3. Results and discussion

3.1. Crystal structure description of complexes *1* and *2*

X-ray single crystal analysis reveals that complexes **1** and **2** are enantiomers (Fig. 1), so only the structure of **1** is described here. Selected bond lengths and angles for **1** and **2** are listed in Tables 2 and 3. Complexes **1** and **2** crystallize in the chiral space group $P2_1$ because of introducing the chiral 2,2′-bipyridine derivative ligands. They have non-centrosymmetric structures. Complex **1** is a mononuclear neutral Eu(III)-based complex. As shown in Fig. 1, each molecule contains three β-diketonate anions, a chiral 2,2′-bipyridine derivative ligand and an eight-coordinated Eu(III) cation. Three diketonate anions each provides two donor O atoms to coordinate to the Eu(III) cation. The other two coordination sites of the Eu(III) cation are occupied by two N atoms from the chiral bipyridine derivative to complete the eight coordination environment. The O–Eu distances range from 2.2696 to 2.4431 Å, while the two N–Eu bonds are 2.570 and 2.579 Å. Eight bonds with different lengths give rise to a strongly distorted square antiprism environment around the Eu(III) cation. O3O4O5O6 (bottom plane) and O1O2N1N2 (top plane) in Fig. 2 compose the two square basic planes of the antiprism, with the mean deviations of 0.0717 and 0.1386 Å from each plane, respectively, and their dihedral angle is 2.63°. For a regular square antiprism, the two square planes are parallel to each other and one square is rotated by 45° with respect to the other. However, for **1**, relative to the bottom plane, the top plane is rotated by the smaller angle of 22.6°. So the Eu(III) cation factually has a geometrical environment intermediate between a square antiprism (SA) and a dodecahedron (D). This kind of coordination configuration around Eu(III) leads to the very low structural symmetry of **1**.

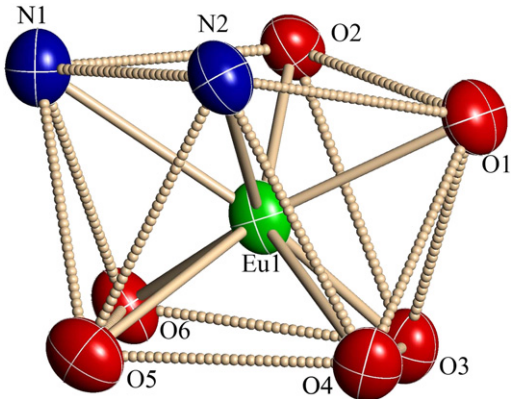

Fig. 2. Coordination geometry of **1** around the Eu(III) ion.

3.2. Optical spectroscopy

Complexes **1** and **2** are a pair of enantiomers and the circular dichroism (CD) spectra are shown in Fig. 3. Complex **1** (*SS*-isomer) shows positive Cotton effects at $\lambda = 250$ and 285 nm with a negative one at $\lambda = 225$ nm, while complex **2** (*RR*-isomer) exhibits Cotton effects with opposite sign at the same wavelength. They are mirror images in the observed CD spectra.

Additionally, the SHG (second harmonic generation) efficiency was measured for the optical activity of **1** and **2**. According to the principle proposed by Kurtz and Perry [33], we estimated the second-order non-linear optical effect of **1** and **2**. They display SHG efficiency with approximate responses of three times that of urea.

As shown in Fig. 4, the photoluminescence spectra of complexes **1** and **2** in the solid state, excited at $\lambda = 370$ nm, are measured at room temperature. The spectra of **1** and **2** are identical with the characteristic peaks of Eu(III) centered transitions from the excited state $^5D_0$ to the ground singlet state ^7F_J ($J = 0$–4) at 580, 591, 613, 650 and 702 nm. Notably, the dominant transition $^5D_0$–$^7F_2$ at $\lambda = 613$ nm is much stronger than that of $^5D_0$–$^7F_1$. This denotes that the local symmetry groups of chemical environment of the Eu(III) ion are not characterized by an inversion centre, which is consistent with the results of the single-crystal X-ray analysis for complexes of **1** and **2**.

In most cases, the intensity of triboluminescence emissions is weaker than that of photoluminescence, so only those strong emission parts of the triboluminescence, especially for centrosymmetric complexes, can be detected in the darkness [34,35]. however, for complexes **1** and **2** a brilliant red light can be observed in daylight by grinding crude crystals. As shown in Fig. 5, the position of the strongest peak (at $\lambda = 613$ nm) in their triboluminescence spectra is the same as that of photoluminescence. According to Rheingold and King's statements [35], the most intense component of triboluminescent emissions of lanthanide complexes is the characteristic photoluminescence of the

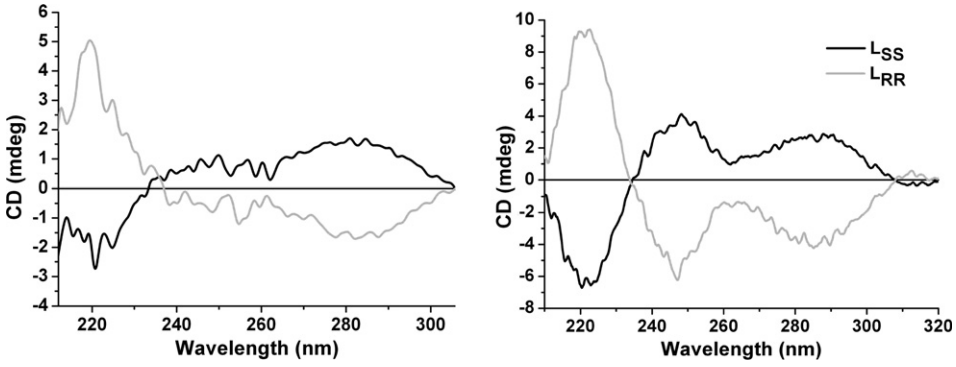

Fig. 3. The CD spectra of complexes **1** (black), **2** (grey) and ligands in THF at room temperature.

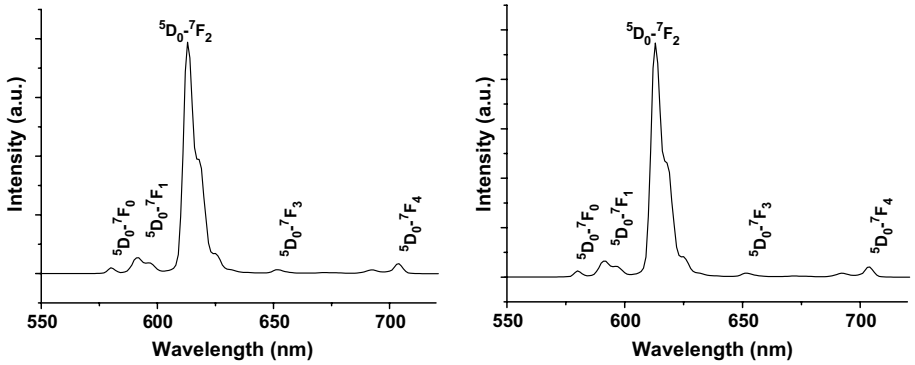

Fig. 4. The photoluminescent spectra of complexes **1** (left) and **2** (right) in the solid state under excitation at $\lambda = 370$ nm at room temperature.

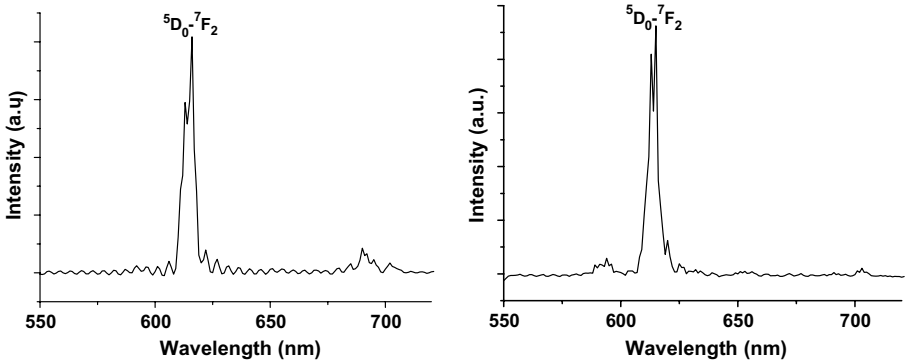

Fig. 5. The triboluminescent spectra of **1** (left) and **2** (right) at room temperature.

metallic elements. In the triboluminescence spectra of **1** and **2**, we can observe a strong peak at wavelength $\lambda = 613$ nm, being assigned to the $^5D_0$–$^7F_2$ transition of Eu(III). Therefore, we can draw the conclusion that the triboluminescence has the same exited state as that of the photoluminescence. Generally, there are two prevalent explanations to the triboluminescence mechanism. One is the discharge of nascent charged surfaces upon cleavage due to piezoelectricity when non-centrosymmetric crystals are mechanically stressed [36–38]. The other is that ionic solids and disorders in the molecular structure are responsible for the triboluminescence in centrosymmetric crystals due to the existence of an intrinsically charged plane [35,36,39]. Zink claimed that non-centrosymmetric crystals are necessary for the observation of triboluminescence [8] and estimated that the correlation of triboluminescence activity with non-centrosymmetric space groups is greater than 95%. Such materials would readily generate opposite charges on opposing surfaces of the cleavage. In our study, complexes **1** and **2** are both non-centrosymmetric structures. The discharge of nascent charged surfaces upon cleavage excites the phenyl rings (in the β-diketone) and the pyridyl rings (in the chiral pyridine derivative) of the ligands which act as 'antennae' and in turn excite the Eu(III) f states. Emission from the chelated Eu(III) provides the observed triboluminescence. It is noteworthy that we have observed the brilliant triboluminescence of **1** and **2** in daylight by grinding them. It may be due to the introduction of the chiral ligand which results in the highly asymmetric molecular structure and sequentially to be in favor of the piezoelectric role [40]. This is confirmed by another reported triboluminescent complex, $[n\text{-}Bu_4N]_2[Tb(2,6\text{-}dhb)_5\ (H_2O)]$ (2,6-Hdhb = 2,6-dihydroxybenzoic acid) [41], which also crystallizes in chiral and non-centrosymmetric space group $P2_1$.

4. Conclusions

In this study, a pair of novel Eu(III)-based enantiomers with a chiral ligand (L_{SS} and L_{RR}) were synthesized and characterized by crystal structure analysis and spectroscopic methods. When ground with a glass rod in daylight, both of them show brilliant triboluminescence which may arise from the high asymmetry of the crystal structures. This work not only presents a successful method for preparing multifunctional materials (luminescence and chirality) but also suggests that a non-centrosymmetric crystal structure is in favor of getting intense triboluminescence observed in the daylight.

Scheme 1.

blies [4a]. In fact, in spite of the above mentioned geometric constraints, tppz is able to act as a bis-tridentate ligand generating homometallic compounds with interesting electronic and magnetic properties [5–14].

A particular emphasis has been paid to magneto-structural studies of tppz-bridged compounds of formula $[M_2(tppz)]^{2m+}$ [M = Ni(II) and Cu(II)] which were found to exhibit significant antiferromagnetic interactions between the paramagnetic metal ions involved [12a,12b, 12f–i,13b]. Additionally, the fact that the mononuclear species $[Co(tppz)_2]^{2+}$ exhibits thermally induced spin crossover behaviour from a high-spin $S_{Co} = 3/2$ at high temperatures to a low-spin $S_{Co} = 1/2$ at lower temperatures increases the interest in the tppz-containing metal complexes [13b]. Given that the ter-imine system has been found to induce a spin transition in several examples of iron(II) complexes [15], we decided to investigate the complex formation between this metal ion and tppz. Although in the initial publication concerning the preparation of tppz the authors synthesized iron(II) complexes with a 1:2 metal to tppz molar ratio [1], no crystal structure was available until 2001 when the X-ray structures of the low-spin $[Fe(tppz)_2](ClO_4)_2 \cdot CH_3CN \cdot H_2O$ and high-spin $[Fe(tppz)Cl_2]$ iron(II) species were reported [13b]. In this work, we present the preparation and structural characterization of two new tppz-containing iron(II) complexes of formula $PPh_4[Fe(tppz)(CN)_3] \cdot 7H_2O$ (**1**) and $[Fe(tppz)_2][Fe(NCS)_4]$ (**2**) where low- (**1** and **2**) and high-spin (**2**) iron(II) occur.

2. Experimental

2.1. Materials and methods

Iron(II) perchlorate hexahydrate, iron(II) chloride tetrahydrate, potassium cyanide, potassium thiocyanate and tetraphenylphosphonium chloride were purchased from commercial sources and used as received. Tppz was prepared by the reported procedure [1]. Elemental analyses (C, H, N) were performed by the Microanalytical Service of the Universidad Autónoma de Madrid. Infrared spectra were obtained on a Nicolet Avatar 320 FT-IR spectrophotometer in the 4000–400 cm^{-1} region with the samples prepared as KBr pellets. Magnetic susceptibility measurements on polycrystalline samples of **1** and **2** were carried out with a Quantum Design SQUID magnetometer at

room temperature. Diamagnetic corrections of the constituent atoms were estimated from Pascal [16] constants.

2.2. Warning

Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only a small amount of compound should be prepared and it should be handled with care and without heating. The severe toxicity of cyanide and most of its compounds must be taken into account in the laboratory. Our syntheses were carried out in a hood and the samples handled with great caution.

2.3. Synthesis

$PPh_4[Fe(tppz)(CN)_3]\cdot 7H_2O$ (**1**): X-ray quality violet prisms of **1** were grown by slow evaporation of an aqueous solution (50 cm^3) containing tppz (0.1 mmol), iron(II) chloride tetrahydrate (0.1 mmol), potassium cyanide (0.3 mmol) and tetraphenylphosphonium chloride (0.1 mmol). The tppz ligand and the iron(II) salt were allowed to react in 20 cm^3 of water under continuous stirring until a deep blue solution resulted. Then, potassium cyanide dissolved in 20 cm^3 was added and the colour turned to violet. Finally, PPh_4Cl dissolved in 10 cm^3 of water was added and the solution allowed to evaporate in a hood at room temperature. Crystals were filtered off and dried on filter paper in the open air. Yield *ca.* 65%. *Anal.* Calc. for $C_{51}H_{50}FeN_9O_7P$ (**1**): C, 62.04; H, 5.06; N, 12.76. Found: C, 61.90; H, 4.94; N, 12.68%.

$[Fe(tppz)_2][Fe(NCS)_4]$ (**2**): Potassium thiocyanate (0.4 mmol) dissolved in a water/acetonitrile 1:1 v/v mixture (10 cm^3) was added to a blue acetonitrile solution of tppz (0.2 mmol) and iron(II) perchlorate hexahydrate (0.2 mmol) under continuous stirring at room temperature. Slow evaporation of the resulting violet solution yielded violet rods of **2** which were suitable for X-ray diffraction. Yield *ca.* 60%. *Anal.* Calc. for $C_{52}H_{32}N_{16}Fe_2S_4$ (**2**): C, 55.74; H, 2.86; N, 19.99. Found: C, 55.38; H, 2.79; N, 19.84%.

2.4. Crystal data collection and refinement

The diffraction data of **1** and **2** were collected with Bruker-Nonius X8 APEX CCD (**1**) and Bruker-AXS SMART 2K CCD area detector (**2**) diffractometers at 293 K and using Mo Kα radiation ($\lambda = 0.71073$ Å). Crystal parameters and refinements results are summarized in Table 1. The structures of **1** and **2** were solved by direct methods and were refined by full-matrix least-squares based on F^2, including all reflections. The water molecules in **1** were disordered over several positions and six oxygen atoms [O(5w)–O(10w)] were refined with a fixed site occupancy factor of 0.5. The remaining non-hydrogen atoms in **1** and all non-hydrogen atoms in **2** were anisotropically refined. The hydrogen atoms of the tetraphenylphosphonium cation (**1**) and the tppz ligand (**1** and **2**) were included at idealized positions and refined according to the riding model. The hydrogen atoms of the water molecules of **1** were not found. The non-optimal refinement of the structure of **1** is related to the disorder of the water molecules. In the case of **2**, the fraction of unobserved reflections were rather high at 2θ values above 50°, and hence this was chosen as the limit in data processing. The final Fourier-difference map showed maximum and minimum height peaks of 0.533 and −0.45 e $Å^{-3}$ for **1** and 0.798 and −0.406 e $Å^{-3}$ for **2**.

The diffraction data were processed through the SAINT [17a] reduction and SADABS [17b] absorption software. Structure solutions and refinements were performed with the Bruker SHELXTL system [18]. The final geometrical calculations for **1** were carried out with the PARST [19]

program. The graphical manipulations were done using the XP utility of the SHELXTL system [18b] and CRYSTALMAKER [20]. Selected bond distances and angles for **1** and **2** are listed in Tables 2 and 3, respectively.

3. Results and discussion

3.1. Description of the structure of *1*

The crystal structure of **1** consists of *mer*-[Fe(tppz)-$(CN)_3$]$^-$ anions, uncoordinated tetraphenylphosphonium cations and crystallization water molecules which are interlinked by electrostatic interactions, hydrogen bonds and van der Waals forces (Figs. 1 and 2). The cation is of meridional configuration with each iron atom being surrounded by three tppz-nitrogen and three cyanide carbon atoms in a somewhat distorted octahedral geometry.

The overall symmetry of the anion is close to C_{2v}. The main source of distortion of the metal surrounding is due to the ring strain, the chelate ring angles N(1)–Fe(1)–N(5) and N(2)–Fe(1)–N(5) are 82.19(16)° and 80.68(15)°, respectively. The Fe(1)–N(tppz) and Fe(1)–C(cyano) bond distances in **1** vary in the range 1.869(4)–1.976(4) and 1.926(5)–1.946(5) Å, respectively, and they are very close to those observed in the related diamagnetic iron(II) complex $AsPh_4$-*mer*-[Fe(terpy)$(CN)_3$]$\cdot 2H_2O$ ($AsPh_4^+$ = tetraphenylarsonium cation and terpy = 2,2′:6′,2″-terpyridine) [Fe–N(terpy) = 1.899(7)–1.979(7) Å and Fe–C(cyano) = 1.952(11)–1.986(10) Å] [21] and in the low-spin iron(III) complex PPh_4-*mer*-[Fe(bpca)$(CN)_3$]$\cdot H_2O$ [bpca$^-$ = bis(2-pyridylcarbonyl)amidate anion] [Fe–N(bpca) = 1.893(2)–1.959(2) Å and Fe–C(cyano) = 1.937(3)–1.951(3) Å] [22]. The presence of the tetraphenylphosphonium cation in **1**, the value of the magnetic moment at room temperature

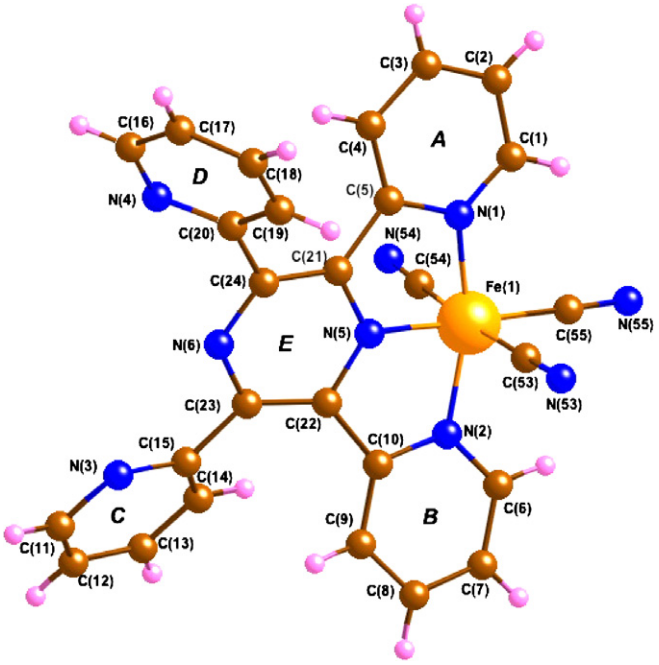

Fig. 1. Perspective view of the *mer*-[Fe(tppz)(CN_3)]$^-$ anion of **1** showing the atom numbering. The hydrogen atoms have been omitted for clarity.

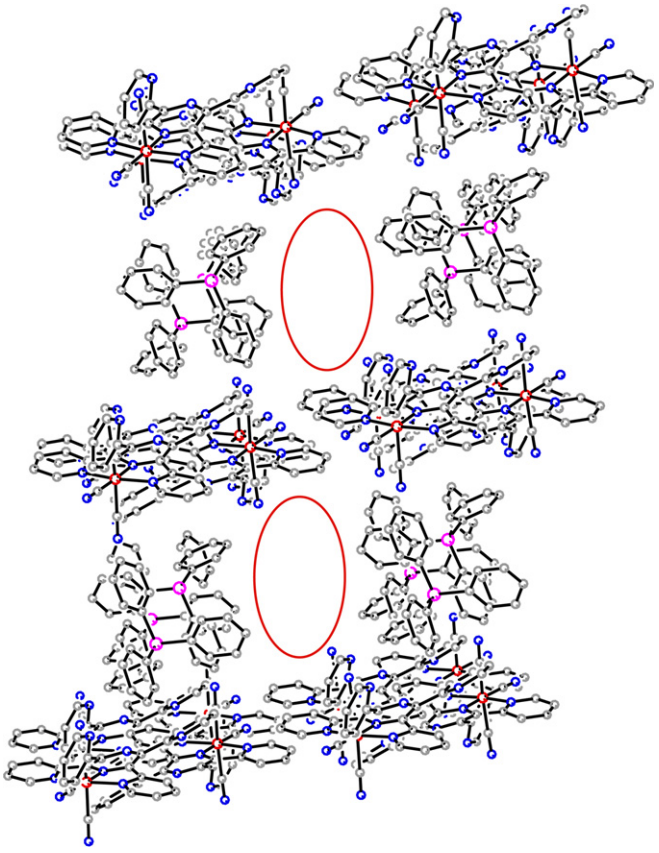

Fig. 2. View of the packing in the unit cell of **1**; red circles refer to occupation of crystallization water molecules that are omitted for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

(*ca.* 0.6 μ_B) [23], and the cyanide stretching frequency [*ca.* 2080 cm^{-1} in **1** *versus* 2126 cm^{-1} in the bpca-containing low-spin iron(III) complex] also demonstrate the singlet spin state of the iron(II) in **1**. For the sake of comparison, the Fe–N(tppz) bond lengths in the five-coordinated mononuclear iron(II) complex [Fe(tppz)Cl_2] are somewhat longer [2.077(3)–2.107(3) Å] than in **1** as expected given the high-spin state ($S_{Fe} = 2$) of the iron(II) ion in that species [13b]. The bond lengths and angles involving the cyanide ligands are all normal [1.164(6), 1.157(6) and 1.161(7) Å for C(53)–N(53), C(54)–N(54) and C(55)–N(55), respectively]. The iron atom and each cyanide are almost linear, the values for the Fe–C–N angle ranging from 177.0(4)° to 178.7(5)°.

The pyridyl rings of the tppz molecule are planar within experimental errors but the tppz ligand as a whole is far from being planar due to the steric effects between the hydrogen atoms on the 3-pyridyl positions. Low energy conformations of tppz are predicted to have each pyridyl ring twisted from coplanarity with the pyrazine by roughly 50° [4a]. In order to describe the relevant structural features of the coordinated tppz molecule in **1** we will adopt the following convention: the pyrazine ring is noted E whereas the four pyridyl rings are labelled as A, B, C and D (see Fig. 1). It deserves to be noted that the free N(3) and N(4) pyridyl nitrogen atoms are up and down from the pyrazine ring. This E ring is considerably twisted, the value of the dihedral angle between the C(21)–N(5)–C(22) and C(23)–N(6)–C(24) planes being 7(1)°. The dihedral angle between the mean planes of the coordinated A and B pyridyl rings is 5.4(3)° whereas that between the uncoordinated C and D rings is 46.8(3)°. These different values are caused by the tridentate coordination of the tppz molecule to the iron atom through the N(1), N(2) and N(3) nitrogen atoms from the A, B and E rings.

Hydrogen bonds involving the nitrogen atoms of the terminal cyanide ligands [N(53), N(54) and N(55)] and some of the water molecules [O(9w), O(4w) and O(1w)] occur in the structure of compound **1**, the N···O_w distances varying in the range 2.80(1)–3.22(1) Å. It is noteworthy that the free nitrogen atoms of the tppz do not form any hydrogen bond. Finally, as expected for compounds with a large number of crystallization water molecules, an extended network of hydrogen bonds occurs involving all water molecules, leading to a water cluster with O···O distances varying in the range 2.66–2.98 Å. π–π type interactions involving the coordinated A [N(1)/N(1a)] and B [N(2)/N(2b)] pyridyl rings of tppz are also present with interplanar distances of *ca.* 3.34 and 3.28 Å for A and A′ and B and B′, respectively [symmetry code: (a) $1-x$, $2-y$, $1-z$; (b) $2-x$, $1-y$, $1-z$]. Considering these interactions, the anions give rise to chains with iron···iron separations of 8.706(3) and 8.249(3) Å (Fig. 2). The bulky tetraphenylphosphonium cation exhibits the expected tetrahedral shape and its bond lengths and angles are as expected. Interestingly, the PPh_4^+ cations are linked along the *a* axis by alternating off-set sextuple phenyl embrace (OSPE) and six phenyl embrace (SPE) interactions (see Fig. 3) with values of the P···P separation of 6.560(3) and 6.767(3) Å, respectively [24].

3.2. Description of the structure of **2**

The building blocks of compound **2** are the $[Fe(tppz)_2]^{2+}$ and $[Fe(NCS)_4]^{2-}$ units (Fig. 4). The tppz ligands of the cation bind to the iron atom in a tridentate fashion. Fe(1) has a distorted octahedral environment, in which the bonds to the two pyrazine nitrogen atoms [1.874(4) and 1.896(4) Å for Fe(1)–N(5) and Fe(1)–N(11), respectively] are significantly shorter than the bonds to the pyridyl nitrogen atoms ($Fe–N_{py}$ 1.960–1.970 Å), which conforms well with the situation in **1**. The same pattern of differences in the bond lengths was previously observed in the structures of the diamagnetic complexes $[Fe(tppz)_2](ClO_4)_2 \cdot CH_3CN \cdot H_2O$ [13b] and $[Fe(terpy)_2](ClO_4)_2 \cdot nH_2O$ ($n = 1$ and 1/2) [25]. The equatorial plane (with respect to the short axis) in **2** has a significant tetrahedral distortion (maximum atomic deviation 0.305 Å), the Fe(1) atom not deviating significantly from the average plane. The individual pyridyl rings are planar within experimental errors, while the two pyrazine rings are significantly puckered (maximum atomic deviation from the average plane 0.099 Å and 0.109 Å, respectively). Dihedral angles between pyridyl rings and the pyrazine ring to which they are connected, are 23.0° (A/E), 14.9° (B/E), 37.7° (C/E), 29.2° (D/E), 24.4° (F/J), 22.0° (G/J), 35.7° (H/J) and

Table 4
S···H–C contacts[a]

S	H	C	S···H (Å)	S···C (Å)	S···H–C (°)
S(1)	H(8c)	C(8c)	3.08	3.677(8)	124
S(2)	H(35d)	C(35d)	2.91	3.724(10)	147
S(3)	H(3d)	C(3d)	3.04	3.582(7)	119
S(4)	H(1d)	C(1d)	3.04	3.709(7)	131

[a] Symmetry transformations used to generate equivalent atoms: (c) x, $y-1$, z; (d) $1+x$, y, z.

33.5° (I/J). It deserves to be noted that the nitrogen atoms of the non-coordinated pyridyl rings of the two tppz ligands in **2** are placed on the side of the ring pointing toward the metalated side of the ligand rather than on the side pointing toward the free nitrogen atom of the pyrazine ring in contrast to what occurs in **1**. These structural features of the coordinated tppz ligand in **1** and **2** would account for the tendency of this ligand to adopt either mono- or bis-chelation in its metal complexes. The iron atom of the anion, Fe(2), has a slightly distorted tetrahedral coordination sphere being bound to four thiocyanate ligands at Fe–N distances ranging from 1.966(8) to 1.986(7) Å. The presence of a strong peak at 2058 cm^{-1} in the infrared spectrum of **2** is consistent with a N-coordination of thiocyanate [26]. The thiocyanate groups in the $[Fe(NCS)_4]^{2-}$ unit display comparable classical N–C and C–S distances. They are nearly linear [values of the N–C–S angle varying in the range 175.5(10)–179.1(8)°] but the Fe–NCS groups are somewhat bent [values of the Fe–N–C angle covering the range 169.7(9)–173.9(7)°]. The value of the magnetic moment of **2** at room temperature (*ca.* 5.9 μ_B) is consistent with the occurrence of both a paramagnetic high-spin iron(II) ($S_{Fe}=2$ for $[Fe(NCS)_4]^{2-}$) species and a low-spin iron(II) ($S_{Fe}=0$ for $[Fe(tppz)_2]^{2+}$) unit. In fact, a singlet spin state was observed for the iron(II) ion in the complex $[Fe(tppz)_2](ClO_4)_2 \cdot CH_3CN \cdot H_2O$ [13b].

The crystal packing of the bulky building block units leaves cavities between the molecules (Fig. 5), voids of approximately 300 $Å^3$. The low density of the material (Table 1) reflects its open structure. Between cations stacked along the *c*-axis weak π–π interactions appear to occur between pyridyl rings. Rings involving N(3)/N(10a), N(4)/N(9b), N(8)/N(8b) and N(7)/N(7a) atoms [symmetry code: (a) $1-x$, $1-y$, $1-z$; (b) $1-x$, $1-y$, $-z$] have some overlap, the latter pair having the stronger interaction with significant overlap at an interplanar spacing of 3.42 Å. There are also several S···H–C contacts between anion and cation, the shortest of these are listed in Table 4.

4. Possibilities of metal assembling through complexes 1 and 2

Previous studies dealing with tppz-bridged metal(II) complexes have illustrated the ability of this polyatomic bridge to mediate significant magnetic interactions between the paramagnetic centres separated by distances larger than

6.5 Å [12a,12b,12f–i,13b]. Also, the mononuclear complexes of Co(II) of formula $[Co(tppz)_2]^{2+}$, where tppz adopts the tridentate coordination mode, exhibit spin crossover [13b].

The diamagnetism of the corresponding complexes with iron(II) demonstrates the strong ligand field character of tppz. Having in mind this information, it is clear that the main interest of the diamagnetic $[Fe(tppz)(CN)_3]^-$ and $[Fe(tppz)_2]^{2+}$ units from **1** and **2** is their use as ligands towards fully solvated or partially blocked metal ions in order to create new polymetallic assemblies where significant electronic and/or magnetic coupling could be involved. In the case of the $[Fe(tppz)(CN)_3]^-$ anion of **1**, its oxidation to the related iron(III) species would provide a paramagnetic low-spin iron(III) species ($S_{Fe} = 1/2$) whose potentiality as a ligand would follow the magneto-structural studies carried out with the related low-spin iron(III) complexes *mer*-$[Fe(bpca)(CN)_3]^-$ [22,27] and *fac*-$[Fe\{HB(pz)_3\}(CN)_3]^-$ [28] [$HB(pz)_3^- =$ hydrotris (1-pyrazolyl)borate] but with the advantage of having also the terminal nitrogen atoms of tppz as donors.

5. Conclusions

The combination of structural knowledge and the magnetic data at room temperature of the complexes **1** and **2** reveal the occurrence of low-spin iron(II) centres in the $[Fe(tppz)(CN)_3]^-$ anion (**1**) and $[Fe(tppz)_2]^{2+}$ cation (**2**) confirming the strong field character of the tppz ligand in its complexes with the iron(II) ion. A search in the CSD shows that complex **2** is the first structurally characterized example containing the tetrahedral iron(II) unit $[Fe(NCS)_4]^{2-}$. The occurrence of non-coordinated pyridyl and pyrazine nitrogen atoms in both the $[Fe(tppz)(CN)_3]^-$ anion (**1**) and $[Fe(tppz)_2]^{2+}$ cation (**2**) together with the free peripheral cyanide-nitrogen atoms in the former, make them suitable building blocks for metal assembling and further studies on electronic coupling.

Scheme 1. Structural representations of the prepared ligands including the atom numbering scheme.

developed worldwide as drugs to block cell cycle progression at a specific point, and thus to inhibit tumour growth. Among known and potent CDK inhibitors, we have chosen *bohemine* {Boh = 2-[(3-hydroxypropyl)amino]-6-benzylamino-9-isopropylpurine} and *roscovitine* (also named as seliciclib or CYC202) {Ros = 2-(*R*)-(1-ethyl-2-hydroxyethylamino)-6-benzylamino-9-isopropylpurine} as model ligands for the preparation of platinum(IV) complexes.

The anticancer activity of platinum(IV) complexes has been noted by Rosenberg and his colleagues, and known since the 1960s [5]. Although the platinum(IV) complexes have been studied less intensively than those of platinum(II), some of them showed promising anticancer activity to enter clinical trials. The bioinorganic chemistry of platinum(IV) antitumour compounds has been reviewed by Hall and Hambley [6]. One of the conclusions of the review is the statement regarding the observations that platinum(IV) complexes can protect the more reactive platinum(II) ones on the way to the target site before reduction allowing activity within the cell.

There exists a wide number of platinum(IV) complexes prepared and X-ray structurally characterized up to now. Among these complexes, a relatively small subset is represented by those bearing a $PtNCl_5$ donor set. Moreover, there is only a limited number of octahedral pentachloroplatinum(IV) complexes involving DNA nucleobases as N-donor ligands [7]. According to the Cambridge Structural Database [8], there exists only one X-ray structurally characterized pentachloro-platinum(IV) complex with a purine derivative as a ligand of the composition $[PtCl_5(9\text{-}MeAH^+)]$ (9-MeA = 9-methyladenine), where the N1 protonated 9-methyladenine ($9\text{-}MeAH^+$) is coordinated through N7 atom of the purine moiety to platinum(IV) which adopts a distorted octahedral geometry with the $PtNCl_5$ donor set [9].

This work has been motivated not only by efforts to broaden our knowledge regarding biologically interesting Pt(IV) complexes, but also by attempts to prepare the first Pt(IV) complexes with 6-benzylaminopurine derivatives (Scheme 1). In our previous works, we have shown that the transition metal complex formation, i.e. the coordination of CKs or CDK inhibitors to a suitable metal ion (e.g. Cu, Pt and Pd) may cause significant increase in *in vitro* cytotoxicity of the formed complexes as compared to the free discussed organic molecules [10–13]. To continue our investigations in this area, herein we report the preparation, characterization and cytotoxic study of the first Pt(IV) complexes with aromatic cytokinins or CDK-inhibitors of the composition $[Pt^{IV}(LH^+)Cl_5]$ (**1**–**14**), where LH^+ stands for protonated forms of 6-benzylaminopurine derivatives (Bap), *bohemine* or *roscovitine*. The complexes have been prepared by the reaction of K_2PtCl_6 with the corresponding organic compound in 2 M HCl solution. Moreover, two X-ray crystal structures of ionic pair compounds $(BohH_2^{2+})[PtCl_6] \cdot H_2O$ (**15**) and $(RosH_2^{2+})_2[PtCl_6][Cl_2 \cdot 4H_2O$ (**16**) have been determined.

2. Experimental

2.1. Reagents and materials

All the reagents used were chemically pure and of analytical reagent grade. K_2PtCl_6 used in preparation of the complexes was purchased from Aldrich Chem. Co. All other reactants and solvents used were supplied by Merck Co., Fluka Co. and/or Fisher Scientific Co.

2.2. Physical measurements

Elemental analyses (C, H, N) of the compounds were performed on a ThermoFinnigan EA 1112 Flash Analyzer. Infrared spectra of the complexes were recorded on a ThermoNicolet NEXUS 670 FT-IR spectrometer using KBr pellets (400–4000 cm^{-1}) and polyethylene discs (150–400 cm^{-1}). Conductivity measurements were made with a WTW Cond340i/SET conductometer in DMF at 25 °C. The concentration of the complexes in solutions was 10^{-3} mol dm^{-3}. ES+ mass spectra of the complexes were

obtained using a direct probe on a Waters ZMD 2000 mass spectrometer. Full scan analyses were performed for a 10-1000 *m/z* mass range. The spectra were collected using 3.0 s cyclical scans and applying the sample cone voltage, 20, 40, 60 or 80 V, at source block temperature of 100 °C, desolvation temperature of 250 °C and desolvation gas flow rate of 400 l/h. The mass spectrometer was directly coupled to a MassLynx data system. All interpretations of *m/z* were based on ^{35}Cl and ^{194}Pt. ^{1}H, ^{13}C, ^{15}N and ^{195}Pt NMR spectra were measured on a Bruker Avance 300 spectrometer operating at 300.13 MHz (^{1}H), 75.47 MHz (^{13}C) and 64.52 MHz (^{195}Pt). The temperature of the measurements was 300 K. The samples were prepared by dissolving the compounds in DMF-d_7. Tetramethylsilane was used as an internal standard (^{1}H, ^{13}C) and $K_2[PtCl_4]$ in D_2O (−1628 ppm) as an external reference (^{195}Pt). ^{15}N NMR chemical shifts were measured relative to DMF-d_7 solvent (adjusted to 104.7 ppm), which was also used as an internal reference standard. The individual ^{1}H and ^{13}C signals were assigned and refined by means of 2D correlation experiments gs-COSY (gradient pulse sequence – correlation spectroscopy), gs-HMQC (gs-heteronuclear multiple quantum correlation) and gs-HMBC ($^{n}J_{H,C} = 7.5$ Hz) (gs-heteronuclear multiple bond correlation). ^{15}N chemical shifts for compounds Boh, Ros, **13** and **14** were obtained at natural abundance by ^{1}H–^{15}N gs-HMQC and ^{1}H–^{15}N gs-HMBC experiments and the spectra were recorded at 27 °C.

2.3. Synthesis of ligands

6-(2-Methoxybenzylamino)purine (2-MeOBap), 6-(3-methoxybenzylamino)purine (3-MeOBap), 6-(4-methoxybenzylamino)purine (4-MeOBap), 6-(2-hydroxybenzylamino)purine (2-OHBap), 6-(3-hydroxybenzylamino)purine (3-OHBap), 6-(4-hydroxybenzylamino)purine (4-OHBap), 6-(2-chlorobenzylamino)purine (2-ClBap), 6-(3-chlorobenzylamino)purine (3-ClBap), 6-(4-chlorobenzylamine)purine (4-ClBap), 6-(2-fluorobenzylamino)purine (2-FBap), 6-(3-fluorobenzylamino)purine (3-FBap) and 6-(4-fluorobenzylamino)purine (4-FBap) were synthesized using a slight modification of the previously described procedure [14]. *Bohemine* (Boh) and *roscovitine* (Ros) were obtained according to the mildly changed reported method [15]. The composition and purity of these organic molecules used as ligands were proved by elemental analysis, melting point, ^{1}H and ^{13}C NMR (for all the ligands), ^{15}N NMR (for Boh and Ros only), and thin-layer chromatography (TLC). ^{1}H and ^{13}C NMR spectral data of the ligands, except for Boh and Ros, are deposited as Supplementary material.

Boh: ^{1}H NMR (DMF-d_7, ppm): δ 7.85 (bs, 1H, N6H), 7.76 (s, 1H, C8H), 7.45 (d, $J = 7.2$ Hz, 2H, C11,15H), 7.30 (tt, $J_a = 7.2$ Hz, $J_b = 1.5$ Hz, 2H, C12,14H), 7.21 (tt, $J_a = 7.2$ Hz, $J_b = 1.5$ Hz, 1H, C13H), 6.29 (t, $J = 6.0$ Hz, 1H, N2H), 4.83 (bs, 2H, C9H), 4.72 (t, $J = 5.3$ Hz, 1H, O21H), 4.62 (sep, $J = 7.0$ Hz, 1H, C16H), 3.65 (q, $J = 5.5$ Hz, 2H, C21H), 3.51 (q, $J = 6.2$ Hz, 2H, C19H), 1.81 (qui, $J = 6.4$ Hz, 2H, C20H), 1.52 (d, $J = 6.8$ Hz, 6H, C17,18H). ^{13}C NMR (DMF-d_7, ppm): 160.49 (C2), 155.70 (C6), 151.81 (C4), 141.66 (C8), 135.61 (C10), 128.76 (C11,15), 128.19 (C12,14), 127.17 (C13), 114.80 (C5), 60.08 (C21), 46.71 (C16), 43.87 (C9), 39.32 (C19), 33.69 (C20), 22.40 (C17,18). ^{15}N NMR (DMF-d_7, ppm): 237.0 (N7), 194.2 (N1), 176.9 (N3), 172.2 (N9), 85.2 (N6), 84.4 (N2).

2.4. Synthesis of Pt(IV) complexes (*1*–*14*): a general procedure

K_2PtCl_6 (0.24 g, 0.5 mmol), dissolved in 30 ml of 2 M HCl, was added to a solution of the corresponding ligand (0.5 mmol in 30 ml of 2 M HCl). The mixture was stirred under reflux for 2 h. A yellow precipitate formed after this time period. It was filtered off, washed with water and dried in air. All complexes were obtained in high yields (ca. 80–90%).

2.4.1. $[Pt(2\text{-}MeOBapH^+)Cl_5]$ (*1*)

Anal. Calc. for $C_{13}H_{14}Cl_5N_5OPt$: C, 24.8; H, 2.3; N, 11.1. Found: C, 24.6; H, 2.6; N, 11.2%. $\lambda_M = 37.6$ S cm^2 mol^{-1} in DMF. IR (cm^{-1}): 534s *ν*(Pt–N), 350s *ν*(Pt–Cl). 2.4.15. ($BohH_2^{2+}$)[$PtCl_6$] · H_2O (**15**)

After two weeks, a few crystals suitable for single crystal X-ray analysis were obtained by slow evaporation of the mother liquor from the first filtrate during the preparation of **13**.

2.4.16. ($RosH_2^{2+}$)$_2$[$PtCl_6$]Cl_2 · $4H_2O$ (**16**)

A few crystals of the complex were obtained similarly as described for complex **15** but the difference is that suitable single crystals were formed after six weeks.

2.5. Single crystal X-ray crystallography

X-ray measurements on the selected crystals of compounds **15** and **16** were performed on a Kuma KM-4 four-circle κ-axis diffractometer equipped with a CCD detector and Oxford Cryostream Cooler. Mo Kα radiation

($\lambda = 0.71073$ Å) from monochromator Enhance (Oxford Diffraction) and rotation ω-scans with different κ and ϕ for covering all reciprocal sphere were used. All data collection, cell refinement, data reduction and correction procedures were performed using the CRYSALIS CCD and CRYSALIS RED software [16]. The phase problem was solved by direct methods using SHELXS-97 [17]. The program SHELXL-97 [18] was used to refine both the structures by full-matrix least-squares procedure on F^2. All non-hydrogen atoms were refined as independent atoms using anisotropic thermal parameters. The coordinates of the O-bound H atoms were refined, with the O–H distances restrained to 0.95(2) Å. All other H atoms were located in a difference map and refined using a riding model, with N–H = 0.88 Å, C–H = 0.95–1.00 Å, and $U_{iso}(H) = 1.2U_{eq}$-(C,N) or $1.5U_{eq}(CH_3)$. Crystal data and structure refinements of **15** and **16** are summarized in Table 1.

2.6. DFT calculations

Preliminary structural data were calculated on HF/6-31* level with respect to structural properties usual for complexes of studied type. Geometries of found minima were than fully optimized at the B3LYP level with the 6-311+G**/LANL2DZ and aug-cc-pVDZ/LANL2DZ basis sets, where LANL2DZ pseudo-potential was used for the Pt atom. Harmonic frequency analysis was used to verify the nature of found stationary points as the minima as well as for the calculation of zero-point vibrational energies. Calculated infrared frequencies were not scaled by any factor. All calculations were performed using the GAUSSIAN-03 program [19].

Table 1
Crystal data and structure refinements for $(BohH_2^{2+})[PtCl_6]\cdot H_2O$ (**15**) and $(RosH_2^{2+})_2[PtCl_6]Cl_2\cdot 4H_2O$ (**16**)

2.7. Cytotoxicity testing

The cytotoxicity of the free ligands and their platinum(IV) complexes were tested *in vitro* by a calcein AM assay against the following human cancer cell lines: malignant meloma *G361*, osteogenic sarcoma *HOS*, chronic myologenous leukemia *K562* and breast adenocarcinoma cell line *MCF7*. The cells were treated with a solution of the tested compound for 72 h at 37 °C, 5% CO_2; in the range 0.41–167 μM for **1**–**6** and 0.35–85 μM for **7**–**14.** Further details regarding the biological activity testing are detailed in [20]. The IC_{50} values are represented by arithmetic mean of three values. The measurement deviation ranges from 12% to 18%.

3. Results and discussion

3.1. General characterization

The proposed molecular formula for all the complexes **1**–**14** are in good agreement with the stoichiometric composition concluded from analytical data. The molar conductance measurements in DMF solutions indicated that the complexes behave as non-electrolytes ($\lambda_M = 34.4$–48.4 S cm^2 mol^{-1}) [21], although partial dissociation had occurred in the solvent used. Moreover, the molar conductance values showed to be time dependent and increased with time. It has been found that the values are higher by about 20–30% after 48 h as compared to the original ones. This observation can be connected with the fact that DMF belongs to a group of alkaline solvents, and thus, it may partially deprotonate the positively charged Bap derivative coordinated within the complex. This deprotonation may cause fractional decomposition of the complexes, and consequently, the conductance of the solutions can be increased. The conclusion relating to the deprotonation can be also supported by NMR spectral data where signals belonging to free organic ligands were detected in the case of solutions measured after 48 h. That is why it has been not possible to use re-crystallizations from common solvents, mainly those behaving like proton acceptors, for the preparation of single crystals of complexes **1**–**14** suitable for X-ray analysis. Thus, we have tried to prepare single crystals by slow evaporation of the solvent used during the synthesis (i.e. 2 M HCl) from the mother liquor after the first filtration. We have been successful in the case of using this method, however, crystals of compounds with different composition have been formed, i.e. complexes **15**

and **16** (see Section 3.6). Based on these findings, we have optimized the geometries of complexes **1**–**14** by means of DFT calculations (see Section 3.5).

3.2. IR spectra

The presence of the appropriate organic ligand in the complexes was indicated by IR spectra measured in the range of 400–4000 cm^{-1}. The spectra show strong peaks near 1640 cm^{-1} which are typical for ν(C=N) stretch vibration of a purine ring. The bands near 3060 and 3300 cm^{-1} can be assigned to $\nu(C_{ar}–H)$, and ν(N–H) stretching vibrations, respectively. The bands recorded in the IR spectra of the complexes **7**–**9** at ca. 1270 cm^{-1} are typical for the $\nu(C_{ar}–F)$ vibration while the peaks at 1112–1160 cm^{-1} (for complexes **10**–**12**) can be ascribed to the $\nu(C_{ar}–Cl)$ vibration [22]. The maxima attributable to ν(Pt–N) and ν(Pt–Cl) were observed at ca. 530 and 350 cm^{-1}, respectively [23].

3.3. ES+ mass spectroscopy

Dominant peaks corresponding to the protonated form of 6-benzylaminopurine ligands, LH^+, were observed in all ES+ mass spectra, i.e. complexes **1**–**3** revealed a peak at 256 *m*/*z*, complexes **4**–**6** at 242 *m*/*z*, complexes **7**–**9** at 244 *m*/*z*, the complexes **10**–**12** at 260 *m*/*z*, complex **13** at 341 *m*/*z*, and complex **14** at 355 *m*/*z*. The molecular ion peaks belonging to $[Pt(LH^+)Cl_5]^+$ were observed at 629, 616, and 728 *m*/*z* for complexes **1**–**3**, **9**, and **14**, respectively. Further fragmentation of the molecular ion peaks can be clearly seen from maxima recorded at 594 *m*/*z* (for **1**–**3**), 580 *m*/*z* (for **4**–**6**), and 582 *m*/*z* (for **7**–**9**) which correspond to $[Pt(LH^+)Cl_4]^+$. The $[Pt(LH^+)Cl_3]^+$, $[Pt(LH^+)Cl_2]^+$, $[Pt(LH^+)Cl]^+$ and $[Pt(LH^+)]^+$ fragments can be characterized by peaks at 545 (for **7**), 562 (for **10**–**12**), 641 (for **13**), and 657 *m*/*z* (for **14**), 523 (for **1**–**3**), 509 (for **4**–**6**), 526 (for **11**) and 622 *m*/*z* (for **14**), 486 (for **1**), 480 (for **4**–**6**), 573 (for **13**) and 586 *m*/*z* (for **14**), and 453 (for **1**–**3**), 437 (for **5** and **6**), 454 (for **11**) and 536 *m*/*z* (for **13**), respectively. As can be evident from the above-mentioned results, the proposed general formula $[Pt(LH^+)Cl_5]$ was clearly confirmed by ES+ mass spectroscopy for all complexes **1**–**14**.

3.4. NMR spectroscopy

^1H and ^{13}C NMR spectra of free ligands as well as the prepared complexes were measured in DMF-d_7 and their interpretation was based on differences between selected chemical shifts of the corresponding atoms in the free organic ligand and complex, where coordination chemical shifts, $\Delta\delta$, are defined as $\Delta\delta = \delta_{complex} - \delta_{ligand}$. Important ^1H, ^{13}C and ^{195}Pt NMR spectral data (δ, ppm) for the free ligand and for the complexes **1**–**14** are summarized in Table 2. Based on the analysis of chemical shifts in ^1H and ^{13}C NMR spectra (see Table 2), we assume that the coordination of CKs as ligands to platinum proceeds via the N9 atom and the ligands are N1 protonated in the case of complexes **1**–**12**. Simultaneously, the proton, originally bonded to N9 atom in the corresponding free cytokinin-derived molecule, is shifted to N7 atom. This statement can be supported by the fact that the signals corresponding to N9-H are missing in ^1H NMR spectra of the complexes **1**–**12**. On the other hand, new signals with chemical shifts of 10.70–11.80 ppm appeared in the same spectra, which can be assigned to N7-H. Most significant changes in chemical shifts were displayed in ^{13}C NMR spectra for C4 and C8 atoms, where $\Delta\delta$ ranging from −2.70 to −4.89 ppm, and 4.56 to 6.80 ppm, respectively. The situation regarding the complexes involving CDK inhibitors (**13** and **14**) is somewhat different as compared to those above-mentioned. The proton at the N9 position is substituted by an *i*-propyl chain, and thus, this site is blocked for possible coordination to platinum(IV). The changes in chemical shifts of atoms forming the adenine moiety clearly showed that the ligand is N1 protonated and coordinated to plati-

Table 2
Selected coordination chemical shifts ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) in ^1H and ^{13}C NMR spectra ($\Delta\delta$, ppm) for the organic ligands and complexes and ^{195}Pt NMR spectral data (δ, ppm)

num(IV) through N7 atom. This can be deduced mainly from chemical shifts of N atoms forming the adenine moiety as determined by ^{15}N NMR spectroscopy, where the following $\Delta\delta$ were found: $\Delta\delta = -47.2$ and -45.8 ppm (for N1), 7.8 and 7.7 ppm (for N2), -13.0 and 2.1 ppm (for N3), -57.3 and -57.9 ppm (for N6), -85.9 and -85.4 ppm (for N7), 7.7 and 7.4 ppm (for N9) for **13** and **14**, respectively.

In conclusion, we can state that the results arising from ^{15}N NMR spectra correlate well with ^{1}H and ^{13}C NMR spectral data (see Table 2) in the case of both complexes **13** and **14**.

Broad signals in the range of 90.0–129.6 ppm with the half height line-widths of 150–200 Hz were found in ^{195}Pt NMR spectra of complexes **1**–**12**, while signals at 332.4 and 339.7 ppm were detected for complexes **13** and **14**, respectively. Chemical shifts for some Pt(IV) complexes with the $PtCl_5N$ chromophore have been reported recently, e.g. $\delta(^{195}Pt) = -184$ ppm for the anion $[PtCl_5(EtCN)]^-$ (in $CDCl_3$), δ (^{195}Pt) = 91 ppm for $[PtCl_5(NH_3)]^-$ (in DMSO) [24], and $\delta(^{195}Pt) = -832$ ppm $[PtCl_5(9\text{-MeAdeH}^+)]$, where 9-MeAdeH$^+$ = 9-methyladeninium cation. These types of compounds are quite uncommon and only a few ^{195}Pt NMR chemical shifts are available in the literature. However, we can deduce that the signals observed for complexes **1**–**14** may indicate the presence of an octahedral Cl_5N donor set in the vicinity of platinum(IV).

3.5. DFT analysis

In order to support conclusions regarding geometries of the complexes and the manner of the ligand coordination to platinum(IV), we have performed DFT analysis using the B3LYP hybrid functional. As model systems, $[PtCl_5(4\text{-FBapH}^+)]$ (**9**) and $[PtCl_5(RosH^+)]$ (**14**) complexes were chosen. Optimized structures are shown in Figs. 1 and 2, respectively, while the most important geometrical parameters characterizing the Pt(IV) coordination sphere are summarized in Table 3. The calculated structure of **9** has a C_s symmetry. Coordination geometry in the vicinity of the central Pt(IV) ion may be described as a slightly deformed octahedron (Fig. 1), where the Pt–N bond length is shortened by approximately 0.3–0.4 Å in comparison with lengths of the Pt–Cl bonds (for details, see Table 3). In agreement with experimental observations, the calculated infrared spectrum (B3LYP/aug-cc-pVDZ/LANL2DZ) shows maxima at 278, 288, 306 and 349 cm^{-1} which may correspond to the stretching Pt–Cl vibrations.

In the case of complex **14**, Pt(IV) ion is coordinated to N7 atom due to substitution at the N9 position. The coordination sphere also has the shape of a slightly deformed square-bipyramid (Fig. 2). Similarly to the geometry of complex **9**, the Pt–N bond length is 2.135 Å, and is shorter by approximately 0.3–0.4 Å than those of Pt–Cl bonds. The calculated geometrical parameters in the vicinity of the central atom correspond well with recently published crystallographic data for the $[PtCl_5(9\text{-MeAdeH}^+)]$ complex

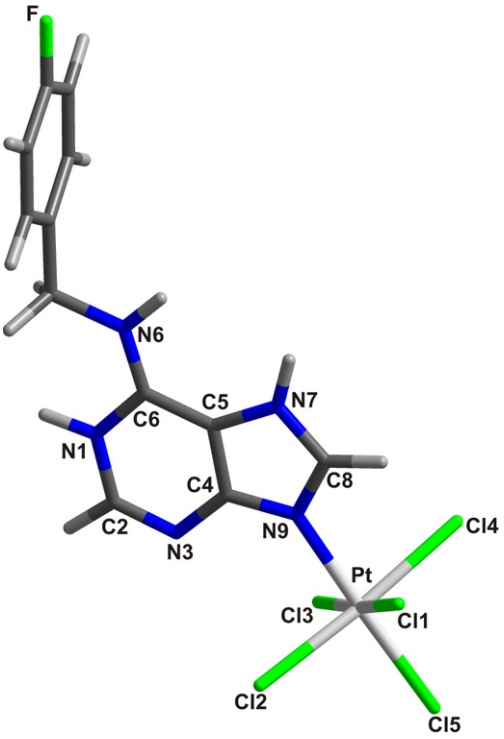

Fig. 1. The geometry of $[Pt(4\text{-FBapH}^+)Cl_5]$ (**9**) calculated on the B3LYP/aug-cc-pVDZ/LANL2DZ level.

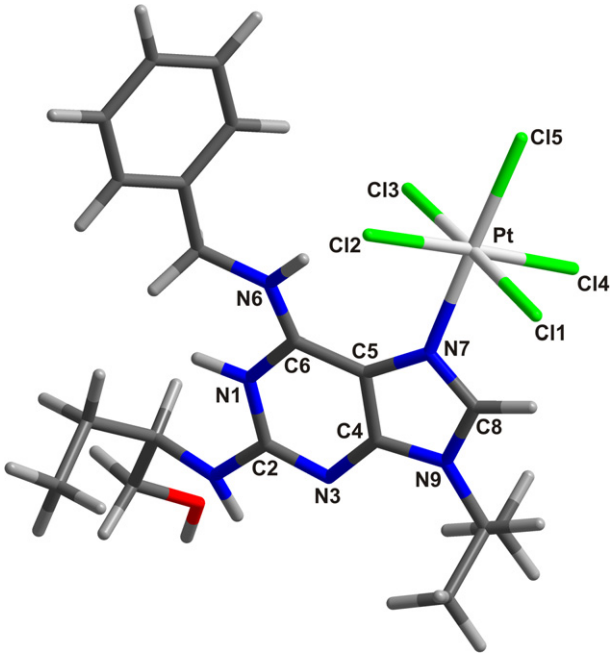

Fig. 2. The geometry of $[Pt(RosH^+)Cl_5]$ (**14**) calculated on the B3LYP/aug-cc-pVDZ/LANL2DZ level.

(Table 3). The calculated infrared spectrum (B3LYP/aug-cc-pVDZ/LANL2DZ) shows maxima at 286, 304, 308 and 342 cm^{-1} corresponding to the stretching Pt–Cl vibrations, which also indicate agreement between the calculated structure and experimental observations. Unfortunately, the maximum belonging to ν(Pt–N) cannot be assigned

unambiguously, although there were observed several more complex skeletal vibrations (about ca. 313 cm^{-1}) including partial contribution to the Pt–N bond vibration.

3.6. X-ray structures of $(BohH_2^{2+})[PtCl_6] \cdot H_2O$ (**15**) and $(RosH_2^{2+})_2[PtCl_6]Cl_2 \cdot 4H_2O$ (**16**)

The molecular structure of compound **15** consists of a double-protonated cation of bohemine, octahedral $[PtCl_6]^{2-}$ anion and one crystal water molecule (Fig. 3, Table 4). Most of the bond lengths and angles in bohemine can be regarded as normal in comparison with other protonated forms of similar CDK inhibitors (e.g. [25]). Atoms forming the benzene (A), pyrimidine (B) and imidazole (C) rings deviate very slightly from planarity [the greatest deviations being 0.005(5) Å for atom C10 in ring A, 0.010(5) Å for atom N(1) in ring B and 0.007(5) Å for atom C4 in ring C]. The dihedral angle between the rings B and C is 1.63(17)°, while the dihedral angle between the ring A and the purine moiety (B + C) is 86.9(2)° (DIAMOND 3.1 [26]). The torsion angles N1–C6–N6–C9, C6–N6–C9–C10 and N6–C9–C10–C11, defining the spatial arrangement of the ring A and purine moiety, are 2.5(8)°, 167.3(5)°, and 86.7(6)°, respectively. The secondary structure of the compound **15** is stabilized by extended network of intermolecular N–H···O, O–H···O, N–H···Cl and O–H···Cl hydrogen bonds (Fig. 3, Table 5).

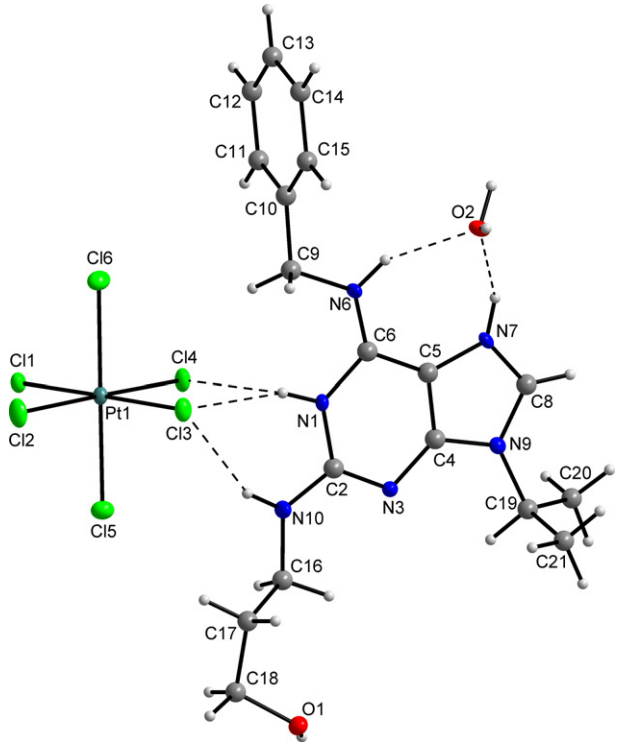

Fig. 3. The molecular structure of $(BohH_2^{2+})[PtCl_6] \cdot H_2O$ (**15**) with the atom labelling scheme. The non-H atoms are drawn as displacement ellipsoids at the 50% probability level and H atoms are shown as small spheres at arbitrary radii. Dashed lines indicate possible hydrogen bonds.

The molecular structure of compound **16** consists of two double-protonated cations of roscovitine, an centrosymmetric octahedral $[PtCl_6]^{2-}$ dianion (at special crystallographic position), two chlorine anions and four molecules of crystal water (Fig. 4, Table 4). Aromatic rings of roscovitine are almost planar, but they are more

tion (IC_{50}). The results of the testing are summarized in Table 6. The *in vitro* cytotoxic properties can be evaluated by comparison of values found for the Pt(IV) complexes as against the starting compounds, i.e. K_2PtCl_6 and free organic molecules. As can be seen from Table 6, significant cytotoxity has been found in the case of complexes involving CDK inhibitor Bohemine or Roscovitine, i.e. complexes **13** and **14**. However, their promising IC_{50} values are probably influenced by the presence of the mentioned organic molecule in the complexes because it is cytotoxic itself. Generally, the best results have been achieved for [Pt(RosH$^+$)Cl$_5$] (**14**), and moreover, the IC_{50} value as determined against the K562 cell line is equal to 17 μM, which is ca. 3 times better value than estimated for free Roscovitine.

4. Conclusion

The paper deals with the synthesis, characterization and *in vitro* cytotoxic study of the first Pt(IV) complexes bearing 6-benzylaminopurine derivatives as ligands, i.e. organic compounds which belong to groups of plant growth hormones (cytokins) and/or cyclin-dependent kinase inhibitors. A series of octahedral Pt(IV) complexes **1**–**14** have been prepared by the reaction of K_2PtCl_6 with the appropriate organic compound in 2 M HCl. The accomplished physical and chemical studies supported complex formation with a formula of [Pt(LH$^+$)Cl$_5$]. Based mainly on multinuclear NMR spectra, it has been found that the cytokinin derivative is coordinated to platinum through N9 atom (for **1**–**12**), while the cyclin-dependent kinase inhibitor (Bohemine or Roscovitine) is bonded via N7 atom (for **13** and **14**), and moreover, organic molecules are protonated at the N1 position in all cases. Unfortunately, we have been unsuccessful with the preparation of single crystals suitable fox X-ray determination of complexes **1**–**14**. For that reason, the geometries of the complexes have been optimized by using DFT calculations. Moreover, we have obtained and determined the structures of (BohH$_2^{2+}$)[PtCl$_6$] · H$_2$O (**15**) and (RosH$_2^{2+}$)$_2$[PtCl$_6$]Cl$_2$· 4H$_2$O (**16**) which crystals have been formed as a consequence of evaporation of mother liquors during the preparation of complexes **13** and **14**, respectively. The results of the cytotoxicity testing of Pt-complexes against *G361*, *HOS*, *K562* and *MCF7* human cancer cell lines exhibited that the coordination of an organic molecule did not have substantial impact on the cytotoxicity of the Pt-complexes (**1**–**12**). However, the IC_{50} values regarding the complexes bearing cyclin-dependent kinase inhibitors (**13** and **14**) are lying in the range of 17–74 μM. It can be deduced that these significant *in vitro* cytotoxicity values are influenced by the presence of the organic molecule which is cytotoxic itself.

Acknowledgements

This research was supported by the Ministry of Education, Youth and Sports of the Czech Republic (MSM6198959218). The authors thank to Dr. Karel Doležal for obtaining of ES+ MS spectral data, Mr. Michal Šipl for help with the preparation of some ligands and Pt(IV) complexes and Mrs. Eva Hirnerová for cytotoxicity testing.

Appendix A. Supplementary material

CCDC 648384 and 648385 contain the supplementary crystallographic data for complexes (BohH$_2^{2+}$)[PtCl$_6$]· H$_2$O (**15**) and (RosH$_2^{2+}$)$_2$[PtCl$_6$]Cl$_2$ · 4H$_2$O (**16**), respectively. These data can obtained free of charge via htpp://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. ^{1}H and ^{13}C NMR spectral data of the free organic ligands used for the preparation

of complexes **1**–**12** are deposited as supplementary data. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.07.026.

An open-chain compound and a bridged derivative were observed as minor products with 1,3-propanediol and 1,4-butanediol, indicating that chain length was a contributing factor in determining the derivative type [4]. On the other hand, for a diol with a much longer chain length, the reaction of (**1**) with the sodium derivative of tetraethylene glycol in THF gave predominantly the *cis*-ansa macrocyclic-cyclophosphazene derivative [5]. It is of interest to investigate the reaction of (**1**) with diols that are longer than 1,4-butanediol but shorter than tetraethylene glycol. In our previous work [6] on the reaction of (**1**) with the sodium derivative of 2,2,3,3-tetrafluorobutane-1,4-diol in THF we isolated six products that involved spiro and/or ansa moieties (viz. mono-spiro, mono-ansa, bis-spiro, spiro-ansa, ansa-ansa and tris-spiro). This suggests that the reaction of $N_3P_3Cl_6$ (**1**) with 2,2,3,3,4,4-hexafluoropentane-1,5-diol (**2**) under the same solution conditions would provide a good comparison for the relative importance of ring size on the formation of spiro and ansa derivatives.

In the reaction of (**1**) with 2,2,3,3-tetrafluorobutane-1,4-diol and 2,2,3,3,4,4-hexafluoropentane-1,5-diol (**2**) in toluene in the presence of triethylamine, Ratz and co-workers [7] obtained the tri-spiro derivatives, whereas the reaction of the silyl derivatives of 2,2,3,3-tetrafluorobutane-1,4-diol, $(Me_3SiOCH_2CF_2)_2$, and 2,2,3,3,4,4-hexafluoropentane-1,5-diol (**2**), $(Me_3SiOCH_2(CF_2)_3CH_2OSiMe_3)$, with $N_3P_3F_6$ afforded the mono-spiro derivatives and derivatives of the singly-bridged compound [8]. Both these sets of results contrast with those in our previous work [6] on the reaction of $N_3P_3Cl_6$ (**1**) with 2,2,3,3-tetrafluorobutane-1,4-diol in THF in the presence of NaH, where the six products isolated resulted from only spiro and/or ansa replacements. In order to assess the importance of ring size on the formation of spiro and ansa moieties we have investigated the reaction of (**1**) with the sodium derivative of 2,2,3,3,4,4-hexafluoropentane-1,5-diol (**2**) in THF and compared the results quantitatively with those obtained previously [6] for the reaction of (**1**) with 2,2,3,3-tetrafluorobutane-1,4-diol under the same solution conditions.

2. Results and discussion

*2.1. Formation of compounds (**3**)–(**7**) and characterisation by ^1H, ^{31}P and ^{19}F NMR spectroscopy*

Cyclophosphazene (**1**) was reacted with the sodium salt of 2,2,3,3,4,4-hexafluoro-1,5-pentanediol (**2**) in THF solution under the same solution conditions as those used previously for the reaction of (**1**) with 2,2,3,3-tetrafluorobutane-1,4-diol [6]. The reaction mixture was investigated by TLC and ^{31}P NMR spectroscopy, which indicated the formation of five products, compounds (**3**)–(**7**) (Scheme 1). The crude reaction mixture was filtered to remove the sodium chloride produced and any insoluble products, such as oligomers or polymers, and then re-dissolved in $CDCl_3$ for NMR measurements. The ^{31}P NMR spectrum of the soluble portion of the reaction mixture, Fig. 1a, shows that other than the five products there are only trace amounts of any other derivatives and no starting compound (**1**) remains, i.e. it is a very clean mixture, as found previously for the reaction of (**1**) with 2,2,3,3-tetrafluorobutane-1,4-diol [6]. Compounds (**3**)–(**7**) were separated by column chromatography and characterised ^1H, ^{31}P and ^{19}F NMR spectroscopy as the mono-spiro com-

Scheme 1. The reaction of hexachlorocyclotriphosphazene with 2,2,3,3,4,4-hexafluoropentane-1,5-diol and structures of the products, compounds (**3**)–(**7**).

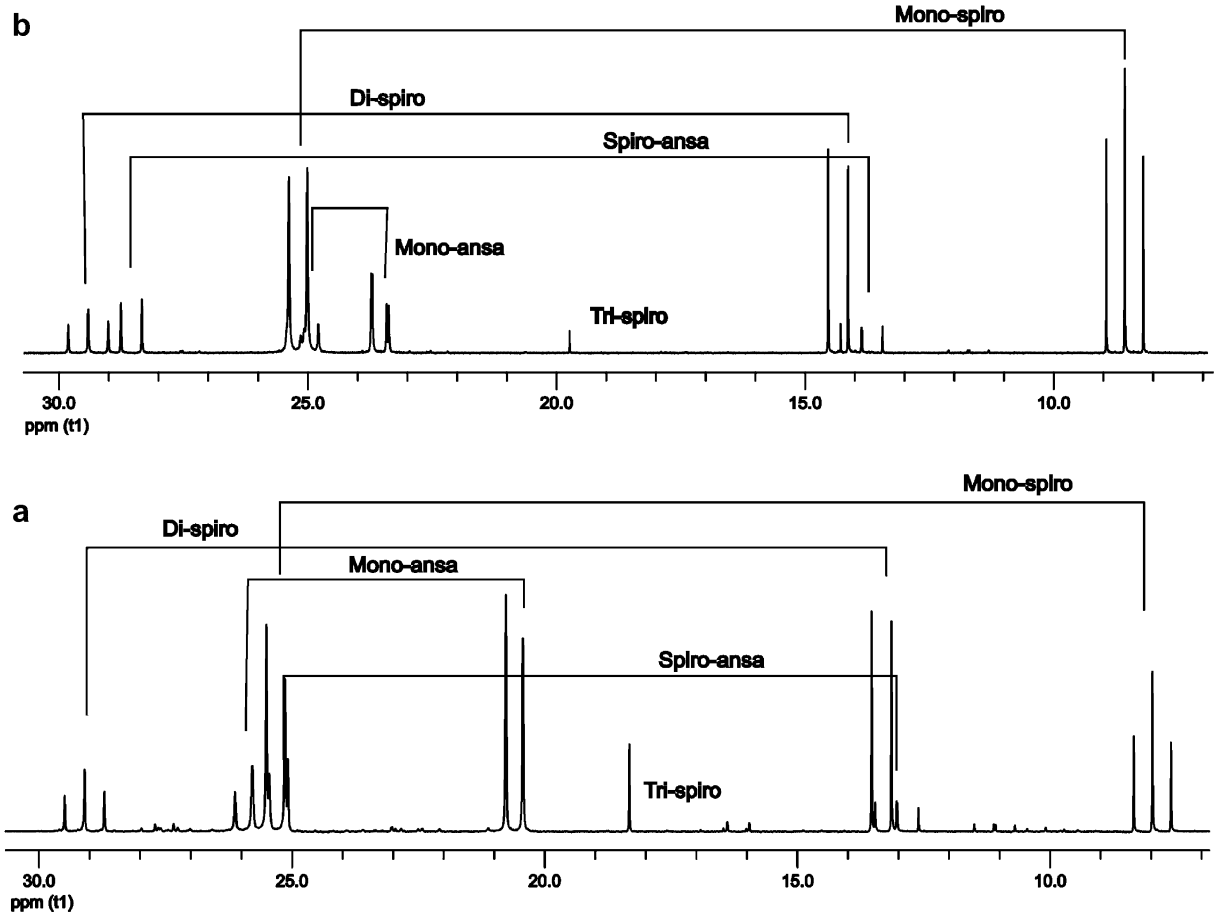

Fig. 1. ^{31}P NMR spectra of the reaction mixtures of $N_3P_3Cl_6$ (**1**) with the sodium derivatives of (a) 2,2,3,3,4,4-hexafluoro-1,5-pentanediol (**2**) and (b) 2,2,3,3-tetrafluoro-1,4-butanediol in THF solution.

pound, $N_3P_3Cl_4(OCH_2CF_2CF_2CF_2CH_2O)$ (**3**), its ansa isomer (**4**), a di-spiro derivative $N_3P_3Cl_2(OCH_2CF_2CF_2CF_2CH_2O)_2$ (**5**), its spiro-ansa isomer (**6**) and the tri-spiro compound $N_3P_3(OCH_2CF_2CF_2CF_2CH_2O)_3$ (**7**).

The ^{31}P NMR spectra of the cyclophosphazene derivatives (**3**)–(**6**), containing the spiro or ansa moieties, are observed as A_2X (or A_2B) spin systems, which can be readily assigned and analysed by comparison with their tetrafluorobutanediol analogues [6], as can the ^{31}P NMR spectrum of the tri-spiro cyclophosphazene derivative (**7**), which contains a single line. The chemical shifts and ^2J(PP) values of compounds (**3**)–(**7**) are summarised in Table 1. It can be seen that the chemical shifts reflect the number of spiro substituents in the compound, i.e. both the $\geq PCl_2$ and $\geq P(OR)_2$ chemical shifts move to high frequencies (downfield) by about 4.5–5.5 ppm per hexafluoropentanedioxy moiety, as observed for other spiro derivatives of cyclophosphazene [9]. Similarly the chemical shift of the $\geq P(OR)Cl$ group of the mono-ansa derivative (**4**) moves to a high frequency as the cyclophosphazene is further substituted with the spiro-hexafluoropentanedioxy moiety in (**6**) (Table 1).

The proton-decoupled ^{19}F NMR spectra of the spiro form of the 2,2,3,3,4,4-hexafluoro-1,5-pentanedioxy moiety of compounds (**3**), (**5**), (**6**) and (**7**) show two single signals at ca. −97.7 and −106.4 ppm, with the relative proportion of 2–1, corresponding to the $(CF_2)_2$ and (CF_2) groups, respectively. On the other hand, the proton-decoupled ^{19}F NMR spectra of the ansa ring in compounds (**4**) and (**6**) give two AB spin systems, one at ca. −93 to −96 ppm is double the intensity of the other at ca. −100 to −106 ppm, corresponding to the $(CF_2)_2$ and (CF_2) groups, respectively. The magnitudes of ^2J(FF) are in line with previous results on geminal coupling [6,10]. The ^{19}F chemical shifts and coupling constants of the products are given Table 1.

The ^{1}H NMR spectra of the ring methylene groups are observed as complex multiplets and the results are summarised with the analytical data for each compound in the section on synthesis. The ^{1}H NMR spectra of the spiro compounds (**3**), (**5**) and (**7**) have similar chemical shifts (ca. 4.5 ppm), whereas those for the mono-ansa moieties in compounds (**4**) and (**6**) are observed as two complex multiplets (ca. 4.5 and 4.9 ppm). In principle, analysis of these complex multiplets could lead to determination of the ^3J(FH) and ^3J(PH) magnitudes and so to a conformational analysis of the spiro and ansa rings, but in practice this is not feasible, partly because of the complexity of the spectra and partly because the appropriate Karplus-type

relations for ^{3}J(FH) and ^{3}J(PH) magnitudes in such cyclophosphazene derivatives are not known. However, the conformations of the spiro and ansa rings in compounds (**3**)–(**7**) in the solid state have been characterised by X-ray crystallography.

2.2. X-ray crystallographic characterisation of compounds (*3*)–(*7*)

The X-ray crystal structures are reported for compounds (**3**)–(**7**) (Figs. 2–6), appropriate crystallographic data are summarised in Table 2 and some derived molecular parameters are summarised in Table 3.

Each structure is composed of a cyclotriphosphazene core which in all cases exhibits no unusual deviations in bond lengths and angles from either that of the parent $N_3P_3Cl_6$ structure (CSD code KAGKUY) [11] or from that observed in similar structures in the Cambridge Structural Database [12]. The cyclophosphazene rings are essentially planar, in which the deviation of individual atoms from the N_3P_3 plane in all the spiro compounds derived from hexafluoropentanediol range from 0.038 to 0.132 Å, with

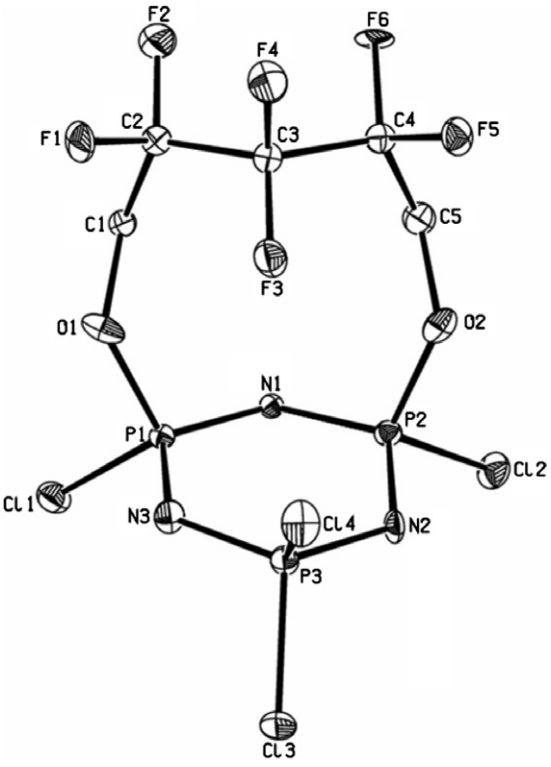

Fig. 3. X-ray crystal structure of (**4**) plotted at 50% probability. The molecular structure of (**4**) showing the atomic numbering scheme and omitting hydrogen atoms for clarity.

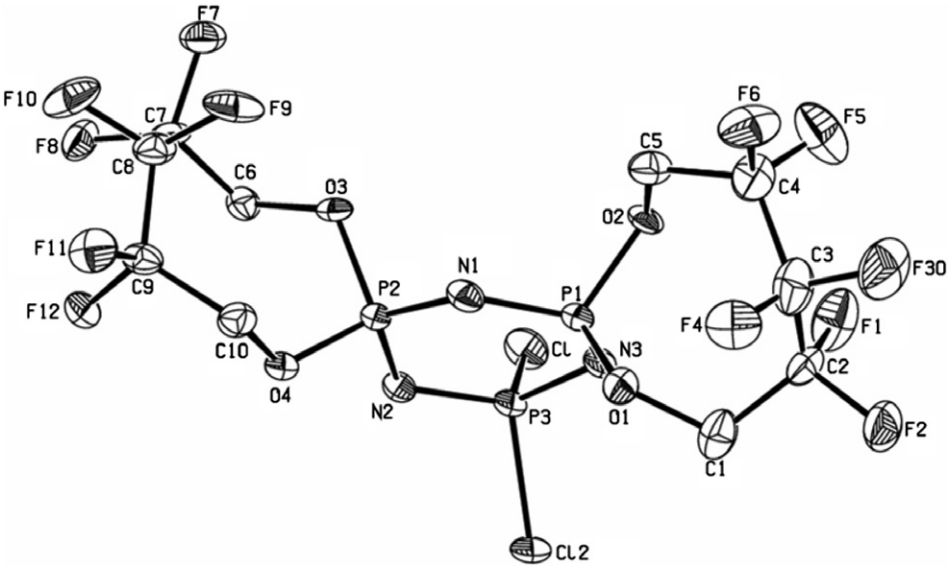

Fig. 4. X-ray crystal structure of (**5**) plotted at 50% probability. The molecular structure of (**5**) showing the atomic numbering scheme and molecular structure for one of the crystallographically independent molecules and omitting hydrogen atoms for clarity.

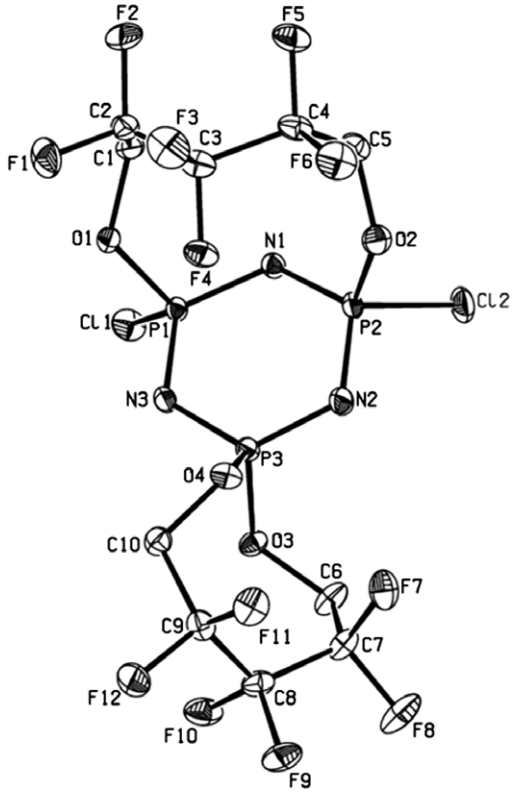

Fig. 5. X-ray crystal structure of (**6**) plotted at 50% probability. The molecular structure of (**6**) showing the atomic numbering scheme and omitting hydrogen atoms for clarity.

an average deviation of 0.092 Å (Table 3). A similar average deviation (0.107 Å) from the N_3P_3 plane was observed within experimental error for the two ansa compounds reported in Table 3. These average deviations from the N_3P_3 plane for hexafluoropentanediol derivatives are similar within experimental error to those for the analogous spiro (0.079 Å) and ansa (0.092 Å) tetrafluorobutanediol derivatives (Table 3) [6]. Unlike previous results on cyclophosphazene ansa derivatives with eight-membered rings, where the cyclophosphazene ring is strained and puckered >0.2 Å [13,14], the results summarised in Table 3 indicate that cyclophosphazene ansa derivatives with nine- and 10-membered rings are not strained and so the cyclophosphazene ring is essentially planar. The effect of different sizes of exocyclic ansa ring on the planarity of the cyclophosphazene ring is also reflected in the minimum value of the P···P distances of the cyclophosphazene ring, which is about 2.6 Å for strained eight-membered ansa compounds [13,14] but is greater than 2.7 Å for unstrained cyclophosphazene rings ([12], and Table 3). The difference in the effect of ansa compounds on the planarity of the cyclophosphazene ring is likely to reflect the higher degree of flexibility of the 16- and even the nine- and 10-membered rings compared to the eight-membered ansa ring system.

The ($OCH_2CF_2CF_2CF_2CH_2O$) moiety forms eight-membered spiro derivatives in compounds (**3**), (**5**) and (**7**), and a 10-membered ansa derivative in (**4**), whereas compound (**6**) exhibits both spiro and ansa functionality. The spiro rings in the spiro-substituted structures are all found to have similar twisted-chair conformations. It was pointed out previously [15] for 1,3-propanedioxy spiro derivatives of cyclophosphazenes that the twist of the P($OCH_2CH_2CH_2O$) spiro moiety gives a sense of chirality to the individual molecules, which has been denoted as positive (p) or negative (n) depending on the sign of the O–P–O–C dihedral angle. For such molecules the sign of the two O–P–O–C dihedral angles is the same and the magnitude of the two twist angles is very similar because the six-membered chair form is symmetrical. For the compounds measured in this work, the P($OCH_2CF_2CF_2CF_2CH_2O$) group forms an eight-membered spiro ring and it

is found that the two O–P–O–C dihedral angles have the same sign but somewhat different magnitudes (Table 3). A similar situation is found for the two O–P–O–C dihedral angles in the seven-membered P($OCH_2CF_2CF_2CH_2O$) spiro ring (Table 3) formed from the reactions of cyclophosphazene with 2,2,3,3-tetrafluorobutane-1,4-diol [6].

[a] Data adapted from Ref. [6].
[b] Maximum deviation from the mean plane of the N_3P_3 ring.
[c] τ is the twist angle defined by (a) the C–O–P–O torsion angle for the spiro ring (Ref. [15]), and (b) the C–O–P–Cl/O torsion angle for the ansa ring.

Hence, the concept of spiro rings having positive (p) or negative (n) twist angles can be applied, so far, to six-, seven- and eight-membered spiro rings. In the present work negative twist angles are observed for the mono-spiro derivative (**3**) and positive twist angles for both spiro rings of the di-spiro compound (**5**), the spiro-ansa derivative (**6**) and all three spiro rings of the tri-spiro derivative (**7**). Puckering analysis [16] is a useful measure of ring conformation, because calculation of the mean plane and puckering parameter affords a unique quantitative descriptor, the total puckering amplitude (Q), for the ring conformation. When subjected to ring puckering analysis, the spiro-substituted structures formed from hexafluoropentanediol with eight-membered rings have a total puckering amplitude, Q, in the range 0.979–1.172, with an average value of 1.086 (Table 3), which can be compared with analogous results for spiro derivatives with seven-membered rings formed from tetrafluorobutanediol, with a total puckering amplitude, Q, in the range 0.797–0.836 and an average value of 0.820 (Table 3).

The ansa hexafluoropentanediol-substituted structures in compounds (**4**) and (**6**) adopt a similar 10-membered ring conformation, which is best described as boat–chair–boat. The total puckering amplitude [16] of the ansa rings is very similar, with an average value of 1.478, which differs from that of the analogous nine-membered ansa rings (1.188, Table 3) formed from tetrafluorobutanediol.

The crystal structure assemblies of compounds (**3**)–(**7**) are very complex, probably as a result of the molecular structure of these compounds, where there are very few classical hydrogen bond donors or acceptors. The structures of (**3**), (**6**) and (**7**) possess a single classical hydrogen bond (C–H···O), which generates a chain structure, whilst structures (**4**) and (**5**) exhibit no classical hydrogen bonds. Apart from the structure of (**4**), there are many short contacts where the separation between donor and acceptor is less than 3.2 Å. These separations are predominantly between halogen atoms and it is currently the subject of much debate (see [17] and references therein) as to whether these give rise to interactions or are simply a result of the close packing of molecules.

2.3. Quantitative analysis of the formation of spiro and ansa derivatives in the reactions of $N_3P_3Cl_6$ with tetraflurobutanediol and hexafluoropentanediol

The relative proportions of the products in the reactions of $N_3P_3Cl_6$ (**1**) with either tetrafluorobutanediol or hexafluoropentanediol under the same solution conditions (sodium alkoxides in THF at ambient temperature) have been compared in terms of both the isolation of the pure compounds and ^{31}P NMR spectra of the filtered reaction mixtures (Fig. 1). The results are summarised in Table 4 for a 1:1.2 molar ratio of (**1**) to diol. In general it can be seen that there is a similar range of spiro and ansa derivatives (mono-spiro, mono-ansa, di-spiro, spiro-ansa and tri-spiro), except that a small amount of the ansa-ansa compound was observed for the reaction of (**1**) with tetrafluorobutanediol [6]. In reactions of (**1**) with the sodium

salts of diols there is a significant proportion of ansa as well as spiro compound(s).

There are some discrepancies in the relative proportions of the compounds that have been isolated or quantified by the ^{31}P NMR spectra of the reaction mixtures (Table 4). The yields of the compounds were given as the amount of very pure product obtained. In our previous work on the reaction of (**1**) with tetrafluorobutanediol, it was found that the relative proportions of isolated products decreased in the sequence spiro > ansa > di-spiro > spiro-ansa > ansa-ansa [6], such that the spiro derivatives were more prevalent than the ansa derivatives (in a molar ratio of about 2.1:1), whereas in the reaction of (**1**) with hexafluoropentanediol in this work, it was found that the relative proportions of isolated products decreased in the sequence ansa > spiro > di-spiro > spiro-ansa > tri-spiro, such that the ansa and spiro derivatives were in about equal proportions (in a molar ratio of about 1.2:1; Table 4). The differences in relative proportions of the isolated compounds are mainly due to the proportions of the mono-spiro and mono-ansa compounds for the two diols with cyclophosphazene (Table 4), suggesting that the 10-membered ansa ring formed with hexafluoropentanediol is more stable than the nine-membered ansa ring formed with tetrafluorobutanediol. However, care should be taken in forming conclusions based on the relative proportions of the isolated compounds, unless one can account for all the products of the reaction. In the present case, the overall yield of the reaction of (**1**) with tetrafluorobutanediol is 55% [6] and it is only 39% for the reaction of (**1**) with the hexafluoropentanediol. The same sets of reactions were observed by ^{31}P NMR spectroscopy for the filtered reaction mixtures of (**1**) with both tetrafluorobutanediol and hexafluoropentanediol (Fig. 1). The ^{31}P NMR results (Table 4) show similar trends to those obtained for the isolated compounds, though the differences between the relative proportions of mono-spiro and mono-ansa compounds are not as marked, leading to a smaller difference in the ratio of spiro:ansa compounds for hexafluoropentanediol (ca. 1.3:1) compared to tetrafluorobutanediol (ca. 1.5:1). Nevertheless, the ^{31}P NMR results on the reaction mixtures also show that there is a small increase in the relative proportion of ansa compounds for the reaction of (**1**) with hexafluoropentanediol compared to tetrafluorobutanediol, which has one less CF_2 group in the chain and so forms smaller rings. The relative proportions of spiro and ansa compounds depends on the fine balance in stabilities of the different medium-sized rings in the fluorinated pentanediol (spiro, 8- and ansa, 10-membered rings) compared to the fluorinated butanediol (spiro, 7- and ansa, nine-membered rings) derivatives of cyclophosphazene.

3. Experimental section

3.1. Materials

Hexachlorocyclotriphosphazene was purified by fractional crystallisation from hexane. Sodium hydride, 60% dispersion in mineral oil (Merck) was removed by washing with dry heptane (Merck) followed by decantation. Hexane, heptane (Merck) and 2,2,3,3,4,4-hexafluoro-1,5-pentanediol (Aldrich) were used as received. THF was distilled over a sodium–potassium alloy under an atmosphere of dry argon. Silica gel (Merck 60, 0.063–0.200 mm) was used for column chromatography. All reactions were performed under a dry argon atmosphere.

3.2. Methods

Elemental analyses were obtained using a Carlo Erba 1106 Instrument. Mass spectra were recorded on a Bruker MicrOTOF LC–MS spectrometer using the electrospray ionisation (ESI) method; ^{35}Cl values were used for calculated masses. Analytical thin layer chromatography (TLC) was performed on Merck Silica gel plates (Merck 60, 0.25 mm thickness) with F_{254} indicator. Column chromatography was performed on silica gel (Merck 60, 0.063–0.200 mm; for 3 g crude mixture, 120 g silica gel was used in a column of 3 cm in diameter and 110 cm in length). ^{1}H, ^{19}F and ^{31}P NMR spectra were recorded for $CDCl_3$ solutions on a Bruker DRX 500 MHz spectrometer

[a] The diols were reacted with (**1**) in a 1.2:1 molar ratio with NaH in THF solution.
[b] The ^{31}P NMR measurements for quantisation were performed with a 45° pulse, a recycle time of 6.4 s and without NOE to allow for full relaxation of the signals.

using TMS as an internal reference for ^{1}H, $CFCl_3$ as an internal reference for ^{19}F and 85% H_3PO_4 as an external reference for ^{31}P. In order to assign the signals of some compounds both proton-coupled and proton-decoupled ^{19}F and ^{31}P NMR spectra were recorded.

3.3. Reaction of hexachlorocyclotriphosphazene (*1*) with 2,2,3,3,4,4-hexafluoro-1,5-pentanediol (*2*)

Cyclophosphazene (**1**) (3.48 g, 10 mmol) and 2,2,3,3,4,4-hexafluoro-1,5-pentanediol (**2**) (2.54 g, 12 mmol) were dissolved in 170 mL of dry THF in a 250 mL three-necked round-bottomed flask. The reaction mixture was cooled in an ice-bath and NaH (60% oil suspension, 1.1 g, 24 mmol) in 30 mL of dry THF was quickly added to the stirred solution under an argon atmosphere. The reaction mixture was stirred for 72 h at room temperature and the reaction was followed on TLC silica gel plates using hexane–DCM (4:1), giving five new products. The reaction mixture was filtered to remove the sodium chloride and any other insoluble material such as oligomeric and polymeric products. The solvent was removed at reduced pressure and the resulting colourless oil was subjected to column chromatography, using hexane–DCM (4:1) as the eluant. The first product is the mono-spiro derivative $[N_3P_3Cl_4(OCH_2CF_2CF_2CF_2CH_2O)]$ (**3**) (0.5 g, 10%, mp 70 °C). *Anal.* Calc. for $C_5H_4Cl_4F_6N_3O_2P_3$ (M, 485): C, 12.34; H, 0.83; N, 8.63. Found (M^+, 485.9): C, 12.38; H, 0.89; N, 8.57%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.52 ppm, 4H, $(OCH_2)_2$, ^{3}J(POCH) 16.0 Hz. The second product is the mono-ansa derivative $[N_3P_3Cl_4(OCH_2CF_2CF_2CF_2CH_2O)]$, (**4**) (0.87 g, 18%, mp 152 °C). *Anal.* Calc. for $C_5H_4Cl_4F_6N_3O_2P_3$ (M, 485): C, 12.34; H, 0.83; N, 8.63. Found (M^+, 485.9): C, 12.30; H, 0.81; N, 8.59%. ^{1}H NMR, $CDCl_3$, 298 K; complex AB multiplet, 4.50 ppm, 2H, (OCH_{2A}) and 4.86 ppm, 2H, (OCH_{2B}). The third separated product is the bis-spiro derivative $[N_3P_3Cl_2(OCH_2CF_2CF_2CF_2CH_2O)_2]$ (**5**) (0.25 g, 4%, mp 87 °C). *Anal.* Calc. for $C_{10}H_8Cl_2F_{12}N_3O_4P_3$ (M, 625): C, 19.19; H, 1.29; N, 6.71. Found (M^+, 625.9): C, 19.22; H, 1.30; N, 6.68%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.49 ppm, 8H, $2\times(OCH_2)_2$. The fourth product is the spiro-ansa derivative $[N_3P_3Cl_2(OCH_2CF_2CF_2CF_2CH_2O)_2]$ (**6**) (0.18 g, 3%, mp 110 °C). *Anal.* Calc. for $C_{10}H_8Cl_2F_{12}N_3O_4P_3$ (M, 625): C, 19.19; H, 1.29; N, 6.71. Found (M^+, 625.9): C, 19.18; H, 1.32; N, 6.75%. ^{1}H NMR, $CDCl_3$, 298 K; complex AB multiplet, 4.49 ppm, 2H, (OCH_{2A}) and 4.89 ppm, 2H, (OCH_{2B}) and complex multiplet, 4.49 ppm, 4H, spiro-$(OCH_2)_2$, ^{3}J(POCH) 16.0 Hz. The fifth product is the tri-spiro derivative $[N_3P_3(OCH_2CF_2CF_2CF_2CH_2O)_3]$ (**7**) (0.09 g, 1%, mp 245 °C); *Anal.* Calc. for $C_{15}H_{12}F_{18}N_3O_6P_3$ (M, 765): C, 23.55; H, 1.58; N, 5.49. Found (M^+, 766): C, 23.55; H, 1.50; N, 5.45%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.46 ppm, 12H, $(OCH_2)_3$. All products were crystallised from hexane–DCM (4:1) and were obtained as white crystals.

3.4. X-ray crystallography

Intensity data were recorded on a Nonius KappaCCD diffractometer driven by COLLECT [18] and DENZO [19] software. Details of data collection and refinement are given in Table 2. X-ray crystallographic data for structure (**5**) was collected on a Bruker SMART area detector situated on the beam-line of station 9.8 at the Daresbury Synchrotron Radiation Source [20]. Structures were determined using the direct methods procedure in SHELXS-97 and refined by full-matrix least squares on F^2 using SHELXL-97 [21].

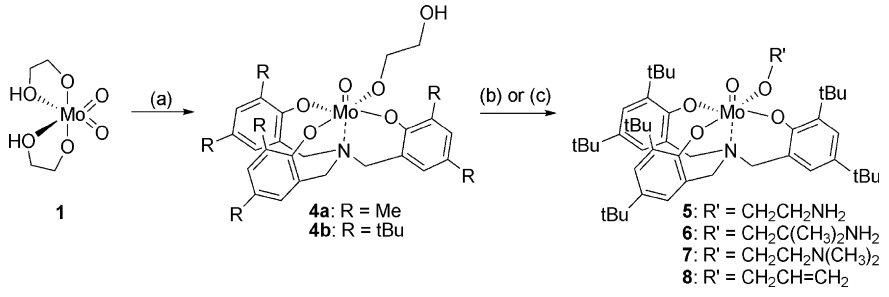
heated to reflux temperature while liberated H_2eg was removed by azeotropic distillation (Scheme 1a). Consequently, the reactions went on efficiently, the colourless mixtures turning rapidly purple solutions. Evaporation of toluene solvent followed by purification by column chromatography on silica gel afforded air-stable molybdenum(VI) compounds as purple solids. The reaction of H_3L^{tBu} produced complex **4b** almost quantitatively, but the reaction involving H_3L^{Me} led also to the formation of some intractable dark solids, therefore **4a** could be isolated in only a moderate yield of 37%. Both crystalline materials are soluble in toluene, ethers and chlorinated solvents though *tert*-butyl derivatives are more soluble than their methyl analogues. The NMR spectra of studied compounds show similar resonances for coordinated aminotris(phenolato) and hydrogendiolato ligands as found for analogous oxotungsten(VI) complexes $[WO(L^R)(Heg)]$ [10a]. The X-ray structure determination of **4b** confirmed that the aminotris(phenolate) has been bonded as a tetradentate, trianionic ligand, whereas the ethanediolato ligand is monoanionic and monodentate (see below).

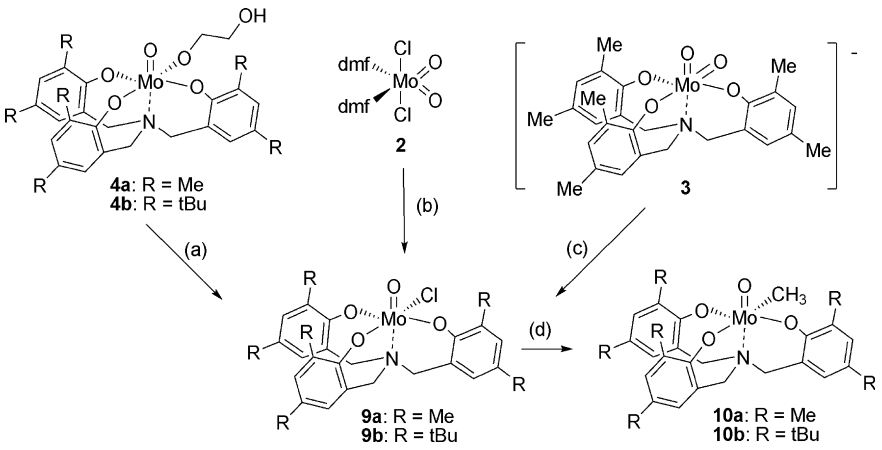
The overall mechanism for the formation of these monooxo complexes includes an alcoholysis of one of the $Mo–O_{diolato}$ bonds as well as a condensation of one of the Mo=O bonds. Based on the literature examples [13] on the related reactions of $[MoO_2Cl_2]$, we may suggest that in the first step the ligand H_3L^R is coordinated to the $MoO_2(Heg)_2$ unit as a neutral nitrogen donor, which process is subsequently followed by an alcoholysis reaction and elimination of a H_2eg molecule. Then, the reaction proceeds via an addition of one of the remaining OH functions across the Mo=O bond to form an intermediate $MoO(OH)(Heg)(HL^R)$, which then reacts to eliminate water and produce the final product.

2.2. Preparation of alkoxide complexes $[MoO(L^{tBu})(OR')]$



The reaction of complex **4b** with high-boiling aminoalcohols in refluxing toluene yields readily new aminoalkoxide derivatives **5**–**7**. The ligand displacement reactions were promoted using the excess of aminoalcohol, while the liberated 1,2-ethanediol was distilled out as a toluene azeotrope. These air-stable purple products are soluble in common organic solvents. All complexes can be isolated by column chromatography followed by crystallization from hot acetonitrile. Compound **8** could not be prepared similarly since allyl alcohol has a lower boiling point than H_2eg-PhMe azeotrope. However, it was formed almost quantitatively in the reaction of **4b** in neat allyl alcohol at reflux temperature.

2.3. Preparation of complexes $[MoO(L^R)Cl]$ and $[MoO(L^R)(Me)]$



Metal alkoxide moieties can be transformed into halides by various substitution reactions [14]. In present study, Me_3SiCl was used as a chlorinating reagent. Intense blue mixtures were obtained when purple solutions of **4** in CH_2Cl_2 were treated with a five-fold excess of Me_3SiCl (Scheme 2a). As a result, complexes **9** were produced as only isolable products in nearly quantitative yields. The NMR spectra of products **9** confirmed the loss of ethanediolato group presenting typical signals for aminotris(phenol) ligands. These intense blue, air-stable solids are soluble in common organic solvents. The IR and NMR data of complexes **9** are closely similar to those recorded earlier for their tungsten analogues [10a]. The molecular structure of **9b** was also verified by X-ray diffraction (see below).

In the alternative syntheses of complexes **9**, the stirred suspensions of finely ground $[MoO_2Cl_2(dmf)_2]$ in toluene were treated with stoichiometric amounts of the ligand precursors H_3L^R (Scheme 2b), while the mixtures were heated at reflux temperature. Filtration of the reaction mixture through a short pad of silica was followed by the evaporation of toluene solvent, which afforded new molybdenum compounds **9** in nearly quantitative yields.

The silylation of Mo=O moieties with Me_3SiCl in toluene has proved a convenient procedure for the chloride-for-oxide substitution of dioxomolybdenum(VI) complexes. [15–17] Accordingly, the reaction of a yellow solid compound $H_4L^{Me}[MoO_2(L^{Me})]$ [10b] with Me_3SiCl in a toluene suspension at reflux temperature led to the formation of a dark blue solution, from which the monooxo complex **9a** was obtained (Scheme 2c). In principle, this reaction can be a direct silylation of a M=O group, but as proton sources (e.g. H_4L^{Me+} cation and traces of water)

Scheme 1. Preparation of complexes $[MoO(L^R)(Heg)]$ and $[MoO(L^{tBu})(OR')]$. Conditions: (a) H_3L^R, toluene, reflux, 4 h. (b) HOR′ (excess), toluene, reflux, 6 h (for **5**–**7**). (c) HOR′ (neat), reflux, 6 h (for **8**).

Scheme 2. Preparation of complexes [MoO(L^R)Cl] and [MoO(L^R)(Me)]. Conditions: (a) Me_3SiCl, CH_2Cl_2, reflux, 2 h. (b) H_3L^R, PhMe, reflux, 18 h. (c) Me_3SiCl, PhMe, reflux, 2 h. (d) MeMgI/Et_2O, PhMe, RT, 1 h.

are present, it is also possible that the actual reacting species is in situ generated HCl.

The methyl complexes **10** were readily prepared from corresponding chloride complexes by treating with Grignard reagent (Scheme 2d). As soon as an etheral solution of MeMgI was added to the intense blue solutions of chlorido complexes in toluene, the reaction mixtures turned rapidly purple. The products were purified by column chromatography to obtain air-stable purple-red solids, which are reasonably soluble in toluene, ether and chlorinated solvents. ^{1}H NMR spectra of methyl compounds in $CDCl_3$ show signals at 0.57 ppm (**10a**) and 0.59 ppm (**10b**) for Mo–CH_3 protons, whereas related signals in ^{13}C NMR spectra are seen at 42.78 ppm and 42.93 ppm for **10a** and **10b**, respectively. Although studied methyl derivatives are rather stable towards hydrolysis in a solid state, they seem to hydrolyse slowly in solutions, acidic impurities hastening this decomposition. When the red toluene solutions of methyl complexes were treated with gaseous HCl under non-aqueous conditions the solutions turned dark blue in two hours, since initial chlorido complexes were formed nearly quantitatively due to the chlorination of a Mo–C bond.

2.4. Structural studies

Molecular structures of complexes **4b**, **7** and **9b** were verified by X-ray diffraction analyses. Studied complexes are formed of monomeric, neutral units in which the tripodal aminotris(phenolate) group has coordinated to the cen-

$R_1 = \sum||F_o| - |F_c||/\sum|F_o|$.
$wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$ and $w = 1/[\sigma^2(F_o^2) + (aP)^2 + (bP)]$, where $P = (2F_c^2 + F_o^2)/3$.

[a] Values in parentheses for reflections with $I > 2.0\sigma(I)$.

tral molybdenum as a tetradentate ligand through three oxygen donors and one nitrogen donor (Figs. 1–3), thus overall bonding between the metal centres and the amino-tris(phenolato) is typical for this ligand. The nitrogen donor is located *trans* to the terminal oxo group, while the sixth coordination site is occupied by a monoanionic, monodentate alcoholate ligand (**4b** and **7**) or by chlorido ligand (**9b**). The distorted octahedral MoO_5N units are

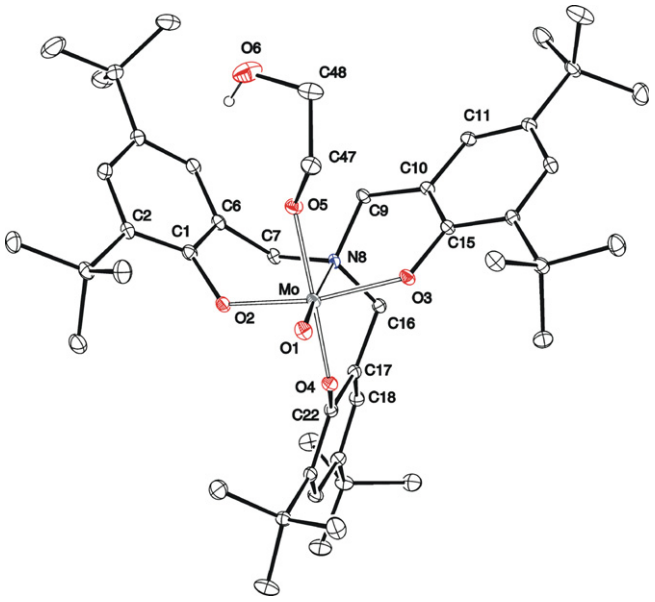

Fig. 1. Molecular structure of [MoO(L^{tBu})(Heg)] (**4b**). Thermal ellipsoids have been drawn at the 30% probability level. The hydrogen atoms are omitted for clarity.

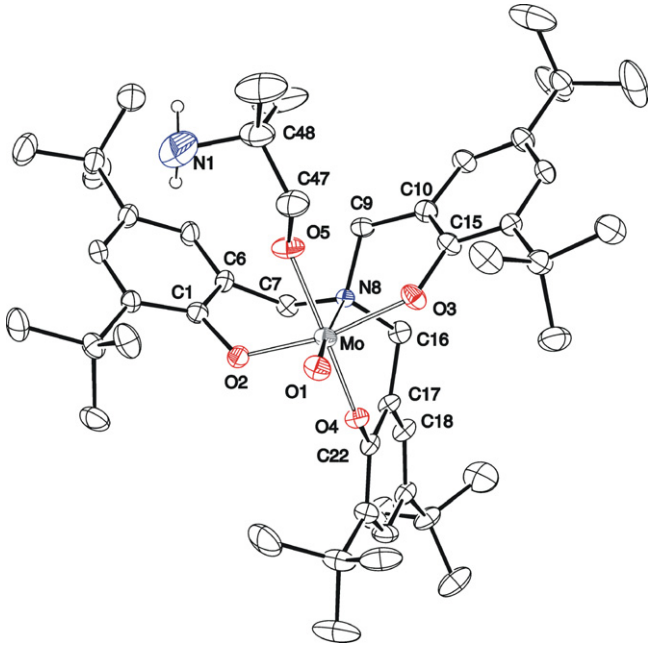

Fig. 2. Molecular structure of [MoO(L^{tBu})($OCH_2C(CH_3)_2NH_2$)] (**7**). Thermal ellipsoids have been drawn at the 30% probability level. The C–H hydrogen atoms are omitted for clarity.

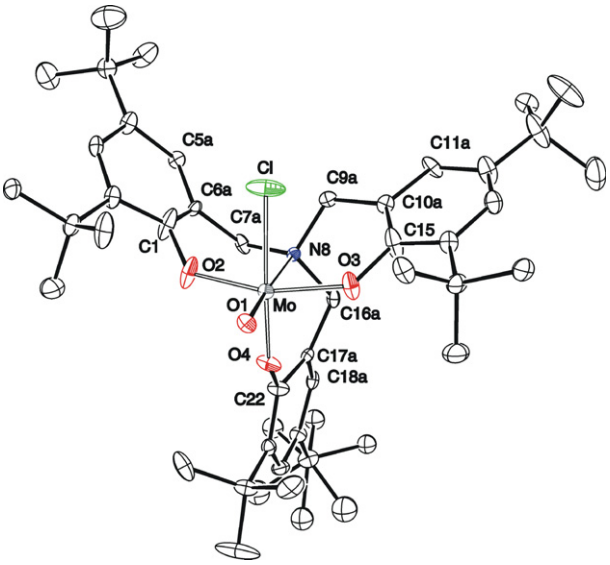

Fig. 3. Molecular structure of the main conformer of [MoO(L^{tBu})Cl] (**9b**). Thermal ellipsoids have been drawn at the 30% probability level. The hydrogen atoms are omitted for clarity. One of the *tert*-butyl groups is disorder almost in 1:1 ratio – the amount of two different rotamers is 56.6% and 43.4%, respectively.

generally similar in complexes **4b** and **7** as indicated by the bond parameters presented in Table 2, whereas Mo–$O_{phenoxide}$ bonds are clearly shorter in the chlorido derivative **9b**. In general, studied structures are closely related to the oxotungsten(VI) complexes with the very same atrane ligand [10a]. Especially **4b**, [Mo(L^{tBu})(Heg)], is isostructural with the tungsten analogue [WO(L^{tBu})(Heg)], as a result the unit cell and all bonding parameters are closely similar in these two complexes. However, the terminal Mo–O1 distances in **4b** and **7** (1.6842(18) and 1.684(3) Å, respectively) are clearly shorter than the corresponding W–O distance in [WO(L^{tBu})(Heg)] (1.706(2) Å).

Compound **9b** adopts a disorder structure in the solid state (see Supplementary material). The tris(benzyl)amino

fraction of the molecule can rotate around the N–Mo=O axis therefore part of the molecule can have two similar conformations in the ratio of 2:1. The Mo–$O_{phenoxide}$ distances are noticeably shorter than in analogous alkoxide complexes **4b** and **7** while the Mo–Cl bond is obviously longer than corresponding Mo–$O_{alkoxide}$ bond.

3. Conclusions

In conclusion, we have found that the dioxomolybdenum(VI) complex $[MoO_2(Heg)_2]$ (Heg = 1,2-ethanediolato monoanion) reacts in refluxing toluene solution with phenolic ligand precursors tris(2-hydroxy-3,5-dimethylbenzyl)amine (H_3L^{Me}) and tris(2-hydroxy-3,5-di-*tert*-butylbenzyl)amine (H_3L^{tBu}) to form oxomolybdenum(VI) complexes $[MoO(L^{Me})(Heg)]$ and $[MoO(L^{tBu})(Heg)]$, respectively. The labile Heg ligands can be replaced by other alcohols (i.e. 2-aminoethanol, 2-amino-2-methylpropan-1-ol, 2-(dimethylamino)ethanol or allyl alcohol) in the reaction at refluxing toluene. Complexes $[MoO(L^R)(Heg)]$ undergo chloride-for-alkoxide substitution when treated with Me_3SiCl in CH_2Cl_2, which leads to the formation of corresponding chlorido complexes $[MoO(L^{Me})Cl]$ and $[MoO(L^{tBu})Cl]$. Identical chlorido complexes can also be made by the reaction these phenolic ligand precursors with $[MoO_2Cl_2(dmf)_2]$. Chloridocomplexes $[MoO(L^R)Cl]$ can react with MeMgI to yield air-stable monomethyl derivatives $[MoO(L^R)(Me)]$.

4. Experiments

Starting compounds $[MoO_2(Heg)_2]$, $[MoO_2Cl_2(dmf)_2]$, H_4L^{Me}[$MoO_2(L^{Me})$] [12,18,10b] and ligand precursors H_3L^R [19] were synthesised and purified according to the published procedures. Other chemicals and solvents were obtained from commercial sources and used as purchased. Syntheses of organometallic compounds were done under N_2-atmosphere, other syntheses and manipulations were carried out under ambient laboratory conditions. ^1H NMR (400 MHz) and ^{13}C spectra (100 MHz) were recorded in $CDCl_3$ solutions and were referenced to the solvent residue signal.

4.1. Reaction of $[MoO_2(Heg)_2]$ with aminotris(phenol)s

Molybdenum precursor **1** (250 mg, 1.00 mmol) was heated with one equivalent of H_3L^{Me} (420 mg) or H_3L^{tBu} (672 mg) in 50 ml of toluene at reflux temperature for 4 h to form a purple solution. The H_2eg and water that formed during the reactions were removed as a toluene azeotrope. Remaining solvent was evaporated and a purple solid residue was purified by a silica column chromatography using CH_2Cl_2 as an eluent.

Found: C, 57.64; H, 5.03; N, 2.68%.

4.4.2. [MoOCl(L^{tBu})] (**9b**)

Yield: 183 mg (89%). IR: 1366 m, 1262 m, 1240 vs, 1204 s, 1171 vs, 1126 w, 1070 w, 954 vs, 931 s, 914 s, 874 vs, 849 vs, 806 m, 760 m, 735 w, 694 w, 601 m, 578 m, 553 m cm^{-1}. ^1H NMR ($CDCl_3$): δ 7.30 (1H, *ArH*), 7.20 (2H, *ArH*), 7.04 (1H, *ArH*), 6.90 (2H, *ArH*), 3.94–3.45 (several broad peaks, 6H, ArC*H*$_2$–N), 1.48 (9H, C(C*H*$_3$)$_3$), 1.39 (18H, C(C*H*$_3$)$_3$), 1.21 (27H, C(C*H*$_3$)$_3$). ^{13}C NMR ($CDCl_3$): δ 158.10, 147.26, 146.50, 139.89, 139.35, 128.23, 127.50, 125.21, 124.58, 123.83, 123.62, 60.58, 35.58, 34.89, 34.86, 31.74, 30.65, 30.52. *Anal.* Calc. for $C_{45}H_{66}ClMoNO_4$: C, 66.07; H, 8.14; N, 1.71. Found: C, 65.84; H, 8.03; N, 1.68%.

4.5. Reaction of $[MoO_2Cl_2(dmf)_2]$ with aminotris(phenol)s

1.00 mmol (345 mg) of milled $[MoO_2Cl_2(dmf)_2]$ and 1.00 mmol of a ligand precursor were mixed with 30 ml of PhMe and the stirred suspension was heated to the reflux temperature for 18 h. Resulting intense blue solution was filtered through a short pad of silica and evaporated to yield complexes [MoO(L^R)Cl] as dark blue solids in 535 mg (95%) and 745 mg (91%) yields for **9a** and **9b**, respectively.

4.5.1. Alternative preparation of **9a**

0.25 mmol (241 mg) of H_4L^{Me}[MoO_2(L^{Me})] was suspended in 20 ml of toluene and subsequently treated with 1.6 mmol (0.20 ml) of Me_3SiCl. The stirred reaction mixture was heated to the reflux temperature for 2 h, cooled and then filtered through a short pad of silica and evaporated to yield 90 mg (63%) of dark solid, which had identical IR and ^1H NMR spectra as described above.

4.6. Preparation of methyl complexes

To the solution of chlorido complex **9** (0.50 mmol) in 30 ml of anhydrous toluene was added a solution of freshly prepared MeMgI (ca. 1 mmol) in diethyl ether (1 ml). The reaction mixture was stirred for an hour at room temperature while the reaction was monitored by TLC. A red product that formed was purified by a silica column chromatography using a hexane–toluene mixture (1:1) as an eluent.

4.6.1. [MoO(Me)(L^{Me})] (**10a**)

Yield: 156 mg (57%). IR: 1248 s, 1238 vs, 1221 vs, 1159 s, 1076 w, 1134 w, 951 vs, 935 m, 899 w, 858 s, 843 s, 833 s, 752 m, 727 w, 694 m, 561 m cm^{-1}. ^1H NMR ($CDCl_3$): δ 6.91 (1H, *ArH*), 6.85 (2H, *ArH*), 6.71 (1H, *ArH*), 6.64 (2H, *ArH*), 3.56–3.24 (6H, overlapping broad peaks, ArCH_2–N), 2.33 (3H, Ar-CH_3), 2.20–2.15 (15H, overlapping singlets, Ar-CH_3) 0.57 (3H). ^{13}C NMR ($CDCl_3$): δ 154.74, 132.95, 131.61, 131.25, 131.07, 129.25, 129.18, 128.62, 128.44, 128.21, 127.67, 126.13, 60.62, 60.08, 42.78, 21.00, 20.96, 16.67, 16.60. *Anal.* Calc. for $C_{28}H_{33}MoNO_4$: C, 61.63; H, 6.10; N, 2.57. Found: C, 61.53; H, 5.97; N, 2.48%.

4.6.2. [MoO(Me)(L^{tBu})] (**10b**)

Yield: 220 mg (69%). IR: 1264 m, 1240 vs, 1204 s, 1170 vs, 1125 w, 1071 w, 954 vs, 912 s, 874 s, 865s, 849 vs, 807 m, 760 m, 694 w, 601 m, 578 m, 553 m cm^{-1}. ^1H NMR ($CDCl_3$): δ 7.27 (1H, *ArH*), 7.20 (2H, *ArH*), 7.00 (1H, *ArH*), 6.89 (2H, *ArH*), 3.99–2.28 (several broad peaks, 6H, ArCH_2–N), 1.47 (9H, C(CH_3)$_3$), 1.34 (18H, C(CH_3)$_3$), 1.21 (27H, C(CH_3)$_3$). ^{13}C NMR ($CDCl_3$): δ 154.94, 144.43, 140.07, 129.26, 128.66, 128.55, 128.51, 126.13, 124.90, 123.80, 123.62, 60.68, 42.93, 35.54, 35.49, 34.78, 34.74, 32.15, 31.83, 31.75, 30.46, 30.31, 29.93, 29.89, 29.59, 22.92. *Anal.* Calc. for $C_{46}H_{69}MoNO_4$: C, 69.22; H, 8.72; N, 1.76. Found: C, 68.94; H, 8.55; N, 1.48%.

4.7. Reactions of [MoO(Me)(L^R)] with HCl

0.050 mmol of complexes **10a** (27 mg) or **10b** (40 mg) were dissolved in 3.0 ml of toluene in screw cap vials and subsequently treated with gaseous HCl (bubbled slowly through the reaction mixture for 1 min). The toluene solutions were then stored at room temperature for 2 h. The blue complexes that formed were separated by silica column chromatography using a hexane–toluene mixture (70:30) as an eluent to obtain 24 mg (85%) of **9a** and 38 mg (93%) of **9b**, respectively.

4.8. X-ray crystallography

The single crystals of complexes **4b**, **7** and **9b** were obtained from acetonitrile solutions upon slow cooling. The crystal data for the compounds are summarized in Table 1. The crystallographic data were collected at 173 K on an Enraf Nonius Kappa CCD area-detector diffractometer using graphite monochromatized Mo K_α radiation ($\lambda = 0.71073$ Å). Data collection was performed using φ and ω scans and the data processed using *DENZO-SMN v0.93.0* [20]. SADABS[21] absorption correction was applied to the data of all compounds. The structures were solved by direct methods using the SHELXS-97 program [22] and full-matrix least-squares refinements on F^2 were performed using the SHELXL-97 program [22]. Compound **9b** crystallized in a chiral space group ($P2_12_12_1$ (19)), so it could be resolved as a racemic twin or as a disordered structure having two orientations of the ligand. The absolute structure given by the structural refinement seems to be correct as suggested by the Flack parameter of 0.03 (7) [23]. The structure of **9b** was finally refined using a split-atom model. For compounds **4b** and **7** the heavy atoms were refined anisotropically and for **9b** the heavy atoms were refined anisotropically and isotropically due to the disorder. The CH hydrogen atoms were included at fixed distances using fixed displacement parameters from their host atoms whilst other H atoms were refined using fixed displacement parameters. Structure figures were drawn using *Ortep-3* for *Windows* [24].

Appendix A. Supplementary material

CCDC 651324, 651325 and 632882 contain the supplementary crystallographic data for **4b**, **7** and **9b**. The data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.07.036.

thiohydroxamic acids are unsymmetrical bidentate ligands, *cis* (C_{2v}) and *trans* (C_{2h}) geometrical isomers are possible for square planar bis complexes [6]. Coloured complexes of thiohydroxamic acids have found application in analytical chemistry for spectrophotometric and gravimetric determination of metals [7]. *N*-Hydroxypyridine-2-thione complexes with Mn(II), Ni(II), Fe(III) and Co(III) can be used for simulation of the action of cysteinyl metalloenzymes [8], while the vanadyl VO^{2+} complexes can act as effective insulin enhancing agents [9], *N*-methylthiobenzohydroxamic acid complexes with dioxomolybdenum(VI) can be used for investigations of active redox enzymes such as xanthine oxidase and sulfide oxidase [10]. Ferric and lead complexes have been used in chelation therapy of iron overload [11] and lead poisoning [12] in humans and animals.

Several voltammetric studies of thiohydroxamic acid complexes have been described. As shown by the X-ray method in a series of mononuclear Co(II) complexes with phosphine or pyridine, the cobalt ion is in a square pyramidal environment with *trans*-oriented *N*-hydroxypyridine-2-thione ligands in the basal plane position [7]. *N*-Hydroxypyridine-2-thione complexes ML_2 and ML_3 [M = Mn(II), Ni(II), Fe(III), Co(III)] have been of interest for the simulation of cysteinyl metalloenzymes. Therefore, Co(II) complexes were investigated by cyclic voltammetry [7], showing two reversible processes following a one-electron change. The complex of Ni(II), which is unstable in air, has the nickel atom in the centre of a S_2O_2 square plane, with the two organic ligands in the *cis* configuration [7].

In this paper, we limit ourselves to bis complexes of *N*-methyl-*N*-thioformylohydroxylamine (*N*-methylthioformohydroxamic acid), customarily called thioformin. This is a bioligand that plays an important role in Fe(III) ion transport through cell membranes to cells of algae, fungi and bacteria. This function is usually carried out by hydroxamic acids, and thioformin appears to be the only thiohydroxamic acid siderophore discovered to date. *Pseudomonas fluorescens* produces two antibiotics, fluopsin C and fluopsin F, which are complexes of Cu(II) and Fe(III), respectively. These exhibit high biological activity in relation to both Gram-positive and Gram-negative bacteria. Thioformin probably acts as a siderophore, but one can presume that it transports copper ions to the cell. The kinetic lability of bis(*N*-methylthioformohydroxamato) Cu(II) and Fe(III) complexes (fluopsin C and F) precludes the isolation of *cis* and *trans* geometrical coordination isomers. As a first step in probing the mechanism of the antibiotic action of thioformin metal complexes, we began this investigation of their coordination chemistry. We have investigated the properties of the square planar complexes of *N*-methylthioformohydroxamic acid with some divalent metals. These labile complexes of thioformin display antibiotic activity against *Escherichia coli* NIHJ [13,14].

The antibiotic YC73 was found to be the cupric complex of thioformin [15], and this was named fluopsin C. Egawa et al. [14] and Shirahata et al. [16] synthesized a number of other analogues, including ones whose properties have been studied here. Fluopsin CA, N and Z are, respectively, the Ca(II), Ni(II) and Zn(II) bis complexes of thioformin. Fluopsin C, the corresponding Cu(II) complex, is also known as antibiotic YC73, or antibiotic B_1. It displays a broad-spectrum of antibiotic activity against both Gram-positive and Gram-negative bacteria and fungi [17]. This naturally occurring antibiotic has been isolated from the culture supernatant fluids of *Pseudomonas* [15,18,19] and *Streptomyces* species [20]. Table 1 summarizes the observed antimicrobial activities of the fluopsins.

In studies on metal-containing biomolecules, metal-ion selectivity, *i.e.*, the varying affinity of a ligand for different metal ions, plays a significant role. This property is often difficult to evaluate, as it is governed by subtle variations in electronic structures that modify the dominant electrostatic interactions between the ligand and the metal [2]. In this paper, we aim to use DFT to calculate the affinity of thioformin in square planar complexes for selected divalent metal ions, chosen for their importance in bio-inorganic chemistry as their metalloprotein complexes are among the most abundant.

2. Computational details

The DFT UB3LYP/6-31G(d) approach [21–23] was used for the calculations reported in this chapter. Since some of the complexes represent open shell systems (Ni(II) and Cu(II) complexes), we performed unrestricted calculations on all complexes. The geometries of all complexes were fully optimized, followed by harmonic vibrational frequency calculations. The calculated vibrational frequencies were used to confirm the nature of all stationary point structures and to account for the zero-point vibrational energy contribution, which was scaled [24] by a factor of 0.9806, and the vibrational frequencies were scaled by a factor of 0.9614. All calculations were performed with the GAUSSIAN 03W suite [25] of programs.

3. Results and discussion

3.1. Relative energies

Ca(II) is a closed-shell system (^1S), as is Zn(II), which is a d^{10} ion. For Cu(II), too, the situation is straightforward as it is a d^9 ion with a doublet ground state (^2D) in its complexes. Ni(II) (d^8) complexes, however, may exist in either the high-spin triplet or low-spin singlet states. The latter, being closed-shell, are expected to be more stable due to electron-pairing, as well as the fact that the high energy $d_{x^2-y^2}$ orbital is avoided. We investigated both multiplicities for the Ni^{2+} ion complexes, and found this to be true. Thus, the ground state is consistent with the high energy $d_{x^2-y^2}$ orbital being unoccupied for the d^8 Ni(II) complexes.

Table 2 gives the complexation energies for the *N*-methylthioformohydroxamate complexes of the four metal ions,

Table 1
Some properties of the fluopsins

Fluopsin	Crystal shape	Melting point (°C)	Antimicrobial activity		Reference
			Organism	MIC	
CA	Colourless needles	>250	*Staphylococcus aureus* FDA 209P	0.39 μg/ml	[14]
			Bacillus subtilis PCI-219	0.78 μg/ml	
N	Dark red needles	~228	*Staphylococcus aureus* FDA 209P	0.39 μg/ml	[14]
			Bacillus subtilis PCI-219	0.39 μg/ml	
C	Dark brown crystals	>182 (decomp.)	*Staphylococcus aureus* FDA 209P	0.50 M	[13]
			Escherichia coli NIHJ	5.00 M	
Z	Colourless prisms	~222 (decomp.)	*Staphylococcus aureus* FDA 209P	0.78 μg/ml	[14]
			Bacillus subtilis	1.56 μg/ml	

Table 2
Complexation energies. ΔE (kcal/mol), for the *N*-methylthioformohydroxamate bis complexes of some metal ions

Metal ion	Complex	Energy
Ca(II)	Fluopsin CA	−511.2
Ni(II) *cis*	Fluopsin N	−752.6
Ni(II) *trans*	Fluopsin N	−752.8
Cu(II) *cis*	Fluopsin C	−705.6
Cu(II) *trans*	Fluopsin C	−705.3
Zn(II)	Fluopsin Z	−684.2

Ca(II), Ni(II), Cu(II) and Zn(II), calculated from the expression

$$\Delta E = E_{\text{complex}} - E_{M^{2+}} - 2E_{\text{thioformohydroxamate}}$$

where E_{complex} is the computed energy of the complex, $E_{M^{2+}}$ is that of the metal ion and $E_{\text{thioformohydroxamate}}$ is that of the *N*-methylthioformohydroxamate anion (−606.8199802 a.u.). The computed metal ion energies are −676.866860724, −1506.99964648, −1639.2130838 and −1778.10700677 a.u., respectively, for Ca^{2+}, Ni^{2+}, Cu^{2+} and Zn^{2+}.

A large variation in complexation energies is apparent from the table. These are all negative, implying that the complexation reactions are highly exothermic. The complexation energies depend only on the metal ion and are relatively insensitive to the coordination geometry (*cis* or *trans*). The Ni(II) complexes are thermodynamically the most stable, followed by Cu(II) and Zn(II). The high-spin triplet Ni(II) complex has a much smaller value of the complexation energy (−106.8 kcal/mol) and is, therefore, much less stable. The rest of the discussion is therefore limited to the square planar low-spin complexes of Ni(II).

3.2. Structures of the complexes

Four-coordinate complexes may have either a tetrahedral or square planar coordination geometry. In protein crystal structures, zinc is tetrahedral, while Cu^{2+} bound to proteins is typically in a distorted 4-coordinate geometry, intermediate between tetrahedral and square planar [26]. As stated previously, low-spin divalent complexes of Ni(II) are also square planar. For the complexes investigated here, it was found that zinc is the only metal ion that forms a perfect tetrahedron, while the nickel complex has a square planar coordination about the metal ion. The calcium complex is a distorted tetrahedron, and the copper complexes are distorted square planar (Fig. 1).

The thiohydroxamate functional group bond lengths in the bound ligand are changed noticeably (Table 3). In the Ni(II) and Cu(II) *trans* thioformin complexes, for example, the C–N bond (−0.022 Å) is shortened and the N–O bond correspondingly lengthened (+0.037 Å), due to delocalization. However, in contrast to hydroxamates [2], in which the C=O bond is considerably lengthened (+0.025 Å), no such change is observed for the thiocarbonyl bond (−0.003 Å).

The metal–ligand bonds are relatively short (Table 4). These short bonds are presumably due to ionic contributions to the bonds. The oxygen, which is deprotonated to form the anion, carries a negative charge, −0.531. In contrast to hydroxamate systems, where both the hydroxyl oxygen and carbonyl oxygen carry large negative charges, the negative charge on sulfur is much smaller (−0.069). The optimized metal–oxygen and metal–sulfur bond lengths for the various metals are given in Table 4, along with the covalent bond orders. The latter are rather small, particularly the metal–oxygen bond orders. Thus, in the thiohydroxamate complexes, the metal–oxygen bonds are largely ionic, while the metal–sulfur bonds are largely covalent. However, the latter bonding is quite weak, while the former is stronger than in hydroxamate complexes because of the higher negative charge on oxygen.

Fig. 1 and Table 4 show that the Cu–S bond in the *trans* complex is 2.323 Å, which is much larger than the Cu–S bond distance (2.304 Å) in the *cis* complex. The metal–sulfur bond order is also much smaller in the latter. From their studies on the relationship between complex labilities and antibiotic action, Bell et al. [13] had concluded that the greater the lability, more potent is the complex. In view of this, we propose that the *trans* isomer is the more active form.

The small covalent contribution to the metal ligand bonds is apparent from the calculated covalent bond orders of 0.23 and 0.29, respectively, for Cu–O and Cu–S in the *trans* complex. The calculated metal–ligand bond orders are smaller than those calculated for Cu–O in hydroxamate

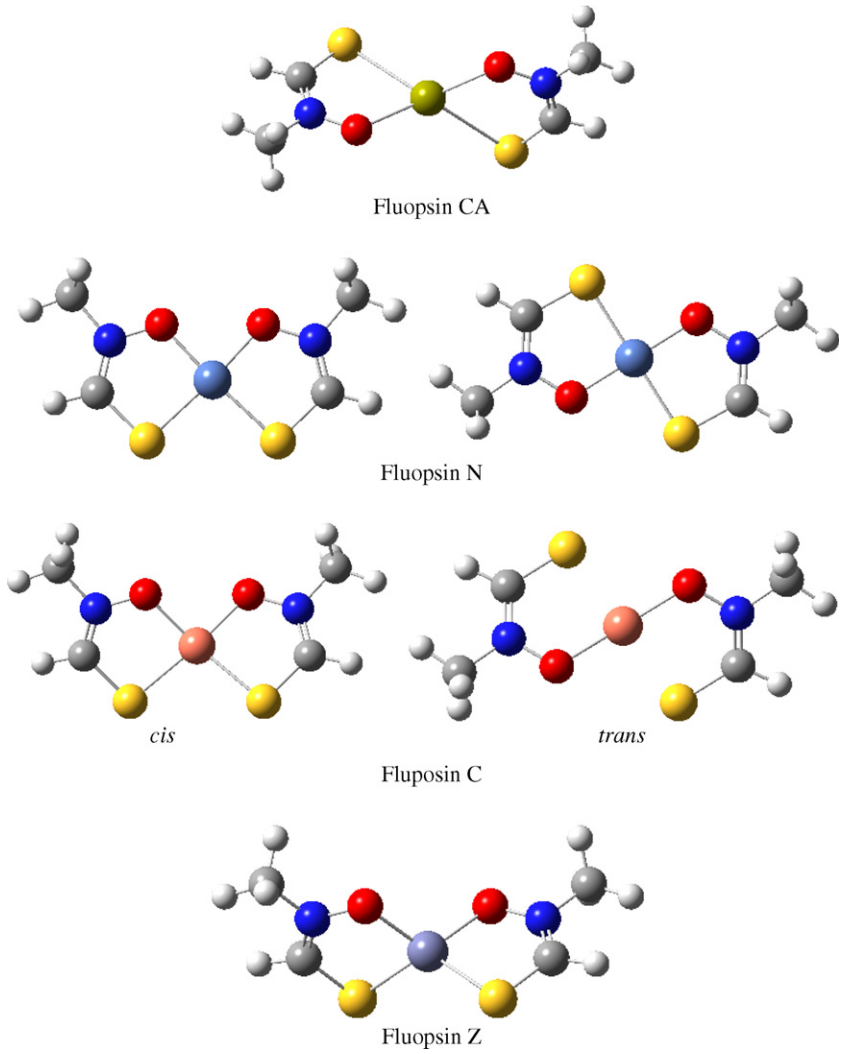

Fig. 1. Structures of Fluopsins-CA = Calcium, N = Nickel, C = Copper, Z = Zinc (Colour code: Sulfur – yellow, oxygen – red, nitrogen – blue, carbon – grey, and hydrogen – white).

Table 3
Optimized C–S, C–N and N–O bond lengths (Å) for the thioformin complexes of the metal ions

Metal (M)	C–S	C–N	N–O
Thioformin	1.706	1.333	1.304
Ca(II)	1.710	1.316	1.331
Ni(II) *cis*	1.704	1.313	1.337
Ni(II) *trans*	1.703	1.311	1.341
Cu(II) *cis*	1.709	1.316	1.330
Cu(II) *trans*	1.703	1.311	1.341
Zn(II)	1.708	1.313	1.337

Table 4
Optimized metal–ligand bond lengths (Å) and Wiberg bond orders for the thioformin complexes of the metal ions

Metal (M)	M–O		M–S	
	Length	Order	Length	Order
Ca(II)	2.277	0.092	2.842	0.132
Ni(II) *cis*	1.846	0.334	2.202	0.489
Ni(II) *trans*	1.831	0.359	2.213	0.452
Cu(II) *cis*	1.906	0.212	2.304	0.310
Cu(II) *trans*	1.894	0.228	2.323	0.285
Zn(II)	1.955	0.181	2.361	0.282

complexes, implying less charge transfer and covalency in the thiohydroxamate complexes [2].

3.3. Complexation energies

The sequence of stability constants for the complexes of various metal ions with thiohydroxamates is expected to depend on the ionic radii and electronegativities of the respective metal ions. The metal–ligand stability constants increase, in general, with increasing ionic potential (charge/radius) of the metals, since all the metal ions are bivalent. A plot of complexation energies in kcal/mol versus reciprocal of the ionic radius in Å [27] is expected to be linear for thioformin complexes. The data was fit to the empirical equation

$$E_{\text{complexation}} = A/r + B \quad (1)$$

and this yielded the regression coefficients $A = -998.4 \pm 22.5$ kcal Å/mol, $B = 447.3 \pm 25.6$ kcal/mol, and a correlation coefficient equal to -0.999. The correlation is much better than that found for formohydroxamic acid complexes [2], indicating a larger ionic component in the thiohydroxamate complexes. Table 5 indicates a good fit considering that the ionic radii pertain to high-spin octahedral complexes, while the complexation energies are for square planar/tetrahedral low-spin complexes. The standard error of the complexation energy estimate is 4.5 kcal/mol.

The complexation energies of the metal ion complexes, calculated in this work, follow the order:

$$\mathrm{Ca(II)} < \mathrm{Zn(II)} < \mathrm{Cu(II)} < \mathrm{Ni(II)}$$

This is in accord with the Irving–Williams order [28], with the exception of Ni(II), which is found to precede Cu(II). It may be noted that the Ni(II) complex is square planar, while the Cu(II) complex is tetrahedrally distorted.

3.4. Charge population analysis

Table 6 presents the partial atomic charges on the metals in the thioformin complexes, along with the electron configuration about the metal ion. The d electron population for all the complexes is consistent with the +2.0 oxidation of the metal ions. It is seen that the positive charge of the metal ion decreases in the complexes coordinating with the *N*-methylthioformohydroxamate ion, which indicates that electron transfer from the ligands to the metal ion occurs and coordination bonds form. This charge transfer is least for the closed-shell metal ion, Ca(II), but for metals containing partially filled d orbitals, particularly the d^8 system, Ni(II), in which 1.6 e electrons get transferred from the ligand to the metal ion, the charge transfer is much larger, indicating the strong covalent character of the complexes. Of the 1.6 e that get transferred in the Ni(II) complexes, only 0.4 e are accepted by the d orbitals (Table 6). Even for Zn(II), almost 1.3 e get transferred from the ligand. The thiohydroxamate ligand has both hard (oxygen) and soft (sulfur) donor atoms. While the hard oxide ion, having a negative charge, is able to form ionic bonds, the soft sulfur can facilitate complex formation through covalent bonding.

To see how the charge transfer occurs, we calculated the partial atomic charges on the ligand, *i.e.*, for the *N*-methylthioformohydroxamate anion, and the values are given in Table 7, along with those in the Cu(II) *trans* complex, which has a high magnitude of the complexation energy and in which there is substantial charge transfer. It can be seen that the atomic charge of the coordinated sulfur atom decreases on complexation. The two sulfur atoms transfer a total of 0.77 e to the metal ion, while the oxygens donate 0.12 e. However, the charge on Cu^{2+} (Table 6) demonstrates that 1.37 e transfer from the ligand to Cu(II) in the complex, suggesting that the electrons move from other parts of the ligand to the coordinated sulfur atoms, from where they are transferred to Cu(II). Surprisingly, the methyl group also has a large role to play in the charge transfer. Each donates 0.36 e to the metal ion.

Likewise, there is relocation of electron density on the nitrogen. Instead of gaining electron density in the anion, the nitrogen acquires a small positive charge. For the Cu(II) aminophenylhydroxamic acid complexes, this was traced to hyperconjugative interactions, as a result of which the nitrogen lone pair puts electron density into the carbonyl π^* orbital, weakening the carbonyl bond prior to complex formation [1]. Here too a similar situation prevails, the nitrogen lone pair donating electron density to the C=S π^* orbital. This is borne out by the calculated total Wiberg index [29] on the nitrogen in the anion (3.71), which is greater than its valency (three), while the C=S bond order is only 1.33 in the anion. The calculated bond order of the nitrogen with the sulfur is 0.18, again showing an interaction between the two in the *N*-methylthioformohydroxamate anion. Because of this, the nitrogen has a small positive charge in the anion and the complex.

The formation of the complex is therefore accompanied by a considerable decrease in the electron density at the

carbon of the thiocarbonyl bond and the methyl group. This implies the important role of the substituent at the nitrogen in the complex formation. Recognizing this, several workers have essayed the role of the substituent at nitrogen in antibiotic action [13,14,17–20,30].

We compared the Wiberg bond orders for bonds between the ligand atoms for thioformin, its anion and in the complexes, and the results are given in Table 8. It can be seen that the O–N bond acquires double bond character on removal of the acidic proton. In the complex, the O–N bond reverts to a single bond, but the C–N bond becomes stronger. It is this π bond that is involved in the charge transfer to the metal ion, along with the oxygen and sulfur atoms.

3.5. Bonding in the complexes

As mentioned above, four coordinate ligand bonding could either be tetrahedral or square planar. We have observed that for the majority of systems, except the d^8 system (Ni(II)), where the complexes are square planar, the metal ions are tetrahedrally coordinated. In a square planar D_{4h} field, the 3d orbitals of the metal are split into four levels, which are, in order of increasing energy, $\{d_{xz}, d_{yz}\}$ $(e_g) < d_{z2}$ $(a_{1g}) < d_{xy}$ $(b_{2g}) < d_{x^2-y^2}$ (b_{1g}). The important feature of the splitting is that the $d_{x^2-y^2}$ orbital goes to a very high energy, as it is in the crowded *xy*-plane, resulting in electronic repulsion with the ligands. Therefore, the most favourable configuration for forming square planar complexes is low spin d^8 (Ni^{2+}). The d^9 case is not so favourable. According to the Valence Bond theory, the vacant $d_{x^2-y^2}$ orbital can form hybrid orbitals with 4s (a_{1g}) and two 4p orbitals $\{p_x, p_y\}$ (e_u), giving dsp^2 hybrid orbitals. These vacant orbitals can accommodate electrons from the ligand.

The electron configuration of the Zn(II) ion is $3d^{10}$. It coordinates with ligands using the 4s and 4p orbitals in sp^3 hybrid orbitals. According to the Valence Shell Electron Pair Repulsion (VSEPR) theory, tetrahedral configurations are favoured for Zn(II) four-coordination complexes, as in $[ZnCl_4]^{2-}$. In this hybridization scheme, the relatively low energy $3d_{x^2-y^2}$ orbital is replaced by a higher energy $4p_z$ orbital, and hence charge transfer from the low-lying ligand orbitals is not so facile. It is therefore not surprising that the Zn(II) thiohydroxamate complexes adopt a tetrahedral geometry. These expectations are borne out by the calculated d electron configurations about the metal ions (Table 6).

To test the hypothesis that charge transfer from the ligand to the metal ions is responsible for the stability of the complexes, we correlated the calculated complexation energies with the partial charge on the metal atom, and found a good correlation between the two. It is found that the complexation energy (kcal/mol) is related to the partial charge on the metal atom by an empirical relation,

$$E_{\text{complexation}} = Aq_{\text{M}} - B \tag{2}$$

where $A = 348.0 \pm 23.9$ kcal/mol, $B = -917.2 \pm 16.9$ kcal/mol and the correlation coefficient is −0.991 (4 degrees of freedom). The standard error of the complexation energy estimate is 13.7 kcal/mol. The positive sign of the slope indicates that as the positive charge on the metal atom increases (signifying less charge transfer from the ligand), the complexation energy becomes less negative. This is in line with expectations, since the smaller the charge transfer, the less the covalent character of the complexes. If instead of the partial charge on the metal ion, the d orbital population is taken for the correlation, the regression coefficient drops to −0.892 and the standard error of the estimate increases to 45.2 kcal/mol.

We also examined the ligand orbitals in the acid form, anion and complex. Fig. 2a gives a plot of the Highest Occupied Molecular Orbital (HOMO) of the *N*-methylthioformohydroxamate anion. This orbital has an energy of −0.224 eV. It is clear that there is charge density at the oxygen, sulfur and in the C–N bonding orbital, and this can be donated to the vacant metal orbitals.

It can be seen from the plots of the HOMOs that the ligand orbitals are retained in the HOMOs of the complexes, but the metal d orbital also becomes a part of the HOMO for the square planar Ni(II) complex, showing an interaction between the Ni(II) d orbitals and the ligand.

3.6. Vibrational spectra

The calculated vibrational spectra of the complexes are remarkably similar, and these are given as Supplementary material. The most intense band is the C–N stretching band at ~1550 cm^{-1}. This band is shifted to a slightly higher wavenumber for the square planar nickel(II) complexes. All the complexes exhibit similar spectra, *i.e.*, the number of dominating bands in the 800–1600 cm^{-1} region. Another prominent band, not reported experimentally, is a band in the 600–700 cm^{-1} region, depending on the structure of the complex (tetrahedral or *cis* or *trans* square planar), and the nature of the metal ion, and this corresponds to the O–M–O antisymmetric stretch. The C–S symmetric stretching band has a small intensity and is dwarfed by the nearby intense N–O stretching band.

In Table 9, we compare the experimental vibrational frequencies with our calculated values, and good agreement

Table 8

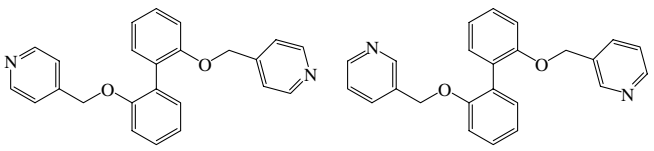
can be seen. The assignment has been made by an analysis of the normal modes. Since the complexes have 51 vibrational degrees of freedom, only the prominent bands, for which experimental data are available, are given in Table 9. The complete set of vibrational frequencies is given as Supplementary material. The C–H band is also not very intense and occurs around 3050 cm^{-1}.

4. Conclusions

In this work, we have reported calculations on *N*-methylthioformohydroxamate complexes of different metal ions. Good correlations between the calculated complexation energies and various parameters, like the reciprocal of the metal ion radius, have been obtained. We have found that the order of stabilities of various complexes is determined almost purely by the ratio of the ionic radius and transition metal ion charge (ionic contribution) and that the covalent contribution to the coordination bond (characterized by a charge transfer between the ligand and transition metal ion) does not play a significant role in determining the thermodynamic stability of the complex. This is also reflected in the calculated M–O bond orders that are quite small, in contrast to hydroxamate complexes [2], in which the covalent character is significant.

The prominent bands in the infrared spectra correspond to the C–N, N–CH_3, O–N and C–S symmetric stretching vibrations. Good agreement between the calculated and the experimental values is observed. Another prominent band in the 600–700 cm^{-1} region, corresponding to the O–M–O antisymmetric stretch, is predicted. The C–H stretching band occurs at ~3050 cm^{-1} and is not very intense.

The copper(II) and nickel(II) complexes of thioformin are almost equally potent against *S. aureus* 209P, but the Zn(II) has almost double the activity of these complexes. These complexes exhibit substitutional lability with a timescale of 6–8 h [31]. The M–O and M–S bond orders are much smaller than those calculated for the hydroxamate analogues. The metal–sulfur bond orders are smallest for the tetrahedral Ca(II) and Zn(II) complexes, and these are hence more kinetically labile. These complexes are also thermodynamically the least stable. Bell et al. [13] demonstrated that the kinetically inert Pt(II) complexes exhibit no antibiotic activity. They also showed that the observed order of potency of trivalent complexes against *S. aureus*



209P is also in accord with the observed order of kinetic lability [31]. They therefore concluded that kinetic lability is an important factor in determining the antimicrobial activity of a complex. It is gratifying to note that the kinetic lability, as determined by the metal–sulfur bond orders, can be correlated to the observed antimicrobial activity. However, the investigated systems are too few in number for a definite quantitative correlation to be made, so in future work, we shall report a detailed study of more such systems.

4,4'-bpp 3,3'-bpp

Scheme 1. Structure of 4,4′-bpp and 3,3′-bpp ligands.

{M–bpp} systems with the introduction of multi-carboxylate ligands. With various flexible coordination modes for carboxylate group ligands, dicarboxylate ligands can bridge two or more different metal centers and produce neutral architectures. These additional ligands could exhibit a variety of bridging abilities and have a strong tendency to form multidimensional structures, which would be markedly different from those of M–(4,4′-bpp) and M–(3,3′-bpp) complexes [11–17]. The combination of bipyridyl and dicarboxylate with d^{10}-metal ions could produce some unique frameworks with beautiful aesthetics and useful properties.

Herein, we report the syntheses, crystal structures, thermal stability and the fluorescence properties of four new complexes: $[Zn(\mu\text{-}4,4'\text{-bpp})Br_2]_n$ (**1**), $[Zn(\mu\text{-}4,4'\text{-bpp})(1,2\text{-bdc})]_n \cdot nH_2O$ (**2**), $[Zn(\mu\text{-}3,3'\text{-bpp})(1,3\text{-bdc})]_n \cdot nCH_3OH \cdot 2nH_2O$ (**3**) and $[Cd(\mu\text{-}3,3'\text{-bpp})(C_4H_2O_4)]_n \cdot 3nH_2O$ (**4**) (bdc = benzenedicarboxylate, $C_4H_4O_4$ = fumaric acid). The research results reported here are of interest with respect to the following aspects: (1) the introduction of multi-carboxylate ligands to {M–bpp} systems via the three-layer diffusion method plays an important role in the formation of fascinating metal–organic frameworks, which is significant for further exploring coordination polymer chemistry; (2) complexes **1**–**4** with flexible bipyridyl ligands present novel and unprecedented topologies such as perpendicularly linked chains, two-leg ladders and macroanionic sheets structures; (3) combination of d^{10} center metals with the conjugated aromatic or pyridine rings from both ligands provides fluorescent materials; (4) complexes such as **1** and **3**, owing to absence of inversion centers, could function for a second harmonic generation (SHG) response.

2. Experimental

2.1. General

2,2′-Biphenol and 4-picolyl chloride hydrochloride were purchased from Acros Ltd. Company and were used without further purification, the other reagents were commercially available and were used as purchased. The 4,4′-bpp and 3,3′-bpp ligands were prepared according to the literature methods [9]. The NMR spectra were recorded on a Varian Inova-500 spectrophotometer at room temperature. The mass spectra were measured on a Fisons VG platform. The IR spectra as KBr discs were recorded on a Magna 750 FT-IR spectrophotometer. C, H and N analyses were determined on an Elemental Vario ELIII elemental analyzer. Fluorescent spectra were measured on an Edinburgh Instruments analyzer model FL920. Thermal analyses were performed using a Thermal Analyst 2100 TA Instrument and a SDT 2960 Simultaneous TGA-DTA Instrument.

2.2. Synthesis of complexes

2.2.1. Synthesis of $[Zn(\mu\text{-}4,4'\text{-bpp})Br_2]_n$ (**1**)

A solution of $ZnBr_2 \cdot 4H_2O$ (0.029 g, 0.10 mmol) in H_2O (5 mL) was carefully covered by a buffer layer, prepared by mixing MeOH and water (in a 1:1 ratio). Then a solution of 4,4′-bpp (0.036 g, 0.10 mmol) in MeOH (5 mL) was slowly added above the buffer layer. Over a period of four weeks, light yellow block crystals formed on the buffer layer. Yield: 0.040 g (68%). Elementary *Anal.* Calc. for $C_{24}H_{20}Br_2N_2O_2Zn$ (593.61): C, 48.56; H, 3.40; N, 4.72. Found: C, 48.51; H, 3.43; N, 4.68%. IR (KBr, cm^{-1}): 3430 (vw), 2923 (w), 1623 (s), 1596 (w), 1505 (s), 1483 (s), 1444 (s), 1328 (m), 1269 (s), 1234 (s), 1147 (s), 1054 (m), 1029 (s), 862 (w), 751 (s), 707 (s), 492 (vw).

2.2.2. Synthesis of $[Zn(\mu\text{-}4,4'\text{-bpp})(1,2\text{-bdc})]_n \cdot nH_2O$ (**2**)

A solution of $ZnBr_2 \cdot 4H_2O$ (0.029 g, 0.10 mmol), NaOH (0.008 g, 0.20 mmol) and 1, 2-H_2bdc (0.017 g, 0.10 mmol) in H_2O (5 mL) was carefully covered by a buffer layer (MeOH:H_2O = 1:1). Then a solution of 4,4′-bpp (0.036 g, 0.10 mmol) in MeOH (5 mL) was slowly added above the buffer layer. Over a period of four weeks, light yellow block crystals of **2** formed at the buffer layer Yield: 0.051 g (83%). Elementary *Anal.* Calc. for $C_{32}H_{26}N_2O_7Zn$ (615.93): C, 62.40; H, 4.25; N, 4.55. Found: C, 62.15; H, 4.61; N, 4.50%. IR (KBr, cm^{-1}): 3435 (w), 3038 (w), 2853 (w), 1621 (w), 1595 (m), 1479 (m), 1432 (s), 1290 (w), 1231 (s), 1162 (m), 1118 (w), 1029 (m), 812 (w), 751 (s), 726 (s), 643 (w), 494 (w).

2.2.3. Synthesis of $[Zn(\mu\text{-}3,3'\text{-bpp})(1,3\text{-bdc})]_n \cdot nCH_3OH \cdot 2nH_2O$ (**3**)

A solution of $ZnBr_2 \cdot 4H_2O$ (0.029 g, 0.10 mmol), NaOH (0.008 g, 0.20 mmol) and 1,3-H_2bdc (0.017 g, 0.10 mmol) in H_2O (5 mL) was carefully covered by buffer layer (MeOH:H_2O = 1:1). Then a solution of 3,3′-bpp (0.036 g, 0.10 mmol) in MeOH (5 mL) was slowly added above the buffer layer. Light yellow block crystals were produced at the buffer layer after a few weeks. Yield: 0.048 g (72%). Elementary *Anal.* Calc. for $C_{33}H_{32}N_2O_9Zn$ (666.01): C, 59.51; H, 4.84; N, 4.21. Found: C, 59.43; H, 4.88; N, 4.16%. 2.3. X-ray crystallography

Single crystals of these complexes with appropriate dimensions were mounted on a glass fiber and used for data collection. Data were collected at 293(2) K on a Siemens Smart CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Empirical absence of the centers of symmetries meets the essential requirement of a SHG response. Absorption corrections were applied by using the SADABS program for the Siemens area detector. The structures were solved with direct methods and all calculations were performed using the SHELXTL package [18]. The structures displacement parameters were calculated for all non-hydrogen atoms. The positions of H atoms were generated geometrically and treated as riding on their parent atoms. Details of the crystal data are listed in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

3.1. Description of crystal structures

3.1.1. $[Zn(\mu\text{-}4,4'\text{-bpp})Br_2]_n$ (1)

Single crystal X-ray diffraction analysis reveals that complex **1** is a chain structure and crystallizes in the orthorhombic space group *C*222. As depicted in Fig. 1a, complex **1** contains two independent Zn(II) centers. Each Zn(II) center has a slightly distorted tetrahedral geometry and is coordinated by two terminal bromide anions (Zn(1)–Br(1) 2.360(5) Å, Br(1)–Zn(1)–Br(1A) 117.84(3)°; and Zn(2)–Br(2) 2.348(8) Å, Br(2)–Zn(2)–Br(2A) 115.14(5)°). The remaining two coordinative sites of the Zn(II) center in each line are occupied by two nitrogen atoms from different 4,4′-bpp ligands. The bond distances between the Zn(II) center and the nitrogen donor are Zn(1)–N(1) 2.044(3), Zn(2)–N(2) 2.061(4) Å.

Because of steric exclusion, the pyridyl rings of two independent 4,4′-bpp ligands are highly twisted, the dihedral angles between the two pyridyl rings are 68.5° and 21.0°. The dihedral angles between the two phenyl rings in two 4,4′-bpp ligands are 127.6° and 71.5°. The Zn(II) centers are linked by the twisted 4,4′-bpp ligands into a zigzag chain structure. It is noteworthy that the two chains in **1** are nearly perpendicular to each other, as shown in

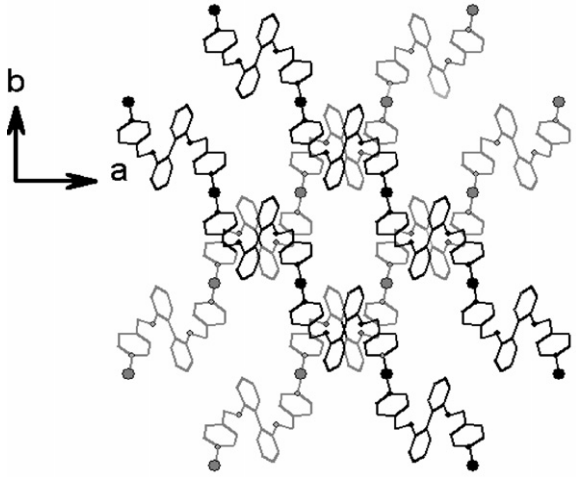

Fig. 1b. View of the vertical polymer chains in **1**.

Fig. 1b. The Zn···Zn separation in both chains is of the same distance, 9.630 Å, while the two nearest Zn(II) centers are at a distance of 11.728 Å. No guest molecules are observed within the distorted rings owing to the high distortion and flexibility of 4,4′-bpp.

3.1.2. *[Zn(μ-4,4′-bpp)(1,2-bdc)]$_n$ · nH$_2$O* (**2**)

The structure of **2** comprises a two-leg ladder running along the [0 0 1] direction. An ORTEP view of complex **2** is shown in Fig. 2a. The Zn(II) ion adopts a distorted tetrahedral coordination geometry and is coordinated by two nitrogen atoms from different 4,4′-bpp ligands (Zn(1)–N(2A) 2.0438(15), Zn(1)–N(1) 2.0751(15) Å) and two carboxyl groups from two different 1,2-bdc ligands (Zn(1)–O(1) 1.9246(13), Zn(1)–O(3B) 1.9534(13) Å, O(1)–Zn(1)–O(3B) 111.45(6)°).

The legs of such a ladder are made up of [Zn(4,4′-bpp)]$_n$ chains, in which Zn(II) ions are bridged by 4,4′-bpp ligands and each ligand acts as an *exo*-bidentate ligand. In the legs, two phenyl rings and two pyridyl rings of each 4,4′-bpp ligand are twisted more evidently than those in **1**. The dihedral angles between them are 111.5° and 51.3°, respectively. The cross rungs of the ladder are made up of 1,2-bdc ligands, where each of the carboxyl groups in a monodentate coordination mode bridges two Zn(II) ions on either side of the ladder. Interestingly, the dihedral angles between the phenyl rings and their corresponding carboxylates are 94.2° and 99.0°, respectively, indicating that the

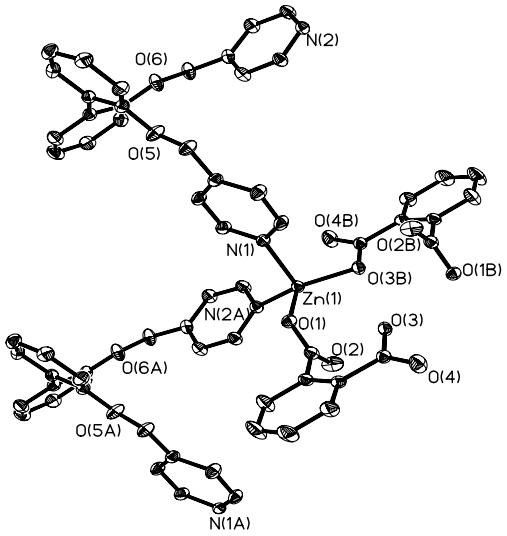

Fig. 2a. View of the coordination environment of the Zn(II) center in **2** (A: $x-1$, y, z; B: $-x+1$, $-y+2$, $-z+1$).

carboxylates are approximately perpendicular, respectively, to phenyl rings. In addition, the Zn···Zn separation among the legs of the ladder is 10.233 Å and the Zn···Zn separation in the cross rungs is 5.153 Å, as shown in Fig. 2b.

3.1.3. $[Zn(\mu\text{-}3,3'\text{-bpp})(1,3\text{-bdc})]_n \cdot nCH_3OH \cdot 2nH_2O$ (**3**)

The structure of **3** consists of neutral 1D chains through the connection of [Zn(3,3′-bpp)] units and 1,3-bdc bridging ligands (Fig. 3a). The central Zn(II) ion is coordinated tetrahedrally by two monodentate carboxylate oxygen atoms from two different 1,3-bdc ligands and two nitrogen atoms from two 3,3′-bpp ligands. The Zn–O bond lengths are 1.9721(17) and 1.9836(16) Å, in good agreement with those bond lengths found in other extended structures constructed from 1,3-bdc and Zn(II) ions, and the Zn–N bond distances are typical, with values of 2.019(0) and 2.052(7) Å. The angles O(1)–Zn(1)–O(3B) of 98.00(7)° and O(3B)–Zn(1)–N(2A) of 116.61(7)° indicate a slight distortion compared with the ideal value of 109°28′. The dihedral angle of the two pyridyl rings attaching to the Zn(II) ion is 83.2°, i.e. they are approximately perpendicular to each other. The 3,3′-bpp ligand acts as *exo*-bidentate, and its pyridyl rings are twisted out of the plane of the linking phenyl rings by 69.0° and 73.7°, while the two phenyl rings of 3,3′-bpp themselves have a drastic twisting with the dihedral angle between them being 25.6°. The combination of these twistings allows 3,3′-bpp to link two Zn(II) ions into a dimetallic ring with the Zn···Zn separation being 8.139 Å.

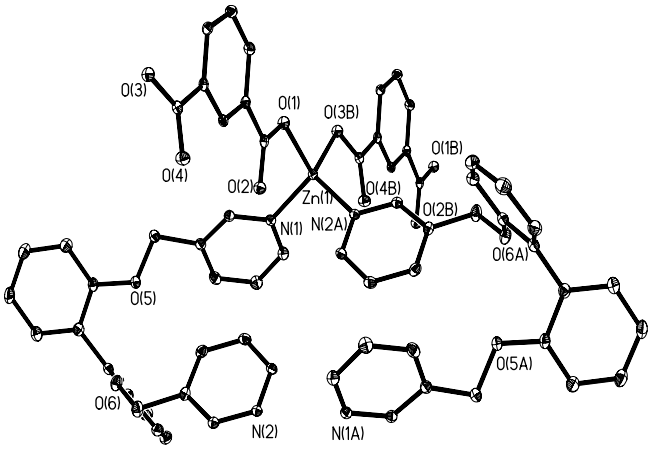

Fig. 3a. View of the coordination environment of the Zn(II) center in **3** (A: $-x$, $-y+2$, $-z+1$; B: $x-1$, y, z).

In addition, both carboxyl groups of the 1,3-bdc ligand link the metal Zn(II) ion in a monodentate fashion and they are deprotonated which is consistent with the IR data (no absorption peaks in the 1715–1680 cm^{-1} region). The Zn···Zn distance separated by 1,3-bdc is 10.132 Å. The dihedral angles between the phenyl rings and their corresponding carboxylates are 33.7° and 49.7°, indicating a slight twist between them. Thus, every two 1,3-bdc ligands, acting in the monodentate mode, connect the neighbouring

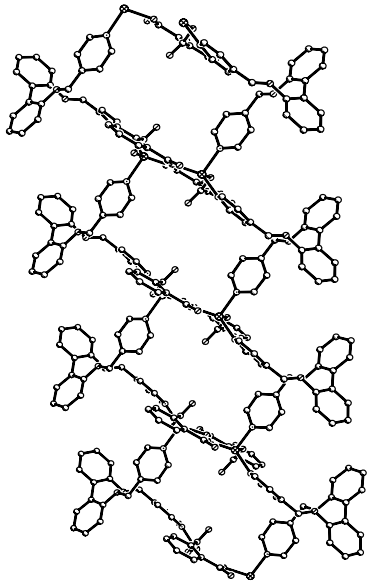

Fig. 2b. View of two-leg ladder structure in **2**.

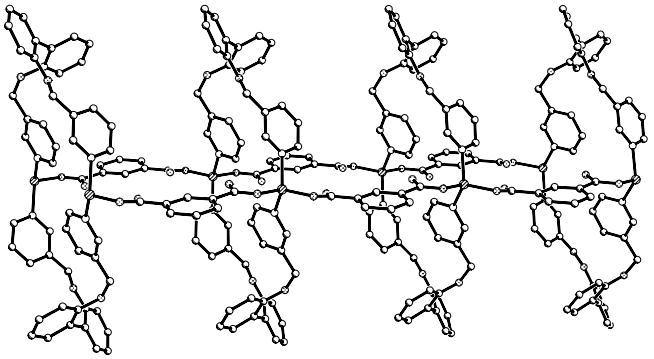

Fig. 3b. View of 1D polymeric chain with dimetallic rings of **3**.

dimetallic rings formed by the 3,3′-bpp ligand and Zn(II) centers into an interesting 1D chain structure as shown in Fig. 3b.

3.1.4. $[Cd(\mu\text{-}3,3'\text{-}bpp)(C_4H_2O_4)]_n \cdot 3nH_2O$ (4)

Complex **4** consists of anionic macrocyclic cadmium dicarboxylate sheets which are separated by 3,3′-bpp. The local coordination environment around the Cd(II) center in **4** can be described as a greatly distorted pentagonal bipyramid, as shown in Fig. 4a. Two nitrogen donors from two 3,3′-bpp ligands take up two vertexes of the coordination polyhedron to stop the layer from developing into a 3D framework (Cd–N(1) 2.302(8), Cd–N(1A) 2.302(8) Å, N(1)–Cd–N(1A) 178.8(4)°). The equatorial plane of the coordination polyhedron is composed of five oxygen atoms belonging to three fumarate ligands. Two of the three fumarate units bind the Cd(II) ions through a chelating interaction, while the remaining one exhibits a chelating/bridging bis-bidentate mode. All of five the Cd–O bond lengths are in the range of the documented Cd–$O_{(carboxy)}$ distances (2.324(9)–2.486(8) Å). The oxygen atom O(1), which participates in the chelate-bridged interaction, bridges two Cd(II) atoms to form Cd_2O_2 dimers (Cd···Cd, 3.825 Å) through the monodentate interaction, and exhibits the shortest coordination distance (Cd–O(1), 2.324(9) Å). The above binuclear Cd_2O_2 subunit is connected to four neighbouring subunits forming a network which is topologically equivalent to a (4,4) network. Thus, the binuclear subunits are inter-connected through fumarate ligands, which bridge the Cd_2O_2 to generate a parallegram-like sheet with dimensions of 16.809 × 14.288 Å, as measured from the centers of the binuclear subunits (Fig. 4b).

Moreover, every two 3,3′-bpp ligands, both in *exo*-bidentate modes, are attached to the hybrid through the Cd–N bonds to form a hybrid layer as shown in Fig. 4c. It is noteworthy that 3,3′-bpp, twisted due to the steric exclusion requirement, links two Cd(II) centers into a big

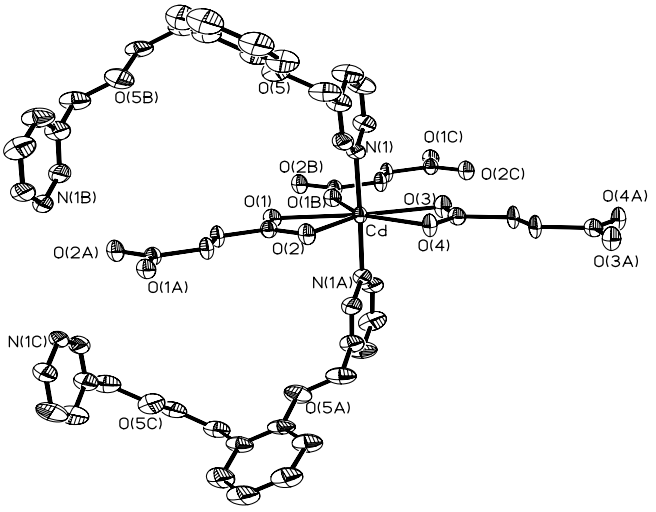

Fig. 4a. View of **4** showing the coordination environment around the Cd(II) center (A: $x, -y, z$, B: $-x, -y, -z+1$, C: $x, -y, -z+2$).

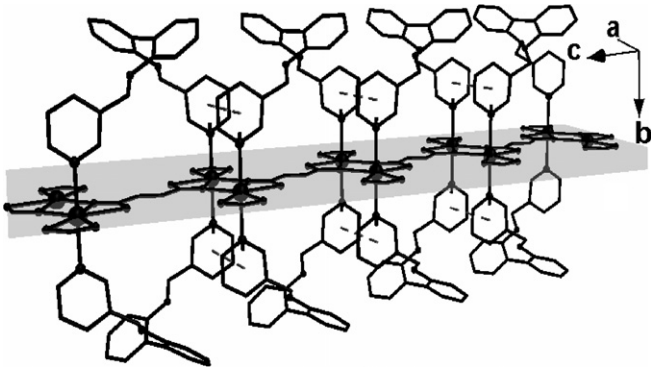

Fig. 4c. View of the hybrid layer of **4**.

dimetallic ring, where the dihedral angles between the two phenyl rings and the two pyridyl rings of the 3,3′-bpp ligand are 75.3° and 3.1°, respectively. Thus, the metal–metal layers are planar with two N atoms from the 3,3′-bpp ligand pointing above and below the plane. The layers are linked by strong π–π interactions, and the adjacent layers stacking mode can be described as the ABAB type in a staggered arrangement, as shown in Fig. 4d.

3.2. TGA results

To study the stability of the polymers, the thermogravimetric analyses (TGA) for these complexes were performed on polycrystalline samples under a nitrogen atmosphere. The TG curves showed neither weight loss nor structural change up to about 260 °C, demonstrating that the frameworks of **1**–**4** were retained up to these high temperatures. Immediately above this point, the samples began to lose ligands, the whole frameworks collapsed in a continuous fashion and finally decomposed into unidentified products.

3.3. Luminescence properties

Luminescent polynuclear d^{10} metal complexes (such as Zn(II) and Cd(II)) are of great interest because of their

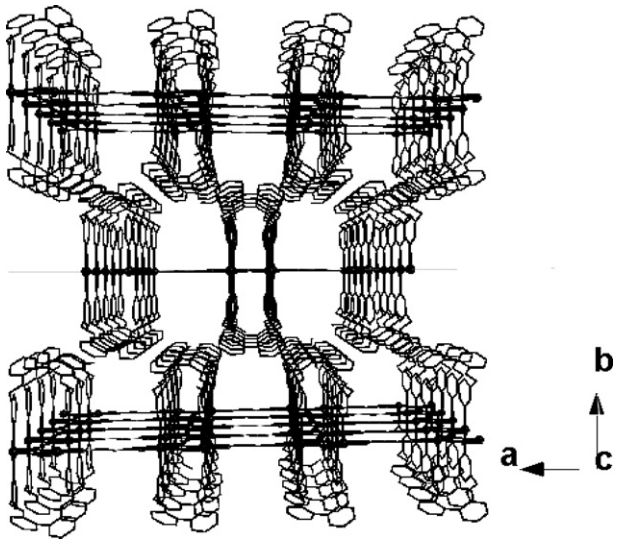

Fig. 4d. View of the layers constructed of the ···ABAB··· type for **4**.

potential application in chemical optical sensors, photosensitization and electroluminescent devices. Here, the photoluminescence of these complexes was examined and the solid-state emission spectra are shown in Fig. 5. Complex **1** exhibits a broad emission band with the maximum intensity at 502 nm upon excitation at 370 nm, while complexes **2** and **3** produce an intense pure blue sharp emission with the maximum at ca. 441 nm and a broad emission band with the maximum intensity at 457 nm, respectively, with excitation at 370 nm. For complex **4**, two broad emissions at 490 and 526 nm can be observed. For contrast, the free 4,4′-bpp and 3,3′-bpp molecules display the luminescence at around 480 nm in the solid state. Generally, the intraligand fluorescence emission wavelength is determined by the energy gap between the π and π* molecular orbitals of the free ligand, which is simply related to the extent of π conjugation in the system. As for the metal complexes, the red or blue shifted emissions of complexes **1**–**4** compared to their free ligands are not only assigned to the intramolecular π–π* and n–π* transitions of the ligands, but are also attributable to ligand-to-metal charge transfers (LMCT) [19].

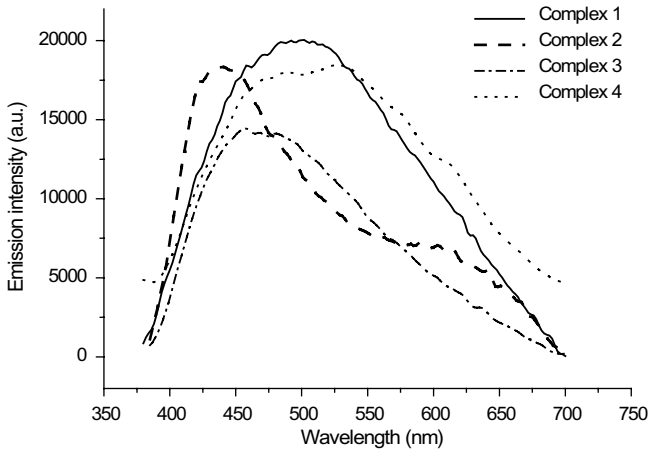

Fig. 5. The emission spectra of **1**–**4** in the solid state at room temperature.

In comparison with complex **1**, a blue-shift of 61 nm has been observed in complex **2**, partially due to the replacement of the Br^- anion by the ligand 1,3-bdc. Although complexes **2** and **3** have different structural motifs, both complexes demonstrate some similar photoluminescence behaviours. The blue-shifted emissions of **2** and **3** may originate from their larger conjugated systems for the two types of ligands as well as their similar distorted tetrahedral coordination geometries of d^{10} metal centers, where each of the Zn(II) ions is coordinated by two pyridyl N atoms and two carboxylate O atoms.

Complexes such as **1** and **3** do not have a center of symmetry, which meets the essential requirement of a SHG response. Thus, Kurtz powder SHG measurements on the acentric **1** and **3** were performed, and very weak SHG emissions were observed for both complexes. The weak SHG efficiency may be due to the following fact: the acentricities of **1** and **3** are caused by their twist of the bpp ligands and the arrangements of the individual chains result in a partial cancellation of the effective dipolar moments [20,21].

4. Conclusions

In summary, a series of novel coordination polymers with interesting structural motifs have been synthesized from the flexible bipyridyl ligands (4,4′-bpp or 3,3′-bpp) and d^{10} metal ions (Zn^{2+} or Cd^{2+}) as well as carboxylate ligands by the three-layer diffusion method. Complex **1** is a chain structure containing two unusual nearly vertical zigzag Zn(II) chains, and **2** comprises a two-leg ladder, where the legs and cross rungs are made of $[Zn(4,4'\text{-bpp})]_n$ chains and bdc ligands, respectively. In **3**, every two 1,3-bdc ligands connect the neighbouring dimetallic rings into an interesting 1D structure, while the 2D structure in **4** consists of macroanionic cadmium fumarate sheets separated by 3,3′-bpp ligands. Moreover, TGA measurements exhibit that complexes **1**–**4** have very similar thermal stability, and studies on the luminescent emissions of these obtained compounds reveal that the d^{10} metal ions cause red or blue shifts of the emissions, assigned to intramolecular π–π* and n–π* transitions of the ligands.

rise to polymeric structures. In this way, we present a series of nitrate and perchlorate Zn(II) complexes with different dipyridinic azamacrocycle ligands: the hexaaza 20-membered macrocycle L^1 (2,8,14,20-tetramethyl-3,7,15,19,25,26-hexaaza-tricyclo[19.3.1.1^{9,13}]hexacosa-1(24),9,11,13(26),21(25),22-hexaene), the hexaaza 18-membered ligand bearing four cyanoethyl pendant groups L^2 (3-[6,14,17-tris-(2-cyano-ethyl)-3,6,14,17,23,24-hexaaza-tricyclo[17.3.1.1^{8,12}]-tetracosa-1(23),8(24),9,11,19,21-hexaen-3-yl]-propionitrile) and the octaaza 24-membered macrocycle L^3 (3,6,9,17,20,23,29,30-octaaza-tricyclo[23.3.1.1[11,15]]triaconta-1(28),1,13,15(30),25(29),26-hexaene). The role of coordination capability of the nitrate and perchlorate counter ions and interaction between π-systems on complex structure are also studied.

2. Experimental

2.1. Chemical and starting materials

The macrocyclic ligands L^2 and L^3 were prepared following the literature methods [8,9]. 2,6-Diacetylpyridine, 1,3-diaminepropane, Ba(II) chloride dihydrated, Zn(II) hydrated nitrate and perchlorate salts were commercial products obtained from Alfa and Aldrich, and were used without further purifications. The solvents used were of reagent grade and purified by usual methods.

Caution: Although no problems were encountered during the course of this work, attention is drawn to the potentially explosive nature of perchlorates.

2.2. Synthesis of the macrocyclic ligands

The ligand L^1 was obtained following a similar method described previously [10] by a result of a barium template condensation of 2,6-diacetylpyridine and 1,3-diaminepropane. To a refluxing solution of 2,6-diacetylpyridine (0.82 g, 5 mmol) and Ba(II) chloride dihydrated (1.22 g, 5 mmol) in methanol (100 ml), a 30 ml of a methanolic solution of 1,3-diaminepropane (0.42 ml, 5 mmol) was added. The mixture was refluxed for 4 h. The solution was allowed to cool at room temperature and excess of sodium tetrahydroborate was added slowly and carefully for *in situ* reduction. The mixture was concentrated to dryness under reduced pressure and the crude solid was extracted with chloroform, concentrated to dryness to obtain a yellow oil. The oil was dissolved in small amount of methanol and bromhydric acid was added until acid pH. After isolation and characterization of the crystalline tetrahydrobromhydric salt of the ligand, it was dissolved in a small amount of water and neutralizing with NaOH. The water solution was extracted with chloroform (3×30 ml). The organic phase was dried with Na_2SO_4 anhydrous and filtered to be concentrated to dryness at reduced pressure to obtain a yellow oil, which was recrystallized in acetonitrile to give the 6*S*,10*S*,16*R*,20*R*-*meso* form L^1. It was characterized by elemental analysis, IR, LSI-MS and ^{1}H, ^{13}C, COSY, DEPT and HMQC NMR spectroscopy.

Anal. Calc. for $C_{24}H_{38}N_6$ (MW: 410): C, 65.9; H, 9.4; N, 19.2. Found: C, 66.2; H, 9.6; N, 19.3%. Yield: 57%. IR (KBr, cm^{-1}): 3291 ν(N–H), 1591, 1575, 1448 [ν(C=N)$_{py}$ and ν(C=C)]. LSI-MS (*m*/*z*): $[L^1+H]^+$ 411. ^{1}H NMR ($CDCl_3$, ppm) $\delta = 7.55$–7.40 [m, 2H, H_{py}]; 7.18–6.82 [m, 4H, H_{py}]; 3.82–3.60 [m, 4H, –CH]; 2.36–2.08 [m, 8H, –CH_2]; 1.31–1.26 [m, 12H, –CH_3]; 1.63–1.50 [m, 4H, –CH_2]. Colour: white.

2.3. Synthesis of the metal complexes – general procedure

The synthesis of metal complexes were carried out in 1:1 and 2:1 metal:ligand molar ratio. The appropriate metal salt (0.25 or 0.5 mmol) was dissolved in acetonitrile (10 ml) and added to a stirred solution of the macrocyclic ligand (0.25 mmol) in acetonitrile (20 ml). The solution was stirred for 2 h and concentrated in a rotary evaporator until *ca.* 5–6 ml. The products obtained were filtered off, dried and re-crystallized in water or acetonitrile.

Anal. Calc. for $C_{22}H_{45}N_8O_{20.5}Cl_4Zn_2$ (MW: 1013.02): C, 25.8; H, 4.4; N, 10.9. Found: C, 24.9; H, 4.2; N, 10.9%.

Yield: 49%. IR (KBr, cm^{-1}): 1608, 1584, 1452 [$\nu(C{=}N)_{py}$ and $\nu(C{=}C)$], 3180, 3289 [$\nu(NH)$], 1143, 1120, 1088, 636, 627 [$\nu(ClO_4^-)$]. LSI-MS (m/z): 841 $[Zn_2L^3(ClO_4)_3]^+$, 741 $[Zn_2L^3(ClO_4)_2]^+$, 536 $[Zn_2L^3]^+$. $\Lambda_M/\Omega^{-1}\,cm^2\,mol^{-1}$ (in CH_3CN): 387 (4:1). Colour: white.

2.4. Physical measurements

Elemental analyses were performed in a Carlo-Erba EA microanalyser. Infra-red spectra were recorded as KBr discs on a Bruker IFS-66V spectrophotometer. LSI mass spectra were recorded using a *Micromass Autospec* spectrometer with 3-nitrobenzyl alcohol as the matrix. Conductivity measurements were carried out in 10^{-3} mol dm^{-3} acetonitrile solutions at 20 °C using a WTW LF3 conductivimeter. ^1H, ^{13}C, COSY, DEPT and HMQC NMR spectra was recorded on a Bruker 500 MHz using CD_3CN or $CDCl_3$ as solvent.

2.5. X-ray crystallographic study

The details of the X-ray crystal structure solution and refinement are given in Table 1. Measurements were made on a Bruker SMART CCD Area Detector. All data were corrected for Lorentz and polarization effects. An empirical absorption correction was also applied for all the crystal structures obtained [11]. Complex scattering factors were taken from the program package SHELXTL [12]. The structures were solved by direct methods, which revealed the position of all non-hydrogen atoms. All the structures were refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters for all non hydrogen atoms [13]. The hydrogen atoms were located in their calculated positions and refined using a riding model.

3. Results and discussion

The hexaaza 20-membered macrocycle L^1, was obtained by a [2 + 2] barium(II) templated cyclocondensation of 2,6-diacetylpyridine and 1,3-diaminepropane in methanol followed by an *in situ* reductive demetallation of the Schiff base macrocyclic using excess sodium borohydride, following a similar method described previously.

Reduction of the tetraiminic barium(II) complex gave an isomeric mixture of the corresponding saturated macrocycles, and by using the partial crystallization method, the

6*S*,10*S*,16*R*,20*R*-*meso* form of L^1 could be separated, as has been previously reported for the 6*S*,9*S*,15*R*,18*R*-*meso* form of the ligand L′, derived form 2,6-diacetylpyridine and ethylendiamine [14].

The elemental analysis confirms the integrity of the ligand, L^1. The IR spectrum, (KBr disc) does not show bands ascribable to carbonyl and primary amine. Also the absence of a strong band at 1620 cm^{-1} attributable to the *v*(C=N), support the reduction of the barium(II) diminic complex. Together with the band at 3300 cm^{-1} corresponding to the *v*(N–H), other absorption bands in the region of 1590–1445 cm^{-1} corresponding to *v*(C=N) and *v*(C=C) vibrations from the pyridine groups can be observed. The LSI-MS of L^1 shows the parent peak at *m*/*z* 411 further confirming the presence of the ligand. The ^1H and ^{13}C NMR data of L^1 have been recorded using $CDCl_3$ as solvent, and confirm the integrity of the ligand and its stability in solution. The assignment of the proton and carbon signals was based upon standard 2D homonuclear (COSY), DEPT-135 and HMQC measurements, using the same deuterated solvent. At room temperature the ^1H NMR spectrum shows different multiplet signals assignable to the different protons in the molecule.

The coordination ability of the L^1, L^2 and L^3 macrocyclic ligands towards hydrated nitrate and perchlorate salts of Zn(II) in 1:1 and 1:2 metal:ligand molar ratio was studied. Elemental analysis are consistent with the presence of mononuclear Zn(II) complex for L^1 and L^2 and dinuclear for L^3, independently of the metal:ligand molar ratio employed.

3.1. Crystal structures

By slow concentration of acetonitrile solutions, crystals suitable for X-ray diffraction of $[ZnL^1](ClO_4)_2 \cdot H_2O$ and $[ZnL^2](NO_3)_2$ were obtained. Colourless crystals of $[Zn_2L^3(NO_3)_2](NO_3)_2 \cdot H_2O$ were obtained by slow recrystallization of the complex in water.

The details of the X-ray crystal structure solutions and refinement are given in Table 1. The molecular structure with the atomic numbering scheme adopted, together with selected bond distances and angles relating to the coordination environment of the metals are shown in Figs. 1–3.

For $[ZnL^1](ClO_4)_2 \cdot H_2O$ and $[ZnL^2](NO_3)_2$ the X-ray structure shows in both cases mononuclear endomacrocyclic complexes, with the Zn(II) ion sited in the middle of the macrocyclic cavity coordinated in a ZnN6 core by the six donor nitrogen atoms from the macrocyclic framework in a distorted octahedral geometry.

The structures show a 'twist-wrap', conformation typical of this kind of ligand, where the macrocycle adopts a helical shape with the two pyridine rings oriented 60.96° and 77.56° relative to each other for $[ZnL^1](ClO_4)_2 \cdot H_2O$ and $[ZnL^2](NO_3)_2$, respectively. The angle between the

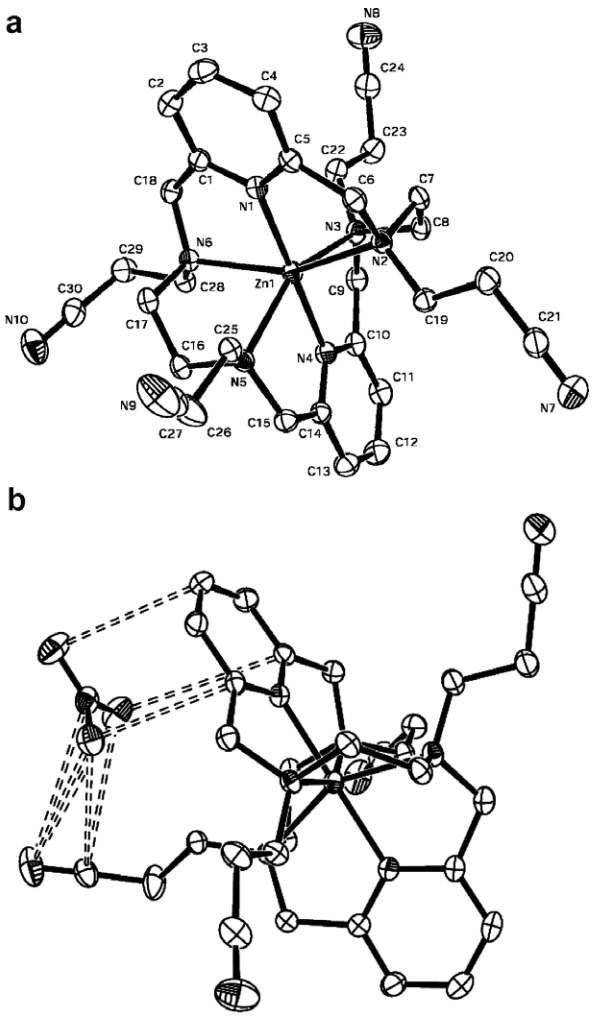

Fig. 2. (a) Crystal structure of the cation $[ZnL^2]^{2+}$, drawn with thermal ellipsoids at 50% confidence level. Nitrate anions and hydrogen atoms have been omitted for clarity. (b) Intermolecular interactions between nitrate ions, pyridine rings and nitrile groups. Selected bond lengths (Å) and angles (°): N(1)–Zn(1) 2.0556(18), N(2)–Zn(1) 2.2801(18), N(3)–Zn(1) 2.2765(18), N(4)–Zn(1) 2.0692(19), N(5)–Zn(1) 2.2822(18), N(6)–Zn(1) 2.3062(17), N(1)–Zn(1)–N(4) 179.48(8), N(1)–Zn(1)–N(3) 103.33(7), N(4)–Zn(1)–N(3) 76.73(7), N(1)–Zn(1)–N(2) 77.07(7), N(3)–Zn(1)–N(2) 82.30(7), N(3)–Zn(1)–N(5) 152.42(7), N(3)–Zn(1)–N(6) 104.82(6), N(2)–Zn(1)–N(6) 153.09(7), N(5)–Zn(1)–N(6) 82.38(6).

pyridinic nitrogen atoms and the metal ion [N(1)–Zn(1)–N(4), 165.2(3)° and 179.48(8)°, for $[ZnL^1](ClO_4)_2 \cdot H_2O$ and $[ZnL^2](NO_3)_2$, respectively], shows that the macrocycle is practically not folded.

A similar structure is observed for Zn(II) complexes with related hexaazamacrocycles [6,15,16].

The pyridine groups provides the shortest bond to the Zn atoms [Zn(1)–N(1) 2.105(9) and Zn(1)–N(4) 2.085(8) Å for $[ZnL^1](ClO_4)_2 \cdot H_2O$; N(1)–Zn(1) 2.0556(18) and N(4)–Zn(1) 2.0692(19) Å for $[ZnL^2](NO_3)_2$]. The bond lengths of the secondary amine groups vary from 2.226(9) to 2.308(8) Å for $[ZnL^1](ClO_4)_2 \cdot H_2O$ and 2.2765(18) to 2.3062(17) Å for $[ZnL^2](NO_3)_2$, not markedly different from those found in similar complexes that have been reported previously [6,15].

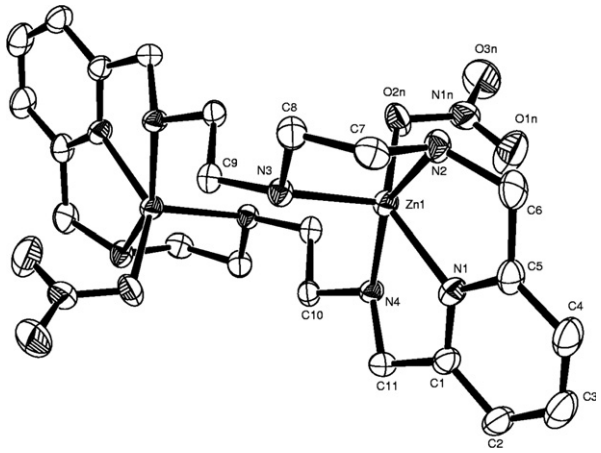

Fig. 3. Crystal structure of the cation $[Zn_2L^3(NO_3)_2]$, drawn with thermal ellipsoids at 50% confidence level. Hydrogen atoms, water molecule and ionic nitrate counterions have been omitted for clarity. Selected bond lengths (Å) and angles (°): N(1)–Zn(1) 2.035(3), N(2)–Zn(1) 2.170(3), N(3)–Zn(1) 2.069(3), N(4)–Zn(1) 2.201(3), O(2N)–Zn(1) 2.027(3), O(2N)–Zn(1)–N(1) 137.65(12), O(2N)–Zn(1)–N(3) 109.92(11), N(1)–Zn(1)–N(3) 111.75(11), O(2N)–Zn(1)–N(2) 99.63(11), N(1)–Zn(1)–N(2) 77.45(12), N(3)–Zn(1)–N(2) 84.38(11), O(2N)–Zn(1)–N(4) 97.61(10), N(1)–Zn(1)–N(4) 77.50(11), N(3)–Zn(1)–N(4) 106.67(11), N(2)–Zn(1)–N(4) 154.88(10).

In $[ZnL^2](NO_3)_2$ the donor atoms of the nitrile pendant groups are not interacting with the central ions.

The nitrate and perchlorate ions are not coordinated to the metal; they were refined with no disorder, giving bond distances and angles typical for these ions.

Inter- or intramolecular π,π-stacking interactions between the pyridine rings are not observed in the crystal structures. However, as in previous metal complexes with L^2, crystal lattice of $[ZnL^2](NO_3)_2$ contains nitrate ions close to pyridine rings and nitrile pendant groups [8]. The dihedral angle between the planes containing the nitrate counterion and the pyridine ring is 13.1°, and the distance (d_{c-N}) between the centroid of the pyridine and the N atom of the nitrate group, as analogous to the centroid-centroid distance, is 3.4 Å, commonly accepted for π,π-stacking interactions (Fig. 2b) [17]. Other nitrate ion is situated between two nitrile groups.

Interactions through hydrogen bonds have been found in the structure of $[ZnL^1](ClO_4)_2 \cdot H_2O$ (**1**) between the perchlorate counterions and amine hydrogen atoms from L^1. [N(3)–H(3N)···O(5P) 3.366 Å, 142.1°, N(3)–H(3N)···O(8P) 3.268 Å, 155.3°, N(6)–H(6N)···O(1P) 3.246 Å, 166.7°, N(6)–H(6N)···O(2P) 3.576 Å, 143.5(0.7)°, N(2)–H(2N)···O(6P)_$1 3.336 Å, 136.2°, N(2)–H(2N)···O-(7P)_$1 3.635 Å, 155.5°. $1 = x + 1, y, z$].

The crystal structure of $[Zn_2L^3(NO_3)_2](NO_3)_2 \cdot H_2O$ (Fig. 3) is consistent with the presence of the cation $[Zn_2L^3(NO_3)_2]^{2+}$, two well-separated nitrate anions and a crystallization water molecule. The cation $[Zn_2L^3(NO_3)_2]^{2+}$ shows a dinuclear endomacrocyclic complex, where both metal ions are five coordinated by one pyridinic nitrogen atom, three secondary amine groups from the macrocyclic backbone and one oxygen atom from a monodentate nitrate anion.

The largest angular difference between N(2)–Zn–N(4) and N(1)–Zn–O(2N) give rise to τ value of 0.29 confirming the distorted square pyramidal arrangement around the metal ion, with the amine nitrogen N(3) at the apical position and N(1)N(2)N(4)O(2N) as the basal plane (rms 0.2543 Å). The dihedral angle between the pyridine groups from the macrocyclic backbone is 0°, showing that the ligand is not twisted, and the planes containing the pyridinic rings are 0.15 Å away. The crystal structure also shows that there is not interaction between the metal ions, as they are 5.44 Å away.

As in the other complexes described before, the pyridine nitrogen bond length [Zn–N1 2.035(3) Å] is shorter than Zn–Namine distances, which are in the range 2.069(3)–2.201(3) Å, whilst the nitrate anion provides the shortest bond to the ion [Zn–O2N 2.027(3) Å].

Perchlorate anions interact through hydrogen bonds with the amine hydrogen atoms from the ligand. [N(4)–H(4A)···O(5N)_$1 3.03 Å, 152.5°; N(4)–H(4A)···O-(6N)_$1 3.18 Å, 128.3°; N(2)–H(2A)···O(4N)_$2 3.14 Å, 141.9°; N(2)–H(2A)···O(6N)_$2 3.11 Å, 139.2°; N(3)–H(3A)···O(4N)_$3 3.08 Å, 155.1°; N(3)–H(3A)···O-(5N)_$3 3.11 Å, 147.9°. $1 $-x+1/2$, $y-1/2$, $-z+1/2$, $2 $-x+1/2+1$, $y-1/2$, $-z+1/2$, $3 $-x+1$, $-y+1$, $-z+1$].

3.2. Spectroscopic and magnetic studies

The IR spectra of the complexes (KBr discs) show in all cases that the ν(C=N) vibration band of the pyridine groups are shifted to higher wavenumber than in the free ligand suggesting coordination to the metal atom [18]. In the case of the complexes with L^1 and L^3 the secondary amine stretches around 3300 cm^{-1} in the free ligand are split and/or shifted relative to that in the free macrocycle suggesting coordination to the metal ion. The position of the νC≡N band from the pendant groups for the perchlorate complex of L^2, is similar than in the free ligand, showing the no coordination of the nitrile groups to the metal ion. However, in the case of the nitrate complex the spectrum shows and additional band at 2426 cm^{-1} that can be related to the interaction with the nitrate ions present in the crystal lattice, as has been found previously [8]. Regarding the counterions absorptions, for $[ZnL^1](ClO_4)_2 \cdot H_2O$ and $[ZnL^2](ClO_4)_2$ the spectra feature absorptions at 1100 and 626 cm^{-1}attributable to ionic groups. The lack of splitting of this band indicates that there is no coordination of these groups to the metal centres [19,20]. However, the IR spectrum of $[Zn_2L^3](ClO_4)_4 \cdot 4H_2O$ shows the presence of several bands in the region associate with perchlorate vibrations that clearly identifies this complex as containing perchlorate coordinated groups. In the IR spectra of $[Zn_2L^3](NO_3)_4 \cdot H_2O$, the band at 1383 cm^{-1} associated with the presence of ionic nitrate is accompanied by several bands showing the presence of coordinated nitrate groups [21], but the spectrum of $[ZnL^2](NO_3)_2$ shows an intense band at 1383 cm^{-1} without splitting, suggesting the no coordination of these groups to the metal.

The LSI mass spectra of the complexes confirm the mononuclear nature of the complexes with L^1 and L^2, and the dinuclear nature for L^3 complexes.

Molar conductivity data, measured at room temperature using acetonitrile as solvent showed the presence of ionic counterions for the mononuclear complexes and the dinuclear Zn^{2+} perchlorate complex with L^3, since they are in the range reported for 2:1 electrolytes in that solvent (4:1 for the dinuclear one), whilst the conductivity data for $[Zn_2L^3](NO_3)_4 \cdot H_2O$ lies within the range reported for 2:1 electrolytes suggesting the coordination of two nitrate groups to the metal ions [22]. These values are indicative of the different coordinative capacity between perchlorate and nitrate anions. This is in agreeing with the results obtained from the IR and X-ray studies.

The ^{1}H NMR spectra of the complexes were recorded in CD_3CN. The spectrum of $[ZnL^1](ClO_4)_2 \cdot H_2O$ is quite complicated due to the low solubility of the complex in the common solvents, but it show the signals in general shifted downfield compared with the free ligands due to the complexation to the Zn(II) ion.

The ^{1}H NMR spectra of $[ZnL^2](NO_3)_2$ and $[ZnL^2](ClO_4)_2$ are similar. The spectra are more complicated than expected showing that fast interconversion of isomers in solution does not occur. The pyridinic protons appear at δ 8.25 and 7.65 ppm as a triplet and a doublet respectively. However, the aliphatic protons appear as different multiplets. The bencylic protons appear at δ 4.13–4.33, whilst the remaining aliphatic protons collapse in a multiplet at δ 2.40–3.16 ppm.

The ^{1}H NMR spectra of $[Zn_2L^3](NO_3)_4 \cdot H_2O$ and $[Zn_2L^3](ClO_4)_4 \cdot 4H_2O$ are similar. The pyridinic hydrogens appear as two multiplets at δ 8.08 an 7.48 ppm as a triplet and a doublet respectively. However, the aliphatic region is complicated, as the spectra show two broad overlapping resonances, one assigned to the bencylic protons and the other assigned to the ethylenic linkages, showing that a rapid conformational interconversion takes place in solution at this temperature.

4. Conclusion

The present work describes the synthesis and characterization of a nitrate and perchlorate Zinc(II) complexes with three different macrocyclic ligands. The different ring sizes of the ligands, the number of suitably disposed donor atoms and the presence or not of pendant-arms bearing additional potential ligating groups, give rise to complexes with different nuclearity and coordination environments. The $[ZnL^1](ClO_4)_2 \cdot H_2O$ and $[ZnL^2](NO_3)_2$ complexes present a mononuclear endomacrocyclic structure with the metal in an octahedral distorted environment coordinated by the six donor nitrogen atoms from the macrocyclic backbone. In contrast, the bigger size and number of donor atoms, let L^3 to accommodate two meal ions into

the macrocyclic cavity, and in this way, the complex $[Zn_2L^3(NO_3)_2](NO_3)_2 \cdot H_2O$ is dinuclear and both metal atoms are five coordinated by four donor nitrogen atoms from the macrocyclic framework and one oxygen atom from one monodentate nitrate anion.

In the $[ZnL^2](NO_3)_2$ complex a π interactions between a nitrate ion, a pyridine ring and a π-shell of the nitrile pendant group were found.

chemical shifts are reported in ppm. IR spectra in KBr pellets were recorded in the range of 4000–600 cm^{-1} on a Bruker Tensor 27.

2.1. Synthesis

2.1.1. [Rh(TropNMe)(CO)$_2$]

$RhCl_3 \cdot xH_2O$ (100 mg, 0.44 mmol) was dissolved in the minimum amount of DMF (ca. 3 ml) and refluxed for 30 min. until the solution turned pale yellow. The solution was treated with HTropNMe (77 mg, 0.57 mmol), precipitated with ice-water and separated by centrifuge. The complex was recrystallised from acetone (ca. 10 ml) (yield: 117 mg, 70%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): 7.32 (m, 2H), 7.12 (d, 1H), 6.95 (d, 1H), 6.81 (t, 1H), 1.56 (s, 3H). ^{13}C NMR (150.97 MHz, CD_2Cl_2, 25 °C): 45.8 (d, $^1J_{N-C}$ 3.6 Hz, CH_3), 118.10 (d, 1.82 Hz), 122.30 (d, 2.72 Hz), 125.07 (s), 135.51 (s), 135.87 (s), 169.41 (d, $^1J_{N-C}$ 1.73 Hz), 181.47 (s), 187.17 (d, $^1J_{Rh-C}$ 64.78 Hz), 187.90 (d, $^1J_{Rh-C}$ 71.55 Hz). IR_{KBr} (ν_{Rh-CO}) 2053, 1978 cm^{-1}, $IR_{Acetone}$ (ν_{Rh-CO}) 2070, 2000 cm^{-1}. Micro-analytical data: *Anal*. Calc. for $RhO_3C_{10}H_8N$: C, 40.98; H, 2.75; N, 4.78. Found: C, 41.53; H, 2.85; N, 4.85%.

2.1.2. [Rh(Trop)(CO)$_2$]

$RhCl_3 \cdot xH_2O$ (100 mg, 0.44 mmol) was dissolved in the minimum amount of DMF (ca. 3 ml) and refluxed for 30 min. until the solution turned pale yellow. The solution was treated with HTrop (66 mg, 0.57 mmol), precipitated with ice-water and separated by centrifuge. The complex was recrystallised from acetone (ca. 10 ml) (yield: 68 mg, 56%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): 7.68 (dd, 2H), 7.54 (m, 2H), 7.25 (dd, 1H). ^{13}C NMR (150.97 MHz, CD_2Cl_2, 25 °C): 128.22 (s), 130.20 (s), 138.28 (s), 184.49 (s), 184.96 (d, $^1J_{Rh-C}$ 72.74 Hz). IR_{KBr} (ν_{Rh-CO}) 2074, 2014 cm^{-1}, $IR_{Acetone}$ (ν_{Rh-CO}) 2078, 2007 cm^{-1}. Micro-analytical data: *Anal*. Calc. for $RhO_3C_{10}H_8$: C, 38.60; H, 1.80. Found: C, 38.62; H, 1.85%.

2.1.3. [Rh(TropNMe)CO(PPh$_3$)] (**1**)

[Rh(TropNMe)(CO)$_2$] (20 mg, 0.068 mmol) was dissolved in the minimum amount of warm acetone (ca. 2 ml) to which was added PPh_3 (20 mg, 0.075 mmol). The reaction mixture was allowed to evaporate and crystals suitable for X-ray crystallography were obtained as yellow blocks (yield: 20 mg, 55%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): 7.67 (m, 5H), 7.39 (m, 10H), 7.12 (dd, 1H), 6.95 (t, 1H), 6.88 (t, 1H), 6.63 (d, 1H), 6.51 (t, 1H). ^{13}C NMR (150.97 MHz, CD_2Cl_2, 25 °C): 45.77 (d, $^1J_{N-C}$ 3.64 Hz), 117.29 (d, 1.74 Hz), 120.04 (d, 1.63 Hz), 122.35 (d, 1.63), 128.74 (d, 9.15 Hz), 130.78 (s), 134.07 (t, 21.55, 25.35. Hz), 134.86 (d, 11.33 Hz), 168.37 (s), 181.77 (d, 5.45 Hz), 192.40 (dd, $^1J_{Rh-C}$ 76.09 Hz, $^2J_{P,C}$ 23.53 Hz). ^{31}P NMR 42.80 (d, $^1J_{Rh-P}$ 146.88 Hz). IR_{KBr} (ν_{Rh-CO}) 1943 cm^{-1}, $IR_{Acetone}$ (ν_{Rh-CO}) 1962 cm^{-1}. Micro-analytical data: *Anal*. Calc. for $RhPO_2C_{27}H_{23}N$: C, 61.49; H, 4.40; N, 2.66. Found: C, 61.94; H, 4.49; N, 2.71%.

2.1.4. [Rh(Trop)CO(PPh$_3$)] · Acetone (**2**)

[Rh(Trop)(CO)$_2$] (20 mg, 0.068 mmol) was dissolved in the minimum amount of warm acetone (ca. 2 ml) to which was added PPh_3 (20 mg, 0.075 mmol). The reaction mixture was allowed to evaporate and crystals suitable for X-ray crystallography were obtained as yellow blocks (yield: 30 mg, 78%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): 7.67 (m, 6H), 7.40 (m, 9H), 7.28 (m, 2H), 6.97 (m, 3H), 2.15 (s, 3H). ^{13}C NMR (150.97 MHz, CD_2Cl_2, 25 °C): 31.16 (s), 126.47 (s), 127.36 (s), 127.46 (s), 128.81 (d, 11.14 Hz), 131.08 (s), 133.43 (d, 51.21 Hz), 134.83 (d, 11.19 Hz), 137.07 (s), 137.23 (s), 184.64 (s), 185.49 (s), 190.15 (dd, $^1J_{Rh-C}$ 76.18 Hz, $^2J_{P,C}$ 25.31 Hz), 206.95 (s). ^{31}P NMR 48.80 (d, $^1J_{Rh-P}$ 173.10 Hz). IR_{KBr} (ν_{Rh-CO}) 1974 cm^{-1}, $IR_{Acetone}$ (ν_{Rh-CO}) 1978 cm^{-1}. Micro-analytical data: *Anal*. Calc. for $RhPO_4C_{28}H_{26}$: C, 60.01; H, 4.68. Found: C, 60.46; H, 4.62%.

2.2. Crystallography

The data collection was done on a Bruker Apex2 4K CCD diffractometer using Mo Kα (0.71073 Å) and ω-scans at 100(2) K. After completion the first 50 frames were repeated to check for decay, of which none was observed. All reflections were merged and integrated with SAINT-PLUS [15] and were corrected for Lorentz, polarization and absorption effects using SADABS [16]. The structures were solved by the heavy atom method and refined through full-matrix least-squares cycles using the SHELX-97 [17] package with $\sum(||F_o| - |F_c||)^2$ being minimized. All non-H atoms were refined with anisotropic displacement parameters, while H atoms were constrained to parent atom sites using a riding model (aromatic C–H = 0.93 Å; aliphatic C–H = 0.96 Å). The graphics were done with the DIAMOND [18] Visual Crystal Structure Information System software. The crystals of **2** included 0.75 acetone solvate molecule per asymmetric unit, which was disordered of two sites along the *a*-axis. The crystal structure of **2** has been reported previously, however, the authors failed to locate and describe the acetone solvate molecule [19] in the asymmetric unit. Details of the crystal data, intensity measurements and data processing are summarized in Table 1. Selected bond distances and angles are given in Table 2.

2.3. Computational data

Calculation results were obtained using the GAUSSIAN-03W [20] software package. DFT calculations were done at the B3LYP [21] level of theory; for the main group elements the 6-31G(d) [22,23] basis set were incorporated while the rhodium core was described by the LanL2DZ [24] basis set. Optimised structures were verified as a minimum through frequency analysis and from this data the stretching frequencies of the carbonyl groups were identified. The isodesmic comparisons between different isomers were calculated using the diketonato rhodium(I) dicarbonyl complexes to minimize error.

3. Results and discussion

Details of the data collections and refinement parameters of [Rh(TropNMe)CO(PPh$_3$)] (**1**) and [Rh(Trop)CO(PPh$_3$)] · Acetone (**2**) are reported in Table 1 and selected geometrical parameters are summarized in Table 2. The molecular structures with thermal ellipsoids and numbering schemes for **1** and **2** are shown in Figs. 1 and 3, respectively.

3.1. Structural description

The molecular structure of [Rh(TropNMe)CO(PPh$_3$)] (**1**) is the first example of a mixed N,O-troponate complex containing carbonyl and triphenylphosphine moieties (Fig. 1). A distorted square planar geometry about the rhodium(I) metal centre can be observed as defined by the coordinated atoms. This distortion is observed as a deviation from linearity of the angle formed by O–Rh–C (carbonyl) and N–Rh–P atoms, 174.98(5)° and 169.29(4)°, respectively. The bidentate bite angle formed by O–Rh–N is close to that observed for the unfunctionalised tropolonato complexes in the order of ca. 80° [7–12]. It was expected that the Rh–N and Rh–O bond distances would differ, but in the current complex this variation is minimal. Similar trends have been observed for O,O-tropolonato

complexes [5,25,12] indicating that the seven-membered ring system reduces the effect of functionalization of the hetero-atoms.

The ordering in the solid state is significantly changed by the presence of π–π stacking between respective 2-(*N*-methylamino)troponato ligands, which is observed in the order of 3.479(7) Å, Fig. 2. The complex **1** adopts an arched configuration as defined by the dihedral angle of 8.81(3)° between the planes from the seven-membered troponato backbone with that of the Rh(I) centre and the two O-donor atoms. The rhodium(I) atom is in close proximity to a hydrogen atom of the π-stacking troponato ring, $Rh\cdots H_4$ [$1-x$, $2-y$, $1-z$], at a distance of 3.4157(1) Å.

The molecular structure of [Rh(Trop)CO(PPh_3)]·Acetone (**2**) shows the coordination of the complex to exhibit a slightly distorted square planar geometry about the rhodium(I) metal centre (Fig. 3). The deviation from planarity can be observed from the angle formed by O–Rh–C (carbonyl) and O–Rh–P atoms, 174.0(1)° and 174.25(6)°, respectively. The rhodium(I) metal centre is elevated above the four coordinating atoms by 0.0143(5) Å. The O–Rh–O bidentate bite angle is close to that observed for unfunctionalised tropolonato complexes in the order of 77.9(1)° [7–12]. The difference in *trans* directing groups (PPh_3 versus CO) does not seem to play such a significant role, as observed from the comparable Rh–O bond distances (Table 2).

The rhodium(I) metal complex co-crystallises with an acetone molecule in the asymmetric unit, exhibiting a 75% statistical disorder over two positions. No significant hydrogen bonding is found between the complex and the solvent molecule. The solvent molecule occupies voids created by the efficient packing of the metal complex. Hydrogen bonding between a tropolonato oxygen atom (O_2) and a corresponding phenyl hydrogen atom (H_{14}–C_{14}) is observed. The intermolecular hydrogen bond [2.585 Å ($O_2\cdots H_{14}$), 3.509(4) Å (O_2, C_{14}), 172.7(2)°] can be classified as a weak interaction but is enhanced by the π–π stacking in the order of 3.39(1) Å of the tropolonato moieties. The

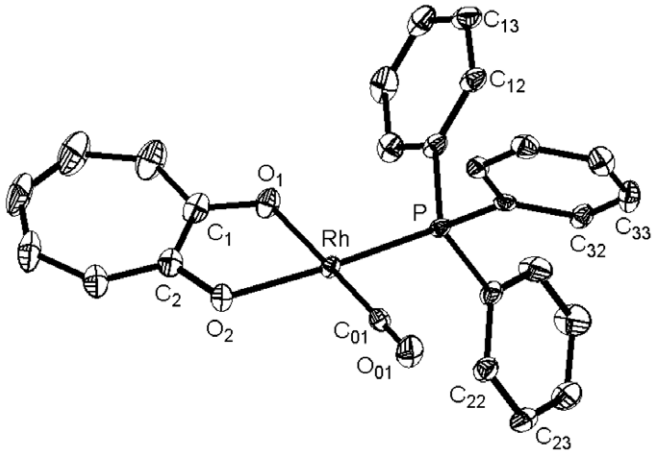

Fig. 3. Molecular diagram showing the numbering scheme and displacement ellipsoids (50% probability) in [Rh(Trop)(CO)(PPh_3)] (**2**). The first digit in the phenyl rings refers to the number of the ring, the second digit to the number of the C atom in the ring (1–6). Hydrogen atoms and disordered solvent molecule (acetone) omitted for clarity.

effect of the intermolecular hydrogen bonding and π-stacking tropolonato functionalities create a three-dimensional chain along the *b*-axis.

The change in geometrical parameters due to the introduction of a methylamino moiety on the troponoid ring system, does not seem to significantly affect the coordination to the rhodium(I) centre (Table 2). The *trans* influence of N(Me) versus O was expected to be more prominent due to the significant change observed in the infrared frequency (solid state ~30 cm^{-1}, solvent ~16 cm^{-1}). A single noteworthy difference between the two solid state structures was the observed change of the Rh–P bond distance in the order of 0.04 Å. The bite angle was also not affected by the change of hetero-atoms and is nearly constant at 77°. This relative insensitivity of functionalization of the troponoid ring might indicate that the cycloheptatriene system counterbalances the different affects of hetero group donor atoms.

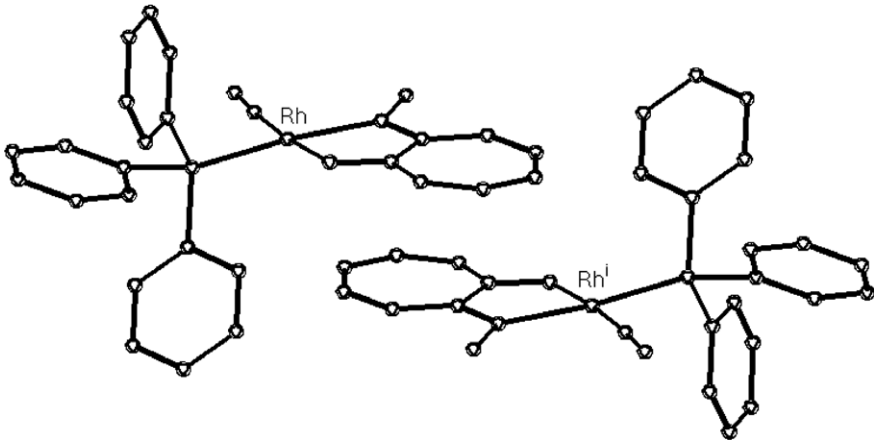

Fig. 2. Packing diagram of [Rh(TropNMe)CO(PPh_3)] (**1**) along the *ac*-plane illustrating the π–π stacking [3.479(7) Å] in the unit cell. Hydrogen atoms omitted for clarity [symmetry code: $1-x$, $2-y$, $1-z$].

3.2. Computational data

Since complexes **1** and **2** tended to behave in a similar fashion with respect to their geometrical parameters in the solid state, a theoretical study was done to determine if any significant differences could be observed at a theoretical level between these compounds. The crystallographically determined structures were first optimised and reported herein as compounds [Rh(TropNMe)CO(PPh_3)] (**I**) and [Rh(Trop)CO(PPh_3)] (**II**), respectively. Secondly, the [Rh(TropNMe)$(CO)_2$] and [Rh(Trop)$(CO)_2$] complexes were optimised to construct an isodesmic reaction scheme to compare complexes **I** and **II** relative to each other in terms of stability. Finally, the *cis*-adduct (PPh_3-*cis*-NMe) of [Rh(TropNMe)CO(PPh_3)] (**I**) was calculated to determine the structural change of the coordination sphere due to steric factors, which could indicate a preference of the *trans*-isomer over the *cis*-isomer. Calculated geometrical parameters and energies are reported in Table 3.

Geometrical results from the calculations confirmed that these two types of complexes (**I** and **II**) have similar structural parameters, Table 3. The close structural relationship between the calculated and crystallographic observed structures is best illustrated with a RMS overlay error of less than 0.376 and 0.133 Å for **1/I** and **2/II**, respectively, see Fig. 4. The increased RMS overlay error of complexes **1/I** are most probably due to solid state interactions as described below.

The calculated Rh–N and Rh–O bond distances for the 2-(*N*-methylamino)troponato complexes (**1** and **I**) do not vary by much in contrast to that observed for the solid state structure (**1**). Compared to the crystallographic data of **1**, an increase is observed in the Rh–P bond distance of ca. 0.16 Å for the optimised structure (**I**). In order to characterise the effect of functionalization, the *cis*-conformation (PPh_3-*cis*-NMe) is included and it clearly indicated a strained orientation with the Rh–N bond distance increasing significantly from the *trans*-conformation (**I**). The affect of the relative strain can also be observed from the energy difference between these two isomers which is in the order of 50 kJ/mol, indicating that isomer **I** is the preferred isomer in the solid state and solution.

Comparing the tropolonato complexes, **2** and **II**, no significant changes (less than 0.1 Å) in Rh–O or Rh–C bond distances are observed. The calculated Rh–P bond distance is slightly shorter than the reported value of 2.223 Å in the crystal structure (Table 3). The effect of rotation of the triphenylphosphine on the O–Rh–O bite angle is less than 1° and is in good agreement with the solid state structure. As an illustrative example the rotation of the triphenylphosphine moiety to its higher energy conformer (a local minimum) is only 25.2 kJ/mol. This clearly indicates that in solution the two complexes (**II** and Rotation, Table 3) are nearly in the same energetic environment.

To obtain a relative measure for the different complexes, an isodesmic reaction scheme was constructed to illustrate the energy difference profile between the 2-(*N*-methylamino)troponato (N,O; **I**) and tropolonato (O,O; **II**) complexes, Table 3. Complex **II** is ca. 26 kJ/mol lower in the energy profile than complex **I**, this is mostly from the addition of the methylamino moiety introducing strain into the five-membered chelating ring of the rhodium(I) complex. Although the energy difference is significantly large, it is still within a comparable range for the two complexes if one considers the rotation of the triphenylphosphine moiety which is only 25.2 kJ/mol.

[a] $E_{iso} = \{[E(\text{RhTrop}(CO)_2) + E(\text{Rh(Trop)CO}(PPh_3)^{ROT})] - [E(\text{RhTrop}(CO)_2) + E(\text{Rh(Trop)CO}(PPh_3)^{(II)})]\} \times 627.5 \times 4.184$.

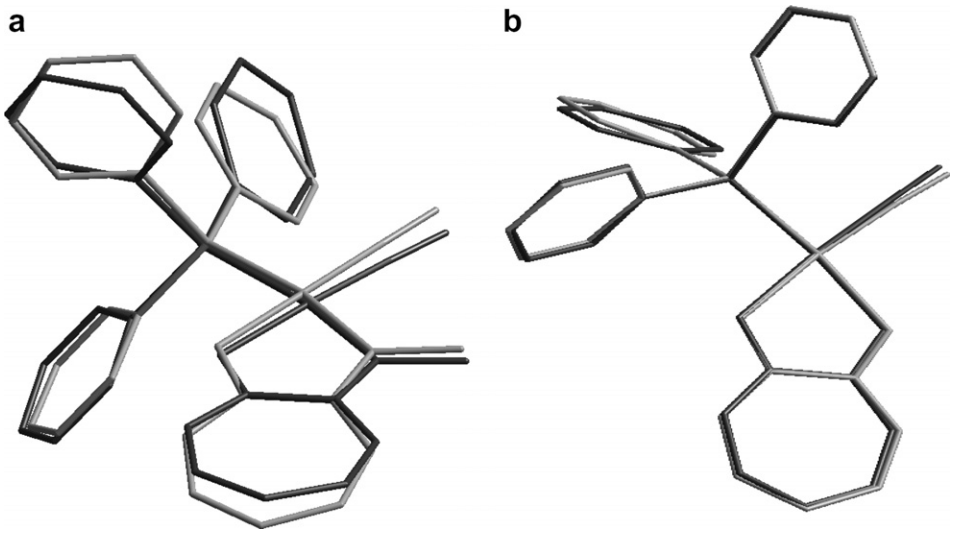

Fig. 4. Overlayed structures of the calculated (grey) and solid state (black) structures of [Rh(TropNMe)(CO)(PPh_3)] (left) and [Rh(Trop)(CO)(PPh_3)] (right). Hydrogen atoms omitted for clarity. The RMS overlay error of 0.376 and 0.133 Å does not include hydrogen atoms for the respective complexes.

4. Conclusion

The effect of substitution of a tropolonato oxygen atom with a *N*-methylamino moiety does not significantly alter the geometrical parameters of the rhodium(I) complex. The structural similarity between **1** and **2** in the solid state was confirmed by computational results. Finally, π–π stacking could be observed for both the functionalised 2-(*N*-methylamino)troponato and tropolonato rhodium(I) complexes.

Acknowledgements

I thank Prof. A. Roodt for his helpful discussions in preparation of this paper. Financial assistance from the University of the Free State is gratefully acknowledged, while Dr. A. Muller, Mr. Leo Kirsten and Mr. J.M. Janse van Rensburg are thanked for the data collections. I also express our gratitude towards SASOL and the South African National Research Foundation (SA-NRF/THRIP) for financial support of this project. Part of this material is based on work supported by the SA-NRF/THRIP under grant number GUN 2068915. Opinions, findings, conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the SA-NRF.

Appendix A. Supplementary material

CCDC 604203 and 624149 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.07.039.

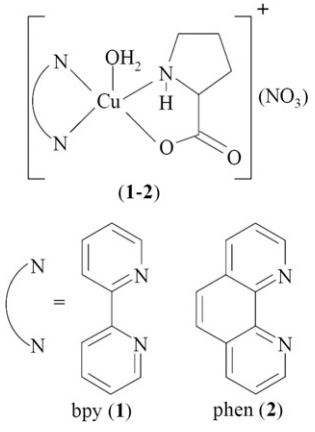
L-proline and N,N-donor heterocyclic bases as DNA groove binders. Our choice of 2,2′-bipyridine (bpy) and 1,10-phenathroline (phen) is based on their difference in DNA binding ability [13,15c]. The distinctive cyclic structure of proline's side chain gives an exceptional conformational rigidity compared to other amino acids. L-proline is essential for the synthesis of collagen, the most abundant protein in mammals [22].

Herein, we present the synthesis, structure, DNA binding and cleavage property of two ternary copper(II) complexes of formulation $[Cu(L\text{-pro})(B)(H_2O)](NO_3)$ (**1**, **2**) where B is N,N-donor heterocyclic base, *viz.* 2,2′-bipyridine (bpy, **1**) and 1,10-phenanthroline (phen, **2**) (Scheme 1). The bpy complex (**1**) has been structurally characterized by X-ray crystallography. Detailed studies have been made to elucidate the role of the DNA binder and the mechanistic pathways involved in the 'chemical nuclease' activity.

2. Experimental



2.1. Materials

All reagents and chemicals were procured from commercial sources. Solvents used for electrochemical and spectroscopic studies were purified by standard procedures [23]. The supercoiled pUC19 DNA (cesium chloride purified) was purchased from Bangalore Genei (India). Calf thymus (CT) DNA, agarose (molecular biology grade), distamycin-A, catalase, superoxide dismutase (SOD) and ethidium bromide (EB) were obtained from Sigma (USA). Tris(hydroxymethyl)aminomethane–HCl (Tris–HCl) buffer solution was prepared by using deionized, sonicated triple distilled water.

2.2. Synthesis

*Preparation of [Cu(L-pro)(B)(H$_2$O)](NO$_3$) (**1**, **2**) (B = bpy, phen).* The complexes were prepared by following a reported [24] synthetic method with modification in which a 10 ml aqueous solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.48 g, 2.0 mmol) was reacted with L-proline (0.23 g, 2.0 mmol) treated with NaOH (0.08 g, 2.0 mmol) in water (10 ml) under magnetic stirring at room temperature. After 30 min, a 20 ml methanol solution of the heterocyclic base [bpy (0.31 g), phen (0.40 g) (2.0 mmol)] was added to the solution and the resulting mixture was stirred for 2 h at room temperature. On cooling the solution to an ambient temperature, it was filtered and the filtrate on slow concentration yielded crystalline solid of the product. The solid was isolated and washed with cold aqueous methanol and finally dried over P_4O_{10} (yield: ~70%). *Anal.* Calc. for $C_{15}H_{18}CuN_4O_6$ (**1**): C, 43.52; H, 4.38; N, 13.53. Found: C, 43.35; H, 4.18; N, 13.26%. λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) in water: 602 (50), 311 (10 820), 300 (10 790), 237sh (11 030). FT-IR, cm^{-1} (KBr disc): 3445br, 3238m, 3018m, 2946m, 2885s, 1627s, 1574w, 1448m, 1384 vs, 1287w, 1191m, 1046m, 922m, 835m, 786m, 733s, 662m, 576m, 518m, 421m (s, strong; m, medium; w, weak; br, broad; vs, very strong). μ_{eff} (solid, 298 K): 1.78 μ_B. Λ_M ($\Omega^{-1}\,cm^2\,M^{-1}$) in water at 25 °C: 128. *Anal.* Calc. for $C_{17}H_{18}CuN_4O_6$ (**2**): C, 46.61; H, 4.15; N, 12.79. Found: C, 46.35; H, 4.07; N, 12.58%. λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) in water: 612 (60), 294 (8740), 272 (29 350), 204 (38 800). FT-IR, cm^{-1} (KBr disc): 3380br, 3150br, 2884m, 1624s, 1519m, 1519m, 1387 vs, 1327w, 1148m, 1041m, 932m, 859s, 825m, 780m, 724s, 628w, 582w, 531m, 468m, 430w. μ_{eff} (solid, 298 K): 1.75 μ_B. Λ_M ($\Omega^{-1}\,cm^2\,M^{-1}$) in water at 25 °C: 190.

The complexes showed high solubility in water, good solubility in methanol and ethanol, dimethylformamide (DMF) and dimethyl sulfoxide (DMSO) and were insoluble in hydrocarbons.

Scheme 1. Complexes **1** and **2** and the heterocyclic bases.

2.3. General methods

The elemental analysis was done using a Thermo Finnigan FLASH EA 1112 CHNS analyzer. The infrared and electronic spectra were recorded on Perkin–Elmer Lambda 35 and Perkin–Elmer spectrum one 55 spectrophotometers, respectively. DNA melting experiments were carried out on a Varian Cary 300 Bio UV–Vis spectrophotometer attached to a Cary Peltier temperature controller. Magnetic susceptibility data at 298 K for the polycrystalline samples of the complexes were obtained using Model 300 Lewis-coil-force magnetometer of George Associates Inc. (Berkeley, USA) make. $Hg[Co(NCS)_4]$ was used as a standard. Experimental susceptibility data were corrected for diamagnetic contributions [25]. Molar conductivity measurements were done using a Control Dynamics (India) conductivity meter. Electrochemical measurements were made at 25 °C on an EG&G PAR model 253 VersaStat potentiostat/galvanostat with electrochemical analysis software 270 using a three electrode setup consisting of a glassy carbon working, platinum wire auxiliary and a saturated calomel reference electrode (SCE) in water containing 0.1 M KCl. The electrochemical data were uncorrected for junction potentials.

2.4. X-ray crystallographic procedures

Dark-blue single crystals of [Cu(L-pro)(bpy)-(H_2O)](NO_3) (**1**) was obtained on slow concentration of the aqueous-methanolic solution of the complex. Crystal mounting was done on glass fiber with epoxy cement. All geometric and intensity data for **1** were collected at room temperature using a Bruker SMART APEX CCD diffractometer, equipped with a fine focus 1.75 kW sealed tube Mo Kα X-ray source ($\lambda = 0.71073$ Å), with increasing ω (width of 0.3°/frame) at a scan speed of 10 s/frame. The SMART software was used for data acquisition and the SAINT software for data extraction. Absorption corrections were made using SADABS [26]. The structure was solved and refined by full-matrix least-squares method using SHELX system of programs [27]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms attached to the heteroatoms were fixed in their calculated positions and refined using a riding model.

Crystal data for **1**: Formula: $C_{15}H_{18}CuN_4O_6$; colour: blue; size: $0.32 \times 0.26 \times 0.20$ mm; $M = 413.87$; triclinic, space group $P\bar{1}$ (no. 1); $a = 7.082(3)$; $b = 10.483(5)$; $c = 11.581(5)$ Å; $\alpha = 89.700(7)$; $\beta = 83.488(8)$; $\gamma = 84.109(8)°$; $V = 849.7(7)$ Å^3; $Z = 2$; $T = 293(2)$ K; $D_c = 1.618$ g cm^{-3}; $\mu = 13.27$ cm^{-1}; $1.77 \leqslant 2\theta \leqslant 26.37$; $R(F_o) = 0.0588$; $wR = 0.1420$ for 6550 reflections with $I > 2\sigma(I)$ and 469 parameters. [$R_1(F^2) = 0.0714$ (all data)]; weighing scheme: $w = 1/[\sigma^2(F_o^2) + 0.0852P^2 + 0.0P]$, where $P = (F_o^2 + 2F_c^2)/3$. The goodness-of-fit and the largest difference peak were 1.020 and 1.080 e Å^{-3}, respectively. Perspective view of the complex was obtained by ORTEP [28].

2.5. Studies on DNA interaction

The UV absorbance at 260 and 280 nm of the CT-DNA solution in 5 mM Tris–HCl buffer (pH 7.2) gave a ratio of ~1.9, indicating the DNA was free of protein [29]. The concentration of CT DNA was measured from the band intensity at 260 nm with a known ε value (6600 M^{-1} cm^{-1}) [30]. The electronic spectra of the complexes were recorded before and after addition of CT-DNA in the 5 mM Tris–HCl/5 mM NaCl buffer (pH 7.2). The equilibrium binding constant (K_b) values for the interaction of the complexes with CT-DNA were obtained from the absorption spectral titration data using the following equation:

$$(\varepsilon_a - \varepsilon_f)/(\varepsilon_b - \varepsilon_f) = (b - (b^2 - 2K_b^2 C_t[\mathrm{DNA}]/s)^{1/2})/2K_b C_t \quad (1)$$

where $b = 1 + K_b C_t + K_b[\mathrm{DNA}]/2s$; ε_a, the extinction coefficient observed for the charge transfer absorption band at a given DNA concentration; ε_f, the extinction coefficient of the complex free in solution; ε_b, the extinction coefficient of the complex when fully bound to DNA; K_b, the equilibrium binding constant; C_t, the total metal complex concentration; [DNA], the DNA concentration in nucleotides; and s, the binding site size in base pairs [31,32].

The apparent binding constant (K_{app}) of the complexes **1** and **2** were also determined by fluorescence spectral technique using ethidium bromide (EB) bound CT DNA solution in Tris–HCl/NaCl buffer (pH 7.2). The fluorescence intensities of EB at 600 nm (546 nm excitation) with an increasing amount of the ternary complex concentration were recorded. Ethidium bromide was non-emissive in Tris-buffer medium due to fluorescence quenching of the free EB by the solvent molecules [33,34]. In the presence of DNA, EB showed enhanced emission intensity due to its intercalative binding to DNA. A competitive binding of the copper complexes to CT DNA could result in the displacement of EB or quenching of the bound EB by the paramagnetic copper(II) species decreasing its emission intensity.

DNA-melting experiments were carried out by monitoring the absorbance of CT-DNA (200 μM NP) at 260 nm with varying temperature in the absence and presence of the complexes in a 2:1 ratio of DNA and the complex with a ramp rate of 0.5 °C/min in phosphate buffer (pH 6.85) using a Peltier system attached to the UV–Vis spectrophotometer.

Viscometric titrations were performed with a Schott Gerate AVS 310 Automated Viscometer. The viscometer was thermostated at 37 °C in a constant temperature bath. The concentration of DNA was 200 μM in NP and the flow times were measured with an automated timer, and each sample was measured three times, and an average flow time was calculated. Data were presented as $(\eta/\eta_0)^{1/3}$ vs. [complex]/[DNA], where η is the viscosity of DNA in the presence of complex and η_0 that of DNA alone. Viscosity values were calculated from the observed flowing time of DNA-containing solutions (t) corrected for that of buffer alone (t_0), $\eta = (t - t_0)$.

2.6. DNA cleavage

The extent of cleavage of supercoiled (SC) DNA in the presence of the complex and reducing agent MPA was determined by agarose gel electrophoresis. In a typical reaction, supercoiled pUC19 DNA (0.2 μg), taken in 50 mM Tris–HCl buffer (pH 7.2) containing 50 mM NaCl, was treated with the complex. The extent of cleavage was measured from the intensities of the bands using UVITEC Gel Documentation System.

For mechanistic investigations, inhibition reactions were done on adding the reagents prior to the addition of the complex. The solutions were incubated for 1 h in a dark chamber at 37 °C followed by addition to the loading buffer containing 25% bromophenol blue, 0.25% xylene cyanol, and 30% glycerol (2 μL), and the solution was finally loaded on 0.8% agarose gel containing 1.0 μg/ml ethidium bromide (EB). Electrophoresis was carried out for 2 h at 60 V in tris-acetate-EDTA (TAE) buffer. Bands were visualized by UV light and photographed for analysis. Due corrections were made to the observed intensities for the low level of NC form present in the original sample of SC

DNA and for the low affinity of EB binding to SC in comparison to nicked-circular (NC) and linear forms of DNA [35].

3. Results and discussion

3.1. Synthesis and general aspects

The ternary copper(II) complexes are prepared in high yield from the reaction of $Cu(NO_3)_2 \cdot 3H_2O$ with L-proline and heterocyclic bases. The complexes are stable and soluble in water and common polar organic solvents. They are characterized from the analytical and physicochemical data (Table 1). The one-electron paramagnetic complexes display intense charge transfer (CT) band in the range of 200–320 nm that can be attributed to the $\pi \rightarrow \pi^*$ transition of the coordinated phenanthroline ligand. The d–d band is observed at ~600 nm in an aqueous medium (Fig. 1). The complexes are redox active and display a cyclic voltammetric response near 0.1 V versus SCE in water–0.1 M KCl. The redox process is assignable to the Cu(II)/Cu(I) couple. The complexes show 1:1 electrolytic behavior in solution.

3.2. Crystal structure of *1*

Complex **1** has been structurally characterized from single-crystal X-ray diffraction technique. It crystallizes in the non-centrosymmetric *P*1 space group of the triclinic crystal system having two independent molecules in the crystallographic asymmetric unit. The copper(II) ion is coordinated in a distorted square-pyramidal (4 + 1) coordination geometry through the carboxylate oxygen atom O(1) and the amino nitrogen atom N(3) of L-proline and two N-atoms of 2,2′-bipyridine and a weakly bound apical water molecule (average trigonal distortion parameter, $\tau_{av} = 0.094$) [36]. The structure resembles to the corresponding structure of reported [Cu(L-pro)(phen)(H_2O)](NO_3) complex [24]. The configuration at the proline nitrogen and the α-carbon is *S* in each complex cation. The copper atom is displaced by ~0.16 Å from the mean plane through its basal atoms in the direction towards the apical water molecule. The conformation of the five-membered ring of the proline ligand can be described as twisted. The ORTEP view of the molecule is shown in Fig. 2. Selected bond distances and angles are given in Table 2.

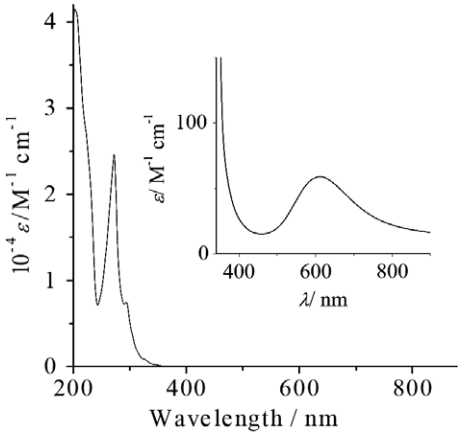


Fig. 1. Electronic spectrum of complex **2** in an aqueous medium. The inset shows the d–d band of the complex **2**.

Table 1
Physicochemical data for the ternary L-proline copper(II) complexes **1** and **2**

Complex	**1** (B = bpy)	**2** (B = phen)
IR[a]: [$\nu(NO_3^-)$/cm^{-1}]	1384	1387

atom of lattice nitrate anion (distance 3.013 Å). The unit cell packing diagram of **1** shown in Fig. S1. The intermolecular hydrogen bonding interactions present in **1** are shown in Fig. S2.

3.3. DNA binding properties

The binding of the complexes **1** and **2** to the calf thymus (CT) DNA has been studied by electronic absorption spectral technique. The absorption spectral traces of the complex **2** with increasing concentration of CT DNA are shown in Fig. 3. We have observed minor bathochromic shift of 3 nm along with significant hypochromicity for complex **2**. The equilibrium DNA binding constants (K_b) along with binding site size (s) determination of the complexes to CT DNA are obtained by monitoring the change of the absorption intensity of the spectral bands with increasing concentration of CT DNA. The bpy complex shows weak binding to the DNA due to less extended planarity compared to phen, which is consistent with the observed trend in hypochromism. K_b and s values for the phen complex, **2** are $3.58(\pm0.2)\times10^5\ M^{-1}$ and 1.53 (±0.1), respectively. The higher binding propensity of the phen complex in comparison to its bpy analogue could be due to the presence of extended planar aromatic ring in phen. Earlier studies on bis-phen copper complex have shown that this complex binds to DNA either by partial intercalation or binding of one phen ligand to the minor groove while the other phen making favourable contacts within the groove [37–40]. The nature of binding of the phen complex is proposed to be similar as observed for the bis-phen species.

The emission spectral method is used to study the relative binding of the complexes to CT-DNA. The emission intensity of ethidium bromide (EB) is used as a spectral probe as EB shows no apparent emission intensity in buffer solution because of solvent quenching and an enhancement of the emission intensity when intercalatively bound to DNA [41]. The binding of the complexes to DNA decreases the emission intensity of EB. Relative binding propensity of the complexes to DNA is measured from the extent of reduction of the emission intensity (Fig. 4). The apparent binding constant (K_{app}) values for **1** and **2** are 1.8×10^3 and $8.28\times10^5\ M^{-1}$, respectively. The comparatively high DNA binding propensity of the phen complex in comparison to its bpy analogue could be due to the presence of extended aromatic ring in planar phen ligand facilitating non-covalent interactions with the DNA molecule. The reduction of the emission intensity of EB on increasing the complex concentration could be due to displacement of the DNA bound EB by the ternary copper(II) complexes.

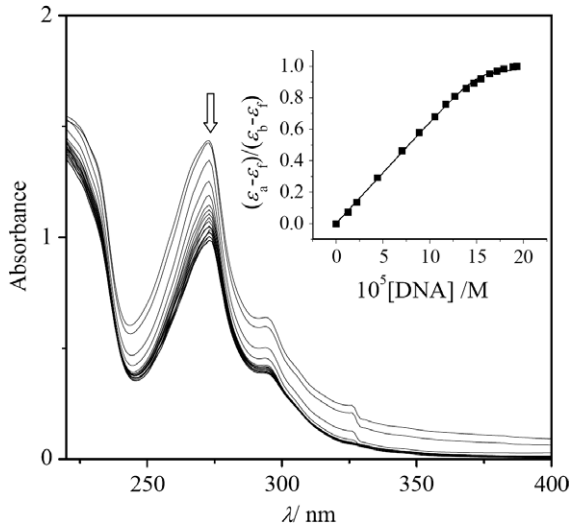

Fig. 3. Absorption spectral traces on addition of CT DNA to the solution of **2** (shown by arrow). The inset shows the best least-squares fit of $\Delta\varepsilon_{af}/\Delta\varepsilon_{bf}$ vs. [DNA].

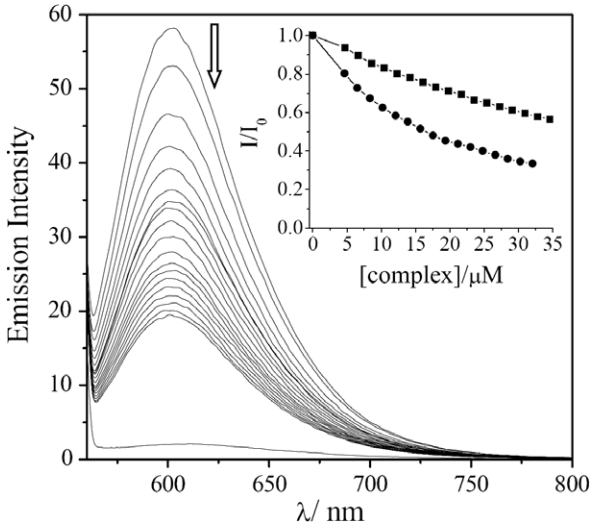

Fig. 4. Emission spectral changes on addition of [Cu(L-pro)(phen)-(H_2O)](NO_3) (**2**) to the CT-DNA bound to ethidium bromide (shown by arrow). Inset: Effect of addition of [Cu(L-pro)(B)(H_2O)](NO_3) [B = bpy (**1**, ■); phen (**2**, ●)] to the emission intensity of 300 μM CT DNA-bound ethidium bromide (1.3 μM) in a 5 mM Tris–HCl/5 mM NaCl buffer (pH 7.2) at 25 °C.

The denaturation of DNA from double-strand to single strand results in absorption hyperchromism around 260 nm. The binding of metal complexes to the double-stranded DNA usually stabilizes the duplex structure to some extent depending on the strength of interaction with nucleic acid [42]. The binding should lead to an increase in the melting temperature (T_m) of DNA as compared to DNA itself. The binding of the complex **2** results in an moderate increase (~2 °C) in the melting temperature (ΔT_m) of CT-DNA suggesting primarily electrostatic and/or groove binding nature of the complexes (Table 1, Fig. 5a).

To investigate further the binding modes of the complexes, viscosity measurements on solutions of calf thymus DNA incubated with the complexes were carried out. Because the viscosity of a DNA solution is sensitive to the addition of organic drugs and metal complexes bound by intercalation, we examined the effect on the specific relative viscosity of DNA upon addition of complexes. Since the relative specific viscosity (η/η_0), (η and η_0 are the specific viscosities of DNA in the presence and absence of the complexes, respectively) of DNA reflects the increase in contour length associated with separation of DNA base pairs caused by intercalation, a classical intercalator such as EtBr could cause a significant increase in viscosity of DNA solutions. In contrast, a partial and/or non-classical intercalation of the ligand could bend or kink DNA resulting in a decrease in its effective length with a concomitant increase in its viscosity [43,44]. The plots of relative viscosities with R = [Cu]/[DNA] are shown in Fig. 5b. The relative viscosity of DNA increases with increase in the concentration of the complex **2** but less compared to that of potential classical intercalators, e.g. ethidium bromide. This is consistent with the observed trend by other optical methods and suggesting primarily electrostatic and/or groove binding nature of the complex.

3.4. DNA cleavage studies

The oxidative DNA cleavage activity of the complexes in the presence of reducing agent 3-mercaptopropionic acid (MPA, 5 mM) is investigated by agarose gel electrophoresis using supercoiled (SC) plasmid pUC19 DNA (0.2 μg, 33.3 μM NP) in 50 mM Tris–HCl/50 mM NaCl buffer (pH 7.2) and the copper(II) complexes (Fig. 6). Selected DNA cleavage data are given in Table 3. The phen complex **2** shows efficient "chemical nuclease" activity. A 30 μM complex shows complete conversion of the SC (form I) to its nicked-circular form (NC, form II) of DNA. Control experiments with MPA or the ternary complexes alone do not show any apparent conversion of SC to its nicked-circular (NC) form. The bpy complex is cleavage inactive due to its poor binding ability to DNA. To determine the groove binding preference of **2**, control experiments have been carried out in the presence of minor groove binder distamycin-A [45,46]. Inhibition of cleavage in presence of distamycin-A for the phen complex, suggesting minor groove binding preference for the phen complex.

Mechanistic aspects of the chemical nuclease reactions are performed using various control experiments (Fig. 6). It is observed that hydroxyl radical scavengers [47] like catalase, DMSO, KI significantly inhibit the DNA cleavage activity of the complex **2** indicating the possibility of the involvement of hydroxyl radical and/or "copper-oxo" intermediate as the reactive species. Addition of superoxide dismutase (SOD) does not show any inhibitory effect on the cleavage activity suggesting the non-involvement of $O_2^{\cdot -}$ in

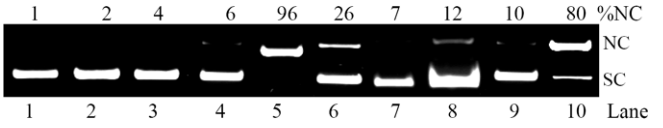

Fig. 6. Gel electrophoresis diagram showing the cleavage of SC pUC19 DNA (0.2 μg, 33.3 μM) by complexes **1** and **2** (30 μM) in 50 mM Tris–HCl/50 mM NaCl buffer (pH 7.2) in the presence of MPA (5 mM): Lane 1, DNA control; Lane 2, DNA + L-pro (30 μM) + MPA; Lane 3, DNA + **2**; Lane 4, DNA + **1** + MPA; Lane 5, DNA + **2** + MPA; Lane 6, DNA + distamycin-A (100 μM) + **2** + MPA; Lane 7, DNA + DMSO (4 μL) + **2** + MPA; Lane 8, DNA + catalase (4U) + **2** + MPA; Lane 9, DNA + KI (100 μM) + **2** + MPA; Lane 10, DNA + SOD (4U) + **2** + MPA.

Scheme 2. Proposed mechanistic pathway for the chemical nuclease activity of complex **2** in Tris-buffer medium.

the cleavage reaction. The pathways involved in the DNA cleavage reactions are believed to be analogous to those proposed by Sigman and co-workers for the chemical nuclease activity of bis(phen)copper species (Scheme 2) [1,39,40].

4. Conclusions

Two ternary copper(II) complexes having N,O-donor α-amino acid L-proline and N,N-donor heterocyclic bases are prepared and characterized. The copper(II) complex with planar phenanthroline base in CuN_3O_2 coordination geometry shows efficient DNA binding ability. The complex shows minor groove binding propensity. The study also confirms that the binding ability of the complexes is important to achieve efficient DNA cleavage activity. Significant chemical nuclease activity is observed for the phen complex **2** under physiological reaction conditions *via* a mechanistic pathway involving formation of hydroxyl radicals in presence of the MPA.

such versatility as well as the steric properties of the precursors, by using the ligand framework to strategically affect the structure of the corresponding group 4 metal complex, and therefore, its reactivity in alkene polymerisation.

Our first deliberate choice was to use nitrogen precursors. Among the huge list of potential nitrogen candidates with an appropriate binding mode and the ability to be linked to a metal, 3,5-disubstituted-pyrazolato derivatives are attracting attention for a number of applied reasons. The use of 3,5-disubstituted-pyrazolato derivatives in coordination and organometallic chemistry has become conspicuous in the literature [27,28], showing the versatility of such a ligand. Excluding hydridotrispyrazolylborato derivatives [29–31] as ligands in organometallic complexes, the 3,5-disubstituted-pyrazol-1-ato moiety acting as principal ligand has been bonded to various metals either in a η^1-coordination fashion [32] (Fig. 1a) or in a chelating η^2-coordination mode (Fig. 1b), affording relatively greater stability in the monometallic system. Non-substituted-pyrazol-1-ato ligand, acting as a pyrazolato anion, can coordinate to two metals in a μ^2-coordination mode [32] (Fig. 2), which usually produces a polymetallic system. In this way, the 3,5-disubstituted-pyrazol-1-ato candidate, which appears to be structurally and electronically attractive, has moderate electron-donating properties according to Fujita's [13] recent classification, which categorised some representative oxygen, nitrogen heteroatom ligands by estimating their electron-donating properties using PM3/MNDO calculations. Some bis(3,5-di-*tert*-butylpyrazol-1-ato) dialkyl and dichloro homo- and bimetallic complexes of titanium [33–36] (alkyl = benzyl, methyl, trimethylsilylmethyl) and neutral or cationic pyrazolato cyclopentadienyl zirconium complexes [37–39] and (η^2-pyrazolato) zirconium compounds with bulky pyrazolato ligands bearing *tert*-butyl [35] indenylmethyl or fluorenylmethyl [40] substituents have been described.

Herein, we report the synthesis of some new bis(3,5-dimethylpyrazol-1-ato) zirconium complexes, the X-ray molecular structures of $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2Cl_2(\eta^1\text{-}3,5\text{-}Me_2PzH)_2]\cdot(3,5\text{-}Me_2PzH)$ and $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2(CH_2Ph)_2]$ (3,5-Me_2Pz = 3,5-dimethylpyrazol-1-ato) and their performance in ethylene and propylene polymerisation upon activation with MAO.

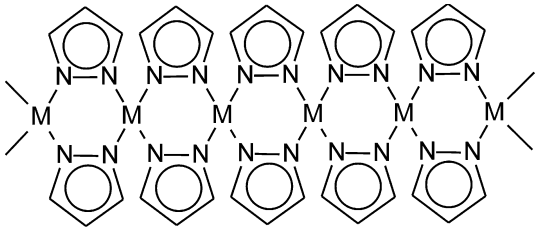

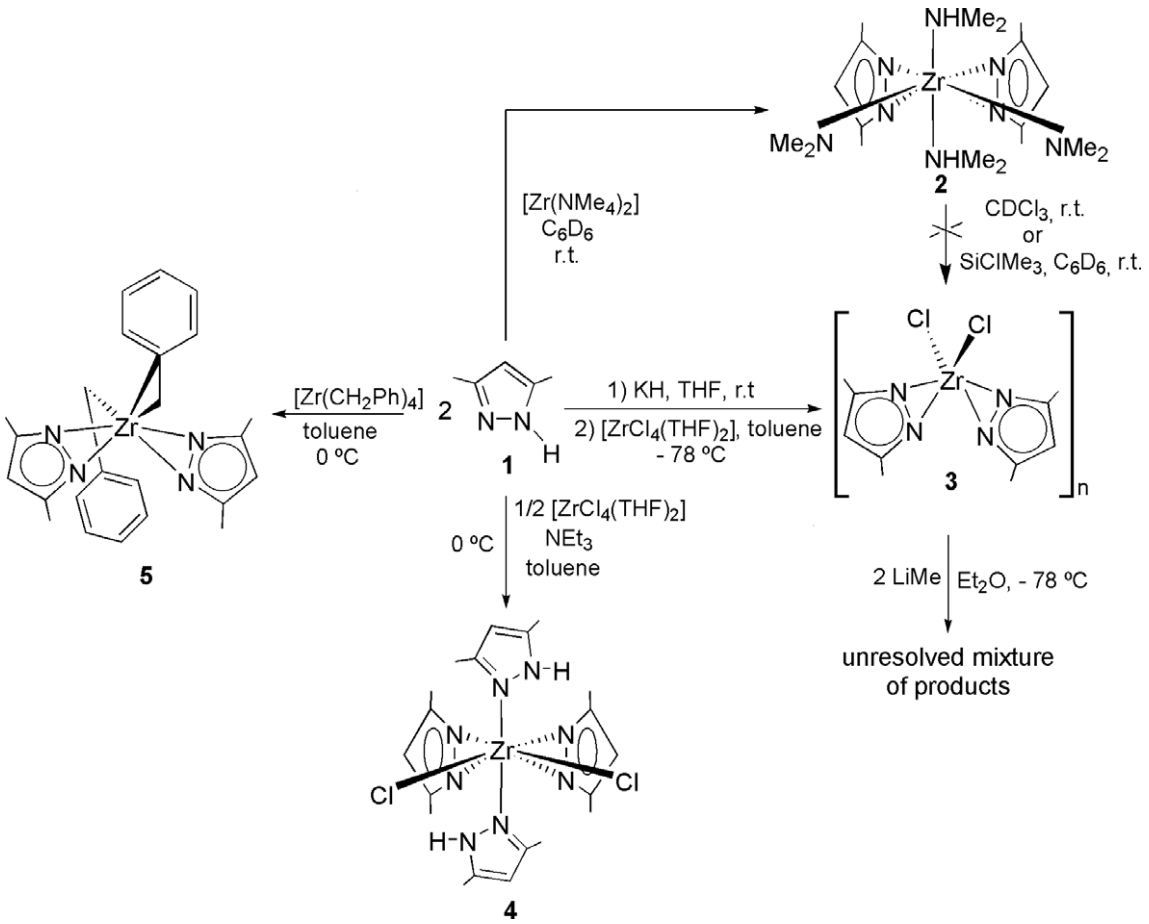

Fig. 2. Bridged pyrazol-1-ato coordination mode.

2. Results and discussion

2.1. Preparation of bis(3,5-dimethylpyrazol-1-ato) zirconium derivatives

3,5-Dimethylpyrazole (3,5-Me_2PzH) (**1**) was purchased from a commercial source or synthesised according to the literature procedure [41] and used after sublimation under high vacuum. Addition of **1** to a toluene solution of $[Zr(NMe_2)_4]$ at room temperature afforded, via amine elimination, the thermally robust bis(dimethylamido) bis(3,5-dimethylpyrazol-1-ato) zirconium(IV) complex **2**, stabilised by coordination of two molecules of the $NHMe_2$ generated. It was isolated in 95% yield as an analytically pure white solid after the solvent was completely removed under reduced pressure (Scheme 1). Compound **2** was subject to a mild chloro-solvolysis in $CDCl_3$ or treated in C_6D_6 with a slight excess of $SiClMe_3$ (2.1 equiv.) at room temperature in an attempt to access the corresponding dichloro derivative $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2Cl_2]$ (**3**). The ^1H and ^{13}C NMR spectra of both resulting reaction mixtures unfortunately provide an unresolved mixture of products. To synthesise the desired dichloro zirconium complex **3**, the $[ZrCl_4(THF)_2]$ adduct was treated at −78 °C with 2 equiv. of K(3,5-Me_2Pz) [42] in a THF–toluene solution (Scheme 1). After elimination of KCl and volatiles, **3** was isolated as an analytically pure white substance in 17% yield. When the $[ZrCl_4(THF)_2]$ adduct was reacted with 4.1 equiv. of **1** in the presence of 2.1 equiv. of NEt_3 in toluene at 0 °C the zirconium complex $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2Cl_2(\eta^1\text{-}3,5\text{-}Me_2PzH)_2]\cdot(3,5\text{-}Me_2PzH)$ (**4**) was exclusively produced as an analytically pure off-white solid in 46% yield after elimination of the ammonium salt (Scheme 1).

Methylation of **3** with 2 equiv. of LiMe in ether at −78 °C (Scheme 1) gave an unstable, intractable and unresolved mixture of products whose ^1H NMR spectrum was regrettably uninformative. Due to the unexpected poor behaviour of the methyl ligand to create a stable coordination environment at the zirconium centre, the use of voluminous ligands was explored to stabilise the new bis(3,5-dimethylpyrazol-1-ato) dialkyl zirconium product. The reaction of $[Zr(CH_2Ph)_4]$ with 2 equiv. of **1** in cold toluene gave, via alkane elimination, the compound $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2(CH_2Ph)_2]$ (**5**) as an analytically pure white solid (98% yield) after elimination of volatiles (Scheme 1). The synthesis of dialkyl titanium compounds $[Ti(\eta^2\text{-}3,5\text{-}tBu_2Pz)_2R_2]$ (R = Me, CH_2Ph, CH_2SiMe_3) [34] has been reported following treatment of the dichloro derivative $[Ti(\eta^2\text{-}3,5\text{-}tBu_2Pz)_2Cl_2]$ [33] with the appropriate alkylating reagent.

Scheme 1.

Compounds **2**–**5** are air-sensitive but thermally stable in solution and in the solid state. They are soluble in aromatic and chlorinated solvents but poorly soluble in aliphatic hydrocarbons. Spectroscopic (^{1}H, ^{13}C NMR analyses in C_6D_6 and $CDCl_3$ solutions) and elemental analyses are in agreement with the proposed structures. The molecular structures of **4** and **5** have been determined by X-ray diffraction methods.

The 300 MHz ^{1}H NMR spectrum of **2** (C_6D_6, 20 °C) exhibits the expected pattern of resonances for the methine and methyl-substituted pyrazol-1-ato protons as singlets at δ 6.08 and 2.35, respectively. The signal at δ 3.37 is assigned to the *N*-methyl-amido protons. The resonance at δ 1.78 with a coupling constant $^3J_{HH}$ of 6.3 Hz and the multiplet signal at δ 0.31 with a 6:1 proton ratio were assigned to the methyl- and proton-amino ligand, respectively, through a ^{1}H–^{1}H-homo decoupling experiment, suggesting the evident coordination of the amino sp^3-nitrogen-donor to zirconium [43,44]. In the absence of a reliable crystal diffraction study, these spectroscopic behaviours allow us to formulate complex **2** as [Zr(η^2-3,5-Me_2Pz)$_2$(N-Me_2)$_2$(NHMe_2)$_2$], which was also confirmed by elemental analysis. According to these data and on the basis of the crystal structure analysis obtained by X-ray diffraction for the analogous dichloro compound **4**, we propose a pseudo-octahedral disposition for **2** with the pyrazolato and amido ligands in the equatorial positions and the amino groups located in a *trans* configuration (Scheme 1).

The $CDCl_3$-solution NMR spectrum of **3** displays one set of proton resonances as singlets at δ 6.04 and 2.47, showing a pattern typical for methine and methyl protons in a heterocyclic moiety. Attempts to obtain X-ray quality monocrystals with a view to corroborating this information were unfruitful. The molecular structure of the analogous bulky-substituted titanium compound [Ti(η^2-3,5-tBu$_2$Pz)$_2$Cl$_2$] [33] indicates a mononuclear disposition showing a pseudo-tetrahedral geometry around the titanium atom where the centres of the N–N bonds of the pyrazolato ligands are considered as unidentate coordination positions. Structural and chemical similarities have been established between pyrazolato and cyclopentadienyl early transition metal complexes and comparison between [Ti(η^2-3,5-tBu$_2$Pz)$_2$Cl$_2$] and [TiCp$_2$Cl$_2$] yields similar structural properties with the pyrazolato group, being a poorer donor ligand than the cyclopentadienyl ring [35]. Nevertheless, the size of the zirconium atom is larger and the zirconium complex is unsaturated. The ESI$^+$-TOF mass spectrum on a sample of **3** dissolved in a chloroform solution has showed the presence of ion peaks *m*/*z* (exact mass *m*/*z*: 964.78) superior to that expected for the mononuclear derivative **3** (exact mass

m/*z*: 349.96), although the corresponding peak for a dinuclear species was not observed. Thus, it seems very reasonable that **3** would form oligomeric species with either bridging chloro or pyrazolato ligands.

At 25 °C, the ^{1}H NMR spectrum ($CDCl_3$, 500 MHz) of **4** shows relatively uninformative broad signals. Nevertheless, it enables us to distinguish three regions of resonances. The first region has a broad signal at δ 10.77 representative of the proton N–*H* corresponding to coordinated 3,5-dimethylpyrazole. The second region features a broad signal at δ 6.08 and a singlet at δ 5.90 assigned to the methine protons of the coordinated 3,5-dimethylpyrazole and the 3,5-dimethylpyrazol-1-ato ligands, respectively. The third region at δ 2.33–2.17 contains broad signals for the methyl protons of the 3,5-dimethylpyrazol-1-ato and the coordinated 3,5-dimethylpyrazole ligands. On cooling at −40 °C, some of the signals became more defined and coalescence of the two methyl resonances of the coordinated pyrazole ligands was observed. Compared to 25 °C spectra, the amino N–*H* proton resonance appears downfield shifted at δ 11.26. Cooling at −60 °C caused a considerable sharpening and splitting of the signals and the resonance for the N–*H* proton of the coordinated 3,5-dimethylpyrazole ligand was observed at δ 11.26. The spectrum shows two singlets at δ 6.02 and 5.80 assigned to the methine protons of the coordinated 3,5-dimethylpyrazole and the 3,5-dimethylpyrazol-1-ato ligands, respectively. Two signals for the methyl protons of the coordinated pyrazole corresponding to two non-equivalent groups and a singlet for the equivalent methyl protons of the pyrazol-1-ato ligand are observed. Fluxional behaviour of **4** in $CDCl_3$ solution, corresponding to a sigmatropic displacement [45,46] of the two consecutive nitrogen of the coordinated pyrazole molecules, was apparent from this variable-temperature ^{1}H NMR study. A Gibbs activation energy $\Delta G^{\#}$(233 K) of 47.71 kJ mol^{-1} (11.4 kcal mol^{-1}) in the coalescence temperature was obtained for this process.

The 500 MHz ^{1}H NMR (C_6D_6, 25 °C) spectrum of **5** exhibits the expected pattern of resonances; two singlets at δ 6.20 and 2.14 for the methine and methyl protons of the pyrazolato ligands, respectively, and four signals, which are composed of two triplets at δ 7.06 (*meta*-C*H*), 6.88 (*para*-C*H*), a doublet at δ 6.65 (*ortho*-C*H*) with coupling constants of 7.6 Hz, 7.4 Hz, and 7.4 Hz, respectively, and a singlet at δ 2.01 (CH_2), assigned to the aromatic ring and methylene protons of the benzyl ligand, for which the pyrazolato/benzyl proton ratio is 1:1. Similar results were also observed in the ^{13}C NMR spectrum in the same conditions.

White single crystals of **4** suitable for X-ray diffraction studies grown in a saturated toluene solution at −40 °C were used to unequivocally establish the spatial arrangement of atoms in this complex (Fig. 3). Selected bond distances and angles for the structure are listed in Table 1.

The Zr atom shows a distorted octahedral geometry where the chloro ligands are mutually *cis*. The two other equatorial positions are occupied by two dimethylpyrazola-

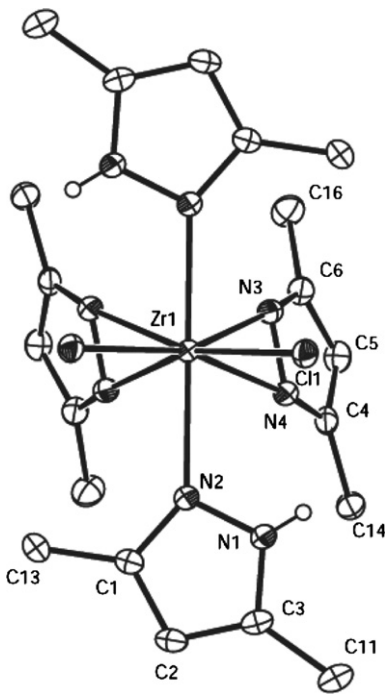

Fig. 3. X-ray ellipsoid plot of one of the independent molecules found for **4** showing the atomic numbering scheme.

to ligands coordinated by their nitrogen atoms. The centres of the N–N bonds are considered as unique coordination positions. The two dimethylpyrazole groups are placed in the apical positions in a *trans* configuration. Both nitrogen atoms of the symmetrically coordinated η^2-fashion pyrazolato ligand are nearly equidistant from the zirconium with the average Zr–N distances of 2.207 Å. The Zr–N bond distances are longer for the coordinated pyrazole groups [Zr(1)–N(2) 2.377(2) Å] than for the pyrazolato ligands [Zr(1)–N(3) 2.188(2) Å, Zr(1)–N(4) 2.226(2) Å] which show a degree of multiple bonding. All the Zr–N distances are within the range observed in similar previously reported zirconium compounds (2.306–2.369 Å for Zr–pyrazole [37] and 2.146–2.263 Å for Zr–pyrazolato [38–40]). It should be noted that only a few examples of group 4 complexes with pyrazolato and/or pyrazole ligands have been described. An intramolecular hydrogen bond with a distance of 3.142 Å for Cl(1)···N(1) and an angle of 122° for Cl(1)–H(1)–N(1) occurs in Cl(1)···H(1)–N(1) and seems to have some impact on the relative disposition of the coordinated pyrazole ligands. In contrast, the related compound [$TiCl_4(\eta^1$-3,5-$Me_2PzH)_2$] shows no such H-bond interaction [33]. Analysis of the intermolecular interactions demonstrates the presence of a weak hydrogen bond (WHB) [47] (Cl(1)···H(14)–C(14) (Cl(1)···C(14) distance of 3.687 Å and Cl(1)–H(14)–C(14) angle of 140.85°) between molecules, forming a chain arrangement in the crystal.

Further characterisation by X-ray diffraction analysis of a suitable single crystal grown from a toluene–pentane solution at −40 °C definitively revealed the structure of **5**

[a] E.s.d's are given in parentheses.

(Fig. 4). Selected bond distances and angles are listed in Table 1.

In the molecular structure, the zirconium atom is bonded to two pyrazol-1-ato and two benzyl ligands in a distorted tetrahedral geometry, considering that the two nitrogens of each pyrazol-1-ato moiety and each benzyl ligand occupy only one coordination position.

The C(11)–C(12) benzyl ligand is coordinated in a terminal η^1-mode while the C(21)–C(22) benzyl ligand coordinates in a η^2-mode with both C(21) and C(22) bonded to the Zr atom. These features in the solid state are well known and well documented elsewhere [48–57]. The distance between Zr and η^1-benzyl [Zr(1)–C(11) and Zr(1)–C(12) of 2.286(2) Å and 2.8708(18) Å, respectively] as well as between Zr and η^2-benzyl [Zr(1)–C(21) and Zr(1)–C(22) of 2.280(2) Å and 2.598(2) Å, respectively] are similar in the solid state in other analogues [48,49,51,53–57]. The benzyl ligands form Zr(1)–C(11)–C(12) and Zr(1)–C(21)–C(22) angles of 97.13(12)° and 84.96(12)°, respectively [58,59]. The two benzyl ligands are reciprocally located adopting a *chair*-type conformation.

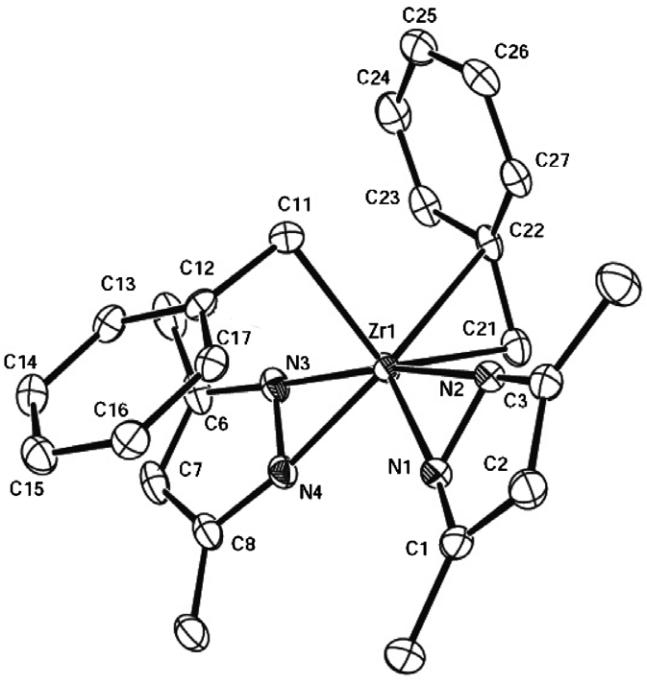

Fig. 4. X-ray ellipsoid plot of the independent molecule found for **5** showing the atomic numbering scheme.

Each pyrazol-1-ato ligand is bonded to the zirconium centre by both nitrogen atoms in a chelating η^2-coordination mode. The N(1)–N(2)-Zr(1)–N(3)–N(4) atoms lie in the same plane (mean deviation 0.026). The N(1)–N(2)–C(1)–C(2)–C(3) and N(3)–N(4)–C(6)–C(7)–C(8) rings are both bent towards the C(11)–C(17) benzyl ligand forming dihedral angles of 10.0° and 14.3°, respectively, with the N(1)–N(2)-Zr(1)–N(3)–N(4) mean plane. The pyrazolyl moieties are bonded to the Zr centre with distances Zr(1)–N(1) 2.1469(18) Å, Zr(1)–N(2) 2.1974(17) Å, Zr(1)–N(3) 2.2037(17) Å and Zr(1)–N(4) 2.1288(16) Å. The Zr–N distances are comparable with other η^2-(pyrazol-1-ato) zirconium analogues [37,40]. The distance between two consecutive nitrogens of the same pyrazol-1-ato moiety coordinated to zirconium, of about 1.391(2) Å for N(1)–N(2) and 1.390(3) Å for N(3)–N(4), is much longer than that of a simple N_{sp2}–N_{sp3} single bond type of an independent preligand **1** whose value is 1.334 Å [60].

2.2. Polymerisation studies

The strategy of searching for new olefin polymerisation catalysts [61] by making new early metal cations and new

generation of "non-metallocene" catalysts for the polymerisation of α-olefins has been recently developed based on group 4 metal complexes containing diamido ligands. These compounds exhibit a close relationship to the half-sandwich metal amido "constrained-geometry" catalyst system and to metallocene derivatives. η^2-Pyrazolato ligands act formally as three-electron donors (covalent criterion) with similar behaviour to amidinato and amido ligands. In this way, the study of the synthesised pyrazolato complexes as precatalysts in α-olefin polymerisation seems to be pertinant [38]. The zirconium complexes **3** and **5** have been preliminary examined as catalyst precursors for ethylene and propylene polymerisations upon activation with methylaluminoxane (MAO). Olefin polymerisations were investigated in toluene at 25 °C and 50 °C with 1 atm and 4 atm of olefin pressure (Al/Zr ratio ~ 1000:1). The results are summarised in Table 2. No polymerisation of propylene using either precursor **3** or **5**, at whichever operating temperature or olefin pressure, occurred. Precursor **3** remained inactive in the polymerisation of ethylene whatever the polymerisation conditions applied. This lack of activity is attributed to the non-generation of catalytically active species in solution, probably resulting from the premature decomposition of the dimethyl zirconium intermediate when the dialkylation of the corresponding dichloro derivative occurs with MAO before abstraction of the methyl ligand. This hypothesis is supported by the results of the dialkylation of **3** with 2 equiv. of LiMe already described. This is a common problem with precursors that contain N-based ligands. Polyethylene was exclusively isolated using precursor **5** (Table 2). At 1 atm of monomer pressure low activity was observed before 30 min, independent of temperature. Activity increased with time from 30 min, but was ca. twofold greater at 60 than 30 min, regardless of temperature (entries 1–4). At 4 atm and 25 °C or 50 °C, the catalytic activity of precursor **5** depends on the polymerisation time. At 25 °C, the highest activity of **5** was reached after 15 min (entry 6), which was ca. twofold greater than at 5 min. After 15 min, a continuous activity rate decrease occurred, probably due to the destruction of active sites. At 50 °C, the highest activity of **5** occurred up to 5 min (entry 9), followed by a rate decrease to roughly constant value of 4 kg of polymer/(mol Zr h atm ethylene) (entries 10–12). This decrease of activity can be explained by a thermal deactivation or by a further reduction of the group 4 transition metal by the MAO co-activator where diffusion control of the propagation reaction can also be postulated [62]. The GPC data indicate great differences in the molecular weight of the resulting polymers with M_w values in the range of 222000–690000 and the polydispersity values larger than 57, indicating the presence of different types of catalytically active species in the reaction mixture. For 1 atm at 25 °C the M_w values increased with polymerisation time, whereas, for 4 atm at 50 °C, the M_w values tend to be constant with polymerisation time. The polymers produced by this precatalyst exhibit single DSC endotherms, with melting point $T_f \approx 133$ °C. These results suggest the utility of these compounds under the used conditions in alkene polymerisation is not very promising.

Table 2
Ethylene polymerisation catalysed with **5**/MAO system[a]

[a] Conditions: 10 μmol of precatalyst, 50 mL of toluene, Al/Zr ratio ~ 1000:1.
[b] Expressed in kg polymer/(mol Zr h atm ethylene).
[c] Determined by GPC.
[d] Melting point (T_f) and crystallisation point (T_c) determined by DSC.
[e] MAO used as a 10% toluenic solution.
[f] MAO used as a $AlMe_3$-free solid dissolved in toluene.

3. Conclusions

In this report, we have provided a contribution to the synthesis and characterisation of new and somewhat unusual bis(3,5-dimethylpyrazol-1-ato) zirconium complexes supported by dimethylamido (**2**), dichloro- (**3** and **4**) and dibenzyl (**5**) ligands. We have demonstrated that **4** presented a highly fluxional behaviour in $CDCl_3$ solution, which was quantified by variable-temperature proton NMR experiments. The new complexes are interesting from basic coordination chemistry perspectives because only a few derivatives of this type are known. Initial studies of their ethylene polymerisation performance under MAO-activation conditions have been developed. Long apparent activation times, low activities, and broad molecular weight distribution are observed.

4. Experimental

4.1. General considerations

All manipulations and reactions were carried out under argon (Air Liquide N45, O_2: 1 ppm; H_2O: 3 ppm) using Schlenk and high-vacuum line techniques or in a dry argon atmosphere MBraun glovebox model MB150B-G. The solvents (Baker and SDS) were of reagent grade and were purified by distillation under argon before use by employing the appropriate drying agent. Deuterated solvents (SDS) were firstly degassed by several freeze–thaw cycles and then stored at room temperature over freshly activated 4 Å molecular sieves (10% w/v). Commercial 3,5-di-

methylpyrazole **1** (Aldrich) was used as received, otherwise prepared [41] and freshly sublimed. $SiClMe_3$, LiMe (a 1.6 M solution in Et_2O) (Aldrich) were used as received. NEt_3 (Aldrich) was treated with KOH pellets and fractionally distilled under argon over CaH_2. KH, as a 30 wt% dispersion in mineral oil (Aldrich), was washed and filtered three times with *n*-hexane, and dried until complete removing of the volatiles. K(3,5-Me_2Pz) [42], $[Zr(NMe_2)_4]$ [63], $[ZrCl_4(THF)_2]$ [64], $[Zr(CH_2Ph)_4]$ [65] were prepared by a known procedure. C, H, and N microanalyses were performed on a Perkin–Elmer 240B microanalyser. NMR spectra were recorded on Varian Mercury VX–300 and Unity^{Plus} 500 spectrometers at room temperature, otherwise as indicated. The chemical shifts δ and coupling constant J are quoted in ppm and in hertz (Hz), respectively, and are referenced with respect to residual proton and carbon resonances of the solvent ($CDCl_3$: ^{1}H: 7.25 ppm, ^{13}C: 77.1 ppm; C_6D_6: ^{1}H: 7.15 ppm, ^{13}C: 128.0 ppm), which is also referenced with respect to $SiMe_4$. Variable-temperature (VT) ^{1}H NMR experiments were recorded on the Varian Unity^{Plus} 500 spectrometer. Polymerisation grade ethylene and propylene (Air Liquide N35) were purified by passage through two columns packed with activated 4 Å molecular sieves. Methylaluminoxane (MAO) (10 wt% solution in toluene) was purchased from CROMPTON GmbH. Solid $AlMe_3$-free methylaluminoxane was obtained by drying MAO under reduced pressure at 50 °C to remove the uncoordinated $AlMe_3$ and used after washing with hexanes and dryness. Polymer melt endotherms were determined using a Perkin–Elmer DSC-4 differential scanning calorimeter at a heating rate of 10 °C min^{-1}. The GPC measurements were performed on a Polymer Laboratories PL-220 instrument, equipped with a refractive index detector. The samples were analysed in trichlorobenzene (TCB) stabilised with 0.0125% BHT on two columns of PLgelMIXED B (length 600 mm) at 160 °C with a flow rate of 1.0 mL min^{-1}. The ESI$^+$-TOF LC/MS experiment was carried out on an Agilent apparatus model 6210 using a mixture of MeOH/water (75/25, v/v) with an aqueous solution of ammonium formate (5 mM) as a mobile phase.

4.2. Synthesis of $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2(NMe_2)_2(NHMe_2)_2]$ (**2**)

$[Zr(NMe_2)_4]$ (250 mg, 0.93 mmol) and **1** (180 mg, 1.87 mmol) were rapidly placed into a Teflon-valved ampoule under dry argon and toluene (5 mL) was immediately introduced. The closed ampoule was coupled with a mechanical stirrer using rubber and T-glass tubes. The ampoule was then stirred slowly at room temperature for 18 h. The solution was filtered and the volatiles were removed under reduced pressure affording 410 mg of an analytically pure white solid identified as **2** (95% yield). NMR ^{1}H (300 MHz, C_6D_6): $\delta = 6.08$ (s, 2H, C*H*), 3.37 (s, 12H, N–CH_3), 2.35 (s, 12H, CH_3-pyrazol-1-ato), 1.78 (d, $^3J_{HH} = 6.3$ Hz, 6H, HN(CH_3)$_3$), 0.31 (m, 1H, *H*N(CH$_3$)$_3$). NMR ^{13}C{^{1}H} (75 MHz, C_6D_6): $\delta = 145.1$ (*C-ipso*), 110.7 (*C*H), 46.0 (N-*C*H$_3$), 38.7 (HN(*C*H$_3$)$_3$), 13.1 (*C*H$_3$-pyrazol-1-ato). *Anal.* Calc. for $C_{18}H_{40}N_8Zr$ (459.79): C, 47.02; H, 8.76; N, 24.37. Found: C, 47.10; H, 8.69; N, 24.44%.

4.3. Synthesis of $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2Cl_2]_n$ (**3**)

Compound **1** (1.17 g, 12.2 mmol) in a one portion was added to a stirred suspension of KH (490 mg, 12.22 mmol) in THF (55 mL) at room temperature, with instantaneous gas evolution. The resulting mixture was stirred for a further 1 h as soon as gas ceased to evolve. The room-temperature mixture was then slowly transferred by cannula to a solution of $[ZrCl_4(THF)_2]$ (2.3 g, 6.1 mmol) in toluene (50 mL) at −78 °C. The turbid pale yellow solution was warmed gradually with stirring overnight when volatiles were completely removed under reduced pressure and the residue was extracted into toluene (60 mL) for 2 days. The resulting precipitate was allowed to settle at 0 °C overnight, and the solution was filtered. The volatiles were completely removed under reduced pressure, yielding the desired compound as an analytically pure white solid identified as **3** (370 mg, 17% yield based on $[ZrCl_4(THF)_2]$). NMR ^{1}H (300 MHz, $CDCl_3$): $\delta = 6.04$ (s, 2H, C*H*), 2.47 (s, 12H, CH_3). NMR ^{13}C{^{1}H} (75 MHz, $CDCl_3$): $\delta = 144.7$ (*C-ipso*), 106.1 (*C*H), 11.1 (*C*H$_3$). *Anal.* Calc. for $C_{10}H_{14}Cl_2N_4Zr$ (as mononuclear: 352.37): C, 34.08; H, 4.00; N, 15.98. Found: C, 33.99; H, 4.15; N, 15.88%. ESI$^+$-TOF, exact mass *m*/*z*: 964.78.

4.4. Synthesis of $[Zr(\eta^2\text{-}3,5\text{-}Me_2Pz)_2Cl_2(\eta^1\text{-}3,5\text{-}Me_2PzH)_2]\cdot(3,5\text{-}Me_2PzH)$ (**4**)

A stirred solution of **1** (2.14 g, 22.34 mmol), and NEt_3 (1.55 mL, 11.17 mmol) in toluene (45 mL) was rapidly transferred by cannula to a stirred solution of $[ZrCl_4(THF)_2]$ (2.01 g, 5.32 mmol) in toluene (50 mL) at 0 °C. The resulting solution was warmed gradually with stirring for 21 h. The stirred mixture was cooled at 0 °C, when stirring was stopped to allow the precipitates to settle. The undesired precipitates (1.57 g) were isolated by filtration and the clean colorless solution was cooled at −40 °C to crystallise. White crystals of X-ray quality of **4** (1.38 g, 46% yield) were carefully isolated by filtration. NMR ^{1}H (500 MHz, $CDCl_3$, −60 °C): $\delta = 11.26$ (s, 2H, N*H*), 6.02 (s, 2H, C*H*-coordinated pyrazole), 5.80 (s, 2H, C*H*-pyrazolato), 2.55 (s, 6H, CH_3-coordinated pyrazole), 2.35 (s, 6H, CH_3-coordinated pyrazole), 1.79 (s, 12H, CH_3-pyrazol-1-ato). NMR ^{13}C{^{1}H} (125 MHz, $CDCl_3$, −60 °C): $\delta = 152.0$ (*C-ipso*-coordinated pyrazole), 145.6 (*C-ipso*-pyrazol-1-ato), 139.1 (*C-ipso*-coordinated pyrazole), 113.3 (*C*H-pyrazol-1-ato) 106.0 (*C*H-coordinated pyrazole), 13.8 (*C*H$_3$-coordinated pyrazole), 11.2 (*C*H$_3$-pyrazol-1-ato), 10.3 (*C*H$_3$-coordinated pyrazole). *Anal.* Calc. for $C_{20}H_{30}Cl_2N_8Zr\cdot 1/4C_5H_8N_2$ (544.64 + 24.03): C, 44.88; H, 5.67; N, 20.93. Found: C, 44.68; H, 5.73; N, 20.34%.

4.5. Synthesis of [Zr(η^2-3,5-Me_2Pz)$_2$(CH_2Ph)$_2$] (5)

A stirred solution of **1** (858 mg, 8.92 mmol) in toluene (60 mL) was added by cannula to a stirred solution of [Zr(CH_2Ph)$_4$] (2.03 g, 4.46 mmol) in toluene (60 mL) at 0 °C. The mixture was slowly warmed to room temperature with stirring and then further stirred for 19 h. The solution was filtered through a short pad of celite and the volatiles were removed under reduced pressure affording 2.03 g of an analytically pure white solid (98% yield). Suitable single crystals of **5** for X-ray diffraction analysis were collected by filtration from a toluene–pentane solution at −40 °C. NMR ^{1}H (500 MHz, C_6D_6): $\delta = 7.06$ (t, $J = 7.6$ Hz, 4H, *meta*-C*H* of phenyl ring), 6.88 (t, $J = 7.4$ Hz, 2H, *para*-C*H* of phenyl ring), 6.65 (d, $J = 7.4$ Hz, 4H, *ortho*-C*H* of phenyl ring), 6.20 (s, 2H, C*H*-pyrazol-1-ato), 2.14 (s, 12H, CH_3-pyrazol-1-ato), 2.01 (s, 4H, CH_2-benzyl). NMR ^{13}C{^{1}H} (125 MHz, C_6D_6): $\delta = 147.1$ (*ipso*-*C*-pyrazol-1-ato), 140.0 (*ipso*-*C* of phenyl ring), 129.3 (*ortho*-*C*H of phenyl ring), 128.5 (*meta*-*C*H of phenyl ring), 122.9 (*para*-*C*H of phenyl ring), 116.1 (*C*H-pyrazol-1-ato), 58.7 (*C*H$_2$-benzyl), 12.6 (*C*H$_3$-pyrazol-1-ato). *Anal.* Calc. for $C_{24}H_{28}N_4Zr$ (463.74): C, 62.16; H, 6.09; N, 12.08. Found: C, 61.89; H, 6.11; N, 12.25%.

4.6. Polymerisation procedure at 1 atm

Toluene (50 mL) was introduced under argon into the Schlenk reactor equipped with a magnetic stirrer and maintained at the desired temperature using external thermal control with vigorous stirring for 30 min. MAO (8 mL, 12.19 mmol) was then injected and the mixture stirred for 15 min. The argon was replaced by the olefin by degassing the solution under vacuum and refilling with the olefin. This procedure was repeated and the solution was finally saturated with the olefin for 15 min. As soon as the zirconium complex was injected to the mixture, polymerisation time was counted. The polymerisation was terminated by methanol injection. The polymer was precipitated with 100 mL of a 5% solution of HCl in MeOH, stirred, filtrated and washed successively with 50 mL of a 5% solution of HCl in MeOH, 100 mL of water, and 100 mL of MeOH. The polymer was finally dried under vacuum at 50 °C for 24 h to constant weight.

4.7. Polymerisation procedure at 4 atm

The sealed ampoule containing precursor **5** at the desired amount was placed into the Büchi reactor. The system, at the desired temperature, was evacuated under vacuum for 1 h. Toluene (50 mL) was introduced under argon into the reactor and MAO (8 mL, 12.19 mmol) was then injected. The mixture was stirred for 15 min. The argon was replaced by the olefin by degassing the solution under vacuum and refilling with the olefin. As soon as precursor **5** was liberated into the solution by breaking the ampoule polymerisation time was counted. The polymerisation was terminated by methanol injection. The polymer was precipitated with 100 mL of a 5% solution of HCl in MeOH, stirred, filtrated and washed successively with 50 mL of a 5% solution of HCl in MeOH, 100 mL of water, and 100 mL of MeOH. The polymer was finally dried under vacuum at 50 °C for 24 h to constant weight.

4.8. X-ray crystallographic study of [Zr(η^2-3,5-Me_2Pz)$_2$$Cl_2$($\eta^1$-3,5-$Me_2PzH$)$_2$] · (3,5-$Me_2PzH$) (4) and [Zr($\eta^2$-3,5-$Me_2Pz$)$_2$($\eta^2$-$CH_2Ph$)$_2$] (5)

Suitable crystals of **4** and **5** were selected, manipulated under perfluoropolyether, mounted on a glass fibre and the data collected on a Nonius KappaCCD diffractometer (**4**) at 200 K and a Rigaku R-Axis IIc image plate diffractometer (**5**) at 150 K. Data were processed using the DENZO/SCALEPACK programs [66]. The structure was determined by direct method routines and refined by full-matrix

Table 3
Crystal data and structure refinement details for **4** and **5**

Compound	**4**	**5**
Molecular formula	$C_{25}H_{38}Cl_2N_{10}Zr$	$C_{24}H_{28}N_4Zr$
Formula weight	640.77	463.72

least-squares methods on F^2 (SHELXS and SHELXL programs) [67]. All non-hydrogen atoms were anisotropically refined. Compound **4**: hydrogen atoms were geometrically placed and left riding on their parent atoms except for H1, H2, H5, and H7 which were found in the difference map and refined isotropically. Half of a disordered molecule of free ligand appeared in the asymmetric unit. Compound **5**: methyl hydrogen atoms were refined as rigid, others riding. Relevant crystallographic data and details of the refinements for the two structures are given in Table 3.

Acknowledgements

Financial support for this research by DGICYT (Project MAT2004-02614), CAM: (Project S-0505-PPQ/0328-02) and by European Commission (Contract No. HPRN–CT2000-00004) is gratefully acknowledged. The authors would like to express the thanks to Prof. Dr. Mikhail V. Galakhov for his helpful assistance for the NMR studies and Dr. Yann Sarazin, from the Department of Prof. Dr. Manfred Bochmann, University of East Anglia for running the GPC measurements.

Appendix A. Supplementary material

CCDC 635011 and 635579 contain the supplementary crystallographic data for **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.001.

antitumor activity studies *(in vitro)* of *cis* dichloride platinum(II) compounds with triazolopyrimidine ligands (HmtpO) [8], (dbtp) and (dptp; dptp -5,7-diphenyl-1,2,4-triazolo[1,5-*a*]pyrimidine) [12] indicate a moderate antiproliferative activity against the cells of rectal, breast and bladder cancer. In our earlier report the spectroscopical and biological parameters of *cis*-$PtCl_2(dbtp)_2$ [12] were presented, while in this work crystal structure has been discussed. It was demonstrated that *cis*-$PtCl_2(dbtp)_2$ exhibits high cytotoxicity against rectal adenocarcinoma SW707 and breast cancer T47D. Cytotoxicity results for this compound indicate, that *cis*-$PtCl_2(dbtp)_2$ exhibits better antitumor properties than *cis*-DDP.

In this paper, we study structural properties of platinum(II) and palladium(II) complexes with 5,7-ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidine (dbtp): *cis*-$PtCl_2(dbtp)_2 \cdot EtOH$ (**1**) and *cis*-$PdCl_2$(dbtp)(dmso)] (**2**). It is a first report which presents the X-ray structure of mixed dichloride Pd(II) complexes with N-donor (5,7-ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidine) and S-donor (dimethylsulfoxide) ligands.

2. Experimental

2.1. Materials

$PdCl_2$, inorganic salts and solvents of analytical grade were purchased from POCh Gliwice (Poland). Dipotassium tetrachloroplatinum(II) and 2,2,6,6-tetramethyl-3,5-heptanedione (98%), were purchased from Aldrich.

5,7-Ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidines were prepared according to Bülow and Haas method [19] by the reaction of 3-amino-1,2,4-triazole with 2,2,6,6-tetramethyl-3,5-heptanedione [20].

2.2. Instrumentation

The contents of C, H, N was determined by elemental semi-microanalysis. IR spectra were measured with a Perkin–Elmer Spectrum-2000 FT–IR spectrometer, using KBr (400–4000 cm^{-1}) and polyethylene discs (100–400 cm^{-1}). The ^1H and ^{13}C spectra were obtained with a Bruker Avance 300 MHz spectrometer. The solvent was dmf-d_7, the concentrations of saturated solutions being *ca.* 0.01–0.05 M, temperature being 298 K. The reference standard was TMS. The ^{13}C CPMAS spectra were performed with a Bruker AMX 300 MHz spectrometer using a Bruker MASVTN500SB BL4 probe head and 4 mm zirconia rotors, at 296 K.

2.3. Preparation of complexes

The *cis*-$PdCl_2(dmso)_2$ [21] was prepared from $PdCl_2$, whereas *cis*-$PtCl_2(dbtp)_2$ was obtained by reaction of K_2PtCl_4 with dbtp in molar ratio M:L = 1:2 [12].

cis-$PtCl_2(dbtp)_2 \cdot EtOH$ (**1**): This compound was isolated by slow evaporation of *cis*-$PtCl_2(dbtp)_2$ from the mixture of ethanol and dichloromethane (1:1 v/v). Its formula and structure were determined by X-ray analysis *(vide infra)*.

cis-$PdCl_2$(dbtp)(dmso) (**2**): A suspension of *cis*-$PdCl_2(dmso)_2$ (0.051 g; 0.15 mmol) in 20 ml of dimethylsulfoxide was treated with the stoichiometric amount of dbtp (0.028 g; 0.12 mmol) in 10 ml of methanol. Reaction mixture was stirred at room temperature for 24 h. After 1 month the crystalline precipitate of this complex was obtained. The precipitate was filtered, washed with acetone, diethyl ether and dried in vacuum. 0.051 g (70%). *Anal.* Calc. for $C_{15}H_{26}Cl_2N_4OSPd$: C, 36.9; N, 11.5; H, 5.4. Found: C, 36.6; N, 11.3; H, 5.7%.

2.4. X-ray structure determination

The pale yellow crystal of *cis*-$PtCl_2(dbtp)_2 \cdot EtOH$ (**1**) was obtained by slow evaporation from the mixture of ethanol and dichloromethane (1:1 v/v) whereas the orange crystal of *cis*-$PdCl_2$(dbtp)(dmso) (**2**) was obtained from dimetylosulfoxide solution.

The X-ray data for (**1**) and (**2**) were collected at 293(2) K with an Oxford Sapphire CCD diffractometer, using Mo

Kα radiation ($\lambda = 0.71073$ Å) and $\omega - 2\theta$ method. The shape-based numerical absorption correction was applied with the minimum and maximum transmissions of 0.3676 and 0.8014 for (**1**) and 0.6176 and 0.8654 for (**2**). The structure was solved by Patterson methods and refined with the full-matrix least-squares method on $F2$ with the use of SHELX-97 program package [22]. The data collection and refinement processes are summarized in Table 1.

3. Results and discussion

3.1. Discussion of the crystal structures of *cis*-$PtCl_2(dbtp)_2 \cdot EtOH$ (*1*)

The crystal structure of (**1**) consists of monomeric *cis*-$PtCl_2(dbtp)_2 \cdot EtOH$ units. The projection of the molecule with the atomic numbering scheme is presented in Fig. 1, whereas the selected bond distances and bond angles are listed in Table 2.

Platinum(II) ion is four-coordinated by two triazolopyrimidine nitrogen atom and two chloride ions. The two molecules of 5,7-ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidine ligands are coordinated to platinum(II) in a monodentate manner through the nitrogen atom in position 3, which is the most frequent binding site for this type of heterocycle ligand [6,8,9,11,13,23]. The geometry of the PtN_2Cl_2 chromophore is characterized by distortion from the square-planar coordination. The angle are different from 90°: N(3)–Pt(1)–N(13) 92.87(11)°, N(13)–Pt(1)–Cl(2) 88.18(9)°, N(3)–Pt(1)–Cl(1) 88.29(8)°, Cl(2)–Pt(1)–Cl(1) 90.68(4)°. In the metal environment PtN_2Cl_2, the bond distance Pt–N and Pt–Cl *via* their nitrogen atoms N(3), the Pt(1)–N(3) distance being 2.043(3) Å and Pt(1)–N(13) 2.036(3) Å. The chloride atoms are in terminal *cis* positions resulting in Pt–Cl bond distances 2.288(1) Å and 2.297(1) Å. The Pt–N and Pt–Cl bond distances are quite comparable with these found in the related *cis*-$PtCl_2(HmtpO)_2 \cdot 2H_2O$ [8], *cis*-$PtCl_2(HmtpO)_2 \cdot 4H_2O$ [9] and *cis*-$PtCl_2(NH_3)(HmtpO)$ [9]. In addition, such a geometry of the Pt(II) coordination sphere is similar to that reported earlier for *cis*-$PtCl_2(HmtpO)_2 \cdot 2H_2O$ [8] and *cis*-$PtCl_2(HmtpO)_2 \cdot 4H_2O$ [9]. Geometry of the dbtp ligand is typical for the triazolopyrimidine ring system, and similar to those reported for dmtp [24,25].

O(92)#1–C(91)–C(91)#1	110.6(7)		

Both dbtp rings are planar, the r.m.s deviation from the best plane for N(11)–C(19) system is 0.0121 Å, whereas for N(21)–C(29) ring system is 0.0136 Å. The r.m.s deviation of atoms from the best plane of coordination is 0.0170 Å. The dbtp ring system planes form a dihedral angle of 52.66(9), while the angles between these planes and the PtN_2Cl_2 best plane are 39.48(9)° and 39.01(8)°. These values are much smaller than the analogous values reported for the *cis*-$PtCl_2(HmtpO)_2 \cdot 4H_2O$ [9].

The crystal packing reveals that all ring systems of the adjacent molecules are involved in the π...π stacking interactions, resulting in the formation of chains of molecules (Fig. 2). These chains are assembled into layers parallel to the crystallographic (100) by hydrophobic interactions of the tert-butyl groups. The complex molecules belonging to different layers seem to be linked by ethanol molecules interacting with the chloride ions. The details of these interactions are not discussed, since the ethanol hydrogen atoms cannot be located on the electron density maps.

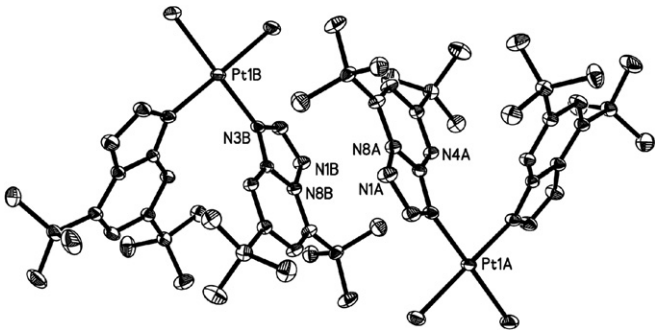

Fig. 2. The π–π interactions between the triazolopyrimidine ring systems. The symmetry codes are: A $[x, y, z]$; B $[-x, 1-y, 1-z]$.

3.2. Discussion of the crystal structures of *cis*-$PdCl_2$(dbtp)(dmso) (**2**)

The crystal structure data of *cis*-$PdCl_2$(dbtp)(dmso) (**2**) are listed in Table 1, whereas selected bond lengths and angles in Table 2. The perspective view of the molecule, with its numbering scheme is shown in Fig. 3. The structure of *cis*-$PdCl_2$(dbtp)(dmso) (**2**) is composed of square planar where the palladium atom is bound to the nitrogen atom of the dbtp (N3), sulfur atom of dimethylsulfoxide and two chloride atoms in *cis* arrangement forming a bond angle 91.58(5)°. This bond angle is smaller than those observed for dichloride palladium(II) complexes with 3-aminopyrrolidine [26], but bigger than those observed by us for *cis*-$PdCl_2$(dbtp) · $0.5C_2H_5OH$ [11]. These results seem to indicate an influence of dimethylsulfoxide molecule. The bond distances: Pd(1)–N(3) 2.041(3), Pd(1)–Cl(1) 2.281(1) and Pd(1)–Cl(2) 2.302(1) Å are similar to those described for palladium(II) compounds with N-donors ligands [26]. The angles in the coordination plane vary between 89.11(9)° and 91.58(5)°, as well as 176.60(9)° and 177.32(6)°. The Pd–S distance of 2.245(1) Å and is longer to the reported for Pt–dmso complexes [11,27–29]. The sulfur atom of the coordinated dimethylsulfoxide ligand is in an approximate tetrahedral environment although the biggest deviation has been observed for the C(11)–S(1)–C(12) 101.5(3)° and O(3)–S(1)–Pd(1) 116.03(17)° angles. Chloride ions are in *cis* position, the Pt–Cl distances being 2.302(1) and 2.281(1) Å as expected for the dichloride palladium compounds [26].

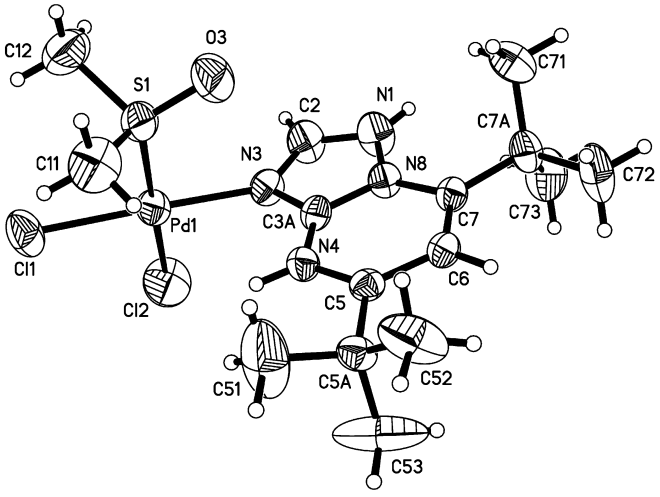

Fig. 3. The drawing of the *cis*-$PdCl_2$(dbtp)(dmso) (**2**) with the numbering scheme. The thermal ellipsoides displayed at 50% probability.

The analysis of the dbtp ligand planarity data indicates that the fused-ring system is essentially planar. The nine atoms comprising the triazolopyrimidine core have the r.m.s. deviation of 0.0147 Å from the least-squares plane. The $PdNSCl_2$ coordination sphere is also planar, the r.m.s. atomic deviation from the best plane is 0.0475 Å. The dihedral angle between the dbtp ring system plane and the $PdNSCl_2$ plane is 75.76(5)°, and is smaller than that of 88.97° reported for the HmtpO ring in the *cis*-$PtCl_2(NH_3)$(HmtpO) complex [9].

The symmetrical intermolecular interactions were found between C(2)–H group of the dbtp and Cl(1) ligand (Fig. 4) and methyl group from dmso C(12)–H and Cl(2). These are responsible for the dimerization of complex molecules related by the center of symmetry. Such interactions can be promoted by polarization of C–H group by of the adjacent heterocyclic N atoms of dbtp or S=O group of dmso.

3.3. NMR studies

The multinuclear spectral data of *cis*-$PtCl_2(dbtp)_2$ have been reported previously [12] and therefore here we presented only ^1H, ^{13}C NMR parameters for *cis*-$PdCl_2$-(dmso)(dbtp) (**2**). ^1H NMR spectrum of (**2**) exhibits signals at 0.95 and 1.53 ppm from the *tert*-butyl groups and singlets from H(2), H(6) (9.17 and 7.28 ppm), respectively. The latter chemical shifts when compared to free ligand, demonstrate deshielding of H(2) ($\Delta_{coord} = 0.53$ ppm), whereas for H(6) the opposite effect has been noted ($\Delta_{coord} = 0.01$ ppm). The deshielding of H(2) can be related to the charge density change in the heterocycle due to N(3) coordination of dbtp. The opposite effect on H(6) is much smaller due to four bonds distance in heterocylcic ring from coordinating N(3). The monodentate coordination mode of dbtp ligand *via* N(3) can be deduced from the large deshelding of H(2) proton. Thus palladium(II) binding to N(3) results in a deshelding of H(2), in a similar way to H(8) of purine bases after metal binding to N(7) [1,30]. In addition, the signals of carbons adjacent to N(3) coordination site C(2) and C(3a) are shielding (0.9–2.9 ppm), whereas: C(5), C(6) and C(7) shifted towards opposite fields (1.5–2.9 ppm). The shielding of the carbon atoms, adjacent to the coordination site N(3), as well as the deshielding of the other carbons and the protons inside the heterocyclic ring [9,11,12].

Moreover, in the ^1H NMR spectrum of (**2**) we observe also the signal of CH_3 groups of dmso molecule. The chemical shift of dmso CH_3 groups ($\delta = 3.25$ ppm), has not varied from other sulfur-bonded ligands [31–33].

The results of ^{13}C CPMAS spectra of dbtp and (**1**), (**2**) are listed in Table 3. The deshielding of aromatic carbons

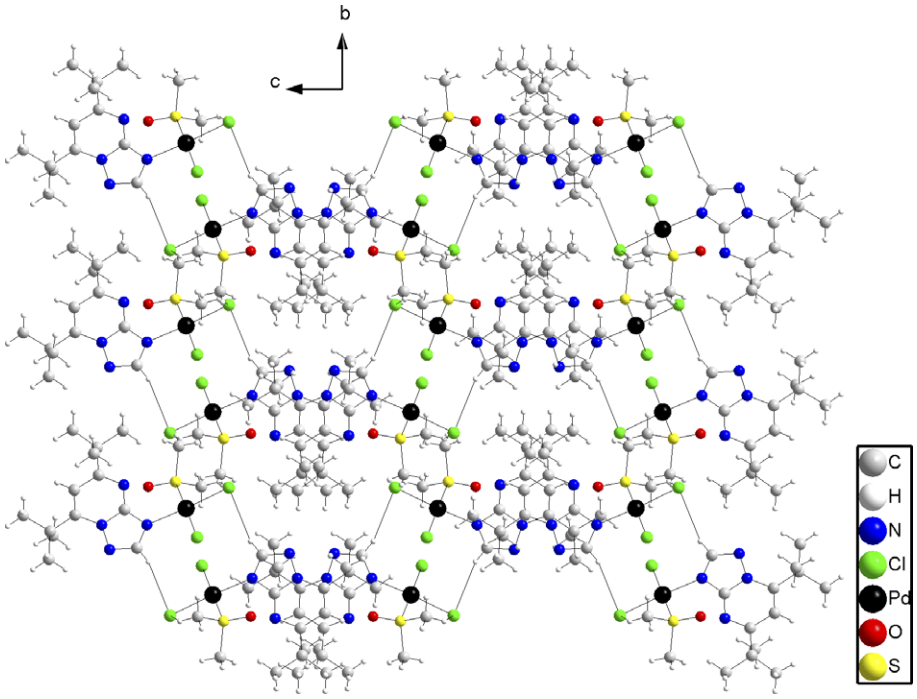

Fig. 4. View of the interaction between the C(2)–H group of the dbtp and Cl(1) ligand interaction.

Table 3
^{1}H and ^{13}C NMR chemical shifts (δ) for the platinum(II) and palladium(II) complexes (coordination shifts in parentheses)

Compound	C(2)	C(3a)	C(5)	C(6)	C(7)
dbtp in solid state	155.8	153.9	176.1	106.3	157.8
cis-$PtCl_2$(dbtp)$_2$ (**1**) in solid state	151.9 (−3.9)	153.1 (−0.8)	179.1 (+3.0)	107.9 (+2.6)	159.8 (+1.6)
cis-$PdCl_2$(dbtp)(dmso) (**2**) in solid state	151.5 (−3.9)	153.5 (−0.4)	178.2 (+2.1)	107.9 (+1.6)	158.1 (+0.3)
dbtp in dmf-d_7	155.3	156.5	175.9	104.6	157.9
cis-$PdCl_2$(dbtp)(dmso) (**2**) in dmf-d_7	154.4 (−0.9)	153.6 (−2.9)	178.8 (+2.9)	107.1 (+2.5)	159.4 (+1.5)

C(5), C(6), C(7) was observed upon complexation, except C(2) and C(3a) was detected. This suggests that the local magnetic fields are strongly influenced by the orientation or packing of the molecules in the crystal lattice present a similar pattern of the coordination shifts as observed in solution (Table 3), what indicates the same way of dbtp coordination.

3.4. Infrared spectra

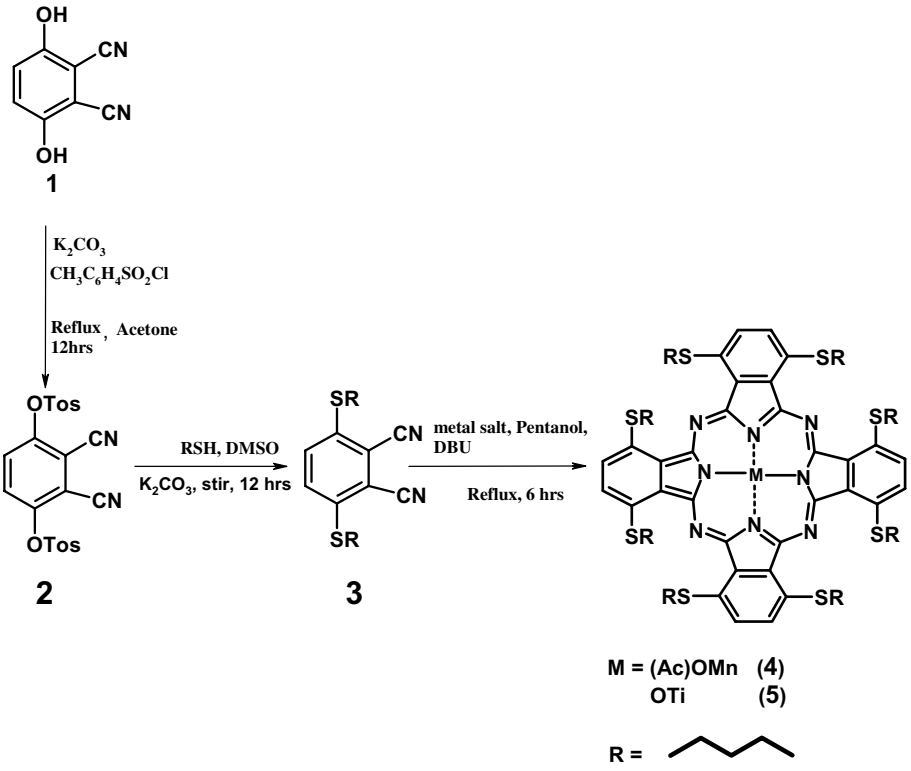
Absorption bands of dbtp in the spectra of (**2**) are affected by coordination. The characteristic bands appeared at ν_{tp}(1617 cm^{-1}) and ν_{py}(1540 cm^{-1}) which are shifted *ca.* 10 cm^{-1} towards lower frequencies, upon coordination. Similar effect has been already observed by us for *cis*-$PtCl_2$(dbtp)$_2$ [12] and different transition metals complexes with triazolopyrimidine derivatives (tp, dmtp, dptp, dbtp, and HmtpO), where the N(3) coordination occurred [9,11–13,34].

In addition in the spectrum of (**2**) two new intensive absorption bands are detected at 1139 and 1033 cm^{-1}, which can be assigned to ρ_{CH_3} rocking vibrations and ν_{SO} stretching vibration, respectively [13,27,35–37]. Similar bands were noted in the spectra of alkyl sulfoxide palladium(II) complexes where S-bonded dmso was postulated [35]. Recently we have found ν_{SO} band in the spectra of $PtCl_2$(dmso)L, where L 1,2,4-triazolo[1,5-*a*]pyrimidine or its 5,7-disubstituted derivatives; thiazole, at similar frequencies (1142–1147 cm^{-1}) [14,27].

Spectrum of (**2**) in the range of metal-ligand vibrations exhibited one new strong absorption band at 321 cm^{-1}, 296 cm^{-1}, which can be assigned to Pd–Cl stretching vibrations. Similar frequency for Pd–Cl bond vibrations were detected in the spectra for other palladium(II) compounds, e.g.: *cis*-$PdCl_2(NH_3)_2$ (327, 306 cm^{-1}) [38], *cis*-$PdCl_2$(en)$_2$ (307, 296 cm^{-1}) [38], *cis*-$PdCl_2$(Him)$_2$ (335, 339 cm^{-1}) [39], *cis*-$PdCl_2$(tp)$_2$ (360, 306 cm^{-1}), *cis*-$PdCl_2$(dmtp)$_2 \cdot H_2O$ (356, 338 cm^{-1}) [11] (en – ethylenodiamine, Him – imidazole). The Pd–N stretching vibrations of the complexes can be tentatively assigned in analogy with *cis*-$PdCl_2(NH_3)_2$, *cis*-$PdCl_2$(en)$_2$ [38] and *cis*-dichloride compounds containing *N*-alkyl-3-pyridine-5-trifluoromethyl pyrazole ligands [40] to the bands appearing in the range 440–428 cm^{-1}. The presence and frequencies of the bands assignments Pd–N and Pd–Cl stretching vibrations therefore indicate coordination of the

palladium(II) *via* nitrogen atom and confirm *cis* geometry of chloride ions.

4. Conclusion



The present work displays the molecular structure of platinum(II) and palladium(II) with 5,7-ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidine. The results described and discussed above have clearly show that in both *cis*-$PtCl_2(dbtp)_2 \cdot EtOH$ and *cis*-$PdCl_2(dbtp)(dmso)$ heterocycle ligand is coordination monodentately *via* N(3). The observed coordination mode *via* N(3) may be regarded as representative for triazolopyrimidines and analogous to N(9) complexation in purine.

5. Supplementary material

CCDC 276451 and 276450 contain the supplementary crystallographic data for (**1**) and (**2**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Synthesis of thiol derivatised MPc complexes.

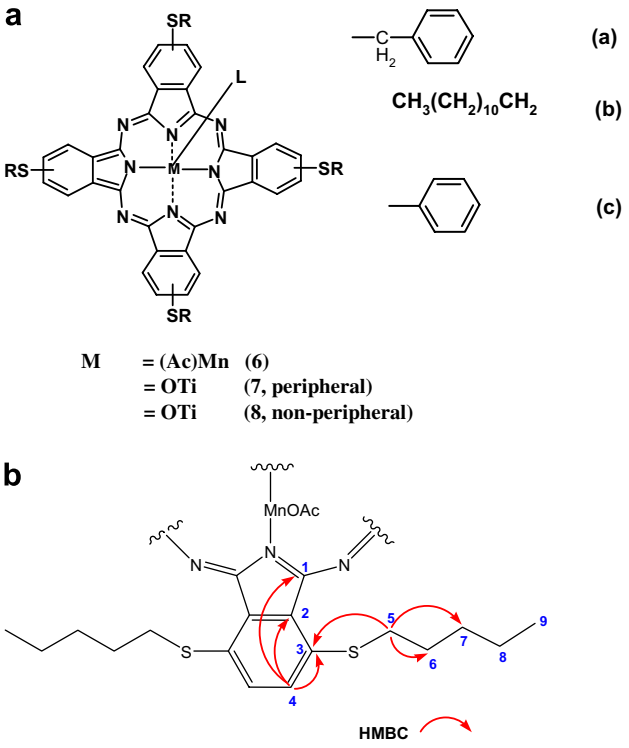

Fig. 1. (a) Molecular structures of published thiol derivatised MPc complexes. (b) Partial structure of four together with key HMBC correlations.

metal exhibits variable oxidation states ranging from Mn^{I} to Mn^{IV} [3–13]. This makes manganese phthalocyanine complexes potential catalysts for many reactions. Substituted manganese phthalocyanine complexes are still relatively few, and their electrochemistry not fully understood. For example the first reduction in $Mn^{II}Pc^{-2}$ complexes has been a subject of some controversy, with some reports proposing ring reduction to the $Mn^{II}Pc^{-3}$ species and others suggesting metal reduction to the $Mn^{I}Pc^{-2}$ species [2]. The spectra of $Mn^{II}Pc$ and $Mn^{III}Pc$ complexes is now well known. However, the spectra of $Mn^{IV}Pc$ complexes are virtually unknown. This work presents a well-defined spectrum of a $Mn^{IV}Pc^{-2}$ complex.

Titanium phthalocyanine (TiPc) also exhibits variable oxidation states. There is a growing interest in the chemistry of TiPc complexes [14–26], though their properties are relatively unexplored. Diamagnetic ions such as Zn^{2+}, Al^{3+}, Ga^{3+} and Ti^{4+} give phthalocyanine complexes comprising both high triplet yields and long triplet lifetimes [27], which are suitable for photodynamic therapy (PDT) applications, hence the need to develop new TiPc complexes. One-step two electron processes are rare but have been reported in some MPc complexes [28]. We have recently reported on TiPc complexes exhibiting overlapping reduction processes [17]. Due to the rarity of such overlapping redox processes in MPc complexes, there is a need to study the electrochemistry of more TiPc complexes in order to understand the electrochemical behaviour of these molecules.

2. Experimental

2.1. Materials

Acetone, manganese acetate, dimethylsulphoxide (DMSO), 1-pentanethiol, titanium butoxide, 1,8-diazabicyclo{5.4.0}-undec-7-ene (DBU), tetrabutylammonium tetrafluoroborate and 1-pentanol were purchased from Sigma–Aldrich. Potassium carbonate, sodium carbonate, deuterated chloroform ($CDCl_3$), 2,3-dicyanohydroquinone, *p*-toluenesulfonyl chloride, chloroform ($CHCl_3$) and dichloromethane (DCM) were procured from Merck. Solvents were dried and distilled before use. Column chromatography was performed on silica gel 60 (0.04–0.063 mm).

2.2. Electrochemical studies

Cyclic (CV) and square wave (SWV) voltammetry data were obtained with the Autolab potentiostat PGSTAT 30 (Eco Chemie, Utretch, The Netherlands) driven by the General Purpose Electrochemical Systems data processing software (GPES, software version 4.9, Eco Chemie), using a three-electrode set-up with glassy carbon electrode (GCE, 3 mm diameter) as a working electrode, platinum wire as counter electrode and Ag|AgCl wire as pseudo-reference electrode. Electrochemical experiments were performed in dry DCM containing tetrabutylammonium tetrafluoroborate ($TBABF_4$) as a supporting electrolyte. Prior to scans, the working electrode was polished with alumina paste on a Buehler felt pad, followed by washing with deionised water and rinsing with DCM. Square wave parameters were: step potential 5 mV; amplitude 20 mV at a frequency of 25 Hz. Spectroelectrochemical data were obtained using a home made optically transparent thin-layer electrochemical (OTTLE) cell which was connected to a Bioanalytical Systems (BAS) CV 27 voltammograph.

2.3. Equipment

UV/Vis spectra were recorded on a Cary 500 UV/Vis/NIR spectrophotometer. IR (KBr discs) was recorded on a Perkin–Elmer spectrum 2000 FTIR spectrometer. ^{1}H and 2-D NMR spectra were recorded using a Bruker AVANCE II+ 600 MHz spectrometer. Elemental analyses were performed at the University of Cape Town.

2.4. Synthesis

For the synthesis of phthalonitriles (**2** and **3**), a procedure similar to that reported in the literature [29–31] was employed with slight modification as follows.

2.4.1. 3,6-Bis(4′-methylphenylsulfonyloxy) phthalonitrile (*2*)

p-Toluenesulfonyl (Tos) chloride (5.2 g, 27 mmol) was added to a mixture of 2,3-dicyanohydroquinone (2 g, 13 mmol) and potassium carbonate (6.9 g, 50 mmol) in acetone (15 ml). The mixture was heated to reflux for 2 h. Thin layer chromatography (TLC) was performed to determine the consumption of compound **1**. The mixture was cooled to room temperature and poured into water (40 ml), and stirred for 1 h. The light brown product was filtered and oven dried. Yield: 4.5 g (79%). IR [(KBr) υ_{max}/cm^{-1}]: 3432, 3239, 3085, 2243, 2226(CN), 1504, 1449, 1315, 1279, 1204, 1174, 1142, 1021, 1004, 979, 934, 847, 749, 694, 638, 614.

2.4.2. 3,6-Di(pentathio)-4,5-dicyanobenzene (*3*)

1-Pentanethiol (2.4 g, 23 mmol) was dissolved in DMSO under a nitrogen atmosphere and **2** (4.3 g, 9.2 mmol) was added. The mixture was stirred for 15 min and finely ground anhydrous potassium carbonate (5.1 g, 37 mmol) was added portionwise for two hours while stirring. The mixture was stirred under a nitrogen atmosphere for 12 h. Water was added and the aqueous phase extracted using chloroform (3×50 ml). The extracts were further treated with 5% sodium carbonate solution (2×250 ml). The solution was further treated with water (2×250 ml), and the solvent evaporated off. The product was recrystallised from ethanol. Yield: 2.2 g (71.7%). IR [(KBr) υ_{max}/cm^{-1}]: 3084, 2951, 2930, 2864, 2378 (S-C), 2225 (C≡N), 1444, 1283, 1202, 1181, 1173, 1145, 877, 847, 827, 725, 547, 447. ^{1}H NMR($CDCl_3$):δ, ppm 7.49 (2H, s, Ar-H), 3.02–2.99 (4H, t, $-CH_2$), 1.71–1.63 (4H, m, $-CH_2$), 1.46–1.37 (4H, m, $-CH_2$), 1.36–1.28, (4H, m, $-CH_2$), 0.91–0.88 (6H, t, $-CH_3$).

2.4.3. 1,4,8,11,15,18,22,25-Octapentylthiophthalocyaninato manganese(III) acetate (*4*)

3,6-Dipentylthiophthalonitrile (**3**) (0.4 g, 1.2 mmol) in 1-pentanol (3.5 ml) was refluxed under a nitrogen atmosphere and manganese(III) acetate (0.069 g, 0.40 mmol) was added. After the addition of DBU (0.13 ml, 0.86 mmol), the reaction was continued for 6 h. The mixture was cooled and column chromatography over silica was done with $CHCl_3$ as eluent. Yield: 0.23 g (42%). UV/Vis (DCM): λ_{max} (nm) ($\log\varepsilon$): 285(5.0), 363(4.5), 553 (4.0), 794(4.3), 893 (4.8). IR [(KBr) υ_{max}/cm^{-1}]: 2959, 2925, 2855, 2369 (S-C), 1557, 1461, 1361, 1310, 1283, 1263, 1225, 1210, 1190, 1149, 1102, 1072, 1024, 932, 802 (υ_{Mn-O}), 750, 584, 560. ^{1}H NMR (600 MHz, $CDCl_3$): δ ppm 7.41 (8H, s, Ar-H-4), 3.01 (16H, t, $J = 7.2$, 7.2 Hz, S-H_2-5), 1.74 (16H, quintuplet, 7.2, 7.2 Hz, H_2-6), 1.46 (16H, quintuplet, 7.2, 7.2 Hz, H_2-7), 1.36 (16H, sextuplet, 7.8, 7.2, 7.2 Hz, H_2-8), 1.2 (3H, s, OAc), 0.91 (24 H, t, $J = 7.2$, 7.2 Hz, H_3-9). ^{13}C NMR (150 MHz, $CDCl_3$): δ ppm 166.6 (s, C-1), 134.7 (s, C-3), 130.3 (d, C-4), 128.0 (s, C-2), 30.7 (t, C-7), 30.5 (t, C-5), 29.2 (q, OAc), 27.7 (t, C-6), 21.8 (t, C-8), 13.5 (q, C-9). HMBC correlations: H-4/C-1, C-2, C-3; H_2-5/C-3, C-6, C-7; H_2-6/C-7, C-8; H_2-7/C-5, C-6, C-8, C-9; H_2-8/C-6, C-7, C-9; H_2-9/C-7, C-9. *Anal.* Calc. for $C_{74}H_{99}N_8S_8O_2Mn$: C, 61.55; H, 6.91; N, 7.76. Found: C, 61.72; H, 7.33; N, 7.03%.

*2.4.4. 1,4,8,11,15,18,22,25-Octapentylthiophthalocyaninato titanium(IV) oxide (**5**)*

Compound **5** was prepared as described above for compound **4**, using compound **3** (0.45 g, 1.2 mmol), titanium butoxide (0.14 ml, 0.40 mmol), DBU (0.25 ml, 1.68 mmol) and 1-pentanol (3.4 ml). The purification was done using column chromatography over silica with $CHCl_3$ as eluent. Yield: 0.12 g (22%). UV/Vis (DCM): λ_{max} (nm) ($\log\varepsilon$): 290(3.9), 352(3.5), 718(3.3), 808(3.9). IR [(KBr) υ_{max}/cm^{-1}]: 2955, 2930, 2961, 2354 (S-C), 1713, 1649, 1560, 1459, 1371, 1274, 1178, 1145, 1108, 1060, 824 (υ_{Ti-O}), 759, 643, 596, 534. ^{1}H NMR (600 MHz, $CDCl_3$): δ ppm 7.47 (8H, s, Ar-*H*), 3.00 (16H, t, $J = 7.2$, 7.2 Hz, S-*CH*$_2$), 1.67 (16H, quintuplet, 7.2, 7.2 Hz, *CH*$_2$), 1.4 (16H, m, *CH*$_2$), 1.3 (16H, sextuplet, $J = 7.8$, 7.8, 7.2 Hz *CH*$_2$–CH$_3$), 0.90 (24H, t, $J = 7.2$, 7.2 Hz, *CH*$_3$). *Anal.* Calc. for $C_{73}H_{99}N_8S_8OTi$: C, 62.04; H, 6.94; N, 8.05. Found: C, 61.74; H, 7.26; N, 7.83%.

3. Results and discussion

3.1. Synthesis and characterisation

The thiol substituted phthalonitrile was prepared via a base-catalysed (K_2CO_3) nucleophilic aromatic displacement reaction of the tosyl group with a thiol. The metallophthalocyanine complexes (**4** and **5**) were then prepared by the template reaction of thiol substituted phthalonitrile precursors with manganese acetate or titanium butoxide in the presence of DBU (Scheme 1). Yields of 42% and 22% were respectively obtained for complexes **4** and **5** after purification by column chromatography. Both MPcs were soluble in solvents such as DCM, $CHCl_3$, THF and toluene.

The new compounds were characterised by IR, UV/Vis and NMR spectroscopies, as well as elemental analysis, which were consistent with the predicted structures as shown in the experimental section. The disappearance of the sharp C≡N vibration at 2225 cm^{-1} confirmed the cyclotetramerisation of phthalonitriles **2** and **3** and typical Mn–O and Ti=O stretches appeared as medium bands at 802 cm^{-1} and 824 cm^{-1} [32], respectively, further confirming MPc formation.

The ^{1}H NMR spectra of these octa-substituted MPcs show simple spectra due to the highly symmetrical nature of the complexes. The ^{1}H NMR spectra of complexes **4** and **5** showed almost identical chemical shifts. The NMR data obtained is in accordance with the expected structures. The aromatic non-peripheral ring protons were observed as a singlet at 7.41 ppm (H-4, Fig. 1b) for complex **4** and 7.47 for complex **5**, integrating for eight protons for each complex. The methylene and methyl proton shifts belonging to the thio-alkyl side chain were clearly observed in the ^{1}H NMR spectrum. The ^{13}C NMR data proved difficult to obtain, thus chemical shifts were obtained using HSQC (Heteronuclear Single Quantum Correlations) and HMBC (Heteronuclear Multiple Bond Correlation) data. The deshielded proton resonating at δ 3.01 for **4** was attributed to the thio-methylene proton H-5, which upon analysis of the HSQC data revealed it to be attached to a carbon resonating at 30.5 ppm. The thio-methylene proton assignment was confirmed by a HMBC correlation (Fig. 1b) to an aromatic carbon resonating at 134.7 ppm (C-3). Thus a HMBC correlation to C-3 from the aromatic proton H-4 was expected, and observed, confirming its assignment. H-5 showed additional HMBC correlations to methylene carbons resonating at 27.7 and 30.7 ppm, which, together with further HMBC and HSQC studies identified them as C-6 and C-7, respectively. The ^{1}H NMR spectrum revealed a further methyl and CH_2 proton signals at δ 0.91 and 1.36 ppm, which were shown to be attached to carbons at 13.5 and 21.8 ppm, respectively. The CH_3 group was thus placed at the end of the pentylthio chain and assigned as H-9. This methyl proton showed HMBC correlations to carbons at 21.8 and 30.7 ppm. With the latter carbon shift having been assigned to C-7 previously, the carbon resonating at 21.8 ppm was attributed to the remaining methylene group C-8, thus completing the assignment of the pentylthio side chain. Finally, the aromatic proton H-4, in addition to the HMBC correlation to C-3, showed two other HMBC correlations which were observed to be aromatic quarternary carbons residing at δ 128.0 and 166.6 ppm. Based on their chemical shifts these were assigned to C-2 and C-1, respectively. Furthermore, a methyl singlet residing at 1.24 ppm in the ^{1}H NMR spectrum was shown in the HSQC spectrum to be attached to a carbon at 29.2 ppm. This methyl showed no HMBC correlations to the ring and is thus tentatively assigned to the acetate attached to the manganese metal ion. The carbonyl chemical shift belonging to acetate was not observed in the HMBC, but elemental analyses and IR spectra confirmed the presence of the acetate group.

The UV/Vis spectra of the complexes **4** and **5** are shown in Fig. 2. In DCM the spectra show typical B-bands

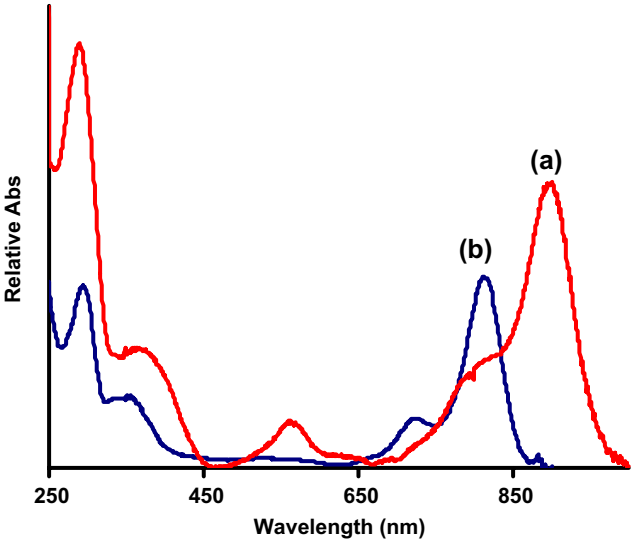

Fig. 2. UV–Vis spectrum of (a) **4** (concentration = 1.5×10^{-5} M) and (b) **5** (9×10^{-5} M) in DCM.

around 360 nm. The Q-bands are highly red-shifted for complex **4** at 893 nm and **5** at 808 nm in DCM. An additional band, typical of Mn(III)Pc [9] derivatives is observed between 450 and 650 nm. The large red shift of the Q-band is due to the electron donating properties of sulphur. In addition, substitution at the α positions enhances the red shift, making the complex **4** in particular to show a highly red-shifted Q-band compared to MPc complexes in general. The red shift for complex **5** is the longest ever reported, while for MnPc red shifts close to 900 nm are rare. The complexes did not show aggregation and Beer's law was obeyed for concentrations lower than 3×10^{-5} M.

3.2. Voltammetric and spectroelectrochemical characterisation

3.2.1. 1,4,8,11,15,18,22,25-Octapentathiophthalocyaninato manganese(III) acetate (4)

The cyclic (CV) and square wave (SWV) voltammetries of complex **4** were performed in de-aerated DCM containing $TBABF_4$ as electrolyte, Fig. 3. The half-wave potentials ($E_{1/2}$) for the complexes are summarised in Table 1. Complex **4** exhibits four main reduction processes labelled **I** ($E_{1/2} = +0.47$ V), **II** ($E_{1/2} = +0.75$ V), **III** ($E_{1/2} = -0.46$ V), and **IV** ($E_{1/2} = -1.24$ V) vs. Ag|AgCl, Table 1. All the redox processes showed both the cathodic and anodic components; however peak separations were larger than the expected 60 mV, suggesting slow electron transfer. The cathodic to anodic peak separation (ΔE) ranged from 70 to 120 mV and a ΔE value of 90 mV was obtained for ferrocene, at a scan rate of 100 mV/s.

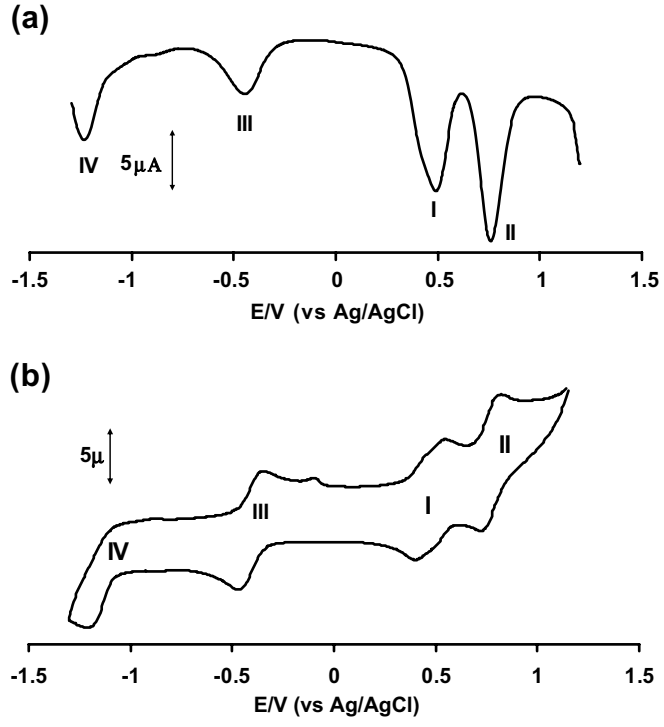

Fig. 3. Square wave (a) and cyclic (b) voltammograms for **4** in DCM containing 0.1 M $TBABF_4$. Scan rate = 100 mV s^{-1}.

The cathodic to anodic peak current ratio (I_{pc}/I_{pa}) were near unity, except for **IV** which showed a weak cathodic component. For all redox couples, plots of peak current (I_p) versus the square root of scan rate ($v^{1/2}$) were linear, thus suggesting diffusion control at the electrode surface. In comparison to other thiol substituted MnPc complexes (Table 1), process **III** may be assigned to $Mn^{III}Pc^{-2}/Mn^{II}Pc^{-2}$, though shifted to more negative potentials. The shift to more negative potentials may be due to the fact complex **4** is octa-substituted with the electron donating thiol substituents, while the rest of the complexes in Table 1 are tetrasubstituted. The plurality of the electron donating thiol groups may make the molecule more difficult to reduce. Also the ring substituents are different in the complexes. Process **IV** may either be due to $Mn^{II}Pc^{-2}/Mn^{II}Pc^{-3}$ or $Mn^{II}Pc^{-2}/Mn^{I}Pc^{-2}$. As stated in the introduction, both $Mn^{I}Pc^{-2}$ and $Mn^{II}Pc^{-3}$ species have been proposed. However, the latter species has been reported by several authors [33,34]. The first oxidation (process **I**) showed an overlap of two peaks, which were not clearly resolved even when using the more sensitive SWV. Such closely spaced redox couples may be associated with the presence of aggregates [28]. On dilution of the solution, the splitting is not evident. The last oxidation process (**II**) is in the range of ring-based processes in comparison to other MnPc complexes. The nature of the couples as well as the number of electrons transferred were confirmed by spectroelectrochemistry below. Using a narrower scan window (−1000 to +1000 mV) did not change the shape of the cyclic voltammograms.

Spectroelectrochemical studies using optically transparent thin layer electrode (OTTLE) cell gave more insight into the origin of the redox couples observed during voltammetric studies of the complexes. Fig. 4a shows the spectral changes observed during the reduction of complex **4** at potentials of process **III**. The starting spectrum in Fig. 4, is slightly more shifted to longer wavelengths compared to Fig. 2, due to the presence of an electrolyte in DCM for the former. Upon reduction, there was a blue shift in the Q-band from 908 to 795 nm with a concurrent decrease of the charge transfer bands at 571 nm, and the colour of the complex changed from purple to blue. These spectral changes occurred with clear isosbestic points at 831, 634 and 536 nm. The blue shift in the Q-band upon reduction is typical of $Mn^{III}Pc^{-2}$ to $Mn^{II}Pc^{-2}$ reduction [2]. Thus spectral changes in Fig. 4a confirmed that process **III** is due to the redox couple $Mn^{III}Pc^{-2}/Mn^{II}Pc^{-2}$. The value of n was calculated using $Q = nFCV$ (n, number of electrons involved, F, Farady's constant, C, solution concentration and V, solution volume) to be approximately 1, $n = 0.8$. Fig. 4b shows spectral changes observed on application of potentials of process **IV**. A drastic decrease in the intensity of the Q-band and the formation of new features between 500 and 700 nm is typical [34] of ring-based processes in MPc complexes. Hence the spectral changes are

assigned to $Mn^{II}Pc^{-2}/Mn^{II}Pc^{-3}$. As stated above, the first reduction in $Mn^{II}Pc^{-2}$ complexes has been reported to occur either at the metal to form $Mn^{I}Pc^{-2}$ species or at the ring to form $Mn^{II}Pc^{-3}$ species. The latter is observed in this work and has been reported by our group [35] and others [33].

To confirm the origin of the oxidation processes (**I** and **II**), controlled potential electrolysis was conducted. Fig. 5 shows spectral changes observed on application of potentials of process **I**. Spectral changes showed a shift in the Q-band from 908 to 920 nm, Fig. 5b. The shift in the Q-band is typical [2] of metal-based oxidation, hence the formation of a $Mn^{IV}Pc$ species. The spectrum of $Mn^{IV}Pc$ species is not well known apart from a recent report [33]. This work provides another example of a well-defined spectrum of the rare $Mn^{IV}Pc^{-2}$ species. Table 2 lists the Q-band maxima of the various oxidation states of the MnPc discussed in this work and those from the literature.

The application of potential of process **II** resulted in the collapse of the Q-band and the formation of new peaks at 809 and 720 nm with an increase in intensity at ~520 nm, Fig. 5c. The collapse of the Q-band and the formation of new less intense bands is typical [34] of ring oxidation in MPc complexes. Thus couple **II** is assigned to a $Mn^{IV}Pc^{-1}/Mn^{IV}Pc^{-2}$ process. Based on the electrochemical data above, we assign processes **I**–**IV** as follows:

$$Mn^{III}Pc^{-2} \rightarrow Mn^{IV}Pc^{-2} + e^- \quad \text{(process I)} \tag{1}$$

$$Mn^{IV}Pc^{-2} \rightarrow Mn^{IV}Pc^{-1} + e^- \quad \text{(process II)} \tag{2}$$

$$Mn^{III}Pc^{-2} + e^- \rightarrow Mn^{II}Pc^{-2} \quad \text{(process III)} \tag{3}$$

$$Mn^{II}Pc^{-2} + e^- \rightarrow Mn^{II}Pc^{-3} \quad \text{(process IV)} \tag{4}$$

*3.2.2. 1,4,8,11,15,18,22,25-Octapentathiophthalocyaninato titanium(IV) oxide (**5**)*

Detailed electrochemical characterisation of substituted OTiPcs is still under-developed. The cyclic (CV) and square wave voltammograms (OSWV) of the complex was performed in de-aerated DCM containing $TBABF_4$ as electrolyte, Fig. 6. The half-wave potentials ($E_{1/2}$) of the couples are listed in Table 1. Four main redox processes (**I**–**IV**) are observed in Fig. 6. Couples **III** (−0.73 V) and **IV** (−1.09 V) are well defined and reversible with cathodic to anodic peak separation (ΔE) of ~100 mV. The cathodic to anodic peak current ratio (I_{pc}/I_{pa}) were near unity and linear plots of I_p versus square root of the scan rate ($\upsilon^{1/2}$) were obtained for couples **III** and **IV**. Couples **III** and **IV** shifted to more positive potentials with scan number (Fig. 6) probably due to polymerisation effects discussed below.

The oxidation process showed a peculiar behaviour in that the anodic process **I** had a broad pre-peak followed by a sharp peak typical of adsorption [36,37]. It is known [36] that the adsorption of a product of the electrode reaction results in the formation of a sharp peak preceded by a more regular peak, the latter being due to the diffusion of

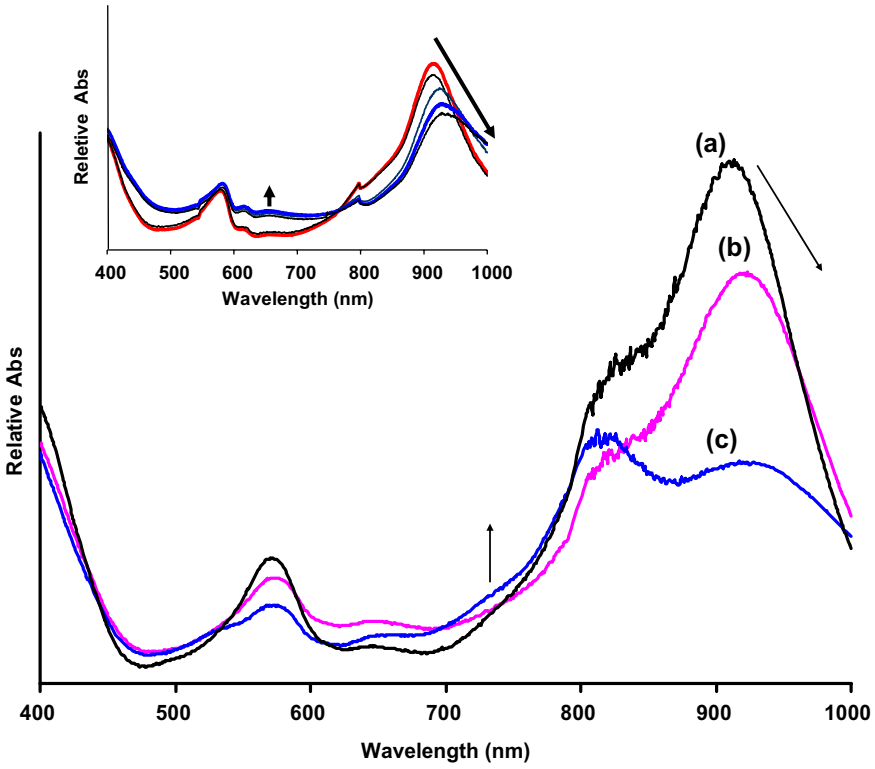

Fig. 5. UV–Vis spectral changes for **4** observed before (a) and after controlled potential electrolysis at +0.9 V (process **I**) (b) and at +1.2 (c) (process **II**). Electrolyte = DCM containing 0.1 M $TBABF_4$.

the electroactive species from solution to the electrode. During the first scan in Fig. 6, a broad peak preceding a sharp peak around 0.5 V was observed. The cathodic (return) scan of process **I** (Fig. 6) showed a sharp peak corresponding to the peak observed in the forward direction. The peak separation for couple **I** was zero confirming that the process is due to adsorption species. On subsequent scans (Fig. 6b) a sharp peak was observed at 0.36 V due to the desorption of adsorbed species. Thus, process **I** moved to less positive potentials again with a peak separation of 0 V due to adsorbed species, on second and subsequent scans. The cyclic voltammograms obtained for second and subsequent scans show more weak peaks (at ~0 V, 0.18 V and 0.79 V) most likely to the polymer formed on cycling the monomer in solution. Polymerisation is judged by the formation of new peaks (as observed in Fig. 6). Electropolymerisation of the complex onto the electrode is probably facilitated through radical polymerisation from sulphur groups, as is the case with amino groups in MPc complexes [10]. Adsorption and sharp peaks have been observed before for thiol substituted ZnPc complexes [38], and the complexes showed decomposition on oxidation. These observations suggest that the oxidation products of some thiol substituted MPc complexes are not soluble in the media and adsorb to the electrode. For process **I**, plots of scan rate versus current were linear (figure not shown) confirming adsorption of the complex. Process **II** in Fig. 6 showed regular (not sharp) anodic and cathodic currents during the first scan, probably due to diffusion of the complex from the solution. An irreversible peak (**II′**) is observed in Fig. 6 near 1 V.

We have reported [39] that depending on the ring substituents, oxidation of the TiPc complexes may or may not be observed, depending on whether the substituents result in the shift of potentials to values where oxidation can no longer be observed since they are outside the usable range of the solvent–electrolyte–electrode system employed. The thiol ligands employed in this work are expected to make oxidation easier, hence allowing the observation of the oxidation peaks. We have also reported [17] an overlap of voltammograms for tetraphenoxy

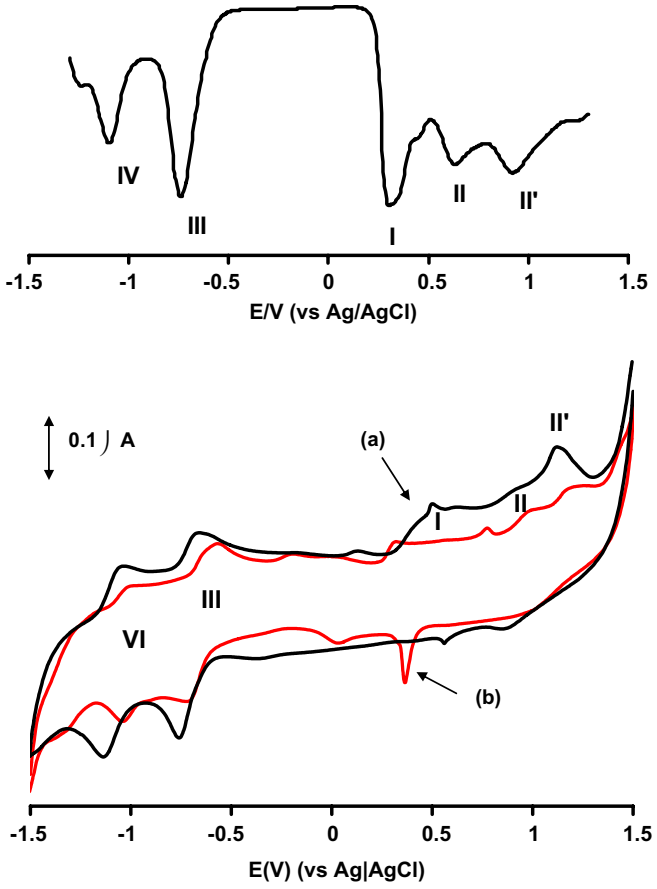

Fig. 6. Square wave (top) and cyclic (bottom) voltammograms of **5** in DCM containing 0.1 M $TBABF_4$. (a) First scan and (b) 20th Scan. The SW voltammogram is for the 10th scan. Scan rate = 100 mV s^{-1}.

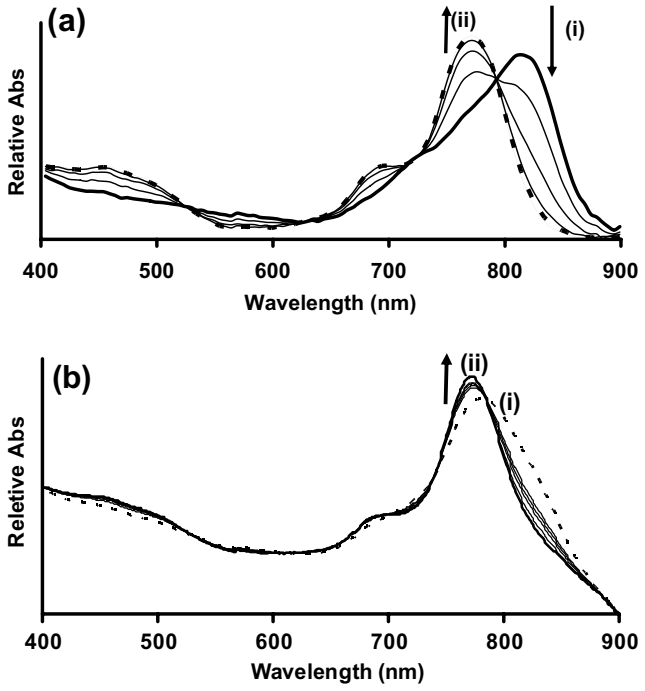

Fig. 7. UV–Vis spectral changes for **5** observed using controlled potential electrolysis at (a) −0.9 V (process **III**) and (b) −1.3 V (process **IV**). (i) Before electrolysis and (ii) at the end of electrolysis. Electrolyte = DCM containing 0.1 M $TBABF_4$.

substituted TiPc, whereby two 1-electron reductions resulted in one couple as follows:

$$Ti^{IV}Pc^{-2} + 2e^- \leftrightarrow Ti^{II}Pc^{-2} \quad \text{(process I)} \tag{5}$$

$$Ti^{II}Pc^{-2} + 2e^- \leftrightarrow Ti^{I}Pc^{-3} \quad \text{(process II)} \tag{6}$$

$$Ti^{I}Pc^{-3} + e^- \leftrightarrow Ti^{I}Pc^{-4} \quad \text{(process III)} \tag{7}$$

However, in this work, overlap of couples is not observed. Such overlap has been observed for distorted (non-planar) porphyrin complexes [40,41]. Therefore, it is possible that the TiPc complexes will show a single step multi-electron transfer process since titanyl phthalocyanine complexes have been reported to be distorted [42–45]. The distortion of MPc complexes is more pronounced when they are substituted with phenoxy groups due to the well known tilting of such groups in MPc complexes [46]. The lack of overlapping voltammogram peaks for TiPc complexes in this work could be a result of the substituents which do not distort the symmetry of the ring. Oxidation of TiPc is expected to occur only at the ring, while reduction is expected to occur at both the central metal as well as the ring. Thus the oxidation processes are due to the ring.

Spectroelectrochemistry was employed to confirm the redox processes. Fig. 7a shows the UV/Vis spectral changes observed on reduction of complex **5** at potentials of process **III**. The Q-band shifts from 814 to 774 nm with isosbestic points at 797, 719, 629, and 534 nm. The spectral changes are typical [2] of metal-based reduction in MPc complexes and are similar to those observed for thiol substituted TiPc complexes [16]. Further reduction at potentials of process **IV**, resulted in spectral changes shown in Fig. 7b and consisted of the shift in the Q-band from 774 nm to 769 nm and the formation of $Ti^{II}Pc^{-2}$ species similar to literature reports [39]. In both cases n was found to be unity confirming one electron transfer. Table 2 lists the Q-band maxima for complex **5** and reported thiol substituted TiPc complexes. Comparing complex **5** with other thiol derivatised TiPc complexes (Table 2) in the same solvent (DCM) shows the former to be more red-shifted due to differences in ring substituents, but the plurality of non-peripheral substituents in **5** will also result in shifting of the Q-band to longer wavelengths.

Attempts to oxidise complex **5** resulted in decomposition, Fig. 8. Such decomposition of oxidation of thiol MPc complexes has been reported as discussed above [38]. Based on the discussed electrochemical techniques, i.e. CV, SWV, and spectroelectrochemistry; the following mechanism for the reduction (Eqs. (8)–(10)) of the TiPc complexes is proposed for **5**:

$$Ti^{IV}Pc + e^- \rightarrow Ti^{III}Pc \tag{8}$$

$$Ti^{III}Pc + e^- \rightarrow Ti^{II}Pc \tag{9}$$

$$Ti^{IV}Pc \text{ (oxidation)} \rightarrow \text{oxidation products} \tag{10}$$

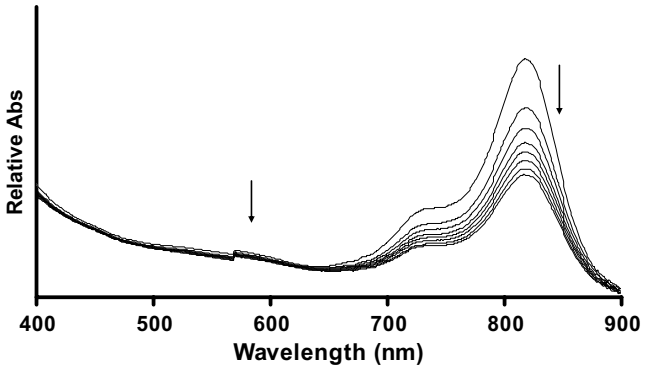

Fig. 8. UV–Vis spectral changes for **5** observed during controlled potential electrolysis at +1.0 V (process **I**), electrolyte = DCM containing 0.1 M $TBABF_4$.

The electrochemical behaviour of TiPc complexes is thus highly influenced by the nature of substituents, and the point of substitution, ie peripheral versus non-peripheral substitution.

4. Conclusions

The octapentylthiophthalocyaninato manganese (III) acetate (**4**) and octapentylthiophthalocyaninato titanium(IV) oxide (**5**) show unusual purple (**4**) and red (**5**) colouration since the Q-band is shifted to the near infra red region with Q-band maxima at 893 nm (908 nm in the presence of $TBABF_4$) and 808 nm (814 nm in the presence of $TBABF_4$) for **4** and **5** in DCM, respectively. For complex **4**, well-defined redox processes are observed and attributed to $Mn^{III}Pc^{-2}/Mn^{II}Pc^{-2}$, $Mn^{II}Pc^{-2}/Mn^{II}Pc^{-3}$, $Mn^{IV}Pc^{-2}/Mn^{III}Pc^{-2}$ and $Mn^{IV}Pc^{-1}/Mn^{IV}Pc^{-2}$. The processes were confirmed by spectroelectrochemistry. The spectrum of the rare $Mn^{IV}Pc^{-2}$ complex is reported. The reduction couples of the Ti complex **5** are assigned to $Ti^{IV}Pc^{-2}/Ti^{III}Pc^{-2}$ and $Ti^{III}Pc^{-2}/Ti^{II}Pc^{-2}$. However, oxidation processes revealed adsorption behaviour and resulted in decomposition on electrolysis using spectroelectrochemistry.

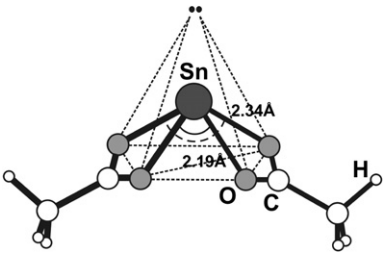

Fig. 1. Structure of the $Sn(CH_3COO)_2$ molecule in the gas phase (after Smart et al. [4]). The overall symmetry is C_2 and the molecule is viewed perpendicular to the twofold axis. The bond angles of 90° (solid line) and 121° (dashed line) are marked. The tentative SnO_4E (E – lone electron pair) trigonal bipyramid is outlined.

2. Experimental

The commercially available starting reagents SnO (''Spektrkhim'', Russia) and glacial acetic acid (Aldrich) were of analytical grade and were used as received. Elemental analysis (C, H) was performed by the Microanalytical Service of the Centre for Drug Chemistry (Moscow, Russia). IR spectra were recorded on a Perkin–Elmer 1600 FTIR spectrophotometer as Nujol and hexachlorobutadiene mulls between KBr plates in the region 4000–400 cm^{-1}. Isothermal dynamic sublimation experiments were run with samples in glass test tubes at a pressure of 10^{-2} Torr.

For the synthesis of $Sn(CH_3COO)_2 \cdot 2CH_3COOH$ the procedure described in Ref. [3] was used: a mixture of SnO (3 g, 22,2 mmol) and glacial acetic acid (11 ml, 192.3 mmol) was refluxed under stirring until the SnO was completely dissolved, and after cooling the yellowish product was collected. $Sn(CH_3COO)_2$ was formed as a white crystalline sublimate by removal of the acetic acid and sublimation at 150–160 °C and at 10^{-2} Torr. Yield ~90%. Mp 183 °C. *Anal*. Calc. for $C_4H_6O_4Sn$: C, 20.25; H, 2.53. Found: C, 19.96; H, 2.52%. IR, cm^{-1}: 661 *v* (COO sym. deformation), 930 *v* (C–C stretch), 1015 *v* (CH_3 rock), 1334 *v* (CH_3 deformation), 1395 *v* (COO sym. stretch), 1530 *v* (COO asymm. stretch). The melting temperature and IR spectra are in good agreement with the data of Donaldson et al. [3].

In spite of the good visual quality of the obtained transparent colorless needle-like crystals, it was found that every needle is composed of numerous finer needles, so that no single crystal suitable for an X-ray diffraction experiment could be selected. The structure solution was performed from X-ray powder diffraction (XRPD) data. The preliminary investigation and unit cell parameter determination were performed with a Huber G670 Guinier diffractometer (Cu $K_{\alpha 1}$-radiation, curved Ge monochromator, transmission mode, image plate). The TREOR90 program was used for indexing the XRPD pattern [5]. The data for the structure determination and Rietveld refinement were collected with a STADI-P diffractometer (Cu $K_{\alpha 1}$-radiation, curved Ge monochromator, transmission mode, linear PSD). FOX software was used for the structure solution [6]. The JANA2000 program package was used for Rietveld refinement of the crystal structure [7].

The initial experiments with matrix-assisted laser desorption/ionization mass spectroscopy (MALDI-TOF-MS) were performed with an Autoflex II (Bruker Daltonics, Germany) instrument. The spectra were recorded in a positive mode (accelerating voltage 19 kV) with a nitrogen laser (337 nm, impulse duration 1 ns). The typical procedure of sample preparation for MALDI was applied [8]. Absolutely dry THF was used as a solvent and anthracene was used as a matrix.

The chemical bonding in tin(II) acetate was analyzed using the electron localization function (ELF) [9]. The ELF distribution was determined from the results of density functional theory (DFT) calculations. A self-consistent DFT calculation was performed with the TB-LMTO-ASA program [10], and the Barth-Hedin exchange-correlation potential was applied. The ELF distribution was obtained using the intrinsic procedure of the LMTO program. The *k* mesh contained 64 points within the first Brillouin zone. The geometrical parameters for the calculation were taken from the XRPD structure refinement. The hydrogen atoms of the methyl groups were attached according to the constraints $d(C–H) = 0.98$ Å, $\angle H–C–H = \angle C–C–H = 109.4°$ typical for acetates [11]. A random mutual orientation of the $C(2)H_3$ and $C(4)H_3$ methyl groups was chosen. We assume that this choice does not influence the basic features of the ELF distribution on the Sn, C and O atoms.

3. Results and discussion

3.1. Crystal structure determination

The XRPD pattern of tin(II) acetate was indexed on a body-centered orthorhombic unit cell with the cell parameters listed in Table 1. The reflection conditions *hkl*: $h + k + l = 2n$, $0kl$, $k,l = 2n$ and $h0l$, $h,l = 2n$ correspond to the space group *Ibam* and its acentric subgroup *Iba*2. The observed unit cell parameters are similar to those reported by Donaldson et al. [2] ($a = 14.11(3)$, $b = 21.35(4)$, $c = 4.96(1)$ Å, given in the *bca* setting), although

the latter are substantially larger (see Table 1 for comparison). Moreover, weak reflections violating the body-centering were observed on the XRPD pattern of tin(II) acetate by Donaldson et al. Careful inspection of the XRPD pattern of the tin(II) acetate prepared in the present work revealed that such forbidden reflections are definitely absent. The reason for this discrepancy is not completely clear.

Because structure solution from XRPD data is not a trivial matter, the applied procedure is explained in detail. The search for the initial structure model was performed using a Monte-Carlo based global optimization [6]. It provided the exact positions of the Sn atoms, whereas the positions of the acetate groups could not be unambiguously determined. The acetate groups were localized using a Rietveld refinement of the crystal structure. One can expect that the reliable determination of the atomic coordinates of such light scatterers as C and O will be hampered by the significant impact of the heavy scattering Sn atoms. In order to overcome this difficulty, the rigid body approximation was used to define the acetate group as a scattering unit. The geometry of the acetate group was assumed to be identical to the one determined for the structure of the $Sn(CH_3COO)_2$ molecule in the gas phase (d(C–C) = 1.51 Å, d(C–O) = 1.26 Å, ∠O–C–O = 122°) [4]. The hydrogen atoms were not taken into account. The positions of the acetate groups in the unit cell were defined by the coordinates of the C atom of the carboxyl groups and the three rotation angles. Thus six positional parameters were used for each acetate group instead of the 12 parameters in the atomic approximation.

Taking into account the assumption about a possible polymeric structure of the tin(II) acetate, the acetate groups were initially located at positions bridging the Sn atoms by the oxygen atoms of their carboxyl groups into infinite chains running along the c-axis. In such an initial model, the m_c plane of the *Ibam* space group becomes a mirror plane of the acetate groups. However, the refinement in the centrosymmetric *Ibam* space group resulted in unacceptably high reliability factors ($R_I = 0.128$, $R_P = 0.128$, $R_{wP} = 0.219$) and large atomic displacement parameters (ADPs) for the atoms of the acetate groups. A significant improvement was achieved by a transformation of the initial model into the *Iba*2 space group. In this group the positions and rotations of the acetate groups are not fixed by symmetry elements. The final refinement was performed with overall ADPs for the carbon and oxygen atoms, whereas the ADP for the Sn atom was refined independently. The preferred orientation along the [0 0 1] axis was taken into account using the March–Dollase formula. Reasonably low values of the reliability factors were achieved: $R9_I = 0.045$, $R_P = 0.037$, $R_{wP} = 0.050$. The crystallographic and atomic parameters (as calculated from the rigid body approximation) and the most relevant interatomic distances are given in Tables 1–3. Fig. 2 represents the experimental, calculated and difference XRD profiles.

3.2. Crystal structure discussion

The crystal structure of tin(II) acetate is shown in Fig. 3. The Sn atoms are arranged in columns oriented along the c-axis and combined in groups of four. The Sn atoms are bridged by two acetate groups along the column, coordinating the Sn atoms by the oxygen atoms of their carboxyl groups. The chains do not directly interact with each other and their packing in groups of four is caused by minimized repulsion between the methyl groups of the acetate anions and the sterical activity of the lone electron pairs (not

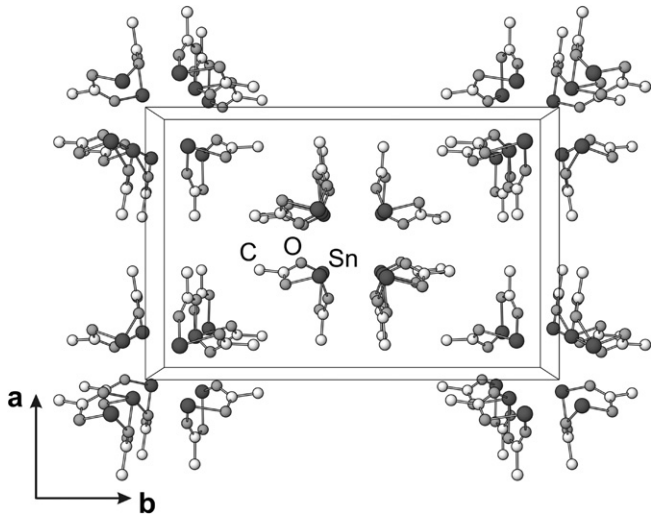

Fig. 3. The arrangement of the $Sn(CH_3COO)_2$ columns in the crystal structure of tin(II) acetate. Hydrogen atoms are not shown.

shown in Fig. 3) on the Sn atoms. The structure of the single $Sn(CH_3COO)_2$ chain is shown in Fig. 4. The experimentally observed positions of the acetate groups demonstrate a large deviation from those dictated by the *Ibam* symmetry. This causes the Sn atoms to be asymmetrically surrounded by four oxygen atoms with two short Sn–O distances (d(Sn–O(1)) = 2.170(6) Å, d(Sn–O(4)) = 2.207(6) Å) and two longer ones (d(Sn–O(2)) = 2.293(7) Å, d(Sn–O(3)) = 2.372(8) Å). The bond valence sum (BVS) for the Sn atoms, calculated using the impacts of the four Sn–O distances given above was found to be equal to 1.8, that is noticeably lower than the nominal value. Much closer agreement (BVS = 1.93) with the formal valence of +2 is achieved if two long Sn–O(2) and Sn–O(3) bonds of 2.961(7) and 2.972(8) Å are taken into account (marked by dashed lines in Fig. 4). Thus the acetate groups can be regarded as tridentate bridging ligands with some chelate character.

The ELF isosurface (Fig. 5) for tin(II) acetate reveals two types of attractors. The first one is presented by large lobes near the tin atoms. Such lobes are usually associated with sterically active (or, in other words, localized) lone pairs, although the nature of these pairs (mixed Sn 5s–5p character or mixed Sn 5s–O 2p antibonding state with empty Sn 5p orbitals) is still being discussed [12]. Attractors of the second type are located between the C atoms of the acetate groups and correspond to covalent non-polar C–C bonds. Thus, the ELF distribution confirms the basic features of the chemical bonding in tin(II) acetate: localized lone pairs on the tin atoms and covalent non-polar C–C bonds. The C–O and Sn–O bonds are polar, therefore the corresponding attractors are shifted to the oxygen atoms and are not visible in Fig. 5 due to the lower ELF values.

The first coordination sphere of the Sn atoms should be discussed considering the localization of the lone electron pair. Along with the four oxygen atoms of the acetate groups, the lone electron pair forms a strongly distorted trigonal bipyramid, SnO_4E (E is the lone electron pair), around the Sn atoms. The lone electron pair and the O(1) and O(4) atoms with the shortest d(Sn–O) = 2.17–2.21 Å distances define the equatorial plane of the trigonal bipyramid. The O(2) and O(3) atoms with longer d(Sn–O) = 2.29–2.37 Å distances are at the apical vertexes of the trigonal bipyramid. The O–Sn–O bond angles deviate significantly from their nominal values for an ideal trigonal bipyramid. The in-plane O(1)–Sn–O(4) angle is only 81.1(2)°, much smaller than its nominal value of 120°. The O(2)–Sn–O(3) angle should be straight in a perfect trigonal bipyramid, whereas its has a value of 155.3(2)° in the

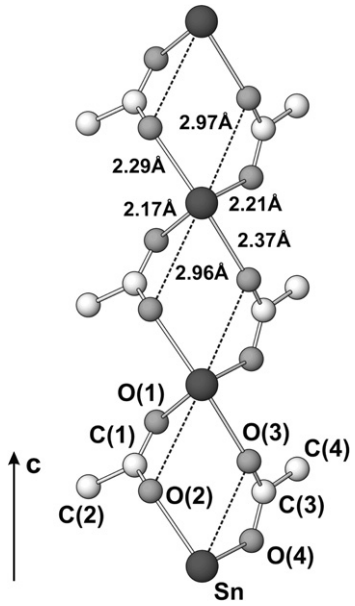

Fig. 4. Structure of the single $Sn(CH_3COO)_2$ chain. The bonding of the Sn atoms to the oxygen atoms of the second coordination sphere with d(Sn–O) = 2.96–2.97 Å is shown with dashed lines.

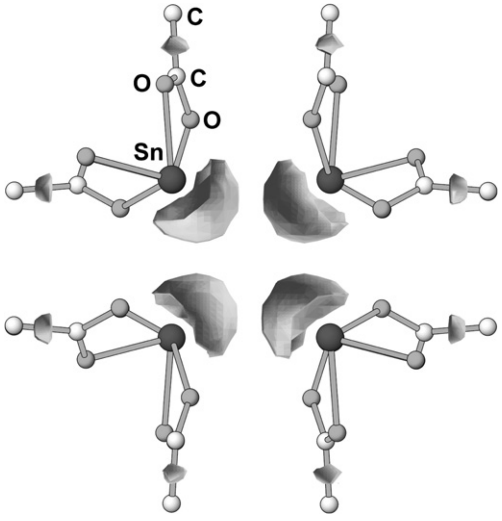

Fig. 5. ELF isosurface ($\eta = 0.85$) for $Sn(CH_3COO)_2$. The [0 0 1] projection of the four $Sn(CH_3COO)_2$ chains is shown along with the lobes of the lone electron pairs. Hydrogen atoms are not shown.

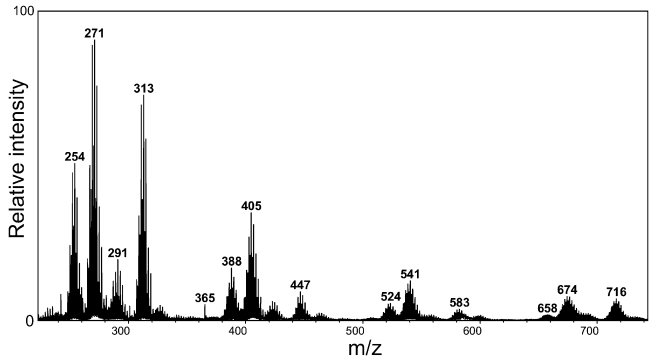

Fig. 6. MALDI-TOF mass spectrum of $Sn(CH_3COO)_2$ with anthracene as a matrix.

tin(II) acetate structure. It should be noted that in spite of the significantly different arrangement of the acetate groups around the Sn atoms in the gaseous and the solid phase, the coordination environment of Sn remains virtually the same. For the $Sn(CH_3COO)_2$ molecule in the gaseous phase (Fig. 1) the in-plane O–Sn–O bond angle (90°) and the O–Sn–O angle (121°) along the threefold axis of the SnO_4E trigonal bipyramid are also significantly smaller than their ideal values of 120° and 180° [4]. Such distortion can be accounted for by a strong repulsion between the oxygen atoms and the lone electron pair that causes the oxygen atoms to move away from the position of the lone electron pair with a decrease of the corresponding bond angles.

3.3. MALDI-TOF spectroscopy

The polymeric nature of the tin(II) acetate crystal structure was indirectly confirmed by a MALDI experiment. The MALDI-TOF spectrum of $[Sn(CH_3COO)_2]$ (Fig. 6) displays polynuclear fragments $[Sn_2O]^+$ (m/z 254.2), $[Sn_2O(CH_3COO)_2]^+$ (m/z 313.0), $[Sn_3O_2(OH)]^+$ (m/z 404.9), $[Sn_3O_2(CH_3COO)]^+$ (m/z 446.8), $[Sn_4O_3(OH)]^+$ (m/z 540.7), $[Sn_5O_4(OH)]^+$ (m/z 674.5), $[Sn_5O_4(CH_3COO)]^+$ (m/z 716.5). The characteristic isotopic abundance of tin was useful in identifying these species. Presumably, polymeric $[Sn(CH_3COO)_2]$ undergoes a deep cleavage of the acetate groups by desorption/ionization by laser irradiation but the Sn–O–Sn fragments are not destroyed so much. A similar behavior of metal–organic coordination compounds during MALDI-TOF experiments was noted in [8]. The extremely low stability of $[Sn(CH_3COO)_2]$ with respect to the UV laser (337 nm) action are in good agreement with the results by Maruyama and Morishita [13], where the deep cleavage of $[Sn(CH_3COO)_2]$ under UV irradiation was described.

4. Conclusion

The crystal structure of tin(II) acetate was solved and refined from X-ray powder diffraction data. Tin(II) acetate adopts a polymeric structure consisting of infinite $Sn(CH_3COO)_2$ chains running along the c-axis and packed into groups of four. The acetate groups bridge the Sn atoms along the chains and can be considered as tridentate bridging ligands with some chelate character. The first coordination sphere of the Sn atoms is described as a strongly distorted trigonal bipyramid, SnO_4E (E is a lone electron pair). This coordination environment is virtually identical to that in the $Sn(CH_3COO)_2$ molecule in the gaseous phase [4]. In both cases the two short Sn–O bonds and the lone electron pair are located in the equatorial plane and the two longer Sn–O bonds are directed towards the apical vertexes. The distortion of the SnO_4E trigonal bipyramid clearly demonstrates the sterical activity of the lone electron pair.

Acknowledgements

The authors thank Prof. Natalya P. Kuz'mina and Prof. Joke Hadermann for fruitful discussions.

Appendix A. Supplementary material

CCDC 653018 contains the supplementary crystallographic data for $Sn(CH_3COO)_2$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.010.

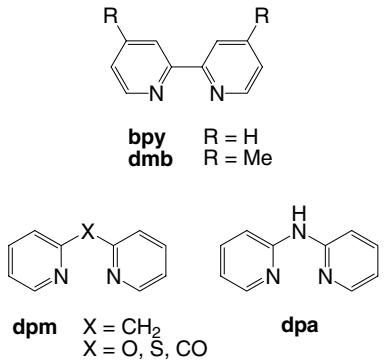

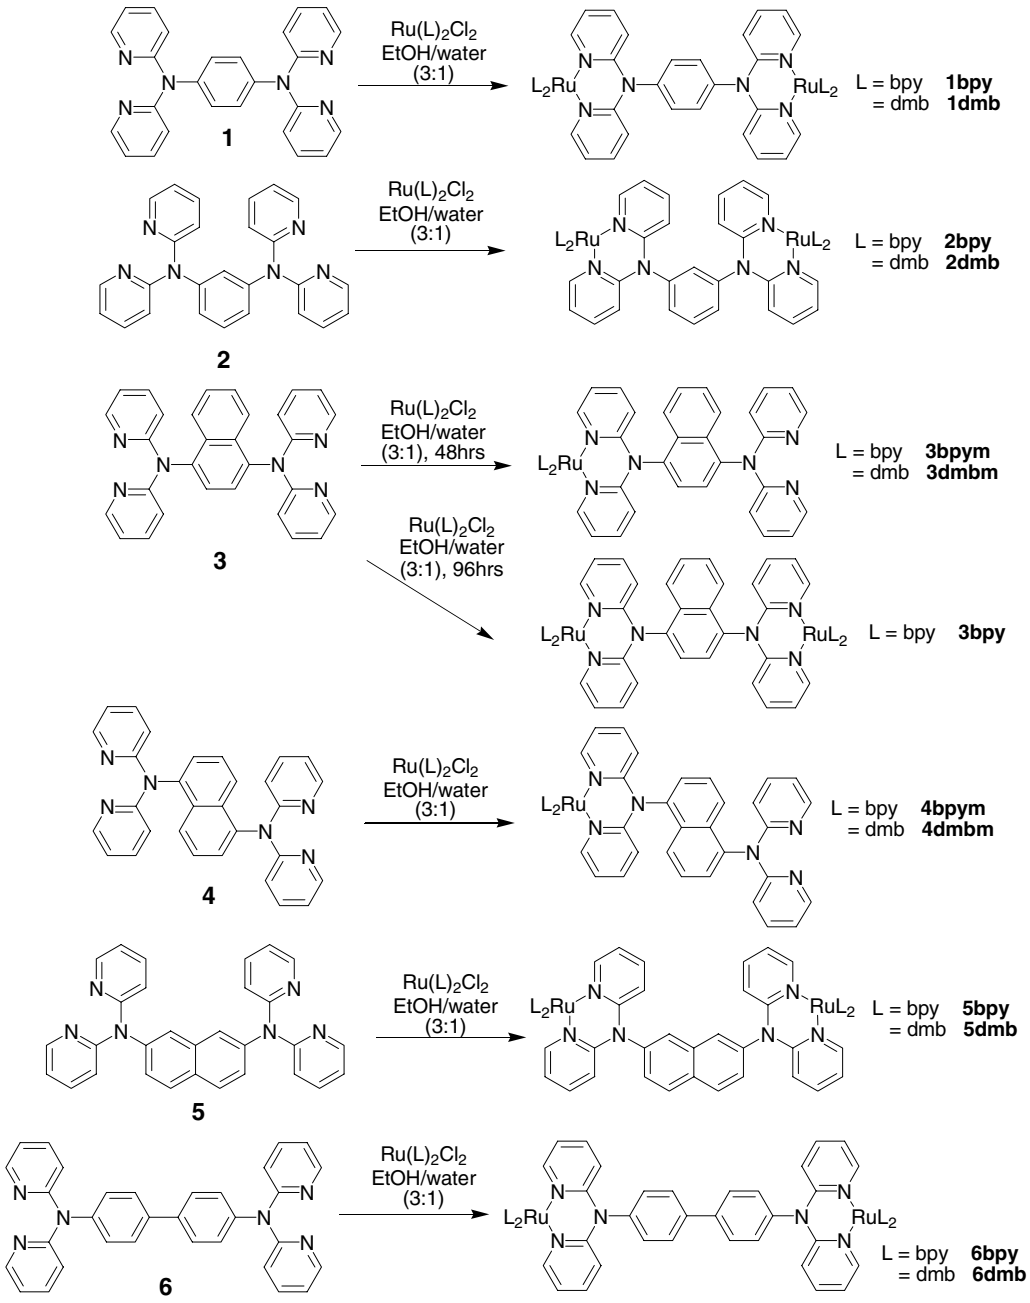

Fig. 1. Bidentate ligands that form five-membered chelate rings, **bpy** and **dmb**, and ligands that coordinate *via* six-membered chelate rings, e.g. **dpm** and **dpa**.

enhanced metal–metal interactions in complexes of bridging ligands incorporating this subunit.

In this paper we describe ruthenium complexes of six known bridging ligands **1**–**6** containing the **dpa** subunit (Scheme 1), and study the nature of the metal–ligand and metal–metal interactions within such complexes. The ligands studied are based around phenyl, naphthalenyl and biphenyl cores which have been appended with two **dpa** subunits to produce a series of potentially doubly bidentate bridging ligands. This array of ligands utilises some of the design principles outlined by us previously [4,5]; including different arene cores and substitution patterns of those cores. Ligands **1** and **6** were first studied and reported by Yang et al. [36], while we recently reported

Scheme 1.

silver(I) coordination polymers, and copper(II) and palladium(II) dinuclear complexes of ligands **1**–**5** [33].

2. Experimental

2.1. General experimental

^{1}H NMR, 1D TOCSY, 1D NOESY and ^{1}H–^{1}H COSY experiments were performed on either a Varian Mercury 300 MHz or Varian 500 MHz NMR spectrometer in CD_3CN. The ^{1}H NMR assignments for the compounds are denoted with primes to indicate the different rings of the multidentate ligands and letters to distinguish the ancillary bipyridine ligands. The different diastereoisomers of the dinuclear complexes are marked with and without an asterisk. Muliplicities are listed based on three-bond coupling only. Electrospray mass spectrometry (ES-MS) was performed on a Micromass LCT-TOF mass spectrometer. Melting points were performed on an Electrothermal melting point apparatus and are uncorrected. Elemental analyses were performed by the Campbell microanalytical laboratory at the University of Otago. Electronic spectra were recorded in acetonitrile using a Cary 5E UV/Vis or a GBC 920 UV/Vis spectrometer.

Cyclic voltammetry measurements were performed on a PAR Model 175 Universal Programmer coupled to a PAR Model 173 potentiostat, under argon. Measurements were recorded in either acetonitrile or dichloromethane/0.1 mol dm^{-3} [(n-C_4H_9)$_4$N]PF_6 solution using a glassy carbon working electrode, a platinum wire auxiliary electrode and an Ag/$AgNO_3$ (0.1 mol dm^{-3} [(n-C_4H_9)$_4$N]PF_6 in acetonitrile or dichloromethane) reference electrode. Ferrocene was added as an internal standard on completion of each experiment and tabulated potentials are given versus the saturated calomel electrode [E^0(Fc/Fc$^+$) = 310 mV versus SCE (acetonitrile)]. Cyclic voltammetry was performed with a sweep rate of 100 mV s^{-1}. Differential pulse voltammetry was recorded with a sweep rate of 4 mV s^{-1} and a pulse amplitude, width, and period of 50 mV, 60 ms and 1 s, respectively.

Unless otherwise stated reagents were obtained from commercial sources and used as received. Solvents were dried by literature procedures and freshly distilled as required. The ligands investigated in this work, **1**–**6** [33,36], bis(2,2′-bipyridine)ruthenium(II) dichloride [Ru(bpy)$_2$Cl$_2$] [40] and bis(4,4′-dimethyl-2,2′-bipyridine)ruthenium(II) dichloride [Ru(dmb)$_2$Cl$_2$] [41] were prepared by literature methods.

2.2. Syntheses of complexes

In a typical reaction, ligand (1 equiv.) was reacted with at least 2 equiv. of either [Ru(bpy)$_2$Cl$_2$] or [Ru(dmb)$_2$Cl$_2$] in 3:1 ethanol–water for a period of 48, 72 or 96 h. After cooling the solvent was removed *in vacuo* and the residue redissolved in water and filtered. The resulting red solution was treated with an excess of ammonium hexafluorophosphate to give a red precipitate of the desired ruthenium complex. Purification is as described, typically by alumina chromatography.

2.2.1. [{Ru(bpy)$_2$}$_2$(**1**)](PF$_6$)$_4$ (**1bpy**)

Ligand **1** (20 mg, 0.048 mmol) and [Ru(bpy)$_2$Cl$_2$] (59 mg, 0.12 mmol) were refluxed for 72 h. Without any chromatography, a red precipitate of **1bpy** as a 1:1 mixture of the two diastereoisomers was obtained with a yield of 81 mg (93%); m.p. 207–211 °C. *Anal*. Calc. for $C_{66}H_{52}N_{14}F_{24}P_4Ru_2 \cdot H_2O$: C, 43.05; H, 2.96; N, 10.65. 3. Results and discussion

3.1. Syntheses and structural characterisation of the complexes

The ruthenium complexes described in this work were prepared by reaction of the ligand with either [Ru(bpy)$_2$Cl$_2$][40] or [Ru(dmb)$_2$Cl$_2$][41] at reflux in 3:1 ethanol–water for a period of between 48 and 96 h (Scheme 1). Ligands **1**, **2**, **5**, and **6** all yielded dinuclear complexes with both ruthenium precursors that were isolated as mixtures of the *rac* and *meso* diastereoisomers [11–13]. Ligands **3** and **4** both readily yielded mononuclear complexes that were characterised by NMR spectroscopy and mass spectrometry. In the case of reaction of [Ru(bpy)$_2$Cl$_2$] and **3**, additional reaction time provided a mixture of mono- and dinuclear

ruthenium complexes that were separated by chromatography on alumina. The products of this series of reactions are summarised in Table 1, which shows the naming used for the complexes, the nature of the complex (mono- or dinuclear), the reaction time and the isolated yield.

The complexes $[\{Ru(bpy)_2\}_2(\mathbf{1})](PF_6)_4$ (**1bpy**) and $[\{Ru(dmb)_2\}_2(\mathbf{1})](PF_6)_4$ (**1dmb**) were obtained as described and characterised as dinuclear complexes by a combination of combustion analysis and ^{1}H NMR spectroscopy. The ^{1}H NMR spectrum of **1bpy** consists of 13 independent multiplets consistent with a dinuclear complex of ligand **1**. The chemical shifts for the pyridine rings of **1** and the ancillary bpy rings of the two diastereoisomers are partially resolved in some instances and overlapped in other cases consistent with slight structural differences between the two diastereoisomers. The two singlets for the protons of the benzene ring, corresponding to the two diastereoisomers, are more clearly resolved indicating there are, as expected, greater structural differences around the central benzene ring. By examination of the spin–spin coupling information and using a combination of 1D TOCSY and 1D-NOESY NMR techniques, the ^{1}H NMR spectrum of **1bpy** was assigned. The ^{1}H NMR spectrum of **1dmb** is likewise consistent with two diastereoisomers, with some multiplets that are partially resolved allowing the chemical shifts of the dmb rings of the two diastereoisomers to be differentiated. The chemical shifts for the pyridine rings of the bridging ligand in the two diastereoisomers were too close to be assigned.

The ^{1}H NMR chemical shifts for ligand **1** in acetonitrile, and for **1** in the two diastereoisomers of both **1bpy** and **1dmb**, are given in Table 2, along with the coordination-induced-shift (*cis*) values, which are given in italics. The *cis* values for the two complexes are very similar, which is consistent with the very subtle changes to the ancillary ligands of the complex. No unusual *cis* values are observed for either complex. The large negative *cis* values for the H6 protons of **1** result from inter-ligand through-space ring-anisotropy effects because, in the complexes, these protons lie over the shielding plane of adjacent bpy or dmb rings.

The crystal structure of a dinuclear copper complex of **1** was previously reported by us [33]. The square pyramidal copper(II) centres are bridged by **1** with a copper–copper separation of 11.179 Å, giving an indication of the likely M–M distance and conformation in the corresponding dinuclear ruthenium complexes of **1**.

Reaction of $[Ru(bpy)_2Cl_2]$ or $[Ru(dmb)_2Cl_2]$ with **2** gave the dinuclear complexes **2bpy** and **2dmb**, as 1:1 mixtures of the *rac* and *meso* diastereoisomers, which were isolated as their hexafluorophosphate salts. Combustion analysis, mass spectrometry and ^{1}H NMR spectroscopy were utilised to identify complexes **2bpy** and **2dmb** as $[\{Ru(bpy)_2\}_2(\mathbf{2})](PF_6)_4$ and $[\{Ru(dmb)_2\}_2(\mathbf{2})](PF_6)_4$, respectively. A dinuclear copper(II) nitrate complex was also prepared with ligand **2** in which the two copper atoms are separated by a distance of 8.785 Å [33]. This is considerably shorter than the metal–metal distance bridged by **1** in the copper complexes referred to above.

Partial separation of the diastereoisomers was achieved by alumina chromatography allowing the signals for the diastereoisomers of both complexes **2bpy** and **2dmb** to be readily assigned to individual spin systems by 1D TOCSY experiments. The different diastereoisomers of complexes **2bpy** and **2dmb** have quite different chemical shifts, in particular for the central benzene ring of the ligand. This indicates that there are significant structural differences in the two diastereoisomers above and below the plane of the central benzene ring as anticipated. The *cis* values for complexes **2bpy** and **2dmb** are shown in Table 2. While there are differences between the diastereoisomers, the general trend of the *cis* values, experienced by the pyridine rings of ligand **2** upon coordination to ruthenium, are very similar to dinuclear complexes of ligand **1**. The *cis* values for the protons of the benzene rings in these two complexes are larger than in the previous complexes with ligand **1**. For complex **2bpy**, the benzene-H2 proton of one diastereoisomer (**2bpy***) has a considerably larger negative *cis* value than the other diastereoisomer. This is also observed for complex **2dmb**, but the difference is far less dramatic. Inversely, for the equivalent H4 and H6 protons, the effect is reversed, with the other diastereoisomer experiencing larger negative *cis* values. Such differences are presumably explained by different conformations around the benzene ring.

After having prepared dinuclear complexes of ligands **1** and **2**, the ligands possessing a naphthalene core were employed to assess the effect of a more bulky arene core and in the case of ligands **4** and **5** increased metal–metal

Table 1
A summary of the synthetic work presented in the paper

	$[\{Ru(dmb)_2\}_2(\mathbf{5})](PF_6)_4$	**5dmb**	48	78
6	$[\{Ru(bpy)_2\}_2(\mathbf{6})](PF_6)_4$	**6bpy**	48	66
	$[\{Ru(dmb)_2\}_2(\mathbf{6})](PF_6)_4$	**6dmb**	72	50

The composition, labelling, reaction time and yield of the products are summarised.

[a] $[Ru(bpy)_2]$ complexes are named with a bpy descriptor, $[Ru(dmb)_2]$ with dmb; mononuclear complexes are designated by an '**m**'.

[b] A 17% yield of mononuclear complex **3bpym** was also obtained in this reaction.

The asterisk indicates the resolved signals of one of the diastereoisomers.

separations. The 1,4-substituted naphthalene ligand, **3**, was investigated first. Reaction of either $[Ru(bpy)_2Cl_2]$ or $[Ru(dmb)_2Cl_2]$ with **3** in a 2:1 stoichiometry, using the standard reaction conditions, provided only the mononuclear complexes **3bpym** and **3dmbm**, respectively. Using a combination of combustion analysis, mass spectrometry and ^{1}H NMR spectroscopy, complexes **3bpym** and **3dmbm** were confirmed as $[Ru(bpy)_2(\mathbf{3})](PF_6)_2$ and $[Ru(dmb)_2(\mathbf{3})](PF_6)_2$, respectively. The dinuclear complex **3bpy** was prepared by undertaking the reaction for a period of 96 h as opposed to 48 h. This provided a mixture of the mononuclear and dinuclear complexes that were separated using alumina chromatography to give the mononuclear complex **3bpym** in 17% yield, and the desired dinuclear complex **3bpy** in 51% yield.

The ^{1}H NMR spectra of **3bpym** and **3dmbm** are complicated by the lower (C_1) symmetry of the complexes, which have restricted rotation about the naphthalene amine–nitrogen single bond of the chelating di-2-pyridylamine unit. Thus, the coordinated pyridine rings of the ligand are non-equivalent, but the non-coordinated pyridine rings of the other di-2-pyridylamine unit are equivalent because of free rotation about this naphthalene amine–nitrogen single bond. Employment of the 1D TOCSY experiment allowed the assignment of all chemical shifts to individual protons for both mononuclear complexes (Table 3).

cis-Values for the mononuclear complexes **3bpym** and **3dmbm** are larger and more variable than the values observed for the previously described dinuclear complexes. The two coordinated pyridine rings have quite different *cis* values, consistent with the restricted rotation of the coordinated arm of the ligand and the different environments for each ring. The naphthalene ring affects one of these coordinated pyridine rings, while the second ring has an environment, and therefore *cis* values, similar to the pyridine rings in the dinuclear complexes previously described with **1** and **2**. The former pyridine ring, denoted with a prime in the table, has a large negative *cis* value for the H3 proton because upon complexation this proton lies over the shielding region of the adjacent naphthalene ring. The non-coordinated pyridine rings are not affected by the remote coordination and the chemical shifts for these protons are relatively unchanged.

The ^{1}H NMR spectrum of **3bpy** is much simpler than the spectra for the corresponding mononuclear complex. The ^{1}H NMR spectrum of **3bpy** is, like previous spectra of other dinuclear complexes, consistent with two diastereoisomers, with some multiplets that are resolved, which allows the chemical shifts of the pyridine rings and bpy rings of the two diastereoisomers to be differentiated (Table 4). The various spin systems were not assigned to a specific diastereoisomer because there was no enrichment of any of the column fractions when the complex was purified. There are considerable similarities in the NMR spectra and the *cis* values of the mononuclear complexes of ligand **3** and the dinuclear complex **3bpy**. The latter complex has higher

The asterisk indicates the resolved signals of one of the diastereoisomers.

symmetry and therefore there are only two non-equivalent pyridine rings in the bridging ligand. One of the pyridine rings of each diastereoisomer is located over the naphthalene ring of the ligand and has a large negative *cis* value for the H3 proton. For both diastereoisomers, one H6 proton of a coordinated pyridine rings has quite a dramatic negative *cis* value, whereas the other has a *cis* value less than the normal value for an H6 proton of a coordinated pyridine ring in such complexes.

Ligand **4** has a 1,5-disubstituted naphthalene core with the di-2-pyridylamine units of the ligand attached to different rings of the naphthalene unit. Reaction of either

$[Ru(bpy)_2Cl_2]$ or $[Ru(dmb)_2Cl_2]$ with **4** provided only the mononuclear complexes **4bpym** and **4dmbm**, respectively. Using mass spectrometry and ^1H NMR spectroscopy, the complexes were confirmed as $[Ru(bpy)_2(\mathbf{4})](PF_6)_2$ and $[Ru(dmb)_2(\mathbf{4})](PF_6)_2$. Ligand **4** is relatively insoluble which appears to have lowered the yields of the mononuclear complexes and hindered the formation of the expected dinuclear complexes. No dinuclear complexes were observed despite repeating the reaction with longer reaction times.

The ^1H NMR spectra of **4bpym** and **4dmbm** are again, like the previous mononuclear complexes, complicated by reduced (C_1) symmetry due to restricted rotation of the coordinated arm of the ligand. The 1D TOCSY technique was used to assign the chemical shifts to individual protons for both mononuclear complexes (Table 3). The *cis* values for the mononuclear complexes **4bpym** and **4dmbm** are similar to those obtained for the previous mononuclear complexes of ligand **3**. The two coordinated pyridine rings of both complexes have quite different *cis* values, consistent with the reduced rotation of the coordinated arm of the ligand and the different environments for each ring. Again, the naphthalene ring affects one pyridine ring of each complex, which has a large negative *cis* value for the H3 proton. A second ring of each complex has an environment similar to the pyridine rings in the dinuclear complexes previously described and has a large negative *cis* value for the H6 proton. However, it also has a negative *cis* value for the H3 proton.

Reaction of $[Ru(bpy)_2Cl_2]$ or $[Ru(dmb)_2Cl_2]$ with **5** gave the dinuclear complexes **5bpy** and **5dmb**, that were confirmed by ES-MS and ^1H NMR spectroscopy as $[\{Ru(bpy)_2\}_2(\mathbf{5})](PF_6)_4$ and $[\{Ru(dmb)_2\}_2(\mathbf{5})](PF_6)_4$, respectively. The ^1H NMR spectra are consistent with a mixture of the two diastereoisomers for both complexes. The signals for both diastereoisomers of complexes **5bpy** and **5dmb** were able to be assigned to individual spin systems by 1D TOCSY experiments (Table 4). The *cis* values for the pyridine and naphthalene rings of ligand **5** upon coordination in these complexes are very similar to previous dinuclear complexes. There are subtle differences in the *cis* values for the different diastereoisomers for the H1/H8 protons of the naphthalene ring of complex **5bpy**, but interestingly not for **5dmb**.

Ligand **6** differs from ligand **1** by insertion of a second benzene ring between the two chelating domains of the ligand giving a significantly longer metal–metal separation. Reaction of $[Ru(bpy)_2Cl_2]$ or $[Ru(dmb)_2Cl_2]$ with **6** gave the dinuclear complexes **6bpy** and **6dmb** which were characterised as $[\{Ru(bpy)_2\}_2(\mathbf{6})](PF_6)_4$ and $[\{Ru(dmb)_2\}_2(\mathbf{6})](PF_6)_4$, respectively, using a combination of combustion analysis, mass spectrometry and ^1H NMR spectroscopy. The ^1H NMR chemical shifts for the ligand **6** in acetonitrile, and for the two diastereoisomers of the two dinuclear ruthenium complexes **6bpy** and **6dmb**, are given in Table 2, along with the *cis* values. An unambiguous assignment of the proton chemical shifts of each diastereoisomer of **6bpy** and **6dmb** was achieved because chromatography on alumina resulted in enrichment of some of the column fractions with one diastereoisomer.

The *cis* values for complexes **6bpy** and **6dmb** are very similar to those observed for the previous set of complexes. Again large negative *cis* values occur for the H6 protons of the coordinated pyridine rings, because they lie over the shielding region of the bpy or dmb rings. The H3 and H5 protons of the biphenyl core are more deshielded in one of the diastereoisomers than the other, which suggests a greater difference in the two structures around the biphenyl core, as expected.

3.2. Electrochemistry and UV–Vis spectroscopy

The electrochemical studies of the ruthenium complexes of the ligands **1**–**6** are potentially complicated because the ligands themselves can undergo two irreversible oxidations. Fig. 2 shows a cyclic voltammogram for the free ligand **1**, showing the two irreversible oxidation waves. These are attributed to the oxidation of the amine nitrogen atoms of the ligand and potentials for the oxidation of ligands **1** and **3** are shown in Table 5. As the results presented for the complexes below show, upon coordination, the amine nitrogen atoms of the chelating unit are no longer susceptible to oxidation, and so this feature is only a consideration for the mononuclear complexes with a non-coordinated di-2-pyridylamine subunit. In all the dinuclear complexes the oxidation waves are reversible, indicating these redox processes are metal based, whereas the amine oxidation waves observed in the free ligand are not.

The electronic absorption maxima and redox potentials, recorded in acetonitrile solution, for the mononuclear complexes **3bpym**, **3dmbm** and **4dmbm** are given in Table 5. The mononuclear complexes all have broad absorption maxima at *ca.* 430 nm, with a shoulder at *ca.* 457 nm. The MLCT transitions into the orbitals of the ligand are at a higher energy than for $[Ru(bpy)_3]^{2+}$ (452 nm) [6], while the shoulder may correspond to MLCT into the bpy ligands. The cyclic voltammograms for the mononuclear complexes, **3bpym**, **3dmbm** and **4dmbm**, all have four one electron redox processes. For complex **3bpym**, the reversible oxidation of the ruthenium centre and the irreversible oxidation of the amine on the non-coordinated arm of the ligand are

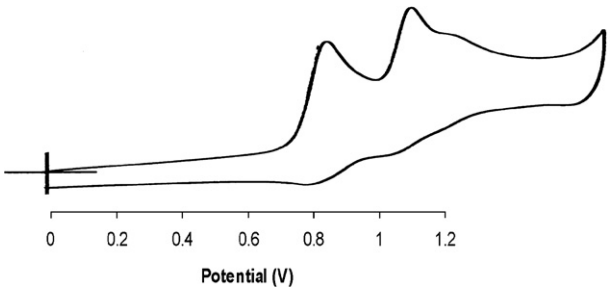

Fig. 2. A cyclic voltammogram of **1** showing the two irreversible oxidations.

[e] Overlapped or irreversible (approximate value estimated from anodic or cathodic half-scan).

overlapped. For the dmb complexes, the ruthenium oxidation potentials are shifted *ca.* 100 mV less positive and the amine nitrogen becomes *ca.* 100 mV more difficult to oxidise. The redox potentials reveal that the ruthenium centre of the bpy complex, **3bpym**, is both easier to oxidise and more difficult to reduce than $[Ru(bpy)_3]^{2+}$ (+1.26, −1.33 V). This is consistent with the electron-rich nature of these ligands. For the dmb complex, **3dmbm**, the reduction potentials are shifted by *ca.* 100 mV related to those of the bpy complex, consistent with the electron donating effect of *ca.* 25 mV per methyl group [42].

The dinuclear ruthenium complexes all exhibit broad visible absorption maxima at *ca.* 442 nm as shown in Table 5. For all the complexes these bands can be assigned to a MLCT, as is the case for $[Ru(bpy)_3]^{2+}$. This indicates that the HOMO–LUMO energy gap in these complexes is comparable to $[Ru(bpy)_3]^{2+}$, but because of the more electron rich nature of the ligands, slightly larger than that of $[Ru(bpy)_3]^{2+}$. By comparison to the mononuclear complexes, addition of a second ruthenium centre into a complex lowers the energy gap further (the absorption maximum of **3bpym** is 429 nm, whereas the maximum occurs at 445 nm for the dinuclear complex **3bpy**).

It was postulated that the sp^2 character of the tertiary amine in the bridging ligands **1**–**6** would aid metal–metal interaction in dinuclear complexes of these ligands. This was investigated in the first instance by cyclic voltammetry. A cyclic voltammogram for complex **1bpy** is shown in Fig. 3. It shows the complex undergoes four redox processes (two partially overlapped), including two bpy-centred reductions at −1.44 and −1.66 V. The oxidation wave appears to be comprised of two redox events with a shoulder on the cathodic and anodic waves. Thus, this oxidation wave is complicated either by differences between

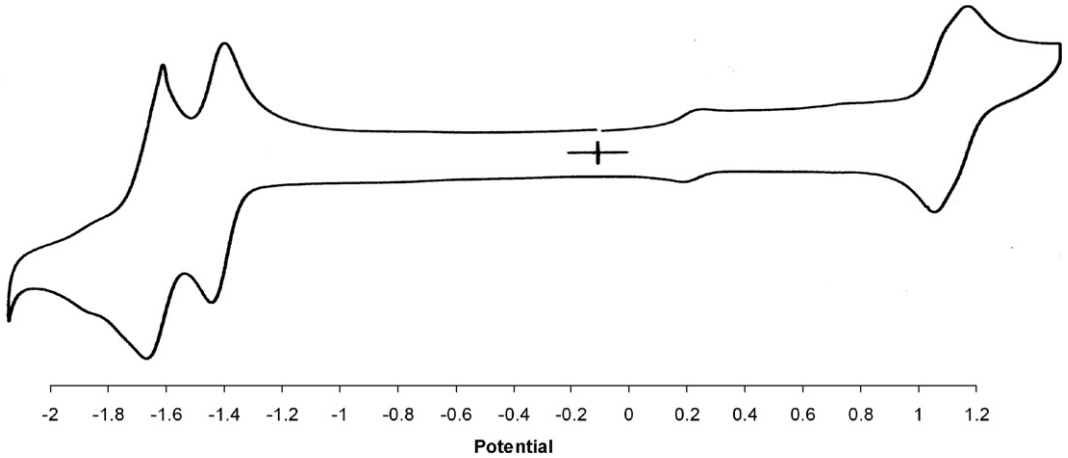

Fig. 3. The cyclic voltammogram of the dinuclear complex **1bpy**.

the two diastereoisomers, or by the interaction between the two metal centres. The flexibility of the ligand suggests that the latter possibility is more likely. Assuming full reversibility, from the cyclic voltammogram for **1bpy**, it can be calculated that these two one-electron processes are occurring *ca.* 60 mV apart. This type of behaviour was also observed for complex **2bpy**, although similar separations of the oxidation potentials for the two ruthenium atoms could not be observed in the corresponding dinuclear dmb complexes, **1dmb** and **2dmb**. Thus, ligands **1** and **2** appear to be facilitating only weak metal–metal interactions.

The differential pulse voltammograms of complex **1bpy** and **2bpy** are shown in Fig. 4, and confirm the weak interactions between metal centres in the two dinuclear complexes. For both the dinuclear bpy complexes, the differential pulse voltammograms confirm two separate, but very closely spaced processes, consistent with the observations made by cyclic voltammetry. For both complexes, the voltage separations of these two one-electron redox potentials are at the boundaries of this technique, and thus in both cases, the drop in current between the two potentials is negligible.

The cyclic voltammetry of the other dinuclear complexes revealed at least three reversible two-electron redox processes for each complex. Unlike the complexes of ligands with a benzene core, the oxidation waves of the dinuclear complexes of the biphenyl and naphthalenyl ligands are reversible two-electron waves, with a E_{ox}/E_{red} peak separation of approximately 65 mV. Thus, the metal centres are not interacting to any significant extent because of the combined effects of distance, and/or greater twisting of the chelating units out of the plane of the ligand core. This distance dependence is consistent with the assumption that the difference in oxidation potentials in **1bpy** and **2bpy** was due to metal–metal interactions and not to differences in the diastereoisomers. All the ruthenium complexes studied have oxidation potentials that are similar to but slightly harder to oxidise than the di-2-pyridylamine (**dpa**) ruthenium complex, $[Ru(bpy)(phen)(\mathbf{dpa})]^{2+}$ (+1.06 V) [6], where phen = 1,10-phenanthroline. Linking the ligands through different rings of the naphthalene core, or by a biphenyl spacer, has little effect on the redox potentials of the metal centres.

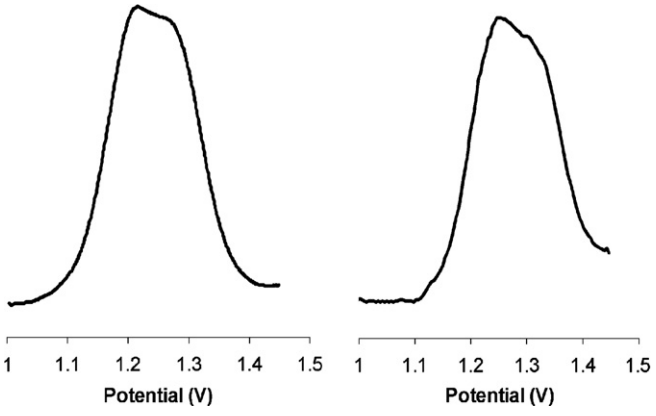

Fig. 4. The differential pulse voltammograms for complexes **1bpy** and **2bpy** (potential scale not referenced against SCE in diagrams).

The dinuclear $[Ru(bpy)_2]$ complexes all undergo ligand centred reductions at *ca.* −1.44 and −1.68 V. These are attributed to the reductions of the ancillary bpy ligands. The potentials of the dinuclear $[Ru(dmb)_2]$ complexes are shifted by *ca.* 100 mV related to those of the analogous bpy complexes, consistent with the electron donating effect of *ca*. 25 mV per methyl group [42] that was noted earlier. The di-2-pyridylamine-based ligands are very difficult to reduce, but in their $[Ru(bpy)_2]$ and $[Ru(dmb)_2]$ dinuclear complexes ligands **2**, **5** and **6** appear to undergo reductions at potentials between *ca.* −1.90 and −2.06 V.

4. Conclusion

In summary, $[Ru(bpy)_2]$ and $[Ru(dmb)_2]$ complexes of the multidentate ligands **1**–**6** have been prepared and characterised by NMR and absorption spectroscopy, electrochemistry and ES mass spectrometry or combustion analysis. Five of the ligands furnished dinuclear complexes, while only mononuclear $[Ru(bpy)_2]$ and $[Ru(dmb)_2]$ complexes of ligand **4** could be prepared. Ligands **3** and **4** were surprisingly resistant to forming dinuclear complexes; longer reaction times furnished the dinuclear complex **3bpy** but similar results could not be obtained for ligand **4**. Given the ability of ligand **3** to form both mono- and dinuclear complexes simply by variation of the reaction time, the possibility exists of using the mononuclear complex in a 'complexes as ligands' approach [43] to prepare multinuclear assemblies.

Electrochemical studies on two examples of the six multidentate ligands revealed that they are susceptible to oxidation of the amine nitrogen atoms unless the di-2-pyridylamine subunits were coordinated to a ruthenium centre. The ligands **1**–**6** are relatively electron-rich, leading to oxidation potentials for the resulting $[Ru(bpy)_2]$ or $[Ru(dmb)_2]$ complexes that are lower than the archetype complex, $[Ru(bpy)_3]^{2+}$. Furthermore, the complexes were harder to reduce than $[Ru(bpy)_3]^{2+}$, with reductions of the multidentate ligands occurring, in some cases, close to the potential limits of the solvent. The metal centres in dinuclear complexes of the ligands **1** and **2**, containing a benzene core, were shown to be weakly interacting by cyclic and differential pulse voltammetry. While the tertiary aryl amine is a potential conduit for metal–metal interactions, the di-2-pyridylamine subunits are not held in plane with the central arene because of steric factors, and thus these interactions are weak.

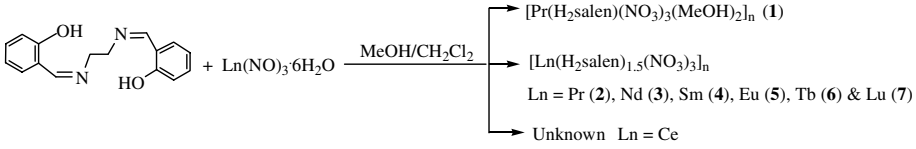
are described and discussed. Further, the luminescent properties of complexes **4**, **5** and **6** are examined and discussed.



2. Results and discussion

2.1. Synthesis

Reactions of the Salen ligand with $Ln(NO_3)_3 \cdot 6H_2O$ in a molar ratio of 1:1 or 1:2 were carried out in $MeOH/CH_2Cl_2$ at ambient temperature. Methylene dichloride was employed to increase the solubility of the Salen ligand. The immediate color change of the solution upon addition of $Ln(NO_3)_3 \cdot 6H_2O$ indicates instant occurrence of the coordination reaction. Single crystals suitable for X-ray analysis were obtained by slow diffusion of diethylether into a methanol solution of the powder sample. Complexes **1**–**7** are stable in air and moderately soluble in polar organic solvents such as methanol, ethanol and DMF. X-ray crystal analyses reveal that two types of coordination complexes, $[Pr(H_2salen)(NO_3)_3(CH_3OH)_2]_n$ (**1**) and $[Ln(H_2salen)_{1.5}(NO_3)_3]_n$ (Ln = Pr (**2**), Nd (**3**), Sm (**4**), Eu (**5**), Tb (**6**) and Lu (**7**)) (Scheme 1) are isolated. Interestingly, both structures can be obtained for the Salen praseodymium(III) complex, while the other Salen lanthanide (Ln = Nd, Sm, Eu, Tb and Lu) complexes favor the composition $[Ln(H_2salen)_{1.5}(NO_3)_3]_n$. Also, initial crystal structural analysis reveals that reaction of the Salen ligand with $Ce(NO_3)_3 \cdot 6H_2O$ yields a complex which differs from complexes **1**–**7**. However, the crystal structure of the Salen cerium complex has not been solved due to the poor quality of the single crystal.

2.2. Spectroscopic analysis

The infrared spectra of complexes **1**–**7** are similar. Taking **3** as an example, the broad but weak O–H stretching vibration of the free Salen ligand at ca. 2847 cm^{-1} is replaced by a band at ca. 3398 cm^{-1} in the complexes due to the N–H vibration in $C{=}N^{+}$–H. This band indicates that the hydrogen atoms are still involved in intramolecular H-bonding with the phenolic oxygen. The C=N stretching vibration in the complexes shifts to higher wavenumber (by 20–30 cm^{-1} to about 1655 cm^{-1}). This is opposite to what was observed for the Salen nickel complex in which the strong ν(C=N) band shifts considerably towards lower wavenumber in comparison to that of the free H_2salen, indicating the coordination of an azomethine nitrogen to the transition metal ion [13]. Four bands near 1480(ν_4), 1278(ν_1), 1152(ν_2) and 816(ν_6) cm^{-1} in the infrared spectra of the complexes can be assigned to the vibrations of the coordinated nitrate group. The difference between the ν_4 and the ν_1 peak positions is ca. 200 cm^{-1}, which is typical for a bidentate nitrate group. This is identical to the lanthanide Schiff base complexes $[Ln(LH)_3(NO_3)_3]$ (LH = 4-alkoxy-*N*-alkyl-2-hydroxybenzaldimine) [14]. The UV spectrum of the free ligand consists of three main absorption maxima that are assigned to the π–π* transition of the Ar–OH chromophores and of the imine group. Accordingly, the UV spectra of the complexes **1**–**7** in methanol display a similar red shift as a result of changes in the energy levels of the ligand orbitals upon coordination. All the complexes **1**–**7** show no clear melting point before decomposing at ca 350 °C. Complex **1** loses approximately 10.43% in weight when heated to 219.8 °C. It suggests the

presence of two moles of crystalline methanol in the empirical molar formula in the crystals.

2.3. Crystal structural analysis

Complex **1** crystallizes in the monoclinic $P2_1/n$ space group. The unit cell contains one $[Pr(H_2salen)(NO_3)_3]$ with two moles of crystalline methanol. An infinite 1D chain structure results from the bridging Salen ligand between each two Pr(III) ions through the Pr–O (hydroxyl oxygen atom) bonds (Fig. 1a). Each Pr(III) ion, showing a 10-coordinated distorted hexadecahedron (Fig. 1b), is ligated by three bidentate nitrate counterions, two methanol oxygen atoms and two oxygen atoms from different ligands. Each

Ln (1)–O(2)/O(2A)/O(2B)	2.604(4)	2.593(3)	2.567(4)	2.553(3)	2.428(3)
O(1B)–Ln(1)–O(3)/O(1A)–Ln(1)–O(3B)/ O(1)–Ln(1)–O(3A)	145.4(1)	145.3(1)	145.1(1)	145.3(1)	144.2(1)
O(1)–Ln(1)–O(3)/O(1A)–Ln(1)–O(3A)/ O(1B)–Ln(1)–O(3B)	120.2(1)	120.9(1)	120.2(1)	121.6(1)	120.3(1)
O(1A)–Ln(1)–O(1B)/O(1A)–Ln(1)–O(1)/ O(1B)–Ln(1)–O(1)	93.9(1)	93.3(1)	92.7(1)	92.5(1)	91.3(1)

Salen group utilizes only one hydroxyl oxygen atom for coordination, whereas the nitrogen atoms remain uncoordinated. As a result, each H_2salen acts a bridge between two Pr(III) atoms. This is identical to the known Salen lanthanide complex $[La(H_2salen)(NO_3)_3(CH_3OH)_2]_n$ [10]. The shorter Pr–O bonds involving the deprotonated phenol oxygen atoms are in the range 2.360(1)–2.394(1) Å, while the Pr–O bonds involving the η^2 chelating nitrate ions vary from 2.547(2) to 2.703(3) Å. The O(1)–Pr–O(2) angle is 71.2(1)°. The hydrogen atoms located on the two nitrogen atoms are involved in intramolecular hydrogen bonding with the deprotonated phenol oxygen atoms, thus indicating that a proton migration occurs in the complexation reactions.

X-ray crystallographic analyses reveal that complexes **2**–**7** are isomorphic. Taking **2** as an example, complex **2** crystallizes in the trigonal $P\bar{3}C1$ space group. The unit cell contains $[Pr(H_2salen)_{1.5}(NO_3)_3]$ without a solvent molecule. Each Pr(III) ion, showing a nine-coordinated tricapped trigonal prismatic geometry (Fig. 2a), is ligated by three bidentate nitrate counterions and three independent Salen ligands that utilize only one hydroxyl oxygen atom. The distorted trigonal prism shown is composed of O(3), O(3A), O(3B), O(1), O(1A) and O(1B) atoms. The O(2), O(2A) and O(2B) atoms are at the vertices of each square pyramid. Each ligand acts as a bidentate linker bridging between two Pr(III) ions through the two hydroxy oxygen atoms (Fig. 2b). In addition, six Pr(III) ions are formed in a circular fashion through the bondings of lanthanide and deprotonated Salen linkers (Fig. 2c). The hexanuclear metal ring exhibiting C_3 symmetry acts as the building unit. Furthermore, the hexanuclear lanthanide ring is extended along the *a* and *b* axes through the bridging of Salen ligand to an infinite 2D network. This results in a uniform and porous planar sheet containing arrays of metals parallel to the *ab* plane (Fig. 2d). The Pr–O bond distances, divided into three groups, are 2.360(3), 2.582(4) and 2.604(4) Å. The O–Pr–O angles are in the range 49.3(1)–161.1(1)°. It is worth noting that the bond angles of O(salen)–Pr–O(salen), namely, O(1A)–Pr(1)–O(1B), O(1A)–Pr(1)–O(1) and O(1B)–Pr(1)–O(1) are identical, being 93.9(1)°, which is almost a right angle (90°). The bond angles O(1)–Ln(1)–O(3), O(1A)–Ln(1)–O(3A) and O(1B)–Ln(1)–O(3B) are 120.2(1)° and the angles of O(1B)–Pr(1)–O(3), O(1A)–Pr(1)–O(3B) and O(1)–Pr(1)–O(3A) are 145.4(1)°. Relevant structural parameters are gathered in Table 1.

2.4. The luminescent property of complexes *4*, *5* and *6*

Excited by the absorption band at 350 nm, the Salen ligand exhibits broad emission bands at $\lambda_{max} = 503$ nm in the solid state (the excitation and emission slit widths are 5.0 nm). Emission spectra of complexes **4** and **5** in the solid state (the excitation and emission slit widths are 5.0 nm), recorded at room temperature (Fig. 3), show characteristic metal-centered luminescence when excited at 370 and 350 nm, respectively. The fluorescence of the Salen ligand is completely quenched. It suggests that the electronic energy of the ligand is transferred to the metal ion. Energy transfer between the Salen ligand and the lanthanide(III) ion appears to follow the well-known intramolecular energy transfer mechanism exhibited by lanthanide Schiff base complexes [4b]. Complexes **4** and **5** emit red fluorescence. The emission spectrum of complex **4** exhibits a narrow band at 645 nm. Four typical emission bands of Sm(III) ion are observed, 565 nm ($^4G_{5/2} \rightarrow {}^6H_{5/2}$), 601 nm ($^4G_{5/2} \rightarrow {}^6H_{7/2}$), 645 nm ($^4G_{5/2} \rightarrow {}^6H_{9/2}$) and 712 nm ($^4G_{5/2} \rightarrow {}^6H_{11/2}$). The emission spectrum of complex **5** exhibits a single narrow band at 615 nm. Five typical emission bands of Eu(III) ion are observed, 580 nm ($^5D_0 \rightarrow {}^7F_0$), 592 nm ($^5D_0 \rightarrow {}^7F_1$), 615 nm ($^5D_0 \rightarrow {}^7F_2$), 650 nm ($^5D_0 \rightarrow {}^7F_3$) and 679 nm ($^5D_0 \rightarrow {}^7F_4$). However, for the terbium complex, the characteristic luminescence

emission of the terbium ion is not observed either in solution or the solid state. It is probably attributed to the fact that the luminescence of lanthanide(III) chelates is correlated to the efficiency of the intramolecular energy transfer between the triple levels of the ligand and the emitting level of the ions, which depends on the energy gap between the two levels. The energy gap between the ligand triple level and the emitting level of the europium and samarium ion may be in favor of the energy transfer process. It is identical to a picrate europium complex [15]. However, this is opposite to the reported Schiff base lanthanide complexes in which the characteristic luminescent emission of europium ions was not found while that for the terbium ion was observed [12b].

3. Conclusion

In summary, the synthesis of complexes **1**–**7** demonstrates clearly that the size of lanthanide ion dominates the structures of these Salen lanthanide complexes. As a result, the Salen lanthanum(III) complex prefers a 1D chain structure, while other Salen lanthanide(III) (Ln = Nd–Lu) complexes favor to yield a unique 2D network structure. The praseodymium(III) complex can give rise to both 1D and 2D topology structures. The crystal structures of these complexes are not dependent on the stoichiometry of the reaction. Also, initial structure analysis of the cerium(III) complex indicates that the structure of Salen cerium(III) may be different from complexes **1**–**7**.

Further, the luminescence of the Salen lanthanide complexes suggests that the matching of the orbital energy level of the lanthanide ions and the Salen ligand determines the luminescence of the Salen lanthanide complexes. These results have provided valuable information for designing new lanthanide complexes with different structural chemistry and luminescent properties, as well as better understanding of the known Schiff base lanthanide complexes. Attempts to solve the structure of the Salen cerium complex and to explore the possibility of substituting the nitrate groups in mononuclear complexes with $[Fe(CN)_6]^{3-}$

and other anionic groups as well as the physical properties of these complexes are being carried out in our laboratory.

4. Experimental

4.1. General

All operations were performed in an open atmosphere. H_2salen was prepared from salicylaldehyde and 1,2-ethylenediamine by a routine method. $Ln(NO_3)\cdot 6H_2O$ was prepared according to the literature method. All other chemicals were used as purchased. Elemental (C, H and N) analyses were performed on a Perkin–Elmer 2400 analyzer. IR spectra were determined on a Perkin–Elmer 60000 spectrophotometer. UV spectra were recorded on a Shimadzu UV2240 spectrophotometer. Fluorescent spectra were taken on a LS-55 fluorescence photometer. Thermal analyses were conducted on a DTA-1700 with a heating rate of 10 °C/min in the temperature range from ambient temperature to 700 °C.

4.2. Preparation of the complexes

4.2.1. Preparation of $[Pr(H_2salen)(NO_3)_3(CH_3OH)_2]_n$ (1) and $[Pr(H_2salen)_{1.5}(NO_3)_3]$ (2)

To a solution of H_2salen (0.268 g, 1 mmol) in CH_2Cl_2 (5 mL) was slowly added $Pr(NO_3)_3\cdot 6H_2O$ (0.435 g, 1 mmol) in MeOH (6 mL) at room temperature. A yellow precipitate formed immediately. After stirring for 2 h, 0.34 g of solid was collected by filtration and washed with CH_2Cl_2. Two different crystals suitable for X-ray determination were obtained by slow diffusion of diethylether into a methanol solution of the powder sample over one week. **1**: Elemental *Anal.* Calc. for $C_{18}H_{20}N_5O_{13}Pr$ (655.30): C, 32.99; H, 3.08; N, 10.69. UV–Vis spectrum in MeOH [λ_{max} (nm)]: 240, 255. m.p.: >260 °C.

4.2.3. Preparation of $[Sm(H_2salen)_{1.5}(NO_3)_3]$ (4)

A mixture of H_2salen (0.268 g, 1 mmol) and $Sm(NO_3)_3\cdot 6H_2O$ (0.444 g, 1 mmol) in CH_2Cl_2/CH_3OH (5 mL/6 mL) was stirred at room temperature for 2 h. Yield: 72%. Elemental *Anal.* Calc. for $C_{24}H_{24}N_6O_{12}Sm$ (738.84): C, 39.01; H, 3.27; N, 11.37. Found: C, 39.20; H, 3.24; N, 11.40%. IR (KBr pellet, cm^{-1}): 3387 w, 3059 w, 1655 vs, 1610 m, 1538 s, 1481 s, 1384 w, 1345 w, 1279 s, 1200 s, 1152 s, 1035 s, 1008 m, 946 w, 874 s, 815 m, 763 s, 738 m, 575 m, 391 m. UV–Vis spectrum in MeOH [λ_{max} (nm)]: 240, 255. m.p.: >260 °C.

4.2.4. Preparation of $[Eu(H_2salen)_{1.5}(NO_3)_3]$ (5)

A mixture of H_2salen (0.268 g, 1 mmol) and $Eu(NO_3)_3\cdot 6H_2O$ (0.445 g, 1 mmol) in CH_2Cl_2/CH_3OH (5 mL/6 mL) was stirred at room temperature for 2 h. Yield: 69%. Elemental *Anal.* Calc. for $C_{24}H_{24}EuN_6O_{12}$ (740.44): C, 38.93; H, 3.27; N, 11.35. Found: C, 38.82; H, 3.24; N, 11.39%. IR (KBr pellet, cm^{-1}): 3400 w, 3061 w, 1655 vs, 1610 m, 1538 s, 1482 s, 1384 w, 1345 w, 1280 s, 1201 s, 1153 s, 1036 s, 1009 m, 947 w, 875 m, 815 m, 764 s, 739 m, 575 m, 393 m. UV–Vis spectrum in MeOH [λ_{max} (nm)]: 240, 255. m.p.: >260 °C.

4.2.5. Preparation of $[Tb(H_2salen)_{1.5}(NO_3)_3]$ (6)

A mixture of H_2salen (0.268 g, 1 mmol) and $Tb(NO_3)_3\cdot 6H_2O$ (0.452 g, 1 mmol) in CH_2Cl_2/CH_3OH (5 mL/6 mL) was stirred at room temperature for 2 h. Yield: 69%. Elemental *Anal.* Calc. for $C_{24}H_{24}N_6O_{12}Tb$ (747.41): C, 38.57; H, 3.24; N, 11.24. Found: C, 38.65; H, 3.27; N, 11.31%. IR (KBr pellet, cm^{-1}): 3413 w, 3070 w, 1647 vs, 1620 m, 1530 s, 1476 s, 1341 w, 1287 vs, 1206 s, 1151 vs, 1034 s, 1007 m, 945 w, 873 s, 809 m, 756 s, 737 m, 575 m, 391 m. UV–Vis spectrum in MeOH [λ_{max} (nm)]: 240, 255. m.p.: >260 °C.

4.2.6. Preparation of $[Lu(H_2salen)_{1.5}(NO_3)_3]$ (7)

A mixture of H_2salen (0.268 g, 1 mmol) and $Lu(NO_3)_3\cdot 6H_2O$ (0.464 g, 1 mmol) in CH_2Cl_2/CH_3OH (5 mL/6 mL) was stirred at room temperature for 2 h. Yield: 70%. Elemental *Anal.* Calc. for $C_{24}H_{24}LuN_6O_{12}$ (763.46): C, 37.76; H, 3.17; N, 11.01. Found: C, 37.65; H, 3.17; N, 11.09%. IR (KBr pellet, cm^{-1}): 3398 w, 3058 w, 1655 vs, 1609 m, 1537 s, 1480 s, 1384 w, 1343 w, 1278 s, 1199 s, 1152 s, 1033 s, 1008 m, 948 w, 877 s, 816 m, 766 s, 735 m, 575 m, 391 m. UV–Vis spectrum in MeOH [λ_{max} (nm)]: 240, 255. m.p.: >260 °C.

4.3. Crystallographic data collection and structure determination

X-ray crystallographic analysis: Diffraction intensity data for single crystals of the complexes were collected on a Rigaku R-AXIS RAPID imaging-plate X-ray diffractometer

at 293 K. The structures were solved by the direct method and refined by full-matrix least squares on F^2 using the SHELXTL-97 software package [16,17]. All non-hydrogen atoms were refined with anisotropic displacement parameters. Crystal data collection and refinement parameters for complexes **1**–**7** are given in Table 2.

As a consequence we have sought to synthesize and identify ruthenium(III)-sulfoxide (bipyridine) complexes. Thus, we report here the synthesis and reactivity of *mer*-[$RuCl_3$(DMSO)(bpy)] and *mer*-[$RuCl_3$(TMSO)(bpy)].

2. Experimental

All reagents used were analytical grade. The reagent grade solvents were dried over 4 Å molecular sieves before use. The IR spectra were measured on a JASCO 480 plus spectrophotometer with samples in compressed KBr discs. UV–Vis spectra were obtained on a JASCO V-550 spectrophotometer. Elemental analysis was performed by Atlantic Microlab, Norcross, Georgia. GC–MS (70 eV) analyses were obtained using a packed SPB-5 (30 m) capillary column. Cyclic voltammetry was carried out with a 3-electrode system comprised of a Pt counter electrode, a Pt disk working electrode, and a saturated calomel electrode (SCE) connected to the main cell compartment by a KCl salt bridge. Potential control was done with a BAS CV-50 W voltammetric analyzer used in the cyclic voltammetry mode. The supporting electrolyte was 0.100 M tetrabutylammonium hexafluorophosphate. Argon was bubbled through the solution for at least 30 min prior to and during cyclic voltammetry. Instrumental iR compensation was used when needed.

2.1. X-ray structure determination

The diffraction data were collected at low-temperature with a Nonius Kappa CCD diffractometer equipped with Mo Kα radiation ($\lambda = 0.71073$ Å), a graphite monochromator, and an Oxford Cryostream low-temperature device. For the solvate **6**. 2DMSO, one solvent molecule is ordered, while the other is disordered into two orientations which share C atom positions. Populations of the two orientations refined to 0.587(10)/0.413(10). All non-hydrogen atoms of **3**, **6**, **7** were treated anisotropically, except in the disordered solvent region of **6**. H-atoms were visible in difference mass, and were placed in calculated positions. Crystal data and details of data collection and refinement are given in Tables 1 and 2.

2.2. Computational studies

DFT computations were carried out using GAUSSIAN 03 [18]. Two possible structures of **9** were optimized and their energy determined. Infrared vibrational frequencies for the structure were also calculated. Pictures of HOMO and LUMO were obtained. The DFT method used was B3PW91 with a LANL2DZ basis set. A scaling factor of 0.9573 [19] was used in calculating the vibrational frequencies. A summary of the Cartesian coordinates, calculated

3. Synthesis of the complexes

$[H(DMSO)_2][trans\text{-}RuCl_4(DMSO)_2]$, [20a] $[H(TMSO)][trans\text{-}RuCl_4(TMSO)_2]$ [20b] and *mer*-$[RuCl_3(TMSO)(bpy)]$ [20c] (**5**) were synthesized according to the literature procedures.

3.1. mer-[RuCl$_3$(DMSO)(bpy)] (3)

To a solution of $[H(DMSO)_2][trans\text{-}RuCl_4(DMSO)_2]$ (**1**) (0.105 g, 0.19 mmol) in ethanol (5 mL) solid 2,2′-bipyridine (0.034 g, 0.22 mmol) was added at room temperature, with constant stirring. An orange–yellow precipitate formed within a few minutes. The product was filtered, washed with chilled ethanol and diethyl ether, and vacuum dried. Yield 0.52 g (62%). *Anal*. Calc. for $C_{12}H_{14}Cl_3N_2ORuS$ (MM = 441.73): C, 32.62; H, 3.2; N, 6.34. Found: C, 32.60; H, 3.74; N, 6.30%. Selected IR absorption bands in KBr (cm^{-1}): ν_{SO} 1115 and 1019 (s)(DMSO), $\nu_{C=N}$ 1604 (ms). UV–Vis (acetone): 404 nm ($\varepsilon = 6070$ L mol^{-1} cm^{-1}) and 210 nm ($\varepsilon = 3674$ L mol^{-1} cm^{-1}).

3.2. mer-[RuCl$_3$(bpy)(im)] · 2DMSO (6)

mer-$[RuCl_3(TMSO)(bpy)]$ (0.126 g, 0.27 mmol) was dissolved in hot 1,2-dichloroethane (30 mL). To this solution, solid imidazole (0.21 g, 0.31 mmol) was added and heated at 80 °C for 3 h. During this period the color changed to brown from orange. The solution was filtered and the volume was reduced to half on a reduced pressure. The flask was kept in a refrigerator. The brown solid was filtered, washed with hexane (3 × 5 mL), and vacuum dried. Yield 0.07 g, (60.5%). *Anal*. Calc. for $C_{13}H_{12}Cl_3N_4Ru$ (MM = 431.7): C, 36.17; H, 2.8; N, 12.98. Found: C, 36.28; H, 2.68; N, 13.02%. Selected IR absorption bands in KBr (cm^{-1}): νCN 1603 (m). UV–Vis (DMSO): 384 nm ($\varepsilon = 5858$ L mol^{-1} cm^{-1}), 296 nm (vs) ($\varepsilon = 19631$ L mol^{-1} cm^{-1}) and 260 nm ($\varepsilon = 10207$ L mol^{-1} cm^{-1}). The solid was recrystallized in DMSO and acetone at −20 °C to get suitable crystals of the disolvate **6** for X-ray diffraction.

3.3. cis-[RuCl$_2$(TMSO)(CO)(bpy)] (7)

mer-$[RuCl_3(TMSO)(bpy)]$ (0.114 g, 0.24 mmol) was dissolved in 1,2-dichloroethane (50 mL), evacuated, and connected to the reservoir of carbon monoxide (1 atm) at 80 °C for 6 h with constant stirring. The yellow–orange solution gradually turned to bright red. The solution was filtered and solvent removed in vacuum. The red solid was recrystallized in dichloroethane and diethyl ether at 4 °C to get a red crystalline solid suitable for X-ray diffraction. Yield 0.06 g, (54%). *Anal*. Calc. for $C_{15}H_{16}Cl_2N_2O_2RuS$ (MM = 459.41): C, 39.44; H, 3.51; N, 6.09. Found: C, 39.50; H, 3.42; N, 6.2%. Selected IR absorption bands in KBr (cm^{-1}): νCO 2040 (vs), νCN 1602 (m), νSO 1116 and 1014 (s) (TMSO). UV–Vis (acetone): 404 nm ($\varepsilon = 6070$ L mol^{-1} cm^{-1}), 298 nm (vs) ($\varepsilon = 20652$ L mol^{-1} cm^{-1}) and 252 (vs) ($\varepsilon = 20143$ L mol^{-1} cm^{-1}).

3.4. cis-[RuCl$_2$(DMSO)(CO)(bpy)] (8)

Brown–red (0.065 g, 47%). Selected IR absorption bands in KBr (cm^{-1}): νCO 2010 (vw) and 1950 (s), νCN 1602 (w), νSO 1120 and 1073 (s) (DMSO).

3.5. K[RuCl$_3$(bpy)(SCN)] (9)

0.034 g, 0.077 mmol of *mer*-$[RuCl_3(DMSO)(bpy)]$ or *mer*-$[RuCl_3(DMSO)(bpy)]$ and KSCN (0.01 g, 0.11 mmol) were dissolved in a separate flask in acetone (6 mL) and in water (1 mL), respectively. The solutions were combined and heated at 80 °C for 4 h to get a brown–orange solution. The solvent was removed on vacuum. The product was recrystallized in the mixture of acetone/water/diethyl ether at 4 °C. Yield 0.022 g (61.5%). *Anal*. Calc. for $C_{11}H_8Cl_3N_3RuSK$ (MM = 460.80): C, 28.67; H, 1.75; N, 9.12. Found: C, 28.8; H, 2.08; N, 8.31%. Selected IR absorption bands in KBr (cm^{-1}): νNCS 2067(s), νCN 1605 (b, m).

4. Results and discussion

In an attempt to substitute bpy ligand for DMSO and/or chloride ligand, we treated **1** with 2,2′-bipyridine in equimolar amounts in ethanol. Two neutral compounds, a major unknown *mer*-$[RuCl_3(DMSO)_2(bpy)]$ (**3**) and a minor known compound *cis*-$[RuCl_2(DMSO)_4]$ (**4**) were isolated. Nonetheless when the amount of bpy was reduced to half-equivalent with respect to **1**, 40% of **3** and 60% of **4** was isolated. The **3** was characterized by spectroscopy and by X-ray diffraction. The spectroscopic measurements of **4** were compared with an authentic sample of *cis*-$[RuCl_2(DMSO)_4]$.

The IR spectra of all the complexes **3, 6, 7, 8, 9** were recorded in KBr pellets and show a weak to medium intensity sharp peak between 1589 and 1603 cm^{-1} due to C=N stretch of the bipyridine ligand [21]. After complexation, there is a distinct bathochromic shift of 4–20 cm^{-1}, which is typical for coordinated imines of this type. The peaks due to (S=O) in the coordinated DMSO for **3, 8** (1115–1022 cm^{-1}) [20b,21] and TMSO coordinated (1115–1014 cm^{-1}) [20a] for **7** are assigned to S-bonded DMSO and TMSO, respectively to ruthenium. IR spectra of **7** and **8** reveal a strong absorption at 2040 cm^{-1} and 1950 cm^{-1}, respectively. The decrease in the CO stretching band in **8** compared to **7**, is presumably due to the bonding of the DMSO ligand to metal through oxygen. Similar results have been reported [22,23]. In contrast to the **8** the electronic spectrum of **3** (acetone) shows a strong absorption band at 404 nm and a weak band at 350 nm attributed to charge transfer transition from chlorides to

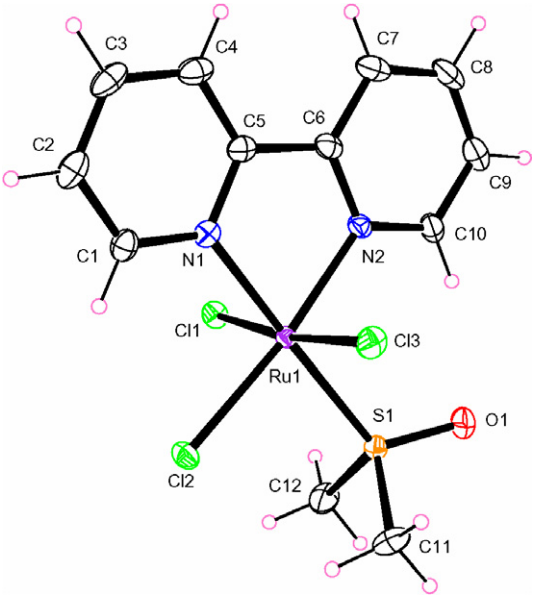

Fig. 1. Structure of mer-[$RuCl_3$(DMSO)(bpy)] **3**.

Ru(III) [24]. A sharp absorption at 210 nm is assigned to a metal-ligand charge transfer state (MLCT) [25].

5. X-ray crystal structure

5.1. *mer-[$RuCl_3$(DMSO)(bpy)] (3)*

The ruthenium (III) ion is surrounded by (Fig. 1, Table 1) six donors: S of DMSO, two nitrogens from 2,2′-bipyridine and three meridonial chloro ligands in a distorted octahedral coordination sphere. The bite angle involving coordinated bpy, N1RuN2 is 78.37(6)°, typical of a 2,2′-bipyridine coordinated to a second and third transition metal and TMSO analog, **5** [20c]. The bond angle of nonchelating ligand, S1RuCl2 is 85.711(18)°, larger than the N1RuN2 angle. The average Ru–N bond length, 2.076(16) Å is close to the distinctive bond length of 2.099 Å reported for Ru(II, III) [11,20c,21]. The average Ru–Cl bond length, 2.3439(5) Å is comparable to the TMSO analog, 2.3439 Å and other related Ru(III) complexes [10,27].

The Ru–S bond distance, 2.3236(5) Å, is near to the average value of 2.34(1) Å found for Ru(III)–S *trans* to DMSO-S in the precursor [20a,28] and slightly larger than **5** [26]. The bond angles of N1RuS1, 177.31(5)°; N2RuCl2, 173.09(5)° and Cl1RuCl3, 172.991(18)° are slightly shorter than the known values of octahedral complexes. Similarly the bond angles N1RuN1, N1RuCl2, Cl2RuS1, and S1RuN2 are varied and range from 78.37° to 101.01°. These distortions from ideal octahedral geometry are probably caused by the acute (∼78°) bite angle of the chelating bipyridine ligand [29].

6. Reactivity of 3 and 5 with imidazole, CO and KSCN

The reaction of *mer*-[$RuCl_3$(TMSO)(bpy)] **5** with imidazole and CO produced compounds **6** (substituting TMSO for imidazole) and **7** (one-electron reduction) at elevated temperature. Likewise, the DMSO analogues have also been synthesized from **3** under similar reaction conditions. Combined spectroscopic (IR, UV–Vis) and microanalysis evidence suggested that the geometry of DMSO analogues is similar to that of **6** and **7**. The reactions of **3** and **5** with KSCN, resulted in the same compound, K[$RuCl_3$-(bpy)(SCN)] **9** formed by the substitution of DMSO or TMSO in **3** and **5**.

6.1. *mer-[$RuCl_3$(bpy)(im)] · 2DMSO (6)*

The compound **6** was formed by the substitution of TMSO ligand from **5**. On recrystallization with DMSO, the compound has 2 molecules of DMSO solvate. One of the DMSO molecules exhibits disorder. As shown in Fig. 2, the coordination sphere is a distorted octahedron as can be seen from the angles subtended at the metal center. The distortion of the coordination sphere is primarily caused by the bite angle, N1RuN2, 79.00(14)° of the bipyridine ligand though the bite angle of **6** is larger than the precursor. The observed three ruthenium–nitrogen bond distances, N1Ru, 2.043(3) Å; N2Ru, 2.062(4) Å and N3–Ru, 2.085(4) fall within the range 2.049–2.085 Å as reported for $[Ru(bpy)_3]^{2+}$ [30–32]. However, the Ru–N bond distance in Ru(III)–bipyridine is slightly shorter than the reported values for Ru(II)–bipyridine complexes. The shorter Ru(III)–N bond length compared to Ru(II)–N is probably due to an increase in oxidation state [20a,33]. Also, the Ru–N bond lengths, N1Ru and N2Ru in **6** are shorter than the precursor, *mer*-[$RuCl_3$(TMSO)(bpy)], (2.0835 Å). The N3Ru bond length is significantly larger than the other two, N1Ru and N2Ru. The imidazole moiety is essentially planar and three chloride ligands occupy meridonial positions.

6.2. *cis-[$RuCl_2$(TMSO)(CO)(bpy)] (7)*

On bubbling carbon monoxide (1 atm) through the solution of **5** in dichloroethane at 80 °C, **7** was isolated. During the course of the reaction, Ru(III) is reduced to Ru(II). The coordination geometry of this complex is distorted octahedral. The coordinated bpy domain exhibits a bite angle, N1RuN2, 77.93(8)°, which falls within the typical limit of those for Ru-bpy complexes, reported earlier [34]. However, the bite angle in **7** is slightly shorter than the parent compound, 78.16 (9)° [20b]. The Ru–Cl2 bond length *trans* to S of the TMSO ligand, 2.4167(9) Å is clearly longer than Ru–Cl1 *trans* to bipyridine Ru–N1, 2.4035 (9) Å, probably due to a strong *trans* effect of the TMSO ligand. The Ru–N2 bond length *trans* to CO, 2.133(2) Å is significantly longer than Ru–N1, 2.064(2) Å *trans* to Cl1 due to the strong *trans* effect of the carbonyl ligand. The Ru(II)–N bond lengths in monodentate bipyridine ligands [12] are systematically longer (2.18–2.20 Å) than in 2,2′-bipryridine chelating complexes (2.15 Å), which in turn are much larger than the average Ru–N bond lengths (2.0985 Å) in

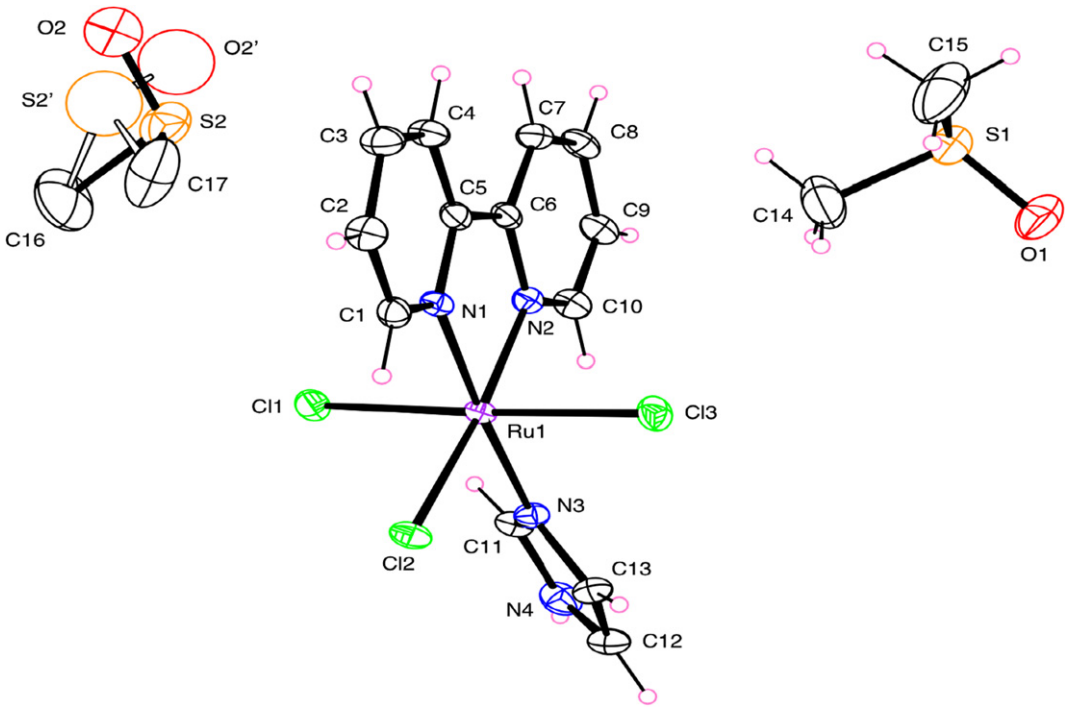

Fig. 2. Structure of *mer*-[$RuCl_3$(bpy)(im)] · 2DMSO (**6**).

complex **7**. The shortness of the Ru–N bond length in **7** is most probably related to the increased π back-bonding compared to monodentate and chelating bipyridine ligand coordination modes [12]. The Ru–C–O bond angle, 178.3(3)°, is close to linear geometry. Also, this angle is greater than the angle in [$RuCl_2(CO)_2$(bpy)], 171.1° [34a]. Similar distortion is reported for $[Ru(bpy)_2(CO)(NO_2)]^+$ and $[Ru(bpy)_2(CO)(Cl)]^+$ [35–37]. The carbonyl ligand is in a *cis* position to one of the chloride ligands and *trans* to the bipyridine nitrogen. The Ru–S bond length, 2.2541(9) Å is shorter than its precursor, *mer*-[$RuCl_3$(TMSO)(bpy)], 2.2969(8) Å (see Fig. 3).

Rather unexpectedly, the Ru–C bond length in **7**, 1.903(3) Å, is longer than in *mer*-[$RuCl_3(TMSO)_2(CO)$], 1.845(3) Å and in *cis*-[$RuCl_2(TMSO)_3(CO)$], 1.865(4) Å. While the C–O bond length in **7,** 1.090(3) Å is shorter than in [$RuCl_3(TMSO)_2(CO)$], 1.149(9) Å and *cis*-[$RuCl_2$(TMSO)$_3$(CO)], 1.132(2) Å [24,38]. It is interesting to note that during the course of synthesis of **7**, Ru(III) is reduced to Ru(II) whereas no reduction of ruthenium takes place when carbon monoxide passes through the solution of *mer*-[$RuCl_3(TMSO)_3$] under similar conditions [38].

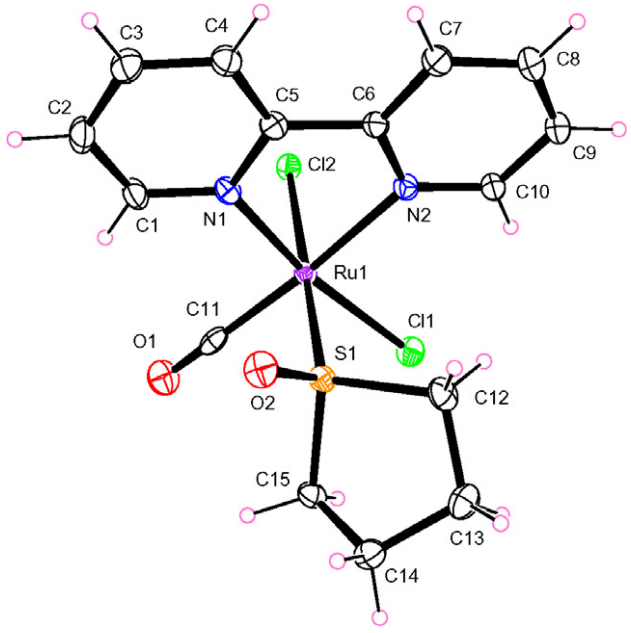

Fig. 3. Structure of *mer*-$RuCl_2$(TMSO)(CO)(bpy)] (**7**).

7. K[$RuCl_3$(bpy)(NCS)] (9)

On the basis of spectroscopic and microanalyses studies complex **9** is formulated as K[$RuCl_3$(bpy)(NCS)], which is derived either from **3** or **5**. In the absence of X-ray diffraction studies of M-thiocyanate complexes, the C–N stretching mode (ν_{SC-N}), the S–C stretching band (ν_{S-CN}), and the NCS deformation mode (δ_{SCN}) as well as the integrated intensity of ν_{SC-N} have been used as indicators of the SCN bonding mode [39]. However, ν_{S-CN} and δ_{SCN} are often weak and are masked by other absorptions, such as those of solvent or other ligands. The C–N stretching is generally at lower frequency in N-bonded complexes (around 2050 cm^{-1}) than in S-bonded complexes (around 2100 cm^{-1}), but this criterion must be applied carefully as counter examples exist [40,41]. With some exceptions *cis*

and *trans* isomers can be distinguished by IR spectroscopy: thus ν_{SC-N} usually appears as a single band in the spectrum of the *trans* isomer.

The IR spectrum of **9** shows a strong single band at 2066–2067 cm^{-1} assignable to ν_{SC-N} for N-bonded thiocyanate complexes. This is also substantiated by HSAB theory. A medium intensity frequency at 2109 cm^{-1} has been reported for the N-bonded thiocyanate complex in $[Ru(dmbpy)(CO)_2(NCS)H]$ [42]. Nonetheless electronic factors play a crucial role in the stability of metal-thiocyanate bonds [42]. In fact, decreasing electron density on the metal center has been suggested to change the bonding mode of the thiocyanate ligand from M-SCN to M-NCS.

8. Computational studies

To clarify further the role of the coordination mode of the thiocyanato ligand with ruthenium(III) in compound **9**, density functional calculations were conducted. DFT calculations of $[RuCl_3(bpy)(NCS)]^-$ and $[RuCl_3(bpy)(SCN)]^-$ were performed. The calculated energy for the former was found to be 12 kcal/mol lower than the latter, which substantiates our earlier statement. For comparing isomer energies, a DFT method had an average error of 2.8 kcal/mol in one comparative study of 45 non-transition metal isomer pairs [43]. For diastereoisomers involving transition metal compounds, accuracies within 1–2 kcal/mol are felt likely [44].

The calculated ν_{SC-N} for the former was 2069 cm^{-1} and 2019 cm^{-1} for the latter. In the ruthenium bipyridine systems, the HOMO contains ruthenium d-orbitals and the LUMO is typically π^*-orbitals of the bipyridine ring.

9. Electrochemistry

Cyclic voltammetry of **3** was carried out (acetone, 1.00 mM, Fig. 4) at sweep rates ranging from 100 to 3011 mV/s. The resulting graphs display a prominent reduction peak and corresponding oxidation peak. The difference in potential between these two peaks (ΔE_p) ranged from 71 to 102 mV. The ratio of anodic to cathodic peak current (i_a/i_c) ranged from 1.1 to 0.90. The intermediate potential of these peaks ranged from 0.026 to 0.031 V versus SCE with an average of 0.028 V versus SCE and is taken as an approximation to the formal potential $E^{\circ\prime}$. These data are consistent with the peaks being due to a nearly reversible one-electron redox couple [45] and it is assumed to be Ru(III)/Ru(II). Another redox couple seems to appear just cathodic of the Ru peaks. It is not defined enough to obtain information from it but it may be due to partial reaction of one of the ligands. Isolating the potential sweep to just this couple had little effect on its appearance.

Semi-derivative analysis [46] of the data was also done. Peak widths at half height of the semi-derivative data ranged from 98 to 118 mV for the anodic peak and 100 to 113 mV for the cathodic peak over the sweep rates used.

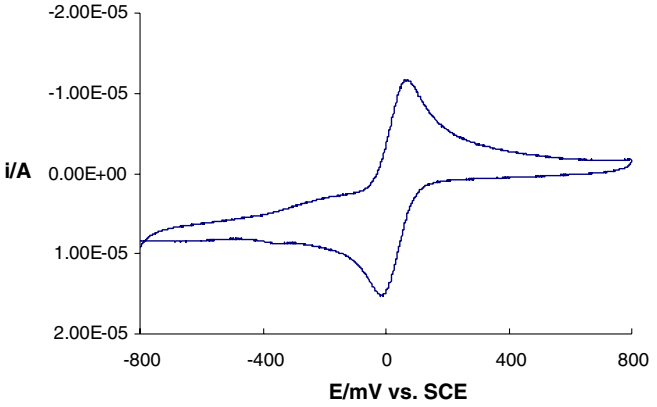

Fig. 4. Cyclic voltammetric curve of *mer*-$[RuCl_3(DMSO)(bpy)]$ (**3**) for 1.0 mM (**3**) and 0.100 M Bu_4NPF_6 in acetone at a sweep rate of 500 mV/s.

This compares to 90.7 for a one-electron reversible process. The ratio of peak heights ranged from 0.995 to 1.06. The formal potential approximated as the average of the intermediate of the anodic and cathodic peak potentials on the semi-derivative graphs was 0.028 V versus SCE.

Cyclic voltammetry of **6** (DMSO, 1.00 mM, Fig. 5) was carried out at sweep rates from 100 to 5120 mV/s. A prominent redox couple appears as a reduction peak and a corresponding oxidation peak on these graphs at an average potential of 0.276 V versus SCE as determined directly from cyclic voltammetry data as well as semi-derivative analysis. These peaks are assumed to be due to Ru(III)/Ru(II) charge transfer. ΔE_p ranged between 66 and 90 mV, indicating quasi-reversible behavior. However, i_a/i_c approached unity only at high sweep rates. Oxidation current was less than reduction current. This may be due to reaction of or mass transfer of the reduction product, an effect that would be more pronounced at lower sweep rates. Peak widths at half heights from the semi-derivative analysis ranged from 104 to 116 mV for the anodic peak and 103 to 116 for the anodic peak.

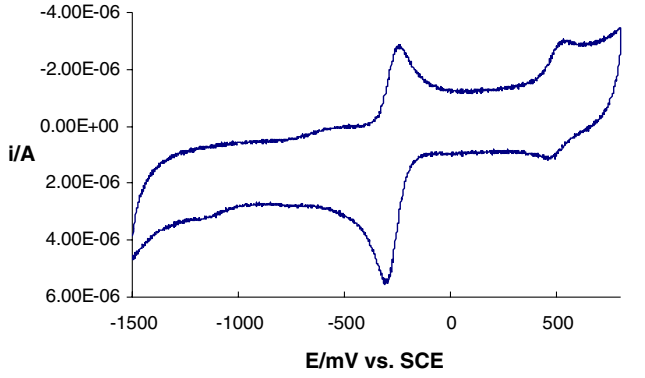

Fig. 5. Cyclic voltammetric curve of *mer*-$[RuCl_3(bpy)(im)]\cdot 2DMSO$ (**6**) for 1.0 mM (**6**) and 0.100 M Bu_4NPF_6 in DMSO at a sweep rate of 500 mV/s.

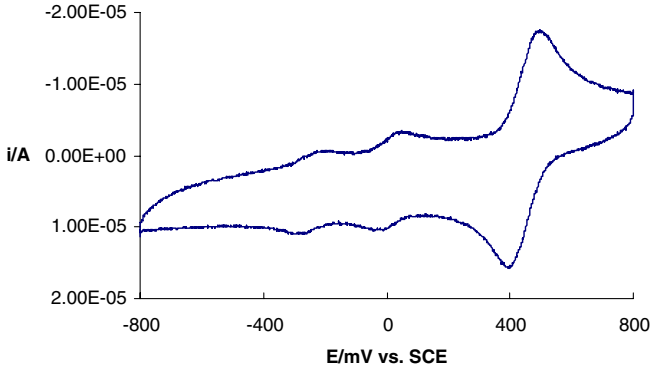
The potentials measured by us for the above two compounds compare favorably with the correlation of Lever [47] which predicts an approximate formal potential of 0.03 V for **3** and −0.32 V for **6**.

Cyclic voltammograms (acetone, 0.37 mM, Fig. 6) were obtained for **7** at sweep rates from 100 to 3011 mV/s. Three pairs of peaks were observed at all sweep rates. The largest pair is centered on an average potential of 0.447 V versus SCE both on the voltammogram and on the semi-derivative graph. i_a/i_c ranges between 1.04 and 1.17. ΔE_p ranges between 69 and 101 mV. The peak widths at half height from the semi-derivative analysis range between 94 and 125 mV. These characteristics are consistent with a quasi-reversible one-electron transfer. However, one expects to see evidence of a Ru(II)/Ru(0) couple. The data may be due to a two-electron process if this couple were not so near to reversibility. Another possibility is that the oxidation and reduction processes in the Ru(II)/Ru(0) couple occur in two consecutive one-electron processes and that the peaks for these are closely overlapping. This has been suggested previously [48]. For this situation, ΔE_p would be expected to be only slightly larger than that predicted for a one-electron reversible process.

The other two smaller pairs of peaks may be due to redox couples involving the ligands. They have average potential values of approximately 0.01 V and −0.25 V and average ΔE_p values of approximately 67 and 58 mV.



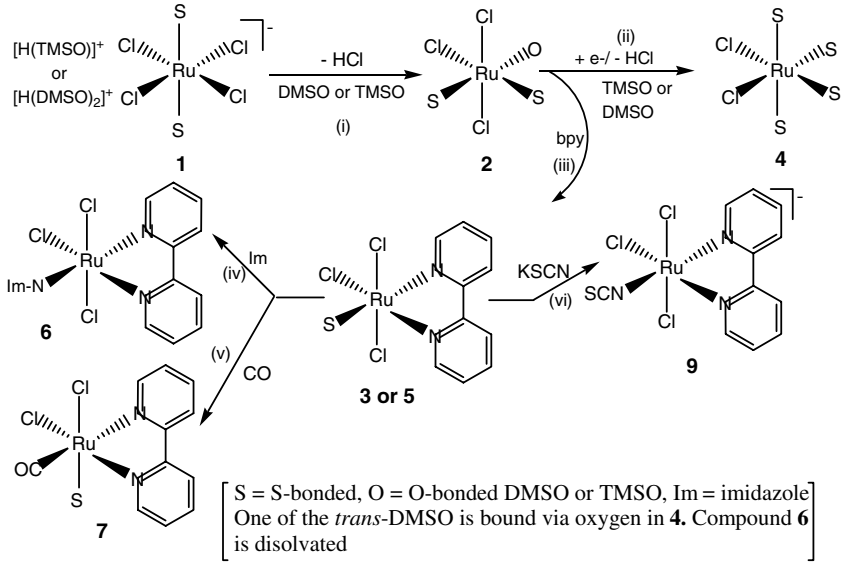


Fig. 6. Cyclic voltammetric curve of *mer*-[$RuCl_2$(TMSO)(CO)(bpy)] (**7**) for 0.37 mM (**7**) and 0.100 M Bu_4NPF_6 in acetone at a sweep rate of 3011 mV/s.

10. Formation scheme of various compounds and their reaction mechanism

On treating **1** with an equimolar amounts of 2,2′-bipyridine, **3** (major) and **4** (minor) is isolated. It is known that **2** is prepared by the reaction of **1** with DMSO/TMSO and $AgBF_4$ in boiling acetone [20b]. In view of these observations, we propose a reaction mechanism (Scheme 1), similar to the one proposed by us [20c] and Alessio earlier [20b]. To ascertain step (iii), we independently synthesized **3** by the reaction of **2** and 2,2′-bipyridine under identical reaction conditions. Thus, it is anticipated that **2** is intermediate in the formation of **3** and **4**. The identity of the reducing agent in step (ii) is ambiguous. However, we believe that sulfoxides and HCl in step (ii) are the probable reductants. In fact, the GC–MS analysis of the reaction mixture, carried out under argon, detected sulfones, substantiating the work reported earlier [20a]. Likewise, carbon monoxide acts as reductant in step (v). To probe the role of 2,2′-bipyridine in the formation of **2** and **4**, a control experiment in the absence of 2,2′-bipyridine was performed with identical conditions. The solid IR spectrum of the product was identical to **1**, suggesting that 2,2′-bipyridine is a prerequisite for the formation of **2** and **4** under present

Scheme 1. Synthetic scheme of various ruthenium complexes.

reaction conditions. Thus, 2,2′-bipyridine ligand is basic enough to pull off HCl from **1** to produce **2**, which in turn forms **3**.

Acknowledgements

We thank Dr. R. D. Braun (UL Lafayette, Chemistry Department) for editing the manuscript and making suggestions. Financial support provided by the Research Corporation (Cottrell College Science Award, #CC 6234 to RSS) and BoR, Louisiana is greatly appreciated. The purchase of the diffractometer was made possible by Grant No. LEQSF(1999–2000)-ESH-TR-13, administered by the Louisiana Board of Regents.

complexes with copper(I) and mercury(II) halides, including an unusual tetrametallic complex, [{L(HgI$_2$)$_2$}$_2$]. A common feature for all the complexes is the occurrence of hydrogen bonding between the hydrazine backbone hydrogens of L and the coordinated halide ions.

2. Experimental

2.1. Materials and instrumentation

All reactions were carried out under an atmosphere of dry dinitrogen. Analytical grade solvents were purchased from standard chemical suppliers and were used without further purification. HgI_2 (M&B), $HgBr_2$ (BDH) and $HgCl_2$ (M&B) were used as received. CuCl, CuBr, CuI and (1,2-diphenylphosphino)hydrazine were prepared according to the literature [18,19,14]. ^{1}H and ^{31}P NMR spectra were recorded on a Bruker Avance 400 spectrometer. IR spectra were run as KBr discs on a Perkin–Elmer FT-IR Paragon 1000 spectrometer. Microanalyses were performed by the Campbell Microanalytical Laboratory, University of Otago.

2.2. Syntheses

2.2.1. 1,2-Bis(diphenylthioylphosphino)hydrazine (L)

To a solution of 1,2-bis(diphenylphosphino)hydrazine (2.585 g, 6.436 mmol) in toluene (20 mL) was added sulfur (0.42 g, 13.1 mmol) and the mixture was heated at reflux over 2 h. The toluene was removed on a rotary evaporator to give a cream coloured solid that was washed with cold acetone (2 × 5 mL). The solid was dissolved in hot acetone (60 mL) and slow evaporation of the solution produced a crop of white crystalline material. Yield 1.15 g (38%). ^{1}H NMR ($CDCl_3$): δ 7.81–7.76 (m, 8H, P*Ph*$_2$), 7.46 (m, 4H, P*Ph*$_2$), 7.34–7.30 (m, 8H, P*Ph*$_2$), 4.62 (m, 2H, N*H*). ^{31}P NMR ($CDCl_3$): δ 66.0 (s, 2P, P=S). ν_{PS}/cm^{-1}: 633, 615. ν_{NH}/cm^{-1}: 3222, 3158. *Anal*. Calc. for $C_{24}H_{22}N_2P_2S_2$: C, 62.05; H, 4.99; N, 6.03. Found: C, 62.18; H, 4.73; N, 6.07%. m.p. 201–204 °C (*lit.* 204 °C).

2.2.2. [{CuLCl}$_2$]

A mixture of L (0.100 g, 0.215 mmol) and CuCl (0.022 g, 0.222 mmol) in MeCN (70 mL) was heated at reflux over 7 h. The reaction mixture was filtered while hot and a white microcrystalline precipitate formed on cooling. Yield 0.105 g. An analytically pure sample and X-ray quality crystals of [{CuLCl}$_2$]·4MeCN were obtained after a second recrystallisation of a portion of the material from hot MeCN. *Anal*. Calc. for $C_{48}H_{44}Cl_2Cu_2N_4P_4S_4$: C, 51.15; H, 3.94; N, 4.97. Found: C, 51.10; H, 4.02; N, 5.01%. ν_{PS}/cm^{-1}: 620, 599. ν_{NH}/cm^{-1}: 3070. m.p. 246–250 °C (dec.).

2.2.3. [{CuLBr}$_2$]

A mixture of L (0.100 g, 0.215 mmol) and CuBr (0.032 g, 0.222 mmol) in MeCN (90 mL) was heated at reflux over 4 h. The reaction mixture was filtered while hot and a white microcrystalline precipitate formed on cooling. Yield 0.097 g. An analytically pure sample and X-ray quality crystals of [CuLBr]$_2$·2MeCN were obtained after a second recrystallisation of a portion of the material from hot MeCN. *Anal.* Calc. for $C_{48}H_{44}Br_2Cu_2N_4P_4S_4$: C, 47.41; H, 3.65; N, 4.61. Found: C,47.64; H, 3.55; N, 5.19%. ν_{PS}/cm^{-1}: 620, 601. ν_{NH}/cm^{-1}: 3075. m.p. 255–270 °C (dec.).

2.2.4. [{CuLI}$_2$]·CH$_3$CN

A mixture of L (0.100 g, 0.215 mmol) and CuI (0.041 g, 0.215 mmol) in $CHCl_3$ (5 mL) was heated at reflux over 1 h. The mixture was allowed to cool and a white precipitate was collected by filtration. Yield 0.075 g. X-ray quality crystals of [{CuLI}$_2$]·2MeCN and an analytically pure crop of the monosolvated complex were obtained by recrystallisation from hot MeCN (20 mL). *Anal.* Calc. for $C_{50}H_{47}Cu_2I_2N_5P_4S_4$: C, 44.45; H, 3.51; N, 5.18. Found: 44.11; H, 3.24; N, 5.62%. ν_{PS}/cm^{-1}: 613, 602. ν_{NH}/cm^{-1}: 3085. m.p. 255–261 °C (dec.).

2.2.5. [{L(HgI$_2$)$_2$}$_2$]

A mixture of L (0.100 g, 0.215 mmol) and HgI_2 (0.196 g, 0.431 mmol) in MeCN (20 mL) was heated at reflux over 1.5 h. The reaction mixture was filtered while hot and a pale yellow crystalline solid formed on cooling. Yield 0.217 g. *Anal.* Calc. for $C_{48}H_{44}Hg_4I_8N_4P_4S_4$: C, 20.99; H, 1.61; N, 2.04. Found: C, 21.06; H, 1.60; N, 2.09%. ν_{PS}/cm^{-1}: 620, 595. ν_{NH}/cm^{-1}: 3154, 3052. m.p. 168–200 °C (dec.).

2.2.6. [HgLCl$_2$]

A mixture of L (0.100 g, 0.215 mmol) and $HgCl_2$ (0.059 g, 0.217 mmol) in MeCN (35 mL) was heated at reflux over 5 h. The reaction mixture was allowed to cool and a white precipitate was collected by filtration. Yield 0.123 g. A small amount of material was recrystallised from hot nitromethane. *Anal.* Calc. for $C_{24}H_{22}Cl_2HgN_2P_2S_2$: C, 39.16; H, 3.01; N, 3.81. Found: C, 38.92; H, 3.04; N, 3.92%. ν_{PS}/cm^{-1}: 619, 594. ν_{NH}/cm^{-1}: 3057. m.p. 215–230 °C (dec.).

2.2.7. [HgLBr$_2$]

A mixture of L (0.100 g, 0.215 mmol) and $HgCl_2$ (0.078 g, 0.216 mmol) in MeCN (10 mL) was heated at reflux over 2 h. The reaction mixture was allowed to cool and a white precipitate was collected by filtration, washed with cold acetonitrile and air dried. Yield 0.140 g. A sample of the material was recrystallised from hot nitromethane and crystals suitable for X-ray analysis were also obtained from this solvent. *Anal.* Calc. for $C_{24}H_{22}Br_2HgN_2P_2S_2$: C, 34.94; H, 2.69; N, 3.40. Found: C, 34.88; H, 2.66; N, 3.41%. ν_{PS}/cm^{-1}: 620, 593. ν_{NH}/cm^{-1}: 3075. m.p. 210–225 °C (dec.).

2.3. Crystallography

The X-ray data were collected on a Siemens P4 four circle diffractometer, using a Siemens SMART 1K CCD area

detector. The crystals were mounted in an inert oil, transferred into the cold gas stream of the detector and irradiated with graphite monochromated Mo-Kα ($\lambda = 0.71073$ Å) X-rays. The data were collected by the SMART program and processed with SAINT to apply Lorentz and polarisation corrections to the diffraction spots (integrated 3 dimensionally). The structures were solved by direct methods and refined using the SHELXTL [20] program. The hydrogen atoms bound to the nitrogen atoms on the hydrazine backbone were located from the electron difference map and refined using a riding model. All other hydrogen atoms were calculated at ideal positions. Refinement, collection and crystal data are given on Table 1.

3. Results and discussion

3.1. Syntheses of the compounds

The free ligand L was prepared from the sulfuration of the parent phosphine, (1,2-diphenylphosphino)hydrazine in toluene. This differs from the previously reported method where it was prepared from the reaction between $Ph_2P(S)Cl$ and anhydrous hydrazine [15]. The ^{31}P NMR chemical shift of L is 66 ppm in $CDCl_3$ and downfield of phosphorus signal in (1,2-diphenylphosphino)ethane (L^1) which occurs at 44 ppm. The ligand exhibits IR bands at 3222 and 3158 cm^{-1}, (assigned to NH) and 633 and 615 cm^{-1}, (assigned to P=S) stretching frequencies, respectively.

Pure samples of copper halide complexes of stoichiometry $[\{CuLX\}_2]$ (X = I, Br or Cl) were obtained from the reactions between the ligand and the appropriate copper(I) halide followed by crystallisation from hot acetonitrile solutions. Satisfactory elemental analyses were obtained in each case. The complexes have poor solubility in common organic solvents at room temperature which precluded characterisation by NMR. In the IR spectra, both the NH and PS stretching bands are shifted to lower wave numbers when compared with the free ligand. Thus the ν(NH) stretching frequencies are observed at 3084, 3070 and 3074 cm^{-1} and the pairs of ν(PS) bands at 612 and 601, 619 and 599 and 620 and 600, respectively, for the series X = I, Cl, Br.

Similarly 1:1 mercury(II) chloride and bromide complexes, $[HgLX_2]$ (X = Cl or Br) were obtained from the reaction of equimolar ligand and mercury(II) halide in MeCN. Initially we attempted to prepare a 1:1 mercury(II) iodide complex in the same way but it was apparent that we were obtaining mixtures, with one of the components being the $[\{L(HgI_2)_2\}_2]$ species reported here. This latter complex was obtained in good yield from the reaction of the metal salt and the ligand in a 2:1 molar ration. The IR spectra for the mercury bromide and chloride complexes are similar with NH stretching frequencies at 3074 and 3056 cm^{-1} and pairs of PS stretching frequencies at 618 and 593 and 619 and 593 cm^{-1}. The tetrametallic mercury iodide complex has a different spectrum with two stretching

frequencies assignable to NH at 3153 and 3051 cm^{-1} and a pair of PS stretching frequencies at 617 and 595 cm^{-1}. The solubilities of the mercury complexes in common organic solvents were also low.

The two P=S stretching frequencies for L at 632 and 614 cm^{-1} are both lowered by about 12–21 cm^{-1} for the complexes, consistent with metal coordination of the sulfur atoms [16]. Similarly, the two N–H stretching frequencies at 3222 and 3158 cm^{-1} for L are replaced with one band at about 3056–3084 cm^{-1} for all the complexes, apart from $[\{L(HgI_2)_2\}_2]$, which displays two bands at 3052 cm^{-1} and 3153 cm^{-1}. The lowering of these frequencies is consistent with the presence of N–H···X hydrogen bonds in the structure, rather than coordination by N–H groups in a strained four-membered ring. Moreover, the trend of the ν(NH) frequencies to lower energies increases along the series $I^- < Br^- < Cl^-$, which parallels the hydrogen-bonding ability of the anions [21].

All of the copper complexes with L remained unchanged upon recrystallization from hot CH_3CN. However, the CuCl complex of 1,2-bis(diphenylphosphino)hydrazine, after initial recrystallization from hot toluene and then left to crystallize for several months, was hydrolytically unstable with cleavage of the P–N bonds [22], and one of the products isolated was diphenylphosphinic acid. Similar reactivity has been observed for aminobis(phosphines) [23]. The polarity of the P–N bond favours attack on the phosphorus atom by the water nucleophile, and this is followed by oxidation of the P atom. This reaction is slowed down when the ligand is already oxidized as in L and does not occur when P–C bonds are present. This is the first reported cleavage reaction for a coordinated hydrazinobis(phosphine).

3.2. Description of the structures

3.2.1. 1,2-Bis(diphenylthioylphosphino)hydrazine (L)

The free ligand L crystallises from an acetone solution in the space group $P2(1)$ with four molecules in the asymmetric unit. Every independent molecule has a similar conformation in which the PNNP backbone has a torsion angle of around 16° and both pairs of N–H and P=S bonds are directed towards the same side of the mean PNNP plane. This arrangement of the sulfur atoms is similar to that observed in the structure of $Ph_2P(S)CH_2CH_2P(S)Ph_2$ (L^1) although the PCCP backbone is slightly more twisted with a torsion angle of *ca.* 25° [24]. However, molecules of L exist as hydrogen bonded dimers in the solid state with both molecules in the dimer contributing one N–H···S bond to the array (Fig. 1), whereas the sulfur atoms in L^1 are only involved in close contacts with aromatic hydrogen atoms on nearby diphenylphosphine groups. In this respect, the packing in L more resembles $Ph_2P(O)CH_2CH_2P(O)Ph_2$, in which two adjacent molecules each supply a close contact between a hydrogen atom on the $(CH_2)_2$ backbone and a P=O bond, although in this compound the P=O bonds on the same molecule are directed towards opposite sides of the PCCP mean plane [25]. Selected bond lengths and angles are given in Table 2. Structural data on hydrazinobis(phosphine) adducts is scarce although the P–N and N–N bond lengths in L (average 1.695 and 1.441 Å) are comparable with those observed in a cyclic example, 3,6-dimethoxy-1,2,4,5-tetraaza-3,6-diphosphacyclohexanedisulfide (average 1.663 and 1.435 Å) and the P–S bond lengths (average 1.945 Å) are comparable to those in L^1 (1.941 Å) [26].

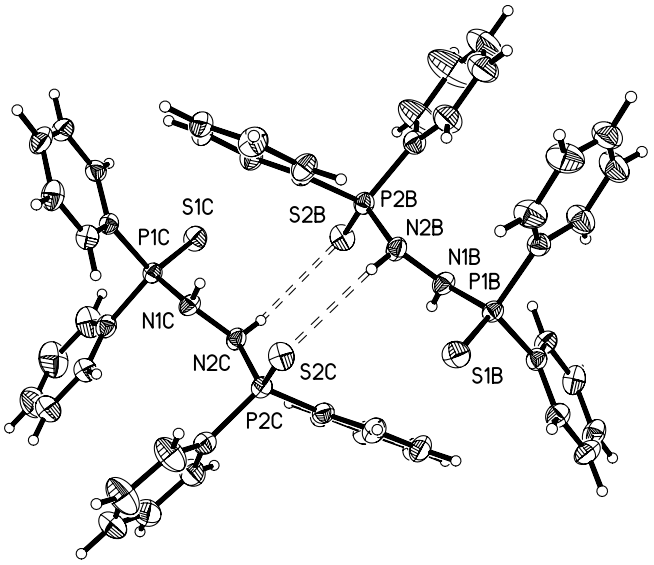

Fig. 1. Diagram of the dimeric form of L in the solid state. Thermal ellipsoids drawn at 50% probability level and most hydrogen atoms removed for clarity.

3.2.2. Copper(I) halide complexes of L

X-ray quality crystals of the copper(I) halide complexes of L were obtained in from MeCN solutions. In each case the overall structure is similar and comprises a dimetallic species of stoichiometry $[\{CuLX\}_2]$ in which L acts as a bridging ligand, bonding to separate copper centres through either sulfur atom (Fig. 2., X = I). Selected bond lengths and angles are given in Table 3.

The coordination spheres of the Cu(I) centres have 'S_2X_2' donor sets with a somewhat unusual geometry, being best described as trigonal pyramidal. The copper bonds to X1, S1 and S2 (sulfur atoms from different ligands) and X1A. The halides link the two symmetry related Cu atoms with the Cu–X1A bond lengths being around 0.5–0.65 Å longer than the Cu–X1 bonds lengths (Table 3). The X1A ion forms the apex of the trigonal pyramid. The sum of the three angles in the coordination planes formed about the copper atom by X1 and the sulfur atoms are approximately 354.7, 357.1 and 356.9°, respectively, for X1 = I, Br and Cl hence approaching an ideal trigonal geometry. The copper atom is displaced from the trigonal plane towards X1A by 0.3210, 0.2318 and 0.2360 Å, respectively, for X = I, Br and Cl.

The overall structures are comparable to the arrangement observed in $[\{CuL^1Cl\}_2]$ [27] but with some subtle dif-

ferences. In the three L Cu(I) complexes there are four strong intramolecular hydrogen bonds (Table 4) of the type N–H···X which have the effect of creating two pairs of fused 6-membered chelate rings. This assembly appears to have an increasing influence on the PNNP backbone as X becomes smaller and more electronegative (in each case the torsion angle for PNNP is 10, 13 and 16° for X = I, Br and Cl). In $[\{CuL^1Cl\}_2]$ the PCCP torsion angle is 4° and the intramolecular contacts from the ligand backbone are long (the relevant C–H···Cl contacts are 2.708 and 2.581 Å) compared with $[\{CuLCl\}_2]$ where N–H···Cl are 2.410 and 2.351 Å. Hence the ligand backbones in the $[\{CuLX\}_2]$ complexes remain twisted in their compression towards the Cu_2X_2 core whereas in $[\{CuL^1Cl\}_2]$ the ligand backbone is somewhat flattened. In $[\{CuLCl\}_2]$the sulfur atoms on the same ligand are further apart (5.989 *cf.* 5.846 Å) even though the phosphorus atoms are closer (4.083 *cf.* 4.424 Å). The impact of this on the coordination spheres is that in $[\{CuL^1Cl\}_2]$ the Cu···Cu separation in $[\{CuLCl\}_2]$ is longer (3.751 *cf.* 3.327 Å) and the bridging Cu–Cl distances (2.869 *cf.* 2.639 Å) are also increased.

3.2.3. $[\{L(HgI_2)_2\}_2]$

The reaction of 2 equiv of HgI_2 with L and subsequent recrystallisation from acetonitrile afforded the unusual tetrametallic complex $[\{L(HgI_2)_2\}_2]$. In this complex L is again acting as a bridging, ligand binding different Hg(II) ions through each sulfur donor with each ligand creating a moiety of stoichiometry '$L(HgI_2)_2$'. Two such moieties are linked by iodide bridges which lie about a centre of inversion to give the tetrametallic complex (Fig. 3). Selected bond lengths and angles are given in Table 5.

Hence the molecule contains two different tetrahedral 'I_3S' coordination spheres. Hg1 is bonded to I1 and I2 [2.6726(4) and 2.6919(3) Å] and is bridged to Hg2 through a slightly longer bond to I3 [3.1084(3) Å]. Hg2 is coordinated by three bridging iodine ligands I3, I4 and I4A; the bond lengths being 2.7244(4), 2.7323(3) and 3.1572(4) Å, respectively. The Hg2–S2 bond length of 2.5587(11) Å is significantly shorter than the Hg1–S1 bond length of 2.6150(11) Å although the P=S bond lengths are similar and longer than in the free ligand [1.9965(16) and 2.0012(16) Å compared to an average of 1.945 Å]. As with the dimetallic copper(I) halide structures, the NH–NH ligand backbones in $[\{L(HgI_2)_2\}_2]$ participate in strong hydrogen bonding interactions with the iodide coligands; H1···I2 is 2.91 Å and H2···I3 is 2.90 Å and the PNNP torsion angle is 17.7°.

Table 4
Hydrogen-bond lengths (Å) and angles (°) in the $[\{CuLX\}_2]$ complexes

	D–H	H···A	D···A	∠(DHA)
N1–H1···I1	0.85	2.84	3.6506(15)	160.7
N2–H2···I1A	0.86	2.75	3.5480(14)	156.4

N2–H2···Cl1	0.89	2.41	3.2674(12)	161.7

3.2.4. $[HgLBr_2]$

From the reaction of 1 equiv of $HgBr_2$ with L, crystals of $[HgLBr_2]$ were obtained from nitromethane in which L acts as a bidentate ligand bonding through the two sulfur atoms to form a seven-membered chelate ring. The complex has a distorted tetrahedral geometry and selected bond lengths and angles are given in Table 6.

The complex (Fig. 4) is comparable with $[HgL^1Br_2]$ which has a similar donor set and distorted tetrahedral coordination geometry [8]. The ligand bite angle of 119.52(3)° in $[HgLBr_2]$ is close to that of 118.85(8)° in $[HgL^1Br_2]$. However the bond lengths in the coordination sphere of each complex are quite different. The two Hg–S bonds in $[HgLBr_2]$ are shorter at 2.5312(9) and 2.5173(9) Å compared to 2.678(2) and 2.552(2) Å in $[HgL^1Br_2]$ while the two Hg–Br

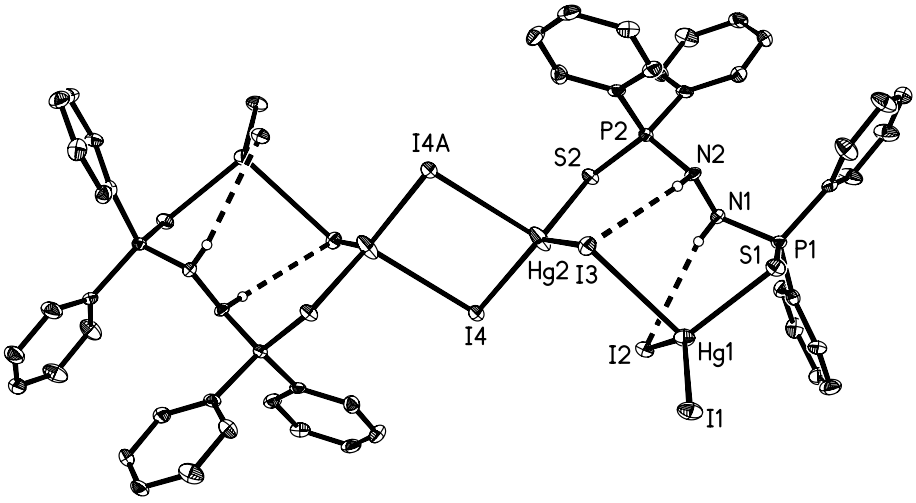

Fig. 3. Diagram of the tetrametallic complex $[\{L(HgI_2)_2\}_2]$. Thermal ellipsoids drawn at 50% probability level and most hydrogen atoms removed for clarity.

N1–N2	1.419(4)		
S1–Hg1–S2	119.52(3)	S2–Hg1–Br1	112.55(2)
S1–Hg1–Br1	98.82(2)	S2–Hg1–Br2	102.19(2)
S1–Hg1–Br2	112.98(2)	Br1–Hg1–Br2	111.107(12)
P1–S1–Hg1	107.43(4)	P2–S2–Hg2	108.36(4)

bonds are considerably longer at 2.6089(4) and 2.6078(4) Å compared to 2.5592(11) and 2.5509(11) Å.

A possible reason for this presents itself from an examination of the packing in [HgLBr$_2$]. Contrary to the conformation found in the bridging structures previously discussed, the N–H bonds on the ligand backbone of L are now directed towards the opposite side of the PNNP mean plane to the sulfur donor atoms. This allows adjacent molecules of [HgLBr$_2$] to engage in intermolecular hydrogen bonding in the crystalline state, with the distances H1···Br2A and H2···Br1A being 2.58 and 2.64 Å, respectively. It also results in a lengthening of the Hg–Br bonds along with any compensating effects due to short Hg–S bonds. The outcome is the formation of a second, seven-membered chelate-type ring *viz.* Hg1A–Br1A···H2–N2–N1–H1···Br2A in a bridging arrangement as columns of [LHgBr$_2$] stack along the *a*-axis (Fig. 5). Further

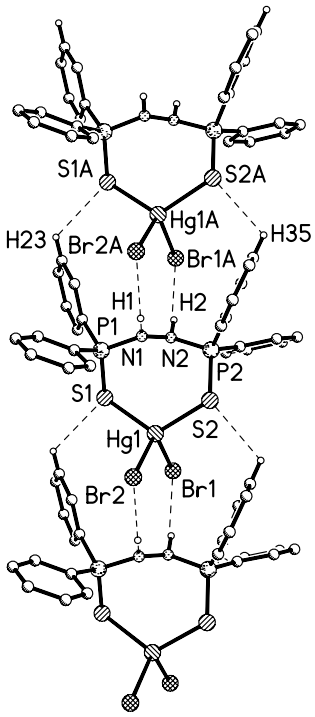

Fig. 5. A diagram showing how [HgLBr$_2$] molecules pack in columns along the *a*-axis.

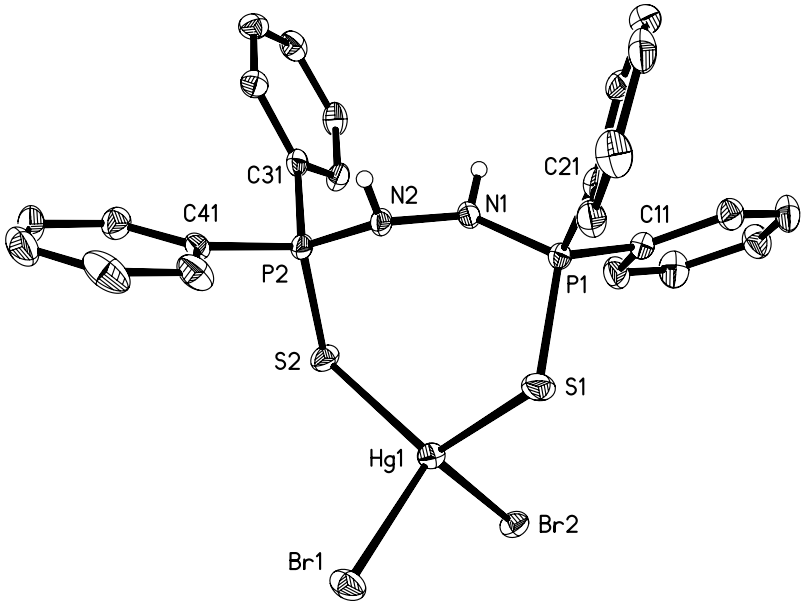

Fig. 4. Diagram of the complex [HgLBr$_2$]. Thermal ellipsoids drawn at 50% probability level and most hydrogen atoms removed for clarity.

reinforcement of the columnar array is provided by the close contacts S1A···H35 and S2B···H23 on adjacent molecules (2.916 and 2.835 Å, respectively). Interestingly, the N–N bond is significantly shorter at 1.419(4) Å than in the other structures described here [1.435(3)–1.450(4) Å] and the PNNP torsion angle is significantly larger (37.8°).

4. Conclusion

The ligand, 1,2-bis(diphenylthioylphosphino)hydrazine (L), reacts with copper(I) and mercury(II) halides affording the complexes, $[\{CuLX\}_2]$ (X = I, Br or Cl), $[HgLX_2]$ (X = Cl or Br) and the tetrametallic complex, $[\{L(HgI_2)_2\}_2]$. The complexes contain the metal in a four coordinate environment which approximates trigonal pyramidal for the copper complexes and distorted tetrahedral for the mercury complexes. In the dimetallic copper complexes L bridges the two metal atoms, with bridging halides completing the coordination sphere. The tetrametallic mercury complex, $[\{L(HgI_2)_2\}_2]$, also contains L bridging two Hg atoms but the two '$L(HgI_2)_2$' moieties are linked by coordinated iodide ions. Hydrogen bonds between the hydrazine N–H hydrogens of L and the halide ligands are an important feature in the structures of the metal complexes. This is a much more dominant effect than is observed with similar complexes of L^1, and is an interesting ligand design strategy.

Appendix A. Supplementary material

CCDC 646490–646494 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.009.

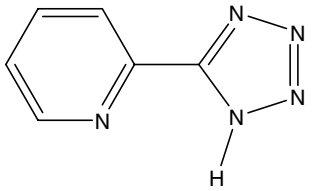

Fig. 1. Structure of 1 *H*, 5-(2′-pyridyl)tetrazole (H**pytz**).

tetrazolate ligands remains largely unexplored, with very few synthetic and structural studies appearing in the literature [11,12]. In previous work we demonstrated the possibility of using H**pytz,** whose structure is shown in Fig. 1, as a substitute for 2-picolinic acid, for the formation of hydrogels containing La^{3+} cations [12]. We showed that the formation of the gel was due to the capability of the tetrazolate ring to coordinate to the metal centre and, at the same time, form an extensive hydrogen-bonded network when water was added to the compound. These results prompted us to continue our investigation of the aqueous chemistry of different lanthanoid cations with **pytz**, focussing mainly on the structural aspects of the crystal lattices. In this work we concentrated our efforts on treating a range of lanthanoid chlorides with the tetrazolate ligands. Instead of using a 1:3 ratio, we systematically decreased the amount of ligand. This approach yielded the formation of cationic disubstituted complexes in the case of La, Gd and Ho, neutral trisubstituted for Ho, and hydroxo-bridged dimers for Y and Yb.

2. Experimental

Chemicals were obtained from Sigma–Aldrich and used as received. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker AM 300 spectrometer. Chemical shifts were recorded on the δ scale and referenced to the solvent. Infrared spectra were recorded on a Perkin–Elmer 1600 Series FTIR using solid state pellets (KBr). Melting points were measured on a Stuart Scientific Melting Point Apparatus SMP3 in an open capillary. Elemental Analyses were performed by Campbell Microanalytical Laboratory, Department of Chemistry, University of Otago, Dunedin, New Zealand. For compounds **2** and **3** elemental analysis on the bulk material revealed for C, H, and N a variable amount between 1.5% and 4% lower than the calculated values. We ascribed this results to the presence of NaCl in the bulk material, which co-precipitated along with the compounds. Crystallographic data were obtained either on an Enraf-Nonius KAPPA CCD or on a Bruker X8 APEX CCD diffractometer at 123 K. All compounds were measured with Mo Kα radiation of 0.71073 Å generated by a fine-focus sealed tube using a graphite monochromator. Scans were performed in ϕ and ω and 0.5° frames. All the molecular structures were solved using the program SHELXS-97 [13]. Refinement was carried out with the program SHELXL-97 against F^2 using least-squares methods [14]. For the X-ray data refer to Tables 1 and 2.

2.1. Synthesis of *Hpytz*

The ligand was synthesised following a literature procedure [15]. HCl 33% (2.1 ml, 23 mmol) was added to toluene (50 ml). After carefully adding triethylamine (3.2 ml, 23 mmol), 2-cyanopyridine (1.9 ml, 20 mmol) and NaN_3 (1.50 g, 23 mmol), the mixture was stirred under reflux for 22 h. The organic layer was then extracted with water, and the aqueous phase acidified to pH 5 by dropwise addition of HCl 10%. The white solid formed was then filtered, washed several times with water, and dried under reduced pressure. Yield 2.10 g, 71%. Mp = 212–213 °C. ^{1}H NMR

2.2. General synthetic procedure for the preparation of the complexes

H**pytz** (1 equiv) and hydrated $LnCl_3$ (2 equiv) were added to water and heated until all the solid was completely dissolved. A NaOH solution (1 M) was then added dropwise until a persistent precipitate appeared (pH ~ 6). The solution was then filtered and left undisturbed at room temperature and block shaped crystals were then harvested after several weeks. Compounds **1**–**6** were obtained with a 25–30% yield, after which crystallisation was stopped to prevent contamination due to co-precipitation of NaCl.

2.2.1. *[La(pytz)$_2$(H$_2$O)$_5$]Cl (**1**)*

IR: ν 3300(sb), 3056(s), 1668(w), 1607(m), 1572(w), 1462(w), 1428(m), 1392(m), 1288(m), 1165(m), 1061(w), 1037(w), 1004(w), 799(w), 694(w) cm^{-1}. *Anal.* Calc. for $C_{12}H_{18}ClLaN_{10}O_5$: C, 25.89; H, 3.26; N, 25.16. Found: C, 26.08; H, 3.32; N 25.02%.

2.2.2. *[Gd(pytz)$_2$(H$_2$O)$_5$]Cl (**2**)*

IR: ν 3300(sb), 1636(w), 1605(s), 1570(w), 1461(w), 1427(s), 1386(s), 1284(s), 1248(w), 1156(w), 1099(w), 1059(w), 1035(w), 1002(w), 796(w), 750(w), 728(w) cm^{-1}. Elemental analysis revealed minor contamination of the bulk material, probably due to co-precipitation of traces of NaCl.

2.2.3. *[Ho(pytz)$_2$(H$_2$O)$_4$]Cl (**3**)*

IR: ν 3448(sb), 1681(w), 1648 (m), 1637(m), 1602(s), 1573(w), 1559(w), 1530(w), 1459(s), 1397(m), 1286(m), 1162(w), 1130(w), 1112(w), 1066(m), 993(m), 750(m), 730(m) cm^{-1}. Elemental analysis revealed minor contamination of the bulk material, probably due to co-precipitation of traces of NaCl.

2.2.4. *[Ho(pytz)$_3$(H$_2$O)$_4$] · 4H$_2$O (**4**)*

Compound **4** was obtained via recrystallisation of **3** in water. IR: ν 3448(sb), 1686(w), 1654(m), 1637(m), 1611(s), 1570(w), 1560(w), 1534(w), 1466(s), 1390(m), 1286(m), 1169(w), 1133(w), 1102(w), 1060(m), 1005(m), 750(m), 732(m) cm^{-1}. *Anal.* Calc. for $C_{18}H_{22}HoN_{15}O_5$: C, 31.18; H, 3.20; N, 30.30. 2.2.5. *[Yb$_2$(pytz)$_4$ (μ-OH)$_2$(H$_2$O)$_4$] · 2H$_2$O (**5**)*

IR: ν 3094(sb), 1612(s), 1572(m), 1467(m), 1423(s), 1399(m), 1288(m), 1252(w), 1174(w), 1155(m), 1138(w), 1101(w), 1063(w), 1042(w), 1007(m), 903(w), 800(m), 751(s), 733(s), 634(m) cm^{-1}. *Anal.* Calc. for $C_{24}H_{34}Yb_2N_{20}O_{10}$: C, 26.00; H, 3.09; N, 25.27. Found: C, 26.08; H, 2.93; N, 24.91%.

2.2.6. *[Y$_2$(pytz)$_4$ (μ-OH)$_2$(MeOH)$_2$](H$_2$O)(MeOH) (**6**)*

Compound **6** was obtained with a different procedure: H**pytz** (0.29 g, 2 mmol) and YCl_3 (0.30 g, 1 mmol) were added to methanol (20 ml) and kept under vigorous stirring. NEt_3 (0.7 ml, 5 mmol) was then added dropwise over a period of 1 h, and the reaction was left stirring at room temperature for 36 h. The solvent was completely evaporated under reduced pressure and the residual solid mixture was washed with isopropanol to remove triethylamonium chloride. The leftover solid was then redissolved in methanol. Colourless block-shaped crystals were obtained after 3 weeks by diffusing isopropanol vapours into the solution. IR: ν 3199(sb), 1654(m), 1609(s), 1570(m), 1464(m), 1430(s), 1287(m), 1168(w), 1068(w), 1042(w), 900(w), 734(s), 634(m) cm^{-1}. *Anal.* Calc. for $C_{26}H_{38}Y_2N_{20}O_{10}$: C, 32.24; H, 3.95; N, 28.92. Found: C, 31.92; H, 3.80; N, 28.82%.

3. Results and discussion

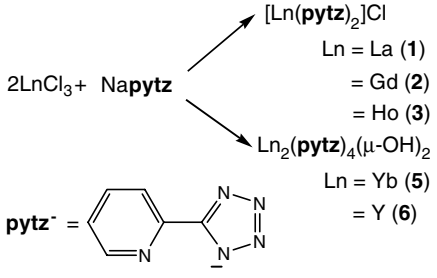
3.1. Synthesis of the lanthanoid complexes

H**pytz** was synthesised, following a literature procedure [15], by treating 2-cyanopyridine with NaN_3 in toluene in the presence of triethylammonium chloride. The ligand, usually in its sodium salt form (generated by treatment of H**pytz** with NaOH *in situ*), was then reacted with the corresponding lanthanoid chloride. The synthesis was performed either in water or methanol as the products were insoluble in these solvents and could be easily purified from unreacted reagents by washing the precipitate after isolation. As previously reported in the literature, a stoichiometry of 1:3

metal to ligand leads to the formation of neutral trisubstituted complexes [11]. Since the tetrazolate anion can chelate forming 5-membered rings, but also bridge through the four remaining electron pairs of the N atoms, we investigated the synthesis using a deficit of ligand in the reaction mixture. Therefore $LnCl_3$ and **pytz** were mixed together in a 2:1 stoichiometric ratio. The purpose of using a lower quantity of ligand was initially to favour the formation of polynuclear compounds such as oxo/hydroxo polynuclear clusters [16]. This same procedure is known to yield such cages using carboxylates as ligands [17]. Instead, either disubstituted cationic complexes or hydroxo-bridged dimers were isolated and characterised (Scheme 1). Interestingly, in a stoichiometric ratio 2:1 metal to ligand, there is a lack of propensity to redistribute (Eq. (1)), which is a relatively common phenomenon in rare earth chemistry [18].

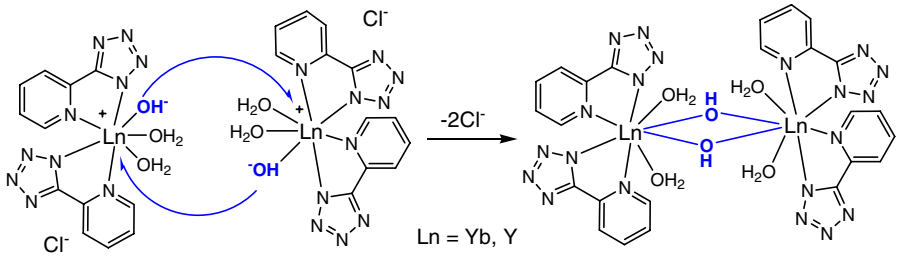
$$3LnL_2Cl \rightarrow 2LnL_3 + LnCl_3 \quad (1)$$

However, recrystallisation of the disubstituted compounds in hot water yielded the trisubstituted analogues, due to the fact that during the recrystallisation the metal to ligand ratio is decreased from 2:1 to 1:2. All the compounds were characterised, along with X-ray diffraction, with standard analytical techniques (IR, elemental analysis). In particular, the IR spectra show common features such as strong absorptions above 3000 cm^{-1} belonging to the water and hydroxo O–H vibration, and between 1660 and 1600 cm^{-1} for the tetrazolate C=N. All the compounds decompose around 300–310 °C.



Compared with the corresponding lanthanoid carboxylates, which tend to form polymeric networks when reacted in 1:3 metal to ligand stoichiometry [19], the tetrazolate complexes are individual molecular entitites with a high tendency to interact via hydrogen bonding and π-stacking. This difference is probably due to the chelating and bridging capability of the carboxylate and the strong oxophilic nature of the lanthanoid cations.

Although we were able to grow single crystals suitable for X-ray diffraction for all the complexes, complete purification and isolation of $[Gd(\mathbf{pytz})_2(H_2O)_5]Cl$ and $[Ho(\mathbf{pytz})_2(H_2O)_4]Cl$ from the bulk material proved to be complicated, as evidenced by elemental microanalysis. This was probably due to co-precipitation of NaCl in the bulk, since cationic disubstituted complexes have a higher water solubility compared with neutral trisubstituted ones. However, since high quality single crystal X-ray data of these two complexes could be collected, we have included their solid state structural information here. Compared with previous literature studies of lanthanoid tetrazolates obtained under anhydrous conditions, in the aquo complexes only the tetrazolate nitrogen, bearing the negative charge, and the pyridine nitrogen bind the metal cations [20], thus forming a chelating five membered ring. The other three nitrogen atoms of the **pytz** ligand are involved in the hydrogen bonding network of the lattice.



In the case of Yb^{3+} and Y^{3+}, the resulting complex is a neutral hydroxo-bridged dimer. This result can be rationalised by the increased Lewis acidity of these smaller cations, which promotes more effectively proton dissociation from the water molecules coordinated to the metal. The resulting hydroxo complex then coordinates to another metal centre displacing the chloride anion and forming the hydroxo-bridged dimers, as illustrated in Scheme 2.

3.2. X-ray crystal structures of the complexes $[Ln(pytz)_2(H_2O)_n]Cl$ Ln = La, Gd, n = 5; Ln = Ho, n = 4

Fig. 2 shows the crystal structure of $[La(\mathbf{pytz})_2(H_2O)_5]Cl$. The complex crystallises in the orthorhombic space group Fddd, with only half of the molecule belonging to the asymmetric unit. The La^{3+} cation is overall nonacoordinated by two chelating **pytz** ligands and five molecules of water. The remaining chloride anion is located outside the first coordination sphere. The two **pytz** are almost coplanar (ca. 145°) in a pseudo trans arrangement, facing each other in an antiparallel fashion with the tetrazolate ring facing the opposing pyridine ring. The five molecules of water are organised into a slightly distorted square based

Scheme 1. Synthesis of the complexes **1**–**6**.

pyramid with the apical water separated from the base by the plane of the two **pytz** ligands. All the five coordinated water molecules and the chloride counterion participate in the formation of an extended hydrogen-bonded network. The chloride anions are trapped in cavities formed between six adjacent complexes. The cavity, shown in Fig. 3a, is approximately rectangular in shape with dimensions of ca. 15.2×6.7 Å. The chloride ion is hydrogen-bonded in the centre of four La bound water molecules (O···Cl 3.1 Å). Each of the four molecules at the base of the pyramid is involved in hydrogen-bonding with Cl^-. The four remaining hydrogen atoms bind to the N3 and N4 atoms of two other ligands. The packing also reveals close contacts of the ligands via formation of π stacking, with a distance of 3.6 Å between the planes of the two **pytz** ligands. The complexes arrange themselves in a "zipper" fashion with strands parallel to the direction of the *a* axis, as shown in Fig. 3b.

$[Gd(\mathbf{pytz})_2(H_2O)_5]Cl$ is isostructural with the lanthanum analogue, with only small differences in the bond lengths between the metal and surrounding ligands and water molecules due to the smaller size of Gd^{3+} [18] (Table 3). In the case of Ho^{3+}, the structure of the disubstituted complex has one less molecule of water in the coordination sphere of the metal, $[Ho(\mathbf{pytz})_2(H_2O)_4]Cl$ (Fig. 4), presumably due to the lanthanoid contraction effect [18]. Interestingly though, this effect is not observed in the case of trisubstituted complexes, $[Ln(\mathbf{pytz})_3(H_2O)_3]$ Ln = La, Gd, Ho, Dy [11], where the solid state structure remains unchanged moving from the larger to the smaller lanthanoid cations. In fact, the crystal structure of $[Ho(\mathbf{pytz})_3(H_2O)_3]$, which was obtained via recrystallisation in hot water from $[Ho(\mathbf{pytz})_2(H_2O)_4]Cl$, is isomorphous with its homologues $[Ln(\mathbf{pytz})_3(H_2O)_3]$ Ln = La, Gd, Eu, Dy [11], with only minor variations in the Ho–O and Ho–N distances between the metal and the ligands (Table 3) due to the difference in the ionic radii [18]. $[Ho(\mathbf{pytz})_2(H_2O)_4]Cl$ crystallises in the monoclinic space group $P2_1/n$. The metal centre is octacoordinated by two ligands and four molecules of water. Compared with the structures of La and Gd, the apical water is lost, causing a closing of the angle between the two **pytz** ligands (ca. 97°). Again the two **pytz** arrange themselves in an antiparallel fashion with the tetrazole ring opposing the pyridine in a pseudo trans arrangement. The bond lengths show no significant variation from the previous two complexes (Table 3), although they are generally shorter due not only to the smaller ionic radii of Ho^{3+} compared with La^{3+} and Gd^{3+}, but also due to the less steric demand of the octacoordinated metal centre. As for the previous compounds, there is an extensive hydrogen bonding throughout the crystal lattice involving the tetrazolate rings, the coordinated water molecules and the chloride anions. The chloride anions are paired at a distance of 3.6 Å and are confined in a large cavity formed by a total of four water molecules (Fig. 5a). The cavity is approximately a rectangle of ca. 4.9×6.9 Å. Each chlorine ion is

hydrogen-bonded by three molecules of water respectively, with an average O···Cl distance of ca. 3 Å. The different arrangement of the tetrazolate favours the formation of a π stacking structure with a distance of ca. 4 Å between the planes of the two **pytz** ligands (Fig. 5b).

3.3. Crystal structures of the complexes $[Ln_2(pytz)_4(\mu\text{-}OH)_2(H_2O)_n(CH_3OH)_m]$ Ln = Yb, n = 4, m = 0; Ln = Y, n = 2, m = 2

Fig. 6 shows the crystal structure of $[Yb_2(\mathbf{pytz})_4(\mu\text{-}OH)_2(H_2O)_4]$. The hydroxo-bridged Yb dimer crystallises in the monoclinic space group centrosymmetric $P2_1/n$, and only half of the molecule belongs to the asymmetric unit. The centre of inversion is located in the middle of the parallelogram formed by the two Yb atoms and the two bridging OH groups. Both metals are octacoordinated by two chelating **pytz** ligands, two hydroxyl groups and two water molecules. Two extra water molecules are present in the lattice and are involved in the hydrogen-bonded network, along with the coordinated waters and the tetrazolate nitrogen atoms. Each of the two units forming the dimer is almost identical to the structure of the disubstituted Ho complex, with just small variations in the angles between the four oxygen and the two **pytz** ligands (Tables 3 and 4). However, in this case, not all the nitrogen atoms of the tetrazolate ligands are involved in the hydrogen-bonded network. All the four water molecules bind through the lattice, but the two bridging OH groups are not involved in any hydrogen bonding. Cavities are present in the lattice where four molecules of water are trapped (Fig. 7). Two of these are lattice waters, at two opposite

vertices of the rectangle, and they are connected to the N3 atom of a tetrazole and to the N4 atom of an adjacent **pytz** ligand. The ligands interact via an offset face to face π stacking (C···pyridine 3.46 Å).

The analogous dimeric complex of Y was obtained following a different synthetic method. We attempted to obtain tetrazolate Y oxo-hydroxo clusters with the methodology proposed by Roesky et al. [21]. Instead only the dimeric hydroxo-bridged complex was obtained (Fig. 8). The molecule crystallises in the triclinic $P\bar{1}$ space group and, as in the case of Yb, it is centrosymmetric with the centre of inversion between the metals and hydroxo groups. Both Y cations are octacoordinated by two ligands, two hydroxo, a molecule of water and a molecule of methanol. An extra molecule of water and one of methanol are present in the lattice forming the hydrogen-bonded network. The distances of the oxygen and nitrogen atoms of the first coordination sphere ligands are smaller for the Yb dimer, as expected due to its smaller ionic radius compared with Y^{3+}. Similarly to the analogous Yb dimer, all the tetrazolate ligands are involved in an offset face-to-face π stacking with an average distance of 3.36 Å between the rings.

4. Conclusions

The preparation and X-ray structural study of several new cationic disubstituted and neutral hydroxo-bridged dimeric lanthanoid tetrazolate (La, Gd, Ho, Yb, Y) has been presented in this work. Due to the intimate relationship between the crystal lattice packing and the properties of the material, we have closely investigated the intermolecular interactions of the crystal structures of all the compounds. Compared with the corresponding lanthanoid carboxylates (such as picolinic acid or benzoic acid and

its corresponding functionalised analogues [19b,19c]), which tend to form polymeric networks due to the chelating and bridging capability of the ligand and the strong oxophilic nature of the lanthanoid cations, the tetrazolate complexes are individual molecular entitites with a high propensity to interact via hydrogen bonding and π-stacking. The chemistry of the tetrazolate anion with the rare earth elements, still largely unexplored, is of potential interest for a variety of fields due to the combination of the coordinating capability of the ligand, the low toxicity of the tetrazole ring and lanthanoid complexes, and properties such as Lewis acidity, luminescence, and magnetism of the f-block elements.

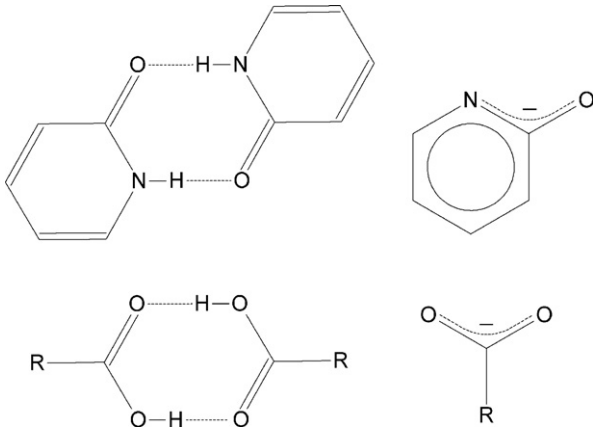
Scheme 1. A tautomeric equilibrium between lactam (a and b) and lactim (c) forms of 2-pyridone (2-hydroxypyridine).

region of the X-band spectrum (9 GHz) [16,23]. On the other hand, only rare cases of H_{x1} and H_{y1} for tetracarboxylates are reported [24], next to the typical four H_{x2}, H_{y2}, H_{z1}, and H_{z2}.

In this paper, we present the structure of $[Cu_2(\mu\text{-}L)_4(HL)_2]$ (**1**) (HL = 2-pyridone) and its characterization, together with a comparison to a mixed pyridin-2-olato/methanoato analogues $[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}L)_2(HL)_2]\cdot 2CH_3CN$ (**2**) and $[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}L)_2(HL)_2]$ (**2a**).

2. Experimental



2.1. Synthesis

Compound $[Cu_2(\mu\text{-}HCO_2)_4(2\text{-mpy})_2]$ was prepared by 2-methylpyridine (75 mmol) in absolute ethanol (40 mL), adding β-$Cu(HCO_2)_2$ (4 mmol). A boiling solution was filtered, cooled down to the room temperature and than to 6 °C for 24 h. The light green product was filtered and dried over KOH for a day. β-$Cu(HCO_2)_2$ was isolated from concentrated methanoic acid (20 mL) and $Cu_2(OH)_2CO_3$ (9 mmol) at room temperature. $Cu_2(OH)_2CO_3$ was prepared from $CuSO_4\cdot 5H_2O$ (60 mmol) and $Na_2CO_3\cdot 10H_2O$ (75 mmol) in water at 65 °C. Other chemicals were readily available from commercial sources and were used as received without further purification.

*$[Cu_2(\mu\text{-}L)_4(HL)_2]$ (**1**) (HL = 2-pyridone).* The compound was prepared by a different procedure as described previously [25]. HL (0.48 g, 5.0 mmol) was dissolved in 20 mL of acetone. $[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}L)_2(HL)_2]$ (**2a**) (0.30 g, 0.50 mmol) was added to the HL solution during heating and stirring. The temperature was stabilized below boiling point for 10 min. A dark green product (**1**) was filtered off, dried on air for 20 min and in a desiccator over KOH for 24 h. Yield: 85%. *Anal.* Calc. for $C_{30}H_{26}Cu_2N_6O_6$ ($M_r = 693.7$): C, 51.9; H, 3.8; N, 12.1; Cu, 18.3. Found: C, 50.9; H, 3.9; N, 11.7; Cu, 18.3%. IR $\bar{\nu}$, 3550–3300 ν(NH), 1656s ν(C=O), 1608s, 1582 ν_{as}(C=O) + ν(ring), 1539, 1507s, 1464, 1441, 1429s, 1349 cm^{-1}. UV/Vis λ_{max}, 300, 380(sh), 610 nm. EPR (95 K) $S = 1$: $g_x = 2.04$, $g_y = 2.05$, $g_z = 2.29$, $A_{z1} = 8.0$ mT, $D = 0.293$ cm^{-1}, $E = 0.0016$ cm^{-1}, $2J = -334$ cm^{-1}. $S = 1/2$: $g_\perp = 2.06$, $g_\parallel = 2.30$. For the powder XRD data see Table 1.

The single crystals for **1**, suitable for the X-ray analysis, were obtained by a similar procedure as described above, but $[Cu_2(\mu\text{-}HCO_2)_4(2\text{-mpy})_2]$ (2-mpy = 2-methylpyridine) was used instead of $[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}L)_2(HL)_2]$ (**2a**) (1.52 g HL, 30 mL acetonitrile, 0.31 g $[Cu_2(\mu\text{-}HCO_2)_4(2\text{-mpy})_2]$). The boiling solution was cooled down and left at 6 °C for 24 h. Crystal data: **1**, $M_r = 693.7$ ($C_{30}H_{26}Cu_2N_6O_6$), monoclinic, $a = 8.2943(4)$ Å, $b = 12.4522(6)$ Å, $c = 13.9052(7)$ Å, $\beta = 106.389(2)°$, $V = 1377.81(12)$ $Å^3$, $T = 150(2)$ K, space group $P2_1/n$, $Z = 2$, $D_x = 1.672$ g/cm^3, $\mu = 1.602$ mm^{-1}, crystal size $0.10 \times 0.04 \times 0.02$ mm^3 (green plate), 13491 reflections measured (integrated), θ_{max} 25.03°, 2420 unique ($R_{int} = 0.06$), 1621 observed [$F^2 > 2\sigma(F^2)$], $R = 0.058$ ($R = \sum(\|F_o| - |F_c\|)/\sum|F_o|$), $wR = 0.032$ ($wR = \sum(w\|F_o| - |F_c\|)/\sum(w|F_o|)$), 199 refined parameters.

*$[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}L)_2(HL)_2]\cdot 2CH_3CN$ (**2**), $[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}L)_2(HL)_2]$ (**2a**) (HL = 2-pyridone).* Compound **2** was prepared as described previously [6]. HL (0.38 g, 4.0 mmol) was dissolved in 27 mL of acetonitrile during heating and stirring. This solution was slowly added to 0.31 g (0.80 mmol) of $[Cu_2(\mu\text{-}HCO_2)_4(2\text{-mpy})_2]$. The boiling solution was filtered to remove the undissolved solid particles and the obtained filtrate was cooled to the room temperature and left at 6 °C for 24 h. Green crystals of **2** were filtered off and dried on air for 20 min and in a desiccator over KOH for 24 h. During the drying, compound **2** decomposes by removal of the solvate acetonitrile, giving **2a**. All the characterization data mentioned in this paragraph are for **2a**. Yield: 60%. *Anal.* Calc. for $C_{22}H_{20}Cu_2N_4O_8$ **2a** ($M_r = 595.5$): C, 44.4; H, 3.4; N, 9.4; Cu, 21.3. Found: C, 43.6; H, 3.5; N, 9.4; Cu, 20.6%. IR $\bar{\nu}$, 3600–3300 ν(NH), 1664s ν(C=O), 1624s, 1611, 1593 ν(C=O) + ν(ring), 1578s $\nu_{as}(CO_2)$, 1541, 1480, 1444, 1430s $\nu_s(CO_2)$, 1348 cm^{-1}. UV/Vis λ_{max}, 310, 380(sh), 670 nm. EPR (95 K) $S = 1$: $g_\perp = 2.05$, $g_\parallel = 2.31$, $A_{z1} = 6.1$ mT, $D = 0.347$ cm^{-1}, $2J = -324$ cm^{-1}. $S = 1/2$: $g_\perp = 2.06$, $g_\parallel = 2.35$.

Scheme 2. A comparison between 2-pyridone and carboxylic acid and their anions. Free neutral molecules form dimeric structures, while deprotonated species enable bridges (O–C–O, N–C–O) with the delocalized double-single bonds.

2.2. Physical measurements

Metal analysis was carried out electrogravimetrically with Pt electrodes. C, H, N analysis was performed with

Table 1
Measured and calculated interplanar spacings (d/Å) with their relative intensities (I_r) for **1** [26]

d_m	9.2	8.0	6.8		6.2	5.5	4.93	4.34	4.23		3.97	3.79	3.53	3.40

a Perkin–Elmer Elemental Analyzer 2400 CHN. Powder XRD data were obtained by a Guinier Enraf Nonius FR 552 camera with Cu Kα, while the calculations $d(I)$ by 'X'Pert HighScore Plus' programme [26]. Infrared spectra were measured on mineral oil mulls, using a Perkin–Elmer FT-IR 1720X spectrometer. Electronic spectra were recorded as nujol mulls with a Perkin–Elmer UV/Vis/NIR spectrometer Lambda 19. X-band EPR spectra of powdered samples were recorded by a Bruker ESP-300 spectrometer. The values of parameters g, A, D, E and $2J$ were calculated directly from the signal positions in the spectra [27,28]. The magnetic susceptibility data of powdered polycrystalline samples were measured with a Quantum Design SQUID magnetometer, equipped with a 5 T magnet. The molar magnetic susceptibility χ_M was investigated in the temperature interval between 300 and 2 K in a magnetic field strength $H = 1000$ Oe. The data were corrected for the experimentally determined contribution of the sample holder. Corrections for the diamagnetic response of the compounds, due to the closed atomic shells as estimated from the Pascal's constants, were applied [29].

2.3. X-ray structure analysis

The diffraction data for **1** were collected on a Nonius Kappa CCD diffractometer with a graphite-monochromated Mo Kα radiation. The data were processed using DENZO [30]. A crystal structure was solved by direct methods using SIR-97 [31] and refined using Xtal 3.6 [32] by a full-matrix least-squares procedure based on F. All of the non-hydrogen atoms were refined anisotropically. The positions of the hydrogen atoms were located using difference Fourier map, while their parameters were not refined. Selected distances and angles for **1** are in Table 2.

3. Results and discussion

3.1. The crystal structure of $[Cu_2(\mu\text{-}L)_4(HL)_2]$ (1) (HL = 2-pyridone) tetrakis(μ-pyridin-2-olato-1κ^{2}O:2κ^{2}N,1κ^{2}N:2κ^{2}O)bis(2-pyridone-κO)dicopper(II)

The centrosymmetric dinuclear coordination molecule of **1** is formed by two copper atoms bridged by four pyridin-2-olato ligands, similarly as for $[Cu_2(\mu\text{-}CH_3CO_2)_4(H_2O)_2]$ type of complexes. Herein, the ligands enable N–C–O bridges in *syn–syn* mode, giving two nitrogen and two oxygen atoms around each copper at a distance (Cu–N2 2.003(5), Cu–N3 2.007(5) Å, Cu–O4 1.978(5), Cu–O11 1.964(4) Å). The square-pyramidal copper coordination sphere is completed by the apical neutral 2-pyridone molecule (Cu–O2 2.227(5) Å) (Fig. 1). Thus, a hydronated nitrogen atom of the apical ligand enables an intramolecular hydrogen bond (N1–H1···O4 2.707(8) Å, 159°) stabilizing the dinuclear molecule. These molecules are intra-connected by π–π stacking interactions via rings of the axial 2-pyridone and one of the pyridin-2-olato ligands (centroid–centroid distance 3.779(4)–3.791(4) Å, mean inter-planar separation 3.248–3.552 Å).

Compound **1** was already reported and partly characterized [25]. The herein shown crystal structure is in agreement with the predictions of the copper acetate hydrate type of complex. Structurally, several compounds show strong similarity to **1** in a form of $[Cu_2(\mu\text{-}L1)_4(L2)_2]$ (L1 = a ligand with a triatomic bridge, L2 = axial ligand), namely, $[Cu_2(\mu\text{-}CH_3CO_2)_4(HL)_2]$ [10], $[Cu_2(\mu\text{-}HCO_2)_2$-

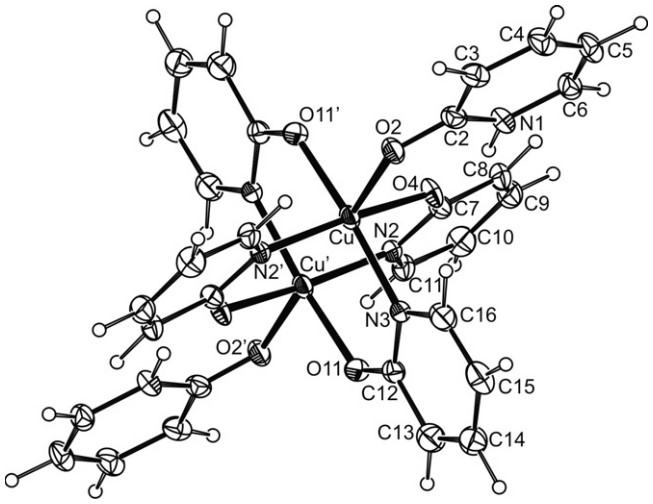

Fig. 1. The dinuclear structure of **1**, with four *paddle-wheel* bridging pyridin-2-olato and two terminal 2-pyridone ligands (Cu···Cu 2.609(1) Å). The thermal ellipsoids are drawn at the 30% probability level [33].

$(\mu\text{-L})_2(\text{HL})_2]\cdot 2CH_3CN$ (**2**) (HL = 2-pyridone) [6], and $[Cu_2(\mu\text{-3-ethyl-2-pyO})_4(DMF)_2]$ [12].

In the EPR spectra of complexes **1** and **2a**, three signals H_{z1}, $H_{\perp 2(x,y)}$ and H_{z2} for $S = 1$ are found. Additionally, a $H_{\perp 1(x,y)}$ at 100 mT is noticed in the 295 and 95 K spectra of **1** without any significant change of its relative intensity. A presence of the $H_{\perp 1}$ signal for **1** is in accordance with a relation of the axial zero-field splitting parameter D and $h\nu$ (0.293 (**1**) < 0.320 ($h\nu$) $< 0.347\ \text{cm}^{-1}$ (**2a**)). On the other hand, no $H_{\perp 1}$, but several temperature dependent signals in the 100–450 mT region are noticed for **2a** (Fig. 2). Since these broad signals are absent in the 95 K spectrum of **2a**, their origin is assumed to be due to $S = 1$ spin inter-dinuclear interactions [34–36]. This assumption is actually not in clear agreement with the shown isolated dinuclear structure of **2** [6], where direct $S = 1$ spin interactions should not be possible, due to an absence of the inter-dinucler bridges. On the other hand, the crystal structure of **2** is not an exact figure of compound **2a** (**2** unstable in air, giving **2a**), since **2** was characterized only by the XRD single crystal structure analysis, while **2a** with all the other herein described methods. The $S = 1$ EPR signals of **2a** confirm the existence of the *paddle-wheel* dinuclear structure. Thus, the inter-dinuclear interactions may take place via partly rearranged ligands (**2** → **2a**) possibly establishing new bridges, or via π–π interactions, noticed already in the structure of **2**, via rings of the apical ligands (centroid–centroid distance 3.622(1) Å, mean inter-planar separation 3.297, 3.302 Å).

A feature of the $S = 1$ system spectra with four N–C–O bridges (**1**) is almost identical to a system with four bridging carboxylate analogues. The $H_{\perp 1}$ signal in the X-band spectra is, however, more commonly observed for the N–C–O bridged complexes [16,23] than for the carboxylates (O–C–O) [24]. It seems that a substitution of oxygen with nitrogen atoms in such a triatomic bridge, plays a crucial role in the arrangement of the $S = 1$ system bands. Namely, in a 4-azabenzimidazole *paddle-wheel* complex [37] with an N–C–N bridge, the $H_{\perp 1}$ is noticed at 250 mT in the X-band spectrum showing significantly smaller axial deviation ($D = 0.124\ \text{cm}^{-1}$). Nevertheless, the rigidity of the bridge should also be taken into account.

The magnetic susceptibility $\chi_M \cdot T$ ($B_0 = 0.1$ T) of compounds **1** and **2a** gradually decreases by lowering temperature (Fig. 3), that is characteristic for the antiferromagnetic interaction typical for *paddle-wheel* dicopper complexes. The experimental data for the dinuclear compounds can be well reproduced by considering the expression of χ_M (Eq. (1)) derived from the Heisenberg Hamiltonian (Eq. (2)) [38].

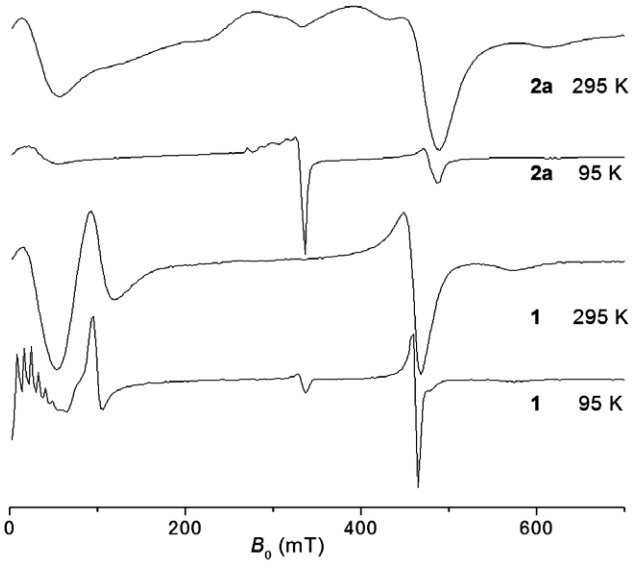

Fig. 2. EPR spectra of **1** and **2a**, respectively, with the regular $S = 1$ signals for the $[Cu_2(\mu\text{-L1})_4(L2)_2]$ type of complexes. Additionally, the $H_{\perp 1}$ signal is present in the spectra of **1**, while several broad signals only in the room temperature spectrum of **2a**.

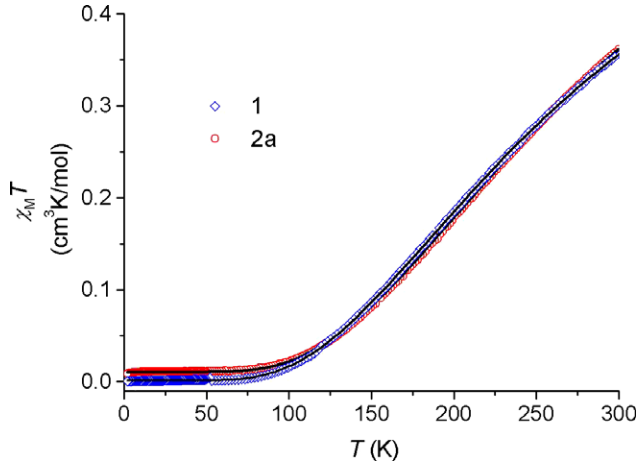

Fig. 3. A strong antiferromagnetism shown in a graph as $\chi_M \cdot T(T)$ of compounds **1** ($2J = -367\ \text{cm}^{-1}$) and **2a** ($2J = -396\ \text{cm}^{-1}$), respectively.

$$\chi_M = (1-\rho)\frac{2N_A g^2 \mu_B^2}{k_B T(3+e^{-2J/k_B T})} + \rho\frac{N_A g^2 \mu_B^2}{2k_B T} \quad (1)$$

$$\widehat{H} = -2J\widehat{S}_1 \cdot \widehat{S}_2 \quad (2)$$

The best-fit parameters give a measure of the gyromagnetic constant g, the magnetic interaction $2J$ and a yield of the non-dinuclear Cu(II) species ρ (**1**: $\rho = 0.2\%$, $g = 2.04$, $2J = -367\ cm^{-1}$; **2a**: $\rho = 1.3\%$, $g = 2.14$, $2J = -396\ cm^{-1}$). The results for **1** generally agree with the reported values $2J = -340\ cm^{-1}$ and $g = 2.10$ [25]. Relatively high amount of the non-dinuclear species noticed for **2a** ($\rho = 1.3\%$, see also Fig. 2, 330 mT signals), confirms an important change in the structure during the decomposition of **2** outside mother-liquid, though the dinuclear cage structure preserves. In relation to this, much larger deviations of $|2J|$ (cm^{-1}) values for **2a**, obtained by the two magnetically based methods are noticed (χ_M(EPR): **1** 367 (334), **2a** 396 (324)). Thus, EPR values seem more accurate in this case than χ_M due to Eq. (1) limitations.

So far we described two ways of extracting the singlet–triplet energy gap $2J$ and the gyromagnetic constant g values of the complexes **1** and **2a**, both derived from quantum mechanics. The EPR approach takes place via six 'Wasserman' equations [27], while Kahn [38–41] established the later introduced magnetic susceptibility path. Despite small differences between the results of both methods, there is clear similarity giving relatively comparable results. According to Kahn [38], it is possible to derive the expression for the magnetic interaction constant $2J$ (Eq. (3)), which relates its ferro-/antiferro-magnetic character with the spatial symmetry of magnetic orbitals.

$$2J = E_S - E_T = 2k + 4\beta s \begin{cases} >0 & (\text{ferromagnetism}, E_S > E_T) \\ <0 & (\text{antiferromagnetism}, E_S < E_T) \end{cases} \quad (3)$$

where k is the Coulomb repulsion integral for two centres >0; s is the overlap integral >0 and β is the Coulomb one electron integral – orbital energy <0.

4. Concluding remarks

The coordination compound $[Cu_2(\mu\text{-L})_4(HL)_2]$ (**1**) (HL = 2-pyridone) shows a dinuclear cage structure with four triatomic N–C–O pyridin-2-olato bridges coordinated in the *syn–syn* mode, similar as in the related copper(II) acetate hydrate type of complexes. The apical positions are fulfilled by neutral 2-pyridone ligands. The EPR spectra show six signals, as suggested for $S = 1$ spin state, although usually only four are observed. The EPR and magnetic susceptibility analysis reveal similar results for g and $2J$ values. A related mixed pyridin-2-olato/methanoato complex $[Cu_2(\mu\text{-HCO}_2)_2(\mu\text{-L})_2(HL)_2]$ (**2a**) shows similarly strong antiferromagnetic properties. Significantly larger axial zero-field splitting parameter D for **2a** than for **1** is in agreement with an appearance of the $H_{\perp 1}$ signal only for **1**. A decomposition of $[Cu_2(\mu\text{-HCO}_2)_2(\mu\text{-L})_2(HL)_2]\cdot 2CH_3CN$ (**2**) giving $[Cu_2(\mu\text{-HCO}_2)_2(\mu\text{-L})_2(HL)_2]$ (**2a**), do not have a noticeable impact on the *paddle-wheel* structure that remain preserved in **2a**, though also shows an important change in the structure, possibly by stronger inter-dinuclear associations than suggested only by the molecular structure of **2**.

amide carbonyl O atom, or only via the pyridyl N atom [10,14–16]. The neutral ligands have been used to synthesize copper(I) [14,16], copper(II) [10] and zinc(II) [15] complexes. Under basic conditions the anionic amidate form additionally coordinates via the amidate N atom, allowing a chelating/bridging coordination mode that gives rise to copper(II) monomers with HL^{SMe} [9] or copper(II) dimers and clusters with the other ligands [10,11]. Here we report the synthesis and structures of mononuclear copper(II) complexes with neutral pyridylmethylamide ligands. Specifically, we report the synthesis and structural characterization of $[Cu(HL)_2(OTf)_2]$ (**1**), $[Cu(HL^{Me})_2](ClO_4)_2$ (**2**), $[Cu(HL)_2Cl]_2[CuCl_4]$ (**3**), $[Cu(HL^{Me3})_2(THF)](OTf)_2$ (**4**), $[Cu(HL^{Me3})_2(H_2O)](ClO_4)_2$ (**5a**), $[Cu(HL^{Me3})_2(H_2O)](ClO_4)_2$ (**5b**), $[Cu(HL^{Ph3})_2(H_2O)](ClO_4)_2$ (**6**), $[Cu(HL)(2,2'\text{-bipy})(H_2O)](ClO_4)_2$ (**7**) and $[Cu(HL^{Ph})(2,2'\text{-bipy})(H_2O)](ClO_4)_2$ (**8**).

2. Experimental

2.0.1. General

All reagents were purchased from commercial sources and used without further purification. Solvents were dried and purified under nitrogen using standard methods and distilled immediately before use. ^1H NMR spectra were measured on a Varian 300 MHz spectrometer using solvent as an internal standard [^1H δ ($CHCl_3$) = 7.27 ppm; ^1H δ (CH_3OH) = 4.87 ppm; ^{13}C δ ($CHCl_3$) = 77.23 ppm]. Elemental analyses were carried out by Atlantic Microlabs (Norcross, GA). Mass spectra were recorded on a Q-TOF quadrupole time-of-flight mass spectrometer equipped with a Z-spray electrospray ionization (ESI) source (Micromass, Manchester, UK). FTIR spectra were recorded on a Nexus 470 FTIR spectrometer. X-band EPR spectra were recorded on a Bruker EMX spectrometer at 77 K as frozen solutions. The ligands *N*-(2-pyridylmethyl)acetamide (HL), 2-phenyl-*N*-(2-pyridylmethyl)acetamide (HL^{Ph}), 2,2-dimethyl-*N*-(2-pyridylmethyl)propionamide (HL^{Me3}) and 2,2,2-triphenyl-*N*-(2-pyridylmethyl)acetamide (HL^{Ph3}) were synthesized according to published procedures [10,11].

Caution: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Although no problems were encountered in this work, only small amounts of material should be prepared and handled with caution.

2.1. N-(2-pyridylmethyl)propionamide (HL^{Me})

The synthesis of HL^{Me} was carried out via a modified procedure based upon an established method [29]. 2-(Aminomethyl)pyridine (1.08 g, 10 mmol) and propionic anhydride (5.50 g, 42.3 mmol) were dissolved in 3 mL of pyridine and stirred at room temperature for 24 h, after which 4 mL of water was added with stirring for another 1 h. Solvent was removed under vacuum, leaving a brown liquid. The desired product was distilled from the byproducts using a Kugelrohr distillation apparatus (170 °C, 0.1 mmHg) giving a yellow oil. Yield: 0.97 g, 60%. *Anal.* Calc. for $C_9H_{12}N_2O \cdot 0.8H_2O$: C, 60.52; H, 7.67; N, 15.68. Found: C, 60.92; H, 7.54; N, 15.65%. ^1H NMR (300 MHz, $CDCl_3$): δ 1.11 (t, 3H), 2.24 (q, 2H), 4.47 (d, 2H), 7.11 (m, 3H), 7.58 (t, 1H), 8.42 (d, 1H) ppm. FTIR (KBr): 3293 (ν_{NH}), 3065, 2977, 2038, 2890, 1653 (ν_{CO}), 1542, 1475, 1436, 1374, 1233, 1149, 1094, 1049, 997, 804, 754, 696, 620, 507, 457, 404 cm^{-1}.

2.2. $[Cu(HL)_2](OTf)_2$ (**1**)

An acetonitrile solution of HL (0.075 g, 0.5 mmol) was added dropwise to an acetonitrile solution of $Cu(OTf)_2$ (0.0904 g, 0.25 mmol) forming a light blue solution. The reaction was stirred for 3 h and vapor diffusion of diethyl ether into this solution resulted in the formation of blue crystals of **1**. Yield: 0.104 g, 56.5%. *Anal.* Calc. for $C_{18}H_{20}CuF_6N_4O_8S_2$: C, 32.66; H, 3.04; N, 8.46. Found: C, 32.09; H, 3.28; N, 8.74%. ESI-MS (CH_3CN): m/z = 363.0 $[Cu(HL)(L)]^+$; 151.1 $[H_2L]^+$. UV–Vis [CH_3CN, λ_{max}, nm (ϵ, $M^{-1}\,cm^{-1}$)]: 260 (16 700), 293 (4800), 640 (540). FTIR (KBr): 3287 (ν_{NH}), 3126, 3003, 2968, 2890, 1605 (ν_{CO}), 1492, 1443, 1381, 1365, 1244, 1162, 1116, 1070, 1032, 869, 837, 781, 759, 639, 618, 591, 573, 529, 518, 440 cm^{-1}. EPR (9.434 GHz, 0.02 mW, mod. amp. 1 G, MeOH, 77 K): $g_\parallel = 2.31$, $g_\perp = 2.06$, $A_\parallel = 146$ G.

2.3. $[Cu(HL^{Me})_2](ClO_4)_2$ (**2**)

A methanol solution of HL^{Me} (0.0834 g, 0.51 mmol) was added dropwise to a methanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.0942 g, 0.25 mmol) forming a dark blue solution. The reaction was stirred overnight and vapor diffusion of diethyl ether into this solution resulted in the formation of blue crystals of **2**. Yield: 0.0999 g, 68%. *Anal.* Calc. for $C_{18}H_{24}Cl_2CuN_4O_{10}$: C, 36.59; H, 4.09; N, 9.48. Found: C, 36.36; H, 4.06; N, 9.41%. ESI-MS (CH_3CN): m/z = 490.0 $[Cu(HL^{Me})_2(ClO_4)]^+$; 390.1 $[Cu(HL^{Me})(L^{Me})]^+$; 165.1 $[H_2L^{Me}]^+$. UV–Vis [CH_3OH, λ_{max}, nm (ϵ, $M^{-1}\,cm^{-1}$)]: 208 (13 100), 261 (9300), 720 (48). FTIR (KBr): 3303 (ν_{NH}), 1598 (ν_{CO}), 1167, 1106, 1012, 975, 933 ($\nu_{ClO_4^-}$), 3853, 3118, 2995, 2949, 2890, 2458, 2362, 2334, 2019, 1491, 1469, 1448, 1390, 1364, 1342, 1325, 1295, 1255, 1233, 897, 855, 836, 804, 781, 762, 693, 655, 621, 604, 529, 476, 439, 401 cm^{-1}. EPR (9.434 GHz, 0.14 mW, mod. amp. 1 G, MeOH, 77 K): $g_\parallel = 2.31$, $g_\perp = 2.05$, $A_\parallel = 146$ G.

2.4. $[Cu(HL)_2Cl]_2[CuCl_4] \cdot 2CH_3CN$ (**3** · $2CH_3CN$)

An acetonitrile solution of HL (0.075 g, 0.5 mmol) was added dropwise to an acetonitrile solution of $CuCl_2$ (0.0672 g, 0.5 mmol) forming a dark green solution. The reaction was stirred for 13 h and vapor diffusion of diethyl ether into this solution resulted in the formation of green crystals of **3**. Yield: 0.050 g, 36.8%. *Anal.* Calc. for

$C_{36}H_{46}Cl_6Cu_3N_{10}O_4$: C, 39.81; H, 4.27; N, 12.90. Found: C, 40.11; H, 4.21; N, 12.81%. ESI-MS (CH_3CN): $m/z = 214.0$ $[CuL]^+$; 151.1 $[H_2L]^+$. UV–Vis [CH_3CN, λ_{max}, nm (ϵ, $M^{-1}\,cm^{-1}$)]: 261 (11000), 295 (4800), 460 (960), 831 (220). FTIR (KBr): 3295 (ν_{NH}), 2925, 1608 (ν_{CO}), 1551, 1486, 1444, 1374, 1360, 1301, 1226, 1156, 1114, 1062, 1031, 1015, 836, 770, 645, 618, 582, 516 cm^{-1}. EPR: no signal.

2.5. $[Cu(HL^{Me3})_2(THF)](OTf)_2$ (**4** · THF)

NaH (0.012 g, 0.5 mmol) was added to a THF solution of HL^{Me3} (0.096 g, 0.5 mmol) and the mixture was stirred for 1 h. Subsequently, this was added to a THF solution of $Cu(OTf)_2$ (0.1808 g, 0.5 mmol). The reaction mixture was stirred for 2 h, during which the color changed to dark blue. The suspension was filtered and slow evaporation of the filtrate produced crystals of **4** suitable for crystallographic characterization. Yield: 0.076 g, 37.1%. *Anal.* Calc. for $C_{28}H_{39}CuF_6N_4O_9S_2$: C, 41.15; H, 4.81; N, 6.86. Found: C, 41.27; H, 5.12; N, 6.64%. ESI-MS (CH_3CN): $m/z = 447.2$ $[Cu(HL^{Me3})(L^{Me3})]^+$; 193.1 $[H_2L^{Me3}]^+$. UV–Vis [CH_3CN, λ_{max}, nm (ϵ, $M^{-1}\,cm^{-1}$)]: 261 (22000), 205 (22700), 671 (330), 483 (150). FTIR (KBr): 3291, 3105, 2976, 2875, 1610, 1593, 1490, 1449, 1369, 1282, 1266, 1249, 1165, 1031, 992, 774, 757, 636, 575, 517 cm^{-1}. EPR (9.436 GHz, 19.9 mW, mod. amp. 1 G, CH_3CN, 77 K): $g_\parallel = 2.35$, $g_\perp = 2.07$, $A_\parallel = 150$ G.

2.6. $[Cu(HL^{Me3})_2(H_2O)](ClO_4)_2$ (**5a**)

A methanol solution of HL^{Me3} (0.06 g, 0.31 mmol) was added dropwise to a methanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.058 g, 0.16 mmol) forming a dark blue solution. The reaction was stirred overnight and vapor diffusion of diethyl ether into this solution resulted in the formation of green crystals of **5a**. Yield: 0.078 g, 75%. *Anal.* Calc. for $C_{22}H_{34}Cl_2CuN_4O_{11}$: C, 39.74; H, 5.15; N, 8.43. Found: C, 39.84; H, 5.10; N, 8.36%. ESI-MS (CH_3OH): $m/z = 546.1$ $[Cu(HL^{Me3})_2(ClO_4)]^+$; 446.2 $[Cu(L^{Me3})(HL^{Me3})]^+$; 255.1 $[Cu(L^{Me3})]^+$. UV–Vis [CH_3OH, λ_{max}, nm (ϵ, M^{-1}, cm^{-1})]: 211 (9900), 261 (10600), 727 (50). FTIR (KBr): 3411 (ν_{OH}), 3375 (ν_{NH}), 2973, 1594, 1548, 1490, 1441, 1370, 1307, 1212, 1164, 1090 ($\nu_{ClO_4^-}$), 992, 932, 864, 841, 781, 625, 537, 443 cm^{-1}. EPR (9.430 GHz, 0.04 mW, mod. amp. 1 G, MeOH, 77 K): $g_\parallel = 2.311$, $g_\perp = 2.061$, $A_\parallel = 145$ G.

2.7. $[Cu(HL^{Me3})_2(H_2O)](ClO_4)_2$ (**5b** · $2CH_3OH$)

A methanol solution of HL^{Me3} (0.07 g, 0.36 mmol) was added dropwise to a methanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.135 g, 0.36 mmol) resulting in the formation of an uncharacterized blue precipitate and a greenish blue filtrate. The precipitate was collected by filtration and vapor diffusion of diethyl ether into the filtrate gave rise to dark blue crystals of **5b**. Yield: 0.02 g, 16%. *Anal.* Calc. for $C_{22}H_{34}Cl_2CuN_4O_{11}$: C, 39.74; H, 5.15; N, 8.43. Found: C, 39.56; H, 5.08; N, 8.35%. ESI-MS (CH_3OH): $m/z = 546.1$ $[Cu(HL^{Me3})_2(ClO_4)]^+$; 446.2 $[Cu(L^{Me3})(HL^{Me3})]^+$; 255.1 $[Cu(L^{Me3})]^+$. UV–Vis [CH_3OH, λ_{max}, nm (ϵ, M^{-1}, cm^{-1})]: 210 (8600), 261 (8400), 728 (50). FTIR (KBr): 3439 (ν_{OH}), 3371 (ν_{NH}), 2970, 1590, 1548, 1506, 1484, 1449, 1362, 1310, 1220, 1145, 1089 ($\nu_{ClO_4^-}$), 994, 932, 864, 841, 771, 636, 626, 536, 443 cm^{-1}. EPR (9.427 GHz, 0.04 mW, mod. amp. 1 G, MeOH, 77 K): $g_\parallel = 2.32$, $g_\perp = 2.06$, $A_\parallel = 144$ G.

2.8. $[Cu(HL^{Ph3})_2(H_2O)](ClO_4)_2$ (**6**)

A methanol solution of HL^{Ph3} (0.100 g, 0.13 mmol) was added dropwise to a methanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.05 g, 0.13 mmol) resulting in a clear blue solution. Slow evaporation resulted in the formation of X-ray quality crystals of **6**. Yield: 0.125 g, 91%. *Anal.* Calc. for $C_{52}H_{46}Cl_2CuN_4O_{11}$: C, 60.20; H, 4.47; N, 5.40. Found: C, 60.03; H, 4.36; N, 5.30%. ESI-MS (CH_3CN): $m/z = 918.3$, $[Cu(HL^{Ph3})_2(ClO_4)]^+$; 819.3 $[Cu(HL^{Ph3})(L^{Ph3})]^+$; 441.0 $[Cu(L^{Ph3})]^+$. UV–Vis [CH_3CN, λ_{max}, nm (ϵ, M^{-1}, cm^{-1})]: 691 (180). FTIR (KBr): 3500 (ν_{OH}), 3397 (ν_{NH}), 1969, 1814, 1603, 1525, 1491, 1444, 1352, 1269, 1254, 1190, 1102 ($\nu_{ClO_4^-}$), 970, 920, 902, 854, 765, 738, 710, 698, 673, 641, 621, 577, 533, 519, 461, 432 cm^{-1}. EPR (9.439 GHz, 20 mW, mod. amp. 1 G, CH_3CN, 77 K): $g_\parallel = 2.298$, $g_\perp = 2.05$, $A_\parallel = 135$ G.

2.9. $[Cu(HL)(2,2'\text{-bipy})(H_2O)](ClO_4)_2$ (**7**)

A 1:1 methanol solution of HL (0.025 g, 0.17 mmol) and 2,2′-bipy (0.025 g, 0.17 mmol) was added to a methanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.061 g, 0.17 mmol) forming a dark blue solution with a blue precipitate. The precipitate was collected by filtration and dissolved in acetonitrile, from which vapor diffusion of diethyl ether resulted in the formation of dark blue crystals of **7**. Slow evaporation of the filtrate also resulted in the formation of dark blue crystals of **7**. Yield: 0.086 g, 87%. *Anal.* Calc. for $C_{18}H_{20}Cl_2CuN_4O_{10}$: C, 36.84; H, 3.44; N, 9.55. Found: C, 37.08; H, 3.44; N, 9.54%. UV–Vis [DMF, λ_{max}, nm (ϵ, $M^{-1}\,cm^{-1}$)]: 300 (13000), 312 (12300), 676 (70). FTIR (KBr): 3280, 3107, 1653, 1610, 1601, 1566, 1473, 1443, 1317, 1146, 1115, 1080, 1024, 1013, 775, 729, 636, 625 cm^{-1}. EPR (9.426 MHz, 2.0 mW, mod. amp. 3 G, DMF, 77 K): $g_\parallel = 2.306$, $g_\perp = 2.06$, $A_\parallel = 154$ G.

2.10. $[Cu(HL^{Ph})(2,2'\text{-bipy})(H_2O)](ClO_4)_2$ (**8** · $0.5H_2O$)

To a 1:1 methanol solution of HL^{Ph} (0.025 g, 0.11 mmol) and 2,2′-bipy (0.017 g, 0.11 mmol) was added a methanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.04 g, 0.11 mmol) forming a dark blue solution with a blue precipitate. The precipitate was collected by filtration and dissolved in acetonitrile, from which vapor diffusion of diethyl ether resulted in the formation of dark blue crystals of **8**. Slow evaporation

of the filtrate also resulted in the formation of dark blue crystals of **8**. Yield: 0.068 g, 92%. *Anal.* Calc. for $C_{24}H_{24}Cl_2CuN_4O_{10}$: C, 43.48; H, 3.65; N, 8.45. Found: C, 43.72; H, 3.58; N, 8.41%. UV–Vis [DMF, λ_{max}, nm (ϵ, $M^{-1}\,cm^{-1}$)]: 301 (14200), 312 (13700), 676 (70). FTIR (KBr): 3468, 3278, 3107, 3067, 3033, 1642, 1610, 1601, 1589, 1567, 1495, 1473, 1444, 1420, 1346, 1317, 1283, 1267, 1247, 1081, 1024, 941, 905, 775, 750, 729, 702, 636, 626 cm^{-1}. EPR (9.423 MHz, 2.0 mW, mod. amp. 3 G, DMF, 77 K): $g_{\|} = 2.316$, $g_{\perp} = 2.06$, $A_{\|} = 154$ G.

2.11. X-ray crystal structure determination

Single crystals of **1**–**8** were obtained by either slow evaporation of methanol or acetonitrile solutions of the complex or by vapor diffusion of diethyl ether into solutions of the complex. Intensity data for **1**–**8** were collected on a Bruker Apex CCD area detector diffractometer with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Cell parameters were determined from a non-linear least-squares fit of the data. The data for the complexes were corrected for absorption by the semi-empirical method. The structures were solved by direct methods by use of the SHELXTL program, and refined by full-matrix least-squares on F^2 by use of all reflections [30,31]. Hydrogen atom positions were initially determined by geometry and refined by a riding model. Non-hydrogen atoms were refined with anisotropic displacement parameters.

The asymmetric unit in **3** contains one monocation, $(C_{16}H_{20}ClCuN_4O_2)^+$, one-half of a dianion, $[CuCl_4]^{2-}$, and a disordered acetonitrile site. The dianion was located on a 2-fold rotation axis. The acetonitrile modeled in two orientations. Note that one atom of one acetonitrile was near the 2-fold rotation axis, so both orientations were

modeled with 0.5 occupancy factors. Restraints on the positional and displacement parameters of the acetonitrile atoms were required. The anion site is disordered in the structure of **5b** and was modeled in three orientations. The occupancies for the anion refined to 0.415(4), 0.293(8), and 0.291(7) for the unprimed, primed and double-primed atoms. Restraints on the positional and displacement parameters of the anion were required.

Restraints on the O–H distances in **7** were required. Hydrogens bonded to N2 and to the water oxygen were located on a difference map and refined independently. One of the perchlorate anions in **8** was disordered and was modeled in two orientations with occupancies refined to 0.570(8) and 0.430(8). One water, that was only bound by hydrogen bonds, O(1S), had an occupancy that refined to 0.575(6). Restraints on the positional and displacement parameters of the disordered anion were required. Crystal data for **1–8** are summarized in Tables 1–3, and selected bond lengths and angles are summarized in Tables 4–6.

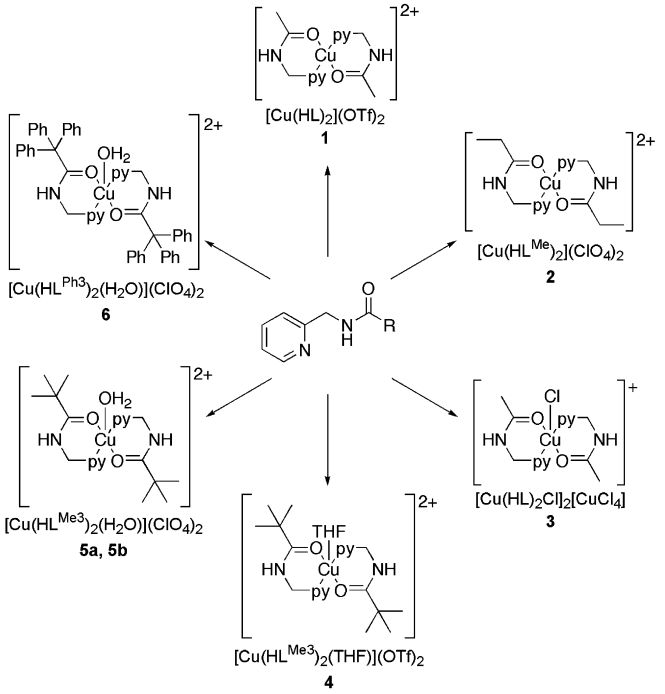
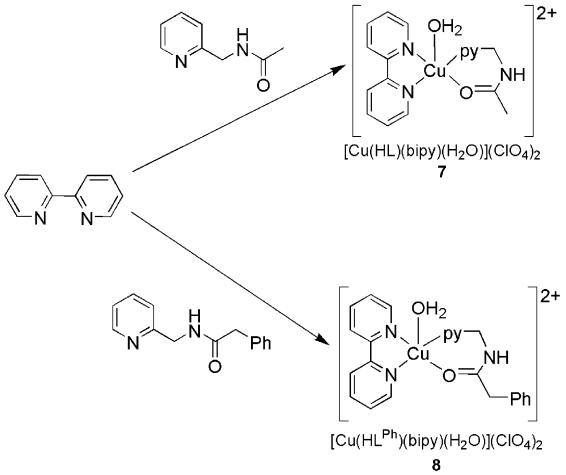
3. Results and discussion



3.1. Synthesis and characterization

Our ligand design and synthesis originates from earlier reports wherein we synthesized a family of copper(I), copper(II), and zinc(II) complexes with pyridylmethylamide ligands [9–11,14–16]. Here we report the synthesis of HL^{Me}, another addition to the family of pyridylmethylamide ligands. HL^{Me} was synthesized by the reaction of 2-(aminomethyl)pyridine and propionic anhydride (Scheme 1). This ligand is nearly identical to HL, for which coordination chemistry has been thoroughly investigated [10,14–16].

Copper complexes **1**–**6**, summarized in Scheme 2, were synthesized by straightforward means via the reaction of copper(II) salts ($Cu(OTf)_2$, $Cu(ClO_4)_2 \cdot 6H_2O$ or $CuCl_2$) with a solution of the ligand in acetonitrile or methanol. They are mononuclear with two molecules of the respective ligand coordinating to the copper center. The ligands are not deprotonated so they coordinate through the carbonyl oxygen and the pyridyl nitrogen rendering them bidentate. Different metal:ligand ratios were attempted, but in all cases the complexes formed were mononuclear with a metal:ligand ratio of 1:2. Interestingly, changing the $Cu(ClO_4)_2$:HL^{Me3} reaction stoichiometry leads to two polymorphs of **5**. When a 1:2 Cu:HL^{Me3} ratio was used, trigonal-bipyramidal **5a** is formed in good yield, while when a 1:1 Cu:HL^{Me3} ratio was used, square-pyramidal **5b** formed in lower yield. Copper complexes **7** and **8** were synthesized, as shown in Scheme 3, by the reaction of a 1:1 solution of



Scheme 1.

Scheme 2.

2,2′-bipyridine (bipy) and the respective ligand with a solution of $Cu(ClO_4)_2 \cdot 6H_2O$ in methanol. All complexes were characterized by elemental analysis and X-ray crystal structure determination. The spectroscopic properties of **1**–**8** are typical of mononuclear copper(II) species, consistent with their structures. All complexes exhibit intense ligand to metal charge transfer transitions (LMCT) transitions in the range of 200–315 nm. The d–d transitions are in the range of 640–690 nm for complexes **1**, **4**, **6**, **7** and **8** with geometries ranging from square-planar to square-pyramidal. For complexes **2**, **5a** and **5b**, the d–d transitions are in the range of 720–728 nm. Complex **3** with a square-pyramidal geometry has a d–d transition at 831 nm. The slight

Scheme 3.

differences in the d–d transitions is attributed to the differing geometries of the copper complexes. The X-band EPR spectra of **1**, **2**, **4**, **5b**, **6**, **7** and **8** in frozen CH_3OH or CH_3CN at 77 K are typical of mononuclear copper(II) complexes with predominantly axial character suggesting a $d_{x^2-y^2}$ ground state [32,33], consistent with the X-ray crystal structures of these complexes. Complex **3** does not exhibit any EPR signal, perhaps suggesting formation of antiferromagnetically coupled pairs in solution. Complex **5a** exhibits an EPR signal that is not typical of a trigonal-bipyramidal complex but closer to a square-pyramidal structure suggesting the possibility of interconversion in solution. This possibility is corroborated by the identical UV–Vis spectra of solutions of **5a** and **5b**.

3.2. X-ray crystal structures

3.2.1. $[Cu(HL)_2](OTf)_2$ (**1**) and $[Cu(HL^{Me})_2](ClO_4)_2$ (**2**)

The cationic portions of complexes **1** and **2** are shown in Figs. 1 and 2 respectively, and their bond parameters are listed in Table 4. Both copper centers in **1** and **2** have square-planar geometries. The similarities in the copper geometries are further supported by the τ_4 geometry index proposed by our group for four-coordinate complexes [16]. The calculated τ_4 values of 0 for complexes **1** and **2**, accurately reflect the perfect square-planar geometry of copper observed in these crystal structures. Complex **1** with triflate as the counterion is structurally very similar to its previously reported perchlorate analogue, $[Cu(HL)_2](ClO_4)_2$ [10]. The copper center has long axial interactions with the perchlorate O atoms at 2.8098(15) Å in the reported analogue. In complex **1**, when triflate is used as the counter-anion, these interactions are at 2.6221(12) Å. The four coordination sites of the copper centers are comprised of two HL ligands for **1** and two HL^{Me} ligands for **2**, via the pyridyl N atom and the carbonyl O atom. The Cu–N and Cu–O bond distances, summarized in Table 4, are typical for this type of complex. The $Cu–O_{carbonyl}$ and $Cu–N_{pyridyl}$ distances for $[Cu(HL)_2](ClO_4)_2$ are 1.9560(13) and 1.9981(15) Å [10], while they are 1.9829(10) and 2.0086(12) Å for complex **1**. These differences are trivial and can be attributed to the differences in the counter-anions, perchlorate versus triflate. For both complexes, the pyridyl rings are coplanar and the dihedral angles between the two pyridyl rings plane and the copper square plane is 46.0° for **1**, and 49.6° for **2**. The long axial interactions between copper and triflate or perchlorate O atoms in complexes **1** and **2** are 2.622 Å and 2.624 Å, respectively. The similarity of structural properties for complexes **1** and **2** indicate only trivial influences of the ethyl group in ligand HL^{Me} in **2**.

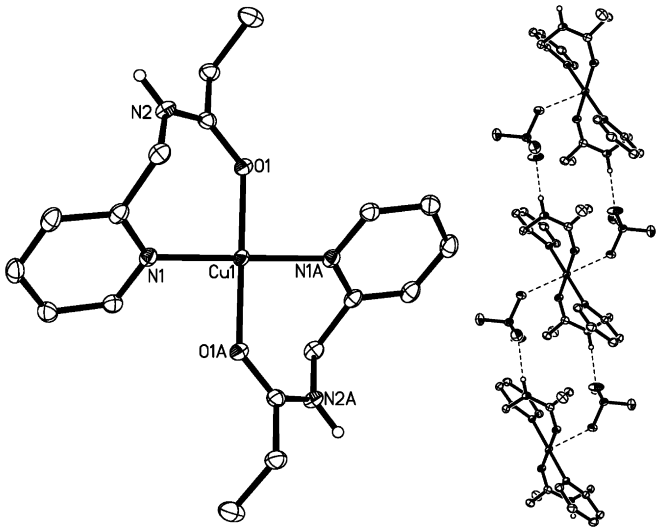


Fig. 2. X-ray crystal structure (left) and packing diagram (right) for $[Cu1(HL^{Me})_2](ClO_4)_2$ (**2**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide H atoms are omitted for clarity.

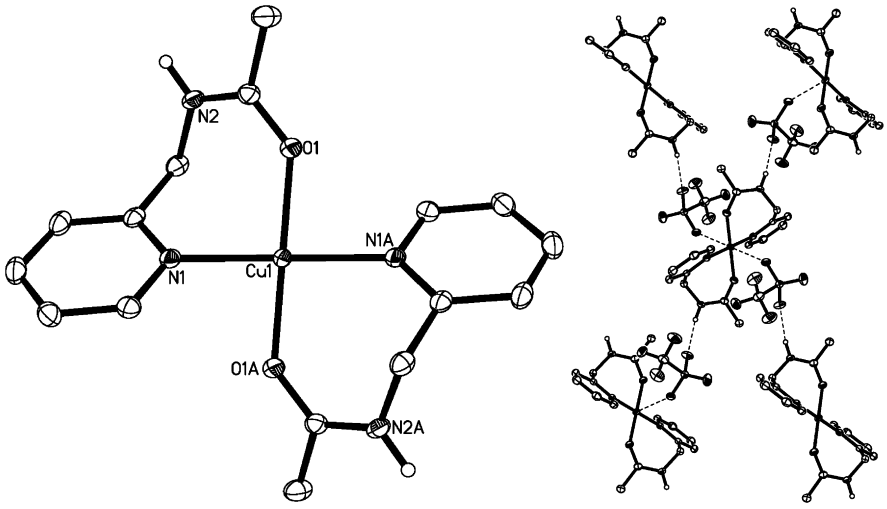

Fig. 1. X-ray crystal structure (left) and packing diagram (right) for $[Cu(HL)_2](OTf)_2$ (**1**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide H atoms are omitted for clarity.

The packing structures and hydrogen bonding interactions in **1** and **2** are quite different because of the difference in the anions present. The triflate anions in the axial positions of the copper coordination sphere of **1** form hydrogen bonds with two N–H groups from two adjacent cationic moieties (see Fig. 1). Every cationic copper complex is also hydrogen bonded via the amide NH groups to triflate anions, which are in turn loosely coordinated to another Cu to create wave-like two dimensional sheets. In the case of **2**, while the two perchlorate anions of the mononuclear unit also form two hydrogen bonds with N–H groups from two adjacent mononuclear units, these hydrogen bonding interactions extend to form a double stranded chains in the packing structure (see Fig. 2). The hydrogen bonding in $[Cu(HL)_2](ClO_4)_2$ follows the same pattern as in **2**, not surprising in light of the similarities in the structures along with the fact that both complexes are perchlorate salts [10].

3.2.2. $[Cu(HL)_2Cl]_2[CuCl_4]\cdot 2CH_3CN$ (**3**) and $[Cu(HL^{Me3})_2(THF)](OTf)_2\cdot THF$ (**4**)

Crystallographic analysis indicates that complex **3** consists of two mononuclear $[Cu(HL)_2Cl]^+$ cations and one $[CuCl_4]^{2-}$ anion (Fig. 3). The geometry of the five-coordinate copper center in the cation is slightly distorted trigonal-bipyramidal. The structural index parameter τ_5 proposed by Addison et al. has been used to describe trigonality of five-coordinate systems [32]. According to this standard, the cation $[Cu(HL)_2Cl]^+$ of complex **3** has a τ_5 value of 0.70, indicating a slight distortion from perfect trigonal-bipyramidal geometry. The pyridyl N atom and amide O atom from two HL ligands chelate to the same copper ion, and the fifth position is occupied by chloride. The two N atoms occupy the axial positions with a N1A–Cu1–N1B bond angle of 179.93(9)°. Two carbonyl O atoms and the Cl^- make up the trigonal plane. The Cu ion lies out of the equatorial plane by a distance of 0.011 Å, and the dihedral angle between the equatorial plane and axial plane formed by N1A, N1B and Cu1 is 88.4°. In the anion, the four-coordinate Cu(II) center displays a slightly distorted square-planar geometry. The four chloride ions of $[CuCl_4]^{2-}$ are involved in H-bonding interactions with the N–H groups from $[Cu(HL)_2Cl]^+$ cation units to form a H-bonding network that extends to create wave-like two dimensional sheets as shown in Fig. 3. The bond distances in **3**, summarized in Table 4, are comparable to previously reported five-coordinate Cu(II) complexes with similar N_2O_2Cl coordination environments [34,35].

The copper center of complex **4** possesses a square-pyramidal geometry. For **4**, the τ_5 value is only 0.06, which is very close to 0 for a perfect square-pyramidal structure. The four equatorial positions of the square plane are occupied by two pyridyl N atoms and two amide O atoms from two HL^{Me3} ligands, and the apical position is occupied by a THF molecule. The angles N1A–Cu1–N1B and O1A–Cu1–O1B are 173.76(15)° and 177.35(13)°, respectively, revealing slight distortion of the square-plane. The mean deviation of the N1A, N1B, O1A and O1B from the least-squares plane formed by these four atoms is only 0.0339 Å, and the copper atom lies out of the plane by a distance of 0.0743 Å. The THF molecule sits in the axial position, and the displacement of the Cu1–O2 bond from the normal to the square plane is only 2.4°. The relatively long Cu1–O2 bond distance of 2.246(3) Å is indicative of a weak interaction between the THF molecule and the copper(II). Both N–H groups of complex **4** are involved in intermolecular N–H···O hydrogen bonding interactions with two triflate anions, having an average H···O distance of around 2.08 Å and ∠N–H···F angle of around 144°.

The distinct copper center geometries of **3** and **4** are attributed to the different substituent groups on the amide side arms of HL and HL^{Me3}. The two trans pyridyl rings in **3** are nearly coplanar with a dihedral angle of 18.8°, and the two amide side arms stay on the same side of the two pyridyl rings with an O1A–Cu1–O1B angle of 92.16(7)°. However, in **4**, instead of forming a similarly small O1A–Cu1–O1B angle, the steric effect of the two *t*-butyl

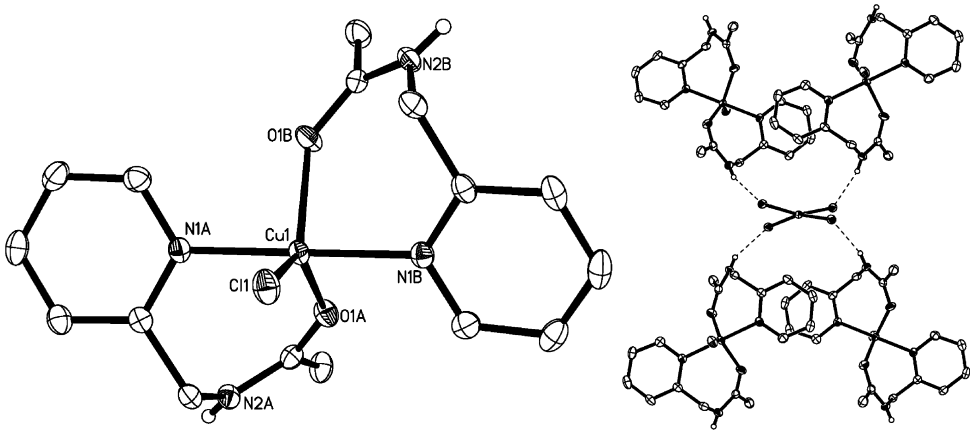

Fig. 3. X-ray crystal structure (left) for the cationic portion of **3**, $[Cu(HL)_2Cl]^+$, and packing diagram for **3** (right) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide H atoms are omitted for clarity.

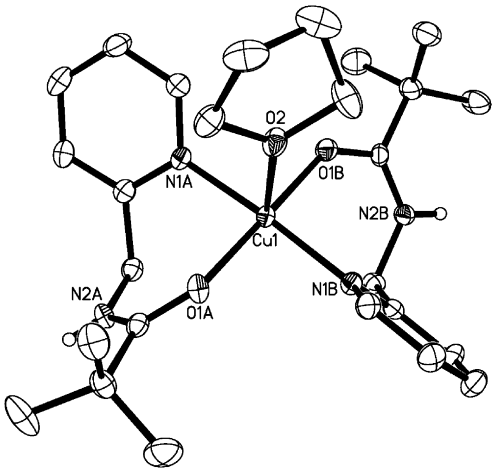

Fig. 4. X-ray crystal structure for $[Cu(HL^{Me3})_2(THF)](OTf)_2$ (**4**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide H atoms are omitted for clarity.

groups force the two side arms to stay *trans* to each other with a nearly linear O1A–Cu1–O1B angle of 177.35(13)°, which further leads to the high dihedral angle of 74.9° between the two *trans* pyridyl rings Fig. 4.

3.2.3. $[Cu(HL^{Me3})_2(H_2O)](ClO_4)_2$ (**5a** and **5b**) and $[Cu(HL^{Ph3})_2(H_2O)](ClO_4)_2$ (**6**)

The crystal structures of **5a** and **5b** are illustrated in Figs. 5 and 6, respectively. Bond distances and angles relevant to the copper coordination sphere of both compounds are listed in Table 5. Complexes **5a** and **5b** have identical ligand donor sets but are structurally different from each other. Both are coordinated by two bidentate HL ligand molecules, and a molecule of water. Complex **5a** is best described as distorted trigonal-bipyramidal with a τ_5 value of 0.67. Cu1 is coordinated to the two carbonyl oxygens (O1A and O1B) at 2.0468(15) and 2.0728(15) Å and a water molecule (O2) at 2.008(2) Å forming the equatorial plane, while the pyridyl nitrogens (N1A and N1B) are located axially. The Cu atom lies 0.01 Å out of the equatorial plane of O1A, O1B and O2. The dihedral angle between the equatorial plane formed by O1A, O1B and O2 and the axial plane formed by N1A, N1B and Cu1 is 93.8°. The pyridyl rings are located *trans* to each other

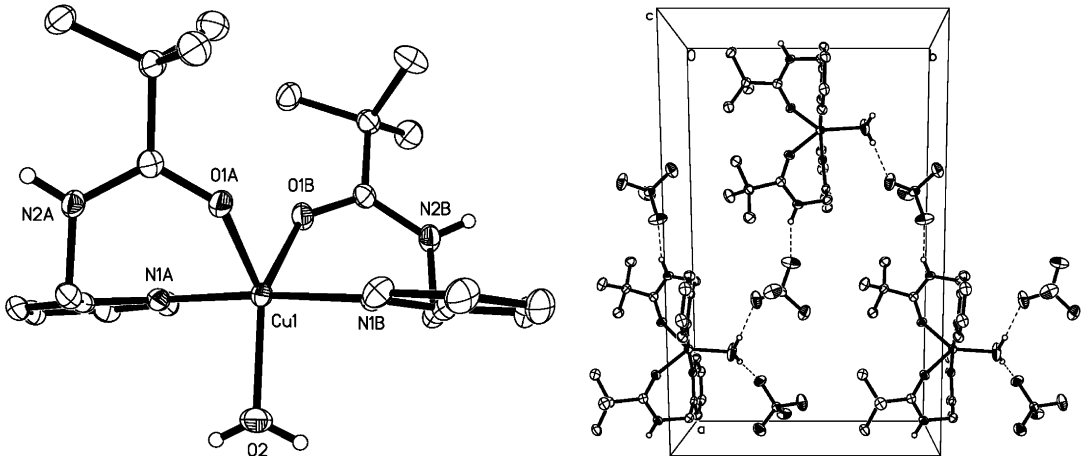

Fig. 5. X-ray crystal structure (left) and packing diagram (right) for $[Cu(HL^{Me3})_2(H_2O)](ClO_4)_2$ (**5a**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide and water H atoms are omitted for clarity.

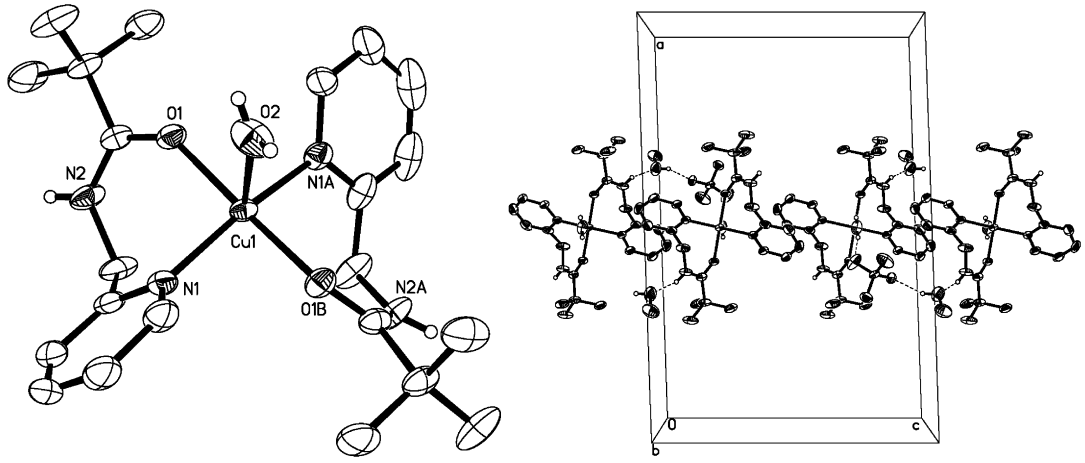

Fig. 6. X-ray crystal structure (left) and packing diagram (right) for $[Cu(HL^{Me3})_2(H_2O)](ClO_4)_2$ (**5b**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide and water H atoms are omitted for clarity.

and are nearly coplanar, with a dihedral angle of 8.6°. The coordinated water molecule (O2) hydrogen bonds to oxygens O1C and O1D of two perchlorate anions, with O2–O1C/O1D distances of 2.758(3) and 2.728(3) Å. The amide nitrogens (N2A and N2B) hydrogen bond to oxygen atoms (O2D and O3C) of adjacent perchlorate anions, with N2A–O2D and N2B–O3C distances of 2.913(3), and 2.873(3) Å.

Complex **5b** is symmetrical with a crystallographic 2-fold rotation axis passing through the metal center and dividing the molecule into two equal halves. In contrast to **5a**, **5b** has a coordination geometry closer to square-pyramidal with a τ_5 geometric index of 0.16. The basal plane of the square-pyramid is made up of two pyridyl nitrogens and two carbonyl oxygens with bond distances of 1.983(3) and 1.977(2) Å, respectively. The fifth coordination site is occupied by a water molecule located axially with a bond distance of 2.207(4) Å. With respect to **5a**, this reflects a contraction of the Cu–$O_{carbonyl}$ bonds and a lengthening of the Cu–O_{water} bond. The mean deviation of N1, N1A, O1 and O1B from the least-squares plane is 0.1597 Å. The Cu atom lies 0.0821 Å out of this plane. The pyridyl rings of the two molecules are twisted at an angle of 79.6°. The amide nitrogen (N2) is hydrogen bonded to a methanol oxygen O1S in the lattice at 2.773(4) Å. The coordinated water O2 hydrogen bonds to the perchlorate oxygens in the range 2.66–3.07 Å. The methanol oxygen O1S also hydrogen bonds to the perchlorate oxygen O2A at 3.083(11) Å and O2A and O1A in the range 2.79–3.2 Å.

The differing geometries of **5a** and **5b** are attributed to the differences in their intermolecular interactions as illustrated in their packing diagrams. In **5a**, the hydrogen bonding interactions of the coordinated water molecule with the perchlorate anions appears to pull the two anions closer to the water molecule, resulting in pushing the side arms of the two HL^{Me3} ligands on the same side of the molecule as the two pyridyl rings, and a O1A–Cu1–O1B angle of 97.18(7)°. Consequently, the two pyridyl rings are nearly coplanar with an angle of 8.6° with respect to each other. In contrast, complex **5b** has no such effect of the perchlorate anions on the water ligand, and the molecules arrange such that there are intermolecular π–π stacking interactions between pyridyl rings on adjacent molecules, and a high dihedral angle of 79.6° between the pyridyl rings *trans* to each other on the same molecule. Consequently, the two side arms are located opposite to each other with a O1–Cu–O1A angle of 175.48(13)°. The two pyridyl rings on each mononuclear unit are perfectly parallel to the pyridyl rings from adjacent mononuclear units with a mean centroid–centroid distance of 3.594 Å and a displacement angle of 21.9°. This indicates strong π–π interactions of pyridyl rings [36]. This is the driving force for the formation of the square-pyramidal geometry in complex **5b**.

The crystal structure of **6** is illustrated in Fig. 7, and bond distances and angles are summarized in Table 5. Similar to complexes **5a** and **5b**, complex **6** is also five-coordinate. The cationic portion of this complex sits on a crystallographic 2-fold rotational axis. The Cu is coordinated by two HL^{Ph3} ligands and a molecule of water in a square-pyramidal geometry. The τ_5 geometry index was calculated to be 0.12 indicating that copper(II) is closest to square-pyramidal geometry. The basal plane of the square-pyramid is made up of two equivalent pyridyl nitrogens and two equivalent carbonyl oxygens, with bond distances of 1.9774(13) and 1.9798(10) Å, respectively. The mean deviation of N1, N1A, O1 and O1B from the least-squares plane is 0.0784 Å. The Cu atom lies 0.0622 Å out of this plane. The fifth coordination site is occupied by a water molecule in the axial position at a distance of 2.2472(17) Å. The coordinated water molecule hydrogen bonds with the perchlorate oxygen O1A, with a O2–O1A distance of 2.8074(15) Å. The metrical parameters for **6** are quite similar to those of **5b**.

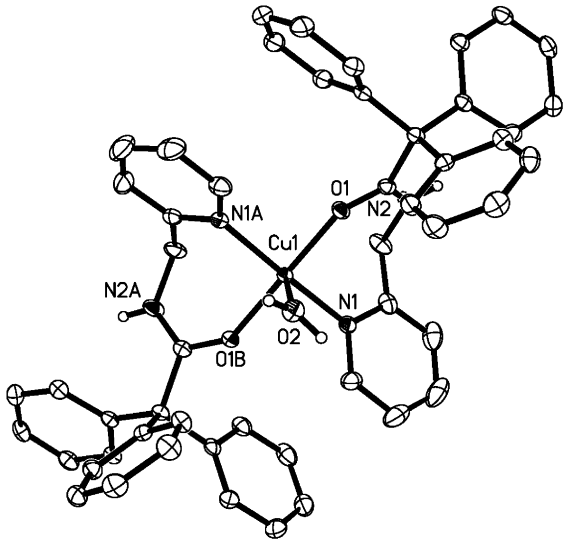

Fig. 7. X-ray crystal structure for $[Cu(HL^{Ph3})_2(H_2O)](ClO_4)_2$ (**6**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide and water H atoms are omitted for clarity.

3.2.4. $[Cu(HL)(bipy)(H_2O)](ClO_4)_2$ (7) and $[Cu(HL^{Ph})(bipy)(H_2O)](ClO_4)_2$ (8)

The crystal structures of **7** and **8** are illustrated in Figs. 8 and 9 with bond distances and angles listed in Table 6. The coordination environments for **7** and **8** are similar to **5b** and **6**, but with one HL^R ligand replaced by a bipy ligand. The Cu atoms in **7** and **8** are coordinated to the $N_{pyridyl}$ and O atoms of HL^R (HL for **7**, and HL^{Ph} for **8**), to two N atoms from bipy, and an axial water ligand. The geometry is distorted square-pyramidal with τ_5 values of 0.013 for **7** and 0.027 for **8**. In both complexes, the basal plane of the square-pyramid is comprised of the carbonyl oxygen and pyridyl nitrogen of the respective ligands and the bipy nitrogens. The mean deviation of these four atoms constituting the basal plane from the least-squares plane is 0.0364 Å for **7**, and 0.0681 Å for **8**. The Cu atom deviates from the least-squares plane by 0.1425 Å for **7**, and 0.121 Å for **8**. The pyridyl ring in **7** is at an angle of

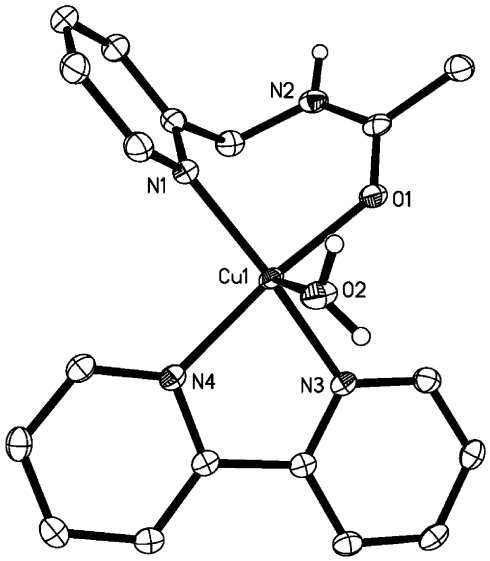

Fig. 8. X-ray crystal structure for $[Cu(HL)(bipy)(H_2O)](ClO_4)_2$ (**7**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide and water H atoms are omitted for clarity.

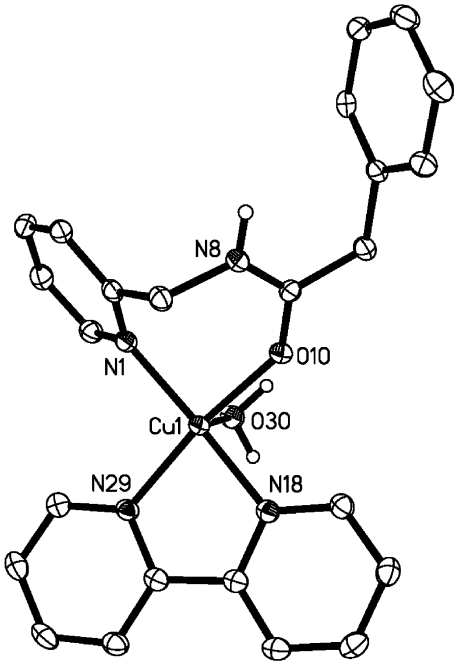

Fig. 9. X-ray crystal structure for $[Cu(HL^{Ph})(bipy)(H_2O)](ClO_4)_2$ (**8**) with thermal ellipsoids at the 50% probability level. All H atoms except for the amide and water H atoms are omitted for clarity.

63.4° with respect to the bipy plane. This angle is nearly identical in **8**, with an angle of 59.4 °. Both complexes **7** and **8** exhibit hydrogen bonding between the coordinated water and perchlorate anions. The amide NH groups in both the complexes is also involved in hydrogen bonding interactions with the perchlorate anions.

The $Cu–O_{carbonyl}$ and $Cu–N_{pyridyl}$ distances of our series of complexes have been compared with examples from the literature. A crystal structure of $[Cu(HL)_2](ClO_4)_2$, similar to **1** with perchlorate as a counter-anion instead of triflate, has been reported [10] and its bond parameters are comparable to those in **1**. Complexes **1**, **2**, **4**, **5b**, **6**, **8**, and **9** have geometries that are square-planar to square-pyramidal with $Cu–O_{carbonyl}$ distances in the range of 1.97–1.99 Å. These values are similar to distorted square-pyramidal copper complexes of the triazacyclononane ligand with amide appendages [8,37,38], and copper complexes of substituted oxamides [18,19] where the Cu–O distances are in the range of 1.98–2.01 Å. These values are slightly higher than square-pyramidal copper complexes with the substituted analogues of 2-aminoethyl pyridine, where the Cu–O distances are in the range of 1.93–1.94 Å [20]. Complexes **3** and **5b** with trigonal-bipyramidal geometries, have Cu–O distances in the range of 2.04–2.13 Å, which are similar to copper complexes with similar geometry and Cu–O distances ranging from 2.11 to 2.16 Å [35]. The $Cu–N_{pyridyl}$ distances, in the range of 1.977–2.008 Å, compare well with the literature [10,11,20]. In complexes **7** and **8**, the $Cu–O_{carbonyl}$ distances are in the range of 1.97–1.99 Å, and the $Cu–N_{pyridyl}$ distances are in the range of 1.98–2.00 Å, consistent with the literature. The $Cu–N_{bipy}$ distances are in the range of 1.98–2.02 Å, and lie in the same range as those of the literature [39–41].

4. Summary and conclusions

Copper(II) complexes **1**–**8** were synthesized with a variety of pyridylmethylamide ligands under neutral conditions. The ligands coordinate in a bidentate fashion via the pyridyl N atom and the carbonyl O atom. With the ligands HL and HL^{Me} and in the absence of strongly coordinating chloride, complexes **1** and **2** form, which are four-coordinate. With strongly coordinating chloride, copper complex **3** with HL forms, which is five-coordinate. With ligands HL^{Me3} and HL^{Ph3}, a different behavior is observed and complexes **4**–**6** are all five-coordinate. Complexes **7** and **8** are five-coordinate as well, with bipy as a co-ligand. The geometries range from square-planar to square-pyramidal to trigonal-bipyramidal. The bidentate coordination mode of pyridylmethylamide ligands under neutral conditions offers fairly limited coordination chemistry. Our laboratory continues to investigate the coordination chemistry of these ligands with copper and other transition metals under basic conditions, and will report those results elsewhere.

redox and magnetic properties which could increase the field of possible applications [9,10]. The growing use of Pcs as advanced materials during the last decade has encouraged the synthesis of new materials [11] which differ in terms of the central metal ion and peripheral substituents [12].

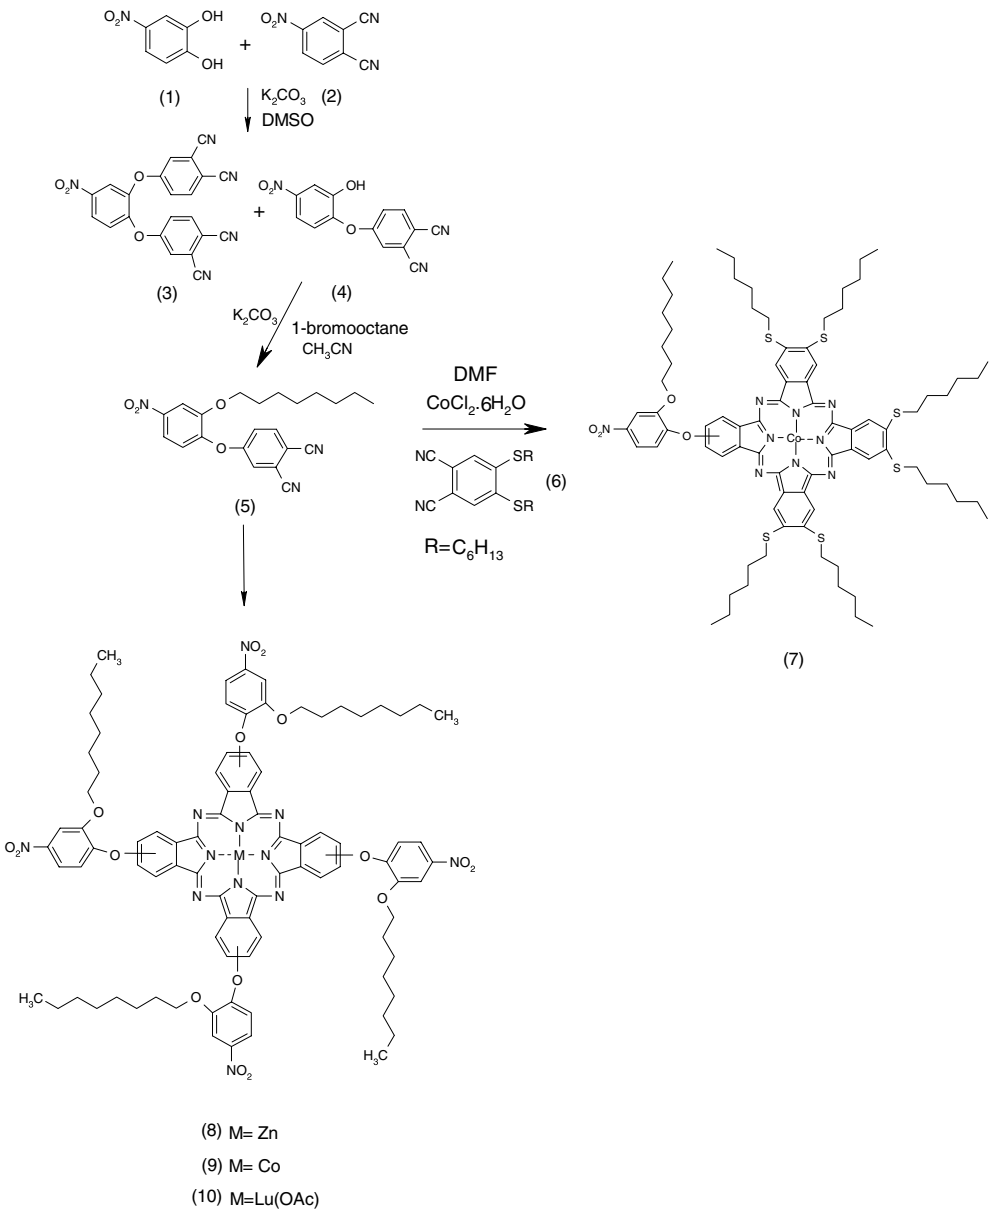
The present paper reports for the first time the synthesis and characterisation of 4-nitro-2-octyloxyphenoxy substituted symmetrical and unsymmetrical MPcs. The electrical and electrochemical properties of the complexes are also presented.

2. Experimental

2.1. Synthesis and characterization

All chemicals used were of reagent grade. The solvents were dried, purified and stored over molecular sieves (4 Å). Compounds **2** and **6** were prepared by the literature methods [13,14]. Compound **1** was obtained from commercial suppliers. The progress of the reactions was monitored by TLC. Column chromotography was used for purification of the complexes. ^{1}H NMR spectra were determined with a Varian Unity Inova 500 MHz NMR spectrometer and a Varian Mercury-Vx 400 MHz NMR spectrometer. IR spectra were recorded as KBr discs in the range 400–4000 cm^{-1} on a Shimadzu FTIR-8300 infrared spectrometer. The electronic absorption spectra were measured in $CHCl_3$ with a Shimadzu UV-1601 UV/Vis spectrometer. Mass spectra were acquired on a Voyager-DE™ PRO MALDI-TOF mass spectrometer (Applied Biosystems, USA) equipped with a nitrogen UV-Laser operating at 337 nm. Spectra were recorded both in linear and reflectron modes with an average of 50 and 100 shots for linear and reflectron modes, respectively. A α-cyano-4-hydroxycinnamic acid (CHCA) MALDI matrix was used and prepared in chloroform at a concentration of 20 mg/mL for symmetrical Pcs **8** and **9**. A 3-indole acrylic acid (IAA) MALDI matrix was used for the unsymmetrical Pc **7**. The positive ion and linear mode spectrum of complex **10** could be obtained only in dithranol matrix. MALDI samples were prepared by mixing sample solutions (4 mg/mL) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® microtube. Finally 1 μl of this mixture was deposited on the sample plate, dried at room temperature and then analyzed.

2.1.1. 3,4-Bis(3,4-dicyanophenoxy)nitrobenzene (*3*) and 4-(3,4-dicyanophenoxy)-3-hydroxynitrobenzene (*4*)



About 2 g (12.90 mmol) of **1**, 4.47 g (25.80 mmol) of **2** and 5.48 g (39.70 mmol) of K_2CO_3 in dry dimethylsulfoxide (DMSO) (30 ml) were stirred at 78–80 °C for 24 h under an argon atmosphere. Then, the reaction mixture was poured into water. The precipitate that formed was filtered, washed with cold water and dried in air. The crude compound **3** was chromatographed on a silica gel column with $CHCl_3$ as the eluent. After that, the separated filtrate was treated with hydrochloridic acid (10%) and the crude solid was filtered, washed with distilled water and ethanol. Column chromatography of this crude product on silica gel gave **4**. Products **3** and **4** were soluble in $CHCl_3$, dimethylformamide (DMF), DMSO and tetrahydrofurane (THF). Yield of **3**: 0.60 g (11%). M.p.: 193–196 °C. IR (γ_{max}/cm^{-1} KBr disc): 3083 (Ar–H), 2235 (–CN), 1588–1485 (–C=C–), 1246–1279 (Ar–O–C), 1569–1350 (–NO_2). ^{1}H NMR (δ_H ppm, 400 MHz, DMSO): 8.31 (d, $J = 2.73$, Ar–H), 8.26 (dd, $J = 2.73$, Ar–H), 8.20 (d, $J = 8.58$, Ar–H), 8.10 (d, $J = 8.58$, Ar–H), 8.06 (d, $J = 8.97$, Ar–H), 7.90 (d, $J = 2.34$, Ar–H), 7.86 (d, $J = 2.73$, Ar–H), 7.68 (dd, $J = 2.34$, Ar–H). Yield of **4**: 3.2 g (88%). M.p.: 213–215 °C. IR (γ_{max}/cm^{-1} KBr disc): 3037–3082 (Ar–H), 2223 (–CN), 1490–1598 (–C=C–), 1265–1136 (Ar–O–C), 1332–1525 (–NO_2), 3276 (Ar–OH). ^{1}H NMR (δ_H ppm, 500 MHz, DMSO): 8.14 (dd, $J = 2.44$, Ar–H), 8.09 (d, $J = 2.44$, Ar–H), 8.07 (d, $J = 8.97$, Ar–H), 7.79 (d, $J = 2.93$, Ar–H), 7.40 (dd, $J = 2.45$, Ar–H), 7.20 (d, $J = 8.79$, Ar–H), 11.6 (s, br, Ar–O–H). D_2O Exc-NMR (δ_H ppm, 500 MHz, DMSO): 8.12 (dd, $J = 2.44$, Ar–H), 8.09 (d, $J = 2.93$, Ar–H), 8.04 (d, $J = 8.79$, Ar–H), 7.72 (d, $J = 2.44$, Ar–H), 7.38 (dd, $J = 2.93$, Ar–H), 7.18 (d, $J = 9.28$, Ar–H).

2.1.2. Preparation of 4-(4-nitro-2-(octyloxy)phenoxy)phthalonitrile (*5*)

About 0.282 g (1 mmol) of **4**, 0.193 g (1 mmol) of 1-bromooctane, 0.278 g (2 mmol) of anhydrous K_2CO_3 and tetrabutylammonium bromide in dry acetonitrile (40 ml) were stirred at 80–85 °C for 48 h under an argon atmosphere. The mixture was cooled and evaporated to dryness. The product was treated with glacial-acetic acid and then flushed several times with water until the filtrate was neutral. After that it was extracted with CH_2Cl_2. Finally, pure **5** was obtained by chromatography with silica gel using $CHCl_3$. Product **5** was soluble in $CHCl_3$, CH_2Cl_2, DMF, DMSO and THF. Yield: 0.30 g (76%). M.p.: 88–92 °C (Scheme 1). IR (γ_{max}/cm^{-1} KBr disc): 3082 (Ar–H), 2234 (–CN), 1484–1606 (–C=C–), 1292–1246 (Ar–O–C), 1347 and 1512 (–NO_2), 2847–2932 (–CH_2–, –CH_3). ^{1}H NMR (δ_H ppm, 400 MHz, $CDCl_3$): 8.23 (dd, $J = 2.73$, Ar–H), 8.08 (d, $J = 2.73$, Ar–H), 7.73 (d, $J = 8.68$, Ar–H), 7.21 (dd, $J = 2.73$, Ar–H), 7.18 (d, $J = 2.34$, Ar–H), 7.10 (d, $J = 9.36$, Ar–H), 4.05 (t, $J = 6.24$, –OCH_2), 1.40 (m, –CH_2–), 0.90 (t, $J = 7.02$, –CH_3).

2.1.3. 2-[4-Nitro-2-(octyloxy)phenoxy]-9,10,16,17,23,24-hexakis(hexylthio)phthalocyaninato cobalt(II) (*7*)

Compounds **5** (0.150 g, 0.382 mmol) and **6** (0.412 g, 1.145 mmol) were dissolved in dry DMF (2–3 ml) in a tube. $CoCl_2 \cdot 6H_2O$ (90.44 mg, 0.382 mmol) was added to this solution. The mixture was heated and stirred at 160–170 °C for 24 h under nitrogen atmosphere to give an unsymmetrical substituted Pc (Scheme 1). After being cooled, the reaction mixture was poured into

Scheme 1. Summary of the synthesis of compounds **3**–**10**.

50 ml of ethanol and the dark green precipitate that formed was separated by centrifugation. The crude Pc mixture was washed with cold acetic acid, water, ethanol and methanol, and then dried in a vacuum. The purification of that aimed Pc **7** was carried out on a silica gel column with a $CHCl_3$:hexane system, changing from 10/1 to 10/2 (v/v). Compound **7** is soluble in chloroform, dichloromethane, ethyl acetate, hexane, DMF, THF and DMSO. Yield of **7**: 0.12 g (20.50%). M.p.: >300 °C. IR (γ_{max}/cm^{-1} KBr disc): 3050 (Ar–H), 1411–1595 (–C=C–), 1222–1274 (Ar–O–C), 1377 and 1517 (–NO_2), 2860–2929 (–CH_2–, –CH_3), 1072–1124 (C–S). UV–Vis λ_{max} ($CHCl_3$) (log ε/dm^{-3} mol^{-1} cm^{-1}): 697(5.4739), 629(5.0012), 424 (4.7700), 327(5.4681). MS(MALDI-TOF): *m*/*z* 1533 Da mass ($M+H^+$) and $(M-32)^+$.

*2.1.4. 2,10,16,24-Tetrakis-[4-nitro-2-(octyloxy)phenoxy]-phthalocyaninatozinc(II) (**8**)*

A mixture of compound **5** (0.168 g, 0.427 mmol), anhydrous zinc acetate (0.094 g, 0.427 mmol) and DMF (3–4 ml) was heated and stirred at 180 °C for 6 h under nitrogen atmosphere. After cooling to room temperature, methanol (5 ml) was added in order to precipitate the product. The blue product was filtered off and then washed several times, first with methanol, then with acetonitrile and acetone. The crude product was isolated by silica gel column chromatography with chloroform as the eluent. This product is soluble in $CHCl_3$, DMSO, DMF and THF. Yield: 0.020 g (11.50%). M.p.: >300 °C. IR (γ_{max}/cm^{-1} KBr disc): 3040 (Ar–H), 1514–1650 (–C=C–), 1222–1282 (Ar–O–C), 1340 and 1558 (–NO_2), 2854–2921 (–CH_2–, –CH_3). UV–Vis λ_{max} ($CHCl_3$) (log ε/dm^{-3} mol^{-1} cm^{-1}): 679 (4.16),

611 (3.47), 342 (3.98). ^{1}H NMR (δ_H ppm, 400 MHz, $CDCl_3$): 8.10 (dd, $J = 2.73$, Ar–H), 7.98 (d, $J = 2.73$, Ar–H), 7.72 (d, $J = 8.19$, Ar–H), 7.60 (dd, $J = 3.12$, Ar–H), 7.12 (d, $J = 2$, Ar–H), 6.98 (d, $J = 8.97$, Ar–H), 4.12 (t, $J = 5.86$, –OCH_2), 3.95 (t, $J = 6.44$, –CH_3), 1.25 (m, $(–CH_2)_6$). MS (MALDI-TOF): m/z 1638.0019 ($M+H^+$).

2.1.5. 2,10,16,24-Tetrakis-[4-nitro-2-(octyloxy)phenoxy]-phthalocyaninatocobalt(II) (9)

A mixture of compound **5** (0.150 g, 0.382 mmol), 90.440 mg (0.3816 mmol) $CoCl_2$ and absolute ethylene glycol (4–5 ml) was heated and stirred at 160 °C for 22 h under nitrogen atmosphere. After cooling to room temperature, the reaction mixture was treated with ethanol to precipitate the dark-blue product, which was then filtered. This product is soluble in $CHCl_3$ and THF, and partially in CH_2Cl_2 and DMF (Scheme 1). Yield 19.5 mg (12.53%). M.p.: >300 °C. IR (γ_{max}/cm^{-1} KBr disc): 3082 (Ar–H), 1467–1600 (–C=C–), 1222–1282 (Ar–O–C), 1340–1508 (–NO_2), 2854–2921 (–CH_2–, –CH_3). UV–Vis λ_{max} ($CHCl_3$) (log ε/dm^{-3} mol^{-1} cm^{-1}): 671 (4.24), 605 (3.63), 327 (4.10); MS (MALDI-TOF): m/z 1633.0136 ($M+H^+$).

2.1.6. 2,10,16,24-Tetrakis-[4-nitro-2-(octyloxy)phenoxy]-phthalocyaninato lutetium(III) acetate (10)

A mixture of $Lu(OAc)_3 \cdot nH_2O$ (0.023 g, 0.065 mmol), **5** (0.400 g, 1.018 mmol) and DBU (1.130 mg, 0.009128 mmol) in pentanol (2.5 ml) was refluxed under nitrogen atmosphere at 175–180 °C for 20 h. The dark green mixture was cooled to room temperature and then was washed with water, acetonitrile, ethanol, methanol and acetone, and then dried in vacuum. Compound **10** is soluble in acetic acid and THF, and partially in DMF and DMSO. Yield 0.155 g (36.70%). M.p.: >300 °C (Scheme 1). IR(γ_{max}/cm^{-1} KBr disc); 3066 (Ar–H), 1469–1666 (–C=C–), 1213–1276 (Ar–O–C), 1334 and 1506 (–NO_2), 2858–2925 (–CH_2–, –CH_3). UV–Vis λ_{max} (DMF) (log ε/dm^{-3} mol^{-1} cm^{-1}): 685 (4.8140), 618 (4.3802), 334 (5.0307). MS (MALDI-TOF): m/z 1808 ($M+H^+$).

2.2. Electrochemistry

The cyclic voltammetry, differential pulse voltammetry and controlled potential chronocoulometry (CPC) measurements were carried out with a Princeton Applied Research Model Versostat II potentiostat/galvanostat controlled by an external PC and utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt plate with a surface area of 0.10 cm^2. The surface of the working electrode was polished with a H_2O suspension of Al_2O_3 before each run. The last polishing was done with a particle size of 50 nm. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and was separated from the bulk of the solution by a double bridge. Electrochemical grade tetrabutylammonium perchlorate (TBAP) in extra pure DMSO was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}. High purity N_2 was used for deoxygenating the solution for at least 20 min prior to each run and to maintain a nitrogen blanket during the measurements. For CPC studies, a Pt gauze working electrode (10.5 cm^2 surface area), a Pt wire counter electrode separated by a glass bridge, and an SCE as a reference electrode were used.

2.3. Electrical measurements

For the electrical and impedance measurements, an interdigital comb structure with a 100 μm gap on glass substrate was used. Thin films of compounds were obtained by the spin-coating method. The substrate temperature was kept constant at 290 K during deposition of the materials over the electrodes. Dc conductivity and impedance spectral measurements were performed between 295 and 433 K using a Keithley 617 electrometer. Ac conductivity and impedance measurements were carried out with a Keithley 3330 LCZ meter in the frequency range 40–10^5 Hz, in the temperature range 295–433 K.

3. Results and discussion

3.1. Synthesis and characterization

Starting from **1** and **2**, a general synthetic route for the synthesis of new symmetrical and unsymmetrical Pcs is given in Scheme 1. Compounds **3** and **4** were obtained by base-catalyzed nucleophilic aromatic nitro displacement, in 10% and 88% yield, respectively. The reaction was carried out in a single step synthesis by using K_2CO_3 as the nitro-displacing base at 78–80 °C in dry DMSO under an argon atmosphere. Starting from **4** and 1-bromooctane, the general alkylation reaction gave **5** in the presence of K_2CO_3 at 80–85 °C for 48 h under an argon atmosphere in 75% yield. The symmetrical MPcs **8**, **9** and **10** were obtained from the dicyano derivative **5** and the corresponding metal salts ($Zn(OAc)_2$, $CoCl_2$, $Lu(OAc)_3 \cdot nH_2O$) in suitable anhydrous solvents under reflux in a sealed tube, in 12%, 13% and 36.7% yields, respectively. The high boiling solvents of choice for these reactions were DMF for Zn(II)Pc **8**, ethylene glycol for Co(II)Pc **9** and pentanol for Lu(III)(OAc)Pc **10**. These symmetrical MPcs were isolated by column chromatography on silica gel using $CHCl_3$ as the eluent. The unsymmetrical Co(II)Pc **7** was synthesized by $CoCl_2$-mediated statistical condensation of a 3:1 molar ratio of **5** and **6** in anhydrous DMF under reflux for 24 h. Product **7** was separated by column chromatography on silica gel using different $CHCl_3$:hexane solvent systems, changing from 10/1 to 10/2 (v/v), as the eluent. All the Pcs **7**, **8**, **9** and **10** show good solubility in common organic solvents such as chloroform, dichloromethane and tetrahydrofuran. The spectroscopic characterization of the newly synthesized compounds included ^{1}H NMR, IR, UV/Vis and mass spectral investigations, and the results are in accordance with the proposed structures.

The IR spectra of **3**, **4** and **5** indicate the presence of –C≡N groups by the intense stretching bands at 2235, 2223 and 2234 cm^{-1}, respectively. The IR spectra of **3**, **4** and **5** exhibit characteristic frequencies at 3037–3083 (Ar–H), 1485–1598 (–C=C–), 1136–1292 (Ar–O–C), 1332 and 1569 ($–NO_2$) cm^{-1}. The IR spectra of **3**, **4** and **5** are very similar, except those of **4** (Ar–OH) with vibrations at 3276 cm^{-1} and of **5** ($–CH_2–$, $–CH_3$) with vibrations at 2847–2932 cm^{-1}. Cyclotetramerization of dinitriles **5** to Pcs **7**, **8**, **9** and **10** was confirmed by the disappearance of the sharp –C≡N vibration at 2234 cm^{-1}. The IR spectra of the symmetrical Pcs **8**, **9** and **10** and the unsymmetrical Pc **7** are very similar, except for the C–S vibrations at 1072–1124 cm^{-1}. The IR spectra of **8**, **9** and **10** exhibit characteristic frequencies at 3230–3066 (Ar–H), 1467–1650 (–C=C–), 1213–1282 (Ar–O–C), 1334–1558 ($–NO_2$) and 2854–2925 ($–CH_2–$, $–CH_3$) cm^{-1}.

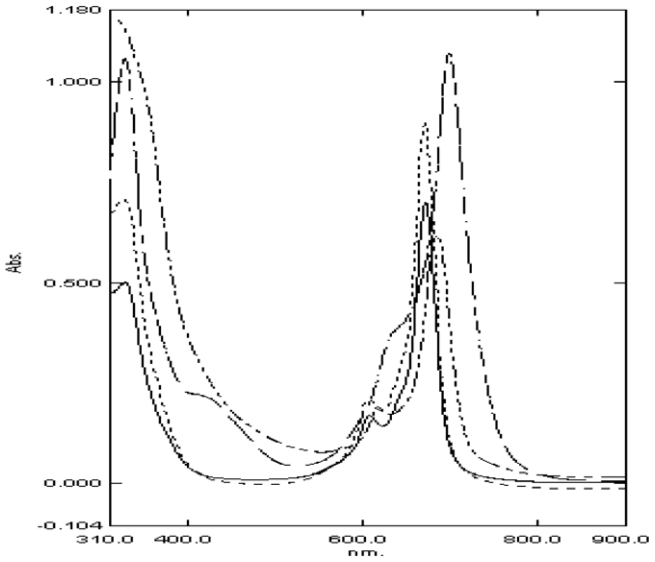


Fig. 1. UV–Vis spectra of **7**, **8**, **9** and **10** (– – – **7**, . . . **8**, — **9**, - - - **10**) (**7**, **8**, **9** in $CHCl_3$, **10** in DMF).

In the ^1H NMR spectra of **3**, **4** and **5**, the aromatic protons of the compounds appear in the low field region around 8.32–7.12 ppm. The octyl protons of **5** are observed between 0.86 and 4.07 ppm. The hydroxy proton of **4** appears at a lower field around 11.6 ppm. In the D_2O exchanged NMR spectrum of **4** this assignment was confirmed by the disappearance of the sharp hydroxy proton peak at 11.6 ppm. The ^1H NMR spectra of Zn(II)Pc **8** are almost identical. The aromatic protons of **8** appear in the low field region around 7.00–8.12 ppm. The octyl protons are observed in the range 0.70–4.14 ppm. The ^1H NMR spectra of the unsymmetrical Co(II)Pc, symmetrical Co(II)Pc and Lu(III)(OAc)Pc could not be determined because of the presence of paramagnetic cobalt and lutetium atoms.

Pcs **7**, **8**, **9** and **10** show typical electronic spectra with two strong absorption regions, one of them in the UV region at about 300–400 nm (B band) arising from the deeper π-levels → LUMO transition and the other in the visible part of the spectrum around 600–700 nm (Q band) attributed to the $\pi \rightarrow \pi^*$ transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the Pc^{2-}ring. Spectra of the symmetrical Zn(II) and Co(II) phthalocyanines **8** and **9** in chloroform are very similar, with intense Q bands at 679 and 671 nm due to a single $\pi \rightarrow \pi^*$ transition with shoulders at 611 and 605 nm and B bands at 342 and 327 nm, respectively. The splitting of the Q band of both compounds shows aggregation. The spectrum of **7** in chloroform shows a characteristic Q band absorption around 697 nm (with a shoulder at 629 nm) and B band absorptions around 424 and 327 nm. The spectrum of **10** in DMF indicates a Q band absorption around 685 nm and a B band absorption around 334 nm (Fig. 1). In the spectra of both compounds, besides the splitting of the Q band, a very strong of soret band indicates strong aggregation of both compounds [15].

Positive ion MALDI-MS spectra of **7**, **8**, **9** and **10** are given in Figs. 2–5, respectively. Many different MALDI matrices were tried to find an intense molecular ion peak

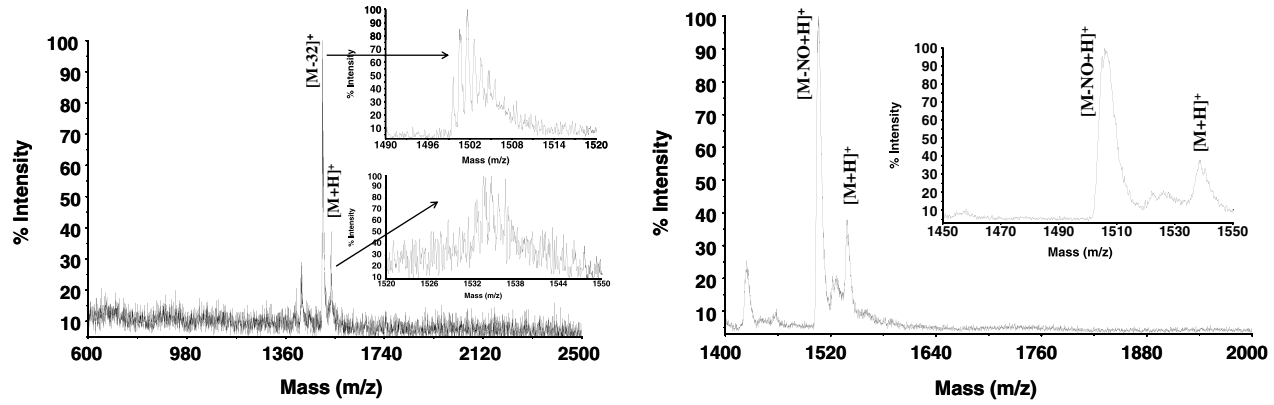

Fig. 2. MALDI-MS spectrum of the unsymmetrical Co(II)Pc **7** (left: linear mode; right: reflectron mode).

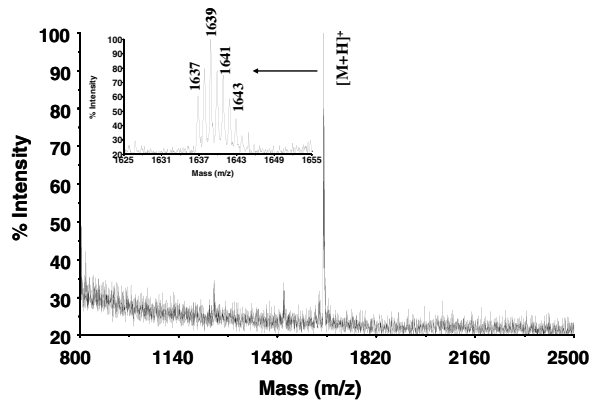

Fig. 3. MALDI-MS spectrum of the symmetrical Zn(II)Pc **8**.

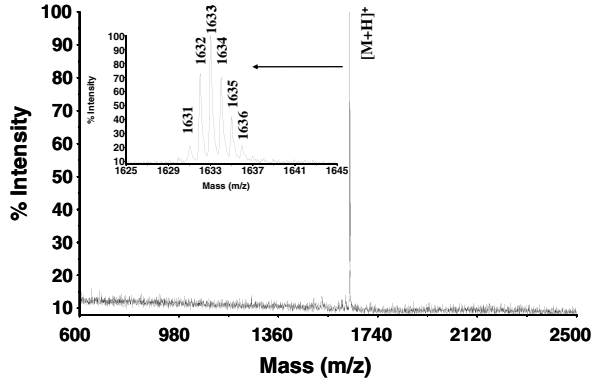

Fig. 4. MALDI-MS spectrum of the symmetrical Co(II)Pc **9**.

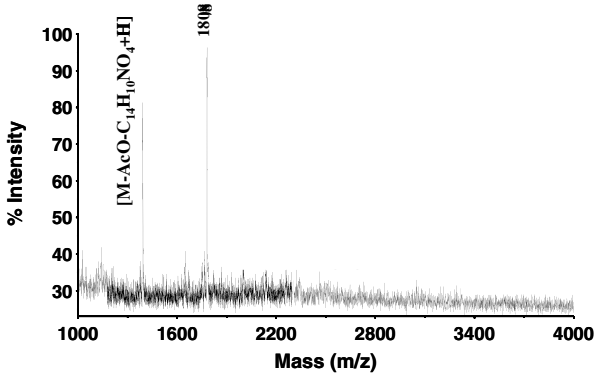

Fig. 5. MALDI-MS spectrum of the symmetrical Lu(III)(AcO)Pc **10**.

and low fragmentation under the MALDI-MS conditions for the complexes.

For complex **7**, 3-indole acrylic acid MALDI matrix yielded the best MALDI-MS spectrum. The peak group representing the protonated molecular ion of the complex was observed, starting with 1533 Da mass and finishing with 1537 Da, following each other by 1 Da mass differences. The intensity of the protonated molecular ion peak was really low when the MALDI-MS spectrum was monitored by the laser shots higher than 20. Therefore, the MALDI-MS spectrum for this complex was accumulated using 10 laser shots so as not to give high fragmentation. In this case, however, the resolution was observed at very low values of about 2500. When the number of laser shots was chosen to be between 1 and 5, more intense spectra could be obtained but the resolution was really diminished this time. Because of all these reasons, the resolution and the intensity of the protonated molecular ion peak were optimized accumulating an average of 10 laser shots for this complex. On the protonated molecular ion peak, there is an isotopic distribution resulting from ^{13}C and the isotopes of cobalt. In the positive ion MALDI-MS spectrum of **7**, beside the protonated molecular ion peak, two peaks were observed, one at high and the other at low intensity. The intense peak is because of the fragmentation of the complex. At the end of this fragmentation, the leaving group was observed as O_2, having 32 Da mass. The O_2 leaving group results from NO_2 functional groups. The second fragment peak is due to side chain elimination ($C_8H_{17}O$ leaving). This pointed out that the complex was not more stable under the MALDI matrix conditions than under the laser energy, but the positive ion MALDI-MS spectra could be carried out by MALDI-MS.

α-Cyano-4-hydroxycinnamic acid MALDI matrix yielded the best MALDI-MS spectra for **8** and **9**. The peak group representing the protonated molecular ion of **8** was observed, starting with 1637 Da mass and finishing with 1644 Da, following each other by 1 Da mass differences. This type of mass distribution resulted from the isotopic mass distribution of carbon (mainly ^{13}C) and the isotopes of zinc and cobalt in the metal complexes. The experimentally obtained isotopic mass distribution of **9** overlapped with the theoretical isotopic mass distribution calculated using isotopes of carbon and cobalt. In the MALDI-MS spectrum of **8**, besides the protonated molecular ion peak, two peaks were observed with very low intensities. These peaks are due to side chain elimination (mainly $C_8H_{17}O$) and also the other whole side chain elimination. This pointed out that the complex was very stable under the MALDI matrix conditions and also under the laser energy. The peak group representing the protonated molecular ion of **9** was observed starting with 1631 Da mass and finishing with 1636 Da, following each other by 1 Da mass differences. In the MALDI-MS spectrum of **9**, besides the protonated molecular ion peak, no fragment ion was observed. This suggests that no leaving group was available for this complex and the complex is very stable under the MALDI matrix conditions and also under the laser energy.

The positive ion and linear mode spectra of **10** could be obtained only in dithranol matrix compared to the other novel MALDI matrices. The protonated molecular ion peak of the complex was observed at 1808 Da. Beside the protonated molecular ion peak, only one another peak was observed, representing the AcO (acetate) and $C_{14}H_{20}NO_4$ groups leaving from the protonated ion peak. Limited fragmentations showed that this complex has high stability under the laser firing and MALDI-MS conditions.

The protonated molecular ion peak mass showed that a lutetium complex containing a single ligand and acetate ion was synthesized instead of the sandwich type lutetium complex. From the clean spectrum, it could be noticed that the purity of the synthesized lutetium complex was very high.

3.2. Electrochemistry

The solution redox properties of the Pc complexes (**7**–**10**) were studied using cyclic voltammetry, differential pulse voltammetry and controlled potential chronocoulometry in DMSO with a platinum electrode. Complete electrolysis of each Pc solution at the working electrode at a suitable constant potential for each redox process was achieved, and the time integration of the electrolysis current was recorded with the controlled potential coulometry studies. The charge, Q, at the end of the electrolysis was calculated using the current–time response of the solution and *Faraday*'s law was used to estimate the number of electrons transferred. The number of electrons was found to be one for all the redox processes observed in this study. Voltammetric data and the assignment of the redox couples recorded for the complexes are listed in Table 1. Fig. 6 shows typical cyclic and differential pulse voltammograms of **9** in DMSO containing TBAP.

Complex **8** gives three one-electron reduction processes labelled as R_1 at −0.67 V, R_2 at −0.98 V and R_3 at −1.76 V, and a one-electron oxidation process labelled as O_1 at 0.85 V vs. SCE at 0.100 V s^{-1} scan rate (Table 1). Voltammetric studies revealed that the redox behaviours of **8** and **10** are very similar to each other and to the metal-free Pcs [16] (Table 1). This similarity suggests that

Table 1
The electrochemical data of the Pc complexes

Complex	Redox processes	$E^{a}_{1/2}$ (V vs. SCE)	ΔE^{b}_{p} (V)	I_{pa}/I^{c}_{pc}	$\Delta E^{d}_{1/2}$ (V)
8	R1	−0.67	0.070	0.96	1.52
	R2	−0.98	0.080	0.98	
	R3	−1.76	0.160	[e]	
	O1	0.85	0.060	[e]	
9	R1	−0.37	0.100	1.00	0.82
	R2	−1.28	0.080	0.96	
	O1	0.45	0.100	0.95	
7	R1	−0.40	0.080	0.97	0.88
	R2	−1.32	0.090	0.96	
	O1	0.48	0.090	0.98	
10	R1	−0.73	0.080	0.94	1.48
	R2	−1.03	0.090	1.00	
	R3	−1.82	0.120	[e]	
	O1	0.75	0.140	0.98	

[a] $E_{1/2} = (E_{pa} + E_{pc})/2$ at 0.100 V s^{-1}.
[b] $\Delta E_p = E_{pa} - E_{pc}$ at 0.100 V s^{-1}.
[c] I_{pa}/I_{pc} for reduction, I_{pc}/I_{pa} for oxidation processes at 0.100 V s^{-1}.
[d] $\Delta E_{1/2} = E_{1/2}$(first oxidation) − $E_{1/2}$(first reduction). This value reflects the HOMO–LUMO gap for **8** and **10**, but not **7** and **9**.
[e] ΔE_p could not be determined due to an ill-defined redox wave.

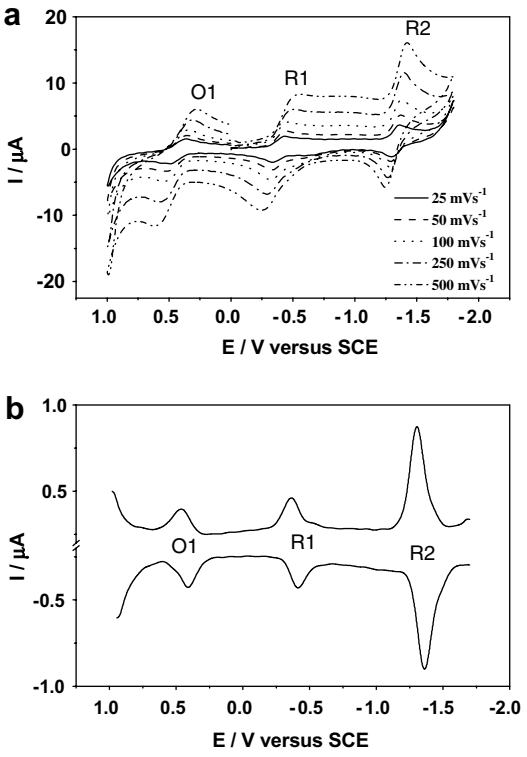

Fig. 6. Cyclic (a) and differential pulse (b) voltammograms of **9** in TBAP/DMSO.

all the one-electron redox processes of these complexes are Pc ring based. However, the redox potentials of **10** occur at potentials slightly more negative as compared to **8**. The shift in the potentials can be attributed to the difference in the polarizing effect of the metal ions. Reduction of the Pc ligand is associated with the position of the LUMO, whereas oxidation of the ligand is associated with the position of the HOMO. Thus the difference between the potentials of the first oxidation and the first reduction processes ($\Delta E_{1/2}$) reflects the HOMO–LUMO gap for metal free Pcs and it is closely related to the HOMO–LUMO gap in MPc species involving a redox inactive metal center. The $\Delta E_{1/2}$ values recorded for **8** and **10** in this study are in agreement with the values reported previously for the relevant Pcs involving a redox-inactive metal center [16]. The ratio of the anodic to the cathodic peak currents for the couples of **8** and **10** is close to unity, suggesting reversible redox processes. The anodic to cathodic peak separations (ΔE_p) changed from 0.070 to 0.140 V within the scan rates from 0.010 to 0.500 V s^{-1}(ΔE_p changed from 0.060 to 0.140 V for ferrocene), providing additional support for the reversible electron transfer. The peak currents increased linearly with the square root of the scan rates for scan rates ranging from 0.010 to 0.500 V s^{-1}, indicating purely diffusion-controlled behavior [17].

The redox potentials of **7** and **9** are considerably similar to each other, but highly different as compared to those of **8** and **10** (Table 1). Within the electrochemical window of TBAP/DMSO, compounds **7** and **9** undergo a reversible

one-electron oxidation and two reversible one-electron reductions with anodic to cathodic peak separations (ΔE_p) changing from 0.080 to 0.100 V within scan rates from 0.010 to 0.500 V s^{-1}. The peak currents increased linearly with the square root of the scan rates for scan rates ranging from 0.010 to 0.500 V s^{-1}, indicating purely diffusion-controlled behavior [17]. The difference in the voltammetric behaviour of these complexes as compared to those of **8** and **10** is due to the fact that metallo phthalocyanines, such as MnPc, CoPc and FePc, having a metal that possesses energy levels lying between the HOMO and the LUMO of the Pc ligand, in general exhibit redox processes centered on the metal [16,18–21]. Moreover, the electrochemistry of CoPc is dependent on the coordinating nature of the solvents. For CoPc complexes, the first oxidation and the first reduction processes occur on the metal center in polar coordinating solvents such as DMF and DMSO, whilst the first oxidation process occurs on the Pc ring in non-polar solvents such as DCM and THF. Therefore, the first reduction and the first oxidation processes of **7** and **9** could be assigned easily to the $[Co(II)Pc(-2)]/[Co(I)Pc(-2)]^-$ and $[Co(II)Pc(-2)]/[Co(III)Pc(-2)]^+$ redox couples and the second reduction process to the Pc ring as $[Co(I)Pc(-2)]^-/[Co(I)Pc(-3)]^{2-}$. The separation between the first oxidation and the first reduction potentials of the metal center for these Co(II) complexes (0.88 for **7** and 0.82 V for **9**) is comparable with the relevant values in the literature [15,17–20], and does not reflect the HOMO–LUMO gap. The small differences between the redox potentials of **7** and **9** can be attributed to the difference in peripheral substituents attached to the Pc core.

3.3. Electrical measurements

Arrhenius-type behavior is clearly observed from the temperature dependent conductivity measurements for all the compounds. A linear fit to $\sigma_{dc} = \sigma_0 \exp(-E_A/kT)$ is shown with different correlation coefficients. The electrical parameters corresponding to the studied compounds are shown in Table 2.

The frequency dependence of the ac conductivity, $\sigma_{ac}(\omega)$, for different values of temperatures between 295 and 433 K was investigated for all samples. The frequency dependence of the ac conductivity is shown in Fig. 7 for all compounds as a plot of $\ln \sigma_{ac}$ versus $\ln \omega$ at 373 K. The general observed frequency dependence of the ac conductivity in disordered systems, such as phthalocyanine, is that the ac conductivity obeys an empirical power law of the form $\sigma_{ac}(\omega) = A(T)\omega^s$, where $A(T)$ and s are temperature dependent parameters. To explain this type of frequency dependence of the ac conduction, two models have been used. According to the first model, which is known as the quantum mechanical tunnelling model (QMT), the conduction occurs by means of thermally assisted Quantum Mechanical Tunnelling. The other model, which is known as the Correlated Barrier Hopping (CBH) model, is based on the concept of charged defects and in this bipolarons hop between two charged defect states D^+ and D^- over the barrier separating them. In these two models, the frequency exponent s is found to have two different trends with temperature and frequency [22]. The values of the frequency exponent s were calculated from the slope of the measured $\ln \sigma_{ac}$ versus $\ln \omega$ graphs. Our results showed that s is definitely a function of temperature for all the compounds and shows a general tendency to decrease with increasing temperature. This is in agreement with the prediction of the CBH model.

Table 2
The electrical parameters of the Pc complexes

Samples	$\sigma_{290\,K}$ (Ω^{-1} cm^{-1})	E_A (eV)	$\sigma_{433\,K}$ (Ω^{-1} cm^{-1})
7	8.76×10^{-9}	0.81	1.41×10^{-4}
8	1.82×10^{-9}	0.79	1.07×10^{-4}
9	2.959×10^{-8}	0.70	1.84×10^{-4}
10	3.16×10^{-7}	0.72	2.1×10^{-4}

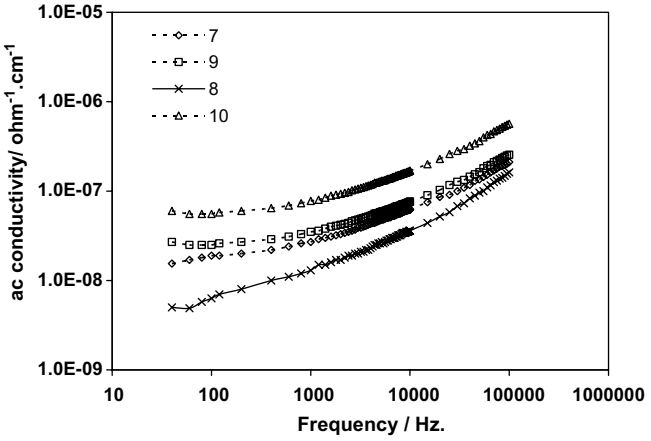

Fig. 7. The variation of the ac conductivity with frequency at 373 K.

To get more detailed information about the electrical properties of the compounds, impedance spectral measurements in the frequency range 40–10^5 Hz were also carried out on a spin coated film of the compounds. The measured impedance spectra, when plotted in a complex plane plot,

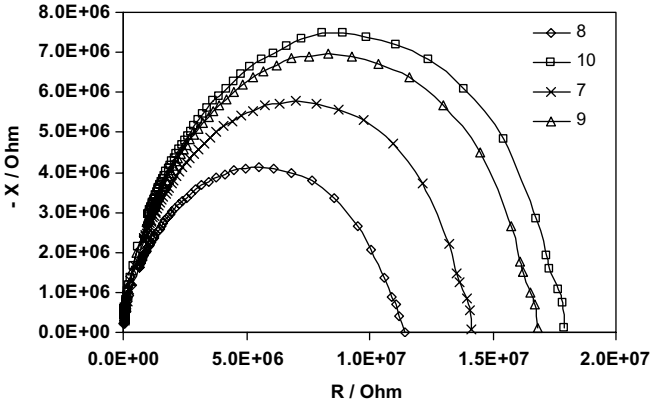

Fig. 8. Impedance spectra of the Pc films at 400 K.

appear in the form of a succession of semi-circles representing the contributions to the electrical properties due to bulk material, grain boundary effect and interfacial polarization phenomena. So, the impedance spectra technique enables us to separate the effects due to each component. At low temperatures, the impedance spectra consist of a quasi-vertical line. The existence of semicircular shaped curves in the Nyquist plot means that the impedance becomes capacitive even at relatively high frequencies. The effect of temperature on the impedance spectra of the films becomes clearly visible with a rise in the temperature. On the complex plane plot at high temperatures, only depressed semicircles with different radii were observed at higher temperatures, indicating deviation from the Debye dispersion relation (Fig. 8). In the case of a depressed semi-circle in the impedance spectra, the relaxation time is considered as a distribution of values, rather than a single relaxation time.

a protective 'shell' around the rare-earth ion can lead to significant enhancement of the luminescent properties of the complex: avoiding the coordination of small but strongly quenching solvent molecules can be done by designing very bulky ligands, or by opting for a tetrakis stoichiometry instead of a tris stoichiometry [16–19].

Complexes of lanthanide ions with a hemicyanine unit have only been scarcely investigated [20–25]. Compounds with a hemicyanine chromophore are well known as dyes [26–29]. Hemicyanine dyes, having a large energy gap between the ground state and the excited states, which is beneficial for high polarisability, have been studied for their nonlinear optical (NLO) properties, e.g. in Langmuir–Blodgett films [30–32]. It was shown that combining a lanthanide complex with a hemicyanine compound enhances the film-forming properties and at the same time increases the charge separation in the chromophore, thus improving the NLO properties [33].

In this paper, we show that the hemicyanine unit in combination with the pyrazolone groups in the lanthanide complexes provide a suitable basis for sensitized near-infrared luminescence. We describe the synthesis of the hemicyanine bromide precursor as well as the final lanthanide complexes. The absorption spectrum of the complexes, as well as the luminescence spectra of the trivalent neodymium, erbium and ytterbium ions are discussed.

3 Ln = Nd (yield: 20%)
4 Ln = Er (yield: 63%)
5 Ln = Yb (yield: 52%)

Scheme 1. Synthetic procedure towards the hemicyanine counterion and the final lanthanide complexes.

2. Results and discussion

To tackle the limitations described in the introduction, we have chosen the β-diketone 1-phenyl-3-methyl-4-benzoyl-5-pyrazolone (see Scheme 1) as ligand. This molecule does not have an α-hydrogen atom, so no C–H vibrational quenching at that site is expected. At the same time, the phenyl groups provide a means of light harvesting. Finally, β-diketones are well known as ligands for rare-earth ions and easy synthetic procedures towards tetrakis complexes (with a metal-to-ligand ratio of 1:4) are available [34,35].

The synthetic procedure towards the hemicyanine counterion and the final lanthanide complexes is displayed in Scheme 1. The hemicyanine bromide was prepared in a two-step reaction: first, 4-picoline was reacted with 1-bromohexadecane. Second, the resulting 1-hexadecyl-4-methylpyridinium bromide **1** was condensed with 4-dimethylaminobenzaldehyde via a Knoevenagel-type reaction, yielding the hemicyanine bromide **2**. The lanthanide complexes **3**–**5** were synthesised by reaction of the hemicyanine bromide **2** with the β-diketone 4-benzoyl-3-methyl-1-phenyl-2-pyrazolin-5-one and the appropriate lanthanide salt. The complexes were obtained in good yields. See Section 4 for more details.

Single crystals, suitable for X-ray structure determination, were obtained of the (*E*)-*N*-dodecyl-*N*′,*N*′-dimethylamino-stilbazolium tetrakis(1-phenyl-3-methyl-4-benzoyl-5-pyrazolonato) lanthanum(III) complex. The crystal structure of the complex consists of the anionic complex molecule with four pyrazolonato ligands, a hemicyanine counterion and some water of crystallization. Fig. 1 shows the complex without the large hemicyanine counterion. The asymmetric unit contains two crystallographically independent molecules with slightly different conformations. The coordination number of the lanthanum ion is eight and the coordination polyeder of the lanthanum ion can be regarded as a slightly distorted square antiprism. No evidence of solvent coordination to the central lanthanum ion was found in the crystal structure.

Each two of the 1-phenyl pyrazolonato parts of the ligands are oriented almost parallel to each other, but with an antipodal orientation with respect to each other. The cations are situated in the cavity between two neighboring pyrazolonato ligands and exhibit weak π–π stacking interactions between the 4-benzoyl groups of the ligands and the pyridinium part of the cation (centroid-to-centroid distances range from 4.13 to 4.39 Å). This is shown in Fig. 2. Hydrogen bonding was found from the nitrogen atom of some of the pyrazolonato ligands to water molecules of crystallization with N···O distances in the range of 2.92–2.97Å. The crystal structure data are summarised in Table 1, whereas the crystal packing is shown in Fig. 3.

The complexes exhibit a strong orange-red colour, due to the charge-transfer band in the hemicyanine chromophore unit. The absorption spectrum of the neodymium complex **3** is given in Fig. 4. The peak maxima have been indicated. Whereas the maxima located at 238 and 276 nm are due to the singlet-to-singlet transitions in the pyrazolonate ligands, the broad band at 475 nm is due to the charge-transfer transition in the hemicyanine chromophore. This band is responsible for the intense orange-red colour of the complexes. Since visible excitation is a much sought-after property in NIR emitting rare-earth complexes, it was our hope that excitation of the pyrazolonato complexes in the hemicyanine band would result in

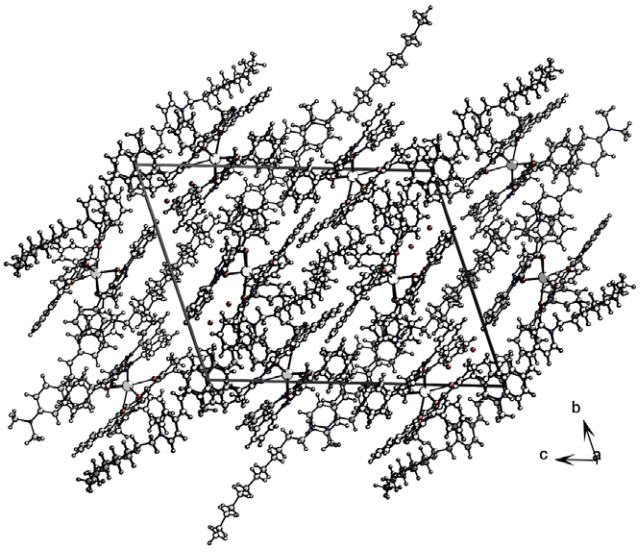

Fig. 3. Molecular crystal packing of the (*E*)-*N*-dodecyl-*N*′,*N*′-dimethylamino-stilbazolium tetrakis(1-phenyl-3-methyl-4-benzoyl-5-pyrazolonato) lanthanum(III) complex.

rare-earth centered NIR luminescence. Unfortunately, this did not turn out to be the case. Moreover, excitation of **3** in the hemicyanine chromophore at 475 nm resulted in the appearance of a strong red fluorescence band with a maximum at 630 nm. This shows that no energy is transferred from the hemicyanine moiety to the pyrazolonato ligands

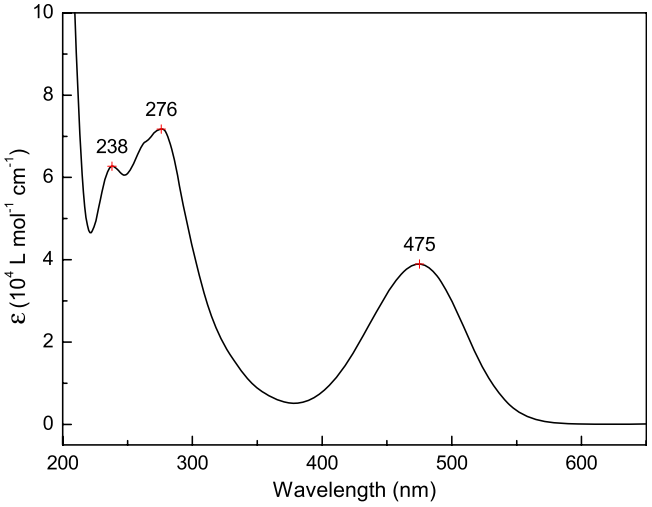

Fig. 4. Absorption spectrum of complex **3** in acetonitrile ($c = 10^{-5}$ mol L^{-1}).

or to the central neodymium ion. On the contrary, excitation of **3** at 276 nm resulted also in the appearance of this band at 630 nm, albeit less intense (about 5 times less intense) then upon excitation at 475 nm. Of course, also the neodymium(III)-centered NIR emission could be easily detected. This indicates that part of the excitation energy in the pyrazolonato ligands is transferred to the neodymium(III) ion, but another part is also transferred to the hemicyanine chromophore, which emits it as red light.

In Fig. 5, the combined emission spectra are shown of complexes **3**, **4** and **5** in acetonitrile upon excitation at 276 nm. Complex **3** shows the typical emission bands at 875 nm, 1060 nm and 1330 nm, corresponding to the $^4F_{3/2} \rightarrow {}^4I_J$ lines ($J = 9/2$, 11/2 and 13/2). The emission spectrum of **4** is shown as the dashed line and exhibits

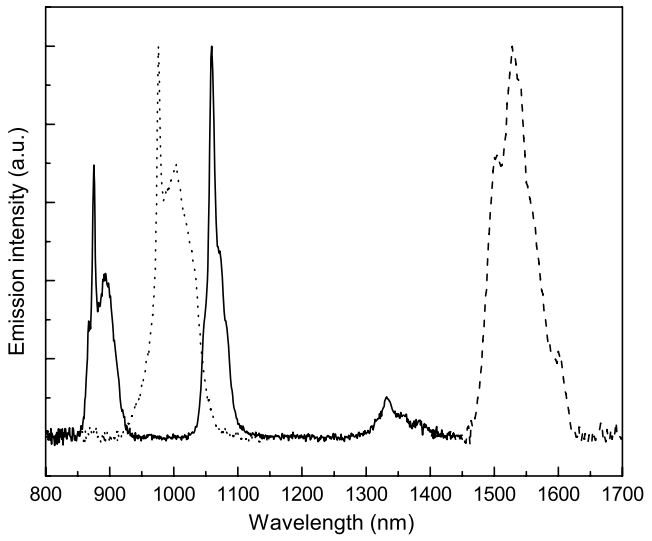

Fig. 5. Combined emission spectra of neodymium complex **3** (solid line), erbium complex **4** (dashed line) and ytterbium complex **5** (dotted line) in acetonitrile ($c = 10^{-5}$ mol L^{-1}, $\lambda_{exc} = 276$ nm, emission intensities are not to scale).

Table 2
Luminescence decay times of the Nd^{3+} ($^4F_{3/2}$), Er^{3+} ($^4I_{13/2}$) and Yb^{3+} ($^2F_{5/2}$) levels in complexes **3**, **4** and **5**, respectively[a]

Complex	Rare-earth ion	Decay time (μs)
3	Nd^{3+}	1.0
4	Er^{3+}	3.2
5	Yb^{3+}	46.4

[a] Lifetimes measured at room temperature; $\lambda_{exc} = 266$ nm; $c = 10^{-5}$ mol L^{-1}; solutions in acetonitrile.

one characteristic band at 1530 nm, corresponding to the $^4I_{13/2} \rightarrow {}^4I_{15/2}$ line. Finally, the spectrum of complex **5**, drawn as the dotted line, exhibits one emission band at 975 nm, corresponding to the $^2F_{5/2} \rightarrow {}^2F_{7/2}$ line.

In Table 2, the luminescence decay times of the Nd^{3+} ($^4F_{3/2}$), Er^{3+} ($^4I_{13/2}$) and Yb^{3+} ($^2F_{5/2}$) levels in (*E*)-*N*-hexadecyl-*N*′,*N*′-dimethylamino-stilbazolium tetrakis(1-phenyl-3-methyl-4-benzoyl-5-pyrazolonato) rare-earth(III) complexes are given. These decay times compare well to decay times of other NIR-emitting rare-earth complexes in organic solution. For example, a tetrakis (5,7-dichloro-8-oxyquinolinato) lanthanide(III) complex with a tetraethyl ammonium counterion dissolved in THF has decay time values of 0.95 μs for the neodymium(III) sample, 2.2 μs for the erbium(III) ion and 11.6 μs for the ytterbium(III) sample [36]. The hemicyanine materials presented here have comparable (neodymium(III) complex), slightly longer (erbium(III) complex) or even significantly longer (ytterbium(III) complex) luminescence decay times. On the other hand, they are not as good as the values obtained by Bassett et al. for the tetraphenylimidophosphinate complexes of NIR-emitting rare-earth ions in dry acetonitrile solution (2.6 μs for the Nd(III) complex, 6.5 μs for the Er(III) complex and 52.8 μs for the Yb(III) complex) [18]. It has to be added that the ytterbium(III) ion can be excited through an alternative redox mechanism [37]. A detailed photophysical study of the materials under investigation, however, falls outside the scope of this paper.

3. Conclusions

In conclusion, we have shown that NIR luminescence can be obtained from (*E*)-*N*-hexadecyl-*N*′,*N*′-dimethylamino-stilbazolium tetrakis(1-phenyl-3-methyl-4-benzoyl-5-pyrazolonato) rare-earth(III) complexes in acetonitrile solution. Because of the absence of the α-hydrogen atom on the pyrazolonato ligand and because of the shielding provided by the tetrakis stoichiometry of the complex, luminescence decay times could be obtained that compare well to the better behaving rare-earth complexes in solution. Nevertheless, the incorporation of the hemicyanine chromophore in the complexes did not lead to enhanced emission properties, nor did it allow visible light sensitisation of the NIR-luminescence. However, it is known from the literature that the combination of hemicyanine units with rare-earth complexes increases the film-forming properties of the hemicyanine compound, creating the possibility of developing NIR-emitting thin films based on pyrazolonato rare-earth complexes.

4. Experimental

4.1. Equipment and techniques

Absorption spectra were recorded on a Varian Cary 5000 spectrophotometer. Visible luminescence spectra were obtained with an Edinburgh Instruments F900 spectrometer, equipped with a 1800 lines/mm grating excitation monochromator and a 1800 lines/mm grating emission monochromator. A 450 W xenon lamp is used as the excitation source and a red-sensitive photomultiplier tube type S900-R is used as the detector. The steady state near-infrared luminescence spectra and the lifetime measurements were done on an Edinburgh Instruments FS920P near infrared spectrometer, with a 450 W xenon lamp as the steady state excitation source, a double excitation monochromator with 1800 lines/mm, an emission monochromator with 600 lines/mm, and a liquid nitrogen cooled Hamamatsu R5509-72 near infrared photomultiplier tube. For luminescence decay time measurements, the setup includes a Continuum Minilite Nd:YAG laser, equipped with 2nd, 3rd and 4th harmonic crystals, allowing excitation at 1064, 532, 355 and 266 nm. Repetition rate is 10 Hz, pulse width is 3–5 ns. Standard quartz 1 cm fluorescence cuvets (Hellma type QS-111) were used. Luminescence lifetime data were extracted from the decay curves using the program Origin®.

^{1}H NMR spectra have been recorded on a Bruker WM 250 spectrometer, operating at 250 MHz or a Bruker AMX 400 spectrometer, operating at 400 MHz, using deuterated chloroform ($CDCl_3$) as the solvent and tetramethylsilane (TMS) as internal standard. ^{13}C NMR spectra have been recorded on a Bruker AMX 400 spectrometer, operating at 100.6 MHz, using deuterated chloroform ($CDCl_3$) as the solvent and tetramethylsilane (TMS) as internal standard.

EI mass spectra have been obtained on a Hewlett–Packard 5989A mass spectrometer.

CHN elemental analyses have been performed on a Perkin–Elmer 2400 elemental analyser, operated by the university of Exeter (School of Chemistry) or on a CE Instruments EA-1110 elemental analyser (K.U.Leuven, Chemistry Department).

IR spectra have been recorded on a Bruker FT-IR IFS66 spectrometer, using KBr pellets.

4.2. Synthesis

The hemicyanine bromide was synthesized by a two-step reaction (Scheme 1). During the first step, 4-picoline was refluxed with *n*-bromohexadecane in ethanol. The crude 1-hexadecyl-4-methylpyridinium bromide **1** was recrystallized twice from a diethyl ether:ethanol mixture. Yield: 85% (67.8 g). ^{1}H NMR (δ_H, $CDCl_3$, 250 MHz): 0.89 (3H,

t, CH_3); 1.26 (26H, m, CH_2); 2.04 (2H, m, CH_2); 2.69 (3H, s, CH_3-aryl); 4.92 (2H, t, N^+-CH_2); 7.94 (2H, d, H-aryl, $J_0 = 6$ Hz); 9.39 (2H, d, H-aryl, $J_0 = 6$ Hz). IR (cm^{-1}, KBr): 3009 (m), 2913 (s), 2846 (s), 1639 (s), 1568 (w), 1519 (m), 1470 (s), 1383 (w), 1322 (w), 1176 (m), 1045 (w), 974 (w), 821 (m), 713 (m), 555 (w). Mass (*m*/*z*, EI, 70 eV): $M^+ = C_{22}H_{40}N^+$; 319 ($[M+1]^+$, 4); 318 (M^+, 25); 317 (M^+-1H, 97); 316 (M^+-2H, 44); 288 ($M^+-C_2H_6$, 42); 274 ($M^+-C_3H_8$, 48); 260 ($M^+-C_4H_{10}$, 55); 246 ($M^+-C_5H_{12}$, 55); 232 ($M^+-C_6H_{14}$, 51); 218 ($M^+-C_7H_{16}$, 42); 190 ($M^+-C_9H_{20}$, 40); 162 ($M^+-C_{11}H_{24}$, 40); 134 ($M^+-C_{13}H_{28}$, 72); 121 ($M^+-C_{14}H_{29}$, 53); 120 ($M^+-C_{14}H_{30}$, 61); 107 ($M^+-C_{15}H_{31}$, 100); 94 ($M^+-C_{16}H_{32}$, 52); 93 ($M^+-C_{16}H_{33}$, 36). CHN Elemental *Anal*. Calc. for $C_{22}H_{40}BrN$ (398.47 g mol^{-1}): C, 66.31; H, 10.12; N, 3.52. Found: C, 66.20; H, 10.32; N, 3.37%.

The 1-hexadecyl-4-methylpyridinium bromide **1** was then condensed with 4-dimethylaminobenzaldehyde via a Knoevenagel-type reaction. The reagents were heated in absolute ethanol with piperidine as the catalyst. The crude hemicyanine bromide **2** was recrystallized twice from an ethanol:hexane mixture. Yield: 71% (18.8 g). ^{1}H NMR (δ_H, $CDCl_3$, 400 MHz): 0.87 (3H, t, CH_3); 1.26 (26H, m, CH_2); 1.93 (2H, quintet, CH_2); 3.06 (6H, s, $(CH_3)_2N$); 4.64 (2H, t, N^+-CH_2); 6.68 (2H, d, H-aryl, $J_0 = 9$ Hz); 6.86 (1H, –CH=, $J_{trans} = 16$ Hz); 7.52 (2H, d, H-aryl, $J_0 = 9$ Hz); 7.62 (1H, –CH=, $J_{trans} = 16$ Hz); 7.88 (2H, d, H-aryl, $J_0 = 7$ Hz); 8.94 (2H, d, H-aryl, $J_0 = 7$ Hz).^{13}C NMR (δ_C, $CDCl_3$, 100.6 MHz): 14.1 (CH_3); 22.6 (CH_2); 26.1 (CH_2); 29.05 (CH_2); 29.30 (CH_2); 29.35 (CH_2); 29.50 (CH_2); 29.55 (CH_2); 29.60 (CH_2); 29.65 (CH_2); 31.6 (CH_2); 31.9 (CH_2); 40.1 ($(CH_3)_2N$); 60.2 (N^+-CH_2); 111.9; 116.3; 122.2 (quaternary C); 122.7 (alkene C); 130.6; 142.9; 152.2 (quaternary C); 154.0 (quaternary C). IR (cm^{-1}, KBr): 3000 (w), 2912 (s), 2852 (m), 1641 (m, alkene C=C), 1591 (s, aryl C=C), 1526 (s, aryl C=C), 1467 (m), 1430 (m), 1362 (m), 1330 (m), 1161 (s), 827 (w), 717 (w), 518 (w). Mass (*m*/*z*, EI, 70 eV): $M^+ = C_{31}H_{49}N_2^+$; 451 ($[M+1]^+$, 7); 450 (M^+, 5); 448 (M^+-2H, 2); 225 ($M^+-C_{16}H_{32}$, 18); 224 ($M^+-C_{16}H_{33}$, 100); 223 ($M^+-C_{16}H_{34}$, 52). CHN Elemental *Anal*. Calc. for $C_{31}H_{49}BrN_2$ (529.65 g mol^{-1}): C, 70.30; H, 9.32; N, 5.29. Found: C, 69.94; H, 9.75; N, 4.88%.

Only the *trans*-product (*E*) is formed. There was no evidence for the formation of the *cis*-isomer, probably because of steric hindrance by the aromatic groups. The 1-hexadecyl-4-methylpyridinium bromide is a white powder, whereas the hemicyanine bromide has a very intense orange-red colour.

The lanthanide complexes **3**–**5** were formed by reaction of the hemicyanine bromide **2** with the β-diketone 4-benzoyl-3-methyl-1-phenyl-2-pyrazolin-5-one and the appropriate lanthanide salt. First, the β-diketone was deprotonated by an equivalent amount of NaOH, then, the hemicyanine bromide and a lanthanide salt were added. The molar ratio β-diketone:hemicyanine bromide:lanthanide salt was 4:1:1. For the lanthanide salt, one can use the hydrated nitrate or chloride salt. All the reactions were carried out in ethanol. The complexes were recrystallized from ethanol:water (1:1). Analysis results for neodymium complex **3**: yield 20% (0.33 g). IR (cm^{-1}, KBr): 3059 (w), 2932 (m), 2849 (m), 1640 (sh, alkene C=C), 1612 (s, C=O stretching), 1595 (s, C=N), 1573 (s, aryl C=C), 1530 (m, C=C stretching), 1491 (s, C=O stretching and CH bending), 1434 (m), 1396 (m), 1361 (m), 1322 (m), 1231 (w), 1162 (m), 1053 (m), 945 (m), 837 (m), 759 (m), 703 (m), 607 (m). 4.3. Crystallography

Red single crystals of the (*E*)-*N*-dodecyl-*N*′,*N*′-dimethylamino-stilbazolium tetrakis(1-phenyl-3-methyl-4-benzoyl-5-pyrazolonato) lanthanum(III) complex were obtained by slow evaporation of diethylether into a solution of the compound in dimethylformamide. X-ray intensity data were collected on a SMART 6000 diffractometer equipped with CCD detector using Cu Kα radiation ($\lambda = 1.54178$ Å). The images were interpreted and integrated with the program SAINT from Bruker [38]. Crystal data can be found in Table 1.

The structure was solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELXTL program package [39]. Non-hydrogen atoms were anisotropically refined and the hydrogen atoms in the riding mode with isotropic temperature factors fixed at 1.2 times U_{eq} of the parent atoms (1.5 times for methyl groups).

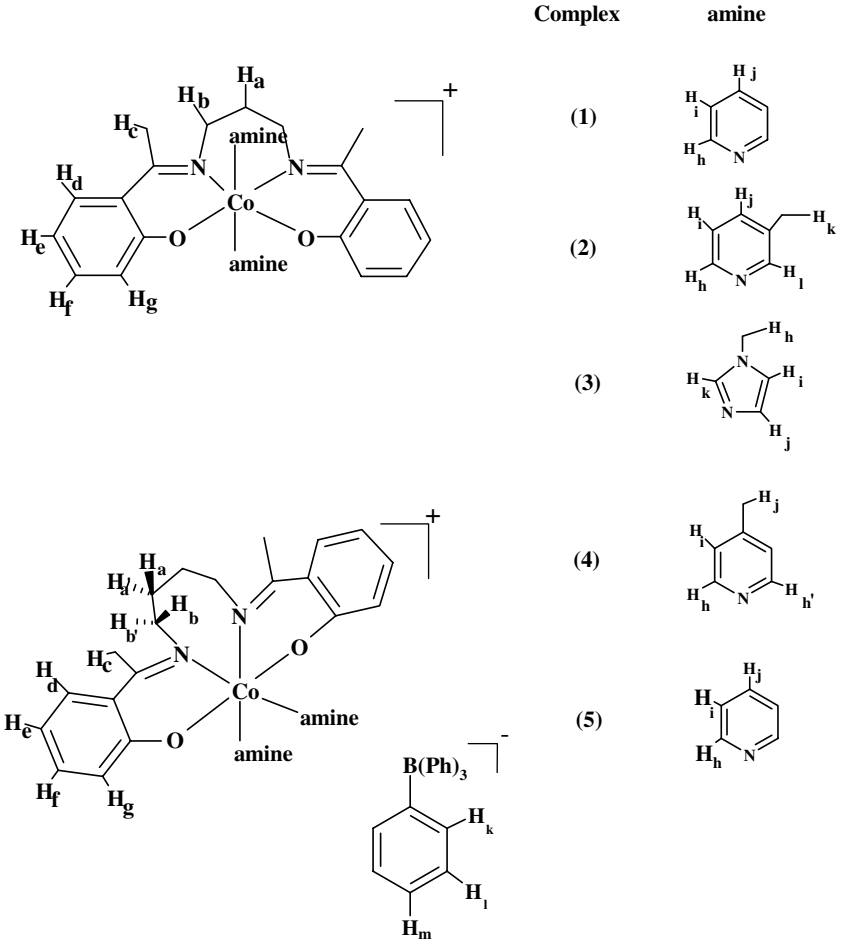
the *cis*-β-isomer, and two equatorial positions in the *cis*-α-isomer (Scheme 1). The molecule of [Rh(Salbn)Cl(py)], for example, has the Cl and pyridine ligands 90° apart with salbn twisted into a *cis*-β-conformation [17].

In continuation of our work on the synthesis and structural studies of Co(III) complexes containing Schiff base ligands [18–21], we herein report the synthesis and spectroscopic characterization of several cobalt(III) complexes of Me-salpn and Me-salbn Schiff base ligands (Scheme 2). In two representative cases, *trans*-[Co^{III}(Me-salpn)$(py)_2$]-PF_6, **1**, and *cis*-α-[Co^{III}(Me-salbn)$(4\text{-Mepy})_2$]$BPh_4 \cdot$ 4-Mepy, **4**, crystal structures have been determined to define the coordination sphere. The results of our studies on the outer coordination sphere effects, obtained by spectroscopy, cyclic voltammetry, and X-ray crystal structure determination is also discussed.



trans (**1**) *cis*-β *cis*-α (**4**)

Scheme 1.

2. Experimental

2.1. Materials and general methods

All solvents and chemicals were used as received, except for the amines which were distilled under reduced pressure prior to use. Elemental analyses were performed by using a Perkin–Elmer 2400II CHNS-O elemental analyzer. UV–Vis spectra were recorded on a JASCO V-570 spectrophotometer. Infrared spectra (KBr pellets) were obtained on a FT-IR JASCO 680 plus spectrophotometer. ^{1}H NMR spectra were obtained on a BRUKER AVANCE DR X500 (500 MHz) and DR X300 (300 MHz) spectrometer. Proton chemical shift are reported in part per million (ppm) relative to an internal standard of Me_4Si. The redox properties of the complexes were studied by cyclic voltammetry. Cyclic voltammograms were recorded by using a SAMA Research Analyzer M-500. Three electrodes were

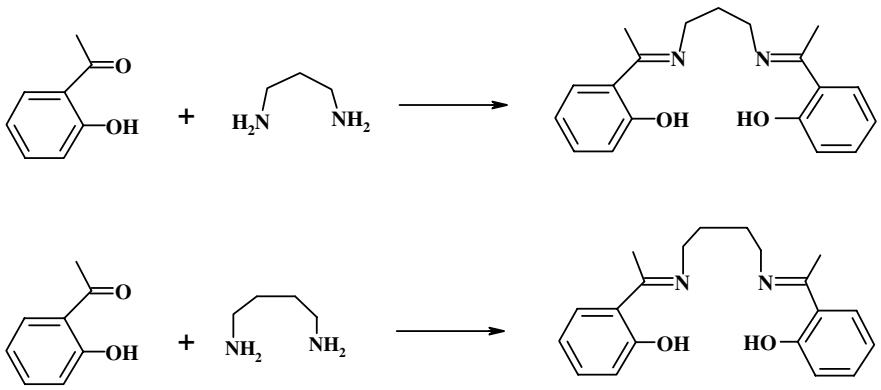
Scheme 2.

utilized in this system, a glassy carbon working electrode, a platinum disk auxiliary electrode and Ag wire as reference electrode. The glassy carbon working electrode (Metrohm 6.1204.110) with 2.0 ± 0.1 mm diameter was manually cleaned with 1μm alumina polish prior to each scan. Tetrabutylammonium hexafluorophosphate (TBAH) was used as supporting electrolyte. Acetonitrile was dried over CaH_2. The solutions were deoxygenated by purging with Ar for 5 min. All electrochemical potentials were calibrated versus internal Fc^+/o ($E^0 = 0.40$ V versus SCE) couple under the same conditions [22].

2.2. Synthesis

2.2.1. H_2Me-salpn

H_2Me-salpn, *N*,*N*′-bis(methylsalicylidene)-1,3-propylenediamine, was prepared as reported in the literature [23] by the condensation of 1,3-propandiamine with 2-hydroxyacetophenone (1:2 mol stoichiometric ratio) in methanol at room temperature (Scheme 3), and was recrystallized from hot methanol. Yield: 95%, m.p. 122 °C. FT-IR (KBr, cm^{-1}): ν_{max} 3370–3470 (m, br, OH), 1614 (s, C=N). UV–Vis: λ_{max} (nm) (ε, L mol^{-1} cm^{-1}) ($CHCl_3$): 392 (2250), 322 (7360), 258 (23410). ^{1}H NMR ($CDCl_3$, 500 MHz): $\delta = 2.25$ (m, $2H_a$), 2.36 (s, $6H_c$), 3.75 (t, $4H_b$), 6.78 (br t, $2H_e$), 6.94 (br d, $2H_g$), 7.29 (br t, $2H_f$), 7.52 (br d, $2H_d$).



2.2.2. H_2Me-salbn

H_2Me-salbn, *N*,*N*′-bis(methylsalicylidene)-1,4-butylenediamine, was prepared by the same method as for H_2Me-salpn, using 1,4-butanediamine and 2-hydroxyacetophenone (1:2 mol stoichiometric ratio) in methanol at room temperature (Scheme 3), and was recrystallized from hot acetonitrile. Yield: 95%, m.p. 189°. *Anal.* Calc. for $C_{20}H_{24}N_2O_2$: C, 74.04; H, 7.46; N, 8.64. Found: C, 74.08; H, 7.52; N, 8.69%. FT-IR (KBr, cm^{-1}): ν_{max} 3409–3580 (w, br, OH), 1614 (s, C=N). UV–Vis: λ_{max} (nm) (ε, L mol^{-1} cm^{-1}) ($CHCl_3$): 394 (2825), 318 (8390), 251 (22660). ^{1}H NMR ($CDCl_3$, 300 MHz): $\delta = 1.96$ (m, 4H, $H_{a,a'}$), 2.36 (s, 6H, H_c), 3.64 (m, 4H, $H_{b,b'}$), 6.76 (td, 2H, H_e), 6.93 (dd, 2H, H_g), 7.29 (td, 2H, H_f), 7.51 (dd, 2H, H_d).

2.2.3. Synthesis of cobalt complexes

*2.2.3.1. Preparation of [Co^{III}(Me-salpn)(py)$_2$]PF_6 (**1**).* To a stirring solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (0.125 g, 0.5 mmol) in methanol (25 ml) was added an equimolar of H_2Me-salpn (0.155 g, 0.5 mmol). The pink solution turned brown immediately upon the formation of [Co^{II}(Me-salpn)] complex. To this solution was added 4 mmol of pyridine, and air was bubbled through the reaction mixture for about 3 h. 0.5 mmol of NH_4PF_6 was then added to the resulting green brown solution and stirred for 5 min. A green microcrystalline solid was produced by slow evaporation of methanol at room temperature. The product was then recrystallized from methanol–propanol (2:1 v/v) and yellow green crystals suitable for X-ray crystallography were obtained. The crystals were filtered off and washed with a small amount of cold methanol and dried under vacuum. Yield: 62%. *Anal.* Calc. for $C_{29}H_{30}CoF_6N_4O_2P$: C, 51.95; H, 4.51; N, 8.36. Found: C, 52.0; H, 4.5; N, 8.3%. FT-IR (KBr, cm^{-1}): ν_{max} 1597 (s, C=N), 839 (s, PF_6). UV–Vis: λ_{max} (nm) (ε, L mol^{-1} cm^{-1}) ($CHCl_3$): 600 (405), 380 (6710), 265 (42585). ^{1}H NMR ($CDCl_3$, 500 MHz): $\delta = 1.5$ (m, $2H_a$), 2.63 (s, $6H_c$), 3.89 (br t, $4H_b$), 6.36 (br t, $2H_e$) 6.97 (br d, $2H_g$), 7.03 (br t, $2H_f$), 7.18 (br t, $4H_i$), 7.25 (br d, $2H_d$) 7.64 (br t, $2H_j$) 8.30 (br d, $4H_h$).

*2.2.3.2. Preparation of [Co^{III}(Me-salpn)(3-Mepy)$_2$]PF_6 (**2**).* This complex was prepared by the same method as for **1** except that 3-methylpyridine was used instead of pyridine. Recrystallization from methanol gave green crystals. The crystals were filtered off and washed with a small amount of cold methanol and dried under vacuum. Yield: 70%. *Anal.* Calc. for $C_{31}H_{34}CoF_6N_4O_2P$: C, 53.30; H, 4.91; N, 8.02. Found: C, 53.2; H, 5.0; N, 8.0%. FT-IR (KBr, cm^{-1}): ν_{max} 1596 (s, C=N), 842 (s, PF_6). UV–Vis: λ_{max} (nm) (ε, L mol^{-1} cm^{-1}) ($CHCl_3$): 598 (455), 380 (7280), 265 (43890). ^{1}H NMR ($CDCl_3$, 500 MHz): $\delta = 1.55$ (m, $2H_a$), 2.1 (s, $6H_k$), 2.61 (s, $6H_c$), 3.87 (br t, $4H_b$), 6.35 (br t, $2H_e$), 7.00 (br d, $2H_g$), 7.04 (br t, $2H_f$), 7.16 (br t, $2H_i$), 7.25 (br d, $2H_d$) 7.41 (br d, $2H_j$), 8.08 ($4H_{h,l}$).

Scheme 3.

*2.2.3.3. Preparation of [Co^{III}(Me-salpn)(1-MeIm)$_2$]PF$_6$ (**3**).* This complex was prepared by the same method as for **1** except that 1-methylimidazole was used instead of pyridine. Recrystallization from chloroform–xylene (2:1 v/v) gave green crystals. The crystals were filtered off and washed with a small amount of cold methanol and dried under vacuum. Yield: 70%. *Anal.* Calc. for $C_{27}H_{32}CoF_6N_6O_2P$: C, 47.94; H, 4.77; N, 12.42. Found: C, 47.20; H, 4.80; N, 12.20%. FT-IR (KBr, cm^{-1}): ν_{max} 1597 (s, C=N), 845 (s, PF_6). UV–Vis: λ_{max} (nm) (ε, L mol^{-1} cm^{-1}) ($CHCl_3$): 578 (384), 380 (6950), 273 (54 610). ^{1}H NMR ($CDCl_3$, 500 MHz): $\delta = 1.58$ ($2H_a$), 2.59 (s, $6H_c$), 3.59 (s, $6H_h$), 3.83 ($4H_b$), 6.38–7.45 (14H, $H_{d,e,f.g,i,j,k}$).

*2.2.3.4. Preparation of [Co^{III}(Me-salbn)(4-Mepy)$_2$]-BPh$_4$ · 4-Mepy (**4**).* To a stirring solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (0.125 g, 0.5 mmol) in methanol (30 ml) was added two drops of H_2O_2 (30%). The pink solution turned green immediately and to this solution was then added a solution of equimolar H_2Me-salbn (0.162 g, 0.5 mmol) in chloroform (10 ml). Air was then bubbled through the reaction mixture for about 3 h, while adding 5 mmol of 4-methylpyridine in one h intervals. The final solution was filtered off and a solution of 0.5 mmol (0.171 g) of $NaBPh_4$ in 5 mL methanol was added drop wise to the filtrate. Red green crystals of complex **4** suitable for X-ray crystallography were obtained after one week by slow evaporation of the solvent. The crystals were filtered off and washed with a mixture of methanol–diethyl ether (1:10 v/v) and dried under vacuum. Yield: 60%. *Anal.* Calc. for $C_{62}H_{63}CoN_5O_2B$: C, 75.99; H, 6.48; N, 7.15. Found: C, 75.21; H, 6.38; N, 7.01%. FT-IR (KBr, cm^{-1}) ν_{max}: 1595 (s, C=N), UV–Vis: λ_{max} (nm) (ε, L mol^{-1} cm^{-1}) ($CHCl_3$): 648 (390), 425 (sh, 2470), 388 (5100), 260 (52600). ^{1}H NMR ($CDCl_3$, 300 MHz): $\delta = 1.58$–1.87 (m, 4H, $H_{a,a'}$), 2.22 (s, 6H, H_j), 2.38(s, H_{Me}, free 4-Mepy) 2.47 (s, 6H, H_c), 3.75–4.4 (m, 4H, $H_{b,b'}$), 6.34–8.65 (40H, ArH).

*2.2.3.5. Preparation of [Co^{III}(Me-salbn)(py)$_2$]BPh$_4$ (**5**).* This complex was prepared by the same method as for **4** except that pyridine was used instead of 4-methylpyridine and a green solid product was obtained after one week. Recrystallization from chloroform–chlorobenzene (3:1 v/v) gave red green crystals after 10 days. The crystals were filtered off and washed with a mixture of methanol–diethyl ether (1:10 v/v) and dried under vacuum. Yield: 50%. *Anal.* Calc. for $C_{54}H_{52}CoN_4O_2B$: C, 75.52; H, 6.10; N, 6.52. Found: C, 74.92; H, 6.30; N, 6.40%. FT-IR (KBr, cm^{-1}) ν_{max}: 1598 (s, C=N). UV–Vis: λ_{max} (nm) (ε, L mol^{-1} cm^{-1}) ($CHCl_3$): 646 (415), 429 (sh, 1890), 386 (4290), 257(52 510). ^{1}H NMR ($CDCl_3$, 300 MHz): $\delta = 1.62$–1.87 (m, 4H, $H_{a,a'}$), 2.47 (s, 6H, H_c), 3.76–4.41 (m, 4H, $H_{b,b'}$), 6.37–8.8 (38H, ArH).

2.3. Crystallography

2.3.1. X-ray crystallography for *1*

Yellow crystals of **1** suitable for data collection were obtained by slow evaporation of a methanol–propanol (2:1 v/v) solution of the complex. The cell and intensities were measured on a Stoe IPSD II at 120 K, using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å).

A crystal-to-detector distance of 100 cm was chosen and 180 one-degree-wide images were exposed for 5 min each. Crystal data and details of the structure determination are given in Table 1. The data were corrected for Lorentz and polarization effects and a numerical absorption correction (X-RED32) was carried out [24]. The structure was solved with the help of DIRDIF-96 [25] and refined, against F^2, using SHELXL-97 [26]. Anisotropic displacement parameters were refined for all atoms, but the hydrogens were made to ride on their carrier atoms, their U-values being coupled to the latter. The measured crystal was bound by {1 0 0} and {0 1 0} pinacoids, and (0 0 1), ($\bar{1}\,\bar{1}$ 9) and ($\bar{1}$ 2 9) pedions, the latter two maybe being part of a {$\bar{1}$ 1 9} prism.

2.3.2. X-ray crystallography for *4*

Red crystals of **4** suitable for X-ray crystallography were obtained by slow evaporation of a methanol–chloroform (3:1 v/v) solution of the complex. Φ-and ω-scan were collected, at room temperature, on a Nonius Kappa CCD diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å) using the COLLECT [27] program. Cell refinement and data reduction were performed with the help of the EVALCCD [28] program. Crystal data, together with other relevant information on structure determination, are listed in Table 1. An empirical absorption correction, based on redundant intensities, was carried out using the SADABS program [29]. The structure was solved by the SIR97 program [30] and refined, against F^2, by means of the SHELXTL program [31]. Anisotropic displacement parameters were assigned to all the non-hydrogen atoms. Hydrogen atoms were placed in idealized positions and allowed to ride on their respective parent atoms, their U-values being coupled to the latter.

3. Results and discussion

3.1. Synthesis

All the cobalt(III) complexes have been prepared by the direct reaction of the corresponding ligands, H_2Me-salpn or H_2Me-salbn, and $Co(CH_3COO)_2 \cdot 4H_2O$ in the presence of the appropriate amine in aerobic conditions (Scheme 2). In the preparation of **1**–**3** complexes, a vigorous stream of air was passed through a solution of Co^{II}(Me-salpn) in methanol to which was gradually added excess amine. The air oxidation was continued for a period of 3 h, during which the color changed from brown to green. Green crystals of these complexes were obtained in good yield (60–70%). In the preparation of **4** and **5** complexes, however, the initial addition of a few drops of H_2O_2 (30%) was

3.2. Description of structures

3.2.1. Complex **1**, $[Co^{III}(Me\text{-}salpn)(py)_2]PF_6$

The structure of complex **1** consists of a mononuclear cobalt(III) unit, depicted in Fig. 1, showing very approximate C_σ symmetry with respect to Co, N(5), N(6) and C(110), but the N(11)–N(21) and O(11)–O(21) distances are quit different indeed (2.910(3) versus 2.548(2) Å). The complex can be described as a distorted octahedron (bond angles and distances are given in Table 2) involving N_2O_2 donors as the basal plane. The pyridine, salicylidene, Co,

N(11), N(21), O(11) and O(21) and N(11), C(19), C(29), N(21) planes feature RMS-values no worse than 0.038 Å, the Co atom therefore perfectly lying in the N_2O_2 plane. The two phenolic oxygen atoms and the two imine nitrogen atoms are located in *cis* positions. The angles between the imino and salicylidine planes are 20.8(1)° and 15.3(3)° for the N(11) and N(21) groups with respect to the C(11) and C(21) rings. The average Co–O distance (1.886 Å) and the O(11)–Co–O(21) angle (85.01(8)°) compare well with those reported for *trans*-[Co(salen)$(py)_2$]BPh_4 (1.884 Å and 85.8°, respectively) [32]. However, increasing the N···N distance in Me-salpn ligand has led to an elongation of the Co–N bond and the enlargement of the N–Co–N angle relative to salen. The average Co–N_{eq} distance (1.963 Å) is considerably longer than that of [Co(salen)-$(py)_2$]BPh_4 (1.888 Å) and the N(11)–Co–N(21) angle (95.69(7)°) is larger than the corresponding angle in the related salen complex (85.5(2)°) [32].

There are two pyridine molecules attached to the metal atom to fill its axial sites with a perpendicular disposition. (88.94(8)°). The N(5)-pyridine, probably for steric reasons, bends away from the six-membered diamine chelate ring N(11), N(21), C(29), C(110), C(28), Co. The axial Co–N(py) bond distances (Co–N(5) 1.991(2), Co–N(6) 1.9538(19) Å) are comparable to those found in the structure of *trans*-[Co(salen)$(py)_2$]BPh_4 (1.975(3) and 1.987(3) Å) [32], but are not equal apparently due to the stereochemical requirements of the central methylene, C(110), whose six-membered diamine chelate ring adopts the thermodynamically unfavorable boat conformation. This steric demand has some influence on the substitution of the axial pyridine ligands and the reduction potential of the cobalt complex (*vide infra*).

There are three intramolecular hydrogen bonds and two intermolecular ones providing weak stabilizing forces (normalized hydrogen bonds lie between 2.27 and 2.54 Å). The former are between the hydrogen on C(110) towards the nitrogen N(5) and between the hydrogen on C(61) towards O(11) and O(21). The latter between one of the methyl hydrogens on C(18) and C(28) towards F(3) and F(4). The intermolecular hydrogen bonds are such as to form [1 1 1] chains of complexes alternating with two hydrogen bonded PF_6 octahedra.

3.2.2. Complex 4, [Co^{III}(Me-salbn)(4-Mepy)$_2$]$BPh_4$4-Mepy

The structure of complexes **4** consist of a six coordinate mononuclear cobalt(III) unit, shown in Fig. 2, with approximate C_σ with respect to O(1)–O(2) (principle bond angles and distances are listed in Table 2). The coordination about Co is pseudo-octahedral, with angles between neighboring vertices of the octahedron varying from 86.69° to 92.02°. The tetradentate Schiff base ligand adopts a *cis*-α-configuration and the two 4-metylpyridine ligands are therefore *cis*, with an angle between them of 87.68(11)°. The Co–O distances (Co(1)–O(1) 1.891(2) Å and Co(1)–O(2) 1.882(2) Å) are similar to those found in

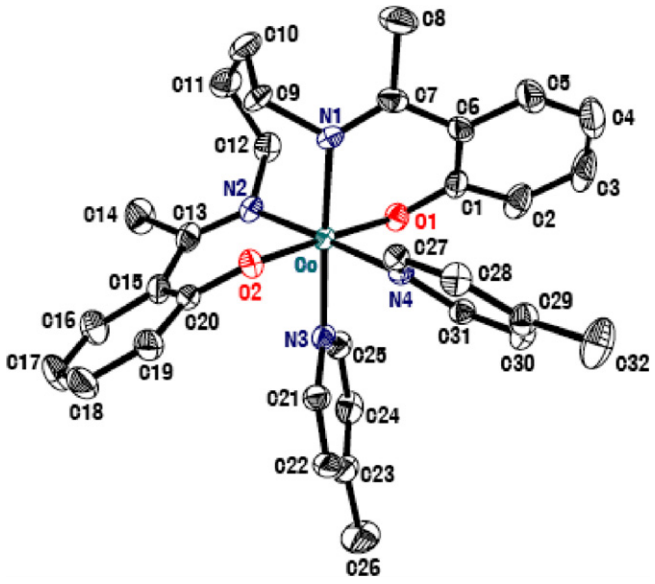

Fig. 2. ORTEP drawing of the cation of complex **4** with the atom numbering scheme. The displacement ellipsoids are drawn at the 50% probability level.

related complexes [32, complex **1**]. The Co–$N_{4\text{-Mepy}}$ distances (Co(1)–N(3) 1.977(3) and Co(1)–N(4) 1.980 (3)) are slightly longer than the Co–N_{imine} distances (Co(1)–N(1) 1.942(3) Å and Co(1)–N(2) 1.957(3)), perhaps indicating weaker coordination. The O(1)–Co(1)–O(2), N(1)–Co(1)–N(3), N(2)–Co(1)–N(4) angles of the *trans* donating atoms are between 177.07° and 177.50° and slightly less than the ideal value. The angles between the imino and the salicylidene planes are 19.0(4)° and 19.7(3)° for the N(1) and N(2) groups with respect to the C(1) and C(15) rings, thus *much more similar* than in complex **1**. The phenyl, pyridine, and salicylidene planes display RMS-values no worse than 0.024 Å (for pyridine N(3)). The coordination planes defined by Co(I) and the appropriate combinations of N(1), N(2), O(1), and O(2), feature RMS-values no worse than 0.038 Å and do contain the Co(1) atom.

As in the case of *cis*-β-[Rh(salbn)(py)(Cl)] [17], the conformation of the tetramethylene bridge in *cis*-α-[Co^{III}(Me-salbn)(4-Mepy)$_2$]$^+$ shows interesting features. While the bond lengths are all normal for C–C single bonds and very similar to that in the ethylene bridge of salen [32], C(9)–C(10)–C(11), and C(10)–C(11)–C(12) of 116.8(3)° and 116.6(3)°, respectively, are much larger than the tetrahedral angle and are closer to the trigonal angle. This suggests considerable strain in the bridge and makes it, perhaps, surprising that regular octahedral coordination is so well preserved with N(1)–Co(1)–N(2) 89.37(12)°.

There are intramolecular hydrogen bonds only in the structure of **4**. Their normalized lengths lie between 2.26 and 2.42Å, their angles between 100.6° and 119.2°. They act between C(9), C(21), and C(27) towards O(2), and between C(12) and C(25) towards O(1) and reflect the importance of the flexibility of the tetramethylene bridge.

3.3. Spectroscopic properties

A comparative study of the FT-IR spectral data of the reported complexes with those of the uncomplexed ligand gives meaningful information regarding bonding sites of the ligand molecules. Both H_2Me-salpn and H_2Me-salbn show a broad band characteristic of the OH group in the 3400–3570 cm^{-1} region. The disappearance of this band in the FT-IR spectra of the complexes is indicative of the fact that the tetradentate ligands are coordinated as dianions. The ν(C=N) band appearing at 1610 cm^{-1} in Me-salpn and 1614 cm^{-1} in Me-salbn is shifted to lower frequencies by 12–20 cm^{-1} in the corresponding cobalt complex, indicating that the ligands are coordinated to the metal ions through the nitrogen atoms of the azomethine groups [20].

The ^{1}H NMR spectral data are presented in Section 2.2. The octahedral geometry of complex **1** is evident from the X-ray structural analysis (Fig. 1). An octahedral *trans*-structure for **2** and **3** can be inferred based on the similarity of the ^{1}H NMR spectra of these complexes with that of complex **1**. The signal appearing as a singlet at ~2.60 ppm in the ^{1}H NMR spectrum of these complexes is assigned to the two CH_3 groups on Me-salpn and indicates that the equatorial coordination sites are occupied by Me-salpn ligand leading to the magnetically equivalent CH_3 protons. The signals due to the aliphatic protons of the propylene chelate ring and the methyl substituent on the axial ligands appear at $\delta = 1.5$–3.9. The aromatic protons of the phenyl rings in the coordinated Schiff base ligand appear in the appropriate region [15,33].

The two Me-salbn complexes, **4** and **5**, show similar features in their ^{1}H NMR spectra. The only noticeable difference is the additional signal at 2.22 ppm due to the methyl protons of the coordinated Mepy in **4** relative to py in **5**. In addition, the signals characteristic of the free Mepy, trapped in the crystallization process in **4**, appear in the appropriate regions. The structures of the two complexes can be considered as being similar with a *cis*-α-configuration of the Me-salbn ligand, as confirmed for complex **4** by X-ray crystallography, Fig. 2.

The electronic absorption spectrum of H_2Me-salpn in chloroform consist of two relatively intense bands centered at 258 and 322 nm, assigned to the $\pi \rightarrow \pi^*$ transitions of the benzene ring of salicylaldehyde and the azomethine group respectively, and a third band at 392 nm, corresponding to $n \rightarrow \pi^*$ which, upon coordination of the ligand, disappears from the UV–Vis spectra of cobalt complexes [33,34]. The intraligand $\pi \rightarrow \pi^*$ transition of the azomethine group is red shifted by about 60 nm in the corresponding cobalt complexes and appears at 380 nm [35]. The first d → d transition in different Me-salpn cobalt complexes (**1**–**3**) appears in the range of 578–599 nm ($\varepsilon = 384$–455).

It is interesting to note that by changing the solvent from chloroform to acetonitrile the electronic spectra of *trans*-[Co(Me-salpn)$(py)_2$]PF_6, **1**, and *trans*-[Co(Me-salpn)-$(3\text{-Mepy})_2$]PF_6, **2**, show appreciable changes with time. The existence of two well defined isosbestic points at 760 and 608 nm indicates that these complexes are presumably undergoing solvolysis and at least one of the axial ligands is substituted by acetonitrile (Fig. 3). This is not the case for *trans*-[Co(Me-salpn)$(MeIm)_2$]PF_6 **3**, however, and the transformation is very slow for this complex. These observations can be rationalized on the basis of the competition between the steric hindrance imposed by the methylene group of Me-salpn and the ligand field strength of the axial ligands.

The electronic absorption spectrum of H_2Me-salbn in chloroform shows features similar to those observed for H_2Me-salpn, consisting of two $\pi \rightarrow \pi^*$ transitions at 251 and 318 nm, and a third band at 394 nm corresponding to $n \rightarrow \pi^*$ excitation. The $n \rightarrow \pi^*$ band appears to be absent in the spectrum of the cobalt complexes. In addition, the intraligand $\pi \rightarrow \pi^*$ transition of the azomethine group is red shifted by about 70 nm, and appears to be split into two components with a well defined peak at ca. 390 and a shoulder at ca. 425 nm. This is presumably due to the change in the symmetry of the Me-salbn ligand upon coordination in a *cis*-α-configuration. The first d → d

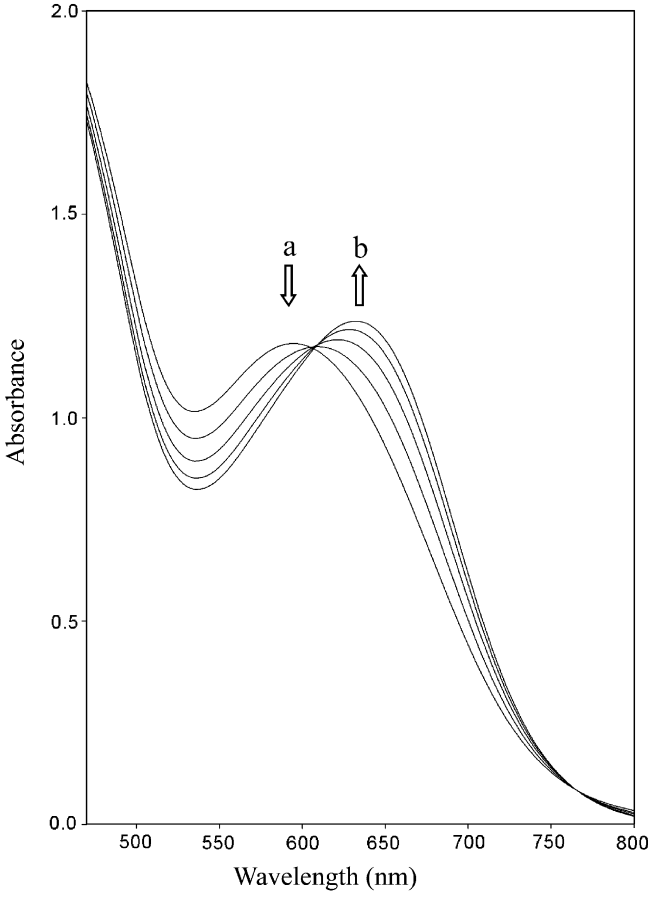

Fig. 3. Electronic absorption spectra of **1** in acetonitrile solution. $c = 2.5 \times 10^{-3}$ mol L^{-1}, time intervals: 10 min: (a) $t = 0$ min and (b) $t = 40$ min. Isosbestic points: 760, 608 nm. Reaction almost completed after 70 min.

transition in the two cobalt Me-salbn complexes (**4** and **5**) appears in the 646–650 nm rage ($\varepsilon = 390$–420). The electronic spectra of these complexes show common features in both non-coordinating and coordinating solvents which is consistent with a less sterically hindered structure for **4** and **5**, as compared to those of Me-salpn complexes (3.2.2 and Table 2).

3.4. Electrochemical studies

The cyclic voltammograms of $[Co(Me\text{-}salpn)(amine)_2]PF_6$ complexes (amine = py **1**, 3-Mepy **2**) and $[Co(Me\text{-}salbn)(amine)_2]BPh_4$ (amine = 4-Mepy **4**, py, **5**) were conducted at 25 °C under an argon atmosphere using acetonitrile solutions containing 0.1 mol dm^{-3} TBAH as supporting electrolyte and complex concentrations of about 3×10^{-3} M. The reduction potential data of cobalt complexes are summarized in Table 3. The ligands are electro-inactive over a range of +0.7 to −2.0 V. The redox properties of cobalt(III) Me-salpn complexes at the scan rates of 20–500 mV/s exhibit grossly similar features consisting of an electrochemically irreversible Co^{III}/Co^{II} reduction at ca. −0.550 V (peak separation ~ 650 mV), which is due to the process $[Co^{III}(Me\text{-}salpn)(R\text{-}py)_2]^+ + e \rightarrow [Co^{II}(Me\text{-}salpn)] + 2R\text{-}py$ [10,20]. During the experiment, the reduction potential gradually shifts to more negative values reaching a value of −0.778 V for **1**, presumably due to the concomitant substitution of the axial ligands by acetonitrile in a solvolysis reaction: $[Co^{III}(Mesalpn)(py)_2]^+ + MeCN \rightarrow [Co^{III}(Me\text{-}salpn)(py)(MeCN)]^+ + py$ (Fig. 4). This value matches the E_{pc} value of an acetonitrile solution of the complex that has been stored for 48 h to let the complete solvolysis of the complex to occur (Fig. 5). As expected, the resulting voltammogram resembles the (b) voltammogram of Fig. 4. Additional evidence comes from the observation of two well defined isosbestic points in the absorption spectra of **1** in acetonitrile solution (Fig. 3) (*vide supra*), which correlates well with the well defined isopotential point at −0.667 V in the cyclic voltammograms of this complex under the same conditions (Fig. 4). It is interesting to note that no substitution occurs in a non-coordinating solvent such as chloroform and an electrochemically irreversible reduction process occurs at −0.576 V, which is close to the initial E_{pc} value of −0.568 V for the acetonitrile solution. A similar electrochemical behavior has been observed for complex **2**, containing 3-Mepy. The Co^{III}/Co^{II} redox process remains electrochemically irreversible in the presence of excess pyridine (Fig. 6), an observation contrary to that of many cobalt Schiff base complexes [10,20].

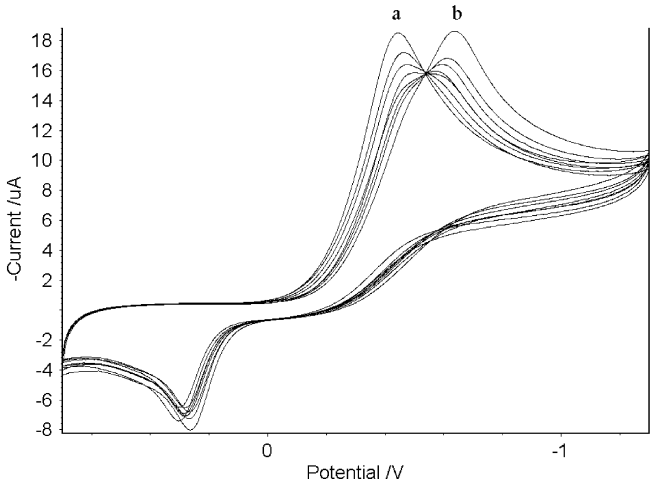

Fig. 4. Cyclic voltammograms corresponding to Co(III) → Co(II) for 4 mM $[Co(Me\text{-}salpn)(py)_2]PF_6$ in acetonitile solution at 293 K during 48 h period: (a) $t = 0$ h and (b) $t = 48$ h. Scan rate: 100 mV/s. $c = 3.2 \times 10^{-3}$.

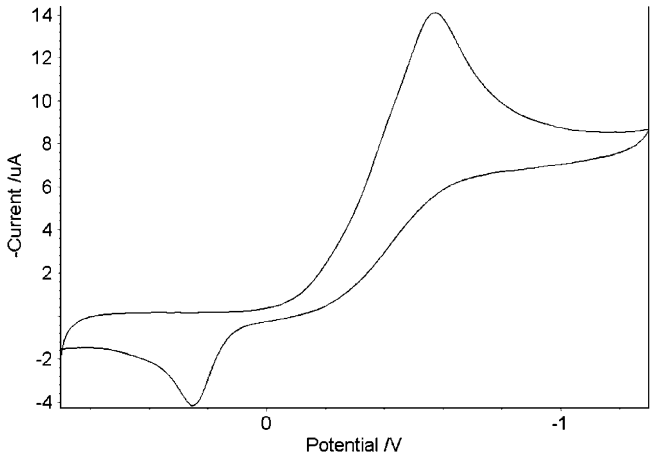

Fig. 5. Cyclic voltammogram corresponding to Co(III) → Co(II) for $[Co(Me\text{-}salpn)(py)_2]PF_6$ in acetonitrile solution stored for 48 h at 293 K. Scan rate: 100 mV/s. $c = 3.0 \times 10^{-3}$.

A similar redox process, however, occurs at −0.803 V for $[Co^{III}(Me\text{-}salbn)(py)_2]^+$, **5**, Fig. 7. It seems reasonable

Table 3
Redox potentials of cobalt complexes of Me-salpn and Me-salbn in acetonitrile[a]

Complex	E_{pc1}	E_{pa1}	E_{pc2}	E_{pa2}
$[Co(Me\text{-}salpn)(Py)_2]PF_6$ (with excess py)	−0.553	0.152	−1.909	−1.773
$[Co(Me\text{-}salpn)(Py)_2]PF_6$ (in acetonitrile solution, stored for 48 h)	−0.778	0.190	−1.914	−1.776
$[Co(Me\text{-}salpn)(3\text{-}Mepy)_2]PF_6$ (with excess 3-Mepy)	−0.546	0.083	−1.899	−1.772
$[Co(Me\text{-}salpn)(3\text{-}Mepy)_2]PF_6$ (in acetonitrile solution, stored for 48 h)	−0.677	0.158	−1.902	−1.775
$[Co(Me\text{-}salbn)(4\text{-}MePy)_2]B(Ph)_4$	−0.784	0.430	−1.884	−1.816

[a] Potentials are vs. $Fc^+/0$ in 0.1 TBAH, $T = 293$ K. Scan rate 100 mV/s. Approximate concentrations: 3×10^{-3} M.

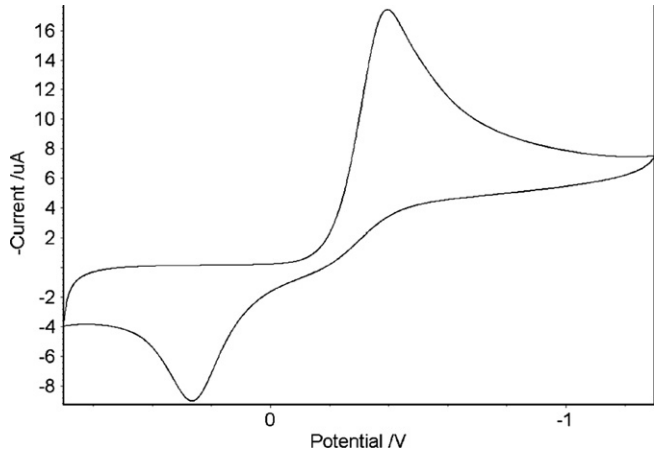

Fig. 6. Cyclic voltammogram corresponding to Co(III) → Co(II) for [Co(Me-salpn)(py)$_2$]PF$_6$ in acetonitrile solution in the presence of excess pyridine at 293 K. Scan rate: 100 mV/s. $c = 3.1 \times 10^{-3}$.

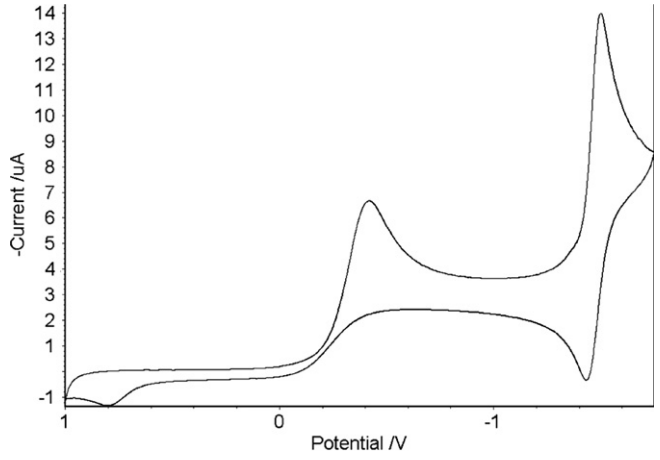

Fig. 7. Cyclic voltammogram of [Co(Me-salbn)(py)$_2$]BPh$_4$ in acetonitrile solution at 293 K. Scan rate: 100 mV/s. $c = 3.0 \times 10^{-3}$.

to assume that the Me-salpn complexes, in which one of the pyridine molecules is subject to the steric effects from the central methylene in the six-membered diamine chelate ring, are more readily reduced relative to the less sterically hindered Me-salbn complexes. Such steric interactions may tend to release the pyridine molecule and thence facilitate the reduction to cobalt(II) species. The Me-salbn, however, shows a stabilizing effect on Co(III), rendering its reduction potential to a more negative value, presumably due to a better orbital overlap leading to an increase in the electron density on cobalt atom. This speculation remains to be tested by further theoretical calculations.

Although a second well defined electrochemically reversible process at ca. −1.807 V is observed with about unit ratio of anodic to cathodic peak currents (i_{pa}/i_{pc}) and peak potential difference of 68 mV for the for [Co^{III}(Me-salbn)(py)$_2$]$^+$, **5** (Fig. 7), which corresponds to the simple one electron process [Co^{II}L] + e$^-$ → [Co^{I}L]$^-$ [10], the corresponding Co(I) salpn complex proved to be unstable, though an electrochemically irreversible Co^{II}–Co^{I} process

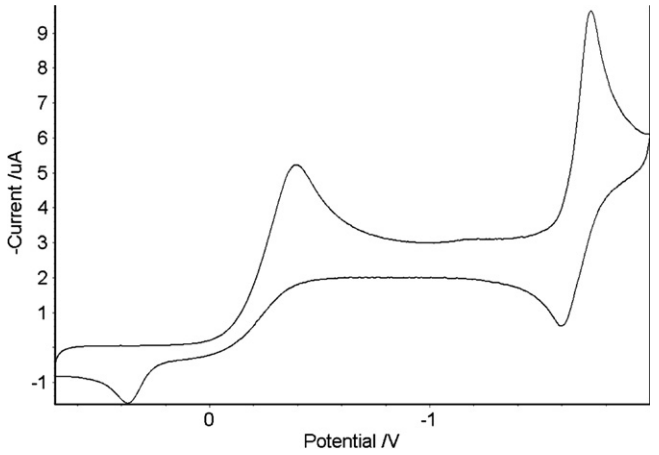

Fig. 8. Cyclic voltammogram of [Co(Me-salpn)(py)$_2$]PF$_6$ in acetonitrile solution at 293 K. Scan rate: 100 mV/s. $c = 2.9 \times 10^{-3}$.

seems to be revealed at the glassy carbon electrode with the initial E_{pc} of −1.909 V and peak potential difference of 136 mV, Fig. 8. These observations are in accord with the results reported for Co(I) complexes of tetradentate Schiff base ligands [36].

4. Conclusion

We have prepared three Co(III) complexes of Me-salpn with two ancillary ligands in the *trans*-positions, and two Co(III) complexes of Me-salbn, in which the tetradentate Schiff base ligand, Me-salbn, adopts a *cis*-α-configuration and the two ancillary ligands are therefore *cis*. In the case of Me-salpn complexes, the central methylene of the chelate ring exerts sufficient steric hindrance to remove one of the axial ligands in coordinating solvents such as acetonitrile, and shifts the Co^{III}–Co^{II} to the positive side, facilitating the reduction to cobalt(II) species. However, Me-salbn complexes with less steric demands do not undergo solvolysis in acetonitrile, and Me-salbn shows a stabilizing effect on Co(III) relative to Me-salpn. This study shows the effect of the outer coordination sphere on the coordination mode of the two Schiff base ligands and the influence on the reduction potentials of the corresponding cobalt(III) complexes.

present, various theoretical researches have been carried out in an attempt to correlate experimental results to theoretical predictions. In particular, quantum chemical studies applying the density functional theory (DFT) method in this field have been reported [16], because the DFT method can better consider electron correlation energies and obviously reduces the computation expenses and suits to compute such complexes with their ground states being a singlet state. It is well documented that the lowest energy transitions of some Ru(II) polypyridyl complexes can be assigned to a metal-to-ligand charge-transfer (MLCT) and the HOMO–LUMO (HOMO: highest occupied molecular orbital; LUMO: lowest unoccupied molecular orbital) energy difference between the corresponding complexes obtained from computations with the DFT/B3LYP method is closely correlative to $\Delta E_{1/2}$ ($E_{1/2ox} - E_{1/2red}$) [17]. The DFT calculations for the stacked DNA base-pair model with backbones have also been reported and it is well established that the energies of the HOMO and the occupied MO (the molecular orbital) near the HOMO are rather high and predominantly populated on the base pairs of DNA [18].

Herein, we report the synthesis and characterization of MIP {MIP = 2-(2,3-methylenedioxyphenyl)imidazo[4,5-*f*]1,10-phenanthroline}, a new polypyridyl ligand, and its ruthenium(II) complexes (Scheme 1) $[Ru(phen)_2(MIP)]^{2+}$ (**1**) (phen = 1,10-phenanthroline) and $[Ru(dmp)_2MIP]^{2+}$ (**2**) (dmp = 2,9-dimethyl-1,10-phenanthroline). The DNA-binding properties of the two complexes were explored by spectroscopic and viscosity measurements, and their photocleavage behavior toward pBR-322 was investigated. Theoretical calculations with the DFT method for the two complexes were also carried out and further applied to explain the obtained experimental observations. We hope that our results will aid in the understanding of DNA recognition and binding by Ru(II) complexes, as well as laying the foundation for the rational design of new photoprobes and photonucleases for DNA.

Scheme 1. Structures, syntheses of the ligand MIP and its Ru(II) complexes **1** and **2**.

2. Experimental

2.1. Materials and chemicals

The compounds 1,10-phenanthroline-5,6-dione [19], *cis*-$[Ru(phen)_2Cl_2]\cdot 2H_2O$ and *cis*-$[Ru(dmp)_2Cl_2]\cdot 2H_2O$ [20] were prepared according to literature procedures. All other materials were commercially available and of reagent grade, and were used without further purification unless otherwise noted.

2.2. Physical measurements

Microanalyses (C, H and N) were carried out on a Perkin–Elmer 240Q elemental analyzer. ^{1}H NMR spectra were recorded on an Avance-400 spectrometer with DMSO-d_6 (dimethyl sulfoxide) as the solvent at room temperature and TMS (tetramethylsilane) as the internal standard. UV–Vis (UV–visible) spectra were recorded on a Perkin–Elmer Lambda-25 spectrophotometer, and emission spectra were recorded on a Perkin–Elmer LS-55 luminescence spectrometer at room temperature. Fast atom bombardment mass spectra (FAB-MS) were recorded on a VG ZAB-HS spectrometer in a 3-nitrobenzyl alcohol matrix. Electrospray mass spectra (ES-MS) were recorded on a LQC system (Finngan MAT, USA) using CH_3CN as the mobile phase. The spray voltage, tube lens offset, capillary voltage and capillary temperature were set at 4.50 KV, 30.00 V, 23.00 V and 200 °C, respectively, and the quoted *m*/*z* values are for the major peaks in the isotope distribution. Circular dichroism (CD) spectra were measured on a JASCO-J715 spectropolarimeter.

Cyclic voltammograms measurements were performed at room temperature on a CHI 660A Electrochemical Workstation. The supporting electrolyte was 0.1 mol/L tetrabutylammonium (Nbu_4) perchlorate. All samples were purged with nitrogen prior to measurement. A standard three-electrode system comprising of a platinum microcylinder working electrode, platinum-wire auxiliary electrode and a saturated calomel reference electrode (SCE) was used. The scan rate of all voltammograms was 200 mV/s.

All spectroscopic titrations were carried out in buffer A (5 mM Tris–HCl, 50 mM NaCl, pH 7.2, *Tris* = Tris-(hydroxymethyl)methylamine) at room temperature. A solution of CT-DNA in the buffer gave a ratio of UV absorbances at 260 and 280 nm of *ca.* 1.8:1–1.9:1, indicating that the DNA was sufficiently free of protein [21]. The concentration of CT-DNA was determined spectrophotometrically ($\varepsilon_{260} = 6600\ cm^{-1}$) [22]. Stock solutions were stored at 4 °C and used within 4 days. Titration experiments were performed by using a fixed Ru(II) complex concentration (20 μM), to which CT-DNA stock solution was added. The ruthenium solutions employed were 20 μM in concentration and CT-DNA was added up to a [DNA]/[Ru] ratio of 0.75:1 and 0.25:1 for complexes **1** and **2**, respectively. The complex-DNA solutions were allowed to equilibrate for 5 min before spectra were recorded.

Viscosity measurements were carried out with an Ubbelodhe viscometer maintained at a constant temperature of 30.0 ± 0.1 °C in a thermostated bath. DNA samples of *ca.* 200-bp average length were prepared by sonication [23]. The flow time was measured with a digital stopwatch, and each sample was tested three times to get an average calculated flow time. Data were presented as $(\eta/\eta_0)^{1/3}$ versus binding ratio [24], where η is the viscosity of DNA in the presence of complex, η_0 being the viscosity of free DNA.

For the gel-electrophoresis experiments, supercoiled pBR-322 DNA (0.1 μg) was treated with **1** or **2** in buffer B (50 mM Tris-acetate, 18 mM NaCl buffer, pH 7.2). After pre-incubation of the solutions in the dark for 1 h, the samples were irradiated for 60 min inside the sample chamber of the spectrofluorimeter (λ_{ex} 400 ± 5 nm, slit-width 5 nm). The samples were then analyzed by gel-electrophoresis for 30 min at 75 V in *Tris*-acetate buffer containing 1% agarose gel. The gel was stained with ethidium bromide (EB; 1 μg/mL^{-1}) and photographed under UV light.

2.3. Synthesis

2.3.1. MIP

A mixture of 2,3-methylenedioxy-benzaldehyde (0.23 g, 1.5 mmol), 1,10-phenanthroline-5,6-dione (0.11 g, 0.5 mmol), ammonium acetate (2.31 g, 30 mmol), and glacial acetic acid (15 ml) was heated at reflux with stirring for 2 h. The cooled solution was filtered, diluted with H_2O and neutralized with concentrated aqueous ammonia. The yellow precipitate was collected and purified by column chromatography on alumina with ethanol–toluene (4:1, v/v) as the eluant to afford MIP as an amorphous yellow solid. Yield: 0.21 g, 41%. *Anal.* Calc. for $C_{20}H_{13}N_4O_{2.5}$: C, 68.75; H, 3.72; N, 16.04. (Note: half a molecule of crystal water has been assumed when calculating the elemental composition.) Found: C, 68.34; H, 3.91; N, 15.70%. FAB-MS: m/z = 341.6 [M+1].

2.3.2. [Ru(phen)$_2$(MIP)](ClO$_4$)$_2$ · 2.5H$_2$O (1)

A mixture of *cis*-[Ru(phen)$_2$(Cl)$_2$] · H_2O (151 mg, 0.25 mmol), MIP (85 mg, 0.25 mmol), and ethylene glycol (15 ml) was thoroughly deoxygenated. The purple mixture was heated for 8 h at 120 °C under Ar atmosphere. When the solution finally turned red, it was cooled to room temperature, and an equal volume of saturated aqueous sodium perchlorate solution was added under vigorous stirring. The red solid was collected and washed with small amounts of H_2O, EtOH, and Et_2O, dried under vacuum, and purified on a neutral alumina column with acetonitrile–toluene (v/v, 4:1) as the eluant. Yield: 0.19 g, 73%. *Anal.* Calc. for $C_{44}H_{33}N_8Cl_2O_{12.5}Ru$: C, 50.13; H, 3.13; N, 10.64. Found: C, 49.97; H, 3.21; N, 10.36%. λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}, CH_3CN): 455 (16150), 264 (81350), 218(77200). ^{1}H NMR (400 MHz, DMSO-d_6 (dimethyl sulfoxide); d, doublet; s, singlet; t, triplet; m, multiplet): 9.08 (d, 2H, J = 8.5), 8.75 (d, 4H, J = 8), 8.37 (s, 4H), 8.11 (d, 2H, J = 1), 8.10 (d, 2H, J = 1), 7.90 (d, 2H, J = 5.5), 7.71–7.77 (m, 8H), 7.03 (d, 1H, J = 5.0), 6.23 (s, 2H). ES-MS (CH_3CN): m/z 900.9 ([M−ClO$_4$]$^+$), 801.3 ([M−2ClO$_4$−H]$^+$), 401.3 ([M−2ClO$_4$]$^{2+}$).

2.3.3. [Ru(dmp)$_2$(MIP)](ClO$_4$)$_2$ · 2H$_2$O (2)

Prepared analogous to **1**, but from *cis*-[Ru(2,9-Me$_2$phen)$_2$(Cl)$_2$] · 2H_2O (0.14 g, 0.25 mmol). Yield: 0.15 g, 57%. *Anal.* Calc. for $C_{48}H_{40}N_8Cl_2O_{12}Ru$: C, 52.74; H, 3.69; N, 10.26. Found: C, 52.55; H, 3.75; N, 10.13%. λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}, CH_3CN): 463 (13810), 271 (69005), 225 (71765). ^{1}H NMR (400 MHz, DMSO-d_6): 8.88 (d, 2H, J = 8.5), 8.77 (d, 2H, J = 8), 8.41 (d, 2H, J = 8.5), 8.39 (d, 2H, J = 8.5), 8.22 (d, 2H, J = 8.5), 7.95 (d, 2H, J = 8.5), 7.22 (d, 1H, J = 9.5), 7.36 (d, 1H, J = 8.5), 7.29 (dd, 2H, J_1 = 6, J_2 = 7.5), 7.08 (d, 2H, J = 4.5), 6.87 (d, 2H, J = 7.5), 6.09 (s, 1H), 1.90 (s, 6H), 1.72 (s, 6H). ES-MS (CH_3CN): m/z 957.2 ([M−ClO$_4$]$^+$), 857.3 ([M−2ClO$_4$−H]$^+$), 429.4 ([M−2ClO$_4$]$^{2+}$).

2.4. Theoretical calculations

Each of these is complexes formed from a Ru(II) ion, one main-ligand (MIP) and two ancillary ligand (phen or dmp). All computations were performed with the G98 quantum chemistry program-package [25], and the DFT-B3LYP method [26–28] and LanL2DZ basis set [29] were adopted (Note: Due to condition limits, we were not able to carry out higher level calculations). The full geometry optimization computations for the ground states of these complexes with a singlet state were carried out. In order to vividly depict the details of the frontier molecular orbital interactions, the stereographs of some related frontier molecular orbitals of the complexes were drawn with the Molden v3.7 program [30] based on the obtained computational results.

3. Results and discussion

3.1. Synthesis and characterization

An outline of the synthesis of the Ru(II) complexes **1** and **2** with the new MIP ligand is presented in Scheme 1. The MIP ligand was prepared through the condensation of 1,10-phenanthroline-5,6-dione (**3**) with 2,3-methylenedioxy-benzaldehyde (**4**) on the basis of the method for the preparation of imidazole rings according to Steck and Day [31]. The complexes [Ru(phen)$_2$(MIP)]$^{2+}$ (**1**) and [Ru(dmp)$_2$(MIP)]$^{2+}$ (**2**) were then prepared in relatively good yield (61% and 73%, respectively) by the reaction of MIP with *cis*-[Ru(phen)$_2$Cl$_2$] · 2H_2O and *cis*-[Ru(dmp)$_2$-(Cl)$_2$] · 2H_2O, respectively, in the appropriate mole ratios, using ethylene glycol as the solvent. The desired Ru(II) complexes were isolated as the corresponding perchlorates, and were purified by column chromatography. In the ESI mass spectra of complexes **1** and **2**, ([M−ClO$_4$]$^+$),

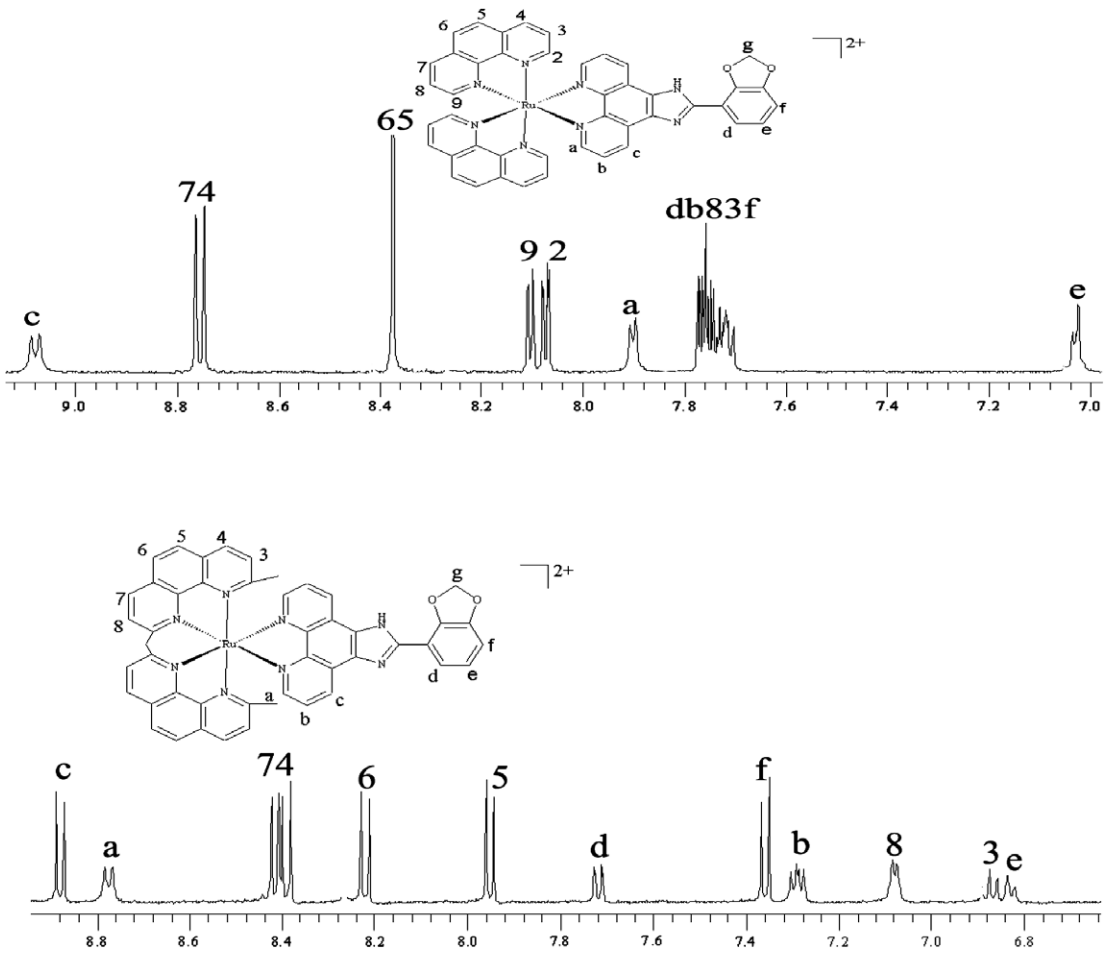

Fig. 1. ^{1}H NMR spectra of complexes **1** (top) and **2** (bottom).

($[M-2ClO_4-H]^+$) and ($[M-2ClO_4^-]^{2+}$) were observed, and the determined molecular weights were consistent with the expected values.

Both complexes **1** and **2** give well-defined ^{1}H NMR spectra (Fig. 1), permitting unambiguous identification and assessment of purity. The ^{1}H NMR chemical shifts were assigned by the aid of ^{1}H, ^{1}H–COSY experiments, and by comparison with the values of similar compounds [32–34]. Due to the shielding influences of the adjacent MIP and phen (or dmp) moieties, the phen (or dmp) H-atoms of complexes **1** and **2** exhibit two distinct sets of signals. In addition, the NH proton of MIP was not observed due to rapid H^+ exchange between the two N atoms of the imidazole ring. A similar case has been reported previously [35].

The electrochemical behaviors of the two complexes have been determined in acetonitrile. Each complex exhibits one oxidation and three reduction waves in the sweep range from −2.0 to +2.0 V (Table 1), the half-wave potentials $E_{1/2}$ being 1.61, −0.66, −1.36 and −1.54 V versus SSCE for complex **1** and 1.59, −0.76, −1.21 and −1.41 versus SSCE for complex **2**. The electrochemical behavior of the Ru(II) polypyridyl complexes have been rationalized in terms of a metal-based oxidation and a series of reductions which are ligand-based occurring in a stepwise manner for each π^* system [36]. As expected, the oxidation potentials of complexes **1** and **2** are more positive than that of $[Ru(bpy)_3]^{2+}$, in accord with the extension of the corresponding π framework. With reference to previous studies on similar systems [37,38], the first reduction, which is

	$Ru^{II/III}$	Ligand reduction			
1	1.61	−0.66	−1.36	−1.54	455 (16150), 264 (81350), 218 (77200)
2	1.59	−0.76	−1.21	−1.41	463 (13810), 271 (69005), 225 (71765)

[a] All complexes were measured in 0.1 M NBu_4ClO_4–CH_3CN, error in potentials was ± 0.02 V; $T = 23 \pm 1$ °C; scan rate = 100 mV S^{-1}.
[b] In CH_3CN.

usually controlled by the ligand having the most lowest unoccupied molecular orbital (LUMO) [39,40], is assigned to a reduction centered on MIP, and the last reductions are characteristic of the co-ligand (phen or dmp) [41].

The UV–Vis absorption spectra of complexes **1** and **2** showed three well-resolved bands in the range 200–600 nm, characterized by intense $\pi \rightarrow \pi^*$ ligand transitions in the UV region, as well as by a metal-to-ligand charge-transfer (MLCT) transition in the VIS region (Table 1). Broad MLCT absorption bands appear at 455 and 463 nm for complexes **1** and **2**, respectively, and are attributed to Ru(dπ)→ MIP(π^*) transitions. These bands are bathochromically shifted relative to those of $[Ru(bpy)_3]^{2+}$ (452 nm) [24], in accord with the extension of the corresponding π framework. The signals below 400 nm are assigned to internal $\pi \rightarrow \pi^*$ transitions of the ligands, by comparison with the spectra of $[Ru(bpy)3]^{2+}$.

3.2. DNA-binding studies

3.2.1. Viscosity measurements

Hydrodynamic measurements sensitive to length changes, as reflected in viscosity and sedimentation, are regarded as the least ambiguous and the most-critical tests of a binding model in solution in the absence of crystallographic structural data [42]. A classical intercalation model demands that the DNA helix lengthens as base pairs are separated to accommodate the binding ligand, which, in turn, leads to an increase in the viscosity of DNA [42].

In Fig. 2, the change in viscosity on rod-like DNA is shown in the presence of complexes **1** and **2**, $[Ru(bpy)_3]^{3+}$ and ethidium bromide (EB). Whereas EB, a well-known DNA intercalator, gave rise to a strong change in DNA viscosity upon complexation, $[Ru(bpy)_3]^{2+}$, which binds by electrostatic intercalations only, exerted essentially no such effect. As can be seen from Fig. 2, upon increasing the amounts of complex **1**, the relative viscosity of DNA increases steadily, similar as in the case of EB. By contrast, on increasing the amounts of complex **2**, the relative viscosity of DNA decreases. The change in relative viscosity, expected to correlate with the compounds DNA-intercalating potential, followed the order EB > complex **1** > complex **2**. These results suggest that complex **1** binds to DNA through a classical intercalation model and complex **2** binds to DNA by the partial, non-classical intercalation model. This difference of the DNA-binding model between complexes **1** and **2** should be caused by the different ancillary ligand of the two complexes. For complex **2**, due to the steric hindrance of the methyl groups located at the 2- and 9-positions of the phen ring in the dmp ancillary ligand, the complex could not completely intercalate into DNA base pairs. The partial intercalation may act as a "wedge" to pry apart one side of a base-pair stack, as observed for Δ-$[Ru(phen)_3]^{2+}$ [43,44], but not fully separate the stack as required by the classical intercalation model. This would cause a static bend or kink in the helix and decrease the viscosity of DNA.

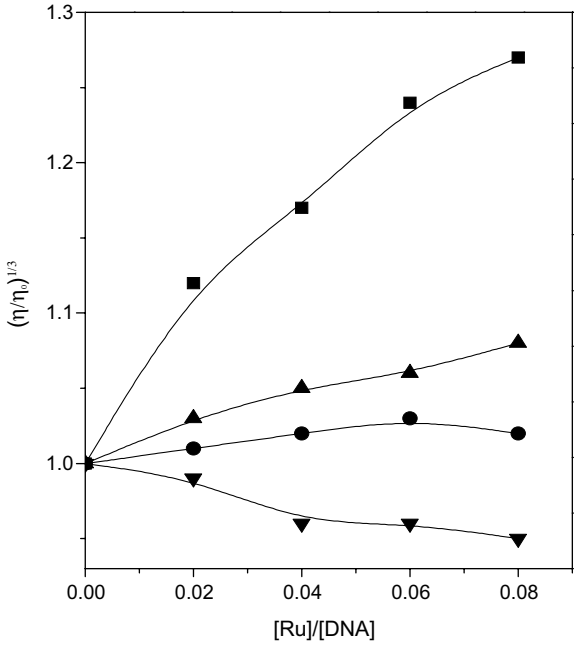

Fig. 2. Effect of increasing amounts of ethidium bromide (■), $[Ru(bpy)_3]^{2+}$ (●), **1** (▲) and **2** (▼) on the relative viscosity of CT-DNA. Total DNA concentration: 0.5 mM, $T = 30 \pm 0.1$ °C.

3.2.2. Absorption spectra studies

The application of electronic absorption spectroscopy in DNA-binding studies is one of the most useful techniques [45]. Complex binding with DNA through intercalation usually results in hypochromism and bathchromism due to the intercalative mode involving a strong stacking interaction between an aromatic chromophore and the base pairs of DNA. The extent of the hypochromism commonly parallels the intercalative binding strength.

The absorption spectra of the Ru(II) complexes **1** and **2** (at constant concentration) in the absence and presence of CT-DNA are shown in Fig. 3. As the concentration of DNA is increased, for complex **1** the hypochromism reaches about 11.4% at 267 nm with a red shift of 8 nm at a [DNA]/[Ru] ratio of 3. The MLCT band at 469 nm shows hypochromism by about 23.5% and a red shift of 2 nm under the same conditions. For complex **2**, upon addition of DNA, the IL band at 276 nm exhibits hypochromism of about 27.4% with a 4 nm red shift at a [DNA]/[Ru] ratio of 9.5. The MLCT band at 477 nm shows hypochromism by about 7.7% and a red shift of 10 nm under the same conditions. Obviously, these spectral characteristics suggest that both complexes interact with DNA most likely through a mode that involves a stacking interaction between the methylenedioxyphenyl chromophore and the base pairs of DNA.

To quantitatively compare the binding strengths of the two complexes, their intrinsic binding constants K_b were determined by UV–Vis titration. This was done by monitoring the change in absorbance at 267 nm for complex **1**

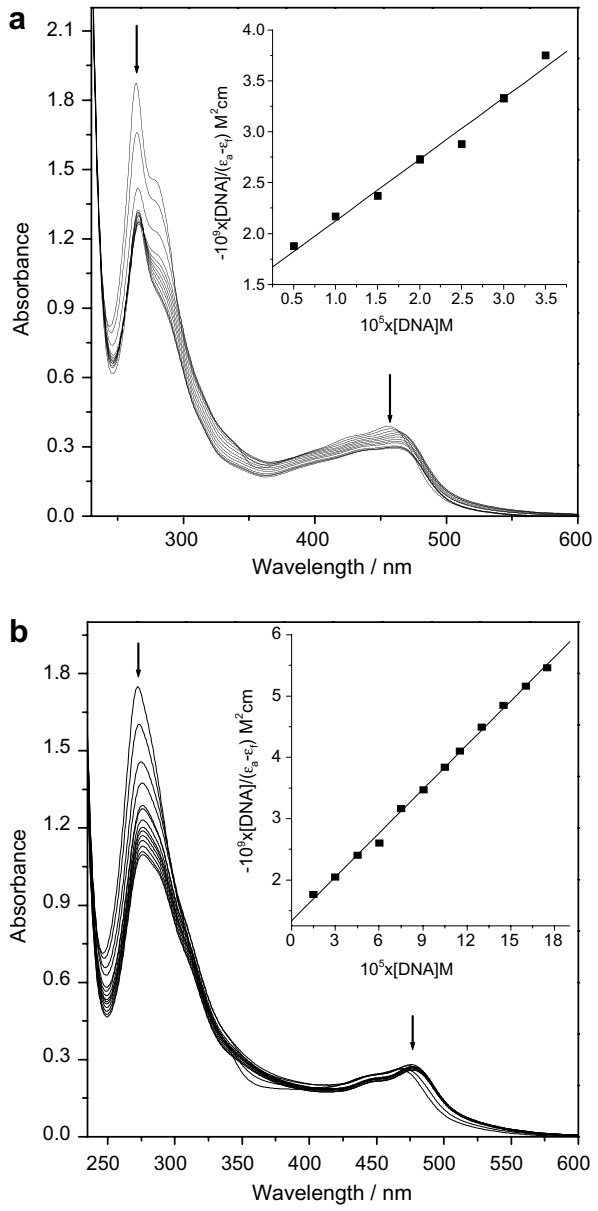

Fig. 3. Absorption spectra of complexes **1** (a) and **2** (b) in aq. Tris–HCl buffer upon addition of CT-DNA. $[Ru] = 2 \times 10^{-5}$ M, $[DNA] = (0–17.5) \times 10^{-5}$ M. Arrow shows the absorbance changes upon increasing DNA concentration. Inset: plots of $-10^9 \times [DNA]/(\varepsilon_a - \varepsilon_f)$ (in M^2 cm) vs. DNA] (in M) for the titration of DNA with the complex for the determination of the binding constant K_b.

and 276 nm for complex **2** with increasing concentration of DNA, using the following equation [46]:

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_b - \varepsilon_f) + 1/[K_b(\varepsilon_b - \varepsilon_f)]$$

Here, [DNA] is the concentration of DNA in base pairs, and ε_a, ε_f and ε_b are the extinction coefficients of the apparent, free and bound metal complexes, respectively. When plotting $[DNA]/(\varepsilon_a - \varepsilon_f)$ versus [DNA], K_b is given by the ratio of the slope to the intercept. The intrinsic binding constants K_b of complexes **1** and **2** were thus determined as $3.96 \times 10^4\ M^{-1}$ and $1.08 \times 10^4\ M^{-1}$, respectively. For comparison, the intrinsic binding constants K_b of typical 'intercalative-type' Ru(II) complexes are in the range 1.1×10^4 to $4.8 \times 10^4\ M^{-1}$ [47], whereas that of the parent complex $[Ru(phen)_3]^{2+}$ is $5.5 \times 10^3\ M^{-1}$ [47]. The intrinsic binding constants K_b of both complexes with DNA follows the order K_b (**1**) > K_b (**2**), in accord with the above viscosity studies, that is complex **1** intercalates more strongly than complex **2**. The result indicates that on going from the ancillary ligand phen to dmp, the hydrophobicity of the ancillary ligand dmp of complex **2** is greater than that of complex **1**, however, the steric hindrance of complex**2** is bigger than that of complex **1**. The later factor is not advantageous to the DNA-binding of complex **2**, in particular, in the circumstances that the ancillary ligands contain a steric hindrance group (methyl) results in lower DNA-binding affinity relative to the ancillary ligand phen. Therefore, synthetically considering these factors, the difference of the DNA-binding affinity of complexes **1** and **2** can be well understood.

3.2.3. Steady-state emission studies

In the absence of DNA, complex **1** is luminescent in *Tris* buffer at ambient temperature, with a fluorescence maximum at 591 nm. As shown in Fig. 4, upon addition of CT-DNA, the fluorescence-emission intensity increases by a factor of *ca.* 2.88 and saturates at a [DNA]/[Ru] ratio of 13.5. This indicates that complex **1** strongly interacts with DNA, which efficiently 'protects' it, since the hydrophobic environment inside the DNA helix reduces the accessibility of solvent H_2O to the complex, and because complex mobility is restricted at the binding site this results in a decrease of the vibrational modes of relaxation and thus higher emission intensity.

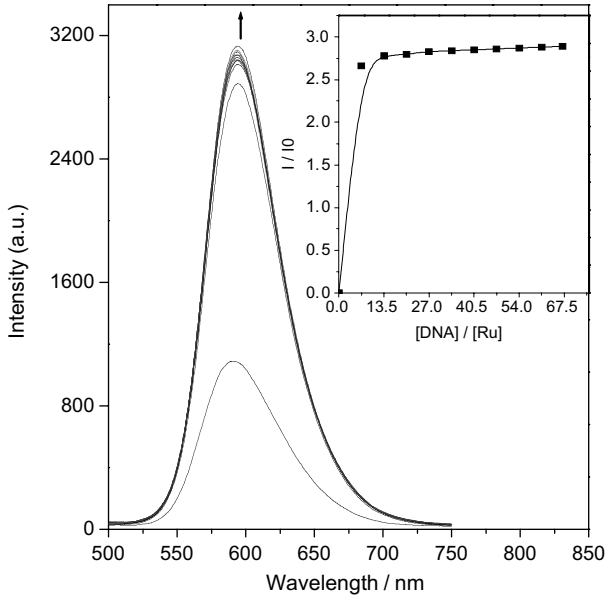

Fig. 4. Fluorescence spectra of **1** in Tris–HCl buffer at 298 K in the absence and presence of CT-DNA. Arrow shows the intensity changes upon increasing the DNA concentration. Insert: plots of relative integrated emission intensity vs. [DNA]/[Ru].

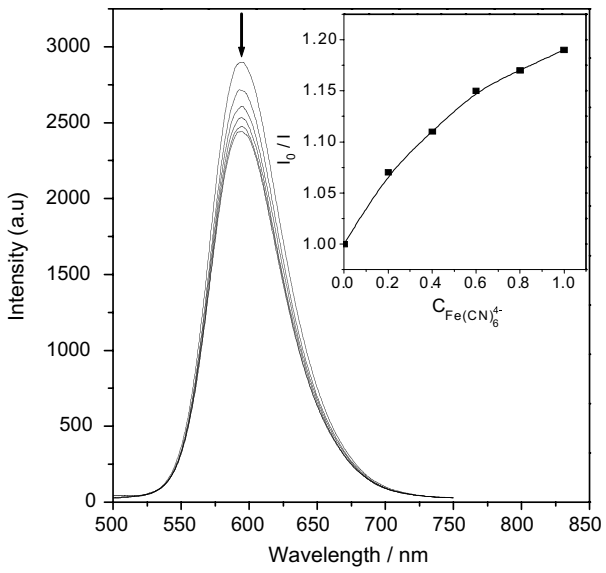

Fig. 5. Fluorescence quenching of **1** by $[Fe(CN)_6]^{4-}$. $[Ru] = 2 \times 10^{-6}$ M, $[DNA]/[Ru] = 40$), $[K^+] = 4 \times 10^{-3}$ M. $[Fe(CN)_6]^{4-} = 0$–1.0 mM. Inset: plots of I_0/I vs. $[Fe(CN)_6]^{4-}$ (in mM). Where I_0 and I are the fluorescence intensities in the absence and presence of the quencher, respectively. Insert: Fluorescence quenching curve of DNA-bound EB by complex **2**.

Steady-state fluorescence quenching experiments with $[Fe(CN)_6]^{4-}$ as a quencher can provide some information about complex binding to DNA, but they do not indicate the binding modes. We decided to perform some experiments at ambient temperature, using a similar method as that described by Satyanarayana et al. [44]. In experiments at constant ionic strength, KCl was added along with $K_4[Fe(CN)_6]$. As illustrated in Fig. 5, the fluorescence quenching curves at constant ionic strength were non-linear. The final fluorescence intensity was originally 83.3%. The result thus further confirms that complex **1** binds to DNA strongly.

For complex **2**, no emission was observed either in *Tris* buffer or in the presence of CT-DNA. It also shows no photoluminescence in any of the organic solvents examined. This could be caused by vibronic coupling between the methyl groups of dmp ligand and solvent, leading to a dissipation of energy in a non-radiative process. Similar results have been observed for this type of Ru(II) complexes [42,48]. On the other hand, this effect could also be caused by a reduced ligand field, making the excited states accessible. The reduced ligand is confirmed by the computed coordination bond lengths (Ru–N), which are 0.2126 nm (main-ligand) and 0.2156 nm (co-ligand) for complex **2**, and 0.2104 (main-ligand) and 0.2106 nm (co-ligand) for complex **1**. Some computed frontier molecular orbital energies are also given in Table 2 and Fig. 6. They show that the energy of the LUMO for complex **2** is much higher than that for complex **1**, so the excited state of complex **2** should be unstable, and can easily return to the ground state through non-radiative energy dissipation. Steady-state competitive binding experiments using complex **2** as a quencher may give further information about the binding of the complex to DNA. As we know, EB emits intense fluorescence light in the presence of DNA, due to its strong intercalation between the adjacent DNA base pairs. It was previously reported that the enhanced fluorescence could be quenched, at least partially, by the addition of a second molecule [49,50]. The extent of quenching fluorescence of EB bound to DNA is used to determine the extent of binding of the second molecule to DNA. The emission spectra of EB bound to DNA in the absence and the presence of complex **2** is shown in Fig. 7. From Fig. 7, we can see that the addition of complex **2** to DNA pretreated EB caused appreciable reduction in the emission intensity of 31.4% than that observed in the absence of complex **2** at a [Ru]/[DNA] ratio of 0.2. This indicated that complex **2** could compete with EB in binding to DNA. The fluorescence quenching curves of DNA-bound EB by complex **2** (insert in Fig. 7) illustrates that the quenching of EB bound to DNA by complex **2** is in good agreement with the linear Stern–Volmer equation. This also proves that the partial replacement of EB bound to DNA by complex **2** results in a decrease of the fluorescence intensity.

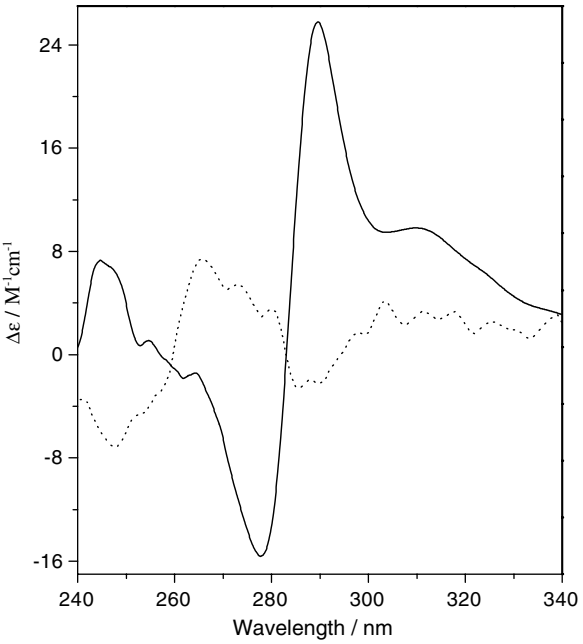

Fig. 8. CD spectra of **1** (…) and **2** (---) after 42 h of dialysis against CT-DNA in stirred aq. solution.

3.2.4. Enantioselective binding

Equilibrium dialysis experiments offer the opportunity to examine the enantioselectivity of complexes binding to DNA. According to the proposed binding model by Barton [49], the Δ enantiomer of the complex, a right-handed propeller-like structure, displays a greater affinity than the Λ enantiomer with the right-handed CT-DNA helix due to more-appropriate steric matching. Thus, complexes **1** and **2** were dialyzed against CT-DNA for 42 h and then subjected to circular dichroism (CD) analysis. In Fig. 8, the CD spectra in the UV region of the dialysates of complexes **1** and **2** are shown. The dialysate of complex **1** (dotted line) shows two CD signals with a positive peak at 265 and a negative peak at 285 nm, while complex **2** (solid line) shows strong CD signals with a positive peak at 289 nm and a negative peak at 278 nm. Furthermore, the CD signals of complex **1** are in opposition to those of complex **2**. Although neither of the complexes was resolved into the pure enantiomers and although we could not determine which enantiomer binds preferentially to CT-DNA, it is evident that both **1** and **2** interact enantioselectively with CT-DNA. The stronger CD signals of complex **2** suggest a large DNA-binding discrimination between its two antipodes. These results indicate that the ancillary ligands have a significant influence on the interaction of the enantioselectivity of Ru(II) complexes with DNA.

3.3. Photoactivated cleavage of pBR-322 DNA by Ru(II) complexes

The cleavage of plasmid DNA can be monitored by agarose–gel electrophoresis. When circular plasmid DNA is subject to electrophoresis, relatively fast migration is generally observed for the intact supercoiled form (I). When scission occurs on one strand (nicking), the supercoil relaxes to generate a slower-moving, open-circular form (II). When both strands are cleaved, a linear form (III) is generated, migrating between type-I and type-II DNA [50].

In Fig. 9, the gel electrophoresis pattern of pBR 322 DNA is shown after incubation with complex **1** or **2** and irradiation at 400 nm. No DNA cleavage was observed for negative controls (line 0). With increasing concentration of the Ru(II) complexes (lines 1–5), the amount of type-I pBR 322 DNA was gradually diminished, whereas type-II increased. At concentrations of 40 μM of complex**1** (line 5), complete conversion of DNA from type-I to type-II was observed, in contrast to complex **2**, where only partial conversion was observed at this concentration. These results indicate that complex **1** is more effective in cleaving DNA than complex **2**. Although DNA photocleavage by $[Ru(phen)_3]Cl_2$ has been reported to involve an $^1O_2$-based mechanism, [51], the nature of the reactive intermediates

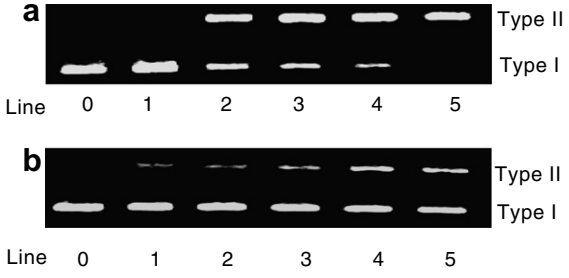

Fig. 9. Photoactivated cleavage of pBR-322 DNA in the presence of **1** (a) or **2** (b) after 60 min of irradiation at 400 nm. Lane 0, DNA alone; Lanes 1–5, at 5, 10, 15, 20 and 25 μM, Ru(II) complex, respectively.

involved in the efficient DNA photocleavage by complexes **1** and **2** observed here is not clarify. Further studies in detail are currently underway to clarify the cleavage mechanism.

3.4. Theoretical explanations of trends in DNA-binding, electrochemical and spectral properties of complexes

As is well known, there are π–π interactions in the DNA-binding of these complexes in the intercalation mode. At present, we cannot yet compute a whole supera-molecular system formed from DNA and the complex using the DFT method because such a system is too large in size to be computed, therefore, it is very important and necessary to theoretically estimate the interaction between both from their individual electronic structural characteristics.

The above-mentioned trends in DNA-binding, electrochemical and spectral properties can be explained by our theoretical computations with the DFT method and frontier molecular orbital theory [52–54]. Some computed frontier molecular energies, the schematic diagram of the max $(\lambda)^1$ MLCT transition, and the stereographs of related frontier molecular orbitals of both complexes are given in Table 2, Figs. 6 and 10 respectively. According to frontier molecular orbital theory, for a reaction controlled by orbital interactions between reactant molecules, a higher HOMO energy of one reactant molecule and a lower LUMO energy of the other are more advantageous to the reaction between the two molecules, because an electron more easily transfers from the HOMO of one reactant to the LUMO of the other in the orbital interaction. A simple and reasonable calculation model and computed results by the DFT method for stacked DNA base-pairs with backbones have been reported by Kurita and Kobayashi [18]. The reported HOMO and NHOMO energies of the DNA section model are much higher (−1.27 and −2.08 eV) [18] than our calculated LUMO and NLUMO energies (−7.07 ∼ −7.26 eV) of complexes **1** and **2**. We believe that such a trend in the relative energies should be kept in the present DNA system, because the attraction of metal complex cations with high positive charges for electrons in the frontier MOs is much stronger than that of various DNA. A lower LUMO energy of the complex in the intercalation mode should be advantageous to accept the electrons from base pairs of DNA, so that the LUMO energies of the complexes should be an important factor (but not the only one) correlating to their DNA-binding constants. The experimental results show that the trend in DNA-binding constants (K_b) is $K_b(\mathbf{1}) > K_b(\mathbf{2})$. It can be explained as follows: $K_b(\mathbf{1})$ is greater because $\varepsilon_L(\mathbf{1})$ (ε_L: energy of the LUMO) is smaller. It is why the DNA-binding constant of complex **1** is much greater than that of complex **2**, and their DNA-binding modes are also different.

The trend in electrochemical half-wave potentials of complexes **1** and **2** can be also explained by our theoretical results. From Fig. 10, we can see that the MO characterized by the metal d-orbital in the occupied frontier MO is

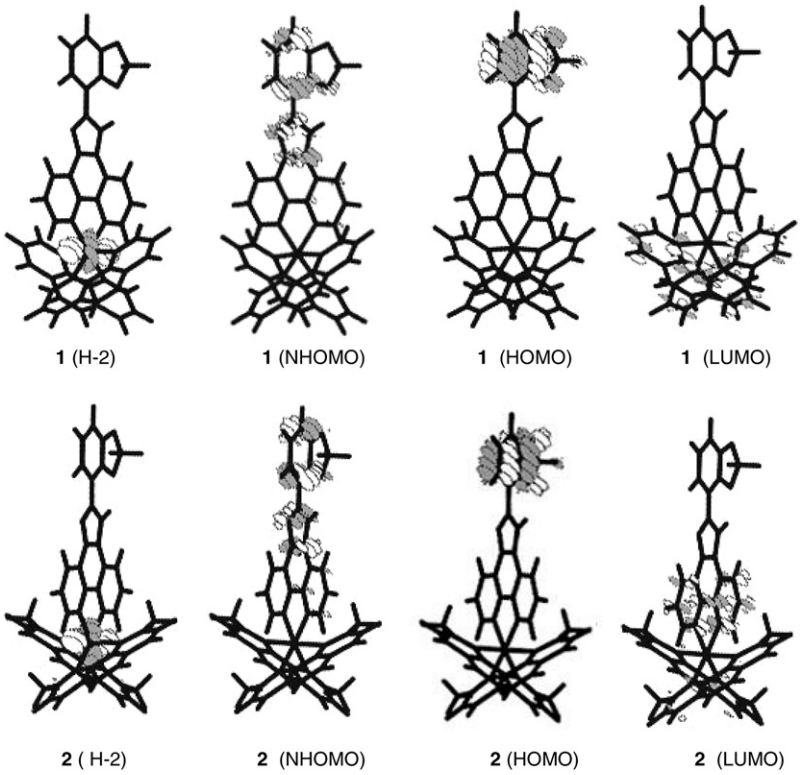

Fig. 10. Stereographs of the HOMOs and LUMOs of complexes **1** and **2**.

NHOMO-2 instead of HOMO, so that oxidation of the central metal should happen on NHOMO-2. Since the NHOMO-2 energy of complex **1** is lower than that of complex **2** (see Table 2 and Fig. 6), its oxidation potential is more positive than that of complex **2**. On the other hand, since a lower LUMO energy of the complex is advantageous for accepting the electrons offered from base-pairs of DNA, and the LUMO energy of complex **1** is also lower than that of complex **2**, the reduction potential of the former is more negative than that of the latter.

Some trends in electronic absorption spectra can also be explained by the theoretical results. From Fig. 10, we can clearly see that the lowest energy singlet metal-to-ligand charge-transfer (^{1}MLCT) bands can be assigned to the transitions from NHOMO-2 to the LUMO of the complexes. Furthermore, according to the approximate correlation of the reverse ratio of the difference between the LUMO and the HOMO energies ($\Delta\varepsilon_{L-H}$) to the experimental wavelength (λ), using the parent complex $[Ru(bpy)_3]^{2+}$ as a standard sample (experimental $\lambda = 452$ nm, $\Delta\varepsilon_{L-H} = 0.1239$ atomic unit, $\Delta\varepsilon_{L-H:}$ energy difference between the LUMO and NHOMO) [55] and $\Delta\varepsilon_{L-H}$ data of complexes **1** and **2** in Table 2, the computed max (λ)^1 MLCT absorption spectra of complexes **1** and **2** are 447 nm and 452 nm respectively, near their experimental wavelengths of 455 nm and 463 nm.

In addition, the absorption spectra also demonstrate that the corresponding energy difference between the presence and absence of DNA is small, and no special pattern changes in the absorption spectra of the complexes in the presence of DNA have been detected, except increases in hypochromism for the absorption spectra. Therefore, we can consider that there is not a great effect on the corresponding orbitals of the complexes binding to DNA (relative to the free complexes). This further suggests that the interaction between the complexes and DNA should be a weak one between the molecules, so that the properties of the ^{1}MLCT electron transition bands in the two Ru(II) complexes binding to DNA should be unchanged, in accordance with the experiments.

4. Conclusions

In summary, two novel complexes, $[Ru(phen)_2MIP]^{2+}$ (**1**) and $[Ru(dmp)_2MIP]^{2+}$ (**2**), have been synthesized and characterized. Spectroscopic studies, viscosity measurements together with equilibrium dialysis and circular dichroism spectroscopy show that complex **1** binds to CT-DNA through intercalation, and complex **2** binds to CT-DNA *via* a partial intercalative mode. Furthermore, both complexes can interact with CT-DNA enantioselectively, and complex **2** is a much better candidate as an enantioselective binder to CT-DNA than complex **1**. When irradiated at 400 nm, complex **1** was found to be a more-effective DNA-cleaving agent than complex **2**. The experimental results suggest that the ancillary ligands of Ru(II) complexes have a significant effect on the spectral properties and DNA-binding behavior of the complexes. The theoretical calculation results applying the DFT method can also be used to discuss the trend in the binding strengths or binding constants (K_b) of the complexes to DNA as well as roughly predict some of their spectral properties.

Scheme 1. The ligand H_2L and its coordinating mode in the title complexes.

material should be prepared and they should be handled with care.

2.1. Physical measurement

Elemental analyses of carbon, hydrogen and nitrogen were carried out with an Elementar Vario EL III microanalyser. Infrared spectra were recorded on a Perkin–Elmer Spectrum 2000 spectrophotometer over the frequency range 4000–400 cm^{-1} using the KBr pellet technique. Solid-state fluorescent studies were conducted at room temperature on an Edinburgh FL-FS920 TCSPC system. Variable-temperature magnetic data were obtained with a C-2000 (American CAHN Instruments Inc.) instrument in a field of 0.2 T.

2.2. Synthesis of the ligand and the complexes

2.2.1. H_2L

The synthesis and structure of H_2L (3-methoxysalicylaldehyde picoloylhydrazone) have already been reported [29].

2.2.2. $[Cu_2L(C_5H_7O_2)(H_2O)_2]ClO_4$ (**1**)

To H_2L (1 mmol) in DMF (5 mL) was added an equimolar amount of $Cu(acac)_2$ in methanol (5 mL). After stirring for 2 h, $Cu(ClO_4)_2 \cdot 6H_2O$ (0.36 g, 1 mmol) was added to the solution. The dark-green solution was stirred at room temperature for 30 min, filtered, and allowed to stand at room temperature for 3 weeks. Dark-green crystals of **1** suitable for X-ray diffraction were formed. Yield: 50%. *Anal.* Calc. for $[Cu_2(C_{14}H_{11}N_3O_3)(C_5H_7O_2)(H_2O)_2]ClO_4$: C, 36.17; H, 3.51; N, 6.66. Found: C, 35.96; H, 3.53; N, 6.88%.

2.2.3. $[Cu_4L_2(C_5H_7O_2)_2(C_5H_5N)_2](ClO_4)_2$ (**2**)

A methanol solution (5 mL) of $Cu(acac)_2$ (0.262 g, 1 mmol) was added to a stirred DMF solution (5 mL) of H_2L (1 mmol). After stirring for 2 h, $Cu(ClO_4)_2 \cdot 6H_2O$ (0.36 g, 1 mmol) and two drops of pyridine were added to the solution. Stirring was continued for 30 min at room temperature. The solution was filtered and kept for crystallization. Brown crystals of **2** suitable for X-ray diffraction were obtained after 2 weeks. Yield: 25%. *Anal.* Calc. for $[Cu_4(C_{14}H_{11}N_3O_3)_2(C_5H_7O_2)_2(C_5H_5N)_2](ClO_4)_2$: C, 42.78; H, 3.44; N, 8.31. Found: C, 42.77; H, 3.11; N, 8.25%.

2.2.4. $(VO_2)_2L_2Cu_2(acac)_2$ (**3**)

To H_2L (1 mmol) in DMF (5 mL) was added dropwise, with stirring, an equimolar amount of $VO(acac)_2$ in absolute methanol (5 mL). After stirring for 2 h, $Cu(ClO_4)_2 \cdot 6H_2O$ (0.36 g, 1 mmol) was added to the solution. The dark-green solution was stirred at room temperature for 30 min, filtered, and allowed to stand at room temperature for 3 weeks. Dark-green crystals of **3** suitable for X-ray diffraction formed. Yield: 45%. *Anal.* Calc. for $(VO_2)_2(C_{14}H_{11}N_3O_3)_2Cu_2(C_5H_7O_2)_2$: C, 44.32; H, 3.52; N, 8.16. Found: C, 44.47; H, 3.48; N, 8.15%.

2.3. X-ray crystallography

Crystals of the three title complexes of suitable size were mounted on glass fibers. Intensity data were collected on a Rigaku RAPID Weissengberg IP diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and the ω scan mode. The structures were solved by direct methods with SHELXS-97 [30] and refined by full-matrix least squares calculations with SHELXL-97 [31]. The high values of the thermal parameters of some oxygen atoms in the perchlorate ions for **1** and **2** suggest that oxygen atom O8 in the perchlorate ion for **1** is disordered and it has been modelled over two sites with equal occupancies of 0.5 and the four oxygen atoms in the perchlorate ion for **2** are disordered and have been modelled over two sites with unequal occupancies (0.65 and 0.35). These oxygen atoms were refined isotropically. All the other non-hydrogen atoms in the three complexes were refined anisotropically. Most of the hydrogen atoms in the three complexes were located in calculated positions or found from difference Fourier maps. Crystallographic data for complexes **1**, **2** and **3** are listed in Table 1.

3. Results and discussion

3.1. Crystal structures

3.1.1. $[Cu_2L(acac)(H_2O)_2]ClO_4$ (**1**)

As shown in Fig. 1, complex **1** consists of one binuclear $[Cu_2L(acac)(H_2O)_2]^+$ cation and one ClO_4^- anion. Selected bond distances and angles are listed in Table 2. The charge balance requires that the ligand H_2L is fully deprotonated. The two copper(II) centers in the title complex molecule **1** are in different coordination environments. Cu(1) atom has a distorted square-pyramidal geometry with the basal plane defined by the N(1) and N(2) atoms from the pentadentate L^{2-} ligand, and O(4) and O(5) atoms from the $acac^-$ group. The O(6) atom from a coordinated water molecule occupies the apical site with a long Cu(1)–O(6) distance of 2.400(3) Å. The Cu–N and Cu–O bond distances in the basal plane range from 1.904(3) to 2.029(3) Å. Cu(2)

atom is coordinated by the O(1), N(3) and O(2) atoms of the ligand L^{2-} and a coordinated water molecule O(7) atom, forming a square plane. The three Cu(2)–O bond lengths are between 1.866(2) and 1.943(3) Å, and the Cu(2)–N(3) length is 1.931(3) Å. The two copper centers are bridged by single N–N bond of the pentadentate ligand L^{2-} with a Cu(1)–Cu(2) separation of 4.823(1) Å and Cu–N–N–Cu torsion angle of 179.2(2)°. The overall cation is close to a plane, with the copper basal planes coinciding with the ligand plane.

There are three kinds of hydrogen bonds in **1** (see Table 3): first, O–H(H_2O)···O(H_2O) between the coordination water molecules (O(7)···O(6) = 2.637(3) Å); second, O–H(H_2O)···O(phenolic) between the coordination water molecules and phenolic oxygen atoms (O(6)···O(2) = 2.770(3) Å); third, O–H(H_2O)···O(ClO_4^-) between the coordination water molecules and the perchlorate oxygen atoms (O(6)···O(8A) = 2.810(6) Å, O(6)···O(8B) = 2.781(7) Å, O(7)···O(11) = 2.726(5) Å). The first two kinds of hydrogen bonds link two adjacent binuclear complex cations into an extended tetranuclear Cu_4 unit with a crystallographic centrosymmetry (Fig. 1). Each extended tetranuclear Cu_4 unit connects four neighboring ClO_4^- anions by hydrogen bonds O–H(H_2O)···O(ClO_4^-). Each ClO_4^- anion links two neighboring tetranuclear Cu_4 units through hydrogen bonds O–H(H_2O)···O(ClO_4^-). Therefore, an extended 2D layer is formed (Fig. 2). The Cu···Cu distances within an extended Cu_4 unit are 3.845(1), 4.589(1), 4.823(1) and 8.594(2) Å, while the shortest Cu···Cu distances between the neighboring extended Cu_4 units is 4.22(3) Å. The adjacent ligands are stacked at a distance of about 3.46 and 3.49 Å.

3.1.2. $[Cu_4L_2(acac)_2(py)_2](ClO_4)_2$ (2)

There is one tetranuclear $[Cu_4(L)_2(acac)_2(py)_2]^{2+}$ cation and two ClO_4^- anions in complex **2**. Selected bond distances and angles are illustrated in Table 4.

Fig. 3 shows the structure of a centrosymmetrically tetranuclear $[Cu_4L_2(acac)_2(py)_2]^{2+}$ cation. A diazine N–N group of the pentadentate ligand L^{2-} bridges the atoms Cu(1) and Cu(2) to form a Cu_2 pair, the Cu(1)–Cu(2) separation and Cu–N–N–Cu torsion angle being 4.822(2) Å and 165.0(1)°, respectively. Two Cu_2 pairs are connected by two phenolic oxygen atoms of two L^{2-} ligands to get a centrosymmetrically tetranuclear $[Cu_4L_2(acac)_2(py)_2]^{2+}$ cation with a (Cu–N–N–Cu–O–)$_2$ core, Cu(2)–O(2), O(2)–Cu(1A) and Cu(2)–Cu(1A) interatomic distances are 1.905(2), 2.493(2) and 3.393(1) Å, respectively. The Cu(2)–O(2)–Cu(1A) angle is 100.1(2)°.

Table 3
Intermolecular hydrogen bond distances and angles in complex **1**

X–H···Y	Symmetry transformation	X···Y (Å)	X–H (Å)	H···Y (Å)	∠(DHA)
O7–H2b···O6	$-x, 1-y, 1-z$	2.637(3)	0.84	1.94	139.4
O6–H1b···O2	$-x, 1-y, 1-z$	2.770(3)	0.92	2.08	130.7
O6–H1a···O8A	$1-x, 1-y, 1-z$	2.810(6)	0.91	1.95	158.3
O6–H1a···O8B	$1-x, 1-y, 1-z$	2.781(7)	0.91	1.88	169.8
O7–H2a···O11	$x-1/2, -y+3/2, z+1/2$	2.726(5)	0.90	1.97	141.0

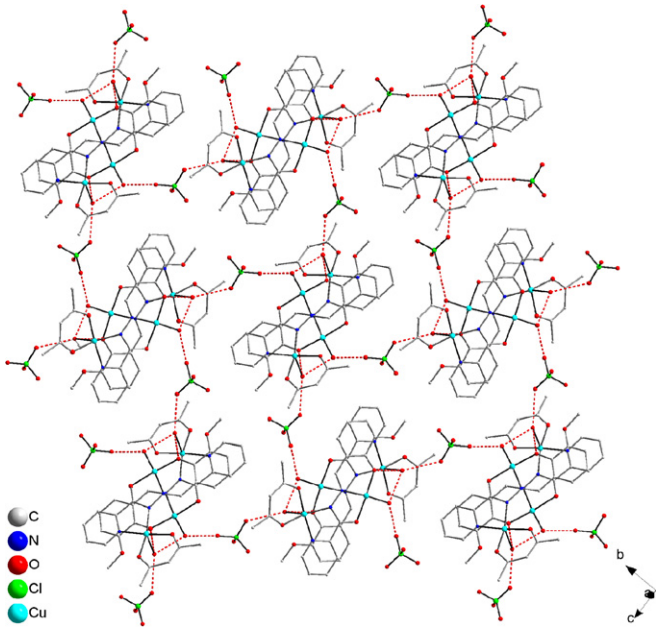

Fig. 2. Extended 2D structure of **1**. Hydrogen atoms are omitted for clarity.

The Cu(1) atom is in a distorted square-pyramidal geometry, which is completed by N(1), N(2), O(4), O(5) in the basal plane and O(2A) in the axial position. The Cu(2) atom has a distorted square-planar geometry, formed by O(1), O(2), N(3) and N(4). Except for the elongated Cu–O bond (Cu(1)–O(2A) = 2.493(2) Å), the other Cu–O and Cu–N distances fall in the ranges 1.905–1.957 and 1.953–2.020 Å, respectively. In distinction from the planar configuration of L^{2-} in **1**, neither of pentadentate ligands L^{2-} in **2** are planar.

As shown in Fig. 4, adjacent ligands within a tetranuclear unit and between the tetranuclear units are packed at a distance of *ca.* 3.60 and 3.47 Å, respectively. The aromatic ring and pyridine ring in a ligand are slightly twisted with a dihedral angle of *ca.* 18.7°. The distances between the centroids of the aromatic ring and the pyridine ring within a tetranuclear unit and between the two neighboring tetranuclear units are *ca.* 3.70 and 3.95 Å, respectively. Therefore, there is an extended 1D structure in **2** formed by weak π···π stacking interactions between the adjacent molecules. The intermolecular Cu···Cu distances are *ca.* 4.36 Å.

3.1.3. $(VO_2)_2L_2Cu_2(acac)_2$ (3)

Complex **3** is a neutral discrete heterotetranuclear molecule. The molecular structure is illustrated in Fig. 5, selected bond distances and angles are given in Table 5.

Table 4

Symmetry code A: $1-x, 1-y, -z$.

centrosymmetrical tetranuclear molecule $(V^VO_2)_2L_2Cu_2(acac)_2$. There is a quadrangle core in the discrete tetranuclear molecule. The interatomic distances of V–Cu are 5.075(1) Å on the long sides of the quadrangle and 3.588(1) Å on the short sides of the quadrangle.

The V(1)–O(6) (oxo oxygen) and Cu(1A)–O(6) bond lengths are 1.645(2) and 2.293(2) Å, respectively, and the V(1)–O(6)–Cu(1A) bond angle is 130.5(1)°. To the best of our knowledge, complex **3** is the first example of a V^VO-Cu^{II} complex where the V^V center and Cu^{II} center are bridged by one oxo oxygen atom. Of course, many V^VO-Cu^{II} complexes have been observed in the references, but the V^V and Cu^{II} centers in those complexes are bridged by one or two oxygen atoms from a polyoxovanadate or phosphate.

The copper (II) center has a distorted square-pyramidal CuN_2O_3 environment. The basal plane is defined by N(1) and N(2) atoms from a pentadentate L^{2-}, and O(4) and O(5) atoms from the $acac^-$ group, the bond lengths of Cu–N are 2.010(3)–2.049(2) Å, the ones of Cu–O are 1.913(2)–1.922(2) Å. One oxo oxygen atom (O(6A)) is at the apical position with a bond distance of 2.293(2) Å.

The vanadium atom is coordinated by two oxo oxygen atoms (O(6) and O(7)) and three donors (O(1), N(3) and O(2)) of a pentadentate L^{2-} ligand. The coordination geometry of vanadium can be described in terms of a tetragonal pyramid, distorted towards a trigonal bipyramid. The τ value is 0.32 {[∠O(2)–V(1)–O(1)–∠O(6)–V(1)–N(3)]/60 = 0.32}, reflecting a common situation encountered with pentacoordinate oxovanadium complexes. The V–O (oxo oxygen) V(1)–O(6) and V(1)–O(7) bond distances are 1.645(2) and 1.610(2) Å, respectively, and the O(6)–V(1)–O(7) angle is *ca.* 108.5°, showing the characteristic of V=O double bonds of dioxovanadium(V) complexes [32–34].

Two L^{2-} ligands in the tetranuclear molecule are essentially planar and parallel to each other, the distance between the two ligands being *ca.* 3.41 Å. The distance between the centroids of an aromatic ring from one VO_2Cu structure unit and the pyridine ring from the other VO_2Cu structure unit in the tetranuclear molecule is *ca.* 3.92 Å.

Therefore, there exists a weak π···π contact between the two L^{2-} ligands.

3.2. Self-assembly reactions involving a bridging pentadentate ligand H_2L

First the binuclear complex **1** was synthesized by a self-assembly reaction between H_2L, $Cu(acac)_2$ and $Cu(ClO_4)_2 \cdot 6H_2O$ with solvents (DMF, methanol and water). The molecular structure of **1** shows that water molecules in the reaction medium are coordinated to the copper atoms. Taking into account that the coordinating ability of pyridine is higher than that of water for the copper atom, pyridine was added to the reaction system and the tetranuclear copper complex **2** was obtained successfully.

On replacing $Cu(acac)_2$ with $VO(acac)_2$, the novel heteronuclear oxovanadium–copper complex **3** has been synthesized, during the reaction process the valence of the vanadium was increased +4 to +5 by air oxidation. Up until now, most oxovanadium–copper complexes were synthesized by hydrothermal reactions. Complex **3** was synthesized by a solution reaction and it is the first oxovanadium–copper complex with an oxo oxygen atom as the bridging atom between the V atom and the Cu atom.

3.3. IR spectroscopic studies and fluorescent properties

The IR spectra of the ligand exhibits two bands at 3272 and 1678 cm^{-1} due to ν(NH) and ν(C=O) stretches, respectively, indicative of its ketonic nature in the solid state. The absence of these bands in the IR spectra of complexes **1**, **2** and **3** is consistent with enolization and replacement of H by the metal ion. The $\nu(C{=}N_{azomethine})$ stretch of the free ligand appears as a weak band at 1608 cm^{-1} along with the ν(C=N) stretches of the pyridine ring. A very sharp band at 1588–1601 cm^{-1} in the complexes is indicative of the coordination of the azomethine nitrogen and pyridine nitrogen atoms. Complex **3** exhibits three sharp bands in the 867–936 cm^{-1} region, corresponding to the *cis*-$[VO_2]^+$ structural unit.

The fluorescent properties of the three title complexes and the pure ligand were investigated in the solid state at room temperature (Fig. 6). The pure ligand shows an intense emission band at 548 nm (λ_{ex} = 381 nm), complex **1** and **2** have almost the same emission spectrum at 396 nm (λ_{ex} = 251 nm and 253 nm, respectively) and complex **3** shows an emission at 492 nm (λ_{ex} = 393 nm). The emission of the pure ligand may be attributed to a $\pi \rightarrow \pi$ transition, while the emission of title complexes show an obvious blue shift compared to that of pure ligand, which may originate from a LMCT [35–37].

3.4. Magnetic properties

The variable-temperature magnetic susceptibility of **1** has been measured on the crystalline samples in a field of 2 kOe. The plots of χ_M and $\chi_M T$ versus T of **1** are shown in Fig. 7, where χ_M is the magnetic susceptibility. The observed $\chi_M T$ value for **1** at 300 K is 0.62 $cm^3\ mol^{-1}$ K, which is somewhat smaller than the value (0.75 $cm^3\ mol^{-1}$ K) expected for two uncorrelated Cu(II) ($S = 1/2$) ions with $g = 2$. Upon cooling, the $\chi_M T$ of **1** is roughly unchanged in the range 300–200 K, then decreases to a minimum value of 0.02 $cm^3\ mol^{-1}$ K at 2 K. The magnetic susceptibility above 40 K obeys the Curie–Weiss law with the Curie constant $C = 0.732\ cm^3\ mol^{-1}$ K and a negative Weiss constant, $\theta = -35.7$ K, which suggests the occurrence of an antiferromagnetic interaction for **1**. This result is consistent with a trans N–N bridge connecting Cu(1) and Cu(2) [38].

The χ_M value increases with decreasing temperature, reaching a maximum value of 0.014 $cm^3\ mol^{-1}$ at around 15.2 K, and then decreases abruptly to 0.007 $cm^3\ mol^{-1}$ at 3.5 K. This is characteristic of a significant antiferromagnetic ordering (T_N = 15.2 K). The origin of the small

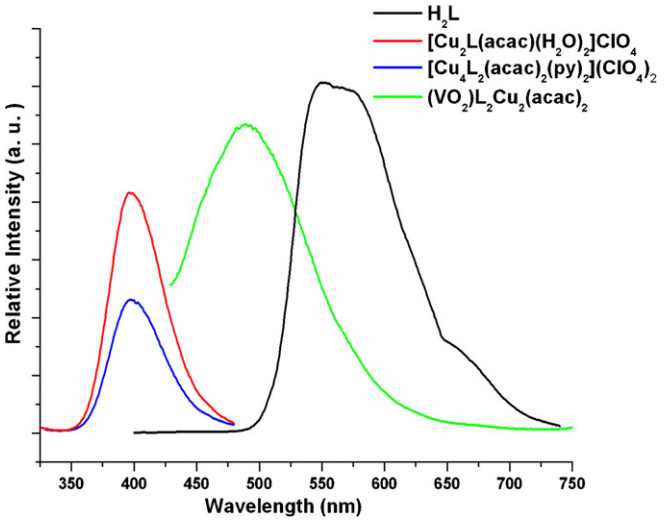

Fig. 6. The emission spectra of the title complexes and the pure ligand in the solid state at room temperature.

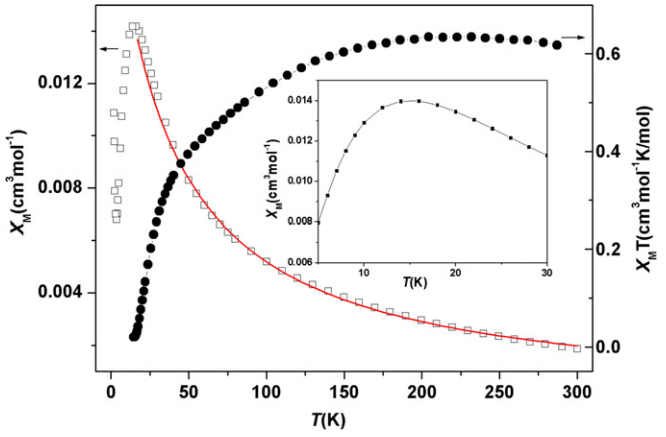

Fig. 7. Temperature dependence of χ_M and $\chi_M T$ for **1** with the solid line showing the best fit obtained through χ_M values. Inset: low temperature region of χ_M.

bump around 3 K in the χ_M versus T curve for **1** is still unclear, though the possibility of a systematic error cannot be completely excluded.

4. Conclusions

Using the same reaction system of H_2L, $Cu(acac)_2$ and $Cu(ClO_4)_2 \cdot 6H_2O$, the binuclear copper complex **1** and tetranuclear copper complex **2** have been synthesized, depending different solvents (DMF, methanol and water for **1** and DMF, methanol, water and pyridine for **2**). The different products are due to the fact that the coordinating ability of pyridine is higher than that of water for the copper atom. Replacing $Cu(acac)_2$ with $VO(acac)_2$, the novel tetranuclear oxovanadium–copper complex **3** has been synthesized. Complex **3** was synthesized by a solution reaction and is the first oxovanadium–copper complex with an oxo oxygen atom as a bridging atom between the V atom and the Cu atom.

The ligation of $\mathbf{L^1}$ and $\mathbf{L^2}$ with Pd(II), Ag(I) and Cu(II) has been investigated. The single crystal structures of $[Pd(\mathbf{L^1})Cl_2]$, $[PdCl_2(\mathbf{L^2})]_2$ and $[Cu\mathbf{L^1}Br_2]$ have been solved. The results of these investigations are the subject of this paper. Both the ligands form metallamacrocyles on complexation.

2. Experimental

The ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded on a Bruker Spectrospin DPX-300 NMR spectrometer at 300.13 and 75.47 MHz respectively. IR spectra in the range 4000–250 cm^{-1} were recorded on a Nicolet Protége 460 FT-IR spectrometer as KBr pellets. The C, H and N analyses were carried out with a Perkin–Elmer elemental analyzer 240C. 2-Bromopyridine, 1,2-bis(dimethylchlorosilyl)ethane, 3-bromoquinoline were obtained from Aldrich (USA) and used without further purification. The melting points determined in open capillary are reported as such.

2.1. X-ray diffraction analysis

Single crystal diffraction studies on $\mathbf{L^1}$ and **2** were carried out on a Bruker SMART CCD diffractometer at 25 °C and Bruker-Nonius Kappa CCD area detector diffractometer was used for **3**, so that ϕ and ω scans gave a complete asymmetric unit. The data for **4** was collected on Oxford Diffraction Gemini-R CCD diffractometer (one degree ϕ and ω scans were used with a 0.8 mm collimator). Table 1 lists the experimental parameters used for single crystal structure analysis. The software SADABS [12] was used for absorption correction, if required. For structure determination and refinement direct methods [13], WinGX version [14] of SHELX-97 and/or SHELXTL [15] were used. All non-hydrogen atoms were located from difference Fourier map and were refined anisotropically. The hydrogen atoms were located using geometrical constraints. The least-squares refinement cycles on F^2 were performed until the model converged.

2.2. Synthesis of 1,2-bis(dimethyl(2-pyridyl)silyl)ethane ($\mathbf{L^1}$)

To a solution of 2-bromopyridine(3.16 g, 20 mmol) made in dry diethyl ether (30 ml) was added drop wise *n*-butyllithium (20.5 mmol, 8.2 ml of 2.5 M solution in *n*-hexane) at −80 °C under nitrogen atmosphere. The mixture was stirred for 1 h. The dark reddish brown suspension thus obtained was mixed dropwise with 1,2-bis(chlorodimethylsilyl)ethane (2.15 g, 10 mmol) dissolved in dry diethyl ether (10 ml). The mixture was slowly allowed to warm to room temperature and left for 12 h. It was shaken with three aliquots (each of 50 ml) of water. The organic layer was separated each time and three aqueous extracts were

mixed. The combined aqueous layer was further extracted twice with diethyl ether (10 ml). These ether extracts were combined with the organic layer first separated. The mixture thus obtained was washed with saturated brine (10–20 ml) and dried over anhydrous Na_2SO_4. After evaporation of the solvent, yellow solid residue of $\mathbf{L^1}$ was obtained. It was purified by column chromatography on silica gel with (40% ethylacetate and 60% hexane). The $\mathbf{L^1}$ was found to be low melting solid (i.e. liquid at room temperature but sold at temperature <10 °C). Yield 1.8 g, ~60%. NMR (^{1}H, $CDCl_3$) δ (ppm), 8.77 (d, $J = 4.65$ Hz, 2H, H_7), 7.57 (t, $J = 6.25$ Hz, 2H, H_5), 7.47 (d, $J = 7.2$ Hz, 2H, H_4), 7.19 (t, $J = 6.24$ Hz, 2H, H_6), 0.77 (s, 4H, $H_1 + H_2$), 0.31 (s, 12H, Me); (^{13}C{^{1}H}, $CDCl_3$) δ (ppm), 166.1 (C_3), 148.7 (C_7), 132.4 (C_5), 127.7 (C_4), 121.3 (C_6), 5.8 (C_1, C_2), −5.3 (Me). IR (KBr, cm^{-1}): 1252, 2956, 1453, 825, 468, 410, 625.

2.3. Synthesis of 1,2-bis(dimethyl(3-quinolyl)silyl) ethane ($\mathbf{L^2}$)

The solution of 3-bromoquinoline (4.16 g, 20 mmol) was made in dry diethylether (30 ml) under nitrogen atmosphere. *n*-Butyllithium (20.5 mmol, 8.2 ml of 2.5 M solution in hexane) was added dropwise to it at −80 °C under nitrogen atmosphere. The resulting mixture was stirred for 1 h. To dark brown suspension thus obtained was added dropwise 1,2-bis(chlorodimethylsilyl)ethane (2.15 g, 10 mmol) dissolved in 10 ml of diethylether. The reaction mixture was slowly allowed to warm to room temperature and kept for 12 h. It was shaken with three aliquots of 50 ml of water and separated from the aqueous layer each time. The three aqueous layers were combined and extracted with two aliquots (10 ml) of diethyl ether. The ether extracts were combined with the organic layer separated earlier. The mixture thus obtained was washed with saturated brine (10–20 ml) and dried over anhydrous Na_2SO_4. After evaporation of the solvent, dark yellow oil was obtained, which was purified by column chromatography (silica gel; 30:70 ethyl acetate–hexane mixture). The colourless crystals of $\mathbf{L^2}$ were obtained by slow evaporation of solvents from the eluent. Yield 1.21 g, ~30%; m.p. 101 °C; *Anal.* Calc. for $Si_2C_{24}H_{28}N_2$: C, 71.97; H, 6.99; N, 6.99. Found: C, 71.79; H, 6.74; N, 6.23%. NMR: (^{1}H, $CDCl_3$) δ (ppm): 8.94 (s, 2H, H_{11}), 8.20 (s, 2H, H_4), 8.08 (d, $J = 6$ Hz, 2H, H_9), 7.77–7.69 (m, 4H, $H_8 + H_6$), 7.53 (t, $J = 7.27$ Hz, 2H, H_7), 0.77 (s, 4H, $H_1 + H_2$), 0.37 (s,12H, Me); (^{13}C{^{1}H}, $CDCl_3$) δ (ppm), 154.0 (C_{11}), 142.6 (C_4), 129.8 (C_9), 129.3 (C_8), 127.8 (C_6), 126.5 (C_7), 7.8 (C_1, C_2), −3.69 (Me). IR (KBr, cm^{-1}): 1250, 2955, 1343, 837.

2.4. Synthesis of [$PdCl_2$($\mathbf{L^1}$)] (1)

To a solution of $\mathbf{L^1}$ (0.09 g, 0.3 mmol) made in 10 ml of acetone was added $Na_2[PdCl_4]$ (0.088 g, 0.3 mmol) dissolved in 10 ml of water. The resulting mixture was stirred for 2 h at room temperature and poured into 100 ml of water. The complex was extracted into chloroform (2 × 50 ml). The extract was dried over anhydrous sodium sulfate, concentrated to ~10 ml and mixed with hexane (20 ml). The resulting red-yellow coloured compound (**1**) was filtered, washed with hexane (3 × 20 ml) and dried in vacuo. The single crystals of the complex **1** were grown from CH_2Cl_2 layered with hexane. Yield 0.11 g, ~76.9%; m.p. 160 °C; *Anal.* Calc. for $C_{16}H_{24}N_2Si_2PdCl_2$: C 40.21; H, 5.02; N, 5.86. Found: C, 39.97; H, 5.01; N, 5.45%. NMR (^{1}H, $CDCl_3$) δ (ppm): 9.06 (d, $J = 5.7$ Hz, 2H, H_7), 7.63–7.55(m, 4H, $H_5 + H_4$), 7.24(br t, 2H, H_6), 1.55 (s, 4H, $H_1 + H_2$), 0.45 (s, 12H, Me); (^{13}C{^{1}H}, $CDCl_3$) δ (ppm): 153.8 (C_7), 135.7 (C_5), 132.8 (C_4), 124.2 (C_6), 8.5 (C_1, C_2), −0.7 (Me). IR (KBr, cm^{-1}): 1249, 2954, 1468, 833, 460, 606, 727.

2.5. Synthesis of [Ag($\mathbf{L^1}$)]ClO_4 (2)

A solution of $\mathbf{L^1}$ (0.09 g, 0.3 mmol) made in acetone (5 ml) was slowly diffused into solution of $AgClO_4$ (0.06 g, 0.3 mmol) made in 3 ml of water (deionized) to give colourless crystals of **2**, which are light and air sensitive and insoluble in water. The crystals can be stored under nitrogen protected from light for several days. Yield 0.122 g, ~81.0%; m.p. 150 °C; *Anal.* Calc. for $C_{16}H_{24}N_2Si_2AgClO_4$: C, 37.90; H, 4.70; N, 5.50. Found: C, 37.21; H, 4.49; N, 5.54%. ^{1}H NMR ($CDCl_3$) δ (ppm) : 9.24 (d, 2H, H_7), 7.84 (br t, 2H, H_5), 7.74 (br, 2H, H_4), 7.50 (br, 2H, H_6), 1.30 (s, 4H, $H_1 + H_2$), 0.35 (s, 12H, Me); (^{13}C{^{1}H}, $CDCl_3$) δ (ppm): 168.1 (C_3), 154.4 (C_7), 137.0 (C_5), 132.2 (C_4), 124.9 (C_6), 6.5 (C_1, C_2), −2.11(Me). IR (KBr, cm^{-1}): 1249, 2955, 1456, 1084, 829, 627.

2.6. Synthesis of [$CuBr_2$($\mathbf{L^1}$)] (3)

The solid $CuBr_2$ (0.066 g, 0.3 mmol) was added to a solution of $\mathbf{L^1}$ (0.09 g, 0.3 mmol) made in 10 ml of methanol and the resulting mixture stirred for 15 min. A clear dark green coloured solution was formed. This solution was kept at 5 °C for 2 days. The dark green coloured crystals of **3** were obtained. Yield 0.065 g, ~41.6%; m.p. 195 °C; *Anal.* Calc. for $C_{16}H_{24}N_2Si_2AgClO_4$: C, 36.67; H, 4.58; N, 5.34. Found: C, 35.93; H, 4.03; N, 5.68%. IR (KBr, cm^{-1}): 2955, 2358, 1249, 1459, 837, 469. Its paramagnetic nature restricted us from recording its NMR data.

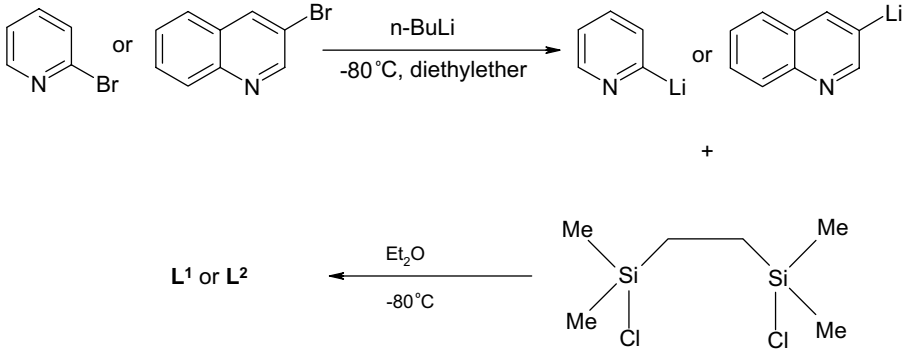
2.7. Synthesis of [$PdCl_2$($\mathbf{L^2}$)]$_2$ (4)

To a solution of $\mathbf{L^2}$ (0.12 g, 0.3 mmol) made in 10 ml of acetone was added $Na_2[PdCl_4]$ (0.88 g, 0.3 mmol) dissolved in 10 ml of water. The resulting mixture was stirred for 2 h at room temperature and poured into 100 ml of water. The complex was extracted into chloroform (2 × 50 ml). The extract was dried over anhydrous sodium sulfate, concentrated to ~10 ml and mixed with hexane (20 ml). The resulting red-yellow compound (**4**) was filtered, washed

with hexane (3 × 20 ml) and dried in vacuo. The single crystals of the complex **4** were grown from chloroform–acetonitrile mixture (1:1). Yield 0.241 g, ~69.65%; m.p. 190 °C; *Anal.* Calc. for $Si_2C_{24}H_{28}N_2PdCl_2$: C, 49.86; H, 4.80; N, 4.80. Found: C, 50.08; H, 4.74; N, 4.71%. NMR (^1H, $CDCl_3$) δ (ppm): 9.95 (s, 2H, H_{11}), 9.40 (s, 2H, H_4), 8.29 (br, 2H, H_9), 8.07 (br, 2H, H_8), 7.7–7.56 (m, 4H, $H_6 + H_7$), 0.90 (s, 4H, $H_1 + H_2$), 0.50 (s, 12H, Me). IR (KBr, cm^{-1}): 1257, 2954, 1411, 794, 637, 749.

2.8. Synthesis of [Ag L^2]ClO_4 (5)

A solution of $\mathbf{L^2}$ (0.12 g, 0.3 mmol) in acetone (5 ml) was slowly diffused into $AgClO_4$ (0.06 g, 0.3 mmol) dissolved in 3 ml of water (deionized) to give white powder, which is light and air sensitive and insoluble in water. The solid can be stored under nitrogen protected from light for several days. Yield 0.264 g, ~72.72%; m.p. >250 °C; *Anal.* Calc. for $Si_2C_{24}H_{28}N_2AgClO_4$: C, 47.47; H, 4.61; N, 4.61. Found: C, 47.72; H, 4.58; N, 4.70%. NMR (^1H, $CDCl_3$) δ (ppm): 9.38 (s, 2H, H_{11}), 8.49 (s, 2H, H_4), 8.20 (d, $J = 9$ Hz, 2H, H_9), 7.92–7.82 (m, 4H, $H_8 + H_6$), 7.65 (t, $J = 6$ Hz, 2H H_7), 0.92 (s, 4H, $H_1 + H2$), 0.46 (s, 12H, Me). IR (KBr, cm^{-1}): 1255, 2955, 1411, 808. ClO_4^- ion gives characteristic IR bands at 1105 and 626 cm^{-1}.



3. Results and discussion

The ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ were synthesized by sequence of reactions given in Scheme 1 using Schlenk techniques. At higher temperatures the reactions of Scheme 1 were not successful. Moreover, dinitrogen atmosphere was found essential for these reactions. The $\mathbf{L^1}$ and $\mathbf{L^2}$ are air stable but $\mathbf{L^1}$ has to be stored at 4 °C. Both the ligands are highly soluble in chloroform, dichloromethane, acetone, diethylether, methanol and ethanol but only sparingly in hexane. Their reactions with metal ions Ag(I), Cu(II) and Pd(II) result in complexes [Ag($\mathbf{L^1}$/$\mathbf{L^2}$)]ClO_4 (**2** and **5**), [Cu$\mathbf{L^1}$]Br_2 (**3**), [Pd($\mathbf{L^1}$)Cl_2] (**1**) and [Pd($\mathbf{L^2}$)Cl_2]$_2$ (**4**). The complexes are stable under ambient conditions except those of Ag, which have to be protected from light as it causes their decomposition. Solubility of all the complexes was found to be good in chloroform, dichloromethane and acetonitrile. In hexane and diethyl ether they were found sparingly soluble. Pd and Cu complexes are additionally soluble in THF, acetone and benzene. Complex of $\mathbf{L^1}$ with Ag is also soluble in ethanol and methanol. The variation in the ratio M:L did not result species other than **1**–**5**.

The silver complexes of both $\mathbf{L^1}$ and $\mathbf{L^2}$ have been found to be 1:1 electrolyte [$\Lambda_M = 141/155$ S cm^2 mol^{-1} (**2**/**5**)]. IR spectra of $\mathbf{L^1}$ and $\mathbf{L^2}$ and their metal complexes were found to be characteristic. In the spectrum of **2** and **5** bands due to uncoordinated ClO_4^- were observed around 626 and 1084/1105 cm^{-1}. In the ligands and their complexes bands between 794 and 837 cm^{-1} appear due to Si–C(py/quin.) vibrations whereas Si–CH_3 vibrations appear between 1249 and 1257 cm^{-1}.

3.1. ^1H and $^{13}C\{^1H\}$ NMR spectra

The proton and carbon-13 NMR spectra of $\mathbf{L^1}$ and $\mathbf{L^2}$ are characteristic. The signals of CH_3 and CH_2 groups of $\mathbf{L^1}$ and $\mathbf{L^2}$ are marginally shielded (up to 0.06 ppm) with respect to those of their precursor halide (Scheme 1). The proton and carbon-13 NMR spectra of all the metal complexes are also characteristic. The H_6 and H_8 merge together in the ^1H NMR spectrum of $\mathbf{L^2}$. The signal of H_7 of $\mathbf{L^1}$ on complexation is deshielded by ~0.29 −0.47 ppm (with respect to that of free ligand) and deshielding is maximum in the case of Pd-complex. The signals of H_1 and H_2 exhibit deshielding in the range 0.53–0.78 ppm. The H_4, H_5 and H_6 signals of Pd-complex of $\mathbf{L^1}$ exhibit small deshielding (<0.1 ppm), however, in case of Ag-complex these signals are deshielded by 0.27 to 0.31 ppm. The signal of H_{11} of $\mathbf{L^2}$ on complex formation is deshielded ~0.44 −1.01 ppm with respect to that of free ligand. Similarly signal of H_9 on complexation is deshielded by ~0.12–0.21 ppm and that of H_4 exhibits deshielding in the range 0.29–1.20 ppm. The deshielding of H_1 and H_2 signals is in the range 0.13–0.15 ppm. The signal of H_6, H_7 and H_8 merge together in the spectrum of Pd- complex **4** but they are deshielded at least 0.17–0.30 ppm with respect to those of free ligand. In the spectrum of Ag complex **5**, H_8 and H_6 have been found merged but deshielded by ~0.15 ppm with

Scheme 1.

respect to those of free $\mathbf{L^2}$. The signal of H_7 in case of **5** shows deshielding of ~0.1 ppm.

In carbon-13 NMR spectra of metal complexes of $\mathbf{L^1}$, C_7 signal appears deshielded (~5.0–5.6 ppm). The deshielding in the case C_5 and C_4 is in the range 3.3–5.1 ppm. The signal of C_6 of $\mathbf{L^1}$on complexation is deshielded by ~2.9–3.6 ppm in all cases. In case of Ag-complex of $\mathbf{L^1}$ small deshielding (<1 ppm) is exhibited in the signals of C_1 and C_2, however, in the spectrum of Pd-complex these signals are deshielded by ~2.9 ppm. The deshielding of various protons and carbon atoms suggests that in all the complexes the ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ coordinate through nitrogen of pyridine or quinoline ring. This has been further corroborated by single crystal structures of **1**, **3** and **4**.

3.2. Crystal structures

The $\mathbf{L^2}$ has been authenticated by X-ray diffraction on its single crystals. In Table 2 selected bond lengths are given and in Fig. 1 molecular structure is shown. The Si–C(alkyl) and Si–C(aryl) bond lengths (Table 2) are consistent with literature reports 1.849(4)–1.863(4) and 1.873(2) Å respectively [16]. The bond angles at Si are around 109° as expected. The bond lengths and bond angles of pyridine ring were found to be normal. The molecular structure of **1** is shown in Fig. 2 and selected bond lengths and angles are given in Table 3. The $\mathbf{L^1}$ coordinates with Pd(II) through pyridyl nitrogen atoms making a nine-membered palladamacrocyclic complex.

The Pd in **1** has a square geometry with two chloride ligands *trans* to each other. The Pd–Cl (2.3102(4)/2.3114(4) Å) bond distances of **1** (Table 3) are consistent with the literature values of 2.3110(4) Å reported [17] for Pd(II)-complex of *N*-{2-(4-methoxyphenyltelluro)ethyl} morpholine, which also has two such bonds*trans* to each other. Similarly Pd–N (2.010(1)/2.015(1) Å) bond distances of **1** are consistent with reported values, 2.095(4) Å [18] for

a *trans* N–Pd–N system. The bond distance (Table 3) Si–C(aryl) is greater than Si-C(alkyl) but both are consistent with the reported values [19] 1.913(3) and 1.882(3) Å for Si–C(aryl) and Si–C(alkyl) respectively. A similar observation is made in case of $\mathbf{L^2}$. The molecular structure of **3** is shown in Fig. 3 and its selected bond distances and angles are given in Table 4. The **3** is also nine-membered metallamacrocylic complex like **1**. The two Br are *trans* to each other. The Cu–Br distance 2.4137(10)/2.4172(10) Å of **3** (Table 4) is consistent with the value of 2.4151(3) Å reported for Cu(II) complex of 4,7-phenathroline [20]. Similarly Cu–N bond distances (Table 4) are in agreement with the literature values 1.983(2) Å reported for Cu(II) complex of 4,7-phenathroline [20]. The Si–C(aryl) and Si–C(alkyl) bond distances were found in case of **3** as 1.908(8)/1.895(6) Å and 1.845(6)–1.873(7) Å. They were also in agreement with the literature values mentioned above [19]. The **4** is a 22-membered metallamacrocyclic system and is the first example of this size which has ligand con-

of **1**. Similarly Pd–N bond lengths 2.014(3)–2.038(3) are close to those of **1**. The sum of covalent radii (Å) are: Pd–N, 2.05, Pd–Cl, 2.30; Cu–N, 2.04 and Cu–Br, 2.44. On comparing these values with those of complexes **1**, **3** and **4** it appears that coordination of Pd as well as that of Cu with the ligands is strong (Fig. 4, Table 5).

4. Conclusion

Organosilicon backbone containing ligands 1,2-bis(dimethyl(2-pyridyl)silyl)ethane ($\mathbf{L^1}$) and 1,2-bis(dimethyl(3-quinolyl)silyl) ethane ($\mathbf{L^2}$), which have CH_2CH_2 spacer, have been synthesized and used to design metallamacrocyclic complexes of Pd(II) and Cu(II) having 9- or 22-membered rings. The **4** having 22-membered metallamacrocyclic is the first example containing ligand of organosilicon backbone. The geometry of Pd as well as Cu is very close to square planar in **1**, **3** and **4**. The Pd–N, Cu–N, Pd–Cl and Cu–Br bond distances are very close to sum of covalent radii indicating strong ligation of $\mathbf{L^1}$ and $\mathbf{L^2}$.

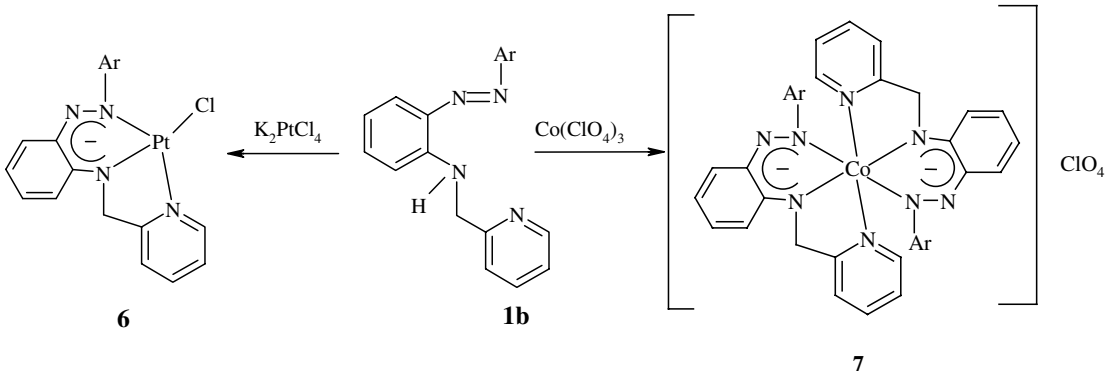
HL^1	H
HL^2	CH_3
HL^3	Cl

1b



HL when X=N of **1b**

Formation of a diazoketiminato chelate, like **5**, supported our mechanistic proposal. The bis complex cation of Co(III) incorporating the tridentate diazoketimine ligand has been isolated for the first time. Synthesis, X-ray structures, redox properties and the plausible nature of the redox orbitals have been reported in this paper.

2. Results and discussion

2.1. Syntheses

The reaction of 1*N*-(2-pyridyl-2-methyl)-2-arylazo aniline, HL, with K_2PtCl_4 in methanol afforded a pink complex of platinum (II) of the composition (L)PtCl **6** incorporating the tridentate (*N*,*N*,*N*) ligand (Scheme 2). Reaction of HL **1b** with $Co(ClO_4)_3 \cdot 6H_2O$ in refluxing methanol afforded the blue-violet bis complex of the composition $[(L)_2Co]ClO_4$ **7** where L^- binds the metal in a tridentate (*N*,*N*,*N*) fashion (Scheme 2). In both cases the

Scheme 2.

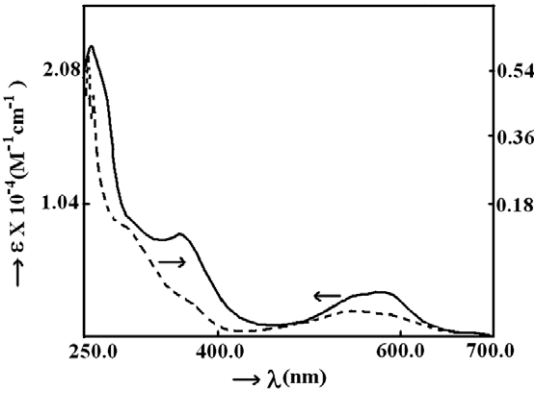


Fig. 1. UV–Vis spectra of $[(L^1)_2Co]ClO_4$ (---) and $(L^1)PtCl$ (—). The arrows indicate scales of the corresponding spectra.

deprotonated secondary amino nitrogen binds the metal forming a six-membered diazoketiminato chelate. Formation of a six-membered diazoketiminato chelate has been attributed to the delocalisation of the negative charge within the ligand backbone [14–17]. Complex **7** is diamagnetic and is consistent with a low spin t_{2g}^6 configuration.

2.2. Characterization

All the Pt(II) complexes, (L)PtCl, exhibited a characteristic low energy absorption near 580 nm which has been assigned to a MLCT transition [14–18]. The low energy absorption due to a MLCT transition for the $[(L)_2Co]ClO_4$ complexes has been observed near 570 nm. Representative UV–Vis spectra of $(L^1)PtCl$ and $[(L^1)_2Co]ClO_4$ are shown in Fig. 1. Relevant data are collected in Section 3.

The IR spectra of HL [17] displayed a sharp singlet near 3189 cm^{-1} for ν_{N-H} which was absent for both the complexes (L)PtCl and $[(L)_2Co]ClO_4$, indicating the dissociation of the amino proton upon complexation. The $\nu_{N=N}$ of the ligands (~1510 cm^{-1}) shifted to lower frequency upon complexation (1400–1410 cm^{-1}), consistent with coordination of the azo nitrogen [14–18]. The ν_{Pt-Cl} of the platinum complexes appeared at 325 cm^{-1} [19,20]. The cobalt complexes exhibited a broad absorption near 1100 cm^{-1}, characteristic of uncoordinated ClO_4^-. Relevant data are included in Section 3.

The N–H resonance of the free ligands (δ 9.37–9.55 ppm) [17] were absent in the ^1H NMR spectra of the platinum and cobalt complexes, signifying the dissociation of the N–H proton upon complexation. The resonance of the methylene protons appeared in the platinum complexes as a singlet (δ 5.29–5.48 ppm), in contrast to the doublet of the ligands (δ 4.68–4.69 ppm), indicating the lack of vicinal coupling due to the absence of the N–H proton [17]. The resonances of the pair of methylene protons in the $[(L)_2Co]^+$ ion appeared as two doublets signifying the substantial difference in chemical shielding within the pair. Resonances for the other aromatic protons are consistent with the structure as determined by X-ray studies (see below). The ^1H NMR data are collected in Section 3.

2.3. X-ray structure of $(L^3)PtCl$

Suitable crystals of $(L^3)PtCl$ were grown by the slow evaporation of a dichloromethane–methanol mixed solution. The X-ray structure of $(L^3)PtCl$ was determined and the perspective view of the molecule along with the atom numbering scheme is shown in Fig. 2. Selected bond distances and angles are collected in Table 1. The geometry about platinum is distorted square planar where the $(L^3)^-$ binds in a tridentate (*N*,*N*,*N*) fashion. A chloride ligand satisfies the tetracoordination. The three nitrogen

N(1)–N(2)	1.265(19)	C(10)–C(11)	1.37(2)
N(2)–C(7)	1.44(2)	C(9)–C(10)	1.39(3)
N(1)–C(1)	1.38(2)	C(8)–C(9)	1.37(2)
N(3)–C(12)	1.345(19)	C(7)–C(8)	1.43(2)
C(13)–C(14)	1.50(2)	N(4)–C(14)	1.352(19)
Pt(1)–Cl(1)	2.540(3)		
Bond angles			
Cl(1)–Pt(1)–N(1)	92.6(4)	Cl(1)–Pt(1)–N(3)	173.5(4)
Cl(1)–Pt(1)–N(4)	93.0(3)	N(1)–Pt(1)–N(3)	92.5(5)
N(1)–Pt(1)–N(4)	174.2(5)	N(1)–C(1)–C(2)	117.3(14)
N(3)–Pt(1)–N(4)	82.0(5)	Pt(1)–N(1)–N(2)	127.7(11)
N(2)–C(7)–C(12)	127.4(13)	N(1)–N(2)–C(7)	122.5(14)
C(12)–N(3)–C(13)	117.7(12)	Pt(1)–N(3)–C(12)	125.0(10)
Pt(1)–N(4)–C(14)	113.0(9)	N(3)–C(13)–C(14)	110.1(12)

donors are azo (*N*(azo)), pyridyl (*N*(py)) and deprotonated amino (*N*(am)) nitrogens. The Pt–N(azo), Pt–N(py) and Pt–Cl lengths (2.004(13), 2.054(12) and 2.540(3) Å, respectively) are within the normal range [15,19,20]. The geometry about platinum is planar (mean deviation 0.067 Å) consistent with a dipositive oxidation state of platinum and the uninegative ligand, since the complex is non-electrolyte.

The C(12)–N(3) length (1.345(19) Å) is shorter compared to a C–N single bond (N(1)–C(1) 1.38(2) Å) in the same molecule and is similar to the imine (C=N) distance [14–17]. The effect of imine formation due to delocalisation has been reflected in the adjacent phenyl ring (C(7)–C(12)) which is distorted with two short (~1.37 Å) and four long (~1.43 Å) bonds [14–17]. Thus, the formation of a diazoketiminato chelate could be inferred from the X-ray results and the structural formula of (L^3)PtCl has been drawn accordingly in **6** of Scheme 2 (*vide supra*). All the non-hydrogen atoms of (L^3)PtCl, excluding the pendant phenyl ring (C(1)–C(6)), make a good plane (mean deviation 0.220 Å).

2.4. X-ray structure of $[(L^3)_2Co]ClO_4$

Suitable crystals of $[(L^3)_2Co]ClO_4$ were obtained from the methanolic mother liquor. The X-ray structure of $[(L^3)_2Co]ClO_4$ was determined and the perspective view of the $[(L^3)_2Co]^+$ cation along with the atom numbering scheme is shown in Fig. 3. Selected bond distances and angles are collected in Table 2. The geometry about the Co(III) centre is distorted octahedral, where the two anionic ligands, $[L^3]^-$, coordinated meridionally give rise to a CoN_6 coordination sphere. A perchlorate (ClO_4^-) ion satisfies the unipositive charge of the complex cation, $[(L^3)_2Co]^+$. The relative orientations of *N*(py), *N*(azo) and *N*(am) pairs are *cis*, *cis* and *trans*, respectively. Extensive electron delocalisation along the ligand backbone is also observed in this case. As a result, the C(12)–N(3) length (1.329(4) Å) and C(30)–N(7) length (1.343(4) Å) are shorter compared to the C–N single bonds (N(1)–C(1) 1.449(4) Å; N(5)–C(19) 1.444(5) Å) in the same molecule and are similar to the imine (C=N) distance [19–22]. The effect of imine formation due to delocalisation has also been reflected in the adjacent phenyl ring (C(7)–C(12)) which is distorted with two short (~1.35 Å) and four long (~1.42 Å) bonds, consistent with the formation of a diazoketiminato chelate [14–17,23]. The structural formula of $[(L^3)_2Co]ClO_4$ has been drawn accordingly in **7** of Scheme 2 (*vide supra*).

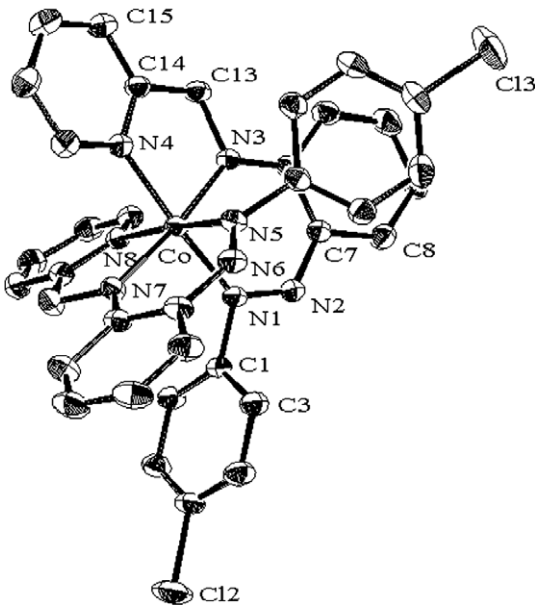

Fig. 3. Perspective view of $[(L^3)_2Co]^+$ with the atom numbering scheme. Hydrogen atoms and the perchlorate ion are omitted.

2.5. Redox processes and nature of redox orbitals

(L^3)PtCl and $[(L^3)_2Co]ClO_4$ displayed one and two irreversible oxidative responses, respectively, in their cyclic voltammograms (0.924 V versus SCE for the Pt(II) complex and 0.78, 1.14 V versus SCE for the Co(III) complex). To have an insight into the nature of the redox orbitals, the EHMO results have been taken into account (Supplementary material). The HOMO of (L)PtCl and $[(L)_2Co]ClO_4$ (Figs. S20 and S22) were found to be primarily ligand orbitals. Thus, the oxidative responses have been attributed to ligand oxidations as given in

$$[(L)Pt^{II}Cl] \xrightarrow{-e} [(L^{\cdot})PtCl]^+ \quad (1)$$

$$[(L)_2Co^{III}]^+ \xrightarrow{-e} [(L^-)(L^{\cdot})CO]^{2+} \xrightarrow{-e} [(L^{\cdot})(L^{\cdot})Co]^{3+} \quad (2)$$

3. Experimental

3.1. Materials

The solvents used in the reactions were of reagent grade obtained from E. Merck, Kolkata, India, and were purified and dried by reported procedures [23,24]. 2-(Arylazo) anilines and 1*N*-(2-pyridyl-2-methyl)-2-arylazoaniline were prepared according to reported procedures [14,15,17]. Chloroplatinic acid, cobalt carbonate, potassium carbonate, perchloric acid and potassium chloride were purchased from E. Merck, Kolkata, India. 2-(Chloromethyl) pyridine hydrochloride was purchased from Lancaster, England. Potassium tetrachloroplatinate was prepared by reported procedures [25]. Cobalt(III) perchlorate was prepared by oxidation of Co(II) perchlorate with H_2O_2 [26].

3.2. Syntheses of the Pt(II) complexes

The complexes $(L^1)PtCl$, $(L^2)PtCl$ and $(L^3)PtCl$ were prepared by a similar procedure. A representative example for $(L^1)PtCl$, is given below.

3.2.1. $(L^1)PtCl$

A solution of HL^1 (0.1 g, 0.35 mmol) in 10 cm^3 methanol was added to a solution of K_2PtCl_4 (0.145 g, 0.35 mmol) in 5 cm^3 water. The mixture was stirred for 15 h. The dark solid precipitate that formed was purified by washing with benzene–petroleum ether (80:20) mixed solvent. The pure solid was then dissolved in dichloromethane with a few drops of methanol and kept for crystallisation. Pure crystalline solid of $(L^1)PtCl$ was obtained. Yield: 50%. *Anal.* Calc. for $C_{18}H_{15}N_4PtCl$, $(L^1)PtCl$: C, 41.75; H, 2.92; N, 10.82. Found: C, 41.73; H, 2.90; N, 10.85%. Electronic spectrum (λ_{max}/nm (ε/dm^2 mol^{-1}), dichloromethane): 578 (2200), 359 (5000), 259 (14 260). IR (KBr pellets, cm^{-1}): $\nu_{N=N}$ 1405, ν_{Pt-Cl} 326. ^1H NMR ($CDCl_3$, ppm): δ 9.67 (d, 1H); 7.99 (d, 1H); 7.88–7.83 (m, 2H); 7.66–7.62 (m, 1H); 7.59 (d, 1H); 7.42–7.39 (m, 3H); 7.36–7.27 (m, 2H); 7.03 (d, 1H); 6.65 (t, 1H); 5.48 (s, 2H).

3.2.2. $(L^2)PtCl$ and $(L^3)PtCl$

Complexes $(L^2)PtCl$ and $(L^3)PtCl$ were prepared using the ligands HL^2 and HL^3 in place of HL^1. Yield: $(L^2)PtCl$, 50% and $(L^3)PtCl$, 55%, respectively.

Anal. Calc. for $C_{19}H_{17}N_4PtCl$, $(L^2)PtCl$: C, 42.89; H, 3.19; N, 10.53. Found: C, 42.92; H, 3.23; N, 10.50%. Electronic spectrum (λ_{max}/nm (ϵ/dm^2 mol^{-1}), dichloromethane): 579 (1230), 358 (2750), 259 (7483). IR (KBr pellets, cm^{-1}): $\nu_{N=N}$ 1402, ν_{Pt-Cl} 325. ^1H NMR ($CDCl_3$, ppm): δ 9.61 (d, 1H); 8.13 (d, 1H); 7.97–7.96 (m, 2H); 7.35–7.29 (m, 3H); 7.26–7.21 (m, 3H); 7.17–7.23 (m, 1H); 6.62 (m, 1H); 5.29 (s, 2H); 2.40 (s, 3H).

Anal. Calc. for $C_{18}H_{14}N_4PtCl_2$, $(L^3)PtCl$: C, 39.14; H, 2.56; N, 10.14. Found: C, 39.10; H, 2.60; N, 10.20%. Electronic spectrum (λ_{max}/nm (ϵ/dm^2 mol^{-1}), dichloromethane): 581 (3200), 359 (7050), 258 (18 380). IR (KBr pellets, cm^{-1}): $\nu_{N=N}$ 1400, ν_{Pt-Cl} 324. ^1H NMR ($CDCl_3$, ppm): δ 9.72 (d, 1H); 7.97 (m, 2H); 7.90 (t, 1H); 7.67 (m, 2H); 7.60 (d, 1H); 7.37–7.29 (m, 3H); 7.04 (d, 1H); 6.67 (t, 1H); 5.47 (s, 2H).

3.3. Syntheses of the Co(III) complexes

The complexes $[(L^1)_2Co]ClO_4$, $[(L^2)_2Co]ClO_4$ and $[(L^3)_2Co]ClO_4$ were prepared by a similar procedure. A representative example for $[(L^1)_2Co]ClO_4$, is given below.

3.3.1. $[(L^1)_2Co]ClO_4$

A solution of HL^1 (0.2 g, 0.70 mmol) in 10 cm^3 methanol was added to a 5 cm^3 methanolic solution of $Co(ClO_4)_3 \cdot 6H_2O$ (0.150 g, 0.35 mmol). The mixture was refluxed for 1 h. The colour of the solution became blue-violet. It was kept for five days. Pure crystalline solid of $[(L^1)_2Co]ClO_4$ was obtained. Yield: 65%. *Anal.* Calc. for $C_{36}H_{30}N_8CoClO_4$, $[(L^1)_2Co]ClO_4$: C, 58.98; H, 4.12; N, 15.28. Found: C, 59.00; H, 4.17; N, 15.25%. Electronic spectrum (λ_{max}/nm (ϵ/dm^2 mol^{-1}), dichloromethane): 552 (5000), 368 (7300), 300 (21 900). IR (KBr pellets, cm^{-1}): $\nu_{N=N}$ 1409, ν_{Cl-O} 1102. ^1H NMR ($CDCl_3$, ppm): δ 7.76 (t, 1H); 7.67 (d, 1H); 7.52–7.48 (m, 2H); 7.29–7.26 (m, 1H); 7.21–7.17 (m, 2H); 7.05 (t, 2H); 6.88 (d, 1H); 6.57 (t, 1H); 6.33 (d, 2H); 5.28 (d, 1H); 4.42 (d, 1H).

3.3.2. $[(L^2)_2Co]ClO_4$ and $[(L^3)_2Co]ClO_4$

Complexes $[(L^2)_2Co]ClO_4$ and $[(L^3)_2Co]ClO_4$ were prepared using the ligands HL^2 and HL^3 in place of HL^1, respectively. Yield: $[(L^2)_2Co]ClO_4$, 70% and $[(L^3)_2Co]ClO_4$, 60%.

Anal. Calc. for $C_{38}H_{34}N_8CoClO_4$, $[(L^2)_2Co]ClO_4$: C, 59.96; H, 4.50; N, 14.72. Found: C, 59.90; H, 4.53; N, 14.70%. Electronic spectrum (λ_{max}/nm (ϵ/dm^2 mol^{-1}), dichloromethane): 569 (6340), 368 (11 000), 310 (22 750). IR (KBr pellets, cm^{-1}): $\nu_{N=N}$ 1410, ν_{Cl-O} 1085. ^1H NMR ($CDCl_3$, ppm): δ 7.88 (t, 1H); 7.64 (d, 1H); 7.53–7.50 (m, 2H); 7.33–7.26 (m, 2H); 6.83 (d, 3H); 6.61 (t, 1H); 6.19 (d, 2H); 5.15 (d, 1H); 4.44 (d, 1H); 2.25 (s, CH_3).

Anal. Calc. for $C_{36}H_{28}N_8CoCl_2ClO_4$, $[(L^3)_2Co]ClO_4$: C, 53.91; H, 3.52; N, 13.97. Found: C, 53.88; H, 3.55; N, 13.95%. Electronic spectrum (λ_{max}/nm (ϵ/dm^2 mol^{-1}), dichloromethane): 570 (5560), 363 (10 120), 304 (21 660). IR (KBr pellets, cm^{-1}): $\nu_{N=N}$ 1408, ν_{Cl-O} 1089. ^1H NMR ($CDCl_3$, ppm): δ 7.78 (t, 1H); 7.67 (d, 1H); 7.53 (d, 1H); 7.45 (d, 1H); 7.35 (t, 1H); 7.24 (d, 1H); 7.01 (d, 2H); 6.94 (d, 1H); 6.61 (t, 1H); 6.27 (d, 2H); 5.37 (d, 1H); 4.47 (d, 1H).

3.4. Physical measurements

Microanalyses (C, H, N) were performed using a Perkin–Elmer 240C elemental analyzer. Infrared spectra were recorded on a Perkin–Elmer L120-00A FT-IR spectrometer with the samples prepared as KBr pellets. Electronic spectra were recorded on a Shimadzu UV- 2401 PC

spectrophotometer. ^{1}H NMR spectra were obtained on Brucker Avance RPX 500 NMR spectrometers in $CDCl_3$ and in DMSO, using TMS as the internal standard. Electrochemical measurements were performed using a PAR Versastat II potentiostat, a platinum disk working electrode, a platinum wire auxiliary electrode and aqueous saturated calomel (SCE) as the reference, (0.1 M) Bu_4NClO_4 supporting electrolyte, and in acetonitrile solvent. Electrochemical measurements were carried out under a dinitrogen atmosphere at 298 K and were uncorrected for junction potentials.

3.5. Crystallography

Data for the crystals, $(L^3)PtCl$ and $[(L^3)_2Co]ClO_4$, were collected by the ω-scan technique on a Brucker smart CCD diffractometer with Mo Kα radiation monochromated by a graphite crystal. The structure solution was done by direct methods with the SHELXS-97 program. Full matrix least square refinements were performed using the SHELX-97 program (PC version). All non-hydrogen atoms were refined anisotropically using reflections $I > 2\sigma(I)$. Hydrogen atoms were included at calculated positions. The crystal data and data collection parameters are listed in Table 3. The asymmetric unit of $(L^3)PtCl$ consists of two independent molecules and a dichloromethane molecule as the solvent of crystallization. Although the bond parameters of the two molecules in the asymmetric unit were not identical, they are consistent with each other.

4. Conclusion

The general coordination mode of 1*N*-(2-pyridyl-2-methyl)-2-arylazoaniline, HL towards Pt(II) and Co(III) has been determined. Formation of diazoketiminato chelates of Co(III) have been reported for the first time. The hypothetical mechanism of reaction between HL and metal substrates has been further supported with the formation of diazoketiminato chelates of Pt(II) and Co(III). The redox properties of the complexes have been assumed to be due predominantly to ligand centered.

Acknowledgement

We are thankful to the DST (New Delhi) for funding and fellowship to J.P. under DST-SERC Project (No. SR/S1/IC-09/2003). The necessary laboratory and infrastructural facilities are provided by the Dept. of Chemistry, University of Kalyani. The support of DST under FIST program to the Department of Chemistry, University of Kalyani is acknowledged. We acknowledge Prof. Jui-Hsien Huang, National Changhua University of Education, Changhua, Taiwan for X-ray studies.

Appendix A. Supplementary material

CCDC 652204 and 652203 contain the supplementary crystallographic data for $(L^3)PtCl$ and $[(L^3)_2Co]ClO_4$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.029.

[a] Crystallization from pentane (−69 °C).
[b] Formation of $Ph_2P–PPh_2$, $P(SiMe_3)_3$ and $Ph_2P–P(SiMe_3)–PPh_2$ was established and tentatively also of the phosphanophosphinidenephosphorane $Ph_2P–P{=}PPh_2Br$.
[c] Crystallization from toluene (−69 °C).
[d] Crystallization from petrol ether (−69 °C).

The reaction of $R_2P–P(SiMe_3)H$ with MH (M = Li, Na, K) was proposed by Scheer [5] as an alternative route.

In order to synthesize $R_2P–P(SiMe_3)Li$ we used the method of Fritz, which is well applicable in the case of R = ^{i}Pr [3,6] and $^i Pr_2N$ (Eq. (1)). Details of the lithiation processes are collected in Table 2.

In the case of $Ph_2P–P(SiMe_3)_2$ (**1a**) the lithiation reaction is accompanied by a significant splitting of the P–P bond in the parent diphosphane [3]. Issleib and Krech reported the cleavage of the P–P bond in $R_2P–PR_2$ in a reaction with PhLi, especially preferred for R = Ph [8], presumably due to a nucleophilic mechanism. As was reported, PhLi and LiPEt(Ph) are able to split a P–P bond in cyclic $(EtP)_n$ [9]. We have found that better results are obtained performing the lithiation of $Ph_2P–P(SiMe_3)_2$ at −70 °C in DME (run 2a.2) than in THF at −30 °C (run 2a.1) but nevertheless the isolated solid has a composition of ca. 50% of $Ph_2P–P(SiMe_3)Li \cdot 3DME$, 33% of $Ph_2P–PPh_2$ and 17% of $LiP(SiMe_3)_2 \cdot DME$. Related products $Ph_2P–PPh_2$ and $Ph_2P–P(SiMe_3)Li$ were reported in a reaction of $Ph_2P–P(SiMe_3)–PPh_2$ with BuLi in THF [3]. Thus, it seems reasonable to assume that these two side reactions proceed through the same mechanism. The formation of $Ph_2P–PPh_2$ suggests that a single electron transfer process (SET) leading to $Ph_2P\cdot$ radicals can be partially responsible for the outcomes of these reactions. To prove this suggestion we have lithiated $Ph_2P–P(SiMe_3)_2$ in THF with ^{t}BuLi at −30 °C and examined the reaction solution with ^{1}H and ^{31}P NMR. To our surprise only a small amount of $Ph_2P–PPh_2$ was detected. The main products are $^t BuPh_2P$ (17.7 ppm), $(Me_3Si)_2PLi$ and **2a**. Thus a SET mechanism leading to $Ph_2P–PPh_2$ was not favoured, instead the nucleophilic splitting of a P–P bond in **1a** is more visible (Eq. (3)).

$$Ph_2P–P(SiMe_3)_2 + {}^t BuLi \rightarrow Ph_2P^t Bu + (Me_3Si)_2PLi \quad (3)$$

The ^{31}P NMR studies of solutions of $Ph_2P–P(SiMe_3)Li$ (**2a)** in DME and in THF indicate significantly different $^1J_{P-P}$ coupling constants: −352.4 Hz in DME and −288.4 Hz in THF. This is probably due to a solvent-separated ionic form of $(Li \cdot 3DME)^+(Ph_2P–PSiMe_3)^-$ in DME and an ion-contacted (partially covalent) form of $Ph_2P–P(SiMe_3)$-$Li \cdot 3THF$ in THF solution.

The stability of $Ph_2P–P(SiMe_3)Li$ (**2a)** in DME solution is limited. It decomposes slowly giving the way to the formation of $Ph_2P–PPh_2$, $(Li \cdot 3DME)^+(Ph_2P–P–PPh_2)^-$, Ph_2PH, $LiP(SiMe_3)_2$. The solvent-separated ionic form of $Ph_2P–PLi–PPh_2 \cdot 3DME$ is suggested due to its $^{31}P\{^1H\}$ NMR data: −8.04 ppm (d), −125.6 ppm (t), $^1J_{P1-P2} = -380.4$ Hz. For $Ph_2P–PLi–PPh_2$ in THF-d_8 Fritz et al. have reported: 5.39 ppm (d), −112.06 ppm (t), $^1J_{P1-P2} = -348.3$ Hz [3].

The lithiation of $^i Pr_2P–P(SiMe_3)_2$ (**1b**) with BuLi in THF was performed at 0 °C yielding moderately stable $^i Pr_2P–$

2c	$^i Pr_2N$	0.029	THF 100	18.0	0.029	−30	66[d]	[7]

[a] In the mother liquor, side products $P(SiMe_3)_2Li$, $Ph_2P–PPh_2$, Ph_2PH, Ph_2PSiMe_3, $P(SiMe_3)_3$ and probably Ph_2PLi were found. Crystallization from 10 ml THF at −30 °C gave 1.8 g of a precipitate of composition 36% $Ph_2P–P(SiMe_3)Li \cdot 3THF$, 53% $P(SiMe_3)_2Li \cdot 3THF$, 11% $Ph_2P–PPh_2$.
[b] Crystallization from 10 ml DME at −30 °C; 1.8 g of orange precipitate of composition 50% $Ph_2P–P(SiMe_3)Li \cdot 3DME$, 33% $Ph_2P–PPh_2$ and 17% $P(SiMe_3)_2Li \cdot DME$ were isolated.
[c] Crystallization from 10 ml pentane and 1 ml THF at −30 °C; 10% of $^i Pr_2P–P(SiMe_3)H$ and a small amount of $LiP(SiMe_3)_2$ was found in the product. When the crystallization residue was stored for a few weeks, $^i Pr_2P–PLi–P^i Pr_2 \cdot 1.5THF$ was isolated as an additional product in form of colourless crystals.
[d] Crystallization from 10 ml pentane and 2 ml THF at −30 °C; 10% of $(^i Pr_2N)_2P–P(SiMe_3)H$ [6] was found in the product.

$P(SiMe_3)Li$ (**2b**) [2,3,6]. $^iPr_2P–P(SiMe_3)Li$ shows very similar ^{31}P NMR data both in DME and in THF. However the ^1H NMR spectrum of **2b** in DME differs substantially from its spectrum in THF solution. In DME solution of **2b** small amounts of $^iPr_2P–PLi–P^iPr_2$ and $LiP(SiMe_3)_2$ were established. Moreover, crystalline $^iPr_2P–PLi–P^iPr_2 \cdot 1.5THF$ [10] was isolated from the mother liquor in run 2b in THF. Thus **2b** decomposes slowly according to Eq. (4):

$$2^iPr_2P–P(SiMe_3)Li \rightarrow {}^iPr_2P–PLi–P^iPr_2 + LiP(SiMe_3)_2 \quad (4)$$

This reaction seems to be a general one. A similar chain extension was reported by Fritz et al. as a proof of the instability of $(Me_3Si)_2P–P(SiMe_3)Li$ [11]. The limited stability of **2a** in DME solution can be partially explained by such a type of reaction, too.

The lithiation of $(^iPr_2N)_2P–P(SiMe_3)_2$ (**1c**) in THF was performed at −30 °C yielding $(^iPr_2N)_2P–P(SiMe_3)Li$ (**2c**) in good yield. Repeated crystallizations did not improve the purity of **2c**. The stability of $(^iPr_2N)_2P–P(SiMe_3)Li$ in C_6D_6 or THF solution is only limited. During two months at ambient temperature we observed a formation of (probably) a phosphetane $(^iPr_2N)_2P–P(\mu_2\text{-}PN^iPr_2)_2PSiMe_3$ (**3c**) [12] and finally of the polyphosphorus compound **4c** (at least 5 P atoms) together with $LiP(SiMe_3)_2$ and $^iPr_2NH$. The initially detectable small amounts of $(^iPr_2N)_2P–P(SiMe_3)H$ disappeared.

2.2. X-ray crystallographic studies of *2a–c*

Diffraction data were recorded on a KUMA KM4 diffractometer with graphite-monochromated Mo Kα radiation using Sapphire-2 CCD detector. The apparatus was equipped with an open flow thermostat (Oxford Cryosystems) which enabled experiments at 120 K. The stream of nitrogen also prevented the specimen from contact with moisture and oxygen. The structures were solved via direct methods and refined with the SHELX97 program package [13] with the full-matrix least-squares refinement based on F^2. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined in geometrically idealised positions with isotropic temperature factors 1.2 times the equivalent isotropic temperature factors U_{eq} of their attached atoms (1.5 for CH_3 groups). Disorder in **2b · 3THF** in the THF molecules: C13 (*s.o.f.* 0.46(3)/0.54(3)); C19–C20 (*s.o.f.* 0.715(15)/0.285(15)); C32–C34 (*s.o.f.* 0.404(13)/0.596(13)); C37 (*s.o.f.* 0.76(3)/0.24(3)); C39–C42 (*s.o.f.* 0.40(2)/0.60(2)). Basic crystal data, description of the diffraction experiment, and details of the structure refinement are given in Table 3.

An Ortep view of **2a · 3DME** is shown in Fig. 1, of **2b · 3THF** in Fig. 2 and of **2c · 3THF** in Fig. 3. **2b · 3THF** consists of two independent molecules. Selected atom distances, bond angles and sums of bond angles around P1 and P2 are collected in Table 4.

2a · 3DME is the first known solvent-separated ionic lithium phosphinophosphide monoanion. The distance Li–P2 of 856.9 pm clearly excludes a covalent or ion-contacted P–Li bond. Some examples of anionic polyphosphides are known, *e.g.* [14]. The ionic form stabilized by crown ether was reported for (12-crown 4)$_2$LiPPh$_2$ [15].

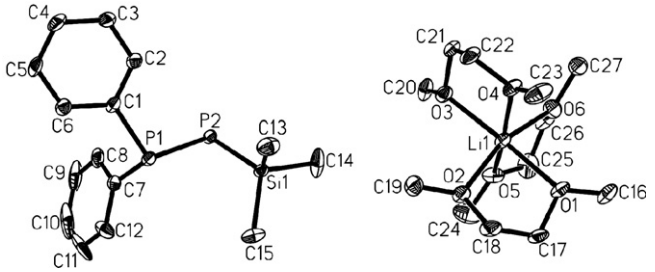

Fig. 1. Molecular structure of $(Li \cdot 3DME)^+(Ph_2P–PSiMe_3)^-$ (**2a · 3DME**). Displacement ellipsoids 30%.

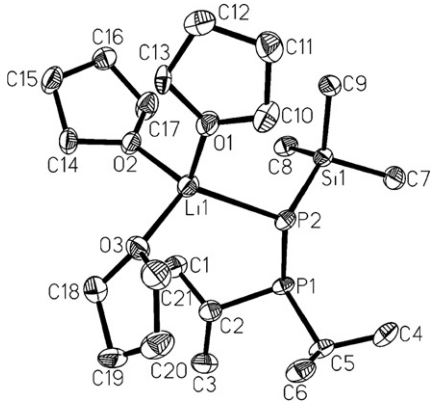

Fig. 2. Molecular structure of ^{i}Pr$_2$P–P(SiMe$_3$)Li · 3THF (**2b · 3THF**). Displacement ellipsoids 30%.

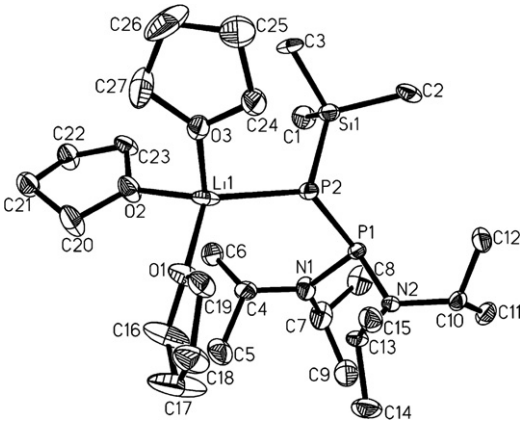

Fig. 3. Molecular structure of (^{i}Pr$_2$N)$_2$ P–P(SiMe$_3$)Li · 3THF (**2c · 3THF**). Displacement ellipsoids 30%.

To our surprise, monomeric Ph$_2$PLi · (**Me**$_2$NCH$_2$CH$_2$)$_2$NMe and dimeric Ph$_2$PLi · **Me**$_2$NCH$_2$CH$_2$NMe$_2$ in cyclic arrangement crystallized as ion-contacted compounds [16]. (Me$_3$Si)$_2$PLi in DME crystallizes as a dimer {(Me$_3$Si)$_2$PLi · **DME**}$_2$ in a cyclic arrangement [17]. However {(Ph(H)P–PPh)Li · THF}$_4$ (similar to **2a · 3DME**) crystallizes as a tetramer with an average P–Li distance of ca. 257 pm [18], and the potassium derivative {(^{t}Bu(H)P–P^{t}Bu)K · pmdeta}$_2$ crystallizes as a dimer [19]. The P2–Li distances in **2b · 3THF** and **2c · 3THF** are in the range reported previously [17–19]. These distances clearly exceed the sum of the normal covalent radii for P and for Li, thus the description of the P–Li bond as partially ionic (ion-contacted) seems to be correct. Generally, the partially anionic character of P2 increased the planarity around P2 as compared to P1. The anionic (**2a · 3DME**) or partially anionic (**2b · 3THF**, **2c · 3THF**) character of P2 in the diphosphane skeleton leads in all compounds described here to a significant shortening of the P–P distances and suggests a partial P–P multiple bond character. The P–P distance in Ph$_2$P–PPh$_2$ is 221.7 pm [20] and in (^{i}Pr$_2$N)$_2$P–P(SiMe$_3$)$_2$ it is 223.9 pm [21]. A shortening of the P–P bonds was also observed in Li derivatives of triphosphanes [22,23]. Similarly the P2–Si bonds in **2a · 3DME**, **2b · 3THF** and **2c · 3THF** are significantly shorter than in (^{i}Pr$_2$N)$_2$P–P(SiMe$_3$)$_2$ (226.9 pm) [21]. The effect of the anionic form of P2 on the distances R–P1 is negligible compared to the related compounds R$_2$P–P(SiMe$_3$)$_2$ or R$_2$P–PR$_2$, however the P1–N distances in **2c · 3THF** (ca. 172.8 pm) are slightly longer than in (^{i}Pr$_2$N)$_2$P–P(SiMe$_3$)$_2$ (170.4 pm) [21].

We have studied the effect of introducing a Li atom coordinated with 3 THF molecules on the conformational preferences of the phosphorus lone pairs measured as a torsion angle along the P–P bonds. In the anion **2a · 3DME** the lone pairs of P2 are in anticlinal conformation to the lone pair of P1 (−119.1° and +116.4°), in Ph$_2$P–PPh$_2$ the lone pairs of P1 and P2 are in antiperiplanar conformation, and in Ph$_2$P–P(N^{i}Pr$_2$)$_2$ almost in antiperiplanar position (177.4°). Thus, the anion has a significantly different lone pair conformation than the related covalent compounds with Ph$_2$P groups. In **2b · 3THF** (−115.06 and 114.30°) the lone pairs are in anticlinal conformation. In **2c · 3THF** the conformation of the lone pairs is synclinal (84.90°), similar as in (^{i}Pr$_2$N)$_2$P–P(SiMe$_3$)$_2$ (80.2°). Thus, the introduction of [Li · 3THF] in place of SiMe$_3$ exerts only a small impact on the conformational preferences in **2 · 3THF**.

3. Experimental

All manipulations were performed in flame-dried Schlenk type glassware on a vacuum line. THF and toluene were dried over Na/benzophenone and distilled under nitrogen. Petrol ether was dried over Na/benzophenone/diglyme and distilled under nitrogen. ^{31}P NMR and ^{1}H spectra were recorded on Varian 500, Bruker AMX300

3.1. General description of the lithiation procedure

The solution of 1.6 M BuLi in hexane was slowly dropped to the cooled THF (DME) solution of an equimolar amount of R_2P–$P(SiMe_3)_2$. The reaction mixture was stirred at reduced temperature for 3 h and finally at ambient temperature for 20 h. The resulting solution was examined with ^{31}P NMR, then evaporated under vacuum (1 mTorr, 3 h). The residue was dissolved in THF or DME for **2a**, and in a mixture of THF and pentane for **2 b** and **2c**. The solution was stored at −30 °C yielding a precipitate of solvated R_2P–$P(SiMe_3)Li$.

The NMR data of **1a**, **1b**, **1c**, **2a**, **2b**, **2c** and some major side products (δ/ppm, J/Hz):

3.1.1. Run 1a.1 (parent liquor, only side products are listed)

$^{31}P\{^1H\}$ NMR (101.26 MHz, THF, tol-d_8): Ph_2PCl 96.92 (s); Ph_2P–PPh_2 −14.19 (s); Ph_2P1–$P2(SiMe_3)$–PPh_2 −25.13 (d, P1), −120.90 (t, P2), $^1J_{P1-P2} = -194.2$; Ph_2P1–P2═P3Ph_2Br 86.07 (dd, P3), −25.84 (dd, P1), −136.00 (dd, P2), $^1J_{P1-P2} = -215.8$, $^1J_{P2-P3} = -568.9$, $^2J_{P1-P3} = 99.0$ [3]; Ph_2P1–$P2(SiMe_3)H$ −33.85 (d, P1), −160.56 (d, P2), $^1J_{P1-P2} = -167.8$; $P(SiMe_3)_3$ −251.68 (s).

3.1.2. Ph_2P1–$P2(SiMe_3)_2$ (**1a**)

^1H NMR (500 MHz, C_6D_6): 7.87 (pst*, 7.5 Hz, $C_6\mathbf{H}_5$); 7.01 (pst, 7.4 Hz, $C_6\mathbf{H}_5$); 6.95 (psd**, 7.1 Hz, $C_6\mathbf{H}_5$); 0.13 (d, PSiC$\mathbf{H}_3$, $^3J_{PSiCH} = 4.2$); $^{31}P\{^1H\}$ NMR (202.51 MHz, C_6D_6): −28.57 (d, P1); −183.55 (d, P2); $^1J_{P1-P2} = -172.4$.

3.1.3. Ph_2P1–$P2(SiMe_3)Li \cdot 3THF$(**2a · 3THF**)

^1H NMR (500 MHz, C_6D_6): 7.81 (pst, 6.9 Hz, $C_6\mathbf{H}_5$); 7.09 (pst, 7.2 Hz, $C_6\mathbf{H}_5$); 6.94 (psd, 7.2 Hz, $C_6\mathbf{H}_5$); 3.48 (m, THF); 1.41 (m, THF); 0.51 (d, PSiC$\mathbf{H}_3$, $^3J_{PSiCH} = 3.4$); $^{31}P\{^1H\}$ NMR (202.51 MHz, C_6D_6): −5.50 (d, P1); −207.05 (d, P2); $^1J_{P1-P2} = -288.4$; contaminations: Li-$P(SiMe_3)_2$, Ph_2P–PPh_2, Ph_2PH (small amount).

3.1.4. Ph_2P1–$P2(SiMe_3)Li \cdot 3DME$(**2a · 3DME**)

^1H NMR (500 MHz, C_6D_6): 8.00 (pst, 7.1 Hz, $C_6\mathbf{H}_5$); 7.14 (pst, 7.4 Hz, $C_6\mathbf{H}_5$); 7.02 (psd, 7.5 Hz, $C_6\mathbf{H}_5$); 3.04 (s, DME), 3.00 (s, DME); 0.47 (d, PSiC$\mathbf{H}_3$, $^3J_{PSiCH} = 3.9$); $^{31}P\{^1H\}$ NMR (202.51 MHz, C_6D_6): −6.79 (d, P1); −211.41 (d, P2); $^1J_{P1-P2} = -352.4$; contaminations ^1H NMR: Ph_2P–PPh_2 7.41 (pst*, 7.0 Hz), 7.10 (pst, 7.1 Hz), 7.05 (psd, 7.1 Hz); $LiP(SiMe_3)_2$; $HP(SiMe_3)_2$ (weak) 0.27 (d, $^3J_{PSiCH} = 4.4$); $P(SiMe_3)_3$ (weak) 0.20 (d, $^3J_{PSiCH} = 4.4$); contaminations $^{31}P\{^1H\}$ NMR: Ph_2P–PPh_2 (strong) −15.30 (s); $LiP(SiMe_3)_2$ (strong); $P(SiMe_3)_3$ (weak), −251.54.

After several weeks $(Li \cdot 3DME)^+(Ph_2P$–P–$PPh_2)^-$ and Ph_2PSiMe_3 (−56.10 ppm) were additionally found. pst* – higher order spectra, pseudotriplet; psd** – higher order spectra, pseudodoublet, the "Hz" data are not coupling constants.

3.1.5. $^iPr_2P1$–$P2(SiMe_3)_2$ (**1b**) [6]

^1H NMR (500 MHz, C_6D_6): 1.99 (d, d, q, q, $^2J_{PCH} = 11.3$, $^3J_{PPCH} = 2.4$, $^3J_{HCCH} = 6.8$, $^3J_{HCCH} = 6.9$, C$\mathbf{H}$–CH_3); 1.11 (d, d, $^3J_{PCCH} = 11.8$, $^3J_{HCCH} = 6.8$, CH–C$\mathbf{H}_3$); 1.05 (d, d, $^3J_{PCCH} = 15.3$, $^3J_{HCCH} = 6.9$, CH–C$\mathbf{H}_3$); 0.29 (d, $^3J_{PSiCH} = 5.3$, PSiC$\mathbf{H}_3$); $^{31}P\{^1H\}$ NMR (202.51 MHz, C_6D_6): 10.01 (d, P1), −215.27 (d, P2), $^1J_{P1-P2} = -316.5$.

3.1.6. $^iPr_2P1$–$P2(SiMe_3)H$

^1H NMR (400 MHz, C_6D_6): 1.83 (d, d, septet, $^2J_{PCH} = 6.5$, $^3J_{PPCH} = 1.7$, $^3J_{HCCH} = 6.9$, C$\mathbf{H}$–CH_3); 1.46 (d, d, $^1J_{PH} = 184.22$, $^2J_{PPH} = 3.25$, P$\mathbf{H}$); 1.10 (d, d, $^3J_{PCCH} = 11.0$, $^3J_{HCCH} = 6.9$, CH–C$\mathbf{H}_3$); 1.06 (d, d, $^3J_{PCCH} = 14.8$, $^3J_{HCCH} = 7.0$, CH–C$\mathbf{H}_3$); 0.30 (d, d, $^3J_{PSiCH} = 4.25$, $^4J_{PPSiCH} = 0.76$, SiC$\mathbf{H}_3$); $^{31}P\{^1H\}$ NMR (202.51 MHz, THF, C_6D_6): −7.69 (d, P1); −200.69 (d, P2); $^1J_{P1-P2} = -188.5$.

*3.1.10. $(^{i}Pr_2N)_2P1–P2(SiMe_3)_2$ (**1c**)*

^{1}H NMR (500 MHz, C_6D_6): 3.38 (d, septet, $^{3}J_{HCCH} = 6.6$, $^{3}J_{PNCH} = 11.9$, N–C**H**–CH_3); 1.26 (d, $^{3}J_{HCCH} = 6.6$, N–CH–C**H**$_3$); 1.19 (d, $^{3}J_{HCCH} = 6.6$, N–CH–C**H**$_3$); 0.44 (d, $^{3}J_{PSiCH} = 4.4$, PSiC**H**$_3$); $^{31}P\{^{1}H\}$ NMR (202.51 MHz, C_6D_6): 80.89 (d, P1); −156.09 (d, P2); $^{1}J_{P1–P2} = -470.3$.

*3.1.11. $(^{i}Pr_2N)_2P1–P2(SiMe_3)Li \cdot 3THF$ (**2c · 3THF**)*

($^{i}Pr_2N)_2P–P(SiMe_3)Li \cdot$ **3THF** (**2c**) was evacuated (0.001 Torr for 6 h) and dissolved in THF-d_8. The signals of THF are however visible. ^{1}H NMR (400 MHz, THF-d_8): 3.37 ppm (d, septet, $^{3}J_{HCCH} = 6.7$, $^{3}J_{PNCH} = 9.4$, N–C**H**–CH_3); 1.25 (d, $^{3}J_{HCCH} = 6.6$, N–CH–C**H**$_3$); 1.19 (d, $^{3}J_{HCCH} = 6.8$, N–CH–C**H**$_3$); 0.27 (d, d, $^{3}J_{PSiCH} = 3.3$, $^{4}J_{PPSiCH} = 1.1$, PSiC**H**$_3$); $^{31}P\{^{1}H\}$ NMR (161.95 MHz, C_6D_6): 86.64 (d, P1); −196.51 (d, P2); $^{1}J_{P1–P2} = -311.6$; contaminations: $^{31}P\{^{1}H\}$ NMR: ($^{i}Pr_2N)_2P1–P2(SiMe_3)H$ 56.20 (d, P1); −164.28 (d, P2); $^{1}J_{P1–P2} = -128.8$; $^{1}J_{P2–H} = 187.3$; $LiP(SiMe_3)_2$ (small amount).

After two months at ambient temperature **2c** was still present in solution, however the initially formed ($^{i}Pr_2N_2)P–P(SiMe_3)H$ disappeared, and **3c** and **4c** were additionally found: *$(^{i}Pr_2N)_2P2–P1(\mu_2\text{-}P3,4N^{i}Pr_2)_2P5\text{-}SiMe_3$* (**3c**): $^{31}P\{^{1}H\}$ NMR (161.95 MHz, THF, C_6D_6): 62.71 (m, P2); 8.52 (m, P1); −20.61 (m, P3,4); −84.80 (m, P5); $^{1}J_{P1–P2} = -186.0$; $^{1}J_{P1–P3} = -190.0$; $^{1}J_{P3–P5} = -177.0$; $^{2}J_{P2–P3} = +170.0$; $^{3}J_{P2–P5} = +36.0$; $^{2}J_{P1–P5} = +25.0$: MAB_2X [12]. **4c** (formula uncertain): 86.67 (d, d, d, P1); 75.33 (d, d, d, P2); 42.89 (d, d, d, P3); −108.84 (d, d, d, d, P4); −177.71 (d, d, t, P5); $J_{P1–P2} = 247.6$, $J_{P1–P4} = 277.2$, $J_{P1–P5} = 117.1$, $J_{P2–P3} = J_{P2–P4} = 167.4$, $J_{P2–P5} = 84.9$, $J_{P3–P4} = 51.6$, $J_{P3–P5} = J_{P4–P2} = 154.7$.

3.1.12. $(Me_3Si)_2PLi$

$^{31}P\{^{1}H\}$ NMR (161.95 MHz, THF, C_6D_6) −303.84 (s); ^{1}H NMR (400.13 MHz, THF, C_6D_6) 0.23 (d, $^{3}J_{PSiCH} = 3.3$); $^{13}C\{^{1}H\}$ NMR (100.62 MHz, THF, C_6D_6) 8.72 (d, $^{2}J_{PSiC} = 20.35$).

3.1.13. $^{i}Pr_2NH$

^{1}H NMR (400.13 MHz, THF, C_6D_6) 2.73 (d, septet, $^{3}J_{HCCH} = 6.22$, $^{3}J_{HCNH} = 6.22$, N–C**H**–CH_3), 0.87 (d, $^{2}J_{HCCH} = 6.22$, N–CH–C**H**$_3$) [24]; ^{13}C NMR (100.62 MHz, THF, C_6D_6) 45.96 (s, N–**C**H–CH_3), 24.12 (s, N–CH–**C**H_3) [25,26].

Acknowledgements

J.P. and R.G. thank the Polish State Committee of Scientific Research (Project No. 4 T09A 146 28) for financial support. W.D.-B. and J.P. thank the Polish State Committee of Scientific Research (Project No. 1 T09A 148 30) for financial support. J.P thanks Dr. L. Ponikiewski for a discussion of crystallographic data. We are especially grateful to Dr. Ilona Kovacs, Budapest, for very valuable experimental hints and for the NMR data of iPr$_2$P–P(SiMe$_3$)H.

Appendix A. Supplementary material

CCDC 634547, 634548 and 634550 contain the supplementary crystallographic data for **2c · 3THF**, **2b · 3THF** and **2a · 3DME**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.008.

Herein, we employed pyridine-2-thionato (HPyS), 4-trifluoromethyl-2-pyrimidinthiol (4-CF_3-2-PymSH) and pyridine-2-selenolato (HPySe) as heterocyclic bidentate (N,X) ligands, X = S, Se to synthesize and characterize corresponding dinuclear μ-oxomolybdenum(V) complexes. The known compound $[Mo_2O_3(PyS)_4]$ was obtained by a different method and did crystallize in a different modification compared to the described procedure and crystal structure by Cotton et al. [10]. The catalytic oxo-transfer abilities of molybdenum(V) complexes with heterocyclic thione and selenone ligands in comparison were successfully investigated by oxo transfer reactions from DMSO to PPh_3 although compounds with the Mo_2O_3-core are often catalytically inactive with respect to the oxo transfer.

2. Experimental

2.1. General procedures

All manipulations were carried out under purified dry nitrogen atmosphere using standard Schlenk-line techniques. All solvents were purified by standard methods with subsequent distillation under nitrogen (dichloromethane over CaH_2 and methanol over $Mg(OMe)_2$), and were stored over 4-Å molecular sieves. Pyridine-2-selenolato (C_5H_4NSeH = PySeH) [11] was prepared by the reported procedure. The starting materials selenium (Aldrich), 2-bromopyridine (Aldrich), glacial acetic acid (Roth) and $NaBH_4$ (Aldrich) were used as received. $[MoO_2Cl_2(DME)]$ [12], $[MoO_2Cl_2]$ [13] and $[MoO_2(acac)_2]$ [14] were prepared according to literature procedures. 2-Pyridine-2-thionato (PySH) (Aldrich), 4-(trifluoromethyl)-2-pyrimidinthiol (4-CF_3-2-PymSH) (Aldrich) and *n*-butyllithium (2.5 M solution in hexanes, ACROS) are commercially available and were used as received.

2.2. Preparation of complexes

2.2.1. $[Mo_2O_3(PyS)_4]$ (1)

Method 1. To a −30 °C pre-cooled solution of PySH (0.222 g, 2 mmol) in 10 mL THF, *n*-BuLi (0.8 mL of a 2.5 M solution in hexane, 2 mmol) was added dropwise *via* syringe. The mixture was warmed to room temperature, stirred for 7 h, and then cooled to −30 °C. A colorless solution of $[MoO_2Cl_2(DME)]$ (0.289 g, 1 mmol) in 10 mL THF was added dropwise to this solution. The mixture was allowed to warm to room temperature and stirred overnight. The solvent was removed *in vacuo* and the obtained solid was extracted with CH_2Cl_2. The red brown solution was filtered and dried under vacuum. The complex was obtained as red brown microcrystalline solid. Yield: 0.16 g (0.235 mmol; 48%).

Method 2. Et_3N (0.30 mL, 2 mmol) was added to a methanolic solution of PySH (0.222 g, 2 mmol). The resulting solution was stirred for 1 h and a solution of $[MoO_2Cl_2]$ (0.199 g, 1 mmol) in dichloromethane was added. The reaction mixture was stirred overnight, the resulting suspension was dried under vacuum and the obtained solid was extracted with CH_3CN. The filtrate was concentrated to approx. 5 mL and left at room temperature for several days. After red brown crystals had formed they were filtered from the solution, washed thoroughly with ether and dried *in vacuo* giving 0.15 g (2.220 mmol; 44%) product.

Crystals of **1** suitable for X-ray studies were obtained by crystallization of the initial product from dichloromethane.

Mp: 215 °C. Elemental *Anal.* Calc. for $C_{20}H_{16}N_4O_3S_4Mo_2$ (680.49 g mol^{-1}): C, 35.30; H, 2.37; N, 8.23. Found: C, 35.12; H, 3.00; N, 7.66%; IR (KBr): $\tilde{\nu}$ = 3059 (m), 1615 (w), 1583 (s), 1558 (s), 1447 (s), 1425 (s), 1367 (m), 1267 (s), 1182 (w), 1151 (m), 1136 (s), 1086 (s), 1037 (s), 1017 (s), 985 (w), 963 (w), 929 (s), 897 (s), 872 (m), 801 (m), 763 (s), 754 (s), 727 (s); 645 (m), 616 (w), 484 (m), 456 (m), 446 (w), 418 (w), 405 (m), 371 (s), 329 (w), 294 (s) cm^{-1}; ^{1}H NMR ($CDCl_3$, 500 MHz): δ 8.46 (m, H_6, 4H), 7.58 (m, H_4, 4H), 7.16 (m, H_3, 4H), 6.95 (m, H_5, 4H) ppm; ^{13}C NMR ($CDCl_3$, 500 MHz): δ 167.0 (s, C_2), 125.6 (s, C_3), 139.9 (s, C_4), 119.6 (s, C_5), 145.2 (s, C_6) ppm; MS (EI): *m*/*z* (%) = 492 (15) [M^+−PyS−Py], 475 (11) [M^+−PyS−Py−O], 348 (100) [M^+−(MoO(PyS)$_2$)], 332 (55) [M^+−(MoO_2-(PyS)$_2$)], 239 (39) [M^+−(MoO(PyS)$_2$)−PyS].

2.2.2. $[Mo_2O_3(PySe)_4]$ (2)

To a −30 °C pre-cooled solution of PySeH (0.316 g, 2 mmol) in 10 mL THF, *n*-BuLi (0.8 mL of a 2.5 M solution in hexane, 2 mmol) was added dropwise *via* syringe. The mixture was allowed to warm to room temperature, stirred for 7 h, and then cooled to −30 °C. A colorless solution of $[MoO_2Cl_2(DME)]$ (0.289 g, 1 mmol) in 10 mL THF was added dropwise to this solution. The mixture was allowed to warm to room temperature and stirred overnight. The solvent was removed *in vacuo* and the obtained solid was extracted with CH_2Cl_2. The red brown solution was filtered and dried *in vacuo*. Five milliliters of CH_2Cl_2 and 30 mL hexane were added to the obtained oily residue. The product precipitated and the mixture was stored in the freezer at −30 °C overnight. The product was collected by filtration and dried under vacuum. Yield: 0.12 g (0.140 mmol; 28%).

Crystals of **2** suitable for X-ray studies were obtained by crystallization of the initial product from dichloromethane.

Mp: 240 °C. Elemental *Anal.* Calc. for $C_{20}H_{16}N_4O_3Se_4Mo_2$ (868.09 g mol^{-1}): C, 27.67; H, 1.86; N, 6.45. Found: C, 27.07; H, 1.94; N, 5.86%; IR (KBr): $\tilde{\nu}$ = 1581 (vs), 1552 (m), 1444 (s), 1421 (s), 1265 (s), 1149 (m), 1122 (s), 1079 (m), 1039 (m), 1014 (w), 939 (w), 926 (s), 892 (s), 873 (m), 804 (w), 763 (s), 753 (s), 728 (w); 701 (m), 642 (w), 468 (w), 435 (w), 418 (w), 406 (w), 364 (w), 336 (w), 296 (w), 269 (s) cm^{-1}; ^{1}H NMR ($CDCl_3$, 500 MHz): δ 8.72 (m, H_6, 4H), 7.51 (m, H_4, 4H), 7.32 (m, H_3, 4H), 6.99 (m, H_5, 4H) ppm; ^{13}C NMR ($CDCl_3$, 500 MHz): δ 159.8 (s, C_2), 129.1 (s, C_3), 139.3 (s, C_4), 120.4 (s, C_5), 147.4 (s, C_6) ppm; ^{77}Se NMR ($CDCl_3$, 500 MHz): δ 428.0 (s) ppm; MS (EI): *m*/*z* (%) = 695 (3) [M^+−PySe−O], 632

(27) [M^+−PySe−Se], 442 (70) [M^+−(MoO(PySe)$_2$)], 426 (48) [M^+−(MoO$_2$(PySe)$_2$)], 285 (100)[M^+−(MoO(PySe)$_2$)−PySe].

2.2.3. [Mo_2O_3(4-CF_3-PymS)$_4$] (3)

To a −30 °C pre-cooled solution of 4-CF_3-PymSH (0.324 g, 1.8 mmol) in 10 mL THF, *n*-BuLi (0.72 mL of a 2.5 M solution in hexane, 1.8 mmol) was added dropwise *via* syringe. The mixture was allowed to warm to room temperature, stirred overnight, and then cooled to −30 °C. A colorless solution of [MoO_2Cl_2(DME)] (0.260 g, 0.9 mmol) in 10 mL THF was added dropwise to this solution. The mixture was allowed to warm to room temperature and stirred overnight. The solvent was removed *in vacuo* and the obtained solid was extracted with CH_2Cl_2. The red brown solution was filtered, concentrated and kept at room temperature for several days. The black-purple prismatic crystals were collected by filtration and dried *in vacuo*. Yield: 0.19 g (0.200 mmol; 45%). Mp: 315 °C dec. Elemental *Anal.* Calc. for $C_{20}H_8F_{12}N_8O_3S_4Mo_2$ (956.44 g mol^{-1}): C, 25.12; H, 0.84; N, 11.72. Found: C, 25.63; H, 0.95; N, 11.90%; IR (KBr): $\tilde{\nu} = 3080$ (w), 1579 (m), 1558 (m), 1429 (m), 1361 (s), 1332 (vs), 1265 (w), 1207 (m), 1193 (m), 1149 (m), 1116 (s), 968 (m), 842 (m), 789 (w), 735 (m), 702 (w), 680 (m); 476 (w), 441 (w) cm^{-1}; ^{1}H NMR ($CDCl_3$, 300 MHz): δ 8.79 (d, 4H), 7.38 (t, 4H) ppm; MS (EI): *m/z* (%) = 818 (100) [M^+−2CF_3], 638 (89) [M^+−2CF_3-(4-CF_3-PymS)], 488 (78) [M^+−(MoO(4-CF_3-PymS)$_2$)].

2.3. Oxygen atom transfer reactions

In a sealed NMR tube a 1:10 mixture of catalyst (0.02 mmol for compounds **1** and **2**) and PPh_3 (0.20 mmol) in degassed, dry DMSO-d_6 (0.6 mL) was monitored with ^{31}P NMR spectroscopy. Only two signals were observed in both experiments: δ −6.5 ppm (PPh_3), δ 26.1 ppm ($OPPh_3$).

2.4. Other physical measurements

Melting points were obtained in sealed capillaries with a Büchi B 540 instrument and were not corrected. Elemental analyses were performed with a Heraeus CHN-O-Rapid elemental analyzer. Infrared spectra were recorded as KBr pellets with a Bio-Rad Digilab FTS-7 spectrometer from 4000 to 300 cm^{-1}. NMR spectra were recorded with a Bruker Avance 500 NMR spectrometer and referenced to the chemical shifts of the deuterated solvent. All NMR-grade solvents were dried prior to use. The chemical shifts are reported in parts per million; external reference $SiMe_4$ for ^{1}H and ^{13}C nuclei, and $SeMe_2$ for ^{77}Se nuclei. Mass spectra were obtained with a Finnigan MAT system 8230 or Varian MAT CH5 instrument by EI-MS methods.

2.5. X-ray structure determinations

Crystallographic data for compounds **1**–**3** were collected on a STOE IPDS II array detector system with four-circle instrument using graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The data for all the compounds were collected at low temperature (for exact values see Table 1). The data reduction and space group determination were carried out using Siemens SHELXTL program [15]. All structures were solved by direct methods (SHELXS-97) [16] and refined with all data by full-matrix least-squares methods on F^2 using SHELXL-97 [17]. All non-hydrogen atoms were refined anisotropically. Hydrogen

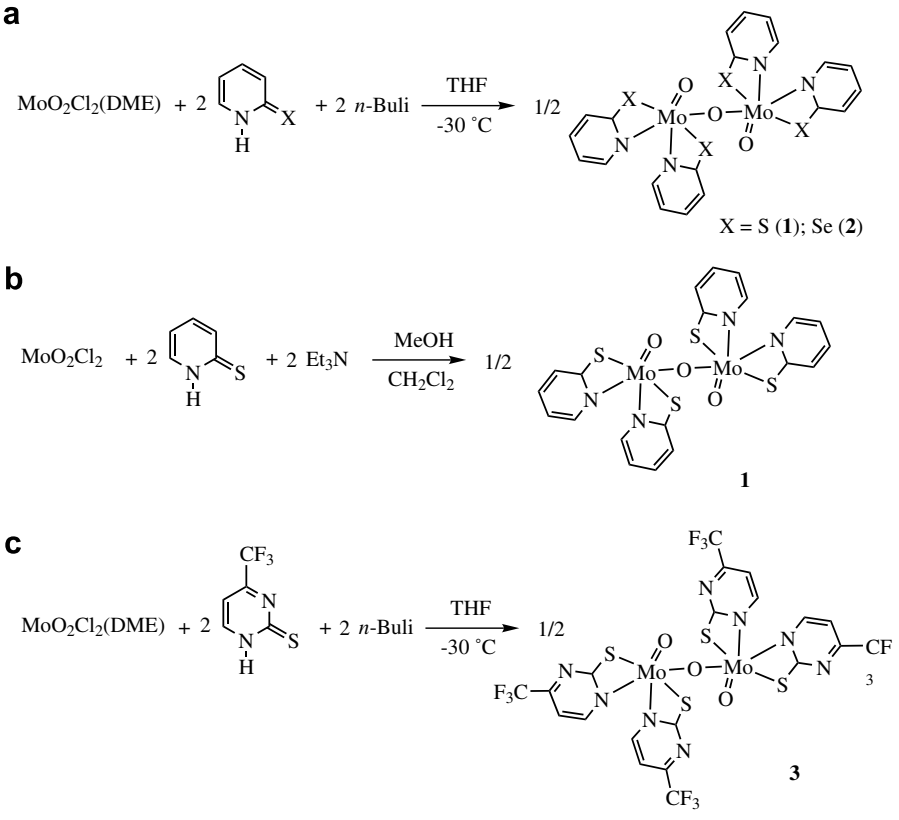
atoms were attached at idealized positions on carbon atoms with U_{iso} related to the U_{iso} of the parent atoms and were refined with the riding model, or by difference Fourier synthesis and refined isotropically. Parameters of the X-ray crystallography are summarized in Table 1.



3. Results and discussion

3.1. Synthesis and characterization

The molybdenum compounds $[Mo_2O_3(PyS)_4]$ (**1**), $[Mo_2O_3(PySe)_4]$ (**2**) and $[Mo_2O_3(4\text{-}CF_3\text{-}PymS)_4]$ (**3**) were all obtained in different yields (48% for **1**, 28% for **2** and 45% for **3**) using analogous methods. At first, the nucleophilic species, lithium thionates or lithium selenate, were obtained by reaction of the corresponding pyridine-2-thiol, 2-pyrimidinthiol or pyridine-2-selenol with *n*-butyllithium in THF at −30 °C. The mixture was allowed to warm to room temperature and stirred overnight. The product was subsequently reacted with the readily available molybdenum precursor $[MoO_2Cl_2(DME)]$ [12] at −30 °C and the mixture was allowed to warm to room temperature and stirred overnight again according to the general process depicted in Scheme 1.

Different purification methods were used for the three products. Compound **1** was obtained by directly drying the filtered CH_2Cl_2 extract. Because the product of the same treatment for **2** was oily the CH_2Cl_2-filtrate of **2** was treated with hexane and stored overnight at −30 °C upon which **2** precipitated as a microcrystalline powder. Compound **3** was obtained directly by crystallizing from the initial concentrated filtered CH_2Cl_2-extract. Compound **1** can also be synthesized in 44% yield by adding a methanolic solution of the ligand and triethylamine to a stirred solution of precursor $[MoO_2Cl_2]$ [13] in dichloromethane (Scheme 1b). All compounds are intensely colored: dark red brown (**1** and **2**) or dark purple (**3**). The three obtained compounds were all dinuclear μ-oxomolybdenum(V) species which were not the initially desired unreduced mononuclear dioxomolybdenum(VI) species. Such behavior may be due to the corresponding ligands acting both as a reductant and as a ligand in the reaction and was observed previously upon the reaction of thiol ligands with Mo(VI) starting materials [18,19]. Interestingly the mononuclear species $[Mo(VI)O_2(PyS)_2]$ was prepared before by two different methods [20,21] one of which even employing the same metal precursor as was used in the here presented procedure: $[MoO_2Cl_2]$ [21]. As stated before [21] it is probable that in all these reactions the mononuclear and the reduced dinuclear species form simultaneously. The reaction medium and conditions as well as the isolation procedure determine the main product, its yield and purity. The description of the mononuclear compound $[Mo(VI)O_2(PyS)_2]$ as being dark purple [20] (contrary to the yellow color described by Arnáiz et al. [21] and to our findings as well) indeed strongly indicates that it was not pure but a mixture with the dinuclear Mo(V) compound [21].

Compound **1** was synthesized before by different methods [10,20,21] and its structure was also determined [10]

Scheme 1. Preparation of compounds **1**–**3**.

even though in a different modification than ours, the latter having a cell volume of double value and contains two molecules per cell instead of only one. By one of the synthetic routes the mononuclear dioxomolybdenum(VI) thionate was quantitatively converted into the dinuclear oxomolybdenum(V) complex by oxygen atom abstraction with common organophosphines and phosphates [20,21]. In the other route the formation of this molybdenum(V) compound from Na(PyS) and molybdenum(II) acetate was achieved with atmospheric oxygen. The preparation methods described here differ from these previous routes. To the best of our knowledge compounds **2** and **3** were unknown until now and furthermore **2** is the first oxomolybdenum complex containing pyridine-2-selenolato. Only one (non-oxo) molybdenum complex with this ligand was described before [11].

IR spectra of the complexes confirm the presence of the ligands coordinated to the metal. For example, the band attributable to the ν(N–H), which appears at 3200–3100 cm^{-1} in the free thione ligands, is absent, indicating that the ligands are in their deprotonated form. The strong ligand bands in the range of 1640–1660 cm^{-1} are caused by the presence of ν(C=N) and ν(C=C) in a non-aromatic system. In the complexes, however, these bands appear in the region of 1545–1590 cm^{-1}, which is characteristic for stretching vibrations in an aromatic group [22]. These observations confirm that the ligand is present in its complexes in the thiolate form. The IR spectrum also shows prominent absorptions in the 750–943 cm^{-1} region consistent with the presence of both terminal and bridging oxo groups.

The ^{1}H and ^{13}C NMR spectra of **1**–**3** (except for ^{13}C NMR spectra of **3** due to its poor solubility in $CDCl_3$) are consistent with their compositions. ^{1}H and ^{13}C NMR spectra of **1** are almost identical to those of **2**. A resonance signal from ^{77}Se NMR spectroscopy of compound **2** ($\delta = 428.0$ ppm) shifted to lower field relative to that of the free ligand PySeH ($\delta = 306.6$ ppm) was observed, confirming the formation of a metal–selenium bond [23].

In all cases the EI mass spectra of the compounds show peaks of the fragment ions of the molecule after partial decomposition such as the loss of heterocyclic ligands or oxo ligands. The peak cluster shows the appropriate isotope distribution.

3.2. Structural characterization

Crystals of **1**–**3** suitable for X-ray studies were obtained by the recrystallization of the initial products from dichloromethane. The crystal structures of **1**–**3** are shown in Figs. 1–3 along with the numbering schemes; solvent molecules of **3** are not shown. The selected bond lengths and angles are given in Tables 2–4.

Compounds **1** and **2** crystallize in the same space group ($P\bar{1}$) and crystal system (triclinic) but with different cell dimensions. They appear to be isostructural. Compound **3** crystallizes in the monoclinic space group $P2_1/c$. The

coordinated by two chelating heterocyclic bidentate ligands, the terminal oxo group, and the bridging oxo group, which is located on a crystallographic inversion center (Figs. 1–3). Thus, the $[Mo_2O_3]^{4+}$ core exhibits a rigorously planar anti geometry. Furthermore, the three structures have a *trans* O=Mo–O–Mo=O chain with rigorous inversion symmetry, resembling previous reported compounds $Mo_2O_3[S_2P(OEt)_2]_4$ and Mo_2O_3(3-SiMe-2-SPy)$_4$ [24], while a *cis* configuration is also found for example in $Mo_2O_3[S_2CNPr_2]_4$ and Mo_2O_3(Etxan)$_4$, where Etxan represents $EtOCS_2$ [25,26]. This indicates that both the *cis* and *trans* arrangements may be of general occurrence.

In compound **2**, the distortions from the ideal octahedral geometry for each molybdenum center mainly arise from the disparate donor atom set and the restricted bite of the Py–Se ligand which subtend angles at the molybdenum center of 64.98(12)° and 68.10(13)°, respectively, considerably distorted from the octahedral limit of 90°. The Py–Se ligands are arranged so that the two selenium atoms are approximately *trans* to each other although with a grossly distorted angle of 152.01(3)°, which compels the nitrogen atoms to occupy approximate *cis*-positions (N–Mo–N, 75.46(17)°). The nitrogen donors occupy positions *trans* to the strongly π-bonding oxo groups, thus minimizing competition between the oxo groups and the weakly π-interacting selenium donors for the Mo t_{2g} orbitals. The strong *trans* influence of the terminal oxo group is evident in the Mo(1)–N(1) distance of 2.314(5) Å, as compared to the Mo(1)–N(2) distance of 2.215(5) Å for the nitrogen *trans* to the less effective bridging oxo group. The Mo–N bond lengths lie in the ranges that are observed in molybdenum complexes with the pyridine-2-selenato ligand [11] (2.247(3) and 2.206(3) Å) and the analogous pyridine-2-thiolato ligand [19,24,27] (2.157(5) [27a]–2.328(5) Å [24]). The two Mo–Se bond lengths (2.624(1) and 2.557(1) Å) which are in agreement with reported values (2.633(2)–2.661(1) Å) [11,28] are not equivalent. The four-membered rings derived from the chelating N,Se-coordination of the two 2-selenopyridines are coplanar with the adjacent pyridine rings. The distances of Mo to the terminal oxo ligand (1.683(4) Å), the bridging oxo group (1.864(1) Å) and the *cis*-O–Mo–O angle (106.41(18)°) are in the range of those reported for μ-oxomolybdenum(V) complexes (1.680(4), 1.863(1) Å and 105°, respectively) [24].

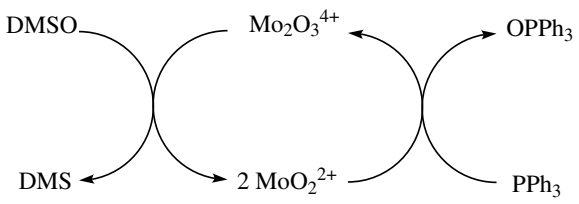
Complex **1** is isostructural to complex **2** and was described previously [10]. Since the distances and angles of our structure – though in a different modification – are almost identical to those published, we do not discuss the structure further but rather compare it with the structure of **2**. The geometrical parameters of both complexes are almost identical (see Tables 2 and 3). The main differences for bond lengths derive from the bonds containing the sulfur or the selenium atom. The differences of the corresponding Mo–Se and Mo–S bond lengths for **2** and **1** are 0.119 and 0.128 Å, and those of the bond lengths of S and Se to the carbon atom of the pyridine ring are 0.133 and 0.157 Å. All these differences can be ascribed to the different radii of both elements (van der Waals radii: 1.80 Å for S and 1.90 Å for Se) [29]. The biggest difference for the angles of **1** and **2** is within 3°. Overall both structures are similar, showing that the nature of the donor atoms in the heterocyclic ligand does not markedly influence the structure of the complex.

Complex **3** has a similar structure as **1** except for pyrimidine rings instead of pyridine rings and CF_3 groups as additional substituents in *para* position to the coordinating nitrogen. Unfortunately the CF_3 groups rotate freely and are therefore heavily disordered. Each of the fluorine atoms was found at three different positions which of course compromises the quality of the structural elucidation. The corresponding geometrical parameters for **3** and **1** are almost identical. The 4-CF_3-2-PymS ligands are also arranged in a way that the two sulfur atoms are approximately *trans* to each other (S–Mo–S, 144.74(3)°) constraining the nitrogen atoms to occupy approximate *cis*-positions (N–Mo–N, 79.90°). Both N-donor atoms occupy positions *trans* to a terminal oxo and a bridging oxo function, respectively. The *trans* influences of the two different oxo groups are responsible for the Mo–N distances being different (2.193(3) and 2.349(3) Å), which leads to different Mo–S distances (2.451(1) and 2.500(1) Å). The configuration of **3** is very close to those of **1** and **2**. Overall the electronic and steric influence of the introduced CF_3 group and an exchange of pyridine versus pyrimidine ligand is very small and does not effect the geometry of the obtained complexes. This behavior was reported for ruthenium and osmium complexes before [30].

3.3. Catalytic oxo-transfer activities

Dioxomolybdenum(VI) complexes are extensively employed as excellent catalysts for oxo transfer reactions as introduced above. A frequently used model reaction developed by Berg and Holm [31] is the oxidation of triphenylphosphine by DMSO. The formation of μ-oxo-dimers during the reduction of MoO_2 complexes is normally considered to be capable of breaking any catalytic cycle unless there is an equilibrium between the dimer and the $Mo^{VI}O_2$ and $Mo^{IV}O$ species. However, the formation of μ-oxo-bridged dimers does not necessarily exclude reversible oxo-transfer reactions. The reactivity of those dimers to catalyze oxygen atom transfer directly without conversion to the $M^{VI}O_2$ complexes was considered in some cases [32,33]. The molybdenum(V) compounds may be oxidized by a common oxidizing agent, such as DMSO, Ph_2SO and pyridine *N*-oxide. The reversibility of the oxo-transfer reactions involving dinuclear oxomolybdenum(V) complexes sometimes strongly depends on electronic features of the ligands rather than steric effects [19].

In order to assess the oxo transfer behavior of such complexes and especially comparing the influence of sulfur versus selenium coordination, oxo-transfer reactions of the molybdenum(V) compounds **1** and **2** were studied by use of PPh_3 in DMSO under analogous conditions. The experiments were performed at room temperature in dry deoxygenated DMSO-d_6 by treating the catalyst (**1** or **2**) with 10 equiv. of PPh_3 (2×10^{-4} mol) in a NMR tube. A figure showing the development of the ^{31}P NMR signals for catalyst **2** as example can be found in the Supplementary material (Fig. S1). The reactions were monitored with ^{31}P NMR spectroscopy. During the reactions only two phosphorous signals were observed: one for PPh_3 and one for $OPPh_3$. During the catalytic process for **1** as catalyst the reaction solution changed rapidly its color from deep red to yellow at the beginning of the reaction (about 7 min). Thereafter the color of the solution remained yellow and unchanged. For **2** as catalyst the color change from deep red to green yellow and finally to light brown was observed as well, but the change was slower in comparison to that for **1**. When the reaction was carried out to about 110 h, the color change stopped and the color light brown was kept to the end of the reaction. The color change for both reactions can be explained by the following assumptions (reactions (1) and (2)):



$$Mo_2^{V}O_3L_4 + DMSO \rightarrow 2Mo^{VI}O_2L_2 + DMS \quad (1)$$

$$2Mo^{VI}O_2L_2 + PPh_3 \rightarrow Mo_2^{V}O_3L_4 + OPPh_3 \quad (2)$$

First, oxidations of the oxomolybdenum(V) complexes to the mononuclear $Mo(VI)O_2$ species occur according to reaction (1). This possibility was well illustrated by previous reports [19,32,33]. It is well in accordance with the observation that the colors of the solutions for **1** and **2** in DMSO without PPh_3 also change from deep red to yellow or light brown respectively. When these solutions were monitored over time with mass spectrometry the molecule peaks for the dinuclear $Mo(V)_2O_3$ compounds decreased while the molecule peaks for the mononuclear species increased up to a total conversion from dimeric to monomeric complex. Subsequently, the reduction of the mononuclear dioxomolybdenum(VI) compounds is achieved by the reaction with PPh_3 that leads to dinuclear μ-oxomolybdenum(V) complexes (reaction (2)). This later process was observed before for the formation of **1** from $[MoO_2(PyS)_2]$ [20,21] and some other dinuclear molybdenum(V) complexes [32]. Due to a large excess of DMSO in contrast with PPh_3, the dinuclear μ-oxomolybdenum(V) complexes and PPh_3 were completely converted to mononuclear dioxomolybdenum(VI) complexes and $OPPh_3$. The similarity of the color change between the catalytic reaction mixtures and the solutions of only complexes in DMSO also provides evidence for the above assumption. The entire process is summarized in Scheme 2.

The development of the conversion of PPh_3 to $OPPh_3$ for both complexes **1** and **2** over time is shown in Fig. 4.

The functions of the reactions for **1** and **2** appear to be almost linear. A plot of $\ln c(PPh_3)$ versus the time t on the

Scheme 2.

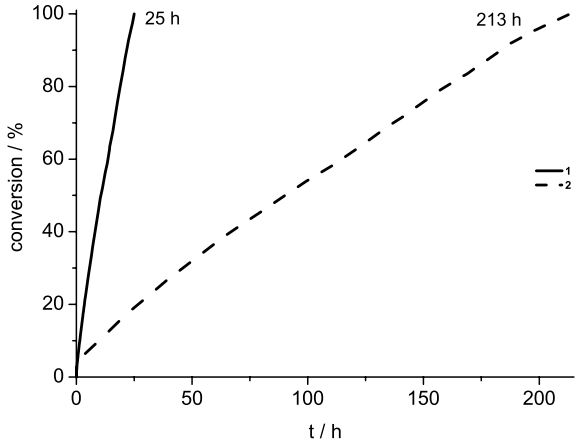


Fig. 4. Oxidation of PPh_3 to $OPPh_3$ by DMSO-d_6 at rt as a function of time for **1** and **2**.

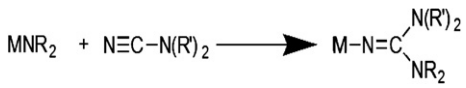
other hand is strictly non-linear. This means the reaction cannot be described as being first order with respect to the PPh_3 concentration, which would have been expected with the large access of the second reactant DMSO. PPh_3 was completely oxidized in only 25 h (about 1 day) for **1**, which is in accordance with a previous study [21], whereas it took 213 h (nearly 9 days) for **2**. The thionato containing complex **1** shows considerably higher catalytic activity than its selenolato containing analogue **2**. This suggests that the catalytical performance of both compounds is strongly influenced by an exchanged of ligand atoms sulfur versus selenium even though no strong influence on the structures could be observed.

4. Conclusion

Molybdenum complexes with bidentate heterocyclic thiones and selenone, $[Mo_2O_3(PyS)_4]$ (**1**), $[Mo_2O_3(PySe)_4]$ (**2**) and $[Mo_2O_3(4\text{-}CF_3\text{-}PymS)_4]$ (**3**), were obtained by similar reactions of the molybdenum precursor $[MoO_2Cl_2(DME)]$ with the corresponding ligands. They all formed dinuclear μ-oxomolybdenum(V) species because the corresponding ligands are acting both as a reductant and as a ligand in the reactions. The crystal structures of **1**–**3** include the common $[Mo_2O_3]^{4+}$ core. Compounds **1** and **2** are isostructural. Through structural analysis and comparison we can conclude that the nature of the donor atoms in the heterocyclic ligand does not markedly influence the structure of the complex and the introduction of the CF_3 group on the heterocyclic ring of the ligands does not have significant influence on the structures of the complexes at least for this kind of complexes. The thionato containing complex **1** shows considerably higher catalytic activity than its selenolato containing analogue **2** for the transfer of one oxygen atom from DMSO to PPh_3. This result indicates that an exchange of ligand atoms sulfur versus selenium of the same ligand system can cause different activities of complexes even though no strong influence on other investigated properties could be observed.



Appendix A. Supplementary material

CCDC 652135, 652136 and 652137 contain the supplementary crystallographic data for **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.020.

Scheme 1. The general synthesis of M(TAG).

The convenient synthesis of Li(TMG) via the reaction of lithium dimethylamide with dimethylcyanamide was first reported by Wade and co-workers [4]. Herein, we report the generalization of this reaction (Scheme 1) to cleanly generate a family of Li(TAG) precursors that are subsequently used in metathesis reactions with lithium bis- trimethylsilylamide and $ZnCl_2$ to form the corresponding hetero-ligated Zn(TAG) complex. This initial investigation utilizes dimethylamino, diethylamino, pyrrolidine, and piperidine functionalities to develop a library of structurally varied Zn(TAG) complexes. AlkylZn amides, homoleptic amides, and Zn guanidinate complexes have been reported as polymerization catalysts, as well as MOCVD and nanocrystal precursors [8]. Therefore, synthesizing, characterizing, and studying the properties of novel Zn(TAG) complexes will illuminate a new direction in metal-nitrogen chemistry while also providing a new class of low-coordinate complexes for material science applications.

2. Experimental

All syntheses were handled with rigorous exclusion of air and water using standard glove box techniques. All anhydrous solvents were stored under argon and used as received in sure seal bottles. The following chemicals were used as received from commercial suppliers: $LiNEt_2$, $LiNMe_2$, $LiN(SiMe_3)_2$, *n*-BuLi (1.6 M in hexanes), dimethylcyanamide, diethylcyanamide, pyrolidinecyanamide, piperidine, pyrrolidine and $ZnCl_2$. FT-IR data were obtained on a Bruker Tensor 27 instrument using KBr under an atmosphere of flowing nitrogen. Elemental analysis was performed on a Perkin–Elmer 2400 Series 2 CHN-S/O Elemental Analyzer. All NMR samples were prepared from dried crystalline materials that were handled and stored under an argon atmosphere and re-dissolved in C_6D_6. All solution spectra were obtained on a Bruker DRX400 spectrometer at 400.1 and 100.5 MHz for ^1H and ^{13}C experiments.

2.1. General synthesis of *1*–*6*

To a lithium dialkylamide dissolved in 15 mL of ether, an equivalent of dialkylcyanamide was added drop-wise under an inert atmosphere of argon. Subsequently, the reaction mixture was allowed to stir for 30 min completing the generation of the lithium 1,1,3,3-tetralkylguanidinate *in situ*. $LiN(SiMe_3)_2$ and $ZnCl_2$ were then added sequentially. After stirring for 24 h, LiCl was removed via centrifugation and the solution was further concentrated and cooled to −35 °C. X-ray-suitable, colorless crystals were grown in 24 h.

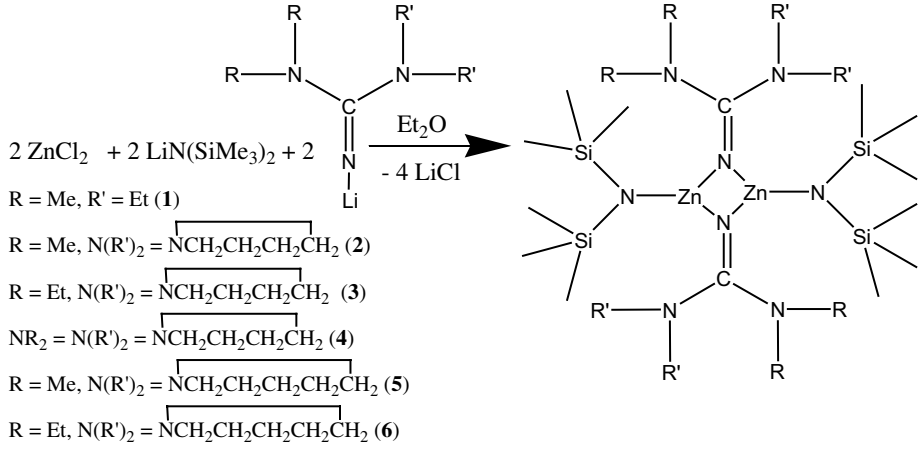
[a] $R_1 = \sum\|F_o\| - |F_c\|/\sum|F_o| \times 100$.
[b] $wR_2 = [\sum w(F_o^2 - F_c^2)_2/\sum(w|F_o|^2)^2]^{1/2} \times 100$.



2.2. Crystallographic data

X-ray crystallography was performed by mounting each crystal onto a thin glass fiber from a pool of Fluorolube™ and immediately placing it under a 100 K N_2 stream, on a Bruker SMART APEX II diffractometer. The radiation used was graphite monochromatized Mo Kα radiation ($\lambda = 0.7107$ Å). The structures were refined by full-matrix least-squares procedures (SHELXL-97), Lorentzian and polarization corrections and absorption corrections (SADABS) were applied.

Each structure was solved using direct methods. This procedure yielded the Zn atoms, along with a number of the Si, C and N atoms. Subsequent Fourier synthesis yielded the remaining atom positions. The hydrogen atoms were fixed in positions of ideal geometry and refined within the XSHELL software. These idealized hydrogen atoms had their isotropic temperature factors fixed at 1.2 or 1.5 times the equivalent isotropic U of the C atoms to which they were bonded. The final refinement of each compound included anisotropic thermal parameters on all non-hydrogen atoms. Additional information concerning the data collection and final structural solutions of compounds **1**–**6** can be found in Tables 1 and 2.

3. Results and discussion

While undertaking a prior investigation correlating the structure and reactivity of dinuclear zinc catalysts stabilized with 1,1,3,3-tetramethylguanidine (H-TMG), it became of interest to evaluate the utility of a broader class of 1,1,3,3-tetralkylguanidine (H-TAG) ligands [9]. Unfortunately, the lack of reported examples of TAG ligands necessitated the development of a new synthetic approach. (Scheme 1) Our initial design utilizes the bulky terminal bistrimethylsilylamide, N{Si(Me$_3$)}$_2$, in conjunction with

a series of sterically varied TAG groups to isolate low-coordinate crystalline Zn complexes. In the following discussion, we detail the successful synthesis and characterization of six Zn complexes with the general formula, $[Zn(\mu\text{-TAG})\{N(SiMe_3)_2\}]_2$.

3.1. Synthesis

Under an argon atmosphere, metathesis reactions were performed to synthesize complexes **1**–**6**. (Scheme 2) The addition of $ZnCl_2$ to an ether solution containing one equivalent of Li(TAG) and one equivalent of $LiN(SiMe_3)_2$ generates a cloudy solution from which a white precipitate is removed via centrifugation after 24 h. Crystals suitable for X-ray structural analysis were obtained for **1**–**6** by cooling the respective saturated ether solutions at −35 °C. The isolated crystals for each complex are air-sensitive and soluble in hexanes, toluene, ether and THF.

3.2. Crystal structures

The thermal ellipsoid plots of **1**–**6** are illustrated in Figs. 1–6, respectively. For each complex, the Zn centers adopt a distorted trigonal planar geometry by utilizing the bulky

hexamethydisilazide ligand as a terminal ligand while two TAG ligands act as a bridge connecting one metal to the other.

The bond distances and angles for the $N(SiMe_3)_2$ ligand in **1**–**6** (Tables 3 and 4) are consistent with previously reported $[Zn(\mu\text{-}L)\{N(SiMe_3)_2\}]_2$ compounds [10]. It is notable that the complexes with NMe_2 substituents (**1**, **2** and **5**) have an asymmetric ligand environment around each Zn center. This can tentatively be attributed to the difference in steric bulk for the NMe_2 group versus the other substituents examined in this study. Complex **4** crystallizes with two crystallographically independent, but chemically equivalent molecules per asymmetric unit. Only one of the centrosymmetric dimers is shown in Fig. 4. In this complex, each three-coordinate Zn is bridged to the adjacent Zn by two symmetric DPYRG ligands.

3.3. Bulk properties

In order to establish that the crystal structures of **1**–**6** are representative of the bulk material, FT-IR spectroscopy and elemental analysis (EA) were collected. The FT-IR

spectra of **1**–**6** show a strong diagnostic shift ranging between 1524 and 1550 cm^{-1} for the υ(C=N) band bonded to Zn. This is shifted to lower frequency than what is typically found for a neutral 1,1,3,3-tetraalkylguanidine [11]. The strong amide stretches for **1**–**6**, associated with M-NR_2, are present between 1400 and 1450 cm^{-1}. For **1**–**6**, the EA of the bulk powders were all found to be consistent with the solid state structure.

3.4. NMR studies – solution behavior

^{13}C and ^{1}H NMR spectra were collected for **1**–**6** in benzene-d_6. Retention of a zinc-bonded $N(SiMe_3)_2$ group for **1**–**6** is implied by the observation of a strong singlet ($\delta \sim 0.3$ ppm) by ^{1}H NMR spectroscopy,. Additional resonances in the ^{1}H NMR spectra could be clearly assigned for each unique TAG ligand. The ^{13}C NMR spectra for **1**–**6** have a characteristic low field resonance at ~160–165 ppm attributed to the 'CN_3' central carbon atom of the guanidinate ligand [11]. Assignment of the additional ^{13}C NMR resonances for the $N(SiMe_3)_2$ and TAG ligands for each complex was straightforward.

4. Conclusions

A novel family of dinuclear zinc guanidinate complexes has been successfully synthesized and characterized. The use of a series of structurally varied monoanionic TAG ligands in conjunction with the bulky $N(SiMe_3)_2$ ligand has demonstrated to be an effective method for generating low-coordinate Zn complexes. We envision that this approach will be amenable to isolating additional transition metal complexes. Work utilizing this approach is currently underway.

ions [14,15]. There has also been substantial interest in the rational design of novel transition metal complexes, which bind and cleave duplex DNA with high sequence and structure selectivity [16–18]. Hence, we report the synthesis and physico-chemical studies of a tetradentate Schiff base ligand, derived from 2-pyridinecarboxaldehyde and *o*-phenylenediamine, and its complexes. Although the complexes of 1,2-diaminophenyl-*N*,*N*′-bis-(2-pyridinecarboxaldimine) have been reported with Ru(III), the Schiff base was generated *in situ* and its catalytic activity was explored [19]. To add to the novelty of the work, we have successfully isolated this ligand and have screened the binding studies of its Cu (II) complex with DNA.

2. Physical measurements

Elemental analyses were obtained from the microanalytical laboratory of C.D.R.I., Lucknow, India. IR spectra (4000–200 cm^{-1}) were recorded as KBr/CsI discs on a Perkin–Elmer 621 spectrophotometer. The ^{1}H and ^{13}C NMR spectra were recorded in DMSO-d_6 using a Bruker AC 200E NMR spectrometer from B.H.U., Varanasi. Metals were estimated volumetrically [20]. The electronic spectra of the complexes in DMSO were recorded on a Pye-Unicam 8800 spectrophotometer. The electrical conductivity (10^{-3} M solution in DMSO) was obtained on a systronic type 302 conductivity bridge equilibrated at 25 ± 0.1 °C. The magnetic moment measurements (Faraday balance) were made at room temperature. Fluorescence measurements on complex **3** were performed on a Shimdzu 5301 PC spectrofluorimeter equipped with a 150 W Xenon lamp and a slit width of 5 nm. A 1.00 cm quartz cell was used for the measurements. For the determination of binding parameters, 2.5 μM of complex solution was taken in a quartz cell and increasing amounts of ct DNA solution was titrated. Fluorescence spectra were recorded at a temperature of 310 K in the range 300–500 nm upon excitation at 296 (λ_{ex} was 296 nm). The UV measurements of calf thymus DNA were recorded on a Shimadzu UV-1700 double beam spectrophotometer using a cuvette of 1 cm path length. The absorbance value of DNA in the absence and presence of complex were made in the range 200–300 nm. The DNA concentration was fixed at 0.1 mM, while the complex concentration was varied from 2.5 μM to 15 μM.

3. Experimental

3.1. Materials

All the metal salts $M(NO_3)_2 \cdot 6H_2O$ and $Cu(NO_3)_2 \cdot 3H_2O$ [where M = Co(II), Ni(II) and Zn(II)] as well as *o*-phenylenediamine and 2-pyridinecarboxaldehyde (all E. Merck) were used as received. Methanol used as solvent was of A.R. grade (E. Merck). Highly polymerized calf thymus DNA sodium salt (7% Na content) was purchased from sigma. Other chemicals were of reagent grade and were used without further purification. Calf thymus DNA was dissolved to 0.5% w/w, (12.5 mM DNA/phosphate) in 0.1 M sodium phosphate buffer (Ph 7.40) at 310 K for 24 h with occasional stirring to ensure formation of a homogeneous solution. The purity of the DNA solution was checked from the absorbance ratio A_{260}/A_{280}. Since the absorption ratio lies in the range $1.8 < A_{260}/A_{280} > 1.9$, no further deproteinization of DNA was needed. A stock solution of complex **3** with 5 mg/ml was also prepared.

4. Synthesis of 1,2-diaminophenyl-*N*,*N*′-bis-(2-pyridinecarboxaldimine) (L)

A methanolic solution of *o*-phenylenediamine (5 mmol, 0.540 g) was magnetically stirred in a three-necked round bottom flask followed by dropwise addition of 2-pyridinecarboxaldehyde (10 mmol, 0.96 ml). The reaction mixture was then refluxed for 4–5 h, resulting in a clear yellow colored solution. The resultant solution was kept for evaporation at room temperature leading to the isolation of a pale yellow microcrystalline product after a few weeks.

5. Synthesis of the complexes, $[ML(NO_3)_2]$ [M = Co(II), Ni(II), Cu(II) and Zn(II)]

A methanolic solution of Schiff base ligand **L** (5 mmol, 0.143 g) was added dropwise to a methanolic solution of the metal salt (5 mmol). The reaction mixture was refluxed for 5 h leading to the formation of a colored solid product. The product thus formed was filtered, washed with methanol and dried in vacuo.

6. Binding analysis of complex 3

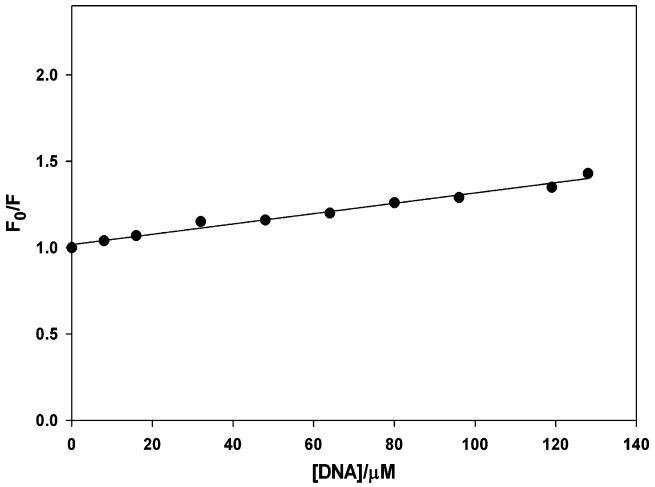
To elaborate the fluorescence quenching mechanism the Stern–Volmer equation was used for data analysis [21]:

$$F_0/F = 1 + K_{SV}[Q] \quad (1)$$

where F_0 and F are the steady-state fluorescence intensities in the absence and presence of quencher, respectively. K_{SV} is the Stern–Volmer quenching constant and $[Q]$ is the concentration of quencher (DNA). The linearity of the F_0/F versus $[Q]$ (Stern–Volmer) plots for the DNA complex **3** depicts that the quenching may be static or dynamic, since the characteristic Stern–Volmer plot of combined quenching (both static and dynamic) is an upward curvature (Fig. 1). The quenching constant (K_{SV}) was calculated to be 2.91×10^3 L mol^{-1}. When ligand molecules bind independently to a set of equivalent sites on a macromolecule, the equilibrium between free and bound molecules is given by the equation [22]:

$$\log[(F_0 - F)/F] = \log K + n \log[Q] \quad (2)$$

where K and n are the binding constant and the number of binding sites, respectively. Thus, a plot of $\log(F_0-F)/F$ versus $\log[Q]$ can be used to determine K as well as n.



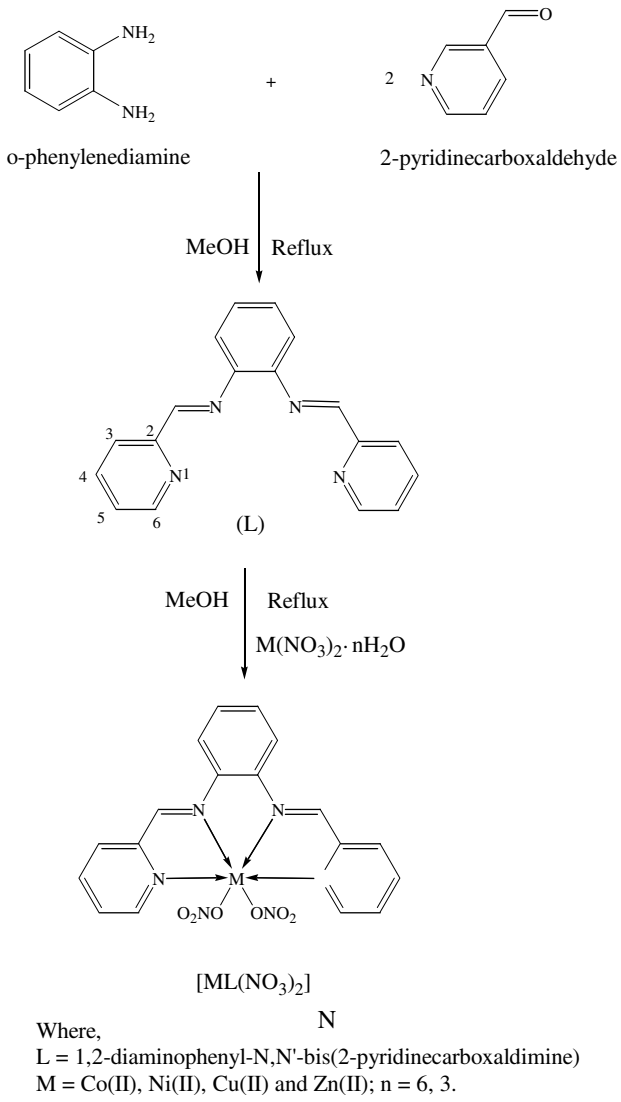


Fig. 1. Stern–Volmer plot for the binding of ct DNA with complex **3** at 298 K.

The values of K and n were found to be $(0.31 \pm 0.19) \times 10^{-3}\ M^{-1}$ and 0.75 respectively.

7. Results and discussion

The Schiff base ligand **L** has been synthesized by the condensation of *o*-phenylenediamine and 2-pyridinecarboxaldehyde in a 1:2 molar ratio in methanolic medium (Scheme 1). The level of the purity of the ligand has been checked by running TLC on a silica gel coated plate using EtOAc–MeOH (6:4 v/v) as the eluent. Complexes of the type $[ML(NO_3)_2]$ [M = Co(II), Ni(II), Cu(II) and Zn(II)] (**1**–**4**) were synthesized by the reaction of the ligand **L** and the metal salts in a 1:1 molar ratio in methanolic medium. The elemental analyses agree well with the proposed composition of the ligand and its complexes (Table 1). Formation of the Schiff base ligand (**L**) and its complexes have been inferred from the results obtained by FT-IR, ^1H and ^{13}C NMR. The geometry around the metal ion in the complexes has been deduced from the absorption bands observed in the UV–Vis spectra and magnetic moment values. All the Schiff base complexes are stable at room temperature, and are soluble in water, DMSO and methanol. The low molar conductivity values of all the complexes suggest their non-ionic nature. However, all attempts to get a single crystal of the ligand or the complexes suitable for X-ray crystallography failed.

Scheme 1. Suggested scheme of the proposed Schiff base and its complexes.

8. IR spectra

Preliminary identification regarding the formation of the Schiff base ligand and its complexes was obtained from IR spectral findings (Table 2). The absence of bands characteristic of the amino groups, $\nu(NH_2)$, of *o*-phenylenediamine and the carbonyl group, $\nu(C{=}O)$, of 2-pyridinecarboxaldehyde, and appearance of a new strong intensity band at 1630 cm^{-1} characteristic of azomethine group, $\nu(C{=}N)$, confirm that condensation between the aforesaid reactants has taken place [23]. This band undergoes a negative shift of 10–20 cm^{-1} in the complexes, which may be attributed to the coordination of the nitrogen atom of the azomethine function to the metal ion [24]. This is further confirmed by the presence of a $\nu(M–N)$ vibration in the region 440–460 cm^{-1} in all the complexes [25]. The main spectral variations of the complexes as compared to the free ligand are found in the regions 420–430 cm^{-1} (out of plane ring deformation) and 630–650 cm^{-1} (in plane ring deformation), where the absorption of the pyridine rings of 2-pyridinecarboxaldehyde occurs [26]. These vibrations are found to be positively shifted, suggesting the coordination of the pyridine nitrogen to the metal [27]. However, pyridine and phenyl ring vibrations in the higher frequency region (1560–1590 cm^{-1}) are not affected appreciably. A strong intensity band appearing in the region 260–280 cm^{-1} may reasonably be assigned to $\nu(M–N_{py})$ vibrations [27]. The IR spectra of ionic NO_3^- shows a very strong band at

Table 1

[CuL(NO_3)$_2$]	1625 s	445 s	425 m	635 s	280 s	240 s	1240, 1050, 870
[ZnL(NO_3)$_2$]	1610 s	460 s	430 m	630 s	275 s	250 s	1245, 1060, 880

Where, m – Medium.
s – Strong.
L – Ligand.

ca. 1380 cm^{-1} ν_3(A) along with sharp bands at ca. 1050 ν_1(A), 830 ν_2(E) and 720 cm^{-1} ν_4(E) [28]. The IR spectra of all the complexes exhibited three bands in the 1230–1245, 1040–1060 and 860–880 cm^{-1} regions, indicating the monodentate coordination of the nitrate moiety [29]. The presence of a band in the region 235–250 cm^{-1} may reasonably be assigned to ν[M–O] of the O–NO_2 group [30].

9. Electronic spectra and magnetic susceptibility data

The electronic spectrum (Table 3) of the Co(II) complex exhibited two spin allowed transitions at 15,300 and 19,100 cm^{-1} assignable to $^4T_{1g}(F) \rightarrow {}^4A_{2g}(F)$ and $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transitions, respectively, consistent with an octahedral geometry around the Co(II) ion [31]. The observed magnetic moment of 4.60 B.M. for the [CoL(NO_3)$_2$] complex further complements the electronic spectral findings [32]. The electronic spectrum of the [NiL(NO_3)$_2$] complex exhibited three bands at 11,200, 17,000 and 28,000 cm^{-1} attributed to three spin allowed transitions, viz. $^3A_{2g}(F) \rightarrow {}^3T_{2g}(F)$, $^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g}(F) \rightarrow {}^3T_{1g}(P)$ respectively, corresponding to an octahedral environment for the Ni(II) complex which is further supported by its magnetic moment value of 3.12 B.M. [31,32]. A broad band at 16,710 cm^{-1} in the electronic spectrum of the Cu(II) complex, assignable to a $^2B_{1g} \rightarrow {}^2B_{2g}$ transition, and a magnetic moment of 1.83 B.M. confirms an octahedral geometry around the Cu(II) ion [31,32].

Table 3
Magnetic moment values and electronic spectral band position (cm^{-1}) with their assignments

Complexes	Magnetic moments (B.M.)	Band position cm^{-1}	Assignments
[CoL(NO_3)$_2$]	4.60	15,300	$^4T_{1g}(F) \rightarrow {}^4A_{2g}(F)$
		19,100	$^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$
[NiL(NO_3)$_2$]	3.12	11,200	$^3A_{2g}(F) \rightarrow {}^3T_{2g}$ (F)
		17,000	$^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)$
		28,000	$^3A_{2g}(F) \rightarrow {}^3T_{1g}(P)$
[CuL(NO_3)$_2$]	1.83	16,710	$^2B_{1g} \rightarrow {}^2B_{2g}$

10. ^{1}H and ^{13}C NMR spectra

The ^{1}H and ^{13}C NMR spectra of the Schiff base ligand **L** and its Zn(II) complex were recorded in DMSO-d_6 at room temperature. In the ^{1}H NMR spectrum, the chemical shift values of the protons of the pyridine ring coordinated to the metal atom in the complex are noticeably different from those observed for the non-coordinated ring of the ligand (**L**). The proton resonances of the coordinated pyridine ring are observed at 8.51 (d H_3), 8.28 (t H_4), 7.39 (t H_5) and 7.67 ppm (d H_6), while the resonance of the non-coor-

dinated pyridine ring protons appear at 7.28 (d H_3), 8.16 (t H_4), 7.28 (t H_5) and 8.20 ppm (d H_6). On the basis of these data, it is possible to justify the corresponding downfield shift induced by the coordination of the pyridine nitrogen atom to the metal atom. The ^{1}H NMR spectrum of the ligand also shows a signal at 8.39–7.74 ppm attributed to the aromatic proton (m, Ar–H). However, a singlet at 9.28 ppm may be assigned to the azomethine proton (s, 2H). The Zn (II) complex shows a slight downfield shift of 0.2–0.4 ppm in the resonance peaks corresponding to the phenyl ring and the azomethine proton, which may be attributed due to the coordination of the ligand to the Zn(II) ion [33].

The ^{13}C NMR spectrum of the Zn(II) complex shows a number of sharp peaks corresponding to various carbon atoms in the proposed schiff base ligand, expected due to the non-equivalence of the various carbon atoms. The spectrum exhibits a sharp resonance signal corresponding to the azomethine carbon at 193.77 ppm and the chemical shifts of the aromatic and pyridine carbons appear at 124.52, 122.96, 121.78 and 150.29, 149.20, 137.75, 137.35, 128.49 ppm [34]. These values have been found to be downfield shifted by 1.0–1.5 ppm as compared to the free Schiff base ligand. A downfield shift of nearly 1.5 ppm has been noticed for the carbons of the phenyl ring attached to the imine nitrogen and the carbons of the imine and pyridine moieties.

11. Fluorescence measurements

11.1. Binding property of DNA to complex 3

Fluorescence spectroscopy provides insight of the changes taking place in the microenvironment of DNA-complex **3**. The interaction of complex **3** with calf thymus DNA was studied by monitoring the changes in the intrinsic fluorescence of complex **3** at varying DNA concentrations (Fig. 2). The spectra show the representative fluorescence emission spectra of complex **3** upon excitation at 296 nm. The addition of DNA causes a gradual decrease in the fluorescence emission intensity of complex **3**, with a conspicuous change in the emission spectra. It can be seen that a higher excess of DNA leads to more effective quenching of the fluorophore molecule fluorescence. The quenching of complex **3** fluorescence clearly indicates that the binding of DNA to complex **3** changes the microenvironment of fluorophore residue. The reduction in the intrinsic fluorescence of complex **3** upon interaction with DNA could be due to masking or burial of the complex **3** fluorophore upon interaction between the stacked bases within the helix and/or surface binding at the reactive nucleophilic sites on the heterocyclic nitrogenous bases of the DNA molecule.

11.2. Absorption spectroscopy

UV–Vis absorption studies were performed to further ascertain the DNA-complex **3** interaction. The UV absorbance showed an increase with the increase in drug concentration (Fig. 3). Since complex **3** does not show any peak in this region (Fig. 3), the rise in the DNA absorbance is indicative of complex formation between DNA complex **3** molecules. Complex **3** at 260 nm exhibited hyperchromism of 30% and bathchromism of 3 nm. Hypochromism and hyperchromism are both spectral features of DNA concerning of its double helix structure, hypochromism means the DNA binding mode of complex is an electrostatic effect or intercalation which can stabilize the DNA

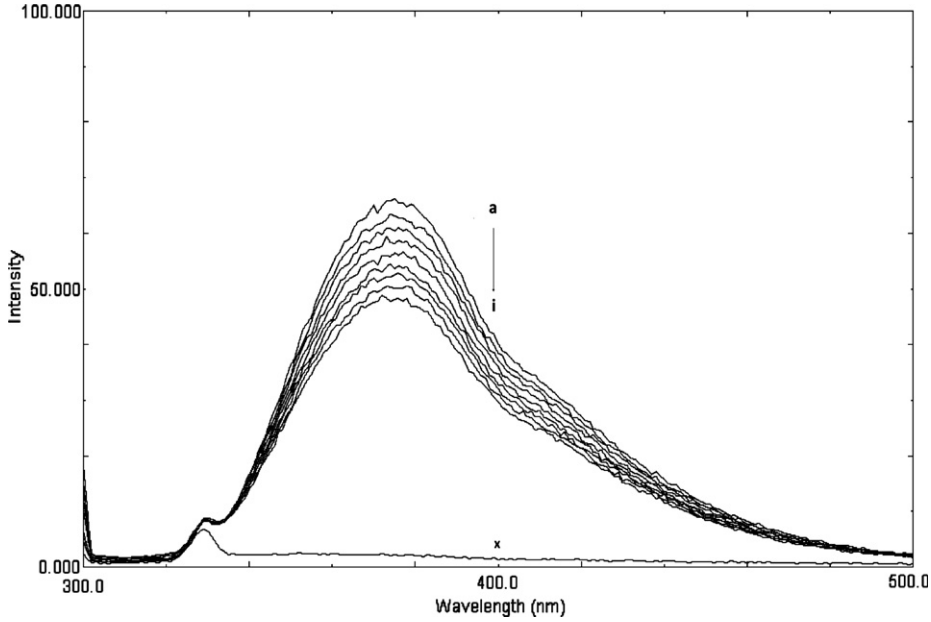

Fig. 2. Fluorescence emission spectra of complex **3** in the presence of ct DNA. The complex concentration was 12 μM (a). DNA concentration was (b) 8 μM (c) 16 μM (d) 32 μM (e) 32 μM (f) 48 μM (g) 64 μM (h) 80 μM (i) 96 μM and (x) DNA alone.

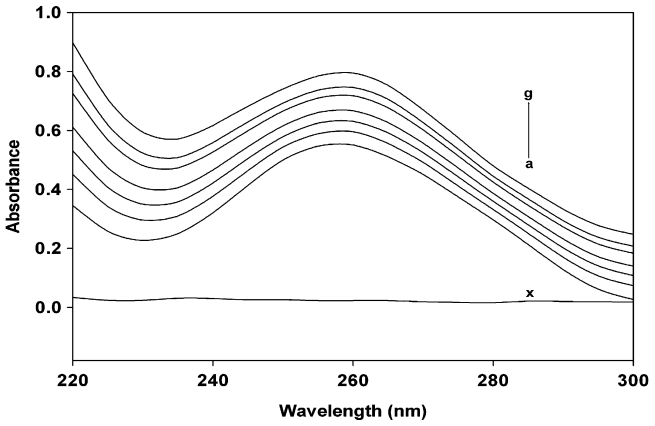

Fig. 3. Absorbance spectra of DNA, complex **3** and the DNA-complex **3** system. DNA concentration was 0.1 mM (a). Complex **3** concentration for the DNA-complex **3** system was 2.5 (b), 5.0 μM (c), 7.5 μM (d), 10 μM (e), 12.5 μM (f), 15.0 μM (g). A concentration of 2.5 μM complex **3** (x) was used for complex **3** alone.

duplex, and hyperchromism means the breakage of the secondary structure of DNA [35,36]. So we primarily speculate that complex interaction with the secondary structure of calf thymus DNA results in its breakage and perturbation. After interaction with the base pairs of DNA, the π–π^* orbital of the bound ligand can couple with the π orbital of the base pairs, due to the decreased π–π^* transition energy, which results in a bathochromic shift [37]. The above two changes are indicative of conformational alteration on complex **3** binding.

Acknowledgements

The authors acknowledge the Chairman, Department of Chemistry, Aligarh Muslim University, Aligarh for providing the necessary research facilities. The authors also thank C.D.R.I., Lucknow for providing the Elemental Analyses data and B.H.U., Varanasi for ^{1}H and ^{13}C NMR spectra.

report the preparation of a new bpy ligand bearing two chiral bornyl substituents and report studies of iron(II) and ruthenium(II) complexes incorporating this species.

2. Experimental

2.1. General procedures

Commercially available chemicals were reagent grade and were used without further purification. ^{1}H and ^{13}C NMR spectra were recorded on Bruker AM 250, DRX 400 or 500 MHz or Bruker Avance 600 MHz spectrometers; chemical shifts are defined with TMS δ 0 ppm for ^{1}H and ^{13}C spectra and are measured relative to residual $CHCl_3$. Infrared spectra were recorded on Mattson Genesis or Shimadzu FTIR 8300 spectrophotometers using compressed KBr discs or on a Shimadzu FTIR-8400S spectrophotometer with neat samples on a Golden Gate diamond ATR accessory. Electronic absorption spectra were recorded on a Shimadzu UV 3101PC or Varian-Cary 5000 spectrophotometer, and luminescence spectra on a Shimadzu RF 5301PC or Perkin–Elmer LS50B spectrofluorophotometer. Electrospray (ES) mass spectra were recorded using a Finnigan MAT LCQ mass spectrometer. Microanalyses were performed with a LECO CHN-900 apparatus. CD spectra recorded on a Applied Photophysics Chirascan CD spectrometer at 298 K. Electrochemical measurements were performed with Autolab PGSTAT 20 or 30 systems using platinum or glassy-carbon working and auxiliary electrodes with an Ag/AgCl electrode as reference or a silver wire as pseudo-reference using purified MeCN as solvent and 0.1 M [^{n}Bu$_4$N][BF$_4$] as supporting electrolyte. Potentials are quoted versus the ferrocene/ferrocenium couple ($Fc/Fc^+ = 0.0$ V), and potentials were referenced to internal ferrocene added at the end of each experiment. 4,4′-Dibromo-2,2′-bipyridine [44] and [Ru(bpy)$_2$Cl$_2$] [45] were prepared by the literature methods; (+)-borneol ((1*R*,2*S*,4*R*)-1,7,7-trimethylbicyclo[2.2.1]heptan-2-ol) and (−)-borneol = ((1*S*,2*R*,4*S*)-1,7,7-trimethylbicyclo[2.2.1]heptan-2-ol) (Aldrich) were used as received.

2.2. (1*S*,2*R*,4*S*)-**1** and (1*R*,2*S*,4*R*)-**1**

(1*S*,2*R*,4*S*)-(−)-Borneol or (1*R*,2*S*,4*R*)-(+)-borneol (1.0 g, 6.5 mmol) was dissolved in DMF (50 cm^3) and NaH (60% dispersion in mineral oil, 0.26 g, 6.5 mmol) was added at room temperature. The mixture was stirred well and heated to 80 °C. After the evolution of gas had ceased, 4,4′-dibromo-2,2′-bipyridine (0.50 g, 1.6 mmol) was added in one portion and stirring was continued at this temperature for 16 h. The solvent was then evaporated and the residue dissolved in 2 M HCl after which the solution was neutralized with aqueous NaOH solution (1 M) and extracted with CH_2Cl_2 (3 × 50 cm^3). The combined organic phases were dried over $MgSO_4$ and the solvent removed *in vacuo*. The excess of borneol was sublimed from the white residue, leaving the desired ligand as white crystals (yield: (1*S*,2*R*,4*S*)-**1**, 0.47 g, 1.0 mmol, 63%; (1*R*,2*S*,4*R*)-**1**, 0.35 g, 0.76 mmol (47%). M.p. 158 °C. *Anal.* Calc. for $C_{30}H_{38}N_2O_2$: C, 78.56; H, 8.35; N, 6.11. Found: C, 78.03; H, 8.67; N, 6.10%. ^{1}H NMR (500 MHz, $CDCl_3$) δ/ppm 8.44 (d, J = 5.7 Hz, 2H, H^{A6}), 7.85 (d, J = 2.5 Hz, 2H, H^{A3}), 6.76 (dd, J = 5.7, 2.5 Hz, 2H, H^{A5}), 4.52 (m, 2H, H^2), 2.47 (m, 2H, H^{3exo}), 2.23 (m, 2H, H^{6exo}), 1.75 (m, 4H, H^{4,5exo}), 1.51 (m, 2H, H^{5endo}), 1.35 (m, 2H, H^{6endo}), 1.10 (m, 2H, H^{3endo}), 0.99 (s, 6H, H$^{8/9}$), 0.94 (s, 6H, H$^{8/9}$), 0.93 (s, 6H, H^{10}). ^{13}C{^{1}H} NMR (125 MHz, $CDCl_3$) δ/ppm 166.0 (C$^{A4/A2}$), 157.8 (C$^{A4/A2}$), 150.2 (C^{A6}), 111.2 (C^{A5}), 108.5 (C^{A3}), 83.2 (C^2), 49.5 (C$^{1/7}$), 48.0 (C$^{1/7}$), 45.1 (C^4), 36.6 (C^3), 27.9 (C^{5,6}), 26.8 (C^{5,6}), 19.7 (C$^{8/9}$), 19.1 (C$^{8/9}$), 13.7 (C^{10}). ESMS (MeCN) m/z 943 [2M+Na]$^+$, 461 [M]$^+$. UV–Vis λ_{max}/nm ($CHCl_3$) 236 (ε/dm^3 mol^{-1} cm^{-1} 104 000), 278 (65 000). $\bar{\nu}$/cm^{-1} (KBr) 2984m, 2953s, 2932s, 2884m, 1588s, 1558s, 1456s, 1289w, 1367w, 1306m, 1290s, 1232m, 1116w, 1050m, 1024s, 994w, 884m, 869w, 806m. CD ($CDCl_3$, 298 K, 5.4×10^{-5} mol dm^{-3}, nm ($\Delta\varepsilon$)) (1*R*,2*S*,4*R*)-**1**, 235 (0.9), 245 (0.6), 255 (−1.8), 270 (3.4), 280 (4.0), 294 (−2.0); (1*S*,2*R*,4*S*)-**1**, 235 (−0.9), 245 (−0.6), 255 (1.8), 270 (−3.4), 280 (−4.0), 294 (2.0). E°/V versus Fc: −2.08, −1.42 (irrev).

2.3. [Fe((1*S*,2*R*,4*S*)-**1**)$_3$][PF$_6$]$_2$

Ligand (1*S*,2*R*,4*S*)-**1** (40.1 mg, 0.0870 mmol) and $FeCl_2 \cdot 4H_2O$ (3.9 mg, 0.0196 mmol) were added to MeOH (4 cm^3) and the reaction mixture was stirred at room temperature for 17 h. Solvent was removed *in vacuo* and the residue was dissolved in MeCN (3 cm^3). The purple product was precipitated by the addition of aqueous ammonium hexafluorophosphate. It was collected by fitration, washed with water (50 cm^3) and dissolved in MeCN. Solvent was removed from the solution, and [Fe((1*S*,2*R*,4*S*)-**1**)$_3$][PF$_6$]$_2$ was isolated as a purple solid (25.0 mg, 0.0145 mmol, 74.0%). ^{1}H NMR (500 MHz, CH_3CN) δ/ppm 7.94 (br s, 6H, H^{A3}), 7.17 (two overlapping doublets, J = 7 Hz, 6H, H^{A6} diastereoisomers A + B), 6.76 (m, 6H, H^{A5}), 4.59 (m, 6H, H^2), 2.51 (m, 6H, H^{3exo}), 2.15 (m, 6H, H^{6exo}), 1.82 (m, 12H, H^{4,5exo}), 1.44 (m, 6H, H^{5endo}), 1.23 (m, 6H, H^{6endo}), 1.04 (dd, J = 13.5, 2.1 Hz, 6H, H^{3endo}), 0.99 (s, 9H, H^8 diastereoisomer A), 0.98 (s, 9H, H^8 diastereoisomer B), 0.95 (br s, 27H, H^9 diastereoisomers A + B, and H^{10} diastereoisomer A), 0.93 (s, 9H, H^{10} diastereoisomer B). ES MS (MeCN) m/z 1520 [M−PF$_6$+2MeCN]$^+$.

2.4. [Ru((1*S*,2*R*,4*S*)-**1**)$_3$][PF$_6$]$_2$

$RuCl_3 \cdot 3H_2O$ (12.5 mg, 0.0478 mmol) was combined with (1*S*,2*R*,4*S*)-**1** (66.0 mg, 0.143 mmol) in ethane-1,2-diol (5 cm^3). After the addition of two drops of *N*-ethylmorpholine, the reaction mixture was heated in a microwave oven (440 W) for 4 min. Water (25 cm^3) was added to the mixture and the mixture was then filtered. The red product was precipitated from the filtrate by adding aqueous

NH_4PF_6, was extracted with CH_2Cl_2 (25 cm^3) and was washed with water (2×25 cm^3). Solvent was removed from the combined organic phases to yield [Ru((1*S*,2*R*,4*S*)-**1**)$_3$][PF_6]$_2$ as a dark red solid (35.4 mg, 0.0200 mmol, 41.8%). ^{1}H NMR (250 MHz, CH_3CN) δ/ppm 7.88 (d, $J = 2.4$ Hz, 6H, H^{A3}), 7.49 and 7.475 (two overlapping doublets, $J = 6.5$ Hz, 6H, H^{A6} diastereoisomers A + B), 6.87 (dd, $J = 6$, 2 Hz, 6H, H^{A5}), 4.59 (m, 6H, H^2), 2.51 (m, 6H, H^{3exo}), 2.15 (m, 6H, H^{6exo}), 1.80 (m, 12H, $H^{4,5exo}$), 1.44 (m, 6H, H^{5endo}), 1.22 (m, 6H, H^{6endo}), 1.03 (m, 6H, H^{3endo}), 0.99 (s, 9H, H^8 diastereoisomer A), 0.98 (s, 9H, H^8 diastereoisomer B), 0.95 (br s, 27H, H^9 diastereoisomers A + B, and H^{10} diastereoisomer A), 0.93 (s, 9H, H^{10} diastereoisomer B). ESMS (MeCN) *m*/*z* 1628 [M−PF_6]$^+$, 1085 [M−PF_6−4bornyl]$^+$. *Anal*. Calc. for $C_{90}H_{120}F_{12}N_6O_6P_2Ru$: C, 60.97; H, 6.82; N, 4.74. Found: C, 59.95; H, 6.63; N, 4.91%. E°/V versus Fc: +0.52, −2.18, −1.81, −1.48 (irrev).

2.5. [Ru((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$][PF_6]$_2$

[Ru(bpy)$_2$Cl$_2$] (0.10 g, 0.21 mmol) was combined with (1*S*,2*R*,4*S*)-**1** (95 mg, 0.21 mmol) in ethane-1,2-diol (10 cm^3). Two drops of *N*-ethylmorpholine were added, and then the mixture was heated in a microwave oven (400 W) for 4 min. After cooling to room temperature, aqueous NH_4PF_6 was added to the orange solution to precipitate the crude product. After column chromatography (silica, MeCN:H_2O:saturated aqueous KNO_3 7:0.5:0.75). [Ru((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$][PF_6]$_2$ was isolated as an orange-red solid which was recrystallized from MeCN/Et_2O (148 mg, 0.127 mmol, 61%). *Anal*. Calc. for $C_{50}H_{56}F_{12}N_6O_6P_2Ru \cdot 3H_2O$: C, 49.30; H, 5.13; N, 6.90. Found: C, 49.57; H, 5.05; N, 6.91%. ^{1}H NMR (600 MHz, CH_3CN) δ/ppm 8.48 (d, $J = 8.4$ Hz, 4H, H^{B3}) and 8.47 (d, $J = 8.4$ Hz, 4H, H^{C3}), 8.04 ($J = 7.8$, 1.2 Hz, 4H, H^{B4}), 8.01 ($J = 7.8$, 1.2 Hz, 4H, H^{C4}), 7.909 and 7.915 (two overlapping d, $J = 2.6$ Hz, 2H, H^{A3} diastereoisomers A + B), 7.84 and 7.83 (two overlapping ddd, $J = 5.6$, 1.3, 0.6 Hz, 2H, H^{B6} diastereoisomers A + B), 7.7 (ddd, $J = 5.6$, 1.3, 0.6 Hz, 2H, H^{C6}), 7.429 and 7.426 (two overlapping dt, $J = 5.6$, 1.2 Hz, 2H, H^{B5} diastereoisomers A + B), 7.373 and 7.369 (two overlapping d, $J = 6.6$ Hz, 2H, H^{A6} diastereoisomers A + B), 7.35 (dt, $J = 5.6$, 1.2 Hz, 2H, H^{C5}), 6.87 and 6.86 (two overlapping dd, $J = 6.6$, 2.6 Hz, 2H, H^{A5} diastereoisomers A + B), 4.58 (m, 2H, H^2), 2.51 (m, 2H, H^{3exo}), 2.15 (m, 2H, H^{6exo}), 1.83 (m, 2H, H^{5exo}), 1.78 (m, 2H, H^4), 1.44 (m, 2H, H^{5endo}), 1.21 (m, 2H, H^{6endo}), 1.05 (dd, $J = 13.4$, 3.1 Hz, 1H, H^{3endo} diastereoisomer A), 0.99 (dd, $J = 13.4$, 3.1 Hz, 1H, H^{3endo} diastereoisomer B), 0.98 (s, 3H, H^8 diastereoisomer A), 0.97 (s, 3H, H^8 diastereoisomer B), 0.95 (s, 3H, H^{10} diastereoisomer A), 0.94 (s, 6H, H^9 diastereoisomers A + B), 0.93 (s, 3H, H^{10} diastereoisomer B). 2.6. [Ru((1*R*,2*S*,4*R*)-**1**)(bpy)$_2$][PF_6]$_2$

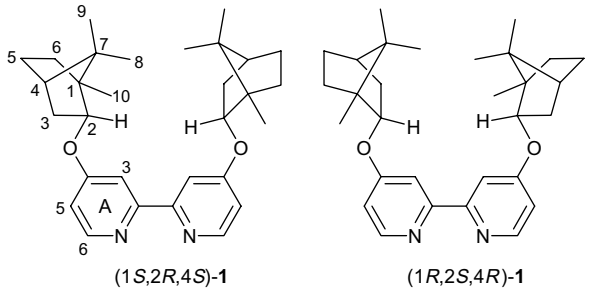
The preparation was as for [Ru((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$][PF_6]$_2$ and was on the same scale. [Ru((1*R*,2*S*,4*R*)-**1**)(bpy)$_2$][PF_6]$_2$ was isolated as a red solid (150 mg, 0.13 mmol, 62%). CD ($CDCl_3$, 298 K, 4.5×10^{-5} mol dm^{-3}, nm ($\Delta\varepsilon$)) 231 (3.6), 244 (0.98), 257 (1.9), 276 (−0.6), 294 (4.2).

2.7. Crystal structure determinations: general



Data were collected on an Enraf Nonius Kappa CCD instrument; data reduction, solution and refinement used the programmes COLLECT [46], SIR-92 [47] and CRYSTALS [48].

2.8. Crystal data for (1*S*,2*R*,4*S*)-**1**

$C_{30}H_{40}N_2O_2$, $M = 460.66$, monoclinic, space group $P2_1$, $a = 15.1961(5)$ Å, $b = 7.3277(2)$ Å, $c = 24.1388(7)$ Å, $\beta = 107.464(2)°$; $V = 2564.0(1)$ Å^3, $Z = 4$, $D^{calc} = 1.193$ Mg m^{-3}, μ(Mo Kα) = 0.074 mm^{-1}, $T = 173$ K, 6345 reflections collected. Refinement of 4908 reflections (613 parameters) with $I > 1.0\sigma(I)$) converged at final $R_1 = 0.0906$ (0.1123 all data), $wR_2 = 0.1166$ (0.1376 all data), goodness-of-fit = 1.036.

3. Results and discussion

Ligands (1*S*,2*R*,4*S*)-**1** and (1*R*,2*S*,4*R*)-**1** (Scheme 1) were prepared by the deprotonation of the (1*S*,2*R*,4*S*)-(−)-borneol or (1*R*,2*S*,4*R*)-(+)-borneol with NaH in DMF followed by subsequent reaction with 4,4′-dibromo-2,2′-bipyridine [44]. After purification, (1*S*,2*R*,4*S*)-**1** and

Scheme 1. Structures of ligands (1*S*,2*R*,4*S*)-**1** and (1*R*,2*S*,4*R*)-**1**, and labelling scheme for NMR spectroscopic data. Ligands are drawn in the configuration in which they bind to a metal centre.

(1*R*,2*S*,4*R*)-**1** were obtained as white crystalline solids in 63% and 47% yield, respectively, and were fully characterized by spectroscopic and mass spectrometric techniques and (1*S*,2*R*,4*S*)-**1** by single crystal X-ray diffraction. The highest mass peak in the electrospray mass spectrum of the ligand appeared at *m*/*z* 943 and corresponded to $[2M+Na]^+$. The parent ion was observed at *m*/*z* 461. Both the ^1H and ^{13}C NMR spectra of the chiral ligand (1*S*,2*R*,4*S*)-**1** were consistent with the formation of a symmetrically substituted ligand. The aromatic region of the ^1H NMR spectrum exhibited three signals with the characteristic coupling patterns of a 4,4′-disubstituted 2,2′-bipyridine. Proton H^2 (see Scheme 1) appeared in the ^1H NMR spectrum at δ 4.52 ppm, well separated from the signals for the remaining bornyl protons. The ^{13}C and ^1H NMR spectra of **1** were assigned by use of COSY, HMQC and HMBC techniques, and the proton assignments were consistent with those reported for 6-{(1*S*,2*R*,4*S*)-(−)-bornyloxy}-2,2′:6′,2″-terpyridine [40]. Fig. 1 shows the CD spectra of acetonitrile solutions of (1*S*,2*R*,4*S*)-**1** and (1*R*,2*S*,4*R*)-**1**, and confirms their optical purity. Crystals (colourless plates) of (1*S*,2*R*,4*S*)-**1** suitable for X-ray diffraction were grown from an MeCN solution of (1*S*,2*R*,4*S*)-**1** layered with Et_2O. There are two crystallographically independent molecules of (1*S*,2*R*,4*S*)-**1** in the asymmetric unit, and their structures are depicted in Fig. 2a. Most bond distances and angles are unexceptional, and only selected bond parameters are listed in the figure caption. It is worth noting that the C–O–C bond angles of ≈118°, and the fact that the $C_{pyridyl}$–O is shorter than the C_{bornyl}–O bond, indicate that each O atom is sp^2 hybridized and that there is delocalization of π-electrons over each pyridyl–O unit. In both molecules, the two pyridine rings of the bpy unit are slightly twisted with respect to one another (angles between the least squares planes of the rings containing N1 and N2, and N3 and N4 are 11.7(3)° and 15.5(3)°, respectively). The most marked difference between the two independent molecules of

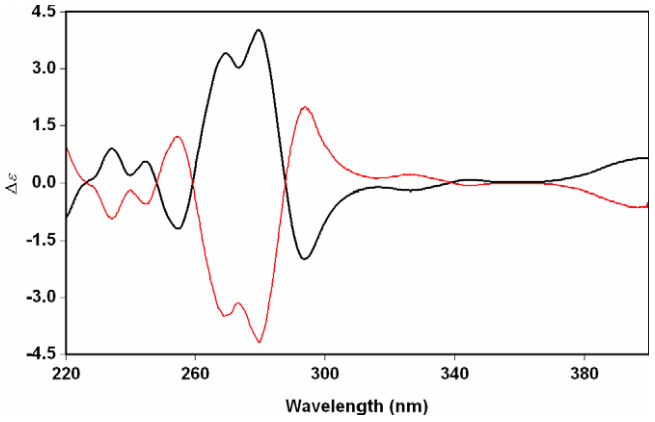


Fig. 1. CD spectra of (1*S*,2*R*,4*S*)-**1** (red line, with minimum at negative Δε) and (1*R*,2*S*,4*R*)-**1** (black line, with maximum at positive Δε) in MeCN solution at 298 K.

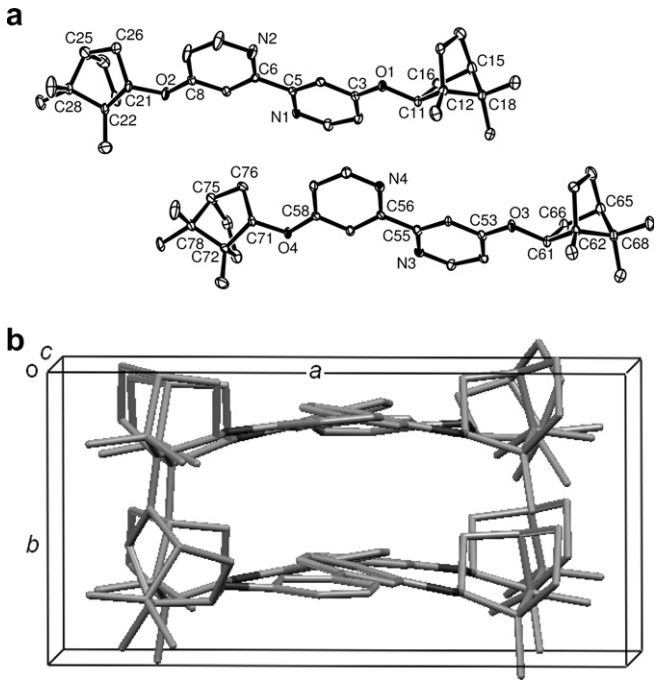

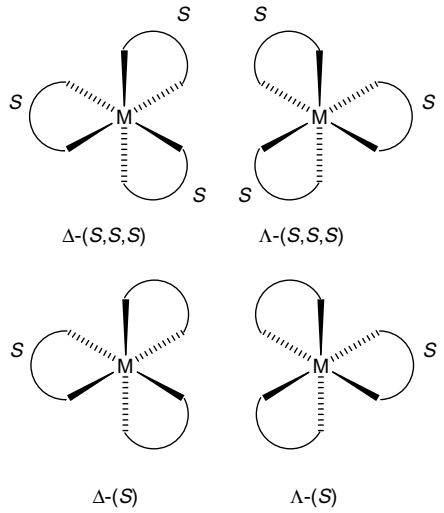

Fig. 2. (a) Molecular structure of compound (1*S*,2*R*,4*S*)-**1** with thermal ellipsoids plotted at 30% probability level. Selected bond lengths (Å) and angles (°): O1–C3 = 1.351(5), O1–C11 = 1.436(5), O2–C8 = 1.345(5), O2–C21 = 1.449(5), O3–C53 = 1.352(5), O3–C61 = 1.438(5), O4–C58 = 1.352(5), O4–C71 = 1.423(5), C5–C6 = 1.493(6), C55–C56 = 1.484(6); C3–O1–C11 = 118.7(3), C8–O2–C21 = 118.6(3), C53–O3–C61 = 118.5(3), C58–O4–C71 = 118.5(3). (b) Packing of four molecules of (1*S*,2*R*,4*S*)-**1** in the unit cell.

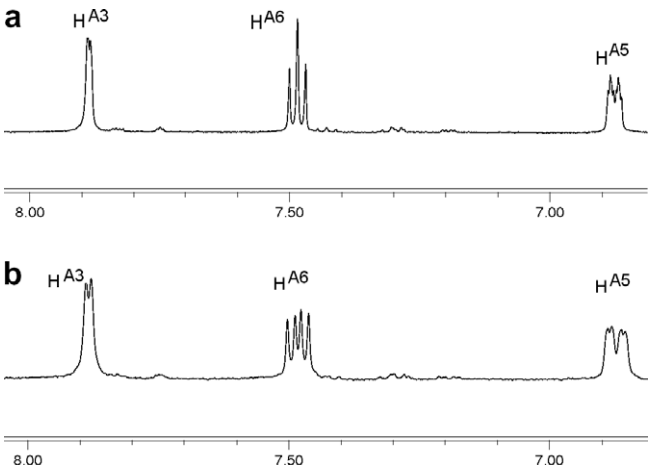
(1*S*,2*R*,4*S*)-**1** lies in the orientation of the bornyl substituents with respect to the pyridine ring to which they are attached. In one molecule, the angles between the least squares planes of the pyridine ring containing N1 and the plane defined by atoms C12, C11, C16 and C15 is 57.4(3)° whereas that of the pyridine ring containing N2 and the plane defined by atoms C22, C21, C26 and C25 is 49.2(4)°. In the second molecule, the corresponding angles are 56.8(3)° and 61.8(3)° for rings containing N3 and N4, respectively. Molecules of (1*S*,2*R*,4*S*)-**1** pack in rows running parallel to the *c* axis and this results in domains of bpy units, between which lie two adjacent domains of bornyl substituents (Fig. 2b). There is no face-to-face π–π stacking between bpy units.

With the enantiomerically pure ligands in hand, our next aim was to prepare a series of tris-chelate octahedral metal(II) complexes in order to investigate whether there was any preference for the formation of diastereoisomers with Δ- or Λ-stereochemistry at the metal centre. Scheme 2 shows the types of complexes studied, exemplified by $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$, $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ and $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$. The complex $[Ru((1R,2S,4R)\text{-}\mathbf{1})(bpy)_2]^{2+}$ has also been studied. $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3][PF_6]_2$ was prepared by the reaction of (1*S*,2*R*,4*S*)-**1** with $FeCl_2 \cdot 4H_2O$ in methanol, and was isolated in good yield as a purple solid. The highest mass peak in the electrospray

Scheme 2. Formation of diastereoisomeric pairs of tris-chelate complexes of type $[M((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ and $[M((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$. For simplicity, the labels define the stereoechemistry at C1 only, e.g. Δ-(*S*,*S*,*S*) corresponds to three (1*S*,2*R*,4*S*)-**1** ligands, and so on.

mass spectrum of a sample injected as an acetonitrile solution was observed at *m*/*z* 1520 and corresponded to $[M-PF_6+2MeCN]^+$. The appearance of the 500 MHz ^1H NMR spectrum of the product confirmed the formation of a symmetrical species. Three signals were observed in the aromatic region at δ 7.94, 7.17 and 6.76 ppm assigned to protons H^{A3}, H^{A5} and H^{A6}, respectively (see Scheme 1). These chemical shifts are characteristic of a coordinated ligand and support the formation of $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$. Significantly, the signal for H^{A6} appeared as an apparent triplet ($J = 7$ Hz) instead of the expected doublet ($J \approx 7$ Hz), while the signal for H^{A5} was broader than expected. These observations can be rationalized if the Δ-(*S*,*S*,*S*) and Λ-(*S*,*S*,*S*) diastereoisomers (Scheme 2) are formed in equal amounts and are distinguishable in the ^1H NMR spectrum, i.e. two overlapping doublets of equal integrals are observed for H^{A6}. In contrast, it is not possible to distinguish the diastereoisomers of $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ using protons H^{A3} and H^{A5} as probes at 500 MHz. The proton signals for the bornyl substituent were assigned using COSY and NOESY techniques. The signal for the H^{3endo} protons is informative. It appears as a pair of doublets of doublets ($J = 13.5$, 2.1 Hz), one part of which is partly obscured by a bornyl methyl signal. The splitting of the H^{3endo} signal is consistent with the H^{3endo} protons in the two diastereoisomers of $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ sensing the presence of the chiral metal centre. The ^1H NMR signals that provide the best indicator of the ratio of diastereoisomers present are the bornyl methyl resonances. Four signals are observed at δ 0.99, 0.98, 0.95 and 0.93 ppm with relative integrals of 9:9:27:9. Use of the NOESY technique permits these signals to be assigned to H^8, H^8, H^{9+10} and H^{10} of the two diastereoisomers, respectively. Thus, the methyl groups (H^8 and H^{10}) which face the stereogenic metal centre sense its presence, whereas the protons H^9 of the remaining methyl group do not. The relative integrals of these signals are consistent with there being no preference for the formation of Δ- or Λ-diastereoisomers of $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$. Even though the complex cation $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ contains 19 stereogenic centres, 18 of which are defined, the chiral auxiliaries appear to be too distant to exert any stereocontrol over the configuration at the metal centre.

The influence of the group 8 metal ion was then investigated: specifically, we were interested in the change from iron(II) which is sufficiently labile to lead to thermodynamic products to ruthenium(II) which is kinetically inert and will give kinetic products. The complex $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ was prepared by treating $RuCl_3 \cdot 3H_2O$ with (1*S*,2*R*,4*S*)-**1** in ethane-1,2-diol in the presence of *N*-ethylmorpholine under microwave heating conditions. The product was isolated as the red hexafluorophosphate salt in 42% yield. In the electrospray mass spectrum, the highest mass peak (*m*/*z* 1628) corresponded to $[M-PF_6]^+$. NMR spectra for ruthenium(II) complexes are typically sharper than those of the analogous iron(II) species in which paramagnetic impurities tend to broaden the signals. Hence, a detailed study of the ^1H NMR spectrum of $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ was made. The ^1H NMR spectrum of a CD_3CN solution of $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3][PF_6]_2$ was recorded at both 400 and 250 MHz. A comparison of the aromatic regions of these spectra (Fig. 3a, 400 MHz, and Fig. 3b, 250 MHz) allows them to be analysed as a doublet (δ 7.88 ppm, $J = 2.4$ Hz) assigned to H^{A3}, a pair of overlapping doublets (δ 7.49 and 7.475 ppm, each $J = 6.5$ Hz, relative integrals $\approx$ 1:1) assigned to H^{A6}, and a pair of overlapping doublets of doublets (centred at δ 6.88, $J = 6$, 2 Hz) arising from H^{A5}. This is consistent with the presence of approximately equal amounts of Δ-(*S*,*S*,*S*) and Λ-(*S*,*S*,*S*) diastereoisomers of $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$. At 400 and 250 MHz, the H^{A6} protons in particular can be used as a probe for the stereogenic



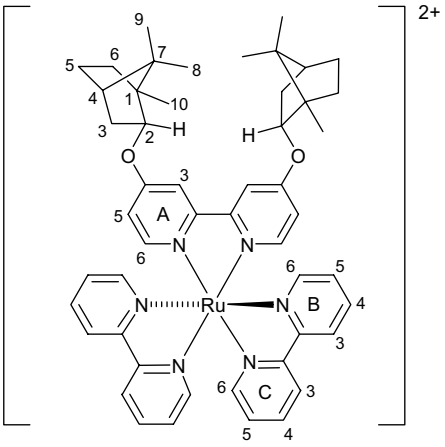


Fig. 3. The aromatic region of the ^1H NMR spectrum of $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3][PF_6]_2$ in CD_3CN at (a) 400 MHz and (b) 250 MHz (chemical shifts are in δ/ppm). See Scheme 1 for atom labelling.

metal centre. The remaining resonances in the ^{1}H NMR spectrum were assigned to the bornyl protons by analogy with the spectrum of $[Fe((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$. Among these signals, the clearest evidence for the approximately 1:1 mixture of diastereoisomers comes from the resonances arising from the methyl protons. These appear as four signals (δ 0.99, 0.98, 0.95 and 0.93 ppm) with relative integrals of 9:9:27:9 arising from the splitting of signals for the methyl groups containing H^8 and H^{10} in the two diastereoisomers. Thus, the formation of $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ occurs without diastereoisomeric discrimination.

Since the formation of the homoleptic tris-chelate complexes $[M((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ (M = Fe or Ru) showed no preference for either Δ-(*S*,*S*,*S*) or Λ-(*S*,*S*,*S*) diastereoisomer, we turned our attention to the heteroleptic complexes $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$ and $[Ru((1R,2S,4R)\text{-}\mathbf{1})(bpy)_2]^{2+}$. These were prepared by treatment of $[Ru(bpy)_2Cl_2]$ with (1*S*,2*R*,4*S*)-**1** or (1*R*,2*S*,4*R*)-**1** in ethane-1,2-diol in the presence of a small amount of the reductant *N*-ethylmorpholine under microwave heating conditions. After purification, the red-orange hexafluorophosphate salts were isolated in ≈60% yield. The number and pattern of signals observed in the ^{1}H NMR spectra of CD_3CN solutions of the two complexes confirmed the presence of coordinated bpy and (1*S*,2*R*,4*S*)-**1** or (1*R*,2*S*,4*R*)-**1** ligands in a 2:1 ratio. The most informative ^{1}H NMR spectrum was that recorded for $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2][PF_6]_2$ at 600 MHz. The ring and atom labelling are shown in Scheme 3, and signals were fully assigned by use of COSY and NOESY techniques. For protons H^{A6}, a pair of overlapping doublets ($J = 6.6$ Hz), reminiscent of those in $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$, was observed confirming the presence of both Δ-(*S*) and Λ-(*S*)-diastereoisomers (see Scheme 2) of $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$. In the 600 MHz ^{1}H NMR spectrum, the signals for H^{A3} and H^{A5} also split and are observed as overlapping doublets ($J = 2.6$ Hz) and overlapping doublets of doublets ($J = 6.6$ and 2.6 Hz), respectively. The two pyridine rings in each bpy ligand are inequivalent (Scheme 3). Approximate inter-ligand H···H separations were determined from an optimized molecular model [49] of $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$. The closest contact is between H^{A6} and H^{B6} (≈3.4 Å) with the separation of H^{A6} and H^{C6} being significantly longer (≈4.8 Å). In the NOESY spectrum, it is therefore possible to distinguish between protons H^{B6} and H^{C6}. Other assignments for the aromatic protons then follow from the COSY (Fig. 4) spectrum. The signals for the protons H^{C6} and H^{B6} are shown in Fig. 5a. Whereas the former appears as the expected doublet of doublets of doublets ($J_{B6-B5} = 5.6$, $J_{B6-B4} = 1.3$, $J_{B6-B3} = 0.6$ Hz), the latter signal responds to the presence of the Δ-(*S*) and Λ-(*S*)-diastereoisomers. This is consistent with H^{B6} being the closest bpy proton to the stereogenic ruthenium(II) centre. In the bornyl region of the ^{1}H NMR spectrum, the H^{3endo} and methyl resonances (Fig. 5b) are the best indicators of the presence of an approximately 1:1 mixture of Δ-(*S*) and Λ-(*S*)-diastereoisomers. For example, the H^{3endo} protons give rise to two doublets of doublets, each with $J = 13.4$ and 3.1 Hz; one part of one of these signals is hidden under one of the methyl resonances (Fig. 5b), but its presence is readily confirmed from the COSY spectrum (Fig. 6).

The electrochemical properties of $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ and $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$ were investigated using cyclic voltammetry and differential pulse voltammetry (DPV). The Ru(II) centre undergoes a well-defined one-electron oxidation at +0.52 V (versus Fc^+/Fc) in $[Ru((1S,2R,4S)\text{-}\mathbf{1})_3]^{2+}$ and +0.76 V in $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$. This compares with +0.88 V in $[Ru(bpy)_3]^{2+}$ [50,51]. Thus, the replacement of a bpy ligand in $[Ru(bpy)_3]^{2+}$ by (1*S*,2*R*,4*S*)-**1** results in a 0.12 V shift per ligand to less positive potential, and this trend illustrates the increasing ease of oxidation of the Ru(II) centre and stabilization of the Ru(III) oxidation state as bpy ligands are replaced by more electron-releasing ligands. This is consistent with the Hammett σ-parameter [52,53] for a

$[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$

Scheme 3. $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2]^{2+}$ with ring and atom labelling for the NMR spectra.

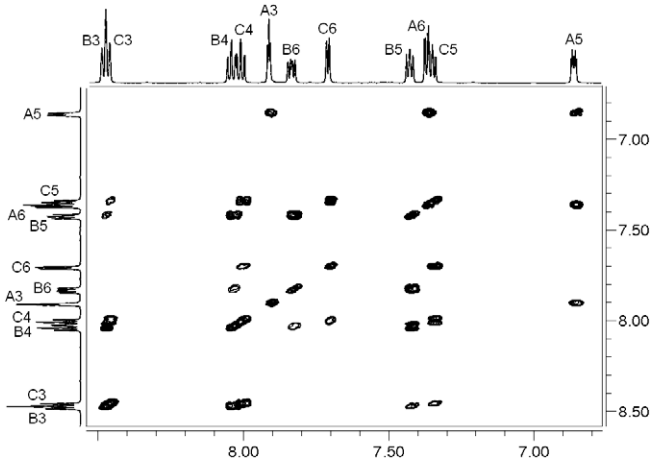

Fig. 4. 600 MHz ^{1}H COSY spectrum of the aromatic region for $[Ru((1S,2R,4S)\text{-}\mathbf{1})(bpy)_2][PF_6]_2$ (in CD_3CN); chemical shifts in δ/ppm.

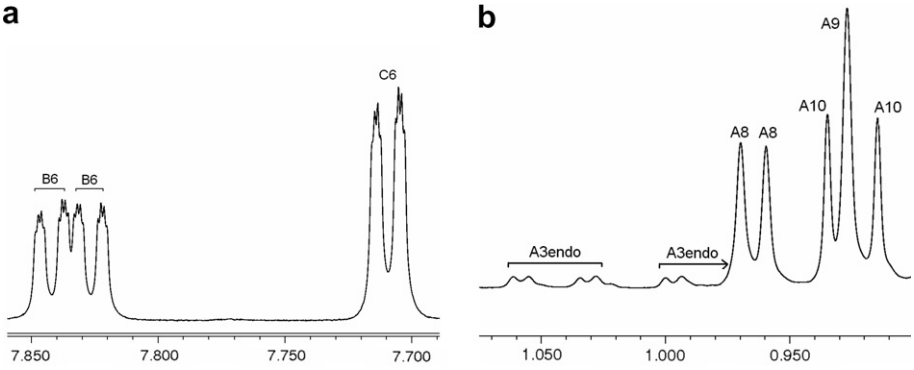

Fig. 5. (a) Part of the 600 MHz ^{1}H spectrum of [Ru((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$][PF$_6$]$_2$ (in CD$_3$CN) showing the signals (δ/ppm) for the H^6 bpy protons (see Scheme 3). (b) Part of the 500 MHz ^{1}H spectrum of [Ru((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$][PF$_6$]$_2$ (in CD$_3$CN) showing the signals (δ/ppm) for the bornyl methyl and H^{3endo} protons of coordinated ((1*S*,2*R*,4*S*)-**1**).

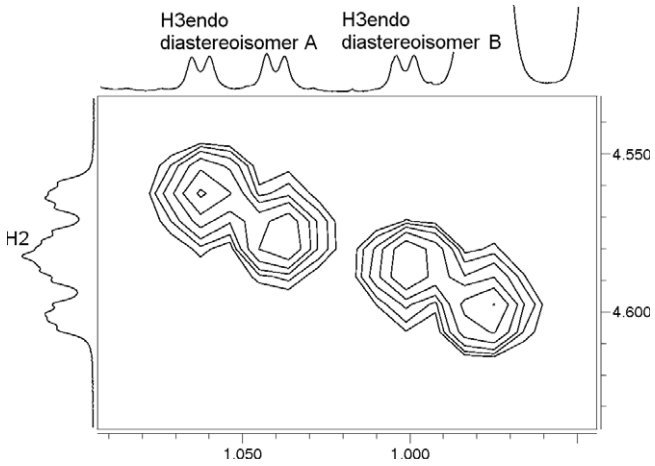

Fig. 6. Part of the 600 MHz ^{1}H COSY spectrum of [Ru((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$][PF$_6$]$_2$ (in CD$_3$CN, chemical shifts in δ/ppm) showing the cross peaks for the bornyl H^2/H^{3endo} proton correlation.

para-alkoxy substituent (which is expected to have a value of about −0.3) and with our earlier observations that the redox potentials in these heteroleptic systems are described by simple additive models [54–59]. Each complex undergoes ligand-centred reduction processes. For [Ru((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$]$^{2+}$, three reversible reductions at −2.23, −2.00 and −1.80 V compare with reduction potentials of −2.17, −1.96 and −1.72 V for [Ru(bpy)$_3$]$^{2+}$ [50,51]. For [Ru((1*S*,2*R*,4*S*)-**1**)$_3$]$^{2+}$, only reversible process is clearly resolved (−1.80 V).

4. Conclusions

We have prepared and fully characterized enantiomers of a 4,4′-disubstitued 2,2′-bipyridine ligand containing chiral auxiliaries. The enantiomerically pure ligands have been incorporated into homoleptic and heteroleptic complexes of type [M((1*S*,2*R*,4*S*)-**1**)$_3$]$^{2+}$ (M = Fe, Ru), [M((1*S*,2*R*,4*S*)-**1**)(bpy)$_2$]$^{2+}$ (M = Fe, Ru) and [Ru((1*R*,2*S*,4*R*)-**1**)(bpy)$_2$]$^{2+}$. ^{1}H NMR spectroscopy has been used to distinguish between the Δ and Λ-diastereoisomers of each complex. Even though complexes with up to 18 defined stereogenic centres have been prepared, no diastereoisomeric selectivity at the metal centre has been observed.

Acknowledgements

We thank the Swiss National Science Foundation and the University of Basel for general financial support and for funds enabling the purchase of a CD spectrometer under the R'Equip programme. Dr. Daniel Häussinger is thanked for recording 600 MHz ^{1}H NMR spectra, and Emma Dunphy is acknowledged for recording CD spectra.

Appendix A. Supplementary material

CCDC 651584 contains the supplementary crystallographic data including atomic coordinates, bond distances and angles for (1*S*,2*R*,4*S*)-**1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.026.

agents, those of ruthenium appear as the most promising [9], and several types of its complexes have shown high anticancer activity [10]. Substantial activity has been shown by ruthenium(II) complexes stabilized with heteroaromatic ligands, such as *cis*-[$RuCl_2(azpy)_2$] (azpy = 2-(phenylazo)pyridine) [11].

In this paper we describe the synthesis and characterization of new ruthenium(II) complexes, containing substituted quinolinediones acting as (N–O) bidentate ligands, of the type [$Ru(CO)_2Cl_2$(N–O)]. The molecular structure of [$Ru(CO)_2Cl_2$(6-methoxybenzo[*g*]quinoline-5,10-dione)] is determined by single-crystal X-ray diffraction. The electrochemical properties and the potential antitumor activities of the free ligands and ruthenium complexes are also studied.

2. Experimental

2.1. General

The ligand 4,6-dichloroquinoline-5,8-dione (**1**) was synthesized according to a literature procedure [12]. Tricarbonyldichlororuthenium(II) dimer was purchased from Aldrich and solvents (reagent grade) from Merck; both were used without further purification. Elemental analyses (C, H, N) were carried out by a Fisons EA 1108 CHNS-O microanalyzer. FTIR spectra were recorded throughout the 4000–250 cm^{-1} region, with samples prepared as KBr discs on a Bruker Vector-22 spectrophotometer. The NMR spectra were recorded on a Bruker AC-200P and Avance-400 spectrometers and the chemical shifts are reported in ppm relative to $SiMe_4$. Column chromatography was performed on silica gel Merck 60 (70–230 mesh). Thin layer chromatography separations were carried out on Merck Kieselgel 60 (70–230 mesh).

2.2. Synthesis of 6-methoxybenzo[g]quinoline-5,10-dione (*2*)

To a solution of 5-methoxynaphthalene-1,4-dione [13] (203.4 mg, 1.081 mmol) in dichloromethane (20 mL) azadiene [14] (259 mg, 2.64 mmol) was added. After stirring the reaction mixture at room temperature for 7 days silica gel was added (1 g) and the mixture stirred again for 24 h. Chloranil (800 mg. 3.24 mmol) was added and the mixture was heated at reflux for 5 h. The resulting suspension was poured into an aqueous sodium bicarbonate solution (5%) and extracted with dichloromethane (3 × 50 mL). The organic layer was washed with water and dried with magnesium sulphate. The solution was evaporated to dryness to give a solid residue, which was purified by chromatography on silica gel using a mixture of dichloromethane-ethyl acetate (8:2) as eluent. Evaporation of solvents gave a yellow solid, which was crystallized from ethanol. Yield 115 mg (45%), m.p. 218–218.5 °C (lit. [15] m.p. 218–219 °C). IR (KBr) ν cm^{-1}: 1656 (C═O). ^{1}H NMR ($CDCl_3$, 295 K): δ 4.08 (s, 3H, MeO), 7.42 (dd, 1H, $J = 1.0$ Hz, $J = 8.0$ Hz, H_7), 7.72 (dd, 1H, $J = 4.6$ Hz, $J = 8.0$ Hz, H_3), 7.79 (dd, 1H, $J = 8.0$ Hz, $J = 8.0$ Hz, H_8), 8.06 (dd, 1H, $J = 1.0$ Hz, $J = 8.0$ Hz, H_9), 8.62 (dd, 1H, $J = 1.6$ Hz, $J = 8.0$ Hz, H_4), 9.06 (dd, 1H, $J = 1.6$ Hz, $J = 4.6$ Hz, H_2). ^{13}C NMR ($CDCl_3$, 295 K): δ 56.6, 118.4, 120.5, 128.1, 131.8, 135.4, 135.6, 147.8, 154.4, 160.5, 181.6, 182.0.

2.3. General procedure for the synthesis of ruthenium(II) complexes (*3*, *4*)

A solution of tricarbonyldichlororuthenium(II) dimer (0.22 mmol) and quinolinedione ligands (**1**, **2**) (0.44 mmol) was heated under reflux in dry ethanol (5 mL). The reaction was monitored by thin layer chromatography. During the reaction time, 30–40 min, a solid complex was formed. The crude solid was filtered off and washed with ethanol.

2.3.1. [$Ru(CO)_2Cl_2$(4,6-dichloroquinoline-5,8-dione)] (*3*)

The complex was obtained by re-crystallization of the crude solid from warm ethanol. Red crystals, yield 35 mg (18%), m.p. >300 °C. *Anal.* Calc. for $C_{11}H_3Cl_4NO_4Ru$ required: C, 29.0; H, 0.7; N, 3.1. Found: C, 28.9; H, 1.0; N, 3.3%. IR (KBr) ν cm^{-1}: 2062 vs, 1992 vs (CO); 1696 s (C═O); 329 m (Ru–Cl). ^{1}H NMR (acetone-d_6, 295 K); δ 5.92 (s, 1H, H_4), 7.92 (d, 1H, $J = 6.0$ Hz, H_3), 9.06 (d, 1H, $J = 6.0$ Hz, H_2). ^{13}C NMR (acetone-d_6, 295 K); δ 125.4, 130.1, 145.6, 154.0, 157.1, 170.0, 173.9, 180.1, 180.2, 197.2 (CO), 197.9 (CO).

2.3.2. [$Ru(CO)_2Cl_2$(6-methoxybenzo[g]quinoline-5,10-dione)] (*4*)

Purified by column chromatography using a dichloromethane-ethyl acetate (1:1) mixture as eluent. Wine-red solid, yield 70 mg (34%). M.p. >300 °C. *Anal.* Calc. for $C_{16}H_9Cl_2NO_5Ru$ required: C, 41.1; H, 1.9; N, 3.0. Found: C, 40.6; H, 1.4; N, 3.1%. IR (KBr) ν cm^{-1}: 2074 vs, 2016 vs (CO); 1671 s (C═O); 343 m (Ru–Cl). ^{1}H NMR ($CDCl_3$, 295 K); δ 4.15 (s, 3H, MeO), 7.67 (dd, 1H, $J = 7.7$, H_7), 7.95 (dd, 1H, $J = 7.95$ Hz, H_8), 8.12 (dd, 1H, $J = 5.3$ Hz, $J = 8.1$ Hz, H_3), 8.30 (dd, 1H, $J = 0.8$ Hz, $J = 7.7$ Hz, H_9), 8.86 (dd, 1H, $J = 1.3$ Hz, $J = 8.1$ Hz, H_4), 9.34 (dd, 1H, $J = 1.3$ Hz, $J = 5.3$ Hz, H_2). ^{13}C NMR ($CDCl_3$, 295 K): δ 56.5, 121.7, 124.0, 128.7, 131.0, 132.5, 133.4, 135.4, 136.5, 137.8, 156.1, 160.8, 181.8, 182.2, 194.9 (CO), 196.7 (CO).

2.4. X-ray crystallography

Suitable red crystals for the X-ray study were obtained by letting a saturated ethanol solution of complex **4** stand at room temperature. A summary of crystal data and refinement parameters is reported in Table 1. Data were obtained at 100(1) K from a Bruker SMART CCD area detector diffractometer equipped with graphite-monochromated Mo-Kα radiation ($\lambda = 0.71073$ Å) using narrow frames. The SMART program package was used for data

Table 1
Crystal data and structure refinement parameters for complex **4**

Empirical formula	$C_{16}H_9Cl_2NO_5Ru$
Formula weight	467.21
Crystal system, space group	monoclinic, $P2_1/n$
a (Å)	6.1204(6)
b (Å)	13.0328(14)
c (Å)	21.172(2)
β °)	94.081(2)
V (Å^3), Z	1684.5(3), 4
D_{calc} (Mg m^{-3})	1.842
Absorption coefficient (mm^{-1})	1.275
Crystal size (mm)	$0.31 \times 0.04 \times 0.04$
Maximum and minimum transmission factor	0.951–0.692
θ Range for data collection (°)	1.84–28.85
Reflections collected	11098
Independent reflections	4038 ($R_{int} = 0.049$)
Data/restraints/parameters	4038/0/262
Goodness-of-fit on F^2	1.113
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0525$, $wR_2 = 0.0911$
R indices (all data)	$R_1 = 0.0753$, $wR_2 = 0.0975$
Largest difference in peak and hole (e Å^{-3})	0.873 and −0.802

collection [16a]. The raw frame data were processed using SAINT [16b] and SADABS [16c]. Subsequent calculations were carried out using the SHELXTL program [16d]. The structure was solved by direct methods and refined on F^2 by full-matrix least-squares techniques. All non-hydrogen atoms were refined with isotropic and subsequent anisotropic displacement parameters. Hydrogen atoms were included in observed positions and refined as free isotropic atoms.

2.5. Electrochemical measurements

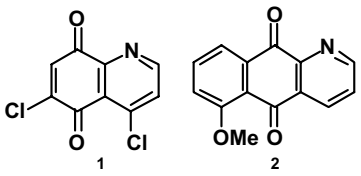
Cyclic voltammograms of ligands and complexes were obtained on a Bioanalytical Systems BAS CV-50W electrochemical analyzer. A small capacity measuring cell was equipped with a platinum disc as working electrode, a Ag/10 mM Ag^+ (CH_3CN) reference electrode for nonaqueous solvent, with a platinum wire auxiliary electrode, a mechanical mini-stirrer, and a capillary to supply an inert atmosphere with argon. A 0.1 M solution of tetrabutylammonium tetrafluoroborate in acetonitrile was used as supporting electrolyte.

2.6. Cell culture

The human leukemia cells line (HL-60) was purchased from ATCC (Rockville, USA). The cells were cultivated at 37 °C, 10% CO_2, 100% humidity in Dulbecco's modified Eagle's medium (DME), enriched with glucose and supplemented with 10% fetal bovine serum, non-essential amino acids, antibiotics (penicillin/streptomycin) and antifungals.

2.7. Cytotoxic assay

Small unilamellar liposomes of compounds **1**–**4** (12 μM) were prepared using the injection method described by Kremer et al. [17]. Typically, 0.126 mmol of compound was dissolved in 0.5 mL of ethanol solution (DPPC/ethanol = 10 mg/mL; DPPC, dipalmitoylphosphatidylcholine), which after homogenization was injected over 10 mL of DME with vigorous stirring at 55 °C.



Growth inhibitory effect toward HL-60 cell line was determined by means of MTT colorimetric assay [18]. The cells were seeded into 24-well plates at 4×10^5 cells/well and 0.833 mL (12 μM) of the above solution was added. Culture medium (DME) was added until completion of 1 mL and the final concentration in each well was 10 μM. Triplicate cultures were established for all compounds and for the control drugs. The mixture was incubated at 37 °C in a humid atmosphere containing 10% CO_2 for 24 h. Cell viability was quantified after 0, 4 and 24 h by the MTT method.

3. Results and discussion

3.1. Synthesis and characterization

4,6-Chloroquinoline-5,8-dione (**1**) was prepared according to a reported synthetic method [12]. 6-Methoxybenzo[*g*]quinoline-5,10-dione (**2**) was synthesized through a Diels-Alder reaction of 5-methoxynaphthalene-1,4-dione with azadiene in dichloromethane (7 days, rt); subsequent aromatization with silica gel and chloranil gave compound **2** in 45% yield (Scheme 1).

The dimer complex $[\{Ru(CO)_3Cl_2\}_2]$ reacts in a 1:2 molar ratio with the quinolinedione ligands (**1**, **2**) in refluxing ethanol by cleavage of the chloride bridges, to give neutral mononuclear complexes of the type $[Ru(CO)_2Cl_2(N–O)]$, where N–O = 4,6-dichloroquinoline-5,8-dione (**3**) and 6-methoxybenzo[*g*]quinoline-5,10-dione (**4**). The complexes were isolated as red solids, stable in air at room temperature, and characterized by elemental analysis and NMR and IR spectroscopy. The ^{1}H NMR spectra of the complexes show very slight variations in the positions of the proton resonances of the coordinate quinolinedione ligands with respect to the free ligands. These resonances were assigned with the aid of COSY experiments and by comparison with known values for similar compounds [9,10]. The ^{13}C NMR spectra show the carbon signals of the carbonyl groups in the δ 94–198 ppm range. Their solid-state infrared spectra in KBr pellets show two strong ν(CO) vibrations in the 1990–2070 cm^{-1} range, which indicates that the carbonyl ligands are in a *cis* arrangement, together with the characteristic absorptions assigned to the quinonic

Scheme 1.

ν(C=O) and ν(Ru–Cl). Since the chloride ligands can be mutually *trans* or *cis*, two isomers with a *cis*(CO)*cis*Cl arrangement – due to the asymmetric nature of the dione ligand – or one isomer with a *cis*(CO)*cis*Cl arrangement could be expected.

To obtain an unambiguous characterization an X-ray structural determination of complex **4** was undertaken. Fig. 1 displays a molecular diagram of the complex together with the atom-numbering scheme. The most relevant bond distances and bond angles are collected in Table 2. In the complex, the ruthenium atom shows a distorted octahedral co-ordination sphere with two carbonyl groups bonded to the metal centre in relative *cis* positions [C(1)–Ru–C(2) 88.30(2)°], and two chloride atoms linked in a *trans* disposition [Cl(1)–Ru–Cl(2) 173.86(4)°]. The coordination sphere is completed with the chelating 6-methoxybenzo[*g*]quinoline-5,10-dione ligand bonded to the metal through the nitrogen and oxygen atoms, [C(1)–Ru–O(3) 174.82(17) and C(2)–Ru–N 173.77(17)°]. The quinolinedione ligand is roughly planar and is inclined 7.24(10)° with respect to the equatorial plane of the complex.

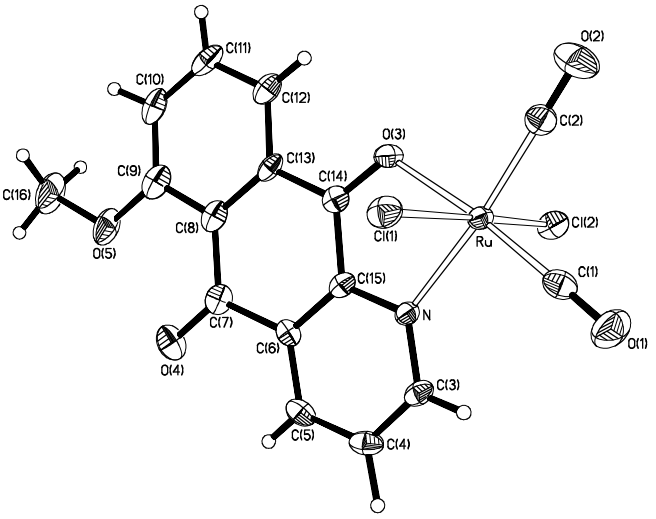


Fig. 1. Molecular structure of complex **4** with the labelling scheme used.

Cl(1)–Ru–C(1)	91.76(15)	O(3)–Ru–C(2)	96.52(17)
Cl(1)–Ru–C(2)	91.08(15)	N–Ru–C(1)	97.83(17)
Cl(2)–Ru–O(3)	88.69(9)	N–Ru–C(2)	173.77(17)
Cl(2)–Ru–N	87.38(10)	C(1)–Ru–C(2)	88.30(2)
Cl(2)–Ru–C(1)	92.83(15)		
Ru–O(3)–C(14)	114.9(3)	Ru–N–C(15)	112.9(3)
Ru–C(1)–O(1)	178.9(5)	Ru–C(2)–O(2)	178.8(5)

The Ru–N [2.123(4) Å], Ru–Cl [2.3819(12) and 2.3827(12) Å] and Ru–C [1.844(5) and 1.897(5) Å] distances compare well to those found in the related ruthenium complexes *trans*(Cl)-[Ru(CO)$_2$Cl$_2$(4,4′-dimethyl-2,2′-bipyridine)] [1b] [Ru–N, average 2.1235(7); Ru–Cl *av.* 2.3975(2); Ru–C *av.* 1.8725(10) Å] and *cis*-[Ru(6,6′-dimethoxicarbonyl-2,2′-bipyridine)(CO)$_2$Cl$_2$] [7] [Ru–N, average 2.1367(14); Ru–Cl *av.* 2.41515(7); Ru–C *av.* 1.897(2) Å]. As expected, the CO quinone group bonded to the metal centre shows a larger C–O distance [1.242(5) Å] than that of the free CO [1.214(5) Å]. The Ru–O bond distance [2.123(3) Å] is identical to that of the Ru–N bond length. The mean carbonyl distances [C–O, average 1.1205(6) Å] are similar to those found in the above-mentioned ruthenium(II) complexes.

3.2. Redox behaviour

The electrochemical properties of the ligands and their ruthenium complexes were studied using acetonitrile as solvent and tetrabutylammonium tetrafluoroborate as the supporting electrolyte. Cyclic voltammograms (CV) show similar chemical redox behaviour for the free ligands. The voltammograms show two quasi-reversible electrochemical reactions [**1**: $E_{1/2} = -0.72$ ($\Delta E = 0.20$) and $E_{1/2} = -1.46$ ($\Delta E = 0.36$) V. **2** (Fig. 2A): $E_{1/2} = -0.96$ ($\Delta E = 0.98$, peak a/a') and $E_{1/2} = -1.37$ ($\Delta E = 0.12$, peak b/b') V] that correspond to the formation of semiquinolinedione $(N–O)^-$ and the dianion $(N–O)^{2-}$, respectively. Moreover, compound **2** shows a quasi-reversible oxidation maximum at $E_{1/2} = 0.84$ ($\Delta E = 0.36$, peak c/c') V that corresponds of the redox reaction of the methoxy group. The i_{pa}/i_{pc} ratio is ≈1 for the two systems, indicating that the electrogenerated semiquinolinedione and dianionic compounds are stable in acetonitrile medium.

In the CV of ruthenium complexes the Ru(II)/Ru(III) peaks were not observed. Complex **3** is slightly unstable in acetonitrile and the CV shows only the peaks of free quinolinquinone (**1**) and free chloride. Complex **4** (Fig. 2B) shows two reversible redox pairs at $E_{1/2} = -0.42$ ($\Delta E = 0.65$, peak a/a') V and $E_{1/2} = -1.20$ ($\Delta E = 0.60$, peak b/b') V. The positive potential displacement of the peaks a/a' and b/b' respect to the free ligand is in accordance with the reduction of coordinated quinolinquinone ligand in the complex. The oxidation maximum of 1.66 V (peak c) corresponds to the redox reaction of the –OMe group in the complex, while for the respective free ligand this reaction occurs at 1.02 V (Fig. 2A, peak c).

3.3. Antitumor activity

The *in vitro* antitumor activity of the free ligands (**1**, **2**) and ruthenium complexes (**3**, **4**) was evaluated against HL-60 leukemia cells (human leukemia), compared with daunorubicine and cisplatin as reference drugs. Due to the low solubility of the ruthenium complexes, the cytotoxic evaluations were carried out at a concentration of 10 μM.

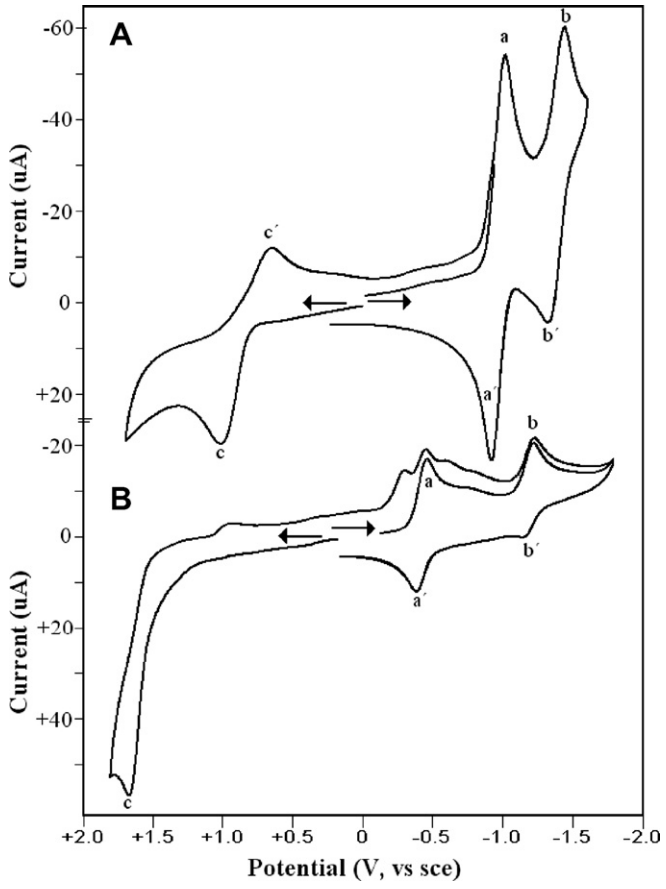

Fig. 2. Cyclic voltammograms in acetonitrile with 0.1 M TFBTBA. Scan rate 200 mV s^{-1}. Pt as working electrode: (A) ligand **2**; (B) complex **4**.

The quinolinedione compounds (**1**, **2**) exhibit cell grown inhibition comparable to that of the reference drug daunorubicine. Thus, at a 10 μM concentration, **2** is the most active with 71.6% of cell inhibition at 4 h and 100% after 24 h, compared with daunorubicine, which showed 12.4% and 99.1% at 4 and 24 h, respectively. Complex **3** shows a very low cytotoxic activity after 4 h, while complex **4** shows 8.7% of inhibition cell after 4 h, a similar value to those shown by *cis*platin (9.7%). Moreover, the cell inhibition values after 24 h decreases dramatically (to 0%), probably due to a decomposition process. In fact, the starting red colour of the solutions darkens with time.

In conclusion, the pronounced in vitro antitumoral activity shown by the quinolinedione compounds decreases after their coordination with the organometallic ruthenium(II) fragment. This effect is possibly associated to the decrease of the oxidizing capability of the quinolinedione system when it is bonded to the ruthenium centre (Fig. 2). Therefore, it seems reasonable to think that the redox cycling process is involved in the cytotoxic activity of the quinone compounds [19].

4. Conclusions

In summary, we report the synthesis of new dicarbonyldichlororuthenium(II) complexes containing quinolinediones as N,O-donor chelate ligands. The complexes were fully characterized by analytical, spectroscopic and electrochemical means. The molecular structure of complex **4** was determined by X-ray diffraction methods, indicating that the chloride ligands are bonded to the metal in relative *trans* position. The *in vitro* biological evaluation showed that the free quinolinediones exhibit a remarkable antitumoral activity against HL-60 leukemia cell lines. However, the corresponding ruthenium(II) complexes show a marginal activity, probably due to the loss of the oxidizing capability of the whole entity after co-ordination of the quinoline moiety.

Acknowledgements

We thank the "Fondo de Desarrollo Científico y Tecnológico" (FONDECYT), Chile (Project Nos. 3040053 and 1060597), and Factoria de Cristalización, CONSOLIDER INGENIO-2010 for financial support. We sincerely thank Dr. Ana María Edwards for the laboratory facilities to evaluate cytotoxic data.

much lesser degree than squarates. Indeed, numerous lanthanide squarates [21] and squarate complexes with transition metals [22] have been reported as well as structures of all the alkaline-earth squarates [23]. On the contrary, less structure of croconate metal complexes are known. Lanthanides and actinides croconates have been reported [24] and also some complexes with transition metal ions [25] and alkalines [26] but only one alkaline-earth croconate is known [27]. These structures have demonstrated that the croconate ligand can act as a polydentate ligand and that high dimensionalities structure involving this dianion are scarce. Only two 3D frameworks have been reported in the literature involving silver and sodium ions [28] or cadmium ions [29]. The present study deals with the synthesis by soft chemistry of two new croconate complexes, $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$ (**I**) and $Ca_2(\mu_4\text{-}C_5O_5)(\mu_6\text{-}C_2O_4)(H_2O)$ (**II**), their crystal structure determination by single-crystal X-ray diffraction, their infra-red spectra and thermal behaviour. The 2D or 3D frameworks display croconates and/or oxalates connected to seven- or eightfold coordinated calcium atoms through unusual bridging and chelating modes emphasizing new rich possibilities to design open-frameworks. The thermal decomposition of mixed calcium oxalato-croconate has revealed a high thermal stability which allows to consider possible applications in catalysis.

2. Experimental

2.1. Syntheses and preliminary characterisations

All chemicals were commercially available and used as received. Crystals of calcium croconate trihydrate $Ca(C_5O_5)(H_2O)_3$ (**I**) and calcium oxalato-croconate hydrate $Ca_2(C_5O_5)(C_2O_4)(H_2O)$ (**II**) were obtained through a mild chemistry route. High purity (98%) croconic acid was purchased from Alfa Aesar and calcium nitrate from BLB (Laboratoire du Bois de Boulogne, Puteaux, France). An aqueous solution of croconic acid (0.70 mmol, 10 mL) was added dropwise to an aqueous solution of calcium nitrate (0.35 mmol, 10 mL). The evaporation of the solution at room temperature led to the formation of yellow transparent crystals after about three days. Actually, both families of crystals **I** and **II** have been indifferently obtained and the major product croconate **II** contains croconate **I** as an impurity. In spite of several repeated attempts, we were not able to prepare croconate **I** in pure form and hence, its characterization dealt only with the single-crystal structure and the infrared measurement. We can suppose that the formation of crystals **I** occurs first and then croconate decomposition into oxalate occurs rapidly leading to **II**, which is the main product. A similar decomposition process has been observed for squarate oxidized into oxalate in lanthanide oxalato-squarates due to the role of metal oxidant agent [21c]. However, the degradation of the croconate into oxalate could have been induced by the pH or dilution as already observed by Deguenon [30].

High-quality X-ray powder diffraction data of grounded crystals of **II** were collected at room temperature with a Siemens D500 diffractometer, with the parafocusing Bragg–Brentano geometry, using monochromatic Cu $K\alpha_1$ radiation ($\lambda = 1.5406$ Å) selected with an incident beam curved-crystal germanium monochromator [31]. The diffraction pattern was collected over the angular range 8–60° (2θ) with a counting time of 13 s step^{-1} and a step length of 0.02° (2θ). The extraction of the peak positions was carried out with the Socabim program PROFILE, which is a part of the DIFFRACT-AT software package supplied by Bruker AXS. Pattern indexing was performed with the program DICVOL-04 [32] and refinement of the unit-cell parameters by means of the evaluation program NBS*AIDS-83 [33].

Infrared spectra of compounds **I** and **II** have been recorded using an Equinox 55 Bruker spectrometer as KBr disks in the range 400–4000 cm^{-1}. In addition to the expected broad and intense absorptions in the 3000–3700 cm^{-1} range assigned to the OH stretching frequency of water molecules, the infrared spectra of both compounds **I** and **II** show a strong absorption centered around 1530 cm^{-1} which is the signature of the presence of the croconate ligand [17,34,35]. This vibrational mode represents a mixture of C–O and C–C stretching motions characteristic of the $(C_nO_n)^{2-}$ dianion. The presence of the oxalate group in **II** is evidenced by a medium isolated absorption at 1325 cm^{-1} which is the signature of the C–O stretching motions of the oxalate [36,37]. Finally, the coordinated carbonyl groups of croconate and oxalate are characterized by a medium absorption in the 1600–1700 cm^{-1} range [34–37].

2.2. Single-crystal data collections

Suitable single-crystals of croconates **I** and **II** were mounted on a four-circle Nonius Kappa CCD area-detector diffractometer (**I**) or an APEX II Bruker-AXS (**II**) diffractometer (Centre de Diffractométrie X, UMR CNRS 6226, Rennes), using Mo $K\alpha$ radiation ($\lambda = 0.71073$ Å). Intensities were collected by means of the program COLLECT [38] for **I** and Bruker SMART included in the APEX-2 programmes suite [39] for **II**. Reflection indexing, Lorentz-polarisation correction, peak integration and background determination were carried out with the program DENZO of the KappaCCD software package [40] for **I** and with the program Bruker SAINT [41] for **II**. Unit-cell parameters refinement and frame scaling were performed with the program SCALEPACK [40] for **I** and with Bruker SMART [39] for **II**. Numerical absorption corrections were performed using the analytical procedure [42] included in the WinGX program suite [43] for **I** and a semi-empirical absorption correction included in the program SADABS [44] for **II**. The resulting sets of hkl reflections were used for structure refinement. Crystallographic data and details on data collection are listed in Table 1.

Structure drawings were carried out with DIAMOND-2.1e, supplied by Crystal Impact [45].

2.3. Thermal analyses

Temperature-dependent X-ray diffraction (TDXD) for **II** was performed under flowing air with a powder diffractometer equipped with a curved-position-sensitive detector (INEL CPS 120) and a high-temperature attachment from Rigaku. The detector was used in a semi-focusing arrangement by reflection (Cu $K\alpha_1$ radiation) as described elsewhere [46]. With this geometry, the stationary sample is deposited on a flat sample holder located at the centre of the goniometer. An angle of 6° was selected between the incident beam and the surface of the sample. To ensure satisfactory counting statistics, a counting time of 2700 s/pattern was selected for the thermal decomposition. Decomposition was carried out in dynamic air with a heating rate of 5 °C h^{-1} between 20 and 400 °C and 25 °C h^{-1} until 600 °C. Temperature calibration was made with standard materials in the involved temperature range.

Thermogravimetric (TG) measurement for **II** was performed with a Rigaku Thermoflex instrument in dynamic air. The measurement was carried out with a heating rate of 5 °C h^{-1} between 20 and 400 °C and 25 °C h^{-1} until 1000 °C.

3. Results and discussion

3.1. Structure resolutions of compounds *I* and *II*

The diffraction lines of the powder pattern of **II** have been indexed with an orthorhombic unit cell, with the following refined parameters $a = 14.907(2)$ Å, $b = 7.2519(8)$ Å, $c = 9.363(1)$ Å, $V = 1012.2(1)$ $Å^3$ [$M_{20} = 41$, $F_{30} = 75(0.0069, 58)$]. These parameters are in agreement with those found from single-crystal X-ray diffraction (Table 1).

The structures of croconates **I** and **II** were solved in the space groups *Pbca* and *Pnma*, respectively, in agreement with the extinction conditions. The heavy atoms, as well as a part of the croconate groups, were located by direct methods with the program SIR-97 [47] for **I** and interpretation of the Patterson function with SHELXS-97 [48] for **II**. The remaining atoms, including hydrogen atoms, have been localized from successive difference Fourier maps with SHELXL-97 [49]. The positions of the hydrogen atoms were refined with soft constraints applied to the distances to their water O atoms [0.96(1) Å] and their isotropic displacement parameters were fixed equal to one and half time the U_{eq} value of their parent O atoms. Details of the final refinement are given in Table 1. The atomic coordinates, together with the equivalent displacement parameters are reported in Tables 2 and 3, and the selected bond distances and angles in Tables 4 and 5.

3.2. Description of the structures

The crystal structure of $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$ (**I**) can be described as a 2D arrangement of eightfold coordinated Ca atoms and croconate dianions. The framework displays infinite corrugated sheets in the *ab*-plane which are piled up along the *c*-axis (Fig. 1). The sheets fit into each other through non-coordinated O5 atom of croconate group and Ow3 coordination water molecule. All the water molecules belong to the CaO_8 polyhedra, and then the intersheets are free any molecule. The cohesion of the structure is provided by hydrogen bonds. Within one sheet, two CaO_8 polyhedra are linked together by O3–O3$^{(ii)}$ shared-edge to form $[Ca_2O_{14}]$ dimers (Fig. 2). The Ca–Ca

distance within one dimer is 4.128(1) Å which is nearly close to those reported in other binuclear calcium carboxylates [50,51]. This short Ca–Ca distance evidences the existence of weak Ca···Ca interactions. Each sheet is constituted by corrugated infinite chains, along the *b*-axis, made of CaO_8 polyhedra connected by croconate dianions. Adjacent chains are connected through common-edge of polyhedra. The resulting framework develops eight-member apertures made of four $[Ca_2O_{14}]$ dimers and four

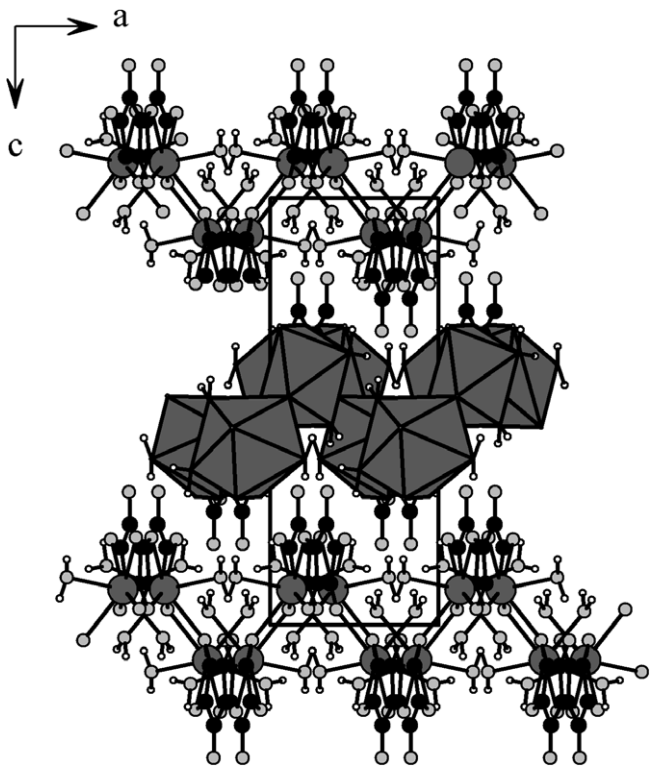

Fig. 1. Projection of the structure of $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$ (**I**) in the *ac*-plane. One sheet is illustrated by polyhedra.

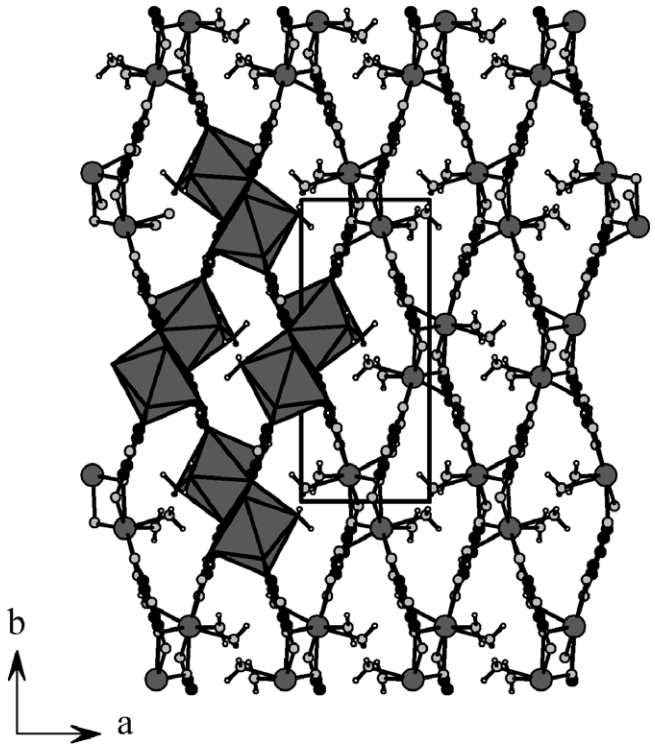

Fig. 2. View of one sheet of the structure $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$ (**I**) in the *ab*-plane showing the infinite chains and an aperture of the honeycomb pattern displayed by polyhedra.

croconate dianions. It can be described as a honeycomb pattern as already reported for numerous oxalate-based compounds [52,53] but arrangement based on dimers is original. Within a sheet, the croconate groups are exactly stacked along *a*-axis like face-to-face π–π alignment. However, the centroid–centroid distance corresponds to the *a* lattice parameter (6.416 Å) which is bigger than 4 Å preventing from π-stacking interactions [54]. Furthermore, the croconate groups are stacked between adjacent sheets in a displaced conformation but the centroid–centroid distance is again too high (~4.4 Å) to allow π-stacking interactions. The network is characterized by the presence of both intra- and inter-sheets hydrogen bonds. It is interesting to note that each coordination water molecule creates two hydrogen bonds, one between two sheets and one within the sheet. The possible hydrogen bonds, according to Desiraju and Steiner criteria [55], are reported in Table 4. Furthermore, the non-coordinated O5 atom is effectively involved in two O5···H bonds. This is simply the manifestation of the multi-chelate nature of the croconate ligand [56].

The Ca atom is surrounded by eight oxygen atoms; five of which are from two croconate dianions and three from water molecules (Fig. 3a). Eightfold coordinated Ca atoms have already been observed in numerous carboxylates in square antiprism [57], bicapped trigonal prism [51,58] or dodecahedron [14,59] configurations. The geometry of the CaO_8 polyhedron can be classified as a distorded bicapped trigonal prism [16th, 17th, 18th lowest O–Ca–O angles are 91.23(5)°, 97.21(6)°, 114.58(5)°] according to Haigh's criteria [60]. The Ca–O bond lengths are asymmetric and can be classified in two groups. The shortest distances [2.406(2) Å, 2.465(2) Å, 2.468(2) Å, 2.479(2) Å], involve Ca atom bonded to O atoms of coordination water molecules and to one atom of croconate dianion (O3) whereas the longest distances [2.502(2) Å, 2.506(2) Å, 2.535(2) Å, 2.552(2) Å] involve Ca atom bonded to only O atoms of croconate dianions. The main bond distances and angles are reported in Table 4.

One croconate group is present in the asymmetric unit. It is close to planarity, with standard deviation from the mean plane lower than 0.02 Å. The croconate dianion adopts a $\mu_3\text{-}(\eta^1{:}\eta^1{:}\eta^2{:}\eta^1)$ bis-bidentate bridging mode (Fig. 3b). To the best of our knowledge, this feature displays a new kind of coordination mode. On one side, the chelating mode is quite symmetric with similar $Ca^{(ii)}$–O3 [2.506(2) Å] and $Ca^{(ii)}$–O4 [2.502(2) Å] distances, whereas at the opposite side of the croconate group, the chelating mode is asymmetric with different $Ca^{(viii)}$–O1 [2.235(2) Å] and $Ca^{(viii)}$–O2 [2.552(2) Å] distances. This phenomenon confirms the intrinsic tendency of croconate to coordinate as an asymmetric bidentate ligand as already reported in other metal–croconate complexes [28,61]. On the other hand, one can also note that the croconate dianion acts as an asymmetric bridging ligand since the distances between O3 atom and the two Ca and $Ca^{(ii)}$ atoms are different [O3–Ca = 2.479(2) Å, O3–$Ca^{(ii)}$ = 2.506(2) Å]. Due to the inversion centre, this discrepancy is also observed for the other oxygen atom $O3^{(ii)}$ of the share-edge within the dimers (Fig. 3b). Finally, bond lengths C1–O1 [1.239(2) Å] and C5–O5 [1.238(2) Å] are shorter than the other C–O distances. The shortening of such distances results in the lengthening of the C1–C5 [1.474(2) Å] distance and thereby the inner angle C4–C5–C1 [106.7(2)°] is more acute than the others. Bond lengths and angles within the croconate group, gathered in Table 4, are in agreement with those previously reported [17,62].

The compound $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$ (**I**) is a polymorph of calcium croconate. Another phase $Ca(\mu_2\text{-}C_5O_5)(H_2O)_3$ has already been reported [27] and crystallizes in the triclinic system with the following parameters: $a = 6.642(3)$ Å, $b = 7.793(4)$ Å, $c = 8.854(5)$ Å, $\alpha = 106.97(5)°$, $\beta = 92.43(4)°$, $\gamma = 106.98(4)°$, $V = 425.1(1)$ Å^3. One can note that the *a* parameter of **I** is almost equal to that of the triclinic polymorph and that *b* and *c* parameters of **I** are twice those of the polymorph. The crystal structure of the triclinic calcium croconate consists in infinite chains of alternating CaO_7 polyhedra and croconate dianions. The Ca atom is surrounded by four O atoms of croconate dianions and three O atoms of coordination water molecules (Fig. 3c). On the contrary, in **I**, the Ca atom is surrounded by eight O atoms and five of which are from O atoms of croconate dianions (Fig. 3a). The additional eighth O atom in the Ca atom environment in **I** allows the formation of dimers $[Ca_2O_{14}]$. The coordination mode of the croconate is also different. Indeed, in the polymorphous triclinic compound,

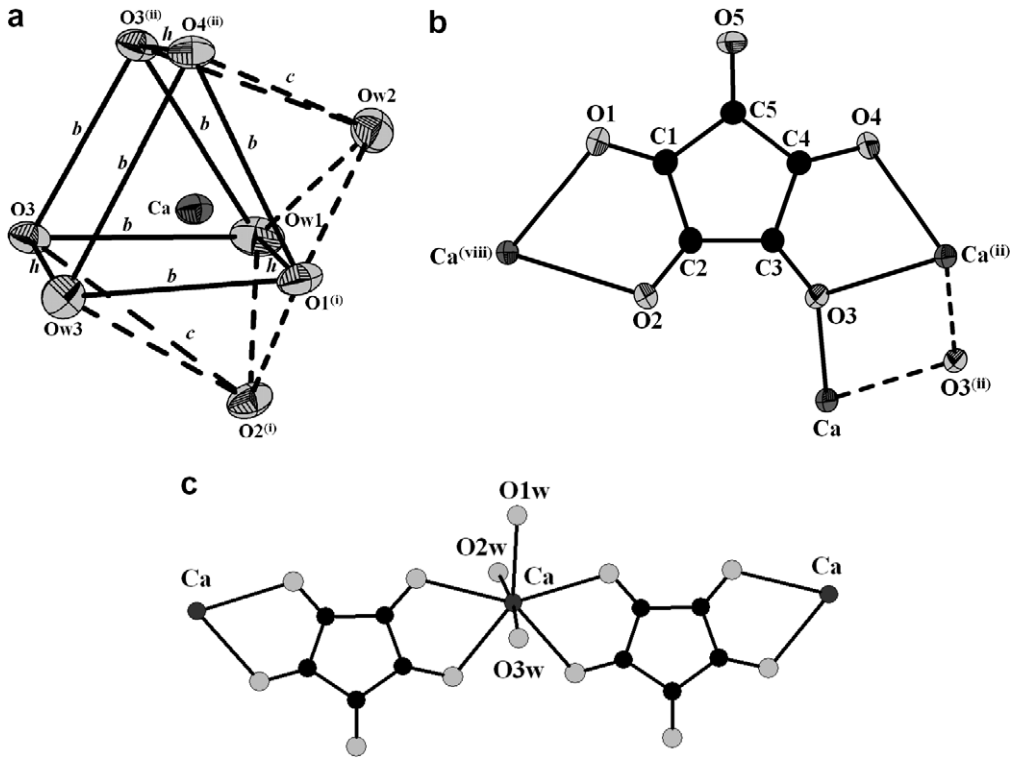

Fig. 3. (a) Eightfold environment of calcium atom in $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$ (**I**). (b) Representation of the connecting mode of the croconate group in (**I**). (c) Representation of the connecting mode of the croconate group in the triclinic polymorph of $Ca(\mu_2\text{-}C_5O_5)(H_2O)_3$ (from [27]). Atomic displacement ellipsoids are plotted at the 50% probability level.

the croconate group acts as a μ_2-(η^1:η^1:η^1:η^1) symmetric bis-bidentate ligand and connects two Ca atoms along only one direction (Fig. 3c), leading to a 1D framework. On the contrary, in **I** the croconate group connects three Ca atoms along two directions, the *a*- and *b*-axes (Fig. 3b), generating a 2D framework.

The 3D open-framework of $Ca_2(\mu_4\text{-}C_5O_5)(\mu_6\text{-}C_2O_4)(H_2O)$ (**II**) consists of layers in the *bc*-plane piled up along the *a*-axis (Fig. 4). Each layer is constituted by seven- and eightfold coordinated Ca atoms and oxalates dianions (Fig. 5). The presence of both seven- and eightfold coordination of Ca has already been observed in carboxylate-based compounds for Ca [57c,59b]. One layer contains infinite corrugated chains along the *b*-axis made of alternated $Ca1O_7$ and $Ca2O_8$ polyhedra linked together by O6–O7 shared-edge. Within this chain, the Ca1–Ca2 distance is 3.735(1) Å. This result emphasizes the tightness of the layer and indicates the existence of Ca···Ca interactions in the compound [50,51]. These chains are connected to each other along the *c*-axis by both oxalate dianion and O2–O4 shared-edge. The whole crystal structure is obtained by piling up these layers along the *a*-axis with the croconate dianion (Fig. 4). This structural arrangement provides in the *ab*-plane rectangular cavities which are free of water molecules and whose dimensions are around 3.9×6.4 Å^2. The croconate groups are stacked in opposite direction in a parallel displaced conformation in the *ac*-plane (Fig. 4) but the shift between the ring centroids is too high (~4 Å) to allow π-stacking interactions [54]. A zigzag network of hydrogen bonds is developed between the layers and the croconate dianions in the *ac*-plane (Fig. 4). These weakly bonds involve H atoms of Ow1 molecules,

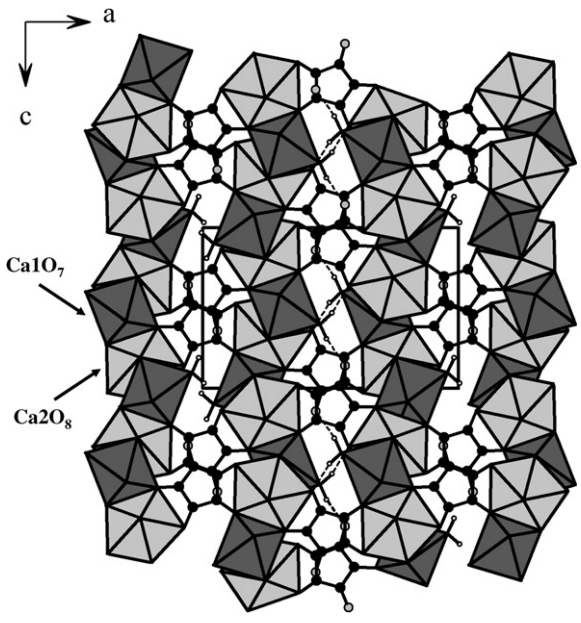

Fig. 4. Projection of the structure of $Ca_2(\mu_4\text{-}C_5O_5)(\mu_6\text{-}C_2O_4)(H_2O)$ (**II**) in the *ac*-plane showing corrugated sheets linked by croconates and hydrogen bonds in dotted lines. $Ca1O_7$ are displayed by medium grey polyhedra and $Ca2O_8$ by light grey polyhedra.

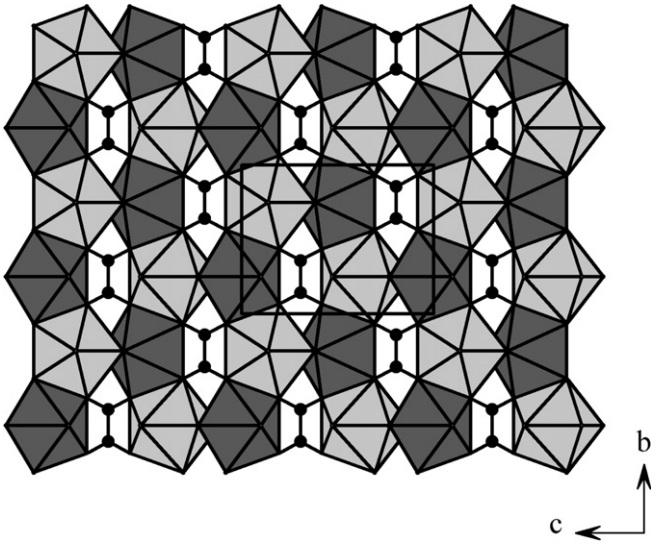

Fig. 5. Projection of one layer of $Ca_2(\mu_4\text{-}C_5O_5)(\mu_6\text{-}C_2O_4)(H_2O)$ (**II**) in the *bc*-plane. $Ca1O_7$ are displayed by medium grey polyhedra and $Ca2O_8$ by light grey polyhedra.

belonging to $Ca1O_7$ polyhedra, and O atoms from croconate dianions. The possible hydrogen bonds, according to Desiraju and Steiner criteria [55], are reported in Table 5.

The two Ca atoms have different coordination numbers and environments (Fig. 6). However, each Ca atom is bonded to the same number of croconate and oxalate dianions. Indeed, the Ca1 atom is surrounded by seven O atoms, two from two different croconate dianions (O2, O4), four from three different oxalate dianions (O6, $O6^{(i)}$, O7, $O7^{(i)}$) and one from a coordination water molecule (Ow1). All the O atoms (except Ow1) act as bridging atoms towards the Ca atom. Sevenfold coordinated Ca1 atoms have already been observed in numerous carboxylates of different structural types in pentagonal bipyramid [59b,59c,63] or capped trigonal prism [59c] configurations. The Ca2 atom is coordinated by eight O atoms: four from three different oxalate dianions ($O6^{(ii)}$, $O6^{(iii)}$, $O7^{(ii)}$, $O7^{(iii)}$) and four from two different croconate dianions (O1, O2, O3, O4). All the O atoms, except O1 and O3, act as bridging atoms towards the Ca atom.

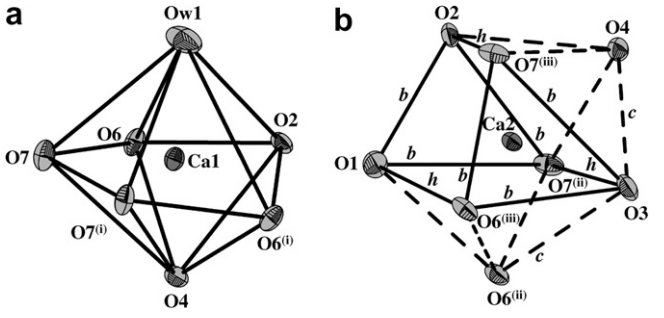

Fig. 6. (a) Sevenfold environment of Ca1 atom in (**II**); (b) eightfold environment of Ca2 atom in (**II**). Atomic displacement ellipsoids are plotted at the 50% probability level.

The geometry of the $Ca1O_7$ polyhedron can be classified as a distorted pentagonal bipyramid (Fig. 6a). The Ca1 atom and its five neighboring equatorial O atoms are approximately planar with a standard deviation from the mean plane equal to 0.2123 Å. The trans angle, involving axial O atoms, Ow1–Ca1–O4 is equal to 173.7(1)°. The Ca1–O distances are asymmetric since the equatorial bonds are longer than the axial ones. The geometry of the $Ca2O_8$ polyhedron can be classified as a bicapped trigonal prism (Fig. 6b) {16th, 17th, 18th lowest O–Ca2–O angles are 95.30(5)°, 95.30(5)°, 127.45(6)° according to Haigh's criteria [60]}. The Ca2–O distances involving oxygen atoms from oxalate groups are shorter than those from croconate dianions. The main bond distances and angles for both polyhedra are reported in Table 5.

One croconate group is present in the asymmetric binuclear unit. It is strictly plane due to the position of the croconate located in a mirror plane. The croconate dianion adopts a μ_4-(η^2:η^1:η^2:η^1) bis-bidentate and bis-bridging modes (Fig. 7a). It connects along the *a*-axis four metals (two Ca1 and two Ca2 atoms) in an original trans bis-bridging manner compared to the other tetradentate with a cis bis-bridging connection mode related in the literature [28]. On one hand, the distances Ca2–O1 [2.523(3) Å] and Ca2–O2 [2.532(2) Å] are similar whereas the distances Ca2–O3 [2.417(3) Å] and Ca2–O4 [2.549(3) Å] are different, which confirms the intrinsic tendency of croconate dianion to coordinate as an asymmetric bidentate ligand as reported for other metal–croconate complexes [28,61] and for **I**. On the other hand, one can also note that the two

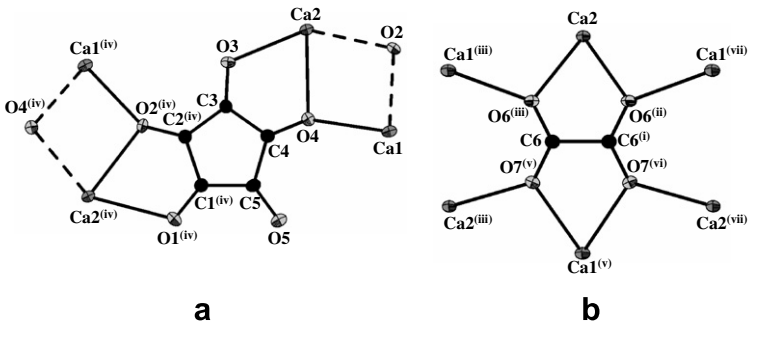

Fig. 7. Representations of the connecting modes of the croconate group (a) and of the oxalate group (b) in (**II**). Atomic displacement ellipsoids are plotted at the 50% probability level.

O2 and O4 atoms which connect the $Ca1O_7$ and $Ca2O_8$ polyhedra act as bridging atoms in an asymmetric manner. Indeed, the distances $O2^{(iv)}$–$Ca1^{(iv)}$ [2.368(2) Å] and $O2^{(iv)}$–$Ca2^{(iv)}$ [2.523(3) Å] are different as also observed for the distances O4–Ca1 [2.332(3) Å] and O4–Ca2 [2.549(3) Å]. Therefore, the croconate dianion can act as bridging and bidentate ligand through both asymmetric and symmetric manners. Finally, bond lengths $C1^{(iv)}$–$O1^{(iv)}$ [1.229(5) Å] and C5–O5 [1.236(4) Å] appear to be shorter than the other C–O distances, as observed in **I**. The shortening of such distances results in the lengthening of the $C1^{(iv)}$–C5 [1.485(5) Å] distance and thereby the inner angle C4–C5–$C1^{(iv)}$ [105.8(3)°] is more acute than the others. Bond lengths and angles within the croconate group are gathered in Table 5.

On the contrary, the oxalate group present in the structure behaves as both a bridging and a bidentate ligand which connects asymmetrically. It is close to planarity, with standard deviation from the mean plane equal to 0.004 Å. The oxalate dianion adopts a μ_6-(η^2:η^2:η^2:η^2) bis-bidentate and tetra-bridging modes (Fig. 7b). It connects along the *b*- and *c*-axes six metals (three Ca1 and three Ca2 atoms) and each O atom acts as a bridging atom. Comparing to the very usual μ_2 bis-bidentate mode, the μ_6 coordination mode has been less reported for the oxalate anion [64]. The distances within the oxalate groups (Table 5) are regular and close to the mean values reported by Hahn [65] for oxalate groups.

3.3. Thermal behaviours

The thermal decomposition of **II** can be described as two steps process. According to the TGA measurement (Fig. 8a), croconate **II** has adsorbed at ambient conditions 1.4 water molecules comparing to the formula deduced from the crystal structure resolution. This phenomenon agrees with the topology of **II** displaying rectangular cavities and demonstrates its zeolite-like behaviour. The departure of adsorbed water molecules occurs without well-defined step until ~320 °C (experimental/theoretical

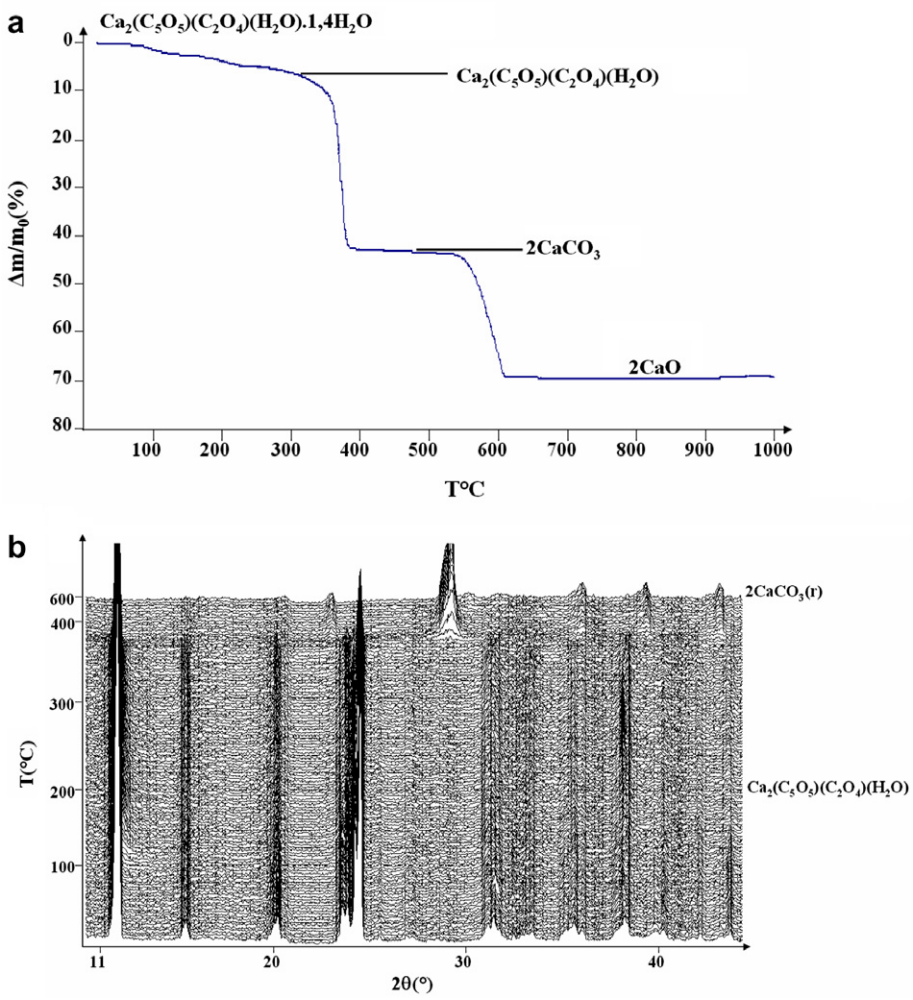

Fig. 8. (a) Thermogravimetric analysis of $Ca_2(C_5O_5)(C_2O_4)(H_2O)$ (**II**) under flowing air (heating rate: 5 °C h^{-1} between 20 and 400 °C and 25 °C h^{-1} up to 1000 °C). (b) Thermodiffractogram of $Ca_2(C_5O_5)(C_2O_4)(H_2O)$ (**II**) under flowing air (heating rate: 5 °C h^{-1} between 20 and 400 °C, then 25 °C h^{-1} up to 600 °C; counting time: 2700 s/pattern); r: rhombohedric.

weight losses: 7.4/7.1%). Then, the loss of the coordination water molecule (Ow1) and the decomposition of the organic ligands occur on one step and provide the collapse of the crystal structure. Indeed, this collapse leads to the formation of calcium carbonate [PDF2 01-0837] in the temperature range 340–390 °C. As seen on the TDXD plot (Fig. 8b), no structural change is observed until 380 °C. Consequently, the crystal structure is stable at high temperature as already observed in other structures involving croconate dianion [26–28]. This behaviour can be assigned to the delocalization of π electrons all over the ring.

Finally, nanocrystalline cubic calcium oxide (experimental/theoretical weight losses: 69.3/68.1%) is formed at about 610 °C but this step is not observed on the TDXD plot since the experiment was carried out until only 600 °C.

4. Conclusion

Attempts to synthesize with the same experimental procedures analogous structures with an alkaline-earth metal of larger radius, such strontium or barium, were successful. However, the low quality of the strontium croconate and the high electronic contrast between Ba and the other light atoms in the barium croconate did not allow to solve their crystal structures. The refined parameters for barium and strontium croconate-based complexes are: $a = 14.203(1)$ Å, $b = 8.0008(6)$ Å, $c = 11.4727(9)$ Å, $V = 1303.7(1)$ Å^3; $a = 10.7274(2)$ Å, $b = 7.7201(2)$ Å, $c = 13.7810(3)$ Å, $\beta = 93.59(2)°$, $V = 1139.06$ Å^3, respectively. These values are close to those of the calcium croconato-oxalate suggesting strong relationships between the structures.

As a conclusion, two original calcium complexes based on croconate, $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$ (**I**) and $Ca_2(\mu_4\text{-}C_5O_5)(\mu_6\text{-}C_2O_4)(H_2O)$ (**II**) have been prepared and characterized. Their structures display frameworks of high dimensionality degree. The structure of **I** is a 2D architecture which consists of corrugated sheets formed by croconate dianions and $[Ca_2O_{14}]$ dimers. The structure of **II** displays a 3D open-framework built from layers of CaO_8/CaO_7 polyhedra and oxalate dianions, connected to each other by croconate dianions. The calcium adopts different coordination polyhedra, pentagonal bipyramid in **II** and distorded bicapped trigonal prisms in **I** and **II**, pointing out the flexibility of its coordination environment. Furthermore, these polyhedra are connected by croconates and oxalates through unusual bridging and chelating coordination modes. Then, the dimensionality of the framework increases with the number of coordinated metals by the organic group. Finally, potential applications in catalysis can be expected for **II** since its open-framework structure is stable up 380 °C.

Acknowledgments

The authors thank Dr. T. Roisnel (Centre de Diffractométrie X, UMR 6226 CNRS, Rennes) and Mr. G. Marsolier (Université de Rennes 1) for their assistance in single-crystal and powder X-ray diffraction data collection, respectively, and Mr. Y. Le Gal (Université de Rennes 1) for IR spectra.

Appendix A. Supplementary material

CCDC 647655 and 647656 contain the supplementary crystallographic data for $Ca_2(\mu_4\text{-}C_5O_5)(\mu_6\text{-}C_2O_4)(H_2O)$ and $Ca(\mu_3\text{-}C_5O_5)(H_2O)_3$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.08.018.

we have synthesized a series of benzoazole palladium complexes and investigated their ability to catalyze Heck coupling reactions. The rigid backbone and the enhanced electron density of these ligands is expected to offer good stability for the active catalysts in the Heck coupling reactions and the absence of any reactive bonds in the fused benzoazole ligands is expected to minimize catalyst deactivation associated with phosphine-based catalysts. In attempts to impart different electronic and steric properties as well as improve solubility of complexes we have also developed a convenient method for the synthesis of substituted benzothiazoles by incorporating alkyl groups in both the pyridine and phenyl rings. In this contribution, we describe the synthesis of benzoazole ligands, their palladium complexes and applications as catalysts for Heck coupling of iodobenzene with butyl acrylates. The ability of the ligands to enhance the catalytic activity of palladium(II) salts when the ligands are added *in situ* in the Heck coupling reactions was also investigated.

2. Experimental

2.1. Materials and methods

Synthetic manipulations were carried out under a nitrogen atmosphere. All solvents were of analytical grade and were dried prior to use. Toluene and Et_2O were dried and distilled from sodium/benzophenone. Dichloromethane was dried and distilled from P_2O_5. Dicyclohexylcarbodiimide (DCC), 4-*tert*-butyl aniline, 4-pyrrolidnino pyridine (4-PP), 6-methyl picolinic acid, Lawesson's reagent and 2-pyridin-2-yl-1*H*-benzoimidazole (**L1**) were purchased from Sigma–Aldrich and used as received. Compounds and 2-pyridin-2-yl-benzothioazole (**L2**) [9], [Pd(COD)MeCl] [10] and $Pd(NCMe)_2Cl_2$] [11] were synthesized following the literature procedures. NMR spectra were recorded on a Varian Gemini 2000 instrument (^{1}H at 300 MHz and ^{13}C at 75 MHz) at room temperature. The chemical shifts are reported in δ (ppm) and referenced to the residual $CHCl_3$ in the NMR solvent. Coupling constants are measured in Hertz (Hz). Mass spectra were recorded on a Waters API Quattro Micro spectrometer at the University of Stellenbosch. Elemental analyses were performed by the micro analytical laboratory at the University of Cape Town, South Africa, as a service. Heck coupling products were analyzed on a Shimadzu GCMS-QP 2010 version 2 gas chromatograph fitted with flame ionization detector and column ZB1, 100% dimethylpolysiloxane with dimensions of 30 m by 0.25.

2.2. Synthesis of ligands and complexes

2.2.1. 2-tert-Butyl-pyridine-2-carboxylic acid (4-tert-butyl-phenyl)-amide (*S1*)

To a mixture of 4-*tert*-butylpicolinic acid (0.50 g, 2.80 mmol), 4-*tert*-butyl aniline (0.41 g, 2.80 mmol), DCC (0.57 g, 2.80 mmol) and 4-PP (5%) was added CH_2Cl_2 (20 mL) and the mixture stirred for 24 h at room temperature. After the reaction period the mixture was filtered and solvent removed under reduced pressure to give the crude product which was purified by column chromatography on silica gel using solvent mixtures of petroleum ether and ethylacetate (9:1). Yield = 0.75 g (85%). ^{1}H NMR ($CDCl_3$): δ 1.30 (s, 9H, ^{t}Bu, phenyl); 1.37 (s, 9H, ^{t}Bu, py); 7.39 (d, 1H, $J = 7.2$, py); 7.41 (d, 2H, $J = 8.1$, ph); 7.72 (d, 2H, $J = 5.7$, ph); 8.33 (s, 1H, py); 8.52 (d, 1H, $J = 8.1$, py); 10.04 (s, 1H, NH). ^{13}C NMR ($CDCl_3$): δ 30.4 (C-(CH_3)$_3$, ph); 31.3 (C-(CH_3)$_3$, py); 34.3 (*C*-(CH_3)$_3$, ph); 35.1 (*C*-(CH_3)$_3$, py); 119.4 (*C3*, py); 120.0 (*C2* and *C6*, ph); 123.0 (*C5*, py); 125.8 (*C5*, ph); 126.6 (*C3*-ph); 135.2 (*C2*, ph); 138.2 (*C1*, ph); 147.8 (*C4*, ph); 151.6 (*C6*, py); 157.3 (*C4*, py); 162.2 (*C*=O). HRMS (ESI) for $C_{20}H_{26}N_2O$: Calc. 310.4315. Found: 310.4322.

2.2.2. 2-tert-Butyl-pyridine-2-carbothioic acid (4-tert-butyl-phenyl)-amide (*S2*)

To a mixture of **S1** (0.80 g, 2.50 mmol) and Lawesson's reagent (0.52 g, 1.28 mmol) was added toluene (20 mL) and the solution refluxed for 48 h. The mixture was then filtered and solvent was removed under reduced pressure to afford an orange solid material which was purified by column chromatography on silica gel using solvent mixtures of petroleum ether and ethylacetate (4:1). Yield = 0.75 g (80%). ^{1}H NMR ($CDCl_3$): δ 1.32 (s, 9H, ^{t}Bu, phenyl); 1.36 (s, 9H, ^{t}Bu, py); 7.40 (d, 1H, $J = 7.8$, py); 7.43 (d, 2H, $J = 7.5$, ph); 7.97 (d, 2H, $J = 6.9$, ph); 8.45 (s, 1H, py); 8.88 (d, 1H, $J = 7.8$, and 1.8 py); 12.11 (s, 1H, NH). ^{13}C NMR ($CDCl_3$): δ 30.8 (C-(CH_3)$_3$, ph); 31.3 (C-(CH_3)$_3$, py); 34.6 (*C*-(CH_3)$_3$, ph); 35.2 (*C*-(CH_3)$_3$, py); 119.4 (*C3*, py); 122.4 (*C2* + *C6*, ph); 125.6 (*C5*, py); 128.1 (*C5*, ph); 128.9 (*C3*-ph); 137.9 (*C3*-ph); 149.6 (*C6*, ph); 150.7 (*C4*, ph); 155.5 (*C4*, py); 187.3 (*C*=S). HRMS (ESI) for $C_{20}H_{26}N_2S$: Calc. 326.5014. Found: 326.5021.

2.2.3. 2-(4-tert-Butyl pyridin-2-yl)-benzoxazole (*L3*)

To a mixture of 2-aminophenol (0.44 g, 4.00 mmol) and 2-carboxy-4-tertbutylpyridine (0.72 g, 4.00 mmol) was added to polyphosphoric acid (3.00 g). The suspension was heated at 170–180 °C. After 4 h, the reaction mixture was poured into an ice-water mixture and the pH of the resulting solution adjusted to 8 using 25% NH_4OH. The product that precipitated was filtered, washed with H_2O and dried. Yield = 0.80 (79%) ^{1}H NMR, ($CDCl_3$): δ 1.39 (s, 9 H, ^{t}Bu, py); 7.36 (m, 2H and 1H, ph, py); 7.67 (m, 1H, ph); 7.84 (m, 1H, ph); 8.37 (s, 1H, py); 8.71 (d, 1H, $J = 8.1$, py). ^{13}C NMR ($CDCl_3$): δ 30.5 (C-(CH_3)$_3$, py); 35.1 (*C*-(CH_3)$_3$, py); 111.3 (*C5*, ph); 120.5 (*C5*, py); 120.7 (*C6*, ph); 122.9 (*C2*, ph); 124.9 (*C3*, ph); 126.0 (*C4*, ph); 141.8 (*C1*, ph); 150.3 (*C6*, ph); 151.1 (*C*=N, oxazole); 161.6 (*C2*, py); 162.0 (*C4*, py). MS (ESI) *m*/*z* (%) 253 (M^+, 100). HRMS (ESI) for $C_{16}H_{17}N_2O$: Calc. 253.1341. Found: 253.1357.

*2.2.4. 2-(4-tert-Butyl pyridin-2-yl)-benzothiazole (**L4**)*

Compound **L3** was prepared following the procedure described for **L2** using 2-mercaptoaniline (0.50 g, 4.00 mmol) and 2-carboxy-4-tertbutylpyridine (0.72 g, 4.00 mmol). Yield = 0.86 g (80%). ^{1}H NMR, ($CDCl_3$): δ 1.38 (s, 9H, ^{t}Bu, py); 6.95 (d, 1H, $J = 7.8$, ph); 7.40 (m, 1H, ph); 7.54 (m, 1H, ph); 7.97 (d, 1H, $J = 9.3$, py); 8.10 (d, 1H, $J = 8.1$, ph); 8.37 (s, 1H, py); 8.60 (d, 1H, $J = 6.0$, py). ^{13}C NMR ($CDCl_3$): δ 30.4 (C-(CH_3)$_3$, py); 35.1 (*C*-(CH_3)$_3$, py); 118.1 (*C5*, py); 122.0 (*C3*, py); 123.3 (*C3* and *C6*, ph); 125.7 (*C5*, ph); 126.4 (*C4*, ph); 135.9 (*C2*, ph); 149.4 (*C6*, py); 151.0 (*C1*, ph); 154.0 (*C* = N, thiazole); 161.4 (*C2*, py); 161.9 (*C4*, py). MS (ESI) *m*/*z* (%) 291 (M^++Na^+, 20) 269 (M^+, 100). HRMS (ESI) for $C_{16}H_{17}N_2S$: Calc. 269.1112. Found: 269.1106.

*2.2.5. 6-tert-Butyl-2-(4-tert-butyl-pyridin-2-yl)-benzothiazole (**L5**)*

To a solution of **S2** (1.00 g, 3.00 mmol) in a minimum amount of ethanol was added 30% NaOH (3.20 mL, 24.00 mmol). The mixture was diluted to give 10% NaOH and stirred for about 5 min. Portions of this mixture were added at 1 min intervals to a stirred solution of $K_3[Fe(CN)_6]$ (3.95 g, 12.00 mmol) in H_2O (5.00 mL) at 85 °C. The resultant mixture was further heated at 85 °C for 1 h, solvent removed *in vacuo* and the residue extracted with CH_2Cl_2 (2 × 20 mL). The combined organic extracts was washed with H_2O (2 × 20 mL), dried over $MgSO_4$ and solvent removed to afford an orange solid. Purification by column chromatography on silica gel using solvent mixtures of petroleum ether:ethylacetate (9:1) as eluent gave **L5** as a pure compound. Yield = 0.53 g (55%). ^{1}H NMR ($CDCl_3$): δ 1.44 (s, 9H, ^{t}Bu, ph); 1.49 (s, 9H, ^{t}Bu, py); 6.90 (s, 1H, ph); 7.46 (t, 1H, ph); 7.58 (t, 1H, ph); 7.97 (d, 1H, py); 8.18 (d, 1H, ph); 8.37 (s, 1H, py); 8.50 (t, 1H, py). δ 30.4 (C-(CH_3)$_3$, py); 35.1 (*C*-(CH_3)$_3$, py); 119.1 (*C5*, py); 122.6 (*C3*, py); 123.7 (*C3* and *C6*, ph); 125.4 (*C5*, ph); 143.5 (*C4*, ph); 135.9 (*C2*, ph); 149.8 (*C6*, py); 152.1 (*C1*, ph); 155.1 (*C*═N, thiazole); 161.9 (*C2*, py); 162.4 (*C4*, py). HRMS (ESI) for $C_{20}H_{24}N_2S$: Calc. 324.4809. Found: 324.4811.

*2.2.6. {2-Pyridin-2-yl-1H-benzoimidazole}PdClMe (**1**)*

To a solution of [Pd(COD)MeCl] (0.12 g, 0.48 mmol) in Et_2O (10 mL) was added **L1** (0.10 g, 0.47 mmol) in Et_2O (10 mL) to give a light yellow compound precipitate. After stirring for 12 h, the mixture was filtered to isolate a light yellow solid. Yield = 0.12 g (71%). ^{1}H NMR (DMSO-d_6): δ 1.12 (s, 3H, Pd–Me); 7.43 (dd, 2H, $J = 7.8$, ph); 7.78 (d, 2H, $J = 8.1$, ph); 7.90 (m, 1H, py); 8.40 (m, 2H, py); 8.85 (m, 1H, py). ^{13}C NMR ($CDCl_3$): δ −5.8 (Pd-CH_3); 113.1 (*C3* and *C6*, ph); 124. 8; 126.9 (*C4* and *C5*, ph); 134.0 (*C4*, py); 139.5 (*C1* and *C2*, py); 140.8 (*C1* and *C6*, py); 148.3 (*C*═N, imidazole). MS (ESI) *m*/*z* (%) 357 (M^++NCMe, 100); 316 (30). *Anal.* Calc. for $C_{12}H_{12}N_3PdCl$: C, 44.34; H, 3.43; N, 11.97. Found: C, 44.73; H, 3.01; N, 11.67%.

*2.2.7. {2-Pyridin-2-yl-benzothiazole}PdClMe (**2**)*

This compound was prepared following the procedure described for **1** using [Pd(COD)MeCl] (0.13 g, 0.50 mmol) and **L2** (0.10 g, 0.50 mmol). Yield = 0.15 g (80%). ^{1}H NMR (DMSO-d_6): δ 1.14 (s, 3H, Pd–Me); 7.59 (d, 2H, $J = 8.1$, ph); 7.80 (d, 2H, $J = 7.8$, ph,); 8.18 (m, 1H, py); 8.31 (m, 2H, py); 8.72 (m, 1H, py). ^{13}C NMR ($CDCl_3$): δ 120.3 (*C3*, ph); 122.6 (*C6*, ph); 123.3 (*C5*, py); 126.1 (*C5*, ph); 28.4 (*C3*, py); 135.4 (*C4*, py); 137.9 (*C2*, py); 140.1 (*C1*, ph); 148.6 (*C*═N, thiazole); 149.9 (*C6*, py); (*C2*, py). MS (ESI) *m*/*z* (%) 372 (M^++NCMe, 100); 331 (40). *Anal.* Calc. for $C_{13}H_{11}N_2SPdCl$: C, 42.29; H, 3.00; N, 7.59. Found: C, 42.35; H, 3.21; N, 7.39%.

*2.2.8. {2-(4-tert-Butyl pyridin-2-yl)-benzooxazole}PdCl$_2$ (**3**)*

To a solution of [Pd(NCMe)Cl_2] (0.15 g, 0.60 mmol) in CH_2Cl_2 (20 mL) was added a solution of **L3** (0.15 g, 0.60 mmol) in CH2Cl2 (10 mL). The resultant orange solution was stirred for 24 h. The solution was then concentrated *in vacuo* and hexane (20 mL) added to precipitate a light orange solid. Yield = 0. 12 g (70%). ^{1}H NMR ($CDCl_3$): δ 1.47 (s, 9H, ^{t}Bu, py); 7.46 (t, 1H, ph); 7.60 (t, 1H, ph); 7.70 (d, 1H, $J = 7.5$, py); 7.73 (d, 1H, $J = 7.8$, ph); 8.11 (s, 1H, py); 8.68 (d, 1H, $J = 8.4$, ph); 9.15 (d, 1H, $J = 7.2$, py). ^{13}C NMR ($CDCl_3$): 31.2 (C-(CH_3)$_3$); 35.4 (*C*-(CH_3)$_3$, py); 110.9 (*C5*, ph); 111.3 (*C5*, py); 119.5 (*C6*, ph); 121.1 (*C2*, ph); 121.5 (*C3*, ph); 121.8 (*C4*, ph); 123.9 (*C1*, ph); 127.4 (*C2*, py); 131.0 (*C6*, ph); 149.4(*C*═N, oxazole); 151.6 (*C4*, py). MS (ESI) *m*/*z* (%) 436 (M^++NCMe, 50); 417 (100). *Anal.* Calc. for $C_{16}H_{16}N_2OPdCl_2$: C, 43.73; H, 3.87; N, 4.67. Found: C, 44.08; H, 3.59; N, 4.52%.

*2.2.9. {2-(4-tert-Butyl pyridin-2-yl)-benzooxazole}PdClMe (**4**)*

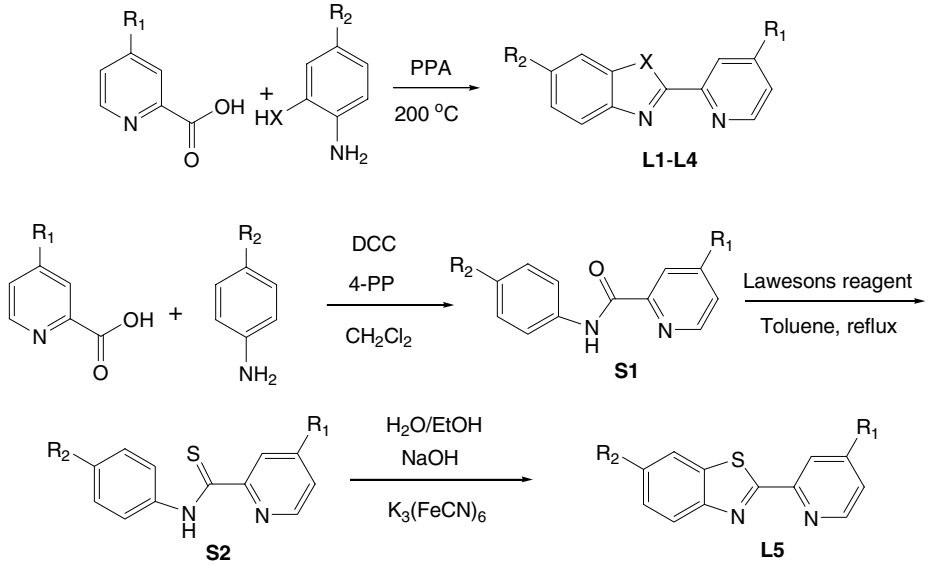
This compound was synthesized in a similar manner to complex **1** using **L3** (0.05 g, 0.20 mmol) and [Pd-(COD)ClMe] (0.05 g, 0.20 mmol). Yield = 0.08 g (72%). ^{1}H NMR, ($CDCl_3$): δ 1.17 (s, 3 H, CH_3, Pd–Me); 1.43 (s, 9H, ^{t}Bu, py); 7.56 (m, 2H, py); 7.64 (m, 1H, py); 8.16 (d, 2H, $J = 7.5$, ph); 8.54 (d, 1H, $J = 7.8$, py); 9.00 (d, 1H, $J = 7.5$, py). ^{13}C NMR ($CDCl_3$): −11.2 (Pd–CH_3); 30.4 (C-(CH_3)$_3$); 35.3 (*C*-(CH_3)$_3$, py); 111.0 (*C5*, ph); 111.6 (*C5*, py); 119.5 (*C6*, ph); 120.1 (*C2*, ph); 121.3 (*C3*, ph); 121.9 (*C4*, ph); 125.2 (*C1*, ph); 126.7 (*C2*, py); 127.7(*C6*, ph); 149.0 (*C*═N, oxazole); 149.4(*C4*, py). (ESI) *m*/*z* (%) 414 (M^++NCMe, 100); 253 (45). *Anal.* Calc. for $C_{17}H_{19}N_2OPdCl \cdot 0.5Et_2O$: C, 51.12; H, 5.38; N, 6.28. Found: C, 50.79; H, 5.71; N, 5.96%.

*2.2.10. {2-(4-tert-Butyl pyridin-2-yl)-benzothiazole}PdCl$_2$ (**5**)*

This compound was synthesized following the procedure described for **3** using **L4** (0.20 g, 0.80 mmol) and of [Pd(NCMe)Cl_2] (0.20 g, 0.80 mmol) to give a pale yellow

solid. Yield = 0.30 g (80%). ^{1}H NMR ($CDCl_3$): δ 1.40 (s, 9H, ^{t}Bu, py); 7.70 (m, 1H, ph); 7.90 (d, 1H, $J = 7.2$, py); 8.20 (m, 1H, ph); 8.39 (d, 1H, $J = 7.5$, ph); 8.65 (s, 1H, py); 9.03 (d, 1H, $J = 8.1$, ph); 9.54 (d, 1H, $J = 7.2$, py). ^{13}C NMR ($CDCl_3$): 30.7 (C-(CH_3)$_3$); 35.2 (*C*-(CH_3)$_3$); 111.5 (*C5*, py); 118.9 (*C3*, py); 120.8 (*C6*, ph); 121.7 (*C3*, ph); 125.6 (*C5*, ph); 127.1 (*C4*, ph); 130.6 (*C2*, ph); 149.4 (*C*=N, thiazole and *C2*, py); 150.5 (*C6*, py). MS (ESI) *m/z* (%) 446 (M^++NCMe, 100); 269 (10). *Anal.* Calc. for $C_{16}H_{16}N_2SPdCl_2 \cdot CH_2Cl_2$: C, 38.71; H, 2.44; N, 5.31. Found: C, 39.10; H, 2.60; N, 5.50%.

2.2.11. {2-(4-tert-Butyl pyridin-2-yl)-benzothiazole} PdClMe (6)



This compound was synthesised in a similar manner to complex **1** using **L4** (0.08 g, 0.20 mmol) and [Pd(COD)-ClMe] (0.07 g, 0.20 mmol). Yield = 0.09 g (82%). ^{1}H NMR ($CDCl_3$): δ 1.20 (s, 3H, CH_3, Pd–Me); 1.45 (s, 9H, ^{t}Bu, py); 7.55 (m, 2H, ph, 1H, py); 7.90 (d, 2H, $J = 8.1$, ph); 8.50 (d, 1H, $J = 7.8$, py); 9.41 (d, 1H, $J = 8.1$, py). ^{13}C NMR ($CDCl_3$): 1.3 (Pd-*C*H_3); 30.6 (C-(*C*H_3)$_3$, py); 35.3 (*C*-(CH_3)$_3$, py); 117.3 (*C3* and *C5*, py); 123.1 (*C3*, and *C6*, ph); 125.2 (*C5*, ph); 127.6 (*C4*, ph); 130.9 (*C2*, ph); 150.1 (*C*=N, thiazole and *C2*, py); 150.4 (*C6*, py). MS (ESI) *m/z* (%) 430 (M^++NCMe, 100); 269 (48). *Anal.* Calc. for $C_{17}H_{19}N_2SPdCl$: C, 48.01; H, 4.50; N, 6.59. Found: C, 47.99; H, 4.14; N, 6.45%.

2.2.12. 6-tert-Butyl-2-(4-tert-butyl-pyridin-2-yl)-benzothiazole} PdMeCl (7)

Complex **6** was prepared in a similar manner to **1** using **L5** (0.07 g, 0.21 mmol) and [Pd(COD)MeCl] (0.05 g, 0.21 mmol). Yield = 0.06 g (60%). ^{1}H NMR ($CDCl_3$): δ 1.21 (s, 3H, CH_3, Pd–Me); 1.40 (s, 9H, ^{t}Bu, ph); 1.45 (s, 9H, ^{t}Bu, py); 7.52 (d, 1H, $J = 7.8$, ph); 7.67 (d, 2H, $J = 10.5$, py); 7.86 (d, 2H, $J = 7.5$, ph); 8.47 (d, 1H, $J = 7.5$, py); 9.28 (d, 1H, $J = 9.0$, py). ^{13}C NMR ($CDCl_3$): 2.1(Pd-*C*H_3); 30.3 (C-(*C*H_3)$_3$, ph); 31.4 (C-(*C*H_3)$_3$, py); 32.9(*C*-(CH_3)$_3$, ph); 35.6 (*C*-(CH_3)$_3$, py); 117.3 (*C3* and *C5*, py) 123.4 (*C3*, ph); 124.3 (*C5*, ph); 124.9 (*C6*, ph); 126.7 (*C2*, ph); 147.8 (*C1* and *C4*, ph); 151.6 (*C1*, thiazole and *C2*, py); 163.9 (*C4*, py). MS (ESI) *m/z* (%) 486 (M^++NCMe, 100); 462 (90); 445 (10); 269 (48). *Anal.* Calc. for $C_{21}H_{27}N_2SPdCl$: C, 52.40; H, 5.65; N, 5.82. Found: C, 52.62; H, 6.03; N, 5.70%.

2.3. Typical procedure for Heck coupling reactions

In a typical experiment butylacrylate (0.06 mmol), iodobenzene (0.06 mmol) and Et_3N (0.06 mmol) were added to a

R_1	R_2	X	Ligand
H	H	N-H	**L1**
H	H	S	**L2**
^{t}Bu	H	O	**L3**
^{t}Bu	H	S	**L4**
^{t}Bu	^{t}Bu	S	**L5**

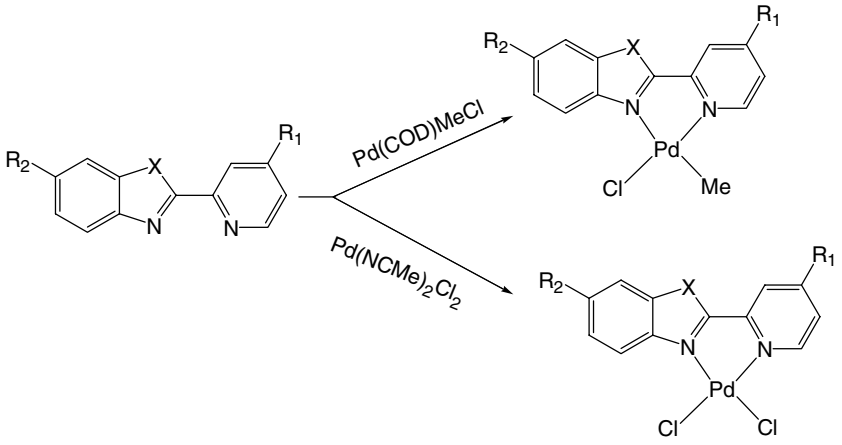
Scheme 1.

solution of the palladium catalyst (0.4%) in DMF (10 mL) at 80 °C and the reaction heated for 24 h. Samples were drawn at regular intervals and analyzed by GC to determine the percentage conversions. The coupling product was isolated by pouring the reaction mixture in water (50.00 mL) and extracted with CH_2Cl_2. The organic extract was dried over anhydrous $MgSO_4$ and the solvent was removed *in vacuo* to give a pure product as determined by ^{1}H NMR.

2.3.1. Reaction carousel experiments

For comparison and duplicate reactions, the Heck coupling reactions were also carried out in a Radley 12-place carousel on the same scale. Reaction mixtures were stirred and heated at (80 °C) heating block. Samples were drawn at regular intervals for GC analyses.

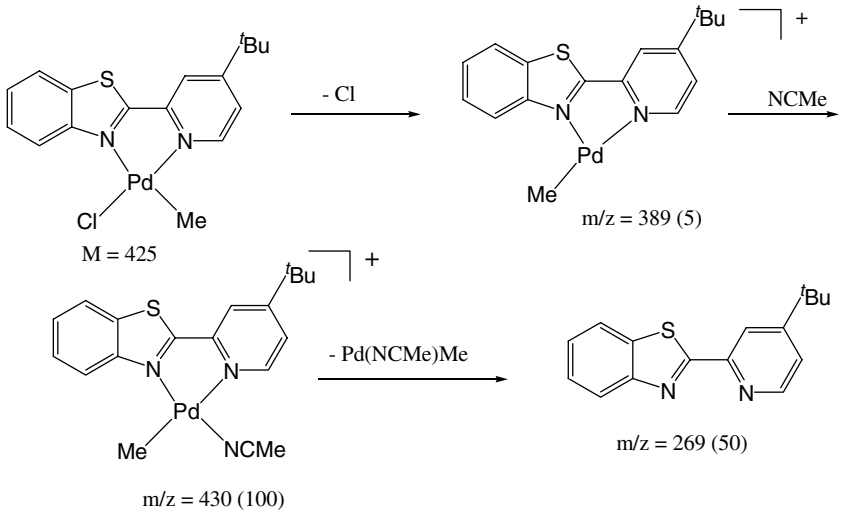
3. Results and discussion



3.1. Synthesis of ligands and palladium complexes

Compounds **L1** and **L2** were prepared by the literature procedures [9] while **L3** and **L4** were prepared using a modified ring closure of 2-aminophenol and 2-aminothiophenol [9] with 4-*tert*-butylpyridine carboxylic acid, respectively (Scheme 1). Both compounds were obtained in good yields. The 4-*tert*-butylpyridine carboxylic acid was synthesized following the procedure described by Fife [12]. However, **L5** could not be synthesized by this method owing to the non-availability of substituted aminophenols or aminothiophenols. It was therefore synthesized by Jacobsen's intramolecular cyclization [13] under alkaline conditions with potassium ferricyanide (Scheme 1).

The carboxylic acid amide (**S1**) was prepared by reacting 4-*tert*-butylaniline with 4-*tert*-butylpyridine carboxylic acid and was obtained in good yields. Reactions of **S1** with 0.5 mol equivalent of Lawesson's reagent gave the corresponding carbothioic acid amide (**S2**), Scheme 1. Cyclization to give **L5** was achieved in quantitative yields by treatment of **S2** with potassium ferricyanide under basic conditions (30% NaOH). Consistent with literature reports, attempted cyclization of **S1** to give the benzooxazole analogue did not give the desired product [9].



Reactions of compounds **L1**–**L5**, with either [Pd(NCMe)Cl_2] or [Pd(COD)MeCl] gave the corresponding palladium complexes (**1**–**7**) in moderate to high yields (Scheme 2). While complexes **1** and **2** showed poor solubility in most organic solvents, **3**–**6** were slightly soluble in chlorinated solvents due to the presence of the bulkier *tert*-butyl group on the pyridine ring. Complex **7**, containing *tert*-butyl groups on both the phenyl and pyridine rings, was completely soluble in chlorinated solvents.

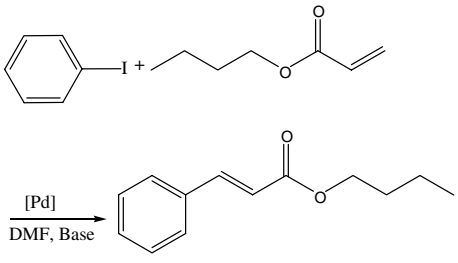
The identities of **S1** and **S2** were established by ^{1}H NMR and ^{13}C NMR spectroscopy and high resolution

R_1	R_2	X	Complex
H	H	N-H	**1**
H	H	S	**2**
^{t}Bu	H	O	**3**
^{t}Bu	H	O	**4**
^{t}Bu	H	S	**5**
^{t}Bu	H	S	**6**
^{t}Bu	^{t}Bu	S	**7**

Scheme 2.

Scheme 3.

mass spectroscopy (HRMS). For example the N–H signal observed at 10.04 ppm (**S1**) confirmed the amide bond formation from the reaction between the pyridine carboxylic acid and the aniline, and a significant downfield shift of the N–H proton from 10.02 ppm (**S1**) to 12.11 ppm in **S2** confirmed the conversion of the C=O to C=S. Consistent with ^{1}H NMR spectra, ^{13}C NMR spectra show significant downfield shifts of the C=S (1873.3 ppm in **S2**) compared C=O (162.2 ppm in **S1**) carbon signals. HRMS spectral data for **S1** and **S2** showed *m*/*z* at 310 and *m*/*z* at 326 as the base peaks corresponding to the molecular ions of **S1** and **S2**, respectively.



Compounds **L1**–**L5** and their complexes **1**–**7** were also characterized by a combination of ^{1}H NMR and ^{13}C NMR spectroscopy, mass spectrometry and micro-analyses. For example the intramolecular cyclization to give **L5** was evident from the disappearance of the N–H signal at 12.11 ppm and loss of symmetry in **S2** in the phenyl ring due to the formation of the C–S bond at one of the *ortho* positions of the phenyl ring. ^{1}H NMR spectra of the complexes showed significant downfield shifts of the aromatic signals in the region 7.20–9.40 ppm. For instance the shift of the *ortho* pridinyl proton from 8.60 ppm (**L4**) to 9.40 ppm in **5** indicates coordination to the palladium.

High resolution MS (ESI) mass spectra for **L3**–**L5** show *m*/*z* peaks at 253, 269 and 324 corresponding to the molecular ions of **L3**, **L4** and **L5**, respectively. The mass spectra and micro-analyses data of complexes **1**–**7** were in good agreement with the proposed structures of the complexes in Scheme 3.

All the complexes exhibited a similar mass spectral fragmentation pattern; starting with the loss of a Cl^{-} to form an unstable 14-electron cationic palladium complexes. In a typical fragmentation, **6** was found to loose a Cl^{-} to form a 14-electron fragment ($m/z = 389$), which was then stabilized by NCMe used to run the mass spectrum to give $[Pd(\mathbf{L4})(NCMe)Me]^{+}$ ($m/z = 430$) as the base peak (Scheme 3). Subsequent loss of $[Pd(NCMe)Me]^{+}$ results in the peak at $m/z = 269$ corresponding to **L4**. Fig. 1 shows the simulated and found isotopic distribution of the NCMe cationic adduct of **5**. This stabilization of the cationic species by NCMe was confirmed by isolation of the cationic adducts of **1** ($m/z = 357$) and **6** ($m/z = 430$) which were characterized by mass spectrometry.[1]

3.2. Heck coupling reactions

Complexes **1**–**7** were tested as catalysts in Heck coupling reaction of iodobenzene with butyl acrylate under different conditions. All the complexes were found to catalyze the coupling of butylacrylate with iodobenzene to form exclusively *trans*-butylcynnamate as established by ^{1}H NMR analysis.

(1)

In order to optimize the reaction conditions, the coupling reactions were performed at different conditions using catalysts **1** and **6** (Table 1). First we investigated the effect of temperature as it is well established that most Heck

[1] To a mixture of complex **6** (0.10 g, 0.24 mmol) and $NaBAr_4$ (Ar = 3,5-$(CF_3)_2C_6H_3$) was added a 1:1 mixture of CH_2Cl_2 and NCMe (20 mL) and the light yellow solution stirred for 24 h. The solvent was removed *in vacuo* to afford a light yellow solid. Yield = 0.20 g (67%). Positive MS (ESI) *m*/*z* (%) 430 (M^{+}, 50); 269 (100). Negative MS (ESI) *m*/*z* (%) 863 (M^{+}, 100). *Anal.* Calc. for $C_{52}H_{37}BF_{24}N_3PdS \cdot 0.5CH_2Cl_2$: C, 44.74; H, 2.79; N, 2.93. Found: C, 44.63; H, 2.45; N, 3.04%.

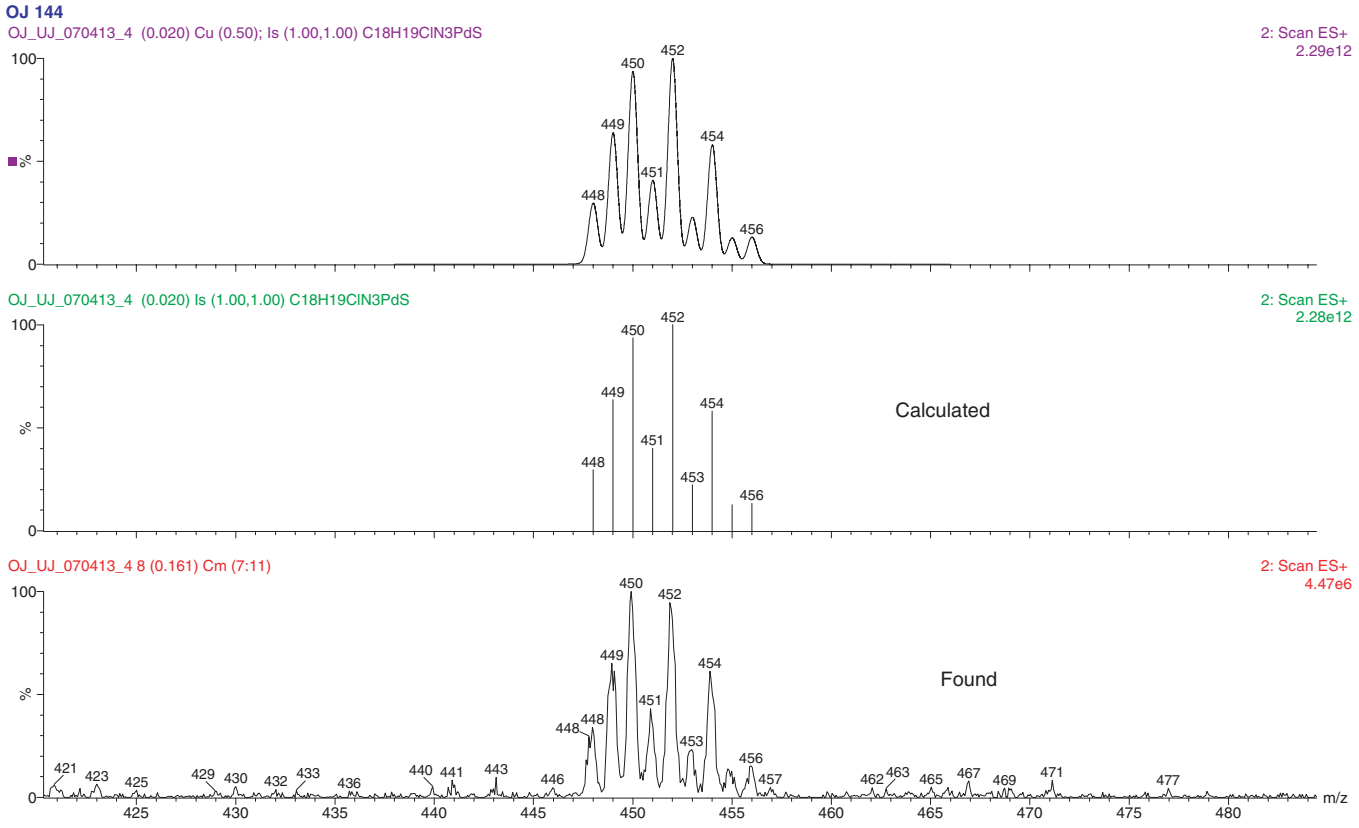


Fig. 1. Simulated and found isotopic distribution of NCMe adduct of **5**.

reactions occur at temperatures of 120–140 °C. However, literature reports also indicate catalyst deactivation at high temperatures as recently reported for the cyclopalladated imine catalysts [14]. Our catalysts are thus more stable at 120 °C than the cyclopalladated imine catalysts which are presumed to be very stable. It was evident that faster induction times were achieved at 120 °C than at 80 °C (Table 1 entries 1 and 4). After 24 h the temperature effect was less pronounced as observed from conversions of 92% at 80 °C and 98% at 120 °C.

Table 1
Effect of reaction conditions on Heck coupling reactions[a]

Entry	Catalyst	Time (h)	Temperature (°C)	[Pd] (%)	% Con[c]
1	**5**	1	120	1	94
1	**5**	4	120	1	98
3	**5**	24	120	1	98
4	**5**	1	80	1	82
5	**5**	4	80	1	90

15	**1**	24	120	0.2	97
16	**1**	24	120	0.1	97
17	**1**	24	120	0.05	74

[a] Conditions: amount of monomer, butylacrylate 0.06 mmol; iodobenzene, 0.06 mmol; base Et_3N solvent: DMF (10 mL).
[b] Equal amount of reactants added in situ after 1 h without addition of catalyst.
[c] Determined by GC.

To probe the stability of the active catalysts, equal amounts of the substrates and Et_3N were added at 1 h intervals to the reaction mixture using complex **1** at 120 °C. After each addition, the reaction was allowed to run for 1 h and an aliquot sampled for GC analysis. The conversions remained the same even after the fourth addition, showing that the catalyst did not deactivate with time (Table 1, entries 9–12). This observation suggests that the catalysts are "living" Heck coupling catalysts as compared to the well established phosphine-based catalysts, for example, $Pd(dippp)_2$ (dippp = 1,3-bis(diispropylphosphino)propane) that rapidly deactivate [2]. Nowotny et al. has observed diminished activity of cyclopalladated imine catalysts when a second addition of an equivalent amount of substrate and base were added, but found a total loss of activity on adding a third equivalent of substrate [14]. Our catalysts were still active even after the fourth run.

We further examined the effect of catalyst loading on the performance of the Heck reactions using catalyst **1** (Table 1, entries 8, 13–17). It is apparent that even at low catalyst loading (0.05%) there is considerable activity

with conversions of 74%. Interestingly increasing catalyst concentration to 1% resulted in reduction of activity with the optimum activity at 0.8%; though this does not differ much from the catalyst loading of 0.1–0.6%. The reduced activity at high catalyst loadings could be the result of agglomeration and thus lower the concentration of the active catalyst.

Having established the optimum catalytic conditions, **1**–**7** were screened at 80 °C to probe the effect of ligand structure on the catalysts' performance (Table 2). The low temperature of 80 °C slowed the initiation process enough to allow the reaction profiles to be established. Table 2, entries 1–6, shows how reaction with **1** gradually increased in conversion from 0% to 97% over 24 h. It is also evident from Table 2 that complexes **2**–**7** containing benzooxazole and benzothiazole exhibit almost 100% conversions within 1 h compared to the benzoimidazole complex (**1**) which showed no activity within 1 h. Thus the induction period for **1** is considerably slower compared to **2**–**7**.

As suggested by Kawano et al. [15] bidentate pyridine Pd(II) complexes catalyze Heck coupling reactions by first undergoing reduction to ligand-stabilized Pd(0). It is therefore conceivable that the electron deficient benzothiazole and benzooxazole in **2**–**7** might play a role in their rapid conversion to ligand-stabilized Pd(0), the active catalysts, as compared to the electron rich benzoimidazole in complex **1**. Bara-Behrens and co-workers [7b] have established that electron withdrawing abilities of azoles to follow the trend thiazole > oxazole > imidazole; an order that explains our observed trend in the initiation rates. We found the rates of initiation of **4** and **6** to be faster than **3** and **5** (Table 2 entries 3–6). This is consistent with earlier research findings that palladium pre-catalysts with Pd–Me show faster induction periods than the Pd-halides complexes [16]. Indeed chloromethylpalladium complexes are generally known to undergo rapid decomposition *via* reductive elimination pathway [17]. Nevertheless, the catalytic activities of all complexes after 24 h did not show any significant differences (Table 2). It is apparent that steric effect plays insignificant role in the catalytic activities of the complexes as seen in the comparable activities of complexes **2**, **6** and **7**. It is note worthy to point that complexes **2**–**7** exhibited relatively higher activity and shorter induction periods than the recently reported pyridyl-imine palladium catalysts [18] under similar conditions. For instance, while **1**–**7** display almost maximum conversion (98%) within 1 h, these palladium-imine catalysts give conversions of 35–75% within 1 h and in some cases achieve maximum conversion of 95% only after 2 h.

Table 2
Influence of catalyst system and stability on Heck coupling reactions[a]

Entry	Catalyst	Time (h)	Temperature (°C)	[Pd] (%)	Con[b] (%)
1	**1**	0.5	80	0.4	
2	**1**	1	80	0.4	
3	**1**	5	80	0.4	10
4	**1**	8	80	0.4	35

12	**4**	24	80	0.4	99
13	**5**	0.5	80	0.4	92
14	**5**	24	80	0.4	99
15	**6**	0.5	80	0.4	97
16	**6**	24	80	0.4	100
17	**7**	0.5	80	0.4	95
18	**7**	24	80	0.4	100

[a] Conditions: amount of monomers, butylacrylate 0.06 mmol; iodobenzene, 0.06 mmol; base, Et_3N; solvent: DMF (10 mL).
[b] Determined by GC.

Table 3
Heck coupling reactions catalyzed by in situ $Pd(OAc)_2$ and ligands **L1** and **L3**[a]

Entry	Ligand	Time (h)	[Pd] (%)[b]	Con[c] (%)
1		1	0.4	77
2		24	0.4	78
3	**L1**	1	0.4	74
4	**L1**	24	0.4	100
5	**L4**	1	0.4	98
6	**L4**	24	0.4	100

[a] Conditions: amount of monomers, butylacrylate 0.06 mmol; iodobenzene, 0.06 mmol; base, Et_3N; solvent: DMF (10 mL); temperature = 80 °C.
[b] Pd:ligand ration = 1:1.
[c] Determined by GC.

The palladium complexes, $[Pd(OAc)_2]$ and $[Pd(PPh_3)_4]$, are known to efficiently catalyze Heck coupling reactions although addition of certain ligands such as diphenylphosphino ferrocene (dppf) help in increasing their activities [1b]. In attempts to establish the comparative activities of **1**–**7** and $[Pd(OAc)_2]$, equimolar amounts of **L1** and **L4** were added to $[Pd(OAc)_2]$ and compared to the activity of $[Pd(OAc)_2]$ alone (Table 3).

We found that addition of **L1** and **L4** enhanced the activity of $[Pd(OAc)_2]$ from 78% to 100% (Table 3, entries 4–6). Consistent with the initiation rates of the corresponding complexes **1** and **6**, **L4** showed shorter induction period than **L1** (Table 3, entries 5). Amatore and Jutanda [19] have identified $[Pd(PPh_3)_2(OAc)_2]$ as the intermediate species formed when $[Pd(OAc)_2]$ and PPh_3 are used to catalyze Heck coupling reactions. The $[Pd^{(II)}(PPh_3)_2(OAc)_2]$ subsequently undergoes reduction to give $[Pd^{(0)}(PPh_3)_2(OAc)]^-$ as the active species. We expect both **L1** and **L4** to form similar palladium intermediates as suggested by Amatore and Jutanda [19] and thus the generation of the active catalysts by a similar mechanism.

4. Conclusions

In summary, this work has resulted in the identification of a convenient synthetic route to substituted

(pyridinyl)benzothiazole compounds. The ligands form mononuclear palladium complexes which catalyze Heck coupling reactions of iodobenzene with butylacrylates under mild conditions and at low catalyst loadings. The catalysts are air and moisture insensitive, thermally stable, and can be used as ''living'' Heck coupling catalysts.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2007, volume 26 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2007, volume 26 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2007, volume 26 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2007, volume 26 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2007, volume 26 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

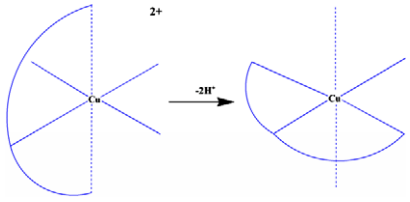
Polyhedron 26 (2007) 1357

A rare ferromagnetically coupled asymmetric doubly azido bridged copper(II) dimer with an N, N, O donor Schiff base

A new end-to-end (EE) doubly azido bridged centrosymmetric dinuclear complex has been synthesized and characterized with elemental and spectroscopic techniques. In the complex, each copper atom is in a distorted square pyramidal geometry with a CuN_4O chromophore. Temperature dependent magnetic susceptibility, fitted using the Bleaney–Bowers expression indicates a ferromagnetic interaction through the double azido bridges connecting the adjacent copper(II) centers.

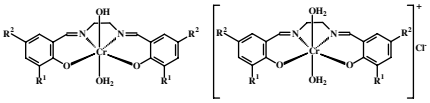


T.K. Prasad and M.V. Rajasekharan

Polyhedron 26 (2007) 1364

$[M(dipicH_2)(H_2O)_3]^{2+}, M = Ni, Cu, Zn$ (dipicH$_2$ = dipicolinic acid) – A combined crystallographic, spectroscopic and computational study

In the three isomeric crystal structures obtained with $[Ce(dipic)_3]^{2-}$ as the counter anions, the transition ions retain the structural features characteristic of their electronic configurations.



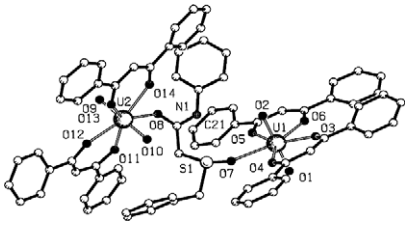
Pedro E. Aranha, Mirian P. dos Santos, Sandra Romera and Edward R. Dockal

Polyhedron 26 (2007) 1373

Synthesis, characterization, and spectroscopic studies of tetradentate Schiff base chromium(III) complexes

Eight chromium(III) complexes of tetradentate Schiff bases have been prepared and characterized by elemental analysis, m.p., IR, molar conductivity and electronic spectra. The free ligands were also characterized by ^1H and ^{13}C NMR spectra. The IR and electronic spectra of the free ligand and the complexes are compared and discussed.

R^1	R^2	L	Complexes
H	H	OH	$[Cr(L^1)(OH)(H_2O)]$
H	Br	OH	$[Cr(L^2)(OH)(H_2O)]$
H	Cl	OH	$[Cr(L^3)(OH)(H_2O)]$
H	MeO	OH	$[Cr(L^4)(OH)(H_2O)]$



R^1	R^2	L	Complexes

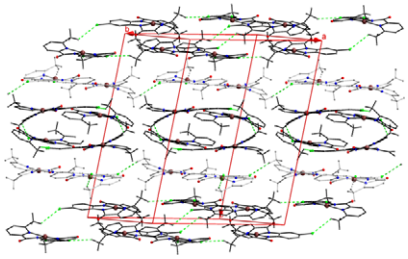
Polyhedron 26 (2007) 1383

Extraction and coordination studies of carbamoyl methyl sulfoxide (CMSO) with uranyl bis(β-diketonates). Synthesis and molecular structure of $[\{UO_2(DBM)_2\}_2C_6H_5CH_2SOCH_2CONHC_6H_5]$

Coordination studies of the carbamoyl methyl sulfoxide (CMSO) ligand with uranyl bis(β-diketonate) show that it acts as a monodentate ligand in 1:1 compounds and a bridging bidentate ligand in 2:1 compounds. An enhancement in the extraction for the uranyl ion from nitric acid medium is observed when a mixture of HTTA and CMSO were employed.

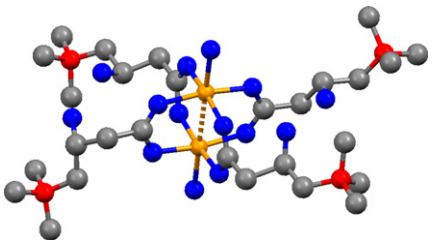


Jung Hwan Lee, Hee Jin Kim, Yun Wee Choi, Young Min Lee, Byeong Kwon Park, Cheal Kim, Sung-Jin Kim and Youngmee Kim

Polyhedron 26 (2007) 1388

Pd(II) polymeric compounds directed by intermolecular C–H···X–C interactions (X = F, Cl): Suzuki–Miyaura cross-coupling catalytic activity by a novel N4-type saturated Pd complex

New palladium polymeric compounds containing novel tetradentate halogen-substituted $6Me_2bpX^{2-}$ ligands ($6Me_2bpX^{2-}$ = 1,2-bis(6-methylpyridine-2-carboxamide) halobenzene dianion, X = F for **4**, Cl for **5**) were constructed by non-classical C–H···X–C interactions, and the novel catalyst **5** was used to carry out Suzuki coupling reactions with aryl iodides and aryl boronic acids under mild conditions.

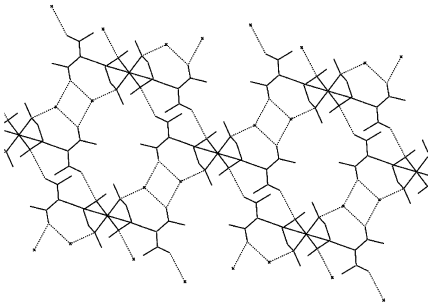


Charalambos Litos, Simon Parsons and Alexandra Karaliota

Polyhedron 26 (2007) 1397

Synthesis of two dicopper(II) complexes of L-carnitine: The first structural determination of a metal complex containing L-carnitine

The first crystal structure of a metal complex containing L-carnitine is described. Two dicopper(II) complexes with formulas $[Cu_2(L\text{-carnitine})_2Cl_2(H_2O)_2] \cdot Cl_2$ (complex **1**) and $[Cu_2(L\text{-carnitine})_4(H_2O)_2] \cdot (ClO_4)_4 \cdot H_2O \cdot CH_2Cl_2$ (complex **2**) were isolated from ethanolic and aqueous solutions, respectively. The complexes were characterized by several techniques, while the structure of complex **2** was identified by X-ray crystallography.

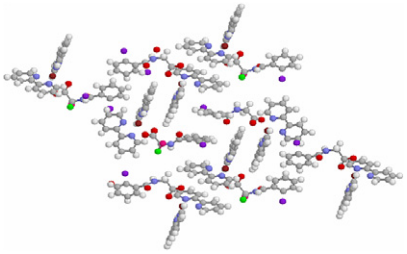


Leandros C. Tzavellas, Sofia Pachini, Chris Tsiamis and Antonis G. Hatzidimitriou

Polyhedron 26 (2007) 1404

Conformation and coordination of β-diketonates in mixed-ligand copper(II) chelates of 1,2-diamines. Theoretical approach and experimental verification. Crystal structure of [bis(*N*,*N*′-dimethyl-1,2-diaminoethane) bis(3-cyano-2,4-pentanedionate)copper(II)]dihydrate

The products of the reaction of the bis(2,4-pentanedionato)copper(II), $Cu(acac)_2$, and cognate compounds, $Cu\beta_2$, with 1,2-diaminoethane (en), and certain of its *N*-substituted derivatives have been investigated and are discussed in the light of DFT calculations. Further, the crystal structure of $[Cu(Me\text{-}en\text{-}Me)_2(NC\text{-}acac)_2] \cdot 2H_2O$ is reported.

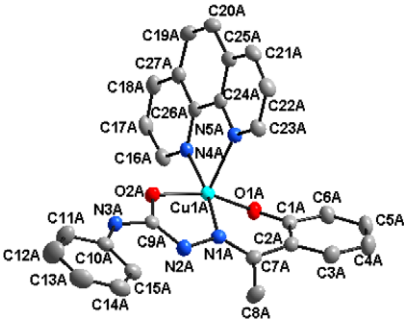


Miquel Barceló-Oliver, Angel Terrón, Angel García-Raso and Elies Molins

Polyhedron 26 (2007) 1417

Models for thyroxine: Aromatic iodine-assisted self-assemblies

Trying to understand the different recognition factors between thyroxine and its binding proteins, the chemistry of the ternary complexes between copper and *o*-iodobenzoylglycine (I-hip) [or *o*-iodobenzoylglycilglycine (B^IGG)] as simple thyroxine models were studied with 2,2′-bipyridyl as secondary ligand.

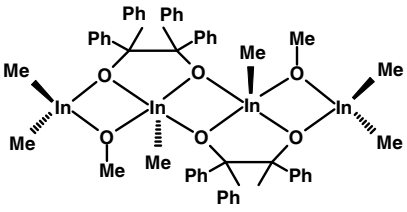


U.L. Kala, S. Suma, M.R. Prathapachandra Kurup, Suja Krishnan and Rohith P. John

Polyhedron 26 (2007) 1427

Synthesis, spectral characterization and crystal structure of copper(II) complexes of 2-hydroxyacetophenone-*N*(4)-phenyl semicarbazone

Copper(II) complexes of 2-hydroxyacetophenone-*N*(4)-phenyl semicarbazone have been synthesized and physico-chemically characterized. The tridentate character of the semicarbazone is inferred from IR spectra. The *g* values, calculated for all the complexes in frozen solution EPR, indicate the presence of the unpaired electron in the $d_{x^2-y^2}$ orbital. The metal–ligand bonding parameters evaluated showed strong in-plane σ and in-plane π-bonding. The crystal structure of CuLphen revealed a monoclinic lattice with space group symmetry $P2_1/c$. The compound adopts a distorted square pyramidal geometry with a N_2O_2 core as the base.



Wanda Ziemkowska, Anna Kubiak, Szymon Kucharski, Robert Woźniak and Romana Anulewicz-Ostrowska

Polyhedron 26 (2007) 1436

Reactions of benzopinacol with group 13 alkyl metals: Crystal structure of $Me_6In_4[OC(C_6H_5)_2C(C_6H_5)_2O]_2(OCH_3)_2$, a new alkylalkoxo indium diolate

$^tBu_3Al$ reacted with an equimolar amount of benzopinacol to form a monomeric complex $^tBuAl[OC(C_6H_5)_2C(C_6H_5)_2O](C_4H_8O)$ (**3**). Re-actions of Me_3Ga and Me_3In with benzopinacol afforded trinuclear complexes $Me_5M_3[OC(C_6H_5)_2C(C_6H_5)_2O]_2$ (**4** (M = Ga), **5** (M = In)). In the presence of water and alcohols, compounds **4** and **5** underwent a decomposition reaction to benzopinacol and mixtures of metalloxanes and alkoxides. An unusual methylmethoxo indium benzopinacolate $Me_6In_4[OC(C_6H_5)_2C(C_6H_5)_2O]_2(OCH_3)_2$ (**6**) was obtained in the reaction of benzopinacol with of Me_3In and Me_2InOMe in a 1:1:1 molar ratio.

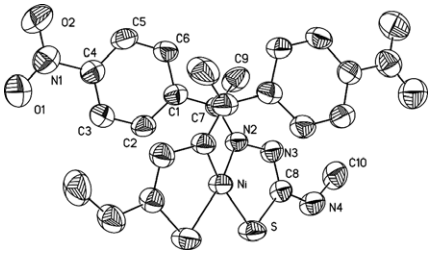
Polyhedron 26 (2007) 1445

A highly active two six-membered phosphinite palladium PCP pincer complex [PdCl{$C_6H_3(CH_2OPPr^i)_2$-2,6}]

The two six-membered phosphinite palladium PCP pincer complex [PdCl{$C_6H_3(CH_2OPPr^i)_2$-2,6}] has been synthesized and its catalytic activity for C–C coupling reactions has been investigated.

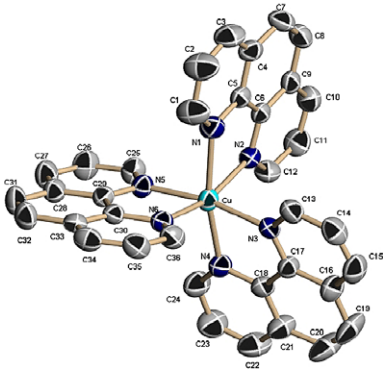


Anayive Pérez-Rebolledo, Isolda C. Mendes, Nivaldo L. Speziali, Philippe Bertani, Jarbas M. Resende, Antônio F. de Carvalho Alcântara and Heloisa Beraldo

Polyhedron 26 (2007) 1449

N(4)-Methyl-4-nitroacetophenone thiosemicarbazone and its nickel(II) complex: Experimental and theoretical structural studies

X-ray structural studies of *N*(4)-methyl-4-nitroacetophenone thiosemicarbazone, $H4NO_2Ac4M$ (**1**) and its nickel(II) complex, $[Ni(4NO_2Ac4M)_2]$ (**2**) revealed that the **1-*E*,*E*** isomer of the thiosemicarbazone and the **2-*cis*** (***E*-Ni-*E***) isomer of the complex are formed in the crystal. NMR data along with Hartree–Fock (HF) and Density Functional Theory (DFT) calculations suggest that the **1-*E*,*E*** isomer probably exists in DMSO-d_6, and the **1-*Z*,*E*** isomer in $CDCl_3$. NMR data along with HF and DFT calculations suggest the presence of **2-*cis*(*Z*-Ni-*Z*)** in DMSO-d_6 as well as in the powder, indicating **2-*cis*(*Z*-Ni-*Z*)** → **2-*cis*** (***E*-Ni-*E***) conversion during crystallization.

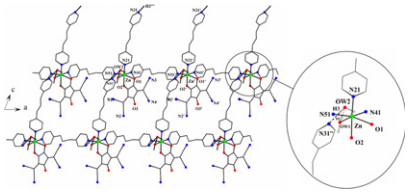


Sujittra Youngme, Nanthawat Wannarit, Chaveng Pakawatchai, Narongsak Chaichit, Eakasit Somsook, Urho Turpeinen and Ilpo Mutikainen

Polyhedron 26 (2007) 1459

Structural diversities and spectroscopic properties of bis and tris(1,10-phenanthroline)-copper(II) complexes

The crystal structures of bis and tris(1,10-phenanthroline)copper(II) complexes $[Cu(phen)_3](S_4O_6)(S_8)$ (**1**), $[Cu(phen)_3](BF_4)_2$ (**2**), $[Cu(phen)_2(OS_2O_7)]$ (**3**) and $[Cu(phen)_2(FBF_3)](BF_4)$ (**4**) have been determined by X-ray crystallography. The Cu(II) ions are octahedrally coordinated by the three phen ligands. As a consequence of the Jahn-Teller effect, the two axial Cu–N bonds are longer than the equatorial Cu–N bonds and the CuN_6 chromophores appear to be elongated rhombic octahedral with tetragonalities of 0.892 and 0.886 for **1** and **2**, respectively. Complexes **3** and **4** consist of mononuclear units, the 5-coordinate Cu(II) environment being distorted square pyramidal ($\tau = 0.31$) and distorted trigonal bipyramidal ($\tau = 0.66$), respectively. The unidentate $S_2O_8^{2-}$ anion in **3** occupies the axial position, while the unidentate BF_4^- anion in **4** is coordinated in the trigonal plane. The crystal structures and their electronic properties (IR and EPR) are discussed and compared to other relevant complexes based on the Jahn-Teller effect.

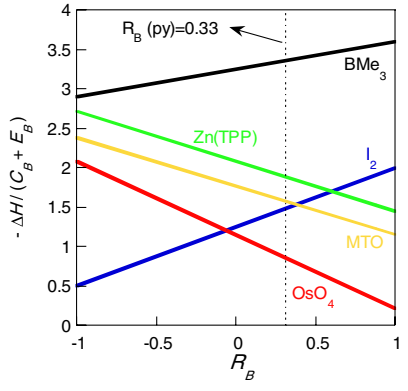


Wagner M. Teles, Regis de A. Farani, Maria Irene Yoshida, Adailton J. Bortoluzzi, Manfredo Hörner, Luiz Fernando C. de Oliveira and Flávia C. Machado

Polyhedron 26 (2007) 1469

Synthesis and crystal structure of a novel Zn(II) 2-D coordination polymer containing 1,3-bis(4-pyridyl)propane ligand and Croconate Violet dianion

Reaction between Zn(II) cation and Croconate Violet dianion (CV^{2-}) in the presence of the flexible nitrogen ligand 1,3-bis(4-pyridyl)propane (BPP) has afforded a novel neutral coordination polymer namely $\{[Zn(\mu\text{-}BPP)(BPP)(CV)(H_2O)] \cdot H_2O\}_n$ (**1**). Compound **1** was characterized by means of elemental analysis, thermogravimetric analysis and vibrational spectroscopy. The crystal structure of **1** reveals 1-D chains extended to a 2-D coordination network through hydrogen bonding.

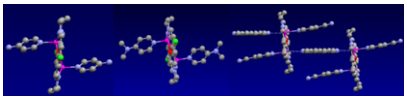


S. Masoud Nabavizadeh and Mehdi Rashidi

Polyhedron 26 (2007) 1476

Acidity of osmium tetroxide (OsO_4) towards coordination with pyridine and its derivatives

Three scales, donor ability of substituted pyridines, the Hammett reaction constant and the ECW model were used to make an acidity scale for OsO_4. The results show that the acid strength order towards pyridine is as follow: $BMe_3 > Zn(TPP) > MTO > I_2 > OsO_4$.

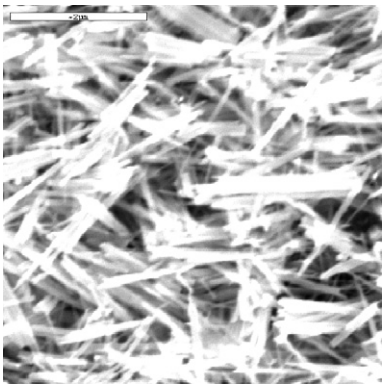


Wei Huang, Zhaolian Chu, Shaohua Gou and Takuji Ogawa

Polyhedron 26 (2007) 1483

Construction of macrocycle-based molecular stairs having pendant 4-aminopyridine, 4-dimethylaminopyridine and isonicotinonitrile groups

Self-assembly directed by dinuclear zinc(II) macrocyclic species with 4-aminopyridine, 4-dimethylaminopyridine and isonicotinonitrile produces three *trans* molecular stair elements and a 1D polymeric stair, which are stabilized by coordination bonding, H-bonding and face-to-face π–π stacking interactions. Controlled synthesis of the *cis* and *trans* isomers is achieved in the case of 4-aminopyridine, which is further verified by theoretic calculations.

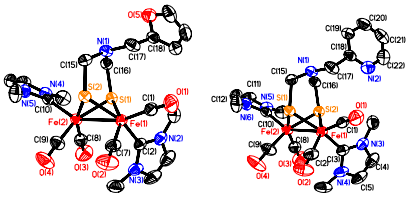


Sobia Ashraf, Russell Binions, Christopher S. Blackman and Ivan P. Parkin

Polyhedron 26 (2007) 1493

The APCVD of tungsten oxide thin films from reaction of WCl_6 with ethanol and results on their gas-sensing properties

The APCVD reaction of WCl_6 with ethanol was examined to deposit tungsten oxide on gas sensor substrates. Deposited films, which were WO_{3-x}, displayed a different morphology than those seen previously for CVD tungsten oxide. The gas-sensing properties of the deposited films were examined.

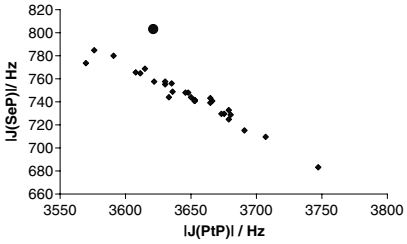


Shi Jiang, Jianhui Liu, Yu Shi, Zhen Wang, Björn Åkermark and Licheng Sun

Polyhedron 26 (2007) 1499

Preparation, characteristics and crystal structures of novel *N*-heterocyclic carbene substituted furan- and pyridine-containing azadithiolate Fe–S complexes

Two novel *N*-heterocyclic carbene di-substituted furan- and pyridine-containing azadithiolate Fe-only models have been synthesized and characterized. They show more negative reductive potential and are easier to capture a proton attributing to the strong electron-donating ligand NHC.

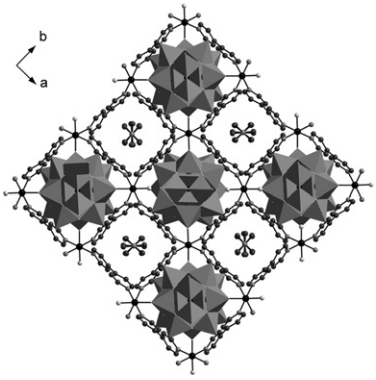


Dave J. Adams, James A. Bennett, Daniel Duncan, Eric G. Hope, Jonathan Hopewell, Alison M. Stuart and Andrew J. West

Polyhedron 26 (2007) 1505

Synthesis and characterisation of trisarylphosphine selenides: Further insight into the effect of fluoroalkylation on the electronic properties of trisarylphosphines

The electronic influence of perfluoroalkyl groups in a range of trisarylphosphines is conveniently assessed using the $^1J_{SeP}$ coupling constant of the trisarylphosphorus(V) selenides.

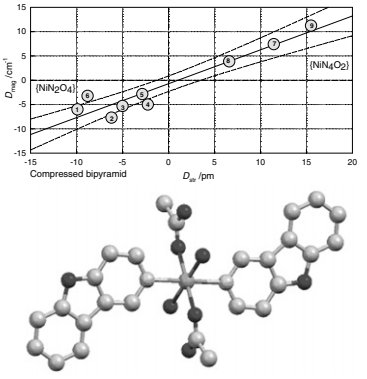


Chun-Dan Zhang, Shu-Xia Liu, Bo Gao, Chun-Yan Sun, Lin-Hua Xie, Miao Yu and Jun Peng

Polyhedron 26 (2007) 1514

Hybrid materials based on metal–organic coordination complexes and cage-like polyoxovanadate clusters: Synthesis, characterization and magnetic properties

Unique organic–inorganic hybrid compounds have been separated under hydrothermal conditions, and are constructed of metal–organic complexes and cage-like vanadium clusters. They indicate novel structures and attractive magnetic properties. Furthermore, two new clusters $[V_{16}O_{38}F]^{4-}$ and $[V_{16}O_{38}Br]^{4-}$ are reported.

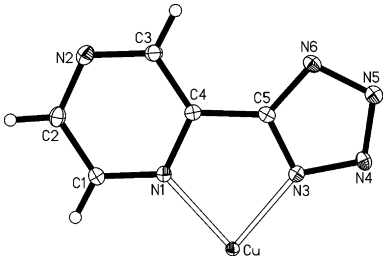


J. Titiš, R. Boča, L'. Dlháň, T. Ďurčeková, H. Fuess, R. Ivaniková, V. Mrázová, B. Papánková and I. Svoboda

Polyhedron 26 (2007) 1523

Magnetostructural correlations in heteroleptic nickel(II) complexes

Heteroleptic nickel(II) complexes with the general formula $Ni(L)_m(H_2O)_n(X)_k$ have been synthesized and structurally characterized; L stands for neutral *N*-donor ligands. The structures of the complexes $[Ni(bzfupy)_2(ac)_2(H_2O)_2]$, $[Ni(Me_2fupy)_2(H_2O)_4](ac)_2$ and $[Ni(Me_2iz)_4(H_2O)_2]Cl_2 \cdot 3H_2O$ are formed from $\{NiO_2O'_2N_2\}$, $\{NiO_4N_2\}$ and $\{NiN_4O_2\}$ chromophores, respectively. These complexes and two other previously characterized complexes were subjected to magnetochemical investigation down to 2 K (susceptibility and magnetization measurements). They show magnetic behaviour typical for zero-field splitting systems. The axial parameter of the zero-field splitting, *D*, adopts either positive or negative values and correlates with the axial distortion of the coordination polyhedra.

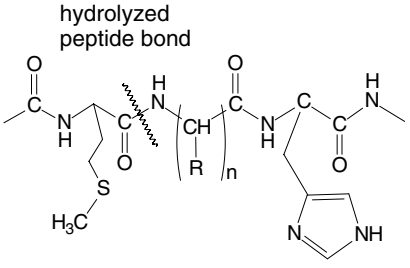


Morsy A.M. Abu-Youssef, Franz A. Mautner, Alshima'a A. Massoud and Lars Öhrström

Polyhedron 26 (2007) 1531

Synthesis, structure, network and thermal analysis of four 5-(pyrazinyl)tetrazolato copper(II) and cobalt(II) complexes

Four new copper(II) and cobalt(II) complexes with 5-(pyrazinyl)tetrazolate as chelating bidentate ligand. Hydrogen bonds connect the mononuclear units to a **3D** network structure. They can be related to the three- and six-connected rutile net (**rtl**) in $[Co(pyztz)_2(H_2O)_2]$ and the four- and six-connected **fsh**-net in $[Cu(pyztz)_2(H_2O)_2] \cdot (H_2O)$.

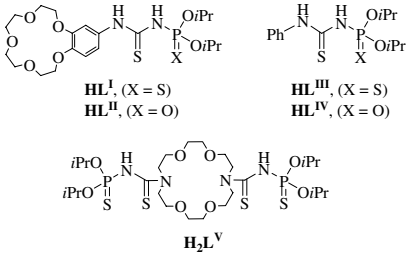


Marija D. Živković, Snežana Rajković, Urszula Rychlewska, Beata Warżajtis and Miloš I. Djuran

Polyhedron 26 (2007) 1541

A study of the reactions of methionine- and histidine-containing peptides with palladium-(II) complexes: The key role of steric crowding on palladium(II) in the selective cleavage of the peptide bond

The modes of coordination of *cis*-$[Pd(dpa)Cl_2]$ and *cis*-$[Pd(dpa)(H_2O)_2]^{2+}$ (dpa is 2,2′-dipyridylamine) in the reactions with Met-Gly and His-Gly peptides, and the regioselective cleavage of the amide bond involving the carboxylic group of methionine in the reactions of *cis*-$[Pd(dpa)(H_2O)_2]^{2+}$ with MeCOMet-Gly or MeCOHis-Gly peptides have been correlated with the steric bulk of the palladium(II) complex.



Felix D. Sokolov, Damir A. Safin, Maria G. Babashkina, Nail G. Zabirov, Vasiliy V. Brusko, Nikolay A. Mironov, Dmitry B. Krivolapov, Igor A. Litvinov, Rafael A. Cherkasov and Boris N. Solomonov

Polyhedron 26 (2007) 1550

A "sodium trap" based on benzo-15-crown-5 with an exocyclic *N*-(thiophosphoryl)thiourea moiety

For *N*-(thio)phosphorylthioureas of the common formula RC(S)NHP(X)(O*i*Pr)$_2$ **HL^{I}**, **HL^{II}**, **HL^{III}**, **HL^{IV}**, and (*N*,*N*′-bis-[C(S)NHP(S)(O*i*Pr)$_2$]$_2$-1,10-diaza-18-crown-6) **H$_2$L^{V}**, salts **LiL^{I,III,IV}**, **NaL$^{I–IV}$**, **KL$^{I–IV}$M$_2$L^{V}** (M = Li$^+$, Na$^+$, K$^+$), **Ba(L^{I,III,IV})$_2$** and **BaL^{V}** have been synthesized and investigated. Compounds **NaL^{I,II}** quantitatively drop out as a deposit in ethanol medium, allowing the separation of Na$^+$ and K$^+$ cations. This effect is not displayed for the other compounds. The crystal structure of **HL^{III}** and the solvate of the composition [**K(Me$_2$CO)L^{III}**] have been investigated by X-ray crystallography.

The Publisher encourages the submission of articles in electronic form thus saving time and avoiding rekeying errors. For detailed instructions on the preparation of manuscripts and of electronic artwork, consult the Author Gateway for Elsevier at http://authors.elsevier.com

Polyhedron 26 (2007) 1159

Synthesis, characterization and bioactivity of mixed-ligand Cu(II) complexes containing Schiff bases derived from *S*-benzyldithiocarbazate and saccharinate ligand and the X-ray crystal structure of the copper-saccharinate complex containing *S*-benzyl-β-*N*-(acetylpyrid-2-yl)methylenedithiocarbazate

Mixed-ligand complexes of general formula, [Cu(NNS)(sac)] (NNS′ = *S*-benzyl-β-*N*-(2-acetylpyrid-2-yl)methylenedithiocarbazate, NNS″ = *S*-benzyl-β-*N*-(2-benzoylpyrid-2-yl)methylenedithiocarbazate and NNS‴ = *S*-benzyl-β-*N*-(6-methylpyrid-2-yl)methylenedithio-carbazate, sac = the saccharinate anion) have been synthesized and characterized. An X-ray crystallographic structural analysis of [Cu(NNS′)(sac)] shows that the complex has a distorted square-planar geometry with the Schiff base coordinated to the copper (II) ion as a uninegatively charged tridentate chelating agent via the pyridine nitrogen atom, the azomethine nitrogen atom and the thiolate sulphur atom while the fourth coordination position is occupied by the N-bonded saccharinate anion. The complexes have been evaluated for their biological activities against selected pathogens and cancer cell lines. They display weak activity against the bacteria and fungi. They are highly active against the leukemic cell line (HL-60) but only [Cu(NNS′)(sac)] exhibits strong cytotoxicity against the ovarian cancer cell line (Caov-3). All complexes are inactive against the breast cancer cell line (MCF-7).

Characterization and properties of the copper(II/I) complexes of macrocyclic hexathiaether ligand [21]aneS_6

The copper(II/I) complexes of hexathiaether macrocyclic ligand, [21]aneS_6, were synthesized, and characterized by electrochemical and spectroscopic techniques. Cu([21]aneS_6)$^{2+/+}$ forms a reversible one-electron redox couple bearing the highest formal potential 0.89 V (against SHE) reported to date for a $Cu^{2+/+}$ macrocyclic system in aqueous solution. Stability constants were also determined for the Cu(I) and Cu(II) complexes.

Polyhedron 26 (2007) 1182

Redox activity of bimetallic complexes based on tris(3,5-dimethylpyrazolyl)borato molybdenum(II) and tungsten(II) nitrosyls. Complexes derived from ethane-1,2-diol and the crystal structure of *anti*-[Mo(NO){HB(3,5-$Me_2C_3HN_2$)$_3$}(OCH_2CH_2O)]$_2$ · 4$CHCl_3$

The bimetallic complexes [{M(NO)(Tp^{Me2})X}$_2$(OCH_2CH_2O)] [Tp^{Me2} = HB(3,5-$Me_2C_3HN_2$)$_3$; M = Mo, X = Cl, Br or I; M = W, X = Cl] have been synthesised and characterised spectroscopically and electrochemically. These species can occur as mixture of two diastereoisomers and one of them could be separated following a thermal treatment of the mixture. A direct synthesis of single diastereoisomers (M = Mo, X = I; M = W, X = Cl) is also described. The bimetallic species exhibit two one-electron reduction processes separated by a modest potential difference, $\Delta E_{1/2}$, ca. 300 mV (M = Mo, X = Cl, Br) indicating an intermediate metal–metal interaction. In the crystal structure of *anti*-[{Mo(NO)(Tp^{Me2})(OCH_2CH_2O)}$_2$] · 4$CHCl_3$ two nonequivalent dinuclear molecules (point group C_{2h}) are found, with crystallographically identical, doubly bridged {Mo(NO)(Tp^{Me2})} distorted octahedral units.

The case of a Cd_2Cu_2 complex containing an apparently C_3-symmetric ligand: Erroneous ligand-structure assignment by X-ray diffraction data analysis

Previously reported complex **4** was resynthesized in order to have a more readily available source of cyclohexane 1. Attempts to liberate the ligand from **4** resulted in the sole formation of pyrane 2. This observation conflicts with X-ray analytical data, but could be resolved by synthetic and mass analytical results.

Dioxovanadium(V) complexes with N,N,O-donor monoanionic ligands: Synthesis, structure and properties

Synthesis and characterization of dioxovanadium(V) complexes having the general formula [VO_2(phsalR)] (HphsalR = 4-R-2-(pyridin-2-yl-hydrazonomethyl)-phenols) are described. X-ray structure of the complex with $phsal^-$ (R = H) reveals a di(μ-oxo) bridged dimeric structure due to weak association of two square-pyramidal [VO_2(phsal)] molecules. In this dimer, the metal centres are in two edge-shared N_2O_4 octahedra.

Polyhedron 26 (2007) 1251

One-dimensional copper(II) compound with a double out-of-plane carboxylato-bridge – Another polymorphic form of Cu(pyridine-2-carboxylate)$_2$

The compound of the formula Cu(pyridine-2-carboxylate)$_2$ was prepared, and then characterized by infrared, ligand field, EPR spectroscopy and magnetic studies. In particular, the crystal structure was determined by X-ray methods. The structure consists of a copper atom *trans* square-planar coordinated by two picolinate anions. The weak bonding interaction between the copper and an oxygen atom of carboxylate groups of neighboring planes permits to define the structure as a one-dimensional chain with a double out-of-plane carboxylate bridge. The variable temperature (1.8–300 K) magnetic susceptibility revealed weak antiferromagnetic coupling within the chain and throughout the hydrogen bond network ($J = -0.73$, $zJ' = -0.06$ cm^{-1}, respectively).

Polyhedron 26 (2007) 1023

Synthesis and characterization of (N→B)-phenyl[*N*-alkyl-*N*-(2-alkyl)aminodiacetate-*O*,*O*′,*N*]boranes and phenyl[*N*-alkyl-*N*-(2-alkyl) aminodiacetate-*O*,*O*′,*N*]boranes

The reaction of boron heterocycles **1** and **2** with *n*-butyl lithium and alkyl halides led to (*N*→*B*) phenyl[*N*-alkyl-*N*-(2-alkyl)aminodiacetate-*O*,*O*′,*N*]boranes, where alkyl can be in *exo* (**a**) and/ or *endo* (**b**) position, and phenyl[*N*-alkyl-*N*-(2-alkyl)aminodiacetate-*O*,*O*′,*N*]boranes (**c**) isomers, which do not display the intramolecular *N*→*B* coordination. The existence of steric interactions between *N*-benzyl and the alkyl group at 2 position was indicated by ^1H and ^{13}C NMR, while, the $\delta(^{11}B)$ values confirm the tetrahedral and trigonal environment of the ^{11}B nucleus in these compounds. Moreover, the compounds were characterized by COSY, HETCOR and homonuclear proton decoupling experiment. The study of the intramolecular *N*→*B* coordination by dynamic NMR afforded a $\Delta G^{\ddagger}$ value of 81.09 kJ/mol for compound (*N*→*B*) phenyl[*N*-benzyl-*N*-(2-methyl)aminodiacetate-*O*,*O*′,*N*]borane.

Polyhedron 26 (2007) 1037

Synthesis and characterization of 1,1′-bis[(*N*-methyl-*N*-phenyl)aminomethyl(ethyl)]ferrocenes. Crystal structures of [Fe{(η^5–C_5H_4)–C(C_6H_5)=N–$CH_2C_6H_4CH_3$-4}$_2$] and 2[Fe{(η^5–C_5H_4)–$CH_2N(CH_3)$–$C_6H_4OCH_3$-4}$_2$] · 1/4H_2O

1,1′-Bis[(*N*-methyl-*N*-phenyl)aminomethyl-(ethyl)]ferrocenes (**7**, **8**) were synthesized by reductive methylation of 1,1′-bis[(*N*-phenyl)-aminomethyl(ethyl)]ferrocenes (**4**, **5**). The latter were obtained by reduction of **1** and **2** with sodium borohydride or lithium aluminum-hydride–aluminum chloride. 1,1′-Bis[{(*N*-methyl-*N*-benzyl)amino}benzyl]ferrocenes (**9**) were not obtained, probably due to their debenzylation under the acidic conditions. The structures of **3g** and **7a** were determined by single crystal X-ray analysis.

Coordination modes of 3-hydroxypicolinic acid: Synthesis and structural characterization of polymeric mercury(II) complexes

Novel polymeric mercury complexes, HgCl(picOH), $HgBr_2$(HpicOH), $Hg(picOH)_2$ and $Hg(picOH)_2 \cdot H_2O$ (HpicOH = 3-hydroxypicolinic acid) were obtained. Crystal structure analysis of the halogeno-derivatives confirmed two different coordination modes of HpicOH. In DMSO solutions these complexes exist in the identical form as in the solid state.

Polyhedron 26 (2007) 1053

A comparison of the solid-state structures of a series of phenylseleno-halogen and pseudo-halogen compounds, PhSeX (X = Cl, CN, SCN)

The solid-state structures of the series of compounds PhSeX (X = Cl, CN, SCN) have been reported. PhSeCl displays a square motif, $Ph_4Se_4Cl_4$, with four PhSeCl units linked by weak Se–Se bonds. In contrast, the pseudo-halogen derivatives PhSeCN and PhSeSCN display essentially monomeric structures, and both exhibit Se···N contacts in their extended structures which appear to be the dominant packing force in these compounds. PhSeSCN is the first crystallographically characterised example of a selenium thiocyanate compound.

Polyhedron 26 (2007) 1087

The effects of steric aliphatic–aliphatic interactions in the coordination polymer of bis(*N*,*N*-diethylglycinato)copper(II): Experimental evidence and theoretical modeling

Discrete polymeric chains of *trans catena*-poly[(*N*,*N*-diethylglycinato-κ*O*,κ*N*)copper(II)-μ-[*N*,*N*-diethylglycinato-κO^1,κN:O^2]] were produced by axial coordinative bonding between copper(II) and carbonyl oxygen atom from adjacent asymmetric unit in the crystal structure. Steric aliphatic–aliphatic interactions between flexible ethyl chains are successfully reproduced, and conformational change of the complex upon crystallization is predicted using molecular mechanics force field.

Complexes of a novel *N*-(diisopropxythiophosphoryl)thiourea derivative of 1,4,8,11-tetraazacyclotetradecane with Na^+, K^+ and $Cu(PPh_3)_2^+$ cations

We have reported a novel *N*-(diisopropxythiophosphoryl)thiourea derivative of 1,4,8,11-tetraazacyclotetradecane and its complexes with Na^+, K^+ and $Cu(PPh_3)^+$ cations. Structures of the obtained compounds were investigated by ES-MS, IR, ^1H and ^{31}P NMR spectroscopy and microanalysis. It was established that the obtained urea has a different composition in CCl_4 and $CDCl_3$, and in the solid state. The reaction of the potassium salt of thiourea with $Cu(PPh_3)_3I$ leads to the tetra-*N*-substituted cyclam. Chelating fragments C(S)NP(S) are coordinated with the copper(I) cation in a didentate mode through sulfur atoms of the thiocarbonyl and thiophosphoryl groups.

Syntheses and study on nickel and copper complexes with 1,3,5-benzenetricarboxylic acid. Crystal and molecular structure of $[Cu_3(mdpta)_3(btc)](ClO_4)_3 \cdot 4H_2O$

Nickel and copper complexes bridged by the 1,3,5-benzenetricarboxylate anion, with N-donor ligands or Schiff bases in the coordination sphere, were prepared and characterized. X-ray analysis of the copper trinuclear complex proved a deformed square-planar arrangement of central atoms and coordination of carboxylato groups. The complex showed a very weak antiferromagnetic interaction among the central atoms.

Polyhedron 26 (2007) 563

Immobilization of a copper-Schiff base complex in a Y-zeolite matrix: Preparation, chromogenic behavior and catalytic oxidation

To mimic the catalytic activity of metalloenzymes, a copper Schiff base complex has been immobilized in Y zeolite. A spectacular color change (green to red) has been observed when the complex [Cu(MeO-salen)(H_2O)] (**1**) is immobilized in a zeolitic matrix. While the prepared catalyst shows excellent catalytic activity and product selectivity, the complex itself remains virtually inactive.

Polyhedron 26 (2007) 572

Synthesis, characterization, DNA interaction and cleavage activity of new mixed ligand copper(II) complexes with heterocyclic bases

Mixed ligand complexes having the formulae $Cu(RPO)_2Py_2$, $Cu(RPO)_2Im_2$ and $Cu(DBO)_2Py_2$ [RPO = resacetophenone oxime, DBO = 2,4-dihydroxybenzophenone oxime, Py = pyridine and Im = imidazole] have been synthesized and characterized by UV–Vis, IR, ESR, cyclic voltammetry and magnetic susceptibility methods. The apparent binding constants for mixed ligand complexes are in order of 10^4–10^5 M^{-1}. Based on the data obtained in the DNA binding studies a partial intercalative mode of binding is suggested for these complexes. All the metal complexes cleaved supercoiled DNA by hydrolytic and oxidative paths. The oxidative path dominates the hydrolytic cleavage. The hydrolytic cleavage of DNA is evidenced from the control experiments showing discernable cleavage inhibition in the presence of the hydroxyl radical inhibitor DMSO or the singlet oxygen quencher azide ion.

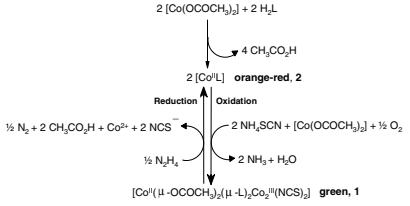
Polyhedron 26 (2007) 679

The new type of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4]$ cluster core: Crystal structure and spectral characterization of $[Zr_6O_4(OH)_4(OOCR)_{12}]$ (R = Bu^t, $C(CH_3)_2Et$)

Hexanuclear Zr(IV) oxo carboxylate derivatives of the general formula $[Zr_6O_4(OH)_4(OOCR')_{12}]$ (R′ = Bu^t (**1**), $C(CH_3)_2Et$ (**2**)) were synthesized from $Zr(OR)_4$ (R = Pr^i, $C(CH_3)_2Et$) and appropriate organic acids (HOOCR′, R′ = Bu^t, $C(CH_3)_2Et$) in a molar ratio 1:2. The structure of these compounds consists of hexanuclear Zr(IV) clusters formed by six zirconium atoms, linked by 4:4 system of μ_3-oxo/hydoxy bridges and stabilized by *syn–syn* carboxylate groups. Results of crystallographic and spectroscopic data suggest that in $[Zr_6(\mu_3\text{-}O_4)(\mu_3\text{-}OH)_4]$ clusters four protons migrate between eight oxide bridges. Thermal stability studies of **1** and **2** using TGA/DTA and VT IR methods have been carried out.



Suparna Banerjee, Jiu-Tong Chen, Can-Zhong Lu

Polyhedron 26 (2007) 686

A new trinuclear mixed-valence Co(II)–Co(III) complex stabilized by a bis(salicylidene) based ligand

Reaction of $Co(OAc)_2$ with H_2L and NH_4SCN in air afforded an octahedral mixed valent trimeric complex, **1** which was reacted with hydrazine resulting in a mononuclear Co(II) square planar complex, **2**. Compound **2** regenerates **1** on treatment with suitable reagents. **1** displayed two oxidative and one reductive response in MeCN and the electron equivalents associated with the redox couples were ascertained from coulometry and DPV. A weak antiferromagnetic interaction (=−6.39 K) is operative in **1** at low temperature. An anisotropic EPR spectrum of **1**, recorded at 4 K, suggests transitions between the ground state Kramers doublet. Synthetic strategies for **1** and other known related trimers have also been compared.

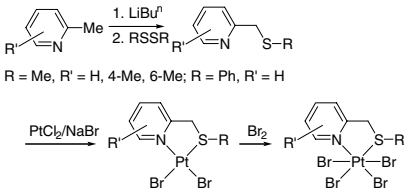
Polyhedron 26 (2007) 695

Synthesis, characterization, and electrochemical, spectroelectrochemical and electrical measurements of novel ball-type four 1,1′-methylenedinaphthalen-2-ol bridged metal-free, zinc(II) and cobalt(II), and metal-free clamshell phthalocyanines

The new binuclear ball-type bisphthalocyanines [metal-free, Zn(II) and Co(II)] and clamshell-type bisphthalocyanine (metal-free) were synthesized from the corresponding 4,4′-[1,1′-methylenebis(naphthalene-2,1-diyl)]-bis(oxy)diphthalonitrile and 4,5-bis(hexylthio)-phthalo-nitrile. The novel compounds have been characterized by elemental analysis, UV/Vis, IR, ^{1}H NMR and MALDI-TOF mass spectroscopies. The electrochemical and spectroelectrochemical measurements showed strong intramolecular interactions between the two phthalocyanine rings. The conduction properties of the compounds have been examined by d.c. and impedance spectroscopy measurements as a function of temperature and frequency.

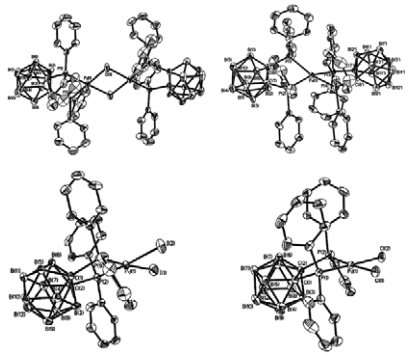


Roderick C. Jones, Brian W. Skelton, Vicki-Anne Tolhurst, Allan H. White, Adele J. Wilson, Allan J. Canty

Polyhedron 26 (2007) 708

Synthesis and solid-state structural characterisation of Pt(II,IV) bromide complexes containing bidentate organothiomethylpyridine heteroleptic ligands

Pyridyl thioether ligands are readily formed by lithiation of 2-picolines followed by reaction with diorgano disulfides, and the synthesis and structural studies of platinum(II) and platinum(IV) complexes are described.



J.-M. Dou, D.-P. Zhang, D.-C. Li, D.-Q. Wang

Polyhedron 26 (2007) 719

Synthesis and crystal structure of four Pd(II) complexes containing *nido* or *closo* carborane diphosphine ligands

Three Pd(II) complexes $[Pd_2(\mu\text{-}Cl)_2\{7,8\text{-}(PPh_2)_2\text{-}7,8\text{-}C_2B_9H_{10}\}_2] \cdot 0.25CH_2Cl_2$ (**1**), $[Pd\{7,8\text{-}(PPh_2)_2\text{-}7,8\text{-}C_2B_9H_{10}\}_2] \cdot 4CHCl_3$ (**2**) and $[PdCl_2(1,2\text{-}(PPh_2)_2\text{-}1,2\text{-}C_2B_{10}H_{10})]$ (**3**) have been synthesized by the reactions of 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$ with $PdCl_2$ in acetonitrile, cyanophenyl and dichloromethane, respectively. A fourth complex $[PdI_2(1,2\text{-}(PPh_2)_2\text{-}1,2\text{-}C_2B_{10}H_{10})]$ (**4**) was obtained by a ligand exchange reaction through substitution of $Cl^-$of complex **3** with I^-. All the four complexes have been characterized by elemental analysis, FT-IR, ^{1}H and ^{13}C NMR spectroscopy and X-ray structure determination.

Polyhedron 26 (2007) 725

Three new dinuclear bis-μ-azido-bridged Cu(II) compounds with di-2-pyridylamine as a ligand: Syntheses, X-ray structure and magnetic measurements

Three new dinuclear copper(II) compounds: $[Cu_2(dpyam)_2(\mu_{1,1}\text{-}N_3)_2(O_2CH)_2]$ (**1**), $[Cu_2(dpyam)_2(\mu_{1,1}\text{-}N_3)_2(O_2CCH_3)_2]$ (**2**) and $[Cu_2(dpyam)_2(\mu_{1,1}\text{-}N_3)_2(O_2CCH_2CH_3)_2]$ (**3**) have been synthesized in order to investigate the magnetic superexchange interaction pathway between coupled copper(II) centers. All three compounds consist of a dinuclear unit in which both Cu(II) ions are bridged by double end-on azido ligands providing a distorted square pyramidal geometry, $\tau = 0.38$, 0.48 and 0.30, with a CuN_4O chromophore. The Cu···Cu separations are 3.195, 3.200 and 3.247 Å for compounds **1**, **2** and **3**, respectively. The magnetic susceptibility measurements, measured from 5 to 300 K, revealed a medium to weak ferromagnetic exchange interactions between the copper(II) ions dominated by the bridging azido ligands, with a singlet–triplet splitting (J) of 63.3, 63.8 and 5.1 cm^{-1}, for compounds **1**, **2** and **3**, respectively. A large zero-field splitting of about 0.4 cm^{-1} is observed in the EPR for compounds **1** and **2**.

Metal–radical complexes [M(NITm-Py)$_2$-(N$_3$)$_2$(DMSO)$_2$] [M = Cu(II), Ni(II), Co(II)]: Syntheses, crystal structures and magnetic properties

Three new metal–radical complexes have been synthesized. The three complexes are three-spin complexes in which two radical ligands are coordinated to the metal ion through the nitrogen atoms of the pyridyl rings. The magnetic properties are analyzed in connection with their structures and the magnetic exchange mechanism is discussed.

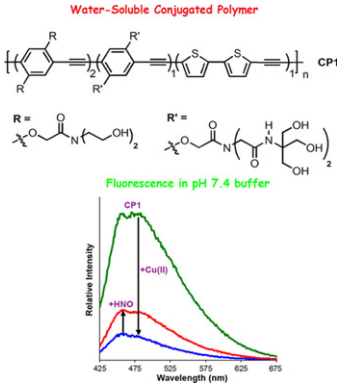
Polyhedron 26 (2007) 4620

Photochemical and pharmacological aspects of nitric oxide release from some nitrosyl ruthenium complexes entrapped in sol–gel and silicone matrices

The entrapped $[Ru(terpy)(L)NO](PF_6)_3$, terpy = 2,2′:6′,2″-terpyridine and L = 2,2′-bipyridine (bpy) and 3,4-diiminebenzoic acid (NH · NHq), complexes into sol–gel and silicone matrices, shows NO release characteristics when submitted to light irradiation. The pharmacological properties of doped matrix showed vasodilator characteristics due to NO release.



Andrew G. Tennyson, Loi Do, Rhett C. Smith and Stephen J. Lippard

Polyhedron 26 (2007) 4625

Selective fluorescence detection of nitroxyl over nitric oxide in buffered aqueous solution using a conjugated metallopolymer

A bithiophene-substituted poly(*p*-phenyleneethynylene) derivative (**CP1**) having water-solubilizing side chains was prepared and characterized. Copper(II)-induced quenching of **CP1** emission was quantified in H_2O, MeCN/H_2O, and pH 7.4 HEPES/KCl buffer. In buffer, treatment of **CP1**-Cu(II) with nitroxyl (HNO) produces an immediate 2.1-fold increase in emission, whereas exposure to NO(g) effects no fluorescence restoration.

Polyhedron 26 (2007) 4631

Ruthenium and rhodium nitrosyl complexes containing dichalcogenoimidodiphosphinate ligands

Interaction of $[Ru(NO)Cl_3(PPh_3)_2]$ or $Ru(NO)Cl_3 \cdot xH_2O$ with $K[N(R_2PQ)_2]$ afforded *trans*-$[Ru(NO)(Cl)\{N(R_2PS)_2\}_2]$ (R = Ph, Pr^i) or *cis*-$[Ru(NO)(Cl)\{N(Ph_2PO)_2\}]$ whereas that with $K[N(Ph_2PSe)_2]$ led to a mixture of *trans*-$[Ru(NO)Cl\{N(Ph_2PSe)_2\}_2]$ and *trans*-$[Ru(NO)Cl\{N(Ph_2PSe)_2\}\{Ph_2P(Se)NPPh_2\}]$. Treatment of $[Rh(NO)Cl_2(PPh_3)_2]$ with $K[N(R_2PQ)_2]$ gave $[Rh(NO)\{N(R_2PSQ)_2\}_2]$ (R = Ph or Pr^i, Q = S or Se), in which the nitrosyl ligand is bent.

Polyhedron 26 (2007) 4638

Thermal and photochemical reactivity of $Os(HNO)(CO)Cl_2(PPh_3)_2$: Evidence for photochemical HNO generation

Photolysis of the nitroxyl complex $Os(N(O)H)(CO)Cl_2(PPh_3)_2$ shows multiple products that are interpreted in terms of two competing, primary photoreactions, the reversible dissociation of HNO (which dimerizes to N_2O) and the dissociation of CO. The relative yields of products varied depending on whether or not excess CO was present.

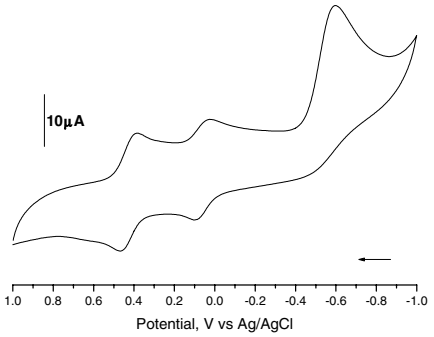
Polyhedron 26 (2007) 4645

Cis–trans Geometrical isomerization of bis(2-pyridinecarboxylato)nitrosylruthenium complex accompanying electrochemical one-electron reduction

cis-$[Ru(NO)(CH_3CN)(pyca)_2]PF_6$ and *trans*-$[Ru(NO)(OH)(pyca)_2]$ (pyca = 2-pyridinecarboxylato) have been synthesized and characterized. Electrochemical behaviors of the two complexes in CH_3CN and the *cis-trans* geometrical change reaction occurring in the electrochemical one-electron reduction of *cis*-$[Ru(NO)(CH_3O)(pyca)_2]$ in CH_3OH–CH_3CN have been studied.

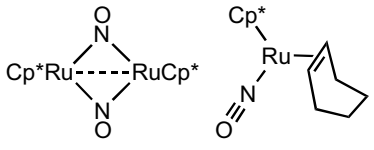


Alda K.M. Holanda, Francisco O.N. da Silva, Idalina M.M. Carvalho, Alzir A. Batista, Javier Ellena, Eduardo E. Castellano, Ícaro S. Moreira and Luiz G.F. Lopes

Polyhedron 26 (2007) 4653

Crystal structure, electrochemical and photochemical studies of the *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex (cyclam = 1,4,8,11-tetraazacyclotetradecane)

The cyclic voltammogram of the *trans*-$[Fe(cyclam)(NO)Cl]^{2+}$ complex showed three electrochemical processes at −0.70, 0.08 and 0.40 V versus Ag/AgCl. The first and last redox processes are centered at the NO ligand, whereas the second is characteristic of the residual aqua species, *trans*-$[Fe(cyclam)Cl(H_2O)]^{2+}$.



Shigeki Kuwata, Satoshi Kura and Takao Ikariya

Polyhedron 26 (2007) 4659

Hydrogenation of cyclohexene catalyzed by ruthenium nitrosyl complexes: Crystal structures of catalyst precursors $[Cp^*Ru(\mu_2\text{-}NO)_2RuCp^*]$ and $[Cp^*Ru(NO)(\eta^2\text{-}C_6H_{10})]$ (Cp^* = $\eta^5\text{-}C_5(CH_3)_5$)

We have demonstrated that the (nitrosyl)ruthenium complex $[Cp^*Ru(NO)(C_6H_5)_2]$ (**1**) serves as a catalyst precursor for hydrogenation of cyclohexene. Two nitrosyl complexes **2** and **3** have been obtained from the reaction mixture. The detailed structures of **2** and **3** have been determined by X-ray crystallography.

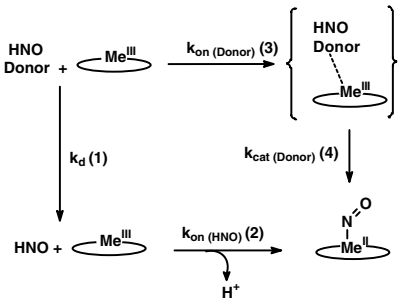
Polyhedron 26 (2007) 4664

Structural and physical characterization of (nitrato)iron(III) porphyrinates [Fe(por)-(NO_3)] – Variable coordination of nitrate

The physical properties of high-spin nitrato-ligated iron(III) porphyrinates show differences depending on the mode of nitrate coordination.

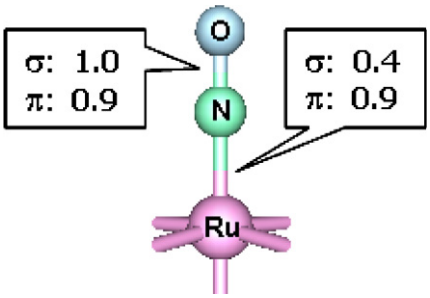


Sebastián A. Suárez, Marcelo A. Martí, Pablo M. De Biase, Darío A. Estrin, Sara E. Bari and Fabio Doctorovich

Polyhedron 26 (2007) 4673

HNO trapping and assisted decomposition of nitroxyl donors by ferric hemes

The reactions between two nitroxyl donors with MP11 and Fe^{III}TEPyP show two alternative modes of reactivity. One comprises the heme assisted decomposition of the donor enhancing its decomposition rate, while in the other the donor produces HNO which subsequently reacts with the porphyrin.

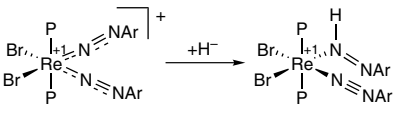


Olga V. Sizova, Alexander Yu. Sokolov, Leonid V. Skripnikov and Victor I. Baranovski

Polyhedron 26 (2007) 4680

Quantum chemical study of the bond orders in the ruthenium, diruthenium and dirhodium nitrosyl complexes

The electronic structure of the ruthenium six-coordinate nitrosyl complexes and paddle-wheel $M_2(BL)_4$ and $M_2(BL)_4(L)_2$ (M = Rh and Ru) complexes is analyzed in terms of Mayer and Wiberg bond order indices. The technique of bond order indices decomposition into σ-, π-, and δ-contributions is proposed.



Gabriele Albertin, Stefano Antoniutti and Tiziana Donadini

Polyhedron 26 (2007) 4691

Reaction of bis(aryldiazenido) complexes of rhenium with bromine: Preparation of new diazo derivatives

The reaction of bis(aryldiazenido) $[Re(ArN_2)_2P_3]BPh_4$ complexes with Br_2 is presented. The synthesis of aryldiazene–aryldiazenido $ReBr_2(ArN_2)(ArN{=}NH)P_2$ derivatives was achieved by reacting bis-(aryldiazenido) with hydride-donor species. Protonation studies on aryldiazene complexes are also reported.

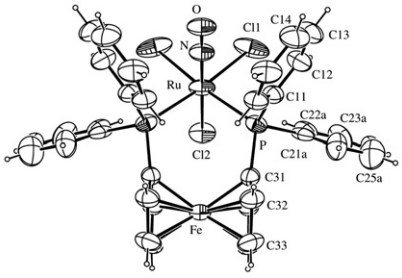
Polyhedron 26 (2007) 4697

Novel platinum pyridinehydroxamic acid complexes: Synthesis, characterisation, X-ray crystallographic study and nitric oxide related properties

On the premise that there is little or no evidence in the literature of nitric oxide (NO)-releasing platinum-based compounds, the NO-releasing ability of a novel series of platinum pyridinehydroxamic acid complexes are described with a view to advancing a new class of bifunctional metallodrug with dual DNA-binding and NO-releasing properties.

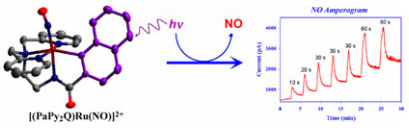


Gustavo Von Poelhsitz, André Luiz Bogado, Márcio Peres de Araujo, Heloisa S. Selistre-de-Araújo, Javier Ellena, Eduardo E. Castellano and Alzir Azevedo Batista

Polyhedron 26 (2007) 4707

Synthesis, characterization, X-ray structure and preliminary *in vitro* antitumor activity of the nitrosyl complex *fac*-[$RuCl_3$(NO)(dppf)], dppf = 1,1′-bis(diphenylphosphine)ferrocene

The reaction of $RuCl_3NO \cdot 2H_2O$ with stoichiometric amount of dppf, 1,1′-bis(diphenylphosphino)ferrocene, afforded the new neutral nitrosyl complex *fac*-[$RuCl_3$(NO)(dppf)] which was characterized by spectroscopical, electrochemical and X-ray crystallography techniques. Preliminary *in vitro* antitumor activity against the MDA-MB-231 tumor cell line was carried with the results indicating a moderate to good cytotoxicity activity (IC_{50} = 10 ± 3 μM).

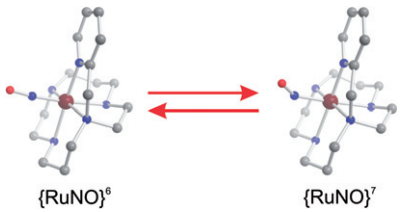


Michael J. Rose, Marilyn M. Olmstead and Pradip K. Mascharak

Polyhedron 26 (2007) 4713

Photoactive ruthenium nitrosyls derived from quinoline- and pyridine-based ligands: Accelerated photorelease of NO due to quinoline ligation

The {Ru–NO}^{6} nitrosyl [($PaPy_2Q$)Ru(NO)]-(BF_4)$_2$ exhibits greater NO photolability (as detected by NO-electrode) compared to analogous nitrosyl [($PaPy_3$)Ru(NO)](BF_4)$_2$ due to the light-harvesting quinoline moiety in the ligand frame.

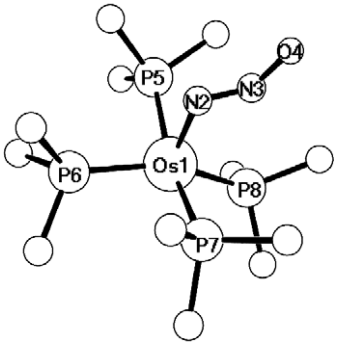


Ariel G. De Candia, Juan P. Marcolongo and Leonardo D. Slep

Polyhedron 26 (2007) 4719

A new ruthenium nitrosyl species based on a pendant-arm 1,4,8,11-tetraazacyclotetradecane (cyclam) derivative: An experimental and theoretical study

The mononuclear {RuNO}^{6} compound *cis*-[$Ru(L^{py})NO]^{3+}$ (L^{py} = *N*-(2-methylpyridyl)-1,4,8,11-tetraazacyclotetradecane) undergoes reversible one-electron reduction in solution to yield a stable {RuNO}^{7} cation.



Hongjun Fan and Kenneth G. Caulton

Polyhedron 26 (2007) 4731

2-Electron reduction of N_2O yields a new ligand binding mode: *N*-Nitrosoimide

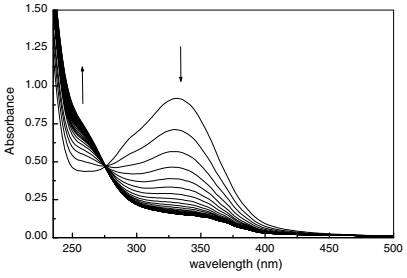
Highly reducing transition metals reduce N_2O to singly bent (at the central nitrogen) or doubly bent (at both N) forms when coordinated; the ligand is therefore properly termed an *N*-nitrosoimide, N_2O^{2-}.

Navamoney Arulsamy, D. Scott Bohle, Jerome A. Imonigie and Raecca C. Moore

Polyhedron 26 (2007) 4737

Group 8 and 10 hyponitrite and dinitrosyl complexes

Group 8 and 10 complexes bind two NO's in very different ways; either as a pair of linear dinitrosyls for group 8, or as coupled hyponitrite in the case of group 10. Thus for polynitrosyl complexes the redox state of pairs of NO ligands need to be considered in addition to their bent/linear or the metal's oxidation state.

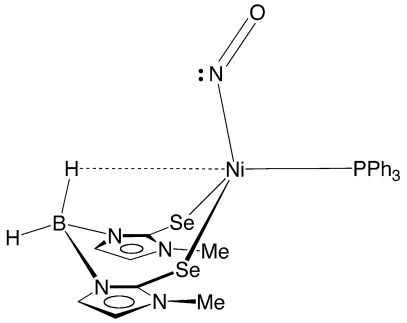


Renata Zachi de Osti and Douglas Wagner Franco

Polyhedron 26 (2007) 4746

Aspects of nitrite association with *trans*-$[Ru(NH_3)_4P(OEt)_3H_2O]^{2+}$

trans-$[Ru(NH_3)_4P(OEt)_3(H_2O)]^{2+}$ is known to reacts with nitrite ions in alkaline media (pH > 10) yielding *trans*-$[Ru(NH_3)_4P(OEt)_3(NO_2)]^+$, $K_N = (5.2 \pm 0.6) \times 10^3\ M^{-1}$ ((25 ± 0.2) °C), which releases the nitrite ligand, $k_{-N} = (1.2 \pm 0.03) \times 10^{-1}\ s^{-1}$. The nitro compound, in acid environment, undergoes quantitative conversion to the corresponding nitrosyl complex ($k_{obs} = 2.2 \times 10^{-3}\ s^{-1}$ at pH 4).

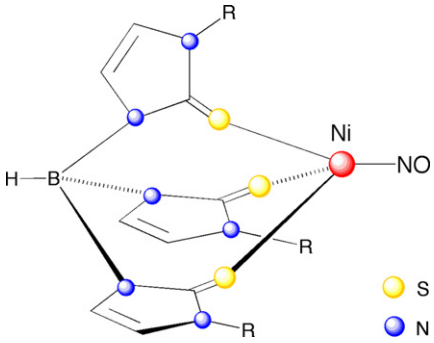


Victoria K. Landry and Gerard Parkin

Polyhedron 26 (2007) 4751

Synthesis and structural characterization of $[Bse^{Me}]Ni(PPh_3)(NO)$, a nickel complex with a bent nitrosyl ligand

The nickel nitrosyl compound $[Bse^{Me}]Ni(PPh_3)(NO)$ has been synthesized by the reaction of $Ni(PPh_3)_2(NO)Br$ with potassium *bis*(2-seleno-1-methylimidazolyl)hydroborate, $[Bse^{Me}]K$. X-ray diffraction studies demonstrate that the B–H group of the $[Bse^{Me}]$ ligand interacts with the nickel center and that the nitrosyl ligand is bent.

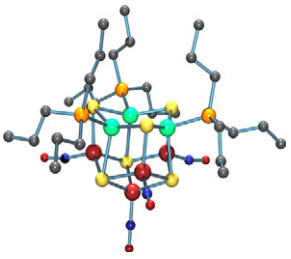


L. Summer Maffett, Kelly L. Gunter, Kevin A. Kreisel, Glenn P.A. Yap and Daniel Rabinovich

Polyhedron 26 (2007) 4758

Nickel nitrosyl complexes in a sulfur-rich environment: The first poly(mercaptoimidazolyl)borate derivatives

The first nickel nitrosyl complexes supported by bis- and tris(mercaptoimidazolyl)borate ligands, $(Bm^R)Ni(PPh_3)(NO)$ (R = Me, Bu^t) and $(Tm^R)Ni(NO)$ (R = Bu^t, *p*-Tol), have been readily prepared and fully characterized using a combination of analytical and spectroscopic techniques. Whereas the Tm^R compounds are tetrahedral and contain linear nitrosyl ligands, the Bm^R derivatives are trigonal pyramidal and display bent NO groups.



Harris Kalyvas and Dimitri Coucouvanis

Polyhedron 26 (2007) 4765

Synthesis and characterization of new heterometallic iron sulfur nitrosyl clusters

The reactivity of the $(PPN)_2[Fe_8S_6(NO)_8]$ and $(PPN)_2[Fe_6S_6(NO)_6]$ clusters is explored and new derivative clusters have been synthesized and structurally characterized. The unique $(PPN)_2Fe_4S_4(NO)_6$ "open-cubane" cluster with a chair like Fe_4S_4 core is obtained by the low temperature reaction of $[Fe_4S_3(NO)_7]^-$ with Bu_4NSH in the presence of $(PPN)_2[Fe_4(CO)_{13}]$. The mixed metal pentandite-like clusters $(PPN)_2[Mo_2Fe_6S_6(NO)_6(CO)_6]$, $(PPr_3)_2Cu_2Fe_6S_6(NO)_6$, $(PPr_3)_4Cu_4Fe_4S_6(NO)_4$, $(PPr_3)_2Ni_2Fe_6S_6(NO)_6$, $(PPr_3)_3Ni_3Fe_4S_6(NO)_4$, are obtained from the reactions of the$(PPN)_2[Fe_6S_6(NO)_6]$ prismanes with thiophilic metals.

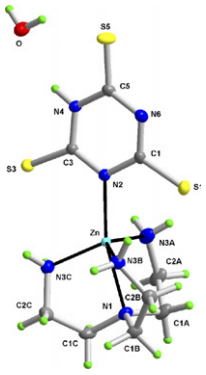
(Cyclopentadienyl){(*N*,*N*-dimethylaminoethyl)-cyclopentadienyl} complexes of zirconium: Crystal structure of $[(\eta^5\text{-}C_5H_5)(\eta^5\text{-}C_5H_4CH_2\text{-}CH_2NHMe_2)ZrCl_2]_2[ZrCl_6]$

The reaction of the coordination polymer $[(C_6H_5)(C_5H_4CH_2CH_2NMe_2)ZrCl_2]_n$ with methanolic solution of HCl results in elimination of C_5H_5 and $C_5H_4CH_2CH_2NMe_2$ ligands from the Zr(IV) metal centre. Formation of the title compound was established by NMR spectroscopy and X-ray structural analysis.

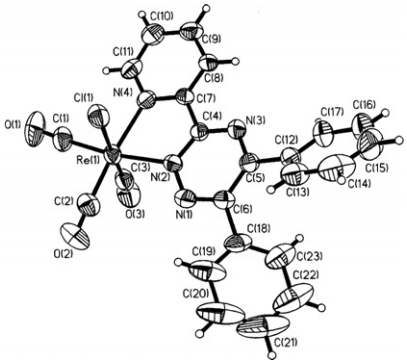


Pavel Kopel, Karel Doležal, Libor Machala and Vratislav Langer

Polyhedron 26 (2007) 1583

Synthesis, characterization and screening of biological activity of Zn(II), Fe(II) and Mn(II) complexes with trithiocyanuric acid

Mixed-ligand Zn(II), Fe(II) and Mn(II) complexes involving the trithiocyanurate anion and nitrogen-donor ligands were prepared and their in vitro antitumor and antimicrobial activities were tested. Two complexes showed good cytotoxicity against four cell lines and four complexes showed specific or extensive antimicrobial activities.



B. Machura, R. Kruszynski and J. Kusz

Polyhedron 26 (2007) 1590

X-ray structure, spectroscopic characterisation and DFT calculations of the $[Re(CO)_3(dppt)Cl]$ complex

The reaction of the complex $Re(CO)_5Cl$ with 5,6-diphenyl-3-(2-pyridyl)-1,2,4-trazine (dppt) has been examined and the $Re(CO)_3^+$ rhenium carbonyl – *fac*-$[Re(CO)_3(dppt)Cl]$ – has been obtained. The compound has been studied by IR, UV–Vis spectroscopy and X-ray crystallography. The molecular orbital diagram of the tricarbonyl has been calculated with the density functional theory (DFT) method. The spin-allowed singlet–singlet electronic transitions of $[Re(CO)_3(dppt)Cl]$ have been calculated with the time-dependent DFT method, and the UV–Vis spectrum of the title compound has been discussed on this basis.

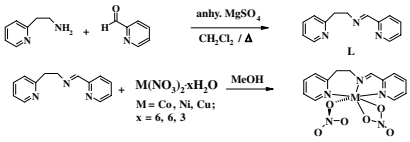
Unusual coordination of a chloride ion to six copper ions: Synthesis and crystal structure of copper(II) complexes with 4-(4-hydroxyphenyl)-1,2,4-triazole

Novel copper(II) complexes with substituted 1,2,4-triazole, molecular and polymeric, have been prepared and characterized. The molecular complex shows interesting coordination of Cl^- to six copper ions with all six Cu–Cl bonds equal to 2.8397(3) Å. It shows mainly antiferromagnetic exchange interactions between the Cu^{2+} centers.



Sumanta Kumar Padhi and Vadivelu Manivannan

Polyhedron 26 (2007) 1619

Synthesis, structure and properties of $[ML(NO_3)_2]$: M = Co, Ni, Cu; **L** = *N*-(2-pyridylethyl)pyridine-2-carbaldimine

Complexes of the type $[ML(NO_3)_2]$, {M = Co(II), Ni(II), and Cu(II), **L** = *N*-(2-pyridylethyl)pyridine-2-carbaldimine} have been synthesized and characterized by spectral, magnetic, and X-ray crystallographic methods. In the cobalt (**1**), nickel (**2**), and copper (**3**) complexes, the bivalent metal ion is coordinated by the three nitrogen atoms of the tridentate **L** with two pyridine-N occupying *trans* positions. Amongst the two nitrates one coordinates in a bidentate fashion while the other coordinates in a monodentate fashion.

Polyhedron 26 (2007) 1625

New insights into the metal ion–peptide hydroxamate interactions: Metal complexes of primary hydroxamic acid derivatives of common dipeptides in aqueous solution

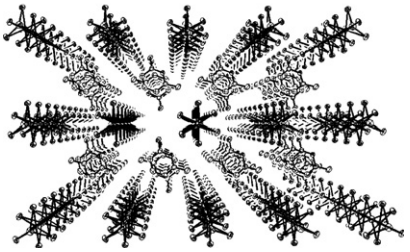
Hydroxamic acid derivatives of common dipeptides have been synthesized and their Fe(III), Al(III), Ni(II), Cu(II) and Zn(II) binding capabilities were studied by combined pH-potentiometric and spectroscopic techniques.

A. Kaltzoglou, P.J. Cox and P. Aslanidis

Polyhedron 26 (2007) 1634

Silver(I) bromide complexes of the rigid diphosphanes 1,2-bis(diphenylphosphano)benzene (dppbz) and 4,5-bis(diphenylphosphano)-9,9-dimethyl-xanthene (xantphos): Crystal structures of $[Ag(\mu_2\text{-}Br)(dppbz)]_2$, [AgBr(xantphos)] and [AgBr(xantphos)(py2SH)]

The behaviour of the diphos ligands 1,2-bis(diphenylphosphano)benzene (dppbz) and 4,5-bis(diphenylphosphano)-9,9-dimethylxanthene (xantphos) towards coordination of Ag(I) bromide in the presence of pyridine-2-thione has been investigated. Both diphosphanes adopt the chelating coordination mode, however two types of products have been obtained, namely a halide bridged dimer with tetrahedrally coordinated Ag^I centers for dppbz and monomeric trigonal complexes in the case of xantphos.



Marek Zuber and Zbigniew Ciunik

Polyhedron 26 (2007) 1643

New type of 1D coordination polymeric anions $[(MCl_3M_1Cl_3)^{2-}]_n$ (M = Rh, Ru; M_1 = Na, K). Crystal structure and IR characterization of Rh(III) and Ru(III) hexachlorometallates with 2-amino-6-methylpyridinium cations

New type of 1D coordination polymeric anions $[(MCl_3M_1Cl_3)^{2-}]_n$ (M = Rh, Ru and M_1 = Na, K) has been obtained in the reaction of $MCl_3 \cdot xH_2O$ and M_1Cl with 2-amino-6-methyl-pyridine in hydrochloric acid solution. Their X-ray structures and IR spectra are presented and discussed. Weak hydrogen bonds occur between the organic cations and inorganic polymeric anions to form layers. Organic anions form stacks because of weak π–π interactions between aromatic rings. All metals in 1D coordination polymeric anions are linked together by bridging chloride anions.

Isomerism in copper(II) chloride complexes of bis(2-pyridylmethyl)amine and *N*-substituted derivatives: Synthesis and X-ray structural characterisation

Copper(II) chloride complexes of tridentate *N*-alkylated bis(2-pyridylmethyl)amine ligands (bpa, Me-bpa and ph-bpa) form coordination oligomers with either terminal or bridging chloride. Two structural types are identified by X-ray diffraction: a mono μ-chloro bridged species (**B**) and a di-μ-chloro bridged species (**C**), both containing five-coordinate copper(II).

Efficient solid-state microwave-promoted complexation of a mixed dioxa-diaza macrocycle with an alkali salt. Synthesis of a sodium ethyl 4-benzeneazophosphonate complex

The simple work-up, eco-friendly microwave-promoted solid-state synthesis of an alkali complex derived from a mixed 15-membered dioxa-diaza macrocycle (L) and sodium monoethyl [4-α-(benzeneazoanilino)-*N*-benzyl]phosphonate (NaEP) has been described and compared with the syntheses carried out under conventional heating in the solid state and solution. The prepared diphosphonate bridged dinuclear complex, $[Na(L)(\mu\text{-}EP) \cdot H_2O]_2$, has been studied by IR, ^1H and ^{13}C NMR, and MS spectroscopy.

Polyhedron 26 (2007) 1677

Studies on some oxovanadium(IV) complexes of acyl pyrazolone analogues

A series of bidentate ligands have been synthesized by condensation of 4-benzoyl-2,4-dihydro-5-methyl-2-(4′-methylphenyl)-3*H*-pyrazol-3-one with various aromatic amines. X-ray structure determination reveals that these ligands exist in the amine-one tautomeric form. With OV(IV), these ligands form distorted octahedral complexes, $[OVL_2(H_2O)]$; TGA, μ_{eff}, electronic spectral studies of which have been carried out. *Ab initio* calculations have been performed on one of the ligand.

DNA binding and cleavage properties of certain ethylenediamine cobalt(III) complexes of modified 1,10-phenanthrolines

Two complexes of the type $[Co(en)_2IP]^{3+}$ (IP = imidazo[4,5-f][1,10]-phenanthroline) and $[Co(en)_2PIP]^{3+}$(PIP = 2-phenylimidazo[4,5-f][1,10]-phenanthroline) have been synthesized and characterized by UV–VIS, IR and ^1H NMR spectral methods. Absorption spectroscopy, emission spectroscopy, viscosity measurements and DNA melting techniques have been used to investigate the binding of these two complexes with calf thymus DNA and photocleavage studies have been used to investigate the binding of these complexes with plasmid DNA. The spectroscopic studies together with viscosity measurements and DNA melting studies support that complexes **1** and **2** bind to CT DNA(=calf thymus DNA) by an intercalation mode via IP or PIP into the base pairs of DNA. Complex **2** binds more avidly to CT DNA than **1**, which is consistent with the extended planar ring π system of PIP. Noticeably, the two complexes have been found to be efficient photosensitisers for strand scissions in plasmid DNA.

New chloro- and trifluoroacetato tricarbonyl-rhenium(I) complexes with a *N*,*N*′-bis(benzophenone)-1,2-diiminoethane Schiff base ligand: Spectral and structural studies

The reaction of $Re(CO)_5Cl$ with the chelating ligand *N*,*N*′-bis(benzophenone)-1,2-diiminoethane (bz_2en) afforded the neutral *fac*-$[Re(CO)_3(bz_2en)Cl]$ (**1**). Subsequent reaction with $AgOCOCF_3$ gave *fac*-$[Re(CO)_3(bz_2en)OCOCF_3]$ (**2**). Their pseudooctahedral *fac* structures have been established by FTIR, UV–Vis, ^1H, ^{13}C NMR and have been confirmed by X-ray diffraction analysis. The electrochemical behaviour of the investigated complexes has been studied by cyclic voltammetry.

Polyhedron 26 (2007) 1725

New cadmium chloride complexes with imidazolidine-2-thione and its derivatives: X-ray structures, solid state and solution NMR and antimicrobial activity studies

Reactions of imidazolidine-2-thione (Imt), 1,3-diazinane-2-thione (Diaz) and 1,3-diazipane-2-thione (Diap) with cadmium(II) chloride in methanol result in the formation of 2:1 complexes. Both solid state and solution NMR, in addition to X-ray structures, confirm the exocyclic sulfur atom to be the donor in all cases. Cadmium shielding tensors and anisotropies were calculated from the solid-state NMR spectra. The X-ray structures of two complexes, $(NMeImt)_2CdCl_2$ and $(NEtImt)_2CdCl_2$, reveal distorted tetrahedral geometries. Antimicrobial activity studies show that the $Cd(Diap)_2Cl_2$ complex exhibits substantial antibacterial activities compared to the corresponding Zn(II) complex.

Polyhedron 26 (2007) 749

Synthesis, spectral characterization and structural investigation on some 4-aminoantipyrine containing Schiff base Cu(II) complexes and their molecular association

Two important antipyrine Schiff base ligands and their Cu(II) complexes have been synthesized and characterized. The single crystal X-ray structures of **1** and **2**, being the first in the series of this type of compound, explored that the mode of weak H-bonding interactions and steric effect profoundly influenced the Cu(II) geometry in **1** and **2**, rearranging from a tetrahedrally distorted square planar geometry into a distorted square planar geometry.

Polyhedron 26 (2007) 763

Interaction of Fe(III) with herbicide-carboxylato ligands – Di-, tri- and tetra-nuclear compounds: Structure and magnetic behavior

Interaction of Fe(III) with phenoxyalkanoic acids and phen leads to dinuclear neutral complexes while the absence of phen favours trinuclear cationic or tetranuclear neutral forms. The magnetic behavior of all nuclearities show antiferromagnetic exchange interaction with the ground state of the binuclear and tetranuclear compounds $S = 0$ and for the trinuclear one $S = 1/2$.

Polyhedron 26 (2007) 773

Synthesis and structural studies on di-oxo-vanadium(V) complexes of *N*(4)-substituted pyrazole based thiosemicarbazones

cis-Dioxo vanadium(V) complexes (**1**–**3**) of three different tridentate thiosemicarbazone ligands synthesized from 5-methyl-3-formylpyrazole and *N*(4)-substituted thiosemicarbazides have been prepared and structurally characterized. All the three complexes have square pyramidal geometry. In **2**, two asymmetric units appreciably differ in their conformations. In **1** and **2**, the pyrazolyl N, the thioimine N (quite unusual) and the thiolato S of the corresponding tridentate ligand molecule coordinate to the vanadium atom whereas in **3**, the respective ligand utilizes the azomethine nitrogen (usual) instead of the thioimine nitrogen to coordinate the vanadium atom along with the other two donor sites.

Polyhedron 26 (2007) 782

Synthesis and characterization of two new coordination supramolecular structures from a versatile unsymmetric 5-(4-pyridyl)-1,3,4-oxadiazole-2-thione (Hpot) ligand

The rigid and unsymmetric building block 5-(4-pyridyl)-1,3,4-oxadiazole-2-thione (Hpot) is first developed as a bridging ligand and exhibits intriguing coordination modes in the process of self-assembling networks, which indicates that the versatile nature of this rigid unsymmetric ligand, together with the coordination preferences of the metal centers, plays a critical role in the construction of these novel coordination polymers or supramolecules.

Palladium complexes of multidentate pyrazolylmethyl pyridine ligands: Synthesis, structures and phenylacetylene polymerization

Bis(pyrazolylmethyl) pyridine ligands react with $[PdCl_2(NCMe)_2]$ or [Pd(COD)ClMe)] to form mononuclear palladium complexes in which the ligands bind in a bidentate fashion with a dangling pyrazolyl unit; but on removal of a chloride from these complexes the dangling arm coordinates to form tridentately bound palladium complexes. These tridentatley bound palladium complexes, however, can open up and catalyze the polymerization of phenylacetylene to polyphenylacetylene.

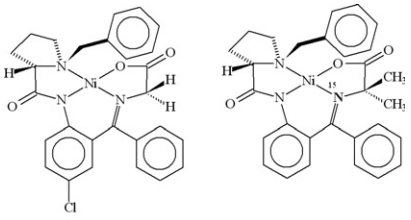
Polyhedron 26 (2007) 904

Synthesis, structures and electrochemical properties of hydroxyl- and pyridyl-functionalized diiron azadithiolate complexes

Hydroxyl- and pyridyl-functionalized diiron azadithiolate complexes, [{(μ-$SCH_2)_2$N(CH_2-CH_2OH)}$Fe_2(CO)_6$] (**1**) and [{(μ-$SCH_2)_2$-N(CH_2CH_2OOCPy)}$Fe_2(CO)_6$] (**2**), were prepared and crystallographically characterized as biomimetic models of the Fe-only hydrogenase active site. A network is constructed by intermolecular H-bonds in the crystals of **1**. An S···O intermolecular contact was found in the crystals of **2**.



Vratislav Langer, Alexander Popkov, Milan Nádvorník, Antonín Lyčka

Polyhedron 26 (2007) 911

Two new Ni(II) Schiff base complexes: X-ray absolute structure determination, synthesis of a ^{15}N-labelled complex and full assignment of its ^{1}H NMR and ^{13}C NMR spectra

The Ni(II) complex of the Schiff base of (*S*)-*N*-(2-benzoyl-4-chlorophenyl)-1-benzylpyrrolidine-2-carboxamide and glycine (**1**) and the hemihydrate of the Ni(II) complex of the Schiff base of (*S*)-*N*-(2-benzoylphenyl)-1-benzylpyrrolidine-2-carboxamide and 2-aminoisobutiric acid (**2**) were prepared and characterized by X-ray diffraction and ^{1}H and ^{13}C NMR.

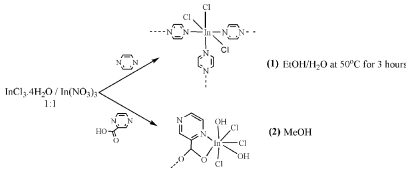
Polyhedron 26 (2007) 918

Nickel(II) and cobalt(II) complexes of methyl(2-aminocyclopentene-1-dithiocarboxy)-S-acetate (ACDASAMe)

The synthesis and characterization of nickel(II) and cobalt(II) complexes of methyl(2-aminocyclopentene-1-dithiocarboxy)-S-acetate (ACDASAMe) are reported. The ligand exhibits the (S, N) coordination mode on interacting with the metal centers. The X-ray structure of Ni(II) complex exhibits a somewhat distorted NiS_2N_2 square planar geometry with the ligands showing a *cis* configuration. The dangling –CH_2COOMe arms of the ligands stay away from coordination forming dimeric association through weak intermolecular hydrogen bonding between neighboring molecules.

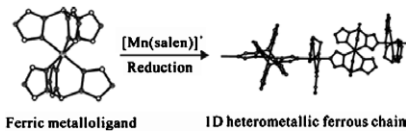


Christian R. Samanamú, Anne F. Richards

Polyhedron 26 (2007) 923

Indium(III) one-dimensional polymers with pyrazine and pyrazine, 2-carboxylic acid as the spacer molecules

The reactions of indium(III) chloride tetrahydrate with pyrazine ($C_4H_4N_2$) and pyrazine, 2-carboxylic acid afford two polymeric frameworks, the structures of which were characterized in the solid state by single crystal analysis. The former is a one-dimensional infinite structure interlinked by the pyrazine spacer, while the latter is a one-dimensional 'zigzag' polymeric structure.

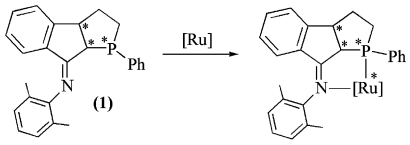


Kyoung-Tae Youm, Min Gyu Kim, Jaejung Ko, Moo-Jin Jun

Polyhedron 26 (2007) 929

1D Mn^{III}–Fe^{II} heterometallic coordination polymer built by an approach of metalloligand

1D heterometallic coordination polymer comprising of [Mn^{III}(salen)] and ferrous moiety [(Fe^{II}(**L**)$_2$)] generated by the reduction of [(Fe^{III}(**L**)$_2$)]$^+$ has been built to be a [(Fe^{II}(**L**)$_2$)(Mn^{III}(salen))(ClO_4)] (**1**) through a metalloligand approach, whether **L** stands for hydrotris(1,2,4-triazolyl)borate.

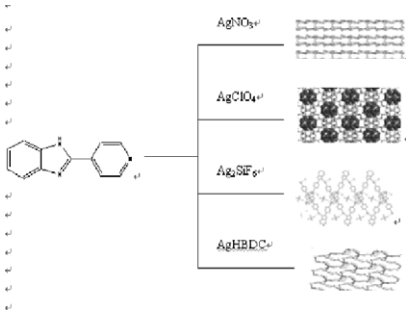


Alba E. Díaz-Álvarez, Pascale Crochet, Maria Zablocka, Victorio Cadierno, Laure Vendier, José Gimeno, Jean-Pierre Majoral

Polyhedron 26 (2007) 933

Half-sandwich ruthenium(II) complexes containing a tricyclic β-iminophosphine ligand: Catalytic activity in Diels–Alder reactions

The diastereoselective coordination of the tricyclic β-iminophosphine ligand **1** to η^6-arene and η^5-cyclopentadienyl ruthenium(II) fragments is described. Spectroscopic data, X-ray crystal structure determinations and catalytic activity in Diels–Alder reactions of the resulting complexes are presented.



Diastereoselective coordination process

Chang-Kun Xia, Can-Zhong Lu, Xiao-Yuan Wu, Quan-Zheng Zhang, Jian-Jun Zhang, Ding-Ming Wu

Polyhedron 26 (2007) 941

Syntheses and crystal structures of four silver(I) complexes based on 2-(4-pyridyl)benzimidazole

Four silver (I) coordination polymers were prepared by the reactions of PyBIm and various silver(I) salts under different conditions. The results show that the anions play important roles in the coordination sphere of the silver(I) atoms as well as the crystal packing of the coordination polymers.

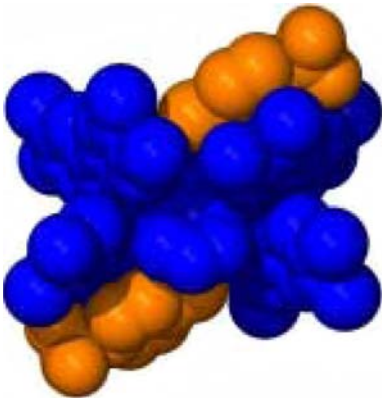
Preface 215



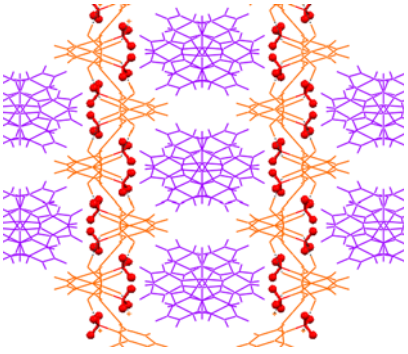
Papers

Deanna M. D'Alessandro, Fiona M. Foley, Murray S. Davies, Peter C. Junk, F. Richard Keene

Polyhedron 26 (2007) 216

Solid-state anion interactions in the diastereoisomers of dinuclear ruthenium complexes based on 2,2′-bipyrimidine

The counter-ions present in the solid-state structures of *meso*-(ΛΔ)-[{Ru(bpy)$_2$}$_2$(μ-bpm)](PF$_6$)$_4$, *meso*-(ΛΔ)-[{Ru(Me$_2$bpy)$_2$}$_2$(μ-bpm)](tos)$_4$ · 2CH$_3$OH · 4H$_2$O and *meso*-(ΛΔ)-[{Ru(Me$_4$bpy)$_2$}$_2$(μ-bpm)](tos)$_4$ · 26H$_2$O (shown) reside in the clefts above and below the plane of the bridging ligand, but show considerable variation in location compared with their known occupancy in solution.

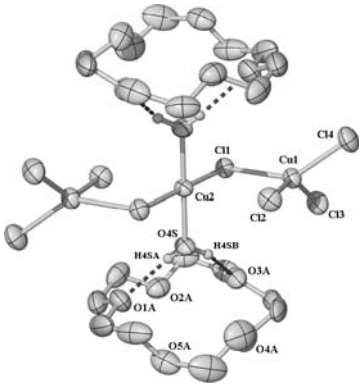


Kay Latham, Anne M. Coyle, Colin J. Rix, Alan Fowless, Jonathan M. White

Polyhedron 26 (2007) 222

Effect of ring substituents on crystal packing and H-bonding in a series of halobis(phen)-copper(II) arylphosphonic acid complexes

The effect of *ortho*-, *meta*-, and *para*-substitution of arylphosphonic acids was explored in a series of copper(II) organophosphonates. In general, the assembly strategy of 'ribbons' of [Cu^{II}(phen)$_2$Cl]$^+$ cations interleaved with H-bonded acid 'chains' was maintained. Packing was affected by substituent-position rather than type, with *para*- being the most disruptive.

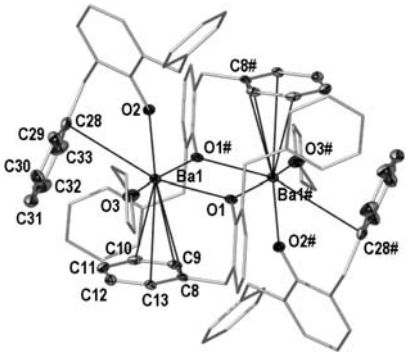


Peter C. Junk, Boujemaa Moubaraki, Keith S. Murray

Polyhedron 26 (2007) 237

Stabilisation of heterobimetallic networks by crown ethers and hydrogen-bonding in [Ni(H$_2$O)$_6$][Cu$_3$Cl$_8$(H$_2$O)$_2$] · (15-crown-5)$_2$ · 2H$_2$O: Structure and magnetism

[Ni(H$_2$O)$_6$][Cu$_3$Cl$_8$(H$_2$O)$_2$] · (15-crown-5)$_2$ · 2H$_2$O can be conveniently prepared by the interaction of NiCl$_2$ · 6H$_2$O, CuCl$_2$ · 2H$_2$O and 15-crown-5 in water and is found to display intra-trimer ferromagnetic coupling and inter-trimer antiferromagnetic interactions, the latter possibly occurring via the H-bonded [Ni(H$_2$O)$_6$]$^{2+}$ cations.

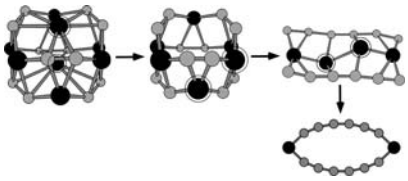


Marcus L. Cole, Glen B. Deacon, Craig M. Forsyth, Peter C. Junk, Kathryn M. Proctor, Janet L. Scott, Christopher R. Strauss

Polyhedron 26 (2007) 244

High temperature synthesis of some strontium and barium 2,6-dibenzylphenolates

The syntheses of $Sr(Odbp)_2$ and $Ba(Odbp)_2$ from the high temperature treatment of 2,6-dibenzylphenol (HOdbp) with Sr or Ba metal and the X-ray crystal structures of $[Sr_9(Odbp)_8(O_2SiMe_2)_4(OH)_2(THF)_6(OH_2)_2] \cdot 6THF$ and $[Ba(Odbp)_2(THF)]_2 \cdot 2THF$, obtained by recrystallisation of $M(Odbp)_2$ (M = Sr, Ba) from THF, are reported.

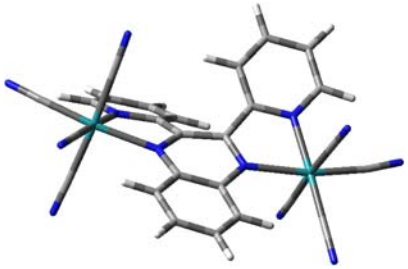


Hugh H. Harris, Ian G. Dance

Polyhedron 26 (2007) 250

Iron–carbon clusters: Geometric structures and interconversions

Possible and probable structures are reported for the experimentally observed ions $[Fe_{12}C_{12}]^+$, $[Fe_{10}C_{12}]^+$, $[Fe_8C_{12}]^+$, $[Fe_6C_{12}]^+$, $[Fe_4C_{12}]^+$, $[Fe_3C_{12}]^+$ and $[Fe_2C_{12}]^+$, together with mechanisms for the observed photodissociation of $[Fe_{12}C_{12}]^+$ to $[Fe_8C_{12}]^+$, and sequential photodissociations of $[Fe_8C_{12}]^+$ to $[Fe_2C_{12}]^+$.

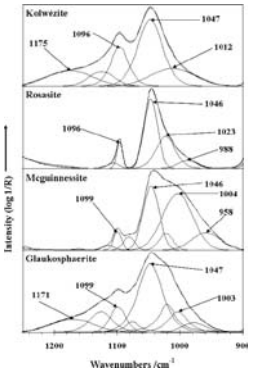


Matthew I.J. Polson, Allan G. Blackman, Keith C. Gordon

Polyhedron 26 (2007) 266

Binuclear ruthenium and osmium mixed-valence complexes containing fused and flexible polypyridyl bridging ligands

Homonuclear binuclear complexes with ligands 2,3-di-(2-pyridyl)quinoxaline and the fused dipyrido[2,3-*a*:3′,2′-*c*]phenazine and $\{Os(bpy)_2\}^{2+}$ and $\{Ru(CN)_4\}^{2-}$ have been prepared. The oxidation potentials are split consistent with the formation of mixed-valence species with comproportionation constants (K_{com}) ranging from 2.5×10^4 to 1.8×10^6. The electronic absorption spectra of the mixed-valence species reveal IVCT transitions in the near infrared region. The absorption maximum for the IVCT band ranges from 5800 to 9980 cm^{-1} and the extinction coefficients from 80 to 6300 M^{-1} cm^{-1}.

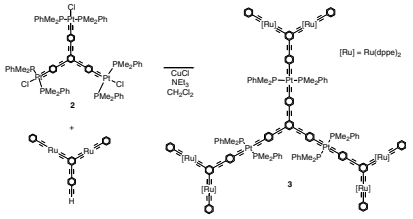


Ray L. Frost, Daria L. Wain, Wayde N. Martens, B. Jagannadha Reddy

Polyhedron 26 (2007) 275

The molecular structure of selected minerals of the rosasite group – An XRD, SEM and infrared spectroscopic study

Minerals in the rosasite mineral group rosasite, glaucosphaerite, kolwezite, mcguinnessite, have been studied by XRD, SEM and infrared spectroscopy. The spectral patterns for the minerals are similar to that of malachite implying the structure is monoclinic.

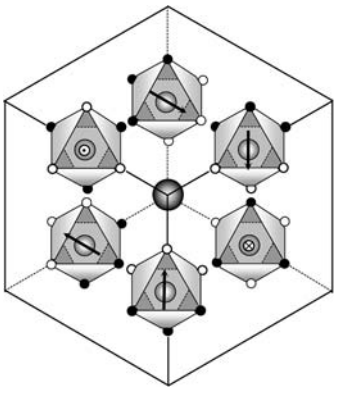


Clem E. Powell, Marie P. Cifuentes, Mark G. Humphrey, Anthony C. Willis, Joseph P. Morrall, Marek Samoc

Polyhedron 26 (2007) 284

Organometallic complexes for nonlinear optics. 37: Synthesis and third-order nonlinear optical properties of a hexaruthenium-tri-platinum dendrimer

The optical limiting merit of *trans*-[Pt(C≡CC$_6$H$_4$-4-C≡CPh)Cl(PMe$_2$Ph)$_2$] (**1**) and 1,3,5-C$_6$H$_3${C≡CC$_6$H$_4$-4-C≡C-*trans*-[PtCl(PMe$_2$Ph)$_2$]}$_3$ (**2**) has been assessed, the effective absorption cross-section for **1** being low, while that of **2** is larger. The third-order nonlinearity of 1,3,5-C$_6$H$_3$(C≡CC$_6$H$_4$-4-C≡C-*trans*-[Pt(PMe$_2$Ph)$_2$]C≡C-4-C$_6$H$_4$-3,5-C$_6$H$_3$-{C≡C-*trans*-[Ru(C≡CPh)(dppe)$_2$]}$_2$)$_3$ (**3**) is larger than that of a related Ru$_6$ dendrimer, but smaller than that of a Ru$_9$ dendrimer, suggesting that increasing metal content and electron richness is correlated to increased nonlinearity in these complexes.

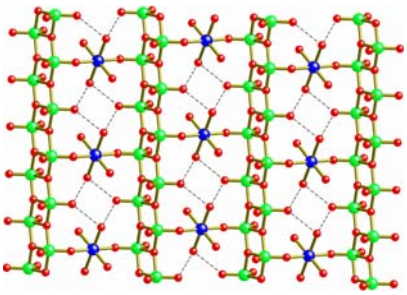


Ray L. Withers, F.J. Brink, Yun Liu, Lasse Norén

Polyhedron 26 (2007) 290

Cluster chemistry in the solid state: Structured diffuse scattering, oxide/fluoride ordering and polar behaviour in transition metal oxyfluorides

Shows one of the 8000 possible local configurations in projection along ⟨1 1 1⟩ which satisfy the local constraint that the sum of the dipole moments of the six Mo^{VI}O$_3$F$_3^{3-}$ octahedra surrounding any central *B* ion (equivalently the sum of the off-centre displacements of the Mo ions) must sum to zero. The F$^-$ ions are represented by the small dark balls while the O^{2-} ions are represented by the small open balls. The induced off-centre shifts of the metal ions are represented by the arrows.

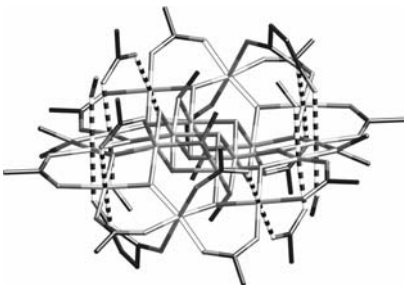


Brendan F. Abrahams, Marissa G. Haywood, Richard Robson

Polyhedron 26 (2007) 300

The structure-directing influence of guanidinium cations in the crystal structures of [C(NH$_2$)$_3$]$_2$[M^{II}(H$_2$O)$_4$(VO$_3$)$_4$] · 4H$_2$O (M = Mn, Co, Ni)

The combination of guanidinium, vanadate and the divalent transition metals Mn^{II}, Co^{II} and Ni^{II} in aqueous solution leads to the generation of crystals of formula [C(NH$_2$)$_3$]$_2$-[M^{II}(H$_2$O)$_4$(VO$_3$)$_4$] · 4H$_2$O (M = Mn, Co, Ni). The structures consist of undulating anionic [M^{II}(H$_2$O)$_4$(VO$_3$)$_4^{2-}$] sheets which stack in an ABAB fashion. Guanidinium ions bind pairs of sheets together by a combination of electrostatic attraction and hydrogen bonding to generate a 3D coordination/hydrogen-bonded network.

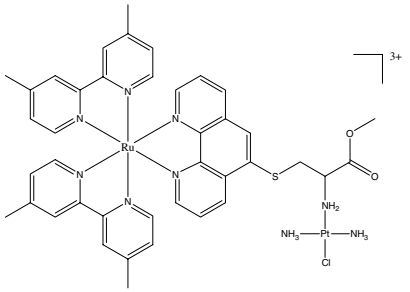


David J. Price, Stuart R. Batten, Boujemaa Moubaraki, Keith S. Murray

Polyhedron 26 (2007) 305

Synthesis, crystal structure and magnetism of a single-molecule magnet, [Mn$_{16}$O$_{16}$(OMe)$_6$-(OAc)$_{16}$(MeOH)$_3$(H$_2$O)$_3$] · 6H$_2$O, and of a mixed bridge 1D chain, [Mn(μ-OMe)-(μ-OAc)$_2$]$_n$

The Mn(III)/Mn(IV) cluster [Mn$_{16}$O$_{16}$(OMe)$_6$-(OAc)$_{16}$(MeOH)$_3$(H$_2$O)$_3$] · 6H$_2$O has an inner [Mn6IVO6(OMe)4]8+ mineral-like core structure surrounded by an outer, non-planar ring of 10 Jahn-Teller distorted Mn(III) atoms. Magnetic measurements show that it is a single-molecule magnet. A 1D Mn(III) material, [Mn(μ-OMe)(μ-OAc)$_2$]$_n$, also obtained when synthesising the Mn$_{16}$ cluster, displays antiferromagnetic coupling without long-range order.

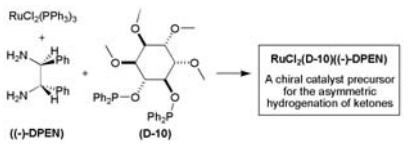


Sarah J. Yousouf, Craig R. Brodie, Nial J. Wheate, Janice R. Aldrich-Wright

Polyhedron 26 (2007) 318

Synthesis of a heterodinuclear ruthenium(II)–platinum(II) complex linked by L-cysteine methyl ester

A potential anticancer heterodinuclear ruthenium(II)–platinum(II) complex, [ruthenium(II)-(4,4′-dimethyl-2,2′-bipyridine)$_2$(5-(L-cysteine-methyl ester)-1,10-phenanthroline)-*trans*-chlorodiamineplatinum(II)] chloride, [Ru(Me$_2$-bipy)$_2$(5-(L-cysteine-Me)-phen)-*trans*-Pt(NH$_3$)$_2$-Cl]Cl$_3$, was synthesised.

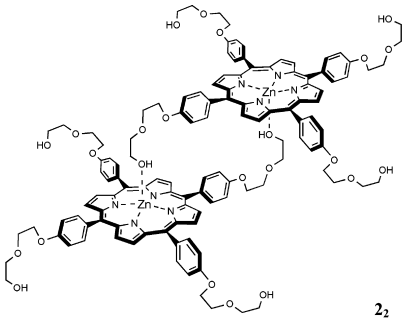


Andrew Falshaw, Graeme J. Gainsford, Cornelis Lensink, Angela T. Slade, L. James Wright

Polyhedron 26 (2007) 329

Ruthenium complexes that incorporate a *chiro*-inositol derived diphosphinite ligand as catalysts for asymmetric hydrogenation reactions

The chiral diphosphinite ligand, 1D-3,4-bis-(*O*-diphenylphosphino)-1,2,5,6-tetra-*O*-methyl-*chiro*-inositol (**D-10**), can be conveniently synthesised from 1D-*chiro*-inositol, and **L-10**, the enantiomer of **D-10**, can also be readily prepared. Ruthenium complexes of **D-10** are effective ketone hydrogenation catalysts with conversions of close to 100% and ee's up to 50% in some cases.

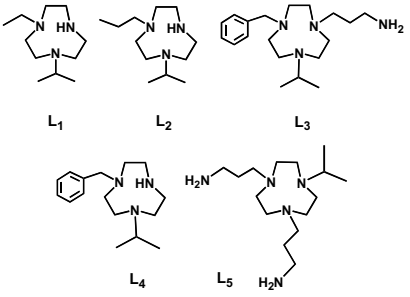


Steven J. Langford, Clint P. Woodward

Polyhedron 26 (2007) 338

Synthesis, characterisation and X-ray structure of a novel porphyrin array employing Zn–O and O–H…O bonding motifs

The crystal structure of **2** dimerises in the solid state (shown schematically) *via* an intermolecular polyether oxygen–Zn(II) interaction to form a 28-membered macrocycle. A bilayer sheeting arrangement of the dimers is achieved through cooperative hydrogen bonding of the ethoxyethanol arms to form 11-membered macrocycles containing four hydrogen bonds.

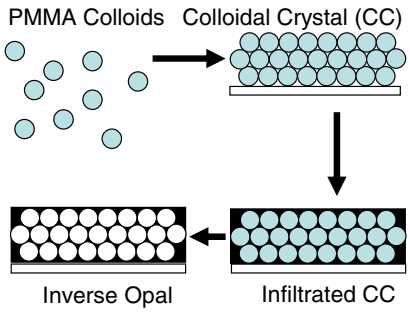


Matthew J. Belousoff, Andrew R. Battle, Bim Graham, Leone Spiccia

Polyhedron 26 (2007) 344

Syntheses, structures and hydrolytic properties of copper(II) complexes of asymmetrically *N*-functionalised 1,4,7-triazacyclononane ligands

A series of square-pyramidal copper(II) complexes of *N*-alkylated derivatives of 1,4,7-triazacyclononane (L1–L5) are reported whose ability to effectively cleave phosphate diesters decreases with the number of copper(II) coordination sites occupied by the ligand.

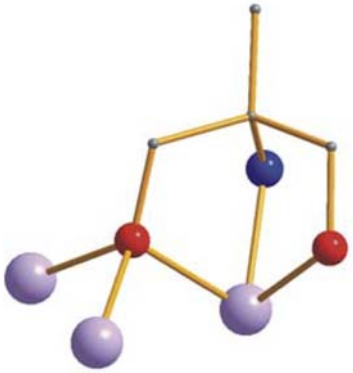


Geoffrey I.N. Waterhouse, Mark R. Waterland

Polyhedron 26 (2007) 356

Opal and inverse opal photonic crystals: Fabrication and characterization

PMMA colloidal crystals have been fabricated and used as templates for the preparation of SiO_2, TiO_2 and CeO_2 photonic crystals with inverse opal structures.

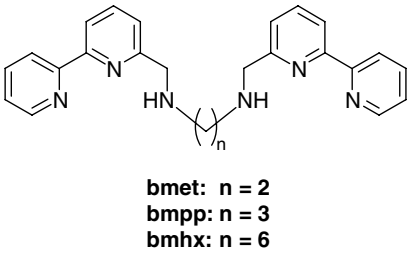


Kerwyn G. Alley, Roland Bircher, Hans U. Güdel, Boujemaa Moubaraki, Keith S. Murray, Brendan F. Abrahams, Colette Boskovic

Polyhedron 26 (2007) 369

Incorporation of a tripodal ligand with a (N,O,O)-donor set into a new family of nickel and cobalt spin clusters

Tetranuclear nickel(II) and cobalt(II) complexes of the monoanion of 2-amino-2-methyl-1,3-propanediol display related low symmetry structures based on distorted cubane units. Magnetic measurements reveal ferromagnetic exchange interactions for all complexes.

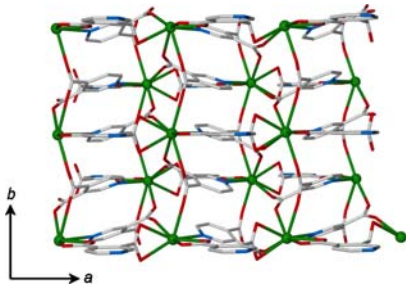


Lynton J. Baird, Cory A. Black, Allan G. Blackman

Polyhedron 26 (2007) 378

A new series of potentially hexadentate ligands derived from 2,2′-bipyridine

The syntheses and characterisation of the new, potentially hexadentate, ligands *N*,*N*′-bis(2,2′-bipyridin-6-ylmethyl)ethane-1,2-diamine (bmet), *N*,*N*′-bis(2,2′-bipyridin-6-ylmethyl)-propane-1,3-diamine (bmpp) and *N*,*N*′-bis-(2,2′-bipyridin-6-ylmethyl)hexane-1,6-diamine (bmhx) are reported and the synthesis and crystal structure of the mononuclear complex $[Co(bmet)](ClO_4)_3 \cdot H_2O$ are detailed. The first transition metal complex of 6-(aminomethyl)-2,2′-bipyridine (amb) is also described.

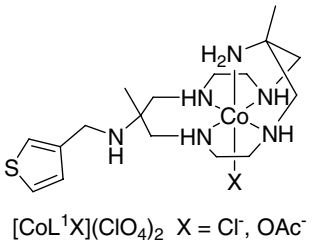


Desmond Ang, Glen B. Deacon, Peter C. Junk, David R. Turner

Polyhedron 26 (2007) 385

Synthesis and structure of the two-dimensional coordination networks $[Ln(PDC)(N\text{-}HPDC)]_\infty$ (PDC = pyridine-3,4-dicarboxylate, Ln = La, Ce, Pr)

Nine coordination of the lanthanoid invloves μ_4-η^1:η^1:η^2:η^1(*N*) coordination of a PDC^{2-} ligand and μ-η^2:η^2 coordination of the N-protonated ligand $N\text{-}HDPC^-$.

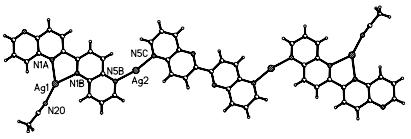


Paul V. Bernhardt, Nathan L. Kilah

Polyhedron 26 (2007) 392

Macrocyclic cobalt(III) complexes as precursors for metal-polythiophene hybrid materials

A thiophene-functionalised macrocyclic ligand (L^1) has been prepared and complexed with Co^{III}. Electro-copolymerisation of $[CoL^1Cl]Cl_2$ with 3,4-ethylenedioxythiophene (EDOT) in a 1:2 ratio on a preformed poly-3,4-ethylenedioxythiophene (PEDOT) film resulted in electroactive metal-polymer hybrid films of high quality, consistency and uniformity in appearance.



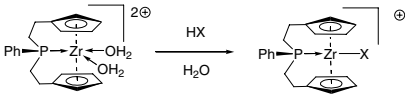
$[CoL^1X](ClO_4)_2$ X = Cl^-, OAc^-

Christopher M. Fitchett, Peter J. Steel

Polyhedron 26 (2007) 400

Synthesis and X-ray structures of two discrete metal complexes of 2,2′-bi-1,5-naphthyridine, a new ambivergent ligand

A new synthesis of 2,2′-bi-1,5-naphthyridine (**1**) is described along with its reactions with copper(II) nitrate, silver(I) tetrafluoroborate and palladium(II) chloride. X-ray crystal structures are described of a mononuclear copper complex, in which **1** acts as a convergent ligand chelating through the two internal nitrogens, and an unusual M_4L_3 silver complex containing both two- and three-coordinate silvers and with ligand **1** acting in two different bridging modes.

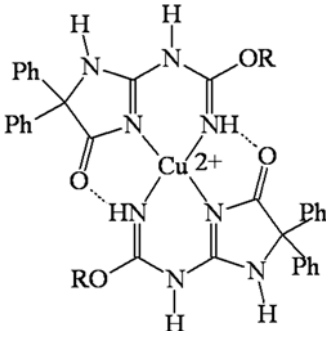


James R. Butchard, Owen J. Curnow

Polyhedron 26 (2007) 406

Aqueous chemistry of the five-coordinate zirconocene dichloride $PhP(CH_2CH_2–\eta^5C_5H_4)_2ZrCl_2$: X-ray structure of the sulfato complex $PhP(CH_2CH_2–\eta^5\text{-}C_5H_4)_2Zr(\eta^2\text{-}SO_4)$

The novel five-coordinate zirconocene(IV) dichloride complex $PhP(CH_2CH_2–\eta^5\text{-}C_5H_4)_2ZrCl_2$ contains an unusual tridentate cyclopentadienyl-phosphine ligand which stabilises the complex in aqueous solutions. Its aqueous solution chemistry has been investigated using largely ^{31}P NMR spectroscopy and ES-MS.



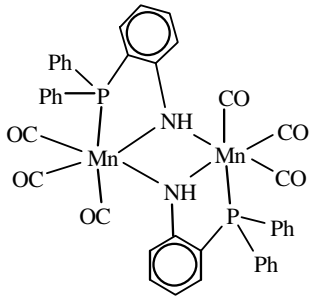
X = F, NO_3, HSO_4, HCO_3

Michael M. Bishop, Leonard F. Lindoy, Mary McPartlin, Andrew Parkin, Oliver T. Thorn-Seshold, Peter Turner

Polyhedron 26 (2007) 415

A systematic study of ligand intermolecular interactions in crystals of copper(II) complexes of bidentate guanidino derivatives

The X-ray structures of several neutral copper(II) complexes and one cationic complex incorporating bidentate alkyl *N*-(4-oxo-5,5-diphenyl-4,5-dihydro-1*H*-imidazol-2-yl)imidocarbamate ligands show extended supramolecular structures based on doublet (DA or DD) hydrogen bonding and/or phenyl embraces.

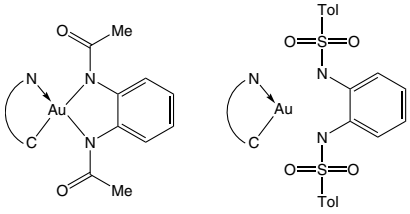


Victor D. Fester, Paul J. Houghton, Lyndsay Main, Brian K Nicholson

Polyhedron 26 (2007) 430

A manganese carbonyl complex derived from the P,N-bonding ligand (2-aminophenyl)diphenylphosphine

The first manganese carbonyl complex derived from (2-aminophenyl)diphenylphosphine is formed on reaction of the ligand with $[H_3Mn_3(CO)_{12}]$. It contains two bridging amido ligands.

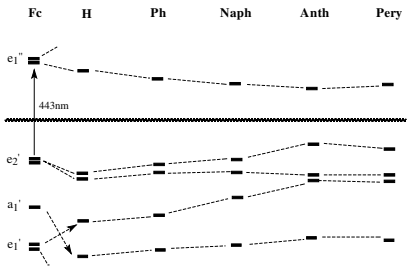


Kelly J. Kilpin, William Henderson, Brian K. Nicholson

Polyhedron 26 (2007) 434

Organogold(III) complexes containing chelating bis(amidate) ligands: Synthesis, characterisation and biological activity

A series of new auracyclic complexes containing the Au–NR–CH_2CH_2–NR (R = SO_2Tol) and Au–NR–C_6H_4–NR (R = COMe or SO_2Tol) five-membered ring systems are formed from reactions of cycloaurated gold(III) dichloride complexes with 1,2-$C_6H_4(NHCOMe)_2$, $C_2H_4(NHSO_2Tol)_2$ (Tol = *p*-tolyl) or 1,2-$C_6H_4(NHSO_2Tol)_2$ and base.

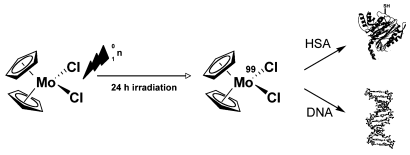


A.H. Flood, C.J. McAdam, K.C. Gordon, H.G. Kjaergaard, A.M. Manning, B.H. Robinson, J. Simpson

Polyhedron 26 (2007) 448

Electronic structure and near-IR transitions of FcC_2R and FcC_4R dyads

DFT calculations show that the frontier orbital configuration of 17e and 18e FcC_2R and FcC_4R dyads, is $(e'_2\text{-a},\pi)^2(e'_2\text{-b, metal})^2(e'_1\text{-a},\pi)^2$, $(a_1, \text{metal})^2$. A strongly solvatochromic transition in the near-IR for 17e dyads is best described as an LMCT transition.

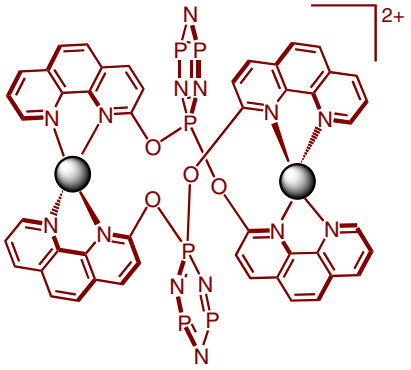


Kate S. Campbell, Carolyn T. Dillon, Suzanne V. Smith, Margaret M. Harding

Polyhedron 26 (2007) 456

Radiotracer studies of the antitumor metallocene molybdocene dichloride with biomolecules

Binding experiments with the radiotracer $Cp_2{}^{99}MoCl_2$ and the thiol containing protein human serum albumin (HSA) or calf thymus DNA, monitored for ^{99}Mo using a gamma counter, are consistent with strong preferential interaction of Cp_2MoCl_2 with thiols versus other donor sites in biomolecules including DNA.

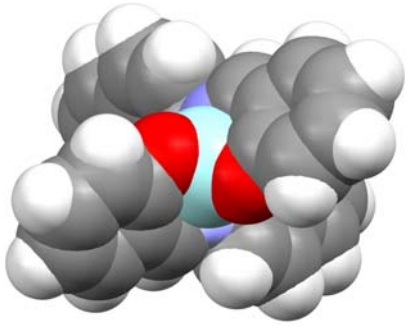


Eric W. Ainscough, Andrew M. Brodie, Geoffrey B. Jameson, Carl A. Otter

Polyhedron 26 (2007) 460

Copper complexes with 1,10-phenanthrolines tethered to a cyclotriphosphazene platform

The reaction of copper salts with 2-oxy-1,10-phenanthroline moieties tethered to a cyclotriphosphazene ring affords dimetallic copper(I) complexes with the ligand coordinating to two metal centres in a helical fashion whereas the copper(II) complexes are five-coordinate monomeric species.

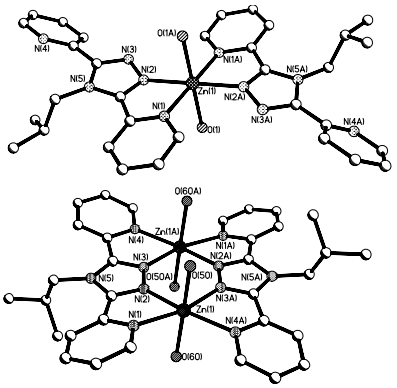


Paul G. Plieger, Kevin D. John, Anthony K. Burrell

Polyhedron 26 (2007) 472

Encapsulating beryllium – Synthesis, characterisation and modelling of a chiral binaphthyldiimine-Be(II) complex

Beryllium has been successfully incorporated into a naphthalene containing Schiff base ligand. Evidence from both experimental and calculated ^{9}Be NMR data and model compounds indicate that the ligand completely encapsulates the beryllium cation via tetradentate tetrahedral coordination using both phenol and imine donors.

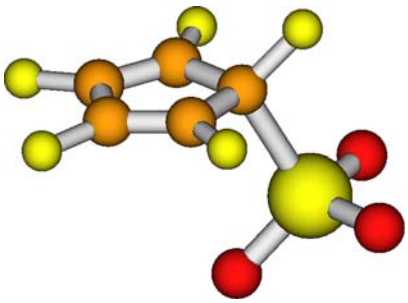


Marco H. Klingele, Andy Noble, Peter D.W. Boyd, Sally Brooker

Polyhedron 26 (2007) 479

Synthesis and X-ray crystal structures of some mononuclear and dinuclear complexes of 4-isobutyl-3,5-di(2-pyridyl)-4*H*-1,2,4-triazole

Control of the metal-to-ligand molar ratio is insufficient to completely dictate the outcome of complexation reactions of bis-bidentate ligands such as 4-isobutyl-3,5-di(2-pyridyl)-4*H*-1,2,4-triazole (ibdpt). Here we show that despite employing a 1:2 molar ratio in some cases both mononuclear $[M^{II}(ibdpt)_2(X)_2]^{y+}$ and dinuclear $[M^{II}_2(ibdpt)_2(X)_4]^{y+}$ complexes are obtained.

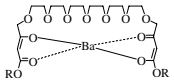


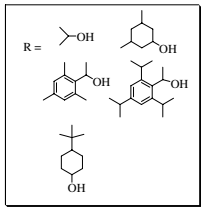
Matthias Lein, Anton Hammerl, Holger L. Hermann, Peter Schwerdtfeger

Polyhedron 26 (2007) 486

Theoretical investigations into trioxo group 7 compounds LRO_3 with perfluorated ligands

Density functional calculations show new and unusual coordination of trioxo group 7 compounds. An experimentally unknown spiecies is suggested as a viable target for synthesis.



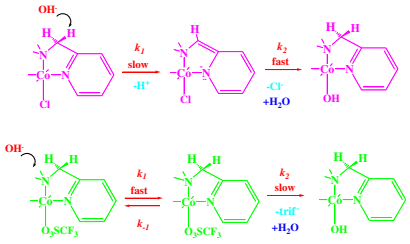


Matthew R. Hill, Jennifer J. Russell, Nicholas K. Roberts, Robert N. Lamb

Polyhedron 26 (2007) 493

Novel monomeric barium complexes as volatile precursors for chemical vapour deposition

A new range of barium complexes with single dianionic encapsulating ligands have been prepared for use in chemical vapour deposition (CVD). Preliminary testing has exhibited promising results with these prospective precursors.



W. Gregory Jackson, Alistair Dickie, Kerrina Wells

Polyhedron 26 (2007) 508

Base catalysed substitution reactions of octahedral cobalt(III) complexes: Mechanism switching by changing the leaving group

The $[Co(pentaamine)X]^{n+}$ complexes studied bear at least one N-coordinated $–CH_2$-pyridine group. The mechanism for base catalysed hydrolysis can be switched from the classic S_N1CB to the pseudo-aminate mechanism, which involves rate limiting deprotonation, by simply changing the leaving group.

Derek W. Smith

Polyhedron 26 (2007) 519

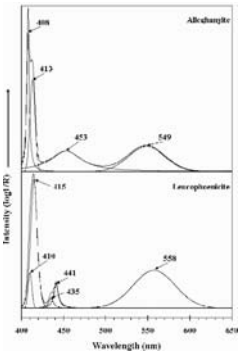
A new approach to the relationship between bond energy and electronegativity

A modified version of Pauling's bond energy equation can be derived from intuitive expressions for homopolar and heteropolar bond energies $D_{A–A}$ and $D_{A–B}$ in terms of the quantities x and y, which are related to electronegativity and hardness/softness.

$$D_{A\text{-}A} = y_A^2 - x_A^2$$

$$D_{B\text{-}B} = y_B^2 - x_B^2$$

$$D_{A\text{-}B} = y_A y_B - x_A x_B$$



$$D_{A\text{-}B} - \tfrac{1}{2}(D_{A\text{-}A} - D_{B\text{-}B}) = \tfrac{1}{2}[(x_A - x_B)^2 - (y_A - y_B)^2]$$

Sara Palmer, B. Jagannadha Reddy, Ray L. Frost

Polyhedron 26 (2007) 524

Application of UV–Vis, near-infrared and mid-infrared spectroscopy to the study of Mn-bearing humites

The combination of electronic and vibrational spectra has been applied to correlate the spectral properties, with composition, structure and cation substitutions such as Mn, Fe, Ca and Zn for Mg in humites: norbergite, alleghanyite, leucophoenicite and sonolite with increasing number of silicate layers, 1, 2, 3 and 4.

Polyhedron 26 (2007) 5203

Studies on Co(II) and Co(III) complexes of di-2-pyridyl ketone *N*(4)-cyclohexyl and *N*(4)-phenyl thiosemicarbazones

Six new Co(II) and Co(III) complexes (**1**–**6**) of di-2-pyridyl ketone *N*(4)-cyclohexyl thiosemicarbazone (HL^1) and di-2-pyridyl ketone *N*(4)-phenyl thiosemicarbazone (HL^2) have been synthesized and spectrochemically characterized. HL^1 is newly synthesized and has been structurally characterized by single crystal X-ray diffraction studies, while HL^2 has been previously reported. HL^1 crystallizes into a monoclinic lattice with the space group $P2_1$. The complexes are characterized by magnetic, EPR, NMR and other spectroscopic studies. The EPR spectra of the paramagnetic complexes reveal axial features with eight hyperfine lines clearly resolved in the perpendicular region.

Synthesis, structures and oxygen atom transfer catalysis of oxo-bridged molybdenum(V) complexes with heterocyclic bidentate ligands (N,X) X = S, Se

The first μ-oxomolybdenum(V) pyridine-2-selenolato complex $[Mo_2O_3(PySe)_4]$ and its pyridine-2-thionato analogue $[Mo_2O_3(PyS)_4]$ as well as $[Mo_2O_3(4\text{-}CF_3\text{-}PymS)_4]$ were synthesized and structurally characterized. The oxygen atom transfer properties of the selenium and the corresponding sulfur compound are compared.

Synthesis and characterization of a series of zinc complexes stabilized by 1,1,3,3-tetraalkylguanidinate (TAG) ligands: $[Zn(\mu\text{-}TAG)\{N(SiMe_3)_2\}]_2$

A series of novel structurally varied low-coordinate zinc complexes utilizing 1,1,3,3-tetraalkylguanidinate (TAG) ligands were synthesized and characterized. Li(TAG) and lithium bis-trimethylsilylamide, $LiN(SiMe_3)_2$, were successfully reacted with $ZnCl_2$ in a 1:1 ratio to yield the corresponding dinuclear complexes with the general formula $[Zn(\mu\text{-}TAG)\{N(SiMe_3)_2\}]_2$.

Crystal structures of three novel dioxotetraperoxodi(molybdenum) heteropolyanions in $[PPh_4]_2[R_2SiO_2\{Mo_2O_2(\mu\text{-}O_2)_2(O_2)_2\}]$ (R_2 = $(CH_3)_2$, $(i\text{-}C_4H_9)_2$ or $(CH_3)(CH_2Cl)$) and characterization of their tungsten analogues

The reaction of MoO_3 [or "$WO_3 \cdot H_2O$"], 30 wt% aqueous H_2O_2 with $R_2Si(OR')_2$ in alkaline hydrogen peroxide–ethanol affords the dimeric title complexes. These compounds represent a type of silicon-based polyoxoperoxo species which are also obtained by grafting on silica surfaces and in the synthesis of organic/inorganic mesophases to prepare MO_x–SiO_2–MCM-41 or MO_x–SiO_2–SBA-15.

Three novel trinuclear zinc(II)/nickel(II) complexes with pentadentate ligands *N*-nitrobenzoylsalicylhydrazidate

Three novel trinuclear complexes $Zn_3(p\text{-nbzshz})_2(C_5H_5N)_4$ (**1**), $Ni_3(p\text{-nbzshz})_2(py)_4$ (**2**) and $Ni_3(o\text{-nbshz})_2(DMF)_2((CH_3)_2O)_2$ (**3**) have been obtained by the reaction of $Zn(OAc)_2 \cdot 4H_2O$ or $Ni(OAc)_2 \cdot H_2O$ with two new ligands, *N*-*p*-nitrobenzoylsalicylhydrazidate and *N*-*o*-nitrobenzoylsalicylhydrazidate. Complex **1** exhibits a one-dimensional wave-like chain structure resulting from the linkage of the phenolate oxygen donor atoms of the ligand between adjacent trinuclear zinc units. Complex **2** is an uncommon bent trinuclear nickel complex, whilst the three nickel atoms in complex **3** are arranged in a strictly linear fashion.

A novel rhenium(III) complex with bis(pyrazol-1-yl)methane: X-ray structure and DFT calculations for $[ReCl_3(bpzm)(PPh_3)]$

The $[ReCl_3(MeCN)(PPh_3)_2]$ complex reacts with bis(pyrazol-1-yl)methane (bpzm) to give $[ReCl_3(bpzm)(PPh_3)]$. The compound has been studied by IR, UV-Vis spectroscopy and X-ray crystallography. The molecular orbital diagram of $[ReCl_3(bpzm)(PPh_3)]$ has been calculated with the density functional theory (DFT) method. The spin-allowed triplet–triplet electronic transitions of $[ReCl_3(bpzm)(PPh_3)]$ have been calculated with the time-dependent DFT method, and the UV–Vis spectrum of the title compound has been discussed on this basis. The magnetic behavior is characteristic of mononuclear complexes with d^4 low-spin octahedral Re(III) complexes ($^3T_{1g}$ ground state) and arise because of the large spin–orbit coupling (ζ = 2500 cm^{-1}), which gives diamagnetic ground state.

Polyhedron 26 (2007) 4841

Pd–Cl cleavage of dichloro-[1-alkyl-2-(naphthylazo)imidazole]palladium(II) complexes by picolinic acid: Kinetic and mechanistic studies

This work describes kinetics and mechanism of the reaction between picolinic acid (picH) and $[Pd(\alpha\text{-}/\beta\text{-NaiR})Cl_2]$ [α-/β-NaiR = 1-alkyl-2-(naphthyl-α/β-azo)imidazole] in acetonitrile (MeCN) medium. The product is characterized as $[Pd(\alpha/\beta\text{-NaiR})(pic)](ClO_4)$ by different spectroscopic routes. It is established that the cleavage of Pd–Cl bond is the rate-determining step. Thermodynamic parameters ($\Delta^{\ddagger}H^{\circ}$ and $\Delta^{\ddagger}S^{\circ}$) are determined from variable temperature kinetic studies.

Crystal structures and spectroscopic properties of copper(II)–bis(2-pyridylcarbonyl)amide–chlorobenzoate complexes

The reaction of 2,4,6-tris(pyridyl)-1,3,5-triazine (ptz) and copper(II) salts in DMF–water resulted in the hydrolysis of ptz, giving rise to the bis(2-pyridylcarbonyl)amide anion (ptO_2^-) and affording the complexes $[Cu(ptO_2)(2\text{-}Clbenz)(H_2O)]$, $[Cu(ptO_2)(3\text{-}Clbenz)]$, and $[Cu(ptO_2)(4\text{-}Clbenz)(DMF)]$. This report includes the chemical, the spectroscopic characterization and the crystal structures of all these compounds.

Rapid reduction and complexation of vanadium by 1-phenyl-3-methyl-4-toluoyl-5-pyrazolone: Spectroscopic characterization and structure modelling

The reduction of vanadium(V) by 1-phenyl-3-methyl-4-toluoyl-5-pyrazolone over the pH range of 1.0–7.0 has been assessed by various spectroscopic techniques. The reaction proceeds by the transfer of one electron to vanadium(V) by the ligand *via* the formation of a free-radical intermediate, and subsequently the reduced vanadium species rapidly complexes with the available free ligand and forms vanadyl complex. These reduction reactions occur under physiological conditions and thus could be important to the reduction of vanadium(V)-containing coordination compounds used as insulin-enhancing agents for treatment of diabetics.

Syntheses, X-ray structures and properties of a dinuclear cadmium(II)azido and a polymeric cadmium(II)thiocyanato compounds containing bis(tridentate) congregators

One-pot reactions of cadmium(II) perchlorate/nitrate, Schiff bases (pbap/pfap) and pseudohalides (sodium azide/ammonium thiocyanate) in a 2:1:4 molar ratio in MeOH–MeCN solvent mixtures at room temperature result in a dinuclear compound $[Cd_2(pbap)(OH_2)_2(N_3)_4]$ (**1**) [pbap = *N*-(1-pyridin-2-ylbenzylidene)-*N*-[2-(4-{2-[(1-pyridin-2-ylbenzylidene)amino]ethyl}piperazin-1-yl)ethyl]amine] and a polymeric compound $[Cd_2(pfap)(\mu_{1,3}\text{-NCS})(\mu_{1,3}\text{-SCN})(NCS)_2]_n$ (**2**) [pfap = *N*-(1-pyridin-2-ylformylidene)-*N*-[2-(4-{2-[(1-pyridin-2ylformylidene) amino]ethyl}piperazin-1-yl)ethyl]-amine]. X-ray crystal structural analyses reveal a bis (tridentate) congregation behaviour of the hexadentate blocker (pbap/pfap) encapsulating two metal centers. Both the complexes display intraligand $^1(\pi\text{–}\pi^*)$ fluorescence and intraligand $^3(\pi\text{–}\pi^*)$ phosphorescence in glassy solutions.

Polyhedron 26 (2007) 5030

Magnetism and crystal structures of $Cu^{II}Mn^{II}$ and $Cu^{II}Ni^{II}$ ordered bimetallic chains

The syntheses, crystal structures and magnetic properties of the new bimetallic compounds $\{CuL_a[Ni(NCS)_4(H_2O)_2]\}$ (**1**) and $\{CuL_a[Mn(NCS)_4(H_2O)_2]\}$ (**2**), where L = *N*-dl-5,12-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene, are reported. Both structures consist of well-separated and magnetically equivalent layers which are composed of thiocyanate-bridged Cu(II)–Mn(II) or Cu(II)–Ni(II) binuclear units and create infinite polymeric zig-zag-like chains in the crystal lattices. The $[Ni(NCS)_4(H_2O)_2]$ and $[Mn(NCS)_4(H_2O)_2]$ molecular fragments have a distorted octahedral symmetry. The geometry of the Cu(II) unit is octahedral with the apical positions occupied by bridging thiocyanate ligands and the basal ones by four nitrogen atoms from the macrocyclic ring. The shortest intramolecular M–M distances are: 6.342 Å (Cu–Ni) and 6.421 Å (Cu–Mn). Magnetic susceptibility and magnetization measurements for the examined compounds have been carried out over the range 1.8–300 K. The data suggest antiferromagnetic interactions through the thiocyanate bridge. Finally, the magnitudes of the Cu(II)–M(II) interactions (M = Ni and Mn) have been compared and qualitatively rationalised.

Experimental and computational study on [2,6-bis(3,5-dimethyl-*N*-pyrazolyl)pyridine](dithiocyanato)mercury(II)

The mercury complex of 2,6-bis(3,5-dimethyl-*N*-pyrazolyl)pyridine (bdmpp) has been synthesized and characterized by X-ray diffraction, IR, UV–Vis and TGA–DTA methods. The structure consists of units in which the mercury atom is a penta-coordinated by two sulfur and three nitrogen atoms. [Hg(bdmpp)(SCN)2] has a distorted square pyramidal geometry. The optimized geometry at both PM3 and DFT methods agrees with the X-ray structure well. The infrared spectra of the title complex was studied in the 4000–400 cm^{-1} frequency range experimentally and theoretically. The experimental results are in better agreement with the DFT results at the B3LYP/LanL2DZ level than the semi-empirical results at the PM3 level.

Synthesis, characterisation and crystal structures of three trinuclear cadmium(II) complexes with multidentate Schiff base ligands

Three novel trimeric Cd(II) complexes have been prepared from two different symmetrical Schiff bases. Crystal structures of all the complexes have been established by single crystal X-ray diffraction methods. The ligands and their metal complexes have been characterised by analytical and spectroscopic techniques. Among the three complexes, **1** and **3** are linear whereas **2** is a cyclic trimer. In **1** and **3**, all the doubly phenoxo bridged Cd(II) metal centres have a distorted octahedral environment. In the complex **2**, two out of the three Cd(II) centres reside in a distorted octahedral environment and the remaining one enjoys a monocapped octahedral geometry. Altogether a variety in the bridging mode of two new salen-type ligands has been established.

Synthesis of mono- and binuclear dioxomolybdenum(VI) complexes derived from N(4)-substituted thiosemicarbazones: X-ray crystal structures of $[(MoO_2L^1)_2]$, $[MoO_2L^1py]$ and $[MoO_2L^2py]$

Four molybdenum(VI) thiosemicarbazonato complexes have been synthesized and characterized. The dinuclear complexes $[(MoO_2L^1)_2]$ (**1**) and $[(MoO_2L^2)_2]$ (**3**) have been prepared by the reaction of $[MoO_2(acac)_2]$ with 2-hydroxyacetophenone N(4)-cyclohexyl (H_2L^1) and N(4)-phenyl (H_2L^2) thiosemicarbazones in alcoholic medium. Mononuclear dioxomolybdenum(VI) complexes of the type $[MoO_2L^1py]$ (**2**) and $[MoO_2L^2py]$ (**4**) have been prepared by the reaction of **1** or **3** with pyridine (py) in alcoholic medium. In all the complexes, molybdenum is coordinated by two terminal oxo-oxygen atoms, (O_t), oxygen, nitrogen and sulfur atoms from the principal ligand and by an oxygen atom from the second unit in **1**, and by a nitrogen atom from pyridine in complexes **2** and **4**. All complexes have been spectroscopically characterized. The molecular structures of complexes **1**, **2** and **4** have been determined by the single crystal X-ray diffraction method.

CO substitution in $H_4Ru_4(CO)_{12}$ by the diphosphine ligands 1,2-bis(diphenylphosphino)benzene (dppbz) and 1,8-bis(diphenylphosphino)naphthalene (dppn): X-ray diffraction structures of the diphosphine-chelated clusters 1,1-$H_4Ru_4(CO)_{10}$(dppbz) and 1,1-$H_4Ru_4(CO)_{10}$(dppn)

The reaction of the tetraruthenium cluster $H_4Ru_4(CO)_{12}$ (**1**) with the unsaturated diphosphine ligands 1,2-bis(diphenylphosphino)-benzene (dppbz) and 1,8-bis(diphenylphosphino)naphthalene (dppn) under thermolysis and Me_3NO activation affords the diphosphine-chelated clusters 1,1-$H_4Ru_4(CO)_{10}$(dppbz) (**2**) and 1,1-$H_4Ru_4(CO)_{10}$(dppn) (**3**), respectively, as the only isolable products. Compounds **2** and **3** have been isolated and fully characterized by IR and NMR spectroscopies and X-ray diffraction analyses. The robust stability of **2** and **3** are discussed with respect to the other ruthenium clusters containing these diphosphine ligands.

A novel blue luminescent high-spin iron(III) complex with interlayer O–H···Cl bridging: Synthesis, structure and spectroscopic studies

The acyclic tridentate salicyl-2-pyridyl hydrazone afforded a blue luminescent high-spin iron(III) complex (s = 5/2, λ_{ex} = 390 nm, λ_{em} = 449 nm) with interesting interlayer O–H···Cl bridging. Deprotonation and insertion of a nucleophile in the ligand frame significantly modulates the photophysical and chemical properties of the complex. Moreover, the ligand and its iron(III) complex undergo photoinduced intramolecular azo-imine tautomerism.

Polyhedron 26 (2007) 3703

Crystal engineering with aroyl hydrazones of diacetyl monooxime – Molecular and supramolecular structures of two Ni(II) and two Zn(II) complexes

Four new Schiff bases of aroyl hydrazides with diacetyl monooxime have been prepared and Ni(II) and Zn(II) complexes of these ligands have been synthesized. Two Ni(II) and two Zn(II) complexes have been characterized by X-ray crystallography. The aroyl hydrazone ligands were designed in such a way that there is a systematic variation in the H-bond forming abilities of their aroyl moiety, e,g. both H-bond acceptor and donor (salicyloyl), only H-bond donor (anthraniloyl), only H-bond acceptor (isonicotinoyl). It is shown in this work that such a variation in the H-bond donor acceptor properties of the ligands leads to considerable diversity in their supramolecular architecture.

Step-by-step synthesis of multifunctionalized linear oligophosphazenes: X-ray crystal structures of compounds issued from the first steps

An inorganic oligomeric chain constituted of P=N linkages is synthesized step-by-step. Such methodology allows the selective grafting of different selected functional groups to the inorganic backbone. The structure of a compound possessing a P=N—P=S linkage and two types of side groups was determined by X-ray crystallography.

Polyhedron 26 (2007) 3893

Synthesis, characterization and structures of copper(II) complexes with amide-based ligands: Unusual formation of a linear trimer and a zig-zag chain and their contrast magnetic behaviour

Novel copper(II) complexes of amide-based ligands are reported having linear trimeric (**1**) and one-dimensional zig-zag chain (**2**) structures. The copper centers bridged by the amidic NCO group (highlighted in pink shade) show interesting but contrast magnetic properties. The complex **1** shows antiferromagnetic coupling ($J = -110\ cm^{-1}$) while **2** shows a weak ferromagnetic interaction ($J = +3\ cm^{-1}$).

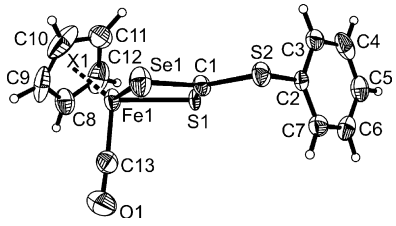
Conformational isomerism of 1,2-bis(imidazol-1′-yl)ethane in five-coordination polymers: Influence of metal ions and *m*-isophthalate ligands bearing different substituents

The solvothermal reactions of 1,2-bis(imidazol-1′-yl)ethane (bime), *m*-isophthalic acid (H_2bdc) or its derivatives 5-hydroxylisophthalic acid (HO-H_2bdc) and 5-nitroisophthalic acid (O_2N-H_2bdc) with different metal ions gave rise to five novel coordination polymers, $\{[Zn(gauche\text{-bime})(bdc)] \cdot 0.5H_2O\}_n$ (**1**), $\{[Zn(anti\text{-bime})(HO\text{-bdc})] \cdot 2.5H_2O\}_n$ (**2**), $\{[Zn(anti\text{-bime})(O_2N\text{-bdc})] \cdot H_2O\}_n$ (**3**), $[Cu(gauche\text{-bime})_{0.5}(anti\text{-bime})_{0.5}(O_2N\text{-bdc})]_n$ (**4**) and $[Ni_2(gauche\text{-bime})(anti\text{-bime})(O_2N\text{-bdc})_2(H_2O)_2]_n$ (**5**). The presence of coexistent electron-donating and electron-withdrawing groups in dicarboxylate ligands and different metal ions play crucial roles on the conformational preference of bime in the five structures.



Solvothermal reaction	Compound	Comoformational isomer of bime
bime + H_2bdc + $Zn(NO_3)_2{\cdot}6H_2O$	**1**	*gauche*
bime + HO-H_2bdc + $Zn(NO_3)_2{\cdot}6H_2O$	**2**	*anti*
bime + O_2N-H_2bdc + $Zn(NO_3)_2{\cdot}6H_2O$	**3**	*anti*
bime + O_2N-H_2bdc + $Cu(NO_3)_2{\cdot}3H_2O$	**4**	*gauche* : *anti* = 1 : 1
bime + O_2N-H_2bdc + $Ni(NO_3)_2{\cdot}6H_2O$	**5**	*gauche* : *anti* = 1 : 1

Solvothermal syntheses and crystal structures of new Cu(II) complexes with phenylsuccinic acid

Five Cu(II) complexes with phenylsuccinic acid and diamine-like ligands were obtained under solvothermal conditions, and complexes **2** and **3** were obtained in one-pot reaction. Complexes **1**–**3** and **5** are composed of $[psa]^{2-}$ and terminal ligands phen, 2bpy, and N_3^- resulting in 2D and 3D supramolecular networks, and complex **4** forms a 3D metal–organic framework by bridging ligands $[psa]^{2-}$ and 4bpy.

Polyhedron 26 (2007) 4187

Synthesis, crystal structure and biological activity of two new heterotrinuclear thiocyanato bridged Cu(II)–Hg(II)–Cu(II) complexes

The mononuclear copper(II) complexes CuL^1 and CuL^2 have been prepared with two tetradentate Schiff base ligands, abbr. L^1H_2 = *N*,*N*′-bis(salicylidene)-1,3-diaminopropane and L^2H_2 = *N*,*N*′-bis(salicylidene)-1,4-butanediamine, and then transformed into the heterotrinuclear complexes, $[(CuL^1)_2Hg(SCN)_2]$ and $[(CuL^2)_2Hg(SCN)_2]$, in the presence of the $Hg(SCN)_2$ salt. Both heterotrinuclear complexes have been characterized by means of elemental analyses, IR and electronic spectra, and their structures determined by X-ray analysis. The ligands and the complexes were screened for antibacterial and antifungal activities by the disc diffusion and microtiter plate techniques using DMF as the solvent. The minimum inhibitory concentration (MIC) values were calculated. It has been found that antimicrobial activities of the complexes are higher than those of the free ligands.

The reactions of 8-hydroxyquinoline with $[RuHCl(CO)(PPh_3)_3]$: A new ruthenium(II) carbonyl complex with a N-donor ligand

The reaction of $[RuHCl(CO)(PPh_3)_3]$ with 8-hydroxyquinoline has been examined and a novel ruthenium(II) complex – $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ – has been obtained. This compound has been studied by IR, UV–Vis (absorption and emission), ^1H and ^{31}P NMR spectroscopy, and X-ray crystallography. The molecular orbital diagram of the complex has been calculated with the density functional theory (DFT) method. The spin-allowed singlet–singlet electronic transitions of the complex have been calculated with the time-dependent DFT method, and the UV–Vis spectrum of the compound has been discussed on this basis.

Polyhedron 26 (2007) 4223

Coordination modes of histidine- or methioninehydroxamic acids in copper(II) mixed-ligand complexes with ethylenediamine in aqueous solution

Equilibrium studies of the mixed-ligand complexes of the copper(II) ion with ethylenediamine and methionine- or histidinehydroxamic acid show that the mixed-ligand species is formed in the basic solution. Their absorption and EPR spectra indicate 4N coordination – both amine and hydoxamic nitrogens of aminohydroxamic acid and two amine nitrogens of ethylenediamine in the equatorial plane. The weak interactions between thioether sulfur of methioninehydroxamic acid or imidazole ring of histidinehydroxamic acid and copper(II) ion are suggested.

Copper(II)–π interaction in *cis*-$[Cu(orotato)(NH_3)_2]$ and the crystal structure of $[Cu(orotato)(H_2O)_4] \cdot H_2O$: X-ray, vibrational spectroscopy and density functional study

Evidence is presented that complex **1** exhibits a Cu–π interaction between the chelated Cu^{2+} cation and the axial C=C bond of a neighboring orotate ligand. This weak interaction is very important in stabilizing the columnar, polymeric structure of **1**. In the novel complex **2**, the coordination geometry around copper(II) can be described as an elongated octahedron. It is suggested that the non-covalent Cu–π interaction of the chelated Cu^{2+} ion can play a significant role in the active sites of copper enzymes.

Self-assembled macrocyclic molecular squares of Ni(II) derived from carbohydrazones and thiocarbohydrazones: Structural and magnetic studies

Four novel molecular square grids were achieved by self-assembly using the flexible ligands bis(di-2-pyridyl ketone) thiocarbohydrazone (H_2L^1), bis(quinoline-2-carbaldehyde) thiocarbohydrazone (H_2L^2), bis(di-2-pyridyl ketone) carbohydrazone (H_2L^3) and bis(2-benzoyl pyridine) carbohydrazone (H_2L^4). Three complexes were given a general formula of [$Ni(HL)]_4[PF_6]_4 \cdot nH_2O$ and one [$Ni_2(HL^2)$-$L^2]_2(PF_6)_2 \cdot 7H_2O$. The MALDI-MS spectra reveal the formation of tetranuclear molecular squares. The square grid of the Ni(II) centers in all the complexes were organized by deprotonated ligands. The complex [$Ni(HL^1)]_4$-$[PF_6]_4 \cdot 11H_2O$ crystallized as [$Ni(HL^1)]_4$-$(PF_6)_4 \cdot 0.5\ CH_3CH_2OH \cdot 2.8H_2O$ and X-ray study revealed octahedral geometries around the Ni(II) centers. Variable temperature magnetic studies suggest intramolecular antiferromagnetic coupling between the Ni(II) electrons by a super exchange mechanism through intervening sulfur/oxygen atoms.

Ring opening reactions of pyromellitic dianhydride for the synthesis of first row transition metal dicarboxylate complexes

The ring opening reaction of pyromellitic dianhydride by methanol is an effective method to prepare first row transition metal carboxylate complexes. The reactions of different first row transition metal salts with pyromellitic dianhydride in the presence of nitrogen donating bidentate ligands such as 1,10-phenanthroline and 2,2′-bipyridine gives different compositions depending on the ligand and the metal salts used.

NMR and fluorescence spectral studies on bisdithiocarbamates of divalent Zn, Cd and their nitrogenous adducts: Single crystal X-ray structure of (1,10-phenanthroline)bis(4-methylpiperazinecarbodithioato) zinc(II)

Six complexes with the MS_4N_2 (M = Zn or Cd) chromophore have been synthesized. IR spectra of the complexes show the contribution of the thioureide form to the structures. NMR and fluorescence spectra of the complexes show interesting properties. Single crystal X-ray structural analysis of one of the complexes showed the zinc atom to be in a highly distorted octahedral environment with the MS_4N_2 chromophore.

Hydrolytic ring opening reactions of anhydrides for first row transition metal dicarboxylate complexes

Ring opening reactions of 2,3-pyridine dicarboxylic anhydride were studied with hydrated cobalt, nickel and zinc salts. Hydrated metal salts preferentially hydrolyze 2,3-pyridine dicarboxylic anhydride over the esterification reaction in alcoholic medium. The bonding and the nature of the metal carboxylate complexes formed in these reactions are dependent on the type of metal as well as on the anion and nitrogen donor ligands.

Polyhedron 26 (2007) 4533

A Raman spectroscopic study of the phosphate mineral pyromorphite $Pb_5(PO_4)_3Cl$

A comparison of Raman spectra of pyromorphites with published infrared and Raman data of similar minerals has been made. Crystals of the pyromorphite–mimetite series are chemically zoned, resulting in changes in the crystal structure with the isomorphic replacement of phosphate by arsenate with the consequential change in crystal structure from monoclinic to hexagonal. Such dimorphic relationships are exemplified by the shift in the Raman spectral band positions of phosphate with increasing arsenate substitution.

Polyhedron 26 (2007) 4609

Structural characterization of a copper(II) complex containing oxidative cyclization of *N*-2-(4-picolyl)-*N*′-(4-methoxyphenyl)thiourea, new ligands of 4-picolylthiourea derivatives and the precursor molecular structure of oxidative cyclization of *N*-(2-pyridyl)-*N*′-(4-methoxyphenyl)thiourea

Some aryl thiourea derivatives, such as *N*-2-pyridine-*N*′-arylthioureas, are able to be oxidized in the presence of a suitable oxidant, but this chemical change depends on the different groups in the aryl ring. Respectively, electron donating and withdrawing groups support and prevent this reaction. The product can also act as a ligand.

Polyhedron 26 (2007) 2997

Synthesis, thermal stability and structural characterisation of iron(II) phthalocyanine complex with 4-cyanopyridine

New complex of bis-axailly coordinated iron(II) phthalocyanine by 4-cyanopyridine (4-CNpy) has been obtained in crystalline form as a adduct with two 4-CNpy molecules. Ligation of the intermediate-spin iron(II) phthalocyanine by 4-CNpy molecules leads to the low spin Fe(II) complex. The coordination polyhedron around the Fe(II) atom approximates to a tetragonal by-pyramid. The thermal analysis of the crystals of $[FePc(4\text{-}CN)_2] \cdot 2(4\text{-}CNpy)$ shows two steps responsible for the lose of solvated (~170 °C) and coordinated (~235 °C) 4-CNpy molecules.

Structural and spectral investigations on some new Ni(II) complexes of di-2-pyridyl ketone *N*(4)-phenylthiosemicarbazone

Ni(II) complexes (**1**–**5**) of di-2-pyridyl ketone *N*(4)-phenylthiosemicarbazone, HL have been synthesized spectrochemically characterized. The elemental analyses revealed a $NiL_2 \cdot 2H_2O$ stoichiometry for the compound **1**. However, the single crystals isolated revealed a composition $NiL_2 \cdot 0.5(H_2O)0.5(DMF)$. The compound crystallizes into a monoclinic lattice with space group $P2_1/n$.

Syntheses, crystal structures and photoluminescence of three coordination polymers with 2,3-pyrazinedicarboxylic acid and N-donor ligands

The reactions between $Cd(OAc)_2/Cu(NO_3)_2$ and mixed ligands (2,3-pyrazinedicarboxylic acid (pzdc) and N-donor ligands) under different reaction conditions give the three title complexes **1**, **2** and **3**. There is a (4,8) net 2D network structure and a rectangular grid network structure in the cadmium complexes $[Cd(pzdc)(phen)] \cdot H_2O$ (**1**) and $Cd_2(pzdc)_2(4,4'\text{-bpy})(H_2O)_2$ (**2**), respectively. The complex $[Cu_4(pzdc)_4(phen)_2(H_2O)_4] \cdot 10H_2O$ (**3**) has a 1D zigzag chain structure. The influences of coordination modes of the pzdc ligand and N-donor ligands on the superstructural diversity have been discussed. Complexes **1** and **2** exhibit strong fluorescent emission bands in the solid state at room temperature.

Aminoalkylbis(phenolate) [O,N,O] donor ligands for uranyl(VI) ion coordination: Syntheses, structures, and extraction studies

The syntheses of five new aminoalkylbis(phenolate) ligands (as hydrochlorides) and their uranyl complexes are described. The reaction between uranyl nitrate hexahydrate and phenolic ligand precursor [(*N*,*N*-bis(2-hydroxy-5-*tert*-butyl-3-methylbenzyl)-aminoalkyl) · HCl], (alkyl = propyl, butyl, hexyl, cyclohexyl or benzyl) (H_2L1–H_2L5), in acetonitrile in presence of a base affords the mononuclear, neutral complexes $[UO_2(HL)_2] \cdot x$S ($x = 0$, 1 or 2 and S = acetonitrile or methanol). Extraction studies of the uranyl ion from water to dichloromethane with these new ligands (H_2L1–H_2L5) are also presented and the ligands $H_2L2 \cdot HCl$ and $H_2L4 \cdot HCl$ are the most effective ones.

Polyhedron 26 (2007) 3409

Multiple one-electron oxidation and reduction of trinuclear bis(2,4-pentanedionato)ruthenium complexes with substituted diquinoxalino[2,3-*a*:2′,3′-*c*]phenazine ligands

Three reversible oxidation steps and at least three reversible reduction processes were found for the title complexes. Analysis via EPR and UV–Vis–NIR spectroelectrochemistry revealed metal-centered oxidation to form mixed-valent intermediates without conspicuous IVCT absorptions in the infrared. Reduction occurs on the bridging ligands with very little participation from ruthenium.

2-Hydroxy-3-carboxy-dihydrocinnamic acid: Complexation properties towards aluminium-(III) and iron(III)

Number, stoichiometry and stability constants of the complexes formed in aqueous (Na)Cl 0.6 m solution by 2-hydroxy-3-carboxy-dihydrocinnamic acid with Al(III) and Fe(III) were obtained at 25 °C by potentiometric titrations, UV–Vis and NMR measurements. Most of the Al(III) and Fe(III) species are either bidentate or mixed ligand-hydroxo complexes. The tridentate chelation is displayed in the AlL species. Molecular modeling confirmed experimental results.

Synthesis and characterization of novel Cd(II), Zn(II) and Ni(II) complexes with 2-quinolinecarboxaldehyde selenosemicarbazone. Crystal structure of bis(2-quinolinecarboxaldehyde selenosemicarbazonato)nickel(II)

A ligand 2-quinolinecarboxaldehyde selenosemicarbazone (Hqasesc) was synthesized and coordinated with Zn(II), Cd(II) and Ni(II). Single crystal X-ray analysis shows that the Ni(II) coordinates two deprotonated qasesc$^-$ ligands giving the octahedral bischelate complex. NMR study showed a difference in structures of Cd(II) and Zn(II) complexes in solid state and in solution. Preliminary results of cytotoxic activity determination showed that the complexes are more active than the ligand.

Conformational study of Co(II), Ni(II), and Cr(III) complexes of the edta-type: Crystal structure of 1D polymeric *trans*(O^6)-Ba[Co(1,3-pddadp)] · $8H_2O$ complex stabilized by infinite water tapes

MM calculations indicate that for the [M-(1,3-pddadp)]$^{n-}$ system [where 1,3-pddadp represents the 1,3-propanediamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate ion, and M = Co(III), Cr(III), Rh(III), Ni(II), and Co(II)], the *trans*(O^5O^6) isomer is of the lowest energy. The least energetically favored *trans*($O)^6$ [Co(1,3-pddadp)]$^{2-}$ complex anion possesses unusual geometry and conformation of the β-alaninate rings, and forms, in a crystal, polymeric chains glued by infinite water tapes.

Polyhedron 26 (2007) 2387

A new water-soluble metal-free phthalocyanine substituted with naphthoxy-4-sulfonic acid sodium salt. Synthesis, aggregation, electrochemistry and in situ spectroelectrochemistry

A new water-soluble metal-free phthalocyanine, 2,9,16,23-tetrakis(4-(1-naphthoxy-4-sulfonic acid sodium salt))phthalocyanine **$NhtH_2Pc$**, was synthesized and its electrochemical and spectroelectrochemical properties were investigated in DMSO solution. The aggregation study of **$NhtH_2Pc$** shows that **$NhtH_2Pc$** exhibits the characteristic monomeric UV–Vis absorption of phthalocyanine in methanol and DMSO. **$NhtH_2Pc$** displays three reversible one-electron reductions waves assigned to Pc^{3-}/Pc^{2-}, Pc^{4-}/Pc^{3-} and Pc^{4-}/Pc^{5-} couples, respectively. The well-defined UV–Vis spectrum of the electro-reduced species **$[NhtH_2Pc]^-$** was obtained with an applied potential (E_{app} = −0.70 V) in a thin-layer cell.

Polyhedron 26 (2007) 2425

Interaction of *para*-substituted *meso*-tetraphenylporphyrins and *meso*-tetra(*n*-propyl)porphyrin with weak and strong carboxylic acids: A UV–Vis spectroscopic study

Porphyrins may be protonated using weak and strong carboxylic acids. The formation of these weak complexes is accompanied by a shift of the Soret and Q(0,0) bands which may be explained on the basis of decreased C_α–C_α and C_α–C_{meso} antibonding interactions upon the saddling of the macrocycle, the enhanced coplanarity of the aryl groups with the porphyrin mean plane which lead to an interaction between the HOMOs of the porphyrin core with the proper orbitals of the aryl substituents, and the protonation of the pyrrolenine nitrogen atoms.

cis- and *trans*-Bis(pyridine)chromium(III) complexes containing mixed-valence chrysene-semiquinonate–chrysenecatecholate ligands: Synthesis, characterization and interpretation of the electronic absorption spectra using ZINDO/S method

Two new geometrical isomers of $[Cr(py)_2$(chrySQ) (chryCat)] were synthesized by two different synthetic procedures. The structures of the two isomers have been modeled using parameterized PM3 semiempirical method. Theoretical harmonic vibrational frequencies of the *cis*- and *trans*-isomers have been computed and compared well with the experimental vibrational frequencies. Theoretical modeling of the magnetic data indicated strong antiferromagnetic exchange interaction between Cr^{III} (S = 3/2) and chrySQ (S = 1/2) with $J = -365 \pm 6$ and -395 ± 4 cm^{-1} for the *cis*- and *trans*-isomers, respectively. The electrochemical behavior of *cis*- and *trans*-[$Cr(py)_2$(chrySQ)(chryCat)] complexes were studied by cyclic voltammetry in acetonitrile solvent. The electronic spectra of the two isomers were dominated by charge-transfer (LMCT, MLCT and ILCT) transitions. In addition, a low-energy intervalence charge-transfer (IVCT) transition was observed for the *cis*-isomer at 1085 nm. Theoretical studies of the electronic spectra by ZINDO/S-CI method were useful in interpreting the observed electronic transitions.

Metal-assisted transformation of *N*-benzoyldithiocarbazate to 5-phenyl-1,3,4-oxadiazole-2-thiol in the presence of ethylenediamine, and its first row transition metal complexes

The potassium salt of *N*-benzoyldithiocarbazate (H_2L) generates 5-phenyl,1,3,4-oxadiazole-2-thiol(pot^-) in an alkaline medium by an internal ring closer reaction *via* desulfurization. The molecular structure of $[Cu(en)_2](pot)_2$ has been determined by a single crystal X-ray diffraction study. Weak interaction studies on the complex reveal the presence of a hydrogen-bonded network in the molecule involving non-coordinating donor atoms of the pot anion with en, resulting in the formation of an extended three-dimensional network.

Polyhedron 26 (2007) 2603

Metal complexes of pyrimidine derived ligands – Syntheses, characterization and X-ray crystal structures of Ni(II), Co(III) and Fe(III) complexes of Schiff base ligands derived from *S*-methyl/*S*-benzyl dithiocarbazate and 2-*S*-methylmercapto-6-methylpyrimidine-4-carbaldehyde

Ni(II), Co(III) and Fe(III) complexes (**1**–**3**) of two similar tridentate Schiff base ligands synthesized from 2-*S*-methylmercapto-6-methylpyrimidine-4-carbaldehyde and *S*-methyl/*S*-benzyl dithiocarbazate have been prepared and structurally characterized. All the three complexes have gross octahedral geometries with a N_4S_2 chromophore. In **1**, one ligand molecule binds the Ni(II) center as a uninegative tridentate and other ligand molecule functions as a neutral tridentate, whereas in **2** and **3** each of the ligand molecules acts as a uninegative tridentate.

Structural variations in self-assembled cadmium benzoate complexes

A series of mixed ligand cadmium(II) complexes having 3,5-dimethylpyrazole and aromatic carboxylate are structurally characterized. Mononuclear complexes are obtained from composition $[Cd(L)_2(L^a)_2]$ where L_a = 3,5-dimethylpyrazole L = R–C_6H_4COO– [R = H (**1**), 2-Cl (**2**), 4-OH (**3**), 2-OH (**4**)]. The cadmium complex (**5**) having composition $[Cd(L)_2(L_a)(H_2O)]$ (L = 2-NO_2–C_6H_4COO–) is tetra nuclear. Cadmium complexes having composition $[Cd(L)_2(L_a)]$ such as R = 4-NO_2 (**6**), 4-Cl (**7**), and 1-naphthoate complex (**8**) are co-ordination polymers with seven co-ordination geometry around cadmium.

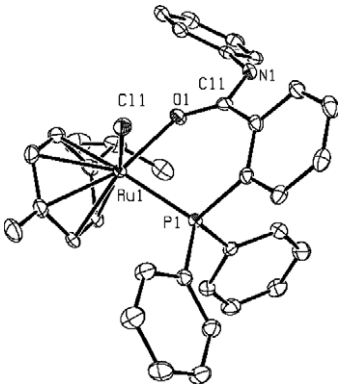
Re(I)(tricarbonyl)(carboxylate) complexes with the [*N*,*N*′-*bis*(2,4,6-trimethylbenzene)-1,4-diazabutadiene] (2,4,6-Me_3G) and [*N*,*N*′-*bis*(2,4-dimethylbenzene)-2,3-dimethyl-1,4-diazabutadiene] (2,4-Me_2D) ligands – Syntheses and spectroscopic studies. The crystal structure of [$Re(CO)_3$(2,4,6-Me_3G)($OCOCF_3$)]

Two new carboxylato complexes, [$Re(CO)_3$(DAB)($OCOCF_3$)] (DAB = substituted diazabutadiene ligands), were prepared by the reaction of [$Re(CO)_5Cl$] with the DAB ligands, and the subsequent reaction with $AgOCOCF_3$ gave the related carboxylate complexes. Their pseudooctahedral *fac* structure has been established by FTIR, UV–Vis and NMR spectroscopies, and has been confirmed by X-ray diffraction analysis. Electrochemical behaviour of the investigated complexes has been studied by cyclic voltammetry.



Gregorio Sánchez, Joaquín García, Juan J. Ayllón, José L. Serrano, Luis García, José Pérez and Gregorio López

Polyhedron 26 (2007) 2911

Synthesis, crystal structure and spectroscopic characterization of new neutral and cationic (η^6-*p*-cymene)–ruthenium(II) complexes with phosphine–amide ligands

The coordination properties of phosphinoamide ligands *o*-$Ph_2PC_6H_4CONHR$ [R = ^{i}Pr (**a**), Ph (**b**), 4-MeC_6H_4 (**c**), 4-FC_6H_4 (**d**)] have been studied by synthesizing and characterizing several (η^6-*p*-cymene)–ruthenium(II) complexes in which P,N- or P,O-bidentate coordination modes are displayed. The strong P,O-chelating ability towards ruthenium shown by these ligands prevent the preparation of complexes with ligands acting as P-monodentate and any hemilabile behaviour. The crystal structures of three new complexes have been determined.

Erratum to: "Lanthanide complexes of 2 + 2 meso-type macrocycle derive from *trans*-1,2-diaminocyclohexane and 2,6-diformylpyridine: X-ray crystal structures of La(III) and Sm(III) complexes" [Polyhedron 25 (2006) 2745–2754] 2919

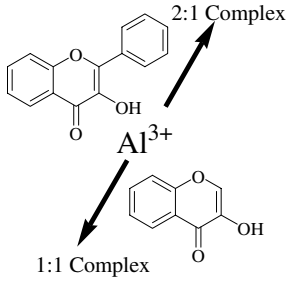
Stabilization of the trivalent oxidation state of copper by tridentate imine–oxime–amine ligands

Two tridentate imine–oxime–amine ligands HL^1 and HL^2 and their corresponding Cu^{II} complexes were synthesized. These complexes are readily oxidized to give diamagnetic d^8Cu^{III} complexes.

(HL^n)



n	R_1	R_2
1	CH_3	CH_3
2	$CH(CH_3)_2$	CH_3

Polyhedron 26 (2007) 6

Binding of hydroxychromones with Al^{3+} in methanol

The coordination of 3-hydroxychromone and 5-hydroxychromones with Al^{3+} in methanol was studied spectrophotometrically. A comparison with the corresponding flavones gives comparable binding for the 5-hydroxy derivatives. However, where the 3-hydroxyflavone binds in a 2:1 ratio, the 3-hydroxychromone forms a 1:1 complex.

Polyhedron 26 (2007) 11

Diverse coordination of two ligands in ferromagnetic $[Cu(\mu\text{-}HCO_2)_2(3\text{-}pyOH)]_n$ and $[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}3\text{-}pyOH)_2(3\text{-}pyOH)_2(HCO_2)_2]_n$

The polynuclear complex $[Cu(\mu\text{-}HCO_2)_2(3\text{-}pyOH)]_n$ (**1**) shows triatomic methanoate bridges of *anti–anti* and *syn–anti* modes, on the other hand $[Cu_2(\mu\text{-}HCO_2)_2(\mu\text{-}3\text{-}pyOH)_2(3\text{-}pyOH)_2(HCO_2)_2]_n$ (**2**) reveals only monoatomic methanoate coordination inside the dinuclear moiety and 3-hydroxypyridine connecting these units by semi-coordination. A ferromagnetic interaction is found in both complexes, however it is significantly important only for **1** ($2J = 9.2\ cm^{-1}$). This interaction takes place via the *syn–anti* methanoates, due to the magnetic Cu(II) $d_{x^2-y^2}$ orbitals on both sides of the bridge. In all the other bridging cases in **1** and **2**, the nonmagnetic d_{z^2} orbital is always involved.

Polyhedron 26 (2007) 17

Increasing transmission of electronic interaction in dinuclear unsymmetric mixed-valent ruthenium complexes

New dinuclear complexes of general formula $[(tpm)(bpy)Ru^{II}(L)Ru^{II/III}(NH_3)_5]^{4+/5+}$, with bpy = 2,2′-bipyridine; tpm = tris(1-pyrazolyl)-methane; L = pz (pyrazine), 4,4′-bpy (4,4′-bi-pyridine), BPE (*trans*-1,2-bis(4-pyridyl)-ethylene) and PCA (4-pyridinecarboxaldehyde azine), have been prepared and characterized. Increased transmission of the metal-to-metal electronic interaction is induced in the mixed-valent species by using tpm as a spectator ligand.

Polyhedron 26 (2007) 24

Three-dimensional supramolecular H-bonding network in the compounds containing hexamethylenetetramine and aquated Ni(II) or Cd(II) salts

The supramolecular H-bonded structures of three compounds, $[Ni(H_2O)_6](ClO_4)_2 \cdot 2\{(CH_2)_6N_4\} \cdot 2H_2O$ (**1**), $[Ni(H_2O)_6]Cl_2 \cdot 2\{(CH_2)_6N_4\} \cdot 4H_2O$ (**2**) and $[Cd(H_2O)_4\{(CH_2)_6N_4\}_2](ClO_4)_2 \cdot 2H_2O$ (**3**) (where $(CH_2)_6N_4$ = hexamethylenetetramine) have been described. Compounds **1** and **2** show R44(16) motif linking the cationic moieties with hexamine which are in turn interwoven with anionic moieties via water molecules whereas the supramolecular structure of **3** shows $R_2^2(12)$ motif.

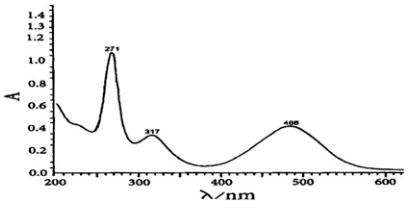
Polyhedron 26 (2007) 33

Synthesis, characterization and structure of nickel(II) complexes of a 16-membered mixed-donor macrocyclic Schiff base ligand, potentially hexadentate, bearing two pendant alcohol functions

Nickel(II) complexes of the potentially hexadentate, two alcohol pendant-arms macrocyclic Schiff base ligand with 16-member mixed N_2O_4 donors, containing different counter ions, were synthesized and characterized by a variety of physico-chemical techniques in both solid and solution states. In all the complexes, the ligand **L** behaves as a pentadentate ligand.

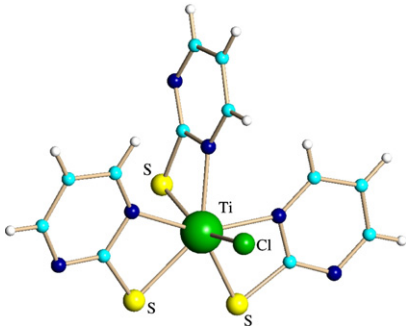


Mohamed A. Eltayeb, Yousif Sulfab

Polyhedron 26 (2007) 39

Synthesis and characterization of silver(III) complexes with tetradentate and tridentate ligands with imine-oxime groups

Silver(I) in the presence of tetradentate and tridentate ligands having imine-oxime groups are readily oxidized to the corresponding silver(III) complexes. The isolated complexes are diamagnetic and their cyclic voltammograms are electrochemically irreversible. The complexes have high molar absorption in the visible region that may be attributed to ligand to metal charge transfer (LMCT).



Claire J. Carmalt, Emily S. Peters, Ivan P. Parkin, Derek A. Tocher

Polyhedron 26 (2007) 43

Synthesis and characterisation of titanium pyridine- and pyrimidine-thiolates and their application as precursors to titanium disulfide

Low pressure chemical vapour deposition (LPCVD) of $[TiCl(SC_5H_4N)_3]$ forms thin films of TiS_2 at 600 °C and TiS_2/TiO_2 films at 500 °C. LPCVD of $[TiCl(SC_4H_3N_2)_3]$ resulted in TiS_2 films contaminated with Cl, C and N.

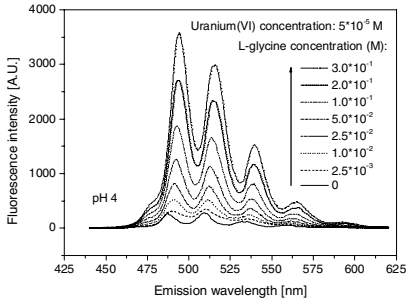
Polyhedron 26 (2007) 49

Transition metal complexes with thiosemicarbazide-based ligands. Part LIV. Nickel(II) complexes with pyridoxal semi- (PLSC) and thiosemicarbazone (PLTSC). Crystal and molecular structure of $[Ni(PLSC)(H_2O)_3](NO_3)_2$ and $[Ni(PLTSC\text{-}H)py]NO_3$

The syntheses of the first Ni(II) complexes with pyridoxal semicarbazone (PLSC): $Ni(PLSC)Cl_2 \cdot 3.5H_2O$ (**1**), $[Ni(PLSC)(H_2O)_3](NO_3)_2$ (**2**), $Ni(PLSC)(NCS)_2 \cdot 4H_2O$ (**3**), $[Ni(PLSC\text{-}2H)NH_3] \cdot 1.5H_2O$ (**4**), and two new complexes with pyridoxal thiosemicarbazone (PLTSC): $[Ni(PLTSC\text{-}H)py]NO_3$ (**5**) and [Ni(PLTSC-H)NCS] (**6**) are described. Complexes **1**–**3** are paramagnetic with an octahedral structure and complexes **4**–**6** are diamagnetic and have a square-planar geometry.

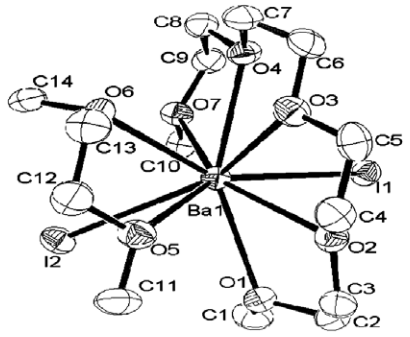


A. Günther, G. Geipel, G. Bernhard

Polyhedron 26 (2007) 59

Complex formation of uranium(VI) with the amino acids L-glycine and L-cysteine: A fluorescence emission and UV–Vis absorption study

The complex formation of uranium(VI) with L-glycine and L-cysteine was studied at low pH values by use of time-resolved laser-induced fluorescence spectroscopy and UV–Vis spectroscopy. Differences in the fluorescence emission and UV absorption properties between free UO_2^{2+} and the several formed uranyl amino acid species were detected.



Shashank Mishra, Liliane G. Hubert Pfalzgraf, Erwann Jeanneau

Polyhedron 26 (2007) 66

Redistribution reactions of heteroleptic barium iodide derivatives: Synthesis and structures of *trans*-BaI_2(DME)(triglyme), *cis*-BaI_2-(DME)(tetraglyme) and $[Ba(tetraglyme)_2]I_2 \cdot C_7H_8$

The reactions between $BaI_2 \cdot 2H_2O$ and sodium hexafluoroisopropoxide or sodium trifluoroacetate in a 1:1 stoichiometry lead to heterometallic Na–Ba compounds. These undergo redistribution reactions in the presence of O-donor ligands affording barium iodide adducts such as *trans*-BaI_2(DME)(triglyme), *cis*–BaI_2(DME)(tetraglyme) and $[Ba(tetraglyme)_2]I_2 \cdot C_7H_8$ which were characterized by analysis, FT-IR, NMR and X-ray diffraction.

Polyhedron 26 (2007) 73

Synthesis, characterization, and electrochemical, electrical and gas sensing properties of a novel *tert*-butylcalix[4]arene bridged bis double-decker lutetium(III) phthalocyanine

A novel *tert*-butylcalix[arene] bridged bis double-decker lutetium(III) phthalocyanine (Lu_2Pc_4) (**5**) has been synthesized by the reaction of dimeric lutetium(III) phthalocyanine (**4**) with two equiv. of dilithium octakis hexylthiophthalocyanine in amyl alcohol. Distinctive differences between the voltametric behaviour of the double decker Lu and precursor Pc were detected. Detailed d.c. and a.c. conductivity and gas sensing measurements all of the Pcs synthesized in this work have been carried out.

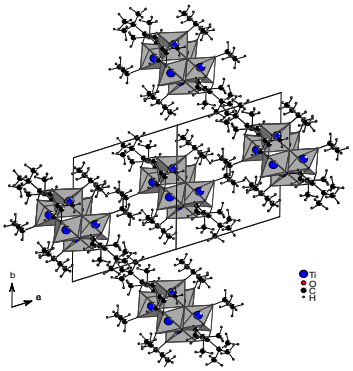
Polyhedron 26 (2007) 85

Synthesis, structures, electrochemistry and catalytic activities of copper(II) and palladium(II) complexes with asymmetric tetraazacycloannulenes

The copper(II) and palladium(II) complexes with 15-membered asymmetric 5,9-dihydro-2,4,10,12-tetramethyl-1,5,9,13-monobenzotetraazacyclo[15]tetradecine have been synthesized and characterized by electrochemical behavior and catalytic activities. The structures of the 15-membered copper(II) and palladium(II) complexes were determined using the X-ray diffraction method.

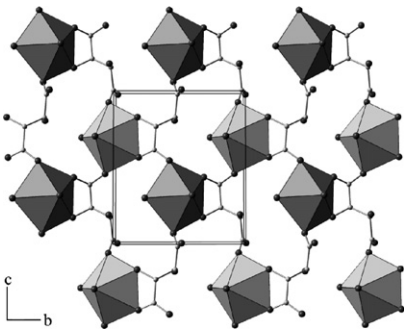


P. Piszczek

Polyhedron 26 (2007) 93

Thermal behaviour of hexanuclear titanium(IV) oxo isopropoxide carboxylates, and their usability as a single-source TiO_2 CVD precursors

Hexanuclear oxo titanium(IV) isopropoxide carboxylates, of the general formula $[Ti_6O_6(OPr^i)_6(O_2CR)_6]$ (R = Bu^t (**1**), CH_2Bu^t (**2**)) and $[Ti_6O_6(OPr^i)_6(O_2CC(CH_3)_2Et)_6] \cdot 0.5(C_7H_8)$ (**3**), have been synthesized as polycrystalline powders in order to study their thermal properties and usability as TiO_2 CVD precursors. Analysis of thermogravimetric and variable temperature (VT-IR) data shows that the thermal stability of the synthesized complexes decreases as follows **3** > **2** > **1**. Composition of vapors formed during thermolysis of **1**–**3** were qualitatively analysed with VT-IR methods and mass spectrometry (MS-EI).

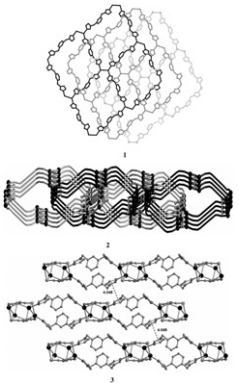


Pierre Thuéry

Polyhedron 26 (2007) 101

Reaction of uranyl nitrate with carboxylic diacids under hydrothermal conditions. Crystal structure of complexes with L(+)-tartaric and oxalic acids

Reaction of uranyl nitrate with L(+)-tartaric acid in the presence of KOH under mild hydrothermal conditions permitted to obtain the first uranyl tartrate complex to be crystallographically characterized. Prolonged heating resulted in oxidative cleavage of tartaric acid and formation of a mixed uranyl/sodium oxalate complex which crystallizes as a three-dimensional assemblage.

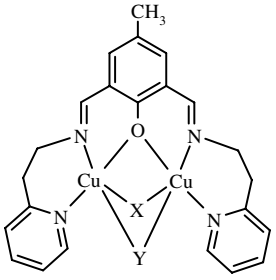


Jian-Di Lin, Zhi-Hua Li, Jian-Rong Li, Shao-Wu Du

Polyhedron 26 (2007) 107

Synthesis and crystal structures of three novel coordination polymers generated from AgCN and AgSCN with flexible N-donor ligands

The solvothermal reactions of AgX (X = CN, SCN) with mbix [mbix = 1,3-bis(imidazole-l-yl-methyl)benzene] or bix [bix = 1,4-bis-(imidazole-l-yl-methyl)benzene] afforded $[AgCN(mbix)]_n$ (**1**), $[(AgCN)_4(bix)_2]_n$ (**2**) and $[(AgSCN)_2(mbix)]_n$ (**3**). The structure of **1** contains 3-fold-interpenetrated 2D networks, while that of **2** exhibits 2-fold parallel interpenetration. There is no interpenetration observed in **3**. These three polymers all contain $\pi \cdots \pi$ interactions.

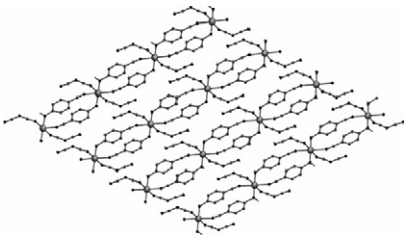


Jorge Manzur, Ana María García, Andrés Vega, Andrés Ibañez

Polyhedron 26 (2007) 115

Synthesis and structure of copper (II) complexes with L–OH (L–OH = 2,6-bis-[*N*-(2-pyridylethyl)-formidoyl]-4-methyl-phenol)

The synthesis and molecular structure of three new copper (II) complexes: $[Cu_2(L–O)(\mu\text{-}OH)(\mu\text{-}ClO_4)](ClO_4)$ (**I**), $[Cu_2(L–O)(\mu\text{-}Cl)_2][Cu_2Cl_6]_{0.5}$ (**II**) and $[Cu_2(L–O)(\mu\text{-}OH)(CH_3OH)]_2[Cu(CAT\text{-}O_2)_2]_{0.5}(ClO_4)_2$ (**III**), with the ligand 2,6-bis-[*N*-(2-pyridylethyl)-formidoyl]-4-methyl phenol (L–OH) is reported. Compound **I** shows a very poor catecholase activity. Compounds **II** and **III** show very uncommon anions: a hexachloro dicuprate (II) and a bis-catecholate cuprate (II) moieties, respectively.



I: $X = OH^-$; $Y = ClO_4^-$
II: $X = Y = Cl^-$
III: $X = OH^-$

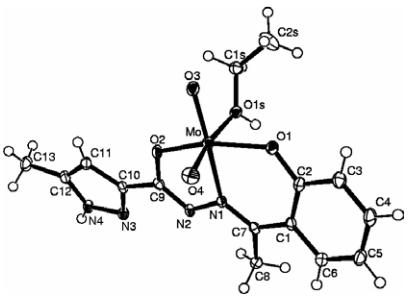
Polyhedron 26 (2007) 123

Synthesis, crystal structures and magnetic properties of five new metal(II) compounds constructed with isomers of aminobenzonitrile and dicyanamide ligands

Five new metal(II) compounds with isomers of aminobenzonitrile and dicyanamido ligands have been synthesized and characterized by structural and low temperature (2–300 K) magnetic properties. This work contains the first example of Cu–ABN compounds. The structural analyses revealed that all the compounds extended their geometry to 2D or 3D networks through hydrogen bonding interactions. The variable temperature magnetic susceptibility measurements show that weak antiferromagnetic interactions propagate through the bridging ligands.

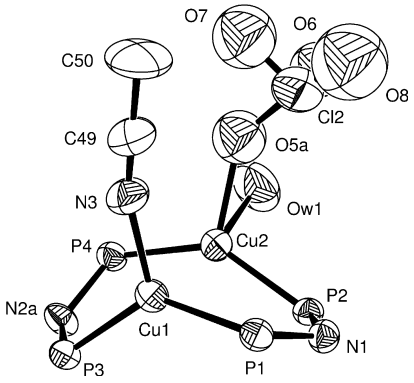


Samik Gupta, Anil Kumar Barik, Sachindranath Pal, Arijit Hazra, Somnath Roy, Ray J. Butcher, Susanta Kumar Kar

Polyhedron 26 (2007) 133

Oxomolybdenum(VI) and (IV) complexes of pyrazole derived ONO donor ligands – synthesis, crystal structure studies and spectroelectrochemical correlation

A few *cis*-dioxomolybdenum(VI) complexes have been prepared with pyrazole derived Schiff base ligands. One of these complexes has been subjected to oxo-transfer reaction with PPh_3 to produce the corresponding oxomolybdenum(IV) complex. A comparative account of the Mo(VI) complexes regarding the redox stability and spectral behavior has been correlated with the variation of electron donating properties of the ligands.

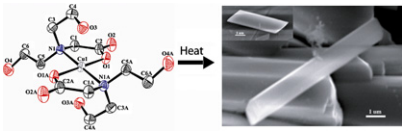


Ritu Ahuja, M. Nethaji, A.G. Samuelson

Polyhedron 26 (2007) 142

Mitigating repulsions in close quarters: Copper tells us how!

Destabilization due to d^{10}–d^{10} repulsion in structurally characterized copper(I) diphosphinoamine $(PPh_2)_2N(R)$ (R = H; dppa, R = ^{i}Pr; dppipa) dimers such as $[Cu_2(dppa)_2(CH_3CN)(H_2O)(OClO_3)]ClO_4$ (**1**), is mitigated by charge transfer interaction promoted by unsymmetrical coordination. Cambridge Structural Database studies support the proposition.

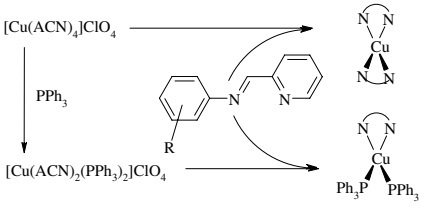


Harjyoti Thakuria, Gopal Das

Polyhedron 26 (2007) 149

CuO micro plates from a 3D metallo-organic framework (MOF) of a binary copper(II) complex of *N*,*N*-bis(2-hydroxyethyl)glycine

The blue colored mononuclear binary complex $[Cu(Bic)_2]$ (**1**) (Bic^- = *N*,*N*-bis(2-hydroxyethyl) glycinate), on heating at 500 °C for 6 h resulted in the formation of black CuO (Tenorite) micro plates

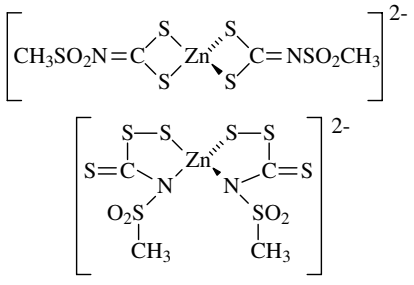


Saeed Dehghanpour, Nouri Bouslimani, Richard Welter, Fresia Mojahed

Polyhedron 26 (2007) 154

Synthesis, spectral characterization, properties and structures of copper(I) complexes containing novel bidentate iminopyridine ligands

The copper(I) complexes $[Cu(LL)_2]ClO_4$ $Cu(LL)(PPh_3)_2]ClO_4$, where LL is iminopyridine derivatives, have been synthesized and characterized by CHN analyses, ^1H, ^{13}C-NMR, IR, and UV–Vis spectroscopy. The crystal structures of some complexes have been determined. The redox behavior of the complexes has been studied.

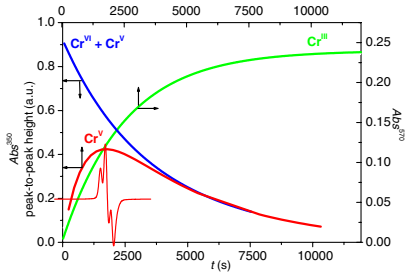


Marcelo R.L. Oliveira, Genivaldo J. Perpétuo, Jan Janczak, Mayura M.M. Rubinger

Polyhedron 26 (2007) 163

Synthesis, structural and spectroscopic characterization of novel zinc(II) complexes with *N*-methylsulfonyldithiocarbimato and *N*-methylsulfonyltrithiocarbimato ligands

A new *N*-*R*-sulfonyldithiocarbimato–zinc(II) complex with the formula $(Ph_4P)_2[Zn(CH_3SO_2NCS_2)_2]$ (**1**) has been obtained by the reaction of potassium *N*-methylsulfonyldithiocarbimate, zinc(II) acetate and tetraphenylphosphonium chloride. A secondary product with the formula $(Ph_4P)_2[Zn(CH_3SO_2N{=}CS_3)_2]$ (**2**) was also obtained. Compounds **1** and **2** were characterized by X-ray diffraction and by IR and NMR spectroscopies.

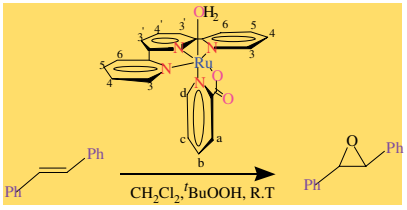


Mabel Santoro, Evangelina Caffaratti, Juan Manuel Salas-Peregrin, Laszlo Korecz, Antal Rockenbauer, Luis F. Sala, Sandra Signorella

Polyhedron 26 (2007) 169

Kinetics and mechanism of the chromic oxidation of *myo*-inositol

The redox reaction of *myo*-inositol with Cr^{VI} yields the inosose and Cr^{III} as final redox products. The reaction occurs through a mechanism that combines $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{II}$ and $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{III}$ pathways.

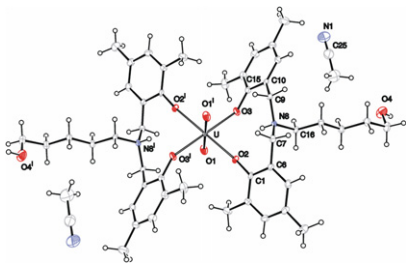


Debabrata Chatterjee, Ayon Sengupta, Anannya Mitra

Polyhedron 26 (2007) 178

Synthesis, characterization and reactivity of a novel ruthenium(II) complex containing polypyridyl ligand

$[Ru^{II}(trpy)(pic)(H_2O)]^+$ complex catalyzes the epoxidation of stilbenes in presence *t*-BuOOH in dichloromethane at room temperature. Formation of a radicaloid [Ru–O(*t*-Bu)–O]˙ type intermediate is proposed for the catalytic process.

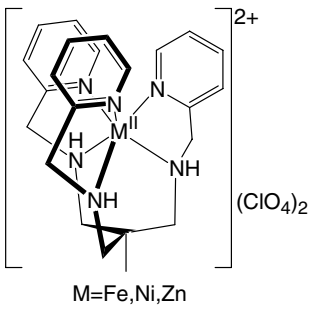


Harri Sopo, Ari Väisänen, Reijo Sillanpää

Polyhedron 26 (2007) 184

Uranyl ion complexes with long chain amino-alcoholbis(phenolate) [O,N,O,O′] donor ligands

The reaction between uranyl nitrate hexahydrate and phenolic ligand precursors *N*,*N*-bis(2-hydroxy-3-methyl-5-alkylbenzyl)-4-aminobutanol (alkyl = methyl or *t*-butyl), *N*,*N*-bis-(2-hydroxy-3-methyl-5-alkylbenzyl)-5-aminopentanol (alkyl = methyl or *t*-butyl) and *N*,*N*-bis(2-hydroxy-3-methyl-5-alkylbenzyl)-6-aminohexanol (alkyl = *t*-butyl) (H_3L1–H_3L5) or their hydrochlorides in acetonitrile in presence of the base affords the mononuclear, neutral complexes $[UO_2(H_2L)_2] \cdot xCH_3CN$ (x = 0, 1 or 2). Extraction studies of the uranyl ion from water to dichloromethane with these new ligands (H_3L1–H_3L5) are also presented.

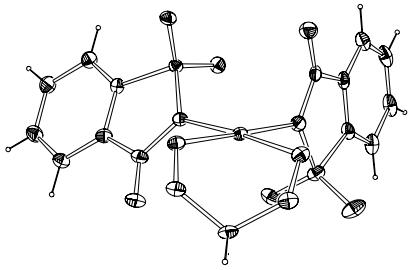


Daniel P. Kennedy, Antonio G. DiPasquale, Arnold L. Rheingold, Roy P. Planalp

Polyhedron 26 (2007) 197

Ni(II)-mediated synthesis of the novel tripodal aminopyridyl ligand *tamepyr*: Coordination geometry and rigidity of complexes with the divalent 3d metals Fe–Zn and with In(III)

The synthesis of the novel tripodal chelator 'tamepyr' (*N*,*N*′,*N*″-tris(2-pyridylmethyl)-1,1,1-tris(aminomethyl)ethane) and complexation of the ligand with Fe(II) and Zn(II) has been studied. The Ni(II) complex of tamepyr was prepared cleanly by a template reaction of the 1,1,1-tris(aminomethyl)ethane framework with 2-pyridinecarboxaldehyde and $Ni(ClO_4)_2 \cdot 6H_2O$ followed by a sodium borohydride reduction to afford the desired material (>40% yield). Treating the Ni(II) complex with excess sodium cyanide liberated the free ligand. A Zn(II) and low-spin Fe(II) complex form readily from free tamepyr.



Kelly J. Kilpin, William Henderson, Brian K. Nicholson

Polyhedron 26 (2007) 204

Synthesis, characterisation and biological activity of cycloaurated organogold(III) complexes with imidate ligands

The synthesis, characterisation and biological activities of a range of gold(III) imidate complexes of saccharin, phthalimide and isatin, containing ancillary cycloaurated benzylpyridine or *N*,*N*-dimethylbenzylamine ligands is reported.

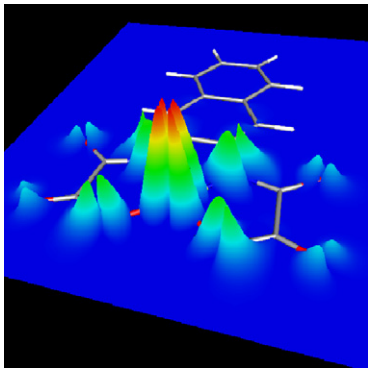
Polyhedron 26 (2007) 1764

The magnetic and structural elucidation of 3,5-bis(2-pyridyl)-1,2,4-triazolate-bridged dinuclear iron(II) spin crossover compounds

The structurally similar families of dinuclear iron(II) complexes of type $[Fe(NCX)(py)]_2(\mu\text{-}L)_2$, where L^- is a bridging pyrazolate or triazolate dinucleating ligand, and X = S, Se, BH_3, display different spin-crossover behaviour that is fundamentally related to the different ligand field strengths provided by the bridging azolate and apical NCX^- ligands.

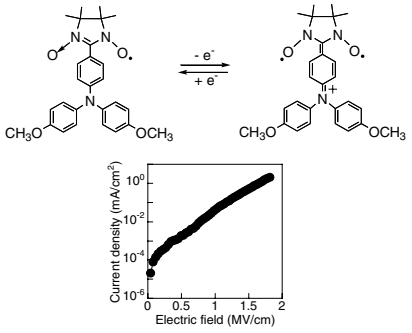


Björn Bräuer, Tobias Rüffer, Reinhard Kirmse, Jan Griebel, Florian Weigend and Georgeta Salvan

Polyhedron 26 (2007) 1773

Spin density distribution in oxamato-type transition metal complexes

The spin density distribution of a paramagnetic Cu-oxamato complex has been derived from angular dependent electron paramagnetic resonance measurements at room temperature. The results indicate a noticeable spin density transfer from the central metal to the coordinated atoms. Quantum chemical studies using density functional theory reinforce the results.



Takashi Kurata, Kenichiroh Koshika, Fumiaki Kato, Junji Kido and Hiroyuki Nishide

Polyhedron 26 (2007) 1776

Triarylamine-combined nitronyl nitroxide and its hole-transporting property

A durable nitronyl nitroxide molecule combined with the triarylamine moiety was prepared as a new hole-transporting molecule. Electrochemical measurements and photoelectron spectroscopy of the radical molecule showed a reversible redox with the ionization potential of −5.4 eV. The hole-transporting property was proved by current density–electric field plots for the single-layer device.

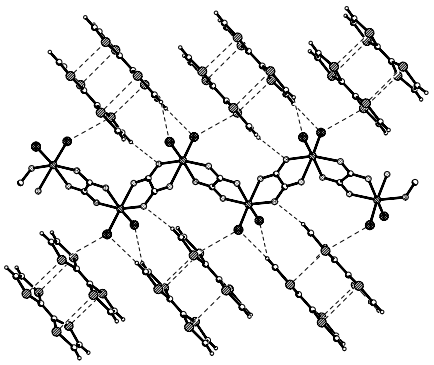
Polyhedron 26 (2007) 1793

Mono- and dinitroxide radicals from 9,9′(10*H*,10′*H*)-spirobiacridine: An approach to a D_{2d} triplet biradical

Is the ground state of a title biradical (**SBDO**) molecule triplet or singlet? The X-ray crystallographic analysis revealed the orthogonality between the two π-spin systems. Although the magnetic measurements on a polycrystalline sample of **SBDO** revealed the presence of antiferromagnetic interaction, the diluted ESR experiments and the DFT calculation on a single **SBDO** molecule indicated the ground triplet state.

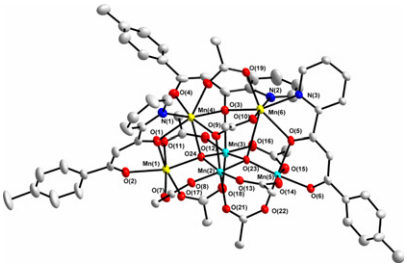


Bin Zhang, Zheming Wang, Yan Zhang, Hayao Kobayashi, Mohamedally Kurmoo, Takehiko Mori, Francis L. Pratt, Katsuya Inoue and Daoben Zhu

Polyhedron 26 (2007) 1800

Dual-function molecular crystal containing the magnetic chain anion $[Fe^{III}(C_2O_4)Cl_2^-]_n$

We report on the structural, optical, electrical and magnetic properties of the charge-transfer salts of TTF (TTF = tetrathiafulvalene) and BETS (BETS = bis(ethylenedithio)tetraselenafulvalene) with the magnetic chain anion $[Fe^{III}(C_2O_4)Cl_2^-]_n$. They have been synthesized by diffusion and electrocrystallization, respectively. The structures from single-crystal X-ray diffraction reveal one-dimensional anions separated by either dimers of TTF^+ or κ-type layers of $BETS^{0.5+}$. Infrared reflectivity and electrical conductivity measurements on single crystals are in good agreement with those of an insulator for TTF and a metal for BETS, as the calculated band-structures predict. Interestingly, the former exhibits π–d interaction leading to a long-range Néel state below 20 K with a small canting of the moments. Similar anomaly is seen below 5 K for the BETS salt which is metallic to 2 K, thus a weak-ferromagnetic conductor.



Chen-I Yang, Yu-Jhe Tsai, George Chung, Ting-Shen Kuo, Minghuey Shieh and Hui-Lien Tsai

Polyhedron 26 (2007) 1805

Synthesis, structure, and magnetic properties of a hexanuclear manganese complex

A mixed-valence $Mn^{II}_3Mn^{III}_3$ hexanuclear $[Mn_6O_2(O_2CPh)_8L_3]$ (**1**) complex has been synthesized by the reaction of 1-(2-pyridyl)-3-(*p*-tolyl)propane-1,3-dione (HL) with $[Mn_3O(O_2CPh)_6(H_2O)(py)_2]$ in CH_2Cl_2. The magnetic data indicate that complex **1** has an $S = 7/2$ with the D value of $-0.46\ cm^{-1}$ and slow magnetic relaxation below 2.5 K.

Structures and magnetic properties of one-dimensional copper(II) complexes bridged with diazaaromatic rings

Seven kinds of polynuclear complexes of $[Cu(hfac)_2]$ (Hhfac = 1,1,1,5,5,5-hexafluoropentane-2,4-dione) with diazaaromatic rings have been prepared. The crystal structures of $[\{Cu(hfac)_2(\mu\text{-}L)\}_n]$ (L = 2,5- and 2,6-dimethylpyrazines, propylpyrazine (prpyz), quinoxaline, phenazine, 4,6-dimethylpyrimidine, and 1,6-naphthyridine) have been determined. These complexes consist of a one-dimensional chain structure, and the geometry around the copper ion is approximately an octahedral structure. The relations between the magnetic properties and coordination structure were discussed from the magnetic measurements.

Self-assembly of carboxylic substituted PTM radicals: From weak ferromagnetic interactions to robust porous magnets

In this short review, the work that have been developed over the last six years in our group on the use of polychlorotriphenylmetyl radicals (PTM) functionalized by carboxylic groups to access to purely organic/molecular magnetic materials is reported. Starting from the seminal work on the monocarboxylic PTM, we will then report the self-assembly of PTM radicals functionalized with two and three carboxylic groups. In those cases, the self-assembly of the paramagnetic units yield robust and porous magnetic 2D-structures. The last part of the review will present the latest results obtained with the idea to increase both the structural and magnetic dimensionality in purely organic PTM-based materials using a PTM radical functionalized by six carboxylic groups.

A new Mn_{25} single-molecule magnet with an $S = 61/2$ ground state arising from ligand-induced 'spin-tweaking' in a high-spin molecule

The replacement of the 12 azide groups in $[Mn_{25}O_{18}(OH)_2(N_3)_{12}(pdm)_6(pdmH)_6]^{2+}$ with 6 $\eta^1{:}\eta^2{:}\mu_2$ hmp^- groups in MeCN/MeOH gives $[Mn_{25}O_{18}(OH)(OMe)(hmp)_6(pdm)_6(pdmH)_6]^{8+}$. The resulting small perturbations to the structure and exchange parameters cause a change to the ground state from $S = 51/2$ to $S = 61/2$. Hysteresis studies below ~1.0 K show the new compound to also be a single-molecule magnet.

Polyhedron 26 (2007) 2353

Synthesis and characterization of one- and two-dimensional octacyanometalate(V) networks: $\{[trans\text{-}M^{II}(DMF)_4][cis\text{-}M^{II}(DMF)_4]_2[M^{V}(CN)_8]_2\}_n$ (M^{II} = Mn, Fe, Ni; M^{V} = Mo, W)

A series of one- and two-dimensional octacyanometalate(V) networks of $\{[M^{II}(DMF)_4]_3[M^{V}(CN)_8]_2\}_n$ (M^{II} = Mn, **5**, **6**; Fe, **10**; Ni; **7**, **8**; M^{V} = Mo, W) stoichiometry have been prepared and characterized via structural, spectroscopic, and magnetic methods. Magnetic measurements indicate that **6** is a ferrimagnet (T_N = 8 K) that exhibits frequency-dependent behavior in χ'' that is qualitatively similar to 1- and 2-D lattices reported by Tang and Holmes, respectively; additional magnetic measurements suggest that **5**, **7**, and **8** exhibit incipient magnetic ordering. Conversion of **5**–**6** requires the presence of counterions and appears to be favored when using wet DMF. The experimental evidence suggests that coordinated DMF ligands are labile and the $M^{II}(\mu\text{-NC})M^{V}$ linkages are susceptible to fragmentation.

Theoretical studies of radical spin arrangements in the cavity of nano-porous complexes

Adsorption properties of magnetic species in nano-porous crystals were studied theoretically. The crystal $[Rh_2bza_4pyz]_n$ (host) and oxygen molecules (guest) were employed. From the results by our MO calculations, weak magnetic interactions between O_2 molecules in cavities existed. Cloud of mass densities of O_2 molecules by our MD simulation showed stacking styles in nano-pores. Number of adsorbed gas was estimated to be 3.00 molecules/unit.

Spin-crossover iron(II) compounds with liquid-crystal properties

The iron(II) compounds $[Fe(1C16\text{-}O\text{-}bzimpy)_2](BF_4)_2$ (**1**) and $[Fe(2C16\text{-}bzimpy)_2](BF_4)_2$ (**2**) were synthesized and their properties were characterized. Both of the compounds **1** and **2** have exhibited crystal-liquid crystal transition. The compound **1** exhibits spin-crossover behavior and photo-induced spin transition, and the compound **2** is in the low-spin state.

Dithiolene vanadium complexes based regulated domain arrangement by colloidal lithography

We have successfully fabricated nanometer-sized ring structures of paramagnetic metal complex of $(n\text{-}Bu_4N)_2[(dcbdt)_2VO]$, (dcbdt) = 4,5-dicyanobenzene-1,2-dithiolato a on glass substrates using a colloidal lithography technique. Obtained nano-scale rings has around 130 nm outer diameter and around 10 nm height on a surface of the substrate reflecting the position of particle templates.
