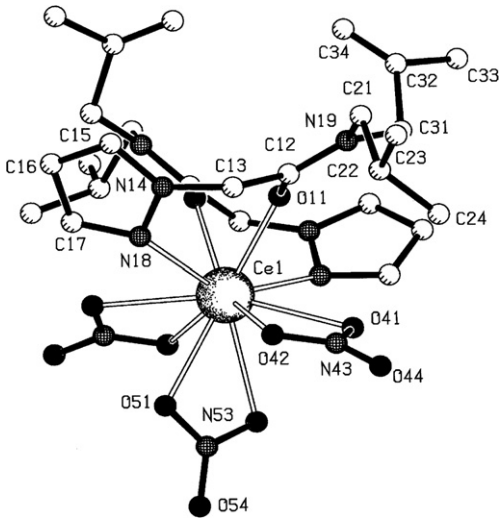

Fig. 3. Diagram of the structure of **11**, hydrogen atoms omitted for clarity.

Ce–N(pyrazole) [40] and agree well with those found previously.

3.6. Thermal studies of the compounds 6 and 7

Thermogravimetric (TG) and differential thermal analyses (DTA) of **6** and **7** (see Supplementary material) were carried out to see whether the bonded ligands can be destroyed completely on heating or not. These compounds decompose in two steps to give U_3O_8 as a final product (identified from the powder X-ray diffraction pattern of the decomposition product), without any other impurities. However, the decomposition of phosphine oxide compounds of uranyl nitrate yielded the corresponding uranyl phosphate as a final product [41]. This observation clearly shows that the CMPz ligands can be completely destroyed on incineration, as indeed can the amide ligands [8b].

3.7. Extraction studies of U(VI), Pu(IV) and Am(III) with L_5 from nitric acid medium

The extraction studies were carried out by using the ligand $\mathbf{L_5}$ in toluene with the U(VI), Pu(IV) and Am(III) ions in tracer level (using the ^{233}U, ^{239}Pu and ^{241}Am tracers) from nitric acid medium to assess the feasibility of using these ligands (0.2F for U(VI) and Am(III) and 0.004F for Pu(IV), where F = weight dissolved in 1 l of the solvent/formula weight) for extraction purposes. Distribution ratios (D) for U(VI), Pu(IV) and Am(III) as a function of nitric acid concentrations (Fig. 4) show clearly that U(VI) and Pu(IV) are extracted significantly from nitric acid at concentrations of 1–10 M. However, Am(III) did not show appreciable extraction under the conditions studied. The observed distribution ratios follow the order of: $D_{Pu(IV)} \gg D_{U(VI)} \gg D_{Am(III)}$ and are similar to those observed for the CMP, CMPO, CMSO or malonamide ligands with these metal ions [28,42].

In order to establish the nature of species extracted during the solvent extraction process, the distribution ratios for the U(VI) and Pu(IV) were measured as a function of $\mathbf{L_5}$ concentrations. The plots of $\log D$ versus $\log[\mathbf{L_5}]$ for U(VI) and Pu(IV) show straight lines with slopes between 1 and 2 (1.5 and 1.9 for U(VI), Pu(IV), respectively, see Supplementary material (Figs. 5 and 6)) indicating, that the species extracted under the solvent extraction conditions are a mixture of $UO_2(NO_3)_2 \cdot CMPz$ and $UO_2(NO_3)_2 \cdot 2CMPz$ and just $Pu(NO_3)_4 \cdot 2CMPz$ for U(VI) and Pu(IV), respectively.

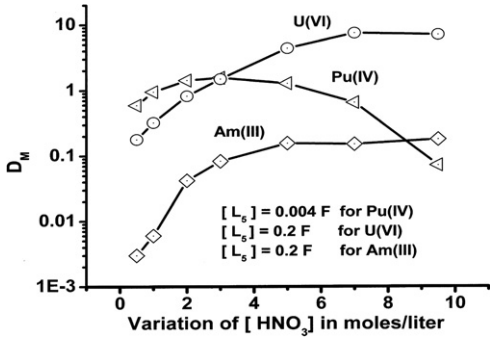

Fig. 4. Extraction data for $\mathbf{L_5}$ with U(VI), Pu(IV) and Am(III).

4. Conclusions

Studies on the coordination ability of the carbamoyl methyl pyrazole ligands with uranyl (VI), lanthanum(III) and cerium(III) nitrates show that the ligands act as bidentate chelating ligands in all these compounds. Preliminary extraction studies of $\mathbf{L_5}$ with the U(VI), Pu(IV) and Am(III) at tracer level show that they can extract U(VI) and Pu(IV) from HNO_3 of concentrations from 1 to 10 M. TG/DTA experiments show that the CMPz ligands can be destroyed easily on incineration.

Acknowledgements

We thank, the Head, Analytical Chemistry Division, BARC, for carbon, hydrogen and nitrogen analysis, the Head, National NMR facilities, TIFR, Mumbai for NMR spectra and the Head, Fuel Chemistry Division for his support. We also thank the EPSRC (UK) and the University of Reading for funds for the Image Plate system.

Appendix A. Supplementary material

CCDC 619366, 619367 and 619368 contain the supplementary crystallographic data for **6**, **7** and **11**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. X-ray crystallographic files in CIF format for **6**, **7**, and **11**, molecular structure for **6** (Fig. 1), crystal and structural refinement details for **6** (Table 2), important bond lengths and bond angles for **6** (Table 4), TG/DTA for **6** and **7** and $\log D$ vs. $\log[\mathbf{L_5}]$ plots for uranium(VI) and plutonium(IV) (Figs. 5 and 6) are deposited with the editor as supplementary material. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.04.005.

2. Experimental

2.1. General procedures

All experiments were carried out under purified argon using standard Schlenk techniques or in a glove box (<1 ppm O_2, 5 ppm H_2O). Diethyl ether and tetrahydrofuran were distilled from Na/benzophenone, toluene and pentane were distilled from Na/K alloy under nitrogen and degassed by freeze-thaw-vacuum cycles prior to use. Chlorinated solvents were distilled from calcium hydride. Deuterated solvents were purchased from Eurisotop and purified before use. *rac*-Lactide (Aldrich) was sublimed twice before use. Mg(*n*Bu)$_2$, *i*-PrMgCl and MeMgI (all Aldrich) were used as received. Bis[2-(3,5-dimethyl-1-pyrazolyl)ethyl]amine (**1**) was synthesized according to the literature [7].

NMR spectra were recorded on Bruker AC-200, AC-300 and AM-500 spectrometers in Teflon-valved NMR tubes at 23 °C otherwise stated. ^{1}H and ^{13}C NMR chemical shifts were determined using residual solvent resonances and are reported versus $SiMe_4$. Assignment of signals was made from ^{1}H–^{13}C HMQC and ^{1}H–^{13}C HMBC 2D NMR experiments. Coupling constants are given in Hertz. Elemental analyses (C, H, N) were performed by the Microanalytical Laboratory at the Institute of Chemistry of Rennes and are the average of two independent determinations. Molecular weights of PLA were determined by gel permeation chromatography (GPC) at room temperature on a Waters apparatus equipped with five PL gel columns (Polymer Laboratories Ltd.), an autosampler Waters WISP 717, and a differential refractometer Shimadzu RID 6A. THF was used as eluent at a flow rate of 1.0 mL min^{-1}. Polystyrene standards were used for molecular weight universal calibration. The microstructure of polymers was determined by ^{1}H NMR in $CDCl_3$.

2.2. [Bis[2-(3,5-dimethyl-1-pyrazolyl)ethyl]amide]$_2$Mg (**3**)

To a solution of pro-ligand **1** (0.301 g, 1.15 mmol) in toluene (5 mL) was slowly added Mg(*n*-Bu)$_2$ (0.58 mL of a 1.0 M solution in heptane, 0.58 mmol) at room temperature. The reaction mixture was stirred for 2 h. Volatiles were removed under vacuum, and the residue was recrystallized from toluene/pentane (ca. 1:3) at −34 °C to give block colorless crystals of **3** (0.22 g, 70%). A suitable crystal was selected for X-ray diffraction analysis. ^{1}H NMR (C_6D_6, 300 MHz): δ 5.66 (s, 4H, pyrazole-*H*), 4.23 (m br, 8H, NCH$_2$C*H*$_2$-pyrazole), 3.48 (m, 8H, NC*H*$_2$CH$_2$-pyrazole), 2.01 (s, 12H, pyrazole-C*H*$_3$), 1.78 (s, 12H, pyrazole-C*H*$_3$). ^{13}C{^{1}H} NMR (C_6D_6, 300 MHz): δ 148.64 (pyrazole-*C*CH$_3$), 137.28 (pyrazole-*C*CH$_3$), 104.62 (pyrazole-*C*H), 60.71 (N*C*H$_2$CH$_2$-pyrazole), 48.18 (NCH$_2$*C*H$_2$-pyrazole), 10.45 (pyrazole-*C*H$_3$), 9.81 (pyrazole-*C*H$_3$). *Anal.* Calc. for $C_{28}H_{44}MgN_{10}$ (545.02): C, 61.70; H, 8.14; N, 25.70. Found: C, 61.52; H, 8.32; N, 25.47%.

2.3. [Bis[2-(3,5-dimethyl-1-pyrazolyl)ethyl]amide]MgCl (**4**)

A 100 mL Schlenk flask was charged with *i*PrMgCl (0.57 mL of a 2.0 M solution in Et_2O, 1.14 mmol) and Et_2O (10 mL). A solution of pro-ligand **1** (298 mg, 1.14 mmol) in Et_2O (10 mL) was added dropwise in at −78 °C, and the mixture was allowed to warm to room temperature and stirred overnight. A large amount of white precipitate formed, which was separated off and recrystallized from CH_2Cl_2/THF (1:10), to give **4** as colorless crystals (0.30 g, 82%). A suitable crystal was selected for X-ray diffraction analysis. ^{1}H NMR (CD_2Cl_2, 300 MHz): δ 5.84 (s, 2H, pyrazole-*H*), 3.98 (t, $^3J = 4.7$, 4H, NCH$_2$C*H*$_2$-pyrazole), 2.76 (m br, 4H, NC*H*$_2$CH$_2$-pyrazole), 2.40 (s, 6H, pyrazole-C*H*$_3$), 2.17 (s, 6H, pyrazole-C*H*$_3$). ^{1}H NMR ($CDCl_3$, 300 MHz): δ 5.84 (s, 2H, pyrazole-*H*), 3.99 (t, $^3J = 3.8$, 4H, NCH$_2$C*H*$_2$-pyrazole), 3.15 (m br, 4H, NC*H*$_2$CH$_2$-pyrazole), 2.57 (s, 6H, pyrazole-C*H*$_3$), 2.09 (s, 6H, pyrazole-C*H*$_3$). ^{13}C{^{1}H} NMR (CD_2Cl_2, 300 MHz): δ149.26 (pyrazole-*C*CH$_3$), 139.29 (pyrazole-*C*CH$_3$), 105.96 (pyrazole-*C*H), 55.25 (N*C*H$_2$CH$_2$-pyrazole), 50.28 (NCH$_2$*C*H$_2$-pyrazole), 13.63 (pyrazole-*C*H$_3$), 10.69 (pyrazole-*C*H$_3$). *Anal.* Calc. for $C_{14}H_{22}ClMgN_5$ (320.12): C, 52.53; H, 6.93; N, 21.88. Found: C, 52.05; H, 6.82; N, 21.34%.

2.4. [Bis[2-(3,5-dimethyl-1-pyrazolyl)ethyl]amide]MgI (**5**)

The same procedure was used as for **4**, starting from **1** (528 mg, 2.02 mmol) and MeMgI (0.67 mL of a 3.0 M solution in Et_2O, 2.02 mmol), to give complex **5** as colorless crystals (0.64 g, 77%). A suitable crystal was selected for X-ray diffraction analysis. ^{1}H NMR (CD_2Cl_2, 300 MHz): δ 6.01 (s, 2H, pyrazole-*H*), 4.04 (m, 4H, NCH$_2$C*H*$_2$-pyrazole), 3.16 (m, 4H, NC*H*$_2$CH$_2$-pyrazole), 2.29 (s, 6H, pyrazole-C*H*$_3$), 2.03 (s, 6H, pyrazole-C*H*$_3$). ^{13}C{^{1}H} NMR (CD_2Cl_2, 300 MHz): δ149.34 (pyrazole-*C*CH$_3$), 143.05 (pyrazole-*C*CH$_3$), 107.03 (pyrazole-*C*H), 53.48 (N*C*H$_2$-CH$_2$-pyrazole), 48.35 (NCH$_2$*C*H$_2$-pyrazole), 13.14 (pyrazole-*C*H$_3$), 11.23 (pyrazole-*C*H$_3$). *Anal.* Calc. for $C_{14}H_{22}IMgN_5$ (411.57): C, 40.86; H, 5.39; N, 17.02. Found: C, 40.53; H, 5.42; N, 16.85%.

2.5. Solid state structure determination of complexes **3**–**5**

A suitable single crystal of **3**–**5** was mounted onto a glass fiber using the "oil-drop" method. Diffraction data were collected at 100 K using either an ENRAF NONIUS Kappa CCD diffractometer (complex **3**) or an APEXII Bruker-AXS CCD plate diffractometer (complexes **4** and **5**) with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). A combination of ω- and ϕ-scans was carried out to obtain at least a unique data set. Crystal structures were solved by means of the Patterson method, remaining atoms were located from difference Fourier synthesis, followed by full-matrix least-squares refinement

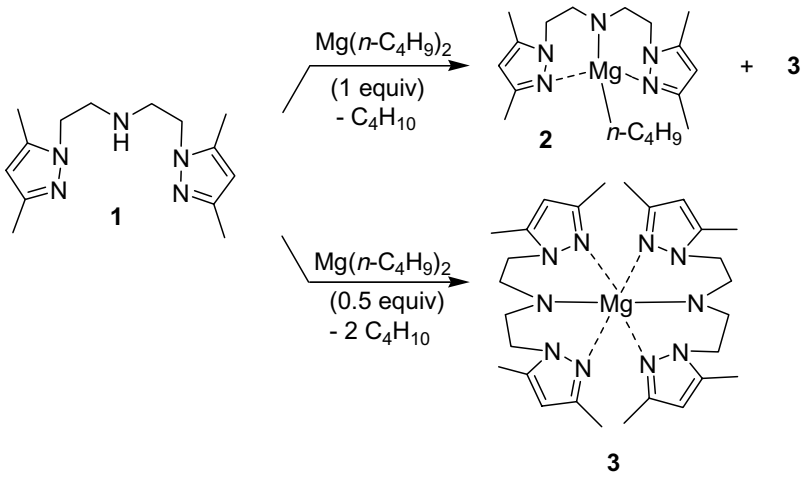
[a] Disordered solvent molecules have been removed using the SQUEEZE function; see Section 2.

based on F^2 (programs SHELXS-97 and SHELXL-97) [10]. Many hydrogen atoms could be found from the Fourier difference. Carbon-bound hydrogen atoms were placed at calculated positions and forced to ride on the attached carbon atom. The hydrogen atom contributions were calculated but not refined. All non-hydrogen atoms were refined with anisotropic displacement parameters. Crystals of compound **5** were found to contain lattice disordered solvent molecules, which could not be sufficiently modeled in the refinement cycles. These molecules were of no chemical/crystallographical importance and were therefore removed using the SQUEEZE procedure implemented in PLATON package. Crystal data and details of data collection and structure refinement are given in Table 1. Crystallographic data for **3**–**5** are also available as cif files (see Supplementary data).

2.6. Typical procedure for rac-lactide polymerization

To a 10 mL Schlenk flask equipped with a magnetic stirrer, and containing the catalyst (0.01 mmol) in toluene or THF (2.5 mL), was introduced the proper amount of *rac*-lactide rapidly. The polymerization was carried out for a given time period and the reaction was then quenched by addition of acidified methanol (3% HCl, 200 mL). The precipitated polymer was filtered, washed with methanol and dried overnight under vacuum at 60 °C.



3. Results and discussion

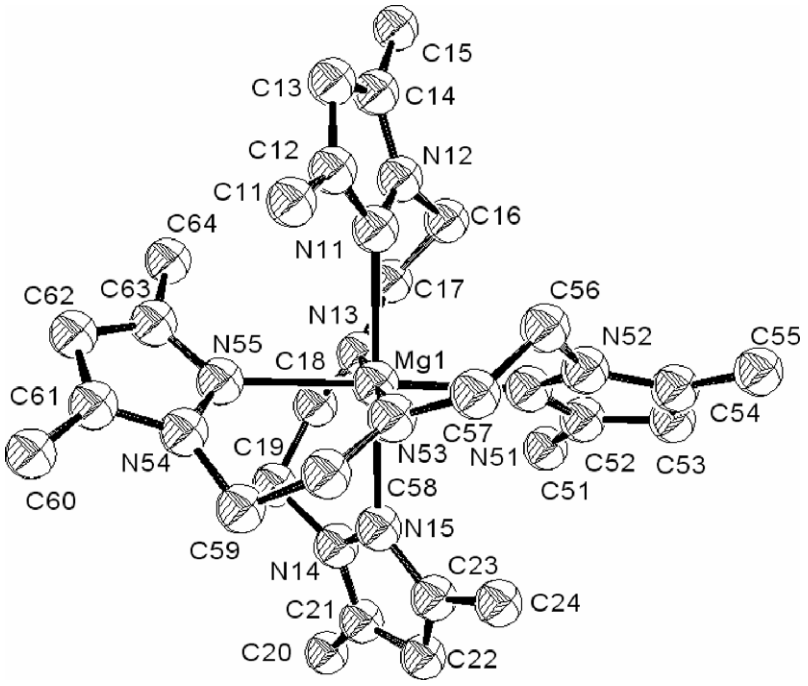
3.1. Syntheses of Mg–NNN complexes

Combination of Mg(nBu)$_2$ with 1 equiv. of pro-ligand **1** (LH) in toluene leads, by alkane elimination, to a mixture of the mono-ligand complex [L]Mg(nBu) (**2**) and bis-ligand complex [L]$_2$Mg (**3**), which could not be efficiently separated (Scheme 1).[1] Attempts to prepare selectively heteroleptic complex **2** by adjusting reaction parameters (temperature, concentration, slow addition of reagents) failed.[2] On the other hand, upon using 2 equiv. of

[1] Key NMR data for **2**: ^{1}H NMR (C_6D_6, 300 MHz): δ 5.52 (s, 2H, pyrazole-*H*), 4.05 (t, $^3J = 6.1$ Hz, 4H, NCH$_2$C*H*$_2$-pyrazole), 3.26 (t, $^3J = 6.1$ Hz, 4H, NC*H*$_2$CH$_2$-pyrazole), 2.28 (s, 6H, pyrazole-C*H*$_3$), 1.69 (s, 6H, pyrazole-C*H*$_3$), 1.16 (m, 7H, MgCH$_2$C*H*$_2$C*H*$_2$C*H*$_3$), 0.08 (m, 2H, MgC*H*$_2$CH$_2$CH$_2$CH$_3$).

[2] Alternative synthesis of **2** via treatment of chloro complex **4** with n BuLi led to complicated mixtures of products, including **2**, **3** and several other unidentified species, which could not be purified.

Scheme 1.



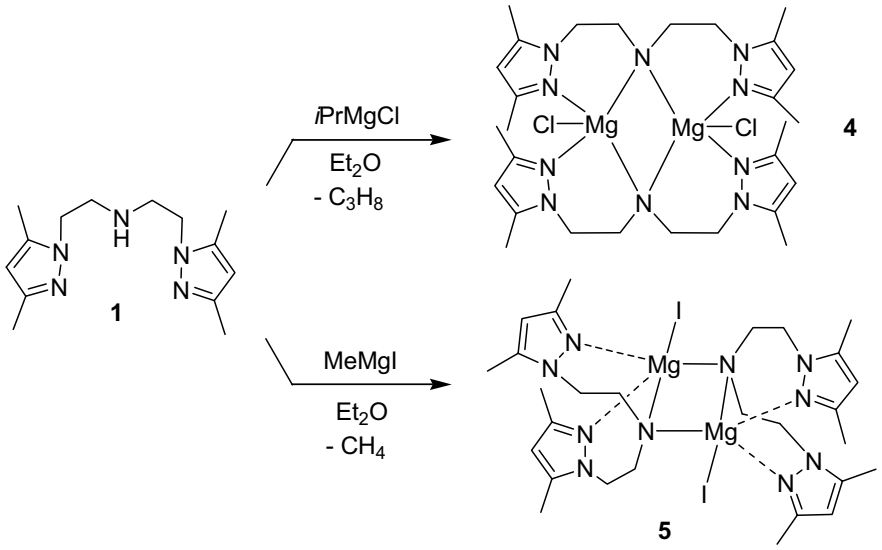


Fig. 1. Solid-state structure of **3** (ellipsoids drawn at the 50% probability; hydrogen atoms omitted for clarity). Selected bond lengths (Å) and angles (deg): Mg(1)–N(13), 2.093(2); Mg(1)–N(11), 2.2965(19); Mg(1)-N(15), 2.2911(19); Mg(1)–N(53), 2.095(2); Mg(1)–N(55), 2.3256(19); Mg(1)–N(51), 2.2897(19); N(13)–C(17), 1.443(3); N(12)–C(16), 1.470(3); N(11)–Mg(1)–N(15), 170.50(7); N(11)–Mg(1)–N(13), 85.36(7); N(13)–Mg(1)–N(15), 85.44(7); N(11)–Mg(1)–N(53), 95.19(7); N(15)–Mg(1)–N(53), 94.03(7); C(17)–N(13)–C(18), 107.17(16); C(17)–N(13)–Mg(1), 127.09(13); C(18)–N(13)–Mg(1), 125.74(14).

pro-ligand **1** (versus Mg), bis-ligand complex **3** was produced selectively and isolated in good yield (70%). Complex **3** was fully characterized by multinuclear NMR in solution and an X-ray diffraction analysis in the solid state (Scheme 1, Fig. 1). Similarly, the reaction of pro-ligand **1** with 1 equiv. of *i*PrMgCl or MeMgI at low temperature cleanly afforded the expected magnesium halide complexes [L]MgX (X = Cl, **4**; I, **5**) in high yields (Scheme 2), which contains either a small (Cl) or large (I) size halide atom for the purpose of comparison.

3.2. Solid-state structures of Mg–NNN complexes

Complexes **3**–**5** have been characterized by single-crystal X-ray diffraction studies. Crystallographic details are reported in Table 1, and the molecular structures as well as selected bond lengths and angles are given in Figs. 1–3. Complex **3** is monomeric in the solid state, while complexes **4** and **5** feature a dimeric structure. As anticipated, the pyrazolyl nitrogen atoms in **3** coordinate to the Mg center, which is six-coordinated showing a slightly dis-

Scheme 2.

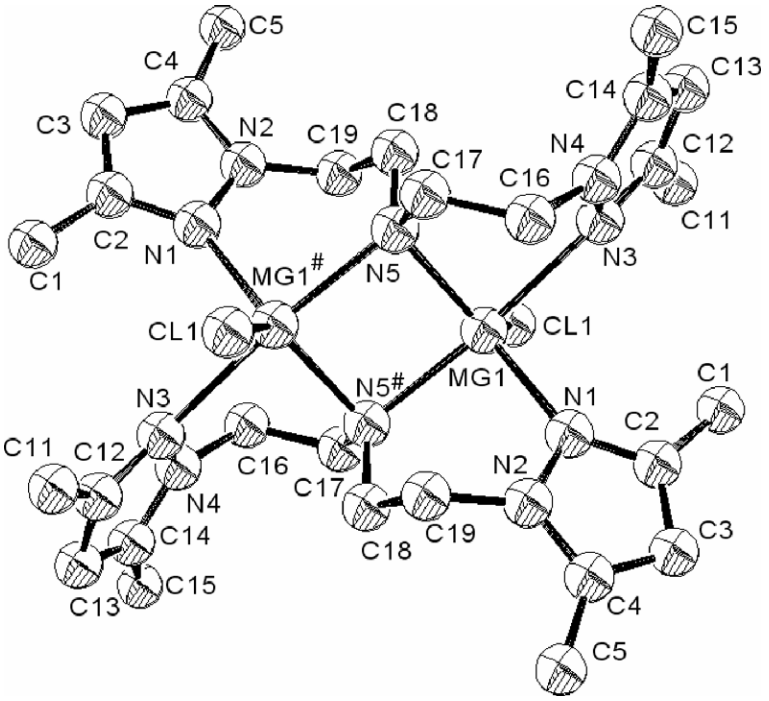

Fig. 2. Solid-state structure of **4** (ellipsoids drawn at the 50% probability; hydrogen atoms omitted for clarity). Selected bond lengths (Å) and angles (deg): Mg(1)–Cl(1), 2.3600(10); Mg(1)–N(5), 2.159(2); Mg(1)-N(3), 2.365(2); Mg(1)–N(5$^{\#}$), 2.205(2); Mg(1)–N(1), 2.161(2); C(16)–N(4), 1.454(3); C(17)–N(5), 1.484(3); Cl(1)–Mg(1)–N(1), 112.16(7); Cl(1)–Mg(1)–N(5), 121.48(7); N(1)–Mg(1)–N(5), 125.81(9); Mg(1)–N(5)–C(17), 114.28(15); Mg(1)–N(5)–C(18), 105.43(16); C(17)–N(5)–C(18), 109.8(2); N(5)–Mg(1)–N(5$^{\#}$), 87.18(9).

torted octahedral environment. The nitrogen atoms of a given ligand (i.e., N11–N13–N15 and N51–N53–N55) and the corresponding pyrazolyl rings are almost individually co-planar with the metal center, while the two pyrazolyl rings are perpendicular to each other. The Mg–N(amido) bond distances (average 2.094(2) Å) involving the sp^2-hybridized N bridge atoms in complex **3** (sum of angles around N(13) and N(53) = 359.96 and 360.00°) are ca. 0.2 Å shorter than the Mg–N(amino) bonds (average 2.3007(19) Å) involving the pyrazolyl N atoms. Those values fall in the usual ranges observed for Mg–N(amido) bonds (2.0040(1)–2.0314(1) Å) [2e] and related coordinating Mg–N bonds (2.2247(18) Å) [4a], respectively.

The solid state structures of complexes **4** and **5** feature two five-coordinated Mg centers, with μ-bonding via the N atom of the ligand bridge (Figs. 2 and 3). The overall structures of **4** and **5** are centrosymmetric around the Mg_2N_2 square plane and the two Mg–X bonds (X = Cl,

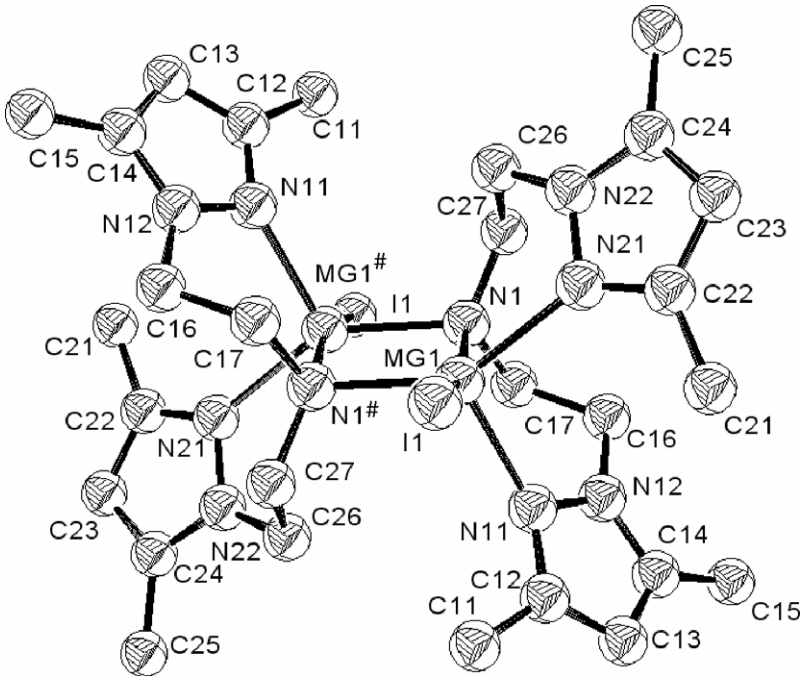

Fig. 3. Solid-state structure of **5** (ellipsoids drawn at the 50% probability; hydrogen atoms omitted for clarity). Selected bond lengths (Å) and angles (deg): Mg(1)–I(1), 2.9540(7); Mg(1)–N(1), 2.1477(18); Mg(1)-N(1#), 2.1153(18); Mg(1)–N(11), 2.1493(19); Mg(1)–N(21), 2.1659(19); N(1)–C(27), 1.477(3); N(22)–C(26), 1.460(3); I(1)–Mg(1)–N(1), 162.47(6); I(1)–Mg(1)–N(11), 103.01(5); I(1)–Mg(1)–N(21), 86.14(5); C(27)–N(1)–C(17), 108.56(15); C(27)–N(1)–Mg(1), 117.50(13); C(17)–N(1)–Mg(1), 110.71(12); Mg(1)–N(1)–Mg(1#), 93.43(7); N(1)–Mg(1)–N(1#), 86.57(7).

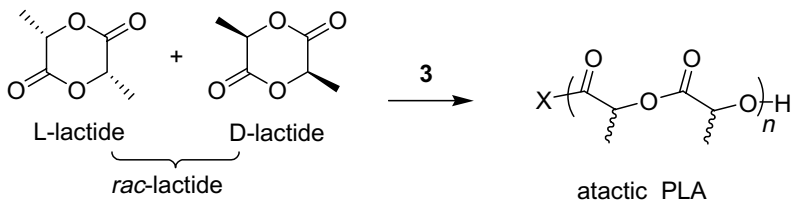
I) are therefore transoid. The Mg–N(μ-amido) bond distances (2.159(2)–2.205(2) Å) in **4** are similar to those in **5** (2.1153(18)–2.1477(18) Å), and are logically slightly longer than the Mg–N(amido) bonds (2.093(2)–2.095(2) Å) in **3**. The Mg–I bond distance of 2.9540(7) Å in **5** is much longer than that reported for $MgI_2(THF)_3$ (2.7458(14) Å) [2a]; on the other hand, the Mg–Cl bond distance (2.3600(10) Å) in **4** is very close to the value reported for other five-coordinated complex (2.3652(14) Å) [5c]. Interestingly, the coordination mode of the $[NNN]^-$ ligand is quite different in the chloride and iodide complexes; i.e., in **4**, each ligand wraps the two Mg metal centers, adopting a "spanned" coordination, while in **5**, each ligand wraps only one metal center. This provides an interesting example of ligand coordination selectivity via external control. Considering the relatively small size Cl atom and larger I atom [11], one may speculate that this difference arises from a steric control. Though, it is difficult to establish unambiguously whether those differences in ligation arise from intrinsic molecular features or from crystal packing forces.[3]

3.3. Polymerization catalysis



Complex **3** was evaluated in the polymerization of *rac*-lactide at room temperature (Scheme 3) [3f,3h,3t,5c]. Representative results are summarized in Table 2. Complex **3** proved significantly active both in toluene and THF solutions, with full conversion of 100 equiv. of monomer observed within 10 min. The produced polylactides (PLAs) had a relatively narrow molecular weight distribution ($M_w/M_n = 1.28$–1.34)[4] and the experimental (corrected) [12] number-average molecular weights were in close agreement with the calculated values, assuming that **3** acts a di-initiator; i.e., both amido groups of bis(ligand) complex **3** initiates a polymer chain.[5] This assumption is supported by the observation in the ^{1}H NMR spectrum of a precipitated PLA sample of resonances attributable to bis[2-(3,5-dimethyl-1-pyrazolyl)ethyl]amido end groups (see Supplementary data). Furthermore, the M_n values of the PLAs increased linearly with the [*rac*-LA]/[**3**] ratio (entries 2–4), indicating overall a well-controlled polymerization. However, the homo-decoupled ^{1}H NMR spectra of the methine regions of PLAs, both prepared in THF and toluene, showed an atactic microstructure.[6]

[3] NMR data for **4** and **5** are uninformative about the actual solution structures of these species; however, it is unlikely that the solution structures deviate much from those in the solid state.

[4] These polydispersity values are usual for amido [–$N(SiMe_3)_2$, –$N(SiHMe_2)_2$]-metal initiators, which are known to be less nucleophilic than other initiating groups such as alkoxides; see Ref. [5b].

[5] For a similar initiation process of lactide polymerization via one ligand of a bis(ligand) magnesium complex, see Ref. [4c].

[6] We speculate that the absence of stereocontrol may be attributed to the initiation of two polymer chains per Mg complex, which rejects the ligand at the termini of growing polymer chains and de facto enables effective chain-end control.

synthesize particular supramolecular systems with diverse architectures and dimensions for exploring new functional materials [18–20]. One of them consists of the ingenious use of compartmental ligands, which are organic molecules able to hold together two or more metal ions. The Schiff's bases derived from 2-formyl-4-methylphenol and 2,6-diformyl-4-methylphenol are among the most popular ligands belonging to this family [21,22].

In earlier literature reports [23,24], several N-substituted macropolycyclic systems were discussed (Chart 1). The macrobicyclic system II (Chart 1) contains two ether O atoms and two tertiary N atoms, the second compartment (N_2O_2) contains two tertiary N atoms and two phenolic O atoms, and the third compartment (N_2O_2) is composed of two phenolic O atoms and two imine N atoms. We have now introduced nitrogen donor atoms instead of the ether oxygens in the macrobicyclic system III. This work focuses on the synthesis of binuclear copper(II) complexes with dissimilar compartmental macrobicyclic ligands containing N-substituted "tet *a*" groups (Scheme 1). The resulting compounds have one hexadentate compartment (N_4O_2) comprised of four "tet *a*" nitrogens and two phenolic oxygens, and one tetradentate compartment (N_2O_2) comprised of two phenolic oxygens and two imine nitrogen. The special feature of this ligand is that the macrocyclic ring size can be varied, which allows more insight to recognize and further understand DNA cleavage.

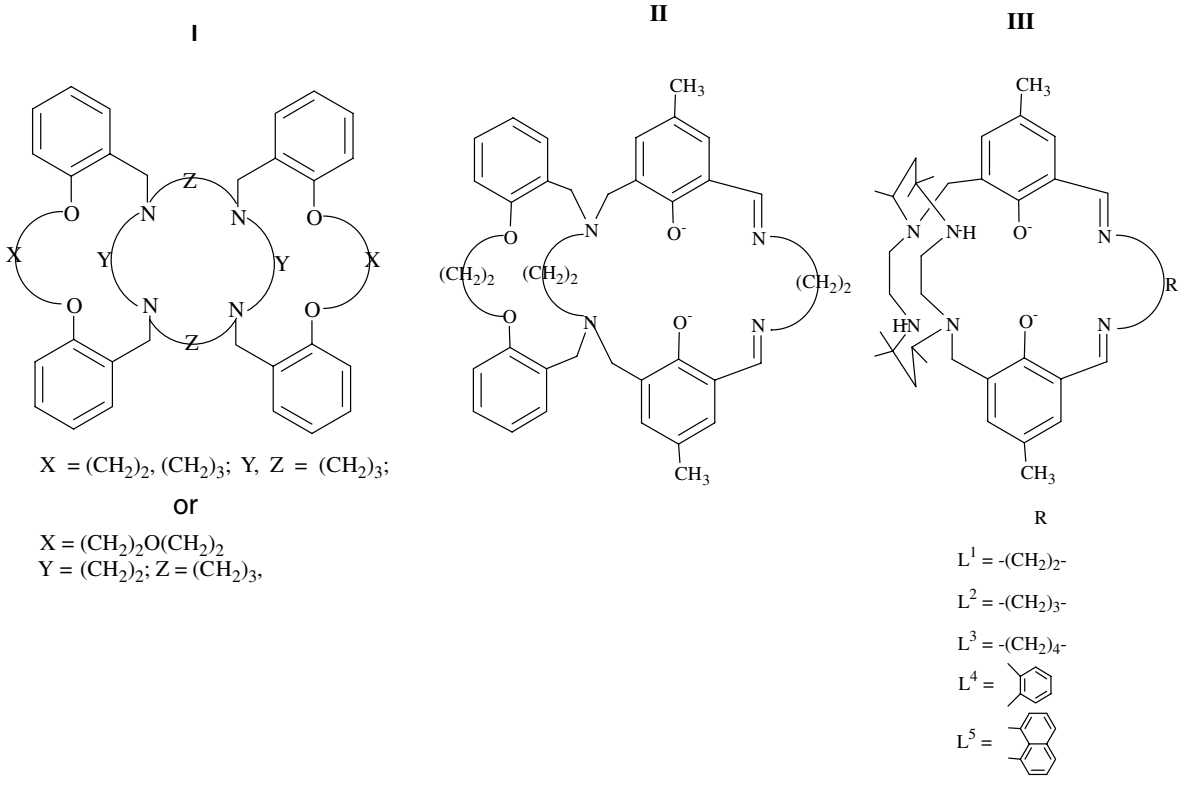
2. Experimental

2.1. Materials

5-methylsalicylaldehyde, 3-chloromethyl-5-methylsalicylaldehyde [25], 1,4,8,11-tetraazatricyclo[9.3.1.1^{4,8}]hexadecane [26,27] and 1,8[*N*,*N*′-bis{(3-formyl-2-hydroxy-5-methyl)benzyl}]-1,4,8,11-tetraaza-5,5,7,12,12,14-hexamethylcyclotetra decane – precursor compound (PC) [28] were prepared from the literature methods. Tetra(*n*-butyl)ammonium perchlorate (TBAP) was used as the supporting electrolyte.

Caution! TBAP is potentially explosive; hence care should be taken in handling the compound. All other solvents and reagents were of the highest grade available and were found to be sufficiently pure for use as supplied.

Elemental analysis was carried out on a Carlo Erba Model 1106 elemental analyzer. The copper content was analyzed using a Varian Spectra 200 atomic absorption spectrometer. Electronic spectral studies were carried out on a Hitachi 320 spectrophotometer in DMF. IR spectra were recorded on a Hitachi 270-50 spectrophotometer on KBr disks in the range of 400–4000 cm^{-1}. FAB mass spectra of the complexes were obtained on a JEOL SX 102/DA-6000; *m*-nitrobenzyl alcohol (NBA) was used as the matrix. The molar conductivity of a freshly prepared solution of the complexes in DMF was measured using an Elico Model SX80 conductivity bridge. Cyclic voltammograms were



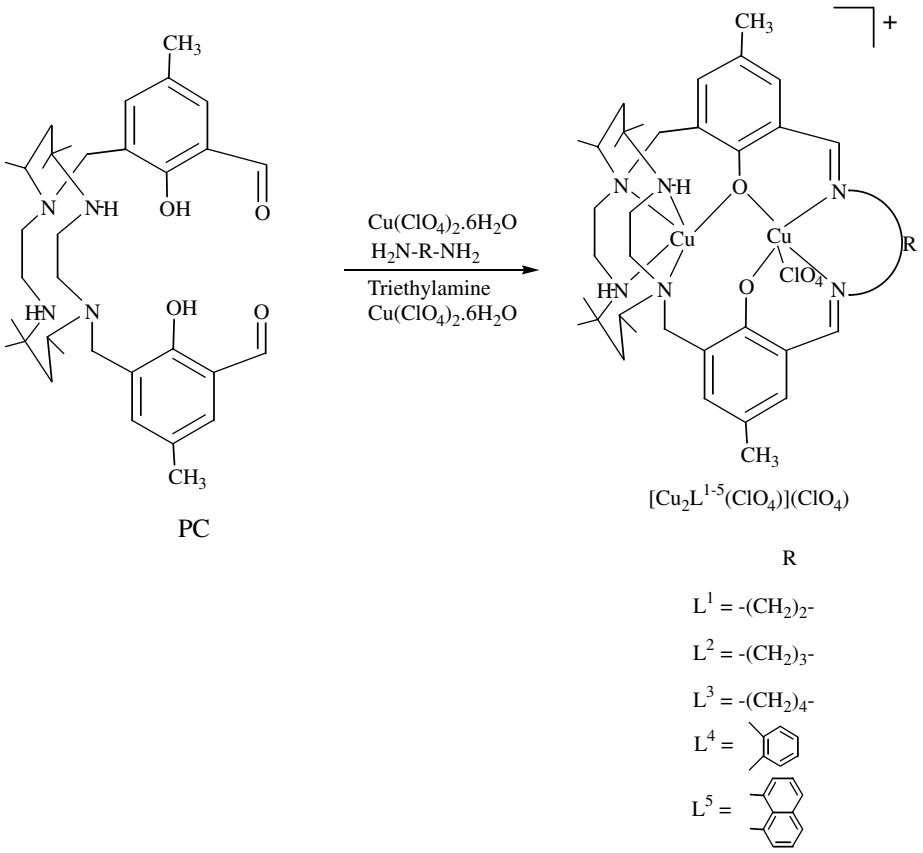


Chart 1.

obtained on a CHI600A electrochemical analyzer using a three-electrode cell in which a glassy carbon electrode was the working electrode, a saturated Ag/AgCl electrode was the reference electrode and a platinum wire was used as an auxiliary electrode under oxygen-free conditions. The concentration of the complexes was 10^{-3} M. Tetra(butyl)ammonium perchlorate (10^{-1} M) was used as the supporting electrolyte. A ferrocene/ferrocenium (1+) couple was used as an internal standard and $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^{+}) couple under the experimental conditions was 470 mV in DMF, and ΔE_p for Fc/Fc^{+} was 70 mV. The room-temperature magnetic moment was measured on a PAR vibrating sample magnetometer (Model-155). Variable-temperature magnetic studies were performed on a PAR model 155 vibrating sample magnetometer in the temperature range 77–300 K, and the instrument was calibrated using metallic nickel as supplied with the instrument. X-band ESR spectra of the Cu(II) complexes were recorded using DMF as a solvent at liquid-nitrogen temperature on a Varian EPR-E 112 spectrometer with diphenylpicrylhydrazine (DPPH) as the reference.

The catalytic oxidation of 3,5-di-tertiarybutylcatechol to the corresponding *o*-quinone was studied using 10^{-3} M of the copper(II) complexes in acetonitrile solution. The reaction was followed spectrophotometrically by choosing the strongest absorbance of the product, 3,5-di-tertiarybutyl-*o*-benzoquinone, around 390 nm and monitoring the increase in the absorbance at this wavelength over time intervals of 10 min. Initial rates (dc/dt) (<2% conversion of 3,5-ditertiarybutylcatechol) were determined by spectrophotometric determination of the released *o*-quinone. The initial reaction rates were also determined from the slope of the trace at 390 nm during the first 30 min of the reactions, when the absorption at 390 nm increases linearly. The kinetic activity of the metal complexes towards the hydrolysis of 4-nitrophenyl phosphate was examined in the presence of tetramethylammonium hydroxide in DMF solvent. Equimolar concentrations (10^{-3} M) of the complex and tetramethylammonium hydroxide were used. The concentration of 4-nitrophenyl phosphate was 10^{-1} M. The initial reaction rates were determined from the slope of the trace at 425 nm during the first 30 min of the reactions, when the absorption at 425 nm increases linearly.

The DNA cleavage was monitored by agarose gel electrophoresis on plasmid pBR 322 DNA. The tests were performed under aerobic conditions with H_2O_2 as a reducing agent. Each reaction mixture contained 1 μg of supercoiled pBR 322 DNA, 10^{-4} to 10^{-6} M of complex, 2 μl of DMSO (1%) and 5 μl of hydrogen peroxide (40 mmol l^{-1}). The reaction was incubated at 37 °C for 2 h. After incubation, 1 μl of loading buffer (0.25% bromophenol blue, 0.25% xylene cyanol, 30% glycerol in H_2O) was added to each tube and the mixed samples were loaded on 1% agarose

gel. The electrophoresis was carried out for 2 h at 50 V in TBE buffer (89 mM tris-borate, pH 8.3, 1 mmol l^{-1} EDTA). Gels were stained with ethidium bromide (1 μg ml^{-1}) for 30 min prior to being photographed under UV light.

2.2. Synthesis of the macrobicyclic binuclear copper(II) complexes

$[Cu_2L^1(ClO_4)](ClO_4)$: A methanolic solution of copper(II) perchlorate hexahydrate (0.63 g, 1.7 mmol) was added to a hot solution of PC (1.00 g, 1.7 mmol) in methanol, followed by the addition of 1,2-diaminoethane (0.11 g, 1.7 mmol) and triethylamine (0.47 g, 3.4 mmol) in methanol. After an hour, another 1 mol of copper(II) perchlorate (0.63 g, 1.7 mmol) was added and the solution was refluxed in a water bath for 24 h. The resulting solution was filtered whilst still hot and allowed to stand at room temperature. After slow evaporation of the solvent at 25 °C, an air-stable dark green compound was collected by filtration, which was washed with methanol and dried in vacuum.

Yield: 1.03 g (65%). *Anal.* Calc. for $C_{36}H_{54}N_6O_{10}Cl_2Cu_2$: C, 46.55; H, 5.81; N, 9.05; Cu, 13.69. Found: C, 46.58; H, 5.75; N, 9.02; Cu, 13.66%. 3. Results and discussion

A series of macrobicyclic binuclear copper(II) complexes were synthesized by Schiff base condensation of the pendant substituted ''tet *a*'' compound (PC) with various diamines in the presence of a copper(II) ion. The synthetic pathway of the complexes is shown in Scheme 1.

Molar conductivity measurements of the copper(II) complexes in DMF resulted in Λ_m values in the range 69–100 S cm^2 mol^{-1}, which indicate that the complexes are 1:1 electrolytes [29]. The positive ion FAB mass spectrum of the complex $[Cu_2L^1(ClO_4)](ClO_4)$ showed a peak at $m/z = 828$, corresponding to the $[Cu_2L^1(ClO_4)]^+$ ion, and the complex $[Cu_2L^2(ClO_4)](ClO_4)$ showed a peak at $m/z = 744$, corresponding to the $[Cu_2L^2–2ClO_4]^+$ ion. The positive ion FAB mass spectral data of the copper(II) complexes confirm the proposed formulation of the complexes.

3.1. Spectral studies

The IR spectra of the binuclear copper(II) complexes showed bands in the region 3220–3260 cm^{-1}, indicating the presence of NH groups, and a peak [30] in the range 1608–1642 cm^{-1} is due to *ν*(C=N). The peak at 1674 cm^{-1} due to *ν*(C=O) of the PC disappeared in the complexes and the formation of a new peak for *ν*(C=N) indicates effective Schiff's base condensation [31]. The binuclear copper(II) complexes showed two peaks near 1100 cm^{-1} and one peak near 620 cm^{-1}. Of the two peaks around 1100 cm^{-1} one is split, indicating the presence of a coordinated perchlorate ion, while the other peak does not show any splitting, indicating the presence of an uncoordinated perchlorate ion [32].

Electronic spectra of all the complexes were obtained in DMF medium. The copper(II) complexes exhibit an absorption maximum in the range 550–610 nm and a shoulder band in the range 755–785 nm, due to a d–d transition of the copper(II) ion [33,34], indicating that the geometry around the copper ion is square-pyramidal. On moving from the complexes of ligands L^1 to L^3, an increase in λ_{max} (red shift) of the d–d transition of the metal ion was observed, which indicates that the distortion of the coordi-

nation geometry around the metal ion increases [35]. A moderate intense band observed in the range 350–400 nm is due to a ligand to metal charge transfer transition and the strong band observed in the range 260–280 nm is due to an intraligand charge transfer transition. The intraligand charge transfer band may be due to the precursor compound which forms part of the ligand and shows a band at 270 nm. Apart from these, additional peaks are observed for the complexes of ligands L^4 to L^5 due to the presence of the aromatic ring in the imine nitrogen compartment.

3.2. Electrochemistry

The electrochemical properties of the copper(II) complexes reported in the present work were studied by cyclic voltammetry and the electrochemical data are summarized in Table 1. Cyclic voltammograms of the copper(II) complexes are shown in Fig. 1.

The binuclear copper(II) complexes of ligands L^1 to L^5 show two irreversible reduction waves in the potential ranges $E^1_{pc} = -0.70$ to -1.10 V and $E^2_{pc} = -0.98$ to -1.36 V. Controlled potential electrolysis indicates that each process corresponds to one electron transfer processes. The two redox processes are assigned as follows:

Table 1
Electrochemical data of the copper(II) complexes

Complexes	E^1_{pc} (V)	E^2_{pc} (V)
$[Cu_2L^1(ClO_4)](ClO_4)$	−0.95	−1.18
$[Cu_2L^2(ClO_4)](ClO_4)$	−0.81	−1.05
$[Cu_2L^3(ClO_4)](ClO_4)$	−0.70	−0.98
$[Cu_2L^4(ClO_4)](ClO_4)$	−1.10	−1.36
$[Cu_2L^5(ClO_4)](ClO_4)$	−1.02	−1.32

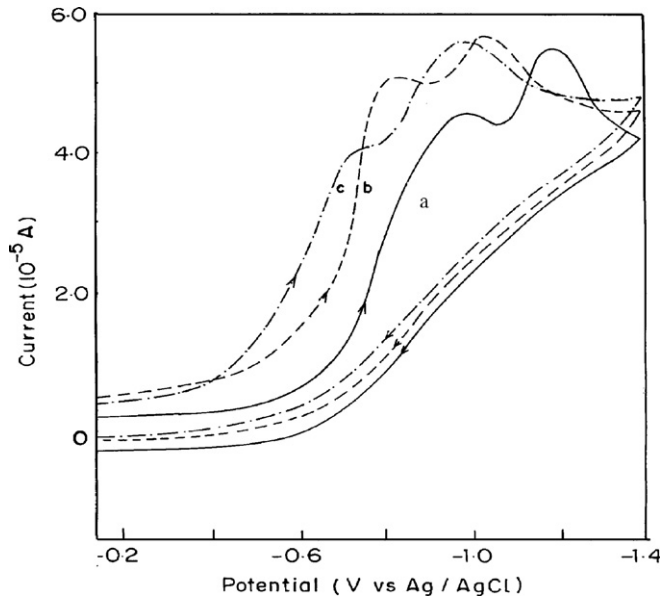

Fig. 1. Cyclic voltammograms of the copper(II) complexes: (a) $[Cu_2L^1(ClO_4)](ClO_4)$; (b) $[Cu_2L^2(ClO_4)](ClO_4)$ and (c) $[Cu_2L^3(ClO_4)](ClO_4)$.

$$Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{I} \rightarrow Cu^{I}Cu^{I}$$

The complexes of ligands L^1 to L^3, which contain an aliphatic diamine, have reduction potentials E^1_{pc} in the range -0.70 to -0.95 V, which is close to the reduction potential of the copper(II) ion in the complex [Cu(salen)] [36], and E^2_{pc} values in the range -0.98 to -1.18 V, which is close to the reduction potential of the complex $[Cu(tet\ a)]^{2+}$ ($E_{pc} = -1.08$ V) [37]. Thus, the first reduction potential (E^1_{pc} is ascribed to the metal ion in the imine nitrogen compartment (N_2O_2) while the second reduction potential (E^2_{pc}) is assigned to the metal ion in the "tet *a*" compartment (N_4O) site. On going from ligand L^1 to L^3, the first and second reduction potentials of the corresponding binuclear copper(II) complexes undergo an anodic shift, with $E^1_{pc} = -0.95$ to -0.70 V and $E^2_{pc} = -1.18$ to -0.98 V as the number of methylene groups increase. As the chain length of the imine compartment increases, the entire macrocyclic ring becomes more flexible, which causes easier reduction [38–40]. The same tendencies were observed for the complexes of ligands L^4 and L^5, which contain aromatic diamines. As the chelate ring size increases, the reduction potential shifts from $E^1_{pc} = -1.10$ to -1.02 V and $E^2_{pc} = -1.36$ to -1.32 V. The complexes with aromatic diimines are reduced at higher potentials than the complexes with aliphatic diimines. The reason for this may be due to the greater planarity and electronic properties that are associated with aromatic rings [41]. Whatever the precise interpretation of the bimetallic redox process, it is clear that their magnitude is subject to variation due to changes caused by the nature of the ligand, geometry and by the presence of the other metal [42].

3.3. Magnetic studies

The ESR spectra of the copper(II) complexes were recorded in frozen dilute DMF solution. The ESR spectra of the copper(II) complexes showed a broad band, centered around $g = 2.10$. The broad ESR spectra of the complexes indicate the presence of an antiferromagnetic interaction between the two copper(II) ions in the complexes [43]. Bimetallic copper(II) complexes containing two contiguous paramagnetic ions give magnetic moments of 1.50 to 1.59 B.M., which are less than the total spin-only values. Presumably the lowering of these magnetic moments is due to antiferromagnetic coupling by superexchange through the phenolic oxygen atoms [44]. To evaluate the singlet–triplet energy separation ($-2J$), variable temperature magnetic studies for the complexes $[Cu_2L^3(ClO_4)](ClO_4)$ and $[Cu_2L^4(ClO_4)](ClO_4)$ were performed in the temperature range 78–298 K, and the experimental magnetic susceptibility values were fitted to the modified Bleaney–Bowers equation [45].

$$\chi_{cu} = (Ng^2\beta^2)/(3kT)[3 + \exp(-2J/kT)]^{-1}(1-\rho) + 0.45(\rho/T) + N_\alpha$$

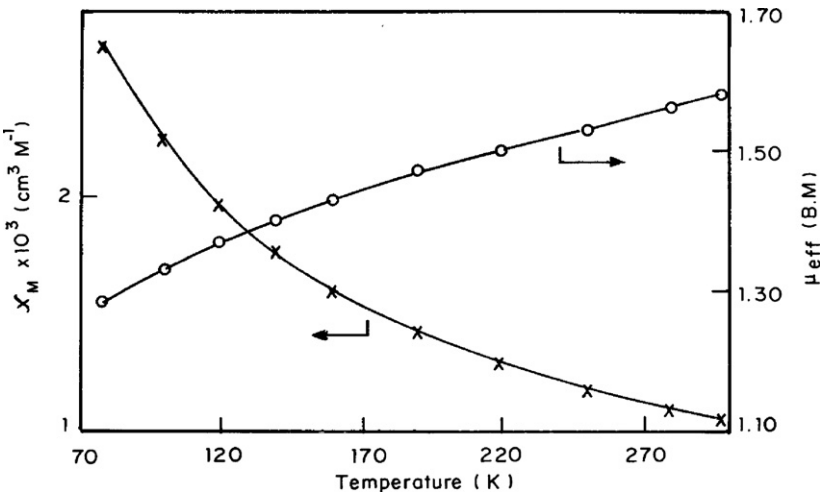

Fig. 2. Temperature dependence of the magnetic properties of the binuclear copper(II) complex $[Cu_2L^3(ClO_4)](ClO_4)$.

where χ_{cu} is the paramagnetic susceptibility per metal atom after correction for diamagnetism, N is Avogadro's number, β is the Boltzmann constant, g is the average gyromagnetic ratio and ρ is the percentage of monomeric impurities, $-2J$ is the singlet-triplet separation, N_α is the temperature independent paramagnetism (60×10^6 $cm^3\,M^{-1}$). A non-linear least-square fitting program was employed to calculate $-2J$, g and ρ. Plots of χ_{Cu} vs T and μ_{Cu} vs T for the complex $[Cu_2L^3(ClO_4)](ClO_4)$ is shown in Fig. 2. A significantly higher $-2J$ value is observed for the complex of L^4 when compared to the complex of L^3. The most probable reason for the strong antiferromagnetic exchange interaction in the L^4 complex may be the greater planarity due to the aromatic diamine ($-2J = 216\ cm^{-1}$) when compared with complex L^3 which contains an aliphatic diamine ($-2J = 144\ cm^{-1}$) and also due to ring size. Studies on magnetostructural correlations for phenoxo-bridged binuclear copper complexes show that the major factor that controls the exchange interactions is the Cu–O–Cu bridge angle; however other factors such as the degree of distortion from planarity and reduction in electron density on the copper atoms reduce the effective overlap of the metal orbitals with those of the bridging ligand, and hence reduce the antiferromagnetic spin exchange between the metal centers [46]. Ruiz et al. [47] found that for hydroxo- and alkoxobridged copper(II) complexes the displacement of the O–R bond in Cu_2O_2 framework also influences the extent of the exchange interaction. If there is out-of-plane displacement of R in O–R, then the antiferromagentic exchange interaction is found to be less. In our earlier complex $[Cu_2L^{1\ b}](ClO_4)_2$ (Chart 1), the observed exchange-interaction value was $-2J = 214\ cm^{-1}$. The possible reason for this low value compared to the present system may be the extent of the out-of-plane displacement of the phenyl ring from the O atom within the Cu_2O_2 framework and deviation from coplanarity as Ruiz et al., already reported [48].

3.4. Kinetic studies of hydrolysis of 4-nitrophenyl phosphate

The hydrolytic activity of the binuclear copper(II) complexes towards 4-nitrophenyl phosphate has been examined spectrophotometrically in DMF. An absorption band typical of the *p*-nitrophenolate ion appeared at 425 nm, the intensity of which increased with time. No significant hydrolysis of the test substrate was observed when the metal complex was absent. The initial rate values for catalytic hydrolysis of 4-nitrophenyl phosphate by the binuclear copper(II) complexes are given in Table 2. The initial rate values are in the range 1.8×10^{-5} to $2.1 \times 10^{-5}\ Ms^{-1}$.

The structural features and electrochemical properties are important factors in determining the catalytic activity of the complexes. Increasing the ring size, varying the donor atoms and changing from a mononuclear to a binuclear system all lead to significant differences in the catalytic properties of the complexes. It is seen that the reactivity of the complexes differs significantly as the size of the macrocycle increases. Comparison of the catalytic activities of the complexes of ligands L^1 and L^2 clearly evinces that the complex of ligand L^2 has enhanced catalytic activity. It is indeed noteworthy to say that the increase in flexibility due to the increase in the ring size of the macrocycle is the possible reason for the observed higher initial rate value of the complex of ligand L^2 because

Table 2
(a) Hydrolysis of 4-nitrophenylphosphate by the copper(II) complexes and (b) catecholase activity of the copper(II) complexes

Complexes	Hydrolysis of 4-nitrophenyl phosphate V_{in} (Ms^{-1})	Catecholase activity V_{in} (Ms^{-1})
$[Cu_2L^1(ClO_4)](ClO_4)$	1.8×10^{-5}	2.7×10^{-5}
$[Cu_2L^2(ClO_4)](ClO_4)$	2.0×10^{-5}	3.1×10^{-5}
$[Cu_2L^3(ClO_4)](ClO_4)$	2.1×10^{-5}	3.5×10^{-5}
$[Cu_2L^4(ClO_4)](ClO_4)$	1.7×10^{-5}	2.4×10^{-5}
$[Cu_2L^5(ClO_4)](ClO_4)$	1.9×10^{-5}	2.6×10^{-5}

the metal ion can more easily get reduced and bind with the substrate. The same was supported by both spectral and electrochemical studies. It was seen that if the reduction potential is too negative, the complex has a decreased catalytic activity due to a more difficult reduction to copper(I), and a more positive reduction potential of the complex gives a higher catalytic activity since the donor atoms stabilize copper(I) at the expense of copper(II). A macrocyclic ring size increase produces a distortion in the geometry around the metal ion, which enhances the accessibility of the metal ion for the bonding of phosphate and OH groups [49]. It can be stated that the planarity that is associated with the aromatic ring imparts a lower catalytic efficiency due to the rigidity of the systems, as observed in the case of the electrochemical reduction of the complexes.

3.5. Kinetic studies of oxidation of catechol (catecholase activity)

The copper(II) complexes were tested for catecholase activity. The amount of DTBQ formed with respect to time is given in Fig. 3. The rate values are also reported in Table 2. The initial rate values for the binuclear copper(II) complexes range from 2.7×10^{-5} to 3.5×10^{-5} Ms^{-1}. The initial rate values of the binuclear complexes are found to increase as the macrocyclic ring size increases. The increase in ring size makes the systems more flexible, which results in easier reduction of the metal ion. It is evidenced from the literature, [23,50] that the initial rate values for the more distorted complexes are higher than those of the less-distorted complexes.

3.6. DNA cleavage studies

The naturally occurring supercoiled DNA form (Form I), when nicked, gives rise to an open circular relaxed form (Form II) and upon further cleavage, results in the linear form (Form III). No cleavage occurs in the absence of

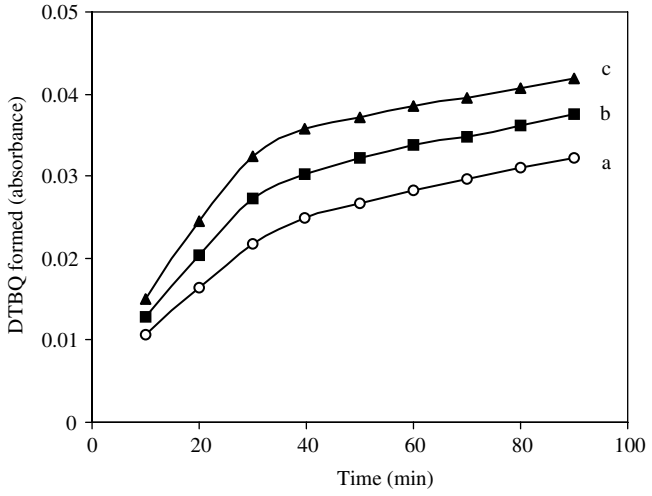

Fig. 3. Catecholase activity of the copper(II) complexes: (a) $[Cu_2L^1(ClO_4)](ClO_4)$; (b) $[Cu_2L^2(ClO_4)](ClO_4)$ and (c) $[Cu_2L^3(ClO_4)](ClO_4)$.

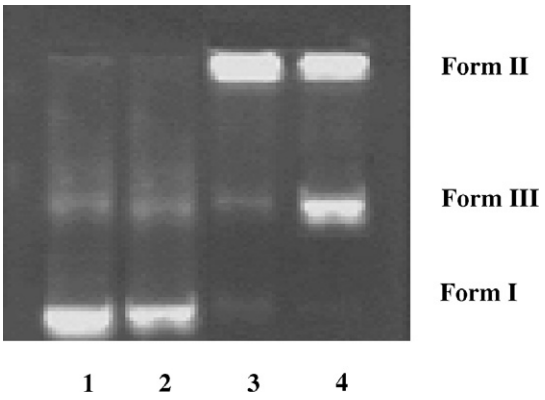

Fig. 4. Cleavage of pBR322 DNA by the copper(II) complexes: Lane 1. DNA control; Lane 2. DNA + H_2O_2; Lane 3. DNA + H_2O_2 + complex $[Cu_2L^1(ClO_4)](ClO_4)$ 20 μmol l^{-1}; Lane 4. DNA + H_2O_2 + complex $[Cu_2L^1(ClO_4)](ClO_4)$ 50 μmol l^{-1}.

H_2O_2 and complexes. As shown in Fig. 4, the complexes can effectively cleave duplex DNA in the presence of H_2O_2. The copper(II) complexes show a very remarkable cleaving ability at very low concentrations. In the presence of the copper(II) complex $[Cu_2L^1(ClO_4)](ClO_4)$ (20 μmol l^{-1}), plasmid DNA was nicked as is evident from the formation of Form II and the disappearance of the supercoiled form in the electrophoretic experiment (lanes 3 and 4). At a slightly higher concentration of then dinuclear complex $[Cu_2L^1(ClO_4)](ClO_4)$ (50 μmol l^{-1}), the cleavage is found to be much more efficient, as is seen from the formation of linear form (Form III) in lane 4. As the complex concentration increases, the probability of double strand scissions is enhanced once the DNA has undergone a single strand break. It is clear that the cleavage of pBR 322 DNA is highly dependent on the concentration of the complexes. The different DNA cleavage efficiency of the complexes was due to the different binding affinity of the complexes to DNA. It is thought that most cleavage cases are caused by copper ions reacting with H_2O_2 to produce the diffusible hydroxyl radical (·OH) or molecular oxygen, which may damage DNA through Fenton type chemistry [51,52].

4. Conclusion

Catechol oxidation and phosphate hydrolysis studies observed that the complex $[CuL^3(ClO_4)](ClO_4)$ has a higher catalytic activity than the other corresponding complexes. The ligand L^3 has a larger chelate ring size and is more flexible when compared to the other ligand systems, which leads to distortion in the geometry of the complex. This distorted complex has a higher catalytic activity than the other rigid complexes and the same was supported by spectral, magnetic and electrochemical studies.

Scheme 1. Structure of 1,8-naphthyridine and its derivatives.

isolated in which each nickel ion has a formal charge of +1.5. The magnetic properties of $[Ni_2(napy)_4Br_2]^+$ reveal that the ground spin-state of the system is in a quartet state. Recently, we have reported the synthesis and structural studies of linear hexa-cobalt and -nickel complexes, in which the metal chain is supported by four 1,8-naphthyridine-based $bpyany^{2-}$ ligands (Scheme 1) [18,19]. On the basis of the X-ray structure analysis, the $Co_6^{11+/12+}$ complexes have delocalized electronic structures whereas the $Ni_6^{11+/12+}$ complexes can be regarded as localized ones.

Here we describe the synthesis, crystal structures, and electrochemical and magnetic properties of novel linear hexanickel string complexes $[Ni_6(\mu_6\text{-bpmany})_4X_2]Cl$ (X = Cl (**1**); X = NCS (**2**)), and their singly oxidized products $[Ni_6(\mu_6\text{-bpmany})_4X_2](BF_4)_2$ (X = Cl (**3**); X = NCS (**4**)), where bpmany is the dianion of 2,7-bis(α-pyrimidylamino)-1,8-naphthyridine.

2. Results and discussion

2.1. Synthesis

The new ligand, 2,7-bis(α-pyrimidylamino)-1,8-naphthyridine (H_2bpmany), was prepared in good yield by palladium-catalyzed cross-coupling of 2-aminopyrimidine with 2,7-dichloro-1,8-naphthyridine, and characterized by ^{1}H NMR and FAB mass spectrometry. The reaction of H_2bpmany with $Ni(OAc)_2 \cdot 4H_2O$ in a 4:6 ratio in refluxing naphthalene, followed by addition of excess LiCl or NaSCN generates $[Ni_6(\mu_6\text{-bpmany})_4X_2]Cl$ (X = Cl (**1**); X = NCS (**2**)). The presence of the Cl^- counter anion in **2** may be explained by the presence of a small amount of Cl^- anion produced by dissociation of CH_2Cl_2 [20], which is the only source of chloride ion in the synthesis of this compound. In this reaction, the desired product was expected to be a hexanickel complex with six Ni^{2+} ions. However, the reaction gave a mixed valence species that has five Ni^{2+} ions and one Ni^+ ion. Based on the electrochemical data, as will be discussed later on, one of the redox potentials was observed at about 0.00 V vs. Ag/AgCl. This indicates that the form $[Ni_6(\mu_6\text{-bpmany})_4X_2]^{2+}$ is relatively easy to reduce to $[Ni_6(\mu_6\text{-bpmany})_4X_2]^+$. Under the reaction conditions, any reagents in an excess amount or even the solvent could be the source of reducing agent. Treatment of **1** or **2** with $[Cp_2Fe]BF_4$ in CH_2Cl_2 gives dark brown crystals of the singly oxidized complexes $[Ni_6(\mu_6\text{-bpmany})_4X_2](BF_4)_2$ (X = Cl (**3**); X = NCS (**4**)). It should be mentioned that complexes **1**–**4** can be prepared under air, and are found to be air-stable in the solid state. The IR active C≡N stretching vibration was observed at 2067 cm^{-1} for both **2** and **4**.

2.2. Structures

Complex **1** crystallizes in space group $C2/c$ and the structure consists of the hexanickel cation $[Ni_6(bpmany)_4Cl_2]^+$ and a Cl^- anion. Complex **2** crystallizes in space group $P4/n$ and the cation resides on an inversion center with 50% disorder of a spiral set of four $bpmany^{2-}$ ligands. The $[Ni_6(\mu_6\text{-}bpmany)_4]^{3+}$ cation in both complexes **1** and **2** is roughly in a D_4 symmetry and the linear Ni_6 unit is supported by four $bpmany^{2-}$ ligands in a spiral configuration (Figs. 1 and 2). Thus, the average bond lengths for complexes **1** and **2** were calculated by a D_4 symmetry (Table 2). In the hexanickel chain of compounds **1** and **2**, the terminal nickel ions (Ni(1) and Ni(6)) are square pyramidal whereas Ni(2)–Ni(5) are square planar. The redox active center should be Ni(3) and Ni(4) which gives a Ni_2^{3+} unit. The average Ni–Ni distances from outer to inner are 2.409(2), 2.289(2) and 2.221(2) Å for **1**, and 2.408(2), 2.304(2) and 2.218(2) Å for **2**. The average Ni–Cl bond distance of 2.307(3) Å in **1** is in the range of Ni–Cl bond lengths for the analogous complexes $[Ni_nL_4Cl_2]$ where L is an oligo-(α-pyridyl)amido ligand. The Ni–N_{pm} distance is 2.08(1) Å, which is longer by about 0.20 Å than Ni–N_{amido} and Ni–N_{napy} distances, suggesting that the terminal Ni^{II} ions are in a high-spin state and the internal ones in a low-spin state.

Table 2
Average bond distances (Å) and torsion angles (°) for complexes **1**, **2** and **4**

N_{napy}–Ni–Ni–N_{napy} torsion	13.79	13.15	15.32

The singly oxidized complex **4** crystallizes in the monoclinic space group $P2_1/c$ with $Z = 2$. The dication resides on an inversion center with 50% disorder of a spiral set of four $bpmany^{2-}$ ligands, and the positive charges are compensated by two BF_4^- ions (Fig. 3). The Ni–Ni distances of **4** from outer to inner are 2.404(1), 2.306(1) and

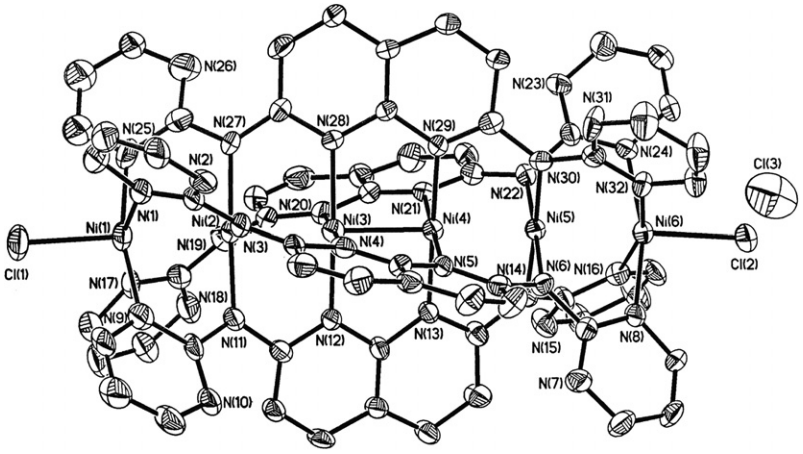

Fig. 1. ORTEP drawing of complex **1**. Thermal ellipsoids are drawn at the 30% probability level. Hydrogen atoms are omitted for clarity.

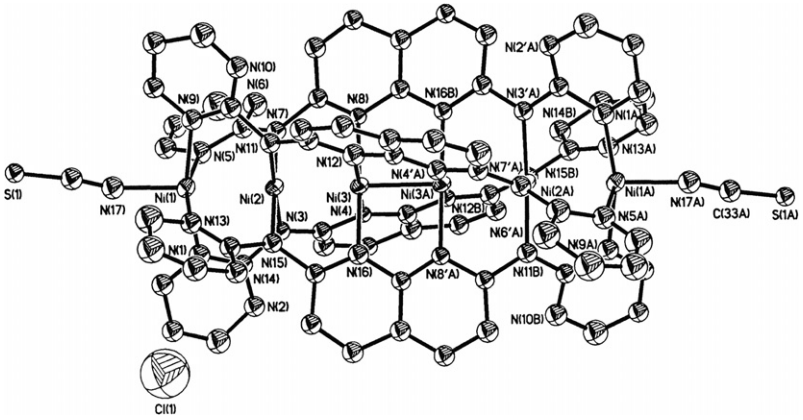

Fig. 2. ORTEP drawing of complex **2**. Thermal ellipsoids are drawn at the 30% probability level. Hydrogen atoms are omitted for clarity.

2.275(1) Å. Removal of one electron from **2** results in an increase in the central Ni–Ni distance from 2.218(2) to 2.275(1) Å and a decrease in the Ni–N_{napy} distance from 2.03(2) to 1.92(1) Å. This indicates that the electron is abstracted from the central Ni_2 unit. In the analoguous complex $[Ni_6(bpyany)_4(NCS)_2](PF_6)$ [19], a similar trend in the structural changes has also been observed when an electron was removed from the Ni_6 chain.

To get further insight on the structures of these complexes, EPR measurements have been performed. The X-band EPR spectra of frozen **1** and **2** are illustrated in Fig. 4, and show signals at $g_\perp = 2.34$ and $g_\parallel = 2.14$ for **1**, and $g_\perp = 2.31$ and $g_\parallel = 2.14$ for **2**, which are consistent with the expected spin-state of $S = 1/2$ in the central Ni_2^{3+} unit. In contrast, no EPR signals were observed for **3** and **4**, consistent with antiferromagnetic coupling of the unpaired electrons in the molecules.

To see if the symmetrical structure of the Ni_6^{11+} complexes persist in solution, the ^1H NMR spectrum of **2** was examined. For a symmetrical molecule, three peaks for the eight equivalent pyrimidyl groups and two peaks for the four equivalent naphthyridyl groups should be observed. As shown in Fig. 5, the spectrum consists of five signals at 72.66, 20.89, 18.81, 15.64 and 12.86 ppm corresponding to the $bpmany^{2-}$ protons, and is consistent with a D_4 symmetry for the $[Ni_6(\mu_6\text{-bpmany})_4(NCS)_2]^+$ core and paramagnetism of the complex.

As mentioned, the Ni_6^{n+} complexes can be considered as roughly D_4. The central Ni_2N_8 unit is practically half way between the eclipsed and staggered conformations. The mixed-valence $[Ni_2(napy)_4X_2]^+$ (X = halogen) cations have a spin state of $S = 3/2$. In contrast, the dinickel unit of **1** and **2** is in a spin-state of $S = 1/2$. A qualitative MO energy-level diagram for the central $Ni_6^{3+/4+}$ units of our complexes in a square planar coordination environment is shown in Scheme 2. This MO picture can be used to rationalize the observed magnetic properties which correspond to a system with one unpaired electron.

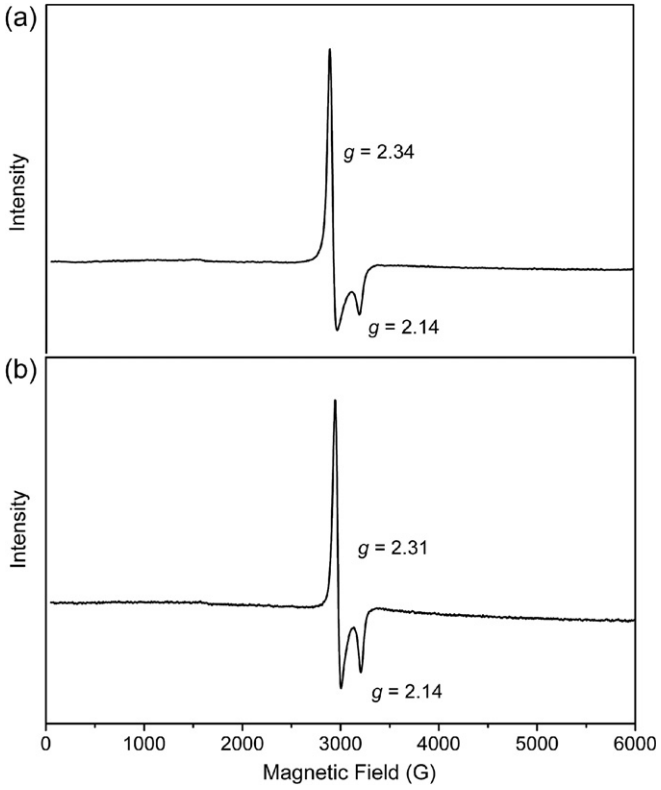

Fig. 4. X-band EPR spectrum of (a) **1** and (b) **2** taken in dichloromethane glass at 77 K.

2.3. Magnetic properties

The magnetic susceptibility of **1**–**4** were measured in the temperature range of 2–300 K. Compounds **1** and **2** exhibit similar magnetic properties. As an example, Fig. 6 shows the magnetic behavior of **2**. At 300 K the effective magnetic moments of 4.54 and 4.58 μ_B for **1** and **2**, respectively, are close to the spin-only value of 4.36 μ_B expected for a system with three spin states of $S = 1$, 1/2 and 1. The μ_{eff} values in the range 30–300 K decrease gradually with decreasing

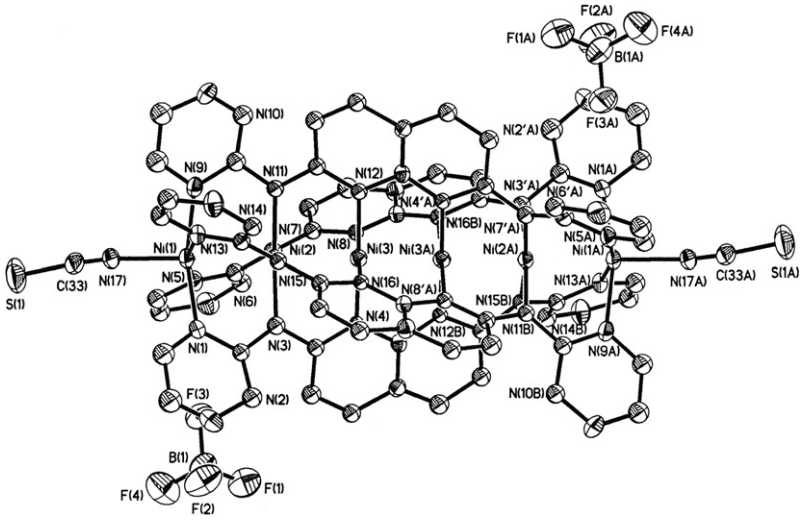

Fig. 3. ORTEP drawing of complex **4**. Thermal ellipsoids are drawn at the 30% probability level. Hydrogen atoms are omitted for clarity.

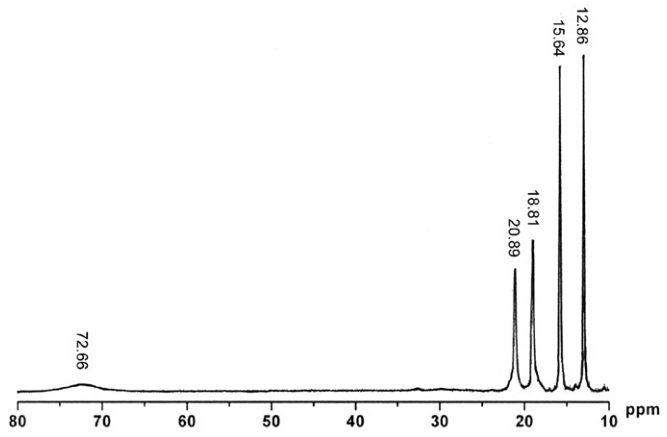

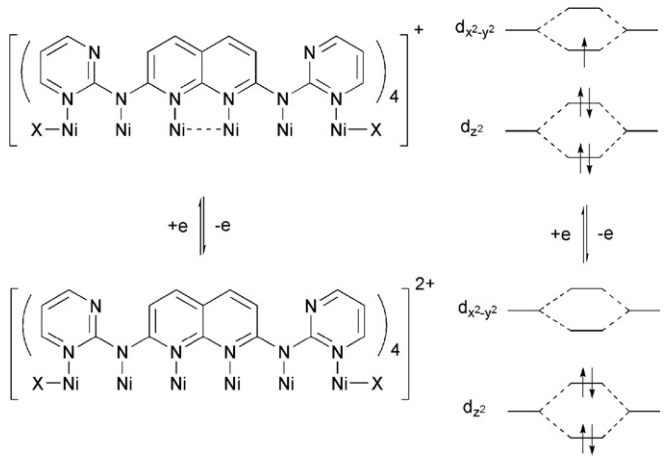

Fig. 5. ^{1}H NMR spectrum of **2** taken at 400 MHz in d_6-DMSO at room temperature.

Scheme 2. The energy level scheme for the central $Ni_2^{3+/4+}$ units in square planar coordination environments in the active electron approximation.

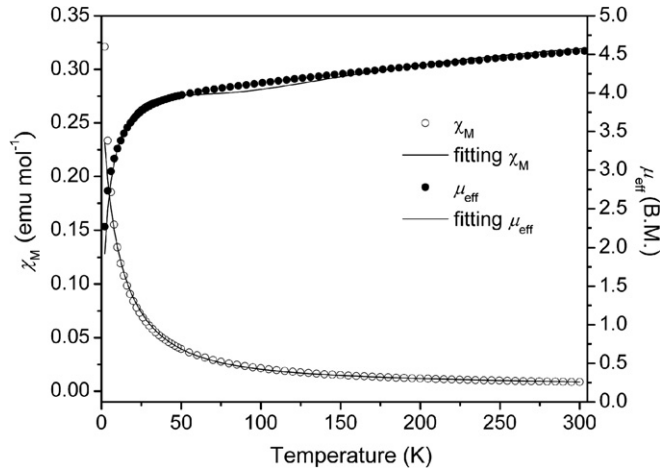

Fig. 6. The magnetic behavior for **2**: molar magnetic susceptibility χ_M (○) and effective magnetic moments μ_{eff} (●). The solid lines are the best-fit curves.

temperature and then decrease sharply to 2.26 and 1.77 μ_B for compounds **1** and **2** at 2 K. These data suggest antiferromagnetic interactions between the terminal Ni^{2+} ion and the central Ni_2^{3+} unit. Taking into account the structural data of this complex, the isotropic spin-exchange for Ni_6^{11+} complex can be given as

$$H = -2J(\widehat{S}_1 \cdot \widehat{S}_{34} + \widehat{S}_6 \cdot \widehat{S}_{34}) - 2J'\widehat{S}_1 \cdot \widehat{S}_6 \quad (1)$$

where J represents the coupling constant to between the terminal Ni^{2+} and central Ni_2^{3+}, and J' is the coupling constant between the two terminal Ni^{2+} ions. Assuming $J' = 0$, the Hamiltonian in Eq. (1) gives rise to five spin states corresponding to the total spin operator $\widehat{S}_T = \widehat{S}_{16} + \widehat{S}_{34}$, i.e., two doublets ($S_T = 1/2$), two quartets ($S_T = 3/2$) and one sextet ($S_T = 5/2$). The molar magnetic susceptibility expression shown in Eq. (2) was then obtained by substituting the energies given in the Heisenberg–Dirac–van Vleck equation [21]

$$\chi_M = \frac{Ng^2\beta^2}{4kT} \times \frac{10 + e^{J/kT} + e^{3J/kT} + 10e^{4J/kT} + 35e^{5J/kT}}{2 + e^{J/kT} + e^{3J/kT} + 2e^{4J/kT} + 3e^{5J/kT}} \quad (2)$$

When impurities are taken into account, χ_M with the Weiss constant is expressed by the following:

$$\chi_M = \frac{Ng^2\beta^2}{4k(T-\theta)} \times \frac{10 + e^{J/kT} + e^{3J/kT} + 10e^{4J/kT} + 35e^{5J/kT}}{2 + e^{J/kT} + e^{3J/kT} + 2e^{4J/kT} + 3e^{5J/kT}} \times (1-\rho) + \frac{2Ng^2\beta^2}{3kT} \times \rho + \chi_{TIP} \quad (3)$$

where N is Avogadro's number, g is the Landé factor, β is the Bohr magneton of the electron, k is the Boltzmann constant, θ is the Weiss constant and T is the temperature in Kelvin. Least-square fitting of the experimental data leads to $J = -46.64\ cm^{-1}$, $g = 2.37$, $\theta = -14.28$ K, $\rho = 0$ and TIP = 0 with a correlation coefficient of 0.9976 for **1** and $J = -47.27\ cm^{-1}$, $g = 2.34$, $\theta = -9.13$ K, $\rho = 0$ and TIP = 0 with a correlation coefficient of 0.9976 for **2**. The negative Weiss constants indicate the presence of a dominant antiferromagnetic exchange interaction between the spin carriers. The g values obtained by magnetic measurements are very close to the EPR results of 2.34 for **1** and 2.31 for **2**.

It should be mentioned that under the limiting conditions, Eq. (2) gives a limiting moment of 3.87 BM. Compounds **1** and **2** have magnetic moments of 2.26 and 1.77 BM at 2 K, which is below the limiting moment. Considering the antiferromagnetic interaction between terminal and central spin centers ($J = -46.64\ cm^{-1}$ and $-47.27\ cm^{-1}$ for **1** and **2**, respectively), the ground state should be a quartet state ($S = 3/2$). The theoretical value of μ_{eff} would be expected to be 3.87 BM at low temperatures. However, the relatively strong intermolecular interactions in **1** and **2** ($\theta = zJS(S+1)/3k = -14.28$ K and -9.13 K) should also be taken into account. Thus, the μ_{eff} values of **1** and **2** decrease significantly at low temperatures.

Such a spin-state structure for compounds **1** and **2** is similar to those in the heterotrinuclear $Ni^{II}Cu^{II}Ni^{II}$ species reported by Kahn [22] and Liao [23]. For example, in Kahn's complex, $\{[Ni(bapa)(H_2O)]_2Cu(pba)\}(ClO_4)_2$ where bapa = bis(3-aminopropyl) and pba = 1,3-propylenebis(oxamato), the two high local spins exhibit an antiferromagnetic interaction with the small local spin and the small central spin polarizing the two high terminal spins in a ferromagnetic-like fashion.

Based on the structural analysis, there are no Ni–Ni bonds in **3** and **4**. The inner Ni^{2+} ions lie in a square planar coordination, and are therefore diamagnetic. The terminal Ni^{2+} ions are in a high-spin state and in a square pyramidal geometry, and have two unpaired electrons each. Fig. 7 shows the molar magnetic susceptibility and effective magnetic moments with respect to absolute temperature (K) for **4**. At 300 K the effective magnetic moment of 4.08 μ_B is close to the expected value of 4.00 μ_B for two non-interacting $S = 1$ spin states. When the temperature is lowered the value steadily decreases and reaches 2.52 μ_B at 2 K. This behavior is indicative of two antiferromagnetically coupled high-spin Ni^{2+} ions in the terminal positions of the Ni_6^{12+} chain. Therefore, Eq. (4) can be used to fit the data for **3** and **4**:

$$\chi_M = \frac{Ng^2\beta^2}{k(T-\theta)} \times \frac{2e^{2J/kT} + 10e^{6J/kT}}{1 + 3e^{2J/kT} + 5e^{6J/kT}} \times (1-\rho) + \frac{2Ng^2\beta^2}{3kT} \times \rho + \chi_{TIP} \quad (4)$$

This equation is based on an isotropic interaction between two $S = 1$ centers with the spin Hamiltonian, $H = -2J\hat{S}_1 \cdot \hat{S}_6$, and taking into account paramagnetic $S = 1$ impurities. The symbol J is the coupling constant between two terminal Ni^{2+} ions and the other symbols have been defined above. Both Ni_6^{12+} complexes reveal weak antiferromagnetic coupling of ca. $-5\ cm^{-1}$ between two terminal Ni^{2+} ions, consistent with our previous reports on multinuclear nickel complexes [14].

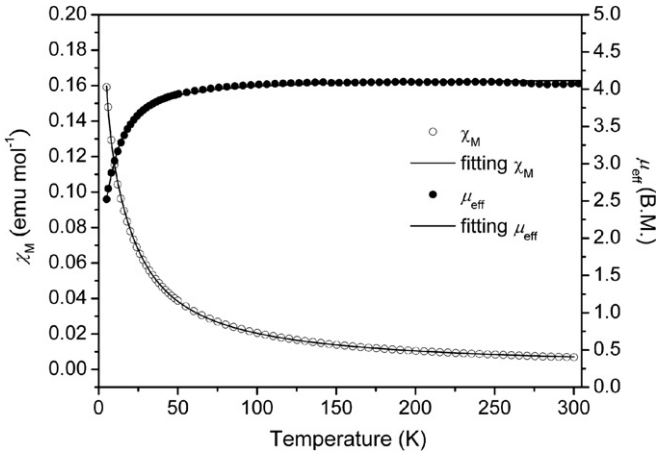

Fig. 7. The magnetic behavior for **4**: molar magnetic susceptibility χ_M (○) and effective magnetic moments μ_{eff} (●). The solid lines are the best-fit curves.

2.4. Electrochemical measurements

The electrochemical properties of **1** and **2** were investigated by cyclic voltammetry in CH_2Cl_2 solution with 0.1 M TBAP as the supporting electrolyte at a scan rate of 100 mV s^{-1}. The cyclic voltammograms exhibit three reversible redox waves at $E_{1/2}^{(1)} = +0.87$, $E_{1/2}^{(2)} = -0.02$ and $E_{1/2}^{(3)} = -0.46$ V for **1**, and $E_{1/2}^{(1)} = +0.96$, $E_{1/2}^{(2)} = -0.01$ and $E_{1/2}^{(3)} = -0.41$ V for **2**, where $E_{1/2}^{(1)}$, $E_{1/2}^{(2)}$ and $E_{1/2}^{(3)}$ correspond to Ni_6^{13+}/Ni_6^{12+}, Ni_6^{12+}/Ni_6^{11+} and Ni_6^{11+}/Ni_6^{10+}, respectively (Table 3). As an example, Fig. 8 shows the cyclic voltammogram of **1**. All of these electrochemical reactions involve one-electron processes, as judged by thin-layer spectroelectrochemical techniques. The oxidation observed at $E_{1/2}^{(2)} = -0.02$ can be assigned to one-electron abstraction from Ni_6^{11+} to generate the corresponding Ni_6^{12+} species. By comparison with the reported values of the analogous complexes $[Ni_6(\mu_6\text{-bpyany})_4X_2](PF_6)_2$ [19], the redox waves of **1** and **2** at $E_{1/2}^{(2)}$ and $E_{1/2}^{(3)}$ are anodically shifted in the range 210–270 mV. The significant difference in the redox potentials can be explained by the electron-withdrawing nature of the pyrimidyl groups of the supporting ligands. The smaller $E_{1/2}^{(2)}$ values for complexes **1** and **2** reflects their good stability under air. Thus, substitution of pyridyl with pyrimidyl groups allows us to fine-tune the redox properties of the complexes.

Spectroelectrochemistry was also conducted to confirm the oxidation states at a certain potential for **1** and **2**. Fig. 9 illustrates the absorption spectral changes of **2** at various applied potentials from −0.10 to +0.20 V in CH_2Cl_2 containing 0.1 M TBAP. As the applied potential

increases, the peaks at 380 and 660 nm decrease in their absorption intensity whereas those at 225, 275, 390 and 544 nm increase with clear isosbestic points. The resulting spectrum is identical with that of complex **4** obtained by chemical methods.

3. Conclusions

The novel linear hexanickel string complexes **1**–**4** have been synthesized, and their magnetic and electrochemical properties have been investigated. Complexes **1**, **2** and **4** were structurally characterized. In the structures, the linear Ni_6 chain is helically wrapped by four all-*syn* type $bpmany^{2-}$ ligands. The two terminal Ni^{2+} ions in all the complexes are in a high-spin state ($S = 1$). While complexes **3** and **4** (Ni_6^{12+}) do not show metal–metal bonding for the adjacent Ni^{2+} ions, the reduced forms **1** and **2** (Ni_6^{11+}) exhibit short Ni–Ni distances for the Ni_2 unit coordinated to the 1,8-naphthyridyl groups, indicating the presence of metal–metal interactions. The magnetic susceptibility and X-band EPR spectra agree well with the electronic structures in that one unpaired electron is located at the central Ni_2 unit for complexes **1** and **2**. These $Ni_6^{11+/12+}$ complexes may be used as molecular switches, since their electronic structure changes drastically upon oxidation or reduction. The STM (scanning tunneling microscopy) studies of complexes **2** and **4**, and the preparation of compounds containing $[M_6(bpmany)_4]^{n+}$ cores with other metal atoms or heterometal string complexes are underway in our laboratory.

4. Experimental

4.1. Materials

All Reagents were obtained from commercial suppliers and were used without further purification unless otherwise noted. The compounds 2-aminopyrimidine, naphthalene, *t*-BuONa and NaSCN were purchased from Acros. Ferrocenium tetrafluoroborate and tetra-*n*-butylammonium perchlortae (TBAP) were purchased from Aldrich. Nickel acetate tetrahydrate, sodium tetrafloroborate, 1,3-bis(diphenylphosphino)propane (dppp) and $Pd_2(dba)_3$ were from Strem Chemicals. 2,7-Dichloro-1,8-naphthyridine was prepared according to literature procedures and modifications thereof [24].

4.2. Physical measurements

^1H NMR measurements were performed with a Varian 400 spectrometer with $SiMe_4$ as the internal reference. Magnetic susceptibility measurements on polycrystalline samples were carried out with a Quantum Design MPMS-7 SQUID magnetometer in the range of 2–300 K and using an applied field of 2000 G. Experimental data were corrected for the diamagnetic contribution calculated from Pascal's constants. Frozen solution X-band EPR spectra were recorded using a Bruker EMX-10 spectrometer. Electronic absorption spectra were measured in CH_2Cl_2 with a Hitachi U-3010 spectrophotometer. Infrared spectra were recorded on a Nicolet Magan 550 FT-IR spectrophotometer using KBr pellets. Elemental analyses were performed on a Perkin–Elmer CHN 2400. FAB mass spectra were obtained with a Hewlett–Packard 5890A spectrophotometer operating in the positive ion detection mode. Electrochemistry was carried out on a CHI 750A potentiostat in CH_2Cl_2 with 0.1 M TBAP. The cyclic voltammograms were recorded with a home-made three-electrode cell equipped with a BAS glassy carbon (0.07 cm^2) disk as the working electrode, a platinum wire as the auxiliary electrode and a home-made Ag/AgCl (saturated) reference electrode. The reference electrode was separated from the bulk solution by a double junction filled with electrolyte solution. Potentials are reported vs. Ag/AgCl (saturated) and referenced to the ferrocene–ferrocenium ($[Cp_2Fe]/[Cp_2Fe]^+$) couple which occurs at $E_{1/2} = +0.54$ V vs. Ag/AgCl (saturated). The working electrode was polished with 0.03 μm aluminium on Buehler felt pads and was subjected to ultrasound for 1 min prior to each experiment. The reproducibility of individual potential values was within ±5 mV. Optical thin layer electrochemical (OTTLE) spectra were accomplished with the use of a 1 mm cuvette, a 100 mesh platinum gauze as the working electrode, a platinum wire as the auxiliary electrode and a Ag/AgCl (saturated) reference electrode.

4.3. Synthesis

4.3.1. 2,7-Bis(α-pyrimidylamino)-1,8-naphthyridine ($H_2bpmany$)

$H_2bpmany$ was synthesized following the reported procedure using palladium catalyst [25]. To a mixture of 2-aminopyrimidine (4.18 g, 44 mmol), 2,7-dichloro-1,8-naphthyridine (3.98 g, 20 mmol) and *t*-BuONa (4.22 g, 44 mmol) in toluene (250 mL) were added $Pd_2(dba)_3$

(549 mg, 0.6 mmol) and 1,3-bis(diphenylphosphino)propane (dppp, 495 mg, 1.2 mmol). This mixture was stirred at 160 °C under an argon atmosphere for 2 d. After cooling to room temperature, the mixture was filtered, and then washed with toluene (3 × 50 mL), H_2O (3 × 100 mL) and MeOH (3 × 50 mL). The product was obtained as pale yellow solid, which was dried under vacuum (5.62 g, 89%). ^1H NMR (400 MHz, d_6-DMSO, 298 K, TMS): δ 10.24 (s, 2H; N*H*), 8.61 (d, $J = 4.8$ Hz, 4H; Pym*H*), 8.38 (d, $J = 8.8$ Hz, 2H; 4,5-Napy*H*), 8.21 (d, $J = 8.8$ Hz, 2H; 3,6-Napy*H*), 7.03 (t, $J = 4.8$ Hz, 2H; Pym*H*); IR (KBr): 3067, 3229, 3415 cm^{-1} (NH); ESI-MS: *m*/*z* (%): 317.31 (100) $[M+H]^+$; Elemental *Anal*. Calc. for $C_{16}H_{12}N_8$: C, 60.75; H, 3.82; N, 35.42. Found: C, 60.84; H, 3.72; N, 35.28%.

4.3.2. $[Ni_6(\mu_6\text{-bpmany})_4Cl_2]Cl$ (1)

A 125 mL Erlenmeyer flask was charged with H_2bpmany (316 mg, 1 mmol), $Ni(OAc)_2 \cdot 4H_2O$ (373 mg, 1.5 mmol) and naphthalene (20 g). The mixture was heated at 200–210 °C for 3 h, and then excess LiCl (84 mg, 2 mmol) was carefully added, during which time the mixture became dark green. After the mixture was cooled to about 60 °C, *n*-hexane (3 × 100 mL) was used to remove naphthalene. The dry solid was extracted with CH_2Cl_2 and crystallized from CH_2Cl_2 and Et_2O to give dark green crystals (173 mg, 40%). UV/Vis (CH_2Cl_2): λ_{max} (ε) 232 (115,700), 278 (130,500), 382 (161,700), 656 nm (8500); FAB-MS: *m*/*z* (%): 1680.1 (40) $[M]^+$, 1644.9 (10) $[M-Cl]^+$, 1176.1 (100); Elemental *Anal*. Calc. for $C_{64}H_{40}Cl_3N_{32}Ni_6$: C, 44.80; H, 2.35; N, 26.12. Found: C, 44.54; H, 2.22; N, 26.28%.

4.3.3. $[Ni_6(\mu_6\text{-bpmany})_4(NCS)_2]Cl$ (2)

Complex **2** was synthesized using a procedure similar to that for **1** except that NaSCN (162 mg, 2 mmol) was used instead of LiCl. Dark green crystals were obtained by slow diffusion of Et_2O into the solution of product in CH_2Cl_2 and CH_3CN (124 mg, 28%). IR (KBr): 2067 cm^{-1} (C≡N); UV/Vis (CH_2Cl_2): λ_{max} (ε) 232 (136,800), 274 (137,800), 384 (172,400), 654 nm (9300); FAB-MS: *m*/*z* (%): 1724.4 (25) $[M]^+$, 1667.4 (20) $[M-NCS]^+$, 1176.5 (100); Elemental *Anal*. Calc. (%) for $C_{66}H_{40}ClN_{34}Ni_6S_2$: C, 45.01; H, 2.29; N, 27.04. Found: C, 44.74; H, 2.42; N, 26.49%.

4.3.4. $[Ni_6(\mu_6\text{-bpmany})_4Cl_2](BF_4)_2$ (3)

A 50 mL round-bottomed flask containing **1** (86 mg, 0.05 mmol) and ferrocenium tetrafluoroborate (14 mg, 0.05 mmol) was charged with CH_2Cl_2 (20 mL) at room temperature. The initially dark green solution became dark brown upon stirring. The solution was stirred for 1 h, and then Et_2O were added to precipitate a dark brown solid. The solid was extracted with CH_2Cl_2 and crystallized from MeCN and Et_2O to give dark brown crystals (26 mg, 28%). UV/Vis (CH_2Cl_2): λ_{max} (ε) 230 (124,700), 274 (136,400), 388 (164,300); FAB-MS: *m*/*z* (%): 1680.0 (50) $[M]^+$, 1645.0 (10) $[M-Cl]^+$, 1176.1 (100); Elemental *Anal*. Calc. for $C_{64}H_{40}B_2Cl_2F_8N_{32}Ni_6$: C, 41.46; H, 2.17; N, 24.18. Found: C, 42.04; H, 2.43; N, 24.71%.

4.3.5. $[Ni_6(\mu_6\text{-bpmany})_4(NCS)_2](BF_4)_2$ (4)

A procedure similar to that for complex **3** was employed. Dark brown crystals were obtained by slow diffusion of Et_2O into the solution of the product in CH_3CN (32 mg, 34%). IR (KBr): 2067 cm^{-1} (C≡N); UV/Vis (CH_2Cl_2): λ_{max} (ε) 232 (117,300), 274 (131,600), 388 (166,100); FAB-MS: *m*/*z* (%): 1723.9 (25) $[M]^+$, 1666.9 (15) $[M-NCS]^+$, 1176.0 (100); Elemental *Anal*. Calc. for $C_{66}H_{40}B_2F_8N_{34}Ni_6S_2$: C, 41.74; H, 2.12; N, 25.08. Found: C, 42.10; H, 2.41; N, 25.43%.

4.4. X-ray crystallographic determinations

Crystallographic information for **1**, **2** and **4** are summarized in Table 1. The chosen crystals were mounted on a glass fiber. X-ray diffraction data for **1**, **2** and **4** were collected at 150 K on a NONIUS Kappa CCD diffractometer installed with monochromatized Mo Kα radiation, $\lambda = 0.71073$ Å. Cell parameters were retrieved and refined using DENZO-SMN software on all observed reflections [26]. Data reduction was performed with the DENZO-SMN software [27]. An empirical absorption was based on the symmetry-equivalent reflections and absorption corrections were applied with the SORTAV program. All the structures were solved by using SHELXS-97 [28] and refined with SHELXL-97 [29] by full-matrix least squares on F^2 values. Hydrogen atoms were fixed at calculated positions and refined using a riding model.

2. Experimental

2.1. General procedures and measurements

All operations were carried out under dry oxygen-free nitrogen atmosphere using standard Schlenck techniques. Diethyl ether and tetrahydrofuran (THF) were distilled over Na-benzophenone ketyl prior to use. Dimethylformamide was dried with barium oxide and distilled under reduced pressure. Amines for the preparation of amine complexes were distilled immediately before use. Triphenylphosphine was recrystallized prior to use and checked by ^{31}P NMR and melting point for purity. All other reagents were commercial products and used without further purification. Elemental analyses (C, H, N) were performed on a LECO CHNS-932 analyzer (Module VTF-900 for O). Chlorine was eventually determined by gravimetry as AgCl and molybdenum by titration with lead(II) nitrate [21]. IR spectra (KBr dispersion, 4000–400 cm^{-1} range) were recorded on a Nicolet Impact 410 (Software Omnic for Windows) spectrometer. NMR spectra were recorded on a Varian Unity Inova-400 spectrometer (400 MHz for ^1H and 161.92 MHz for ^{31}P) at 20 °C. Chemical shifts are relative to TMS (^1H), or external 85% H_3PO_4 (^{31}P), with downfield values reported as positive. Coupling constants *J* are given in Hertz.

2.2. Preparation of the complexes

2.2.1. Preparation of $Mo_2O_3Cl_4(DMF)_4$

To a solution of 0.315 g (1.2 mmol) of PPh_3 in 8 ml of DMF, 0.690 g (2 mmol) of $MoO_2Cl_2(DMF)_2$, dissolved in 4 ml of DMF, was added. The mixture was stirred under nitrogen at room temperature for 10 h to obtain a dark brown solution, then 60 ml of diethyl ether was added. After stirring the mixture for 6 h the brown precipitate was filtered, washed with three 5-ml portions of diethyl ether and dried under vacuum.

$Mo_2O_3Cl_4(DMF)_4$: Yield 0.540 g (80.4%). IR(cm^{-1}): *ν*(Mo=O) 972(s); *ν*(Mo–O–Mo) 794(s). ^1H NMR (acetone-d_6): 8.09 ppm (s, 1H, H–CO); 3.01 ppm (s, 3H, $–CH_3$); 2.84 ppm (s, 3H, $–CH_3$). *Anal.* Calc. for $C_{12}H_{28}Mo_2Cl_4N_4O_7$: C, 21.38; H, 4.19; N, 8.31; Cl, 21.04; Mo, 28.47. Found: C, 21.86; H, 4.07; N, 8.35; Cl, 21.95; Mo, 28.61%.

2.2.2. Preparation of $Mo_2O_3Cl_4(L)_4$ (L = HMPA, $OPPh_3$, py, 1/2 bipy, 1/2 1,10-phen, 1/2 $dppmO_2$)

To a solution of 0.134 g (0.2 mmol) of [$Mo_2O_3Cl_4(DMF)_4$] in 30 ml of THF, a solution of 0.8 mmol of L in 5 ml THF was added with stirring. The resulting mixture was stirred for 5 min and the microcrystalline precipitate filtered, washed with three 3-ml portions of THF and dried under vacuum. The complexes were brownish for O-donor and reddish for N-donor ligands.

$Mo_2O_3Cl_4(HMPA)_4$: Yield 0.192 g (88%). IR(cm^{-1}): *ν*(Mo=O) 961(s); *ν*(Mo–O–Mo) 799(m). ^1H NMR (acetone-d_6): 2.86 ppm (d, $^3J_{H–P} = 9.9$ Hz, 18H, $–CH_3$). $^{31}P\{^1H\}$ NMR (acetone-d_6): 29 ppm. *Anal.* Calc. for $C_{72}H_{60}Mo_2Cl_4O_7P_4$: C, 26.24; H, 6.61; N, 15.30. Found: C, 26.01; H, 6.43; N, 14.98%.

$Mo_2O_3Cl_4(OPPh_3)_4$: Yield 0.236 g (79%). IR(cm^{-1}): *ν*(Mo=O) 974(s); *ν*(Mo–O–Mo) 768(m). ^1H NMR (acetone-d_6): 8.10–7.38 ppm (m, 15H, –Ph). $^{31}P\{^1H\}$ NMR (acetone-d_6): 40.2 ppm. *Anal.* Calc. for $C_{72}H_{60}Mo_2Cl_4O_7P_4$: C, 57.85; H, 4.05; Cl, 9.49; Mo, 12.84. Found: C, 58.05; H, 4.07; Cl, 9,80; Mo, 12.54%.

$Mo_2O_3Cl_4(py)_4$: Yield 0.144 g (81%). IR(cm^{-1}): *ν*(Mo=O) 953(s); *ν*(Mo–O–Mo) 764(m). ^1H NMR (acetone-d_6): 8.83 ppm (br s, 2H, for protons on C_2 and C_6); 8.35 ppm (t, $^3J_{H–H} = 6.5$ Hz, 1H, for proton on C_4); 7.92 ppm (br s, 2H, for protons on C_3 and C_5). *Anal.* Calc. for $C_{20}H_{20}Mo_2Cl_4N_4O_3$: C, 34.41; H, 2.89; N, 8.03. Found: C, 34.14; H, 2.93; N, 8.18%.

$Mo_2O_3Cl_4(bipy)_2$: Yield 0.118 g (85%). IR(cm^{-1}): *ν*(Mo=O) 955(s); *ν*(Mo–O–Mo) 770(s). ^1H NMR (acetone-d_6): 9.65–8.41 ppm (m, 8H, bipy). *Anal.* Calc. for $C_{20}H_{16}Mo_2Cl_4N_4O_3$: C, 34.61; H, 2.32; N, 8.07. Found: C, 34.59; H, 2.61; N, 8.11%.

$Mo_2O_3Cl_4$ (1,10-phen)$_2$: Yield 0.130 g (87%). IR(cm^{-1}): *ν*(Mo=O) 961(s); *ν*(Mo–O–Mo) 775(m). ^1H NMR (acetone-d_6): 9.23–8.15 ppm (tm,8H, phen). *Anal.* Calc. for $C_{24}H_{16}Mo_2Cl_4N_4O_3$: C, 38.84; H, 2.17; N, 7.55. Found: C, 38.75; H, 2.85; N, 7.17%.

$Mo_2O_3Cl_4(dppmO_2)_2$: Yield 0.188 g (78%). IR(cm^{-1}): *ν*(Mo=O) 975(s); *ν*(Mo–O–Mo) 785(m). ^1H NMR (acetone-d_6): 8.03–7.81 ppm (m, 8H, Ph); 7.60–7.32 ppm (m, 12H, Ph); 3.9 ppm (t, $^2J_{H–P} = 12.5$ Hz, 2H, $–CH_2$). $^{31}P\{^1H\}$ NMR (acetone-d_6): 39.9 ppm. *Anal.* Calc. for $C_{50}H_{44}Mo_2Cl_4O_7P_4$: C, 49.45; H, 3.65; Cl, 11.68; Mo, 15.80. Found: C, 49.78; H, 3.41; Cl, 11.05; Mo, 16.01%.

2.2.3. Preparation of $Mo_2O_3Cl_4(L)_4$ (L = isoquin, 4-pic)

To a solution of 0.134 g (0.2 mmol) of [$Mo_2O_3Cl_4(DMF)_4$] in 30 ml of THF, a solution of 0.8 mmol of L in 60 ml of diethyl ether was added with stirring. The resulting mixture was stirred for 15 min and the reddish precipitate filtered, washed with three 5-ml portions of diethyl ether and dried under vacuum.

$Mo_2O_3Cl_4(isoquin)_2$: Yield 0.164 g (91%). IR(cm^{-1}): *ν*(Mo=O) 947(s); *ν*(Mo–O–Mo) 800(m). ^1H NMR (acetone-d_6): 9.61 ppm (s, 1H, for protons on C_1); 8.62–8.21 ppm (qd, $^3J_{H–H} = 7.9$ Hz, 4H, for protons on C_3, C_4, C_5 and C_8); 8.16–7.92 ppm (dt, $^3J_{H–H} = 7.9$ Hz, 2H, for protons on C_6 and C_7). *Anal.* Calc. for $C_{36}H_{28}Mo_2Cl_4N_4O_3$: C, 48.13; H, 3.14; N, 6.24. Found: C, 47.98; H, 2.96; N, 6.51%.

$Mo_2O_3Cl_4(4\text{-pic})_2$: Yield 0.140 g (93%). IR(cm^{-1}): *ν*(Mo=O) 935(s); *ν*(Mo–O–Mo) 795(m). ^1H NMR (acetone-d_6): 8.65 ppm (d, $^3J_{H–H} = 6.5$ Hz, 2H, for protons on C_2 and C_6); 7.84 ppm (d, $^3J_{H–H} = 6.5$ Hz, 2H, for protons on C_3 and C_5); 2.65 ppm (s, 3H, $–CH_3$). *Anal.* Calc. for $C_{24}H_{28}Mo_2Cl_4N_4O_3$: C, 38.22; H, 3.74; N, 7.43. Found: C, 38.51; H, 3.84; N, 7.63%.

2.2.4. Formation of $Mo_2O_4Cl_2(L)_4$ (L = DMF, 1/2 bipy)

Single crystals of $Mo_2O_4Cl_2(DMF)_4$ and $Mo_2O_4Cl_2(bipy)_2$ were grown by slow diffusion of diethyl ether, and a solution of 0.156 g (1 mmol) of bipy in 20 ml of diethyl ether, respectively, on a solution containing 0.345 g (1 mmol) of $MoO_2Cl_2(DMF)_2$ and 0.158 g (0.6 mmol) of PPh_3 in 4 ml of DMF.

2.3. Crystal-structure determinations

Crystal data for the complexes $Mo_2O_4Cl_2(DMF)_4$ and $Mo_2O_4Cl_2(bipy)_2$ were collected using a KappaCCD diffractometer with graphite-monochromated Mo Kα radiation. Hydrogen atoms positions were located from difference Fourier maps. Both structures were solved using OpenMoleN 2.2. Table 1 provides crystallographic details for these compounds.

Table 1

3. Results and discussion

3.1. Synthesis and characterization of the dinuclear (μ-oxo)oxomolybdenum(V) chlorocomplexes

The complexes of Mo(V), containing the Mo_2O_3 unit, that have been structurally characterized possess one Mo–O–Mo bridge and two terminal oxygen atoms in either *cis* or *trans* configuration with respect to the Mo centers. They are usually prepared via reduction of the corresponding dioxomolybdenum(VI) compounds with P oxo-acceptors followed by comproportion and, more rarely, by substitution in other Mo(V) species [22] and oxidation of compounds with molybdenum in lower oxidation states [23].

As part of our studies [24,25] on molybdenum complexes in oxotransfer reactions, we have examined the behavior of several addition compounds of MoO_2Cl_2 with common phosphines and phosphites in several solvents.

Phosphites, such as $P(OBu)_3$ and $P(OPh)_3$, were thought to be superior to phosphines for reduction due to the fact that the resulting phosphates are considerably less basic than the corresponding phosphine oxides, and so they were initially investigated. As expected, the formation of dinuclear (μ-oxo)oxomolybdenum(V) complexes was observed. However, we were unable to obtain pure products in a wide range of conditions. A similar result was obtained in most cases when using PBu_3 and PPh_3.

However, we found that $Mo_2O_3Cl_4(DMF)_4$ could be prepared, in a pure form and in high yield, by reacting $MoO_2Cl_2(DMF)_2$ with PPh_3 in DMF as solvent. This compound was always obtained whenever the ratio $PPh_3/MoO_2Cl_2(DMF)_2$ was 0.5 or superior and the reactions were carried out at room temperature. This is consistent with the well known fact that, in absence of serious steric restrictions, oxomolybdenum(IV) and dioxomolybdenum(VI) species have a strong tendency to associate leading to stable comproportion products of oxomolybdenum(V), which are considerably more resistant to reduction [26]. As could be expected, the use of pure MoO_2Cl_2 instead of $MoO_2Cl_2(DMF)_2$ gave rise to similar results. However, the readily available air stable $MoO_2Cl_2(DMF)_2$ complex [24] is more appropriate for this synthesis by cost and resistance to hydrolysis.

When the reduction was performed in THF the originally green solution changed to brown and the composition of the isolated solid was consistent with a mixture of $Mo_2O_3Cl_4(OPPh_3)_4$ and $Mo_2O_3Cl_4(DMF)_4$ complexes. An excess of additional $OPPh_3$ was required to avoid the formation of the DMF adduct.

Taking into account the easy formation of $Mo_2O_3Cl_4(DMF)_4$, we investigated the possibility of using it as starting material for the preparation of other addition

compounds of $Mo_2O_3Cl_4$, having in mind the limitations derived from the basicity of the amide.

In this way we were able to prepare in good yield a number of $Mo_2O_3Cl_4$ derivatives with phosphine oxides and aromatic amines by mixing solutions of $Mo_2O_3Cl_4(DMF)_4$ and the corresponding ligand in THF. However, it should be noted, that the yield obtained for the isoquinoline and 4-picoline derivatives could be significantly improved by using diethyl ether.

The analytical data (C, H, N, Cl, Mo) for the products were in agreement with those expected for dinuclear (μ-oxo)oxomolybdenum(V) chlorocomplexes.

Not surprisingly, tertiary aliphatic amines afforded ill-defined products, even operating in strictly anhydrous conditions. This fact had been previously observed in substitution reactions on $MoO_2Cl_2(DMF)_2$ and in the catalytic deoxigenation of *N*-oxides [25].

As could be expected, sulfoxides which are also usually able to displace DMF from the coordination sphere of molybdenum, led to slow re-oxidation of $\{Mo_2O_3\}^{4+}$ to $\{MoO_2\}^{2+}$ species. Thus, solutions of $Mo_2O_3Cl_4(DMF)_4$ slowly decolorized when treated with sulfoxides at room temperature.

The compounds here reported are insoluble in hexane and diethyl ether; moderately soluble in THF, acetone and acetonitrile, solvents from which they could be recovered; and very soluble in DMF and DMSO, usually with reaction. They can be stored for months, at room temperature and in a dry atmosphere, without noticeable decomposition.

No relevant features are observed in the IR spectra of these compounds. They are characterized by one strong band in the region 930–980 cm^{-1} that has been assigned to ν(Mo=O) [27], and another band in the region 750–810 cm^{-1} similarly assigned to ν(Mo–O–Mo) in the $\{Mo_2O_3\}^{4+}$ core [5]. The position of the band ν(Mo=O) seems to be sensitive to the nature of the coordinated ligands. As could be expected, the value for ν(Mo=O) appears at lower wavelength for oxygen- than for nitrogen-coordinated ligands. This behavior is similar to that observed in several dioxomolybdenum(VI) complexes [19,20].

With regard to ^1H and ^{31}P NMR spectra of these complexes, the characteristic signals for the free ligands are shifted, as usual, to lower fields upon coordination. It should be noted that the ^{31}P NMR spectra for $Mo_2O_3Cl_4(dppmO_2)_2$ shows only one signal at 39.9 ppm for the coordinated ligand, a similar position to that found in $MoO_2Br_2(dppmO_2)$ [19].

3.2. Formation of the dinuclear bis (μ-oxo)oxomolybdenum(V) chlorocomplexes

To the best of our knowledge there are no reports on rational syntheses for this kind of molecular complexes. However, Mitchell postulated the formation of several Mo(V) oxochlorocomplexes depending on the extent of the hydrolysis of $MoCl_5$ during the synthetic procedure [27].

This fact prompted us to attempt the preparation of dinuclear bis(μ-oxo)oxomolybdenum(V) species from $Mo_2O_3Cl_4(L)_4$ by adding controlled amounts of water to the dinuclear bis(μ-oxo)oxomolybdenum(V) chlorocomplexes. However, we are unable to obtain the desired products.

Then, we also tried to remove one chlorine atom from $MoO_2Cl_2(DMF)_2$ using metals, namely copper, silver and magnesium. In all runs we observed reduction, but were unable to get well defined products, except in the case of copper with $MoO_2Cl_2(DMF)_2$ in DMSO at 70 °C, where we isolated the previously reported, yet here undesired, $(Cu_4Cl_6O)(DMSO)_4$ [28].

However, while attempting to grow crystals of $Mo_2O_3Cl_4(DMF)_4$ a mixture of compounds was obtained. This mixture consisted of a brown microcrystalline precipitate of the starting product along with pale yellow crystals, corresponding to $Mo_2O_4Cl_2(DMF)_4$. Similar procedure with $Mo_2O_3Cl_4(bipy)_2$ yielded red crystals of $Mo_2O_4Cl_2(bipy)_2$, which crystallized as the dimethylformamide monosolvate. These compounds are presumably formed by hydrolysis of the parent $Mo_2O_3Cl_4(L)_4$ compounds with traces of water.

3.3. Molecular structure of dinuclear bis (μ-oxo)oxomolybdenum(V) chlorocomplexes

The molecular structure for $Mo_2O_4Cl_2(DMF)_4$ and $Mo_2O_4Cl_2(bipy)_2$ was determined from single-crystal X-ray diffraction analysis. The molecular structure of $Mo_2O_4Cl_2(DMF)_4$ (CC enantiomer) is shown in Fig. 1, and that of $Mo_2O_4Cl_2(bipy)_2$ (CC enantiomer) in Fig. 2. Selected bond lengths and angles are listed in Table 2.

The compounds are dinuclear species, with the two molybdenum atoms linked through two μ-oxo bridges and a Mo–Mo interaction. The geometry around each

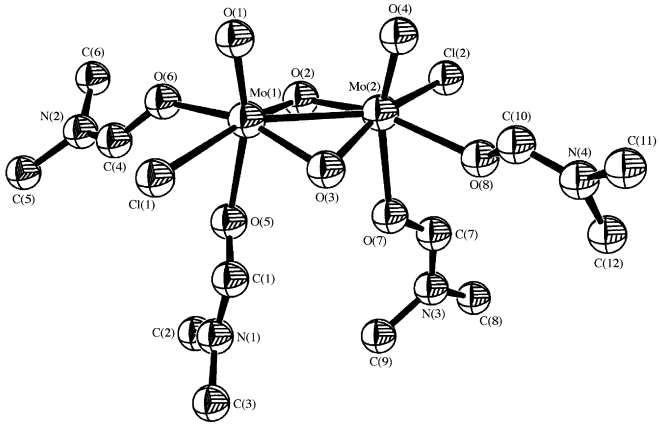

Fig. 1. Molecular structure and atom-labeling scheme for $Mo_2O_4Cl_2(DMF)_4$, CC enantiomer, with thermal ellipsoids at the 50% probability level; hydrogen atoms are omitted.

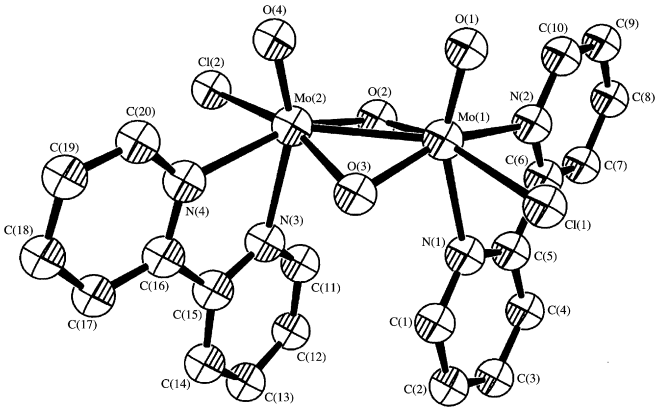

Fig. 2. Molecular structure and atom-labeling scheme for $Mo_2O_4Cl_2(Bipy)_2$, CC enantiomer, with thermal ellipsoids at the 50% probability level; hydrogen atoms are omitted.

molybdenum atom is best described as a distorted octahedron formed by an oxo terminal group *cis* with respect to the two oxo bridges, a chloride *cis vs.* the oxo terminal group and two *cis* positions for neutral ligands. Distortions from the theoretical octahedral geometry are explained in terms of interligand repulsions and Mo–Mo interaction.

Selected bond lengths and angles are listed in Table 2. The bond length for Mo(1)–Mo(2) is indicative of a Mo–Mo single bond resulting from a d^1–d^1 interaction, in good agreement with those previously reported (2.541–2.690 Å) [11,29]. All distances Mo=O are similar, considering the experimental error, and within the narrow range usually found for oxomolybdenum compounds (1.65–1.75 Å).

The strong interaction of the molybdenum atom with the terminal oxo ligand is shown by a pronounced *trans* influence with the Mo–(O or N) distances *trans* to the Mo=O, longer than the *cis* Mo–(O or N) distance.

The bond lengths for Mo–Cl are slightly different, shorter in the bipy derivative than in the DMF analogous. In the $Mo_2O_4Cl_2(DMF)_4$ complex the bond lengths for Mo–Cl (2.474 and 2.507 Å) are longer than in $MoO_2Cl_2(DMF)_2$ (2.341 Å) [30] probably due to the *trans* influence of the bridging oxygen atom in the dinuclear complex.

The molecular structure of $Mo_2O_4Cl_2(bipy)_2 \cdot DMF$ here reported, shows some differences with respect to the previously described $Mo_2O_4Cl_2(bipy)_2 \cdot CH_3NO_2$ [13]. In our compound the bond lengths Mo=O are slightly longer (1.69 Å) than those in the nitromethane solvate (1.60 Å) and the bond lengths Mo–N (2.22 and 2.32 Å) are markedly different. Also, in $Mo_2O_4Cl_2(bipy)_2 \cdot DMF$ the two pyridine rings are not coplanar, forming an angle of 12°.

It should be noted that in the crystal packing of $Mo_2O_4Cl_2(DMF)_4$ the unit cell contains two pairs of enantiomers. The crystal structure can be described as formed by the stacking of alternate planes, each of them formed by one of the enantiomers in the same relative orientation, linked only by Van der Waals forces.

Ring 1: N(1)–C(1)–C(2)–C(3)–C(4)–C(5). Ring 2: N(1A)–C(1A)–C(2A)–C(3A)–C(4A)–C(5A). DC, distance between the centroids of the aromatic rings *i* and *j*; ANG, angle between the least-squares planes; DZ, distance between the centroid of *j* ring and the least-squares of *i* ring; ; DZ′, distance between the centroid of *i* ring and the least-squares of *j* ring; DXY, distance between the centroids of *i* and *j* projected onto the least-squares plane of *i*; DXY′, distance between the centroids of *j* and *i* projected onto the least-squares plane of *j*; DS, distance from the centroid of *j* to the nearest hydrogen atom of *i* ring; CC, the angle formed between the vector between the ring centroids and the ring normal to the least-squares plane of *j*; CC′, the angle formed between the vector between the ring centroids and the ring normal to the least-squares plane of *i*.

viewed as an alternating sequence of parallel planes, each of them formed by only one enantiomer. The arrangement into each plane is better described as formed by couples of molecules of the same enantiomer, twisted one with respect to the other, repeated along the plane to form the 2D structure. It is noteworthy that, the shortest C(2)···C(4A) and C(4)···C(2A) distances between the pyridine rings involving N(1) from two molecules of different enantiomers (3.332 Å), and the disposition of the planes of these two pyridine fragments (closely parallel, with an angle between the pyridinic ring planes of ca. 1°) suggest the existence of π–π stacking interactions between the aromatic rings. Also, the coordination of a metal center to the nitrogen heteroatom from pyridines and other heterocycles enhances the electron-withdrawing effect through its positive charge, so that the stability of the π–π interaction increases [31,32]. In addition, the stacking does not exhibits a perfect face-to-face alignment of the atoms, as shown in Fig. 3, but can be described as a slipped packing [33]. The results of the structural analysis shown in Table 3 are in good agreement with the presence of strong π–π stacking interactions [34,35], where both molecules from the couple are linked in this way (involving the N(1) pyridinic ring), one of them to another molecule in the upper plane whereas the other one is linked similarly to the lower plane.

Scheme 1. Binding models of sal^{2-} in complexes **1**–**4** and binding mode of shi^{3-} and $xshz^{3-}$ ligands.

Scheme 2. Formation pathways of complexes **1**–**4**.

to $xshz^{3-}$ (*N*-substituted salicylhydrazidate, H_3xshz) or shi^{3-} (substituted salicylhydroxamic acid, H_3shi) [1a,6,7]. There is a weak coordination between M2 and O2 in model I*b*. The alternation between the existence and the non-existence of weak coordination may lead to polymorphs.

As a continuation of our effort in the formation of metallamacrocycles, we attempted to explore the assembly of metallamacrocycles by hydrothermal reactions, using 3d-series metals M(II), 3,5-dinitrosalicylate (3,5-$(NO_2)_2$sal) and 2,2′-bipyridine (2,2′-bipy). Herein, we report the syntheses, crystal structures and properties of four Co/Zn 3,5-$(NO_2)_2$sal complexes. Among the four title compounds, the cyclic tetranuclear cobalt compounds **1** and **2** are polymorphic, and the zinc compounds **3** and **4** are polymorphic too. Complex **3** has a 1D chain structure while the complex **4** has a cyclic tetranuclear structure. Compounds **1** and **4** form an isomorphous pair. The title complexes **1**, **2** and **4** are the first examples of a 3,5-$(NO_2)_2$sal complex with a metallamacrocyclic structure. The formation pathway of the title compounds **1**–**4** is shown in Scheme 2. This research represents an interesting fact that different isomeric complexes can be obtained by a simple change of the reaction time.

2. Experimental

2.1. Materials and general procedures

All of the chemicals were obtained from commercial sources and were used without further purification. Elemental analyses were conducted on a Perkin-Elmer 2400 CHN elemental analyzer. Magnetic measurements were carried out in the "Servei de Magnetoquímica (Universitat de Barcelona)" on polycrystalline samples (30 mg) with a Quantum Design SQUID MPMS-XL magnetometer working in the 2–300 K range. The magnetic field was 0.1 T. The diamagnetic corrections were evaluated from Pascal's constants. Fluorescence spectroscopy was performed on a Perkin-Elmer LS 55 luminescence spectrometer.

2.2. Synthesis of complexes

2.2.1. Synthesis of $Co_4(2,2'\text{-bipy})_4\{3,5\text{-}(NO_2)_2sal\}_4$ (*1*)

A mixture of $Co(OAc)_2 \cdot 4H_2O$ (0.1 mmol), 2,2′-bipy (0.1 mmol), 3,5-dinitrosalicylic acid (0.2 mmol) and distilled water (10 ml), with the pH value adjusted to 7 by addition of 1 M NaOH solution, was put into a Teflon-lined autoclave (20 mL) and then heated at 180 °C for 48 h. Deep brown block-like crystals of **1** in 93% yield based on Co were obtained. *Anal.* Calc. for $C_{68}H_{40}N_{16}O_{28}Co_4$: C, 46.27; H, 2.2; N, 12.70. Found: C, 46.22; H, 2.25; N, 12.75%.

2.2.2. Synthesis of $Co_4(2,2'\text{-bipy})_4\{3,5\text{-}(NO_2)_2sal\}_4$ (*2*)

The same mixture as that for **1** was used, with the reaction at 180 °C for 72 h, resulting in deep brown block-like crystal of **2** in 92% yield based on Co. *Anal.* Calc. for $C_{68}H_{40}N_{16}O_{28}Co_4$: C, 46.27; H, 2.2; N, 12.70. Found: C, 46.19; H, 2.23; N, 12.76%.

*2.2.3. Synthesis of [Zn(2,2′-bipy){3,5-(NO_2)$_2$sal}]$_n$ (**3**)*

The same synthetic procedure as that for **1** was used except that $Co(OAc)_2 \cdot 4H_2O$ was replaced by $Zn(NO_3)_2 \cdot 6H_2O$, giving yellow block-like crystals of **3** in 92% yield based on Zn. *Anal*. Calc. for $C_{17}H_{10}N_4O_7Zn$: C, 45.61; H, 2.25; N, 12.52. Found: C, 45.55; H, 2.30; N, 12.54%.

*2.2.4. Synthesis of Zn$_4$(2,2′-bipy)$_4${3,5-(NO_2)$_2$sal}$_4$ (**4**)*

The same mixture as that for **3** was used, with the reaction at 180 °C for 72 h, resulting in **3** in about 70% yield and light yellow block-like crystals of **4** in about 15% yield based on Zn. *Anal*. Calc. for $C_{68}H_{40}N_{16}O_{28}Zn_4$: C, 45.61; H, 2.25; N, 12.52. Found: C, 45.52; H, 2.26; N, 12.48%.

2.3. X-ray crystallography

X-ray diffraction measurements were carried out at 293 K with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) on a Bruker SMART CCD 1000 diffractometer for **2** and on a Rigaku R-AXIS RAPID Weissenberg IP diffractometer for **1**, **3** and **4**. The structures were solved by direct methods (SHELXTL-97) and refined on F^2 by full-matrix least-squares techniques. The high values of the thermal parameters of the oxygen atoms of the NO_2 groups in complexes **1**, **2** and **4** suggest disordered positions of these oxygen atoms. Therefore, these oxygen atoms are in disordered positions and were refined isotropically. The crystallographic data for **1**–**4** are summarized in Table 1.

3. Results and discussion

3.1. Structural description

As illustrated in Fig. 1, the centrosymmetrical molecular square structure of **1** is built up of four cobalt(II) cations (Co1, Co2, Co1A and Co2A, symmetry code A, $-x+1$, $-y$, $-z+1$), four bridging 3,5-(NO_2)$_2$sal ligands and four 2,2′-bipy ligands. Selected bond lengths and angles are listed in Table 2.

Each Co^{II} ion is pentacoordinated by three oxygen atoms from two 3,5-(NO_2)$_2$sal ligands and two nitrogen atoms from a 2,2′-bipy ligand. The Co1 atom has a distorted square-pyramidal geometry with a τ value of 0.03 [8]. However, the coordination sphere of Co2 is between square-pyramidal and the trigonal bipyramidal, with a τ value of 0.40. When the Co1–O9 and Co2–O2A distances (2.504(1) Å and 2.705(4) Å) are considered as weak coordination, the Co1 and Co2 centers may be regarded as having distorted octahedral conformations.

Every one of the four 3,5-(NO_2)$_2$sal ligands exhibits a bichelating coordination mode (Scheme 1(I*b*)). Therefore, neighboring cobalt atoms are connected by one 3,5-

$(NO_2)_2$sal ligand through the bridging oxygen atoms (O9, O2A, O9A and O2), generating a Co_4O_4 core of the molecular square. The four Co^{II} ions in the core are exactly coplanar. The Co…Co distances in the core are 4.319(2) and 4.617(9) Å along the side and 6.594(19) and 6.038(1) Å across the diagonal. The angles Co2–Co1–Co2A and Co1–Co2–Co1A in the core are 84.95(1)° and 95.05(1)°, respectively, indicating a slight deviations from an ideal square geometry.

Adjacent tetranuclear metallamacrocycles are further connected to each other by C–H…O hydrogen bonds [9] between the C–H group of the 2,2′-bipy ligand and the oxygen atom in the NO_2 groups of the 3,5-$(NO_2)_2$sal ligand, resulting in an extended 3D network structure (Fig. S1). The H…O distances are in the range of 2.43–2.53 Å. Detailed data are given in Table S1.

On comparison with the many substituted salicylhydroxamic acid and *N*-substituted salicylhydrazidate complexes, only a few 3,5-$(NO_2)_2$sal complexes have been found [10]. There are two types of structure for the known five 3,5-$(NO_2)_2$sal complexes, i.e. a 1D structure for $[Co^{II}(phen)\{3,5\text{-}(NO_2)_2sal^{2-}\}]$ [10b] and $[Mn(phen)\{3,5\text{-}(NO_2)_2sal^{2-}\}]$ [10c] and a discrete multinuclear structure for the other three complexes. To our knowledge, the title complexes **1**, **2** and **4** are the first examples of any 3,5-$(NO_2)_2$sal complex with a metallamacrocycle structure.

The molecular structure of complex **2** is shown in Fig. 2. Selected bond lengths and angles are listed in Table 3. The cyclic tetranuclear complex molecule Co_4(2,2′-bipy)$_4$-$\{3,5\text{-}(NO_2)_2sal\}_4$ (**2**) contains four cobalt(II) cations (Co1, Co2, Co3 and Co4), four 3,5-$(NO_2)_2$sal ligands and four 2,2′-bipy ligands. Two of the four 3,5-$(NO_2)_2$sal ligands bridge two neighboring $[Co(2,2'\text{-bipy})]^{2+}$ corners through one bridging carboxylate oxygen atom (O2 or O16). For the other two 3,5-$(NO_2)_2$sal ligands, each one bridges two neighboring $[Co(2,2'\text{-bipy})]^{2+}$ corners through two oxygen atoms (O8 and O9 or O22 and O23) in the carboxylate group. Therefore, four cobalt cations and four 3,5-$(NO_2)_2$sal ligands construct a molecular rhomboid structure with a $Co_4O_6C_2$ core. The molecular rhomboid structure in **2** is different from the molecular square structure in **1**. The four neighboring Co…Co distances in the $Co_4O_6C_2$ core are 5.116(1), 4.247(1), 5.209(2) and 4.370(1) Å. The Co–Co–Co angles in the core are 101.10(1)°, 79.83(1)°, 101.35(1)° and 77.71(1)°.

There are two kinds of coordination modes for the four 3,5-$(NO_2)_2$sal ligands in complex **2**; the two of four ligands act in the monochelating-bridging mode (Scheme 1a), and the other two act in the bichelating mode (Scheme 1b), to give the $Co_4O_6C_2$ core of the molecular rhomboid.

The coordination geometry of two cobalt atoms, Co1 and Co3, is distorted trigonal bipyramidal, with τ values of 0.78 and 0.90, respectively. However, the coordination geometry of Co2 and Co4 can be described as a distorted octahedron because of the weak coordination (Co2–O16 = 2.431(3) Å, Co4–O2 = 2.518(3) Å).

There are some intermolecular C–H...O hydrogen bonds which form an extended 3D structure (Fig. S2). The H...O distances are in the range 2.396–2.523 Å (Table S1).

The 1D chain structure of complex **3** is given in Fig. 3. Selected bond lengths and angles are illustrated in Table 4. Each Zn^{II} ion is pentacoordinated by three oxygen atoms of two 3,5-$(NO_2)_2$sal ligands and two nitrogen atoms of a 2,2′-bipy ligand. The coordination sphere is between square-pyramidal and trigonal bipyramidal, with a τ value of 0.32. Each 3,5-$(NO_2)_2$sal ligand adopts a monochelating-bridging mode (Scheme 1(I*a*)) and links two Zn^{II} ions into a 1D chain structure along the *c* axis. The chain core is with a $[–Zn–O–C–O–]_n$ repeat. The neighboring Zn1...Zn1A distance (Symmetry code: A x, $-y+1/2$, $z-1/2$) is 5.132(1) Å, and the Zn–Zn–Zn angle is 116.35(1)°. The 1D chains are further connected by C–H...O hydrogen bonds, resulting in a 3D supramolecular network structure (Fig. S3). The H...O distances are in the range 2.602–2.670 Å (Table S1).

The zinc compound **4** and the cobalt compound **1** are isomorphous. The centrosymmetrical molecular square structure in **4** (Fig. S4) is the same as that in **1**. Selected bond lengths and angles of complex **4** are listed in Table 2. In compound **4**, each one of four bridging oxygen atoms (O2, O9, O2A and O9A, symmetry code A, $-x+1$, $-y$, $-z+1$) of the carboxylate groups from four 3,5-$(NO_2)_2$sal ligands bridges two zinc(II) cations to form an Zn_4O_4 core in the molecular square structure. The Zn...Zn distances in **4** are 4.746(4) and 4.663(2) Å along the side and 6.558(4) and 6.747(1) Å across the diagonal. The vertex angles for Zn2–Zn1–Zn2A and Zn1–Zn2–Zn1A are 91.63(1)° and 88.37(1)°, respectively. It indicates a quite ideal square geometry.

The coordination geometry for the four zinc(II) cations in **4** is between square-pyramidal and the trigonal bipyramidal, the τ values of the Zn1 and Zn2 polyhedra being 0.47 and 0.49, respectively. The Zn1–O9 distance is 2.881(4) Å, and the Zn2–O2A distance is 2.744(4) Å. When Zn1–O9 and Zn2–O2A are considered as weakly coordi-

nating, the coordination geometries of the Zn^{II} ions can be described as distorted octahedra. Each 3,5-$(NO_2)_2$sal ligand exhibits a bichelating coordination mode (Scheme 1 I*b*).

The C–H...O hydrogen bonds in complex **4** (Table S1) bridge the adjacent tetranuclear metallamacrocycles to create an extended 3D network structure (Fig. S5).

3.2. Weak coordination interactions and coordination orientations

There exist weak coordination interactions M2...O2 between the O,O′,O″-tridentate ligand 3,5-$(NO_2)_2$sal and the metal cation (I*b* in Scheme 1) in compounds **1**, **2** and **4**. As shown in Table 5, the absolute value of the torsion angles O2–C–O1–M2 are between 0.2° and 8.7°, and the C–O1–M2 bridging angles are in the range 100.2–115.5°. When there are no weak coordination interactions of M2...O2 (I*a* in Scheme 1), the torsion angles O2–C–O1–M2 in **2** and **3** are between 26.7° and 33.4°, and the C–O1–M2 bridging angles are in the range 125.6-128.1°. The strength of the weak coordination interactions among the four title compounds is of the following order: **1**, **4** > **2** > **3**. Coincidentally, compounds **1** and **4** have the molecular square structure, compound **2** has the molecular rhomboid structure while compound **3** has the chain structure. This suggests that the weak coordination interactions have significant influence on the space orientations of the 3,5-$(NO_2)_2$sal ligand, and may affect the crystallization processes and solid state architectures.

3.3. Magnetism

The temperature dependences of $\chi_M T$ (χ_M being the magnetic susceptibility for four Co^{II}ions) in complexes **1** and **2** are shown in Figs. 4 and 5 (from 300 K to 2 K), respectively. $\chi_M T$ at 300 K in **1** and **2** is close to 9 and 10.5 $cm^3\,mol^{-1}\,K$, respectively, and these values are as expected for four isolated pentacoordinated Co^{II} ions. $\chi_M T$ in **1** monotonously decreases to reach 0.2 $cm^3\,mol^{-1}\,K$ at 2.00 K. $\chi_M T$ in **2** monotonously decreases to reach 1.0 $cm^3\,mol^{-1}\,K$ at 2.00 K. The shape of these curves for complexes **1** and **2** is characteristic of the occurrence of weak antiferromagnetic interactions between the Co^{II} centres. The antiferromagnetic behaviour in the two complexes is corroborated by plotting the reduced magnetization (M/Nβ) versus H at 2 K. In both cases the shape of the curve is typical for an antiferromagnetic coupling, not very strong, and the values at 5 T are close to 4 Nβ instead of 12 (the theoretical values assuming $g = 2.00$ for four Co^{II} ions fully isolated). The pentacoordinated Co^{II} ion does not present spin–orbit coupling, such as occurs with the octahedral analogues. Thus, they can be treated as systems with $S = 3/2$ with the spin-hamiltonian formalism. Taking into account the tetranuclear character of **1** and **2** we have done the fit assuming two different J values (alternated) by means of the CLUMAG program [11]. The best fit is given by the exchange parameters $J_1 = -0.41\ cm^{-1}$, $J_2 = -0.33\ cm^{-1}$ and $g = 2.21$ for **1** and $J_1 = -0.36\ cm^{-1}$, $J_2 = -0.23\ cm^{-1}$ and $g = 2.30$ for **2**. The two set of values are similar, it being interesting to emphasize that for complex **1** the two J values are more similar, which agrees with

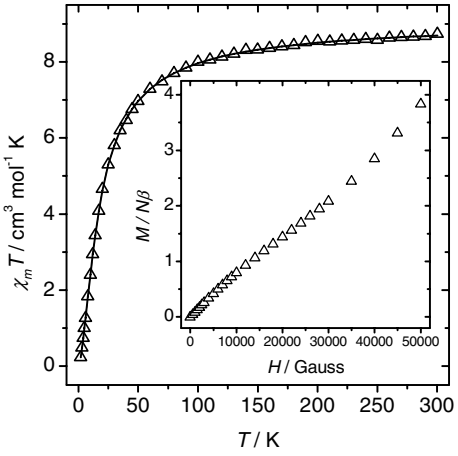

Fig. 4. Plot of $\chi_M T$ vs. T for complex **1**. The solid line represents the best fit. Inset: plot of the reduced magnetization (M/Nβ) at 2 K.

Table 5
A comparison between weak coordination, torsion angles and bridging angles in complexes **1**–**4**

[a] The symbols M2, O2, C, and O1 are the same as those in Scheme 1(I*b*).

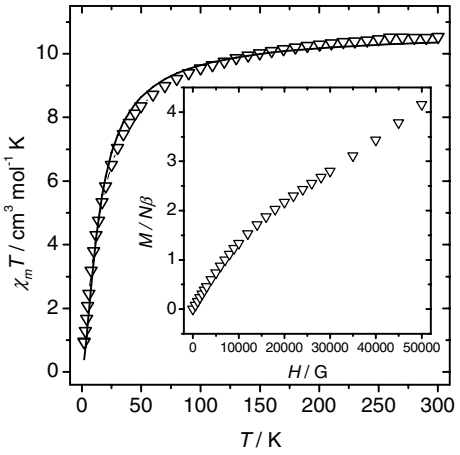

Fig. 5. Plot of $\chi_M T$ vs. T for complex **2**. The solid line represents the best fit. Inset: plot of the reduced magnetization (M/Nβ) at 2 K.

a structure that it is more square-like in **1** and more rhomboid-like in **2**. The small J values are due, in both cases, to the magnetic pathway created by the carboxylate bridging groups in a *syn–anti* configuration. The small overlap between the magnetic orbitals accounts for the weak coupling observed. This qualitative approach was already introduced by Kahn when studying this kind of *syn–anti* coordination mode [12].

3.4. Photoluminescence

The emission spectra of complex **3** and the free 3,5-$(NO_2)_2$sal ligand in the solid state at room temperature have been investigated. Complex **3** exhibits blue fluorescent emission bands at ca. 485 nm upon excitation at ca. 360 nm (Fig. S6). These emissions are assigned to the intraligand fluorescent emission because similar emissions are observed for the free 3,5-$(NO_2)_2$sal (Fig. S7) [13].

4. Conclusion

In summary, three cyclic tetranuclear complexes and one 1D chain structure complex have been prepared by the hydrothermal reactions of $Co(OAc)_2 \cdot 4H_2O$/$Zn(NO_3)_2 \cdot 6H_2O$, 3,5-$(NO_2)_2$sal and 2,2′-bipy with different reaction times. The cobalt complexes **1** and **2** constitute a pair of polymorphs. There is a molecular square structure with a Co_4O_4 core in **1** and a molecular rhomboid structure with a $Co_4O_6C_2$ core in **2**. The zinc complexes **3** and **4** constitute a pair of polymorphs too. There is a 1D structure in **3** and a molecular square structure in **4**. Our results demonstrate an interesting fact that polymorphic compounds with different structure types can be obtained by a simple change of the reaction time. Compounds **1** and **4** form an isomorphous pair.

The weak coordination interactions have a significant influence on the space orientations of the 3,5-$(NO_2)_2$sal ligand. There are antiferromagnetic interactions in the cyclic tetranuclear pentacoordinated cobalt(II) complexes **1** and **2**.

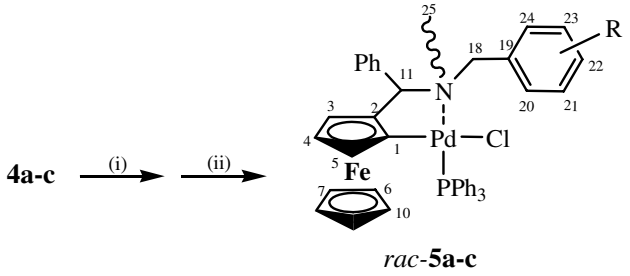
phenylboronic acid. In addition, the Heck reaction of bromobenzene with styrene catalyzed by these palladacycles, as mentioned above, will also be discussed.



2. Results and discussion

2.1. Synthesis of ferrocenylamines 4a–c and their cyclopalladated complexes 5a–c

The preparation of *tert*-ferrocenylamines **4a–c** is shown in Scheme 1. Condensation of benzoylferrocene and 4 equiv. of benzylamine catalyzed by titanium tetrachloride [8] in toluene produced the dark-red ferrocenylketimines **2a–c** in good yields. Reduction of **2a–c** with $LiAlH_4$-$AlCl_3$ [9] in THF gave *sec*-amines **3a–c**, respectively in moderate yields. An attempt at the synthesis of **4a–c** from **3a–c** by our earlier used protocol, i.e. using aqueous HCHO, $NaCNBH_3$ in HOAc, [10] was unsuccessful due to the easier debenzylation of the former reactant [9,11] under such reaction conditions. Thus, CH_3I was chosen as the methylation reagent and *t*-BuOK as the base to synthesize **4a–c** from **3a–c** (Scheme 1). **4a–c** were finally obtained as orange solids in yields of 50–65%.

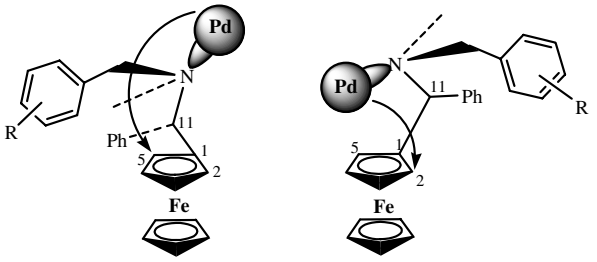
The synthesis of palladacycles **5a–c** is outlined in Scheme 2. Treatment of **4a–c** with 1 equiv. of Na_2PdCl_4–PPh_3 in methanol produced red-brown solids **5a–c** in 70–80% yields after purification by column chromatography (see Section 4). Similar to our earlier obtained palladacycles [7a,7b,7c], **5a–c** are very stable in air and easily soluble in CH_2Cl_2, $CHCl_3$, ethyl acetate, acetone and benzene, but are insoluble in ethanol and hexane.

Compounds **2–5** were characterized by elemental analysis, IR and ^1H NMR. Elemental analyses of **2–5** are in good agreement with their proposed formula. The IR and ^1H NMR spectra of **2–4** are very similar to those observed in imines, *sec*-amines and *tert*-amines derived from the starting materials formylferrocene and benzylamines [7b,7c]. The IR spectra of **5a–c** show two medium absorption bands at $\nu \sim 1100$ and 1000 cm^{-1}, implying that each of these palladacycles contains a free cyclopentadienyl (Cp) ring [12]. The ^1H NMR spectra of **5a–c**clearly demonstrate that the chemical shifts of N–CH_3 are located downfield ($\delta \sim 2.80$ ppm) compared to those of the free *tert*-amines **4a–c** ($\delta \sim 1.99$ ppm). This change can be rationalized by N–Pd coordination, which decreases the electron density

Scheme 2. (i) Na_2PdCl_4/NaOAc/CH_3OH. (ii) PPh_3/CH_3OH. R = H (a), 4-OCH_3 (b), 4-CH_3 (c).

of the N atom and causes the δ-values of N–CH_3 to shift downfield. In addition, the satellites of H20–H24 in the phenyl ring all exhibit their unique AA′XX′ splitting patterns (except **5a**), indicating that palladacycles **5a–c** are formed *via* the activation of the $C_{Ferrocenyl}$–H bond rather than the C_{phenyl}–H bond [13].

Since the nitrogen atom in **4a–c** connects directly to three different groups and a rapid N-inversion [14] exists, after the coordination of the nitrogen atom with palladium, the forms of the N–Pd coordinated intermediates (Fig. 1) can be simplified as two kinds, i.e., one has a R_N configuration, and another has the opposite, regardless of the chirality of C11. Accordingly, the following activation of the C–H bond in the Cp ring will produce theoretically four isomeric palladacycles (two pairs of racemes, *i.e.*, R_NR_P and S_NS_P, S_NR_P and R_NS_P). Similar to our earlier observations [7], only one pair of raceme R_NR_P and S_NS_P was found to dominate in these reactions, the other pair of raceme R_NS_P and S_NR_P was observed in trace amounts and can be easily removed by



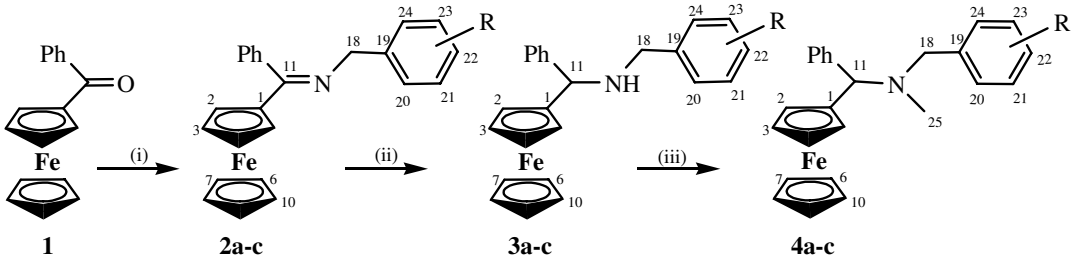


Fig. 1. The possible activation modes of C–H bonds in the Cp ring for N–Pd coordinated intermediates (left: R_N, right: S_N).

Scheme 1. (i) $RC_6H_4CH_2NH_2$/$TiCl_4$/toluene, reflux. R = H (a), 4-OCH_3 (b), 4-CH_3 (c). (ii) $LiAlH_4$/$AlCl_3$/THF. (iii) CH_3I/*t*-BuOK, THF.

chromatography. This stereoselective C–H bond activation is probably attributed to the preferred N–Pd orientations in the intermediates (Fig. 1), which allow the palladium atom to approach preferably to the C2–H or C5–H bond and then activate each of them. To some extent, the preferred N–Pd orientations in these intermediates are relevant to the geometries of the *tert*-ferrocenylamines [15]. In addition, zero optical rotations of **5a**–**c** measured at the given conditions ($\lambda = 5893$ Å, CH_2Cl_2, 293 K) also indicate that these palladacycles consist of racemes.

The structure of **5a** was determined by single crystal X-ray analysis (Fig. 2, S_NS_P). Crystallographic data for **5a** are given in Table 1, selected bond lengths and angles are listed in Table 2. X-ray diffraction studies demonstrates that **5a** consists of the discrete molecule {Pd[(η^5-C_5H_5)Fe(η^5-C_5H_3CHPhN(CH_3)$CH_2C_6H_5$)](PPh$_3$)Cl} separated by van der Waals contacts. The palladium atom is in a slightly distorted square-planar environment, bonded to Cl(1), P(1), N(1) and C(1). The deviation of each atom from the mean plane is Pd(1), −0.1015; Cl(1), −0.0489; P(1), 0.1071; N(1), 0.1149; C(1), −0.0716 Å, respectively. **5a** contains a bicycle, which is formed by the substituted Cp ring of the ferrocenyl fragment and a five-membered palladacycle with an envelope-like conformation. The N(1)–Pd(1) bond length of 2.224(3) Å is slightly longer than those observed in cyclopalladated [(*N*,*N*-dimethylamino)methyl]ferrocene (FcN, 2.170 Å) [16] and [({*N*-methyl-*N*-4-nitrobenzyl}-amino)methyl]ferrocene (BFcN, 2.195 Å) [7c]. In addition, the PPh$_3$ moiety in **5a** adopts a *trans*-configuration to N(1), with a N(1)–Pd(1)–P(1) bond angle of 167.53(7)°, which is slightly less than that in cyclopalladated BFcN (169.00(9)°). The Pd(1)–C(1) bond length of 2.002(3) Å is nearly the same as those observed in cyclopalladated FcN (1.983(1) Å) and BFcN (1.988(4) Å). The average C–C bond length (1.418 Å) in the ferrocenyl moiety is very close to the reported values of other ferrocene derivatives [17]. The Fe–C (Cp ring) bond lengths range from 2.036 to 2.082 Å. The eclipsed two Cp rings are planar and nearly parallel (interplanar angle of 2.2°).

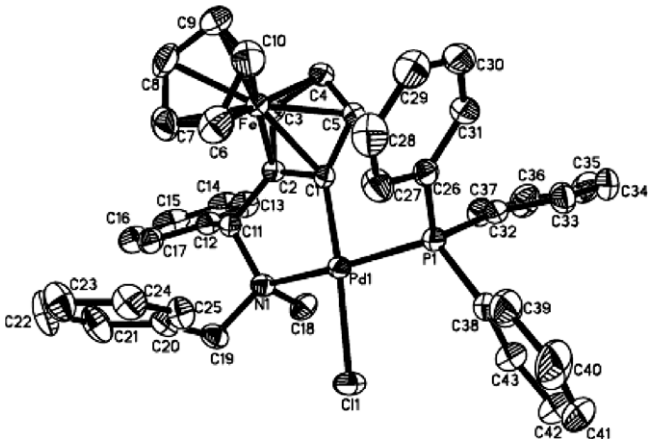

Fig. 2. X-ray crystal structure of **5a** (H atoms are all omitted for clarity).

2.2. Suzuki coupling

Before investigation of the Suzuki coupling for aryl chlorides, the coupling of bromobenzene and phenylboronic acid catalyzed by **5a**–**c** (under the conditions K_2CO_3, THF) was studied. The coupling results showed that 100% of biphenyl was obtained, indicating that palladacycles **5a**–**c** are excellent catalysts for activation of the C_{phenyl}–Br bond. To examine the catalytic efficiency of **5** for the coupling of aryl chlorides, a quick survey of solvents including dioxane, toluene, THF and DMF/H_2O was made (Table 3). Table 3 revealed that using K_2CO_3 as the base and 0.1 mol% of **5a** as the catalyst the coupling reaction in dioxane gave the best results (Entry 1, 89%, Table 3). We further investigated the effect of the bases, e.g., K_2CO_3, Cs_2CO_3, K_3PO_4 and *t*-BuOK in the same reaction (Table 3). It was found that K_2CO_3 was better than the others (Entries 4–7). Therefore, K_2CO_3 was ultimately chosen as the base for this system.

Table 3
Influence of solvents and bases on the Suzuki coupling of chlorobenzene with phenyl-boronic acid[a]

Entry	Solvent	Base	Yield (%)[b]
1	dioxane	K_2CO_3	89.1
2	toluene	K_2CO_3	45.9
3	THF	K_2CO_3	51.3
4	DMF/H_2O	K_2CO_3	36.2
5	dioxane	Cs_2CO_3	67.6
6	dioxane	K_3PO_4	15.0
7	dioxane	*t*-BuOK	26.7

[a] Reaction conditions: catalyst *rac*-**5a** (0.1 mol%), PhCl (1 mmol), $PhB(OH)_2$ (1.5 mmol), base (2 mmol), solvent (10 cm^3), reflux, 10 h.
[b] Determined by GC, based on PhCl, average of two runs.

Under the optimized conditions as mentioned above, the relative activities of **5a**–**c** for the Suzuki coupling of aryl chlorides and phenylboronic acid were studied (Table 4). When the reactions were carried out at 100 °C for 10 h, **5a**–**c** all exhibited good activity with the loading as low as 0.1 mol % (Entries 1–3). However, when 0.01% of **5a** was used, the coupling yield was lower (Entry 4, 22.3%). Under the optimized reaction conditions (K_2CO_3, dioxane, 100 °C, 10 h) phenylboronic acid could couple efficiently with the aryl chlorides ranging from electron-donating to electron-withdrawing groups (Entries 5–10). In particular, for 4-$CH_3C_6H_5Cl$ the coupling yield was up to 98.0% (Entry 6). Even for the bulky 2,4-dinitrophenyl chloride, its coupling with phenylboronic acid was also achieved and the resulting biaryl yield was moderate.

2.3. Heck reaction

We initially examined the Heck reaction of chlorobenzene with styrene catalyzed by **5a**–**c**. Unfortunately the product yields were much lower (yield < 3%), and these results were consistent with the another group's observations [6]. Later we paid attention to the reaction of bromobenzene with styrene, and the results are summarized in Table 5. It was found that using DMF as the solvent and K_2CO_3 as the base at 140 °C for 7 h, an excellent yield of product could be obtained when the loading of palladacycle **5b** was as low as 0.1 mol% (Entry 6). Similar to the Suzuki coupling, when 0.01% of catalyst was used, the coupling yield was lower (Entry 8, 39%).

3. Conclusions

tert-Ferrocenylamines were easily synthesized by *N*-methylation of the corresponding *sec*-amines with CH_3I. Treatment of these *tert*-amines with Na_2PdCl_4 afforded racemic palladacycles with a σ Pd–C_{sp^2}, Ferrocenyl bond. These palladacycles have been proven to be highly efficient catalysts for the Suzuki coupling of aryl chlorides with phenylboronic acid and the Heck reaction of bromobenzene with styrene under the given conditions.

4. Experimental

4.1. Materials and instruments

Benzoylferrocene, enzylamines, $TiCl_4$, $LiAlH_4$, $AlCl_3$, CH_3I, *t*-BuOK, NaOAc, PPh_3 were obtained commercially and were used without further purification. Na_2PdCl_4 was prepared in our laboratory. All of the solvents were purified with standard methods prior to use. Melting points were obtained on a Yanaco micro melting point apparatus and were uncorrected. Elemental analyses were measured on a Carlo Erba 1106 Elemental analyzer. ^1H NMR spectra were obtained with Bruker AV-400 spectrometer using $CDCl_3$ as the solvent and TMS as the internal standard. IR spectra were recorded on a BIO-RAD 3000 spectrophotometer.

4.2. Preparation of ferrocenylketimines (*2*)

General procedure: **2a**–**c** were prepared according to the literature method [8].

4.2.1. $\{(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4C(C_6H_5)=NCH_2C_6H_5)\}$ (*2a*)

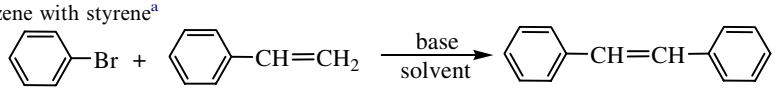
[a] Reaction conditions: ArCl (1 mmol), $PhB(OH)_2$ (1.5 mmol), K_2CO_3 (2 mmol), dioxane (10 cm^3), 100 °C, 10 h.
[b] Determined by GC, based on aryl chloride used, average of two runs.

NMR ($CDCl_3$): δ 2.15 (s, 3H, CH_3), 3.85 (bs, 2H, H2, H5), 4.10 (bs, 2H, H3, H4), 4.16 (s, 5H, η^5-C_5H_5), 4.53 (s, 2H, H18), 7.13–7.25 (m, 4H, H20, H21, H23, H24), 7.43–7.55 (m, 5H, Ph).



4.3. Preparation of sec-ferrocenylamines (*3*)

General procedure: **3a**–**c** were prepared with a modification of the 'Cais' method [8]. The difference was the reduction conditions. In our experiment, 3% mmol of $AlCl_3$ was used as the catalyst and THF as the solvent.

4.3.1. {(η^5-C_5H_5)Fe(η^5-$C_5H_4CH(C_6H_5)NHCH_2C_6H_5$)} (*3a*)

Yield: (77%); an orange solid; m.p. 68–70 °C. *Anal.* Calc. for $C_{24}H_{23}FeN$: C, 75.60; H, 6.08; N, 3.67. Found: C, 75.63; H, 6.25; N, 3.82%. FT-IR (KBr): 3328(s), 3084(m), 3022(m), 2948(m), 2857(m), 1598(m), 1493(vs),

Table 5
The Heck reaction of bromobenzene with styrene[a]

Entry	Solvent	Catalyst (mol%)	T (°C)	Base	Yield (%)[b]
1	1,4-dioxane	*rac*-**5b**(0.1)	80	K_2CO_3	3.0
2	1,4-dioxane	*rac*-**5b**(1)	100	K_2CO_3	5.0
3	toluene	*rac*-**5b**(1)	100	K_2CO_3	3.0
4	DMF	*rac*-**5b**(0.1)	100	K_2CO_3	22.0
5	DMF	*rac*-**5b**(1)	140	K_2CO_3	100
6	DMF	*rac*-**5b**(0.1)	140	K_2CO_3	100
7	DMF	*rac*-**5b**(0.1)	140	*t*-BuOK	87.0
8	DMF	*rac*-**5b**(0.01)	140	K_2CO_3	39.0
9	DMF	*rac*-**5a**(0.1)	140	K_2CO_3	96.0
10	DMF	*rac*-**5c**(0.1)	140	K_2CO_3	98.0

[a] All reactions were carried out with 1 mmol of PhBr, 1.5 mmol of styrene and 2 mmol of base in 10 cm^3 of solvent for 7 h.
[b] Determined by GC, based on PhBr, average of two runs.

1452(vs), 1283(m), 1197(m), 1105(vs), 1022(s), 996(s), 820(vs), 699(vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.17 (s, 1H, NH), 3.58–3.80 (q, 2H, H18) 4.06 (s, 1H, H11), 4.04 (s, 5H, η^5-C_5H_5), 4.30 (bs, 2H, H2, H5), 4.48 (bs, 2H, H3, H4), 7.23–7.43 (m, 10H, Ph).

4.3.2. {(η^5-C_5H_5)Fe(η^5-$C_5H_4CH(C_6H_5)NHCH_2C_6H_4$-$OCH_3$-4)} (**3b**)

Yield: (72%); a yellow solid; m.p. 57–60 °C. *Anal*. Calc. for $C_{25}H_{25}FeNO$: C, 73.00; H, 6.13; N, 3.41. Found: C, 73.09; H, 6.31; N, 3.55%. FT-IR (KBr): 3324(m), 3083(m), 3022(m), 2954(s), 2827(m), 1610(vs), 1512(vs), 1452(s), 1300(m), 1247(vs), 1174(s), 1105(vs), 1036(s), 1001(s), 821(vs), 700(vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.17 (s, 1H, NH), 3.51–3.74 (q, 2H, H18), 3.82 (s, 3H, OCH_3), 4.04 (s, 5H, η^5-C_5H_5), 4.05 (s, 1H, H11), 4.30 (bs, 2H, H2, H5), 4.46 (bs, 2H, H3, H4), 6.90–7.41 (m, 4H, H20, H21, H23, H24), 7.23–7.34 (m, 5H, Ph).

4.3.3. {(η^5-C_5H_5)Fe(η^5-$C_5H_4CH(C_6H_5)NHCH_2C_6H_4$-$CH_3$-4)} (**3c**)

Yield: (81%); a yellow solid; m.p. 93–94 °C. *Anal*. Calc. for $C_{25}H_{25}FeN$: C, 75.96; H, 6.37; N, 3.54. Found: C, 75.89; H, 6.15; N, 3.90%. FT-IR (KBr): 3324(m), 3073(m), 3013(m), 2924(m), 2821(m), 1597(m), 1508(vs), 1451(s), 1333(m), 1179(m), 1104(vs), 1021(s), 996(s), 817(vs), 699(vs) cm^{-1}. ^1H NMR ($CDCl_3$) δ 2.17 (s, 1H, NH), 2.14 (s, 3H, CH_3), 3.54–3.76 (q, 2H, H18), 4.04 (s, 5H, η^5-C_5H_5), 4.05 (s, 1H, H11), 4.30 (bs, 2H, H2, H5), 4.47 (bs, 2H, H3, H4), 7.12–7.21 (m, 4H, H20, H21, H23, H24), 7.41–7.53 (m, 5H, Ph).

4.4. Synthesis of tert-ferrocenylamines (**4**)

General procedure: To a stirred solution of **3** (2 mmol) in 20 cm^3 of THF was added CH_3I (3 mmol) in 5 cm^3 THF and *t*-BuOK (3 mmol). The mixture was kept in the dark at room temperature and stirred for 48 h. TLC monitored the reaction progress until it was complete. The solvent was removed under reduced pressure and 30 cm^3 of water was then added. The mixture was extracted with diethyl ether (3×20 cm^3) and separated. The extracts were combined, dried over Na_2SO_4 and removed to give crude products which were purified by column chromatography (silica gel, ethyl acetate/hexane = 1:5, v/v) to afford **4a**–**c**.

4.4.1. {(η^5-C_5H_5)Fe(η^5-$C_5H_4CH(C_6H_5)N(CH_3)CH_2$-$C_6H_5$)} (**4a**)

Yield: (58%); an orange solid; m.p. 64–66 °C. *Anal*. Calc. for $C_{25}H_{25}FeN$: C, 75.96; H, 6.37; N, 3.54. Found: C, 75.88; H, 6.60; N, 3.81%. FT-IR (KBr): 3081(s), 3019(s), 2957(s), 2783(s), 1596(s), 1493(vs), 1452(vs), 1366(m), 1286(m), 1106(vs), 1002(vs), 818(vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 1.95 (s, 3H, H25), 3.22–3.51 (q, 2H, H18), 3.79 (s, 5H, η^5-C_5H_5), 4.13 (s, 1H, H11), 4.11 (bs, 2H, H2, H5), 4.34 (bs, 2H, H3, H4), 7.19–7.52 (m, 10H, Ph).

4.4.2. {(η^5-C_5H_5)Fe(η^5-C_5H_4 $CH(C_6H_5)N(CH_3)CH_2$-$C_6H_4OCH_3$-4)} (**4b**)

Yield: (50%); an orange solid; m.p. 72–73 °C. *Anal*. Calc. for $C_{26}H_{27}FeNO$: C, 73.42; H, 6.40; N, 3.29. Found: C, 73.37; H, 6.58; N, 3.36%. FT-IR (KBr): 3088(m), 3024(m), 2953(s), 2831(m), 2775(m), 1605(vs), 1510(vs), 1452(vs), 1296(m), 1242(vs), 1106(vs), 1002(vs), 818(vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 1.98 (s, 3H, H25), 3.23–3.51 (q, 2H, H18), 3.85 (s, 3H, OCH_3), 3.81 (s, 5H,η^5-C_5H_5), 4.14 (s, 1H, H11), 4.13 (bs, 2H, H2, H5), 4.36 (bs, 2H, H3, H4), 6.91–7.42 (m, 4H, H20, H21, H23, H24), 7.26–7.35 (m, 5H, Ph).

4.4.3. {(η^5-C_5H_5)Fe(η^5-$C_5H_4CH(C_6H_5)N(CH_3)CH_2$-$C_6H_4CH_3$-4)} (**4c**)

Yield: (65%); an orange solid; m.p. 70–72 °C. *Anal*. Calc. for $C_{26}H_{27}FeN$: C, 76.29; H, 6.65; N, 3.42. Found: C, 76.23; H, 6.43; N, 3.60%. FT-IR (KBr): 3091(m),

3023(m), 2956(s), 2776(m), 1600(m), 1513(vs), 1452(vs), 1286(m), 1106(vs), 1002(vs), 805(vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 1.99 (s, 3H, H25), 2.35 (s, 3H, CH_3), 3.24–3.52 (q, 2H, H18), 3.83 (s, 5H, η^5-C_5H_5), 4.16 (s, 1H, H11), 4.15 (bs, 2H, H2, H5), 4.38 (bs, 2H, H3, H4), 7.13–7.22 (m, 4H, H20, H21, H23, H24), 7.44–7.55 (m, 5H, Ph).

4.5. Synthesis of cyclopalladated tert-ferrocenylamines (5)

General procedure: To a stirred solution of **4** (1 mmol), sodium acetate (82 mg, 1 mmol) in 30 cm^3 of methanol was added dropwise a solution of Na_2PdCl_4 (0.29 g, 1 mmol) in 15 cm^3 of methanol. The mixture was stirred for 4 h at room temperature under argon and TLC monitored the reaction's progress. Then PPh_3 (0.41 g, 1.5 mmol) was added and the mixture was stirred for another 30 min. The solvent was removed in vacuo, and the residues were purified by column chromatography (silica gel, ethyl acetate/hexane = 1:2, v/v) to give **5**.

4.5.1. [PdCl(PPh$_3$){(η^5-C$_5$H$_5$)Fe(η^5-C$_5$H$_3$CH(C$_6$H$_5$)N-(CH$_3$)CH$_2$C$_6$H$_5$)}] (5a)

Yield: (72%); a red solid; m.p. > 193 °C (dec.). *Anal.* Calc. for $C_{43}H_{39}ClFeNPPd$: C, 64.68; H, 4.92; N, 1.75. Found: C, 64.60; H, 4.89; N, 1.82%. FT-IR (KBr): 3054(w), 2955(w), 2922(w), 1486(m), 1450(m), 1435(vs), 1095(s), 999(s), 823(m), 752(s), 701(vs) cm^{-1}. ^1H NMR($CDCl_3$): δ 2.88 (m, 2H, H18), 3.21 (s, 3H, H25), 4.84 (s, 1H, H11), 3.85 (s, 5H, η^5-C_5H_5), 3.76 (d, 1H, H5), 4.08 (m, 1H, H4), 4.16 (d, 1H, H3), 7.73–7.82 (m,10H, 2Ph), 7.35–7.54 (m, 15H, PPh_3).

4.5.2. [PdCl(PPh$_3$){(η^5-C$_5$H$_5$)Fe(η^5-C$_5$H$_3$CH(C$_6$H$_5$)N-(CH$_3$)CH$_2$C$_6$H$_4$OCH$_3$-4)}] (5b)

Yield (80%); a red solid; m.p. > 189 °C (dec.). *Anal.* Calc. for $C_{44}H_{41}ClFeNOPPd$: C, 63.79; H, 4.99; N, 1.69. Found: C, 63.72; H, 4.81; N, 1.96%. FT-IR (KBr): 3045(w), 2954(w), 1512(vs), 1454(m), 1435(vs), 1246(s), 1178(s), 1100(s), 995(m), 816(s), 747(s), 702(vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.79 (s, 3H, H25), 3.24 (m, 2H, H18), 3.43 (s, 3H, OCH_3), 3.73 (s, 5H, η^5-C_5H_5), 3.74 (m, 1H, H5), 3.80 (m, 1H, H4), 3.95 (d, 1H, H3), 4.96 (s, 1H, H11), 6.90–7.05 (m, 4H, H20, H21, H23, H24), 7.39–7.66 (m, 15H, PPh_3), 7.70–7.85 (m, 5H, Ph).

4.5.3. [PdCl(PPh$_3$){(η^5-C$_5$H$_5$)Fe(η^5-C$_5$H$_3$CH(C$_6$H$_5$)N-(CH$_3$)CH$_2$C$_6$H$_4$ CH$_3$-4)}] (5c)

Yield (70%); a red solid; m.p. > 172 °C (dec.). *Anal.* Calc. for $C_{44}H_{41}ClFeNPPd$: C, 65.04; H, 5.09; N, 1.72. Found: C, 65.12; H, 4.85; N, 1.65%. FT-IR (KBr): 3051(w), 2954(w), 2920(w), 1484(s), 1455(s), 1437(vs), 1185(m), 1103(s), 1002(m), 823(m), 751(s), 693(vs) cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.43 (s, 3H, CH_3), 2.79 (s, 3H, H25), 3.21 (m, 2H, H18), 3.50 (s, 5H, η^5-C_5H_5), 5.16 (s, 1H, H11), 3.73 (m, 1H, H5), 3.82 (d, 1H, H3), 4.10 (m, 1H, H4), 7.13–7.22 (m, 4H, H20, H21, H23, H24), 7.39–7.56 (m, 15H, PPh_3), 7.70–7.85 (m, 5H, Ph).

4.6. General procedure for the Suzuki coupling

Palladacycles **5** (0.1 mmol%), aryl chlorides (1.0 mmol), phenylboronic acid (1.5 mmol), K_2CO_3 (2 mmol), dioxane (10 cm^3) were added to a 25 cm^3 round-bottomed flask and the mixture was heated at 100 °C for 10 h. Upon cooling, the reaction mixture was poured into water and extracted with CH_2Cl_2, concentrated and purified by flash chromatography on silica gel. The purity of the compounds was checked by GC and yields are based on aryl chlorides.

4.7. General procedure for the Heck reaction

Palladacycles **5** (0.1 mmol%), bromobenzene (1.0 mmol), styrene (1.5 mmol), K_2CO_3 (2 mmol), DMF (10 cm^3) were added to a 25 cm^3 round-bottomed flask and the mixture was heated at 140 °C for 7 h. Upon cooling, the reaction mixture was poured into water and extracted with CH_2Cl_2, concentrated and purified by flash chromatography on silica gel. The purity of the compounds was checked by GC and yields are based on bromobenzene.

4.8. X-ray crystallographic study of 5a

Crystals of **5a** were grown at room temperature by slow evaporation of a mixture of hexane and ethyl acetate over a period of one week. A single crystal of this complex was mounted on a Bruker SMART CCD diffractometer equipped with monochromated graphite Mo Kα (λ = 0.71073 Å) radiation at ambient temperature (T = 293 K) using the ω–2θ multi-scans technique for data collection. Semi-empirical absorption corrections were applied using the SABABS program [18]. The structure was solved by direct methods and refined by the full-matrix least-squares procedure on F^2 using the SHELX suite of programs [19]. The values of R_1 were given based on F_o with a typical threshold of $F^2 \geqslant 2\sigma(F^2)$. The weighted R-factors wR were based on F^2 with calc. $w = 1/[\sigma^2(F_o^2) + (0.0000P)^2 + 0.0827P]$ where $P = (F_o^2 + 2F_c^2)/3$ for **5a**. Crystallographic data for **5a** are summarized in Table 1. Selected bond lengths and angles for **5a** are presented in Table 2.

5. Supplementary material

CCDC 603093 contains the supplementary crystallographic data for **5a**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Results and discussion

2.1. Syntheses of tetra(tert-butyl)metallate complexes of lanthanide elements

The preparation of the salt $[Li(THF)_4][Er(t\text{-}Bu)_4]$ has been reported previously [19]. In our hands, the reported preparation proceeded as described, but we were not able to obtain analytically pure material. Instead, we obtained materials with low carbon and hydrogen analyses that retained chloride. Attempts to prepare the terbium analog $[Li(THF)_4][Tb(t\text{-}Bu)_4]$ gave similar results.

In order to obtain crystalline and analytically pure samples, we have investigated the corresponding $[Li(DME)_3^+]$ salt, where DME is 1,2-dimethoxyethane. Thus, slow addition of a pentane solution of *tert*-butyllithium to a suspension of anhydrous erbium trichloride in DME/pentane at −78 °C, followed by warming to room temperature gives a pink solution, from which pink crystals of $[Li(DME)_3][Er(t\text{-}Bu)_4]$ (**1**) can be obtained by layering a saturated ether solution with pentane and cooling to −20 °C. The material so obtained is analytically pure. The corresponding Tb complex $[Li(DME)_3][Tb(t\text{-}Bu)_4]$ (**2**) can be made similarly, but the cerium analog could not be successfully isolated by the same route.

The IR spectrum of the erbium complex **1** shows ν_{CH} bands due to the *tert*-butyl groups at 2753, 2724, and 2667 cm^{-1}. In comparison, for the $[Li(THF)_4^+]$ salt of this same anion, Evans et al. reported similar bands at 2760, 2730, 2670 and 2620 cm^{-1} [19]. The low frequencies of these C–H modes are characteristic of *tert*-butyl groups [26,27], and are not consequences of CH_3–Li or agostic interactions, as verified by the X-ray structure (see below). The IR spectrum of the terbium analog **2** is essentially identical to that of **1**. ^1H NMR spectra of paramagnetic **1** and **2** contain broad resonances for the *tert*-butyl groups at δ −11 and −76.6, respectively.

2.2. Molecular structure of [Li(DME)$_3$][Er(t-Bu)$_4$] (1)

General crystallographic data, selected bond lengths and angles for **1** are listed in Tables 1 and 2, respectively; views of one of the cations and one of the anions are given in Fig. 1. In the asymmetric unit there are two anions, one full cation, and two half-cations. Except for some disordering of the *tert*-butyl groups on Er(2), the two crystallographically inequivalent anions have very similar metric parameters. The DME ligands about one of the lithium centers are also disordered, but again the coordination geometries of all three independent cations are very similar.

The erbium(III) center in **1** is ligated by four *tert*-butyl groups in an approximately tetrahedral arrangement. The C–Er–C angles between the *tert*-butyl groups range from 108.4(3)° to 111.2(3)° and the Er–C distances range from 2.352(6) to 2.395(6) Å. These values are similar to those seen for the $[Lu(t\text{-}Bu)_4^-]$ anion [18], in which the C–Lu–C angles range from 107.3° to 109.8° and the Lu–C distances range from 2.32(2) to 2.43(2) Å. In $Cp_2Lu(t\text{-}Bu)(THF)$ [28], the Lu–C distance to the *tert*-butyl group was much longer at 2.47(2) Å, probably because the coordination number of this compound is higher.

Each lithium cation in **1** is surrounded by three DME molecules, which form a distorted octahedral coordination

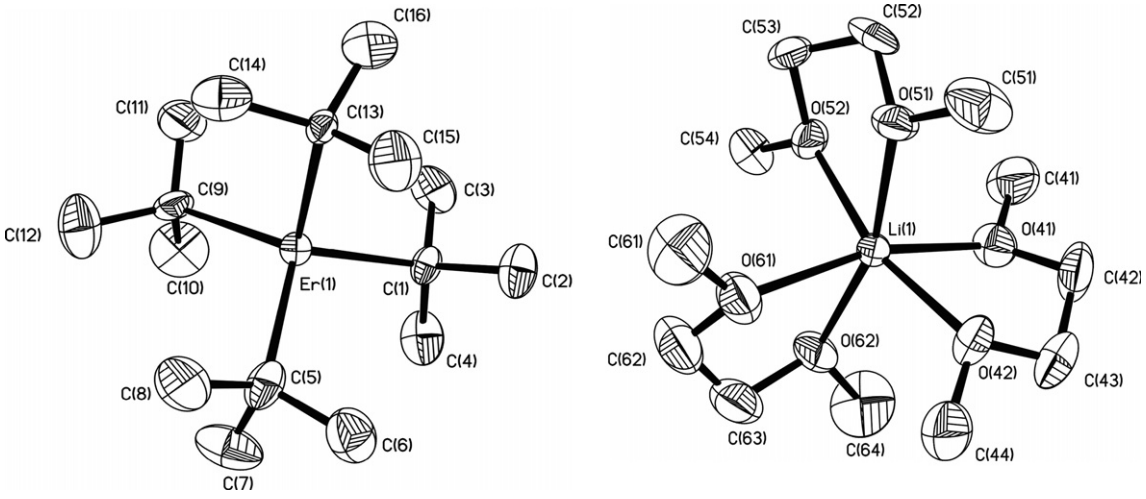

Fig. 1. Molecular structure of $[Li(DME)_3][Er(t\text{-}Bu)_4]$ (**1**); anion at left, cation at right.

sphere. The Li–O distances, which lie between 2.07(2) and 2.14(2) Å, agree with the 2.07(1)–2.17(1) Å range found in $[Li(DME)_3][(Cp_3Sm)_2(\mu\text{-}Cl)]$ [29] and the 2.12(1) Å value in $[Li(DME)_3][Zr(SCMe_3)_5]$ [30]. Some $[Li(DME)_3^+]$ cations are known in which the Li–O distances vary over a wider range: from 2.03(2) to 2.37(2) Å in $[Li(DME)_3][(C_5H_4Me)La(NPh_2)_3]$ [31] and from 2.07(2) to 2.34(2) Å in $[Li(DME)_3][Cp_2Nd(NPh_2)_2]$ [32]. The O–Li–O angles in **1** range from 77.4(5)° to 77.7(5)°, a range that is consistent with previous values for this cation.

Colorless crystals of the terbium analog **2** were also obtained by diffusion of pentane into an ether solution at −20 °C. The crystals were twinned and the diffraction data set, which approximated to cubic symmetry, could not be solved.

2.3. Attempts to prepare tetra(alkyl)lanthanide(IV) species

Alkyl groups are reasonably strongly donating and are well-known to stabilize higher oxidation states of transition metals [33]. Among alkyl groups, *tert*-butyl substituents are among the most strongly donating [34]. In addition, because four *tert*-butyl groups are able to saturate the coordination sphere of a Ln^{3+} metal – as the existence of $[Ln(t\text{-}Bu)_4^-]$ anions shows – they should also be able to saturate the coordination sphere of a somewhat smaller Ln^{4+} metal center. Such Ln^{4+} centers are still large enough to accommodate four *tert*-butyl substituents, as shown by the existence of a tetra(*tert*-butyl) complex of an even smaller ion: the Cr^{4+} center in $Cr(t\text{-}Bu)_4$ [35].

Of all the lanthanide elements, cerium has the most accessible tetravalent oxidation state and is the natural starting point for efforts to prepare a tetra(alkyl) derivative. Although we were unable to isolate pure salts of the tetra(*tert*-butyl)cerate(III) ion (see above), we attempted to prepare this species and oxidize it *in situ*. After treatment of $CeCl_3$ with 4 equivalents of *tert*-butyllithium in THF/ pentane at −78 °C, the mixture was exposed to dry O_2 at −40 °C. No color change occurred. Filtration and removal of the solvent gave an oily liquid, from which no organometallic species could be isolated.

The significance of this result is unclear, in part because the organocerium(III) starting material was not isolated but prepared *in situ*. To complement this result, we investigated whether pure samples of the anionic terbium(III) compound $[Li(DME)_3][Tb(t\text{-}Bu)_4]$ (**2**) react with oxidants to generate $Tb(t\text{-}Bu)_4$. Terbium (along with Pr) has the most accessible +4 oxidation state after cerium, its stability deriving in part from its f^7 electronic configuration.

Injection of 4 equivalents of dioxygen into solutions of **2** immediately caused a color change from colorless to yellow. When this reaction was followed by NMR spectroscopy, the broad ^1H NMR resonance at δ −76.6 due to the starting material disappeared after the addition of oxygen. Two new resonances appeared at δ 0.88 and 4.62, which are due to *iso*-butane (1.67 mol/mol Tb), and *iso*-butene (0.80 mol/mol Tb), respectively [36–38]; these assignments were confirmed by GC analysis. No new NMR resonances appeared that could be ascribed to an organolanthanide product. Similar addition of O_2 to the erbium complex **1** caused an exotherm but did not result in a change in the solution color. The broad ^1H NMR peak at δ −11 due to the starting material disappeared after dioxygen was added, but no peaks due to new organolanthanide species were apparent.

We also examined the action of one-electron chemical oxidants on the terbium compound **2**. Addition of silver acetate or silver chloride to a solution of **2** in diethyl ether resulted in the immediate precipitation of silver metal and a color change similar to that seen upon the addition of oxygen. Neither of these reactions resulted in the formation of pentane-soluble organolanthanide species. Addition of one equivalent of 1,1′-dimethylferrocenium tetrakis[3,5-bis(trifluoromethyl)phenyl]borate to **2** in diethyl ether caused the solution to change color from blue (the color of the ferrocenium salt) to yellow (the color of dimethylferrocene),

but again there was no evidence from the NMR spectra of the formation of a new organolanthanide species.

The present studies suggest that Ln(*t*-butyl)$_4$ species, if they exist, are not readily obtained by direct oxidation of their [Ln(*t*-butyl)$_4^-$] analogs with common oxidizing agents, possibly because the alkyl groups are more easily oxidized than the metal center.

3. Experimental

All syntheses were carried out under an argon atmosphere, using a glove box and Schlenk techniques. Solvents were dried over Na/benzophenone and distilled under nitrogen immediately before use. The starting materials $ErCl_3$ and $TbCl_3$ (99.9% pure, Alfa-Aesar), pentane solutions of *tert*-butyllithium (Aldrich), and oxygen gas (S. J. Smith) were used as received. Microanalyses were performed by the University of Illinois Microanalytical Laboratory. The IR spectra were recorded on a Nicolet Impact 410 instrument as Nujol mulls between KBr plates. The gas chromatographs were recorded on an Agilent 6890/5973 GCMS equipped with FID and TCD detectors; the inlet temperature was 250 °C, the oven temperature was 275 °C, the carrier gas was He (20.0 mL/min), and the separations were carried out on a 30 m long, 0.32 mm diameter, 1.5 μm thick carbon PLOT column with a deactivated SiO_2 guard column (J&W Scientific). The ^{1}H NMR data were collected on a Varian Unity U400 instrument at 400 MHz. Chemical shifts are reported in δ units (positive shifts to high frequency) relative to tetramethylsilane.

3.1. Tris(1,2-dimethoxyethane)lithium tetra(tert-butyl)erbate, [Li(DME)$_3$][Er(t-Bu)$_4$] (1)

To a slurry of $ErCl_3$ (0.30 g, 1.10 mmol) suspended in 1,2-dimethoxyethane (9 mL) and pentane (5 mL) at −78 °C was added a solution of *tert*-butyllithium (2.82 mL of a 1.7 M solution in pentane, diluted to 35 mL with pentane) dropwise over 90 min. The mixture was stirred for two hours at −78 °C and then slowly warmed to room temperature. After two hours at room temperature, the mixture had separated into a colorless layer (pentane and DME), a pink suspension (crude product), and a white powder (LiCl). The colorless layer was carefully decanted and the solid was washed with pentane (30 mL) and extracted with diethyl ether (2 × 30 mL). The bright pink extract was filtered, concentrated to about 30 mL, layered with pentane (~10 mL), and cooled to −20 °C. The pink prisms were isolated and dried in vacuum. Yield: 0.3 g (40%). Mp: 105 °C (dec). *Anal.* Calc. for $C_{28}H_{66}LiO_6Er$: C, 49.9; H, 9.88; Li, 1.03; Er, 24.9. Found: C, 49.1; H, 9.69; Li, 1.02; Er, 24.1%. ^{1}H NMR (d_8-THF): δ −11 (s, fwhm = 680 Hz, *t*-Bu), δ 3.2 (br, DME). IR (cm^{-1}): 2753 s, 2724 s, 2667 s, 2615 w, 1267 m, 1194 m, 1127 m, 1085 s, 1031 m, 870 s, 784 s.

3.2. Tris(1,2-dimethoxyethane)lithium tetra(tert-butyl)terbate, [Li(DME)$_3$][Tb(t-Bu)$_4$] (2)

The procedure is the same as that for the preparation of **1** except that the reagents used were $TbCl_3$ (0.30 g, 1.13 mmol) and *tert*-butyllithium (2.9 mL of a 1.7 M solution in pentane). The product was isolated as colorless prisms. Yield: 0.31 g (41%). Mp: 80 °C (dec). *Anal.* Calc. for $C_{28}H_{66}LiO_6Tb$: C, 50.6; H 10.0; Li, 1.04; Tb, 23.9. Found. C, 49.8; H, 9.78; Li, 1.02; Tb, 23.4%. ^{1}H NMR (d_8-THF): δ −76.6 (s, fwhm = 300 Hz, *t*-Bu) δ 3.3 (s, MeO), 3.4 (s, OCH_2). IR (cm^{-1}): 2752 s, 2722 s, 2668 s, 1246 s, 1195 s, 1130 s, 1088 s, 1030 m, 985 m, 871 s, 777 s.

3.3. Attempts to oxidize tetra(tert-butyl)terbate, [Li(DME)$_3$][Tb(t-Bu)$_4$] (2)

Colorless crystals of **2** (0.31 g, 0.47 mmol) were dissolved in diethyl ether (30 mL) and O_2 gas (45 mL, 1.85 mmol) was injected by syringe into the solution at room temperature. The solution color changed from colorless to yellow and a small amount of a flocculent precipitate formed. An aliquot was removed for analysis by GCMS, which showed the presence of *iso*-butene and *iso*-butane, in addition to peaks for the solvent and 1,2-dimethoxyethane.

In a separate experiment, a sample of **2** was placed in a 5 mm diameter NMR tube capped with a rubber septum, and the crystals were dissolved in d_8-THF (1 mL) to give a colorless solution. O_2 gas was bubbled into the solution until the solution color became yellow. ^{1}H NMR spectra were taken before and after the introduction of O_2. ^{1}H NMR (d_8-THF): δ 0.88 (s, CH*Me*$_3$), δ 4.62 (s, *CH*$_2$=CMe$_2$). The methine peak of *iso*-butane and the methyl peak of iso-butene were obscured by the resonance at δ 1.72 due to the solvent; peaks at δ 3.44 and 3.28 due to 1,2-dimethoxyethane were also present. By assuming that the 1,2-dimethoxyethane peaks corresponded to 3 mol/(mol Tb), the peak integrations suggested that 1.67 mol of *iso*-butane and 0.80 mol of *iso*-butene were formed per mol of Tb.

3.4. X-ray crystallographic studies [39]

Pink crystals of [Li(DME)$_3$][Er(*t*-Bu)$_4$] (**1**) were grown by diffusion of pentane into a diethyl ether solution at −20 °C. The crystal was twinned but the twinning was non-merohedral, and the two partially overlapping diffraction patterns were indexed separately. Systematic absences for *hkl* ($h + k \neq 2n$), and *h*0*l* ($l \neq 2n$) were consistent with the space groups *Cc* and *C*2/*c*. The structure was solved in *Cc* and later symmetrized to *C*2/*c*, which is correct space group. No corrections for crystal decay were necessary and, owing to the twinning, no absorption correction was applied. Systematically absent reflections were deleted.

The structure was solved using direct methods by using the SHELXTL software package. The correct positions for the

erbium atoms were deduced by direct-methods from an E-map. Subsequent least-squares refinement and difference Fourier calculations revealed the positions of the remaining non-hydrogen atoms. Non-hydrogen atoms were refined with independent anisotropic displacement parameters. Hydrogen atoms were fixed in "idealized" positions and their displacement parameters were tied to those of the attached non-hydrogen atom. The $Li(DME)_3$ cation centered on Li(3) was disordered about the two-fold axis. The disorder involved overlapping atoms, and was modeled in terms of three complete DME molecules, the atoms of which were assigned site occupancy factors of exactly 0.5. In addition, two of the *tert*-butyl groups on Er(2) were disordered over two rotameric conformations. The site occupancy factors for these groups were initially refined, but later set equal to exactly 0.5.

At this point, it became clear that several classes of reflections were affected by the twinning. Reflections with $|l| = 0$, 1, 11, 12, 13, 14, 24, 25, and 26 were systematically more intense than calculated. For reflections with these values of l, the calculated intensity was set equal to the formula $I_{calc} = xI_{hkl} + (1 - x)I_{h'k'l'}$, where $h' = -h - \mathrm{rnd}(l/6)$, $k' = -k$, and $l' = l$, and x is the volume fraction of the major twin individual; "rnd" indicates that the quotient $l/6$ was rounded to the nearest integer. About 100 of the reflections with $|l| = 1$, 11, and 14 were not modeled well by this function ($F^2 > 4.5F^2$), evidently because the two reciprocal lattices were sometimes distinguishable and only one reflection had been measured; such reflections were either reassigned calculated intensities based solely on the major twin, or deleted from the reflection file. The intensities of symmetry-equivalent reflections were *not* averaged, and 72 825 unique reflections were used in the least-squares refinement. The twin ratio refined to 0.682(1) for the major twin individual.

Similarity constraints were imposed on the Li–O, C–O, and C–C distances of the disordered DME ligands attached to Li(3), on the C–C distances in the disordered *tert*-butyl groups on Er(2), and on the displacement parameters of adjacent atoms. In the final cycle of least squares, anisotropic displacement factors were refined for all erbium and for all ordered oxygen carbon atoms; isotropic displacement parameters were refined for the lithium atoms and all disordered oxygen and carbon atoms. Hydrogen atoms were placed in idealized positions (for methyl protons, they were placed in positions staggered with respect to the substituents on the vicinal atom). The displacement parameters for methylene hydrogens were set equal to 1.2 times U_{eq} for the attached carbon; those for methyl hydrogens were set to 1.5 times U_{eq}. Successful convergence was indicated by the maximum shift/error of −0.009 for the last cycle. Final refinement parameters are given in Table 1. The largest peak in the final Fourier difference map (2.69 e $Å^{-3}$) was located 1.2 Å from Er(2). A final analysis of variance between observed and calculated structure factors showed that the intensities of many of the reflections with $|l| = 1$, 11, and 14 (and some with $|l| = 2$) were still not modeled well; otherwise, there were no systematic errors.

4. Supplementary material

CCDC 635390 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgments

We thank the National Science Foundation for support of this research under Grant Nos. DMR03-54060 and DMR04-20768, and Scott R. Wilson and Teresa Prussak-Wieckowska for collecting the X-ray crystallographic data.

known for their analogues $[Cu(PhCN)_4][BF_4]$ (**2**) and $[Cu(BzCN)_4][BF_4]$ (**3**). In fact, to the best of our knowledge, no report has been given regarding the characterization of the complex **3**. We started our studies motivated by the possibility of using such compounds as starting materials for the preparation of new Cu(I) complexes. In addition, the evaluation of the factors that can affect detection of copper by NMR spectroscopy on these related systems will enlarge the application of this tool for the study of copper(I)-containing materials.

2. Experimental

2.1. General

Solvents and starting materials were used as received from the suppliers. Preparation of complex **2** was conducted using standard Schlenk techniques, under argon atmosphere.

2.2. Instrumentation

Elemental analyses (C, H, N) were performed on a Fisions MOD EA 1108 analyser. The infrared spectra (4000–400 cm^{-1}) were recorded on BOMEM BM 100 FT-IR spectrometer. NMR spectra were recorded on a Varian MERCURY plus spectrometer 7.05 T, operating at 300.07 MHz for ^{1}H, 96.27 MHz for ^{11}B, 75.46 MHz for ^{13}C, 282.31 MHz for ^{19}F and 79.58 MHz for ^{63}Cu. The ^{1}H, $^{11}B\{^{1}H\}$, $^{13}C\{^{1}H\}$, and ^{19}F NMR spectra were obtained in acetone-d_6 as solvent at room temperature. Chemical shifts (δ) are given in ppm relative to $SiMe_4$ (internal reference for ^{1}H and ^{13}C), neat $BF_3 \cdot OEt_2$ (external reference for ^{11}B) and CCl_3F (external reference for ^{19}F), respectively. The solution NMR studies were performed using broad band probe heads equipped with a variable-temperature unity precise to 0.5 °C. ^{63}Cu NMR spectra were acquired at 300 K (unless otherwise stated) in a 5 mm tube (o.d.) and were externally referenced to a 0.1 mol/L solution of **1** in CD_3CN by using a capillary ($\delta = 0$). A single pulse sequence was used. Typical NMR parameters were the following: spectroscopic window 55 866 Hz, pulse 10.7 μs (π/2 pulse length), acquisition time 0.293 s, 2048 scans, FT size 65 536 points. An exponential function Lb = 10 has been applied before Fourier transform. The ^{63}Cu line width at half-height, $\Delta\nu_{1/2}$, was determined by fitting it to Gaussian line shape using the VNMR 6.1C software. The $\Delta\nu_{1/2}$ for **1** was determined to be 530 Hz in accord with previous results [10].

2.3. Preparation of the complexes

The copper-nitrile complexes have been obtained based on the reported method for the preparation of **1** [11]. Typically, the complex $[Cu(BzCN)_4][BF_4]$ (**3**) was prepared as follows: Cu_2O (72 mg, 0.5 mmol) was suspended in phenylacetonitrile – BzCN (5 mL). Under continuous stirring, HBF_4 40% (0.16 mL, 1.0 mmol) was added at once. The red suspension was stirred until the color has discharged (approximately 1 h). After that, the product started to crystallize from the medium and the crystallization process was completed by adding toluene (1:1 v/v). The microcrystalline solid was filtered off, washed with ethyl ether and vacuum dried. Yield 405 mg (65%). M.p. 90–92 °C. *Anal.* Calc. for $C_{32}H_{28}BCuF_4N_4$: C, 62.10; H, 4.56; N, 9.05; Cu, 10.27. Found: C, 62.61; H, 4.50; N, 8.84; Cu, 9.48%. NMR (acetone-d_6) ^{1}H δ 7.31–7.16 (m, 20H, CH arom.), 3.95 (s, 8H, CH_2); $^{13}C\{^{1}H\}$ δ 130.8, 129.2, 128.3, 128.0, 118.5 (broad, CN), 23.0; $^{11}B\{^{1}H\}$ δ 2.2; ^{19}F δ −146.7. Selected IR bands (Nujol mull): 2284 (ν CN), 1050 cm^{-1} (br, ν_{asym} BF_4^-).

The complex $[Cu(PhCN)_4][BF_4]$ (**2**) was prepared as described above but in argon atmosphere to prevent its decomposition.

NMR (acetone-d_6) ^{1}H δ 7.8–7.6 (m); $^{13}C\{^{1}H\}$ δ 132.3, 130.7, 127.9, 109.3 (broad, CN); $^{11}B\{^{1}H\}$ δ 0.2; ^{19}F δ −147.1.

2.4. Crystallographic determination of 3

Suitable crystal of **3** for X-ray diffraction studies was grown by slow diffusion of ethyl ether into its BzCN solution.

Crystallographic measurements were made on a Bruker Kappa X8 Apex II CCD area detector with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 100(1) K. Raw image data were processed with SAINT and SADABS [12] to produce the final intensity data corrected for polarization, Lorentz and absorption effects. The structure was solved by direct methods (SHELXS-97) and additional atoms were located in the difference Fourier map and refined on F^2 (SHELXL-97) [13]. Hydrogen atoms were refined using a riding model.

Crystal data for **3** $C_{32}H_{28}BCuF_4N_4$: $M = 618.93$, colorless plate, $0.09 \times 0.43 \times 0.44$ mm^3, monoclinic, $P2(1)/n$ (no. 14 alternate), $a = 9.9620(11)$ Å, $b = 29.881(3)$ Å, $c = 10.2236(12)$ Å, $\beta = 90.363(5)°$, $V = 3043.3(6)$ $Å^3$, $Z = 4$, $D_{calc} = 1.351$ g cm^{-3}, $F_{000} = 1272$, $2\theta_{max} = 30.48°$, 53 060 reflection collected, 9250 independent, $R_{int} = 4.58\%$. Final goodness-of-fit = 1.036, R_1 [$I > 2\sigma(I)$] = 0.0367, wR_2 [all data] = 0.096, 380 parameters, $\Delta\rho_{min} = -0.52$, $\Delta\rho_{max} = 0.71$ e $Å^{-3}$.

3. Results and discussion

3.1. Solution ^{63}Cu NMR

3.1.1. Concentration effect

A stock solution of **2** 0.50 mol/L in benzonitrile, PhCN, was prepared and used to make the desired solutions for ^{63}Cu NMR studies. A dependence of the line width at half-height ($\Delta\nu_{1/2}$) on the concentration of **2** has been noticed (Fig. 1). It is worth mentioning that a 1.0 mol/L solution of **2** shows no ^{63}Cu NMR signal i.e. the bandwidth is so broad that it is beyond detection.

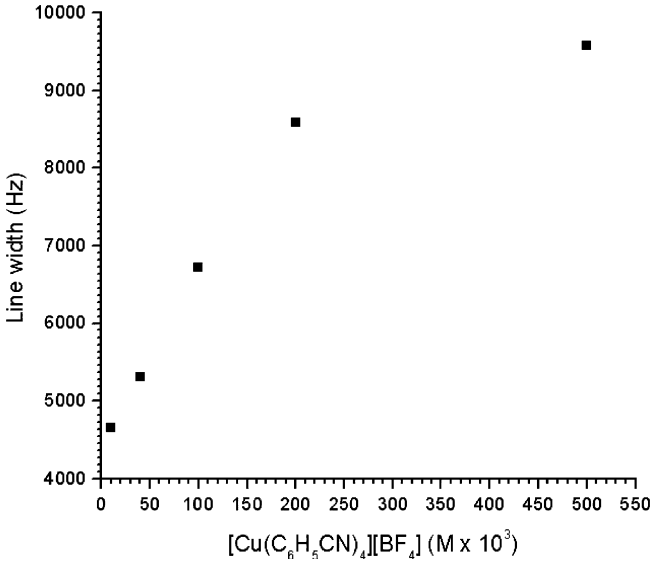

Fig. 1. Dependence of line width of the ^{63}Cu resonance on the concentration of $[Cu(PhCN)_4][BF_4]$ (**2**) in benzonitrile solution.

3.1.2. Temperature effect

The effect of the temperature on the ^{63}Cu chemical shift has been known to depend on the complex studied. For **1**, a negative effect of −0.75 ppm/K has been observed with the temperature increase [3]. A larger effect of about −1.0 ppm/K has been observed for **2** within the temperature range of 268–343 K (Fig. 2). As can be seen in Fig. 3, a line width minimum is observed at 313 K.

3.2. Solid-state ^{63}Cu NMR

While the solution of **3** could not be studied by ^{63}Cu NMR spectroscopy since its resonance is extremely broad, the ^{63}Cu MAS NMR spectrum of microcrystalline **3** (Fig. 4) shows a resonance whose line width is comparable to that of the standard CuCl.

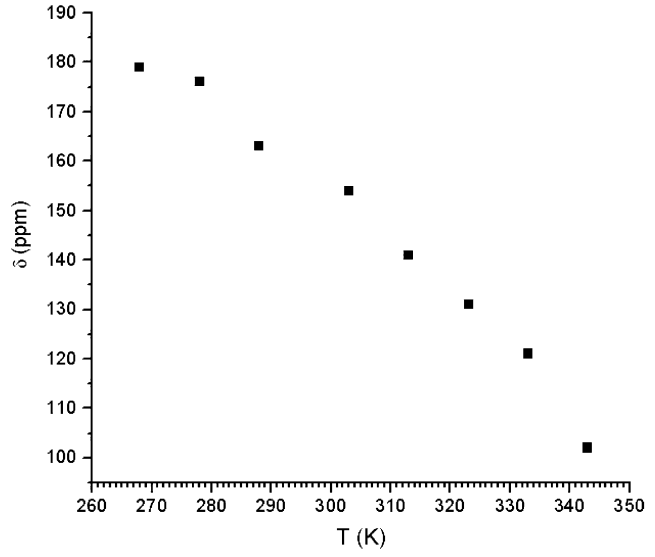

Fig. 2. Dependence of the ^{63}Cu chemical shift on the temperature of a 0.05 mol/L solution of $[Cu(PhCN)_4][BF_4]$ (**2**) in benzonitrile solution.

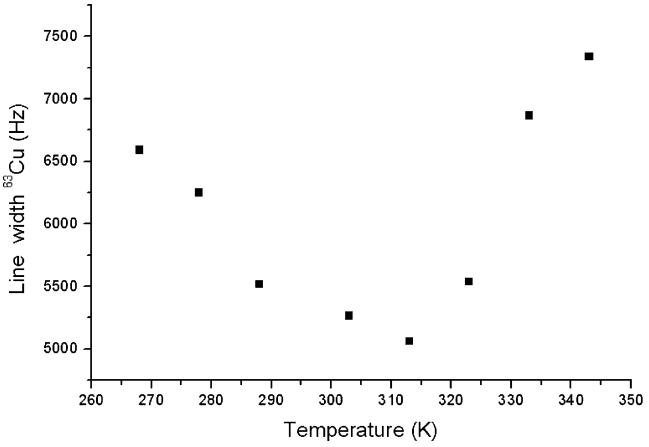

Fig. 3. Dependence of the ^{63}Cu line width on the temperature of a 0.05 mol/L solution of $[Cu(PhCN)_4][BF_4]$ (**2**) in benzonitrile solution.

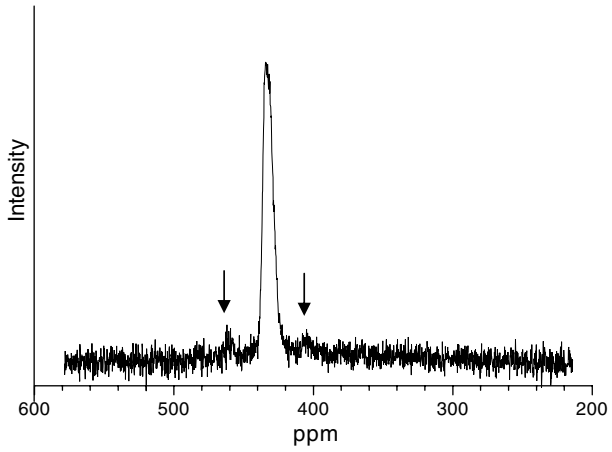

Fig. 4. ^{63}Cu MAS NMR spectrum of complex $[Cu(BzCN)_4][BF_4]$ (**3**) referenced against static CuCl ($\delta = 0$) [20]. Spectroscopic window 100 kHz, pulse width 5.5 μs, acquisition time 0.05 s, 256 scans, FT size 32768, spin rate 4 kHz. An exponential function Lb = 10 has been applied before Fourier transform. The two arrows point to spinning sidebands.

3.3. Solution structure by ^{63}Cu spectroscopy

It has been known that detectable narrow lines for ^{63}Cu NMR are usually obtained if the coordination sphere around Cu(I) is rigorously tetrahedral. These line widths are governed essentially by the quadrupolar relaxation rate, $(1/T_2)_Q$ [7], which depends on the symmetry. The $(1/T_2)_Q$ depends, in addition to some other parameters, on the reorientational correlation time, τ_R, which in turns depends on the viscosity of the solvent, η_S, and the radius of the complex, r_c, (Stokes–Einstein model).

$$\tau_R \propto \eta_S r_c^3 \quad (1)$$

In complex **2**, an increase in the ^{63}Cu line width occurs with the increase of the complex concentration. This result is in line with previous reports concerning the complexes [Cu

$(MeCN)_4]X$, where $X = BF_4^-$, ClO_4^- in acetonitrile as solvent [2,8,10]. It is also known that a dramatic increase of the line width occurs with an increase of the mole ratio benzonitrile/acetonitrile [7]. This phenomenon has been interpreted as a consequence of an increase of the viscosity of the medium as the concentration of the complex increases (Eq. 1). Attempts to acquire ^{63}Cu NMR spectra of **2** in $(CD_3)_2CO$ were unsuccessful. It is concluded that the ligand benzonitrile tends to dissociate giving the three-coordinate, or even two-coordinate, species as depicted below (Eq. 2). When benzonitrile is employed as solvent such dynamic equilibrium favors the tetra-coordinated species and so the signal can be detected.

$$[Cu(PhCN)_4]^+ = [Cu(PhCN)_{(4-n)}]^+ + n\text{PhCN} \quad (2)$$

Complex **2** exhibited an anomalous profile in the variable-temperature ^{63}Cu spectra above 213 K, since decreasing of the line width would be expected with increasing temperature for quadrupolar relaxation. This same profile has been observed for $[Cu(MeCN)_4]X$ although their line width minimum is located at about 268 K [2]. Such anomaly has been interpreted based on ligand exchange becoming more severe with increasing temperature.

In the case of **3**, no signal could be detected either in the phenylacetonitrile solution 0.05–0.2 mol/L range or in acetone-d_6 as solutions in the 0.005–0.25 mol/L range, in spite of much effort devoted to this task. Since compound **3** is much more inert in the air compared to **2**, its reluctance to give NMR signal should not be attributed to the presence of Cu^{2+}. The white solid **3** has been kept in a stopped vessel for about two years with no apparent change although it has been opened a couple of times. We hypothesized that this behavior is a consequence of dynamic equilibrium taking place in solution between the tetra- three- and two-coordinated species, with exchange rate in the order of the NMR time scale. Even MeCN, which is less crowding compared to BzCN, can form low-coordinated copper(I) complexes, demonstrated recently by the X-ray structure of two-coordinated $[Cu(MeCN)_2][B(C_6F_5)_4]$ [14]. In order to confirm our hypothesis we set out to study **3** by solid-state ^{63}Cu NMR spectroscopy and X-ray crystallography. Accordingly, ^{63}Cu MAS NMR spectrum has been acquired for the microcrystalline solid **3** and it turned out to give a reasonably sharp resonance, namely, $\Delta\nu_{1/2}$ 1.06 kHz (Fig. 4) which is comparable to the reference's line width obtained at the same speed. The NMR data of **3** suggest that the copper atom is tetra-coordinated in the solid-state while in solution an equilibrium between tetra- and lower coordinated species is operative. In fact, the X-ray diffraction study confirmed that the copper(I) atoms is tetra-coordinated by four nitrile ligands in a slightly distorted tetrahedral geometry (Fig. 5).

The ^1H and $^{13}C\{^1H\}$ NMR of **2** and **3** spectra show no indication of free nitrile in acetone-d_6 solution at room temperature. It can be concluded that one only see averaged signals in such conditions, consistent with the proposed equilibrium depicted in (2).

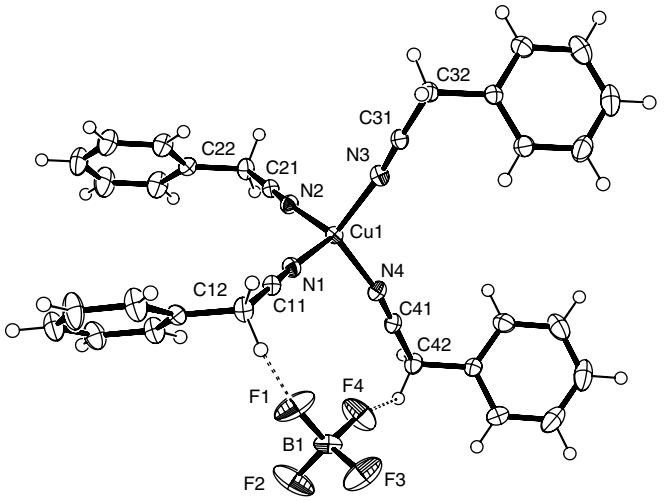

Fig. 5. ORTEP [21] plot of $[Cu(BzCN)_4][BF_4]$ (**3**) with the atom numbering. Thermal ellipsoids are scaled at 50%. Selected bond distances (Å) and bond angles (°): Cu(1)–N(1), 1.9828(12); Cu(1)–N(2), 1.9869(12); Cu(1)–N(3), 1.9815(12); Cu(1)–N(4), 1.9838(12); N(3)–Cu(1)–N(1), 102.14(5); N(3)–Cu(1)–N(4), 114.74(5); N(1)–Cu(1)–N(4), 111.90(5); N(3)–Cu(1)–N(2), 110.78(5); N(1)–Cu(1)–N(2), 114.89(5); N(4)–Cu(1)–N(2), 102.85(5); C(11)–N(1)–Cu(1), 170.74(12); C(21)–N(2)–Cu(1), 170.72(12); C(31)–N(3)–Cu(1), 169.69(12); C(41)–N(4)–Cu(1), 168.37(12).

3.4. X-ray structure of 3

The X-ray crystallographic study of the complex $[Cu(BzCN)_4][BF_4]$ (**3**) reveals a slightly distorted tetrahedral copper(I) center with four BzCN ligands coordinated via their nitrogen atoms. The Cu–N distances, which are almost equal varying from 1.9815(12) Å to 1.9869(12) Å, are close to the average found for similar compounds, 1.99(3) Å for 47 compounds found in the Cambridge Structural Database [15]. The angle between the planes N1–Cu1–N4 and N2–Cu1–N3 is 81.42(3)° showing a slightly flattening of the tetrahedron; the N–Cu–N bond angles range from 102.85(5)° to 114.89(5)°. The Cu–N–C angles fall between 168.37(12)° and 170.74(12)°, which is normal compared to the average for the similar compounds, 172(4)°. The geometry of the BzCN ligands is not remarkable. No π–π interactions are seen in the structure of **3**, unlike those of similar $[Cu(NCPh)_4]^+$ compounds [16–18] where the Cu–N–C angles are much more distorted from the average and the geometry around the copper(I) atom is more flattened. There are non-classic hydrogen bonding interactions between one hydrogen atom of each methylene

Table 1
Non-classic hydrogen bonds for **3**, $[Cu(BzCN)_4][BF_4]$ (Å and °)

D–H···A	d(D–H)	d(H···A)	d(D···A)	∠(DHA)
C(12)–H(12B)···F(1)	0.99	2.62	3.1777(19)	115.7
C(42)–H(42B)···F(4)	0.99	2.67	3.248(2)	117.7
C(32)–H(32B)···F(3)[a]	0.99	2.61	3.2010(19)	118.3

group of the BzCN ligands and the fluorine atoms of the BF_4 anion, Table 1, to form a continuous chain along the crystallographic *z* direction.

3.5. Chemical properties of $[Cu(PhCN)_4][BF_4]$ (2) and $[Cu(BzCN)_4][BF_4]$ (3)

Crystalline **3** can be handled on a bench top since it is more air-stable copper(I) complex compared to **1** or **2**. It is also stable in BzCN solution. Apparently, the benzyl groups block more effectively the access of dioxygen molecule compared to methyl groups, for example. Compound **3** seems to be a more convenient starting material for the preparation of copper(I) complexes since it is: (i) easily prepared, (ii) safely handled, and (iii) labile regarding ligand displacement. For instance, the reaction of **3** with 4,6-dimethylpyrimidine-2-thione (dmpymtH) proceeds in phenylacetonitrile/toluene mixture (1:1), under reflux, with displacement of all BzCN molecules by the heterocyclic ligand giving the already known complex $[Cu(dmpymtH)_3]_2[BF_4]_2 \cdot 2H_2O$ [19]. The lability of **3** is also supported by the fact that when it was treated with a coordinating anion containing salt, i.e., KSCN, pure CuSCN precipitated, confirmed by comparison of its infrared spectrum with that of an authentic sample.

accommodate tridentate ligands via displacement of three pre-coordinated ligands and, more importantly, its proven efficiency to bring about C–H activation of organic molecules [2b,2c,2i]. Reaction of the *N*-(2′-hydroxyphenyl)benzaldimines (**1**) with $[Ru(PPh_3)_2(CO)_2Cl_2]$ has indeed been observed to afford a family of organoruthenium complexes containing chelate **3** (M = Ru). An account of the chemistry of these organoruthenium complexes is presented here, with special reference to their formation, structure and, spectral and electrochemical properties.

2. Experimental

2.1. Materials

Commercial ruthenium trichloride was purchased from Arora Matthey, Kolkata, India. Triphenylphosphine, 2-aminophenol and the *para*-substituted benzaldehydes were obtained from Merck, India. All other chemicals and solvents were reagent grade commercial materials and were used as received. $[Ru(PPh_3)_2(CO)_2Cl_2]$ was prepared following a reported procedure [8]. The *N*-(2′-hydroxyphenyl)-benzaldimines (**1**) were prepared by reacting equimolar amounts of respective *para*-substituted benzaldehyde and 2-aminophenol in ethanol. Purification of acetonitrile and dichloromethane, and preparation of tetrabutylammonium perchlorate (TBAP) for electrochemical work were performed as reported in the literature [9].

2.2. Synthesis

The $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes were synthesized by following a general procedure. Specific details are given below for a particular complex.

[Ru(PPh$_3$)$_2$(CO)(L-OCH$_3$)]: *N*-(2′-hydroxyphenyl)-4-methoxybenzaldimine (30 mg, 0.13 mmol) was dissolved in 2-methoxyethanol (40 mL) and triethylamine (30 mg, 0.30 mmol) was added to it followed by $[Ru(PPh_3)_2(CO)_2Cl_2]$ (100 mg, 0.13 mmol). The resulting mixture was then refluxed for 24 h, whereby a violet solution was obtained. Evaporation of the solution gave a violet solid, which was subjected to purification by thin layer chromatography on a silica plate. Using benzene as the eluant a violet band separated, which was extracted with acetonitrile. On evaporation of the acetonitrile extract $[Ru(PPh_3)_2(CO)(L\text{-}OCH_3)]$ was obtained as crystalline solid. Yield: 70%. *Anal.* Calc. C, 69.70; H, 4.66; N, 1.59. 2.3. Physical measurements

Microanalyses (C, H, N) were performed using a Heraeus Carlo Erba 1108 elemental analyzer. ^{1}H NMR spectra were recorded in $CDCl_3$ solution on a Bruker Avance DPX 300 NMR spectrometer using TMS as the internal standard. IR spectra were obtained on a Shimadzu FTIR-8300 spectrometer with samples prepared as KBr pellets. Electronic spectra were recorded on a JASCO V-570 spectrophotometer. Electrochemical measurements were made using a CH Instruments model 600A electrochemical analyzer. A platinum disc working electrode, a platinum wire auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in the cyclic voltammetry experiments. All electrochemical experiments were performed under a dinitrogen atmosphere. All electrochemical data were collected at 298 K and are uncorrected for junction potentials.

2.4. X-ray crystallography

Single crystals of $[Ru(PPh_3)_2(CO)(L\text{-}H)]$ were obtained by slow evaporation of an acetonitrile solution of the complex. Selected crystal data and data collection parameters

[2] Chemical shifts are given in ppm and multiplicity of the signals along with the associated coupling constants (*J* in Hz) are given in parentheses. Overlapping signals are marked with an asterisk.

are given in Table S1. Data were collected on a Bruker SMART APEX CCD area detector system using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). X-ray data reduction, structure solution and refinement were done using SHELXS-97 and SHELXL-97 programs [10]. The structure was solved by the direct methods. The absolute configuration of the $[Ru(PPh_3)_2(CO)(L\text{-}H)]$ complex was determined by Flack parameter 0.12(4). Expected values of Flack parameter are 0 for correct and +1 for inverted structure. Using the option TWIN/BASF, the refined BASF is found to be identical with the Flack parameter, which confirmed the correct enantiomer.

Crystal data for $C_{50}H_{39}NO_2P_2Ru$, $M = 848.83$, $0.08 \times 0.11 \times 0.18$ mm^3, monoclinic, space group Cc, $a = 23.531(4)$ Å, $b = 8.988(2)$ Å, $c = 20.553(4)$ Å, $\beta = 115.15(2)°$, $V = 3934.8(15)$ Å^3, $Z = 4$, $D_{calc} = 1.433$ Mg m^{-3}, $F(000) = 1744$, $\lambda = 0.71073$ Å, $T = 293$ K, $\mu = 0.523$ mm^{-1}, 19 776 reflections collected, 7677 unique ($R_{int} = 0.019$). 3. Results and discussion

3.1. Synthesis and crystal structure

Five *N*-(2′-hydroxyphenyl)benzaldimines (**1**) have been used in the present study, differing in the inductive effect of the *para*-substituents (R), in order to observe their influence, if any, on the redox properties of the complexes. These ligands are in general abbreviated as H_2L-R, where H_2 stands for the two protons, the phenolic proton and one ortho proton of the phenyl ring in the benzaldehyde fragment, which are expected to undergo dissociation upon formation of chelate **3** and R for the *para*-substituent. Reactions of the *N*-(2′-hydroxyphenyl)benzaldimines (**1**) with $[Ru(PPh_3)_2(CO)_2Cl_2]$ proceed smoothly in refluxing 2-methoxyethanol in the presence of triethylamine, affording a family of violet complexes of type $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ in good yields. Microanalytical (C, H, N) data of

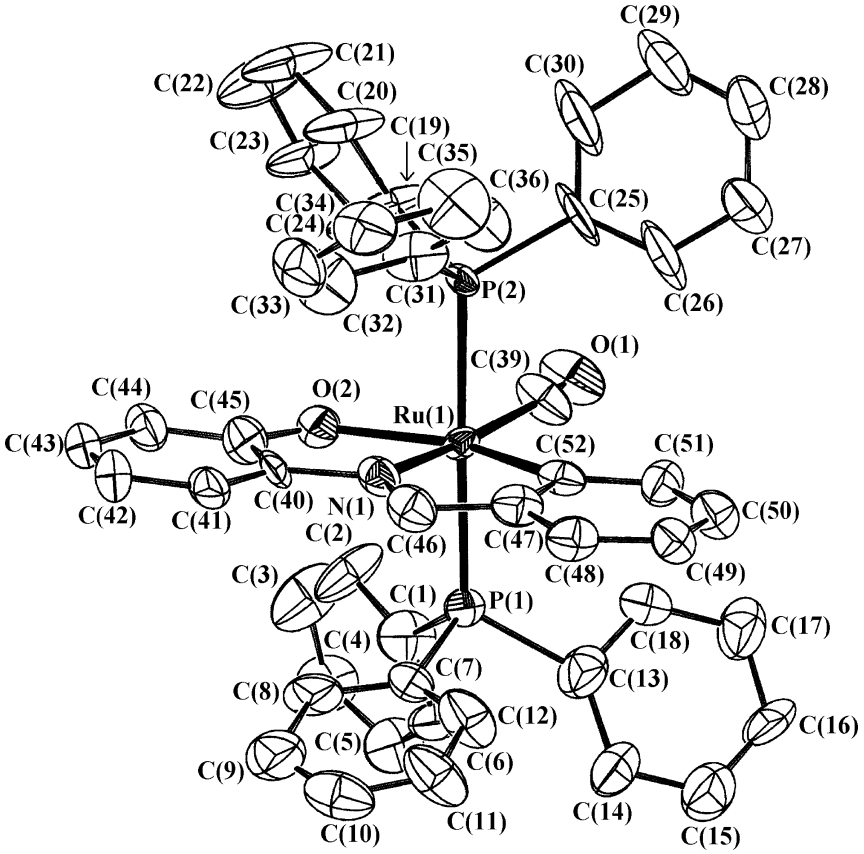

Fig. 1. Structure of the $[Ru(PPh_3)_2(CO)(L\text{-}H)]$ complex. The thermal ellipsoids of several carbon atoms are not of proper shape, probably due to overestimated empirical absorption correction.

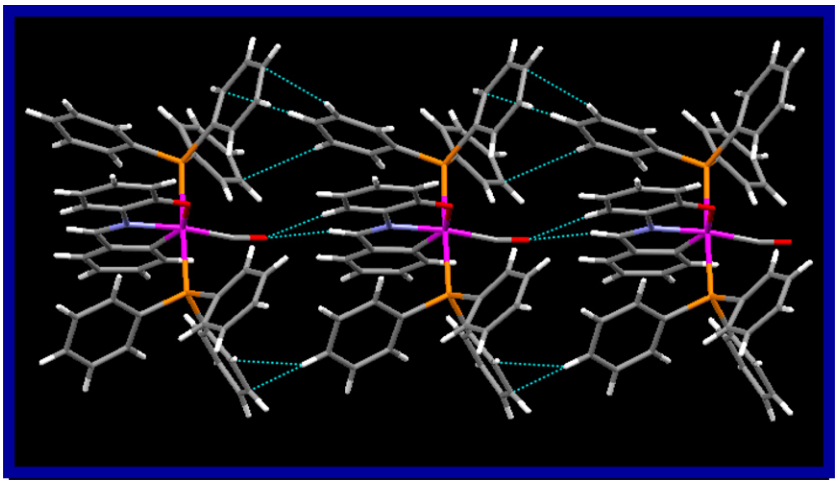

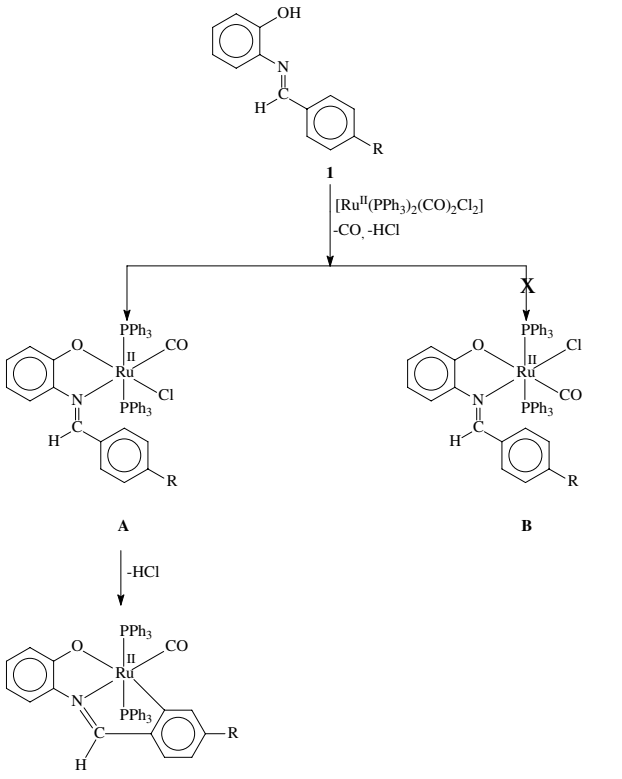

Fig. 2. The hydrogen bonding interactions in the crystal lattice of $[Ru(PPh_3)_2(CO)(L\text{-}H)]$.

the complexes are in well agreement with their compositions. The complexes are diamagnetic, which corresponds to the bivalent state of ruthenium (low-spin d^6, $S = 0$). These preliminary characterization data of the complexes indicate that the benzaldimines are probably serving as dianionic tridentate ligands in them. In order to authenticate the coordination mode of the benzaldimines in these complexes, as well as to find out their stereochemistry, structure of a representative member of this family, *viz.* $[Ru(PPh_3)_2(CO)(L\text{-}H)]$, has been determined by X-ray crystallography. The structure is shown in Fig. 1, and selected bond parameters are listed in Table 1. The structure shows that the *N*-(2′-hydroxyphenyl)benzaldimine is coordinated to ruthenium in the tridentate C,N,O-fashion (**3**, M = Ru), via loss of the phenolic proton and another proton from one ortho position of the phenyl ring in the benzaldehyde fragment. Thus two adjacent five-membered rings are formed with O–Ru–N and N–Ru–C bite angles of 77.5° and 77.2°, respectively. Two triphenylphosphines and a carbonyl are also coordinated to the metal center. Ruthenium is therefore sitting in a C_2NOP_2 coordination environment, which is distorted octahedral in nature as reflected in all the bond parameters around ruthenium. The coordinated benzaldimine ligand and the carbonyl have constituted one equatorial plane with the metal at the center, while the PPh_3 ligands have occupied the remaining axial positions and hence they are mutually trans. The Ru–P and Ru–C (carbonyl) and C–O (carbonyl) distances are all quite normal [2b,2c,2i]. Within the Ru-(L-H) fragment, the Ru–C, Ru–N and Ru–O distances are also quite usual [2b,2c,2i,11] and so are the C–O and C–N distances [4]. However, the Ru–C–O angle (168.0°) in the Ru-carbonyl fragment is found to deviate significantly from linearity. The absence of any solvent of crystallization in the crystal lattice of $[Ru(PPh_3)_2(CO)(L\text{-}H)]$ indicates possible existence of non-covalent interaction(s) between the individual complex molecules. A closer look at the packing pattern of the crystal reveals that non-covalent interactions of two types, viz. C–H···O and C–H···π interactions, are active in the lattice, which are illustrated in Fig. 2. The carbonyl oxygen in each complex molecule is hydrogen-bonded simultaneously to a phenyl C–H and the azomethine C–H of the benzaldimine ligand belonging to an adjacent complex molecule. Several phenyl C–H fragments of the triphenyl phosphines are involved in hydrogen-bonding with the π-cloud over the phenyl rings of the triphenylphosphines of neighboring complex molecules. Each complex molecule is thus linked with the surrounding complex molecules through C–H···O and C–H···π interactions, and this extended intermolecular hydrogen-bonding interactions seem to be responsible for holding the crystal together. As all the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes have been synthesized similarly and they show similar properties (*vide infra*), the other four $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ ($R \neq H$) complexes are assumed to have similar structures as the $[Ru(PPh_3)_2(CO)(L\text{-}H)]$ complex.

Although the exact mechanism behind formation of the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes is not completely clear to us, the sequences shown in Scheme 1 seem probable. In the first step the benzaldimine ligand binds to ruthenium, via loss of the phenolic proton, as a bidentate N,O-donor with simultaneous dissociation of a carbon monoxide and a chloride ion from $[Ru(PPh_3)_2(CO)_2Cl_2]$, thereby producing a reactive intermediate (**A**). In **A** the coordinated chloride and the pendent phenyl ring of the benzaldimine are appropriately disposed for the C–H activation to occur at the ortho position of the phenyl ring and hence it is believed to undergo the expected cyclometallation via elimination of HCl to produce the final organoruthenium complex, $[Ru(PPh_3)_2(CO)(L\text{-}R)]$. Presence of triethylamine seems to have facilitated initial dissociation of the phenolic proton, as well as elimination of HCl during orthometallation.[3] Attempts to isolate the intermediate **A** have failed, probably because it

[3] From the same reactions the complexes are obtained in very poor yield in the absence of triethylamine.

Scheme 1. Probable steps of the formation of the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes.

undergoes rapid cyclometallation to afford the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complex. Formation of another stereoisomer of the intermediate (**B**), keeping the *trans* disposition of the two triphenylphosphines unaltered and differing only in the relative disposition of carbonyl and chloride, is, in principle, possible. This stereoisomer **B** is unlikely to undergo a similar cyclometallation due to unfavorable disposition of the chloride. However, this isomer **B** has never been obtained from the synthetic reactions, which suggests that isomer **A** is the only intermediate formed under the prevailing reaction conditions.

3.2. Spectral properties

Infrared spectra of the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes show many bands of varying intensities within 4000–400 cm^{-1}. Assignment of each individual band to a specific vibration has not been attempted. However, three strong bands observed around 518, 695 and 743 cm^{-1} in all the complexes are attributable to the coordinated triphenylphosphines, and a very intense band observed near 1920 cm^{-1} to the coordinated carbonyl. Comparison with the spectrum of $[Ru(PPh_3)_2(CO)_2Cl_2]$ shows presence of some new bands (*viz*. 1090, 1314, 1434, 1462, 1566, 1588 cm^{-1}) in the spectra of the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes, which are probably due to the coordinated benzaldimine ligand.

^1H NMR spectra of the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes, recorded in $CDCl_3$ solution, show broad signals for the coordinated triphenylphosphines within 7.1–7.6 ppm. The methyl signals of the benzaldimine ligand in the $[Ru(PPh_3)_2(CO)(L\text{-}CH_3)]$ and $[Ru(PPh_3)_2(CO)(L\text{-}OCH_3)]$ complexes are observed, respectively, at 1.89 and 3.48 ppm. However, signal for the azomethine proton could not be identified probably due to its overlap with the triphenylphosphine signals. All other signals expected for the coordinated benzaldimine ligand are observed clearly in all the complexes. Thus the infrared and ^1H NMR spectral data of the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes are found to be consistent with their compositions.

All the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes are readily soluble in dichloromethane, chloroform, acetone, etc., and sparingly soluble in methanol, ethanol, acetonitrile, etc., producing violet solutions. Electronic spectra of the complexes have been recorded in dichloromethane solution. Spectral data are presented in Table 2. Each complex shows several intense absorptions in the visible and ultraviolet region. The absorptions in the ultraviolet region are believed to be due to transitions within the ligand orbitals. To have an insight into the nature of absorptions in the visible region, semi-empirical EHMO calculations have been performed on computer-generated models of all the complexes [12], where phenyl rings of the triphenylphosphines have been replaced by hydrogens. The results are found to be qualitatively similar for all the complexes.[4] Compositions of some selected molecular orbitals are given in Table 3 and partial MO diagram of a representative complex is shown in Fig. 3. The calculations show that the highest occupied molecular orbital (HOMO) and the next two filled molecular orbitals, viz. HOMO − 1 and HOMO − 2, have major contribution (>47%) from the metal d-orbitals and hence they may be considered as ruthenium t_2 orbitals. The lowest unoccupied molecular orbital (LUMO) is localized almost entirely on the benzaldimine ligand and is concentrated mostly (>50%) on the imine fragment. The next two vacant molecular orbitals, viz. LUMO + 1 and LUMO + 2, are localized on different parts of the coordinated benzlaldimine ligand. Hence the lowest energy absorption in the visible region may be assigned to an electronic transition from the filled ruthenium t_2 orbital (HOMO) to the vacant π^*(imine) orbital of the benzaldimine ligand (LUMO). The other absorptions in the visible region are attributable to transitions occurring from the ruthenium t_2 orbitals to the higher energy vacant orbitals.

3.3. Electrochemical properties

Electrochemical properties of the $[Ru(PPh_3)_2(CO)(L\text{-}R)]$ complexes have been studied by cyclic voltammetry in 1:9

[4] In the $[Ru(PPh_3)_2(CO)(L\text{-}NO_2)]$ complex, the LUMO has significant contribution (57%) from the NO_2 group.

dichloromethane–acetonitrile solution (0.1 M TBAP).[5] Voltammetric data are presented in Table 2 and a representative voltammogram is deposited as supplementary data (Fig. S1). All the complexes show two oxidative responses on the positive side of SCE[6] and a reductive response on the negative side. The first oxidative response is reversible in nature, characterized by a peak-to-peak separation (ΔE_p) of 70–80 mV, which remains unchanged upon changing the scan rate and the anodic peak-current (i_{pa}) is almost equal to the cathodic peak-current (i_{pc}). The other two responses are irreversible in nature. In view of the composition of the HOMO, the first reversible oxidation, observed within 0.3–0.7 V, is assigned to Ru(II)–Ru(III) oxidation. However, the second irreversible oxidation, observed within 1.0–1.3 V, is tentatively attributed to oxidation of the C,N,O-coordinated benzaldimine ligand.[6] Based on the composition of the LUMO, the irreversible reductive response observed around −1.1 V may be assigned to reduction of the imine fragment in the coordinated benzaldimine ligand. One-electron nature of the two oxidative responses has been verified by comparing their current heights with that of ferrocene–ferrocenium couple under identical experimental conditions. However, the irrerversible reductive response shows non-stoichiometric current (i_{pc}). Potential of the first oxidation is found to be sensitive to the nature of the substituent R in the coordinated benzaldimine ligand. The potential increases with increasing electron-withdrawing character of the substituent R. The plot of $E_{1/2}$ versus σ [σ = Hammett constant of R [13], $OCH_3 = -0.27$, $CH_3 = -0.17$, $H = 0.00$, $Cl = 0.23$ and $NO_2 = 0.78$] is linear (Fig. S2) with a slope (ρ) of 0.28 V

[5] A little dichloromethane was necessary to take the complex into solution. Addition of large excess of acetonitrile was necessary to record the redox responses in proper shape.
[6] The second irreversible oxidation has not been observed in the $[Ru(PPh_3)_2(CO)(L\text{-}NO_2)]$ complex.

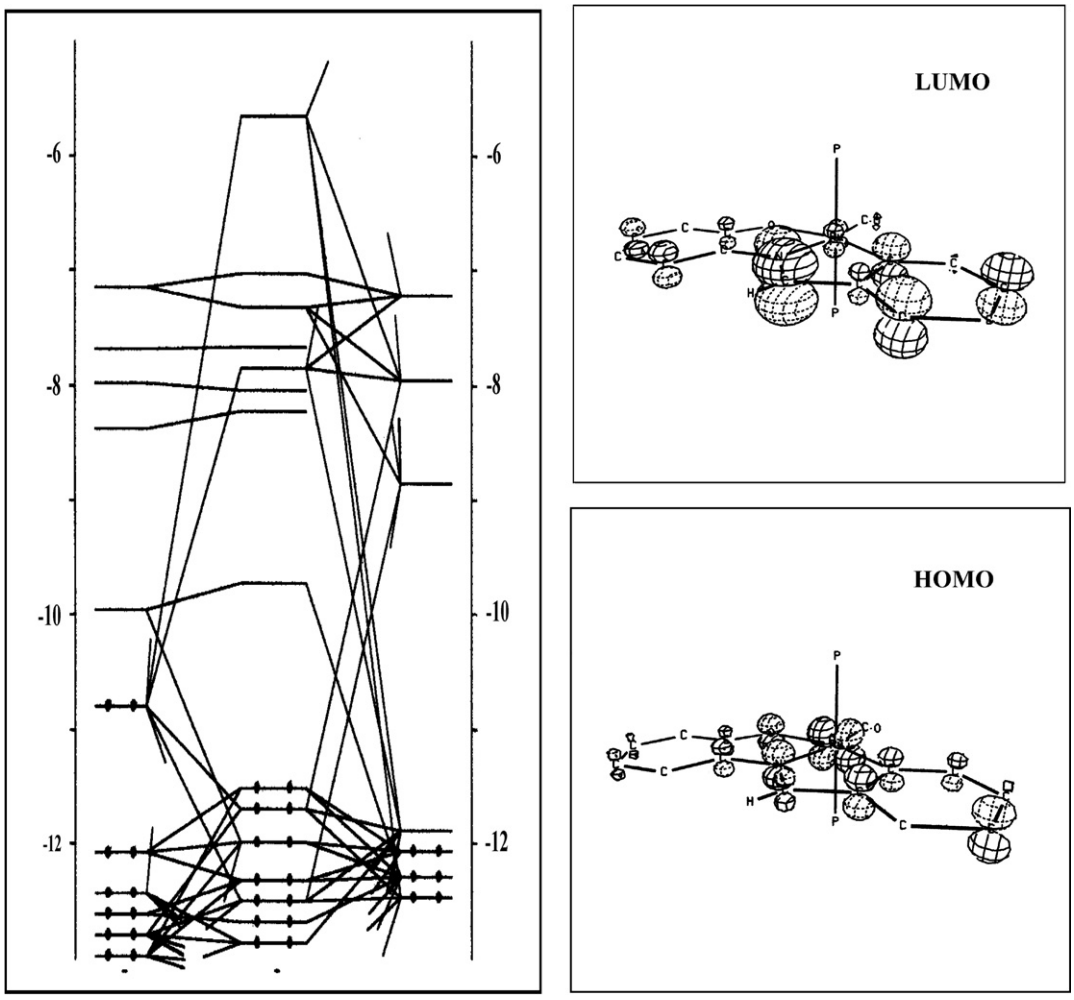

Fig. 3. Partial molecular orbital diagram of $[Ru(PPh_3)_2(CO)(L\text{-}H)]$ complex.

(ρ = reaction constant of this couple [14]), which shows that the substituent (R) on the coordinated benzaldimine ligand, which is four-bonds away from the metal center, can still influence the metal-centered oxidation potential in a predictable manner.

4. Conclusions

The present study shows that the *N*-(2′-hydroxyphenyl)benzaldimines (**1**) can undergo facile C–H activation at one ortho position of the aryl ring in the benzaldimine fragment, mediated by $[Ru(PPh_3)_2(CO)_2Cl_2]$. This study also indicates that similar C–H activation of organic molecules having structural similarity with the *N*-(2′-hydroxyphenyl)benzaldimines may also be possible upon their reaction with $[Ru(PPh_3)_2(CO)_2Cl_2]$ and other suitable transition metal complexes, and such possibilities are currently under exploration.

step-by-step synthesis allowed us for the first time to generate oligophosphazenes having up to five different types of side groups [23]. Unexpectedly, in contrast with results previously reported [6,7], the X-ray diffraction study of the structure of a compound possessing one P=N—P=S linkage gave identical values for the P=N and P–N bond lengths (1.5806(15) and 1.5734(14) Å, respectively) [23].

In order to determine the influence of substituents on the reaction process and on the properties, we report here the synthesis and characterization of new oligophosphazenes bearing different types of end groups. The X-ray diffraction structure of three new compounds including one possessing a P=N—P=S linkage is also reported.

2. Results and discussion

As indicated in the introduction, the step-by-step synthesis of oligophosphazenes through Staudinger reactions necessitates the use of $N_3P(S)(R')_2$ derivatives which must be first synthesized. As previously shown [9], $P(S)Cl_3$ is a suitable precursor, which reacts easily with two equivalents of phenols **1** in basic conditions, to afford $ClP(S)(OAr)_2$ derivatives **2**. In order to avoid the presence of two azides on the same phosphorus atom (potentially explosive), the presence of $Cl_2P(S)(OAr)$ derivatives must be avoided, thus a slight excess of phenol is used, and a small amount of trisubstituted derivative of type **3** is also obtained. In the case of the **a** series, the trisubstituted compound **3a** is isolated by crystallization in ethylacetate/pentane (1:3), and its structure determined by X-ray diffraction. The ORTEP drawing of compound **3a** is shown in Fig. 1 and the X-ray data are gathered in Table 1 (see Scheme 1).

The next step to obtain the thiophosphorylazide consists of the reaction of the remaining Cl in compounds **2** with sodium azide, to afford compounds **4**, which are isolated by column chromatography. These compounds, as well as all the other compounds reported in this paper, are characterized by multinucleus NMR (^{31}P, ^{1}H, and ^{13}C) and elemental analyses. Few compounds possessing a λ^4,σ^5-phosphorus azide linkage were previously characterized by X-ray diffraction [14,24–29], thus single crystals of **4b** are grown from ether/pentane (1:4). The crystal contains two isomeric forms of compound **4b** (forms a and b, 50% each) which are shown in Fig. 2. The difference between both isomers concerns the N3(a,b)N2(a,b)N1(a,b)—P=S linkage, which is disordered. All these atoms are in a plane in both cases, but N3a and S are in s-*cis* position relative to the P–N1a bond in form a, whereas N3b and S are in s-*trans* position relative to the P–N1b bond in form b.

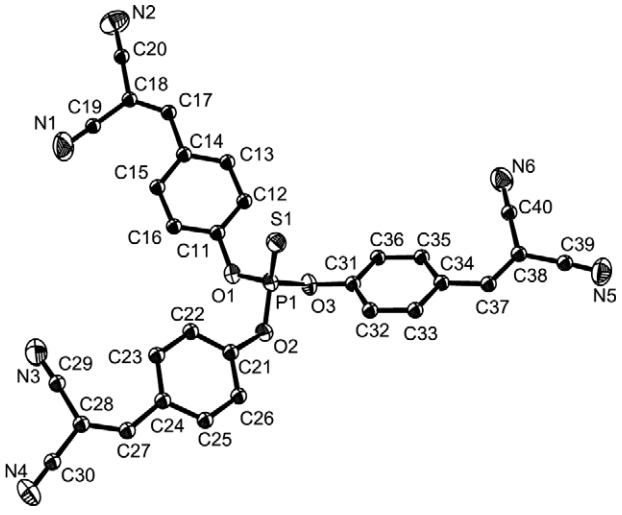

Fig. 1. Structure of compound **3a** (ORTEP drawing, hydrogen atoms are omitted for clarity). Selected bond lengths (Å) and angles (°): P1–S1 1.9000(7); C–N 1.137–1.152(3); O1–P1–O2 101.52(8); O1–P1–O3 99.83(8); O2–P1–O3 100.44(8); O1–P1–S1 117.07(6); O2–P1–S1 117.36(6); O3–P1–S1 117.55(6).

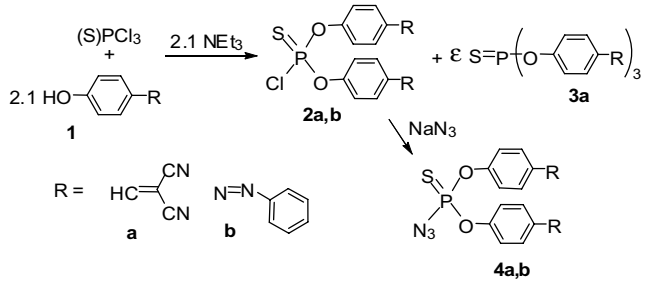

Azides **4a** and **4b** as well as **4c** and **4d** [14] are reacted with Ph_3P to create the phosphazene linkage. The Staudinger reaction occurs easily and quantitatively to afford compounds **5a–d**, each of them possessing one P=N—P=S linkage (Scheme 2). The reaction is easily monitored by ^{31}P NMR, which displays the appearance of two doublets at ca. 14 ppm for P=N and ca. 50 ppm for P=S. The structure of compound **5d** is confirmed by X-ray diffraction (Fig. 3). The bond lengths and angles for the P=N—P fragment are slightly different from the data previously obtained for compound **5c** [23] (P=N 1.5686(18) for **5d**, 1.5806(15) Å for **5c**; P–N 1.5733(18) for **5d**, 1.5734(14) Å for **5c**; P=N—P 141.46(13) for **5d**, 134.67(10)° for **5c**), however the lack of bond length alternation is observed in both cases for the P=N—P linkage. The P1···P2 distance is 2.9659(11) Å, a value typically found for cyclotriphosphazenes.

The next step to continue the synthesis is the reaction with methyltriflate to alkylate the P=S group. This reaction is attempted with compounds **5a,c,d**, but not with **5b**, due to the propensity of the azo group to isomerize spontaneously (*trans* → *cis*) with ambiant light, which complicates the work-up. The reaction with **5d** fails, due to a partial alkylation of the NMe_2 groups, whereas the cationic derivatives **6a** and **6c** are isolated (Scheme 3). The alkylation of sulfur induces a dramatic shielding of the signal corresponding to the PS group in ^{31}P NMR from ca. 50 ppm for **5a,c** to ca. 23 ppm for **6a,c**. A deshielding of the signal corresponding to the phosphazene is also observed from ca. 15 ppm to ca. 23 ppm. Two doublets are observed for **6a,c** as expected, but their attribution is ambiguous because both signals corresponding to P=N—P resonate at ca. 23 ppm.

The desulfurization of both compounds is attempted using the nucleophilic phosphine $P(NMe_2)_3$ to transfer the S–Me group from the phosphazene to $P(NMe_2)_3$ (Scheme 3). The reaction works nicely with **6c** to afford **7c** in quantitative yield [23]. Unexpectedly, the same reaction fails with compound **6a**, as shown by ^{31}P NMR, with the appearance of numerous signals. The second phosphazene linkage is thus obtainable only from **7c**, illustrating the sensitivity of this reaction process to the type of substituents.

Table 1
Crystal data and structure refinement for **3a**, **4b**, and **5d**

Compound	**3a**	**4b**	**5d**
Formula	$C_{30}H_{15}N_6O_3PS$	$C_{12}H_9N_5OP_{0.5}S$	$C_{34}H_{35}N_3O_2P_2S$

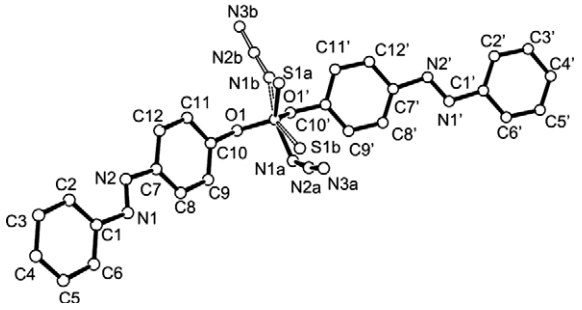
Scheme 1.

The reaction of the azides **4a** and **4d** with **7c** affords the diphosphazene **8ca** and **8cd**, respectively, which possess two types of functional groups (Scheme 3). In both cases, the central phosphorus atom (labeled P_1) is coupled with its two neighbors with two very different coupling constants (ca. 24 Hz for $^2J_{P0P1}$ with PPh_3 and ca. 58 Hz for $^2J_{P1P2}$ with P(S)) giving a doublet of doublets in the ^{31}P NMR spectra. The chemical shift value (ca. −15 ppm) compares well with that found for polyphosphazenes substituted by phenols [30].

The behavior of compounds **8ca** and **8cd** toward alkylation is comparable to that of **5a** and **5d**, respectively. Indeed, alkylation of some NMe_2 groups occurs in the case of **8cd**, hampering the formation of **9cd**, whereas the alkylation of **8ca** occurs only on the PS group as expected, leading to the cationic derivative **9ca** (Scheme 3). A charge



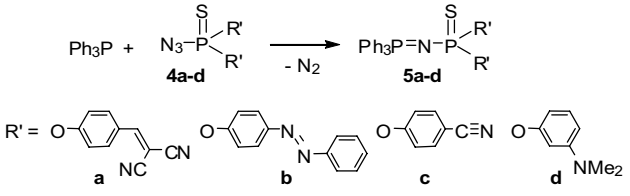


Fig. 2. Forms a (50%) and b (50%) of compound **4b** (hydrogen atoms are omitted for clarity). Selected bond lengths (Å) and angles (°): P–N1a 1.724(14), P–N1b 1.721(14); P–S1a 1.851(4), P–S1b 1.861(15); N1a–N2a 1.262(11), N1b–N2b 1.255(11); N2a–N3a 1.255 (11), N2b–N3b 1.256(12); N1–N2 1.250(7) (a and b); N2a–N1a–P 122.1(18), N2b–N1b–P 127.0(14); N3a–N2a–N1a 164(2), N1b–N2b–N3b 177(2); N1a–P–S1a 119.8(7), N1b–P–S1b 109.8(6). The diedral angle S–P–N1–N2 is 82.76° for form a, and 179.98° for form b.

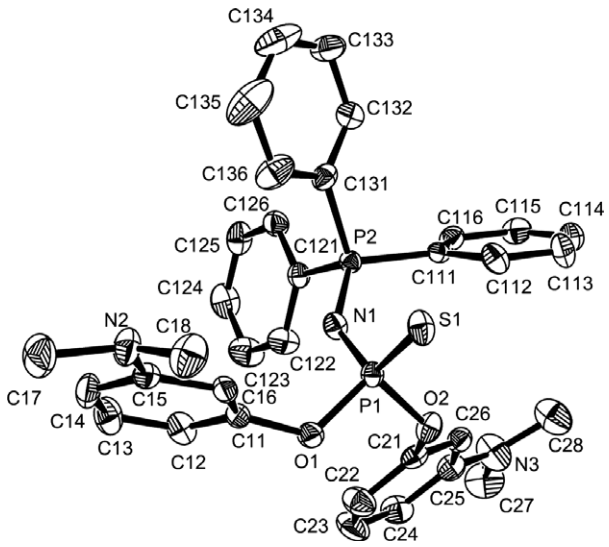
Scheme 2.



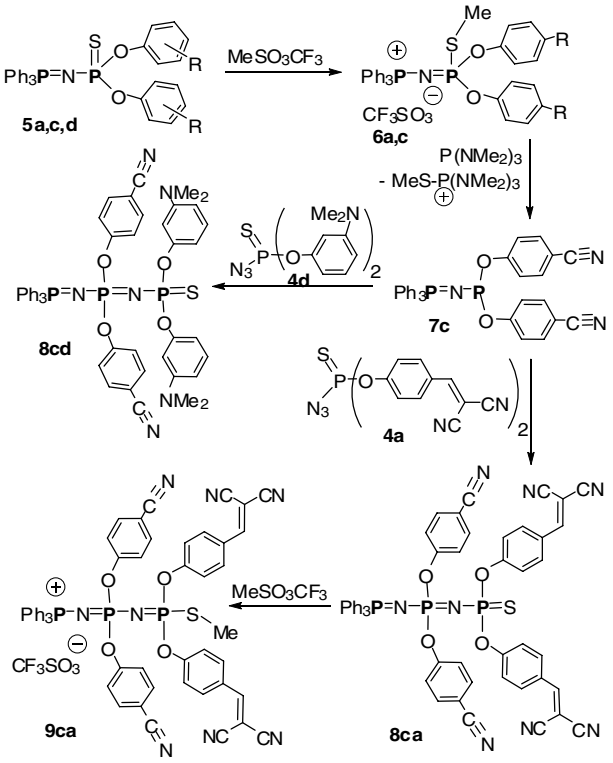


Fig. 3. Structure of compound **5d** (ORTEP drawing, hydrogen atoms are omitted for clarity). Selected bond lengths (Å) and angles (°): P1–S1 1.9375(10); P1–N1 1.5733(18); P2–N1 1.5686(18); N1–P1–S1 120.36(8); P2–N1–P1 141.46(13).

Scheme 3.

transfer through the whole PNPNPS linkage is observed, as shown by ^{31}P NMR. Indeed, the signal corresponding to the PS group (labeled P_2) is shielded from 45.1 to 23.8 ppm, whereas the signal corresponding to Ph_3P (labeled P_0) is deshielded from 16.5 to 23.7 ppm. The attribution of the signals for **9ca** is non ambiguous (contrarily to what was observed for **6a** and **6c**) because the $^2J_{PP}$ coupling constants with the central phosphorus (P_1) are very different ($^2J_{P0P1} = 25.8$ Hz for **8ca** and 26.2 Hz for **9ca**; $^2J_{P1P2} = 58.4$ Hz for **8ca** and 53.2 Hz for **9ca**). On the contrary, the chemical shift value for P_1 does not change on going from **8ca** to **9ca** ($\Delta\delta = 0.6$ ppm) (Fig. 4). Thus, the positive charge is delocalized along the phosphazene linkage of **9ca**, up to the PPh_3 group.

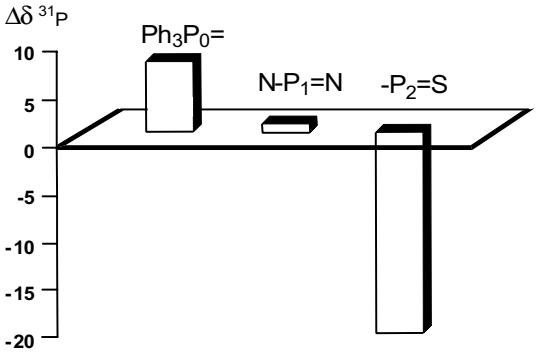

Fig. 4. Variation of the ^{31}P NMR chemical shifts on going from **8ca** to **9ca** for each individual phosphorus of the chain $Ph_3P_0{=}N{-}P_1{=}N{-}P_2{=}S$.

As could be expected from the reaction of $P(NMe_2)_3$ with **6a**, its reaction with **9ca** affords numerous signals in ^{31}P NMR, and the product of desulfurization cannot be isolated.

In conclusion, we have reported the synthesis and the characterization of a new series of compounds possessing phosphazene linkages, obtained by Staudinger reactions. The X-ray diffraction structure of a compound of type $R_3P{=}N{-}PR'_2(S)$ give an identical length for both PN bonds in accordance with the observation we previously reported [23], but contrarily to what was reported for $Cl_3P{=}N{-}PCl_2(O)$ [5], emphasizing the role of the substituents. The synthetic process used for lengthening the oligophosphazene chain is also highly dependant on the substituents, and two new compounds of type $R_3P{=}N{-}PR'_2{=}PR''_2(S)$ possessing three different substituents have been isolated and characterized. Alkylation of sulfur allows to demonstrate the delocalization of the charge up to the other side of the inorganic phosphazene chain (the R_3P group) using ^{31}P NMR, and contributes to a better understanding of the phosphazene bond.

3. Experimental section

All reactions were carried out in the absence of air using standard Schlenk techniques and vacuum-line manipulations. Commercial samples were used as received. All solvents were dried before use (THF and ether over sodium/benzophenone, pentane and dichloromethane over phosphorus pentoxide). ^{1}H, ^{13}C, ^{19}F, ^{31}P NMR measurements were performed on Bruker AC 200, AM 250, ARX 250, or DPX 300. References for NMR chemical shifts are 85% H_3PO_4 for ^{31}P NMR, $SiMe_4$ for ^{1}H and ^{13}C NMR, CF_3CO_2H for ^{19}F NMR. The attribution of ^{13}C NMR signals has been done using J_{mod}, two dimensional HMBC,

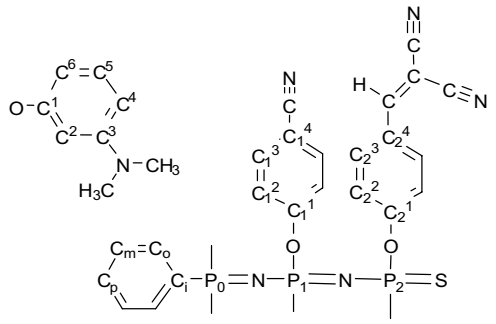

Fig. 5. Numbering used for NMR assignments. The lower script number of substituents refers to the phosphorus to which they are connected.

and HMQC, Broad Band or CW ^{31}P decoupling experiments when necessary. The numbering used for NMR assignments is depicted in Fig. 5. Syntheses of compounds **4c** and **4d** [14], as well as compounds **5c**, **6c** and **7c** [23] were already published.

3.1. Synthesis of compounds *3a, 4a and 4b*

A solution of phenol derivative (for **4a**: 0.35 g, 2.07 mmol of 4-hydroxybenzylidenemalononitrile; for **4b**: 0.275 mL, 1.97 mmol of 4-hydroxyazobenzene) and triethylamine (for **4a**: 0.300 mL, 2.15 mmol; for **4b**: 0.275 mL, 1.97 mmol) in THF (20 mL), was added dropwise at −100 °C under stirring to a solution of trichlorophosphine sulphide (0.1 mL, 0.985 mmol) in THF (10 mL). The temperature was slowly allowed to rise to room temperature at the end of the addition. The resulting mixture was stirred for 12 h, then the precipitate of triethylamine hydrochloride was removed by filtration, and the solution was evaporated to dryness. The resulting oil mainly consisted of compound **2a** or **2b**; it was solubilized in acetone (20 mL), then sodium azide was added (0.064 g, 0.985 mmol). Acetone was evaporated after 24 h at room temperature, then THF (20 mL) was added. Sodium chloride and excess azide were eliminated by centrifugation. THF was evaporated to afford a viscous liquid (yellow for **4a**, orange for **4b**), which contained derivatives **4** contaminated by a small amount of derivatives **3**. Compounds **4** were purified by column chromatography on silica (eluent: AcOEt/Pentane: 1/3 for **4a**; AcOEt/Hexane: 3/7 for **4b**). In the case of **4a**, chromatography also allowed to isolate **3a**, obtained as a side-product. Slow evaporation of this fraction afforded single crystals of **3a** suitable for X-ray diffraction.

3a: Yellow crystals. ^{31}P $\{^1H\}$ NMR ($CDCl_3$): $\delta = 49.2$ (s). ^1H NMR ($CDCl_3$): $\delta = 7.41$ (dd, $^3J_{HH} = 8.8$ Hz, $^4J_{HP} = 1.6$ Hz, 6H, H–C^2), 7.77 (s, 3H, H–C^5), 7.99 (d, $^3J_{HH} = 8.8$ Hz, 6H, H–C^3). ^{13}C $\{^1H\}$ NMR ($CDCl_3$): $\delta = 112.5$ (s, C–CN), 113.7 (s, CN), 121.8 (d, $^3J_{CP} = 7$ Hz, C^2), 129.0 (s, C^4), 129.8 (s, C^3), 154.0 (d, $^2J_{CP} = 9$ Hz, C^1), 158.3 (s, C^5). 4a: Yellow powder isolated in 35% yield. ^{31}P $\{^1H\}$ NMR ($CDCl_3$): $\delta = 57.5$ (s). ^1H NMR ($CDCl_3$): $\delta = 7.41$ (dd, $^3J_{HH} = 8.7$ Hz, $^4J_{HP} = 1.7$ Hz, 4H, H–C^2), 7.78 (s, 2H, H–C^5), 7.98 (d, $^3J_{HH} = 8.8$ Hz, 4H, H–C^3). ^{13}C $\{^1H\}$ NMR ($CDCl_3$): $\delta = 112.7$ (s, C–CN), 113.8 (s, CN), 121.9 (d, $^3J_{CP} = 5.3$ Hz, C^2), 129.4 (d, $^5J_{CP} = 2.1$ Hz, C^4), 133.2 (d, $^4J_{CP} = 1.6$ Hz, C^3), 154.2 (d, $^2J_{CP} = 8.1$ Hz, C^1), 158.5 (d, $^6J_{CP} = 1.3$ Hz, C^5). IR (KBr): 2230 (ν-CN), 2172 (ν-N_3) cm^{-1}. Mass (CI, NH_3) m/z: $[M]^+ = 443$, $[M+NH_4]^+ = 461$. *Anal.* Calc. for $C_{20}H_{10}N_7O_2PS$ (443.4): C, 54.18; H, 2.27; N, 22.11. Found: C, 54.25; H, 2.31; N, 22.06%.

4b: Single crystals suitable for X-ray diffraction were grown at −20 °C in Ether/Pentane (1:4).

3.2. Synthesis of compounds *5a, 5b and 5d*

A solution of triphenylphosphine (for **5a**: 0.051 g, 0.195 mmol; for **5b**: 0.061 g, 0.23 mmol; for **5d**: 0.233 g, 0.888 mmol) in THF (3 mL for **5a**) or CH_2Cl_2 (3 mL for **5b** or **5d**) was added at room temperature to a solution of azide (**4a**: 0.085 g, 0.19 mmol; **4b**: 0.110 g, 0.22 mmol; **4d**: 0.319 g, 0.845 mmol) in degazed THF (3 mL for **5a**) or CH_2Cl_2 (3 mL for **5b** or **5d**), and stirred for 12 h. Then, the solution was evaporated to dryness, and the resulting powder was washed three times with THF/Pentane (1/20), to afford compounds **5**.

5a: Yellow powder, 99% yield. ^{31}P $\{^1H\}$ NMR (THF): $\delta = 14.1$ (d, $^2J_{PP} = 32.0$ Hz, P_0=N), 49.5 (d, $^2J_{PP} = 32.0$ Hz, P_1=S). ^1H NMR ([D_8] THF): $\delta = 7.46$ (dd, $^3J_{HH} = 8.7$ Hz, $^4J_{HP} = 1.3$ Hz, 4H, H–C_1^2), 7.50–7.73 (m, 9H, H–C^m, H–C^p), 7.81 (ddd, $^3J_{HH} = 8.4$ Hz, $^4J_{HH} = 1.6$ Hz, $^3J_{HP} = 13.2$ Hz, 6H, H–C^0), 8.00 (d, $^3J_{HH} = 8.7$ Hz, 4H, H–C_1^3), 8.19 (s, 2H, H–C_1^5). ^{13}C $\{^1H\}$ NMR ([D_8] THF): $\delta = 114.2$ (s, C_1^6), 115.2 (s, CN), 123.6 (d, $^3J_{CP} = 5.5$ Hz, C_1^2), 128.8 (s, C_1^4), 129.8 (dd, $^1J_{CP} = 105.0$ Hz, $^3J_{CP} = 4.3$ Hz, C^i), 129.8 (d, $^3J_{CP} = 13.0$ Hz, C^m), 133.4 (s, C^p), 133.9 (s, C_1^3), 134.0 (d, $^2J_{CP} = 11.2$ Hz, C^0), 158.0 (d, $^2J_{CP} = 8.8$ Hz, C_1^1), 160.3 (s, C_1^5). IR (KBr): 2227 (ν-CN) cm^{-1}. M.P.: 69–71 °C. *Anal.* Calc. for $C_{38}H_{25}N_5O_2P_2S$ (677.7): C, 67.35; H, 3.72; N, 10.34. Found: C, 67.48; H, 3.77; N, 10.24%.

5b: Red oil, 99% yield. ^{31}P $\{^1H\}$ NMR (CH_2Cl_2): $\delta = 13.9$ (d, $^2J_{PP} = 29.7$ Hz, P_0=N), 50.8 (d, $^2J_{PP} = 29.7$ Hz, P_1=S). ^1H NMR ([D_8] THF): $\delta = 7.45$ (dd, $^3J_{HH} = 8.8$ Hz, $^4J_{HP} = 1.5$ Hz, 4H, H–C_1^2), 7.50–7.60 (m, 12H, H–C^m, H–C_1^7, H–C_1^8), 7.68 (ttd, $^3J_{HH} = 8.8$ Hz, $^4J_{HH} = 1.5$ Hz, $^5J_{HP} = 1.9$ Hz, 3H, H–C^p), 7.81 (ddd, $^3J_{HH} = 8.4$ Hz, $^4J_{HH} = 1.5$ Hz, $^3J_{HP} = 13.1$ Hz, 6H, H–C^0), 7.92–8.02 (m, 8H, H–C_1^3, H–C_1^6). ^{13}C $\{^1H\}$ NMR ([D_8] THF): $\delta = 127.4$ (d, $^3J_{CP} = 6.0$ Hz, C_1^2), 128.0 (s, C_1^6), 129.1 (s, C_1^3), 133.9 (s, C_1^7), 134.2 (d, $^3J_{CP} = 19.8$ Hz, C^m), 134.5 (dd, $^1J_{CP} = 106.4$ Hz, $^3J_{CP} = 3.8$ Hz, C^i), 136.1 (s, C_1^8), 137.9 (s, C^p), 138.4 (d, $^2J_{CP} = 9.8$ Hz, C^0), 154.6 (s, C_1^4), 158.2 (s, C_1^5), 160.4 (d, $^2J_{CP} = 10.2$ Hz, C_1^1). *Anal.* Calc. for $C_{42}H_{33}N_5O_2P_2S$ (733.8): C, 68.75; H, 4.53; N, 9.54. Found: C, 68.84; H, 4.62; N, 9.32%.

5d: White powder, 99% yield. Single crystals suitable for X-ray diffraction were obtained by slow evaporation at room temperature of a solution in THF/pentane (1/20). ^{31}P $\{^1H\}$ NMR ($CDCl_3$): $\delta = 12.4$ (d, $^2J_{PP} = 28.8$ Hz, P_0═N), 51.2 (d, $^2J_{PP} = 28.8$ Hz, P_1═S). ^1H NMR ($CDCl_3$): $\delta = 2.78$ (s, 12H, NMe_2), 6.46 (d, $^3J_{HH} = 8.2$ Hz, 2H, H–C_1^6), 6.59 (d, $^4J_{HP} = 1.8$ Hz, 2H, H–C_1^2), 6.66 (d, $^3J_{HH} = 8.1$ Hz, 2H, H–C_1^4), 7.07 (“t”, $^3J_{HH} = 8.1$ Hz, 2H, H–C_1^5), 7.37 (“td”, $^3J_{HH} = 7.7$ Hz, $^4J_{HP} = 3.2$ Hz, 6H, H–C^m), 7.49 (ttd, $^3J_{HH} = 7.5$ Hz, $^4J_{HH} = 1.4$ Hz, $^5J_{HP} = 1.8$ Hz, 3H, H–C^p), 7.63 (ddd, $^3J_{HH} = 7.6$ Hz, $^4J_{HH} = 1.4$ Hz, $^3J_{HP} = 13.1$ Hz, 6H, H–C^0). ^{13}C $\{^1H\}$ NMR ($CDCl_3$): $\delta = 40.4$ (s, NMe_2), 106.2 (d, $^3J_{CP} = 5.6$ Hz, C_1^2), 108.3 (s, C_1^4), 109.7 (d, $^3J_{CP} = 4.7$ Hz, C_1^6), 128.4 (d, $^3J_{CP} = 12.9$ Hz, C^m), 129.0 (dd, $^1J_{CP} = 107.2$ Hz, $^3J_{CP} = 4.0$ Hz, C^i), 129.1 (s, C_1^5), 132.3 (sl, C_p), 132.7 (d, $^2J_{CP} = 11.1$ Hz, C_0), 151.4 (s, C_1^3), 153.2 (d, $^2J_{CP} = 10.1$ Hz, C_1^1). *Anal.* Calc. for $C_{34}H_{35}N_3O_2P_2S$ (611.7): C, 66.76; H, 5.77; N, 6.87. Found: C, 66.83; H, 5.81; N, 6.80%.

3.3. Synthesis of compound *6a*

Methyltriflate (40 μL, 0.35 mmol) was added dropwise at room temperature to a solution of **5a** (0.338 g, 0.35 mmol). The resulting solution was stired for 20 min then evaporated to dryness. The residue was washed thrice with THF/pentane (1:20) to give compound **6a** as a pale green powder in 96% yield.

6a: ^{31}P $\{^1H\}$ NMR ($CDCl_3$): $\delta = 23.5$ and 23.8 (2d, $^2J_{PP} = 22.1$ Hz, P_0 and P_1). ^1H NMR ($CDCl_3$): $\delta = 2.58$ (d, $^3J_{HP} = 18.0$ Hz, 3H, SCH_3), 7.25 (d, $^3J_{HH} = 9.0$ Hz, 4H, H–C_1^2), 7.44 (dd, $^3J_{HH} = 8.1$ Hz, $^3J_{HP} = 14.0$ Hz, 3H, H–C^0), 7.56 (“td”, $^3J_{HH} = 7.7$ Hz, $^4J_{HP} = 4.0$ Hz, 6H, H–C^m), 7.75 (t, $^3J_{HH} = 7.7$ Hz, 3H, H–C^p), 7.95 (s, 2H, H–C_1^2), 7.97 (d, $^3J_{HH} = 9.0$ Hz, 4H, H–C_1^3). ^{13}C $\{^1H\}$ NMR ($CDCl_3$): $\delta = 13.8$ (d, $^2J_{CP} = 5.0$ Hz, S–CH_3), 113.2 (s, C_1^6), 113.8 (s, CN), 121.9 (d, $^3J_{CP} = 5.3$ Hz, C_1^2), 124.3 (d, $^1J_{CP} = 110.0$ Hz, C^i), 129.8 (d, $^3J_{CP} = 12.0$ Hz, C^m), 129.9 (s, C_1^4), 132.1 (d, $^2J_{CP} = 11.1$ Hz, C^0), 134.6 (br s, C^p), 134.8 (s, C_1^3), 153.5 (d, $^2J_{CP} = 10.1$ Hz, C_1^1), 158.7 (s, C_1^5). ^{19}F $\{^1H\}$ NMR ($CDCl_3$): $\delta = -1.5$ (s, CF_3). IR (KBr): 2227 (ν-CN) cm^{-1}. *Anal.* Calc. for $C_{40}H_{28}F_3N_5O_5P_2S_2$ (841.76): C, 57.08; H, 3.35; N, 8.32. Found: C, 57.20; H, 3.39; N, 8.25%.

3.4. Synthesis of compounds *8ca* and *8cd*

A solution of **4a** (0.300 g, 0.68 mmol) or **4d** (0.061 g, 1.61 mmol) in THF (5 mL) was added to a solution of **7c** (for **8ca**: 0.350 g, 0.64 mmol; for **8cd**: 0.088 g, 1.61 mmol) in THF (5 mL) at room temperature. The resulting solution was stirred for 12 h, then evaporated to dryness, to afford a powder, which was purified by column chromatography on silica (eluent: AcOEt/Pentane 1/1 for **8ca**, 1/2 for **8cd**).

8ca was obtained as a pale green powder in 85% yield. ^{31}P $\{^1H\}$ NMR ($CDCl_3$): $\delta = -14.6$ (dd, $^2J_{P1P2} = 58.4$ Hz, $^2J_{P0P1} = 25.8$ Hz, P_1), 16.5 (d, $^2J_{P0P1} = 25.8$ Hz, P_0), 45.1 (d, $^2J_{P1P2} = 58.4$ Hz, P_2). ^1H NMR ($CDCl_3$): $\delta = 7.10$ (dd, $^3J_{HH} = 8.7$ Hz, $^4J_{HP} = 1.1$ Hz, 4H, H–C_1^2), 7.13 (dd, $^3J_{HH} = 8.8$ Hz, $^4J_{HP} = 1.0$ Hz, 4H, H–C_2^2), 7.46 (tl, $^3J_{HH} = 7.6$ Hz, 6H, H–C^m), 7.46 (d, $^3J_{HH} = 8.7$ Hz, 4H, H–C_1^3), 7.56 (ddd, $^3J_{HH} = 8.4$ Hz, $^4J_{HH} = 1.3$ Hz, $^3J_{HP} = 13.3$ Hz, 6H, H–C^0), 7.64 (ttd, $^3J_{HH} = 7.4$ Hz, $^4J_{HH} = 1.3$ Hz, $^5J_{HP} = 1.8$ Hz, 3H, H–C^P), 7.69 (s, 2H, H–C_2^5), 7.74 (d, $^3J_{HH} = 8.8$ Hz, 4H, H–C_2^3). ^{13}C $\{^1H\}$ NMR ($CDCl_3$): $\delta = 109.2$ (d, $^5J_{CP} = 1.2$ Hz, C_1^4), 113.6 (s, C_2^6), 114.3 (s, $CN^{(2)}$), 118.6 (s, $CN^{(1)}$), 122.3 (d, $^3J_{CP} = 5.4$ Hz, C_2^2), 122.6 (d, $^3J_{CP} = 5.9$ Hz, C_1^2), 127.4 (d, $^5J_{CP} = 1.0$ Hz, C_2^4), 127.8 (dd, $^1J_{CP} = 107.7$ Hz, $^3J_{CP} = 4.2$ Hz, C^i), 129.6 (d, $^3J_{CP} = 13.2$ Hz, C^m), 132.8 (s, C_1^3), 132.9 (d, $^2J_{CP} = 11.6$ Hz, C^0), 133.9 (d, $^4J_{CP} = 3.0$ Hz, C^p), 134.2 (s, C_2^3), 154.8 (d, $^2J_{CP} = 9.2$ Hz, C_2^1), 157.0 (d, $^2J_{CP} = 8.5$ Hz, C_1^1), 159.2 (s, C_2^5). 8cd was obtained as a pale green powder in 95% yield. ^{31}P $\{^1H\}$ NMR ($CDCl_3$): $\delta = -14.9$ (dd, $^2J_{P1P2} = 59.0$ Hz, $^2J_{P0P1} = 22.6$ Hz, P_1), 14.6 (d, $^2J_{P0P1} = 22.6$ Hz, P_0), 47.6 (d, $^2J_{P1P2} = 59.0$ Hz, P_2). ^1H NMR ($CDCl_3$): $\delta = 2.79$ (s, 12H, NMe_2), 6.35–6.55 (m, 6H, H–C_2^2, H–C_2^4, H–C_2^6), 7.01 (“t”, $^3J_{HH} = 8.0$ Hz, 2H, H–C_2^5), 7.04 (dd, $^4J_{HP} = 1.1$ Hz, $^3J_{HH} = 8.7$ Hz, 4H, H–C_1^2), 7.40 (d, $^3J_{HH} = 8.7$ Hz, 4H, H–C_1^3), 7.47 (”td”, $^4J_{HP} = 3.4$ Hz, $^3J_{HH} = 7.7$ Hz, 6H, H–C^m), 7.55–7.70 (m, 9H, H–C^0, H–C^p). ^{13}C $\{^1H\}$ NMR ($CDCl_3$): $\delta = 40.4$ (s, NMe_2), 105.9 (d, $^3J_{CP} = 5.8$ Hz, C_2^2), 107.9 (s, C_1^4), 108.2 (s, C_2^4), 109.4 (d, $^3J_{CP} = 4.9$ Hz, C_2^6), 118.5 (s, CN), 121.8 (d, $^3J_{CP} = 5.7$ Hz, C_1^2), 127.8 (dd, $^1J_{CP} = 107.8$ Hz, $^3J_{CP} = 3.7$ Hz C^i), 128.9 (d, $^3J_{CP} = 13.2$ Hz, C^m), 129.1 (s, C_2^5), 132.6 (d, $^2J_{CP} = 11.7$ Hz, C^0), 133.0 (d, $^4J_{CP} = 2.9$ Hz, C^p), 133.4 (s, C_1^3), 151.4 (s, C_2^3), 153.1 (d, $^2J_{CP} = 9.2$ Hz, C_2^1), 154.6 (d, $^2J_{CP} = 8.8$ Hz, C_1^1). IR (KBr): 2230 (ν-CN) cm^{-1}. *Anal.* Calc. for $C_{48}H_{43}N_6O_4P_3S$ (892.9): C, 64.57; H, 4.85; N, 9.41. Found: C, 64.62; H, 4.89; N, 9.28%.

3.5. Synthesis of compound *9ca*

Methyl triflate (26 μl, 0.22 mmol) was added dropwise at room temperature to a solution of **8ca** (0.200 g, 0.21 mmol) in CH_2Cl_2 (2 mL). After stirring for 20 min. the solution was evaporated to dryness to afford a powder, which was washed three times with THF/Pentane (1/20). Compound **9ca** was isolated as a pale green powder in 95% yield.

9ca: ^{31}P $\{^1H\}$ NMR ($CDCl_3$): $\delta = -14.0$ (dd, $^2J_{P1P2} = 53.2$ Hz, $^2J_{P0P1} = 26.2$ Hz, P_1), 23.7 (d, $^2J_{P0P1} = 26.2$ Hz, P_0), 23.8 (d, $^2J_{P1P2} = 53.2$ Hz, P_2). ^1H NMR ($CDCl_3$): $\delta = 2.60$ (d, $^3J_{HP} = 18.5$ Hz, 3H, S-CH_3), 7.03 (dd, $^3J_{HH} = 8.9$ Hz, $^4J_{HP} = 1.5$ Hz, 4H, H–C_1^2), 7.26 (dd, $^3J_{HH} = 9.0$ Hz, $^4J_{HP} = 1.5$ Hz, 4H, H–C_2^2), 7.45 (ddd, $^3J_{HH} = 8.5$ Hz, $^4J_{HH} = 1.3$ Hz, $^3J_{HP} = 13.6$ Hz, 6H,

H–C^0), 7.58 (''td'', $^3J_{HH} = 7.7$ Hz, $^4J_{HP} =$ Hz, 6H, H–C^m), 7.62 (d, $^3J_{HH} = 8.9$ Hz, 4H, H–$C_1{}^3$), 7.77 (ttd, $^3J_{HH} = 7.5$ Hz, $^4J_{HH} = 1.3$ Hz, $^5J_{HP} = 1.9$ Hz, 3H, H–C^P), 7.96 (s, 2H, H–$C_2{}^5$), 7.97 (d, $^3J_{HH} = 9.0$ Hz, 4H, H–$C_2{}^3$). ^{13}C {^1H} NMR ($CDCl_3$): $\delta = 14.0$ (d, $^2J_{CP} = 5.3$ Hz, S–CH_3), 110.7 (d, $^5J_{CP} = 1.2$ Hz, $C_1{}^4$), 113.0 (s, $C_2{}^6$), 113.7 (s, $CN^{(2)}$), 118.0 (s, $CN^{(1)}$), 121.7 (d, $^3J_{CP} = 5.4$ Hz, $C_2{}^2$), 121.8 (d, $^3J_{CP} = 5.3$ Hz, $C_1{}^2$), 126.0 (dd, $^1J_{CP} = 108.0$ Hz, $^3J_{CP} = 4.2$ Hz, C^i), 130.0 (d, $^3J_{CP} = 13.5$ Hz, C^m), 130.1 (s, $C_2{}^4$), 132.6 (d, $^2J_{CP} = 11.4$ Hz, C^0), 133.5 (s, $C_1{}^3$), 134.7 (d, $^4J_{CP} = 2.9$ Hz, C^p), 134.9 (s, $C_2{}^3$), 153.1 (d, $^2J_{CP} = 10.9$ Hz, $C_2{}^1$), 153.2 (d, $^2J_{CP} = 9.9$ Hz, $C_1{}^1$), 158.6 (s, $C_2{}^5$). ^{19}F {^1H} NMR ($CDCl_3$): $\delta = -0.8$ (s, CF_3). IR (KBr): 2228 (ν-CN) cm^{-1}. M.P.: 106–108 °C. *Anal.* Calc. for $C_{54}H_{36}F_3N_8O_7P_3S_2$ (1123): C, 57.76; H, 3.23; N, 9.98. Found: C, 57.83; H, 3.27; N, 9.85%.

3.6. X-ray structure determination for compounds **3a**, **4b**, and **5d**

Measurement were carried out on a one circle IPDS STOE X-ray diffractometer system (Mo-radiation, $\lambda = 0.71073$ Å, 50 KV/30 mA power). All compounds were collected at low temperature, at $T = 160(2)$ K for **3a** and **5d**, and 180(2) K for **4b**. Frames were integrated with the aid of STOE, X-RED, data reduction for STADI4 and IPDS, Revision 1.08, Stoe software [31].

In all cases a hemisphere of reflections was collected. Structures were solved by using direct methods, with the aid of SIR92 [32] and refined by least-squares procedures on F^2, using SHELXL-97 included in the WINGX programs version 1.64 04[1]. Direct methods of phase determination followed by subsequent Fourier cycles of refinement led to an electron density map, from which most of the non-hydrogen atoms were identified for all compounds. All of the non-hydrogen atoms were identified with subsequent isotropic refinement. Atomic coordinates, isotropic and anisotropic displacement parameters of all the non-hydrogen atoms were refined by means of a full matrix least-squares procedure on F^2. The hydrogen atoms were included in the refinement in calculated positions, riding on the carbon atoms to which they were attached. Drawings of molecules were realized with the aid of ORTEP32 [33]. Atomic scattering factors were taken from International tables for X-ray crystallography [34]. Due to the presence of a strong disorder on the N_3 groups for compound **4b**, restraints put on interatomic distances, angles and on ADP's were necessary to use in order to get a chemically reasonable model, some residuals electronics densities very close to N_3 groups are also still visible on the difference Fourier maps but all attempts to try to fit them failed.

simultaneously coordinating two or more metal centers also provide the bridge for the magnetic interaction; especially when the metal ions are relatively far from each other. In this category, $X_2C_2Y_2$ bridge, where X and Y atoms bound to different metal ions may be O, N, or S, has been used efficiently to propagate the magnetic interactions between two and in very few cases three metal centers. The examples include highly symmetrical bridge oxalato, $O_2C_2O_2^{2-}$ [21–23], oxamido, $N_2C_2O_2^{2-}$ [24–27], and dithiooxamido, $N_2C_2S_2^{2-}$ [28–30]. In particular, the oxamido ligand provide two planar NCO bridge between the metal centres and the result is a very strong antiferromagnetic coupling [24–27].

In this paper, we describe the design and synthesis of two amide-based ligands and their copper coordination chemistry. The ligands coordinate the copper ion via deprotonated $N_{amidate}$ and neutral N_{amine} donors. Interestingly, in one case, flipping of the amide containing arm take place to afford a linear copper trinuclear complex. This is a rare example, where deprotonated amide group coordinate via both ends, $N_{amidate}$ as well as $O_{amidate}$ [31,32]. The second complex also shows sharing of the amide group between copper centres affording a one-dimensional zig-zag chain. The bridging ligand present between the copper(II) ions is NCO, thus we have chopped off one unit (one NCO fragment) of the oxamido ligand. The result of this alteration on the structure and magnetic properties of the copper complexes is presented.

2. Experimental

2.1. Materials

All reagents were obtained from the commercial sources and used as received. *N*,*N*-dimethyl formamide (DMF) was dried and distilled from 4 Å molecular sieves and was stored over sieves. Acetonitrile (MeCN) was dried by distillation from anhydrous CaH_2. Diethyl ether and petroleum ether (boiling range 60–80 °C) were dried by refluxing over sodium metal under inert atmosphere. Tetrahydrofuran (THF) was dried by refluxing and distilling from sodium metal and benzophenone. Ethyl alcohol (C_2H_5OH) and methyl alcohol (CH_3OH) were distilled from magnesium ethoxide and magnesium methoxide, respectively. Chloroform ($CHCl_3$) and dichloromethane (CH_2Cl_2) were purified by washing with 5% sodium carbonate solution followed by water and finally dried over anhydrous $CaCl_2$, before a final reflux and distillation. *N*,*N*′-bis(chloroacetyl)ethylenediamine and *N*,*N*′-bis(chloroacetyl)-*o*-phenylenediamine were synthesized according to a reported procedure [33,34].

2.2. Physical measurements

The conductivity measurements were done in organic solvents using the digital conductivity bridge from Popular Traders, India (model number: PT-825). The elemental analysis data were obtained from Elementar Analysensysteme GmbH Vario EL-III instrument. The NMR measurements were done using an Avance Bruker (300 MHz) instrument. The infra-red spectra (either as KBr pellet or as a mull in mineral oil) were recorded using the Perkin–Elmer FTIR 2000 spectrometer. The absorption spectra were recorded using the Perkin–Elmer Lambda-25 spectrophotometer. The mass spectra were obtained on a Jeol SX102/DA-6000 instrument. The thermal analyses were performed with a Shimadzu DTG-60 instrument in the temperature range of 25–800 °C. EPR spectra of the polycrystalline samples were recorded at X-band (9.4 GHz) frequencies with a Bruker ESP-300E spectrometer, from room temperature to 4 K at the Servei de Magnetoquimica of the Universitat de Barcelona. Room temperature solution EPR spectra were recorded with a Jeol JES-3XG spectrometer.

2.3. Crystallography

Single crystals suitable for X-ray diffraction studies were grown by the vapour diffusion of diethyl ether to a DMF solution of complex **1** and slow evaporation of a saturated MeOH solution of **2**. The suitable crystals of **1** and **2** were mounted lengthways with the largest dimension in a sealed capillary. The intensity data for **1** were collected at 295 K on a Siemens P4 X-ray diffractometer by using scanning mode with graphite monochromatized Mo Kα radiation. A total of 15503 reflections were measured of which 10999 reflections ($I > 2\sigma(I)$) were used in the structure refinement. The data were corrected for Lorentz and polarization effects and a psi-scan absorption correction was also applied. The structure was solved by direct methods and refined by full-matrix least-squares refinement techniques on F^2. There are two crystallographically independent molecules of the complex and the solvent DMF in the unit cell. All calculations were performed using SHELXTL-PC. One of the DMF molecules showed rotational disorder which has been treated by refining all five non-hydrogen atoms of this molecule (C60, C61, C62, N20, O12) being split at two sites with total site occupancy of 1.00 for each one of them. This DMF molecule was refined isotropically with similar U_{iso} values assigned to two atoms of the pair. The molecule was refined with restraints on the bond distances of this disordered molecule being C(sp^3)–N 1.440(3), C(sp^2)–N 1.350(3), C=O 1.226(3) Å and non-bonding distances being 2.20(3) Å. All non-hydrogen atoms except for one DMF molecule were refined anisotropically. All hydrogen atoms were attached geometrically except for those belonging to the water molecules which were determined from the difference Fourier map. For **2**, the intensity data were collected on a BRUKER AXS SMART-APEX CCD diffractometer equipped with a molybdenum sealed tube (Mo Kα = 0.71073 Å) and a highly orientated graphite monochromator [35]. Frames were collected at $T = 293$ K by ω, ϕ and 2θ-rotation at 10 s per frame with SMART [35]. The measured intensities were reduced to F^2 and corrected for absorption with

SADABS [36]. The structure of **2** was solved by SIR 92 expanded by Fourier difference syntheses and refined with the SHELXL 97 package incorporated in WINGX 1.64 crystallographic collective package [37–39]. The positions of the hydrogen atoms were calculated by assuming ideal geometries but not refined. All non-hydrogen atoms were refined with anisotropic thermal parameters by full-matrix least-squares procedures on F^2. Details of the crystallographic data are given in Table 1.

2.4. Magnetic measurements

Magnetic susceptibility measurements for crushed crystalline samples of **1** and **2** were carried out at the Servei de Magnetoquimica of the Universitat de Barcelona with a Quantum Design SQUID MPMS-XL susceptometer. The magnetic susceptibility data were recorded in the 2–300 K temperature range under magnetic fields of 500 G (2–30 K) and 10 000 G (2–300 K). Diamagnetic corrections were estimated from Pascal Tables. The fits were performed minimizing the function $R = \Sigma(\chi_M T_{exp} - \chi_M T_{cal})^2/\Sigma(\chi_M T_{exp})^2$. Magnetic fields ranging from 0 to 50 000 G were used for magnetization measurements at 2 K.

2.5. Ligand Syntheses

2.5.1. Synthesis of H_2L^1

To a solution of diethylamine (1.37 g, 18.76 mmol) in MeCN (30 cm^3), K_2CO_3 (39 g, 282 mmol) and *N*,*N*′-bis(chloroacetyl)ethylenediamine (2 g, 9.38 mmol) were added and the mixture was refluxed for 24 h. The mixture was cooled, filtered and the solvent was removed under reduced pressure to afford an off-white solid. The crude product was recrystallized by layering the $CHCl_3$ solution with the petroleum ether (boiling range 60–80 °C). Yield: 2.24 g, 83%. Microanal. Calc. for H_2L^1, $C_{14}H_{30}N_4O_2$: C, 58.74; H, 10.57; N, 19.58. Found: C, 58.28; H, 10.96; N, 19.52%. M.p. 80 °C. Selected IR bands (FT-IR, KBr) ν (cm^{-1}): 3301s (NH), 2965m, 2933m, 2873w, 2814w (CH), 1649s (C=O). ^1H NMR spectrum ($CDCl_3$): δ 1.023 (t, $J = 6.8$ Hz, 12H, ethyl CH_3), 2.54 (quartet, $J = 6.7$ Hz, 8H, ethyl CH_2), 3.01 (s, 4H, CH_2CO), 3.42 (s, 4H, ethylene CH_2), 7.65 (br s, 2H, amidic NH). ESI mass spectrum (CH_3CN): $m/z = 287.24$ [M+H^+].

2.5.2. Synthesis of H_2L^2

To a solution of *N*,*N*′-bis(chloroacetyl)-*o*-phenylenediamine (2 g, 7.6 mmol) in ethanol (25 cm^3), 40% aqueous solution of dimethylamine (5.2 g, 46 mmol) was added and the mixture was refluxed for 24 h. The mixture was cooled and the solvent was removed under reduced pressure. The resultant oil was washed with a saturated solution of $NaHCO_3$ (10 cm^3) and the ligand was then extracted with dichloromethane (3×10 cm^3). The combined extracts were dried over Na_2SO_4 and evaporated under reduced pressure to leave a pale yellow solid. The crude product was then recrystallized by layering the $CHCl_3$ solution with the petroleum ether (boiling range 60–80 °C). Yield: 1.8 g, 85%. Microanal. Calc. for H_2L^2, $C_{14}H_{22}N_4O_2$: C, 60.31; H, 7.8; N, 20.10. Found: C, 59.59; H, 7.6; N, 19.86%. M.p. 82 °C. Selected IR bands (FT-IR, KBr) ν (cm^{-1}): 3231m (NH), 2952w, 2826m, 2780m (CH), 1693s (C=O), 1601m (C=C). ^1H NMR spectrum ($CDCl_3$): δ 2.30 (s, 12H, methyl CH_3), 3.03 (s, 4H, CH_2CO), 7.10 (m, 2H, benzyl CH) 7.56 (m, 2H, benzyl CH), 9.17 (br s, 2H, amidic NH). ESI mass spectrum (CH_3CN): $m/z = 279.4$ [M+H^+].

2.6. Syntheses of the copper complexes

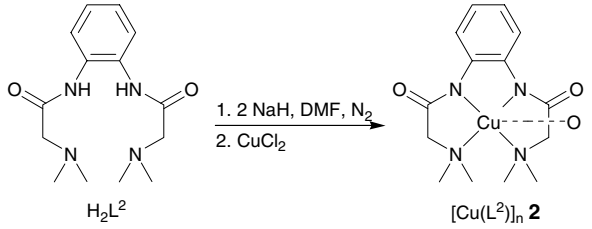
2.6.1. $[Cu_3(L^1)_2(Cl)_2(H_2O)] \cdot 2H_2O$ (**1**)

To a stirred solution of H_2L^1 (0.200 g, 0.699 mmol) in DMF (10 cm^3), solid NaH (0.033 g, 1.398 mmol) was added under dinitrogen atmosphere. The resulting mixture was stirred until H_2 evolution ceased. To this $CuCl_2$ (0.141 g, 1.048 mmol) was added as solid followed by the addition of few drops of water. The resulting green-blue solution was stirred at room temperature for 2 h. During this time the colour changed to dark blue. The solution was passed through a celite pad in a medium porosity frit. The resultant solution was layered with diethyl ether and stored at 4 °C. This afforded dark blue microcrystalline product within a day. Yield: 0.18 g, 61%. Microanal. Calc. for **1**, $C_{28}H_{58}N_8O_5Cl_2Cu_3 \cdot 2H_2O$: C, 38.03; H, 7.01; N, 12.68. Found: C, 38.36; H, 7.20; N, 12.56%. Selected IR bands (FT-IR, KBr) ν (cm^{-1}): 3367m br. (OH), 2967m, 2930m, 2874m (CH), 1610s, 1572s (C=O). UV–Vis

spectrum (MeCN: λ_{max} (nm) [ε_{max}] (M^{-1} cm^{-1})): 625 [390], 515sh [280], 350sh [4230], 317sh [7700], 264 [14050]. UV–Vis spectrum (MeOH: λ_{max} (nm) [ε_{max}] (M^{-1} cm^{-1})): 625 [370], 260 [15200], 215 [27800]. Conductivity (CH_3CN, ~1 mM solution, 298 K): $\Lambda_M = 12\ \Omega^{-1}\ cm^2\ mol^{-1}$. ESI mass spectrum ($CH_3OH$) $m/z = 852.5$ ($[Cu_3(L^1)_2(CH_3OH)(OCH_3)_2]+H^+$).

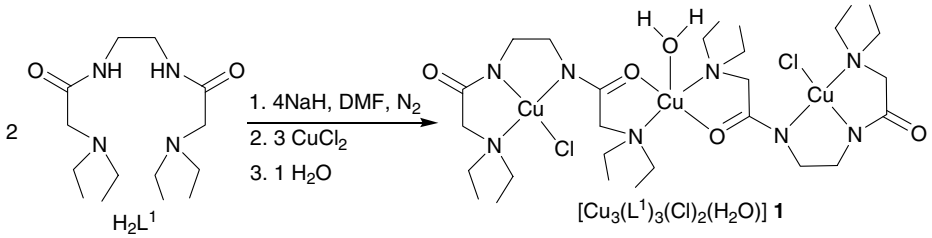
2.6.2. $[Cu(L^2)]_n$ (2)

To a stirred solution of H_2L^2 (0.200 g, 0.719 mmol) in DMF (10 cm^3), solid NaH (0.034 g, 1.438 mmol) was added under dinitrogen atmosphere. The resulting solution was stirred until H_2 evolution ceased. Solid $CuCl_2$ (0.097 g, 0.719 mmol) was added to the above mixture. The resulting indigo-blue solution was stirred at room temperature for 2 h. The DMF was then removed under reduced pressure and the residue was redissolved in CH_3OH (50 cm^3). The solution was passed through the celite pad in a medium porosity frit and allowed to evaporate for a day to afford dark blue microcrystalline product. The product was filtered and dried under vacuum. Yield: 0.20 g, 82%. Microanal. Calc. for **2**, $C_{14}H_{20}N_4O_2Cu$: C, 49.33; H, 5.89; N, 16.49. Found: C, 49.33; H, 6.03; N, 16.33%. Selected IR bands (FT-IR, KBr) ν (cm^{-1}): 3060w, 2893w, 2793w (CH), 1616s, 1598s (C=O), 1564s, 1478m, 1454w (C=C). UV–Vis spectrum (MeOH: λ_{max} (nm) [ε_{max}] (M^{-1} cm^{-1})): 550 [410], 413sh [180], 311sh [12270], 302sh [18600], 270 [47050], 250sh [52500], 240 [62050]. UV–Vis spectrum (MeCN: λ_{max} (nm) [ε_{max}] (M^{-1} cm^{-1})): 530 [360], 405sh [175], 311sh [11050], 280 [31000], 242 [50400], 214 [28000]. conductivity (CH_3OH, ~1 mM solution, 298 K): $\Lambda_M = 16\ \Omega^{-1}\ cm^2\ mol^{-1}$. ESI mass spectrum ($CH_3OH$) $m/z = 362.18$ ($[Cu(L^2)]+Na^+$).



3. Results and discussion

3.1. Ligand design and synthesis



The ligands H_2L^1 and H_2L^2 are designed to simultaneously provide two amide and two amine coordinations to the metal centre while maintaining an identical primary coordination environment around it. While the ligand H_2L^1 has a flexible ethylenediamine backbone, the ligand H_2L^2 incorporates a rigid *o*-phenylenediamine backbone. These ligands are synthesized in two steps starting from the corresponding primary diamines. In the first step, the diamine is converted to the respective bis(chloroamide) by treating with 2 equiv. of chloroacetyl chloride [33,34]. In the second step, the bis(chloroamide) was subsequently treated with diethyl- or dimethyl-amine to afford the ligands, H_2L^1 and H_2L^2, respectively. Excess Me_2NH (6 equiv.) was used for the synthesis of H_2L^2, where it also functioned as a base in the reaction. Both ligands were characterized thoroughly and gave satisfactory microanalyses results.

3.2. Synthesis and characterization of copper complexes

Complex **1** was synthesized by the initial reaction of 2 equiv. of deprotonated ligands with 3 equiv. of $CuCl_2$. The reaction mixture was then treated with few drops of water to afford the final compound (Scheme 1). The complex **2** was also synthesized in an analogous fashion by treating deprotonated ligand, $[L^2]^{2-}$, with $CuCl_2$ (Scheme 2). In the FTIR spectra, the absence of ν(N–H) stretching frequency confirms the deprotonated nature of the amide ligands. Moreover, a *red* shift was observed for the amidate C=O group compared to the free ligand, thus indicating coordination through anionic amidate-N center. The complex **1** also shows the ν(OH) stretches in the region of ~3370 cm^{-1} for the coordinated as well as lattice water [40]. Solution conductivity data [41] confirms the non-electrolytic nature of both copper complexes, whereas elemental analyses results authenticate the purity of the bulk samples. In the electrospray mass spectrum for complex **1** in CH_3CN, the molecular ion peak was observed at 887.35 that matches well with the following composition, $[Cu_3(L^1)_2(Cl)_2(H_2O)] + H_2O + Na^+$ (calculated $m/z = 887.64$). This is to be noted, however, when recorded in CH_3OH, a new molecular ion peak was observed at 852.5 which fits well with the following composition,

Scheme 2. Synthesis of complex **2**.

Scheme 1. Synthesis of complex **1**.

$[Cu_3(L^1)_2(OCH_3)_2(CH_3OH)] + H^+$ (calculated $m/z = 852.3$). Interestingly, while recording the spectrum in CH_3OH, two chloride ions were replaced by methoxide ions while the coordinated water got exchanged with methanol. Complex **2**, on the other hand, shows the molecular ion peak at 362.18 that matches well with $[Cu(L^2)] + Na^+$ (calculated $m/z = 362.25$).

3.3. Solid state structures

3.3.1. Structure of complex *1*

The molecular structure of **1** contains two slightly different independent trinuclear motifs of $[Cu_3(L^1)_2(Cl)_2(H_2O)]$, hereafter referred as molecule A and molecule B. The thermal ellipsoidal representation of molecules A and B are shown in Fig. 1 while important structural parameters are presented in Table 2. Each trinuclear assembly is composed of two $[L^1]^{2-}$ ligands, three copper ions, two chloride ions, and a water molecule. The terminal copper ions (Cu1 and Cu3 in molecule A; and Cu4 and Cu6 in molecule B) are coordinated by two amidate-N centres, one amine-N centre, and a chloride ion completing a distorted square-planar geometry. The central copper ion (Cu2 and Cu5 in molecules A and B, respectively) is coordinated by two amine-N centres, two amidate-O centres, and an apical water molecule. The geometry around the central copper(II) ion is distorted square-pyramidal. The τ value [42], which is an indication of the distortion of the 5-coordinate geometry towards square-pyramidal ($\tau = 0$) or trigonal bipyramidal ($\tau = 1$), is 0.14 and 0.04, for central copper ion in molecules A and B, respectively. It is clear from the value of τ that the central Cu(II) ion has much more distorted geometry in molecule A. The displacement from the basal plane (defined by two amide-N, one amine-N, and a Cl^-) for the terminal copper centres (Cu1, Cu3, Cu4, and Cu6) is quite small, 0.028–0.087 Å. On the other hand, the central coppers are significantly displaced out of basal plane (defined by two amide-Os and two amine-Ns) towards the apical water molecule; displacement for Cu2 and Cu5 is 0.210 and 0.171 Å, respectively. These values again indicate that the copper ion in molecule A has much more distorted geometry than in B. The bond length difference for the coordination of two amidate-N centres to the terminal Cu(II) ions (for example, between Cu1–N2 and Cu1–N3 for molecule A) is quite significant, ~0.1 Å. This difference may be attributed due to the presence of a delocalized structure of one of the amide group which is involved in the bonding with the central Cu(II) ion. This

delocalization of the electron density has contributed in inducing a partial negative charge on the amidate-O atom that eventually coordinate to the central copper ion to afford the linear trinuclear complex. The implication of this delocalized resonance structure is the lengthening of the C=O bond involved in the bonding than the un-coordinated one. The C=O bond length increased from a average value of ~1.23(2) Å (uncoordinated one) to ~1.28(2) Å (coordinated one). This lengthening is lower for molecule B (0.03–0.04 Å) than for molecule A (0.05–0.06 Å). The $Cu–O_{amide}$ distances for the central metal ion, are in the range of 1.923(3)–1.942(3) Å for molecules A and B. These distances are on the lower side than the examples reported in the literature and indicate a stronger bond to the copper ion [31,32]. The $Cu–OH_2$ bond distances are also on the lower side compared to the similar distance in other structurally characterized complexes [43–47]. The Cu–Cl distances are comparable to other structurally characterized complexes [48–50]. The average distance between the neighbouring copper centres is ~5.74(3) Å, while the terminal copper ions are separated by ~11.5(3) Å. The coordinated water molecule forms hydrogen bonds with the carbonyl oxygen atoms from the neighbouring complexes, the distance are within the range of ~2.62(3)–2.68(4) Å.

There are strong H-bonding interactions involving the amide oxygens, water molecules and the DMF molecule resulting in an interesting crystal structure of the molecule. The water molecule O3 of molecule A shows strong intermolecular O···O bonding with amide oxygens O1 and O5 of its centrosymmetrically related molecules (Table S1). This gives rise to polymeric, pleated ribbon like chains running along the *c* axis in the *bc* plane (Fig. S1) constituting lattice I. The DMF molecule close to this is not involved in any O···O bonding but is merely being held in space by weak C···O H-bonding interactions. On the other hand second DMF molecule is acting as H-bond acceptor to water molecule O8 of molecule B, which is also behaving as a H-bond donor to amide oxygen O10. These interactions give rise to a H-bonded 2B:2DMF tetrameric synthon as shown in Fig. S2, constituting lattice II. There are only some weak C···O H-bonding interactions between these synthons. Thus involvement of DMF in H-bonding interactions with the trinuclear coordination compound destroys the polymeric nature of molecule B. Taken together the crystal structure may be looked at as two interpenetrating lattices I and II (Fig. S3).

The alignment of the basal plane containing metal centers plays a very important role in the magnetic exchange interactions in any multimetallic system [51,52]. If these planes are coplanar with each other, a strong antiferromagnetism results and deviation from this planarity results in the alteration of the extent of orbital overlapping. The angle between the basal planes containing copper ion is within the range of 20–40°. For example, in molecule B, the angle between the planes containing Cu(4) and Cu(5) is 39.61°. These numbers suggest a moderate to weak antiferromagnetic interaction between the magnetic orbitals emerging from the planes containing copper ions (cf. magnetic properties).

3.3.2. Structure of complex **2**

The molecular structure of this complex is shown in Fig. 2 and the selected bonding parameters are presented in Table 3. The complex **2** exists as a one-dimensional (1D) chain of infinite length. The copper(II) ion is coordinated by the ligand $[L^1]^{2-}$, in a tetradentate fashion via two deprotonated amidate-N and two amine-N centers. The 5th coordination comes from the oxygen atom of the amide group of the neighbouring complex, with the distance of 2.354(2) Å. This additional interaction leads to the generation of an infinite length chain in the solid state. The geometry around the Cu(II) ion is almost perfect square – pyramidal with a very small τ value [42] of 0.01. The average $Cu–N_{amide}$ distance at 1.935(2) Å is shorter by 0.14 Å than the average $Cu–N_{amine}$ bond lengths of 2.075(3) Å, thus indicating a tight chelation from the

anionic amidate donors. The lateral 5-membered chelate rings are making an angle of ~13° with each other, while they make an angle of 8–10° with the central 5-membered chelate ring. The copper(II) ion is 0.202 Å out of the least square basal plane (defined by N1, N2, N3, and N4) towards the apical amide oxygen atom from the neighbouring molecule. Any of the two copper ions in the chain are separated by ~6 Å. The two neighbouring molecular planes containing copper ions make an angle of ~74(1)° with each other. This significant number suggests that any of the two monomeric units in the 1D chain are almost orthogonal to each other and gave us a clue about their expected magnetic behaviour (cf. magnetic properties).

Vagg and co-workers [53] have reported a copper(II) complex with a pyridine-amide based ligand (*N*,*N*′-bis-(6′-methylpyridine-2′-carboxamide)-1,2-benzene) where oxygen atoms of the neighbouring molecules coordinate to form a chain. However, this is to be noted that here two O-atoms from two neighbouring molecules coordinate to complete an octahedral geometry around the copper ion. The two $Cu–O_{amide}$ bond distances are 2.693(6) and 2.798(6) Å, respectively, and are quite longer than that of **2**. The average $Cu–N_{amide}$ and $Cu–N_{pyridine}$ distances are 1.934(7) and 2.079(7) Å, respectively, and are quite similar to that of complex **2**. Interestingly, when the authors used the un-substituted pyridine-amide ligand (*N*,*N*′-bis(2′-pyridinecarboxamide)-1,2-benzene), only one water molecule coordinate axially to afford a square-pyramidal copper complex [54]. The authors have reasoned that the presence of methyl substituents on the pyridine ring in the former case caused the distortion around the metal centre and resulted in the twisting of the basal plane. The implication of this twisting is the availability of the coordination sites both from top and bottom of the basal plane, thus O_{amide} coordinate to the copper ion affording the octahedral geometry in the former case. Despite an interesting chain structure of the Cu(II) complex of Vagg and co-workers, magnetic properties have not been carried out.

3.4. Magnetic properties

The magnetic properties of **1** and **2** in the form of $\chi_M T$ versus T plot are shown in Figs. 3 and 4. For **1**, the value of $\chi_M T$, at room temperature is 1.13 $cm^3\ mol^{-1}$ K, close to the expected value for three uncoupled Cu(II) ions. The $\chi_M T$ product decreases upon cooling, reaching a plateau at 23 K, with $\chi_M T$ value equal to 0.4 $cm^3\ mol^{-1}$. This value is close to the expected value for a spin state $S = 1/2$. This behaviour is characteristic of an antiferromagnetic

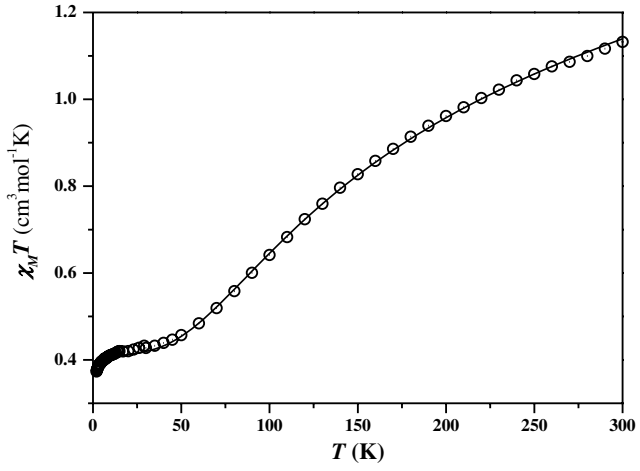

Fig. 3. $\chi_M T$ vs. T plot for compound **1**. The solid line was calculated with the parameters reported in the text.

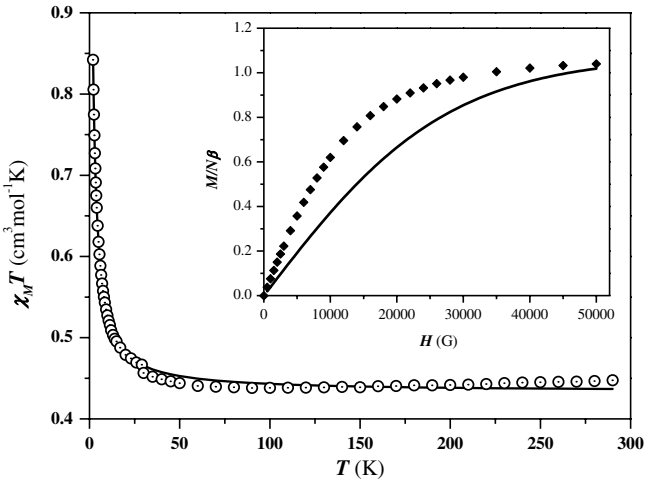

Fig. 4. $\chi_M T$ vs. T plot for compound **2**. The solid line was calculated with the parameters reported in the text. In the inset, experimental $M/N\beta$ vs. H plot (♦) and calculated from the brillouin equation for a $S = 1/2$ (solid line).

coupling. Below 4 K, $\chi_M T$ product decreases again, indicating that an intermolecular antiferromagnetic interaction also occur in this compound.

The experimental data were fitted using the theoretical expression deduced from the following Heisenberg Hamiltonian $H = -J(S_1 \cdot S_2 + S_2 \cdot S_3) - J'(S_1 \cdot S_3)$. Taking into account the geometry of this compound (the terminal copper centres are separated by the distance in the range of 11.4–11.5 Å), the interaction between the two terminal Cu(II) ions was assumed to be nil ($J' = 0$). The best fit was obtained for $J = -110.34\ \text{cm}^{-1}$ and $g = 2.06$ ($R = 1.8 \times 10^{-4}$).

For **2**, the $\chi_M T$ value at room temperature is $0.45\ \text{cm}^3\ \text{mol}^{-1}$ K, which is as expected for one magnetically quasi-isolated Cu(II) ion ($g > 2.0$). On cooling, the $\chi_M T$ values smoothly increases up to $0.84\ \text{cm}^3\ \text{mol}^{-1}$ K at 2 K. The shape of this curve clearly indicates weak ferromagnetic coupling among the Cu(II) ions. The mathematical formula derived by Baker et al. [55] for ferromagnetic 1D systems with $S = 1/2$ is valid only at relatively high temperatures. Thus, when the ferromagnetic coupling is weak, this formula is not very accurate. For this reason, the fit of the experimental data was performed in the numerical form from a full-matrix diagonalization of the Hamiltonian corresponding to a ring of 12 local $S = 1/2$ centers with the adequate J coupling parameter using the CLUMAG program [56]. With this program, the use of 12 cycled centers give a good approximation for the system, which is actually infinite. The best fit parameters of the data are $J = +3.08\ \text{cm}^{-1}$ and $g = 2.15\ \text{cm}^{-1}$ ($R = 8.6 \times 10^{-5}$). The reduced molar magnetization ($M/N\beta$) per Cu entity tends to be 1 $N\beta$ (electron) (Fig. 4 inset) but the shape of the experimental curve is clearly above the theoretical ones for the Brillouin law. These features agree with the global ferromagnetic coupling between the copper(II) ions.

Compounds **1** and **2** show the same bridging motif, NCO, between the Cu(II) ions, nevertheless the magnetic behaviour is very different. For the trinuclear complex (compound **1**) strong antiferromagnetic coupling is observed, while the one-dimensional system (compound **2**) shows a ferromagnetic interaction.

In the trinuclear compound, the coordination around the two terminal ions is square planar, while for the central ion is a square pyramidal, and its basal plane is quite coplanar with the coordination planes of the terminal ions. For the three copper(II) ions, the single electron is in the $x^2 - y^2$ orbital, and taking into consideration that these orbitals are almost coplanars, a good overlap through the bridging motif NCO could be attended (Fig. 5). In the one-dimensional system, the coordination polyhedra of the Cu(II) ion is a square pyramidal, but, in this case, the basal planes between neighbours ions are almost perpendicular (in the crystal structure, two planes make an angle of 74° with each other), and as a result of this, the $x^2 - y^2$ orbital are orthogonal, and a very small overlap through the bridge must be attended (Fig. 6). So, the different magnetic behaviour observed for compounds **1** and **2**, could be explained by the different disposition of the magnetic orbitals.

Several trinuclear compounds with oxamide bridging ligands have been reported in the literature [24–30]. These trinuclear compounds show significant antiferromagnetic coupling with the J value ranging between −80 and

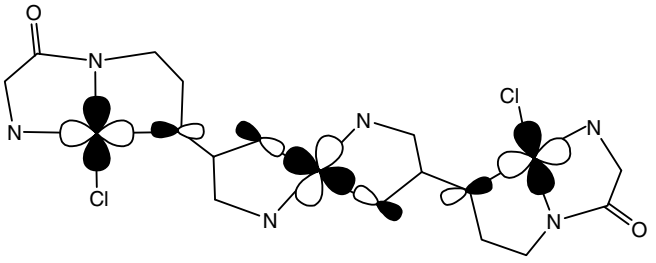

Fig. 5. Schematic drawing of the disposition of the $x^2 - y^2$ orbital in the trinuclear compound **1**.

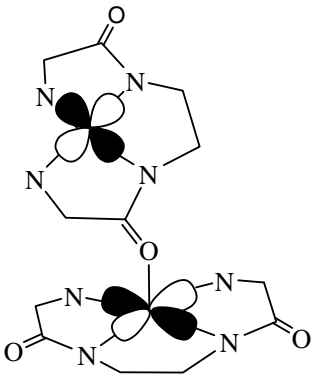

Fig. 6. Schematic drawing of the disposition of the $x^2 - y^2$ orbital in the one-dimensional system **2**.

$-600\ cm^{-1}$ [51,52]. The extent of coupling (J value) has been found to be very sensitive to the geometry around the terminal Cu(II) ions with respect to the central copper(II) ion. For the square-planar, 4-coordinate, or square-based geometries (such as (4 + 1)- or (4 + 2)-coordinate), the magnetic orbitals are predominantly $d_{x^2-y^2}$ in nature. These terminal metal-based magnetic orbitals are approximately coplanar with that of the central ion and have $x^2 - y^2$ symmetry. Thus, the magnetic coupling is well described by the antibonding combination of the $d_{x^2-y^2}$ metallic orbitals with the symmetry-adapted molecular orbitals of the oxamido bridge. However, in case of trigonal bipyramidal geometry for the terminal copper ions, the magnetic orbitals are predominantly d_{z^2} in character; this reduces the effective overlap and the magnitude of the interaction is smaller (lower value of $-J$) [25–27]. Basically, when the magnetic orbitals of the three Cu(II) ions are not coplanar with respect to each other, the J value decreases. The oxamido ligand provides two coplanars NCO bridging motifs, while for compound **1**, only one NCO group bridge the two Cu(II) ions. Therefore, in compound **1**, with only one way for the magnetic exchange, the antiferromagnetic coupling must be smaller than in the oxamide complexes. This agrees nicely with the smaller J value found for **1** ($-110\ cm^{-1}$) compared to the oxamido bridged complexes.

The solution state magnetic moment were also determined for both complexes using Evans' method [57]. The room temperature magnetic moment (μ_{eff}) for complex **2** in $(CH_3)_2SO$, was found to be 1.85 μ_B which matches very well with the solid state value of 1.90 μ_B. The similarity between the results from the solid and the solution state indicate a similar structure. However, taking into account that at room temperature if the magnetic coupling is small, the values are close to the uncoupled ions; it is, therefore, not possible to be sure if the 1D structure is maintained or if it is a mononuclear structure in the solution. For trinuclear complex **1**, however, a value of 2.68 μ_B/trimer was obtained at room temperature in $(CH_3)_2SO$ or DMF. This value is lower by ~0.3 μ_B/trimer than the solid state value. The difference in the magnetic moment is indicative of some changes in the geometry of the trinuclear complex and indicate that the copper centres are better antiferromagnetically coupled in the solution state at room temperature. This could happen due to a more relaxed geometry around the copper ions allowing better overlap of the metal based magnetic orbitals through ligand based magnetic orbitals.

3.5. EPR spectra

Powder electron paramagnetic resonance spectra (EPR) were recorded at 298, 77 and 4 K for compounds **1** and **2** (Figs. 7, S4 and S5). The trinuclear complex **1**, with an appreciable antiferromagnetic coupling ($J = -110.34\ cm^{-1}$), shows a ground state of $S = 1/2$, and a narrow signal ($\Delta H_{p-p} = 62$ G) centered at $g = 2.08$ was observed in the EPR spectrum at 4 K. The experimentally observed g value of 2.08 in EPR measurement matches very well with the g value (=2.06) obtained after fitting the magnetic data. For one-dimensional compound, **2**, the EPR spectrum at 4 K, shows two superimposed bands at 2.11 and 2.06, with a $\Delta H_{p-p} = 145$ G (Fig. 7). The two different g values clearly indicate the anisotropy [58] around the copper centre caused due to the coordination of the O-atom of the neighbour molecule, as observed structurally (cf. crystal structure of **2**). The effect of the temperature in the peak-to-peak gap is opposite in both compounds. For compound **1**, a narrowing of the band was observed on cooling, from 190 to 62 G. However, for **2**, a little broadening of the band was observed, from 130 to 145 G. The observed temperature-dependent behaviour for both complexes clearly indicates that they significantly differ with each other and support their opposite magnetic properties (cf. magnetic measurements).

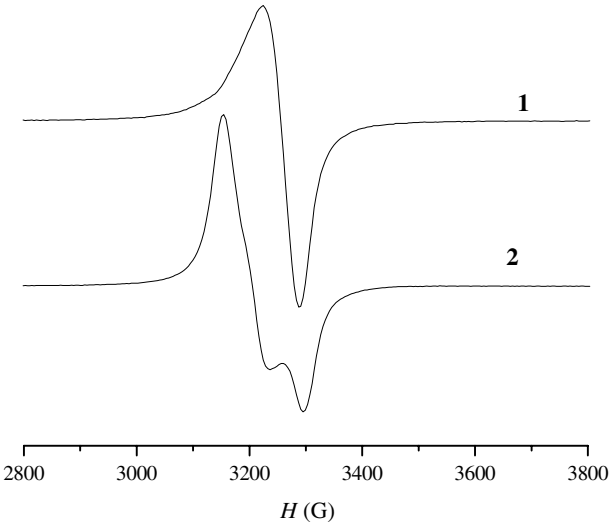

Fig. 7. Powder EPR spectra for compounds **1** and **2** at 4 K.

The EPR spectra were also recorded in the solution state to understand the solution-based geometry and the effect of solvent (CH_3OH and pyridine). For **1**, a broad feature, with the g_{iso} at 2.107 and 2.097 was observed in methanol and pyridine, respectively. In solution, at room temperature there is only one isotropic g value. For complex **2**, a four lines signal was observed in methanol or pyridine at room temperature. This feature is characteristic of the hyperfine coupling with the nuclear spin of the Cu ($I = 3/2$) and typically observed for a tetragonal copper ion in solution [58]. The g_{iso} was observed at ~2.12 with the $A(Cu)_{iso}$ value of 106 G.

3.6. Absorption spectra

The electronic spectra of both complexes were recorded in the solid state (dispersed in mineral oil) as well as in solutions (CH_3OH, CH_3CN, and pyridine) to gain insight into the coordination geometry around the copper ion (Figs. S6

and S7). The solid state spectrum of **1** displays a broad band in the visible region at 655 with a low energy shoulder at ~850 nm, suggestive of a square-pyramidal geometry [59,60]. A less clear feature was also observed at ~515 nm which we assign due to the square-planar Cu(II) ion. This corroborate the findings from the crystal structure of **1** that clearly show that terminal copper ions are square-planar while the central ion is square-pyramidal. In CH_3OH or CH_3CN, a main peak was observed at 625 nm while a less intense peak at ~515 nm was also noticed. We tentatively assign the former from the square-pyramidal ion (central copper) while the later due to the square-planar ion (terminal coppers). For **2**, a broad band at 590 nm with a weak shoulder at ~760 nm was displayed in the solid state spectrum. These features clearly support a 5-coordinate geometry around the Cu(II) ion [59,60] as seen in the crystal structure of **2**. However, a shift in the λ_{max} was noticed when the spectra were recorded in various solvents; the λ_{max} changed from 530 in CH_3CN to 548 in MeOH to 555 nm in pyridine. This experiment strongly suggests that the axial position(s) occupied by the O_{amide} in the solid state (as seen in the crystal structure) are displaced by the solvent molecule(s) when the spectrum is recorded in the solution state.

4. Conclusions

The present work show interesting coordination behaviour of the amide-based ligands towards copper(II) ion. The backbone flexibility of the ligand $[L^1]^{2-}$, resulted in the flipping of one of the arm to accommodate the second copper ion; this generates the trinuclear complex, $[Cu_3(L^1)_2(Cl)_2(H_2O)]$ **1**. This trinuclear complex belongs to a rare group of complexes where both amidate-N and amidate-O participate in the coordination [31,32]. The ligand $[L^2]^{2-}$, incorporating the rigid *o*-phenylene backbone affords a simple mononuclear complex. The substituted methyl groups restricted the coordination of any additional axial ligand. However, the molecular basal plane tilt in a unique way to allow the coordination of the neighbouring amidate-O to the Cu(II) centre [53,54]. This generates a zig-zag one-dimensional chain, $[Cu(L^2)]_n$ **2**. Both complexes, **1** and **2** have *NCO* bridge between the copper ions and show interesting but contrast magnetic properties. The **1** shows moderately strong antiferromagnetic coupling ($J = \sim -110\ cm^{-1}$). The moderate nature of antiferromagnetic coupling in **1** is due to the availability of only one magnetic exchange pathway (*NCO* bridge) between the copper ions compared to two in the oxamido-bridged systems. Whereas **2** shows a weak ferromagnetic interaction ($J = \sim +3\ cm^{-1}$) due to the accidental orthogonality of the magnetic orbitals from two copper containing basal planes.

dures. The dimethyl calixarene derivative **1** [16], [Pd(COD)Cl_2] [17] and chlorophosphazane $Ph_2PN(^iPr)$-PPhCl [18] were prepared by following the literature procedures. The NMR spectra were recorded on Bruker Avance-400 MHz spectrometer using standard pulse sequences; $CDCl_3$ was used as solvent throughout. For the NOESY experiments, the mixing time was chosen as 300 ms.

2.2. Synthesis of the calix[4]arene diphosphazane ligand $Ph_2PN(CHMe_2)P(Ph)$\{1,3-dimethoxycalix[4]arene\} (2)

A suspension of 25,27-dihydroxy-26,28-dimethoxy-*p*-*tert*-butyl-calix[4]arene (**1**) (2.703 g, 0.004 mol) and NaH (60% dispersion in oil) (0.322 g, 0.0084 mol) in THF (100 mL) was heated under reflux for 12 h. $Ph_2PN(CHMe_2)P(Ph)Cl$ (0.01 mol) in THF (50 mL) was added at 0 °C and the reaction mixture stirred for 2 h at 25 °C. The reaction was followed by TLC [$R_f = 0.5$ (ligand **2**); silicagel; EtOAc/petrol(bp 60–80 °C) 3/97-v/v]. Solvent was evaporated under reduced pressure and the residue was subjected to column chromatography [SiO_2, EtOAc/petrol 3/97-v/v] to obtain the title compound **2** as a colorless solid. Yield: 1.1 g (26.8%). Mp 185–190 °C. *Anal.* Calc. for $C_{67}H_{81}NO_4P_2$ (mol wt.: 1025.26): C, 78.4; H, 7.9; N, 1.4. Found: C, 78.0; H, 7.7; N, 1.5%. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 162 MHz): δ 34.1 (PPh_2, d, $^2J_{P-P} = 23.0$ Hz), 36.0 (PPh_2, d, $^2J_{P-P} = 25.1$ Hz), 37.7 (PPh_2, d, $^2J_{P-P} = 25.3$ Hz), 124.3 (PPhO, d, $^2J_{P-P} = 32.1$ Hz), 126.8 and 127.1 (PPhO, two doublets overlapping) (three conformers). ^1H NMR ($CDCl_3$, 400 MHz): δ 2.80 and 3.28 (2s, 3H each, OMe), 3.57 and 3.73 (2s, 3H each, OMe), 3.85 and 3.96 (2s, 3H each, OMe) [other peaks were not resolved].

2.3. Synthesis of [$Cl_2Pd(2)$] (3)

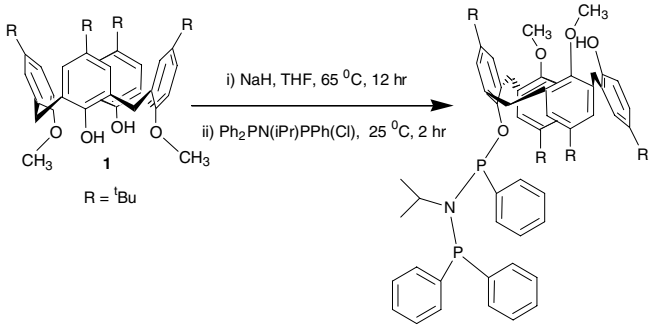
A mixture of 95 mg (8.84×10^{-5} mol) of ligand **2** and 25 mg (8.84×10^{-5} mol) of [Pd(COD)Cl_2] was dissolved in 20 mL of benzene. The solution was stirred for 1 h at 25 °C. The reaction mixture was washed with hot petrol and the residue crystallized from petrol–chloroform solution (5:1 ratio v/v) to which a few drops of acetone were added, to obtain the title compound **3** as light green crystals. Yield: 0.055 g (40%). Mp 168–172 °C (dec.). *Anal.* Calc. for $C_{67}H_{81}NO_4P_2PdCl_2$ (mol wt.: 1202.4): C, 66.9; H, 6.7; N, 1.2. Found: C, 66.5; H, 6.8; N, 1.0%. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 162 MHz): δ 36.9 (d, PPh_2, $^2J_{P-P} =$ 18.3 Hz), 64.3 (d, POPh, $^2J_{P-P} = 18.3$ Hz). ^1H NMR ($CDCl_3$, 400 MHz): δ −0.05 (d, 6H, Me_2CH–), 0.81, 1.01 (2s, 9H each, –$C(CH_3)_3$), 1.29 (s, 18H, –$C(CH_3)_3$), 3.07 and 3.72 (2s, 3H each, –OCH_3); 3.20, 3.28, 3.45, 3.59, 3.67, 4.58, 4.81, 5.00 (8d, 1H each, $ArCH_2Ar$, four AB systems); 4.48 (m, 1H, Me_2CH–); 6.6–9.2 (m, ArH).

2.4. X-ray crystallographic studies

The X-ray diffraction data were collected on a Bruker SMART APEX CCD diffractometer (graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å). The SMART [19] software was used for cell refinement and data acquisition and the SAINT [20] software was used for data reduction. An absorption correction was made on the intensity data using the SADABS [21] programme. The structures were solved using SHELXTL [22] and the WinGX graphical user interface [23]. Least square refinements were performed by the full-matrix method with SHELXL-97 [24]. All non-hydrogen atoms were refined anisotropically and hydrogen atoms were refined isotropically. Details of data collection and refinement are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and NMR analysis of conformationally flexible diphosphazane 2



When a suspension of 1,3-dimethoxy *p*-*tert*-butylcalix[4]arene (**1**) in toluene is treated with $Ph_2PN(CHMe_2)PPh(Cl)$ in the presence of NaH, the diphosphazane derivative (**2**) of calix[4]arene is obtained in 26.8% yield (Scheme 1). The main reason for the low yield is the loss of material during the chromatographic separation step (see Section 2). Crystallization of the crude product from petrol (bp 60–

80 °C) gave single crystals of the partial-cone conformer (B) of **2**. The structure of the partial cone conformer (B) has been established by X-ray crystallography. When a solid sample of conformer (B) was dissolved in $CDCl_3$, the solution showed the presence of three conformers (A)–(C) as revealed by three pairs of doublets in the ^{31}P NMR spectrum in the region of δ 30–40 and δ 120–130 for the PPh_2 and OPPh phosphorus nuclei, respectively. The ratio of the conformers A–C is 3.2:2.6:1 as shown by the relative intensities of the corresponding ^{31}P NMR signals. The observed $^2J_{P-P}$ values (23–25 Hz) indicate a *trans*-type of ligand conformation [18,25,26] in which the lone pairs on the two phosphorus atoms are far apart from each other. Assignment of the methylene protons to the respective conformers was not possible because of the overlapping of the resonances. A pair of singlets at δ 2.78 [$-OCH_3(1)$] and 3.26 [$-OCH_3(2)$] may be assigned to the conformer A; another pair of singlets at δ 3.55 [$-OCH_3(3)$] and 3.71 [$-OCH_3(4)$] may be assigned to the methoxy protons of the other conformer (B). The intensity ratio of the signals arising from A and B is 1:1.2. The ^1H–^1H NOESY experiment shows the presence of several cross peaks with the same phase as that of the diagonal indicating exchange among the conformers (see Electronic supplementary information (ESI)). The ^{31}P–^{31}P NOESY experiment shows clear cross peaks among the three different phosphorus atoms in the $-PPh_2$ region (Fig. 1) and confirms that all the three conformers undergo exchange among each other. Careful analysis of the ^1H–^1H NOESY spectrum (see ESI) reveals that the major conformer has an 1,2-alternate conformation (A in Fig. 2) and the minor conformer adopts a partial cone conformation (B in Fig. 2) in which the calix[4]arene aryl ring containing the P–N–P moiety is in inverted (anti) orientation. The same partial cone structure is observed in the solid state as established by X-ray crystallography. The solution structure of the remaining conformer (C) could not be determined owing to its low abundance and hence low intensity of the peaks in the ^1H NMR spectrum.

A variable temperature NMR study ($CDCl_3$, 400 MHz) of ligand **2** has been carried out between −50 °C and +50 °C. The ^{31}P NMR spectra do not show any significant change but the ^1H NMR spectra show considerable changes. The resonances of the hydroxyl protons show

Scheme 1. Synthesis of calix-diphosphazane ligand (**2**).

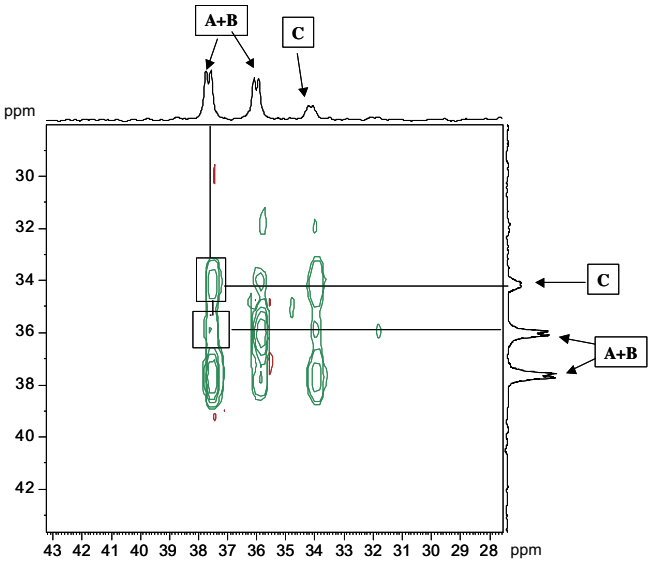

Fig. 1. The ^{31}P–^{31}P NOESY spectrum of the calix[4]arene diphosphazane ligand **2**.

appreciable up-field shift with an increase in temperature, indicating the breaking of hydrogen bonds (see later) and consequently facile movement of the corresponding phenolic rings towards the calix[4]arene cavity. Broadening of almost all ^1H resonances upon increasing the temperature suggests the existence of dynamic exchange processes among the conformers A–C.

3.2. Synthesis and NMR analysis of palladium dichloride complex of ligand 2

Reaction of ligand **2** with $[Pd(COD)Cl_2]$ yields the dichloride complex **3** in which the calixarene is frozen in the cone conformation. Crystallization of the crude prod-

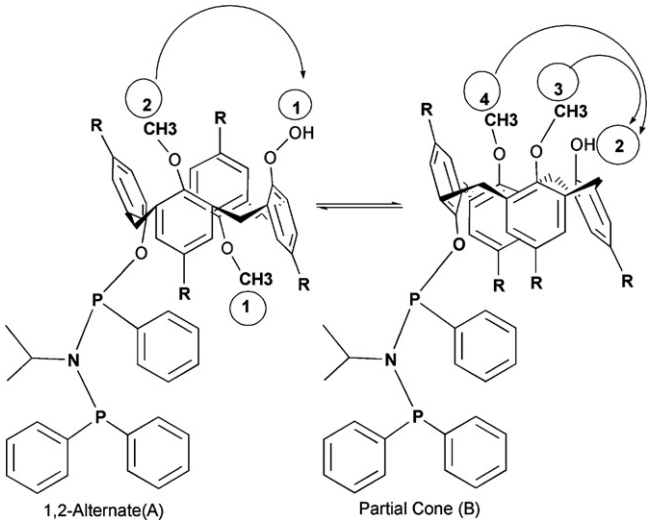

Fig. 2. Two major conformers of ligand **2** in solution; arrows represent the protons showing "through-space" interaction in the NOESY spectrum.

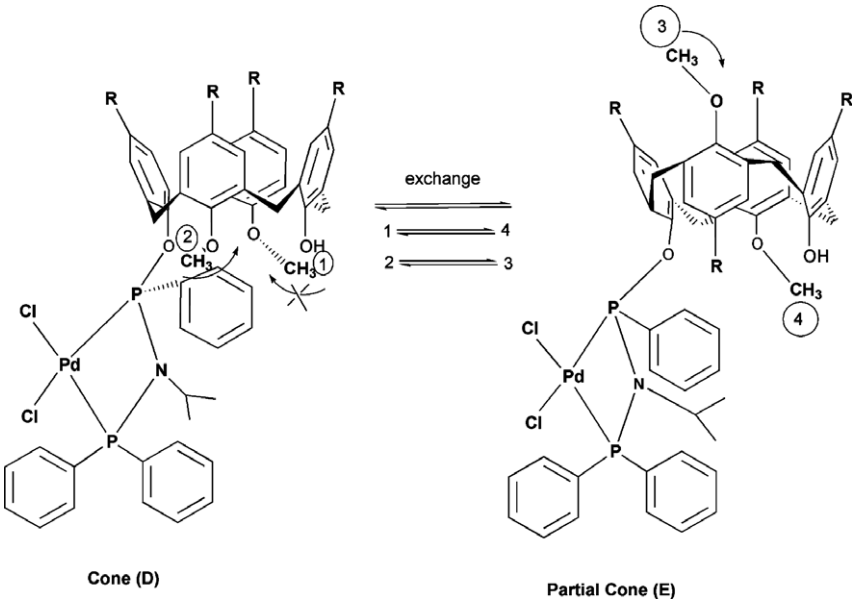

Fig. 3. A schematic representation of exchange process between the conformers of complex **3** in solution (arrows represents movement of aryl rings).

uct from chloroform–petrol gave single crystals of cone conformer (D) (Fig. 3). The cone conformation of calixarene framework in the solid-state has been confirmed by single crystal X-ray analysis. When the solid sample of conformer (D) is dissolved in $CDCl_3$, the solution shows the presence of two conformers (D) and (E) as revealed by the ^1H and ^{31}P NMR spectra (see ESI, Fig. S3). The ^{31}P NMR spectrum of the product shows two doublets at δ 36.9 and 64.3 for the major conformer and two doublets at δ 38.2 and 57.0 for the minor conformer. The ratio of the major to minor conformer in the reaction mixture is 15:1. The ^1H NMR spectrum of complex **3** shows four AX patterns for the eight methylene bridge protons and two singlets at δ 3.07 [–OCH_3(1)] and 3.72 [–OCH_3(2)] for the protons of two methoxy groups. This NMR pattern suggests that the major isomer of **3** does not contain any element of symmetry. The singlet in the comparatively shielded region (δ 3.07) may be assigned to the protons of the methoxy group which is near to the aryl ring of the OP(Ph) fragment. The 2D COSY and NOESY experiments show that the major isomer in solution adopts the cone conformation (see ESI, Fig. S4) which is also the conformation observed in the solid state as revealed by X-ray crystallography. Two singlets at δ 1.88 [–OCH_3(3)] and 3.70 [–OCH_3(4)] arising from the protons of two nonequivalent methoxy groups of the minor conformer could be identified. Two-dimensional ^1H–^1H NOESY experiment (see ESI, Fig. S5) indicates the movement of one of the aryl rings through the calix[4]arene cavity (Fig. 3). The possible rotation of a single aryl ring is also supported by the molecular structure of the complex which is shown in Fig. 5. The perspective view along an axis which passes through the center of the calix[4]arene cavity shows that the aryl ring of OP(Ph) fragment resides at a corner of the cavity and thus prevents the movement of the three of the aryl rings. Only the remaining aryl ring can rotate through the cavity to give rise to the partial cone conformer in solution as the minor isomer.

3.3. Solid state structures of the calix "P–N–P" ligand, $Ph_2PN(CHMe_2)P(Ph)$\{1,3-dimethoxycalix[4]arene\} (2) and its palladium dichloride complex (3)

The structures of the *p-tert*-butyl-calix[4]arene diphosphazane ligand (**2**) and the corresponding palladium dichloride complex (**3**) have been determined by X-ray crystallography and are shown in Figs. 4 and 5, respectively. Selected bond lengths and bond angles for both the compounds are listed in Tables 2 and 3, respectively. The calix[4]arene framework in ligand **2** adopts the partial

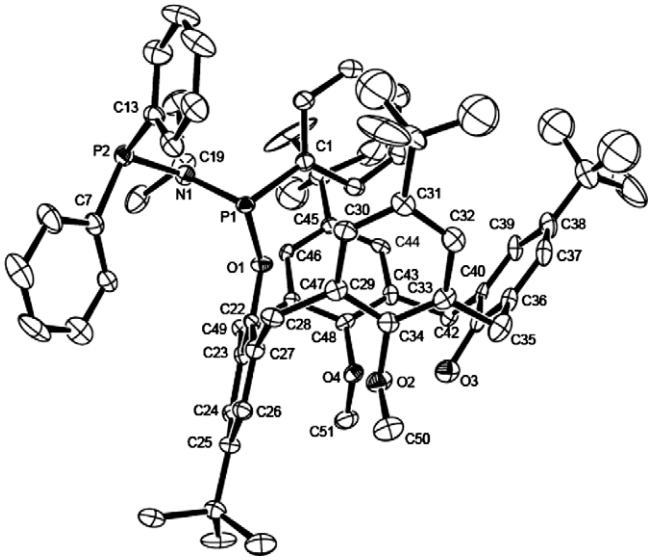

Fig. 4. ORTEP picture of ligand **2** showing the atom labeling scheme.

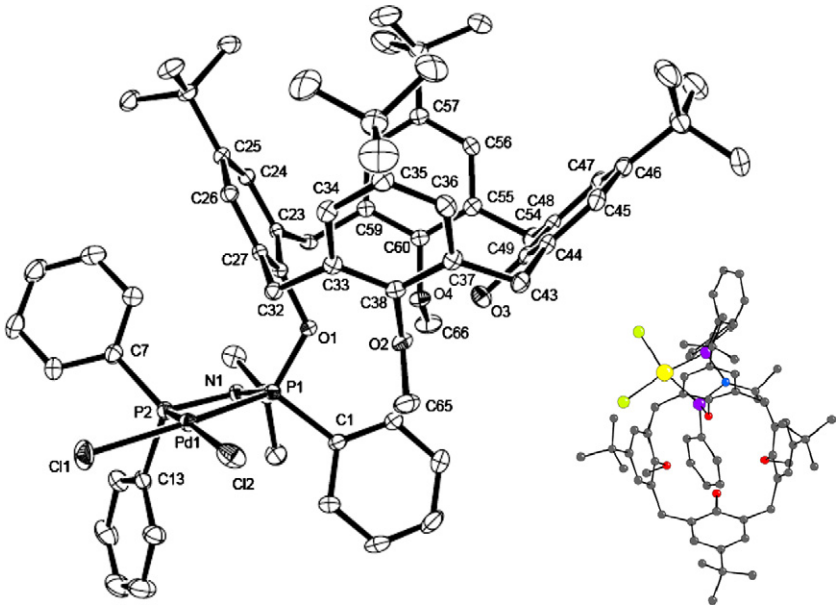

Fig. 5. ORTEP picture of complex **3** showing the atom labeling scheme (inset: view through the axis passing through the calix[4]arene cavity and perpendicular to the plane of the $-CH_2-$ carbon atoms).

cone conformation; in contrast, in the palladium dichloride complex **3**, the calixarene framework adopts the cone conformation. The two Pd–P bond lengths are different; Pd1–P1 bond is 0.02 A° longer than the Pd1–P2 bond. This difference may be attributed to the greater π-acceptor ability of P1 phosphorus atom owing to its attachment to the electronegative oxygen atom. This trend is also reflected in the Pd–Cl bonds; the Pd1–Cl1 (*trans* to the phosphorus atom which is bonded to oxygen) is shorter than Pd1–Cl2 bond.

The dihedral angles of the aryl rings, directly attached to the phosphorus atoms with respect to the P1–N1–P2 plane in **2** and **3** indicate a considerable change in the relative orientation of the aryl rings with respect to the P–N–P plane upon complexation. The P–N bond distances fall within the range of values reported for P–N–P ligands and their complexes. There is a considerable decrease (∼20°) in the P1–N1–P2 angle of the ligand upon chelate formation. The central nitrogen atom in both the ligand and the complex shows a trigonal planar geometry as observed for numerous other diphosphazanes and their complexes [1a,4,5,27].

The conformations of the calixarene framework in **2** and **3** can be defined by torsion angles or dihedral angles. The torsion angles are listed in Tables 4 and 5 for **2** and **3**, respectively. An examination of torsion angles shows the sequence of signs for ϕ and χ to be $+-$, $++$, $--$, $+-$ and $-+$, $-+$, $-+$, $-+$ for **2** and **3**, respectively, as expected for partial cone and cone conformations, respectively. For ligand **2**, four of the eight torsion angles differ significantly from the ideal cone torsion angles [$\phi = 90°$ and $\chi = 90°$]. These values indicate that one of the aryl rings of the calix[4]arene framework is oriented in the inverted direction in the molecule. A low value (40.8°) of the dihedral angle between the plane of the aryl ring (D) (which contains the OH group in the lower rim) and the methylene bridge plane (*X*) observed for complex (**3**) (Table 6) indicates considerable flattening of the ideal cone conformation and as a result, the conformation is intermediate between that of an ideal cone and a pinched cone [28].

Complex **3** crystallizes with a solvent (acetone) molecule trapped inside the cavity of the calix[4]arene framework.

Table 2
Selected bond distances (Å) for **2** and **3**

Distance	Ligand (**2**)	Complex (**3**)
O(1)–P(1)	1.665(5)	1.604(2)
P(1)–N(1)	1.704(7)	1.684(2)
P(2)–N(1)	1.705(7)	1.705(2)
P(1)–Pd(1)		2.225(1)
P(2)–Pd(1)		2.206(1)
Cl(1)–Pd(1)		2.343(1)
Cl(2)–Pd(1)		2.354(1)

Table 3
Selected bond angles (°) for **2** and **3**

Angle	Ligand (**2**)	Complex (**3**)
P(1)–N(1)–P(2)	119.1(4)	100.3(1)
O(1)–P(1)–N(1)	105.9(3)	108.6(1)
O(1)–P(1)–C(1)	93.4(3)	98.5(1)
N(1)–P(2)–C(7)	107.3(4)	111.0(1)
N(1)–P(2)–C(13)	104.5(4)	110.0(1)

Table 4
Torsion angles to define the conformation of calix[4]arene diphosphazane ligand (**2**)

Torsion angle	ϕ (°)	Torsion angle	χ (°)
C37–C36–C35–C33	90 (1)	C36–C35–C33–C32	−77 (1)
C30–C29–C28–C27	137.8 (8)	C29–C28–C27–C26	116.8 (8)
C24–C23–C49–C47	−119.3 (8)	C23–C49–C47–C46	−139.1 (7)
C44–C43–C42–C40	89.9 (9)	C43–C42–C40–C39	−94.4 (1)

Table 5
Torsion angles to define the conformation of palladium dichloride complex (**3**)

Torsion angle	ϕ (°)	Torsion angle	χ (°)
C58–C59–C70–C23	−74.5(4)	C59–C70–C23–C24	77.4(3)

C36–C37–C43–C44	−83.1(4)	C37–C43–C44–C45	105.2(4)
C47–C48–C54–C55	−103.2(4)	C48–C54–C55–C56	73.1(4)

Table 6
Dihedral angles between the planes[a] of the aryl rings of the calixarene framework and the mean plane (*X*) defined by methylene carbon atoms

Planes	Dihedral angles (°) [ligand (**2**)]	Dihedral angles (°) [complex (**3**)]
A–*X*	64.9(2)	62.5(1)
B–*X*	78.4(2)	65.7(1)
C–*X*	60.0(2)	72.0(1)
D–*X*	52.9(2)	40.8(1)

[a] *A*–*D* are the planes of aromatic rings defined by C29–C34, C22–C27, C43–C48 and C36–C41, respectively for **2** and C33–C38, C22–C27, C55–C60 and C44–C49, respectively for **3**.

The unit cell of complex **3** contains four molecules. The molecules are held together by C–H–O and C–H–Cl hydrogen bonds (see ESI, Fig. S6, Tables S2 and S3). The acetone molecule plays an important role in holding the molecules together.

3.4. Application of palladium dichloride complex (3) in catalytic Heck reaction

In recent years, Pd(II) complexes bearing multidentate ligands that contain significantly different types of hard (N, O) and soft (P) donor functions have been studied in catalytic Heck reaction [29,30]. In contrast, application of Pd(II) complexes of P–N–P ligands in Heck coupling reactions has not been studied. Palladium catalyzed Heck coupling reaction between styrene and aryl halides (X = Br, I) is investigated using the Pd(II) complex (**3**). Although the results show that complex **3** is able to catalyze the Heck reaction, the yield of the product (*trans* stilbene) is considerably less compared to most of the other Pd(II) catalysts known in literature [31,32] (see ESI for details of the catalytic studies).

3.5. Reactions with other palladium precursors

Reactivity of ligand **2** with other Pd(0) e.g. $[Pd(dba)_2]$ and Pd(II) e.g. $[Pd(\eta^3\text{-allyl})Cl]_2$ precursors has been investigated. The ^{31}P NMR spectra show definite evidence for the formation of complexes but none of the complexes could be isolated in a pure form (see ESI).

4. Conclusions

A "P–N–P" ligand containing a calix[4]arene backbone (which could be a forerunner to a new series of "calixphosphine" ligands) and its Pd dichloride complex have been synthesized. The partial cone conformation of the calixarene framework in the ligand changes to the cone conformation upon complexation to palladium as shown by X-ray crystallographic studies. Movement of the aryl rings of calix[4]arene fragment to generate different conformers in solution has been demonstrated by a two-dimensional NMR study. Preliminary investigations on the application of palladium dichloride complex in Heck coupling reaction have been carried out. In spite of the presence of bulky calix[4]arene framework, this diphosphazane ligand shows a tendency to form complexes when treated with Pd(II) and Pd(0) precursors. It would be interesting to investigate the coordination chemistry of this type of calix-diphosphazane ligands with various transition metals including catalytic applications of the complexes.

Scheme 1. Two different conformations of 1,2-bis(imidazol-1′-yl)ethane.

which two different conformations (*gauche* and *anti*) were included [14]. However, the control of different conformation of flexible ligands in the synthetic reactions is still a tremendous challenge to chemists owing to the influence of many subtle factors, such as solvent, pH value, metal ions and additional ligands.

1,2-Bis(imidazol-1′-yl)ethane (bime), an analogue to well-investigated 1,2-bis(4-pyridyl)ethane, also possesses *gauche* and *anti* conformations (Scheme 1) as a consequence of the free rotation of the ethyl group. However, the effect of its isomerism and manifestation on structures and properties remains to be less explored. To our knowledge, only one copper–bime complex was prepared, in which both of its isomers (*gauche*:*anti* = 1:1.5) were observed [15]. As a part of our ongoing research about the effect of neutral, electron-donating and electron-withdrawing groups in dicarboxylate ligands on structures and properties of metal–organic compounds [16], herein, we wish to report the syntheses, crystal structures and characterizations of four-coordination polymers $\{[Zn(gauche\text{-bime})(bdc)]\cdot 0.5H_2O\}_n$ (**1**), $\{[Zn(anti\text{-bime})(HO\text{-bdc})]\cdot 2.5H_2O\}_n$ (**2**), $[Cu(gauche\text{-bime})_{0.5}(anti\text{-bime})_{0.5}(O_2N\text{-bdc})]_n$ (**4**) and $[Ni_2(gauche\text{-bime})(anti\text{-bime})(O_2N\text{-bdc})_2(H_2O)_2]_n$ (**5**) (H_2bdc = *m*-isophthalic acid, HO-H_2bdc = 5-hydroxyisophthalic acid, O_2N-H_2bdc = 5-nitroisophthalic acid), in which the conformational isomerisms of bime are heavily influenced by the coexistent groups of dicarboxylate ligands and used metal ions. At the same time, previously reported $\{[Zn(anti\text{-bime})(O_2N\text{-bdc})]\cdot H_2O\}_n$ (**3**) [17] as a comparable substance in the research system was also mentioned.

2. Experimental

2.1. Materials and general methods

All the reagents were commercially available and used as purchased except that 1,2-bis(imidazol-1′-yl)ethane was synthesized by the literature method [15]. Thermogravimetric experiments were performed using a TGA/SDTA851 instrument (heating rate of 10 °C/min, air stream). IR spectra as KBr pellets were recorded on a Magna 750 FT-IR spectrophotometer. Elemental analyses of C, H, and N were determined using a Perkin–Elmer 240C elemental analyzer. X-ray powder diffraction measurements were recorded on RIGAKU DMAX2500PC diffractometer using Cu Kα radiation.

2.2. Synthesis of $\{[Zn(gauche\text{-bime})(bdc)]\cdot 0.5H_2O\}_n$ (*1*)

A mixture of $Zn(NO_3)_2\cdot 6H_2O$ (0.074 g, 0.25 mmol), 1,2-bis(imidazol-1′-yl)ethane (0.040 g, 0.25 mmol), H_2bdc (0.042 g, 0.25 mmol) and KOH (0.028 g, 0.50 mmol) was dissolved in CH_3OH (8 mL) and H_2O (10 mL). The mixture was transferred to a 25 mL stainless-steel reactor with Teflon liner and heated to 160 °C automatically. The temperature was kept at 160 °C for 4 days and cooled to room temperature during 24 h. Colorless block crystals of **1** were obtained (yield: 0.042 g, 42%, based on Zn). Elemental *Anal*. Calc. for $C_{16}H_{15}ZnN_4O_{4.5}$ (400.69): C, 47.96; H, 3.77; N, 13.98. Found: C, 47.91; H, 3.65; N, 14.02%. IR (KBr, cm^{-1}): 3427 (bs), 1622 (vs), 1347 (vs), 1236 (m), 1104 (m), 1227 (w), 835 (m), 746 (s), 652 (m), 567 (w).

2.3. Synthesis of $\{[Zn(anti\text{-bime})(HO\text{-bdc})]\cdot 2.5H_2O\}_n$ (*2*)

The process was similar to the synthesis of **1** except that H_2bdc was replaced by HO-H_2bdc (0.045 g, 0.25 mmol). Colorless block crystals of **2** were obtained (yield: 0.041 mg, 36% based on Zn). Elemental *Anal*. Calc. for $C_{16}H_{19}ZnN_4O_{7.5}$ (452.72): C, 42.45; H, 4.23; N, 12.38. Found: C, 42.39; H, 4.17; N, 12.42%. IR (KBr, cm^{-1}): 3462 (bs), 1622 (vs), 1349 (vs), 1244 (m), 1100 (m), 956 (w), 777 (s), 726 (s), 652 (m), 629 (w).

2.4. Synthesis of $[Cu(gauche\text{-bime})_{0.5}(anti\text{-bime})_{0.5}(O_2N\text{-bdc})]_n$ (*4*)

The process was similar to the synthesis of **1** except that H_2bdc and $Zn(NO_3)_2\cdot 6H_2O$ were replaced by O_2N-H_2bdc (0.053 g, 0.25 mmol) and $Cu(NO_3)_2\cdot 3H_2O$ (0.060 g, 0.25 mmol), respectively. Blue prism crystals of **4** were obtained (yield: 0.031 g, 29% based on Cu). Elemental *Anal*. Calc. for $C_{16}H_{13}CuN_5O_6$ (434.85): C, 44.19; H, 3.01; N, 16.10. Found: C, 44.21; H, 3.05; N, 16.08%. IR (KBr, cm^{-1}): 1614 (vs), 1594 (s), 1344 (vs), 1276 (m), 1100 (m), 843 (w), 726 (s), 703 (s), 653 (m), 551 (w).

2.5. Synthesis of $[Ni_2(gauche\text{-bime})(anti\text{-bime})(O_2N\text{-bdc})_2(H_2O)_2]_n$ (*5*)

The process was similar to the synthesis of **1** except that H_2bdc and $Zn(NO_3)_2\cdot 6H_2O$ were replaced by O_2N-H_2bdc (0.053 g, 0.25 mmol) and $Ni(NO_3)_2\cdot 6H_2O$ (0.075 g, 0.25 mmol), respectively. Green prism crystals of **5** were obtained (yield: 0.037 g, 33% based on Ni). Elemental *Anal*. Calc. for $C_{32}H_{30}Ni_2N_{10}O_{14}$ (896.08): C, 42.89; H, 3.37; N, 15.63. Found: C, 42.92; H, 3.25; N, 15.66%. IR (KBr, cm^{-1}): 3412 (bs), 1614 (vs), 1528 (vs), 1376 (vs), 1341 (vs), 1287 (w), 1084 (m), 995 (w), 777 (s), 723 (s), 653 (m), 524 (w).

2.6. Crystal structure determinations

Measurements of **1**, **4** and **5** were conducted on a Rigaku Mercury CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at low temperature (−100 °C) [18]. Intensity data for **2** were measured on a Siemens Smart CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature, the empirical absorption corrections were applied by using the SADABS program [19]. All of the four structures were solved by direct methods with the SHELX-97 programs [20] and refined on F^2 by full-matrix least-squares using the SHELXL-97 program package [21]. The positions of H atoms were generated geometrically (C–H bond fixed at 0.96 Å), assigned isotropic thermal parameters, and allowed to ride on their parent carbon atoms before the final cycle of refinement. Crystal data and structure determination summaries for **1**, **2**, **4** and **5** are listed in Table 1. The selected bond lengths and angles for the four complexes are listed in Table 2.

3. Results and discussion

3.1. Syntheses

Similar to neutral N-donor dipyridyl ligands, bime is a promising ligand towards the syntheses of extended structural frameworks owing to its simple bridging mode and strong coordination ability to transition metal ions. Usually, assembly of this ligand with metal ions requires the presence of counterions to balance the charge [22]. Deprotonated di- or polycarboxylate ligands are another excellent candidates for the preparation of coordination networks owing to the rich coordination modes of carboxylate groups [23], they can serve as anions and balance charge by themselves. The combination of the foregoing two types of ligands not only can simplify the effect of counterions on the final products, but also can produce compounds with intriguing structures and useful properties.

Our research aims at synthesizing desired coordination polymers *via* combining bime, isophthalic acid or its derivatives (Scheme 2) and metal ions, and at further studying the influence of coexistent groups of carboxylate group and different metal ions on the isomerisms of bime. The presence of the electron-donating (–OH, –Me) and electron-withdrawing (–NO_2) uncoordination groups in dicarboxylate ligands changes their electronic property and steric hindrance, which can generate complexes different from those from the common dicarboxylate ligands [24]. The solvothermal reaction of bime and H_2bdc with $Zn(NO_3)_2 \cdot 6H_2O$ gave rise to **1**, in which only *gauche*-bime was observed. While H_2bdc replaced by HO-H_2bdc bearing electron-donating group and O_2N-H_2bdc bearing

Symmetry codes for **1**: A $x-1$, y, z; B $-x+2$, $-y$, $-z+1$. For **2**: A $x-1$, y, z; B $-x$, $y-1/2$, $-z+1/2$. For **4**: A x, $-y+1/2$, $-z-1/2$, B x, y, $z+1$; **5** A x, $y+1$, z, B $-x-1/2$, $y+1/2$, $z-1/2$.

electron-withdrawing group, respectively, **2** and **3** were generated, in which only *anti*-bime were exhibited. As compared with **3**, when using $Cu(NO_3)_2\cdot 3H_2O$ and $Ni(NO_3)_2\cdot 6H_2O$ instead of $Zn(NO_3)_2\cdot 6H_2O$, **4** and **5** were generated, respectively, where both *gauche*- and *anti*-conformations (1:1) of bime were displayed. This may indicate that the coordination geometries of different metal ions are also critical factors in the control of different conformation of bime ligand.

R = -OH, 5-hydroxylisophthalic acid

R = -NO_2, 5-nitroisophthalic acid

Scheme 2.

3.2. Description of crystal structures

3.2.1. $\{[Zn(gauche\text{-}bime)(bdc)]\cdot 0.5H_2O\}_n$ (**1**)

Single-crystal X-ray diffraction analysis reveals that **1** is a 1D linear coordination polymer containing only *gauche* isomer of bime. As shown in Fig. 1, each Zn^{II} center is coordinated by two oxygen atoms and two nitrogen atoms from different bdc and bime ligands, respectively, in a distorted tetrahedral geometry. The bond angles range from 98.41(9)° to 118.26(8)°, and the average bond lengths of Zn–O and Zn–N are 1.9596(19) and 2.003(2) Å, respectively. The deprotonated bdc serves as [a] bridge through its bis-monodentate carboxylate groups. The bime ligand adopts *gauche*-conformation to connect two zinc(II) centers, and the dihedral angle between two imidazolyl rings is 50.5°. Therefore, two bime link two zinc(II) centers to generate a –Zn–bime–Zn–bime– closed circuit, and the bis-monodentate bdc further extend the closed circuits into a 1D bamboo-like chain, in which the distances of adjoining zinc(II) centers separated by bime and bdc are 6.244 and 9.611 Å, respectively (Fig. 2). The crystal packing

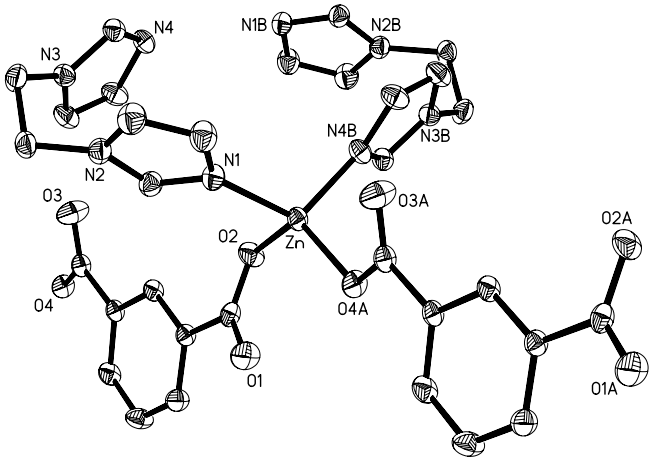

Fig. 1. The coordination geometry of Zn^{II} in **1** with the thermal ellipsoids at 30% probability level, free water molecule and hydrogen atoms were omitted for clarity.

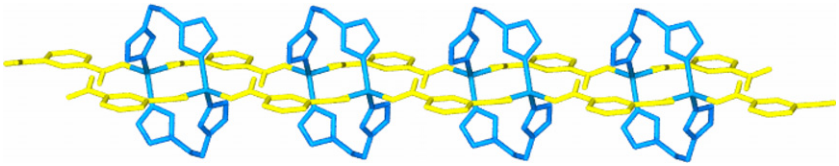

Fig. 2. View of the 1D bamboo-like chain, in which the –Zn–bime–Zn–bime– closed circuits are exhibited.

diagram for **1** is shown in Fig. 3, which reveals that there are free water molecules situated in the crystal lattice.

*3.2.2. $\{[Zn(anti\text{-}bime)(HO\text{-}bdc)]\cdot 2.5H_2O\}_n$ (**2**)*

When HO-H_2bdc replaced H_2bdc under the same condition, **2** was successfully isolated. Different from the 1D linear structure of **1**, **2** is a 3D supramolecular architecture in which only *anti* isomer of bime is included. The asymmetric unit consists of one Zn^{II}, one HO-bdc, one bime and two and half free water molecules (Fig. 4). Similar to that in **1**, each Zn^{II} center is in a distorted tetrahedral geometry, determined by two oxygen atoms and two nitrogen atoms from the carboxylate groups of different HO-bdc and bime ligands with the average bond lengths of Zn–O and Zn–N being 1.997(4) and 1.992(5) Å, respectively. Each HO-bdc ligand bridges two Zn^{II} centers through its bis-monodentate carboxylate groups, the hydroxyl group (–OH) is involved in hydrogen bonding interactions with another adjacent hydroxyl group [O5–H···O5A^{i} 2.840 Å, (i) $-x+1, -y, -z+2$], although it does not take part in coordination. Different from that found in **1**, bime adopts only *anti*-conformation to coordinate to two zinc centers. The two imidazolyl rings are almost coplanar with the dihedral angle between them being 163.0°. Thereby, the bis-monodentated HO-bdc and the *anti*-conformational bime connect Zn^{II} centers into a 2D (4,4) network with cavities of 10.246×11.358 Å^2 determined by adjoining Zn···Zn distances separated by HO-bdc and bime, respectively (Fig. 5). In order to minimize the void cavities and stabilize the whole framework, the crystal packing adopts ABAB mode, and the abundant hydrogen bonding interactions between free water molecules and carboxylate groups, free water molecules and free water molecules as well as the above-mentioned the hydroxyl groups and the hydroxyl groups, connect the 2D layer into a 3D supramolecular architecture [OW1–H···O2^{ii} 2.798 Å; OW2–H···O3^{iii} 2.790 Å; OW1–H···OW3 2.699 Å; OW2–H···OW3

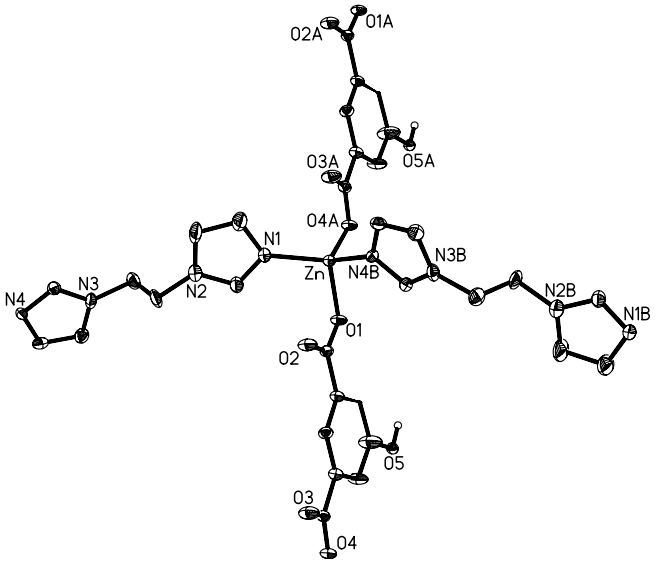

Fig. 4. The coordination geometry of Zn^{II} in **2** with the thermal ellipsoids at 30% probability level, free water molecules and hydrogen atoms were omitted for clarity.

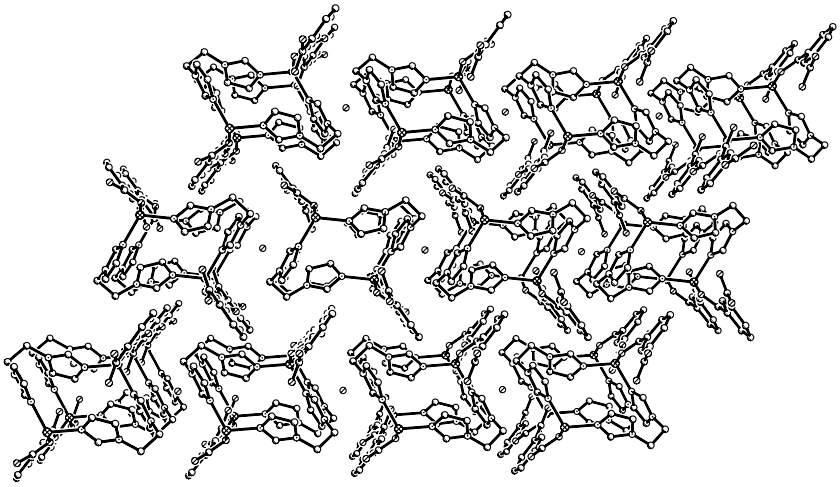

Fig. 3. View of the packing diagram of **1** along *c*-axis.

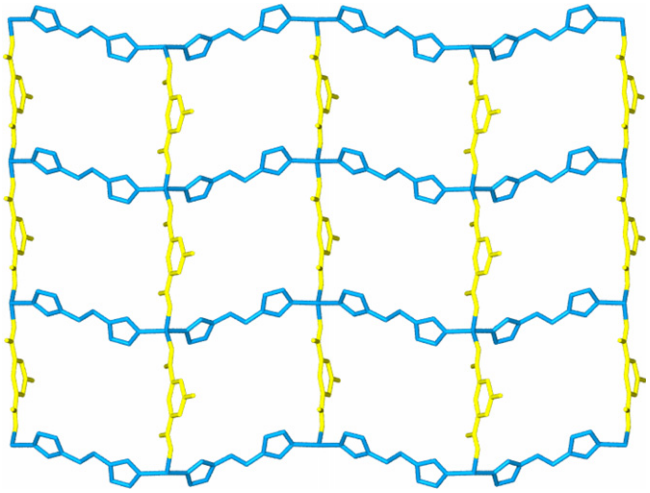

Fig. 5. View of the 2D (4,4) network.

2.690 Å; symmetry codes: (ii) $x, -y + 1/2, -z + 1$; (iii) $x, y, z + 1$] (Fig. 6). Compared to **1**, it is notable that the electron-donating hydroxyl group in the dicardoxylate ligand plays an important role in the change of the conformational isomerism of bime in **2**.

3.2.3. $\{[Zn(bime)(O_2N\text{-}bdc)] \cdot H_2O\}_n$ (**3**)

When selected bime, O_2N-H_2bdc and $Zn(NO_3)_2 \cdot 6H_2O$ as starting materials, **3** was generated. As previously reported, **3** is a tetrahedrally four-connected $6.6.6.6.6_2.8_3$ topological network. Similar to that in **2**, the Zn^{II} center is in a distorted tetrahedral geometry and the bime ligand also behaves in *anti*-conformation to link zinc^{II} centers (see Fig. S1). The Zn···Zn distance across bime is 11.762 Å, slightly longer than that in **2**. Based on **3**, different metal ions possessing different coordination geometries were induced into the reaction system in order to further study the conformation preference of bime. Therefore, the following **4** and **5** were generated from the solvothermal reactions of bime and O_2N-H_2bdc with $Cu(NO_3)_2 \cdot 3H_2O$ and $Ni(NO_3)_2 \cdot 6H_2O$, respectively, in which both *gauche*- and *anti*-conformations (1:1) of bime were exhibited.

3.2.4. $[Cu(gauche\text{-}bime)_{0.5}(anti\text{-}bime)_{0.5}(O_2N\text{-}bdc)]_n$ (**4**)

Compound **4** is a 2D wave-like layer consisting of dinuclear units, in which both *gauche*- and *anti*-conformations of bime are observed. There is only one unique Cu^{II} center in **4**, its coordination environment is shown in Fig. 7. Cu^{II} is surrounded by five atoms in a distorted trigonal bipyramidal coordination geometry. The equatorial plane is determined by three carboxylate oxygen atoms from different O_2N-bdc with the bond angles ranging from 92.59(6)° to 161.06(7)°, while the axial positions are occupied by two nitrogen atoms from different bime with the N1–Cu–N3 bond angle and the average Cu–N bond length being 173.26(9)° and 1.982 (2) Å, respectively. Each O_2N-bdc

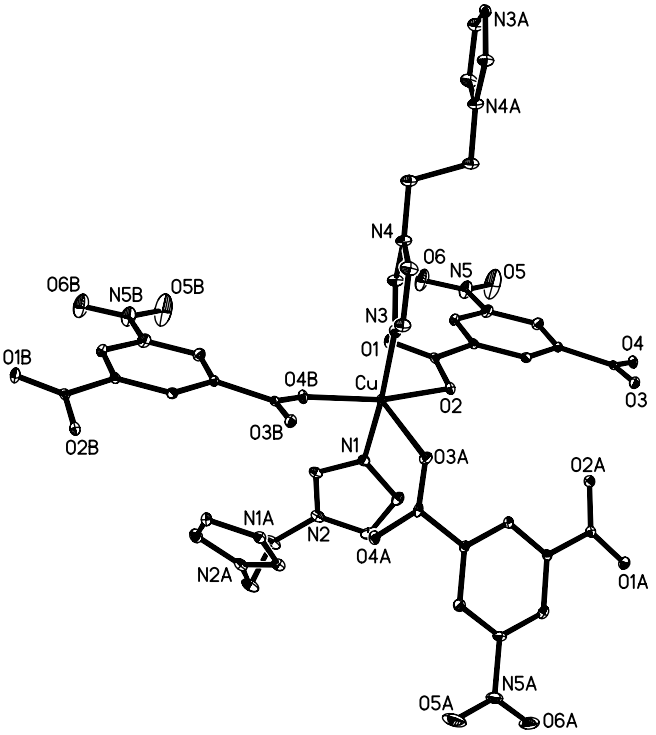

Fig. 7. The coordination geometry of Cu^{II} in **4** with the thermal ellipsoids at 30% probability level, hydrogen atoms were omitted for clarity.

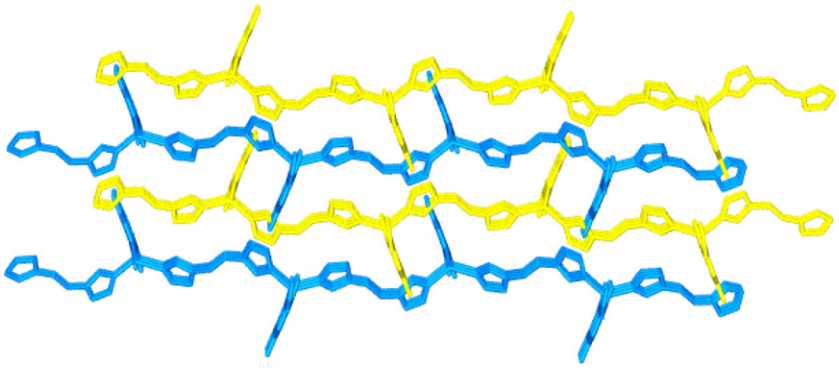

Fig. 6. View of the 3D supramolecular architecture of **2** along *a*-axis.

behaves as a μ_3-bridge linking three Cu^{II} centers through one monodentate carboxylate and one μ_2,η^2-carboxylate groups into a 1D double-chain, in which dinuclear units are exhibited (Fig. 8), the nitro group ($-NO_2$) neither takes part in coordination nor involves in hydrogen bonding interaction. Interestingly, there are two kinds of bime: one adopts *gauche*-conformation and acts as a bridge between two Cu^{II} centers in the dinuclear unit; while the other adopts *anti*-conformation to extend the 1D double-chain into a 2D wave-like layer (Fig. 9). The ratio of bime conformation is 1:1, which is different from that found in another copper–bime complex [7]. With respect to the *gauche*-bime, the dihedral angle between two imidazolyl rings is 30.9°, smaller than that in **1**, and the Cu···Cu distance across it is 4.445 Å. The two imidazolyl rings in *anti*-bime are almost coplanar with the dihedral angle between them being 180.0°, and the adjoining Cu···Cu distance separated by it is 11.543 Å. The packing diagram displays that no guest molecules and weak interactions are included between layers, although there are large void spaces in the wave-like layer (Fig. S2).

3.2.5. $[Ni_2(gauche\text{-}bime)(anti\text{-}bime)(O_2N\text{-}bdc)_2(H_2O)_2]_n$ (**5**)

Compound **5** is also a 2D wave-like layer including both *gauche*- and *anti*-conformations of bime, but the bridging fashion of O_2N-bdc and coordination environments of metal centers are different from those in **4**. The coordination environments of Ni^{II} centers are shown in Fig. 10. Both Ni^{II} ions adopt distorted octahedral coordination geometries, in which two nitrogen atoms from different bime stand at the apical positions, and three carboxylate oxygen atoms and one water molecule consist of the equatorial plane. Firstly, the O_2N-bdc acts as a bridge linking adjoining Ni^{II} centers to give rise to a 1D chain through its monodentate and chelating carboxylate groups, the nitro group ($-NO_2$) neither participates in coordination nor involves in hydrogen bonding interaction (Fig. 11). Secondly, the 1D chain is extended by two kinds of bridging bime to generate a 2D wave-like layer, in which the intramolecular hydrogen bonding interaction between coordinated water molecule and carboxylate group further stabilize the framework (Fig. 12 and Fig. S3). Similar to

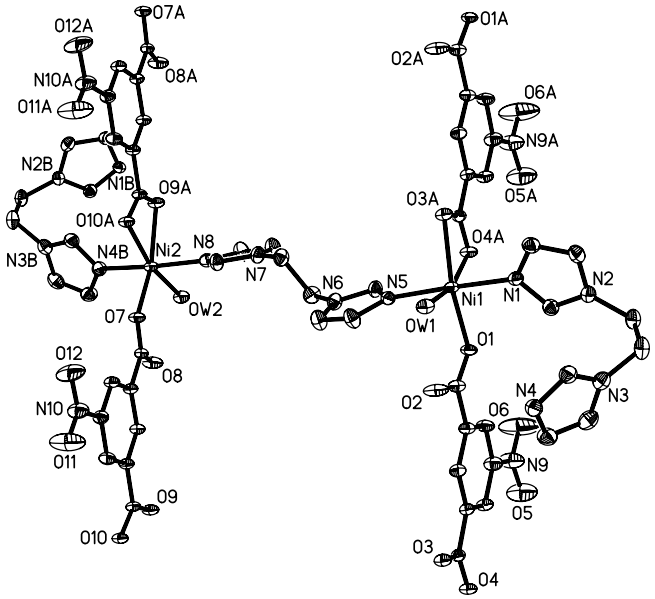

Fig. 10. The coordination geometries of Ni^{II} ions in **5** with the thermal ellipsoids at 30% probability level, hydrogen atoms were omitted for clarity.

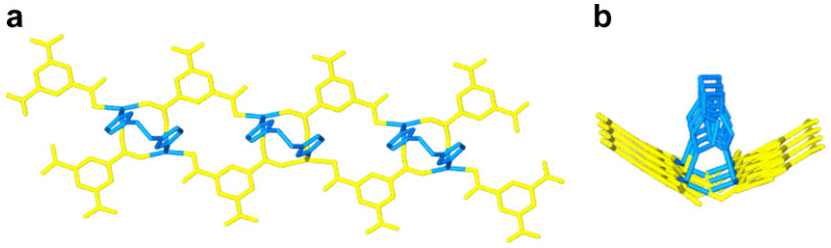

Fig. 8. View of the 1D double chain along different directions, (a) for *a*-axis, (b) for *c*-axis, in which the dinuclear units are exhibited.

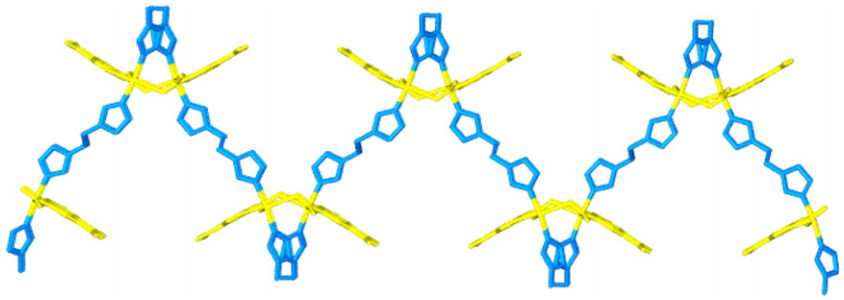

Fig. 9. View of the 2D wave-like layer.

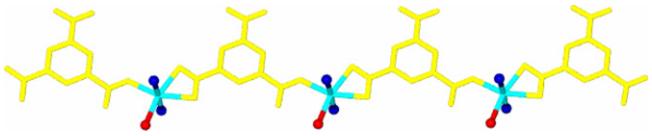

Fig. 11. View of the 1D chain.

those found in **4**, both *gauche*- and *anti*-isomers of bime are observed in **5**, and the ratio of the different conformations is also 1:1. The dihedral angle between two imidazolyl rings in *gauche*-bime is 50.6°, almost equivalent to that in **1** but larger than that in **4**, while the two imidazolyl rings in *anti*-bime is approximately coplanar with the dihedral angle being 166.3°. The neighboring Ni···Ni distances separated by *gauche*- and *anti*-bime are 5.873 and 11.715 Å, respectively.

3.3. Infrared spectroscopy

The IR spectrum of **1** shows a strong and broad peak at 3427 cm^{-1}, which indicates the presence of water molecules. The strong peaks at 1622 cm^{-1} and 1347 cm^{-1} are attributed to the asymmetric and symmetric vibrations of carboxylate groups, respectively. For **2**, similar to that in **1**, the strong and broad peak at 3462 cm^{-1} suggests the existence of water molecules, the characteristic bands of carboxylate groups are shown at 1622 cm^{-1} for asymmetric stretching vibration and 1349 cm^{-1} for symmetric stretching vibration. The similar splitting of **1** and **2** reveals the similar bis-monodentate coordination fashion of dicarboxylate ligands. For **4**, the characteristic bands of asymmetric and symmetric stretching vibrations of carboxylate groups are shown at 1614 cm^{-1}, 1594 cm^{-1} and 1344 cm^{-1}, respectively. For **5**, the strong and broad peak at 3412 cm^{-1} suggests the presence of hydrogen bonding interactions. The strong peaks at 1614 cm^{-1}, 1528 cm^{-1} and 1376 cm^{-1}, 1341 cm^{-1} are attributed to the asymmetric and symmetric stretching vibrations of carboxylate groups, respectively.

3.4. Thermogravimetric analyses

The thermal stability of the four complexes was determined by thermogravimetric analysis (TGA) on polycrystalline samples in an air atmosphere (Figs. S4–S7). For **1**, the first weight loss of 1.98% from 45 to 130 °C is equivalent to the loss of half free water molecule [$0.5H_2O$/[Zn(*gauche*-bime)(bdc)] · $0.5H_2O$, calculated: 2.25%]. The second weight loss of 77.18% from 386 to 582 °C, corresponds to the decomposition of **1**. The residual weight of 20.40% is ascribed to ZnO (ZnO/[Zn(*gauche*-bime)(bdc)] · $0.5(H_2O)$, calculated 20.31%). Similar to **1**, the TGA curve of **2** also shows two significant weight losses: 9.76% between 49 and 120 °C, and 71.98% between 365 and 552 °C. The former can be ascribed to the loss of two and half free water molecules ($2.5H_2O$/[Zn(*anti*-bime)(HO-bdc)] · $2.5H_2O$, calculated 9.94%), while the latter suggests the chemical decomposition of **2**. The residue composition is attributed to ZnO (ZnO/[Zn(*anti*-bime)(HO-bdc)] · $2.5H_2O$, calculated 17.97%, found 18.26%). For **4**, the TGA curve exhibits only one weight loss (80.91% from 281 to 520 °C), which indicates the decomposition of **4**. The residual weight of 19.09% corresponds to CuO (CuO/Cu(*gauche*-bime)$_{0.5}$(*anti*-bime)$_{0.5}$-(O_2N-bdc), calculated 18.29%). For **5**, the TGA curve displays two weight losses: one (3.96% from 124 to 162 °C) corresponds to the loss of coordinated water molecule ($2H_2O$/Ni_2(*gauche*-bime)(*anti*-bime)(O_2N-bdc)$_2$(H_2O)$_2$, calculated 4.02%); the other (78.96% from 396 to 538 °C) indicates the decomposition of **5**. The residue is attributed to NiO (2NiO/Ni_2(*gauche*-bime)(*anti*-bime)(O_2N-bdc)$_2$-(H_2O)$_2$, calculated 16.67%, found 17.08%).

3.5. X-ray powder diffraction

The original samples of the four complexes were also characterized by X-ray powder diffraction (XRPD) at room temperature (Figs. S8–S11). The experimental patterns are in good agreement with the theoretical ones generated from the single-crystal X-ray data of the complexes, which clearly indicate the good purity of the four complexes.

4. Conclusions

The solvothermal reactions of *m*-isophthalic acid or its derivatives bearing electron-donating and electron-withdrawing coexistent groups, bime and different metal ions generated five novel coordination polymers, in which bime adopt *gauche* (**1**), *anti* (**2** and **3**) and mixed conformations of *gauche* and *anti* (1:1) (**4** and **5**), respectively. This

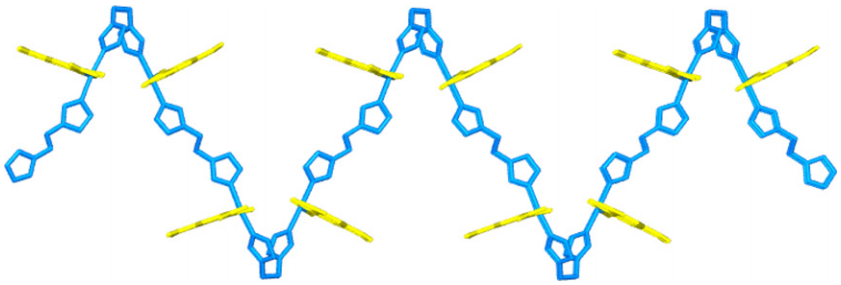

Fig. 12. View of the 2D wave-like layer.

research reveals that (i) the electron-donating and electron-withdrawing coexistent groups in dicarboxylate ligands are not involved in coordination, but they have important effect on the conformational preference of bime; (ii) the coordination geometries of different metal ions also play critical roles on the conformational preference of bime; and (iii) the conformational isomerisms of bime make it a good candidate to the construction of supramolecular networks.

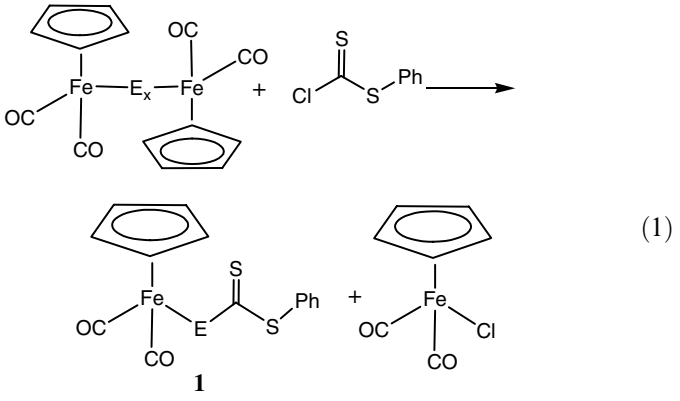
dithiocarbonato ligand [14]. Treatment of the latter complexes with phosphine or phosphite ligands gave the mixed carbonyl-phosphine or phosphite complexes Cp′Fe(CO)-(L)(κ*S*-S_2COEt) (L = PBu_3, PPh_3, $P(OEt)_3$, $P(OPh)_3$) [14].



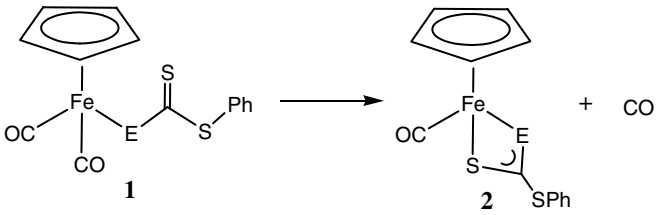
The trithiocarbonato complexes $CpFe(CO)_2$(κ*S*-SCS_2R) have been made by substitution of the iodide ligand of $CpFe(CO)_2I$ by the trithiocarbonate anions $RSCS_2^-$ (R = Me, Et, Ph) [15]. The chelated forms, CpFe(CO)-(κ^2*S*,*S*-S_2CSR) were obtained by photolysis of the dicarbonyl analogs [15].

In continuation of our work on the area of organoiron complexes containing thio- and selocarbonate ligands, this paper describes the syntheses and X-ray structures of iron trithiocarbonate and selenodithiocarbonate complexes.

2. Results and discussion

2.1. Synthesis and characterization

The trithio- and the dithioselenocarbonate complexes are obtained in good yields by the reactions of the iron chalcogenide complexes (μ-E_x)[$CpFe(CO)_2]_2$ (E = S; *x* = 2, 3. E = Se; *x* = 1) with PhSC(S)Cl, as shown in Eq. (1).



(1)

E= S (**a**), Se (**b**).

The orange complex **1a** and the brown complex **1b** are air stable as solids and in solution. They are soluble in common polar organic solvents but insoluble in hydrocarbons. The identities of **1** and **2** have been confirmed by IR, ^{1}H NMR spectroscopy, elemental analysis and crystal structure determination. The ^{1}H NMR spectra of **1** reveal one singlet in the range of 5.06–5.11 ppm for the Cp-proton resonances. These chemical shifts fall within the typical range reported for analogous thiocarbonato and selenocarbonato complexes of iron [8–11]. The protons of the phenyl group appear as two multiplets in the ratio of 3:2, as expected. The bands at 2050 and 2002 cm^{-1} in the IR spectrum of **1a** are due to *ν*(CO) of the two terminal carbonyl groups. For **1b**, these bands are found at lower wavenumbers (2040, 1990 cm^{-1}) due to stronger *σ*-donor and/or weaker π-acceptor properties of the selenodithiocarbonate ligand compared to the trithiocarbonate ligand. A similar shift for simple thiocarboxylato versus selenocarboxylato complexes has been reported [2–5].

Photolyzing THF solutions of complexes **1** in the absence of added ligand produces the chelate complexes CpFe(CO)(κ^2*E*,*S*-ECS_2Ph) (**2**) as shown in Eq. (2). The trithiocarbonate ligand of **2a** is bonded to the metal through the two sulfur atoms. In a similar fashion, the dithioselenocarbonate ligand of **2b** is bonded through the selenium and sulfur atoms. These dark red complexes are soluble in most organic solvents, including hydrocarbons.

E= S (**a**), Se (**b**).

(2)

Complexes **2** have been characterized by IR, ^{1}H NMR, as well as elemental analysis. The IR spectra of **2** in CH_2Cl_2 show the characteristic *ν*CO absorption in the range of 1947–1954 cm^{-1}. This absorption is similar to those of CpFe(CO)(κ^2*S*,*E*-EC(S)OR) (1941–1957 cm^{-1}) [10,11] and are lower than those of the starting complexes **1**. The latter difference might be attributed to the weak π-acid character of the chelate trithio- or selenodithio-carbonate ligand compared to that of carbonyl ligand. Complexes **2** exhibit ^{1}H NMR spectra showing a singlet in the range of 4.65–4.66 ppm for the Cp-protons. This chemical shift range is lower than that for the corresponding Cp resonances in complexes **1** and is similar to the analogous range reported for CpFe(CO)(κ^{2}S,E-EC(S)OR) complexes (4.63–4.69 ppm) [10,11].

2.2. Crystal structures

The structures of complexes **1a** and **1b** are shown in Figs. 1 and 2, respectively. Selected bond distances and angles for these complexes are collected in Table 1. These complexes display a three-legged piano-stool configuration at Fe. The Fe–C(Cp) and Fe–C(CO) bond lengths in **1a** and **1b** are similar to those found in $CpFe(CO)_2$-containing complexes [5,8–10]. The Fe–S bond distance of 2.2677(4) Å in **1a** is comparable to that found in $CpFe(CO)_2SX$ complexes [$X = SO_2CCl_3$ (2.2803(13) Å), CO_2Et (2.2675(10) Å), CO-2-$C_6H_4NO_2$ (2.266(1) Å), C(S)O–C_6H_4Cl (2.2765(5) Å)] [5,8,16,17]. The Fe–Se bond distance in **1b** of 2.3839(4) Å is also comparable to that found in $CpFe(CO)_2SeY$ complexes [$Y = SO_2Ph$ (2.394(3) Å), CO_2Et (2.3829(8) Å), C(S)O-4-C_6H_4Cl (2.3985(2) Å)] [7,10,18].

The crystal structure of **2b** is presented in Fig. 3. Selected bond distances and angles of **2b** are listed in Table 1. The Fe–Se bond distance in **2b** is 2.3872(18) Å, which is similar to that of **1b.** The Fe–S bond length in **2b** of 2.310(2) Å is longer than that of **1a**. The Fe–CO bond length of **2b** (1.732(14) Å) is shorter than the corresponding lengths observed for **1a** and **1b** in line with higher π-back donation from the Fe-*d* orbitals to the empty π*-orbital of CO in **2b** compared to those of **1a** and **1b**.

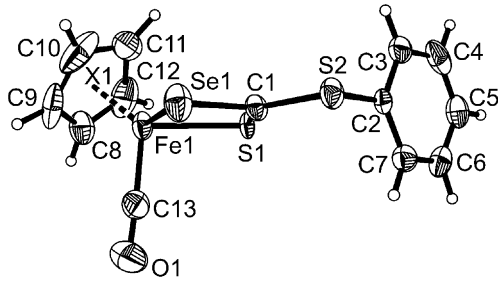

Fig. 3. An ORTEP representation of the structure of $CpFe(CO)(\kappa^2 Se,S\text{-}SeCS_2Ph)$ (**2b**). The thermal ellipsoids are drawn at the 30% probability level.

3. Experimental

3.1. General

All manipulations were performed using standard Schlenk and inert-atmosphere techniques under an argon atmosphere. Diethyl ether, hexane, and benzene were dried over sodium and benzophenone, and were freshly-distilled under nitrogen prior to use. Dichloromethane was heated under reflux over P_2O_5, and was freshly-distilled under nitrogen prior to use. The compounds $(\mu\text{-}S_x)[CpFe(CO)_2]_2$ [1] and $(\mu\text{-Se})[CpFe(CO)_2]_2$ [2] were prepared by previously published procedures. The iron dimer $[CpFe(CO)_2]_2$, the PhSC(S)Cl precursor, selenium, and sulfur were purchased from Aldrich and were used as received.

Nuclear magnetic resonance (NMR) spectra were recorded on a Bruker 400 MHz spectrometer. Chemical shifts are given in ppm relative to TMS at 0 ppm. Infrared (IR) spectra were recorded on a Nicolat-Impact 410 FT-IR spectrometer. Elemental analyses of C, H and S were performed in the Institute of Organic Chemistry, Vienna University, Austria. Melting points were reported on an electrothermal melting point apparatus and are uncorrected. The photolytic reactions were carried out using a conventional tungsten lamp (100 W).

3.2. General procedure for the preparation of $CpFe(CO)_2(\kappa E\text{-}ECS_2Ph)$ (**1**)

A solution of PhSC(S)Cl (1.20 mmol) in 10.0 mL of diethyl ether was dropwise added to a solution of the iron chalcogenides $(\mu\text{-}E_x)[CpFe(CO)_2]_2$ (1.00 mmol) in 50.0 mL of diethyl ether. The deep red solution was stirred for 2 h under protection of light. The solution was stripped to dryness and the resulting solid was redissolved in a minimum amount of dichloromethane and introduced to a silica gel column made up in hexane. Elution with hexane removes the unreacted PhSC(S)Cl. A red band of the product was eluted with diethyl ether:hexane solution (1:1 v:v ratio), followed by another red band which was also collected and identified as $CpFe(CO)_2Cl$. The products $CpFe(CO)_2(\kappa E\text{-}ECS_2Ph)$ were recrystallized from dichloromethane/hexane.

3.2.1. $CpFe(CO)_2(\kappa S\text{-}SCS_2Ph)$ (**1a**)

Yield: 85%. m.p. = 57–59 °C. IR (CH_2Cl_2, cm^{-1}): 2044(s), 1999(s) ($\nu_{C\equiv O}$). ^1H NMR ($CDCl_3$): δ 5.11 (s, 5H, C_5H_5); 7.45 (m, 3H, C_6H_5); 7.55 (m, 2H, C_6H_5). *Anal.* Calc. for $C_{14}H_{10}FeO_2S_3$: C, 46.42; H, 2.78; S, 26.55. Found: C, 46.31; H, 2.62; S, 26.80%.

3.2.2. $CpFe(CO)_2(\kappa Se\text{-}SeCS_2Ph)$ (**1b**)

Yield: 83%. m.p. = 130–131 °C. IR (CH_2Cl_2, cm^{-1}): 2038(s), 1993(s) ($\nu_{C\equiv O}$). ^1H NMR ($CDCl_3$): δ 5.14 (s, 5H, C_5H_5); 7.48 (m, 3H, C_6H_5); 7.56 (m, 2H, C_6H_5). *Anal.* Calc. for $C_{14}H_{10}FeO_2S_2Se$: C, 41.10; H, 2.46; S, 15.67. Found: C, 41.00; H, 2.36; S, 15.71%.

3.3. General procedure for the preparation of $CpFe(CO)(\kappa^2 E,S\text{-}ECS_2Ph)$ (**2**)

A THF solution (30 mL) of $CpFe(CO)_2(\kappa E\text{-}ECS_2Ph)$ (0.25 mmol) was irradiated under a stream of N_2 for 15 min. The colour of the reaction mixture turned from orange to dark red. The volatile components were removed by vacuum and the resulting solids were purified by column chromatography using silica gel columns. The columns were eluted with (1:5 v:v ratio) of CH_2Cl_2/hexane to separate the products, which were subsequently recrystallized by slow evaporation of hexane solutions.

3.3.1. $CpFe(CO)(\kappa^2 S,S\text{-}SCS_2Ph)$ (**2a**)

Yield: 75%. m.p. = 121–122 °C. IR (CH_2Cl_2, cm^{-1}): 1955(s) ($\nu_{C\equiv O}$). ^1H NMR ($CDCl_3$): δ 4.64 (s, 5H, C_5H_5); 7.30 (m, 3H, C_6H_5); 7.51 (m, 2H, C_6H_5). *Anal.* Calc. for $C_{13}H_{10}FeOS_3$: C, 46.71; H, 3.02; S, 28.78. Found: C, 46.31; H, 3.09; S, 27.80%.

3.3.2. $CpFe(CO)(\kappa^2 S,Se\text{-}SeCS_2Ph)$ (**2b**)

Yield: 78%. m.p. = 98–99 °C. IR (CH_2Cl_2, cm^{-1}): 2049(s) ($\nu_{C\equiv O}$). ^1H NMR ($CDCl_3$): δ 4.61 (s, 5 H, C_5H_5); 7.48 (m, 3H, C_6H_5). *Anal.* Calc. for $C_{13}H_{10}FeOS_2Se$: C, 40.96; H, 2.64; S, 16.83. Found: C, 41.25; H, 2.62; S, 15.21%.

3.4. X-ray crystal structure analysis

Details of data collections and structure refinement for complexes **1a**, **1b** and **2b** are collected in Table 2. Single crystals suitable for X-ray structure determination were obtained by re-crystallization of **1a** and **1b** from THF/hexane mixtures, and from hexane for **2b**. X-ray diffraction measurements were performed on X8APEXII CCD diffractometer with graphite monochromated Mo Kα radiation, $\lambda = 0.71073$ Å at 100, 100 and 296 K for **1a**, **1b** and **2b**, correspondingly. Single crystals were positioned at 40 mm from the detector and 3099, 1936 and 1487 frames were measured, each for 5, 5 and 40 s over 1° scan width. The data were processed using SAINT software while absorption corrections were performed using the program SADABS [16]. The structures were solved by direct methods and refined by full-matrix least-squares techniques. Non-hydrogen atoms were refined with anisotropic displacement parameters. H atoms were placed in geometrically-calculated positions and were refined as riding atoms in subsequent least-squares model refinements. The isotropic thermal parameters were estimated to be 1.2 times the values of the equivalent isotropic thermal parameters of the atoms to which hydrogens were bonded. The following computer programs were used: structure solution, SHELXS-97 [17]; refinement, SHELXL-97 [18]; molecular diagrams, ORTEP [19]. Scattering factors were taken from the literature [20].

4. Supplementary material

CCDC 632056, 632055 and 632057 contain the supplementary crystallographic data for **1a**, **1b** and **2b**. These data can be obtained free of charge via http://www.ccdc.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

M.E. thanks the Jordan University of Science and Technology for financial support and the Alexander von Humboldt Foundation for a scholarship. We thank Prof. V. Arion for his help in the crystallographic analysis.

symmetry of the donating units L and the geometries of the vacant metal coordination sites [5]. Recently, we focused our attention to ligands which feature conjugated π-systems with aromatic and heteroaromatic linker units because such species accept a planar conformation [6]. As a consequence thereof, any M_2L_2 square can approve such a structure, which would allow efficient stacking of the metallomacrocycles in the solid state. Furthermore, we are currently working on the exploitation of novel π-conjugated *exo*-polydentate molecules, *i.e.* heterocyclic dienones and derivatives of cyclic ketones (Chart 1). Their use as multidentate ligands in coordination chemistry is being developed as well [7]. The reaction behavior, and hence coordination ability, of the latter type of ligands relates to the nature of their central linking unit Z and the size of the central ring (Chart 1). These parameters together with the pyridine isomers 2-, 3-, or 4-py allow the control of the orientation of the donating vector of the respective pyridyl ligands ($Z = (CH_2)_n$, NR) (Chart 1 and Fig. 1).

Recently, it was shown that in the reaction of 3-pyridyl cyclohexanones with silver salts, such as [$AgNO_3$], coordination polymers are formed, which preferably possess conformation I in the solid state (Fig. 1) [7]. We report herein the straightforward synthesis of a discrete 26-membered disilver macrocyclic molecule by treatment of 2,5-bis[(*E*)-(3-pyridyl)methylene]cyclopentanone with [$AgClO_4$] as well as our attempts on the synthesis of analogous compounds with [AgOTf] and [$AgNO_3$].

2. Experimental

Safety notes! Silver perchlorate should be handled with appropriate precaution because perchlorates are known for their potential hazardous behavior.

2,5-Bis[(*E*)-(3-pyridyl)methylene]cyclopentanone (**2**) was synthesized according to reference [8]. All other chemicals were purchased from commercial suppliers and were used without further purification.

2.1. Synthesis

2.1.1. $[Ag(C_{17}H_{14}N_2O)(CH_3CN)]_2(ClO_4)_2$

An acetonitrile solution (3 mL) containing [$AgClO_4$] (**1**) (26 mg, 0.125 mmol) was layered with a chloroform solution containing **2** (33 mg, 0.125 mmol) (3 mL) at room temperature. The flask was protected from sunlight by aluminum foil. After 3 days yellow crystals suitable for single X-ray diffraction studies could be isolated by decanting the supernatant solution. Mp = 240–242 °C. ^{1}H NMR (300 MHz, DMSO-d_6, 27 °C, δ, ppm, J, Hz): 2.07 (3H, s), 3.15 (4H, br s), 7.50 (2H, s), 7.54 (2H, dd, $J = 4.8$, $J = 7.9$), 8.13 (2H, br d, $J = 7.9$), 8.60 (2H, dd, $J = 1.4$, $J = 4.8$), 8.90 (2H, br d, $J = 1.4$). Microanalysis: Calc. for $C_{19}H_{17}AgClN_3O_5$: C, 44.69; H, 3.36; N, 8.23. Found: C, 44.68; H, 3.38; N, 8.21%. IR (KBr disc) ν/cm^{-1}: 2253 (CN), 1684 (C=O), 1627 (C=C), 1601, 1585, 1563 (py); 1145, 1090 (ClO_4). ESI-TOF (MeCN): m/z 147.9/149.9 $[AgMeCN]^+$, 189.0/191.0 $[Ag(MeCN)_2]^+$, 263.0 $[HL]^+$, 410.0/412.0 $[AgLMeCN]^+$, 631.1/633.1 $[AgL_2]^+$, 369.0/371.0 $[Ag_2L_2]^{2+}$, 839.0/841.0 $[Ag_2L_2ClO_4]^+$.

2.2. X-ray single-crystal analysis

$C_{19}H_{17}AgClN_3O_5$ 510.68 g/mol, triclinic, $P\bar{1}$, $a = 9.8310(5)$ Å, $b = 10.0617(5)$ Å, $c = 10.3599(5)$ Å, $\alpha = 92.9340\ (10)°$, $\beta = 102.4490(10)°$, $\gamma = 101.3510(10)°$, $V = 976.40(8)$ Å^3, $Z = 2$, $D_{calc} = 1.737$ g/cm^3, μ(Mo Kα) = 1.206 mm^{-1}. 11 233 reflections collected, 4006 unique, $R_{int} = 0.0241$, 301 parameters and 156 restraints. Final R indices: R_1 ($I > 2\sigma(I)$) = 0.0299, wR_2 ($I > 2\sigma(I)$) = 0.0819 and R_1 (all data) = 0.0336, wR_2 (all data) = 0.0844. Largest difference in peak and hole: 0.673 and −0.486 e Å^{-3}. Data were collected on a Bruker Smart 1k CCD diffractometer at $T = 298(2)$ K using Mo Kα radiation ($\lambda = 0.71073$ Å). Reflections were collected in the θ scan modus in 0.4° steps and an exposion time of 20 s per frame. The structure was solved by direct methods using SHELXS-97 [9]. The structure was refined by full-matrix least-squares procedures on F^2 using SHELXL-97 [9]. All non-hydrogen atoms were refined anisotropically. All hydrogen atom positions were refined using a riding model. All hydrogen atom positions have been selected from the difference Fourier map and refined freely.

3. Results and discussion

Layering an acetonitrile solution containing [$AgClO_4$] (**1**) with 2,5-bis[(*E*)-(3-pyridyl)methylene]cyclopentanone (L) (**2**) dissolved in chloroform produced yellow crystals of [$Ag(MeC{\equiv}N)(OClO_3)(\mu\text{-}L)]_2$ (**3**) at room temperature after three days. Applying the same procedure to [AgOTf] and [$AgNO_3$] led to a yellow powder for the former salt (product **4**) and to a mixture of pale yellow and colorless powders for the later one. From the crystals of **3** a single-crystal X-ray structure determination was performed. The molecular view of **3** is shown in Fig. 2. Selected bond

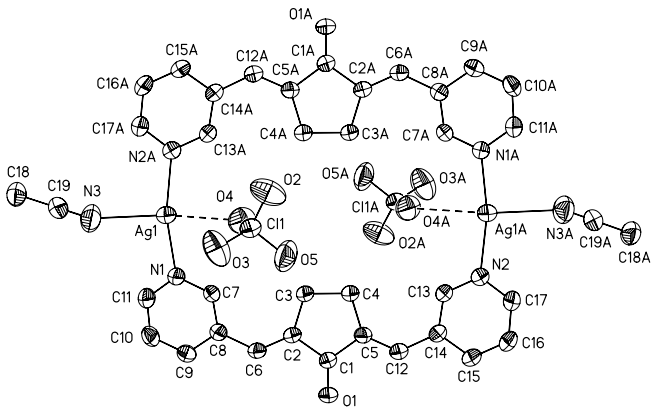

Fig. 2. ORTEP plot (50% probability level) of **3** with the atom numbering scheme (the hydrogen atoms and one position of the disordered $OClO_3^-$ anion are omitted for clarity). Selected bond distances (Å) and angles (°): Ag1–N2A 2.199(2), Ag1–N1 2.208(2), Ag1–N3 2.573(3), C2–C6 1.334(3), C5–C12 1.342(3), C6–C8 1.469(3), C12–C14 1.466(3) N2–Ag1A 2.199(2), Ag1–O4 2.829(14) N1–Ag1–N2A 163.87(8), N2A–Ag1–N3 98.38(10), N1–Ag1–N3 93.98(10), Ag1–N3–C19 153.9(3).

distances (Å) and angles (°) are given in the legend of Fig. 2.

Complex **3** forms a 26-membered disilver macrocycle in the solid state, with the asymmetric unit containing half of the ring (Fig. 2). The other half of the metallomacrocycle is generated by an inversion center positioned halfway between the two silver(I) centers, Ag1 and Ag1A. The perchlorate anion was refined on two disordered positions with occupation factors of 0.369 and 0.631 (Cl1–O5).

In **3** the silver(I) ions possess coordination number 4, showing a distorted tetrahedral environment from two *trans*-oriented pyridyl units of neighboring ligand molecules, a coordinated acetonitrile molecule and a weakly-coordinated perchlorate counter-anion (Fig. 2). The M_2L_2 fragment of **3** is almost planar (r.m.s. deviation 0.142 Å). The vectors of the donating nitrogen lone-pair of electrons are not parallel oriented, the deviation angles from the normal is 16.16°. Thus, the distances between the nitrogen centers N1–N2A and N2–N1H is 10.35 Å, which is shorter than the distance between Ag1 and Ag1A within the dimer (10.85 Å). The Ag1–O4 separation is 2.829(14) Å, indicating that the perchlorate group is weakly coordinated by O4 to the silver(I) center (Fig. 2). This structural motif is common for silver(I) perchlorate molecules with coordinated nitrogen ligands [10].

In the solid state the dimeric **3** forms infinite 2D layers in which distinct molecules are linked to each other via a system of short C–H···O contacts (Fig. 3). These contacts mainly consist of interactions between the perchlorate oxygen atoms and the hydrogen atoms of pyridines (range of distances 2.42–2.59 Å) as well as acetonitrile methyl groups (2.65 Å). Short contacts also exist between the carbonyl oxygen atoms and the hydrogen atoms in the gamma position of the pyridine rings (2.52 Å).

The shortest interlayer distances (2.38 Å) are those between the carbonyl atom O1 and the hydrogen atom

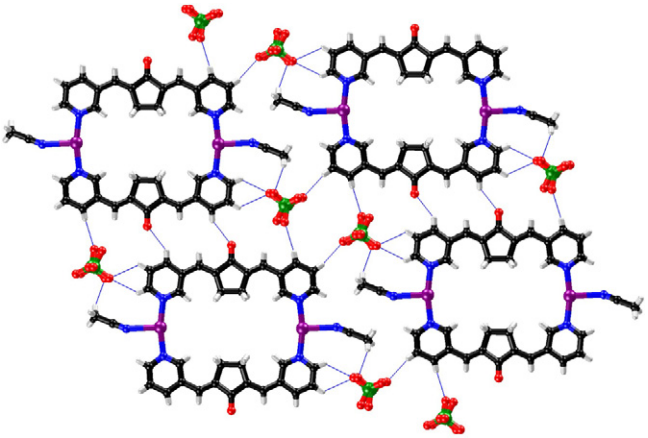

Fig. 3. C–H···O contacts within the layer formed by dimers of **3** in the crystal.

H16 of an adjacent acetonitrile molecule. The neighboring layers stack with such an offset so as to allow accommodation of perchlorate anions, which additionally interact with dimers of **3** via C–H···O contacts (2.39–2.65 Å, Fig. 4). An interlayer contact exists between the silver atom Ag1 and the methyne hydrogen atom H10 (3.25 Å), the appropriate Ag1···C10 distance is 3.28 Å. As a result thereof, infinite narrow channels filled with perchlorate anions run through the crystal along the crystallographic *c* axis (Fig. 5).

To define the geometrical conditions for the solid state [2+2] photochemical transformations, one has to analyze the distance in between and the mutual orientation of the reactive double bonds. If these data are in accord with the so-called principle of "minimal atomic and molecular movements" (parallel double bonds with the distance between carbon atoms <4.2 Å [11a]), there is a possibility for topochemical reactions. Although this approach was criticized recently [11b], we did analyze the relevant data from the X-ray study of **3**. Due to the interlayer offset in

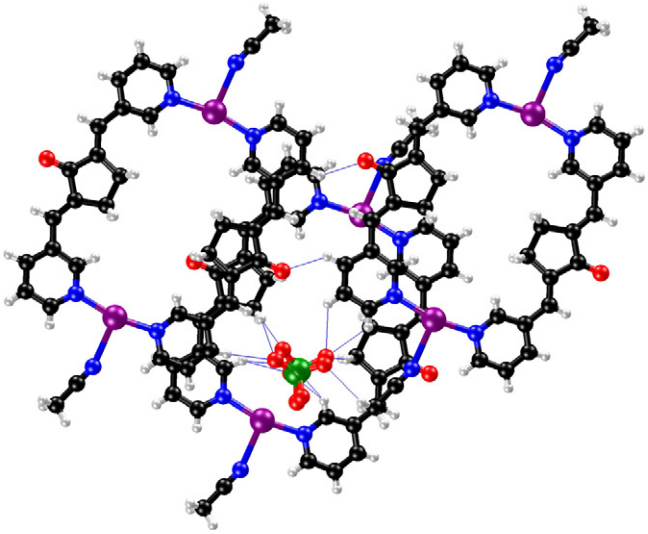

Fig. 4. C–H···O contacts within adjacent layers in **3**.

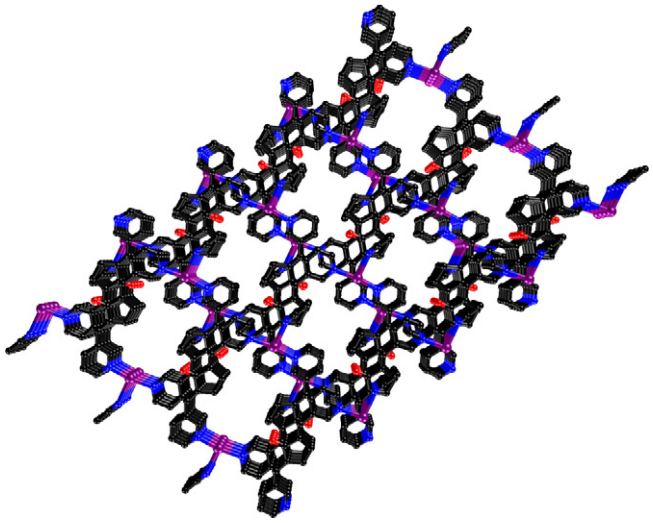

Fig. 5. A view of the structure of **3** along the crystallographic *c* axis (perchlorate anions and hydrogen atoms are omitted).

crystals of **3**, the closest dimethylencyclopentanone units lie in a head-to-tail orientation with the carbonyl carbon C1 superimposed on the tertial olefinic carbon C2 (C1···C2B 3.55 Å, symmetry transformations $-x+1$; $-y+2$; $-z+1$). The distances between possible cycloaddition partner double bonds are 3.95 Å (C2···C5) and 3.99 (C6···C12); the angle between the bonds is 48.3°. According to Schmidts' rules [11a], the solid state topochemical [2+2]-cycloaddition reaction is prohibited, but if it did occur, the only product would be cyclobutane with C_2 symmetry (Fig. 6, structure b).

During the study of the photostability of *crystals* of **3**, we did not find any significant changes in the NMR spectra after 6 months of exposure to direct sunlight. At the same time, *solutions* of **3** in DMSO undergo rapid photochemical changes upon exposure to ambient light (*vide infra*). Due to the insolubility of **3** in common deuterated chlorinated organic solvents, the ^{1}H NMR spectra of the title compound were recorded in DMSO-d_6. It was found that the spectrum of **3** is identical concerning the chemical shifts and signal patterns with that of pure L, indicating that **3**

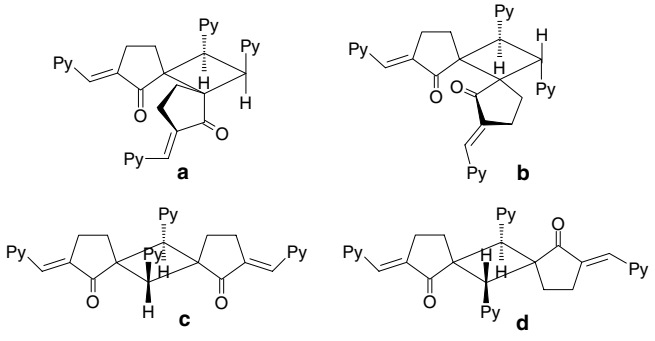

Fig. 6. Possible isomers which could be derived from [2+2]-cycloaddition reactions of **2**.

dissociates from its dimeric form (found in the solid state) into its starting components upon dissolution in DMSO. Alternatively, a fast equilibrium between free L, solvated metal ions $[Ag(N{\equiv}CMe)_n]^+$ and **3** (and several intermediate complexes) is possible [12].

ESI-TOF mass-spectrometric studies were carried out with **3** in acetonitrile solutions. Ion peaks at *m*/*z* 147.9/149.9 (100%), 189.0/191.0, 263.0 (53%), 410.0/412.0, 631.1/633.1, 369.0/371.0 and 839.0/841.0 are typical for the fragments $[AgMeCN]^+$, $[Ag(MeCN)_2]^+$, $[HL]^+$, $[AgLMeCN]^+$, $[AgL_2]^+$, $[Ag_2L_2]^{2+}$ and $[Ag_2L_2ClO_4]^+$, respectively, (L = 2,5-bis[(*E*)-(3-pyridyl)methylene]cyclopentanone). Obviously, in coordinating solvents such as acetonitrile complex **3** dissociates forming more stable silver–acetonitrile fragments, indicating that in **3** labile silver–nitrogen(pyridyl) bonds exist [12c,13].

During the ^{1}H NMR studies we observed spontaneous changes in spectra of those samples which were exposed to sunlight. The samples protected from light remained unchanged. Careful examination of the spectral changes allowed us to conclude that we are dealing with *trans*/*cis*-isomerization and [2+2] cycloaddition reactions of L in solution, because the same behavior was observed for the pure ligand L earlier [8]. The [2+2] cycloaddition process yields the only a cyclobutane product which possesses C_2 symmetry (Fig. 6, structure b). These findings prove again the dissociative nature of complex **3** in coordinating solvents.

Attempts to form products by the reaction of L and silver(I) triflate furnished the yellow powder **4**, whose composition, according to elemental analysis, was closer to $[Ag_2L_4(OTf)_2CHCl_3CH_3CN]$ rather than $[Ag_2L_2(OTzf)_2(CH_3CN)_2]$, as in **3**. NMR spectroscopy was of little use as no changes compared to the spectra of L and **3** were detected. However, in the NMR spectra of **4** we did not observe the peaks of chloroform or acetonitrile molecules; this would indicate that the experimental composition does not correspond to the compounds with the composition shown above, but rather to some products which do not contain both chloroform and acetonitrile. In ESI-TOF mass-spectra of **4** (DMSO) peaks corresponding to $[AgL_2]^+$ and $[Ag_2L_2ClO_4]^+$ were found. This indicates the possible presence of dimeric structural units within the whole structure of **4**. The coexistence of different products cannot be ruled out at this stage.

In conclusion, we found the cisoid conformation III (Fig. 1) in **2** clearly favors the formation of the bimetallic macrocycle **3** rather than polymers in the solid state by a self-assembly process. It has been demonstrated by ^{1}H NMR spectroscopy and ESI-TOF mass-spectrometry that complex **3** dissociates to the starting components **1** and **2** in coordinating solvents. Light-driven reactivity of the rectangular metallocycle **3** in polar solvent solution has been investigated by ^{1}H NMR studies: on exposure to sunlight the organic component of the solution undergoes *trans*/*cis* isomerization and [2+2]-cycloaddition reactions.

4. Supplementary material

CCDC 623859 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. General comments

All starting materials were obtained from Aldrich chemical company, and with the exception of 2-ethyl-4-methyl-imidazole which was vacuum distilled before use, all chemicals were used as received. Oleum was rated at 26–33% SO_3. NMR spectra of sulfonated imidazoles and their derivatives were recorded in D_2O on a 300 MHz Bruker instrument and referenced to DSS. Trimethylsilyl derivatives and other air sensitive materials were handled in the Dri-Lab or on the vacuum line, and their NMR spectra were obtained in a C_6D_6 solution referenced to TMS using the carbons or the residual protons of the solvent. Ethylene glycol ditosylate was prepared from ethylene glycol and tosyl chloride using pyridine as a base according to standard methods. Water was triple distilled. Potassium amide was prepared by a reaction of K with anhydrous NH_3 (l) in a Hoke SS316 cylinder. Fluorescence spectra in the visible region were obtained with an Ocean Optics spectrometer using a standard 4 W longwave UV lamp as an excitation source. Elemental analysis was done by Complete Analysis Laboratories, Parsippany, NJ.

2.2. Crystal structures

Single crystals of **1** through **5** were chosen and glued to the end of a thin glass fiber and transferred to a Bruker SMART 1K CCD diffractometer equipped with Mo Kα radiation and a graphite monochromator. Cell dimensions and other relevant crystal data were collected by standard methods [7] and are listed in Table 1. A semi-empirical absorption correction was obtained from equivalents in all cases.

2.3. 2-Methylimidazole-5-sulfonic acid (*1*)

2-Methylimidazole (1.529 g, 18.6 mmol) added to 10 mL oleum, with stirring, for 30 h. The mixture is neutralized with $BaCl_2$, forming a precipitate. After the sulfuric acid is fully precipitated out as $BaSO_4$, mixture is filtered, and the volume of the filtrate is reduced by vacuum evaporation. Crystals form overnight, and the supernatant is decanted and the crystals of $\mathbf{1}\cdot H_2O$ (1.15 g, 34%) dried under vacuum at room temperature. NMR: ^{1}H 2.67 (s, Me), 4.83 (N–H, exch), 7.64 (C–H); ^{13}C, 13.5 (Me), 121.2 (C–H), 136.2, 149.0.

2.4. 2-Ethyl-4-methylimidazole-5-sulfonic acid (*2*)

Oleum (59 mL, ~350 mmol SO_3) was slowly added to an Erlenmeyer flask containing 2-ethyl-4-methyl-imidazole (36 g, 327 mmol), while stirring on a hotplate. The temperature reached 110 °C from the exotherm, and was maintained at 125 °C for 1 h. NMR of an aliquot shows that the reaction is complete. The product was poured into H_2O in a large beaker, and brought to a boil. Barium carbonate (227 g) was slowly added until the mixture was alkaline to pH paper. The $BaCO_3$ must be added very slowly near the endpoint since the mixture has a tendency to froth over as the last acid is neutralized. After filtration

and washing with H_2O, the filtrate was reacidified with H_2SO_4 until no more $BaCO_3$ precipitated, and then filtered again. After rotary evaporation, the filtrate was recrystallized from MeOH with H_2O added to increase solubility by allowing a hot concentrated solution to cool to room temperature, and crystals (41.77 g, 67%) were dried at 100 °C under vacuum. *Anal.* Calc. for $C_6H_{10}N_2SO_3$: C, 37.89; H, 5.30; N, 14.73. Found: C, 38.36; H, 5.25; N, 14.65%. NMR: ^{1}H 1.24 (t), 2.32 (s), 2.87 (q), 4.76 (N–H, exch) ; ^{13}C 11.6, 13.2 (Me), 21.5 (CH_2), 131.2, 131.9, 151.1 (C_3N_2 ring).

2.5. Lithium 2-ethyl-4-methylimidazole-5-sulfonate (*3*)

Lithium carbonate (1.13 g, 15.3 mmol) and **2** (2.89 g, 15.2 mmol) were combined in 25 mL H_2O and heated to boiling on a hotplate. Mixture was decanted hot from 0.49 g (recovered) undissolved Li_2CO_3, and vacuum evaporated to dryness, redissolved in cold H_2O, filtered, and the solvent removed affording 2.98 g **3** (100%), which was identified by its NMR spectrum. Lithium hydroxide was prepared by slow addition of Li powder (0.232 g, 33.4 mmol) to water under inert atmosphere and added to **2** (3.16 g, 16.6 mmol). A portion was crystallized by slow evaporation under N_2 affording crystals of $\mathbf{3 \cdot H_2O}$ that were used for the X-ray structure. NMR: ^{1}H 4.84 (N–H, exch), 2.63 (q), 2.34 (s), 1.20 (t); ^{13}C 152.2, 136.8, 131.2 (C_3N_2 ring), 23.5 (CH_2), 14.5 (Me), 12.2.

2.6. Silver 2-ethyl-4-methylimidazole-5-sulfonate (*4*)

The free acid **2** (21.70 g, 114 mmol) was dissolved in H_2O (250 mL) and Ag_2O (13.02 g, 56.2 mmol) was added with stirring. The mixture was mildly heated with a heat gun and five drops of NH_4OH were added to help dissolve the Ag_2O. The next day, 1 g (4.3 mmol) more Ag_2O was added and the mixture was heated to reflux for 3 h and filtered while hot. On cooling, a white solid crystallized and was isolated by filtration and dried under vacuum. Isolated yield, 28.70 g (85%). *Anal.* Calc. for $C_6H_9N_2SO_3Ag$: C, 24.26; H, 3.05; N, 9.43; Ag, 36.31. Found: C, 24.80; H, 2.92; N, 10.18; Ag, 37.86%. NMR: ^{1}H, 1.29 (t), 2.40 (s, Me), 2.81 (q, Et), 4.77 (N–H, exch); ^{13}C, 12.4 (br), 14.7, 24.6, 131.3 (br), 136.3 (br), 153.1.

3. Attempts to make dialkali metal salts

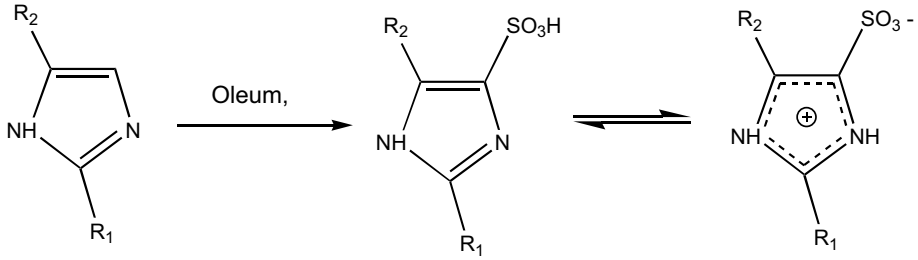
(a) In a 10 mL flask **2** (3.00 g, 15.7 mmol) was dissolved in a minimum amount of water and KOH (1.7 g, 30.3 mmol) was added. After rotary evaporation, the material was recrystallized from hot water/MeOH containing several grams of excess KOH, affording clear crystals (1.64 g). A crystal from this batch was used for the poor crystal structure that is in the supplementary material. (b) Reaction of **2** with NaOMe. Sodium spheres (0.75 g, 32.6 mmol) were loaded onto one side of an H-tube and **2** (3.00 g, 15.8 mmol) loaded onto the other side under vacuum. Dry MeOH condensed into both sides. Once the Na dissolved, the MeONa solution was added to the free acid. Initially a soluble salt was formed then a thick white solid precipitated. The solid would not dissolve in the MeOH even when hot. Mixture was filtered and the white solid removed and heated under dynamic vacuum to 100 °C affording an isolated yield of 2.93 g. *Anal.* Calc. for $C_6H_{8.5}N_2SO_3Na_{1.5}$: C, 32.29; H, 3.84; N, 12.55; Na, 15.45. Found: C, 31.25; H, 3.68; N, 11.63; Na 15.92%. *Anal.* Calc. for $C_6H_{8.45}N_2SO_3Na_{1.55}$: C, 32.13; H, 3.80; N, 12.49; Na, 15.89. Found: C, 31.25; H, 3.68; N, 11.63; Na 15.92%.

3.1. Bis(trimethylsilyl)-2-ethyl-4-methylimidazole-5-sulfonate (*5*)

In an H-tube, anhydrous ammonia (~100 mL) was condensed (at −78 °C) on the free acid **2** (8.92 g, 46.9 mmol) and potassium amide (5.20 g, 94.3 mmol) which causes a substantial volume expansion of the solid. After standing at −78 °C for an hour, it was allowed to warm up naturally. The mixture did not stir, but was agitated a bit by shaking. The NH_3 was allowed to slowly boil off over several hours through a bubbler attached to the vacuum line, and the remaining NH_3 was removed under dynamic vacuum by heating to 110 °C. THF (50 mL) and Me_3SiCl (13.5 mL) were added and the mixture was heated with stirring at 110 °C for 16 h. The mixture was filtered and the solids washed several times with recondensed solvent. A crude liquid product of 5.5 g was distilled under dynamic vacuum in an all-glass H-tube/still at a pot temperature of 140 °C, and the distillate was recrystallized from heptane twice and pumped dry, affording 2.71 g of a product that contains both mono and disilylated product (by NMR). Vacuum sublimation of the material to an ice-cooled cold finger from a flask heated in a 100 °C oil bath afforded 2.07 g (13%) **5**. NMR: (C_6D_6) 1H, −0.12, 0.40 (Me_3Si), 1.29 (t, Et), 2.29 (q, Et), 2.35 (s, Me); ^{13}C, 0.67, 1.55 (Me_3Si), 12.48, 12.65 (CH_3), 24.17 (CH_2), 135.09, 137.06, 153.68 (C_3N_2 ring).

3.1.1. Reaction of *4* with 1,4-dibromobutane

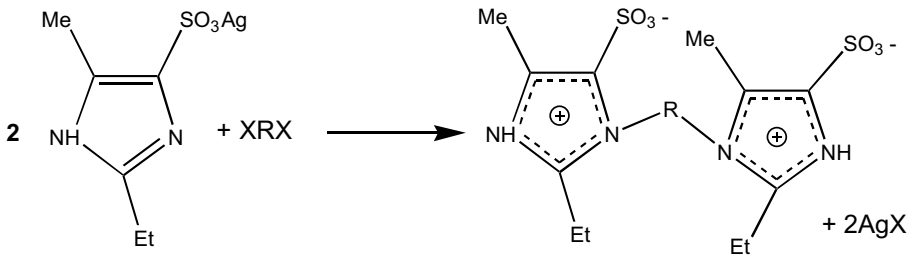
Reaction was conducted in both NMP and tetraglyme. (a) 1,4-dibromobutane (0.26 g, 1.2 mmol) and **4** (0.74 g, 2.5 mmol) were combined in 2 mL NMP under inert atmosphere and stirred for 3 d in a 120 °C oil bath. The NMP was removed under dynamic vacuum and the crude product mixed with water, filtered and the filtrate was vacuum evaporated to dryness. The crude product was mixed with hot ethanol, filtered, and the filter residue was dried under vacuum. A total of 0.14 g (27%) 6 isolated. NMR: (D_2O) ^{1}H, 4.76 (NH, exch), 4.29, 4.10* (br, CH_2–N), 2.92 (q, CH_2 on Et), 2.45*, 2.38 (s, Me), 1.88 (br, CH_2), 1.30 (t, CH_3) (* = minor isomer); ^{13}C, 151.48, 133.24, 131.93 (C_3N_2 ring), 48.17 (CH_2–N), 28.79 (CH_2), 20.99 (CH_2 on Et), 12.59, 12.54 (CH_3) (b) 1,4-dibromobutane (3.34 g, 15.5 mmol) and **4** (9.11 g, 30.7 mmol) were combined in



15 mL tetraglyme in a bulb with a Kontes valve under inert atmosphere and heated at 130 °C for 6 d. Water and HCl (to neutralize unreacted **4**) added, and the mixture filtered. The filtrate was vacuum evaporated and recrystallized from hot isopropanol. The solid was heated under vacuum to remove most of the solvent residue, but a small amount of tetraglyme remains. Yield 1.18 g (17%) *Anal.* Calc. for $C_{16}H_{26}N_4S_2O_6$: C, 44.23, H, 6.03, N, 12.89. Found: C, 44.91, H, 6.52, N, 11.63%.

4. Results and discussion

4.1. Synthesis



Both 2-methylimidazole and 2-ethyl-4-methyl imidazole are readily sulfonated with fuming sulfuric acid (oleum). The 2-methylimidazole appears to sulfonate in both the 4- and 5-positions according to NMR data, but the disulfonate readily decomposes to 2-methylimidazole-5-sulfonic acid (**1**) during isolation. The synthesis of **1**, but not its NMR or crystal structure, was reported previously [6e]. The imidazole sulfonic acids are readily isolated from the concentrated acid by formation of the barium salt, which is water soluble, and easily separated from the insoluble $BaSO_4$ by filtration, which is then reacidified to liberate the free acid [6]. The remainder of this work concentrates on the 2-ethyl-4-methyl substitution so as to avoid any complications from multiple sulfonation of the imidazole ring (see Scheme 1).

However, 2-ethyl-4-methylimidaziole-5-sulfonic acid (**2**) does not act as a nucleophile toward either $Br(CH_2)_4Br$ or $TosCH_2CH_2Tos$. Since these sulfonic acids actually exist as zwitterionic compounds (see crystal structures) this is not too surprising. One might expect a metal salt of these acids to react with an alkyl halide much more readily. The mono Li salt (**3**) and the Ag salt (**4**) of **2** are easily prepared in H_2O from the acid and Li_2CO_3 or Ag_2O, respectively. However, reaction between **4** and $Br(CH_2)_4Br$ or $TosCH_2CH_2Tos$ in H_2O or protic solvents such as dry MeOH result in the formation of **2** and AgBr. Substitution does take place very slowly at elevated temperatures in dry non-protic solvents in which **3** or **4** have some solubility, such as NMP or tetraglyme. The inability of sulfonated imidazoles to partake in many standard reactions of sulfonic acids (esterification, etc.) was noted previously [6e], but not explained, and is probably due to hydrolytic instability of the products or intermediates. Presumably, the attachment of an alkyl group onto a nitrogen atom by reaction of a sulfonate salt with an alkyl halide goes through an organosulfate intermediate, which apparently hydrolyzes in protic solvents before a nucleophillic substitution on an N atom can take place. By doing the substitution in NMP or tetraglyme, a linked dimer **6** can be prepared from a 2:1 reaction of **4** with a dihalide (Scheme 2). Naturally, three different isomers are formed since the $CH_2CH_2CH_2CH_2$ moiety can be bonded to either N1 or N3 on each imidazole ring. The isolated yields are relatively low. The reaction in NMP resulted in primarily the most symmetrical isomer (based on NMR) while doing the reaction in tetraglyme produced larger amounts of the other isomers. The reaction seemed to work better in NMP, possibly due to the much greater solubility of **4** in that solvent.

R_1 = Me, R_2 = H (**1**)
R_1 = Et, R_2 = Me (**2**)

Scheme 1.

R = $(CH_2)_4$ (**6**)

Scheme 2.

Multiple deprotonation of **2** also takes place, and is readily apparent in the NMR spectra of **2** combined with various amounts of base. Fig. 1 shows the ^{13}C chemical shifts of the aromatic carbons in **2** as different amounts of NaOH are added to its solution in D_2O, and the chemical shifts stabilize around 3 equiv. of base. The NMR spectra of all the monoalkali metal salts (Li, Na, K) in D_2O are virtually identical as is expected for an ionic compound. A titration with NaOH using a pH meter as indicator (supplementary material) shows an ordinary neutralization at 1 equiv. NaOH and a small, barely perceptible change at 1.5 equiv., but the pH meter may not have the range to observe a second neutralization. Products with full removal of both protons did not crystallize in water with an excess of KOH or LiOH or in methanol with NaOMe. In all cases, the maximum amount of deprotonation observed in the solid products is 3/2 as determined by a poor crystal structure of a $K_{3/2}$ salt (not shown, supplementary material), elemental analysis of an Na derivative, and the chemical shifts of the solid products in D_2O solution, which matched either the mono or the 3/2 equiv. shifts (supplementary material). Also, the product from reaction of Me_3SiCl with the solid product of **2** + 2 equiv. KOH, NMR clearly shows both a mono and disilylated product are present. The evidence seems to indicate that fully deprotonated species are present in strongly basic aqueous solutions, but do not crystallize from water. However a fully deprotonated product does appear to precipitate in liquid anhydrous NH_3 using 2 equiv. KNH_2 as the base, and K_2 salt prepared by this method was used to prepare the pure bis(trimethylsilyl) derivative (**5**). However, the yield is low, possibly due to low solubility of the intermediate K_2 salt in THF.

These materials all exhibit fluorescence under irradiation with a UV lamp. Fig. 2 shows the change in the emission spectrum of the 2-ethyl-4-methyl-imidazole ligand upon sulfonation. The emission spectra of the Ag salt **4** and the monopotassium salt have the same emission peaks as the free acid, with some changes in relative intensity. Although some Ag complexes are highly luminescent, all emissions from **4** can be attributed to ligand emission bands. Luminescent Ag complexes tend to have Ag···Ag bonding [8], which is not present in **4**.

4.2. Crystal structures

Crystal structures were obtained for **2**, **4**, and **5** and the monohydrates of **1** and **3**, the crystal data are listed in Table 1, and selected lengths and bond angles are listed in Tables 2 and 3. By convention, the imidazole atoms are numbered consecutively from N1 to C5, the carbon between the nitrogens is C2, and the sulfonate group in **1**–**5** always attached to C5. There is little variation in the C-S distances which range from 1.737(1) to 1.757(1) Å. By comparison, a sulfonamide attached to an imidaz-

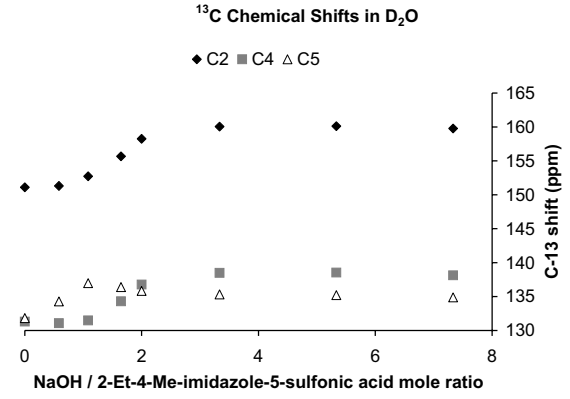


Fig. 1. ^{13}C chemical shifts of the aromatic carbons in **2** (in D_2O) with varying amounts of NaOH added.

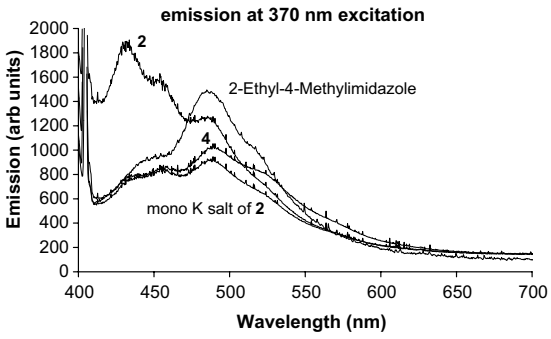

Fig. 2. Emission spectra of 2-ethyl-4-methyl-imidazole and several of its sulfonated derivatives. The absolute intensity is meaningless as all spectra were not obtained with the same instrument and conditions. The peak at 404 nm is from the light source (longwave UV lamp).

ole ring in the 5-position has a C–S distance of 1.726(5) Å [9]. Several structures are known of imidazoles sulfonated at the 2-position, and the C–S distances in those compounds are slightly longer at 1.76(2), 1.788(4), and 1.822(2) Å [10].

Fig. 3 shows the asymmetric units of all compounds, except for the Ag complex **4** which is pictured in Fig. 5. The nearly equal C2–N bond distances show the positive charge to be equally delocalized over both N atoms in **1 · H_2O**, **2**, and **4** [10b]. In **3 · H_2O** the distance to N3 is significantly longer, possibly indicating that the positive charge is concentrated on N1, the nitrogen coordinated to the Li cation. In the bis(trimethylsilyl) derivative **5**, one silicon is bonded to N3 and the other one is attached to O1 of the sulfonate, and **5** is the only derivative that has no hydrogen or coordinate bonding between imidazole units. As the S1–O1 bond distance of 1.5470(9) Å shows that oxygen to be only singly bonded to the sulfur, and the N1–C2 bond distance is much less than the C2–N3 distance, **5** is really a trimethylsilyl ester and not a sulfonate. The Si–O and Si–N distances in **5** are normal for single bonds. In **1 · H_2O**–**4** the S–O bond lengths are nearly equal (range 1.4394(4)–1.471(5), average 1.455 Å) and similar to those in other zwitterionic sulfonates [10b], which shows that the negative charge is equally distributed over the O atoms (see Table 4).

In **1 · H_2O**–**4**, hydrogen bonding and metal coordination link the sulfonated imidazoles into extended networks. The imidazole sulfonate moieties are clearly directed by hydrogen bonding into puckered sheets and ribbons that have some similar features to BEDT-TTF fluorosulfonates [11] and several series of guanidinium sulfonates [12]. The high favorability of hydrogen bonding in these compounds may offer a partial explanation as to why the doubly deprotonated imidazole sulfonic acids are not crystallized from water, as such compounds would lack N–H bonds. In the hydrate of **1**, strong H bonds between the water and the sulfonates and the N–H groups link the lattice tightly in all 3 dimensions (Fig. 4). In contrast, **2**, which has more steric bulk and no coordinated water, has pleated two-dimensional sheets that are formed from by the strong NH···O–S hydrogen bonds. There are also short CH···O–S approaches (weak H-bonds) between these layers, that are considerably less than 2.62 Å, the H···O vdW contact value. Hydrogen bonds between CH and OS are present in **1 · H_2O** also. A fair amount of precedent exists for H-bonding between C–H moieties and sulfonates, as for example in 1-butylimidazolium-3-*n*-butanesulfonate which has seven weak H-bonds between the ring hydrogens and the sulfonate oxygens with O···H–C distances of 3.067(3)–3.515(3) Å [13]. In the monolithium salt (**3 · H_2O**), coordination of the Li cation to N1 and a O1 creates an asymmetric unit consisting of two fused 5-membered rings. These units form a puckered chain (Fig. 4) by linkage of the nearly tetrahedrally coordinated Li atoms to a neighboring sulfonate O2A and the water oxygen, and by H-bonding between a water hydrogen and O3. Additional H-bonding between O3 and another water hydrogen, and between O1 and a N–H on a neighboring asymmetric unit, link these chains in all three dimensions.

The Ag salt **4** (Fig. 5) has the most interesting structure of these compounds. Its asymmetric unit is a dimer, with a nearly linear Ag1 linking both N1 nitrogens, and Ag2 linking both sulfonate O1s resulting in a 10-membered ring. The Ag–N bond distances of 2.097(5) and 2.106(5) and nearly linear geometry are very similar to those reported (2.05(1)–2.12(1) Å, 167.6(1)–178.2(1)°) for a series of Ag(I) imidazolates where a negatively charged imidazole ion links Ag(I) ions into chains [14]. Since compounds where Ag^+ ions are coordinated to neutral organic nitrogen ligands can have a very similar geometry [15], one can not conclude much more than **4** displays the normal coordination mode for 2-coordinate silver. These dimers are additionally linked together through Ag2 and sulfonate oxygens O2B and O3A into 8-membered $(Ag–O–S–O)_2$ rings, which are joined through the Ag2 atoms into an infinite chain. The geometry around Ag2 is a highly distorted tetrahedron, with the angles ranging from 80.77(15) to 131.87(16)°. These

chains are hydrogen bonded together by the H atoms on the N3s to the O2s of both sulfonates into a 3-dimensional network.

Silver sulfonate networks have received increased attention within the last decade [15,16]. Part of this is due to the observation that silver is an exception to the general rule that sulfonate is a weakly coordinating anion to transition metals, and partly a result of a search for new materials that reversibly intercalate various substances including alcohols and amines. As d^{10} ions have a lot of coordinative flexibility, a wide variety of structural motifs can be obtained with Ag. Eight-membered $(Ag–O–S–O)_2$ rings have been observed in a series of pyrazine complexes of Ag sulfonates [16d], and appear in Ag complexes of sulfosalicylic acid as well [16a]. Chains of linked eight-membered rings similar to those in **4** appear in the Ag salt of 4-pyridinesulfonic acid, which like **4**, also has 2-coordinate linear Ag atoms bonded to the ligand nitrogens [16b]. Most of the previously reported Ag sulfonate structures are layered, and their ability to intercalate alcohols and/or amines have been studied [16b,16e,16g]. A zwitterionic imidazolium propanesulfonate complex with silver salts is also linked into an extended network by bonding between the sulfonate and the Ag ions, and has been explored as an ion exchange membrane [17].

5. Conclusions

Contrary to previous belief, imidazoles sulfonated in the 4/5 position can engage in substitution reactions that make sulfonic esters or *N*-alkyl substituted products. However, the use of non-protic solvents and the rigorous

exclusion of water is necessary, and the substitution reactions are slow. Sulfonated imidazoles and their salts form hydrogen bonded networks in the solid state. The silver salt of 2-ethyl-4-methylimidazolesulfonic acid crystallizes in an elaborate 3-dimensional network structure, and shows that it may be possible to use sulfonated imidazoles as a building block for new metal-ligand frameworks.

Scheme 1. Schematic diagrams of bis(phthalocyaninato) rare earth complexes (a) $R_1 = R_2 = H$, $M(Pc)_2$, (b) $R_1 = R_2 = OC_6H_4OCH_3$, $M[Pc(MeOPhO)_8]_2$, (c) $R_1 \neq R_2 = H$, *tert*-C_4H_9, $M(TBPc)_2$ and mixed [tetrakis(4-chlorophenyl)porphyrinato](phthalocyaninato) rare earth complexes M(TClPP)(Pc).

the electronic absorption properties for bis(phthalocyaninato) rare earth compounds $M(Pc)_2$, $M(TBPc)_2$, $M[Pc(MeOPhO)_8]_2$ (M = Y, La...Lu except for Pm) and mixed [tetrakis(4-chlorophenyl)porphyrinato](phthalocyaninato) complexes M(TClPP)(Pc) (M = Y, La...Lu except for Pm), as shown in Scheme 1. The influence of the symmetry of bis(phthalocyaninato) rare earth molecules, the effects of ionic radius of the rare earth metal and the influence of substituent species (*tert*-butyl and 4-methoxyphenoxy groups) onto the peripheral benzene rings on the electronic absorption characteristics of sandwich-type compounds have also been tentatively studied.

2. Experimental

The bis(phthalocyaninato) rare earth double-decker complexes were prepared according to published procedures [6,7]. The mixed [tetrakis(4-chlorophenyl)porphyrinato](phthalocyaninato) rare earth complexes M(TClPP)(Pc) were prepared by means of phthalonitrile tetramerization method using M(TClPP)(acac) as template [8]. Their sandwich nature has been well established through a series of spectroscopic methods including IR, ^{1}H NMR, MCD, ESR, and in particularly the X-ray single crystal molecular structure analysis result [4,7–9]. High resolution mass spectroscopic and NMR characterization for these complexes confirm the purity of these materials. The UV–Vis and near-IR spectra were obtained on HP 8543 and Hitachi U-4100 Spectrophotometer.

3. Results and discussion

3.1. UV–Vis characteristics of bis(phthalocyaninato) rare earth complexes $M(Pc)_2$ (M = Y, La...Lu except Pm)

The electronic absorption spectral data of the unsubstituted phthalocyaninato double-deckers $M(Pc)_2$ in $CHCl_3$ are collected in Table S1. Due to the similar molecular structure among the whole series of bis(phthalocyaninato) lanthanide compounds, all these compounds (except Ce) show similar UV–Vis characteristics. Fig. 1 shows the UV–Vis spectra of La, Ce, Dy, and Lu double-deckers. It can be seen from Fig. 1 and Table S1 that all these homoleptic tervalent double-deckers (except La, Ce and Pr) exhibit a weak split Soret band with maxima around 320–327 and 334–343 nm, an intense Q band at 661–691 nm and a π-radical band at 454–491 nm [9,10]. Along with the decrease of rare earth ionic size from La to Lu, all the corresponding absorptions are systematically blue-shifted as shown in Table S1, clearly revealing the rare earth size effect. As for the unsubstituted bis(phthalocyaninato) complexes, a linear correlation exists between the energy of the Soret/Q bands and the M^{III} ionic radii as shown in Fig. 2. All these observations indicate that the interaction between the two rings becomes stronger as the ring-ring separation

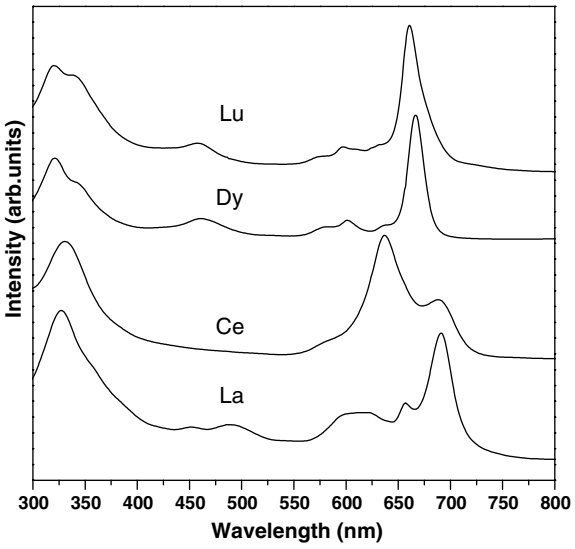

Fig. 1. Electronic absorption spectra of $M(Pc)_2$ (M = La, Ce, Dy and Lu) in $CHCl_3$.

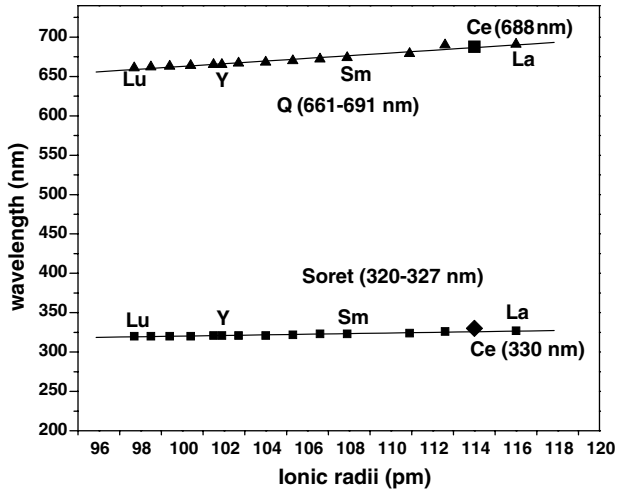

Fig. 2. Plot of wavelengths of the Soret and Q band absorptions of $M(Pc)_2$ as a function of the ionic radius of M^{III}/Ce^{IV}.

decreases because of the contraction of the radius of the rare earth metal ion [4]. Moreover, the extent of splitting of the Soret bands also undergoes a systematic change with this parameter.

Among the whole series of unsubstituted bis(phthalocyaninato) rare earth complexes, the cerium double-decker is particularly interesting. As indicated from the Raman and IR spectra [11,12], both the phthalocyanine rings exist as dianions in bis(phthalocyaninato) cerium $Ce(Pc^{2-})_2$ despite of the intermediate valence state between III and IV of the cerium, which differs from other analogues in the rare earth series in the form of $M^{III}(Pc^{2-})(Pc^{\cdot-})$ as shown in Fig. 1. The UV–Vis spectrum of $Ce(Pc^{2-})_2$ is very much resembling those of the reduced double-deckers of tervalent rare earths $[RE(Pc)_2]^-$ and $HRE(Pc)_2$ [9b,13], which in reverse demonstrates the dianion nature of the phthalocyanine rings in $Ce(Pc)_2$. The absence of the phthalocyanine π-radical anion around 454–491 nm clearly indicates the absence of a phthalocyanine radical anion in this double-decker. $Ce(Pc)_2$ shows strong band at 330 nm, which is attributed to the Soret band absorption of this complex. It is worth noting that $Ce(Pc)_2$ showed obvious Q-band splitting around 637 and 688 nm compared with those of tetravalent metal $M^{III}(Pc)_2$ (M = La...Lu, except Pm).

3.2. Electronic absorption spectra characteristics of bis[2,3,9,10,16,17,23,24-octakis(4-methoxyphenoxy)-phthalocyaninato] rare earth complexes M[Pc(MeO-PhO)$_8$]$_2$ (M = Y, La...Lu except Pm)

The electronic absorption spectra $M[Pc(MeOPhO)_8]_2$ were recorded in $CHCl_3$ and the data are summarized in Table S2. The spectral features resembled those of unsubstituted bis(phthalocyaninato) rare earth complexes [4,7], except that all the absorption bands were significantly red-shifted due to larger aromatic substituents.

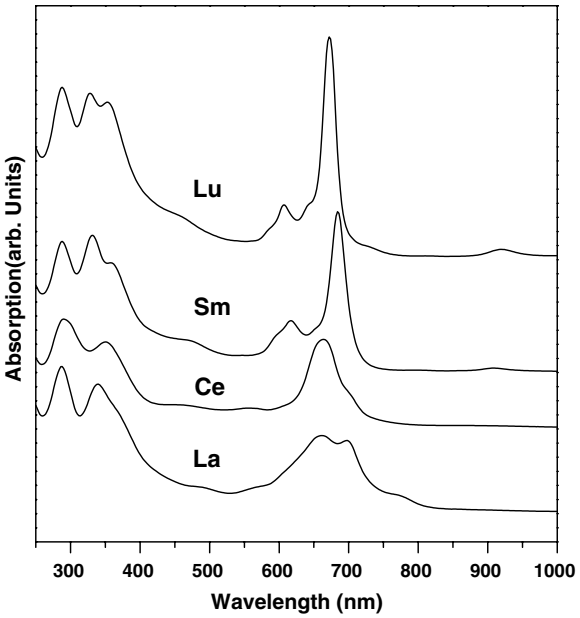

Fig. 3. Electronic absorption spectra of $M^{III}[Pc(MeOPhO)_8]$ (M = La, Ce, Sm and Lu) in $CHCl_3$.

Fig. 3 gives the electronic absorption spectra of La, Ce, Sm, and Lu sandwich complexes. It can be seen from Fig. 3 and Table S2 that all these homoleptic double-deckers (M = Y, La...Lu except Ce and Pm) exhibit split Soret band with maxima around 328–340 and 352–359 nm, which are analogous to those of related counterparts $M(Pc)_2$. Particularly, the introduction of electron-donating groups onto the Pc macrocycles induces a redshift for all the corresponding absorption bands compared with their unsubstituted analogs, indicating that the ring-ring interaction does not change significantly by introduction of these substituents onto the Pc macrocycle [4]. Both the Q band at 672–698 (M = Y, La...Lu except Ce and Pm) nm as the

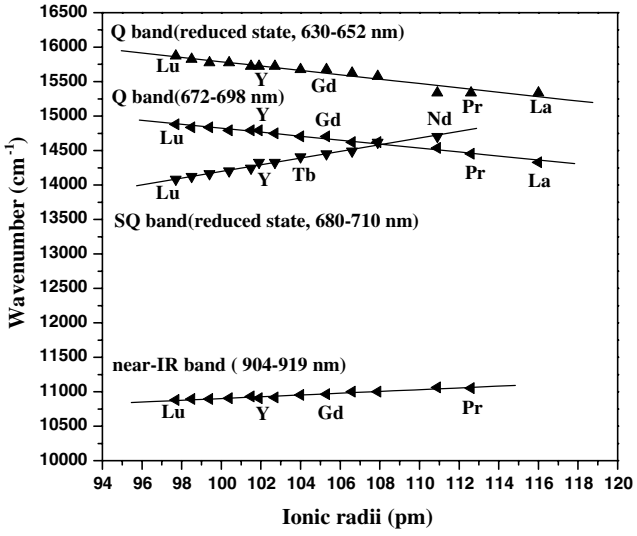

Fig. 4. Plot of wavenumbers of the three Q and one near-IR bands of $M^{III}[Pc(MeOPhO)_8]$ and $\{RE[Pc(MeOPhO)_8]_2\}^-$ as a function of the ionic radius of M^{III}.

most intense absorption band and the π-radical anion band at 455–485 nm as the very weak absorption band are shifted to the blue as the ionic radius of the tervalent metal cation decreases form La to Lu, as shown in Fig. 4. A similar trend was also observed for the broad near-IR band at 1542–2132 nm, which is characteristic of sandwich-type complexes with one unpaired electron in one of the rings [7,8], as shown in Fig. 5. Similar to the Pc and Por analogs [3,7,8], a linear correlation could be established between the wavenumbers of these absorptions and the rare earth ionic radii as shown in Fig. 4. All these observations indicate that the interaction between the two rings becomes stronger as the ring-ring separation decreases because of the contraction of the radius of the rare earth metal ion. Moreover, a weak near-IR absorption in the region of 904–919 nm from Pr to Lu also has a plot of the wavenumber against the ionic radius of M^{III} (except La and Ce), as illustrated in Fig. 4. It might be attributed to the electron transition from the semi-occupied HOMO orbital to the first unoccupied LUMO orbital [7]. It should be pointed out that the origins of the Near-IR absorptions at ca. 1257–1262 and 1419–1443 nm are not very clear. On the other hand, the compound of La[Pc(MeOPhO)$_8$]$_2$ shows a split Q band at 662 and 698 nm (Fig. 3), which is different from those of other complexes due to its unique electronic structure($4f^0 5d^1 6s^2$) [7].

Upon addition of hydrazine hydrate to solutions of the whole series (except Ce) in $CHCl_3/CH_3OH$ (5:1), the absorption spectra were remarkably changed and the resulting spectra could be attributed to the monoanions $\{M[Pc(MeOPhO)_8]_2\}^-$, in which both macrocycles are dianionic [7,8]. The spectral data for these anions are summarized in Table S3, and the spectra for La, Sm, and Lu double-deckers after being treated with hydrazine hydrate by comparison with Ce are shown in Fig. 6.

It is worth noting that no splitting of the Soret band was observed at about 350 nm for $\{M[Pc(MeOPhO)_8]_2\}^-$, which is unshifted upon reduction. These facts seem to suggest that the splitting of Soret band is due to the presence of $\{Pc[(MeOPhO)_8]\}^{\cdot -}$. The π-radical anion band was not exhibited and the Q band is splitted for these anions giving an intense and blue-shifted main band at 630–652 nm from Pr to Lu together with a weak and red-shifted satellite Q band (SQ) at 680–710 nm from Nd to Lu, as shown in Fig. 4. Fig. 4 shows plot of the wavenumbers of the two Q band components for these reduced bis(phthalocyaninato) rare earth compounds against the radii of the rare earth ions. It can be seen from Table S3 and Fig. 4 that the intense Q band (630–652 nm) of $\{M[Pc(MeOPhO)_8]_2\}^-$ undergoes a linear blue-shift with the decrease of the radius of the sandwiched metal ion, while conversely the satellite Q band at 680–710 nm shifts linearly to the red. Along with the lanthanide contraction, the satellite band shifts to lower energy (Table S3) and the intensity increases gradually, becoming a distinguishable band for Lu as shown in Fig. 6. So the energy gap between these two Q bands is enhanced by the decrease of ionic radius from La to Lu.

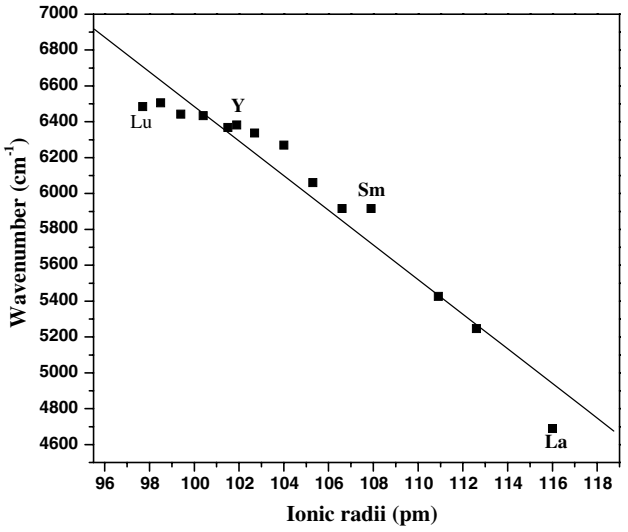

Fig. 5. Plot of wavenumber of the near-infrared band at 1542–2132 nm of $M^{III}[Pc(MeOPhO)_8]$ as a function of the ionic radius of M^{III}.

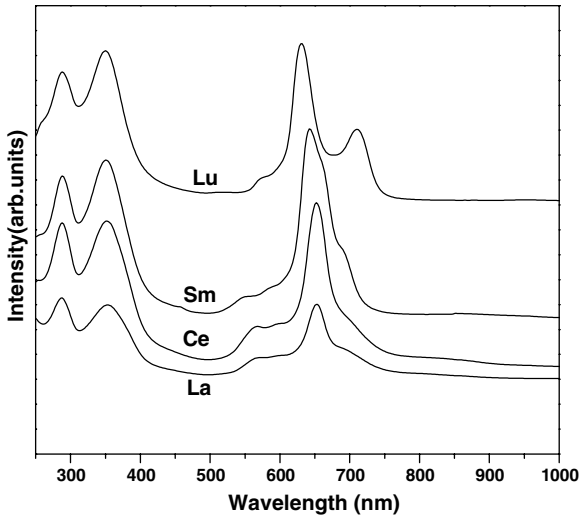

Fig. 6. Electronic absorption spectra of $\{M[Pc(MeOPhO)_8]_2\}^-$ (M = La, Ce, Sm and Lu) in $CHCl_3$/MeOH by addition of hydrazine hydrate.

As expected, the characteristic Near-IR band was not seen for these anions, showing that the single-hole species (except for M = Ce) underwent a one-electron ring-reduction. However, the extent of their Q-band splitting is different for different ionic size of the sandwiched metal. The light rare earths from La to Nd almost exhibited no distinguishable Q-band splitting in the electronic absorption spectra of their reduced sandwich-type bis(phthalocyaninato) compounds. Conversely, the middle and heavy rare earths after Nd usually showed obvious Q-band splitting in their electronic spectra, which was enhanced with the decrease of ionic size of the sandwiched metal. The enhanced splitting of the Q-bands obviously reflects the extent of π–π interaction of two Pc rings in the double-deckers.

As in $Ce(Pc)_2$, cerium in Ce[Pc(MeOPhO)$_8$]$_2$ also employs an intermediate valence state between III and IV [11,12] while both the substituted phthalocyanine rings

exist as dianions. $Ce[Pc(MeOPhO)_8]_2$ shows clear Soret band splitting at 290 and 350 nm, however, the Q band does not show obvious splitting compared with unsubstituted $Ce(Pc)_2$, as shown in Fig. 3. This observation is not consistent with that found in the double-decker $Ce(Pc)_2$. It might be attributed to the introduction of huge electron-donating substituents according to scattered reports [1,5,7].

3.3. UV–Vis characteristics of bis[3(4),12(13),21(22),30(31)-tetra(tert-butyl)-phthalocyaninato] rare earth complexes $M(TBPc)_2$ (M = Y, La...Lu except Pm)

The electronic absorption spectra of the whole series of sandwich double-decker compounds were measured in $CHCl_3$ and the data are collected in Table S4. The spectral characteristics resembled those of unsubstituted bis(phthalocyaninato) rare earth complexes [4]. However, it is noteworthy that the intensity of phthalocyanine π-radical anion band at 470–501 nm and the band at 603–621 nm and the extent of their Soret band splitting increase by comparison with those of $M(Pc)_2$, showing obvious molecular symmetry effect (Table S4). The possible reason is that the presence of *tert*-butyl substituents on the phthalocyanine rings multiplies the intensity of certain UV–Vis absorptions due to the lower symmetry and probably distortions in the macrocycle rings. As might be noticed from Fig. 7 and Table S4, the complexity in the number of the UV–Vis spectra of $M(TBPc)_2$ compared with those of unsubstituted and octa(4-methoxyphenoxy)-substituted bis(phthalocyaninato) rare earth complexes indeed reminds us of the decreased molecular symmetry of these compounds.

Fig. 7 shows the UV–Vis spectra of four compounds $M^{III}(TBPc)_2$ (M = La, Ce, Sm and Lu), typical for the light, middle, and heavy rare earths, respectively. Due to the similar molecular structure among the whole series of

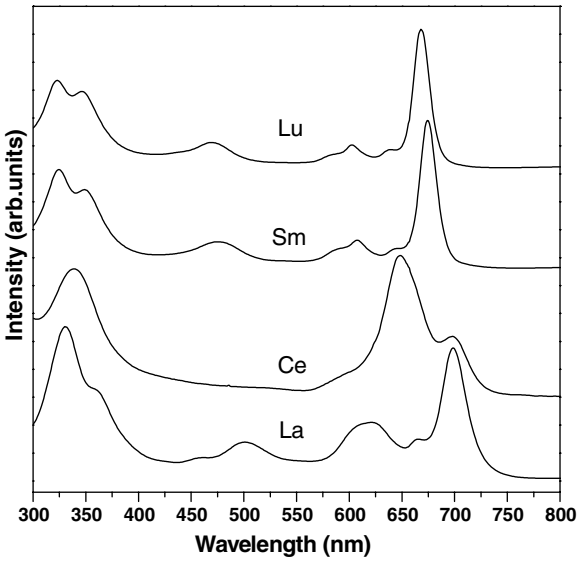

Fig. 7. Electronic absorption spectra of $M(TBPc)_2$ (M = La, Ce, Dy and Lu) in $CHCl_3$.

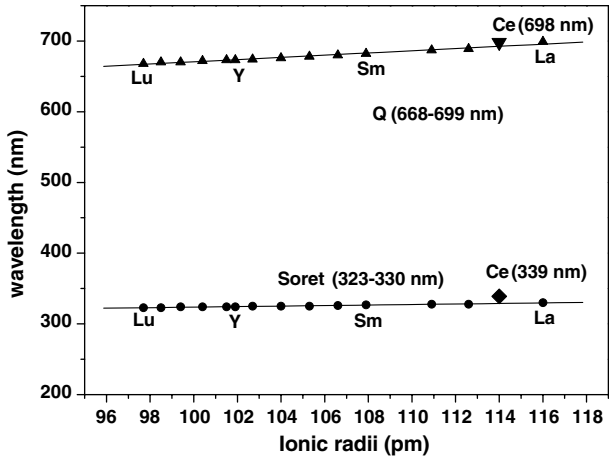

Fig. 8. Plot of wavelengths of the Soret and Q band absorptions of $M(TBPc)_2$ as a function of the ionic radius of M^{III}.

bis(phthalocyaninato) lanthanide compounds, all these compounds show similar UV–Vis characteristics [1–4]. As can be clearly seen from Table S4 that $M^{III}(TBPc)_2$ (except Ce) exhibit a obvious split Soret band with maxima around 323–330 and 335–351 nm, an intense Q band at 668–699 nm and a π-radical band at 470–501 nm. Because of the introduction of *tert*-butyl substituents and the contraction of the lanthanides, the number of the UV–Vis absorption bands increases and all the corresponding absorption wavelengths are systematically red-shifted compared with those unsubstituted $M^{III}(Pc)_2$, clearly showing molecular symmetry effect and substituent effect. Meanwhile, all the corresponding absorptions are systematically blue-shifted along with the decrease of rare earth ionic size from La to Lu as shown in Fig. 8, displaying evident the rare earth ionic size effect.

We now move to the cerium compound, whose UV–Vis spectroscopic data are different from those of the rest of the whole series, but resembles those of $[RE(Pc)_2]^-$ and $HRE(Pc)_2$ due to their similar electronic structures [9,13,14], as shown in Fig. 7. As indicated by the IR absorption and ^1H NMR spectra [15], the two phthalocyanine rings exist as dianions in $Ce(TBPc^{2-})(TBPc^{2-})$ despite the XANES results that suggest a valence state intermediate between III and IV for the cerium [1–4]. This makes the complex differ from other analogues that have the form $M(TBPc^{2-})$-$(TBPc^{\bullet-})$. This is supported by the fact that the UV–Vis absorption of characteristic π-radical band at 470–501 nm was not observed (Table S4). However, the Q band shows obvious splitting at 648 and 698 nm. This observation is well consistent with that found in the double-decker $Ce(Pc)_2$.

3.4. Electronic absorption spectra characteristics of mixed [tetrakis(4-chlorophenyl)porphyrinato](phthalocyaninato) rare earth double-decker complexes M(TClPP)(Pc) (M = Y, La...Lu except Pm)

The electronic absorption spectra of the series of sandwich double-decker compounds were measured in $CHCl_3$

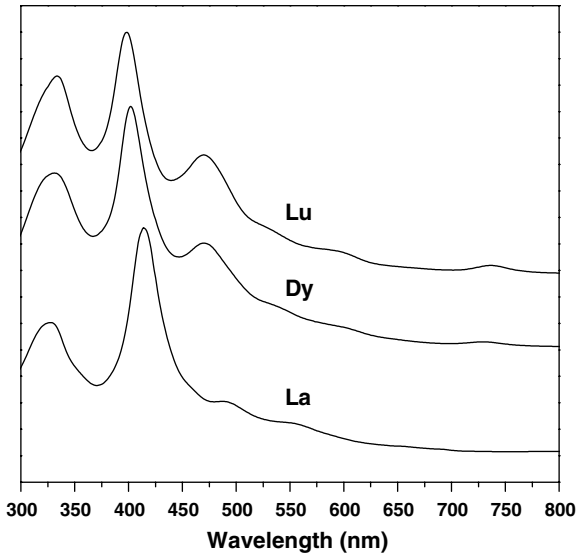

Fig. 9. Electronic absorption spectra of M(TClPP)(Pc) (M = La, Dy and Lu) in $CHCl_3$.

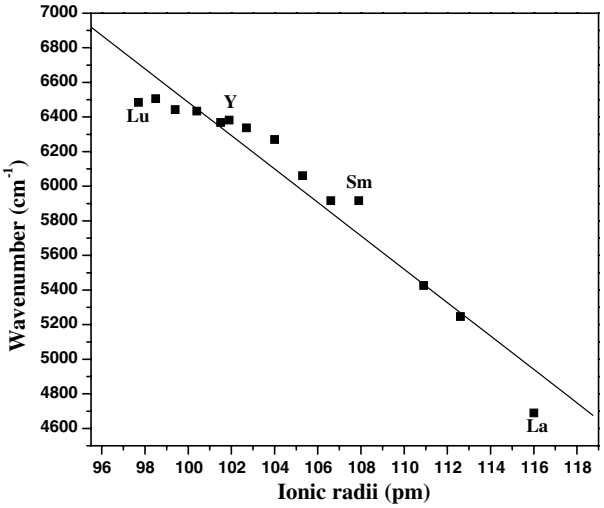

Fig. 10. Plot of wavenumber of ring-to-ring charge transfer transition from the second HOMO to the first semi-occupied HOMO of M^{III}(TClPP)(Pc) at ca. 1148–1418 nm as a function of the ionic radius of M^{III}.

and the data are compiled in Table S5. The dependence of the spectral features of the double-deckers on the metals is illustrated with electronic absorption spectra of M(TClPP)(Pc) for M = La, Dy, Lu as shown in Fig. 9, which are analogous to those reported for related counterparts M(Por)(Pc) (Por = TPP, TBPP, TMPP, TPyP) [16–19]. M(TClPP)(Pc) show strong Pc and TClPP Soret bands at 328–334 and 398–414 nm, respectively. The absorptions at 469–492 and 923–1089 nm for the various rare earth complexes are attributed to the electron transition related to the hole localized on the Pc ring. Similar to the Soret bands of Pc and TClPP, the absorption positions of these two bands are also sensitive to the ionic radii of the metal center. When the metal center becomes smaller, the longer-wavelength near-IR band (923–1089 nm) shifts gradually to the red, while the former one is blue-shifted (Table S5). Furthermore, for the whole series of tervalent rare earth double-deckers M(TClPP)(Pc), an additional near IR band at 1148–1418 nm with a shoulder at 1587–1693 nm can also be observed (Table S5). This band, which is highly characteristic for the single-hole homoleptic double-decker tetrapyrrole compounds $M^{III}(Pc')_2$ (Pc′ = Pc [20], OOPc [21]) and $M^{III}(Por)_2$ (Por = OEP, TPP) [22], can be similarly attributed to an electron transition from the second HOMO which contains primarily TClPP character to the first semi-occupied HOMO with mainly Pc character [23]. Meanwhile, the frequency of this charge-transfer transition is also dependent on the rare earth ionic size, shifting linearly to the higher energy along with the decrease of rare earth radius as shown in Fig. 10, making the separation between the two near-IR band at 923–1089 and 1148–1418 nm get smaller along with the same order (Table S5). As shown in Fig. 11, the two near-IR bands for Lu(TClPP)(Pc) almost coalesce to form a broad signal. This result is in line with that observed for

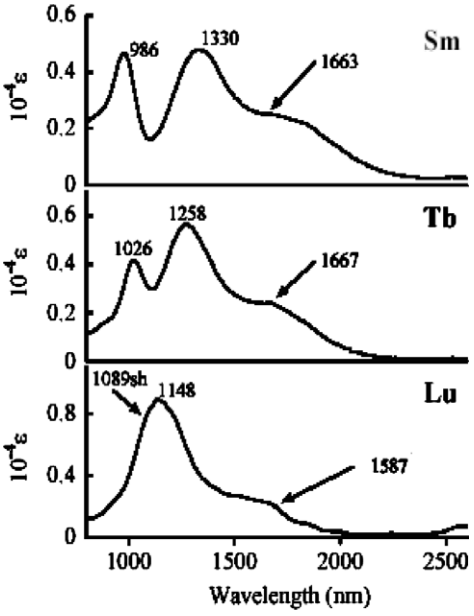

Fig. 11. Near-IR regional electronic absorption spectra of M(TClPP)(Pc) for M = Sm, Tb, and Lu in $CHCl_3$.

M(OEP)(Nc) [24]. It is likely that this absorption was overlapped by the one in the region of 1025–1146 nm for all the rare earth complexes in their spectra [25]. Interestingly, a weak absorption in the region of 689–738 nm, which is ignored for analogous compounds in the previous work [16–19], was observed for the series of tervalent rare earth mixed ring double-deckers. Both the intensity and the wavelength of this band are sensitive to the rare earth metal. Along with the lanthanide contraction, this band gradually gets some intensity, becoming an obviously distinguishable band for Lu(TClPP)(Pc), as shown in Fig. 9, and shifts to the lower energy (Table S5). This absorption

is mainly contributed from the Q absorptions of phthalocyanine ligand together with some contribution also from the Q absorptions of Porphyrin ring [8].

In mixed double-deckers M(TClPP)(Pc), the close proximity of the TClPP and Pc conjugated π-systems, in a face-to-face configuration induces the splitting of the monomer (one TClPP and one Pc) molecular orbital due to the interactions between the rings, resulting in two doubly degenerate (e_g) lowest unoccupied molecular orbital (the LUMO and second LUMO) and two non-degenerate (a_{1u}) highest occupied molecular orbital (the HOMO and second HOMO), as shown in Fig. 12 [8,26]. Due to the intrinsic difference between the molecular composition and electronic structure of TClPP and Pc, the a_{1u} orbital of Pc is higher in energy than that of TClPP while the e_g orbitals are lower than those of TClPP. Therefore both the HOMO and LUMO of M(TClPP)(Pc) are mainly contributed from the phthalocyanine ligand whereas the second HOMO and second LUMO with more TClPP character. However, the Pc-dominated HOMO level of the mixed (porphyrinato)(phthalocyaninato) double-deckers is semi-occupied, making for some unique spectral features. In the spectra of M(TClPP)(Pc), the absorption band at 923–1089 nm, which shifts slightly to the red with decreasing the metal ionic radius, is proposed to be due to the electronic transition from the semi-occupied HOMO to the degenerate LUMO [8,26]. Meanwhile, the absorption of even lower energy at 1148–1418 nm is due to the transition from the second HOMO to the semi-occupied HOMO [8]. The energy of the latter transition reflects the extent of electronic coupling between the macrocycles, which increases as the size of the metal center decreases. As mentioned above, the absorption positions of the band at 470–492 nm are also dependent on the central rare earth metal. This absorption is attributed to the electron transition from a deeply-occupied molecular orbital with both TClPP and Pc character to the semi-occupied HOMO [8].

When the Pc macrocycle in the homoleptic phthalocyaninato rare earth double-deckers are replaced by the porphyrin ring, which possesses a nearly extended π-system, a very similar electronic absorption spectrum is observed [4,8]. To summarize, it is obvious that there are many common features and correlations between the homoleptic and the mixed sandwiches. The characteristics of electronic spectra for the mixed porphyrinato and phthalocyaninato metal double-deckers could be easily understood and explained by analogy with their homoleptic counterparts, not clearly showing macrocycle effect due to similar extended π-system between the porphyrin and phthalocyanine rings. For instance, a linear correlation between the energies of near-IR absorptions and the sandwiched rare earth metal radii also exists in the double-decker M(TClPP)(Pc) [8]. Moreover, both the Soret and Q bands in the absorption spectra of mixed (porphyrinato)(naphthalocyaninato) rare earth complexes undergo evident redshift compared with those in mixed (porphyrinato)(phthalocyaninato) derivatives, as expected because of the introduction of naphthalocyanine chromophores, showing obvious macrocycle ring effect [27].

The absorption spectra of Ce(TClPP)(Pc) resembles those of [M^{IV}(TPP)(Pc)] (M = Zr, Hf, Th and U) [28], Li[M^{III}(TPyP)(Pc)] (M = Eu and Gd) [19], in which both of the rings are regarded as dianionic. For instance, the spectrum of Ce(TClPP)(Pc) shows strong Pc and TClPP Soret bands at 332 and 400 nm, respectively, and the Q bands at 562, 626, and 826 nm as shown in Fig. 13. The spectrum also shows the shoulder at 468 nm, which can be attributed to transitions from delocalized orbital involving both macrocycles [28]. The spectrum of Ce(TClPP)(Pc) is very different from those of [M^{III}(Por)(Pc)] [19,29]. Particularly, the characteristic near-IR absorption due to π-radical anion was not detected, as shown in Fig. 13. These data strongly suggest that the cerium center in Ce(TClPP)(Pc) is predominantly tetravalent.

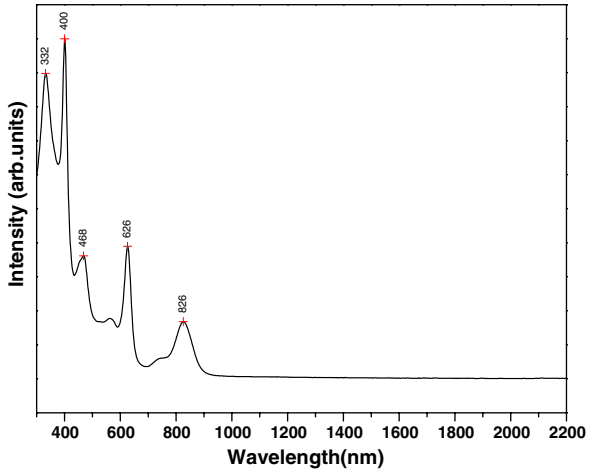

Fig. 13. Electronic absorption spectra of Ce(TClPP)(Pc) in $CHCl_3$.

4. Conclusions

According to the electronic absorption spectra investigation, all the corresponding absorptions are systematically blue-shifted, clearly revealing the rare earth size effect. In conclusion, the influence of the symmetry of macrocycle rare earth molecules, the effects of ionic radius of the rare earth metal and the influence of substituent species (*tert*-butyl and 4-methoxyphenoxy groups) onto the peripheral benzene rings on the electronic absorption characteristics of sandwich-type compounds have also been detailed studied by means of comparative research over the electronic absorption spectra of unsubstituted, substituted bis(phthalocyaninato) and mixed [tetrakis(4-chlorophenyl)porphyrinato](phthalocyaninato) rare earth complexes of the whole lanthanide series, namely $M(Pc)_2$, $M[Pc(MeOPhO)_8]_2$, $M(TBPc)_2$, and M(TClPP)(Pc).

solution [21–24] and other methods [24–26]. It remains a challenge to find a novel and simple synthetic route for one-dimensional nanosized materials. The use of single-source molecular precursors for nanoparticles, was initially reported by Trindade and O'Brien [27,28] and such methods have provided efficient routes to high quality crystalline monodispersed nanoparticles of semi-conducting material. This method has been used with alkylthiourea complexes to prepare metal sulfide nanoparticles [7,29]. The cadmium(II) complexes of thiourea and *N*-alkylthioureas (where alkyl groups = methyl, ethyl, isopropyl and cyclohexyl) have been reported as precursors for the preparation of TOPO-capped CdS nanoparticles [7,30].

In this paper we report on the use of *N*,*N*′-diisopropylthiourea and *N*,*N*′-dicyclohexylthiourea cadmium(II) complexes as single-source precursors for the synthesis of the HDA-capped CdS nanoparticles. These alkyl substituted thiourea cadmium complexes are very easy to prepare, air-stable for very long periods and the HDA provides a more stable capping environment on the surface of nanoparticles. The crystal structures of the two complexes are also discussed.

2. Experimental

2.1. General

HDA (hexadecylamine) and TOP (tri^{n}octylphosphine) were purchased from Aldrich. Toluene and methanol were obtained from BDH. Toluene was stored over molecular sieves (40 Å, BDH) before use. Cadmium acetate, *N*,*N*′-diisopropylthiourea, *N*,*N*′-dicyclohexylthiourea and ethanol (analytical grade) obtained from Aldrich, were used as purchased to prepare the precursors.

2.2. Optical characterization

A Perkin–Elmer Lambda 20 UV–Vis Spectrophotometer was used to carryout the optical measurements and the samples were placed in silica cuvettes (1 cm, path length), using toluene as a reference solvent. A Jobinyvon-spex-Fluorolog-3-Spectrofluorimeter with a xenon lamp (150 W) and a 152 P photo multiplier tube as a detector was used to measure the photoluminescence of the particles. The samples were placed in quartz cuvettes (1 cm path length).

2.3. Electron microscopy

The TEM and HRTEM images were obtained using a Philips CM 200 compustage electron microscope operated at 200 kV with a EDS analyzer. The samples were prepared by placing a drop of a dilute solution of sample in toluene on a copper grid (400 mesh, agar). The samples were allowed to dry completely at room temperature.

2.4. X-ray diffraction

X-ray diffraction patterns on powdered samples were measured on Phillips X'Pert materials research diffractometer using secondary graphite monochromated Cu Kα radiation ($\lambda = 1.54060$ Å) at 40 kV/50 mA. Samples were supported on glass slides. Measurements were taken using a glancing angle of incidence detector at an angle of 2°, for 2θ values over 20–60° in steps of 0.05° with a scan speed of $0.01°2\theta\ s^{-1}$.

2.5. Microanalysis

Microanalysis was performed on a CARLO ERBA elemental analyzer for C, H, N, S.

2.6. X-ray crystallography

X-ray data were collected on a Bruker APEX CCD [31] diffractometer with Mo Kα radiation ($\lambda = 0.71069$ Å) using ϕ and ω scans. The crystals were mounted using a drop of fomblin (perfluoropolymethylisopropyl ether) oil in a Hamilton Cryoloop and sample cooling was achieved using a nitrogen gas stream from an Oxford Cryosystems 700 Series Cryostream Cooler. The data were processed using SAINT [32] and empirical absorption corrections were applied using SADABS [31]. Because the crystals of compound **I**, $[Cd(CH_3COO)_2(SC(NHC_6H_{11})_2)_2]$ diffracted very weakly, the data were cut at 0.95 Å resolution for this sample. The structures were solved by direct methods using SHELXS97 [33] and refined anisotropically (non-hydrogen atoms) by full-matrix least-squares on F^2 using SHELXL-97 [33]. The H atoms were calculated geometrically and refined with a riding model. In compound **II**, $Cd(CH_3COO)_2(SC(NHC_3H_7)_2)_2]$ atoms O1 and O2 were disordered over two sites whose occupancies were constrained to sum to 1.0, with the highest fraction refining to an occupancy of 0.579(9). The SHELXTL package [31] was used for all the calculations and preparation of the plots for publication.

2.7. NMR and FT-IR spectroscopy

Infrared spectra were recorded on FT-IR Perkin–Elmer paragon 1000 spectrophotometer using Nujol mull. NMR spectra were recorded on a Varian Associates Inova spectrometer (400 and 300 MHz).

2.8. Synthesis of precursors

2.8.1. $[Cd(CH_3COO)_2(SC(NHC_6H_{11})_2)_2]$ (**I**)

A hot solution of *N*,*N*′-dicyclohexylthiourea (1.00 g, 4.17 mmol) in ethanol (20 mL) was added into a heated solution of cadmium acetate (0.48 g, 2.08 mmol) in ethanol (25 mL). The mixture was stirred while hot for 1 h and allowed to cool to room temperature. The solution was filtered and left in a covered beaker at room temperature to

give yellow crystalline product after 24 h. The product was filtered, washed twice with ethanol and dried under vacuum. Yield 1.26 g, 87.9%; m.p. 138.5–142.7 °C. *Anal.* Calc. for $C_{30}H_{54}N_4O_4S_2Cd$: C, 50.68; H, 7.60; N, 7.80; S, 9.01. Found: C, 49.73; H 7.47; N 7.46; S 8.51%. IR (Nujol mull)/cm^{-1}: 3240(m), 2931(s), 2854(m), 1543(vs), 1419(vs), 1342(sh), 1234(w), 1157(vw), 1095(vw), 987(vw), 894(w), 756(m). ^1H NMR (δ, $CDCl_3$) ppm: 2.21 (s, 3H, CH_3COO); 2.10 (br, s, 1H), 1.78 (br, s, 4H), 1.64 (br, d, 4H) and 1.25 (m, 2H, $-C_6H_{11}$). $^{13}C\{^1H\}$ NMR (δ, $CDCl_3$) ppm: 53.51(s, CH_3–CH_3COO), 32.79, 31.21, 25.59 and 25.02 (s, C_6H_{11}).

2.8.2. *[Cd(CH$_3$COO)$_2$(SC(NHC$_3$H$_7$)$_2$)$_2$] (**II**)*

A hot solution of *N*,*N*′-diisopropylthiourea (1.00 g, 6.25 mmol) in ethanol (20 mL) was added into a heated solution of cadmium acetate (0.72 g, 3.13 mmol) in ethanol (20 mL). The mixture was stirred and refluxed for 1 h. The yellow solution was filtered hot to remove any traces of unreacted materials and was left in an open beaker at room temperature. Yellow crystalline product was obtained after 24 h. The product was filtered, washed twice with ethanol and dried under vacuum. Yield 1.44 g, 83.5%; m.p. 148.5–152.7 °C. *Anal.* Calc. for $C_{18}H_{38}N_4O_4S_2Cd$: C, 39.54; H, 6.90; N, 10.71; S, 11.83. Found: C, 40.34; H 7.37; N 11.02; S 12.51%. IR (Nujol mull)/cm^{-1}: 3255(m), 2878(s), 1558(vs), 1404(vs), 1280(s), 1156(s), 1002(m), 941(w), 848(vw). ^1H NMR (δ, $CDCl_3$) ppm: 2.19 (s, 3H, CH_3COO); 2.07 (s, 1H, $CH(CH_3)_2$); 1.24 (d, 6H, $CH(CH_3)_2$). ^{13}C $\{^1H\}$ NMR (δ, $CDCl_3$) ppm: 207.35 (s, COO), 179.38 (s, CS); 46.52 (s, CH_3, CH_3COO), 31.19 (s, CH) and 22.58 (s, CH_3–CH_3COO).

2.8.3. *Method for the preparation of CdS nanoparticles*

In a typical experiment, $[Cd(CH_3COO)_2(SC(NHC_6H_{11})_2)_2]$ (1.0 g, 2.12 mmol) was dissolved in TOP (10–20 mL). This solution was then injected into 6.25 g (25.9 mmol) of hot HDA at 180 or 240 °C, a decrease in temperature of 20–30 °C was observed. The solution was allowed to stabilize at 180 °C and heated for 60 min at this temperature. The solution was then allowed to cool to about 70 °C, and methanol was added to remove excess HDA. A flocculent precipitate formed and this solid product was separated by centrifugation and redispersed in toluene. Toluene was removed by evaporation under reduced pressure to give yellow HDA-capped CdS nanoparticles. The particles were washed three times with methanol and redispersed in toluene.

3. Results and discussion

3.1. Description of structures of complexes

Both complexes were subjected to single crystal X-ray structural analysis after recrystallization from ethanol or methanol by slow evaporation at room temperature which gave transparent cubic crystals. These were stable to air and moisture with melting points in the range between 138 and 152 °C and reasonably good yields. The formulae of the resulting complexes were consistent with the molecular structures and other forms of analyses such as microanalysis, infrared and NMR spectroscopy. Details of the crystal data and structure refinements are provided in Table 1. ORTEP diagrams of complexes **I** and **II** with the non-hydrogen atomic labelling scheme are shown in Figs. 1 and 2, respectively. Selected bond lengths and angles are given in Tables 2 and 3.

The structure of complex $[Cd(CH_3COO)_2(SC(NHC_6H_{11})_2)_2]$ (**I**) (Fig. 1) comprises a six coordinate Cd(II) ion in a distorted octahedron with two S atoms and four O atoms from the acetate ligands. The Cd–S bond distances are slightly longer than for the corresponding chloro complex, dichlorobis(*S*-thiourea)cadmium(II) (Cd–S; 2.517(1) Å) [34] and are 2.588(4) Å for Cd(1)–S(1) and 2.568(4) Å for Cd(1)–S(2). The first acetate ligand has unequal bond distances to Cd of 2.279(8) Å for Cd(1)–O(1) and 2.612(10) Å for Cd(1)–O(2) indicating that it is verging on being monodentate. The second acetate ligand has nearly equal bond distances to Cd of 2.425(12) Å for Cd(1)–O(3) and 2.382(14) Å for Cd(1)–O(4). The C–S

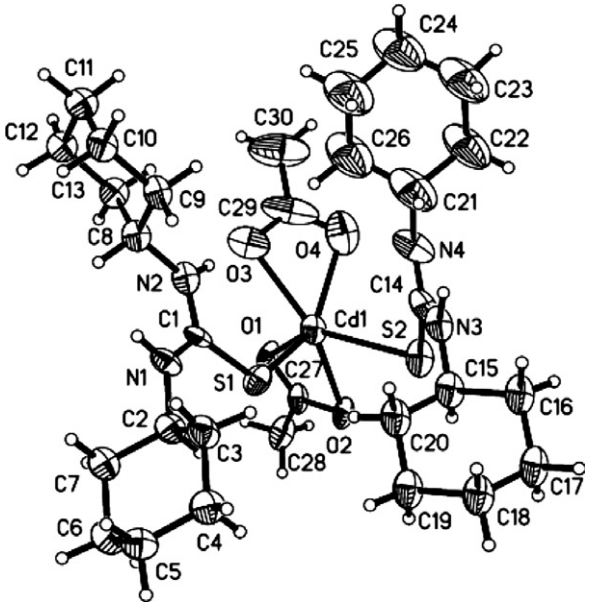

Fig. 1. Molecular structure of complex **I**, $[Cd(CH_3COO)_2(SC(NHC_6H11)_2)_2]$ with thermal ellipsoids drawn at the 50% probability level.

and C–N bonds in alkylthiourea ligands show intermediate character between a single and a double bond length. These bond distances are in good agreement with those of thiourea molecules reported in the Cambridge Structural database (CSD by Allen et al. [35] in 1991) i.e. 1.726 (C–S) and 1.322 Å (C–N). The additional C–N bond due to the hexyl carbon atoms attached to the nitrogen atoms are of a single bond character with an average bond distance of 1.455 Å. The C–O bond distances average at 1.28 Å, is intermediate between a single and double bond length for the bidentate acetate ligands. The bond angles around the O–Cd–O in each acetate ligand gave an average of 54.1°. This also confirms the chelating effect of the acetate ligand. The bond angle between the alkylthiourea ligands, S(2)–Cd(1)–S(1) is 92.6(1)°, whereas those angles between the oxygen atoms and sulfur atoms of the ligands vary from 78.0(2)° (S(2)–Cd(1)–O(2)) to 137.3(3)° (O(3)–Cd(1)–S(2)). All the bond angles show a large degree of distorted octahedral geometry (Table 2).

The structure of complex **II**, $[Cd(CH_3COO)_2(SC(NHC_3H_7)_2)_2]$ (Fig. 2) has as a four/five coordinate cadmium with two diisopropylthiourea ligands and two/three oxygen atoms of the acetate ligands, one of which has disordered oxygen atoms. The Cd–S bond distances are similar to those in complex **I**, $[Cd(CH_3COO)_2(SC(NHC_6H_{11})_2)_2]$, (Tables 2 and 3) One of the acetate groups is monodentate, whilst the oxygen atoms of the other are disordered over two sites each, with the higher occupancy fraction monodentate and the lower occupancy fraction bidentate. The monodentate components of the two acetate ligands have bond distances to Cd(1) which are shorter than those for complex **I**, 2.212(5) Å for Cd(1)–O(2) and 2.240(2) Å for Cd(1)–O(3). The bidentate component has Cd–O bond distances of 2.338(6) Å (Cd(1)–O(1B)) and 2.395(6) Å (Cd(1)–O(2B)). The C–O distances average at 1.25 Å. The co-ordination around

Fig. 2. 		S(2)–Cd(1)–O(2)	78.0(2)
		S(1)–Cd(1)–O(2)	107.4(2)
		S(2)–Cd(1)–S(1)	92.63(14)

Table 3
Selected bond distances (Å) and bond angles (°) for complex **II**

Bond distances (Å)		Bond angles (°)	
Cd(1)–O(1B)	2.338(6)	O(2)–Cd(1)–O(3)	104.24(19)
Cd(1)–O(2)	2.212(5)	O(2)–Cd(1)–O(1B)	36.9(2)
Cd(1)–O(3)	2.240(2)	O(1B)–Cd(1)–O(2B)	53.6(2)
Cd(1)–S(1)	2.5362(7)	O(3)–Cd(1)–S(1)	130.12(5)
Cd(1)–S(2)	2.5803(8)	O(3)–Cd(1)–S(2)	97.54(7)
Cd(1)–O(2B)	2.395(6)	O(1B)–Cd(1)–S(1)	122.4(2)
		O(2B)–Cd(1)–S(1)	98.09(19)
		S(2)–Cd(1)–S(1)	103.45(3)
		O(3)–Cd(1)–O(1B)	99.3(3)
		O(3)–Cd(1)–O(2B)	84.7(3)

the Cd(II) ion is a distorted tetrahedral geometry for the disordered component with the monodentate acetate and distorted square pyramidal for the component with the bidentate acetate. The O–Cd–O bond angle between the two monodentate acetate ligands is 104.2(2)° (O(2)–Cd(1)–O(3)). The bond angle between the alkylthiourea ligands, S(2)–Cd(1)–S(1) is 103.45(3)°, which is larger than for complex **I** (92.6(1)°). Other geometric parameters are shown in Table 3.

3.2. Synthesis of HDA-capped CdS nanoparticles

The precursors **I** and **II** were subjected to thermolysis in HDA at the temperatures of 180 °C and 240 °C and also varying the concentration of reactants. The amount of HDA used were 3.13 g, 6.25 g, 12.50 g and 25.00 g in each case with 1.00 g of precursor. The nanoparticles were synthesized at different precursor concentration using between 1.25 g and 12.50 g of HDA. Previous reports suggest that high concentrations favour anisotropic growth whereas lower concentrations favour isotropic growth [36]. Particles showed some degree of dependence on concentration of their shapes with higher concentration giving rod-shaped material and lower temperatures one with spherical shapes. It is evident that thermolysis of these precursors produced CdS nanoparticles with a variety of properties which are not directly influenced by the alkyl groups on the thiourea ligands but by other factors such as temperature, time and concentration. Cadmium complexes of thiosemicarbazide have been reported to produce CdS nanorods, in which their morphology is thought to affect their optical properties [28]. It was also observed by Li et al. [21] that temperature in combination of other conditions such as concentration greatly influences the morphology of nanoparticles from spherical to rod-shaped.

3.3. Optical properties of CdS nanoparticles

3.3.1. Effect of concentration on CdS nanoparticles

Macrocrystalline hexagonal CdS particles have an optical band gap of 2.41 eV (515 nm) at room temperature. The band-edges for CdS samples prepared in this study are blue-shifted in relation to the bulk material. This effect is associated with the CdS nanoparticles being smaller than the exciton radius of bulk CdS. During preparation there is generally an increase of particle size of the nanoparticles with time, which is consistent with an Ostwald ripening process. After injection of the precursor there is a critical size dependence on the concentration of the precursor. The depletion of the precursor causes the size distribution to broaden because smaller, less stable particles aggregate to form larger particles.

Figs. 3 and 4 shows absorption and photoluminescence spectra of CdS nanoparticles prepared from complex **I**, respectively, those for complex **II** are shown in Figs. 5 and 6. The optical band-edge showed a blue-shift in relation to bulk of 515 nm indicative of the decrease in particle size. As the concentration is decreased, from a 1:1 ratio to 1:8, there was a decrease in absorption band-edge, relating to a decrease in particle sizes. The sizes can be approximated to 5.96 nm (1:8) to 6.2 nm (1:1), for precursor **I**, and 5.7 nm (1:8) to 6.3 nm (1:1) for precursor **II** using Brus equation [37,38]. The photoluminescence spectra in Fig. 4 were all red-shifted from the absorption edges. They also

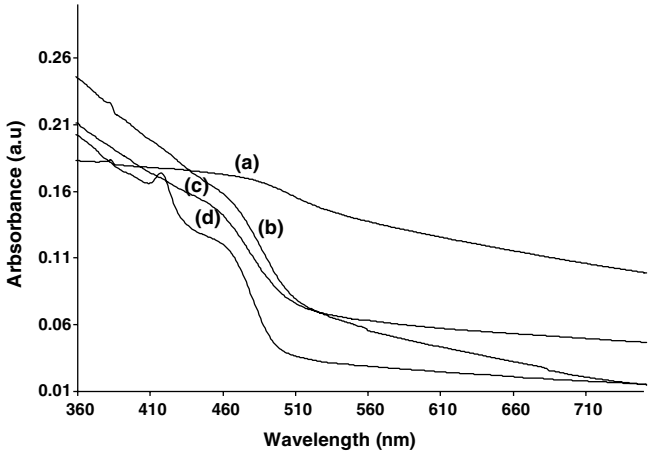

Fig. 3. Absorption spectra of HDA-capped CdS nanoparticles from complex **I** synthesized at 180 °C by varying the concentration, (a) 1:1 (b) 1:2 (c) 1:4 and (d) 1:8.

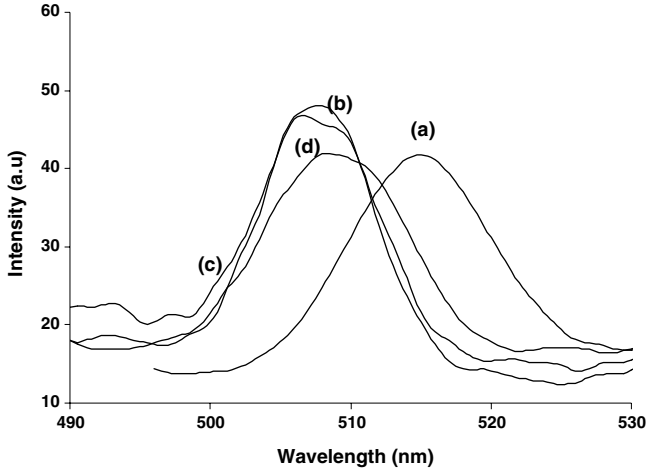

Fig. 4. Photoluminescence spectra of HDA-capped CdS nanoparticles from complex **I** synthesized at 180 °C by varying the concentration, (a) 1:1 (b) 1:2 (c) 1:4 and (d) 1:8.

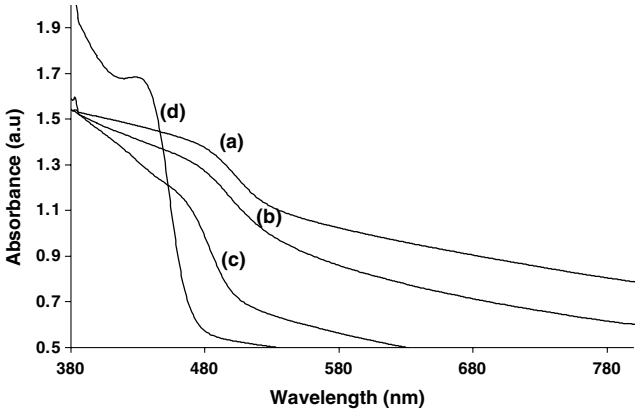

Fig. 5. Absorption spectra of HDA-CdS nanoparticles from complex **II** synthesized at 180 °C by varying the concentration, (a) 1:1 (b) 1:2 (c) 1:4 and (d) 1:8.

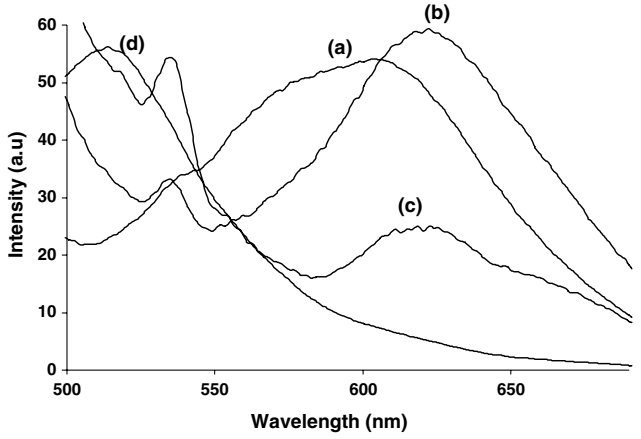

Fig. 6. Photoluminescence spectra of HDA-capped CdS nanoparticles from complex **II** synthesized at 180 °C by varying the concentration, (a) 1:1 (b) 1:2 (c) 1:4 and (d) 1:8.

showed good particle size distribution due to the relatively narrow peaks as well as good surface passivation evident from single smooth peaks being obtained. At higher concentration (1:1 ratio) the absorption band-edge for complex **I** indicate tailing which is usually associated with wide size distribution of particles but in this case caused by the formation of rod-shaped particles. It was observed by Cheon and co-workers [36] that the formation of rod shape particles changes the optical properties. The lower concentration shows a well-defined excitonic peak characteristic of spherical CdS nanoparticles. The CdS particles showed the largest emission maxima (with the large red-shift) for the concentration ratio 1:2 obtained from complex **II** at the same excitation and temperature in relation to other concentration ratios (Fig. 6). In contrast the concentration ratio 1:8 gave the lowest emission maximum (515 nm). The second emerging peaks at lower wavelength for the emission spectra of complex **II** could be associated with the surface defects. This is in comparison to the well passivated CdS nanoparticles prepared from complex **I** (Fig. 4).

3.3.2. Effect of temperature on CdS nanoparticles

Temperature has been proven to have a major effect on size, generally with particle sizes increasing with increasing temperatures [28,29]. The CdS nanoparticles were prepared using 1:2 molecular ratio of precursor in HDA at temperatures 180–240 °C. The absorption spectra in Fig. 7 have band-edges (491, 508 nm) blue-shifted from bulk. The sample prepared at a higher temperature had a well-defined excitonic peak with a sharp band-edge, an indication of monodispersity. The difference in the quality of the samples is further substantiated by their photoluminescence spectra (Fig. 8). The samples prepared at a lower temperature have a narrow PL peak with an emission maximum at 521 nm, red-shift in relation to the band-edge. The higher temperature sample shows a slightly broader peak with the maximum at 539 nm.

3.4. Structural properties of CdS nanoparticles

CdS nanoparticles can exist either as the cubic, orthorhombic or hexagonal phase and the existence of a mixture

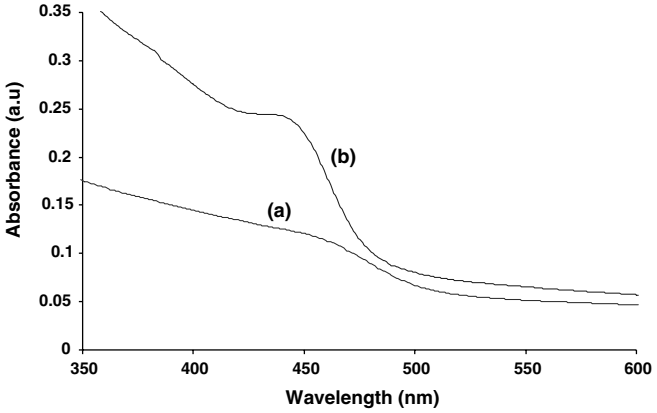

Fig. 7. Absorption spectra of CdS nanoparticles prepared from dicyclohexylthiourea (**I**) at (a) 180 °C and (b) 240 °C.

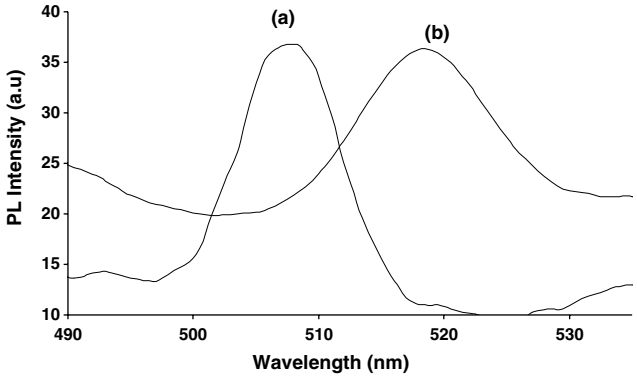

Fig. 8. Photoluminescence spectra of CdS nanoparticles prepared from dicyclohexylthiourea (**I**) at (a) 180 °C and (b) 240 °C.

of cubic and hexagonal phase with the predominance of one over the other was reported by Bawendi et al. [39] for CdSe. The powder X-ray diffraction patterns of CdS nanoparticles synthesized from the alkylthiourea complexes at 180 °C using a ratio of 1 mol of the precursor: 2 mol HDA, are shown in Fig. 9. Both patterns can be

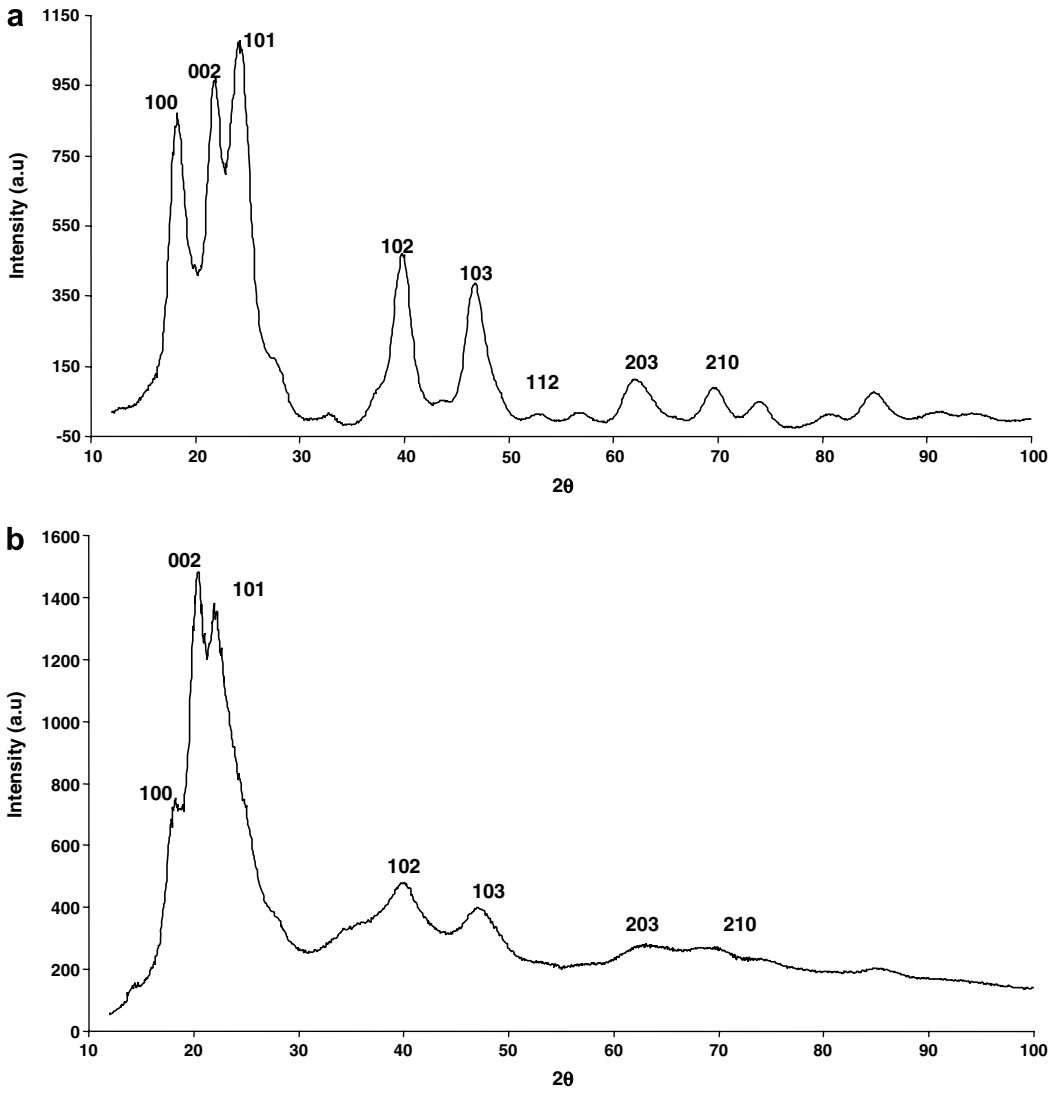

Fig. 9. X-ray diffraction pattern of CdS nanoparticles (1.00 g: 6.25 g) synthesized at 180 °C from (a) dicyclohexylthiourea complex (**I**) and (b) diisopropylthiourea complex (**II**).

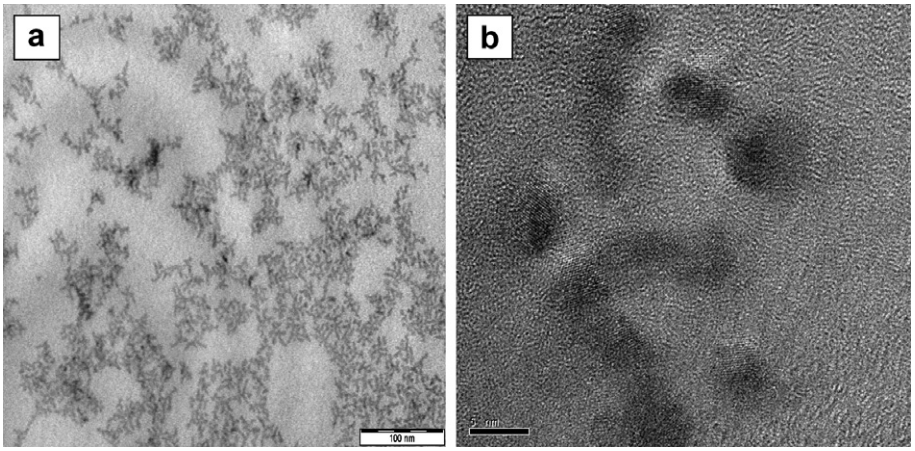

Fig. 10. (a) TEM and (b) HRTEM image of CdS nanoparticles (1.00 g: 6.25 g) synthesized at 180 °C from dicyclohexylthiourea complex (**I**).

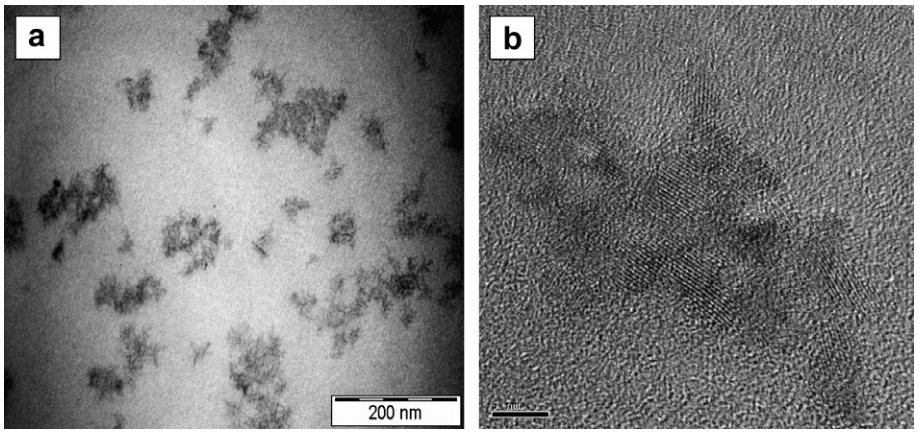

Fig. 11. (a) TEM and (b) HRTEM image of CdS nanoparticles (1.00 g: 6.25 g) synthesized at 180 °C from diisopropylthiourea complex (**II**).

Table 4
Absorption and PL spectral data of HDA-capped nanoparticles at different concentrations (at 180 °C) and different temperatures for precursors **I** and **II**

I			**II**			Mole ratio at 180 °C
Band-edge (nm)	Particle size (nm)	Emission maxima (nm)	Band-edge (nm)	Particle size (nm)	Emission maxima (nm)	
502	6.2	517	508	6.3	539	1:1
494	6.1	509	503	6.2	620	1:2
491	6.0	508	494	6.0	535	1:4
487	5.9	508	472	5.7	515	1:8
						Temperature (°C)
491		521	478		536	180
508		539	509		543	240

indexed to the hexagonal phase. The three predominant peaks between 10° and 30° can be indexed to 100, 002 and 101 planes and the rest of the peaks (40° = 102, 47° = 103, 54° = 112, 63° = 203 and 70° = 210) are further confirming the hexagonal phase. Both the patterns have broadened peaks, which is a good indication of both the crystallinity as well as the small size of the particles.

The TEM image of the CdS synthesized from complex **I** at 180 °C using a 1:2 ratio shows particles with well-defined 1D 'rod-shaped' which are *ca.* 5 nm in length and 2 nm in width (Fig. 10a). At similar reaction conditions, the TEM image (Fig. 11a) of CdS from complex **II** show particles with an oblate shape. These particles are approximately 3–5 nm in size, which is in agreement with the estimated sizes from the absorption band-edges (Table 4). Previous reports using similar precursors thermolysed in TOPO yielded hexagonal QD particles [30]. Therefore it is evident that the capping agent has a marked influence on the morphology of the particles. The morphology and the size of the nanoparticles synthesized from the thiourea precursors are consistent with their optical properties. The small blue-shift in absorption band-edge of the CdS nanoparticles could have been influenced by the relative lengths of the nanorods, thus making the overall particle size large, with diameter well within the range of typical nanoparticles. The HRTEM images in Fig. 10b and 11b show CdS nanocrystals from diisopropyl and dicyohexylthiourea respectively with crystal lattice planes.

4. Conclusions

The cadmium complexes of diisopropyl and dicyclohexylthioureas were easy to prepare, highly stable and proved to be good precursors for the synthesis of CdS nanoparticles. The variation of the amounts of HDA and temperature of thermolysis are factors influencing the optical properties and morphology of particles. The particles are rod-shaped irrespective of the type of precursor with hexagonal phase from their XRD patterns.

5. Supplementary material

CCDC 628913 and 628914 contain the supplementary crystallographic data for $[Cd(CH_3COO)_2(SC(NHC_6H_{11})_2)_2]$ and $[Cd(CH_3COO)_2(SC(NHC_3H_7)_2)_2]$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

UV–Vis spectrophotometry for functional group characterization [11–13]. On the other hand, nuclear magnetic resonance in the form of the solid state was found to provide valuable information about the modified physisorbed or chemisorbed silica via measurements of ^{1}H, ^{13}C, ^{15}N, ^{29}Si and ^{31}P by magic-angle spinning techniques [14–18]. However, hydration processes of chemisorbed or physisorbed silica gel phases can affect the chemical environments and functional groups in these phases as previously reported [18]. The mass spectrometric technique is well known for characterization of organic as well as inorganic species [19,20]. However, direct use of mass spectrometry, especially electron impact mode of ionization, for characterization of surface modification of chemisorbed or physisorbed silica phases is limited to only few reports due to the consideration of the high thermal stability of these modified silica gel phases [21,22].

Chemical or physical modification of silica with nitrogen and oxygen containing chelating compounds for the sake of applications as chelating sorbents were reported [23]. Among these are silica-modified-diethylenetriamine, with naphthaldehyde and salicylaldehyde [24]. Formylsalicylic acid derivatives on the surface of an amino group containing silica were previously reported [25,26]. Octadecyl-bonded silica membrane disks modified with a synthesized Schiff's base 2,2′–[1,2-ethanediyl-bis- (nitriloethylidyne)]-bis-(1-naphthalene) was also reported [27]. Silica impregnated with a mixture of Aliquat 336 and Titan Yellow was investigated [28]. Immobilization of mixed-donor (O, N) crown ether macrocycles to a silica matrix was described [29]. A number of methods for the immobilization of 8-hydroxyquinoline (8HQ) onto silica substrates were proposed, characterized and optimized [30–34].

2,5-Dioxypiperazine (DOPZ) is an example of a nitrogen and oxygen containing compound, known for its high biological activity [35,36] and is an important part of many reports concerned with the synthesis of a variety of biologically important compounds including peptides [37–39]. 2,5-Dioxypiperazine is also identified to have certain chelating characters via these two donor atoms. Chemical or physical binding of 2,5-dioxypiperazine to the surface of silica matrix has not been previously reported. Therefore, the aim of this work is to synthesize chemisorbed and physisorbed silica-immobilized-DOPZ for the sake of metal chelation applications. In addition, characterization and differentiation between newly chemisorbed and physisorbed silicas were also targeted by the aid of the direct insertion probe-mass spectrometric technique via the electron impact ionization mode.

2. Experimental

2.1. Apparatus

The electron impact mass spectra (EI-MS) of silica and the metal complexes were carried out using a Varion MAT 212 mass spectrometer equipped with a direct insertion probe (DIP) and the elemental analysis was performed by a GmbH Vario EL (III) system in the Institute for Inorganic and Analytical Chemistry, Muenster University, Germany. Differential scanning calorimetry (DSC) was conducted in an inert atmosphere (flowing nitrogen at a rate of 50 ml/min) on a Metter TA 3000 system (sample mass 20 mg, heating rate 20 K/min). Infrared spectra were performed using a Perkin–Elmer spectrophotometer model 1430, covering the frequency range 200–4000 cm^{-1}. Flame atomic absorption spectrophotometric measurements of metal ions were determined by a Perkin–Elmer 2380 atomic absorption spectrophotometer in the microanalytical laboratory of Faculty of Science, Alexandria, Egypt.

2.2. Chemicals and materials

3-Chloropropyltrimethoxysilane was received from Aldrich Chemical Company, USA. Silica (70–230 mesh, 60 Å pore diameter) was purchased from Riedel de Haën, Hannover, Germany. 2,5-Dioxypiperazine (DOPZ), also known as piperazine-2,5-dione or glycine anhydride, was purchased from Aldrich Chemical Company, USA. Metal salts were all of analytical reagent grade and were purchased from BDH Chemical Company, Poole, UK and Fluka Chemie AG, Switzerland. All chemicals were used as received and organic solvents were dried according to conventional methods. Metallic ion solutions were prepared from doubly distilled water (DDW).

2.3. Synthesis of modified silica and their metal complexes

Si–Cl, a silica-chemically immobilized-chloropropyl derivative, was prepared by the reaction of active silica with 3-chloropropyltrimethoxysilane as previously reported [6,7]. [Si–$(CH_2)_3$–DOPZ] was synthesized by the reaction of Si–Cl with DOPZ according to this method. Five millimol (~0.60 g) of 2,5-dioxypiperazine was completely dissolved in 50 ml methanol/50 ml toluene. Si–Cl, 5.0 g, was then suspended in this solution and the reaction mixture was stirred under reflux for four hours. [Si–$(CH_2)_3$–DOPZ] was filtered, washed with toluene, methanol and diethyl ether and dried in an oven at 70 °C for 6 h. Silica-physically adsorbed-DOPZ, [Si–DOPZ], was synthesized by the direct reaction of 5.0 g-active silica with 0.60 g-DOPZ already dissolved in 50 ml methanol/50 ml toluene. This reaction mixture was stirred at room temperature for 4 h. [Si–DOPZ] was filtered, washed with toluene, methanol and diethyl ether and dried in an oven at 70 °C for 6 h.

Cadmium(II), lead(II), mercury(II) and copper(II) complexes of [Si–$(CH_2)_3$–DOPZ] were synthesized by the reaction of 0.300 g-[Si–$(CH_2)_3$–DOPZ] with 60 ml of 0.1 mol/L of the selected metal ion in buffer solution, pH 6. This reaction mixture was automatically shaken for 1 h. The products [Si–$(CH_2)_3$–DOPZ]–Cd(II), [Si–$(CH_2)_3$–DOPZ]–Pb(II), [Si–$(CH_2)_3$–DOPZ]–Cu(II) and [Si–$(CH_2)_3$–

DOPZ]–Hg(II) were filtered, washed with DW and dried in an oven at 70 °C for 6 h.

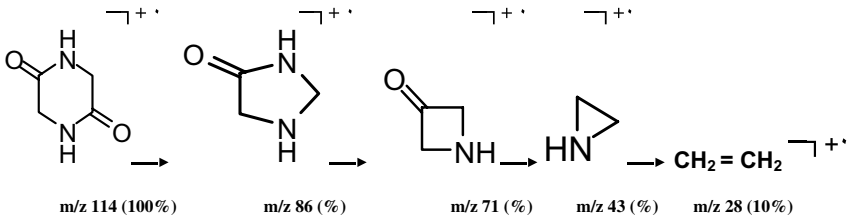
2.4. Determination of the metal chelating values of [Si–$(CH_2)_3$–DOPZ]

1.0 ml of 0.1 mol/L–metal ion {Mg(II), Ca(II), Mn(II), Cr(III), Fe(III), Co(II), Ni(II), Cu(II), Zn(II), Cd(II), Hg(II) and Pb(II)} and 9.0 ml of selected acidic and buffer solutions pH 1–6 were mixed, and to this mixture 50.0 ± 0.1 mg of [Si–$(CH_2)_3$–DOPZ] was added. This mixture was shaken by an automatic shaker for 30 min at room temperature. The unextracted metal ion by solid phase in the reaction solution was filtered, washed with 50 ml of DDW and subjected to complexometric titration or atomic absorption analysis.

2.5. Distribution coefficient and separation factor values

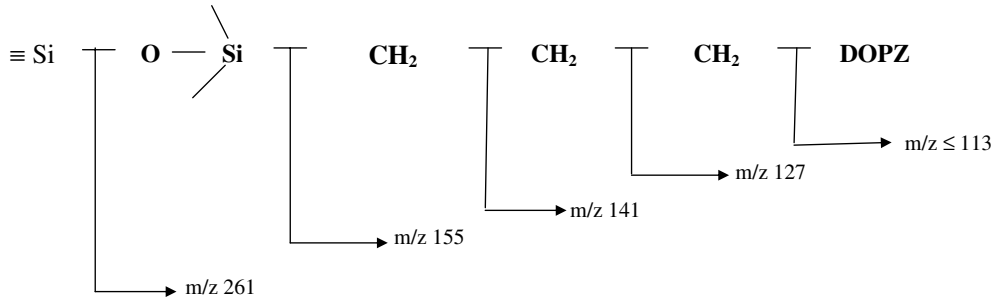
Standard solutions, 1.0 mg/L each, of these metal ions in buffer solution with pH 6 as the optimized solution were prepared to determine the distribution coefficient values of Mg(II), Ca(II), Mn(II), Cr(III), Co(II), Ni(II), Cu(II), Zn(II), Cd(II), Hg(II) and Pb(II). Fe(III) was prepared in a buffer solution with pH 4. In a 25 ml measuring flask, 100 mg ± 1 mg of the modified silica [Si–$(CH_2)_3$–DOPZ] was weighed. Ten milliliters of 1.0 mg/L metal ion was then added and shaken by an automatic shaker for 1 h. This mixture was filtered and washed with 10 ml DDW. The volume of metal ion was completed to 50 ml by 5% nitric acid solution. Standard and blank solutions of the metal ions were also prepared. The concentration of metal ions in the sample, standard and blank solutions were determined by atomic absorption analysis.

3. Results and discussion



3.1. Surface characterization of chemisorbed [Si–$(CH_2)_3$–DOPZ] and physisorbed [Si–DOPZ]

The 70-eV EI-MS of the organic modifier, DOPZ, silica-chemically immobilized-DOPZ, [Si–$(CH_2)_3$–DOPZ], and silica gel-physically adsorbed-DOPZ, [Si–DOPZ] were studied and evaluated. It was found that DOPZ exhibited a characteristic molecular ion peak at m/z 114 (100%) as the base peak. Several other fragment ion peaks located at m/z 86 (8%), 71 (44%), 43 (18%), 30 (36%) and 28 (20%) were found to be correlated to the successive losses of CO, NH, CO and either CH or NH ions from the molecular ion. Scheme 1 represents the suggested fragmentation pathways for DOPZ by 70-eV EI-MS.



The use of a direct insertion probe (DIP) is a common method for the introduction of volatile and low melting point samples into the mass spectrometer and ionization chamber by direct heating of the sample either in the solid or liquid state. A temperature range of 400–500 °C is always used as the maximum heating temperature of the probe. This temperature range is sufficient to volatilize the analyte of interest and deliver it to the ion source in the gas phase. According to this procedure silica, either chemically or physically modified, is considered to be thermally non-volatile. However, heating these silica matrices to the maximum temperature of the DIP can lead to a desorption process of the organic modifier as DOPZ or other similar compounds. The desorbed or volatilized species from the modified silica can then be detected by the mass spectrometer, and the EI-MS spectrum can be further used to confirm the direct binding of the organic modifier to the surface of thermally stable silica matrix.

The 70-eV EI-MS of chemically modified silica [Si–$(CH_2)_3$–DOPZ] was found to show no evidence for the existence of the ion peak at m/z 114, but only a peak at m/z 113 with a relative abundance of 12%. The presence of this fragment ion clearly proves the suggested chemical binding of DOPZ to the surface of Si–Cl phase via the elimination of a HCl molecule and formation of a covalent bond between the two reacting species [7]. This trend can be also confirmed by the absence of the major fragment ions shown in Scheme 1. Only other fragment ions at m/z 85 (8%), and 70 (12%) were found to exist in the EI-MS of [Si–$(CH_2)_3$–DOPZ]. Other evidences for the chemical binding of DOPZ to the surface of Si–Cl can be concluded and outlined from the presence of other higher mass ion peaks at m/z 127 (7%), 141 (3%), 155 (3%) and 261 (13%). Mass assignment of these fragment ion peaks is given in Scheme 2.

The 70-eV EI-MS of physically adsorbed silica, [Si–DOPZ] was found to exhibit interesting results which can be outlined as follows. First are the identical mass spectra of both DOPZ and [Si–DOPZ]. Second is the identification of the same fragment ion peaks at m/z 114 (100%) as the base peak, 86 (5%), 71 (31%), 43 (13%), 30 (31%), 29 (10%) and 28 (13%). Third is the absence of direct evidence for the existence of any type of chemical binding of DOPZ to the surface of active silica.

Scheme 1. 70-eV EI-MS fragmentation pathways of DOPZ.

Scheme 2. Mass assignment of [Si–$(CH_2)_3$–DOPIZ].

Table 1
Thermal data of DOPZ, [Si–$(CH_2)_3$–DOPZ] and [Si–DOPZ]

Compound	Step	T_{max} (K)	Thermal effect	n	Ea (kJ mol^{-1})	ΔS^* (J mol^{-1} K^{-1})	ΔH^* (kJ mol^{-1})
DOPZ	1	610.6	exothermic	0.58	377.02	−0.223	−136.33
[Si–$(CH_2)_3$–DOPZ]	1	568.6	exothermic	1.7	367.72	−0.222	−126.32
[Si–DOPZ]	1	576.4	exothermic	1.16	212.28	−0.227	−128.89

Thus, 70-eV EI-MS studies by the application of the DIP technique was found to provide good information about silica modification with the DOPZ moiety on the basis of fragment ion peaks generated with the mass spectrometric technique. In addition, this technique was confirmed to give good and valuable information about the thermal desorption process of the loaded organic compound on the surface of the modified silica gel phase. Moreover, EI-MS fragment ion peaks to account and differentiate between the chemical binding or physical adsorption of the organic modifier DPOZ is considered as another dimension in such an investigation.

The infrared studies of [Si–$(CH_2)_3$–DOPZ] and [Si–DOPZ] were also used to confirm the possible binding of DOPZ to the surface of the silica gel phase via some characteristic peaks. Several characteristic IR peaks were detected in the infrared spectrum of DOPZ and these are centered at 1682, 2987 and 3330 cm −1 due to the presence of υC=O, υC–H aliphatic and υN–H, respectively. No evidence was observed for the existence of υO–H in the infrared spectrum of DOPZ and this trend can be used to report the existence of DOPZ in the keto form, not the enol form. The appearance and intensity of these peaks in [Si–$(CH_2)_3$–DOPZ] and [Si–DOPZ] are very low compared to their intensity in the infrared spectrum of DOPZ. This is mainly due to the low percentage value of DOPZ that was found to be bound on the surface of silica gel. In addition, the infrared spectra of [Si–$(CH_2)_3$–DOPZ] and [Si–DOPZ] were characterized by the presence of a strong and broad peak at <1400 cm $^{-1}$ due to the presence of the silica gel matrix. Based on the infrared and EI-MS results, chemical binding of the silica gel matrix is confirmed to occur on either one of the two N–H groups of DOPZ due to their positional similarities.

Differential scanning calorimetry (DSC) was also applied to DOPZ as well as the chemically modified silica gel phase [Si–$(CH_2)_3$–DOPZ] and physically adsorbed silica gel phase [Si–DOPZ] in order to compare and evaluate their thermal and kinetic characteristics. DOPZ was found to exihibt an exothermal peak at a T_{max} value of 610.6 K. The same exothermal peak was also detected for the two newly modified silica gel phases at 568.6 and 576.4 K for [Si–(CH_2)–DOPZ] and [Si–DOPZ], respectively. The calculated order of the thermal decomposition steps indicated that those thermal steps are not kinetically simple. Table 1 compiles the different thermal parameters.

3.2. Surface coverage and metal chelation properties of [Si–$(CH_2)_3$–DOPZ] and [Si–DOPZ]

The surface coverage values of [Si–$(CH_2)_3$–DOPZ] in mmol g^{-1} were determined on the basis of elemental analysis of nitrogen content [6] as well as by the metal probe testing method by considering the highest metal chelating capacity of the tested metal ions as a direct indicative and representative value of surface coverage [8,9]. These values were found to correspond to 0.179 and 0.160 for [Si–$(CH_2)_3$–DOPZ] by elemental analysis of nitrogen content and the cadmium (II) probe testing method, respectively. The determined mmol g^{-1} value of [Si–DOPZ] was only determined by nitrogen analysis and was found to be 0.251. The stability of the newly chelating silica [Si–$(CH_2)_3$–DOPZ] and [Si–DOPZ] in various acidic and buffer solutions (pH 1–7) [8] was also studied to evaluate their performance and leaching process. Chemically modified silica [Si–$(CH_2)_3$–DOPZ] was found to be highly stable in these acidic buffer solutions, with a maximum leaching percentage of $\leqslant$5.5% in acidic solutions of pH 1 and 2. In higher acidic buffer solutions, pH > 2, [Si–$(CH_2)_3$–DOPZ] displayed good chemical stability behavior. On the other hand, the degree of leaching of the organic modifier from the surface of [Si–DOPZ] was found to be higher than

the chemically modified one. The maximum leaching percentage of DOPZ in [Si–DOPZ] was found to be in the range of 17–39% in acidic solutions with pH 1–3. Thus, one can conclude a higher chemical stability of [Si–$(CH_2)_3$–DOPZ] in buffer solutions compared to [Si–DOPZ] and this trend can be attributed to the covalent binding of DOPZ. The metal chelating properties of chemically modified silica [Si–$(CH_2)_3$–DOPZ] toward various metal ions was only studied and evaluated due to its high chemical stability compared to the silica-physically adsorbed-DOPZ phase. Table 2 compiles the data in μmol g^{-1} for a series of metal ions, as well as the distribution coefficient values.

Evaluation of the metal chelation properties of newly modified silica [Si–$(CH_2)_3$–DOPZ] is considered more convenient by the metal capacity values expressed in either mmol g^{-1} or μmol g^{-1} or by the distribution coefficient (K_d) when the concentrations of the tested metal ions are very low, especially in the range of part per million (mg/L) or part per billion (μg/L). Therefore, both methods were used and applied in this study for better evaluation and comparison. The listed metal capacity values are the optimum ones based on determination in various acidic and buffer solutions (pH 1–6). The reported metal capacity and distribution coefficient values for this series of metal ions refer to high similarities in the behavior of newly modified silica gel phases for chelation or binding with the tested metal ions as listed in Table 2. The low metal chelating capacity values given in Table 2 can be related to the low surface coverage values identified for these phases. The same trends for the high selective chelating characters of [Si–$(CH_2)_3$–DOPZ] towards Cd(II), Pb(II), Cu(II) and Hg(II) compared to other metal ions are also observed in Table 2. This behavior is mainly attributed to the presence of donor atoms as N and O on the surface of the newly modified silica via the immobilization of (DOPZ) [23].

The possible separation efficiency and selective chelating character incorporated into chemically or physically adsorbed silica with organic chelating compounds towards various metal ions can be evaluated on the basis of the separation factor (α) expression [21,22]. In order for the silica gel-modified-chelating compound to accomplish any separation of two ions, it is necessary that one of these cations is extracted by the silica gel phase in a distinct preference to the other. This can be calculated from the distribution coefficient values of the two metal ions as given by the following equation:

$$\alpha_{A/IMI} = \frac{K_d(A)}{K_d(IMI)}$$

where $\alpha_{A/IMI}$ is the separation factor for the analyte (A) versus the interfering metal ion (IMI), K_d (A) is the distribution coefficient value of the analyte (A) and K_d (IMI) is the distribution coefficient value of the interfering metal ion (IMI). The values of the distribution coefficient were calculated according to the following equation.

$$K_d, \text{ml g}^{-1} = \frac{C_{i,\,ex}(\mu g g^{-1})}{C_{i,\,sol}(\mu g\ \text{ml}^{-1})}$$

where as $C_{i,ex}$ and $C_{i,\,sol}$ are the concentration values of surface-bound metal ion and solution-free metal ion, respectively.

Table 3 lists the separation factors for Cd(II), Pb(II), Hg(II) and Cu(II) versus other interfering metal ions as determined by [Si–$(CH_2)_3$–DOPZ]. Based on the listed values, one can conclude that the metal ions Cd(II), Pb(II), Hg(II) and Cu(II) are individually separated from the interfering ions Mg(II), Ca(II), Mn(II), Co(II), Ni(II), Cr(III), Fe(III) and Zn(II) by the use of [Si–$(CH_2)_3$–DOPZ]. On the other hand, possible interference of Pb(II), Hg(II) and Cu(II) in selective extraction of Cd(II) is expected due to the low separation factor of these three metal ions ($\alpha_{Cd(II)/\,IMI} = 1.1$–$1.3$). The outlined order of the metal ions chelating selective property by [Si–$(CH_2)_3$–DOPZ] based on the values of the distribution coefficient and separation factor can be listed as: Cd(II) > Pb(II) > Hg(II) > Cu(II) >>> Zn(II) > Fe(III) > Cr(III) > Ni(II) > Co(II) > Mn(II) > Ca(II) > Mg(II).

3.3. Stoichiometric properties of metal ions with [Si–$(CH_2)_3$–DOPZ]

Cd(II), Pb(II), Hg(II) and Cu(II) were selected to study the stoichiometric properties of metal binding with chemi-

Table 2
Metal capacity (μmol g^{-1}) and distribution coefficient K_d

Metal ion	μmol g^{-1} (buffer range)	K_d (buffer solution)
Mg(II)	0–10 (pH 3–6)	212 (pH 6)
Ca(II)	0–10 (pH 3–6)	240 (pH 6)
Mn(II)	5–20 (pH 3–4)	450 (pH 6)
Cr(III)	20–30 (pH 3–6)	820 (pH 6)
Fe(III)	30–50 (pH 3–4)	1125 (pH 4)
Co(II)	5–20 (pH 4–6)	560 (pH 6)
Ni(II)	5–20 (pH 3–6)	590 (pH 6)
Cu(II)	30–80 (pH 4–6)	32 620 (pH 6)
Zn(II)	20–30 (pH 4–6)	5230 (pH 6)
Cd(II)	70–160 (pH 3–6)	41 560 (pH 6)
Hg(II)	40–70 (pH 3–6)	33 485 (pH 6)
Pb(II)	50–90 (pH 3–6)	37 500 (pH 6)

Table 3
Separation factor ($\alpha_{A/IMI}$) of some metal ions by [Si–$(CH_2)_3$–DOPZ]

Interfering metal ion	($\alpha_{Cd(II)/IMI}$)	($\alpha_{Pb(II)/IMI}$)	($\alpha_{Hg(II)/IMI}$)	($\alpha_{Cu(II)/IMI}$)
Mg(II)	196.0	176.9	157.9	153.9
Ca(II)	173.2	156.3	139.5	135.9
Mn(II)	92.4	83.3	74.4	72.5
Co(II)	74.2	67.0	59.8	58.3
Ni(II)	70.4	63.6	56.8	55.3

Hg(II)	1.2	1.1		
Pb(II)	1.1			
Cd(II)				

cally modified silica [Si–$(CH_2)_3$–DOPZ] due to their high affinity and selectivity characteristics compared to the other tested metal ions and based on the determined and calculated distribution and separation factors. According to the elemental analysis of nitrogen and metal contents, these metal ions were proved to give surface coverage values of 0.097–0.105, 0.093–0.110, 0.082–0.992 and 0.079–0.996 mmol g^{-1} for [Si–$(CH_2)_3$–DOPZ]–Cd(II), [Si–$(CH_2)_3$–DOPZ]–Pb(II), [Si–$(CH_2)_3$–DOPZ]–Hg(II) and [Si–$(CH_2)_3$–DOPZ]–Cu(II), respectively. Simple comparison of these values with the surface coverage of [Si–$(CH_2)_3$–DOPZ], 0.160–179 mmol g^{-1}, confirms the possible binding of all the tested metal ions, Cd(II), Pb(II) and Hg (II) and Cu(II), with [Si–$(CH_2)_3$–DOPZ] according to a molar stoichiometric ratio of 1:2.

The EI-MS via 70-eV was also used and applied to confirm the binding of the tested metal ions to the surface of [Si–$(CH_2)_3$–DOPZ]. The EI-MS of [Si–$(CH_2)_3$–DOPZ]–metal complexes were found to exhibit several characteristic fragment ion peaks that can be classified into three main groups. The first is mainly related to DOPZ, the second is referred to [Si–$(CH_2)_3$–DOPZ] and the third group due to [Si–$(CH_2)_3$–DOPZ]–metal complex. In the case of [Si–$(CH_2)_3$–DOPZ]–Cd(II), the first identified fragment ions group in the EI-MS was found to correspond to DOPZ at *m*/*z* 113 (4%), 112 (7%), 111 (4%), 85 (7%), 84 (4%), 71 (10%), 70 (7%), 69 (6%), 42 (8%), 41 (8%), 29 (4%) and 28 (3%) and the second group of identified fragment ions contains *m*/*z* 261(5%), 233 (25%), 155 (2%), 141 (3%) and 127 (3%), and these are related to [Si–$(CH_2)_3$–DOPZ]. The third group of ions attributed to fragmentation of [Si–(CH_2)–DOPZ]–Cd(II) were found at *m*/*z* 224 (2%), 210 (2%), 196 (2%) and 168 (7%). Table 4 compiles the major fragment ion peaks, their mass assignments and origin of these ions identified in the case of [Si–$(CH_2)_3$–DOPZ]–Cd(II). The same three groups of fragment ions were also characterized from the EI-MS of [Si–$(CH_2)_3$–DOPZ]–Pb(II) and these are listed as first, *m*/*z* 113 (8%), 112 (8%), 111 (19%), 85 (18%), 84 (10%), 71 (22%), 70 (13%), 69 (25%), 42 (8%), 41 (21%), 29 (8%) and 28 (73%). The second group of ions contains *m*/*z* 261(8%), 155 (5%), 141 (5%) and 127 (4%). The fragment ions at *m*/*z* 320 (4%), 252 (23%), 208 (15%) and 207 (6%) represents the third group. The identified three fragment ions groups in the EI-MS of [Si–$(CH_2)_3$–DOPZ]–Hg(II) were identified as first, *m*/*z* 113 (13%), 112 (13%), 111 (12%), 85 (26%), 84 (10%), 71 (32%), 70 (13%), 69 (16%), 42 (3%), 41 (14%), 29 (7%) and 28 (27%), second, at *m*/*z* 261(6%), 155 (8%), 141 (7%) and 127 (11%) and third group of fragment ions is located at *m*/*z* 341 (4%), 327 (4%) and 313 (2%). In the case of [Si–$(CH_2)_3$–DOPZ]–Cu(II) the identified fragment ions were found at *m*/*z* 113 (13%), 112 (10%), 111 (14%), 85 (28%), 84 (7%), 70 (12%), 69 (16%), 42 (27%), 41 (14%) and 29 (8%) as the first group of ions. The second group of fragment ions were found at *m*/*z* 127 (12%), 141 (9%) and 155 (8%) and there was no evidence for the formation of fragment ions that are related to [Si–$(CH_2)_3$–DOPZ]–Cu(II). This may be due to the high thermal stability of [Si–$(CH_2)_3$–DOPZ]–Cu(II) compared to the other metal complexes.

Table 4
EI-MS assignment of the major fragment ions of [Si–$(CH_2)_3$–DOPZ]–Cd(II)

Ion (Relative abundance, %)	Ion assignment	Origin of ions
113 (4)	M−H	DOPZ
112 (7)	M−2H	
111 (4)	M−3H	
85 (7)	M−[H + CO]	
84 (4)	M−[2H + CO]	
71 (10)	M−[H + CO + NH]	
70 (7)	M−[2H + CO + NH]	
69 (6)	M−[3H + CO + NH]	
42 (8)	C_2H_4N	
41 (8)	C_2H_3N	
29 (4)	C_2H_5	
28 (3)	C_2H_4	
261 (5)	M+$C_3H_6SiO_3(CH_3)_2$–[H]	[Si–$(CH_2)_3$–
233 (25)	M+$C_3H_6SiO_3(CH_3)_2$−[H + CO]	DOPZ]
155 (2)	M+C_3H_6−[H]	
141 (3)	M+C_2H_4–[H]	
127 (3)	M+CH_2–[H]	
224 (2)	DOPZ + Cd–[H_2]	[Si–$(CH_2)_3$–
210 (2)	DOPZ + Cd–[H_2+N]	DOPZ]–Cd(II)
196 (2)	DOPZ + Cd–[H_2+CO]	
168 (2%)	DOPZ + Cd–[H_2+2CO]	

Differential scanning calorimetry (DSC) was also used to study and evaluate the thermal characteristics of the same four metal complexes with chemically modified silica. The thermal analysis data are calculated as previously reported [40,41] and compiled in Table 5. These species

Table 5
Thermal data of the [Si–$(CH_2)_3$–DOPZ]–metal complex

Compound	Step	T_{max} (K)	Thermal effect	*n*	Ea (kJ mol^{-1})	ΔS^* (J mol^{-1} K^{-1})	ΔH^* (kJ mol^{-1})
Cd-complex	1	572.2	exothermic	2.19	629.69	−0.212	−124.90
	2	637.9	exothermic	1.88	664.73	−0.218	−139.09
Pb-complex	1	568.7	exothermic	0.66	144.28	−0.231	−131.162
Cu-complex	1	719.6	exothermic	0.613	70.56	−0.241	−178.28
Hg-complex	1	572.6	exothermic	1.92	766.50	−0.215	−123.09
	2	688	exothermic	1.21	91.986	−0.237	−136.60

were found to exhibit exothermic peaks at 572.2, 568.7, 572.6 and 719.6 K for [Si–$(CH_2)_3$–DOPZ]–Cd(II), [Si–$(CH_2)_3$–DOPZ]–Pb(II), [Si–$(CH_2)_3$–DOPZ–Hg(II) and [Si–$(CH_2)_3$–DOPZ]–Cu(II), respectively. However, the cadmium and mercury complexes were found to give an extra exothermic peak at 637.9 and 688 K, respectively. A remarkable feature was observed and detected in the DSC of [Si–$(CH_2)_3$–DOPZ]–Cu(II) and this corresponds to the pronounced high stability character due to formation of only one exothermic peak at the highest identified temperature, 719.6 K, compared to the other metal complexes. This observation is also confirmed and found to be consistent with the 70-eV EI-MS of [Si–$(CH_2)_3$–DOPZ]–Cu(II). The activation energy changes of the decomposition processes (first step) for the metal complexes were found to follow this order: [Si–$(CH_2)_3$–DOPZ]–Cu(II) < [Si–$(CH_2)_3$–DOPZ]–Pb(II) < [Si–$(CH_2)_3$–DOPZ]–Cd(II) < [Si–$(CH_2)_3$–DOPZ]–Hg(II). In addition, the fractions appeared in the calculated order of the thermal decomposition steps, indicating that those thermal steps are not kinetically simple. The narrow range of the entropy changes (−0.212 to −0.241) given in Table 5 illustrate the similarity of the thermal behavior. The negative sign indicates that the transition state of the thermal reaction is more ordered.

4. Conclusion

Surface modification of silica gel with DOPS via covalent binding was proved to change the chelating character of the silica matrix. The strong affinity of [Si–$(CH_2)_3$–DOPZ] to chelate toxic heavy metals such as Cd(II), Hg(II) and Pb(II) compared to other tested metals can add another dimension to this work and direct more interest towards the potential application of this new chelating sorbent for extraction, removal, separation and preconcentration of these metals from their environments in a pure state and without interference of other metal ions.

to examine the mode of binding and possible synergetic effects. The resultant mononuclear complexes have been characterized with elemental analysis and various spectroscopic techniques (IR, UV–Vis and NMR spectroscopy). Molecular modeling techniques have been employed to assess the lowest energy model structure of the complexes $VO(oxo)_2(H_2O)$, $Mn(oxo)_2(H_2O)_2$ and $Fe(oxo)_3$. The interaction of all the complexes with calf-thymus (CT) DNA has been studied with UV and circular dichroism (CD) spectroscopy.

2. Experimental

2.1. Materials

Oxolinic acid and CT DNA were purchased from Sigma, $VOSO_4 \cdot 5H_2O$, $MnCl_2 \cdot 4H_2O$, $FeCl_3 \cdot 3H_2O$, $CoCl_2 \cdot 6H_2O$, $NiCl_2 \cdot 6H_2O$, $ZnCl_2$, $CdCl_2 \cdot 2.5H_2O$, KOH and all the solvents were purchased from Aldrich Co, NaCl was purchased from Merck and trisodium citrate was purchased from Riedel–de Haen. All the chemicals were reagent grade and were used as purchased. Dimethylformamide (dmf) was distilled from calcium hydride (CaH_2) and CH_3OH from magnesium (Mg) and were stored over 3 Å molecular sieves. Diethyl ether, anhydrous grade and absolute ethanol were used without any further purification.

DNA stock solutions (5 mM) were prepared by dilution of CT DNA to the 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) followed by exhaustive stirring at 4 °C for three days [31], and kept at 4 °C for no longer than a week. The nucleotide concentrations were determined by their absorption at 260 nm using $\varepsilon = 6600\ M^{-1}\ cm^{-1}$ (expressed as phosphate).

2.2. Synthesis of the complexes

2.2.1. $VO(oxo)_2(H_2O)$ (1)

A methanolic solution (15 mL) of oxolinic acid (0.4 mmol, 105 mg), deprotonated with KOH (0.4 mmol, 22 mg), was added to a methanolic solution (10 mL) of $VOSO_4 \cdot 5H_2O$ (0.2 mmol, 51 mg) and the reaction mixture was refluxed for 2 h. The solution was filtered and left for slow evaporation. After a few days a green microcrystalline product was deposited, collected with filtration, washed with methanol and dried. Yield: 96 mg, ~80%. *Anal.* Calc. for $VO(oxo)_2(H_2O)$ ($C_{26}H_{22}N_2O_{12}V$) (MW = 605.41): C, 51.58, H, 3.66, N, 4.63. Found: C, 51.15; H, 3.53; N, 5.02%. The complex is soluble in dmso, dmf and H_2O and is non-electrolyte.

Complexes **2**–**7** were prepared in a similar way with the use of the corresponding metal salt. All the resultant complexes are non-electrolytes.

2.2.2. $Mn(oxo)_2(H_2O)_2$ (2)

$MnCl_2 \cdot 4H_2O$ (0.2 mmol, 40 mg) was used. A yellow microcrystalline product was collected. Yield: 90 mg, ~75%. *Anal.* Calc. for $Mn(oxo)_2(H_2O)_2$ ($C_{26}H_{24}N_2O_{12}Mn$) (MW = 611.42): C, 51.07; H, 3.96; N, 4.58. Found: C, 50.82; H, 4.15; N, 3.89%. The complex is soluble in dmso.

2.2.3. $Fe(oxo)_3$ (3)

$FeCl_3 \cdot 3H_2O$ (0.2 mmol, 44 mg) and oxolinic acid (0.6 mmol, 158 mg) were used. An orange microcrystalline product was collected. Yield: 130 mg, ~80%. *Anal.* Calc. for $Fe(oxo)_3$ ($C_{39}H_{30}N_3O_{15}Fe$) (MW = 836.53): C, 56.00; H, 3.62; N, 5.02. Found: C, 55.93; H, 3.91; N, 5.21%. The complex is soluble in dmso, dmf and H_2O.

2.2.4. $Co(oxo)_2(H_2O)_2$ (4)

$CoCl_2 \cdot 6H_2O$ (0.2 mmol, 48 mg) was used. A pink microcrystalline product was collected. Yield: 86 mg, ~70%. *Anal.* Calc. for $Co(oxo)_2(H_2O)_2$ ($C_{26}H_{24}N_2O_{12}Co$) (MW = 615.42): C, 50.74; H, 3.93; N, 4.55. Found: C, 50.84; H, 4.07; N, 4.65%. The complex is soluble in dmso and dmf.

2.2.5. $Ni(oxo)_2(H_2O)_2$ (5)

$NiCl_2 \cdot 6H_2O$ (0.2 mmol, 48 mg) was used. A light green microcrystalline product was collected. Yield: 98 mg, ~80%. *Anal.* Calc. for $Ni(oxo)_2(H_2O)_2$ ($C_{26}H_{24}N_2O_{12}Ni$) (MW = 615.19): C, 50.76; H, 3.93; N, 4.55. Found: C, 50.41; H, 4.01; N, 4.27%. The complex is soluble in dmso.

2.2.6. $Zn(oxo)_2(H_2O)_2$ (6)

$ZnCl_2$ (0.2 mmol, 28 mg) was used. A pale yellow microcrystalline product was collected. Yield: 95 mg, ~75%. *Anal.* Calc. for $Zn(oxo)_2(H_2O)_2$ ($C_{26}H_{24}N_2O_{12}Zn$) (MW = 621.86): C, 50.22; H, 3.89; N, 4.51. Found: C, 50.41; H, 3.83; N, 4.33%. The complex is soluble in dmso and dmf.

2.2.7. $Cd(oxo)_2(H_2O)_2$ (7)

$CdCl_2 \cdot 2.5H_2O$ (0.2 mmol, 46 mg) was used. A pale yellow microcrystalline product was collected. Yield: 95 mg, ~70%. *Anal.* Calc. for $Cd(oxo)_2(H_2O)_2$ ($C_{26}H_{24}N_2O_{12}Cd$) (MW = 668.89): C, 46.69; H, 3.62; N, 4.19. Found: C, 46.51; H, 3.85; N, 4.25%. The complex is soluble in dmso and dmf.

2.3. Instrumentation

Infrared (IR) spectra (400–4000 cm^{-1}) were recorded on a Nicolet Magna-IR 550 with samples prepared as KBr pellets. UV–visible (UV–Vis) spectra were recorded as nujol mulls and in solution at concentrations in the range 10^{-5}–10^{-3} M on a Thermo Electron Corporation Helios α dual beam spectrophotometer. C, H and N elemental analysis were performed on a Perkin–Elmer 240B elemental analyzer. Electric conductance measurements were carried out with a WTW model LF 530 conductivity outfit and a type C cell, which had a cell constant of 0.996. Nuclear magnetic resonance (NMR) spectra were recorded with a Bruker Avance 500 MHz instrument and were processed by X-WIN NMR 2.6 (Bruker Analytik GmbH).

The interaction of the complexes with CT DNA has been investigated with UV and CD spectroscopies. In both techniques, the spectra of CT DNA in the presence of each complex have been recorded for a constant CT DNA concentration ($3.125x10^{-4}$ M) in diverse complex:CT DNA mixing ratios (r). All the UV and CD spectra were recorded after incubation of the complex with CT DNA for 24 h at 37 °C.

The CD spectra were recorded on a Jasco J-700 spectropolarimeter using a 1.0 cm path quartz cell and the following acquisition parameters: $\lambda = 190$–400 nm, scan speed 50 nm min^{-1}, resolution step 0.2 nm, sensitivity 50 mdeg, response 1 s, bandwidth 1.0 nm, accumulations 10. In some cases, the spectra were averaged over an appropriate number of scans.

2.4. Molecular modeling

Although diverse crystallization techniques were employed, we did not manage to obtain a crystal suitable for the structure determination with X-ray crystallography. With the aim to present a molecular model for each new complex that is unbiased by the starting structure, we have used Langevin dynamics with a simulated annealing protocol. Using this method, the mean total energy of an ensemble of structures guides the selection of the most favorable configuration for each complex. Starting structures were constructed using the program HyperChem and the MM^+ force field that is based on the Allinger's MM2 force field [32]. For all the metal ions we used a default parameter set with $R^* = 2.20$ Å and $e^* = 0.02$ kcal mol^{-1}, since their van der Waals interactions are not expected to play a major role in such bonded representations as in octahedral complexes. Metal–ligand bond lengths were corrected in the final models using harmonic restraints with equilibrium values that were extracted from crystallographic data of similar compounds [33–52] (Tables S1, S3, S5). Nonbonded interactions were calculated in vacuo with no cutoff and the electrostatic energy term was treated using bond dipoles. Initial energy minimizations were carried out by a conjugate gradient method with rms gradient <0.01 as convergence criterion.

Each model (Schemes S1, S2, S3) was subjected to 20 individual rounds of simulated annealing setting different value to the seed for the assignment of the starting velocities. To integrate the Langevin equation [53] the step size was set to 1 fs and the collision frequency to 1 ps^{-1}. The annealing calculation comprised three phases: (i) raising the temperature of the system from 10 to 1000 K over 2 ps, (ii) keeping the system at 1000 K for 3 ps and (iii) cooling the system down to 0 K over 15 ps. A tight coupling of the system with temperature (0.1 ps) was used for the heating and equilibration phases. During the cooling phase the bath relaxation time was gradually decreased from 5.0 ps (7000 steps), 2.0 ps (3000 steps), 1.0 ps (2000 steps), 0.5 ps (2000 steps) to 0.05 ps (1000 steps). At the final step all structures had rms gradient <0.01 and their total energy was recorded (Tables S2, S4, S6). The models presented herein were selected among the lowest energy structures that were generated for each starting geometry. A final minimization of their energy was performed as above, but having applied the metal–ligand distance restraints.

3. Results and discussion

3.1. Synthesis of the complexes

All the complexes have been prepared at high yield (70–80%) via the addition of a methanolic solution of deprotonated oxolinic acid to a methanolic solution of the metal ion at a ratio 3:1 for Fe^{3+} and 2:1 for the remaining divalent metal ions according to the reaction:

$$M^{n+} + n\,\text{oxo} \rightarrow M(\text{oxo})_n(H_2O)_x$$

where $M^{n+} = Fe^{3+}$ ($n = 3$, $x = 0$), VO^{2+} ($n = 2$, $x = 1$), and Mn^{2+}, Co^{2+}, Ni^{2+}, Zn^{2+} and Cd^{2+} ($n = 2$, $x = 2$). The resultant complexes **1**–**7** are mainly soluble in dmso and dmf and are non-electrolytes.

3.2. IR spectroscopy

In Table 1 the characteristic absorptions of the IR spectra of all the complexes are listed. In the IR spectra of the

Table 1
Characteristic absorptions (in cm^{-1}) of IR spectra of the complexes

	ν(O–H)	ν(C=O)$_p$	$\nu(CO_2)_{asym}$	$\nu(CO_2)_{sym}$	Δ[a]	ν(M=O)
Hoxo		1633	1712[b]

$Cu(oxo)_2(H_2O)$, [24]	3410	1639	1599	1388	211	

[a] $\Delta = \nu(CO_2)_{asym} - \nu(CO_2)_{sym}$.
[b] as ν(COOH).

complexes **1**–**7**, the absorption at 1712 cm^{-1} in the spectrum of oxolinic acid attributed to the absorption of the $\nu(C{=}O)_{carb}$ has disappeared. Two very strong characteristic bands are present in the range of 1592–1606 cm^{-1} and 1375–1395 cm^{-1} that could be assigned as ν(O–C–O) asymmetric, $\nu_{asym}(CO_2)$, and symmetric, $\nu_{sym}(CO_2)$, stretching vibrations, respectively, whereas $\nu(C{=}O)_p$ is slightly shifted from 1633 to 1636–1645 cm^{-1} upon bonding. The difference $\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$ is a useful characteristic for determining the coordination mode of the carboxylato ligands. The Δ values fall in the range 202–226 cm^{-1} indicating a monodentate coordination mode of the carboxylato group of oxolinato ligands [54,55]. These changes of the IR spectra suggest that the oxolinato ligand is coordinated to the metal via the pyridone oxygen and one carboxylato oxygen [4,24].

The existence and the number of the $\nu(V{=}O)$ absorptions is a useful diagnostic tool of the vanadyl complexes characterization. The appearance of the V=O stretching frequency in complex **1** at ~930 cm^{-1} implies that a monoanionic ligand lies in *trans* position to the vanadyl oxygen (O_v) [56]. This acceptance is indicative of the arrangement of one O_c or O_p atom in the axial position of the octahedron around V atom and excludes the O_w atom.

The band at ~3400–3410 cm^{-1} in the IR spectra of the complexes **1**, **2** and **4**–**7** can be attributed to ν(O–H) vibration of one or two coordinated water molecules [30,54].

3.3. Electronic spectroscopy

The UV–Vis spectra of all the complexes have been recorded as nujol mulls and in dmso solution. Practically, the spectra in dmso solution are identical with those in nujol with the exception of a few nm shifts in some cases. The UV–Vis spectral data of all the complexes in dmso solution are given in Table 2.

The UV spectra of the complexes are practically identical with that of the oxolinic acid but slightly shifted, indicative of coordination through the pyridone oxygen and one carboxylate oxygen.

In the visible spectra, there are characteristic bands attributed to d–d transitions only for VO^{2+}, Fe^{3+}, Co^{2+} and Ni^{2+} complexes. In the visible spectrum of $VO(oxo)_2(H_2O)$, three low-intensity bands at 790 (band I), 600 (band II) and 498 (band III) nm attributed to d–d transitions are observed. Band I at $\lambda = 790$ nm ($\varepsilon = 10\ M^{-1}\ cm^{-1}$) can be attributed to a $b_2(d_{xy}) \rightarrow e_\pi^*(d_{xz}, d_{yz})$ transition of the $V^{IV}O^{2+}$ and band II at $\lambda = 600$ nm ($\varepsilon = 20\ M^{-1}\ cm^{-1}$) to a $b_2(d_{xy}) \rightarrow b_1^*(d_{x^2-y^2})$ transition [57]. Band III at $\lambda = 498$ nm ($\varepsilon = 28\ M^{-1}\ cm^{-1}$) is also observed and can be attributed to a $d_{xy} \rightarrow d_{z^2}$ transition although it usually lies under the much stronger ligand-to-metal charge-transfer transition (LMCT) at $\lambda = 433$ nm ($\varepsilon = 150\ M^{-1}\ cm^{-1}$) and can be difficulty distinguished [58,59]. These bands are typical for distorted octahedral VO^{2+} complexes [38,39,41,56].

The spectrum of $Fe(oxo)_3$ exhibits two bands that can be attributed to d–d transitions: one weak band I at $\lambda = 605$ nm ($\varepsilon = 35\ M^{-1}\ cm^{-1}$) which can be assigned as a $^6A_{1g} \rightarrow {}^5T_{1g}$ transition and an intense one, band II, at $\lambda = 510$ nm ($\varepsilon = 80\ M^{-1}\ cm^{-1}$) assigned as a $^6A_{1g} \rightarrow T_{2g}$ (G) transition [60,61]. These bands are typical for distorted octahedral Fe^{3+} [33–37] complexes.

In the spectra of $Co(oxo)_2(H_2O)_2$ and $Ni(oxo)_2(H_2O)_2$ one band at $\lambda = 560$ nm ($\varepsilon = 40\ M^{-1}\ cm^{-1}$) for **4** and at $\lambda = 650$ nm ($\varepsilon = 35\ M^{-1}\ cm^{-1}$) for **5** attributed to d–d transition has been found as it is expected for octahedral high-spin Co^{2+} [62,63] and Ni^{2+} [64,65] complexes, respectively. Similar behavior has been observed for the octahedral high-spin Co^{2+} [66] and Ni^{2+} [67] cinoxacin complexes.

All the complexes also exhibit an absorption band (as a shoulder) in the range $\lambda = 429$–438 nm ($\varepsilon \sim 140$–

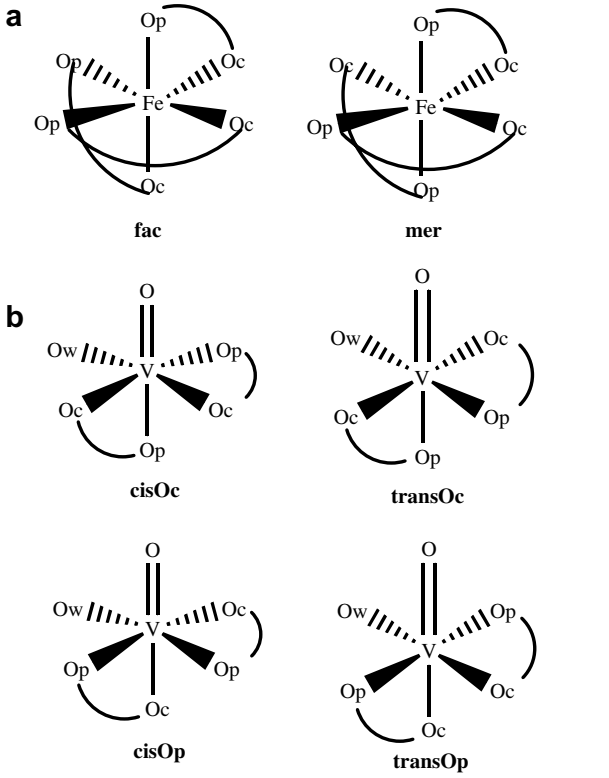
H12	6.26	6.32	6.34

200 M^{-1} cm^{-1}) which can be assigned to the LMCT transition for the quinolone ligand [24–30].

3.4. NMR spectroscopy

^{1}H NMR spectra of Hoxo, $Zn(oxo)_2(H_2O)_2$ and $Cd(oxo)_2(H_2O)_2$ were recorded in d_6-dmso. Full assignment of every signal in the ^{1}H NMR spectrum of complexes **6** and **7** was achieved by comparing the spectrum of each complex with the spectrum of the ligand and those reported in the literature [28,30,68]. The results are shown in Table 3.



Comparison of the ^{1}H NMR spectra of $Zn(oxo)_2(H_2O)_2$ and $Cd(oxo)_2(H_2O)_2$ with that of Hoxo shows a significant perturbation of the chemical shifts of the aromatic protons H2 (up to 0.3 ppm) and H5 (up to 0.8 ppm) indicating that H2 and H5 are close to the coordination site of the ligand. The signals for the aliphatic protons H1a and H1b as well as those of H8 and H12 (perturbations of the chemical shifts up to 0.1 ppm) are practically unchanged since they lie further than H2 and H5 from the binding site. The overall changes of the NMR spectra of the complexes are indicative of coordination of oxolinato ligand to the metal via the pyridone oxygen and one carboxylate oxygen [28,30].

3.5. Molecular dynamics

Diverse crystallization techniques were employed in order to obtain a crystal suitable for the structure determination with X-ray crystallography. Nevertheless, all the complexes were collected as microcrystalline product. In order to propose a possible structure for the complexes, the lowest energy model structures of $Fe(oxo)_3$, $VO(oxo)_2(H_2O)$ and $Mn(oxo)_2(H_2O)_2$ have been determined with molecular modeling calculations.

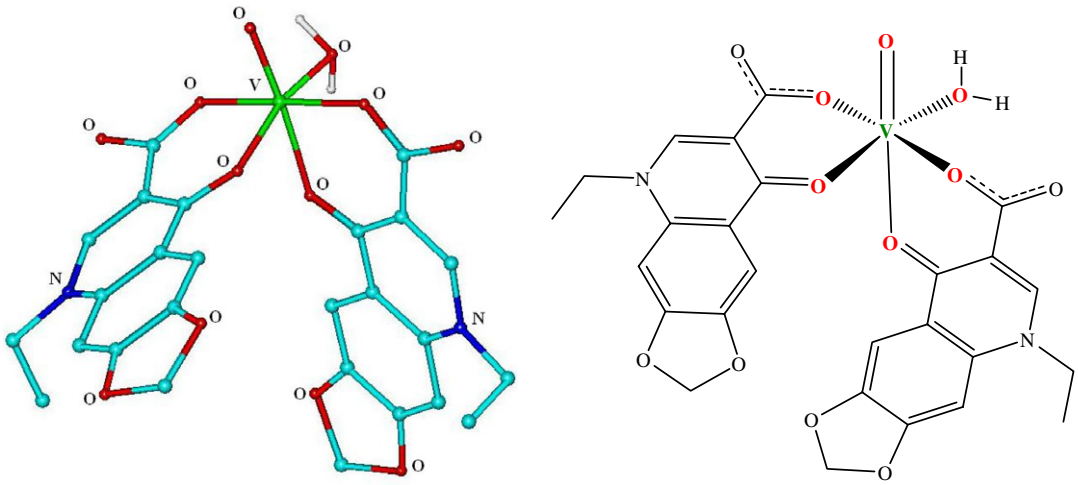
3.5.1. $Fe(oxo)_3$

We have constructed the two *fac* and the two *mer* $Fe(oxo)_3$ enantiomers (Scheme S1) in order to present a model for the complex $Fe(oxo)_3$. The average energy of each set of enantiomers is almost equal (Table S2), as it is expected from such molecular mechanics calculations [69]. However, the final structures of *mer*-[$Fe(oxo)_3$] isomers (Scheme 1a) exhibit lower energies by more than 1.7 kcal mol^{-1} in comparison to the energies of the *fac* isomers. For the *mer* isomers we have applied a set of harmonic restraints at the metal–ligand bonds [33–37] during an additional minimization phase (Table S1). Based on these results we present the lowest energy model of one *mer*-[$Fe(oxo)_3$] enantiomer as the favorable configuration of the complex (Figure S1). However, we can neither exclude the formation of any of the other isomers, nor unambiguously distinguish between the favorable enantiomers.

Scheme 1. The isomers of (a) $Fe(oxo)_3$ and (b) $VO(oxo)_2(H_2O)$ employed in the simulated annealing calculations. Oc and Op are the carboxylate and the pyridone oxygen atoms, respectively, of oxolinic acid.

3.5.2. $VO(oxo)_2(H_2O)$

Using the same approach as above, we have constructed eight diastereoisomers of $VO(oxo)_2(H_2O)$ complex (Scheme S2). In all these models, the water molecule occupies a *cis* position with respect to the V=O, in accordance with the experimental results and just as in similar vanadyl complexes [15,38–41,69]. The resultant models of all $VO(oxo)_2(H_2O)$ isomers exhibit comparable average total energy with the two *transOc* and the two *cisOc* enantiomers (as are arbitrarily designated in Scheme S2) being more stable than the other four isomers by ~1 kcal mol^{-1} (Table S4). The difference between the average total energy of *transOc* and *cisOc* isomers is ~0.3 kcal $mol^{-1}$with the two *transOc* enantiomers exhibiting the lower value. Applying the distance restraints to M–L bonds (Table S3) and making corrections of the geometry by minimizing the energy of the complex, the structure of the predicted most stable isomer (a *transOc* isomer) has been obtained (Fig. 2). However, we can neither distinguish between *transOc* or *cisOc* isomers (Scheme 1b), nor unambiguously choose between the favorable enantiomers.



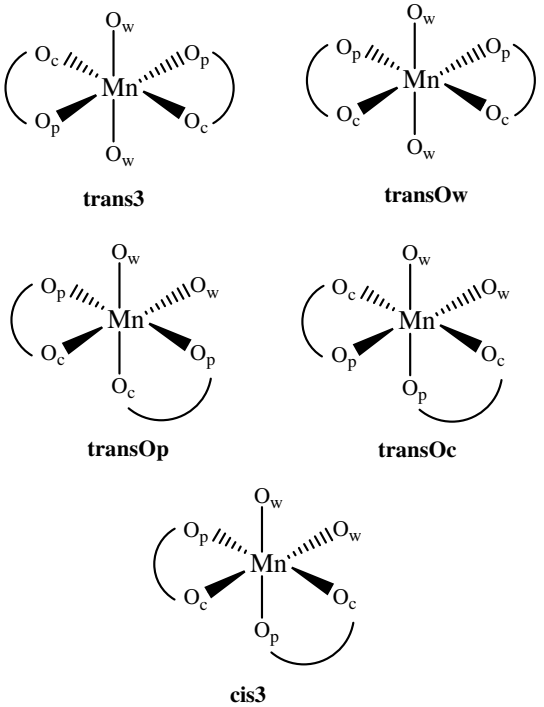


Fig. 2. Lowest energy model of $VO(oxo)_2(H_2O)$.

3.5.3. $Mn(oxo)_2(H_2O)_2$

We have constructed ten diastereoisomers as starting models of $Mn(oxo)_2(H_2O)_2$ (Scheme S3). The total number of all the possible diastereoisomers could not be limited since, according to similar Mn(II) complexes reported in the literature, the two Ow atoms can lie either at *trans* [43–47] or at *cis* [48–52] positions. After the Langevin dynamics simulated annealing calculations, we obtained the total energy results of 20 different conformations for each starting model (Table S6). The average energy of each set of enantiomers is almost equal, as it is expected from such molecular mechanics calculations [69]. However, the final structures of the isomers with Ow and Op at *cis* positions (*cis3* and *transOc* isomers, Scheme 2) exhibit lower average energies by more than 1.6 kcal mol^{-1} than the other isomers (*trans3*, *transOp* and *transOw*, Scheme 2).

The difference between the average total energy of *transOc* and *cis3* isomers is ~0.48 kcal $mol^{-1}$with the two *transOc* enantiomers being more stable since they exhibit the lower energy. Applying the distance restraints (Table S5) to M–L bonds [42–52] for the *transOc* model with the lowest energy and making corrections of the geometry by minimizing the energy of the complex once again, the structure of the predicted most stable isomer (a *transOc* isomer) has been obtained (Fig. 3). However, we cannot exclude the formation of any of the other isomers.

Scheme 2. The isomers of $Mn(oxo)_2(H_2O)_2$ employed in the simulated annealing calculations. Oc and Op are the carboxylate and the pyridone oxygen atoms, respectively, of oxolinic acid.

3.6. Interaction of the complexes with CT DNA

DNA can provide three distinctive binding sites for the quinolone metal complexes; namely, groove binding, binding to phosphate group and intercalation [70]. This behavior is of great importance with regard to the relevant biological role of quinolone antibiotics in the body [71].

3.6.1. UV spectroscopy

The absorption spectra of the interaction of the complexes **1**–**7** with CT DNA have been recorded for a constant CT DNA concentration (3.125×10^{-4} M) in different complex:CT DNA mixing ratios (r). Representative UV spectra of complexes **1**, **3** and **6** with CT DNA are shown in Fig. 4. The changes (mainly the increase of the intensity at $\lambda_{max} = 258$ nm) observed in the UV spectra of all the complexes (the UV spectra of complex **3** with CT DNA at diverse r values are shown in Fig. 5) after mixing

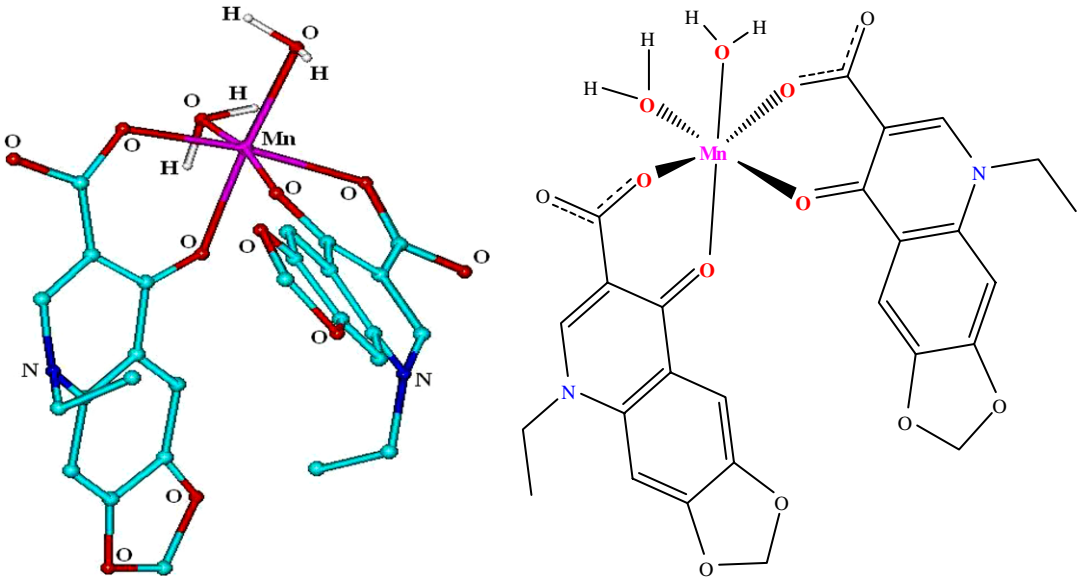

Fig. 3. Lowest energy model of $Mn(oxo)_2(H_2O)_2$.

with CT DNA indicate that the interaction of each complexes **1**–**7** with CT DNA takes place by a direct formation of a new complex with double-helical CT DNA [72].

3.6.2. CD spectroscopy

CD spectroscopy is useful in diagnosing changes in DNA morphology during drug–DNA interactions, as the positive band due to base stacking (275 nm) and the negative one due to right-handed helicity (248 nm) are quite sensitive to the mode of DNA interactions with small molecules [73,74]. The changes in the CD signals of CT DNA observed on interaction with drugs may often be assigned to the corresponding changes in CT DNA structure [75]. Thus, simple groove binding and electrostatic interaction of small molecules show less or no perturbation on the base-stacking and helicity bands, while intercalation enhances the intensities of both the bands stabilizing the right-handed B conformation of CT DNA as observed for the classical intercalator methylene blue [76].

The CD spectra of each complex with double-stranded CT DNA for different *r* values can provide us with useful information concerning the complex–nucleotide interaction. The CD spectra of the interaction of the free oxolinic acid with CT DNA do not show any shifts of the maxima or increase of the intensity because there is not any asymmetry or chirality in the molecule of the ligand [24,72]. The CD spectrum of free CT DNA is conservative and consists of a negative band at 246 nm and a positive one at 274 nm, characteristic of the B-form of DNA [77].

The CD spectra of CT DNA in the presence of complex $VO(oxo)_2(H_2O)$ (**1**) are shown in Fig. 6. They consist of a strong negative band I at 246 nm and two discrete positive

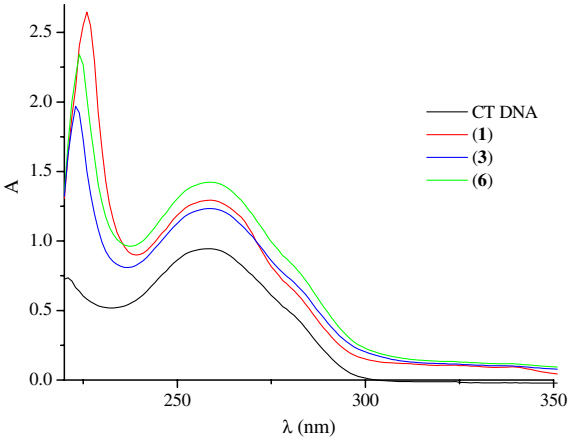

Fig. 4. Absorption spectra of complexes **1**, **3** and **6** in the presence of CT DNA. The *r* value is 1:200. The spectra were recorded at 25 °C after complexes had been incubated with CT DNA for 24 h at 37 °C.

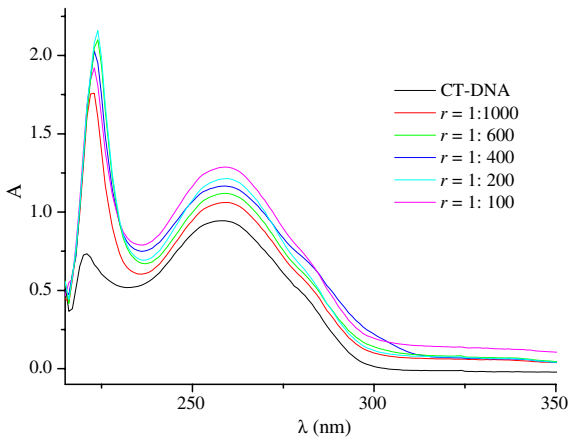

Fig. 5. UV spectra of complex **3** in the presence of CT DNA in different *r* values. The spectra were recorded at 25 °C after complex had been incubated with CT DNA for 24 h at 37 °C.

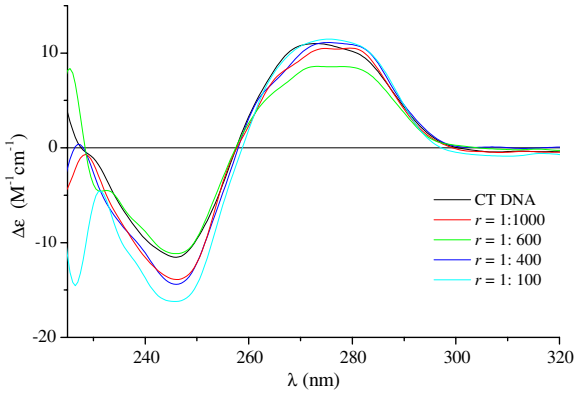

Fig. 6. CD spectra of CT DNA in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of complex **1** $VO(oxo)_2(H_2O)$ in different r values. The spectra were recorded at 25 °C after complex had been incubated with CT DNA for 24 h at 37 °C.

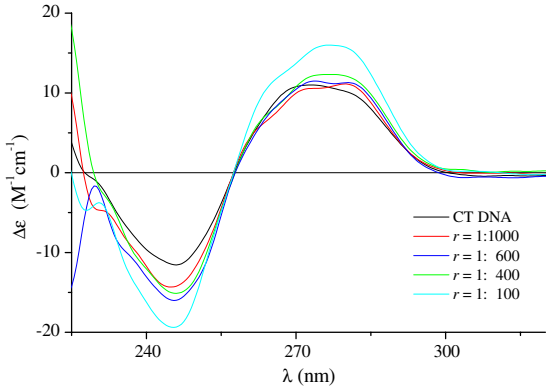

Fig. 7. CD spectra of CT DNA in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of complex **3** $Fe(oxo)_3$ in different r values. The spectra were recorded at 25 °C after complex had been incubated with CT DNA for 24 h at 37 °C.

bands II at 273 nm and III at 281 nm. More specifically, for r values up to 1:400, each CD spectrum consists of one negative band I at 246 nm and two positive bands II at 273 nm and III at 281 nm. Upon increase of the r value, the λ_{max} of these three bands remain, in general, unchanged while the intensity of helicity band I is increased and the intensity of bands II and III is decreased. Nevertheless, the exact mode of binding cannot be safely concluded. When r increases further (up to 1:50), the two positive bands II and III cannot be distinguished resulting to a unique broad band at $\lambda_{max} = 276$ nm while the intensity increases marginally. On the other hand, the negative band I at $\lambda_{max} = 246$ nm of remains unchanged in all the spectra, although an slight increase of the intensity is observed. The dominating spectral feature for this series of spectra is the slight increase of the intensities of both the bands of CT DNA. Taking into account all the changes observed, the exact mode of binding of **1** to CT DNA cannot be safely concluded.

Similar behavior is observed in the CD spectra of CT DNA in the presence of complexes $Mn(oxo)_2(H_2O)_2$, $Co(oxo)_2(H_2O)_2$ and $Ni(oxo)_2(H_2O)_2$.

The CD spectra of CT DNA in the presence of complex $Fe(oxo)_3$ (**3**) are shown in Fig. 7. They consist of a strong negative band I at 246 nm and two discrete positive bands II at 273 nm and III at 281 nm. When **3** is incubated with CT DNA at diverse r values, the CD spectrum of CT DNA undergoes changes in both the positive and negative bands. Taking into account all the changes observed in the CD spectra of Fig. 6 for diverse r values, the interaction of complex **3** with CT DNA could be summarized into the following points:

(a) For r values up to 1:400, each spectrum consists of one negative band I at 246 nm and two positive bands II at 273 nm and III at 281 nm. Upon increase of the r value, the λ_{max} of these three bands remain practically unchanged while the intensity of helicity band I is increased and the intensity of bands II and III is decreased. Nevertheless, the exact mode of binding cannot be safely concluded.

(b) When r increases further (up to 1:50), the two positive bands II and III cannot be distinguished resulting to a unique broad band at λ_{max} of 276 nm while the intensity increases. On the other hand, the λ_{max} at 246 nm of negative band I remains unchanged in all the spectra, although an increase of the intensity is observed. The dominating spectral feature for this series of spectra is the increase of the intensities of both the bands of CT DNA. Although the exact mode of binding cannot be safely concluded, the binding of complex **3** to CT DNA by the intercalative mode that enhances the intensities and possibly stabilizes the right-handed B-conformation of CT DNA cannot be ruled out [73,76].

The CD spectra of CT DNA in the presence of complex $Zn(oxo)_2(H_2O)_2$ (**6**) are shown in Fig. 8. They consist of a strong negative band I at 246 nm and two discrete positive

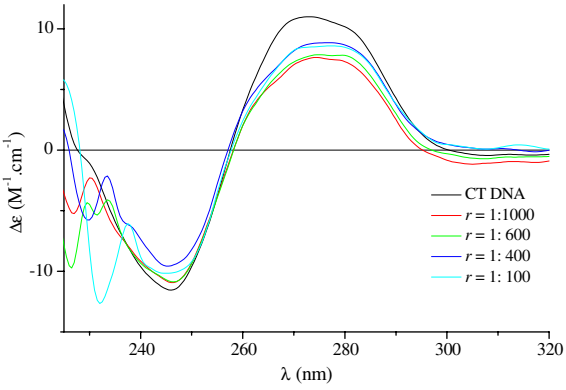

Fig. 8. CD spectra of CT DNA in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of complex **6** $Zn(oxo)_2(H_2O)_2$ in different r values. The spectra were recorded at 25 °C after complex had been incubated with CT DNA for 24 h at 37 °C.

bands II at 273 nm and III at 280 nm. More specifically, for r values up to 1:400, each spectrum consists of one negative band I at 246 nm and two positive bands II at 274 nm and III at 280 nm. Upon increase of the r value, the λ_{max} of these three bands remain practically unchanged while the intensities of all the bands are marginally decreased. In these spectra, the exact mode of binding cannot be safely concluded. For further increase of r (up to 1:50), the two positive bands II and III are consolidated and cannot be distinguished resulting to a unique broad band at $\lambda_{max} = 276$ nm while the intensity remains practically unchanged. On the other hand, the λ_{max} of the negative band I at 246 nm remains unchanged in all the spectra. The dominating spectral feature for this series of spectra is the lack of any perturbation on both the bands of CT DNA and shows the possible existence of simple groove binding or electrostatic interaction [76].

Quite similar behavior is observed in the CD spectra of CT DNA in the presence of complex $Cd(oxo)_2(H_2O)_2$.

In conclusion, the behavior of CT DNA in the presence of complexes **1**–**7** is interesting. All the complexes can bind to CT DNA and, at low r values, the exact mode of binding cannot be safely concluded. At high r values, especially for complex **3** the dominating spectral feature is indicative of binding by the intercalative mode and for complexes **6** and **7** the dominating spectral feature shows possible simple groove binding or electrostatic interactions.

4. Conclusions

The synthesis and characterization of seven new oxolinato complexes with VO^{2+}, Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Zn^{2+}, and Cd^{2+} has been realized with physicochemical and spectroscopic methods. In all the complexes, oxolinic acid is on deprotonated mode and acts as a bidentate ligand coordinated to the metal ion through the pyridone oxygen and one carboxylate oxygen.

Each metal is six-coordinate and the environment around each metal could be described as distorted octahedron. With the use of molecular modeling, the lowest energy model structures of $Fe(oxo)_3$, $VO(oxo)_2(H_2O)$ and $Mn(oxo)_2(H_2O)_2$ have been determined revealing the possible arrangement of the ligands around the metal.

The interaction of complexes **1**–**7** with CT DNA has been investigated with diverse spectroscopic techniques. It has been found that all the complexes can bind to CT DNA and the exact mode of binding cannot be safely concluded. Nevertheless, at high r values, the intercalative binding mode for complex **3** and the simple groove binding or electrostatic interactions for complexes **6** and **7** cannot be ruled out.

Acknowledgments

The work was partially supported by the ''Excellence in the Research Institutes'' Program, Action 3.3.1 co-funded by the Greek Ministry of Development and E.U. We thank Dr. A. Papakyriakou, Institute of Physical Chemistry, NCSR ''Demokritos'', Greece, for the supply of the molecular modeling routine.

Appendix A. Supplementary material

IR and UV–Vis spectral data for Hoxo and complexes **1**–**7** and ^{1}H NMR chemical shifts for Hoxo, $Zn(oxo)_2(H_2O)_2$ and $Cd(oxo)_2(H_2O)_2$ in d_6–dmso. Three schemes (Schemes S1, S2 and S3) for the diastereoisomers of $Fe(oxo)_3$, $VO(oxo)_2(H_2O)$ and $Mn(oxo)_2(H_2O)_2$ employed in the simulated annealing calculations. Three tables (Tables S1, S3, S5) for the metal–ligand distance restraints applied during the energy minimization phase in order to adjust the geometry of $Fe(oxo)_3$, $VO(oxo)_2(H_2O)$ and $Mn(oxo)_2(H_2O)_2$ models. Three tables (Tables S2, S4, S6) for the energy statistics from the simulated annealing results of $Fe(oxo)_3$, $VO(oxo)_2(H_2O)$ and $Mn(oxo)_2(H_2O)_2$ diastereoisomers, respectively. Three figures (Figures S1, S2, S3) for the lowest energy models of the $Fe(oxo)_3$, $VO(oxo)_2(H_2O)$ and $Mn(oxo)_2(H_2O)_2$ enantiomers. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.04.031.

$MoO_2[S_2CNR_2]_2$ (R = Et [18], *n*-Pr [19]) have been reported but none with *O*-alkyl dithiocarbonates or *O*,*O*′-dialkyl(alkylene) dithiophosphates. However, several structures have been reported of binuclear oxomolybdenum(V) complexes with *N*,*N*′-dialkyl dithiocarbamates, $Mo_2O_3[S_2CNEt_2]_4$ [20], and $Mo_2O_3[S_2CN(n\text{-}Pr)_2]_4$ [19], *O*-alkyl dithiocarbonates, $Mo_2O_3[S_2COEt]_4$ [21] and $Mo_2O_3[S_2CO\textit{i}\text{-}Pr]_4$ [22] and *O*,*O*′-dialkyl dithiophosphates, $Mo_2O_3[S_2P(OR)_2]_4$ (R = Me [16], Et [23,24], *n*-Pr[25], Ph [26]). We report the synthesis and characterization of several new binuclear oxomolybdenum(V) complexes involving dithiophosphate ligands and dioxomolybdenum(VI) complexes with *O*,*O*′-ditolyl dithiophosphates, along with the crystal structures of $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$, $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ and $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$.

2. Experimental

Sodium molybdate dihydrate, phosphorus pentasulfide, *o*-cresol, *m*-cresol, *p*-cresol and benzyl alcohol were purchased from E. Merck. All solvents (ether and benzene) were dried by standard methods before use. Stringent precautions were taken to exclude moisture during experimental manipulations. Literature methods were used for the preparation of the ammonium salt of *O*,*O*-ditolyl dithiophosphoric acids [27,28].

2.1. Synthesis of $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ (1), $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ (2), $Mo_2O_3[S_2P(OC_6H_4Me\text{-}p)_2]_4$ (3)

An aqueous solution (15 mL) of the ammonium salt of *O*,*O*-di(2-tolyl)dithiophosphoric acid (1.87 g, 5.71 mmol) was added drop wise to an aqueous solution (10 mL) of sodium molybdate (0.69 g, 2.86 mmol) with constant stirring. A purple precipitate was obtained immediately which was filtered and washed with ether and dried over P_2O_5. Purple crystals were obtained on recrystallization from benzene:diethyl ether (1:2). $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ (**1**). Purple crystalline solid. Yield: 4.01 g, 95%; m.p. 112 °C. *Anal.* Calc. for $C_{56}H_{56}O_{11}P_4S_8Mo_2$: Mo, 12.99; S, 17.36. Found: Mo, 13.29; S, 17.51%.

Method as above gave $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ (**2**). Purple crystalline solid. Yield: 90%; m.p. 118 °C. *Anal.* Calc. for $C_{56}H_{56}O_{11}P_4S_8Mo_2$: Mo, 12.99; S, 17.36. Found: Mo, 12.72; S, 17.66%.

Method as above gave $Mo_2O_3[S_2P(OC_6H_4Me\text{-}p)_2]_4$ (**3**). Purple crystalline solid. Yield: 90%; m.p. 120 °C. *Anal.* Calc. for $C_{56}H_{56}O_{11}P_4S_8Mo_2$: Mo, 12.99; S, 17.36. Found: Mo, 12.86; S, 17.52%.

2.2. Synthesis of $MoO_2[S_2P(OC_6H_4Me\text{-}o)_2]_2$ (4), $MoO_2[S_2P(OC_6H_4Me\text{-}m)_2]_2$ (5), $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (6) and $MoO_2[S_2P(OCH_2C_6H_5)_2]_2$ (7)

$Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ (0.22 g, 0.15 mmol) was dissolved in benzene (25 mL) and a benzene solution of triphenylphosphine oxide was added (0.05 g, 0.18 mmol) with constant stirring. The colour of the solution changed from purple to yellow after 30 min. The volume of the solvent was reduced to 2–3 mL by pumping and then n-hexane (10 mL) was added. Yellow crystals were obtained on keeping the solution in the refrigerator overnight. $MoO_2[S_2P(OC_6H_4Me\text{-}o)_2]_2$ (**1**): Yellow solid. Yield: 0.18 g, 82%; m.p. 118 °C. *Anal.* Calc. for $C_{28}H_{28}O_6P_2S_4Mo$: Mo, 12.85; S, 17.18. Found: Mo, 12.66; S, 17.43%.

Method as above gave $MoO_2[S_2P(OC_6H_4Me\text{-}m)_2]_2$ (**5**). Yellow solid. Yield: 85%; m.p. 114 °C. *Anal.* Calc. for $C_{28}H_{28}O_6P_2S_4Mo$: Mo, 12.85; S, 17.18. Found: Mo, 13.21; S, 17.56%.

Method as above gave $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_4$ (**6**). Yellow solid. Yield: 80%; m.p. 124 °C. *Anal.* Calc. for $C_{28}H_{28}O_6P_2S_4Mo$: Mo, 12.85; S, 17.18. Found: Mo, 12.86; S, 17.23%.

Method as above gave $MoO_2[S_2P(OCH_2C_6H_5)_2]_4$ (**7**). Yellow solid. Yield: 80%; m.p. 124 °C. *Anal.* Calc. for $C_{28}H_{28}O_6P_2S_4Mo$: Mo, 12.85; S, 17.18. Found: Mo, 12.86; S, 17.23%.

2.3. Physical measurements

Molybdenum was estimated by precipitation as molybdenum oxinate, $MoO_2(C_9H_6ON)_2$ and sulfur as barium sulfate [Messenger's method]. IR spectra were recorded in the range 4000–200 cm^{-1}on a Perkin–Elmer 983G spectrophotometer (Nujol mull). ^1H NMR and ^{31}P NMR spectra were recorded on a Bruker DRX-300 Spectrometer in $CDCl_3$ using TMS as an internal and 85% H_3PO_4 as an external reference, respectively.

2.4. X-ray diffraction analysis

The data for **1** and **6** were collected on an Enraf Nonius Kappa CCD area detector diffractometer, with Φ and ω scans chosen to give a complete asymmetric unit, and for **2** on a Siemens SMART System CCD diffractometer with the collection of a hemisphere of data. Cell refinements [29] corresponded to monoclinic cells for **1** and **6** and triclinic for **2**. Dimensions are given in Table 3 along with other experimental parameters. Absorption corrections were applied [30]. The structures were solved by direct methods [31] and were refined using the WinGX version [32] of SHELX-97 [33]. All of the non-hydrogen atoms were treated anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. The final cycle of full-matrix least-squares refinement was based on 7211 (**1**), 5792 (**2**) and 5450 (**6**), observed reflections and 5894 (**1**), 2633 (**2**), and (4103 (**6**) for $F^2 > 4s(F^2)$) and 368 (**1**), 365 (**2**), and 374 (**6**) variable parameters and converged (largest parameter shift was 0.001 times its esd). Distances and bond angles are given

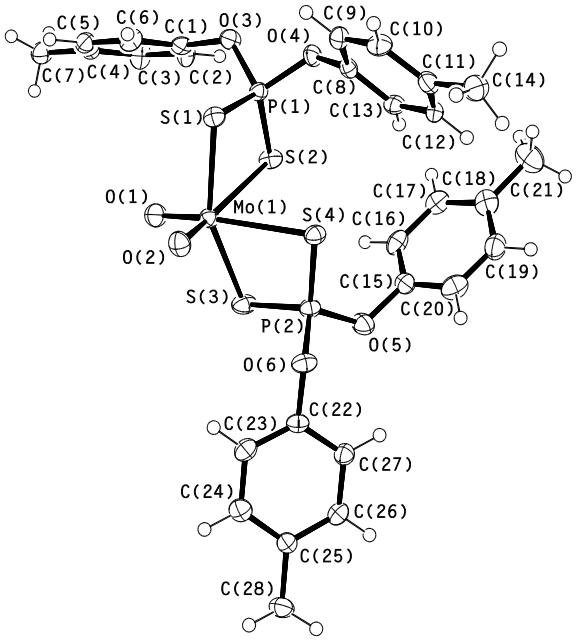

Fig. 1. ORTEP plot of $MoO_2[S_2P(OC_6H_4CH_3\text{-}p)_2]_2$. The non-hydrogen atoms are drawn with 50% probability ellipsoids.

in Table 4 for molecules **1**, **2** and **6**, respectively and ORTEP diagrams are displayed in Figs. 1–3.

3. Results and discussion

Binuclear oxomolybdenum(V) *O*,*O*-ditolyl dithiophosphate complexes, $Mo_2O_3[S_2P(OR)_2]_4$ were synthesized by the drop wise addition of aqueous solution of the ammonium salt of *O*,*O*-ditolyl dithiophosphoric acid into an acidic solution of sodium molybdate with constant stirring to yield purple solids:

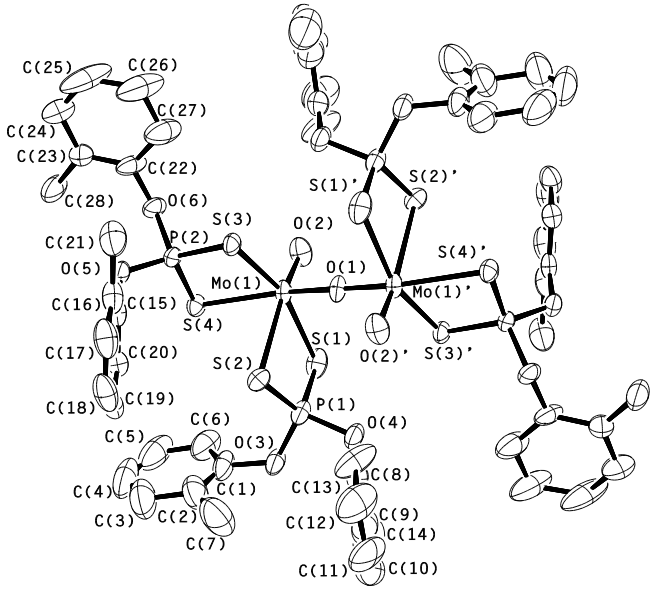

Fig. 2. ORTEP plot of the molecule $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$. The non-hydrogen atoms are drawn with 50% probability ellipsoids. Hydrogen atoms omitted for clarity.

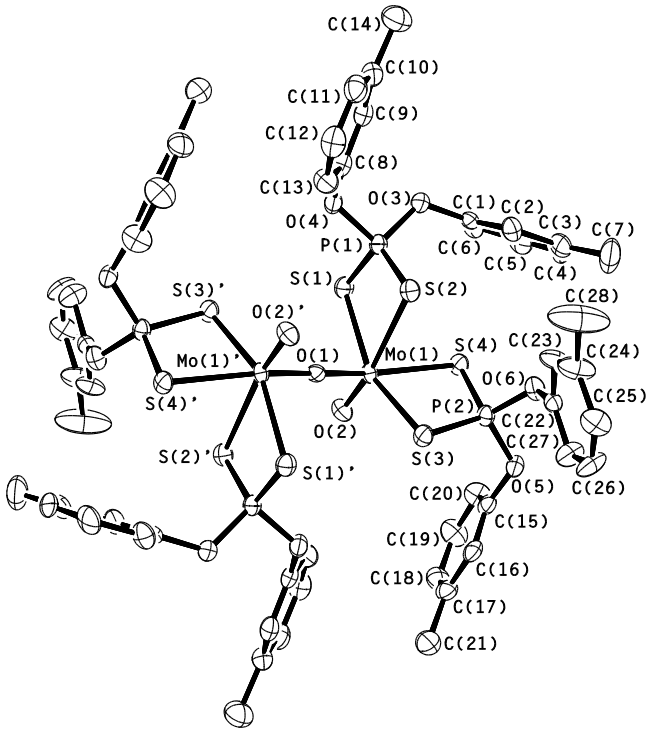

Fig. 3. ORTEP plot of $Mo_2O_3[S_2P(OC_6H_4Me\text{-}p)_2]_2$. The atoms are drawn with 50% probability ellipsoids. Hydrogen atoms are omitted for clarity.

$$Na_2MoO_4\cdot 2H_2O + 2NH_4S_2P(OR)_2 \rightarrow 0.5Mo_2O_3[S_2P(OR)_2]_4$$
(R = *o*-, *m*- and *p*-C_6H_4Me)

Dioxomolybdenum(VI) *O*,*O*-ditolyl dithiophosphates were prepared by oxygen atom transfer reactions of binuclear oxomolybdenum(V) *O*,*O*-ditolyl dithiophosphate complexes with triphenylphosphine oxide in benzene.

$$Na_2MoO_4\cdot 2H_2O + 2NH_4S_2P(OR)_2 \rightarrow MoO_2[S_2P(OR)_2]_2$$
(R = *o*-, *m*-, *p*-C_6H_4Me and $CH_2C_6H_5$)

These dioxomolybdenum(VI) complexes are yellow powdery solids that are soluble in common organic solvents viz. benzene, chloroform and dichloromethane etc. and were characterized by elemental analysis, IR, ^1H and ^{31}P NMR spectroscopy.

3.1. IR spectra

The assignments of the IR bands for binuclear oxomolybdenum(V) *O*,*O*-ditolyl dithiophosphate and dioxomolybdenum(VI) *O*,*O*-ditolyl dithiophosphate complexes (Table 1) were made by comparison with the spectra of the precursors of the complexes; the ammonium salts of *O*,*O*-ditolyl dithiophosphates [27,28]. The bands due to *ν*[(P)–O–C] and *ν*[P–O–(C)] which occur in the regions 1139–1102 and 833–792 cm^{-1}, respectively, in the parent ammonium salts, are unalterred in the molybdenum complexes. The band due to *ν*(P═S) present at 694–670 cm^{-1} in the ammonium salts shows a small but notable shift

Table 1

7	$MoO_2[S_2P(OCH_2C_6H_5)_2]_2$	1072,s	997,m	968,s	827,s	688,s	541,s	338,w

[a] Key: s = strong; m = medium; w = weak.

($\nu = 22$–$25\ cm^{-1}$) to lower wave-number in the molybdenum complexes indicating attachment of the ligand to the metal atom. New peaks of medium to strong intensity that are present at 993–953 and 778–758 cm^{-1} in the binuclear oxomolybdenum(V) complexes **1**–**3** are assigned to ν(Mo=O) and ν(Mo–O–Mo), respectively. Two strong bands in the dioxomolybdenum(VI) complexes **4**–**7**, due to ν(Mo=O), are found in the region 997–918 cm^{-1}. Similarly, additional peaks for ν(Mo–S) stretching bands of weak intensity are observed in the region 341–327 cm^{-1}.

3.2. ^1H NMR spectra

The chemical shifts and integrated intensity ratios of the protons in the binuclear oxomolybdenum(V) *O,O*-ditolyl dithiophosphate and dioxomolybdenum(VI) *O,O*-ditolyl dithiophosphate complexes are presented in Table 2. These spectra were recorded in $CDCl_3$ solutions at room temperature. The ^1H NMR data of complexes **1**–**7**, are remarkably similar to those of the salts of *O,O*-ditolyl dithiophosphates [27,28] probably due to the large separation between the molybdenum and the protons.

3.3. ^{31}P NMR spectra

The ^{31}P NMR spectra were recorded in $CDCl_3$ solutions (Table 2) and show a singlet in the region δ, 96.57–85.90 ppm, indicating the equivalent nature of the phosphorus nuclei as well as the symmetric nature of the species in solution. The ^{31}P NMR chemical shifts for the binuclear oxomolybdenum(V) complexes **1**–**3** and dioxomolybdenum(VI) complexes **4**–**7**, are shifted ~20 and ~10 ppm upfield, respectively, from those of the corresponding salts of dithiophosphoric acids indicating the bidentate and anisobidentate nature [34] of the dithiophosphate moieties in Mo(V) and Mo(VI) complexes, respectively.

3.4. Molecular structures of $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ (**1**), $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ (**2**) and $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (**6**)

The molecular structure of $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (**6**) is the first of this type reported with dithiophosphate ligands. Fig. 1 and the selected bond distances and angles in Table 4 show that Mo has a distorted octahedral environment in which cis oxo groups are typical of dioxomolybdenum(VI) species. The M=O distances of 1.694(3) and 1.700(3) Å and the O=Mo=O angle of 104.7(2)° are similar to those reported for $MoO_2[S_2CNEt_2]_2$ [18], $MoO_2[S_2CN(n\text{-}Pr)_2]_2$ [19], $MoO_2[S_2CNC_4H_8]_2$ [35] (ave 1.701(2) Å and 106.1(7)°). The dithiophosphate ligands in (**6**) are anisobidentate with one short (ave 2.467(10)) and one long (ave 2.74(2) Å) Mo–S bond. The longer bond is trans, S–Mo=O angle (ave 163.3(4)°), to a Mo=O bond. The trans influence was also evident in the three related dithiocarbamate derivatives $MoO_2[S_2NCR_2]_2$, (R = Et, *n*-Pr) and $MoO_2[S_2CNC_4H_8]_2$ [18,19,35] where the shorter (ave 2.452(7)) and longer Mo–S bonds (ave 2.645(26) Å) were both slightly shorter than those in **6**, and the trans S–Mo=O angles ranged from 155.8(6) to 157.56(9)°. The S–Mo–S bite angles in $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (**6**) (76.32(4) and 76.90(4)^o) are, as is to be expected, larger than those in the three dithiocarbamates (ave 68.8(3)°) [18,19,35]. Further, in **6** the longer Mo–S bond is associ-

Table 2
^1H and ^{31}P NMR Chemical shifts for the binuclear oxomolybdenum(V) *O,O*-ditolyl dithiophosphate and dioxomolybdenum(VI) *O,O*-ditolyl dithiophosphate complexes[a,b]

S. no.	Compound	CH_3/OCH_2	C_6H_4	^{31}P
1	$Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$	2.20 (24H, s)	6.72–7.12 (32H, m)	85.90
2	$Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$	2.20 (24H, s)	6.75–7.16 (32H, m)	86.61
3	$Mo_2O_3[S_2P(OC_6H_4Me\text{-}p)_2]_4$	2.24 (24H, s)	6.94–7.12 (32H, m)	86.35
4	$MoO_2[S_2P(OC_6H_4Me\text{-}o)_2]_2$	2.22 (12H, s)	6.70–7.15 (16H, m)	96.57
5	$MoO_2[S_2P(OC_6H_4Me\text{-}m)_2]_2$	2.24 (12H, s)	6.64–7.08 (16H, m)	95.56
6	$MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$	2.20 (12H, s)	6.70–7.06 (16H, m)	96.03
7	$MoO_2[S_2P(OCH_2C_6H_5)_2]_2$	4.90 (8H, s, $J = 10$ Hz)	6.70–7.06 (20H, m)	95.56

[a] The spectra were recorded in $CDCl_3$ and reported in δ ppm from MeSi for ^1H and from H_3PO_4 for ^{31}P.
[b] Number of protons and multiplicities are in parentheses (s = singlet; m = multiplet).

ated with the shorter P–S bond and vice versa, with S(2)–P(1) and S(4)–P(2) (ave 1.955 (2) Å) and S(1)–P(1) and S(3)–P(2) (ave 2.024 (4) Å) as was observed in the three dithiocarbamate derivatives with shorter (ave 1.702(9) Å) and longer (1.737(4) Å) C–S bonds.

The molecular structures of $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ (**1**) and $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ (**2**) in Figs. 2 and 3 show the distorted octahedral geometry of the MoO_2S_4 cores. The terminal Mo=O bonds are mutually in the syn conformation and cis to the Mo–O bonds of the linear Mo–O–Mo bridge in **1** and **2**, as is to be expected on the basis of the structures of the related compounds, $Mo_2O_3[S_2P(OPh)_2]_4$ [26], $Mo_2O_3[S_2P(OMe)_2]_4$ [16], $Mo_2O_3[S_2P(OEt)_2]_4$ [23] and $Mo_2O_3[S_2P(O\{n\text{-}Pr\})_2]_4$ [25]. The Mo–O(bridge) bonds (1.8540(3) and 1.8578 (8) Å in **1** and **2**, respectively) are considerably longer than the Mo=O(terminal) bonds (1.669(3) and 1.668(5) Å in **1** and **2**, respectively). The two bond distances are essentially the same as in the dithiophosphate analogues $Mo_2O_3[S_2P(OPh)_2]_4$ (1.8567(5) and 1.66(1) Å) [26], and $Mo_2O_3[S_2P(OR)_2]_4$, where R = Me, Et or *n*-Pr, (ave 1.86(2) and 1.65(2) Å) [16,23,25], as well as in the related dithiocarbonate $Mo_2O_3[S_2COEt]_4$ and $Mo_2O_3[S_2CO\text{-}i\text{-}Pr]_4$ (ave 1.87(1) and 1.68(2) Å) [21,22] and dithiocarbamate derivatives $Mo_2O_3[S_2CNEt_2]_4$, $Mo_2O_3[S_2CN(n\text{-}Pr)_2]_4$, and $Mo_2O_3[S_2CN(CH_2Ph)_2]_4$, (ave 1.869(9) and 1.682(6) Å) [20,19,22].

In contrast with **6**, in both **1** and **2** one of the dithiophosphate ligands is bidentate and only one is anisobidentate with the Mo–S bond that is trans to the Mo=O(terminal) bond being considerably longer (2.800(1) and 2.815(2) Å in **1** and **2**, respectively) than the other three Mo–S bonds (ave 2.50(4) Å). This pattern is identical to those in the $Mo_2O_3[S_2P(OR)_2]_4$ analogues (ave 2.81(2) for the long Mo–S bond and 2.50(3) Å for the rest) as well as in the dithiocarbonate $Mo_2O_3[S_2COR]_4$, R = Et and *i*-Pr (ave 2.72(2) for the long Mo–S bond and 2.51(4) Å for the rest) [21,22] and dithiocarbamate derivatives $Mo_2O_3[S_2CNR_2]_4$, R = Et, *n*-Pr and $[(CH_2Ph)_2]_4$, (ave 2.692(2) for the long Mo–S bond and 2.48(4) Å for the rest) [20,19,22], although the longer bond is shorter than in the dithiophosphates suggesting a slightly weaker trans influence. The additional restraint of the smaller bite angles (67–71°) in the dithiocarbonate and -carbamate ligands compared to 75.33(4)–80.23(7)° for **1** and **2** results in the S–Mo=O(terminal) angle being further from 180° ranging from 156.0(2) to 161(1) in $Mo_2O_3[S_2COR]_4$, [21,22] and 154.7(1)–159(1)° in $Mo_2O_3[S_2CNR_2]_4$ [20,19,22], compared to 166.8(1) in **1**

Table 4
Selected bond lengths (Å) and angles (°) for $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ (**1**), $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ (**2**) and $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (**6**)

and 168.2(2)° in **2**. By comparison, the two S–Mo=O(terminal) angles in **6** are slightly smaller 163.0(1) and 163.5(1)°. In **1** and **2**, the S–Mo–O(bridge) angle (160.54(3) and 160.71(6)°, respectively) is similar to the S–Mo–S angle (159.28(4) and 157.11(8)°, respectively); both of these angles being slightly larger than the S–Mo–S angle of 156.11(5)° in **6**. The O=Mo–O(bridge) angle (ave 104.4(2)° in **1** and **2**) also only differs slightly from the O=Mo=O angle in **6** (102.4)°. Table 4 shows the similarities, along with the slight differences, of the overall environment around the Mo atoms in the structures of both the monomeric and dimeric complexes.

4. Concluding comments

We have successfully prepared and characterized the binuclear oxomolybdenum(V) *O*,*O*′-ditolyl dithiophosphate complexes, $Mo_2O_3[S_2P(OR)_2]_4$ (R = *o*-, *m*-, *p*-C_6H_4Me) and dioxomolybdenum(VI) *O*,*O*′-ditolyl dithiophosphate complexes, $MoO_2[S_2P(OR)_2]_2$ (R = *o*-, *m*-, *p*-C_6H_4Me and $CH_2C_6H_5$). The IR, ^1H and ^{31}P NMR spectra of all of these oxomolybdenum complexes and the molecular structures of $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ (**1**), $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ (**2**) and $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$ (**6**) were determined. The geometry of the MoO_2S_4 core in all of these molecules, whether in the dimeric $Mo_2O_3[S_2P(OR)_2]_4$ Mo(V) species **1** and **2** or the monomeric Mo(VI) species **6**, is that of a distorted octahedron, with the Mo–O bonds *cis* to one another. Apart from the bond length differences of Mo=O(terminal) and Mo–O(bridge) bonds, the clearest difference in the molybdenum surroundings is the presence of one long Mo–S bond in **1** and **2** compared to two such bonds in **6**. This is consistent with the larger *trans* influence of Mo=O.

ical properties of compounds such as $[Ru(bpy)_3]^{2+}$ (bpy = 2,2′-bipyridine) have been studied in great detail and these studies have led to a better general understanding of photochemical processes in inorganic compounds [3]. The properties of the excited state, such as the temperature dependence of the luminescence lifetime and quantum yield of emission have been investigated as a function of the electronic properties of the coordinated ligands [4,5]. Especially, ruthenium(II) complexes containing symmetrical bipyridine-like ligands, such as substituted bipyridines, phenanthrolines and biquinolines, have been investigated in detail [6,7]. However, less attention has been paid to ruthenium(II) complexes containing asymmetric bidentate diimine ligands with two chemically different coordinating sites, although complexes with the following asymmetric ligands, pyridylpyrazoles, pyridylbenzimidazoles, pyridyltriazines, pyridyltriazoles, pyridylthiazoles and pyridylpyrimidine, have been reported [5,8–11]. So we became interested in synthesising and studying the properties of mixed-ligand ruthenium(II) complexes containing the asymmetric ligand 3-(pyridin-2-yl)-5,6-diphenyl-1,2,4-triazine (dppt, Scheme 1). Our choice of this ligand was because it is used as a sensitive reagent in the quantitative determination of Ru(II) and Fe(II) [12]. Further, it would be interesting to determine whether the coordination of the ambidentate triazine ring of dppt occurs through N2 or the sterically hindered N4 donor atom. In fact, we have shown that N2 is coordinated to Cu(II) in $[Cu(dppt)_2(H_2O)_2](ClO_4)_2$ [13]. It is obvious that the mode of coordination will have a critical role on the electronic properties of the complexes, e.g. its π-acceptor properties, because of the localised nature of the double bonds in 1,2,4-triazine [11]. The ligand is also of interest as it has rather low energy LUMO levels, as revealed by Resonance Raman spectral measurements [11] and electrochemical data [11]. The triazine nitrogen has a weak σ-donor but strong π-acceptor property [11], the two coordinating nitrogen atoms therefore will confer quite different electronic properties on the Ru(II) complexes.

We have already shown that mixed-ligand complexes [14] of the symmetrical ligands bpy and 1,10-phenanthroline (phen) can be isolated by the facile ring cleavage reaction of di-μ-chloro dimers $[Ru(pdto)Cl]_2(ClO_4)_2$ and $[Ru(bbdo)Cl]_2(ClO_4)_2$, where pdto is 1,8-bis(pyrid-2-yl)-3,6-dithiaoctane and bbdo is 1,8-bis(benzimidazol-2-yl)-3,6-dithiaoctane (Scheme 1), with bidentate ligands. In the present work we have reacted the di-μ-chloro dimers with the asymmetric ligand dppt to obtain new mononuclear Ru(II) complexes, which are of interest for the following reasons: (i) as they are mixed-ligand complexes, their electronic, emission and electrochemical properties can be easily tuned and illustrated in comparison with the corresponding symmetric bpy and phen mixed-ligand complexes; (ii) they constitute a family of mononuclear complexes containing *cis* coordinated thioether sulfur donors and an asymmetric ligand and provide an opportunity to evaluate the effect of thioether sulfur coordination on the metal to ligand charge-transfer (MLCT) involving the dppt ligand; (iii) the σ-donor properties of dppt are weaker than those of bpy, which would lead to higher Ru(II)/Ru(III) oxidation potentials. The effect of the asymmetric dppt on the electronic and redox properties of the complexes involving thioether sulfur ligands will be investigated. In this paper we report the synthesis, characterisation, electronic and electrochemical properties of the mixed-ligand complexes.

2. Results and discussion

2.1. Synthesis and characterisation

The mixed-ligand complexes $[Ru(pdto)(dppt)]^{2+}$ (**1**) and $[Ru(bbdo)(dppt)]^{2+}$ (**2**) have been prepared using the facile bridge cleavage reaction employed for isolating the bpy analogues [14]. The di-μ-chloro dimers $[Ru(pdto)Cl]_2^{2+}$ and $[Ru(bbdo)Cl]_2^{2+}$ were treated with stoichiometric amounts of the dppt ligand in aqueous ethanol (Scheme 2). To the reaction mixture was added a saturated aqueous solution of $NaClO_4$ to isolate the complexes as their perchlorates in good yields. Purification was effected by chromatography on alumina with ethanol as the eluent, followed by crystallisation of the complexes from a water–acetonitrile (2:1 v/v) mixture.

pdto bbdo

dppt

Scheme 1.

Scheme 2.

The complexes are soluble in water and other polar solvents. Their microanalytical data are in good agreement with the mixed-ligand composition of the chelates [Ru(pdto)(dppt)]$(ClO_4)_2$ (**1**) and [Ru(bbdo)(dppt)]$(ClO_4)_2$ (**2**). The conductivity of the complexes in acetonitrile solution (Λ_M: **1**, 284; **2**, 288 Ω^{-1} cm^2 mol^{-1}) show that they behave as 1:2 electrolytes and both the dications are essentially diamagnetic. A very strong and broad IR band near 1100 cm^{-1} and a strong and sharp band near 630 cm^{-1}, characteristic of ionic perchlorate, [15] are observed for both the complexes. Because of the presence of bis(pyrid-2-yl)- and bis(benzimidazol-2-yl)-dithioether ligands, neither the electronic nor electrochemical properties of the compounds can be used to identify unambiguously the way in which the ligand is bound to ruthenium. It is expected that NMR, in particular, will yield sufficient information.

2.2. ^1H NMR spectra

The chemical shifts of the free and coordinated ligands are provided in Section 4, along with the coordination-induced shifts (c.i.s. $= \delta_{complex} - \delta_{ligand}$). The assignment of ^1H and ^{13}C spectra of the complexes was made by comparison with those of the free ligands (Fig. 1) and the corresponding bpy complexes $[Ru(pdto)(bpy)]^{2+}$ (**3**) and $[Ru(bbdo)(bpy)]^{2+}$ (**4**) [14]. Also, ^1H–^1H COSY experiments [10] were carried out to unambiguously assign the spectra of the complexes.

On coordination to ruthenium, the five- and six-membered chelate rings involving the –S–CH_2–CH_2–S– and –S–CH_2–CH_2-py/bzim bridges in **1** and **2** are expected to exist in the envelope (Fig. 2a) and boat [33] (Fig. 2b–e) conformations, respectively, as in the X-ray crystal structures [14] of the related complexes **3** and **4**. Thus the two protons of each of the six methylene groups in both **1** and **2** become

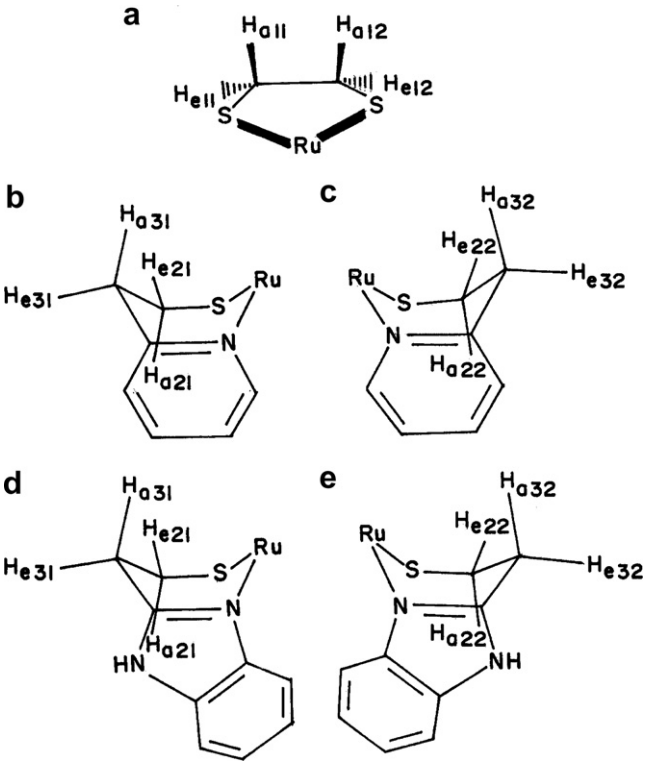

Fig. 2. Schematic view of chelation-imposed conformations of [Ru(L)(dppt)]$(ClO_4)_2$.

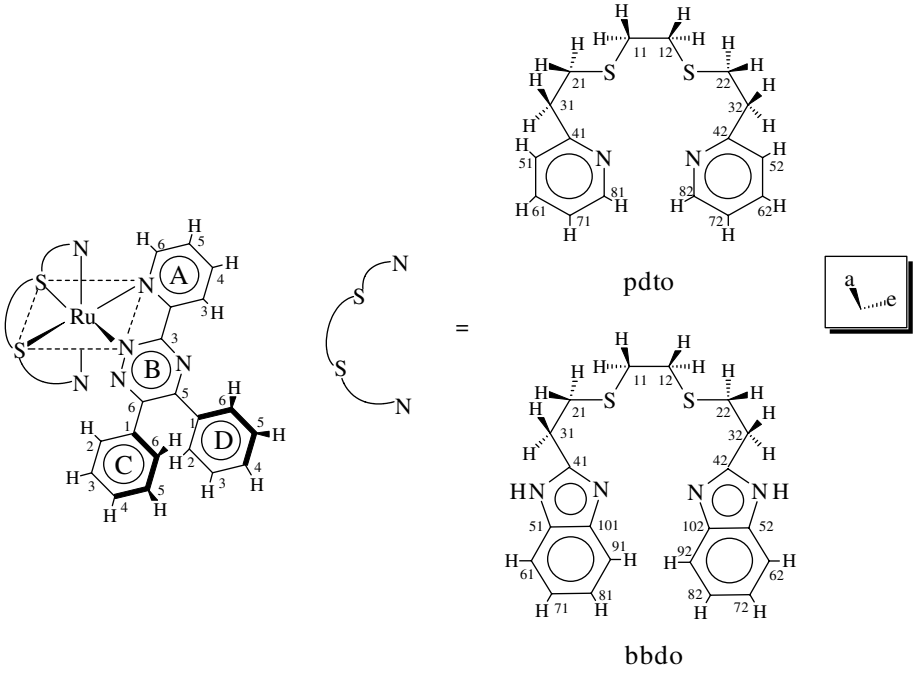

Fig. 1. Ligand orientation and proton numbering pattern for [Ru(N_2S_2)(dppt)]$(ClO_4)_2$ complexes (N_2S_2 = pdto or bbdo).

diastereotopic, axial (a) and equatorial (e), and give rise to, interestingly, 12 individual resonances. It is interesting to note that in **3** and **4** only six individual resonances have been observed, illustrating the effect of coordination of the asymmetric dppt ligand. For both **1** and **2**, the observed c.i.s. values for H_{a11} and H_{a12} are negative whereas those for H_{e11} and H_{e12} are positive. It is likely that the H_{a11} and H_{a12} protons are in close proximity to the metal, experiencing metal electron density in the envelope conformation imposed by the five-membered chelate ring (Fig. 2a). The negative c.i.s. values observed for the H_{a21} and H_{a22} protons are undoubtedly due to intraligand through-space ring-current anisotropy effects since on complexation the protons involved all lie over the shielding plane of the aromatic rings (Fig. 2b–e). The c.i.s. values for the H_{e21}, H_{e22}, H_{a31}, H_{e31}, H_{a32} and H_{e32} protons are all positive on account of chelation-imposed conformational changes.

For **1** and **2** totally four different types of aromatic rings are expected (Fig. 1): two non-equivalent py (**1**, H_{51}–H_{81} and H_{52}–H_{82}) or bzim (**2**, H_{61}–H_{91} and H_{62}–H_{92}) rings in axial positions and one py (**A**, H_{A3}–H_{A6}) and one triazine (tra, **B**) ring of dppt ligand occupying the two equatorial positions. This is in contrast to the observation of only two types of aromatic rings for **3** and **4**. Thus the magnetic non-equivalence of py (**1**) or bzim (**2**) ring protons may originate from the steric clashes of these rings with the asymmetric dppt ligand to different extents, which are expected to be more pronounced in **2** than in **1** due to the bulky bzim moieties in the former. This leads to the appearance of H_{71} (and H_{72}) and H_{81} (and H_{82}) protons of **1** as a triplet (7.735 ppm) and a doublet (7.352 ppm), respectively. Interestingly, the two bzim N–H protons in **2**, which experience lesser repulsion than the py ring protons, become magnetically equivalent and appear as a singlet (13.188 ppm). An examination of the c.i.s. values for the aromatic ring protons reveal that the chemical shifts of H_{61}, H_{62} and H_{81} (and H_{82}) (**1**) and H_{72} and H_{81} (**2**) show upfield shifts, while H_{51}, H_{52} and H_{71} (and H_{72}) (**1**) and H_{82}, H_{71}, H_{92}, H_{91}, H_{62} and H_{61} (**2**) protons exhibit downfield shifts due to ligand-to-metal σ-donation. A similar positive shift is expected for the H_{61} and H_{62} (**1**) and H_{72} and H_{81} (**2**) protons, but interestingly, only negative shifts are exhibited. In fact, these protons show downfield shifts in the corresponding bpy complexes **3** and **4**. The upfield shifts for the protons H_{61} and H_{62} (**1**) and H_{72} and H_{81} (**2**) are interesting and anomalous, as similar shifts have not been observed previously [16,17] for the Ru(II) complexes of py and bzim ligands. As coordination forces the py and tra rings of dppt to be coplanar, the py/bzim rings in pdto/bbdo are obliged to rotate away from dppt in order to minimise the steric interactions with dppt, and hence the H_{61} and H_{62} (**1**) and H_{72} and H_{81} (**2**) protons are exposed to the shielding magnetic anisotropy due to the ring currents of the py and tra rings of dppt. This reveals an unusual effect of the coordination by the aromatic ring nitrogens of the pdto or bbdo ligand wherein steric interactions are relieved by lengthening the $Ru–N_{py}$ or $Ru–N_{bzim}$ bond and by rotation of the py and bzim rings about the bond between the aromatic ring and the adjacent aliphatic carbon atom. The large negative c.i.s. values observed for the H_{81} (and H_{82}) proton of **1** may be due to metal-to-ligand π-back donation, which would increase the electron density at these sites adjacent to the py nitrogens of pdto.

The ^{1}H NMR spectra of **1** and **2** consist of four sets of signals for the **A** ring protons of dppt (Figs 3 and 4) and they should be significantly different from other resonances as the ring experiences a *trans* effect of the thioether ligand. The H_{A3} signal of **1** (10.116 ppm) and **2** (10.634 ppm) appear at fields lower than that of $[Ru(dppt)_3]^{2+}$ (9.110 ppm) [11]. This is expected as the thioether sulfur atom should cause a *trans* effect higher than that of the aromatic nitrogen atom. The dppt ligand is expected to coordinate through N2 of the tra ring and *via* the py nitrogen atom, as observed for $[Ru(dppt)_3]^{2+}$, as it would involve a much smaller steric interaction between the phenyl rings and aromatic rings of pdto or bbdo. In fact, the crystal structures [13,18] of $[Cu(dppt)_2(H_2O)_2](ClO_4)_2$ and $[Ru(tpy)(dppht)](ClO_4)_2$ [dppht = 3-(1,10-phenanthroline-2-yl)-5,6-diphenyl-*as*-triazine] reveal the coordination of N2 to Cu(II) and Ru(II), respectively. A negative c.i.s. value observed for the H_{A6} proton, adjacent to the coordinating nitrogen in both the complexes, would result from interligand through-space ring-current anisotropy effects and there is a lesser influence on the H_{A4} and H_{A5} protons, as expected. The large positive c.i.s. value for the H_{A3} proton of dppt suggests that the ligand-to-metal σ-donation is more important (as this will decrease the electron density at this site leading to a positive c.i.s. value) than the metal-to-ligand π-back donation in the ground state of these complexes. The chemical shifts of the protons of the phenyl rings **C** and **D** are not affected so much (free dppt, 7.423–7.656 ppm; **1** and **2**, 7.425–7.800 ppm) upon coordination, indicating that the effect of steric hindrance is not appreciable.

For **1** the c.i.s values of the primary ligand are less positive than those for **2** suggesting that the bbdo ligand is a better σ-donor for ruthenium(II) than the pdto ligand. Interestingly, the py (**1**) protons are shifted upfield, in contrast to the bzim (**2**) protons, which are shifted downfield. This illustrates that the ring-current-induced fields depend upon the aromaticity and π-polarisability of the heterocycles, which differ significantly for different types of heterocycles [19]. This is expected as the py nitrogen is a weaker σ-donor [20] than the bzim nitrogen, given the higher ligand basicity of the bzim ring system and probably the lower geometric constraints on the chelate bite of the bzim ring. Thus the sign and magnitude of the c.i.s. values throw light on the nature of the metal–ligand bonding and changes in conformations of the chelate rings as well.

As shown in Scheme 3, there are two sets of potentially possible diastereoisomers, depending upon whether the N_2S_2 donors of pdto or bbdo occupy positions "*cis*-α" (**A** and **B**) or "*cis*-β" (**C** and **D**) to each other. If they are coordinated in a "*cis*-α" fashion (**A** and **B**), a plane of

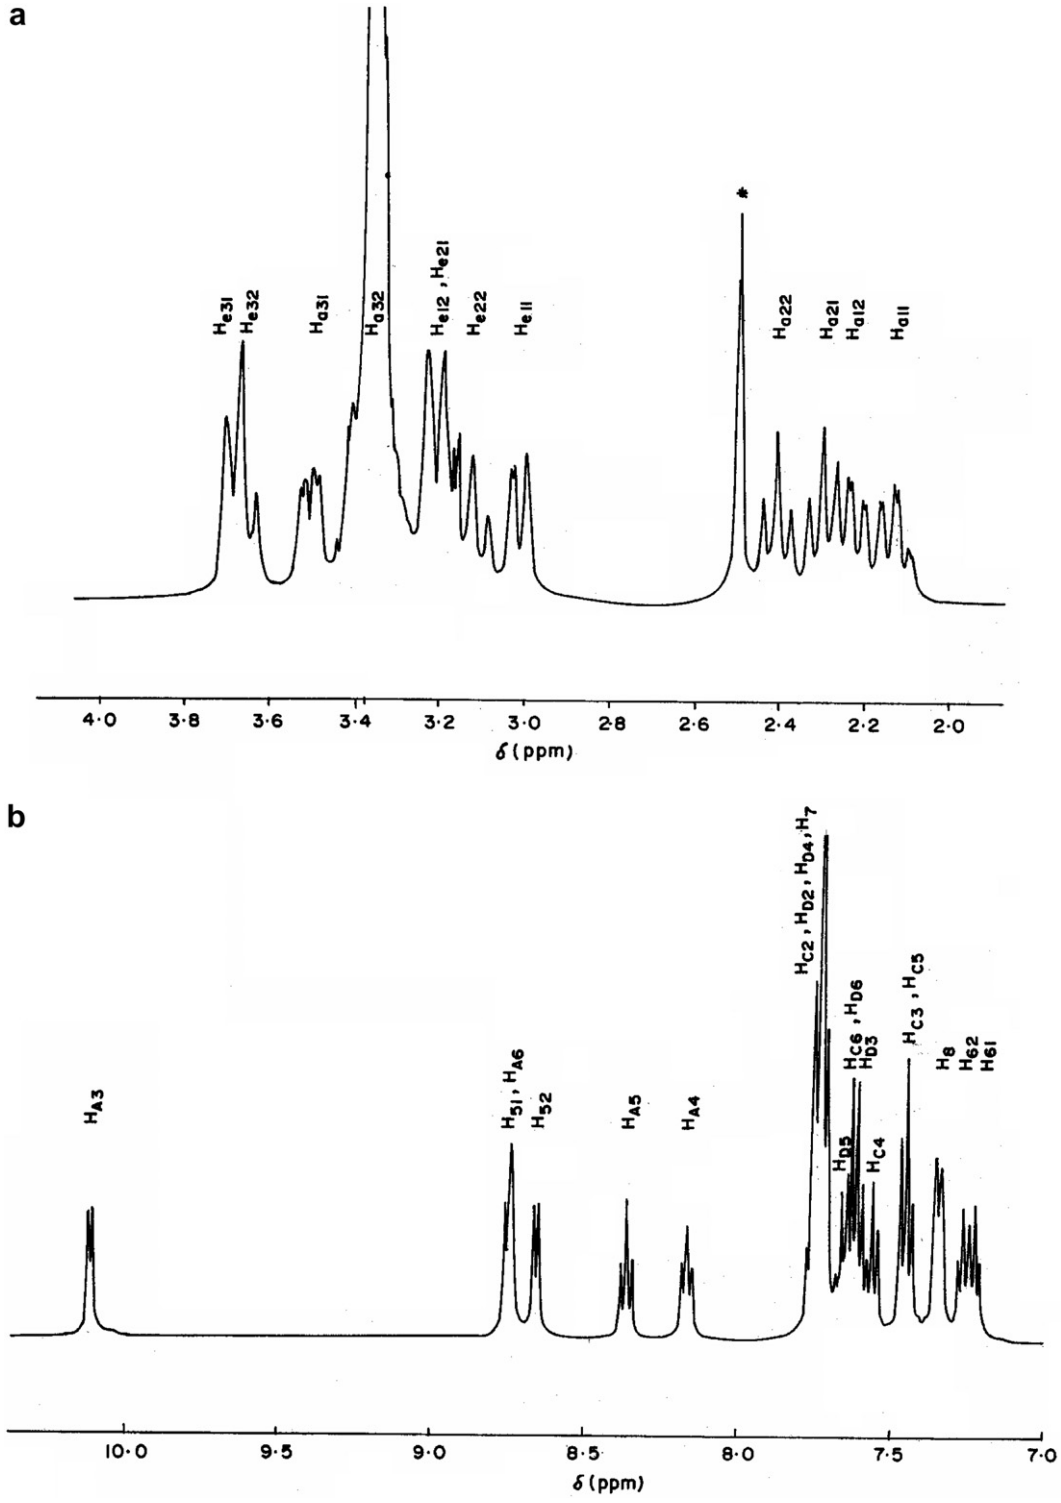

Fig. 3. ^{1}H NMR spectrum of [Ru(pdto)(dppt)]$(ClO_4)_2$ (**1**) in $(CD_3)_2SO$.

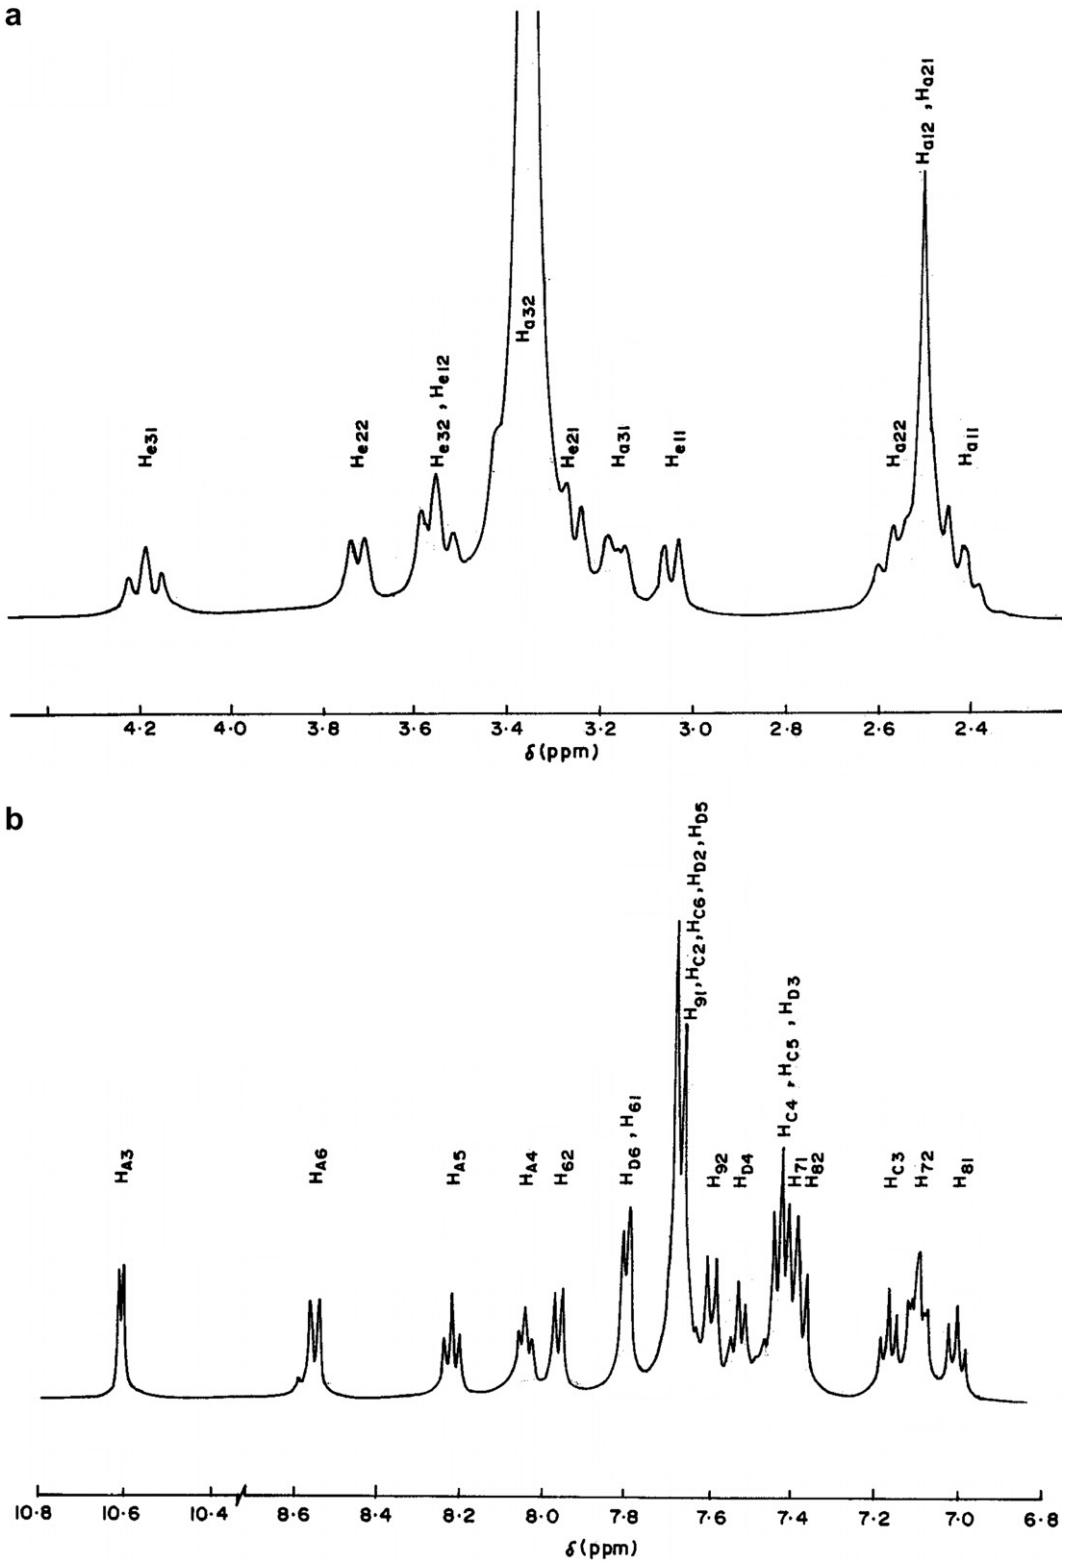
symmetry (ignoring the two nitrogens of dppt) that would contain the ruthenium atom and the two sulfur atoms would transform both the aromatic rings of the N_2S_2 ligand. The RuN_2S_2 core would also have an inversion center that would transform the aromatic rings of the N_2S_2 ligand. As a result both the aromatic rings would end up being equivalent and therefore only one set of aromatic resonances are expected to be observed in the NMR spectra. On the other hand, the coordination of two aromatic nitrogens of the N_2S_2 ligand in a "*cis*-β" fashion (**C** and **D**), would leave the aromatic rings magnetically non-equivalent since a plane of symmetry and a center of inversion would be absent, leading to the observation of two sets of aromatic resonances. Actually, both the complexes **1**



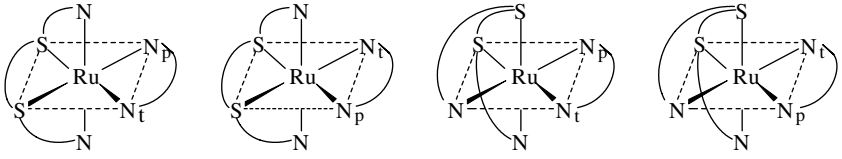


Fig. 4. ^{1}H NMR spectrum of [Ru(bbdo)(dppt)](ClO$_4$)$_2$ (**2**) in (CD$_3$)$_2$SO.

and **2** display two sets of aromatic signals (Figs. 3 and 4) corresponding to the two aromatic rings of the N_2S_2 ligand; however, H_{71} and H_{72} (7.735 ppm) and H_{81} and H_{82} (7.352 ppm) protons of **1** and the two bzim-NH (13.188 ppm) protons of **2** resonate at the same field, revealing that the two aromatic rings are magnetically equivalent and hence the possibility of a "*cis*-α" configuration (**A** and **B**) for the present complexes. The magnetic non-equivalence of the other protons in the two aromatic rings of the N_2S_2 ligand arise from the incorporation of

Scheme 3.

the asymmetric dppt ligand. Further, the ^{1}H NMR spectra of **1** and **2** show only single resonances for all the aromatic protons, substantiating the possibility of the presence of only one set of diastereoisomers. Thus the enantiomers **A** and **B** are formed in equal proportions and therefore a racemic mixture of **1** and **2** is obtained. Even though the formation of two sets of diasteroisomers ("*cis*-α" and "*cis*-β") is expected for ruthenium complexes [21], it is not observed. The "*cis*-β" enantiomers **C** and **D** are not formed, possibly due to the strong steric interaction between the aromatic rings of the N_2S_2 ligand and dppt. Single crystal X-ray structures are needed to confirm the *cis*-α configuration, but attempts to grow good single crystals of **1** and **2** were fruitless.

2.3. ^{13}C NMR spectra

The ^{13}C NMR chemical shifts of the free ligands and complexes are provided in Section 4 along with c.i.s. values. The asymmetry introduced by the dppt ligand in both complexes render all the six aliphatic carbons non-equivalent, leading to the observation of peaks for each of the carbon atoms. In contrast, the analogous bpy (**3**, **4**) complexes exhibit three aliphatic carbon signals due to the identical environment introduced by coordination of the symmetrical bpy ligand. The ^{13}C NMR c.i.s. values do not correlate in sign or magnitude with those for the ^{1}H NMR spectra because the relative contribution of the through-space ring-current anisotropy should be less important in ^{13}C than in ^{1}H NMR [19]. All the aliphatic carbons, except C_{21} and C_{22}, exhibit the largest negative c.i.s. values for **1**, suggesting that the C_{21} and C_{22} carbons are more sensitive to σ-donation effects. As the aliphatic carbons are not sensitive to π-back donation, their ^{13}C NMR shifts are more shielded in **2** than in **1**. These results support the suggestion [22] that ^{13}C NMR shifts of aliphatic carbons are susceptible to upfield shifts due to steric-compression effects, since the aliphatic carbons of both pdto and bbdo undergo changes in conformation upon complexation due to 'folding' of the flexible N_2S_2 ligand in the presence of the asymmetric dppt ligand. However, the effect is weaker in the presence of the symmetric bpy ligand.

Like the aliphatic carbons, the py (**1**) and bzim (**2**) ring carbons are non-equivalent resulting in the observation of up to 10 and 14 resonances, respectively. Interestingly, the analogous bpy complexes show only five (**3**) and seven (**4**) resonances for the symmetrical bpy ligand. The high positive c.i.s. values (+2.15 to +7.85 ppm) observed for the py (**1**) ring carbons are consistent with the presence of predominant ligand-to-metal σ-donation. The highly negative c.i.s. values observed for the C_{91} and C_{92} carbons of the bzim (**2**) ring are attributed to upfield steric-compression effects [23]. The c.i.s. values of the C_{61}, C_{62}, C_{81} and C_{82} bzim (**2**) ring carbons are lower than these carbons indicating a smaller steric-compression effect for these carbons. It is noteworthy that the C_{71} and C_{72} carbons in the bzim ring show significant positive c.i.s. values suggesting an effective dπ–π metal–ligand interaction involving these carbon sites [19].

The main contributor to the ^{13}C NMR c.i.s. values appears to be ligand-to-metal σ-donation, which generally leads to positive c.i.s. values for the **A** and **B** ring carbons (+1.27 to +4.64 ppm), except the C_{A3} (**1**) and C_{B6} (**2**) carbons of dppt in both complexes. The relatively large negative c.i.s. values for the phenyl carbons C_{C1}, C_{C2}, C_{C4}, C_{C6} and C_{D1} indicate that the metal-to-ligand π-back donation is predominant; however, the other carbons show positive c.i.s. values mainly due to ligand-to-metal σ-donation. Interestingly, the c.i.s. value (−3.29 ppm) of the C_{A3} carbon of dppt ligand in **1** is quite different from that (+4.4 ppm) of C_3 of bpy in **3**, which is systematically shifted upfield. This carbon is probably very much affected by the change in conformation of the free ligand on complexation and may experience an upfield shift due to steric-compression [22] from the lone pair of electrons on N4 of triazine. In contrast, the C_{A3} (+1.27 ppm) carbon in **2** is shifted downfield, which is quite similar to the C_3 carbon of bpy in **4**. The py carbon C_{A4} (**1**, +2.65; **2**, 2.16 ppm), *para* to the coordinated nitrogen atom of dppt (**1** and **2**), and C_{61} (+2.15 ppm) and C_{62} (+2.30) of pdto (**1**) are shifted upfield compared to the other py carbon atoms of dppt and pdto (**1**). This reveals that the coordinated nitrogen reflects the degree of π-back bonding [22,24] on the *para* carbon. However, this result has been contested on the basis of π-electron density calculations [25].

2.4. Electronic absorption and emission spectra

Complex **1** exhibits an intense band around 470 nm while **2** shows a band at 515 nm with a shoulder around 450 nm (Table 1, Fig. 5), with the absorptivity of the former being higher. These spectra are similar to the bpy (**3** and **4**) analogues and are assigned to the $d\pi(Ru^{II}) \rightarrow \pi^{*}$(dppt) metal-to-ligand charge-transfer (MLCT) transition [11]. The higher energy bands (235–325 nm) for the

complexes **1** and **2** observed in solution arise from intraligand π–π* type transitions [26]. These bands are slightly lower in energy and higher in absorptivity than the analogous bpy complexes [**3**, 430 nm (3710 $M^{-1}\,cm^{-1}$); **4**, 450 nm (2720 $M^{-1}\,cm^{-1}$)]. This is because the LUMO levels [11] of dppt are lower in energy than the symmetric bidentate diimine ligand bpy, with the MLCT transition being affected by the enhanced π-acceptor and decreased σ-donor properties of the dppt ligand compared to bpy. The negative charge built on Ru(II) by the strongly σ-donating bzim moieties in **2** would be expected to destabilise the metal dπ orbital and hence lower the $d\pi(Ru^{II}) \rightarrow \pi^*$ MLCT band energy (~45 nm) from 470 nm in **1** to 515 nm in **2**. The different electronic transitions originating from different metal d orbitals [27], as observed in $[Ru(dppt)_3]^{2+}$, may contribute to the higher intensities of these absorption bands, which renders it difficult to discern the $Ru(d\pi) \rightarrow S(\pi^*)$ MLCT bands and hence evaluate the effects of the Ru–S bond on the electronic properties.

When **1** and **2** are excited at 510 and 550 nm, respectively, at room temperature in CH_3CN solution a strong luminescence is observed for both the complexes (**1**, **2**, 650 nm; Fig. 6). The emission spectral band is suggested to be MLCT in origin, which is supported by the excitation spectra of the corresponding solutions of the complexes. The emission bands are rather narrow (half-width, 1430–1520 cm^{-1}), which is typical of a ^{3}MLCT emission, as observed for $[Ru(dppt)_3]^{2+}$ and certain other Ru(II)-polypyridine complexes [11,28]. This is further substantiated by the energy differences between the intense absorption and emission bands for **1** (5400 cm^{-1}) and **2** (4000 cm^{-1}), [4a] which are lower than those for the corresponding binu-

clear complexes $[Ru(pdto)Cl]_2^{2+}$ and $[Ru(bbdo)Cl]_2^{2+}$ exhibiting ^3MC emission [14].

2.5. Electrochemical behaviour

The electrochemical properties of both **1** and **2** have been studied by cyclic voltammetry (CV) and differential pulse voltammetry (DPV) on a Pt working electrode in acetonitrile solution in the potential range ± 2 V at 25.0 ± 0.2 °C. Both the complexes exhibit a redox wave ($E_{1/2}$, **1**, 1.18; **2**, 0.90 V versus Ag/Ag^+, Table 1, Fig. 7) assignable to the Ru(II)/Ru(III) couple based on the magnitude of the diffusion coefficients (D, $4.7–7.2 \times 10^6$ $cm^2\ s^{-1}$) calculated from the CV responses at different scan rates (30–500 mV). The linearity of the i_{pa} versus $v^{1/2}$ plots [29], which pass through the origin, indicates that the redox processes occurring at the electrode are diffusion controlled. The peak potential separations ΔE_p (74–90 mV) are generally larger than the ideal Nernstian value of 59 mV for a one-electron transfer, but commonly observed for complexes of this type apparently due to uncompensated solution resistance [30].

The Ru(II) → Ru(III) oxidation of the bzim based complex **2** is more facile than the py-based complex **1**, which is consistent with the higher MLCT band energy of the former (see above). Obviously, the σ-bonding ability of the bzim nitrogen is higher than that of the py nitrogen leading to stabilisation of the Ru(III) oxidation state. The Ru(II)/Ru(III) redox potentials in chelates containing thioether donors are attributed to the π-acceptor ability of thioether donors in stabilising the lower oxidation state. Further, the $E_{1/2}$ values of the present complexes are higher than the analogous bpy complexes **3** and **4** ($E_{1/2}$, **3**: 1.14; **4**: 0.85 V), which may be attributed to the weak σ-bonding ability of the N2 nitrogen of the dppt ligand, conferred by the strongly electron withdrawing phenyl groups. Also, Huckel calculations have shown that the LUMO of pyridyltriazine in dppt with phenyl substituents is lower than that of bpy [11], leading to the weaker σ-donor but stronger π-acceptor property of dppt. Therefore, it is evident that coordination of the strongly π-accepting dppt ligand tends to stabilise the lower Ru(II) oxidation state better than that of the analogous bpy complexes **3** and **4**.

Both the complexes display two ligand based reduction waves (**1**, −0.97, −1.09; **2**, −1.06, −1.42 V, Table 1), the one-electron nature of which is established by the magnitude of the peak currents. Since the free pdto or bbdo ligand does not exhibit any ligand reduction within the potential range used for the complexes, the observed reduction waves are assigned to two successive reductions of the coordinated dppt ligand, involving triazine (tra) and pyridine (py) moieties (Eqs. (1) and (2)). Further, the ligand reduction potential of **1** is more positive than **2** indicating that the extent of π-delocalisation of the

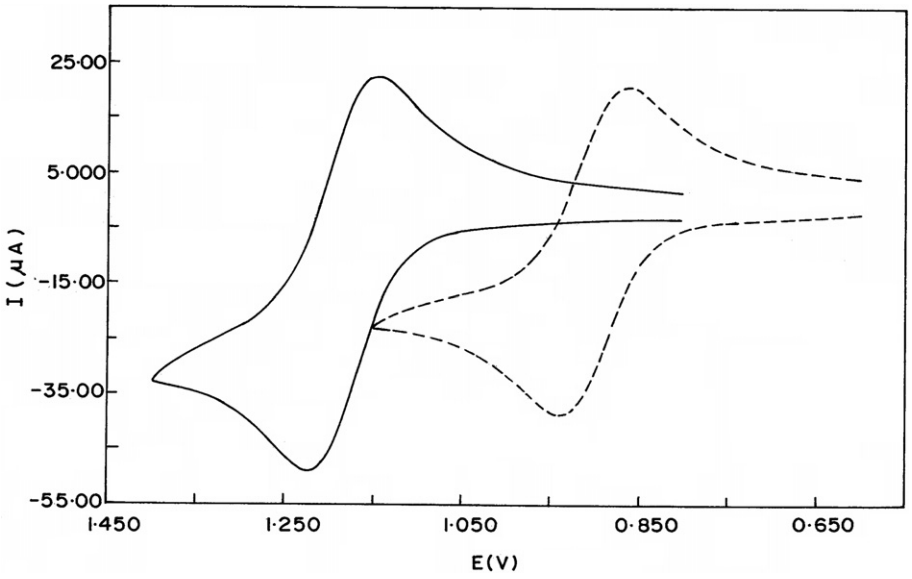

Fig. 7. Cyclic voltammograms of 0.001 M complexes $[Ru(pdto)(dppt)](ClO_4)_2$ (**1**) (—) and $[Ru(bbdo)(dppt)](ClO_4)_2$ (**2**) (----) in CH_3CN at 25 °C at 0.05 V s^{-1} scan rate.

$$[Ru^{II}(L)(py\text{-}tra)]^{2+} + e^- \rightleftharpoons [Ru^{II}(L)(py\text{-}tra^{\cdot-})]^{+} \quad (1)$$

$$[Ru^{II}(L)(py\text{-}tra^{\cdot-})]^{+} + e^- \rightleftharpoons [Ru^{II}(L)(py^{-}\text{-}tra^{\cdot-})] \quad (2)$$

asymmetric dppt ligand is stronger in pdto than in bbdo. Interestingly, the first ligand reduction potential of the present complexes is approximately the same as that of $[Ru(dppt)_3]^{2+}$ (tra-based reduction) [11], while the second ligand reduction potential is the same as that of the first ligand reduction potential of $[Ru(bpy)_3]^{2+}$ (py-based reduction) [31], thus substantiating that two chemically different imine fragments of dppt ligand are reduced at different potentials.

The excited-state redox potentials ${E_{1/2}}^{3+/2+*}$ and ${E_{1/2}}^{2+*/+}$ of the complexes were calculated by Eqs. (3) and (4), respectively, [32], where $E_{1/2}(Ru^{III/II})$ is the observed

$$E_{1/2}^{3+/2+*} = E_{1/2}(Ru^{III/II}) - E_{em} \quad (3)$$

$$E_{1/2}^{2+*/+} = E_{1/2}(L') + E_{em} \quad (4)$$

reduction potential for the Ru(III/II) couple, $E_{1/2}(L')$ is the first ligand reduction potential and E_{em} is the excited-state luminescent energy in electron volts (approximate value estimated from the luminescence maximum observed at room temperature rather than for a frozen solution). The calculated excited-state redox potentials of **1** and **2** indicate that the complexes would behave as both photooxidants and photoreductants. As photoreductants, the driving force for the py-based complex is higher than that for the bzim based complex (${E_{1/2}}^{3+/2+*}$, **1**, −0.43; **2**, −0.70 V versus SCE); however, as photooxidants, the potentials (${E_{1/2}}^{2+*/+}$, **1**, 0.64; **2**, 0.60 V versus SCE) show only a little variation.

Lever [33] introduced a ligand electrochemical parameter, $E_L(L)$, based upon the observed Ru(II)/Ru(III) redox potential (E_{obs}) as an electrochemical standard. He also proposed a relationship (Eq. (5)) between $E_L(L)$ and E_{obs} for a series of complexes $[Ru(bpy)_nL_{6-2n}]^{m+}$ ($n = 0$–3; L may be a mono-, di-, tri- and polydentate ligands). Using Eq. (5) and the data from the ligand electrochemical series proposed by Lever

$$E_{obs}(Ru^{II}/Ru^{III}) = 2n \times 0.255 + (6 - 2n)E_L(L) \quad (5)$$

[33,34], the $E_L(L)$ values for pdto, bbdo, dppt and related pyridyltriazines were calculated[1] and then used to calculate the Ru(II)/Ru(III) potentials for compounds containing substituted pyridyltriazine ligands (Table 2). The calculated values are plotted against experimental values in Fig. 8 to obtain, interestingly, a straight line. Further, the value of $E_L(L)$ for pdto is higher than that of bbdo, revealing that the role of the coordinated pdto and bbdo ligands is to raise the redox potentials of the Ru(II)/Ru(III) couple.

[1] Thus $E_L(L)$ value of dppt was calculated from the observed [11] $E_{1/2}$ of $[Ru(dppt)_3]^{2+}$ (1.790 V) and $[Ru(bpy)_2(dppt)]^{2+}$ (1.640 V) by assuming $n = 0$ and 2, respectively. Similarly those of tpt [3,5,6-tris(pyridin-2-yl)-1,2,4-triazine] and dmpt [5,6-dimethyl-3-(pyridin-2-yl)-1,2,4-triazine] were calculated from the literature $E_{1/2}$ values of $[Ru(bpy)_2(tpt)]^{2+}$ (1.710 V) [11] and $[Ru(bpy)_2dmpt]^{2+}$ (1.600 V) [11] by assuming $n = 2$. For pdto and bbdo, the $E_L(L)$ values were calculated from $[Ru(pdto)(bpy)]^{2+}$ (1.682 V) [14] and $[Ru(pdto)(bpy)]^{2+}$ (1.682 V) [14] by assuming $n = 1$.

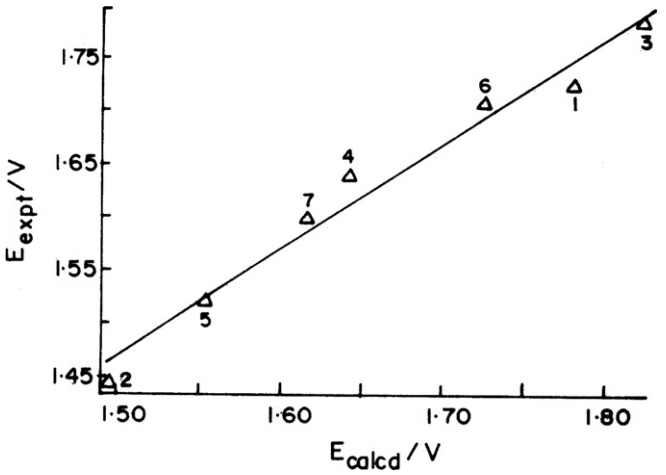

Fig. 8. Correlation between the calculated (E_{calc}) and experimental (E_{expt}) potentials of $Ru^{III/II}$ (with reference to NHE). Points **1**–**7** are for $[Ru(pdto)(dppt)]^{2+}$ (**1**), $[Ru(bbdo)(dppt)]^{2+}$ (**2**), $[Ru(dppt)_3]^{2+}$ (**3**), $[Ru(bpy)_2(dppt)]^{2+}$ (**4**), $[Ru(bpy)_3]^{2+}$ (**5**), $[Ru(bpy)_2(tpt)]^{2+}$ (**6**) and $[Ru(bpy)_2(dmpt)]^{2+}$ (**7**).

2.6. Correlation between electronic and electrochemical data

When the absorption or emission maxima (in eV) of Ru(II) complexes are plotted against the difference in the oxidation and reduction potentials of the Ru(II) complex and ligand, respectively, a linear correlation (Fig. 9) is obtained for the new mixed-ligand ruthenium complexes of dppt, including $[Ru(dppt)_3]^{2+}$, $[Ru(bpy)_2(dppt)]^{2+}$ [11], $[Ru(bpy)_3]^{2+}$ [31] and Ru(II) complexes of pyridyltriazoles [9]. A similar correlation has been reported previously for other Ru(II) systems. The linearity illustrates that the same type of orbitals are involved in the absorption and emission processes as well as the metal oxidation and ligand

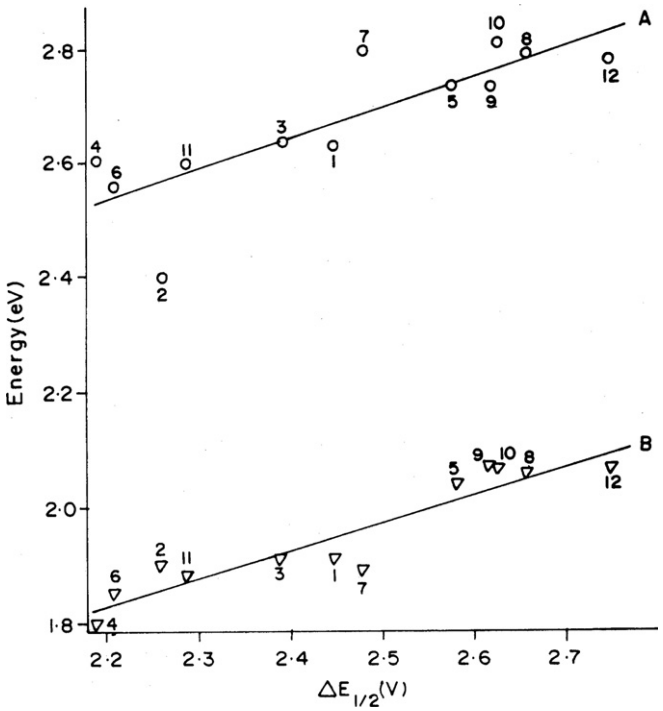

Fig. 9. Correlation between $\Delta E_{1/2}$ and the energy of absorption (A) and emission (B) maxima as measured in acetonitrile at room temperature. Points **1** and **2** refer to the compounds presented in Table 1, while points **3**–**12** are for $[Ru(dppt)_3]^{2+}$ (**3**), $[Ru(bpy)_2(dppt)]^{2+}$ (**4**), $[Ru(bpy)_3]^{2+}$ (**5**), $[Ru(bpy)_2(tpt)]^{2+}$ (**6**), $[Ru(bpy)_2(dmpt)]^{2+}$ (**7**), $[Ru(bpz)_3]^{2+}$ (**8**), $[Ru(bpy)_2(1Mptr)]^{2+}$ (**9**), $[Ru(bpy)_2(4Mptr)]^{2+}$ (**10**), $[Ru(bpy)_2(5Mptr)]^{+}$ (**11**) and $[Ru(bpy)_2(5MHptr)]^{2+}$ (**12**), taken from Refs. [25,29,38].

reduction processes of the complexes [7,9,35]. In an MLCT absorption process, an electron is removed from the filled metal orbital (dπ) to an empty orbital of the ligand (π*). Also, an electron removed from the d orbitals on electrochemical oxidation is excited to the LUMO of the complex revealing that similar processes are involved in the MLCT emission also [36]. The electrochemical and emission spectral results indicate that the lowest π* orbital of the present complexes is dppt-based, as in $[Ru(dppt)_3]^{2+}$ [11] and related complexes [37]. Hückel calculations reveal that all these pyridyltriazine ligands exhibit stronger π-acceptor properties (lower π* orbitals) but weaker σ-donor properties, which would lead to destabilisation of Ru(III) and hence higher Ru(II)/Ru(III) oxidation potentials.

3. Conclusions

Two new mixed-ligand Ru(II) complexes of the type $[Ru(L)(dppt)]^{2+}$, where L represents the bis(pyrid-2-yl)-dithioether (pdto) and bis(benzimidazol-2-yl)-dithioether (bbdo) ligands, each with a N_2S_2 donor set, and dppt is 3-(pyridin-2-yl)-5,6-diphenyl-1,2,4-triazine, have been isolated and characterised. The ^1H and ^{13}C NMR spectral studies on the complexes reveal the exclusive formation of an isomer in which the N_2S_2 ligands are *cis*-α coordinated to ruthenium and with the involvement in coordination of both triazine N2 and pyridine nitrogen atom of dppt. The observed c.i.s. values provide useful information about the structure and bonding, which reinforce the data obtained from electronic and electrochemical studies. The complexes show ^{3}MLCT luminescence at room temperature, which is mainly due to the involvement of the low-lying LUMO level of dppt in the charge transfer. Further, the weak σ-donor property of dppt as well as the *cis* coordination of 'soft' sulfur atoms appear to be responsible for the higher Ru(II)/Ru(III) redox potentials and lower energies of the MLCT absorption and ^{3}MLCT emission bands of the complexes in comparison with the corresponding symmetric bpy complexes. The Ru(II) to Ru(III) oxidation in the bzim complex is more facile than in the py analogue, which is reflected in the energies of the MLCT bands and the NMR chemical shifts. Interestingly, the difference between the oxidation and reduction potentials of the complexes correlates linearly with the energy of the absorption or emission spectral band, illustrating that the orbitals involved in the redox and absorption and emission processes are the same. Electrochemical parameterisation of the Ru(II)/Ru(III) redox potentials has been carried out using Lever's method to illustrate the contribution of the ligand donors to the Ru(II)/Ru(III) redox potentials of the present complexes.

4. Experimental

4.1. Materials

Ruthenium(III) chloride trihydrate (Arora-Matthey Limited) and 3-(pyridin-2-yl)-5,6-diphenyl-1,2,4-triazine (dppt, Aldrich) were used without further purification. *Tetra*-butylammonium perchlorate was prepared from *tetra*-butylammonium bromide (G.F. Smith, USA) by a standard procedure [38]. The product was recrystallised twice from water, dried at 110 °C for 24 h and was tested for the absence of bromide. All the common chemicals were of reagent grade and were used as received. Reagent grade solvents were dried and distilled by usual methods and the solvents were stored over molecular sieves (4 Å). The ligands 1,8-bis(pyrid-2-yl)-3,6-dithiaoctane (pdto) and 1,8-bis(benzimidazol-2-yl)-3,6-dithiaoctane (bbdo) were prepared as reported in the literature [39,40].

4.2. Synthesis of the complexes

The di-μ-chloro dimers $[Ru(pdto)Cl]_2(ClO_4)_2$ and $[Ru(bbdo)Cl]_2(ClO_4)_2$ were synthesised by the procedure described elsewhere [14]. The mononuclear mixed-ligand complexes $[Ru(pdto)(dppt)](ClO_4)_2$ (**1**) and $[Ru(bbdo)(dppt)](ClO_4)_2$ (**2**) were prepared by using the following general procedure. A sample of $[Ru(pdto)Cl]_2(ClO_4)_2$ (0.27 g, 0.25 mmol) or $[Ru(bbdo)Cl]_2(ClO_4)_2$ (0.31 g, 0.25 mmol) was refluxed with dppt (0.16 g, 0.5 mmol) for 5 h in 60 mL of ethanol–water (1:1 v/v) mixture. After evaporation to dryness, the remaining solid was dissolved in 15 mL of methanol and then gradually added to an

excess of aqueous $NaClO_4$ solution (5 mmol in 3 mL of water). The precipitate, which was filtered off and dissolved in 3 mL of acetone, was purified by using column chromatography (neutral alumina; ethanol as eluent). The compound was finally crystallised from water–acetonitrile (2:1 v/v) mixture. The resulting red orange (**1**) or pinkish violet (**2**) precipitate was isolated by slow evaporation at 10 °C, filtered off and dried in *vacuo*. Yield: **1**, 0.30 g, 65%; **2**, 0.34 g, 68%. *Anal.* Calc. for $C_{36}H_{34}Cl_2O_8N_6S_2Ru$ (**1**): C, 47.27; H, 3.75; N, 9.19. IR (KBr): $\nu(ClO_4^-)$, cm^{-1} 1098vs, 629s.

Caution. All the complexes described in this paper contain the perchlorate anion. Perchlorate salts of metal complexes with organic ligands are potentially explosive! Only a small quantities of material were prepared and they were handled with great caution.

4.3. Physical measurements

The elemental analyses were performed at the Central Drug Research Institute, Lucknow. The solution electrical conductivity was obtained using a Systronic 305 conductivity bridge. The IR spectra of the complexes were measured on a Shimadzu IR 435 spectrophotometer. The electronic spectra were recorded using an Hitachi U3410 double beam UV–Vis–NIR spectrophotometer. The solution emission properties were obtained using a Jasco FP 6500 spectrofluorometer. The NMR spectra were obtained at room temperature using a Bruker 400 MHz spectrometer. The chemical shift values in DMSO-d_6 are reported with respect to tetramethylsilane as an internal standard and the values are reported as: δ-values (multiplicity, integration, assignment). Cyclic voltammetry and differential pulse voltammetry on a platinum sphere electrode were performed at 25 ± 0.2 °C. The temperature of the electrochemical cell was maintained by a cryocirculator (HAAKE D8-G). Voltammograms were generated with the use of an EG&G PAR Model 273 potentiostat. An IBM PS-2 computer along with EG&G M270 software was employed to control the experiments and acquire data. An EPSON FX-850 printer and HP plotter (DMP-40) were used to print and plot out the cyclic voltammograms, respectively. A three-electrode system consisting of a platinum sphere

(0.2866 cm^2), a platinum auxiliary electrode and a reference electrode was used. The reference electrode for non-aqueous solution was $Ag(s)/Ag^+$ which consists of an Ag wire immersed in a solution of $AgNO_3$ (0.01 M) and *tetra-N*-hexylammonium perchlorate (0.1 M) in acetonitrile placed in a tube fitted with a vycor plug using a sleeve [41]. The $E_{1/2}$ and ΔE_p values observed under identical conditions for the Fc/Fc^+ couple in acetonitrile were 0.100 V and 76 mV, respectively, with respect to the Ag/Ag^+ reference electrode. The cyclic voltammograms (CV) and differential pulse voltammograms (DPV) of **1** and **2** were obtained in CH_3CN solutions with 0.1 M $[(C_4H_9)_4N]ClO_4$ as the supporting electrolyte at ambient temperatures under N_2. Redox potentials were measured relative to the Ag/Ag^+ reference electrode.

Acknowledgements

We thank the Department of Science and Technology, India (Grant No. SP/S1/F-10/92 and SP/S1/F-20/2001) for financial support. M.M. thanks Council of Scientific and Industrial research, New Delhi for a Senior Research Fellowship. We thank Dr. R. Ramaraj, School of Chemistry, Madurai Kamaraj University, Madurai for providing the emission spectral facility. Sophisticated Instrumentation Facility, Indian Institute of Science, Bangalore is acknowledged for NMR spectra.

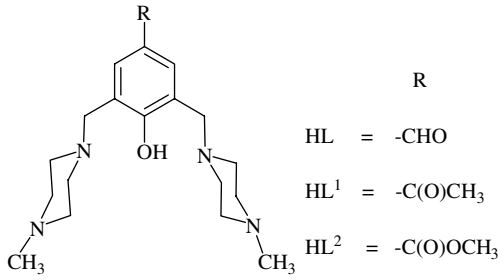

Chart 1.

metallobiosites. However, the complexes derived with macrocyclic and side-off ligands have some limitations when used as models for metallobiosites because such systems are so rigid with restricted coordination geometries. Also they do not favour the formation of exogenous bridges due to the small distance between the bimetal centres when compared to the biosites [22]. Phenol based end-off ligands having two chelating arms attached to the *ortho* positions of the phenolic –OH provide phenolato endogenous bridging units such as acetato, hydroxo, azido, cyanato, chloro, bromo, etc. They have better coordination environments with an ideal distance between the donor sites and the endogenous bridges [23–25].

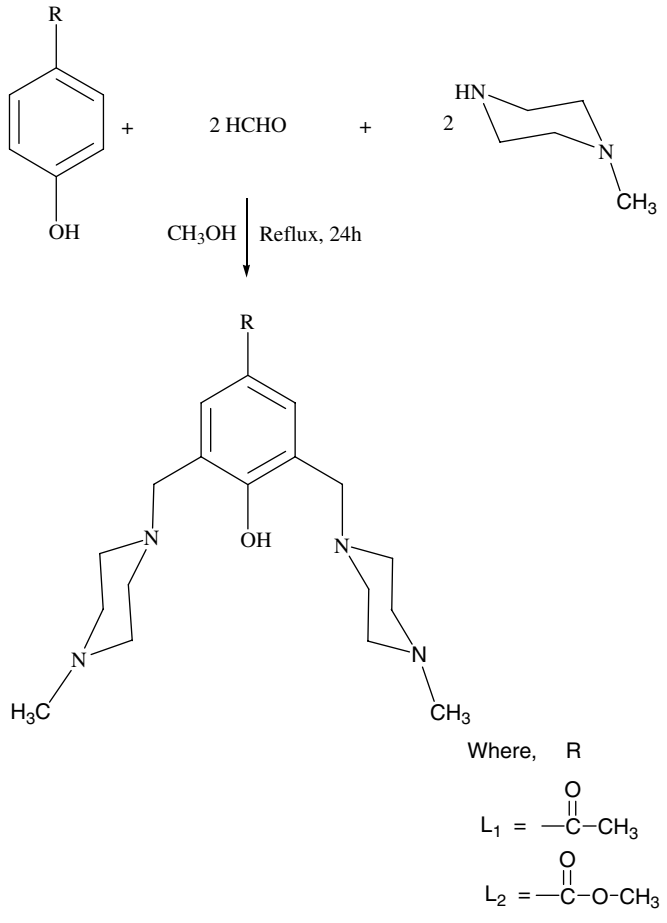
Protein binuclear copper sites effect remarkable reactions with dioxygen, including reversible binding (haemocyanin), activation (tyrosinase) and reduction (laccase) [5,26]. Non-redox-active metals such as Ni(II) and Zn(II) are potentially of interest as hydrolytic cleaving agents and their reactivity in model systems may lead to functional DNA cleaving molecules [27].

Complexes of end-off ligands with various *p*-substituents on the phenolic ring and their comparative study of spectral, magnetic, electrochemical and kinetic studies are sparse. We have already reported a group of end-off complexes having CHO as the *p*-substituent on the phenolic ring [28]. Thus, in the present work, we have synthesized two new end-off ligands that contain N and O donor atoms, by varying the *p*-substituents ($COCH_3$ and $C(O)OCH_3$) of the phenolic ring, and their mono and binuclear copper(II), nickel(II) and zinc(II) complexes. A comparative study of spectral, magnetic, electrochemical and kinetic studies was carried out on the basis of the varying electron withdrawing nature of the *p*-substituents of the phenolic ring. The chemical structure of the ligand [HL] has already been reported [28], and it is shown alongside the target ligands, HL^1 and HL^2 in Chart 1.

2. Experimental

2.1. Physical measurements

Elemental analyses of the complexes were obtained using a Haereus C, H, N; rapid analyzer. ^1H NMR spectra were recorded using a JEOL GSX 400 MHZ NMR spectrometer. Electronic spectral studies were carried out on a Hitachi 320 spectrophotometer in the range 200–850 nm. IR spectra were recorded on a Shimadzu FT-IR 8300 series spectrophotometer on KBr disks in the range 4000–400 cm^{-1}. Mass spectra were obtained on a JEOL DX-303 Mass spectrometer. Molar conductivity was measured by using an Elico digital conductivity bridge model CM-88 using a freshly prepared solution of the complexes in dimethyl formamide. Cyclic voltammograms were obtained on CHI-600A electrochemical analyzer. The measurements were carried out under oxygen free conditions using a three-electrode cell in which a glassy carbon electrode was the working electrode, a saturated Ag/AgCl electrode was the reference electrode and platinum wire was used as the auxiliary electrode. A ferrocene/ferrocenium (1+) couple was used as an internal standard and $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^+) couple under the experimental conditions is 470 mV. Tetra (*n*-butyl)ammonium perchlorate (TBAP) was used as the supporting electrolyte. The room temperature magnetic moment was measured on a PAR vibrating sample magnetometer Model-155. Variable temperature magnetic moments were measured on an EG&G Princeton applied research VSM model 4500. X-band ESR spectra were recorded at 25 °C on a Varian EPR-E 112 spectrometer using diphenylpicrylhydrazine (DPPH) as the reference. The atomic absorption spectral data were recorded using a Varian spectra AA-200 model atomic absorption spectrophotometer. The catalytic oxidation of catechol to *o*-quinone by the copper complexes and the hydrolysis of 4-nitrophenylphosphate by the copper, nickel and zinc complexes were studied in a 10^{-3} M dimethylformamide solutions. The reaction was followed spectrophotometrically by choosing the strongest absorbance of *o*-quinone at 390 nm and monitoring the increase in the absorbance, and the hydrolysis of *p*-nitrophenyl phosphate was monitored by following the UV absorbance change at 420 nm (assigned to the 4-nitrophenolate anion) as a function of time. A plot of $\log(A_\infty/A_\alpha - A_t)$ versus time was made for each complex and the rate constant for the catalytic oxidation and the hydrolysis of 4-nitrophenyl phosphate was calculated.



2.2. Materials and safety note

Formaldehyde solution, *N*-methyl piperazine, *p*-hydroxy acetophenone and *p*-hydroxy methylbenzoate were purchased from Qualigens and used as such. Methanol, acetonitrile and dimethyl formamide were purchased from Qualigens and distilled before the usage. TBAP, used as a supporting electrolyte in the electrochemical measurements, was purchased from Fluka and recrystallised from hot methanol. (*Caution!* TBAP is potentially explosive; hence care should be taken in handling the compound.) All other chemicals and solvents were of analytical grade and were used as received without any further purification.

2.3. Synthesis of ligands

2.3.1. Synthesis of 2,6-bis(4-methyl piperazin-1-yl-methyl)-4-acetyl phenol (HL^1)

The ligand HL^1 was synthesized by taking *p*-hydroxy acetophenone (4.76 g, 0.035 mol) in methanol (100 ml) mixed with *N*-methyl piperazine (7.76 ml, 0.07 mol) and the solution was refluxed for 1 h. Then a formaldehyde solution (37%) (5.28 ml, 0.07 mol) was added slowly with stirring and the mixture was kept at this temperature for 24 h. Two 5 ml portions of formaldehyde were added at approximately 8 h intervals. After that time, methanol was evaporated under vacuum and the resulting oil was extracted with chloroform (Scheme 1). A light brown oily compound was obtained. Yield: 7.56 g (60%) Mass (EI) *m*/*z*: 361.46. *Anal*. Calc. for $C_{20}H_{32}N_4O_2$: C, 66.64; H, 8.95; N, 15.54. Found: C, 66.56; H, 8.89; N, 15.57%. Selected IR data (KBr disc, ν/cm^{-1}): 1685 (C=O) s, 3395 (OH) br, 1453 (N-CH_3) br. ^1H NMR (δ ppm in $CDCl_3$) ~2.28 (s, 3H, –C(O)CH_3), ~2.30 (s, 6H, N-CH_3), ~2.52 (br s, 16H, methylene protons), ~3.68 (s, 4H, benzylic protons), ~7.71 (s, 2H, Ar-H). UV–Vis [λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)] in MeOH: 288 (21 300).

Scheme 1.

2.3.2. Synthesis of 2,6-bis[(4-methyl piperazin-1-yl-methyl)]-(4-methylcarboxy) phenol (HL^2)

The ligand HL^2 was synthesized by taking *p*-hydroxy methylbenzoate (5.32 g, 0.035 mol) in methanol (100 ml) mixed with *N*-methyl piperazine (7.76 ml, 0.07 mol) and the solution was refluxed for 1 h. Then formaldehyde solution (37%) (5.28 ml, 0.07 mol) was added slowly with stirring and it was kept at this temperature for 24 h. Two 5 ml portions of formaldehyde were added at approximately 8 h intervals. After that time, methanol was evaporated under vacuum and the resulting oil was extracted with chloroform and recrystallised with diethylether (Scheme 1). A colourless compound was obtained. Yield: 8.29 g (63%), m.p.: 72 °C. Mass (EI) *m*/*z*: 376.24. *Anal*. Calc. for $C_{20}H_{32}N_4O_3$: C, 63.80; H, 8.57; N, 14.88. Found: C, 63.75; H, 8.63; N, 14.83%. Selected IR data (KBr disc, ν/cm^{-1}): 1720 (C=O) s, 3397 (OH) br, 1455 (N-CH_3) br. ^1H NMR (δ ppm in $CDCl_3$) ~2.27 (s, 6H, N-CH_3), ~2.47 (br s, 16H, methylene protons), ~3.63 (s, 4H, benzylic protons), ~3.83 (s, 3H, –OCH_3 protons), ~7.72 (s, 2H, Ar-H). UV–Vis [λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)] in MeOH: 290 (20 900).

2.4. Synthesis of mono and binuclear complexes

2.4.1. Synthesis of mononuclear complexes of HL^1

2.4.1.1. Synthesis of the $[CuL^1(OAc)]\cdot H_2O$ complex. To a 40 ml methanol solution of the ligand HL^1 (1.081 g, 0.003 mol) was added $Cu(OAc)_2\cdot H_2O$ (0.598 g, 0.003 mol) dissolved in 20 ml of methanol and the resulting solution was refluxed for 4 h. After the reaction was over, the solution was filtered when hot and allowed to stand at room temperature. After slow evaporation of the solvent at 25 °C, a dark green compound was obtained. The compound was recrystallised from acetonitrile. Yield: 1.05 g (70%). *Anal*. Calc. for $[C_{22}H_{34}N_4O_4Cu]\cdot H_2O$: C, 52.84; H, 7.26; N, 11.20; Cu, 12.71. Found: C, 52.76; H, 7.31; N, 11.13; Cu, 12.63%. Selected IR data (KBr disc, ν/cm^{-1}): 3447, 1683, 1449. UV–Vis [λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)] in MeOH: 597 (132), 358 (17 900), 294 (24 100), $g_{\|} = 2.25$, $g_{\perp} = 2.07$ and $A_{\|} = 183$. $\mu_{eff} = 1.73$ BM.

2.4.1.2. Synthesis of the $[NiL^1(OAc)]\cdot H_2O$ complex. The Ni(II) complex was prepared by following the above procedure using the ligand HL^1 (1.081 g, 0.003 mol) and $Ni(OAc)_2\cdot 4H_2O$ (0.746 g, 0.003 mol). A pale green compound was obtained on recrystallisation from acetonitrile. Yield: 1.01 g (68%) *Anal*. Calc. for $[C_{22}H_{34}N_4O_4Ni]\cdot H_2O$: C, 53.36; H, 7.33; N, 11.31; Ni, 11.85. Found: C, 53.28; H, 7.28; N, 11.25; Ni, 11.89%. Selected IR data (KBr disc, ν/cm^{-1}): 3454, 1679, 1454. UV–Vis [λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)] in MeOH: 579 (151), 362 (16 900), 293 (22 800).

2.4.1.3. Synthesis of the $[ZnL^1(OAc)(H_2O)_2]$ complex. The Zn(II) complex was prepared by following the above procedure using the ligand HL^1 (1.081 g, 0.003 mol) and $Zn(OAc)_2\cdot 2H_2O$ (0.658 g, 0.003 mol). A colourless

compound was obtained on recrystallisation from acetonitrile. Yield: 1.04 g (67%) *Anal.* Calc. for $[C_{22}H_{34}N_4O_4Zn(H_2O)_2]$: C, 50.82; H, 7.37; N, 10.78; Zn, 12.58. Found: C, 50.89; H, 7.27; N, 10.72; Zn, 12.55%. Selected IR data (KBr disc, ν/cm^{-1}): 3456, 1683, 1456. UV–Vis [λ_{max}/nm ($\varepsilon/M^{-1}\,cm^{-1}$)] in MeOH: 289 (21 900).

2.4.2. Synthesis of binuclear complexes of HL^1

2.4.2.1. Synthesis of the $[Cu_2L^1(OAc)_2](ClO_4)\cdot H_2O$ complex. A solution of the ligand HL^1 (0.721 g, 0.002 mol) in MeOH (40 ml) was added to $Cu(OAc)_2\cdot H_2O$ (0.798 g, 0.004 mol) in MeOH (20 ml) and the resulting solution was refluxed for 7 h. The mixture was then reacted with one equivalent of $NaClO_4$ dissolved in 10 ml of methanol and refluxed for a further hour. A dark green precipitate was collected on evaporation of the resulting solution to half the volume and then allowing the solution to cool by standing at room temperature (25 °C). A dark green coloured compound was obtained on recrystallisation from acetonitrile. Yield: 1.02 g (71%). *Anal.* Calc. for $[C_{24}H_{37}N_4O_6Cu_2](ClO_4)\cdot H_2O$: C, 39.92; H, 5.44; N, 7.76; Cu, 17.60. Found: C, 39.87; H, 5.41; N, 7.68; Cu, 17.54%. Selected IR data (KBr disc, ν/cm^{-1}): 3445, 1682, 1482, 1107, 651. Conductance ($\Lambda_m/S\,cm^2\,mol^{-1}$) in DMF 86. 3. Results and discussion

We have synthesized an end-off ligand and its mono and binuclear Cu(II), Ni(II) and Zn(II) complexes having CHO as a *p*-substituent on the phenolic ring, and reported it earlier [28] (Chart 1). Two new end-off ligands having $C(O)CH_3(HL^1)$ and $C(O)OCH_3(HL^2)$ as *p*-substituents on the phenolic ring have been synthesized by means of the Mannich reaction (Scheme 1) and characterized. The electron withdrawing nature of the *p*-substituents is in the order CHO [28] > $C(O)CH_3$ > $C(O)OCH_3$. Using these two end-off ligands, mono and binuclear Cu(II), Ni(II) and Zn(II) complexes were prepared as shown in Scheme 2. Their spectral, magnetic, electrochemical and catalytic behaviours are discussed and compared on the basis of the nature of the *p*-substituent of the phenolic ring.

3.1. Spectral studies

The IR spectra of the ligands show a broad band around 3395 cm^{-1} due to the presence of the phenolic OH group. The sharp band around 1680 cm^{-1} for HL^1 and 1720 cm^{-1} for HL^2 shows the presence of an aromatic carbonyl in the ligands and it remains unchanged in all the complexes, indicating that the carbonyl group is undisturbed on complexation. The absence of a peak around 3395 cm^{-1} in all the complexes indicates the absence of ν(OH) due to deprotonation followed by complexation [29]. The strong $\nu(CO_2)$ bands at around 1450 cm^{-1} in the mononuclear complexes indicates the presence of acetate linkage. The biacetato bridged binuclear complexes showed strong $\nu(CO_2)$ bands at 1460–1490 cm^{-1} [30]. A broad band in the region around 3450 cm^{-1} indicates the presence of ν(OH) of water molecules for all the complexes. The presence of uncoordinated perchlorate anions in all of the binuclear complexes are inferred from a single broad band around 1100 cm^{-1} (ν_3-antisymmetric stretching) which are not split and a band around 650 cm^{-1} (ν_4-antisymmetric bending). The band around 930 cm^{-1} (ν_2-symmetric stretching) due to coordinated perchlorate is not observed and this indicates that no perchlorate ions are coordinated in the complexes [31,32].

The absorption spectra of the complexes exhibit three main features: one or two intense peaks below 300 nm assigned to an intraligand charge transfer transition [33], a peak or shoulder in the range 350–380 nm due to

Scheme 2.

phenolate to copper charge transfer transitions [34,35] and a band around λ_{max} at 600 nm for the mononuclear Cu(II) complexes due to the d–d transition, characteristic of a square planar geometry, and the d–d transition for the binuclear Cu(II) complexes observed around 670 nm, which is indicative of a distorted square-pyramidal geometry [36,37]. The mononuclear Ni(II) complexes show a single weak d–d band observed around 580 nm due to an $^1A_{1g} \rightarrow {}^1A_{2g}$ transition and this indicates that the complexes have a square planar geometry [38,39]. The binuclear Ni(II) complexes show three d–d transitions around 800, 620 and 560 nm assigned to $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3A_{2g} \rightarrow {}^3T_{1g}$, $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ spin allowed electronic transitions, which are characteristic of Ni^{2+} in an octahedral site [40,41]. The mono and binuclear Zn(II) complexes display only ligand centred charge transfer transitions in the UV region [42].

The position of the phenolato-to-copper LMCT charge-transfer band is sensitive to the electron density on the central copper atom [43,44]. There is a slight decrease in wavelength for the complexes having *p*-substituents in the order: $-C(O)OCH_3$ (362–376 nm) > $-C(O)CH_3$ (358–370 nm) > –CHO (352–363 nm) [28]. The *para* position of the phenolic ring substituted by the higher electron withdrawing nature of –CHO [28], when compared to other two groups, increases the Lewis acidity of the copper centre, thus shifting the phenolato-to-copper LMCT band to higher energy, and lower wavelength [45], whereas for the complexes of HL^1 and HL^2, the less electron withdrawing nature of $-C(O)CH_3$, and $-C(O)OCH_3$ at the *para* position of the phenolic ring, decreases the Lewis acidity of the copper and hence causes a red shift in the LMCT band, i.e., a shift to the lower energy region.

3.2. ESR spectra

The solid state ESR spectra of the copper(II) complexes were recorded in the X-band region at room temperature. The ESR spectra of mononuclear copper(II) complex **1** and binuclear copper(II) complex **4** are shown in Fig. 1. The ESR spectra of the mononuclear copper(II) complexes **1** and **7** show four lines [46] with a nuclear hyperfine spin 3/2, having $g_\parallel$ values of 2.25 and 2.26, $g_\perp$ values of 2.07 and 2.09, and $A_\parallel$ values of 183 and 185 cm^{-1}, respectively. A broad spectrum [47] with no hyperfine splitting was obtained for both the dicopper complexes **4** and **10** with $g = 2.1$ centred at 3200 G, indicating the presence of an antiferromagnetic interaction between the two copper ions. Owing to the favourable relative orientation of the magnetic orbitals and in spite of the Cu–Cu separation, an antiferromagnetic interaction is observed. All the nickel(II) complexes are diamagnetic in nature.

3.3. Magnetic studies

The measured magnetic moment of both the mononuclear copper(II) complexes $[CuL^1(OAc)] \cdot H_2O$ and

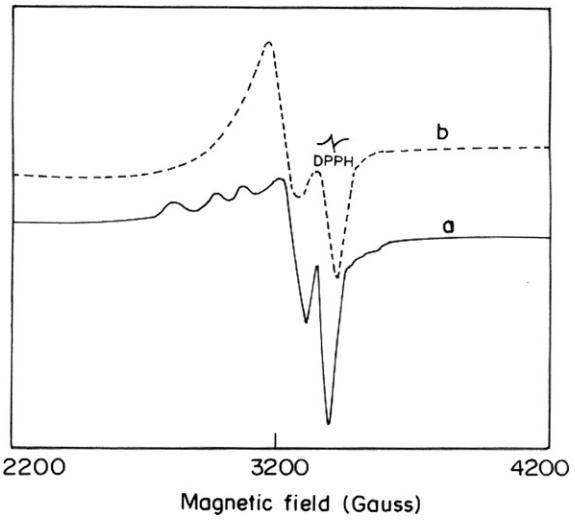

Fig. 1. ESR spectra of: (a) mononuclear $[CuL^1(OAc)] \cdot H_2O$ (**1**) and (b) binuclear $[Cu_2L^1(OAc)_2](ClO_4) \cdot H_2O$ (**4**) complexes.

$[CuL^2(OAc)] \cdot H_2O$ is 1.73 BM and that is equal to the spin only value. Room temperature magnetic moment of the binuclear copper(II) complexes $[Cu_2L^1(OAc)_2](ClO_4) \cdot 2H_2O$ and $[Cu_2L^2(OAc)_2](ClO_4) \cdot 2H_2O$ are 1.56 and 1.55 BM which are lower than the spin only value. In order to find out the magnetic exchange interaction, the magnetic moment of the complexes **2** and **8** were measured in the temperature range 77–300 K. The variable temperature magnetic study of the binuclear copper complex of HL^1 is shown in Fig. 2. The temperature dependence of the magnetic property of the complex was interpreted using the modified Bleany–Bowers equation [48]

$$\chi_m = (Ng^2\beta^2/3kT)[3 + \exp(-2J/kT)]^{-1}(1 - P) + (0.45P/T) + N_\alpha,$$

where χ_m is the paramagnetic susceptibility per metal atom after the correction for diamagnetism, N is Avogadro's number, g is the average gyromagnetic ratio, β is the Boltz-

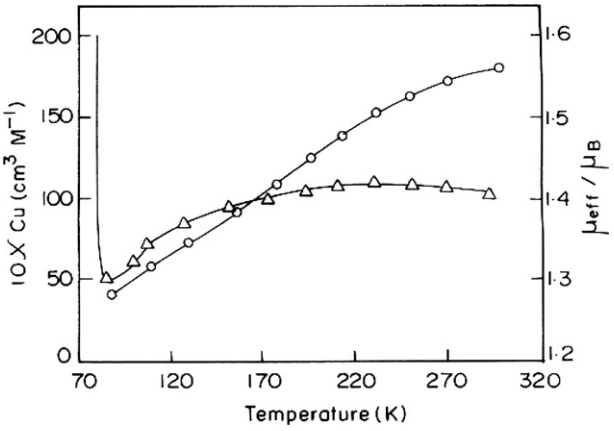

Fig. 2. Temperature-dependence magnetic properties for complex $[Cu_2L^1(OAc)_2](ClO_4) \cdot H_2O$ (**4**) where ○ is μ_{eff}/μ_B, △ is χ.

man constant, P is the fraction of monomeric copper(II) impurities, $-2J$ is the singlet–triplet energy separation, N_α is the temperature independent fraction, usually assumed to be 120×10^{-6} cgs units for copper(II) compounds. The values of the exchange integral $-2J$ for the binuclear copper complexes are 149 and 158 cm^{-1}, indicative of weak antiferromagnetic coupling between the copper(II) ions. This higher value shows formation of additional bridges between the copper(II) centres apart from the phenolate bridge.

The antiferromagnetic exchange interaction $-2J$ values observed for the binuclear copper complexes **4** and **10** are comparable to that of the analogous end-off complex reported by Narayanan and co-workers [28]. A higher $-2J$ value is observed for complex **8** than complex **6** and the complex of the parallel component with –CHO as a *p*-substituent [28]. This higher $-2J$ value may be due to the geometry around the Cu(II) ions and also due to the substitution effect in the ligand. Complexes **4** and **10** show λ_{max} around 667 and 671 nm, respectively. This small difference does not have much influence on the structure of the complexes, which may have the same geometry. So the change in the magnetic exchange interaction is mainly influenced by the *p*-substituent of the phenolic ring. The electron withdrawing group in the *para* position of the phenolic ring decreases the electron density on the copper centres [34,43], and so the antiferromagnetically coupling. Reduction in the electron density weakens the Cu–O bond and reduces the spin exchange interaction [49–51]. The electron withdrawing nature is decreasing in the order $CHO > C(O)CH_3 > C(O)OCH_3$. Hence, the $-2J$ values of the complexes having the *p*-substituent increase in the order CHO [28] $< C(O)CH_3 < C(O)OCH_3$ (134 [28], 149 and 158 cm^{-1}, respectively). The mononuclear Ni(II) complexes **2** and **8** have a square planar geometry and are diamagnetic [52]. The binuclear Ni(II) complexes **5** and **11** have a magnetic moment value of 2.96 and 2.95 BM, respectively, which is characteristic of Ni^{2+} in an octahedral site [41,53].

3.4. Electrochemical studies

The conductance measurement of all the complexes was carried out in DMF. For the mononuclear complexes, the conductance value was found to be in the range 10–15 (Λ_m/S cm^2 mol^{-1}) indicating that the complexes are neutral. Conductance values of the binuclear complexes are in the range 80–90 (Λ_m/S cm^2 mol^{-1}) indicating that they are of the 1:1 electrolyte type [54].

3.4.1. Reduction process at negative potential

The electrochemical properties of the complexes were studied by cyclic voltammetry in the potential range 0 to −1.7 V in DMF containing 0.1 M TBAP as the supporting electrolyte, and the data are summarized in Table 1. The electronegativity and hard nature of the phenoxide ligands influence the electrochemical properties of the complexes

Table 1
Electrochemical data[a] for the complexes (reduction at cathodic potential)

No.	Complexes	E_{pc}^1 (V)	E_{pc}^2 (V)
1	$[CuL^1(OAc)] \cdot H_2O$	−0.78	
2	$[NiL^1(OAc)] \cdot H_2O$	−0.87	
3	$[ZnL^1(OAc)(H_2O)_2]$	−0.90	
4	$[Cu_2L^1(OAc)_2](ClO_4) \cdot H_2O$	−0.77	−1.25
5	$[Ni_2L^1(OAc)_2(H_2O)_2](ClO_4)$	−0.76	−1.40
6	$[Zn_2L^1(OAc)_2(H_2O)_2](ClO_4)$	−0.79	−1.76
7	$[CuL^2(OAc)] \cdot H_2O$	−0.80	
8	$[NiL^2(OAc)] \cdot H_2O$	−0.89	
9	$[ZnL^2(OAc)(H_2O)_2]$	−0.93

[a] Measured by CV at 50 mV s^{-1}. *E* vs. Ag/AgCl conditions: GC working and Ag/AgCl reference electrodes; supporting electrolyte TBAP; concentration of complex 1×10^{-3} M, concentration of TBAP 1×10^{-1} M.

[55–57]. In general, this type of end-off complexes shows irreversible reduction waves at the cathodic potential region [36]. The cyclic voltammograms for the binuclear copper(II) and nickel(II) complexes are depicted in Figs. 3 and 4, respectively. Cyclic voltammograms with different scan rates show no corresponding anodic peak in the cathodic direction, which indicates that the electrode process is irreversible in nature. The mononuclear copper(II), nickel(II) and zinc(II) complexes **1**–**3** and **7**–**9** show an irreversible one-electron transfer reduction in the cathodic region. The binuclear copper(II), nickel(II) and zinc(II) complexes **4**–**6** and **10**–**12** show two step irreversible one-electron transfer reductions. Controlled potential electrolysis was also carried out for the complexes at 100 mV s^{-1} more negative to the cathodic peak, and these consumed one electron per molecule ($n = 0.95$), which indicates that each wave corresponds to a one-electron transfer process. So, the two reduction processes are assigned generally as follows:

$$M^{II}M^{II} \rightarrow M^{II}M^{I} \rightarrow M^{I}M^{I}$$

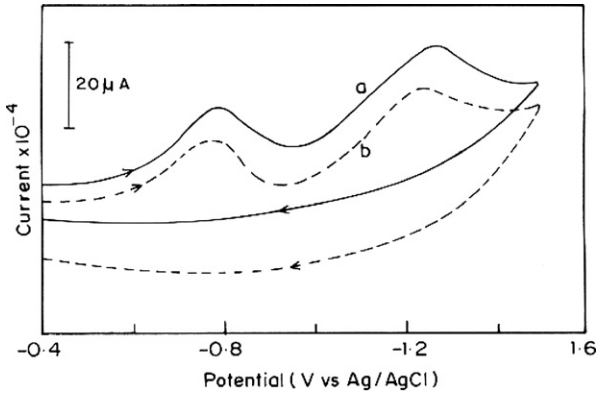

Fig. 3. Cyclic voltammograms of the binuclear copper(II) complexes: (a) $[Cu_2L^2(OAc)_2](ClO_4) \cdot H_2O$ (**10**) and (b) $[Cu_2L^1(OAc)_2](ClO_4) \cdot 2H_2O$ (**4**) (reduction process).

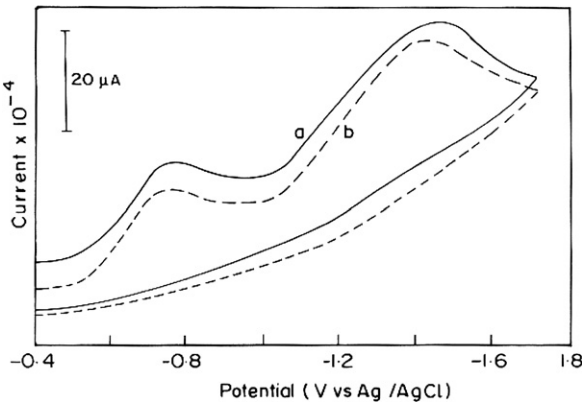

Fig. 4. Cyclic voltammograms of the binuclear nickel(II) complexes: (a) $[Ni_2L^2(OAc)_2(H_2O)_2](ClO_4)$ (**11**) and (b) $[Ni_2L^1(OAc)_2(H_2O)_2](ClO_4)$ (**5**) (reduction process).

The reduction potentials for all the mononuclear complexes of HL^1 are slightly lower than those of the mononuclear complexes of HL^2. In the same way, the reduction potentials of the binuclear complexes of HL^1 are also slightly lower than those of the binuclear complexes of HL^2. This is because the reduction potential is affected by the substituents at the *para* position of the phenoxide of the phenyl ring. The electron withdrawing nature of the *p*-substituents decreases the electron density around the metal ion and favours easy reduction [43,50]. When the electron withdrawing nature of the *p*-substituents increases, the reduction potential decreases, i.e., it favours an anodic shift, and it is in the order CHO [28] < $C(O)CH_3$ < $C(O)OCH_3$ (−0.74 [28], −0.78 and −0.80 V, respectively, for mono nuclear copper complexes – all the other complexes also have the same trend).

3.4.2. Oxidation process at anodic potential

The cyclic voltammogram of the binuclear nickel(II) complexes **5** and **11** in the anodic potential region is given in Fig. 5. The mononuclear Ni(II) complexes **2** and **8** show an irreversible oxidation wave in positive potential at +0.74 V and +0.73 V. The binuclear Ni(II) complexes **5** and **11** show two-step one-electron transfer processes in the potential range from +0.79 V to +1.35 V and from +0.75 V to +1.30 V. The mono and binuclear Ni(II) complexes are all found to be irreversible in nature. The two oxidation processes for the binuclear Ni(II) complexes are assigned generally as follows:

$$M^{II}M^{II} \rightarrow M^{III}M^{II} \rightarrow M^{III}M^{III}$$

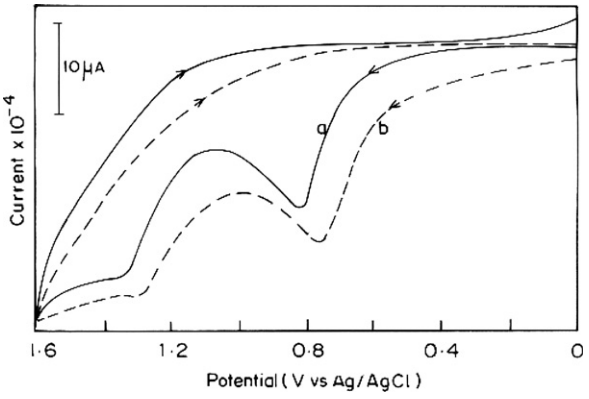

Fig. 5. Cyclic voltammograms of the binuclear nickel(II) complexes: (a) $[Ni_2L^1(OAc)_2(H_2O)_2](ClO_4)$ (**5**) and (b) $[Ni_2L^2(OAc)_2(H_2O)_2](ClO_4)$ (**11**) (oxidation process).

3.5. Kinetic studies

3.5.1. Oxidation of pyrocatechol (catecholase activity)

Efforts have also been made to investigate the catecholase activity of both mono and binuclear copper(II) complexes using pyrocatechol as a convenient model substrate for the identification of functional models for the metalloenzymes [58,59]. All the mono and binuclear copper(II) complexes synthesized were subjected for catecholase activity. The course of the reaction was followed spectrophotometrically at 390 nm nearly for 45 min at regular time intervals of 5 min. The slope was determined by the method of initial rates by monitoring the growth of the 390 nm band of the product *o*-quinone. A linear relationship for initial rate and the complex concentration obtained for all the complexes shows a first-order dependence on the complex concentration for the systems. It was found that under anerobic conditions little product was formed, so the solvent was saturated with O_2 before the kinetic experiments. Oxygen must participate directly in the catalytic cycle of the oxidation reaction, acting as a thermodynamic driving force by reoxidizing any generated copper(I) species back to the active copper(II) species.

A plot of $\log(A_\alpha/A_\alpha - A_t)$ versus time for catecholase activity of the mono and binuclear copper complexes of HL^1 and HL^2 were obtained and their observed initial rate constant values are given in Table 2. The catecholase activities of the copper complexes of HL^1 are shown in Fig. 6. It is found that the binuclear copper(II) complex shows a higher reactivity than the mononuclear complex. This is due to the fact that the oxidation of pyrocatechol to *o*-quinone requires two metal ions in close proximity [60]; hence the rate constant for the binuclear copper complex is high. Copper(II) complexes of HL^2 show higher catecholase activities than those of HL^1. This may be due to the easier reduction of the Cu(II) ions on increasing the electron withdrawing nature of the *p*-substituent [43,50] ($C(O)CH_3 > C(O)OCH_3$) of the phenolic ring.

3.5.2. Kinetic studies of hydrolysis of 4-nitro phenyl phosphate

The kinetics of hydrolysis of 4-nitro phenyl phosphate by the mono and binuclear copper(II), nickel(II) and zinc(II) complexes was determined spectrophotometrically by monitoring the increase of the 4-nitrophenolate anion characteristic absorption at 420 nm over time in DMF at 25 °C. For this purpose, 10^{-3} mol dm^{-3} solutions of the

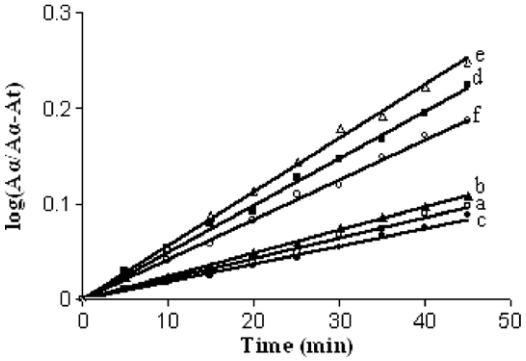

Fig. 7. Hydrolysis of 4-nitrophenylphosphate by the copper(II), nickel(II) and zinc(II) complexes: (a) $[CuL^1(OAc)] \cdot H_2O$ (**1**); (b) $[NiL^1(OAc)] \cdot H_2O$ (**2**); (c) $[ZnL^1(OAc)(H_2O)_2]$ (**3**); (d) $[Cu_2L^1(OAc)_2](ClO_4) \cdot H_2O$ (**4**); (e) $[Ni_2L^1(OAc)_2(H_2O)_2](ClO_4)$ (**5**); and (f) $[Zn_2L^1(OAc)_2(H_2O)_2](ClO_4)$ (**6**).

complexes in dimethyl formamide and a 2.5×10^{-3} M solution of tetramethylammonium hydroxide were treated with 100 equivalents of nitrophenyl phosphate in the presence of air.

The course of the reaction was followed at 420 nm for nearly 45 min at regular time intervals. The slope was determined by the method of initial rates by monitoring the growth of the 420 nm band of the product, the 4-nitro phenolate anion. A linear relationship for all the complexes shows a first-order dependence on the complex concentration for the systems. Plots of $\log(A_\alpha/A_\alpha - A_t)$ versus time for the hydrolysis of 4-nitro phenyl phosphate activity of the complexes are obtained and are shown in Fig. 7. The observed initial rate constant values for the mononuclear and binuclear copper(II) complexes are given in Table 2. It is found that the binuclear complexes show higher reactivity than their corresponding mononuclear complexes due to the fact that this kind of mechanism requires two metal ions in close proximity. The mechanism of action has already been explained with the help of model complexes [61].

On the comparison of hydrolysis of 4-nitrophenylphosphate by the Cu(II), Ni(II) and Zn(II) complexes, the Ni(II) complexes have a higher rate constant value than those of the Cu(II) and Zn(II) complexes, which is similar to our earlier report [28]. From the results, it is found that the catalytic activity of the Cu(II) complexes towards oxidation of pyrocatechol is more than that of the phosphate hydrolysis.

4. Summary

Two new phenol based "end-off" acetate bridged binuclear Cu(II), Ni(II) and Zn(II) complexes have been prepared and characterized. Both the variable temperature magnetic and ESR spectral studies of the binuclear Cu(II) complexes show the presence of a magnetic exchange interaction between the two copper atoms. The complexes show a significant change in their characteristics by varying the nature of the *p*-substituent of the phenolic ring. On lowering electron withdrawing nature of the *p*-substituent of the phenolic ring, (a) there is a red shift in LMCT-charge transfer band in electronic spectra of the complexes and (b) there is an increase in the antiferromagnetic interaction between the two copper(II) centres. Increasing the electron

withdrawing nature of the *p*-substituent of the phenolic ring, (a) causes an anodic shift in the reduction potential of the metal complexes and (b) causes a decrease in the catecholase activity of the copper complexes.

hexacoordinate ferrous TPA starting compound, possible coordination of a solvent molecule or weak anionic ligands to the Fe^{IV}=O center was suggested [10]. For example, $[TMCFe^{IV}=O(MeCN)]^{2+}$ was prepared from the oxidation of $TMCFe(OTf)_2$ with PhIO or H_2O_2, and the hexacoordinate ferrous center did not change its coordination geometry through the reaction [6a]. Herein, we report the structure and physical properties of the pentacoordinated $[TPAFeCl]^+$ complex, which suggests the possible formation of the pentacoordinated $[TPAFe^{IV}=O]^{2+}$ or dinuclear $[TPA_2Fe^{IV}_2(\mu\text{-}O)_2]^{4+}$ complex in the presence of non-coordinating solvents. The $[TPAFeCl]^+$ complex has been characterized by physical methods to elucidate its ground spin-state. Additionally, free energy values of the possible ground spin-states were obtained with semi-empirical ZINDO/S calculations.

2. Experimental

2.1. General

All experiments and reactions were carried out under a dinitrogen atmosphere using standard Schlenk line techniques or in an inert atmosphere glove box. All solvents were distilled under dinitrogen and nitrogen gas was bubbled through before each use in the glove box. $FeCl_2$, PEt_3 and P^nPr_3 were purchased from Aldrich and were used without further purification. $H_3TPA(ClO_4)_3$ was prepared from the published method [11]. $Fe(PEt_3)_2Cl_2$ and $Fe(P^nPr_3)_2Cl_2$ were prepared from a 1:2 molar ratio of $FeCl_2$ and P^nPr_3 in THF [12].

^1H NMR spectra were recorded on a Bruker 400 MHz NMR spectrometer in DMSO-d_6, using non-deuteriated solvent as the internal standard. FT-IR spectra were collected on a Nicolet DX V. 4.56 FT-IR spectrometer in KBr pellets and the spectra were corrected for background effects. UV–Vis spectra were obtained on a Shimadzu UV-1601 UV–VIS spectrometer in the range 200–1000 nm. Elemental analyses were performed in the Microanalytical Laboratory at the University of Michigan and the data were corrected using acetanilide as a standard. ESI-Mass spectra were obtained on a Finnigan LCQ-DECA mass spectrometer by direct injection. Cyclic voltammetry was performed on a BAS-voltammograph. Three electrodes consisting of a glassy carbon working electrode, Pt auxiliary electrode and a saturated calomel electrode (SCE) as a reference electrode were used for the measurements. The complexes were dissolved in 1,2-dichloroethane together with 0.1 M tetrabutylammonium hexafluorophosphate as a supporting electrolyte, and the scanning rate was 100 mV/s. Under the same condition, 0.1 M of ferrocene showed an oxidation wave at 650 mV. The magnetic susceptibility of $[TPAFeCl]_2(FeCl_4)(MeCN)_2$ was measured in the temperature ranges 20–300 K with a Quantum Design MPMS SQUID. The magnetic field of the measurements was 5000 G for the temperature-dependent experiments. The crystalline sample was put into a cellophane capsule under a dinitrogen atmosphere. The magnetic susceptibility of the holder was determined separately and diamagnetic corrections were estimated from Pascal's constants [13].

The energy and molecular orbital calculations were carried out with ZINDO/S Hamiltonian using the unrestricted Hartree–Fock (UHF) method [14]. The geometries of the $[TPAFeCl]^+$, $TPAFeCl_2$ and $[TPAFe(MeCN)_2]^{2+}$ complexes were obtained from the X-ray crystallographic structures [15,16]. The same optimized geometry with different spin-states was used as an input of ZINDO/S UHF single point calculation to obtain the energies of $S = 1$, $S = 3$ and $S = 5$ spin-states.

2.2. $[TPAFeCl]_2(FeCl_4)(MeCN)_2$

$(H_3TPA)(ClO_4)_3$ (296 mg, 0.5 mmol) and $FeCl_2(P^nPr_3)_2$ (224 mg, 0.5 mmol) were dissolved in 10 mL of MeCN

2.3. X-ray crystallography

Greenish yellow needle-shaped crystals of $[TPAFeCl]_2(FeCl_4)(MeCN)_2$ were obtained from the mother liquor. The diffraction data were collected at 123(2) K, using a Bruker SMART area diffractometer equipped with a monochromator in the Mo Kα ($\lambda = 0.71073$ Å) incident beam. The CCD data were integrated and scaled using the BRUKER-SAINT software package [17], and the structure was solved and refined using SHEXTL V5.10 (Fig. 1) [18]. The crystal data and structural parameters are shown in Tables 1 and 2. The structure for $[TPAFeCl]_2(FeCl_4)(MeCN)_2$ was solved by direct methods to locate heavy atoms, and the non-hydrogen atoms were located through subsequent difference Fourier syntheses. Structural refinement was carried out by full-matrix least squares on F^2. All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were placed in calculated positions, allowed to ride on their corresponding atoms and refined isotropically.

3. Results and discussion

From the equimolar reaction between $(H_3TPA)(ClO_4)_3$ and $Fe(P^nPr_3)_2Cl_2$ in MeCN, $[TPAFeCl]_2(FeCl_4)(MeCN)_2$ was isolated as greenish yellow crystals. The same reaction with $Fe(PEt_3)_2Cl_2$ also produced same product in a similar yield (Eq. (1)). On the contrary, the reaction of $(H_3TPA)(ClO_4)_3$ in the presence of triethylamine produced the mononuclear $TPAFeCl_2$ or dinuclear $[TPA_2Fe_2(\mu\text{-}Cl)_2](ClO_4)_2$ complex [19] (Eqs. (2) and (3)). The $TPAFeCl_2$ complex appears to dimerize under certain conditions with the formation of $[TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$ and $(HNEt_3)Cl$, but the conditions that lead to the dimerization are not clear yet. Thus, although trialkylphosphine is not found from the product, the product formation seems to require presence of PR_3. Trialkylphosphine appears to have a role in preventing the pentacoordinated mononuclear $[TPAFeCl]^+$ complex from being dimerized to the dinuclear $[TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$ complex, but we could not find any related examples of reaction product control by trialkylphosphine.

$$2(H_3TPA)(ClO_4)_3 + 3Fe(PR_3)_2Cl_2(R = Et,{}^nPr) \rightarrow [TPAFeCl]_2(FeCl_4) + 6(HPR_3)(ClO_4) \quad (1)$$

$$2(H_3TPA)(ClO_4)_3 + 2FeCl_2 + 6NEt_3 \rightarrow [TPA_2Fe_2(\mu\text{-}Cl)_2](ClO_4)_2 + 4(HNEt_3)(ClO_4) + 2(HNEt_3)Cl \quad (2)$$

$$(H_3TPA)(ClO_4)_3 + FeCl_2 + 3NEt_3 \rightarrow TPAFeCl_2 + 3(HNEt_3)(ClO_4) \quad (3)$$

From Eq. (1), formation of the five-coordinated $[TPAFeCl]^+$ complex seemed to be achieved by de-chlorination of the six-coordinated $TPAFeCl_2$ in the presence of excess $FeCl_2$, due to the thermodynamic stability of $FeCl_4^{2-}$

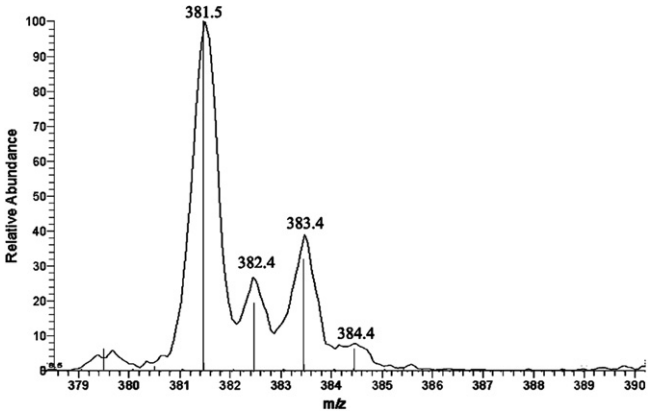

Fig. 2. ESI-MS spectrum of $[TPAFeCl]^+$. The bars represent theoretical isotope distributions of the $[TPAFeCl]^+$ ion peak.

under the reaction conditions. When the reaction proceeds in the presence of NEt_3, the synthesis of $TPAFeCl_2$ could be achieved with the formation of $(HNEt_3)(ClO_4)$. The ESI-MS spectrum of $[TPAFeCl]^+$ in MeCN showed only the peak corresponding to mononuclear complex at 381.5 *m/z* with the expected isotope distribution (Fig. 2).

Since the pyridyl groups of TPA are not parallel to the axial axis of Cl–Fe–N_{amino}, two different absolute configurations are possible from the crystallographic structure of the trigonal bipyramidal $[TPAFeCl]^+$ complex (Fig. 1). The configuration of the five-membered ring formed by the Fe, N_{pyr}, C_{pyr}, $C_{methylenyl}$ and N_{amino} atoms around the Cl–Fe–N_{amino} axial axis was used to determine the Δ and Λ stereoisomers. Formation of an enantiomeric mixture in the solid state seems to be due to the low transition state energy. Simple out-of-plane bending of the methylenyl groups is required for the transformation between the isomers. The average Fe–Cl bond distance is 2.3089(6) Å, which is slightly shorter than the average Fe–Cl distance of 2.3126(41) Å in the $[FeCl_4]^{2-}$ anion.[3] Two different Fe–Cl distances of 2.370(2) and 2.582(2) Å are reported for the dinuclear $[TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$ complex and the octahedral $TPAFeCl_2$ complex also shows two significantly different Fe–Cl bond distances of 2.337(3) and 2.463(2) Å [15]. The Fe–Cl bond distances increase in the order $[TPAFeCl]^+ < TPAFeCl_2 < [TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$.

It has been known that ferrous TPA complexes can have two different spin states depending on the terminal ligand. When two MeCN solvent molecules are coordinated $[TPAFe(MeCN)_2]^{2+}$ forms a low spin complex, but $TPAFe(OTf)_2$ and $TPAFeCl_2$ complexes form high spin complexes [16]. Fe–N distances and chemical shifts of ^1H NMR spectra have been used as characteristic parameters to determine the spin state [20]. The average bond distances of Fe–N_{pyr} and Fe–N_{amino} in $[TPAFeCl]^+$ are 2.1077(54) and 2.2483(20) Å, respectively. The average bond distances of Fe–N_{pyr} and Fe–N_{amino} in $TPAFeCl_2$ are 2.206(11) and 2.270(4) Å, respectively, and this complex was reported as a high spin complex. These are much longer than the Fe–N distances between 1.934(3) and 1.978(3) Å in the low spin $[TPAFe(MeCN)_2]^{2+}$ complex [16]. The corresponding Fe–N distances in the $[TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$ complex are 2.165(5) and 2.231(3) Å, respectively. Hence, the Fe–N distances in the pentacoordinated $[TPAFeCl]^+$ complex are close in value to those of a high spin complex, and the Fe–Cl and Fe–N bond distances in $[TPAFeCl]^+$ are generally shorter than those of the dinuclear $[TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$ complex. The ^1H NMR spectrum of the $[TPAFeCl]^+$ complex shows chemicals shifts between 145 ppm and −1 ppm, which is another evidence for a high spin complex. It is unlikely that the Δ and Λ stereoisomers show different NMR signals due to a low transition energy. The high spin $TPAFeCl_2$ complex is reported to show similar chemical shifts in the ^1H NMR spectrum [15], while the low spin $[TPAFe(MeCN)_2]^{2+}$ complex showed a narrow chemical shift distribution between 12 ppm and 8 ppm [16].

The trigonal bipyramidal coordination geometries between the two Δ and Λ isomers are a little different. The angles of N(1)–Fe(1)–Cl(1), N(2)–Fe(1)–Cl(1), N(3)–Fe(1)–Cl(1) and N(4)–Fe(1)–Cl(1) in the Δ isomer are found to be 103.50(5)°, 103.93(5)°, 101.67(5)° and 178.61(4)°, respectively. The Fe center is about 13° above the N_{pyr} trigonal plane and the Δ isomer is an axially distorted trigonal bipyramidal complex. On the contrary, Cl(2) in the Λ isomer is more bent towards the N(7) atom and the N(5)–Fe(2)–Cl(2), N(6)–Fe(2)–Cl(2), N(7)–Fe(2)–Cl(2) and N(8)–Fe(2)–Cl(2) angles are found to be 105.13(5)°, 105.03(5)°, 99.51(5)° and 176.38(5)°, respectively. Such a distortion is due to the van der Waals interaction between Cl(2) and H6B, a methylenyl proton of the Δ isomer, with a distance of 2.801 Å.

Cyclic voltammetric measurements of $[TPAFeCl]_2(FeCl_4)$ showed two quasireversible oxidation waves at 0.30 and 0.62 V, which can be assigned to the oxidation of the $FeCl_4^{2-}$ counter anion and $[TPAFeCl]^+$, respectively. In fact, the first oxidation of $FeCl_4^{2-}$ in 1,2-dichloroethane occurs at $E^{0'} = +0.30$ V versus SCE (or, −0.35 V versus Fc/Fc^+). In confirmation, the oxidation of $(^nBu_4N)_2FeCl_4$ in DMF was reported to be localized at −0.41 V (versus Fc/Fc+) [21] and the reduction of $FeCl_4^{2-}$ in MeCN was reported at −0.37 V (versus Fc/Fc^+) [22]. The oxidation of $[TPAFeCl]^+$ at 0.62 V (Fe^{II}/Fe^{III}) was much higher than that of $TPAFeCl_2$, which showed two reversible oxidation waves at 0.22 V and 0.40 V under the same conditions (Fig. 3). The reduction potential of $[TPAFeCl_2]^+$ was reported at −0.014 V [23]. Oxidation of the $[TPAFeCl]^+$ complex requires a higher oxidation potential and it seems the trigonal bipyramidal $[TPAFeCl]^+$ complex with one less chloride ligand is more stable to oxidation, compared to the octahedral $TPAFeCl_2$ complex. The oxidation potential difference between the $[TPAFeCl]^+$ and $TPAFeCl_2$ complexes is probably due to the more covalent

[3] The number in the parenthesis of average bond distances represents the larger of the individual standard deviations or the standard deviation from the mean, $\sigma = \mathrm{SQRT}[\Sigma_{i=1}{}^{n}(x_i - x)^2/n(n-1)]$, where x_i is an individual standard deviation, x is the average of individual standard deviations.

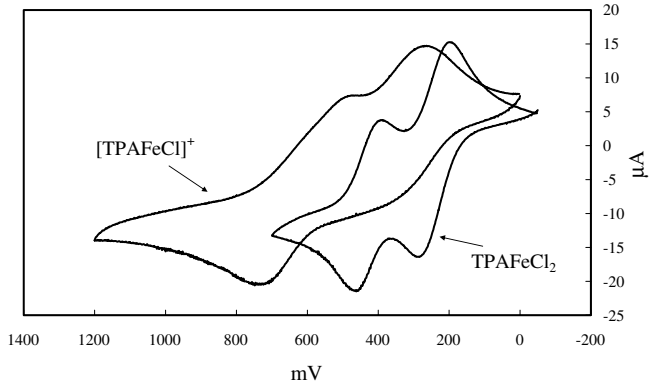

Fig. 3. Cyclic voltammograms of $[TPAFeCl]^+$ and $TPAFeCl_2$ in CH_2ClCH_2Cl at a scan rate of 100 mV/s. Supporting electrolyte: 0.1 M $^nBu_4NPF_6$.

Table 3
Relative UHF energies (in kcal/mol) for the spin-states projected from different UHF wavefunctions for the Δ and Λ isomers of the $[TPAFeCl]^+$, $[TPAFeCl_2]$ and $[TPAFe(MeCN)_2]^{2+}$ complexes

Spin-state	Δ $[TPAFeCl]^+$	Λ $[TPAFeCl]^+$	$TPAFeCl_2$	$[TPAFe(MeCN)_2]^{2+}$
$S=0$	44.89	46.14	33.79	0.00 (256.67)
$S=1$	18.03	19.11	25.34	31.41
$S=2$	0.00 (233.29)	0.00 (233.49)	0.00 (205.45)	36.38

The lowest spin states are denoted as of zero energy. The numbers in the parentheses show the energy differences of the one-electron oxidized complexes.

bond characteristics of the Fe–Cl bond of the $[TPAFeCl]^+$ complex and the coulombic effect of the charged $[TPAFeCl]^+$ complex [24].

The energies of $[TPAFeCl]^+$, $TPAFeCl_2$ and $[TPAFe(MeCN)_2]^{2+}$ at different ground spin states were obtained with the ZINDO/S Hamiltonian (Table 3). From the results, $TPAFeCl_2$ has the lowest energy at $S=2$ ground spin-state, while $[TPAFe(MeCN)_2]^{2+}$ has lowest energy at $S=0$ ground spin-state. Because the $TPAFeCl_2$ and $[TPAFe(MeCN)_2]^{2+}$ complexes have been reported as a high spin and a low spin complex, respectively, the ZINDO/S UHF calculation is considered valid for ground spin-state assignment of the $[TPAFeCl]^+$ complex. The energy of $[TPAFeCl]^+$ at $S=2$ is lower than the next accessible spin-state of $S=1$ by 19.11 kcal/mol. Besides spectroscopic and magnetic measurements, the results obtained from the calculations also suggest $S=2$ ground spin-state of the $[TPAFeCl]^+$ complex. The net charges of the Fe centers were found to be +0.184 and +0.144 for ground state $[TPAFeCl]^+$ and $TPAFeCl_2$, respectively. Thus, oxidation of the $[TPAFeCl]^+$ complex would requires a higher potential. The first oxidation potential waves for $[TPAFeCl]^+$ and $TPAFeCl_2$ are found at 0.62 V and 0.22 V, respectively. The energy differences between the ferrous and ferric complex were 233.39 kcal/mol and 205.45 kcal/mol for $[TPAFeCl]^+$ and $TPAFeCl_2$, respectively (Table 3). The oxidation potential of $[TPAFe(MeCN)_2]^{2+}$ in MeCN was reported at 0.62 V versus SCE [20]. The energy difference between $[TPAFe(MeCN)_2]^{2+}$ and $[TPAFe(MeCN)_2]^{2+}$ was the largest and was found at 256.67 kcal/mol from the calculations.

In summary, we have successfully synthesized and characterized the pentacoordinated trigonal bipyramidal $[TPAFeCl]^+$ complex. The $[TPAFeCl]^+$ complex is expected to produce high valent reactive species of pentacoordinated $[TPAFe^{IV}{=}O]^{2+}$ or dinuclear $[TPA_2Fe^{IV}_2(\mu\text{-}O)_2]^{4+}$ and the catalytic properties of the reactive species will be of a great interest.

A considerable number of Schiff-base complexes have potential biological interest, being used as more or less successful models of biological compounds [8]. Transition metal complexes of Schiff-bases containing tetradentate ligands have also showed antimicrobial activity [9]. It has been reported that transition metal complexes with redox active ligands bearing sterically hindered salicylaldimines undergo one or two electron transfers [10]. Redox-active transition metal complexes that stabilize various oxidation states of the metal centers are of considerable interest, because of their potential significance as models of redox metalloenzymes [11,12] and as effective redox reactants or catalysts [13]. Furthermore, a recently emerged field of research concerns the use of redox-active metal complexes, for instance, copper(II) complexes with salen and related Schiff-bases, as synthetic chemical nucleases or DNA damaging agents [14]. For a specific metal ion, the main factors that determine the redox properties include the nature and the arrangement of the donor atoms around the metal bonding site and the nature and the position of the substituents. Among the various ligands, many Schiff-bases derived from salicylaldehyde and related aromatic aldehydes have been found to stabilize copper(I), with respect to the Cu(II/I) potential [15]. Although the redox behavior of a number of metal complexes containing Schiff-base ligands have been reported, the electrochemical properties of such complexes are not completely clear [16–18]. Several researches have proposed that the redox potential of macrocyclic and Schiff-base complexes is directly related to many of the biologically relevant chemical characteristics of the entire complex, e.g. dioxygen binding ability and nucleophilicity [19]. Thus, there has been a strong interest in determining thermodynamically meaningful redox potentials of copper Schiff-base complexes and in understanding the relationship between these potentials and the detailed structure of the Schiff-base ligand [20].

In the present paper we report the synthesis and characterization of two new Schiff- base ligands (L^1 and L^2, where L^1 = *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,4-cyclohexane bis(methylamine) and L^2 = *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,8-diamino-3,6-dioxaoctane) involving N_2O_2 and N_2O_4 donor sites, and their copper(II) and cobalt(II) complexes. It is known that the combination of electrochemical and spectroelectrochemical methods provides a power tool to reveal the complementary nature of the molecular structure and electrochemical information of the electroactive molecules [21–26]. Very little work has been done on spectroelectrochemical characterization of Schiff-base metal complexes [27,28]. The aim of this study is to establish a comparative electro-spectrochemical study on the new Schiff-base copper and cobalt complexes based on the different molecular structures with N_2O_2 and N_2O_4 donor sites. In this study, the different binding modes of the new Schiff-base ligands for complexing with some transition metals such as copper and cobalt were confirmed by electrochemical and thin-layer spectroelectrochemical techniques, in addition to other spectroscopic methods such as IR, magnetic susceptibility, ^1H and ^{13}C NMR.

2. Experimental

2.1. Material and methods

Unless otherwise stated, all chemicals were of analytical reagent-grade and were purchased from Sigma, Merck and Across Organics. 3,5-Di-*tert*-butyl-2-hidroxybenzaldehyde (3,5-DTB) was synthesized according to the literature procedure [29a]. *N*-*N*′-Bis(3,5-di-*tert*-butylsalicylaldimine)-1,4-cyclohexane bis(methylamine) (L^1) and *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,8-diamino-3,6-dioxaoctane (L^2) were prepared here for the first time. The elemental analyses and ^1H NMR and ^{13}C NMR spectra were carried out in the laboratory of Tubitak (Scientific and Technical Research Council of Turkey), IR spectra were recorded on a Perkin Elmer Spectrum RXI FT-IR Spectrometer as KBr pellets, Magnetic Susceptibilities were determined on a Sherwood Scientific Magnetic Susceptibility Balance (Model MK1) at room temperature (20 °C) using $Hg[Co(SCN)_4]$ as a calibrant; diamagnetic corrections were calculated from Pascal's constants [29b]. Thermogravimetric (TGA) studies were recorded on a Seteram Labsys TG-16 thermobalance. UV–Vis spectra were recorded on an Agillent Model 8453 diode array spectrophotometer. Cyclic voltammograms (CV) were carried out using CV measurements with a Princeton Applied Research Model 2263 potentiostat controlled by an external PC. A three electrode system (BAS model solid cell stand) was used for CV measurements in DMSO and consisted of a 2 mm sized platinum disc electrode as the working electrode, a platinum wire counter electrode and an Ag/AgCl reference electrode. The reference electrode was separated from the bulk solution by a fritted-glass bridge filled with the solvent/supporting electrolyte mixture. The ferrocene/ferrocenium couple (Fc/Fc^+) was used as an internal standard, but all potentials in the paper are referenced to the Ag/AgCl reference electrode. Solutions containing the complexes were deoxygenated by a stream of high purity nitrogen for at least 5 min before running the experiment, and the solution was protected from air by a blanket of nitrogen during the experiment. Controlled potential electrolysis (CPE) was performed with a Princeton Applied Research Model 2263 potentiostat/galvanostat. A BAS model electrolysis cell with a fritted glass to separate the cathodic and anodic portions of the cell was used for bulk electrolysis. The sample and solvent were placed into the electrolysis cell under nitrogen. UV–Vis spectroelectrochemical experiments were performed with a home-built thin-layer cell that utilized a light transparent platinum gauze working electrode [30]. Potentials were applied and monitored with a Princeton Applied Research Model 2263 potentiostat. Time-resolved UV–Vis spectra were recorded on an Agillent Model 8453 diode array spectrophotometer.

2.2. Synthesis of the ligands L^1 and L^2

The ligands *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,4-cyclohexane bis(methylamine) (L^1) and *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,8-diamino-3,6-dioxaoctane (L^2) were synthesized by the reaction of 6 mmol 3,5-di-*tert*-butyl-2-hidroxybenzaldehyde in 20 ml absolute ethanol with 3 mmol 1,4-cyclohexane bis(methylamine) and 3 mmol 1,8-diamino-3,6-dioxaoctane in 10 ml ethanol, respectively. Also, 3–4 drops of acetic acid were added. The mixtures were refluxed for 3 h, followed by cooling to room temperature. The crystals were filtered in vacuum, then the products were recrystallized from ethanol. The products are soluble in common solvents such as $CHCl_3$, DMF and DMSO.

2.3. Synthesis of the metal complexes

2 mmol of the ligands L^1 and L^2 were dissolved in 40 ml absolute methanol and 2 mmol $Cu(Ac)_2 \cdot 2H_2O$ and $Co(Ac)_2 \cdot 4H_2O$ in 20 ml methanol were mixed. The mixtures were heated at 50 °C with constant stirring until they were concentrated. The mixtures were evaporated to a volume of 15–20 ml in vacuum and left to cool to room temperature. The compounds were precipitated after adding 5 ml ethanol. The products were filtered in vacuum and washed with a small amount of methanol and water. The products were recrystallized from methanol. All the complexes are stable at room temperature and soluble in solvents such as $CHCl_3$, DMF and DMSO.

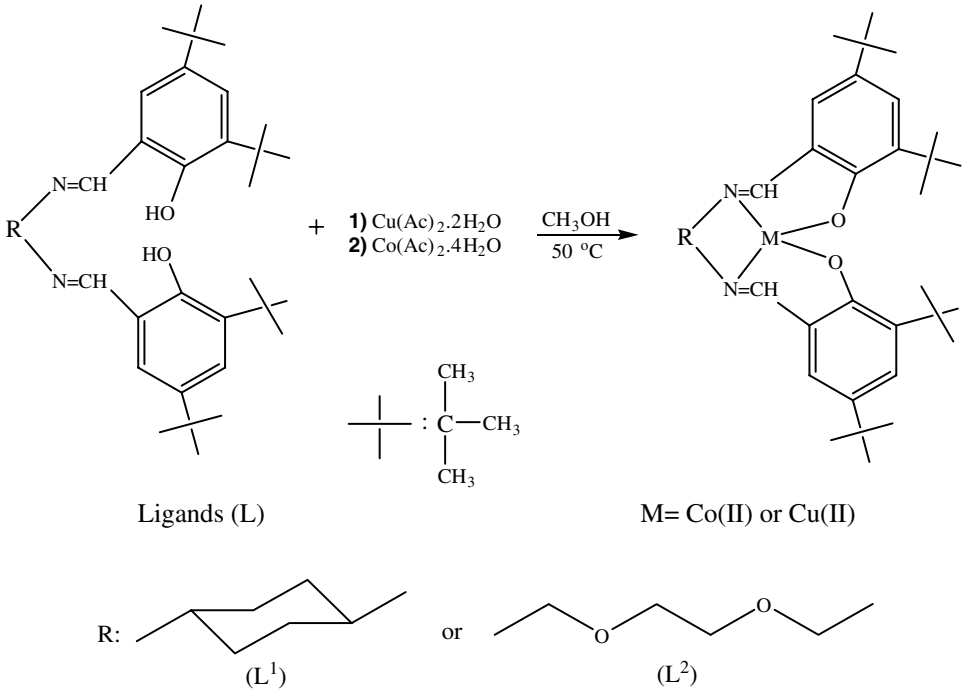
3. Results and discussion



3.1. Synthesis

The reaction for the synthesis of the ligands is given in Scheme 1. The first step is the synthesis of *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,4-cyclohexane bis(methylamine) (L^1) and *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,8-diamino-3,6-dioxaoctane (L^2) from the reaction of 3,5-di-*tert*-butyl-2-hidroxybenzaldehyde with 1,4-cyclohexane bis(methylamine) and 1,8-diamino-3,6-dioxaoctane, respectively. The second step is the synthesis of [CuL^1], [CuL^2] and [CoL^1], [CoL^2] complexes from the reaction of *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,4-cyclohexane bis(methylamine) (L^1) and *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,8-diamino-3,6-dioxaoctane (L^2) with the corresponding metal salts (Scheme 2).

The metal to ligand ratios of the Co(II) and Cu(II) complexes were found to be 1:1. Infrared spectra of ligands and their complexes were recorded in KBr pellets from 4000 to 400 cm^{-1}. The IR spectra of the ligands are characterized by the appearance of a band at 3410 cm^{-1} for L^1 and 3413 cm^{-1} for L^2 due to the *v*(O–H) groups [31]. In the spectra of the Cu(II) and Co(II) complexes, these bands disappear. The vibrations of the azomethine groups of the free ligands are observed at 1633 cm^{-1}. In the case of

Scheme 1. Synthetic route to the ligands.

Scheme 2. Synthetic route to the complexes.

the complexes, these bands are shifted to the lower frequencies, indicating that the nitrogen atom of the azomethine groups is coordinated to the metal ion, as expected [32]. The bands at 1175 cm^{-1} for L^1 and 1173 cm^{-1} for L^2 are ascribed to the phenolic C–O stretching vibrations. These bands are shifted to lower frequencies due to O-metal coordination [33]. Additionally, a peak observed at 1139 cm^{-1} in the free ligand (L^2) has been assigned to the etheric C–O–C stretching. On complexation, this band is shifted to a lower frequency range 1124–1112 cm^{-1}, indicating coordination through the etheric oxygen. The coordination of the azomethine nitrogen is confirmed with the presence of a new band between 534 and 546 cm^{-1}, assignable to ν(M–N) for the Co(II) and Cu(II) complexes [34]. The coordination of the azomethine oxygen group is confirmed with the presence of a new band at between 465 and 493 cm^{-1}, assignable to ν(M–O) for the Co(II) and Cu(II) complexes.

The ^1H NMR and ^{13}C NMR spectra of the ligands L^1 and L^2 were recorded in $CDCl_3$ solution at 400 MHz. The ^1H NMR spectrum of L^2 and the ^{13}C NMR spectrum of L^1 are given in Fig. 1. The ^1H NMR spectra of the ligands L^1 and L^2 showed one singlet peak at $\delta = 13.78$ ppm and $\delta = 13.66$ ppm due to –OH protons, respectively. Also, the L^1 and L^2 ligands indicate the presence of two equivalent azomethine groups. Due to the equivalent chemical environments, two signals for L^1 at 8.30 and 8.33 ppm (d, 2H) and one signal for L^2 at 8.35 ppm (s, 2H) are recorded for the azomethine protons [35]. However, the protons of the *tert*-butyl groups of the ligands exhibit two sharp singlet peaks between 1.31 and 1.45 ppm, indicating that the *tert*-butyl protons of these compounds are magnetically non-equivalent [36,37]. On the other hand, the ^1H and ^{13}C NMR spectra of the ligand L^1 showed signals at 166.07 and 166.03 ppm belonging to C_{11}, 66.63 and 63.79 ppm belonging to C_{12}, CH=N (8.30 and 8.33 ppm) and N–CH_2 (3.53–3.57 and 3.45–3.46 ppm). These carbon and proton resonances have a double resonance indicating that ligand (L^1) has *cis–trans* isomerism [38]. The isomer ratio was found to be 60% *cis*-isomer and 40% *trans*-isomer from the ^1H and ^{13}C NMR data. The NMR data of the ligands and their complexes are given in Section 2. Since the Co(II) and Cu(II) complexes are paramagnetic nature, their NMR spectra could not be obtained.

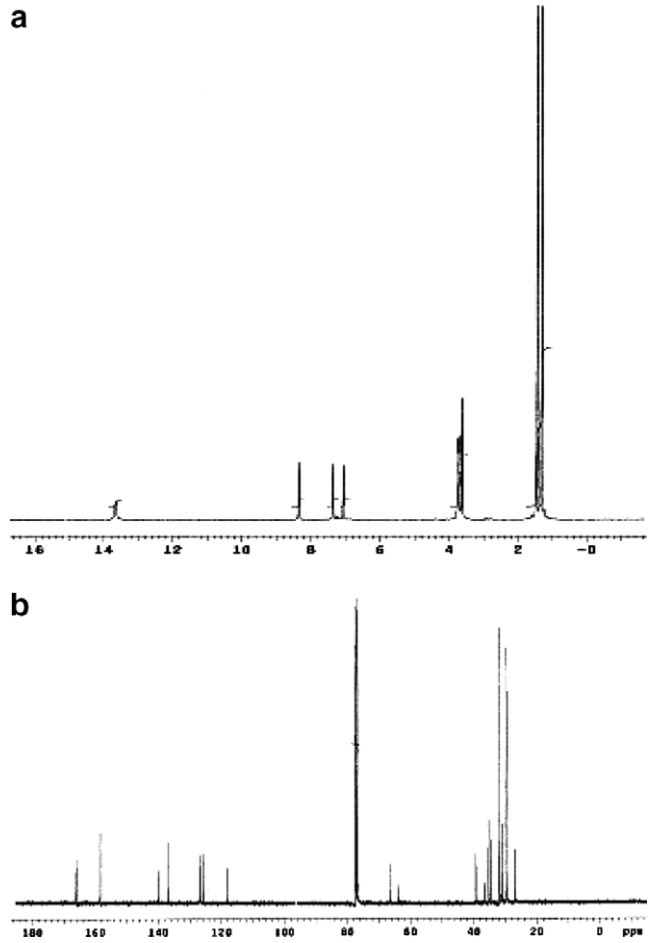


Fig. 1. The ^1H NMR spectrum of L^2 (a); the ^{13}C NMR spectrum of L^1 (b).

The electronic spectra of the ligands and their metal complexes were recorded in C_2H_5OH for the ligands and in $CHCl_3$ for the complexes. The bands below 331 nm are attributable to intramolecular $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions. The very intense bands at low wavelengths have been assigned to charge transfer transitions [39,40], for metal complexes with aromatic bridges these bands occur at longer wavelengths, as expected from the higher aromaticity of the ligands which eases delocalization of electron density.

3.2. Magnetic measurements

Room temperature magnetic moments of the Cu(II) complexes are between 1.89 and 1.95 BM, which is typical for mononuclear compounds of Cu(II) with a $S = 1/2$ spin-state and does not indicate antiferromagnetic coupling of the spins at this temperature. The room temperature magnetic moment of between 3.61 and 3.76 BM determined for the Co(II) complexes are close to the spin-only magnetic moments ($\mu = 3.87$ BM) for three unpaired electrons.

3.3. Thermal analysis

The thermal stability of the ligands and the Co(II) and Cu(II) metal complexes was investigated by TGA. The TGA curves were obtained at a heating rate of 5 and 10 °C min^{-1} under a nitrogen atmosphere over the 20–900 °C range, and they show that L^1 and L^2 and the Cu(II) and Co(II) complexes are thermally stable up to 198 for L^1, 164 for L^2, 240 for [Cu(L^1)], 214 for [Co(L^1)], 174 for [Cu(L^2)] and 189 for [Co(L^2)] °C. As a results of the thermal analysis, the most thermally stable complex is [Cu(L^1)], whereas the least stable complex is [Cu(L^2)] [35c].

3.4. Molar conductivity

The molar conductivities (Λ_M) of the Cu(II) and Co(II) metal complexes in DMF (dimethyl formamide) at 10^{-3} M were found to be in the range 1.2–3.9 Ω^{-1} cm^2 mol^{-1}. These low values indicate that all of the metal complexes are non-electrolytes due to no counter ions in the proposed structures of the Cu(II) and Co(II) metal complexes (Scheme 2) [35b,35c]. The difference in the number of protons in the Cu(II) and Co(II) metal complexes probably points to the difference in size of the +2 oxidation state of these metal ions, with the different polarizing ability due to the different sizes. Thus, the electrical conductivities of the Cu(II) complexes are higher than the Co(II) metal complexes [41,42].

3.5. Electrochemistry

The electrochemical behavior of [Cu(L^1)], [Cu(L^2)] and [Co(L^1)], [Co(L^2)] was investigated using the cyclic

Table 1
The electrochemical potentials of the copper and cobalt complexes

Complexes	Electrolyte	Solvent	M(II)/M(I) E_{pc}^{b}	ΔE^{a} (V)	M(II)/M(III) E_{pa}^{b}	ΔE^{a} (V)
[Cu(L$_1$)]	TBAP	CH_2Cl_2			1.40	
[Cu(L$_2$)]	TBAP	CH_2Cl_2	−1.07	358	1.09	
[Co(L$_1$)]	TBAP	CH_2Cl_2			0.859	
[Co(L$_2$)]	TBAP	CH_2Cl_2			0.348	248

[a] $\Delta E_p = (E_{pa} - E_{pc})$.
[b] Anodic peak potential and cathodic peak potential for the irreversible process.

voltammetric (CV) technique in CH_2Cl_2 solution containing 0.1 M TBAP. The data obtained in this work are listed in Table 1. Fig. 2 shows the CVs of [Cu(L^1)] and [Cu(L^2)] at 0.100 V s^{-1} scan rate. As can be seen from Fig. 2a, [Cu(L^1)] displayed one oxidation wave in CH_2Cl_2 containing the Ag/AgCl electrode system. The anodic peak potential for the oxidation process displayed at $E_{pa} = 1.40$ V versus Ag/AgCl. The oxidation process has a large value for the cathodic to anodic peak separation, and deviates from unity for the peak cathodic and peak anodic current ratios, i_{pc}/i_{pa}, at 0.100 V s^{-1} scan rate. The results show that the redox process is irreversible in the scan range of 0.025–0.250 V s^{-1} in CH_2Cl_2 solution, and can be indicative of a decomposition reaction occurring under the CV conditions. As can be seen from Fig. 2b, [Cu(L^2)] exhibited a totally irreversible oxidation process without a corresponding anodic wave at 0.100 V s^{-1} scan rate, and its anodic potential displayed at $E_{pa} = 1.09$ V versus Ag/AgCl. On reverse scan, a cathodic wave (II′) appeared at 0.200 V following the oxidation potential (II), which was assigned to an EC process. [Cu(L^2)] also showed one reduction process (I_c) at $E_{pc} = -1.07$ V. This reduction wave is an irreversible process because of the large value of the cathodic to the anodic peak separation ($\Delta E = 358$ V at 0.100 V s^{-1} scan rate), even if it has the corresponding anodic wave (I_a). The results reveal that the [Cu(L^1)] and [Cu(L^2)] complexes exhibit different electrochemical behavior under the same experimental conditions. It is well known from the literature [43] that redox potentials of Schiff-base complexes are markedly dependent on the ligand, solvent and geometry of the complexes. Electron-withdrawing substituents on the ligands shift the redox potential positively, whereas electron-donating groups have the opposite effect. On the other hand, the oxidation potentials are also dependent on the imine bridge of the Schiff-base, with the more positive potentials observed for complexes with aromatic bridges. Two possible explanations can be invoked to explain this behavior. (i) An increase in unsaturation that would ease electron-density delocalization from the metal to the ligand, and (ii) higher rigidity of the ligand, imparted by the aromatic bridge, that would hinder a contraction of the hole cavity. Moreover, the redox potentials show a cathodic shift with an increase in the donor capacity of the solvent. For example, oxidation of square-planar metal(II) complexes to metal(III) takes place with a concomitant increase in coordination number, as these latter complexes are normally six-coordinate. The cathodic shift in the redox potentials ongoing from DMF to DMSO is attributed to the stronger axial bonds that are established between the metal(III) center and the molecules of the better donor, and that help to stabilize the high oxidation state of the metal [43a]. The size of the coordination cavity in the complexes, and the geometric requirements and the size of the metal ions in different oxidation states also affect the redox potential [44]. For example, a tetrahedral structure of the Schiff-base complex enhances the ease of reduction of Cu(II) to Cu(I) compared to a planar coordination about the copper atom [43e]. In our case, the experiments

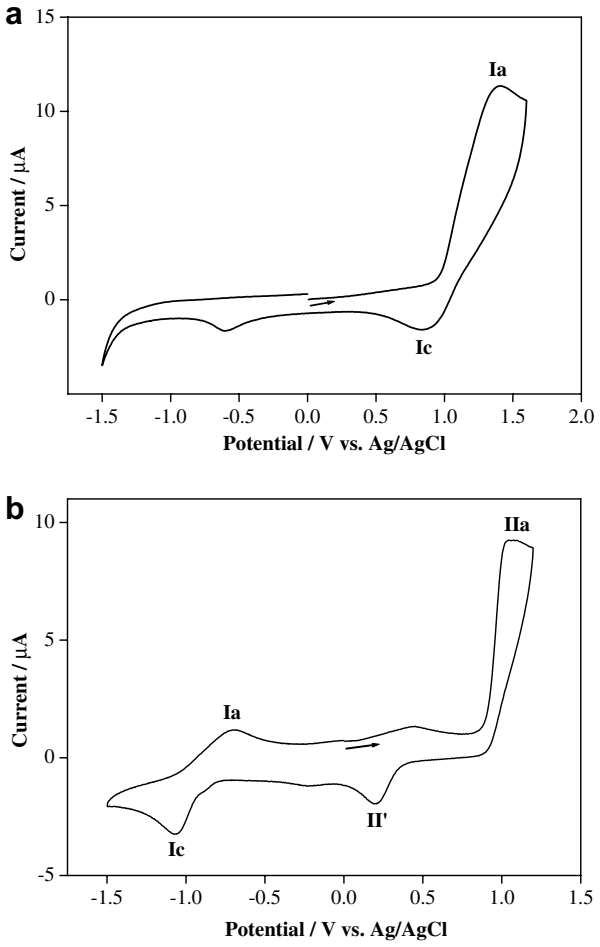

Fig. 2. Cyclic voltammograms of [Cu(L^1)] (a); [Cu(L^2)] (b) in CH_2Cl_2 solution containing 0.1 M TBAP. Scan rates = 0.100 V s^{-1}.

were carried out in CH_2Cl_2 solution so any solvent effect can be eliminated on comparing the electrochemical behavior. Taking into account substituent effects for the two copper Schiff-base complexes, both cyclohexane and dioxaoctane bridged on the imine group of the Schiff-base can be considered as weak electron-donating groups, thus a large potential shift could not be expected for these copper complexes. However, the structural differences of the [Cu(L^1)] and [Cu(L^2)] complexes should be taken into account for the different electrochemical behavior of the complexes under the same experimental conditions. Because the CV of [Cu(L^2)] showed a lower oxidation potential compared to [Cu(L^1)], it was seen that the oxidation wave (II) of [Cu(L^2)] was accompanied by an EC process (II′), which was not observed for [Cu(L^1)]. Also, [Cu(L^2)] gave a reduction process but [Cu(L^1)] did not. If the anodic scan was limited to the potential $E = 0.6$ V, the EC process was not observed. These results indicate that the Cu(II) ion in [Cu(L^2)] is coordinated by N_2O_4 donor sites where two complementary lone pairs come from dioxaoctane binding on the imine group of the Schiff-base responsible for this binding mode of the ligand. On the other hand, [Cu(L^1)] presents a square-planar structure with four donor atoms, as observed for several Schiff-base complexes with N_2O_2 donor groups. In the case of [Cu(L^2)], the oxidation of Cu(II) (d^9) to Cu(III) (d^8) involves a drastic decrease in the metal radius and a conformation change from octahedral to square-planar. This structural reorganization of the oxidized complex resulted in the observation of the EC process. This process (II′), following the oxidation wave (II) in the CV of the complex, exhibited re-reduction of the oxidized copper ion (Cu(III) → Cu(II)) where the complex changed into its original form. The reduction process was observed for octahedral [Cu(L^2)] complex but not for the square-planar [Cu(L^1)] complex. The reduction of Cu(II) (d^9) to Cu(I) (d^{10}) involves a drastic increase in the metal radius, so [Cu(L^2)] favors its original geometry. Therefore, no EC process was observed following the reduction process (Ic). The fact that [Cu(L^2)] exhibits a reduction process can be attributed to the different geometry of the complex compared to [Cu(L^1)].

The electrochemical behavior of the [Co(L^1)] and [Co(L^2)] complexes is presented in Fig. 3. On the positive scan, [Co(L^1)] gave one oxidation wave without a corresponding cathodic wave (Ia) (Fig. 2a). The process is totally irreversible and its anodic peak potential is at $E_{pa} = 0.859$ V versus Ag/AgCl. On the other hand, [Co(L^2)] exhibited one oxidation wave with a corresponding cathodic wave. This oxidation process is diffusion controlled with the anodic current function ($I_{pa}/v^{1/2}$) independent of the scan rate (v) over the scan range 0.025–0.250 V s^{-1}. The peak potentials separation is $\Delta E_p = 248$ mV and the ratio of cathodic to anodic peak current deviates from unity. So the oxidation process is irreversible at all sweep rates in the range 0.025–0.250 V s^{-1}. Both oxidation processes for [Co(L^1)] and

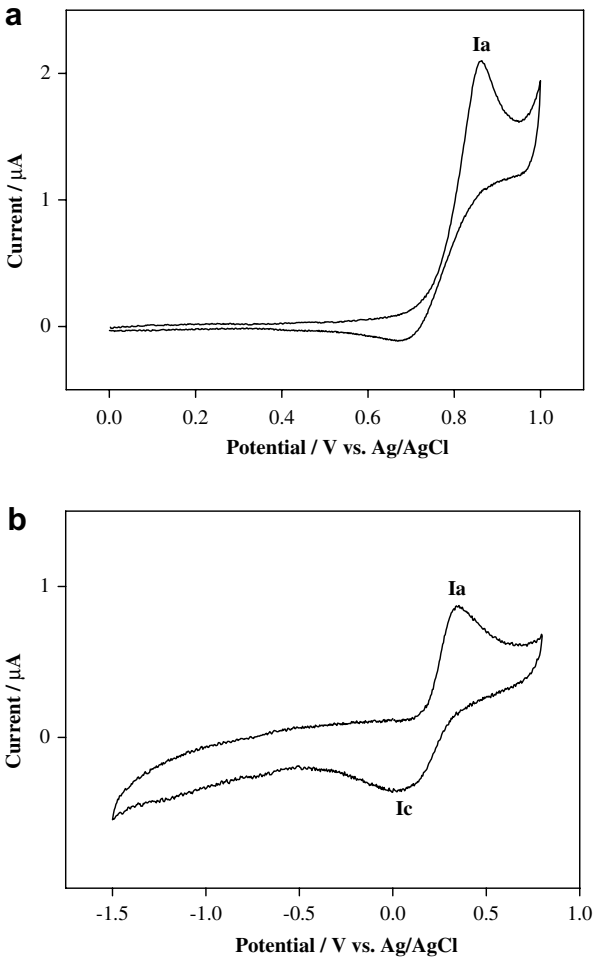

Fig. 3. Cyclic voltammograms of [Co(L^1)] (a); [Co(L^2)] (b) in CH_2Cl_2 solution containing 0.1 M TBAP. Scan rates = 0.100 V s^{-1}.

[Co(L^2)] are based on the cobalt center and are assign to the Co(II) → Co(III) process. The electrochemical behavior of [Co(L^2)] differs from that of [Co(L^1)] under the same experimental conditions due to their different structures, as observed for the copper complexes. The oxidation potential of [Co(L^2)] cathodically shifts compared with that of [Co(L_1)]. An EC process following the oxidation wave (II) in the CV of the [Co(L_2)] was not observed, probably due to favoring an octahedral structure in the case of Co(III) (d^6), which indicates no structural change during the oxidation process.

3.6. UV–Vis spectra of the electro-oxidized and electro-reduced complexes

The spectroelectrochemical behavior of the copper and cobalt complexes was investigated using an *in situ* spectroelectrochemical technique including chronoamperometry and UV–Vis spectroscopy in CH_2Cl_2 solution containing 0.2 M TBAP. The UV–Vis spectral changes for the reduced and oxidized species of the corresponding complexes were obtained in a thin-layer cell with the applied potentials.

The absorption spectra of the neutral complexes and their electrochemically generated species are given in Figs. 4–6. The convenient applied potentials values for the *in situ* spectroelectrochemical experiment were determined for each process by taking CVs of the complexes in the thin-layer cell.

Fig. 4a shows the changes of the electronic spectrum of [Cu(L^1)] that is accompanied by the oxidation process in the thin-layer cell. Well-defined isosbestic points are observed at $\lambda = 321$ and 328 nm, confirming that the electrode reaction proceeds in a quantitative fashion and therefore the absence of any coupled chemistry. The band at 327 nm, assigned to the Cu(II) $d_{x^2-y^2}$-to-phenolate (π) LMCT transition for the neutral copper complex [Cu(L^1)], changed into two new bands. The first, with higher intensity, shifted to a lower energy ($\lambda = 362$ nm) and the second, also with higher intensity, appeared at a higher energy (293 nm) as a result of removing one electron from the copper(II) ion in the complex. The one electron oxidation results in a Cu(II) (d^9) → Cu(III) (d^8) process

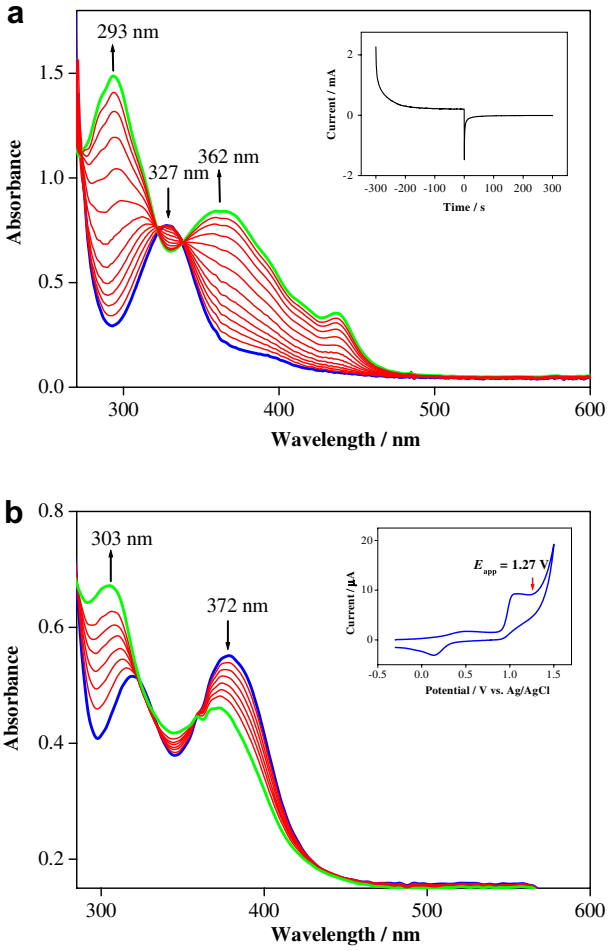

Fig. 4. Time-resolved UV–Vis spectral changes of [Cu(L^1)] (a); [Cu(L^2)] (b) during the oxidation at $E_{app} = 1.27$ V in CH_2Cl_2 solution containing 0.2 M TBAP. For (a), the inset figure shows chronoamperometry of [Cu(L^1)]. For (b), the inset figure shows the thin-layer CV of [Cu(L^2)] under the same experimental conditions.

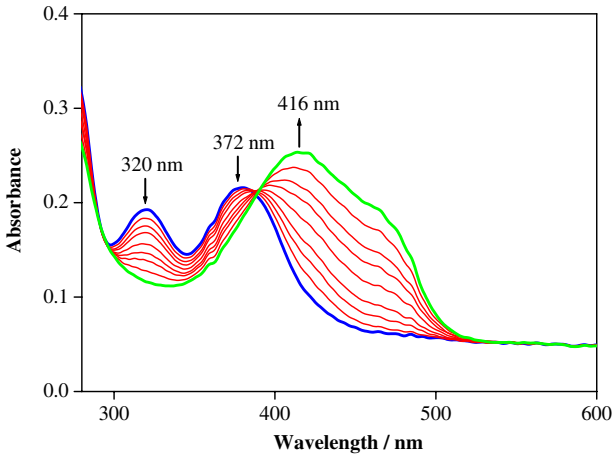

Fig. 5. Time-resolved UV–Vis spectral changes of [Cu(L^2)] during the reduction at $E_{app} = -1.52$ V in CH_2Cl_2 solution containing 0.2 M TBAP.

which makes the electron transition from the ligand to the metal easier, as expected. So the LMCT was observed at a lower energy compared with that of the neutral com-

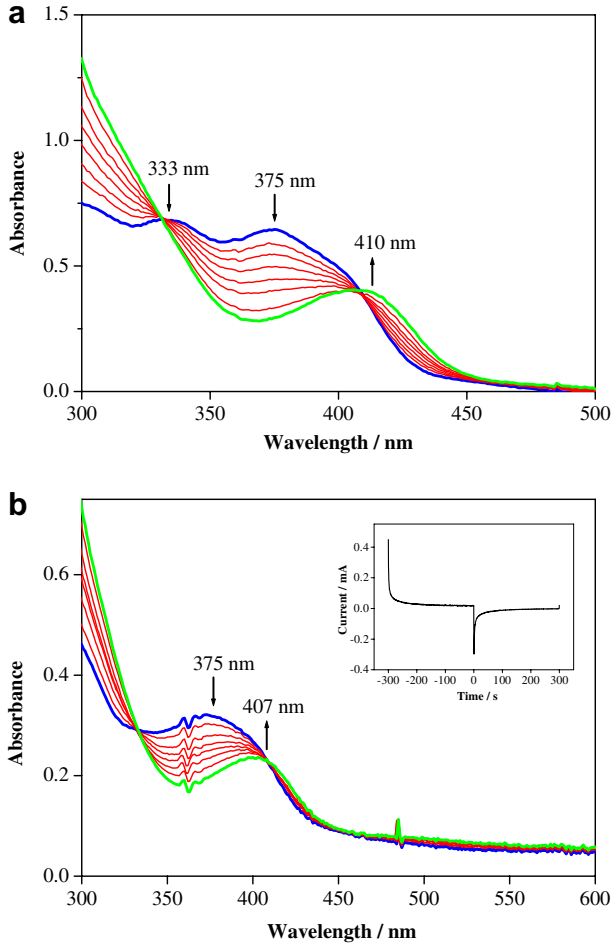

Fig. 6. Time-resolved UV–Vis spectral changes of [Co(L^1)] (a); [Co(L^2)] (b) during oxidation at $E_{app} = 1.00$ V for the first and $E_{app} = 0.75$ V for the latter in CH_2Cl_2 solution containing 0.2 M TBAP. For (b), the inset figure shows chronoamperometry of [Co(L^2)].

plex. The second band, observed at 293 nm and corresponds to an intramolecular $\pi \rightarrow \pi^*$ transition, dominated when the LMCT transition shifted to lower energy. As seen from Fig. 4a and b, the final spectra (green solid lines[1]) of the oxidized species for the [Cu(L^1)] and [Cu(L^2)] complexes exhibited similar features. The corresponding main bands of the oxidized species of [Cu(L^1)] and [Cu(L^2)] appeared at 293 and 362 nm, and 303 and 372 nm, respectively. Comparing the main bands, a small red shift for the oxidized [Cu(L^2)] complex is seen, probably due to its different environment. However, one can also observe an absorption band at about 450 nm in the final spectrum of the oxidized [Cu(L^1)], but, as seen Fig. 4a, this band appears with a very low intensity compared the main bands, which is probably due to the result of the different solubility degree of the resultant products in the thin layer cell. It is evident that the bands of [Cu(L^2)] are seen with a lower intensity compared with those of [Cu(L^1)] under the same experimental conditions. Hence, this weak band could not be attributed to structural changes for the oxidized product of [Cu(L^1)]. These spectral changes are similar to those previously observed for some copper Schiff-base complexes [28]. Although the oxidation process was observed to be electrochemically irreversible from the CV of [Cu(L^1)], the original spectrum of the complex was obtained upon re-reduction during the spectroelectrochemical measurements. The controlled potential coulometric (CPC) study indicated that the number of electrons transferred for the forward and reverse electrochemical reactions of the complex was one for both the oxidation and re-reduction processes, based on the Cu(II)/Cu(III) couples. Thus, the oxidized [Cu(L^1)] complex remained chemically stable throughout the experiment indicating the oxidized [Cu(L^1)] complex remains in its original geometry.

The UV–Vis spectral changes upon oxidation of [Cu(L^2)] are shown in Fig. 4b where the inset figure exhibits the CV of [Cu(L^2)] in a CH_2Cl_2 solution in the thin-layer cell, containing 0.2 M TBAP. The neutral complex showed two intense bands at 320 and 372 nm, which can be attributed to an intramolecular $\pi \rightarrow \pi^*$ transition and Cu(II) $d_{x^2-y^2}$-to-phenolate (π) LMCT transition, respectively [45]. The LMCT transition of [Cu(L^2)] is shifted to a lower energy compared with that of [Cu(L^1)] as a result of the different binding mode of the ligand of [Cu(L^2)] where two additional oxygen lone pairs coming from dioxaoctane coordinate to the copper ion. As can be seen from Fig. 4b, the isosbestic points of the UV–Vis spectral changes were found at 329 nm and 359 nm, which clearly verify the formation of the mono-oxidized species of [Cu(L^2)]. The band intensity corresponding to the 372 nm peak decreased, but a shift to a lower energy was not observed. The final spectrum of the oxidized species of [Cu(L^2)] is similar to that of [Cu(L^1)] with the only difference being that the absorption bands of the oxidized [Cu(L^2)] are shifted to a lower energy compared with those of [Cu(L^1)] because of their different coordination environment. Finally, the oxidized species of the two copper complexes present a square-planar structure. The original spectrum of the neutral complex [Cu(L^2)] was not recovered upon re-reduction at the applied potential $E_{app} = 0.6$ V, but could be recovered upon re-reduction at the applied potential $E_{app} = -0.3$ V. These result indicate that the geometry of [Cu(L^2)] changed into square-planar after the complex was totally oxidized and the neutral complex was only recovered following the EC process observed in the CV of [Cu(L^2)].

The well-defined UV–Vis spectral changes observed during the reduction of [Cu(L^2)] are shown in Fig. 5. After the reduction process, one electron was included in the metal system, thus a Cu(II) (d^9) → Cu(I) (d^{10}) process took place. As expected, the ligand to metal charge transfer (LMCT) at 372 nm decreases and a relatively strong peak at 416 nm develops. The absorption maximum at 416 nm is attributed to an MLCT transition in the Cu(I) complexes. These changes are in agreement with the expected results for a metal-centered reduction, Cu(II) → Cu(I) [27,28].

The UV–Vis spectral changes upon oxidation of [Co(L^1)] and [Co(L^2)] are shown in Fig. 6. The electronic spectra of the Co(II) complexes showed intense absorption bands at 330 and 375 nm that are assigned to a $\pi \rightarrow \pi^*$ transition associated with the imine linkage. For the two cobalt complexes, the bands corresponding to the $\pi \rightarrow \pi^*$ transition disappeared and new bands with small red shifts and of lower intensity were observed during the oxidation process. These new bands are attributed to the LMCT transition. Isosbestic points are observed at 330 and 408 nm for [Co(L^1)] and 330 and 408 nm for [Co(L^2)]. The final spectra of the oxidized species of the cobalt complexes are similar to each other and to those previously reported for the oxidations of Schiff base cobalt complexes [28]. Re-reduction at a negative potential of the oxidized species of [Co(L^2)] generates the neutral complex [Co(L^2)] indicating that the oxidized species is chemically stable throughout the spectroelectrochemical timescale, probably due to the six coordination of the [Co(L^2)] complex, which is able to stabilize the oxidized species compared to the tetrahedral [Co(L^1)] complex for which the original spectrum could not be recovered upon re-reduction [43a].

4. Conclusion

New Schiff-base copper and cobalt complexes, [Cu(L^1)], [Cu(L^2)], and [Co(L^1)], [Co(L^2)] (where L^1 = *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,4-cyclohexane bis(methylamine) and L^2 = *N*-*N*′-bis(3,5-di-*tert*-butylsalicylaldimine)-1,8-diamino-3,6-dioxaoctane), were synthesized and their electro-spectrochemical properties were investigated using cyclic voltammetric and thin-layer spectroelectrochemical techniques in a dichloromethane solution (CH_2Cl_2). The combination of the electrochemical and

[1] For interpretation of color in Fig. 4, the reader is referred to the web version of this article.

spectroelectrochemical methods provided a powerful tool to reveal the complementary nature of the molecular structure and electron-transfer reactions of the oxidized and reduced species of the new electroactive Schiff-base complexes. The comparative electro-spectrochemical studies revealed that the [Cu(L^1)] and [Co(L^1)] complexes showed four coordination with the ligand (L^1), having two N and two O donor sites, while the [Cu(L^2)] and [Co(L^2)] complexes resulted in six coordination with the ligand (L^2) carrying two N and four O donor sites. The electro-oxidized species of the [Cu(L^1)] and [Co(L^2)] complexes remained stable on the spectroelectrochemical timescale, although the complexes exhibited an irreversible oxidation processes in their CV measurements. Finally, the CVs and the well-defined spectral changes observed with the applied potentials in the thin-layer cell spectral data support the corresponding structures of the copper and cobalt Schiff-base complexes.

$Pr[Co(CN)_6]\cdot 5H_2O$ belongs to $P6_3/m$ just as for other pentahydrates reported before. In the present study, we have reinvestigated the crystal structures of $Pr[M(CN)_6]\cdot 5H_2O$ (M = Cr, Fe, Co) and established a reassignment of the space group to $P6_3/mmc$ (no. 194). The spectral characteristics of these compounds have been interpreted and a clear spectral distinction is made between the tetrahydrate and pentahydrate series.

2. Experimental

$PrCl_3\cdot xH_2O$ was prepared from Pr_6O_{11} (Strem, 99.9%) by repeated evaporation with concentrated HCl (AR grade, Reidel-de-Haen). $K_3M(CN)_6$ (M = Cr, Fe, Co) was purchased from Strem Chemicals.

2.1. Syntheses

$Pr^{III}[M^{III}(CN)_6]\cdot 5H_2O$ (M = Cr, Fe, Co) were prepared by slow evaporation of aqueous solutions of $PrCl_3\cdot xH_2O$ and $K_3M(CN)_6$ containing stoichiometric amounts of M:Pr. The crystals were dried by tissue and used immediately.

2.2. Spectral measurements

The UV–Visible absorption spectra of aqueous solutions of the complexes were recorded using a HP UV-8453 spectrophotometer to measure the range between 200 and 1100 nm in H_2O at 298 K. Room temperature and 10 K luminescence spectra were excited by the 355 nm line of a Continuum Nd-YAG laser. The emission was dispersed through an Acton 0.5 m monochromator with an 1800 $g\,mm^{-1}$ grating blazed at 250 nm and detected by a back-illuminated SpectruMM CCD detector. The sample was housed in an Oxford Instruments closed cycle cryostat, with a base temperature of 10 K. The emission from $Pr[Co(CN)_6]\cdot 5H_2O$ was very weak with two broad features at 16257, 16361 cm^{-1} due to Pr^{3+} emission, and a lower energy band at 14488 cm^{-1}. Infrared absorption spectra were recorded at 295 K using KBr discs. A Perkin–Elmer 2000 FTIR spectrometer was employed with resolution 2 cm^{-1}.

2.3. X-ray crystallography

The X-ray intensity data of the three isomorphous complexes were collected on a Bruker SMART 1000 CCD diffractometer with graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K. In each hkl file, reflections $(hh\bar{2}hl)$ with $l = 2n + 1$ are systematically absent, indicating that the space group is $P6_3/mmc$. In the scenario that such reflections all happen to be too weak to be observed, space group $P6_3/m$ is also possible though unlikely. The structure was solved by direct methods and refined by full-matrix least squares based on F^2 using the SHELXTL program package. All the non-hydrogen atoms were subjected to anisotropic refinement. The aqua ligand O1W and lattice water molecule O2W respectively occupy sites of symmetry m and 3 in space group $P6_3/m$, and mm and $3m$ in space group $P6_3/mmc$. The hydrogen atoms, which are necessarily disordered when the oxygen atoms occupy the latter three sites, cannot be reliably located in the structure refinement.

3. Results and discussion

3.1. Crystal structures

Table 1 presents experimental and statistical summaries for compounds $Pr[M(CN)_6]\cdot 5H_2O$ (M = Co, Cr, Fe) refined in space groups $P6_3/m$and $P6_3/mmc$. The structural parameters refined in both space groups show insignificant differences, and consequently the space group of higher symmetry, namely $P6_3/mmc$, should be assigned according to convention. Interestingly, Pretsch et al. [7] reported that when orthorhombic $Cmcm$ $Er[Co(CN)_6]\cdot 4H_2O$ loses all its bound and unbound water molecules, it is transformed to hexagonal $Er[Co(CN)_6]$ which belongs to space group $P6_3/mmc$.

The crystal and molecular structure of $Pr[M(CN)_6]\cdot 5H_2O$ herein are almost identical to those reported for $La[Co(CN)_6]\cdot 5H_2O$ [19] and $La[Fe(CN)_6]\cdot 5H_2O$ [8]. The structural characteristics of $Pr[Cr(CN)_6]\cdot 5H_2O$ are specified by listing their Wyckoff positions and site symmetries: Pr(1) in 2(*c*), $\bar{6}m2$; Cr(1) in 2(*a*), $\bar{3}m$; C(1) in 12(*k*), *m*; N(1) in 12(*k*), *m*; O(1 W) in 6(*h*), *mm*; and O(2 W) in 4(*f*), 3*m* (see Fig. 1 for the atom labeling). The Pr^{3+} ion is nine-coordinated in the form of a $PrN_6(H_2O)_3$ group; the Cr^{3+} ion is six-coordinated in the form of an octahedral CrC_6 group; and cyanide linkages between $PrN_6(H_2O)_3$ and CoC_6 groups build an infinite polymeric array (see Fig. 2). Two uncoordinated water molecules occupy zeolitic holes on a 6-fold rotatory-inversion axis above and below the Pr^{3+} ion. The Pr^{3+} ion is coordinated to three aqua ligands in the mirror plane and to the N atoms of six cyanides, with three on each side of the mirror plane. The coordination geometry of Pr^{3+} is thus approximately D_{6h}. The uncoordinated water molecule O(2W) is linked to the coordinated water molecule O(1W) through a weak hydrogen bond, as in $Pr[Co(CN)_6]\cdot 5H_2O$ [21], $La[Co(CN)_6]\cdot 5H_2O$ [19] and $La[Fe(CN)_6]\cdot 5H_2O$ [8].

The bond lengths and angles in $Pr[M(CN)_6]\cdot 5H_2O$ are reported in Table 2. The C≡N bond distances do not differ from standard values [22]. The M–C bond distance is 8.5% shorter for the low-spin $3d^6$ ion compared with low-spin $3d^3$, and the trend with atomic number exhibits the linear relation shown in Fig. 3. A similar linear regression, but with a 7% more negative slope, is found for the M–C bond distances in $K_3M(CN)_6$ (M = Cr, Mn, Fe, Co [22]) where there is no cyanide bridging. The involvement of covalency in the M–C bond in $Pr[M(CN)_6]\cdot 5H_2O$ is exhibited by its strict directional character with the angle N–C–M being linear.

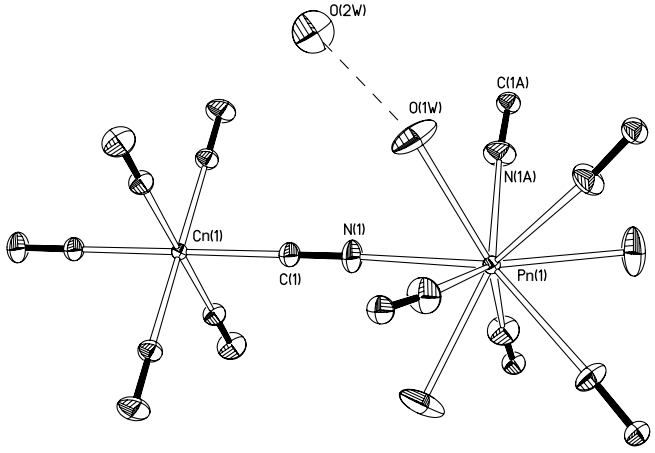

Fig. 1. Coordination environment of the metal atoms in $Pr[Cr(CN)_6]\cdot 5H_2O$ (50% thermal ellipsoids) with atom labeling.

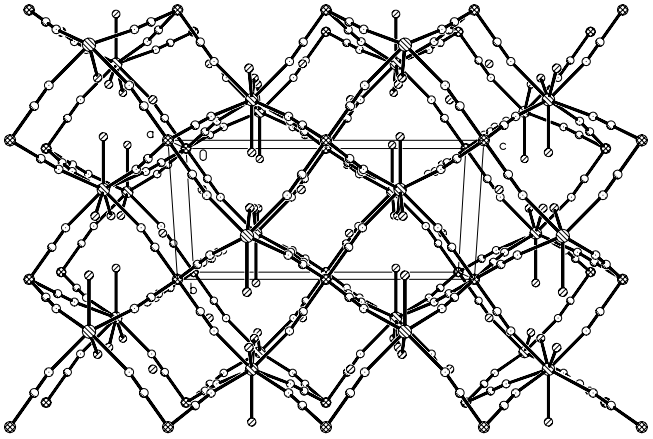

Fig. 2. Three-dimensional coordination network of $Pr[Cr(CN)_6]\cdot 5H_2O$ bridged by cyanide groups viewed along the a-axis. Uncoordinated water molecules are omitted for clarity.

In contrast, the C–N–Pr angle is bent, and the Pr-O distance is longer whereas the Pr–N distance is shorter for M = Cr than for M = Co. However, these changes are minor (<1.5%) and of similar magnitudes to measurement errors. The La–O and La–N bond distances in $La[M(CN)_6]\cdot 5H_2O$ (M = Fe, Co) [8,19]; refined in space group $P6_3/m$) are slightly longer (~2–3%) than those in the corresponding $Pr[M(CN)_6]\cdot 5H_2O$ compounds.

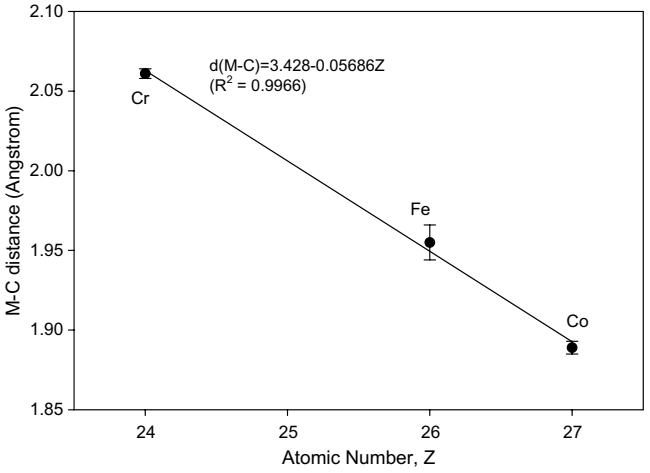

Fig. 3. Plot of M–C bond distance versus atomic number of M for $Pr[M(CN)_6] \cdot 5H_2O$.

is observed at 2142 cm^{-1} (M = Co) and at 2138 cm^{-1} (M = Cr) [22]. For $Ln[M(CN)_6] \cdot nH_2O$, members of the $n = 5$ series easily transform at room temperature into $n = 4$, but the two series are readily distinguished by the characteristic water and CN stretching peaks in the IR spectra, as shown for $Pr[Cr(CN)_6] \cdot 5H_2O$ and $Pr[Fe(CN)_6] \cdot 4H_2O$ in Fig. 4, where the appropriate structures are also drawn. The inset in the figure shows the spectral region of $Pr[Cr(CN)_6] \cdot 5H_2O$ between 2100 and 2200 cm^{-1} in detail. Note that only one strong CN stretch band is observed (corresponding to $^{12}C^{14}N$ at 2156 cm^{-1}) for the pentahydrate. From their positions and relative intensities, the weak features at 2112, 2125 cm^{-1} in the inset correspond to $^{13}C^{14}N$ and $^{12}C^{15}N$ stretching bands, respectively. By contrast, two prominent CN stretching bands are observed for the tetrahydrate system $Pr[Fe(CN)_6] \cdot 4H_2O$. Furthermore, the water bending mode region (~1610 cm^{-1}) shows one broad band for the pentahydrate but two prominent sharper bands for the tetrahydrate. The large breadth of this band in $Pr[Cr(CN)_6] \cdot 5H_2O$ (Fig. 4) illustrates the large thermal amplitude of the coordinated aquo ligand. The water stretching region (3000–3610 cm^{-1}) is complex for both the tetrahydrate and pentahydrate systems because bands due to both coordinated and hydrogen-bonded water appear together with vibrational overtones. The lowest energy band in Fig. 4 for the spectrum of $Pr[Cr(CN)_6] \cdot 5H_2O$ is the Cr–C stretch at 435 cm^{-1}.

3.3. UV–Vis spectra of aqueous solutions of $Pr[M(CN)_6]$

The UV–Vis absorption spectra of aqueous solutions of $Pr[M(CN)_6] \cdot 5H_2O$ are compared with $K_3[Co(CN)_6]$(aq) in Fig. 5 and serve to show the presence of free $M(CN)_6^{3-}$ ions in solution. The sharp, weak features between 443 nm and 485 nm are due to $4f^2$–f^2 intra-configurational transitions of Pr^{3+}. Although the lowest energy band (485 nm) clearly corresponds to the $^3P_0 \leftarrow {}^3H_4$ transition, the higher energy features are not clearly resolved and too broad to permit specific assignments. The bands at 306, 379 nm for M = Cr occur at similar wavelengths (308, 375 nm) to corresponding features in the room temperature absorption spectrum of crystalline $Cs_2KCr(CN)_6$ [23]. These features have been assigned to spin-allowed ligand field transitions corresponding to $^4T_{1g}$, $^4T_{2g} \leftarrow {}^4A_{2g}$, respectively [23]. The much stronger bands at 262 and ~200–220 nm correspond to charge-transfer transitions. The features at ~257 and 307 nm in the spectrum of aqueous $Pr[Co(CN)_6]$ are at similar wavelengths to the spectrum of aqueous $K_3Co(CN)_6$ and correspond to $^1T_{2g}$, $^1T_{1g} \leftarrow {}^1A_{1g}$ transitions, respectively [22]. The sharp increase in absorbance at ~200 nm corresponds to a charge transfer transition. This band is at higher energy than in $Cr(CN)_6^{3-}$ due to the greater cation polarizing power and shorter M–C bond distance.

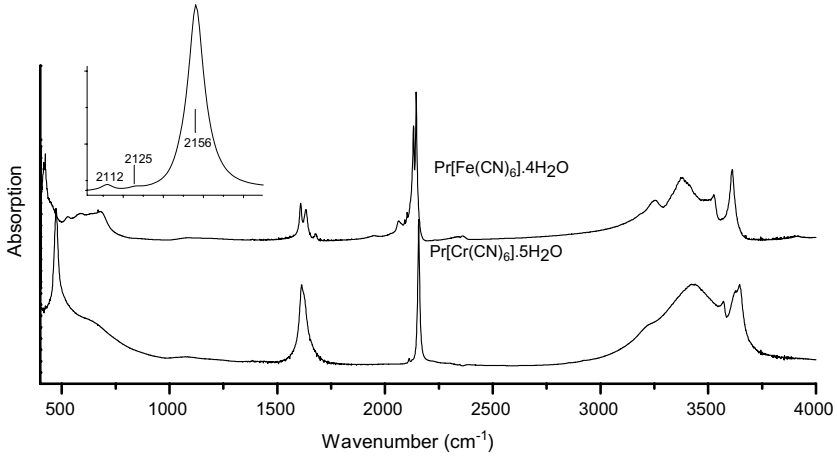

Fig. 4. FTIR spectra of $Pr[Fe(CN)_6] \cdot 4H_2O$ and $Pr[Cr(CN)_6] \cdot 5H_2O$. The inset shows the expanded CN stretch region of the latter.

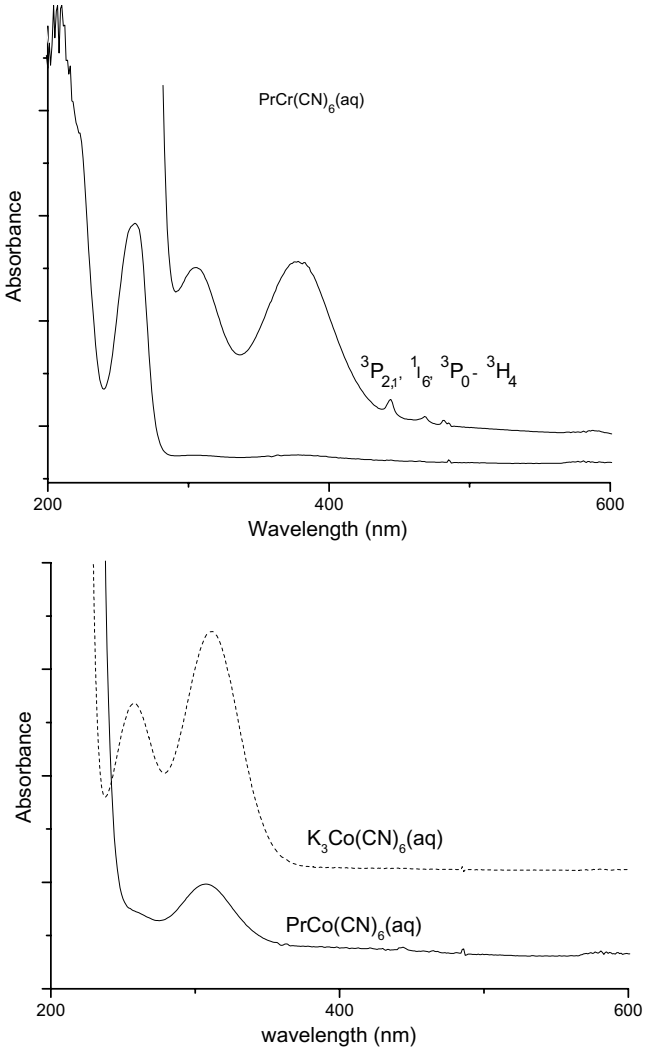

Fig. 5. UV–visible absorption spectra between 200 and 600 nm of aqueous solutions of $Pr[M(CN)_6]$ (M = Cr, Co) and comparison with $K_3Co(CN)_6$(aq). The scale expansion is shown in the top figure.

4. Conclusions

The space group $P6_3/m$ previously reported for the crystal structure of $Pr[Co(CN)_6]\cdot 5H_2O$ [21] has been revised herein to $P6_3/mmc$, which also holds for the isomorphous Cr and Fe compounds. The distinction between the $Ln[M(CN)_6]\cdot nH_2O$ tetrahydrate ($n = 4$) and pentahydrate ($n = 5$) series has been demonstrated on the basis of IR spectral assignments. Our spectra for the pentahydrates are in essential agreement with that reported for $La[Co(CN)_6]\cdot 5H_2O$ [19], but show differences from the spectra reported for $Ln[Fe(CN)_6]\cdot 5H_2O$ (Ln = La, Pr, Nd) where some decomposition to the tetrahydrates may have occurred [18]. Our IR spectrum of $Pr[Fe(CN)_6]\cdot 4H_2O$ is similar to that reported for $Nd[Fe(CN)_6]\cdot 4H_2O$ [24].

higher-dimensional metal–organic frameworks easily [7b,9]. In the present work, we chose H_2psa as a bridging ligand to link Cu(II) ions. Auxiliary ligands, phen, 2bpy, 4bpy, and N_3^-, were introduced to the Cu(II)/$[psa]^{2-}$ system under solvothermal conditions, five new complexes $[Cu(psa)(phen)]\cdot 3H_2O$ (**1**), $[Cu(psa)(2bpy)]\cdot 0.5H_2O$ (**2**), $[Cu(psa)(2bpy)(H_2O)]\cdot 3H_2O$ (**3**), $[Cu(psa)(4bpy)]\cdot H_2O$ (**4**), and $[Cu(psa)_{0.5}(N_3)(2bpy)]$ (**5**) were obtained. The details of their synthesis, structure, and thermal stability are reported.

2. Experimental

2.1. Materials and characterization

All reagents were used as received without further purification. The C, H, N microanalyses were carried out with a Vario EL elemental analyzer. Thermogravimetric analyses were conducted on a ZRY-2P thermal analyzer using a heating rate of 10 °C/min from room temperature to 1000 °C under nitrogen. The IR spectra were recorded with a Nicolet Avatar 360 FT-IR spectrometer using the KBr pellet technique.

2.2. Synthesis

2.2.1. Synthesis of $[Cu(psa)(phen)]\cdot 3H_2O$ (*1*)

A mixture of H_2psa (0.019 g, 0.1 mmol), phen (0.020 g, 0.1 mmol), $Cu(Ac)_2\cdot H_2O$ (0.019 g, 0.1 mmol), NaOH aqueous solution (0.15 ml, 0.65 mol/L), 10 ml distilled water and 1 ml ethanol was placed in a 25 ml Teflon-lined stainless steel autoclave, and the vessel was sealed and heated to 140 °C for 72 h, then cooled at 10 °C h^{-1} to 100 °C, followed by slowly cooling to room temperature. The resulting blue wedge shape crystals of complex **1** were obtained. Yield: 0.032 g (64.2%). *Anal.* Calc. for $C_{22}H_{22}CuN_2O_7$: C, 53.87; H, 4.52; N, 5.71. Found: C, 53.93; H, 4.85; N, 5.33%. IR data (KBr pellet, cm^{-1}): 3450s, 1592s, 1519w, 1494w, 1429m, 1397m, 1313w, 850m, 720m.

2.2.2. Synthesis of $[Cu(psa)(2bpy)]\cdot 0.5H_2O$ (*2*) and $[Cu(psa)(2bpy)(H_2O)]\cdot 3H_2O$ (*3*)

The synthesis of complex **2** was similar to that of complex **1** expect that 2bpy (0.016 g, 0.1 mmol) was used instead of phen. The blue square flake crystals of complex **2** were obtained. Yield: 0.004 g (9.5%). We left the mother solution at room temperature for two days and obtained the light green crystal of complex **3**. Yield: 0.018 g (37.2%). *Anal.* Calc. for $C_{20}H_{17}CuN_2O_{4.5}$ (**2**): C, 57.01; H, 4.07; N, 6.65. Found: C, 57.38; H, 4.68; N, 6.82%. IR data (KBr pellet, cm^{-1}): 3442s, 1587s, 1568s, 1495w, 1473w, 1447m, 1410s, 1395s, 1381s, 1273w, 773s, 715m. *Anal.* Calc. for $C_{20}H_{24}CuN_2O_8$ (**3**): C, 49.63; H, 4.99; N, 5.79. Found: C, 49.39; H, 5.77; N, 6.07%. IR data (KBr pellet, cm^{-1}): 3447s, 1569s, 1494w, 1468w, 1446m, 1412s, 1385s, 775m, 744w, 731w, 701w.

2.2.3. Synthesis of $[Cu(psa)(4bpy)]\cdot H_2O$ (*4*)

The synthesis of complex **4** was similar to that of complex **1** expect that 4bpy (0.018 g, 0.1 mmol) was used instead of phen. Dark blue column crystals of complex **4** were obtained. Yield: 0.030 g (69.9%). *Anal.* Calc. for $C_{20}H_{18}CuN_2O_5$: C, 55.87; H, 4.22; N, 6.52. Found: C, 56.24; H, 4.23; N, 6.38%. IR data (KBr pellet, cm^{-1}): 3441s, 1610s, 1575s, 1487w, 1411m, 1375m, 1320w, 1215w, 1065m, 826m, 734m, 701m, 627m.

2.2.4. Synthesis of $[Cu(psa)_{0.5}(N_3)(2bpy)]$ (*5*)

A mixture of H_2psa (0.019 g, 0.1 mmol), 2pby (0.016 g, 0.1 mmol), $Cu(Ac)_2\cdot H_2O$ (0.019 g, 0.1 mmol), NaN_3 (0.007 g, 0.1 mmol), 10 ml distilled water and 3 ml ethanol was placed in a 25 ml Teflon-lined stainless steel autoclave, and the vessel was sealed and heated to 140 °C for 72 h, then cooled at 10 °C h^{-1} to 100 °C, followed by slowly cooling to room temperature. Dark green block crystals of complex **5** were obtained. Yield: 0.029 g (80.9%). *Anal.* Calc. for $C_{15}H_{12}CuN_5O_2$: C, 50.34; H, 3.38; N, 19.57. Found: C, 50.12; H, 3.90, N, 19.39%. IR data (KBr pellet, cm^{-1}): 3441br, 2048s, 1607s, 1567m, 1493m, 1472m, 1447m, 1361m, 1158w, 1029w, 772m, 732m.

2.3. X-ray structure determination

The single-crystal X-ray data collections for the five complexes were performed with a Bruker SMART 1000 CCD diffractometer, using graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Semi-empirical absorption corrections were applied using the SADABS program [10]. The structures were solved by direct methods [11] and refined by full-matrix least squares method on F^2 using SHELXS97 and SHELXL97 programs, respectively [11,12]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were generated geometrically and treated by a mixture of independent and constrained refinement. The crystallographic data for complexes **1**–**5** are listed in Table 1, selected bond lengths (Å) and angles (°) are listed in Table 2, the details of the hydrogen bonds for complexes **1** and **3** are listed in Table 3.

3. Results and discussion

3.1. Structure description of $[Cu(psa)(phen)]\cdot 3H_2O$ (*1*)

In the asymmetric unit of complex **1**, there are one Cu(II) ion, one $[psa]^{2-}$ ligand, one chelating phen ligand and three lattice water molecules. As shown in Fig. 1, the Cu(II) ion is four-coordinated by two nitrogen atoms (N1, N2) from one phen ligand, two oxygen atoms (O1, O4A) of the carboxylate groups from two $[psa]^{2-}$ ligands. The average Cu–N bond length is slightly longer than that of Cu–O distance. In complex **1**, $[psa]^{2-}$ ligand displays cis-configuration and adopts bis(monodentate) mode (see Scheme 1a). Cu(II) ions are bridged by $[psa]^{2-}$ ligands into 1D chains (see Fig. 1). The phen ligands are arranged at

one side of the chains, while the benzene rings of the $[psa]^{2-}$ ligands locate at the other side of the chains, which may be contributed to the steric effect from both the phen and H_2psa ligands. The similar coordination geometry and structure can be observed in the complex of Cu(II) with 1,4-phenylenediacetic acid (H_2pda) [13] which is an isomer of H_2psa. In this $[pda]^{2-}$ complex, the auxiliary ligand phen has π–π stacking interactions, while in complex **1**, the π–π interactions could not be found.

In complex **1**, three lattice water molecules form a trimer through hydrogen bonds (O5–H5B···O7, O6–H6A···O5), which acts as bridges between adjacent chains forming a 2D supramolecular network in *ab* plane by three kinds of hydrogen bonds, as shown in Fig. 2. The details of hydrogen bonds are listed in Table 3. Undoubtedly, the hydrogen bonds play an important role in the formation of the 2D supramolecular network.

3.2. Structure description of $[Cu(psa)(2bpy)] \cdot 0.5H_2O$ (**2**)

The asymmetric unit of complex **2** contains one Cu(II) ion, one $[psa]^{2-}$ ligand, one 2bpy ligand and one half of an non-coordinated water molecule. Similar to complex **1**, in complex **2**, $[psa]^{2-}$ is also cis-configuration (see Scheme 1a) and bis(monodentate) coordination mode, the Cu(II) ion is four-coordinated by two N atoms from a chelating 2bpy ligand and two oxygen atoms of two $[psa]^{2-}$ ligands, and Cu(II) ions are linked by $[psa]^{2-}$ ligands into 1D chains too, as shown in Fig. 3. However, in complex **2**, the approximately parallel 2bpy ligands allow pairing of two related single chains to generate double zipper-like chain, in which aromatic π–π stacking interactions exist between 2bpy pairs. The face-to-face distance between the paired 2bpy rings is 3.258 Å, and the centroid–centroid distance is 3.466 Å [14], indicating moderately strong aromatic π–π stacking interactions. The disordered water molecules exist between the zippers and the hydrogen bonds (O(5)–H(5A)···O(3), O···O distance 2.987 Å) between water molecules and the uncoordinated carboxyl oxygen atoms connect parallel zippers to give a 2D supramolecular structure, as shown in Fig. 4.

3.3. Structure description of $[Cu(psa)(2bpy)(H_2O)] \cdot 3H_2O$ (**3**)

In the symmetric unit of complex **3**, there are one Cu(II) ion, one $[psa]^{2-}$ ligand, one 2bpy ligand, one coordinated water molecule and three lattice water molecules. In complex **3**, the Cu(II) ion is five-coordinated with two nitrogen atoms (N1, N2) from 2bpy ligand, two oxygen atoms (O1, O3A) of two $[psa]^{2-}$ ligands, and one oxygen atoms(O5) from one coordinated water molecule forming a distorted tetragonal pyramid geometry, as shown in Fig. 5. The Cu–O5(W) bond length (2.245 Å) is much longer than the mean Cu–O(carboxyl) distance (1.978 Å) indicating that the O5 coordinates to the Cu(II) ion weakly.

In complex **3**, the $[psa]^{2-}$ ligand shows cis-configuration (see Scheme 1a) and adopts bis(monodentate) coordination mode, the Cu(II) ions are bridged by $[psa]^{2-}$ into 1D chains, and the 2bpy ligands locate at the same side of the chains. In complex **3**, the lattice water molecules constitute trimers as in complex **1**. And an interesting feature of

complex **3** is that the water trimer, the coordinated water molecule and the uncoordinated carboxyl oxygen atom (O4) form hydrogen bonds ring in a graph set $R_5^5(10)$ [15] which link the neighbor chains by hydrogen bond between H8A(W) and uncoordinated carboxyl oxygen atom(O2), resulting in a 2D supramolecular structure (see Fig. 6). The details of hydrogen bonds are listed in Table 3.

3.4. Structure description of $[Cu(psa)(4bpy)]\cdot H_2O$ (**4**)

X-ray diffraction analysis reveals that complex **4** possesses a 3D porous metal–organic framework with twofold interpenetration. The asymmetric unit of **4** consists of one Cu(II) ion, one $[psa]^{2-}$ ligand, one 4bpy ligand, and one lattice molecule. Cu(II) ion is also four-coordinated by two oxygen atoms (O1, O4A) of two $[psa]^{2-}$ ligands and two nitrogen atoms (N1, N2A) from two independent 4bpy, the geometry can be described as a slightly distorted square (see Fig. 7).

In complex **4**, the $[psa]^{2-}$ ligand shows trans-configuration (see Scheme 1b) and also adopts bis(monodentate) coordination mode. 4bpy ligands link the Cu(II) ions into

1D chains along two different directions, and the two sets of the chains (angle 33.5°) are bridged by $[psa]^{2-}$ ligand into a 3D $CdSO_4$-like structure with large 1D channels along the [1 1 0] direction, as shown in Fig. 8. The distances between the Cu(II) ions at the corners of the rectangular channels are 17.509 and 11.189 Å, respectively. Without the existence of large inclusion ions or molecules in such

network, twofold interpenetration happens (see Fig. 9). And thus the volume of the effective void calculated using PLATON [16] is 5.3% of the unit-cell volume in the self-inclusion structure which is occupied by the non-coordinated water molecules. Hydrogen bonds (O5–H5B···O2, O···O distance 2.781 Å) can be found between the non-coordinated water molecules and the 3D metal–organic framework.

3.5. Structure description of $[Cu(psa)_{0.5}(N_3)(2bpy)]$ (5)

Complex **5** is a dinuclear compound, and in the asymmetric of complex **5**, there are one Cu(II) ion, one half of $[psa]^{2-}$ ligand, one N_3^- ligand and one 2bpy ligand. In complex **5**, each Cu(II) ion is four-coordinated by two nitrogen atoms (N1, N2) from one chelating ligand 2bpy, one nitrogen atoms (N3) of one N_3^- ligand, and one oxygen atom (O1) from $[psa]^{2-}$ ligand (see Fig. 10). Thus Cu(II) ion is in a slightly distorted square geometry. The mean Cu–N bond length is longer than the Cu–O distance.

In complex **5**, the $[psa]^{2-}$ ligand adopts bis(monodentate) coordination mode and is also trans-configuration (see Scheme 1b) bridging two Cu(II) ions. While the terminal ligands 2bpy and monodentate N_3^- hinder the extension of the structure, forming a dinuclear structure. The dinuclear structures are interlinked by hydrogen bonds (C–H···O) and cooperated with π–π interactions (face to face distance 3.243 Å) to form 3D brick-wall supramolecular structure viewed along *b*-axis (Fig. 11).

Comparing complexes **1**, **2**, and **4**, their synthetic conditions are very similar, and the main difference among them is the employment of different auxiliary ligands. However, the differences in the auxiliary ligands have a significant effect on the structure of the complexes. In complexes **1**, **2**, and **4**, Cu(II) ions are all four-coordinated, while the $[psa]^{2-}$ ligands are transformed from cis-configuration in complexes **1** and **2** by the introduction of phen and 2bpy ligands to trans-configuration in complex **4** because of the application of the bridging 4bpy ligand. And chelating ligands phen and 2bpy tend to forming low-dimensional structure, while the linear ligand 4bpy is able to construct 3D metal–organic framework. Complexes **2** and **3** were

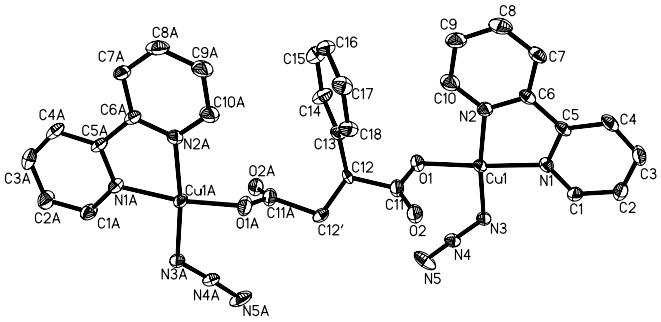

Fig. 10. The coordination environment of Cu(II) ion in complex **5**.

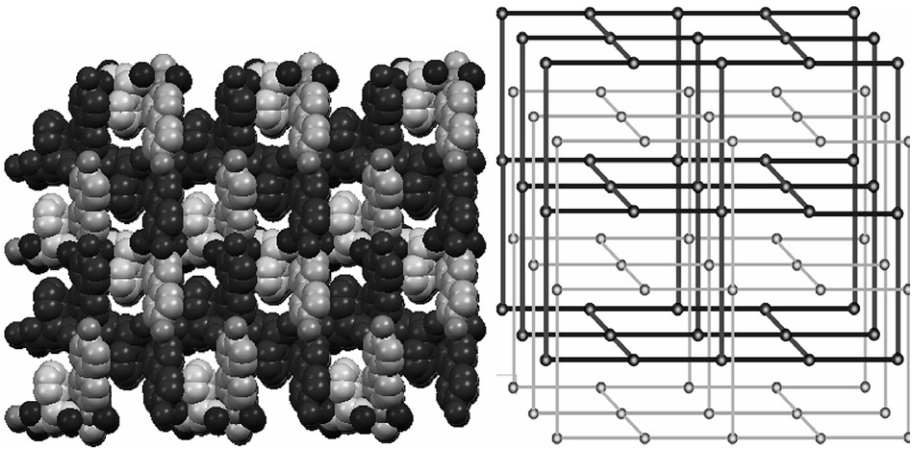

Fig. 9. The twofold interpenetrated spacefilling diagram of complex **4**, the water molecules occupied the channels are omitted (left). The simplified representation structure of complex **4** viewed along [1 1 0] (right).

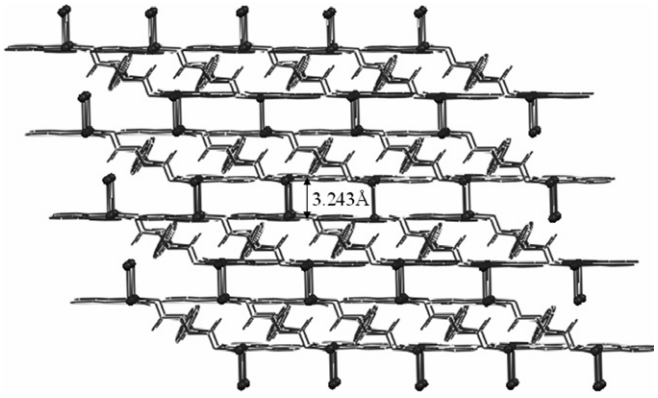

Fig. 11. 3D supramolecular structure of complex **5** viewed along *b*-axis.

formed in one-pot reaction. Complex **3** was obtained by leaving the mother solution of complex **2** at room temperature. Probably with the decrease of temperature, the water molecules attack the axial site of the square and coordinated to the Cu(II) ions leading to formation of complex **3**. And the coordinated water molecules result in different stacking patterns for 1D chains and thus the final network. With addition of N_3^- to system **2**, the half of $[psa]^{2-}$ ligands are replaced by the N_3^- ligands, complex **5** is formed. In complex **5**, two Cu(II) ions are bridged by one $[psa]^{2-}$ ligand. While both 2pby and N_3^- ligands as terminal ligands hinder the extending of the structure, forming a dinuclear structure. The results show the importance of the selection of auxiliary ligands in assembly of complexes.

3.6. Thermal analyses of complexes *1*, *3*–*5*

Complexes **1**–**5** are very stable in air at ambient temperature and almost insoluble in common solvents such as water, alcohol, acetonitrile, chloroform, methanol, and acetone. In order to examine their thermal stability, we carried out thermal gravimetric analyses (TGA) of the five complexes expect complex **2** because of the lower yield. The result shows that complex **1** is stable up to 75 °C. A total weight loss of 10.5% occurred in the temperature range 75–126 °C, corresponding to the loss of the three lattice water molecules in the complex (Calc. 11.0%), the further decomposition occurred at 205 °C, and the final pyrolysis was completed at 670 °C, giving the powder of CuO. For complex **3**, the TG curve exhibits that complex **3** is stable up to 73 °C with the first weight loss of 13.4% from 73 °C to 107 °C, which corresponds to the loss of four water molecules (Calc. 13.2%), and unknown decomposition reactions took place over 200 °C. The thermal decomposition behavior of complex **4** shows that complex **4** began complicated decomposition up to 207 °C, and the structure collapsed with the loss of the guest water molecule since no flateau in TG curve was observed during the decomposition of complex **4**. The TG curve shows that complex **5** is stable up to 213 °C, and decomposes rapidly in the temperature range 213–229 °C. The residue CuO powder in 23.3% was obtained at 580 °C (Calc. 22.3%).

4. Conclusions

In summary, using solvothermal reaction conditions, we obtained five new Cu(II) complexes **1**–**5** with $[psa]^{2-}$ ligand and different auxiliary ligands phen, 2bpy, 4bpy, and N_3^-. Complexes **1**–**3** are composed of 1D chains, extending into 2D supramolecular structure by hydrogen bonds (complexes **1** and **3**) or hydrogen bonds and π–π stacking interactions (complex **2**), in which $[psa]^{2-}$ ligand shows cis-configuration and adopts bis(monodentate) coordination mode. Interestingly, complexes **2** and **3** were obtained by one-pot reaction, showing that different complexes can be obtained by controlling the reaction condition in the same system. Complex **4** is of a 3D $CdSO_4$-like metal–organic framework formed by bridging ligands $[psa]^{2-}$ and 4bpy linking Cu(II) ion, and $[psa]^{2-}$ is in trans-configuration. The different structures of complexes **1**–**5** show that the auxiliary ligands have a significant effect on the formation and the construction of the complexes **1**–**5**.

of which have contributed significantly to the development of the respective fields. The successes of phenoxy-imines are presumably due to the availability of scope for suitable tuning of the sterics and the electronics of the ligand ancillary and also due to their easy synthetic accessibility, as the phenoxy-imines are often prepared by Schiff base condensation reactions. Interestingly enough, despite extensive utility of phenoxy-imines in many important chemical transformations, their application in ring-opening polymerization (ROP) of L-lactide largely remains unexplored [20].

Our interest in the ring-opening polymerization (ROP) of L-lactide arises mainly because of its eco-friendly nature as the polylactide polymer (PLA) is biodegradable and also because the lactide monomer can be generated from renewable resources like the corn fermentation process or from agricultural starch wastes [21,22]. The PLAs are biocompatible and exhibit good mechanical properties and, hence, are long known for their use in medical and pharmaceutical related applications [23,24]. One of our core programs is centered around designing novel initiators for the bulk ring-opening polymerization of L-lactide, and in this regard we have recently reported Ag(I) [25] and Au(I) [26] complexes of N-heterocyclic carbenes (NHC) as initiators for the bulk polymerization of L-lactide under solvent-free melt conditions. It is noteworthy that the PLAs can be synthesized by both solution polymerization [27] and bulk polymerization [28], however, the solution polymerization suffers from certain disadvantages like being susceptible to the impurity levels and to various unwanted reactions namely racemization, transesterifications, etc. The bulk polymerization, which does not suffer from such limitations, is thus, often preferred for the large-scale production of PLAs [29].

With regard to designing new initiators for our ROP program we observed that the phenoxy-imine ligands, despite their proven successes in chemical catalysis, remain to be tried for ring-opening polymerization (ROP) of L-lactide [20] and so we became interested in exploring the scope of phenoxy-imine based transition metal complexes as catalysts for bulk polymerization of L-lactide. Furthermore, phenoxy-imine metal complexes, bearing a metal–alkoxide bond, are natural candidates for the catalysis, as the well accepted catalysts for the ring-opening polymerization (ROP) of L-lactide are often the metal–alkoxide complexes [21,30–33] (see Fig. 1).

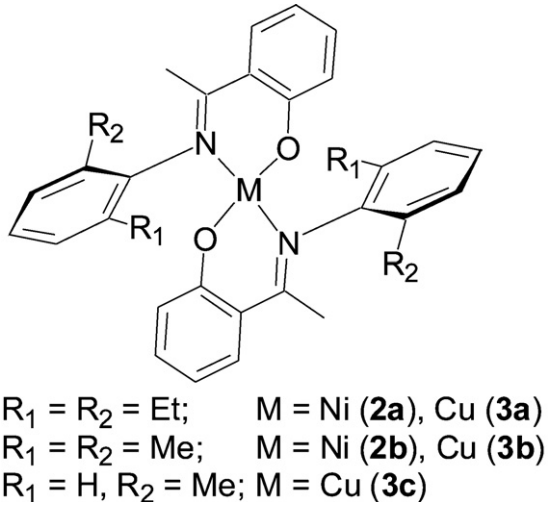
Here in this contribution, we report the synthesis, structural characterizations and catalysis studies of a series of nickel (**2a** and **2b**) and copper (**3a**, **3b** and **3c**) complexes of phenoxy-ketimine ligands with varying steric demands, namely 2-[1-(2,6-diethylphenylimino)ethyl]phenol (**1a**), 2-[1-(2,6-dimethylphenylimino)ethyl]phenol (**1b**) and 2-[1-(2-methylphenylimino)ethyl]phenol (**1c**). Furthermore, we disclose that while the copper complexes (**3a**, **3b** and **3c**) were found to be efficient initiators for ring-opening polymerization of L-lactide at elevated temperatures under solvent-free melt conditions, producing polylactide polymers

Equation 1. Polymerization of L-lactide by **3a**, **3b** and **3c**.

of moderate molecular weights with narrow molecular weight distributions (Eq. (1)), the nickel complexes (**2a** and **2b**) failed to yield a polylactide polymer.

2. Results and discussion

A series of monoanionic phenoxy-ketimine ligands, namely 2-[1-(2,6-diethylphenylimino)ethyl]phenol (**1a**), 2-[1-(2,6-dimethylphenylimino)ethyl]phenol (**1b**) and 2-[1-(2-methylphenylimino)ethyl]phenol (**1c**) were synthesized by a modification of a $TiCl_4$ catalyzed procedure reported in the literature for the condensation of α-haloketones with amines [34]. Specifically, the condensation reaction of *o*-hydroxyacetophenone with the respective anilines in presence of a catalytic amount of $TiCl_4$ gave the phenoxy-



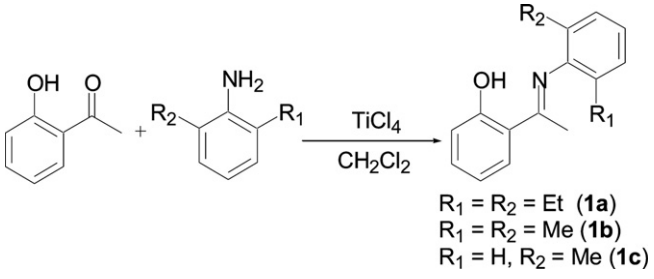


Fig. 1. Ni(II) and Cu(II) complexes of a series of phenoxy-ketimine ligands with controlled variation of sterics.

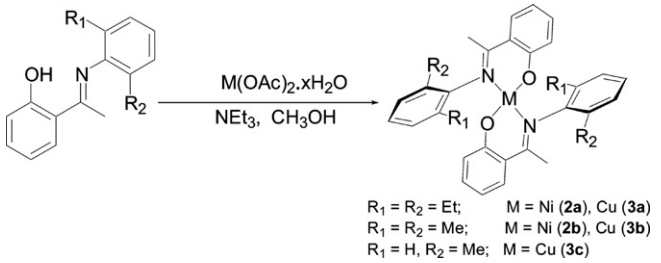
Scheme 1. Synthesis of phenoxy-ketimine ligands **1a**, **1b** and **1c**.



ketimine ligands, **1a**, **1b** and **1c** [35], in ca. 21–23% yield (Scheme 1). It is interesting to note that the ketimine ligands are often synthesized by two different methods, namely: (i) Schiff base condensation of ketones with amines in the presence of a catalytic amount of an acid like HCO_2H [36] or *p*-toluenesulfonic acid [16] and (ii) Friedel-Crafts acylation of the imidoyl chloride with the *ortho*-unsubstituted phenol [37]. The compounds **1a**, **1b** and **1c** have been characterized by ^{1}H NMR, ^{13}C NMR, IR, UV–Vis and mass spectrometry. The ^{1}H NMR spectra of **1a**, **1b** and **1c** showed the ketimine methyl (*Me*C=N) resonances as singlets at 2.09–2.17 ppm, while the phenolic –O*H* protons appeared as broad peaks at 14.7–14.8 ppm. The substantially high downfield shifts of the phenolic –O*H* protons in **1a**, **1b** and **1c** are attributed to an intramolecular hydrogen bonding interaction, [phenolic –OH···N=C (imine N)]. A similar downfield shift of the phenolic –O*H* proton (16.8 ppm) due to an intramolecular hydrogen bonding interaction has been reported for the Schiff base ligand 1-(2-hydroxy-3,5-dichlorophenyl)-2,5-diaza-6-methylnona-1,6-diene-8-one [38]. Furthermore, the ketimine moieties (MeC=N) appeared at 171.1–171.9 ppm (Me*C*=N) in the ^{13}C NMR spectra and at 1609–1614 cm^{-1} ($\nu_{C=N\ str}$) in the infrared spectra. The electronic spectra of the phenoxy-ketimine ligands **1a**, **1b** and **1c** in $CHCl_3$ exhibited two distinct absorption bands in the UV region which have been identified as high energy π–π^* and low energy n–π^* transitions, based on the assignment made for a series of related phenoxy-imine ligands, namely 2-[1-(R)methyl]phenol (where R = –CH_3, –C_6H_{11} and –C_5H_4N) [39]. The high energy bands due to the π–π^* transitions showed absorptions at 256 nm for **1a** ($\varepsilon = 17263$ L mol^{-1} cm^{-1}), 256 nm for **1b** ($\varepsilon = 17933$ L mol^{-1} cm^{-1}) and 257 nm for **1c** ($\varepsilon = 21873$ L mol^{-1} cm^{-1}), while the low energy n–π^* transition appeared at 323 nm for **1a** ($\varepsilon = 5945$ L mol^{-1} cm^{-1}), 322 nm for **1b** ($\varepsilon = 5919$ L mol^{-1} cm^{-1}) and 324 nm for **1c** ($\varepsilon = 8776$ L mol^{-1} cm^{-1}). Electrospray mass analysis gave peaks at $m/z = 268$ (**1a**), 240 (**1b**) and 226 (**1c**), corresponding to the respective M+1 ions in 100% abundances.

The nickel (**2a** and **2b**) and copper (**3a**, **3b** and **3c**) complexes were synthesized by the reaction of the ligands with $M(OAc)_2 \cdot xH_2O$ (M = Ni, Cu) in the presence of NEt_3 in methanol in 71–75% and 70–87% yields, respectively (see Scheme 2). Both of the nickel complexes, **2a** and **2b**, were diamagnetic in nature, consistent with a square planar geometry of the Ni(II) d^8 configuration. The ketimine methyl moieties (MeC=N) in **2a** and **2b** appeared as singlets at 1.87–1.94 ppm (*Me*C=N) in the ^{1}H NMR spectra and at 168.6–168.9 ppm (Me*C*=N) and 19.7–20.6 ppm (*Me*C=N) in the ^{13}C{^{1}H} NMR spectra. Comparison of infrared spectra for the $\nu_{C=N}$ stretching frequencies for **2a** (1574 cm^{-1}) and **2b** (1571 cm^{-1}) showed red shifts of ca. 35–43 cm^{-1} relative to the respective parent ligands **1a** (1609 cm^{-1}) and **1b** (1614 cm^{-1}). The $\nu_{C=N}$ stretching frequency values observed for **2a** and **2b** are similar to that of a related complex, {2-[1-(2,6-diisopropylphenylimino)-methyl]phenoxy}$_2$Ni(II) [36] (1602 cm^{-1}).

The paramagnetic copper complexes **3a**, **3b** and **3c** were characterized by IR, electronic spectroscopy, ESR, elemental analysis and X-ray diffraction studies. The $\nu_{C=N}$ stretching frequencies in the copper complexes, **3a** (1599 cm^{-1}), **3b** (1601 cm^{-1}) and **3c** (1599 cm^{-1}), are comparable to the closely related complex, {2-[1-(2-methoxyphenylimino)-methyl]phenoxy}$_2$Cu(II) [40], (1600 cm^{-1}) and, as was observed in the case of the nickel complexes **2a** and **2b**, the $\nu_{C=N}$ stretching frequencies are all red shifted by ca. 10–13 cm^{-1} relative to the ligands, **1a** (1609 cm^{-1}), **1b** (1614 cm^{-1}) and **1c** (1611 cm^{-1}).

The electronic spectra of the nickel complexes, **2a** and **2b**, in $CHCl_3$ showed absorption bands due to d–d transitions at 601 nm ($\varepsilon = 118$ L mol^{-1} cm^{-1}) and 592 nm ($\varepsilon = 102$ L mol^{-1} cm^{-1}), respectively, which are comparable to those reported for other square planar Ni(II) complexes. For example, square planar Ni(II) complexes of a series of [N_2O_2] chelating salen type ligands with varying spacer lengths showed similar low intensity absorbances due to d–d transitions at 532–550 nm ($\varepsilon = 240$–260 L mol^{-1} cm^{-1}) [41]. The Cu complexes, **3a**, **3b** and **3c**, on the other hand showed the d–d transitions at 696 nm ($\varepsilon = 89.4$ L mol^{-1} cm^{-1}), 670 nm ($\varepsilon = 130$ L mol^{-1} cm^{-1}) and 630 nm ($\varepsilon = 125$ L mol^{-1} cm^{-1}), respectively, which are also similar to other square planar copper complexes, like *bis*-[(N2-(2-pyridylmethyl)-3-thenyl-carboxamido)copper(II)]perchlorate [42] (675 nm). Similar comparisons of the d–d transitions in **3a**, **3b** and **3c** can also be drawn with another set of Schiff base copper complexes, {3-methoxy-2-[1-(2-pyridylmethylimino)methyl]phenoxy}Cu(II)X [43] (X = Cl, Br), based on a phenolato-pyridine ligand, which showed weak broad bands in the 600–700 nm region which were attributed to d–d transitions. The differences in the absorption bands amongst the copper complexes **3a**, **3b** and **3c** is notable, showing marked shifts of ca. 30 nm with the decrease in steric bulk of the 2,6-*di*-substituted phenyl ring on going from **3a** to **3b** to **3c**. In contrast, the Ni complexes did not show any appreciable difference in the d–d transitions on going from **2a** to **2b**.

The EPR spectra of the copper complexes **3a**, **3b** and **3c**, recorded in the frozen state in CH_2Cl_2 at 77 K (Table 1), showed a commonly observed axial pattern consisting of two well resolved peaks and two overlapping peaks of low intensities in the low field region ($g_{\|}$) due to hyperfine

Scheme 2. Synthesis of the metal complexes.

Table 1
EPR parameters of **3a**, **3b** and **3c** in CH_2Cl_2 at 77 K

Complex	$A_{\parallel}$	$A_{\perp}^{a}$	$g_{\parallel}$	$g_{\perp}$
3a	143	NR	2.2517	2.0399
3b	140	NR	2.2517	2.0463
3c	140	NR	2.2447	2.0465

[a] NR, not resolved.

splitting by the copper nucleus ($I = 3/2$) along with a high intensity peak in the high field region ($g_{\perp}$). In this context, it is worth mentioning that in square planar copper complexes, an unpaired electron when residing in the $d_{x^2-y^2}$ orbital ($^2B_{1g}$ ground state) exhibits $g_{\parallel} > g_{\perp}$ whereas the same when present in the other axial d_{z^2} orbital ($^2A_{1g}$ ground state) displays $g_{\perp} > g_{\parallel}$ [44–46]. Quite notably, in all the three copper complexes **3a**, **3b** and **3c**, the observed $g_{\parallel} > g_{\perp}$ is consistent with a square planar geometry at the metal center with the unpaired electron placed in the $d_{x^2-y^2}$ orbital [44–46]. Furthermore, the observed g and A values of **3a**, **3b** and **3c** are comparable to those of other reported copper complexes. For example, the average g and A values recorded at 77 K for the square planar complex {2-[1-(*N*,*N*-diethylethyleneimino)methyl]phenol)}$_2$Cu-$(ClO_4)_2$ [47] are $g_{\parallel}$ (2.225), $g_{\perp}$ (2.070) and $A_{\parallel}$ (179.7) and that of {4-[1-(4-methoxyphenylimino)-pent-2-ene-2-oxy]}$_2$-Cu(II) [45] are $g_{\parallel}$ (2.328), $g_{\perp}$ (2.067) and $A_{\parallel}$ (140).

The molecular structures of the nickel (**2a** and **2b**) (Figs. 2 and 3) and copper complexes (**3a**, **3b** and **3c**) (Figs. 4–6) have been determined by X-ray diffraction studies, which revealed the formation of metal complexes having 2:1 ligand to metal stoichiometries. The metal ions in these complexes reside at the center of a *trans*-N_2O_2 core which is perfectly square planar in case of the nickel (**2a** and **2b**) and two of the copper complexes (**3a** and **3c**), whereas it is distorted square planar in the other copper complex **3b**.

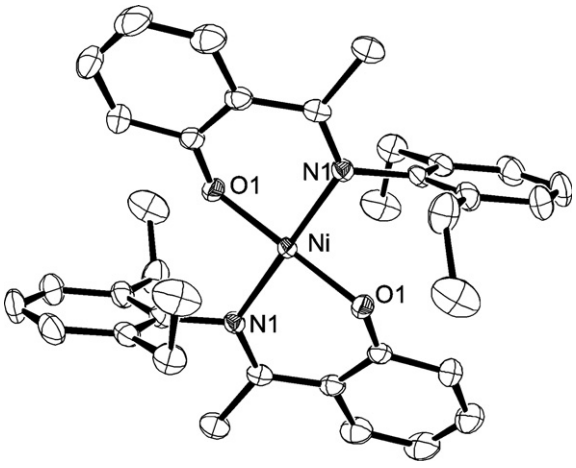


Fig. 2. ORTEP of **2a**. Thermal motion ellipsoids are drawn at the 50% probability level for the non-hydrogen atoms. Selected bond lengths (Å) and angles (°): Ni1–N1 1.9085(14), Ni1–N1 1.9085(14), Ni1–O1 1.8258(11), Ni1–O1 1.8258(11), N1–Ni1–N1 180.00(13), O1–Ni1–O1 180.00(9), N1–Ni1–O1 91.10(6), N1–Ni1–O1 88.90(6).

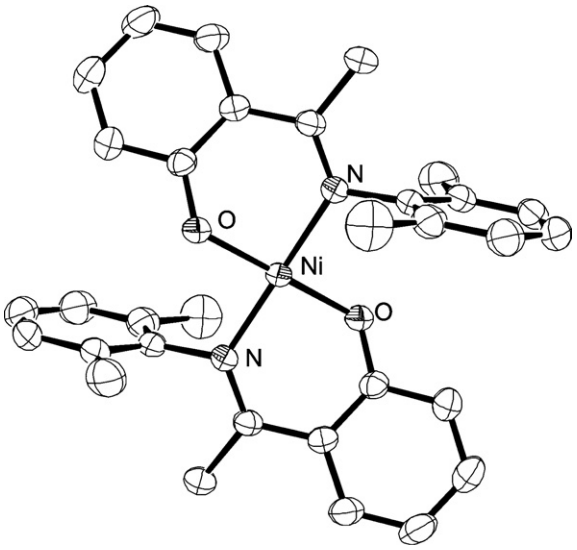

Fig. 3. ORTEP of **2b**. Thermal motion ellipsoids are drawn at the 50% probability level for the non-hydrogen atoms. Selected bond lengths (Å) and angles (°): Ni–N 1.9199(11), Ni–N 1.9199(11), Ni–O 1.8248(10), Ni–O 1.8248(10), N–Ni–N 180.00(4), O–Ni–O 180.00(5), N–Ni–O 90.93(5), N–Ni–O 89.07(5).

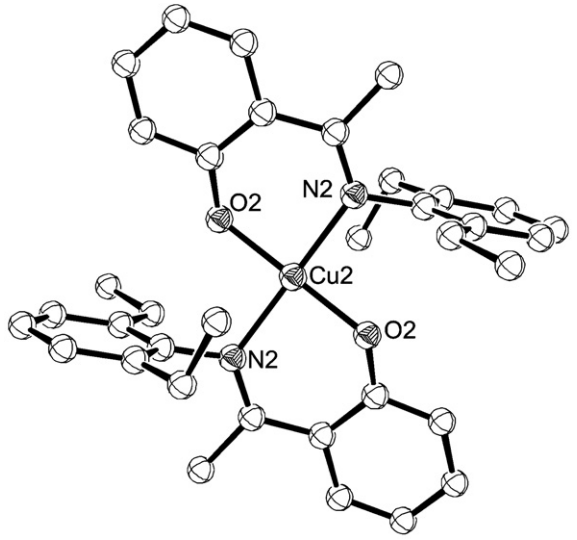

Fig. 4. ORTEP of **3a**. Thermal motion ellipsoids are drawn at the 50% probability level for the non-hydrogen atoms. Selected bond lengths (Å) and angles (°): Cu2–N2 2.0161(14), Cu2–N2 2.0161(14), Cu2–O2 1.8631(11), Cu2–O2 1.8630(11), N2–Cu2–N2 180.00(12), O2–Cu2–O2 180.00(7), O2–Cu2–N2 90.50(5), O2–Cu2–N2 89.50(5).

Consistent with a square planar geometry, the Ni(II) centers in **2a** and **2b** are surrounded by two equidistant Ni–N [**2a**: 1.9085(14) Å (Fig. 2); **2b**: 1.9199(11) Å (Fig. 3)] and two equidistant Ni–O [**2a**: 1.8258(11) Å (Fig. 2); **2b**: 1.8248(10) Å (Fig. 3)] bond distances. The Ni–N and the Ni–O bond distances in **2a** and **2b** are, however, somewhat longer than the sum of the individual covalent radii of the respective atoms (Ni–N = 1.854 Å, Ni–O = 1.814 Å) [48]. Quite expectedly, the complementary ∠O–Ni–N and ∠N–Ni–O angles at the nickel centers in **2a** [91.10(6),

Selected bond lengths (Å) and angles (°): Cu1–N1 2.001(2), Cu1–N1 2.001(2), Cu1–O1 1.872(2), Cu1–O1 1.872(2), N1–Cu–N1 180.00(16), O1–Cu1–O1 180.00(12), O1–Cu1–N1 89.16(9), N1–Cu1–O1 90.84(9).

88.90(6)°] and **2b** [89.07(5), 90.93(5)°] are equal to ca. 90°. The *trans* disposition of the phenyl rings of the 2,6-disubstituted-phenyl moieties in both complexes **2a** and **2b** is a consequence of the reduction of steric strain.

The comparison of the molecular structures of **2a** and **2b** with the other reported nickel phenoxy-ketimine and phenoxy-aldimine complexes is important. For example, the Ni–O and Ni–N bond distances in the phenoxy-ketimine complex, {2-[1-(2,6-diisopropylphenylimino)ethyl]phenoxy}$_2$Ni(II) [36] [Ni–O = 1.8081(10) Å; Ni–N = 1.9262 (11) Å], and in the phenoxy-aldimine nickel complex, {3-*t*-butyl-5-methyl-2-[1-(ethylimino)methyl]phenoxy}$_2$Ni(II) [49], [Ni–O = 1.861(2), 1.852(2) Å; Ni–N = 1.905(2), 1.893(2) Å] are in good agreement with those in the complexes **2a** and **2b**.

The copper complexes **3a**, **3b** and **3c** are isostructural with their nickel counterparts, **2a** and **2b**, though certain variations were observed. The *di*-ethyl derivative **3a** and the *mono*-methyl derivative **3c** exhibit square planar geometries like the nickel complexes **2a** and **2b**, whilst a slightly distorted square planar geometry was observed in case of the *di*-methyl derivative **3b**. Thus, unlike the square planar nickel (**2a** and **2b**) and copper (**3a** and **3c**) complexes, in which two sets of equidistant M–O and M–N (M = Ni, Cu) bond lengths were observed, the Cu–N and Cu–O bond lengths of the *trans*-N_2O_2 core in **3b** are all marginally unequal, a consequence of the slight distortion of the square planar geometry around the copper center. For example, in **3b** the Cu1–N11 and Cu1–N12 bond lengths are 2.007(5) Å and 2.006(4) Å, while the Cu1–O11 and Cu1–O12 distances are 1.858(4) Å and 1.856(4) Å, respectively (Fig. 5). Owing to the presence of the distortion, the four ∠N–Cu–O bond angles at the copper center in **3b** are also marginally different from the ideal value of 90° [∠N12–Cu1–O12 = 89.36(17)° and ∠N12–Cu1–O11 = 91.96(18)°], while the diagonal angles [∠N11–Cu1–N12 = 161.58(19)° and ∠O11–Cu1–O12 = 159.8(2)°] at the copper in **3b** are significantly deviated from the expected value of 180°. The extent of the distortion of the square planar structure in **3b** becomes apparent upon comparison with the perfectly square planar nickel analog **2b** (Fig. 7b). It is interesting to note that although significant square planar distortion (as reflected in the angles, θ and ϕ, in Fig. 7b) is observed in the *di*-methyl derivative **3b** (θ = 21.4°, ϕ = 17.7°) relative to the square planar nickel counterpart **2b**, no such distortion was visible in case of the *di*-ethyl copper complex **3a** (θ = 1.0°, ϕ = 1.8°) relative to the nickel analog **2a** (Fig. 7a). The *mono*-methyl copper complex **3c** also showed no distortion and closely resembled the square planar copper complex **3a**.

The Cu–O and Cu–N bond distances in **3a**, **3b** and **3c** are comparable to those observed in other analogous copper phenoxy-ketimine complexes, {2-[1-(2-phenylethylimino)ethyl]phenoxy}$_2$Cu(II) [50] [Cu–O = 1.865(2) Å, Cu–N = 1.977(2) Å] and {2-[1-(2-methylpropylimino)ethyl]-phenoxy}$_2$Cu(II) [51] [Cu–O = 1.891(2) Å, Cu–N = 2.003(2) Å], as well as in the related copper phenoxy-aldimine complexes, {5-bromo-2-[1-(3-methylphenylimino)methyl]-phenoxy}$_2$Cu(II) [52] [Cu–O = 1.884(8) Å, Cu–N = 2.005(7) Å] and {2-[1-(phenylimino)methyl]phenoxy}$_2$-Cu(II) [53] [Cu–O = 1.878(3) Å, Cu–N = 1.993(4) Å].

3. Polymerization studies

Quite significantly, the copper complexes **3a**, **3b** and **3c** efficiently catalyzed the ring-opening polymerization (ROP) of L-lactide at elevated temperatures under solvent-free melt conditions [28]. In stark contrast to the

copper complexes **3a**, **3b** and **3c**, the nickel complexes **2a** and **2b**, however, failed to yield the polylactide polymer.

Specifically, a typical polymerization experiment involved heating L-lactide with any of the copper initiators **3a** or **3b** or **3c**, taken in the desired ratio, in a sealed vessel under vacuum at designated temperatures for stipulated periods of time. Under these conditions the reaction mixture would form a monomer melt in which the polymerization would occur. A study of the variation of monomer to initiator ratio [M]:[I] ratio (M = monomer, I = initiator) at 160 °C showed that the maximum molecular weights for **3a** ($M_w = 18.5 \times 10^3$ entry 1, Table 3), **3b** ($M_w = 10.4 \times 10^3$ entry 1, Table 4) and **3c** ($M_w = 15.9 \times 10^3$ entry 1, Table 5) were obtained at ratios of 50:1 in each case. The observed polydispersity indices (PDIs) were in the range 1.05–1.46 (**3a**), 1.08–1.43 (**3b**) and 1.10–1.58 (**3c**). An interesting correlation between the initiator structure and the polymer molecular weight that emerges is the structurally similar square planar complexes **3a** and **3c**, which differ significantly from the distorted square planar complex **3b**, also exhibit a similar resemblance in their polymer molecular weights [**3a** ($M_w = 18.5 \times 10^3$ entry 1, Table 3); **3c** ($M_w = 15.9 \times 10^3$ entry 1, Table 5)] that are significantly greater than that observed in the case of **3b** ($M_w = 10.4 \times 10^3$ entry 1, Table 4) obtained at the 50:1 [M]:[I] ratio. Consistent with the observed molecular weight distributions, no correlation of the polymer molecular weight with time was seen in the time dependency studies (**3a**: entries 1 and 9–12, Table 3, **3b**: entries 1 and 9–12, Table 4, **3c**: entries 1 and 9–12, Table 5). The temper-

ature dependence study carried out at the 50:1 [M]:[I] ratio in the range (100–180 °C)[1] showed that the molecular weight of the polymer increased with temperature for the initiators **3a** (Table 3: M_w: 9.9×10^3, 16.5×10^3, 18.5×10^3, 26.3×10^3) and **3b** (Table 4: M_w: 5.3×10^3, 8.2×10^3, 10.4×10^3, 12.0×10^3) whereas a slight decrease in molecular weight was observed in the case of **3c** at higher temperatures (Table 5: M_w: 8.6×10^3, 11.1×10^3, 15.9×10^3 and 13.8×10^3) at 120, 140, 160 and 180 °C, respectively.

Worth comparing are the copper initiators **3a**, **3b** and **3c** with other known catalysts for the ring-opening polymerization of L-lactide under solvent-free melt conditions, particularly the copper ones. Interestingly enough, even though very many metals like Mg [54,27a,31c], Ti [55], Zn [56,20a,33b,30a,30b,30d,32a], Al [57,20b,20d], Sn [58,30c], etc. have been reported for lactide polymerization, we are aware of only a single report of lactide polymerization by a Cu catalyst, K[LCu(II)].nH_2O (H_3L = L-aspartic acid–salicylidene Schiff base) [20c]. The viscosity average molecular weight ($M_v = 4.86\times10^3$) obtained at a 200:1 [M]:[I] ratio after 24 h at 130 °C for K[LCu(II)]$\cdot n H_2O$ (H_3L = L-aspartic acid–salicylidene Schiff base [20c] is slightly smaller than that observed for **3a** (M_w: 18.5×10^3), **3b** (M_w: 10.4×10^3), **3c** (M_w: 15.9×10^3) obtained at a 50:1 [M]:[I] ratio after 4 h at 160 °C. Similar comparisons of **3a**, **3b** and **3c** can also be extended to other metal catalysts. For example, the polymer molecular weights and the polydispersity indices observed at a 50:1 [M]:[I] ratio for **3a** (M_w: 18.5×10^3, PDI = 1.28), **3b** (M_w: 10.4×10^3, PDI = 1.32), **3c** (M_w: 15.9×10^3, PDI = 1.36), obtained after 4 h at 160 °C, are also comparable to several other melt polymerization catalysts, such as [3-mesityl-1-picolylimidazol-2-ylidene]Zn(Et)I [30a] (M_w: 29.4×10^3, PDI = 2.45, 100:1 [M]:[I] ratio, 140 °C, 5 min), {[3-mesityl-1-picolylimidazol-2-ylidene]$_2$ZnI}I [30a] (M_w: 15.3×10^3, PDI = 2.51, 50:1 [M]:[I] ratio, 140 °C, 5 min), [(1-*i*-propyl-3-{*N*-phenylacetamido}imidazol-2-ylidene)$_2$Ag]$^+$Cl$^-$ [25] (M_w: 12.2×10^3, PDI = 1.40, 100:1 [M]:[I] ratio, 160 °C, 4 h), [1-(2-hydroxy-cyclohexyl)-3-(*N*-*t*-butylacetamido)imidazol-2-ylidene]AgCl [26] (M_w: 6.27×10^3, PDI = 1.23, 100:1 [M]:[I] ratio, 160 °C, 4 h) and [1-(2-hydroxy-cyclohexyl)-3-(*N*-*t*-butylacetamido)imidazol-2-ylidene]AuCl [26] (M_w: 6.31×10^3, PDI = 1.17, 100:1 [M]:[I] ratio, 160 °C, 4 h). Furthermore, comparable viscosity-average molecular weights (M_v) were also reported for a series of late-transition metal based initiators of the type K[LM(II)]$\cdot n H_2O$ (H_3L = L-aspartic acid–salicylidene Schiff base) [20c] where M = Co (5.15×10^3), Ni (11.1×10^3) and Zn (5.23×10^3), obtained at a 200:1 [M]:[I] ratio after 24 h at 130 °C. However, several other initiators have also been reported, which produced higher molecular weight polymers, e.g., anhydrous Fe(OAc)$_2$ [59] (M_w: 65.9×10^3, PDI = 5.25, 0.24 weight % of catalyst, 170 °C, 10 h), iron isobutyrate [59] (M_w: 148×10^3, PDI = 1.60, 0.12 weight % of catalyst, 190 °C, 2 h) and [L]TiO(2,6-*i*-Pr$_2$C$_6$H$_3$) [28c] (H_3L = triethanolamine) (M_w: 66.1×10^3, PDI = 1.97, 300:1 [M]:[I] ratio, 130 °C, 24 h). Thus, the detailed comparison with other known catalysts revealed that the copper initiators **3a**, **3b** and **3c** are moderately active for lactide polymerization.

[1] The bulk polymerization temperatures were chosen higher than the melting point of the lactide monomer (96 °C).

4. Experimental

4.1. General procedures

All manipulations were carried out using a combination of a glovebox and standard Schlenk techniques. Solvents were purified and degassed by standard procedures. 2,6-Dimethylaniline and 2,6-diethylaniline were purchased from Sigma–Aldrich, Germany and o-hydroxyacetophenone was purchased from SD-fine Chemicals (India), and they were used without any further purification. ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra were recorded on a Varian 400 MHz NMR spectrometer. ^{1}H NMR peaks are labelled as singlet (s), doublet (d), triplet (t) and multiplet (m). Infrared spectra were recorded on a Perkin Elmer Spectrum One FT-IR spectrometer. The electronic spectra were recorded in chloroform by using a Perkin–Elmer Lamda 35 UV-Visible spectrophotometer and JASCO V-570 UV/Vis/NIR spectrophotometer. Mass spectrometry measurements were done on a Micromass Q-Tof spectrometer. The EPR measurements were made with a Varian model 109C E-line X-band spectrometer fitted with a quartz Dewar for measurements at 77 K. The spectra were calibrated by using tetracyanoethylene (tcne) ($g = 2.0037$). The polymer molecular weights were determined using a Waters GPC (Waters 2414 RI Detector) with PL-gel, 5μ Mixed-D (2×300 mm) Column, with polystyrene standards in chloroform, covering molecular weight ranging from l40 to 4×10^5.

4.2. Synthesis of the ligands

4.2.1. Synthesis of 2-[1-(2,6-diethylphenylimino)ethyl]-phe- nol (*1a*)

o-Hydroxyacetophenone (4.31 g, 31.7 mmol) and 2,6-diethylaniline (14.3 g, 96.0 mmol) were taken in CH_2Cl_2 (ca. 75 mL) maintained at 0 °C and a solution of $TiCl_4$ (3 mL, 27.3 mmol) in CH_2Cl_2 (ca. 10 mL) was added. The reaction mixture was stirred in an ice bath for 1 h, after which it was allowed to warm up to room temperature over a period of 3 h. An aqueous NaOH solution (20 mL, 2 M) was added to the reaction mixture and washed thoroughly. The organic layer was separated, dried over anhydrous $MgSO_4$ and the solvent removed under vacuum to get the crude product as a yellow oil. The crude compound was purified by the removal of excess 2,6-diethylaniline and *o*-hydroxyacetophenone by vacuum distillation (180 °C, 0.2 mbar) to obtain the product as a yellow solid (1.83 g, 22%). ^{1}H NMR ($CDCl_3$, 400 MHz, 25 °C) δ 14.8 (s, 1H, O*H*), 7.64 (d, 1H, $^{3}J_{HH} = 8$ Hz, *o*-C_6H_4(OH)), 7.40 (t, 1H, $^{3}J_{HH} = 8$ Hz, *p*-C_6H_4(OH)), 7.16–7.11 (m, 3H, *m*/*p*-$C_6H_3(CH_2CH_3)_2$), 7.04 (d, 1H, $^{3}J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 6.91 (t, 1H, $^{3}J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 2.48–2.32 (m, 4H, CH_2CH_3), 2.17 (s, 3H, CH_3(C=N)), 1.13 (t, 6H, $^{3}J_{HH} = 8$ Hz, CH_2CH_3). ^{13}C NMR ($CDCl_3$, 100 MHz, 25 °C) δ 171.9 (*C*=N), 162.4 (C_6H_4(OH), 143.8 (*ipso*-$C_6H_3(CH_2CH_3)_2$), 133.0 (*o*-C_6H_4(OH)), 133.1 (*o*-$C_6H_3(CH_2CH_3)_2$), 128.9 (*p*-C_6H_4(OH)), 126.1 (*m*-$C_6H_3(CH_2CH_3)_2$), 124.8 (*p*-$C_6H_3(CH_2CH_3)_2$), 119.1 (*ipso*-C_6H_4(OH)), 118.3 (*m*-C_6H_4(OH)), 118.0 (*m*-(C_6H_4-(OH)), 24.7 ($C_6H_3(CH_2CH_3)_2$), 17.3 ((C=N)CH_3), 14.0 ($C_6H_3(CH_2CH_3)_2$). LRMS (ES): *m*/*z* 268 $(M+H)^+$ 100%. HRMS (ES): calcd. for $[M+H]^+$ 268.1701, found *m*/*z* 268.1696. IR data cm^{-1} KBr pellet: 1609 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 256 nm ($\varepsilon = 17263$ L mol^{-1} cm^{-1}), 323 nm ($\varepsilon = 5945$ L mol^{-1} cm^{-1}).

4.2.2. Synthesis of 2-[1-(2,6-dimethylphenylimino)ethyl]-phenol (*1b*)

o-Hydroxyacetophenone (8.51 g, 62.5 mmol) and 2,6-dimethylaniline (12.4 g, 102 mmol) were taken in CH_2Cl_2 (ca. 75 mL) maintained at 0 °C and a solution of $TiCl_4$ (2 mL, 18.2 mmol) in CH_2Cl_2 (ca. 10 mL) was added. The reaction mixture was stirred in an ice bath for 1 h, after which it was allowed to warm up to room temperature over a period of 3 h. An aqueous NaOH solution (20 mL, 2 M) was added to the reaction mixture and washed thoroughly. The organic layer was separated, dried over anhydrous $MgSO_4$ and the solvent removed under vacuum to get the crude product as a yellow oil. The crude compound was purified by column chromatography (4% EtOAc–hexane mixture) followed by the removal of excess 2,6-dimethylaniline by vacuum distillation (180 °C, 0.2 mbar) to obtain the product as a yellow solid (3.09 g, 21%). ^{1}H NMR ($CDCl_3$, 400 MHz, 25 °C) δ 14.7 (s, 1H, O*H*), 7.57 (d, 1H, $^{3}J_{HH} = 8$ Hz, *o*-C_6H_4(OH)), 7.32 (t, 1H, $^{3}J_{HH} = 8$ Hz, *p*-C_6H_4(OH)), 7.03 (d, 2H, $^{3}J_{HH} = 8$ Hz, *m*-$C_6H_3(CH_3)_2$), 6.98–6.92 (m, 2H, *p*-$C_6H_3(CH_3)_2$and *m*-C_6H_4(OH) overlapped), 6.83 (t, 1H, $^{3}J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 2.09 (s, 3H, CH_3(C=N)), 1.99 (s, 6H, $C_6H_3(CH_3)_2$). ^{13}C NMR ($CDCl_3$, 100 MHz, 25 °C) δ 171.7 (*C*=N), 162.2 (C_6H_4-(OH), 145.0 (*ipso*-$C_6H_3(CH_3)_2$), 132.9 (*o*-C_6H_4(OH)), 128.8 (*p*-C_6H_4(OH)), 127.9 (*m*-$C_6H_3(CH_3)_2$), 127.5 (*p*-$C_6H_3(CH_3)_2$), 124.3 (*ipso*-C_6H_4(OH), 119.1 (*m*-C_6H_4-(OH)), 118.1 (*m*-C_6H_4(OH)), 117.9 (*o*-$C_6H_3(CH_3)_2$), 18.1 (CH_3(C=N)), 16.8 ($C_6H_3(CH_3)_2$). LRMS (ES): *m*/*z* 240 $(M+H)^+$ 100%. HRMS (ES): calcd. for $[M+H]^+$ 240.1388, found *m*/*z* 240.1380. IR data cm^{-1} KBr pellet: 1614 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 256 nm ($\varepsilon = 17933$ L mol^{-1} cm^{-1}), 322 nm ($\varepsilon = 5919$ L mol^{-1} cm^{-1}).

4.2.3. Synthesis of 2-[1-(2-methylphenylimino)ethyl]phenol (*1c*)

o-Hydroxyacetophenone (7.25 g, 53.2 mmol) and 2-methylaniline (8.62 g, 80.5 mmol) were taken in CH_2Cl_2 (ca. 60 mL) maintained at 0 °C and a solution of $TiCl_4$ (2 mL, 18.2 mmol) in CH_2Cl_2 (ca. 10 mL) was added. The reaction mixture was stirred in an ice bath for 2 h, after which it was allowed to warm up to room temperature over a period of 3 h. An aqueous NaOH solution (40 mL, 2 M) was added to the reaction mixture and washed thoroughly. The organic layer was separated, dried over anhydrous $MgSO_4$ and the solvent removed under vacuum to get the crude product as a yellow oil. The crude

compound was purified by the removal of excess 2-methylaniline and *o*-hydroxyacetophenone by vacuum distillation (180 °C, 0.2 mbar) to obtain the product as a yellow oil (2.72 g, 23%). ^{1}H NMR ($CDCl_3$, 400 MHz, 25 °C) δ 14.7 (s, 1H, O*H*), 7.63 (d, 1H, $^3J_{HH} = 7$ Hz, *o*-C_6H_4(OH)), 7.37 (t, 1H, $^3J_{HH} = 9$ Hz, *p*-C_6H_4(OH)), 7.25 (d, 1H, $^3J_{HH} = 8$ Hz, *m*-$C_6H_4(CH_3)$), 7.21 (t, 1H, $^3J_{HH} = 8$ Hz, *m*-$C_6H_4(CH_3)$), 7.10 (t, 1H, $^3J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 7.02 (d, 1H, $^3J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 6.89 (t, 1H, $^3J_{HH} = 8$ Hz, *p*-$C_6H_4(CH_3)$), 6.76 (d, 1H, *o*-$C_6H_4(CH_3)$), 2.26 (s, 3H, $C_6H_4(CH_3)$), 2.15 (s, 3H, CH_3(C=N)). ^{13}C NMR ($CDCl_3$, 100 MHz, 25 °C) δ 171.1 (*C*=N), 162.0 (C_6H_4(OH), 145.8 (*ipso*-$C_6H_4(CH_3)$), 133.0 (*o*-C_6H_4(OH)), 130.5 (*o*-$C_6H_4(CH_3)$), 128.8 (*p*-C_6H_4(OH)), 126.4 (*m*-$C_6H_4(CH_3)$), 124.8 (*p*-$C_6H_4(CH_3)$), 120.5 (*o*-$C_6H_4(CH_3)$), 119.5 (*ipso*-C_6H_4(OH), 118.1 (*m*-C_6H_4(OH)), 118.0 (*m*-(C_6H_4(OH)), 17.9 ((C=N)CH_3), 17.0 ($C_6H_4(CH_3)$). LRMS (ES): *m*/*z* 226 $(M+H)^+$ 100%. HRMS (ES): calcd. for $[M+H]^+$ 226.1232, found *m*/*z* 226.1234. IR data cm^{-1} KBr pellet: 1611 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 257 nm ($\varepsilon = 21873$ L mol^{-1} cm^{-1}), 324 nm ($\varepsilon = 8776$ L mol^{-1} cm^{-1}).

4.3. Synthesis of the Ni complexes

4.3.1. Synthesis of {2-[1-(2,6-diethylphenylimino)ethyl]-phenoxy}$_2$Ni(II) (**2a**)

$Ni(OAc)_2 \cdot 4H_2O$ (0.449 g, 1.81 mmol) and 2-[1-(2,6-diethylphenylimino)ethyl]phenol (**1a**) (0.478 g, 1.79 mmol) were taken in methanol (ca. 30 mL) and stirred at room temperature until a clear solution was obtained. To the solution was added NEt_3 (0.274 g, 2.70 mmol) with constant stirring. The reaction mixture was refluxed for 12 h and then allowed to cool to room temperature, when the product precipitated out as a green solid and was isolated by filtration and air dried (0.493 g, 71%). Crystals suitable for X-ray structure determination were obtained by slow evaporation from a saturated methanol solution. ^{1}H NMR ($CDCl_3$, 400 MHz, 25 °C) δ 7.31 (d, 1 H, $^3J_{HH} = 8$ Hz, *o*-C_6H_4(OH)), 7.21 (t, 1H, *p*-C_6H_4(OH)), 7.11 (d, 2H, $^3J_{HH} = 8$ Hz, *m*-$C_6H_3(CH_2CH_3)_2$), 6.84 (t, 1H, $^3J_{HH} = 8$ Hz, *p*-$C_6H_3(CH_2CH_3)_2$), 6.38 (t, 1H, $^3J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 5.50 (d, 1H, $^3J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 3.29–3.19 (m, 2H, CH_2CH_3), 2.90–2.80 (m, 2H, CH_2CH_3), 1.94 (s, 3H, CH_3(C=N)), 1.45 (t, 6H, $^3J_{HH} = 8$ Hz, CH_2CH_3). ^{13}C NMR ($CDCl_3$, 100 MHz, 25 °C) δ 168.9 (*C*=N), 163.6 (C_6H_4(OH), 145.8 (*ipso*-$C_6H_3(CH_2CH_3)_2$)), 136.1 (*o*-C_6H_4(OH)), 132.2 (*p*-C_6H_4(OH)), 129.0 (*p*-$C_6H_3(CH_2CH_3)_2$), 125.0 (*m*-$C_6H_3(CH_2CH_3)_2$ and *ipso*-(C_6H_4(OH)), 123.2 (*m*-C_6H_4-(OH), 122.1 (*o*-$C_6H_3(CH_2CH_3)_2$), 113.9 (*m*-C_6H_4(OH)), 24.6 ($C_6H_3(CH_2CH_3)_2$), 20.6 (CH_3(C=N)), 13.7 ($C_6H_3(CH_2CH_3)_2$). IR data cm^{-1} KBr pellet: 1574 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 601 nm ($\varepsilon = 118$ L mol^{-1} cm^{-1}). *Anal.* Calc. for $C_{36}H_{40}NiO_2N_2$: C, 73.11; H, 6.82; N, 4.74. Found: C, 72.78; H, 7.06; N, 3.87%.

4.3.2. Synthesis of {2-[1-(2,6-dimethylphenylimino)ethyl]-phenoxy}$_2$Ni(II) (**2b**)

$Ni(OAc)_2 \cdot 4H_2O$ (0.543 g, 2.19 mmol) and 2-[1-(2,6-dimethylphenylimino)ethyl]phenol (**1b**) (0.508 g, 2.12 mmol) were taken in methanol (ca. 30 mL) and stirred at room temperature until a clear solution was obtained. To the solution was added NEt_3 (0.324 g, 3.20 mmol) with constant stirring. The reaction mixture was stirred at room temperature for another 6 h when the product precipitated out as a green solid and was isolated by filtration and air dried (0.459 g, 75%). Crystals suitable for X-ray structure determination were obtained by slow evaporation from a saturated benzene solution. ^{1}H NMR ($CDCl_3$, 400 MHz, 25 °C) δ 7.26 (d, 1H, $^3J_{HH} = 8$ Hz, *o*-C_6H_4(OH)), 7.19 (br, 1H, *p*-C_6H_4(OH)), 7.02 (br, 2H, *m*-$C_6H_3(CH_3)_2$), 6.83 (t, 1H, $^3J_{HH} = 8$ Hz, *p*-$C_6H_3(CH_3)_2$), 6.35 (t, 1H, $^3J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 5.66 (d, 1H, $^3J_{HH} = 8$ Hz, *m*-C_6H_4(OH)), 2.53 (s, 6H, $C_6H_3(CH_3)_2$), 1.87 (s, 3H, CH_3(C=N)). ^{13}C NMR ($CDCl_3$, 100 MHz, 25 °C) δ 168.6 (*C*=N), 163.7 (C_6H_4(OH), 146.4 (*ipso*-$C_6H_3(CH_3)_2$)), 132.3 (*o*-C_6H_4(OH)), 130.9 (*p*-C_6H_4(OH)), 129.0 (*p*-$C_6H_3(CH_3)_2$), 127.6 (*m*-$C_6H_3(CH_3)_2$), 124.9 (*ipso*-C_6H_4(OH), 122.0 (*m*-C_6H_4(OH)), 118.2 (*m*-(C_6H_4(OH)), 114.1 (*o*-$C_6H_3(CH_3)_2$), 19.7 (CH_3(C=N)), 19.2 (C_6H_3-$(CH_3)_2$). IR data cm^{-1} KBr pellet: 1571 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 592 nm ($\varepsilon = 102$ L mol^{-1} cm^{-1}). *Anal.* Calc. for $C_{32}H_{32}NiO_2N_2$: C, 71.80; H, 6.03; N, 5.23. Found: C, 71.14; H, 6.21; N, 4.88%.

4.4. Synthesis of the Cu complexes

4.4.1. Synthesis of {2-[1-(2,6-diethylphenylimino)ethyl]-phenoxy}$_2$Cu(II) (**3a**)

$Cu(OAc)_2 \cdot H_2O$ (0.266 g, 1.33 mmol) and 2-[1-(2,6-diethylphenylimino)ethyl]phenol (**1a**) (0.709 g, 2.62 mmol) were taken in methanol (ca. 40 mL) and stirred at room temperature until a clear solution was obtained. To the solution was added NEt_3 (0.298 g, 2.94 mmol) with constant stirring. The reaction mixture was stirred at reflux for 24 h and then allowed to cool to room temperature when the product was obtained as dark brown crystals which were isolated by filtration and vacuum dried (0.542 g, 70%). Crystals suitable for X-ray structure determination were obtained by slow evaporation from a saturated benzene solution. IR data cm^{-1} KBr pellet: 1599 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 696 nm ($\varepsilon = 89.4$ L mol^{-1} cm^{-1}). *Anal.* Calc. for $C_{36}H_{40}CuO_2N_2$: C, 72.52; H, 6.76; N, 4.70. Found: C, 72.07; H, 7.06; N, 4.39%.

4.4.2. Synthesis of {2-[1-(2,6-dimethylphenylimino)-ethyl]phenoxy}$_2$Cu(II) (**3b**)

$Cu(OAc)_2 \cdot H_2O$ (0.418 g, 2.14 mmol) and 2-[1-(2,6-dimethylphenylimino)ethyl]phenol (**1b**) (0.512 g, 2.14 mmol) were taken in methanol (ca. 30 mL) and stirred at room temperature until a clear solution was obtained. To the solution was added NEt_3 (0.282 g, 2.78 mmol) with constant stirring. The reaction mixture was stirred at room

temperature for another 6 h when the product precipitated out as a dark brown solid and was isolated by filtration and vacuum dried (0.505 g, 87%). Crystals suitable for X-ray structure determination were obtained by slow evaporation from a saturated benzene solution. IR data cm^{-1} KBr pellet: 1601 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 670 nm ($\varepsilon = 130$ L mol^{-1} cm^{-1}). *Anal.* Calc. for $C_{32}H_{32}CuO_2N_2$: C, 71.15; H, 5.97; N, 5.19. Found: C, 71.18; H, 6.41; N, 5.34%.

4.4.3. Synthesis of {2-[1-(2-methylphenylimino)ethyl]-phenoxy}$_2$Cu(II) (3c)

$Cu(OAc)_2 \cdot H_2O$ (0.582 g, 2.92 mmol) and 2-[1-(2-methylphenylimino)ethyl]phenol (**1c**) (0.677 g, 3.00 mmol) were taken in methanol (ca. 40 mL) and stirred at room temperature until a clear solution was obtained. To the solution was added NEt_3 (0.314 g, 3.10 mmol) with constant stirring. The reaction mixture was stirred at reflux for 12 h and then allowed to cool to room temperature when the product was obtained as reddish-brown solid which was isolated by filtration and vacuum dried (0.573 g, 75%). Crystals suitable for X-ray structure determination were obtained by slow evaporation from a saturated benzene solution. IR data cm^{-1} KBr pellet: 1599 (s) ($\nu_{C=N}$). λ_{max} (ε) $CHCl_3$: 630 nm ($\varepsilon = 125$ L mol^{-1} cm^{-1}). *Anal.* Calc. for $C_{30}H_{28}CuO_2N_2$: C, 70.36; H, 5.51; N, 5.47. Found: C, 69.84; H, 5.55; N, 5.40%.

4.5. Polymerization experiments

Typical polymerization experiments: L-lactide (1.000 g, 6.94 mmol) and **3a**, **3b** and **3c**, in a stipulated molar ratio, were charged in an ampoule inside a glove box. The ampoule was taken out and put under vacuum at 50 °C for 30 min, after which the ampoule was sealed under vacuum and heated at 160 °C for 4 h. Under these conditions the reaction mixture turned into a monomer melt in which polymerization occurred. Subsequently, the molten reactive polymer mixture was cooled by immersing the sealed ampoule in liquid nitrogen to stop the polymerization. Conversion of L-lactide monomer was determined using the size exclusion chromatography method. The analyses were performed on the crude reaction mixture and no precipitation was executed to avoid fractionation of the sample in order to not influence the results.

4.6. X-ray analyses

X-ray diffraction data were collected either on a Bruker P4 diffractometer equipped with a SMART CCD detector or on an Oxford Diffraction XCalibur-S, and crystal data collection and refinement parameters are summarized in Table 2. The structures were solved using direct methods and standard difference map techniques, and were refined by full-matrix least-squares procedures on F^2 with SHELXTL (Version 6.10).

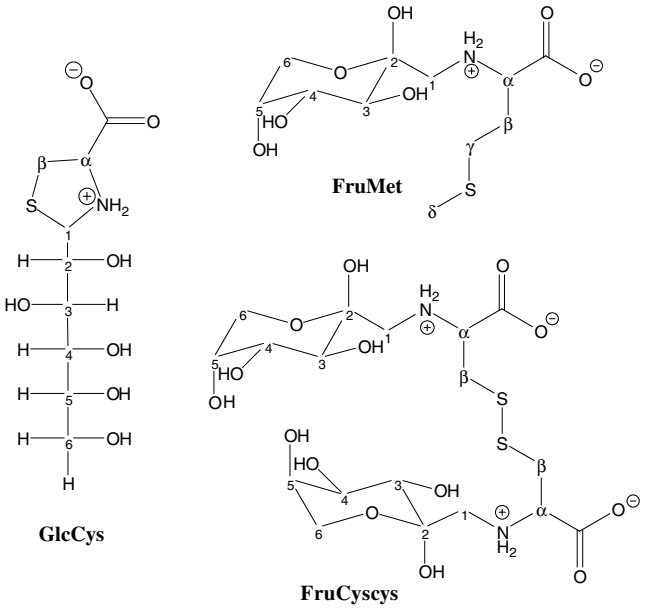
5. Conclusion

In summary, a series of new nickel (**2a**, **2b**) and copper (**3a**, **3b**, **3c**) complexes, bearing a 2:1 ligand:metal stoichiometry, has been synthesized from the respective ligands, 2-[1-(2,6-diethylphenylimino)ethyl]phenol (**1a**), 2-[1-(2,6-dimethylphenylimino)ethyl]phenol (**1b**) and 2-[1-(2-methylphenylimino)ethyl]phenol (**1c**), by the reactions with the corresponding $M(OAc)_2 \cdot xH_2O$ (M = Ni, Cu) in the presence of NEt_3 as a base in moderate to high yields. The complexes **2a**, **2b**, **3a**, **3b** and **3c** have been structurally characterized by X-ray diffraction studies, which revealed that the geometry around the metal center is square planar in the nickel (**2a**, **2b**) and copper (**3a**, **3c**) complexes whilst it is distorted square planar in the copper **3b** complex. The catalysis studies revealed that while the copper complexes **3a**, **3b** and **3c**, efficiently catalyzed the ring-opening polymerization of L-lactide under solvent-free melt conditions, producing polylactide polymers of moderate molecular weights and having narrow molecular weight distributions, the nickel counterparts **2a** and **2b** failed to yield any polylactide polymer.

Acknowledgements

We thank Council of Scientific and Industrial Research (CSIR), New Delhi, for financial support of this research. We are grateful to the National Single Crystal X-ray Diffraction Facility at IIT Bombay as well as to Professor Gerard Parkin, Columbia University for the crystallographic results. PG thanks Professor Goutam Kumar Lahiri, IIT Bombay, for valuable discussion and Professor M. Ravikanth, IIT Bombay, for help with the electronic studies. AJ thanks CSIR, New Delhi for a research fellowship.

Appendix A. Supplementary material



CCDC 609004, 605462, 607766, 605461 and 609526 contain the supplementary crystallographic data for **2a**, **2b**, **3a**, **3b** and **3c**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.04.039.

Scheme 1.

geometry is an important parameter in anti-tumor activity and added other criteria, stating that: (i) a pair of good leaving groups is necessary but not sufficient, anyway the presence of ligands with intermediate leaving ability is preferred to reduce systemic toxicity; (ii) the complex should be uncharged; (iii) the maximum activity is observed with maximum solubility, since diffusion is the principal way of penetration through cell membranes. In order to satisfy all these requirements we have now synthesized glycosylated adducts of cystine, cysteine and methionine and here, we report a study on Pt(II) coordination properties of the ligands listed in Scheme 1. The presence of carbohydrate moiety may provide enhanced water solubility, cell penetration, and drug–receptor interaction of the complexes.

NMR is a powerful technique that gives useful information about Pt(II) coordination, although literature reports only few examples of 2D ^{1}H–^{195}Pt heterocorrelated experiments on Pt(II)–aminoacids systems [13]. Here, we report a complete NMR study on Pt(II)-Amadori compounds based on 1D and 2D ^{1}H, ^{13}C and ^{195}Pt homo and heteronuclear techniques.

2. Experimental

2.1. NMR measurements

NMR spectra were registered with a Bruker FT-NMR Avance 400 spectrometer (Broad Band 5 mm probe, inverse detection). Nominal frequencies are 400.13 MHz for ^{1}H, 100.61 MHz for ^{13}C and 86.02 MHz for ^{195}Pt. An internal lock on the deuterium of D_2O was used for all spectra. The chemical shift references, at 300 K, were as follows: ^{1}H and ^{13}C, TSP; ^{195}Pt (external) at −1614 ppm (referred to $[PtCl_6]^{2-}$) [14], 1 M K_2PtCl_4 containing 1 M NaCl in D_2O. The negative sign of ^{195}Pt chemical shifts indicates a lower frequency (higher field) with respect to the reference.

^{1}H NMR conditions were as follows: 30° pulses (2.03 μs); 8–16 k data points; 0.5–1 s relaxation delay; collection of 32–128 transients; for 2D H,H-Homonuclear Correlated Spectroscopy (COSY [15]) and nuclear Overhauser effect spectroscopy (NOESY [16]) typical parameters were used. For the latter, a mixing time ranging from 800 to 300 ms was used. For 1D ^{13}C NMR spectra acquisition conditions were as follows: 90° pulses (14.9 μs); 16–32 k data points; 0.5–1 s relaxation delay; collection of 32 k transients. ^{195}Pt NMR spectra were typically the result of 90° pulses (20 μs), 16–32 k data points, 0.1–1 s relaxation delay; 1–4 k transients. It was not possible to scan the whole ^{195}Pt spectral region (13 000 ppm) in a single experiment, since maximum instrumental frequency width is 1000 ppm. For 2D H,X-Hetero Correlated Spectroscopy HMBC [17] and HMQC [18] opportune parameters were used (50–90° pulses; 32 k data points; 1-s relaxation delay; 8–64 k transients; $^{1}J_{H-C}$ 125–145 Hz; $^{3}J_{H-C}$ 5–15 Hz; $^{2}J_{H-Pt}$ 50–250 Hz). H_2O resonance was suppressed with a presaturation pulse [19].

The temperature was increased from 300 K to 330 K and maintained within ±0.1 K using the variable-temperature controller BVT3200.

2.2. General procedure for the synthesis of Amadori compounds [20]

A suspension of 0.010 mol of anhydrous β-D-glucose and 0.2 g of sodium bisulfite in a mixture of 6 mL of methanol and 3 mL of glycerol was refluxed for 30 min, followed by the addition of 0.007 mol of aminoacid (methionine or cystine) and 1 mL of acetic acid. The solution was refluxed until almost all the aminoacid had reacted, as evidenced by TLC. TLC was performed on silica gel $60F_{254}$ glass plates and employing the mixture *n*-butanol–acetic acid–water 4:1:1 as moving phase. For detection of aminoacid derivatives as well as sugars the plates were sprayed with a 0.2% ninhydrin in ethanol solution and heated at 120 °C. The solvent (methanol) was removed in vacuum at 35 °C, the resulting brown syrup was diluted with 1 vol. of water and placed on a 2×45 cm column filled with DOWEX 50WX8-200 (H^+) ion-exchange resin conditionated with water. The column was eluted with water followed by 0.075 M ammonia solution. Early water fractions contained glucose, glycerol, pigments and glucose-derived degradation products. The Amadori compound was eluted at the beginning of the ammonium hydroxide wash, followed by unreacted amino acid. Fractions containing only Amadori compound were evaporated in vacuum at 35 °C. A solution methanol–ethanol 50/50 V/V was added to the resulting syrup, and the mixture was stirred at room temperature for a night. The light brown solid was filtered off and washed with ethanol and dried in vacuum over calcium chloride. *N*-(1-deoxy-β-fructos-1-yl)-L-methionine [FruMet]: *Anal.*

Calc. for $C_{11}H_{21}NO_7S$: C, 42.43; H, 6.80; N, 4.50; S, 10.30. Found: C, 42.45; H, 6.77; N, 4.58; S, 10.26% (Yield: 35%); *N*,*N*′-di-(1-deoxy-β-fructos-1-yl)-L-cystine [FruCyscys]: *Anal*. Calc. for $C_9H_{16}NO_7S$: C, 38.29; H, 5.71; N, 4.96; S, 11.36. Found: C, 38.26; H, 5.72; N, 4.93; S, 11.30% (Yield: 20%).

2.3. Synthesis of 2-(1,2,3,4,5-pentahydroxypentyl)-1,3-thiazolidine-4-carboxylic acid [GlcCys] [21]

A methanol suspension of anhydrous β-D-glucose and L-cysteine in equimolar ratio was refluxed for 2 h. The reaction was filtered off and the product was recrystallized from a water–methanol 1:1 V:V solution. *Anal*. Calc. for $C_9H_{17}NO_7S$: C, 38.16; H, 6.05; N, 4.94; S, 11.32. Found: C, 38.09; H, 6.08; N, 5.00; S, 11.26% (Yield: 80%).

2.4. Synthesis of Pt(II) complexes

A solution of 2×10^{-4} mol of FruMet in 10 ml of water was added dropwise, under stirring, to a solution of 1×10^{-4} mol of K_2PtCl_4 in 5 ml of water. The solution was kept in the dark and under stirring at 50 °C for 5 h to avoid metallic Pt formation. The reaction was filtered and concentrated to 2 mL, in order to favour precipitation 4 mL of ethanol were added. The product [Pt(FruMet-*N*,*S*)$_2$Cl$_2$] was recrystallized from ethanol. *Anal*. Calc. for $C_{22}H_{42}Cl_2N_2O_{14}PtS_2$: C, 29.73; H, 4.76; N, 3.15; S, 7.22. Found: C, 29.64; H, 4.63; N, 3.07; S, 7.16% (Yield: 60%). The same procedure using 1×10^{-4} mol of FruMet and 1×10^{-4} mol of K_2PtCl_4 separates a Pt/L 1:1 complex [Pt(FruMet-*N*,*S*)Cl$_2$]. *Anal*. Calc. for $C_{11}H_{21}Cl_2NO_7PtS$: C, 22.93; H, 3.50; N, 2.43; S, 5.56. Found: C, 23.01; H, 3.55; N, 2.39; S, 5.48% (Yield: 70%). The same procedure was used to obtain the Pt(II) complex of FruCyscys: [Pt$_2$FruCyscysCl$_4$]. *Anal*. Calc. for $C_9H_{16}Cl_2NO_7PtS$: C, 19.72; H, 2.94; N, 2.55; S, 5.85. Found: C, 19.78; H, 2.90; N, 2.62; S, 5.83% (Yield: 50%).

2.5. Partition coefficient

The shake-flask method is performed: 2 mL of the ligand stock solution (10^{-4} M) at pH 4 and 7.4 are mixed in a vessel with a known volume of high purity analytical grade *n*-octanol (0.5–2 mL) and shaken at 37 °C for 4 h. The two phases are then separated and the concentration of the ligand is determined in the aqueous solution by spectrophotometric method using a Perkin–Elmer Lambda 20 spectrophotometer.

2.6. Cytotoxicity study

The 2008 cell line, established from a patient with serious cystadenocarcinoma of the ovary and the cDDP-resistant C13* subline, generated as previously described [22] were grown as monolayers in RPMI 1640 medium (BioWhittaker Europe) containing 10% heat-inactivated fetal bovine serum (BioWhittaker Europe) and 50 μg/ml gentamycin sulfate. Cultures were equilibrated with humidified 5% CO_2 in air at 37 °C. Cells were treated for three days with different concentrations of [Pt(FruMet-*N*,*S*)Cl$_2$] (0–600 μM). All studies were performed in Mycoplasma negative cells, as routinely determined with the Mycotest detection kit (Euroclone, Switzerland). Cell growth was determined by a modification of the crystal violet dye assay [23]. On selected days, after removal of the tissue culture medium, the cell monolayer was fixed with methanol prior to staining with 0.25% crystal violet solution in 80% absolute ethanol for at least 30 min. After washing several times with distilled water to remove the dye excess, the cells were let to dry. The incorporated dye was solubilized in acidic isopropanol (1 N HCl: 2-propanol, 1:10). After appropriate dilution, dye was determined spectrophotometrically at 540 nm. The extracted dye was proportional to cell number. Percentage of cytotoxicity was calculated by comparing the absorbance of exposed to non-exposed (control) cultures.

3. Results and discussion

3.1. [FruMet]

^{1}H and ^{13}C FruMet NMR spectra were registered in D_2O and H_2O/D_2O (95/5) in order to completely characterize the ligand, chemical shifts are reported in Table 1. The addition of K_2PtCl_4 to a solution of FruMet in 1:2 M/L molar ratio, at room temperature and in acid conditions (pH 3), brings slowly to the formation of different complex species, as shown by the presence of many peaks in ^{195}Pt NMR spectrum (Fig. 1), and to a line broadening of proton signals close to the coordination site. Even if it is difficult to define the nature and stoichiometry of the formed complexes, ^{1}H NMR spectra suggest an *N*,*S* metal coordination, since significant downfield shifts are observed mainly for H-1, H-α and H-δ and slightly for H-β and H-γ (Scheme 1). The carboxylic group is in the protonated form. On increasing pH from 3 to 7 a downfield shift is observed for carboxylic carbon (from 172.5 ppm to 176 ppm) as a consequence of the deprotonation reaction. The same coordination mode is reported for analogous sulphur containing aminoacid complexes of Pt(II) [24].

To better investigate the 1:2 Pt/FruMet system, the solid complex [Pt(FruMet-*N*,*S*)$_2$]Cl$_2$ was synthesized in acid condition (pH ∼ 1.9) and studied in solution at physiological pH.

^{195}Pt NMR spectrum of [Pt(FruMet-*N*,*S*)$_2$]Cl$_2$ (Fig. 2) shows two main peaks at −3438(2) and −3445(2) ppm, attributed to two different isomers. Each platinum signal correlates with a different set of protons. The main cross peaks are due to platinum scalar coupling with aminic hydrogen (∼7 ppm) and δ-methyl group (∼2.7 ppm), suggesting an *N*,*S* coordination mode, which is furthermore supported by long-range couplings of platinum with H-α and H-γ. Methylenic H-β protons, that are almost chemical

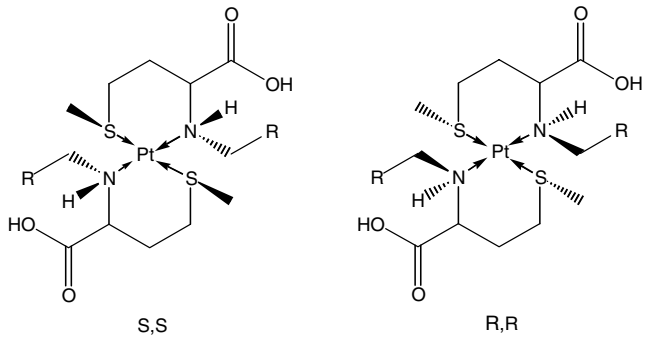
shift equivalent in the pure ligand, result strongly splitted since their free rotation is removed in the chelate ring formation. A same behaviour is observed for H-γ protons.



A correlation between ^{195}Pt chemical shift (δ) and the coordination geometry of platinum ion is reported [14]. For PtX_2L_2 species the *cis* isomer is usually upfield shifted with respect to *trans*; the shift is as big as the difference in the hard-soft nature of the ligands is increased [14]. As previously reported [25] the difference in δ ($\Delta\delta$) between *cis* and *trans* isomers in PtS_2N_2 type is around 200 ppm; in our system $\Delta\delta$ is around 10 ppm, therefore the same geometry for the two species is suggested: both *cis* or both *trans*. The *trans* isomer is here proposed because δ values are similar to those found for *trans* platinum–methionine complexes [25]. In order to substantiate this assumption a NOESY experiment was performed; the spectrum shows the presence of cross peaks relating *S*-CH_3 group with aminic proton and glycosidic moiety. This spatial proximity of

S-CH_3 and aminic group is consistent with a *trans* configuration that favours a reduction of the steric hindrance of the bulky nitrogen atoms and enhances a strong *trans* effect of sulphur atom [10]. Taking into account [^{1}H, ^{195}Pt] HMBC data (Fig. 2), each Pt atom correlates with a unique type of nitrogen atom therefore both *N* atoms coordinated to the same Pt ion must have the same *R* or *S* configuration, the same is observed for sulphur atom. As a consequence sulphur and nitrogen possible combinations of configurations are: *R*,*R*; *R*,*S*; *S*,*R* and *S*,*S*. According to NMR data only two of these combinations are present in solution, so we propose their attribution to *R*,*R* and *S*,*S* configurations on the basis of steric hindrance as shown in Scheme 2. On increasing temperature until 330 K all the peaks show a shift but no ^{195}Pt signals coalescence is observed, anyway epimerization at the chiral sulphur atom cannot be excluded at lower temperature, as previously observed in methionine containing Pt(II) complexes [11]. Although numerous examples exist in literature of possible N inversion in Pt(II) complexes [26], the presence in ^{1}H NMR spectrum of two different signals for aminic proton suggests no reversible configuration on N atom, probably due to the steric hindrance of the bulky nitrogen substituents.

Typically $^3J_{Pt-S-CH}$ is 50 Hz [27] and $^2J_{Pt-NH}$ is 85 Hz [24], anyway a value of 250 Hz was modulated in [^{1}H, ^{195}Pt] HMBC experiments in order to decrease evolution time and not to lose signals because of fast relaxation.

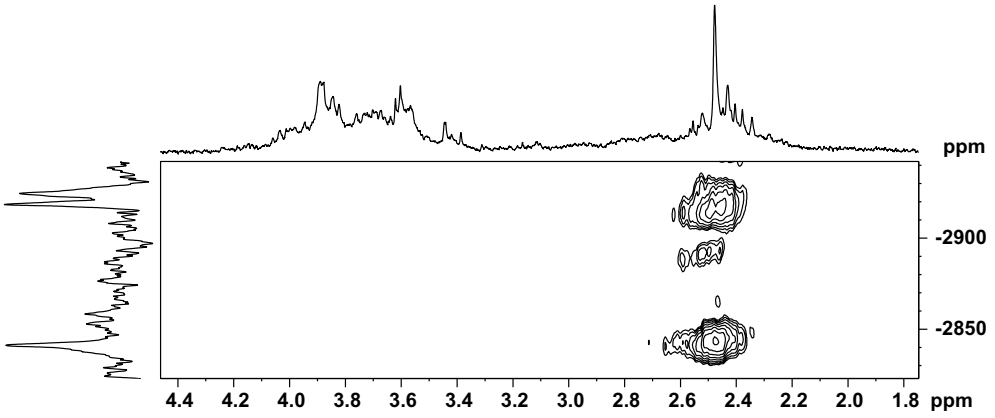
By addition of K_2PtCl_4 to a FruMet solution up to 1:1 M/L molar ratio a broad ^{195}Pt peak around −2790 ppm immediately appears, suggesting the formation of polymeric species. By standing the solution at 50 °C for few hours three quite sharp main peaks appear, at the same time a decrease of the broad signal (−2790 ppm) is registered, hinting the rearrangement of the polymeric species to form more ordinate complexes. Two kinds of 1:1 Pt/FruMet systems can be proposed. In a series of closely related chloride complexes, platinum signal moves to high field in the order P > S > N > Cl^- > O [14]. Thus the signals at upper field (−2918 and −2924 ppm) (Fig. 3) are attributed to the species [Pt(FruMet-*N*,*S*)Cl_2], in which platinum is coordinated by an hexatomic *N*,*S*-chelate ring, as also suggested by Norman et al. for similar platinum–methionine complexes [25]. The chelate complexes show two different signals related to the possible *R* or *S* configurations of the sulphur centre, the chirality of nitrogen atom does not influence platinum spectrum. The same behaviour is observed dissolving the solid [Pt(FruMet-*N*,*S*)Cl_2] in water.

The signal at lower field (−2841 ppm) is ascribed to the species [Pt(FruMet-*S*)Cl_3]$^-$ in which only the sulphur atom is involved in metal coordination, as a consequence no ring closure is observed (Scheme 3). The equilibrium between the two complexes slowly moves towards the formation of the thermodynamic more stable chelate species, which is totally formed in three days.

Scheme 2.

3.2. [GlcCys]

The condensation reaction of β-D-glucose and L-cysteine leads to the formation of the thiazolidine ring, NMR data (Fig. 4a, Table 2) confirm the presence of two configurational isomers as regards C-1. We found some discrepancies with what previously reported in literature, according to which thiazolidine rings are stable and do not open under mild conditions [21]. In our experiments GlcCys is



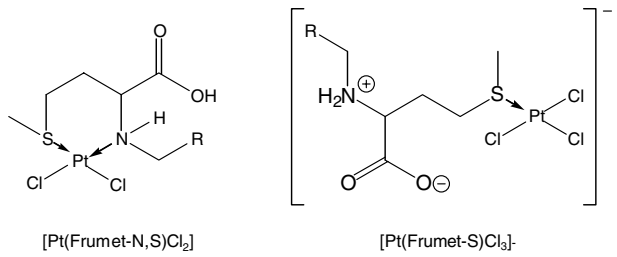


Fig. 3. [^{1}H, ^{195}Pt] HMBC spectrum of a mixture of [Pt(FruMet-*S*)Cl_3]$^-$ and [Pt(FruMet-*N*,*S*)Cl_2] in D_2O at 300 K.

Scheme 3.

very unstable, regardless solvent, pH, temperature and ionic strength. Thiazolidine ring break goes through the equilibria reported in Scheme 4.

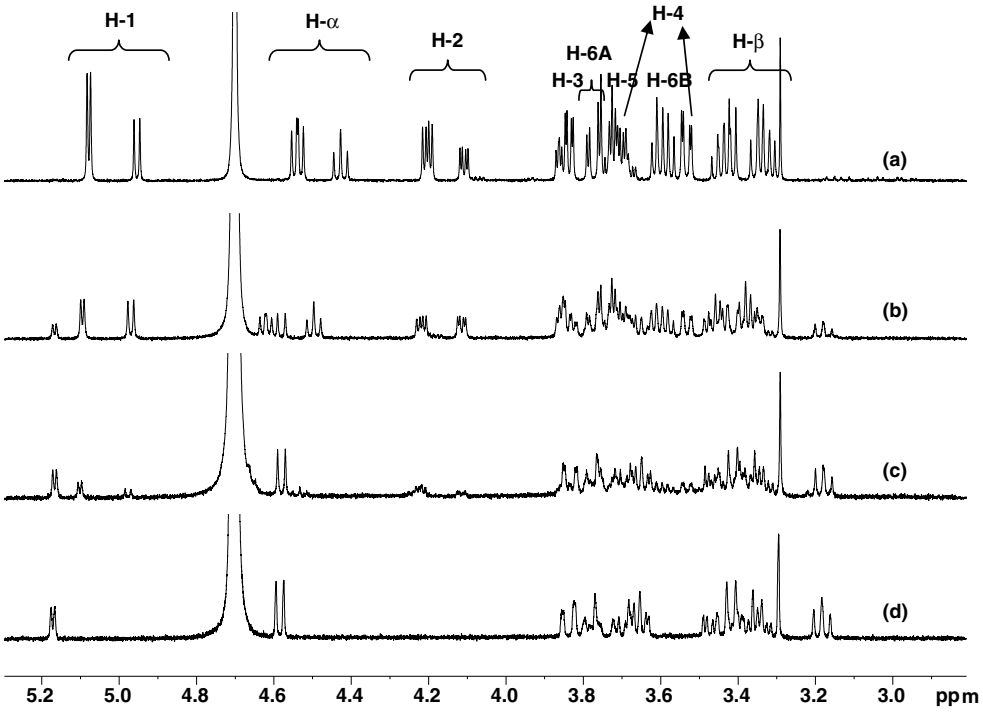
^{1}H NMR spectrum of a freshly prepared D_2O GlcCys solution at 300 K in acid conditions (pH 2.7) shows only one species, the thiazolidinic one (Fig. 4a). After 24 h the presence of free β-D-glucose and L-cysteine tests the breakage of the thiazolidinic ring. This process is made faster as pH is increased (>7.0) or decreased (<1.0), as well as temperature is raised (from 300 K to 330 K). The great stability of [Pt(Cys-*N*,*S*)$_2$] and its low solubility in aqueous media make it suddenly precipitate when K_2PtCl_4 reacts with GlcCys solution with the immediate breaking of thiazolidine ring, so it is not possible to obtain Pt(II)-GlcCys complexes. The formation of [Pt(Cys-*N*,*S*)$_2$] is confirmed by elemental analysis of the separated solid compound (*Anal*. Calc. for $C_6H_{12}N_2PtS_2$: C, 16.55; H, 2.78; N, 6.43; S, 14.73. Found C, 16.53; H, 2.75; N, 6.44; S, 14.75%) and by NMR spectrum that shows an increase in free glucose signals as far as Pt(II) is added (Fig. 4).

3.3. [FruCyscys]

Maillard reaction between β-D-glucose and L-cystine, and the following Amadori rearrangement give rise to only one symmetric species, confirming that both aminic nitrogens are involved in the condensation process. In order to verify the stability of disulfide bridge polarographic measurements (cyclic voltammetry) were made, but the results were not useful since the solvents implied (MeOH, EtOH, and acetonitrile) discharged before Amadori's compound.

FruCyscys IR spectrum shows a weak band at 520 cm^{-1} typical of S–S stretching, furthermore the absence of a strong signal around 2550 cm^{-1} due to S–H stretching supports the hypothesis that disulfide bridge is enough stable in our reaction conditions.

Pt-FruCyscys system behaves very differently from the previously reported Pt/FruMet. The reaction with Pt(II), independently on the M/L ratio (1:1 or 2:1), separates the yellow solid [Pt_2FruCyscysCl_4], where the ligand bridges two Pt(II) ions. The stoichiometry of the complex was suggested on the basis of elemental analysis. The retaining in the IR spectrum of S–S stretching band confirm the stability of the S–S bond also in the complex. The NMR study is made difficult by the extreme line broadening of proton signals. Many measurements, varying spectral range and relaxation delay, were performed in order to improve spectral resolution, some results were obtained for proton while for platinum spectrum all kind of efforts failed and no signal was observed. The presence of disulfide bridge in which



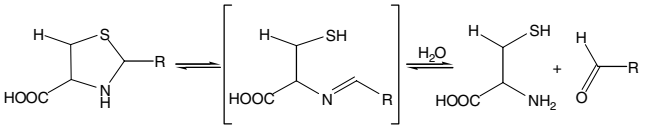


Fig. 4. ^{1}H NMR titration of a GlcCys D_2O solution with increasing addition of K_2PtCl_4 in acid condition (pH 2.7) at 300 K. The free ligand (a) shows the two sets of resonances corresponding to C-1 isomers; as platinum is added (b,c) [Pt(Cys-*N*,*S*)$_2$] separates, and when M/L 1:2 molar ratio is reached (d) only α and β-glucose species are present in solution.

Scheme 4.

the formal oxidation state of sulphur atom (−1) is higher than in FruMet (−2), is responsible for an evident decrease in electronic charge density and an increased polarizability. These factors favour the "soft" Lewis base character of sulphur atom, which is able to strongly interact with Pt(II) ion with the formation of an almost covalent bond.

This strong ligand interaction with two different metal ions is responsible for the very fast relaxation observed in NMR spectra.

In order to better explain this behaviour, the analogous Pt(II)–cystine system was analysed. Neither in this system signals' assignment was possible, because of extreme line broadening due to fast relaxation; anyway, taking into account that even in deficit of metal ion the only separated solid species is [Pt_2cystineCl_4], we can suggest the same stoichiometry for both cystine and FruCyscys. H-α, H-β and H-1 undergo the greatest line-broadening and shifts, therefore we suppose that both cystine and FruCyscys bind Pt(II) with the formation of an *N*,*S* five membered chelate ring and that the sugar moiety is not involved in the complex formation. The extremely fast relaxation in ^{1}H NMR spectra of these dinuclear platinum(II) complexes with respect to the NMR time scale may be due to the spatial proximity of the two metal ions that enhances the positive charge density on the ligand and probably favour dipolar phenomena [28]. In addition, dynamic effects due to fluxional rearrangement of the disulphide bridge may contribute to line broadening, as previously observed in Pt(IV)–disulphide complexes [29].

3.4. Biological study

[Pt(FruMet-*N*,*S*)Cl_2] compound apparently sums different properties of potential anticancer drug. It is uncharged and could penetrate cell membranes mainly through diffusion processes. It is commonly assumed that for cisplatin like compounds the interaction with DNA occurs after chloride ligands are lost through aquation so to yield positively charged monoaqua and diaqua species [30]. Differently from cisplatin, this compound is characterized by only one amine group and, as second carrier ligand, a sulphur atom, which has a stronger *trans* effect than nitrogen and so can better promote chloride lost. Furthermore, steric hindrance of fructose moiety inhibits access to platinum by bulky molecules. To better investigate the biological activity of this complex we have also tested its cytotoxicity.

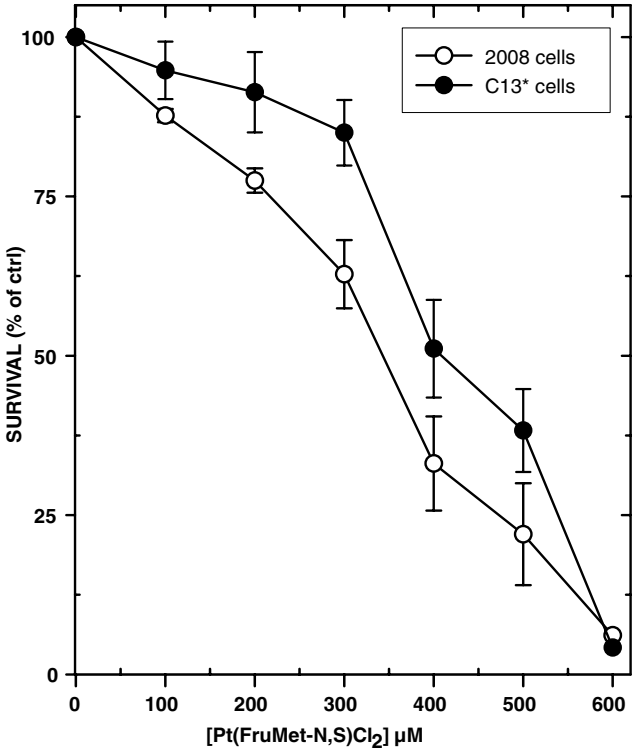

Fig. 5. Survival of colonies of 2008 cells and C13* cells following treatment with [Pt(FruMet-*N*,*S*)Cl_2]. Each point represents mean values ± SE of three separate experiments, each conducted with triplicate plates.

As shown in Fig. 5, the C13* human ovarian carcinoma cisplatin-resistant cells are as sensitive to [Pt(FruMet-*N*,*S*)Cl_2] as their parental 2008 cells. The IC_{50} values are about 340 μM and about 400 μM for 2008 and C13* cells,

respectively. Unfortunately, the cytotoxic activity of [Pt(FruMet-*N*,*S*)Cl_2] is much lower than cisplatin (0.04 μM) [31,32]. The maximal difference in cytotoxicity is achieved at 300 μM, while at higher concentrations the sensitivity of the two cell lines becomes similar.

We have also compared lipophilicity of our complex with that of cisplatin. Lipophilicity is commonly assessed by measuring partition coefficient between two phases, typically *n*-octanol and water [33]. The measured log *P* (−2.04) for [Pt(FruMet-*N*,*S*)Cl_2] is consistent with the presence of a sugar moiety that enhances water solubility and it is close to the value of cisplatin (log *P* −2.35) [34].

This low lipophilicity does not exclude that in vivo metabolic processes may allow good biodisponibility since we cannot reject a possible role of sugar moiety in mediated transport by specific receptors.

the organic one) and the metal ion, scientists aim to tune the physical properties and, thus, realize various applications of coordination polymers in catalysis, electrical conductivity, luminescence, magnetism, non-linear optics, molecular electronics, sensing and zeolitic behaviour [2,4]. Coordination polymers are also significant from a structural chemistry perspective with new, intriguing molecular topologies being discovered, as well as providing numerous examples of interesting phenomena such as the interpenetration of networks [5]. Some structures of minerals, such as diamond [6], quartz [7], rutile [8], perovskite [9], PtS [10], zeolite [11] and feldspar [12] have been artificially produced by "replacing" monoatomic anions (O^{2-}, S^{2-}) with polyatomic organic ligands as linkers and utilizing metal centers (with well-defined coordination geometries) as nodes.

An interesting family of coordination polymers consists of complexes that *simultaneously* contain a bridging, *anionic* organic ligand and a bridging, *anionic* inorganic ligand [2,4]. Their simplest general formula is $MLX_n^{0,a+ora-}$. The pyridine *mono*carboxylate 3-pyridinecarboxylate (nicotinate) and 4-pyridinecarboxylate (isonicotinate) ligands have been shown to act as connecting units in metal coordination networks [2,4,13] with a variety of topologies. In contrast to the obtained large body of knowledge, the isomeric 2-pyridinecarboxylate (picolinate) ligand has been less employed, mainly because of its inherent tendency to form a chelating ring which favours the formation of mononuclear or polynuclear complexes. The most frequently used bridging inorganic ligands are *mono* anionic, e.g. Cl^-, Br^-, CN^-, N_3^-, SCN^- etc. [2,4,13]. In contrast, the use of *di*- or *trianions*, e.g. SO_4^{2-}, PO_4^{3-}, VO_4^{3-}, etc., for the construction of coordination polymer is rather restricted [2,4,13].

With the above information in mind, we set forth in 2005 to systematically use the picolinate(−)/sulfate(−2) ligand "blend" in the construction of coordination polymers of 3d- and 4f-metal ions. The picolinate ion (pic^-) contains two carboxylate oxygen atoms and one pyridyl nitrogen atom as potential donor sites, exhibiting a variety of ligation modes. The up-to-now crystallographically established coordination modes of pic^- and the Harris notation [14] that describes these modes are conveniently presented in Fig. 1. Beyond its terminal behaviour (monodentate, chelating), the pic^- ligand can bridge up to four metal ions. A great number of picolinate metal complexes have been reported in the last two decades, but only few of them have a polymeric structure [15]. On the other hand, the sulfate ion is currently an inorganic ligand of great interest [16,17]. The great coordinative flexibility and versatility of the pic^- ligand, as well as the μ_2, μ_3, μ_4, $\mu_5$or μ_6 potential of SO_4^{2-} (Fig. 2) [16], prompted us to combine the pic^- ligand with the SO_4^{2-} anion for the *first time in coordination chemistry* to aim for new types of coordination

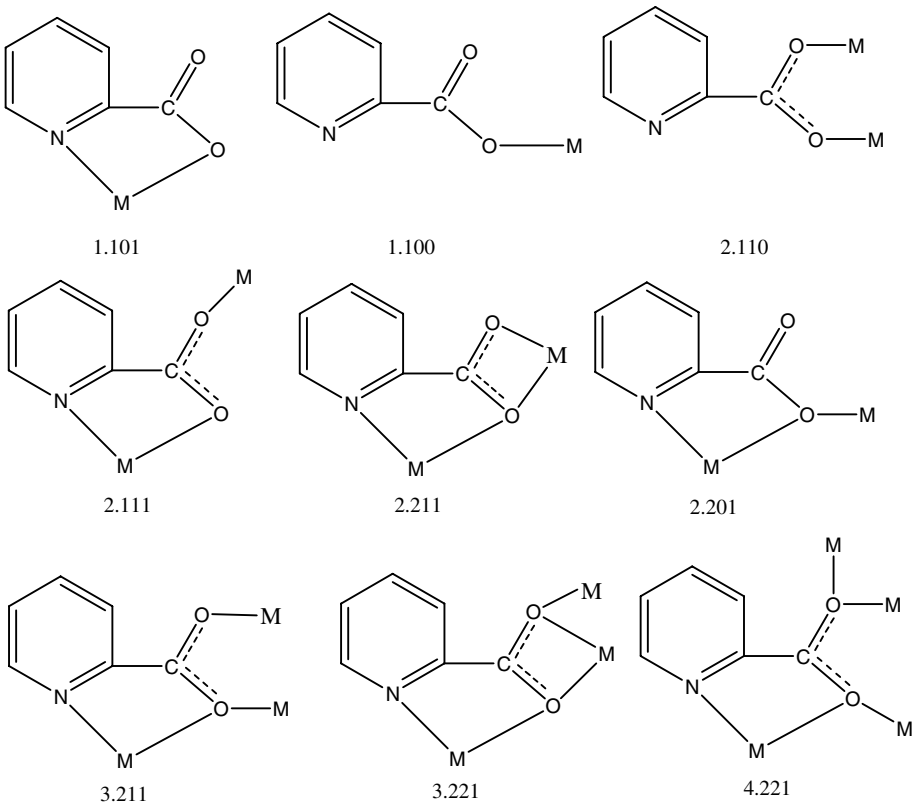

Fig. 1. The up-to-now crystallographically established coordination modes of the picolinate ligand and the Harris notation [14] that describes these modes.

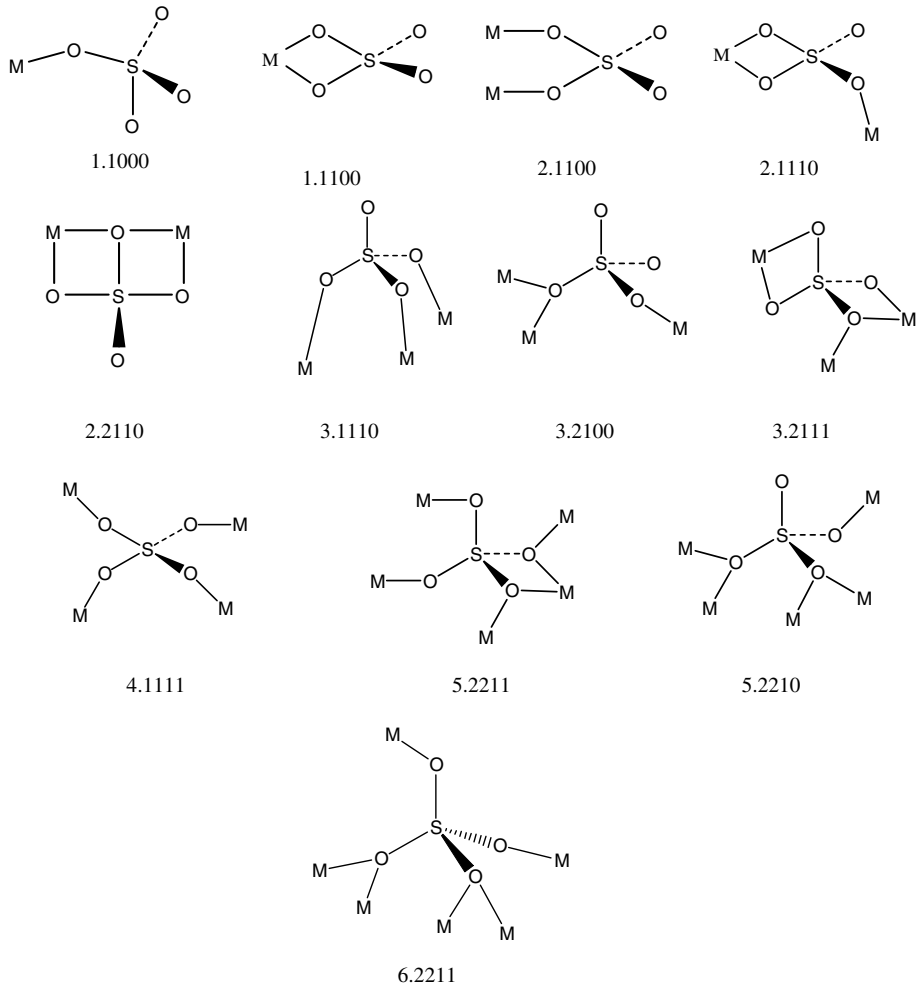

Fig. 2. The hitherto crystallographically established coordination modes of the sulfato ligand and the Harris [14] notation that describes these modes.

polymers. Our belief was that the simultaneous employment of the two ligand systems in transition metal chemistry would give structural flexibility in the pic^-/SO_4^{2-} "blend". The possible advantages of using SO_4^{2-} instead of *mono* anionic inorganic ligands include (i) the possibility of triggering aggregation of preformed smaller species containing only pic^- into new, polymeric products, and (ii) the possible diversion of known reaction systems developed using inorganic *mono*anions to new polymeric species as a result of the higher charge and higher density/bridging capability of SO_4^{2-}.

We illustrate herein how the pic^-/SO_4^{2-} ligand combination leads to two interesting coordination polymers of Zn(II) and Cd(II). The two complexes have the same metal: SO_4^{2-}: pic^- ratio, but different structures. The initial choice of Zn^{II} and Cd^{II} for our study is due to the fact that these d^{10} metal ions are particularly suited for the construction of coordination networks [13,18]. The spherical d^{10} configuration is associated with a flexible coordination environment so that geometries for each metal ion can vary; thus, severe distortions of the ideal polyhedra occur easily. Further, due to their general lability, the formation of coordination bonds is reversible, and this enables Zn^{II} or Cd^{II} and ligands to rearrange during the polymerization process to give highly ordered network structures [13]. Consequently, these metal ions can accommodate all kinds of architectures. The present work can be considered as continuation of our research efforts on 3d- and 4f-metal coordination polymers [19,20].

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer.

IR spectra (4000–400 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT-spectrometer with samples prepared as KBr pellets. Thermogravimetric (TG), differential thermogravimetric (DTG) and differential thermal analysis (DTA) experiments were performed on the SDT-2960

module from TA-instruments under a dinitrogen gas flow; sample weights of 5–15 mg and heating rates of 1 and 5 °C min^{-1} were used. The Raman spectrum of the Cd(II) complex was measured in the micro-Raman backscattering geometry. The spectra were excited with the 441.6 nm line of an air-cooled HeCd laser of Kimmon Electric Co. (Dual, 325/442 nm, UV/blue, 20/80 mW, IK5651R-G model laser). A narrow-bandpass interference filter was used for the elimination of the laser plasma lines. The excitation beam was directed to the sample compartment of a confocal open microscope attachment for punctual analysis. The microscope was used for the delivery of the excitation laser beam on the sample. The focusing objective was a Long Working distance (8 mm) 50×/0.55 Olympus lens. The spectrum was obtained using a ~5 mW laser power on the specimen for a total integration time of 5 s. The Raman scattered radiation was focused on a confocal entrance slit (of 100 μm width) of an achromatic flat field spectrograph of 800 nm focal length. The integrated laser Raman system employed was the UV–Vis Labram HR of the Jobin Yvon-Horiba group. The dispersion and the detection of the Raman photons were done by an 1800-grooves/mm grating on a 2D CCD detector (operating at 140 K), respectively. The spectral slit width was approximately 3 cm^{-1}.

2.2. Compound preparation

2.2.1. $[Zn_2(SO_4)(pic)_2(H_2O)_3]_n$ (1)

A colourless aqueous solution (5 ml) of picH (0.037 g, 0.30 mmol) was added to a solution of $ZnSO_4 \cdot 7H_2O$ (0.086 g, 0.30 mmol) in H_2O (5 ml). The reaction solution was stirred for about 1 h and layered with Me_2CO (20 ml). Slow mixing gave well-formed, X-ray quality colourless prismatic crystals, which were collected by filtration, washed with Me_2CO (24 × 3 ml) and dried in air. Typical yields were in the 50–60% range. IR (KBr pellet): ν = 3336sb, 1624s, 1594s, 1568s, 1478m, 1448m, 1406s, 1374s, 1294m, 1260w, 1144s, 1110s, 1068s, 1022m, 984m, 836m, 794s, 702s, 646s, 612m, 568m, 460m, 455s. *Anal.* Calc. for $C_{12}H_{14}O_{11}N_2SZn_2$ (525.05): C, 27.46; H, 2.69; N, 5.34. Found: C, 28.19; H, 2.60; N, 5.46%.

2.2.2. $[Cd_2(SO_4)(pic)_2(H_2O)_3]_n \cdot nH_2O$ ($2 \cdot nH_2O$)

A colourless aqueous solution (5 ml) of picH (0.049 g, 0.40 mmol) was added to a solution of $3CdSO_4 \cdot 8H_2O$ (0.103 g, 0.13 mmol) in H_2O (5 ml). The reaction solution was stirred for about 1 h and layered with Me_2CO (20 ml). Slow mixing gave well-formed, X-ray quality colourless needles of the product, which were collected by filtration, washed with Me_2CO (2 × 3 ml) and dried in air. Typical yields were in the 55–65% range. IR (KBr pellet): ν = 3374 mb, 1621s, 1590s, 1562m, 1476m, 1445m, 1379s, 1290m, 1237w, 1160sh, 1116s, 1014m, 961w, 850m, 762m, 702m, 617s, 560sh, 455m. *Anal.* Calc. for $C_{12}H_{16}O_{12}N_2SCd_2$ (637.13): C, 22.62; H, 2.54; N, 4.40. Found: C, 23.01; H, 2.28; N, 4.52%.

2.3. Single-crystal X-ray crystallography

Crystals of **1** and $\mathbf{2} \cdot nH_2O$ were mounted in air and covered with epoxy glue. The X-ray data set for **1** was collected with a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic using graphite-monochromated Cu radiation. Diffraction measurements for $\mathbf{2} \cdot nH_2O$ were made on a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo radiation. Complete crystal data and parameters for data collection and processing are listed in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the ranges $22° < 2\theta < 54°$ (for **1**) and $11° < 2\theta < 23°$ (for $\mathbf{2} \cdot nH_2O$). Intensity data were recorded using the θ–2θ scan method. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and Ψ-scan absorption were applied using the Crystal Logic software package.

The structures were solved by direct methods using SHELXS-86 [21] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [22]. For the structure of **1**, all hydrogen atoms were located by difference maps and

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum(|F_o|)$.
[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

refined isotropically. In the case of $\mathbf{2}\cdot n\mathrm{H_2O}$, the hydrogen atoms of the water molecules were located by difference maps and refined isotropically, while the rest were introduced at calculated positions as riding on bonded atoms. For both structures, all non-hydrogen atoms were refined using anisotropic thermal parameters.

3. Results and discussion

3.1. Brief synthetic comments

Reaction of $\mathrm{MSO_4}\cdot x\mathrm{H_2O}$ (M = Zn, $x = 6$; M = Cd, $x = 8/3$) with one equivalent of picH in $\mathrm{H_2O}$ and conventional workup leads to the isolation of the polymeric complexes $[\mathrm{Zn_2(SO_4)(pic)_2(H_2O)_3}]_n$ (**1**) and $[\mathrm{Cd_2(SO_4)(pic)_2(H_2O)_3}]_n\cdot n\mathrm{H_2O}$ ($\mathbf{2}\cdot n\mathrm{H_2O}$) according to the balanced equations (1) and (2), respectively:

$$2n\mathrm{ZnSO_4}\cdot 7\mathrm{H_2O} + 2n\mathrm{picH} \xrightarrow{\mathrm{H_2O}} \underset{\mathbf{1}}{[\mathrm{Zn_2(SO_4)(pic)_2(H_2O)_3}]_n} + n\mathrm{H_2SO_4} + 11n\mathrm{H_2O} \quad (1)$$

$$2n\mathrm{CdSO_4}\cdot 8/3\mathrm{H_2O} + 2n\mathrm{picH} \xrightarrow{\mathrm{H_2O}} \underset{\mathbf{2}\cdot n\mathrm{H_2O}}{[\mathrm{Cd_2(SO_4)(pic)_2(H_2O)_3}]_n\cdot n\mathrm{H_2O}} + n\mathrm{H_2SO_4} + 4n/3\mathrm{H_2O} \quad (2)$$

In both complexes the picolinate ligands are deprotonated as it is expected from the value of pK_a of the carboxylic group (5.25).

Few features of the reactions represented by chemical equations (1) and (2) deserve comments: First, the appearance of $\mathrm{H_2SO_4}$ in the products might imply that complexes **1** and $\mathbf{2}\cdot n\mathrm{H_2O}$ (which contain deprotonated organic ligands) decompose under "acidic" conditions. We did not have such evidence probably due to high dilution. A second point of synthetic interest is the absence of a base from the reaction mixtures that lead to **1** and $\mathbf{2}\cdot n\mathrm{H_2O}$. The employment of base in the $\mathrm{ZnSO_4}\cdot 7\mathrm{H_2O}$/picH reaction system in $\mathrm{H_2O}$ leads to the precipitation of a colourless, microcrystalline solid. Microanalyses indicated the formula $\mathrm{Zn(pic)_2}\cdot 4\mathrm{H_2O}$, while there are no bands in the IR spectrum attributable to sulfate ions/ligands. Thus, this solid appears to be complex *trans*-$[\mathrm{Zn(pic)_2(H_2O)_2}]\cdot 2\mathrm{H_2O}$, which has been structurally characterized in two polymorphic forms [23,24]. Similarly, the 1:2:2 $\mathrm{CdSO_4}\cdot 8/3\mathrm{H_2O}$/picH/$\mathrm{OH^-}$ reaction mixture in $\mathrm{H_2O}$ gives the known complex $[\mathrm{Cd_2(pic)_4}]_n$ [15g]. And third, complexes **1** and $\mathbf{2}\cdot n\mathrm{H_2O}$ seem to be the only products from the general reaction system $\mathrm{M^{II}/SO_4^{2-}}$/picH (M = Zn, Cd) in $\mathrm{H_2O}$. The metal to ligand reaction ratio, the presence of counterions (e.g. $\mathrm{NBu_4^n}$ or $\mathrm{ClO_4^-}$ for the possible isolation of anionic or cationic compounds) and the precipitation/crystallization (the products can also be precipitated by slow evaporation of $\mathrm{H_2O}$ at room temperature over a period of 1–2 weeks) method have no influence on the identity of the products.

From the use of $\mathrm{H_2O}$ viewpoint, the preparation of the two polymeric complexes may be considered as a "green" procedure [25]. The use of environmentally benign solvents (and solventless systems) has been one of the most active areas of green chemistry over the past 10 years [25].

3.2. Description of structures

The structure of **1** is based on 1D helical chains, which interact to each other through hydrogen bonding and stacking interactions. The asymmetric unit of the architecture is presented in Fig. 3, and selected interatomic distances and angles are listed in Table 2.

The asymmetric unit of **1** contains pairs of $\mathrm{Zn^{II}}$ atoms and bridging picolinato ligands, one bridging sulfato ligand and three terminally coordinated water molecules. One of the $\mathrm{Zn^{II}}$ atoms [Zn(1)] is five-coordinate in a distorted trigonal bipyramidal environment, while the other [Zn(2)] is in an octahedral coordination environment. Both metal ions are bonded to the $\mathrm{NC_2O}$ chelating part of different

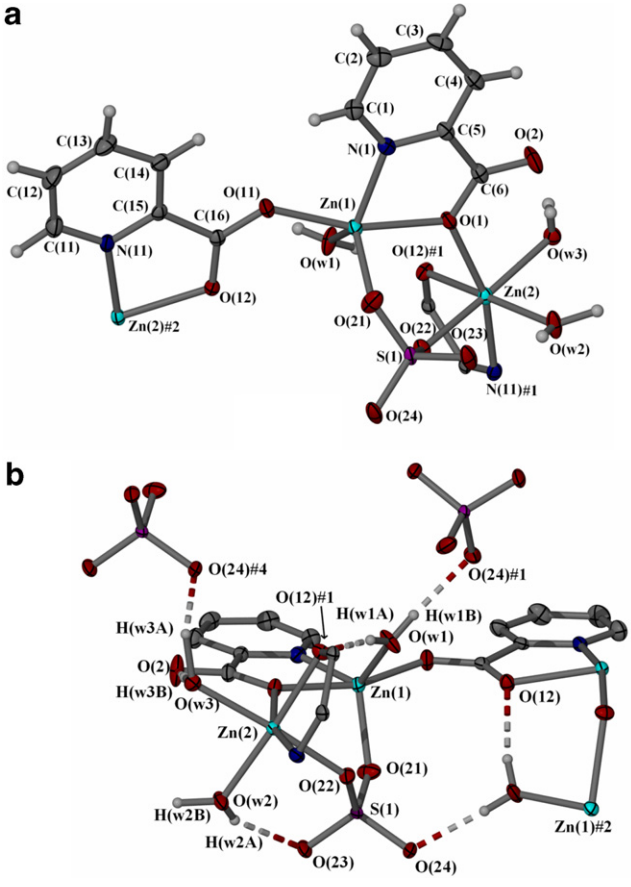

Fig. 3. (a) A thermal ellipsoid (40%) plot of the asymmetric unit of **1**, extended to show the coordination spheres of the metal ions and the coordination modes of the ligands. Symmetry operations to generate equivalent atoms: #1 $-x+3/2$, $y-1/2$, $-z-1/2$; #2 $-x+3/2$, $y+1/2$, $-z-1/2$. (b) The intra-helix H-bonds present in the 1D polymer **1**. Symmetry operations to generate equivalent atoms: #1 $-x+3/2$, $y-1/2$, $-z-1/2$; #2 $-x+3/2$, $y+1/2$, $-z-1/2$; #4 x, $y-1$, z.

ligands and to an oxygen atom belonging to an adjacent bridging picolinate [Zn(1)–O(11), 2.048(2); Zn(2)–O(1), 2.138(2) Å]. The coordination polyhedra are completed by one and two aqua ligands for Zn(1) and Zn(2), respectively. The two Zn^{II} atoms of the asymmetric unit are bridged by the 2.1100 [14] sulfato ligand and one of the picolinates which utilizes only one of the carboxylate oxygen atoms [O(1)] for the bridge; thus, this pic^- ion behaves as a 2.201 ligand (Fig. 1) [14]. The C(6)–O(2) bond distance [1.237(4) Å] involving the "free" picolinate oxygen atom is shorter than the C(6)–O(1) bond length [1.286(4) Å] involving the bridging picolinate oxygen atom, as expected. The second picolinato ligand is 2.111 [14] and bridges two asymmetric units through its syn, anti carboxylate group leading to the formation of an infinite helical chain. The planes defined by the different organic ligands in the asymmetric unit are almost parallel [the angle between them is 7.61(8)°], and responsible for the formation of the helix is the angle between the planes of the 2.111 pic^- ligand with a symmetry related $(-x+3/2,\ y+1/2,\ -z-1/2)$ 2.201 pic^- ligand. The helices run along the b axis with a pitch of 8.51 Å. The one-dimensional structure is stabilized by an extended array of H-bonds (five per asymmetric unit) (see Table 2 and Fig. 3b).

The ranges of the Zn(1)–(O,N) and Zn(2)–(O,N) bond lengths are typical for five- [19c,19d,26] and six-coordinate [23,24,26a,26b,27] zinc(II) complexes, respectively. The Zn(1)–O(11), Zn(1)–O(21), Zn–O(w1) and Zn(1)–N(1) distances are shorter than the corresponding Zn(2)–O(12) $[-x+3/2,\ y-1/2,\ -z-1/2]$, Zn(2)–O(22), Zn(2)–O(w2,w3) and Zn(2)-N(11) $[-x+3/2,\ y-1/2,\ -z-1/2]$ distances, respectively. The decreased bond lengths for Zn(1) may be a consequence of the lower coordination number of this metal ion compared to that for Zn(2) (five versus six). However, an analogous trend does not hold true for the Zn(1,2)–O(1) bond distances involving the bridging oxygen of the 2.201 pic^- ligand; the Zn(1)–O(1) bond distance [2.169(2) Å] is longer than the Zn(2)–O(1) bond distance [2.138(2) Å].

As depicted in Fig. 4, homochiral right-handed *P*-chains interact through two, symmetry related, H-bonds per asymmetric unit giving rise to the formation of a 2D layer parallel to the *bc* plane. The water molecule w2 acts as a donor to a symmetry related sulfate [O(w2)–H(w2B)···O(23)$(-x+3/2, y-1/2, -z+1/2)$] connecting two different helices. The same interaction occurs from the other site of the helix with the sulfate's O(23) being the acceptor. A stacking interaction between the aromatic rings of one pic^- ligand proceeds parallel to the [1 0 1] direction of the unit cell, alternately connecting *P*- and *M*-helical chains, resulting in the supramolecular structure shown in Fig. 5. The characteristics of the stacking interaction are: centroid distance = 3.57 Å, least square planes distance = 3.48 Å, offset = 0.82 Å. The architecture is racemic due to the existence of equal amount of *P*- and *M*-helices.

Taking into account the above mentioned interactions and considering the asymmetric unit as a node (i.e. the centroid of the two metal ions) a 3D 5-connected network is formed as shown in Fig. 6. The topological type is sqp and the total Schlafli symbol is $[4^4.6^6]$. To our knowledge this topological type is rather scarce in MOFs' chemistry [28].

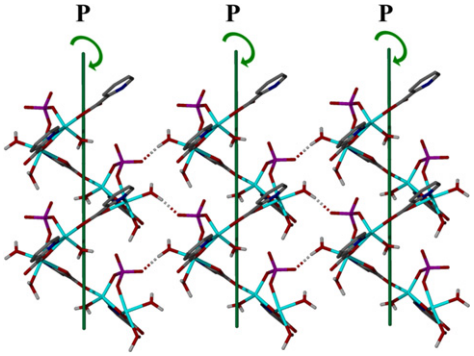

Fig. 4. A view of the inter-helix H-bonding interaction of the 1D *P*-helical chains in the *bc* plane of complex **1**. Organic protons and intra-helix H-bonds have been omitted for clarity. The rods represent the helical axes.

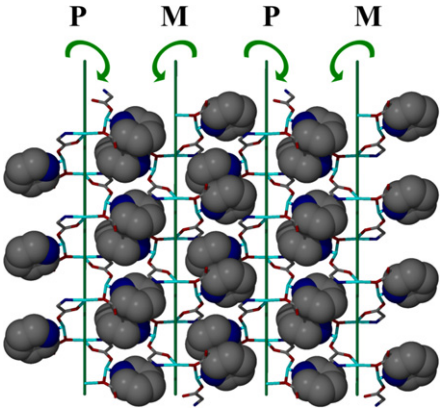

Fig. 5. A view of the alternate arrangement of the *P*- and *M*- helices, showing the stacking interactions that lead to the 3D supramolecular architecture in **1**. The water molecules, the non-stacked aromatic rings and the aromatic protons have been omitted for clarity. The rods represent the helical axes.

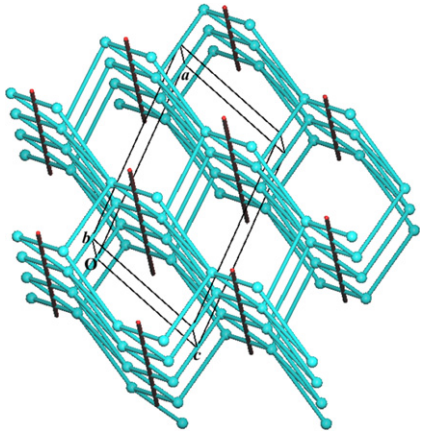

Fig. 6. The 5-connected sqp network formed in **1**, when intra-chain H-bonds and stacking interactions are taken into account. Spheres represent the centroids of the two metal ions in the asymmetric unit. The rods are the helical axes.

The structure of $\mathbf{2}\cdot n\mathrm{H_2O}$ is based on a 2D 4-connected network. The asymmetric unit of the polymer is presented in Fig. 7, and selected interatomic distances and angles are listed in Table 3.

The asymmetric unit consists of two Cd^{II} atoms, two picolinato ligands, one bridging sulfate anion, three coordinated (two terminal and one bridging) and one lattice water molecules. The coordination geometry of Cd(1) can be better described as distorted pentagonal bipyramidal. The equatorial plane is occupied by one oxygen and one nitrogen atom belonging to one 2.201 picolinato ligand [Cd(1)–O(1), 2.338(8); Cd(1)–N(1), 2.343(9) Å], two oxygen atoms belonging to the chelating/bridging carboxylate of the 2.211 pic^- [Cd(1)–O(11)#1, 2.497(8); Cd(1)–O(12)#1, 2.378(9) Å; #1: $-x+1$, $y-1/2$, $-z+1/2$] and one bridging H_2O molecule [Cd(1)–O(w1), 2.490(9) Å], while the axial positions are held by two terminal H_2O molecules

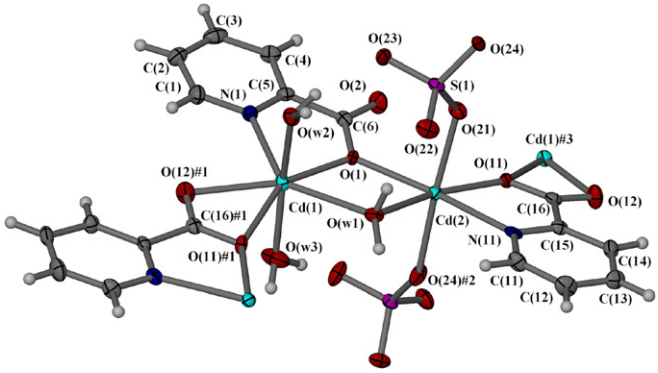

Fig. 7. A thermal ellipsoid (40%) plot of the asymmetric unit of $\mathbf{2}\cdot n\mathrm{H_2O}$, extended to show the coordination spheres of the metal ions and the coordination modes of the ligands. The lattice water molecule has been omitted for clarity. Symmetry operations to generate equivalent atoms: #1 $-x+1$, $y-1/2$, $-z+1/2$; #2 x, $-y+1/2$, $z-1/2$; #3, $-x+1$, $y+1/2$, $-z+1/2$.

Symmetry operations used to generate equivalent atoms: #1 $-x+1$, $y-1/2$, $-z+1/2$; #2 x, $-y+1/2$, $z-1/2$; #4 $-x+1$, $-y$, $-z+1$; #5 $-x+1$, $-y$, $-z$.

[Cd(1)–O(w2), 2.282(8); Cd(1)–O(w3), 2.198(10) Å]. Cd(2) is sited in the centre of a rather distorted octahedron, bonded to the bridging aquo ligand [Cd(2)–O(w1), 2.517(9) Å], to one oxygen atom belonging to the 2.201 picolinato ligand [Cd(2)–O(1), 2.189(8) Å], and to the 2.211 picolinato residue through N(11) and O(11) [Cd(2)–N(11), 2.324(10); Cd(2)–O(11), 2.240(8) Å] in the equatorial plane, while the axial positions are occupied by two oxygen atoms belonging to two symmetry related (#2: x, $-y+1/2$, $z-1/2$) bridging sulfates [Cd(2)–O(21), 2.289(8); Cd(2)–O(24)#2, 2.239(8) Å].

Each picolinate anion bridges two metal ions through the carboxylate moiety; one forms a monoatomic bridge, O(1), and behaves as a 2.201 ligand [14], while the other uses its carboxylate group as chelating/bridging acting as a 2.211 [14] ligand.

The ranges of the Cd(1)–(O,N) and Cd(2)–(O,N) bond lengths are typical for seven- [20e,29] and six-coordinate [11,18b,30] cadmium(II) complexes, respectively. The Cd(1)–O bond distance for the bridging H_2O molecule [Cd(1)–O(w1), 2.490(9) Å] is longer than the Cd(1)–O distances exhibited by the terminal H_2O ligands [2.282(8) and 2.198(10) Å]. The Cd(1)–O(carboxylate) distances are longer than the Cd(2)–O(carboxylate) distances, probably due to the higher coordination number of the former metal ion (seven versus six). The Cd(1)–O(11) [$-x+1$, $y-1/2$, $-z+1/2$] bond distance for the bridging carboxylate oxygen atom is longer than the distance exhibited by the terminal oxygen atom, O(12) [$-x+1$, $y-1/2$, $-z+1/2$], to the same Cd^{II} atom [2.497(8) versus 2.378(9) Å]. The increase in bond length upon bridging relative to terminal ligation has been observed previously [31] in many complexes containing carboxylate ligands with one bridging oxygen atom. Based on theoretical and experimental studies which have indicated that the *syn* lone pairs of the carboxylate groups are more basic than the *anti* lone pairs [32], one might expect that the Cd(1)–O(11) [$-x+1$, $y-1/2$, $-z+1/2$] distance to be shorter or approximately equal (to compensate for the change in coordination number) to the Cd–O(11) distance; however, the reverse relation holds for $\mathbf{2}\cdot n\mathrm{H_2O}$ (see Table 3). This result, which is in accordance with results obtained for many cadmium(II) carboxylate complexes [31], suggests that the Cd–O bond distances involving $\eta^1{:}\eta^2{:}\mu_2$ (2.21) RCO_2^- groups are mainly influenced by geometrical factors rather than the electronic properties of the carboxylate group.

From the first point of view the topological description of the 2D polymer looks relatively difficult. This is due to the two different Cd^{II} atoms; only one of them [Cd(2)] can be considered as a node, while the other [Cd(1)] is part of a linker formulated as $\{Cd(pic)_2(\mu\text{-}H_2O)(H_2O)_2\}$. Eventually these moieties form a ribbon (Fig. 8) that propagates parallel to b axis, and this is additionally stabilized by an intra-chain hydrogen bond between the bridged H_2O ligand and the non-coordinated carboxylate oxygen O(2). The ribbons are crosslinked by the bridging sulfato ligands which are bound only to Cd(2) [Cd(2)–O(21), 2.289(8); Cd(2)–O(24)#2, 2.238(8) Å; #2 : x, $-y+1/2$, $z-1/2$]. This way undulating 2D thick layers (the approximate width is 14 Å) representing a 4-connected net with Schläfli symbol [$4^4.6^2$] are formed (see Fig. 9).

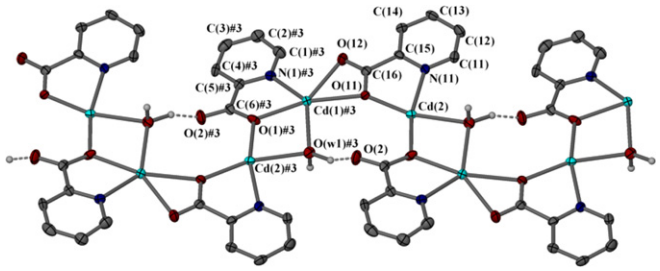

Fig. 8. The cadmium(II) ribbon formed in $\mathbf{2}\cdot n\mathrm{H_2O}$ viewed down to c. The organic protons, the terminal water molecules and the sulfato ligands have been omitted for clarity. Symmetry operation to generate equivalent atoms: #3 $-x+1$, $y+1/2$, $-z+1/2$.

There are extensive H-bonding interactions within the layer which assist the stabilization of the net (Table 3). All the water molecules and the sulfate anions are involved in those interactions leading to the formation of infinite H-bonded chains, proliferating parallel to b, between the Cd^{II} ribbons (see Fig. 10).

Besides the coordination bonds and the H-bonds within the layers, which propagate parallel to the bc plane, stacking interactions play their role for the stabilization of the 3D supramolecular architecture present in the crystal of

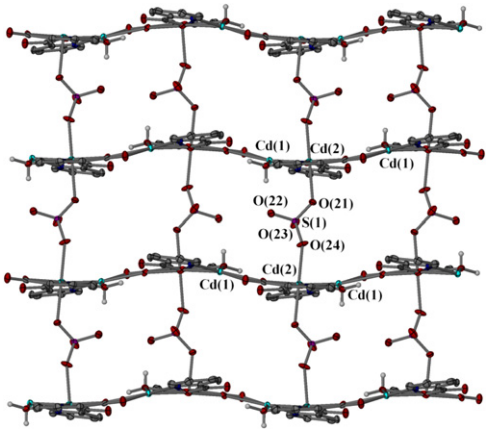

Fig. 9. A part of the grid-like 2D network formed in $\mathbf{2}\cdot n\mathrm{H_2O}$ viewed on the bc plane. Organic hydrogen atoms, terminal and lattice water molecules are omitted for clarity.

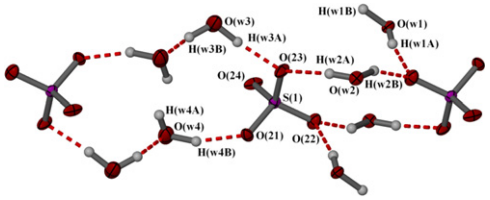

Fig. 10. A part of the water–sulfate chain formed in $\mathbf{2}\cdot n\mathrm{H_2O}$ showing the hydrogen bonding motif present.

2 · nH$_2$O. The 2D layers are arranged parallel in a way that the pyridine rings of one layer are situated in the void spaces between the pyridine rings of an adjacent layer. The pyridine moieties of different layers are involved in π–π stacking. Though the least square planes are not strictly parallel (the corresponding dihedral angles are 7.42 and 9.23°), the average distance of the defining atoms is ca. 3.4 Å, indicating strong interactions [2,33] (see Fig. 11).

Complexes **1** and **2** · nH$_2$O join a small group of structurally characterized, non-organometallic zinc(II) [15o,23,24,34] and cadmium(II) [15c,15f,15g,15o,35] picolinate complexes, some of which are polymeric [15c,15f,15g,15o]. These complexes are also new members of the still growing family of metal picolinate coordination polymers which are gathered in Table 4 (this table lists complexes in which at least one pic$^-$ ligand is bridging). Inspection of Table 4 reveals that (i) **1** and **2** · nH$_2$O are the first metal coordination polymers which have the pic$^-$/SO$_4^{2-}$ ligand combination, (ii) compound **1** is the second, structurally characterized zinc(II) picolinato coordination polymer, and (iii) the 2.201 and 2.211 coordination modes for the pic$^-$ ligand are observed simultaneously for the first time in **2** · nH$_2$O. Complexes **1** and **2** · nH$_2$O are new additions to the family of zinc(II) and cadmium(II) sulfato complexes [16–18b,26b,29a,29b,36].

3.3. Vibrational spectra

The IR spectrum of freshly prepared crystals of complex **2** · nH$_2$O is shown in Fig. 12. The prepared complexes exhibit a medium to strong intensity IR band at ~3350 cm^{-1}, assignable to ν(OH) vibrations of the coordinated (in both complexes) and lattice H$_2$O (in **2** · nH$_2$O). The broadness and relatively low frequency of this band are both indicative of hydrogen bonding.

The IR spectrum of the free, i.e. ionic, sulfate (the ion belongs to the T_d point group) consists of two bands at ~1105 and ~615 cm^{-1}, assigned to the $\nu_3(F_2)$ stretching [ν_d(SO)] and $\nu_4(F_2)$ bending [δ_d(OSO)] modes, respectively [16,17f,37]. The coordination of SO$_4^{2-}$ to metal ions decreases the symmetry of the group and the ν_3 and ν_4 modes are split [16,37]. Furthermore, the Raman-active $\nu_1(A_1)$ stretching [ν_d(SO)] and ν_2(E) bending [δ_d(OSO)] modes of the free SO$_4^{2-}$ become IR-active upon coordination, i.e. once the symmetry is lowered [37]. In the case the

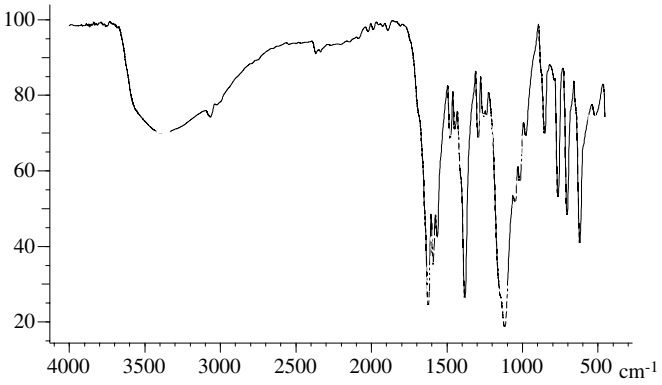

Fig. 12. The IR (KBr pellet) spectrum of the crystalline complex **2** · nH$_2$O.

SO_4^{2-}-site symmetry is lowered from T_d to C_{3v} (monodentate coordination), both ν_1 and ν_2 appear in the IR spectrum with weak to medium intensity, while ν_3 and ν_4 each splits into two bands in both IR and Raman spectra [37]. In the case the SO_4^{2-}-site symmetry is lowered from T_d to C_{2v} (bidentate chelating or bridging coordination), again both ν_1 and ν_2 appear in the IR spectrum (ν_2 splits into two Raman modes), while ν_3 and ν_4 each splits into three IR-active and Raman-active vibrations [37].

Both complexes have C_{2v} symmetry at the sulfato ligand, and the IR bands at ~1020, ~1115 and ~1150 cm^{-1} are therefore attributable [37] to the ν_3 modes. The bands/shoulders at ~565, ~615 and ~700 cm^{-1} are assigned [37] to the ν_4 modes, with the higher wavenumber band being superimposed by a ligand vibration. The band at 970 cm^{-1} and the shoulder at ~455 cm^{-1} are assigned to the ν_1 and ν_2 modes, respectively [17f,37]. The Raman sulfato lines (Fig. 13) of $\mathbf{2}\cdot n\mathrm{H_2O}$ appear at 1178 (ν_3), 1069 (ν_3), 1027 (ν_3), 994 (ν_1), 695 (ν_4), 635 (ν_4), 627(ν_4), 477 (ν_2) and 452 (ν_2) cm^{-1}. Thus, the number and wavenumbers of the IR and Raman bands are both in agreement [37] with the crystallographically established coordination mode of the sulfato ligand in $\mathbf{2}\cdot n\mathrm{H_2O}$.

Several bands (six in $\mathbf{2}\cdot n\mathrm{H_2O}$, seven in **1**) appear in the 1625–1370 cm^{-1} region. Contributions from picolinate $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ modes would be expected in this region, but overlap with the stretching vibrations of the aromatic ring and δ(HOH) renders assignments difficult [15p]. The bands at ~1620, ~1590 and ~1450, ~1380 are assigned to $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$, respectively [15c,34b]. The appearance of two bands for each vibrational modes may be due to the presence of two different types of carboxylate groups in **1** and $\mathbf{2}\cdot n\mathrm{H_2O}$ [20e]. The difference Δ [$\Delta = \nu_{as}(CO_2) - \nu_{as}(CO_2)$] for any $\nu_{as}(CO_2)/\nu_s(CO_2)$ pair is less than the Δ value of Napic (263 cm^{-1}) [34b], as expected for the bridging modes of carboxylation ligation for the pic^- ligands in the two complexes [38]. In the Raman spectrum of the cadmium(II) complexes, two $\nu_s(CO_2)$ lines appear at wavenumbers higher than 1400 cm^{-1}, while the $\nu_{as}(CO_2)$ vibrations appear weak (as expected [39]) and are masked under the aromatic stretch at 1610 cm^{-1}. The Raman lines at 180–240 cm^{-1} are assigned to ν(Cd–N) vibrations [15c].

3.4. Thermal decomposition studies of complex $2\cdot n\mathrm{H_2O}$

The thermal decomposition of complex $\mathbf{2}\cdot n\mathrm{H_2O}$ was studied using thermogravimetric (TG), differential thermogravimetric (DTG) and differential thermal analysis (DTA) techniques under nitrogen. TG and DTG data are shown in Fig. 14.

Complex $\mathbf{2}\cdot n\mathrm{H_2O}$ decomposes via an anhydrous stable intermediate. Between room temperature and ~140 °C an initial, endothermic mass loss of 8.8% is observed that corresponds satisfactorily to the release of the lattice H_2O molecules and two aqua ligands (Calc. 8.9%). Between 150 °C and 210 °C there is a second endothermic mass loss of 3.0% that corresponds to the release of the stronger bonded third coordinated H_2O molecule (Calc. 2.8%). A clear plateau is reached at about 215 °C up to ~310 °C, suggesting that the anhydrous species with the empirical formula "$Cd_2(SO_4)(pic)_2$" is thermally stable. The formation of this intermediate is summarized by Eq. (3). The IR spectrum of the completely anhydrous product (obtained after a TG experiment up to 220 °C by keeping the heating rate at 1 °C min^{-1}) is different in the sulfate and carboxylate bands' regions compared to that of the original complex $\mathbf{2}\cdot n\mathrm{H_2O}$. This may indicate formation of an anhydrous coordination polymer through bridging sulfato and picolinato ligands with higher (than in $\mathbf{2}\cdot n\mathrm{H_2O}$) density levels. Unfortunately, attempts for the preparation (and subsequent crystallization) of compound "$Cd_2(SO_4)(pic)_2$" from solution have been unsuccessful.

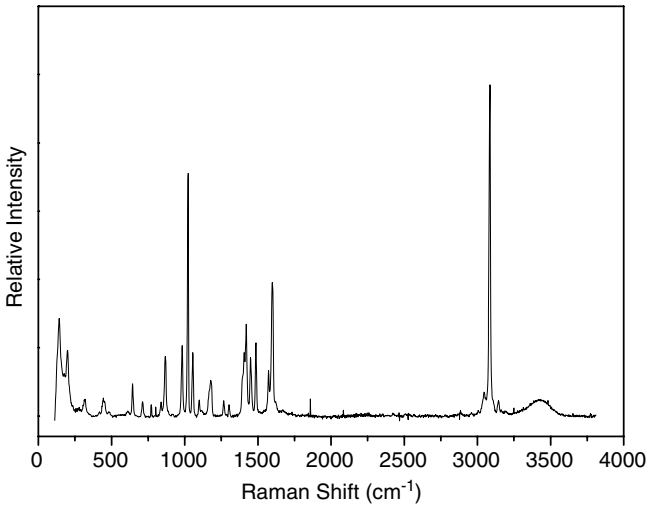

Fig. 13. The Raman spectrum of the crystalline complex $\mathbf{2}\cdot n\mathrm{H_2O}$.

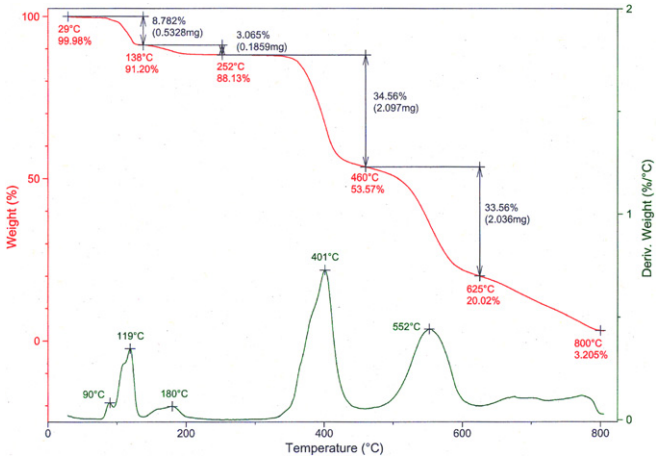

Fig. 14. Thermogravimetric (up) and differential thermogravimetric (down) data for complex $\mathbf{2}\cdot n\mathrm{H_2O}$.

$$\underset{\mathbf{2}\cdot n\mathrm{H_2O}}{[\mathrm{Cd_2(SO_4)(pic)_2(H_2O)_3}]_n\cdot n\mathrm{H_2O}} \xrightarrow[30\text{–}215\ ^\circ\mathrm{C,2\ steps}]{\mathrm{N_2}} n[\mathrm{Cd_2(SO_4)(pic)_2}] + 4n\mathrm{H_2O} \quad (3)$$

The anhydrous intermediate decomposes above 310 °C with a complicated degradation mechanism, as revealed by the appearance of five DTG maxima and without the formation of new thermally stable intermediates. The very low residue at 800 °C (~3%) clearly indicates that sublimation has occurred.

4. Concluding comments and perspectives

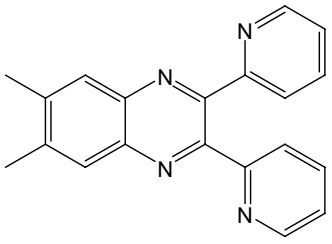
The initial use of the pic^-/SO_4^{2-} "ligand blend" in Zn(II) and Cd(II) chemistry has provided access to two new neutral coordination polymers with interesting structures and topologies, namely $[Zn_2(SO_4)(pic)_2(H_2O)_3]_n$ (**1**) and $[Cd_2(SO_4)(pic)_2(H_2O)_3]_n\cdot nH_2O$ ($\mathbf{2}\cdot nH_2O$). In both complexes, the organic ligand is coordinated to the metal centres in two different ligation modes (2.111 and 2.201 in **1**; 2.211 and 2.201 in $\mathbf{2}\cdot nH_2O$), while the sulfate ion acts as a bidentate bridging ligand. **1** and $\mathbf{2}\cdot nH_2O$ join a rather small family of structurally characterized picolinato coordination polymers and they are the first complexes of any metal in which picolinato and sulfato ligands coexist.

Complexes of other 3d-metal ions with the pic^-/SO_4^{2-} ligand combination are not known to date, and it is currently not evident whether the structure of such compounds is dependent on the particular nature of the metal ion. We are studying this matter. Synthetic efforts are also in progress to "activate" higher bridging capabilities, e.g. μ_3 or μ_4, of the pic^- and SO_4^{2-} ligands as a means to get access to 3D coordination polymers.

Acknowledgements

S.P.P. and C.P. thank the European Social Fund (ESF), the Operational Program for Educational and Vocational Training II (EPEAEK II) and particularly the Program PYTHAGORAS (Grant b. 365.037) for funding the above work. We are also grateful to Dr. G.A. Voyatzis (Applied Molecular Spectroscopy group of FORTH/ICE-HT, Patras, Greece) for recording the Raman spectrum of the cadmium(II) coordination polymer.

Appendix A. Supplementary material



CCDC 642386 and 642387 contain the supplementary crystallographic data for (**1**) and ($\mathbf{2}\cdot nH_2O$) in CIF format. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.05.022.

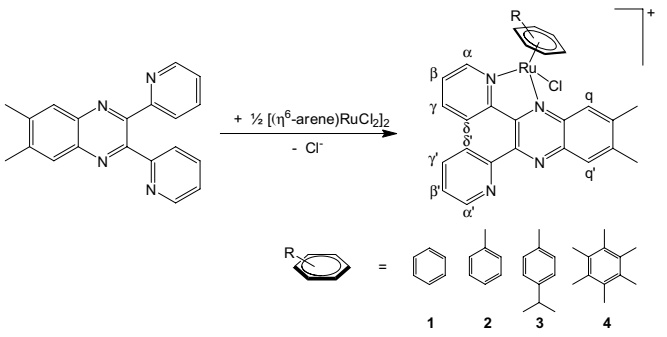
various dinuclear arene ruthenium and osmium complexes containing 2,2′-bipyrimidine as bridging chelate ligand have shown that the two chloro ligands can be found in both *cis* and *trans* orientations [6]. Therefore, in order to determine if the increase in the catalytic activity is correlated to the *cis–trans* conformations, we prepared a series of exclusively *trans* oriented dinuclear arene ruthenium complexes with the sterically hindered chelate ligand, 6,7-dimethyl-2,3-di(pyridine-2-yl)quinoxaline ($dpqMe_2$). The catalytic activity of the dinuclear complexes and of their corresponding mononuclear congeners for the transfer hydrogenation of aromatic ketones to give the corresponding secondary alcohol with sodium formate as the hydrogen donor in aqueous solution is reported. We also present the single-crystal X-ray structure analysis of some representatives.



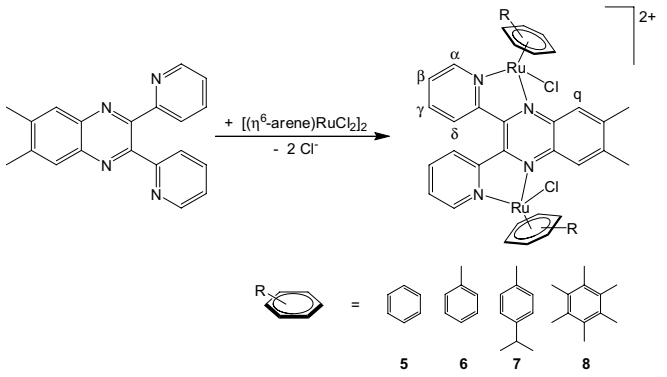
$dpqMe_2$

2. Results and discussion

2.1. Synthesis of the mononuclear complexes 1–4 as hexafluorophosphate salts

The arene ruthenium complexes $[(\eta^6\text{-arene})Ru(\mu\text{-}Cl)Cl]_2$ (arene = C_6H_6, C_6H_5Me, $p\text{-}Pr^iC_6H_4Me$, C_6Me_6) react with 2 equiv. of 6,7-dimethyl-2,3-di(pyridine-2-yl)quinoxaline ($dpqMe_2$) in methanol at 50 °C in the presence of KPF_6 to form the cationic arene ruthenium complexes $[(\eta^6\text{-}C_6H_6)RuCl(dpqMe_2)]^+$ (**1**), $[(\eta^6\text{-}C_6H_5Me)RuCl(dpqMe_2)]^+$ (**2**), $[(\eta^6\text{-}p\text{-}Pr^iC_6H_4Me)RuCl(dpqMe_2)]^+$ (**3**) and $[(\eta^6\text{-}C_6Me_6)RuCl(dpqMe_2)]^+$ (**4**), which are isolated as their hexafluorophosphate salts (Scheme 1). The hexafluorophosphate salts of complexes **1**–**4** are red-purple, non-hygroscopic, air-stable, crystalline solids. They are sparingly soluble in methanol and chloroform, but well soluble in dichloromethane, acetone and acetonitrile. All compounds have been characterised on the basis of elemental analysis, ^1H NMR, IR, UV–Vis and mass spectroscopy.

Scheme 1. Synthesis of cations **1**–**4**.



In the mass spectra they give rise to the corresponding $[M]^+$ molecular peaks m/z at 527, 541, 583 and 611, respectively. The ^1H NMR spectra of **1**–**4** exhibit, other than the signals corresponding to the aromatic ligand, a characteristic set of 12 independent signals for the diastereotopic protons of the $dpqMe_2$ ligand. The ruthenium atom is stereogenic due to the coordination of four different ligator atoms. Upon coordination to the ruthenium atom, the aromatic protons of the $dpqMe_2$ ligand are shifted downfield, especially the H_α of the coordinated pyridyl group which is observed at $\delta \sim 9.4$ ppm, while the $H_{\alpha'}$ of the non-coordinated pyridyl group is observed at only 8.65 ppm. Accordingly, the aromatic protons of the quinoxaline moiety are observed at $\delta \sim 8.6$ (H_q) and 8.1 ($H_{q'}$), respectively. The ^1H NMR spectrum of **3** exhibits two doublets for the diastereotopic methyl protons of the isopropyl group. Likewise, the diastereotopic CH protons of the *p*-cymene ligand give rise to four doublets observed between $\delta = 5.7$–6.1 ppm. A septet at $\delta = 2.51$ ppm is observed for the CH proton of the isopropyl group. Similarly, the aromatic protons of the toluene ligand in **2** give rise to five multiplets observed between $\delta = 5.7$–6.2 ppm and a singlet at $\delta = 2.36$ ppm for the methyl group.

The UV–Vis data of complexes **1**–**4** have been recorded in acetonitrile. The electronic spectra display a medium intensity band in the visible region at ~385 nm and an intense band at ~280 nm. The low intensity band at ~385 nm is assigned to the metal-to-ligand charge transfer transition (MLCT), while the high-energy band at ~280 nm is assigned to intra-ligand π–π^* transitions [7].

2.2. Synthesis of the dinuclear complexes 5–8 as hexafluorophosphate salts

The reaction of the dimeric chloro complexes $[(\eta^6\text{-arene})Ru(\mu\text{-}Cl)Cl]_2$ (arene = C_6H_6, C_6H_5Me, $p\text{-}Pr^iC_6H_4Me$, C_6Me_6) with 1 equiv. of 6,7-dimethyl-2,3-di(pyridine-2-yl)quinoxaline ($dpqMe_2$) in refluxing methanol in the presence of KPF_6 results in the formation of the red-purple coloured, air-stable dinuclear complex dications $[\{(\eta^6\text{-}C_6H_6)RuCl\}_2(\mu\text{-}dpqMe_2)]^{2+}$ (**5**), $[\{(\eta^6\text{-}C_6H_5Me)RuCl\}_2(\mu\text{-}dpqMe_2)]^{2+}$ (**6**), $[\{(\eta^6\text{-}p\text{-}Pr^iC_6H_4Me)RuCl\}_2(\mu\text{-}dpqMe_2)]^{2+}$ (**7**) and $[\{(\eta^6\text{-}C_6Me_6)RuCl\}_2(\mu\text{-}dpqMe_2)]^{2+}$ (**8**), which can be isolated as their hexafluorophosphate salts (Scheme 2).

Complexes **5**–**8** have been characterised by mass, UV–Vis, ^1H NMR spectroscopy and elemental analysis. In the mass spectra the hexafluorophosphate salts give rise to two main peaks; a minor peak with an approximately 50% intensity attributed to $[M^{2+}+PF_6^-]^+$ at m/z 887, 915, 999 and 1055, respectively, and a major peak which corresponds after decomplexation of an $[(arene)RuCl]^+$

Scheme 2. Synthesis of the dications **5**–**8**.

fragment to the mononuclear cations **1**–**4** at $m/z = 527$, 541, 583 and 611, respectively. The UV–Vis data of complexes **5**–**8** in acetonitrile show that the position of the MLCT transitions of the dinuclear complexes **5**–**8** is significantly red shifted (~490 nm) as compared to their mononuclear congeners.

The ^{1}H NMR spectra of **5**–**8** exhibit, other than the signals corresponding to the aromatic ligand, a characteristic set of six signals for the protons of the dpqMe$_2$ ligand. Despite the fact that the two ruthenium atoms are stereogenic and therefore should generate a mixture of *rac* and *meso* diastereoisomers, only the *rac* isomer is observed. The sterically hindered dpqMe$_2$ ligand forces the chloro ligands to adopt exclusively a *trans* orientation, thus giving rise to only the (*R*,*R*) and (*S*,*S*) enantiomers and consequently six signals for the dpqMe$_2$ bridging ligand. As observed in **1**–**4**, the aromatic protons of the dpqMe$_2$ ligand are shifted downfield, especially the H$_\alpha$ of the pyridyl groups which are observed at $\delta \sim 9.4$ ppm, while the aromatic protons of the quinoxaline moiety are observed at $\delta \sim 8.7$ ppm.

2.3. Crystal structure analysis of [(η^6-C$_6$H$_6$)RuCl(dpqMe$_2$)][PF$_6$] ([**1**][PF$_6$]), [(η^6-*p*-Pr^{i}C$_6$H$_4$Me)RuCl(dpqMe$_2$)][PF$_6$] ([**3**][PF$_6$]) and [(η^6-C$_6$H$_5$Me)RuCl(μ-dpqMe$_2$)][PF$_6$]$_2$ ([**6**][PF$_6$]$_2$)

The molecular structures of [(η^6-C$_6$H$_6$)RuCl(dpqMe$_2$)]$^+$ (**1**) and [(η^6-*p*-Pr^{i}C$_6$H$_4$Me)RuCl(dpqMe$_2$)]$^+$ (**3**) have been established by single-crystal X-ray structure analysis of their hexafluorophosphate salts. Both complexes show a typical piano-stool geometry with the metal centres coordinated by the arene ligand, a terminal chloride and the chelating dpqMe$_2$ ligand. The molecular structures of [**1**][PF$_6$] and [**3**][PF$_6$] are presented in Figs. 1 and 2, respectively, while selected geometrical parameters are presented in Table 1.

In the mononuclear complexes **1** and **3**, the metal centre is stereogenic. However, since none of the ligand contains a chiral information, **1** and **3** are obtained as racemic mixtures and crystallised in the centrosymmetric space group *C*2/*c* and *P*2$_1$/*n*, respectively.

The Ru–N bond distances ranging from 2.057(3) to 2.118(2) Å in **1** and **3** are comparable to those in [(η^6-*p*-Pr^{i}C$_6$H$_4$Me)RuCl(2,3-bis(2-pyridyl)pyrazine)][BF$_4$] [8] and [(η^6-*p*-Pr^{i}C$_6$H$_4$Me)RuCl(2,3-bis(α-pyridyl)quinoxaline)][PF$_6$] [9a]. Accordingly, there is no significant difference in the Ru–Cl bond length in **1** or **3** [2.389(1) and 2.3878(9) Å] and reported values [9–11]. The N(1)–Ru(1)–N(2) bond angle in complexes **1** [76.04(15)°] and **3** [76.33(10)°] are similar to those of complexes [(η^6-*p*-Pr^{i}C$_6$H$_4$Me)RuCl(2,3-bis(2-pyridyl)pyrazine)]$^+$ [N(1)–Ru(1)–N(2) = 76.5(2)°] [8] and [(η^6-*p*-Pr^{i}C$_6$H$_4$Me)RuCl(2,3-bis(α-pyridyl)quinoxaline)]$^+$ [N(1)–Ru(1)–N(2) = 76.2(2)°] [9a].

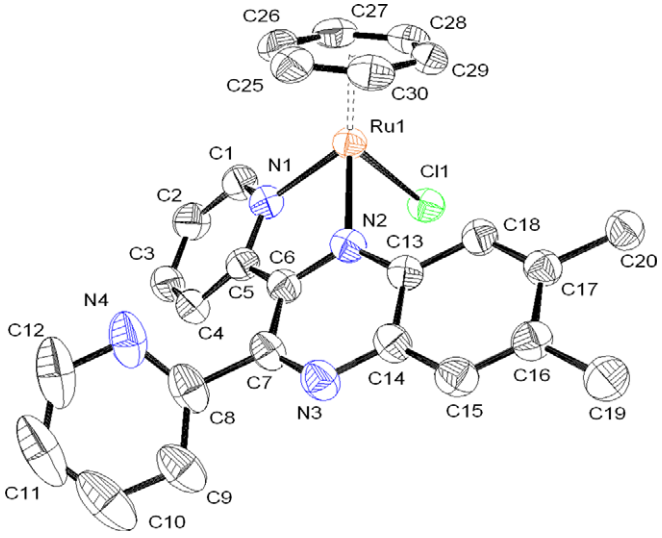


Fig. 1. Molecular structure of **1** at 50% probability level with hydrogen atoms, acetonitrile molecules and hexafluorophosphate anion being omitted for clarity.

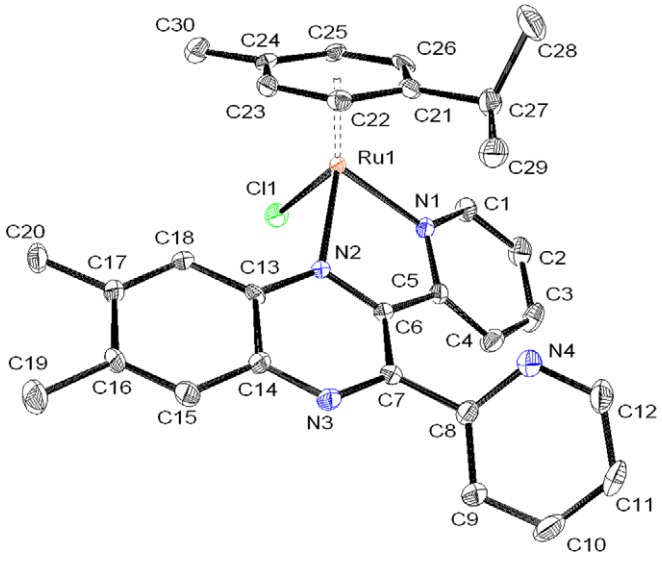

Fig. 2. Molecular structure of **3** at 50% probability level with hydrogen atoms, acetonitrile molecule and hexafluorophosphate anion being omitted for clarity.

Table 1
Selected bond lengths (Å) and angles (°) for [**1**][PF_6], [**3**][PF_6] and [**6**][PF_6]$_2$

N3–C7–C8–N4	131.8(5)	−131.2(3)	12.5(10)	
C5–C6–C7–C8	−23.1(8)	18.3(4)	32.9(12)	

In the crystal packing of [**1**][PF_6] · $2CH_3CN$, two molecules of **1** form a dimer through π-stacking interactions, see Fig. 3. The centroid–centroid separations are 3.73 and 4.32 Å. The distance observed between the π–π interacting systems is in accordance with the theoretical value calculated for this stacking mode [10].

Cation **6** crystallises in the space group P-1 with both enantiomers *R*,*R*-**6** and *S*,*S*-**6** being present in the crystal. As mentioned earlier, the sterically hindered $dpqMe_2$ ligand forces the chloro atoms to adopt a *trans* orientation, thus generating only the *rac* isomers. An ORTEP drawing with the atom labelling scheme for **6** is shown in Fig. 4 and the selected geometrical parameters are presented in Table 1. As expected, cation **6** contains two metal centres bonded to η^6-C_6H_5Me and chloro ligands and bridged by a $dpqMe_2$ ligand through its nitrogen atoms. The distance between the ruthenium atoms is 6.96 Å, which is in accordance with the metal–metal distances observed in the homo-bimetallic complex [(η^6-*p*-$Pr^iC_6H_4Me$)$_2$$Ru_2Cl_2$-(μ-2,3-di(pyridine-2-yl)pyrazine)][PF_6]$_2$ (Ru–Ru distance = 6.84 Å) [9b] and in the hetero-bimetallic $dpqMe_2$ complex [(bipy)$_2$Ru(μ-$dpqMe_2$)Cu(PPh_3)$_2$][BF_4]$_3$ (bipy = 2,2′-bipyridine) (Ru–Cu distance = 6.82 Å) [11].

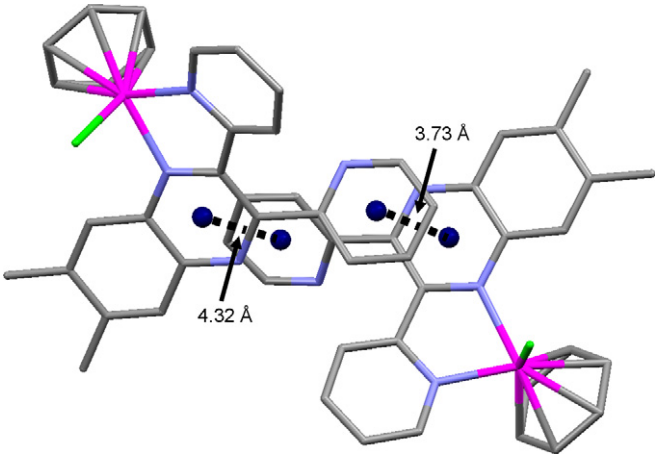

Fig. 3. Dimeric structure of **1** showing the intermolecular π-stacking interactions.

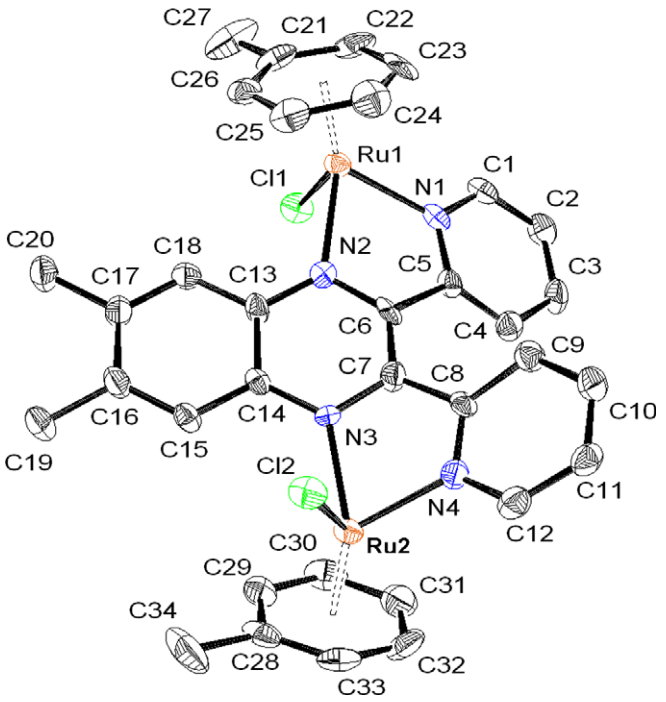

Fig. 4. Molecular structure of **6** at 50% probability level with hydrogen atoms, acetonitrile molecules and hexafluorophosphate anions being omitted for clarity.

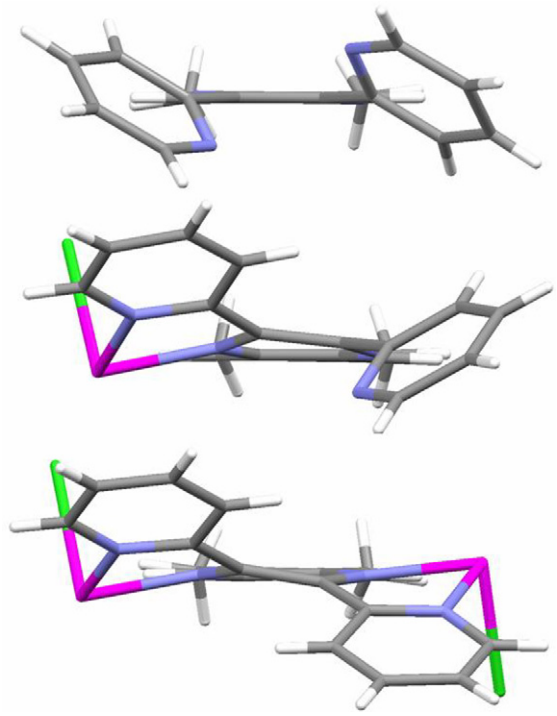
Upon formation of mono or dinuclear complexes, the bond lengths between the connecting carbon atoms between the pyridyl and the quinoxaline moieties of the $dpqMe_2$ ligand are slightly reduced. Indeed, as compared to the free 6,7-dimethyl-2,3-di(pyridine-2-yl)quinoxaline in which the C–C distances (C5–C6 and C7–C8) are both at 1.493 Å [12], the corresponding C–C distances in the mononuclear complexes **1** and **3** are 1.472(6) and 1.466(4) Å, respectively, while in the dinuclear complex **6** the distances are 1.473(10) and 1.482(9) Å. These bond length changes are in agreement with a back-donation from the metallic fragments to the $dpqMe_2$ system, thus increasing the inter-ring bond order [6,13].

The major distortion imposed on the $dpqMe_2$ structure upon coordination is encountered by the pyridyl groups, see Fig. 5. In the free ligand the two pyridyl groups are twisted by 39.6° relative to the plane of the quinoxaline moiety. However, in **1** and **3** the twist of the coordinated pyridyl unit is 26.0(2) and 28.1(1)°, respectively, while the non-coordinated pyridyl unit remains at 41.7(1) and 41.1(1)°, respectively. Finally, the twist imposed on the pyridyl rings is raised to a maximum at 28.8(3) and 29.4(3)° in **6**.



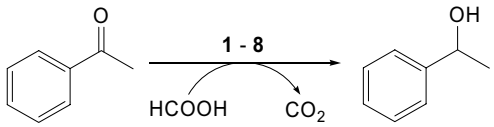


Fig. 5. Axial views of the free $dpqMe_2$ ligand (top), the mononuclear cation **3** (middle) and the dinuclear dication **6** (bottom). The quinoxaline moiety points away and the arene ligands are omitted for clarity.

2.4. Catalytic evaluation of *1–8* for the transfer hydrogenation of acetophenone in aqueous solution

Based on the pioneering study of Ogo et al. on the use of 2,2′-bipyridine complexes $[(\eta^6\text{-}C_6Me_6)Ru(bipy)(OH_2)]^+$ [14] and $[(\eta^5\text{-}C_5Me_5)Ir(bipy)(OH_2)]^+$ [15] and on our previously reported results on arene ruthenium phenanthroline (phen) complexes $[(\eta^6\text{-arene})Ru(phen)(OH_2)]^+$ (arene = C_6H_6, *p*-Pr^{i}C$_6$H$_4$Me, C_6Me_6)[16], the catalytic potential of the 6,7-dimethyl-2,3-di(pyridine-2-yl)quinoxaline complexes **1**–**8** was evaluated for the transfer hydrogenation of acetophenone in water using formic acid as hydrogen source (Table 2).

All complexes were found to poorly catalyse the transfer hydrogenation of acetophenone to give phenylethanol in aqueous solution at pH 4, which corresponds to the pK_a of the formic acid (3.77). In the best cases (complexes **6** and **7**, entries 6 and 7) the conversion of acetophenone does not exceed 6% within 16 h. This means that, in comparison to the corresponding 2,2′-bipyrimidine complexes [5], the introduction of a sterically hindered ligand system which forces the dinuclear complexes to adopt a *trans* configuration causes a pronounced drop in the catalytic activity.

Table 2
Catalytic transfer hydrogenation of acetophenone using the mononuclear $[(\eta^6\text{-arene})RuCl(dpqMe_2)]^+$ (**1**–**4**) and dinuclear complexes $[\{(\eta^6\text{-arene})RuCl\}_2(\mu\text{-}dpqMe_2)]^{2+}$ (**5**–**8**) as catalysts and formate as hydrogen donor in water[a]

Entry	Catalyst	$(\eta^6$-arene)Ru	Conversion % (h)[b]	TOF (h^{-1})[c]

8	**8**	$\{(C_6Me_6)Ru\}_2$	1 (15)	0.1

[a] Conditions: Reactions carried out at 50 °C, at pH = 4, in 5 mL of water, acetophenone (0.64 mmol), the ratio catalyst/substrate/formate being 1:100:500.
[b] Determined by gas chromatography.
[c] TOF: turnover frequencies are expressed in mol of product/(mol of Ru · h).

3. Experimental

3.1. General

6,7-Dimethyl-2,3-di(pyridine-2-yl)quinoxaline ($dpqMe_2$) and KPF_6 were purchased from Aldrich and used as received. $[Ru(\eta^6\text{-arene})(\mu\text{-}Cl)Cl]_2$ (arene = C_6H_6, C_6H_5Me, *p*-Pr^{i}C$_6$H$_4$Me, C_6Me_6) were prepared according to published methods [17]. The NMR spectra were recorded on a Varian Gemini 200 MHz spectrometer using the residual protonated solvent as internal standard. Infrared spectra were recorded as KBr pellets on a Perkin–Elmer FTIR 1720-X spectrometer. UV–Vis absorption spectra were recorded on an Uvikon 930 spectrophotometer. Microanalyses were performed by the Laboratory of Pharmaceutical Chemistry, University of Geneva (Switzerland). Electrospray mass spectra were obtained in positive-ion mode with an LCQ Finnigan mass spectrometer.

3.2. Preparation of the mononuclear complexes *1–4*

3.2.1. $[(\eta^6\text{-}C_6H_6)RuCl(dpqMe_2)][PF_6]$ ($[\mathbf{1}][PF_6]$)

In a typical experiment, $[(\eta^6\text{-}C_6H_6)Ru(\mu\text{-}Cl)Cl]_2$ (100 mg, 0.20 mmol) is dissolved in methanol (50 mL). The resulting solution is added dropwise to a two-necked flask equipped with a reflux condenser and containing a methanol solution (50 mL) of $dpqMe_2$ (125 mg, 0.40 mmol) and KPF_6 (73.6 mg, 0.40 mmol). The mixture is heated to 50 °C and stirred for 24 h. After cooling to room temperature, the volume is reduced and the product is precipitated by addition of diethylether. The yellow-orange solid is filtered, washed with *n*-pentane and dried under vacuum to give $[(\eta^6\text{-}C_6H_6)RuCl(dpqMe_2)][PF_6]$ (80 mg, 0.12 mmol, yield 30%). ^{1}H NMR (400 MHz, CD_3CN): δ (ppm) =

9.40 (d, 1H, $^3J = 7.8$ Hz, H_{pyr}), 8.65 (d, 1H, $^3J = 7.5$ Hz, H_{pyr}), 8.63 (s, 1H, H_{qnox}), 8.11 (m, 2H, H_{pyr}), 8.08 (s, 1H, H_{qnox}), 7.77 (dd, 1H, H_{pyr}), 7.62 (m, 2H, H_{pyr}), 7.06 (d, 1H, $^3J = 7.1$ Hz, H_{pyr}), 6.13 (s, 6H, H_{ar}), 2.74 (s, 3H, Me_{qnox}), 2.65 (s, 3H, Me_{qnox}); IR (KBr, cm^{-1}): 840 s ν(P–F); 558 m. UV–Vis (1.19×10^{-5} M, CH_3CN): λ_{max} 386 nm ($\varepsilon = 2.07 \times 10^4$ M^{-1} cm^{-1}), 274 nm ($\varepsilon = 3.78 \times 10^4$ M^{-1} cm^{-1}). ESI-MS (*m/z*): 527 [M^+]; *Anal.* Calc. for $C_{26}H_{22}N_4ClF_6PRu$: C, 46.47; H, 3.30; N, 8.34. Found: C, 46.12; H, 3.69; N, 7.77%.

3.2.2. [(η^6-C_6H_5Me)RuCl(dpqMe$_2$)][PF_6] ([**2**][PF_6])

The compound is prepared by the same procedure as described above for [**1**][PF_6] using [(η^6-C_6H_5Me)Ru(μ-Cl)Cl]$_2$ (100 mg, 0.19 mmol), dpqMe$_2$ (118.2 mg, 0.38 mmol) and KPF_6 (69.7 mg, 0.38 mmol) and affording [(η^6-C_6H_5Me)RuCl(dpqMe$_2$)][PF_6] (140 mg, 0.20 mmol, yield 54%). ^{1}H NMR (400 MHz, CD_3CN): δ (ppm) = 9.32 (d, 1H, $^3J = 7.1$ Hz, H_{pyr}), 8.66 (d, 1H, $^3J = 7.4$ Hz, H_{pyr}), 8.55 (s, 1H, H_{qnox}), 8.13 (m, 2H, H_{pyr}), 8.08 (s, 1H, H_{qnox}), 7.77 (dd, 1H, $^3J = 8.3$ Hz, H_{pyr}), 7.61 (m, 2H, H_{pyr}), 7.07 (d, 1H, $^3J = 9.5$ Hz, H_{pyr}), 6.16 (dd, 1H, H_{ar}), 5.99 (dd, 1H, $^3J = 5.9$ Hz, H_{ar}), 5.92 (d, 1H, $^3J = 6.1$ Hz, H_{ar}), 5.74 (d, 1 H, H_{ar}), 5.68 (dd, 1H, $^3J = 5.8$ Hz, H_{ar}), 2.73 (s, 3H, Me_{qnox}), 2.65 (s, 3H, Me_{qnox}), 2.36 (s, 3H, Me_{ar}); IR (KBr, cm^{-1}): 840s ν(P–F); 558 m. UV–Vis (1.16×10^{-5} M, CH_3CN): λ_{max} 385 nm ($\varepsilon = 4.46 \times 10^4$ M^{-1} cm^{-1}), 278 nm ($\varepsilon = 8.82 \times 10^4$ M^{-1} cm^{-1}). ESI-MS (*m/z*): 541 [M^+]; *Anal.* Calc. for $C_{27}H_{24}N_4ClF_6PRu$: C, 47.27; H, 3.53; N, 8.17. Found: C, 47.00; H, 3.70; N, 8.19%.

3.2.3. [(η^6-*p*-Pr^iC_6H_4Me)RuCl(dpqMe$_2$)][PF_6] ([**3**][PF_6])

The compound is prepared by the same procedure as described above for [**1**][PF_6] using [(η^6-*p*-Pr^iC_6H_4-Me)Ru(μ-Cl)Cl]$_2$ (100 mg, 0.16 mmol), dpqMe$_2$ (102.0 mg, 0.32 mmol) and KPF_6 (60.1 mg, 0.32 mmol) and affording [(η^6-*p*-Pr^iC_6H_4Me)RuCl(dpqMe$_2$)][PF_6] (150 mg, 0.20 mmol, yield 63%). ^{1}H NMR (400 MHz, CD_3CN): δ (ppm) = 9.37 (d, 1H, $^3J = 7.1$ Hz, H_{pyr}), 8.69 (d, 1 H, $^3J = 6.5$ Hz, H_{pyr}), 8.52 (s, 1H, H_{qnox}), 8.09 (m, 2H, H_{pyr}), 8.06 (s, 1H, H_{qnox}), 7.70 (m, 2H, H_{pyr}), 7.60 (dd, 1H, H_{pyr}), 7.00 (d, 1H, H_{pyr}), 6.09 (d, 1H, $^3J = 6.9$ Hz, H_{ar}), 5.85 (m, 2H, H_{ar}), 5.72 (d, 1H, $^3J = 6.6$ Hz, H_{ar}), 2.73 (s, 3H, Me_{qnox}), 2.64 (s, 3H, Me_{qnox}), 2.51 (sept, 1H, $^3J = 6.9$ Hz, C$H_{ar}$$Me_2$), 2.36 (s, 3H, Me_{ar}), 1.11 (d, 3H, CH$_{ar}$$Me_2$), 1.04 (d, 3H, CH$_{ar}$$Me_2$); IR (KBr, cm^{-1}): 840 s ν(P–F); 557 m. UV–Vis (5.50×10^{-6} M, CH_3CN): λ_{max} 436 nm ($\varepsilon = 19\,695.82$ M^{-1} cm^{-1}), 387 nm ($\varepsilon = 8.53 \times 10^4$ M^{-1} cm^{-1}), 278 nm ($\varepsilon = 17.55 \times 10^4$ M^{-1} cm^{-1}). 3.3. Preparation of the dinuclear complexes **5**–**8**

3.3.1. [{(η^6-C_6H_6)RuCl}$_2$(μ-dpqMe$_2$)][PF_6]$_2$ ([**5**][PF_6]$_2$)

In a typical experiment, [(η^6-C_6H_6)Ru(μ-Cl)Cl]$_2$ (150 mg, 0.30 mmol), dpqMe$_2$ (93.6 mg, 0.30 mmol) and KPF_6 (110.0 mg, 0.60 mmol) are dissolved in methanol (30 mL). The resulting solution is heated to 60 °C and stirred for 4 h. After cooling to room temperature, the volume is reduced and the product is precipitated by addition of diethylether. The red solid is filtered, washed with *n*-pentane and dried under vacuum to give [{(η^6-C_6H_6)-RuCl}$_2$(μ- dpqMe$_2$)][PF_6]$_2$ (150 mg, 0.14 mmol, yield 48%). ^{1}H NMR (400 MHz, CD_3CN): δ (ppm) = 9.43 (d, 2H, $^3J = 6.4$ Hz, H_{pyr}), 8.69 (s, 2H, H_{qnox}), 8.56 (d, 2H, $^3J = 8.2$ Hz, H_{pyr}), 8.08 (dd, 2H, $^3J = 7.8$ Hz, H_{pyr}), 7.81 (dd, 2H, $^3J = 6.9$ Hz, H_{pyr}), 6.15 (s, 12H, H_{ar}), 2.80 (s, 6H, Me_{qnox}); IR (KBr, cm^{-1}): 840 s ν(P–F); 559 m. UV–Vis (6.20×10^{-5} M, CH_3CN): λ_{max} 486 nm ($\varepsilon = 0.53 \times 10^4$ M^{-1} cm^{-1}), 330 nm ($\varepsilon = 2.25 \times 10^4$ M^{-1} cm^{-1}). 3.4. Single-crystal X-ray structure analyses

Crystals of complexes [**1**][PF$_6$]·2CH$_3$CN, [**3**][PF$_6$]·CH$_3$CN and [**6**][PF$_6$]$_2$·2CH$_3$CN were mounted on a Stoe Image Plate Diffraction system equipped with a φ circle goniometer, using Mo Kα graphite monochromated radiation (λ = 0.71073 Å) with φ range 0–200°. The structures were solved by direct methods using the program SHELXS-97 [18]. Refinement and all further calculations were carried out using SHELXL-97 [18]. The H-atoms were included in calculated positions and treated as riding atoms using the SHELXL default parameters. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares on F^2. Crystallographic details are summarised in Table 3. Figs. 1, 2 and 4 were drawn with ORTEP [19] and Figs. 3 and 5 with the software MERCURY [20].

[a] Structures were refined on F_o^2: $wR_2 = [\sum[w(F_o^2 - F_c^2)^2]/\sum w(F_o^2)^2]^{1/2}$, where $w^{-1} = [\sum(F_o^2) + (aP)^2 + bP]$ and $P = [\max(F_o^2, 0) + 2F_c^2]/3$.

3.5. Transfer hydrogenation catalysis

The transfer hydrogenation reactions of acetophenone (0.64 mmol) using **1**–**8** as their hexafluorophosphate salts (6.4 μmol) with formate (3.2 mmol) are carried out in water (5 mL) using a buffer of HCOOH/HCOONa at pH 4 under inert atmosphere. The reaction is quenched by cooling the mixture to 0 °C. The products are extracted by Et_2O and identified (and turnover determined) by gas chromatography. The pH is monitored using a pH meter (Mettler Toledo InLab® 413).

the level of ROS produced during normal cellular metabolism and the amount of endogenous antioxidants (such as ROS scavengers and enzymes) present in the cells which protect tissues from oxidative damage. If this balance is disrupted a condition referred to as oxidative stress develops which is implicated in numerous pathophysiological processes such as rheumatoid arthritis, aging, inflammation and carcinogenesis [1]. Recently, it has been found that ROS such as the superoxide radical ($O_2^{\cdot-}$) or hydrogen peroxide (H_2O_2) are important regulators of cell death [2]. Particularly, H_2O_2 is implicated as a mediator of apoptosis in cells [3]. The cellular damage caused by H_2O_2 is likely produced in part through $OH^{\cdot}$ radical production formed when H_2O_2 reacts with Fe^{2+} or Cu^{2+} [4]. Enzymatic antioxidants regulate superoxide concentration by dismutation of $O_2^{\cdot-}$ to hydrogen peroxide (SOD activity) which is then converted to water (peroxidase activity) or dismutated to water and dioxygen (catalase activity).

Many tumour cells have increased rates of metabolism compared with normal cells, which would typically lead to increased numbers of ROS [5]. Manganese SOD (MnSOD) is found in the matrix of mitochondria and has been shown to be depleted in most cancers when compared to normal tissue [6]. The activity of cytoplasmic SOD (CuZnSOD) has also been shown to vary in cancer cells [6]. This suggests that a large amount of intracellular $O_2^{\cdot-}$ is found in such cancerous cells and that in the absence of significant SOD activity this $O_2^{\cdot-}$ can further metabolise to peroxynitrite ($OONO^-$) and the perhydroxyl radical ($HO_2^{\cdot}$) which play a role in the tumour formation [7]. It has been demonstrated that returning MnSOD and CuZnSOD enzyme activity to levels close to those found in non-malignant cells has resulted in conversion of the excess $O_2^{\cdot-}$ to H_2O_2 which leads to decreased tumour cell growth in a number of model systems [8–10].

The use of SOD enzymes as pharmaceutical agents is limited by cost and because of instability and low membrane permeability resulting from their high molecular weight. Low molecular weight copper SOD mimetic complexes can dismutate excess intracellular $O_2^{\cdot-}$ to H_2O_2 and O_2, suggesting that they may increase the concentration of H_2O_2 in cancer cells thus inducing cell death by apotosis. Furthermore, compared to manganese systems copper complexes are less likely to act as catalase mimics and catalytically disproportionate the H_2O_2 to water and molecular oxygen but rather react with it to form the desirable cytotoxic hydroxyl radical (Fenton chemistry). However, a small number of copper carboxylate complexes have recently been reported in the literature that show significant catalase mimetic functionality [11,12].

Recently, we have been studying the anticancer activities of a range of simple copper complexes incorporating different types of nitrogen donor ligands [13–17]. We have found that the bis- or tris-chelate copper complexes incorporating 1,10-phenanthroline and 1,10-phenanthroline-5,6-dione (which possess N_4 or N_6 ligation) are potent anticancer agents in vitro and that they appear to have a mechanism of action significantly different to that of the clinically used drug cisplatin [16,17]. Furthermore, a number of these copper complexes are excellent SOD mimics [14,18] and have been shown to induce apoptosis in cultured mammalian cells [19].

In an effort to throw some light on the structure–activity-relationship of this class of simple copper complexes we have studied systems in which only two nitrogen atoms (either as chelates or monodentate ligands) are bound to the copper centre. Herein, we detail the preparation, catalase and SOD mimetic activities and the chemotherapeutic potentials of copper acetate, salicylate and benzoate complexes incorporating phen, bipy and simple benzimidazole ligands. The X-ray crystal structures of $[CuBZA_2(bipy)(H_2O)]$, $[Cu(salH)_2(BZDH)_2]$ and $[Cu(CH_3CO_2)_2(5,6\text{-DMBZDH})_2]$ are also reported.

2. Results and discussion

2.1. Synthesis and characterisation of the complexes

$[Cu_2(CH_3COO)_4(H_2O)_2]$ (**1**) was obtained commercially and was not further purified. $[Cu(salH)_2(H_2O)_2]$ (**2**) ($salH_2$ = salicylic acid) was generated using a method previously published [20]. $\{Cu(BZA)_2(H_2O)\}_n$ (**3**) was the major product from a reaction between copper(II) hydroxide and benzoic acid. Reaction of **1** with 1,10-phenanthroline (phen) in ethanol gave $[Cu(CH_3COO)_2(phen)]$ (**4**) in good yield and a similar reaction between **2** and phen resulted in the generation of [Cu(sal)(phen)] (**5**). $[Cu(BZA)_2(bipy)(H_2O)]$ (**6**) was obtained in good yield when **1** reacted with 2,2′-bipyridine (bipy) in the presence of benzoic acid. $[Cu(CH_3COO)_2(5,6\text{-DMBZDH})_2]$ (**7**), $[Cu(salH)_2(BZDH)_2]$ (**8**) and $[Cu(BZA)_2(BZDH)_2]$ (**9**) were easily produced when **1**, **2** and **3** were treated with the relevant benzimidazoles in refluxing ethanol (where 5,6-DMBZDH = 5,6-dimethylbenzimidazole and BZDH = benzimidazole, respectively).

The physico-chemical properties for **2** are the same as a compound that was previously reported for which the crystal structure revealed a square planar geometry with the salicylate ligands *trans* to one another and bound through the carboxylate groups in a monodentate fashion [21]. In the IR spectrum of **3**, the asymmetric and symmetric OCO bands of the benzoate ligands are split [$\nu(OCO)_{assym}$: 1597 cm^{-1} and 1556 cm^{-1}; $\nu(OCO)_{sym}$: 1408 cm^{-1} and 1376 cm^{-1}] and thus two modes of interaction are likely for the carboxylate ligands with the copper centres. The microanalysis and the magnetic moment of **3** are similar to those of an anhydrous copper benzoate complex previously reported which had an empirical formula of $Cu(BZA)_2$ [22]. The magnetic moment (1.56 BM) for **3** is slightly lower than that expected for simple copper(II) species (i.e. those lacking Cu–Cu interactions) [23]. Thus, it is likely that at least one of the benzoate ligands is in some type of bridging mode as reported recently for several copper(II) complexes of substituted benzoates [24–26]. The

crystal structure of copper benzoate trihydrate has been reported and the complex incorporates both coordinated and uncoordinated benzoate anions [27]. The structure comprises linear chains of $\{Cu(BZA)(\mu\text{-}H_2O)_2\}_n$ with uncoordinated H_2O molecules and BZA^- anions intervening between them. The room temperature magnetic moment for the trihydrate was reported as being unusual for a (μ-H_2O)(μ-BZA) bridged complex (1.87 BM) and therefore it seems that the structure of **3** is not quite the same as this trihydrate. Indeed it is significant that three magnetically different modifications of anhydrous copper(II) benzoate have been previously reported [28].

When compared to those of **1**, **2** and **3** the spectra of **4**, **5** an **6** are far more complex and contain new absorption bands which are characteristic of the presence of chelating phen {723 and 851 cm^{-1} (**4**); 721 and 847 cm^{-1} (**5**)} [29] and bipy {775 cm^{-1} and 729 cm^{-1} (**6**)} [30]. As well as the bands that have been assigned to the chelating phen and bipy ligands the spectra of **4**–**6** also contain bands that are characteristic of carboxylate anions with $\nu(OCO)_{asym}$ {1631 cm^{-1} (**4**), 1598 cm^{-1} (**5**) and 1599 cm^{-1} (**6**)} and $\nu(OCO)_{sym}$ {1431 cm^{-1} (**4**), 1360 cm^{-1} (**5**) and 1379 cm^{-1}(**6**)} values. The calculated Δ_{OCO} of 200 cm^{-1} (**4**), 238 cm^{-1} (**5**) and 220 cm^{-1} (**6**) are quite similar and in the region expected for monodentate carboxylate ligands [30]. Complex **4** has very similar physico-chemical properties to those of the copper complex [Cu(*N*-baa)$_2$(phen)] (*N*-baaH = *N*-benzoylanthanilic acid) [12]. The X-ray crystal structure of [Cu(*N*-baa)$_2$(phen)] has revealed it to have a mononuclear structure with two asymmetrical bidentate chelating carboxylates which both have one very long Cu–O bond (2.626 Å). The overall geometry around what is effectively a four-coordinate copper ion is described as a distorted tetragonal motif which contains a *trans*-$N_2O_2 + O_2$ chromophore. It is likely that **4** has a similar structure to this complex. Complex **5** clearly contains a doubly deprotonated chelating sal^{2-} ligand and its physico-chemical data fit for a square planar geometry similar to that of the structurally characterized bipy analogue [Cu(sal)(bipy)] · EtOH · H_2O [20]. A peak at 844 cm^{-1} in the spectrum of **6**, which does not appear in the spectra of either **4** or **5** is characteristic of the presence of a coordinated water molecule supporting its inclusion in the formulation of **6** (also observed in the crystal structure) [31].

Complexes **7**–**9** formulate as having the same metal:benzimidazole:carboxylate ratio of 1:2:2 and their IR spectra are very similar suggesting that the three complexes share a common structure. The N–H stretching and bending bands in the spectra of the BZDH and 5,6-DMBZDH free ligands also appear (although shifted slightly) in the spectra of the three complexes indicative of the fact that the ligands are present in their neutral state. Furthermore, the bands associated with the imidazolic υ(C=N) in the free ligands (1587 cm^{-1} and 1553 cm^{-1}, respectively) have shifted significantly in the spectra of **7**, **8** and **9** (1499 cm^{-1}, 1581 cm^{-1} and 1615 cm^{-1}, respectively) indicating that the benzimidazoles are bound to the metals through the nitrogen atom. For all three complexes the $\nu(OCO)_{asym}$ and $\nu(OCO)_{sym}$ bands are not split and are in similar positions. The Δ(OCO) values of 161 cm^{-1}, 173 cm^{-1} and 177 cm^{-1} for **7**–**9**, respectively, are all lower than the values expected for monodentate carboxylate ligands (>200 cm^{-1}) but the relative reduction in the Δ(OCO) values are typical where such carboxylate groups are involved in hydrogen bonding [32].

The room temperature magnetic susceptibility values for **4**–**9** (1.65–2.11 BM) are in the range expected for the observed or proposed mononuclear structures in which there are no significant Cu–Cu interactions [23]. Furthermore, the electronic spectra of the complexes obtained in the solid state as Nujol mulls all exhibit broad bands in the region 531–662 nm due to d–d transitions and are in the range expected for mononuclear copper(II) complexes that contain either a CuN_2O_2 or a CuN_2O_3 chromophore and have square planar or related geometries [33]. When the electronic spectra are recorded in DMSO solution these bands all shift to higher energy indicative of changes in geometry as a possible consequence of DMSO solvation. The molar conductivities of complexes **2**–**9** in DMSO were found to be in the range 0.9 and 7.9 S cm^2 mol^{-1} indicating that they are essentially non-electrolytes and thus do not dissociate in that solvent.

2.2. Crystal structures of 6, 7 and 8

The X-ray crystal structures of [Cu(BZA)$_2$(bipy)(H_2O)] (**6**), [Cu(CH_3COO)$_2$ (5,6-DMBZDH)$_2$] (**7**) and [Cu(salH)$_2$-(BZDH)$_2$] (**8**) are shown in Figs. 1–6 and selected bond lengths and angles are listed in Table 1.

The crystal structure determination of **6** showed that the square pyramidal copper centre has an axially coordinated water molecule. An aqua H forms an intramolecular hydrogen bond with unbound carboxylate oxygen O_2 (Fig. 1 and Table 2). Consequently, this carboxylate group

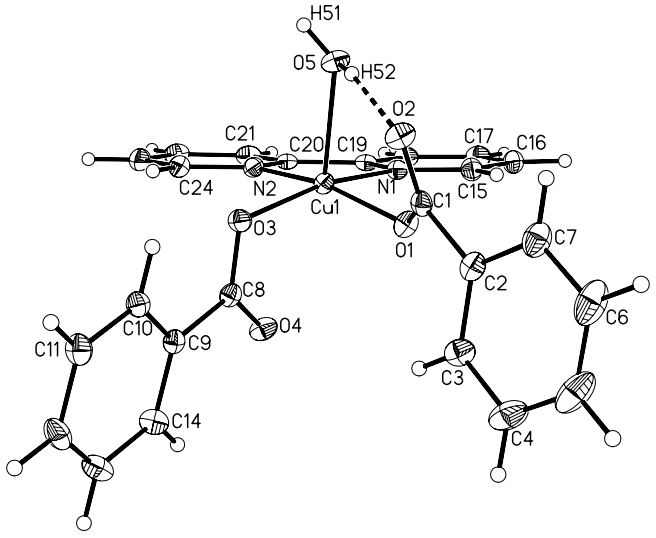

Fig. 1. The structure of [Cu(BZA)$_2$(bipy)(H_2O)] (**6**).

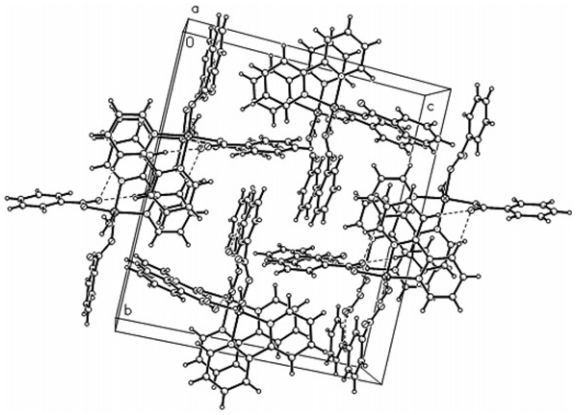

Fig. 2. The packing diagram for $[Cu(BZA)_2(bipy)(H_2O)]$ (**6**) showing stacking and hydrogen bonding.

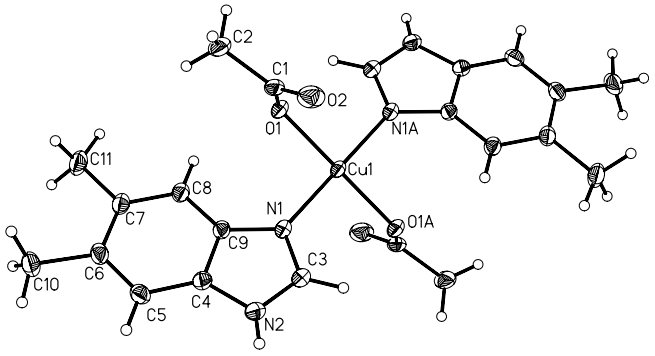

Fig. 3. The structure of $[Cu(CH_3COO)_2$ (5,6-DMBZDH)$_2]$ (**7**).

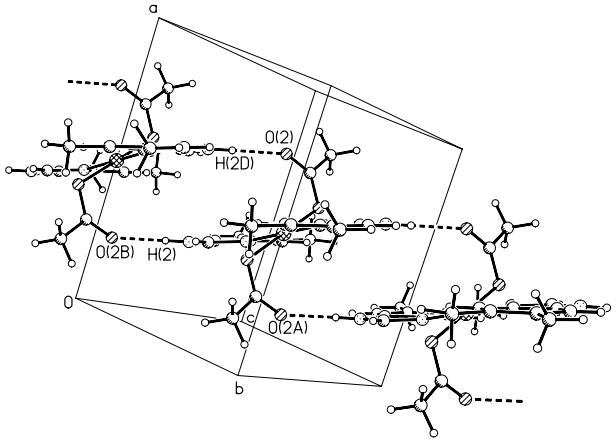

Fig. 4. The packing diagram for $[Cu(CH_3COO)_2$(5,6-DMBZDH)$_2]$ (**7**) showing the hydrogen bonding where suffixes on labels correspond to the symmetry operations A: $x+1, -y+2, -z$; B $-x+1, -y+1, -z$.

is significantly twisted, by 36.31(9)°, with respect to the phenyl ring. This is in contrast to the other chemically identical benzoate which takes part in intermolecular hydrogen bonding with water bound to another molecule. In this case the phenyl-carboxylate twist angle is 6.56(9)°. Thus, this hydrogen bonding motif generates a chain parallel to the *a*-axis. The bipyridyl ligand is inclined at 85.18(7)° to phenyl C2–C7 (bound to the intramolecular hydrogen bonding carboxylate) and 77.04(6)° to the other phenyl group (C9–C14). There are no close π-stacking interactions (Fig. 2) but several close H…H distances, the shortest being 2.43 Å between H4A and H7A in neighbouring molecules.

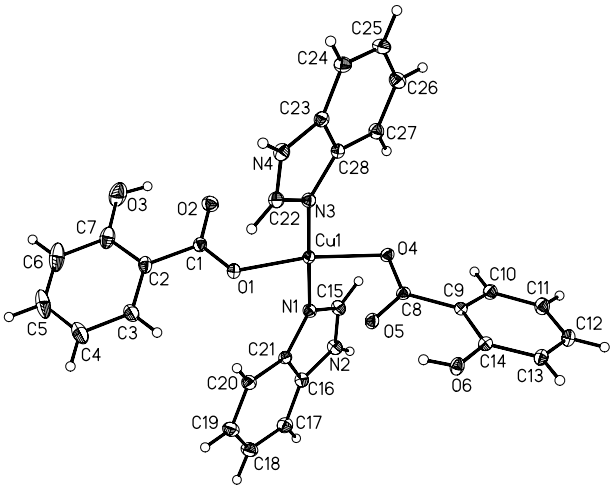

Fig. 5. The structure of $[Cu(salH)_2(BZDH)_2]$ (**8**).

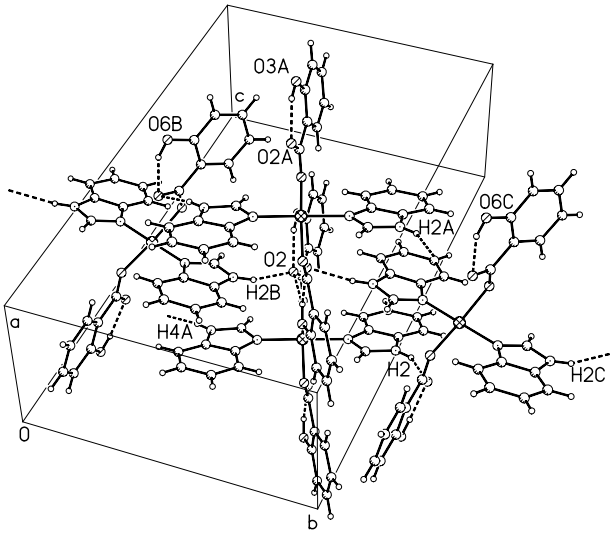

Fig. 6. The packing diagram for $[Cu(salH)_2(BZDH)_2]$ (**8**) where suffixes on labels correspond to the symmetry operations A: $1+x, y, z$; B: $-x+3/2, y+1/2, -z+1/2$; C: $-x+3/2, y+3/2, -z+1/2$.

In contrast both **7** and **8** have square planar copper centres (Figs. 3 and 5, respectively) which contain two *trans* benzimidazole and two acetate (**7**) or two salicylate (**8**) ligands. Whereas the copper atom is situated on an inversion centre in **7**, it is not so in **8** where the hydrogen bonding motif differs between the two carboxylate groups. The protonated benzimidazole N is capable of hydrogen bonding and makes intermolecular hydrogen bonds with carboxylate O atoms in both cases (Fig. 4; Table 3 and Fig. 5; Table 4, respectively) thus forming a double linked chain which is propagated along the shortest axis (*b*) in **7** so that the hydrogen bonding pattern is similar to **6** apart

from two NH···O hydrogen bonds forming the link rather than the single OH...O seen in **6**. In **8**, the *ortho* hydroxy group makes hydrogen bonds to one carboxylate O atom and so would be expected to keep the carboxylate co-planar with the phenyl ring which is the case for the carboxylate containing O1, O2. However, for the other benzoate ligand the carboxylate is twisted by 18.33(6)° with respect to the plane made by the phenyl ring and O6. In this case, the hydroxyl O makes intermolecular hydrogen bonds to a carboxyl O and a longer NH...O link (Table 4). In contrast O3 makes just an intramolecular hydrogen bond to O2. As seen in **6** and **7**, **8** forms hydrogen bonded chains parallel to the shortest axis, although there is an extra NH...O bond in **7** and **8**. However, in **8** these chains interdigitate such that the benzimidazoles form a stack and the distance between the imidazole centroids in these stacks alternates between 3.6622(7) and 3.8424(7) Å, albeit rather too long for significant p–p stacking interactions. In the structure of **7** neighbouring molecules are link by significant π–π stacking involving the benzimidazole ligands (Fig. 4). Despite these differences, the major hydrogen bonding motif, a chain propagated by OH...O (**6**, **8**) or NH...O (**7**) bonds along the shortest axis, is common to all three crystal structures.

2.3. Catalase activity

The catalytic activity of complexes **1**–**9** towards the disproportionation of hydrogen peroxide was investigated by measuring the volume of evolved oxygen during the course of the reaction. None of the nine complexes exhibited catalytic activity on their own. We have previously shown that the catalase mimetic activity of manganese complexes is significantly improved in the presence of the base imidazole [29,34,35], a phenomenon also observed by others [36]. Consequently, we examined the catalase mimetic properties of complexes **1**–**9** in the presence of this base. The results from these reactions are summarised in Tables 5 and 6. The catalytic activity of the complexes is relatively poor when compared to the double salt $[\{Mn_2(oda)(phen)_4(H_2O)_2][Mn_2(oda)_3(phen)_4\}]$ ($odaH_2$ = octanedioic acid) which had been shown to be the best manganese catalase mimic previously produced in this laboratory [29,37]. Table 5 shows the rate of evolution of oxygen from the respective reactions for the complexes over the first 20 min. Examination of Table 6 shows that over the first minute of reaction **5** appears to be the most efficient catalyst with 1012 molecules of peroxide disproportionated by one molecule of the complex. Complex **8** appears to be the least efficient catalyst over the first minute with one molecule of the compound knocking down just 216 molecules of the peroxide.

Table 5

9	606	416
{$[Mn_2(oda)(phen)_4(H_2O)_2][Mn_2(oda)_3(phen)_4]$}	24 570	19 500

It should be noted that imidazole itself causes only a very slight disproportionation of the peroxide (Table 5).

2.4. Superoxide dismutase activity

The SOD mimetic activities of the complexes **1**–**9** were examined with an indirect method in which the xanthine/xanthine-oxidase system served as the source for superoxide radicals [38]. The activities of the complexes were compared to that of $[Cu_2(indo)_4(H_2O)_2]$ {indoH = indomethacin [1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-indole-3-acetic acid]} which is considered to be an excellent SOD mimetic [39] and which is used therapeutically as an oral anti-inflammatory drug in veterinary medicine [40,41]. The results are given in Table 7 as concentrations equivalent to one unit of SOD activity (IC_{50} values).

Significant activities were seen for all compounds tested with one unit of SOD activity arising from the range of 0.63–1.98 μM aqueous solutions. Interestingly, the complexes all have activities comparable with that (1.31 μM in this study) of $[Cu_2(indo)_4L_2]$ (L = DMSO or DMF) for which the IC_{50} values vary significantly in the literature and appear to be solvent dependent (the reported value in DMSO is 2 μM [39]). It is interesting that the SOD activity of the copper(II) acetate complexes decreases in the order $[Cu_2(CH_3COO)_4(H_2O)_2]$ (**1**) > $[Cu(CH_3COO)_2$ (5,6-DMBZDH)$_2]$ (**7**) > $[Cu(CH_3COO)_2(phen)]$ (**4**) where it appears that the inclusion of the nitrogen donor ligands reduce the SOD activity. Whereas **4** and **7** are monomeric complexes **1** is dimeric and has a similar "paddle wheel" structure to that of $[Cu_2(indo)_4(DMF)_2]$ [42]. The copper(II) complexes $[Cu_2(valp)_4(H_2O)_2]$ and $[Cu(valp)_2(phen)]$ [valpH = valproic acid {$(CH_3CH_2CH_2)_2CHCOOH$}] were recently reported and are iso-structural to **1** and **4**, respectively [43]. Their SOD mimetic activities were much lower relative to **1** and **4** (10.4 and 4.5 μM) with the phen derivative being the superior catalyst. Clearly there is no correlation between solid state nuclearity (monomeric versus dimeric structures) and SOD mimetic activity but the type of carboxylate present appears to be important. The three monomeric copper(II) salicylates exhibit SOD activity in the order $[Cu(salH)_2(BZDH)_2]$ (**8**) > [Cu(sal)(phen)] (**5**) > $[Cu(salH)_2(H_2O)_2]$ (**2**) where the activity increases upon inclusion of the nitrogen bases in the inner sphere of the complexes. The activities of complexes **2** and **5** fall in the lower end of the range (0.17–29 μM) previously reported for copper(II) salicylate derivatives, a number of which are used therapeutically as anti-inflammatory agents in human and veterinary medicine [40,44]. The benzoate complex $\{Cu(BZA)_2(H_2O)\}_n$ (**3**) displays potent SOD activity (0.9 μM) and is approximately twice as active as its bipy derivative $[Cu(BZA)_2(bipy)(H_2O)]$ (**6**).

Table 7
Superoxide dismutase (SOD) activities of complexes **1**–**8**, $[Cu_2(indo)_4(H_2O)_2]$ [39], $CuSO_4$ and native CuZnSOD as assessed by the NBT assay

Complex	Concentration (μM) equivalent to 1 U SOD (IC_{50})
$[Cu_2(CH_3COO)_4(H_2O)_2]$ (**1**)	0.63
$[Cu(salH_2)(H_2O)_2]\cdot 0.5H_2O$ (**2**)	1.23
$\{Cu(BZA)_2(H_2O)\}_n$ (**3**)	0.90
$[Cu(CH_3COO)_2(phen)]$ (**4**)	1.18
[Cu(sal)(phen)] (**5**)	1.01
$[Cu(BZA)_2(bipy)(H_2O)]$ (**6**)	1.98
$[Cu(CH_3COO)_2(5,6\text{-DMBZDH})_2]$ (**7**)	0.91
$[Cu(salH)_2(BZDH)_2]$ (**8**)	0.74
$[Cu_2(indo)_4(H_2O)_2]$ [39,40]	1.31
$CuSO_4$ [41]	30
Native CuZnSOD [39]	0.04

Where $salH_2$ = salicylic acid; BZAH = benzoic acid; phen = 1,10-phenanthroline; bipy = 2,2′-bipyridine; 5,6-DMBZDH = 5,6-dimethylbenzimidazole; BZDH = benzimidazole; indoH = indomethacin {1-(4-Chlorobenzoyl)-5-methoxy-2-methyl-1H-indole-3-acetic acid}.

$[Cu(BZA)_2(BZDH)_2]$ (**9**) was insoluble in DMSO and its SOD activity could not be determined. Attempts to dissolve **9** in hot DMSO caused an immediate precipitation of the known red polymeric Copper(II) complex $\{Cu(BZD)_2\}_n$ [45]. All of the other complexes were stable in hot DMSO (no change in their UV spectra) again demonstrating how changing the type of carboxylate ligand may influence the reactivity of this class of simple copper(II) complexes.

2.5. Cytotoxicity studies

To evaluate their cancer chemotherapeutic potential the ability of the DMSO soluble copper complexes **1**–**8** to kill human derived cancer cells was investigated using the hepatocellular carcinoma (Hep-G_2), kidney adenocarcinoma (A-498) and lung cancer (A-549) cell lines and was determined by calculation of IC_{50} (the drug concentration causing a 50% reduction in cellular viability). Cells were continuously exposed to test agent for 96 h, and their effects on cellular viability was evaluated. It was intended that the results from these studies would allow the identification of those derivatives with cancer chemotherapeutic potential. Therefore, profiles of cell viability against complex concentration were established and used to calculate the IC_{50} values for each derivative (Table 8). Comparison of IC_{50} values, allowed the relative potency of each of the test compounds to be determined and ranked.

With the exception of phen all of the free ligands are essentially inactive. A number of the compounds screened displayed a concentration-dependent cytotoxic profile across the three cell lines studied here. The most sensitive cell line was the A-549 lung cancer with seven of the compounds showing significant improvements in activity when compared to the uncoordinated free ligands. The overall order of the observed cytotoxicity was seen as (**4**) > (**5**) > (**6**) > (**7**) > (**8**) > (**1**) > (**2**) ⋙ (**3**) with (**4**) appearing as the most potent and (**3**) as the least potent effectively displaying no activity. The results presented in Table 8 also illustrates that the $CuSO_4$ (free Cu^{2+}) was incapable of eliciting a cytotoxic response. The inclusion of the *N*,*N*-donor ligands 1,10-phenanthroline (phen) and 2,2′-bipyridine (bipy) in the simple Cu(II) complexes of the acetic, salicylic and benzoic acids significantly increased the potency of the system. However, it is also noteworthy that the metal free phenanthroline is itself significantly cytotoxic and that the best copper complex containing it (**4**) is approximately 2, 6 and 2 times more potent for the respective cell lines. Complexes **4** and **5** were capable of killing all three cancer

Table 8
The anti-cancer activity of the free ligands, complexes **1**–**8** and cisplatin against human hepatic (Hep-G_2), renal (A-498) and lung (A-549) cancer cell lines expressed as IC_{50} (μM)[a]

Cisplatin	15 ± 2.7	14 ± 1	11.0 ± 4.7

[a] IC_{50} (μM), indicates the compound concentration that inhibits the proliferation rate of tumour cells by 50% as compared to the control untreated cells. The values are means ± S.D. of 9 independent experiments.

derived cell lines at very low concentrations (IC_{50} values: 1.8, 1.0 and 1.55 μM for **4** and 2.5, 1.6 and 1.44 μM for **5** for the liver, kidney and lung cell lines, respectively). The activities of **4** and **5** fall well within the accepted activity parameters adopted for in vitro screening of potential chemotherapeutic drugs [46]. Furthermore, the IC_{50} values for them are superior to those of the clinically used drug *cis*-platin [47]. Significantly, no correlation was found between the potencies of SOD mimic capabilities and cell growth inhibitory activity for the eight complexes. However, with the exception of **3** all of the complexes do show significant activity against the renal and lung cell lines. It is of course possible that the complexes act on the cancer cells through mechanism other than (or in conjunction with) SOD activity. Indeed the bis-1,10-phenanthroline copper(II) complex $[Cu(phen)_2]^{2+}$ is known as a potent nuclease agent which causes oxidative cleavage of DNA in the presence of reducing agents [48].

3. Conclusion

The carboxylate complexes **1**–**8** exhibit potent SOD mimicking activity and are inactive as catalase mimics in the absence of added imidazole. Upon addition of the base they display only poor catalytic potential for the disproportionation of hydrogen peroxide. Complexes **4**–**8** exhibit significant cytotoxicity with the mono-phen derivatives **4** and **5** being the most potent displaying activity approximately seven times that of the clinical anticancer drug cisplatin. Significantly, **4** and **5** are relatively soluble compared to the other six complexes and they have cytotoxicity comparable with the copper(II) bis-phenanthroline complexes previously studied in this laboratory [17] but are one quarter as active as the copper(II) tris-phenanthroline-diones [16]. The lack of correlation between the SOD and cytotoxicity IC_{50} values supports the notion that mechanisms other than SOD mimicking may also be responsible for the anticancer properties of these complexes. Indeed complexes **4** and **5** are structurally related to the novel anticancer agent casiopeina II {[Cu(1,4-dimethyl-1,10-phenanthroline)-(glycine)]NO_3} which has been shown to have a very complex in vivo cytotoxicity [49]. An interesting compound is the benzoate complex **3** which is an excellent SOD mimic but has little or no cytotoxicity. Such a non-toxic compound might have potential use as a therapeutic agent for treatment of other disorders where SOD activity is pathologically reduced.

4. Experimental

4.1. Chemistry

Chemicals were purchased from commercial sources and used without further purification. IR spectra were recorded in the region 4000–400 cm^{-1} on a Nicolet-400 Impact spectrometer. UV spectra were recorded in the region of 400–1000 nm on a Specord 200 spectrophotometer. Magnetic susceptibility measurements were made using a Johnson Matthey Magnetic Susceptibility balance. $[HgCo(SCN)_4]$ was used as a reference. Conductivity readings were obtained using an Orion model 150 plus conductivity meter. Satisfactory microanalytical data for the complexes were reported by the Microanalytical Laboratory, University College Cork, Ireland. $[Cu_2(indo)_4(H_2O)_2]$ (indoH = indomethacin) was synthesised and characterised using the method previously published [39].

4.1.1. $[Cu_2(CH_3COO)_4(H_2O)_2]$ (1)

$[Cu_2(CH_3COO)_4(H_2O)_2]$ was obtained commercially from the Aldrich Chemical Company and used without further purification.

4.1.2. $[Cu(salH)_2(H_2O)_2]$ (2)

$[Cu(salH)_2(H_2O)_2]$ (**2**) was synthesised using a method previously published [20] as follows: $Cu(OH)_2$(0.97 g, 9.94 mmol) and salicylic acid ($salH_2$) (2.76 g, 19.98 mmol) were refluxed in ethanol (50 cm^3) for 4 h giving a brown suspension. On cooling to room temperature the brown product was filtered off, washed with two portions of water and ethanol, and then air-dried. Yield: 1.42 g, 56%. *Anal.* Calc. C, 40.3; H, 2.4. Found: C, 41.09; H, 2.3%. IR (KBr): 3438, 1603, 1568, 1529, 1485, 1455, 1410, 1303, 1232, 1149, 1099, 1037, 891, 838, 808, 775, 763, 711, 673, 621, 595, 512, 451, 428, 415, 406 cm^{-1}. μ_{eff}: 1.81 BM. Solubility: insoluble in water, ethanol, methanol, acetone, trichloromethane. Soluble in DMSO. λ_{max} (Nujol Mull): $\lambda_{d-d} = 742$ nm. λ_{max} (DMSO): $\lambda_{d-d} = 754$ nm, $\varepsilon = 169.5\ M^{-1}\ cm^{-1}$. Λ_M (DMSO): 4.2 S $cm^2\ mol^{-1}$.

4.1.3. $\{Cu(BZA)_2(H_2O)\}_n$ (3)

To a solution of freshly prepared $Cu(OH)_2$ (1.0 g, 10.25 mmol) in ethanol (50 cm^3) was added an ethanolic solution (25 cm^3) of benzoic acid (2.5 g, 20.5 mmol) and the resulting suspension was refluxed for 3 h. The blue-green powder that deposited was filtered off, washed with a small volume of ethanol, and then air-dried. Yield: 1.6 g, 49%. *Anal.* Calc. C, 51.93; H, 3.73. Found: C, 53.3; H, 3.3%. IR (KBr): 3061, 2970, 1597, 1561, 1520, 1509, 1445, 1402, 1309, 1179, 1146, 1071, 1026, 929, 845, 718, 685, 510, 481 cm^{-1} μ_{eff}: 1.57 BM. Solubility: insoluble in water, ethanol, methanol, acetone, and trichloromethane. Soluble in DMSO. λ_{d-d} (Nujol Mull) = 686 nm. λ_{d-d} (DMSO) = 734 nm, $\varepsilon = 125\ M^{-1}\ cm^{-1}$. Λ_M (DMSO) = 1.17 S $cm^2\ mol^{-1}$.

4.1.4. $[Cu(CH_3COO)_2(phen)]$ (4)

To a solution of phen (1 g, 5.6 mmol) in EtOH (50 cm^3) was added $[Cu_2(CH_3COO)_4(H_2O)_2]$ (**1**) (0.5 g, 1.25 mmol) and the resulting blue solution refluxed for 1 h. The solution was reduced by rotary evaporation to 5 cm^3 and acetone (20 cm^3) then added. This solution was further reduced to 10 cm^3. The resulting blue powder which deposited was filtered off washed with two por-

tions of water and ethanol, and then air-dried. Yield: 0.28 g, 62%. *Anal*. Calc. C, 50.6; H, 4.3; N, 7.4. Found: C, 51.0; H, 4.1, N, 7.9%. IR (KBr): 3442, 3012, 2925, 2854, 1632, 1608, 1587, 1544, 1524, 1448, 1431, 1401, 1341, 1255, 1220, 1143, 1107, 1054, 1020, 962, 942, 875, 851, 785, 723, 683, 648, 627, 482, 432 cm^{-1}. μ_{eff}: 1.89 BM. Solubility: soluble in water, EtOH, MeOH and DMSO. λ_{max} (Nujol Mull): $\lambda_{d-d} = 630$ nm. λ_{max} (DMSO): $\lambda_{d-d} = 682$ nm, $\varepsilon = 51.6\ M^{-1}\ cm^{-1}$. Λ_M (DMSO): 7.9 S $cm^2\ mol^{-1}$.

4.1.5. [Cu(sal)(phen)] (5)

[Cu(sal)(phen)] (**5**) was synthesised using a method previously published [20] as follows: $[Cu(salH)_2(H_2O)_2]$ (**2**) (0.4 g, 1.92 mmol) and 1,10-phenanthroline (0.427 g, 2.37 mmol) were refluxed in EtOH (50 cm^3) for 2 h giving a green suspension. On cooling to room temperature the green product was filtered, washed with two portions of water and ethanol, and then air-dried. Yield: 0.73 g, 72%. *Anal*. Calc. C, 60.1; H, 3.2; N, 7.4. Found: C, 58.9; H, 3.3, N, 7.0%. IR (KBr): 3416, 3089, 3059, 2360, 2342, 1629, 1599, 1574, 1543, 1519, 1492, 1461, 1450, 1429, 1360, 1342, 1320, 1243, 1223, 1136, 1107, 1032, 911.884, 874, 847, 809, 772, 741, 721, 710, 667, 651, 628, 585, 543, 432 cm^{-1}. μ_{eff}: 2.11. Solubility: insoluble in water acetone and trichloromethane. Soluble in EtOH, MeOH and DMSO. λ_{max} (Nujol Mull): $\lambda_{d-d} = 589$ nm. λ_{max} (DMSO): $\lambda_{d-d} = 635$ nm, $\varepsilon = 134.3\ M^{-1}\ cm^{-1}$. Λ_M (DMSO): 1.8 S $cm^2\ mol^{-1}$.

4.1.6. [Cu(BZA)$_2$(bipy)(H$_2$O)] (6)

To a heated solution of $[Cu_2(CH_3COO)_4(H_2O)_2]$ (**1**) (0.5 g, 1.25 mmol) and benzoic acid (0.31 g, 2.5 mmol) in ethanol (50 cm^3) was added 2,2-bipyridine (0.39 g, 2.5 mmol). The resulting dark blue solution was stirred for 30 min and allowed to cool and stand. After 48 h blue needle-like crystals formed that were suitable for X-ray crystallography. Yield: 0.37 g, 61.67%. *Anal*. Calc. C, 60.0 ; H, 4.2; N, 5.83. Found: C, 59.40; H, 4.18; N, 5.66%. IR (KBr): 3357.11, 3111.63, 3081.23, 3030.09, 1599.59, 1555.06, 1493.96, 1473.36, 1445.49, 1397.01, 1379.35, 1313.09, 1285.66, 1260.50, 1254.75, 1170.95, 1156.30, 1142.41, 1105.07, 1070.15, 1054.39, 1031.28, 1019.61, 977.99, 930.12, 913.08, 846.41, 820.11, 775.38, 729.24, 678.25, 665.38, 650.65, 639.83, 548.40, 455.46, 432.92, 416.63 cm^{-1}. μ_{eff}: 1.87 BM. Solubility: insoluble in water, ethanol, methanol, acetone, and trichloromethane. Soluble in DMSO. λ_{max} (Nujol): $\lambda_{d-d} = 662$ nm. λ_{max} (DMSO): $\lambda_{d-d} = 677$ nm, $\varepsilon = 117.77\ dm^3\ mol^{-1}\ cm^{-1}$. Λ_M (DMSO): 7.2 S $cm^2\ mol^{-1}$.

4.1.7. [Cu(CH$_3$COO)$_2$ (5,6-DMBZDH)$_2$] (7)

To a solution of $Cu_2(CH_3COO)_4(H_2O)_2]$ (**1**) (0.5 g, 1.25 mmol) in ethanol (100 cm^3) was added 5,6-dimethylbenzimidazole (0.73 g, 5 mmol) and the resulting dark green solution refluxed for 4 h. A quantity of blue crystals suitable for X-ray structural analysis, were obtained from the solution upon standing for one week. Yield: 0.25 g, 42%. *Anal*. Calc. C, 55.7; H, 5.5; N, 11.8. Found: C, 55.9; H, 5.6; N, 11.4%. IR (KBr): 3432, 3102, 3062, 2966, 2934, 2879, 2815, 2656, 1772, 1706, 1559, 1500, 1474, 1448, 1408, 1337, 1307, 1271, 1251, 1212, 1191, 1159, 1087, 1047, 1006, 968, 931, 882, 856, 841, 823, 784, 732, 675, 647, 618, 575, 486, 452, 435 cm^{-1}. μ_{eff}: 1.65 BM. Solubility: insoluble in water, ethanol, methanol, acetone, trichloromethane. Soluble in DMSO. λ_{max} (Nujol Mull): $\lambda_{d-d} = 531$ nm. λ_{max} (DMSO): $\lambda_{d-d} = 726$ nm, $\varepsilon = 123.4\ M^{-1}\ cm^{-1}$. Λ_M (DMSO): 0.9 S $cm^2\ mol^{-1}$.

4.1.8. [Cu(salH)$_2$(BZDH)$_2$] (8)

$[Cu(salH)_2(H_2O)_2]$ (**2**) (0.5 g, 2.39 mmol) and benzimidazole (0.846 g, 7.17 mmol) were refluxed in ethanol (100 cm^3) for 3 h giving a red suspension. On cooling to room temperature a small amount of red powder ($\{Cu(bzd)_2\}_n$) was filtered off, and the blue filtrate allowed to stand for several days where a quantity of blue crystals of **8** which were suitable for X-ray structural analysis deposited. Yield: 0.51 g, 37%. *Anal*. Calc. C, 58.6; H, 3.9; N, 9.8%. Found: C, 58.9; H, 3.8; N, 9.8%. IR (KBr): 3238, 3145, 3112, 3064, 2990, 2916, 2839, 1760, 1741, 1619, 1595, 1582, 1568, 1509, 1497, 1479, 1454, 1395, 1355, 1323, 1305, 1272, 1224, 1195, 1141, 1113, 1086, 1031, 1010, 977, 971, 925, 864, 849, 832, 817, 777, 756, 733, 716, 705, 669, 634, 606, 560, 548, 536, 443, 420 cm^{-1}. μ_{eff}: 1.83 BM. Solubility: insoluble in water, ethanol, methanol, acetone, trichloromethane. Soluble in DMSO. λ_{max} (Nujol Mull): $\lambda_{d-d} = 579$ nm. λ_{max} (DMSO): $\lambda_{d-d} = 738$ nm, $\varepsilon = 84.1\ M^{-1}\ cm^{-1}$. Λ_M (DMSO): 13.2 S $cm^2\ mol^{-1}$.

4.1.9. [Cu(BZA)$_2$(BZDH)$_2$] (9)

To a solution of $\{Cu(BZA)_2(H_2O)\}_n$ (**3**) (1.0 g, 3.0 mmol) in ethanol/water (100 cm^3, 1:1) was added benzimidazole (1.25 g, 10.0 mmol) and the resulting suspension was stirred for 24 h. The purple powder that deposited was filtered off, washed with a small volume of ethanol and water, and then air-dried. Yield: 1.53 g, 94.09%. *Anal*. Calc. C, 62.04; H, 4.09; N, 10.33. Found: C, 61.33; H, 4.03; N, 10.05%. IR (KBr): 3326.11, 3139.56, 3056.98, 2985.24, 2915.51, 2887.72, 2845.62, 2754.33, 1964.64, 1911.00, 1783.54, 1615.42, 1597.55, 1557.91, 1487.96, 1464.43, 1446.28, 1428.34, 1405.57, 1381.42, 1361.48, 1315.83, 1302.93, 1270.64, 1252.56, 1176.14, 1150.84, 1125.03, 1107.73, 1068.13, 1024.20, 1010.63, 973.86, 933.40, 906.24, 886.97, 846.44, 840.40, 827.51, 788.77, 776.50, 764.82, 742.46, 714.43, 685.37, 631.93, 613.62, 577.07, 548.59, 447.32, 425.24 cm^{-1}. μ_{eff}: 1.86 BM. Solubility: insoluble in all common solvents. λ_{max} (Nujol): $\lambda_{d-d} =$ 593 nm.

4.2. X-ray crystallography

Intensity data were collected in single crystals of **6**, **7** and **8** at 100 K on a Bruker Nonius X8 Apex2 diffractometer with monochromatic Mo Kα radiation. Solution and

refinement were performed using the BRUKER suite of programs [50]. All H atom positions were calculated (except N-bound H2 in 7) and all H atom displacement parameters were treated as riding on the bound atom. Further details are given in Table 9.

4.3. Catalase activity

The ability of the complexes to disproportionate hydrogen peroxide was assayed using a method previously published by this laboratory [29] as follows: To a solid sample (ca. 10 mg) of the copper complex was added aqueous H_2O_2 (35% w/w, 10 cm^3, 114 mmol). The mixture was stirred and thermostated at 25 °C and the evolved O_2 was measured volumetrically (volume ± 0.10 cm^3). In cases where imidazole (50 mg) was added, this was introduced into the reaction vessel before the addition of H_2O_2.

4.4. Superoxide dismutase (SOD) activity

The $O_2^{\cdot-}$ dismutase activities of the metal complexes were assessed using a modified Nitro-Blue-Tetrazolium (NBT) assay with xanthine–xanthine oxidase system as the source of $O_2^{\cdot-}$ [38]. The quantitative reduction of NBT to blue Formazan by the $O_2^{\cdot-}$ was followed spectrophotometrically at 550 nm. All reagents were obtained from Sigma–Aldrich Chemical Co. Ltd. and assays were run in 3 ml of solution. Results are graphed as the % inhibition of NBT reduction for three concentrations. Tabulated results were derived from linear regression analyses and are given as the concentration (μM) equivalent to 1 U of bovine erythrocyte SOD activity. A unit SOD activity is the concentration of the complex or enzyme which causes 50% inhibition in the reduction of NBT (referred to as the IC_{50} value).

4.5. Cytotoxicity testing

Dimethyl sulphoxide (DMSO) and all cell culture reagents and media were purchased from Signa–Aldrich Ireland, Ltd., unless otherwise stated. Cytotoxicity assays were performed using three human malignant model cell lines in order to assess the cancer chemotherapeutic potential of the Cu complexes. Hepatocellular carcinoma (Hep-G2), kidney adenocarcinoma (A-496) and lung cancer (A-549) cell lines were purchased from the ATCC.

The hepatocellular carcinoma (Hep-G2) and kidney adenocarcinoma (A-496) cell lines were grown as monolayers in Eagle's minimum essential medium, supplemented with 2 mM L-glutamine and Earle's balanced salt solution, containing 1.5 g dm^{-3} sodium bicarbonate, 0.1 mM non-essential amino acids, 1.0 mM sodium pyruvate, 100 U cm^{-3} penicillin and 100 μg cm^{-3} streptomycin supplemented to contain 10% (v/v) foetal bovine serum (Flow Laboratories, Herts, UK). All cells were grown at 37 °C in a humidified atmosphere, in the presence of 5% CO_2 and were in the exponential phase of growth at the time of assay. Cytotoxicity was assessed using MTT assay. Each of the two cell lines (100 μl) were seeded at a density of 5×10^4 cells cm^{-3} into sterile 96 well flat-bottomed plates (Falcon Plastics, Becton Dickinson) and grown in 5% CO_2 at 37 °C. Test compounds were dissolved in DMSO and diluted with culture media. The maximum percentage of DMSO present in all wells was 0.2% (v/v). Each drug solution (100 μl) was added to replicate wells in the concentration range of 0.1–1000 μM and incubated for 96 h A miniaturised viability assay using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) was carried

out according to the method described by Mosman [51]. The IC_{50} value, defined as the drug concentration causing a 50% reduction in cellular viability, was calculated for each drug. Each assay was carried out using five replicates and repeated on at least three separate occasions. Viability was calculated as a percentage of solvent-treated control cells, and expressed as a % of the control. The significance of any reduction in cellular viability was determined using one-way ANOVA (analysis of variance). A probability of 0.05 or less was deemed statistically significant.

The lung (A-549) cells were cultured in Kaighn's medium (F12K) with 2 mM L-glutamine supplemented with 10% foetal calf serum (FCS) and 45 IU ml^{-1} penicillin and 45 μg ml^{-1} streptomycin at 37 °C in 5% CO_2 humidified incubator. For subcultivation, the cells were detached using a Versene/trypsin solution (1 mM EDTA/0.25% trypsin) in Ca^{2+}- and Mg^{2+}-free Hanks Balanced Salts Solution (HBSS). For cytotoxicity assays cells were seeded in 96-well microplates (Sarstedt) at a density of 2×10^4 cells/ml. This density was found to be optimal to achieve the desired confluence at the end of the exposure period. After 24 h of cell attachment, plates were washed with 100 μl/well phosphate buffered saline (PBS) and cells treated with each compound for 96 h. Six replicate wells were used for each control, and test concentration per microplate. Cytotoxicity was assessed using the MTT assay. Following 96 h of exposure, control or test exposures were removed, cells rinsed with PBS and 100 μl of fresh media (without phenol-red sodium salt, FCS or supplements) was added to each well. Ten microlitres of MTT (5 mg/ml) prepared in PBS was then added to each well and plates incubated for 3 h at 37 °C in a 5% CO_2 humidified incubator. After this incubation period the medium was discarded, cells washed with 100 μl of PBS and 100 μl of DMSO was added to each well to extract the dye. The plate was shaken at 240 rpm for 10 min and absorbance measured at 570 nm. Experiments were conducted in triplicate (three independent experiments). Raw data from cell cytotoxicity assays were collated and analysed using Microsoft Excel® (Microsoft Corporation, Redmond, WA). Cytotoxicity is expressed as mean percentage survival relative to the unexposed control ±standard error of the mean (SEM). Control values were set at 100%. Coefficient of variation (CV) for the controls of each test was calculated to ascertain reproducibility. Cytotoxicity data were fitted to a sigmoidal curve and a four parameter logistic model used to calculate IC_{50} values. This analysis was performed using XLFIT3™ a curve fitting add-in for Microsoft® Excel (ID Business Solutions, UK).

5. Supplementary material

CCDC 634440, 634441 and 634442 contain the supplementary crystallographic data for **6**, **7** and **8**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

voltammograms were recorded using a CH Instruments 660 electrochemical workstation. 200 MHz ^{1}H and 50 MHz ^{13}C NMR spectra were obtained at room temperature in $CDCl_3$ using a Varian 200.

Caution: Although we have experienced no difficulties with the perchlorate salts, these should be regarded as potentially explosive and handled with care.

2.2. Synthesis of 1,8-bis(nicotinyloxy)-9,10-anthracenedione (1)

2.00 g (16.3 mmol) of nicotinic acid was stirred in 15 mL thionyl chloride with formation of a white precipitate. Pyridine was added (~20 mL) to yield a clear solution and excess thionyl chloride was removed using a stream of air. 1.95 g (8.12 mmol) of 1,8-dihydroxyanthraquinone in 30 mL of pyridine was added and the solution stirred for 10 min. This mixture was poured into cold water and the resulting precipitate filtered, washed with water and air dried. Yield: 3.6 g (~96%). Melting point = 228–31 °C. ^{1}H NMR: 7.19 (d, 2H, 5-pyridine rings); 7.51 (d, 2H, 2,7-anthraquinone); 7.81 (t, 2H, 3,6-anthraquinone); 8.20 (d, 2H, 4-pyridine rings); 8.27 (d, 2H, 4,5-anthraquinone); 8.69 (d, 2H, 6-pyridine rings); 9.16 (d, 2H, 2-pyridine rings). ^{13}C NMR: δ 123.2, 125.4, 125.8, 130.2, 134.4, 134.94, 137.4, 149.8, 151.2, 153.6, 163.7. Elemental *Anal.* Calc. for $C_{26}H_{14}N_2O_6$: C, 69.33; H, 3.13, N, 6.22. Found: C, 69.17; H, 3.24; N, 6.10%.

2.3. Synthesis of 1,8-bis(thiazolyloxy)-9,10-anthracenedione (2)

Thiazole-4-carboxylic acid was purchased from Aldrich and reacted with 1,8-dihydroxyanthraquinone in a procedure identical to **1**, yielding a yellow solid in 98% yield. Melting point = 260–262 °C. ^{1}H NMR: 7.59 (d, 2H, 2,7-anthraquinone), 7.81 (t, 2H, 3,6-anthraquinone), 8.25 (d, 2H, 4,5-anthraquinone), 8.31 (d, 2H, 5-thiazole rings), 8.83 (d, 2H, 2-thiazole ring). Elemental *Anal.* Calc. for $C_{22}H_{10}N_2O_6S_2$: C, 57.14; H, 2.18; N, 6.06. Found: C, 56.63; H, 2.04; N, 5.97%.

2.4. Synthesis of [1,8-bis(nicotinyloxy)-9,10-anthracenedione · 2H](ClO$_4$)$_2$ (3)

Crystals of **3** are obtained by dissolving **1** in acetonitrile in the presence of a drop of concentrated perchloric acid. Lemon yellow colored crystals were obtained upon slow evaporation of the solvent. Elemental analyses confirm that the diprotonated form is produced. Melting point = 148–150 °C. Elemental *Anal.* Calc. for $C_{26}H_{16}N_2Cl_2O_{14}$: C, 47.95; H, 2.48; N, 4.30. Found: C, 48.09; H, 2.39; N, 4.53%. ESI-MS calculated for $[\mathbf{1}\cdot H]^+ = 451.4$; found 451.07 *m*/*z*.

2.5. Synthesis of [(1,8-bis(nicotinyloxy)-9,10-anthracenedione)$_2$ · Cd · (CH$_3$CN)$_2$](ClO$_4$)$_2$ (4)

0.040 g (0.088 mmol) of **1** was dissolved in 25 mL of CH_2Cl_2 and 0.014 g (0.044 mmol) of $Cd(ClO_4)_2\cdot H_2O$ in 10 mL CH_3CN was added to the ligand solution drop wise. The mixture was stirred for 3 h. A pale yellow colored solid was obtained, filtered and washed with diethyl ether. The solid was recrystallized in warm CH_3CN and yellow crystals were obtained. Melting point = 278–81 °C. ^{1}H NMR: 7.59 (d, 2H, 5-from pyridine); 7.81 (d, 2H, 2,7-anthraquinone); 8.12 (t, 2H, 3,6-anthraquinone); 8.53–8.57 (m, 4H, 4-pyridine rings + 4, 5-anthraquinone), 8.95 (d, 2H, 6-pyridine); 9.39 (s, 2H, 2-pyridine rings). ^{13}C NMR: δ 125.7, 127.7, 132.1, 136.3, 137.0, 140.2, 145.6, 151.6, 152.4, 154.9, 165.6. Elemental *Anal.* Calc. for $[Cd(\mathbf{1})_2(CH_3CN)_2](ClO_4)_2$; $C_{56}H_{34}N_6O_{20}Cl_2Cd$: C, 51.96; H, 2.65; N, 6.49. Found: C, 51.52; H, 2.46; N, 6.51%. ESI-MS calculated for $[Cd(\mathbf{1}_2)(ClO_4)]^+ = 1112.7$; found 1112.68 *m*/*z*.

2.6. Synthesis of [{1,8-bis(thiazolyloxy)-9,10-anthracenedione}Pb](ClO$_4$)$_2$ (5)

0.150 g (0.324 mmol) of ligand **2** was dissolved completely in 25 mL of a $CHCl_3/CH_3OH$ mixture (2:1 ratio). 0.149 g (0.324 mmol) of $Pb(ClO_4)_2\cdot 3H_2O$ was dissolved in 10 mL of CH_3OH and added to the ligand solution dropwise. The solution turns orange-brown and the mixture was stirred for 3 h and the solvent removed. The dried product was dissolved in CH_3CN and crystallized by vapor diffusion using diethyl ether. Elemental *Anal.* Calc. for $[Pb(\mathbf{2})](ClO_4)_2$; $C_{22}H_{10}Cl_2N_2O_{14}PbS_2$: C, 30.42; H, 1.16; N, 3.22. Found: C, 30.69; H, 1.42; N, 3.25%.

2.7. Synthesis of RuCl$_2$(1,8-bis(nicotinyloxy)-9,10-anthracenedione)(DMSO)$_2$ (6)

cis-$RuCl_2(DMSO)_4$ [19] (0.248 g, 0.51 mmol) and **1** (0.231 g, 0.51 mmol) were mixed in 40 mL of benzene and refluxed for 5 h. The mixture was cooled to room temperature and all solvent removed under reduced pressure. The residue was dissolved in 10 mL of methylene chloride and mixed with hexane. A yellow colored solid was

obtained, filtered and air dried. The product was dissolved in 20 mL of chloroform–methanol (8:2) mixture and diffused with hexane. Fine orange-colored blocks were obtained. Yield: 0.3 g (75%) and the melting point = 240–245 °C (dec.). ^{1}H NMR: δ 3.32 (s, 12H, coordinated DMSO); 7.45 (t, 2H, 5-pyridine); 7.60 (d, 2H, 2,7-anthraquinone); 7.86 (t, 2H, 3, 6 from anthraquinone); 8.24 (d, 2H, 4-pyridine); 8.39 (d, 2H, 4,5-anthraquinone); 9.95 (d, 2H, 6-pyridine) and 10.49 (s, 2H, 2-pyridine). ^{13}C NMR ($CDCl_3$, 25 °C): δ 45.2 (S-coordinated DMSO); 124.1, 125.9, 125.8, 127.0, 130.6, 134.5, 134.8, 139.2, 149.1, 154.5, 157.9, 163.5, 180.5, 181.6. Elemental *Anal*. Calc. for [Ru(**1**)Cl_2(DMSO)$_2$]; $C_{30}H_{26}Cl_2N_2O_8S_2Ru$: C, 46.28; H, 3.37; N, 3.60; S, 8.23. Found: C, 45.86; H, 3.81; N, 3.59; S, 7.67%. ESI-MS calculated for [Ru(**1**)Cl_2(DMSO)$_2$]: 778.7; found 779.00 *m*/*z*.

2.8. Synthesis of [Ru(1,8-bis(nicotinyloxy)-9,10-anthracenedione)(bpy)$_2$Cl]ClO$_4$ (7)

cis-$RuCl_2(bpy)_2 \cdot 2H_2O$ [20] (0.2311 g, 0.44 mmol) and ligand **1** (0.29 g, 0.44 mmol) were mixed together in 30 mL of 95% ethyl alcohol. This mixture was refluxed for 8 h under nitrogen atmosphere with constant stirring. The solution was cooled to room temperature and the solvents were evaporated under reduced pressure. The residue was dissolved in 10 mL of methanol and mixed with an excess of lithium perchlorate in water. A brick red colored precipitate was obtained. The solid was filtered, washed with a small amount of water, diethyl ether and dried under vacuum. The crude product was recrystallized from hot ethanol–ethyl acetate (2:1). Melting point is >200 °C (dec.). ^{1}H NMR (CD_3CN-d_6): 7.39 (d, 2H, bipyridine); 7.62–8.84 (m, 26H, anthraquinone + bipyridine); 9.78 (s, 2H, 2-pyridine rings). Elemental *Anal*. Calc. for [Ru(**1**)-(bpy)$_2$Cl]ClO_4; $C_{46}H_{30}N_6O_{10}RuCl_2$: C, 55.33; H, 3.00; N, 8.41. Found: C, 55.12; H, 3.05; N, 8.31%. ESI-MS calculated for $[RuCl(bpy)_2(\mathbf{1})]^+ = 899.3$; found 899.17 *m*/*z*.

2.9. X-ray crystallography

Crystallographic data for **3** and **4** were collected at 293(2) K using Mo Kα radiation on a Nonius CAD4 serial diffractometer. Cell constants were calculated from 25 reflections. Psi-scan data were used for absorption corrections. Date reduction and refinement were completed using the WinGX suite of crystallographic software [21,22]. Structures were solved using SIR-97 [23]. All hydrogen

atoms were placed in ideal positions and refined as riding atoms with relative isotropic displacement parameters. Table 1 lists additional crystallographic and refinement information. Compound **3** has one perchlorate, Cl(4), disordered over two positions in a 84:16 ratio. Crystals of compound **4** have one perchlorate rotationally disordered around the O(15)–Cl(1) bond in a 70:30 ratio, and a second perchlorate is also rotationally disordered around the O(17)–Cl(2) bond in a 77:23 ratio. Crystallographic data for **2** and **5** were collected at 173(2) K using Mo Kα radiation on a Bruker CCD diffractometer. Final cell constants were calculated from the *xyz* centroids of typically more than 3000 reflections from the data collection after integration [24]. Structures were solved by direct methods using SIR-97 [12] and refined using SHELXL-97 [25]. The high residual electron density in **5** is centered around the lead and is due to an absorption correction error. Attempts to correct for the error were unsuccessful.

3. Results

3.1. Synthesis and crystallography

Two new anthraquinone ligands containing nicotinyl (**1**) and thiazolyl (**2**) chelating elements have been synthesized beginning from common, inexpensive starting materials in high yield. Using a simple, one-step synthetic pathway, 1,8-dihydroxyanthraquinone and the corresponding carboxylic acids are condensed in a 1:2 molar ratio via the acid chloride (Scheme 1). Yields are almost quantitative and characterization is complete by NMR, elemental analyses, and X-ray crystallography.

The X-ray crystal structure of **3**, grown by evaporation of **1** in acetonitrile/perchloric acid, confirms the chelating potential of the bipodand and shows that both nicotinyl nitrogens have been protonated (Fig. 1). Hydrogen bonds exist between the protonated nitrogens and the perchlorate anions, N(1)–O(23) = 2.840(8) and N(2)–O(32) = 2.864 (8) Å. The two nicotinyl pyridine rings are parallel to each other with the two pyridine nitrogen atoms facing in opposite directions. The bond distances for the two nicotinyl carbonyls, C(15)–O(4) and C(21)–O(6), are 1.183(8) and 1.186(8) Å, respectively, and they also face in opposite directions. The quinone carbonyl bond distances, C(13)–O(1) and C(14)–O(2), equal 1.212(8) and 1.205(8) Å.

The crystal structure of the anthraquinone ligand (**2**) also confirms that two thiazolyl groups add to form the bis-substituted product (Fig. 2). Each side of the molecule is identical by symmetry and the thiazolyl rings are rotated 66.9° out of the plane of the anthraquinone. Thiazolyl carbonyl oxygen, nitrogen and sulfur atoms face in opposite directions and the anthraquinone is itself virtually planar producing π–π stacks with 3.6–3.7 Å separations. Because thiazole contains both basic nitrogen and sulfur Lewis sites, either heteroatom could potentially chelate with metal ions. Rotation of one of the thiazolyl ligands by 180°, orientates the nitrogens face-up towards the anthraquinone; while the sulfurs could also potentially orientate in a traditional chelating fashion with the opposite conformation of the thiazolyls.

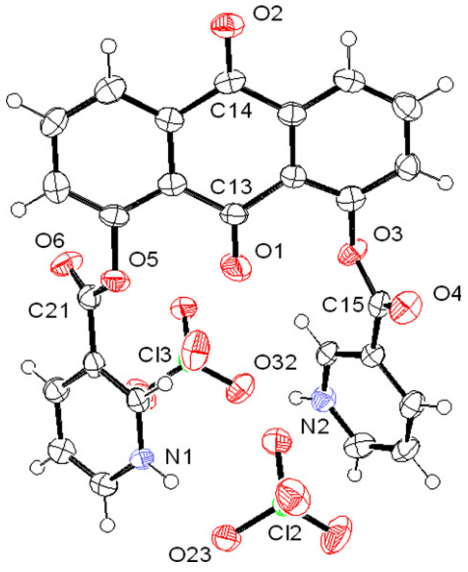

Fig. 1. Thermal ellipsoid diagram (50%) of [1,8-bis(nicotinyl)anthraquinone · 2H](ClO$_4$)$_2$ (**3**). Only one of the protonated 1,8-bis(nicotinyl)-anthraquinone adducts in the asymmetric unit is shown.

Preliminary exploration of the complexation chemistry of these ligands has been conducted using perchlorate salts of transition and main group metal ions and confirms that both **1** and **2** can act as chelating, polydentate ligands. Addition of two equivalents of **1** and one equivalent of cadmium perchlorate yields the bis-chelate complex **4**. Crystals grown from acetonitrile confirm that two bis-nicotinyl anthraquinone ligands chelate the cadmium metal center in an equatorial arrangement, which is capped axially by

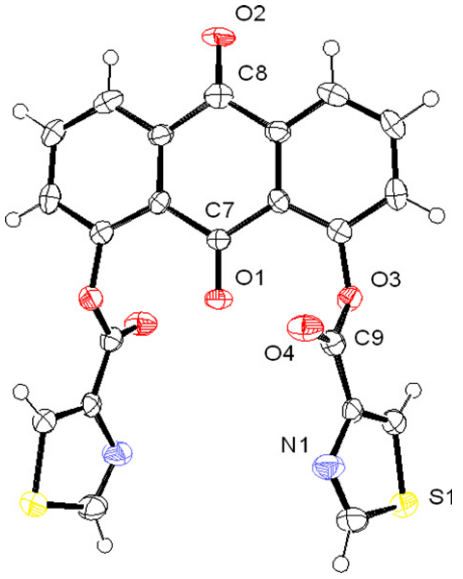

Fig. 2. Thermal ellipsoid diagram (50%) of 1,8-bis(thiazolyl)anthraquinone (**2**).

two acetonitrile ligands in a near perfect octahedral geometry (Fig. 3). Two nearly identical cadmium–nicotinic complexes comprise the asymmetric unit. The bond distances between the nicotinyl nitrogens and the cadmium average 2.36 Å, and the average bond distance between the cadmium and the acetonitrile nitrogen is approximately the same, 2.38 Å. In order to adopt a chelate structure, the nicotinyl carbonyl groups and the pyridine nitrogens orientate '*cis*' with respect to the anthraquinone plane, and the nicotinyl rings are rotated $51 \pm 4°$ out of the plane of the anthraquinone. The plane of the anthraquinone rings are slightly bent (8° and 10°, respectively, for the two complexes found in the asymmetric unit), and packing within the unit cell shows π–π stacking interactions between the anthraquinones (~3.5–3.6 Å separation). All the carbonyl carbon-oxygen bond distances in the structure are 1.20 ± 0.01 Å. Combination of cadmium perchlorate with three equivalents of **1** yields only the bis-substituted complex **4**, which may indicate a steric limitation to the number of bis-substituted anthraquinone ligands that can coordinate to metal centers.

In the case of the dithiolyl ligand **2**, a 1:1 complex forms between Pb^{2+} and **2** when combined together in equal amounts (Fig. 4). Crystals were grown from acetonitrile and show both thiazolyl units bind to the lead ion as a chelating bidentate ligand. A seven-coordinate Pb^{2+} complex forms where the coordination sphere is completed by one acetonitrile solvate, Pb(1)–N(3) = 2.653(9) Å, one H_2O molecule, Pb(1)–O(7) = 2.532(8) Å, and an additional oxygen from a nearby perchlorate anion, Pb(1)–O(8) = 2.837 (10) Å. The sulfur atoms do not participate in bonding in this structure. For the dithiazolyl ligand, bond distances between the thiazolyl nitrogens, N(1) and N(2), and the lead ion are identical, 2.624(8) Å and 2.625(8) Å. Bond distances from the metal to the carbonyl oxygens are unequal, however, Pb(1)–O(5) = 2.556(7) and Pb(1)–O(6) = 2.740(7) Å. To form the chelate, the carbonyl groups of the thiazolyl rings are located on the same side of the anthraquinone plane and the thiazolyls are rotated 53.7° and 61.1° out of the anthraquinone plane. The coordinated carbonyl bond distances are normal, C(15)–O(5) = 1.213(11) and C(19)–O(6) = 1.205(12) Å, and the anthraquinone carbonyl carbon-oxygen bond distances are very similar, C(6)–O(1) = 1.229(11) and C(13)–O(2) = 1.220(12) Å. A carbonyl oxygen, O(2), from a neighboring anthraquinone is the other closest coordinating atom with a bond distance of 3.27 Å from the lead. Hydrogen bonds also form between the water and the two perchlorate anions, O(7)–H···O(11) = 2.846(12) and O(7)–H···O(13) = 2.905(15). The anthraquinone plane is bent by 8.0°, and anthraquinones within the unit cell exhibit π–π stacking (3.7–3.8 Å separations).

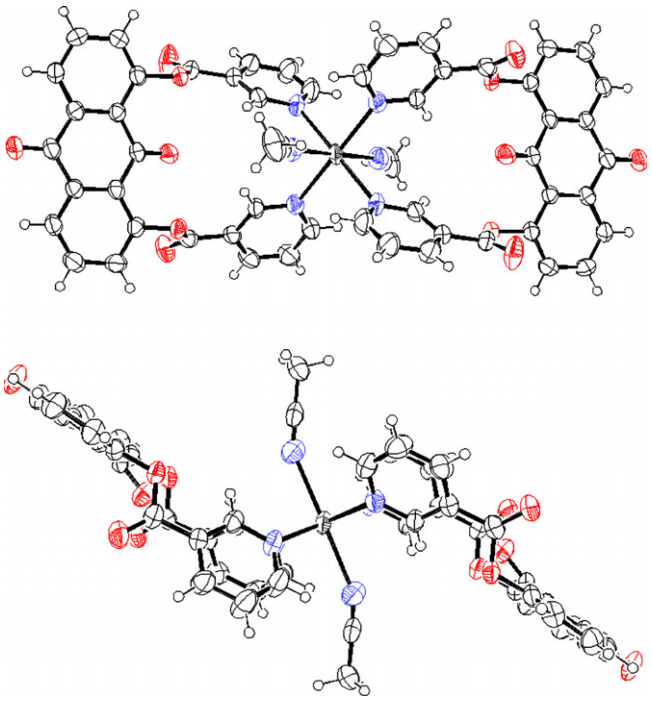

Fig. 3. Thermal ellipsoid diagrams (50%) of $[\{1,8\text{-bis(nicotinyl)anthraquinone}\}_2 \cdot Cd \cdot (CH_3CN)_2](ClO_4)_2 \cdot H_2O \cdot CH_3CN$ (**4**). The solvates and perchlorate anions have been removed for clarity. There are two nearly identical cadmium complexes within the asymmetric unit. Only one is shown.

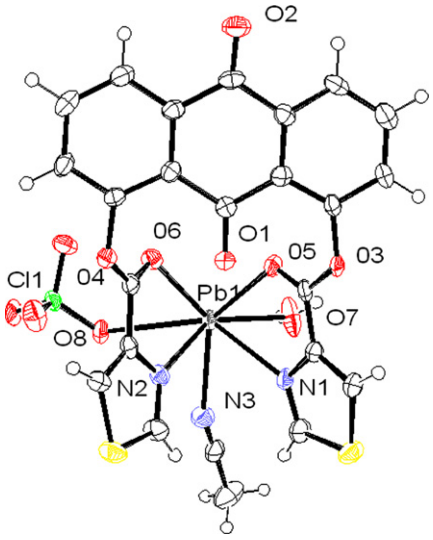

Fig. 4. Thermal ellipsoid diagram (50%) of $[(1,8\text{-bis(thiazolyl)anthraquinone})Pb \cdot CH_3CN \cdot H_2O](ClO_4)_2$ (**5**). One perchlorate anion has been removed for clarity.

3.2. Electrochemistry

$E_{1/2}$ values for free and complexed ligands were obtained by cyclic voltammetry in 0.1 M TBAH in either CH_2Cl_2 or DMF versus Ag/AgCl and are listed in Table 2. In all cases, the first, reversible one-electron reduction of the anthraquinone to the radical anion was observed at approximately −0.70 V in DMF and −0.90 V in CH_2Cl_2. The second one-electron anthraquinone reductions were within −1.03 to −1.14 V. Reduction of com-

pound **4** and **5** were conducted in DMF due to poor solubility in CH_2Cl_2 and is complicated by the reduction of M(II) at the same potential as the first one-electron anthraquinone reduction. This is confirmed by reduction of $[Cd(bpy)_3]^{2+}$ and $[Pb(bpy)_2]^{2+}$ under the same conditions which exhibit either quasi-reversible or irreversible reductions at the same potential [26–28].[1] Similar to **4**, $[Cd(bpy)_3]^{2+}$ has an inner coordination sphere that includes six nitrogen atoms.

Towards the goal of constructing complexes with potential electron transfer properties, ruthenium-containing anthraquinone compounds **6** and **7** were synthesized. Addition of equal molar ratios of **1** and *cis*-$RuCl_2(DMSO)_4$ results in substitution of two of the DMSO ligands by the chelating nicotinyl ligand to form $[RuCl_2(DMSO)_2(\mathbf{1})]$ (**6**). Elemental analyses, mass spectrometry and cyclic voltammetry confirm the formula and the presence of the anthraquinone in the complex. Two one-electron anthraquinone reductions are observed at almost the same potentials as the free ligand with the addition of the ruthenium III/II couple centered at $E_{1/2} = 1.09$ V (Fig. 5a). Reaction of compound **6** with 2,2′-bipyridine did not produce further substitution of the chloride or DMSO ligands, however, even using high boiling solvents such as ethylene glycol. Addition of Ag salts to **6** did not displace chloride, and reactions with an excess of **1** (up to three equivalents) with *cis*-$RuCl_2(DMSO)_4$ produced only compound **6**.

As an alternate route to synthesizing a ruthenium complex containing both an anthraquinone and a complete pyridyl coordination sphere, substitution of the chlorides in *cis*-$RuCl_2(bpy)_2$ by **1** was also attempted. Characterization data show that the resulting product does contain one molecule of **1**; however, only one of the nicotinic nitrogens is complexed to the ruthenium which forms $[RuCl(bpy)_2(\mathbf{1})]^{+}$ (**7**). Both elemental analyses and mass spec data (parent ion) indicate a chloride remains coordinated to the ruthenium and that **1** does not bridge two ruthenium metal centers to form a dimer. Reduction peaks for the anthraquinone as well as the bipyridine ligand are

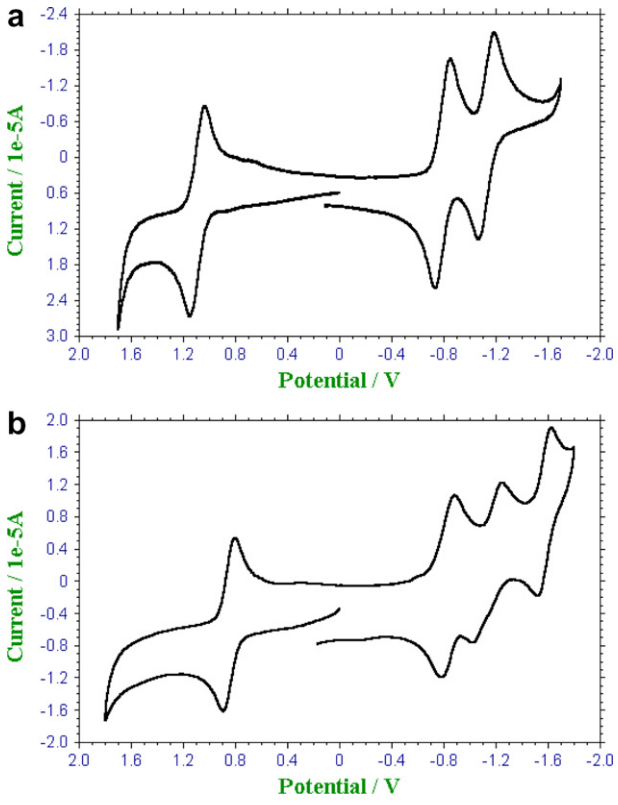

Fig. 5. Cyclic voltammograms of (a) 1.0 mM $[RuCl_2(DMSO)_2(\mathbf{1})]$ (**6**) and (b) 1.0 mM $[RuCl(bpy)_2(\mathbf{1})](ClO_4)$ (**7**) in CH_2Cl_2/0.1 M TBAH vs. Ag/AgCl on glassy carbon.

[1] We have determined that the addition of three equivalents of 2,2′-bipyridine to $Pb(ClO_4)_2$ results in the formation of the bis(bipyridine)lead(II) perchlorate complex. This is consistent with the X-ray structure of this complex reported in Ref. [28]. The X-ray crystal data for the hexafluorophosphate metathesis product, $[Pb(bpy)_2](PF_6)_2$, will be reported elsewhere.

well resolved in addition to the $Ru^{III/II}$ oxidation wave (Fig. 5b).

4. Discussion

Both cadmium(II) and lead(II) complexes of nicotinic acid have been previously synthesized. Often the nitrogen atom on the pyridine ring acts as a Lewis base and forms a number of monodentate ligand metal complexes [29–31]. Bidentate nicotinic cadmium complexes (binding through both the pyridine and carboxylate functionalities) have also been produced resulting in three-dimensional supramolecular structures [30]. Numerous 4,4′-bithiazole and thiazolylbenzimidazole complexes that contain the thiazolyl group have been reported in the literature; however, no metal complexes using thiazolyl itself have been reported; although the same type of bidentate chelating ability as **2** has been previously observed between lead(II) and *ortho*-substituted carboxylato-pyridine ligands [32]. Picolinic acid (containing a pyridine nitrogen located *ortho* to the carboxylic acid group) has the same arrangement of chelating nitrogen and oxygen atoms as thiazolyl and may be expected to exhibit the same type of coordination chemistry as **2**. However, we have been unsuccessful in synthesizing the disubstituted, picolinic–anthraquinone derivative, when substituting picolinic acid for nicotinic acid under the same reaction conditions as in the preparation of **1**.

On two occasions steric limitations in the coordination of these new ligands to metal centers have been observed. In the first case, only the bis-substituted complex **4** (Fig. 3) can be produced, even when an excess of **1** is employed in the synthesis, and the two chelating anthraquinone ligands remain decidedly *trans* to one another. In the second case, substitution of *cis*-$RuCl_2(bpy)_2$ with **1** does not produce a chelate complex, rather the anthraquinone ligand remains monodentate, even after extended treatment in higher boiling solvents.

The work by Hambley and co-workers [1] and Meyer and co-workers [18] report anthraquinones that are pendent to either cyclam or bipyridine groups coordinated to metal cations. The anthraquinones attached to these ligands are connected via short alkane or amide linkages. Crystallographic studies in the case of Hambley's anthraquinone–cyclam structure [1] show a metal–quinone carbonyl oxygen interatomic distance of 6.2 Å. Crystallographic data for Meyer's $[(AQbpy)Ru(bpy)_2]^{2+}$ complex is not available; however, molecular modeling studies indicate a metal–quinone oxygen interatomic distance ranging from 9 to 13 Å, depending upon the conformation of the connecting chain. In comparison, the interatomic, through-space distances between the metal centers and the intraannular anthraquinone carbonyl oxygen in **4** and **5** are much shorter than previously observed. In **4** this distance equals 5.6 Å, while the interatomic distance between the lead and the carbonyl oxygen in **5** is much shorter due to coordination of the thiazolyl carbonyl oxygen and is equal to 4.4 Å. However, electrochemical evidence suggests that no electrostatic communication between the metal centers and the quinones are established. Although the first one-electron reduction in **4** is obscured by the overlapping $cadmium^{0/II}$ reduction, the second one-electron reduction is still observed at approximately the same reduction potential as the free ligand. The close proximity of the electropositive metal center near the intraannular quinone oxygen would produce an anodic shift in reduction potential, which does not seem to occur for **4**. For **5** where the anthraquinone carbonyl is much closer to the metal center (4.4 Å), the second one-electron reduction is unfortunately not observed likely due to passivation of the electrode surface by the $Pb^{0/II}$ reduction at -0.72 V making any metal–quinone interaction unobservable. The first one-electron reductions in the ruthenium complexes **6** and **7** are observed at slightly more anodic potentials than the free ligands, but this can be attributed to an electronic inductive effect due to the greater charge-to-size ratio of the ruthenium metal center. The potentials of the second one-electron reductions in **6** and **7** remain unchanged.

5. Conclusion

Two new chelating anthraquinone ligands have been made and the complexation chemistry with transition and main group metals has been explored. Nicotinyl and thiazolyl ligands, pendent to the anthraquinone, are free to rotate as observed by the '*trans*' conformations in the protonated and free ligands (structures **2** and **3**) versus the '*cis*' conformations of the metal complexes **4** and **5**. These new ligands represent a new architecture that involves a chelating approach rather than singly-attached pendant anthraquinones as has been demonstrated in the past and should be amenable to incorporation into a wide variety of different metal complexes and applications. Two different chelating geometries have been demonstrated: (a) using the bidentate chelating anthraquinone–nicotinyl ligand **1**, and (b) using the tetradentate chelating anthraquinone-thiazolyl ligand **2**, which has not previously been demonstrated. Quinone reduction chemistry is complicated by overlapping metal-centered reductions, but initial results indicate that electrostatic interaction between the metal center and the intraannular carbonyl does not take place. We are currently exploring the synthesis of other bis and possibly tris-substituted anthraquinone complexes using ligands of this type. We are also pursuing the coordination chemistry of the 1,8-bis(isonicotinyl)anthraquinone derivative, where the pyridine nitrogens are located in the *para* positions and has the potential to form new bridging anthraquinone metal complexes.

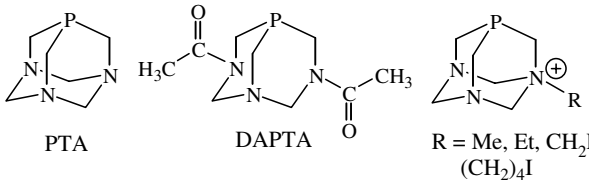

Fig. 1. 1,3,5-Triaza-7-phosphaadamantane (PTA) and some of its derivatives.

has recently been extensively studied [9]. While the water-solubility of PTA is approximately 1.5 M [10], the solubility of its complexes is variable and is sometimes extremely low [11]. This is problematic in that its ultimate utility is as a ligand for aqueous catalysis. In fact, PTA complexes have recently been shown to catalyze many hydrogenations reactions [12] and the intramolecular hydroamination of alkynylamines [11a,13] in water (see Fig. 1).

In an effort to enhance the water-solubility of the phosphine and its metal complexes, PTA has been derivatized by reacting it with acetic anhydride [10], MeI [8] or MeO-SO_2CF_3 [14], EtI [15], $I(CH_2)_4I$ [16], and $PhCH_2Cl$ [17] to respectively form the di-*N*-acylated compound 3,7-diacetyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]nonane (DAPTA), and the *N*-alkylated compounds [PTA(R)]X (R = Me, Et, $(CH_2)_4I$, and CH_2Ph). A library of water-soluble ligands, such as this, is important in that it allows for the preparation of a series of metal complexes that differs by only the phosphine, and this may permit the electronic properties of the compounds to be tuned. For example, it was recently shown that the oxidation potentials of $[CpRuL_2X]$ (L = PTA, $PTA(Me)^+$; X = I, Cl) complexes could be raised by over 300 mV by switching from PTA to $[PTA(Me)]^+$ [18].

To further add to the existing library of water-soluble phosphines, the di-*N*-formylated analog of DAPTA, 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]nonane (**1**, DFPTA), and the *N*-methylpyridyl derivative of PTA, 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (**2**, [pymePTA]Br) were prepared, fully characterized, and their solubilities explored. Compound **1** is only the second acyl derivative of PTA to be prepared while **2** is only the second derivative of PTA reported that contains an aromatic appendage. The findings of this study are presented herein.

2. Experimental

2.1. Methods, measurements, and materials

All manipulations were carried out under a purified N_2 atmosphere with use of standard Schlenk techniques unless otherwise noted. This airless procedure was used even though the final compounds were air stable. Elemental analyses were carried out by Galbraith Laboratories, Inc., Knoxville, TN. Fast atom bombardment mass spectrometric (FAB-MS) experiments were carried out at Michigan State University with the use of a JEOL HX-110 double-focusing mass spectrometer. Infrared spectra were measured in KBr pellets on a Jasco 460 Plus spectrometer. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded at 300 MHz and 75.5 MHz respectively, with use of a Bruker ARX 300 MHz spectrometer. $^{31}P\{^1H\}$ NMR spectra were recorded at 121.5 MHz on a Varian Mercury 300 MHz spectrometer. The ^{13}C and ^{31}P spectra were run with proton decoupling and ^{31}P spectra are reported in ppm relative to an external H_3PO_4 standard, with positive shifts down field. ^{13}C NMR spectra are reported in ppm relative to external tetramethylsilane (TMS), with positive shifts downfield. The solvents were distilled and dried prior to use. Formic acid, 1,3-dicyclohexylcarbodiimide (DCC), and 2-bromomethylpyridine hydrobromide were obtained from Aldrich and used without further purification. 1,3,5-Triaza-7-phosphaadamantane (PTA) was prepared as described in the literature [8].

2.2. Synthesis of compounds

2.2.1. 3,7-Diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]heptane (*1*, DFPTA)

A 100 mL Schlenk flask was charged with a 6.56 g (31.8 mmol) sample of 1,3-dicyclohexylcarbodiimide (DCC) and 25 mL diethyl ether and put into a −5 °C KCl-ice bath. A separate 100 mL Schlenk flask was charged with 2.50 mL formic acid (66.3 mmol) and 25 mL diethyl ether and put into a −5 °C KCl-ice bath. The DCC solution was added to the formic acid under N_2 over a 10 min period to form a colorless solution of formic anhydride and solid 1,3-dicyclohexylurea. A 250 mL round-bottom flask equipped with a jacketed frit, gas inlet, and rubber septum was charged with 1.01 g PTA (6.43 mmol) and 20 mL H_2O. The jacketed frit and round-bottom flask were then cooled to −5 °C. After stirring for 90 min at −5 °C, the formic anhydride/1,3-dicyclohexylurea slurry was transferred under N_2 to the jacketed frit. This mixture was filtered over a 10-min period into the 250 mL round-bottom flask to remove the 1,3-dicyclohexylurea. After stirring for 15 min at −5 °C, vacuum was applied to the reaction for 30 min to remove the diethyl ether. After this time, the solution was stirred at 0 °C for an additional 30 min. The cloudy solution was cold filtered in the air into a 100 mL round bottom flask that was previously cooled to 0 °C. Over a 10 min period, 6.85 mL of cold $NHEt_2$ (66.2 mmol) was added dropwise to deprotonate any remaining formic acid. The solution was transferred to the rotary evaporator and vacuum was applied at 5 °C. Under vacuum, the solution was allowed to gradually warm to 20 °C and ultimately to 35 °C. The solvents were removed in vacuo to form a white residue. 10 mL of 95% EtOH was added to the flask to dissolve any ammonium salts that may have formed during the workup. The slurry was stirred for 15 min and filtered on a medium frit. The resulting white solid was washed with EtOH (2 × 5 mL), DMSO to remove unreacted PTA

(2×3 mL), and Et_2O (3×5 mL), and dried in vacuo (yield: 655 mg, 3.25 mmol: 50.5% calculated for PTA). Compound **1** was recrystallized by two methods. Needles that were not suitable for X-ray analysis were grown by layering a CH_2Cl_2 solution of **1** with Et_2O. X-ray quality crystals of **1** were prepared by the slow evaporation of solvent from a CH_2Cl_2 solution. Data for **1** were as follows. Elemental *Anal*. Calc. for $PO_2N_3C_7H_{12}$ (mol. wt. 201.17): C, 41.79; H, 6.01; N, 20.89. Found: C, 41.42; H, 6.01; N, 20.37%. IR (KBr): ν(C=O) 1670 (br) cm^{-1}; ν(C(O)–H) 2785, 2801 (br) cm^{-1}. ^1H NMR ($CDCl_3$, 20 °C): δ 3.39 (m, $J_{H^AH^B} = 2.6$ Hz, $J_{PH} = 15.4$ Hz, 1H, PCH^AH^BN); δ 3.75 (d, $J_{PH} = 11.7$ Hz, 2H, PCH_2N); δ3.85 (d of d, $J_{H^AH^B} = 2.6$Hz, $J_{PH} = 15.4$ Hz, 1H, PCH^AH^BN); δ 4.09 (d, $J_{H^AH^B} = 14.3$ Hz, 1H, NCH^AH^BN); δ 4.16 (d, $J_{H^AH^B} = 14.3$ Hz, 1H, NCH^AH^BN); δ 4.64 (m, $J_{H^AH^B} = 5.4$ Hz, $J_{PH} = 10.5$ Hz, 2H, PCH^AH^BN); δ 4.99 (d, $J_{HH} = 14.4$ Hz, 1H, NCH^AH^BN); δ 5.52 (d, $J_{HH} = 14.4$ Hz, 1H, NCH^AH^BN); δ7.90 (s, 1H, C(O)H); δ7.95 (s, 1H, C(O)H). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 20 °C): δ36.37 (d, $J_{PC} = 27.6$ Hz, PCH_2N); δ 42.51 (d, $J_{PC} = 27.6$ Hz, PCH_2N); δ 48.40 (d, $J_{PC} = 18.4$ Hz, PCH_2N); δ 60.40 (s, NCH_2N); δ 67.25 (s, NCH_2N); δ 161.43 (d, $J_{PC} = 11.6$ Hz C(O)H); δ162.33 (d, $J_{PC} = 10.5$ Hz, C(O)H). $^{31}P\{1H\}$ NMR ($CDCl_3$, 20 °C): $\delta -74.2$ ppm. FABMS (*m*-nitrobenzyl alcohol matrix): observed *m*/*z* 202.2 {calc. 202.2 for $PO_2N_3C_7H_{13} = MH^+$}.

2.2.2. 1-Pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (*2*, *[pymePTA]Br*)

A 1.65 g sample of $Na_2CO_3 \cdot H_2O$ (13.3 mmol)was dissolved in 5 mL of H_2O in the air. A 0.169 g sample of 2-bromomethylpyridine hydrobromide (0.668 mmol) was dissolved in 1 mL H_2O in the air. In the absence of light, the pyridinium salt was added to the base over a 10 min period to form a red solution. After 60 min, the organic product was extracted with Et_2O (3×10 mL). The ethereal solution was dried over magnesium sulfate, transferred to a 100 mL Schlenk flask and degassed. A 100 mL, 3-necked, round-bottom flask equipped with a reflux condenser, gas inlet, and rubber septa was charged with 0.100 g PTA (0.636 mmol) and 25 mL acetone. The solution of 2-bromomethylpyridine was added to the 3-necked flask via cannula, and the ether was removed in vacuo. The resulting clear, colorless solution was heated to reflux in the absence of light. Within 2 min, a white solid formed. After refluxing for 30 min, the mixture was cooled to room temperature. The white precipitate was collected on a frit, washed with acetone (2×5 mL) and Et_2O (3×5 mL), and dried in vacuo (yield: 139 mg, 0.422 mmol: 66.5% calculated for PTA). Compound **2** was recrystallized by layering a wet MeOH solution with Et_2O. Data for **2** were as follows: Elemental *Anal*. Calc. for crystalline $PBrN_4C_{12}H_{18} \cdot H_2O$ (mol. wt. 347.19): C, 41.51; H, 5.81; N, 16.14. Found: C, 41.79; H, 5.72; N, 15.98%. ^1H NMR (d_6-DMSO, 20 °C): δ 3.84, 3.89 (m, $J_{H^AH^B} = 14.7$ Hz, $J_{PH^A} = 13.8$ Hz, $J_{PH^B} = 9.9$ Hz, 4H, PCH^AH^BN); δ4.24 (s, 2H, CCH_2N^+); δ 4.36 (d, $J_{PH} = 6.3$ Hz, 2H, PCH_2N^+);δ 4.41 (d, $J_{H^AH^B} = 13.2$ Hz, 1H, NCH^AH^BN); δ 4.55 (d, $J_{H^AH^B} = 13.2$ Hz, 1H, NCH^AH^BN); δ 5.05 (d, $J_{H^AH^B} = 11.4$ Hz, 2H, $NCH^AH^BN^+$); 5.18 (d, $J_{H^AH^B} = 11.4$ Hz, 2H, $NCH^AH^BN^+$); δ7.56 (m, 1H, H_{py}); δ 7.66 (d, $J_{HH} = 7.8$ Hz, 1H, H_{py}); δ 7.98 (t, $J_{HH} = 7.8$ Hz, 1H, H_{py}); δ8.74 (d, $J_{HH} = 4.5$ Hz, 1H, H_{py}). $^{13}C\{^1H\}$ NMR (d_6-DMSO, 20 °C): δ 46.17 (d, $J_{PC} = 20.4$ Hz, PCH_2N); δ 53.01 (d, $J_{PC} = 32.4$ Hz, PCH_2N^+); δ 66.24 (s, $pyCH_2N^+$); δ79.98 (s, NCH_2N); δ 79.98 (s, NCH_2N^+); δ 125.64 (s, C_{py}); δ128.72 (s, C_{py}); δ138.46 (s, C_{py}); δ148.39 (s, C_{py}); δ150.95 (s, C_{py}). $^{31}P\{1H\}$ NMR (d_6-DMSO, 20 °C): δ −82.8 ppm. FABMS (*m*-nitrobenzyl alcohol matrix): observed *m*/*z* 249.2 {calc. 249.3 for $PN_4C_{12}H_{18} = M^+$}.

2.3. X-ray structure determination of 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]heptane (*1*, *DFPTA*) and 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (*2*, *[pymePTA]Br*)

2.3.1. Collection and reduction of data

A summary of crystallographic data for **1** and **2** are presented in Table 1 and as Supplementary Material. An X-ray quality crystal of **1** was prepared by the slow evaporation of solvent from a CH_2Cl_2 solution. An appropriate crystal of **2** was prepared by layering a methanol solution with Et_2O. Compound **1** was mounted on a thin glass fiber while **2** was mounted in a glass capillary. Both samples were transferred to a Bruker/Nonius MACH3S diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Relevant crystallographic information is given in Table 1. Unit cell constants were determined from a least squares refinement of the setting angles of 25 machine-centered reflections in the range $8.63° < \theta < 16.21°$ for **1** and 24 reflections in the range $5.34° < 2\theta < 34.24°$ for **2**. Intensity data was collected using the $\omega/2\theta$ scan technique to a 2θ maximum value of 53.90° for **1** and 43.9° for **2**. The sample of **2** had very limited intensity beyond 22°θ. An absorption correction was not applied for **1** as the calculated maximum and minimum transmission factors differed by less than 5%. An absorption correction, based on azimuthal scans of three reflections, was applied for **2** which resulted in transmission factors ranging from 0.49 to 1.00. A correction for crystal decay was not required for either sample. The intensity data of **1** were corrected for Lorentz and polarization effects and converted to structure factors using the program XCAD4 [19].

2.3.2. Solution and refinement of structure

Systematic absences, packing considerations, and a statistical analysis of intensity distribution allowed the space groups of **1** and **2** to be determined as $C2/c$ and $R\bar{3}$, respectively. Successful direct-methods solutions were calculated which provided the positions of most of the non-hydrogen

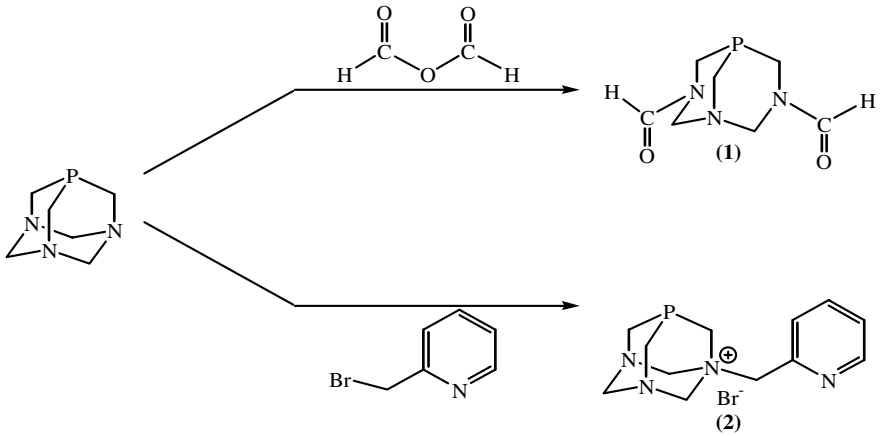
atoms of **1**. The remaining non-hydrogen atoms were located after several cycles of structure expansion and full-matrix least squares refinement. The structure of **2** was solved by direct methods and expanded using Fourier techniques. All non-hydrogen atoms of **1** and **2** were refined with anisotropic displacement parameters. The hydrogen atoms of **1** were added geometrically unless otherwise noted. Carbon-bound hydrogen atoms of **1** were refined as riding atoms with group isotropic displacement parameters fixed at $1.2 \times U_{eq}$ of the host carbon atom. The hydrogen atoms of **2** were included but not refined. The final difference map of **1** was featureless, with the largest residual peak (0.34 e$^-$ Å^{-3}) located 0.91 Å from C1. The maximum and minimum peaks on the final difference Fourier map of **2** corresponded to 1.42 and −0.81 e$^-$ Å^{-3}, respectively. The final structure of **2** had three independent bromide ions, each residing on a special position with 1/3rd occupancy.

2.4. Water solubility of *1* and *2*

The water-solubility of compounds **1** and **2** were quantified by the slow addition of water via 100 μL syringe to a 100 mg sample of the respective phosphine. The process was repeated several times. In a typical trial, a 450 μL aliquot of water was required to dissolve 100 mg of **1** and a 125 μL aliquot was required for **2**.

3. Results

3.1. Synthesis and spectroscopic characterization of *3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]heptane (1, DFPTA) and 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (2, [pymePTA]Br)*



Characterization data for compounds **1** and **2** are included in Section 2 and, when appropriate, discussed below.

DAPTA is quite water-soluble (7.4 M), but its neutral metal complexes often have very limited water-solubility [10]. It was hypothesized that this problem could be alleviated by preparing a related ligand that contained less carbon. To probe this theory, the di-*N*-formylated analog of DAPTA, 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo [3.3.1]- nonane (**1**, DFPTA) was synthesized by producing formic anhydride in situ [20] and reacting it with an aqueous solution of 1,3,5-triaza-7-phosphaadamantane (PTA) at −5 °C. Upon low temperature removal of the solvent and work-up in ethanol, **1** was produced in good yield. Once isolated, compound **1** was found to be air and thermally stable.

To further add to the existing library of water-soluble phosphines, the *N*-pyridylmethyl derivative of PTA, 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1] decane bromide (**2**, pymePTA), was prepared. This was accomplished by deprotonating 2-bromomethylpyridine hydrobromide [21] and refluxing the resulting amine in an acetone solution of PTA. After 30 min, **2** precipitated in good yield as an air stable, white solid (see Scheme 1).

Fast atom bombardment–mass spectrometry and elemental analysis data were employed to confirm the empirical formulae of compounds **1** and **2** as $PO_2N_3C_7H_{12}$ and $PBrN_4C_{12}H_{18}$, respectively. The IR spectrum of **1** possessed an intense band at 1670 cm^{-1} (br) and two smaller signals at 2785 and 2801 cm^{-1} (br) that were collectively indicative of a formamide functionality. The C=O stretch is 30 cm^{-1} higher than that of the acetyl analog ($\nu_{co} = 1640$ cm^{-1}) [10]. A shift of this magnitude is common when comparing formamides and acetamides. For example, the C=O stretch of DMF appears at 1675 cm^{-1} and the corresponding resonance of *N*,*N*-dimethylacetamide is at 1646 cm^{-1}.

The most striking features of the ^{1}H NMR spectrum of **1** were the sharp singlets at 7.90 and 7.95 ppm, the expected region for formamide protons. The presence of two formamide signals indicated that the C=O moieties were in an *anti*conformation [10]. This hypothesis was confirmed by the presence of two doublets at 4.99 and 5.52 ppm that possessed identical $^2J_{H-H}$ values of 14.4 Hz. These signals were due to the geminal protons of one of the N–CH_2–N moieties (Fig. 2). The axial proton (H_A) appeared further down field than its equatorial counterpart because it was more shielded by the C=O group on the adjacent N than was the equatorial proton (H_B).

Scheme 1. The synthetic reactions which formed DFPTA (**1**) and [pymePTA]Br (**2**).

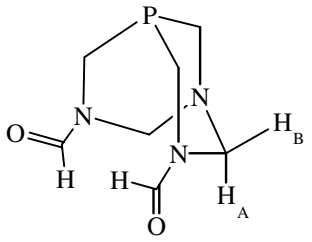


Fig. 2. The *anti* confirmation of DFPTA (**1**).

The fact that each doublet integrated as only 1 proton indicated that the hydrogens of the other N–CH_2–N group must not encountering this shielding, and hence that the adjacent C=O group must be in a different confirmation.

The presence of two inequivalent formamide groups was further confirmed by the ^{13}C NMR spectrum. Two doublets were observed at 161.4 and 162.3 ppm ($^3J_{P-C}$ = 11.6 Hz and 10.5 Hz), and these corresponded to the C atoms of the N*C*(O)H moieties. It is interesting to note that the ^{31}P coupling encountered by these C atoms was not observed with the C atoms of the N–C–N groups even though they were also 3 bond lengths away from the P. These C atoms were simply observed as singlets at 60.40 and 67.25 ppm. The P–C–N carbons were observed as doublets at 36.37, 42.51, and 48.40 ppm with $^1J_{P-C}$ coupling constants of 27.6, 27.6, and 18.4 Hz, respectively.

As is often the case with *N*-alkyl derivatives of PTA [22], the ^1H NMR spectrum of [pymePTA]Br (**2**) was more complicated than that of its precursor. The reduction of molecular symmetry from that of PTA caused the methylene protons of **2** to become inequivalent, and in some cases, to be diastereotopic. As a result, these hydrogens were observed as doublets with either phosphorous-proton or proton–proton coupling. For example, the N–CH_2–N protons appeared as two separate doublets at 4.41 ppm and 4.55 ppm with identical $^2J_{H-H}$ coupling constants of 13.2 Hz. A similar set of doublets ($^2J_{H-H}$ = 11.4 Hz) was observed further downfield at 5.05 and 5.18 ppm. These corresponded to the geminal N–CH_2–N^+ protons. The ^1H spectrum of **2** also showed the presence of a pyridyl moiety. The methylene group that linked the PTA moiety to the aromatic ring appeared as a sharp singlet at 4.24 ppm, and the four protons of the ring produced a multiplet, a doublet, a triplet, and another doublet at 7.56, 7.66, 7.98, and 8.74 ppm with $^3J_{HH}$ coupling constants on the order of 4.5 or 7.8 Hz. The presence of a pyridine ring was further proven by the 5 singlets of the ^{13}C spectrum at 125.64, 128.72, 138.46, 148.39, and 150.95 ppm. The carbon atoms of the $pyCH_2N^+$, NCH_2N, and NCH_2N^+ moieties also appeared as singlets at 66.24, 69.98, and 79.98 ppm, respectively. Due to P–C coupling, the PCH_2N and PCH_2N^+ carbons appeared as doublets at 46.17 and 53.01 ppm with $^1J_{P-C}$ values of 20.4 and 32.4 Hz, respectively. This is similar to the ^{13}C spectrum of the benzyl analog [23]. As expected, the $^{31}P\{^1H\}$ spectra of **1** and **2** were very simple. Each contained only a singlet at −74.2 ppm and −82.8 ppm, respectively.

*3.2. Crystallographic characterization of 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]heptane (**1**, DFPTA) and 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (**2**, [pymePTA]Br)*

*3.2.1. Solid-state structure of 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]nonane (**1**, DFPTA)*

An X-ray quality, colorless block crystal of compound **1** was formed by the slow evaporation of a CH_2Cl_2 solution, and it was found to form in the *C*2/*c* space group. Table 1 contains the collection parameters and crystallographic data of the experiment. The structure of the phosphine is shown in Fig. 3. Selected interatomic distances and angles are given in Table 2. Additional crystallographic data are provided as Supplementary Material.

The geometry about the P was compressed pyramidal as evidenced by the small C–P–C bond angle average of 98.36(10)°. N(3) also possessed a distorted pyramidal

Table 2
Selected bond distances (Å) and bond angles (°) with estimated standard deviations of 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]nonane (**1**, DFPTA)

Bond distances			
P1–C1	1.847 (2)	C6–O1	1.218 (3)
N1–C1	1.456 (3)	C7–O2	1.223 (3)
N1–C6	1.339 (3)		
Bond angles			
C1–P1–C2	102.89 (10)	C4–N3–C5	115.13 (18)
C1–P1–C3	95.72 (10)	C1–N1–C6	120.48 (19)
C2–P1–C3	96.47 (11)	C1–N1–C5	117.69 (17)
C3–N3–C4	111.92 (18)	C5–N1–C6	121.82 (19)
C3–N3–C5	112.22 (17)	N1–C6–O1	125.0 (2)

geometry but deviated less from ideality as shown by an average C–N–C bond angle of 113.09(18)°. The average C–N–C bond angles around N(1) and N(2) were 120.00(19)° and 119.92(19)°, respectively thus illustrating that the geometry around each of these atoms was trigonal planar, and hence, that they were involved in forming a Schiff base (N=C) double bond. This was supported by the observation that the N(1)–C(6) and N(2)–C(7) bond lengths (each 1.339(3) Å) were shorter than the other N–C bond lengths within the molecule (1.444(3)–1.467(3) Å). Darensbourg reported a similar finding with the acetyl analog, DAPTA [10], and it is believed that this character caused the phosphine to exhibit remarkable water-solubility. The solid-state structures of **1** and DAPTA differ in two important ways. First, the average P–C bond distance in **1** (1.849(3) Å) was substantially longer than the corresponding average (1.728(14) Å) of DAPTA [10]. The average P–C length of **1** was instead similar to that of PTA (1.857(3) Å) [24]. Second, the C(O)R (R = H, CH_3) moieties were *syn* to each other in **1** but *anti* to each other in DAPTA. The *anti* confirmation of **1** was observed, but only in solution (vide supra).

*3.2.2. Solid-state structure of 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (**2**, [pymePTA]Br)*

X-ray quality crystals of **2** were grown by slow diffusion of Et_2O into a MeOH solution of [pymePTA]Br. Complex **2** was found to crystallize in an R-centered trigonal cell (laue class: −3). Experimental data are presented in Table 1. A thermal ellipsoid representation of **2** is shown in Fig. 4. Selected interatomic distances and angles are given in Table 3 while complete crystallographic data are provided as supplementary material.

The small average C–P–C bond angle (96.6(5)°) illustrated that the geometry about the P of **2** was compressed pyramidal. This is more compact that the average C–P–C bond angle of **1** and comparable to the corresponding angle of PTA (96.1(1)°) [17]. The geometries around N(2) and N(3) were also distorted pyramidal but deviated less from ideality as shown by average C–N–C bond angles of 110.8(8)° and 111.1(9)°, respectively. A nearly ideal, tetrahedral geometry was observed around the quaternary nitrogen, N(1), as evidenced by its average C–N–C bond angle of 109.8(7)°. The average N–C bond distance involving this nitrogen (1.53(1) Å) was slightly longer than that around N(2) (1.45(1) Å) and N(3) (1.46(2) Å). A similar

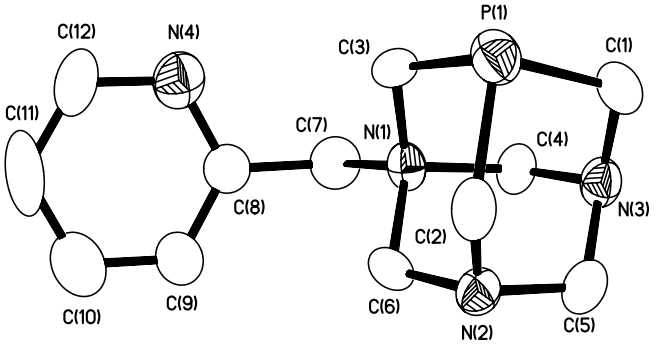

Fig. 4. Thermal ellipsoid representation of 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (**2**, [pymePTA]Br). Thermal ellipsoids are drawn at the 50% probability level.

Table 3
Selected bond distances (Å) and bond angles (°) with estimated standard deviations for 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]-decane bromide (**2**, [pymePTA]Br)

C2–P1–C3	96.5 (6)	C8–N4–C12	117 (1)
C3–N1–C4	109.2 (8)	C8–C7–N1	114.7 (7)

result has previously been observed with the *N*-butyl iodide analog of PTA, [PTA-$(CH_2)_4$ I]I [16]. In this species, the average N–C bond length about the quaternary N was 1.53 Å while the average N–C bond length around the remaining N atoms was 1.44 Å. The N–C(alkyl) bond lengths of **2** and [PTA-$(CH_2)_4$I]I were comparable as the N(1)–C(7) distance of **2** was 1.52(1) Å and the N–C span of the *N*-butyl iodide analog was 1.53 Å [16].

*3.3. Solubility studies of 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]heptane (**1**, DFPTA) and 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (**2**, [pymePTA]Br)*

The primary purpose of this study was to prepare phosphines that could possibly function as water-soluble ligands. Therefore, the solubilities of **1** and **2** in aqueous and organic media were examined.

Compound **1** was found to be insoluble in DMSO and only sparingly soluble in halogenated hydrocarbons and alcohols. This is in marked contrast from its acetyl analog, DAPTA, which was reported to be soluble in many common organic solvents and water [10]. In fact, the water-solubility of DAPTA was reportedly quite high (7.4 M). Unfortunately, in this study, only 1.1 M aqueous solutions of **1** could be prepared. This is quite striking in light of the fact that both DFPTA (**1**) and DAPTA form Schiff bases, and it is believed that this characteristic gives DAPTA its remarkable water solubility [10].

The solubility of compound **2** in the previously mentioned organic solvents was found to be better than that of **1**. The improved solubility in halogenated hydrocarbons is surprising in light of the fact that **2** is an ionic compound while **1** is neutral. Not surprisingly, this characteristic caused **2** to be much more water-soluble than **1**. In fact, the water-solubility of **2** was found to be 2.4 M. This solubility is greater than that of PTA (1.5 M) [10] and even the trisulfonated derivative of triphenylphosphine, TPPTS (1.9 M) [24].

4. Conclusion

Through this study, two new phosphines have been added to the library of water-soluble ligands. The second acyl derivative of PTA, 3,7-diformyl-1,3,7-triaza-5-phosphabicyclo[3.3.1]heptane (**1**, DFPTA), and the second derivative of PTA containing an aromatic appendage, 1-pyridylmethyl-3,5-diaza-1-azonia-7-phosphatricyclo[3.3.1.1]decane bromide (**2**, [pymePTA]Br), have been prepared and fully characterized. The solubility of **1** in all solvents, including water, was far less than that of its acetyl analog, DAPTA. This was surprising in light of the fact that both species were believed to from Schiff bases. Phosphine **2** was found to be more soluble than **1** in water and common organic solvents, including halogenated hydrocarbons. We are presently expanding this work to further derivatize PTA with hopes of increasing the water-solubility of the ligand and its transition metal complexes.

(H_2L)

In the present work, we have used the Schiff base H_2L which is analogous to H_2salhn to look at the efficacy of a sterically bulky N_2O_2-donor diazine system (L^{2-}) in providing dinuclear triple helical structures. Three dinuclear complexes of manganese(III), iron(III) and cobalt(III) are synthesized. In the following account, the characterization and the physical properties of $[Mn_2(\mu\text{-}L)_3]$ (**1**), $[Fe_2(\mu\text{-}L)_3]$ (**2**) and $[Co_2(\mu\text{-}L)_3]$ (**3**) are described. The triple helical structures of **2** and **3** are confirmed by X-ray crystallography.

2. Experimental

2.1. Materials

The Schiff base H_2L was prepared in ~90% yield by reacting one mole equivalent of hydrazine with two mole equivalents of 2-hydroxy-1-naphthaldehyde in methanol [32,35–38]. All other chemicals and solvents used in this work were of analytical grade available commercially and were used without further purification.

2.2. Physical measurements

Microanalytical (C, H, N) data were obtained with a Thermo Finnigon Flash EA1112 series elemental analyzer. Infrared spectra were collected by using KBr pellets on a Jasco-5300 FT-IR spectrophotometer. Solution electrical conductivities were measured with a Digisun DI-909 conductivity meter. A Shimadzu 3101-PC UV/vis/NIR spectrophotometer was used to record the electronic spectra. The proton NMR spectrum of $[Co_2(\mu\text{-}L)_3]$ (**3**) was recorded with the help of a Bruker 400 MHz NMR spectrometer. The variable temperature (18–300 K) magnetic susceptibility measurements with powdered samples were performed using the Faraday technique with a set-up comprising a George Associates Lewis coil force magnetometer, a CAHN microbalance and an Air Products cryostat. $Hg[Co(NCS)_4]$ was used as the standard. Diamagnetic corrections calculated from Pascal's constants [39] were used to obtain the molar paramagnetic susceptibilities.

2.3. Syntheses of complexes

2.3.1. $[Mn_2(\mu\text{-}L)_3]$ (1)

H_2L (100 mg, 0.3 mmol) and KOH (34 mg, 0.6 mmol) were taken in a mixture of methanol (20 ml) and acetonitrile (10 ml). The mixture was heated until a clear orange solution was obtained. Solid $MnCl_2 \cdot 4H_2O$ (40 mg, 0.2 mmol) was added to this solution and the mixture was stirred for 2 h at room temperature followed by slow evaporation in air. The brown solid separated was collected by filtration, washed with water and cold methanol and finally dried in air. Yield, 70 mg (62%). *Anal*. Calc. for $Mn_2C_{66}H_{42}N_6O_6$: C, 70.47; H, 3.76; N, 7.47. Found: C, 70.18; H, 3.61; N, 7.24%. Electronic spectral data in CH_2Cl_2 (λ_{max} (nm) (ε ($M^{-1}\,cm^{-1}$))): 480sh (9,300), 430 (26,700), 410 (29,900), 390sh (23,400), 333 (23,200), 263 (55,600).

2.3.2. $[Fe_2(\mu\text{-}L)_3]$ (2) and $[Co_2(\mu\text{-}L)_3]$ (3)

Complexes **2** and **3** were synthesized in comparable yields by following procedures very similar to that described above using $FeCl_3$ and $CoCl_2 \cdot 6H_2O$, respectively, as the metal ion source.

Anal. Calc. for $Fe_2C_{66}H_{42}N_6O_6$ (**2**): C, 70.35; H, 3.76; N, 7.46. Found: C, 70.23; H, 3.59; N, 7.32%. Electronic spectral data in CH_2Cl_2 (λ_{max} (nm) (ε ($M^{-1}\,cm^{-1}$))): 585 (9,300), 485sh (11,000), 430sh (21,900), 390 (30,500), 320 (44,000).

Anal. Calc. for $Co_2C_{66}H_{42}N_6O_6$ (**3**): C, 69.97; H, 3.74; N, 7.42. Found: C, 69.65; H, 3.52; N, 7.17%. Electronic spectral data in CH_2Cl_2 (λ_{max} (nm) (ε ($M^{-1}\,cm^{-1}$))): 476 (15,100), 430sh (12,700), 367sh (24,500), 355 (28,400), 267 (92,100).

2.4. X-ray crystallography

Single crystals of **2** were grown by slow evaporation of a dichloromethane–acetonitrile (1:1) solution of the complex. On the other hand, single crystals of **3** were obtained directly from the reaction mixture. In each case, unit cell parameters and the intensity data were obtained on a Bruker-Nonius SMART APEX CCD single crystal diffractometer, equipped with a graphite monochromator and a Mo Kα fine-focus sealed tube ($\lambda = 0.71073$ Å) operated at 2.0 kW. The detector was placed at a distance of 6.0 cm from the crystal. Data were collected at 298 K with a scan width of 0.3° in ω and an exposure time of 15 s/frame. The SMART software was used for data acquisition and the SAINT-PLUS software was used for data extraction [40]. The absorption corrections were performed with the help of SADABS program [41]. The complexes crystallize as **2**·$2CH_2Cl_2$ and **3**·$2CH_3CN$ in the space groups $P\bar{1}$ and $Pna2_1$, respectively. The structures were solved by direct methods and refined on F^2 by block-matrix and full-matrix least-squares procedures for **2**·$2CH_2Cl_2$ and **3**·$2CH_3CN$, respectively. The asymmetric unit of **2**·$2CH_2Cl_2$ contains two molecules of **2** and four molecules of CH_2Cl_2. Among the four CH_2Cl_2 molecules, three are of full occupancy,

whereas the last one is found at two different sites with half occupancy for each. The chlorine atoms of one of the full occupancy CH_2Cl_2 molecule are disordered and were located at four different sites. In this context, it may be noted that structure of a solvatomorph of **2** was reported before. This species (**2**·3HC(=O)N$(CH_3)_2$) also crystallizes in the space group $P\bar{1}$ [42]. In **2**·2CH_2Cl_2, the non-hydrogen atoms of the CH_2Cl_2 molecules having partial occupancies were refined isotropically. All other non-hydrogen atoms in both structures were refined using anisotropic thermal parameters. The hydrogen atoms were included in the structure factor calculation at idealized positions by using a riding model. The SHELX-97 programs [43] of the WINGX package [44] were used for structure solution and refinement. The ORTEX6a [45] and PLATON [46] packages were used for molecular graphics. Selected crystallographic data are listed in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

The complexes were synthesized in moderate yields by reacting metal chlorides, H_2L and KOH (2:3:6 mole ratio) in methanol–acetonitrile media. The elemental analysis data for all the complexes are in good agreement with the general molecular formula $[M_2L_3]$ (M = Mn (**1**), Fe (**2**) and Co (**3**)). Complexes **1** and **2** are paramagnetic, while complex **3** is diamagnetic. The diamagnetic character of **3** and the room temperature (300 K) magnetic moments of **1** and **2** (*vide infra*) indicate that both metal ions are trivalent in each complex. All the three complexes are soluble in non-polar solvents such as dichloromethane and chloroform and they are electrically non-conducting in solutions. During the synthesis of **2**, $FeCl_3$ was used as the metal ion source. However, hydrated chloride salts of manganese(II) and cobalt(II) were used as the starting materials for the synthesis of **1** and **3**, respectively. As the synthetic reactions were performed under aerobic conditions the oxygen in air is the most likely oxidant for the oxidation of the metal ions during the synthesis of **1** and **3**.

3.2. Spectroscopic characteristics

Absence of any band assignable to the phenolic OH group in the infrared spectra of the complexes suggests that the ligands are dianionic in each complex. The strong band observed at ~1616 cm^{-1} is most likely due to the C=N stretch [32,35]. The infrared spectra of **1**, **2** and **3** are essentially identical except for some insignificant shifts of frequencies. The similarity of all the three spectra indicates similar molecular structures of **1**, **2** and **3**.

The electronic spectra of the complexes in dichloromethane solutions display several strong absorptions in the visible as well as ultra-violet region. The absorptions in the visible region are attributed to the ligand-to-metal charge transfer transitions [32,35]. The higher energy bands are likely to be due to ligand based transitions.

A $CDCl_3$ solution of the diamagnetic dicobalt(III) complex (**3**) was used to record the proton NMR spectrum. For an ideal triple helical D_3 symmetric structure of **3**, the six halves of the three twisted ligands (L^{2-}) are expected to be essentially equivalent. It may be expected that H6 and H9 protons of the naphthalene moiety will have similar chemical shifts. Likewise H7 and H8 protons should also have similar chemical shifts. Slightly different chemical shifts can be anticipated for H3 and H4 protons. The signal for the azomethine proton in twisted L^{2-} may display high-field shift due to its proximity to the naphthalene rings of the same ligand or other ligands. The spectrum of **3** displays closely spaced signals centred at δ 7.75, 7.56, 7.19 and 6.50 ppm in the ratio 2:2:2:1. The resonances at δ 7.75, 7.56 and 7.19 are ascribable to the three pairs of protons (H6, H9), (H7, H8) and (H3, H4), respectively. The one at δ 6.50 ppm has been assigned to the azomethine proton. The observation of this pattern suggests a nearly ideal triple helical structure of **3** in solution.

3.3. Magnetic properties

The magnetic susceptibilities of **1**, **2** and **3** were measured with powdered samples of the complexes. The dicobalt(III) complex (**3**) is diamagnetic. The magnetic susceptibilities of the paramagnetic dimanganese(III) and the diiron(III) complexes (**1** and **2**) were measured in the temperature range 17–300 K at a constant magnetic field of 5 kG. For both **1** and **2** the effective magnetic moment (μ_{eff}) decreases gradually with the decrease of temperature indicating antiferromagnetic interaction between the two

metal ions (Fig. 1). At 300 K the μ_{eff} value (6.58 μ_B) of **1** is slightly smaller than the spin-only moment (6.93 μ_B) expected for a dimer containing two metal ions with $S = 2$ spin states. The moment of **1** decreases to 4.89 μ_B at 17 K. In the case of **2**, the μ_{eff} value (8.39 μ_B) at 300 K is essentially identical with the spin-only moment (8.37 μ_B) expected for a diiron(III) complex where both the metal ions are high spin ($S = 5/2$). At 17 K the μ_{eff} value decreases to 6.30 μ_B. The data were fitted using the expressions for χ_M versus T derived from the isotropic spin-exchange Hamiltonian $H = -2JS_1 \cdot S_2$, where $S_1 = S_2 = 2$ (for **1**) and $S_1 = S_2 = 5/2$ (for **2**) [47]. The best least-squares fits [48] were obtained with $J = -1.57(1)$ cm^{-1} and $g = 1.927(4)$ for **1** and $J = -1.13(1)$ cm^{-1} and $g = 2.035(1)$ for **2**. The extent of intramolecular antiferromagnetic coupling in dicopper(II) species having one or two =N–N= bridges is largely determined by the twisting of the dinucleating ligand along the N–N single bond [23–27]. It is reported that the effective orthogonality between the magnetic orbitals of the Cu(II) centers and that between the nitrogen p-orbitals involved in the spin-exchange process is attained when the twist angle (dihedral angle between the two chelating sites) is ~70° [24–26]. Magnetic properties of very few dinuclear complexes of 3d metal ions other than copper(II) having the diazine bridge are reported. These are the diiron(III) complexes of salhn^{2-} and its derivative [32,35] and some dimetal(II) (M = Ni, Co and Mn) complexes with *N*,*N*′-bis(picolinylidene)hydrazine or its derivatives [20,21,26]. In all these complexes, the metal ions are connected by three =N–N= bridges and they exhibit no spin-exchange or very weak spin-exchange. In the two structurally characterized diiron(III) complexes, the average twist angles between the two chelate rings along the N–N single bonds are 42.6 and 63.5° [32,35]. On the other hand, the average twist angles are very similar in the dimanganese(II) (~68°) and the dinickel(II) complexes (~70°) [26]. Except for one diiron(III) complex, these twist angles are essentially identical or very close to the twist angle found as the orthogo-

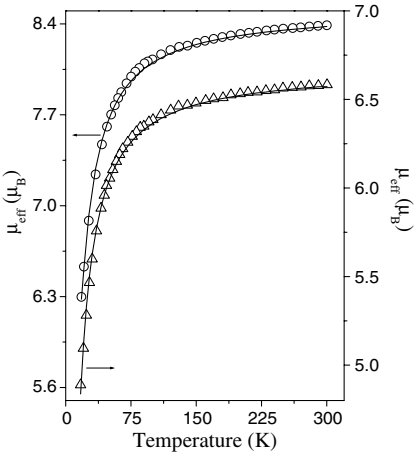

Fig. 1. The effective magnetic moments of $[Mn_2(\mu\text{-}L)_3]$ (△) and $[Fe_2(\mu\text{-}L)_3]$ (○) as a function of temperature. The continuous lines were generated from the best least-squares fit parameters given in the text.

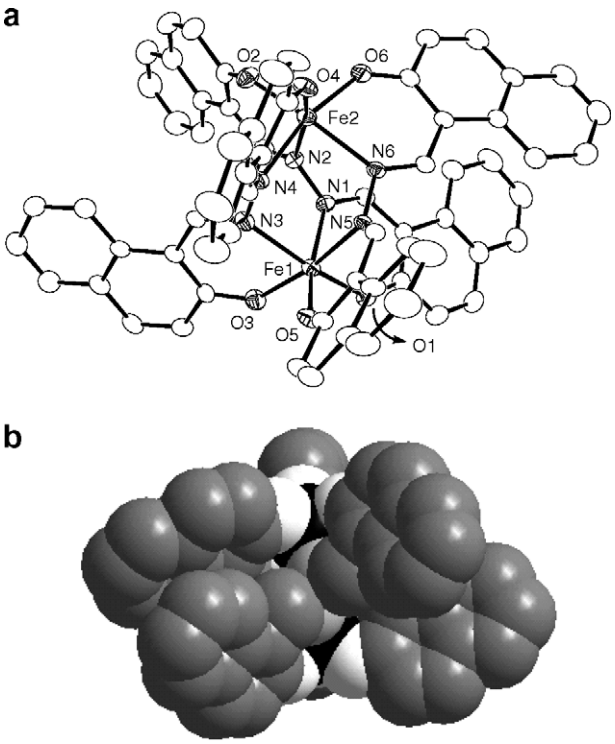

Fig. 2. Molecular structure of $[Fe_2(\mu\text{-}L)_3]$. Out of two molecules present in the asymmetric unit one is shown. Hydrogen atoms are omitted for clarity. (a) ORTEP diagram depicting the 30% probability thermal ellipsoids. (b) Space filling representation of the triple helical structure.

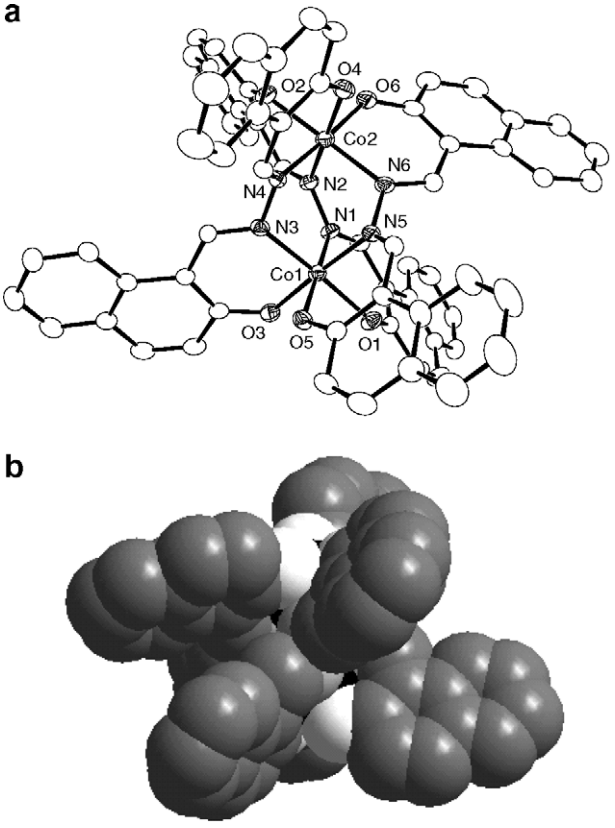

Fig. 3. Molecular structure of $[Co_2(\mu\text{-}L)_3]$. Hydrogen atoms are omitted for clarity. (a) ORTEP diagram depicting the 30% probability thermal ellipsoids. (b) Space filling representation of the triple helical structure.

nal limit for the dicopper(II) complexes with similar ligands. Although the X-ray structure of **1** could not be determined due to the lack of single crystals but for **2** the twist angles (73.1(1)–87.08(6)°) (*vide infra*) are not far off from the above orthogonal limit.

3.4. X-ray structures of 2 and 3

The molecular structures of **2** and **3** are shown in Figs. 2 and 3, respectively. The bond parameters associated with the metal centres in **2** and **3** are listed in Tables 2 and 3, respectively. The asymmetric unit of **2** contains two complex molecules. The bond parameters (Table 2) indicate that both molecules are essentially identical. In both complex molecules, each of the three dinucleating ligands coordinates the two metal ions via the two phenolate-O and the two imine-N atoms. As a result the metal ions are in facial O_3N_3 coordination spheres and connected by three diaza (=N–N=) bridges. The M–O(phenolate) and M–N(imine) bond lengths (Tables 2 and 3) in the diiron complex (**2**) as well as in the dicobalt complex (**3**) are consistent with the +3 oxidation state of the metal ions [32–35,42]. The Fe···Fe distances (3.920(1) and 3.896(1) Å) observed in the two molecules of **2** are significantly longer than the Co···Co distance (3.4156(7) Å) observed in **3**. In each complex, all the three ligands are twisted along the N–N single bonds to accommodate the two metal ions and consequently the triple helical structure is generated (Figs. 2 and 3). The average twisting of the three ligands is larger in **2** compared to that in **3**. For **2**, the dihedral angles between the two bidentate chelating sites of the three ligands are 79.36(7)°, 87.08(6)° and 78.26(7)° in molecule 1 and 81.30(7)°, 86.71(7)° and 73.05(10)° in molecule 2. These dihedral angles are 30.60(8)°, 50.93(6)° and 54.91(8)° in **3**. The values of these dihedral angles indicate that the helical twist of L^{2-} in **2** is significantly larger than the helical twist of L^{2-} in **3**. Perhaps this difference is responsible for the longer Fe···Fe distance in **2** compared to the Co···Co distance in **3**.

4. Conclusion

Three dinuclear triple helical complexes having the general formula $[M_2(\mu\text{-}L)_3]$ (M = Mn(III), Fe(III) and Co(III)) with a tetradentate diazine ligand (L^{2-}) are reported. The complexes are characterized with the help of elemental analysis, solution electrical conductivity, various spectroscopic and cryomagnetic measurements. Dicobalt(III) complex is diamagnetic while the temperature dependent magnetic susceptibility data of the dimanganese(III) and

the diiron(III) complexes indicate a weak intramolecular antiferromagnetic spin-exchange between the metal ions. The molecular structures of the diiron(III) and the dicobalt(III) complexes are determined by X-ray crystallography. The dinucleating tetradentate ligand (L^{2-}) coordinates the metal ions via the two phenolate-O and the two imine-N atoms. In each complex, both metal ions are in facial N_3O_3 coordination spheres. The triple helical structure of $[M_2(\mu\text{-}L)_3]$ is generated due to the twisting of the two N,O-donor chelating sites of each L^{2-} along the N–N single bond enforced by the two pseudo-octahedral metal ions.

Supplementary material

CCDC 642656 and 642657 contain the supplementary crystallographic data for $\mathbf{2}\cdot 2CH_2Cl_2$ and $\mathbf{3}\cdot 2CH_3CN$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

Financial support for this work was provided by the Council of Scientific and Industrial Research, New Delhi (Grant No. 01(1880)/03/EMR-II). We thank the University Grants Commission, New Delhi for the facilities provided under the UPE and CAS programs. Our sincere thanks are due to Prof. A. R. Chakravarty for providing the cryomagnetic data. X-ray crystal structures were determined at the National Single Crystal Diffractometer Facility, School of Chemistry, University of Hyderabad (established by the Department of Science and Technology, New Delhi).

[18]. Here we report the synthesis and characterization of five new Zn(II) complexes of a recently reported salicylaldehyde 3-hexamethyleneiminyl thiosemicarbazone [19] with different coligands, pyridine, 2,2′-bipyridine, 1,10-phenanthroline and γ-picoline.

2. Experimental

2.1. Materials

All the solvents used for the synthesis of the thiosemicarbazone ligands and their complexes were purified by distillation. Pyridine, γ-picoline, 1,10-phenanthroline and 2,2′-bipyridine were used as received. The synthesis of the ligand H_2L is reported elsewhere [19].

2.2. Synthesis of complexes

Complex **1** was synthesized by refluxing an ethanolic solution of H_2L^1 (2 mmol, 0.554 g) with an ethanolic solution of $Zn(OAc)_2 \cdot 2H_2O$ (1 mmol, 0.219 g) for 4 h. The complex formed was filtered, washed with ethanol, then ether and dried over P_4O_{10} *in vacuo*. All the other complexes were prepared by refluxing an ethanolic solution of the ligand H_2L^1 (1 mmol, 0.277 g) and heterocyclic bases like pyridine, bipyridine, 1,10-phenanthroline and γ-picoline (1 mmol) with an ethanolic solution of $Zn(OAc)_2 \cdot 2H_2O$ (1 mmol, 0.219 g) 1:1:1 molar ratio for 4 h. The complexes that separated were filtered, washed with ethanol and finally with ether and dried over P_4O_{10} *in vacuo*. Crystals suitable for X-ray analysis for compound **1** were obtained by slow evaporation of a solution of the compound from an ethanol solution in eight days.

2.3. Physical measurements

Elemental analyses were carried out using a Vario EL III CHN analyzer at SAIF, Kochi, India. Infrared spectra were recorded on a Thermo Nicolet, AVATAR 370 DTGS model FTIR spectrophotometer as KBr pellets at SAIF, Kochi, India. Electronic spectra were recorded on a UVD 3500 UV–Vis-Double beam spectrophotometer from solutions in DMF. ^{1}H NMR spectra were recorded on a Brucker AMX 400 in $CDCl_3$ with TMS as an internal standard.

2.4. X-ray crystallography

The molecular structure of compound **1** was determined by single crystal X-ray diffraction method. Intensity data and cell parameters were recorded at room temperature (293 K) on a Nonius, MACH3 diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Crystallographic and experimental details for the structure are summarized in Table 1. Maxus (Nonius software) was used for data reduction [20]. Two atoms, C11 and C12 in the ring containing N(3), are disordered as the two carbons split over two sets of positions. Restraints were applied to assist the geometry of the disordered atoms. The ratio of major to minor disorder component is 56.8:43.2. The trial structure was solved using SHELXS-97 [21] and refinement was carried out by full- matrix least squares on F^2 (SHELXL-97) [22]. The non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were geometrically fixed and refined using a riding model. The intensity data were collected by the ω-scan mode within $1.59° < \theta < 24.99°$ for *hkl* ($-12 \leqslant h \leqslant 12$, $-13 \leqslant k \leqslant 13$, $-15 \leqslant l \leqslant 0$) on a triclinic system. The molecular graphics employed were ORTEP [23] and PLATON [24].

Table 1
Crystal refinement parameters of compound (**1**)

Empirical formula	$C_{28}H_{36}N_6O_2S_2Zn$
Formula weight	618.12
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system, space group	triclinic, $P\bar{1}$

Z, calculated density (Mg/m^3)	2, 1.418
Absorption coefficient (mm^{-1})	1.030
F(000)	648
Crystal size (mm)	$0.30 \times 0.15 \times 0.15$
θ Range for data collection (°)	1.59–24.99
Index ranges	$-12 \leqslant h \leqslant 12$, $-13 \leqslant k \leqslant 13$, $-15 \leqslant l \leqslant 0$
Reflections collected/unique (R_{int})	5298/5053 (0.0260)
Completeness to 2θ	24.99 99.2%
Absorption correction	ψ-scan
Maximum and minimum transmission	0.8609 and 0.7476
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	5053/0/371
Goodness-of-fit on F^2	1.012
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0417$, $wR_2 = 0.0891$
R indices (all data)	$R_1 = 0.1122$, $wR_2 = 0.1049$
Largest difference in peak and hole (e Å^{-3})	0.425 and −0.509

3. Results and discussion

The colors and partial elemental analysis data of all the complexes are listed in Table 2. All the complexes except **1** were assigned the general formula MLB, where B represents heterocyclic bases, pyridine, 2,2′-bipyridine, 1,10-phenanthroline and γ-picoline. The complexes **3** and **4** contain uncoordinated water molecules also. From the structural, elemental and spectral studies, compounds **1**–**5** were assigned the empirical formulae $[Zn(HL)_2]$, [Zn(L)py], $[Zn(L)bipy] \cdot 3.5H_2O$, $[Zn(L)phen] \cdot H_2O$ and [Zn(L)γ-pic] respectively.

Table 2
Stoichiometries, colors and partial elemental analyses of the complexes

3.1. Crystal structure of $[Zn(HL)_2]$ (1)

The molecular structure of compound **1**, along with the atom numbering scheme, is given in Fig. 1 and selected bond lengths and bond angles are summarized in Table 3. The ligands coordinate to the Zn(II) ion through the azomethine nitrogen and thiolate sulfur to form a highly distorted tetrahedral geometry. The phenolic group of the ligand is retained as such and is placed away from the metal center. This is because of the change of conformation of the ligand from the *E* form to the *Z* form about the azomethine bond. The free ligand H_2L in its solid form is in a position to bond the metal in a tridentate ONS manner [19]. The conformation change of a ligand from a bidentate to a tridentate manner on coordination is known, but this reverse case is seen for the first time for thiosemicarbazone ligands of Zn(II) complexes. However a CSD search shows a similar conformation in Zn(II) hydrazones [25–27].

The NS chelation results in two five membered planar rings, Zn1, N1, N2, C8, S1 having a maximum deviation of −0.053(4) Å for C8 and Zn1, S2, N4, N5, C22 with a maximum deviation of 0.002(3) Å for N4. The dihedral angle between these planar rings is 89.28(9)°. The smaller angles around Zn(II) are 86.29(9)° for N4–Zn1–S2 and 86.57(10)° for N1–Zn1–S1. These factors clearly point out the rigidity of the core thiosemicarbazone moiety, even after coordination, and the highly distorted tetrahedral coordination. The other angles around zinc are between 110.90(12)° and 134.39(5)°. The Zn–N distances in the complex are smaller compared to $[Zn(Acehexim)_2]$ (Zn–N12 2.044(9) and Zn–N22 2.068(10) Å) [28]; $[Zn(PzAm4M)_2]\cdot 2CH_3CN$ (Zn1–N12 2.072(2) and Zn1–N22 2.071(2) Å) [29]; $[ZnL^1_2MeOH]$ (Zn–N3 2.114(2) and Zn–N13 2.108(2) Å) [30], $[Zn(Am4m)(OAc)_2]_2$ (Zn1–N2 2.050(2) Zn1–N2 2.227(2) Å) [31] and $[Zn(HAm4E)I_2]$ (Zn–N12 2.120(7) Å) [32]. This indicates stronger coordination of the azomethine nitrogen in compound **1**. The

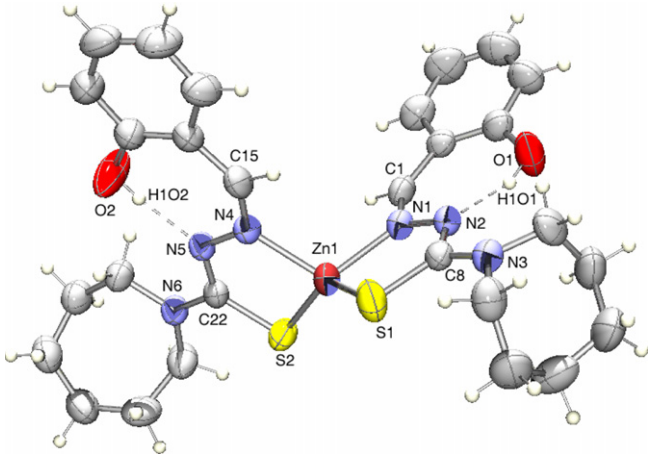

Fig. 1. ORTEP diagram for compound **1** with 50% probability ellipsoids. Minor disorder components at C11/C12 are removed for clarity.

Table 3
Comparison of bond lengths (Å) and bond angles (°) of H_2L and $[Zn(HL)_2]$ (**1**)

	H_2L[a]	$[Zn(HL)_2]$

N5–C22–S2		126.3(3)
N6–C22–S2		117.8(3)

[a] Ref. [19].

Zn–S bond distance is found to be smaller than that for the other zinc compounds, $[Zn(Am4M)(OAc)]_2$ (Zn1–S1 2.370(1) Å) [31] $[Zn(Am4E)(OAc)]_2$ (Zn1–S1 2.431(6) Å) [32] and $[Zn(HAm4E)I_2]$ (Zn–S1 2.502(3) Å) [32] and $[ZnL_2^4]\cdot 0.5H_2O$ (Zn1–S1 2.3731(10) Å) [33]. This may be due to the bulkiness of the thiosemicarbazone moiety. The coordination results in the changes of bond lengths and angles of the thiosemicarbazone moiety, as expected. The C–S bond length increases from 1.684(3) Å to 1.744(4) and 1.749(4) Å. Similarly C8–N2 (and C22–N5) suffers a significant decrease from 1.362(3) Å seen in the free ligand. These changes indicate the coordination of the deprotonated sulfur after enolization. The other bond lengths and angles also suffer some changes, but not significantly. The chair conformation of the hexamethyleneiminyl ring is retained in the complex. The intramolecular hydrogen bond $O–H\cdots N_{azomethine}$ seen in the free ligand is retained in compound **1**, but the O–H···S bond disappears. Relevant hydrogen bonding interactions are given in Table 4. However no significant π–π or C–H···π interactions are found in the packing. In the unit cell, the molecules are packed in a 'face-to-face' manner along the *a* axis and the weak intermolecular hydrogen bonds, C18–H18···O1, link the molecules into one-dimensional sheets along the *c* axis (Fig. 2).

3.2. Infrared spectra

The IR spectral bands most useful for the determination of the mode of coordination are given in Table 5. The bands corresponding to *ν*(N–H) appear at 3315 cm^{-1} for H_2L, but disappear in the spectra of all the complexes. The band at 1612 due to *ν*(C=N) of the thiosemicarbazone moiety shifts to ~1590 cm^{-1} upon coordination [32]. This confirms the coordination *via* the azomethine nitrogen. Coordination of the azomethine nitrogen is also consistent with the presence of a band in the range 405–420 cm^{-1}, assignable to *ν*(Zn–N), for these complexes [32]. A small shift in the absorption bands due to the *ν*(N–N) stretching vibrations from 1037 to a higher region is due to the increase in the double bond character off-setting the loss of electron density *via* donation to the metal and is a confirmation of the coordination of the ligand through the azomethine nitrogen atom [3]. Coordination *via* the thiolate sulfur is indicated by a decrease in the frequency of the thioamide band *ν*(C=S), found at 1324 and 861 cm^{-1} in the uncomplexed thiosemicarbazone, by 20–100 cm^{-1} in the complexes [34,35]. This decrease in stretching frequency of thiolate sulfur in the complexes is indicated by

Table 4
H-bonding interactions in compound **1**

D–H···A	D···H (Å)	H···A (Å)	D···A (Å)	D–H···A (°)
O1–H1O1···N2^{i}	0.79(5)	1.77(5)	2.556(5)	174(5)
O2–H1O2···N5^{i}	0.85(6)	1.73(6)	2.568(5)	172(6)

D = donor, A = acceptor, equivalent position code: i = *x*, *y*, *z*.

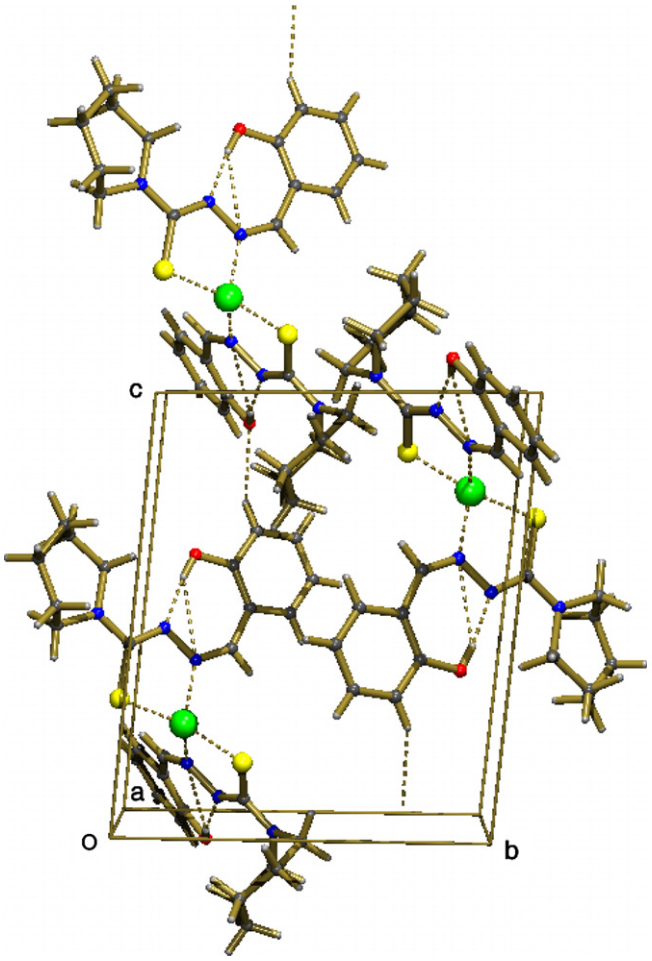

Fig. 2. Unit cell packing of the compound **1** along the *a* axis.

Campbell [36]. Another strong band is found in the region of 1535–1545 cm^{-1} and is due to the newly formed *ν*(N=C) bond in the spectra for these complexes. The bands at 325–380 cm^{-1}, assignable to *ν*(Zn–S) in the complexes, are consistent with sulfur coordination [1,37]. The new peaks observed in the range 520–570 cm^{-1} are due to the Zn–$O_{(phenolic)}$ bond [38]. Except in complex **1**, coordination via the phenolic oxygen is indicated by a decrease in the frequency of *ν*(CO), found at 1271 cm^{-1} in the uncomplexed thiosemicarbazone, by 60–80 cm^{-1} in the spectra of the complexes. In complex **1**, *ν*(CO) does not shift to a much lower frequency, indicating that coordination does not occur through the phenolic oxygen.

3.3. ^1H NMR spectra

The numbering schemes used in the ^1H NMR spectra of the ligand and its complexes are shown in Fig. 3. The ^1H NMR spectrum of H_2L shows a sharp singlet, integrating as one hydrogen, at $\delta = 11.31$ (s, 1H) ppm which is assigned to the proton attached to the oxygen atom. The downfield shift of this proton is assigned to its intra and intermolecular hydrogen bonding interactions. The hydrogen bonding decreases the electron density around the pro-

ton and thus moves the proton absorption to a lower field [39]. Absence of any coupling interactions by ^{2}NH due to the unavailability of protons on neighboring atoms render a singlet peak for the imine proton at $\delta = 8.89$ (s, 1H). A sharp singlet at $\delta = 7.99$ (s, 1H) ppm corresponds to the ^{7}CH = proton. The downfield shift of this proton is due to the presence of the aromatic ring present in the thiosemicarbazone moiety. Aromatic protons ^{4}CH, ^{6}CH, ^{3}CH, ^{5}CH appear in the range 6.68–7.14 ppm. Aliphatic protons of the hexamethyleneiminyl ring were observed as three signals *viz* 3.36 (s, 4H), 1.66 (s, 4H) and 1.42 (s, 4H), assigned to positions a, b and c respectively. ^{1}H NMR assignments are in agreement with values already reported [2,3,40,41].

^{1}H NMR assignments for the Zn(II) complexes are included in Table 6. The signals for the phenolic OH (except in **1**) and ^{2}NH are absent from the spectra of the complexes, as expected because of their loss on complex formation, which is evidence for the coordination of the ligand as a doubly deprotonated anion. This confirms the coordination through the phenolic oxygen and also *via* the thiolate sulfur atom in those complexes. Complex **1** shows a peak at $\delta = 13.36$ ppm due to the presence of the uncoordinated hydroxyl group. The more downfield shift of the OH protons compared to the uncomplexed thiosemicarbazone is due to overall loss of electron density and intra and intermolecular hydrogen bonding interactions. This is confirmed from the crystal structure. There is considerable downfield shifting of the signals for the ring protons in the spectra of complexes compared to the uncomplexed thiosemicarbazone. This is due to the loss of electron density *via* coordination of the ligand to the metal center. Protons due to the heterocyclic bases appear in the region 8.49–7.15 ppm. The downfield shift of the proton peaks corresponding to ^{6}H Ph, H^1 of the heterocyclic bases are the result of the withdrawal of electron density from the thiosemicarbazone moiety and the

heterocyclic base due to coordination with the metal atom [42]. A small downfield shift occurs for the aliphatic protons in the complexes due to the overall loss of electron density.

3.4. Electronic spectra

The electronic spectrum of the ligand H_2L recorded in DMF shows bands at 280 and 321 nm assignable to $\pi\rightarrow\pi^*$ transitions of the phenyl ring [3,41,43] and $n\rightarrow\pi^*$ transitions of the azomethine and thioamide functions respectively. A second $n\rightarrow\pi^*$ band is found at 339 nm [44,45]. These intraligand bands are slightly shifted on complexation. In the spectra of the complexes these bands are found in the region of 280–290 nm and 325–340 nm respectively. The shift of the $\pi\rightarrow\pi^*$ bands to a longer wavelength region in the complexes is the result of the C–S bond being weakened and the conjugation system enhanced on complexation [46,47].

A moderately intense broad band for the complex in the region 370–400 nm is assigned to Zn(II) → S transitions. MLCT maxima of the phenolate complex shows line broadening with a tail running into the visible part of the spectrum. This may result from a phenolate to Zn(II) LMCT band being superimposed on the low energy side of Zn(II) → S transitions [1]. No appreciable absorptions occurred above 500 nm in DMF solution, indicating the absence of d–d bands which is in accordance with the d^{10} configuration of the Zn(II) ion.

prepared by metathesis reactions between $MnCl_2 \cdot 4H_2O$ and the alkaline salt of the corresponding ligand by Szekely et al. [14].

1

2

In this study, we are reporting the preparation of cationic palladium(II) complexes containing $[Ph_2P(S)NP(S)Ph_2]^-$ [disulfideimidodiphosphinato] of the type $[Pd(L\text{-}L)(dppaS_2\text{-}H)]ClO_4$ [L-L = dppm (**1**), dppe (**2**), dppp (**3**)]. Complex **2** was also synthesized **2a** by using of $Pd(dppe)Cl_2$ and $K[N(PSPh_2)_2]$ as starting materials. All of these complexes have been characterized $^{31}P\{^1H\}$ NMR, IR and elemental analyses. Complex **2** was recrystallized from acetone/hexane, complex **3** was recrystallized from acetone/diethyl ether and complex **2a** was recrystallized from dichloromethane/diethyl ether for X-ray crystallography.

2. Results and discussion

Previous works have demonstrated that the iminobis(phosphinechalcogenide) ligands can be deprotonated to afford coordinated dichalcogenoimidodiphosphinato anions by the reaction of metal–halides or starting complexes containing metal–halide bonds [15]. The starting complexes, $Pd(L\text{-}L)Cl_2$ (L-L = dppm, dppe, dppp) and $K[N(PP_2S)_2]$ were synthesized according to the literature (see Section 2). $^{31}P\{^1H\}$ NMR spectra of these compounds only a singlet δP values are −51.17, 67.67, 13.64 and 36.70 ppm, respectively. $[Pd(L\text{-}L)(dppaS_2\text{-}H)]ClO_4$ complexes (**1**, **2**, **3**) were prepared by the mixing of solution of $Pd(L\text{-}L)Cl_2$ complexes in CH_2Cl_2 and $dppaS_2$ ligand and $NaClO_4 \cdot H_2O$ salt in $(CH_3)_2CO$. Another method was used to prepared $[Pd(dppe)(dppaS_2\text{-}H)]ClO_4$ (**2a**). In this method, the solution of $K[N(PP_2S)_2]$ salt in CH_3OH was added solution of $Pd(dppe)Cl_2$ in CH_2Cl_2 as a molar ratio 1:1 in the presence of $NaClO_4 \cdot H_2O$ salt.

Solid state IR spectra of the complexes (**1**–**3**) showed the characteristic absorption of P=S group at 570.0, 573.0 and 570.0 cm^{-1}. These absorptions are shifted to the lower frequencies according to the free ligand, $dppaS_2$, absorption which is at 612.9 cm^{-1}. This shows that the ligand is coordinating to Pd(II) center via S donor atoms in the complexes. ClO_4^- group vibrations give rise to two bonds in 1100 and 620 cm^{-1} region. IR spectra of free acid, $dppaS_2$, exhibits absorption of medium intensity at 2630.8 cm^{-1} and very strong absorption at 922.0 cm^{-1} which were assigned to υ(N–H) stretching vibration and $\upsilon_{as}(P_2NH)$ stretching vibration, respectively. In IR spectra of complexes **1**, **2**, **3**, presence of strong absorptions in the regions 1150–1170 cm^{-1}, assigned to the $\upsilon_{as}(P_2NH)$ stretching vibrations, indicate that the $dppaS_2$ ligand is coordinated to the palladium center in the deprotonated form [6]. In $K[N(PP_2S)_2]$ salt, which is prepared to obtain $[Pd(dppe)(dppaS_2\text{-}H)]ClO_4$ **2a** by different method, $\upsilon_{as}(P_2N)$ vibration is at 1171.2 cm^{-1}. This absorption is at 1146.7 cm^{-1} in complex **2a**. Analytical data of four complexes are in accordance with the proposed formulation.

In complexes **1**, **2**, **3** and **2a**, the resonance due to the diphosphines (dppm, dppe, dppp) phosphorus atoms appear at –42.25, 72.06, 11.35 and 69.55 ppm, respectively. It has been seen that the signals of chelate dppm and dppe ligands are shifted to the downfield related to the starting complexes $[Pd(L\text{-}L)Cl_2]$ (L-L = dppm, dppe), but dppp ligand is shifted to the upfield on relative to the starting complex, $Pd(dppp)Cl_2$. Phosphorus chemical shifts of $dppaS_2$-H are 36.16, 38.67 and 37.63 ppm in complexes **1, 2** and **3**, respectively.

In $^{31}P\{^1H\}$ NMR of pottassium salt, $K[N(PP_2S)_2]$, there is a shifted at 38.69 ppm. This resonance is at 38.65 ppm in complex **2a** and is suitable with value of the complex **2**.

Solid state structures of complexes **2**, **2a,** and **3** were determined by single crystal X-ray diffraction. Complex **2** was recrystallized from acetone/hexane and includes one molecule acetone, complex **2a** was recrystallized from CH_2Cl_2/diethyl ether and has one molecule CH_2Cl_2. Complex **3** was recrystallized from acetone/diethyl ether and includes one molecule acetone. The perspective view of complexes **2**, **2a** and **3** are given in Figs. 1–3, respectively. The selected bond distances and angles are listed in Table. 1. Complexes **2** and **2a** are monoclinic and complex **3** is triclinic crystal systems. The solvent $(CH_3)_2CO$ and CH_2Cl_2 lie in the lattice on non-bonded molecules in the complexes **2** and **3**, respectively. All of the data for complex **2** and **2a** are similar. Palladium atoms in every complex are distorted square planar environments with from P(3)Pd(1)S(1) and P(4)Pd(1)S(2) are 168.90(4)° and 169.99(4)° for complex **2**, 170.66(3)° and 170.92(3)° for complex **2a** and 171.57(2)° and 173.96(2)° for complex **3**. The bite angles of iminobis(diphenylphosphine sulfide) in complexes **2** and **2a** [102.94(3)° and 102.69(3)°) are different from complex **3** (98.82(2)°]. This difference can be explained by diphosphine bite angle [P(4)Pd(1)P(3); 84.85(4)° for complex **2** and 84.61(3)° for complex **2a** and 91.62(2)° for complex **3**]. These values are comparable with the complexes $[Pd(dppaS_2\text{-}H)_2]$ [5].

Pd–S bond lengths are slightly different from each other. Pd(1)–S(1) and Pd(1)–S(2) are 2.3933(10) and 2.4114(10) Å for complex **2**; 2.3853(9) and 2.4110(9) Å for complex **2a**; 2.4017(6) and 2.3674(6) Å for complex **3**. These are comparable with the literature values [16].

In complex **3**, six membered dppp chelate ring has chair conformation with Pd(1)P(3)C(13)C(14) and Pd(1)P(4)-C(15)C(14) torsion angles of −44.4(3)° and 60.2(2)°, respectively, and with Pd(1) and C(14) atoms are located at −0.6932(21) Å below and 0.7342(45) Å above the plane defined by the atoms P(3)–P(4)–C(13)–C(15).

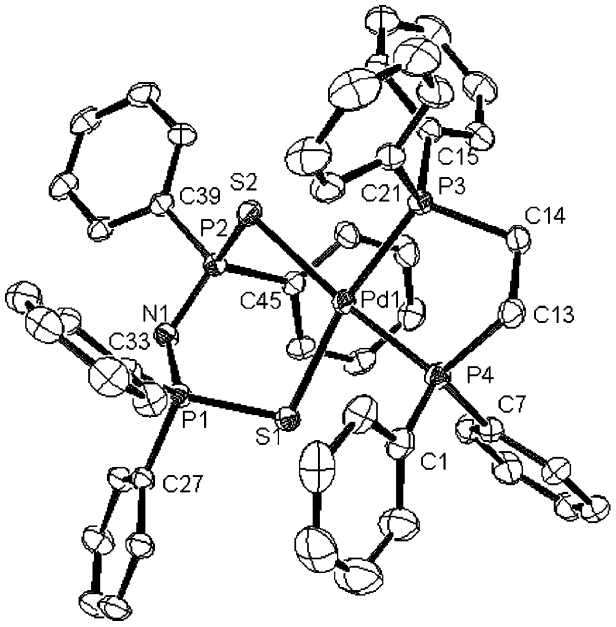

Fig. 1. The perspective view of **2** (20% thermal probability). Hydrogen atoms, anions and solvent molecule are omitted for clarity.

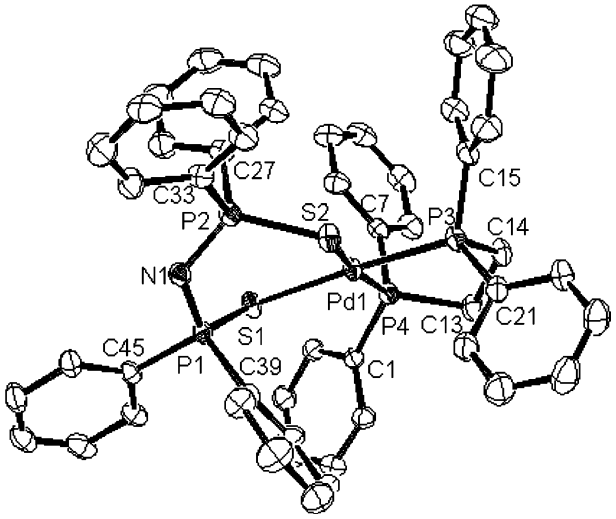

Fig. 2. The perspective view of **2a** (20% thermal probability). Hydrogen atoms, anions and solvent molecule are omitted for clarity.

Six membered dppaS_2-H rings are twist boat conformations in three complexes and are very similar to that observed related platinum analogue [Pt(PEt_3)$_2${Ph_2P(S)-NHP(S)Ph_2}]PF_6 in the literature [17].

PNP bond angles are 122.41(19)°, 120.74(17)° and 121.47(13)°, respectively. These angles show the sp^2 character at the nitrogen atoms [5].

P–S bond lengths are 2.0184(14) and 2.0170(15) Å for complex **2**; 2.0165(11) and 2.0239(12) Å for complex **2a** and 2.0304(9) and 2.0152(9) Å for complex **3**. P–S bond distances, as expected, are longer than the analogous P=S distances in the sulfur compounds and are suitable with the similar compounds in the literature [6,7,14].

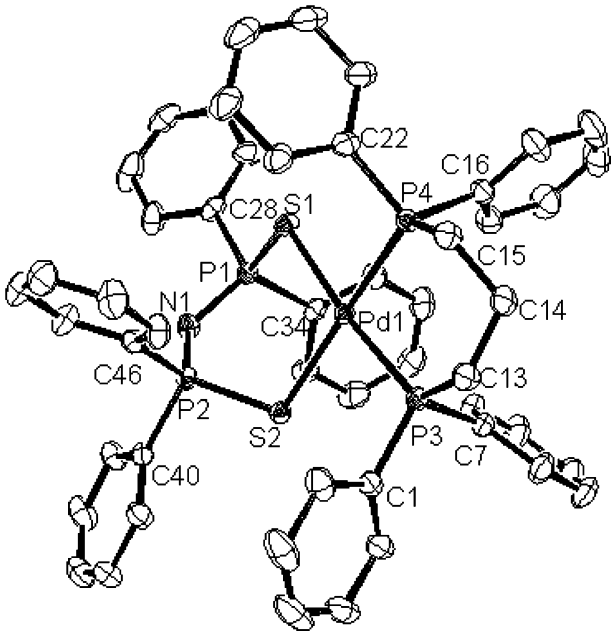

Fig. 3. The perspective view of **3** (20% thermal probability). Hydrogen atoms, anions and solvent molecule are omitted for clarity.

Table 1
Selected bond angles (°) and distances (Å) for [Pd(dppe)(dppaS_2-H)]-(ClO_4) · $(CH_3)_2CO$ (**2**), [Pd(dppe)(dppaS_2-H)](ClO_4) · CH_2Cl_2 (**2a**) and [Pd(dppp)(dppaS_2-H)](ClO_4) · $(CH_3)_2CO$ (**3**)

P(4)–Pd(1)–S(1)	84.72(4)	86.06(3)	85.66(2)

As a result, three new complexes have been synthesized. Two different synthetic route was used for one of them and their structures were determined by spectroscopic methods.

3. Experimental

Solvents were dried according to the methods given in the literature and were purified under inert conditions [18]. All synthesis were carried using standard Schlenk tube techniques under inert atmosphere.

dppm, dppe, dppp, $NaClO_4 \cdot H_2O$ and acetone were purchased from Merck Chemical; dichloromethane, toluene, methanol, hexane and diethylether were purchased from Lab-Scan. The starting complexes, [$PdCl_2$(COD)] (COD = 1,5-cyclooctadiene) [19], which is used for prepar-

ing the [$PdCl_2$(L-L)] complexes [L-L = dppm ($Ph_2PCH_2PPh_2$), dppe ($Ph_2PCH_2CH_2PPh_2$), dppp ($Ph_2PCH_2CH_2CH_2PPh_2$)] [20], dppa ($Ph_2PNHPPh_2$) and $dppaS_2$ ($Ph_2P(S)NHP(S)Ph_2$) were synthesized according to the method given in the literature [21].

$^{31}P\{^1H\}$ NMR spectra were recorded on Varian AS 400+Mercury instruments, chemical shifts, in ppm, related to external 85% H_3PO_4. Coupling constants are in Hz. IR spectra were recorded from 4000 to 400 cm^{-1} with a Perkin–Elmer 100 FT-IR instrument. Melting points were determined by Electrothermal melting point detection apparatus. Elemental analyses were performed by the TÜBİTAK-Ankara Test and Analyse Laboratories. There is potential explosion hazard arising from the use of perchlorates in the presence of organic material, so quantities should be kept small and heating (especially to dryness) avoided.

3.1. Method I

3.1.1. [Pd(dppm)(dppaS$_2$-H)](ClO$_4$) (1)

$PdCl_2$(dppm) (0.18 mmol, 0.10 g) and $dppaS_2$ (0.18 mmol, 0.08 g) were placed in 30 mL $CH_2Cl_2$and stirred. The solution of $NaClO_4 \cdot H_2O$ (0.71 mmol, 0.10 g) in 20 mL acetone was added dropwise to the stirring solution. Stirring was continued for 24 h at room temperature. After that, the solution was removed in vacuo. Yellow solid was dissolved in CH_2CI_2 and then it was filtered through celite in order to separate NaCI. The solution was removed in vacuo again. Complex **1** was recrystallized from acetone/diethyl ether (1:3 v/v) to give yellow crystals. Yield 0.08 g, 41.9%. Data for **1**: $^{31}P\{^1H\}$ NMR (DMSO): −42.30 ppm (s), 36.18 ppm (s). Selected IR data (KBr): *v*(PS) 570.0 cm^{-1}, 1098.5 (s) and 622.7 (m) cm^{-1} (ClO_4^-). *Anal.* Calc. for $C_{49}H_{42}NClO_4P_4PdS_2$: C, 56.65; H, 4.04; S, 6.17; N, 1.34. Found: C, 56.12; H, 4.16; S, 5.80; N, 1.65%.

3.1.2. [Pd(dppe)(dppaS$_2$-H)](ClO$_4$)$_2$ (2)

[$PdCl_2$(dppe)] (0.17 mmol, 0.10 g), $dppaS_2$ (0.17 mmol, 0.08 g) were placed together in 30 mL CH_2CI_2 and stirred. The solution of $NaClO_4 \cdot H_2O$ (0.71 mmol, 0.10 g) in 20 mL acetone was added dropwise to the stirring solution. After 24 h, the solution was removed in vacuo. The solid was dissolved in CH_2CI_2 and then it was filtered through celite to separate NaCI. After the resulting solution was removed in vacuo this complex was obtained as a cream solid and it was recrystallized from acetone/hexane. (1:3 v/v). Yield 0.07 g, 40%. Data for **2:** $^{31}P\{^1H\}$ NMR (DMSO): 72.13 ppm (s), 38.76 ppm (s). Selected IR data (KBr): *v*(PS) 573.0 cm^{-1}, 1098.5 (s) and 622.7 (m) cm^{-1} (ClO_4^-). *Anal.* Calc. for $C_{50}H_{44}NClO_4P_4PdS_2$: C, 57.04; H, 4.21; S, 6.09; N, 1.33. Found: C, 56.44; H, 4.15; S, 5.53; N, 1.76%.

3.1.3. [Pd(dppp)(dppaS$_2$-H)](ClO$_4$)$_2$ (3)

This complex was obtained as a yellow solid, in a manner similar to **1** and **2** from [$PdCl_2$(dppp)] (0.17 mmol, 0.10 g), $dppaS_2$ (0.17 mmol, 0.08 g) and $NaClO_4 \cdot H_2O$ (0.71 mmol, 0.10 g). Yellow crystals, suitable for X-ray analysis, were obtained by slow diffusion

3.2. Method II

3.2.1. *[Pd(dppe)(dppaS$_2$-H)](ClO$_4$)$_2$ (**2a**)*

$dppaS_2$ (0.45 mmol, 0.2 g) and $KOBu^t$ (0.45 mmol, 0.05 g) were stirred in diethyl ether and $K[N(SPPh_2)_2]$ synthesized.

$K[N(SPPh_2)_2]$ (0.17 mmol, 0.085 g) in 5 mL methanol and $NaClO_4 \cdot H_2O$ (0.71 mmol, 0.10 g) in 2 mL methanol was added to $PdCl_2$dppe (0.17 mmol, 0.1 g) in 15 mL CH_2Cl_2. After 24 h, the solvent was removed in vacuo. Complex **2a** was recrystallized from CH_2Cl_2/diethyl ether (1:3 v/v). Yield 0.11 g, 58.08%. Data for **2a**: $^{31}P\{^1H\}$ NMR ($CDCl_3$): 69.5 ppm (s), 38.6 ppm (s). Selected IR data (KBr): ν(PS) 576.0 cm^{-1}, 1093.7 (s) and 623.1 (m) cm^{-1} (ClO_4^-). *Anal.* Calc. for $C_{50}H_{44}NClO_4P_4PdS_2$: C, 57.04; H, 4.21; S, 6.09; N, 1.33. Found: C, 56.09; H, 4.38; S, 5.5; N, 1.65%.

3.2.2. *X-ray crystallographic study of **2**, **2a** and **3***

The intensity data of the complexes **2**, **2a** and **3** were collected using a STOE IPDS 2 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$) at 296 K. Details of crystal data, data collection, structure solution and refinement are given in Table 2. Data collection: Stoe X-AREA [22]. Cell refinement: Stoe X-AREA [22]. Data reduction: Stoe X-RED [22]. The structure was solved by direct-methods using SHELXS-97 [23] and anisotropic displacement parameters were applied to non-hydrogen atoms in a full-matrix least-squares refinement based on F^2 using SHELXL-97 [24]. All hydrogen atoms were included using a riding model. Molecular drawings were obtained using ORTEP-III [25].

4. Supplementary material

CCDC 622361, 622362 and 622363 contains the supplementary crystallographic data for $C_{50}H_{44}NClO_4P_4PdS_2 \cdot (CH_3)_2CO$, $C_{50}H_{44}NClO_4P_4PdS_2 \cdot CH_2Cl_2$ and $C_{51}H_{46}NClO_4P_4PdS_2 \cdot (CH_3)_2CO$ respectively. These data can be obtained free of charge via http://www.ccdc.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

The authors acknowledge the Faculty of Arts and Sciences, Ondokuz Mayis University, Turkey, for the use of the STOE IPDS II diffractometer (purchased under Grant F.279 of the University Research Fund).

are strongly influenced by the type of derivatization of the ligand skeleton, as has been demonstrated on the H_4dota derivatives with phosphorus acid pendant arms [11]. These macrocyclic ligands have some similarities to the acetic parent compound due to the acid character of the groups, but the other properties (bulkiness, basicity, hydrogen bond formation ability) are different [11]. Generally, they form more stable complexes with lanthanide(III) ions than do the respective macrocyclic dota-like ligands [11,12].

The thermodynamic and kinetic properties of europium(III) complexes with macrocyclic ligands (see Scheme 1) were studied for H_2do2a [13], H_3do3a [14], H_4dota [15–19], H_5do3ap [12] and H_8dotp [20,21] with the application of various experimental techniques; mostly pH glass-electrode potentiometry [13,15,18–20], molecular absorption spectroscopy in the UV/VIS region [14–21] and luminescence spectroscopy [14,16,17,21]. Also, the thermodynamic and kinetic studies of other lanthanides (mostly gadolinium(III)) complexes were performed, *e.g.* Gd(III)-H_3do3a [22,23], Gd(III)-H_4dota [24] and Gd(III)-H_8dotp [25]. In addition, the analogous system Y(III)-H_4dota was studied from theoretical [26,27] and experimental [28] points of view. In this contribution, the kinetic properties of europium(III) complexes of cyclen derivatives containing acetic and phosphonic/phosphinic acid pendant groups were investigated (Scheme 1) by means of UV/VIS molecular absorption spectroscopy. Time-resolved laser-induced fluorescence spectroscopy (TRLIFS) was applied for determination of the hydration numbers of the europium(III) ion during the course of complex formation and dissociation in order to elucidate the intimate reaction mechanism.

2. Experimental

A stock solution of europium(III) perchlorate/chloride (0.05 mol l^{-1}) was obtained by dissolving Eu_2O_3 (spectroscopically pure, prepared at the Department of Rare Earths, Faculty of Chemistry, Adam Mickiewicz University, Poznań or from Alfa, Darmstadt, Germany) in a perchloric/hydrochloric acid solution (Analar grade, Fluka). The H_3do3a · H_2SO_4 was a kind gift of Bracco SpA (Italy). The other ligands were prepared according to previously described procedures: H_4dota [29], H_5do3ap [30] and H_5do3ap^{PrA} [28]. Stock solutions of the ligands were prepared by dissolving a weighed amount in bidistilled water. All other chemicals of the highest available purity were used as received.

R^1	R^2	Ligand
CO_2H	H	H_3do3a
CO_2H	CH_2CO_2H	H_4dota
CO_2H	$CH_2PO_3H_2$	H_5do3ap
CO_2H	$CH_2P(O)(OH)(CH_2)_2CO_2H$	H_5do3ap^{PrA}
PO_3H_2	$CH_2PO_3H_2$	H_8dotp

Scheme 1.

The experimental methodology for the kinetic study of the europium(III) complexation and decomplexation was the same as for other lanthanide(III) complexes with H_5do3ap, and details are given elsewhere [12].

All spectrophotometric kinetic measurements were carried out on a diode array spectrophotometer HP-8453 A (Hewlett–Packard, USA) at the temperature of 25.0 ± 0.1 °C. The formation kinetics of the $[Eu(H_2O)(do3ap)]^{2-}$ complex was followed under pseudo-first order conditions ($c_{Eu} = (0.8–4.0) \times 10^{-3}$ mol l^{-1}, $c_{do3ap} = 8 \times 10^{-5}$ mol l^{-1}, $I = 0.1$ mol l^{-1} KCl) in the pH range 4.0–5.5 and in the wavelength region 290–340 nm. Dissociation kinetics of the europium(III) complexes were measured in the proton concentration range 0.10–3.00 mol l^{-1} and ionic strength $I = 3.00$ mol l^{-1} (Na,H)ClO_4 ($c_{EuL} \sim 5 \times 10^{-3}$ mol l^{-1}). The decomplexation of the europium(III) complexes was followed by a decrease of its CT band [15,21]. Data from kinetic experiments were processed by non-linear regression using EXCEL, HP and/or PROK-II [31] software, giving identical results. The measured values of absorbances were corrected for background analytical signals.

The luminescence lifetime measurements at room temperature were carried out using a detection system consisting of a nitrogen laser and a tunable dye laser ($\lambda_{exc} = 394$ nm), as described earlier [32,33]. The kinetics of the formation reaction of the europium(III) complexes were studied in 1-cm sample cells where the ligand excess over europium(III) was ensured: $c_{Eu} = 0.005$ mol l^{-1}, $c_L = 0.01$ mol l^{-1}, $c_{MES} = 0.3$ mol l^{-1} (pH 5.6). The formation kinetics experiments were initiated by the addition of the Eu(III) stock solution to the cell containing the ligand and a buffer. After mixing of all the reagents, the first decay curve was usually measured between the 10th and the 15th second (reaction dead time). The experiments were stopped when the luminescence decay became constant. The kinetics of the dissociation reaction of the europium(III) complexes ($c_{EuL} \sim 0.01$ mol l^{-1}) was followed in acidic media (perchloric, hydrochloric acids) with acid concentrations between 0.3 and 3.0 mol l^{-1}. The reaction was initiated by the addition of the complex solution to the cell containing an acid. The first measurement was usually done between the 30th and the 60th second after the reaction was started (reaction dead time). Experiments were stopped when the measured lifetime of the luminescent decay was equal to the lifetime of the "free" Eu(III) hydrated ion (~110 μs). All lifetime experiments were repeated at least three times in order to get average values, and they were corrected for the dead time in the kinetic treatment. The experimental luminescence decay data were fitted by one-term, two-term or three-term exponential equations as follows:

$$I_{tot} = I_1 \times e^{-\frac{t}{\tau_1}} + I_2 \times e^{-\frac{t}{\tau_2}} + (I_3 \times e^{-\frac{t}{\tau_3}}) \quad (1)$$

where I_{tot} is measured intensity of fluorescence as a function of time (μs), I_n are the fluorescence intensities and τ_n are the lifetimes of the luminescence decay of the individual species. Monoexponential decay was observed only for the

formation (H_3do3a, H_5do3ap, H_5do3ap^{PrA}) and dissociation kinetic studies (H_3do3a) whilst a two-exponential decay was found for the study of the dissociation of the europium(III) complexes of the H_4dota, H_5do3ap and H_5do3ap^{PrA}. In agreement with the literature [19], tri-exponential decay was observed for the formation of the europium(III) complex with H_4dota. The luminescence decay measurements were used for the estimation of the number of water molecules as discussed earlier [10,33–35]. In this work, the hydration numbers, q, of the complexes were determined by means of the equation below [33,36]

$$q_B = 1.05 \times \tau^{-1} - 0.7 \quad (2)$$

which is a simplified modification of Horrock's equation [33,35,37,38], demonstrated in our previous work. Results based on both equations are in a good agreement [33]. The calculated parameters for the luminescent decay as functions of time were used for the calculation of rate constants.

3. Results and discussion

3.1. Thermodynamic stability of europium(III) complexes of the macrocyclic ligands

The europium(III) ion forms stable complexes [11–20] of EuL stochiometry with the H_4dota-like ligands (see Table 1). The solid-state structure of the sodium salt of the $[Eu(H_2O)(dota)]^-$ complex was determined by X-ray crystallography [42]. The eight coordination sites of the europium(III) ion are occupied by four nitrogens atoms of the cyclen ring and four oxygen donor atoms from each of the four carboxylate arms of the ligand. The coordination sphere is completed by a water molecule, leading to a distorted capped square antiprismatic arrangement [42] which is crystallographically isostructural with sodium salts of the $[Y(H_2O)(dota)]^-$ and $[Gd(H_2O)(dota)]^-$ complexes [43]. The water molecule in the first coordination sphere of the complex is also present in solution [33].

The presence of the phosphonic acid pendant arm in H_5do3ap leads to an increase in the stability of the $[Eu(H_2O)(do3ap)]^{2-}$ complex in comparison to those of the europium(III) complexes of H_3do3a and H_4dota (Table 1) [12]. Attachment of other functional groups to the phosphorus atom, as in the bifunctional chelator (BFC) H_5do3ap^{PrA}, caused a slight decrease in the stability of its europium(III) complex compared with that of H_4dota [28]. Since the europium(III) complexes of H_5do3ap and H_5do3ap^{PrA} bind one water molecule in the first coordination sphere [33] all pendant arms have to be coordinated to europium(III) ions, similarly to other lanthanide(III) complexes of H_5do3ap [30], its monoethyl ester [44] and its aminobenzylphosphinic acid analogs [45] in solution.

Table 1
The summary of dissociation constants of the macrocyclic ligands and their stability constants with the europium(III) ion ($T = 298.2$ K, $I = 0.1$ mol l^{-1})

3.2. Formation kinetics

The formation of the europium(III) complex with H_5do3ap was studied by molecular absorption spectroscopy and a monotonic increase of absorbance in the 270–300 nm region was observed. The same phenomena was described for the europium(III)-H_4dota system [15].

Pseudo-first order reaction conditions were employed (10–50 molar excess of europium(III) ion over ligand), and the resulting data follow a rate law for complex formation given by Eq. (3) (the charges of the complexes are omitted for the sake of clarity).

$$\frac{d[EuL]}{dt} = {}^{Eu}k_{f,obs} \times [L]_{tot} \quad (3)$$

The model frequently used to describe the complexation reaction assumes fast formation of a reaction intermediate characterized by the conditional stability constant ${}^{Eu}K^{**}$ (Eq. (4))

$${}^{Eu}K_n^{**} = \frac{[Eu(H_nL)]}{[Eu^{3+}] \times [L]_{tot}} \quad (4)$$

This reaction step is followed by a slow rate-determining step, leading to the final product which is defined by rate constant ${}^{Eu}k_f$.

$${}^{Eu}k_{f,obs} = \frac{{}^{Eu}k_f \times {}^{Eu}K_n^{**} \times [Eu^{3+}]_{tot}}{1 + {}^{Eu}K_n^{**} \times [Eu^{3+}]_{tot}} \quad (5)$$

As a consequence of this fact, the conditional pseudo-first order rate constant ${}^{Eu}k_{f,obs}$ is dependent on the total (analytical) concentration of europium(III) (Eq. (5)). The pseudo-first order rate constant ${}^{Eu}k_{f,obs}$ (for $c(Eu^{3+}) \geqslant 10\ c(H_5do3ap)$) was observed to be practically independent on total europium(III) concentration in the pH regions 4.0–5.5. The same effect was observed for the cerium(III)-H_5do3ap system (metal ion or ligand excess with respect to the other reactant [12]). This means that the formation

of the reaction intermediate is quantitative ($^{Eu}K^{**} \times [Eu^{3+}]_{tot} \gg 1$ in the denominator of Eq. (5)), and the relationship can be simplified as $^{Eu}k_{f,obs} \approx {}^{Eu}k_f$.

The measured conditional equilibrium constant $^{Eu}K^{**}$ is dependent on the pH of the solution [13,15], while other protonated species of ligand are presented in solution (Eq. (6), $K_{p,n}$ are stepwise ligand protonation constants),

$$^{Eu}K_3^{**} = \frac{[Eu(H_3L)]}{[Eu^{3+}] \times [H_3L] \times (1 + K_{p,4} \times [H^+] + K_{p,4} \times K_{p,5} \times [H^+]^2)} = \frac{^{Eu}K_3^*}{\alpha_{H_3L(H)}} \quad (6)$$

and therefore the equilibrium constant $^{Eu}K^*$ is defined by the following equation:

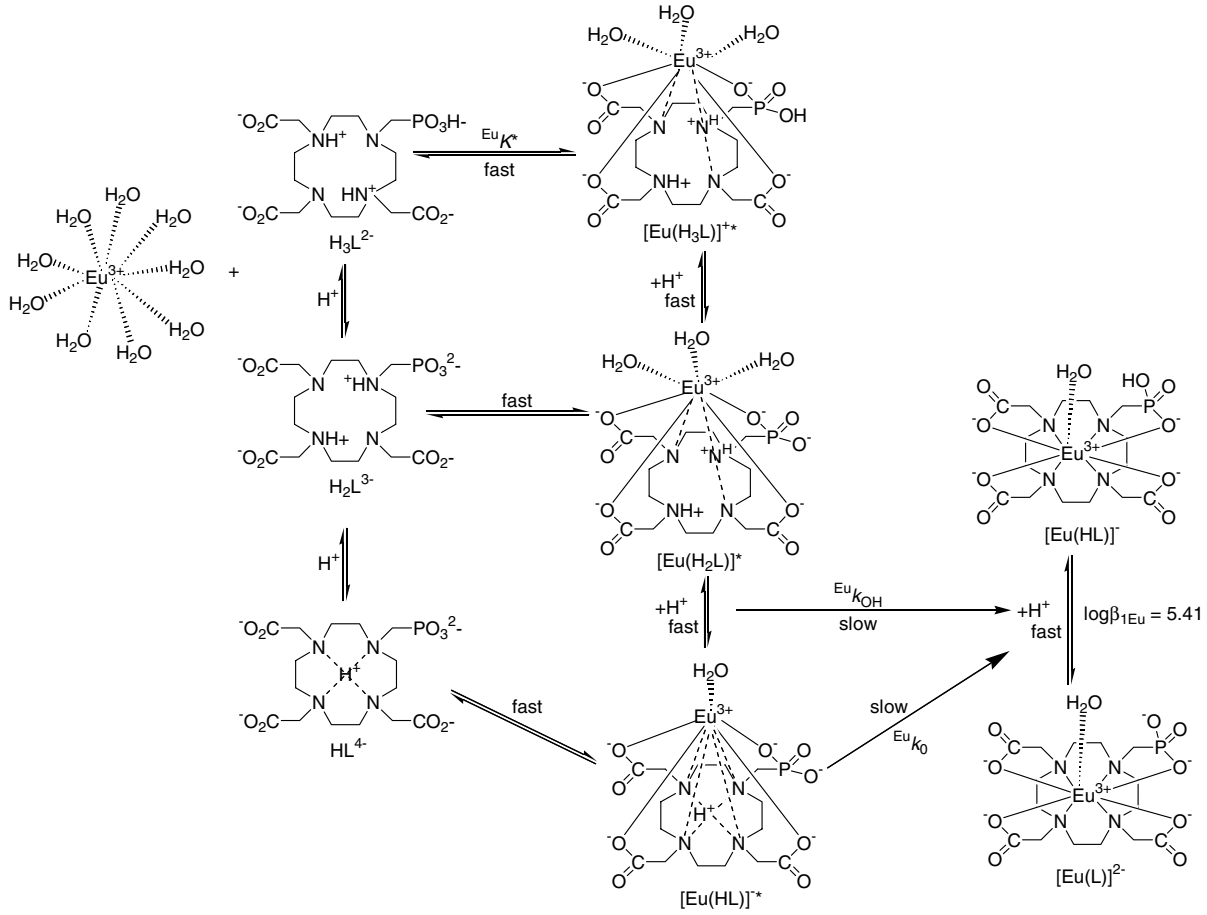
$$^{Eu}K_3^* = \frac{[Eu(H_3L)]}{[Eu^{3+}] \times [H_3L]} \quad (7)$$

The equilibrium constant $^{Eu}K_3{}^{**}$ is a pH-dependent parameter, and it can be calculated from the absorbance values extrapolated to zero time ($A_{t=0}$) [12,15]. The conditional equilibrium constant $^{Eu}K_3{}^{**}$ is corrected according to Eq. (7) in order to calculate $^{Eu}K_3{}^*$, and the value $\log {}^{Eu}K_3{}^* = 3.01 \pm 0.03$ was estimated. This value should be constant for the intermediate species prevailing in solution under the given experimental conditions. However, this requirement was not fulfilled for the $[Eu(H_2do3ap)]^*$ species. The value of $^{Eu}K_3{}^*$ of the $[Eu(H_3do3ap)]^{*+}$ species differs from that $\log {}^{Eu}K_2{}^*$ of the $[Eu(H_2dota)]^{*+}$ species obtained by UV molecular absorption spectroscopy (4.4 ± 0.1) or potentiometry (4.32 ± 0.05) [15]. However, different values for the same $[Eu(H_2dota)]^{*+}$ intermediate species (5.88 and 6.26) were obtained by means of TRLIFS [16,17]. The hypothesis is confirmed by the fact that the most abundant protonated species of the monophosphonate ligand in the pH region of the study is H_3do3ap^{2-} [12]. In order to determine the composition of the most probable reaction intermediate, knowledge about the kinetics of the other lanthanide(III) systems with H_5do3ap (Ce^{3+} and Gd^{3+} [12]) or other europium(III)-macrocyclic ligand systems (H_2do2a [13], H_3do3a [14] and H_4dota [15,17–19]) should be taken into account. Thus, the $[Eu(H_3do3ap)]^{*+}$ reaction intermediate should be considered as the most abundant species in the studied pH region. The $[Eu(H_2do3ap)]^*$ and the $[Eu(Hdo3ap)]^{*-}$ species are minor ones and all the species are in a fast protonation equilibrium (Scheme 2); the $[Eu(Hdo3ap)]^{*-}$ species, present in only a trace concentration, is probably kinetically the most reactive species.

The rate-limiting step of the formation reaction is the deprotonation of the nitrogen atoms in the intermediate species, catalyzed by hydroxide ions and simultaneous translocation of the metal ion inside the ligand cavity (Eq. (8), Scheme 2, Fig. 1)

$$^{Eu}k_f = {}^{Eu}k_{f,obs} = {}^{Eu}k_{OH} \times [OH^-] + {}^{Eu}k_0 \quad (8)$$

The rate constant $^{Eu}k_{OH} = (2.7 \pm 0.2) \times 10^6\ M^{-1}\ s^{-1}$ is given by the slope of the linear dependence, and $k_0 = (0.9 \pm 0.5) \times 10^{-3}\ s^{-1}$ is its intercept (Fig. 1). The water-assisted (proton-transfer) pathway characterized by k_0 was neglected in the description of the formation reaction of europium(III) ion with some macrocyclic ligands (Table 2). Both hydroxide- and solvent-assisted reaction pathways were also observed for the formation of the gadolinium(III) complex with H_5do3ap [12]. The rate constant $^{Eu}k_{OH}$ for H_5do3ap is slightly lower than the respective rate constant for H_4dota (see Table 2) and comparable with the value $^{Eu}k_{OH} = (4.8 \pm 0.07) \times 10^6\ M^{-1}\ s^{-1}$ ($I = 1.0$ M KCl, $T = 298.2$ K) for the do3a-butriol derivate [13].



The formation kinetics in the europium(III)-H_5do3ap system was also followed by means of TRFLIS under similar experimental conditions as studied by molecular absorption spectroscopy in the UV region (see Fig. 2). In addition, to determine the kinetic parameters the technique provides information about the nature of the reaction intermediates. The luminescent decays recorded at different reaction times were monoexponential (see Eq. (1)), and the number of water molecules obtained from the lifetimes of luminescent decay decreased during the reaction time. The mechanism of europium(III) complex formation discussed above can be briefly written as (the charges of complexes and protons bound to the ligand are omitted for the sake of clarity)

$$Eu(H_2O)_n^{3+} + L \underset{+(m-n)H_2O}{\overset{K^{**}}{\rightleftarrows}} EuL(H_2O)_m^* \overset{^{Eu}k_f}{\rightarrow} EuL(H_2O)_p \quad (A)$$

The reaction intermediate is formed in a fast equilibrium, and its transformation to the final product proceeds *via* a slower rate-determining step characterized by the first-order rate constant $^{Eu}k_f$. If there is a ligand excess with respect to the europium(III) ion, as in our experiment, only the reaction intermediate and the final product (see reaction (A)) are present in solution. Both species differ in the number of coordinated water molecules and their normalized concentrations can be followed by TRFLIS with assumptions that the average number of water molecules consists of contributions from both species and that the number of water molecules is independent of species concentration. Thus, the average number of water molecules as function of time is defined as

$$q_t = q_t(EuL^*) + q_t(EuL) \quad (9)$$

The change in the number of water molecules is driven by the first-order kinetics:

Scheme 2. The proposed reaction mechanism for complexation of europium(III) with H_5do3ap (sites of the protonations are tentative). The thermodynamic dissociation constant of $[Eu(H_2O)(Hdo3ap)]^-$ is taken from [12].

$$q_t(\mathrm{EuL}^*) = q_{t=0}(\mathrm{EuL}^*) \times e^{-{}^{Eu}k_f \times t} \quad (10)$$

$$q_t(\mathrm{EuL}) = q_{t=\infty}(\mathrm{EuL}) \times (1 - e^{-{}^{Eu}k_f \times t}) \quad (11)$$

The combination of Eq. (9) with Eqs. (10) and (11) leads to relationship (12)

$$q_t = q_{t=0}(\mathrm{EuL}^*) \times e^{-{}^{Eu}kf \times t} + q_{t=\infty}(\mathrm{EuL}) \times (1 - e^{-{}^{Eu}k_f \times t})$$
$$= e^{-{}^{Eu}k_f \times t}(q_{t=0}(\mathrm{EuL}^*) - q_{t=\infty}(\mathrm{EuL})) + q_{t=\infty}(\mathrm{EuL}) \quad (12)$$

After rearrangement, the final relationship (13) is obtained:

$$\ln(q_t - q_{t=\infty}(\mathrm{EuL})) = \ln(q_{t=0}(\mathrm{EuL}^*) - q_{t=\infty}(\mathrm{EuL})) - {}^{Eu}k_f \times t \quad (13)$$

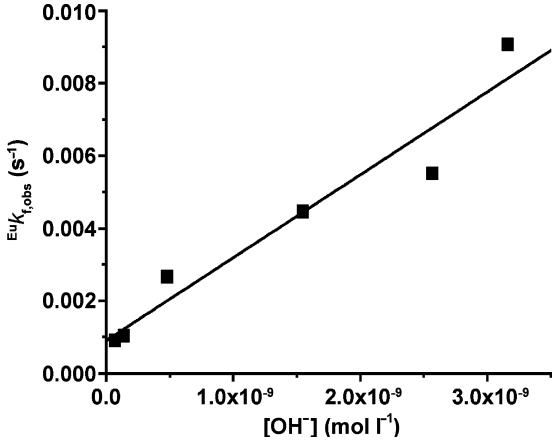


Fig. 1. Dependence of the observed pseudo-first order rate constants $^{Eu}k_{f,obs}$ on $[OH^-]$ for the formation of the $[Eu(H_2O)(do3ap)]^{2-}$ complex (UV–Vis measurements).

The linearized relationship (13) or relationship (12) combined with a non-linear least-square procedure, can be used for determination of the rate constant $^{Eu}k_f$ and the number of water molecules in the final product and in the reaction intermediate at the beginning of the reaction, *i.e.* immediately after mixing of the reactants. The results of the non-linear fit for the reactions of europium(III) with the three macrocyclic ligands (H_3do3a, H_5do3ap and H_5do3ap^{PrA}) are given in Table 3. Also the number of water molecules determined from equilibrium and the kinetic measurements are in fair agreement (see Table 3, [33]). A special case is the europium(III) complexation by H_4dota. It was shown that two reaction intermediates ($[EuH_n(dota)(H_2O)_5]^{(n-1)**}$ (intermediate **1**) and $[EuH_n(dota)(H_2O)_3]^{(n-1)*}$ (intermediate **2**)) and the final product ($[Eu(dota)(H_2O)]^-$ (**3**)) are formed at pH ≈ 2.5–

3.0 [19]. The intermediates are stable for several days and were characterized by EXAFS and luminescence spectroscopy; they differ in the number of coordinated water molecules (5 and 3) [19]. By analyzing NMR spectra recorded immediately after mixing of europium(III) and H_4dota at pD ≈ 4.3–4.6, it was shown that the intermediate(s) demonstrate the rigidity of the tetraaza macrocycle ring [24]. The measured luminescence decay traces measured here were deconvoluted with published lifetimes (taken from [19]: $\tau_1 = 0.6427$ ms, $\tau_2 = 0.2851$ ms and $\tau_3 = 0.2013$ ms; see Eq. (1)), and the intensities calculated for the intermediate species (after normalization) are presented in Fig. 3. As it can be seen, a decrease in solution acidity (a pH rise from 2.5–3.0 in [19] to 5.5 here) accelerates the rate of complex formation from days to minutes, and the same effect was observed in the studies with the pH range 2.5–4.6 [15,19].

On the basis of these observations, a reaction mechanism for formation of the $[Eu(H_2O)(do3ap)]^{2-}$ complex can be postulated. In the first fast step, the reaction intermediate $[Eu(H_2O)_3(H_3do3ap)]^{*+}$, having three water molecules in the first coordination sphere, is formed. Analogously, the $[Ce(H_3do3ap)]^{*+}$ species was also found in the cerium(III)-H_5do3ap system in weakly acidic medium [12], and this species is probably rather stable towards further deprotonation under those conditions. The same phenomena was

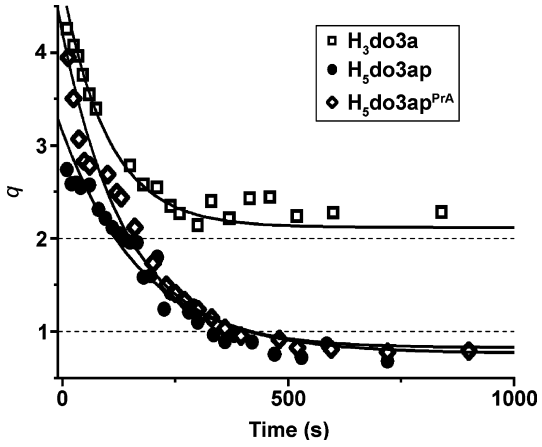

Fig. 2. Time dependence of change in the number of bound water molecules (q) during formation of the europium(III) complexes with given macrocyclic ligands ($c_{Eu} = 0.005$ mol l^{-1}, $c_L = 0.006$ mol l^{-1}, pH 5.6).

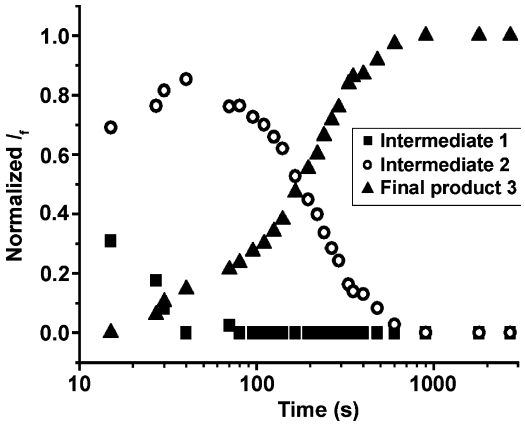

Fig. 3. Time dependence of abundance of the kinetic species during formation of the $[Eu(H_2O)(dota)]^-$ complex ($c_{Eu} = 0.005$ mol l^{-1}, $c_L = 0.006$ mol l^{-1}, pH 5.6).

observed in the case of the europium(III)-H_4dota system [15,18] where the presence of the corresponding double-protonated species $[Eu(H_2dota)]^{*+}$ is crucial. The structure of the reaction intermediates for both ligands (H_5do3ap and H_4dota) is probably similar under the assumption that two nitrogen atoms of the cyclen ring are protonated. In the $[Eu(H_2O)_3(H_3do3ap)]^{*+}$ species, the third proton is probably attached to the phosphonate moiety coordinated to the lanthanide(III) ion. Recently, such double nitrogen protonation was observed in the solid-state structure of the $[Er(H_2O)_2(H_2do3ap^{Ph})]_2Cl_2$ dimeric complex crystallized from acid solutions (pH < 4.5; H_4do3ap^{Ph} is the phenylphosphinic acid analog of H_5do3ap) [46] as well as in the gadolinium(III) complex of the diprotonated form of dotam (dotam is the tetraamide of H_4dota) in the solid state where four water molecules are bound to the central metal ion [47]. On the other hand, a different structure (protonated on one nitrogen atom) was predicted for an intermediate in complexation in the yttrium(III)-H_4dota system by quantum chemical calculations [26]. Such a monoprotonated species $[Eu(HL)]^*$ is supposed to be a crucial intermediate for the transformation of the reaction intermediate(s) to the final product having one water molecule. This scenario, with participation of the monoprotonated species, is very probable because of the increase in values of the rate constant k_f with increasing ionic strength for yttrium(III) complexation by the same H_4dota-like ligands [28]. This supports the hypothesis that the reaction takes place between reactants of the same charge (i.e. here $[Eu(HL)]^-$ vs. OH^- for the phosphorus acid derivatives) [28].

The proposed reaction mechanism can be also assumed for complexation of europium(III) ion by the other macrocyclic ligands (H_3do3a, H_5do3ap^{PrA}) as was proved for the yttrium(III) complex formation [28]. The reaction intermediates formed differ in the number of bound water molecules and in the number of protons (see Scheme 2), but their structure should be similar. In the case of H_4dota, the reaction mechanism proposed in the literature [19] was verified in the present study.

3.3. Dissociation kinetics

Acid-assisted decomplexation was investigated in order to determine the kinetic inertness of the europium(III) complexes with the macrocyclic ligands under study since the rate of complex dissociation is slow in slightly acidic media [48]. The kinetic inertness of the europium(III) complexes with H_4dota-like ligands is attributed to the rigid structure of the coordinated cyclen ring. The proton-assisted dissociation kinetics is usually studied in the presence of strong mineral acids ($c = 0.1$–1.0 mol l^{-1}) since the europium(III) complexes are thermodynamically unstable under these experimental conditions. In the literature, the mechanism for dissociation of the europium(III) complex with the H_4dota has been established [15,48]. Assuming the $[Eu(H_nL)]^*$ species as the active ones in the dissociation process with respective protonation constants

$$ {}^{H}K_n = \frac{[Eu(H_nL)]}{[Eu(L)] \times [H^+]^n} \tag{14} $$

then generally, the rate of dissociation of the europium(III) complexes is defined as

$$ -\frac{d[EuL]}{dt} = {}^{Eu}k_{d,obs} \times [EuL]_{tot} = \sum_{i=1}^{n} k_{d,i} \times [Eu(H_iL)] \tag{15} $$

taking into account the mass-balance equation (Eq. (16))

$$ [EuL]_{tot} = \sum_{i=0}^{n} [Eu(H_iL)] \tag{16} $$

Combining Eqs. (14)–(16), the following relationship (17) can be written as

$$ {}^{Eu}k_{d,obs} = \frac{k_{d,1} \times {}^{H}K_1 \times [H^+] + k_{d,2} \times {}^{H}K_1 \times {}^{H}K_2 \times [H^+]^2}{1 + {}^{H}K_1 \times [H^+] + {}^{H}K_1 \times {}^{H}K_2 \times [H^+]^2} \tag{17} $$

In weakly acidic medium ($[H^+] < 0.0001$–0.001 mol l^{-1}), the simplified Eq. (18) was described for the acid-assisted dissociation of lanthanide(III) complexes with H_3do3a or H_4dota [15,16,48]:

$$ {}^{Eu}k_{d,obs} = k_{d,1} \times {}^{H}K_1 \times [H^+] \tag{18} $$

An additional term k_0, that characterizes the spontaneous dissociation of the complex, can be determined, but with large errors [12,15,21].

For H_5do3ap and the H_5do3ap^{PrA}, one extra proton is attached to the phosphonate group or the carboxyl group of the phosphinate side chain, and therefore, in the acidity region employed for complex dissociation, there is no $[Ln(H_2O)(do3ap)]^{2-}$ species present in the solution and our systems are formally shifted by one proton (Scheme 3a) compared to the complexes with H_3do3a or H_4dota, and the dependence of ${}^{Eu}k_{d,obs}$ on the proton concentration can be reformulated as follows:

$$ {}^{Eu}k_{d,obs} = \frac{k_{d,1} \times {}^{H}K_2 \times [H^+] + k_{d,2} \times {}^{H}K_2 \times {}^{H}K_3 \times [H^+]^2}{1 + {}^{H}K_2 \times [H^+] + {}^{H}K_2 \times {}^{H}K_3 \times [H^+]^2} \tag{19} $$

From Scheme 3a, one can suggest that $k_{d,1} \ll k_{d,2}$. Furthermore, $1 \ll {}^{H}K_2 \times [H^+] + {}^{H}K_2 \times {}^{H}K_3 \times [H^+]^2$ (compare data in Table 2) and therefore Eq. (22) can be simplified in the following way:

$$ {}^{Eu}k_{d,obs} \approx \frac{k_{d,2} \times {}^{H}K_3 \times [H^+]}{1 + {}^{H}K_3 \times [H^+]} \tag{20} $$

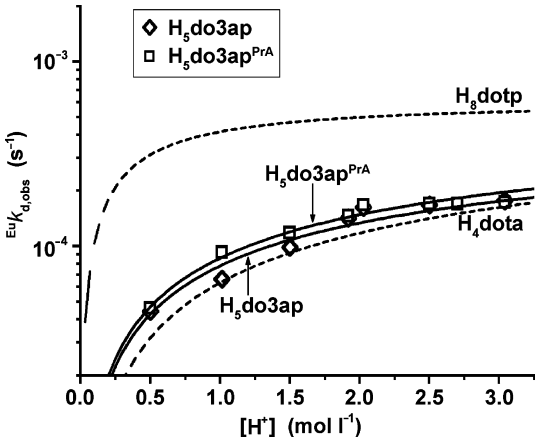
For a low value of ${}^{H}K_3$ or low acidity of the solution ($1 \gg {}^{H}K_3 \times [H^+]$), this equation can be rewritten as Eq. (21):

$$ {}^{Eu}k_{d,obs} \approx k_{d,2} \times {}^{H}K_3 \times [H^+] = k_{H,1} \times [H^+] \tag{21} $$

The kinetics of the proton-assisted decomplexation of the europium(III) complexes with the phosphorus acid ligands H_5do3ap and H_5do3ap^{PrA} were studied in the region 0.50–3.00 mol l^{-1} $HClO_4$. The dependence of the pseudo-first order rate constants ${}^{Eu}k_{d,obs}$ on the proton

concentration for both complexes is presented in Fig. 4. As it can be seen, the experimental points for both europium(III) complexes fall together. Eq. (20) was used to fit the experimental points, and the following parameters were estimated: $k_{d,2} = (4.6_2 \pm 0.9_8) \times 10^{-4}\ s^{-1}$, $^{H}K_3 = 0.21_2 \pm 0.04_6\ M^{-1}$, $k_{H1} = 0.977 \times 10^{-5}\ M^{-1}\ s^{-1}$ (H_5do3ap); $k_{d,2} = (5.2_5 \pm 0.9_1) \times 10^{-4}\ s^{-1}$, $^{H}K_3 = 0.19_6 \pm 0.03_5\ M^{-1}$, $k_{H1} = 1.027 \times 10^{-4}\ M^{-1}\ s^{-1}$ (H_5do3ap^{PrA}). The estimated parameters are almost identical, however they are uncertain because of the simplifying assumptions made in deriving the relationship used for the fitting. Therefore, the parameters k_{H1} were calculated in order to compare them with the parameters of dissociation for other lanthanide(III) complexes with H_5do3ap, see Refs. [12,28]: $k_{H1} = 1.22 \times 10^{-3}\ M^{-1}\ s^{-1}$ (Ce^{3+}); $k_{d,2} = 7.0 \times 10^{-3}\ s^{-1}$, $^{H}K_3 = 0.2\ M^{-1}$, $k_{H1} = 1.09 \times 10^{-3}\ M^{-1}\ s^{-1}$ (Y^{3+}), $k_{d,2} = 5.8 \times 10^{-2}\ s^{-1}$, $^{H}K_3 = 0.048\ M^{-1}$, $k_{H1} = 2.78 \times 10^{-3}\ M^{-1}\ s^{-1}$ (Gd^{3+}); and the similar kinetic inertness of the $[Y(H_2O)(do3ap^{PrA})]^{2-}$ complex ($k_{d,2} = 3.4 \times 10^{-3}\ s^{-1}$, $^{H}K_3 = 1.3\ M^{-1}$, $k_{H1} = 4.4 \times 10^{-3}\ M^{-1}\ s^{-1}$ [28]). The results are in agreement with the kinetic behaviour of both europium(III) complexes demonstrated above.

The rate of the $[Eu(H_2O)(do3ap)]^{2-}$ complex dissociation is about 10 times slower than that of the other lanthanide(III) complexes, and it seems that the europium(III) complex is the most inert among the studied lanthanide(III) complexes of H_5do3ap. A similar exceptional behaviour was described for acid-assisted dissociation of lanthanide(III) complexes of a triacetate derivative of the pyridine-containing cyclen analog [49] or the H_4edta ligand [50]. It can be possibly explained by a different hydration of the "free" ions. It is known that the europium(III) aqua ion



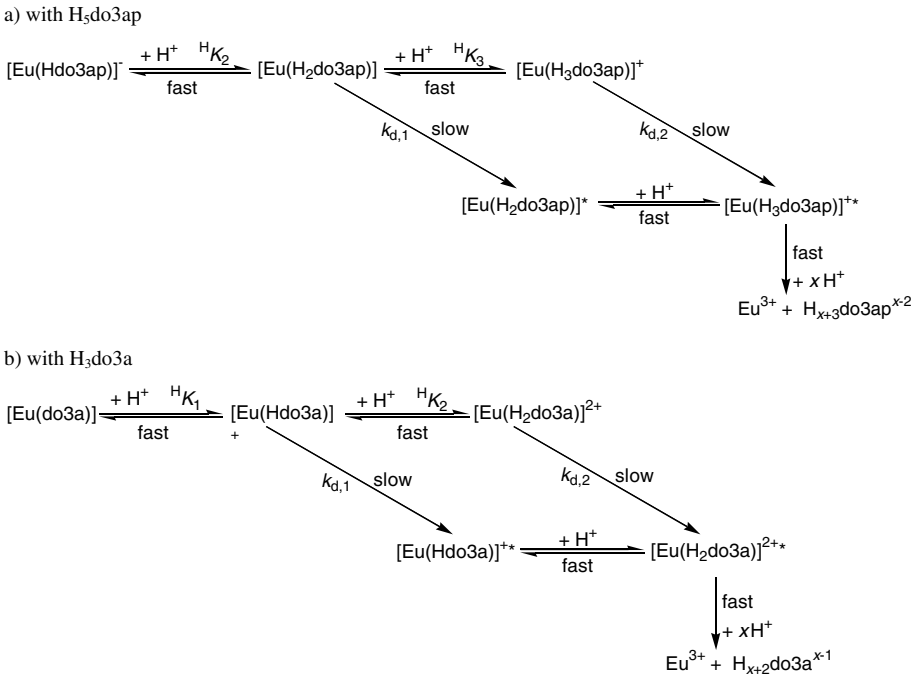


Fig. 4. Dependence of the pseudo-first rate constants $^{Eu}k_{d,obs}$ on the solution acidity for the dissociation of europium(III) complexes with phosphorus-containing macrocyclic ligands ($c_{EuL} = 0.015\ mol\ l^{-1}$, $I = 3.00\ mol\ l^{-1}$ (Na/H)ClO_4, UV–Vis measurements). The dashed lines were calculated according to Eq. (22) using the parameters given in Table 2.

varies its hydration number between 8 and 9, lying just on the borderline between lighter (hydration number 9) and heavier (hydration number 8) lanthanide(III) ions [34]. An equilibrium was observed between the differently hydrated europium(III) complex species with H_2do2a and H_3do3a, and the squaric acid derivative of H_3do3a, deviating by one water molecule in the first coordination sphere of the complex [51–53]; the corresponding constants and thermodynamic parameters describing the equilibrium were determined. The formation of the species with higher coordination and hydration numbers (more abundant at

Scheme 3. The proposed reaction mechanism for the dissociation of the europium(III) complex: (a) with H_5do3ap and (b) with H_3do3a.

room temperature) is preferred at lower temperature in comparison with the species with lower coordination and hydration numbers [18,51–53], which would be probably more kinetically inert species. It can be assumed that the nine-coordinated complexes of lighter lanthanides(III) ions would be less kinetically inert than the eight-coordinated complexes of heavier lanthanides(III) ions. Another effect, having an influence on the kinetic inertness, can be a difference in protonation constants of the complexes (*e.g.* Eu(III) vs. Gd(III) complex in Table 2 and Ref. [12] or Ref. [49]).

In order to elucidate the intimate reaction mechanism of the complex dissociation, TRFLIS was again employed. The decay traces of the europium(III) complexes with the macrocyclic ligands were recorded at different time points during the course of the dissociation reaction (see example in Fig. 5). The europium(III) complexes can be divided into two groups according to their behavior in the presence of an acid.

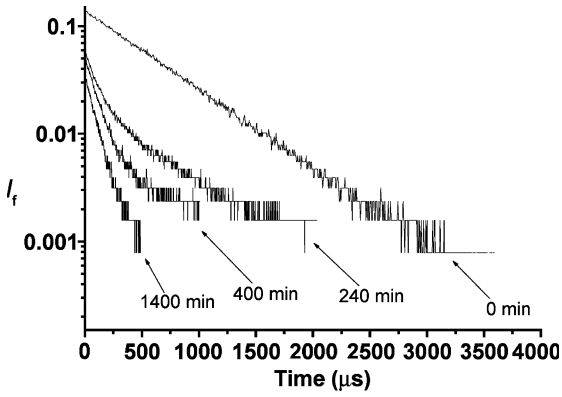

Fig. 5. Examples of TRFLS traces during decomplexation of the $[Eu(H_2O)(do3ap)]^{2-}$ complex recorded at different times ($[HClO_4] = 3.00$ mol l^{-1}, $c_{complex} = 0.01$ mol l^{-1}).

For the first group, involving europium(III) complexes of H_4dota and H_5do3ap, their luminescence decay traces recorded at the beginning and the end of the dissociation reaction can be deconvoluted monoexponentially (see Eq. (1) and Fig. S1 in the supplementary material) and the decay lifetimes τ are related to the number of coordinated water molecules in the complex and the free europium(III)-aqua ion, respectively (see Table 3). Thus, the luminescent decays recorded during the dissociation reaction have to be deconvoluted with two exponentials giving lifetimes (see Eq. (1)) corresponding to the starting monoaqua europium(III) complex and the final free nona-aqua europium(III) ion, while no other intermediate luminescence-active europium(III) species were detected in these systems. The decreasesing intensity of the luminescence signal of the monoaqua europium(III) complex species determined by luminescent decay deconvolutions (see Eq. (1)) for different time points recorded during the dissociation reaction (see Fig. S1) can be used for the determination of rate constants (see Table 4). In the case of H_4dota (Fig. S1A) and H_5do3ap (see Fig. S1B), the pseudo-first rate constants in perchloric and hydrochloric acids calculated from the TRFLIS experimental data are almost identical (see Table 4). The agreement between the results obtained from TRFLIS and UV spectroscopy is also satisfactory taking into account the precision of the measurements, and the slight difference between the values can be ascribed to the different experimental techniques and conditions employed in these studies. In addition, the dissociation of the europium(III) complexes of H_4dota and H_5do3ap is similar (see Fig. 4), and the process is not dependent on the nature of the anion (perchlorate vs. chloride) as was described for the luminescence behavior of the europium(III)-aqua ion [54–58]. Our results presented above confirm that the inner coordination sphere of the europium(III) ion in the $[Eu(H_2O)(dota)]^-$ complex is not affected by protonation in strongly acidic medium [15,18].

Table 4
The summary of the results obtained for the dissociation of Eu^{3+} complexes with H_4dota-like ligands (the ionic strength was not adjusted)

Species	Method	Acidity	Rate constant $k_{d,obs}$ (s^{-1})	Hydration number q of the intermediate
[Eu(do3a)]	TRFLIS (q)	0.3 mol l^{-1} $HClO_4$	$k_{d,1} = (8.2_0 \pm 0.4_7) \times 10^{-4}$	5.6
			$k_{d,2} = (1.80 \pm 0.04) \times 10^{-3}$	2.8
	TRFLIS (q)	1.0 mol l^{-1} $HClO_4$	$(6.1_2 \pm 0.2_0) \times 10^{-3}$	2.1
	TRFLIS (q)	3.0 mol l^{-1} $HClO_4$	$(1.22 \pm 0.08) \times 10^{-2}$	3.1
$[Eu(dotp)]^{5-}$[a]	TRFLIS (q)	3.0 mol l^{-1} $HClO_4$	$(1.53 \pm 0.08) \times 10^{-4}$[a]	0.4[a]
$Eu(dota)^-$]	TRFLIS (intensity)	3.0 mol l^{-1} $HClO_4$	$(2.95 \pm 0.08) \times 10^{-4}$	
	TRFLIS (intensity)	3.0 mol l^{-1} HCl	$(3.1_4 \pm 0.1_7) \times 10^{-4}$	
	UV spectroscopy	3.0 mol l^{-1} $HClO_4$	$(1.6_2 \pm 0.3_3) \times 10^{-4}$[b]	
$[Eu(do3ap)]^{2-}$	TRFLIS (intensity)	3.0 mol l^{-1} $HClO_4$	$(2.1_6 \pm 0.6_1) \times 10^{-4}$	
	TRFLIS (intensity)	3.0 mol l^{-1} HCl	$(2.9_1 \pm 0.1_1) \times 10^{-4}$	
	UV spectroscopy	3.0 mol l^{-1} $HClO_4$	$(1.8_0 \pm 0.5_5) \times 10^{-4}$[c]	
$[Eu(do3ap^{PrA})]^{2-}$	UV spectroscopy	3.0 mol l^{-1} $HClO_4$	$(1.9_4 \pm 0.4_8) \times 10^{-4}$[c]	

[a] Ref. [21]; for $q_{t=\infty} = 4.1$.
[b] Recalculated from Ref. [15].
[c] Recalculated from parameters in Table 2 and Fig. 4.

On the contrary, for the second group of europium(III) complexes, of H_3do3a (this work) and H_8dotp [21], the lumininiscence-decay traces are always deconvoluted monoexponentially (see Eq. (1)). The lifetime decay τ was used for the determination of the average number of bound water molecules in the europium(III) complex (see Eq. (2)) as a function of the time of the dissociation reaction (Fig. 6a). The average number of water molecules (q) is a weighted value defined analogously as in the section on the formation kinetics

$$q_t = q_{t=0}(\mathrm{EuL}^*) \times \mathrm{e}^{-{}^{\mathrm{Eu}}k_d \times t} + q_{t=\infty}(\mathrm{Eu}) \times (1 - \mathrm{e}^{-{}^{\mathrm{Eu}}k_d \times t}) = \mathrm{e}^{-{}^{\mathrm{Eu}}k_d \times t}(q_{t=0}(\mathrm{EuL}^*) - q_{t=\infty}(\mathrm{Eu})) + q_{t=\infty}(\mathrm{Eu}) \quad (22)$$

The final relationship (23) is obtained after rearrangement:

$$\ln(q_{t=\infty}(\mathrm{Eu}) - q_t) = \ln(q_{t=\infty}(\mathrm{Eu}) - q_{t=0}(\mathrm{EuL}^*)) - {}^{\mathrm{Eu}}k_{\mathrm{d}} \times t \quad (23)$$

For H_3do3a, Eq. (23) was used for treatment of the experimental data. The rate of dissociation was not dependent on the nature of the anion (perchlorate vs. chloride).

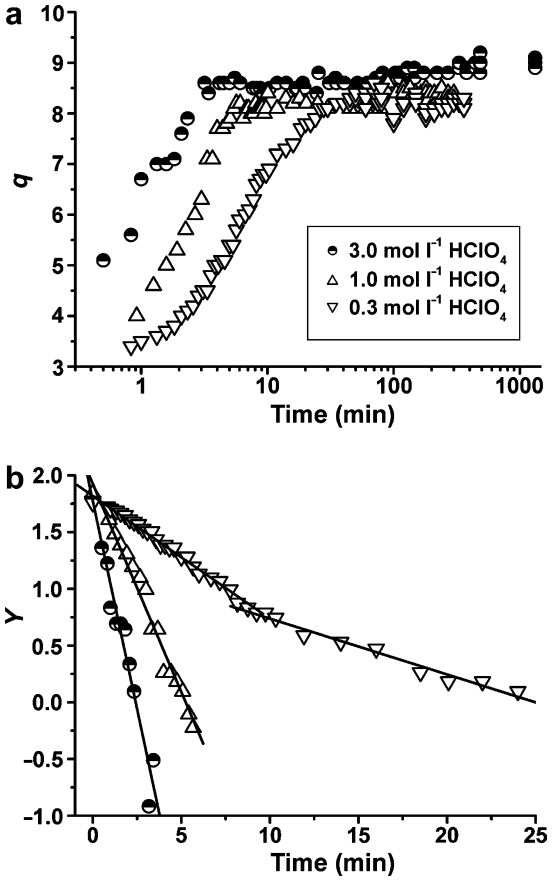

Fig. 6. (a) Time course of change in the number of coordinated water molecules (q) during dissociation of the [Eu(H_2O)$_2$(do3a)] complex ($c_{\mathrm{EuL}} = 0.01$ mol l^{-1}); (b) the linearized transformation ($Y = \ln(9 - q_{\mathrm{ML}})$) of the change in the number of coordinated water molecules for the Eu(III)-H_3do3a system measured at different solution acidities. The ionic strength of the solutions was not kept constant; it is identical with the acid concentration.

Two steps were observed at lower acidity while only one step was identified at higher acidities (Fig. 6b). The analysis gives the values of the rate constants with estimates of the number of water molecules in the reaction intermediates (the precision of the measurement is ±0.5) and the values are given in Table 4. The number of water molecules in the starting [Eu(H_2O)$_2$(do3a)] complex is equal to two, as it was determined formerly (see Chapter Formation Kinetics or Refs. [33,52]), while the reaction intermediate has three water molecules in its coordination sphere. The value of the first protonation constant of the [Eu(H_2O)(dota)]$^-$ complex was estimated to be $\log K \approx 1$ [15,18] and this value can also be taken as an approximation for the corresponding constant of the [Eu(H_2O)$_2$(do3a)] complex. This means that the [Eu(Hdo3a)(H_2O)$_3$]$^+$ species should be considered as a reactive intermediate at the beginning of the dissociation reaction. Taking into account the reaction mechanism proposed for the dissociation of the [Eu(H_2O)(dota)]$^-$ complex [15], an identical reaction mechanism can be adopted for the [Eu(H_2O)$_2$(do3a)] complex (see Scheme 3b). The reaction step, represented by the rate constant $k_{\mathrm{d},1}$ can be detected only at lower acidities while the pathway with the $k_{\mathrm{d},2}$ rate constant is fully dominating at higher acidities (see Eq. (19)) [15,18]. The same reaction mechanism (see Scheme 3b) has been proposed for the acid-catalysed dissociation of the [Eu(dotp)]$^{5-}$ complex, when the final product for the given reaction timescale has four (for perchlorate) or five (for chloride) coordinated water molecules (see Table 4, [21]); this means that the phosphonic acid pendant arms can coordinate the europium(III) ion even in strongly acidic media. The same effect was observed for lanthanide(III) complexation by diphosphonate ligands [59] and it can be an explanation of the differences in the apparent kinetic inertness among europium(III) complexes of H_8dotp and the other H_4dota-like ligands (see Fig. 4, Tables 2 and 4).

It is interesting to note that the kinetic inertness seems to be related to the spectroscopic properties. It was postulated recently [60,61] that the luminescence band intensity ratio ($\Delta J = 2/\Delta J = 1$) related to the $^5D_0$–$^7F_2$ (619 nm) and $^5D_0$–$^7F_1$ (594 nm) transitions of europium(III) in complexes is a sensitive and useful parameter for evaluation of changes in the ion coordination environment. The first group of europium(III) complexes (H_4dota, H_5do3ap, H_5do3ap$^{\mathrm{PrA}}$) shows a luminescence intensity ratio ($\Delta J = 2/\Delta J = 1$) of about 0.65–0.75, while the ratio ($\Delta J = 2/\Delta J = 1$) is equal to 1.60–1.70 for the second group (H_3do3a, H_8dotp) [33]. It was shown for H_4dota-like ligands that this ratio is a relative measure of the thermodynamic stability of ternary europium(III) complexes (having the third ligand in the axial position) and the free energy describing the formation of the complex is an expression of the strength of the interaction between the europium(III) ion and the donor atom of the axial ligand [61]. This effect was correlated with structural information obtained by NMR spectroscopy [61]. Here, it can be suggested that this parameter can be used for a prediction of

the kinetic behaviour. However, more europium(III) complexes should be investigated.

4. Conclusions

Formation kinetics of the $[Eu(H_2O)(do3ap)]^{2-}$ complex was studied and the results show that the reactivity is similar to that observed in the europium(III)-H_4dota system. TRLIFS, as a new experimental tool for the study of such chemical reactions, seems to be suitable for kinetic investigations. It can be used for the detailed study of the reaction mechanism of complex formation, also in cases when this process is a multistep one. This methodology has some limitations for the study of the reaction mechanism of complex dissociation as this method gives reliable results in the case where the number of coordinated water molecules changes during the course of the reaction. Kinetic constants obtained by UV–Vis spectroscopy and TRLIFS are comparable. The bifunctional phosphinate ligand H_5do3ap^{PrA} shows similar chemical properties towards europium(III) as do H_4dota and H_5do3ap.

study in representative cases. The photoluminescence properties of the complexes are also examined.

2. Experimental

2.1. Materials

The metal salts $Zn(NO_3)_2 \cdot 6H_2O$, $ZnCl_2$, $Zn(OAc)_2 \cdot 2H_2O$, $Cd(NO_3)_2 \cdot 4H_2O$, $CdCl_2 \cdot 2H_2O$, $Cd(OAc)_2 \cdot 2H_2O$, $Hg(NO_3)_2$, $HgCl_2$ and $Hg(OAc)_2$, and NaN_3 and NH_4SCN were purchased from Loba Chemi, Bombay. $Zn(ClO_4)_2 \cdot 6H_2O$, $Cd(ClO_4)_2 \cdot 6H_2O$ and $Hg(ClO_4)_2 \cdot 6H_2O$ were prepared by adding the corresponding MCO_3 [M = Zn(II), Cd(II), Hg(II)] to a warm 1:1 $HClO_4$ solution followed by slow evaporation in a fused $CaCl_2$ desiccator. 8-Aminoquinoline was purchased from Aldrich. All other chemicals and solvents were used after drying [17].

2.2. Physical measurements

Microanalyses (C, H, N) were performed using a Perkin–Elmer 2400 CHN/O elemental analyzer. Spectroscopic measurements were carried out using the following instruments: UV–Vis spectra, Perkin–Elmer, model Lambda 25; FT-IR spectra (KBr disk, 4000–200 cm^{-1}), Perkin–Elmer FT-IR Spectrophotometers. Molar conductances (Λ_M) were measured in a Systronics conductivity meter 304 model using *ca.* 10^{-3} M solutions in DMF. ^1H NMR spectra were recorded using a Brucker 300 MHz FT NMR in DMSO-d_6. The luminescence properties were measured using a LS-55 Perkin–Elmer fluorescence spectrophotometer at room temperature (298 K) in DMF solution with a 1 cm path length quartz cell.

The fluorescence quantum yield of 8-aq and its complexes were determined using carbazole laser dye as a reference with a known ϕ_R of 0.42. The complex and the reference dye were excited at 330 nm, maintaining nearly equal absorbance (~0.1), and the emission spectra were recorded from 350 to 700 nm in DMF (because of insolubility or sparing solubility in common organic solvents. $CHCl_3$ is used additionally to check for a solvent effect for 8-aq). The area of the emission spectrum was integrated using the software available in the instrument and the quantum yield is calculated according to the following equation:

$$\phi_S/\phi_R = [A_S/A_R] \times [(Abs)_R/(Abs)_S] \times [\eta^2{}_S/\eta^2_R]$$

Here, ϕ_S and ϕ_R are the fluorescence quantum yield of the sample and reference, respectively. A_S and A_R are the area under the fluorescence spectra of the sample and the reference, respectively $(Abs)_S$ and $(Abs)_R$ are the respective optical densities of the sample and the reference solution at the wavelength of excitation, and η_S and η_R are the values of the refractive index for the respective solvent used for the sample and reference.

CAUTION! Azide and ClO_4^- complexes of transition metal ions containing organic ligands are potentially explosive. Only a small amount of materials should be prepared, and it should be handled with care.

2.3. Synthesis of the complexes

2.3.1. Di-aquo-bis-(8-aminoquinoline)zinc(II) nitrate, $[Zn(8\text{-}aq)_2(H_2O)_2]\ (NO_3)_2$, 1

49 mg (0.34 mmol) 8-aminoquinoline (8-aq) in 20 ml MeOH was added to a clear solution of 50 mg (0.17 mmol) $Zn(NO_3)_2 \cdot 6H_2O$ in 20 ml MeOH and stirring was continued for 1 h; the colour changed to light yellow. The volume of the solution was reduced to 10 ml, filtered and kept for crystallization after addition of 2 drops of 2-methoxy ethanol. Yellowish crystals were obtained by slow evaporation of the solvent. Yield was 58.9 mg, (67.20%).

The other complexes were prepared following an identical procedure and the yields of products varied in the range 65–75%. Microanalytical data: Anal. Cal. $C_{18}H_{20}N_6O_8Zn$ (**1**): C, 42.11; H, 3.92; N, 16.37. Found: C, 42.26; H, 3.83; N, 16.50%. $C_{18}H_{20}N_4\ Cl_2O_{10}Zn$ (**2**): C, 36.73; H, 3.40; N, 9.52. Found: C, 36.67; H, 3.37; N, 9.65%. $C_9H_8N_2Cl_2Zn$ (**3**): C, 38.57; H, 2.86; N, 10.00. Found: C, 38.45; H, 2.80; N, 9.92%. $C_{18}H_{20}N_6O_8Cd$ (**6**): C, 38.57; H, 3.57; N, 15.00. Found: C 38.66; H, 3.48; N, 15.13%. $C_{18}H_{20}N_4Cl_2O_{10}Cd$ (**7**): C, 34.01; H, 3.17; N, 8.82. Found: C, 34.19; H, 3.15; N, 8.73%. $C_9H_8N_2Cl_2Cd$ (**8**): C, 33.03; H, 2.46; N, 8.56. Found: C, 33.12; H, 2.54; N, 8.75%. $C_{18}H_{20}N_6O_8Hg$ (**11**): C, 33.30; H, 3.10; N, 12.95. Found: C, 33.19; H, 2.93; N, 13.04%. $C_{18}H_{20}N_4Cl_2O_{10}Hg$ (**12**): C, 29.88; H, 2.78; N, 7.75. Found: C, 30.00; H, 2.85; N, 7.86%. $C_9H_8N_2Cl_2Hg$ (**13**): C, 25.99; H, 1.94; N, 6.74. Found: C, 25.86; H, 2.03; N, 6.85%.

2.3.2. Bis-azido-(8-aminoquinoline)zinc(II), $[Zn(8\text{-}aq)(N_3)_2]n$, 4

65 mg (0.45 mmol) 8-aminoquinoline (8-aq) in 5 ml MeOH was added to a clear solution of 100 mg (0.46 mmol) $Zn(OAc)_2 \cdot 2\ H_2O$ in 20 ml MeOH and stirring was continued for 1 h. To this solution 30 mg (0.47 mmol) NaN_3 in MeOH (5 ml) was added and stirred for another 5 min; the colour changed to light yellow. The volume of the solution was reduced to 15 ml, filtered and kept for crystallization after addition of 2 drops of 2-methoxy ethanol. Yellowish crystals were obtained by slow evaporation of the solvent. Yield was 81 mg (61%).

The other azido and thiocyanato derivative complexes were synthesized following an identical procedure. Microanalytical data: Anal. Calcd. for $C_9H_8N_8Zn$ (**4**): C, 36.86; H, 2.75; N, 38.22; found: C, 36.95; H, 2.82; N, 38.14%. $C_{11}H_8N_4S_2Zn$ (**5**): C, 40.62; H, 2.48; N, 17.23. Found: C, 40.74; H, 2.41; N, 17.33%. $C_9H_8N_8Cd$ (**9**): C, 31.76; H, 2.37; N, 32.94; Found: C, 31.70; H, 2.32; N, 33.02%. $C_{11}H_8N_4S_2Cd$ (**10**): C, 35.48; H, 2.17; N, 15.05. Found: C, 35.55; H, 2.08; N, 15.00%. $C_9H_8N_8Hg$ (**14**): C, 25.20; H, 1.88; N, 26.13. Found: C, 25.13; H, 1.94; N, 26.00%. $C_{11}H_8N_4S_2Hg$ (**15**): C, 28.66; H, 1.75; N, 12.16. found: C, 28.51; H, 1.83; N, 12.24%.

2.4. X-ray crystal structure analysis of $[Zn(8\text{-aq})_2(H_2O)_2](NO_3)_2$ (1) and $[Cd(8\text{-aq})(N_3)_2]_n$ (9)

The crystals were grown by slow evaporation of the reaction mixture over a week. Data were collected with a Bruker CCD area detector diffractometer using fine-focus sealed graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 295(2) K for **1** (with crystal dimensions $0.20 \times 0.20 \times 0.05$ mm) and a CAD4 single crystal X-ray diffractometer for **9** (with crystal dimensions $0.26 \times 0.24 \times 0.18$ mm) by the ω-scan method. Diffractions were recorded with 2θ in the range $2.90 \leqslant 2\theta \leqslant 56.58°$ for **1** and $3.22 \leqslant 2\theta \leqslant 49.94°$ for **9**. A summary of the crystallographic data and structure refinement parameters are given in Table 1. Reflection data were recorded using the ψ and ω scan techniques. Data were corrected for Lp and an empirical absorption correction in the $h\ k\ l$ range: $-11 \leqslant h \leqslant 11$; $-11 \leqslant k \leqslant 9$; $-18 \leqslant l \leqslant 19$ for **1** and $0 \leqslant h \leqslant 7$; $0 \leqslant k \leqslant 26$; $-18 \leqslant l \leqslant 18$ for **9**. Data reduction was carried out using the SAINT program. The structures were solved by the direct method using SHELXS-97 [18] and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed geometrically and refined using the riding model. The molecular graphics were carried out using the ORTEP-3 for Windows [19] and PLATON-99 [20] programs. The residual electron density was in the range 0.316 and −0.260 for **1** and +1.020 to −0.768 e Å^{-3} for **9**.

Table 1

GOF	0.846	1.407

[a] $R = \|\|F_o\|-\|F_c\|\|/\Sigma|F_o|$.
[b] $wR_2 = [\Sigma(w|F_o|^2-|F_c|^2)^2/\Sigma w(|F_o|)]^{1/2} w = 1/[\sigma^2(F_o^2) + (0.0299P)^2]$ for **1** and $1/[\sigma^2(F_o^2) + (0.0516P)^2 + 1.8227P]$ for **9**, $P = (F_o^2 + 2F_c^2)/3$.
[c] GOF (Goodness of Fit) is defined as $[w(F_o-F_c)/(n_o-n_v)]^{1/2}$ where n_o and n_v denote the number of data and variables, respectively.

3. Results and discussion

3.1. Synthesis and formulation

The complexes were synthesized by reacting a methanolic solution of the requisite number of moles of 8-aminoquinoline (8-aq) and Group 12 metal salts for mononuclear complexes, $[M(8\text{-aq})_2(H_2O)_2]\,(X)_2$ (X = NO_3 or ClO_4) and $M(8\text{-aq})Cl_2$. Addition of 2 equivalents of NaN_3 or NH_4CNS to the mixture of $M(CH_3COO)_2$ and 8-aq (1:1 mole ratio) in MeOH has synthesized bridged polymeric complexes, $[M(8\text{-aq})(Y)_2]_n$ (Y = N_3 or CNS). Microanalytical data suggest complexes of following composition: $[M(8\text{-aq})_2(H_2O)_2]\,(X)_2$ (X = NO_3 (**1**, **6**, **11**) or ClO_4 (**2**, **7**, **12**) where M = Zn(II) (**1**, **2**); Cd(II) (**6, 7**), Hg(II) (**11, 12**); $[M(8\text{-aq})Cl_2]$ (M = Zn(II), **3**; Cd(II), **8**; Hg(II), **13**) and $[M(8\text{-aq})(Y)_2]$n (Y = N_3 (**4**, **9**, **14**) or NCS (**5**, **10**, **15**) where M = Zn(II), (**4**, **5**); Cd(II), (**9**, **10**); Hg(II), (**14, 15**)). We have carried out experiments with different metal:-ligand ratios (1:1, 1:2; 2:3), but in all the experiments we ended up with the complexes of the noted composition. Molar conductance data show that the complexes $[M(8\text{-aq})_2(H_2O)_2]\,(X)_2$ are 1:2 electrolytes in nature while the others are non-conducting. Spectral and single crystal structure determination in some cases support the composition. Because of the explosive nature of NO_3^-, ClO_4^-, N_3^- we did not perform thermal studies of the complexes.

3.2. Spectral studies

The FT-IR bands were assigned by comparing with the free ligand values. All the complexes show a moderately sharp absorption at 3100–3200 cm^{-1} which is assigned to the asymmetric stretching of coordinated $-NH_2$ (the free ligand shows $\nu(NH_2)$ at 3448 and 3348 cm^{-1}). Besides, complexes **1**, **2**, **6**, **7**, **11** and **12** show medium intense broad band(s) centred at 3390–3410 cm^{-1} which is assigned to a coordinated H_2O band. The complexes $[M(8\text{-aq})_2(H_2O)_2]\,(NO_3)_2$ (**1**, **6**, **11**) show an intense sharp absorption at 1380–1390 cm^{-1} which is assigned to non-coordinated $\nu(NO_3)$ (this is supported by conductance data and single crystal X-ray data) [21], while $\nu(ClO_4)$ in $[M(8\text{-aq})_2(H_2O)_2](ClO_4)_2$ appears as a sharp absorption at 1090–1105 cm^{-1} and a weak shoulder at 625–630 cm^{-1} for the uncoordinated ClO_4 anion [21]. It is assumed that infrared active M–Cl stretchings appear at 258–280 cm^{-1} in the complexes, $M(8\text{-aq})Cl_2$ [22–24]. The azide complexes show a sharp peak at 2070–2080 cm^{-1} whereas the Cd- and Hg-azide show a sharp absorption at 2040–2048 cm^{-1}; this spectral feature supports azido bridging structures, $[M(8\text{-aq})(N_3)_2]_n$. Similarly the thiocyanato complexes also exhibit ν(NCS) at 2083–2109 cm^{-1} and support the composition $[M(8\text{-aq})(NCS)_2]_n$. One of the structures has been supported by single crystal X-ray structure data.

* In $CHCl_3$: 340 (2464), 260 (9079); $\lambda_{ex} = 340$ nm; $\lambda_{em} = 451$ nm; $\Phi = 0.048$.

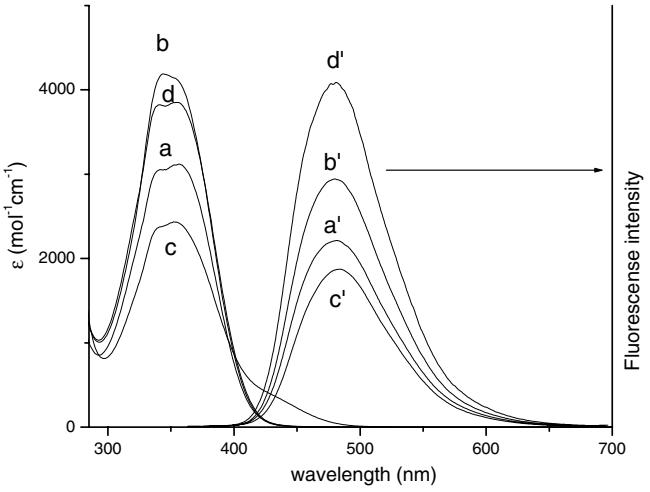

Fig. 1. UV–Vis spectra of (a) $Zn(8\text{-aq})Cl_2$, (b) $Cd(8\text{-aq})Cl_2$, (c) $Hg(8\text{-aq})Cl_2$ and (d) 8-aq. Fluorescence spectra of (a′) $Zn(8\text{-aq})Cl_2$, (b′) $Cd(8\text{-aq})Cl_2$, (c′) $Hg(8\text{-aq})Cl_2$, (d′) 8-aq in DMF.

The solution electronic spectra of the complexes were recorded in DMF solution in the range 250–550 nm. The data are listed in Table 2. All the complexes exhibit an intense band in the 350–400 nm range. These transitions are presumably due to intra-ligand π–π^*/and n–π^* transitions (Fig. 1). A red shift of the band in the UV–Vis spectra of <10 nm from the free ligand values for the metal complexes has been observed. A weak transition in the visible region (440–500 nm) is assigned to a MLCT band.

From a close inspection of the ^{1}H NMR data (Table 3), a small shift in the δ values of the C–H signals and the NH_2 proton indicate bonding with the d^{10} metal (Zn(II), Cd(II), Hg(II)) system. The C–H protons appear at a slightly lower δ value due to weak back-bonding from M(II) to 8-aminoquinoline. On the other hand, a higher δ value of the NH_2 proton (5.89–5.97 ppm) is observed because of the lowering of electron density during complexation.

3.3. Crystal structures

3.3.1. [Zn(8-aq)(H_2O)$_2$](NO_3)(1)

The ORTEP view of the structure of **1** is shown in Fig. 2. The octahedral molecule bears N_{amine}–Zn–$N_{quinoline}$ chelate bite angles of 80.26 and 80.95°, all the N–Zn–O bond angles vary from 85.70 to 90.47° and the O(1)–Zn–O(2) bond angle is 179.03°, which is in agreement with the octahedral geometry. Two chelate planes Zn–N(3)–C(18)–C(17)–N(4) and Zn–N(1)–C(9)–C(8)–N(2) make a dihedral angle of 7.85°; every chelate plane is almost planar with the corresponding 8-aminoquinoline ring (the dihedral angle varies from 1.42 to 2.18°), which supports that the two ligands are almost planar to each other.

The molecule shows a C–H – π and π–π interaction with the 8-aminoquinoline ring of an adjacent molecule (Fig. 3). The molecule shows a H-bonding network through the oxygen atom of the nitrate anion and a hydrogen atom of a water molecule (coordinated with Zn), and also through the oxygen atom of the nitrate anion and the hydrogen atom of C-19 and C-20 of the 8-aminoquinoline ring. The bond parameters are given in Table 4.

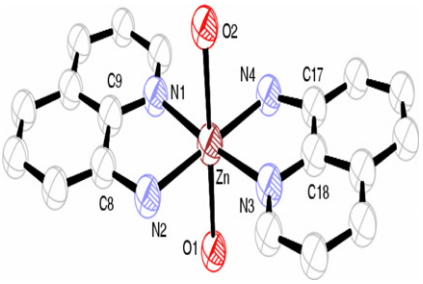

Fig. 2. ORTEP structure of **1**, hydrogen atoms and NO_3^- have been removed for clarity.

3.3.2. [Cd(8-aq)(N_3)$_2$]n, (9)

The ORTEP view of **9** is shown in Fig. 4 and selected bond parameters are listed in Table 5. The cadmium atom is in a distorted octahedral environment with CdN_6 coordination. 8-aq acts as an unsymmetric N,N′ chelating ligand (quinoline-N refers to N and NH_2 refers to N′). The azido (N_3) groups act as end-on (μ−1,1 EO) double bridging agents with two neighboring cadmium atoms. The bridging Cd_2N_4 unit constitutes a quadrilateral unit with bond lengths Cd(1)–N(5) 2.503(7), Cd(1)–N(8) 2.280(8), Cd(2)–N(5) 2.320(7), Cd(2)–N(8) 2.398(8) Å and bond angles Cd(1)–N(8)–Cd(2) 107.5(3), Cd(1)–N(5)-Cd(2) 103.7(3), N(5)–Cd(1)–N(8) 73.9(3)°, N(5)–Cd(2)–N(8) 75.2(3)°. The small chelate angle (∠N(1)–Cd(1)–N(2), 72.5(3)°) may cause the structural distortion. The bridge angles (103–107°) lie in the reported angular range [25]. A 1D neutral chain runs along the a-direction due to a repeating Cd_2N_4 unit. The distortion in the CdN_6 coordination is supported by six unequal Cd–N bond distances. One of the bridging azido–N bonds shows the longest distance in the series of Cd–N distances (Cd(1)–N(5) 2.503(7), Cd(2)–N(11) 2.516(7)). The Cd–N(amine) distance is expectedly longer (by 0.01–0.04 Å) than that of the Cd–

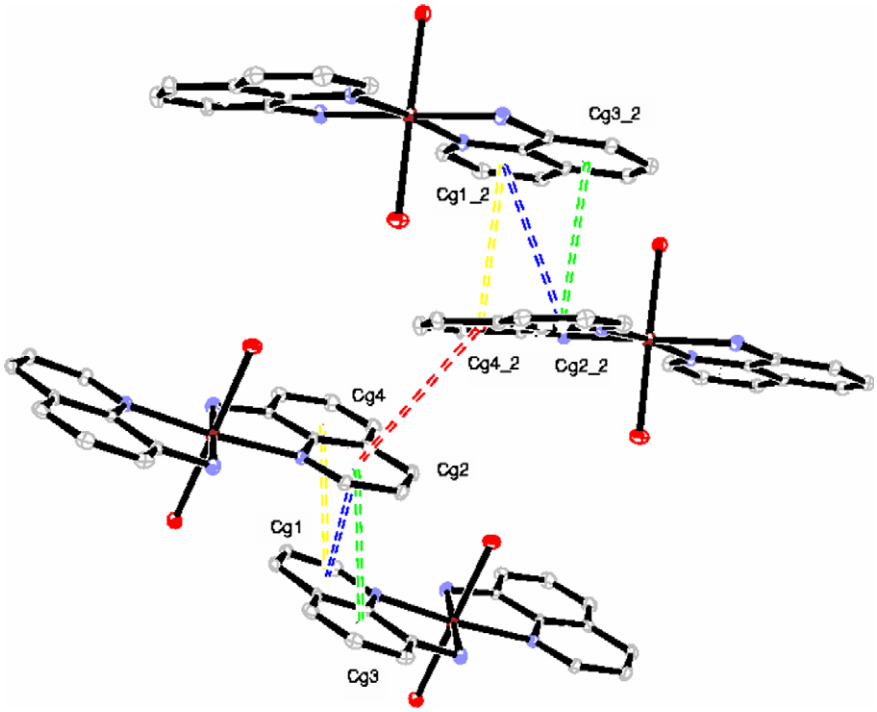

Fig. 3. π–π interaction.

N(quinoline) distances. The azide N–N distances are within the reported range [26].

The 1D chains are self-assembled to form a molecular sheet *via* C–/N–H–N(azido) and π–π interactions between aromatic rings, and are described in Figs. 5 and 6. The π–π interaction with the aromatic rings (Fig. 5) ((Cg(7)–Cg(8) 3.816 Å (symmetry $3/2-x$, $-1/2+y$, $3/2-z$), Cg(8)–Cg(7) 3.832 Å (symmetry $5/2-x$, $1/2+y$, $3/2-z$), Cg(9)–Cg(6) 3.776 Å (symmetry $3/2-x$, $-1/2+y$, $3/2-z$) and Cg(9)–Cg(6) 3.764 Å (symmetry, $5/2-x$, $-1/2+y$, $3/2-z$), where Cg(6): N(1), C(1), C(2), C(3), C(4), C(9); Cg(7), N(4), C(17), C(16), C(15), C(14), C(18); Cg(8): C(4), C(5), C(6), C(7), C(8), C(9); Cg(9): C(10), C(11), C(12), C(13), C(14), C(18)). The robustness of the supramolecular geometry has been enhanced through intermolecular hydrogen bondings (Fig. 6). It is observed that the $-NH_2$ protons and some of the aromatic C–H protons act as H-donors and the bridged azido–N (both coordinated and free N) act as H-acceptors. The acceptable hydrogen bonds are: N(2)–H(2A)–N(16): N(2)–H(2A) 0.90, H(2A)–N(16) 2.409(2), N(2)–N(16) 3.222(12) Å, ∠N(2)–H(2A)–N(16) 150.36° and symmetry $1/2+x$, $1/2-y$, $-1/2+z$. N(2)–H(2B)–N(7): N(2)–H(2B) 0.90, H(2B)–N(7) 2.2251, N(2)–N(7) 3.103(12) Å ∠N(2)–H(2B)–N(7) 164.82° and symmetry $-1+x, y, z$. N(3)–H(3A)–N(13): N(3)–H(3A) 0.90, H(3A)–N(13) 2.2218, N(3)–N(13) 3.106(11) Å, ∠N(3)–H(3A)–N(13) 167.28°. N(3)–H(3B)–N(13): N(3)–H(3B) 0.90, H(3B)–N(13) 2.3144, N(3)–N(13) 3.121(10) Å, ∠N(3)–H(3B)–N(13) 149.07° and symmetry $2-x$, $-y$, $1-z$. 3.4. Photoluminescence properties

The photoluminescence properties of 8-aq and its complexes were studied at room temperature (298 K) (Fig. 1) in DMF solution. Because of the very low solubility of the complexes we have been forced to study the spectral and emission measurements in DMF solution. Since, the ligand, 8-aq, is soluble in several organic solvents we have carried out emission measurements in DMF and $CHCl_3$ to make a comparison when using polar and non-polar solvents. Data are collected in Table 2. The spectrum shows two intense transitions in DMF corresponding to 267 nm, π–π^* and 354 nm, n–π^* transitions. They are shifted to higher energy positions when the spectrum is recorded in

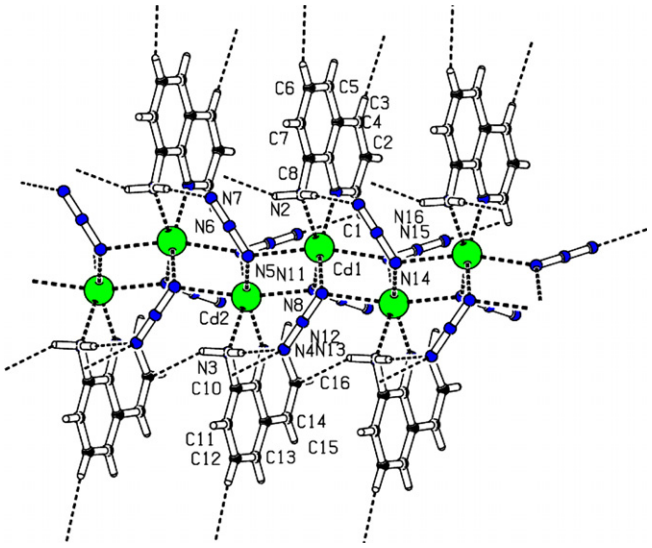

Fig. 6. Hydrogen bonded 1D chain of the azido bridged $[Cd(8\text{-aq})(N_3)_2]_n$.

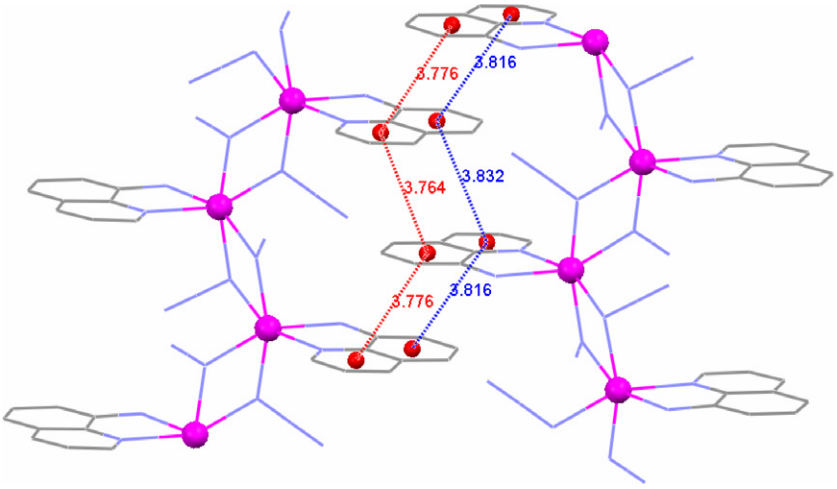
$CHCl_3$. 8-aq exhibits photoluminescence with an emission at 481 nm upon excitation at 354 nm in DMF, while the emission appears at 451 nm upon excitation at 340 nm in $CHCl_3$. The complexes show strong fluorescence with a high quantum yield in DMF solvent (shown in Table 2), excitation of the molecule at 330–350 nm gives an emission at 478–486 nm. No emissions originating from metal-centered excited states are expected for the Zn(II), Cd(II) and Hg(II) complexes, since they are difficult to oxidize or reduce due to their d^{10} configuration. Thus, the emission observed in the complexes is assigned to the $(\pi - \pi^*)$ intraligand fluorescence and these are red shifted by >120 nm. The intensity of the emission is found to be higher than that of the free ligand. It has been reported that metal ions can enhance or quench the fluorescence emission of pyridine containing compounds [27,28]. In the absence of metal ions the fluorescence of the ligand is probably quenched by



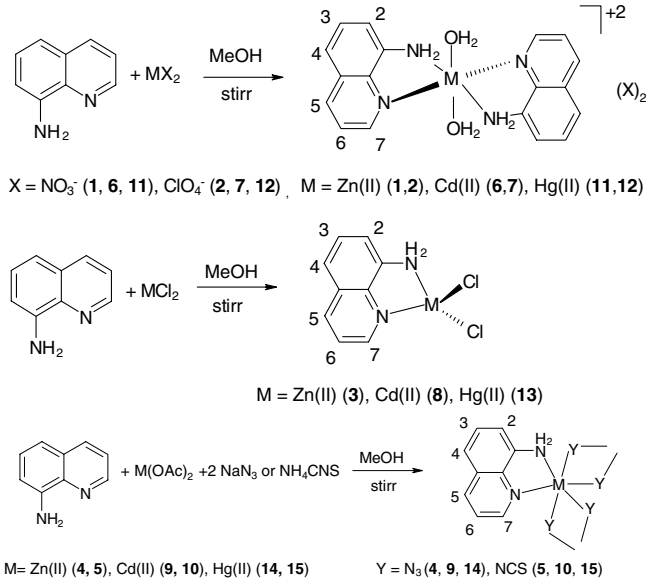


Fig. 5. The zig–zag π–π complementary interactions in the packing of $[Cd(8\text{-aq})(N_3)_2]_n$ (**9**).

Scheme 1.

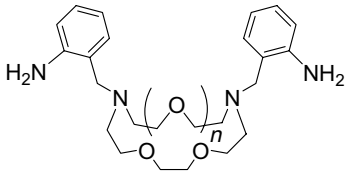
the occurrence of a photoinduced electron transfer (PET) process due to the presence of a lone pair of the nitrogen atoms. Such a PET process is prevented by complexation of the ligand with metal ions; thus the fluorescence intensity may be greatly enhanced by coordination to M(II), which is defined as chelation enhanced fluorescence intensity. The chelation of the ligands increases the rigidity and reduces the loss of energy by thermal vibrational decay. The quantum yields are estimated with reference to carbazole (Table 2) and appear at 0.01 to 0.04. Because of the insolubility of $[Hg(8\text{-aq})(N_3)_2]_n$ and $[Hg(8\text{-aq})(NCS)_2]$ we could not perform luminescence measurements.

4. Conclusion

This paper describes mononuclear MX_2 complexes (M = Zn, Cd, Hg; X = Cl, NO_3, ClO_4) of 8-aminoquinoline. The complexes are characterized by different physicochemical methods. The single crystal X-ray structure determination of $[Zn(8\text{-aq})_2(H_2O)_2](NO_3)_2$ shows an octahedral ZnN_4O_2 coordination arrangement. The azido complexes are end-on bridging polymers and in one case, $[Cd(8\text{-aq})(N_3)_2]$, the structure determination shows a supramolecular structure of an azido bridged 1D chain *via* hydrogen bonding and π–π interactions. The complexes show ligand centered potential photoluminescence properties.

5. Supplementary material

Crystallographic data for the structures have been deposited with the Cambridge Crystallographic data center, CCDC No. 639302 for $[Zn(8\text{-aq})_2(H_2O)_2](NO_3)_2$ (**1**) and 639303 for $[Cd(8\text{-aq})(N_3)_2]_n$ (**9**). Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (e-mail: deposit @ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).



Acknowledgement

Financial support from the University Grants Commission and the All India Council for Technical Education, New Delhi, are gratefully acknowledged. One of us, MP, thanks CSIR for a fellowship. Our sincere thanks to Prof. Debasis Ray, Department of Chemistry, Indian Institute of Technology, Kharagpur, Paschim Medinipur, West Bengal, India for his help in the structure solution of $[Cd(8\text{-aq})(N_3)_2]$.

Scheme 1.

mimetic showed antitumor [15], anti-inflammatory [16] and pain-relieving [17] activities. Therefore, the investigation of seven-coordinate Mn(II) metal complexes can provide useful information for the understanding of these metalloenzymes and therapeutic agents.

Herein, we describe the synthesis and structure of Mn(II) complexes with the heptadentate and octadentate receptors *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5 ($\mathbf{L}^1$) and *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-18-crown-6 ($\mathbf{L}^2$), derived from azacrowns (Scheme 1). These receptors are structurally related and $\mathbf{L}^2$ may be seen as being derived from $\mathbf{L}^1$ by incorporation of a $-CH_2-O-CH_2-$ fragment into the ligand backbone. $\mathbf{L}^1$ has been revealed as an excellent receptor to impose seven-coordination on divalent first-row transition metal ions [18,19], whereas $\mathbf{L}^2$ is a versatile receptor able to adapt to the coordinative preferences of the particular metal cation guest. It has been reported that $\mathbf{L}^2$ forms binuclear complexes with first-row transition metal ions such as Co(II), Ni(II) and Cu(II) [18,21], and mononuclear complexes with main group cations such as Pb(II) and alkaline earth metal ions, as well as with Cd(II) and Zn(II) [20,22–24].

2. Experimental

2.1. Reagents

N,*N*′-Bis(2-aminobenzyl)-1,10-diaza-15-crown-5 ($\mathbf{L}^1$) [25] and *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-18-crown-6 ($\mathbf{L}^2$) [18] were prepared as previously reported by us. All other chemicals were purchased from commercial sources and were used without further purification. The solvents were of reagent grade, and were purified by the usual methods.

Caution! Although we have experienced no difficulties with the perchlorate salts, these salts combined with organic ligands are potentially explosive and should be handled in small quantities and with the necessary precautions [26].

2.2. Synthesis

2.2.1. $[Mn(L^1)](ClO_4)_2$ (**1**)

A mixture of $\mathbf{L}^1$ (0.051 g, 0.119 mmol) and $Mn(ClO_4)_2 \cdot 6H_2O$ (0.043 g, 0.119 mmol) in acetonitrile (15 mL) was stirred and heated to reflux over a period of 6 h. Slow evaporation of the resultant solution gave rise to colourless single crystals suitable for X-ray diffraction. Yield 0.039 g (48%). *Anal.* Calc. for $C_{24}H_{36}Cl_2MnN_4O_{11}$: C, 42.24; H, 5.32; N, 8.21. Found: C, 42.40; H, 5.26; N, 8.17%. FAB-MS: *m*/*z* (%BPI) = 582 (70) $[Mn(L^1)(ClO_4)]^+$, 482 (99) $[Mn(L^1-H)]^+$. IR (KBr discs): 3310, 3277 ($\nu(NH_2)$), 1618 (δ (NH_2)), 1092 ν_{as} (Cl–O), 620 δ_{as} (O–Cl–O) cm^{-1}. Λ_M (acetonitrile $\sim 10^{-3}$ M, 20 °C): 336 $cm^2\,\Omega^{-1}\,mol^{-1}$ (2:1 electrolyte).

2.2.2. $[Mn(L^2)](ClO_4)_2$ (**2**)

A solution of $Mn(ClO_4)_2 \cdot 6H_2O$ (0.080 g, 0.221 mmol) in absolute ethanol (8 mL) was added dropwise to a solution of $\mathbf{L}^2$ (0.099 g, 0.209 mmol) also in absolute ethanol (12 mL). After the addition was complete, a white precipitate appeared. The reaction mixture was stirred and heated to reflux over a period of 6 h. The precipitate was collected by filtration and air-dried. Yield 0.128 g (84%). *Anal.* Calc. for $C_{26}H_{40}MnCl_2N_4O_{12}$: C, 42.99; H, 5.55; N, 7.71. Found: C, 43.39; H, 5.49; N, 7.77%. FAB-MS: *m*/*z* (%BPI) = 626 (61) $[Mn(L^2)(ClO_4)]^+$, 526 (41) $[Mn(L^2-H)]^+$. IR (KBr discs): 3402, 3310, 3277 ($\nu(NH_2)$), 1620 (δ (NH_2)), 1096 ν_{as} (Cl–O), 624 δ_{as} (O–Cl–O) cm^{-1}. Λ_M (acetonitrile $\sim 10^{-3}$ M, 20 °C): 288 $cm^2\,\Omega^{-1}\,mol^{-1}$ (2:1 electrolyte).

2.2.3. $[Mn(L^2)](NO_3)_2$ (**3**)

A solution of $Mn(NO_3)_2 \cdot 4H_2O$ (0.059 g, 0.235 mmol) in absolute ethanol (15 mL) was added dropwise to a solution of $\mathbf{L}^2$ (0.100 g, 0.211 mmol) also in absolute ethanol (8 mL). The reaction mixture was stirred and heated to reflux over a period of 6 h. After the reaction was complete, the black solid formed was filtered off. Slow diffusion of diethyl ether into the resultant solution gave rise to a few colourless single crystals suitable for X-ray diffraction. Yield 0.017 g (12%). *Anal.* Calc. for $C_{26}H_{40}MnN_6O_{10}$: C, 47.93; H, 6.19; N, 12.90. Found: C, 48.37; H, 6.37; N, 12.42%. M.p.: 138.7 °C. FAB-MS: *m*/*z* (%BPI) = 590 (8) $[Mn(L^2)(NO_3)]^+$, 526 (9) $[Mn(L^2-H)]^+$. IR (solid sample): 3471, 3281 ($\nu(NH_2)$), 1617 (δ (NH_2)), 1320 $\nu(NO_3)$ cm^{-1}. Λ_M (acetonitrile $\sim 10^{-3}$ M, 20 °C): 245 $cm^2\Omega^{-1}$ mol^{-1} (2:1 electrolyte).

2.3. Measurements

Elemental analyses were carried out on a Carlo Erba 1180 elemental analyser. FAB mass spectra were recorded on a Fisons Quatro mass spectrometer with a Cs ion gun using 3-nitrobenzyl alcohol as the matrix. IR spectra were recorded using a Bruker Vector 22 spectrophotometer. Conductivity measurements were carried out at 20 °C with a Crison Micro CM 2201 conductivimeter using *ca.* 10^{-3} M solutions of the complexes in acetonitrile. UV–Vis spectra were recorded on a Perkin–Elmer Lambda 900 spectrophotometer, with quartz cells (path length: 1 cm). The cell holder was thermostated at 25 °C, through circulating water. Spectrophotometric titrations were performed at 25 °C on 10^{-5} M solutions of $\mathbf{L}^1$ or $\mathbf{L}^2$ in MeCN

(polarographic grade). Typically, aliquots of a fresh $Mn(ClO_4)_2 \cdot 6H_2O$ standard solution were added and the UV–Vis spectra of the samples were recorded. All spectrophotometric titration curves were fitted with the HYPERQUAD program [27].

2.4. X-ray crystallography

Three-dimensional X-ray data for compounds **1** and **3** were collected on a Bruker Smart 1000 CCD. Data were corrected for Lorentz and polarisation effects and for absorption by semi-empirical methods. Complex scattering factors were taken from the program package SHELXTL [28], as implemented on a Pentium computer. The structure was solved by direct methods and refined by full-matrix least-squares on F^2. Hydrogen atoms were included in calculated positions and refined in the riding mode, except the hydrogen atoms H(3A), H(3B), H(4A) and H(4B) for **1**, and H(1N) and H(2N) for **3**, which were left to refine freely. Refinement converged with anisotropic displacement parameters for all non-hydrogen atoms. Crystal data and details of data collection and refinement are summarised in Table 1.

3. Results and discussion

The UV–Vis spectrum of *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-18-crown-6 ($\mathbf{L}^2$) shows two bands at 250 and 290 nm (E_2 and B bands of the aromatic rings), resulting from the $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions on the aromatic subunits of the ligand [19]. Upon addition of Mn(II) perchlorate both absorption bands shift towards shorter wavelengths while their intensity decreases. Fig. 1 shows the spectral changes observed during the formation of the Mn(II) complex with $\mathbf{L}^2$. The titration profile indicates a 1:1 reaction stoichiometry, since the data display a single inflection point when the M:Ligand molar ratio is close to 1, with no evidence for the formation of binuclear species. The steep curvature of the titration profiles corresponds to an especially high

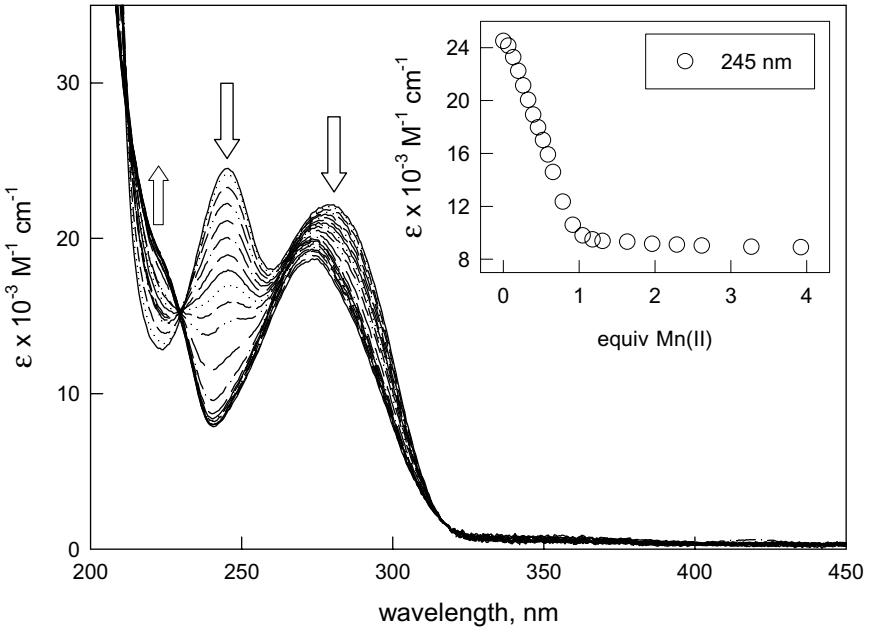

Fig. 1. UV–Visible spectrum of $\mathbf{L}^2$ in acetonitrile solution and spectral changes upon addition of aliquots of a solution of $Mn(ClO_4)_2 \cdot 6H_2O$ in the same solvent.

equilibrium constant ($\log K > 7$). In particular, the p parameter (p = [concentration of complex]/[maximum possible concentration of complex]) was found to be higher than 0.8, a condition which does not permit the determination of a reliable equilibrium constant [29]. Similar behaviour was previously observed for the Mn complex of $\mathbf{L}^1$ [19]. These results indicate that both $\mathbf{L}^1$ and $\mathbf{L}^2$ only form mononuclear complexes with Mn(II) in acetonitrile solution.

Reaction of stoichiometric amounts of $\mathbf{L}^1$ or $\mathbf{L}^2$ with Mn(II) salts (perchlorates or nitrates) in acetonitrile or ethanol solution gives compounds of formula $[Mn(L^1)](ClO_4)_2$ (**1**), $[Mn(L^2)](ClO_4)_2$ (**2**) and $[Mn(L^2)](NO_3)_2$ (**3**). The FAB-mass spectrum of each compound displays very intense peaks corresponding to the $[Mn(L–H)]^+$ and $[Mn(L)(X)]^+$ fragments ($L = \mathbf{L}^1$ or $\mathbf{L}^2$, $X = ClO_4^-$ or NO_3^-), thereby confirming the formation of the complexes. In the region 3500–3300 cm^{-1} the infrared spectra show bands corresponding to both $\nu_{as}(NH_2)$ and $\nu_s(NH_2)$ stretching frequencies of the coordinated amine groups. Likewise, the IR spectra (KBr discs) of the perchlorate complexes **1** and **2** also show bands corresponding to the ν_{as}(Cl–O) stretching and δ_{as}(O–Cl–O) bending modes of the perchlorate groups at *ca.* 1090 and 620 cm^{-1} [30], whereas the spectrum of the nitrate complex **3** exhibits an intense band centred at 1320 cm^{-1} due to uncoordinated nitrate [30]. The low yield of compound **3** (12%) is probably due to a dismutation processes, as evidenced by the formation of a black powdery solid during the reaction, which was rejected.

The solid state structures of compounds **1** and **3** were determined by single-crystal X-ray diffraction analyses. Crystals of **1** contain the $[Mn(L^1)]^{2+}$ cation and two crystallographically independent perchlorate anions, both involved in hydrogen-bonding interactions with the aniline groups [N(3)···H(3A) 0.86(3), H(3A)···O(10) 2.19(3), N(3)···O(10) 3.0193(3)Å, N(3)–H(3A)–O(10) 166(3)°; N(4)···H(4A) 0.93(3), H(4A)···O(6) 2.17(3)Å, N(4)–H(4A)–O(6) 178(3)°]. The structure of the cation is shown in Fig. 2, while selected bond lengths and angles are given in Table 2. The cation $[Mn(L^1)]^{2+}$ contains a MnN_4O_3 core with the seven heteroatoms of $\mathbf{L}^1$ coordinated to the Mn(II) ion, showing a slightly distorted C_2 symmetry. The metal ion resides in the macrocyclic cavity bound to the three ether oxygen atoms and the two pivotal nitrogen atoms of the azacrown moiety, while the donor atoms of the pendant arms coordinate apically. The receptor adopts an *anti* conformation, with both pendant arms pointing to opposite sides of the crown moiety, and the coordination sphere of the manganese ion can be described as a distorted pentagonal bipyramid whose equatorial plane is defined by the three oxygen atoms and the two pivotal nitrogen atoms. The mean deviation from planarity of the plane containing the five equatorial donor atoms and the metal ion amounts to 0.211 Å. The N(3)–Mn(1)–N(4) angle is 174.06(10)°, whereas the angles O(1)–Mn(1)–O(2), N(2)–Mn(1)–O(2), O(3)–Mn(1)–N(2), O(3)–Mn(1)–N(1) and N(1)–Mn(1)–O(1) take values close to 72° (Table 2). Likewise, the vectors

defined by the metal ion and the axial donors [N(3) and N(4)] form angles close to 90° with the vectors containing the metal ion and the equatorial donor atoms, as expected for a pentagonal bipyramidal coordination environment. On the other hand, the Mn-crown ether oxygen bonds are

in line with those observed for a seven coordinate Mn(II) complex of 15-crown-5, which shows average Mn–O distances of 2.23 Å [31]. Although the Mn-donor distances found for **1** are close to those found in the $[Mn(L^1)](NO_3)\cdot 2CH_3CN$ analogue [19] (with the most important difference occurring for the Mn–O(1) distance, which is *ca.* 0.06 Å longer in **1**), the structure of the $[Mn(L^1)]^{2+}$ cation found in the nitrate salt [19] is somewhat more symmetrical than the one found in the perchlorate salt described here. Inspection of the X-ray crystal data reveals that compound **1** crystallises in the $P2_1/c$ monoclinic space group, as previously found for the $[M(L^1)](ClO_4)_2$ (M = Ni, Cu, Zn) analogues [18–20], whereas the corresponding nitrate salts, $[M(L^1)](NO_3)_2$ (M = Mn, Co, Zn) [19,20], crystallise in the $C2/c$ group. It has been also found that the corresponding $[M(L^1)]^{2+}$ cations (M = Co, Zn) present in the nitrate salts are more symmetrical than those found in the perchlorate salts. These results show that even when the anions (nitrate or perchlorate) remain uncoordinated in this family of complexes, the nature of the anion present in the crystal appears to have a certain influence on the structure of the cation in the solid state due to crystal packing effects [32].

Crystals of **3** consist of the $[Mn(L^2)]^{2+}$ cation (Fig. 3) and nitrate anions involved in hydrogen-bonding interactions with the aniline groups [N(1)···H(2N) 0.81(4), H(2N)···O(1S) 2.29(4), N(1)···O(1S) 3.065(4) Å, N(1)–H(2N)–O(1S) 160(4)°; N(1)···H(1N), 0.82(4), (1N)···O(1S), 2.40(4), N(1)···O(1SB) 3.192(4) Å, N(1)–H(1N)–O(1SB) 163(3)°]. The crystal presents a disorder

on two carbon atoms of the crown moiety that has been solved, so that for each carbon atom two atomic sites have been observed [site occupancy factors C(10A) 0.500, C(11A) 0.500]. As observed for $[Mn(L^1)]^{2+}$, the Mn(II) ion in $[Mn(L^2)]^{2+}$ is placed in the crown hole, with the organic receptor also adopting an *anti* conformation. However, due to the larger cavity of the crown receptor, only six of its eight available donor atoms form part of the Mn(II) coordination sphere in $[Mn(L^2)]^{2+}$ (see Fig. 3 and Table 3). The Mn(II) ion is only bound to two of the four oxygen donor atoms [O(1) and O(1A)], as well as to both aniline nitrogen atoms [N(2) and N(2A)] and to both pivotal nitrogen atoms [N(1) and N(1A)]. The distances between the Mn(II) ion and the other two oxygen atoms [O(2) and O(2A)] is 2.791(3) Å, considerably longer than an unequivocal Mn–O bond. The Mn–$N_{aniline}$ distances are slightly shorter than those found in $[Mn(L^1)]$, whereas the Mn–O and Mn–N_{pivot} distances are 0.1–0.15 Å longer. The coordination polyhedron can be best described as a distorted octahedron. The structure of $[Mn(L^2)]^{2+}$ resembles the Pb(II) analogue $[Pb(L^2)]^{2+}$ [24], in which the Pb(II) ion is also symmetrically placed in the crown hole, with the organic receptor in an *anti* conformation. However, in the lead complex the Pb(II) guest ion fits very well in the crown hole, so that the eight donor atoms of the macrocyclic receptor are bound to the metal ion, which results in a very different coordination polyhedron around the Pb(II) ion that is described as a slightly distorted cube [24]. The distances between the two aniline nitrogen atoms and between the two pivotal nitrogen atoms are shorter in the Mn(II) complex [N(1)···N(1A) = 4.543(6), N(2)···N(2A) = 4.982(6) Å] than in the Pb(II) analogue [N(1)···N(1A) = 5.367, N(2)···N(2A) = 5.590 Å]. This shows that the receptor $\mathbf{L}^2$ possesses a certain degree of flexibility to adapt its conformation to the coordinative and sterical preferences of the metal ion guest.

4. Concluding remarks

Receptors *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-15-crown-5 ($\mathbf{L}^1$) and *N*,*N*′-bis(2-aminobenzyl)-1,10-diaza-18-crown-6

($\mathbf{L}^2$) form stable mononuclear Mn(II) complexes, and no evidence for the formation of binuclear complexes was obtained. In $[Mn(L^1)](ClO_4)_2$, the Mn(II) ion is deeply buried in the receptor cavity, and the good fit between the macrocyclic cavity of $\mathbf{L}^1$ and the ionic radius of the metal ion gives a seven-coordinate Mn(II) complex where the perchlorate anions are forced to remain outside the metal coordination sphere. The particular architecture of this receptor allows it to impose a relatively unusual pentagonal bipyramidal geometry on the Mn(II) guest. On the other hand, in spite of the higher denticity of $\mathbf{L}^2$ this receptor is unable to form the expected Mn(II) binuclear complexes, while previous studies have shown the formation of binuclear complexes with other first-row transition metal ions [Co(II), Ni(II) and Cu(II)]. In fact, $\mathbf{L}^2$ only gives mononuclear complexes with this metal ion, as observed with main group cations such as Pb(II), alkaline earth ions, Cd(II) and Zn(II). The fact that the Mn(II) and Zn(II) complexes of $\mathbf{L}^2$ show a different nuclearity with respect to the corresponding Co(II), Ni(II) and Cu(II) complexes is probably related to the high-spin d^5 and d^{10} configurations of the former metals, which provide no crystal-field stabilisation energy. The X-ray crystal structure of $[Mn(L^2)]^{2+}$ present in $[Mn(L^2)](NO_3)_2$ shows the Mn(II) ion also placed in the crown hole but now the large crown cavity of this receptor provokes that only six of its eight available donor atoms form part of the coordination sphere, with the Mn(II) ion found in a distorted octahedral environment.

solvents. Crystals of [$GaCl_3(Me_3PO)$] were obtained from CH_2Cl_2–hexane and showed the expected pseudo-tetrahedral structure (Table 1, Fig. 1). The *d*(P–O) (1.518(7) Å) is lengthened from the value in Me_3PO itself (1.489(6) Å) [31] and *d*(Ga–O) 1.828(6) Å is similar to the value in [$GaCl_3(Ph_3PO)$] (1.818(10) Å) [28], although in the latter the phosphine oxide coordination is linear by symmetry (although adp ellipsoids suggest some disorder [28]), compared to the significantly bent geometry in the present complex (angle Ga–O–P = 148°). The three [$GaX_3(Me_3PO)$] complexes show strong *ν*(P=O) stretches in the IR spectra at ~1100 cm^{-1}, lowered from 1166 cm^{-1} in Me_3PO, and *ν*(GaX) are typical of tetrahedral Ga(III) (Table 2, Section 6). In chlorocarbon solvents the ^1H NMR spectra show sharp doublets for the Me resonances, and the $^{31}P\{^1H\}$ NMR spectra are sharp singlets with substantial high frequency coordination shifts from Me_3PO ($\delta = 38$). The chemical shifts fall with halogen: $\delta = 73.5$ (Cl), 72.0 (Br), 70.5 (I), suggesting the Lewis acidity of the GaX_3 also falls in this order. All exhibit relatively sharp singlets in the ^{71}Ga NMR spectra[1] at ambient temperatures (Table 2), which will be discussed further below. Although the spectroscopic data on [$GaI_3(Me_3PO)$] showed only the neutral species present, a solution in CH_2Cl_2–hexane produced a small number of colourless crystals which were shown to be the ionic product, [$GaI_2(Me_3PO)_2$][GaI_4]. The structure is shown in Fig. 2 (Table 3) and contains a tetrahedral $[GaI_4]^-$ anion (d(Ga–I) = 2.548(2) Å) and a pseudo-tetrahedral cation with *d*(Ga–O) = 1.854(8), 1.848(8) Å and *d*(Ga–I) = 2.488(2), 2.500(2) Å, with Ga–O–P angles of 136.8(6) and 140.6(6)°. The Ga–I distances are somewhat shorter in the cation than the anion as expected, but the notable difference is the longer *d*(Ga–O) (1.851 (av) Å), compared to the neutral [$GaCl_3(Me_3PO)$] (1.828 Å) (above). In spite of the crystallographic evidence for $[GaI_2(Me_3PO)_2]^+$, $[GaCl_2(Me_3PO)_2]^+$ could not be prepared from [$GaCl_3(Me_3PO)$], Me_3PO and either $FeCl_3$ or $SbCl_5$ (as chloride abstractors).

The structure of [$(GaBr_3)_2\{\mu$-*o*-$C_6H_4(CH_2P(O)Ph_2)_2\}$] (Table 4, Fig. 3) shows a bridging diphosphine dioxide coordinated to two pseudo-tetrahedral gallium moieties, which are staggered to minimise steric crowding. The Ga–O distances 1.892(4) and 1.858(4) Å are surprisingly

[1] ^{71}Ga, $I = 3/2$, 39.9%, $\Xi = 30.49$ MHz, $Q = 0.112 \times 10^{-28}$ m^2; ^{69}Ga, $I = 3/2$, 60.1%, $\Xi = 24.00$ MHz, $Q = 0.178 \times 10^{-28}$ m^2 [32].

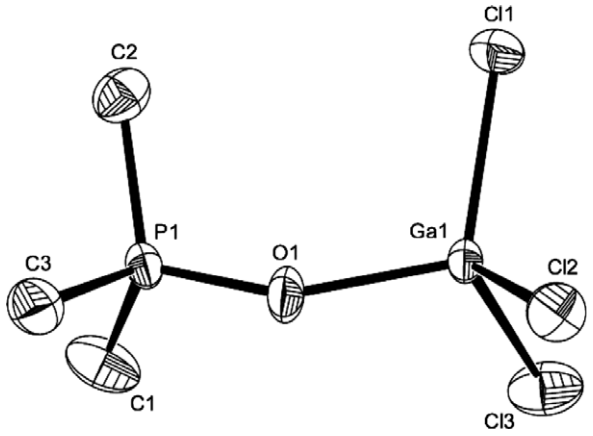

Fig. 1. View of the structure of [$GaCl_3(Me_3PO)$] with atom numbering scheme adopted. Ellipsoids are drawn at the 50% probability level and H atoms are omitted for clarity.

different, but the other parameters seem unexceptional, including the non-linear Ga–O–P angles of 148° and 153°. Spectroscopically the three [$(GaX_3)_2\{\mu$-*o*-C_6H_4-$(CH_2P(O)Ph_2)_2\}$] complexes show similar trends to those with Me_3PO described above, notably the significant fall in *ν*(PO) on coordination and the high frequency coordination shifts in $\delta(^{31}P)$ which vary with halogen Cl > Br > I (Table 2). Curiously, we were unable to observe a ^{71}Ga NMR resonance for any of the diphosphine dioxide complexes over the temperature range 295–180 K, presumably due to the line broadening resulting from fast relaxation of the quadrupolar gallium nucleus in these large and asymmetric molecules.

2.2. Gallium phosphine and arsine complexes

As indicated in Section 1, it is of interest to compare the spectroscopic and structural consequences of changing the hard R_3PO donor for a soft R_3P or R_3As ligand. Initially [$GaX_3(Me_3P)$] were prepared, but were found to be very poorly soluble in solvents suitable for spectroscopic studies (cf. Ref. [19]), and we have therefore used [$GaX_3(Ph_3P)$] and [$GaX_3(Ph_3As)$] as comparator complexes (the R group is expected to have a minimal effect on the trends). These complexes have been reported previously and some data presented [20–23,26]. The complexes were obtained in high yield by reaction of the appropriate GaX_3 and Ph_3E in anhydrous diethyl ether. X-ray crystal structures were determined for [$GaX_3(Ph_3P)$] (X = Cl or Br) (Table 5, Figs. 4 and 5). There are two reports [20,21,26] of the crystal structure of [$GaI_3(Ph_3P)$] both in the trigonal space group $R\bar{3}$, but with one using hexagonal and the other rhombohedral basis vectors. The Ga–P (2.416(5), 2.413(4) Å) and Ga–I (2.5212(9), 2.518(2) Å) are in excellent agreement, as are the I–Ga–I (*ca.* 113.8°) and I–Ga–P (*ca.* 104.6°) angles. [$GaCl_3(Ph_3P)$] and [$GaBr_3(Ph_3P)$] show the expected pseudo-tetrahedral monomer geometry. The Ga–P distances increase along the series Cl (2.372(2)) → Br (2.385(1)) → I (2.416(5) Å) consistent with reduced Lewis

acidity of the gallium as the halide becomes less electronegative, whilst the changes in Ga–X follow the changes in covalent radii of X. The literature structure of $[GaI_3(Ph_3As)]$ [20,21] is isomorphous with the Ph_3P analogue ($R\bar{3}$) with a slightly shorter Ga–I (2.509(1) Å) and with Ga–As = 2.490(1) Å. We note that in the series containing the silyl phosphine, $[GaX_3\{P(SiMe_3)_3\}]$ (X = Cl, Br, I), [17] the Ga–P distances decrease Cl → Br → I, which is the reverse of that observed in organophosphine complexes.

The $^{31}P\{^1H\}$ NMR spectra of $[GaX_3(Ph_3P)]$ are notable in showing resolved ^{31}P–$^{69/71}Ga$ couplings. $[GaCl_3(Ph_3P)]$ in CH_2Cl_2 solution shows no $^{31}P\{^1H\}$ NMR resonance at room temperature, but a broad feature appears on cooling the solution to 273 K, and at 183 K this has resolved into a broad multiplet which approximates to two overlapping quartets due to coupling to the $I = 3/2$ ^{69}Ga and ^{71}Ga. For $[GaBr_3(Ph_3P)]$ the room temperature $^{31}P\{^1H\}$ NMR resonance is an ill-defined multiplet, becomes a quartet at 273 K (although the lines are too broad to show resolved couplings to the separate gallium isotopes). For $[GaI_3(Ph_3P)]$ two superimposed quartet couplings are

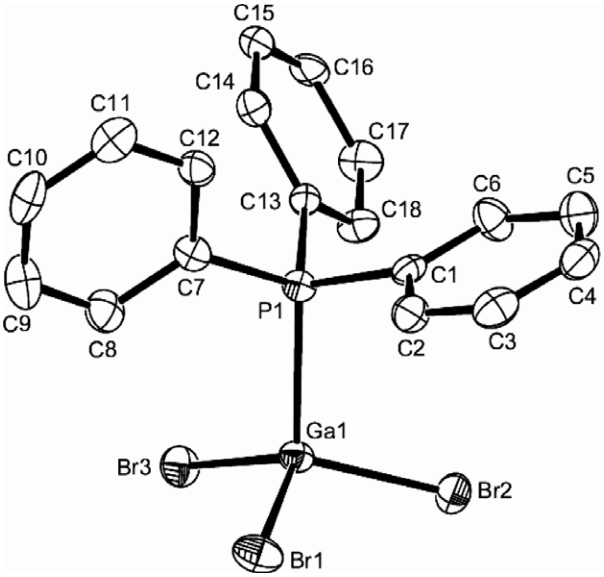

Fig. 5. View of the structure of $[GaBr_3(Ph_3P)]$ showing the atom numbering scheme adopted. Ellipsoids are drawn at the 50% probability level and H atoms are omitted for clarity. The other molecule in the asymmetric unit is very similar.

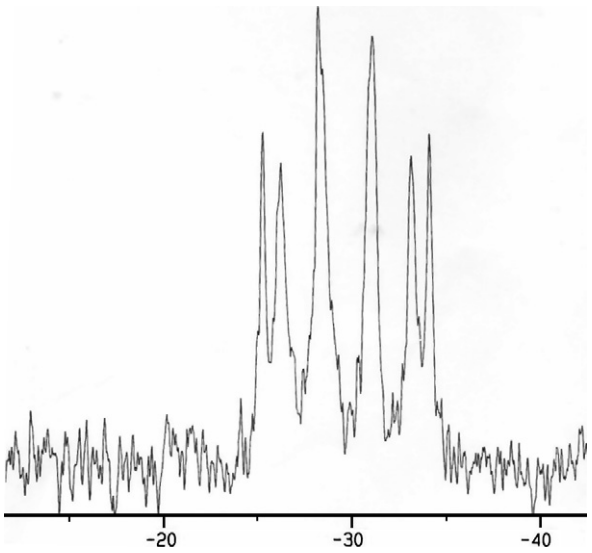

Fig. 6. $^{31}P\{^1H\}$ NMR of $[GaI_3(Ph_3P)]$ in CH_2Cl_2 at 273 K.

clearly resolved at ambient temperatures; the lines sharpen on cooling to 273 K (Fig. 6) and then broaden on further cooling. The changes with halide and temperature reflect the different electric field gradients in the three compounds and how these affect the quadrupolar relaxation rates of the gallium nuclei over this temperature range. The ^{71}Ga NMR spectra of all three compounds show clear doublet couplings to ^{31}P (Table 2) with $^1J(^{31}P\text{-}^{71}Ga)$ falling from Cl → Br → I.

The *o*-xylyl diphosphine *o*-$C_6H_4(CH_2PPh_2)_2$ is somewhat pre-organised for chelation by the central *o*-phenylene backbone, and functions as a chelate to many late transition metals, despite forming a seven-membered ring in the process [33]. However, on reaction with GaX_3 it behaves as a bridging bidentate, forming $[(GaX_3)_2\text{-}\{o\text{-}C_6H_4(CH_2PPh_2)_2\}]$ as confirmed by the crystal structure of the iodo-complex (Table 6, Fig. 7). The molecule has approximate twofold symmetry and the ligand conformation places the two GaI_3 groups '*anti*' to minimise steric interactions (Ga1–P1···P2–Ga2 = 161°). Spectroscopically these complexes (Table 2) are similar to those of Ph_3P, but provide a useful comparison with the diphosphine dioxide compounds described above.

3. Some comparisons of the effect of donor types on gallium(III)

The spectroscopic and structural data set out in previous sections clearly support the expected conclusion that Lewis acidity decreases in the gallium(III) halides Cl > Br > I,

Table 6

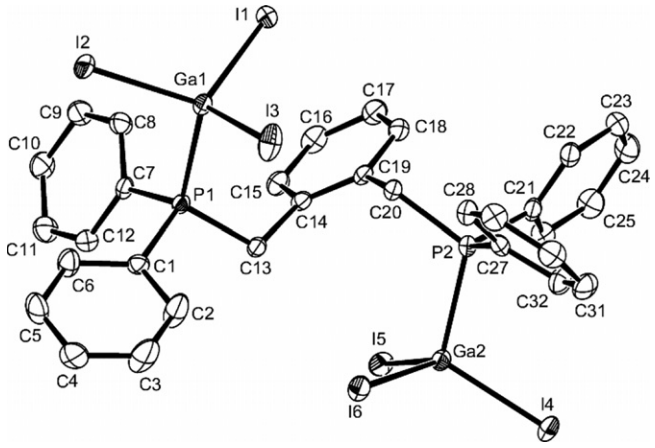

Fig. 7. View of the structure of $[(GaI_3)_2\{o\text{-}C_6H_4(CH_2PPh_2)_2\}]$ showing the atom numbering scheme adopted. Ellipsoids are drawn at the 50% probability level and H atoms are omitted for clarity.

towards both hard and soft donor ligands. The second point to note is the trends in bond lengths about the gallium centre with Ga–Cl (~2.15 Å), Ga–Br (~2.3 Å), Ga–I (~2.5 Å), Ga–O (~1.85 Å), Ga–P (~2.4 Å) and Ga–As (~2.5 Å). It is clear that the Ga–X and the Ga–O bond lengths are *ca.* 0.1 Å shorter than the sum of the covalent radii, [34] whilst the Ga–P(As) are rather longer than expected, suggesting that the softer donors are more weakly bound. Support for this came from *in situ* $^{31}P\{^1H\}$ NMR measurements (CH_2Cl_2 solution) which showed that Me_3PO displaced Ph_3P or Ph_3As (L) from their $[GaCl_3L]$ complexes, but that $[GaCl_3(Me_3PO)]$ was unaffected by the presence of excess L.

The ^{71}Ga NMR spectra show progressive low frequency shifts with halide Cl → Br → I, but the trends with neutral donor are more variable, giving evidence that several competing factors are involved.

4. Studies on oxidation and hydrolysis of gallium phosphines

In the presence of dioxygen, tin(IV) halides readily convert phosphines to phosphine oxides [8,10,29] and similar behaviour, although less thoroughly explored, is observed with Bi and Sb halides [11,30]. In order to explore whether $[GaX_3(Ph_3P)]$ forms Ph_3PO in chlorocarbon solvents, solutions of all three complexes in anhydrous CH_2Cl_2 were placed in 10 mm o.d. NMR tubes, the tubes filled with dry O_2 and the $^{31}P\{^1H\}$ NMR spectra monitored at regular intervals over a three week period. The spectra showed no evidence for phosphine oxide formation (although some $[R_3PH][GaX_4]$ were evident due to trace hydrolysis). We conclude that, in marked contrast to the Group 15 MX_3 and especially the Sn(IV) systems, gallium halides do not promote phosphine oxidation under these conditions.

In rigorously anhydrous chlorocarbons (CH_2Cl_2 or $CHCl_3$ and their deuterated analogues), gallium(III) halide phosphine and diphosphine complexes exhibit $^{31}P\{^1H\}$ NMR spectra consistent with the presence of a single species in each. In favourable cases with the (C_{3v}) $GaPX_3$ donor sets, ^{71}Ga NMR spectra lead to the same conclusions. However, even brief exposure of the solutions of $[GaX_3(R_3P)]$ to air resulted in the appearance of new resonances. In the $^{31}P\{^1H\}$ NMR spectra the new features were broad with ill-defined structure and typically to high frequency of that of the gallium complex, and were assigned to the corresponding phosphonium cations $[R_3PH]^+$ both by comparison of their chemical shifts with literature values [35], and from the ^1H-coupled ^{31}P NMR spectra which showed doublets due to $^1J_{PH}$ (300–700 Hz).[2] The ^{71}Ga spectra also showed resonances due to the corresponding $[GaX_4]^-$ anion at X = Cl: $\delta = 251$; X = Br: $\delta = 64$; X = I: $\delta = -455$ [32]. All of the complexes we examined showed a tendency to form phosphonium salts, although it is particularly evident with alkyl phosphines, probably because these are the strongest proton bases [36].

Addition of small amounts of water to the solutions resulted in immediate and complete loss of the resonances due to $[GaX_3(R_3P)]$ and the only species evident in the ^{71}Ga NMR spectra were the $[GaX_4]^-$ anions. The formation of phosphonium salts was also observed in the gallium–diphosphine complexes, and we note that Sigl et al. [37] identified the hydrolysis product of $[GaCl_2\{o\text{-}C_6H_4(PPh_2)_2\}][GaCl_4]$ as $[o\text{-}C_6H_4(PPh_2)(PPh_2H)][GaCl_4]$ by an X-ray crystal structure.

Final confirmation of the identity of the hydrolysis products comes from the crystal structure of $[Me_2PhPH][GaCl_4]$ (Fig. 8). Colourless crystals of which were obtained from a solution shown by NMR spectroscopy to contain mainly $[GaCl_3(Me_2PhP)]$, showing the ionic species crystallise preferentially. $[GaCl_3(Ph_3P)]$ is quantitatively converted into $[Ph_3PH][GaCl_4]$ by treatment with HCl gas in CH_2Cl_2 solution, which provides the most convenient synthesis for these phosphonium species.

[2] The broad lines arise from incomplete decoupling of the P–H proton under normal broad band decoupling settings.

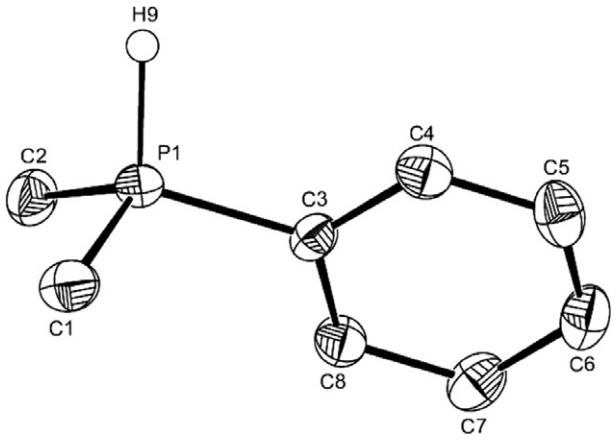

Fig. 8. View of the structure of the cation in $[Me_2PhPH][GaCl_4]$ with numbering scheme adopted. Ellipsoids are drawn at the 50% probability level and H atoms (except that on P1) are omitted for clarity. Selected bond lengths (Å) and angles (°): P1–C1 1.788(4); P1–C2 1.784(3); P1–C3 1.788(3); C–P1–C 110.08(16)–111.50(17); Ga1–Cl 2.1657(11)–2.1770(11).

5. Conclusions

These results show that the Lewis acidity of GaX_3 decreases as the halide becomes heavier and that the maximum coordination number at the gallium in these species is four. With only one exception, all the complexes were neutral with X_3O or X_3E (X = Cl, Br or I; E = P or As) donor sets. Competitive NMR studies on the $GaCl_3$ systems show that R_3PO are preferred to R_3E suggesting that $GaCl_3$ is quite a hard Lewis acid.

6. Experimental

All the reactions and manipulations were performed in an inert atmosphere (N_2) glovebox or using Schlenk techniques. Diethyl ether and hexane were dried by distillation over sodium/benzophenone and dichloromethane was dried by distillation from CaH_2. Infrared spectra were measured as Nujol mulls between CsI plates on a Perkin–Elmer PE983 spectrometer. ^1H NMR spectra were recorded in $CDCl_3$ solution on a Bruker AV300, $^{31}P\{^1H\}$ and ^{71}Ga NMR spectra on a Bruker DPX400 and referenced to 85% H_3PO_4 and $[Ga(H_2O)_6]^{3+}$ respectively. Me_3PO (Aldrich) was freshly sublimed prior to use. *o*-$C_6H_4(CH_2P(O)Ph_2)_2$ was obtained as a white solid by stirring a CH_2Cl_2 solution of *o*-C_6H_4-$(CH_2PPh_2)_2$ in dry air with a catalytic amount of SnI_4 [29] followed by hydrolysis, extraction with CH_2Cl_2 and drying ($MgSO_4$). ^1H NMR ($CDCl_3$): $\delta = 3.90$ (d, [4H], CH_2, $^2J_{PH} = 13.0$ Hz), 6.68 (m, [2H], *o*-C_6H_4), 6.78 (m, [2H], *o*-C_6H_4), 7.30–7.67 (m, [20H], Ph). $^{13}C\{^1H\}$ NMR ($CDCl_3$): $\delta = 35.9$ (d, CH_2, $^1J_{PC} = 66.4$ Hz), 126.6–133.3 (aromatic C). $^{31}P\{^1H\}$ NMR ($CDCl_3$): 30.8. IR (Nujol): $\nu = 1181$ br s (P=O) cm^{-1}.

6.1. [$GaCl_3(Me_3PO)$]

$GaCl_3$ (0.19 g, 1.09 mmol) in CH_2Cl_2 (5 mL) was combined with a CH_2Cl_2 solution (10 mL) of Me_3PO (0.10 g, 1.09 mmol) and the reaction mixture was stirred under N_2 for *ca.* 2 h. The volatiles were then removed *in vacuo* and the white solid rinsed with hexane and dried *in vacuo*. Yield 0.26 g, 88%. *Anal.* Calc. for $C_3H_9Cl_3GaOP$: C, 13.4; H, 3.4. IR (Nujol): $\nu = 1102$ (P=O), 250 (Ga–I) cm^{-1}.

6.4. [$(GaCl_3)_2\{\mu$-*o*-$C_6H_4(CH_2P(O)Ph_2)_2\}$]

Method as above, but using a 2:1 $GaCl_3$:diphosphine ratio. White solid (89%). *Anal.* Calc. for $C_{32}H_{28}Cl_6Ga_2O_2P_2 \cdot 0.25CH_2Cl_2$: C, 44.0; H, 3.3. Found: C, 44.1; H, 2.6%. ^1H NMR ($CDCl_3$, 298 K): $\delta = 4.08$ (d, CH_2, 4H, $^2J_{PH} = 12.4$ Hz), 6.51 (m, *o*-C_6H_4, 2H), 6.98 (m, *o*-C_6H_4, 2H), 7.50–7.78 (m, Ph, 20H). $^{13}C\{^1H\}$ NMR ($CDCl_3$): $\delta = 33.7$ (d, CH_2, $^1J_{PC} = 68.1$ Hz), 124.3–135.4 (aromatic C). $^{31}P\{^1H\}$ NMR ($CDCl_3$): $\delta = 52.5$. ^{71}Ga NMR ($CDCl_3$): not observed. IR (Nujol): $\nu = 1088$ br s, 1070 sh (P=O), 397, 356 (Ga–Cl) cm^{-1}.

6.5. [$(GaBr_3)_2\{\mu$-*o*-$C_6H_4(CH_2P(O)Ph_2)_2\}$]

Method as above, but using a 2:1 $GaBr_3$:diphosphine ratio. White solid (94%). *Anal.* Calc. for $C_{32}H_{28}Br_6Ga_2O_2P_2 \cdot CH_2Cl_2$: C, 32.8; H, 2.5. Found: C, 32.4; H, 2.1%. ^1H NMR ($CDCl_3$, 298 K): $\delta = 4.11$ (d, CH_2, 4H, $^2J_{PH} = 12.3$ Hz), 6.50 (m, *o*-C_6H_4, 2H), 6.95 (m, *o*-C_6H_4, 2H), 7.50–7.77 (m, Ph, 20H). $^{13}C\{^1H\}$ NMR ($CDCl_3$): $\delta = 34.1$ (d, CH_2, $^1J_{PC} = 68.0$ Hz), 124.2–135.4 (aromatic C). $^{31}P\{^1H\}$ NMR ($CDCl_3$): $\delta = 52.0$. ^{71}Ga NMR ($CDCl_3$): not observed. IR (Nujol): $\nu = 1091$ s, 1080 s (P=O), 296, 230 (Ga–Br) cm^{-1}.

6.6. [(GaI$_3$)$_2${μ-o-C$_6$H$_4$(CH$_2$P(O)Ph$_2$)$_2$}]

Method as above, but using a 2:1 GaI$_3$:diphosphine ratio. White solid (65%). *Anal.* Calc. for $C_{32}H_{28}Ga_2I_6O_2P_2$: C, 27.3; H, 2.0. Found: C, 27.4; H, 1.7%. ^{1}H NMR ($CDCl_3$, 298 K): $\delta = 4.15$ (d, CH_2, 4H, $^2J_{PH} = 12.6$ Hz), 6.50 (m, *o*-C_6H_4, 2H), 6.95 (m, *o*-C_6H_4, 2H), 7.50–7.80 (m, Ph, 20H). ^{13}C{^{1}H} NMR ($CDCl_3$): $\delta = 33.6$ (d, CH_2, $^1J_{PC} = 68.1$ Hz), 124.1–135.3 (aromatic C). ^{31}P{^{1}H} NMR ($CDCl_3$): $\delta = 51.4$. ^{71}Ga NMR ($CDCl_3$): not observed. IR (Nujol): $\nu = 1086$ s, 1076 s (P=O), 240 (Ga–I) cm^{-1}.

6.7. [GaCl$_3$(Ph$_3$P)]

A solution of Ph_3P (0.300 g, 1.14 mmol) in diethyl ether (5 mL) was added dropwise to a stirred solution of $GaCl_3$ (0.201 g, 1.14 mmol) in diethyl ether (4 mL). After stirring at room temperature for 15 h, the resultant white precipitate was filtered off, washed with diethyl ether (2 mL) and dried *in vacuo*. Yield 0.32 g, 65%. *Anal.* Calc. for $C_{18}H_{15}Cl_3GaP$: C, 49.3; H, 3.5. Found: C, 48.7; H, 3.8%. ^{1}H NMR ($CDCl_3$, 295 K): δ 7.69–7.41 (m, Ph). ^{31}P{^{1}H} NMR ($CDCl_3$): 295 K not observed; 273 K $\delta = -5.4$ (m). ^{71}Ga NMR ($CDCl_3$): $\delta = 264$ (br d, $J = 721$ Hz). IR (Nujol): $\nu = 387$ s, 347 m (Ga–Cl) cm^{-1}.

6.8. [GaBr$_3$(Ph$_3$P)]

Made similarly to the chloro compound. White solid (64%). *Anal.* Calc. for $C_{18}H_{15}Br_3GaP$: C, 37.8; H, 2.9. Found: C, 38.1; H, 2.8%. ^{1}H NMR ($CDCl_3$, 295 K): δ 7.81–7.38 (m, Ph). ^{31}P{^{1}H} NMR ($CDCl_3$): $\delta = -10.7$. ^{71}Ga NMR ($CDCl_3$): $\delta = 152$ (d, $J = 693$ Hz). IR (Nujol): $\nu = 289$ s, 234 m (Ga–Br) cm^{-1}.

6.9. [GaI$_3$(Ph$_3$P)]

Made similarly to the chloro compound. White solid (66%). *Anal.* Calc. for $C_{18}H_{15}GaI_3P$: C, 30.3; H, 2.1. Found: C, 30.5; H, 2.0%. ^{1}H NMR ($CDCl_3$, 295 K): δ 7.81–7.38 (m, Ph). ^{31}P{^{1}H} NMR ($CDCl_3$): $\delta = -29.7$. ^{71}Ga NMR ($CDCl_3$): $\delta = -151$ (d, $J = 466$ Hz). IR (Nujol): $\nu = 241$ m (Ga–I) cm^{-1}.

6.10. [(GaBr$_3$)$_2${o-C$_6$H$_4$(CH$_2$PPh$_2$)$_2$}]

Made similarly using a 2:1 Ga:ligand mol. ratio. White solid (76%). *Anal.* Calc. for $C_{32}H_{28}Br_6Ga_2P_2$: C, 35.2; H, 2.6. Found: C, 35.5; H, 2.5%. ^{1}H NMR ($CDCl_3$): 3.72 (d, 4H, CH_2), 6.53–6.97 (m), 7.45–7.75 (m, aromatic H). ^{31}P{^{1}H} NMR ($CDCl_3$): $\delta = -14.2$ (s). ^{71}Ga NMR ($CDCl_3$): $\delta = 156$ (br). IR (Nujol): $\nu = 281$ s, 227 m (Ga–Br) cm^{-1}.

6.11. [(GaI$_3$)$_2${o-C$_6$H$_4$(CH$_2$PPh$_2$)$_2$}]

Prepared similarly to the previous compound. White solid (75%). *Anal.* Calc. for $C_{32}H_{28}Ga_2I_6P_2$: C, 27.9; H, 2.1. Found: C, 28.2; H, 1.9%. ^{1}H NMR ($CDCl_3$): 3.60 (d, 4H, CH_2), 6.97–6.69 (m), 7.63–7.40 (m, aromatic H). ^{31}P{^{1}H} NMR ($CDCl_3$): $\delta = -33.7$ (s). ^{71}Ga NMR ($CDCl_3$): $\delta = -146$ (s). IR (Nujol): $\nu = 234$ m (Ga–I) cm^{-1}.

6.12. [GaCl$_3$(Ph$_3$As)]

A solution of Ph_3As (0.220 g, 0.718 mmol) in diethyl ether (10 mL) was added dropwise to a stirred solution of $GaCl_3$ (0.126 g, 0.718 mmol) in diethyl ether (5 mL). After stirring at room temperature for 4 h, removal of Et_2O gave a white solid, which was dried *in vacuo*. (Yield 0.32 g, 92%). ^{71}Ga NMR ($CDCl_3$): $\delta = 264$ (s, $W_{1/2} = 4000$ Hz). IR (Nujol): $\nu = 392$ s, 365 m (Ga–Cl) cm^{-1}.

6.13. [GaBr$_3$(Ph$_3$As)]

Prepared similarly to the chloro compound. White solid (93%). ^{71}Ga NMR ($CDCl_3$): $\delta = 132$ (s, $W_{1/2} = 3000$ Hz). IR (Nujol): $\nu = 285$ br s, 219 m (Ga–Br) cm^{-1}.

6.14. [GaI$_3$(Ph$_3$As)]

Prepared similarly to the chloro compound. White solid (90%). ^{71}Ga NMR ($CDCl_3$): $\delta = -203$ (s, $W_{1/2} = 2500$ Hz). IR (Nujol): $\nu = 244$ m (Ga–I) cm^{-1}.

6.15. [Me$_2$PhPH][GaCl$_4$]

Crystals of [$PPhMe_2H$][$GaCl_4$] were isolated from solutions of the corresponding [$GaCl_3$(Me_2PhP)] in CH_2Cl_2 solution by vapour diffusion of *n*-hexane under nitrogen. ^{1}H-coupled ^{31}P NMR ($CDCl_3$): δ −0.47 (d, $^1J = 511$ Hz). ^{71}Ga NMR: $\delta = +251$ (s).

6.16. X-ray experimental

Crystallographic parameters are given in Table 7. All the crystals were grown from CH_2Cl_2 solutions of the complexes by vapour diffusion of *n*-hexane under dinitrogen. Data collections were carried out with a Bruker-Nonius Kappa CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and with the crystals held at 120 K in a nitrogen gas stream. The structure solutions were straightforward [38–40] except as indicated below with the hydrogen atoms being introduced into the models in calculated positions with default C–H distances. The phosphonium H atom had P–H fixed at 1.40 Å. [$GaCl_3$(Me_3PO)] is reported in the space group *Cc* although the 'checkcif' software raised the possibility of missed symmetry. The *Cc*-*C*2/*c* problem is well known [41,42], but with *Z* of 4 a *C*2/*c* solution would require the molecule to have symmetry (or to be disordered). Attempts to find a *C*2/*c* solution failed. [$GaI_2(Me_3PO)_2$][GaI_4] belongs to one of the 11 pairs of enantiomorphous space groups and the fit to the data was slightly improved by the inclusion of a TWIN command. The data for

$[GaCl_3(Ph_3P)]$ was collected in the triclinic system and yielded a solution with $Z = 4$ in the space group $P\bar{1}$. Inspection of the data and the cell dimensions showed the data could be transformed to a $C2/c$ monoclinic system with $Z = 8$ with one molecule in the asymmetric unit and this is the solution reported.

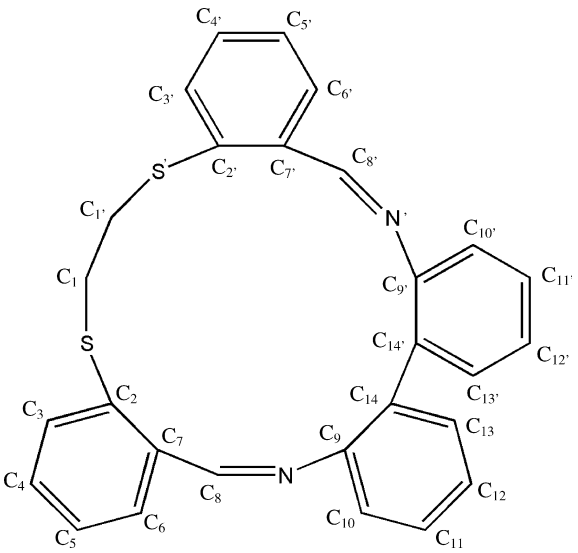

Fig. 1. Atom notation in the bite ligand.

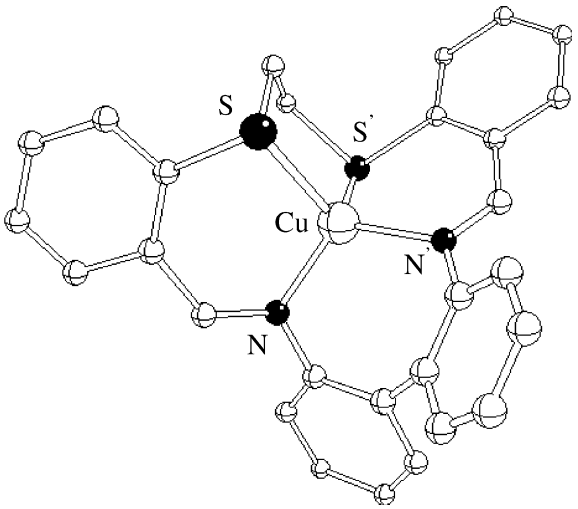

Fig. 2. The structure of quasi-tetrahedral Cu(bite)$^{+}$ (H atoms omitted).

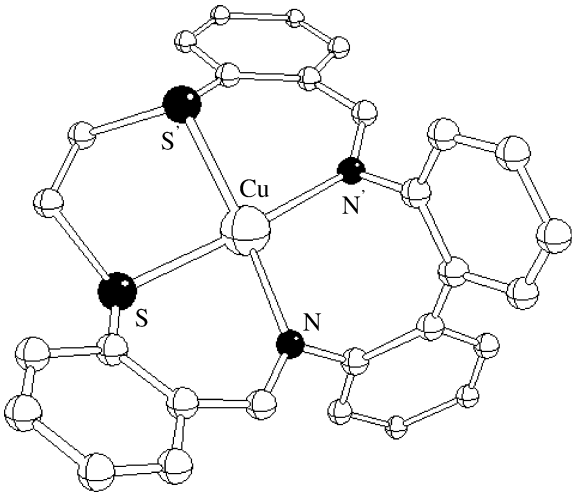

Fig. 3. The structure of quasi-square planar Cu(bite)$^{2+}$ (H atoms omitted).

ESR experiments [4] confirmed the presence of two different $[Cu^{II}(bite)]^{2+}$ forms (tetrahedral and square-planar) in frozen acetonitrile solution at 77 K.

Many experts denote the macrocyclic compounds as very poor model systems of blue copper proteins (blue copper proteins cannot be modelled by strained complexes, their electronic structure is quite different, their electron transfer rate is very low, etc.). Nevertheless, DFT quantum-chemical calculations [6] indicate that the reorganization and strain energy values of Cu(bite)$^{+/2+}$ complexes are comparable with analogous DFT/MM data for tetracoordinate copper complexes with monodentate imidazole and thiolate ligands that are generally used as model systems for blue copper proteins. Thus these complexes are worth of further experimental as well as theoretical investigation as blue protein model systems. The aim of this study is AIM (atoms-in-molecule) topological analysis of the electron density of Cu(bite)$^{+/2+}$ complexes as well as of the bite ligands in both the above mentioned conformers.

2. Method

Ab initio MP2 calculations were performed using the standard Gaussian98 program package [7] with standard 6-31G basis sets [8]. For comparison, the 6-311G basis set [9] has been used for the sulfur atoms. The optimal geometries of all the systems under study have been obtained by the DFT method in the previous part of this study [4,5]. AIM topological analysis of electron density [10] has been elaborated using the AIM2000 program package [11] and the results have been evaluated in terms of atomic volumes, and AIM atomic charges that have been obtained using the electron density integrated over atomic basins (up to 0.001 e/bohr^3 level) as well as in terms of electron density ρ, density Laplacian L

$$L = \lambda_1 + \lambda_2 + \lambda_3 \quad (1)$$

and bond ellipticity ε

$$\varepsilon = \lambda_1/\lambda_2 - 1 \quad (2)$$

at bond critical points (BCP) where $\lambda_1 < \lambda_2 < 0 < \lambda_3$ are the eigenvalues of the Hessian of the BCP electron density. Alternatively, the electronic structures of the compounds under study have been evaluated in terms of natural bond orbital (NBO) analysis [7,12] (natural atomic charges, overlap weighted NBO bond orders).

3. Results and discussion

The results of AIM topological analysis of the electron density of Cu(bite)$^{+}$, Cu(bite)$^{2+}$ and bite with tetrahedral and square-planar geometries of the S_2N_2 polyhedron are collected in Tables 1–5, and the analogous NBO data in Tables 6 and 7. The results of MP2 calculations with the 6-311G basis on the sulfur atoms in the tetrahedral Cu(bite)$^{+}$ system (if different from the 6-31G ones) are in parentheses. It is evident that the differences are not significant

and are restricted to Cu and S atoms only. Thus it may be concluded that the basis set extension should not lead to any significant changes in the electronic structure parameters of our systems.

It may be seen (Table 1) that the S atoms have the largest atomic volumes, those of Cu and N atoms are significantly lower. The C_1 atoms have the lowest atomic volume. The lower values of this parameter for the C_2, C_7, C_8, C_9 and C_{14} atoms in comparison with the remaining aromatic carbon atoms may be ascribed to their non-aromatic character (C_2, C_8) or to their partial non-aromatic bonding. Atomic volumes of the Cu, S and C_8 atoms decrease with oxidation whereas the N and C_7 atoms exhibit the reverse trend. The copper atoms in a tetrahedral coordination have larger volumes than in a square-planar geometry, whereas the reverse relation holds for N atoms. As expected, the S and N atoms volumes in a free bite ligand are larger than in its Cu complexes.

[a] With 6-311G basis on sulfur.

The most positive AIM charges are at the Cu atoms (Table 2). Positive charges at C_8 atoms are higher than the nearly equal C_9 and S positive charges. The most negative charges are at the N atoms, and the C_2 atoms have more negative charge than the C_1 atoms. The charges at the remaining carbon atoms are minimal. The electron density at the Cu and C_8 atoms decreases with oxidation whereas the N atoms exhibit the reverse trend (lower electron density corresponds to lower atomic volume – compare to Table 1). On the other hand, the Cu electron density is higher in tetrahedral compared to square-planar coordination. A larger atomic volume with lower electron density indicates increasing mechanical strain at the square-planar coordinated Cu atom [10]. Lower electron density at S and N in the free bite ligand than in its copper complexes may be ascribed to the missing Cu atom. The same trend at C_9 and the reverse trend at C_8 with nearly constant atomic volumes indicates the important role of mechanical strain at these sites.

[a] With 6-311G basis on sulfur.

According to ρ_{BCP} data (Table 3) the bond strengths increase in the order:

$$Cu–S < Cu–N < S–C_1 < S–C_2 < C_{14}–C'_{14}$$

The remaining aromatic bonds are stronger; the C_8–N bond is the strongest one. The Cu–S and Cu–N bonds are stronger in a tetrahedral than in a square-planar conformation. The N–C_9 bond in the free bite ligand is stronger than in its copper complexes.

Positive L_{BCP} values of Cu–S and especially Cu–N bonds are in agreement with their ionic ('non-sharing' [10]) character (Table 4). The 'sharing' or covalent character ($L_{BCP} < 0$) of the other bonds increases in the sequence:

$$S–C_1 < S–C_2 < C_1–C'_1 < C_{14}–C'_{14}$$

The remaining bonds are of more "sharing" character (more negative L_{BCP}), the most negative L_{BCP} corresponds

to the N–C_8 bond. The L_{BCP} values of Cu–S, Cu–N, C_7–C_8 and N–C_8 bonds decreases with oxidation whereas the S–C_1 one increases. The ionic character of the Cu–S and Cu–N bonds is higher in a tetrahedral than in a square-planar conformation. The covalent character of the C_7–C_8 and N–C_9 bonds is stronger in the free bite ligand than in its copper complexes.

The highest ellipticity ε_{BCP} and thus the π bonding character may be ascribed to the C_9–C_{14} and C_9–C_{10} bonds (Table 5) whereas the lowest ones belong to the C_{14}–$C_{14'}$, N–C_9 and C_1–$C_{1'}$ bonds, with the lowest π bond contributions. Increasing ellipticities of the Cu–N, C_9–C_{14} and C_9–C_{10} bonds with oxidation as well as the reverse trend of the N–C_8 and C_6–C_7 ones in connection with their nearly constant bond strengths (see Table 3) indicate the significant role of mechanical strain rather than the changes in their π bonding character. On the other hand, higher S–C_1 and S–C_2 bond ellipticities in the free bite ligand than in its copper complexes are explainable by increasing π bonding only.

The trends in natural atomic charges (Table 6) are only in partial agreement with the AIM ones (Table 2). In both cases the most positive charges are at the Cu atoms, electron density at the Cu and C_8 atoms decreases with oxidation whereas the N atoms exhibit the reverse trend and the electron density at S and N in the free bite ligand is lower than in its copper complexes. On the other hand, the most negative charges at the N atoms is in the oxidized systems only. The most negative charges at the C_1 atoms in the remaining systems do not seem realistic. Unlike AIM data, all the carbon atoms except C_8 and C_9 have negative charges. Moreover, the natural electron density at the S atom increases with oxidation whereas the C_4, C_6 and C_7 ones exhibit the reverse trend. Unlike AIM, the natural electron density at the Cu and C_8 atoms is lower in a tetrahedral than in a square-planar coordination and the C_9 value is lower in the free ligand, unlike that of C_8. Additional information represents a Cu^{II} d electron population of ca. 9.0 and the Cu^{I} one of ca. 9.6.

It is surprising that unlike the above differences in atomic charges, the overlap weighted NBO bond orders (Table 7) exhibit the same trends like the analogous AIM data with only one exception related to the reverse order of Cu–N and Cu–S bond strengths. In this connection the question of the reliability of both types of electronic structure parameters arises. According to the authors' opinion, the AIM treatment should be preferred.

Finally it may be concluded that AIM topological analysis of electron density of the compounds under study grants valuable information on their electron structure as well as on mechanical strain and thus on their reactivity. Energy considerations [6] point out the role of mechanical strain but say nothing on its localization. Our results indicate the highest mechanical strain at the central copper atom and at the carbons bonded to nitrogen atom. Future model studies on the redox properties of $Cu(bite)^{+/2+}$ should be related preferentially to these sites.

substituents in $[\{Cu(HL\text{-}R)\}_2]\cdot 2NO_3\cdot nH_2O$ and $[\{Cu(L\text{-}R)\}_2]\cdot nH_2O$ has been also studied [18]. In the present work, we report the synthesis and characterization of some nickel(II) complexes of the type $[\{Ni(L\text{-}R)\}_2]$ and $[Ni(HL\text{-}R)_2]$ obtained from the reaction of substituted aroylhydrazoneoximes (**I**) with nickel(II) acetate.

R	Abbreviated as
C_6H_5	H_2L-H
p-$CH_3C_6H_4$	H_2L-CH_3
p-$CH_3OC_6H_4$	H_2L-CH_3O
p-ClC_6H_4	H_2L-Cl
p-$NO_2C_6H_4$	H_2L-NO_2

I

II III

In metal complexes having pyrazole as coligand, the N–H of the coordinated pyrazole is usually involved in hydrogen bond formation with available hydrogen donor or hydrogen acceptor sites giving rise to supramolecular assemblies [3,19–24]. In this context, nickel (II) complexes with dinegative tridentate aroylhydrazoneoximes having pyrazole (HPyr) as coligand have been also prepared and characterized. The X-ray molecular and supramolecular structures of [Ni(L-H);HPyr], [Ni(L-OCH_3)HPyr] and [Ni(L-Cl)HPyr] will also be discussed.

2. Experimental

2.1. Materials

Diacetylmonoxime was obtained from Sigma and used without further purification. Aroylhydrazoneoximes (**I**, R = C_6H_5, p-$CH_3C_6H_4$, p-$CH_3OC_6H_4$, p-ClC_6H_4 and p-$NO_2C_6H_4$) were prepared as previously described [18]. Pyrazole was obtained from Aldrich and was used without further purification.

2.2. Synthesis of nickel(II) complexes

2.2.1. Synthesis of $[\{Ni(L\text{-}R)\}_2]\cdot nH_2O$ (**II**, R = C_6H_5, p-$CH_3C_6H_4$, p-$CH_3OC_6H_4$, p-ClC_6H_4 and p-$NO_2C_6H_4$) (**1–5**)

A solution of nickel(II) acetate tetrahydrate (0.01 mole) in ethanol (30 cm^3) was added to a suspension of the appropriate aroylhydrazoneoxime (**I**, R = C_6H_5, p-$CH_3C_6H_4$, p-$CH_3OC_6H_4$, p-ClC_6H_4 and p-$NO_2C_6H_4$) (0.01 mole) in ethanol (50 cm^3). The resulting mixture was treated with a solution of KOH (0.02 mole) in ethanol (20 cm^3). The mixture was then refluxed, with constant stirring, for 3 h. The isolated complex was then filtered off, washed several times with ethanol then dried in vacuo.

2.2.2. Synthesis of $[Ni(HL\text{-}R)_2]\cdot nH_2O$ (**6–10**)

A solution of nickel(II) acetate tetrahydrate (0.01 mole) in ethanol (30 cm^3) was added drop wise, with constant

Table 1

9	Cl		58	47.59 (46.85)	4.11 (3.93)	14.48 (14.90)
10	NO_2		57	44.45 (44.47)	3.91 (3.90)	18.62 (18.86)
(iii) [Ni(L-R)HPyz]						
11	H		51	48.82 (48.88)	4.42 (4.39)	20.13 (20.36)
12	CH_3		50	50.06 (50.32)	4.76 (4.97)	19.47 (19.56)
13	CH_3O		63	48.30 (48.17)	4.60 (4.58)	18.80 (18.72)
14	Cl		65	44.24 (44.43)	3.99 (3.73)	18.61 (18.51)
15	NO_2		65	43.16 (43.23)	3.68 (3.64)	21.29 (21.60)

stirring, to a suspension of the aroylhydrazoneoxime (0.02 mole) in ethanol (50 cm^3). The reaction mixture was then refluxed with constant stirring for 3 h. The isolated complex was filtered off, washed several times with ethanol and then dried in vacuo.

2.2.3. Synthesis of [Ni(L-R)(HPyr)] (*III*, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4 and *p*-$NO_2C_6H_4$) (*11–15*)

To a suspension of the $[\{Ni(L\text{-}R)\}_2]\cdot nH_2O$ complex (**II**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4 and *p*-$NO_2C_6H_4$) (0.01 mole) in ethanol (40 cm^3), a sufficient amount of solid pyrazole (0.05 mole) was added and the reaction mixture was heated under reflux until complete dissolution. The resulted solution was filtered and the filterate solution was further heated for ca. 1/2 h. On cooling the imidazole-nickel complex which was precipitated was isolated by filtration then washed with diethyl ether and dried in vacuo.

The prepared nickel(II) complexes (**1–15**) together with their elemental analyses are listed in Table 1.

2.3. Physical measurements

The infrared spectra were recorded on a Perkin–Elmer 1430 Data system and/or a Perkin–Elmer (FT-IR) Paragon 1000 PC spectrophotometer. Solid samples were examined as KBr discs. The ultraviolet and visible absorption spectra were recorded on double beam ratio recording Lambada 4B Perkin–Elmer spectrophotometers. Electrospray ionization mass spectra (ESI MS) were recorded on Esquire-LC from Bruker with Daltonic Nebulizer 10 psi (dry gas 8 L/min, dry temp. 250 °C). Theoretical isotopic distribution patterns for ionic species were generated using ISOFORM program and/or Sheffield University Chemputer software [25]. ^{1}H NMR spectra were recorded on Brucker WM 300 using tetramethylsilane (TMS) as an internal standard. Magnetic susceptibilities of powdered dried samples were recorded on a Faraday-type magnetometer using a sensitive computer controlled D-200 Cahn RG microbalance. The magnetic field applied was ~1.5 T. Experimental susceptibility data were corrected for the underlying diamagnetism using Pascal's constants [26].

3. Results and discussion

3.1. Synthesis and characterization

In methanol, the reaction of 3-hydroxyimino-2-butanone aroylhydrazones (H_2L-R) (**I**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4, *p*-$NO_2C_6H_4$) with nickel(II) acetate tetrahydrate, using (1:1) molar ratio, in presence of KOH afforded the neutral complexes of stoichiometric composition $Ni(L\text{-}R)\cdot nH_2O$. Similar to the corresponding copper(II) complexes [17,18], nickel(II) and copper(II) complexes with tridentate 3-hydroxyimino-2-butanone thiosemicarbazones [27,28] and other copper(II) complexes of tridentate 3-hydroxyimino-2-butanone Schiff bases [29–31], a dimeric structure $[\{Ni(L\text{-}R)\}_2]$ (**II**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-CH_3 OC_6H_4, *p*-ClC_6H_4, *p*-$NO_2C_6H_4$) can be proposed for the prepared solid nickel(II) complexes where the oximate group functions as a bridge between two nickel(II) ions. Elemental analyses of the prepared $[\{Ni(L\text{-}R)\}_2]\cdot nH_2O$ complexes, Table 1, are in a good agreement with the proposed formulation. The actual structure of these complexes must remain in doubt until complete X-ray molecular structures are available. Attempts to isolate single crystals suitable for X-ray structural analysis were unsuccessful.

The IR spectra of $[\{Ni(L\text{-}R)\}_2]$ (**I**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4 and *p*-$NO_2C_6H_4$) lack absorptions attributable to oxime *ν*(O–H), hydrazide

Table 2
Solution electronic absorption spectra of nickel(II) complexes

Complex R	Sovent	λ_{max} (nm) (log ε)

ν(N–H), amide I [ν(C=O)], and amide II [δ(N–H)] bands, implying the deprotonation of both oxime and aroylhydrazone residues. The spectra, however, show intense band at ca. 1600 cm^{-1} due to the ν(C=N–N=C). Both oxime ν(C=N) (1520–1480 cm^{-1}) and ν(N–O) (1125–1135 cm^{-1}) appear at lower frequencies while the amide III band [ν(C–N)] (1300–1320 cm^{-1}) is shifted to higher frequencies as compared to the corresponding metal free aroylhydrazoneoxime. Both elemental analyses and IR spectral data suggest that the aroylhydrazoneoxime in [{Ni(L-R)}$_2$] complexes acts as a dinegative NNO tridentate ligand and is coordinated to the central Ni(II) via deprotonated oximate oxygen, hydrazone imine nitrogen and deprotonated enolimine oxygen. The two nickel(II) centers in [{Ni(L-R)}$_2$] complexes are bridged by the deprotonated oximate function forming six membered rings (**I**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4, *p*-$NO_2C_6H_4$) [17,18,27–31].

At room temperature (298 K), the dimeric neutral Ni(II) complexes [{Ni(L-R)}$_2$] (**I**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4, *p*-$NO_2C_6H_4$) are diamagnetic, indicating square planar arrangement with $^1A_{1g}$ ground state. The solution electronic absorption spectra of these complexes, in DMF, Table 2, are in agreement with this assignment. The high energy bands at ca. 280 and 360 nm are assigned to (L–L*) interligand transitions. The shoulder at 400 nm is assigned to LMCT transition while absorption at 460 ± 5 nm may originate from d–d transitions ($^1A_g \rightarrow {}^1B_{1g}$, $^1B_{3g}$). The two absorptions at ca. 510–535 and 570–600 nm can be related to the different d(π^*) → L(π^*) (MLCT) transitions [32,33].

For solubility reasons, the ^{1}H NMR spectra of diamagnetic [{Ni(L-R)}$_2$] complexes in deuterated chloroform could not be recorded. However, in deuterated DMSO, the spectra suggest the formation of paramagnetic solvated species as evident from the broadening of ^{1}H NMR signals.

Reaction of nickel(II) acetate tetrahydrate with 2 equiv. of aroylhydrazoneoxime **I** (R = H, *p*-CH_3, *p*-CH_3O, *p*-Cl, *p*-NO_2) in methanol afforded the bisligand complexes [Ni(HL-R)$_2$]. The aroylhydrazoneoxime in [Ni(HL-R)$_2$] complexes acts as mononegative NNO tridentate ligand. The IR spectra lack absorptions due to hydrazone ν(N–H), amide I [ν(C=O)] and amide II [δ(N–H)] bands, but show intense absorptions attributed to oxime ν(O–H) (3440 cm^{-1}), ν(C=N–N=C) (1601–1610 cm^{-1}), oxime ν(C=N) (1520– 1510 cm^{-1}) and amide III [ν(C–N)] (1330–1320 cm^{-1}) indicating the deprotonation of the aroylhydrazone residue while the oxime residue remains protonated.

Solid bisligand nickel(II) complexes are paramagnetic with magnetic moments being within the range 3.20–3.33 μ_β (298 K) suggesting octahedral structure. Deprotonation of the paramagnetic green bisligand complexes with KOH in methanol gave the diamagnetic brown dinuclear complexes [{Ni(L-R)}$_2$]. The electronic absorption spectra of bisligand complexes [Ni(HL-R)$_2$] display a series of bands at ca. 585, 650, 670 and 845 nm which can be, respectively, assigned to d–d transitions from $^3B_{1g}$ to $^3A_{2g}$, ^3E_g, $^3A_{2g}$ and $^3B_{2g}$ characteristic of distorted octahedral Ni(II) complexes in D_{4h} symmetry [34]. Both $^3B_{1g} \rightarrow {}^3E_g$ and LMCT transitions are most probably hidden under the intense L–L* absorption band at ca. 370 nm.

Reaction of **I** (R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4, *p*-$NO_2C_6H_4$) with excess pyrazole in methanol proceeds by the rupture of the oximate bridges and eventually gives the corresponding monomeric complexes [Ni(L-R)HPyr] (**III**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$, *p*-ClC_6H_4, *p*-$NO_2C_6H_4$) with pyrazole as coligand. The IR

typical for square planar nickel(II) complexes [32]. The shoulder(s) at lower energy side (430–455 nm) of the ligand intense absorption band can be assigned to $^1A_{1g} \rightarrow {}^1A_{2g}$ transition, however the contribution of LMCT transitions to this absorption cannot be ruled out. The spectra also show a series of absorption bands in the 460–600 nm range which can be attributed to different MLCT transitions. The well resolved absorption band in the 525–585 nm range is attributed to $d(\pi^*) \rightarrow L(\pi^*)$ MLCT transition and suffers a blue shift on introducing electron releasing substituents (**III**, R = *p*-$CH_3C_6H_4$ and *p*-$CH_3OC_6H_4$) while electron withdrawing substituents (**III**, R = *p*-ClC_6H_4 and *p*-$NO_2C_6H_5$) cause a red shift relative to that of the unsubstituted complexes. The energy of this MLCT band, measured in wavenumber (cm^{-1}) can be correlated with Hammett's σ_p constants and plots of wavenumbers recorded for pyrazole complexes against σ_p, Fig. 1, gave straight line with a negative slope, in agreement with the MLCT nature of this transition.

The ^1H NMR spectra of [Ni(L-R)HPyr] complexes in DMSO, Table 3, reveal that the two methyl groups of the diimine residue are magnetically nonequivalent. The methyl group adjacent to the hydrazone residue (Me–C=N–N–) is more shielded and appears in the 1.82–2.00 ppm range while the methyl group adjacent to the oxime residue appears at 1.96–2.15 ppm. The aroyl protons appear as two multiplets centered at (6.90–7.20 ppm) and (7.60–8.2 ppm) depending on the substituent R. The C–H and N–H protons of the pyrazole ring appear as very broad signals (6.60–7.7 ppm), most probably due to rapid exchange between coordinated and free uncoordinated pyr-

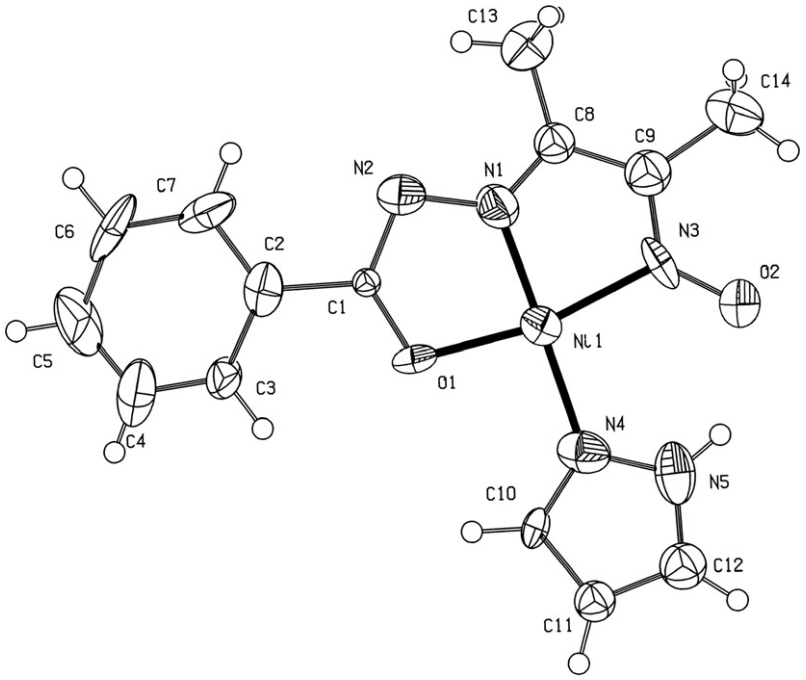

Fig. 2. ORTEP representation of [Ni(L-H)HPyr] (**11**) with labeling of atoms.

MeOH (50v:50v) as solvent, Table 4, are dominated by the parent dinickel(II) species $[\{Ni(L\text{-}R)\}_2 + H]^{1+}$. The spectra also show peaks of lower relative intensities corresponding to the dipositive dinuclear cation $[\{Ni(L\text{-}R)\}_2 + 2H]^{2+}$ and monopositive trinuclear cation $[\{Ni(L\text{-}R)\}_3 + H]^{1+}$. Different from the positive ion ESI MS of **I** with electron releasing substituents ($R = C_6H_5$, p-$CH_3C_6H_4$ and p-$CH_3OC_6H_4$), the spectra of **I** with electron withdrawing substituents ($R = p$-ClC_6H_4 and p-$NO_2C_6H_4$) are dominated by the dipositive trinuclear cation $[\{Ni(L\text{-}R)\}_3 + 2H]^{2+}$. It seems that the presence of electron withdrawing substituents in the aroyhydrazone residue results in an increase of the positive formal charge of the central nickel(II), thus favouring the preferential formation of the trinuclear rather than the dinuclear species. The positive ion ESI MS of **I** complexes with both electron releasing and withdrawing substituents ($R = C_6H_5$, p-$CH_3C_6H_4$, p-$CH_3OC_6H_4$ and p-ClC_6H_4 p-$NO_2C_6H_4$) display a set of

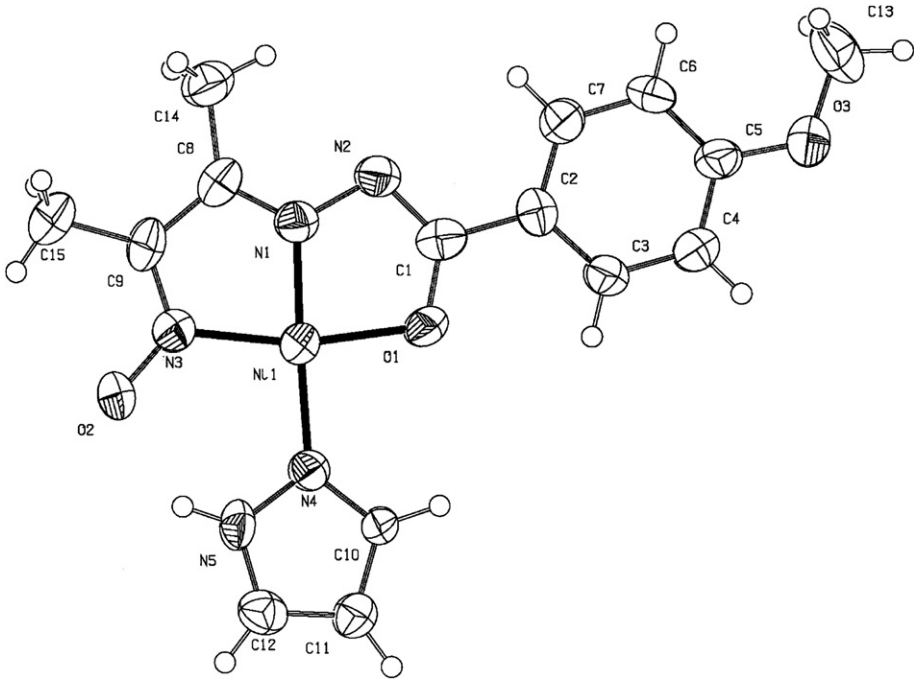

Fig. 3. ORTEP representation of [Ni(L-CH_3O)HPyr] (**13**) with labeling atoms.

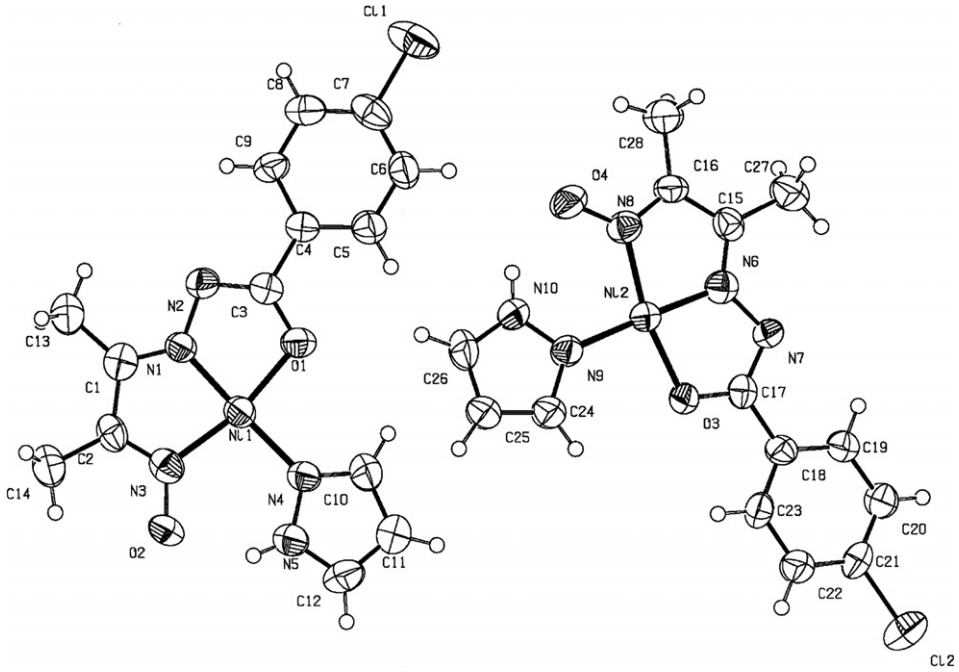

Fig. 4. ORTEP representation of [Ni(L-Cl)HPyr] (**14**) with labeling atoms.

peaks corresponding to the solvated mononuclear species $[Ni(HL\text{-}R)Solv]^{1+}$ (Solv. = MeOH, H_2O or DMF), besides peaks corresponding to the $[Ni(HL\text{-}R)_2 + H]^{1+}$ and $[Ni_2(HLR)_3 + H]^{2+}$ cations. These cations apparently arise from the parent intact dinuclear cation $[\{Ni(L\text{-}R)\}_2 + H]^{1+}$ via the protonation of the oximate oxygens followed by the rupture of the oximate bridges to give the mononuclear solvated cations $[Ni(HL\text{-}R)(Solv)]^{1+}$. This cation may undergo a series of disproportionation reactions and eventually gives $[Ni(HL\text{-}R)_2 + H]^{1+}$ and $[Ni_2(HL\text{-}R)_3 + H]^{2+}$ cations.

The positive ESI MS of [Ni(L-R)HPyr] complexes in CH_3Cl/MeOH, Table 4, show intense peaks corresponding to protonated monomeric species $[Ni(L\text{-}R)HPyr + H]^{1+}$, besides the dipositive solvated trimeric cations $[\{Ni(L\text{-}R)HPyr\}_3 + n\text{MeOH} + 2H]^{2+}$ ($n = 0$–3). The spectra also display peaks corresponding to dimeric $[\{Ni(L\text{-}R)\}_2 + H]^{1+}$ and trimeric $[\{Ni(L\text{-}R)\}_3 + H]^{1+}$cations. The positive mode ESI MS data of [Ni(L-R)HPyr] suggest the following equilibria (Scheme 1).

5. X-ray molecular and supramolecular structures

The crystal data and structure refinement parameters for [Ni(L-H)HPyr] (**11**), $[Ni(L\text{-}CH_3O)HPyr]$ (**13**) and [Ni(L-Cl)HPyr] (**14**) are given in Table 5. Selected bond distances and angles for **11**, **13** and **14** are collected in Table 6. The molecular structures of both **11** and **13** consist of one type of discrete molecular units, while the crystal structure of **14** consists of two types of molecular units, namely Ni1 and Ni2 molecular units, which are crystallographically independent but chemically similar. The structure of **11**, **13** and **14** together with the atomic numbering scheme are, respectively shown in Figs. 2–4. These nickel(II) complexes

Cg1 (*p*-methoxyphenyl ring centriod); Cg2 (Pyrazole ring centriod) and CgC (diimine chelate ring centroid).

have square planar geometry, where the Ni(II) is coordinated to the oximate nitrogen (N3), hydrazone nitrogen (N1), deprotonated enolimine oxygen (O1) of the dinegative NNO tridentate aroylhydrazoneoxime anion. The fourth coordination site is occupied by the pyrazole nitrogen (N4). In **11**, **13** complexes the angles between the pyrazole plane and the Ni(II) mean coordination plane (Ni, O1, N1, N3, N4) are 3.03° and 4.81°, respectively, while the corresponding angles in Ni1 and Ni2 molecular units of **14** are 9.92° and 10.82°, respectively. The phenyl planes in **11** (C2–C7) and **13** (C2–C7) are, respectively, deviated from the Ni(II) mean coordination plane by 6.58°and 4.98° angles while the deviation of the phenyl planes (C4–C9) and (C18–C23) from the Ni(II) mean coordination planes in Ni1 and Ni2 molecular units of **14** are 9.46° and 6.70° respectively. The diimine (N1–Ni–N3) and the aroylhydrazone (N1–Ni–O1) bite angles in **11**, **13**, **14**, Table 6, are more or less similar with a mean value of 82.8° and 83.4°, respectively. In these complexes, the Ni–N3 (oxime) bond lengths [1.882–1.964 Å] are within the range reported for other Ni(II) oximate complexes [27,28,35–41], but longer than the Ni–N1 (hydrazone) bond distances [1.794–1.828 Å] as shown in Table 6. The elongation of Ni–N3 relative to Ni–N1 can be attributed to the presence of the more electronegative oximate oxygen (O1) which decreases the electron density on the oximate nitrogen (N3), thus decreasing bond strength of the Ni–N3 relative to that of Ni–N1 bond. Both Ni–N1 (1.794–1.828 Å) and Ni–O1 (1.868–1.912 Å) bond distances are within the range reported for other Ni(II) complexes with dinegative tridentate aroylhydrazones [21,42–44]. The Ni–N4 bond distances (1.872–1.929 Å) are within the normal range reported for square planar Ni(II) complexes with dinegative tridentate ligands having pyrazole as coligand [21]. The N3–O2 bond lengths (1.294–1.317 Å) reveal appreciable double bond character and are comparable to those reported for nonbridged oximate N–O bonds [37].

The bond distances between the central Ni(II) and the donor atoms (O1, N1, N3 and N4) in these complexes, are affected by the nature of substituents in the aroylhydrazone residue. The presence of both electron releasing (**III**, R = *p*-$CH_3OC_6H_4$) or electron withdrawing (**III**, R = *p*-ClC_6H_4) substituent in the aroylhydrazone residue resulted in a pronounced decrease in Ni–O1, Ni–N1, Ni–N3 and Ni–N4 bond distances relative to that of the unsubstituted complex (**III**, R = C_6H_5). This behaviour may suggest that both σ- and π-back donation are operative. Electron releasing substituent will favour σ-donation while electron withdrawing substituent will enhance π-back donation, in both cases a decrease in bond distances is expected.

The oximate O2 oxygen of **11**, **13** and **14** is involved in intramolecular hydrogen bond with the pyrazole N5–H proton (Table 7). This hydrogen bond motif of graph set descriptor **S(6)** [45,46] forms a six-membered ring which is almost coplanar with the two five-membered chelate rings as well as the pyrazole ring. The molecular units of both **11** and **13** are linked together by two reciprocal intermolecular hydrogen bonds between oximate O2 and pyrazole N5H proton of the adjacent molecular units. This hydrogen bond of graph set descriptor **C(6)**, forms a rectangular helical chain propagating, respectively, along *a*- and *b*-axis as shown in Fig. 5. No such intermolecular hydrogen bonding was observed in the structure of **14**. In both **11** and **13**, the molecular units of the helical chains are arranged parallel to each other on both sides of a backbone of intra- and intermolecular hydrogen bonds. The Ni mean coordination planes of the molecular units on one side make, respectively, angles of 72.1° (for **11**) and 77.2° (for**13**) with the corresponding coordination plane on the other side. In the crystal lattice of **11** and **13**, the parallel arrangement of the molecular units on both sides of the helical chains are stabilized by $\pi\cdots\pi$ interactions between the delocalized diimine chelate ring, which acts as an aromatic ring [47,48], and the aromatic heterocyclic pyrazole rings of the adjacent molecular units [48,49]. The mean plane of the diimine chelate ring is almost parallel to that of the pyrazole plane and the dihedral angles between these planes are 4.10° and 5.58°, respectively. The perpendicular molecular units are also stabilized by CH···O [50,51] intrachain interactions between pyrazole C12H protons and the oximate oxygens (O2) of the neighboring molecular units. In **11** the perpendicular arrangement is further stabilized by an additional CH14···π (pyrazole) intrachain interaction [52,53]. The intrachain noncovalent interactions of both **11** and **13** are listed in Table 7.

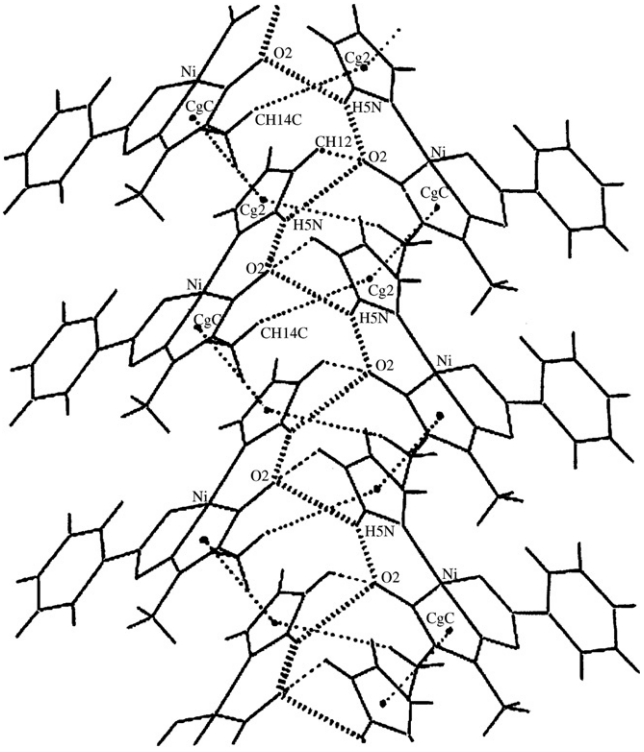

Fig. 5. Diagrammatic representation of inter and intramolecular noncovalent bond interactions in the helical chain of [Ni(L-H)HPyr] (**11**).

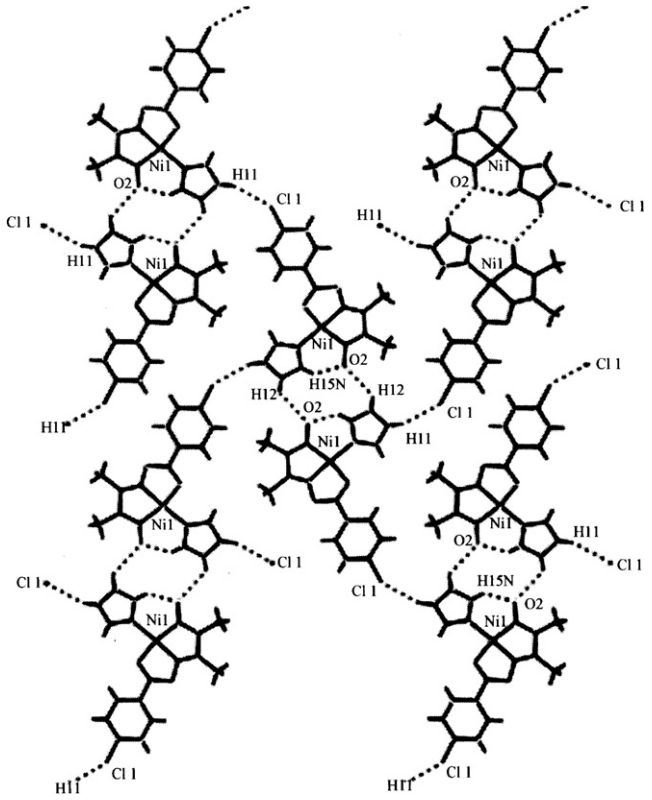

Fig. 6. Diagrammatic representation of noncovalent bond interactions between Ni1 molecular units of [Ni(L-Cl)HPyr] (**14**).

The helical chains in **11** are linked together by Van der Waals forces and no other interchain interactions were observed. However, in **13**, the helical chains are jointed together by reciprocal CH···π interchain interactions between CH13C protons of the methoxy groups of one chain and the π system of the *p*-methoxy phenyl ring (C2–C7) of the adjacent chain , forming a two dimensional array of helical chains propagating parallel to the ac plane. The CH14C protons of the methyl group adjacent to the hydrazone imine in one chain are also involved in CH···π interactions with the aromatic rings (C2–C7) of the neighboring chains forming three dimensional arrays of helical chains.

In addition to intramolecular N5H···O2 hydrogen bond, the oxime O2 in **14** is also involved in weak hydrogen bond with the pyrazole CH12 proton of the adjacent Ni1 molecular unit giving rise to a dimeric structure as shown in Fig. 6. Each dimer is connected to four neighboring dimeric units via two pairs of reciprocal weak hydrogen bonds between the pyrazole CH11 proton and the Cl1, Table 7, thus forming a ^{2}D wavy sheet. The Ni1 molecular units in this sheet are arranged in rows. In each row the Ni1 coordination planes are arranged parallel to each other, but make an angle of 17.28° with the corresponding planes in the next neighboring row. Similarly, the Ni2 molecular units are joined together by CH···O hydrogen bonds between the oximate O4 and phenyl CH20 proton, as well as a weak noncovalent interaction between the CH27A proton of the methyl group adjacent to the hydrazone residue and the pyrazole C26 forming a chain of Ni2 molecular units propagating along the *b*-axis. In this chain, the Ni2 coordination plane makes an angle of 23.36° with the next coordination plane. Each Ni1 molecular unit in Ni1 sheet is connected to three Ni2 molecular units of different Ni2 chains by three noncovalent interactions namely: (i) CH13B···π (pyrazole) and (ii) CH14B···C20 and Cl1···H24, respectively. These interactions gives rise to multidimensional arrays of Ni2 chains enclosed between sheets of Ni molecular units.

2. Experimental

2.1. General

All procedures were performed under an atmosphere of dry, purified nitrogen using standard Schlenk techniques. Solvents were distilled and dried by standard methods [15]. Thiophene and 1-bromo-3-chloropropane were purchased from Across. *n*-Butyllithium (1.55 M solution in hexane) was purchased from Aldrich. Potassium diphenylphosphide (0.5 M solution in THF) and palladium(II) chloride were purchased from Fluka. Benzonitrile was purchased from Wardle Chemicals. $[PdCl_2(PhCN)_2]$ [16], and 2-(3-chloropropyl)thiophene [17,18] were prepared as reported. The IR Spectra were recorded, as KBr discs, on Nicolet Impact-400 FT-IR spectrometer. The NMR spectra were recorded on a Bruker DPX 300 MHz spectrometer using TMS as internal reference. The chemical shifts for the ^{31}P NMR spectra are relative to external H_3PO_4. Melting points were determined with Philip-Harris melting point apparatus and are uncorrected. Elemental analyses were performed by the Microanalytical Laboratories of AL al-Bayt University, Jordan.

2.2. Syntheses

2.2.1. Preparation of 2-[3-(diphenylphosphino)propyl]-thiophene (*P-S3*)

The compound was prepared following literature procedure [17,18] with modifications. A solution of 2-(3-chloropropyl)thiophene (8.0 g, 0.05 mol) in dry THF (50 mL) was introduced into a 250-mL three-necked round bottomed flask equipped with a nitrogen inlet, dropping funnel, and a condenser that is connected to an oil bubbler. A solution of potassium diphenylphosphide (100 mL of 0.5 M, 0.05 mol) was then slowly added at −45 °C. After the addition was complete, the cooling bath was removed and the reaction mixture was stirred for 2 h at room temperature. Solvent was completely removed under reduced pressure. The residue was dissolved in diethyl ether (100 mL), and the ether solution was washed with distilled water (2 × 100 mL). The ether layer was dried over anhydrous sodium sulfate over night. After filtration, ether was removed under reduced pressure, and the thick yellow residue was dissolved in methanol (50 mL). When the solution was stored at 0 °C a white precipitate was formed. The precipitate was filtered, washed three times with cold methanol, and dried under vacuum at room temperature. Yield: 14.3 g (92%). White powder; m.p. 65–67 °C. Selected IR bands (KBr pellet, cm^{-1}): 3071 (m), 3050 (m), 2931 (m), 2856 (m), 1120 (s) (P–Ph). ^1H NMR (300 MHz, $CDCl_3$): $\delta = 1.81$ (m, 2H, $-CH_2C\boldsymbol{H}_2CH_2P-$), 2.09 (m, 2H, $-C\boldsymbol{H}_2P-$), 2.94 (t, $J = 13.5$ Hz, 2H, $-C\boldsymbol{H}_2CH_2CH_2P-$), 6.75 (d, $J = 3.1$ Hz, $1H_{thiophene}$), 6.89 (t, $J = 4.2$ Hz, $1H_{thiophene}$), 7.10 (d, $J = 5.0$ Hz, $1H_{thiophene}$), 7.31–7.76 (m, 10H, H_{phenyl}). ^{13}C NMR (75 MHz, $CDCl_3$): δ: ($C_{aliphatic}$) 27.3 (d, $^2J_{C-P} = 11.5$ Hz, 1C), 28.0 (d, $^1J_{C-P} = 17.0$ Hz, 1C), 31.2 (d, $^3J_{C-P} = 13.5$ Hz, 1C); δ: ($C_{thiophene}$) 123.2 (s, 1C), 124.5 (s, 1C), 126.8 (s, 1C), 144.6 (s, 1C); δ: (C_{phenyl}) 128.5 (d, $^3J_{C-P} = 6.6$ Hz, 4C), 128.6 (s, 2C), 132.8 (d, $^2J_{C-P} = 18.3$ Hz, 4C), 138.6 (d, $^1J_{C-P} = 12.5$ Hz, 2C). $^{31}P\{^1H\}$ NMR (121 MHz, $CDCl_3$): $\delta = -12.25$.

2.2.2. Preparation of trans-[Pd(μ-Cl)Cl(P-S3)]$_2$ (*I*)

A sample of **P-S3** (0.31 g, 1.0 mmol) in dry benzene (20 mL) was slowly added to a filtered solution of $[PdCl_2(PhCN)_2]$ (0.40 g, 1.0 mmol) in dry benzene (30 mL). The solution was stirred for 1 h at room temperature. During that time, the solution changed color gradually from dark brown to orange. Solvent was removed under reduced pressure till a volume of about 10 mL. Upon addition of pet. ether (boiling range of 40–60 °C), an orange precipitate was separated, the product was recrystallized from CH_2Cl_2/pet. ether, washed with pet. ether and dried under vacuum at 50 °C. Yield: 0.48 g (92%). Orange solid; m.p. 225–227 (dec). Selected IR bands (KBr pellet, cm^{-1}): 3056 (m), 2936 (m), 2896 (m), 1102 (s) (P–Ph). ^1H NMR (300 MHz, $CDCl_3$): $\delta = 1.89$ (m, 4H, $-CH_2C\boldsymbol{H}_2CH_2P-$), 2.50 (m, 4H, $-C\boldsymbol{H}_2P-$), 2.87 (t, $J = 7.2$ Hz, 4H, $-C\boldsymbol{H}_2CH_2CH_2P-$), 6.69 (d, $J = 2.8$ Hz, $2H_{thiophene}$), 6.87 (dd, $J = 3.4$, 5.1 Hz, $2H_{thiophene}$), 7.07 (d, $J = 5.1$ Hz, $2H_{thiophene}$), 7.22–7.68 (m, 20H, H_{phenyl}). ^{13}C NMR (75 MHz, $CDCl_3$): δ: ($C_{aliphatic}$) 25.9 (s, 2C), 26.5 (d, $^1J_{C-P} = 35.9$ Hz, 2C), 30.5 (d, $^3J_{C-P} = 17.5$ Hz, 2C); δ: ($C_{thiophene}$) 123.5 (s, 2C), 124.9 (s, 2C), 126.9 (s, 2C), 143.1 (s, 2C); δ: (C_{phenyl}) 127.7 (s, 4C), 128.8 (d, $^3J_{C-P} = 11.9$ Hz, 8C), 131.4 (s, 4C), 133.3 (d, $^2J_{C-P} = 10.2$ Hz, 8C). $^{31}P\{^1H\}$ NMR (121 MHz, $CDCl_3$): $\delta = 31.81$. *Anal.* Calc. for $[C_{38}H_{38}Cl_4P_2Pd_2S_2]$ (975.34): C, 46.79; H, 3.93; S, 6.57. Found: C, 46.23; H, 3.66; S, 5.51%.

2.2.3. Preparation of trans-[PdCl$_2$(P-S3)$_2$] (*II*)

A filtered solution of $[PdCl_2(PhCN)_2]$ (0.40 g, 1.0 mmol) in dry benzene (30 mL) was slowly added to a sample of **P-S3** (0.78 g, 2.5 mmol) in dry benzene (20 mL). The solution was stirred for 1 h at room temperature. Solvent was removed under reduced pressure till a volume of about 10 mL. Upon addition of pet. ether (boiling range of 40–60 °C), a yellow precipitate was formed. The product was collected, recrystallized from CH_2Cl_2/pet. ether washed with pet. ether and dried under vacuum at 50 °C. Yield: 0.50 g (60%). Yellow solid; m.p. 143–144 °C. Selected IR bands (KBr pellet, cm^{-1}): 3081 (m), 3051 (m), 2919 (m), 1431 (s), 1105 (s) (P–Ph). ^1H NMR (300 MHz, $CDCl_3$): $\delta = 1.88$ (m, 4H, $-CH_2C\boldsymbol{H}_2CH_2P-$), 2.50 (m, 4H, $-C\boldsymbol{H}_2P-$), 2.87 (t, $J = 7.2$ Hz, 4H, $-C\boldsymbol{H}_2CH_2CH_2P-$), 6.68 (d, $J = 2.7$ Hz, $2H_{thiophene}$), 6.86 (dd, $J = 3.4$, 5.1 Hz, $2H_{thiophene}$), 7.07 (dd, $J = 1.1$, 5.1 Hz, $2H_{thiophene}$), 7.34–7.73 (m, 20H, H_{phenyl}). $^{13}P\{^1H\}$ NMR (121 MHz, $CDCl_3$): $\delta = 17.53$. *Anal.* Calc. for $[C_{38}H_{38}Cl_2P_2PdS_2]$ (798.04): C, 57.19; H, 4.80; S, 8.04. Found: C, 57.21; H, 4.79; S, 8.08%.

2.3. Reaction of compound *I* with *P-S3*

To an orange solution of **I** (0.40 g, 0.41 mmol) in dry $CHCl_3$ (30 mL) was slowly added a solution of **P-S3** (0.31 g, 1.0 mmol) in dry $CHCl_3$ (20 mL). The solution was stirred for 2 h at room temperature. During that time, the solution changed color gradually from orange to yellow. Solvent was removed under reduced pressure till a volume of about 10 mL. Upon addition of pet. ether (boiling range of 40–60 °C), a precipitate was separated, washed with pet. ether and dried under vacuum at 50 °C. The product was characterized by its melting point and ^{1}H NMR and found to be identical to compound **II**.

2.4. Crystal structure determination of *trans*-[Pd(μ-Cl)Cl(P-S3)]$_2$ (*I*)

A suitable single crystal (yellow platelets) of compound **I** was selected for collecting X-ray data. All measurements were made at 293(2) K using a Bruker/Siemens SMART APEX instrument (Mo Kα radiation, $\lambda = 0.71073$ Å) equipped with a Cryocool NeverIce low temperature device. Data were measured using omega scans of 0.3° per frame for 5 s, and a full sphere of data was collected. A total of 2400 frames were collected with a final resolution of 0.83 Å. Cell parameters were retrieved using SMART [19] software and refined using SAINTPLUS [20] on all observed reflections. Data reduction and correction for Lp and decay were performed using the SAINTPLUS software. Absorption corrections were applied using SADABS [21]. The structure was solved by direct methods and refined by least squares method on F^2 using the SHELXTL program package [22]. The structure was solved in the space group $P\bar{1}$ (#2) by analysis of systematic absences. All non-hydrogen atoms were refined anisotropically. The thiophene group was rotationally disordered and refined in two positions with refined occupancies of 49:51%. Bond lengths and thermal parameters were loosely restrained. No decomposition was observed during data collection. Details of the data collection and refinement are given in Table 1. Further details are provided in the Supporting Information. Hydrogen atoms were placed geometrically and refined with a riding model, with U_{iso} constrained to be $1.2U_{eq}$ of the carrier atom.

2.5. Crystal structure determination of *trans*-[PdCl$_2$(P-S3)$_2$] (*II*)

A suitable crystal (yellow parallelopiped) of compound **II** was selected, attached to a glass fiber and data were collected at 293(2) K using a syntax diffractometer "upgraded to Bruker's P4 specifications" instrument (Mo Kα radiation, $\lambda = 0.71073$ Å) equipped with a Cryocool NeverIce low temperature device. Collection and treatment of data were done similar to compound **I** with the exception that cell parameters were retrieved and refined using XSCANS [23] software on all observed reflections. Data reduction and correction for Lp and decay were performed using the SHELXTL [22] software. Absorption corrections were applied using psi scans. Details of the data collection and refinement are given in Table 1. Further details are provided in the Supporting Information.

Table 1
Crystal data for complexes *trans*-[Pd(μ-Cl)Cl(P-S3)]$_2$ (**I**) and *trans*-[PdCl$_2$(P-S3)$_2$] (**II**)

Parameter	[Pd(μ-Cl)Cl(P-S3)]$_2$ (**I**)	[PdCl$_2$(P-S3)$_2$] (**II**)
Chemical formula	$C_{38}H_{38}Cl_4P_2Pd_2S_2$	$C_{38}H_{38}Cl_2P_2PdS_2$
Formula weight	975.34	798.04
Temperature (K)	293(2)	293(2)
Wavelength (Å)	0.71073	0.71073
Crystal system	triclinic	triclinic
Space group	$P\bar{1}$	$P\bar{1}$
Unit cell dimensions		
a (Å)	9.3962(19)	7.9828(10)
b (Å)	9.954(2)	10.699(2)
c (Å)	11.100(2)	10.9374(19)
α (°)	84.62(3)	91.761(17)
β (°)	77.96(3)	105.217(5)
γ (°)	73.51(3)	96.463(14)
V (Å^3)	972.9(4)	893.9(3)
Z	1	1
D_{calc} (Mg/m^3)	1.665	1.483
Absorption coefficient (mm^{-1})	1.416	0.902
F(000)	488	408
Crystal dimensions (mm)	0.40 × 0.20 × 0.05	0.40 × 0.30 × 0.15
θ Range for data collection (°)	1.88–25.25	1.92–25.50
Index ranges	$-11 \leqslant h \leqslant 11$, $-11 \leqslant k \leqslant 11$, $-3 \leqslant l \leqslant 13$	$-9 \leqslant h \leqslant 1$, $-12 \leqslant k \leqslant 12$, $-13 \leqslant l \leqslant 13$
Reflections collected	14 345	4081
Independent reflections [R_{int}]	3527 [0.0250]	3293 [0.0000]
Data/restraints/parameters	3527/10/224	3318/0/205
Goodness-of-fit on F^2	1.046	1.068

3. Results and discussion

3.1. Syntheses

The phosphorus–sulfur ligand, 2-[3-(diphenylphosphino)propyl]thiophene (**P-S3**), was prepared *via* reaction of 2-(3-chloropropyl)thiophene [17,18] with potassium diphenylphosphide in dry THF. The product was collected and recrystallized several times from methanol. It was fully characterized by its IR, ^{1}H, ^{13}C and ^{31}P NMR spectroscopy. The ^{1}H NMR spectrum of **P-S3** shows, in addition

to the signals due to phenyl protons, two multiplets centered at $\delta = 1.81$ (–$CH_2C\boldsymbol{H}_2CH_2P$–) and 2.09 (–$C\boldsymbol{H}_2P$–), and a triplet centered at $\delta = 2.94$ (–$C\boldsymbol{H}_2CH_2CH_2P$–). The three protons of thiophene appear as two doublets centered at $\delta = 6.75$, 7.10 and a triplet centered at $\delta = 6.89$. The ^{13}C NMR spectrum of **P-S3** shows, δ: ($C_{aliphatic}$) at 27.3 (d, $^2J_{C-P} = 11.5$ Hz, 1C), 28.0 (d, $^1J_{C-P} = 17.0$ Hz, 1C), and 31.2 (d, $^3J_{C-P} = 13.5$ Hz, 1C); δ: ($C_{thiophene}$) at 123.2 (s, 1C), 124.5 (s, 1C), 126.8 (s, 1C), and 144.6 (s, 1C); δ: (C_{phenyl}) at 128.5 (d, $^3J_{C-P} = 6.6$ Hz, 4C), 128.6 (s, 2C), 132.8 (d, $^2J_{C-P} = 18.3$ Hz, 4C), and 138.6 (d, $^1J_{C-P} = 12.5$ Hz, 2C). The above ^{13}C NMR assignment was confirmed by running Dept-135 experiment that shows, disappearance of the two quaternary carbons at $\delta = 138.6$, and 144.6. The ^{31}P NMR spectrum shows one signal at $\delta = -12.25$.

Reaction of **P-S3** with equimolar amount of $[PdCl_2(PhCN)_2]$ afforded the binuclear complex *trans*-$[Pd(\mu\text{-}Cl)Cl(P\text{-}S3)]_2$ (**I**). Complex **I** is soluble in acetone, chloroform, and dichloromethane, and insoluble in diethyl ether, dioxane, and hexane. Elemental analysis of **I** for C, H, and S is consistent with the above formulation. The ^1H NMR spectrum of **I** shows, in addition to the phenyl proton signals, two multiplets centered at $\delta = 1.89$ (–$CH_2C\boldsymbol{H}_2CH_2P$–) and 2.50 (–$C\boldsymbol{H}_2P$–), and a triplet centered at $\delta = 2.87$ (–$C\boldsymbol{H}_2CH_2CH_2P$–). The signals of the thiophene protons appear as doublets centered at $\delta = 6.69$, and $\delta = 7.07$, and a doublet of doublet centered at $\delta = 6.87$. Compared with the free ligand, the ^{31}P NMR signal of complex **I** is downfield shifted to $\delta = 31.81$. The ^{13}C NMR spectrum of **I** shows, δ: ($C_{aliphatic}$) at 25.9 (s, 2C), 26.5 (d, $^1J_{C-P} = 35.9$ Hz, 2C), and 30.5 (d, $^3J_{C-P} = 17.5$ Hz, 2C); δ: ($C_{thiophene}$) at 123.5 (s, 2C), 124.9 (s, 2C), 126.9 (s, 2C), and 143.1 (s, 2C); δ: (C_{phenyl}) at 127.7 (s, 4C), 128.8 (d, $^3J_{C-P} = 11.9$ Hz, 8C), 131.4 (s, 4C), and 133.3 (d, $^2J_{C-P} = 10.2$ Hz, 8C). Comparing the ^{13}C NMR spectrum of **I** with that for the **P-S3** ligand shows no difference on the chemical shift of the thiophene ring carbons, which is consistent with the ligand being coordinated through the phosphorus atom only. The ^{13}C NMR signal for $\boldsymbol{C}_{phenyl}$–P was shifted upfield upon coordination with the palladium metal to 127.7 ppm and appeared as a singlet. Similarly, the signal for $\boldsymbol{C}H_2$–P was shifted upfield upon coordination with the palladium metal to 26.5 ppm with an increase in J value ($J = 35.9$ Hz). The bidentate mode of bonding for **P-S3** seems to be unfavorable with respect to the formation of the 7-membered chelate ring and the poor donor ability of thiophene sulfur. In view of the above data the complex is believed to have a dimeric structure which was confirmed by single X-ray structure analysis (Fig. 1).

As expected, reaction of the chlorobridged palladium complex **I** with triphenylphosphine in a 1:2 molar ratio afforded the monomeric complex, $[PdCl_2(P\text{-}S3)(PPh_3)]$. This complex was characterized by its ^1H NMR spectrum which shows two multiplets centered at $\delta = 1.89$ (–$CH_2C\boldsymbol{H}_2CH_2P$–), 2.52 (–$C\boldsymbol{H}_2P$–) and a triplet centered at $\delta = 2.85$ (–$C\boldsymbol{H}_2CH_2CH_2P$–). The thiophene protons show

two doublets centered at $\delta = 6.67$, 7.06 and a triplet centered at $\delta = 6.85$. The phenyl protons appear as a multiplet at $\delta = 7.57$–7.73. Comparing the ^1H NMR spectra of **I** and $[PdCl_2(P\text{-}S3)(PPh_3)]$ shows no appreciable differences on the chemical shift of aliphatic and thiophene protons.

In a similar way, reaction of complex **I** with **P-S3** in a 1:2 molar ratio afforded the monomeric complex, $[PdCl_2(P\text{-}S3)_2]$ (**II**), which is characterized by elemental analysis and NMR spectroscopy. The ^1H NMR spectrum of **II** shows, in addition to the phenyl proton signals, a multiplet centered at $\delta = 1.88$ (–$CH_2C\boldsymbol{H}_2CH_2P$–), $\delta = 2.50$ (–$C\boldsymbol{H}_2P$–), and a triplet centered at $\delta = 2.87$ (–$C\boldsymbol{H}_2CH_2CH_2P$–). The signals of the thiophene protons appear as a doublet centered at $\delta = 6.68$ and two (doublet of doublet) centered at $\delta = 6.86$ ($J = 3.4$, 5.1 Hz) and $\delta = 7.07$ ($J = 1.1$, 5.1 Hz). Comparing the ^1H NMR spectrum of **I** and **II** shows no appreciable differences in both spectra, indicating similar mode of bonding for the ligand in both complexes. The ^{31}P NMR spectrum of **II** shows one signal at $\delta = 17.53$. The greater downfield shift of the ^{31}P peak in complex **I** relative to complex **II** is attributed to the increase in Pd–P bond strength, that is *trans* to bridging Cl ligand.

Complex **II** was also prepared by the direct reaction of $[PdCl_2(PhCN)_2]$ with **P-S3** in a 1:2.5 molar ratio. The isolated yellow compound was characterized by ^1H and ^{13}C NMR and found to be identical with an authentic sample of complex **II** that has been prepared previously by the reaction of complex **I** with **P-S3**.

3.2. The molecular structure of $[Pd(\mu\text{-}Cl)Cl(P\text{-}S3)]_2$ (**I**)

Yellow platelet-like crystals of **I** were grown from double layer system of CH_2Cl_2/pet. ether. The solid state structure was established by X-ray crystallography (Fig. 1). Selected bond lengths and angles are collected in Table 2. The two **P-S3** ligands bind to the Pd metal through the phosphorus atoms in a *trans* position. The two chlorobridged ligands form with the palladium atoms a four-membered ring with Cl–Pd–Cl angles of 85.24(3)°, and Pd–Cl–Pd angles of 94.76(3)°. The Pd–Cl bond dis-

Table 2
Selected bond distances (Å) and angles (°) for *trans*-[Pd(μ-Cl)Cl (P-S3)]$_2$

Bond distances (Å)		Bond angles (°)	
Pd(1)–P(1)	2.2239(11)	P(1)–Pd(1)–Cl(2)	86.21(4)
Pd(1)–Cl(2)	2.2747(11)	P(1)–Pd(1)–Cl(1A)	96.89(3)
Pd(1)–Cl(1A)	2.3081(11)	Cl(2)–Pd(1)–Cl(1A)	176.89(3)
Pd(1)–Cl(1)	2.4156(12)	P(1)–Pd(1)–Cl(1)	177.44(2)
Cl(1)–Pd(1A)	2.3080(11)	Cl(2)–Pd(1)–Cl(1)	91.67(4)
P(1)–C(7)	1.812(3)	Cl(1A)–Pd(1)–Cl(1)	85.24(3)
P(1)–C(1)	1.818(3)	Pd(1A)–Cl(1)–Pd(1)	94.76(3)
P(1)–C(13)	1.823(3)	C(7)–P(1)–C(1)	104.28(12)

tance of the terminal chloride is shorter than that of the bridging chloride. It is interesting to note that, the two Pd^1–Cl_{bridge} (Fig. 1) bond distances are different; the Pd^1–Cl_{bridge} *trans* to terminal chloride is shorter than the one *trans* to the P-atom. This is consistent with the higher *trans* influence of phosphine ligand compared with Cl. The thiophene ring was rotationally disordered and refined in two positions with refined occupancies of 50% (Fig. 2).

3.3. The molecular structure of [$PdCl_2$(P-S3)$_2$] (**II**)

Yellow crystals of complex **II** were grown by slow evaporation of CH_2Cl_2/pet. ether solution at room temperature. The solid state structure of **II** is shown in Fig. 3, and selected bond length and angles are collected in Table 3. As indicated in Fig. 3, the two **P-S3** ligands bind to the Pd metal atom through their phosphorus atoms in *trans* positions. The palladium atom is in the center of the symmetry and it displays square planar stereochemistry. The Pd–P distance in **II** is longer than that in **I**, which is consistent with the competition for π-bonding between the *trans* phosphorus atoms in **II**.
