In particular, it was shown that 4-picoline (4-Mepy) formed isostructural complexes with iron and cobalt phthalocyanines, in which the central M is biaxially ligated by 4-Mepy, and the compounds crystallized with the composition $[MPc(4\text{-}Mepy)_2]\cdot 2(4\text{-}Mepy)$ [18]. For these reasons, we expected that the beryllium, magnesium and zinc phthalocyanines, when recrystallized in 4-Mepy, will show significant individuality in features of the eventually formed crystalline complexes, in particular for the coordination geometry of the central metal. Additionally, all of the new metallophthalocyanine complexes are potentially interesting colorants and materials for modern industry [19].

2. Experimental

2.1. Synthesis

Firstly, it should be stressed here that an attempt was made to perform the reactions of BePc as well as MgPc and ZnPc with 4-Mepy in water-free conditions.

The BePc sample used in the synthesis was obtained as described elsewhere [3]. The magnesium phthalocyanine (90% dye content) and zinc phthalocyanine (97% dye content) as well as 4-picoline (bp 145 °C) were purchased from Sigma–Aldrich Co. Before use, the magnesium and zinc phthalocyanines were zone refined. The transformative recrystallization processes of the BePc, MgPc and ZnPc samples with 4-picoline were performed as follows. A sample of one of the selected M(II)Pc's was pressed into a pellet, about 0.5 g in mass. The pellet was inserted in a glass ampoule and covered with c.a. 8 mL 4-picoline. The sample was then degassed and sealed off. Next, the suspension was thermally processed over the several days to ensure the completeness of the transformative process as well as effective crystallization. Next the crystalline product was immediately filtered after opening the ampoule. The best single crystals of the respective compounds, [BePc(4-Mepy)]-(4-Mepy) – (**I**), $MgPc(4\text{-}Mepy)_2$ – (**II**) and ZnPc(4-Mepy) – (**III**), were obtained by prolonged heating of the suspension of the beryllium phthalocyanine at 80 °C, the magnesium phthalocyanine at 120 °C and the zinc phthalocyanine at 160 °C. Routinely the crystalline products (**I**, **II** and **III**) were checked by X-ray powder diffraction and energy dispersive spectroscopy for their uniformity and composition. Elemental *Anal.* Calc. for $C_{44}H_{30}N_{10}Be$ (**I**): Be, 1.27; C, 74.67; N, 19.79, H, 4.27. Found: Be, 1.25; C, 74.72; N, 19.73; H, 4.30%. Elemental *Anal.* Calc. for $C_{44}H_{30}N_{10}Mg$ (**II**): Mg, 3.36; C, 73.09; N, 19.37; H, 4.18. Found: Mg, 3.30; C, 73.27; N, 19.29; H, 4.09%. Elemental *Anal.* Calc. for $C_{38}H_{23}N_9Zn$ (**III**): Zn, 9.74; C, 68.02; N, 18.79; H, 3.46. Found: Zn, 9.60; C, 68.12; N, 18.87; H, 3.40%.

2.2. X-ray single crystal diffraction

Single crystals of **I**, **II** and **III** were used for data collection on a four-circle KUMA KM4 diffractometer equipped with a two dimensional CCD area detector. Graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) and the ω-scan technique ($\Delta\omega = 1°$) were used for data collection. Data collection and reduction along with absorption correction were performed using the CRYSALIS software package [20].

The structures were solved by direct methods using SHELXS-97, revealing positions of almost all the non-hydrogen atoms. The remaining atoms were located from subsequent difference Fourier syntheses. The structures were refined using SHELXL-97 [21] with anisotropic thermal displacement parameters. Hydrogen atoms were located from the difference Fourier maps, but in the final refinement the positions of all hydrogen atoms were constrained. Details of the data collection parameters, crystallographic data and final agreement parameters are collected in Table 1. Selected geometrical parameters are listed in Table 2.

2.3. Thermal measurements

The thermogravimetric measurements (TG) and differential thermal analyses (DTA) were carried out on a Linseis L-81 thermobalance with Pt crucibles. The initial sample masses were about 15 mg. Powder Al_2O_3 was used as a reference. The measurements of the sample were performed under static air and recorded at the heating rate of 5 °C min^{-1}. Upper temperature limits were introduced to prevent eventual contamination of the apparatus, as indicated by our previous experiences. The observed weight loss is ~26.5%, 25.5% and 13.9% for compounds **I**, **II** and **III**, respectively. The respective values calculated for these compounds are 26.30%, 25.74% and 13.87%.

2.4. X-ray powder diffraction measurement

The rest of the sample left after thermogravimetric analyses was measured on a STOE powder diffractometer equipped with a linear PSD detector [22] using Cu Kα1 radiation ($\lambda = 1.54060$ Å) at room temperature.

3. Results and discussion

3.1. Synthesis: equilibrium in solution

The procedure described in Section 2.1 gave for each complex (**I**, **II** and **III**) well developed crystals suitable for X-ray analysis, showing the typical red-violet colour for the phthalocyanines. However, we want here to add some observation registered during the thermal processing of the ampoule with the beryllium phthalocyanine in 4-picoline suspension. Namely, it occurs that by heating the ampoule resting in the oven, the liquid seen over the sedimented solid species is practically non-transparent, as could be expected, but it was so only till up ca. 100 °C. With further temperature increase, being however still

below the boiling point of the 4-picoline, it becomes markedly brilliant and eye transparent. This phenomenon is fully reversible if subsequently the temperature is lowered, and is undoubtedly connected with the releasing and, respectively, binding of the 4-picoline molecules by beryllium ions of the BePc molecules. The observed strong light absorption changes are evidently correlated with the appropriate TG plot as shown in Fig. 1. The crystals of all compounds have been obtained in water-free conditions, since, especially for Be and Mg complexes, the crystals in the 4-Mepy solution under conditions of moist atmosphere transform into a polycrystalline form after several days. During this process the crystals of BePc-(4-Mepy) · 4-Mepy (**I**), as well as the crystals of MgPc-(4-Mepy)$_2$ (**II**), interact with water molecules and convert into aqua(phthalocyaninato) complexes according to the equation illustrated in Scheme 1. The speed of the conversion takes place several times quicker in a solution of non-purified 4-Mepy.

Studies of the aqua complexes formed during the transformations of complexes **I** and **II** in the 4-Mepy/H_2O solution are still under investigation.

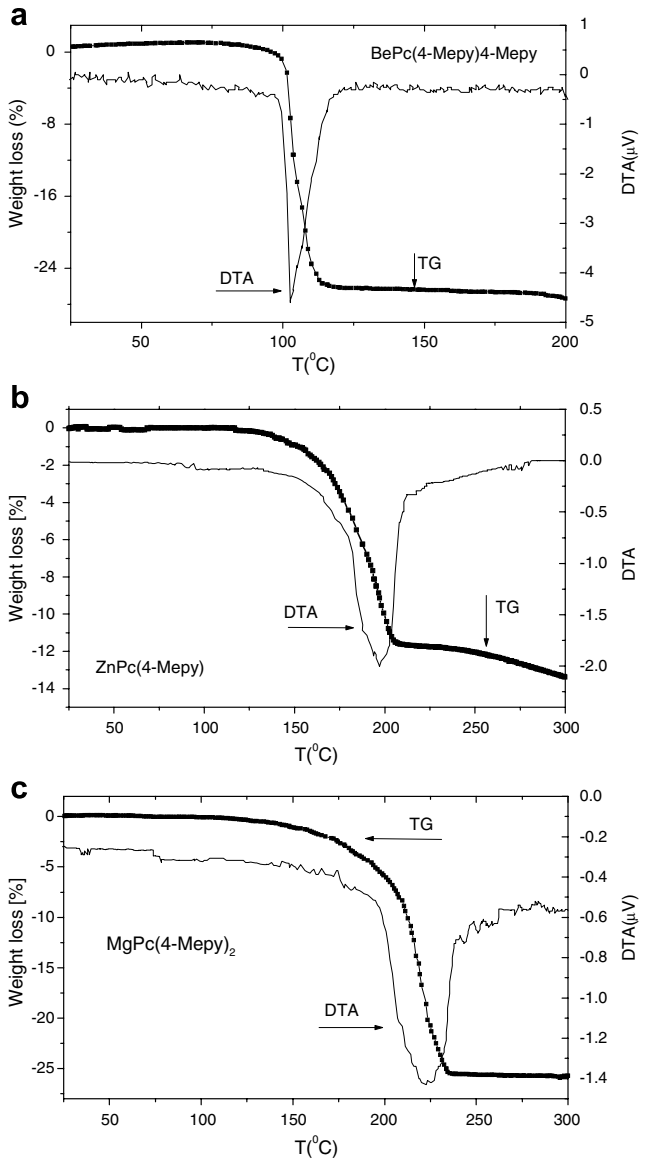
3.2. Thermal measurements and analysis

The thermogravimetric analyses (TG) together with the differential thermal analyses (DTA) of the solid state samples of compounds **I**, **II** and **III** are shown in Fig. 1a, b and c, respectively. For a better comparison, the most characteristic data resulting from the TG and DTA plots and XRD powder measurements of the residues left are collected in Table 3.

As can be seen from Fig. 1a, compound **I** losses the solvated as well as coordinated 4-Mepy molecules at the same



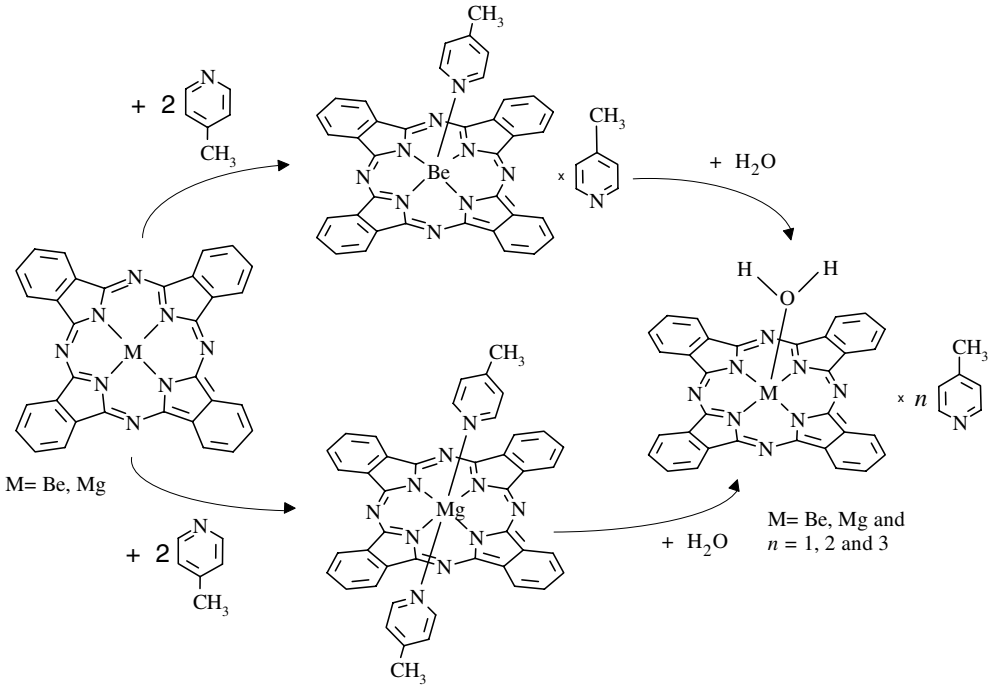


Fig. 1. Thermograms for the solid state samples of **I** (a), **II** (b) and **III** (c).

temperature (~100 °C), although in the crystal of **I** there are two crystallographically independent units (BePc-(4-Mepy) · 4-Mepy) and different 4-Mepy molecules. One of them is the 4-Mepy molecule coordinated to Be(II) of the BePc molecule and the other one is solvated. As seen in the TG analysis of **I** (the weight loss of ~26.5%), both solvated and coordinated 4-Mepy molecules are released simultaneously. This can be understood, if we take into account the arrangement of the (BePc(4-Mepy) · 4-Mepy) units and solvated 4-Mepy molecules in the crystalline network. The ligated and solvated 4-Mepy molecules are located in channels formed by the BePc molecules that are aligned almost parallel to the [100] direction in the crystal. The high thermal vibration of solvated 4-Mepy molecules at $T \sim 100$ °C accounts for the breaking of the Be–N bond of the coordinated 4-Mepy molecule in the solid sample of **I**, and as a result we have in the TG only one slope down (Fig. 1a). We suppose that in the case of compound **I**, besides the molecular arrangement, the exclusively narrow temperature range for the loss of the ligand molecules results from the extremely small radius of the beryllium ion [6,7], which in relation to the Mg and Zn ions in **II** and **III**, respectively, is over two times smaller. Therefore, as the temperature only reaches the value of the $Be(N_{iso})_4$–N(4-Mepy) bonding energy, the 4-Mepy molecule is released and the beryllium ion comes back to its equilibrium position in the BePc center, where the beryllium ion is no longer able to attract the ligand molecules. This is because it sits between the four N_{iso} atoms as in a square well, as described in [3]. In consequence, only the repulsion forces between the basal N_{iso} atoms and apical N(4-Mepy) atom become effective and at these conditions the ligand can readily be liberated.

The compounds **II** and **III** liberate the coordinated 4-Mepy molecules at significantly higher temperatures and also with wider temperature ranges. The slightly different decomposition temperature of **II** and **III**, corresponding to the release of the 4-Mepy molecules (see Fig. 1b and c), is connected not only with the strength of the axial M(II)–N bonds joining the 4-Mepy molecules, but also with the molecular arrangement. In **II**, both axial Mg–N bonds break simultaneously, releasing the 4-Mepy molecules. In all samples, the thermal process leading to the loss of 4-Mepy molecules and conversion of the remaining samples into the respective M(II)Pc's in the β-form was verified by powder X-ray diffraction. For these three compounds, the process of releasing of 4-Mepy molecules is endothermic.

3.3. Stereochemistry and crystal structures

All three structures are built up of independent moieties of **I**, **II** and **III** arranged in a different fashion. The crystalline network of the beryllium compound (**I**) consists of BePc and 4-Mepy molecular units in the proportion 1:2. One of the two 4-Mepy molecules is axially coordinated to Be of the BePc unit and the another one is a solvated molecule. Thus the Be(II) ion has a 4 + 1 coordination. In the crystal, there are two independent BePc-(4-Mepy) · 4-Mepy units (Fig. 2a). However, in the two independent units we have not observed any geometrical differences greater than 3 e.s.d's, but they show a different orientation of the ligated 4-Mepy in relation to BePc. Additionally, the geometries of the ligated and solvated 4-Mepy molecules are also very similar. The BePc(4-Mepy) molecule is not planar. The planar BePc molecule adopts a saucer-shape form due to the axial ligation by 4-Mepy. Interaction between the N atom of 4-Mepy, with a lone-pair of electrons, and the positively charged Be(II) ion of the BePc molecule leads to the deviation of Be by 0.302(3) and 0.320(3) Å from the plane defined by the four *N*-isoindole atoms of Pc in both crystallographically independent BePc(4-Mepy) units. The orientation of the 4-Mepy molecule in one of the two crystallographically independent BePc(4-Mepy) molecules is stabilized by a

Scheme 1.

Table 3
Comparison of the TG, DTA and XRD data for the complexes **I**, **II** and **III**

Compound	TG, 4-Mepy loss	DTA, 4-Mepy releasing guide	XRD identified residue
I	at 100 °C, sharp steep	endothermal	β-form
II	at 180–220 °C range, gradual diffused	endothermal	β-form
III	at 190 °C, diffused	endothermal	β-form

C–H···N(azamethine) interaction between the H atom in the ortho- position of 4-Mepy and the azamethine N atoms of the Pc ring (the N1a–Be1–N9a–C37a torsion angle is equal to −46.8°). In the second independent BePc(4-Mepy) molecule, the interaction in the crystalline network with the neighbouring molecule makes the respective torsion angle (N1b–Be2–N9b–C37b) equal to −29.3°. Two pairs of symmetrically equivalent BePc(4-Mepy) molecules related by an inversion center are π–π stacked in a back-to-back fashion as dimers with an interplanar distance of ∼3.4 Å (see Fig. 3), indicating the interaction between the π-clouds of the phthalocyaninato(2-) macrorings, since the distance is comparable to the typical distance between aromatic rings in systems with such an interaction [23]. This mutual arrangement of BePc(4-Mepy) molecules forms channels in which the solvated 4-Mepy molecules are located. The solvated 4-Mepy molecules possess relatively higher thermal ellipsoids in comparison with the BePc(4-Mepy) molecules, since they are taking more than the necessary space in the structure at room temperature. The voids in the solvent region have been found by the SQUEEZE procedure of the PLATON software package [24,25], but no significant residual electron density was observed. So, the thermal displacement of solvated 4-Mepy is considered as the effect of the high temperature crystallization process of compound **I** (at ∼80 °C), in which these molecules possess quite high kinetic energy. Therefore, they require more space in the crystal structure, in comparison with the room temperature at which the X-ray measurement was performed.

The crystalline network of the magnesium compound (**II**) consists of MgPc and 4-Mepy molecular units, similar to **I**, in the proportion 1:2. However, in the magnesium compound two 4-Mepy units are biaxially coordinated to the central Mg(II) atom of the MgPc molecule (Fig. 2b). The central Mg(II) cation, lying on the inversion center and in the plane defined by the four isoindole nitrogen atoms of the Pc macroring, coordinates all four nitrogen atoms of the Pc macroring and two nitrogen atoms of the 4-Mepy molecules in a distorted tetragonal bi-pyramid (4 + 2 coordination). The axial Mg–N bonds are longer by ∼0.4 Å than the four equatorial Mg–N_{iso} bonds (see Table 2). The axial M–N(4-Mepy) bonds are slightly weaker (2.412(2) Å) than the corresponding axial Mg–N(py) bonds (2.376(2) Å) in the biaxially ligated complex of $MgPc(py)_2$ [26]. The phthalocyaninato macroring in the $MgPc(4\text{-}Mepy)_2$ molecule is almost planar. The 4-Mepy molecules, ligated on both sides of the MgPc molecular plane, are not perpendicular to it. The dihedral angle between the N_4–isoindole plane and the 4-Mepy molecular plane is equal to 83.2(2)° and the torsion N1–Mg–N5–C21 describing the orientation of the coordinated 4-Mepy molecule in relation to the Pc ring is equal to −19.1(2)°. This inclination is similar to that in $CoPc(4\text{-}Mepy)_2$ and is slightly greater than that in $FePc(4\text{-}Mepy)_2$ [18]. This incli-

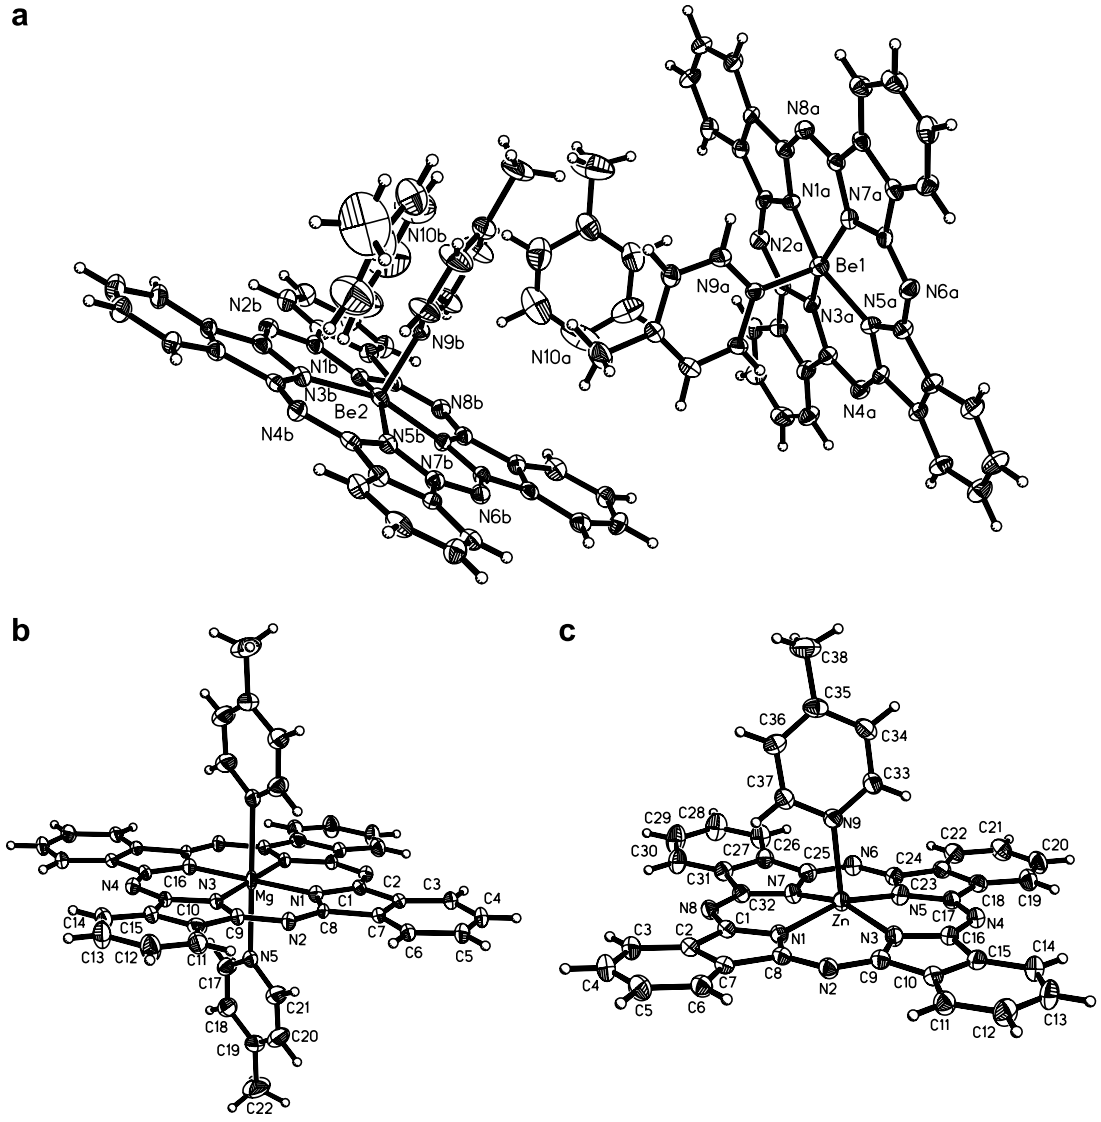

Fig. 2. Molecular structure of independent parts of **I** (a), **II** (b) and **III** (c).

nation correlates well with the molecular arrangement in the crystal, where one $MgPc(4\text{-}Mepy)_2$ molecule is oriented by the coordinated 4-Mepy molecules close to the phenyl ring of the Pc ring of a neighbouring $MgPc(4\text{-}Mepy)_2$ molecule, forcing the non-perpendicular coordination. Additionally, this interaction causes the rotation of the ligated 4-Mepy molecules in relation to the Pc ring from 45°, for the most stable conformation, to 19.1(2)° (N1–Mg–N5–C21). In the biaxially coordinated $MgPc(py)_2$ analogue [26] and in the other $CoPc(py)_2$, $FePc(py)_2$ and $MnPc(py)_2$ complexes, the corresponding angles are close to 90° [27,28]. The arrangement of $MgPc(4\text{-}Mepy)_2$ molecules in the crystal is shown in Fig. 4. The $MgPc(4\text{-}Mepy)_2$ molecules are arranged in a herring-bone fashion and form alternating sheets parallel to the *ac*-plane. The MgPc planes are parallel within one sheet (and separated by ~3.26 Å), whereas they make an angle of ~72° in relation to the neighbouring sheets.

The crystal structure of **III** consists of mono-axially coordinated ZnPc(4-Mepy) molecules (Fig. 2c). The planar ZnPc molecule, upon ligation by the 4-Mepy molecule, adopts the saucer-shape form, due to the interaction of the positively charged Zn(II) central atom of ZnPc with the ring N atom of the 4-Mepy molecule. This interaction leads to a deviation of Zn(II) from the centre cavity of the Pc macroring toward the coordinated 4-Mepy molecule, making the four equatorial $Zn–N_{iso}$ bonds longer by 0.04 Å in relation to ZnPc [5]. The deviation of the Zn atom from the plane defined by the four isoindole nitrogen atoms is equal to 0.352(2) Å toward the coordinated 4-Mepy molecule, thus the Zn atom has a 4 + 1 coordination environment. The displacement of Zn(II) from the N_4–isoindole plane in **III** is smaller than that in ZnPc(*n*-hexylamine), ~0.48 Å [29] and ZnPcCl, ~0.59 Å [30] and is comparable to $ZnPc(H_2O)\cdot 2DMF$, ~0.38 Å [31]. The molecular plane of the ligated 4-Mepy is not perpendicular

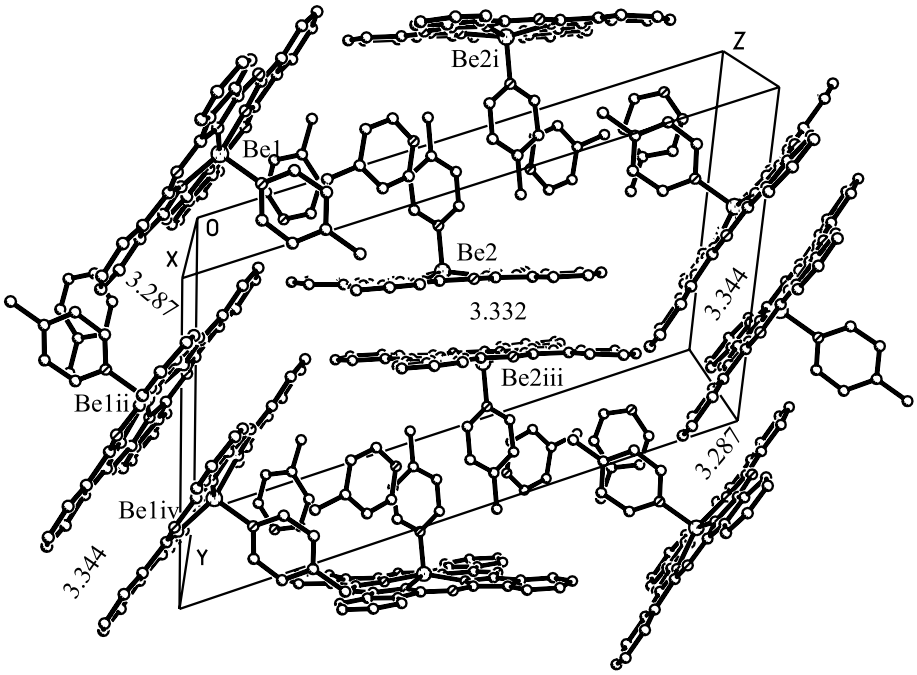

Fig. 3. View of the molecular arrangement of **I** showing the channels of the 4-Mepy solvent along the [001] direction and the π–π interacting stacked back-to-back dimers. H atoms are omitted for clarity. Symmetry code: (i) $1-x, -y, -z$; (ii) $2-x, -y, -z$; (iii) $1-x, 1-y, 1-z$ and (iv) $x,1-y, z$.

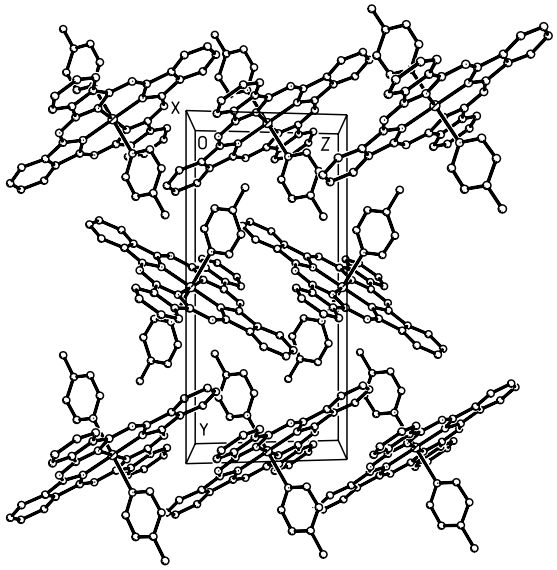

Fig. 4. Arrangement of the $MgPc(4\text{-}Mepy)_2$ molecules in the unit cell. H atoms are omitted for clarity.

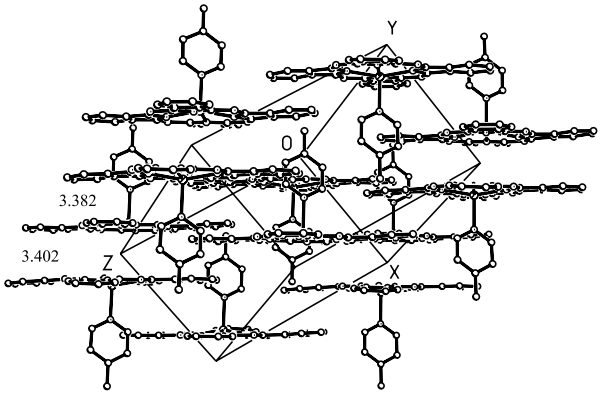

Fig. 5. Arrangement of the ZnPc(4-Mepy) molecules in the unit cell showing the π–π interacting stacked back-to-back molecules. H atoms are omitted for clarity.

to the N_4–isoindole plane of the Pc ring, but is inclined. The dihedral angle between the N_4-plane and the plane of the coordinated 4-Mepy molecule is equal to 77.8(1)°. The inclination of the 4-Mepy to ZnPc plane results from the mutual interaction of the ligated 4-Mepy with the Pc ring of a neighbouring ZnPc(4-Mepy) in the crystal. The ZnPc(4-Mepy) molecules related by an inversion center are stacked in a back-to-back fashion as dimers with an interplanar distance of ~3.4 Å between the N_4–isoindole planes (see Fig. 5).

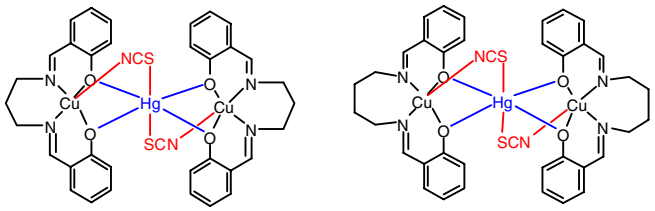
In these three compounds, the chemically equivalent C–N and C–C bonds of the Pc(2-) macroring and 4-Mepy molecules are similar and very typical, and corresponding well with $MPc(4\text{-}Mepy)_2$ (M = Fe, Co) [18]. The main stereo chemical data for the metal atoms in the complexes **I**, **II** and **III** are collected in Table 4. For completeness, the data of the Fe and Co analogue compounds [18] are also included. As can be seen from the table, only in the case of the beryllium compound is the axial M–N(4-Mepy) distance smaller than the four equatorial M–N distances. It is noteworthy that also in the case of the BePc complex with an O-donor ligand such an exclusive correlation between the axial and equatorial bonds is observed [3]. It may be, however, easier understood if we recognize that for the

Table 4
Comparison of the coordination of the central M(II) atom in mono- and biaxially coordinated by 4-Mepy complexes

Compound	Average equatorial M–N distance (Å)	Axial M–N distance (Å)	Deviation of M from the N_4 plane	Coordination geometry of M
BePc(4-Mepy) · 4-Mepy	1.914(6) (Be1)	1.839(4)	0.320(3)	square pyramid
	1.892(6) (Be2)	1.830(4)	0.302(3)	
$MgPc(4\text{-}Mepy)_2$	2.007(2)	2.412(2)	0	elongated octahedral
ZnPc(4-Mepy)	2.020(2)	2.166(2)	0.352(2)	square pyramid
$FePc(4\text{-}Mepy)_2 \cdot 2(4\text{-}Mepy)$	1.935(3)	2.040(3)	0	elongated octahedral
$CoPc(4\text{-}Mepy)_2 \cdot 2(4\text{-}Mepy)$	1.930(4)	2.322(5)	0	

beryllium ion the central hole of the essentially planar and rigid Pc moiety is far too big. For comparison in the case of a compound in which the beryllium ion is, as is normal for it, tetrahedrally coordinated, the relative two Be–N(py) bonds are only 1.753 (Å) long and another two Be–N(thiocyanate) bonds completing the tetrahedra are yet shorter by 0.1 Å [32].

4. Conclusions



In the compounds studied here, the central M(II) ion of BePc and ZnPc is mono-axially ligated by the ring nitrogen atom of the 4-Mepy molecule, while in MgPc biaxial ligation has been observed. These complexes differ significantly in the axial M(II)–N(4-Mepy) bond strength and the ligand releasing temperature increases in the order Be < Zn < Mg. The BePc(4-Mepy) and $MgPc(4\text{-}Mepy)_2$ complexes transform into the aqua complexes $M(II)PcH_2O \cdot n(4\text{-}Mepy)$ in a solution of 4-Mepy/H_2O(M(II) = Be, Mg and $n = 1$, 2 and 3).

Appendix A. Supplementary material

CCDC 639016, 639017 and 639018 contain the supplementary crystallographic data for **I**, **II** and **III**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK, fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.05.018.

$[(CuL^1)_2Hg(SCN)_2]$ (**1**) $[(CuL^2)_2Hg(SCN)_2]$ (**2**)

Scheme 1. Chemical diagram of the heterotrinuclear complexes.

in contrast to this expectation the thiocyanate ligands bound the copper atoms in the synthesized complexes.

Here, as a part of our ongoing research on homo-[11] and heteropolynuclear complexes with pseudohalide ligands, the synthesis and structures of two novel heterotrinuclear copper(II)–mercury(II)–copper(II) complexes, bridged by phenolate oxygen atoms of the Schiff bases L^1H_2 and L^2H_2, and thiocyanate anions are presented. The biological activities of these Schiff bases, their mononuclear and heterotrinuclear complexes are comparatively reported. Scheme 1 shows the chemical diagram of the complexes, $[(CuL^1)_2Hg(SCN)_2]$ and $[(CuL^2)_2Hg(SCN)_2]$.

2. Experimental

2.1. Materials and measurements

All reagents and solvents were purchased from Merck, Aldrich or Carlo Erba and were used without further purification. The elemental analysis for the ligands and the complexes were carried out at on a Eurovector 3018 CHNS analyzer. Melting points were measured using a Gallenkamp melting point apparatus. A Hitachi 8200 atomic absorption spectrometer was used for copper analyses. IR spectra were obtained by using IR grade KBr disks on a Perkin–Elmer 1600 Series FTIR spectrophotometer in the range 4000–250 cm^{-1}. Electronic spectra were obtained using a Cary |1E| UV–Visible Spectrophotometer (Varian).

2.2. Synthesis

2.2.1. Synthesis of the ligands (LH_2)

L^1H_2 [12] and L^2H_2 [13] were obtained by the condensation reaction of salicylaldehyde and the relevant diamino compounds, 1,3-diaminopropane and 1,4-diamino butane, respectively, in ethanolic solution.

2.2.2. Synthesis of the copper(II) precursors, CuL^1 and CuL^2

CuL^1 [14] and CuL^2 [15] were prepared by reacting an alkaline ethanolic solution of L^1H_2 and L^2H_2 with $CuCl_2 \cdot 2H_2O$, as described previously in the literature.

2.2.3. Synthesis of $[(CuL^1)_2Hg(SCN)_2]$ (**1**)

$Hg(SCN)_2$ (1 mmol) was dissolved in ethanol (25 mL) and added to a DMF (50 mL) solution of CuL^1 (2 mmol). The mixture was stirred for 5 min. and then the solution was left to stand in atmospheric conditions for 3 to 4 days. The dark green crystalline precipitate that formed was filtered off and dried in the open air. Yield: 59%. *Anal.* Calc. for $Hg[Cu(C_{17}H_{16}N_2O_2)SCN]_2$: C, 43.04; H, 3.18; N, 8.36; S, 6.38. Found: C, 42.84; H, 3.08; N, 8.24; S, 6.31%. The crystals were suitable for X-ray diffraction study.

2.2.4. Synthesis of $[(CuL^2)_2Hg(SCN)_2]$ (**2**)

This compound was obtained following the same procedure as in the case of compound **1**. Yield: 48%. *Anal.* Calc. for $Hg[Cu(C_{18}H_{18}N_2O_2)SCN]_2$: C, 44.20; H, 3.49; N, 8.13; S, 6.21. Found: C, 44.08; H, 3.32; N, 7.98; S, 6.12%. The crystals were suitable for X-ray diffraction study.

2.3. X-ray diffraction structure analyses

To determine the crystal structures of compounds **1** and **2**, X-ray diffraction data were collected at room temperature with graphite-monochromated Mo Kα radiation on an Enraf-Nonius CAD4 diffractometer [16], operating in $\omega/2\theta$ scan mode. Cell refinement was carried out using CAD-4 EXPRESS. During the data collection, three standard reflections were periodically measured every 120 min, both of the compounds showed no significant intensity variation. Data reduction was carried out using SHELXL97 [17].

The structures were solved by direct methods using the program SHELXS97 [17] in the WINGX package [18]. A full-matrix least-squares refinement on F^2 was done. For all non-hydrogen atoms anisotropic displacement parameters were refined. All hydrogen atoms of the compounds were placed geometrically and a riding model was used with $U_{iso}(H) = 1.2\,U_{eq}(C)$. The ORTEP drawings [19] of the molecules for **1** and **2** are shown in Figs. 1 and 2, respectively.

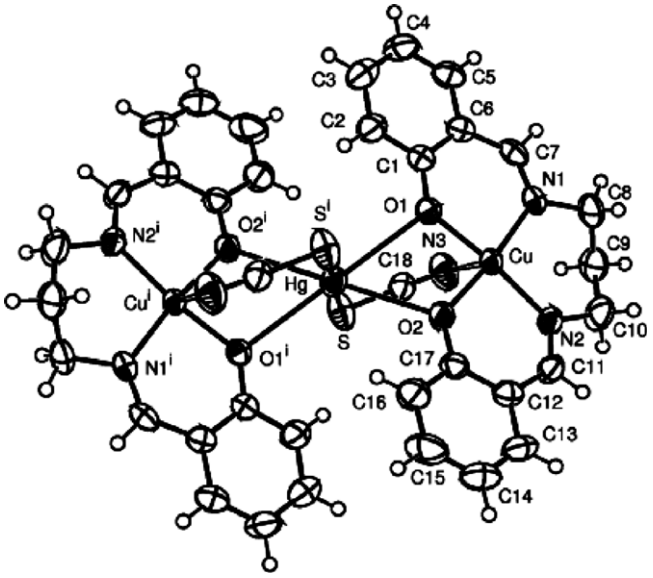

Fig. 1. ORTEP diagram for the complex $[(CuL^1)_2Hg(SCN)_2]$ showing the atom labelling scheme. Displacement ellipsoids are drawn at the 50% probability level and H atoms are shown as small circles of arbitrary radii.

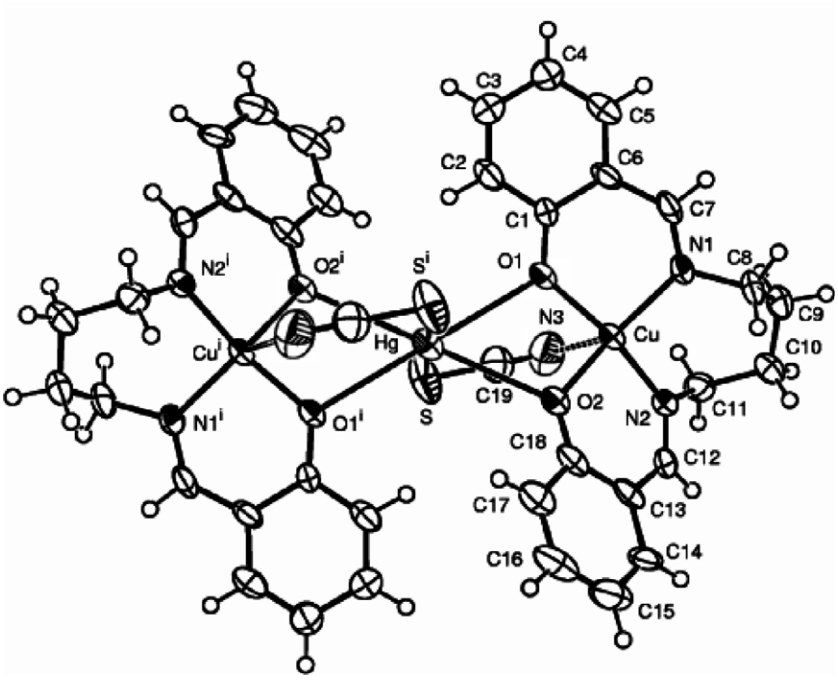

Fig. 2. ORTEP diagram for the complex $[(CuL^2)_2Hg(SCN)_2]$ showing the atom labelling scheme. Displacement ellipsoids are drawn at the 50% probability level and H atoms are shown as small circles of arbitrary radii.

Crystal and experimental data are given in Table 1, selected bond lengths and angles are given in Table 2.

2.4. Biological activity of the complexes

The agar disc diffusion method, microdilution broth susceptibility assay [20,21] and spore culture technique (for filamentous fungi) [22] were employed for the determination of antimicrobial activities. The MIC of the complexes and the free ligands against the test microorganisms were employed to the microdilution broth susceptibility assay. All tests were performed in duplicate to check the results. The screening effects of the investigated compounds in vitro were tested against the bacteria *Escherichia coli*

[i] $-x, -y, -z$.

ATCC 25292, *Staphylococcus aureus* ATCC 6538, *Pseudomonas aeruginosa* ATCC 27853, *Enterobacter aerogenes* NRRL 3567, *Proteus vulgaris* NRLL B 123, *Listeria monocytogenes* ATCC 7644 and *Serratia marcescens* (Clinic isolate) using the disc diffusion and microtitter well plate techniques with an incubation period of 24 h at 37 °C. The test solutions were prepared in DMF.

2.4.1. Antimicrobial screening

The agar disc diffusion method was employed for the determination of antimicrobial capacities of the free ligands and their metal complexes. A suspension of the tested microorganisms (10^8 CFU/μl) was spread on the solid media plates. Each test solution was prepared in DMF. Filter paper discs (6 mm in diameter) were soaked with 20 μl of the stock solutions and placed on the inoculated plates. After keeping the plates at 2 °C for 2 h, they were incubated at 37 °C for 24 h for bacteria and *Candida albicans*. The diameter of the inhibition zones were measured in millimeters (Table 3).

2.4.2. Determination of minimum inhibitory concentration (MIC)

For the determination of MICs, the microdilution broth susceptibility assay was used. Stock solutions of the compounds were prepared in DMF. Serial dilutions of the compounds were prepared in sterile distilled water in 96-well microtitter plates. A freshly grown bacterial suspension in double strength Mueller Hinton Broth and a yeast suspension of *Candida albican*s in Saboroud Dextrose Broth were standardized 10^8 CFU/ml (McFarland No: 0.5). Sterile distilled water served as the grown control. 100μl of each tested compound were then added to each well. The last row containing only the serial dilutions of the title compounds without microorganisms was used as a negative control. After incubation at 37 °C for 24 h, the first well without turbidity was determined as the minimal inhibitory concentration (Table 4).

2.4.3. Antifungal studies

In order to obtain conidia, the fungi were cultured on Czapex Dox Agar and Malt Extract Agar medium in 9 cm Petri dishes at 25 °C, for 10 days. Harvesting was carried out by suspending the conidia in a 1% (w/v) sodium chloride solution contain 5% (w/v) DMSO. The spore suspension was then filtered and transferred into tubes and stored at −20 °C, accordingly Hadecek and Greger [23].

Screening for antifungal activities of the stock solutions of the metal complexes and the free ligands was performed qualitatively using the disc diffusion method (Table 5) against saprophytic fungi, namely *Aspergillus flavus*, *Aspergillus niger*, *Penicillium expansum*, and *Alternaria brassicola* cultured on Malt Extract and Czapex Dox Agar medium.

C: Diameter of fungal growth on the control.
T: Diameter of fungal growth on the test plate.
Inh.: Inhibition.

One loop drop of the spore suspension was applied onto the centre of the Petri dishes. Twenty microliters of each complex and the free ligands were applied onto sterile paper discs (6 mm in diameter) and placed in the Petri dishes and incubated at 25 °C for 3 days. The test solution was prepared in DMF. The inhibition of fungal growths expressed in percentage terms was determined on the growth in test plates compared to the respective control plates, given as % inhibition [24].

$$\%\text{Inhibition} = 100(C - T)/C$$

C is the diameter of fungal growth on the control and T is the diameter of fungal growth on the test plate.

The activities of the complexes have been compared with the activity of the standard antifungicide Ketoconazole.

3. Results and discussion

3.1. General characterizations

3.1.1. Crystal and molecular structure

In this work, two similar Cu–Hg–Cu Schiff base complexes were prepared and characterized by X-ray crystallography. The complexes, bis{[μ-*N*,*N*′-bis(salicylidene)-1,3-propanediaminato-copper(II)](μ-thiocyanato)mercury(II)}, $Hg[Cu(C_{17}H_{16}N_2O_2)SCN]_2$, compound **1** and bis{[μ-*N*,*N*′-bis(salicylidene)-1,4-butanediamine-*N*,*N*′,*O*,*O*′-copper(II)]-(μ-thiocyanato)mercury(II)}, $Hg[Cu(C_{18}H_{18}N_2O_2)SCN]_2$, compound **2** are heterotrinuclear complexes, with inversion centres of triclinic (**1**) and monoclinic (**2**) unit cells, respectively.

The central Hg atom of each complex, which is located on the inversion centre, has a distorted octahedral coordination geometry. In compound **1**, the equatorial plane consists of four bridging O atoms from two *N*,*N*′-bis(salicylidene)-1,3-propanediaminate ligands [Hg–O1 2.775(3), Hg–O2 2.680(3) Å]. In compound **2**, the equatorial plane consists of four bridging O atoms from two *N*,*N*′-bis(salicylidene)-1,4-butanediamine ligands [Hg–O1 2.736(6), Hg–O2 2.846(7) Å]. In both compounds, the S atoms of the bridging thiocyanate (SCN) group occupy the axial positions of the octahedron [Hg–S 2.3926(13) Å (**1**), 2.363(4) Å (**2**)]. The greatest deviation of bond angles from the ideal octahedral angles is found for O1–Hg–O2 [54.70(7)° (**1**) and 56.1(2)° (**2**)]. The distortion from an ideal octahedral geometry is a consequence of the limited opening of the tetradentate ligands, which reduces the bridging O1–Hg–O2 angle. All other bond angles are close to the ideal values.

The inversion-related terminal Cu atoms of compounds **1** and **2** are coordinated by two O and two N atoms from the *N*,*N*′-bis(salicylidene)-1,3-propanediaminate and *N*,*N*′-bis(salicylidene)-1,4-butanediamine ligands in the equatorial plane, respectively. The Cu atom is located

0.040(2) Å (**1**) and 0.051(1) Å (**2**) from the basal plane. The planes through the atoms N1–Cu–N2 and O1–Cu–O2 have a dihedral angle of 178.6(2)° (**1**) and 145.3(3)° (**2**). The basal plane around the Cu atom is almost planar in compound **1**, but in compound **2** these two planes are twisted by nearly 35° (Fig. 2). In both compounds, there is a long range interaction between the Cu and N3 atoms of the bridging SCN group at the axial position. The observed distances of Cu–N3 2.843(4) Å in complex **1** and 3.037(13) Å complex **2** are smaller than the sum of the van der Waals radii of these two atoms (3.84 Å). In complex **1** the interactive force between Cu and N3 is bigger than in complex **2** because the steric effect of the N1···N2 bridge in the propane case is larger than the steric effect of the N1···N2 bridge in the butane case. To define the five coordination shape, the index (τ) [25] is defined in terms of the two largest bond angles (α and β) around the central atom as [$\tau = (\beta - \alpha)/60$]. If τ is equal to 0, the coordination is an ideal square pyramid and if τ is equal to 1, the coordination is an ideal trigonal bipyramid. The observed τ values for the Cu coordination sphere are $\tau = 0.02$ (**1**) and $\tau = 0.10$ (**2**). These values show that in both compounds, the Cu atoms have a slightly distorted square-pyramidal coordination geometry. As shown in Fig. 3, the distortion from an ideal square pyramidal geometry in compound **2** is more than in compound **1**. The Cu–Hg pairs are bonded by the O atoms of the Schiff base ligands and by the SCN groups. The Cu···Hg distances are 3.7623(9) Å in complex **1** and 3.7778(17) Å in complex **2**. The bridging plane is not flat, the dihedral angle between O1–Cu–O2 and O1–Hg–O2 are 149.6(1)° and 158.8(3)° for complex **1** and **2**, respectively.

The conformations of the rings were analysed using PLATON [26]. The Cremer-Pople puckering parameters [27] given below for the Hg–SCN–Cu–O1 ring and Hg–SCN–Cu–O2 ring show that these rings are in half-chair forms. The dihedral angle between the least square planes defined by the atoms of these rings is 3.33(3)° (**1**) and 2.84(9)° (**2**). In the complex (**2**), a maximum and minimum residual electron densities of 2.68 and 3.29 e/Å^3 was observed at a distance of 0.98 and 0.94 Å, respectively from Hg atom.

Ring	**1**	**2**
Hg–SCN–Cu–O1	$Q = 1.039(3)$ Å, $\theta = 129.0(2)°$, $\phi = 86.6(2)°$	$Q = 1.023(6)$ Å, $\theta = 132.7(6)°$, $\phi = 91.2(7)°$
Hg–SCN–Cu–O2	$Q = 0.984(2)$ Å, $\theta = 44.8(2)°$, $\phi = 330.4(2)°$	Q=1.070(5) Å, $\theta = 44.2(7)°$, $\phi = 317.5(5)°$

3.2. Infrared spectra

The interest in the IR spectra of the titled complexes lies mainly in the bands due to the thiocyanate and azomethine groups. The IR spectra of the complexes show strong typical absorptions at 1615 cm^{-1} (**1**) and 1619 cm^{-1} (**2**) related to the C=N stretching vibration of the Schiff base imino group. The strong band at 1619–1631 cm^{-1} attributed to the C=N stretching vibration in the ligands is shifted to the region 1615–1619 cm^{-1} in the complexes, indicating the coordination of the azomethine nitrogen. In the free ligands, strong bands at 1570–1577 cm^{-1}, assigned to uncoordinated phenolic O–H stretching vibrations, shift to higher energy by 5–10 cm^{-1} in the complexes, indicating the coordination of the phenolic oxygen atom to the metal ion. The FTIR spectra of the thiocyanate anion for complexes **1** and **2** show characteristic strong absorption bands (ν_{as}.(CN)) at 2123 and 2132 cm^{-1}, due to the presence of the bridging thiocyanato ligands, and several weak bands (ν_{sym}.(CN)) at 758 and 769 cm^{-1}, respectively. These data are consistent with literature values [28].

3.3. Absorption spectra

The absorption spectra of the ligands L^1H_2 and L^2H_2, and the complexes $[(CuL^1)_2Hg(SCN)_2]$ and $[(CuL^2)_2Hg(SCN)_2]$, were recorded in 10^{-4} M DMF, as the complexes

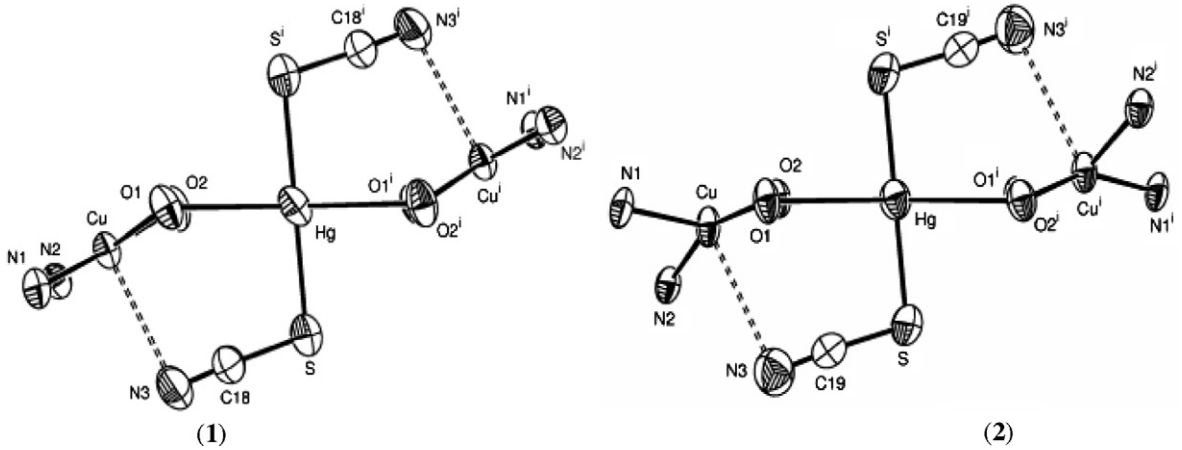

Fig. 3. Coordination geometry of the Hg and Cu metal ions in the compounds.

only show good solublity in DMF. The spectra of the ligands exhibit two quite similar absorption bands in the regions 265 and 315 nm attributable to the $\pi \rightarrow \pi^*$ transitions associated with the azomethine chromophore and n–π^* .transitions of the phenolic oxygen respectively. In the case of the complexes, the azomethine transitions shifted from 265 to 275 nm. The n-π^* transitions were shifted to a much greater extent, from 315 to 380 nm, as the phenolic oxygen had lost a hydrogen.

3.4. Biological activity

Preliminary screening for antimicrobial activities of the stock solutions of the Schiff bases and the metal complexes were performed qualitatively using the disc diffusion method (Table 3). In addition to the complex and ligands mentioned above, the biological activity of the copper complex of the ligands has also been investigated. The metal complexes and their free ligands yielded clear inhibition zones around the disc. If the inhibition zone measures 2–3 mm, then the complex has a good antimicrobial action. If the inhibition zone is more than 3 mm across, then it is considered very effective, but if there is no inhibition zone then the complex has no activity on the bacterium, and will not be retained for treatment [29].

The complexes showed more activity than the free ligands against all the tested microorganisms. The MIC values of the compounds that showed positive results in the screening process were determined as a quantitative measurement of antibacterial activity (Table 4). The results revealed $(CuL^1)_2Hg(SCN)_2$ and $(CuL^2)_2Hg(SCN)_2$ are most effective against *E. coli* ATCC 25292, *S. aureus* ATCC 6538, *P. aeruginosa* ATCC 27853, *E. aerogenes* NRRL 3567 and *L. monocytogenes* ATCC 7644 with a MIC value of 31.25 μg/ml, while CuL^1 and CuL^2 proved to be the best against the same bacteria and CuL^2 was also effective against *P. vulgaris* NRRL 123 at the same concentration (62.5 μg/ml). Also, $(CuL^1)_2Hg(SCN)_2$ and $(CuL^2)_2Hg(SCN)_2$ are effective against *C. albicans* (125 μg/ml). From a comparative study of the results in Tables 3 and 4, it was concluded that the antibacterial activity of the ligands are enhanced when it is chelated with metal ions. The growth inhibition capacity of the chelates and ligands follow the order against the tested bacteria: $(CuL^1)_2Hg(SCN)_2 > CuL^1 > L^1$; $(CuL^2)_2Hg(SCN)_2 > CuL^2 > L^2$.

At the same time these compounds were screened in order to evaluate their antifungal activity against the flamentous fungi *A. flavus*, *A. niger*, *P. expansum* and *A. brassicola* (Table 5).

The results showed that *A. brassicola* was much more sensitive against all the tested compounds compared with other filamentous fungi. On the other hand, $(CuL^1)_2Hg(SCN)_2$ and $(CuL^2)_2Hg(SCN)_2$ show more toxicity compared with other tested compounds and the standard antifungal drug, chloramphenicol, against all filamentous fungi under identical experimental conditions.

The results of antimicrobial activity show that the metal-complexes exhibit antimicrobial properties and it is important to note that they show enhanced inhibitory activity compared to their parent ligands. It may be suggested that these complexes and their ligands deactivate various cellular enzymes, which play a vital role in various metabolic pathways of these microorganisms [24]. It has also been proposed that the ultimate action of the toxicant is the denaturation of one or more proteins of the cell, which as a result, impairs normal cellular processes. Therefore, these compounds have good chemotherapeutic potential for use as antimicrobial agents against these microorganisms.

4. Conclusion

The synthetic strategy for homo- and heteropolynuclear complexes can be described in two stages: Firstly metal complexes could contain potential donor atoms for another metal ion or metal complex with an empty coordination site. Secondly, to link complexes to each other one can use bridging ligands, for example pseudohalide ligands, acting as ligands toward a second metal ion or use complexes as ligands. By this approach, we have synthesized two new heterotrinuclear complexes using Schiff bases and the thiocyanate anion. Both of the structures have been characterized by means of X-ray diffraction, elemental analyses, IR and electronic spectra. The biological activities of the characterized complexes and the ligands used were also studied. The complexes showed more activity than the free ligands against all tested microorganisms. Studies along these lines are currently in progress in our laboratory.

5. Supplementary data

CCDC 623505 and 623506 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

engineering, [8] in the present paper we wish to report the synthesis and X-ray crystal structure and thermal study of two Cu(II) complexes, namely $\{[Cu(H_2biim)(H_2O)(suc)](H_2O)\}_n$ (**1**) and $\{[Cu(H_2biim)_2(H_2O)][Cu(H_2biim)_2(glut)](glutH)(NO_3)\cdot 2.5H_2O\}_n$ (**2**).

2. Experimental

2.1. Materials

2,2′-Biimidazole was synthesized following a slightly modified procedure [11a] of that reported by Fieselmann et al. [11b]. All other chemicals were of AR grade and were used as received.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were measured from KBr pellets on a Nicolet 520 FTIR spectrometer. Thermogravimetric analyses were carried out on a Mettler Toledo Star system.

2.3. Synthesis

2.3.1. $\{[Cu(H_2biim)(H_2O)(suc)](H_2O)\}_n$ (1)

An aqueous solution (5 mL) of copper nitrate trihydrate (1 mmol, 0.242 g) was poured slowly dropwise into a hot methanolic solution (10 mL) of biimidazole (2 mmol, 0.268 g). Disodium succinate (1 mmol, 0.162 g), dissolved in water (5 mL), was added to this mixture. The resultant mixture was refluxed for ~12 h. and then allowed to cool to ambient temperature. This was filtered and the filtrate was kept in a $CaCl_2$ containing desiccator. Green colored single crystals suitable for X-ray analysis were obtained from the filtrate after a few weeks. Yield 78%. *Anal.* Calc. for $C_{10}H_{14}CuN_4O_6$: C, 34.31; H, 4.00; N, 16.01. Found: C, 33.79; H, 3.89; N, 15.58%.

2.3.2. $\{[Cu(H_2biim)_2(H_2O)][Cu(H_2biim)_2(glut)](glutH)(NO_3)\cdot 2.5H_2O\}_n$ (2)

An aqueous solution (5 mL) of copper nitrate trihydrate (1 mmol, 0.242 g) was poured slowly dropwise into a hot methanolic solution (10 mL) of biimidazole (2 mmol, 0.268 g). Disodium glutarate (1 mmol, 0.176 g), dissolved in water (5 mL), was added to this mixture. The resultant mixture was refluxed for ~12 h. and then allowed to cool to ambient temperature. This was filtered and the filtrate was kept in a $CaCl_2$ containing desiccator. Green colored single crystals suitable for X-ray analysis were obtained from the filtrate after two weeks. Yield 78%. *Anal.* Calc. for $C_{34}H_{44}Cu_2N_{17}O_{14.5}$: C, 38.86; H, 4.19; N, 22.67. Found: C, 38.53; H, 4.07; N, 22.06%.

2.4. Crystal structure determination

Diffraction data for the structures reported (Table 1) were recorded at room temperature on a Nonius DIP-1030H system (Mo Kα, $\lambda=0.71073$ Å). Cell refinement, indexing and scaling of the data sets were carried out using Denzo and Scalepack [12]. Both the structures were solved by Patterson and subsequent Fourier analyses and refined by the full-matrix least-squares method based on F^2 with all observed reflections [13]. In complex **2** the difference Fourier map evidenced two disordered nitrate anions (site occupancy of 0.5 each, isotropically refined) and the electroneutrality of the compound requires a glutarate anion to be present as a monoprotonated species. Beside the coordinated aquo ligand, the ΔFourier map showed some residuals interpreted as 2.5 lattice water molecules (per asymmetric unit). The contribution of the H atoms of the water molecules O3w and O4w (0.5 occupancy, isotropically refined) was not included in the final cycles of refine-

ment. All the calculations were performed using the WINGX System, Ver 1.70.01 [14].

3. Results and discussion

3.1. IR spectra of the complexes

The complexes exhibit strong peaks at 1387, 1540 and 1593 cm^{-1} for **1**; 1384, 1526 and 1577 cm^{-1} for **2**, which are assigned to C–O stretching vibrations of the dicarboxylate. Moreover, broad peaks are present in the range 2931–3084 cm^{-1} and 2934–3124 cm^{-1} for complexes **1** and **2**, respectively, assigned to C–H stretching vibrations of the dicarboxylate [15]. Both the complexes show peaks in the region 3167–3426 cm^{-1}, assigned to O–H stretching vibrations of water molecules [15]. For complex **2**, peaks at 1128, 1347 and 1434 cm^{-1} correspond to N–O stretching vibrations of the NO_3^- anions [15]. Additional peaks for both the complexes appear in the range 681–851 cm^{-1}, indicating the presence of a N-donor ligand.

3.2. Crystal structure of the complexes

3.2.1. Complex *1*

The structure of complex **1** consists of a 1D zigzag coordination polymer extended along the crystallographic *b*-axis, built up by $Cu(H_2biim)(H_2O)$ units connected by the succinate anion acting as a μ-bidentate ligand through the carboxyl oxygens. The complex represents a rare example of a copper coordination polymer with H_2biim, since bidentate nitrogen donors preclude chain formation and only two examples of polymeric structures containing $Cu(H_2biim)$ units have been reported to date. A 2D network is formed by using the dicyanamide anions, $Cu(H_2\text{-biim})(dca)_2$, [16a] while chlorides give rise to a 1D polymer, $[Cu_{1.5}(H_2biim)_2Cl_2]$ [16b].

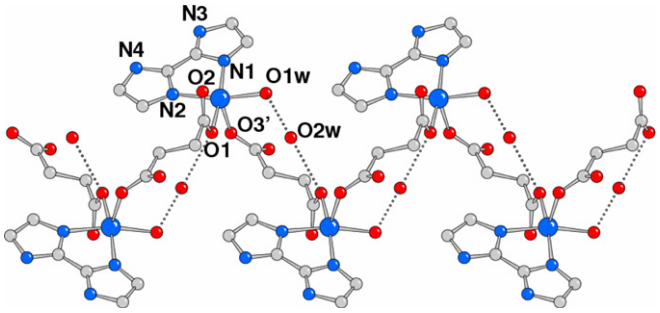

Fig. 1. Coordination polymer of complex **1** with intrachain H-bonds indicated by dotted lines. Selected bond lengths (Å): Cu–N(1) 2.017(1), Cu–N(2) 2.019(2), Cu–O(1) 1.944(1), Cu–O(1w) 2.004(1), Cu–O(3′) 2.266(2).

In the chain of **1**, the metals are separated by 7.391(1) Å along the dicarboxylate direction, with a Cu–Cu–Cu angle of 75.15(2)°. The copper has a distorted square pyramidal coordination environment with a chelating H_2biim ligand (mean Cu–N distance = 2.018(2) Å), an aquo (Cu–O(1w) = 2.004(1) Å) and succinate oxygen in the basal plane (Cu–O(1) = 1.944(1) Å). Another oxygen of a symmetry related dicarboxylate anion occupies the apical position at a longer distance (Cu–O(3′) = 2.266(2) Å). The metal is slightly displaced, by 0.138(1) Å, from the basal mean plane towards the apical oxygen donor. The polymer is reinforced by an intrachain H-bond from the lattice water molecule O(2w) bridging O(1w) and O(1) (Fig. 1, Table 2). This lattice water molecule plays a crucial role in the crystal packing since it acts also as a H-bond donor towards a symmetry related O(2) of a close polymer. The packing of complex **1** shows interdigitation of adjacent

chains with imidazole rings engaged in face-to-face π–π interactions (with a distance between the centroids of ca. 3.6 Å) (Fig. 2). This arrangement favors both oxygen atoms of a succinate carboxylate group attached to the H_2biim N–H donors (NH–O distances 2.76 Å) via a charge assisted hydrogen bond, allowing the formation of a "robust" 3D architecture. The flexible succinate dianions (the torsion angle of the carbon skeleton is 176.35(14)° and the dihedral angle between the carboxylate groups is 60.5(1)°) assist the described crystal packing.

3.2.2. Complex **2**

The structure of **2** is built up of bischelated $[Cu(II)(H_2biim)_2]^{2+}$ complexes, glutarate and nitrate anions, and water molecules, held together with extensive H-bonding. To assure the electroneutrality of the complex, a glutarate anion is present as a monoprotonated species at O(7) (see Section 2), according to the C–O distance and H-bond connection. Both the independent copper ions show a distorted square pyramidal coordination environment with chelating H_2biim ligands in the basal plane and with Cu–N bond distances ranging from 1.992(3) to 2.061(2) Å. The apical position of the Cu(1) and Cu(2) coordination environment is occupied by an aquo and a glutarate oxygen, respectively. The Cu(1)–O(1w) and Cu(2)–O(2) bond lengths are 2.261(2) and 2.600(2) Å and Cu(1) is displaced by 0.2 Å from the N_4 donor mean plane towards the aquo ligand, while Cu(2) is located in the basal plane. The planarity observed for the H_2biim ligands is indicative of π-electron delocalization in the imidazole rings. It is worth noting the H-bonding scheme occurring between the H_2biim ligands and glutarate anions. The NH groups of $Cu(1)(H_2biim)_2$ are bridged by a single carboxylate oxygen while those at Cu(2) interact with both glutarate carboxylate oxygens, likewise to that observed in complex **1** (Figs. 3 and 4). Correspondingly the former H-bonding interactions appear weaker (NH–O distances between 2.712 and 2.842 Å) with respect to the other, falling in the range

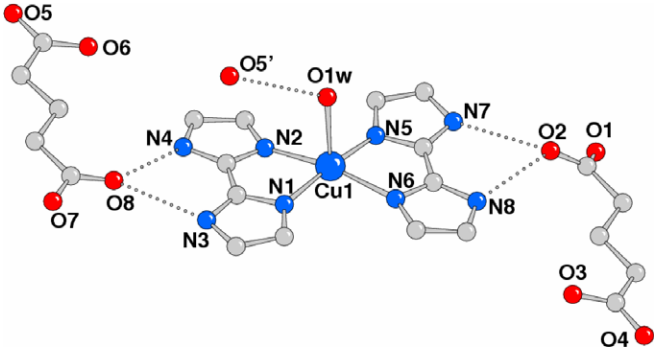

Fig. 3. Details of the crystal packing of complex **2** with indication of the metal coordination sphere about Cu(1) and H-bonds. Selected bond lengths (Å): Cu(1)–N(5) 1.992(3), Cu(1)–N(1) 1.995(3), Cu(1)–N(2) 2.049(2), Cu(1)–N(6) 2.061(2), Cu(1)–O(1w) 2.261(2).

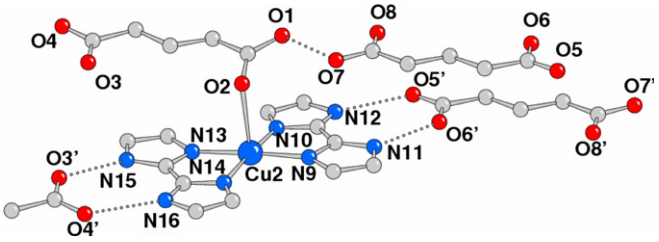

Fig. 4. The metal coordination sphere about Cu(2) of complex **2** with H-bonds indicated. O(7) represents the protonated glutarate oxygen. Selected bond lengths (Å): Cu(2)–N(9) 2.007(2), Cu(2)–N(13) 2.012(2), Cu(2)–N(14) 2.017(3), Cu(2)–N(10) 2.017(3), Cu(2)–O(2) 2.600(2).

2.641–2.691 Å (Table 2). These connections, together with the H-bonds taking place between the coordinated water (O1w) and dicarboxylate anions, give origin to a double-layered structure. The resulting crystalline architecture is enhanced to a 3D structure through weak hydrogen bonds involving the lattice water molecule O(2w). Fig. 5 shows a view of the net down the *b*-axis, evidencing channels filled by lattice water molecules and disordered nitrate anions. The results for complex **2** confirm the strong tendency of the H_2biim ligands to form bischelated species (specially

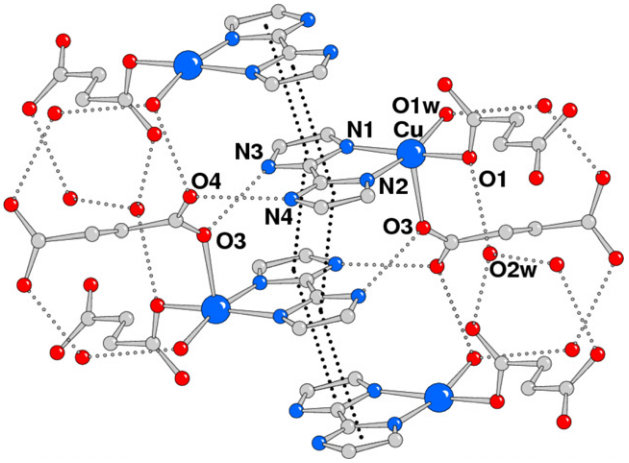

Fig. 2. 3D structure of complex **1** with π–π interactions between biim rings and H-bonds (dotted lines) occurring between NH of 2,2′-biimidazole ligands and carboxylate groups.

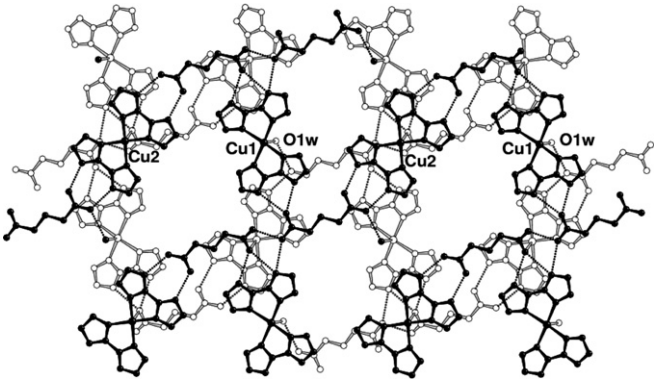

Fig. 5. Double layered net built up by $Cu(H_2biim)_2$ units and glutarate anions in complex **2** forming channels . The lattice water molecules and disordered nitrate anions filling the voids are not shown.

for square planar and octahedral complexes, [17] as for example when M = Cu^{2+} [2b], Co^{2+} [3a], Ni^{2+} [3a], Fe^{2+} [3b] and Zn^{2+} [3c]) and the dimensionality is extended through the formation of a hydrogen-bonding network. As a matter of fact, the crystal of $[Cu_{1.5}(H_2biim)_2Cl_2]$ [16b], also contains cationic species $[Cu_{1.5}(H_2biim)_2]^{2+}$ beside the 1D polymer mentioned above. Consequently the 2,2′-biimidazole-dicarboxylate hydrogen bond link appears to be a suitable motif in crystal engineering to form supramolecular networks.

3.3. Thermal analysis

Complex **1** is thermally stable up to 45 °C and on further heating it starts to lose water molecules and becomes deaquated at ~150 °C in two steps. The first step (50–80 °C) corresponds to the loss of half a lattice water molecule, whereas the second step (100–150 °C) indicates the loss of half lattice and one coordinated water molecule (Fig. S1). The elimination of the lattice water molecule in two steps is probably due to the different strengths of the H-bond (2.787 Å and 2.831 Å) (Fig. 1, Table 2) involved with the lattice water. The deaquated species does not revert on exposure to humid atmosphere, reflecting the attainment of a pentacoordinated geometry, even after dehydration, which is possible if the pendent O-atom of succinate takes part in coordination.We could not verify this as isolation of the pure species was not possible as it starts to collapse slowly upon further heating. Thermogravimetric analysis of complex **2** reveals that it loses lattice water molecules at ~100 °C in two overlapping steps (Fig. S2). Here also elimination of lattice water molecules occuring into two steps is due to the difference in strength of the H-bonds (2.764 Å and 2.864 Å) (Table 2). The structure collapses at the threshold of the deaquation.

4. Conclusion

Two Cu(II) complexes, synthesized by combining neutral H_2biim ligands and dicarboxylate anions, show that succinate in **1** acts as coordination ligand while the glutarate anion in **2** functions as a good acceptor of H-bonds, leading to supramolecular architectures. 1D zigzag coordination polymers are obtained in **1** via μ-bidentate succinate anions, and the dimensionality is extended to a ''robust'' 3D architecture through H-bonding between NH donors of H_2biim and succinate anions and through π–π interactions of interdigitated imidazole rings. In complex **2** bischelated $[Cu(II)(H_2biim)_2]^{2+}$ units, glutarate, nitrate anions and water molecules are held together through extensive H-bonding contacts, resulting in a 3D supramolecular network.

compounds containing 8-hydroxyquinoline and transition metals has recently increased [38–41]. The title compound joins the benefits of ruthenium coordination compounds and complexes containing 8-hydroxyquinoline and carbonyl groups, thus its synthesis and determination of its properties were undertaken.

In this paper we present the synthesis, crystal, molecular and electronic structure, and luminescence and spectroscopic characterization of a new ruthenium(II) carbonyl complex with the 8-hydroxyquinoline ligand.

2. Experimental

All reagents used in the synthesis of the complex are commercially available and were used without further purification. The $[RuHCl(CO)(PPh_3)_3]$ complex was synthesized by a published procedure [42].

2.1. Physical measurements

Infrared spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of a KBr pellet. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 800–200 nm in dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elemer CHN–2400 analyzer. The ^1H NMR spectrum was obtained at room temperature in $CDCl_3$ using an INOVA 300 spectrometer. Luminescence measurements were made on a Jobin-Yvon (SPEX) FLUOROLOG-3.12 spectrofluorometer at room temperature.

2.2. DFT calculations

The GAUSSIAN-03 program [43] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [44,45]. The electronic transitions were calculated with the PCM model [46] with dichloromethane as the solvent. The calculation was performed using the DZVP basis set [47] with f functions with exponents 1.94722036 and 0.748930908 on the ruthenium atom, and polarization functions for all other atoms: 6-31g(2d,p) – chlorine, 6-31g** – carbon, nitrogen, oxygen and 6-31g(d,p) on hydrogen atoms. Natural bond orbital (NBO) calculations were performed with the NBO code [48] included in GAUSSIAN-03.

2.3. Synthesis of $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$

A suspension of $[RuHCl(CO)(PPh_3)_3]$ (0.95 g; 1×10^{-3} mol) and 8-hydroxyquinoline (0.36 g; 2×10^{-3} mol) in dimethoxyethane (100 cm^{-3}) was refluxed until the solid dissolved, then the solution was cooled and filtered. Yellow crystals suitable for X-ray crystal analysis were obtained by slow evaporation of the reaction mixture. Yield: 81%.

Anal. Calc. for $C_{46}H_{36}ClNO_2P_2Ru$: C, 66.31; H, 4.35; Cl, 4.25; N, 1.68; O, 3.84; P, 7.43; Ru, 12.13. Found: C, 66.30; H, 4.33; N, 1.66%.

2.4. Crystal structure determination and refinement

A yellow prism of the studied complex was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at the temperature 291.0(3) K, with the ω scan mode. The full Ewald sphere reflections were collected up to $2\theta = 50.24°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 9369 strongest reflections for the complex. Details concerning crystal data and refinement are given in Table 1. Monitoring of 173 reflection intensities on reference frames measured every 40 frames show 7.32% decay of intensity. During the data reduction the above decay correction coefficient was taken into account. Lorentz, polarization, and numerical absorption [49] cor-

rections were applied. The structure was solved by the Patterson method combined with a partial structure expansion procedure. All the non-hydrogen atoms were refined anisotropically using the full-matrix least-squares technique on F^2. The hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as ''riding'' on the adjacent atom with individual isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent atom, with geometry idealization after each cycle. SHELXS-97 [50], SHELXL-97 [51] and SHELXTL [52] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Results and discussion

The reaction of the complex $[RuHCl(CO)(PPh_3)_3]$ with 8-hydroxyquinoline has been performed. Refluxing a ruthenium carbonyl hydrido complex with an excess of 8–hydroxyquinoline in dimethoxyethane leads to the complex $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ in good yield. The elemental analysis of the complex is in good agreement with its formulation. The IR spectrum of the complex is consistent with its molecular structure. The bands of C≡O and C=N stretching modes are observed at 1938 and 1569 cm^{-1}, respectively. The $\nu_{Ph(P-Ph)}$ absorption band at 1434 cm^{-1} indicates the presence of triphenylphosphine ligands. The singlet at 31.41 ppm in the ^{31}P NMR spectrum indicates both triphenylphosphoine ligands in the studied complex are equivalent and are mutually *trans* disposed.

3.1. Crystal structure

The $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ complex crystallises in the monoclinic $P2_1/c$ group and the crystal structure is built up of two independent molecules in the asymmetric unit. Both molecules have the same conformation (the root mean square deviation of superimposed molecules atoms is 0.133 Å and the most distant O(2) atoms are separated by 0.335 Å). The relative orientation of the molecules is depicted in Fig. 1, which also shows the displacement ellipsoids of the non-hydrogen atoms. These two molecules are twisted with respect to one another by 62.81(4)°, which prevents the existence of higher crystallographic symmetry. The structural drawing is presented in Fig. 2. The most important angles and bond lengths for the complex are reported in Table 2. The weak intra- and intermolecular hydrogen bonds [53,54] are presented in Table 3.

The ruthenium atom in the complex $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ is in a distorted octahedral environment with *trans* triphenylphosphine ligands (average P–Ru–P

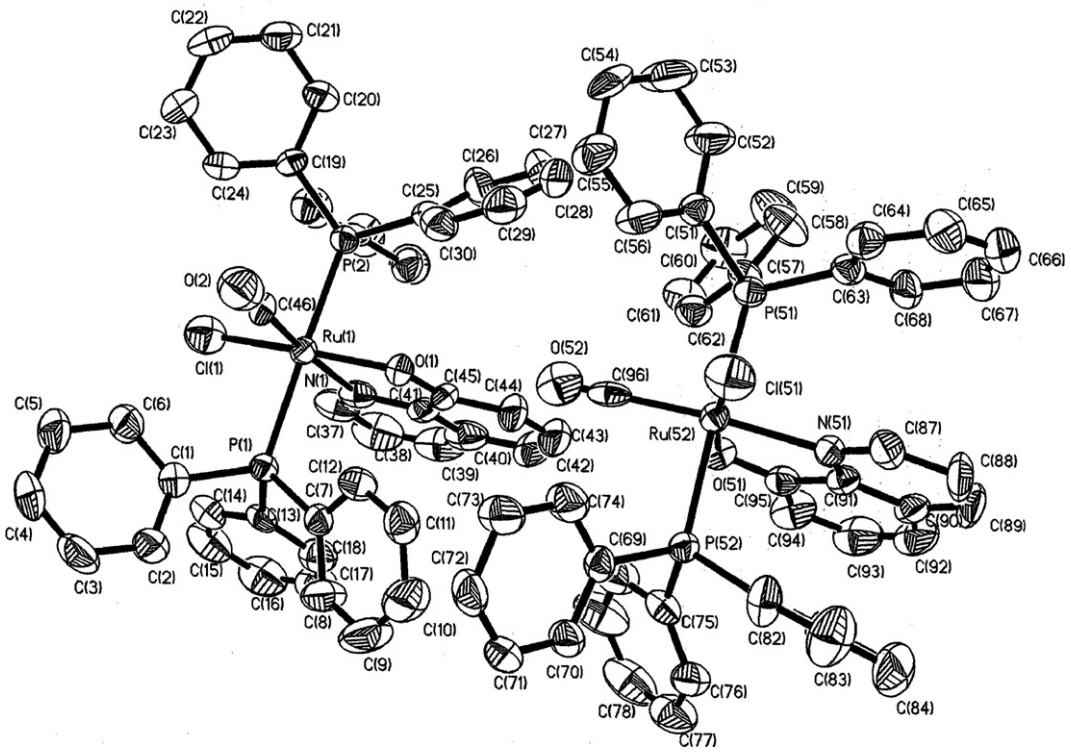

Fig. 1. Relative orientation of two molecules of the $[RuHCl(CO)(PPh_3)_2(C_9H_6NO)]$ complex in the asymmetric unit. The displacement ellipsoids are drawn with 50% probability.

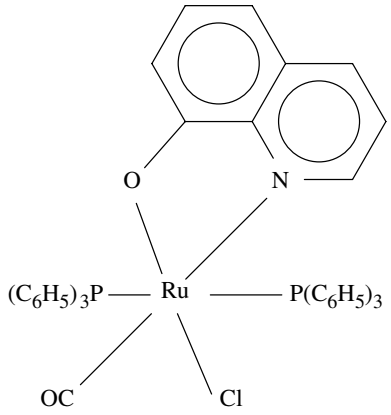

Fig. 2. Structural drawing of $[RuHCl(CO)(PPh_3)_2(C_9H_6NO)]$.

angle 177.62(5)°). The carbonyl ligand is in *trans* position to the hydroxyquinoline N donor atom (average C–Ru–N angle 170.8(3)°) and the chloride ion lies *trans* to the hydroxyquinoline oxygen atom with an average angle of 171.07(11)°. All Ru–ligand distances, such as Ru–Cl 2.4183(18), Ru–P 2.4105(14), 2.4106(14), Ru–N 2.1270(4), Ru–C 1.9585(7) and Ru–O 2.0770(3) Å, are normal and are comparable with distances in other ruthenium complexes containing heterocyclic ligands [55–58]. The C(46)–O(2) bond shows some shortening in comparison with typical distances in CO substituents, but similar distances can be found in several compounds [59–76].

The conformation of the molecule is stabilized by five weak intramolecular hydrogen bonds, three between the phenyl CH and the Cl ligand (D···A distance varies from 3.334(7) to 3.492(6) Å and D–H···A angle varies from 122.5° to 146.8°) and two linking the phosphine phenyl C–H and O (D···A distance 2.885(6) and 2.884(6) Å and D–H···A angle 117.0° and 100.1°). One intermolecular hydrogen bond is observed, C(89)–H(89)···O(52)(#1 $-x+1,\ y-1/2,\ -z+1/2$) (D···A distance 3.470(9) Å; D–H···A angle 171.1°).

3.2. Geometry optimization

The geometry of the studied complex was optimized by the DFT method with the B3LYP functional. The optimized geometry parameters for the $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ complex are gathered in Table 2. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are reproduced in the calculations. The calculated bond lengths and angles for $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ agree with the experimental results; the largest difference is found for the C(43)–O(2) bond (~0.25 Å). The maximum difference between the calculated and experimental angles are visible for N(1)–Ru(1)–P(1) and C(46)–Ru(1)–O(1) and are close to 2.1° and 2.0°, respectively.

3.3. Electronic structure and NBO analysis

In the studied complex, the occupied d_{xy} and d_{xz} ruthenium orbitals participate in backdonation from the central metal ion to the carbonyl ligand. The largest contribution of the π_{Ru-CO} bonding interaction is visible in the H−1 and H−3 orbitals. The π^*_{Ru-CO} orbitals are also distributed

Table 2
Selected bond lengths (Å) and angles (°) for $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$

Experimental				Calculated
Bond lengths (Å)

Symmetry transformations used to generate equivalent atoms: #1 $-x+1$, $y-1/2$, $-z+1/2$.

among several unoccupied molecular orbitals. Their contribution is visible in L+14, L+15. The HOMO orbital of the $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ complex is composed of the d_{xz} metal orbital and the hydroxyquinoline oxygen π orbital in an anti-bonding arrangement. The LUMO orbital is localized on the hydroxyquinoline ring. The d_{z^2} orbital of the Ru atom makes the largest contribution to L+2 and, whereas L+4, L+14 and L+15 have $d_{x^2-y^2}$ character.

In some of the lowest unoccupied molecular orbitals of $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$, the contribution of the phosphorous orbitals is visible (L+1, L+2, L+3). In classical concepts empty phosphorous 3d orbitals are used in the π-back bonding between the metal center and the phosphine ligand. Now it is generally recognized that d orbitals have very high energy and play only a minor role in the π_{M-PR3} bond formation [77]. In the π-back bonding between the metal center and the phosphine ligand, the σ*(P–C) orbitals are involved. The HOMO–LUMO gap is 3.24 eV. The energy and character of the selected frontier molecular orbitals are given in Table 4.

The natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (HHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between "filled" Lewis-type NBOs and "empty" non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as "delocalization" corrections to the zeroth-order natural Lewis structure.

For the carbonyl group of the investigated complex, three natural bond orbitals were detected for the C–O bond, and one for the Ru–C bond. The Ru–C bond orbitals are polarized towards the carbon atom, and the C–O bond orbitals are polarized towards the oxygen end. The oxygen atom of the carbonyl ligand has one lone pair (LP) orbital. The occupancies and hybridization of the CO and Ru–C bonds are gathered in Table 5 (*anti*-bonding NBOs are given in round brackets).

Not detected in NBO analysis, the $Ru–N_{(hq)}$ and $Ru–O_{(hq)}$ bonds have a character consisting of predominantly Coulomb-type interactions between the central ion and the 8-hydroxyquinoline ligand [78].

The calculated charge on the ruthenium atom in the complex $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ is considerable lower than the formal charge of +2, and is close to 0.21.

Table 4
The energy and character of selected occupied and virtual MOs for $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$

MO	Energy	Character
H−15	−6.797	π_{PPh_3}
H−14	−6.776	π_{PPh_3}
H−13	−6.723	π_{PPh_3}
H−12	−6.651	π_{PPh_3}
H−11	−6.614	π_{PPh_3}
H−10	−6.596	π_{PPh_3}
H−9	−6.581	π_{PPh_3}
H−8	−6.514	$\pi_{PPh_3} + \pi_{Cl}$
H−7	−6.486	$\pi_{PPh_3} + \pi_{hq}$
H−6	−6.404	$\pi_{PPh_3} + \pi_{Cl}$
H−5	−6.365	$\pi_{PPh_3} + \pi_{hq}$
H−4	−6.019	$d_{Ru} + n_P$
H−3	−5.748	$d_{Ru} + \pi^*_{CO}$
H−2	−5.095	$d_{Ru} + \pi^*_{Cl}$
H−1	−4.788	$d_{Ru} + \pi^*_{Cl} + \pi^*_{CO}$
H	−4.272	$d_{Ru} + \pi^*_{O}$
L	−1.034	π^*_{hq}
L+1	−0.563	$\pi^*_{PPh_3} + n_P$
L+2	−0.487	$d_{Ru} + \pi^*_{PPh_3} + n_P$
L+3	−0.408	$\pi^*_{PPh_3} + n_P$
L+4	−0.249	$d_{Ru} + \pi^*_{PPh_3}$
L+5	−0.134	$\pi^*_{PPh_3}$
L+6	−0.027	$\pi_{PPh_3} + \pi^*_{hq}$
L+7	0.052	$\pi^*_{PPh_3}$
L+8	0.106	$\pi^*_{PPh_3}$
L+9	0.180	$\pi^*_{PPh_3}$
L+10	0.207	$\pi^*_{PPh_3}$
L+11	0.268	$\pi^*_{PPh_3}$
L+12	0.301	$\pi^*_{PPh_3}$
L+13	0.312	$\pi^*_{PPh_3}$
L+14	0.537	$d_{Ru} + \pi^*_{CO}$
L+15	1.140	$d_{Ru} + \pi^*_{CO}$

H denotes HOMO; L denotes LUMO.

Table 5
The occupancies and hybridization of the calculated Ru–C and C–O natural bond orbitals (NBOs) of $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$

BD (2-center bond)	Occupancy	Hybridization of NBO
Ru(1)–C(46)	1.955 (0.309)	$0.513(sd^{3.75})_{Ru} + 0.859(sp^{0.47})_C$
C(46)–O(2)	1.998 (0.080)	$0.533(sp^{61.70}d^{0.20})_C + 0.846(sp^{34.32}d^{0.23})_O$
	1.997 (0.091)	$0.532(sp)_C + 0.847(p)_O$
	1.995 (0.018)	$0.546(sp^{2.26})_C + 0.838(sp^{0.39})_O$

The charge on the carbon atom of the carbonyl ligand is positive (+0.59), whereas the oxygen atom is negatively charged (−0.30).

The charges on the P atoms are positive and close to 1.15; the charge on the chloride ligand is smaller than −1 (−0.62), the charge on the hydroxyquinoline ligand is close to −0.53. The occupancies of the ruthenium d orbitals, obtained from NBO analysis, are as follows: d_{xy} −1.84; d_{xz} −1.89; d_{yz} −0.86; $d_{x^2-y^2}$ −1.25; d_{z^2} −1.60.

3.4. Electronic spectrum

The experimental and calculated electronic spectra of $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$ are presented in Fig. 3. The contour of calculated spectrum was broadening by the Lorentzian function, calculated by the formula:

$$I = \frac{I_0}{1 + \left(\frac{\nu - \nu_0}{\gamma}\right)^2};$$

where $\gamma = 1/2$ spectral width on 1/2 height.

Ninety electronic transitions were calculated using the TDDFT method and they do not comprise all the experimental absorption bands. The UV–Vis spectrum was calculated up to ~225 nm, so the shortest wavelength experimental bands cannot be assigned to the calculated transitions. However, considering that the solution spectra of PPh_3 and 8-hydroxyquinoline exhibit intense absorption bands in the 260–200 nm region, some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations.

The assignments of the calculated transitions to the experimental bands are based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions only the main components of the molecular orbitals are taken into consideration.

The longest wavelength experimental unsymmetrical broad band, with a maximum at 417.4 nm, is assigned to the transitions from the HOMO to LUMO and LUMO + 2 orbitals. As the LUMO orbital is composed of the π^* orbitals of the 8-hydroxyquinoline ring, the transition is of the *Metal–Ligand Charge Transfer* type with a d → d (Ligand Field) contribution.

The next band, with maximum at 328.2 nm, is ascribed to the metal–ligand charge transfer transitions $d \rightarrow \pi^*_{PPh_3}$ and $d \rightarrow \pi^*_{hq}$. In this region the transitions between HOMO and HOMO − 2 MOs were calculated.

The last calculated transition, attributed to experimental one at 259.6 nm, proceeds mainly from the d ruthenium

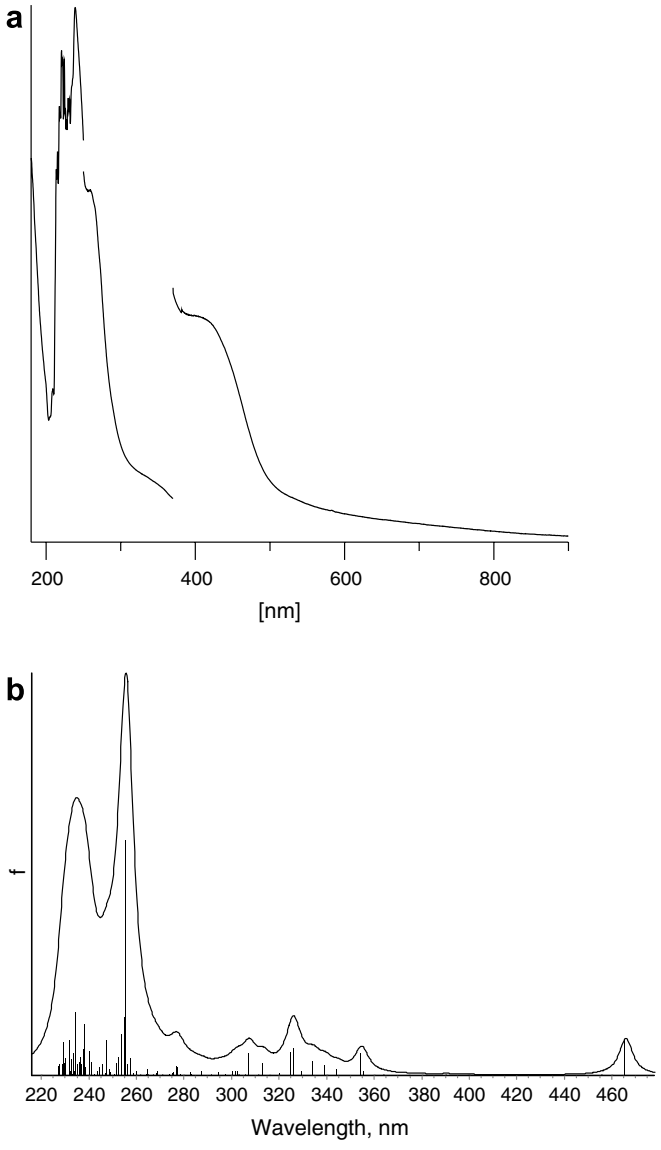

Fig. 3. The UV–Vis spectra of $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$: (a) experimental and (b) calculated.

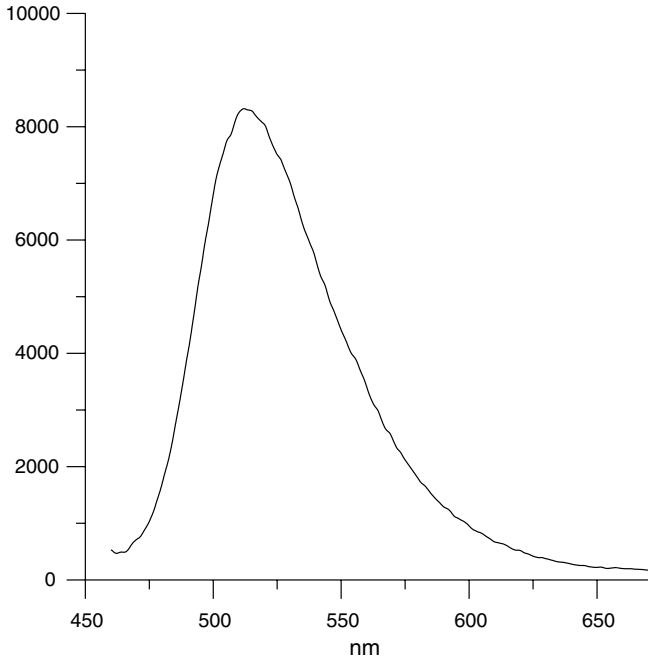

Fig. 4. The emission spectrum of $[RuCl(CO)(PPh_3)_2(C_9H_6NO)]$.

orbitals with an admixture of π chloride and π carbonyl orbitals to π^*_{Ph} and π^*_{hq}, with an admixture of *Ligand–Ligand Charge Transfer* transitions ($\pi_{PPh_3} \rightarrow \pi^*_{hq}$; HOMO − 5/6 → LUMO + 1).

The intraligand transition $\pi_{PPh_3} \rightarrow \pi^*_{PPh_3}$ was calculated at 229.9 nm and it can be assumed that the experimental band at 221.2 nm (not assigned on the basis of the calculated transitions) is composed of the transitions in the PPh_3 ligands and from $\pi \rightarrow \pi^*$ excitations in the hydroxyquinoline ligand. As it was pointed out in the literature, the TDDFT method gives such transitions at too small energies [79–87] and we may expect also that this is the case in our calculations.

The emission property of the studied complex has been examined in dichloromethane solution at room temperature. The luminescence spectrum is presented in Fig. 4. On excitation at 417 nm, an emission peak was observed at 513 nm and it was independent of the concentration of the solution. The emission originates from the lowest energy metal to ligand charge transfer (MLCT) state, derived from the excitation involving a $d_\pi \rightarrow \pi_{hq}$ transition (similar MLCT transitions are observed in ruthenium(II) bipyridyl complexes [88,89]).

4. Supplementary material

CCDC 635757 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

The crystallographic part was financed by funds allocated by the Ministry of Science and Higher Education to the X-ray Crystallography and Crystal Chemistry Group, Institute of General and Ecological Chemistry, Technical University of Łódź. The GAUSSIAN-03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland under calculational Grant No 51/96.

isolated in good yields whatever the ratio between the trinuclear 2/1 Cu/Ca complex and the lanthanide ion. An explanation for the failure of the template effect has been put forward.

2. Experimental

2.1. Materials

The metal aldimine complexes, $L^1Cu \cdot H_2O$ [9], $L^2Cu \cdot 2H_2O$ [10] (L^1H_2: *N*,*N*′-ethylenedi(3-methoxysalicylideneimine); L^2H_2: *N*,*N*′-2,2-dimethylpropylenedi(3-methoxysalicylideneimine)), were prepared as previously described. $Ca(NO_3)_2 \cdot 4H_2O$, $Ca(OH)_2$, $Ba(OH)_2 \cdot 8H_2O$, $Sr(OH)_2 \cdot 8H_2O$, 2,2,6,6-tetramethyl-3,5-heptanedione (Aldrich) were used as purchased. High-grade solvents were used for the syntheses of complexes.

2.2. Syntheses

2.2.1. Complexes

*2.2.1.1. $L^1CuCa(thd)_2 \cdot MeOH$ (**1**).* A mixture of $L^1Cu \cdot H_2O$ (0.41 g, 1×10^{-3} mol) and $Ca(OH)_2$ (0.15 g, 2×10^{-3} mol) in methanol (20 mL) was stirred for 15 min and then filtered off. Addition of tetramethylheptanedione (0.38 g, 2×10^{-3} mol) under stirring yielded a red precipitate that was filtered off 30 min later and dried. Yield: 0.3 g (36%). *Anal.* Calc. for $C_{41}H_{60}CaCuN_2O_9$: C, 59.4; H, 7.3; N, 3.4. Found: C, 59.4; H, 7.2; N, 3.4%. Characteristic IR absorptions (KBr): 3434, 2957, 1634, 1604, 1558, 1548, 1475, 1449, 1419, 1309, 1242, 1223, 1081, 987, 974, 961, 856, 741, 643, 609 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 612$ (100), $[L^1CuCa(thd)]^+$. Crystals suitable for a X-ray study were obtained from a dichloromethane/methanol solution. They contain a dichloromethane molecule.

Use of $Sr(OH)_2 \cdot 8H_2O$ or $Ba(OH)_2 \cdot 8H_2O$ in place of $Ca(OH)_2$ with the same experimental process and the same amount of the copper complex precursor yielded the corresponding complexes.

*2.2.1.2. $L^1CuSr(thd)_2$ (**2**).* Yield: 0.36 g (43%). *Anal.* Calc. for $C_{40}H_{56}CuN_2O_8Sr$: C, 56.9; H, 6.7; N, 3.3. Found: C, 56.3; H, 6.6; N, 3.2%. Characteristic IR absorptions (KBr): 2941, 1644, 1603, 1546, 1475, 1446, 1322, 1242, 1219, 1087, 987, 978, 968, 856, 743, 724, 646, 607 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 660$ (100), $[L^1CuSr(thd)]^+$.

*2.2.1.3. L^1 $CuBa(thd)_2$ (**3**).* Yield: 0.5 g (56%). *Anal.* Calc. for $C_{40}H_{56}BaCuN_2O_8$: C, 53.8; H, 6.3; N, 3.1. Found: C, 53.5; H, 6.3; N, 3.1%. Characteristic IR absorptions (KBr): 2937, 1634, 1604, 1547, 1475, 1446, 1314, 1246, 1224, 1083, 988, 968, 855, 736, 644, 608 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 710$ (100), $[L^1CuBa(thd)]^+$.

*2.2.1.4. $(L^1Cu)_2Ca(NO_3)_2 \cdot 2H_2O$ (**4**).* A mixture of $L^1Cu \cdot H_2O$ (0.41 g, 1×10^{-3} mol) and $Ca(NO_3)_2$ (0.24 g, 1×10^{-3} mol) in methanol (15 mL) was stirred for three hours. The precipitate which appeared was filtered off and dried. Yield: 0.31 g (65%). *Anal.* Calc. for $C_{36}H_{40}CaCu_2N_6O_{16}$: C, 46.0; H, 4.1; N, 8.6. Found: C, 45.6; H, 3.9; N, 8.4%. Characteristic IR absorptions (KBr): 3459, 1642, 1626, 1606, 1450, 1412, 1384, 1314, 1247, 1224, 1083, 979, 962, 857, 752, 740, 648, 609 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 880$ (2.5), $[(L^1Cu)_2Ca(NO_3)]^+$, 818 (3.6), $[(L^1Cu)_2Ca]^+$, 491 (100), $[(L^1Cu)Ca(NO_3)]^+$.

The following complexes were prepared similarly with use of the corresponding salts.

*2.2.1.5. $(L^1Cu)_2Ba(NO_3)_2 \cdot 2H_2O$ (**5**).* Yield: 0.38 g (70%). *Anal.* Calc. for $C_{36}H_{40}BaCu_2N_6O_{16}$: C, 40.1; H, 3.7; N, 7.8. Found: C, 39.7; H, 3.6; N, 7.7. Characteristic IR absorptions (KBr): 3434, 1631, 1603, 1449, 1474, 1450, 1384, 1301, 1243, 1226, 1080, 986, 966, 853, 740, 646, 609 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 978$ (32.0), $[(L^1Cu)_2Ba(NO_3)]^+$, 916 (19.3), $[(L^1Cu)_2Ba]^+$, 589 (100), $[(L^1Cu)Ba(NO_3)]^+$.

*2.2.1.6. $(L^1Cu)_2Ba(ClO_4)_2$ (**6**). Caution*: Due to their explosive character, perchlorate salts should be handled with care and in very low amounts. Acetone was used as solvent. Yield: 0.4 g (74%). *Anal.* Calc. for $C_{36}H_{36}BaCl_2Cu_2N_4O_{16}$: C, 38.7; H, 3.2; N, 5.0. Found: C, 39.6; H, 3.2; N, 4.9%. Characteristic IR absorptions (KBr): 1647, 1666, 1604, 1550, 1472, 1443, 1392, 1301, 1243, 1222, 1120, 1081, 1055, 1046, 981, 977, 966, 854, 737, 641, 628, 620 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 1017$ (48.6), $[(L^1Cu)_2Ba(ClO_4)]^+$, 916 (34.2), $[(L^1Cu)_2Ba]^+$, 626 (100), $[(L^1Cu)Ba(ClO_4)]^+$.

*2.2.1.7. $L^1CuMg(H_2O)(NO_3)_2$ (**7**).* Yield: 0.5 g (90%). *Anal.* Calc. for $C_{18}H_{20}CuMgN_4O_{11}$: C, 38.9; H, 3.6; N, 10.1. Found: C, 39.0; H, 3.6; N, 9.9%. Characteristic IR absorptions (KBr): 3401, 1638, 1601, 1556, 1474, 1440, 1384, 1316, 1243, 1221, 1082, 977, 964, 858, 742, 642, 611 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 475$ (100), $[(L^1Cu)Mg(NO_3)]^+$.

*2.2.1.8. $(L^2Cu)_2Ca(NO_3)_2 \cdot H_2O$ (**8**).* Yield: 0.34 g (65%). *Anal.* Calc. for $C_{42}H_{50}CaCu_2N_6O_{15}$: C, 48.2; H, 4.8; N, 8.0. Found: C, 47.9; H, 4.6; N, 7.8%. Characteristic IR absorptions (KBr): 3419, 1617, 1558, 1472, 1384, 1312, 1229, 1170, 1082, 1067, 983, 855, 742, 646, 623 cm^{-1}. Mass spectrum (FAB^+, 3-nitrobenzyl alcohol matrix): $m/z = 966$ (28.5), $[(L^2Cu)_2Ca(NO_3)]^+$, 902 (20.2), $[(L^2Cu)_2Ca]^+$, 533 (100), $[(L^2Cu)Ca(NO_3)]^+$.

2.3. Physical measurements

Elemental analyses were carried out at the Laboratoire de Chimie de Coordination Microanalytical Laboratory

in Toulouse, France, for C, H, and N. IR spectra were recorded on a GX system 2000 Perkin–Elmer spectrophotometer; samples were run as KBr pellets. Mass spectra (FAB^+) were recorded in dmf as solvent and 3-nitrobenzyl alcohol matrix with a Nermag R10-10 spectrometer. Magnetic data were obtained with a Quantum Design MPMS SQUID susceptometer. All samples were 3 mm diameter pellets molded from ground crystalline samples. Magnetic susceptibility measurements were performed in the 2–300 K temperature range in a 0.1 T applied magnetic field, and diamagnetic corrections were applied by using Pascal's constants [11]. The magnetic susceptibilities have been computed by exact calculations of the energy levels associated to the spin Hamiltonian through diagonalization of the full matrix with a general program for axial symmetry,[12] and with the MAGPACK program package [13,14]. Least-squares fittings were accomplished with an adapted version of the function-minimization program MINUIT [15].

2.4. Crystallographic data collection and structure determination for $[L^1Cu(CH_3OH)Ca(thd)_2]$ (1) and $[(L^2Cu)_2Ca(NO_3)_2]$ (8)

Crystals suitable for X-ray analyses were obtained by slow evaporation of the corresponding methanol solutions. Data were collected at 160 K for **1** on a IPDS STOE diffractometer and at 180 K for **8** on an Xcalibur Oxford Diffraction diffractometer using graphite-monochromated Mo Kα radiation sources ($\lambda = 0.71073$ Å) and equipped with Oxford Cryosystems Cryostream Cooler Devices. 46391 reflections were collected for **1**, 43468 for **8**, of which 9047 independent ($R_{int} = 0.08$) for **1** and 6185 ($R_{int} = 0.13$) for **8**. Multiscan absorption corrections were applied ($T_{min-max} = 0.76$–0.89 for **1**, 0.82–0.94 for **8**). The structures were solved by direct methods using SIR92 [16], and refined by means of least-squares procedures on F using the programs of the PC version of CRYSTALS [17]. Atomic scattering factors were taken from the International tables for X-ray crystallography [18]. All non-NO_3 groups and non-hydrogen atoms were refined anisotropically. The maximum and minimum peaks on the final difference Fourier maps were 0.62 and -0.63 e A^{-3} for **1**, 1.79 and -1.13 e A^{-3} for **8**. Drawings of the molecule were performed with the program CAMERON [19]. Crystal data collection and refinement parameters are given in Table 1, and selected bond distances and angles are gathered in Table 2.

Table 1

3. Results

3.1. Syntheses

Reaction of the *N*,*N*′-ethylenedi(3-methoxysalicylideneiminato) copper complex with calcium, strontium and barium hydroxide in the presence of 2,2,6,6-tetramethyl-3,5-heptanedione (thd) yielded a series of complexes formulated $L^1CuCa(thd)_2$ (**1**), $L^1CuSr(thd)_2$ (**2**) and $L^1CuBa(thd)_2$ (**3**), which are characterized by a 1/1 copper/alkaline-earth ratio. At variance, using alkaline-earth nitrate or perchlorate yielded complexes characterized by the 2/1 copper/alkaline-earth ratio, $(L^1Cu)_2Ca(NO_3)_2 \cdot 2H_2O$ (**4**), $(L^1Cu)_2Ba(NO_3)_2 \cdot 2H_2O$ (**5**), $(L^1Cu)_2Ba(ClO_4)_2$ (**6**). The copper complex involving the more flexible *N*,*N*′-2,2-dimethylpropylenedi(3-methoxysalicylideneiminate) L^2 ligand yielded a

similar entity $(L^2Cu)_2Ca(NO_3)_2 \cdot H_2O$ (**8**), with again a 2/1 ratio. The only exception to this 2/1 ratio occurred with magnesium ions that yielded the $L^1CuMg(NO_3)_2 \cdot H_2O$ complex (**7**). The different ionic radius of magnesium is most probably responsible for the change in Cu/alkaline-earth ratio.

3.2. Spectroscopic data

The infrared spectra of the structurally determined complexes **1** and **8** are of prime interest for the study of the remaining entities. The ν_{CN} bands of the coordinated ligands are observed at 1604 and 1617 cm^{-1} for **1** and **8**, respectively. A strong band at 1384 cm^{-1} is attributable to the monodentate NO_3 anion in **8** [20], while a strong band at 1634 cm^{-1} may be assigned to the coordinated keto functions of the thd ligands in **1** [21].

Mass spectra also yield interesting information. The three $L^1CuM(thd)_2$ complexes display very similar mass spectra (FAB^+). In all mass spectra we observe peaks corresponding to the $[L^1CuM(thd)]^+$ ions. They appear at $m/z = 612$ for **1** (M = Ca), 660 for **2** (M = Sr), and 710 for **3** (M = Ba). A different spectral pattern characterizes complex **8** with peaks at $m/z = 964$, 902 and 533, attributable to $[(L^2Cu)_2Ca(NO_3)]^+$, $[(L^2Cu)_2Ca]^+$ and $[L^2CuCa(NO_3)]^+$, respectively. If the peaks at 964 and 533 u are expected, the peak at 902 u is more surprising for it suggests a change in the oxidation state of the metal ions. Such an observation has been previously made [22]. Complexes **4** and **5** show similar peaks at 1017, 916 and 626, and 978, 916 and 589 u, respectively. For these three complexes, although it should be underlined that the most intense peak corresponds to the $[L^1CuM(NO_3)]^+$ ion, the presence of peaks at 1017 (**4**) 978 (**5**) and 964 (**8**) μm confirms their trinuclear character. Complex **7**, $L^1CuMg(NO_3)_2(H_2O)$, where $[L^1CuMg(NO_3)]^+$ is the only cationic species observed, is an exception.

3.3. Structural determinations

The molecular structure of **1** is built from isolated dinuclear complex molecules $[L^1Cu(CH_3OH)Ca(thd)_2]$. A perspective view of this dinuclear molecule with the corresponding labeling scheme is depicted in Fig. 1 while significant bond lengths and angles appear in Table 2. In each bimetallic unit, the Cu^{II} and Ca^{II} cations occupy the inner N_2O_2 and outer O_2O_2 sites, respectively. The two ions are doubly bridged to each other by phenoxo oxygen atoms, with a Cu···Ca distance of 3.460(1) Å. The copper is surrounded by five donor atoms. The equatorial N_2O_2 donors afforded by L^1 are nearly coplanar and the axial position is occupied by the methanol oxygen atom at 2.416(3) Å from the copper ion. While the copper ion is located in the N_2O_2 mean plane, the calcium ion is located 0.741(2) Å out of this plane. The five-membered ring formed by the diimine moiety chelating the copper ion is in a δ conformation. The Cu–O bond lengths do not differ significantly from the values reported for similar complexes

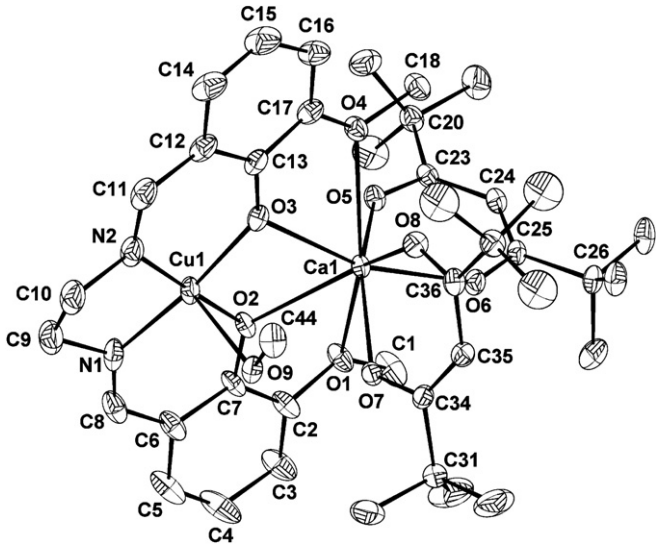

Fig. 1. Molecular structure of $[L^1Cu(CH_3OH)Ca(thd)_2]$ (**1**). The thermal ellipsoids are drawn at the 30% probability level.

[3,4]. The eight-coordinate Ca cation is surrounded by four oxygen atoms belonging to the Schiff base and by four oxygen atoms brought by two tetramethylheptanedionato anions acting as bidentate η^2 chelating auxiliary ligands. The two longer Ca–O bonds involve the OMe side arms (2.666(3) and 2.724(3) Å) while the shorter ones concern the keto oxygen atoms from the thd ligands (from 2.310(3) to 2.369(3) Å); the Ca–O bonds involving the phenoxo oxygen atoms are comprised in between these values (2.444(3) and 2.488(3) Å). π–π stacking interactions established between the aromatic cycles located around the copper coordination spheres are responsible for the presence of short intermolecular Cu(1)···Cu(1)′ (3.819(1) Å) and large Ca(1)···Ca(1)′ (8.951(2) Å) distances.

The molecular structure of complex **8**, along with the atom labeling scheme, is depicted in Fig. 2, while the rele-

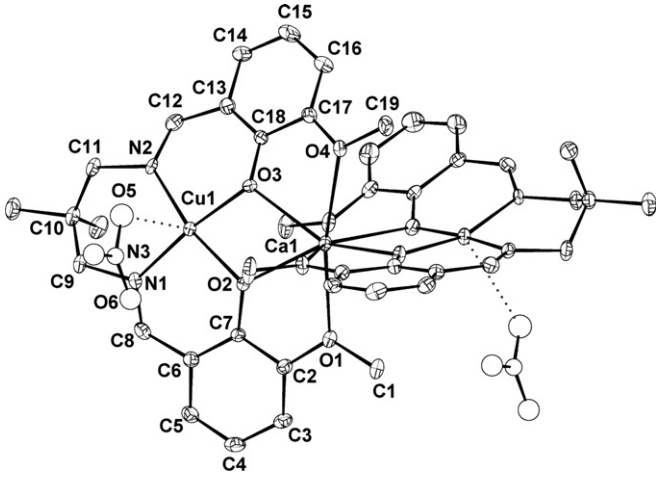

Fig. 2. Molecular structure of $(L^2Cu)_2Ca(NO_3)_2 \cdot H_2O$ (**8**). The thermal ellipsoids are drawn at the 30% probability level.

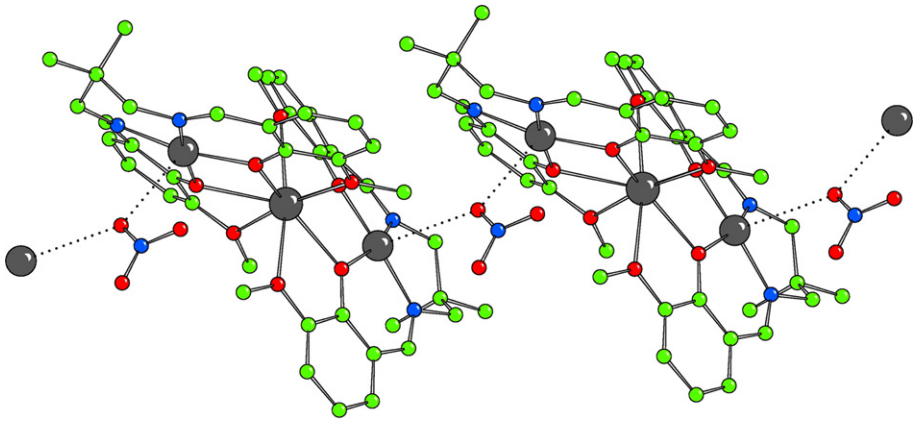

Fig. 3. Fragment of the 1D chain resulting from the η^1:μ nitrato bridging for **8**.

vant interatomic bonds lengths are collated in Table 2. The N_2O_2 donor set of $(L^2)^{2-}$ is at the basal plane of the pentacoordinate copper cation, to which an oxygen atom of the nitrato anion is axially bonded. Cu(1) is displaced from the mean equatorial N_2O_2 plane by 0.128(2) Å toward the axially coordinated nitrato oxygen atom. The two Cu(OO)Ca cores including the two bridging phenoxo oxygen atoms are essentially planar and roughly orthogonal, with a related Cu(1)···Ca(1) separation of 3.5375(6) Å yielding an intramolecular Cu(1)···Cu(1)′ separation of 7.044(3) Å through (Ca(1) (′:, $-x+1/2$, $-y+5/2$, z)). The Ca^{II} cation is eight-coordinate through two sets of four oxygen atoms from each L^2Cu building unit, and linked to each copper ion by two phenoxo bridges. The shortest intermolecular Cu(1)···Cu(1) distance is equal to 5.212(1) Å for the nitrato ion bridges two copper ions through the same oxygen atom, thus forming a 1D chain of trinuclear units (Fig. 3). As a consequence, the intermolecular Cu(1)···Cu(1)′ (9.127(1) Å) and Ca(1)···Ca(1) (10.429(3) Å) distances are large. This η^1:μ nitrato bridging mode is not common [20].

3.4. Magnetic properties

The dinuclear complexes **1**, **2**, **3**, **7**, in which the copper ion is in presence of diamagnetic centres, behave as paramagnetic entities devoid of any intermolecular interactions. The intermolecular contacts established by π–π stacking in **1** are not able to transmit a magnetic interaction. The temperature dependence of the magnetic susceptibility for **8** in the 2–300 K temperature range is shown in Fig. 4 as the $\chi_M T$ versus T variation. The $\chi_M T$ product remains constant and equal to 0.77 $cm^3\ mol^{-1}$ K in the whole temperature range. Identical results have been obtained for the complexes **4** and **5**. These results confirm that the copper ions are well isolated from each other by the alkaline-earth cations and that the bridging nitrato anions are not active. In complex **6**, the decrease of the $\chi_M T$ product is due to weak antiferromagnetic interactions operating at low temperature. These interactions must be intermolecular for the previous complexes **4**, **5** and **8** demonstrate clearly that there is

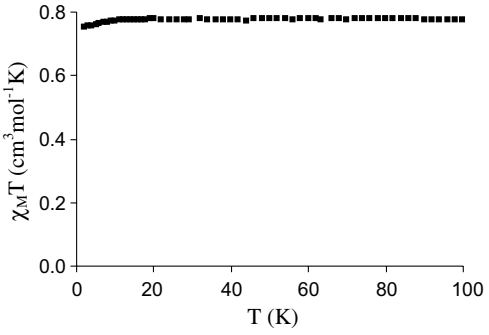

Fig. 4. Thermal dependence of the $\chi_M T$ product for $(L^2Cu)_2$-$Ca(NO_3)_2 \cdot H_2O$ (**8**).

no significant intramolecular magnetic interaction through the alkaline-earth cations. They originate from the presence of perchlorate ions that are not able to bind copper at the axial coordination site: as the copper cations are thus in a square planar environment, intermolecular Cu···Cu interactions through the phenoxo oxygen atoms must be responsible for such a weak interaction. Fitting the magnetic susceptibility data of **6** to the Bleaney–Bowers [23] equation for an exchange coupled pair of $S = 1/2$ spins with a 2J singlet–triplet energy gap yields an estimate of the intermolecular interaction equal to $-0.75\ cm^{-1}$ with $g = 2.05$ and an agreement factor R ($\sum[(\chi_M T)_{obs} - (\chi_M T)_{calc}]^2/\sum[(\chi_M T)_{obs}]^2$) equal to 1×10^{-4} (see Fig. 4).

4. Discussion

We have previously shown that compartmental Schiff base ligands resulting from the reaction of 3-methoxysalicylaldehyde with different diamines may yield discrete heterodinuclear 3d/4f complexes [5,10] with the 3d ion coordinated in the N_2O_2 site and the 4f ion in the O_2O_2 site. Very similar 3d/alkali-metal complexes have also been isolated, with the alkali-metal in the outer O_2O_2 coordination site [3,4]. The isolated complexes are formulated LMM′X or $LMLnX_3$, L standing for the ligand, M for the 3d ion (most often Ni^{2+} and Cu^{2+}), M′ for Na^+, Li^+, K^+, Ln

for the 4f ion and X for the anionic species (most often NO_3^- or ClO_4^-). The presence of methoxy groups in the 3,3′ positions of the Cu–salicylaldimine precursor complexes implies that these building units are potential ligands able to chelate metal ions in the plane of the donor atoms or to sandwich them between two sets of such Cu–salicylaldimine ligands, depending on the size of the M′ or Ln cation. These O_2O_2 compartments can be preformed or can result from self-assembling of the 3d precursor complex in the presence of alkaline or lanthanide ions [4,10]. Another factor that affects the complexing ability is the number of carbon atoms involved in the imine bridge. With a 1,3-propylene bridge, metal ions linked to the outer O_2O_2 site are located in the plane of the four donor atoms while there is a lesser adaptability with a 1,2-ethylene bridge [3]. The third factor influencing the complexation stoichiometry originates from the anions present in the reaction medium. Indeed, these anions can compete with the precursor ligand-complex, depending on their affinity with the introduced metal ion. Concerning the outer O_2O_2 coordination site, it may be considered as a polyether in which a carbon atom spacer ($O–CH_2–CH_2–O$) has been replaced by a metal ion (O–M–O), as in metallacrowns [24]. In addition, the oxygen atoms linked to the metal ion are deprotonated and capable of better bonding than the ether-type oxygen atoms. Because calcium(II) ions have a chemistry closely related to that of lighter lanthanide ions, and are thus easily replaced by lanthanide ions [25], we have studied their reaction with the 3d precursor complexes. The analytical results and the structural determinations demonstrate that the isolated complexes may be formulated as $[(L^2Cu)_2Ca(NO_3)_2]$, with a 2/1 3d/alkaline-earth ratio. This observation is really surprising for the previously studied 3d/alkaline or 3d/lanthanide complexes were characterized by a 1/1 ratio. This result is puzzling if we remember that the ionic radii of sodium, calcium and gadolinium ions span the same range of values, depending on their coordination number [25]. It is also worth noting that the flexibility of the L^2 ligand used in the present case, with its three carbon atoms chain in the diimino fragment [3], is not a factor able to introduce a change in the Cu/Ca ratio. On the contrary, the magnesium ions, with their smaller ionic radius, yield a 1/1 Cu/Mg ratio even with the more rigid L^1 ligand, while the barium ions, with their larger ionic radius, yield a 2/1 ratio in all cases. These data indicate that the ionic radius cannot be considered as the only factor responsible for the stoichiometry of the isolated complexes. In the present case, the results may be explained by the higher affinity of the alkaline-earth for the outer coordination site of the Cu–salicylaldimine precursor complex, a factor which prevails over the chelating power of the nitrato anions, thus yielding 2/1 entities which are not observed under similar experimental conditions in the case of lanthanide ions. In the latter case, the chelating effect of the nitrato anions toward the Ln ions is the most important factor, explaining why the observed 1/1 3d–4f ratio in the presence of nitrato anions is always obtained.

Increasing the number of oxygen atoms involved in the outer coordination site by introducing polyether-like chains does not modify the 3d/alkaline earth ratio, as reported earlier [7]. The only way to change this ratio is to introduce auxiliary ligands with a strong chelating ability, such as diketones. Then discrete species with a 1/1 3d/alkaline earth ratio may be isolated, as demonstrated by the structural determination of the $L^1Cu(MeOH)Ca(thd)_2$ complex **1**. Again the calcium ion is eight-coordinate, with two auxiliary thd ligands substituting one Cu–salicylaldimine building unit. Mass spectra data (FAB^+) confirm the presence of these entities in solution. Peaks corresponding to the $[L^1CuM(thd)]^+$ ions appear at $m/z = 612$ (M = Ca), 660 (M = Sr) and 710 (M = Ba), thus demonstrating that the corresponding complexes are also obtained with larger alkaline-earth ions. Again, the only exception was observed for magnesium which failed to yield such a 1/1 complex.

The magnetic data indicate that the copper ions are magnetically well isolated in the dinuclear (**1**, **2**, **3**, **7**) and trinuclear (**4**, **5**, **8**) entities. The presence of a nitrato anion or a solvent molecule at the apical position of the copper coordination sphere prevents intermolecular interactions. Furthermore, the lack of magnetic interactions through the diamagnetic alkaline-earth cations of the trinuclear species is clearly evidenced by these results. Complex **6** behaves differently. From the magnetic results and UV–Vis data, we can conclude that the copper ions are in a square planar environment, the perchlorate anion being unable to enter the coordination sphere at an axial site, thus favouring intermolecular contacts which are responsible for the slight $\chi_M T$ decrease at low temperature corresponding to weak antiferromagnetic interactions (see Fig. 5).

Up to now, we have not been able to obtain 3d–4f complexes in a 2/1 ratio with symmetrical Schiff base ligands, in presence of nitrato anions. As the 2/1 3d-alkaline-earth complexes are easily obtained, we have tried to use the template effect of the calcium ions to prepare the corresponding 2/1 3d-Ln complexes. It is known for a long time that such a replacement is possible [25]. Unfortunately all our experiments failed to yield the expected 3d–4f complexes, our attempts leading to the isolation of 1/1 3d–4f com-

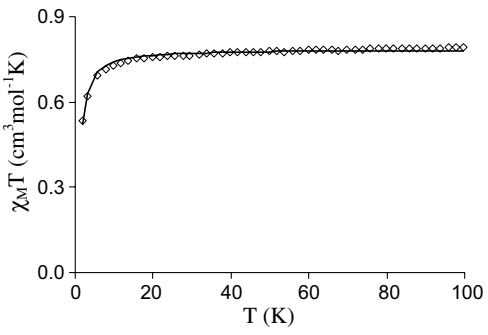

Fig. 5. Thermal dependence of the $\chi_M T$ product for $(L^1Cu)_2Ba(ClO_4)_2$ (**6**). The solid line is the best fit to the Bleaney–Bowers equation, see text.

plexes equivalent to those previously characterized. This result confirms the ready replacement of calcium by lanthanide ions. Unfortunately, the template effect of the calcium ion is not able to give the expected trinuclear 3d–4f–3d entities.

5. Conclusion

It is well known that the lanthanide ionic radii depend on their coordination number and that they span the values of the calcium ionic radii. Furthermore, the Ln ions, which are the chameleons of coordination chemistry, replace with much ease the Ca ions in coordination compounds [25]. The present work demonstrates that this replacement is in fact easy but that it yields complexes with stoichiometries different from those of the starting 3d/Ca compounds. This behaviour is explained by the different affinities of the Ln and Ca ions for the anionic species present in the reaction medium: the tetradentate donor ligand and the nitrato anions. The alkaline-earth affinity for the outer coordination site of the metal–salicylaldimine complex prevails over the chelating power of the nitrato anions while the reverse is true for the lanthanide ions. Using auxiliary ligands such as diketones, which have a strong chelating power, allows to vary the 3d-alkaline earth ratio from 2/1 to 1/1. Playing with these different factors yields a large and rich palette to the synthetic chemist. This work demonstrates that synthesis of a desired complex is not always straightforward. Eventually, the possible variation of the 3d/alkaline-earth ratio gives a supplementary interest to these complexes as single-source precursors for the MOCVD deposition of heterometallic materials.

developed, and the products have potential applications in many diverse areas, including medicine, agents for the extraction of metal ions, supramolecular chemistry and as ligands for metals [20,21]. In view of the situation of the above two types of clusters, it would be very significant to incorporate them into one compound, both for the study of carborane chemistry and Mo(W)–S cluster chemistry. As a part of our study, we turned our interest to the diphosphine carborane-1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$, which is a typical bidentate ligand and has been widely used in transition metal chemistry [22]. Recently, we have successfully introduced this ligand into Mo–Cu–S clusters [23]. In this paper further studies on these types of reactions have been made and five heterobimetallic trinuclear clusters with two different metal skeleton cores which contain the *closo* carborane diphosphine 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$, including their spectroscopy study and crystal structure, are reported.

2. Experimental

2.1. Materials and measurement

All the reactions were carried out under the protection of dry oxygen-free dinitrogen at room temperature. Solvents were dried with appropriate drying agents, distilled under dinitrogen and deoxygenated prior to use. $(NH_4)_2Mo(W)S_4$ and $(NH_4)_2Mo(W)OS_3$ were synthesized according to the literature procedures [24]. 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$ was prepared as described in the literature [25]. All chemicals were purchased and used as received. UV/Visible electronic spectra were recorded on an HP-8453 UV/Visible Spectrophotometer and infrared spectra were recorded in the range 400–4000 cm^{-1} from KBr pellets on a Nicolet-460 FT-IR spectrophotometer. Elemental analysis (C, H) was carried out with a Perkin–Elmer 2400 II elemental analyzer. The ^1H and ^{13}C NMR were recorded on a Varian Mercury 400 spectrometer in $CDCl_3$ solution with tetramethylsilane (TMS) as an internal standard at 400.15 and 100.63 MHz, respectively. The ^{13}C spectra are broadband proton decoupled. The chemical shifts are reported in parts per million with respect to the references and are stated relative to external TMS for ^1H and ^{13}C NMR.

2.2. Synthesis procedures

2.2.1. Synthesis of $Cu_2MS_4[1,2\text{-}(PPh_2)_2\text{-}1,2\text{-}C_2B_{10}H_{10}]_2$ (M = Mo(1), W(3))

To a solution of 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$ (102.4 mg, 0.20 mmol) in 10 ml of CH_2Cl_2 was added CuSCN (12.2 mg, 0.10 mmol) and $(NH_4)_2MoS_4$ (13.0 mg, 0.050 mmol) or $(NH_4)_2WS_4$ (17.4 mg, 0.050 mmol). After the mixture was stirred for 10 h at room temperature under the protection of the dry N_2, the suspension was filtered to remove any insoluble inorganic material. Concentration of the filtrate to 5 ml and followed by addition 20 ml *n*-hexane caused clusters **1** and **3** to precipitate as red solids. Single crystals suitable for X-ray diffraction were grown from a dichloromethane solution layered with *n*-hexane. **1**: 46.8 mg, 68.01%. M.p. 232–233 °C; FT-IR ν_{KBr} (cm^{-1}): 2960s, 2574m, 1636s, 1434m, 1090m, 741m, 472m. ^1H NMR (400.15 MHz, $CDCl_3$, ppm): 7.21–8.11 (phenyl-H); ^{13}C NMR (100.63 MHz, $CDCl_3$, ppm): 128–135 (48C), 77.1 (4C). *Anal.* Calc. for $C_{52}H_{60}B_{20}P_4Cu_2MoS_4$: C, 45.38; H, 4.39. Found: C, 45.30; H, 4.41%. **3**: 33.4 mg, 45.62%. M.p. 265–266 °C, FT-IR ν_{KBr} (cm^{-1}): 2968s, 2564m, 1640s, 1430m, 1095m, 731m, 465m. ^1H NMR (400.15 MHz, $CDCl_3$, ppm): 7.29–8.17 (phenyl-H); ^{13}C NMR (100.63 MHz, $CDCl_3$, ppm): 127–135 (48C), 77.2 (4C). *Anal.* Calc. for $C_{52}H_{60}B_{20}P_4Cu_2WS_4$: C, 42.65; H, 4.13. Found: C, 42.58; H, 4.11%.

2.2.2. Synthesis of $Cu_2MoS_4[1,2\text{-}(PPh_2)_2\text{-}1,2\text{-}C_2B_{10}H_{10}]_2 \cdot CH_2Cl_2$ (2)

A suspension of CuSCN (12.2 mg, 0.10 mmol), $(NH_4)_2MoS_4$ (13.0 mg, 0.050 mmol) and 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$ (102.4 mg, 0.20 mmol) in 10 ml CH_2Cl_2 were refluxed for 5 h under the protection of dry N_2. After being filtered, the filtrate was concentrated to 5 ml, and 20 ml ether was added to precipitate a red solid. Yield: 44.8 mg, 61.32%. FT-IR ν_{KBr} (cm^{-1}): 2975s, 2573m, 1641s, 1433m, 1097m, 739m, 472m. ^1H NMR (400.15 MHz, $CDCl_3$, ppm): 7.24–8.13 (phenyl-H); ^{13}C NMR (100.63 MHz, $CDCl_3$, ppm): 128–135 (48C), 77.1 (4C). *Anal.* Calc. for $C_{53}H_{62}B_{20}P_4Cl_2Cu_2MoS_4$: C, 43.56; H, 4.28. Found: C, 43.51; H, 4.23%.

2.2.3. Synthesis of $Cu_2MOS_3[1,2\text{-}(PPh_2)_2\text{-}1,2\text{-}C_2B_{10}H_{10}]_2$ (M = Mo(4), W(5))

The procedures are similar to those for clusters **1** and **3**, except that $(NH_4)_2MS_4$ was replaced by $(NH_4)_2MoOS_3$ (12.2 mg, 0.050 mmol) or $(NH_4)_2WOS_3$ (16.6 mg, 0.050 mmol). Yields: 26.9 mg, 39.6% and 29.8 mg, 41.2% for clusters **4** and **5**, respectively. M.p. 220–221 °C for **4** and 203–204 °C for **5**. Single crystals for X-ray diffraction were grown from a dichloromethane–ether solution. Cluster **4**: FT-IR ν_{KBr} (cm^{-1}): 2920s, 2568m, 1638s, 1437m, 1107m, 920m, 746m, 470m. ^1H NMR (400.15 MHz, $CDCl_3$, ppm): 7.26–8.19 (phenyl-H); ^{13}C NMR (100.63 MHz, $CDCl_3$, ppm): 127–135 (48C), 77.0 (4C). *Anal.* Calc. for $C_{52}H_{60}B_{20}P_4Cu_2MoOS_3$: C, 45.91; H, 4.45. Found: C, 45.80; H, 4.48%. Cluster **5**: FT-IR ν_{KBr} (cm^{-1}): 2990s, 2569m, 1636s, 1435m, 1090m, 927m, 744m, 459m. ^1H NMR (400.15 MHz, $CDCl_3$, ppm): 7.20–8.23 (phenyl-H); ^{13}C NMR (100.63 MHz, $CDCl_3$, ppm): 128–135 (48C), 77.3 (4C). *Anal.* Calc. for $C_{52}H_{60}B_{20}P_4Cu_2WOS_3$: C, 43.12; H, 4.18. Found: C, 42.89; H, 4.23%.

2.3. X-ray structure determination

The collection of crystallographic data for all the clusters was carried out on a Bruker Smart-1000 CCD diffractometer, using graphite-monochromatized Mo Kα (λ = 0.71073 Å) at 298(2) K. The structures were solved by

direct methods and expanded using Fourier difference techniques with the SHELXTL-97 program package [26]. The non-hydrogen atoms were refined anisotropically by full-matrix least-squares calculations on F^2. All the H atoms were located in a difference Fourier map and thereafter refined isotropically. Details of the crystal parameters, data collection and refinement are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

Clusters constructed from thiomolybdates and thiotungstates with other transition metal ions have been extensively studied not only because of the possible relevance to the Mo–Cu biological antagonism, but also for their potential applications as materials with non-linear physical properties [27]. Many these types clusters with various nuclearity and different skeleton cores have been synthesized either by reactions carried out in solution or by solid-state reactions under comparable low temperatures [13,28]. Some terminal ligands in these Mo(W)–Cu–S clusters, such as Cl^-, Br^-, I^- and SCN^-, are only loosely bound. By substitution of these weak ligands with strong ones, such as PhS^- and neutral PPh_3 [29], many new clusters can be afforded. The *closo* carborane diphosphine 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$, which can form a five-member chelating ring between the ligand and a metal, is a good bidentate ligand and has an outstanding chelating ability to the metal. With these two points in mind, we tentatively introduced this moiety into Mo(W)–Cu–S clusters.

To start with, we carried out the reaction with a reactant ratio of Cu(I) to 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$ of 1:1 (according to the stoichiometric proportion from the clusters obtained by using PPh_3 to substitute the terminal ligand), but no SCN^- was found to be substituted by the *closo* carborane diphosphine ligand. Then, we tentatively changed the reactant ratio. Under the protection of dry N_2, on reaction of CuSCN, $(NH_4)_2MoS_4$ and the *closo* diphosphine 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$, with a ratio of 2:1:4 in CH_2Cl_2

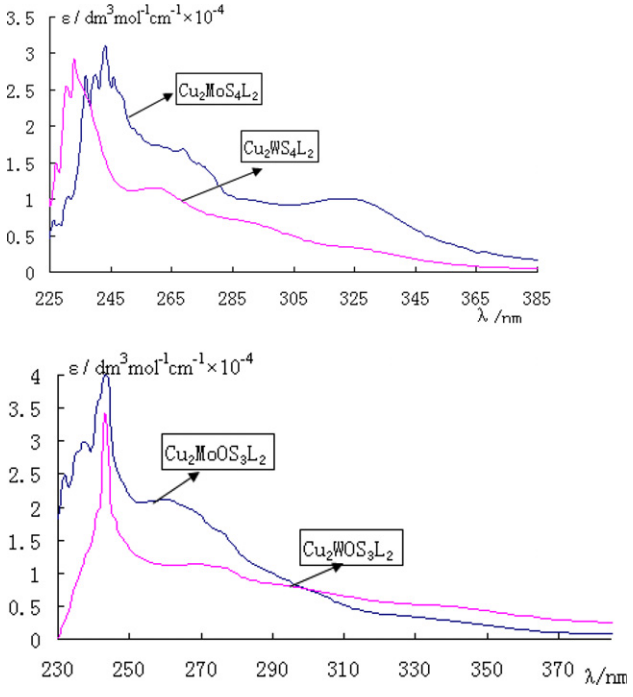
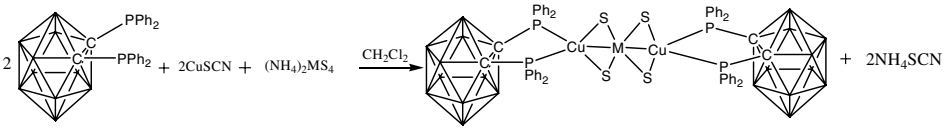
under stirring conditions at room temperature, we obtained a heterobimetallic cluster containing the Cu_2Mo core, in which the three metal atoms were almost in a linear conformation and the diphosphine ligand was introduced into the cluster. This result indicated that to substitute the terminal SCN^- anion with the neutral diphosphine ligand, the ligand must be in excess. Subsequently, a similar experiment was carried out and cluster **3** was afforded. To investigate if the result of the reaction could be affected by the temperature, we carried out the reaction of CuSCN, $(NH_4)_2MoS_4$ and the ligand in CH_2Cl_2 with the ratio 2:1:4 under refluxing conditions. A cluster with a similar structure to cluster **1** was obtained. According to the crystal data listed in Table 1, the structures of these two clusters are not isostructural because of the different crystal system, space group and the solvent molecule in cluster **2**. The reactions are given in Scheme 1.

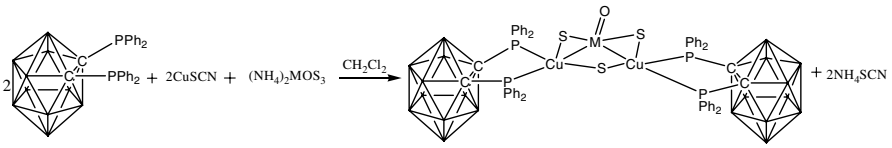


Accordingly, further experiments were carried out under the same conditions. After stirring the mixture of CuSCN, $(NH_4)_2MoOS_3$ or $(NH_4)_2WOS_3$ and 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$ for 8–10 h, clusters **4** and **5** were obtained. These two clusters also contain a heterobimetallic $Cu_2Mo(W)$ core, but the difference between them and the above three clusters is that the skeleton of these two clusters is a butterfly-shaped conformation rather than a linear one. These two reactions are shown in Scheme 2.



3.2. Spectral characterization

All these clusters were characterized by FT-IR, UV/Visible, ^1H and ^{13}C NMR spectroscopy. The IR spectra of these clusters have many similarity to each other and exhibit absorptions characteristic of terminal B–H vibrations from 2574 to 2564 cm^{-1}, which are in the normal range of B–H vibrations from 2625 to 2450 cm^{-1} [30]. The absorption at ca. 2970 cm^{-1} may be attributed to the ν_{C-H} stretching vibration of the benzene rings. The peaks at 470 and 920 cm^{-1} are the vibrations of M–S and Mo=O, respectively. The ^1H NMR spectra (400.15 MHz) of these clusters displayed a cluster pattern of resonances at about 7.2–8.2 ppm that can be attributed to phenyl-H of the PPh_2 groups. In the ^{13}C NMR spectra (100.63 MHz), the resonance at ca. $\delta = 127$–135 ppm can be assigned to the benzene ring C atoms, and that at ca. $\delta = 77.0$ can be assigned to the carbon atom of the carborane cage [31].



3.3. Electronic spectra

Fig. 1 depicts the UV/Visible absorption spectra of the four clusters. Comparable to the three intense bands in the 210–700 nm region exhibited by free MoS_4^{2-} or WS_4^{2-} [13], the formation of the trinuclear clusters from MoS_4^{2-} or WS_4^{2-} cause some changes in the intensity and location of the bands. These changes of the absorption bands of MoS_4^{2-} or WS_4^{2-} upon formation of these clusters probably arises from the interaction between the tetrathiometallate and the [Cu(1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$)] moieties (such interactions should disturb the molecular orbitals of the tetrathiometallates). For $Cu_2MS_4L_2$ (L = 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$), their electronic spectra retain the three bands of the free tetrathiometallates, but obvious changes in the intensities and locations have been taken place. These absorptions are at about 242, 270, 325 nm, which are different from the location of 242, 317, 467 nm for MoS_4^{2-} and 216,277, 392 nm for WS_4^{2-} [13], especially for the ν_3 band. We also noticed that these two clusters exhibit several poorly resolved shoulders, which could be assigned to p(P) →d(Mo) transitions [32]. For $Cu_2MOS_3L_2$, their electronic spectra are very similar to each other, in which only two typical absorption bands could be found. The locations for the two absorption bands in the two clusters (ca. 240 and 270 nm) are basically consistent with the two bands for the free MOS_3^{2-}. However, on comparison to the absorption of the free trithiometallates, the other two bands at about 460, 390 nm for $MoOS_3^{2-}$ and 330, 370 nm for WOS_3^{2-} disappeared.

Scheme 1. The reaction for the preparation of clusters **1**–**3** (M = Mo (**1**, **2**); M = W (**3**)).

Scheme 2. The reactions for the preparation of the clusters **4** and **5** (M = Mo (**4**); M = W (**5**)).

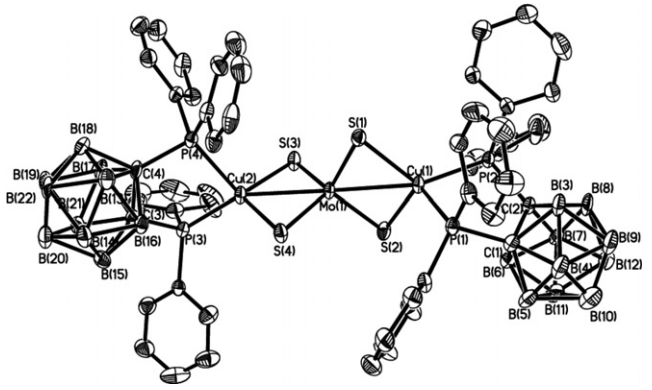


Fig. 1. The molecular structure of cluster **1**. The H atoms are omitted for clarity.

4. Crystal structure

The molecular structures of clusters **1** and **2** are shown in Figs. 1 and 2, respectively. Selected bond lengths and angles for clusters **1**–**3** are given in Table 2. The clusters **1** and **3** crystallize in the monoclinic space group $C2/c$, while cluster **2** crystallizes in the triclinic space group $P\bar{1}$. In clusters **1** and **3**, MS_4^{2-} (M = Mo, W), as a tetradentate ligand, is coordinated to two Cu atoms at the same time, in which an almost linear arrangement between the three metal atoms is formed with Cu–M–Cu–Cu (M = Mo, W) angles of 172.10(5)° and 172.06(5)°, respectively. The geometry at the central M atom is a distorted tetrahedron formed by two pairs of bridged-S atoms, in which the dihedral angle between the two MSSCu planes is about 90°.

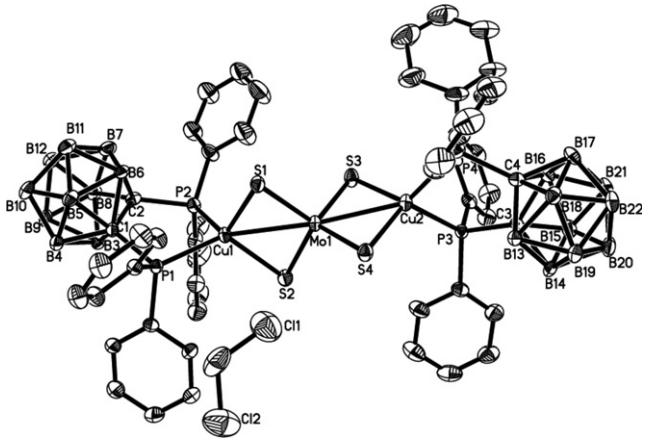

Fig. 2. The asymmetric unit consisting of a trinuclear cluster and a solvate molecule of cluster **2**. The H atoms are omitted for clarity.

The average distances of Mo–Cu and W–Cu are 2.708 and 2.7422 Å, respectively, which are in agreement with the corresponding bond lengths of 2.687 Å in $[^nBu_4N]_4[Mo_4Cu_{10}S_{16}O_3]\cdot H_2O$ and 2.748 Å in $[Et_4N]_4[Cu_4W_4S_{12}O_4]$ [33,34]. The M–S bond lengths listed in Table 2 are also consistent with the corresponding distances in other linear M–Cu–S clusters [35,36]. For each Cu atom, the coordination sphere is a distorted tetrahedron with angles varying between 89.80(9)° and 124.32(11)° in cluster **1**, 90.30(11)° and 124.65(12)° in cluster **3**, in which two positions result from two bridged-S atoms, and the other two are occupied by the *closo* carborane diphosphine 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$. A similar coordination mode can also be found in Cu complexes containing other diphosphinocarborane ligands [37]. The P–Cu bond lengths, as listed in Table 2, are comparable to the average distance of 2.265 Å in $[Cu(PPh_3)\{7,8\text{-}(PPh_2)_2\text{-}7,8\text{-}C_2B_9H_{10}\}]\cdot Me_2CO$ [38] and 2.254 Å in $[Cu_2(\mu\text{-}Cl)_2(1,2\text{-}(PPh2)2\text{-}1,2\text{-}C_2B_{10}H_{10})_2]\cdot 2CH_2Cl_2$ [39], and this is also the case for the P–Cu–P angle, with the value being very close to 90°. On comparison of other parameters of the 1,2-$(PPh_2)_2$-1,2-$C_2B_{10}H_{10}$ moiety in these clusters and the free ligand [40], such as the P–Cc (Cc is the carbon atom of the carborane), Cc–Cc and the P–Cc–Cc angles, no noticeable differences have been found.

Fig. 3 shows the crystal structure of cluster **4**, and selective bond lengths and angles for clusters **4** and **5** are also listed in the Table 2. These two clusters crystallized in the monoclinic space group $P2(1)/c$, and have similar structures which could be characterized as a butterfly-shaped conformation. This structural conformation may also be regarded as defective cubane-like with two corners missing. Within the structures of the two clusters there is an approximate molecular mirror plane passing through the O(1), M(1) and S(1) atoms. The coordination sphere of the M atom is a distorted tetrahedron formed by three bridging S atoms and one terminal O atom. The distances between the terminal O atom and the M atom are 1.671(7) and 1.765(9) Å, respectively, The corresponding distances are 1.715(7) Å in $[MoCu_3OS_3(PPh_3)_3(CH_3COO)]$ and 1.693(8) Å in $[Cu_3WOS_3CN(py)_4]_n$ [41,42]. The three M–(μ-S) bond lengths are not equivalent, with the common feature that the M–S(1) bond length is slightly longer than the other two M–S bond lengths. The average Cu–Mo bond length of 2.722 Å in cluster **4** is almost equal to that of 2.710 Å in $[MoCu_3OS_3(PPh_3)_3(CH_3COO)]$, while the average Cu–W bond length of 2.7985 Å in **5** is slightly longer than that of 2.719 Å in $[Cu_3WOS_3CN(py)_4]_n$. The Cu–Mo–Cu angle of 91.80(6)° is obviously bigger than that of 81.56(4)° in

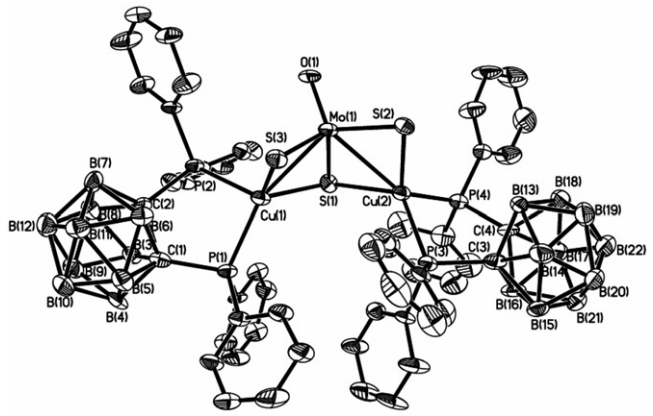

Fig. 3. The molecular structure of cluster **4**. The H atoms are omitted for clarity.

$[MoCu_3OS_3(PPh_3)_3(CH_3COO)]$, characterized as cube-like, while the value of the Cu–W–Cu angle of 92.46(8)° agrees well with the average value of 91.76° in the above W–Cu–S cluster polymer. The ranges of Cu–S bond lengths are 2.272(3) to 2.306(3) Å for **4** and 2.332(4) to 2.378(4) for **5**, which are consistent with the corresponding ranges in the above two clusters. Similar to that in clusters **1** and **3**; the coordination geometry of the two Cu atoms should also be described as distorted tetrahedral. The Cu–P distances are in the narrow range 2.226(3) to 2.397(4) Å, which is comparable to the corresponding distance 2.255 Å in $[Cu_2(\mu\text{-}Cl)_2(1,2\text{-}(PPh_2)_2\text{-}1,2\text{-}C_2B_{10}H_{10})_2]\cdot 2CH_2Cl_2$. The two P–Cu–P angles in the two clusters are 90.29(11)° and 90.59(15)°, respectively, and in the above complex it is 93.63(8)°.

5. Conclusion

In summary, we have studied the reactions of the *closo* carboranylphosphine $1,2\text{-}(PPh_2)_2\text{-}1,2\text{-}C_2B_{10}H_{10}$, MS_4^{2-} (MOS_3^{2-}) and the d^{10} metal ion Cu(I). The carborane skeleton was connected to the Mo(W)–Cu–S clusters through its two phosphorus atoms, and five heterobimetallic trinuclear clusters containing the above ligand were obtained, in which the metal skeleton could be classified into two types. With MS_4^{2-} as a starting material, the metal skeleton is in a linear conformation, while with MOS_3^{2-} it is butterfly-shaped.

6. Supplementary material

CCDC 607841, 607836, 607842, 607838 and 607837 contain the supplementary crystallographic data for **1**, **2**, **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

purchased from Sigma-Aldrich Chemical Co. All ligands were used without further purification and their purity was greater than 99%. The exact concentrations of the ligand solutions used for potentiometric measurements were determined by the Gran method [7]. Copper(II) chloride solution was purchased from Merck as a Titrisol concentrate for the preparation of standard solutions. The concentration of metal ion stock solution was standardized by complexometric ethylenediaminetetraacetate (EDTA) titration. Carbonate-free potassium hydroxide solution (the titrant) was prepared and standardized against a standard potassium hydrogen phthalate solution. All solutions were prepared with deionized water. The formulae of the fully protonated form of the ligands used in this study are shown in Scheme 1.

2.2. Potentiometric measurements

The stability constants of the proton and copper(II) complexes were determined by pH-metric titration of 5 cm^3 samples in aqueous solutions. All the measurements were carried out at 0.2 mol dm^{-3} ionic strength (KCl) and 25.0 ± 0.1 °C using a constant-temperature water-bath. The titrations were performed with carbonate-free KOH solution of known concentration (ca. 0.2 mol dm^{-3}) under argon atmosphere over the pH range 2.0–11.0. The data for the Cu^{2+}-en, Cu^{2+}-Metha and Cu^{2+}-Hisha binary system were reported previously [1,3]. For the ternary systems the ratios of copper(II):en:Metha/Hisha were 1:1:1, 1:1:2, 1:2:1 and 1:2:2. Titrations were made on samples containing the copper(II) ion at 4×10^{-3} mol dm^{-3}. Number of titration curves per copper(II)-en-Metha/Hisha systems was 6–8.

Scheme 1. Ligands ethylenediamine $[H_2\text{-en}]^{2+}$ histidinehydroxamic acid $[H_3\text{-Hisha}]^{2+}$methioninehydroxamic acid $[H_2\text{-Metha}]^{+}$.

The pH-metric titrations were performed with a Radelkis Op-208/1 instrument equipped with a combination pH electrode (SINGLE PORE, Hamilton) using an ABU-80 autoburette (Radiometer).The electrode system was calibrated by periodic titrations of HCl solution (1×10^{-2} mol dm^{-3} in KCl) against standard KOH solution. The resulting titration data were used to calculate the standard electrode potentials, E^0, and the dissociation constant for water ($pK_w = 13.73$). These values were then used to calculate the hydrogen ion concentration $[H^+]$ from emf readings [8]. The pH-metric results were used to establish the stoichiometry of the species and to calculate the stability constants of the species formed $\beta_{pqrs} = [M_p(en)_qL_rH_s]/[M]^p[en]^q[L]^r[H]^s$ in the ternary systems. Calculations were performed with the aid of the HYPERQUAD 2006 computer program [9]. The reported standard deviations were calculated by assuming random errors.

The charges of the complexes have been omitted in the text and tables. However, for clarity, it should be mentioned here that the fully deprotonated form of aminohydroxamic acids (Metha and Hisha) is L^- while the amine (en) is neutral.

3. UV/Vis spectroscopy

The electronic absorption spectra in the visible range were obtained on a BECKMAN DU68 spectrophotometer using 2-cm quartz cells at room temperature. The spectra were recorded digitally (0.5 nm step) over the range 400–900 nm. The metal ion concentration was 4×10^{-3} mol dm^{-3}. For the systems copper(II):en:Metha/Hisha the concentration ratio was 1:1:2.

Even at the pH value where the distribution of the species has a maximum, the other complexes coexist in a greater or a smaller extent. Therefore, in the absorption spectra measured at this pH the contributions from the other species should be included to extract the net ligand-field absorption band of each mixed-ligand species. Hence, the spectrum measured at a pH value where each of these species exhibits maximal contribution was resolved into the components corresponding to the individual species existing at that pH (as described in Ref.[2]). The molar absorptivity for the individual species was then calculated taking into account their distribution.

4. EPR spectroscopy

Electron paramagnetic resonance (EPR) spectra were performed on a Bruker 300E X-band spectrophotometer equipped with a Bruker NMR gaussmeter ER 035 M and a Hewlett-Packard frequency counter HP 5350B at 77 K in water/ethylene glycol (4:1 v/v) solution. The EPR parameters were calculated by computer simulation of the experimental spectra using Bruker's WIN-EPR SIMFONIA Software Version 1.25. The metal ion concentration was 4×10^{-3} mol dm^{-3} and the metal ion to ligands molar ratios was 1:2:2.

5. Results and discussion

The values of the protonation constants for ethylenediamine are $\log \beta_1^H = 9.95(1)$, $\log \beta_2^H = 17.13(1)$. The respective values for Metha and Hisha were determined previously [3]. The detailed discussion about the acid–base properties of these ligands can be found in our early paper [3].

The equilibrium models for the studied ternary systems and corresponding stability constants giving the best fits of the pH-metric titration curves are presented in Table 1. It can be seen that, mixed-ligand complexes with stoichiometry $[Cu(en)L]^+$ are formed in both ternary systems.

Different methods are known to estimate the formation of mixed-ligand complexes. It is possible to calculate the log X_{MAB} values for all systems (the constant due to the equilibrium $[MA_2] + [MB_2] \rightleftharpoons 2[MAB]$, Table 1, row 5). These values are higher than that expected on a statistical basis (0.6) [10], indicating that the formation of mixed complexes is favoured in these systems.

In most cases the relative stability of the mixed-ligand species [MAB] is expressed in terms of $\Delta \log K$ parameter (the constant due to the equilibrium $[MA] + [MB] \rightleftharpoons [MAB] + M$). The statistical value of $\Delta \log K$ depends on the geometry of the complex and for the distorted octahedral coordination sphere of Cu^{2+} with two different bidentate ligands was deduced as -0.9 [11,12]. It can be seen that, the $\Delta \log K$ value for the $[Cu(en)Metha]^+$ species is -1.16. For the $[Cu(en)Hisha]^+$ mixed-ligand species the $\Delta \log K$ value cannot be calculated, since the complex with 1:1 ratio is not formed in the Cu^{2+}-Hisha binary system [3].

Concentration distribution curves for the Cu^{2+}-en-Metha and Cu^{2+}-en-Hisha system are shown in Figs. 1 and 2, respectively.

Evaluation of the experimental pH-metric data on Cu^{2+}-en-Metha/Hisha systems demonstrate that the formation of mixed-ligand species is preceded mainly by the appearance of simple and polynuclear complexes with

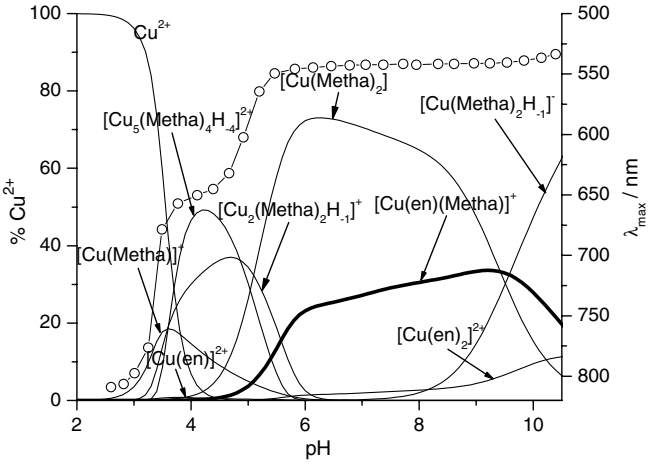

Fig. 1. Species distribution curves as a function of pH and variations of visible absorption maximum wavelength (circle) for Cu^{2+}–en-Metha ternary system at 1:1:2 molar ratio; $c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}.

Metha or Hisha ligand (Figs. 1 and 2). In the Cu^{2+}-en-Metha system with 1:1:2 molar ratio the only mixed-ligand complex $(Cu(en)[Metha])^+$ is seen above pH 5 and reaches maximum concentration of ca. 35% in pH range 8.5–9.5, whereas in the Cu^{2+}-en-Hisha system the analogous mixed ligand species is formed just above pH 6 and has the maximum concentration in the pH range 9–9.5 (~32%). Additional information on the structure of the simple and mixed-ligand complexes may be gained from the analysis of their spectroscopic data. The formation of the mixed-ligand complexes $[Cu(en)(Metha)]^+$ and $[Cu(en)(Hisha)]^+$ does not generate significant changes in the absorption spectra if compared with the spectra of the binary systems.

The distribution-corrected absorption spectra for the mixed-ligand species exhibit a band with a maximum at 547 nm ($\varepsilon \sim 93.5$ dm^3 mol^{-1} cm^{-1}) and 552 nm ($\varepsilon \sim 87$ dm^3 mol^{-1} cm^{-1}) for $[Cu(en)(Metha)]^+$ and $[Cu(en)(Hisha)]^+$, respectively. The energy of this d–d transition

Table 1
Cumulative formation constants (log β), derived equilibrium constants (log K) and characteristic parameters for the stability of complexes formed in the ternary systems Cu^{2+}–ethylenediamine (en)–L (L = aminohydroxamic acids (Metha and Hisha)) – at 25 °C and $I = 0.2$ mol dm^{-3} (KCl)

No.	Assignments	System

8	Total number of titration points	295	235

Charges are omitted for simplicity.
[a] $\log K_{Cu(en)L} = \log \beta_{Cu(en)\ L} - \log \beta_{Cu(en)}$.

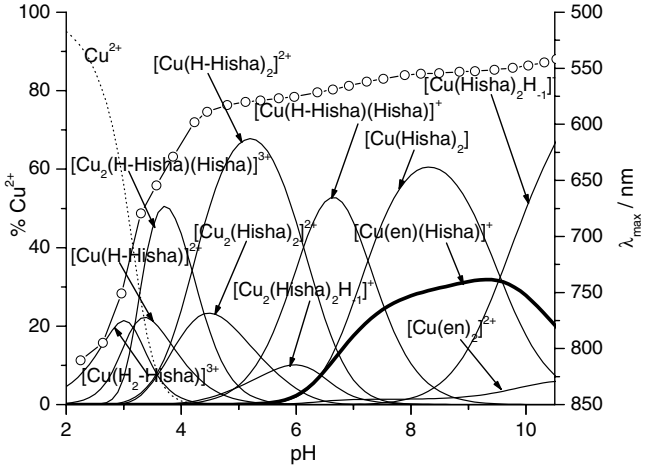

Fig. 2. Species distribution curves as a function of pH and variations of visible absorption maximum wavelength (circle) for Cu^{2+}–en-Hisha ternary system at 1:1:2 molar ratio; $c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}.

is similar to the energies of the d–d transitions of $[Cu(en)_2]^{2+}$ ($\lambda_{max} = 549$ nm), $[Cu(Metha)_2]^{+}$ ($\lambda_{max} = 543$ nm) and $[Cu(Hisha)_2]^{+}$ ($\lambda_{max} = 553$ nm) species with four nitrogen donor atoms in the equatorial position of the metal site [3].

The EPR parameters of the spectra observed in pH range 3.0–6.0 for the ternary Cu^{2+}-en-Hisha system are almost identical with those observed for the binary Cu^{2+}-Hisha, i.e. in this pH range the same species are formed (Fig. 1, Table 2). However, the spectra at pH between 8.4 and 10.0 for liquid and frozen solution show a small but detectable change in g_{iso} and A_{iso} as well as g_z and A_z parameters, in general a little increase in relation to those observed for the Cu^{2+}-Hisha system. These parameters differ significantly from those observed for the Cu^{2+}-en system at pH 9.2. These EPR results support the formation of mixed-ligand species in basic solution with 4N coordination in the copper(II) equatorial plane ($g_z = 2.200$ and $A_z = 204 \times 10^{-4}$ cm^{-1}, Table 2). So, it can be concluded on the basis of the EPR and the absorption spectra studies that the coordination in the mixed-ligand species formed in the studied ternary system is probably realised by amine nitrogens of en (NH_2, NH_2) and both amine and hydroxamic nitrogens of Hisha (NH_2,N_{ha}) in the equatorial plane with two five-membered chelate rings. Similarly, the comparison of the EPR spectra for the binary and ternary system with Metha allow to detect the formation process of the $[Cu(en)(Metha)]^{+}$ species above pH 5.5 with 4N coordination around copper(II).

It is interesting to compare the above mentioned results with those studied previously for the ternary system of Cu^{2+}-diethylenetriamine (dien) – Metha/Hisha [3]. It was reported that the presence of dien suppresses the formation of parent polynuclear species in the ternary systems and leads to the formation of protonated mixed-ligand species apart from $[Cu(dien)(Metha)]^{+}$ and $[Cu(dien)(Hisha)]^{+}$. In the studied Cu^{2+}–en-Metha/Hisha ternary systems parent polynuclear species still exist up to pH 6.

Furthermore, the formation of mixed-ligand species in the ternary system with tridentate dien, instead of en, is accompanied by a distinct spectral change. The red shift of the d–d absorption band going from the simple to mixed-ligand species was assigned to the transition from a six to a five-co-ordination geometry [3].

Table 2
EPR parameters of the complexes formed in the binary and ternary systems

Systems	pH	g_{iso}	A_{iso}	g_z	g_x	g_y	A_z	A_x	A_y

	10.2–11.5	2.097	85	2.191	2.045	2.045	206	19	19

The anisotropic and isotropic parameters are estimated on the basis of computer simulation of the experimental spectra measured at 77 K and 295 K, respectively. Parameters A are given in [10^{-4} cm^{-1}]. The parameters in the parentheses correspond to the species existing in an apparently smaller contribution.

It is worthwhile to compare the values of basicity-adjusted stability constants, $\log K_{Cu(en)L} - pK_{NH_3^+} - pK_{CONHOH}$, which take into account the difference in basicity of the coordinating donor groups of ligand L (L = Metha/Hisha/α-Alaha). The resulting values −6.50, −6.41 and −6.86 [13] for $[Cu(en)(Metha)]^+$, $[Cu(en)(Hisha)]^+$ and $[Cu(en)(\alpha\text{-Alaha})]^+$, respectively (Table 1) show that the relative stabilities of complexes with Metha or Hisha are about 0.4 order of magnitude higher than with α-Alaha. This stabilizing effect may derive from weak interactions between thioether sulfur of Metha or imidazole ring of Hisha and metal ion.

6. Conclusion

In the copper(II)-en-Metha or Hisha systems, the potentiometric, VIS and EPR results suggest the formation of mixed-ligand species in basic solution with 4N coordination – both amine and hydroxamic nitrogens of Metha or Hisha (NH_2, N_{ha}) and two amine nitrogens of en ($2 \times NH_2$) in the equatorial plane. The relative stabilities of complex with Metha or Hisha reveal weak interactions between thioether sulfur of Metha or imidazole ring of Hisha and copper(II) ion.

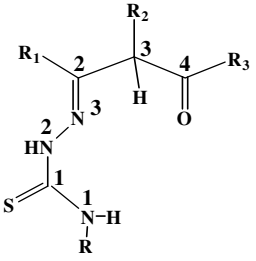
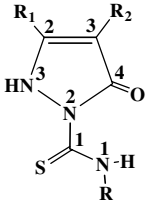
symmetrical spatial distribution of ligand-metal bonds. The greater length of Pb–donor distances on the SALP side of hemidirected Pb(II) centres, which is usually attributed to repulsion between the SALP and the electron pairs of the donor atoms, is sometimes so marked that the existence of a real bonding interaction is questionable [7].



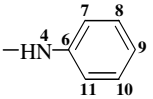
An interesting aspect of lead(II) SALPs is the possibility of their enabling the metal centre to act as a Lewis base, as tin(II) does in some of its complexes [8]. Interactions of this kind could be considered as non-conventional bonds [9]. Their existence has been hypothesized in the case of some short Pb···H [10], Pb···aromatic ring [11] and Pb···Pb [12] contacts, but the evidence has mostly been inconclusive.

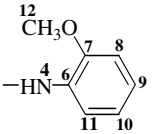
New light is thrown on the above issues by the structures of certain complexes of Pb(II) with 5-pyrazolones resulting from metal-induced cyclization of thiosemicarbazones [13]. In this paper we report the synthesis of these and other Pb(II) complexes, with ligands derived from β-keto esters and β-keto amides (Scheme 1).

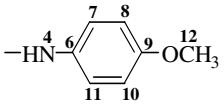


2. Experimental

2.1. Physical measurements







Elemental analyses were performed on a Fisons Instruments EA1108CHNS-O microanalyser. Melting points (mp) were determined with a Büchi apparatus. The electrospray mass spectra of the complexes were recorded on a Hewlett–Packard model LC-MSD 1100 instrument (positive ion mode, 98:2 MeOH/HCOOH as mobile phase, 20–100 V). IR spectra were recorded from KBr discs on a Bruker IFS66V FT-IR spectrometer and are reported in cm^{-1}. The ^{1}H and ^{13}C NMR spectra of DMSO solutions were recorded on Bruker WM-250, AMX-300 or AMX-500 instruments; chemical shifts are expressed on the δ

Scheme 1.

scale (downfield shifts positive) relative to tetramethylsilane. All physical measurements were carried out in the RIAIDT services of the University of Santiago de Compostela.

2.2. Materials

Thiosemicarbazide (Merck), N^1-ethylthiosemicarbazide (Merck), methyl acetoacetate (Aldrich), ethyl benzoylacetate (Aldrich), methyl 4-methoxyacetoacetate (Aldrich), methyl propionoylacetate (Aldrich), ethyl 2-methylacetoacetate (Aldrich), ethyl 2-ethylacetoacetate (Aldrich), acetoacetanilide (Merck), *o*-acetoacetanisidide (Aldrich), *p*-acetoacetanisidide (Aldrich) and lead(II) acetate trihydrate (Probus) were used as received.

2.3. Synthesis of ligands

The thiosemicarbazones derived from β-ketoesters and β-ketoamides (HTSC^n, $n = 1$–10; see Scheme 1) were prepared as per Jayasree and Aravindakshan [14]. Their physical and analytical properties, and those of the pyrazolonates HL^n that were derived from them by cyclization, have been reported elsewhere [13]. Crystals of HTSC^6, HTSC^7, HL^6 and HL^7 that were suitable for X-ray studies were obtained from the mother liquors.

2.4. Syntheses of complexes

General procedure. A solution of $Pb(OAc)_2$ in methanol was mixed in 1:2 or 1:1 mole ratio with a solution or suspension of the thiosemicarbazone ligand in the same solvent. The mixture was stirred for 6 h at room temperature or under reflux. The experimental conditions and the complexes obtained are summarized in Table 1. All these reactions are described in detail in the supporting information.

Analytical, physical and spectroscopic data of the complexes isolated are as follows.

[Pb(L^1)$_2$]. Colour yellow. Yield: 80 mg (64%). M.p.: 171 °C. *Anal.* Calc. for $C_{10}H_{12}N_6O_2S_2Pb$ (519.56): C, 23.12; H, 2.33; N, 16.18; S, 12.34%. Found: C, 22.98; H, 2.38; N, 17.08; S, 11.83%. MS (ESI$^+$): *m/z* 332 [M−{(L^1)+CH$_3$+NH$_3$}], 304 [M−{(L^1)+(C(S)NH$_2$)}]. [a] Also obtained when the reaction mixture was refluxed for 6 h.
[b] Also obtained when the reaction mixture was refluxed for 6 h, for both 1:1 and 1:2 M:L ratios.
[c] Obtained under all M:L and temperature conditions.
[d] The same results were obtained refluxing a 1:1 M:L mixture for 6 h.
[e] Also obtained with a 1:1 M:L ratio at room temperature and a 1:2 ratio under reflux.
[f] Also obtained with a 1:1 M:L ratio, both at room temperature and under reflux.
[g] Also obtained with a 1:2 M:L ratio under reflux.
[h] With a 1:1 M:L ratio under reflux, and with a 1:2 M:L ratio under reflux or at r.t., unidentified products were obtained.

The compounds for which crystals suitable for X-ray diffractometry were obtained were $[Pb(L^6)_2]\cdot 0.5H_2O\cdot 0.3MeOH$, isolated as the second harvest of crystals from the mother liquor of the reaction of $Pb(OAc)_2$ with HTSC^6 in 1:1 mole ratio under reflux; and $[Pb(L^7)_2]$, obtained as a second crystal harvest from the mother liquor of the reaction of $Pb(OAc)_2$ with HTSC^7 in 1:2 mole ratio at room temperature.

2.5. X-ray crystallography

Crystal data were collected at room temperature (HL^6) or low temperature (all others) on an Enraf–Nonius CAD-4 (RIAIDT, University of Santiago de Compostela) or an Enraf–Nonius Kappa CCD (Sao Carlos Institute of Physics, University of Sao Paulo). The data were corrected for absorption by multi-scan [15] or psi-scan [16]. Structures were solved using direct methods for the ligands and the Patterson method for the complexes, followed by normal difference Fourier techniques. All hydrogen atoms were included at ideal geometrical positions. The program used was SHELX97 [17]. Molecular graphics were obtained with ORTEP [18], PLATON [19] and MERCURY [20]. Crystal and refinement data are listed in Table 2. Selected bond lengths and angles are listed in Table 3 (for HTSC^6, HTSC^7, HL^{6}and HL^7) and Table 4 (for $[Pb(L^6)_2]\cdot 0.5H_2O\cdot 0.3MeOH$ and $[Pb(L^7)_2]$). Hydrogen bond lengths and angles are listed in Table S1.

2.6. Computational details

Single-point density functional theory (DFT) calculations were performed using the Gaussian 03 package [21] on three structures modelling fragments of [Pb(L^6)$_2$] · 0.5H$_2$O · 0.3MeOH. Structure A consisted of three type 1 molecules arranged as depicted in Fig. 4a; structure B of one type 2 molecule sandwiched between two type 3

molecules; and structure C of one type 3 molecule between two type 2 molecules, as shown in Fig. 4b. All the geometries were taken from the crystallographic data. The exchange/correlation functional was B3LYP, which combines Becke's three-parameter nonlocal hybrid exchange potential [22] with the nonlocal correlation functional of Lee, Yang, and Parr [23]. The standard 6-31+G(d,p) basis set was employed for all atoms except Pb, for which the LanL2DZ effective core potential basis function [24] was used. In addition, the program AIMPAC [25] was used to analyse the DFT electron densities by means of quantum theory of atoms in molecules (QTAIM) [26] in order to assess the strength of Pb–N, Pb–S and possible Pb–Pb bonds. QTAIM identifies the critical point of minimum electron density on the bond path between mutually bonded atoms. The use of effective core potentials instead of all-electron basis sets for this purpose has been reported to afford acceptable results [27].

3. Results and discussion

3.1. Synthesis and physical properties of the complexes

All the ligands reacted with lead(II) acetate in methanol, the products being in some cases thiosemicarbazonates and in others complexes with a deprotonated pyrazolone derivative formed *in situ* by cyclization of the starting ligand. Also, the acetate was in some cases fully displaced from the coordination sphere of the metal, and in others only partially. Usually, but not always, complete displacement occurred in reactions with 1:2 M:L mole ratio, which sometimes allowed sequential isolation of both heteroleptic and homoleptic complexes (see Table 1). Thus the stoichiometry of the complexes isolated was influenced not only by the metal:ligand mole ratio used in the synthesis, but also by some more elusive factor, possibly solubility differences between the complexes.

HTSCs derived from β-ketoesters afforded hetero- or homoleptic pyrazolonates, both at room temperature and under reflux (Scheme 2). By contrast, two of the HTSCs derived from β-ketoamides, HTSC[9] and HTSC[10], gave thiosemicarbazonates, suggesting that this kind of thiosemicarbazone is less prone to cyclization.

Most of the complexes obtained in this work are coloured solids that are stable in air and decompose at temperatures of 146–232 °C. The $[Pb(L^n)_2]$ and $[Pb(OAc)(L^n)]$ complexes are soluble in methanol, ethanol, acetone, DMSO and DMF, but insoluble in water. $[Pb(TSC^{10})_2]$ is soluble in DMSO and DMF but only poorly soluble in the other solvents, and $[Pb(TSC^9)_2]$ is insoluble in all the above solvents, among others.

Scheme 2.

3.2. X-ray studies

3.2.1. Ligands

Fig. 1 shows the molecular structures of HTSC[6] and HTSC[7] together with the numbering schemes used. The asymmetric unit of HTSC[6] comprises two independent molecules, 1 and 2. Both ligands adopt *E* configuration around the C(2)–N(3) bond and place the sulphur atom *trans* to N(3), so allowing the formation of the intramolecular hydrogen bond N(1)–H(1)···N(3) (see Table S1, and Figures S1 and S2). Bond lengths and angles (Table 3) are similar to those previously found in other thiosemicarbazones [28]. Both ligands are basically arranged so as to form two planes at dihedral angles of 71.57(0.07)° [HTSC[6], molecule 1: C(11)S(1)N(11)N(12)N(13)C(12), rms = 0.0803° and C(14)O(11)O(12)C(13)C(16)C(17)C(18), rms = 0.0934], 87.31(0.06)° [HTSC[6], molecule 2: C(21)S(2)N(21)N(22)N(23)C(22)C(23)C(25), rms = 0.1403 and C(23)C(24)O(21)O(22)C(28), rms = 0.0103] and 63.51(0.05)° [HTSC[7], SC(1)N(1)N(2)N(3)C(2)C(3)C(5)C(7), rms = 0.0663 and C(3)C(4)O(1)O(2)C(8), rms = 0.0108].

In HTSC[6] each molecule of type 1 interacts with a second *via* an N(11)–H(11B)···O(11)^{i} hydrogen bond, giving rise to infinite chains parallel to the *a*-axis, and N(12)–H(12)···S(1)^{ii} hydrogen bonds connect these chains in pairs (see Table S1 and Figure S1). Type 2 molecules are con-

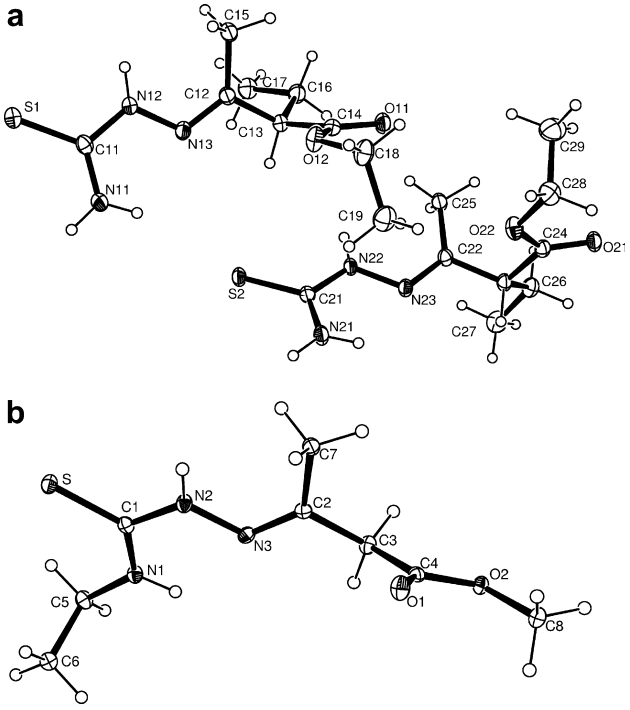

Fig. 1. Molecular structures and numbering schemes of the ligands HTSC[6] (a) and HTSC[7] (b).

nected by similar interactions, and also by an N(21)–H(21A)···O(21)[iii] hydrogen bond, resulting in a two-dimensional network parallel to the *ab*-plane (Table S1 and Figure S1).

The ethyl group on N(1) in HTSC[7] makes it less capable of hydrogen bond formation than HTSC[6]. In fact, its only intermolecular bond is N(2)–H(2)···O(1)[i], which associates the molecules in dimers (Table S1 and Figure S2).

The molecular structures of HL[6] and HL[7] are shown in Fig. 2, together with the numbering schemes used. Both ligands have bond lengths and angles (Table 3) comparable to those found in the previously studied similar molecules HL[1] [13a], HL[2] [13c], HL[4] [13c], and HL[5] [29]. In the solid state, both adopt the ketothione form and can be considered as almost planar if the terminal methyls of ethyl substituents are ignored (rms 0.063 and 0.030, respectively). Both have two intramolecular hydrogen bonds [N(1)–H(1A)···O and N(3)–H(3)···S (see Table S1, and Figures S3 and S4)] and an intermolecular bond [N(3)–H(3)···O[x]] that associates the molecules in chains. In HL[6], an additional hydrogen bond [N(1)–H(1B)···S[i]] links the chains in sheets parallel to the *bc*-plane.

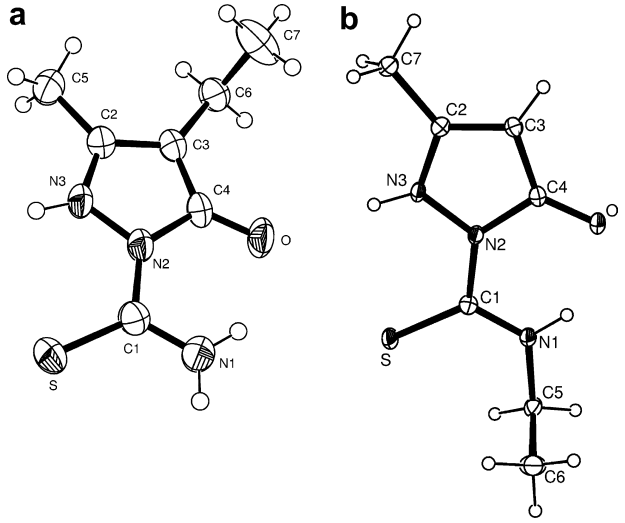

Fig. 2. Molecular structures and numbering schemes of the ligands HL[6] (a) and HL[7] (b).

3.2.2. Complexes

Crystals of $[Pb(L^6)_2]\cdot 0.5H_2O\cdot 0.3MeOH$ contain $[Pb(L^6)_2]$ molecules with the three crystallographically independent geometries shown, together with the numbering scheme used, in Fig. 3. Selected bond lengths and angles are listed in Table 4. The asymmetric unit comprises one complete molecule of type 1, half a molecule of type 2, half a molecule of type 3, a water molecule, and 0.6 molecules of MeOH. In all the ligands, the usual evolution to the thiol form upon coordination [13] is reflected in the lengthening of the C–S bond from 1.6703(15) Å in the free ligand (Table 3) to 1.708(11)–1.736(11) Å in molecules 1–3 (Table 4).

In all three independent molecules the metal forms four strong primary bonds with two N,S-dentate pyrazolonates. In molecule 1 both the two Pb–N distances and the two Pb–S distances differ, and the fact that all these bonds lie on one side of the metal atom suggests the existence of a SALP on the other side, which would make the coordination polyhedron a distorted trigonal bipyramid with the hypothesized SALP in one of the equatorial positions. Molecules 2 and 3, in both of which the two ligands are mutually symmetrical, resemble each other quite closely, although the Pb–N and Pb–S bonds are a little shorter in 2 than in 3; in both 2 and 3, as in 1, there seems likely to be a SALP on one side of the metal atom, but in these cases the coordination polyhedron is a slightly distorted square pyramid in which the hypothesized SALP occupies the apex and the donor atoms come close to defining a perfect plane (rms = 0.0308 in 2, 0.0286 in 3). In all three molecules the chelate rings are bent around the line S–N so that the two ligands are almost parallel, but whereas in molecules 2 and 3 this results in the ligands also being quasi-coplanar, in molecule 1 they are bent the other way so that they face each other (Fig. 4).

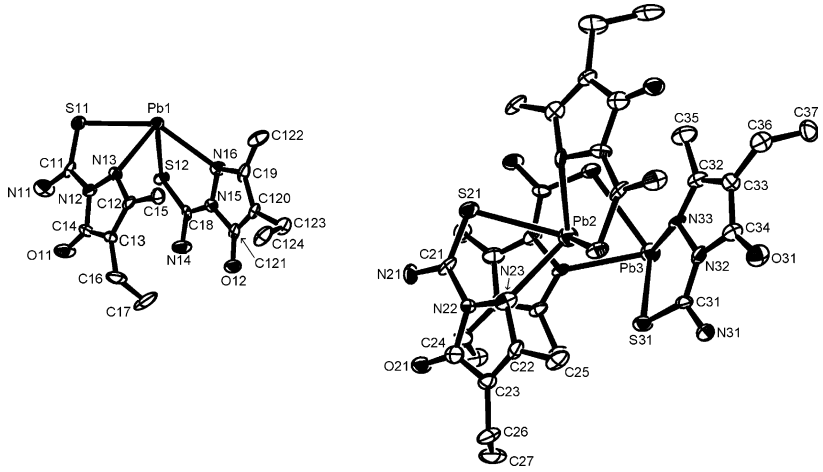

Fig. 3. Molecular structures of the three independent molecules of $[Pb(L^6)_2]$ in $[Pb(L^6)_2]\cdot 0.5H_2O\cdot 0.3MeOH$.

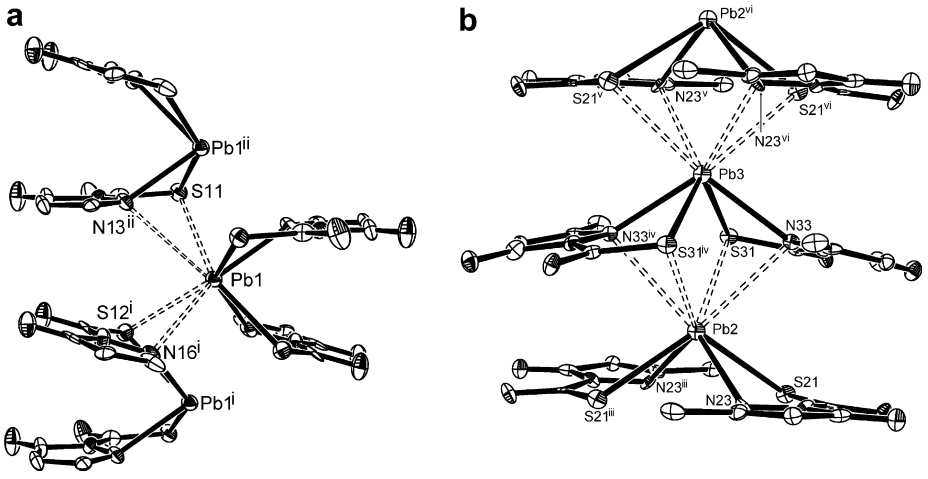

Fig. 4. Primary and secondary interactions of Pb(1) (a) and Pb(2) and Pb(3) (b) in $[Pb(L^6)_2]\cdot 0.5H_2O\cdot 0.3MeOH$.

The structural differences between molecule 1 and molecules 2 and 3 regarding their primary coordination spheres and the arrangement of their ligands are accompanied by significant differences in their intermolecular interactions, notably as regards the weak secondary bonds that, as is usual in Pb(II) complexes with hemidirected coordination [3c], appear to border the volume presumably occupied by the SALP (Fig. 4). Comparison with the sums of van der Waals radii (3.55 Å for Pb···N, 3.80 Å for Pb···S) suggests that Pb(1) has secondary bonds with the chelating N and S atoms of the nearest ligands of two neighbouring type 1 molecules [Pb(1)–N(16)^{i} = 3.003(8) Å, Pb(1)–S(12)^{i} = 3.317(3) Å, Pb(1)–N(13)^{ii} = 3.371(8) Å, Pb(1)–S(11)^{ii} = 3.180(3) Å; (i): $-x+1/2$, $-y+1/2$, $-z+2$; (ii): $-x+1/2$, $-y-1/2$, $-z+2$]. These bonds, which link the type 1 molecules in slightly zig-zag chains along the *b*-axis (Pb–Pb–Pb = 163°; see Fig. 4), are similar to those observed in other Pb(II) complexes with Pb···N and Pb···S secondary interactions [30,31]. In molecules 2 and 3, which alternate in stacks (likewise along the *b*-axis), the Pb atoms have secondary bonds with all four primary donor atoms of one of their type 3 or type 2 neighbours (see Fig. 4 and Table 4 for bond lengths). The existence of all these secondary bonds is supported by the detection of the corresponding critical points by the QTAIM calculations, which among both primary and secondary bonds showed the expected negative correlation between bond length and charge density at the critical point (Table 5).

In both the chains of molecules 1 and the stacks of type 2/3 units, the Pb···Pb distances [3.6096(8)–3.7562(8) Å] (see Fig. 5) are shorter than in $[Pb^{II}(XS_2)_2]$ complexes, where $(XS_2)^-$ is a monoanionic didentate ligand [12], and are close to the upper limit for Pb–Pb bonds in diplumbene dimers, 3.527 Å [32]. As in the case of bis(pyrrolidinecarbodithioato)lead(II), the molecules of which are stacked with a Pb···Pb distance of 3.886(1) Å [12], the possibility of weak SALP-mediated Pb–Pb bonds therefore arises. However, our QTAIM calculations failed to detect critical points of electron density supporting the existence of such bonds, so the short Pb···Pb distances in the present complex seem likely to be due simply to the secondary Pb–L^6 donor bonds.

Table 5
Electron charge densities (ρ_c, in atomic units) at the critical points of bonds with Pb(1), Pb(2) and Pb(3) in the model compounds A, B and C[a], together with the corresponding bonds lengths (Å)

	Bond length	ρ_c
Pb(1)–N(13)	2.556(8)	0.0326
Pb(1)–N(16)	2.691(9)	0.0275
Pb(1)–S(12)	2.838(3)	0.0317
Pb(1)–S(11)	2.920(3)	0.0281
Pb(1)–N(16)^{i}	3.003(8)	0.0178
Pb(1)–N(13)^{ii}	3.371(8)	0.0102
Pb(1)–S(12)^{ii}	3.180(3)	0.0196
Pb(1)–S(12)^{i}	3.317(3)	0.0161
Pb(2)–N(23)	2.599(9)	0.0311
Pb(2)–S(21)	2.905(3)	0.0295
Pb(2)–N(33)	3.092(9)	0.0160
Pb(2)–S(31)	3.274(3)	0.0169
Pb(3)–N(33)	2.637(9)	0.0293
Pb(3)–S(31)	2.922(3)	0.0285
Pb(3)–N(23)^{v}	3.002(8)	0.0183
Pb(3)–S(21)^{v}	3.201(3)	0.0185

i: $-x+1/2$, $-y+1/2$, $-z+2$; ii: $-x+1/2$, $-y-1/2$, $-z+2$; v: $-x+1$, $y+1$, $-z+1/2$.
[a] See Section 2.

Each type 1 molecule is linked to molecule 3 of its nearest type 2/3 unit by a direct N(11)–H(11B)···O(31)^{ix} bond, and to molecule 2 by a chain of hydrogen bonds that starts at N(14) and proceeds via the methanol and water molecules to N(21) (see Table S1, and Figs. S6 and S7, for these and other hydrogen bonds).

In $[Pb(L^7)_2]$, in which the two L^- ligands are mutually symmetrical (Fig. 6), the presence of the four primary bonds within quite a small solid angle suggests that, like the preceding complex, it has a SALP (see Table 4 for bond lengths and angles). In fact, it seems that it may be only steric hindrance between their N(1) ethyl groups that prevents the two ligands from drawing even closer together (which may be why the primary coordination polyhedron is not

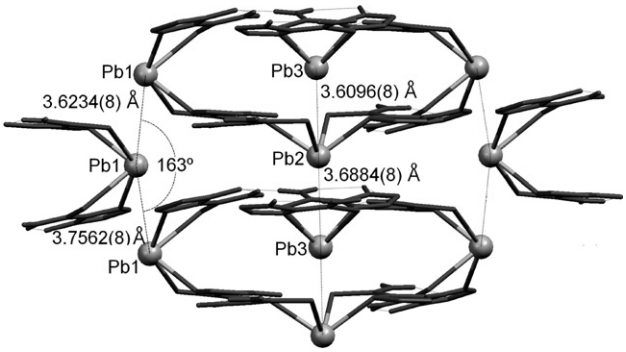

Fig. 5. Assembly of the chains of molecules 1 and the stacks of molecules 2 and 3, together with Pb···Pb distances (view perpendicular to the *b*-axis).

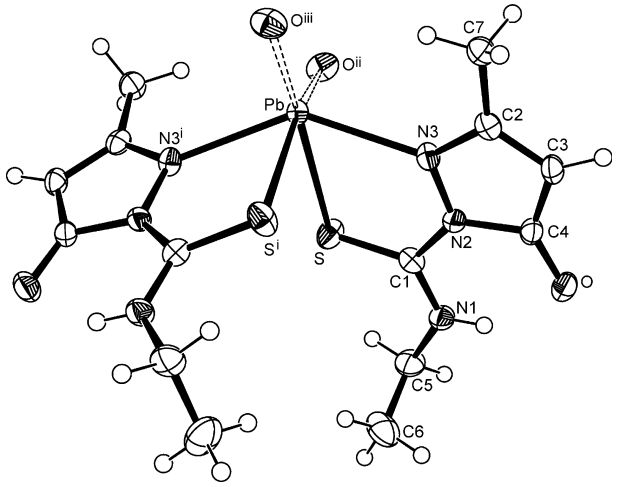

Fig. 6. Molecular structure of $[Pb(L^7)_2]$.

a square pyramid but a trigonal bipyramid with the hypothesized SALP equatorial and the N atoms apical). However, this complex has just a single type of molecule, and the chelate rings are, as usual, flat (and almost coplanar with the corresponding pyrazolonate ring), with a dihedral angle of about 70° between them. It is perhaps this, with the concomitant orientation of the C(2) methyl groups, that prevents secondary bonding to the N and S atoms of neighbouring molecules. The secondary bonds that do exist, with the O atoms of two neighbouring molecules [Pb···O^{ii} = 2.727(3) Å, O^{ii}–Pb–O^{iii} = 126.7°], link the molecules in a three-dimensional network (Figs. S8–S10). Thus in this complex the molecular and packing geometry appears to be determined largely by steric effects; because of the partial substitution of N(1) and the absence of solvent molecules, hydrogen bonding is limited to the intramolecular N(1)–H···O bond (Table S1).

3.3. IR spectroscopy

Whether or not the thiosemicarbazone ligands had undergone cyclization upon coordination was easily detected by examination of the main IR bands of the complexes (see Section 2), since the spectra of pyrazolones differ clearly from those of thiosemicarbazones [13].

In the spectra of the $[Pb(L^n)_2]$ compounds the ν(ring) band shifts to higher frequencies upon metallation while the ν(C=S) band shifts to lower frequencies or becomes weaker, which is in keeping with the observation of N,S-coordination in the L^6 and L^7 derivatives and in previously studied pyrazolonates [13].

To judge by the positions of ν(ring) and ν(C=S), the L^- ligand of the $[Pb(OAc)(L^n)]$ complexes is also N,S-coordinated. The value of $\Delta\nu = \nu_{as}(COO^-) - \nu_{sym}(COO^-)$ ranges from 151 to 173 cm^{-1}, which suggests that the carboxylate group acts as a bismonodentate bridging ligand [33].

Upon coordination, the spectra of the thiosemicarbazone ligands $HTSC^9$ and $HTSC^{10}$ undergo significant modification in the 3000–3500 cm^{-1} region due to deprotonation of N(2) and concomitant alteration of the hydrogen bond network. By contrast, the position of the strong ν(C=O) band at 1650–1670 cm^{-1} is unchanged, suggesting that this group is not involved in coordination. The slight shift of ν(C=N), the weakening, and slight shift to lower wavenumbers, of the ν(C=S) band at 800 cm^{-1}, and the vanishing of the ν(C=S) band at 1100 cm^{-1}, are all suggestive of N,S-coordination [13b].

3.4. ^1H and ^{13}C NMR spectroscopy

For assignments of the ^1H and ^{13}C NMR signals of all the complexes except $[Pb(TSC^9)_2]$ (which is insoluble in DMSO-d_6), see Section 2.

In the proton spectra of $[Pb(L^n)_2]$ and $[Pb(OAc)(L^n)]$, the non-appearance of the $HTSC^n$ signals corresponding to the R_3 group and one C(3) proton is in keeping with the release of HR_3 (methanol, ethanol or an aniline) during cyclization. Similarly, the R_3 signals are missing from the ^{13}C NMR spectra of the complexes, and C(3) is deshielded ca. 40 ppm with respect to $HTSC^n$.

The differences between the spectra of the complexes and those of the free HL^n ligands are similar to those found for the pyrazolonate derivatives of Zn(II) [13], Cd(II)[13] and Re(I) [13], and can be summarized as follows: (i) absence of the N(3)H signal due to deprotonation; (ii) deshielding of the protons on N(1); and (iii) deshielding of C(2) and C(4) by 5–13 ppm and 3–5 ppm, respectively, and shielding of C(3) by 5–8 ppm. These modifications suggest that the solid state coordination mode of $[Pb(L^6)_2]$ and $[Pb(L^7)_2]$ (see crystallographic results) persists in DMSO and is probably that of all the complexes of this type.

In the ^1H NMR spectrum of $[Pb(TSC^{10})_2]$ the signals assigned to N(2)H disappear, confirming deprotonation, and those belonging to N(4)H are split into four. The signals corresponding to the two $N(1)H_2$ groups are shifted upfield and lie closer to each other than in the free ligands, probably due to deprotonation and coordination *via* the S atom. In the ^{13}C spectrum, there is no C(1) signal and C(2) is deshielded ca. 6 ppm, suggesting the involvement of N(3) in coordination to the metal.

larger and more complicated organic molecules such as phthalocyanines (Pcs). This led us to undertake this investigation.

Pcs and their symmetrically substituted derivatives have received extensive interest in recent decades since their special properties such as electrical conductivity [10], electrochromism [11], mesophase formation [12] and photosensitivity [13] makes them interesting substrates for novel materials [14]. The synthesis and study of binuclear or oligonuclear and sandwich type Pcs containing two metal centers are among the priorities of modern phthalocyanine (Pc) chemistry [15–21]. These complexes show a wide range of interactions between the Pc ring, mainly depending on the metal center, bridging links and the presence or absence of axial ligands. The species having flexible bridging units usually do not exhibit any measurable interaction while rigid systems such as the anthracene and naphthalene bridged species do exhibit strong interactions. Many Pc dimers and multimers, having various kinds of linkage, have been reported to date. These dimers and multimers, especially those with rigid cofacial configurations, usually show spectroscopic, electrochemical and electrical properties which differ significantly from the parent monomers. The synthesis and properties of binuclear Pcs with great numbers of cross-links have rarely been reported in the literature. Recently, a binuclear ball-type ZnPc containing phenylidene bridges has been reported [15,16]. Introducing electron donor and acceptor groups into the Pc ring also strongly affects the electrical properties of the molecule. From the viewpoint of organic semiconductors, it is known that substitution of electron donor and acceptor groups leads to p-type and n-type characteristics of the Pc ring, respectively [22,23].

We have reported on the synthesis and characterisation of novel *s*-triazines bearing three oxygen-linked metallo Pcs and lutetium bisphthalocyanine sandwich complexes [21,24]. The synthesis, characterization, conduction and gas sensing properties of novel multinuclear metallo Pcs with alkylthio substituents were also reported in the literature [25]. We achieved for the first time the synthesis of a novel ball-type four *t*-butylcalix[4]arene bridged binuclear zinc(II)Pc, namely compound **2** [26]. It was synthesized by the tetramerization of compound **1** with $Zn(OAc)_2 \cdot 2H_2O$ in dry DMF. This novel compound exhibited mixed-valence behaviour and non-Arrhenius type dependence of conductivity [26]. We have also reported *t*-butylcalix[4]arene bridged bis double-decker lutetium (III) phthalocyanine [27]. In addition to compound **2**, we report here in detail the synthesis, characterization and electrochemical properties of compounds **3** and **4**. The metal-free Pc of ball type **3** was synthesized by the condensation of compound **1** in the presence of lithium metal in dry amyl alcohol. The binuclear Pc of clamshell type **4** was obtained by the reaction of compound **1** with 4,5-bis(hexylthio)phthalonitrile and $Zn(OAc)_2 \cdot 2H_2O$.

2. Experimental

2.1. Synthesis and characterization

All reagents and solvents were of reagent grade quality, obtained from commercial suppliers. The solvents were stored over molecular sieves (4 Å). The progress of the reactions was monitored by TLC. 4-Nitrophthalonitrile [28] and 4,5-bis(hexylthio)phthalonitrile [29] were prepared by the literature methods.

Routine IR spectra were recorded on a Shimadzu IR-470 Infrared spectrometer as KBr pellets, electronic spectra on a Unicam UV 500 UV–Vis spectrometer. Elemental analysis was performed by a LECO CHNS 932 in the Instrumental Analysis Laboratory of TUBITAK Ankara Research Center. ^{1}H NMR spectra were recorded on a Bruker Avance DPX-400 spectrometer. Mass spectra were acquired on a Voyager-DE™ PRO MALDI-TOF mass spectrometer (Applied Biosystems, USA) equipped with a nitrogen UV-laser operating at 337 nm. Spectra were recorded both in linear and reflectron modes with an average of 50 shots. A 3,5-dinitrobenzoic acid (DNB) MALDI matrix was used and prepared in chloroform ($CHCl_3$) at a concentration of 20 mg/mL for the binuclear Zn(II)Pc **2**, and 3-indole acyrylic acid was prepared in methanol for the binuclear metal-free Pc **3** and in $CHCl_3$ for the binuclear Zn(II)Pc of clamshell type **4**, at a concentration of 20 mg/mL. MALDI samples were prepared by mixing sample solutions (4 mg/mL) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® micro tube. Finally 1 μL of this mixture was deposited on the sample plate, dried at room temperature and then analyzed.

2.1.1. Preparation of 1,3-bis(3,4-dicyanophenoxy)-4-tert-butylcalix[4]arene (1)

1,3-Dimethoxy-4-*tert*-butylcalix[4]arene (1.9 g, 2.8 mmol) and 4-nitrophthalonitrile (0.972 g, 5.6 mmol) were added successively with stirring to dry dimethylsulfoxide (DMSO) (60 ml). After they were dissolved, anhydrous K_2CO_3 (1.16 g, 8.4 mmol) was added and the reaction mixture was stirred at 85 °C for 76 h. Reaction was monitored by TLC. Then, the reaction mixture was poured into 200 ml of cold water, acetic acid (2 ml) was added and it was stirred for 15 min. The precipitate was filtered off, flushed several times with cold water until the filtrate was neutral and dried in air, then at 70 °C. This compound was readily soluble in the majority of organic solvents such as ethanol, methanol, $CHCl_3$, THF, acetone, diethyl ether, DMF and DMSO. Yield: 2.26 g (87%). M.p. 165–168 °C; ^{1}H NMR ($CDCl_3$): δ, ppm 7.78–6.31 (m, 14H, arom.), 3.73–3.23 (m, 6H, OCH_3), 2.66 (s, 8H, Ar–CH_2), 1.63–1.12 (m, 36H, tBu CH_3). IR (KBr): ν, cm^{-1} 3046 (CH arom.), 2959–2869 (CH aliph.), 2822, 2357, 2323, 2229 (C≡N), 1734, 1596 (Ar C=C), 1476, 1359, 1290, 1245 (Ar–O–Ar), 1193, 1117, 1017, 949, 873, 834, 523. *Anal.* Calc. for $C_{62}H_{64}N_4O_4$ (928): C, 80.17; H, 6.89; N, 6.03. Found: C, 79.83; H, 6.68; N, 5.94%.

*2.1.2. Synthesis of binuclear zinc(II) phthalocyanine of ball type **2***

A mixture of compound **1** (0.40 g, 0.437 mmol) and $Zn(OAc)_2 \cdot 2H_2O$ (0.047 g, 0.218 mmol) was heated in a sealed glass tube for 24 h under stirring and N_2 in dry DMF (2.7 ml) at 190 °C. After cooling to room temperature, 5 ml of distilled water was added to the blue-green mixture to precipitate the product. The precipitate was suction filtered, multiply washed at first with hot water and then with hot ethanol in order to eliminate the unreacted starting materials, and dried in vacuo. Then, the crude product was repeatedly flushed with $CHCl_3$. After the filtrate had been evaporated to dryness, it was washed with ethanol until the filtrate was colorless and dried in vacuo. This compound is soluble in ethyl acetate, acetic acid, hot DMSO and $CHCl_3$. Yield: 0.071 g, 17%. M.p. > 300 °C. UV–Vis λ_{max} ($CHCl_3$, 51.98 μM) ($\log \varepsilon/dm^{-3}\,mol^{-1}\,cm^{-1}$): 350 (4.575), 620 (4.117), 688 (4.706) nm. ^1H NMR ($CDCl_3$): δ, ppm 8.57–7.11 (m, 56H, arom.), 3.23–3.18 (t, 24H, OCH_3), 2.85 (d, 32H, Ar–CH_2), 1.68–1.57 (t, 144H, tBuCH_3). MS (MALDI-TOF): *m/z* 3849.6 $[M+H]^+$, 3704.6 $[M^+-(C_{10}H_9O)]$, 3559.6 $[M^+-2(C_{10}H_9O)]$. IR (KBr): *v*, cm^{-1} 3057 (CH arom.), 2956–2866 (CH aliph.), 2330, 1730, 1658, 1605, (Ar C=C), 1472, 1359, 1285 (Ar–O–Ar), 1193, 1118, 1021, 942, 871, 757, 675, 621. *Anal.* Calc. for $C_{248}H_{256}N_{16}O_{16}Zn_2$ (3847.608): C, 77.41; H, 6.70; N, 5.82. Found: C, 77.14; H, 6.74; N, 6.18%.

*2.1.3. Synthesis of binuclear metal-free phthalocyanine of ball type **3***

A suspension of **1** (0.200 g, 0.215 mmol) in 1.8 ml of dry amyl alcohol was heated in a sealed tube at 80 °C under N_2. After addition of elemental lithium (0.035 g, 5.043 mmol) to the reaction mixture, a blue-green colour appeared in 15 min. The reaction mixture was stirred at 170 °C for 18 h. After cooling to room temperature, EtOH (20 ml) was added to the mixture and it was filtered. After the filtrate had been evaporated to dryness, the residue was washed successively with water then with diethyl ether (3 × 30 ml), $CHCl_3$ (3 × 30 ml), CH_2Cl_2 (3 × 30 ml), ethyl acetate (3 × 30 ml), THF (3 × 30 ml) and acetone (3 × 30 ml) prior to drying in vacuo (70 °C) to give the pure product **3**. The blue-green coloured product is soluble in methanol, acetic acid, DMF, hot ethanol and hot DMSO. Yield: 0.110 g, 55%. M.p. > 200 °C. UV–Vis λ_{max} (MeOH, 107.5 μM) ($\log \varepsilon/dm^{-3}\,mol^{-1}\,cm^{-1}$): 336 (3.924), 626 (3.303), 674 (3.968), 710 (4.042) nm. ^1H NMR (DMSO): δ, ppm 8.21–6.97 (m, 56H, arom.), 3.27 (s, 24H, OCH_3), 2.94 (s, 32H, Ar–CH_2), 1.63 (t, 144H, tBu CH_3). IR (KBr): *v*, cm^{-1} 3410, 3057 (CH arom.), 2952–2860 (CH aliph.), 2332, 1731, 1658, 1607, (Ar C=C), 1470, 1357, 1285 (Ar–O–Ar), 1191, 1118, 1019, 945, 871, 755, 620. *Anal.* Calc. for $C_{248}H_{260}N_{16}O_{16}$ (3716): C, 80.08; H, 6.99; N, 6.02. Found: C, 79.84; H, 6.85; N 6.24%.

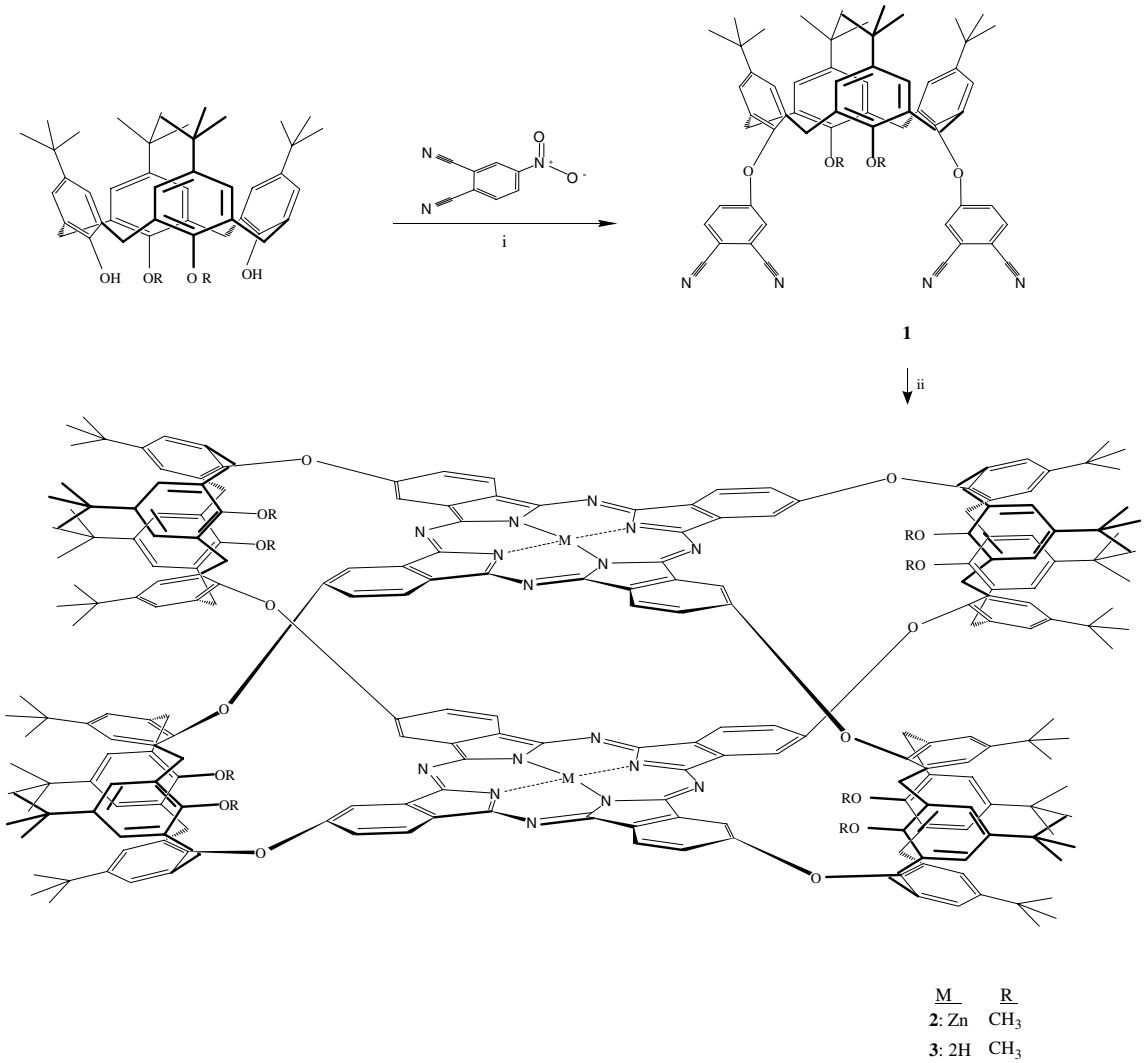
*2.1.4. Synthesis of binuclear zinc(II) phthalocyanine of clamshell type **4***

A mixture of compound **1** (0.140 g, 0.15 mmol), 4,5-bis(hexylthio)phthalonitrile (0.331 g, 0.92 mmol), $Zn(OAc)_2 \cdot 2H_2O$ (0.071 g, 0.32 mmol) and dry quinoline (2 ml) was heated and stirred in a sealed glass tube at 190 °C under N_2 for 24 h. After cooling to room temperature, the dark green mixture was diluted with ethanol (10 ml) to precipitate the product, and then it was filtered. After having been washed successively with hot water, hot ethanol (3 × 20 ml), hot DMSO (3 × 20 ml) (60 °C) and methanol (3 × 20 ml) to remove the unreacted organic materials, the dark green product was dissolved in $CHCl_3$ (40 ml), the solution was filtered and the filtrate evaporated to a smaller volume (ca. 10 ml) from which a dark green precipitate was obtained by addition of ethyl acetate/diethyl ether (20 ml/15 ml). It was filtered off, washed successively with hot ethyl acetate (3 × 20 ml), acetone (3 × 20 ml) and diethyl ether (3 × 20 ml) prior to drying in vacuo to give pure product **4**. The dark green product was soluble in $CHCl_3$, CH_2Cl_2, benzene and DMF. Yield: 0.058 g, 12%. M.p. > 200 °C. UV–Vis λ_{max} ($CHCl_3$, 62.15 μM) ($\log \varepsilon/dm^{-3}\,mol^{-1}\,cm^{-1}$): 360 (4.675), 694 (4.650) nm ^1H NMR ($CDCl_3$): δ, ppm 7.64–6.45 (m, 26 H, arom.), 3.23–3.16 (t, 6H, OCH_3), 2.91 (d, 8H, Ar–CH_2), 1.93 (br s, 24H, SCH_2), 1.67–1.62 (t, 36H, tBu CH_3), 1.23 (d, 96 H, –CCH_2C–), 0.83 (d, 36H, –CH_3). IR (KBr): *v*, cm^{-1} 3040 (CH arom.), 2910–2845 (CH aliph.), 2356, 2217, 1590 (Ar C=C), 1542, 1508, 1454, 1403, 1285 (Ar–O–Ar), 1195, 1065, 1020, 939, 755, 692, 540. *Anal.* Calc. for $C_{182}H_{232}N_{16}O_4\,S_{12}Zn_2$ (3218): C, 67.86; H, 7.20; N, 6.96; S, 11.93. Found: C, 67.46; H, 7.04; N, 6.64; S, 11.48%.

2.2. Electrochemistry

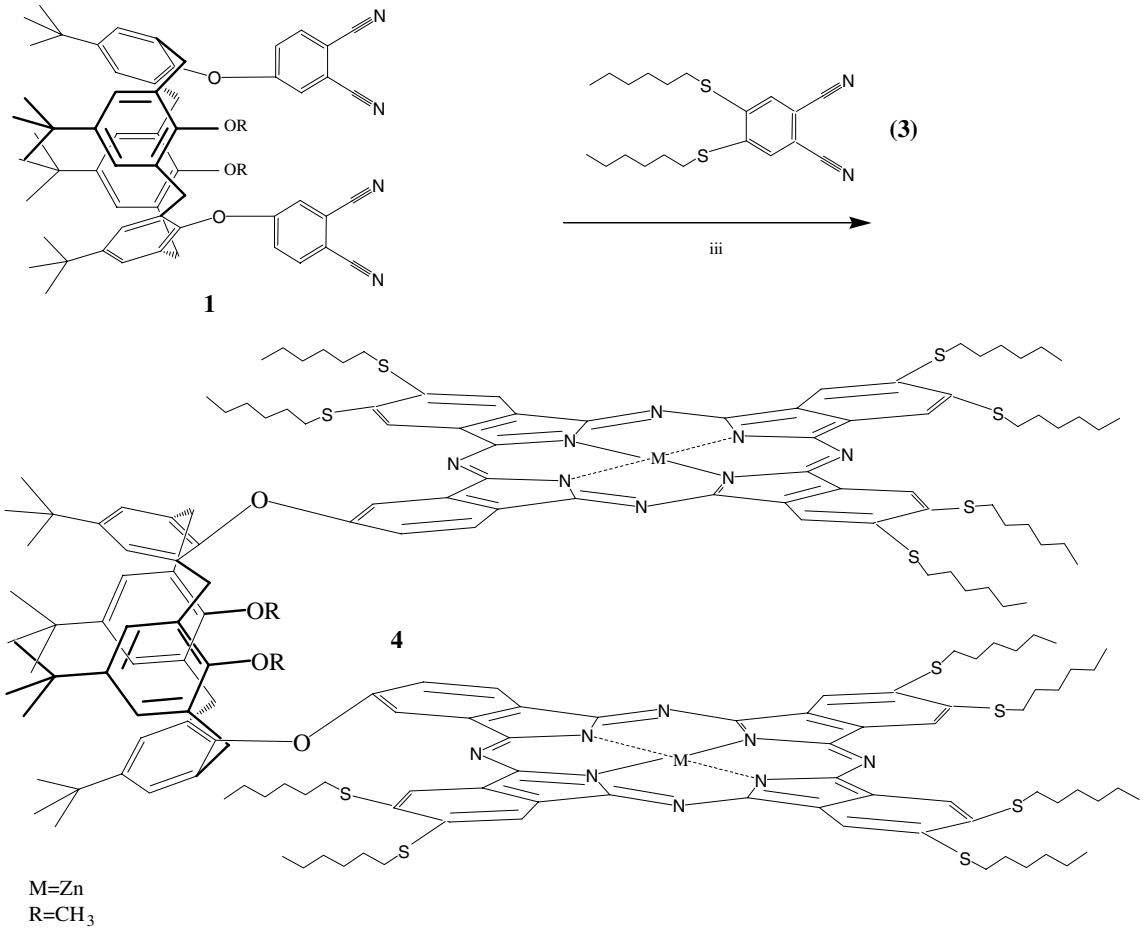
Electrochemical measurements were carried out with a PAR Model VersoStat II potentiostat/galvanostat controlled by an external PC, and utilizing a three electrode configuration at 25 °C. Tetrabutyammonium perchlorate (TBAP) (Electrochemical grade, Fluka Chemical Co.) was used as the supporting electrolyte in extra pure DCM and DMSO (Fluka Chemical Co). A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a fritted glass bridge filled with the solvent/supporting electrolyte mixture. The ferrocene/ferrocenium couple (Fc/Fc^+) was used as an internal standard, but potentials were reported with respect to SCE. The working electrode was platinum in the measurements. The surface of the platinum working electrode was polished with a H_2O suspension of Al_2O_3 before each run. The last polishing was done with a particle size of 50 nm. A platinum spiral wire was used as the auxillary electrode. Solutions containing **2**–**4** were deoxygenated by a stream of high-purity nitrogen for at least 20 min prior to running the experiment, and the solution was protected from air by a blanket of nitrogen during

the experiment. For the controlled-potential coulometry (CPC) studies, a platinum gauze working electrode, a platinum wire counter electrode separated with a bridge, a SCE as reference electrode and a model 377/12 synchronous stirrer were used.



3. Results and discussion

3.1. Synthesis and characterization



Scheme 1 shows the synthesis of the target Pcs **2** and **3**. Our key starting material is compound **1** which can be obtained via a single step reaction of 1,3-dimethoxy-4-*t*-butyl calix[4]arene with 4-nitrophthalonitrile in dry DMSO as the solvent, in the presence of the base K_2CO_3 in a yield of 87%. A new binuclear zinc(II)Pc of ball type **2** was prepared by the reaction of compound **1** and $Zn(OAc)_2$ $2H_2O$. Compound **1** was also readily condensed to a novel metal-free Pc of ball type **3** in the presence of elemental lithium. The elegance of the synthesis arises from the fact that the cone conformation of the *t*-butylcalix[4]arene directs the tetramerization of the four nitriles to a Pc of the ball-type structure.

We have previously shown that bisphthalonitrile derivative **1** is a precursor to binuclear Pc **2**, but the yield of the expected product was low (6.5%). Refluxing a solution of bisphthalodinitrile derivative **1** in dry DMF, containing a stoichiometric amount of $Zn(OAc)_2 \cdot 2H_2O$ in a nitrogen atmosphere for 23 h, leads to binuclear Pc **2** formation in a yield of 6.5% [14]. When a mixture of the starting compounds were heated in a sealed glass tube under the same reaction conditions, the yield of **2** was increased to 17%.

The binuclear Pc of clamshell type **4** was also obtained by the reaction of compound **1** with 4,5-bis(hexylthio)phthalonitrile by the method of statistically mixed condensation (Scheme 2). The high boiling solvents of choice for these reactions were DMF for **2**, amyl alcohol for **3** and quinoline for **4**.

Scheme 1. Reagents and conditions: (i) K_2CO_3, DMSO, 76 h, 85 °C; (ii) for compound **2**: DMF, $Zn(OAc)_2 \cdot 2\,H_2O$, 24 h, 190 °C; for compound **3**: Lithium metal, amyl alcohol, 18 h, 170 °C.

Scheme 2. Reagents and conditions: iii: quinoline, $Zn(OAc)_2 \cdot 2H_2O$, 24 h, at 190 °C.

Characterisation of the new products involved a combination of methods including elemental analysis, IR, UV–Vis (Table 1), MS and ^1H NMR spectroscopic techniques. The spectroscopic data of the new compounds were in accordance with the structures. The IR spectra, taken as KBr pellets, showed a –CH aliph. peak at 2959–2869 cm^{-1} and an intense absorption attributable to C≡N at 2229 cm^{-1}, Ar C=C peak at 1596 cm^{-1} and an aromatic CH peak at 3046 cm^{-1} for compound **1**.

A diagnostic feature of Pc formation from the phthalodinitrile derivative **1** is the disappearance of the sharp C≡N vibration at 2229 cm^{-1} of the reactant. The remaining spectrum is very similar to that of compound **1** for **2**–**4**. The IR spectra of **2**–**4** showed Ar–O–Ar peaks at 1285 cm^{-1}, Ar C=C peaks at around 1590–1607 cm^{-1} and aromatic CH peaks at around 3040–3057 cm^{-1}. In addition, the stretching vibrations at 2956–2866, 2952–2860 and 2910–2845 cm^{-1} indicated the presence of –CH and $–CH_3$ groups for **2**–**4**, respectively. The weak band around 3410 cm^{-1} for **3** can be attributed to the N-H stretching frequency of the inner core of the metal-free Pc.

Table 1
UV–Vis data for the phthalocyanines **2**–**4**

Compound	λ/nm (log ε/dm^3 mol^{-1} cm^{-1})
2[a]	688 (4.706), 620 (4.117), 350 (4.575)
3[b]	710 (4.042), 674 (3.968), 626 (3.303), 336 (3.924)
4[a]	694 (4.650), 632 (4.406), 360 (4.675)

[a] In $CHCl_3$.
[b] In methanol.

The ^1H NMR spectra were also in good correlation with the structures of the synthesized compounds. In the ^1H NMR spectrum of **1**, which was taken in $CHCl_3$, the aromatic protons appeared at 7.78–6.31 ppm as multiplets and the $ArCH_2$ protons at 2.66 ppm. The peaks at 3.73–3.23 and 1.63–1.12 ppm indicated the presence of a $–OCH_3$ group and a *tert*-butyl CH_3 group in the structure, respectively. In the ^1H NMR spectrum of pc **2**, which was taken in $CHCl_3$, the aromatic protons appeared at 8.57–7.11 ppm, $ArCH_2$ protons at 2.85 ppm, OCH_3 protons at 3.23–3.18 ppm and *tert*-butyl CH_3 protons at 1.68–1.57 ppm. The ^1H NMR spectrum of **3**, which was taken in DMSO, was similar to that of **2**. In the spectra of **3**, the aromatic protons appeared at 8.21–6.97 ppm, $ArCH_2$ protons at 2.94 ppm, OCH_3 protons at 3.27 ppm and *tert*-butyl CH_3 protons at 1.63 ppm. NH protons could not be observed, probably due to the broad nature of these

peaks in the presence of the intense resonances of the Pc ring [30]. In the ^{1}H NMR spectrum of **4**, which was taken in $CHCl_3$, the aromatic protons appeared at 7.64–6.45 ppm, the peaks at 3.23–3.16, 2.91 and 1.67–1.62 ppm indicated the presence of $–OCH_3$, $–CH_2$ and *tert*-butyl CH_3 groups of 1,3 dimethoxy-4-*tert*-butylcalix[4]arene, respectively, in the structure. The $–CH_3$ protons at the end of the chain appeared at 0.83 ppm, $–CCH_2C–$ protons at 1.23 ppm, and the $–SCH_2$ group neighboring an aromatic ring at 1.93 ppm.

A close investigation of the mass spectra of **2**–**4** confirmed the proposed structures. For **2**, the protonated molecular ion peak was observed at 3849.6 Da, and that exactly overlapped with the mass of **2** calculated theoretically from the elemental composition of the molecule (Fig. 1). Beside the protonated molecular ion peak of the molecule, two other peaks were observed at 3704.6 and 3559.6 in the high mass range. These two peak masses indicated a fragmentation occurred from the protonated molecular ion of **2** with 145 Da mass losses from both sides of the molecule. This fragment pointed out that the leaving group could be $C_{10}H_9O$ which exists as an end group of the molecular structure. All the MALDI-MS results showed that compound **2** was successfully synthesized and the MALDI-MS spectrum of this molecule was obtained only in 3,5-dinitrobenzoic acid matrix with a high protonated molecular ion peak intensity.

The positive ion MALDI-MS spectrum of **3** is given in Fig. 2. Many different MALDI matrices were tried to find an intense molecular ion peak and low fragmentation under the MALDI-MS conditions for this compound. Only 3-indole acrylic acid yielded a good MALDI-MS spectrum, as seen in Fig. 2. The protonated molecular

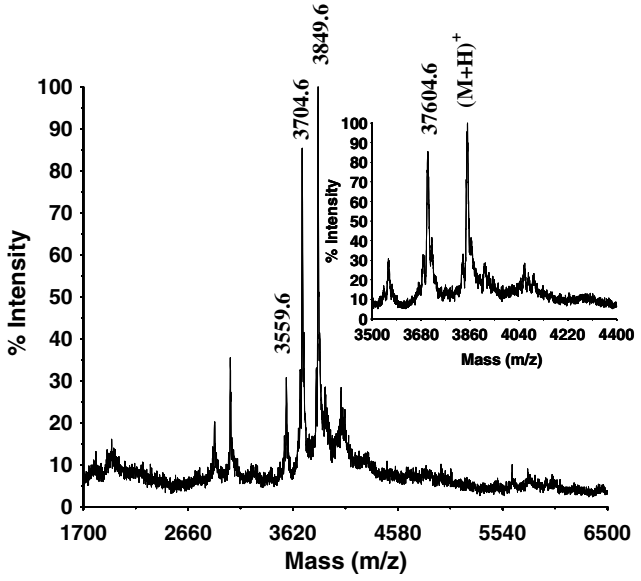


Fig. 1. Positive ion and linear mode MALDI-TOF mass spectrum of **2**, obtained in 3,5-dinitrobenzoic acid MALDI matrix using nitrogen laser accumulating 50 laser shots. Inset spectrum shows the expanded molecular mass region of the complex.

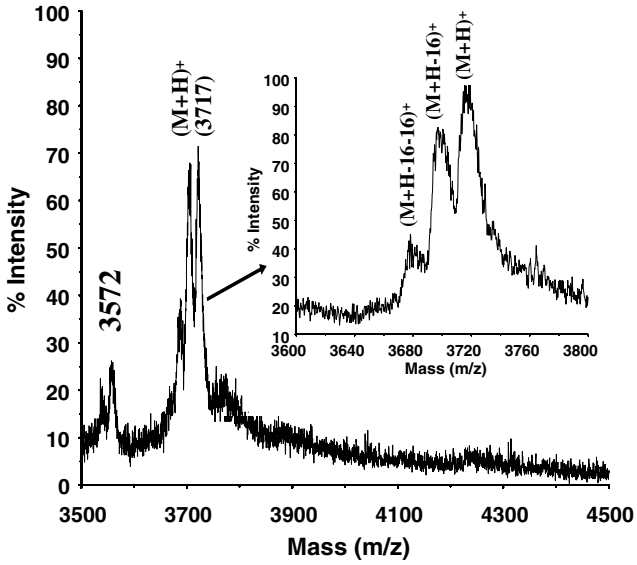

Fig. 2. Positive ion and linear mode MALDI-TOF mass spectrum of **3**, obtained in 3-indole acrylic acid MALDI matrix using nitrogen laser accumulating 50 laser shots. Inset spectrum shows the expanded molecular mass region of the complex.

ion peak of the ligand was observed at 3717 Da, with two fragment ion peaks. The mass difference between these peaks corresponds to 16 Da mass, resulting from methane elimination from the ligand at the side etheric groups. The low intensity for the protonated molecular ion peak shows the low stability of the ligand under the laser firing and mass spectrometric conditions compared to the mass spectrum of **2**, which is given in Fig. 1. In the MALDI-MS spectrum of **3**, beside methane elimination, one fragment ion was observed at 3572 Da mass, resulting from the leaving group having 145 Da mass, being lost from the molecular ion peak from one side chain. This fragment indicates that the leaving group could be $C_{10}H_9O$ which exists as an end group of the molecule.

The MALDI-MS spectrum of **4** was obtained in the best form only in a 3-indole acrylic acid MALDI matrix, though many other different matrices were tried. The positive ion MALDI-MS spectrum of this complex is given in Fig. 3. The protonated molecular ion peak intensity of this complex is dramatically lower than **2** and **3**. Also fragmentation of **4** yielded many different forms in the MALDI-MS spectrum of this complex. This is because of the less stable side alkyl chain connected to the main core of the complex, with a weak C–S linkage. The protonated molecular ion peak of this complex was observed at 3219 Da with low intensity. The following fragment peaks represented two and four cyclohexane leaving groups, from both sides of the complex. When the number of leaving groups increased, the remaining part of the complex was more stable and yielded two intense fragment peaks that appeared at 2843 and 2621 Da masses.

High resolution MALDI-MS spectra for **2**–**4** in reflectron mode could not be obtained as clear, intense spectra.

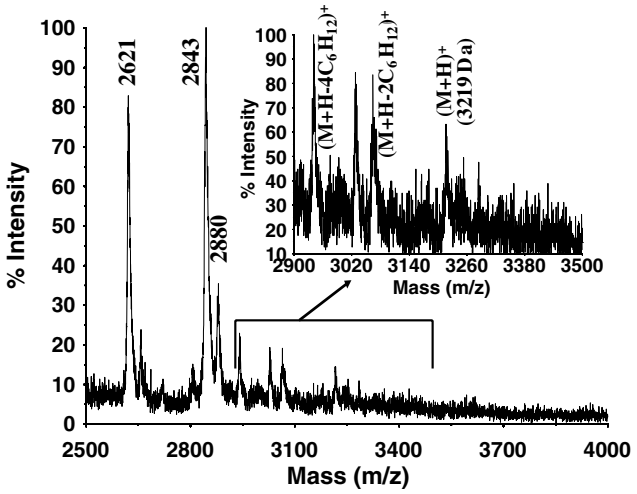

Fig. 3. Positive ion and linear mode MALDI-TOF mass spectrum of **4**, obtained in 3-indole acrylic acid MALDI matrix using nitrogen laser accumulating 50 laser shots. Inset spectrum shows the expanded molecular mass region of the complex.

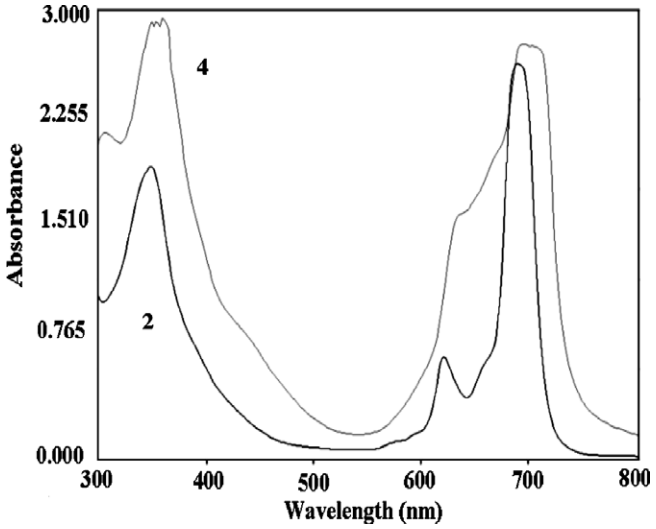

Fig. 4. UV–Vis spectra for phthalocyanines **2** and **4** in $CHCl_3$.

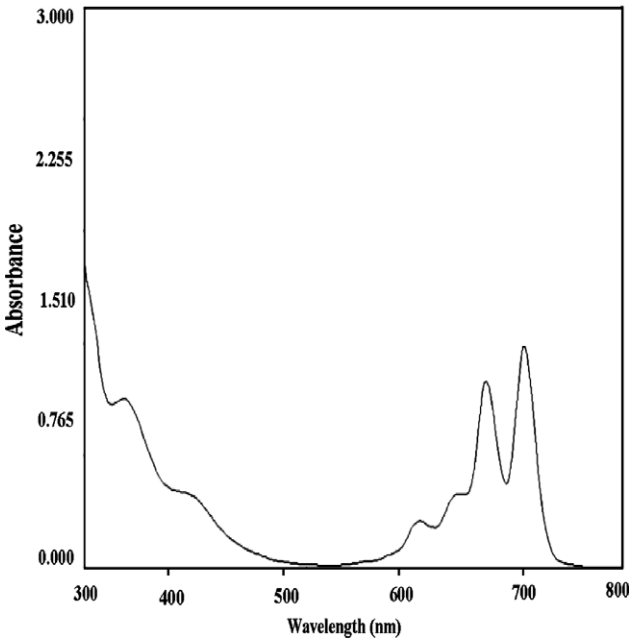

Fig. 5. UV–Vis spectrum for **3** in methanol.

This shows that the stability and also the lifetime of the ions are very low and short in the reflectron mode in MALDI-MS. When negative ion mode MALDI-MS spectra were recorded for these three different complexes no meaningful or intense spectra were obtained (data not shown).

The UV–Vis absorption spectra of the Pc system exhibited characteristic Q and B bands. Pcs **2**–**4** showed typical electronic spectra with two strong absorption regions, one in the visible region at about 600–700 nm (Q-band), which is attributed to the $\pi \rightarrow \pi^*$ transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the Pc(−2) ring, and the other in the UV region at about 300–400 nm (B-band), arising from the deeper π-levels → LUMO transition [31,32].

In the electronic spectra of **2** in chloroform at room temperature, an intense Q absorption band was observed at 688 nm and another in the UV region at 350 nm (B-band) arose from the deeper π-levels → LUMO transition. It shows an additional weak vibrational satellite band at ca. 68 nm to the blue of the normal Q-band as a result of exciton coupling between the Pc units [17] (Fig. 4). Although the Q-band in the spectrum of **2** is not a split, a well-defined absorption at 620 nm might also be interpreted in terms of intramolecular interactions between the Pc rings. The energies and relative intensities, and broadening of the bands observed are in accordance with the pattern that would be anticipated on the basis of the excitation coupling theory for the Pc complexes. The electronic absorption spectrum of **3** in methanol at room temperature is shown in Fig. 5. The Q-band is split, as expected, and there are two strong bands in the visible region. The split Q-band, which is characteristic for metal-free Pcs, is observed at λ_{max} 710 and 674 nm, indicating a monomeric species; the monomeric species with D_{2h} symmetry shows two intense absorptions at around 700 nm [29,33–36]. On the other hand, such split Q-band absorptions are due to $\pi \rightarrow \pi^*$ transitions of these fully-conjugated 18π electron systems. In addition, a third band at 626 nm to the blue side of the double Q-band of the metal-free complex was observed. This band, in addition to the broadness of the spectrum, is indicative of strong intramolecular interactions between the Pc rings, probably due to the ball-type cofacial structure.

The electronic spectrum of **4** shows the characteristic Q-band absorption as a single peak at 694 nm, attributed to the $\pi \rightarrow \pi^*$ transition from the HOMO to the LUMO of the Pc(−2) ring (Fig. 5). Usually aggregation of Pcs results in a spectral effect that extends from band broadening to

blue shifts of the Q and B bands. The shoulder at 632 nm indicates aggregation of **4**. Aggregation occurs readily at low concentrations, making the spectral data more difficult to interpret for many peripherally substituted Pc complexes. It is also known that aggregation is enhanced by solvent polarity and the presence of aliphatic side chains [12,37–39]. The other bands in the UV region at 336 and 360 nm (B-band) for **3** and **4**, respectively, arise from the deeper π-levels → LUMO transition.

3.2. Electrochemistry

The voltammetric measurements were carried out on platinum in DMSO for **2**, **3** and in DCM for **4**. The relevant data are given in Table 2. Compound **4** displays two reductions at $E_{1/2} = -0.90$ V and $E_{1/2} = -1.18$ V versus SCE, and a single oxidation at $E_{1/2} = 0.64$ V versus SCE. The CPC studies showed that each redox process involves the transfer of two electrons. A typical steady state cyclic voltammogram (CV) recorded after several scans for **4** at 0.100 V s^{-1} is shown in Fig. 6. The transfer of two electrons in each redox step suggests that there is not any considerable interaction between the two Pc rings in **4**, and that the two rings are reduced and oxidized at the same potentials. The overall splitting of the molecular orbitals to a high degree on going from the monomeric to dimeric, trimeric or oligomeric Pcs, depending on the intermolecular interactions between the rings, is expected to occur only in the case where the rings are positioned in a face to face orientation, as in the sandwich-type Pcs. Thus, it can be predicted that the two Pc rings are approximately planar in nature. The half-peak potential

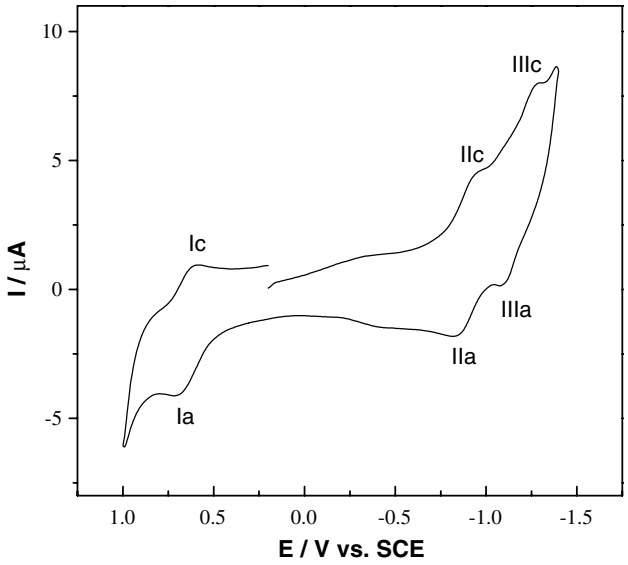

Fig. 6. Cyclic voltammogram of **4** (1.50×10^{-4} M) at 0.100 V s^{-1} on Pt in DCM/TBAP.

difference between the first ring oxidation and the first ring reduction, $\Delta E_{1/2}$ also provides additional support for the absence of or very weak interactions between two Pc rings. $\Delta E_{1/2}$ values ranging from 1.36 to 1.70 V have been reported for monomeric Pc compounds [40–44]. The separation between the first ring oxidation and the first ring reduction for **4** was found to be 1.54 V. In the case where there is a strong interaction between two Pcs in a dimer, this separation is expected to decrease as a result of the splitting of the molecular orbitals [18,19].

Table 2

[i] It corresponds to the equilibrium, $[H_2Pc(-1)]_2^{2+} + [H_2Pc(-2)]_2 \rightleftarrows 2[H_2Pc(-1)H_2Pc(-2)]^+$.
[j] The $E_{1/2}$ difference between couples III and IV.
[k] It corresponds to the equilibrium, $[H_2Pc(-3)]_2^{2-} + [H_2Pc(-2)]_2 \rightleftarrows 2[H_2Pc(-3)H_2\ Pc(-2)]^-$.

The voltammetric behaviour of ball-type Pcs **2** and **3** are considerably different from that of **4**. These compounds show four one-electron redox processes. Typical voltammograms for these compounds are presented in Figs. 7 and 8. The transfer of one electron in each step indicates that the splitting of the molecular orbitals occurs as a result of the strong interaction between the two Pc rings in **2** and **3**, and thus each Pc ring reacts at a potential. The strong interaction between the HOMO and LUMO molecular orbitals of two Pcs in a dimer causes remarkable changes in the redox potentials, compared with the corresponding mono Pcs and non-interacting planar dimers. Generally, the oxidation potentials shift to less positive potentials while the reduction potentials shift to less negative potentials, the shift in oxidation potentials being more remarkable. Taking this observed behaviour into consideration, it can be concluded from a comparison of the voltammetric behaviour of **2** and **3** with the behaviour of **4** that the one-electron redox processes, I and II of each dimer **2** and **3** should correspond to the oxidation of two Pcs rings in each dimer while the processes III and IV are their reduction. High splitting of the Pc(−1)/Pc(−2) and Pc(−2)/Pc(−3) redox processes, i.e. mixed-valence behaviour, is observed, and thus each Pc ring in **2** and **3** is reduced and oxidized at highly different potentials as a result of the expected strong interactions between the cofacial Pc rings. The electrode reactions are schematically illustrated in Chart 1 for **2** and **3**, where the oxidations are labelled as I and II, and the reductions as III and IV.

The high splitting of the redox processes was detected with mixed-valence splitting, ΔE_s, values of 0.44 V for the first reduction, Pc(−2)/Pc(−3) and 0.69 V for the first oxidation, Pc(−1)/Pc(−2), for **2**, and 0.55 V for first reduction and 0.62 V for first oxidation for **3**. The splitting of a redox process, i.e. Pc(−1)/Pc(−2), for **2**, due to formation of a stable mixed-valence intermediate, $[ZnPc(-1)ZnPc(-2)]^+$,

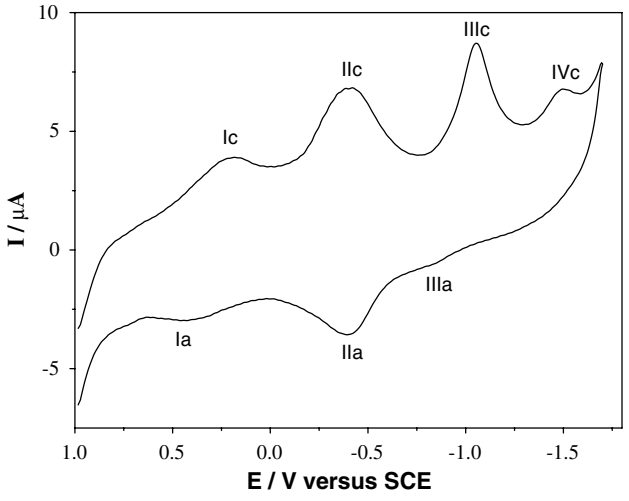

Fig. 7. Cyclic voltammogram of **2** (1.50×10^{-4} M) at 0.100 V s^{-1} on Pt in DMSO/TBAP.

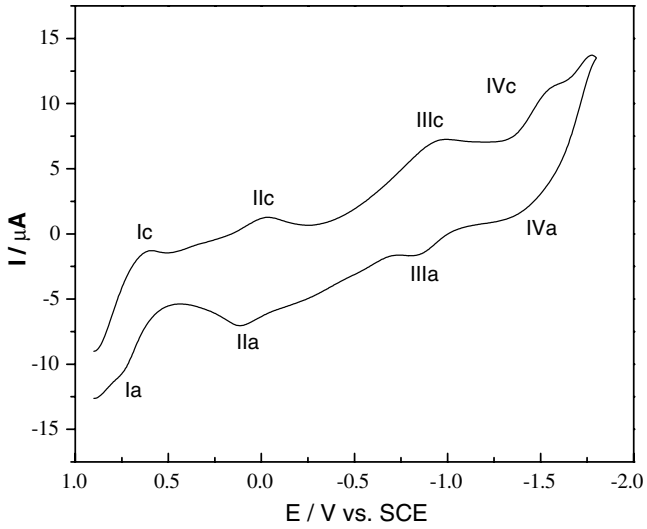

Fig. 8. Cyclic voltammogram of **3** (1.50×10^{-4} M) at 0.100 V s^{-1} on Pt in DMSO/TBAP.

is a measure of the equilibrium (comproportionation) constant, K_c, for a reaction such as [40]:

$$[ZnPc(-1)]_2^{2+} + [ZnPc(-2)]_2^{2} \rightleftarrows [ZnPc(-1)ZnPc(-2)]^+$$

where the mixed-valence splitting ΔE_s is related to K_c via:

$$\Delta E_s = (RT/nF)\ln(K_c) \quad (1)$$

The values of K_c so obtained for the other mixed-valence species, $[ZnPc(-3)ZnPc(-2)]^-$, $[H_2Pc(-1)H_2Pc(-2)]^+$ and $[H_2Pc(-2)H_2Pc(-3)]^-$, are collected in Table 2. The high mixed-valence splitting values give evidence of the delocalization of charge among the cofacial Pc rings in each ball-type Pc, **2** and **3**, and thus the formation of electrochemically stable oxidized and reduced mixed-valence species.

Some binuclear and tetranuclear Pcs [45–50] show metal-centered type or ring-centered type mixed-valence behaviour, but some of them do not. The difference is attributed mainly to the presence or absence of axial ligands, respectively inhibiting or facilitating the close approach of the rings, and to other steric factors. The least strongly coupled systems include some zinc complexes of binuclear Pcs with flexible bridging links [46–48]. However, the splitting of the first reduction and first oxidation processes of the Pc rings for **2** and **3**, and thus the comproportionation constants are considerably higher (Table 2), as compared with those observed previously in the literature for a series of mixed-valence Pc complexes of zinc, aluminum and copper, involving a redox-inactive metal center [40,46–48,50]. The comproportionation constants for these compounds are in the range from 24 to 6.0×10^6, thereby showing a wide range of stability. The results obtained in this study are compatible with the rigid structure of ball-type Pcs, **2** and **3**. The calixarene bridges in these compounds probably facilitate the close approach of the Pc rings. Moreover, mixed-valence ring reduction, Pc(−2)·Pc(−3), was observed previously only in strongly coupled silicon species [50], but not unequivocally observed with

$$[MPc(-1)]_2^{2+} \underset{I}{\overset{e^-}{\rightleftarrows}} [MPc(-1)MPc(-2)]^{+} \underset{II}{\overset{e^-}{\rightleftarrows}} [MPc(-2)]_2 \underset{III}{\overset{e^-}{\rightleftarrows}} [MPc(-3)MPc(-2)]^{-} \underset{IV^a}{\overset{e^-}{\rightleftarrows}} [MPc(-3)]_2^{2-}$$

Chart 1. Electrode reactions for **2** and **3**. M: Zn(II) for **2** and M: 2H for **3**. [a]irreversible for $[ZnPc(-2)]_2$.

the other bridged binuclear species. The presence of an extra π-electron repels the π-electron density in the other ring and therefore inhibits formation of these species unless they are constrained to lie close together. The large K_c values (2.7×10^8 for mixed valence ring oxidation and 6.0×10^6 for mixed valence ring reduction) for the silicon species was attributed to the shorter Pc···Pc contacts than in the bridged systems. As expected, a large K_c value (2.86×10^9) for mixed valence ring reduction was obtained for **3** in this study (Table 2). It could not be determined for **2** since the equation is not appropriate due to the irreversibility of couple IV (Fig. 7 and Table 2). However, the large mixed-valence splitting energy for the mixed-valence reduction of **2** (0.44 V, taking the difference between the cathodic peak potentials of processes III and IV into consideration) reflects strong interactions between the two Pc rings.

4. Conclusion

We have reported on the preparation of a phthalodinitrile derivative of a new type. This compound is used as a base for the preparation of a novel binuclear metal-free Pc of the ball type and zinc(II) Pcs of ball and clamshell types. The preparations of the new products are supported by elemental analysis, IR, UV-Vis, ^{1}H NMR and by mass spectra. It can be concluded from the voltammetric studies that the ball-type complexes **2** and **3** show ring-centered type mixed-valence behaviour as a result of the strong interaction between the two Pc rings, while there is no considerable interaction between the two Pc rings in **4**. The mixed-valence splitting energies and the comproportionation constants for **2** and **3** suggest that the mixed valence species are highly stable.

Scheme 1.

P–N–P–N cycle was formed, whereas the pyridinium salt of 1,3,4-triaza-2λ^5-phospholane with a five-membered P–N–N–C–S cycle was prepared in the absence of a HCl acceptor.

The reaction of **9** with urea leads to the formation of the cyclic ammonium salt of 4,6-dioxo-2-sulfido-2-thioxo-1,3,5-triaza-2λ^5-phosphinane [7]. The reaction of **9** with *N*,*N*′-diphenylthiourea, $(PhNH)_2CS$ (**8**), yields, in the presence of triethylamine and depending on the reaction temperature, two different heterocyclic compounds containing P–N–C–N and P–N–P–N cycles [8] (see Scheme 1).

The reaction of $pyPS_2Cl$ (**9**) with $(PhNH)_2CO$ (**2**), as well as reactions of phosphorus pentasulfide (**1**) with **2** and **8** had not been studied as yet. Therefore they became the subject of our investigation in this work.

2. Results and discussion

2.1. Reaction of P_4S_{10} (*1*) with *N,N′*-diphenylurea (*2*)

The course of the reactions between **1** and nucleophilic reagents has commonly the character of nucleophilic reduction in which, depending on the reaction conditions, a wide variety of compounds arise [11,12].

The reaction of **1** with **2** was carried out in acetonitrile and in the presence of pyridine in the molar ratio 1:4:4. A number of reaction products arose in the course of the reaction. The composition of the reaction mixture was followed by ^{31}P NMR spectroscopy. The integral rates of all resonance signals presented in the ^{31}P NMR spectrum are shown in Table 1. Compound **13**, containing unexpectedly an oxygen atom in the molecule, is probably the product of partial hydrolysis of sulfur containing precursors. Yellow needle crystals were also formed at the same time and they were assigned to the previously undescribed compound **7**.

2.2. Reaction of P_4S_{10} (*1*) with *N,N′*-diphenylthiourea (*8*)

This reaction was carried out in a similar way to that described above. Yellow crystals were formed after 15 min heating. The resonance signals, which were found in the ^{31}P NMR spectrum of the reaction mixture, are mentioned in Table 1. After cooling the reaction mixture, the solvent was partially evaporated in vacuum at ambient temperature, the solid was filtered off and rinsed with acetonitrile. The ^{31}P NMR spectrum of this solid, dissolved in acetonitrile, proved that the solution contained only compound **4**.

2.3. Reaction of $pyPS_2Cl$ (*9*) with *N,N′*-diphenylurea (*2*)

The reaction between **9** and **2** (1:1) was carried out in acetonitrile solution in the presence of pyridine as a HCl acceptor. At first, the reaction mixture was refluxed for

Table 1
Identified ^{31}P NMR signals in the studied reaction mixtures

Compound	δ (ppm)	Reaction partners			
		$P_4S_{10} + (PhNH)_2CO$		$P_4S_{10} + (PhNH)_2CS$	$pyPS_2Cl + (PhNH)_2CO$
		Reflux (2 h) (%)	After standing 3 months (20 °C) (%)	Reflux (20 min) (%)	Reflux (1.5 h) (%)
3	88.1	89	83		9
4	109.1	4	1	94	4
5 [16]	120.3	7	1		1
6 [16]	130.4		7	4	
10 [18]	84.0				25
12 [17]	87.4		1	2	
13 [16]	32.1		7		

1.5 h. Greenish crystals precipitated in the course of the reaction and the ^{31}P NMR chemical shift (88.1 ppm) corresponds to compound **3**. The composition of the remaining reaction mixture is given in Table 1.

Further standing of the filtrate led to the crystallization of another brown solid. Its resonance signal at 120.3 ppm was found in the ^{31}P NMR spectrum, and corresponds to the resonance of compound **5**. The final solid, which was isolated from the filtrate after several weeks of standing, was elemental sulfur, as identified by MS spectrometry.

2.4. Identification and properties of the prepared compounds

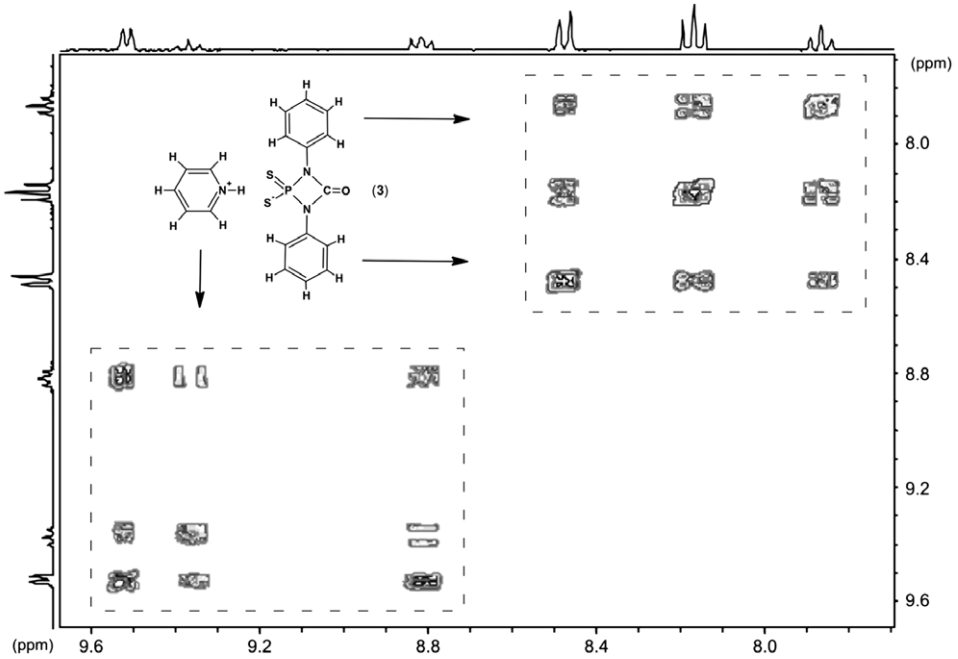
2.4.1. Identification of *3*

Two independent spin systems in the regions $\delta = 7.8$–8.5 ppm and $\delta = 8.7$–9.6 ppm, and not linked together by cross peaks, were identified in the 2D ^{1}H–^{1}H COSY NMR spectrum of **3** (Fig. 1). These regions are sufficiently apart from each other to enable their resolution without difficulties. The integral rate of the first spin system is approximately twice the integral rate of the second one, which is in agreement with integral values in the 1D ^{1}H NMR spectrum. From this and from comparison with the ^{1}H NMR spectra of **9** and **2** it follows that the molecule of **3** contains one aromatic group coming from **9** (pyridine) [19] and two aromatic phenyl groups coming from **2** [20].

The molecular peak at $m/z = 306$ in the MS spectrum of **3** corresponds to the mass of the anionic part (exact mass 304.997219). The thermal behavior of **3** was followed by thermal analysis. There are two minima on the DTA curve. The first endothermic minimum at 174 °C corresponds to the melting point of **3**, and the second one at 184 °C belongs to the beginning of the thermal decomposition, accompanied by a continuous mass loss. In the region 310–400 °C, a few undistinguished minima were observed, which can be ascribed to gradual decomposition of the compound. At 424 °C, the weight loss reached 72.9%, which corresponds to the formation of $POSN_2$ (theoretical weight loss 72.2%). At 632 °C further weight loss of up to 88.0% of the starting mass of the sample was observed. This stage of decomposition corresponds to the expected end-product of the composition PN (theoretical weight loss 88.3%). X-ray diffraction analysis of **3** confirmed that this substance is the pyridinium salt of 1,3-diphenyl-2-sulfido-2-thioxo-1,3-diaza-2λ^5-phosphetidine.

2.4.2. Identification of *4*

The formation of compound **4** was detected in all the studied reaction systems (**1** with **2** or **8**; **9** with **2**). The resonance signal of **4** was found at $\delta = 109.1$ ppm (s). This chemical shift is characteristic for phosphorus (V) compounds containing the PS_2 group. The substance **4** was also studied by ^{1}H NMR spectroscopy. Resonance signals in the aromatic region ($\delta = 7.18$–7.59 ppm) belong to a phenyl group, and signals in the region 7.99–8.68 ppm are characteristic of the pyridinium cation [19]. Another resonance signal at $\delta = 8.47$ ppm in the ^{1}H NMR spectrum can be assigned to the acid hydrogen bonded to pyridine. MS spectrometry of **4** identified the molecular peak at $m/z = 436$. This mass corresponds to a compound of the composition $C_{12}H_{10}N_2P_2S_6$ (exact mass 435.864356). Therefore it was concluded that substance **4** is the pyridi-



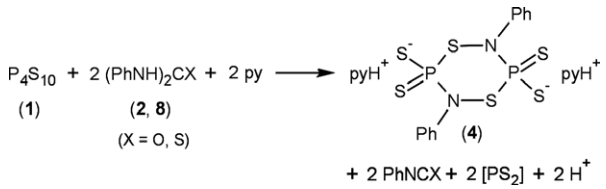


Fig. 1. 2D ^{1}H–^{1}H COSY NMR spectrum of compound **3**.

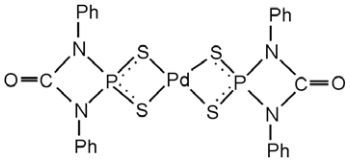
nium salt of 1,4-diphenyl-2,5-disulfido-2,5-dithioxo-1,4-dithiadiaza-2λ^5, 5λ^5-diphosphinane. Its possible formation is shown in the following equations:



(1)

$$2\ \underset{(9)}{\mathrm{pyPS_2Cl}} + 2\ \underset{(2)}{(\mathrm{PhNH})_2\mathrm{CO}} + 1/4\ \mathrm{S_8} \rightarrow (4) + 2\ \mathrm{PhNCO} + 2\ \mathrm{H^+} + 2\ \mathrm{Cl^-} \quad (2)$$

$$2\ \underset{(10)}{[\mathrm{pyH}][\mathrm{PS_2Cl_2}]} + 2\ \underset{(2)}{(\mathrm{PhNH})_2\mathrm{CO}} + 1/4\ \mathrm{S_8} \rightarrow (4) + 2\ \mathrm{PhNCO} + 4\ \mathrm{H^+} + 4\ \mathrm{Cl^-} \quad (3)$$

2.4.3. The complex properties of 3

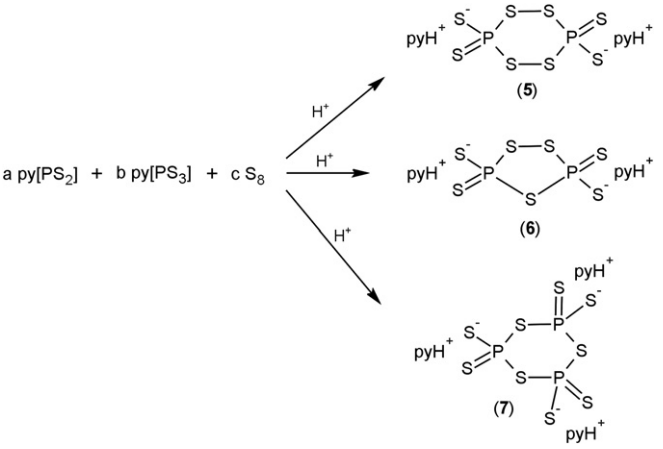
The presence of two sulfur atoms in the PS_2 group of **3** indicates that this substance can have an affinity to metal ions such as Ni [21], Pd [22] and Pt [23]. Therefore we allowed compound **3** to react with $Pd(CH_3COO)_2$ with the aim of preparing the Pd complex (**11**). The reaction was carried out in acetonitrile, with the starting compounds in a molar ratio of 2:1. Immediately, a brown precipitate appeared. Mass spectrometry gave a molecular peak at *m*/*z* 717, which corresponds to the mass of the expected compound $C_{26}H_{20}N_4O_2P_2PdS_4$ (exact mass 715.897915).

Compound **11** is sparingly soluble in common solvents such as CH_3CN, CH_2Cl_2 or pyridine, and is insoluble in CH_3OH. It is poorly soluble in dimethylformamide, in which it decomposes within a few hours.

The thermal behavior of **11** was followed by thermal analysis. The compound did not melt and only slow decomposition was observed with increasing temperature. The first endothermic effect occurs on DTA curve at 140.9 °C and corresponds to the beginning of the decomposition of **11**. The sample was further heated up to 1000 °C. The weight loss was 82.0% at the temperature 999 °C, which corresponds to the formation of PdO (theoretical weight loss 82.9%).

2.4.4. The formation of [pyH][PS$_2$Cl$_2$] (10)

The formation of pyridinium dichlorodithiophosphate, $[pyH][PS_2Cl_2]$ (**10**) in the reaction between **2** and **9**, can be explained as proceeding via two routes. The first one is that HCl, evolved in the first step of the substitution reaction between **2** and **9**, reacts with compound **9** with the formation of $[pyH][PS_2Cl_2]$ (**10**) [18]. The second route is based on the assumed reaction between the heterocyclic compound **3** and evolved HCl. This mechanism was proved by carrying out the direct reaction of **3** with HCl, and $(PhNH)_2CO$ (**2**) was found in the reaction mixture. The presence of both compounds was confirmed by ^{1}H NMR (**2**) [20] and ^{31}P NMR (**10**) spectroscopy.



2.4.5. The formation of cyclic thiophosphates 5, 6 and 7

Cyclic phoshpates have been known for a long time. A mixture of the anions $[P_2S_8]^{2-}$ (present in **5**) and $[P_3S_9]^{3-}$ (in **7**) is formed as a result of disproportionation $[P_2S_7]^{2-}$ (in **6**) [16]. The anion $[P_3S_9]^{3-}$ is known as $[NH_4]_3[P_3S_9]$ [24] and was obtained in the reaction of P_4S_{10} and P_4S_9 in liquid ammonia below −33 °C. It was also prepared, together with $[P_2S_7]^{2-}$ and $[P_2S_8]^{2-}$, as the triethylammonium salts in the reaction mixture of triethylamine, white phosphorus and sulfur [16]. We also prepared $[pyH]_3[P_3S_9]$ (**7**) in the reaction of **9** with benzamide in a yield 67% (with respect to **1**). The anion of compound **5** was identified (as a salt with the cation $[py_2H]^+$) amongst the products of the reaction of **1** and pyridine [25], and also in the reaction mixture of **9** with 4-*iso*-propylthiosemicarbazide [10].

The formation of bis(pyridinium)-bis(μ-disulfido)-tetrathio-*cyclo*-diphosphate, $[pyH]_2[P_2S_8]$ (**5**), bis(pyridinium)-μ-disulfido-pentathio-*cyclo*-diphosphate, $[pyH]_2[P_2S_7]$ (**6**) and tris(pyridinium)-nonathio-*cyclo*-triphosphate, $[pyH]_3[P_3S_9]$ (**7**) can be explained in our reaction systems on the basis of the formation of $[PS_2]$ and $[PS_3]$ units and S_8 (Scheme 2).

2.4.6. Crystal structures of 3 and 7

Crystals of compound **3** are monoclinic and were grown from acetonitrile solution. The molecular structure (Fig. 2) has certain common features. The structure is formed by a

Scheme 2.

four-membered approximately planar heterocycle containing P–N–C–N atoms. Each of the two *N*-phenyl ring planes is tilted with respect to the plane of the P–N–C–N heterocycle [6.83(5)° or 3.34(6)°]. The plane formed by the S–P–S bonds is oriented almost perpendicularly (88.94(6)°) to the plane of the heterocycle. The values of these angles are in agreement with the expected sp^3 hybridization of the P-atom. The π-electron density of the proposed P═S bond is delocalized over the exocyclic PS_2 group, which was confirmed by the almost equal P–S bond lengths (1.94–1.96 Å). These values are comparable to those in similar substances, $[pyH][PS_2(NPh)_2CS]$ and $[pyH][PS_2NPh]_2$ [8]. Compound **3** can be considered as an almost ionic substance. In fact, the pyridinium cation is bonded to the S atoms of the PS_2 group (H3A···S1 and H3A···S2) through a van der Waals interaction; the distances between the atoms are 2.671(5) and 2.580(4) Å. This type of interaction can also be observed in similar substances, such as $[pyH][PS_2(NPh)_2CS]$ (2.42(4) Å) and $[pyH][PS_2NPh]_2$ (3,3145(3) Å) [8]. Compound **3** does not contain any other relevant H-bridges. A comparison of the corresponding bond lengths with the literature data [8] shows that there is no significant difference either in the four-membered ring, or in the exocyclic bonds. Only isolated molecules of **3** can be found in the crystal structure. Selected crystallographic data are given in Table 2.

The structure and composition of solid **7** were determined by X-ray diffraction to be tris(pyridinium)-nonathio-*cyclo*-triphosphate, $[pyH]_3[P_3S_9]$, and the structure is shown in Fig. 3. The molecular structure of the $[P_3S_9]^{3-}$ anion was previously determined by Falius et al. Compound $[pyH]_3[P_3S_9]$ was prepared in the reaction between elemental phosphorus and alkylammonium polysulfides [16]. The anion is packed together with triethylammonium cations, and the P_3S_3 ring adopts a nearly perfect chair conformation. In our compound **7**, the six-membered ring takes on a skew-boat arrangement. The bond distances and angles are comparable between $[Et_3NH]_3[P_3S_9]$ and **7**. The intracyclic P–S bond lengths range within 2.122(1) and 2.147(1) Å, while the terminal P═S bonds are shorter, reflecting their increased π-character [1.966(1)–1.986(1) Å].

3. Experimental

3.1. Physical measurements

^{1}H, ^{13}C and ^{31}P NMR spectra were recorded on 300 and 500 MHz Bruker DRX Avance NMR spectrometers. Chemical shifts are given in ppm (δ scale) relative to tetramethylsilane (for ^{1}H and ^{13}C nuclei), or 85% H_3PO_4 for ^{31}P. All samples were measured at 303 K in dimethylsulfoxide or acetonitrile in a coaxial cuvette system (an inner 4 mm cuvette with the sample placed in a 5 mm cuvette containing a small amount of D_2O). Compound **7** (dissolved in D_2O) was measured directly in the 5 mm cuvette. ^{13}C NMR spectra were measured with ^{1}H decoupling. The

2D ^1H–^1H COSY NMR spectrum was measured with two 90° pulses.

Mass spectra were measured using a multifunctional quadrupole spectrometer TRIO 1000 Series II, Finnigan MAT, Fisons Instruments. The ionization energy was 70 eV. The sample was inserted into the spectrometer by the Direct Insert Probe.

FT-IR spectra were measured in Nujol using an Equinox 55/S/NIR FT-IR Bruker spectrometer. Vibration frequencies were compared with the literature data [26,27].

Elemental analyses (C, H, N, S) were performed on a Fisons Instruments EA-1108 elemental analyzer. Phosphorus was determined gravimetrically as chinolinium molybdatophosphate.

Thermal analysis up to 1000 °C was carried out using a Derivatograph C, MOM, in a ceramic pot in static air atmosphere. The heating rate was 5 K min^{-1}.

Crystal structure determinations were performed using a four-circle diffractometer KUMA KM-4 with Mo Kα radiation ($\lambda = 0.71069$ Å), and the software packages Xcalibur CCD system for the data collection/reduction [28] and SHELXTL for the structure solution, refinement and drawing preparation [29]. The structures were solved by direct methods. Non-hydrogen atoms were refined anisotropically while hydrogen atoms were inserted in calculated positions and isotropically refined assuming a ''ride-on'' model. Selected crystallographic data of compounds **3** and **7** are shown in Table 2.

3.2. Procedures

All reactions and subsequent manipulations were carried out in an atmosphere of dry nitrogen. $pyPS_2Cl$ (**9**) was prepared according to a known procedure [30]. P_4S_{10} (**1**) was purchased from Merck, diphenylurea (**2**) and diphenylthiourea (**8**) (Fluka) and $Pd(CH_3COO)_2$ (Sigma–Aldrich) were used without further purification. Acetonitrile and pyridine were purified according to known procedures [31] and distilled before use.

3.2.1. Synthesis of the pyridinium salt of 1,3-diphenyl-2-sulfido-2-thioxo-1,3-diaza-2λ^5-phosphetidine $[pyH][PS_2(NPh)_2CO]$ (**3**)

2.786 g (13.29 mmol) of **9** and 2.800 g (13.19 mmol) of **2** in 40 ml CH_3CN were placed into a Schlenk vessel and 1.026 g (12.97 mmol) of pyridine was added to the suspension. The reaction mixture was refluxed for 1.5 h. Compound **2** gradually dissolved and the reaction mixture turned yellow. After cooling, the first portion of greenish crystals appeared. The supernatant solution was partially evaporated and greenish crystals of **3** were filtered off. The yield after recrystallization from acetonitrile was 73% (with respect to **9**).

Anal. Calc. for $C_{18}H_{16}N_3OPS_2$: N, 10.90; P, 8.04; S, 16.64. Found: N, 11.17; P, 7.91; S, 16.05%. M.p. 174.2 °C. IR (Nujol): $\nu(pyH^+)$: 1634 (m), 1611 (sh), 1525 (m), 1496 (vs); $\nu_{CH}(pyH^+)$: 3196 (vw), 3125 (w), 3082 (m), 3060 (m); $\delta(C_{arom}–H)$: 1283 (sh), 1265 (sh), 1195 (m), 1168 (w), 1103 (w), 1058 (vw), 1047 (vw), 1023 (w), 1003 (m), 987 (w), 893 (w); PS: 756 (vs), 739 (vs), 693 (vs), 674 (s), 646 (vs).

3.2.2. Synthesis of the pyridinium salt of 1,4-diphenyl-2,5-disulfido-2,5-dithioxo-1,4-dithiadiaza-2λ^5,5λ^5-diphosphinane $[pyH]_2[PS_2(SNPh)]_2$ (**4**)

A suspension of **1** (0.226 g, 0.51 mmol) and 0.458 g (2.01 mmol) of **8** in 25 ml of acetonitrile and 0.33 ml pyridine (4.1 mmol) was refluxed for 20 min. Yellow crystals of compound **4** formed after 15 min heating. The solvent was partially evaporated after cooling of the reaction mixture. The crystals that formed were filtered off and rinsed with acetonitrile. Compound **4** was obtained in 48% yield (with respect to **1**).

Anal. Calc. for $C_{22}H_{22}N_4P_2S_6$: N, 9.39; P, 10.38; S, 32.24. Found: N, 10.44; P, 11.78; S, 32.03%. M.p. 169.8–172.5 °C. IR (Nujol): $\nu_{CH}(pyH^+)$: 3121 (vw), 3085 (sh), 3051 (vw); $\nu(pyH^+)$: 1629 (w), 1606 (sh), 1595 (m), 1537 (sh), 1481 (s); 1530 (sh), 1496 (sh), 1328 (w); $\delta(C_{arom}–H)$: 1279 (m), 1261 (w), 1237 (w), 1195 (w), 1159 (w), 944 (sh), 937 (sh), 900 (m), 876 (m), 865 (sh); PS: 755 (w), 743 (sh), 740 (w), 696 (m), 670 (sh), 666 (sh), 661 (s), 606 (w), 540 (s).

3.2.3. Synthesis of tris(pyridinium)-nonathio-cyclo-triphosphate $[pyH]_3[P_3S_9]$ (**7**)

A solution of **1** (0.313 g, 0.70 mmol) and **2** (0.610 g, 2.87 mmol) in 15 ml of acetonitrile and 0.46 ml (5.64 mmol) of pyridine was refluxed for 2 h. Compound **2** dissolved gradually during heating and the reaction mixture turned yellow. The reaction mixture was kept at ambient temperature for 3 months and yellow needle crystals of **7**, soluble only in H_2O, were formed in 15% yield (with respect to **1**).

Anal. Calc. for $C_{15}H_{18}N_3P_3S_9$: C, 28.97; H, 2.92; N, 6.76; P, 14.94; S, 46.41. Found: C, 27.62; H, 2.81; N, 6.80; P, 14.92; S, 46.38%. M.p. 138.7–139.1 °C. IR (Nujol): δ(C–H): 3041 (sh), 3062 (sh); $\nu(pyH^+)$: 1628 (m), 1610 (m), 1540 (m), 1485 (sh); 1517 (s), 1476 (s), 1377 (m), 750 (s); ν(PS): 667 (s), 676 (s), 609 (w), 649 (sh); ν(P–S–P): 485 (s), 496 (s), 549 (s), 559 (s).

3.2.4. Synthesis of bis(2,2-disulfido-4-oxo-1,3-diphenyl-1,3-diaza-2λ^5-phosphetidino)palladium(II) $[Pd(Ph_2N_2COPS_2)_2]$ (**11**)

0.341 g (0.88 mmol) of **3** and 0.099 g (0.44 mmol) of $Pd(CH_3COO)_2$ was stirred in acetonitrile at ambient temperature for 12 h. The reaction product (**11**), a brown powder, was filtered off. Yield: 57% (with respect to **3**).

Anal. Calc. for $C_{26}H_{20}N_4O_2P_2PdS_4$: C, 43.55; H, 2.81; N, 7.81; P, 8.64; S, 17.89. Found: C, 42.66; H, 2.66; N, 7.84; P, 8.63; S, 15.28%. Temperature 140.9 °C (dec.). 4. Conclusion

New heterocyclic compounds with exocyclic PS_2 and P–N atoms in the cycle (pyridinium salts of 1,3-diphenyl-2-sulfido-2-thioxo-1,3-diaza-2λ^5-phosphetidine, [pyH][$PS_2(NPh)_2CO$] (**3**) and 1,4-diphenyl-2,5-disulfido-2,5-dithioxo-1,4-dithiadiaza-2λ^5,5λ^5-diphosphinane, $[pyH]_2[PS_2(SNPh)]_2$ (**4**)) were prepared from two P–S precursors – P_4S_{10} (**1**) and $pyPS_2Cl$ (**9**). In the reactions cyclic thiophosphates were formed. We proved the formation of bis(μ-disulfido)-tetrathio-*cyclo*-diphosphate, $[pyH]_2[P_2S_8]$ (**5**), bis(pyridinium)-μ-disulfido-pentathio-*cyclo*-diphosphate, $[pyH]_2[P_2S_7]$ (**6**) and tris(pyridinium)-nonathio-*cyclo*-triphosphate, $[pyH]_3[P_3S_9]$ (**7**). A Pd-complex, bis(2,2-disulfido-4-oxo-1,3-diphenyl-1,3-dia- za-2λ^5-phosphetidino)palladium(II), [$Pd(Ph_2N_2COPS_2)_2$] (**11**) was also prepared.

Acknowledgements

We thank our colleagues from the Faculty of Science, Palacky University, Olomouc, Czech Republic for carrying out the elemental analyses.

Appendix A. Supplementary material

CCDC 638838 and 638971 contain the supplementary crystallographic data for **3** and **7**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.05.032.

CD_3OD and $CDCl_3$. Melting points are uncorrected and were obtained by a Kofler Heizbank Rechart type 7841 melting point apparatus.

2.2. Synthesis of [Fe(bipy)Cl4][bipy·H] (1)

2,2′-Bipyridine (0.31 g, 2 mmol) in 20 ml HCl 0.1 M was added to a solution of $FeCl_3 \cdot 6H_2O$ (0.27 g, 1 mmol) in water (15 ml). The resulting red solution was stirred at 55–60 °C for 3 h. The yellow coloured precipitated product that was obtained was recrystallized from CH_3CN. After three days, yellow prismatic crystals of **1** were isolated (yield 0.39 g, 76.3%, m.p 216 °C). IR (KBr, cm^{-1}): 3060m (υCH), 1615m, 1599s, 1583s, 1529s, 1494w, 1473m, 1456m, 1443s, 1433m, 1384w, 1367w, 1320m, 1311s, 1270m, 1248w, 1229w, 1174m, 1158m, 110w, 1102w, 1088w, 1068w, 1058w, 1020m, 1010m, 993 sh, 929m, 908w, 881m, 808w, 764s, 733m, 724m, 652m, 630m, 610m, 524w, 425w, 441w, 418m, 400w, 393w, 362w, 333w, 308s (υFe–Cl), 290s (υFe–Cl), 255s (υFe–N). *Anal.* Calc. C, 46.96; H, 3.33; N, 10.95. Found: C, 46.58; H, 3.51; N, 10.76%.

2.3. Synthesis of [Fe(dmbipy)2Cl2][FeCl4] (2)

5,5′-Dimethyl-2,2′-bipyridine (0.2 g, 1.08 mmol) in 10.8 ml HCl 0.1 M was added to a solution of $FeCl_3 \cdot 6H_2O$ (0.147 g, 0.54 mmol) in water (10 ml), and the resulting red solution was stirred at 50–55 °C for 3 h. The orange colored precipitated product that was obtained was recrystallized from H_2O:CH_3OH (1:4). After two weeks, orange prismatic crystals of $[Fe(dmbipy)_2Cl_2][FeCl_4]$ were isolated (yield 0.14 g, 74.83%, decompose <260 °C). IR (KBr, cm^{-1}): 3053w, 1599m, 1573m, 1478s, 1504m, 1447m, 1386s, 1315s, 1285w, 1253s, 1142m, 1049s, 991w, 854w, 837s, 819m, 762w, 727s, 692m, 654m, 539w, 495w, 480w, 418m, 381s (υFe–Cl), 331s (υFe–Cl), 258s (υFe–N). *Anal.* Calc. C, 41.56; H, 3.46; N, 8.08. Found: C, 41.23; H, 3.52; N, 7.91%.

2.4. Crystal structure determination and refinement

The X-ray diffraction measurements were made on a STOE IPDS-II diffractometer with graphite monochromated Mo-Kα radiation. For $[Fe(bipy)Cl_4][bipy{\cdot}H]$, **1**, a yellow prismatic crystal with dimensions of $0.50 \times 0.25 \times 0.25$ mm and for $[Fe(dmbipy)_2Cl_2][FeCl_4]$, **2**, an orange prismatic crystal with dimensions of $0.30 \times 0.25 \times 0.13$ mm were mounted on a glass fiber and used for data collection. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 4272 unique reflections for **1** and 12577 for **2**. Data were collected at a temperature of 293(2) K to a maximum 2θ value of 53.36° for **1** and 53.66° for **2** and in a series of ω scans in 1° oscillations, and were integrated using the Stoe X-AREA [14] software package. The numerical absorption coefficients, μ, for Mo-Kα radiation are 1.212 mm^{-1} for **1** and 1.524 mm^{-1} for **2**. A numerical absorption correction was applied using X-RED [15] and X-SHAPE [16] software. The data were corrected for Lorentz and Polarizing effects. The structures were solved by direct methods [17] and subsequent difference Fourier maps and then refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [18]. All the hydrogen atoms were located in a difference Fourier map and then refined isotropically. Subsequent refinement then converged with R factors and parameter errors significantly better than for all attempts to model the solvent disorder. Atomic factors are from International Tables for X-ray Crystallography [19]. All refinements were performed using the X-STEP32 crystallographic software package [20]. A summary of the crystal data, experimental details and refinement results is given in Table 1.

3. Results and discussion

3.1. Synthesis of [Fe(bipy)Cl4][bipy·H] (1) and [Fe(dmbipy)2Cl2][FeCl4] (2)

Compound **1** was obtained from the reaction of 1 equiv of $FeCl_3 \cdot 6H_2O$ with 2 equiv of 2,2′-bipyridine in a 0.1 M

aqueous solution of HCl at around 55 °C for 3 h, with 76% yield, Eq. (1):

$$FeCl_3 \cdot 6H_2O + 2bipy \xrightarrow[H_2O,\ HCl\ 0.1\ M]{(55\text{–}60)\ ^\circ C,\ 3\ h} [Fe(bipy)Cl_4][bipy \cdot H] \quad (1)$$

Coordination of iron(II) with 2,2′-bipyridine ligands, L, generally leads to the highly stable tris-bipy complex and to a lesser extent to $[FeL_2X_2]$, $X = CN^-$, SCN^- and Cl^- [3]. However, the presence of Fe(III) and HCl in the solution caused the formation of complex **1**. Almost the same reaction conditions as for the formation of complex **1** was employed with methanol as the solvent and with the absence of HCl, and the result was the formation of $[Fe_2L_2Cl_4]$, in which two chlorides are terminal and two are bridged to make a bimetallic iron complex [4]. Here, it seems that the presence of an aqueous HCl solution is a driving force for the formation of the bipy complex in its monomeric form with only one bipy coordinated to the iron (in spite of that stoichiometry of the metal to ligand ratio is 1:2). Note, the formation of $[Fe^{III}(bipy)_2Cl_2]$-$[Fe^{III}Cl_4]$ has even been reported with a stoichiometric amount of $FeCl_3$ and bipy in the absence of HCl [21]. Treatment of $FeCl_3 \cdot 6H_2O$ with 5,5′-dimethyl-2,2′-bipyridine, Me_2L, under exactly the same reaction conditions to those for complex **1**, produces complex **2** in 74.83% yield, Eq. (2):

$$2FeCl_3 \cdot 6H_2O + 4dmbipy \xrightarrow[H_2O,\ HCl\ 0.1\ M]{(55\text{–}60)\ ^\circ C,\ 3\ h} [Fe(dmbipy)_2Cl_2][FeCl_4] + 2dmbipy \cdot HCl \quad (2)$$

To our surprise, the formation yields of complexes **1** and **2** are similar and Eq. (2) illustrates that a slight increase in the basic ability of Me_2L compared to that of L results in the formation of the $[Fe(Me_2L)_2Cl_2]^+$ complex. Complexes **1** and **2** are stable in the solid state. They dissolve in basic solvents such as alcohol, H_2O and DMSO. However, complex **1** readily gives a ligand substitution reaction in donor solvents such as water and DMSO, whereas complex **2** is fairly stable in these solvents.

3.2. Spectroscopic characterizations of *[Fe(bipy)Cl4][bipy·H]* (*1*) and *[Fe(dmbipy)2Cl2][FeCl4]* (*2*)

IR spectra of iron bipyridine complexes have been extensively studied in the literature and their vibrations are well established [22–25]. They contain several bands in the regions 1400–1600 and 700–900 cm^{-1}, which are related to the ring modes [υ(C–C) and υ(C–N)] and the ring deformation vibrations, respectively [25]. For instance, the bands observed in the IR spectrum of the free bpy ligand at 1414, 1452, 1456 and 1578 cm^{-1} are shifted to higher frequencies upon coordination and are observed at 1433, 1456, 1583 and 1599 cm^{-1} in the spectrum of **1**. The peaks connected with the ring deformation of the aromatic N-donor heterocycles are observed in the IR spectra of all the complexes at ca. 630, 724, 764, 808 and 881 cm^{-1} [26]. The bands observed near 3060 cm^{-1}can be assigned to $\upsilon(C_{aromatic}–H)$ vibrations. Two strong bands in complex **1** at 308 and 290 cm^{-1} were assigned to Fe–Cl and the band at 255 cm^{-1} to Fe–N, based on literature reports [24,27]. The IR spectrum of compound **2** is distinguished from that of **1**, mainly by bands at 3423 and 1386 cm^{-1}, which are due to absorptions of the methyl groups. The Fe–N stretching vibration for complex **2** is seen at 258 cm^{-1}, and that for Fe–Cl is seen at 381 cm^{-1} in the anion and at 331 cm^{-1} in the cation species. The stretching vibrations of Fe–N in complex **1** and **2** are consistent with the high spin character of these complexes. Low spin frequencies for Fe–N appear around 50–70 cm^{-1} higher frequency to that of high spin compounds containing bipy [28].

The ^1H NMR data for complexes of **1** and **2** at room temperature show a multiplet in the 7–8.7 ppm region for the bipyridine protons. Protons of the methyl groups in **2** are too broad and were placed at 10–12 ppm. Solvents such as water and methanol did not affect the ^1H NMR data of complex **2**. However, complex **1** is highly sensitive to the coordinating solvent and its spectrum readily changed in polar solvents. We were able to observe its ^1H NMR in $CDCl_3$ even though its solubility is low. Details of NMR investigation and the reactivity of this compound is under investigation. In addition, magnetic susceptibility

measurements for **1** and **2** by the Evans method confirms the high spin character of these complexes ($\mu_{eff} = 6$ and 6.5, respectively).

UV–Vis spectra of **1** and **2** have no spin allowed signals for d–d transitions (their color is yellow in solution) but a charge transfer band is seen around 353 nm, in accord with the high spin character of iron(III).

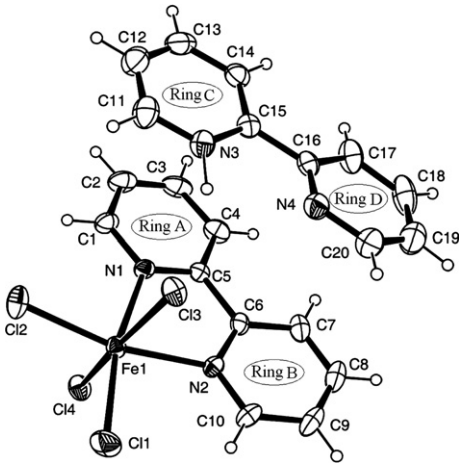

Fig. 1. The labelled diagram of [Fe(bipy)Cl_4][bipy·H] (**1**). Thermal ellipsoids are at the 30% probability level and H-atoms are shown as small spheres of arbitrary radii.

3.3. Description of the molecular structures of [Fe(bipy)Cl_4][bipy·H] (*1*) and [Fe(dmbipy)$_2Cl_2$][$FeCl_4$] (*2*)

Orange prismatic crystals of **1** were obtained by re-crystallization of micro crystals of **1** in CH_3CN. For complex **2** crystals were grown in a mixture of H_2O and CH_3OH (1:4) over two weeks. Crystallographic data for **1** and **2** are given in Table 1 and selected bond lengths and angles are presented in Table 2.

3.3.1. Structure of [Fe(bipy)Cl_4][bipy·H] (*1*)

The structure of complex **1** consists of $[Fe(bipy)Cl_4]^-$ anions and protonated bipyridine cations, Fig. 1. The iron(III) environment consists of four chloride ions and a bipyridine ligand, giving a distorted octahedral geometry. The different bond length values of the Fe(1)–Cl bonds trans to Cl and those trans to N (bipy), accompanied with the short bite angle of bipy [73.91(1)° for N(1)–Fe(1)–N(2)] are the main factors accounting for this distortion. The Fe–N (bipy) average bond distance is 2.193(3) Å and the Fe–Cl average bond distance is 2.3458(1) Å. These bond distances

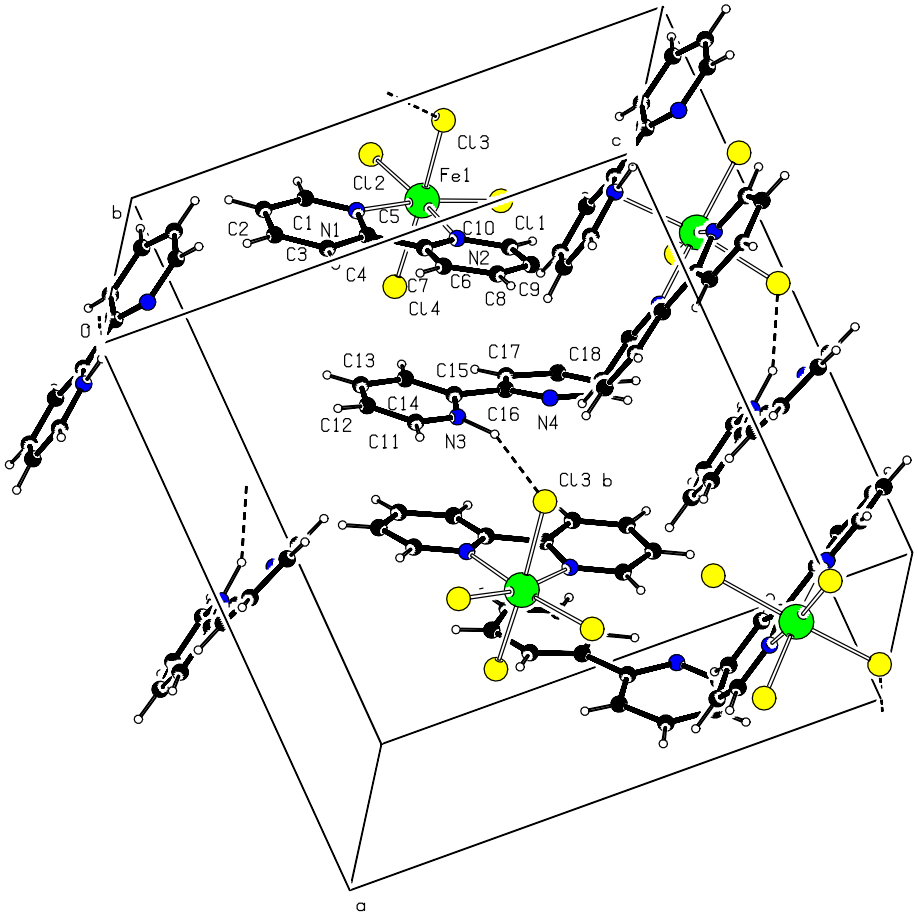

Fig. 2. Crystal packing diagram for [Fe(bipy)Cl_4][bipy·H] (**1**). Hydrogen bonds are shown as dashed lines.

are longer than those observed for similar low spin complexes [29]. The longer bond distance in complex **1** confirms that this complex is high spin with $S = 5/2$, in accord with data obtained by magnetic moment measurements. Good agreement is observed between the Fe–Cl bond distances of **1** and those reported for other chloro containing mononuclear high spin iron(III) complexes [30]. The Fe–N and Fe–Cl stretching frequencies in the infrared spectrum at 255, 308 and 290 cm^{-1} provide additional evidence for the high spin character.

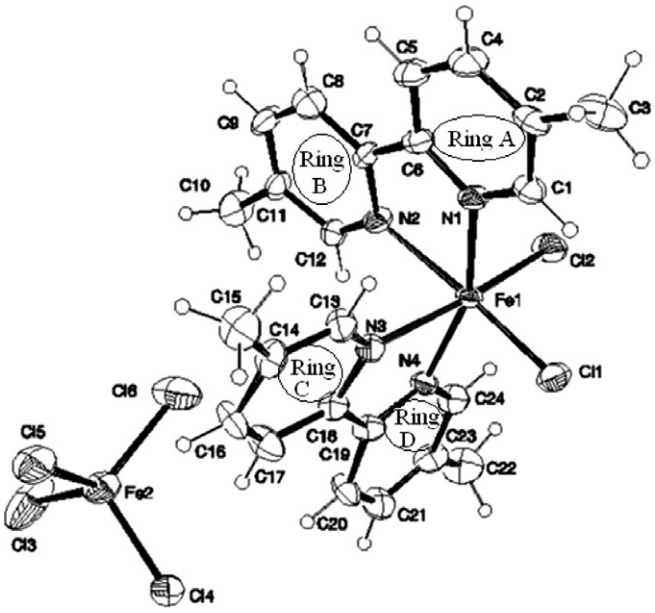

Fig. 3. The labelled diagram of cis-[Fe(dmbipy)$_2$Cl$_2$][FeCl$_4$], **2**. Thermal ellipsoids are at the 30% probability level and H-atoms are shown as small spheres of arbitrary radii.

The unit cell-packing diagram of complex **1** is presented in Fig. 2. From this packing diagram, the intermolecular bond distances and angle for N–H···Cl (H3A···Cl3 = 2.33(9), N3···Cl3 = 3.241(4) Å and N3–H3A···Cl3 = 153.47(7)°), confirms hydrogen bond formation between the counter ions. These intermolecular hydrogen bonds seem to be an effective factor in the stabilization of the crystal structure. In complex **1**, the rings A (N1/C1–C5), B (N2/C6–C10), C (N3/C11–C15) and D (N4/C16–C20) are almost planar and the dihedral angles between them are A/B = 8.90° and C/D = 11.40(3)° (A and B for pyridine rings in the coordinated bipy and C and D for bipyH$^+$ cations, Fig. 1). Further distortion of the bipyridine rings in cationic part can be related to hydrogen bondings between N–H and Cl atoms, as is shown in Fig. 2. The closest distance between the bipyridine planes in the packing is 3.7 Å and pyridine rings are not placed on the top of each other. So π–π stacking in this structure is negligible.

3.3.2. Structure of cis-[Fe^{III}(dmbipy)$_2$Cl$_2$][FeCl$_4$] (**2**)

The crystal structure of **2** is composed of cis-[Fe^{III}(dmbipy)$_2$Cl$_2$]$^+$ cations and [Fe^{III}Cl$_4$]$^-$ anions. Fig. 3 illustrates the molecular structure of complex **2** and the atom numbering scheme. The asymmetric unit of the crystal contains

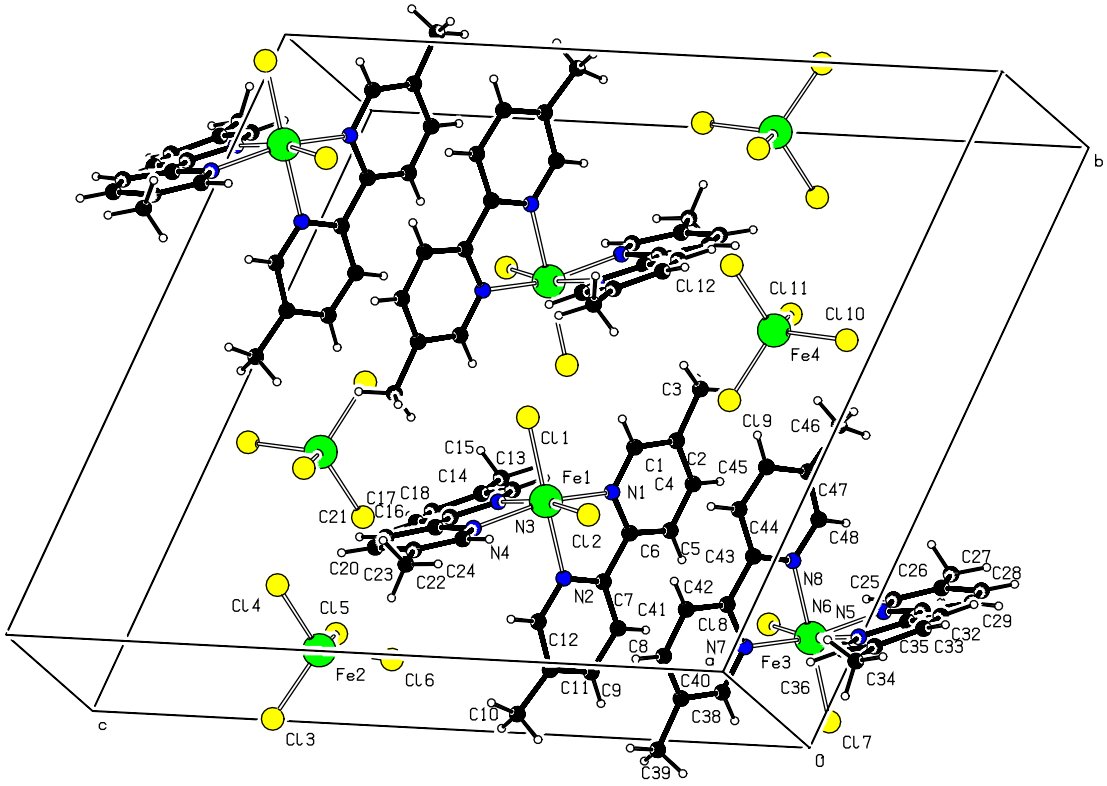

Fig. 4. Unit cell-packing diagram of cis-[Fe(dmbipy)$_2$Cl$_2$][FeCl$_4$], **2**.

two separate counter ions. Since both parts of the asymmetric unit have the same coordination behavior, here we explain only one ion pair. The Fe atom of the cation lies on a twofold axis. Two dmbipy nitrogen atoms coordinate to the iron atom in the cation with two chloride atoms coordinated to it in a cis fashion, producing a distorted octahedral geometry. The Fe atom environment in the anion is approximately tetrahedral.

The average values of the Fe–N (dmbipy) bonds in **2** is 2.171(5) Å and this distance is slightly smaller than that found in **1**, 2.193(3) Å. The average bond distance of chloride atoms for complex **2**, 2.2568(19) Å, is ≈0.1 Å smaller than that found in **1**. These values of Fe–N(dmbipy) and Fe–Cl bonds in **2** are the same as those found in the complex cis-$[Fe^{III}(bipy)_2Cl_2][FeCl_4]$ {[Fe–N(bipy) = 2.146(2) Å and Fe–Cl = 2.254(2) Å}[21]. However the Fe–N(bipy) distances in the low spin $[Fe^{III}(bipy)_2(CN)_2]$ complex are 1.972(2) and 1.973(2) Å, which are considerably smaller than the distances reported here, in accord with the high spin character of **2** [29].

The bite angle of the chelates (dmbipy) N(1)–Fe(1)–N(2) and N(3)–Fe(1)–N(4) are 75.2(2) and 76.01(19)°, close to that found for **1** (73.94° for **1**). Here also, the rings A (N1/C1–C2/C4–C6), B (N2/C7–C9/C10–C11), C (N3/C13–C14/C16–C18) and D (N4/C19–C21/C23–C24) are planar and the dihedral angles between them are A/B = 2.47(4)° and C/D = 9.82(3)°. As is shown in Fig. 4, in complex **2** there is a π–π interaction between the A–B rings in two adjacent iron complexes, whereas there is no interaction between C–D bipy rings in neighboring complexes. The close contact distance between adjacent aromatic rings is 3.41 Å. In the anion structure, $[FeCl_4]^-$, the bond angles and distances are in good agreement to that of $[FeCl_4]^-$ anions which have been found in other structures [21].

X = H, CH_3, OCH_3

Fig. 1. 1 *meso*-Tetraarylporphyrins (H_2t(Xp)p).

was dried over anhydrous calcium chloride for 3 days. The substituted *meso*-tetraarylporphyrins and H_2tpp were prepared by the literature methods [11], and $SbCl_3$ was obtained from Merck, and was used as received. Trifluoroacetic acid (TFA) for the diprotonation of the porphyrins was purchased from Merck and was used as received. For the quantitative analysis of the Cl ion in the $[(H_2t(Xp)p)_2Sb_2Cl_6]$ compounds, 0.05 mmol of the molecular complexes were dissolved in $CHCl_3$ (20 ml) and then decomposed by addition of double distilled water (15 ml) to the solution. $SbCl_3$ was hydrolyzed in water and the porphyrins remained in the organic solvent. Then the two phases were separated by a decanter. For the percentage of chloride ion in the molecular complex, the mercury thiocyanato method was used [12].

The NMR spectra (^1H, ^{13}C) were recorded on a Bruker 500 Ultrashield spectrometer in $CDCl_3$. To obtain good integration results (for the ^1H NMR spectra), the concentration of the molecular complexes was 0.006 M. The residual $CHCl_3$ in the conventional 99.8% atom $CDCl_3$ gives a signal at $\delta = 7.26$ ppm, which was used for calibration of the chemical shift scale. The electronic absorption spectra were recorded in chloroform solutions on an ATI UNICAM-UV\VIS Vision SOFTWARE V-2011 spectrophotometer. The cell had an optical pathlength of 1 cm. FT-IR spectra were recorded on a Magna 550 Nicolet spectrometer using KBr pellets. Far-IR spectra were recorded on a Jasco FT/IR-680 Plus spectrometer using CsI pellets in the range 200–600 cm^{-1}.

2.2. Preparation of $[(H_2tpp)_2Sb_2Cl_6]$

Equimolar quantities (0.5 mmol) of solid H_2tpp and $SbCl_3$ ground together in a pestle and mortar at ambient temperature produces the green molecular complex, $[(H_2tpp)_2Sb_2Cl_6]$, without excess of the reactants after 30 minutes. The progress of the reaction was monitored by UV–VIS spectra. The mixture had no absorption band related to the free base *meso*-tetraarylporphyrin, and the porphyrins completely change to the related molecular complex. *Anal*. Calc. for $C_{88}H_{60}N_8Sb_2Cl_6$: C, 62.7; H, 3.6; N, 6.6; Cl, 12.6. Found: C, 63.3; H, 3.7; N, 6.5; Cl, 12.3%. ^1H NMR ($CDCl_3$) δ, ppm: 0.21 (s, 2H, NH), 8.62–8.64 (d, 8H, o, o′), 8.02-8.05 (t, 8H, m, m′), 7.97–8.00 (d, 4H, p), 8.61 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.3. Preparation of $[(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6]$

This molecular complex is synthesized in free solvent media using the above method. *Anal*. Calc. for $C_{96}H_{76}N_8Sb_2Cl_6$: C, 64.1; H, 4.3; N, 6.2; Cl, 11.8%. Found: C, 63.8; H, 4.1; N, 6.3; Cl, 11.6%. ^1H NMR ($CDCl_3$) δ, ppm: 0.19 (s, 2H, NH), 2.8 (s, 12H, CH_3), 8.50–8.52 (d, 8H, o, o′), 7.82–7.83 (d, 8H, m, m′), 8.57 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.4. Preparation of $[(H_2t(4\text{-}OCH_3p)p)_2Sb_2Cl_6]$

This complex is synthesized in free solvent media using the above method. *Anal*. Calc. for $C_{96}H_{76}N_8O_8Sb_2Cl_6$: C, 59.4; H, 3.9; N, 5.8; Cl, 10.9%. Found: C, 58.7; H, 4.1; N, 5.8; Cl, 11.1%. ^1H NMR ($CDCl_3$) δ, ppm: 0.57 (s, 2H, NH), 4.12 (s, 12H, OCH_3), 8.53–8.55 (d, 8H, o, o′), 7.54–7.56 (d, 8H, m, m′), 8.49 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.5. Preparation of $[(H_2t(3\text{-}CH_3p)p)_2Sb_2Cl_6]$

Equimolar quantities (0.5 mmol) of solid H_2t(3-CH_3)pp and $SbCl_3$ ground together in a pestle and mortar at room temperature produces the green molecular complex $[(H_2t(3\text{-}CH_3p)p)_2Sb_2Cl_6]$ after 60 min. Then, hot chloroform (5 ml) was added, and the mixture was ground until complexation was complete, which was determined by the disappearance of the Soret band ($\sim$418 nm) of the porphyrin in the UV–VIS spectrum. The result of elemental analyses for the complex, which was dried in a vacuum oven for 12 h at 50 °C, was consistent with $C_{96}H_{76}N_8Sb_2Cl_6$. *Anal*. Calc. for $C_{96}H_{76}N_8Sb_2Cl_6$: C, 64.1; H, 4.3; N, 6.2; Cl, 11.8. Found: C, 63.1; H, 4.1; N, 6.4; Cl, 12.0%. ^1H NMR ($CDCl_3$) δ, ppm: 0.27 (s, 2H, NH), 2.84 (s, 12H, CH_3), 8.41–8.44 (s, 4H, o), 8.41–8.44 (d, 4H, o′), 7.89–7.92 (t, 4H, m), 7.75–7.78 (d, 4H, p), 8.64 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.6. Preparation of $[(H_2t(3\text{-}OCH_3p)p)_2Sb_2Cl_6]$

This molecular complex was synthesized using the method used for the $[(H_2t(3\text{-}CH_3p)p)_2Sb_2Cl_6]$ complex. *Anal*. Calc. for $C_{96}H_{76}N_8O_8Sb_2Cl_6$: C, 59.4; H, 3.9; N, 5.8; Cl, 10.9. Found: C, 60.0; H, 3.8; N, 5.7; Cl, 10.7%. ^1H NMR ($CDCl_3$) δ, ppm: 0.26 (s, 2H, NH), 4.17 (s, 12H, OCH_3), 8.18 (s, 4H, o), 8.18 (d, 4H, o′), 7.90–7.93 (t, 4H, m), 7.51–7.53 (d, 4H, p), 8.64 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.7. Preparation of $[(H_2t(2\text{-}CH_3p)p)_2Sb_2Cl_6]$

H_2t(2-CH_3p)p (0.5 mmol) and $SbCl_3$ (0.6 mmol) were ground together in a mortar for 60 min at room tempera-

ture, affording a green molecular complex. Then hot chloroform (10 ml) was added, and the mixture was ground until complexation was complete, which was determined by the disappearance of the Soret band (~418 nm) of the porphyrin in the UV–VIS spectrum. The solvent was evaporated and the excess $SbCl_3$ removed by washing the residue with dry benzene. The result of elemental analyses for the molecular complex, which was dried in a vacuum oven for 24 h at 50 °C, was consistent with $C_{96}H_{76}N_8Sb_2Cl_6$. *Anal.* Calc. for $C_{96}H_{76}N_8Sb_2Cl_6$: C, 64.1; H, 4.3; N, 6.2; Cl, 11.8. Found: C, 63.1; H, 4.1; N, 6.5; Cl, 11.5%. ^{1}H NMR ($CDCl_3$) δ, ppm: −1.02 (br, 2H, NH), 2.09 (s, 12H, CH_3), 8.33–8.38 (d, 4H, o), 7.76–7.88 (d, 4H, m), 7.76–7.88 (t, 4H, m′), 7.76–7.87 (t, 4H, p), 8.63–8.68 (s, 8H, β). IR (KBr): υ_{NH} (~3320 cm^{-1}).

2.8. Preparation of $[(H_2t(2\text{-}OCH_3p)p)_2Sb_2Cl_6]$

This complex was synthesized using the method of the $[(H_2t(2\text{-}CH_3p)p)_2Sb_2Cl_6]$ complex. *Anal.* Calc. for $C_{96}H_{76}N_8O_8Sb_2Cl_6$: C, 59.4; H, 3.9; N, 5.8; Cl, 10.9. Found: C, 58.8; H, 4.0; N, 6.0; Cl, 11.2%. ^{1}H NMR ($CDCl_3$) δ ppm: 0.30 (br, 2H, NH), 3.76 (s, 12H, OCH_3), 8.25–8.34 (d, 4H, o), 7.44-7.47 (t, 4H, m), 7.52–7.56 (t, 4H, m′), 7.79–7.92 (t, 4H, p), 8.45–8.50 (s, 8H, β). IR (KBr): υ_{NH} (~3320 cm^{-1}).

3. Results and discussion

^{1}H NMR spectra for the mixing of different equivalents of $SbCl_3$ (0.25, 0.5, 0.75, 1.0 and 2.0) with $H_2t(4\text{-}CH_3p)p$ are shown in Fig. 2. The ^{1}H NMR spectra results show that using an amount of $SbCl_3$ less than that of $H_2t(4\text{-}CH_3p)p$ leads to a superimposition of the porphyrin and the related molecular complex spectra. An excess of $SbCl_3$ to the 1:1 molar ratio causes no changes in the spectrum of the 1:1 molecular complex. Consequently, the molecular complex between $H_2t(4\text{-}CH_3p)p$ and $SbCl_3$ had a 1:1 ratio, ($SbCl_3$:$H_2t(4\text{-}CH_3p)p$). ^{1}H NMR spectra of $H_2t(4\text{-}CH_3p)p$ and the 1:1 molecular complex in $CDCl_3$ solution are shown in Fig. 2a and e, respectively. It is clearly revealed that the reaction of $SbCl_3$ with $H_2t(4\text{-}CH_3p)p$ is similar to 1:2 (donor:acceptor) complexation [1–3] and diprotonation of the *meso*-tetraarylporphyrin [10] affords an upfield shift of the β-protons (0.28 ppm) and downfield shifts of the N–H signal (2.96 ppm) and aryl ring protons, see Fig. 2. The NH and β-proton chemical shifts for the molecular complexes are listed in Table 1.

The direction of the NH and β-protons shifts of the molecular complex, $[(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6]$, are similar to the related diprotonated porphyrin species [10]. The remarkable spectral correspondence between $[(H_2t\text{-}(4\text{-}CH_3p)p)_2Sb_2Cl_6]$ and $H_4t(4\text{-}CH_3p)p^{2+}$ suggested analogous tilted porphyrin core structures in these species, and is not related to the formation of a diprotonated porphyrin species in our reaction system. The integration of the pyrrolic NH hydrogen peak in 0.006 M $CDCl_3$ solution of

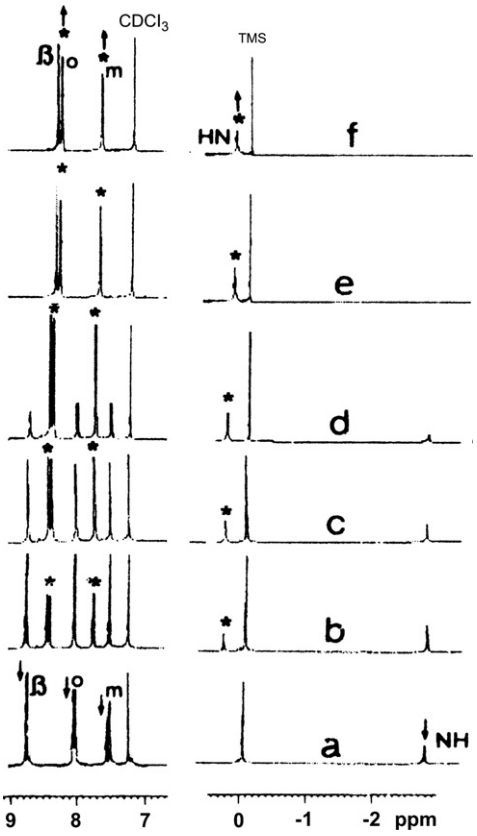

Fig. 2. ^{1}H NMR spectra for the mixing of different equivalents of $SbCl_3$ (0.25, 0.5, 0.75, 1.0 and 2.0) with $H_2t(4\text{-}CH_3p)p$ in $CDCl_3$ at 20 °C. *The peaks are related to the molecular complex $[(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6]$.

$\Delta\delta_1$: chemical shifts of the proton signals for the porphyrins upon molecular complexation. $\Delta\delta_2$: Chemical shifts of the proton signals for the $H_2t(4\text{-}CH_3p)p$ upon diprotonation with excess of TFA.

the $[(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6]$ molecular complex was 2.1, whereas for $H_4t(4\text{-}CH_3p)p^{2+}$ it was 3.9. An excess of $SbCl_3$ had no effect on the ^1H NMR spectrum of $[(H_2t\text{-}(4\text{-}CH_3p)p)_2Sb_2Cl_6]$, but the ^1H NMR spectrum of $H_4t(4\text{-}CH_3)pp^{2+}$ was quite sensitive to the concentration of trifluoroacetic acid (TFA) [4].

The UV–VIS spectrum of $H_2t(4\text{-}CH_3p)p$ has absorption bands at 418.3 (soret), 518.4, 554.0, 593.0 and 649.0 nm [1–3,13], whereas the molecular complex shows two new absorption bands at 448.1 (soret) and 670.3 nm. Upon the addition of $SbCl_3$ to free base $H_2t(4\text{-}CH_3p)p$, the UV–VIS spectrum of the porphyrin is 21–31 nm red shifted. This is interpreted as evidence for an increased resonance interaction of the tolyl ring with the porphyrin nucleus in going from the free base to the molecular complex, which would be allowed by the tilting of the pyrroles [13b]. The results of the UV–VIS spectra for the other molecular complexes are shown in Table 2.

Table 2
UV–VIS spectral results of the different *meso*-tetraarylporphyrins, $[(H_2t(Xp)p)_2Sb_2Cl_6]$ molecular complexes and their diprotonated species in $CHCl_3$

[a] $\Delta\lambda_1$: Red shifts for the bands of the porphyrins upon molecular complexation.
[b] The data are taken from Ref. [4].
[c] $\Delta\lambda_2$: Red shifts for the bands of the porphyrins upon diprotonation.

The UV–VIS spectral data of the $[(H_2t(4\text{-}CH_3p)p)_2\text{-}Sb_2Cl_6]$ molecular complex are closely related to the UV–VIS spectra of $H_4t(Xp)p^{2+}$ (Table 2). The spectrum of $H_4t(Xp)p^{2+}$ was sensitive to additional amounts of TFA[4] while an excess of $SbCl_3$ had no effect on the UV–VIS spectrum of the $[(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6]$ molecular complex. The similarity of the spectra of $[(H_2t\text{-}(4\text{-}CH_3p)p)_2Sb_2Cl_6]$ and $H_4t(Xp)p^{2+}$ suggest an analogous porphyrin core structure in these species.

The ^{13}C NMR spectrum of $H_2t(4\text{-}CH_3p)p$ gives rise to seven sharp signals (one signal for the methyl group (19.9 ppm) and six signals for the porphine core and aryl rings (118.4, 125.7, 129.3, 132.7, 135.6, 137.7 ppm)) and a very broad signal (at 145 ppm) for the α-carbons [2,3,14]. The 1:1 interaction of $H_2t(4\text{-}CH_3p)p$ with $SbCl_3$ also leads to changes in the ^{13}C NMR spectrum of the porphyrin (it sharpens the α-carbons signal and causes small shifts in all the lines). These peaks are revealed at 22.1, 123.0, 128.4, 129.6, 137.8, 140.9, 146.5 ppm. The changes are completely similar to diprotonation [14] and 1:2 (donor:acceptor) molecular complexation of *meso*-tetra arylporphyrins with DDQ [1] or TCNE [2].

UV–VIS, ^1H and ^{13}C NMR correspondences between spectral data of 1:2 (donor:acceptor) molecular complexes of σ- or π-acceptors with *meso*-tetraarylporphyrins [1,2] or H_4tpp^{2+} [10,13,14] and $[(H_2t(Xp)p)_2Sb_2Cl_6]$ leads to the proposition of a similar structure for the porphyrin core in all of the species, with non-coplanar pyrrole rings tilted alternatively up and down. This conformation causes the lone pairs of two pyrrolenine nitrogens to act as the electron donors to one molecule of $SbCl_3$, which is located above or below the mean plane of the porphyrin, and so two hydrogen atoms of pyrroles (N-H) are located on the other side of the porphyrin plane, Fig. 3.

UV–VIS and ^1H NMR spectral shifts for the molecular complexation of various *meso*-tetraarylporphyrins with $SbCl_3$ showed that steric hindrance from ortho and meta-substituents of the aryl rings in the porphyrins is more than from the para-substituent, and causes weakening of the electron donation for ortho and meta-substituents. Further, these shifts indicate that π-resonance rather than σ-induction effects the electron donation of the porphyrins

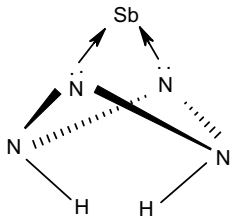

Fig. 3. In the scheme only the tetrahedrally tilted pyrrolenine nitrogens of the porphyrin core are shown. Two nitrogen atoms of pyrrolenine in one side of the porphyrin plane act as the electron donors to an antimony atom of $SbCl_3$.

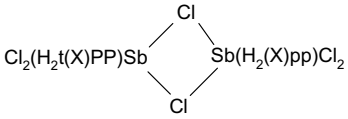

Fig. 4. Scheme for the proposed structure and bonding interactions for the $[(H_2t(Xp)p)_2Sb_2Cl_6]$ molecular complexes.

(Tables 1 and 2) [1,2,13]. The trend in electron donating ability for the substituted *meso*-tetraarylporphyrins was *para* > *meta* > *ortho*.

The mass electrospray spectrum of $[(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6]$ (MW = 1797.8) had a peak at *m/z* 1839.1 ($[M+CH_3CN]$). The results of elemental analyses for the $[(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6]$ molecular complex was consistent with $C_{96}H_{76}N_8Sb_2Cl_6$. *Anal*. Calc. for $C_{96}H_{76}N_8Sb_2Cl_6$: C, 64.1; H, 4.3; N, 6.2. Found: C, 63.8; H, 4.1; N, 6.3%. The far-IR spectrum (200-400 cm^{-1}) of the complex shows seven bands at 316, 299, 283, 268, 256, 240 and 224 cm^{-1}. The close correspondence between the vibration bands of Sb–Cl (268, 240, 224 cm^{-1}) in the studied complex and the complexes of $SbCl_3$ with diphosphine and diarsine ligands [15], suggests similar structures in these species. Consequently, the antimony coordination geometry was a distorted octahedron composed of the chelating $H_2t(4\text{-}CH_3p)p$, two terminal Sb–Cl's and a $(\mu\text{-}Cl)_2$bridge (Fig. 4). Two vibration bands in the 250–270 cm^{-1} region are assigned to the chloro bridge between two bismuth atoms [16]. Furthermore, the IR spectrum of free base ($H_2t(Xp)p$) shows a N–H stretching band at 3320 cm^{-1} [17], that upon the molecular complexation with $SbCl_3$ does not change. This indicates that there is no intramolecular or intermolecular hydrogen bonding for N–H of the molecular complex, to be consistent with the proposed structure.

Gunter and Rabinson [18] attributed the large downfield shift of the NH signal upon diprotonation of $H_2t(4\text{-}N(CH_3)_2p)p$ to a "decrease of ring current of the macrocyclic system". This cannot be correct as stated [10]. For the internal NH protons, the effect of the ring current in the free base is additional shielding of these protons, which is lost in the diprotonated porphyrins. Walter et al. suggested that "the downfield of the N–H signal on diprotonation could result from geometric distortion of the porphyrin ring by twisting or by rocking the four pyrrole rings to accommodate four protons and the double positive electric charge, but it is not clear how this distortion could move these protons so far as to be outside the field produced by the ring current. Alternatively, this might result from a direct decrease in ring current at the interior of the ring system which is not dependent upon geometric distortion. In either case, the evidence is that the effect of ring current on the peripheral protons is not greatly disturbed though these changes" [10].

Although for the molecular complexes a large shift for the NH signal in ^1H NMR spectra is observed, the IR spectra do not show hydrogen bonding for these complexes. This indicates that the shift of the NH signal in the ^1H NMR spectra upon molecular complexation cannot be related to intramolecular hydrogen bonding. Furthermore, the large downfield shift of the NH signal of the porphyrin in molecular complexes could not relate to distortion of the porphyrin plane, because a large out of plane deformation of the porphyrin core leads only to about 5% change in the ring current [19]. Consequently, there is one other reason for the large shift of NH. Meso-tetraarylporphyrins have 22 π-electrons in the porphyrin cores, and are aromatic systems. Upon molecular complexation of the *meso*-tetraarylporphyrin with $SbCl_3$ (donating two lone pairs electrons to one Sb atom) a double positive charge in the porphyrin core is created (the macrocycle is converted to an 18 π-electron system and the positive charges are distributed over the entire porphine core), Fig. 5. In the proposed structure, four nitrogen atoms of the pyrroles in the porphyrin are oriented to out of the resonance and are changed to 2° amines. Consequently, the unusually large downfield shifts observed for the NH signals upon molecular complexation or diprotonation of the porphyrins can related to changing of pyrrole NHs to 2° amines. This change could move these protons so far as to be outside the field produced by the ring current. For the molecular complexes, $[(H_2t(Xp)p)_2Sb_2Cl_6]$, the lone pairs of pyrrole and pyrrolenine nitrogens make no contribution to the ring current of the porphyrin molecule. Also, the observed chemical shifts for the NH signal of the molecular complexes were upfield than that of usual aliphatic 2° amines (0.5–3 ppm) [20]. This small difference may be related to the ring current effect of the porphyrin core on the internal NH protons of $H_2t(Xp)p$.

The symmetrical ^1H NMR spectra of the molecular complexes (i.e. Fig. 2e) appear to be in contrast to the presence of unsymmetrical pyrrole rings in the proposed structure. The ring inversion of the tilted core conformation of the porphyrin is probably fast on the NMR time scale. The low temperature ^1H NMR spectrum of

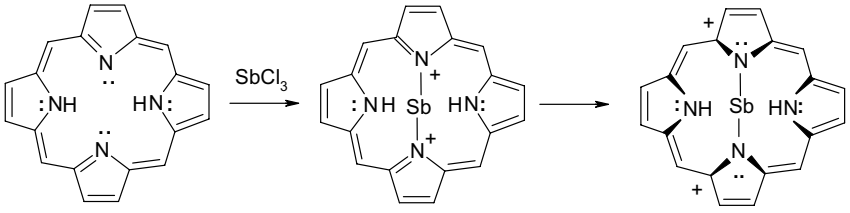

Fig. 5. Molecular complexation of *meso*-tetraarylporphyrins with $SbCl_3$ and changing of pyrrolic NHs to 2° amines.

[$(H_2t(4\text{-}CH_3p)p)_2Sb_2Cl_6$] (at −60 °C, in $CDCl_3$) was quite sharp and showed virtually no changes with respect to that at room temperature (20 °C). However, downfield (0.05 ppm) and upfield (−0.28 ppm) shifts in the β- and NH-protons signals, respectively, were observed. It may be that the lowering of temperature caused the porphyrin core to be less flexible or less planar, i.e., with greater ring currents, so the NH and β signals shifted upfield and downfield respectively [4].

4. Conclusion

Meso-tetraarylporphyrins ($H_2t(Xp)p$) with antimony(III) chloride react with the formation of dimer molecular complexes, [$(H_2t(Xp)p)_2Sb_2Cl_6$]. UV–VIS, ^1H and ^{13}C NMR spectra data show that the porphyrin core of the molecular complexes, similar to 1:2 (donor:acceptor) molecular complexes of *meso*-tetraarylporphyrins [1–4] and porphyrin diacid [10], is distorted and two nitrogen atoms of pyrrolenine are located in a side of the porphyrin plane and act as electron donors to an antimony atom of $SbCl_3$. There is no hydrogen bonding for the molecular complexes but a large downfield shift for the NH signal of the complexes is seen. The unusually large downfield shifts for the NH signals upon molecular complexation or diprotonation of the porphyrins can be related to the changing of the pyrrole NHs to 2° amines and moving the NH protons outside of the field produced by the ring current. This causes the lone pairs of the pyrrole and pyrrolenine nitrogens to make no contribution to the ring current of the porphyrin molecule.

recorded with a Perkin–Elmer 883 Infrared Spectrophotometer (4000–200 cm^{-1}). Electronic spectra of the complexes in DMF solution (ca. 20 °C) were recorded with a Varian Cary 3E spectrophotometer (300–900 nm). ^1H and ^{13}C NMR spectra were recorded at 25 °C with a Varian Unity Plus 300 MHz spectrometer. For referencing, known solvent (or residual solvent) signals were used.

2.2. Crystallographic analysis

X-ray diffraction measurements were made using a Bruker SMART CCD area-detector diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å) [48]. Suitable single crystals of the complexes were mounted in glass fibers. Intensities were integrated from several series of exposures, each exposure covering 0.3° in ω, the total data set being a hemisphere [49]. Absorption corrections were applied based on multiple and symmetry-equivalent measurements [50]. The structures were solved by direct methods and refined by least squares on weighted F^2 values for all reflections [51]. All non-hydrogen atoms were assigned anisotropic displacement parameters and refined without positional constraints. Hydrogen atoms were taken into account at calculated positions and refined as riding atoms. Complex neutral-atom scattering factors were used [52].

2.3. Synthesis of the ligand S-benzyl dithiocarbazate (*HL*)

S-benzyl dithiocarbazate was prepared according to the method published by Akbar Ali et al. [46].

NMR [DMSO-d_6] δ_H: 10.86 (s, NH, thione form), 7.42–7.20 (m, 5H, C_6H_5), 4.38 (s, CH_2, thione form), 4.37 (s, CH_2, thioenol form); δ_C: 199.96 (CS_2, thione form), 186.18 (CS_2, thioenol form), 138.10, 137.83, 129.11, 128.94, 128.67, 128.43, 127.82, 127.02 (C_6H_5), 37.16 (CH_2, thione form), 36.71 (CH_2, thioenol form).

2.4. Synthesis of the ligand S-benzyl-N-isopropylidenedithiocarbazate (*HL′*)

Solid *S*-benzyl dithiocarbazate was dissolved in excess acetone and left to evaporate slowly, yielding white crystals of *S*-benzyl-*N*-isopropylidenedithiocarbazate, which was recrystallized from warm absolute ethanol (50 °C).

Melting point: 119.7 °C. *Anal.* Calc. for $C_{11}H_{14}N_2S_2$: C, 55.42; H, 5.92; N, 11.75. Found: C, 55.77; H, 5.60; N, 11.66%. NMR [$CDCl_3$] δ_H: 12.13 (s, 1H, NH), 7.40–7.23 (m, 5H, C_6H_5), 4.42 (s, 2H, CH_2), 1.98, 1.93 (s, each 3H, *gem*-$(CH_3)_2$); δ_C: 196.52 (CS_2), 157.58 (C=NN), 137.01, 129.12, 128.37, 127.15 (C_6H_5), 37.62 (CH_2), 24.93, 18.41 (*gem*-$(CH_3)_2$).

2.5. Preparation of [PdL_2] (*1*)

A solution of *S*-benzyl dithiocarbazate (0.3808 g, 1.92 mmol) in warm ethanol (20 mL) was added dropwise to a solution of K_2PdCl_4 (0.1959 g, 0.60 mmol) in water (30 mL) under magnetic stirring. A sticky brown solid was formed that was attached to the stirring bar. The beaker was positioned so that the stirring bar hit the walls and the solution was ''stirred'' in this manner overnight. The next day a beige solid had been formed. The solid was filtered, dried and dissolved in DMF. Layering of methanol yielded a golden leaf-like crystalline solid. Crystals suitable for X-ray analysis were found in this solid.

Pyrochemical detection of chloride in the golden crystalline solid was negative.

Anal. Calc. for $C_{16}H_{18}N_4PdS_4$: C, 38.36; H, 3.62; N, 11.18. Found: C, 38.25; H, 3.31; N, 11.47%. NMR [DMSO-d_6] δ_H: 8.13 (s, 2H, NH_2), 7.33–7.25 (m, 5H, C_6H_5), 4.21 (s, 2H, CH_2); δ_C: 174.11 (CS_2), 137.76, 128.93, 128.48, 127.50 (C_6H_5), 39.37 (CH_2).

2.6. Preparation of [PdL_2'] (*2*)

The same procedure as above was used, with *S*-benzyl-*N*-isopropylidenedithiocarbazate (0.4577 g, 1.92 mmol) as the ligand. The colour of the resulting solid was orange. Dissolution of the orange compound in DMF and layering of ethanol yielded orange crystals, suitable for X-ray analysis.

Pyrochemical detection of chloride in the orange crystalline solid was negative.

Anal. Calc. for $C_{22}H_{26}N_4PdS_4$: C, 45.47; H, 4.51; N, 9.64. Found: C, 45.80; H, 4.68; N, 9.77%. NMR [$CDCl_3$] δ_H: 7.40–7.27 (m, 5H, C_6H_5), 4.40, 4.32 (AB system, $^2J_{H,H} = 13.2$ Hz, 2H, CH_2), 2.42, 2.15 (s, each 3H, *gem*-$(CH_3)_2$); δ_C: 177.05 (CS_2), 172.05 (C=NN), 136.55, 128.85, 128.50, 127.30 (C_6H_5), 39.63 (CH_2), 27.41, 21.15 (*gem*-$(CH_3)_2$).

3. Results and discussion

3.1. Synthesis

We have found that the synthesis of *S*-benzyl-*N*-isopropylidenedithiocarbazate can be carried out under mild conditions, by simply dissolving *S*-benzyl dithiocarbazate in acetone. Upon standing in an open beaker, the product is formed and crystallized. In the method published by Akbar Ali et al. [47] a solution of equimolar quantities of *S*-benzyl dithiocarbazate and acetone in ethanol is refluxed for 12 h.

The preparation of complexes **1** and **2** in the mixture of solvents used (ethanol–water) is not straightforward. Initially a brown solid is formed, which sticks around the stirring bar. Upon stirring overnight, with the beaker positioned so that the stirring bar hits the walls, and thus the complexes are formed.

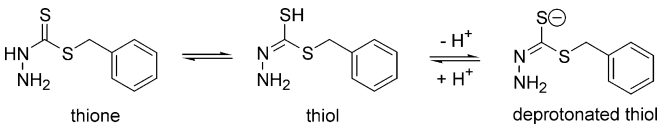
3.2. Electronic spectra

The electronic spectra of both complexes consist of one band overlapped with a strong band extending to the UV region, $\lambda_{max} = 440$ nm (complex **1**) and $\lambda_{max} = 456$ nm (complex **2**). These bands can be attributed to d–d transi-

tions and they indicate that *S*-benzyl dithiocarbazate is a somewhat stronger ligand than *S*-benzyl-*N*-isopropylidenedithiocarbazate.

3.3. IR spectra

S-benzyl dithiocarbazate and *S*-benzyl-*N*-isopropylidenedithiocarbazate can exhibit thione–thioenol tautomerism. In the solid state the absence of νSH at ca. 2570 cm^{-1} from the IR spectra shows that only the thione forms exist (Table 1).



The IR spectrum of **1** exhibits νNH_2 bands at frequencies lower than those of the free ligand (Table 1), due to coordination of the NH_2 group. The νNH and νC=S bands, as well as a νSH band at ca. 2570 cm^{-1}, are missing from the IR spectra of **1** and **2** (Table 1), suggesting that the ligands exist in both complexes in their deprotonated thioenol forms. This is further supported by the positive shift of the νCN bands for both complexes with respect to the free ligands, indicating shorter C–N bond lengths, as is expected from the thioenol versus the thione forms of the ligands.

3.4. NMR spectra

In the case of *S*-benzyl dithiocarbazate, the tautomerism (Scheme 1) was certified in DMSO-d_6 solution by ^{1}H and ^{13}C NMR spectroscopy. The ^{13}C NMR spectrum reveals the existence in solution of both the thione and thioenol forms, while in the ^{1}H NMR spectrum the existence of the thioenol form is denoted by the presence of two overlapping signals for CH_2 at 4.37 and 4.38 ppm, and by the reduced intensity of the NH signal at 10.86 ppm; analysis of the CH_2 overlapping signals into Lorentzian components shows that about 30% of the molecules are in the thione form.

The ^{1}H and ^{13}C NMR spectra of *S*-benzyl-*N*-isopropylidenedithiocarbazate in $CDCl_3$ reveal the existence of only the thione form.

The ^{1}H and ^{13}C NMR spectra of the complexes suggest that the coordinated ligands are in one form. The missing NH signals suggest that this is the thioenol form, in accordance with findings from the IR spectra. Although the NH_2 signal does not appear in the ^{1}H NMR spectrum of **LH**, it appears in the spectrum of **1** at 8.13 ppm.

Scheme 1.

Coordination by the β N atom in **2** is confirmed by the shift of the CH_3 signals of the isopropylidene group from 1.93 and 1.98 ppm for the free ligand to 2.15 and 2.42 ppm.

Coordination of **LH** in **1** causes a shift of the CH_2 signal from 4.37 ppm for the free thioenol form to 4.21 ppm. Such a shift is also apparent in **2**. It is noted that while the CH_2 protons are equivalent in **1**, **LH** and **L′H**, they are diastereotopic in **2**, giving an AB pattern ($^2J_{H,H} = 13.2$ Hz).

3.5. Crystallographic analysis

For both complexes, there are two possible configurations, *cis* and *trans* (Fig. 1, Table 2).

Analysis of the crystal structure of **1** showed that the coordination geometry around Pd is square planar (Fig. 2). This complex has a *trans* configuration. In the solid state two species of **1** exist in equimolar quantities: One is highly symmetric (point group C_i); atomic coordinates for equivalent atoms are given from the transformation $(x, y, z) \rightarrow (-x, -y, -z)$. The other is slightly distorted; atomic coordinates for equivalent atoms are given from the transformation $(x, y, z) \rightarrow (-x+1, -y+1, -z+2)$.

Crystallographic analysis of **2** showed that the coordination geometry around Pd is distorted square planar (Fig. 3). This complex has a *cis* configuration. The planes of the two phenyl rings are practically vertical to the PdN_2S_2 "plane" and form a dihedral angle of ca. 130°. Such a configuration has been found elsewhere in the literature [21].

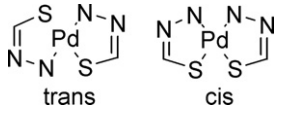


Fig. 1. Possible configurations of the complexes.

Refinement method	full-matrix least squares on F^2	full-matrix least squares on F^2

The crystal lattice of **1** shows packing of molecules along the *b*-axis of the crystal, with an arrangement of these packings in a parallel orientation (Fig. 4). The intermolecular distance between Pd atoms of consecutive molecules in the packing is 9.39 Å. This long distance excludes the existence of any covalent intermolecular interactions.

Similarly for **2**, the complexes are packed along the *b*-axis of the crystal with an intermolecular separation between Pd atoms of 11.8 Å. However, in contrast to **1**, in **2** these packings are arranged in an antiparallel disposition (Fig. 5).

For both complexes (Tables 3 and 4), the bond lengths and angles around Pd are in the ranges found in the literature for complexes of Pd(II) with Schiff bases [21,33–35,37] and other *N*-substituted derivatives [45] of dithiocarbazates.

The Pd–N bonds in the two species of **1** (2.021(2) and 2.031(2) Å) are shorter than those in **2** (2.085(2) and 2.087(2) Å); as expected, substitution of NH_2 leads to weaker N–M bonds. In contrast, the Pd–S bonds in **1** (2.2829(8) and 2.2873(8) Å) are longer than those in **2** (2.2563(14) and 2.2625(11) Å). The N–Pd–S angles for the ligand in **1** (84.41(6) and 84.33(7)°) are bigger than those for the ligand in **2** (82.72(5) and 81.76(5)°).

In accordance with the findings from the IR spectra, the C–N bonds in **1** (1.270(4) and 1.282(4) Å) are shorter than that in the free ligand [53] (1.320(3) Å). As expected, the C–S bonds (1.748(3) and 1.745(3) Å) and N–N bonds (1.461(3) and 1.467(3) Å) are longer than those in the free ligand (1.678(3) and 1.406(3) Å, respectively).

This also applies to **2**: the C–N bonds (1.278(3) and 1.281(3) Å) are shorter than those in the free ligand [54] (1.34 Å), while the C–S bonds (1.735(3) and 1.739(3) Å) and N–N bonds (1.420(3) and 1.420(2) Å) are longer than those in the free ligand (1.65 and 1.39 Å, respectively).

The *cis* square planar **2** is monoclinic (space group $P2_1/n$), while the *cis* square planar bis(*S*-methyl-*N*-isopropylidenedithiocarbazato)palladium(II) (**3**) [37] is orthorhombic (space group $P2_12_12_1$), probably due to the effect of the phenyl rings in **2**. The Pd–S (2.2563(14) and 2.2625(11) Å) and Pd–N (2.085(2) and 2.087(2) Å) bond lengths in **2** are almost identical to those of Pd–S (2.263(6) and 2.263(5) Å) and one of the Pd–N (2.090(16) Å) bonds in **3**, while the other Pd–N bond in **3** is longer (2.135(15) Å). In general, the bond lengths and angles do not differ much between the two chelate rings of **2**, while differences arise between the chelate rings of **3**.

X-ray diffraction analysis and ^{1}H and ^{13}C NMR data show that complexes **1** and **2** exist both in the solid state and in solution in one form. The difference in the preference of the isomer formed for each complex (*cis*-**1**, *trans*-**2**) has been discussed in the past in the general context of "equilibrium between *cis* and *trans* forms of square planar d^8 metal complexes" [55–58].

The geometries of **1** and **2** are the cumulative results of the influence of many factors. In a recent paper theoretical

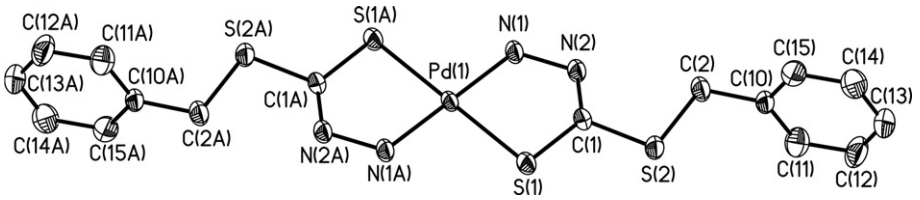

Fig. 2. Molecular structure of **1**.

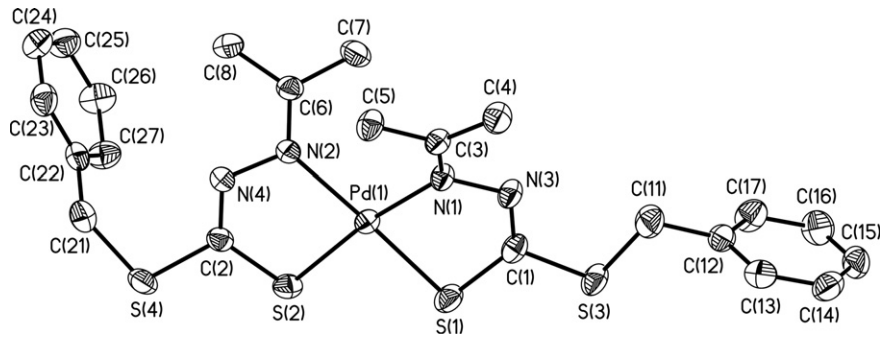

Fig. 3. Molecular structure of **2**.

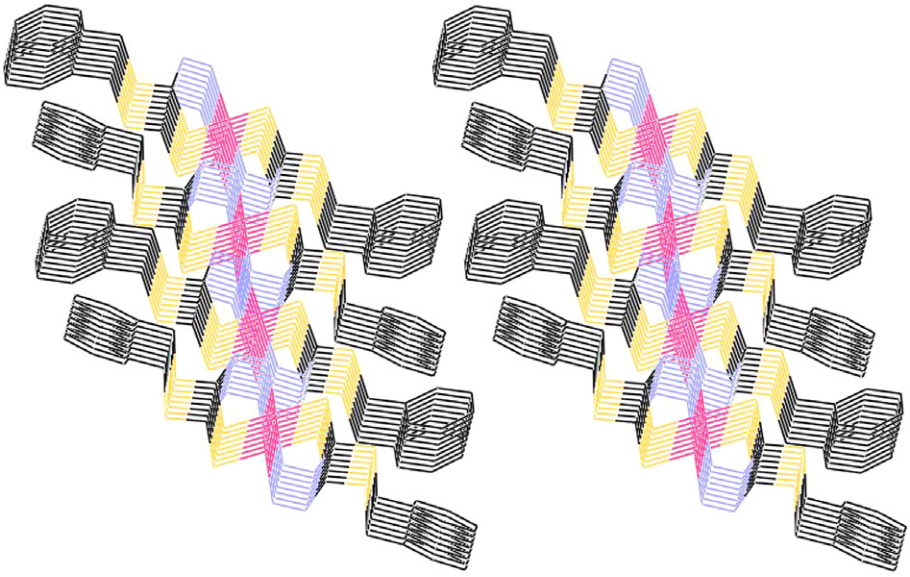

Fig. 4. Packing of molecules along the *b*-axis and arrangement of packings in the crystal lattice of **1**.

calculations have shown that electrostatic interactions stabilize the *trans* isomers [59]. On the other hand it is known that the use of polar solvents favours *cis* configurations [56].

It can also be claimed that a major contribution to the total stabilization of one configuration over the other results from the different *trans* influences of the N (NH_2 and $N{=}C(CH_3)_2$) and S "groups" of the ligands, which lead to different Pd–N and Pd–S bond energies in the *cis* and *trans* isomers.

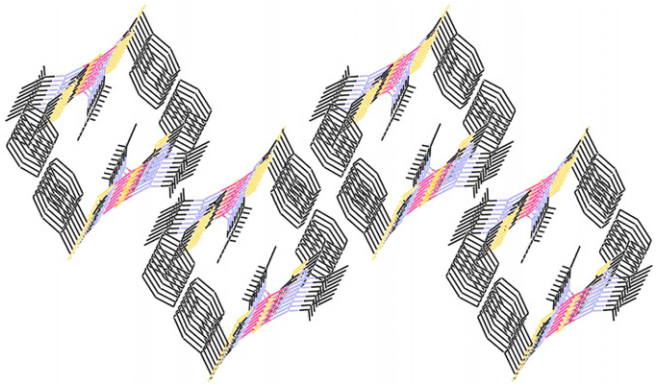

Fig. 5. Packing of molecules along the b-axis and arrangement of packings in the crystal lattice of **2**.

C(3)–N(1)–Pd(1)	130.09(15)	C(6)–N(2)–Pd(1)	129.15(16)

Thus the preference for the *trans* configuration in **1**, as opposed to the *cis* configuration in **2** and other square planar chelates of the form $Pd(NS)_2$ [33–35], where NS is a deprotonated Schiff base of an *S*-alkyl/aryl dithiocarbazate, can be attributed to $–NH_2$ having a larger *trans* influence than $–N{=}C(CH_3)_2$ and $–N{=}CRR'$ in general, close enough to that of $–S^-$ to unbalance the influences that would lead to the formation of the *cis* isomer.

To our best knowledge, this is the first time the crystal structure of a complex of the form $Pd(NS)_2$, where NS is an unsubstituted deprotonated *S*-alkyl/aryl dithiocarbazate, has been reported.

$[Pt_2(\mu\text{-}o\text{-}SC_6H_4(CF_3))_2(dppe)_2](SO_3CF_3)_2$ (**4d**) are also described.

2. Results and discussion

IR spectra of compounds **1**–**4** show the expected absorptions arising from the common dppe ligands and the corresponding thiolate moiety present in each compound. In addition, complexes **3** and **4** exhibit the characteristic bands of the $SO_3CF_3^-$ anion.

In terms of NMR, the magnetic systems corresponding to the fluorinated rings C_6F_5, p-C_6HF_4 and p-$C_6F_4(CF_3)$ can be described as AA′BB′C, AA′BB′X and AA′BB′X_3 respectively. All three systems share *ortho* (A = F) and *meta* (B = F) fluorine nuclei, bearing different *para* substituents, namely, C = F, X = H, and $X_3 = CF_3$. For the o-$C_6H_4(CF_3)$ fragment, the magnetic system can be described as ABCDX_3. ^{1}H, ^{19}F and ^{31}P NMR parameters for compounds **1** and **4**, in agreement with the descriptions above, are listed in Section 4.

^{31}P NMR spectra of compounds **1** and **3** exhibit a single absorption whereas platinum derivatives **2** and **4** show, in addition, the expected ^{195}Pt satellites. Platinum–phosphorous coupling constants show differences of up to *ca.* 150 Hz from compound **2a** to compound **2d** and increases with the fluorination degree of the ring, from 2879 Hz when Rf = o-$C_6H_4(CF_3)$ to 3033 Hz when Rf = $C_6F_4(CF_3)$, probably reflecting the *trans* influence order in this series. On the other hand palladium complexes show ^{31}P chemical shifts 7–13 ppm upfield when compared with the corresponding δ ^{31}P from the platinum analogs.

2.1. Monometallic complexes

Metathesis reactions of $[MCl_2(dppe)]$ M = Pd or Pt with the corresponding lead thiolate (Eq. (1)) render the metalloligands **1** and **2** as stable, diamagnetic yellow microcrystalline solids, soluble in acetone, dichloromethane and chloroform. Although other metallic thiolates can be used successfully to accomplish these reactions, the extremely low solubility of the resulting lead dichloride affords higher yields and cleaner products [11].

$$[MCl_2(dppe)] + Pb(SRf)_2 \rightarrow [M(SRf)_2(dppe)] + PbCl_2 \quad (1)$$

M = Pd, Rf = p-$C_6F_4(CF_3)$ **1a**, C_6F_5 **1b**, p-C_6HF_4 **1c**, o-$C_6H_4(CF_3)$ **1d**
M = Pt, Rf = p-$C_6F_4(CF_3)$ **2a**, C_6F_5 **2b**, p-C_6HF_4 **2c**, o-$C_6H_4(CF_3)$ **2d**

As expected [12], reactions with palladium compounds left over relatively long reaction times, give rise to red insoluble powders of $[\{Pd(SRf)_2\}_n]$ similar to those described earlier [13]. In order to minimize the formation of these polymeric species, relatively short reaction times were used.

Variable temperature ^{19}F NMR experiments (25 °C down to −90 °C) have been carried out for compounds **2a** to **2c** which remained as sharp signals showing no changes on their absorption spectra.

The molecular structures of $[Pd(p\text{-}SC_6HF_4)_2(dppe)]$ (**1c**), $[Pt(SC_6F_5)_2(dppe)]$ (**2b**) and $[Pt(o\text{-}SC_6H_4(CF_3))_2(dppe)]$ (**2d**) are shown in Figs. 1–3 respectively, selected bond distances and angles are shown in Table 1.

Coordination around metal centers in compounds **1c**, **2b** and **2d** are distorted square-planar (the angles around palladium and platinum add to 360.02°, 360.18° and 357.11° (molecule 1) and 360.36° (molecule 2) respectively).

The Pd–S (2.3642(7) Å) and Pd–P (2.2703(7) Å) bond lengths in **1c** are slightly longer than those found by Wei and Liu [14] in $[Pd(SC_6H_5)_2(dppe)]$ for which these bonds are Pd–S 2.3486(7) Å and Pd–P 2.2612(7) Å whereas in $[Pd(SC_6F_5)_2(dppe)]$ these distances are Pd–S 2.354(1) and 2.361(1) and Pd–P 2.268(1) and 2.258(1) [15]. The analogous nickel complex $[Ni(p\text{-}SC_6HF_4)_2(dppe)]$ has also been structurally characterized [16] showing shorter Pd–S bond distance than those found for **1c**.

The bonding angles in **1c** vary between 85.07° and 100.37° with the widest angle opposite to the P(1)–Pd–P(1)^i (symmetry code i: see Table 1) which, due to the chelating bite, is necessarily the smallest one.

For the molecular structure of compound $[Pt(o\text{-}SC_6H_4(CF_3))_2(dppe)]$ (**2d**) the asymmetric unit allocates two independent molecules of the platinum complex with significantly different conformations of the phenyl groups at the chelate ligand in the molecule. Both platinum complexes **2b** and **2d** show shorter Pt–S bond distances than

the palladium analogues, 2.3585(17) Å for [Pt(SC_6F_5)$_2$-(dppe)] (**2b**) and 2.3481(16), 2.3604(14), 2.3636(15), 2.3685(14) Å for [Pt(*o*-$SC_6H_4(CF_3)$)$_2$(dppe)] (**2d**). The bonding angles in **2b** vary between 85.95° and 99.57° whereas in **2d** they vary between 82.21° and 102.12° for molecule 1 and between 86.13° and 97.01° for molecule 2.

2.2. Bimetallic complexes

Dinuclear complexes **3** to **4** were prepared according to Scheme 1, where the mononuclear complexes **1** and **2** were used as metalloligands. These compounds were isolated as air stable yellow microcrystalline solids soluble in acetone, dichloromethane and chloroform.

2.3. Variable temperature NMR studies

^{1}H, ^{19}F and ^{31}P NMR spectra show the expected magnetic systems discussed above for each of the fluorinated rings. The corresponding parameters are listed in the experimental section. In addition, room temperature ^{31}P NMR for dinuclear platinum complexes **4**, exhibit single absorptions with platinum satellites. Coupling constants $^1J_{Pt-P}$ are larger in dinuclear compounds than in the mononuclear analogues, as expected if the change from terminal to bridged sulfur–metal bonds results in stronger metal–phosphorus bonds.

We have examined the variable temperature ^{1}H and ^{19}F NMR spectra of all compounds **3** and **4**. Unfortunately, at the limiting low temperature (−90 °C) all spectra of palladium containing compounds show poorly defined, very broad bands because, as has been reported before [17], the energy involved for processes on palladium complexes

Scheme 1.

is significantly smaller than that observed for platinum compounds undergoing a similar process. Therefore, the following discussion is focused on platinum compounds mainly through the ^{19}F NMR results.

The room temperature ^{19}F NMR spectra of the perfluorinated compound $[Pt_2(\mu\text{-}p\text{-}SC_6F_4(CF_3))_2(dppe)_2](SO_3CF_3)_2$ (**4a**) shows four signals: a *pseudo*triplet at −56.7 ppm (integral = 3, C–CF_3); a singlet at −77.4 ppm (integral = 3, S–CF_3); a double set of doublets at −124.0 ppm (integral = 2, *ortho*-fluorine) and a multiplet at −139.4 ppm (integral = 2, *meta*-fluorine). Increasing the temperature from ambient to 50 °C does not affect the spectra.

Decreasing the experimental temperature down to *ca.* −70 °C (see Fig. 4) broadens both the *ortho* and the *meta* fluorine signals and at −90 °C the *ortho* fluorine band is unfolded into a pair of signals with the same intensity (−122.0, −125.1, $\Delta\delta$ 3.1 ppm) although the *meta* fluorine absorption remains broad (−139.30 ppm) and unresolved at this temperature. On the other hand, the absorption arising from the *para*-CF_3 group of the thiolate ligands remains unchanged along the complete low temperature interval.

Since *ortho* and *meta* but not the *para* substituents are affected at low temperatures, the fluxional process more likely to be observed in this case is the restricted rotation of the sulfur–carbon bonds. The calculated free activation energy for this process is $\Delta G^{\neq} = 38.71 \pm 0.3$ kJ mol^{-1}, which is *ca.* 3 kJ mol^{-1} lower than the average found for bimetallic complexes of the type $[Pt_2(\mu\text{-}SR)_2(SR)_4](NBu_4)_2$ [18].

As expected, the room temperature ^{19}F NMR spectrum of $[Pt_2(\mu\text{-}SC_6F_5)_2(dppe)_2](SO_3CF_3)_2$ (**4b**), shows four signals: a singlet at −77.8 ppm (integral = 3, S–CF_3); a double set of doublets at −122.2 ppm (integral = 2, *ortho*-fluorine), a *pseudo*triplet at −148.0 ppm (integral = 2, *para*-fluorine) and a multiplet at −155.8 ppm (integral = 3, *meta*-fluorine). As before, none of these signals are modified by increasing the temperature to 50 °C.

At lower temperatures (Fig. 5) *ortho* and *meta*-fluorine absorptions become broad and in the lowest temperature limit, the *meta*-fluorine signal is split into a broad doublet (−154.5, −156.0, $\Delta\delta = 1.5$ ppm) which is also interpreted as resulting from the restricted rotation of the S–C_6F_5 bond. The calculated free activation energy for this process is $\Delta G^{\neq} = 37.39 \pm 0.4$ kJ mol^{-1}.

The fact that in **4b** the *meta*-fluorine nuclei absorption is split instead of the *ortho*-fluorine band as in **4a**, is probably due to differences in steric requirements between the thiolate rings and the phosphine benzene substituents which share a densely occupied space.

The room temperature ^{19}F NMR spectra of $[Pt_2(\mu\text{-}p\text{-}SC_6HF_4)_2(dppe)_2]^{2+}$ (**4c**) exhibits three absorptions: a singlet at −74.0 ppm (integral = 3, S–CF_3), a multiplet at −126.7 ppm (integral = 2, *ortho*-fluorine) and a multiplet at −137.6 ppm (integral = 2, *meta*-fluorine).

High temperature (Fig. 6) ^{19}F NMR experiments with compound **4c** show no changes of the absorptions up to 50 °C. As before, decreasing the temperature results in broad signals until at −90 °C the *ortho*-fluorine absorption splits into a pair of broad signals (−125.5, −126.9, $\Delta\delta = 1.4$ ppm). Unfortunately, since the experiment does not reach the point of slow exchange, the free activation energy cannot be calculated with a reliable accuracy.

Compound $[Pt_2(\mu\text{-}o\text{-}SC_6H_4(CF_3))_2(dppe)_2]^{2+}$ (**4d**), with no fluorine atoms on the *S*-phenyl rings have the less electronegative, more basic thiolate ligand, among the compounds studied here. Having an *ortho* CF_3 group, these

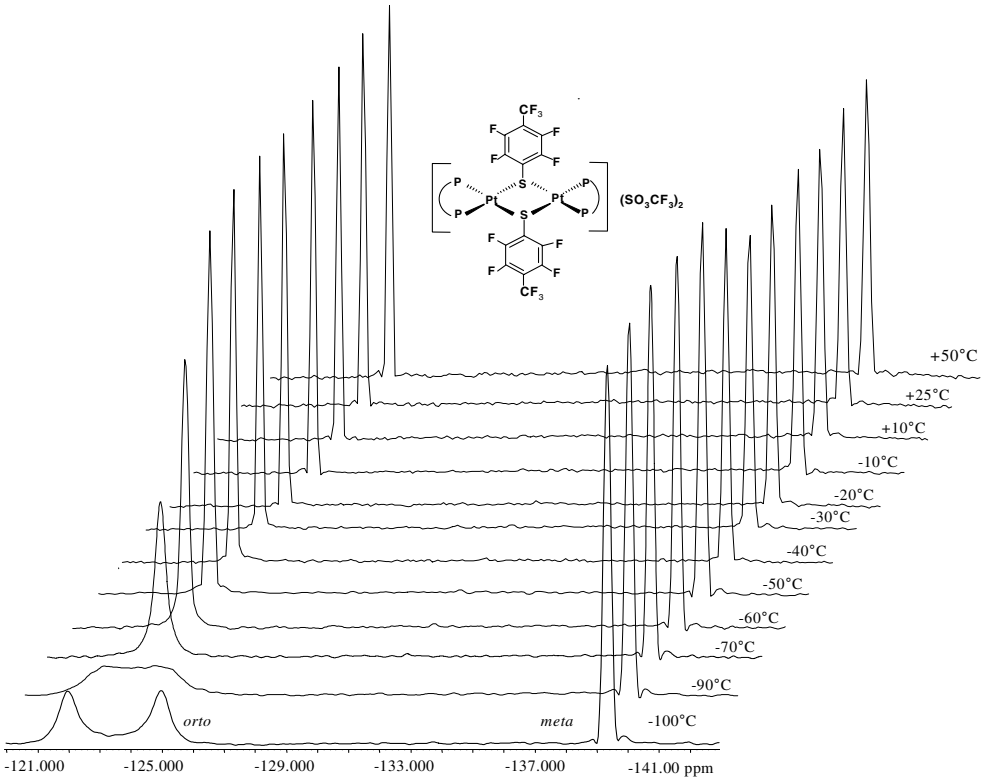

Fig. 4. Variable temperature ^{19}F NMR spectra (*ortho* and *meta* thiolate ligand signals) of $[Pt_2(\mu\text{-}p\text{-}SC_6F_4(CF_3))_2(dppe)_2](SO_3CF_3)_2$ (**4a**).

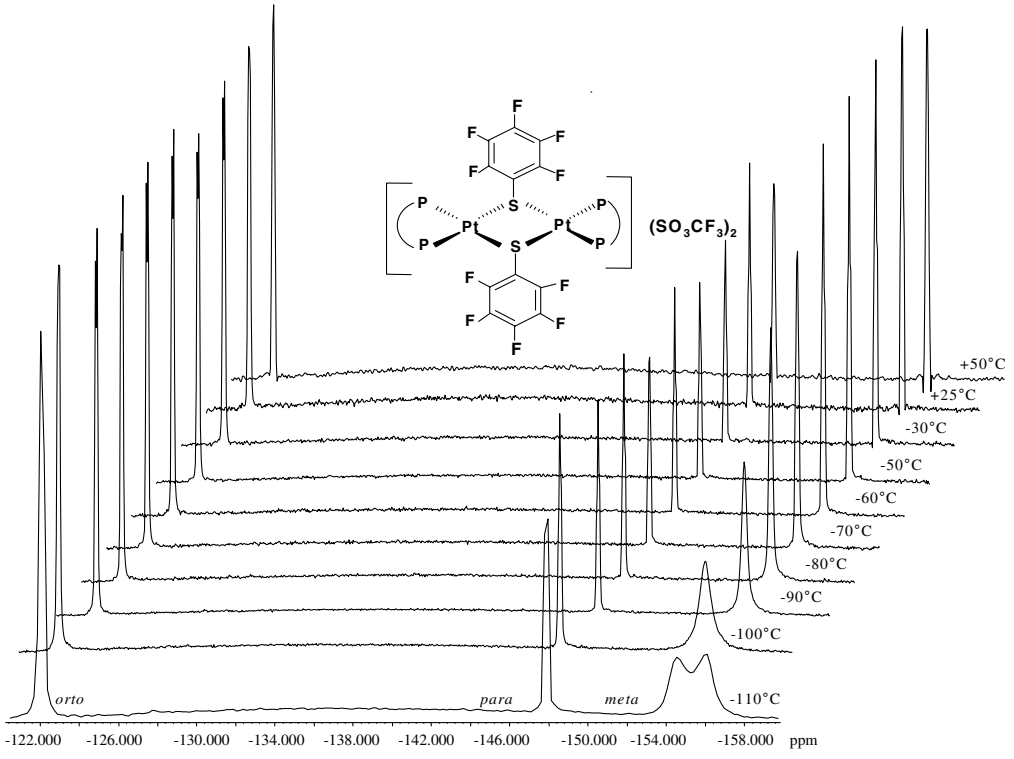

Fig. 5. Variable temperature ^{19}F NMR spectra showing the thiolate region of $[Pt_2(\mu\text{-}SC_6F_5)_2(dppe)_2](SO_3CF_3)_2$ (**4b**).

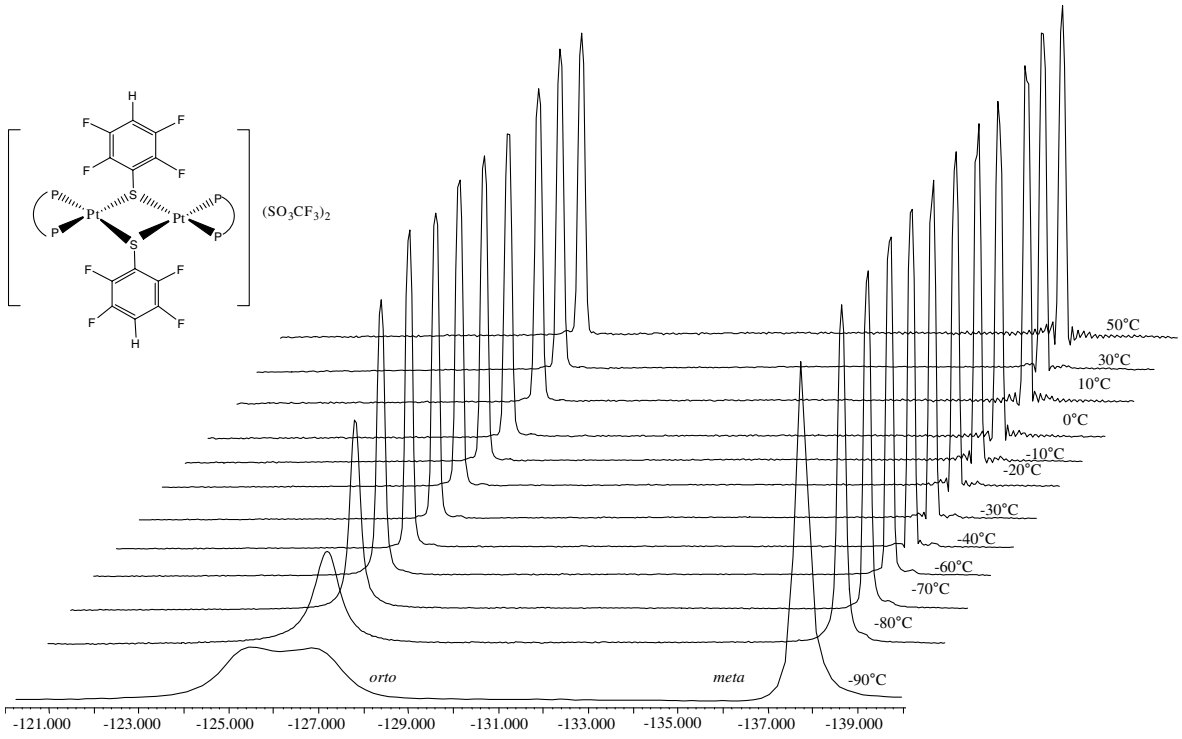
thiolate ligands are asymmetric. The orientation of these substituents relative to the Pt–S_2–Pt ring defines the isomers *cis* and *trans* as shown in Scheme 2.

At room temperature the ^{19}F NMR spectra of **4d** exhibit a pair of singlets at −57.5 ppm (integral = 1) arising from the thiolate–CF_3 and at −79.1 ppm (integral = 1) from



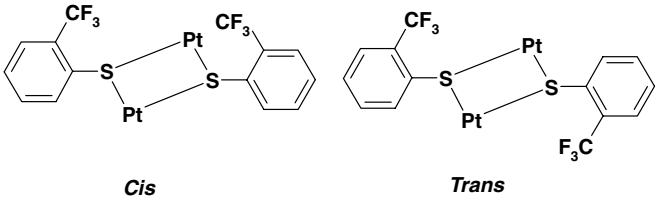


Fig. 6. Variable temperature ^{19}F NMR spectra showing the thiolate region of $[Pt_2(\mu\text{-}p\text{-}SC_6HF_4)_2(dppe)_2](SO_3CF_3)_2$ (**4c**).

Scheme 2.

the triflate–CF_3. ^1H NMR spectra are also clearly defined showing an ABB′C magnetic system for the *o*-$SC_6H_4CF_3$ substituents.

Increasing the temperature to 50 °C has no noticeable effect on the ^{19}F NMR spectra of **4d**, Fig. 7, but upon lowering the temperature, the singlet that is initially centered at δ −57.5 ppm broadens and eventually collapses at −90 °C giving rise to two broad bands centered at −58.1 and −58.6 ppm. The intensity of the downfield signal is *ca.* 11 times larger than that of the upfield absorption. Proton NMR signals undergo a similar broadening and collapsing as the temperature is lowered.

The ^{19}F NMR spectral data are consistent with the rapid interconversion of both *cis* and *trans* isomers at high temperatures and with C–S restricted rotation at low temperatures. Under these conditions the population of each isomer, in solution, is different (1:11), and it is assumed, on steric grounds, that the more intense downfield absorption corresponds to the *anti* isomer as has been found in the solid state (*vide infra*).

The calculated free activation energy for this process is $\Delta G^{\neq} = 40.1 \pm 0.6$ kJ mol^{-1}.

Although a sulfur inversion process cannot be completely discarded for this complex [19,20], it seems unlikely considering that the NMR evidence is consistent along the series studied here and that the calculated $\Delta G^{\neq}$ is nearly 17 kJ mol^{-1} lower than the energy for complexes exhibiting sulfur inversion [18].

2.4. Crystal and molecular structure

Fig. 8 shows the molecular structure of $[Pt_2(\mu\text{-}o\text{-}SC_6H_4(CF_3))_2(dppe)_2](SO_3CF_3)_2$ **4d** and main bond distances and angles are collected in Table 2. This compound has a centrosymmetric square-planar $[Pt_2(\mu\text{-}SR)_2]$ core. The crystallographic isomer stabilized in the solid state has the *anti* configuration with the substituents on the bridging thiolate ligands pointing towards opposite directions. The trifluoromethyl groups in *ortho* positions at the thiolate rings are also pointing in opposite, *trans*, directions. The thiolate $C_6H_4CF_3$ ring and two phenyl rings of neighboring phosphines are aligned in an almost coplanar fashion, allowing strong intra-cation π–π interactions, with centroid to centroid separations in the range 3.526–3.568 Å. As expected, the bridging Pt–S bond distances (2.3759(10) and 2.3749(10)) are longer than the corresponding terminal Pt–S bond distances (2.36 Å, mean) in the monometallic complex $[Pt(o\text{-}SC_6H_4(CF_3))_2(dppe)]$ (*vide supra*) and longer than the bridging Pt–SR bond lengths (2.316 Å, mean) in compounds $[Pt_2(\mu\text{-}SR)_2(SR)_4]^{2+}$, probably reflecting the different *trans* influence of the dppe ligand as compared with that of the thiolate ligand. The Pt–S bond lengths *trans* to phosphine compare with published values

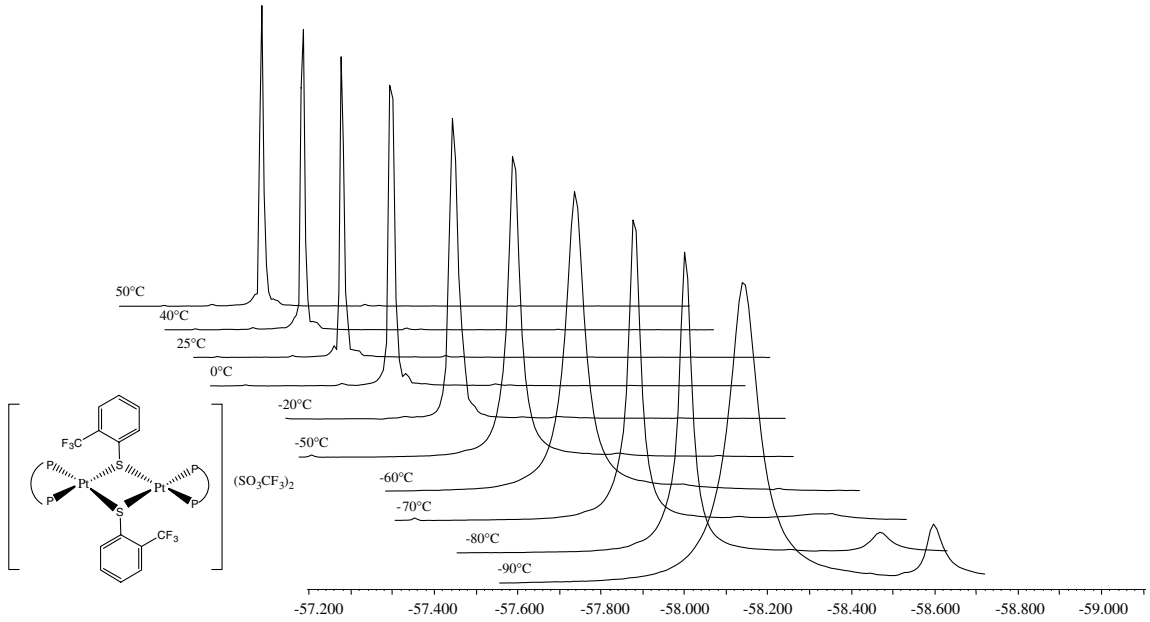

Fig. 7. Variable temperature ^{19}F NMR showing the thiolate–CF_3 region of $[Pt_2(\mu\text{-}o\text{-}SC_6H_4(CF_3))_2(dppe)_2](SO_3CF_3)_2$ (**4d**).

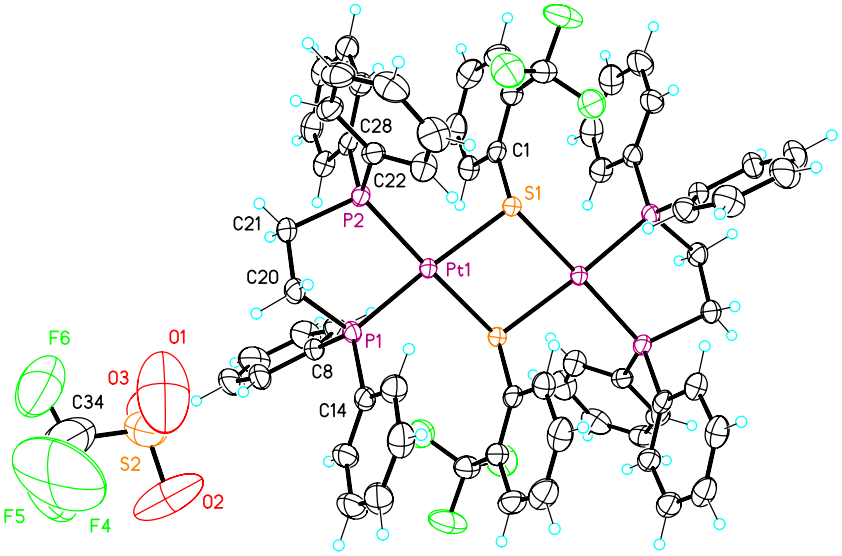

Fig. 8. ORTEP drawing and numbering scheme of $[Pt_2(\mu\text{-}o\text{-}SC_6H_4(CF_3))_2(dppe)_2](SO_3CF_3)_2$ (**4d**). Ellipsoids are shown at the 30% probability level.

Table 2

for dinuclear compounds with thiolate ligands [21–23]. The Pt···Pt distance, 3.6386(3) Å, is rather long, and any possibility of direct magnetic interaction may be ruled out.

3. Conclusions

Homobimetalic, fluorothiolate bridged compounds of Pd and Pt, $[M_2(\mu\text{-}SRf)_2(dppe)_2]$, can conveniently be prepared by reacting the metalloligands $[M(SRf)_2(dppe)]$ with the solvato-complexes $[M(SO_3CF_3)_2(dppe)]$.

In contrast with the behavior of the monometallic compounds included in this study, all members of the bimetallic series of $[M_2(\mu\text{-}SRf)_2(dppe)_2]^{2+}$ complexes are fluxional on the NMR time scale when they are in solution. The available data suggest that the nature of the process is common to all examples. Thus the ligands $p\text{-}SC_6F_4(CF_3)$, SC_6F_5, $p\text{-}SC_6HF_4$ and $o\text{-}SC_6H_4(CF_3)$ on complexes $[M_2(\mu\text{-}SRf)_2(dppe)_2]^{2+}$, are involved in hindered C–S bond rotation

processes. Apparently, the possible rotamers experience different steric interactions, therefore, *ortho*-fluorine atoms are specially affected for *p*-$SC_6F_4(CF_3)$ and *p*-SC_6HF_4 containing compounds, *meta*-fluorine atoms are rendered distinct for the compound with SC_6F_5 bridging ligands whereas *o*-$SC_6H_4(CF_3)$, which is intrinsically asymmetric, defines *cis* and *trans* isomers.

The structure of the bimetallic complex studied bears a square-planar $[M_2(\mu\text{-SRf})_2]$ ring with sulfur substituents pointing towards opposite sites of the plane in an *anti* configuration.

4. Experimental

4.1. Materials

All reactions were carried out under a dry, oxygen-free N_2 atmosphere, using Schlenk techniques [24]. All reagents were purchased from Aldrich Chem. Co. and used as received. $[PdCl_2(dppe)]$ [25], $[PtCl_2(dppe)]$ [25], $Pb(SRf)_2$ [26], $[Pd(SC_6F_5)_2(dppe)]$ [15,27] (**1b**), $[Pd(p\text{-}SC_6HF_4)_2(dppe)]$ [16] (**1c**), $[Pt(SC_6F_5)_2(dppe)]$ [15,27] (**2b**) and $[Pt(p\text{-}SC_6HF_4)_2(dppe)]$ [16] (**2c**) were prepared by published methods.

4.2. Instruments

Microanalyses were performed using a Fisons EA1108 instrument. FT-IR spectra were recorded over the 4000–200 cm^{-1} range on a Perkin–Elmer 1600 spectrophotometer with samples prepared as CsI pellets. Data are expressed in wavenumbers (cm^{-1}) with relative intensities (vs = very strong, s = strong, m = medium, w = weak).

^1H, ^{19}F and ^{31}P NMR spectra were measured with a Varian spectrometer operating at 299.7, 282.0 and 121.5 MHz respectively. Chemical shifts are relative to TMS ($\delta = 0$ (^1H)), $CFCl_3$ ($\delta = 0$ (^{19}F)) and H_3PO_4/D_2O ($\delta = 0$ (^{31}P)). A standard variable temperature unit was used to control the probe were within ±1 °C. Complexes were dissolved in deuterated acetone. FAB mass spectra were obtained on a JEOL JMS-SX102A.

All variable temperature NMR experiments were carried out in deuterated acetone. The activation parameters for dynamic processes were calculated from simulation spectra [28] and the Eyring equation using curve fitting techniques [29–31].

4.3. *[Pd(SRf)$_2$(dppe)]* complexes **1**

A solution of 0.348 mmol of $Pb(SRf)_2$ in acetone (15 mL) was added slowly to a solution of 0.348 mmol of $[PdCl_2(dppe)]$ in acetone (10 mL). The reaction was magnetically stirred for 15 min at room temperature and the white $PbCl_2$ precipitated filtered off. The yellow product was purified by column chromatography with silica gel, using acetone/hexanes (1:2) as eluent.

4.3.1. *[Pd(p-SC$_6$F$_4$(CF$_3$))$_2$(dppe)]* (**1a**)

M.p. 192–194 °C. *Anal.* Calc. for $C_{40}H_{24}F_{14}P_2PdS_2$: C, 47.90; H, 2.41; S, 6.39. Found: C, 47.8; H, 2.5; S, 6.6%. IR (cm^{-1}): 3055w, 3029w, 1642m, 1471vs, 1436s, 1383m, 1323vs, 1167s, 1133s, 1102m, 998m, 971s, 878w, 830s, 746w, 713s, 690s, 651w, 530m, 478m. ^1H NMR (C_2D_6CO, 298 K): 7.9, 7.6 (m, 20H, phenyl from phosphine), 2.9 (m, 4H, CH_2–CH_2). ^{31}P NMR (C_2D_6CO, 298 K): 62.6. ^{19}F NMR (C_2D_6CO, 298 K): −129.1 (pd, *o*-F), −143.3 (m, *m*-F), −52.6 (t, *p*-CF_3).

4.3.2. *[Pd(o-SC$_6$H$_4$(CF$_3$))$_2$(dppe)]* (**1d**)

M.p. 212–214 °C. *Anal.* Calc. for $C_{40}H_{32}F_6P_2PdS_2$: C, 55.92; H, 3.75; S, 7.46. Found: C, 56.7; H, 4.0; S, 6.8%. IR (cm^{-1}): 3424m, 3055w, 2925w, 1676w, 1637w, 1588m, 1559w, 1483w, 1460w, 1434s, 1310vs, 1245m, 1156s, 1124vs, 1102vs, 1042s, 1029s, 999w, 876w, 817w, 751m, 702s, 689s, 646w, 597w, 529vs, 481m. ^1H NMR (C_2D_6CO, 298 K): 7.1 (m, *o*-H, thiolate), 7.6, 6.7 (m, *m*-H, thiolate), 6.7 (m, *p*-H, thiolate), 7.8, 7.5 (m, 20H, phenyl from phosphine), 2.7 (m, 4H, CH_2–CH_2). ^{31}P NMR (C_2D_6CO, 298 K): 57.1. ^{19}F NMR (C_2D_6CO, 298 K): −62.4 (pt, *o*-CF_3).

4.4. *[Pt(SRf)$_2$(dppe)]* complexes **2**

A solution of 0.211 mmol of $Pb(SRf)_2$ in acetone (10 mL) was added to a suspension of 0.211 mmol of $[PtCl_2(dppe)]$ in acetone (10 mL). The reaction was magnetically stirred for 24 h at room temperature. The $PbCl_2$ precipitated was separated by filtration through silica gel and the solution evaporated to yield a yellow powder which was recrystallized from acetone.

4.4.1. *[Pt(p-SC$_6$F$_4$(CF$_3$))$_2$(dppe)]* (**2a**)

Yield: 90.7%, m.p. 212–214 °C. *Anal.* Calc. for $C_{40}H_{24}F_{14}P_2PtS_2$: C, 44.01; H, 2.22; S, 5.87. Found: C, 44.1; H, 2.2; S, 5.6%. IR (cm^{-1}): 3433w, 3055w, 1642m, 1471vs, 1437m, 1384m, 1324vs, 1168s, 1130s, 1103m, 998w, 972vs, 880w, 750w, 713s, 690s, 653w, 532s, 483m. ^1H NMR (C_2D_6CO, 298 K): 8.0, 7.6 (m, 20H, phenyl from phosphine), 2.8 (m, 4H, CH_2-CH_2). ^{31}P NMR (C_2D_6CO, 298 K): 52.3 ($J_{Pt-P} = 3033$. Hz). ^{19}F NMR (C_2D_6CO, 298 K): −132.9 (pd, *o*-F), −147.2 (m, *m*-F), −56.9 (t, *p*-CF_3).

4.4.2. *[Pt(o-SC$_6$H$_4$(CF$_3$))$_2$(dppe)]* (**2d**)

Yield: 84.63%, m.p. 197–199 °C. *Anal.* Calc. for $C_{40}H_{32}F_6P_2PtS_2$: C, 50.69; H, 3.40; S, 6.76. Found: C, 50.8; H, 3.5; S, 6.5%. IR (cm^{-1}): 3434w, 3052w, 1710w, 1558w, 1483w, 1461m, 1435vs, 1308vs, 1246s, 1167vs, 1121vs, 1104vs, 1042s, 1029vs, 997m, 878w, 824m, 754s, 715s, 702s, 691s, 655w, 645m, 532vs, 496w, 480m, 461m, 432w, 157m. ^1H NMR (C_2D_6CO, 298 K): 7.1 (m, *o*-H, thiolate), 7.7, 6.8 (m, *m*-H, thiolate), 6.8 (m, *p*-H, thiolate), 8.0, 7.5 (m, 20H, phenyl from phosphine), 2.7 (m, 4H,

CH_2–CH_2). ^{31}P NMR (C_2D_6CO, 298 K): 50.3 (J_{Pt-P} = 2879 Hz). ^{19}F NMR (C_2D_6CO, 298 K): −68.3 (pt, *o*-CF_3).

4.5. *[Pd(μ-SRf)(dppe)]$_2$(SO_3CF_3)$_2$ complexes (**3**)*

A solution of 0.139 mmol of $AgSO_3CF_3$ in 10 mL of acetone was added to a solution of 0.07 mmol of [$PdCl_2$(dppe)] in acetone (15 mL) and stirred for 24 h at room temperature. After filtration trough Celite, 0.07 mmol of [Pd(SRf)$_2$(dppe)] in 15 mL of acetone were added and stirred for 7 h. The reaction was followed by TLC until completeness. Slow evaporation of the solvent yield a yellow powder which was recrystallized from diffusion of hexanes in acetone.

4.5.1. *[Pd(μ-p-$SC_6F_4(CF_3)$)(dppe)]$_2$(SO_3CF_3)$_2$ (**3a**)*

M.p. 168–170 °C. *Anal.* Calc. for $C_{68}H_{48}F_{20}O_6P_4Pd_2S_4$: C, 45.22; H, 2.68; S, 7.10. Found: C, 45.0; H, 2.8; S, 7.3%. IR (cm^{-1}): 3439w, 3058w, 2918w, 1643m, 1586w, 1479vs, 1437s, 1325vs, 1257vs, 1224m, 1144s, 1102m, 1029s, 997w, 978s, 942w, 881w, 825m, 749m, 714s, 690s, 656w, 637s, 531s, 480m, 437w. ^1H NMR (C_2D_6CO, 298 K): 7.7, 7.6 (m, 20H, phenyl from phosphine), 2.9 (m, 4H, CH_2–CH_2). ^{31}P NMR (C_2D_6CO, 298 K): 74.7. ^{19}F NMR (C_2D_6CO, 298 K): −122.1(pd, *o*-F), −138.4 (m, *m*-F), −54.4 (t, *p*-F), −76.4 (s, SO_3CF_3).

4.5.2. *[Pd(μ-SC_6F_5)(dppe)]$_2$(SO_3CF_3)$_2$ (**3b**)*

Yield: 70.14%. M.p. 200–201 °C and at 210 °C decomposition. *Anal.* Calc. for $C_{66}H_{48}F_{16}O_6P_4Pd_2S_4$: C, 46.48; H, 2.84; S, 7.51. Found: C, 46.0; H, 2.9; S, 7.3%. IR (cm^{-1}): 3462s, 3059w, 1639w, 1513vs, 1484vs, 1437s, 1276vs, 1258vs, 1223s, 1159s, 1102s, 1083s, 1031vs, 997m, 977s, 877w, 853m, 816m, 754m, 721s, 707m, 690s, 637vs, 573m, 531vs, 480s, 432m. ^1H NMR (C_2D_6CO, 298 K): 7.7, 7.6 (m, 20H, phenyl from phosphine), 2.8 (m, 4H, CH_2–CH_2). ^{31}P NMR (C_2D_6CO, 298 K): 68.9. ^{19}F NMR (C_2D_6CO, 298 K): −125.5 (pd, *o*-F), −160.1 (m, *m*-F), −153.5 (pt, *p*-F), −77.4 (s, SO_3CF_3).

4.6.4. *[Pt(μ-o-SC$_6$H$_4$(CF$_3$))(dppe)]$_2$(SO$_3$CF$_3$)$_2$ (**4d**)*

Yield: 54.72%. M.p. 267–269 °C. *Anal.* Calc. for $C_{68}H_{56}F_{12}O_6P_4S_4Pt_2$: C, 44.39; H, 3.07; S, 6.96. Found: C, 45.0; H, 3.1; S, 6.8%. IR (cm^{-1}): 3515w, 3054w, 2963w, 1707w, 1586w, 1572w, 1482m, 1437vs, 1309vs, 1259vs, 1222s, 1153vs, 1139vs, 1103vs, 1028vs, 997s, 887m, 828m, 753s, 713s, 687s, 660m, 636vs, 595w, 571w, 534vs, 516m, 445m. ^{1}H NMR (C_2D_6CO, 298 K): 7.0 (m, *o*-H, thiolate); 8.4, 7.3 (m, *m*-H, thiolate); 7.3 (m, *p*-H, thiolate), 7.7, 7.5 (m, 20H, phenyl from phosphine), 2.5 (m, 4H, CH_2–CH_2). ^{31}P NMR (C_2D_6CO, 298 K): 54.4 (J_{Pt-P} = 3117 Hz). ^{19}F NMR (C_2D_6CO, 298 K): −58.5 (pt, *o*-CF_3), −79.1 (s, SO_3CF_3).

4.7. X-ray diffraction data

Suitable single crystals of complexes **1c**, **2b**, **2d** and **4d** were obtained by slow evaporation of acetone solutions and were found to be stable in air. Pertinent crystal data and other crystallographic parameters are listed in Table 3. The diffraction data were collected on a Bruker P4 diffractometer [32] using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and $\theta/2\theta$ or ω scan mode with variable scan speed. Absorption corrections were applied using ψ-scans.

For all four complexes non-H atoms were refined anisotropically and H atoms were placed in idealized positions [33]. In the case of **2b**, C and F atoms were restrained so that their U_{ij} components approximate to isotropic behavior. In the case of **4d**, the triflate ion was restrained to converge to a sensible geometry, through suitable restraints on bond lengths.

Selected geometric parameters for **1c**, **2b**, **2d** and **4d** are listed in Tables 2 and 3. Complete data have been deposited as a CIF, and raw data, as structure factors, are available on request to authors.

Acknowledgements

We thank Mr. Francisco Irby for his helpful assistance. We are grateful to DGAPA-UNAM (IN119305) and CONACYT (44494) for financial support of this research.

Appendix A. Supplementary material

CCDC 626895, 626896, 626897 and 626898 contain the supplementary crystallographic data for **1c**, **2b**, **2d** and **4d**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.05.025.

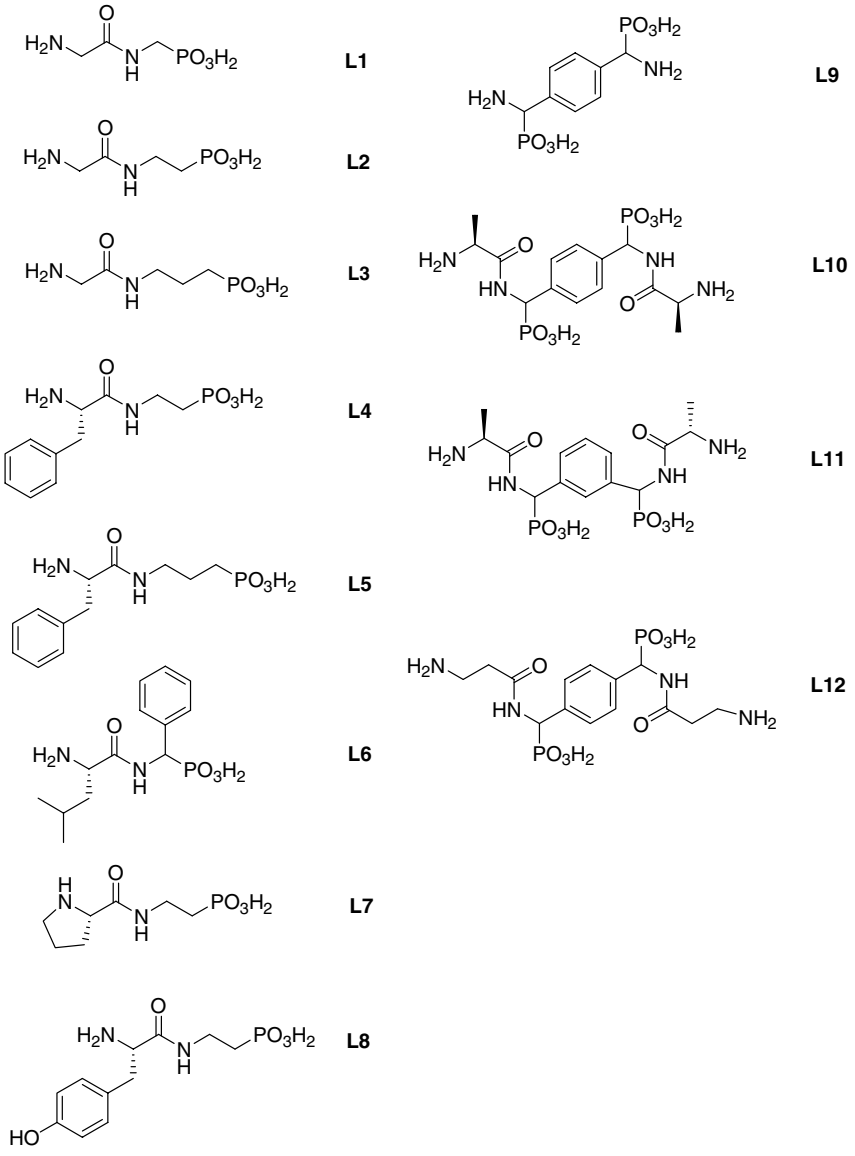

Fig. 1. Chemical structures of studied ligands.

liquids and were purified by precipitation of their oxalates from diethyl ether solutions.

Phosphono dipeptides were obtained according to previously described procedures using mixed carboxylic–carbonic acid procedure. They were purified by recrystallization from water–ethanol mixtures [10,11].

2.1.2. Diphosphonic ligands

*2.1.2.1. Synthesis of tetraethyl 1,4-phenylene-di(aminomethylphosphonate) and **L9**.* The reaction was carried out according to the procedure reported previously [12,13]. Terephthalaaldehyde (0.014 mol, 1.85 g) and benzylamine (0.028 mol, 2.98 g) were dissolved in 100 ml of methanol and stirred overnight at room temperature. The resulting crystalline Schiff base was filtered and analyzed by means of ^{1}H NMR ($CDCl_3$): δ: 4.86 (s, 2H, C**H**$_2$); 7.24–7.42 (m, 10H, benzyl protons), 7.86 (s, 4H, phenylene protons), 8.42 (s, 2H, C**H**=N), yield 80%, t.t. 102 °C. This product was of a good purity and therefore it was not purified. It was dissolved in 50 ml of toluene, and diethylphosphite (0.012 mol, 1.61 g) was added followed by refluxing the reaction mixture for 8 h. Then the volatile components of the solution were evaporated, crude product dissolved in dry diethyl ether and precipitated as oxalate upon addition of appropriate amount of anhydrous oxalic acid in ethyl ether. The formed precipitate was filtered, dried and suspended in dichloromethane (DCM). The suspension was washed with 1 M NaOH until all soil material was dissolved. After evaporation of the solvent, crude product was dissolved in 2.4 M solution of hydrogen chloride gas in methanol and hydrogenated over Pd/C catalyst at atmospheric pressure during 8 h. The progress of hydrogenation reaction was controlled by ^{31}P NMR spectroscopy. When the hydrogenation process was completed, reaction mixture was filtered through 4 cm layer of Cellite and solution was evaporated under reduced

pressure. The crude hydrochloride was purified by recrystallization from methanol/ethyl acetate mixture. In order to obtain **L9**, the tetraethyl 1,4-phenylene-di(aminomethylphosphonate) was refluxed in 36% hydrochloric acid during 8 h, then evaporated, treated with ethanol, and collected by filtration. The crude **L9** was purified by dissolving in base solution and acidification with concentrated hydrochloric acid. During this process, pure compound **L9** precipitated. For coordination studies this compound was used as dihydrochloride or tetra-sodium salt.

*2.1.2.2. Synthesis of **L10**, **L11** and **L12**.* The synthesis of these phosphono peptides **L10**, **L11** and **L12** was carried out accordingly to the general procedure described previously [14]. A solution of 0.005 mol of the Boc-L-Ala or Z-β-Ala and 0.0052 mol of triethylamine in 40 ml of dry chloroform was cooled to −5 °C and treated with (0.0055 mol) of ethyl chloroformate. After 40 min, 0.0025 mol of tetraethyl 1,4-phenylene-di(aminomethylphosphonate) (see Section 2.1.2.1) was added with stirring and the solution was left to reach room temperature, followed by slow warming up to the boiling point. The resulting solution was washed successively with water, 1 M hydrochloride acid, water, saturated solution of sodium bicarbonate and water. Finally, it was extracted with brine and dried over sodium sulphate. The solvent was distilled off and the oily residue representing crude diester of phosphono peptide was dissolved in 20 ml of 40% hydrogen bromide (for **L10**) in glacial acetic acid and left overnight. Then volatile reagents and solvents were removed under reduced pressure. The residues were dissolved in absolute ethanol and by addition of propylene oxide crude peptide precipitated. In order to hydrolyze crude diesters of **L11** and **L12** 0.041 mol (5.4 ml) of bromotrimethylsilane with each compounds were mixed during three days. Then reaction mixtures were evaporated, dissolved in methanol and stirred for 1 day. After that, the solutions were again evaporated and products precipitated by addition of ethanol. The peptides were re-crystallized from ethanol and/or ethanol–water solutions.

*2.1.3. Spectroscopic characterization of ligands: **L1**–**L12***

*2.1.3.1. N-Glycylaminomethylphosphonic acid – **L1**.* This peptide melted with decomposition at 279–284 °C. ^{1}H NMR (D_2O + NaOD) δ (ppm): 3.55 (d, 2H, $J = 13.5$ Hz, PCH_2), 4.18 (s, 2H, glycyl CH_2); ^{31}P NMR, δ: 21.52. Yield: 58%.

*2.1.3.2. N-Glycyl-2-aminoethylphosphonic acid – **L2**.* This peptide decomposed over 270 °C. ^{1}H NMR (D_2O + NaOD) δ (ppm): 1.3–2.05 (m, 2H, PCH_2CH_2), 3.05–3.85 (m, 2H, PCH_2CH_2), 3.87 (s, 2H, glycyl CH_2);^{31}P NMR, δ: 22.06. Yield: 58%.

*2.1.3.3. N-Glycyl-3-aminopropylphosphonic acid – **L3**.* M.p. 247–248 °C. ^{1}H NMR (D_2O + D_2SO_4) δ (ppm): 1.75–2.4 (m, 4H, PCH_2CH_2), 3.63 (t, 2H, $J = 6.5$ Hz, NCH_2), 4.14 (s, 2H, glycyl CH_2); ^{31}P NMR, δ: 22.75. Yield: 66%.

*2.1.3.4. N-L-Phenylalanyl-2-aminoethylphosphonic acid – **L4**.* This peptide melted with decomposition at 288–289 °C. ^{1}H NMR (D_2O + NaOD) δ (ppm): 1.25–1.90 (m, 2H, PCH_2CH_2), 2.84 (d–d, 2H, $J = 6.5$ and 7.0 Hz, CH_2Ph), 3.10–3.75 (m 3H, CH_2P and phenylalanyl α-CH), 7.08–7.50 (m, 5H, aromatic protons); ^{31}P NMR, δ: 25.61. Yield: 55%.

*2.1.3.5. N-L-Phenylalanyl-3-aminopropylphosphonic acid – **L5**.* This peptide melted with decomposition at 279–281 °C. ^{1}H NMR (D_2O + D_2SO_4) δ (ppm): 1.6–2.25 (m, 4H, PCH_2CH_2), 3.2–3.9 (m, 4H, CH_2Ph and NCH_2), 4.55 (t, 1H, $J = 7.0$ Hz, phenylalanyl α-CH), 7.68 (bs, 5H, aromatic protons); ^{31}P NMR, δ: 21.65. Yield: 93%.

*2.1.3.6. N-L-Leucyl-D,L-aminobenzylphosphonic acid – **L6**.* This peptide melted with decomposition at 266–267 °C. ^{1}H NMR (D_2O + D_2SO_4) δ (ppm): 1.24 and 1.41 (d, 3H each, $J = 7.0$ Hz, CH_3), 2.0–2.4 (m, 3H, CH_2CH), 4.70 (t, 1H, $J = 7.0$ Hz, leucyl α-CH), 5.71 (d, 1H, $J = 23.0$ Hz, CHP), 7.88 (bs, 5H, aromatic protons); ^{31}P NMR, δ: 14.89, 14.66. Yield: 55%.

*2.1.3.7. N-L-Prolyl-2-aminoethylphosphonic acid – **L7**.* This peptide melted with decomposition at 281–282 °C. ^{1}H NMR (D_2O + NaOD) δ (ppm): 1.5–2.65 (m, 6H, prolyl CH_2CH_2CH and PCH_2CH_2), 3.15–3.80 (m, 4H, PCH_2CH_2 and prolyl NCH_2), 4.35 (t, 1H, $J = 7.5$ Hz, prolyl α-CH); ^{31}P NMR, δ: 21.09. Yield: 65%.

*2.1.3.8. N-L-Tyrosyl-2-aminoethylphosphonic acid – **L8**.* This peptide melted with decomposition at 293–295 °C. ^{1}H NMR δ (ppm): 1.42–1.70 (m, 2H, PCH_2CH_2), 1.79–2.00 (m, 2H, PCH_2CH_2), 3.01 (m, 2H CH_2Ph), 3.98 (t, 1H, CHCO, $J = 6.7$ Hz), 6.81–7.10 (d, 2H each, $J = 7$ Hz aromatic protons); ^{31}P NMR, δ: 19.42. Yield: 55%.

*2.1.3.9. 1,4-Phenylene-di(aminomethylphosphonic) acid – **L9**.* Compound **L9** decomposed upon heating over 278 °C. ^{1}H NMR (D_2O + NaOD) δ: 3.55 (d, 2H, $J = 14.4$ Hz, CH), 7.10 (s, 4H, aromatic protons); ^{31}P NMR, δ: 16.26. Yield: 55%.

*2.1.3.10. 1,4-Phenylene-di(N-L-alanylaminomethylphosphonate) – **L10**.* The compound **L10** decomposed upon heating over 300 °C. ^{1}H NMR (D_2O) δ: 1.38 and 1.50 (d, 3H each, $J = 6.0$ Hz, alanyl CH_3); 4.10 (m, 2H, $J = 6.0$ Hz, alanyl α-CH), 4.99 and 4.96 (d, 1H each, $J = 19.5$ Hz, phosphonate α-CH), 7.37 (s, 4H, aromatic protons); ^{31}P NMR, δ: 14.51; 14.41. Yield: 65%.

*2.1.3.11. 1,3-Phenylene-di(N-L-alanylaminomethylphosphonate) – **L11**.* The compound **L11** decomposed upon heating over 320 °C. ^{1}H NMR (D_2O) δ: 1.40 and 1.51 (d, 3H each,

$J = 7.0$ Hz, alanyl C**H**$_3$); 4.10 (m, 2H, alanyl α-C**H**, $J = 6.0$ Hz), 4.97 and 5.00 (d, 1H each, phosphonate α-C**H**, $J = 19.0$ Hz), 7.28 (m, 4H, aromatic protons); ^{31}P NMR, δ: 14.64 (m). Yield: 23%.

*2.1.3.12. 1,3-Phenylene-di(N-β-alanylaminomethylphosphonate) – **L12**.* The compound **L12** decomposed upon heating over 320 °C. ^{1}H NMR (D_2O) δ:2.69 (m, 4H, CH_2CH_2–); 3.16 (t, 4H, CH_2CH_2, $J = 6.4$ Hz), 5.03 (d, 2H, $J = 20$ Hz, phosphonate α-C**H**), 7.29 (m, 4H, aromatic protons); ^{31}P NMR, δ: 16.1 (broad signal). Yield: 45%.

2.2. Potentiometric studies

Stability constants both for protons and complexes were determined by pH-metric titration of 1.8–2.0 cm^3 samples at 25 °C over pH range of 2.5–11. The ligand concentration in the various samples was 2×10^{-3} mol dm^{-3} and metal

ion to ligand ratio was set as 1:2 to 1:6. Initial solutions were titrated with NaOH (Merck) delivered by a 0.25 ml micrometer syringe previously calibrated by weight titrations of standard materials. The purities and exact concentrations of the solutions of the ligands were determined by the method of Gran [15]. The pH-metric titrations were performed involving 0.1 M KNO_3 background using a MOLSPIN automatic titration system with a Russell CMAW 711 microcombined electrode calibrated daily in hydrogen-ion concentration using HNO_3 (Aldrich) [16]. The SUPERQUAD computer program was used for calculations of stability constants [17]. Standard deviations quoted refer to random errors only. They are, however, a good indication of the importance of a particular species present in the equilibrium.

2.3. Spectroscopic studies (UV–Vis, EPR and CD)

The absorption spectra were recorded on Beckman DU 650 spectrofotometr termostated at 25 °C. Electron paramagnetic resonance (EPR) spectra were performed in ethylene glycol-water (1:2 v/v) solution at 77 K using Bruker ESP 300 spectrometer at the X-band frequency (9.3 GHz). Circular dichroizm (CD) spectra were recorded on a Jasco J-715 spectropolarimeter in the 800–235 nm range. The values of $\Delta\varepsilon$, i.e. $\varepsilon_l - \varepsilon_r$, and ε were calculated at the maximum concentration of the particular species obtained from the potentiometric data. The ligand concentration used in the spectroscopic samples was $4–6 \times 10^{-3}$ mol dm^{-3}, and metal concentration was $1–2 \times 10^{-3}$ mol dm^{-3}.

3. Results and discussion

3.1. Protonation studies

The protonation constants of the studied ligands are given in Tables 1 and 3. The dipeptides **L1**–**L7** contain three protonation sides, whereas **L8** contains one more proton located in a tyrosine side chain (pK 10.28). These are protons of the amine (pK 7.29–9.04) and phosphonic (pK 6.10–7.10) groups. One phosphonic proton is very acidic (p$K \approx 1.0$) [18,19] and it was only approximately evaluated. The ligands **L9**, **L10** and **L12** possess five protonation sides (H_5L) and **L11** peptide four (H_4L) (Table 3). The highest pK belongs to the amine groups and the remaining to the phosphonic functions.

3.2. Complexation studies

3.2.0.13. *L1–L8*

The stability constants obtained for the Cu(II) complexes are given in Tables 2 and 3. To clarify the binding modes of the complexes formed – visible, CD and EPR spectra were also measured (Tables 4 and 5). Low pH species of the CuHL type are formed for all study ligands except for **L4** and **L7**. In this species Cu(II) ion coordinates in bidentate mode *via* N-terminal amino nitrogen and peptide carbonyl group. In almost every case, CuHL is a minor species except for **L3** and **L5**, which possess longer linker between terminal phosphonic group and a peptide bond (Fig. 1). Deprotonation of CuHL results in formation of CuL, a minor species in pH range of 5–7, followed by formation of $CuH_{-1}L$. In the latter complex, the binding mode involves $\{NH_2, N^-, PO_3^{2-}\}$ donor set characteristic for dipeptides [20,21]. The binding mode in $CuH_{-1}L$ is clearly confirmed by the spectroscopic parameters with maximum of d–d transitions located at 620–650 nm and

Metal to ligand ratio = 1:3; [Cu(II)] = 0.002 M.

EPR parameters with $A_{\parallel}$ between 174–182 G and $g_{\parallel}$ close to 2.25 (Table 4) [18].

For first three ligands **L1**, **L2** and **L3**, the major impact on the $CuH_{-1}L$ formation has the size of the chelating ring with $\{N^-, PO_3^{2-}\}$ donor set. This size depends on the linker between two donor atoms. p*K* values of the reaction of $CuH_{-1}L$ formation which are 5.16, 5.26 and 6.95, respectively, the conclusion about five – the most favourable, six and seven-membered chelating ring can be made due to the rising p*K*.

The deprotonation of **L1**, **L6** and **L7** copper complexes in high pH leads to $CuH_{-2}L$ or $CuH_{-1}LOH$ species formation and can be assigned to hydrolysis of water molecules from the complex coordination sphere as in the simple dipeptides. Because the measurements were performed in the presence of excess of ligand, a 1:2 species were detected potentiometrically, although CuL_2 species can not be determined by spectroscopic measurements due to a overlapping with the major equimolar $CuH_{-1}L$ species. We may assume the $\{NH_2, N^-, PO_3^{2-}; NH_2, CO\}$ coordination pattern for CuL_2 form.

3.2.0.14. *L9–L12*

The interaction of Cu(II) ions with core ligand **L9** yields in the formation of CuH_2L complex (Fig. 2) in which one

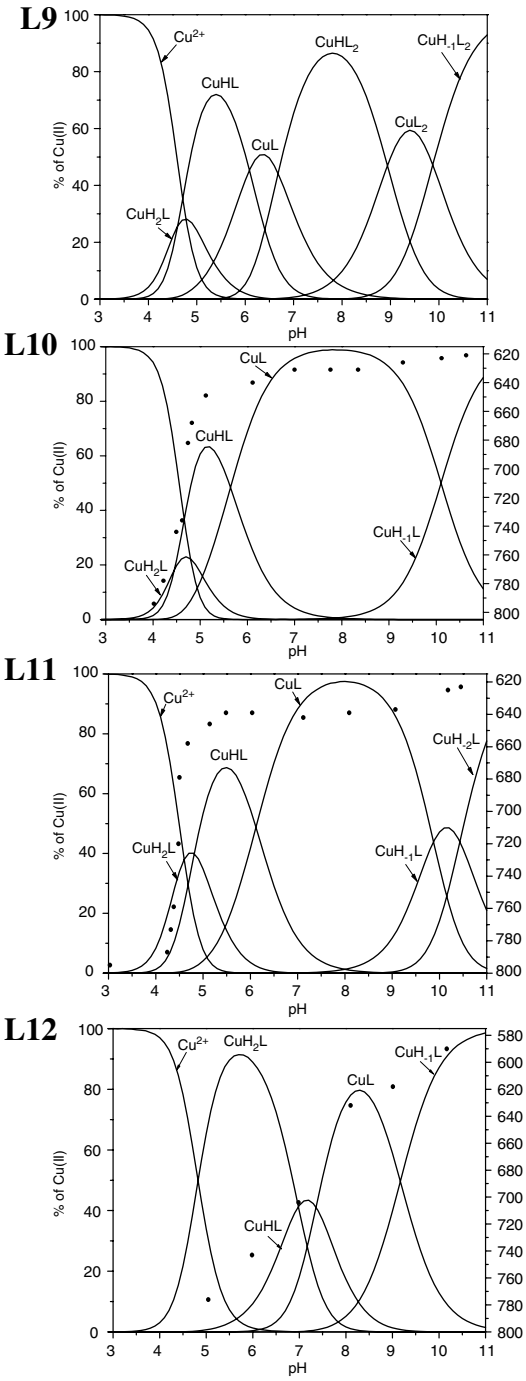

Fig. 2. Species distribution curves for the Cu(II)–**L1**, **L2**, **L3** and **L4** complexes as a function of pH. For **L10**, **L11** and **L12** overlapped with UV–Vis d–d transitions (in the same concentration conditions).

set of $\{NH_2, PO_3^{2-}\}$ donors is involved in the metal ion coordination. The formation of two other species CuHL and CuL results from the consecutive proton dissociation from amino and phosphonic functions. The coordination of Cu(II) ion causes distinct decrease of the p*K* values of the two functions located on the other side of the molecule (Table 3). The further increase of pH results in the CuL_2 complex formation with the coordination mode $\{2 \times NH_2, 2 \times PO_3^{2-}\}$. This coordination is supported by

the spectroscopic parameter, the d–d transitions centered at 637 nm. The formation of the $CuH_{-1}L_2$ species at high pH indicates the beginning of the hydrolysis process.

Two peptides **L10** and **L11** possessing two dipeptide units in *para* and *meta*-positions (Fig. 1) were found to coordinate Cu(II) ions in the same mode as X–Y–PO_3^{2-} phosphonic dipeptides. Despite different positions of attached peptide units, both ligands demonstrate similar binding properties towards Cu(II) ion, in which only one peptide moiety is involved. CuH_2L, the first formed complex, involves most likely the $\{NH_2, C{=}O, PO_3^{2-}\}$ donor set [21]. The proton dissociation in the ligand results in the formation of CuHL species. This reaction is accompanied by the significant change in the d–d transitions shifted to 628 nm in UV–Vis and to 629 nm in CD spectra. Also the EPR parameters $A_{\parallel} = 175$ and $g_{\parallel} = 2.25$ correspond to formation of the 2 N species resulting from the $\{NH_2, N^-, PO_3^{2-}\}$ binding mode [21]. The comparison of $\log K$ values of proton release from amide of these peptides and simple phosphono dipeptides due to its copper binding, showed that they are much lower. Thus, in the case of compounds **L10** and **L11**, they are 4.46 and 4.81, respectively, whereas for structurally corresponding dipeptides Ala-Leu(P) and Leu-Ala(P) they are 5.58 and 5.23 [20]. The formation of CuL and $CuH_{-1}L$ species is associated with deprotonation of phosphonic and amino groups from the unbound peptidyl fragment of the molecule.

The replacement of L-Ala residue in **L11** with β-Ala moiety leading to **L12** results in the lack of a chiral center and elongation of the peptidic chain. This change forces a little variation in the coordination properties of the ligand. The differences in stability constants derive from the different protonation constants, which for this β-Ala peptide are much higher in the case of amino group and in the change of the size of the $\{NH_2,N^-\}$ chelate ring (Table 3).

4. Conclusions

Phosphono-peptides containing simple aminophosphonic acids **L1**–**L8** exhibited a typical coordination mode which is very similar to classic dipeptides. The main species formed is the $CuH_{-1}L$ complex with $\{NH_2, N^-, PO_3^{2-}\}$ coordination mode. Phenylene-1,4-di(aminomethylphosphonic) acid **L9** coordinates Cu(II) ions using 1x or $2x\{NH_2, PO_3^{2-}\}$ donor sets deriving from aminophosphonic units located either on one or on two ligand molecules. Dipeptide derivatives of **L9** form the 1:1 complexes, in which copper ion is coordinated by only one dipeptidyl moiety. The comparison of the co-ordination abilities of **L11** and **L12** has shown that also elongation of a peptide chain does not favor the second peptidic amino nitrogen coordination.

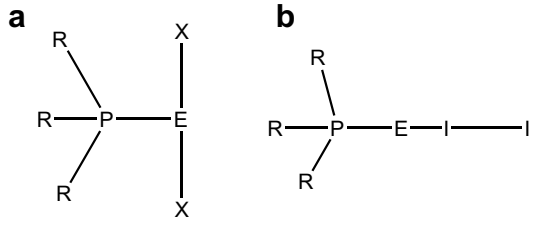

Fig. 1. Structural isomers for R_3PEX_2 (E = S, Se and Te) compounds; (a) T-shaped motif, (b) charge-transfer "molecular spoke" adduct.

formation of a stable compound, Et_3PTeCl_2 [7]. This compound has been crystallographically characterised and features a T-shaped motif at tellurium, as shown in Fig. 1a. Molecules of Et_3PTeCl_2 are linked by weak tellurium···chlorine interactions to form centrosymmetric dimers.

R_3PSeBr_2 adducts were first reported by Williams and Wynne in 1976 ($R_3 = Ph_3$, (*m*-tolyl)$_3$ and (*p*-tolyl)$_3$) [8], who assigned a T-shaped geometry to these adducts on the basis of vibrational spectroscopic data. A T-shaped geometry has subsequently been confirmed crystallographically for a series of R_3PSeBr_2 compounds, R = $(Me_2N)_3$, Cy_3 [9], $^iPr_3$, $^iPr_2{}^tBu$, $^iPr{}^tBu_2$ [10], and for a number of dibromine adducts of bidentate phosphine selenides, $dppmSe_2Br_4$ and $dppeSe_2Br_4$ [11]. These selenium(II) compounds feature a T-shaped geometry as predicted by VSEPR theory (based on a pseudo trigonal bipyramidal arrangement, taking into account the two lone pairs on selenium). Typically, in such compounds the Br–Se–Br angle should be distorted from linear as a result of repulsion from the lone pairs. These adducts do show distorted Br–Se–Br angles, but the distortion appears to be *towards* the lone pairs and away from the bulky groups on the phosphine. The distortion is more extreme where there is a higher degree of steric hindrance, e.g., in the structure of $^iPr{}^tBu_2PSeBr_2$, where Br–Se–Br: 159.16(4)° [10]. A T-shaped geometry has also been observed for the only reported R_3PTeBr_2 adduct, Et_3PTeBr_2 [7], although here the Br–Te–Br angle is distorted away from the lone pairs, possibly as a consequence of the presence of weak intermolecular tellurium···bromine interactions: similar interactions are not observed in the T-shaped selenium compounds. In contrast, the reactions of tertiary phosphine sulfides, R_3PS, with dibromine usually result in cleavage of the P–S bond and subsequent formation of R_3PBr_2 [12]. Some exceptions are known, for example, R_3PSBr_2 can be isolated when R = Cy (although this compound also undergoes P–S bond cleavage in polar solvents), and the reaction of dibromine with $(Me_2N)_3PS$ results in formation of an S_3 bridged dinuclear ionic species, $[(Me_2N)_3P–S–S–S–P(NMe_2)_3][Br_3]_2$ in moderate yield [12].

The reaction of Et_3PTe with diiodine also yields a T-shaped compound, Et_3PTeI_2 [7], but the reactions of R_3PE (E = S and Se) result in the formation of charge-transfer (CT) spoke adducts of the type shown in Fig. 1b [2,5,11–16]. These adducts consist of a 3c–4e CT system, and display I–I bonds which are lengthened with respect to diiodine in the solid state, 2.715(6) Å [17], as a consequence of donation of electron density from the chalcogen atom to the σ^* antibonding orbital of the diiodine molecule. Tertiary phosphine selenides are better donors towards diiodine than the analogous tertiary phosphine sulfides, as illustrated by a comparison of $(Me_2N)_3PSeI_2$ and $(Me_2N)_3PSI_2$. In the former, the I–I distances are 2.959(2)/2.965(2) Å [13], considerably longer than the I–I bond in the latter, 2.856(1) Å [12], and consistent with the greater donating ability of the phosphine selenide. The geometry at the chalcogen atom is bent in the CT adducts as a result of the presence of the two lone pairs at selenium. The P–E–I (E = S and Se) angles in these molecules are typically 100–108° and thus show distortion from the idealised angle for a pseudo-tetrahedral arrangement due to a combination of repulsion from the lone pairs, and retention of some double bond character in the phosphorus–chalcogen bonds, unlike the situation observed in the T-shaped R_3PSeBr_2 compounds, which feature single P–Se bonds. This phenomenon is illustrated by a comparison of the P–Se bond lengths between $(Me_2N)_3PSeBr_2$, where there is a P–Se single bond of 2.262(2) Å [9], $(Me_2N)_3PSeI_2$, where the P–Se bonds range between 2.185(7) and 2.175(8) Å [13], and $(Me_2N)_3PSe$, which has a P=Se double bond of 2.114(1) Å [18]. These observations agree with spectroscopic data *viz*. (i), a reduction in ^1J(PSe) coupling constants in the $^{31}P\{^1H\}$ NMR spectra, and (ii), a shift to lower frequencies of the ν(P–Se) band in the IR spectra upon adduct formation. Addition of excess iodine to the R_3PSeI_2 systems results in the formation of either $[R_3PSeI]^+$ or $[R_3PSe–I–SePR_3]^+$ cations linked by weak I–I interactions to polyiodide anions [19–21].

The only reported adducts of R_3PE with interhalogens are the IBr and ICl adducts of Ph_3PS, both of which display a CT spoke motif, as observed for the I_2 analogues [22]. In both cases the interhalogen is bound by the heavier iodine atom. In contrast, the Ph_3PS/I_2 system is more complex, and despite the fact that the 1:1 Ph_3PSI_2 adduct was identified in solution, it was initially believed it could not be isolated in the solid-state due to the poor donating capability of Ph_3PS [4]. The 2:3 adduct $Ph_3PSI–I–I_2–I–ISPPh_3$ was instead isolated and crystallographically characterised [23]. Later work by Kaur and Lobana showed that formation of the 1:1 adduct was solvent dependent, and could be synthesised in CH_2Cl_2, whilst the 2:3 adduct was favoured in CCl_4 [24]. The 1:1 adduct, Ph_3PSI_2, was subsequently crystallographically characterised by Bricklebank and coworkers [14], and shown to adopt the same linear E–I–I motif as Ph_3PSeI_2. A 3:1 adduct has also been reported when excess iodine is added to the system, and consists of a 1:1 Ph_3PSI_2 adduct interacting with two further molecules of diiodine in a head-to-tail fashion [25].

We now present the results obtained from the reactions of the related fluoro-substituted phosphine chalcogenides

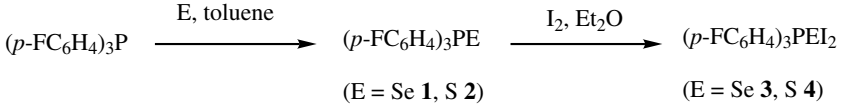
(p-$FC_6H_4)_3PE$ (E = S and Se) with diiodine. This work has been undertaken in order to observe the effect that the presence of the electron-withdrawing fluorine atom has upon the nature of the adducts formed between these donors and diiodine.

2. Results and discussion

2.1. Synthesis and structures of phosphine chalcogenides

The reaction of (p-$FC_6H_4)_3P$ with elemental selenium powder in refluxing toluene yields the phosphine selenide (p-$FC_6H_4)_3PSe$ (**1**) in 86% yield, and the analogous reaction with sulfur yields the corresponding phosphine sulfide (p-$FC_6H_4)_3PS$ (**2**) in 77% yield, according to Scheme 1.

These reactions were followed by $^{31}P\{^1H\}$ NMR spectroscopy with the resonance of the starting phosphine, (p-$FC_6H_4)_3P$ (δ_P:–8.8) [26] being replaced in both cases by resonances at higher frequencies (δ_P: 33.6 for **1** and 42.2 for **2**). These resonances correlate well with previously reported shifts for **1** and **2** [26–28]. Additionally, the resonance for **1** displays satellites as a result of coupling to the spin active ^{77}Se nucleus ($I = 1/2$, 7.6% abundance). The magnitude of the coupling, $^1J(Se–P) = 741$ Hz, is consistent with previously reported data [26–28], and correlates with the coupling observed on the doublet resonance at −246.1 ppm in the $^{77}Se\{^1H\}$ NMR spectrum of **1**. Although compounds **1** and **2** have been previously reported [26–28], only spectroscopic data has appeared, therefore we recrystallised the materials in order to obtain structural information. Crystals of **1** and **2** were grown by slow evaporation of dichloromethane/hexane layered solutions of the compounds. The structures of **1** and **2** are shown in Figs. 2 and 3, respectively, along with selected bond lengths and angles.



(p-$FC_6H_4)_3PSe$ (**1**) (monoclinic, $P2_1/c$), crystallises with two independent molecules in the asymmetric unit, whilst in contrast (p-$FC_6H_4)_3PS$ (**2**) (monoclinic, $P2_1/n$), crystallises with just one molecule present. The P═Se bond lengths in the two molecules of **1** are essentially identical, P(1)–Se(1): 2.1100(13) Å, Se(2)–P(2): 2.1115(12) Å. These values are consistent with other Ar_3PSe systems, for example, the P═Se bond in Ph_3PSe is 2.106(1) Å [29]. The P═Se bond lengths in **1** are also consistent with other reported phosphine selenides containing partially fluorinated aryl groups, for example, (m-$CF_3C_6H_4)_3PSe$, d(P═Se): 2.094(2) Å [30], (p-$CF_3C_6H_4)_3PSe$, d(P═Se): 2.100(1) Å, (3,5-$(CF_3)_2C_6H_3)_3PSe$, d(P═Se): 2.085(1) Å [26]. Malito and Alyea have previously described an inverse correlation whereby the P═Se in Ar_3PSe systems decreases with an increase in the ^1J(PSe) coupling [28]. Compound **1** displays a ^1J(PSe) coupling of 741 Hz (compared with a ^1J(PSe) coupling of 729 Hz for Ph_3PSe [28]), which would suggest that a decrease should be observed in the P═Se bond length for **1** compared with that of Ph_3PSe, although in fact these bond lengths are similar to each other. It should also be noted that the P═Se bond length falls over a fairly small range for all the reported Ar_3PSe structures. The P═S bond in compound **2** [P(1)–S(1): 1.9540(9) Å] is also consistent with other Ar_3PS systems, e.g., Ph_3PS, d(P═S): 1.950(3) Å [31], and (o-$CH_3C_6H_4)_3PS$, d(P═S): 1.947(4) Å [32].

One difference between the two structures is the orientation of the aryl rings. In **2** a near propeller orientation is observed, with S–P–C_i–C_o torsion angles of −49.9(2)°, −47.7(2)° and −39.9(2)°, whilst in **1** both molecules display a conformation where the rings are all twisted in the same direction, although one ring is twisted to a greater degree than the other two. The Se–P–C_i–C_o torsion angles for molecule 1 are 67.4(4)°, 16.3(4)° and 23.7(5)°, whilst for the second molecule they are −71.0(4)°, −24.8(4)° and −21.4(4)°.

2.2. Synthesis and structures of diiodine adducts

Compounds **1** and **2** were reacted in a 1:1 ratio with diiodine to form the adducts (p-$FC_6H_4)_3PSeI_2$ (**3**) and (p-$FC_6H_4)_3PSI_2$ (**4**), respectively, see Scheme 1. In both cases the $^{31}P\{^1H\}$ NMR spectra of these adducts exhibited a resonance shifted slightly to higher frequencies when compared with the starting phosphine chalcogenide, i.e., δ_P changes from 33.6 (**1**) to 44.5 (**3**), and from 42.2 (**2**) to 47.5 (**4**). Due to the poor solubility of these adducts in a variety of deuterated solvents we were unable to resolve any selenium satellites in the $^{31}P\{^1H\}$ NMR spectrum of **3**, and were also unable to obtain a $^{77}Se\{^1H\}$ NMR spectrum of this adduct. Microanalytical results showed that both **3** and **4** analyse to a 1:1 ratio of phosphine chalogenide:iodine. Formation of the 1:1 adduct is particularly surprising in the case of **4**, in view of the weak nature of the 1:1 adduct Ph_3PSI_2 [4,14,23,24]. The 1:1 adduct formed between (p-$FC_6H_4)_3PS$ and diiodine would be expected to be even weaker in view of the less basic character of (p-$FC_6H_4)_3PS$ compared with Ph_3PS. Crystals of **3** and **4** were both grown from dichloromethane:ether solutions of the compounds. The structure of **3** is shown in Fig. 4, along with selected bond lengths and angles.

The structure of (p-$FC_6H_4)_3PSeI_2$ (**3**) (orthorhombic, $Pca2_1$), contains two independent molecules within the unit cell, both of which exhibit a 1:1 CT system, with a linear

Scheme 1. Synthesis of (p-$FC_6H_4)_3PEI_2$ (E = Se and S).

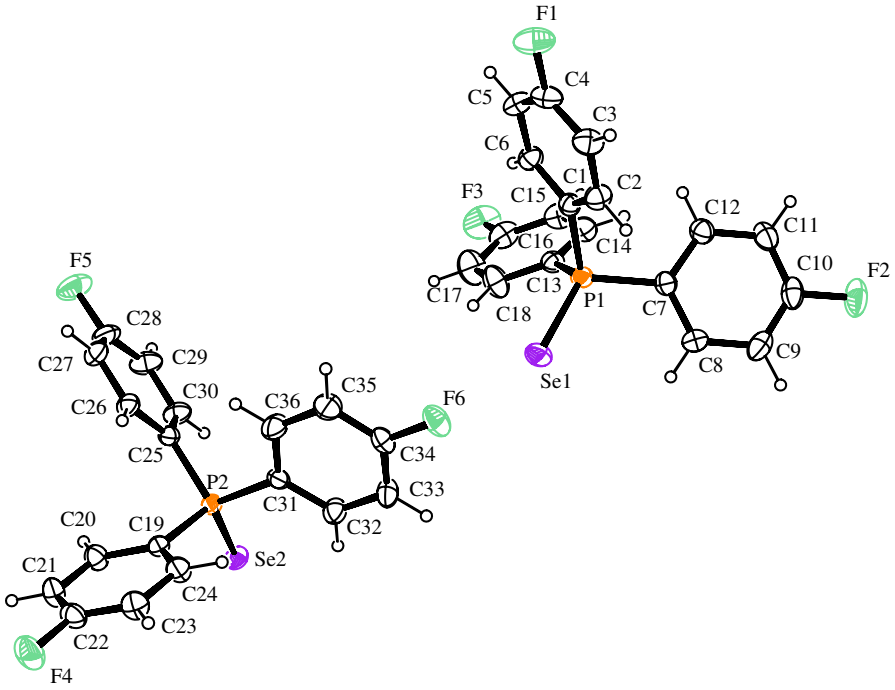


Fig. 2. The molecular structure of $(p\text{-}FC_6H_4)_3PSe$ (**1**). Thermal ellipsoids are shown at the 30% probability level. Fig. 3. The molecular structure of $(p\text{-}FC_6H_4)_3PS$ (**2**). Thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): P(1)–S(1): 1.9540(9), C(4)–F(1): 1.358(3), C(10)–F(2): 1.362(3), C(16)–F(3): 1.362(4); S(1)–P(1)–C(1): 113.29(8), S(1)–P(1)–C(7): 113.27(8), S(1)–P(1)–C(13): 113.59(8).

Se–I–I angle typical of the molecular spoke adducts. The Se–I–I angles in both molecules are close to 180°; Se(1)–I(1)–I(2): 178.17(2)°, Se(2)–I(3)–I(4): 178.02(2)°. The I–I distances display some variation between the two molecules, I(1)–I(2): 2.8888(12), I(3)–I(4): 2.8950(11) Å, as do the Se–I distances, Se(1)–I(1): 2.8153(12), Se(2)–I(3): 2.8198(12) Å, with one of the molecules [that based on Se(1)], showing both shorter I–I and Se–I bonds than the

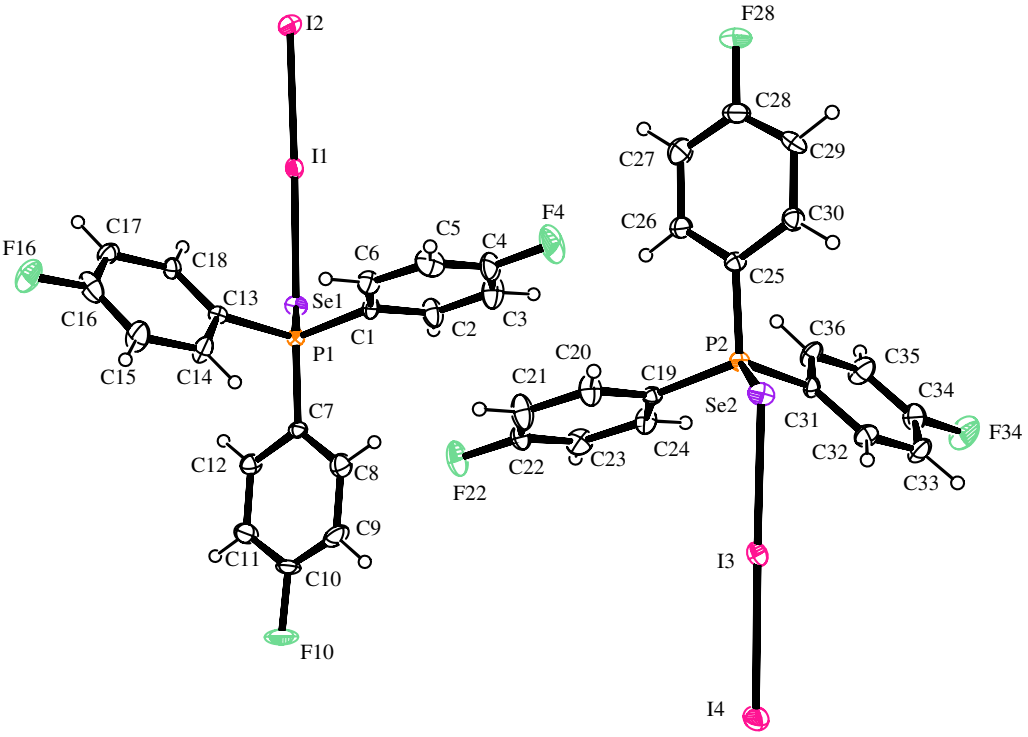

Fig. 4. The molecular structure of $(p\text{-}FC_6H_4)_3PSeI_2$ (**3**). Thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): Se(1)–I(1): 2.8153(12), Se(2)–I(3): 2.8198(12), I(1)–I(2): 2.8888(12), I(3)–I(4): 2.8950(11), P(1)–Se(1): 2.1659(18), P(2)–Se(2), 2.1673(18), C(4)–F(4): 1.374(8), C(10)–F(10): 1.378(9), C(16)–F(16): 1.323(9), C(22)–F(22): 1.361(8), C(28)–F(28): 1.376(9), C(34)–F(34): 1.385(9); Se(1)–I(1)–I(2): 178.17(2), Se(2)–I(3)–I(4): 178.02(2), P(1)–Se(1)–I(1): 100.03(5), P(2)–Se(2)–I(3): 100.66(5), Se(1)–P(1)–C(1): 112.1(2), Se(1)–P(1)–C(7): 108.9(2), Se(1)–P(1)–C(13): 113.57(18), Se(2)–P(2)–C(19): 111.8(2), Se(2)–P(2)–C(25): 107.5(2), Se(2)–P(2)–C(31): 114.23(18).

other. The Se–I and I–I distances have been compared with the small number of previously reported R_3PSeI_2 structures. The I–I distances in **3** are considerably shorter than is observed in trialkyl or tris(alkylamino) substituted R_3PSeI_2 systems, such as $(Et_2N)_3PSeI_2$, where the I–I bond is 2.985(2) Å [13]. This is expected as the weaker donor power of $(p\text{-}FC_6H_4)_3PSe$ compared to those ligands will result in a weaker Se–I bond and a stronger I–I bond. The I–I bonds in **3** would also be expected to be shorter than observed for Ph_3PSeI_2, $d(I–I) = 2.881(2)$ Å [13], as $(p\text{-}FC_6H_4)_3PSe$ is also a weaker donor than Ph_3PSe, however, contrary to expectations the I–I bonds in **3** are slightly longer than in Ph_3PSeI_2. The Se–I bonds in **3** are also slightly longer than the Se–I distance of 2.803(3) Å observed for Ph_3PSeI_2, which is consistent with the weaker donating ability of $(p\text{-}FC_6H_4)_3PSe$. The P–Se–I angles, [P(1)–Se(1)–I(1): 100.03(5)°, P(2)–Se(2)–I(3)°: 100.66(5)°] are lower than the idealised angle of 109.5° expected for a pseudo-tetrahedral arrangement around the selenium atom (taking into account the lone pairs). More significantly, the P–Se–I angles in **3** are more acute than that of 106.0(1)° observed for Ph_3PSeI_2, although P–Se–I angles of 99.6(2)° and 101.2(2)° were observed in $(Me_2N)_3PSeI_2$ [13]. We have reported that this deviation in the P–Se–I angle is probably due to a combination of repulsion from the lone pairs and the retention of partial double bond character in the P–Se bond. A comparison of the P–Se bonds in **3** [P(1)–Se(1): 2.1659(18), P(2)–Se(2), 2.1673(18) Å] with that of 2.1100(13) Å observed for **1** confirms the lengthening of the P–Se bond upon adduct formation. However, the P–Se bonds are intermediate in length between the P=Se bond of **1** and values observed for compounds which contain P–Se single bonds, for example [Cy_3PSePh]Br, where the P–Se bond is 2.2260(16) Å, [33] and P_4Se_3 which has an average P–Se bond length of 2.24(1) Å [34]. The P–Se bonds in **3** are slightly longer than that of 2.156(4) Å observed for Ph_3PSeI_2 [13].

The partial double bond character of the P–Se bonds in **3** is reflected in the shifting of the ν(P–Se) band of the IR spectra of the compound (532 cm^{-1}), compared with the ν(P–Se) band of **1** (552 cm^{-1}). The ν(P–Se) band is shifted to a value intermediate between the P=Se values observed for phosphine selenides and ν(P–Se) bands for P–Se single bond species which are typically found at lower frequencies, such as 517 cm^{-1} for Cy_3PSeBr_2 [9] and 450 cm^{-1} for [Cy_3PSePh]I [35].

Orange crystals of $(p\text{-}FC_6H_4)_3PSI_2$ (**4**) were obtained, (monoclinic, $P2_1/c$); which also feature two independent molecules in the asymmetric unit, as was observed for **3**, although the two structures are not isomorphous. The molecular structure of **4** is shown in Fig. 5, along with selected bond lengths and angles.

The structure of **4** is thus confirmed as the 1:1 diiodine adduct of $(p\text{-}FC_6H_4)_3PS$, with both of the molecules

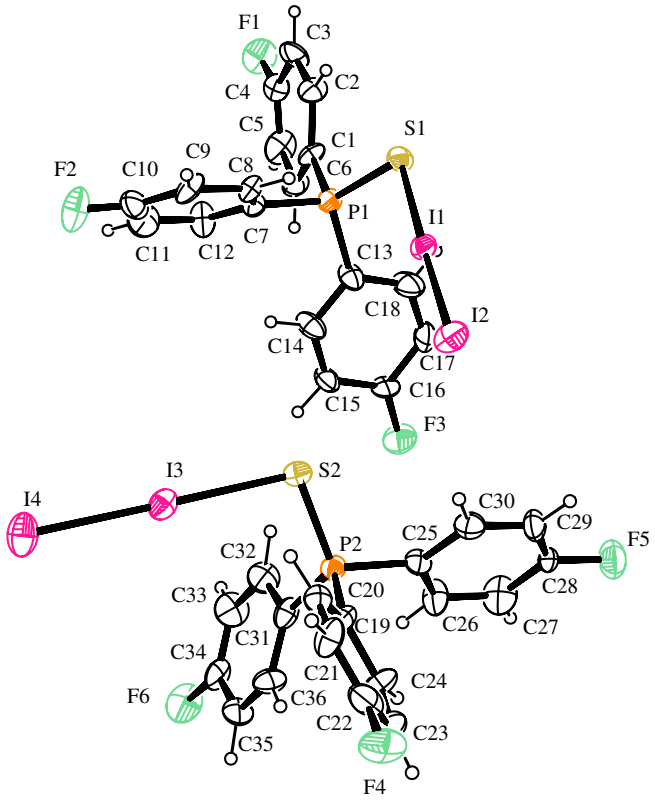

Fig. 5. The molecular structure of $(p\text{-}FC_6H_4)_3PSI_2$ (**4**). Thermal ellipsoids are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): S(1)–I(1): 2.787(5), S(2)–I(3): 2.792(6), I(1)–I(2): 2.8042(17), I(3)–I(4): 2.835(2), P(1)–S(1): 1.997(6), P(2)–S(2): 1.984(5), C(4)–F(1): 1.35(2), C(10)–F(2): 1.29(3), C(16)–F(3): 1.319(19), C(22)–F(4): 1.39(2), C(28)–F(5): 1.37(2), C(34)–F(6): 1.38(2); S(1)–I(1)–I(2): 177.88(10), S(2)–I(3)–I(4): 178.94(9), P(1)–S(1)–I(1): 102.9(2), P(2)–S(2)–I(3): 100.4(3), S(1)–P(1)–C(1): 110.3(6), S(1)–P(1)–C(7): 115.0(5), S(1)–P(1)–C(13): 111.9(7), S(2)–P(2)–C(19): 112.4(5), S(2)–P(2)–C(25): 109.4(6), S(2)–P(2)–C(31): 111.6(8).

showing the expected linear S–I–I motif, S(1)–I(1)–I(2): 177.88(10)°, S(2)–I(3)–I(4): 178.94(9)°. The I–I distances in the two molecules are significantly different, I(1)–I(2): 2.8042(17) Å, I(3)–I(4): 2.835(2) Å. These values are consistent with the range of I–I distances observed for other R_3PSI_2 compounds, although the expected decrease in the I–I distances seen in **4** (compared to Ph_3PSI_2) is not consistently observed, with one of the I–I bonds in **4** being longer, and the other shorter, than was observed for Ph_3PSI_2, *d*(I–I): 2.8230(11) Å [14]. The S–I bond lengths of 2.787(5) and 2.792(6) Å in **4** are longer than that of 2.753(2) Å in Ph_3PSI_2 [14], and therefore do follow the expected trend. The P–S bonds in **4** [P(1)–S(1): 1.997(6), P(2)–S(2): 1.984(5) Å], are lengthened with respect to the free phosphine sulfide **2**, where the P–S bond was 1.9540(9) Å. These findings are consistent with the elongation observed in the analogous phosphine selenide system **3**, and once more partial retention of double bond character is observed, as the P–S bonds are shorter than observed for P–S single bonded species, such as $[Ph_3PSPh][ClO_4]$ and $[Ph_3PSCH_2C_6H_5][ClO_4]$, which have P–S bond lengths of 2.074(2) and 2.050(1) Å, respectively [36]. The reduction in the magnitude of the P–S bond is again reflected in the IR spectrum where the ν(P–S) band of **4** (571 cm^{-1}) is again shifted to lower frequency compared with the phosphine sulfide **2** (632 cm^{-1}). The P–S–I angles in the two molecules are 102.9(2)° and 100.4(3)° and are smaller than the P–S–I angle of 108.78(7)° in Ph_3PSI_2. This variation in the P–S–I angles result in the iodine atoms of one of the molecules in the asymmetric unit being held closer to the aryl ring than is the case in the other molecule. This may explain the difference in the I–I distances between the two molecules. However, the differences between the two are relatively small, and therefore lie within a range where packing effects may also be significant.

The conformation of the aryl rings are similar in both **3** and **4**, but differ slightly to that seen for **1** and **2**. The rings are in all cases twisted in the same direction, but with one of the rings twisted much less than the other two. The Se–P–C_i–C_o torsion angles for **3** are −44.0(6)°, −51.7(5)° and −13.4(6)° for molecule 1, and 51.4(6)°, 43.4(6)° and 14.1(7)° for molecule 2. The S–P–C_i–C_o torsion angles for **4** are −38.7(16)°, −9.5(13)° and −45.7(17)° for molecule 1, and 10.3(18)°, 53.4(15)° and 38.0(18)° for molecule 2. The different conformations observed for the aryl rings for compounds **1**, **2**, **3** and **4** suggest that no particular conformation is energetically preferred for the $p\text{-}FC_6H_4$ rings in these systems.

2.3. Conclusion

The introduction of fluorine in the *para*-positions in Ar_3PEI_2 (E = S and Se) systems appears to have only a minor effect on the I–I bonds in these charge-transfer adducts. Both $(p\text{-}FC_6H_4)_3PSe$ and $(p\text{-}FC_6H_4)_3PS$ react with diiodine to form 1:1 adducts, but the magnitude of the I–I bonds in these compounds are not consistently shorter than their non-fluorinated counterparts, which would be expected on the basis of the weakly basic nature of the $(p\text{-}FC_6H_4)_3PE$ donors. It is not easy to rationalise these observations on the basis of electronic arguments, but both $(p\text{-}FC_6H_4)_3PSeI_2$ and $(p\text{-}FC_6H_4)_3PSI_2$ display more acute P–E–I angles than the non-fluorinated Ph_3PEI_2 (E = S and Se) adducts. The narrowing of this angle holds the dihalogen part of the molecule closer to the aryl rings than in Ph_3PEI_2, and this may be responsible for the variation of the I–I bond lengths in the compounds reported herein. However, it should be noted that the differences in the I–I bonds are relatively small, and thus packing effects may also be responsible for these variations.

3. Experimental

3.1. Reagents and physical measurements

$(p\text{-}FC_6H_4)_3PSI_2$, and $(p\text{-}FC_6H_4)_3PSeI_2$ are moisture sensitive, therefore their synthesis was performed under anhydrous conditions. Diethyl ether and toluene (BDH) were

distilled over sodium/benzophenone ketyl before use. Tris-(*para*-fluorophenyl)phosphine, iodine, sulfur, and selenium powder were all purchased commercially (Aldrich) and used as received. ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra were recorded on a Bruker DPX400 machine operating at 399.9 and 100.6 MHz, respectively. ^{19}F, $^{31}P\{^{1}H\}$ and $^{77}Se\{^{1}H\}$ NMR spectra were recorded on a Bruker DPX200 machine operating at 188.3, 81.8 and 38.2 MHz, respectively. Peak positions are quoted relative to external TMS [$^{1}H/^{13}C$], $CFCl_3$ [^{19}F], 85% H_3PO_4 [^{31}P] and Me_2Se [^{77}Se], using the high frequency positive convention throughout. All spectra were recorded at 300 K. All chemical shifts are given in ppm, and coupling constants in Hz. Infra-red spectra were recorded on a Nicolet-Nexus combined FT-IR/FT-Raman spectrometer, with samples prepared as nujol mulls held between KBr plates. Melting points were recorded on a Bibby SMP10 melting point apparatus and elemental analyses were performed by the University of Manchester School of Chemistry Microanalytical Service.

3.2. Crystallographic details

Details of the structural analyses for $(p\text{-}FC_6H_4)_3PSe$ (**1**), $(p\text{-}FC_6H_4)_3PS$ (**2**), $(p\text{-}FC_6H_4)_3PSeI_2$ (**3**) and $(p\text{-}FC_6H_4)_3PSI_2$ (**4**) are all summarised in Table 1. Diffraction data for **1**, **2** and **4** were recorded on a Nonius κ-CCD four circle diffractometer at 150(2) K. Graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) was used for all three compounds. Data for compound **3** was recorded on a Bruker SMART 1K CCD diffractometer (synchrotron $\lambda = 0.69280$ Å) at 150(2) K at station 9.8 at the Daresbury SRS laboratories. The structural data for all the compounds was solved by direct methods (SHELXS97) and refined by full-matrix least squares against F^2 using all data (SHELXL97) [37], with the hydrogen atoms located in ideal positions. Absorption corrections were carried out via the multiscan method, and were applied with the SORTAV program [38]. Non-hydrogen atoms were refined with anisotropic thermal parameters. Figures were generated using ORTEP-3 for Windows [39].

3.3. Synthetic details

3.3.1. Synthesis of $(p\text{-}FC_6H_4)_3PSe$ (1)

Five grams (1.58×10^{-2} mol) of $(p\text{-}FC_6H_4)_3P$ was dissolved in 100 cm^3 of dry toluene in a 500 cm^3 flask fitted with a reflux condenser. To this flask was added 1.250 g (1.58×10^{-2} mol) of selenium powder with vigorous stirring. The solution was then refluxed under nitrogen for 3 h, after which time all the selenium powder had been consumed. The solution was allowed to cool and concentrated to half its volume. 20 cm^3 of 40:60 petroleum ether was added and the solution refrigerated overnight. The white precipitate formed was then filtered off and dried *in vacuo* for 2 h to yield **1** as a white powder, (m.p. 174–75 °C, 86.2% yield). *Anal.* Calc. for $C_{18}H_{12}F_3PSe$: C, 54.7; H, 3.0; Se, 20.0. Found: C, 54.5; H, 2.9; Se, 19.9%. ^{1}H

NMR ($CDCl_3$): δ 7.18 [m, 6H, H_m], 7.73 [m, 6H, H_o]. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 115.0 [dd, C_m, $J = 13.6$, 21.3], 126.3 [d, C_i, $^1J(PC) = 78.2$], 133.9 [dd, C_o, $J = 8.7$, 12.6], 163.9 [d, C_p, $^1J(CF) = 255.0$]. ^{19}F NMR ($CDCl_3$): $\delta -107.1$ [s]. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 33.6 [s + satellites, $^1J(PSe) = 741$]. $^{77}Se\{^1H\}$ NMR ($CDCl_3$): $\delta -246.1$ [d, $^1J(PSe) = 741$]. IR (cm^{-1}): 552 (P–Se).

3.3.2. Synthesis of (p-FC_6H_4)$_3$PS (2)

(p-FC_6H_4)$_3$PS was synthesised by the method used for compound **1** above, using 5.00 g (1.58×10^{-2} mol) of (p-FC_6H_4)$_3$P and 0.506 g (1.58×10^{-2} mol) of sulfur. The product was isolated as above to yield **2** as a white powder, (m.p. 171–73 °C, 77.3% yield). *Anal.* Calc. for $C_{18}H_{12}F_3PS$: C, 62.1; H, 3.4; S, 9.2. Found: C, 62.0; H, 3.2; S, 9.4%. ^1H NMR ($CDCl_3$): δ 7.18 [m, 6H, H_m], 7.74 [m, 6H, H_o]. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 115.0 [dd, C_m, $J = 13.6$, 21.3], 127.5 [dd, C_i, $^1J(PC) = 88.9$, $^4J(PF) = 2.9$], 133.6 [dd, C_o, $J = 9.7$, 12.6], 163.9 [dd, C_p, $^1J(CF) = 251.1$, $^4J(PC) = 2.9$]. ^{19}F NMR ($CDCl_3$): −107.2 [s]. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 42.2 [s]. IR (cm^{-1}): 632 (P–S).

3.3.3. Synthesis of (p-FC_6H_4)$_3$PSeI$_2$ (3)

0.655 g (1.66×10^{-3} mol) of (p-FC_6H_4)$_3$PSe was dissolved in 50 cm^3 of anhydrous diethyl ether in a rotaflo tube against a stream of dry nitrogen. To this solution was added 0.421 g (1.66×10^{-3} mol) of diiodine. An orange solid precipitated from solution and was left to stir for 3 days. The solid was isolated using standard Schlenk techniques to yield **3** as an orange powder, (m.p. 135 °C, 74.3% yield). *Anal.* Calc. for $C_{18}H_{12}F_3I_2PSe$: C, 33.3; H, 1.8; Se, 12.2; I, 39.1. Found: C, 33.1; H, 1.8; Se, 12.0; I, 39.0%. ^1H NMR ($CDCl_3$): δ 7.20 [m, 6H, H_m], 7.67 [m, 6H, H_o]. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 116.5 [dd, C_m, $J = 14.5$, 21.3], 125.8 [d, C_i, $^1J(PC) = 91.6$], 134.9 [dd, C_o, $J = 9.7$, 13.6], 163.6 [d, C_p, $^1J(CF) = 255.6$]. ^{19}F NMR ($CDCl_3$): $\delta -101.7$ [s, br]. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 44.5 [s]. IR (cm^{-1}): 532 (P–Se).

3.3.4. Synthesis of (p-FC_6H_4)$_3$PSI$_2$ (4)

(p-FC_6H_4)$_3$PSI$_2$ was synthesised by the method used for compound **3** above, using 0.741 g (2.13×10^{-3} mol) of (p-FC_6H_4)$_3$PS and 0.541 g (2.13×10^{-3} mol) of diiodine. The solid was isolated using standard Schlenk techniques to yield **4** as an orange powder, (m.p. 165 °C, 61.5% yield). *Anal.* Calc. for $C_{18}H_{12}F_3I_2PS$: C, 35.9; H, 2.0; S, 5.3; I, 42.2. Found: C, 35.9; H, 2.1; S, 5.2; I, 41.9%. ^1H NMR ($CDCl_3$): δ 7.21 [m, 6H, H_m], 7.72 [m, 6H, H_o]. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 117.0 [dd, C_m, $J = 15.5$, 20.3], 126.2 [d, C_i, $^1J(PC) = 90.8$], 135.4 [s, br, C_o], 165.7 [d, C_p, $^1J(CF) = 256.0$]. ^{19}F NMR ($CDCl_3$): $\delta -105.4$ [s, br] $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 47.5 [s]. IR (cm^{-1}): 571 (P–S).

rings were situated in almost ideal axial positions, hence the coordination sphere of this complex should be described as a (4+2)-geometry. However, the position of the sixth coordination site was slightly ambiguous, therefore, we have decided to reexamine the structure of this complex by single crystal X-ray diffraction and vibrational spectroscopic methods.

Ha et al. [13] determined the crystal and molecular structure of the polymeric $[(orotato)Cu(H_2O)_2]_n$ complex. These authors have shown that Cu is also chelated by one carboxylate O atom and the deprotonated N_1 atom, while the remaining two sites of the basal plane are occupied by two water molecules. The coordination sphere at copper is extended to five by the second carboxylic oxygen atom of another complex molecule, which acts as a bridge between the copper(II) ions, forming one-dimensional polymeric chains. Icbudak et al. [15] studied the crystal and molecular structure of $[Cu(orotato)(en)(H_2O)] \cdot H_2O$, where the basal plane was formed by the O(carboxylate) and N_1 (deprotonated nitrogen) atoms, and by the two N atoms from the ethylenediamine ligand. One water molecule completed the square-pyramidal coordination around copper(II) in this complex. Wu et al. reported the crystal structure of $[Cu(orotato)(H_2O)_3] \cdot 2H_2O$, in which "the Cu(II) atom had a slightly distorted square pyramid coordination with additional three water molecules" [14], but these authors did not show the position of the lattice water molecules.

Therefore, in this study we have reinvestigated the crystal structure of *cis*-$[Cu(orotato)(NH_3)_2]$ (**1**) and can reveal some new, very important, structural features of this complex. The novel copper complex, $[Cu(orotato)(H_2O)_4] \cdot H_2O$ (**2**) has been synthesized and its structure has been determined by single crystal X-ray diffraction and vibrational spectroscopic methods.

2. Experimental

2.1. Preparation

Complex **1** was obtained similarly to the procedure used in Ref. [12]. Orotic acid (1 mmol) and $CuCl_2 \cdot 2H_2O$ (1 mmol) in a solution of concentrated ammonia (90 cm^3) and ethanol (90 cm^3) were heated at 313 K under reflux for an hour. Upon cooling, complex **1**, *cis*-$[Cu(orotato)(NH_3)_2]$, precipitated in the form of dark-purple plates. When the resulting blue solution was evaporated for several hours and then cooled, complex **2**, $[Cu(orotato)(H_2O)_4] \cdot H_2O$, precipitated in the form of blue-needles. Frequently, the two complexes co-crystallize. Suitable crystals of the two complexes were selected for single crystal X-ray analyses.

2.2. X-ray analysis

The X-ray diffraction data were collected using an automatic X-ray four-circle EXCALIBUR single crystal diffractometer with CCD area detectors (graphite monochromator, Mo Kα radiation, $\lambda = 0.071073$ nm). The intensity data were corrected for Lorentz, absorption and polarization effects. The structures were solved by direct methods using the program SHELXS-97 [17] and refined by the full-matrix least-squares method based on F^2 using SHELXL-97 [18]. All non-hydrogen atoms were refined anisotropically by unit-weighted full-matrix least square methods. Hydrogen atoms were included from the difference Fourier $\Delta\rho$ maps and refined with isotropic thermal parameters. Molecular drawings were obtained using DIAMOND [19]. The crystal data and the refinement details of **1** and **2** are given in Table 1.

2.3. Raman and infrared spectra measurements

The FT-Raman spectra of orotic acid were recorded on a Nicolet 2000 spectrometer equipped with a Nd:YAG laser operating at 1064 nm. The spectra were measured at a resolution of 2 cm^{-1}. The FT-Raman spectra of the copper(II) complexes were recorded on a Jobin Yvon spectrometer model T6400 using a CCD camera as a detector (Princeton Instruments). Excitation was provided by an argon laser (514.5 nm line). For the FT-Raman spectral measurements, a few milligrams of each compound were placed in a capillary tube and measured directly (3000 scans were collected with a resolution of 4 cm^{-1}).

The FT-IR spectra of the compounds in KBr pellets were collected on a Bruker IFS 113 V spectrometer in the

region of 4000–400 cm^{-1} (with a resolution of 2 cm^{-1}). The far-infrared spectra (600–50 cm^{-1}) were recorded on an IFS 66/S Bruker spectrometer using the Nujoll mull technique. The accuracy of the readings was ±1 cm^{-1}.

3. Theoretical

The structures of *cis*-[Cu(orotato)$(NH_3)_2$] and [Cu(orotato)$(H_2O)_2$] were fully optimized by the density functional theory DFT(UB3LYP) [20,21]. In both complexes the copper(II) ion has one unpaired electron (d^9 electron configuration and doublet ground-state). Thus, the unrestricted UB3LYP method has been used for an open-shell electronic structure. In unrestricted methods a spin contamination of the UHF wave-function may occur, therefore the expectation value of the total spin, $\hat{S}^2$, should be examined. The final $\hat{S}^2$ value was equal to 0.7503 for **1**, and 0.7504 for **2**. Both these values are very close to 0.7500, which corresponds to the doublet ground state wave-function with no spin contamination, and confirm validity of the UB3LYP results [22]. The effective core potential (ECP) of Hay and Wadt and the concomitant LanL2DZ basis set [23] were used for the copper atom. For all the other atoms the D95V(d,p) basis set [24] was employed. The latter basis set includes d polarization functions on C, N and O atoms, and p polarization functions on hydrogen atoms. Natural bond orbital (NBO) analysis [25] has been performed to obtain the natural charges on the atoms. All computations were carried out with the GAUSSIAN 03 package [26].

4. Results and discussion

4.1. Copper(II)–π interaction in cis-[Cu(orotato)$(NH_3)_2$] (1)

The structure of the complex is shown in Fig. 1. The numbering of the atoms refers to that used for uracil and other pyrimidine bases in the literature. The primary coordination sphere around the Cu atom is square-planar with the orotate ligand chelating through the carboxylate oxygen atom O1 and the deprotonated N1 atom. Two ammonia nitrogen atoms, N4 and N5, complete the basal plane. One of the coordinated ammonia molecules is involved in an interligand hydrogen bond to the exocyclic O2 carbonyl oxygen atom of the uracil ring, with a N5···O2 distance of 2.782(2) Å and N5–H53···O2 angle of 153(2)°. The bond lengths and bond angles of **1** are listed in Table 2, together with the corresponding structural parameters reported earlier [12]. It is evident from this comparison that the structure of these complexes should be the same. However, Mutikainen and Lumme concluded that in this complex the coordination sphere is extended to the (4+2) geometry by two exocyclic carbonyl oxygen atoms, $O4^i$ and $O4^{ii}$, from neighboring uracilate rings (it should be noted that a different numbering of the oxygen atoms was used in Ref. [12]).

The stereoview of the coordination sphere of this complex is illustrated in Fig. 2. As follows from our study, the structure of **1** consists of centrosymmetric dimers, in which each copper atom is coordinated to one exocyclic carbonyl oxygen atom $O4^i$ from the neighboring molecule. The Cu–$O4^i$ distance of 2.927(3) Å is close to that reported by Mutikainen and Lumme, 2.930(4) Å [12]. However, it should be emphasized that the oxygen atom, $O4^{ii}$, from the other complex molecule is not situated at the axial position to copper. The $O4^i$–Cu–$O4^{ii}$ angle of 133.5(2)° shows significant deviation from linearity. Furthermore, the Cu–$O4^{ii}$ distance of 4.845(4) Å (Fig. 2) is too long to allow for any effective interaction between these atoms. The displacement of the Cu atom from the least-squares plane (formed by the chelating N1, O1, N4 and N5 atoms) amounts to only 0.021(1) Å. If only one axial Cu–O bond were present in the complex, the copper atom should reveal a bigger deviation from the equatorial plane. For example, in square-pyramidal *cis*-[Cu(5-nitroorotato)$(NH_3)_2$] complex, the Cu atom lies 0.120(1) Å out of the equatorial plane [27].

The coplanar location of the copper atom in **1** implies that there is another axial interaction on the other side of the basal plane, which may counteract the Cu–$O4^i$ binding

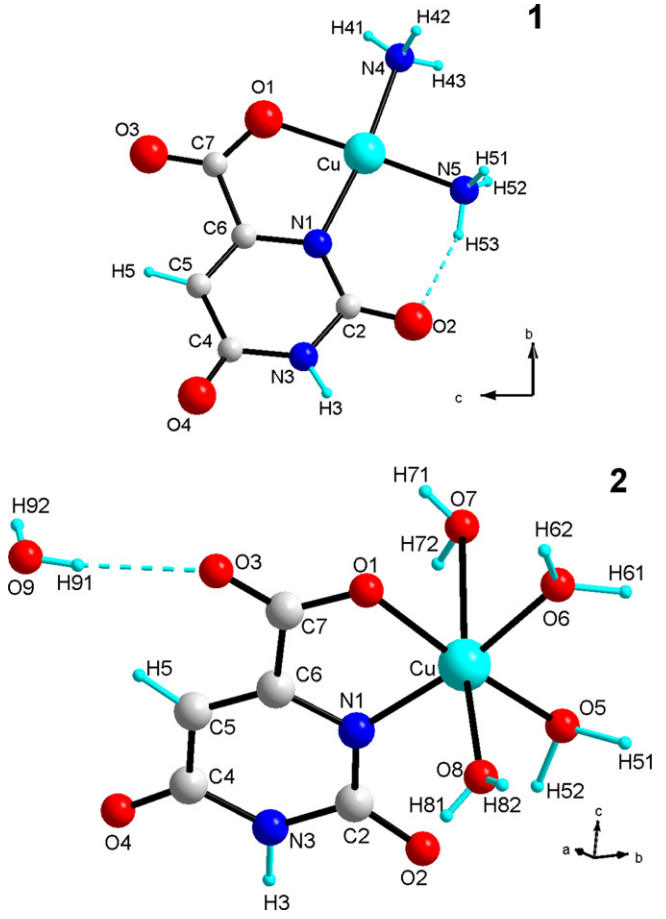

Fig. 1. The molecular structures of Cu(orotato)$(NH_3)_2$ (**1**) and [Cu(orotato)$(H_2O)_4]\cdot H_2O$ (**2**) with the labelling of the atoms. Important hydrogen bonds are indicated by dashed lines.

Table 2
Comparison of the experimental and theoretical interatomic distances (Å) and bond angles (°) of Cu[(orotato)$(NH_3)_2$] (**1**) and [Cu(orotato)$(H_2O)_4$] · H_2O (**2**)

The numbering of the atoms is shown in Figs. 1a and b.

force. A close inspection of the structure has revealed that the sixth coordination site is positioned at the π bond of the neighboring uracil ring (X denotes the middle of the C5═C6 bond), as illustrated in Fig. 2. The Cu–X^{ii} distance of 3.293(9) Å is close to the van der Waals contacts between the stacking bases in DNA. It should be emphasized that the $O4^{i}$–Cu–X^{ii} angle is approximately linear (169.6(1)°).

Fig. 3 shows the packing in the crystal of Cu(orotato)$(NH_3)_2$ (**1**) and displays the pseudooctahedral environment around the copper(II) ions (in each complex, the O4 atom and the middle of the π bond form the apexes on the elongated octahedron). The most important structural feature is the Cu–π axial interaction which connects the dimers into a columnar polymer along the *a*-axis (the view is down the *b*-axis). The non-covalent binding forces between the chelated copper(II) ion and the π-electron system are probably weak, nevertheless, they are very important in stabilizing the polymeric structure of complex **1**.

The stability of the columns is further enhanced by the formation of extensive intermolecular hydrogen bonds (indicated by dashed lines). Each two complex molecules are linked by a pair of Watson–Crick type hydrogen bonds, involving the O4═C4 and N3–H3 groups of each uracil ring, with a N3···$O4^{a}$ distance of 2.860(2) Å and N3–H3···$O4^{a}$ angle of 171(2)° (the symmetry codes are listed under Table 3). It is worth noting that a very similar type of intermolecular hydrogen bonding was reported for crystals of 1-methylthymine with corresponding N···O distances of 2.83 Å [28]. The remaining intermolecular hydrogen bonds in **1** involve two ammonia groups and all the oxygen atoms, as shown in Table 3.

Reedijk and coworkers [29], in their studies on copper(II) complexes with some pyrimidin-2-yl ligands, have concluded that crystal growth is driven by several synergistic intermolecular interactions: metal–ligand bonds and hydrogen bonding, as well as π–π stacking and anion–π stacking interactions. Our study of the crystal structure

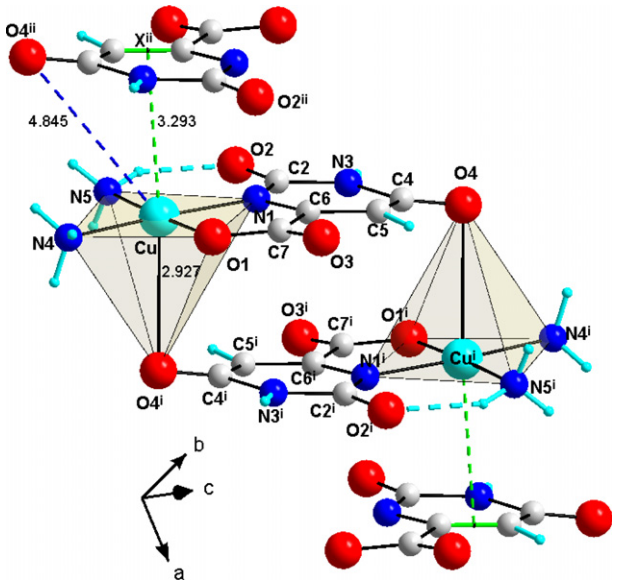

Fig. 2. The view of the dimer unit of Cu(orotato)$(NH_3)_2$ showing the axial Cu–$O4^{i}$ bonds and Cu–X^{ii} interactions (dashed lines). X^{ii} denotes the middle of the $C5^{ii}$═$C6^{ii}$ double bond of the uracilate ring. In contrast to an earlier suggestion [12], the Cu–$O4^{ii}$ distance of 4.845(3) Å is too long to allow for any effective interaction between these atoms. Symmetry codes are as follows: (i) $1.5 - x$, $-0.5 + y$, $1.5 - z$; (ii) $0.5 - x$, $-0.5 + y$, $1.5 - z$.

of **1** have revealed another type of synergistic interaction, the non-covalent binding force between the chelated copper(II) cation and the π-electrons of the uracil ring.

In the literature, there are only a few reports on a possible direct interaction between chelated copper(II) ions and an aromatic π system. The X-ray diffraction studies of Cu(II) complexes with L-tyrosine [30], glycyl-L-leucyl-L-tyrosine [31] and glycyl-L-tryptophane [32] have shown that the aromatic rings of the tyrosine or tryptophane groups are located beneath the basal plane of the copper coordination pyramid at a distances of about 3.2–3.3 Å. Thus, the Cu–π distances in all these complexes are close to the van der Waals contacts between the stacking bases in DNA.

π–π stacking interactions between uracilate rings have been observed in other Cu(II) complexes with orotic acid derivatives, the distance between partially overlapping uracilate rings varies from 3.250(3) Å in the mononuclear [Cu(5-fluoroorotato)$(NH_3)(H_2O)$] complex [16] to 3.40 Å in diammine(5-nitroorotato)copper(II) hydrate [27]. On the other hand, in the structure of the polymeric $[(orotato)Cu(H_2O)_2]_n$ complex (obtained from orotic acid methyl ester), the π–π base stacking is not retained due to some steric effects [13]. It is interesting to note that in the crystal structure of [Cu(orotato)(en)$(H_2O)] \cdot H_2O$, reported by Icbudak et al. [15], the vertical distances between the copper atom and the uracilate ring are between 3.156 and 3.274 Å (private communication).

Thus, it seems that the Cu(II)–π direct interaction can occur in copper(II) complexes containing aromatic rings, provided that some steric effects do not prevent it.

4.2. Description of the structure of $[Cu(orotato)(H_2O)_4]\cdot H_2O$ (2)

Complex **2** crystallizes in the monoclinic system (crystal data are given in Table 1). Our results (unit cell constants) are consistent with those reported by Wu et al. (refined to $wR = 0.1015$) [14], however the bond lengths and bond angles determined in this work are more accurate and the interpretation of the coordination sphere around Cu is different. The molecular structure of **2** and the numbering of atoms are shown in Fig. 1. It should be emphasized that, in contrast to the polymeric complex $[(orotato)Cu(H_2O)_2]_n$ [13], complex **2** is a mononuclear species. The copper(II) ion is chelated by the deprotonated N1 nitrogen atom and by the carboxylate O1 oxygen atom of the bidentate orotate ligand. Two water oxygen atoms (O5 and O6) complete a slightly distorted square-planar environment around Cu. The coordination sphere in **2** can be described as (4+2) geometry, where the O7 and O8 aqua ligands occupy axial coordination sites. It is worth noting that the water of crystallization (O9) acts as a proton-donor in an intermolecular hydrogen bond with the non-chelating carboxylic oxygen atom at an O9···O3 distance of 2.835(2) Å and O9–H91···O3 angle of 174(2)°.

The bond lengths and bond angles of two complexes are compared in Table 2. As follows from this comparison, the Cu–N1 atom distance in **2** is very similar to that in **1**, but the Cu–O1(carboxylate) bond length in **2** (1.984(1) Å) is slightly longer than that in **1** (1.959(1) Å). Furthermore, in the equatorial plane of **2**, the Cu–OH_2 atom distances, Cu–O5 (1.992(1) Å) and Cu–O6 (2.005(1) Å), are also slightly longer than the corresponding Cu–NH_3 distances, (1.955(1) and 1.996(1) Å), in **1**.

In complex **2**, the axial Cu–O7 bond length is equal to 2.400(1) Å. A similar Cu–O(water) atom distance of 2.480(1) Å has been found in the octahedral *trans*-$[Cu(malonamato)_2(H_2O)_2]$ complex [33]. The Cu–O8 axial bond in **2** is rather long, 2.873(2) Å, but is similar to that between the Cu and $O4^{i}$ oxygen atom found in **1** (2.927(3) Å). It should be emphasized that the O7 and O8

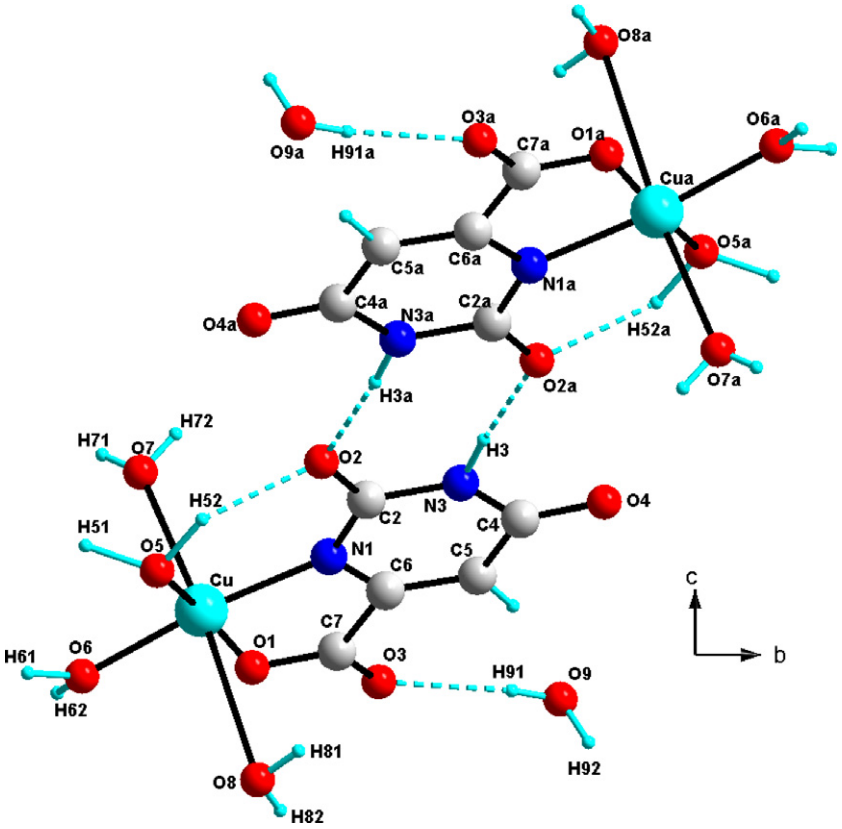

Fig. 4. The centrosymmetric dimer of $[Cu(orotato)(H_2O)_4]\cdot H_2O$ (**2**). Hydrogen bonds are indicated by dashed lines. The symmetry codes are given in Table 4.

axial ligands make an almost linear arrangement, the O7–Cu–O8 bond angle is equal to 174.7(1)°. This indicates that the O8 water molecule is weakly coordinated to the copper (II) ion, and the molecular structure of **2** can be described as an asymmetric elongated octahedron. It is worth noting that the long Cu–O distance of 2.873(2) Å in this complex can be compared with those encountered in the literature on Cu(II) complexes. Keene et al. [34] reported a Cu–O bond of 2.906(10) Å for an octahedral CuO_6 coordination sphere in the $[Cu(oxalato)_2(H_2O)]^{2-}$ dimer units. Warda [35] showed that in the Cu(II) complex with mixed ligands (*N*-ethylurea and *N*-pyruvidene-β-alanine dianion) the oxygen atom of *N*-ethylurea is weakly coordinated to the Cu(II) atom at a distance of 3.062(2) Å. He concluded on the basis of structural and spectroscopic results, that Cu(II) is near the critical point of square-pyramidal/octahedral geometry, but is still in the octahedral region, and he described the structure of this complex as an asymmetric elongated octahedron [35].

The least-squares plane through the six non-hydrogen atoms of the uracil ring in **2** reveals that the ring is approximately planar, the largest deviation being 0.021(1) Å for N1. The carboxylate group is slightly twisted, the angle between the uracil ring and the plane of the carboxylate group is 6.4(1)°. The displacement of the Cu atom from the equatorial least-squares plane (formed by the N1, O1, O5 and O6 atoms) is 0.058(1) Å.

The corresponding bond angles of the uracilate ring are similar in **1** and **2** (Table 2). Some differences are noted for the corresponding bond lengths, in particular for the exocyclic carbonyl and carboxylic C=O bonds. This effect is caused by a different pattern of intermolecular hydrogen bonding in the two title complexes.

As illustrated in Fig. 4, two molecules of complex **2** are arranged in a centrosymmetric dimer linked by two nearly linear N3–H3···O2^a hydrogen bonds between the uracil rings (the symmetry code for a is: $-x, -y, -z+1$). The intermolecular N3···O2^a distance of 2.835(2) Å is slightly shorter than the intermolecular N3···O4^a distance (2.860(2) Å) (a: $-x+1, -y, -z+1$) in the crystal of **1**. The exocyclic carbonyl O2 atom in **2** is involved in a weak H-bond contact with the water molecule (O5) coordinated to the copper(II) ion (the O5···O2 distance is 2.862(2) Å and the O5–H52···O2 angle is 140(2)°). The coordinated water molecules take part in an extensive net of intermolec-

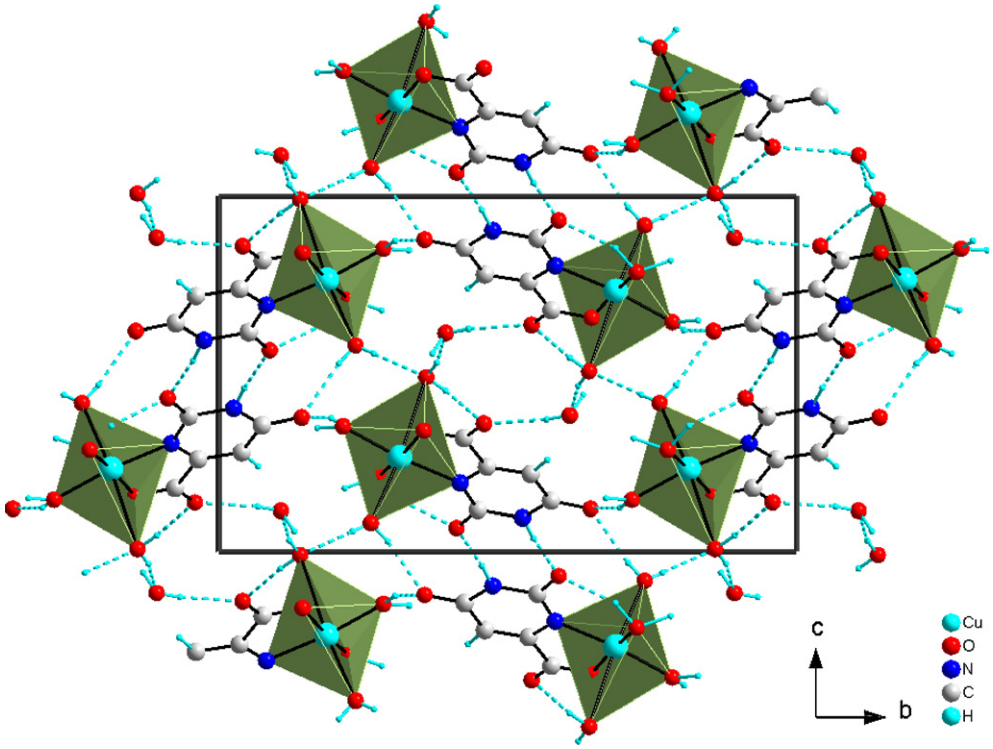

Fig. 5. The arrangement of (**2**) in the unit cell, projected down the *a*-axis hydrogen bonds are indicated by dashed lines.

ular hydrogen bonds. For example, the axial O8 atom (on a long axis), acts as the proton-donor to the O3[d] and O9[e] atoms, and simultaneously acts as a proton acceptor from the O7[b] atom of the neighboring complex molecules (Table 4). These chains of hydrogen bonds lead to an extensive three-dimensional network (Fig. 5).

5. Theoretical results

The molecular parameters predicted for Cu(orotato)$(NH_3)_2$ and Cu(orotato)$(H_2O)_2$ are in good agreement with the X-ray data. In particular, the bond lengths and angles in the uracil ring are very well predicted at this level of theory. Some discrepancies between the theoretical and experimental C=O bond lengths are attributed to intermolecular hydrogen bonding in the crystal (the calculations have been performed for an isolated molecule). It should be noted that an attempt to optimize the molecular structure of **2**, under the assumption that the (N,O)-chelated copper(II) ion is coordinated to four water molecules, has lead to dissociation of the two axial H_2O molecules. In the successive steps of the optimization process, the two axial water molecules are transferred to the basal plane and they form intermolecular hydrogen bonds with the equatorial water molecules. This result indicates that in the crystal of **2** the extensive intermolecular hydrogen bonds are very important in stabilizing the axial positions of the water molecules and the pseudooctahedral environment around the copper atom.

The calculated natural atomic charges are compared in Table 5. We have shown earlier [22] that atomic charges obtained from NBO analysis are more reliable than Mulliken charges. As shown in Table 5, the natural charges on the coordinated O1 and N1 atoms in **1** are very similar to those in **2**. The charge on the copper atom is equal to +1.237e for **1** and +1.287e for **2**. A lower positive charge on the Cu atom in **1** is due to stronger electron donation from the coordinated ammonia nitrogen atoms to Cu in **1**, as compared to the electron donation from the coordinated water oxygen atoms in **2**.

It should be emphasized that the natural charge on the copper atom in **1** is quite close to (+1e). Numerous experimental and theoretical studies [36,37] have revealed that a bare Cu^+ cation forms a stable cation–π complex with benzene. Thus, it is possible that in **1** the non-covalent Cu(II)–π binding force resembles that between the Cu^+ ion and aromatic compounds. However, the theoretical prediction of a Cu(II)–π interaction between the chelated Cu^{2+} ion and the C=C double bond in the investigated complex **1** is not an easy task. Such calculations should be performed for a large molecular model consisting of three layers of molecules: the planar *cis*-[Cu(orotato)$(NH_3)_2$] complex; the uracilate ring above the equatorial coordination plane, and some amide with the carbonyl oxygen atom coordinated to copper(II) in an axial position. Moreover, to account for the dispersion energy, which is very important in cation–π interactions, it is necessary to use the post-Hartree-Fock methods, for example, the second-order

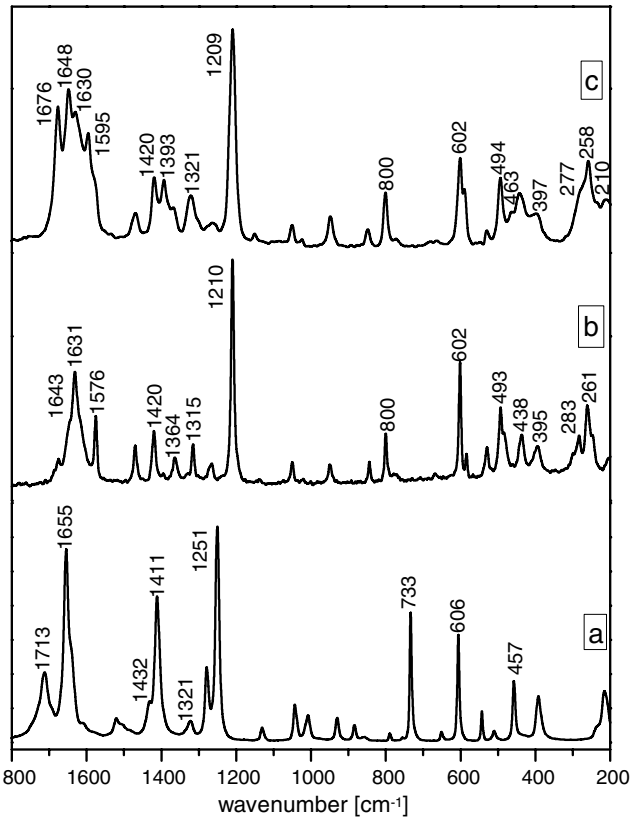

Fig. 6. The FT-Raman spectra of anhydrous orotic acid (**a**), Cu(orotato)$(NH_3)_2$ (**b**) and [Cu(orotato)$(H_2O)_4]\cdot H_2O$ (**c**), in the region 1800–200 cm^{-1}.

Möller-Plesset perturbation theory (MP2), as demonstrated in our earlier studies [38]. We hope to be able to perform such calculations, in the near future.

5.1. FT-Raman and FT-infrared spectroscopic studies

The Raman spectra of anhydrous orotic acid, Cu(orotato)$(NH_3)_2$ (**1**) and [Cu(orotato)$(H_2O)_4]\cdot H_2O$ (**2**) are illustrated in Fig. 6. The most characteristic bands are collected in Table 6. Band assignment for the ligand has been made by comparison with the results from vibrational spectroscopic studies and the calculated potential energy distributions (PEDs) for Pt(orotato)$(NH_3)_2$ [10], 1-methylthymine (1-MeT) [39] and 1-methyluracil (1-MeU) [40]. The copper–ligand stretching vibrations were assigned by comparison with the spectra of similar Cu(II) complexes [41].

The exocyclic ν(C4=O4) stretching vibration contributes to the strong band at 1661 cm^{-1} in the infrared spectrum of **1**, and at 1685 cm^{-1} in the IR spectrum of **2** (1676 cm^{-1} in the Raman spectrum). A lower frequency of the ν(C4=O4) mode in the former complex is caused by intermolecular N3–H3···O4′ hydrogen bonding in the crystal of **1**. The corresponding ν(C4=O4) vibration in 1-MeT was observed in the range 1660–1680 cm^{-1} [39]. The very strong and broad Raman bands with maxima at 1631 cm^{-1} for **1** and 1648 cm^{-1} for **2** can arise from an overlap of several transitions of similar energy. Thus, both the ν(C5=C6) and ν(C7=O3) stretching vibrations should occur in this range of frequencies. Moreover, the bending vibrations of the coordinated ammonia groups in **1**, or bending $\delta(H_2O)$ vibrations in **2**, should also be observed at about 1620–1650 cm^{-1} [41].

In the Raman spectrum of Cu(orotato)$(NH_3)_2$ we have assigned the band at 1576 cm^{-1} to the ν(C2=O2) stretching vibration. A large downward shift of this band, in comparison to the other ν(C=O) bands, is caused by the strong hydrogen bond which involves the O2 carbonyl oxygen atom and the N5 atom of the ammonia group coordinated to the copper atom.

In **2**, the Raman band at 1595 cm^{-1} can be assigned to the ν(C2=O2) stretching vibration, however, the ν(C7=O3) stretching may also contribute to this band. As revealed by the X-ray data, the non-chelating C7=O3 group in **2** is involved in intermolecular hydrogen bonding with a lattice water molecule, which may cause a shift of ν(C7=O3) to a lower frequency, in comparison to **1**. A similar band at 1593 cm^{-1} in the spectrum of Cu(glycine)$_2$ dihydrate was also assigned to a carboxylate ν(C=O) vibration [41].

The most intense bands in the FT-Raman spectra of **1** and **2** are observed at 1210 and 1209 cm^{-1}, respectively (Fig. 6). It should be noted that in the Raman spectrum of Pt(orotato)$(NH_3)_2$, the strongest band was located at 1217 cm^{-1} [10], while in the FT-Raman spectrum of [Ni(orotato)$(H_2O)_4$], a very strong band was observed at 1215 cm^{-1} [11]. On the basis of the calculated potential energy distributions (PEDs), these bands were assigned to the stretching vibration of the uracilate ring [10,11]. For anhydrous orotic acid, the corresponding very strong band occurs at 1251 cm^{-1} (Table 6). Thus, it can be concluded that the shift of the very strong Raman band from 1251 cm^{-1} (orotic acid) to the range 1209–1217 cm^{-1} (transition metal complexes) is diagnostic for N_1-deprotonation of the ligand and formation of the N_1–metal bond in these complexes.

The ν(Cu–NH_3), ν(Cu–H_2O), ν(Cu–N1) and ν(Cu–O1) stretching frequencies are of particular interest since they provide direct information about the strength of the copper–ligand bonds. In the spectra of **1**, the new bands

		261m	258m	258m	ov	ν Cu–N1
			213m	210m	210m	ν Cu–N1, δ coor

[a] Abbreviations: br, broad; m, medium; ov, overlapped bands; s, strong; sh, shoulder; w, weak; v, very; ν, stretching; δ, in-plane bending; γ, out-of-plane bending; τ, torsion; coor, coordination ring; U, uracilate ring.

at 438 cm^{-1} (Raman) and 406 cm^{-1} (IR) have been assigned to the ν(Cu–NH_3) stretching vibrations. Similar bands at 426 and 420 cm^{-1} were reported for $[Cu(NH_3)_4]^{2+}$ [41]. In the spectra of **2**, the new Raman bands arising at 463 cm^{-1} (sh) and 397 cm^{-1} are due to the ν(Cu–H_2O) stretching vibrations. These frequencies are also similar to those reported for Cu–aqua complexes, at about 440 cm^{-1} [41].

It follows from this comparison that the Cu–NH_3 and Cu–H_2O bonds in **1** and **2**, respectively, have a strong covalent character.

The new Raman bands at 283 cm^{-1} for **1** and 277 cm^{-1} for **2** are assigned to the ν(Cu–O1) stretching vibrations. It should be noted that the corresponding ν(Cu–O) stretching frequency in Cu(glycine)$_2$ was reported at 337 cm^{-1} [41], which indicates that the Cu–O1 bonds in the title complexes are more ionic than the Cu–O bond in the glycine complex.

In the FT-Raman spectra (Fig. 6), new distinct bands appear at 261 cm^{-1} for **1** and 258 cm^{-1} for **2**. Both these bands can be assigned to the ν(Cu–N1) stretching vibrations in these complexes. It should be noted that the corresponding ν(Cu–N) mode in the Cu(II) complex with pyridine occurs at a very similar frequency, 268 cm^{-1} [41]. Thus, it can be concluded that the strength of the Cu–N1 bond in **1** and **2** is comparable to that in copper(II) complexes with N-aromatics. This implies that the N1-deprotonated orotate ligand displays a strong π-donating capability.

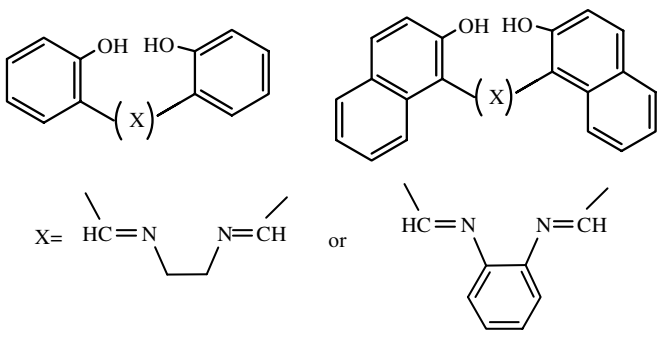
6. Conclusions

The presence of Cu^{2+}/Cu^{+} centers is mainly responsible for the oxidase activity of copper-containing enzymes and proteins, e.g. galactose oxidase (GAO) and ceruloplasmin (C_p). The experimental study on the *cis*-[Cu(orotato)(NH_3)$_2$] complex has revealed the great importance of the non-covalent Cu(II)–π binding force between the chelated Cu^{2+} ion and the uracilate ligand. The natural bond orbital analysis (NBO) indicates that the natural atomic charge on the copper(II) ion is about +1.2e in this complex. It is known that a bare Cu cation with a +1 charge is capable of interacting with simple aromatics, therefore, it is possible that the Cu(II)–π interaction can exist in aromatic systems, provided that some steric affects do not prevent it.

Thus, it is suggested that the non-covalent Cu–π interaction between the chelated Cu^{2+} ion and aromatic compounds can play a significant role in many biological processes, e.g. in binding a substrate at the active site of an enzyme. This hypothesis may shed new light on the mechanism of action of certain copper-containing enzymes.

Acknowledgements

The authors dedicate this paper to the memory of Professor Tadeusz Głowiak, a wonderful friend and great crystallographer, who first indicated the possibility of a copper(II)–π interaction in the studied complex. We gratefully acknowledge helpful discussions with Professor Jan Reedijk from Leiden University. We also thank Professor Leonard Proniewicz from the Jagiellonian University in Cracow for measuring the Raman spectra of the copper(II) complexes. The Poznań Supercomputer and Networking Center and the Wrocław Centre for Networking and Supercomputing are acknowledged for generous computer time. This work was supported by a grant from Wrocław University of Technology.



Appendix A. Supplementary material

CCDC 638205 and 638259 contain the supplementary crystallographic data for *cis*-[Cu(orotato)(NH_3)$_2$] (**1**) and [Cu(orotato)(H_2O)$_4$] · H_2O (**2**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.05.052.

H_2sal-en, **1**; H_2nap-en, **2**;

H_2sal-*o*-pndn, **3**; H_2nap-*o*-pndn, **4**

2. Experimental

2.1. Materials

All chemicals used were of Analar grade and solvents were dried following the literature procedure [26]. *cis*-$[RuCl_2(DMSO)_4]$ and the ligands (H_2sal-en, **1**; H_2nap-en, **2**; H_2sal-*o*-pndn, **3**; H_2nap-*o*-pndn, **4**) were prepared as reported earlier [27,28].

2.2. Physical methods

Infrared spectra of the ligand and the complexes have been recorded on a Nicolet Avatar model FT-IR spectrophotometer using KBr discs in the range 4000–400 cm^{-1}. Electronic spectra were recorded on a Systronics 119 UV–Vis spectrophotometer using methanol as the solvent. Elemental analyses were performed with a Vario EL III Elementar analyzer. ^1H NMR spectra were recorded on an AMX 400 instrument in DMSO solvent. Melting points were recorded with a Lab India apparatus.

2.3. X-ray crystallography

Single crystals of $[RuCl_2(DMSO)_2(o\text{-pndn})]$ suitable for X-ray diffraction studies were obtained from slow evaporation of an ethanolic solution of the complex. Diffraction data were collected on a Bruker AXS SMART APEX CCD diffractometer at 100(2) K using monochromatic Mo Kα radiation with the omega scan technique. The unit cell was determined using SMART and SAINT+ [29]. The structure was solved by direct methods and refined by full-matrix least-squares against F^2 with all reflections using SHELXTL [30]. Refinement of an extinction coefficient was found to be insignificant. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were placed in calculated positions and were refined with an isotropic displacement parameter of 1.5 (CH_3) or 1.2 (all others) times that of the adjacent carbon or nitrogen atom. The crystal data and refinement parameters are summarized in Table 1.

2.4. Synthesis of the new Ru(II) complexes

All the new mononuclear ruthenium(II) complexes were prepared by the following general procedure. An ethanolic solution of *cis*-$[RuCl_2(DMSO)_4]$ and the appropriate ligand in a 1:1 mole ratio was heated under reflux for 4 h. The solution was filtered and left for slow evaporation. The crystalline product that separated out was filtered off, washed with ethanol and dried under vacuum. The filtrate along with the ethanol washings were evaporated to dryness. The aldehyde formed was extracted with petroleum ether and then quantified. The individual syntheses are given below.

$[RuCl_2(DMSO)_2(o\text{-pndn})]$ (**5**) was prepared from *cis*-$[RuCl_2(DMSO)_4]$ (0.100 g, 0.2 mmol) and H_2sal-*o*-pndn (0.062 g, 0.2 mmol) as dark red brown crystals. Yield: 80%. *Anal.* Calc. for $RuC_{10}H_{20}N_2O_2Cl_2S_2$: C, 27.52; H, 4.60; N, 6.4; S, 14.69. Found: C, 27.44; H, 4.39; N, 6.61; S, 14.11%. IR: 3280, 3269, 1557, 1072, 1129 cm^{-1}. UV λ_{max}: 248, 289. M.p.: >200 °C (dec.).

Table 1
Crystal data and structure refinement parameters for $[RuCl_2(DMSO)_2(o\text{-pndn})]$

Empirical formula	$C_{10}H_{20}Cl_2N_2O_2RuS_2$
Formula weight	436.37
Temperature (K)	100(2)
Wavelength (Å)	0.71073
Crystal system	monoclinic
Space group	$P2_1/n$
Unit cell dimensions	
a (Å)	12.5947(8)
b (Å)	8.1650(5)
c (Å)	15.4946(9)
α (°)	90
β (°)	98.4880(10)
γ (°)	90
Volume (Å^3)	1575.95(17)
Z	4
D_{calc} (Mg/m^3)	1.839
Absorption coefficient (mm^{-1})	1.597
F(000)	880
Crystal size (mm)	$0.68 \times 0.37 \times 0.27$
θ Range for data collection (°)	1.95–28.28
Limiting indices	$-16 \leqslant h \leqslant 16$, $-10 \leqslant k \leqslant 10$, $-20 \leqslant l \leqslant 20$
Reflections collected/unique (R_{int})	15551/3899 (0.0209)
Completeness to $\theta = 28.28°$ (%)	99.8
Absorption correction	multi-scan
Maximum and minimum transmission	0.650 and 0.446
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	3899/0/176
Goodness-of-fit on F^2	1.191
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0211$, $wR_2 = 0.0522$
R indices (all data)	$R_1 = 0.0212$, $wR_2 = 0.0524$
Largest difference in peak and hole (e Å^{-3})	1.240 and −0.600

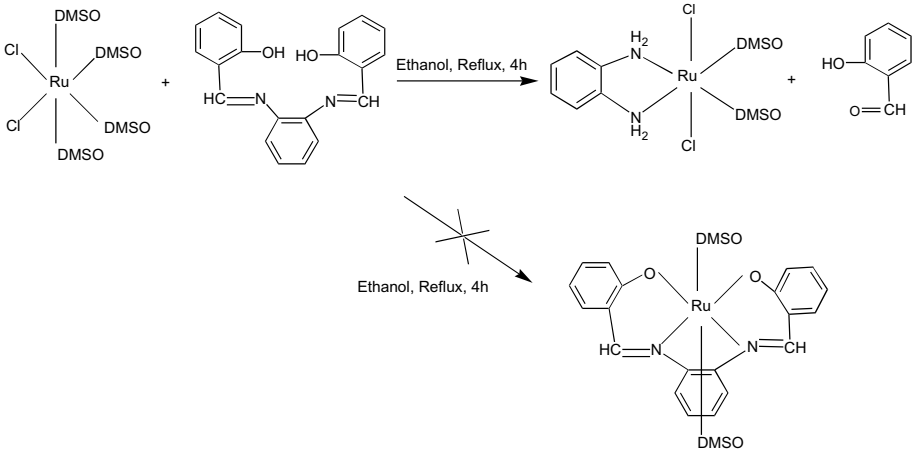
[$RuCl_2(DMSO)_2$(*o*-pndn)] (**5**) was also prepared from *cis*-[$RuCl_2(DMSO)_4$] (0.100 g, 0.2 mmol) and H_2nap-*o*-pndn (0.082 g, 0.2 mmol) as dark red brown crystals. Yield: 80%. *Anal*. Calc. for $RuC_{10}H_{20}N_2O_2Cl_2S_2$: C, 27.52; H, 4.60; N, 6.4; S, 14.69. Found: C, 27.03; H, 4.40; N, 6.14; S, 14.77%. IR: 3282, 3269, 1555, 1072, 1129 cm^{-1}. UV λ_{max}: 248, 289 (nm). M.p.: >200 °C (dec.).

[$RuCl_2(DMSO)_2$(en)] (**6**) was prepared from *cis*-[$RuCl_2(DMSO)_4$] (0.100 g, 0.2 mmol) and H_2sal-en (0.053 g, 0.2 mmol) as dark green crystals. Yield: 85%. *Anal*. Calc. for $RuC_6H_{20}N_2O_2Cl_2S_2$: C, 18.55; H, 5.19; N, 7.20; S, 16.51. Found: C, 18.22; H, 5.04; N, 7.21; S, 16.57%. IR: 3263, 3220, 1558, 1070, 1130 cm^{-1}. UV λ_{max}: 270, 258. M.p.: >200 °C (dec.).

[$RuCl_2(DMSO)_2$(en)] (**6**) was also prepared from *cis*-[$RuCl_2(DMSO)_4$] (0.100 g, 0.2 mmol) and H_2nap-en (0.073 g, 0.2 mmol) as dark green crystals. Yield: 85%. *Anal*. Calc. for $RuC_6H_{20}N_2O_2Cl_2S_2$: C, 18.55; H, 5.19; N, 7.20; S, 16.51. Found: C, 18.29; H, 5.08; N, 7.23; S, 16.37%. IR: 3265, 3216, 1553, 1073, 1127 cm^{-1}. UV λ_{max}: 270, 258. M.p.: >200 °C (dec.).

We were also able to synthesize compounds **5** and **6**, by refluxing an ethanolic solution of *cis*-[$RuCl_2(DMSO)_4$] and the corresponding diamine in a 1:1 mole ratio.

2.5. Antimicrobial activity



The new complexes have been tested in vitro to assess their growth inhibitory activity against the pathogenic bacteria *Aeromonas hydrophila*, *Eschericia coli*, *Salmonella typhi*, *Streptococcus faecalis*, *Klebsiella pneumonia*, *Staphylococcus aureus* and *Proteus mirabilis* by the disc diffusion method (Kirby–Bauer method) [31]. The bacteria were cultured in nutrient broth medium and used as inoculum for this study. Bacterial cells were swabbed on the surface of Mueller Hinton Agar medium [prepared from NaCl (5 g), peptone (5 g), beef extract powder (3 g), yeast extract powder (3 g) and agar (20 g) in 100 mL distilled water; pH 7.3 ± 0.2] in Petri plates. The compounds to be tested were dissolved in dimethyl sulfoxide to a final concentration of 0.25%, 0.5%, 0.75%, 1% and 1.5% and soaked in sterile discs (7 mm diameter). These discs were placed on the already seeded plates and incubated at 37 °C for 24 h. After incubation, the diameter (mm) of the inhibition zone around each disc was measured and classified as resistant (>15 mm), intermediate (13–14 mm) and sensitive (<13 mm) (Hi-media). A clear zone around the disc indicated the inhibitory activity of the compound on the organism. The data are presented in Table 4.

3. Results and discussion

New hexa-coordinated Ru(II) complexes of the type [$RuCl_2(DMSO)_2$(diamine)] (diamine = *o*-phenylenediamine and ethylenediamine) have been prepared by reacting *cis*-[$RuCl_2(DMSO)_4$] with the appropriate Schiff bases (H_2sal-en, **1**; H_2nap-en, **2**; H_2sal-*o*-pndn, **3**; H_2nap-*o*-pndn, **4**) in a 1:1 ratio. The ligands, which were expected to act as tetradentate (N_2O_2) chelates under the normal reaction conditions, were found to undergo hydrolytic cleavage to form the diamine and the corresponding aldehyde. The diamine formed reacted with [$RuCl_2(DMSO)_4$] to give complexes of the type [$RuCl_2(DMSO)_2$(diamine)], while the corresponding aldehydes were isolated in quantitative yield. The reaction scheme for one of the Schiff bases is given below and the other Schiff bases were found to follow the same route (see Scheme 1).

3.1. Elemental analysis

The analytical data obtained for the new Ru(II) complexes were entirely different from the one calculated for the expected hexa-coordinate Ru(II) complex containing the tetradentate dibasic ligand and dimethylsulfoxide. The analytical data conform to the stoichiometry of the new ruthenium complexes as [$RuCl_2(DMSO)_2$(diamine)]. The complexes obtained from H_2sal-en (**1**) and H_2nap-en (**2**) were identical and their analytical data were also

Scheme 1.

the same as that corresponding to $[RuCl_2(DMSO)_2$(ethylenediamine)]. Similarly, the complexes obtained from H_2sal-*o*-pdn (**3**) and H_2nap-*o*-pdn (**4**) were identical and their analytical data were also the same as that corresponding to $[RuCl_2(DMSO)_2$(*o*-phenylenediamine)].

3.2. Infrared spectroscopy

The IR spectra of the free ligands showed a strong band in the region 1642–1614 cm^{-1} assignable to $\nu_{-C=N}$ [32]. This band disappeared completely in the new complexes indicating the absence of any –C=N group, because if coordination of the ligand has occurred through the azomethine nitrogen then this band will undergo a bathochromic shift of 40–10 cm^{-1} [33] and not completely disappear. A new band around 1557 cm^{-1} (absent in the starting complex) appeared in the new complexes, indicating the presence of an aromatic –C=C– group [34]. Two new bands in the region 3280 and 3215 cm^{-1}, assignable to ν_{N-H}, indicate the introduction of the $-NH_2$ group (absent in the ligand and the starting complex) [35]. Two bands in the region 1120 and 1070 cm^{-1} due to $\nu_{S=O}$, characteristic of S-bonded DMSO, are present while the absence of a band around 935 cm^{-1} (due to O-bonded S=O) indicates elimination of O-bonded DMSO [27].

3.3. ^1H NMR spectroscopy

The ^{1}H NMR spectral data for complex **5** showed two signals at δ 7.2 ppm (m, 2H) and δ 7.41 ppm (t, 2H) that were assigned to the aromatic protons from *o*-phenylenediamine. A peak at δ 6.5 ppm (s, 4H) is due to the two NH_2 groups present in *o*-phenylenediamine. A sharp signal at δ 3.22 ppm (s, 12H) due to the $-CH_3$ group of S-bonded dimethylsulfoxide was also found [27]. The ^{1}H NMR spectral data for complex **6** showed no signals around δ 7 ppm indicating the absence of aromatic protons. A peak at δ 6.5 ppm (s, 4H) is due to the two NH_2 groups present in ethylenediamine. A sharp signal at δ 3.22 ppm (s, 12H) due to the $-CH_3$ group of S-bonded dimethylsulfoxide was also found.

3.4. Crystal structure of $[RuCl_2(DMSO)_2$ (*o*-pndn)]

The ORTEP diagram of $[RuCl_2(DMSO)_2$(*o*-pndn)] is shown in Fig. 1. Selected bond lengths and bond angles are given in Table 2 and details of hydrogen bonding in Table 3. The coordination environment around the ruthenium metal consists of an $N_2S_2Cl_2$ octahedron. The planar diamine ligand occupies the equatorial position along with two S-bonded dimethylsulfoxide groups, while the two chlorine atoms occupy the axial positions. The chlorine atoms, which were originally present in a *cis* position, now occupies a *trans* position, as evident from the Cl(2)–Ru(1)–Cl(1) bond angle of 170.686(15)°. Moreover the two chlorine atoms are bent away from the two dimethylsulfoxide ligands towards the diamine, as seen from the other *cis* angles, where the N–Ru–Cl angles are less (<90°) when compared to the S–Ru–Cl angles (>90°).

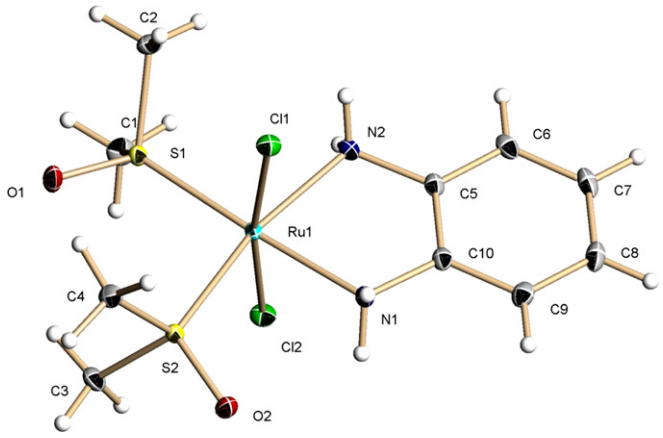


Fig. 1. ORTEP diagram of $[RuCl_2(DMSO)_2$(*o*-pndn)].

Table 2
Selected bond lengths (Å) and bond angles (°) for $[RuCl_2(DMSO)_2$(*o*-pndn)]

Bond lengths (Å)

3.5. Antimicrobial activity

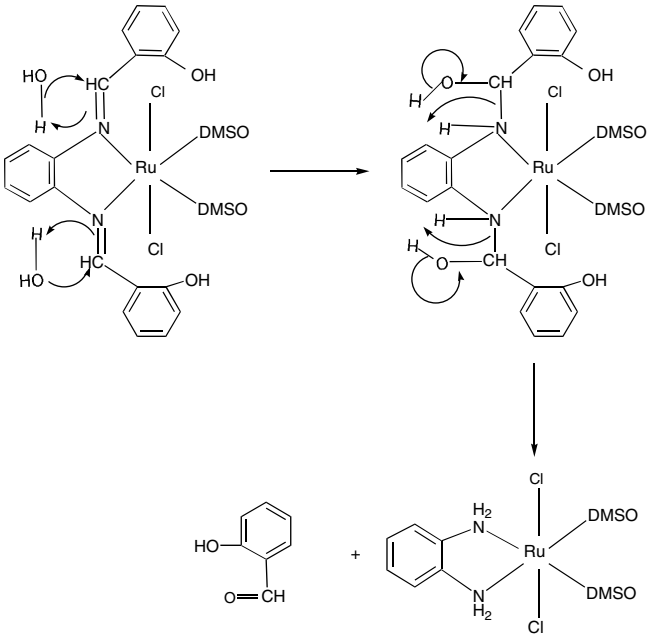
The antimicrobial activities of the new complexes were screened against seven pathogenic bacteria. A clear zone around the disc indicated inhibitory activity of the compound on the organism. Depending upon the diameter of the inhibition zone the new complexes were graded as sensitive (<13 mm), intermediate (14–15 mm) or resistant (>15 mm) against pathogenic bacteria. The intermediate strains were also scored as resistant. Both complexes **5** and **6** were found to exhibit good activity against the species under study. The activity was found to increase with an increase in concentration of the metal complex used. The complexes were found to exhibit moderate activity in certain cases and in a few cases, against *A. hydrophila* and *S. faecalis*, their sensitivity reached almost the values of standard Chloramphenicol and Gentamicin.

4. Mechanism for cleavage

In order to propose a cause and route for the –C=N– cleavage, a number of reactions were carried out. To start with, the ligands were refluxed in ethanol in the absence of a metal complex for various time intervals, and no cleavage was observed even after 96 h. The very fact that cleavage does not occur in the absence of metal complex indicates the involvement of the metal centre. The Schiff bases constitute a series of molecules that are susceptible both to hydrolytic cleavage and to coordination with metal ions. It is believed that the formation of bonds between the positive metal ion and nitrogen brings about a labilization of the nitrogen carbon double bonds, which are thereby rendered more susceptible to hydrolytic cleavage [36].

It is known from our previous work [37] that the same Schiff bases have acted as tetradentate ligands to form complexes with $[RuX_3(PPh_3)_3]$. Hence, we arrived at the conclusion that mere ruthenium alone is not sufficient for the cleavage. To find out if DMSO alone can cause the cleavage, the reaction was carried out with an excess of DMSO along with ethanol for various time intervals, from 1 h up to 16 h. The presence of DMSO alone was not sufficient to cause the cleavage, so the combination of ruthenium and DMSO might be the cause for the cleavage.

From this, it is evident that the Schiff base first associates itself to the $[RuCl_2(DMSO)_4]$ complex and then the cleavage occurs. Coordination to metal can cause weakening or strengthening of the –C=N– group [38] and here the former occurs resulting in hydrolytic cleavage immediately, and the intermediate could not be isolated. The cleavage is expected to be caused by trace amounts of water present in ethanol. Bravo has reported a similar type of –C=N– cleavage in platinum and palladium complexes and have found that the hydrolysis is suppressed when the reaction was handled under argon in dry solvents [39].



A few reports found relevant to our discussion is the hydrolysis of N-benzylimines $PhCH_2N{=}C(H)Ar$ (Ar = Ph, *p*-$MeOC_6H_4$) by trace water promoted by the ruthenium complex $[Ru_2Cl_4(dppb)_2]$ [dppb = 1,4-bis(diphenylphosphino)butane, $Ph_2P(CH_2)_4(PPh_2)$]. This reaction [40] is found to proceed through an intermediate containing a η^1-bonded imine ligand, viz., $[Ru_2Cl_4(dppb)_2(PhCH_2N{=}C(H)Ph)]$, characterized by ^1H and ^{31}P NMR spectroscopy, to yield free benzaldehyde and $[Ru_2Cl_4(dppb)_2(NH_2CH_2Ph)]$. Similarly, $CuCl_2 \cdot nH_2O$ has been found to promote the hydrolysis of semicarbazones in acetonitrile, through a mechanism involving simultaneous coordination of the lone pair of the nitrogen and the C=O bond of the semicarbazone to the metal ion [41]. A recent article [42] describes the chemo selective hydrolysis of the iminic moiety in salicylaldehyde semicarbazone promoted by $[RuCl_2(DMSO)_4]$. In concurrence with this, the following mechanism (Scheme 2) has been suggested.

The cleavage is found to occur in the presence of a metal centre, which brings about weakening of the coordinated –C=N– bond. The presence of a trace amount of water brings about cleavage. As a consequence of coordination to the metal, the C=N group is highly polarized and nucleophilic attack on the carbon atom of the C=N group may occur. Attack of water on the C=N carbon leads to an unstable amino-alcohol, which spontaneously breaks up

Table 4
Antimicrobial activity data for the new ruthenium(II) complexes

Scheme 2.

to yield salicylaldehyde and the Ru complex containing the corresponding bound diamine. The chlorine ligands that were originally in the *cis* position in the starting complexes now occupy *trans* positions in the final complex.

In order to find out if a catalytic amount of the complex could bring out the cleavage, the reaction was carried out in 1:10 molar ratio of metal to Schiff base ligand. The Schiff base was not completely cleaved and the amount of Schiff base that cleaved depends on the ratio of the metal present. This is because the diamine formed from the initial cleavage coordinates with metal to form $[RuCl_2(DMSO)_2$-(diamine)] which could not further support cleavage. This was further confirmed by carrying out the reaction in the presence of $[RuCl_2(DMSO)_2$(diamine)] in ethanol instead of $[RuCl_2(DMSO)_4]$, where the Schiff base remained unchanged even after two days of refluxing. The reason for the disability of $[RuCl_2(DMSO)_2$(diamine)] to cause cleavage is the chelating nature of the diamine which restricts free Schiff base association with the metal centre. The effect of solvent could not be monitored due to poor solubility of $[RuCl_2(DMSO)_4]$ in non-polar solvents like benzene and acetone.

5. Conclusion

Schiff bases that were expected to act as tetradentate dibasic ligands, underwent hydrolytic cleavage at the –C=N– group to give back the aldehyde and diamine from which the Schiff base was originally formed. The diamine thus formed reacted with *cis*-$[RuCl_2(DMSO)_4]$ to give new complexes of the type $[RuCl_2(DMSO)_2$(diamine)]. The aldehyde was isolated and quantified in stoichiometric amounts.

6. Supplementary material

CCDC 622118 contains the supplementary crystallographic data for $[RuCl_2(DMSO)_2$(*o*-pndn)]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

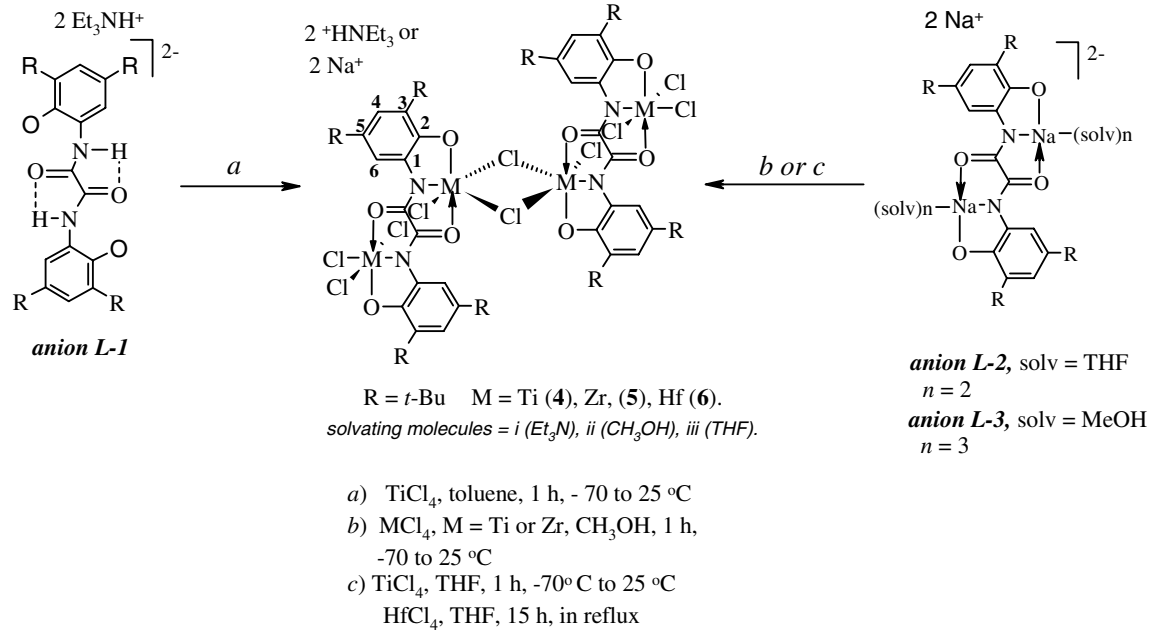
thiolates [13], bis(imino)pyridines [14], α-diimines [15], and phosphines [16]. These catalysts are used together with a suitable activator (co-catalyst) such as methylalumoxane (MAO), which promotes the formation of active species [17].

On the other hand, oxamide type compounds comprise a very interesting family in Coordination Chemistry [18]. These compounds may be synthesized in high yields and have a good stability as chemical ligands, which make them suitable for the formation of non-metallocenic polymerization catalysts. In particular, 1,2-bis(3,5-di-*tert*-butyl-2-hydroxiphenyl)oxamide (**L**) presents a good solubility in organic solvents and it has various potential coordination sites that would permit the formation of metal complexes [19]. As we mention before, there are catalysts with several types of ligands bearing nitrogen or oxygen atoms donors, but there are not examples of oxamides complexes used to olefins polymerization.

Thus, our work focused on the synthesis of new coordination compounds of this family and their application as catalysts for ethylene polymerization, which could open the way to a new family of non-metallocene polymerization catalysts derived from the coordination of 1,2-bis(3,5-di-*tert*-butyl-2-hydroxiphenyl)oxamide (**L**) to transition metals of the Group IV.

2. Experimental



The transition metal reagents and oxamide (**L**) precursors were commercially available, thus the reactions were performed with freshly distilled solvents. The melting points were determined using a Mel-Temp II apparatus. The IR spectra in the 4000–400 cm^{-1} range were recorded on an FT-IR 1600 Perkin–Elmer spectrophotometer, using KBr pellets. The elemental analyses were performed using a Eager 300 apparatus. The fast atom bombardment mass spectra (FAB+ mass) were obtained with a JEOL SX102A instrument featured with an inverted geometry, in a matrix of 3-nitrobenzyl alcohol, in the 0–2200 *m*/*z* range. The NMR spectra were recorded at room temperature using several spectrometers: JEOL GSX-270; Jeol eclipse + 400 MHz and Bruker Advance 300 MHz. The syntheses were carried out using different bases and solvents (Et_3N/toluene, NaH/THF and NaOH/methanol) as shown in Scheme 1.

2.1. 1,2-Bis(3,5-di-tert-butyl-2-hydroxiphenyl)oxamide (*L*)

The precursor, 4,6-di-*tert*-butyl-2-amino-1-phenol, was obtained by two synthesis routes: (1) ethylenediamine and 2-propanol [19], and (2) NH_3/BH_4OH in a mixture of methanol and water [20], both involved the use of 4,6-di-*tert*-butyl-1,2-benzoquinone, which, in turn, can be synthesized from 3,5-di-*tert*-butylcathecol.

The ligand 1,2-bis(3,5-di-*tert*-butyl-2-hydroxiphenyl)-oxamide (**L**) was synthesized following some the literature procedure with slight modifications, as shown recently, using oxalyl chloride and triethylamine in ethyl ether [21]. In our case, oxalyl bromide and triethylamine in THF (yield 70%, m.p. 200 °C) were used.

The coordination complexes of Ti, Zr, Hf were finally obtained by deprotonation of the oxamide **L** using three different bases (Et_3N/toluene, NaH/THF and NaOH/methanol).

Scheme 1. Synthesis of group IV oxamide derivatives by three synthetic routes.

2.2. Anions

2.2.1. Bis(triethylamonium)-bis(4,6-di-tert-butyl-1-oxo-phenyl)oxamide, **L-1**

Compound **L** (0.5 g, 1 mmol) was dissolved in dry toluene (15 mL) and then, triethylamine (0.28 mL, 2 mmol) was added. The reaction mixture was stirred for 30 min. Removal of the solvent under reduced pressure resulted in a yellow solid. IR (KBr): ν(CO) 1647.1 s. ^{1}H NMR (CD_3OD): δ/ppm: 7.19 {s, 2H, H4}; 7.77 {s, 2H, H6}; $\Delta\delta$ (H6–H4): 0.58; 1.44 {s, 9H, H3(*t*-Bu)}; 1.32 {s, 9H, H5(*t*-Bu)}. ^{13}C{^{1}H} NMR (CD_3OD): δ/ppm: 126.9 {s, C1}; 146.0 {s, C2}; 141.7 {s, C3}; 120.6 {d, C4}; 138.9 {s, C5}; 117.0 {d, C6}; 158.2 {s, C=O}; 34.1 {s, C3(*t*-Bu)}; 35.0 {s, C5(*t*-Bu)}; 29.4 {q, C3(*t*-Bu)}; 30.9 {q, C5(*t*-Bu)}.

2.2.2. Dianion bis(4,6-di-tert-butyl-1-oxo-phenyl)oxamido-bis(sodium), **L-2**

Compound **L** (0.5 g, 1 mmol) was dissolved in dry THF (15 mL) and then, NaH (0.28 mL, 2 mmol) was added. The reaction mixture was stirred for 30 min. Removal of the solvent under reduced pressure resulted in a yellow solid. IR (KBr): ν(CO) 1646.5 s. ^{1}H NMR (CD_3OD): δ/ppm: 6.98 {s, 2H, H4}; 8.12 {s, 2H, H6}; $\Delta\delta$ (H6–H4): 1.14; 1.42 {s, 9H, H3 (*t*-Bu)}, 1.27 {s, 9H, H5(*t*-Bu)}. ^{13}C{^{1}H} NMR (CD_3OD): δ/ppm: 128.0 {s, C1}; 154.8 {s, C2}; 136.5 {s, C3}; 118.8 {d, C4}; 133.1 {s, C5}; 113.4 {d, C6}; 157.7 {s, C=O}; 33.7 {s, C3(*t*-Bu)}; 34.8 {s, C5(*t*-Bu)}; 29.4 {q, C3(*t*-Bu)}; 31.1 {q, C5(*t*-Bu)}.

2.2.3. Dianion bis(4,6-di-tert-butyl-1-oxo-phenyl)oxamido-bis(sodium), **L-3**

Compound **L** (0.5 g, 1 mmol) was dissolved in methanol (15 mL) and a 1 M solution of NaOH (2 mL, 2 mmol) was added. The reaction mixture was stirred for 30 min. Removal of the solvent under reduced pressure resulted in a yellow solid. IR (KBr): ν(CO) 1651.0 s. ^{1}H NMR (CD_3OD): δ/ppm: 8.12 {s, 2H, H6}; 6.98 {s, 2H, H4}; $\Delta\delta$ (H6–H4): 1.14; 1.44 {s, 9H, H3(*t*-Bu)}; 1.28 {s, 9H, H5(*t*-Bu)}. ^{13}C{^{1}H} NMR (CD_3OD): δ/ppm: 127.9 {s, C1}; 155.1 {s, C2}; 136.5 {s, C3}; 118.9 {d, C4}; 132.9 {s, C5}; 113.3 {d, C6}; 157.7 {s, C=O}; 33.7 {s, C3(*t*-Bu)}; 34.8 {s, C5(*t*-Bu)}; 29.3 {q, C3(*t*-Bu)}; 31.1 {q, C5(*t*-Bu)}.

2.3. General synthesis of complexes **4–6**

2.3.1. Dimeric (triethylamonium)-[(μ-Cl)-bis[(3,5-di-tert-butyl-2-oxo-phenyl)oxamido-bis(dichloride titanium (IV))] **4**

This complex was obtained following three different routes, only the counter ion is changed by Na^+ in routes b and c:

(a) A solution of 0.5 g (1 mmol) of **L** in toluene (15 mL) and triethylamine (0.28 mL, 2 mmol) was mixed with a 1 M solution of titanium chloride(IV) in methylene dichloride (2 mL, 2 mmol) at −70 °C. Upon mixing, the color instantly changed to brown-red. The solution was filtered and the solvent was evaporated for afford a brown-red solid precipitated (1.7 g, 98%), with a m.p. > 400 °C. MS-FAB$^+$ (*m*/*z*): 1573 $[C_{60}H_{83}Cl_{10}N_4O_8Ti_4+HCl]^+$. *Anal.* Calc. for $C_{60}H_{80}Cl_{10}N_4O_8Ti_4/5Et_3N$: C, 53.06; H, 7.67; N, 6.19. Found: C, 53.57; H, 8.15; N, 6.27%.

(b) A solution of 0.5 g (1 mmol) of **L** in methanol (15 mL) and a 1 M solution of NaOH (2 mL, 2 mmol) were mixed with a 1 M solution of titanium chloride(IV) in methylene dichloride (2 mL, 2 mmol). Upon mixing, the color instantly changed to brown-red. The solution was filtered and the solvent was evaporated for afford a brown-red solid precipitated (1.5 g, 98%).

(c) A solution of 0.5 g (1 mmol) of **L** in THF (15 mL) and NaH (0.48 g, 2 mmol) was mixed with 1 M solution of titanium chloride(IV) in methylene dichloride (2 mL, 2 mmol) at −70 °C. Upon mixing, the color instantly changed to brown-red. The solution was filtered and the solvent was evaporated for afford a brown-red solid precipitated (1.5 g, 98%).

2.3.2. Dimeric (sodium)-(μ-Cl)-bis[(3,5-di-tert-butyl-2-oxo-phenyl)oxamido-bis(dichloride zirconium(IV))] **5**

A solution of 0.5 g (1 mmol) of **L** in methanol (15 mL) and 1 M solution of NaOH (2 mL, 2 mmol) were mixed with zirconium chloride(IV) (0.47 g, 2 mmol) at room temperature. An orange solid (1.7 g, 98%) appeared after evaporation, with m.p. > 400 °C. MS-FAB$^+$ (*m*/*z*): 1703 $[C_{60}H_{82}Cl_{10}N_4O_8Zr_4]^+$. *Anal.* Calc. for $C_{60}H_{80}Cl_{10}N_4O_8Zr_4/CH_3OH$: C, 41.10; H, 4.75; N, 3.14. Found: C, 41.26; H, 4.80; N, 3.00%.

2.3.3. Dimeric (sodium)-(μ-Cl)-bis[(3,5-di-tert-butyl-2-oxo-phenyl)oxamido-bis(dichloride hafnium(IV))] **6**

A solution of 0.5 g (1 mmol) of **L** in THF (15 mL) and NaH (0.48 g, 2 mmol) were mixed with hafnium chloride (IV) (0.64 g, 2 mmol) and refluxed for 15 h. A green-brown solid (2.1 g, 98%) appeared after evaporation, with m.p. > 400 °C. MS-FAB$^+$ (*m*/*z*): 1888 $[C_{60}H_{81}Cl_{10}N_4O_8Hf_4Na_2\text{-}6Cl]^+$. *Anal.* Calc. for $C_{60}H_{80}Cl_{10}N_4O_8Hf_4Na_2/TH\ F,10H_2O$: C, 32.74; H, 4.46; N, 2.39. Found: C, 32.74; H, 5.11; N, 2.63%.

2.4. Polymerization

2.4.1. Materials

Toluene and heptane (J.T. Baker) were used as reaction solvents. Methylaluminoxane (WITCO) was used as a co-catalyst without purification. All the procedures were carried out under nitrogen atmosphere using the Schlenk technique.

2.4.2. Polymerization

Polymerization was carried out in a 600 mL Parr reactor equipped with mechanical agitation, a temperature control

unit and continuous measurement system for ethylene consumption. The reagents were introduced into the reactor by means of syringes, following the order: solvent + MAO + ethylene and, finally, the non-metallocene catalyst. The reaction was terminated by the addition of acidified methanol and the final product was washed with acetone.

2.4.3. Polymer characterization

The catalytic activity was evaluated from the polymer weight obtained in each polymerization, expressed as g-polymer/mmol(cat) *Pt*, where *P* is the pressure and *t* is the reaction time. A Bruker Vector 22 spectrometer was used for obtaining the FTIR spectra of the polyethylene films. The molecular weight and molecular weight distribution were determined by chromatography using trichlorobenzene in a Waters 2000 apparatus, at 135 °C. The differential scanning calorimetry (DSC) measurements were performed on a TA Instrument DSC 2920 under nitrogen atmosphere. The samples were melted at 180 °C and quenched from 180 °C to room temperature, then reheated from room temperature to 180 °C at a rate of 10 °C/min. The melting temperatures were determined from the second heating curve.

3. Results and discussion

3.1. Synthesis

Once the oxamide (**L**) was prepared, its anions were obtained with triethylamine, NaH and NaOH. The total deprotonation was effected with four equivalents of NaH and NaOH; however, when (**L**) was treated with an excess of triethylamine, only the phenolic hydrogens were deprotonated, leaving the NH function intact. ^{1}H NMR spectroscopy suggests the formation of a sodium complex when total deprotonation is achieved.

Table 1
^{1}H NMR data (in methanol-d_3)

Complexes	δ(H4)	δ(H6)	$\Delta\delta$(H6–H4)	δ(3-*t*-Bu)	δ(5-*t*-Bu)
L	7.14	7.31	0.17	1.43	1.31
Ti (**4**)	7.15	7.72	0.57	1.37	1.29
Zr (**4**)	7.14	8.11	0.97	1.44	1.35
Hf (**4**)	7.16	8.15	0.99	1.45	1.36

The difference between the chemical shifts of H3 and H5 (structure numbering in Scheme 1) in both anions amounts to 1.14 ppm. This result suggests that anions **L-2** and **L-3** reach, upon coordination, a conformational stabilization which renders the anion planar and this characteristic conformation has been observed in the well-known tin oxamide derivatives [19].

It is noticeable that the preferred conformation of the free ligand, as detected by X-ray crystal analysis [19] shows that both OH functions lie opposite to the NH group. Free rotation around the C2–N bond allows the sodium coordination of the O, N atoms to produce the planar conformation as mentioned above.

The ^{13}C NMR analysis shows that C1 and C2 are shifted to lower fields in comparison with the free ligand; this chemical shift is more evident for the anions obtained with NaH and NaOH, while carbon atoms C3 and C5 are protected.

IR Spectroscopy showed a slight displacement of the carbonyl band to lower wave numbers, the C=O bond becomes weaker due to intramolecular coordination; nevertheless, there is hardly a difference among the ν(CO) of the anions.

Later on, the transition metal group 4 compounds were prepared. A titanium derivative was obtained by means of the three synthetic routes mentioned above, in order to form the oxamide anion. For zirconium derivative, anion **L-3** was used, due to the solubility of $ZrCl_4$ in methanol. For the hafnium derivative the best result was obtained with NaH/THF under reflux for 15 h. ^{1}H and ^{13}C NMR displacements for the titanium, zirconium and hafnium complexes appear in Tables 1 and 2.

One can observe that the difference between the chemical shift, $\Delta\delta$ (H3–H5), is higher for the hafnium derivative, probably because its large size and low electronegativity; this marks a compensatory result between the inductive effect of the metal towards nitrogen and the oxygen carbonyl coordination.

For derivatives **4**–**6**, the ν(CO) shifts to lower frequencies (Table 3), with respect to the anions, because the coordination of the oxygen belonging to the carbonyl group linked to the metal is stronger. These shifts are similar to those reported in other transition metal complexes [21].

Mass spectroscopy (FAB^+) indicated formation of dimeric complexes bonded by chloride atoms as is indi-

cated in Scheme 1. Polymeric chains formation can also be possible; some similar derivatives examples with $GeCl_4$ [22], $SbCl_5$ [22], and Me_2SnCl_2 [23] and this oximade ligand have shown this behavior. On the other hand, presence of coordinated molecules (triethylamine, THF or methanol) by NMR spectroscopy is observed, Fig. 1. For that reason, they are proposed into elemental analyses.

3.2. Ethylene polymerization

The catalytic activities for gaseous monomers such as ethylene [24] are usually classified as very high (>1000), high (1000–100), moderate (100–10), low (10–1), and very low (<1) with reference to the units: g $mmol^{-1}$ h^{-1} bar^{-1}. In the present study, the highest activity was observed for zirconium catalyst (**5**) in *n*-heptane, as shown in Table 4.

The polymers obtained with this catalyst present the highest molecular weight, i.e., 98,000 Da. A change in solvent might increase both the activity as well as the molecular weight, for instance the activity of the Zr catalyst in *n*-heptane is 1.7 times greater with respect to toluene, while M_w from *n*-heptane is 1.32 times greater than the one obtained from toluene. This type of solvents effect might be explained on the basis of polarity of different solvents allowing the proximity of monomer for polymerization. In terms of T_m and crystallinity, catalyst (**5**) produces a higher density linear polyethylene (Table 4). Overall, these results suggest the exchange of the chloride atoms by the methyl groups to form cationic species as it occurs with "non-metallocene" complexes. In this way, cationic monomeric compounds are formed. The titanium atom probably generates more chloride bridges and a bigger polymeric complex with respect to the zirconium

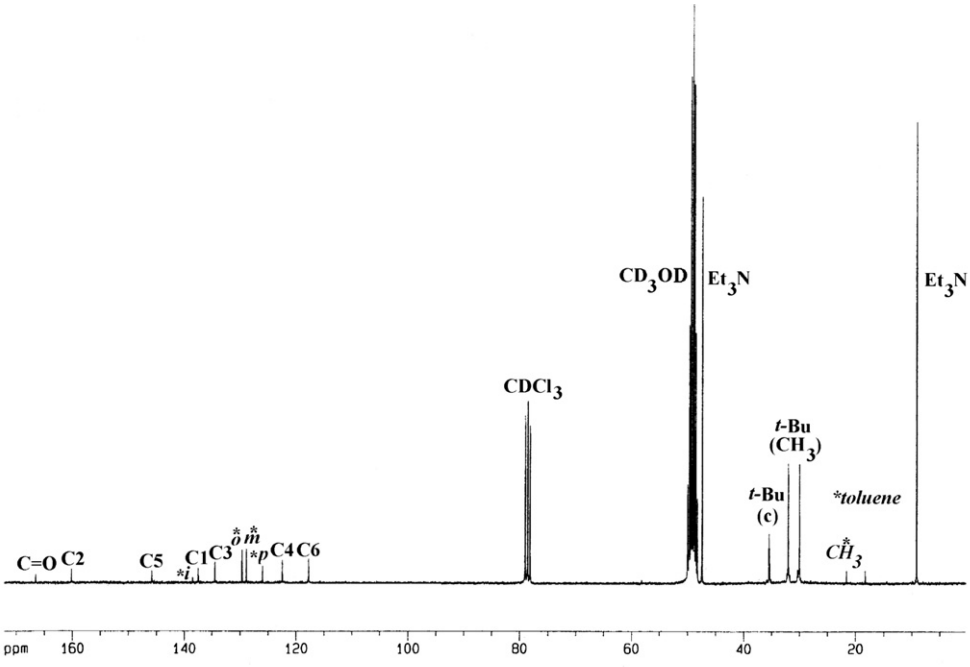

Fig. 1. ^{13}C NMR spectra of Ti (**4**) complex with triethylamine coordinated.

Table 4
Catalytic activity and polymer characterization

Catalyst in toluene	Polymer mass (g)	Activity g(polymer)/mmol(cat). h bar	M_w	M_w/M_n	T_m (°C)	Crystallinity (%)
Ti (**4**)	0.39	26.3	55,000	1.8	136	56
Zr (**5**)	1.75	118	73,700	1.8	137.4	56.5
Zr (**5**)[a]	2.75	201	98,000	2.0	136.4	57.5
Hf (**6**)	0.35	23	34,000	2.0	135.6	54

Polymerization conditions: $P = 4$ bar, time = 60 min, $T = 60$ °C, 10 mL of MAO to 10%, Al/Metal = 4000, mols cat $\sim 3.5 \times 10^{-6}$ (it is different for each one), $\Omega = 1000$ rpm. In all reactions one pre-contact with MAO was made. GPC. Universal curve, new calibration curve.

[a] In heptane.

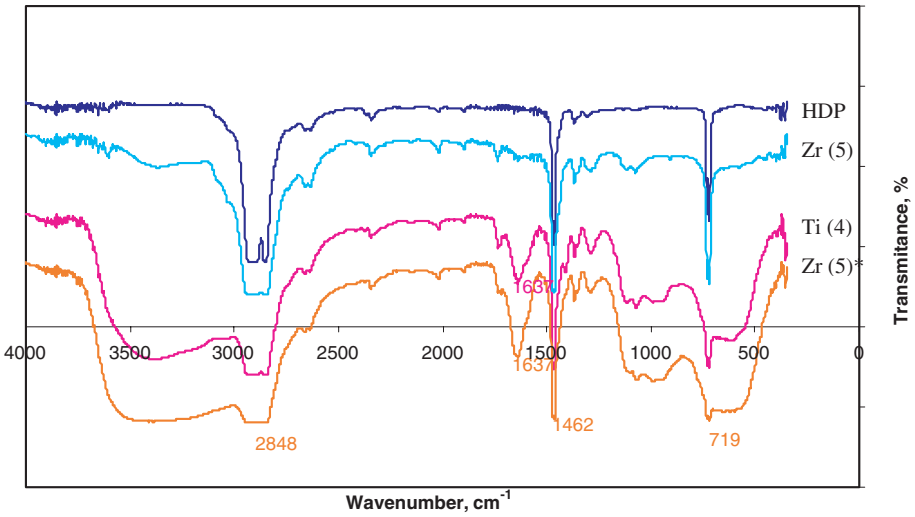

Fig. 2. FTIR spectra of polyethylene obtained with Zr (**5**), Zr (**5**)* and Ti complex **4**/MAO.

atom. The terminal chloride atoms react first with MAO, which may be the reason of higher activity of zirconium complexes. Also, it is known that hafnium, like other elements of the sixth period, exhibit lower activities due to kinetic factors (slow olefin coordination and insertion step) [2].

On the other hand, the polydispersity index M_w/M_n was determined to change from 1.8 with a solvent like toluene to about 2.0 with *n*-heptane. These values are typical for metallocene based catalysts, indicating the polymerization occurs mostly by a single-site mechanism [25].

The melting temperature (T_m) of the polymers corresponded to linear polyethylene [26]. The FTIR spectrum of Zr(**5**) displays the typical bands corresponding to high density linear polyethylene at 2930 and 2845 cm^{-1}, which can be assigned to C–H stretching of the $–CH_2$ and $–CH_3$ groups. At about 1462 cm^{-1} there is a band corresponding to the $–CH_2$ group bending, and at 719 cm^{-1} another band is verified, which corresponds to the $(–CH_2–CH_2–)_n$ rocking group, with $n > 3$ [27]. In the case of Zr (**5**)* and Ti (**4**) there is an additional signal at 1637 cm^{-1}, which can be interpreted as the one arising from double bonds originated from β-H elimination or vinyl unsaturation of the polymer chain (Fig. 2).

4. Conclusions

The 1,2-bis(3,5-di-*tert*-butyl-2-hydroxiphenyl)oxamide (**L**) was synthesized following two conventional methods. Oxamide salts were obtained by using three different bases (Et_3N/toluene, NaH/THF and NaOH/methanol); the sodium complex was formed in the last two methods. The coordinating capacity of oxamide (**L**) was corroborated by the formation of complexes with early transition metals (Ti, Zr, Hf). These complexes have a planar structure similar to the tin derivatives reported in the literature [19]. The best synthetic method for titanium and zirconium involves the use of NaOH and methanol as base and solvent, respectively. The hafnium derivative was obtained by means of NaH in THF. Finally, a study on the polymerization of ethylene showed that the oxamide series were active catalysts, with zirconium complex presenting the highest activity of the series and a marked solvent effect. Based on these results, the higher activity of Zr oxamide derivative and the promotion effects towards high density linear PE, could motivate further research for developing new catalysts with potential applications in low olefin polymerization reactions.

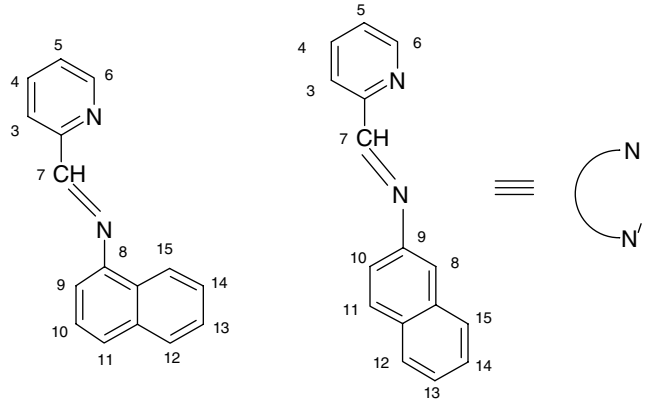
characterized by X-ray diffraction measurements. A theoretical calculation using a model optimized system is very useful in predicting the electronic structure; the electron transitions to rationalize the spectral properties and electron transfer chemical, electrochemical and photophysical properties are elegantly explained by using Density Functional calculations. We have also explained the electronic structures of the complexes by DFT and TD-DFT calculations.



2. Results and discussion

2.1. Synthesis and infrared spectra

N-[(2-Pyridyl)methyliden]-α(and β)-aminonaphthalene (α and β-NaiPy) have been used in the present work. They were synthesized [10] by reacting pyridine-2-carboxaldehyde and α-naphthyl-amine (for α-NaiPy) and β-naphthyl-amine (for β-NaiPy) in a 1:1 mol ratio in dry ethanol solution under reflux. The compounds are recrystallised from an ethanol–chloroform mixture (Scheme 1).

The complexes were synthesized by the reaction of the ligand and $Pd(MeCN)_2Cl_2$ in a 1:1 mol ratio in MeCN solution (Eq. 1). Upon slow evaporation of the reaction mixture orange-red crystals were deposited on the wall of the beaker, and these were separated by filtration and dried over $CaCl_2$. Microanalytical data support the composition Pd(α-NaiPy)Cl_2 (**1**)/Pd(β-NaiPy)Cl_2 (**2**). The solution conductance measurement suggests a non-electrolytic nature of these complexes.

Pd(α-NaiPy)I_2 (**3**)/Pd(β-NaiPy)I_2 (**4**) were synthesized by Ag^+ assisted de-chlorination in THF, followed by addition of KI (aq) solution (Eq. (2)). Bis-chelated palladium(II) complexes have been synthesized by Ag^+ assisted de-chlorination from Pd(α-NaiPy)Cl_2 (**1**) or Pd(β-NaiPy)-Cl_2 (**2**) followed by reaction with various ligands (Eq. (3)). The reaction of $[Pd(\alpha\text{-NaiPy})(S)]^{2+}$ with α-NaiPy or $[Pd(\beta\text{-NaiPy})(S)]^{2+}$ with β-NaiPy could synthesise $[Pd(\alpha\text{-NaiPy})_2]^{2+}$ (**5**) or $[Pd(\beta\text{-NaiPy})_2]^{2+}$ (**6**), while the reaction of $[Pd(\alpha\text{-NaiPy})(S)]^{2+}$ with β-NaiPy led to the isolation of $[Pd(\alpha\text{-NaiPy})(\beta\text{-NaiPy})]^{2+}$ (**7**) as the perchlorate salt, using excess $NaClO_4$. Similarly the reaction of [Pd-

$$Pd(MeCN)_2Cl_2 + NaiPy \longrightarrow Pd(NaiPy)Cl_2 \quad \textbf{1-2} \qquad (1)$$

$$Pd(NaiPy)Cl_2 + 2KI \xrightarrow{AgNO_3\,(aq),\ THF} Pd(NaiPy)I_2 \quad \textbf{3-4} \qquad (2)$$

$$Pd(NaiPy)Cl_2 + L \xrightarrow[NaClO_4]{AgNO_3} [Pd(NaiPy)(L)](ClO_4)_2 \quad \textbf{5-13} \qquad (3)$$

Pd(α-NaiPy)Cl_2 (**1**); Pd(β-NaiPy)Cl_2 (**2**); Pd(α-NaiPy)I_2 (**3**); Pd(β-NaiPy)I_2 (**4**); $[Pd(\alpha\text{-NaiPy})_2](ClO_4)_2$ (**5**); $[Pd(\beta\text{-NaiPy})_2](ClO_4)_2$ (**6**); $[Pd(\alpha\text{-NaiPy})(\beta\text{-NaiPy})](ClO_4)_2$ (**7**); $[Pd(\alpha\text{-NaiPy})(bpy)](ClO_4)_2$ (**8**), $[Pd(\alpha\text{-NaiPy})(phen)](ClO_4)_2$ (**9**), $[Pd(\beta\text{-NaiPy})(bpy)](ClO_4)_2$ (**10**), $[Pd(\beta\text{-NaiPy})(phen)](ClO_4)_2$ (**11**), $[Pd(\alpha\text{-NaiPy})(Tai\text{-}Me)](ClO_4)_2$ (**12**) and $[Pd(\beta\text{-NaiPy})(Tai\text{-}Me)](ClO_4)_2$ (**13**).

Scheme 1. Pd(α-NaiPy)Cl_2 (**1**); Pd(β-NaiPy)Cl_2 (**2**); Pd(α-NaiPy)I_2 (**3**); Pd(β-NaiPy)I_2 (**4**); $[Pd(\alpha\text{-NaiPy})_2](ClO_4)_2$ (**5**); $[Pd(\beta\text{-NaiPy})_2](ClO_4)_2$ (**6**); $[Pd(\alpha\text{-NaiPy})(\beta\text{-NaiPy})](ClO_4)_2$ (**7**); $[Pd(\alpha\text{-NaiPy})(bpy)](ClO_4)_2$ (**8**), $[Pd(\alpha\text{-NaiPy})(phen)](ClO_4)_2$ (**9**), $[Pd(\beta\text{-NaiPy})(bpy)](ClO_4)_2$ (**10**), $[Pd(\beta\text{-NaiPy})(phen)](ClO_4)_2$ (**11**), $[Pd(\alpha\text{-NaiPy})(Tai\text{-}Me)](ClO_4)_2$ (**12**) and $[Pd(\beta\text{-NaiPy})(Tai\text{-}Me)](ClO_4)_2$ (**13**).

(α-NaiPy)(S)]$^{2+}$ or [Pd(β-NaiPy)(S)]$^{2+}$ with bpy (2,2′-bipyridine), phen (1,10-phenanthroline) or Tai-Me (1-methyl-2-(*p*-tolylazo)imidazole) yielded [Pd(α-NaiPy)(bpy)]$(ClO_4)_2$ (**8**), [Pd(α-NaiPy)(phen)]$(ClO_4)_2$ (**9**), [Pd(β-NaiPy)(bpy)]-$(ClO_4)_2$ (**10**), [Pd(β-NaiPy)(phen)]$(ClO_4)_2$ (**11**), [Pd(α-NaiPy)(Tai-Me)]$(ClO_4)_2$ (**12**) and [Pd(β-NaiPy)(Tai-Me)]-$(ClO_4)_2$ (**13**). The composition of the complexes are supported by C, H, N elemental analyses data, and the complexes exhibit 1:2 electrolytic conductivity in MeCN solution ($\Lambda_M = 130$–$160\ \Omega^{-1}\ mol^{-1}\ cm^2$).

The IR stretching frequencies of the complexes have been assigned by comparing with the free ligand data [9]. The *ν*(C=N) bands are shifted to lower frequency by 5–10 cm^{-1} compared to the free ligand value (~1600 cm^{-1}), which supports coordination of N(imine) to Pd(II). Pd(NaiPy)Cl_2 (**1**, **2**) show two *ν*(Pd–Cl) bands at *ca* 325 and 295 cm^{-1}, which support a *cis*-$PdCl_2$ configuration [13,14]. We could not confirm *ν*(Pd–I) of Pd(NaiPy)I_2 (**3**, **4**), which may appear $\leqslant$200 cm^{-1}. This is due to the non-availability of a suitable instrument in our local area. The *ν*(ClO_4) bands of **5**–**13** appear at 1082–1091 cm^{-1}, with a weak stretch at 624–627 cm^{-1}.

2.2. Molecular structure of Pd(β-NaiPy)Cl_2

An ORTEP view of Pd(β-NaiPy)Cl_2 (**2**) is shown in Fig. 1. β-NaiPy acts as a bidentate *N*,*N*′ chelator (*N*,*N*(pyridine); *N*′,*N*(imine)). Bond parameters (Table 1) show that the Pd–N(imine) and Pd–N(pyridine) distances are the same (2.037 Å). This is rarely observed in structural studies of platinum metal diimine/azoimine complexes [15–17]. Usually the M–N(pyridine) distances are shorter than the M–N(imine) distances. The Pd–Cl distances are nearly equal (Pd(1)–Cl(1), 2.2801(17); Pd(1)–Cl(2), 2.2822(17) Å). The β-NaiPy bite angle, N(2)–Pd–N(1) 80.3(2)°, is comparable with the Pd(azoheterocycle)Cl_2 system [13–17]. The pendant naphthyl group is severely distorted from the chelate plane and the dihedral angle is 56.5°. All other bond lengths and angles are comparable with reported structures [13,14].

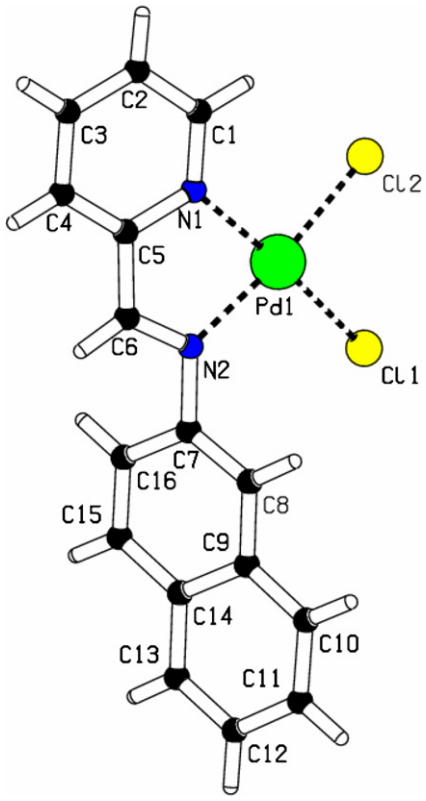


Fig. 1. ORTEP of Pd(β-NaiPy)Cl_2.

An unusual Cl–π interaction (Pd(1)–Cl(1)–Cg(2): Cl(1)–Cg(2), 3.711(4) Å and ∠Pd(1)–Cl(1)–Cg(2), 86.89 (7)°; where Cg(2) refers to N(1), C(1), C(2), C(3), C(4), C(5) and symmetry – x, $1-y$, $-z$) constitutes an intermolecular dimer which brings two Pd centres of two molecules closer to each other, with a distance of 3.679 Å (Fig. 2). Each dimer interacts weakly with a neighbouring molecule by π–π interactions between the pyridyl and naphthyl rings as evident from the long distance (the Cg(2)–Cg(3) distance is 4.245(4) Å and the perpendicular Cg(3)–Cg(3) distance is 3.929(5) Å, where Cg(3) refers to the naphthyl ring and the symmetry is $1/2 + x$, $1/2 - y$, $-z$). This interaction generates a sinusoidal sheet in the *ab* plane (Fig. 3a). The brick wall topology of the sheet is shown in Fig. 3b.

2.3. Optical absorption spectra and electronic structure calculation

The optical absorption spectra of NaiPy and the Pd(NaiPy)-complexes (**1**–**13**) in MeCN solution are reported in Fig. 4 and the data are set out in Table 2. The absorption spectra of α/β-NaiPy in MeCN illustrates the characteristics common to diimine derivatives: a structured absorption band around 330–350 nm with a molar absorption coefficient of the order of $10^4\ M^{-1}\ cm^{-1}$, and an intense high energy absorption around 250–290 nm. From the analogy with the absorption spectrum of *N*-[(2-pyridyl)methyliden]-aminobenzene, it is likely that the large absorption band around 330–350 nm corresponds to n–π* transitions, while the shorter wavelength transitions correspond to a π–π* transition. However, the bands exhibit bathochromic shifts by ~20 nm compared with *N*-[(2-pyridyl)methyliden]-aminobenzene [6].

The complexes Pd(NaiPy)Cl_2 show a weak absorption at 460–510 nm ($\varepsilon \sim 500$–$1000\ M^{-1}\ cm^{-1}$) along with intense absorptions at 400–440 nm ($\varepsilon \sim 1000$–$1500\ M^{-1}\ cm^{-1}$), and in the UV region at 350–370 nm and 265–280 nm ($\varepsilon \sim 10^4\ M^{-1}\ cm^{-1}$) (Fig. 4; Table 2). The UV-region of the spectra is comparable with the spectra of the free ligands and has been assigned to n–π* and π–π* transitions. The visible region weak transition (410–490 nm) may be due to a $d^{10}(Pd) \rightarrow \pi^*$ (ligand) state of the diimine/azoimine function.

To understand the nature of the UV–visible transitions of the ligand and [Pd(NaiPy)X_2], a series of DFT and

Table 1

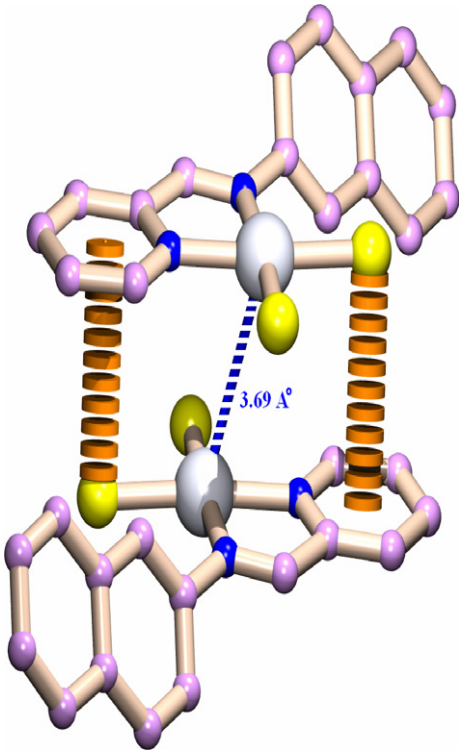

Fig. 2. Dimer unit is formed *via* the Cl–π interaction (Pd—Pd distance, 3.69 Å).

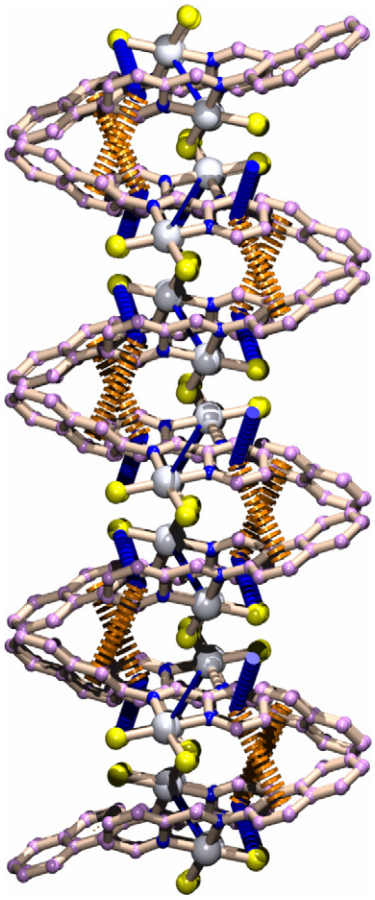

Fig. 3a. An edge-on view of the π-sheet (sinusoidal sheet) generated by π–π interactions.

TD-DFT calculations have been conducted on the optimized geometry of the compounds. To reduce the work load we have confined the calculation to β-NaiPy, Pd(β-NaiPy)Cl_2 and Pd(β-NaiPy)I_2. The structure of Pd(β-NaiPy)Cl_2 obtained from the optimized geometry calculation is comparable to the metric parameters of the X-ray determined structure (Table 1). The bond lengths are elongated by 0.04–0.1 Å in the calculated structure of the gas phase DFT study. Similarly the bond angles are also changed by 1–2°. The structural data of β-NaiPy and Pd(β-NaiPy)I_2 are also included in Table 1. In general, the iodo complex, Pd(β-NaiPy)I_2, shows longer bond parameters compared to Pd(β-NaiPy)Cl_2, which is usual because of better electron influx in I^- compared to Cl^-.

Selected electronic structures of the compounds in the gas phase and in acetonitrile solution are given in Figs. 5 and 6, while the composition of selected molecular orbitals are listed in Table 3. In β-NaiPy, the composition of the frontier orbitals are as follows: HOMO and HOMO-1 have large contributions from the naphthyl unit (Naph) (>75%)

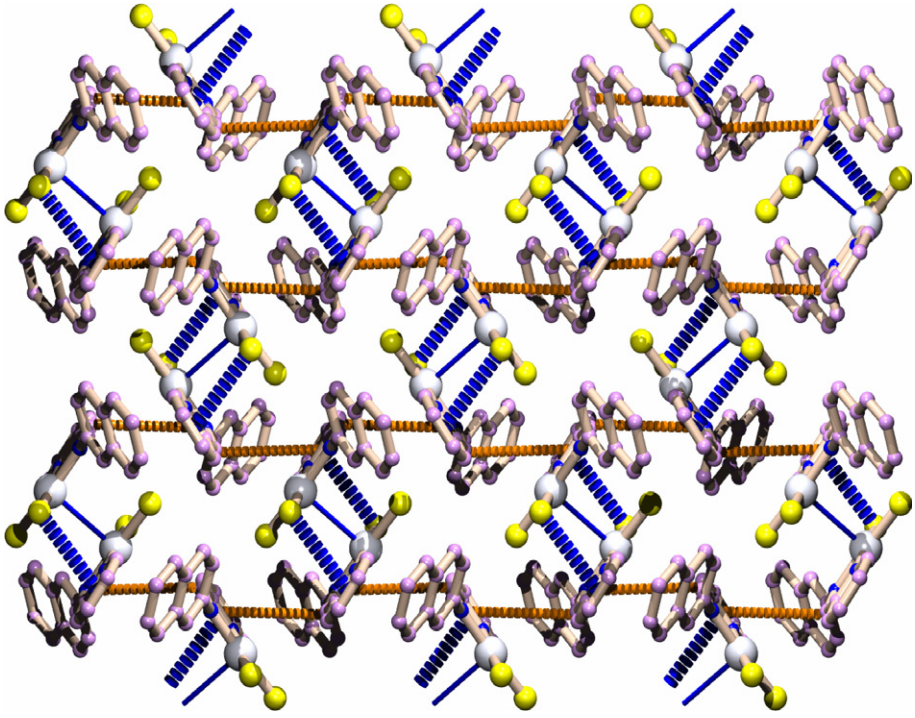

Fig. 3b. The brick wall topology of the sheet in the ab plane, a is to the right and b vertical.

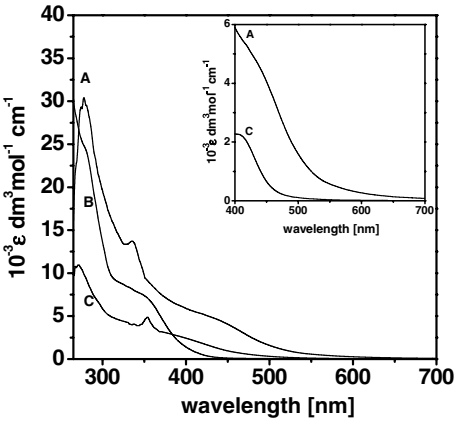

Fig. 4. Absorption spectra of A. [Pd(β-NaiPy)(phen)](ClO$_4$)$_2$, B. β-NaiPy, and C. Pd(β-NaiPy)Cl$_2$ in MeCN at room temperature.

while HOMO-2 and HOMO-3 have a larger share from the pyridyl (Py) group (>55%) (Fig. 7). Also, the energy separation between the HOMO and HOMO-1 ($\Delta E = 0.65$ eV (gas); 0.63 eV (MeCN)) is larger than HOMO-2 and HOMO-3 ($\Delta E = 0.32$ eV (gas); 0.22 eV (MeCN)). Other occupied orbitals show a substantial contribution from the Naph and Py units, and in some cases from the C=N function. Amongst the unoccupied orbitals, the LUMO has a major share from the Py group (68%) while LUMO+1 has 89% Naph character. Similarly, the composition of other orbitals are as follows: LUMO+2, 86% (Py); LUMO+3, 83% (Naph); LUMO+4, 90% (Naph), etc. Thus, the frontier molecular orbitals in the β-NaiPy ligand indicate that the most possible mechanism for the ligand–metal interaction involves the Naph and Py orbitals, and metal centered orbitals. That means in the metal–ligand σ-bonding the Naph orbitals of the ligand are used, while in the π-bonding the Py orbitals of β-NaiPy are used.

In Pd(β-NaiPy)Cl$_2$ the frontier orbitals are composed of Pd(d), ligand and Cl orbitals (Table 3). The occupied MOs HOMO, HOMO-1, HOMO-2 and HOMO-3 have a major contribution from Cl orbitals (55–75%, Fig. 8). The metal orbitals are referred to d-orbitals only. Surprisingly the HOMO has the least contribution from ligand functions while HOMO-1 has 40% ligand character. The unoccupied MOs have a very high contribution from β-NaiPy (54–98%). These results are collected from gas phase DFT calculations. However, a drastic difference is observed in the solution phase calculation using MeCN as the solvent. The HOMO, HOMO-1 and HOMO-2 are composed of 95, 42 and 60% β-NaiPy functions, respectively, while in the gas phase they have 1, 40 and 10% ligand contributions, respectively. The solvent polarity may be acting in a critical role to stabilize polar ligand functions compared to Cl dominated orbitals. The unoccupied MOs in the MeCN phase have a very large contribution from ligand functions (>90%), except LUMO+1 which has 28% ligand character and 42% Cl character. The DFT calculations of Pd(β-NaiPy)I$_2$ also support a similar conjecture (Fig. 9) with reference to gas and solution phase calculations. A correlation amongst the energy levels of the free ligand, and complexes in the gas phase and MeCN phase are given separately in Figs. 5 and 6.

The calculated transitions are listed in Table 4. They are assigned to n(Py) → π*(Py), n(Py) → π*(Naph), π(Naph)

[a] λex – excitation wavelength; λem – emission wavelength; O_f – fluorescence quantum yield, τ_f – mean fluorescence lifetime, χ^2 – goodness of fit, k_r – radiative rate constant, k_{nr} – non-radiative rate constant.

→ π*(Py), π(Naph) → π*(Naph) and π(Py) → π*(Py). On comparing with the oscillator strength (*f*), two major absorption bands in the electronic spectra may be assigned to n(Py) → π*(Py) (calculated band 340–360 nm and experimental 346 nm) and π(Naph) → π*(Py) (calculated band 270–320 nm and experimental 282 nm). The calculated transitions are grouped in three different spectral zones: 470–500 nm, 360–390 nm and 280–330 nm. The intensity of these transitions has been assessed from oscillator strengths (*f*). In fact, the observed spectrum of Pd(β-NaiPy)Cl_2 shows a similar absorption pattern whilst the transitions are shifted to a lower wavelength zone (Fig. 10, Tables 2 and 4). The basic difference between the experimental optical spectrum and theoretical one in the acetonitrile phase is that the main absorption band in the visible region in the experimental spectrum appears at a shorter λ value than that of the theoretically calculated data of acceptable oscillator strength. This may be accounted for in two ways: (i) the non-equilibrium implementation of the polarizable continuum model (PCM), which we have used during the calculation, is insufficient considering the functional constrain given by the heavy metal function of Pd and (ii) acetonitrile is a coordinating solvent and may coordinate to a square planar Pd(II) complex additionally to the solvent cage interaction with the molecular orbitals, and this has not been considered in the PCM model. The longer wavelength band at 470–500 nm may be assigned to the combination of MLCT (d_π(Pd) → π* (ligand)), ^{1}XLCT (X refers to Cl and I): n(X) → π* (ligand), π(ligand) → π* (ligand). The observed transitions appear at 508 and 409 nm. Similarly the 360–390 nm transitions correspond to d_π(Pd) → π* (ligand) and π(ligand) → π* (ligand) transitions. The experimental spectral band appears at 353 nm. The calculated UV band at 280–330 nm is assigned to d_π(Pd) → π* (ligand) and π(ligand) → π* (ligand) transitions. The observed transitions appear at 304 and 272 nm for Pd(β-NaiPy)Cl_2 (**2**) and 387 and 269 nm for Pd(β-NaiPy)I_2 (**4**).

2.4. ^{1}H NMR spectra

Table 5 summaries the ^{1}H NMR spectral data for the free ligand, NaiPy and the palladium(II) complexes. The spectra are recorded in DMSO-d_6 solution. The assignment has been made on the basis of spin–spin interaction, and on comparing with the free ligand values [10]. *N*-[(2-Pyridyl)methyliden]-α(or β)-aminonaphthalene exhibits a singlet at 8.6–8.8 ppm for –HC═N– (7H). The pyridyl protons (3-H to 6-H) appear at 7.7–8.5 ppm, with a higher δ than the naphthyl protons (8-H to 15-H) at 7.3–8.0 ppm. In the complexes the NMR signals are, in general, shifted downfield. The 6-H signal appears at 8.4–9.0 ppm as a doublet ($J = 8.0$ Hz); 3-H shows a doublet at 8.1–8.2 ppm ($J = 8.0$ Hz); 4- and 5-H appear as a triplet at 7.6–8.3 ppm ($J = 8.0$ Hz). On comparing with the NMR data of naphthylazo compounds [15,16] we have assigned the resonances to the naphthyl protons of the coordinated

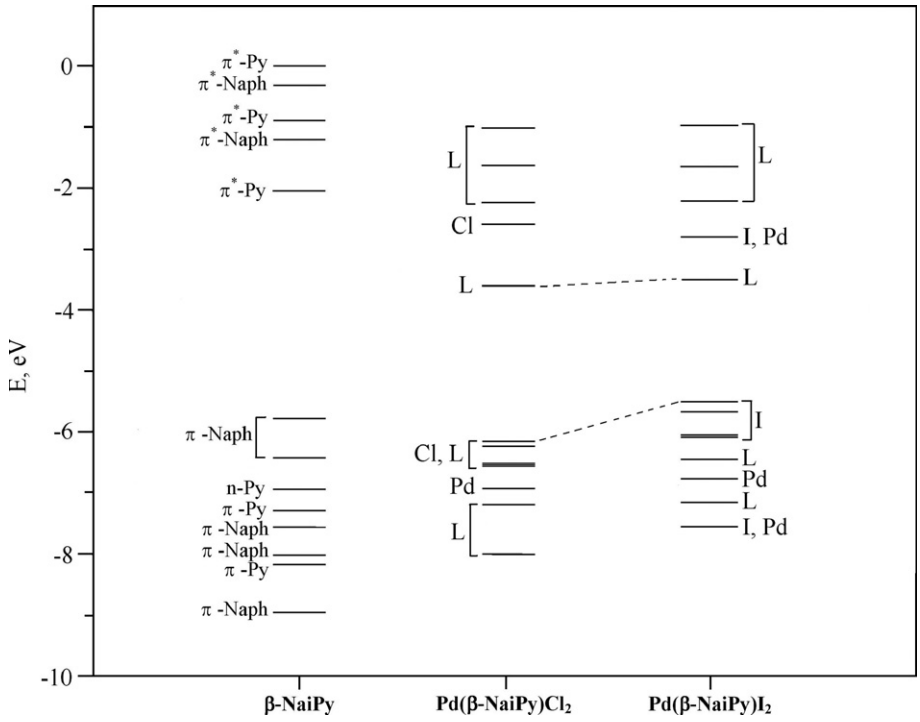

Fig. 5. Energy level correlation diagram in the gas phase.

ligand. 8-H (or 9-H) appears at higher δ because of a closer proximity of the electron withdrawing imine (–C═N–) group. 10-H to 15-H appear as a multiplet at 7.2–8.0 ppm. The bis-chelated complexes, $[Pd(\alpha\text{-}/\beta\text{-NaiPy})_2]^{2+}$ (**5** or **6**) may exist in two isomeric forms (*cis*: **I** and *trans*: **II**) but the *cis* form must not be very favoured because of steric crowding. However, the ^{1}H NMR signals are not sufficiently resolved to identify the composition.

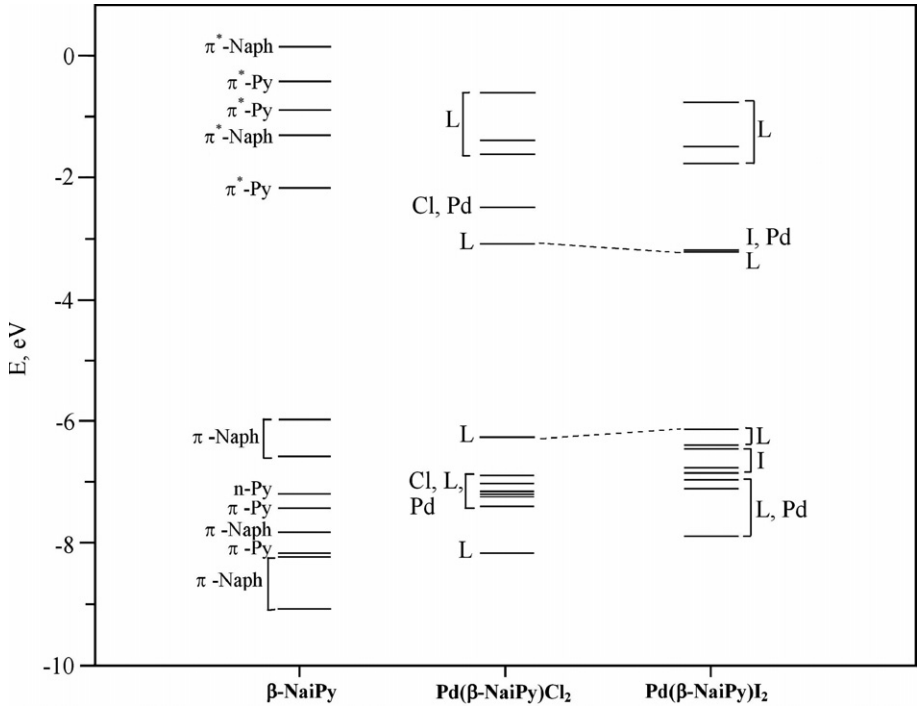

Fig. 6. Energy level correlation diagram in acetonitrile phase.

[Pd(α-NaiPy)(bpy)](ClO$_4$)$_2$ (**8**), [Pd(α-NaiPy)(phen)](ClO$_4$)$_2$ (**9**), [Pd(β-NaiPy)(bpy)](ClO$_4$)$_2$ (**10**) and [Pd(β-NaiPy)(phen)](ClO$_4$)$_2$ (**11**) may exist only in one isomeric form and the NMR spectra show a single set of resonances which support the existence of one isomer only. The isomers of **12** and **13** have been easily identified from the 1-Me and 9-Me signals which appear in a 4:1 intensity ratio. This may suggest the existence of two isomers in a 4:1 proportion. Because of *trans*, *trans*-*N*,*N* and *trans*, *trans*-*N*′,*N*′, isomer **II** may be in a higher yield than **I**.

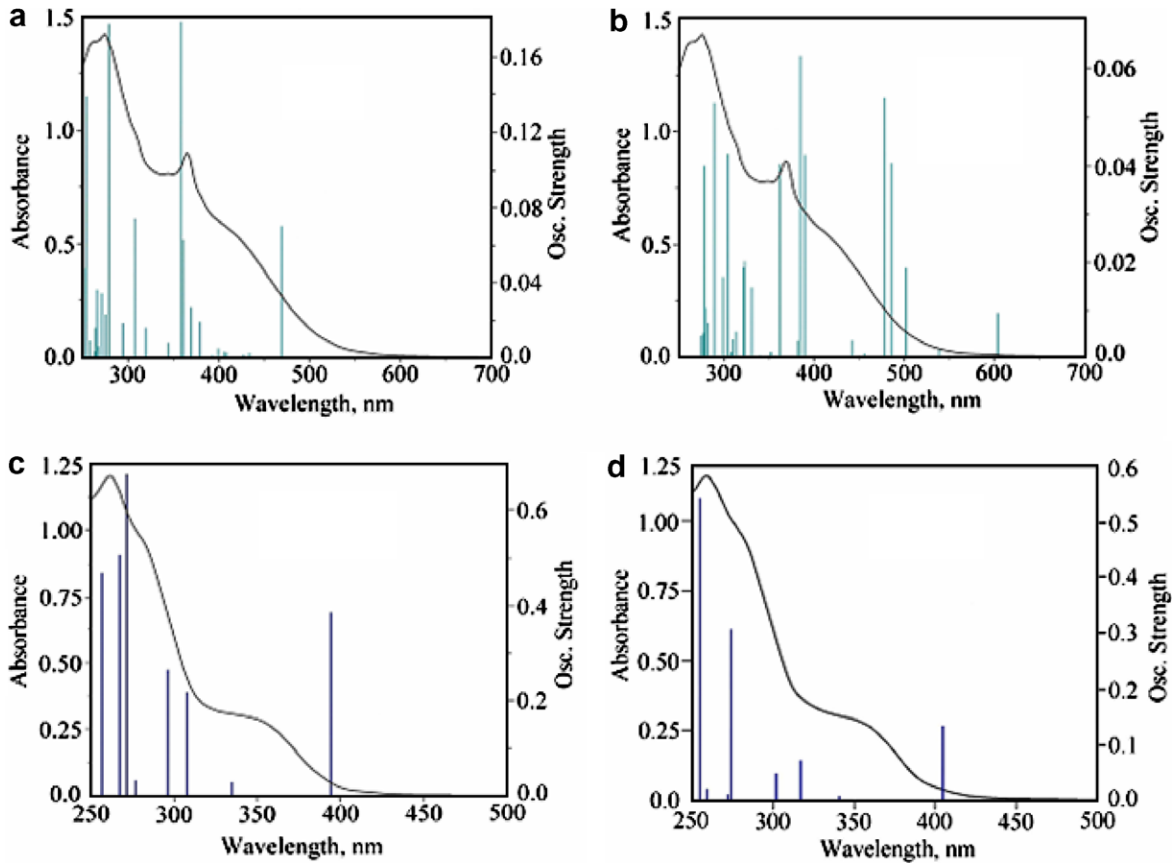

Fig. 10. Experimental optical spectra and calculated (TDDFT) transition energies of (a) Pd(β-NaiPy)Cl_2 in CH_3CN ; (b) Pd(β-NaiPy)Cl_2 in the gas phase; (c) β-NaiPy in CH_3CN and (d) β-NaiPy in the gas phase.

2.5. Luminescence studies

The photoluminescence properties of the ligands and complexes were studied at room temperature. The Schiff bases exhibit emissions at 417 and 409 nm for α-NaiPy and β-NaiPy respectively at 298 K in MeCN solution upon excitation at 338 and 282 nm, respectively. Excitation and emission wavelengths, and quantum yields are summarized in Table 2. No emissions originating from metal-centred and MLCT excited states are expected for the Pd(II) complexes, since it is difficult for the Pd(II) ion to change its electronic configuration. The main reason for Pd(II) complexes to be non-emissive is deactivation via low-lying d–d states. Thus the emission observed (Fig. 11) in the complexes is assigned to (π–π^*) fluorescence. It is interesting that the Pd(II) complexes show higher intensities than the free ligands. It has been reported that the metal ions can enhance or quench the fluorescence emission of pyridine containing compounds [18]. In the absence of metal ions the fluorescence of the ligand is probably quenched by the occurrence of a photoinduced electron transfer (PET) process due to the presence of a lone pair of nitrogen atoms. Such a PET process is prevented by the complexation of the ligand with metal ions which introduces rigidity to the organic motif; thus the fluorescence intensity may be greatly enhanced by coordination to Pd(II). Quantum yields (ϕ), in general, are higher for complexes of α-NaiPy than β-NaiPy (Table 2). The difference in photoluminescence intensity between the free ligands and the complexes is sometime interpreted in terms of free ligand impurity or free ligand produced as a result of photodissociation. This possibility is not ruled out [18d], but we have run ^{1}H NMR spectra of Pd(α-NaiPy)Cl_2 (**1**) and [Pd(α-NaiPy)(bpy)]$^{2+}$ (**8**) after irradiation for 5 min in $CDCl_3$ solution. The spectra of the non-radiated and irradiated complexes are identical in all respects. Besides, the luminescence intensity remains unchanged upon repetitive irradiation, which supports a fairly stable C=N bond.

Lifetime data of the complexes are taken in acetonitrile solution when excited at the specified wavelength (Table 2). The fluorescence decay curve was deconvoluted with respect to the lamp profile. The observed florescence decay fits nicely with a bi-exponential nature for the ligands and complexes (Fig. 12), which is supported by goodness-of-fit (χ^2) (Table 2) data in the regression analyses. Instead of placing emphasis on the magnitude of the individual decay constants in such bi-exponential decays, we have used the mean fluorescence lifetime ($\tau_f = a_1\tau_1 + a_2\tau_2$ where a_1 and a_2 are the relative amplitudes of decay processes). Radiative and non-radiative rate constants (k_r and k_{nr}) are calculated and the data show the usual higher k_{nr} than k_r value.

Table 5

3. Experimental

3.1. Materials

α-Naphthylamine and β-naphthylamine were purchased from Thomas Baker & Co,. Pyridine-2-carboxyaldehyde was purchased from Lancaster Ltd, England. $PdCl_2$ was purchased from Arrora Mathey, Kolkata, India. *N*-[(2-Pyridyl)methyliden]-α (and β)-aminonaphthalene (α and β-NaiPy) were synthesized by condensation of pyridine-2-carboxyaldehyde and the respective naphthylamine in ethanol [9]. All other chemicals used were of A.R. quality and were used as received from SRL, India. The solvents were used after drying [19].

UV–Vis spectra were recorded using a Lambda 25 Perkin–Elmer spectrophotometer and FT-IR spectra were obtained from Spectrum RX-1 Perkin–Elmer (KBr pellet, 4000–450 cm^{-1}) and JASCO model 420 (KBr pellet, 4000–200 cm^{-1}) spectrophotometers. Microanalyses were collected on a Perkin–Elmer 2400 CHN elemental analyser. ^1H NMR spectra were recorded on a Brucker 300 MHz FT-NMR. Solution electrical conductivity was measured by a Systronics 305 digital conductivity meter. Luminescence properties were measured using an LS-55 Perkin–Elmer fluorescence spectrophotometer at room temperature (298 K) in CH_3CN solution with a 1 cm path length quartz cell.

The fluorescence quantum yield of the Schiff bases (α/β-NaiPy) and their palladium(II) complexes (**1**–**13**) were determined using Coumarin-120 laser dye as a reference with a known ϕ_R (fluorescence quantum yield of reference) of 0.63 in MeCN. The complex and the reference dye were excited at 340 nm, maintaining nearly equal absorbance (~0.1), and the emission spectra were recorded from 350 to 600 nm. The area of the emission spectrum was integrated using the software available in the instrument and the quantum yields were calculated according to the following equation:

$$\phi_S/\phi_R = [A_S/A_R] \times [(Abs)_R/(Abs)_S] \times [\eta_S^2/\eta_R^2]$$

Here, ϕ_S and ϕ_R are the fluorescence quantum yields of the sample and the reference, respectively; A_S and A_R are the areas under the fluorescence spectra of the sample and the reference, respectively, $(Abs)_S$ and $(Abs)_R$ are the respective optical densities of the sample and the reference solution at the wavelength of excitation, and η_S and η_R are the values of refractive index for the respective solvents used for the sample and the reference. Fluorescence lifetimes were measured using a time-resolved spectrofluorometer from IBH, UK. The instrument uses a picosecond diode laser (NanoLed-07, 408 nm) as the excitation source and works on the principle of time-correlated single photon counting [20]. The instrument responses function is ~230 ps at FWHM. To eliminate depolarization effects on the fluorescence decays, measurements were done with magic angle geometry (54.7°) for the excitation and emission polarizers. The observed decays of α-NaiPy and β-NaiPy and their palladium(II) complexes fitted well with a bi-exponential function, as in Eq. (1), where the τ values are the fluorescence lifetimes and 'a' is the pre-exponential factor. For the fits, the reduced χ^2 values were within 0.9–1.3 and the distribution of the weighted residuals were random among the data channels. τ_f is the mean fluorescence lifetime (the meaning of the symbols are as usual [21]).

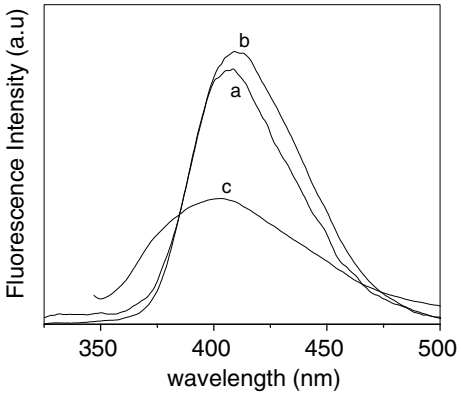

Fig. 11. Fluorescence spectra of (a) β-NaiPy, (b) $Pd(\beta\text{-NaiPy})Cl_2$, (c) $[Pd(\beta\text{-NaiPy})(Phen)](ClO_4)_2$ in CH_3CN solution at room temperature (298 K).

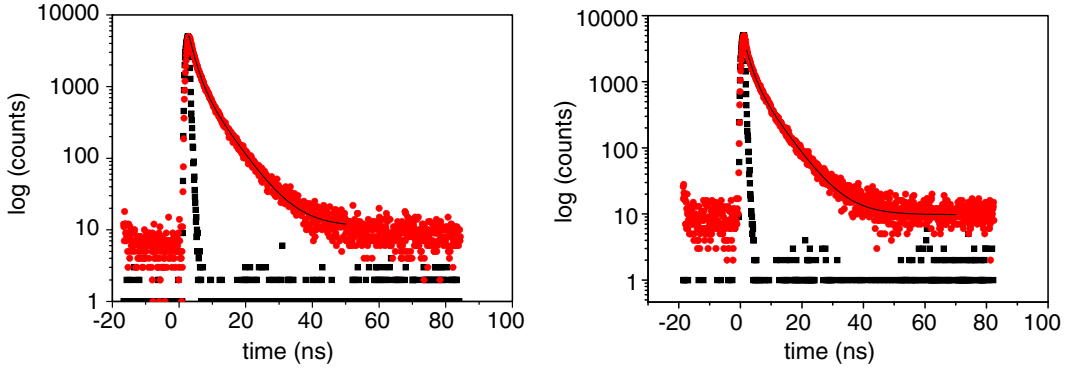

Fig. 12. Bi-exponential decay profile (•) and fitting curve (—) of (a) $[Pd(\alpha\text{-NaiPy})(bpy)](ClO_4)_2$ and (b) $[Pd(\alpha\text{-NaiPy})(\beta\text{-NaiPy})](ClO_4)_2$ in MeCN. Excitation is carried out at 370 nm.

$$I(t) = [a_1 \exp(-t/\tau_1) - a_2 \exp(-t/\tau_2)] \quad (1)$$

$$\tau_f = a_1\tau_1 + a_2\tau_2 \quad (2)$$

3.2. Preparation of the complexes

3.2.1. Synthesis of di-chloro-(N-[(2-pyridyl)methyliden]-α-aminonaphthalene)- palladium(II), Pd(α-NaiPy)Cl_2 (1)

$PdCl_2$ (0.18 g, 1.015 mmol) was taken in MeCN (15 ml) and refluxed until fully dissolved. *N*-[(2-Pyridyl)methyliden]-α-aminonaphthalene (α-NaiPy) (0.25 g, 1.08 mmol) in MeCN (10 ml) was added dropwise to above solution (10 ml) of $Pd(MeCN)_2Cl_2$ at room temperature and stirred for 2 h. The solution colour turned orange. The volume was reduced to half of its original volume by slow evaporation in air. Orange-red crystals then separated. These were filtered, washed with water and then water–MeCN (1:1, v/v). The product was then crystallized by diffusion of CH_2Cl_2 solution into hexane. The yield was 0.22 g (52%). *Anal.* Calc. for $C_{16}H_{12}N_2Cl_2Pd$ (**1**): C, 46.94; H, 2.93; N, 6.84. Found: C, 47.05; H, 2.86; N, 6.85%. [Pd(*N*-[(2-pyridyl)methyliden]-β-aminonaphthalene)$(Cl)_2$] was prepared similarly in 48% yield. *Anal.* Calc. for $C_{16}H_{12}N_2Cl_2Pd$ (**2**): C, 46.94; H, 2.93; N, 6.84. Found: C, 46.88; H, 2.85; N, 6.68%.

3.2.2. Synthesis of di-iodo-(N-[(2-pyridyl)methyliden]-α-aminonaphthalene)- palladium(II), Pd(α-NaiPy)I_2 (3)

To a THF solution (10 ml) of Pd(α-NaiPy)Cl_2 (0.1 g, 0.244 mmol) an aqueous solution of $AgNO_3$ (0.09 g, 0.53 mmol) was added with stirring. The orange brown mixture was heated to reflux for 30 min, then cooled and filtered through a G-4 Gooch funnel. To this filtrate KI (aq) solution (0.09 g, 0.54 mmol) was added and stirred for 3 h. The solution was then evaporated slowly in air. Orange-red crystals were deposited on the glass wall. They were filtered, water washed and their purity was checked by TLC. The crystals were pure and dried over P_4O_{10}. Yield, 0.07 g (48%). *Anal.* Calc. for $C_{16}H_{12}N_2I_2Pd$ (**3**): C, 32.41; H, 2.03; N, 4.73. Found: C, 32.35; H, 2.06; N, 4.85%. [Pd(*N*-[(2-pyridyl)methyliden]-β-aminonaphthalene)$(I)_2$] was prepared similarly in 44% yield. *Anal.* Calc. for $C_{16}H_{12}N_2I_2Pd$ (**4**): C, 32.41; H, 2.03; N, 4.73. Found: C, 32.48; H, 1.96; N, 4.68%.

3.2.3. Synthesis of mixed chelate palladium(II) complexes

The bis-chelated palladium(II) complexes are [Pd(α-NaiPy)$_2$]$(ClO_4)_2$ (**5**) or [Pd(β-NaiPy)$_2$]$(ClO_4)_2$ (**6**), [Pd(α-NaiPy)-(β-NaiPy)]$(ClO_4)_2$ (**7**), Pd(α-NaiPy)(bpy)]$(ClO_4)_2$ (**8**), [Pd-(α-NaiPy)(phen)]$(ClO_4)_2$ (**9**), [Pd(β-NaiPy)(bpy)]$(ClO_4)_2$-(**10**), [Pd(β-NaiPy)(phen)]$(ClO_4)_2$ (**11**), [Pd(α-NaiPy)-(Tai-Me)]$(ClO_4)_2$ (**12**) and [Pd(β-NaiPy)(Tai-Me)]$(ClO_4)_2$ (**13**).

They have been synthesized by following common procedure. Synthesis of [Pd(α-NaiPy)(bpy)]$(ClO_4)_2$ (**6**) is given in detail below.

To an acetonitrile solution (10 ml) of Pd(α-NaiPy)Cl_2 (0.1 g, 0.244 mmol) an aqueous solution of $AgNO_3$ (0.09 g, 0.53 mmol) was added with stirring. The orange brown mixture was heated to reflux for 30 min, then cooled and filtered through a G-4 Gooch. To this filtrate 2,2′-bipyridine (0.04 g, 0.26 mmol) was added and the resulting solution was stirred for 3 h. It was then filtered and aqueous $NaClO_4$ (1 g in 3 ml water) was added to it. The deep brown precipitate that fomed was filtered, washed with water and dried over P_4O_{10}. Yield, 0.1 g (59%). *Anal.* Calc. for [Pd(α-NaiPy)(bpy)]$(ClO_4)_2$ (**8**); *Anal* Calc. for $C_{26}H_{20}N_4O_8Cl_2Pd$: C, 45.02; H, 2.88; N, 8.08. Found: C, 45.15; H, 2.80; N, 7.95%.

Microanalytical data of the other complexes are as follows: [Pd(α-NaiPy)$_2$]$(ClO_4)_2$ (**5**), *Anal.* Calc. for $C_{32}H_{24}N_4O_8Cl_2Pd$: C, 49.93; H, 3.12; N, 7.28. Found: C, 50.02; H, 3.06; N, 7.35%. [Pd(β-NaiPy)$_2$]$(ClO_4)_2$ (**6**) *Anal.* Calc. for $C_{32}H_{24}N_4O_8Cl_2Pd$: C, 49.93; H, 3.12; N, 7.28. Found: C, 50.00; H, 3.00; N, 7.20%. [Pd(α-NaiPy)(β-NaiPy)]$(ClO_4)_2$ (**7**), *Anal.* Calc. for $C_{32}H_{24}N_4O_8Cl_2Pd$: C, 49.93; H, 3.12; N, 7.28. Found: C, 49.84; H, 2.96; N, 7.33%. [Pd(α-NaiPy)(phen)]$(ClO_4)_2$ (**9**) *Anal.* Calc. for $C_{28}H_{20}N_4O_8Cl_2Pd$: C, 46.86; H, 2.78; N, 7.81. Found: C, 46.95; H, 2.66; N, 7.70%. [Pd(β-NaiPy)(bpy)]$(ClO_4)_2$ (**10**), *Anal.* Calc. for $C_{26}H_{20}N_4O_8Cl_2Pd$: C, 45.02; H, 2.88; N, 8.08. Found: C, 45.10; H, 2.80; N, 8.00%. [Pd(β-NaiPy)-(phen)]$(ClO_4)_2$ (**11**) *Anal.* Calc. for $C_{28}H_{20}N_4O_8Cl_2Pd$: C, 46.86; H, 2.78; N, 7.81. Found: C, 46.90; H, 2.84; N, 7.74%. [Pd(α-NaiPy)(Tai-Me)]$(ClO_4)_2$ (**12**), *Anal.* Calc. for $C_{27}H_{24}N_6O_8Cl_2Pd$: C, 43.96; H, 3.25; N, 11.39. Found: C, 43.87; H, 3.36; N, 11.20% and [Pd(β-NaiPy)(Tai-Me)]-$(ClO_4)_2$ (**13**) *Anal.* Calc. for $C_{27}H_{24}N_6O_8Cl_2Pd$: C, 43.96; H, 3.25; N, 11.39. Found: C, 43.82; H, 3.30; N, 11.47%.

3.3. Crystallographic data collection and refinement of [Pd(β-NaiPy)Cl_2] (2)

Crystals were grown by slow diffusion of a CH_2Cl_2 solution of Pd(β-NaiPy)Cl_2 into hexane. Crystal parameters and refined data are summarized in Table 6. The crystal dimensiona are $0.34 \times 0.16 \times 0.13$ mm^3 and data were collected using a fine focus sealed tube at 173(2) K using graphite monochromated Cu-Kα radiation, ($\lambda = 1.54184$ Å). Unit cell parameters were determined from least-squares refinement of setting angles with θ in the range $3.40 \leqslant \theta \leqslant 73.28°$. Of 27224 collected data 2964 with $I > 2\sigma(I)$ were used for the structure solution. The hkl ranges are $-12 \leqslant h \leqslant 12$, $-14 \leqslant k \leqslant 14$, $-32 \leqslant l \leqslant 32$. Reflection data were recorded using the ω scan technique. Data were corrected for Lorentz polarization effects and for linear decay. Semi-empirical absorption corrections based on ψ-scans were applied. Data were computed by MacScience Xpress. Data reduction was carried out by Denzo and Scalepack. The structure was solved by a direct method using SHELXS-97 [22] and successive difference Fourier syntheses. A slightly elevated R value (0.0747) may due to inclusion of poor quality diffraction data which may arise from the X-rays generated from the Cu-Kα radiation source. All non-hydrogen atoms were refined anisotropi-

[b] $wR_2 = [\Sigma w(F_o^2 - F_c^2)/\Sigma wF_o^4]^{1/2}, w = 1/[\sigma^2(F^2) + (0.1461P)^2 + 9.1603P]$.

cally. The hydrogen atoms were fixed geometrically and refined using the riding model. In the final difference Fourier map the residual minima and maxima, −0.237 and 0.418 e/Å^3, were evaluated using SHELXL-97 [23]. Figures were drawn by using the molecular graphics maXus.

3.4. Computational details

All computations were performed using the GAUSSIAN03 (G03) [24] software package running under Windows. The Becke's three-parameter hybrid exchange functional and the Lee-Yang-Parr non-local correlation functional [25] (B3LYP) was used throughout. A lanL2DZ basis set [26] for Pd, 6-31G(d) for C, N, Cl, H atoms and 6-311G* for the I atom were used for all types of calculations. For Pd, N, C, Cl and H atoms we used the basis sets contained in the G03 library, while the 6-311G* basis set for I was downloaded from the EMSL basis set library [27]. Gas and solution-phase geometry optimization was carried out from the geometry obtained from the crystal structure without any symmetry constraints. In all cases, vibrational frequencies were calculated to ensure that optimised geometries represented local minima. The excitation energies were calculated by the TDDFT approach using the same basis sets used in the geometry optimization. To check the effect of salvation on the calculated optical absorption spectra, we performed TDDFT calculations of the low lying excitation at the singlet optimized geometry, including solvation effects by means of the non-equilibrium implementation of the polarizable continuum model (PCM) [28]; as in the experimental conditions, the chosen solvent was acetonitrile.

Acknowledgements

Financial support from All India Council of Technical Education (AICTE), New Delhi is gratefully acknowledged. We thank Dr. A. Mallick, Physical Chemistry Section, Department of Chemistry, Jadavpur University for lifetime measurements. Our sincere thanks are due to Mr. Atish Dipankar Jana, Department of Physics, Jadavpur University for their kind help in the X-ray crystallographic structure drawing.

Appendix A. Supplementary material

CCDC 622525 contains the supplementary crystallographic data for [Pd(β-NaiPy)Cl_2]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.05.049.

systems containing Me_5dien and aminohydroxamic acid (Metha or Hisha) using pH-metric, UV–Vis and EPR methods. The ternary system containing α-Alaha was reinvestigated as the reference which is expected to form similar chelate rings to those with participation of Metha or Hisha; the measurements were made at the same experimental conditions and the data were analyzed analogously.

2. Experimental

2.1. Materials

L-Histidinehydroxamic acid and DL-methioninehydroxamic acid were purchased from Sigma–Aldrich Chemical Co, *N*,*N*,*N*′,*N*″,*N*″-pentamethyldiethylenetriamine from Fluka, L-α-alaninehydroxamic acid was prepared via the methyl ester of α-alanine as described in Ref. [7]. All the chemicals with highest purity (greater than 99%) were used without further purification.

The exact concentrations of the ligand solutions used for potentiometric measurements were determined by the Gran method [8]. Copper(II) chloride solution was purchased from Merck as a Titrisol concentrate for the preparation of standard solutions. The concentration of metal ion stock solution was standardized by complexometric ethylenediaminetetraacetate (EDTA) titration. Carbonate-free KOH solution (the titrant) was prepared and standardized against a standard potassium hydrogen phthalate solution. All solutions were prepared with triply deionized water. The formulae of the fully protonated form of the ligands used in this study are shown in Scheme 1.

Scheme 1.

2.2. Potentiometric measurements

The stability constants of the proton and copper(II) complexes were determined by pH-metric titration of 5 cm^3 samples in aqueous solutions. All the measurements were carried out at 0.2 mol dm^{-3} ionic strength (KCl) and 25.0 ± 0.1 °C using a constant-temperature water-bath. The titrations were performed with carbonate-free KOH solution of known concentration (ca. 0.2 mol dm^{-3}) under argon atmosphere over the pH range 2.0 to ≈11.0. The data for the Cu^{2+}–Me_5dien [4,5,9] and Cu^{2+}-α-Alaha/Metha/Hisha [2,3] binary systems were reported previously but for a comparison we had to determine stability constants under identical conditions to these of ternary systems. For the binary systems the ligand concentration was 4×10^{-3} or 8×10^{-3} mol dm^{-3}. The metal ion to ligand ratios were 1:1, 1:2 or 1:4. The obtained results for Cu^{2+}–Me_5dien and Cu^{2+}–Hisha binary systems are in good agreement with earlier findings and the stability constants obtained for the complexes formed in this system are almost the same. For the Cu^{2+}–α-Alaha/Metha binary systems the only difference is observed, i.e. both dinuclear and pentanuclear species coexist in the equilibrium in the acid region of the solution in place of only the dinuclear one. Our assumption relating to the bonding modes in complexes formed in the binary systems is the same as that published previously.

For the ternary systems the ratios of copper(II):Me_5dien:α-Alaha/Metha/Hisha were 1:1:1, 1:1:2, 1:2:1 and 1:2:2. Titrations were made on samples containing the copper(II) ion at 4×10^{-3} mol dm^{-3}. The values of stability constants of the complexes formed in the binary systems were kept constant during calculating the potentiometric data of the ternary systems.

The pH-metric titrations were performed with a Radelkis Op-208/1 instrument equipped with a combination pH electrode (SINGLE PORE, Hamilton) using an ABU-80 autoburette (Radiometer). The electrode system was calibrated by periodic titrations of HCl solution (1×10^{-2} mol dm^{-3} in KCl) against standard KOH solution. The resulting titration data were used to calculate the standard electrode potentials, $E°$, and the dissociation constant for water ($pK_w = 13.73$). These values were then used to calculate the hydrogen ion concentration $[H^+]$ from emf readings [10]. The pH-metric results were used to establish the stoichiometry of the species and to calculate the stability constants of the species formed $\beta_{prs} = [M_pL_rH_s]/[M]^p[L]^r[H]^s$ and $\beta_{pqrs} = [M_p(Me_5dien)_qL_rH_s]/[M]^p[Me_5dien]^q[L]^r[H]^s$ in the binary and ternary systems, respectively. Calculations were performed with the aid of the HYPERQUAD 2006 computer program [11]. The reported standard deviations were calculated by assuming random errors.

The charges of the complexes have been omitted in the text and tables. However, for clarity, it should be mentioned here that the fully deprotonated form of aminohydroxamic acids (Metha and Hisha) is L^- while the amine (Me_5dien) is neutral.

2.3. UV/Vis spectroscopy

The electronic absorption spectra in the visible range were obtained on a BECKMAN DU68 spectrophotometer using 1-cm quartz cells at room temperature. The spectra were recorded digitally (0.5 nm step) over the range 400–900 nm. The metal ion concentration was 4×10^{-3} mol dm^{-3}. The metal ion to ligand ratios was 1:2 for the binary systems. For the ternary systems copper(II):Me_5dien: Metha/Hisha the concentration ratios were 1:2:1.

Even at the pH value where the distribution of the species has a maximum, the other complexes coexist in a greater or a smaller extent. To extract the net ligand-field absorption band of each mixed-ligand species and calculate their molar absorptivity the procedure as described in Ref. [2] was applied.

2.4. EPR spectroscopy

The measurements of electron paramagnetic resonance (EPR) spectra were performed on a Bruker 300E X-band spectrophotometer equipped with a Bruker NMR gaussmeter ER 035M and a Hewlett–Packard frequency counter HP 5350B at 77 K in water/ethyleneglycol (4:1 v/v) solution. The EPR parameters were calculated by computer simulation of the experimental spectra using Bruker's WIN-EPR SimFonia Software Version 1.25. The metal ion concentration was 4×10^{-3} mol dm^{-3} and the metal ion to ligands molar ratios were the same as those used in the absorption spectra.

3. Results and discussion

The values of the protonation constants for Metha, Hisha and Me_5dien together with the detailed discussion about the acid–base properties of these ligands can be found in our early papers [3,4]. In the wide pH range of 2–11, the fully protonated form of Me_5dien (H_3L^{3+}) is able to release three protons, Metha (H_2L^{+}) – two protons and Hisha (H_3L^{2+}) – three (the third proton from the imidazole nitrogen).

The equilibrium models for ternary systems and relevant stability constants resulting in the best fits of the pH-metric titration curves are presented in Table 1.

The four-component equilibria can be described as:

$$pM + q(Me_5dien) + r(L) + sH \rightleftharpoons M_p(Me_5dien)_q(L)_rH_s$$

where p, q, r and s are the stoichiometric coefficients corresponding to the metal ion M, Me_5dien, L (L = α-Alaha, Metha or Hisha), and H, respectively; charges are omitted.

The overall formation constants are defined as:

$$\beta_{pqrs} = [M_p(Me_5dien)_q(L)_rH_s]/[M]^p[(Me_5dien)]^q[(L)]^r[H]^s$$

The β_{1111}, β_{1110} and $\beta_{212\bar{1}}$ constants express the stability of the $[Cu(Me_5dien)(HL)]^{2+}$, $[Cu(Me_5dien)(L)]^{+}$ and $[Cu_2(Me_5dien)L_2H_{-1}]^{+}$ mixed-ligand species, respectively. Although the β_{1110} constant express the stability of the $[Cu(Me_5dien)(L)]^{+}$ mixed-ligand species, it does not represent directly the binding strength between L and copper(II) ions in the presence of Me_5dien. This effect is much better reflected by the equilibrium constant, $K_{[Cu(Me_5dien)L]^+}$

Table 1
Cumulative formation constants ($\log\beta$) and derived equilibrium constants ($\log K$) for the complexes formed in the ternary systems Cu^{2+}–*N*,*N*′,*N*″,*N*‴-pentamethyldiethylenetriamine (Me_5dien)–L (L = aminohydroxamic acids: α-Alaha, Metha or Hisha) at 25 °C and $I = 0.2$ mol dm^{-3} (KCl)

[a] $\log K_{[Cu(Me_5dien)L]} = \log\beta_{[Cu(Me_5dien)L]} - \log\beta_{[Cu(Me_5dien)]}$; $\log\beta_{[Cu(Me_5dien)]} = 12.47$, $\log\beta_{[Cu(Me_5dien)H-1]} = 3.49$ [4].

calculated according to the equation: $\log K_{[Cu(Me_5dien)L]} = \log \beta_{[Cu(Me_5dien)L]} - \log \beta_{[Cu(Me_5dien)]}$. It shows how tightly L (aminohydroxamic anion) is bound to the simple $[Cu(Me_5dien)]^{2+}$ complex.

The difference in stability between the binary and ternary complexes, $\Delta\log K$ (the constant due to the equilibrium $[MA] + [MB] = [MAB] + M$), is a way to characterize the tendency toward formation of mixed-ligand complexes. The constant for this equilibrium can be calculated from the experimentally measured stability constants according to the equation: $\Delta\log K = \log \beta_{[MAB]} - (\log \beta_{[MA]} + \log \beta_{[MB]})$. The statistical value of $\Delta\log K$ is affected by the geometry of the complex; for the distorted octahedral coordination sphere of Cu^{2+} with two different bidentate ligands was deduced as -0.9 [12,13]. It can be seen that, the $\Delta\log K$ value for the $[Cu(Me_5dien)\alpha\text{-Alaha}]^+$ and $[Cu(Me_5dien)Metha]^+$ species are low (-4.57 and -4.46, respectively). This effect of the mixed-ligand complex is due to the lower (than six) coordination number of Cu^{2+}. For the $[Cu(Me_5dien)Hisha]^+$ mixed-ligand species the $\Delta\log K$ value cannot be calculated, since the complex with 1:1 ratio is not formed in the Cu^{2+}-Hisha binary system (Table 1).

It is noteworthy that the Cu^{2+} mixed-ligand species of diethylenetriamine (dien) with α-Alaha, Metha or Hisha show lower $\log K_{[Cu(dien)L]+}$ values and $\Delta\log K$ parameter, compared with the corresponding systems with Me_5dien.

The formation constants which gave the best fit of the potentiometric data for the Cu^{2+}–Me_5dien–Metha ternary system are collected in Table 1 and the concentration distribution curves for this system are presented in Fig. 1a. It can be seen that when respective molar ratio is 1:2:1, the formation of mixed-ligand species is preceded by the appearance of simple species with Me_5dien and Metha: $[Cu(Me_5dien)]^{2+}$ and $[Cu(Metha)]^+$. The presence of Me_5-dien in the solution does not suppress the formation of the polynuclear species with Metha $[Cu_2(Metha)_2H_{-1}]^+$ and $[Cu_5(Metha)_5H_{-4}]^+$complexes in the pH range 3.5–6. The equilibrium model involves two mixed-ligand species $[Cu_2(Me_5dien)(Metha)_2H_{-1}]^+$ and the minor one – $[Cu(Me_5dien)(Metha)]^+$. Although the concentration of the mononuclear mixed-ligand species is low (~9–10% in the pH range 8.5–9.5 under these experimental conditions), the assumption of this species improves the fit between the experimental and the calculated titration data and furthermore its presence is observed in the EPR spectra (see below). The formation of $[Cu_2(Me_5dien)(Metha)_2H_{-1}]^+$ starts at pH ca. 5 and it is predominant in the solution in the wide pH range 6–11 (the concentration ca. 90%). The complexes $[Cu(Me_5dien)H_{-1}]^+$ and $[Cu(Metha)_2H_{-1}]^-$ exist above pH 10 as a minor products (ca. 5%), so their contribution is negligible (Fig. 1a). The same equilibrium model was obtained for the Cu^{2+}–Me_5-dien–α-Alaha ternary system (Table 1) but the concentration of the mononuclear mixed-ligand species is little higher (~12% in the pH range 8.5–9.5 under the same experimental conditions).

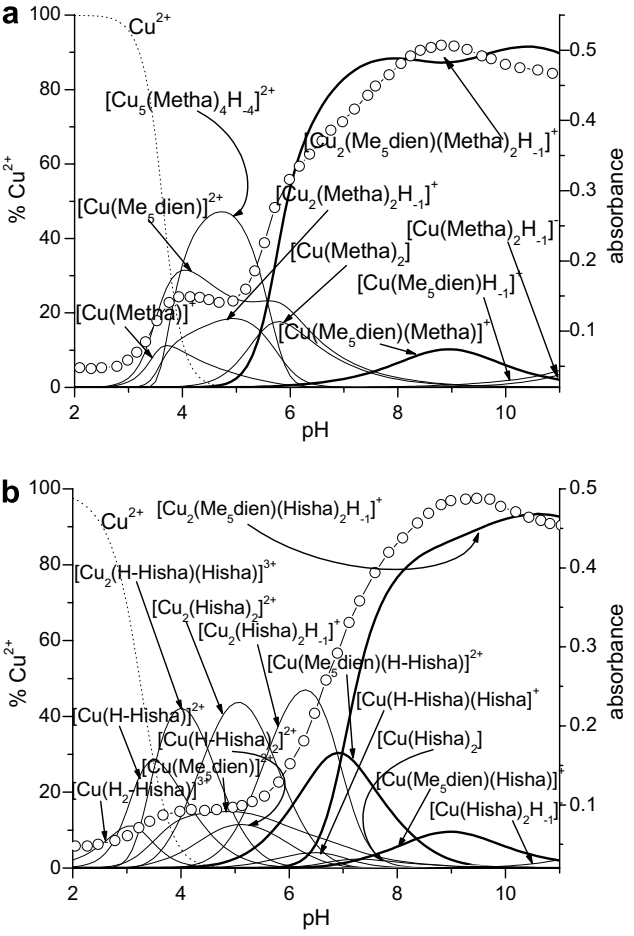

Fig. 1. Species distribution curves as a function of pH and variations of visible absorption $\lambda = 850$ nm (-o-o-) for the Cu^{2+}–Me_5dien–Metha system (a) and Cu^{2+}–Me_5dien–Hisha system (b) at 1:2:1 molar ratio; $c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}.

In order to confirm the calculated equilibrium model and to get information about the geometry of the species formed in the Cu^{2+}–Me_5dien–Metha ternary system the measurements of the EPR spectra were performed and correlated with the species distribution curves. The analysis of the EPR spectra reveals that up to pH 5 the spectra for the Cu^{2+}–Me_5dien–Metha (1:2:1) system are the same as for Cu^{2+} complex with Me_5dien and H_2O molecules (Fig. 2). At pH between 4 and 5, the EPR parameters, $g_z = 2.240$, $g_x = 2.065$, $g_y = 2.050$ and $A_z = 183$, $A_x = 29$, $A_y = 14 \times 10^{-4}$ cm^{-1}, reflect slightly distorted geometry of $[Cu(Me_5$-$dien)]^{2+}$ complex as a result of *N*-methyl groups bulky effect. Above pH 6 the intensity of the spectral lines rapidly decreases. Because total concentration of Cu(II) ions in the solution remains unchanged this effect is most likely associated with their aggregation and with at least a weak Cu(II)–Cu(II) exchange interactions what supports the formation of $[Cu_2(Me_5dien)(Metha)_2H_{-1}]^+$ predicted by potentiometric studies. A disappearance of the EPR signals due to majority of Cu(II) species involved in the polynuclear species allows to observe the spectrum corresponding to the mononuclear $[Cu(Me_5dien)(Metha)]^+$ species which

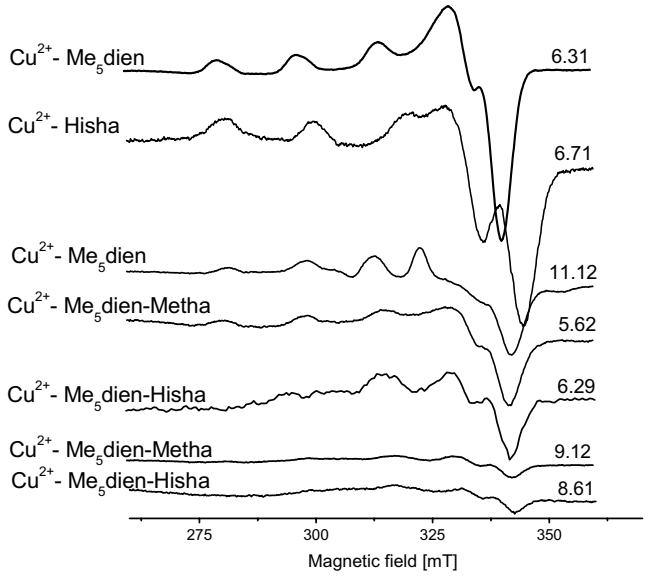

Fig. 2. EPR spectra of Cu^{2+} complexes formed in the Cu^{2+}–Me_5dien–Metha and Cu^{2+}–Me_5dien–Hisha ternary systems as a function of pH. For a comparison, the spectra for Cu^{2+}–Me_5dien and Cu^{2+}–Hisha binary systems are added.

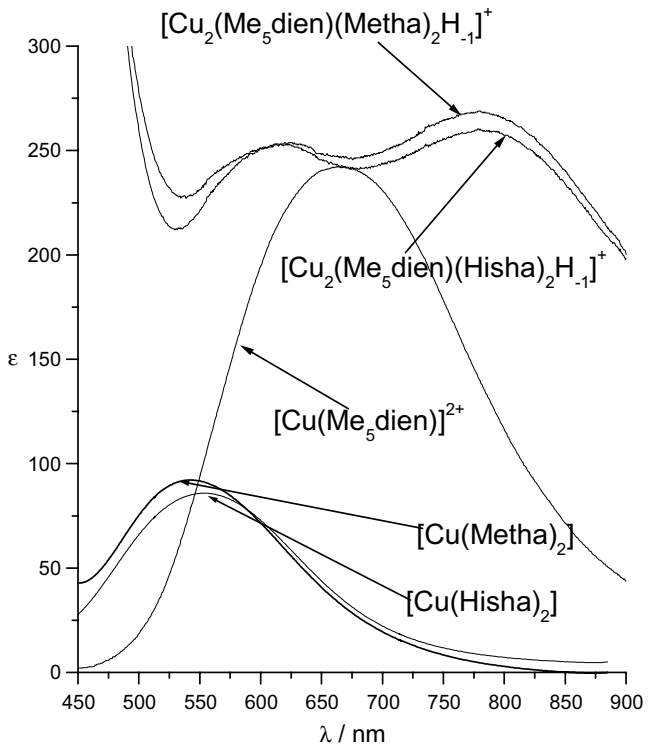

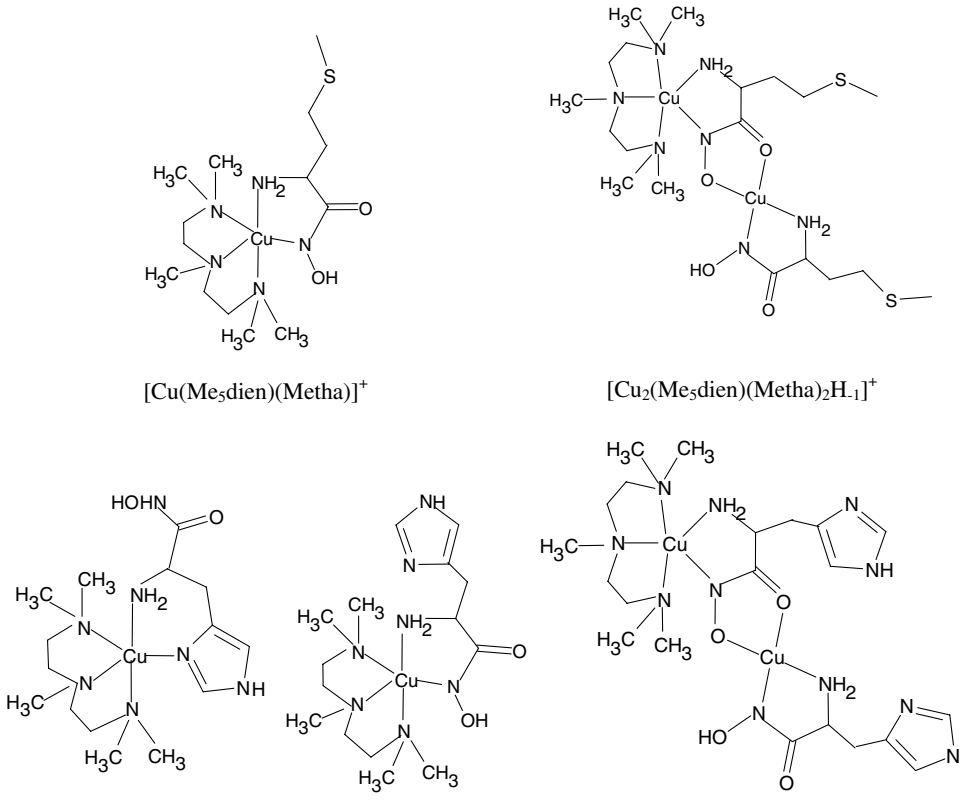

Fig. 3. Distribution-corrected absorption spectra for the $[Cu(Me_5dien)]^{2+}$, $[Cu(Metha)_2]$, $[Cu(Hisha)_2]$, $[Cu_2(Me_5dien)(Metha)_2H_{-1}]^{+}$ and $[Cu_2(Me_5dien)(Hisha)_2H_{-1}]^{+}$ species.

concentration ~10 % is anticipated by potentiometric studies in the pH range 8.5–9.5. The spectral parameters: $g_z \sim 2.23$, $g_x \sim 2.1$, $g_y \sim 2.03$ and $A_z \sim 176$, $A_x \sim 87$, $A_y \sim 17 \times 10^{-4}$ cm^{-1}, suggests that $[Cu(Me_5dien)(Metha)]^{+}$ displays a significant degree of distortion from square-pyramid to trigonal bipyramid [4,5] similarly to that observed for $[Cu(Me_5dien)(\alpha\text{-Alaha})]^{+}$ and close to that for $[Cu(Me_5dien)H_{-1}$ [4]. The spectrum with rhombic parameters is typical for the complex geometry being intermediate between square-pyramidal and trigonal-bipyramidal [4,9,14]. The coordination in the Cu^{2+} plane in this mixed-ligand complex may be realized by three nitrogen atoms of Me_5dien and N_{amino} and $N_{hydroxamate}$ donor atoms of α-Alaha or Metha. Above pH 10 a further decrease of the intensity of the EPR signals is observed and at pH 11.5 only very broad and weak line is seen supporting that the dinuclear species predominates in the solution.

The effect of the mixed-ligand species formation is observed distinctly in the electronic spectral changes (Fig. 4d). The absorption spectra exhibit the intense charge-transfer transition band in the near-UV region (at about 357 nm), which is not observed in the spectra of the $[Cu(Me_5dien)]^{2+}$ and $[Cu(Metha)_2]$ species formed at the analogous pH range of the binary systems (Fig. 3). This CT band can be reasonably assigned to the transition from hydroxamic oxygen to copper(II) (the N^{-}–$O^{-}_{(oxygen)} \rightarrow Cu^{2+}$ CT band is expected at wavelengths ca. 350 nm [15–17]). The presence of N^{-}–$O^{-}_{(oxygen)} \rightarrow Cu^{2+}$ CT band confirms the formation of dinuclear $[Cu_2(Me_5dien)(Metha)_2H_{-1}]^{+}$ species in which hydroxamic oxygens are involved in the copper(II) coordination apart from nitrogen-donor atoms (Scheme 2). The same spectral behaviour was observed in the case of the ternary system with α-Alaha [4]. For the Cu^{2+}–Me_5dien–Metha system in an acid solution the existence of a broad band in the visible region is observed. As the pH of the solution increases, the absorbance in the longer wavelength region is greatly enhanced. These spectral changes correspond well to the formation of the mixed-ligand species (Fig. 1a). From pH 8.6 to 9.7 absorption spectra are very similar, what indicates the predominance of the mixed-ligand complex in this pH range. Furthermore, the absorption spectra exhibit two noticeable maxima at pH 9 with the latter one more intense: at 624 nm ($\varepsilon = 254$ dm^3 mol^{-1} cm^{-1}) and 780 nm ($\varepsilon = 268$ dm^3 mol^{-1} cm^{-1}). This absorption pattern, two peaks with one more intense being near the IR region, suggests the structural change around the Cu^{2+} ion towards five coordinate copper(II) complexes [4,18]. A similar spectral behaviour was observed for five coordinate mixed-ligand species formed in other ternary systems with α-aminohydroxamic ligands and polyamines (dien and Me_5dien) with the involvement of all nitrogen-donor atoms in the coordination sphere [2–4]. This fact can imply that in the coordination to the metal ion in the dinuclear $[Cu_2(Me_5dien)\text{-}(Metha)_2H_{-1}]^{+}$ species formed above pH 6, in the Cu^{2+}–Me_5dien–Metha system three nitrogen atoms of polyamine and two nitrogen atoms of Metha (N_{amino}, $N_{hydroxamate}$) are involved (Scheme 2).

The stability constants obtained for the complexes formed in Cu^{2+}–Me_5dien–Hisha system are given in Table 1. The concentration distribution curves for this system

Scheme 2.

together with the variations of visible absorption at $\lambda = 850$ nm are presented in Fig. 1b. It can be seen, that in this system with 1:2:1 molar ratio, up to pH 5 mainly simple and dinuclear complexes with Hisha ligand are formed: $[Cu(H_2\text{–Hisha})]^{3+}$, $[Cu(H\text{–Hisha})]^{2+}$, $[Cu(H\text{–Hisha})_2]^{2+}$ and $[Cu_2(H\text{–Hisha})(Hisha)]^{3+}$, $[Cu_2(Hisha)_2]^{2+}$, $[Cu_2(Hisha)_2H_{-1}]^{+}$. The EPR parameters of the spectra observed in the pH range 3–3.5 for the Cu^{2+}–Me_5dien–Hisha ternary system (with 1:2:1 molar ratio) of the liquid and frozen solution are very similar to these stated for Cu^{2+}–Hisha binary system. The values of $g_{\|} = 2.250$ and $A_{\|} = 188 \times 10^{-4}$ cm^{-1} EPR parameters confirm the formation of the $[Cu(H\text{–Hisha})]^{2+}$ and $[Cu(H\text{–Hisha})_2]^{2+}$ simple species with the coordination realised through imidazole and amino nitrogens [3]. In contrast to the Cu^{2+}–dien–Hisha ternary system, the presence of Me_5dien instead of dien does not suppress the formation of parent dinclear species of Hisha [3]. In the acid solution of the Cu^{2+}–Me_5dien–Hisha ternary system the $[Cu(Me_5dien)]^{2+}$ simple species exists in the concentration less than 20% showing at pH 5 a weak EPR spectrum with parameters $g_z \sim 2.24$, $g_x \sim 2.07$, $g_y \sim 2.05$ and $A_z \sim 183$, $A_x \sim 29$, $A_y \sim 14 \times 10^{-4}$ cm^{-1}. The $[Cu(H\text{–Hisha})(Hisha)]^{+}$, $[Cu(Hisha)_2]$ and $[Cu(Hisha)_2H_{-1}]^{-}$ species are formed at very low concentration (<5%) and can be regarded as negligible (Fig. 1b).

The equilibrium model for the Cu^{2+}–Me_5dien–Hisha ternary system involves three mixed-ligand complexes: $[Cu(Me_5dien)(H\text{–Hisha})]^{2+}$, $[Cu(Me_5dien)(Hisha)]^{+}$ and dinuclear one $[Cu_2(Me_5dien)(Hisha)_2H_{-1}]^{+}$. Similarly as it was observed in the ternary system with Metha, the $[Cu(Me_5dien)(Hisha)]^{+}$ species is formed as a minor one and the maximum concentration of this species is about 9.5% at pH ~9. The first mixed-ligand species, $[Cu(Me_5dien)(H\text{–Hisha})]^{2+}$, starts to form above pH 5.5 and reaches a maximum concentration (ca. 30%) at about pH 7 (Fig. 1b). Generally, a possible mode of coordination of Hisha in the mixed-ligand species is the formation of six-membered chelate ring (N_{im}, NH_2) or five-membered chelate ring (N_{ha}, NH_2) in the plane. The $pK_{[Cu(Me_5dien)(H\text{-}Hisha)]^{2+}}$ value equal to 8.37 (Table 1), characteristic of the deprotonation step for this mixed-ligand complex is lower than the deprotonation constant of the hydroxamic group in the free ligand. Thus, it can be assigned to the deprotonation of the hydroxamic group promoted by the copper(II) binding.

The EPR spectra observed within pH range 6.7–7.4 that are ascribed to this mixed-ligand species display parameters of rhombic character reflecting a distorted geometry of $[Cu(Me_5dien)(H\text{–Hisha})]^{2+}$. A significant decrease of A_z as well as the spectrum corresponding to three different val-

ues of g and A parameters reveal the formation of the five-coordinate type of the complex ($g_z \sim 2.22$, $g_x \sim 2.08$, $g_y \sim 2.02$ and $A_z \sim 173$, $A_x \sim 50$, $A_y \sim 15 \times 10^{-4}\,cm^{-1}$) [3]. In the pH range 8–10 the weak EPR signals which may be assigned to the spectrum of mononuclear deprotonated mixed-ligand species $[Cu(Me_5dien)(Hisha)]^+$ (Fig. 2). The spectrum of $[Cu(Me_5dien)(Hisha)]^+$ with contribution about 10% may be observed because it accompanies the dinuclear species which is practically EPR not-detectable. The parameters $g_z \sim 2.22$, $g_x \sim 2.10$, $g_y \sim 2.02$ and $A_z \sim 165$, $A_x \sim 81$, $A_y \sim 19 \times 10^{-4}\,cm^{-1}$ indicate stronger rhombic distortion than for the former mixed-ligand species, $[Cu(Me_5dien)(H–Hisha)]^{2+}$. This EPR spectral difference between both mixed-ligand species may be assigned to the dissimilar chelate rings formed by Hisha ligand – a five-membered ring for deprotonated species and a six-membered ring for the protonated one (Scheme 2). The same effect was observed in the case of the mixed-ligand species of α-Alaha (five-membered chelate ring) and β-Alaha (six-membered chelate ring) with Me_5dien. In the case of the former one the stronger rhombic distortion was detected [4].

Additional evidence for the presence of mixed-ligand species provide absorption spectral data (Fig. 4a). Similarly as it was observed in the ternary system with Metha, in the Cu^{2+}–Me_5dien–Hisha system the CT transition band from hydroxamic oxygen to copper(II) is present in the near-UV region of the absorption spectra recorded at the basic solution. This corresponds to the formation of the dinuclear mixed-ligand species, $[Cu_2(Me_5dien)(Hisha)_2H_{-1}]^+$. Furthermore, a comparison between the species distribution curves (Fig. 1b) and the pH-dependent curves of the absorption (Fig. 4a) clearly indicates that the spectral changes in the visible region are attributable to the formation of the mixed-ligand species. The absorption curve at pH 9, exhibits two peaks at 625 ($\varepsilon = 250\,dm^3\,mol^{-1}\,cm^{-1}$) and 786 nm ($\varepsilon = 256\,dm^3\,mol^{-1}\,cm^{-1}$) (the latter one is more intense) as it was observed for the mixed-ligand complex in the system with Metha. This spectral characteristic strongly supports the formation of a five-coordinated mixed-ligand species with 5N in the coordination sphere in the Cu^{2+}–Me_5dien–Hisha system (Fig. 3, Scheme 2).

It is very interesting to compare the relative stabilities of the complexes formed in the ternary systems with hydroxamic acids with those of amino acids (Table 2). The order of decreasing stability ($\log K_{Cu(Me_5dien)L} - pK_{NH_3^+} - pK_{COOH}$, when L = aminoacid or $\log K_{Cu(Me_5dien)L} - pK_{NH_3^+} - pK_{CONHOH}$, when L = aminohydroxamic acid)

is: $[Cu(Me_5dien)(Met)]^+ \approx [Cu(Me_5dien)(\alpha\text{-Ala})]^+ > [Cu(Me_5dien)(\alpha\text{-Alaha})]^+ \approx [Cu(Me_5dien)(Hisha)]^+ \approx [Cu(Me_5dien)(Metha)]^+ > [Cu(Me_5dien)(\beta\text{-Ala})]^+ \approx [Cu(Me_5dien)(His)]^+ > [Cu(Me_5dien)(\beta\text{-Alaha})]^+$ which corresponds to the existence of $(N,O) \approx (N,O) > (N,N) \approx (N,N) \approx (N,N) > (N,O) \approx (N,N_{im}) > (N,N)$ chelate donors of the ligands L consequently relevant to (5) ≈ (5) > (5) ≈ (5) ≈ (5) > (6) ≈ (6) > (6) chelate rings of these ligands.

This order reflects the dependence between the type of the chelate rings formed by L and the stability of the five-coordinated mixed-ligand [Cu(Me_5dien)L] species. The stability is favoured for the complexes with L forming involving the mixed-bonding mode (N,O) and five-membered chelate rings over that for the complexes with pure type of donors (N,N) and the same type of chelate rings. Furthermore, the complexes containing only five-membered rings are favoured over systems with the five- and six-membered rings.

However, in the case of dien the mixed-bonding mode (N,O) seems to be more important factor and the complexes involving that kind of six-membered ring are even more stable than those with five-membered rings and pure type of donors.

The order of decreasing stability ($\log K_{Cu(dien)L} - pK_{NH_3^+} - pK_{COOH}$, when L = aminoacid or $\log K_{Cu(dien)L} - pK_{NH_3^+} - pK_{CONHOH}$, when L = aminohydroxamic acid) is: $[Cu(dien)(Met)]^+ \approx [Cu(dien)(\alpha\text{-Ala})]^+ > [Cu(dien)(\beta\text{-Ala})]^+ \approx [Cu(dien)(His)]^+ > [Cu(dien)(Hisha)]^+ \approx [Cu(dien)(Metha)]^+ \approx [Cu(dien)(\alpha\text{-Alaha})]^+ > [Cu(dien)(\beta\text{-Alaha})]^+$ which corresponds to the existence: $(N,O) \approx (N,O) > (N,O) \approx (N,N_{im}) > (N,N) \approx (N,N) \approx (N,N) > (N,N)$ chelate donors of the ligands L and (5) ≈ (5) > (6) ≈ (6) > (5) ≈ (5) ≈ (5) > (6) chelate rings of these ligands.

4. Conclusion

The presence of Me_5dien in the Cu^{2+}–Me_5dien–Metha/Hisha ternary systems does not suppress the formation of parent polynuclear species. Furthermore, for the first time it could be observed that in these ternary systems the dinuclear mixed-ligand species is formed as a predominant one in the basic solution. The mononuclear mixed-ligand species $[Cu(Me_5dien)L]^+$ which are usually formed in the ternary systems with aminohydroxamic acids and polyamines, in these ternary systems are formed in remarkably lower concentrations. Our spectroscopic data show that the geometry of these mixed-ligand five-coordination complexes is strongly distorted towards trigonal-bipyramid probably because of the steric effects caused by Me_5dien. The analogous five-coordinate species formed in the ternary systems with dien have a geometry in smaller degree deviated from square-pyramidal [3]. In the case of ternary systems with bidentate amine – ethylenediamine (en), in the mononuclear mixed-ligand species $[Cu(en)(Metha)]^+$ and $[Cu(en)(Hisha)]^+$ that are formed in basic solution both amine and hydroxamic nitrogens of Metha/Hisha and two amine nitrogens of en are coordinated in the copper(II) plane [4,6].

The increasing geometry distortion of the complexes formed in the Cu^{2+}–Me_5dien–L ternary system (L = aminoxydroxamic acid) in comparison to those formed in the Cu^{2+}–dien–L ternary system results in the higher relative stability of the mixed-ligand species with Me_5dien than those with dien ($\log K_{Cu(Me_5dien)L} - pK_{NH_3^+} - pK_{CONHOH} > \log K_{Cu(dien)L} - pK_{NH_3^+} - pK_{CONHOH}$). The same tendency can be observed for the ternary systems in which ligand L is replaced by an amino acid such as α-alanine and methionine, except of the systems with histidine and β-alanine.

Acknowledgments

We express our gratitude to Ms. Jadwiga Kędzierska for her technical assistance in the EPR measurements.

In the field of preparative coordination chemistry, hexacyanometallate ions are commonly employed with additional metal ions. Complex moieties are selected to obtain desirable hybrid functional Prussian Blue like complexes by self-assembling bottom-up processes. It has been shown that the reaction of $[M(SB)]^{n+}$ (SB = the salen-substituted chelating ligand) with hexacyanometallates leads to a variety of topologies depending on (i) the steric accessibility of the metal centre in $[M(SB)]^{n+}$, (ii) the total charge of the cationic precursor, (iii) the lability of the coordination sites, (iv) the steric hindrance of the Schiff base ligand and (v) the geometry of the cyanometallate tecton [4]. By introducing terminal blocking ligands, a number of heteroleptic complexes of lower symmetry have been reported. The range includes dimers [5], clusters [6], molecular squares [7], linear chains [8], ladders [9], two-dimensional honeycomb [10] and square grid [11] topologies as well as three-dimensional networks [12] exhibiting interesting electrochemical and zeolitic properties [1b,1c,12,13].

In particular, some cyano-bridged compounds exhibit spontaneous magnetism at significantly higher temperatures [1b,1c,12] and ambient temperature [1b,1c,2,14–18]. Moreover, Prussian Blue is ferromagnetic with $T_C = 5.6$ K [5]. Considering that the magnetic interactions are caused by diamagnetic $[Fe(CN)_6]^{4-}$ or $[Co(CN)_6]^{3-}$ anions, it is useful to investigate the magnetic properties of polynuclear μ-cyanido complexes derived from hexacyanoferrate(II) or hexacyanocobaltate(III). Since copper(II) is normally four-, five- or six-coordinate, it was anticipated that the coupling of a copper(II) amine to the $[Fe(CN)_6]^{4-}$ ion might lead to the formation of a novel family of magnetic compounds with potential control over the structure of the compound.

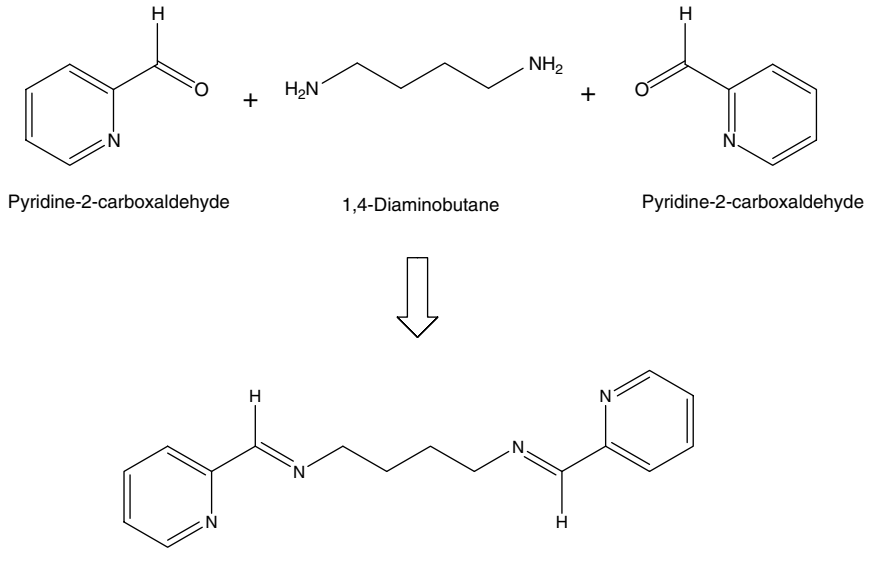
We have focused our interest on a series of polycyano copper(II) complexes that have been reported [19–28]. In this context, our group has already reported the synthesis of two new heterobimetallic cyano-bridged systems obtained from the reaction of monocationic Schiff base complexes of divalent and trivalent metal ions like Cu(II), Ca(II), Sr(II), Ba(II) and Y(III) with hexacyanometallates [29,30]. In a continuation of the earlier works, the present work is devoted to the study in some details of the crystal structure and the magnetic properties of two new trinuclear heterobimetallic compounds [(Cu L)-$[Co(CN)_6]$(CuL)]$ClO_4 \cdot 3.5H_2O$ (**1**) and [(CuL)$[Fe(CN)_6]$(CuL)] $\cdot 13H_2O$ (**2**) where [L = (3*E*,5*E*)-N^1,N^4-bis ((pyridin-2-yl)methylene) butane-1,4-diamine], using $[Co(CN)_6]^{3-}$ and $[Fe(CN)_6]^{4-}$ as template anions. The present work incorporates a study of the magneto-structural correlation for heterometallic cyano-bridged copper(II) Schiff base complexes. It is also noteworthy that the steric demand of the Schiff base ligand apparently directs the self-assembly of building blocks towards the exclusive formation of a crystallographically characterized non-racemic cyano-bridged Cu–Co mixed-metallic (two different species in the same unit) complex unlike those found in our previous investigation. The versatile nature of the metallo-salen building block to form bimetallic complexes of structural diversity has been proven in this report. Here the formation of a non-racemic Cu–Co cyano bridged complex is a function of the steric nature of the Schiff base ligand of the cation. In complex **1** the steric demand of the methyl groups of the Schiff base molecule perhaps directs the formation of the non-racemic cyano-bridged Cu–Co mixed-metallic complex, unlike in $[C_{38}H_{38}CoCu_2N_{14}O]\,[C_{22}H_{18}CoCuN_{10}] \cdot 7H_2O$.

2. Experimental

2.1. Materials

All the chemicals and solvents used for the syntheses were of analytical grade. Pyridine-2-carboxaldehyde; 1,4-diaminobutane, $K_3[Co(CN)_6]$ and $K_4[Fe(CN)_6]$ were all purchased from Aldrich Chemical Co. Inc. and were used without further purification. Copper(II) perchlorate hexahydrate, $Cu(ClO_4)_2 \cdot 6H_2O$, was prepared by treatment of basic copper(II) carbonate, $CuCO_3 \cdot Cu(OH)_2$ (E. Merck, India) with 60% perchloric acid (E. Merck, India) followed by slow evaporation. It was then filtered through a fine glass-frit and preserved in a $CaCl_2$ desiccator for further use.

2.2. Syntheses



Caution! Although no problems were encountered in this work, perchlorate salts in the presence of organic ligands are potentially explosive in nature. They should be prepared in small quantities and handled with care.

2.2.1. Synthesis of the Schiff base ligand $[NC_5H_4C{=}N(CH_2)_4N{=}CNC_5H_4]$ (**L**)

The Schiff base ligand [(3*E*,5*E*)-N^1,N^4-bis((pyridin-2-yl)methylene)butane-1,4-diamine], **L** ($C_{18}H_{22}N_4$) was prepared by the condensation of a methanolic solution of pyridine-2-carboxaldehyde with 1,4-diaminobutane (2:1 mmol ratio) after refluxing for half an hour according to the literature procedure [15] (Scheme 1).

2.2.2. Synthesis of the complexes: $[(CuL)[Co(CN)_6](CuL)]ClO_4 \cdot 3.5H_2O$ (**1**) and $[(CuL)[Fe(CN)_6](CuL)] \cdot 13H_2O$ (**2**)

$Cu(ClO_4)_2 \cdot 6H_2O$ (1.05 g, 3 mmol) in 10 cm^3 methanol was added drop by drop to a vigorously stirred 20 cm^3 methanolic solution of the ligand, $[NC_5H_4CH{=}N{-}(CH_2)_4{-}N{=}CHC_5H_4N]$, (**L**) (4 mmol). A greenish precipitate appea- red. It was then dissolved on addition of methylene chloride drop by drop, avoiding excess. Hexacyanometallate compounds are very sensitive to heating and sunlight. So after filtration, the solution was cooled to 0 °C in ice bath followed by the slow addition of an aqueous solution (15 ml) of $K_3[Co(CN)_6]$ (0.33 g, 1 mmol) for complex **1** and the resulting solution was kept in a dark place. Blue plate shaped crystals for **1** suitable for X-ray analysis appeared after one day and were collected by filtration, washed with a minimum volume of ethanol and dried in air. *Anal.* Calc. for $C_{42}H_{51}ClCoCu_2N_{14}O_{7.50}$: C, 46.13; H, 4.70; N, 17.93. Found: C, 46.15; H, 4.72; N, 17.94%.

Scheme 1. Synthetic route to ligand **L**.

Green prism shaped crystals of complex **2** were prepared in the same way as that of complex **1** by using $K_4[Fe(CN)_6]$ (332 mg, 1 mmol) instead of $K_3[Co(CN)_6]$. *Anal.* Calc. for $C_{42}H_{70}Cu_2FeN_{14}O_{13}$: C, 43.41; H, 6.07; N, 16.88. Found: C, 43.42; H, 6.05; N, 16.90%.

2.3. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin–Elmer 2400 CHN Elemental Analyser. The Fourier Transform infrared spectra were recorded on a Perkin–Elmer RXI FT-IR spectrophotometer in the range 4000–400 cm^{-1} with a KBr disc and electronic spectra on a Perkin–Elmer Lambda-40 spectrophotometer using HPLC grade acetonitrile as the solvent at 300 K in 1 cm quartz cuvettes.

Magnetic susceptibility measurements for the compounds were carried out on polycrystalline samples at the Servei de Magnetoquímica of the Universitat de Barcelona, with a Quantum Design SQUID MPMS-XL susceptometer apparatus working in the range 2–300 K under a magnetic field of approximately 10,000 G. Diamagnetic corrections were estimated from Pascal's Tables.

2.4. X-ray crystallographic data collection and structure refinements

A good diffraction quality air stable single crystal of **1** (dimensions $0.40 \times 0.25 \times 0.03$ mm) and **2** (dimensions $0.18 \times 0.13 \times 0.08$ mm) was selected and mounted in a Nonius KappaCCD diffractometer equipped with graphite monochromated Mo-$K\alpha$ radiation ($\lambda = 0.71073$ Å). Crystal data were collected using COLLECT [31] at a temperature of 123 K. The unit cell parameters were determined from the least-squares refinement of 25 centered reflections in the range 1.75–23.15° for **1** and 1.97–25.61° for **2** using φ and ω scans. Cell refinements were carried out using DENZO-SMN for **1** and HKL SCALEPACK for **2** [32]. No significant intensity variation was observed. A total of 14,627 reflections (6524 unique reflections, $R_{int} = 0.0539$) for **1** and 13,422 reflections (4898 unique reflections, $R_{int} = 0.0310$) for **2** were collected applying the boundary condition $I \geqslant 2\sigma(I)$. Absorption correction was applied to intensity values ($T_{max} = 1.0$, $T_{min} = 0.568$ for **1** and $T_{max} = 1.0$, $T_{min} = 0.817$ for **2**) empirically using SADABS [33]. Data reduction was carried out using DENZO-SMN for **1** while HKL DENZO and SCALEPACK were used for **2**. The final structures were solved by direct methods using the program SHELXS-97 [34] and refined with full-matrix least-squares based on F^2 using SHELXL-97 [34]. The molecular graphics and crystallographic illustrations were prepared using the ORTEP-III [35] and XSEED [36] programs for **1** and **2**, respectively. For all non-hydrogen atoms, the anisotropic displacement parameters have been refined. Hydrogen atoms of the aromatic rings and the imino groups were placed geometrically and refined using the riding model taken from a difference Fourier map and refined with isotropic thermal parameters. Maximum and minimum peaks (e $Å^{-3}$) in the final difference Fourier synthesis were 1.172 and −0.665 for **1** and 0.71, −0.43 for **2**. Selected crystallographic data and structure refinement parameters are summarised in Table 1.

3. Results and discussion

3.1. Infrared spectra

The IR spectra of complexes **1** and **2** are consistent with the structural data presented in this paper. A broad absorption band for the ν_{str}(O–H) appears at 3400 cm^{-1} for both complexes, indicating the presence of water molecules in the crystals. The sharp bands at 1628 and 1635 cm^{-1} for complexes **1** and **2**, respectively, indicate the δ(H–O–H) mode. Again sharp bands at 418 and 421 cm^{-1} for complex **1** and **2**, respectively, may be assigned to $\rho_w(H_2O)$. The presence of $\rho_r(H_2O)$ can be correlated to the bands at 747 and 788 cm^{-1} for complex **1** and at 775 and 788 cm^{-1} for complex **2**. These results show the presence of both coordinated and lattice water molecules [26]. Two main band systems of comparable intensities are observed in the crystal lattices for the ν(C≡N) mode of $[M(CN)_6]^{3-}$. The low intensity bands at 2045 cm^{-1} for **1** and 2130 cm^{-1} for **2** are assigned to inter-metallic bridging C≡N stretching and the high intensity band that appears around 2076 cm^{-1} for **1** and 2166 cm^{-1} for **2** can be correlated to the non-bridging terminal C≡N stretching mode. In complex **1** a strong band near 1016–1104 cm^{-1} and a sharp band at 590–624 cm^{-1} indicate the presence of the uncoordinated perchlorate anion [26]. All the other peaks appear at their usual positions, except for a slight difference between the complexes due to the absence of the perchlorate anion in complex **2**.

3.2. UV/Vis spectra

Although the electronic spectra of copper complexes with multidentate Schiff base ligands are not in general good indicators of geometry, they can help to support it. The electronic spectra of complexes in acetonitrile solution show two strong absorption bands in the region 225, 276 and 235, 279 nm for **1** and **2**, respectively. They can be assigned to the high intensity charge transfer bands [25]. The bands in the region 464–337 nm can be correlated to the n–π^* transition of the azomethine group. The absorption bands observed at 380 and 388 nm for complexes **1** and **2**, respectively, can be attributed to the ligand to Cu(II) charge transfer transition (LMCT) [26,27]. The very weak low-intensity absorption bands at 670, 675 and 676 nm are assigned to Cu(II) d–d transitions [26–29] for **1** and **2**, and support the five coordinated geometry around the copper(II) ions with the CuN_5 chromophore.

3.3. Crystal structures of the complexes

The crystal structure with atom numbering scheme and important bond lengths and angles of **1** are presented in Fig. 1 and Table 2, respectively, while those of **2** are presented in Fig. 4 and Table 4, respectively.

3.3.1. $[(Cu(C_{18}H_{22}N_4))_2Co(CN)_6]ClO_4 \cdot 3.5H_2O$ (1)

The asymmetric unit of **1** contains one trinuclear Cu_2Co unit, one perchlorate counter ion and four lattice water molecules, out of which O(8) was refined at half occupancy. The trinuclear monocation (Fig. 2) contains two chemically similar but crystallographically unique $(CuL)^{2+}$ moieties bridged in a *trans*-fashion by a $Co^{III}(CN)_6^{3-}$ moiety. All the copper atoms are pentacoordinated. The coordination number five for copper(II) is very common and it possesses either a square pyramidal (SP) or a trigonal bipyramidal (TBP) geometry. Recently some complexes have been reported in which the copper(II) ion adopts a geometry intermediate between SP and TBP configurations [28,29]. In order to ascertain a more precise geometry of the metal environment, several parameters are used to quantify the distortion. One of them is the so called tetragonality, T^5, defined as the ratio between the mean in-plane Cu–L bond distance and the out of the plane Cu–L bond distance [37a]. The percentage of trigonal distortion from SP geometry is described by the structural index parameter or Addison parameter, τ, defined as $\tau = [(\theta - \Phi)/60] \times 100$, where θ and Φ are the two largest coordination angles; $\tau = 0$ for perfect square pyramidal and 100 for ideal trigonal bipyramidal geometry [37b]. For complex **1** the Cu(1) ion adopts a distorted trigonal bipyramidal arrangement, having a τ value of 59, with the three nitrogen atoms N(1), N(109) and N(122) in the equatorial plane and the other two

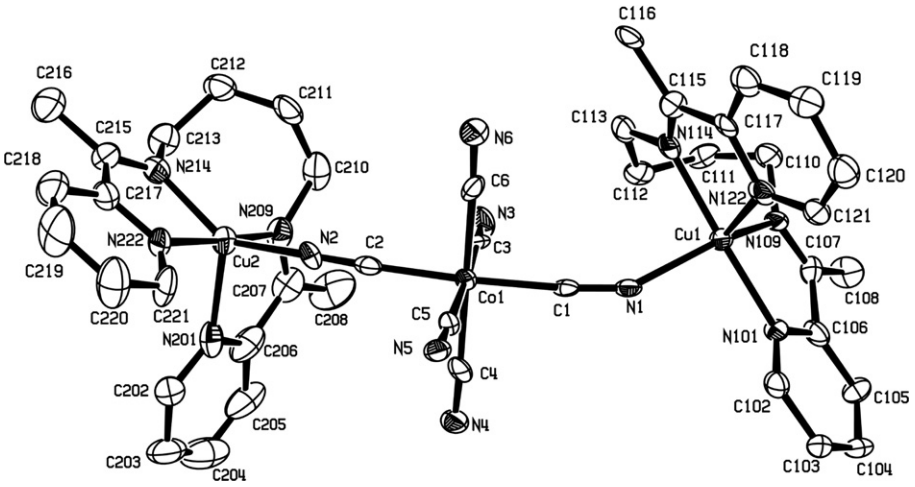

Fig. 1. The trinuclear monocation in the structure of **1** (Hydrogen atoms have been omitted for clarity; Ellipsoids are drawn at the 40% probability level.).

Table 2
Selected bond lengths and bond angles for **1**

Bond lengths	(Å)	Bond angles	(°)
Co(1)–C(1)	1.886(12)	C(2)–Co(1)–C(1)	175.4(5)
Co(1)–C(2)	1.885(13)	C(2)–Co(1)–C(3)	86.0(5)
Co(1)–C(3)	1.895(13)	C(3)–Co(1)–C(5)	177.0(5)
Co(1)–C(4)	1.913(13)	C(6)–Co(1)–C(4)	178.3(5)
Co(1)–C(5)	1.913(12)	C(5)–Co(1)–C(4)	89.9(5)
Co(1)–C(6)	1.899(12)	N(109)–Cu(1)–N(101)	80.3(4)
Cu(1)–N(1)	2.039(9)	N(109)–Cu(1)–N(114)	95.2(4)
Cu(1)–N(101)	2.006(9)	N(101)–Cu(1)–N(114)	175.5(4)
Cu(1)–N(109)	1.998(9)	N(109)–Cu(1)–N(1)	139.7(4)
Cu(1)–N(114)	2.013(9)	N(101)–Cu(1)–N(1)	94.1(3)
Cu(1)–N(122)	2.107(10)	N(114)–Cu(1)–N(1)	89.0(3)
Cu(2)–N(2)	2.008(10)	N(109)–Cu(1)–N(122)	116.3(4)
Cu(2)–N(201)	2.137(11)	N(101)–Cu(1)–N(122)	102.3(4)
Cu(2)–N(209)	1.976(10)	N(114)–Cu(1)–N(122)	80.1(4)
Cu(2)–N(214)	1.988(10)	N(1)–Cu(1)–N(122)	104.0(4)
Cu(2)–N(222)	1.984(10)	N(209)–Cu(2)–N(222)	175.4(2)

nitrogen atoms, N(101) and N(114), in the axial plane. The distortion from the ideal trigonal bipyramidal geometry is evident from the fact that the axial N(101)–Cu(1)–N(114) angle of 175.5(4)° is significantly bent from linearity and the equatorial angles vary from 104.0(4)° to 139.7(4)°. The equatorial Cu(1)–N distances fall in the range 1.998(9)–2.107(10) Å, while the mean axial Cu(1)–N distance is 2.009 Å. Similarly the Cu(2) atom, with a τ value of 54.5, can also be better described as having a distorted trigonal bipyramidal geometry with the three nitrogen atoms N(2), N(201) and N(214) in the equatorial plane and the other two nitrogen atoms, N(209) and N(222), in the axial plane.

Each hexacyanocobaltate(III) anion has the usual expected hexacoordinated octahedral geometry with slight distortions and coordinates to two adjacent $(CuL)^{2+}$ cations through two *trans*-cyano nitrogens, N(1) and N(2).

* Symmetry operations: $1-x, -y, -z$.

Distortion in the geometry is indicated by the variation of the *cis*-angles [86.0(5)–93.7(5)°] and *trans*-angles [175.4(5)–178.3(5)°] from the ideal values of 90° and 180°, respectively. The Co–C and C≡N distances are grouped together in narrow ranges, 1.885(13)–1.913(12) Å and 1.120(17)–1.164(15) Å, respectively. The Cu–N≡C bond angles range from 149.5(9)° to 163.9(10)°, i.e., the bridging –CN– ligands coordinate to the Cu(II) ions in a bent fashion, whereas the Co–C–N bonds are almost linear, as indicated by the angles of 174.5(11)–178.4(9)°. The shortest distances between the nearest metal centers are 4.875 Å for Co(1)···Cu(1) and 4.974 Å for Co(1)···Cu(2).

Hydrogen bonding and van der Waals cohesive forces are important in the intermolecular network of the crystal lattices of this type of compound. The molecular units in the crystal system are separated by normal van der Waals contacts. Three of the four uncoordinated nitrile nitrogen atoms from the hexacyanocobaltate moiety form hydrogen bonds to the intercalated water molecules (Table 3). The water molecules also have hydrogen bonding interactions between themselves and to the perchlorate anions, generating 2D sheets (Fig. 2). The sheets pack in an interdigitated fashion (Fig. 3), with a number of other weaker C–H···O, C–H···N interactions between the molecules.

3.3.2. *[(Cu(C$_{18}$H$_{22}$N$_4$))$_2$ Fe(CN)$_6$] · 13H$_2$O (**2**)*

The asymmetric unit of [*trans*-Fe(CN)$_4$(CNCuL)$_2$] · 3 H$_2$O contains half of a trinuclear molecule (the central Fe atom lies on an inversion centre) and seven lattice water molecules, of which O(7) is disordered over two symmetry related positions and refined at half occupancy. The trinuclear complex (Fig. 4) contains two symmetric $(CuL)^{2+}$ moieties bridged with a *trans*-$[Fe^{II}(CN)_6]^{4-}$ moiety. The local coordination of both the two copper(II) ions is the same, resembling a distorted trigonal bipyramidal geometry as indicated by the τ value of 50.5. The basal plane is formed by the N(5) and N(7) atoms of the Schiff base and the N(1) atom of the bridging cyanide, while the axial sites are occupied by the N(4) and N(6) atoms of the Schiff base [N(4)–Cu–N(6) = 171.86(10)°]. The Cu center is very slightly displaced out of the basal plane by 0.001(2) Å towards N(4). The bond distances around the copper atom are very similar to those already reported [38], the Cu–N distances ranging from 1.956(2) to 2.135(3) Å. Each cyanometallate group links the adjacent copper ions giving a one-dimensional compound. The iron(II) ion in this species is also octahedral, with Fe–C and C–N distances ranging from 1.901(3) to 1.923(3) and 1.155(4) to 1.160(4) Å, and the Cu–N(1)–C(1) bond angle is 173.0(3)°, close to values in the literature [38]. The Fe–C(1)–N(1) angle deviates slightly from linearity, 178.4(3)°.

The water molecules undergo hydrogen bonding interactions to create 2D sheets containing large windows (Table 5; Fig. 5). The complexes lie within the windows, with the uncoordinated nitrile ligands hydrogen bonded to the surrounding water molecules. The layers stack in an interdigitated fashion, as shown in Fig. 6, but there are no significant interlayer interactions.

3.4. Variable temperature magnetic susceptibility studies

Due to the diamagnetic nature of the $[Co^{III}(CN)_6]^{3-}$ and $[Fe^{II}(CN)_6]^{4-}$ anions, the paramagnetism of the prepared [Cu$_2$Co] and [Cu$_2$Fe] complexes is caused by the copper(II) atoms. The temperature dependence of $\chi_M T$ (χ_M = molar magnetic susceptibility) of complexes **1** and **2** per [Cu$_2$Co] and [Cu$_2$Fe] unit, respectively, is shown in Fig. 7. The values of $\chi_M T$ at 300 K are 0.8408 cm^3 mol^{-1} K for **1** and 0.8612 cm^3 mol^{-1} K for **2**, as expected for two isolated copper(II) ions ($S = 1/2$) with diamagnetic cobalt(III) or iron(II) ions ($S = 0$) (0.826 cm^3 mol^{-1} K per two Cu(II) with $g = 2.1$). With decreasing temperature, the $\chi_M T$ value in the two cases remains almost constant until 12 K and then it decreases sharply, giving a minimum value of 0.704 cm^3 mol^{-1} K for **1** and 0.730 cm^3 mol^{-1} K for **2** at very low temperature (2 K). We attempted to reproduce theoretically the experimental susceptibility by using the Bleaney–Bowers expression for an isotropically coupled pair of $S = 1/2$ ions, [Eq. (1)], where N is Avogadro's

number, μ_B is the Bohr magneton and K is the Boltzmann constant. The best fit parameters, as shown in Fig. 7, are $J=-0.81\ \mathrm{cm}^{-1}$ and $g=2.12$ with $R=2.7\times10^{-5}$ for **1**, and $J=-0.73\ \mathrm{cm}^{-1}$ and $g=2.14$ with $R=3.3\times10^{-5}$ for **2**. $R=\Sigma_i(\chi T_{i\mathrm{calc}}-\chi\ T_{i\mathrm{exp}})^2/(\chi T_{i\mathrm{exp}})^2$

$$\chi_M=\frac{Ng^2\mu_B^2}{KT}\frac{2\exp(J/KT)}{1+3\exp(J/KT)} \quad (1)$$

The field dependence of the magnetization (0–5 T) measured at 2 K is shown in Fig. 7 (inset), in the form of $M/N\beta$ (per Cu_2Co and Cu_2Fe units) vs H. The magnetization reaches a value of 1.9 $N\beta$ for **1** and 1.99 $N\beta$ for **2** at 5 T, which

is close to the expected $S = 1/2$ value of two isolated Cu(II) atoms.

The two complexes show a very weak coupling, as may be expected from the diamagnetic –NC–Co–CN– and –NC–Fe–CN– bridges. The weak magnetic exchange can be understood considering the large copper–copper distance.

4. Conclusion

We have described the synthesis, spectroscopic, structural and magnetic characterization of two trimetallic complexes containing divalent and distorted trigonal bipyramidal $[Cu(C_{18}H_{22}N_4)]^{2+}$ cation centers with slightly distorted octahedral hexacyanometallate ion. The assembly of the two components is achieved through the bridging mode of the CN^- ligand and is also due to the coordination properties of the copper ion. Interestingly, weak antiferromagnetic interactions, resulting from intermolecular interactions between the Cu(II) ions in the network, were observed for both **1** and **2** below 2 K. It can be proposed that the cooperativity arising from the network structure through hydrogen bonds plays an important role in molecular magnetization for this series of compounds.

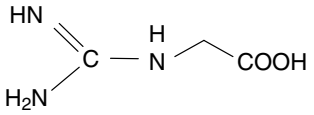

Fig. 1. Structure of guanidinoacetic acid.

extrapyramidal movements, epilepsy, as well as autistic or self-aggressive behavior in older patients [6–11].

Besides being involved in GAMT deficiency, GAA participates in a number of other biological processes. First, since it is synthesized prior to creatine and in the renal tubules, its urinary excretion rate may be used as a sensitive indicator of early-stage nephropathy [12–14]. GAA can also act as a neurotoxin and neuromodulator since it is a partial agonist of the GABA-A receptor and inhibitor of Na^+–K^+-ATPase activity [15,16]. Other GAA biological roles are related to cholesterol production [17], thyroid dysfunction [18], epileptic seizures [19], hepatic encephalopathy [20] and insulin regulation [21]. It is also well known that levels of GAA are increased in the cerebral cortex after hyperbaric oxygenation, probably due to a decrease in arginase activity, which causes an increase of both Mn and Cu, Zn-superoxide dismutase [18]. In addition, a significant decrease in the urinary excretion of GAA has been observed after cisplatin treatment in patients with urinary tract neoplasm [22].

This diversity in participation of GAA in several subject areas should be related to the pool of possible chemical reactions that it can present. We have already studied some of GAA properties by analyzing its coordination to some metal ions of biological interest. GAA complexes with Mn(II), Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pb(II) were studied potentiometrically in aqueous solution where besides determining the stability constants of the principal species, an α-nitrogen and oxygen-carboxylate coordination to the metals was proposed [23]. From synthesized GAA powder complexes with Cr(III), Co(II), Ni(II), Cu(II) and Zn(II), the same kind of coordination, that is, through α-nitrogen and oxygen-carboxylate, was observed by infrared, ultraviolet–visible spectroscopies and electron paramagnetic resonance [24]. The involvement of α-nitrogen from GAA in the metal coordination is in agreement with the biological step of its methylation that occurs at the same site/atom.

We have also studied the guanidino-carboxylate interactions between GAA and glutamic acid or aspartic acid in the presence of Cu(II) in aqueous solution [25]. These interactions are biologically very important since they are observed in the substrate fixation of Cu, Zn-superoxide dismutase and of carboxypeptidase A besides being identified in the complex formed by a human immunodeficiency virus and the receptor on the cell wall [26,27]. From our studies we could observe that the values of stability constants of the ternary complexes involving both GAA and Glu or Asp (Cu(II):GAA:L systems, L = Glu or Asp) were higher than the expected due to the possibility of occurrence of these interactions [25].

Meanwhile, we obtained two different Cu(II) crystal complexes of GAA. One of them was a dimeric-copper(II)-bridge-carboxylate complex, tetrakis(μ-guanidinoacetic acid-κ^2O:O')bis[nitrate-κO-copper(II)], $[Cu_2(NO_3)_2(GAA)_4]$ [28]. This complex, in contrast with previous ones, presented an exclusive-oxygen coordination. The other complex, aqua[μ-(N^1-carboxylato-methylguanidino)oxidoacetato](μ-guanidinoaceticacid)di-copper(II) nitrate dehydrate, $[Cu_2(C_5H_6N_3O_5)(C_3H_7N_3O_2)\text{-}H_2O]NO_3 \cdot 2H_2O$, presented a new ligand, $C_5H_6N_3O_5$ N,N'-guandinodiacetic acid (Oag), a guanidine derivative, formed from GAA and copper(II) solution [29]. In this complex, GAA is again coordinated through both oxygen atoms of the bridged carboxylate group whereas the new ligand Oag was coordinated to two Cu(II) ions through three oxygen atoms and one nitrogen atom from the guanidino group. In order to understand the formation of we made an EPR study during different steps of the complex synthesis [30]. We proposed a mechanism of Oag formation based on a reaction between two CuH_2GAA precursor species, followed by a nucleophilic attack of the coordinated water to the α-carbon of GAA, causing its desamidination as a consequence. The fragment resultant from the latter reaction then reacts with a non-coordinated GAA and forms Oag.

Following our studies on GAA, we have investigated its complexation behavior in the presence of Cu(II) and two amino acids, glycine (Gly) and serine (Ser) separately. With Gly, the aforementioned guanidino-carboxylate interactions with GAA should not be possible if Gly were coordinated through its carboxylate group. Ser besides presenting an interesting hydroxyl group in its structure, which may involve other interactions, is present in some enzymes, specifically serine endopeptidases, which are inhibited by guanidino groups [31]. Moreover, reduced serine phosphorylation of the creatine transporter is associated with increments in myocellular creatine content after starvation [32].

Herein, we report two novel Cu(II) complexes synthesized from GAA and a copper(II) solution in the presence of Gly or Ser. Each of such complexes presents a condensed amino acid residue formed by GAA and Gly or Ser with an elongation of the carbon chain. The X-ray structures of both complexes as well as their spectroscopic characterization are herein presented. In addition, we attempt to propose a mechanism for the formation of the new ligands, serine-3-*N*-methylguanidino acetic acid and glycine-3-*N*-methylguanidino acetic acid. Another interesting point for discussion, in addition to the elongation of the carbon chain, is the methylation on the N3 atom from GAA instead of on the α-nitrogen. The synthesis of new guanidines has been intensively investigated since they play an important role in biological recognition sites and catalysis [33] and some of them are used in the design of drugs for different areas of application [34].

2. Experimental

2.1. Syntheses of the complexes O,O′,N,N′-glycine-N-3-methylguanidinoacetic acid copper(II) [CuGly-mGAA] (1) and O,O′,N,N′-serine-N-3-methylguanidinoacetic acid copper(II) [CuSer-mGAA] (2)

An aqueous solution of 3 mmol of guanidinoacetic acid (0.3513 g, Sigma-Aldrich) and 3 mmol of glycine (0.2252 g, Merck) or serine (0.3153 g, Merck) in 30 mL of deionized water was stirred at a temperature of 60 °C for 6 h until complete dissolution. A solution of 3 mmol (0.7248 g, Merck) of copper(II) nitrate in 5 mL of deionized water was then slowly added to the previous mixture, followed by stirring at a temperature of 60 °C for approximately 8 h. After that the mixture was cooled until 4 °C for 24 h. The mixture was filtered and the pH of the filtrate was adjusted to 4.3 with KOH 3 mol/L (Merck). After cooling the solution until 4 °C for 24 h, it was stocked in a glass vessel at room temperature. Slow evaporation of the solution resulted in blue needle crystals, which were washed with absolute ethanol (Merck) and dried at 50 °C for 2 h.

2.2. X-ray analyses

The crystal structures of the two complexes (CuGly-mGAA and CuSer-mGAA) were determined by X-ray diffraction. Data were collected in a Nonius KappaCCD diffractometer at $T = 293$ K. The HKL DENZO and SCALEPACK programs [35] were used for cell refinement and data reduction.

2.3. Infrared spectroscopy

The infrared spectra were recorded on a Perkin–Elmer 2000 FT-IR spectrometer. Data were collected with a 0.5 cm^{-1} interval with a resolution of 4 cm^{-1}. The scanning speed was 0.2 cm s^{-1} and 120 scans were performed. The samples were measured in the range of 4000–370 cm^{-1} as KBr pellets, and in the range of 710–30 cm^{-1} as polyethylene pellets.

2.4. DFT calculations

In order to correlate the structures obtained by X-ray diffraction with the IR spectra of the complexes we have chosen one of the complexes, complex **2**, to compare the experimental and calculated spectrum.

Vibrational assignments of the complex CuSer-mGAA (complex **2**) were carried out with the aid of density functional theory (DFT) calculations.

Ab initio optimization of the geometrical parameters, and hence structural analysis of the guanidoacetic–serinate Cu(II) complex, was carried out employing DFT levels [36–38] with B3LYP/6-31G and with B3LYP/6-311G basis sets, and the RHF/6-311G procedure.

3. Results and discussion

3.1. X-ray structure of the complexes

The equatorial coordination of copper atoms is similar for the two compounds herein described (Table 1). The ligands coordinate toward two oxygen atoms (O2 and O3) of different carboxylate groups and two nitrogen atoms (N1 and N4) to form the equatorial plane of the metal. Nitrogen N1 is positioned *trans* to oxygen O3. The equatorial planes of CuGly-mGAA and of Cu-Ser-mGAA present almost planar *cis* configurations. Similar configurations were observed in other Cu(II) amino acids complexes, $[Cu(l\text{-}Arg)_2](NO_3)_2 \cdot 3H_2O$ [39], $[Cu(l\text{-}isoleu)_2] \cdot H_2O$ [40] and $[Cu(Gly)_2] \cdot H_2O$ [41]. Bond angles in the equatorial plane of copper in CuSer-mGAA are similar to the values obtained for the Cu(II) amino acid complexes (Table 2). The O–Cu–N bond angles, inside each Cu-peptide ring, are acute (around 85°). Angles O–Cu–O and N–Cu–N, outside the Cu-peptide rings of these compounds, are obtuse. Compound Cu-Gly-mGAA, on the other hand, has all angles in the equatorial plane of copper close to 90°.

It is interesting to note the differences between N1 and N4: distances from least square planes (Table 3) show C2 and C3 closer to the least square plane towards Cu, O2, C1, N1 and O1 than C4 and C5 to the plane toward Cu, O3, C6, N4 and O4. As can be seen in Table 3, the deviation from the planes is stronger for CuSer-mGAA than for CuGly-mGAA. Atoms C2 and C3 of CuGly-mGAA are in the plane towards Cu, O2, C1, N1 and O1.

Copper axial coordination is different in the two compounds. One weak interaction between copper and the oxygen O4 (d[Cu–O4^2] = 2.380(7) Å) of a second ligand (Fig. 2) is present in CuGly-mGAA. The structure of CuSer-mGAA (Fig. 3), on the other hand, has the axial neighborhood of the metal fulfilled by two copper–water interactions. One of these is weak, with d[Cu–O7] = 2.500(4) Å; the other is very weak, with d[Cu–O6] = 2.820(4) Å. The ligands on the axial direction appear to affect the deviation of Cu from the least square planes towards its equatorial neighbor (Table 4), which is stronger in the axially less symmetric CuGly-mGAA (0.146(5) Å) than in the more symmetric CuSer-mGAA (0.084(2) Å).

The packing of Cu-Ser-mGAA (Fig. 3b) is formed by parallel layers of molecules. Molecules of neighbor layers are connected through hydrogen bonds involving the water molecules and the carboxylate oxygens (Tables 4 and 5). N–H···O hydrogen bonds also contribute to stabilize the crystal structure. The packing of Cu-Gly-mGAA (Fig. 2b), differently, is stabilized by the polymeric structure formed by molecules oriented perpendicularly to each other and linked through Cu–O4 bonds, as well as hydrogen bonds involving the water molecule and the carboxylate oxygens O4 and O1 of neighbor molecules.

3.2. Infrared spectroscopy analyses

3.2.1. Infrared spectroscopy analysis of CuGly-mGAA (complex 1)

The following discussion on infrared analysis has been based on comparisons with analogous complexes. The principal infrared data of complex **1** as well as of Gly [42], GAA [24], *trans*-Cu(Gly)$_2$ [42] and *cis*-Cu(GAA)$_2$ [24] are presented in Table 6.

Several bands can be observed in the 3500–3200 cm^{-1} range. The first in 3536 cm^{-1} is relative to the stretching modes of O–H of lattice water [42]. In addition, several other bands were observed in the same range, relative to stretching N–H modes of amines, in 3332 cm^{-1}, 3422 cm^{-1} and 3199 cm^{-1}. The band in 1670 cm^{-1} attributed to νC=N of the guanidino group from GAA was shifted to 1667 cm^{-1} in *cis*-Cu(GAA)$_2$, whereas it was not observed in complex **1**, probably indicating that this group has suffered significant modifications. This makes sense since complex **1** presents a methyl group bound to the terminal nitrogen from its guanidino group.

In the 1630–1380 cm^{-1} range, the carboxylate asymmetric and symmetric stretching modes were observed probably coupled with amine deformation modes. Considering the number of carboxylate groups as well as the number of amines, the attempted assignments become very difficult.

Several new bands were observed in the 450–300 cm^{-1} range. By comparing the same spectral region observed in *trans*-Cu(Gly)$_2$ and *cis*-Cu(GAA)$_2$, the bands in 464 cm^{-1} and 409 cm^{-1} may be related approximately to ν(Cu–N) coupled with other vibrational modes while those in 361 cm^{-1} and 341 cm^{-1} to ν(Cu–O), also coupled with other framework vibrational modes. It has also been observed that the skeletal modes of GAA (436 cm^{-1} and 319 cm^{-1}) were absent, reflecting the modifications that occurred in its structure.

3.2.2. Infrared spectroscopy analysis of CuSer-mGAA (complex 2)

Table 7 presents the principal infrared bands and their assignments of complex **2**, GAA [24], Ser [43] and *cis*-Cu(GAA)$_2$ [24].

The band in 3454 cm^{-1} is relative to the stretching mode of O–H of lattice water. The other bands in the 3400–3200 cm^{-1} range are probably relative to stretching N–H modes of amines. Analogously to complex **1**, the band in 1670 cm^{-1} was not observed in **2**, for the same reasons mentioned above.

The bands in 1646 cm^{-1}, 1558 cm^{-1}, 1544 cm^{-1}, 1466 cm^{-1} and 1369 cm^{-1} are assumed to correspond to asymmetric and symmetric stretching modes of the carboxylate group, probably coupled with amine deformation modes.

Several new bands were observed in the 450–300 cm^{-1} range. The bands in 466 cm^{-1} and 429 cm^{-1} may be related to ν(Cu–N), while those in 390 and 376 cm^{-1} to ν(Cu–O).

Table 2
Geometrical parameters of the Cu coordination sphere (Å, °)

	CuGly-mGAA	CuSer-mGAA	$[Cu(l\text{-}Arg)_2](NO_3)_2 \cdot 3H_2O$	$[Cu(l\text{-}isoleu)_2] \cdot H_2O$	$[Cu(gly)_2] \cdot H_2O$
Cu–O2	1.925(7)	1.937(3)	1.930(4)	1.948	1.957(9)

N1–Cu–N4	91.4(3)	95.51(17)	96.7(2)	98.6	96.6(4)
O2–Cu–N1	89.0(4)	84.97(17)	84.5(2)	84.2	85.0(4)
O3–Cu–N4	90.4(3)	84.34(17)	84.3(2)	84.5	85.4(4)

Table 3
Distances (Å) of selected atoms to selected least square planes of CuGly-mGAA and CuSer-mGAA

Plane	Atom	Cu-Gly-mGAA	Cu-Ser-mGAA
O2C1N1O1Cu	C2	0.008(12)	0.113(7)
	C3	0.057(16)	0.200(9)
O3C6N4O4Cu	C4	0.669(22)	0.797(9)
	C5	0.100(14)	0.243(7)
N1N4O3O2	Cu	0.146(5)	0.084(2)

Similarly to complex **1**, the GAA bands in 436 cm^{-1} and 319 cm^{-1}, relative to skeletal modes, were absent in **2**.

3.3. Vibrational assignments

For the discussion of vibrational assignments, we will take the DFT values corrected by a scale factor of 0.9613 as a base of comparison with the 81 experimental wave numbers of the infrared spectra joined to second derivative bands. For an accurate description of the normal modes in the metal-ligand spectral range, as we have proposed in other works [44,45], we use the percentage of deviation of geometrical parameters (PDGP) from the equilibrium position. The PDGP can be also normalized to obtain the percentage of participation of each internal vibrational coordinate that describes the framework vibrations.

3.3.1. NH and CH stretching

We expected to observe a total of four bands pertaining to the asymmetric and symmetric N–H stretching normal modes. Within a large band centered on 3333 cm^{-1}, we could identify absorption bands at 3676, 3568, 3452, 3340, 3299, 3263, 3242, 3140, 2922, 2896 and 2852 cm^{-1}. These bands can be assigned according to DFT results to the vibrational modes ν_{as}(NH), ν(OH), ν_s(NH), ν_s(NH), ν_s(NH), ν_s(NH), ν_{as}(CH) ν_{as}(CH) ν_{as}(CH) ν_{as}(CH), ν(CH)methane, ν_s(CH) and ν(CH), respectively. The second derivative spectrum shows bands at 3571, 3459, 3343, 3299, 3264, 242, 3129, 2961, 2898 and 2851 cm^{-1}, presenting good correlation with the experimental ones. When we applied the Bellamy–Williams relationship [46] for primary amines $\nu(a') = 345.5 + 0.876\nu(a'')$ to the experimental band found at 3676 cm^{-1}, we obtained the value of 3565 cm^{-1}, so we can conclude that the value calculated at 3695 cm^{-1} by the DFT method could not be considered as the ν(OH) vibrational mode. The DFT calculated bands for these NH and CH stretching vibrational modes are in good agreement with experimental ones.

3.3.2. C=O stretching

Observing the geometrical structure of the guanidoacetic–serinate Cu(II) complex depicted in Fig. 4, we can infer only one asymmetrical and one symmetrical C=O stretching. As it is well known, the band absorption of carbonyl groups is located in the region of ~1700–1500 cm^{-1}, commonly in a higher energy region than the absorption bands pertaining to the HNH bending vibrational modes. In the infrared spectrum, we can observe two bands at 1650 cm^{-1} and at 1623 cm^{-1}. The second derivative of the spectrum and the band deconvolution analysis include values at 1650 cm^{-1} and at 1623 cm^{-1}, respectively. By means of the DFT procedure with B3LYP/6-311G and 6-311G basis sets we can assign the experimental band found at 1650 cm^{-1} (IR, second derivative) to the ν_s(C=O) vibrational mode, and the band found at 1623 cm^{-1} to the ν_{as}(C=O) vibrational mode. The match between calculated and experimental values for the ν(C=O) stretching was excellent.

3.3.3. HNH and HCH bending

In the infrared spectrum we can observe four bands at 1721, 1500 (1511 second derivative), 1470 (second derivative), 1466, 1423 (1428 second derivative), 1390, 1320 (1322 second derivative), 1283 (second derivative) 1279 and 1256 (second derivative), which can be correlated with the scaled DFT:B3LYP/6-311G values: 1642, 1518, 1487, 1483, 1427, 1388, 1317, 1295, 1283 and 1248 cm^{-1}. These bands can be assigned principally to δ(HNH)wagg, δ(HCH)wagg, δ(HCH)wagg, δ(HCH)wagg, δ(NH), δ(HCH)wagg, δ(HCH)twist, δ(HCH)twist, δ(HCH)twist and δ(HCH)twist, respectively. Rocking vibrations according to the DFT calculations can be assigned as follows: 1103 cm^{-1} to $\rho(CH)_2 + \rho(NH_2)$, 1071 cm^{-1} to ρ(OH) + $\rho(NH_2)$, 1043 cm^{-1} to $\rho(CH)_2 + \delta$(HNH)twist.

3.3.4. CN, CO, and CC stretching vibrations

A natural and considerable mixture of the internal coordinates describing isolated C–N, C–O, C–C stretching is

Table 6

found in the normal modes and is physically meaningful. For the guanidoacetic-serinate Cu(II) complex, the following infrared coupled bands can be assigned principally as 1227 (IR) cm^{-1} to ν_s(CO); 1143 cm^{-1} to ν_s(CN); 1008 cm^{-1} to ν_s(CN); 993 cm^{-1} to ν_s(CN); 956 to ν(CO) and 878 cm^{-1} to ν(CC).

3.3.5. Skeletal framework vibrations

As we have pointed out in other publications [44,45,47,48], a clear identification of the metal–ligand vibrations is not straightforward due to the higher mixture of different internal coordinates that take part in the description of the normal mode. In order to analyze the normal modes below 600 cm^{-1} we will describe the most accurate assignment we were able to deduce through the study of the distorted geometries of the normal modes described by the ab initio DFT:B3LYP/6-311G procedures. Our goal was to identify which bond lengths and

bond angle bending parameters had greater participation in the description of the normal mode.

Fig. 4 displays the distorted geometry of the normal modes for the metal–ligand vibrations obtained through the free CHEMKRAFT program [49].

3.4. Proposal of a mechanism for the formation of Gly-mGAA and Ser-mGAA

Due to the interesting formation of new amino acid derivatives, a preliminary mechanism for their synthesis is proposed here (Fig. 5). We have based this proposal on previous work on the desamidination of copper(II) complexes of GAA analyzed by epr [30] as well as on data on guanidination reactions involving amino acids, phosphates and collagen [50–57] and also on methyltransferases. Some of guanidination [50] and methyltransferases [53] reactions are mediated by zinc(II) ions or zinc(II) coordination in a similar way that we propose here for Cu(II).

Nevertheless, we omitted copper(II) complexes from this mechanism because we were not be able to analyze intermediate species. However, we do know that Cu(II) or its complexes may act both as a catalysts or template sites.

The proposed mechanism comprises two steps, both of them involving nucleophilic attack. It is interesting to note the similarity with the catalytic mechanism proposed for arginine deimination, with the difference of which carbon atom is attacked: the amidino one in the case of arginine deimination and the α-carbon in our proposed mechanism [58].

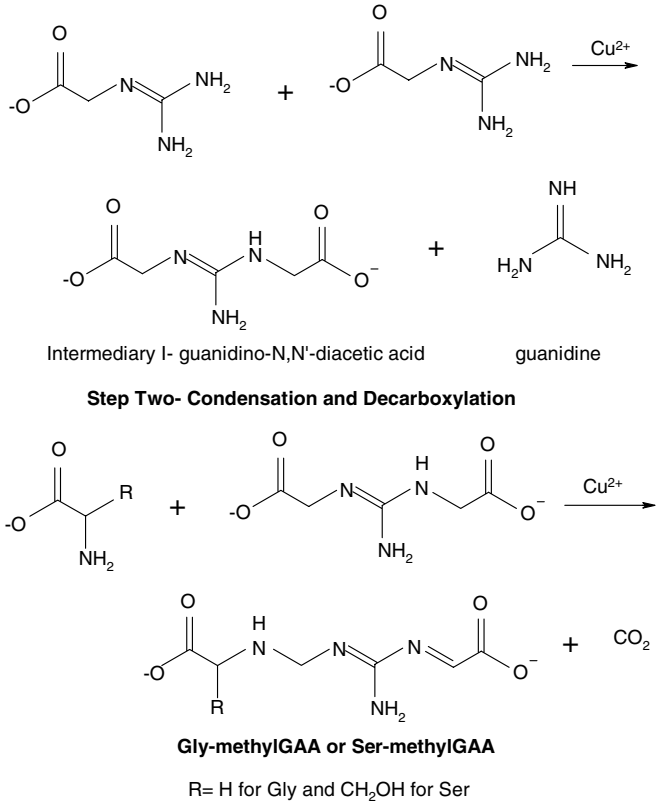

Fig. 5. Proposed mechanism for Gly-mGAA and Ser-mGAA.

Step one is based on a deguanidination reaction between two GAA species in the presence of Cu(II). Guanidination reactions are used in reactions of biological relevance such as the synthesis of L-canavanine [50], the modification of a toxic enzyme from snake venom [51], the synthesis of thrombin inhibitor [52] and also the guanidination of the phosphate linkage towards cationic phosphoramidate oligonucleotides [55]. Deguanidination modified monomeric collagen in such a way that it prevented it from polymerization and to inducing platelet aggregation [54].

In step one, the terminal amino group from GAA makes a nucleophilic attack at α-carbon from another GAA, followed by a deguanidination reaction, generating intermediate I: guanidino-*N*,*N*′-diacetic acid and guanidine (a good leaving group). A rather similar process has already been proposed between two GAA copper(II) complexes [30] by our group. Cu(II) is probably involved in the coordination through the oxygen atoms from the carboxylate group, similarly to what happens in the desamidination process [30], which favors the nucleophilic attack on the α-carbon. The proposed intermediate I, guanidino-2,4-*N*,*N*′-diacetic acid, is essential to the elongation of the carbon chain.

In step two the α-amino group from glycine or serine makes a nucleophilic attack at C-2 from intermediate I, followed by a decarboxylation process. The copper coordination is also assumed to mediate this nucleophilic attack and a Cu(II)/Cu(I) redox system may help on the decarboxylation reaction in addition to the heating experimental conditions.

As a final result, glycine-2-*N*-methyl guanidinoacetic acid or serine-2-*N*-methyl-guanidino acetic acid are formed and both of them act as a quadridentate ligand, using the oxygen atoms from the carboxylate groups and two nitrogen atoms (Fig. 4).

4. Conclusions

Two novel Cu(II) complexes were synthesized involving new condensed synthetic amino acids: one is glycine-3-*N*-methylguanidino acetic acid (Gly-mGAA), which results from the reaction between GAA and glycine, with an increase of one carbon in the chain; and the second is a similar ligand that is the product of the reaction between GAA and serine, that is, serine-3-*N*-methylguanidino acetic acid (Ser-mGAA). It is important to remark that this elongation of the carbon chain in both cases was performed in aqueous solution in the presence of Cu(II).

This can represent important mechanisms both for the synthesis of new guanidines derivates and for methylation or peptide formation with biological molecules. Modifications in the precursor of GAA, arginine, for example, can be related to changes in the immunogenicity of proteins and peptides and can create self-antigens that induce autoimmune responses [57]. If these serine or glycine GAA adducts are catalyzed by enzymes in our organisms

through an alternative biological pathway, creatine biosynthesis will be impaired, resulting in a dysfunction similar to guanidinomethyltransferase deficiency.

Deguanidination reactions instead of desamidination should also prevent GAA biosynthesis, formed by the desamidination of arginine.

In addition, an important contribution on how GAA can react with other amino acids was proposed as well as how elongation of their carbon chain can be made in aqueous solution in the presence of Cu(II).

Scheme 1.

Scheme 2.

has three bidentate positions, we have prepared complexes with one, two or three metals occupying these positions. The incorporation of three metallic centres was only possible with a small metallic fragment. As far as the fluxionality of the compounds is concerned, two types of processes were found: metallotropic shift and rotation of the uncoordinated pyrazolyl rings.

In the free ligand, each pyrazol-1-yl group can adopt two perpendicular conformations depending on the orientation of the N-2 lone pair ($u = up$, $d = down$) with regard to the benzene plane. This situation leads to several isomers. The hpzb ligand exists in the solid state in two conformations (polymorphism) – *ududud* and *udduud*. According to AM1 and SAM calculations [26], these conformations have torsion angles close to 90° with the *ududud* disposition giving the most stable conformer. NMR studies in solution have shown that, depending on the solvent and/or concentration, the *ududud* isomer is either the only one detected or is the major isomer along with the *udduud* isomer as the minor component. The fact that two isomers can be observed separately indicates that restricted rotation of the pyrazolyl rings exists in the free hpzb ligand at room temperature. The same conclusion was deduced for the monometallic derivatives, while those containing two metallic centres exhibited free rotation at room temperature of the two uncoordinated pyrazolyl rings situated *para* to one another [31].

In this work we decided to focus our attention on the study of the coordination ability of hpzb with the chiral fragment *cis*-$[Ru(bpy)_2]^{2+}$. Although complexes have been described that contain the $[Ru(bpy)_2]^{2+}$ fragment bonded to pyrazolyl-derived ligands [33–35], the coordination of hpzb to this potentially octahedral fragment has not previously been explored. It was of interest to evaluate if any selectivity existed in the coordination and also to assess the possible presence of fluxional processes.

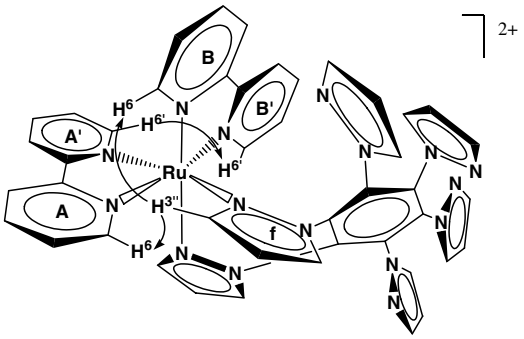
On the other hand, ruthenium-based anticancer drugs are making significant advances as an attractive alternative to classical platinum chemotherapies. Specifically, polypyridyl–Ru complexes have been investigated as potential anticancer drug candidates, given their photoluminescence properties and both the ability of Ru to coordinate DNA nucleobases and the ability of polypyridyl ligands to intercalate DNA [36]. Because of that, we decided to explore the possible anticancer activity of the ruthenium complexes containing bpy and our ligand hpzb.

2. Results and discussion

2.1. Synthesis and characterization

The reaction of hpzb [27,28] with the system $[RuCl_2(bpy)_2]/2NH_4PF_6$ [37] was carried out (Eq. (1)) [35]. The ruthenium containing precursor has been used in anticipation that such a compound, besides providing the possibility of its substitution by two N donors, could also be exploited for its biological studies in view of earlier reports [36]. The reaction was performed in 1:1, 1:2 and 1:3 hpzb:Ru ratios. The same product, **1**, was obtained in all cases (even after prolonged reaction times of 36 h) as a dark-red solid. Elemental analysis of complex **1** shows the stoichiometry to be $[Ru(bpy)_2(hpzb)](PF_6)_2$ (see Eq. (1)) (clearly a racemic mixture would be present). The mass spectrum is also consistent with coordination of the ligand to only one metal fragment. In fact, peaks corresponding to the loss of one or two counteranions or other fragments from the proposed formula are also observed. It is worth highlighting the selectivity in the coordination of the ligand to only one metal fragment. It is possible that the ruthenium centre is sufficiently electrophilic to reduce considerably the donor ability of the uncoordinated pyrazolyl rings once the first metal centre is present. Undoubtedly, bonding of one hpzb ligand to three metal centres would involve a high level of steric hindrance:

$$[RuCl_2(bipy)_2] + hpzb + 2NH_4PF_6 \rightarrow [Ru(bipy)_2(hpzb)](PF_6)_2, 1 + 2NH_4Cl \quad (1)$$



A different behaviour to that found with hpzb has been observed with the similar ligand hexakis(3,5-dimethylpyrazol-1-yl)benzene that contains substituted pyrazolyl rings. It did not react with the same ruthenium complex, possibly due to steric factors.

The ^1H NMR spectrum of compound **1** shows a very complicated pattern that consists of 34 different signals, all of which have the same integration. This observation is consistent with the presence of six different spin systems for the pyrazolyl rings and four different spin systems for

the pyridyl rings. The evidence indicates a total lack of symmetry, which can be explained as a consequence of hpzb coordination to the $[Ru(bpy)_2]^{2+}$ moiety and the boat conformation expected for the chelate ring (see Fig. 1 and Scheme 3).

COSY and NOESY experiments enabled signals corresponding to the same pyrazole ring to be grouped together. Coupling constants enabled the assignment of $H^{4''}$ and allowed us to distinguish between $H^{3''}$ and $H^{5''}$, since it is well-known that $^3J_{4-5} > {}^3J_{4-3} > {}^4J_{3-5}$. Chemical shifts can also be used to identify $H^{4''}$ protons, since all of these exhibit higher field resonances (between 6.04 and 6.34 ppm) than the other two protons in the same ring. However, the chemical shifts are not particularly useful to distinguish between $H^{5''}$ and $H^{3''}$, because both types of proton show very similar δ values and, in addition, they are strongly affected by factors such as bpy shielding. All of the pyrazolyl resonances are gathered in Table 1 and the assignments to the pyrazolyl rings labelled from **a** to **f** are given (see Table 1).

As previously stated, the bipyridine ligands give four different spin systems in the ^{1}H NMR spectrum. It was possible to identify the signals forming each spin system and to relate pairs of systems belonging to the same bpy ligand. This was achieved by means of NOESY and COSY experiments (see Figs. 2 and 3). Moreover, an additional NOE effect was detected between the two $H^{6'}$ resonances, which is reasonable given the octahedral geometry expected for the metallic centre. In fact, a second cross-peak could be expected in the NOESY spectrum between the two H^6 signals. However, these signals appear too close to one another in the 1-D spectrum. Interestingly, two cross-peaks

Scheme 3. Expected structure and some NOEs observed for complex **1**. The labelling of the bpy ligands could be opposite to that shown.

Table 1
^{1}H NMR chemical shifts (acetone-d_6) for the six pyrazolyl rings

Pz ring	$H^{3''}$	$H^{4''}$	$H^{5''}$
a	6.97	6.04	7.21
b	6.72	6.15	7.74
c	7.55	6.18	7.05
d	7.37	6.26	7.58
e	7.49	6.29	7.75
f	7.72	6.34	7.61

are observed between $H^{3''}$ of pyrazolyl ring **f** and the aforementioned H^6 resonances of the two bipyridines. This means that $H^{3''}$ of the pyrazolyl ring **f** is located in between these two H^6 protons as a consequence of the boat conformation adopted by the chelate ring. Therefore, the pyrazole labelled **f** is coordinated to the metal centre (see Scheme 3, Table 2 and Scheme 4). The free bpy ligand in solution has

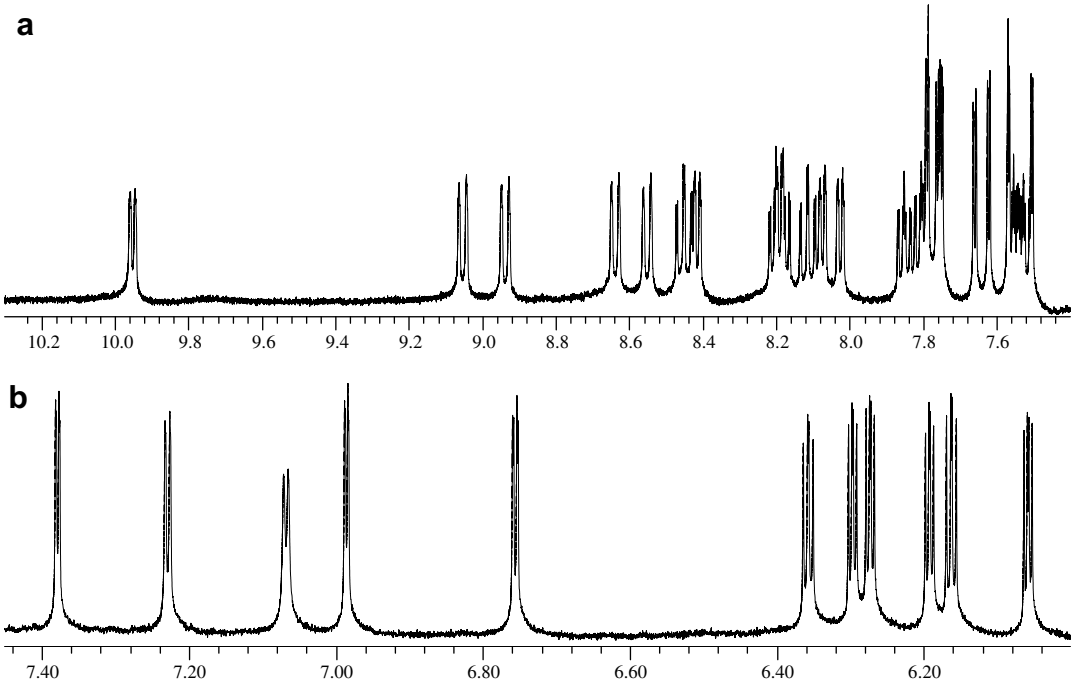


Fig. 1. ^{1}H NMR spectrum of complex **1** in the aromatic region (divided into sections a and b).

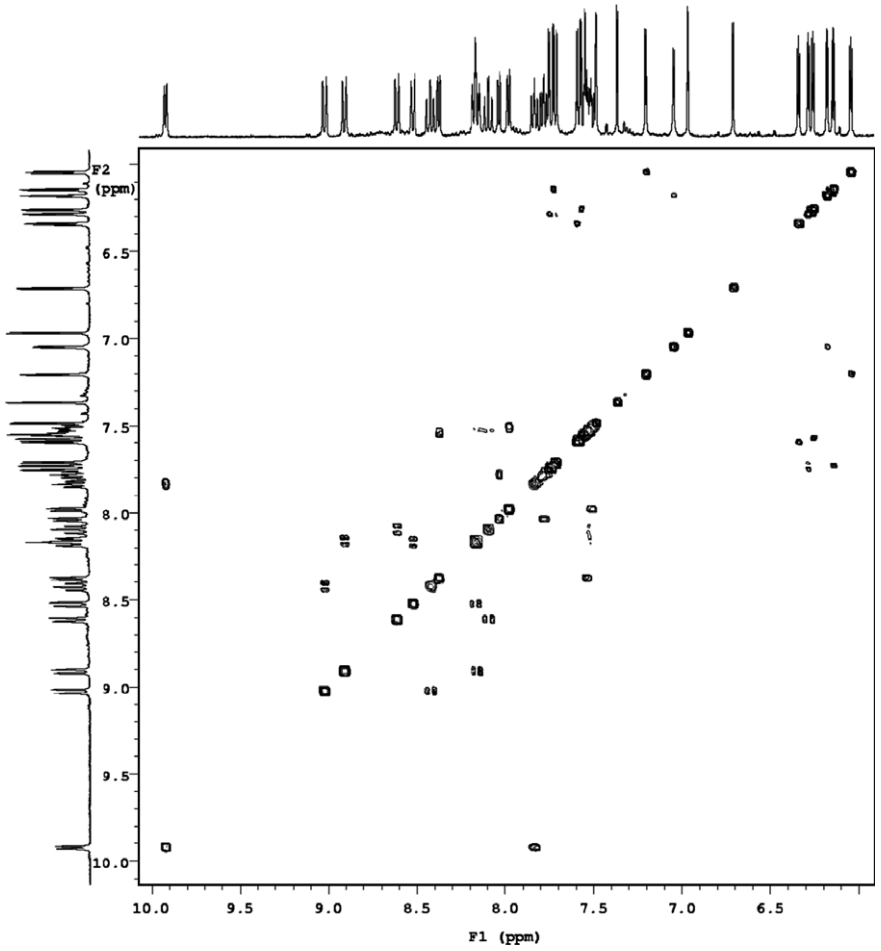

Fig. 2. 2D COSY ^{1}H–^{1}H spectrum (400 MHz) for complex **1**, in acetone-d_6 at room temperature.

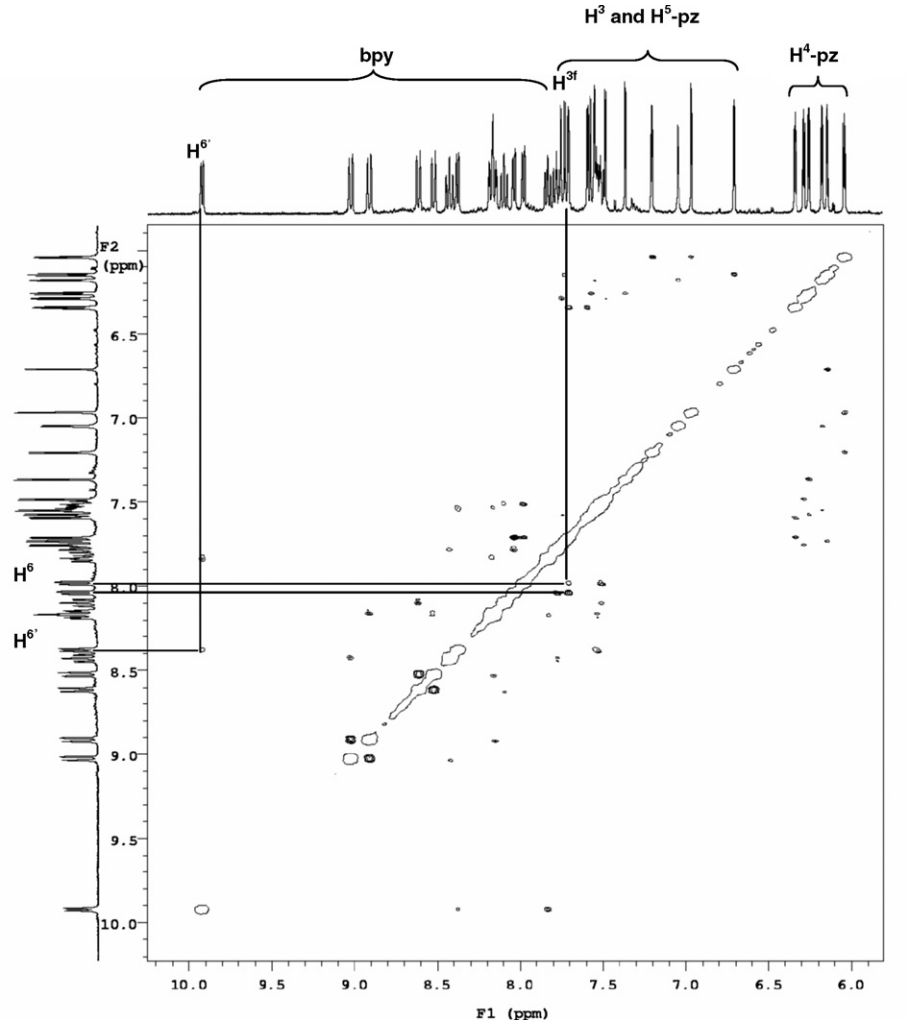
a *transoid* (*trans*-coplanar) equilibrium conformation, even though the energy barrier for rotation around the interannular C–C bond is not very high. In this conformation the observed δ value can be listed from lowfield to highfield in the following order: $\delta(H^6) > \delta(H^3) > \delta(H^4) > \delta(H^5)$ [38]. However, when the ligand is coordinated to a metal centre a *cisoid* conformation is adopted and $\delta(H^3)$ moves downfield due to steric interactions between H^3 and $H^{3'}$. In contrast, some H^6 resonances may be shifted upfield because of the location of these protons directly above the π electron density of a pyridine or pyrazolyl ring in the complex (see Table 2).

Although we were able to identify all the signals in the ^{1}H NMR spectrum of **1**, we synthesized a partially deuterated bpy ligand (bpy-d_7 with H in the 4-position) and the corresponding complex [Ru(bpy-d_7)(hpzb)][PF_6)$_2$ (**1-*d***) in order to confirm the data. The ^{1}H NMR spectrum of **1-*d*** is consistent with our previous assignments. The spectrum contained all the pyrazolyl signals and the H^4 and $H^{4'}$ bpy resonances.

A $^{13}C\{^{1}H\}$ NMR spectrum of **1** was recorded and the signals were assigned by means of HMQC and HMBC experiments. The spectrum consisted of 44 singlets, as one would expect for the structure discussed above. Twenty of these signals belong to the bpy ligands, eighteen to the six non-equivalent pyrazolyl rings and six to the hpzb benzene group. The data are gathered in Section 3.

When a solution of complex **1** was heated (acetone-d_6 solution) to 50 °C, changes were not observed in the spectra. A decrease in temperature down to −90 °C did not lead to evidence of splitting of the resonances. On the basis of these data we propose that, in a similar way to the free ligand and to other mononuclear derivatives [31], in this complex there is a restricted rotation of the uncoordinated pyrazolyl rings even at room temperature. According to the number of NMR resonances only one isomer is present in solution. The possible relative pyrazolyl dispositions for a restricted rotation situation are reflected in Scheme 5 (from **I** to **X**); a black circle represents N-2 *up* and a white circle represents N-2 *down*. If the two coordinated pyrazoles were equivalent, these ten dispositions would be the ten possible conformers. However, when these two pyrazoles are not equivalent due to the asymmetry of the metallic fragment, as in this case, some of these dispositions (**I**, **II**, **IV**, **VI, VII** and **VIII**) would give rise to two different conformers: **a** and **b**. This situation occurs for the dispositions where there is not a symmetry plane on considering the local symmetry of the hpzb group. The interconversion between



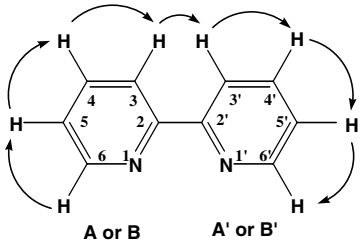


Fig. 3. 2D NOESY ^1H–^1H spectrum (400 MHz) of complex **1** in acetone-d_6 at room temperature.

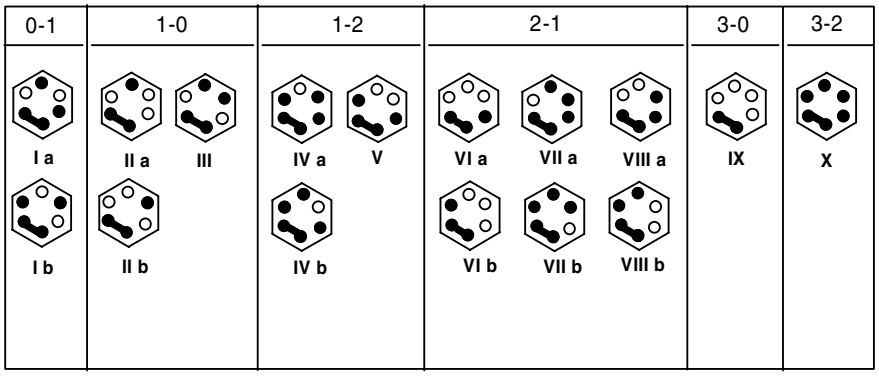
Table 2
^1H NMR chemical shifts (acetone-d_6) for the two bipyridine groups, labelled with letters **AA′** and **BB′**



bpy ring	H^6	H^5	H^4	H^3	$H^{3'}$	$H^{4'}$	$H^{5'}$	$H^{6'}$
AA′	8.05	7.79	8.43	9.03	8.92	8.17	7.54	8.39
BB′	7.99	7.52	8.10	8.62	8.53	8.18	7.83	9.93

conformers **a** and **b** would be possible through a boat-to-boat inversion of the metallacycle – as observed in metallic bis(pyrazolyl-1-yl)methane derivatives [39]. When two contiguous pyrazoles have the same relative orientation, a repulsion between the two nitrogen electron pairs is expected (although to a lesser extent there will also be a steric interaction between two contiguous $CH^{5''}$ groups). The conformers in the Scheme are grouped according to the number of these interactions. The first number refers to the number of times where two consecutive uncoordinated pyrazoles have the same orientation and the second number refers to the same disposition but for contiguous free and coordinated pyrazolyl rings.

Scheme 4. NOE correlations and numbering scheme for the bipyridine signals.

If we assume that the free pyrazole-free pyrazole interaction (same orientation) destabilizes the molecule more than the interaction between free pyrazole and coordinated pyrazole (for a coordinated pyrazole the electron pair is involved in the coordination to the metal centre), then the most stable conformers would be **Ia** and **Ib**. We cannot conclusively establish whether complex **1** corresponds to a situation of rapid interconversion between **Ia** and **Ib** through a boat-to-boat inversion or to only one conformer that has been selectively formed.

Scheme 5.

The UV–Vis spectrum of **1** consists of three bands at 282, 334 and 449 nm. The band centred at $\lambda_{max} = 282$ nm is assigned to a $\pi \rightarrow \pi^*$ transition of the bpy ligands, that centred at $\lambda_{max} = 334$ nm to a $\pi \rightarrow \pi^*$ transition of the hpzb ligand and that at $\lambda_{max} = 449$ nm to a metal-to-ligand charge transfer (MLCT) $d \rightarrow \pi^*$ transition. A luminescence response was not observed for **1**, a situation in contrast to that found for $[Ru(bpy)_3]^{2+}$ and the majority of complexes of the type $[Ru(bpy)_2(NN)]^{2+}$ [40,41]. However, it has been reported that for $[Ru(bpy)_2Meprv]^{2+}$ luminescence is not observed either [Meprv = 1,5-dimethyl-3-(1′-methyl-3′-pyrazolyl)-6-oxoverdazyl] [34].

Electronic spectra for solutions of **1** (10^{-4} M) and HCl (10^{-4} M) and also of **1** (10^{-4} M) and HCl (5×10^{-4} M) in acetone were recorded. The spectra did not show distinct features compared to those of complex **1** in acetone. Consequently, the UV–Vis absorption spectrum is not pH dependent. The electronic spectrum of **1** is also not affected by the addition of 1 equiv. of $Zn(NO_3)_2 \cdot 6H_2O$ (10^{-4} M). Luminescence experiments were repeated in the presence of both $Zn(NO_3)_2 \cdot 6H_2O$ and HCl. No response was observed.

The molar conductivity was measured for a 10^{-3} M solution of complex **1** in acetone. The recorded value was 176 S cm^2 mol^{-1}, in agreement with a 2:1 electrolyte [42].

2.2. Electrochemistry

Cyclic voltammetry measurements were carried out in order to determine the redox behaviour of complex **1** in CH_2Cl_2. A degassed solution of $[Ru(bpy)_2(hpzb)][PF_6]_2$ (**1**) (4.08×10^{-4} M) and tetrabutylammonium hexafluorophosphate ($TBAPF_6$, 2.06×10^{-2} M), as the supporting salt, in dry CH_2Cl_2 was used. The potentiostat was equipped with a conventional three electrode cell, and the latter was purged with nitrogen gas saturated with CH_2Cl_2 during the experiment.

On the oxidation side (see Fig. 4 and Table 3), three reversible waves were recorded at $E_{1/2} = +0.21$ V, $E_{1/2} = +0.74$ V and $E_{1/2} = +1.24$ V. The first two were assigned to the oxidation of the hpzb ligand, and the third to the metal based oxidation couple (Ru^{2+}/Ru^{3+}). Several additional experiments were done to confirm this assignment. First of all, the redox behaviour of the solvent and the ligand hpzb were separately examined under the same conditions, but no oxidation processes were detected for either of them, although in both cases a dramatic increase in the intensity was observed at potentials over 1.0 V. Moreover, the starting material was also investigated and the literature Ru^{2+}/Ru^{3+} oxidation potential at $E_{1/2} = +0.4079$ was successfully confirmed. On the other hand, most of the complexes $[Ru(L–L)_3]^{2+}$, where L–L is a N-donor bidentate chelate ligand, have characteristic oxidation waves in a rather narrow range around that of the reference complex $[Ru(bpy)_3]^{2+}$, $E_{1/2}$ being between +1.27 V and +1.35 V in CH_2Cl_2 depending on the author [40,43]. Thus, these data justify our assignation of the wave at +1.24 V to the oxidation Ru^{2+}/Ru^{3+} process. Assignation of the two other waves is more speculative, though they could correspond to a two step oxidation process of the pyrazolyl groups on the coordinated ligand.

On the reduction side, the voltammogram exhibits two reversible waves at −0.85 and −1.48 V respectively, corresponding to the reduction of the bpy ligands. The reference complex $[Ru(bpy)_3]^{2+}$ shows three peaks in this region assigned to the three bpy ligands according to the literature (see Table 3).

2.3. Anticancer activity

Complex **1** has been tested in vitro, as a potential anticancer drug in two different cell lines, A2780, human ovarian carcinoma cell lines, and NCI-H460, human lung carcinoma cell lines. Unfortunately, the activity was not high enough to build the corresponding dose–response graph when tested in the second line. On the other hand, cytotoxicity was higher in the first cell line, A2780, but the maximum inhibitory effect could not be reached as a consequence of interference with the solvent DMSO. Consequently, the cytotoxicity was determined with this restriction, as both the E_{max} value (the maximum replication inhibitory effect relative to control experiments and expressed as percentage) and the IC_{50} value (the concentration that inhibits cell replication by 50%, interpolated from dose-response representations and relative to control experiments). The E_{max} value can be considered as

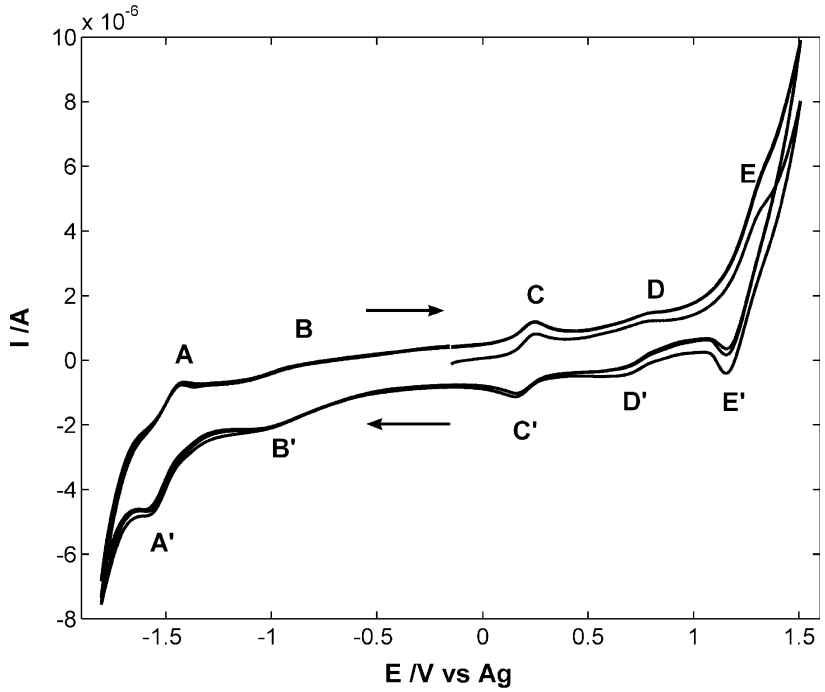


Fig. 4. Cyclic voltammogram of complex **1** (4.08×10^{-4} M) in 0.02 M of n-Bu_4NPF_6/CH_2Cl_2 at a scan rate of 100 mV/s.

Table 3
Electrochemical data, $E_{1/2}$ (ΔE_p) (V), for complex **1** (4.08×10^{-4} M) and reference $[Ru(bpy)_3]^{2+}$

100 mV	Reduction			Oxidation		
Complex		**A/A′**	**B/B′**	**C/C′**	**D/D′**	**E/E′**
1[a]		−1.48 (0.18)	−0.85 (0.16)	+0.21 (0.11)	+0.74 (0.13)	+1.24 (0.26)
$[Ru(bpy)_3]^{2+}$ [b]	−1.76 (0.07)	−1.51 (0.07)	−1.32 (0.07)			+1.35 (0.07)

[a] Recorded in CH_2Cl_2 0.02 M $TBAPF_6$ with a scan rate of 100 mV/s, using two commercial platinum disk electrodes ($d = 2$ mm) as working and counter electrode and a silver wire as the pseudo-reference electrode.
[b] Ref. [43b].

Table 4
Results of anticancer activity of complex **1** compared with cisplatin

Drug	E_{max} (% inhibition)	IC_{50} (μM)
1	64	56
Cisplatin	94	0.4

an efficiency measurement, whilst the IC_{50} value can be considered as a power measurement for a particular drug with regard to a particular cell line. The results for **1** are given in comparison to those reported for cisplatin [44] and are gathered in Table 4. The results indicate that **1** is less efficient and less powerful than cisplatin and also less powerful than analogous complexes of the type $[RuL(bipy)_2]PF_6$ [45].

3. Experimental

3.1. General methods

All manipulations were carried out under N_2 using standard Schlenk techniques. Solvents were dried and distilled under N_2 prior to use. NMR spectra were recorded at room temperature (~22 °C), unless otherwise stated, on VARIAN UNITY INOVA-400 or VARIAN UNITY INOVA-500 spectrometers. Chemical shifts (ppm) are relative to TMS (^1H, ^{13}C NMR). ^1H–^1H COSY spectrum: standard pulse sequence with an acquisition time of 0.239 s, width 4288.2 Hz, 2D width 4288.2, relaxation delay 1 s, number of repetitions 2, number of increments 200. NOESY spectrum (VARIAN INOVA-400) standard parameters: relax delay 1.000 s, mixing 0.500 s, acquisition time 0.236 s, width 4341.2 Hz, 2D width 4341.2 Hz, 64 repetitions, 2×200 increments, DATA PROCESSING Gauss apodization 0.109 s, F1 DATA PROCESSING Gauss apodization 0.042 s. HMQC standard parameters: relax delay 1.000 s, acquisition time 0.134 s, width 1906.8 Hz, 2D width 17097.7 Hz, 16 repetitions, 2×512 increments, DATA PROCESSING Gauss apodization 0.062 s, F1 DATA PROCESSING Gauss apodization 0.055 s. HMBC standard parameters: relax delay 1.000 s, acquisition time of 0.131 s, width 1947.8 Hz, 2D width 24132.7 Hz, 16 repetitions, 512 increments, DATA PROCESSING Sine bell 0.066 s, F1 DATA PROCESSING Sine bell 0.011 s. IR spectra were recorded on a Nicolet

Impact 410 spectrophotometer as KBr pellets (4000–400 cm^{-1} range) or on a Jasco FT/IR-6300 spectrophotometer (630–150 cm^{-1} range) in Nujol mulls. Elemental analyses were performed in a LECO CHNS-932 microanalyser. FAB^+ mass spectra were recorded in a Micromass AutoSpec using ionization Liquid Secondary Ion Mass Spectrometry (LSMIS+) and Cs and NBA ions as the matrix. The UV–Vis spectrum was recorded in a Hewlett-Packard 8453 spectrophotometer (±0.2 nm). The fluorescence was studied with a SHIMADZU RF-5301PC Spectrofluorophotometer. The conductivity measurements were made with a CRISON conductimeter 522. The electrochemical measurements were performed with a PGSTAT 20 (Eco Chemie B.V., The Netherlands) equipped with a conventional three electrode cell. Two commercial platinum disk electrodes ($d = 2$ mm) were used as the working electrode and counter electrode. The pseudo-reference electrode was a silver wire. The in vitro studies were performed at the Screening Unit of the Institute for Industrial Pharmacy (USEF) of the University of Santiago de Compostela (USC). The ligands hexakis(pyrazol-1-yl)benzene (hpzb) [26,28] and hexakis(3,5-dimethylpyrazol-1-yl)benzene [25] have been previously described. The derivative *cis*-$[RuCl_2(2,2'\text{-bpy})_2]$ was prepared as reported previously [37].

3.2. Synthesis of *1*

Complex **1** was synthesized using a method similar to that described in Ref. [37]: $[RuCl_2(2,2'\text{-bpy})_2]\cdot 2H_2O$ (114.6 mg, 0.22 mmol) was refluxed in an ethanol/water mixture (30 mL/10 mL) for 1 h. The ligand hpzb (104.4 mg, 0.22 mmol) was then added and heating was maintained for 24–26 h. The resulting dark-red solution was cooled to room temperature. Next, the solvent was removed from the solution obtained under vacuum and with smooth heating. The crude product was dissolved in 20 mL of distilled water and the final product was precipitated after adding NH_4PF_6 solution, drop by drop (71.7 mg, 0.44 mmol in a minimum amount of water). The product is soluble in acetone, dichloromethane, ethanol and THF but insoluble in hexane or diethyl ether. The product was recrystallized from a mixture of CH_2Cl_2/Et_2O (1:2). Yield after recrystallization: 159.8 mg (0.1357 mmol, 62%). *Anal.* Calc. for $C_{44}H_{34}N_{16}RuP_2F_{12}$: C, 44.87; H, 2.91; N, 19.03. IR in KBr disk ($cm^{-1}$): 3130, 3107, 2366, 2340, 1633, 1604, 1530, 1489, 1466, 1446, 1417, 1397, 1306, 1269, 1128, 1083, 1046, 956, 918, 841 (PF_6^-), 759, 670, 641, 558 (PF_6^-), 474, 447, 430. IR in Nujol mull (630-150 cm^{-1} range): 376, 359, 259, 245, 203, 194, 178. UV–Vis (λ nm, ε $dm^3\ mol^{-1}\ cm^{-1}$): 282 (2061); 334 (8303); 449 (7375).

3.3. Synthesis of *1-d*

The ligand bpy-d_7 was obtained following a similar procedure to that described in the bibliography for perdeuterated bpy [46]: 2,2′-bipyridine,1,1′-dioxide (1.88 g, 0.01 mol) was treated with 32 mL of a 1 N solution of NaOD in D_2O (0.032 mol). The mixture was heated at 150 °C for 65 h in a Fisher-Porte tube. After that time, the solution was filtered, partially evaporated and left to precipitate while cooling. The colourless needles obtained where made to react with 10 mL of PCl_3 (0.11 mol) and the solution was heated for 1.5 h at reflux. After cooling, the solution was neutralized with a solution of KOH (20%). The product was extracted

with ether (2 × 40 mL) and the solution treated with anhydrous magnesium sulfate, filtered and evaporated to dryness. The product was purified by vacuum sublimation while heating in a water bath at 60 °C. The derivative $[RuCl_2(2,2'\text{-bpy-}d_7)_2]\cdot 2H_2O$ was obtained similarly to the non-deuterated counterpart. Complex **1-*d*** is made similarly to **1**. The amounts were as follows: hpzb: 47.9 mg, 0.10 mmol; $[RuCl_2(2,2'\text{-bpy-}d_7)_2]\cdot 2H_2O$, 52.0 mg, 0.2 mmol; NH_4PF_6, 32.6 mg, 0.2 mmol. **1-*d*** obtained: 93 mg, 0.078 mmol. Yield: 78%.

3.4. Cytotoxicity: experimental procedure

3.4.1. Cell line and growth conditions

Human ovary carcinoma (A2780) cell line was purchased from ECACC and was grown in RPMI-1640 medium (Sigma-RBI, Spain) supplemented with 10% foetal bovine serum (FBS) (Sigma-RBI, Spain) and 2 mM L-glutamine (Sigma-RBI, Spain) in a humidified atmosphere of 5% CO_2 at 37 °C. Non-small cell lung cancer (NCI-H460) cell line was purchased from ATCC and was grown in RPMI-1640 medium (LGC-Promochem, Spain) supplemented with 10% foetal bovine serum (FBS) (Sigma-RBI, Spain), in a humidified atmosphere of 5% CO_2 at 37 °C. The cells were harvested using trypsin-EDTA (Sigma-RBI, Spain).

3.4.2. In vitro chemosensitivity assay on the human A2780 cell line

The cells were seeded into 96-well plates (Becton-Dickinson, Spain) in a volume of 100 μL in a number of 4000 cells/well. After attachment to the culture surface, the cells were incubated in an atmosphere containing 5% CO_2 at 37 °C for 24 h. Test drugs were dissolved in DMSO and administered maintaining the DMSO proportion at 1%. After the proper incubation time (96 h) the cells were fixed by adding 50 μL of a solution of 30% trichloroacetic acid over 60 min at 4 °C. After this time the cells were washed with H_2O and 100 μL of 0.4% sulforhodamine B in 1% acetic acid was added to the wells over 10 min at room temperature. Then cells were washed with 0.1% acetic acid and 100 μL of 10 mM Trizma were added. The plate was shaken for 15 min at room temperature and absorbance was read at a wavelength of 515 nM in a Tecan Ultra Evolution reader.

3.4.3. In vitro chemosensitivity assay on the human NCI-H460 cell line

The cells were seeded into 96-well plates (Beckton-Dickinson, Spain) in a volume of 100 μL in a number of 15000 cells/well. After attachment to the culture surface, the cells were incubated in an atmosphere containing 5% CO_2 at 37 °C for 24 h. Test drugs were dissolved in DMSO and administered maintaining the DMSO proportion at 1%.

After the proper incubation time (48 h) the growth inhibition induced by the compounds was evaluated as described before for the A2780 cell line.

3.5. Data analysis

The effects of the complex were expressed as corrected % inhibition values according to the following equation:

$$\%\ \text{inhibition}_{\text{corr}} = [1 - (T/C)] \times 100$$

where T is the mean absorbance of the treated cells and C the mean absorbance of the controls with DMSO.

$$E = \frac{E_{\max}}{1 + \left(\frac{IC_{50}}{C}\right)^n}$$

The inhibitory potency of compounds was measured by calculating concentration–% inhibition curves, these curves were adjusted to the indicated equation where E is the percentage of inhibition observed, $E_{\max}$ is the maximal effect; IC_{50} is the concentration that inhibits 50% of maximal growth, C is the concentration of compound tested and n is the slope of the semi-logarithmic dose–response curves. This non-linear fitting was performed using GraphPad Prism 2.01 Software (GraphPad Software Inc.).

For comparison purposes, the cytotoxicity of cisplatin was evaluated under the same experimental conditions.

Acknowledgements

We gratefully acknowledge financial support from the Dirección General de Investigación, Spain (Project No. CTQ2005-01430/BQU) and from the Junta de Comunidades de Castilla-La Mancha- FEDER funds (Project No. PBI-05-003). The Physical Chemistry group of the University of Burgos (UV–Vis spectra), Dr. Alvaro Colina for stimulating suggestions regarding electrochemical discussions and the SCAI service of the University of Burgos are also acknowledged.

appreciable intermolecular forces of face-to-face π–π interactions and edge-to-face CH–π contacts are essentially pertinent to planar aromatic moieties that comprise π orbitals on the rings [5]. Such interactions are often found in systems with aromatic groups, for instance, 2,2′-bypridine and 1,10-phenanthroline as coligands, which facilitate supramolecular stacks between the flat pyridyl rings [6]. It is beneficial if ligands of interest are able to concurrently generate all the three types of intermolecular contacts in view of the resulting increment of dimensionality [7]. To this end, the tp and triazole groups mentioned above should be indeed good candidates to create complicated non-covalent bonds and subsequently build up multi-dimensional assemblies because they possess the required planar aromatic rings. Besides, triazole-bridged Cu(II) complexes have been well characterized structurally and magnetically, but examples containing Co(II) and Ni(II) ions, especially triply-bridged by triazoles, are still scarce to date [8].

Herein we report the synthesis, molecular structures and magnetic properties of two dimeric complexes $[M_2(atrz)_3(H_2O)_4(tp)_2]\cdot 11H_2O$ [M = Co(**1** · $11H_2O$), Ni(**2** · $11H_2O$); atrz = 4-aminotriazole], in which triple triazole bridges and end-capped tp ligands are present. The terminal end-on binding mode for tp is a rare example among coordination systems containing tp that function mostly as end-to-end bridges, and rarely as isolated anions [3,9]. The dinuclear entities are interconnected through multiple intermolecular forces (hydrogen bond, face-to-face π–π and edge-to-face CH–π interactions), forming 3D frameworks. Magnetic analyses reveal that antiferromagnetic intradimer couplings transmitted by triazoles and weak antiferromagnetic interdimer interactions through intermolecular contacts coexist.

2. Experimental

2.1. Preparation of $[Co_2(atrz)_3(H_2O)_4(tp)_2]\cdot 11H_2O$(**1** · $11H_2O$)

To a 10 ml aqueous solution of cobalt(II) perchlorate hexahydrate (0.25 mmol, 91 mg) was added 4-aminotriazole (0.375 mmol, 32 mg) dissolved in 10 ml water, with stirring. The pink solution was treated with potassium tp (0.25 mmol, 60 mg) dissolved in 10 ml water. The filtrate of the resulting solution was allowed to stand for several days, providing pink crystals of **1** in 50% yield. *Anal.* Calc. for $C_{22}H_{34}N_{12}O_{15}Co_2$ (**1** · $3H_2O$): C, 32.05; H, 4.16; N, 20.39. Found: C, 31.89; H, 3.83; N, 19.89%.

2.2. Preparation of $[Ni_2(atrz)_3(H_2O)_4(tp)_2]\cdot 11H_2O$ (**2** · $11H_2O$)

Compound **2** was prepared by the same synthetic procedure as **1** except for the use of nickel(II) perchlorate hexahydrate instead of the Co(II) ion. Blue crystals were separated in a yield of 61%. *Anal.* Calc. for $C_{22}H_{34}N_{12}O_{15}Ni_2$ (**2** · $3H_2O$): C, 32.07; H, 4.26; N, 20.40. Found: C, 32.00; H, 3.97; N, 20.06%.

2.3. Physical measurements

Elemental analyses for C, H and N were performed at the Elemental Analysis Service Center of Seoul Branch, Korea Basic Science Institute. Infrared spectra were obtained from KBr pellets with a Bomen MB-104 spectrometer. Magnetic susceptibilities for **1** and **2** were carried out using a Quantum Design MPMS-7 SQUID susceptometer. Diamagnetic corrections of **1** and **2** were estimated from Pascal's tables.

2.4. X-ray structural analysis

X-ray data for **1** and **2** were collected on a Bruker SMART APEXII diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The preliminary orientation matrix and cell parameters were determined from three sets of ω-scans at different starting angles. Data frames were obtained at scan intervals of 0.5° with an exposure time of 10 s per frame. The reflection data were corrected for Lorentz and polarization factors. Absorption corrections were carried out using SADABS [10]. The structures were solved by direct methods and refined by full-matrix least-squares analysis using anisotropic thermal parameters for non-hydrogen atoms with the SHELXTL program [11]. All hydrogen atoms except for hydrogens bound to water molecules and amino groups to atrz were calculated at idealized positions and refined riding on the corresponding carbon atoms with isotropic thermal parameters [$U = 1.2U(C_{methylene})$]. Crystallographic data and the details of data collection are listed in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

A stoichiometric reaction of M^{2+} (M = Co and Ni):atrz:dipotassium tp in a ratio of 2:3:2 allowed the formation of **1** and **2**. In the IR spectra, strong and broad bands are observed at 3277 cm^{-1} (**1**) and 3275 cm^{-1} (**2**), which can be assigned to hydrogen bonds among water molecules, N–H groups of atrz ligands and carboxylate oxygens of tp. The secondary amine of atrz is detected at 3148 and 3121 cm^{-1} for **1**, and 3145 and 3130 cm^{-1} for **2**. The most particular peaks for the carboxylate groups of tp are characterized as the difference (Δ) between the antisymmetric stretching $\nu_a(CO_2^-)$ and symmetric frequency $\nu_s(CO_2^-)$ [12]. The calculated values of 193 cm^{-1} (**1**) and 189 cm^{-1} (**2**) are fairly large compared to the ionic value (=170 cm^{-1}) of dipotassium tp. This indicates that the binding mode of tp appears to be quasi-bridging, which was confirmed by the X-ray analysis.

3.2. Description of the structures

Compounds **1** and **2** crystallize in the monoclinic system with space group $P2/c$. The molecular structures are shown in Fig. 1. Selected distances and angles of both complexes are summarized in Tables 2 and 3. The M (M = Co and Ni) center adopts a distorted octahedral geometry, comprising one oxygen from tp, two water oxygens and three nitrogens from atrz ligands, with average M–N(O) distances of 2.10(2) Å for **1** and 2.08(2) Å for **2**. The two M atoms in a molecule are triply bridged by planar atrz groups and separated by 3.8228(6) Å for **1** and 3.7473(9) Å for **2**. The dihedral angles among the triazole rings of the bridging atrz ligands are 64.46(11)° (**1**), 64.03(16)° (**2**) between the N1-containing ring and N4- or N5-containing rings and 52.08(9)° (**1**), 52.60(13)° (**2**) between N4- and N5-containing rings. The dihedral angle between the carboxylate group and the benzene ring of tp is somewhat small, 5.96(18)° for **1** and 4.98(27)° for **2**, which fall in the lower range for tp-based complexes [3]. The benzene rings of the two terminal tp ligands lie almost coplanar, having dihedral angles of 3.24(7)° for **1** and 4.49(11)° for **2**. The dimeric structures are completed by two terminal tp ligands, among which one carboxylate group of a tp ligand is connected to the M atom in a monodentate mode while the other remains free. It deserves to be noted that tp serving as a terminal group in an end-on mode is a rare example because the ligand coordinates frequently as a bridge in the end-to-end mode to unsaturated metal centers or acts, very exceptionally, as an isolated counter anion [3,9]. The unbound oxygen atom (O2) of the coordinated carboxylate group is linked to the water

[a] Symmetry transformations used to generate equivalent atoms: #1 $-x+1, y, -z+1/2$.

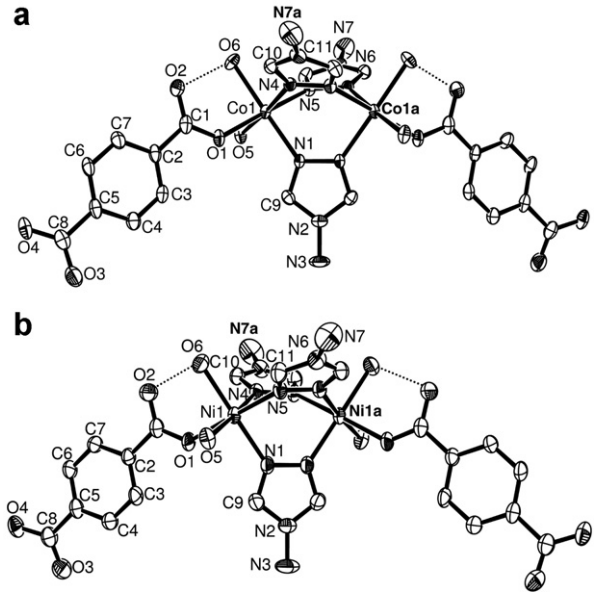

Fig. 1. ORTEP diagrams of (a) **1** and (b) **2** with the atom numbering schemes. The dotted lines represent intramolecular hydrogen bonds between coordinated water molecules and carboxylate oxygens. Symmetry code: $a = 1 - x, y, 0.5 - z$.

oxygen (O6) and one lattice water molecule (O12) via hydrogen bonds (O2···O6 = 2.630(3) Å for **1**; 2.636(5) Å for **2**). Moreover, the free carboxylate oxygens (O3 and O4) undergo multiple hydrogen bonds with lattice water molecules. Thus, the carboxylate group virtually functions as a pseudo-bridging ligator, consistent with the IR data. Hydrogen bonding is not found for the amino group (N3) of one atrz ligand while additional hydrogen bonds between the amino groups of the other two atrz ligands and lattice water molecules are observed.

Fig. 2a illustrates a 2D sheet architecture constructed by extended intermolecular face-to-face π–π interactions between the benzene rings of tp ligands operative in the crystal lattice. There exist two types of π–π contacts: for type I the planar benzene rings are stacked in the range 3.737–3.764 Å for **1** and 3.819–3.848 Å for **2** whereas type II varies in the range 3.445–4.034 Å for **1** and 3.442–4.087 Å for **2**, which are in the usual range for π–π interactions [13]. The 2D sheet is further stabilized with the assistance of edge-to-face CH–π interactions between H6-containing benzene moieties of tp ligands and N6-containing triazole rings, and the distances between H6 and the centroid of the corresponding triazole are 3.120 Å for **1** and 3.146 Å for **2** (Fig. 2b) [7]. It is thus noted that three types of intermolecular interactions are entangled in the structures and the incorporation of hydrogen bonding, π–π and CH–π contacts results in the formation of a 3D network structure. The shortest intermolecular M–M distances are 7.3562(7) Å for **1** and 7.3442(12) Å for **2**.

3.3. Magnetic properties

The magnetic susceptibility data of **1** were measured at 0.5 T from 2 to 300 K. The $\chi_m T$ value of 5.61 cm^3 K mol^{-1} at 300 K is much higher than the spin-only one (3.75 cm^3 K mol^{-1}) expected for two magnetically independent Co(II) ions, which is due to an orbital contribution from an octahedral Co(II) atom [14]. Upon cooling, $\chi_m T$ decreases slowly and then abruptly, reaching 0.127 cm^3 K mol^{-1} at 2 K. To examine the magnetic couplings between the magnetic centers, the Curie–Weiss equation was employed at $T > 80$ K yielding $C = 6.152$ cm^3 K mol^{-1} and $\theta = -28$ K. The obtained Curie constant is consistent with the normal range of 5.6–6.8 cm^3 K mol^{-1} for two hexacoordinated high-spin Co(II) centers [14,15]. The negative Weiss constant concerns a phenomenological consequence of antiferromagnetic interactions and/or spin–orbit coupling for Co(II) ions in an octahedral crystal field. In the plot of χ_m versus T (Fig. 3a), a maximum is evident at $T_{max} = 20$ K. From the ratio ($|J|/kT_{max} = 0.648$) for antiferromagnetically coupled $S = 3/2$ pairs, J was estimated to be -9.01 cm^{-1} [16].

To scrutinize the magnetic exchange coupling between Co(II) ions in the dimeric structure we modelled the present system on the basis of the spin Hamiltonian $H = -JS_{Co1} \cdot S_{Co1a}$. The fitting of the experimental data with the equation derived from the above Hamiltonian afforded a poor result (dashed line in Fig. 3a), especially around T_{max}. In

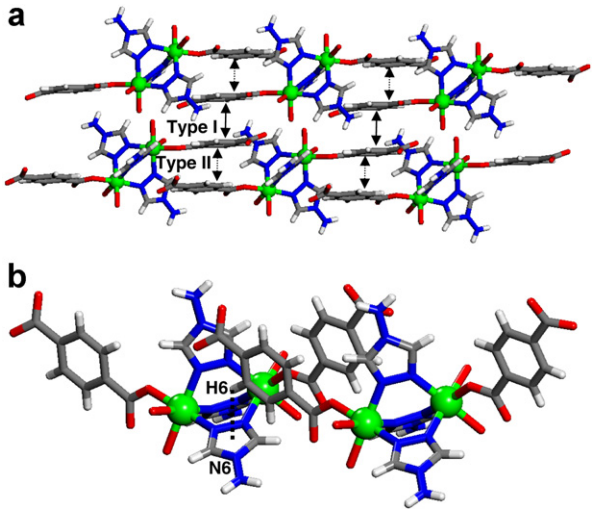

Fig. 2. (a) Extended view of **1** showing a 2D sheet formed by π–π contacts of types I and II between the benzene rings of tp ligands. (b) Additional intermolecular CH–π interaction (dashed line) between a hydrogen atom (H6) on the benzene ring and triazole rings.

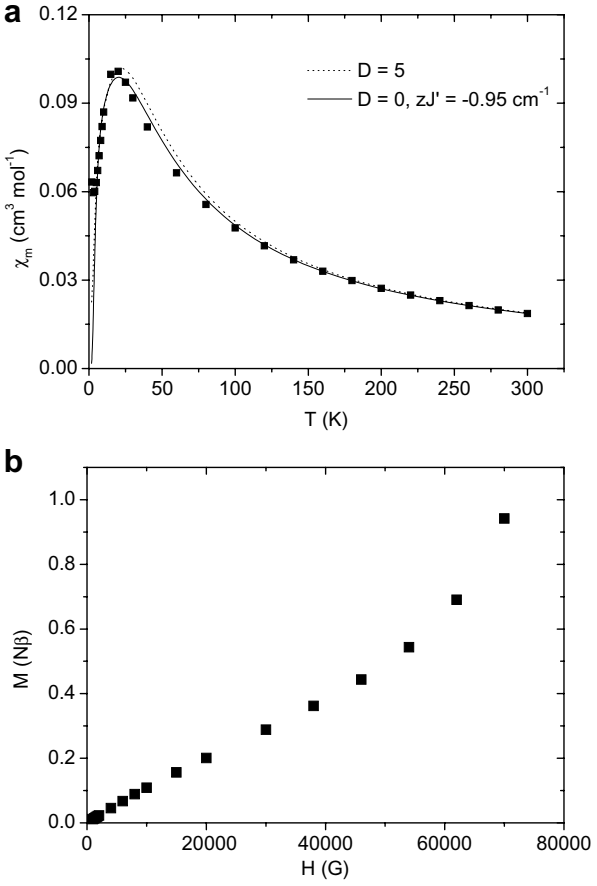

Fig. 3. Plots of: (a) χ_m vs. T and (b) M vs. H for **1**. The solid line and dotted lines represent the magnetic results with the intermolecular interaction term (zJ') and with the zero-field splitting parameter (D), respectively.

view of the presence of π–π interactions and hydrogen bonds among the dimers it is reasonable to consider an intermolecular interaction term (zJ') induced from the molecular field approximation, equated to $\chi^{corr} = \chi_m/[1 - (zJ'/Ng^2\beta^2)\chi_m]$. A better fit results and the parameters obtained with the modified formula are $g = 2.53$, $J = -9.21\ cm^{-1}$ and $zJ' = -0.95\ cm^{-1}$ (solid line in Fig. 3a). It is noticed that the J value, quite close to the estimated one from the aforementioned relation, agrees well with those of triazole-bridged Co(II) complexes [4a]. The zJ' component supports that weak interdimer antiferromagnetic interactions are mediated through the indirect linkage of the intermolecular contacts. Since the Co(II) ion is magnetically anisotropic it is necessary to include a zero-field splitting (ZFS) parameter, arising from the ZFS Hamiltonian $H_{ZFS} = D[S_z^2 - S(S+1)/3]$, in the fitting procedure. Fixing $g = 2.53$ and $J = -9.21\ cm^{-1}$, simulations with the MAGPACK program [17] to include the ZFS contribution allowed a good agreement with $D = 5\ cm^{-1}$ in the high temperature region, but significantly deviated around the peak temperature, which is due to the limit of the model adopted for explaining the magnetic properties of this dinuclear high-spin Co(II) complex. Consequently, two terms (zJ' and D) cannot be neglected to account for the observed magnetic data. It is worth mentioning that the zJ' part affects more critically the magnetic properties of **1** than D since the magnetic analysis with zJ' has a better fit than that with the D term only. The field dependence of the magnetization collected at fields from 0 to 7 T at 2 K shows a typical antiferromagnetic behavior, as depicted in Fig. 3b.

The variable temperature magnetic susceptibility data of **2** were plotted in the form of χ_m versus T (Fig. 4a). The room temperature $\chi_m T$ value of 1.97 $cm^3\ K\ mol^{-1}$ is a little lower than the expected one for two isolated Ni(II) ions. As the temperature diminishes $\chi_m T$ lessens gradually and then more rapidly, which is characteristic of antiferromagnetic interactions. The magnetic phenomenon obeys the Curie–Weiss equation at $T > 30$ K, giving $C = 2.295\ cm^3\ K\ mol^{-1}$ and $\theta = -46$ K. A cusp temperature in the $\chi_m(T)$ plot is visible at 30 K, which can be utilized to estimate the magnetic exchange coupling constant (J) from the relation $|J|/kT_{max} = 0.976$ for an antiferromagnetically coupled Ni(II) dimer, giving $J = -20.4\ cm^{-1}$ [16]. Applying the spin Hamiltonian $H = -JS_{Ni1} \cdot S_{Ni1a}$, and considering intermolecular interactions (zJ'), we obtained best-fit parameters of $g = 2.07$, $J = -21.9\ cm^{-1}$ and $zJ = -1.54\ cm^{-1}$. When zJ' is ignored and the ZFS term (D) is exclusively included in the fitting process, the resultant curves (dashed and dotted lines in Fig. 4a) are unsatisfactory, despite the unrealistic D values used. Hence, the interdimer antiferromagnetic interactions should play much more dominant role than the ZFS term in the observed magnetic behavior for **2**. The $M(H)$ data definitely suggest the presence of overall antiferromagnetic couplings (Fig. 4b).

The pair contribution J_{ij} in a simple exchange scheme between pairs of magnetic orbitals can be described on

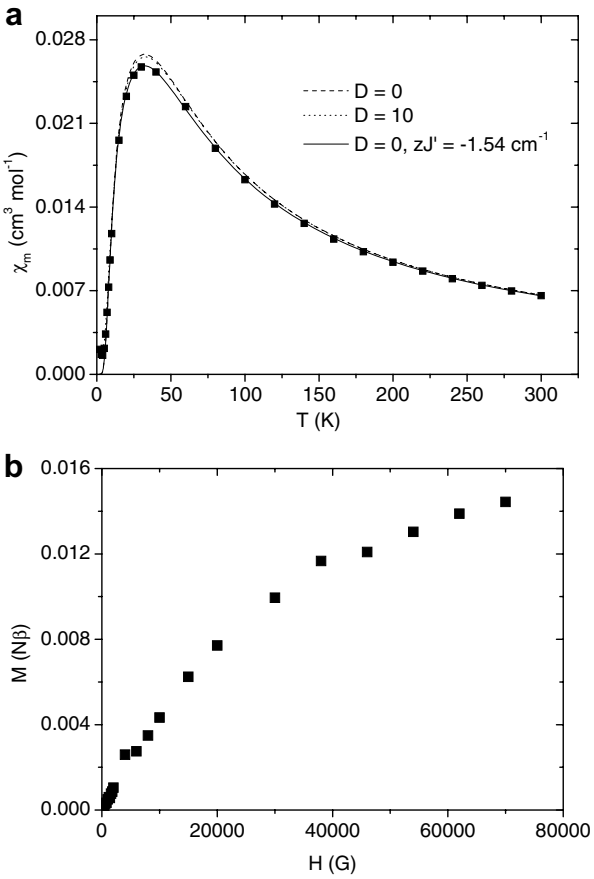

Fig. 4. Plots of: (a) χ_m vs. T and (b) M vs. H for **2**. The solid line and the other lines denote the magnetic results with the intermolecular interaction term (zJ') and with the zero-field splitting parameter (D), respectively.

the basis of coexisting ferromagnetic ($J_{ij}^F > 0$) and antiferromagnetic terms ($J_{ij}^{AF} < 0$), that is, $J = (1/n^2)\sum_{ij} J_{ij} = (1/n^2)\sum_{ij}(J_{ij}^F + J_{ij}^{AF})$ where n is the number of unpaired electrons [16]. The absolute value of n^2J, which relies on the individual contributions of the ferromagnetic (J_{ij}^F) and antiferromagnetic (J_{ij}^{AF}) interactions, corresponds to 82.9 cm^{-1} for **1** and 87.6 cm^{-1} for **2**. Moving from Ni(II) to Co(II) brings about an increase in the number of orthogonal magnetic orbitals, eventually causing an enhanced ferromagnetic contribution [18]. It is therefore manifest that the $|n^2J|$ value is reduced on going from Ni(II) to Co(II).

4. Conclusion

In summary, we have prepared two dimeric complexes constructed by triply-bridged triazole ligands and, notably, terminal end-on tp groups. An intriguing structural feature is that among dimeric molecules three types of intermolecular interactions (hydrogen bond, face-to-face π–π, and edge-to-face CH–π contacts) and intramolecular hydrogen bonds coexist, displaying a 3D architecture. Magnetic studies demonstrate that moderate intradimer antiferromagnetic interactions are evidenced together with non-negligible interdimer antiferromagnetic contributions.

NMR spectra were recorded on a Bruker DPX-400 spectrometer in $CDCl_3$ with TMS as an internal standard. High-resolution mass spectra were measured on a Waters Q-Tof Micro™ spectrometer. Preparative TLC was performed on dry silica gel plates and developed with selected appropriate solvents as eluent. Solvents were dried and freshly distilled prior to usage. 2-Arylnaphthoxazole derivatives **1a**–**1c**, **3** [9,10] and $Pd(OAc)_2$ [11] were prepared according to previously reported procedures. All aryl halides were purchased and used without further treatment.

2.2. Synthesis of palladium complexes

2.2.1. General method for the synthesis of palladacycles *2a*–*2c*

A mixture of 2-arylnaphthoxazoles **1a**–**1c** (0.2 mmol) and palladium(II) acetate (0.2 mmol) in 2 mL of acetic acid was heated at 100 °C under nitrogen for 6 h. After cooling to room temperature, water was added and the mixture was extracted with dichloromethane. Then the combined organic phases were dried over $MgSO_4$, filtered and the solvent was removed under reduced pressure. The residue was purified by preparative TLC giving yellow product.

Compound **2a***:* Yield 82%. Yellow solid, m.p. 190 °C (dec.); *Anal*. Calc. for $C_{38}H_{26}N_2O_6Pd_2$: C, 55.70; H, 3.20; N, 3.42. Found: C, 55.58; H, 3.11; N, 3.35%. IR (KBr): υ_{max} 1598, 1572, 1522, 1452, 1414, 1382, 1345, 1297, 1279, 1246, 1128, 1092, 1041, 1001, 963, 884, 802, 767, 743, 724, 695 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$): δ 2.33 (s, 6H, CH_3), 5.62–5.66 (m, 2H, Ar–H), 6.25–6.28 (m, 4H, Ar–H), 6.92 (d, $J = 7.0$ Hz, 2H, Ar–H), 7.43 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.50–7.58 (m, 4H, Ar–H), 7.69 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.86 (d, $J = 8.4$ Hz, 2H, Ar–H), 8.85 (d, $J = 8.0$ Hz, 2H, Ar–H) ppm; ^{13}C NMR (100 MHz, $CDCl_3$): δ 25.0(CH_3), 110.4(CH), 123.1(CH), 123.7(CH), 124.1(C), 124.3(CH), 125.8(CH), 126.6(CH), 126.7(CH), 128.1(CH), 128.3(CH), 128.9(C), 129.6(CH), 131.1(C), 133.8(C), 142.8(C), 146.0(C), 168.6(C=N), 181.5(C=O) ppm.

Compound **2b***:* Yield 78%. Yellow solid, m.p. 199 °C (dec.); *Anal*. Calc. for $C_{40}H_{30}N_2O_6Pd_2$: C, 56.69; H, 3.57; N, 3.31. Found: C, 56.59; H, 3.46; N, 3.24%. IR (KBr): υ_{max} 2921, 1599, 1572, 1518, 1463, 1406, 1385, 1346, 1278, 1248, 1140, 1103, 1039, 1001, 960, 884, 803, 739, 694 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$): δ 1.09 (s, 6H, CH_3), 2.33 (s, 6H, CH_3), 6.06 (d, $J = 7.7$ Hz, 2H, Ar–H), 6.13 (s, 2H, Ar–H), 6.82 (d, $J = 7.5$ Hz, 2H, Ar–H), 7.44 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.49–7.52 (m, 2H, Ar–H), 7.55–7.59 (m, 2H, Ar–H), 7.68 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.86 (d, $J = 8.0$ Hz, 2H, Ar–H), 8.89 (d, $J = 8.3$ Hz, 2H, Ar–H) ppm; ^{13}C NMR (100 MHz, $CDCl_3$): δ 21.1(CH_3), 25.1(CH_3), 110.5(CH), 123.0(CH), 124.0(C), 124.3(CH), 124.5(CH), 125.8(CH), 126.1(C), 126.2(CH), 126.6(CH), 128.2(CH), 131.6(C), 131.7(CH), 133.9(C), 140.3(C), 142.7(C), 145.9(C), 168.9(C=N), 181.4(C=O) ppm.

Compound **2c***:* Yield 76%. Yellow solid, m.p. 201 °C (dec.); *Anal*. Calc. for $C_{40}H_{30}N_2O_8Pd_2$: C, 54.62; H, 3.44; N, 3.19. Found: C, 54.55; H, 3.38; N, 3.10%. IR (KBr): υ_{max} 2927, 1599, 1567, 1520, 1467, 1412, 1388, 1346, 1315, 1264, 1230, 1178, 1130, 1101, 1036, 1000, 960, 884, 800, 742, 696 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$): δ 2.31 (s, 6H, CH_3), 2.79 (s, 6H, CH_3), 5.79–5.84 (m, 4H, Ar–H), 6.86 (d, $J = 8.3$ Hz, 2H, Ar–H), 7.40 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.48–7.50 (m, 2H, Ar–H), 7.52–7.54 (m, 2H, Ar–H), 7.66 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.86 (d, $J = 8.0$ Hz, 2H, Ar–H), 8.85 (d, $J = 8.2$ Hz, 2H, Ar–H) ppm; ^{13}C NMR (100 MHz, $CDCl_3$): δ 25.0(CH_3), 53.8(CH_3), 110.5(CH), 111.4(CH), 114.0(CH), 121.2(C), 123.7(C), 124.1(CH), 124.4(CH), 125.5(CH), 125.8(CH), 126.4(CH), 128.2(CH), 131.5(C), 133.7(C), 145.5(C), 145.7(C), 158.7(C), 169.0(C=N), 181.3(C=O) ppm.

2.2.2. General method for the synthesis of palladium complex *4*

To a solution of Li_2PdCl_4 (0.2 mmol) in methanol (2 mL), a methanolic solution (2 mL) of corresponding 2-arylnaphthoxazole **3** (0.2 mmol) and NaOAc (0.2 mmol) was added at room temperature. Then, the solution was stirred for about 10 h and a precipitate was formed. The precipitate was filtered and washed with methanol.

Compound **4***:* Yield 94%. Red solid, m.p. >270 °C; IR (KBr): υ_{max} 1601, 1555, 1528, 1465, 1429, 1383, 1322, 1248, 1151, 1133, 1069, 1004, 976, 885, 857, 797, 747, 704 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$): δ 6.21 (d, $J = 8.5$ Hz, 2H, Ar–H), 6.58–6.62 (m, 2H, Ar–H), 6.96–6.70 (m, 2H, Ar–H), 7.57–7.61 (m, 2H, Ar–H), 7.64–7.68 (m, 2H, Ar–H), 7.71 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.87 (d, $J = 8.0$ Hz, 2H, Ar–H), 7.90 (d, $J = 8.9$ Hz, 2H, Ar–H), 7.99 (d, $J = 8.0$ Hz, 2H, Ar–H), 9.46 (d, $J = 8.4$ Hz, 2H, Ar–H) ppm; HRMS (positive ESI) Calc. for $C_{34}H_{20}N_2O_4Pd$: 627.0536 $[M+H]^+$, Found: 627.0533 $[M+H]^+$.

2.3. General procedure for Heck reactions

A 5 mL round-bottom flask was charged with appropriate aryl halides (0.5 mmol), ethyl acrylate (0.75 mmol), *n*-Bu_4NBr (1.0 mmol) and base (1 mmol). The catalyst was introduced as a solvent solution (0.4 mg/mL) *via* syringe, and additional solvent was added to give a total volume of 2 mL. The reaction mixture was then placed in an oil bath and heated at 140 °C until the starting aryl halides had been completely consumed, as monitored by thin-layer chromatography. After cooling to room temperature, water was added and the mixture was extracted with dichloromethane. Then the combined organic phases were dried over $MgSO_4$, filtered and the solvent was removed under reduced pressure. The residue was purified by column chromatography on silica gel (the purified products were identified by comparison of melting points with the literature data or by ^1H NMR).

2.4. X-ray structure determination

Intensity data of the complexes **2c** and **4** were measured on a Rigaku-Raxis-IV X-ray diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 291(2) K. All data were collected using $\omega - 2\theta$ scan technique and corrected for Lorebtz-polarization effects. A correction for secondary extinction was applied. The two structures were solved by direct methods [12] and expanded using Fourier techniques. The full-matrix least-squares calculations on F^2 were applied on the final refinement. Their raw data were corrected and the structures were solved using the SHELXTL-97 program [13]. Details of crystal structure determination of the complexes **2c** and **4** are summarized in Table 1.

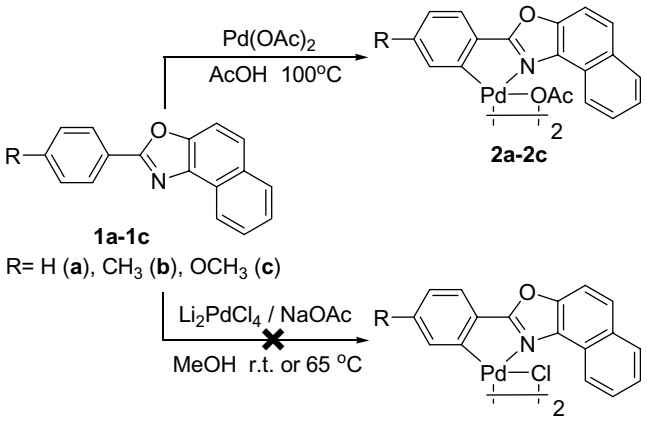

Table 1
Crystal and structure refinement data for **2c** and **4**

Compound	**2c**	**4**

3. Results and discussion

3.1. Synthesis and characterization of palladium complexes

Cyclopalladation of 2-arylnaphthoxazole derivatives **1a**–**1c** readily occurred using $Pd(OAc)_2$ in acetic acid at 100 °C under nitrogen to give yellow cyclopalladated complexes **2a**–**2c** in moderate yields (Scheme 1). Unfortunately, the μ-Cl bridged cyclopalladated complexes were not obtained by the reaction of 2-arylnaphthoxazole derivatives **1a**–**1c** with Li_2PdCl_4 in MeOH in the presence of NaOAc as a proton scavenger at room temperature or 65 °C, respectively. Complexes **2a**–**2c** were fully characterized by elemental analysis, IR, ^{1}H and ^{13}C NMR. The IR spectra of **1a**–**1c** show a sharp band at about 1637 cm^{-1} [9,10], while for complexes **2a**–**2c**, this band shifted to 1599 cm^{-1}, indicating that the nitrogen atom was coordinated to palladium through its lone pair. The appearance of the signal at about δ 2.3 ppm in ^{1}H NMR spectra and the signal at δ 181 ppm in ^{13}C NMR spectra suggested the presence of acetate group. Finally, the structure of complex **2c** has been confirmed by X-ray diffraction study (Fig. 1).

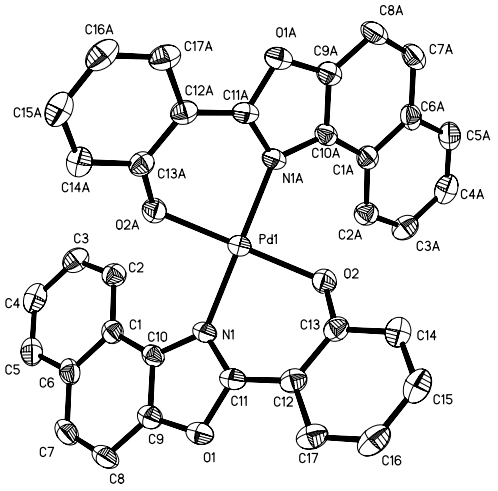

Fig. 3. Molecular structure of complex **4**.

The reaction of 2-arylnaphthoxazole derivative **3** with Li_2PdCl_4 in MeOH in the presence of NaOAc as a proton scavenger at room temperature afforded quantitatively red coordination compound **4**, but no cyclopalladated complex formed. On the other hand, when $Pd(OAc)_2$ was stirred in CH_2Cl_2 with **3** at room temperature, the same product – complex **4** was obtained (Scheme 2). Complex **4** was fully characterized by elemental analysis, IR and ^1H NMR. The $\upsilon_{C=N}$ at 1601 cm^{-1} in the IR spectrum of **4** is lower than that of **3** (1641 cm^{-1}) [9], due to the intramolecular coordination of nitrogen to palladium. Nevertheless, because of its low solubility in $CDCl_3$ and other solvents, we were unable to obtain its ^{13}C NMR spectra with high enough resolution. Fortunately, the structure of complex **4** was unequivocally confirmed by X-ray diffraction analysis (Fig. 3).

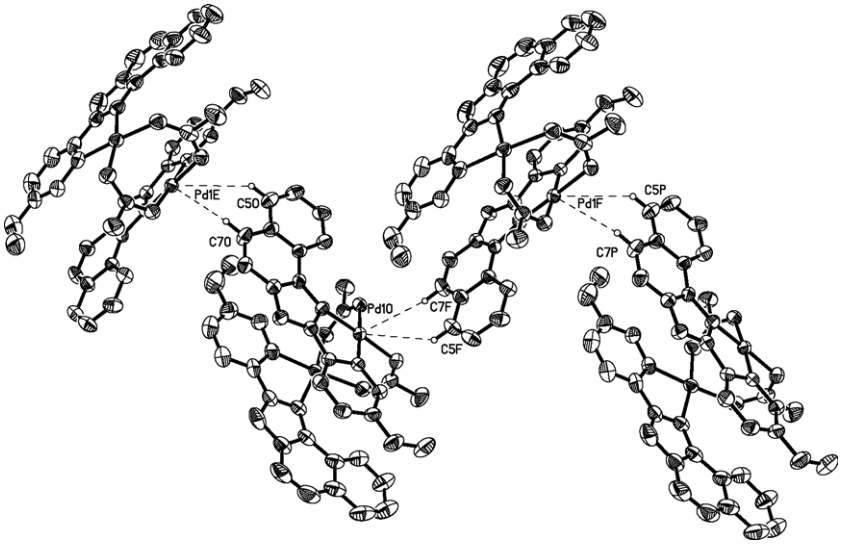

Fig. 2. One-dimensional chain structure of complex **2c**.

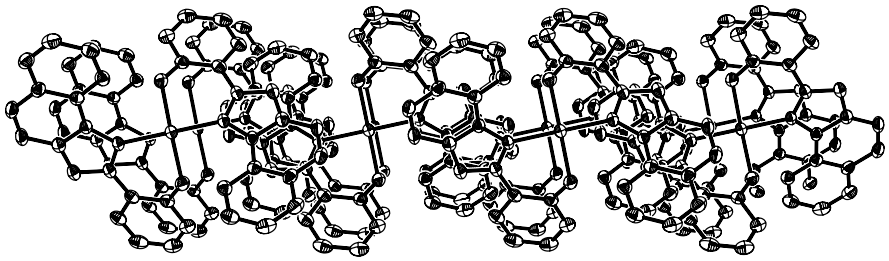

Fig. 4. The π–π interactions in complex **4**.

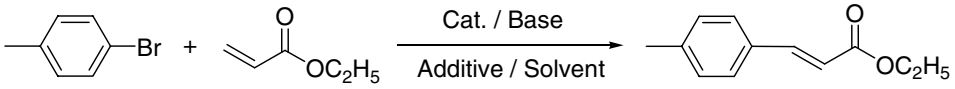
3.2. X-ray diffraction studies: crystal structures of palladium complexes *2c* and *4*

The crystal structures of complexes **2c** and **4** were determined, and the crystal data and refinement details for both structures are listed in Table 1. Selected bond length (Å) and angles (°) are listed in Table 2.



Perspective view of the molecular structure for complex **2c**, together with the corresponding atom-labeling scheme, is given in Fig. 1. The Pd atom in complex **2c** is in a square-planar environment bonded to nitrogen, carbon atoms of the naphthoxazole ligand and two oxygen atoms (one from each of the acetate ligands). The Pd–N and Pd–C bonds form the basis for five-membered chelate rings. The Pd1···Pd2 distance is 2.8735(8) Å, which is regarded as non-bonding, the covalent radius of square-planar Pd(II) has been estimated as approximately 1.31 Å [14]. The Pd1 and Pd2 are bridged by two acetate ligands and the coordination planes of the Pd atoms are not coplanar (dihedral angle is 24.0°). This leads to interligand repulsions on the "open" side of the molecule. Fig. 2 shows that in the crystal of **2c** there exist intermolecular Pd···H hydrogen bonds (Pd1F···H5P = Pd1O···H5F = 3.162 Å, Pd1F···H7P = Pd1O···H7F = 3.020 Å), which are attributed to construct the 1D chain structure of complex **2c**.

Fig. 3 shows that the Pd atom in complex **4** is in a slightly distorted square-planar environment (deviation from plane 0.1016 Å), ligand **3** coordinates to Pd(II) as a ON bidentate ligand. In contrast to complex **2c**, the Pd–N and Pd–O bonds form the basis for six-membered chelate rings in complex **4**. The Pd–N (2.029(3) Å) bond length is similar to that of the related complex (2.026(7) Å and 2.014(6) Å) [15], while it is shorter than that of complex **2c** (2.071(4) Å and 2.091(5) Å). It can be seen from Fig. 4 that the two naphthoxazole rings of neighboring molecules are almost parallel with each other with mean interplanar distance of 3.3305 Å (dihedral angle is 0.0°), indicating strong intermolecular π–π stacking interaction between the two neighboring molecules.

3.3. Catalytic activity of palladium complexes in Heck reactions

Palladacycles have been thoroughly investigated as pre-catalysts in C–C bond formation reactions. One of the

Reaction conditions: ArX (0.5 mmol), ethyl acrylate (0.75 mmol), K_2CO_3 (1.0 mmol), *n*-Bu_4NBr (1.0 mmol), DMF (1 mL), 140 °C, 24 h reaction time.
[a] Isolated yields (average of two runs) based on ArX.

most popular cross-couplings is Heck reactions. A wide variety of substrates has been used to design catalyst precursors endowed with good activity in Heck reactions. So we thought it interesting to study whether the air-stable palladium(II) complexes **2a**–**2c** and **4** would be efficient catalysts for Heck reactions.

Our initial exploration of reaction conditions focused on the coupling of 4-bromotoluene with ethyl acrylate. The results are shown in Table 3. It showed that the reaction occurred smoothly in air and afforded the product in excellent yield in the presence of additive *n*-Bu_4NBr which could react as reducing agent to generate active Pd(0) species and stabilize the intermediates by coordination or formation of ion-pairs in the catalytic cycle [16] (entries 1 and 2). After screening a variety of bases, K_2CO_3 was found to give the best result (entries 2–8). Then, a quick survey of solvents indicated that DMF was superior to others (entries 2, 9–12). With the appropriate base (K_2CO_3) and solvent (DMF) in hand, the relative activities of palladium complexes **2a**–**2c** and **4** for the same model reaction were studied (entries 2, 13–15). All the complexes exhibited high activity with catalyst loadings as low as 0.01%. Among them, complex **2c** was slightly more active than others probably because of its electron-donating methoxy group (entry 14).

Under the optimized conditions (K_2CO_3, DMF, 140 °C), the substrate scope of Heck reactions was examined. As shown in Table 4, a variety of electronically and structurally diverse aryl bromides including heteroaryl bromides could be coupled efficiently with ethyl acrylate catalyzed by 0.01 mol% of complex **2c**. The coupled products were isolated in moderate to high yields for non-activated and deactivated aryl bromide substrates in this catalytic system after 16 or 24 h (entries 1–4). For activated aryl bromides, such as 4-bromochlorobenzene, and 4-bromobenzotrifluoride, it was not surprising that excellent yields were obtained (entries 5–7). When *ortho*-substituents were used, Heck reactions also could occur efficiently (entries 8–11).

Even with the very sterically hindered 1-bromo-2-methylnapthalene, the reaction gave the coupled product in 90% isolated yields (entry 11). Coupling of heteroaryl bromides with ethyl acrylate proceeded smoothly and moderate yields were obtained (entries 12–15). In contrast to corresponding aryl bromides, this catalyst system showed decreased or even no activity for the coupling of aryl chlorides (entries 1 and 16). In the case of chlorobenzene, **2c** was almost inactive under the optimized reaction conditions (entry 16). Increasing catalyst loading to 0.1% gave 19% yield (entry 17). For activated aryl chlorides, such as 4-chloronitrobenzene, the yield of the coupled product could be reached 45% by using 0.1% of **2c** (entry 19).

4. Conclusions

In summary, we have found that air- and moisture-stable new palladium complexes **2a**–**2c** and **4**, especially palladacycle **2c**, behave as efficient phosphine-free catalysts for Heck reactions of aryl bromides with ethyl acrylate. Further investigations on the catalytic activity of this kind of palladium complexes are currently underway in our laboratory.

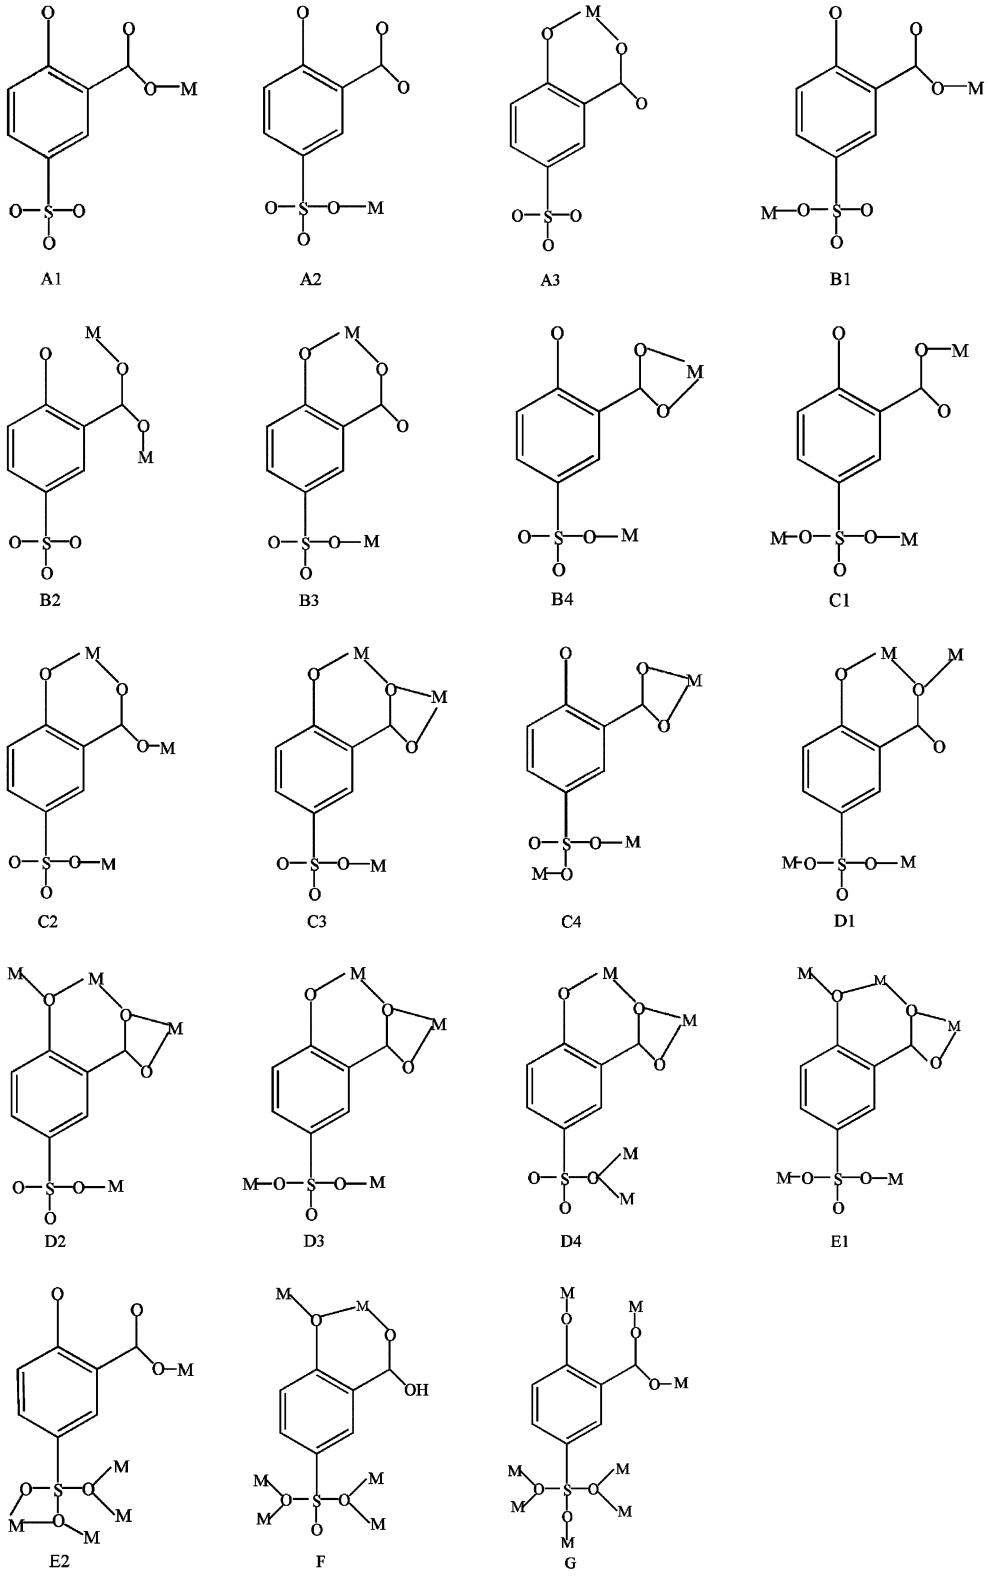

Chart 1. Coordination modes of 5-sulfosalicylates in recent reports (A, B, C, D, E, F, G denote that the 5-sulfosalicylate ligand acts as μ_1, μ_2, μ_3, μ_4, μ_5, μ_6, μ_8 connectors to link metal ions, respectively).

novel metal–organic supramolecular network through specific and directional hydrogen bonds as well as π–π stacking due to the presence of aryl rings [5–7], (2) 5-sulfosalicylic acid has been found to have biological activity and its metal complexes with Cu(II), Ni(II), Co(II), Mn(II), Fe(II), Zn(II) and VO(II) exhibit antimicrobial activity

stronger than that of the free ligand [5b,8]. In order to avoid the formation of higher dimensional coordination networks, polycyclic aromatic chelating ligands such as 2,2′-bipyridyl (2,2′-bipy) and 1,10-phenanthroline (1,10-phen) were introduced based on the following considerations: (1) chelating bipyridyl-like ligands may provide supramolecular recognition sites for π–π, C–H···π stacking and C–H···O hydrogen bonding to form interesting supramolecular structures [4b,4f,9], (2) the conjugated π systems containing (hetero) aromatic rings are currently of interests in the development of fluorescent materials [10].

In order to understand the coordination chemistry of H_3ssal and to prepare new supramolecular materials with intriguing structures and potential physical properties, we have recently focused our research on coordination complexes based on 5-sulfosalicylic acid and chelating bipyridyl-like ligands. Here, we report the syntheses and crystal structures of six new complexes, namely, $[Cu_4(OH)_2(ssal)_2(phen)_4 \cdot 7H_2O]$ (**1**), $[Cu_4(OH)_2(ssal)_2(bipy)_4 \cdot 2H_2O]$ (**2**), [Cd(Hssal)(bipy)] (**3**), $[Cd(HL)_2(phen)_2]$ (**4**), $[Cr(ssal)(bipy)(H_2O)_2 \cdot 2H_2O]$ (**5**) and $[Cr(ssal)(phen)_2]$ (**6**), together with the magnetic properties of complexes **1** and **2**. The crystal structures of complexes Mn(Hssal)$(bipy)_2(H_2O) \cdot 2H_2O$ (**7**) [6b] and Zn(Hssal)$(bipy)(H_2O)_2$ (**8**) [7d] were reported previously. The results demonstrate that the discrete or polymeric complexes may build up higher network connectivity through π–π stacking, C–H···π, O···π and hydrogen-bonding interactions including weak C–H···O contacts.

2. Experimental

2.1. Materials and physical measurements

All chemicals purchased were of reagent grade and were used without further purification. Elemental analyses (C, H, N) were performed on a Perkin–Elmer 240C elemental analyzer. IR spectra were measured on a Perkin–Elmer Spectrum One FT-IR spectrometer using KBr pellets. Magnetic measurements were obtained using an MPMS-XL magnetometer at H = 1000 Oe in the temperature range 5–300 K. The magnetic susceptibility data were corrected for the diamagnetism of the constituent atoms using Pascal's constants.

2.2. Syntheses of the complexes

2.2.1. $Cu_4(OH)_2(ssal)_2(phen)_4 \cdot 7H_2O$ (*1*)

A mixture of $CuSO_4 \cdot 5H_2O$ (0.131 g, 0.5 mmol), 5-sulfosalicylic acid (0.130 g, 0.5 mmol), phen (0.103 g, 0.5 mmol), KOH (0.062 g, 1.1 mmol) and water (15 ml) was stirred for 30 min at room temperature, transferred to and sealed in a 25 ml Teflon-lined stainless steel reactor, and then heated at 150 °C for 72 h. Upon cooling to room temperature, the dark green crystals that were obtained were filtered and washed with water. Yield: 58% based on Cu. *Anal*. Calc. for $C_{62}H_{56}N_8O_{21}Cu_4S_2$ **1**: C, 47.47; H, 3.57; N, 7.15; S, 4.08. Found: C, 47.52; H, 3.48; N, 7.13; S, 4.12%. IR (KBr, cm^{-1}): 3407vs, 1603s, 1563m, 1522w, 1472m, 1414m, 1320m, 1221m, 1167m, 1131s, 1146s, 1020s, 849s, 722vs, 604m, 479w.

2.2.2. $Cu_4(OH)_2(ssal)_2(bipy)_4 \cdot 2H_2O$ (*2*)

The hydrothermal procedure for the synthesis of complex **2** is similar to that for **1** except for the replacement of phen with 2,2-bipy (0.082 g, 0.5 mmol). Yield: 82% based on Cu. *Anal*. Calc. for $C_{54}H_{44}N_8O_{16}Cu_4S_2$ **2**: C, 46.98; H, 3.19; N, 8.12; S, 4.64. Found: C, 46.85; H, 3.02; N, 8.09; S, 4.58%. IR (KBr, cm^{-1}): 3444m, 1602s, 1562m, 1470m, 1413w, 1341w, 1253w, 1211m, 1186m, 1150m, 1030s 771m, 604m, 470w.

2.2.3. Cd(Hssal)(bipy) (*3*)

A mixture of $3CdSO_4 \cdot 8H_2O$ (0.403 g, 0.5 mmol), 5-sulfosalicylic acid (0.132 g, 0.5 mmol), 2,2′-bipy (0.081 g, 0.5 mmol), KOH (0.08 g, 1.4 mmol) and water (15 ml) was stirred for 30 min at room temperature, transferred to and sealed in a 25 ml Teflon-lined stainless steel reactor, and then heated at 150 °C for 72 h. Upon cooling to room temperature, the light red crystals that were obtained were filtered and washed with water. Yield: 58% based on Cd. *Anal.* Calc. for $C_{17}H_{12}N_2O_6CdS$ **3**: C, 42.08; H, 2.48; N, 4.95; S, 6.60. Found: C, 41.94; H, 2.52; N, 4.87; S, 6.63%. IR (KBr, cm^{-1}): 3112m, 1626w, 1596m, 1559m, 1478m, 1440m, 1254m, 1158m, 1127s, 1017s, 769m, 676m, 602m.

2.2.4. $Cd(HL)_2(phen)_2$ (*4*)

A mixture of $3CdSO_4 \cdot 8H_2O$ (0.407 g, 0.5 mmol), 5-sulfosalicylic acid (0.132 g, 0.5 mmol), phen (0.108 g, 0.5 mmol), KOH (0.071 g, 1.3 mmol) and water (15 ml) was stirred for 30 min at room temperature, transferred to and sealed in a 25 ml Teflon-lined stainless steel reactor, and then heated at 150 °C for 72 h. Upon cooling to room temperature, a colorless solution and a spot of white precipitate were obtained. The solution was filtered and the filtrate was allowed to stand at room temperature. After slow evaporation over several days, red block single crystals were obtained. Yield: 62% based on Cd. *Anal*. Calc. for $C_{36}H_{26}N_4O_8CdS_2$ **4**: C, 52.74; H, 3.17; N, 6.84; S, 7.81. Found: C, 52.67; H, 3.23; N, 6.79; S, 7.83%. IR (KBr, cm^{-1}): 3168m, 1586m, 1506m, 1424m, 1237s, 1156s, 1122s, 1031s, 844s, 728s, 566m, 451w.

2.2.5. $Cr(ssal)(bipy)_2(H_2O)_2 \cdot 2H_2O$ (*5*)

A mixture of $Cr_2(SO_4)_3 \cdot 6H_2O$ (0.255 g, 0.5 mmol), 5-sulfosalicylic acid (0.134 g, 0.5 mmol), 2,2′-bipy (0.082 g, 0.5 mmol), KOH (0.051 g, 0.9 mmol) and water (15 ml) was stirred for 30 min at room temperature, transferred to and sealed in a 25 ml Teflon-lined stainless steel reactor, and then heated at 150 °C for 72 h. Upon cooling to room temperature, the green crystals that were obtained were filtered and washed with water. Yield: 5% based on Cr. *Anal*. Calc. for $C_{17}H_{19}N_2O_{10}CrS$ **5**: C, 41.18; H, 3.84;

N, 5.65; S, 6.46. Found: C, 41.11; H, 3.90; N, 5.57%. IR (KBr, cm^{-1}): 3446s, 1608s, 1571m, 1447m, 1472m, 1150s, 1031s, 763m, 602m.

2.2.6. Cr(ssal)(phen)$_2$ (6)

A mixture of $Cr_2(SO_4)_3 \cdot 6H_2O$ (0.253 g, 0.5 mmol), 5-sulfosalicylic acid (0.136 g, 0.5 mmol), phen (0.106 g, 0.5 mmol), KOH (0.062 g, 1.1 mmol) and water (15 ml) was stirred for 30 min at room temperature, transferred to and sealed in a 25 ml Teflon-lined stainless steel reactor, and then heated at 150 °C for 72 h. Upon cooling to room temperature, a red solution was obtained, which was filtered and the filtrate was allowed to stand at room temperature. After slow evaporation over several days, red block single crystals were obtained. Yield: 35% based on Cr. *Anal*. Calc. for $C_{31}H_{19}N_4O_6CrS$ **6**: C, 59.28; H, 3.03; N, 8.92; S, 5.10. Found: C, 59.35; H, 2.84; N, 8.97; S, 5.18%. IR (KBr, cm^{-1}): 3078vw, 1608s, 1574m, 1517m, 1469s, 1426s, 1311m, 1167s, 1033s, 845m, 721m, 601m, 451m.

2.2.7. Mn(Hssal)(bipy)$_2$(H$_2$O) · 2H$_2$O (7)

The hydrothermal procedure for the synthesis of complex **7** is similar to that for **6** except for the replacement of $Cr_2(SO_4)_3 \cdot 6H_2O$ with $MnCl_2 \cdot 4H_2O$ (0.108 g, 0.5 mmol). The yellow solution was obtained, filtered, and the filtrate was allowed to stand at room temperature. After slow evaporation over several days, yellow block single crystals were obtained. Yield: 65% based on Mn. *Anal*. Calc. for $C_{27}H_{26}N_4O_9MnS$ **7**: C, 50.82; H, 4.08; N, 8.78; S, 5.02. Found: C, 50.65; H, 3.96; N, 8.97; S, 5.18%. IR (KBr, cm^{-1}): 3453s, 1592s, 1517m, 1469s, 1426m, 1311m, 1167vs, 1033s, 845m, 721s, 601m, 451m.

2.2.8. Zn(Hssal)(bipy)(H$_2$O)$_2$ (8)

The hydrothermal procedure for the synthesis of complex **8** is similar to that for **6** except for the replacement of $Cr_2(SO_4)_3 \cdot 6H_2O$ with $ZnCl_2$ (0.074 g, 0.5 mmol). A colorless solution and a spot of white deposition were obtained. The solution was filtered and the filtrate was allowed to stand at room temperature. After slow evaporation over several days, colorless block single crystals were obtained. Yield: 72% based on Zn. *Anal*. Calc. for $C_{17}H_{16}N_2O_8SZn$ **8**: C, 43.06; H, 3.38; N, 5.91; S, 6.75. Found: C, 44.12; H, 3.66; N, 5.97; S, 6.68%. IR (KBr, cm^{-1}): 3283s, 1584s, 1441s, 1153vs, 1053s, 672s, 567s.

2.3. X-ray diffraction data and crystal structure determination

The crystal structures were determined by a single-crystal X-ray diffraction experiment. The reflection data were collected on a Bruker SMART CCD area-detector diffractometer (Mo Kα radiation, graphite monochromator) at room temperature with the ω-scan mode. Empirical adsorption corrections were applied to all data using the SADABS

program. The structures were solved by direct methods and refined by full-matrix least squares on F^2 using SHELXTL97 software [11]. Non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located from difference maps and refined with isotropic temperature factors in complexes **1**–**6**. All calculations were carried out using SHELXTL97 [11] and PLATON99 [12]. The crystallographic data and pertinent information are summarized in Table 1, and any additional refinement information is given below.

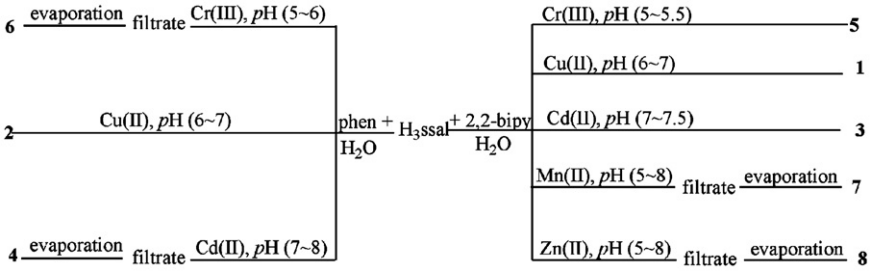
Complex **1** O1w showed disorder over two positions and was refined at 0.50 and 0.50 occupancy for each position. The hydrogen atoms of O1 w, O2w and O3w were not located from difference Fourier maps, and the O–H distances of O4w were refined with a DFIX restraint of 0.85 Å.

Complex **2** Hydrogen atoms of O1w were not located from difference Fourier maps.

Complex **5** O2 and O3 atoms of the sulfonate group both showed disorder over two positions and were refined at 0.50 and 0.50 occupancy, and 0.41 and 0.59 occupancy, respectively.

Selected bond lengths and angles for complexes **1**–**6** are summarized in Table 2. Geometrical parameters of the hydrogen bonds in complexes **1**–**6** are summarized in Table 3.

3. Results and discussion



3.1. Synthesis

5-Sulfosalicylic acid and bipyridyl-like mixed ligands were reacted in aqueous medium with different metal salts ($Cr_2(SO_4)_3 \cdot 6H_2O$, $MnCl_2 \cdot 4H_2O$, $CuSO_4 \cdot 5H_2O$, $ZnCl_2$, $3CdSO_4 \cdot 8H_2O$) in a molar ratio of 1:1:1 at different pH levels ranging from 5 to10 in an attempt to investigate the reactivity. The reactions were carried out in a 25 ml Teflon-lined stainless steel reactor at 150 °C for 72 h. We obtained compounds **1**–**8** (Scheme 1) at different pH values. Coordination complexes of Cr(III), Cu(II) and Cd(II) were obtained under weakly acidic, neutral and weakly basic conditions, respectively. Complexes **7** and **8** were easily obtained for the wider pH range 5–8. It is worth noting that complexes **1**, **2**, **3** and **5** were all directly obtained through the hydrothermal method, however, complexes **4**, **6**, **7** and **8** were synthesized through evaporation of the filtrate after the hydrothermal reaction. We tried to synthesize complexes **4**, **6**, **7** and **8** at room temperature, but failed. This demonstrates that complexes **4**, **6**, **7** and **8** were synthesized under hydrothermal conditions.

3.2. Crystal structures of the complexes

3.2.1. Structure description of $Cu_4(OH)_2(ssal)_2(phen)_4 \cdot 7H_2O$ (**1**)

X-ray single crystal diffraction reveals that compound **1** possesses a centrosymmetric Cu_4O_4 core based on a stepped topology (Fig. 1) [13]. The Cu_4O_4 core is composed of two crystallographically independent Cu (II) atoms [namely, Cu1 and Cu2]. Cu1 and Cu2 both possess the configuration of a distorted square pyramid, however, there are two sets of coordination environments around the copper atoms. Cu1 is located in a plane consisting of two nitrogen atoms (N3 and N4) from a chelating phen molecule and two hydroxides (O7 and O7#1), and the axial position is occupied by the phenolato oxygen atom (O3). For Cu2, the plane is composed of two nitrogen atoms (N1 and N2) from the phen molecule, one carboxylate oxygen (O1) and one phenolato oxygen atom (O3), and the corresponding axial position is taken by one hydroxide ion (O7#1). Cu1 and Cu2 atoms, with two symmetry-related copper centres, are connected into a Cu_4O_4 core by two μ_3-hydroxo groups and two phenolato oxygen atoms. The Cu_4O_4 core consists of a stepped structure in which three Cu_2O_2 planes are formed by Cu2 Cu1 O3 O7#1 I, Cu1 Cu1#1 O7 O7#1 II and Cu2#1 Cu1#1 O3#1 O7 III. Planes I and III, with a maximum deviation of 0.1308 Å from their least-squares planes, are parallel to each other, but both have the same bihedral angle of 103° with plane II. In the Cu_4O_4 core, we observed that the four Cu atoms form a flat rhomboid with sides Cu1···Cu2 and Cu1#1···Cu2 of lengths 3.18 and 3.59 Å, respectively, a short diagonal (Cu1···Cu1#1) of 2.94 Å and a long diagonal (Cu2···Cu2#1) of 6.10 Å. Offset π–π interactions between phen molecules with a face-to-face distance of 3.43 Å and offset angle of 28.74° stabilize the tetranuclear complex. To the best of our knowledge, only one copper complex constructed from mixed organic ligands with a stepped topology has previously been reported [13a].

Scheme 1. The reactions to prepare complexes **1**–**8**.

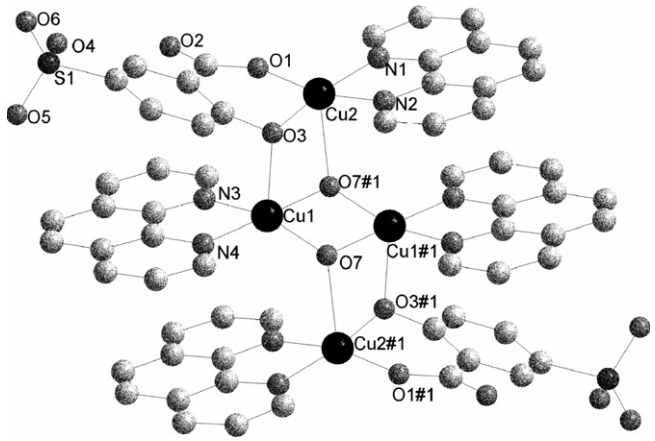


Fig. 1. The molecular structure of complex **1**.

Each $Cu_4(OH)_2(ssal)_2(phen)_4$ molecule is linked to four neighboring tetrameric units to form a 2D supramolecular layer (S-Fig. 1) of rhombic windows (with dimensions of 6.05×13.44 Å) through hydrogen bonding between μ_3-hydroxo groups (O7) and the uncoordinated sulfonate oxygen atoms (O4). The 2D layers are connected into a 3D supramolecular network by water heptamers (Fig. 2), the geometrical parameters of the hydrogen bonds are given in Table 3. In addition to hydrogen bonding, inter-layer contacts are strengthened by intermolecular π–π interactions between adjacent $Cu_4(OH)_2(ssal)_2(phen)_4$ units (offset π–π interaction between phen molecules with a face-to-face distance of 3.47 Å and offset angle 36.53°). Interestingly, the water heptamers and sulfonate anions are interconnected into a 2D supramolecular layer with very large rhombic windows (with dimensions of 12.57×17.77 Å) through hydrogen bonding (Fig. 3). The tetranuclear Cu (II) units are right inside the large rhombic windows between the 2D layers (S-Fig. 2).

3.2.2. Structure description of $Cu_4(OH)_2(ssal)_2(bipy)_4 \cdot 2H_2O$ (**2**)

Complexes **1** and **2** have the same space group, $P2_1/c$. The molecular structures of complexes **1** and **2** show some similarities as follows: (a) Both possess the centrosymmetric Cu_4O_4 (S-Fig. 3) core based on a stepped topology. (b) The central copper atoms in both complexes have the same coordination geometry, and the bond lengths and angles, as shown in Table 2, are also similar. (c) Both possess similar 2D supramolecular layers based on tetranuclear Cu (II) units. However, the replacement of phen by bipy, a chelating aromatic ligand of a smaller size, leads to some subtle differences. One difference worth noticing between the crystal structures of **1** and **2** concerns the numbers of water molecules in their asymmetric units: 3.5 water molecules for **1** and one water molecule for **2**. This results in the formation of a 3D supramolecular network (Fig. 4) for compound **2** differing from that of compound **1**. In compound **2**, the 2D layers are connected into a 3D supramolecular network through O1w with symmetry-related layers and π–π interactions between adjacent $Cu_4(OH)_2(ssal)_2(bipy)_4$ units (offset π–π interactions between 2,2′-bipy molecules with a face-to-face distance of 3.54 Å and offset angle of 24.71°).

3.2.3. Structure description of Cd(Hssal)(bipy) (**3**)

The crystal analysis of complex **3** reveals that it is a one-dimensional ladder coordination polymer containing Cd_2O_8 (2,2′-bipy)$_2$ units (Fig. 5a) with Hssal as the bridge ligands. The asymmetric unit of complex **3** consists of one Cd atom, one Hssal anion and one 2,2′-bipy ligand. The Cd center adopts a distorted capped-octahedral conformation (Fig. 5b) in which the basal plane is formed by two nitrogen atoms (N1 and N2) from a chelating 2,2′-bipy ligand, a carboxylate oxygen atom (O2) and a sulfonate oxygen atom (O6) from two different Hssal anions. The axial positions are taken by a carboxylate oxygen atom

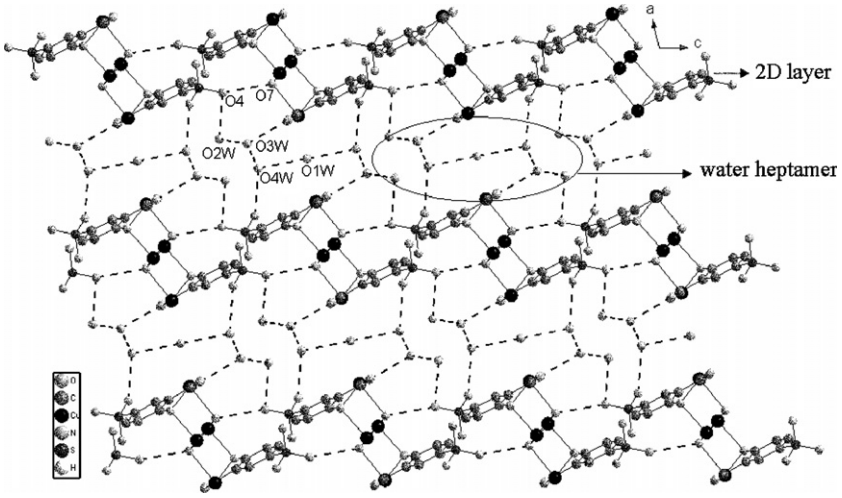

Fig. 2. Perspective view of the 3D supramolecular network of complex **1**, phen ligands and H atoms were removed for clarity.

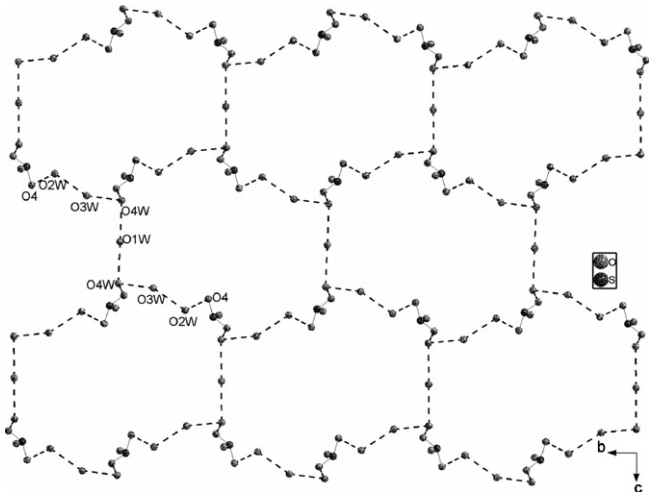

Fig. 3. 2D supramolecular layer consisting of hydrogen bonded water heptamers and sulfonate anions in complex **1**.

(O1) and a sulfonate oxygen atom (O6#3). The sulfonate oxygen atom (O4) occupies the capped position. Each pair of Cd ions is bridged by a sulfonate oxygen atom (O6) with symmetry-related partner (O6#3) to form a Cd_2O_8 (2,2′-bipy)$_2$ unit. These dimeric Cd_2 units, featuring a 1D ladder (Fig. 6a) along the crystallographic*a* axis, are interconnected by Hssal^{2-} anions. Each Hssal^{2-} anion connects three Cd (II) atoms (Fig. 6b) with the carboxylic group and sulfonate group, adopting $\mu_1 - \eta^1{:}\eta^1$-chelating and $\mu_2 - \eta^0{:}\eta^1{:}\eta^2$-bridging/chelating coordination modes [14]. As far as we know, this kind of new coordination mode of the Hssal^{2-} group has not been reported previously. The adjacent chains are further aggregated into a 2D sheet (S-Fig. 4) through π–π interactions between phen ligands, with a face-to-face distance of 3.47 Å and offset angle 36.52°, chelating C–H···O hydrogen bonding (C4···O5 = 3.39, C7···O5 = 3.41 Å) and C–H···π interactions between C8 and H5 from 2,2′-bipy ligands and Hssal^{2-} rings containing C16 (S-Fig. 5, H5···π = 2.72 and C8···π = 3.59 Å).

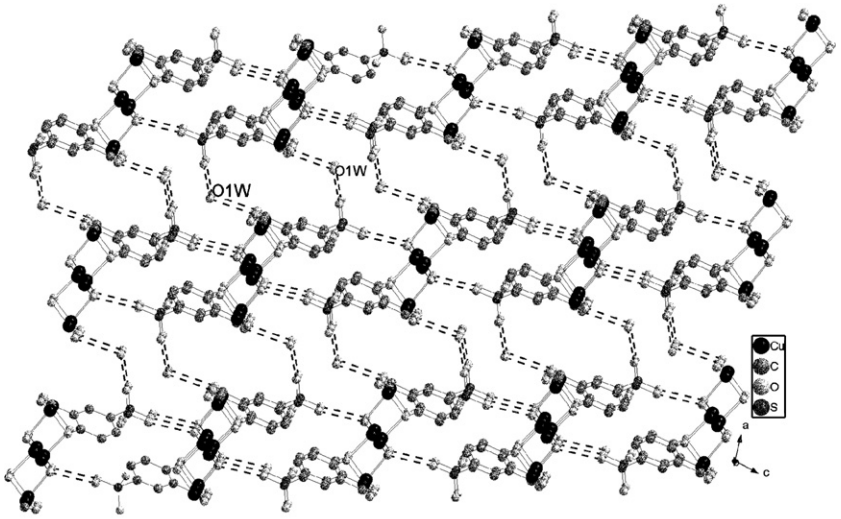

Fig. 4. Perspective view of the 3D supramolecular network of complex **2**, 2,2-bipy ligands were removed for clarity.

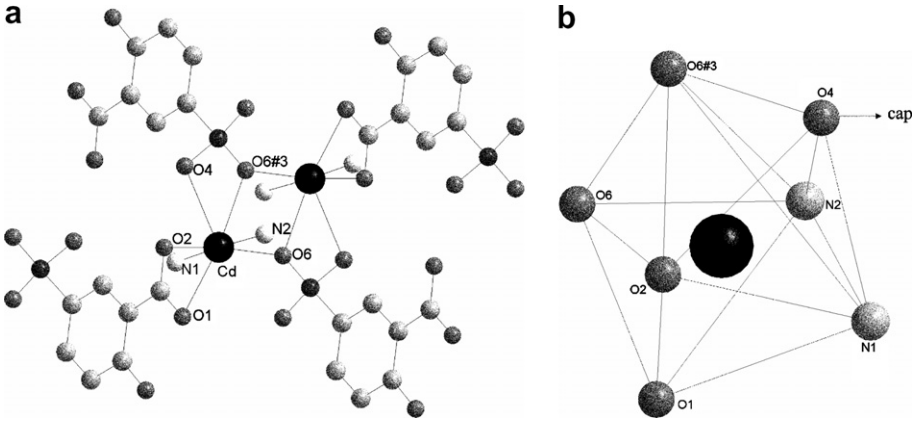

Fig. 5. (a) Perspective view of a dimeric Cd unit in complex **3**, the C atoms of 2,2′-bipy are omitted for clarity. (b) A distorted capped-octahedral conformation of the Cd (II) ion.

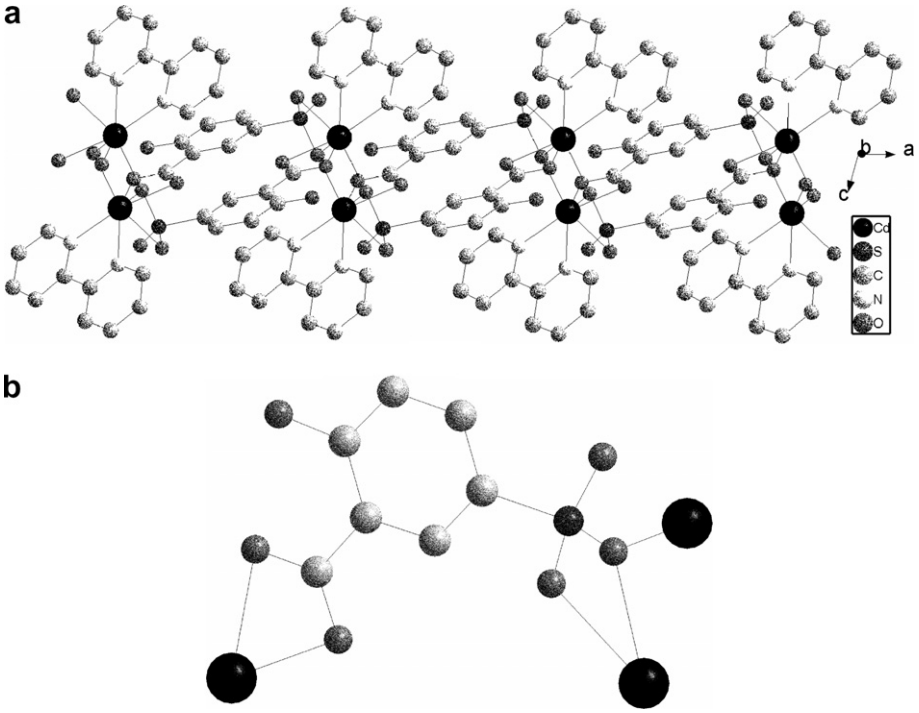

Fig. 6. (a) A 1D ladder constructed by dimeric $Cd_2O_8N_4$ units along the *a*-axis. (b) The coordination mode of the $Hssal^{2-}$ ligand in complex **3**.

3.2.4. Structure description of $Cd(HL)_2(phen)_2$ (**4**)

The crystal analysis of complex **4** reveals that it is a mononuclear complex consisting of one Cd (II) ion, two phen molecules and two *p*-hydroxybenzenesulfonic acid anions. The Cd (II) center exhibits a distorted octahedral surrounding (Fig. 7), in which the basal plane is formed by three nitrogen atoms (N1, N1#4 and N2) from two symmetry-related phen molecules and one sulfonate oxygen atom (O1#4). The axial positions are occupied by a nitrogen atom (N1#4) from a phen molecule and a sulfonate oxygen atom (O1). The π–π interactions between the aromatic rings of the different ligands are favorable to stabilize complex **4**. The closest centroid separation is 3.76 Å from the *p*-hydroxybenzenesulfonic ligand to the C_6 ring of the phen ligand, with an offset angle of 19.85°. Interestingly, the $Cd(L)_2(phen)_2$ molecules are connected into 1D supramolecular double chains (S-Fig. 6), sharing $Cd(phen)_2$ units by O–H···O hydrogen bonding (O4···O3 = 2.71 Å) along the crystallographic *c*-axis. The adjacent double chains are further aggregated into a 3D supramolecular network (Fig. 8) through π–π interactions between phen ligands (the closest centroid separation is 3.679 Å between C_6 rings with an offset angle of 16.31°) and C–H···O hydrogen bonding (C18···O2 = 3.20 Å).

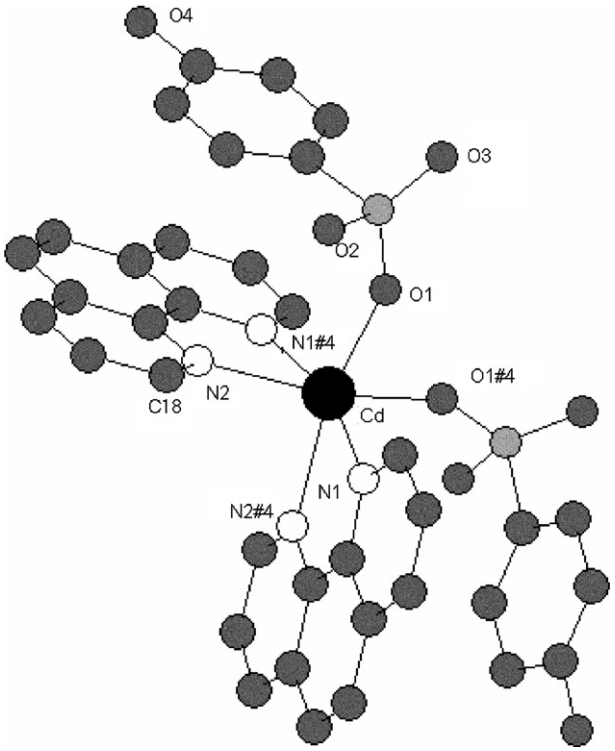

Fig. 7. The molecular structure of complex **4**.

3.2.5. Structure description of $Cr(ssal)(bipy)(H_2O)_2 \cdot 2H_2O$ (**5**)

X-ray single crystal diffraction reveals that the asymmetric unit of **5** contains one Cr(III) ion, one ssal anion, one 2,2′-bipy molecule, two coordinated water and two lattice water molecules. The Cr(III) center exhibits a distorted octahedral surrounding (Fig. 9), in which the basal plane is formed by two nitrogen atoms from a chelating 2,2′-bipy ligand (N1 and N2) and one carboxylate oxygen (O2) and one phenolic oxygen (O3) from a ssal ligand.

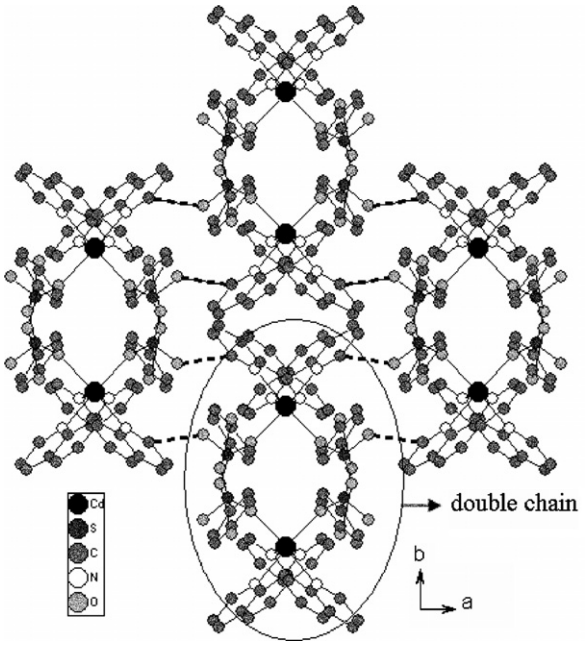

Fig. 8. The 3D supramolecular network in complex **4**.

The axial positions are occupied by O3w and O4w. Each $Cr(ssal)(bipy)_2(H_2O)_2$ unit is hydrogen bonded to two other units to form a 1D supramolecular helical chain (Fig. 9) resulting from O–H···O hydrogen bonds involving O3w, O2w, O1, O1w and O4. Within the chain, the π–π interactions between the aromatic rings of the different ligands may stabilize the polymeric supramolecular chain. The closest centroid separation is 4.01 Å from the $ssal^{3-}$ ligand to the C_5N ring (containing the N2 atom) of the 2,2′-bipy ligand with an offset angle of 26.09°. The 1D chains are further linked into a 2D layer (Fig. 10) through O–H···O hydrogen bonding (O2w···O5, O1w···O4w), the geometrical parameters of the hydrogen bonds of compound **5** are collected in Table 3. The most remarkable feature of this 2D layer is that there exist a supramolecular ring (S-Fig. 7) consisting of four coordinated water molecules (O3w and O4w), six lattice water molecules (O1w and O2w), three $ssal^{3-}$ anions and three Cr^{3+} ions, formed through covalent bonds and hydrogen bonds. Only the 2,2′-bipy molecules occupy the supramolecular rings, preventing interpenetration. Finally, the 2D layers are hydrogen bonded through O4wB-H4wB···O6 to afford a 3D supramolecular network (S-Fig. 8). Compared with some active transition metals (Zn, Cd, Cu, etc.), coordination complexes of Cr are relatively fewer due to its inertness (slow polymerization and difficulty of substitution) [15,16]. To the best of our knowledge, complex **5** is the first example of a chromium 5-sulfosalicylate complex.

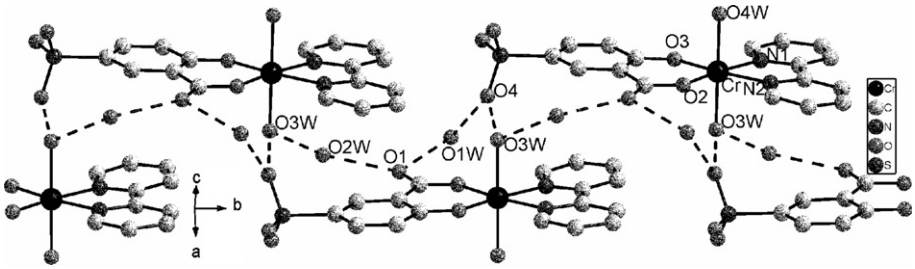

Fig. 9. 1D supramolecular helical chains consisting of $Cr(ssal)(bipy)_2(H_2O)_2$ units in complex **5**.

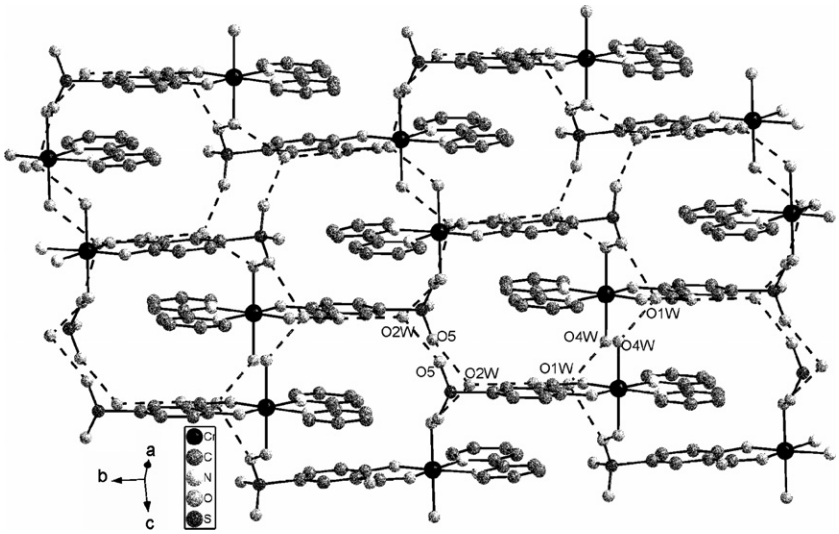

Fig. 10. Perspective view of the 2D supramolecular layer in complex **5**.

3.2.6. Structure description of Cr(ssal)(phen)$_2$ (6)

The asymmetric unit of **6** (Fig. 11) contains one Cr (III) ion, one ssal anion and two phen molecules. The Cr(III) center exhibits a distorted octahedral surrounding, in which the basal plane is formed by two nitrogen atoms from two different phen ligands (N2 and N4) and two bidentate chelating coordination oxygen atoms from one carboxylate oxygen (O1) and one phenolic oxygen (O3). The axial positions are occupied by N1 and N3 from two different phen ligands. Each Cr(ssal)(phen)$_2$ unit is hydrogen bonded to four other units to form a 2D puckered supramolecular layer (S-Fig. 9) through C–H···O (C10–H8···O5, C22–H9···O4). Moreover, O···π (S-Fig. 10, the distance of O5 to the C_5N ring containing the N3 atom is 3.10 Å) [17] and π···π interactions between the aromatic rings of different ligands (the closest centroid separation is 3.91 Å from the aryl of the ssal anion ligand to the C_6 ring of the phen ligand with an offset angle of 23.91°) stabilize the 2D puckered supramolecular layer. The 2D layers are held together into a 2D supramolecular double-layer through π···π interactions between phen ligands (the closest centroid separation is 3.79 Å between the C6 rings of phen ligands with an offset angle of 25.79°). The 2D double layers are further aggregated into a 3D supramolecular network (Fig. 12) through infinite π-stacking between the phen ligands in head-to-tail way (the closest centroid separation is 3.86 Å with an offset angle of 13.27°).

3.3. Magnetic studies of complexes 1–2

The variable temperature magnetic susceptibility of complexes **1** and **2** was measured at 1000 G in the temperature range 5–300 K. The magnetic behaviors of **1** are depicted in Fig. 13 in the forms of χ_M and μ_{eff} versus T plots (χ_M being the molar magnetic susceptibility). As the temperature is lowered, χ_M increases slowly until about 50 K, then it dramatically increases at lower temperatures. The data between 300 and 5 K can be fit to the Curie–Weiss expression, $\chi_M = C/(T-\theta)$, $[C = 0.125\, g^2 \sum S(S+1)]$, with the Curie constant $C = 1.71$ cm^3 K mol^{-1}, Weiss constant $\theta = 7.5$ K and $g = 2.14$. On the other hand, at room temperature the effective magnetic moment (μ_{eff}) equals 3.701 μ_B, which is slightly higher than the spin-only value of four

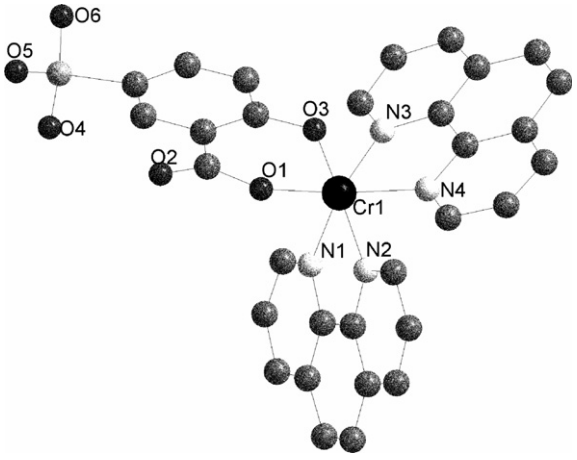

Fig. 11. The molecular structure of complex **6**. Hydrogen atoms are removed for clarity.

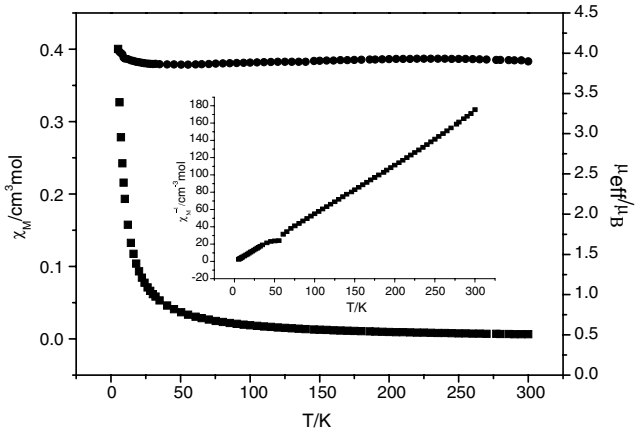

Fig. 13. Plots of χ_M and μ_{eff} vs. T for complex **1**. The inset is the plot of $1/\chi_M$ vs. T.

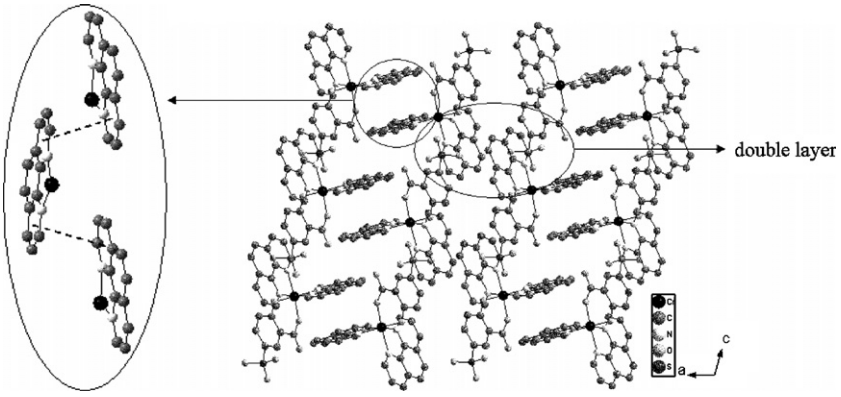

Fig. 12. The 3D representation of the packing arrangement for complex **6**. The insets show the existence of infinite π-stacking in a head-to-tail way. H atoms have been removed for clarity.

uncoupled copper (II) $S = 1/2$ ions (theoretical value for $g = 2$, $\mu_{eff} = 3.464\ \mu_B$). The μ_{eff} value increases gradually until 5 K, reaching a value of 4.037 μ_B. This feature is characteristic of the presence of significant ferromagnetic interactions between the copper (II) ions [13b,13f]. Moreover, the positive sign of the Weiss constant also indicates there exist ferromagnetic interactions between the Cu (II) centers.

The magnetic behavior of complex **2** is shown in Fig. 14 in the forms of χ_M and μ_{eff} versus T plots. As the temperature is lowered, χ_M increases slowly until about 38 K, then it dramatically increases at lower temperatures. The data between 300 and 38 K can be fit to the Curie–Weiss expression, $\chi_M = C/(T-\theta)$, $[C = 0.125\, g^2 S(S+1)]$, with the Curie constant $C = 0.784\ cm^3\ mol^{-1}$ K and Weiss constant $\theta = -0.401$ K. The effective magnetic moment (μ_{eff}) in **2** decreases slowly from 3.43 μ_B at 300 K to 3.21 μ_B at 55 K, and then falls rapidly, reaching 2.46 μ_B at 5 K. At room temperature the effective magnetic moment (μ_{eff}) equals 3.43 μ_B, which is slightly lower than the spin-only value of four uncoupled copper (II) $S = 1/2$ ions (theoretical value for $g = 2$, $\mu_{eff} = 3.46\ \mu_B$). These features indicate that there exist anti-ferromagnetic interactions amongst the Cu (II) centers [13e]. The difference in the magnetic properties of complexes **1** and **2** is possibly the result of the different intermolecular contacts.

3.4. Fluorescent properties of complexes 3–4

The solid-state fluorescent spectra of complexes **3** and **4** are depicted in Figs. 15 and 16, respectively. In order to understand the nature of the emission bands of complex **3** and **4**, we also investigated the luminescence of the free 2, 2-bipy, phen · H_2O and H_3ssal · $2H_2O$ ligands in the solid state at room temperature. The emission bands for free phen · H_2O are at 365, 381, 403 and 437 nm ($\lambda_{exc.} = 344$ nm), which may be attributed to the $\pi^* \rightarrow \pi$ transition (S-Fig. 11). Similar to free phen · H_2O, the emission bands for the free 2, 2-bipy ligand, at 390, 413 and 438 nm ($\lambda_{exc.} = 352$ nm), are also attributed to the $\pi^* \rightarrow \pi$ transition (S-Fig. 12). However, the emission bands for free H_3ssal · $2H_2O$ are mainly located at about 387 nm with a shoulder peak at 440 nm (H_3ssal · $2H_2O$: $\lambda_{exc.} = 335$ nm) and are attributed to $\pi^* \rightarrow n$ transitions (S-Fig. 13). Complex **3** exhibits intense green photoluminescence with an emission maximum at ca. 520 nm upon excitation at 347 nm (Fig. 15). Compared with the emission spectra of the free 2, 2-bipy and H_3ssal · $2H_2O$ ligands, the band at 520 nm for **3** might be assigned to the emission of a ligand-to-metal charge transfer (LMCT), similar to reported Cd complexes [18]. Complex **4** displays intense blue photoluminescence with an emission maximum at ca. 440 nm upon excitation at 329 nm (Fig. 16), compared with the emission spectra of the free phen · H_2O and H_3ssal · $2H_2O$ ligands, the band at 440 nm for **4** is neither LMCT (ligand-to-metal charge transfer) nor MLCT (metal-to-ligand charge transfer) in nature, and tentatively might be assigned to an intraligand fluorescent emission [19,20].

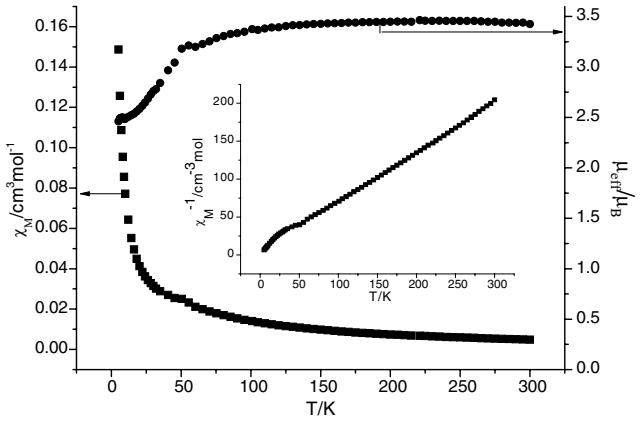

Fig. 14. plots of χ_M and μ_{eff} vs. T for complex **2**. The inset is the plot of $1/\chi_M$ vs. T.

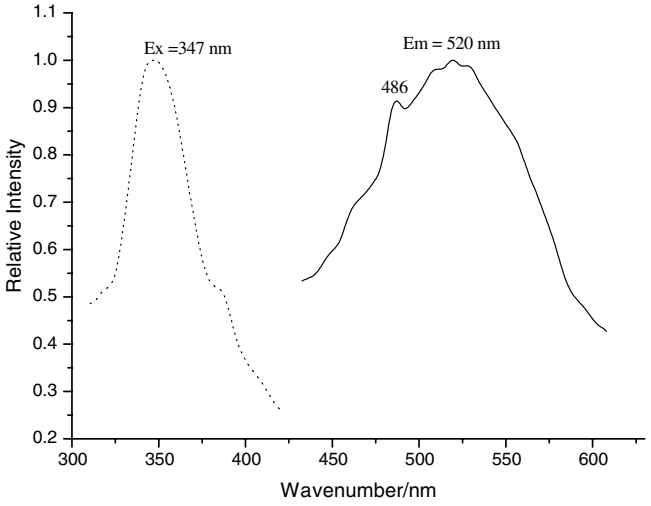

Fig. 15. Solid-state excitation fluorescent (dashed line) and emission (full line) spectra of complex **3** at room temperature.

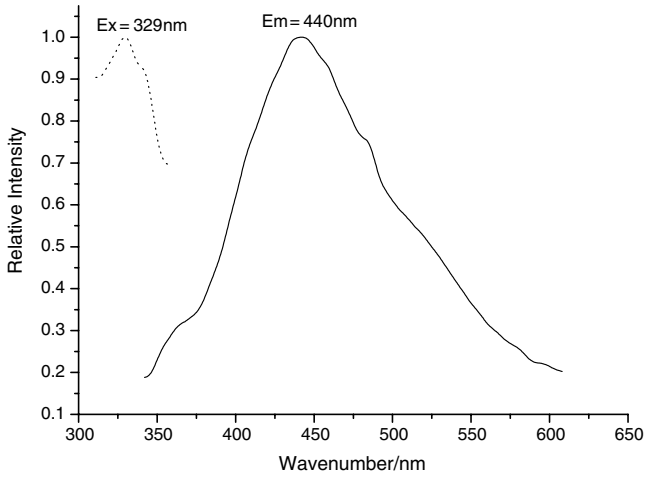

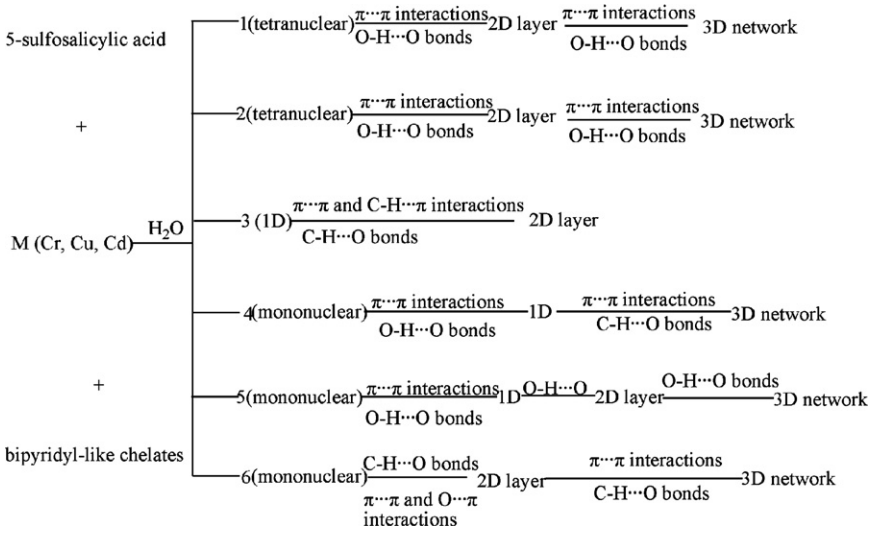

Fig. 16. Solid-state excitation fluorescent (dashed line) and emission (full line) spectra of complex **4** at room temperature.

Scheme 2.

4. Conclusion

Six new complexes constructed from 5-sulfosalicylic acid and bipyridyl-like ligands (2,2′-bipy and 1,10-phen), namely $[Cu_4(OH)_2(ssal)_2(phen)_4 \cdot 7H_2O]$ (**1**), $[Cu_4(OH)_2(ssal)_2(bipy)_4 \cdot 2H_2O]$ (**2**), [Cd(Hssal)(bipy)] (**3**), $[Cd(HL)_2(phen)_2]$ (**4**), $[Cr(ssal)(bipy)(H_2O)_2 \cdot 2H_2O]$ (**5**) and $[Cr(ssal)(phen)_2]$ (**6**), (H_3ssal = 5-sulfosalicylic acid, H_2L = *p*-hydroxybenzenesulfonic acid, bipy = 2,2′-bipy, phen = 1,10-phen) were prepared under hydrothermal conditions and their structures were determined by single-crystal X-ray diffraction. Complexes **1** and **2** are both tetranuclear copper complexes with a stepped topology. In complex **3**, a new coordination mode of the $Hssal^{2-}$ group is reported in this work. During the synthetic process of complex **4**, *in situ* decarboxylation of 5-sulfosalicylic acid into *p*-hydroxybenzenesulfonic acid is involved. Two chromium 5-sulfosalicylates (**5** and **6**) are reported for the first time. These new complexes display different supramolecular structures by O–H···O, C–H···O hydrogen bonds as well as π···π, C–H···π and O···π interactions (Scheme 2). Of the six complexes described in this work, the π-stacking interactions (O···π, C–H···π and π···π) play an important role in the observed structural stability. It is likely that studies on similar systems would be favorable for understanding the nature of the π-stacking and its role in structural stability.

with 4,4′-bipyridine for the synthesis of di- or poly-nuclear complexes.

Here, we report the synthesis and crystal structure of a di-nuclear copper(II) complex using HAMAH and 4,4′-bipyridine. During the synthesis, the Schiff base ligand undergoes hydrolysis. Hydrolysis of Schiff bases containing acetylacetone is considered as a common problem in the synthesis of their complexes and sometimes leads to the formation of different Schiff base complexes than are expected [6]. However, to our knowledge no attempt has previously been made to characterize structurally the non-Schiff base complexes that are formed as the result of hydrolysis. In the present work, we have isolated two different Cu(II) compounds containing acetylacetone and 4,4′-bipyridine in the course of hydrolytic reaction. A crystal structure determination reveals that one of the complexes, $[\{Cu(acac)(CH_3OH)(\mu\text{-}4,4'\text{-bipy})\}(ClO_4)]_n$ (**3**) possesses a zigzag chain structure although its benzoylacetone analogue is a discrete tetranuclear species [7]. In this paper, we also put forward for the first time a probable explanation for the different shape and size of the thermodynamically stable polynuclear complexes that are formed by Cu(II) and 4,4′-bipyridine.

2. Experimental

2.1. Reagents

All chemicals were commercial products of reagent grade and used without further purification.

Caution! Although no problems were encountered in this work, perchlorate salts containing organic ligands are potentially explosive. They should be prepared in small quantity and handled with great care.

2.2. Preparations

2.2.1. Synthesis of the tridentate ligand 7-amino-4-methyl-5-aza-3-hepten-2-one (HAMAH)

The ligand HAMAH was prepared as viscous oil following the literature method [5,8] using 1,2-diaminoethane and acetylacetone (acac).

2.2.2. Synthesis of $[\{Cu(AMAH)\}_2(\mu\text{-}4,4'\text{-bipy})](BF_4)_2$ (**1**) and $[Cu(acac)_2(\mu\text{-}4,4'\text{-bipy})]_n$ (**2**)

A solution of $Cu(BF_4)_2 \cdot 6H_2O$ (5 mmol, 1.726 g) in methanol (5 cm^3) was added to a solution of HAMAH (5 mmol) in methanol (10 cm^3) followed by the addition of methanol solution (10 cm^3) of 4,4′-bipyridine (2.5 mmol, 0.391 g). The mixture was stirred for about half an hour and filtered to remove a small amount of precipitate that appeared immediately. The filtrate was left at room temperature. Overnight, reddish-blue single crystals of **1**, suitable for X-ray diffraction were obtained.

After separation of the crystals of compound **1**, the filtrate was left for several days for slow evaporation of the methanol. The solution became concentrated and dark green in color. However, no more crystals of **1** appeared in this period. After about 4 days crystalline compounds

of **2** were obtained in good yield. Some of these crystals were of diffraction quality.

Complex ***1***: Yield: 0.35 g (19%). *Anal.* Calc. for $C_{24}H_{34}B_2Cu_2F_8N_6O_2$: C, 38.99; H, 4.64; N, 11.37; Cu, 17.19. Found: C, 38.78; H, 4.8; N, 11.19; Cu, 17.42%. UV–Vis spectrum, λ_{max} (nm), [ε_{max} ($dm^3\,mol^{-1}\,cm^{-1}$)] (methanol): 610 (187), 318 (11943), 274 (9329); $\mu_{eff} = 1.77$ BM (per copper ion). IR (KBr, cm^{-1}): 3349 and 3295 cm^{-1} for $\nu(NH_2)$; 1521 cm^{-1} for $\nu(C{=}N)$; 1075 cm^{-1} for $\nu(BF_4^-)$.

Complex ***2***: Yield: 0.48 g (46%). *Anal.* Calc. for $C_{20}H_{22}CuN_2O_4$: C, 57.47; H, 5.31; N, 6.7O; Cu, 15.20. Found: C, 57.25; H, 5.45; N, 6.83; Cu, 15.16%. UV–Vis spectrum, λ_{max} (nm), [ε_{max} ($dm^3\,mol^{-1}\,cm^{-1}$)] (methanol): 852 (25), 637 (98), 293 (9478); $\mu_{eff} = 1.77$ BM.

2.2.3. Synthesis of [{Cu(acac)(CH$_3$OH)(μ-4,4′-bipy)}-(ClO$_4$)]$_n$ (3)

Compound **3** was obtained in a similar way as **1**, but $Cu(ClO_4)_2 \cdot 6H_2O$ was used instead of $Cu(BF_4)_2 \cdot 6H_2O$. A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (5 mmol, 1.852 g) in methanol (5 cm^3) was added to a solution of HAMAH (5 mmol) in methanol (10 cm^3) followed by the addition of methanol solution (10 cm^3) of 4,4′-bipyridine (2.5 mmol, 0.391 g). The mixture was stirred for about half an hour and filtered to remove a small amount of precipitate that appeared immediately. Overnight, the filtrate yielded **3** as a green crystalline compound which was separated by filtration. The filtrate on being concentrated in open atmosphere yielded compound **2** in several days.

Yield: 0.54 g (48%). *Anal.* Calc. for $C_{16}H_{18}ClCuN_2O_7$: C, 42.77; H, 4.04; N, 6.23; Cu, 14.14. Found: C, 42.69; H, 4.11; N, 6.37; Cu, 14.06%. UV–Vis spectrum, λ_{max} (nm), [ε_{max} ($dm^3\,mol^{-1}\,cm^{-1}$)] (methanol): 729 (74), 303 (21234); $\mu_{eff} = 1.77$ BM. IR (KBr, cm^{-1}): 3438 cm^{-1} for ν(O–H); 1094 cm^{-1} for $\nu(ClO_4^-)$.

2.3. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra in KBr (4500–500 cm^{-1}) were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer. Electronic spectra in acetonitrile (1200–350 nm) were recorded in a Hitachi U-3501 spectrophotometer. The magnetic susceptibility measurements were done with an EG & PAR vibrating sample magnetometer, model 155, at room temperature and diamagnetic corrections were made using Pascal's constants. The thermal analyses (TGA–DTA) were carried out on a Mettler Toledo TGA/STDA 851 thermal analyzer in a dynamic atmosphere of dinitrogen (flow rate: 30 $cm^3\,min^{-1}$). The samples were heated in an alumina crucible at a rate of 10 °C min^{-1}.

2.4. X-ray crystallography

Crystal data and refinement details for **1** and **3** are given in Table 1. Intensity data were measured via the Oxford X-Calibur CCD System using Mo Kα radiation. The crystals were positioned at 50 mm from the CCD. 321 frames were measured with a counting time of 3 s. Data analyses were carried out with the CRYSALIS program [9]. The structures were solved using direct methods with the SHELX-97 program [10]. The non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. Empirical absorption corrections were carried out using the ABSPACK program [11]. The structures were refined on F^2 using SHELX-97.

3. Results and discussion

3.1. Synthesis of the complexes

It is well known that the tridentate Schiff base, HAMAH reacts readily with Cu(II) to occupy its three coordination sites whereas several anionic or neutral ligands can be coordinated to the fourth coordination site to yield different type of complexes [5]. Thus there is a possibility that the two ends of a 4,4′-bipyridine molecule can join two $[Cu(AMAH)]^+$ units and with this expectation, we added HAMAH to a methanol solution of Cu(II) perchlorate followed by 4,4′-bipyridine. On keeping the mixture overnight, a crystalline compound, $[\{Cu(acac)(CH_3OH)(\mu\text{-}4,4'\text{-bipy})\}(ClO_4)]_n$ (**3**)

resulted (Scheme 1). After separation of the compound, the filtrate was kept at open atmosphere when its color changed to deep green and finally yielded the crystalline compound $[Cu(acac)_2(\mu\text{-}4,4'\text{-bipy})]_n$ (**2**) in a few days. The reactions clearly show that the Schiff base undergoes hydrolysis in the reaction conditions. Previously, it was observed that when a proton is liberated from the Schiff base during complex formation, then this causes the hydrolysis of Schiff base ligands [6]. In the present case use of triethyl amine or any other base to neutralise the reaction mixture in an attempt to prevent the hydrolysis, however, resulted in the formation of the hydroxo-bridged trinuclear complex, $[\{Cu(AMAH)\}_3OH]^{2+}$ [5b]. To synthesize the desired 4,4′-bipyridine bridged Cu(II) containing unhydrolyzed Schiff base, we changed the counter anion of the copper salt to BF_4^- and were able to obtain the complex $[\{Cu(AMAH)\}_2(\mu\text{-}4,4'\text{-bipy})](BF_4)_2$ (**1**). Interestingly, if the crystals of **1** are not separated from mother liquor after ca. 24 h, they start to dissolve and after several days compound **2** is formed, indicating that **1** is hydrolyzed in the reaction medium. The isolation of **1** with BF_4^- counter ion but not with ClO_4^- may be due to the slight difference in the solubility of the complexes in methanol.

3.2. Crystal structures of complexes *1* and *3*

All three complexes have been characterized by single crystal X-ray analysis. However, the crystal structure of **2** has been reported previously [12]. Therefore, we report here only the structure of complexes **1** and **3**. Structural data for **2** are given in Supplementary material.

3.2.1. Complex *1*

An ORTEP view of **1** is shown in Fig. 1. Table 2 shows the selected bond lengths and angles. The structure of **1** contains discrete dimeric cations and BF_4^- anions. The centrosymmetic dimeric structure of **1** shows a planar 4,4′-bipyridine ligand bridging two copper atoms with a Cu(1)–N(21) distance of 2.026(2) Å. In addition, each copper atom is bonded to three atoms of the ligand, with the two nitrogen atoms N(15) at 1.930(2) Å and N(18) at 2.005(2) Å and an oxygen O(18) at 1.888(1) Å. The metal coordination sphere is approximately square planar with the CuN_3O equatorial plane. The sum of the four angles around the Cu atom is 363.3° indicating the slightly distorted square-planer geometry around the metal atom. The distortion may also conveniently be measured by the *trans* angles that are ideally 180° for a square-planar complex and 109.5° in a tetrahedral complex. In complex **1**, the *trans* angles are found to be 165.85(8)° (O11–Cu1–N18) and 166.14(7)° (N15–Cu1–N21). Deviations of the coordinating atoms O11, N15, N18, N21 from the least-square mean plane through them are 0.239(1), −0.247(1), 0.233(1), −0.2259(1) Å, respectively, and that of copper atom from the same plane is 0.001(1) Å. The 4,4′-bipyridine ligand intersects the equatorial plane at an angle of 34.0(1)°. The acetyl acetone ring around the metal ion is essentially planar. The Cu···Cu separation in the dimeric unit is 11.12 Å. The five-membered ring Cu(1)–N(15)–C(16)–C(17)–N(18) has an envelope conformation on C(17) with puckering parameters $Q(2) = 0.427(2)$ and $\phi(2) = 106.9(2)°$ [13]. The closest contact between the copper atom and the anion is 2.94 Å to F(13) in an axial position but this cannot be considered to be other than van der Waals interaction.

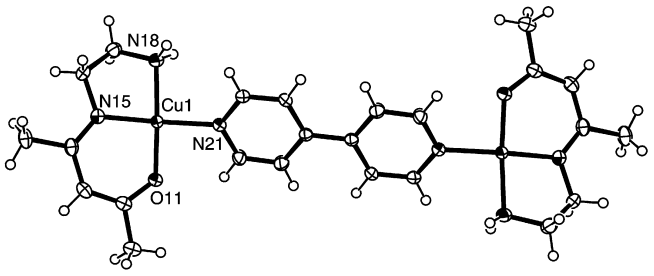

Fig. 1. The structure of the dimeric cation of **1** with ellipsoids at 25% probability.

Table 2
Selected bond lengths (Å) and bond angles (°) for complex **1**

Bond lengths (Å)	
Cu(1)–N(15)	1.930(2)
Cu(1)–O(11)	1.888(2)
Cu(1)–N(18)	2.005(2)
Cu(1)–N(21)	2.026(2)
Bond angles (°)	
O(11)–Cu(1)–N(15)	94.10(7)
O(11)–Cu(1)–N(18)	165.85(8)
N(15)–Cu(1)–N(18)	85.22(7)
O(11)–Cu(1)–N(21)	89.30(6)
N(15)–Cu(1)–N(21)	166.14(7)
N(18)–Cu(1)–N(21)	94.72(7)

In complex **1**, a 2-D hydrogen bonded sheet structure with rectangular channels along the *b*-direction is formed. The uncoordinated tetrafluoroborate anions play a significant role in the H-bonding and function as a bridge connecting two neighboring Cu(II) dimeric units. Both hydrogen atoms on the amine nitrogen (N18) form hydrogen bonds to F14 of the counter tetrafluoroborate anion (Table 3). However, while H181 is directed towards F14 at x, y, z, H182 is directed towards F14 at symmetry element $3/2 - x, -1/2 + y, 3/2 - z$) thus leading to the formation of a 1-D zigzag H-bonded structure (Fig. 2a). These 1-D zigzag H-bonded chains are further linked to each other

Table 3
Hydrogen bonding distances (Å) and angles (°) for the complex **1**

D–H···A	D–H (Å)	D···A (Å)	A···H (Å)	∠D–H···A (°)
N18–H181···F14	0.87(2)	2.13(2)	2.95(3)	157(2)
N18–H182···F14′	0.83(2)	2.21(3)	2.95(2)	148(2)

Symmetry element ′: $3/2 - x, y - 1/2, 3/2 - z$.

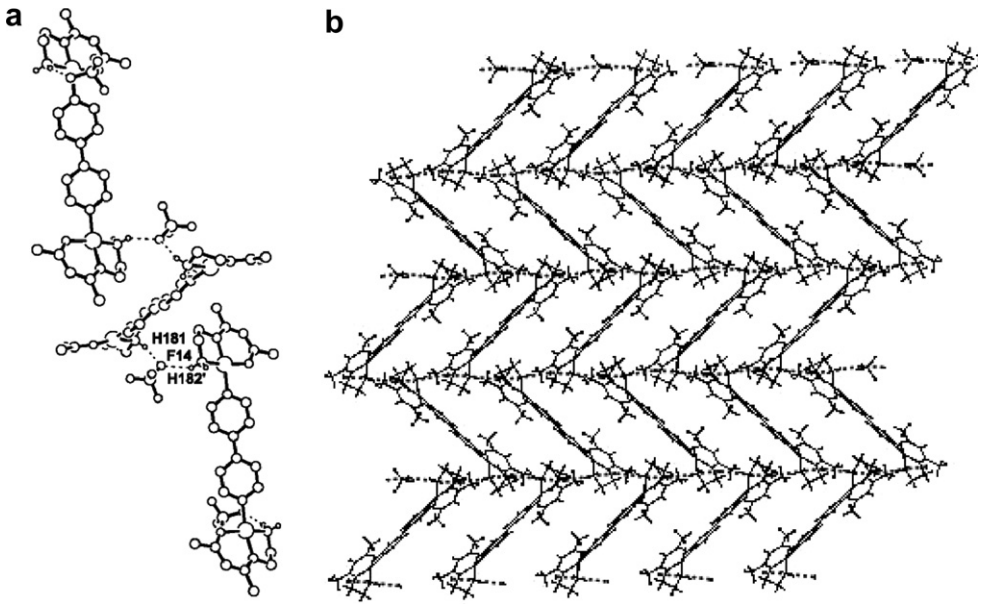

Fig. 2. Extended hydrogen-bonding network in complex **1**.

through hydrogen-bonding interactions via centrosymmetrically related fluorine and hydrogen atoms to form the final 2-D hydrogen-bonded rectangular grid network (Fig. 2b) with dimensionality of 10.178 Å × 12.208 Å.

3.2.2. Complex *3*

An ORTEP view of compound **3** together with the atom-numbering scheme is shown in Fig. 3. Selected bond lengths and angles are summarized in Table 4. The structure of **3** is a one-dimensional polymer with $[\{Cu(acac)(CH_3OH)(\mu\text{-}4,4'\text{-bipy})\}_n]^{n+}$ cations in which the metal centres are bridged via 4,4′-bipyridyl units and discrete perchlorate anions. Each copper atom has a square pyramidal five-coordinate environment with O(35) from a methanol molecule in an axial position. The equatorial plane consists of two *cis*-coordinated 4,4′-bipyridine ligands and two oxygen atoms of the acac moiety. The deviations of the equatorially coordinating four donor atoms N(11), N(21), O(31), O(315) from the least-square mean plane through them are −0.040(4), 0.044(4), −0.047(3), −0.044(3) Å, respectively. The copper atom is displaced 0.12 Å from the plane towards the epically coordinated oxygen (O35) of the methanol molecule as is usual for square-pyramid structures. Each 4,4′-bipyridine ligand links adjacent $[Cu(acac)(CH_3OH)]^+$ units, which gives rise to the 1-D zigzag chain. The two independent 4,4′-bipyridine ligands are perforce planar with the centres positioned on crystallographic centres of symmetry. The two ligands intersect the equatorial plane of the metal at angles of 17.4(2)° and 59.2(2)°, respectively. Bond lengths are within expected ranges, Cu(1)–O(31) 1.919(3) Å, Cu(1)–O(315) 1.920(3) Å, Cu(1)–N(11) 2.032(3) Å, Cu(1)–N(21) 2.038(3) Å with the axial bond Cu(1)–O(35) at 2.313(3) Å. The Cu···Cu separation is 11.16 Å. There is a slight distortion of the square pyramidal environment of copper atom towards trigonal bipyramid geometry as is evident form its Addition parameter ($\tau = 0.046$) [14].

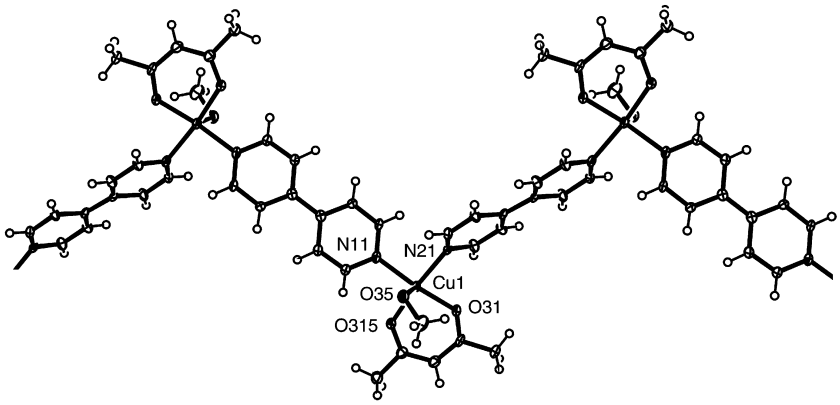

Fig. 3. The structure of **3** with ellipsoids at 25% probability.

Table 4
Selected bond lengths (Å) and bond angles (°) for complex **3**

Bond lengths (Å)	
Cu(1)–O(31)	1.919(3)
Cu(1)–O(35)	2.313(3)
Cu(1)–O(315)	1.920(3)

N(11)–Cu(1)–O(35)	89.5(1)
N(21)–Cu(1)–O(35)	93.1(1)

3.3. Discussion

The bifunctional ligand, 4,4′-bipyridine has extensively been used to link the metal ions by coordination driven self-assembly to form discrete 2-D and 3-D species with well defined shape and sizes [15]. It is well established that square planar Pt(II) and Pd(II) in which two *cis* positions are occupied by blocking ligands, act as 90° acceptor units and that a 180° donor unit, e.g. 4,4′-bipyridine on reaction with such acceptor units forms a self-assembled molecular square. First row transition metal ions, on the other hand, mostly produce dimers or one- to three-dimensional extended structures with 4,4′-bipyridine. Apparently, it seems that unlike Pt(II) and Pd(II), the shape, size and structure of such self-assembled species cannot be predicted. We attempt here to rationalize the formation of thermodynamically stable polynuclear complexes of Cu(II) containing 4,4′-bipyridine.

The reported complexes of Cu(II) containing 4,4′-bipyridine reveal that a wide variety of structures can be obtained ranging from discrete dinuclear species to 3-D polymers. Cu(II) being a d^9 system is liable to undergo Jahn–Teller distortion resulting in a (4 + 2) coordination. The strong field ligands coordinate to the four equatorial sites leaving the two axial positions to be occupied by weakly coordinating ligands (e.g. solvent molecules). Therefore, the number of coordination sites of the blocking ligands and their crystal field strength are very important for the nuclearity and shape of resulted species. 4,4′-Bipyridine being a strong field ligand prefers to occupy the equatorial position of the Cu(II). However, if the blocking ligands are stronger field than the 4,4′-bipyridine and thus occupy all four equatorial positions, it may be forced to coordinate to the axial position(s) [16]. When there is a tridentate blocking ligand in the equatorial position, then 4,4′-bipyridine usually coordinates to the remaining fourth position of two units to result in the formation of a dinuclear entity in almost all cases [17]. On the contrary, when two *cis* positions of the equatorial plane are available for its coordination, either a zigzag chain [1q,18] (as is found in compound **3**) or a molecular square as in Pt(II) and Pd(II) complexes may result [19]. Four such complexes are reported and it is found that only one is a molecular square whereas the other three are infinite chains [1q,18]. Therefore, a chain structure seems to be preferred for Cu(II) in contrast to finite supra-molecules which are preferred for 2nd or 3rd row transition metals [15]. In this context, it is worthwhile to compare the structure of **3** with that of the reported molecular square as the blocking ligand in both cases is very similar – acetylacetonate in **3** and 1-benzolyacetonate in the square [7]. The bond angles and distances of the two compounds are also very similar. The only significant difference is found in *cis*-O–Cu–N angles. In **3** the two bipy ligands intersect the equatorial plane of the metal at angles of 17.4(2)° and 59.2(2)°, respectively, which is responsible for the two very different N–Cu–O *cis* angles, 81.9(1)° and 91.0(1)°. The steric repulsion between the phenyl group and the adjacent bipyridine ligand as well as the smaller difference of the angle between the 4,4′-bipy ring and the equatorial plane in the square widens one O–Cu–N angle appreciably to 86.2(1)° which in turn decreases the other *cis*-O–Cu–N angle 88.0(1)° [7]. The angle subtended by the two donor nitrogen atoms in the two *cis*-4,4′-bipyridine moieties is 93.3(1)° in the square compared to 94.5(1)° in **3**. These small differences seem responsible for the drastic variation in the supra-molecular structure of the two compounds.

It is to be mentioned here that this rationalization is made considering the formation of only thermodynamically stable products which may well not be the case – kinetic products of lower solubility can preferentially crystallize and make the situation complicated. However, in most cases it is found that for the coordination driven self-assembly the thermodynamically controlled product is the only one that is finally formed in high yield [15,18].

3.4. Thermal analysis

The thermo-gravimetric analysis of the complex **3** shows that a weight loss of 6.8% takes place in the temperature range 35–60° corresponding to the loss of methanol molecule (calculated 7.1%). The heated species neither shows any change in color nor absorbs any water molecule on keeping in open atmosphere. In its IR spectra there is no band at ca. 3400 cm^{-1} confirming the elimination of methanol molecule.

4. Conclusions

The tridentate Schiff base ligand, HAMAH reacts with copper(II) to occupy its three equatorial positions. A 4,4′-bipyridine ligand coordinates to the fourth equatorial position of two copper units to yield the dimeric species **1**. The isolation of such dimeric species in the solid state, however, is dependent on the counter anion. As is found

in this study, the BF_4^- ion allows the separation of the complex from the reaction mixture but ClO_4^- does not although they have very similar geometry. Compound **1** is susceptible to hydrolysis in the reaction medium and the acetylacetone moiety that is one of the hydrolysis products coordinates to Cu(II) and along with 4,4′-bipyridine yields two different one-dimensional chain compounds **2** and **3**. In **2**, the two chelating acetylacetonate moieties being stronger field ligand, occupy the equatorial plane. The 4,4′-bipyridine molecule then coordinates weakly to the axial positions to form the linear chain. On the contrary, in **3** only one acetylacetonate is found and two equatorial positions are therefore blocked making it a 90° acceptor and hence a very good candidate for the formation of a molecular square with a linear donor such as 4,4′-bipyridine. However, the crystal structure of **3** shows that it is a one-dimensional chain compound although the closely related benzoylacetonate analogue with Pd(II) is a molecular square. Thus, unlike the more straightforward chemistry of Pt(II) and Pd(II) complexes, prediction of the size and shape of any supra-molecular assembly involving Cu(II) is more difficult as small changes in electronic or steric factors can lead to very different structures. Nevertheless, the rationalization of the formation of different polynuclear structures on the basis of coordination sites and crystal field strength of the blocking ligands and the Jahn–Teller effect present in Cu(II) center would be helpful to design the coordination polymers of such systems.

particles using a simple modification of the well-known Tollen's reduction in the presence of SDS. Utilization of silver nano particles as anti-microbial agent is well established though the underlying mechanism behind the activity is still ambiguous. In this paper the most important aspect of the synthesized Ag nano particles is its high efficacy as anti-microbial agent against a range of harmful microbes [*Escherichia coli* (ATCC 10536), *Vibrio cholerae* (7), *Shigella flexneri* (80903), *Salmonella typhimurium* (NCTC 74) and three varieties of *Staphylococcus aureus* (ATCC 29737, ML 276 and ML 422)] with a very low MIC value (2 μg/ml) in aqueous solution. To the best of our knowledge such a low value of MIC showed by silver nano particles is unprecedented.

2. Experimental

2.1. Reagents

All the reagents were of analytical grade. $AgNO_3$ (Aldrich) was used as received. Sodium dodecyl sulphate (SDS), *m*-hydroxy benzaldehyde, ammonia were purchased from Merck and also used as received. De-ionized water was used throughout the reaction.

2.2. Instruments

The prepared samples were characterized by FESEM and EDAX analyzer (JEOL JSM-6700 F), X-ray Powder Diffractometer (Bruker D-8 Advance) and the UV–Vis spectra of the as prepared colloidal solutions was recorded in a Perkin–Elmer UV Lambda 25 spectrophotometer.

2.3. Synthesis of Ag nano particles and study of anti-microbial activity by Agar dilution technique

Silver nitrate solution {0.02 (M)} was prepared by dissolving the required amount of $AgNO_3$ in (1:1) ammonia. Similarly, the aldehyde solution and the surfactant solution having equal concentration to that of the silver nitrate solution were prepared in dehydrated ethanol and water, respectively. Then 1 ml silver nitrate solution was taken in a well-cleaned dry beaker; 1 ml SDS solution was added to it and was mixed well for a few minutes (5 min for each set) by continuous stirring.1 ml aldehyde solution was finally added to this mixture. A light yellow color appeared at room temperature (30 °C). The solution was heated on a water-bath and the temperature was noted. When the temperature of the solution reached 80 °C, the light yellow color of the solution started turning into deep yellow. Then the color gradually changed through yellowish brown (82 °C) to reddish brown (84 °C) and finally turned into brownish black (86 °C) (Fig. 1). On further increasing the temperature of the solution, no perceptible change in color was observed. It is interesting to note that the range of reduction temperature is nearly identical to that reported by Chu et al. [33] for the case of Au. The gradual change of color in this temperature range indicated the formation of Ag nano particles of different dimensions [34]. So we have continued our study by preparing five different set solutions at the above-mentioned temperatures (i.e. at 30, 80, 82, 84 and 86 °C).

The anti-microbial study was carried out with the Ag nano particles (i.e. prepared at 86 °C) by standard agar dilution technique [36]. In short: (i) different amounts of the Ag nano particles were dispersed in phosphate buffer to get colloidal suspension; (ii) agar powder was dissolved in ultra pure water under mild heating; (iii) the molten agar solution was mixed with the prepared suspension in culture plates; (iv) the plates were cooled to turn the mixture into hydrogel; (v) diluted bacterial suspensions were transferred to the wells of an inoculum-replicating apparatus which in turn was used to transfer the inocula to the series of culture plates including a control plate without silver nano particles; and (vi) the inoculum spots were allowed to dry at room temperature and then the plates were incubated at 35 °C in air for 18 h. Finally, growth was observed and MIC values were determined in each case.

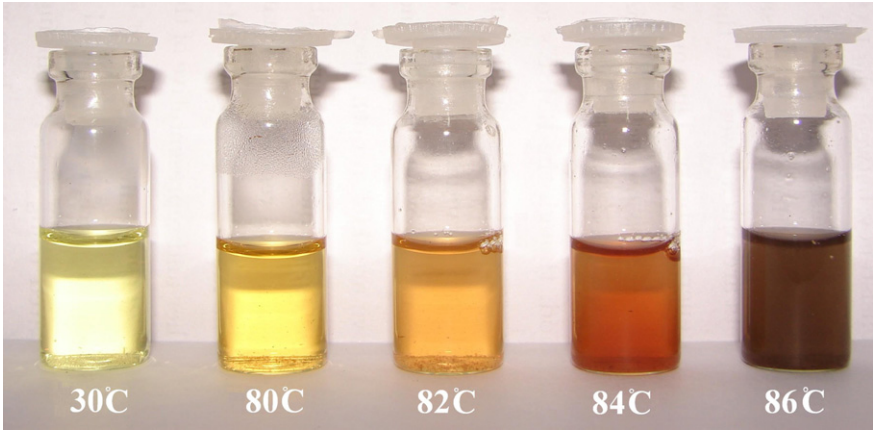

Fig. 1. The temperature-dependent color change during the progression of the reaction.

3. Results and discussion

3.1. FE-SEM analysis

Figs. 2–5 depict the SEM images of the samples obtained from the colloidal Ag solutions prepared at 80, 82, 84 and 86 °C. Fig. 2 is the SEM image of the sample prepared from the Ag colloidal solution of 80 °C that shows the existence of very few spherical nano particles. At 82 °C the SEM feature (Fig. 3A) clearly reveals the globular nano clusters in the diameter range 45–50 nm. This is the dominant morphology at this temperature, but a small number of stacked nano-disks could also be seen (Fig. 3B). Fig. 4A–D are the SEM images of the samples corresponding to 84 °C colloidal silver solution. In this temperature also the predominant morphology is the spherical nano-aggregates but the proportion of nano-disks is higher compared to the 82 °C sample. The overall morphological features are depicted in (Fig. 4A). An interesting feature of the globular nano-aggregates is its hierarchical growth nature from multiple nucleating centers leading to the 'cauliflower' like morphology of the whole spherical assembly (Fig. 4B). A minute proportion of triangular, truncated triangular nano-structures (Fig. 4C) could also be seen. In this temperature the nano-disks were ~90–120 nm long and ~54 nm in diameter. The SEM images for the sample, prepared from the colloidal solution at 86 °C are most interesting because of the equal proportion of spherical (3D) nano particles and flat nano-disks (2D) prevailing at this temperature (Fig. 5A–C). This figure that shows the overall feature of the sample at the micrometer level is a uniform distribution of disk-like structures interspersed with 'cauliflower'-like globular aggregates. The disks in the SEM image have been obtained as edge on and face on. It is to be noted that the width of individual disk is in the range 45–50 nm and they could be grown as long as a few micrometers in diameter (Fig. 5B). The spherical nano-globules have dimensions as large as 260 nm, but are composites of smaller spherical nano particles, which become as small as 15 nm (Fig. 5B and C). A 'cauliflower'-like morphology (Fig. 5C) is due to the hierarchical growth of spherical nano particles of different diameters simultaneously from different nucleating centers that are positioned very close to each other and ultimately form larger globular aggregates of different diameters. A closer look at the SEM images (Fig. 5B) also reveals that the nano-disks are not monolithic; they are composed of smaller plates which join edge on to form a disk of larger diameter.

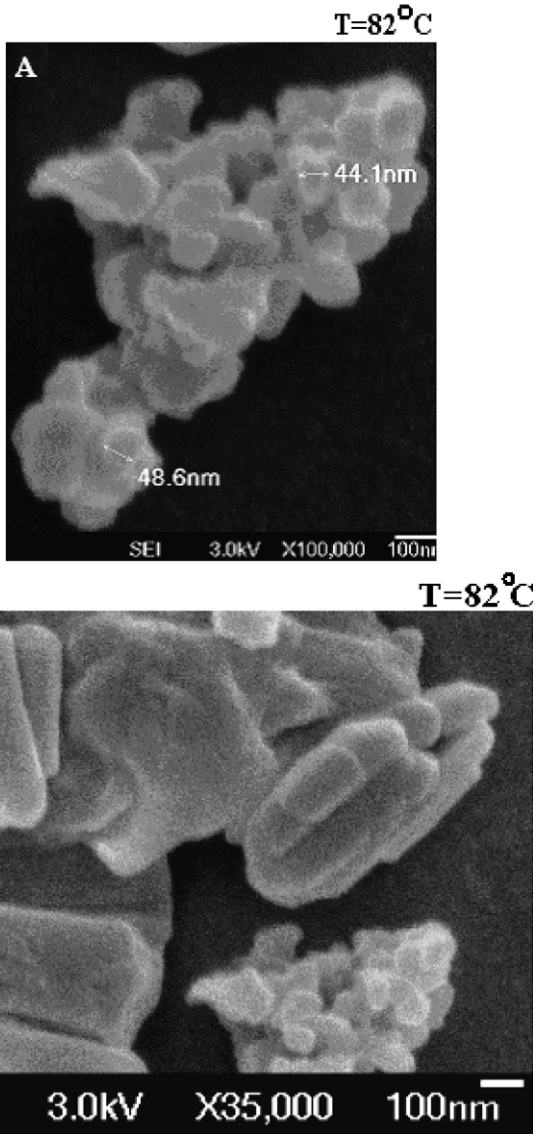

Fig. 3. Aggregated Ag nano particles (A) and Stacked nano-plates (B).

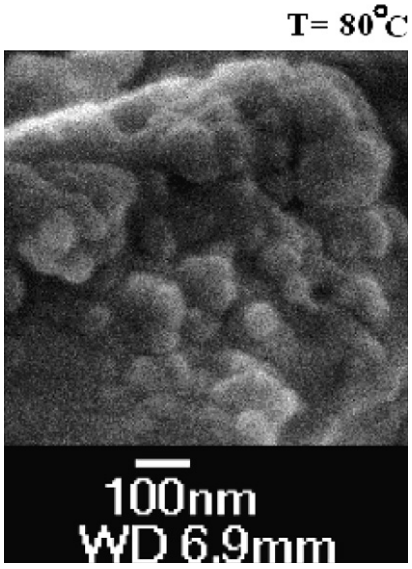

Fig. 2. Beginning of clusterization of spherical nano particles.

3.2. EDAX analysis

The purity of the prepared sample was determined by the energy dispersive X-ray analysis (EDAX). The EDAX

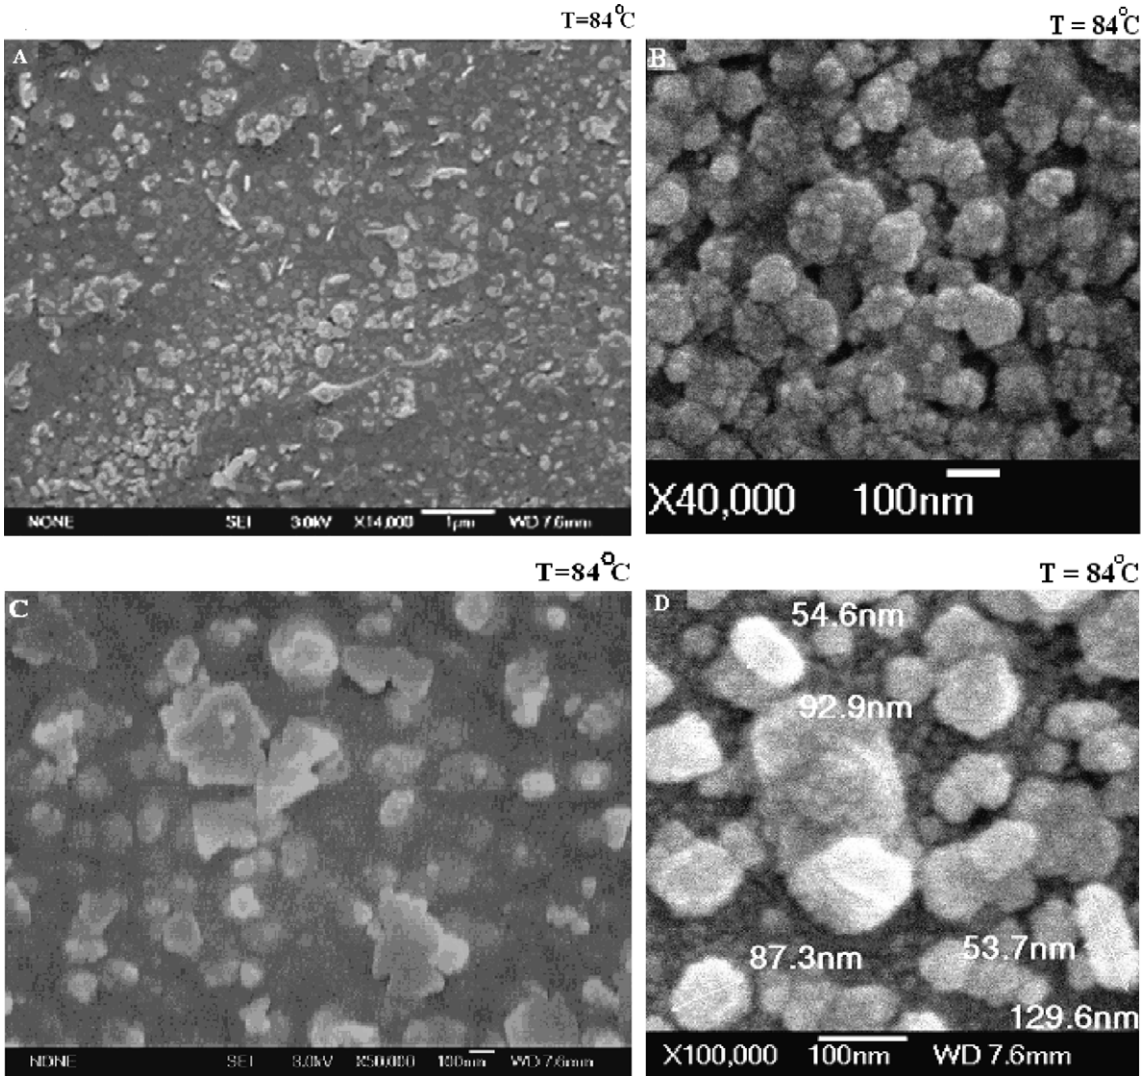

Fig. 4. Simultaneous presence of nano-plates and nano-globules (A); Cauliflower like morphology of globular nano-clusters (B); triangular and truncated triangular nano-plates (C) and dimension of nano-plates and nano-globules at 84 °C (D).

spectrum of the nano-structures prepared using SDS is shown in Fig. 6. The other peaks of Si, Mn, O, and Na appear probably due to the contribution from the borosilicate glass on which the samples were drop coated for the FESEM.

3.3. UV–Vis spectroscopic study

Fig. 7 is the UV–Vis spectrum of the sample solutions prepared at a temperature interval of 2 °C along with the solution prepared at room temperature (i.e. without aging). From the spectra it is noted that (a) there is almost no shift in the peak position and (b) the maxima are at the wavelength ~ 350 nm.This observed peak position is ascertained with the formation of silver nano-clusters $\{Ag\}_n$ made up from very low dimensional nano particles and agreed well with previous reports on silver clusters [35]. The increasing intensity demonstrates the gradual increase in surface plasmon absorption by the colloidal silver particles in solution in which the concentrations of the particles were raised due to the rise in temperature.

3.4. Powder X-ray diffraction pattern

The crystallinity of the silver nano-clusters was established by performing the Powder X-ray diffraction (Fig. 8) the data of which was collected with Cu Kα radiation, in the range 26–80° in steps of 0.02° per second. The four diffraction peaks, obtained at an angle 39.98°, 44.28°, 64.46° and 77.32°, respectively, could be completely attributed to the face-centered cubic (fcc) crystalline nature of the sample. As shown in the above figure, the highly intense diffraction peak was located at $2\theta = 39.98°$. This peak is from the (1 1 1) plane of the fcc silver. Referring to the above pattern, the lattice constant for the Ag was estimated to be $a = 4.0875$ Å which was consistent with the reported value ($a = 4.0862$ Å; JCPDS File No. 04-0783). The (2 0 0), (2 2 0) and (3 1 1) peaks are less intense. It is worth noting

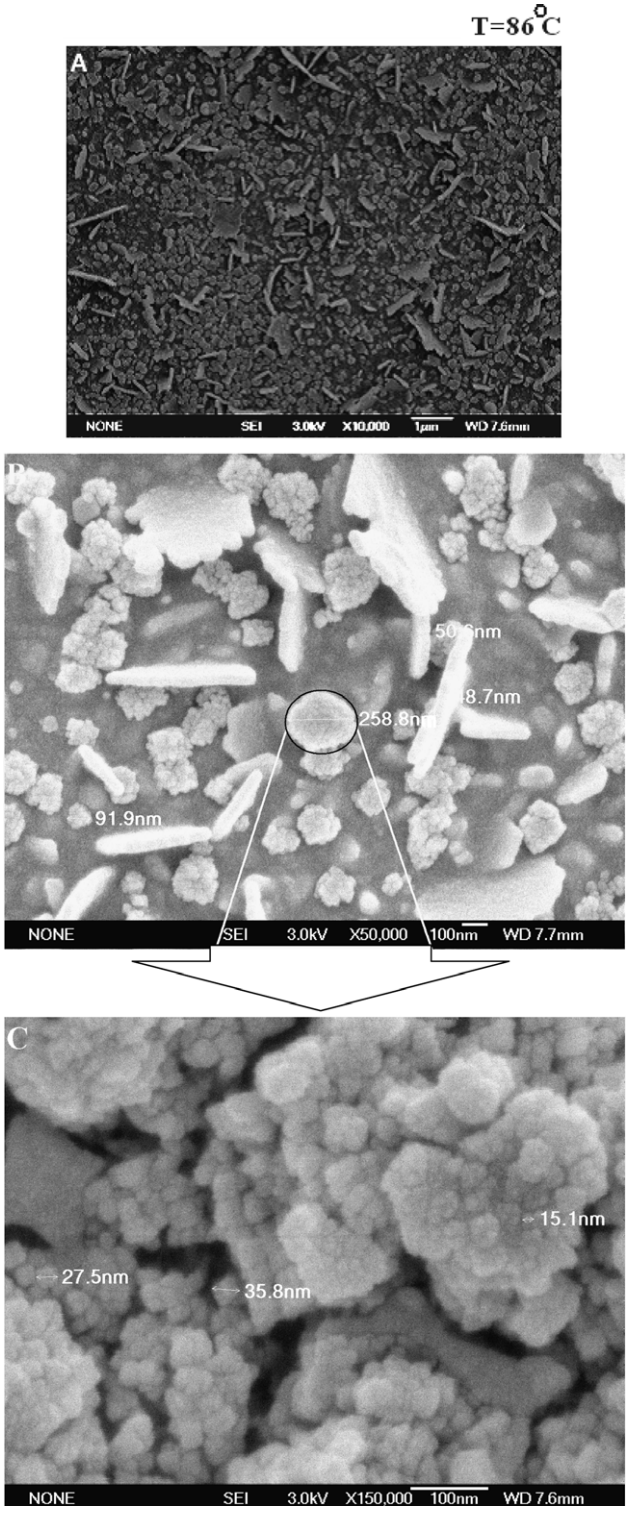

Fig. 5. Almost equally concentrated nano-disks and nano-globules (A); Nano-disks and nano-globules at high resolution (B) and "Cauliflower" like morphology of a 3D aggregate in high resolution (C).

that here the ratio of the intensities of (200) and (111) peak is lower than the conventional value (0.34 versus 0.4) and also that the ratio of (220) to (111) peak is higher than the reported one (0.32 versus 0.25), both of which clearly demonstrate the great abundance of the (111) peak. So, in this case, we might conclude that the nano-assemblies were mainly composed of (111) lattice planes. This might be the result of the lower surface free energy of that plane relative to (100) and (110) planes. This reflection is in good agreement with the previous results obtained during the structural characterization of silver nano-structures [3].

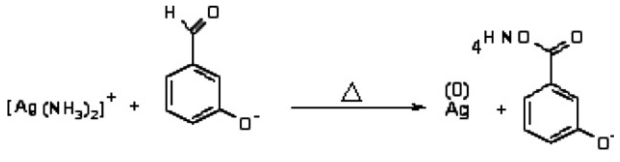
3.5. Anti-microbial activity study

The antibacterial study was carried out against seven of the most devastating bacterial strains: 1. *E. coli* (ATCC 10536); 2. *V. cholerae* (7); 3. *S. flexneri* (80903); 4. *S. aureus* (ML 422); 5. *S. typhimurium* (NCTC 74); 6. *S. aureus* (ATCC 29737) and 7. *S. aureus* (ML 276). Curiously, two strains 1 and 4 showed no growth in 2 μg/ml concentration of Ag nano particles in agar solution but they showed growth when penicillin is taken as the reference drug. None of the seven bacterial strains showed a positive growth at 4 μg/ml Ag concentration. The activity data are given in Table 1. To the best of our knowledge such a low MIC as 4 μg/ml is unprecedented.

3.6. Correlation of reaction temperature with the growth of nano particles

Hydrated silver ion, $[Ag(H_2O)x]^+$ in the presence of NH_3 form more stable silver–ammine complex ion, $[Ag(NH_3)_2]^+$. The reduction potential for the aquated and the ammoniated complex is given below:

$$[Ag(H_2O)x]^+ + e- = Ag + xH_2O \quad E^0 = 0.799\ V \qquad (I)$$



$$[Ag(NH_3)_2]^+ + e- = Ag + 2NH_3 \quad E^0 = 0.373\ V \qquad (II)$$

From the above data it is easy to understand that the ammoniated complex is more difficult to reduce than the hydrated one. But the reductant aldehyde is oxidized more easily in the presence of base (NH_3) than in its absence in aqueous medium, which is clear from the following half-cell reaction involved with this oxidation phenomenon:

$$RCHO + H_2O = RCOOH + 2H^+ + 2e^- \qquad (III)$$

Thus, from Eqs. (I) and (II) it is clear that due to the difficulty in reduction in ammoniacal medium, silver ions are slowly reduced. But this process is continuous due to the facile oxidation of the aldehyde in the same medium. This slow and steady formation of silver particles helps in effective capping by SDS.

The reduction reaction is given below:

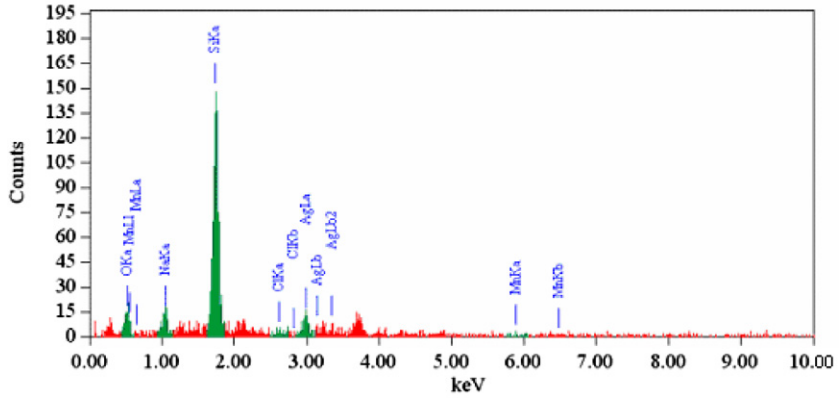


Fig. 6. EDAX spectra of the sample.

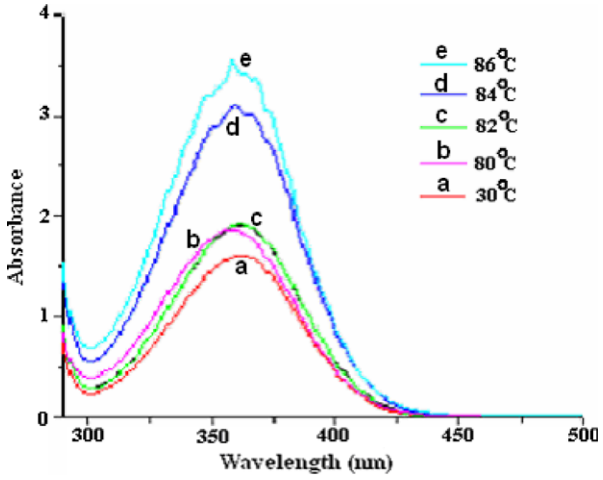

Fig. 7. The UV–Vis spectra taken for the freshly prepared colloidal solutions at the mentioned temperatures.

It is worth noting that the temperature required for the initiation of the reduction is quite low as compared to relatively higher temperatures of other reported thermally assisted solution phase nano synthesis procedures [3,37,38]. Here, the formation of the nano-aggregates could be explained on the basis of classical chemical kinetics theory [39]. The SEM images clearly demonstrate the strong dependence of the reaction on temperature. We have noticed the morphological change of the nano assemblies with the increasing temperature. The observed dimensional change was ~15 nm (80 °C) to ~45 nm (82 °C) to ~50–100 nm (84 °C) to ~120–260 nm and this change in dimensionality was qualitatively noticed through the sequential change in color of the solutions prepared at the said temperatures. With the increase of temperature, the kinetic energy of the Ag nano particles in the solution increases; as a result the collision fre-

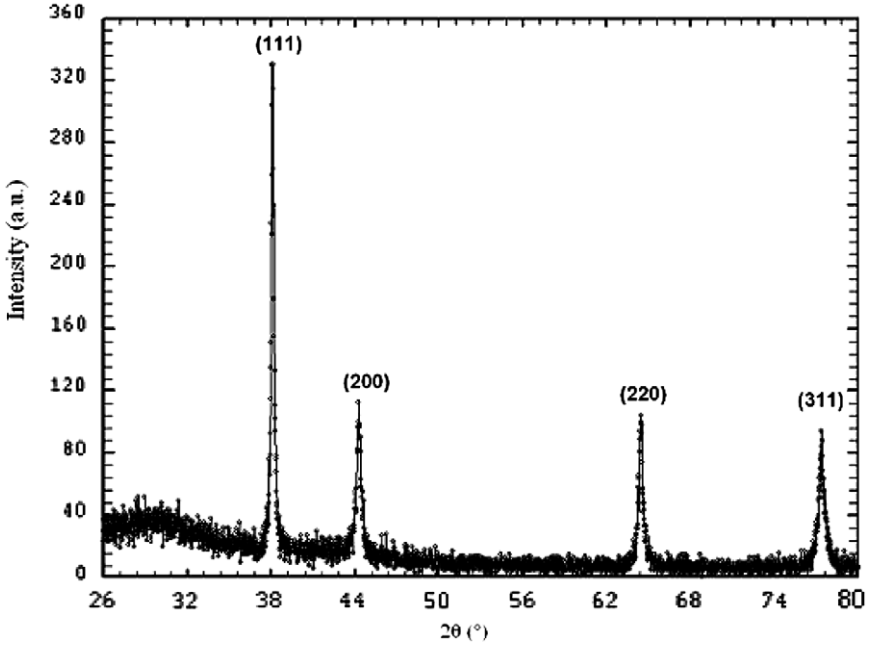

Fig. 8. Powder Diffraction Pattern of the silver nano materials.

Table 1
Activity of Ag nano particles in different concentrations against seven bacterial strains

Bacterial strains	Penicillin (Pc) concentration (2 μg/ml)	Concentration (0 μg/ml)[a]	Concentration (1 μg/ml)	Concentration (2 μg/ml)	Concentration (4 μg/ml)
Escherichia coli (ATCC 10536)	+	+	+	–	–
Vibrio cholerae (7)	–	+	+	–	–
Shigella flexneri (80903)	–	+	+	–	–

Staphylococcus aureus (ML 276)	–	+	+	+	–
Staphylococcus aureus (ML 422)	+	+	+	–	–

+, Growth.
–, No growth.
[a] Control plate without Ag nano particles.

quency between the particles also rises and this leads to the higher rate of agglomeration. The outcome of this is the formation of the higher dimensional nano-disks and nano-globules. As reported by Zukoski et al. [40], surface potential of silver particles is inversely related to temperature. With increasing temperature the gradual decrease in that potential of the particles accelerates the aggregation and thus the cluster formation, as observed in our case.

4. Conclusions

We have been able to synthesize both 2D and 3D Ag nano-structures having disk and globular morphology by carrying out the simple silver-mirror reaction in the presence of an anionic surfactant. The aldehyde-mediated reduction of silver nitrate occurred at relatively low temperatures (80–86 °C), which is easily producible, making the process facile and faster. SEM study revealed the temperature-dependent morphological variation of the nano particles. While at lower temperatures, only globular morphology was observed, at higher temperatures disk morphology proportionately increased and at 86 °C they appeared with equal proportion. Nano-disks of uniform thickness could be grown up to micron size. The antibacterial study established the hitherto highest activity of Ag nano-structures against a series of most devastating bacterial strains. It is more powerful than Penicillin for two bacteria (*E. coli* {ATCC 10536} and *S. aureus* {ML 422}).

In summary we have successfully designed a facile and faster synthesis route to produce Ag nano particles and the nano particles so produced exhibit unprecedented efficiency as anti-microbial agents. The synthesis method adopted here is very simple and can be easily implemented for any kind of scientific as well as industrial application due to its cost effective nature. An important characteristic of the Ag nano particles obtained in the present report is its homogeneous colloidal dispersion in water which is one of the essential requirements for biologically relevant nano-device applications. A detailed study is in progress towards unraveling the underlying mechanism behind the high activity of Ag nano particles as anti-microbial agents.

In this report we focus on the examination of the reaction of $[ReOCl_3(PPh_3)_2]$ with 5,6-diphenyl-3-(2-pyridyl)-1,2,4-trazine (dppt). The isolated $[ReCl_3(OPPh_3)(dppt)]$ complex easily reacts with an excess of triphenylphosphine to give $[ReCl_3(PPh_3)(dppt)]$. The last one can be also prepared in the reaction of $[ReCl_3(MeCN)(PPh_3)_2]$ with 5,6-diphenyl-3-(2-pyridyl)-1,2,4-trazine. Here we present spectroscopic characterization, crystal, molecular and electronic structure of $[ReCl_3(OPPh_3)(dppt)]$ (**1**) and $[ReCl_3(PPh_3)(dppt)]$ (**2**) complexes. The molecular orbital diagrams of **1** and **2** have been calculated with the density functional theory (DFT) method. Currently density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [7]. The electronic spectra of **1** and **2** have been discussed on the basis of time-dependent DFT calculations. Recent studies have supported the TD-DFT method to be applicable for open- and closed-shell of 5d-metal complexes (including rhenium complexes) giving good assignment of experimental spectra [8–10].

2. Experimental

2.1. General procedure

The reagents used to the synthesis were commercially available and were used without further purification. The $[ReOCl_3(PPh_3)_2]$ complex was prepared according to the literature method [11].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000-400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 1000–200 nm in chloroform solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReCl_3(OPPh_3)(dppt)]\cdot CH_2Cl_2$ ($\mathbf{1}\cdot CH_2Cl_2$)

To a solution of $[ReOCl_3(PPh_3)_2]$ (0.50 g, 0.6 mmol) in 30 ml dichloromethane was added 0.19 g (0.61 mmol) of 5,6-diphenyl-3-(2-pyridyl)-1,2,4-trazine (dppt). The resulting solution was magnetically stirred for 2 h at room temperature, and during this time the colour changed from light green to violet. 20 ml of CH_2Cl_2 was distilled off and 50 ml of diethyl ether was added. $[ReCl_3(OPPh_3)(dppt)]\cdot CH_2Cl_2$ was filtered off, washed with ethanol, diethyl ether and dried (yield 90%). The dark violet crystals of $\mathbf{1}\cdot CH_2Cl_2$ for X-ray investigation were obtained by recrystallization from dichloromethane.

IR (KBr; ν/cm^{-1}): 1601 (m), 1590(m) and 1504 (m) ν_{CN} and $\nu_{C=C}$; 1141(s) and 1115(s) $\nu_{P=O}$.

Anal. Calc. for $C_{39}H_{31}Cl_5N_4OPRe$: C, 48.48; H, 3.23; N, 5.80. Found: C, 48.60; H, 3.18; N, 5.85%.

2.3. Preparation of $[ReCl_3(PPh_3)(dppt)]$ (**2**)

Method A: To a solution of complex **1** (0.20 g, 0.23 mmol) in chloroform (20 ml), PPh_3 (0.24 g, 0.92 mmol) was added and the solution was refluxed for 1 h. The solvent was then removed under reduced pressure. The precipitate was washed several times with ethanol and hexane, and finally dried *in vacuo*. The crystals of **2** suitable for X-ray investigation were obtained by recrystallization from chloroform (yield 95%).

Method B: $[Re(MeCN)Cl_3(PPh_3)_2]$ (0.5 g, 0.58 mmol) and dppt (0.19 g, 0.61 mmol) in chloroform (40 cm^3) were refluxed for 4 h. The starting material gradually dissolved and the colour of the reaction solution became dark red. The volume was condensed to 10 cm^3, diethyl ether (100 cm^3) was added and dark violet microcrystalline solid was filtered. The product was washed with EtOH and cold ether, and dried *in vacuo* (yield 90%).

IR (KBr; ν/cm^{-1}): 1599(m), 1572(w) and 1507 (w) ν_{CN} and $\nu_{C=C}$.

Anal. Calc. for $C_{38}H_{29}Cl_3N_4PRe$: C, 52.75; H, 3.38; N, 6.48. Found: C, 52.62; H, 3.45; N, 6.37%.

2.4. Crystal structures determination and refinement

The X-ray intensity data of $\mathbf{1}\cdot CH_2Cl_2$ and **2** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz polarization and absorption correction [12] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as ''riding'' on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent atom. SHELXS-97 [13], SHELXL-97 [14] and SHELXTL [15] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.5. Computational details

GAUSSIAN-03 program [16] was used in the calculations. The geometry optimizations of **1** and **2** were carried out with the DFT method with the use of B3LYP functional [17,18]. The electronic spectra of **1** and **2** were calculated with the TD-DFT method [19]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+G** basis for chlorine, oxygen, and nitrogen, 6-31G* for carbon and 6-31G for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [20] was used for the valence electrons. Additional *d* function with exponent $\alpha = 0.3811$

and f function with exponent $\alpha = 2.033$ on the rhenium atom were added.

2.6. Magnetic measurement

Magnetic measurements in the temperature range 1.8–300 K were performed using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The SQUID magnetometer was calibrated with the palladium rod sample (Materials Research Corporation, measured purity 99.9985%). The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T. Measurements were made at a magnetic field of 0.5 T. Corrections are based on subtracting the sample – holder signal and contribution χ_D estimated from the Pascal constants [21] and equal – 425×10^{-6} cm^3 mol^{-1} for complex [$ReCl_3$(OPPh$_3$)(dppt)]. The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83(\chi_M T)^{1/2}$ (BM).

3. Results and discussion

3.1. Preparation and infrared data

The [$ReCl_3$(dppt)(OPPh$_3$)] (**1**) complex has been prepared in good yield in the reaction of [$ReOCl_3(PPh_3)_2$] with 5,6-diphenyl-3-(2-pyridyl)-1,2,4-trazine (dppt) in dichloromethane:

$$[ReOCl_3(PPh_3)_2] + dppt \rightarrow [ReCl_3(dppt)(OPPh_3)] + PPh_3$$

It can be supposed that the [$ReOCl_3$(dppt)] oxocompound, formed in the first step reaction, is an oxidant transferring an oxygen atom to PPh$_3$. The oxygen atom transfer is believed to proceed *via* initial nucleophilic attack on the Re≡O π^* orbitals, the π acidity of the dppt ligand facilitates the attack of triphenylphosphine [22]. The produced triphenylphosphine oxide remains bonded to the reduced rhenium ion in complex **1**. Many instances of formation of phosphine oxides from $Re^{V}O$ and tertiary phosphines can be given, but examples when the phosphine oxide remain firmly bonded to the reduced metal centre are rare [22–25]. The complex **1** easily reacts with an excess of PPh$_3$ to give [$ReCl_3$(dppt)(PPh$_3$)] (**2**). The last one has been also isolated in the reaction of [$ReCl_3(MeCN)(PPh_3)_2$] with dppt.

The elemental analyses of the **1** · CH_2Cl_2 and **2** complexes are in good agreement with their formulation. The characteristic bands corresponding to the ν(CN), ν(C=C) modes of the dppt ligand appear in the range 1610-1500 cm^{-1}in the IR spectrum of **1** and **2**. The absence of the characteristic strong ν(Re=O) band at ~980 cm^{-1} is clear indication that there is no oxo-Re(V) starting material left in the samples **1** and **2**. The strong bands at 1141 and 1115 cm^{-1} in the IR spectrum of **1** confirm the presence of the coordinated OPPh$_3$ molecule [26].

3.2. Crystal structures

The complex **1** crystallises as dichloromethane solvate **1** · CH_2Cl_2, and the dichloromethane molecule is not bonded to any atom of the Re(III) complex. The structure of **2** consist of discrete and well-separated [$ReCl_3$(dppt)-(PPh$_3$)] monomers. Any intermolecular interactions with enough strength to govern crystal packing or molecule conformation were not found in the structures of **1** and **2**. Only weak intramolecular and intermolecular hydrogen bonds [25–27] were detected in crystals **1** and **2**, and they are gathered in Table 2.

The molecular structures of **1** and **2** are presented in Figs. 1 and 2, respectively, and the selected bond distances and angles are collected in Tables 3 and 4, respectively. Both complexes show distorted octahedral geometry about Re with the three chloride ions arranged in *meridional* fashion in complex **1** and in *facial* configuration in complex **2**. The coordination polyhedron least squares planes are inclined at 88.54(6)°, 82.95(11)°, and 74.58(13)° in compound **1** and at 89.05(5)°, 86.90(8)°, and 87.87(5)° in

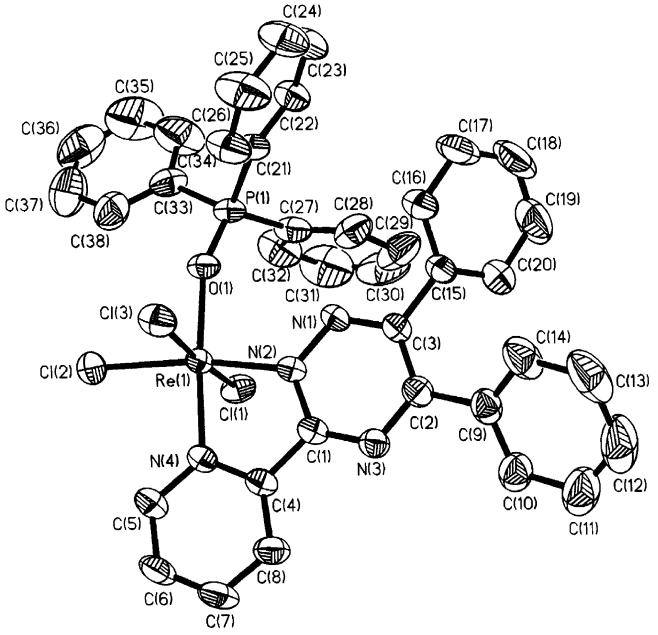

Fig. 1. The molecular structure of **1**.

compound **2** what shows that polyhedron distortion is distinctly smaller in compound **2**. The $OPPh_3$ ligand is pure donor and $PPh_3P{=}O \rightarrow Re \rightarrow \pi^*$(dppt) interaction is suited to the *meridional* configuration. In the presence of PPh_3 the electronic situation is affected by π acidity of the phosphine ligand. In complex **2**, two good π acceptor, dppt and PPh_3, are coordinated to rhenium (III) centre, and the back-bonding effect is maximized in the *facial* disposition which ensures minimum competition between the two ligands for identical metal orbitals. It is significant that the Re–N distances in **2** are longer than those in **1** where the dppt ligand alone is available for back bonding. The presence of Re–PPh_3 back-bonding diminishes the demand on π^*(dppt) orbitals. Some differences are observed between the Re–N(pyridine) and Re–N(triazine) bond lengths in **1** and **2** complexes. It indicates different π acidity strength of the two rings – the triazine ring favours π-back donation from the rhenium ion. Nevertheless, the Re–N bond lengths of both complexes are similar to those found for the other rhenium(III) polypirydyl compounds: in $[ReCl_2(bipy)_2]PF_6$ – 2.094(5) and 2.096(5) Å [27] and in the $[ReL(terpy)_2]^{2+}$ (L = Cl, OH, NCS) complexes – about 2.10 Å [28]. These values are significantly shorter than comparable distances for saturated amine complexes, where metal-to-ligand π-back bonding is not possible, for instance, the Re–NH_2 distance in the $[Re(N_2)(ampy)(tbpy)(PPh_3)]PF_6$ compound is 2.197(7) [29].

The Re–Cl(3) distance of **2** is affected by *trans* influence of triphenylphospnie and is therefore longer than the Re–Cl(1) and Re–Cl(2) bond lengths located in *trans* positions to the dppt ligand. In both compounds the 3-(2-pyridyl)-1,2,4-trazine moiety is close to planarity (maximum least squares plane atom deviation of 0.073(3) Å exists for C(2) atom in compound **1** and of 0.122(3) Å exists for N(4) atom in compound **2**). The dppt phenyl rings are

inclined to the 3-(2-pyridyl)-1,2,4-trazine moiety at 37.95(16)° and 50.37(16)° in compound **1** and at 32.37(13)° and 39.62(16)° in compound **2**.

3.3. Geometry optimization

The geometries of **1** and **2** were optimized in triplet and singlet states using the DFT method with the B3LYP functional. The energies of the singlet states are of 15.2 and 15.7 kcal/mol higher for **1** and **2**, respectively. The optimized geometric parameters of the triplet states are gathered in Tables 3 and 4. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

3.4. Molecular orbitals

The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of **1** and **2** are presented in Tables 5 and 6. The selected HOMO and LUMO orbitals of **1** and **2** with α spin are depicted in Figs. 3 and 4. Among the highest occupied MOs of **1** and **2**, the largest numbers constitute π orbitals of the dppt and phenyl rings of PPh_3 or $OPPh_3$ with a contribution from the Cl and O (for **1**) atoms. For both **1** and **2**, the highest molecular orbital with α-spin can be represented as a combination of π^*_{Re-Cl}, and π^*_{dppt}, with predominant involvement of the former component. The same character have the HOMO orbitals with β-spin of **1** and **2**, but contribution of π orbitals of dppt ligand is considerable larger. The H-2 and H-1 α molecular orbitals of **1** correspond to combination of π^*_{Re-Cl} and $\pi^*_{Re-OPPh3}$ interaction, whereas the H-2 and H-1 α molecular orbitals of **2** have π^*_{Re-Cl} character. To a large extent, the L + 1 and L + 3 β orbitals of **1** and L and L + 2 β orbitals of **2** are also formed by rhenium d_π atomic orbital (d_{xz}, d_{yz} or d_{xy}). Among the lowest unoccupied MOs of **1** and **2**, the largest numbers constitute π orbitals of the dppt and phenyl rings of PPh_3 or $OPPh_3$. For both complexes the LUMO and LUMO + 1 with α-spin have π*(dppt) character. The π* phenyl ring orbitals

of the triphenylphosphine or triphenylphosphine oxide ligands participates in the higher unoccupied orbitals.

3.5. Electronic spectra

The spin-allowed triplet–triplet electronic transitions calculated with the TD-DFT method for **1** and **2** are gathered in Tables 7 and 8. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.020 are listed in Tables 7 and 8.

The investigated complexes are of large size; the numbers of basis functions are equal to 969 and 799 for **1** and **2**, respectively. The calculated electron transitions (110 and 100 for **1** and **2**) do not comprise all the experimental absorption bands. The UV–Vis spectrum was calculated to ~290 nm for **1**, and to 300 nm for complex **2**. Thus

ε, molar absorption coefficient ($dm^3\ mol^{-1}\ cm^{-1}$); f, oscillator strength; H, highest occupied molecular orbital; L, lowest unoccupied molecular orbital.

the shortest wavelength experimental bands of **1** and **2** are not assigned to the calculated transitions; some additional intraligand and interligand transitions are expected to be found at higher energies in the calculations for **1** and **2**.

In the visible region (400–1000 nm), complexes **1** and **2** display multiple transitions of moderate intensity in the form of peaks and shoulders. The longest wavelength experimental band of **1** with maximum at 705.9 nm and shoulder at 840 nm is very broad. It is assigned to the transition of d → d/π*(dppt) character with relatively large oscillator strength. The calculated transition (at 929.2 nm) lies in the low energy end of the experimental band. For complex **2**, two absorption bands are observed in this range, and this arrangement is reproduced in the calculations. The experimental bands of **2** at 998.9 and 674.1 nm are attributed to the d → d/π*(dppt) transitions

calculated at 976.3 and 806.0 nm. The same character [d → d/π*(dppt)] have the experimental absorption bands at 549.7 nm for complex **1** and at 520.3 nm for complex **2**. The observed shift of the d → d/π*(dppt) bands to higher energy in going from triphenylphosphine oxide (**1**) to triphenylphosphine (**2**) coordination is consistent with the stabilization of the t_{2g} shell of complex **2** *via* back-bonding.

Some differences can be noticed in the assignment of the experimental absorption bands at 420.8 nm and 432 nm for **1** and **2**, respectively. The first one is assigned to the d → d/π*(dppt) transition, whereas the absorption band of complex **2** corresponds to ligand–ligand charge transfer ($\pi(Cl)/\pi(PPh_3)/\pi$(dppt) → d/π*(dppt)) transitions.

For both complexes the absorption bands below 400 nm are attributed to metal–ligand charge transfer, ligand–metal charge transfer and ligand–ligand charge transfer and interligand (IL) transitions (Tables 7 and 8).

3.6. Magnetic properties

The magnetic properties of **1** complex under the form μ_{eff} versus T (μ_{eff} the effective magnetic moment) is shown in Fig. 5. The chloro-derivative of the rhenium(III) shows room temperature magnetic moment 2.01 BM (0.502 $cm^3\ mol^{-1}\ K$). The magnetic moment of the solid is temperature independent between 300 and 60 K. In the temperature range 55–14 K it is observed only slightly

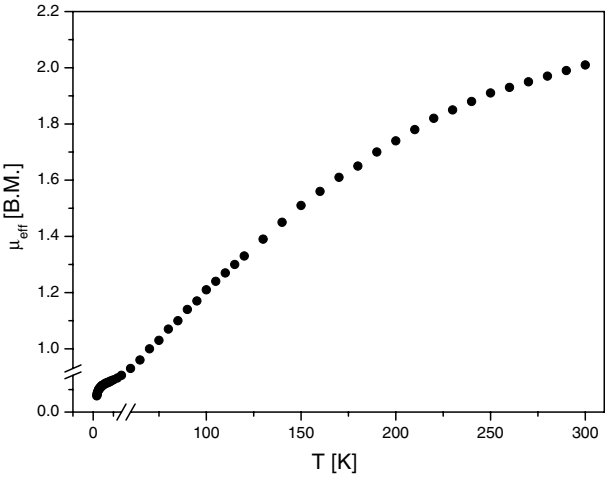

Fig. 5. Plots of the experimental effective magnetic moment μ_{eff} (●) vs. temperature for complex **1**.

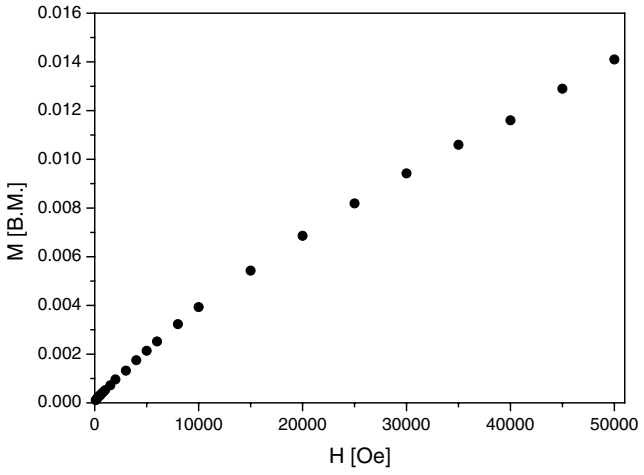

Fig. 6. Field dependence of the magnetization for complex **1** at 2 K.

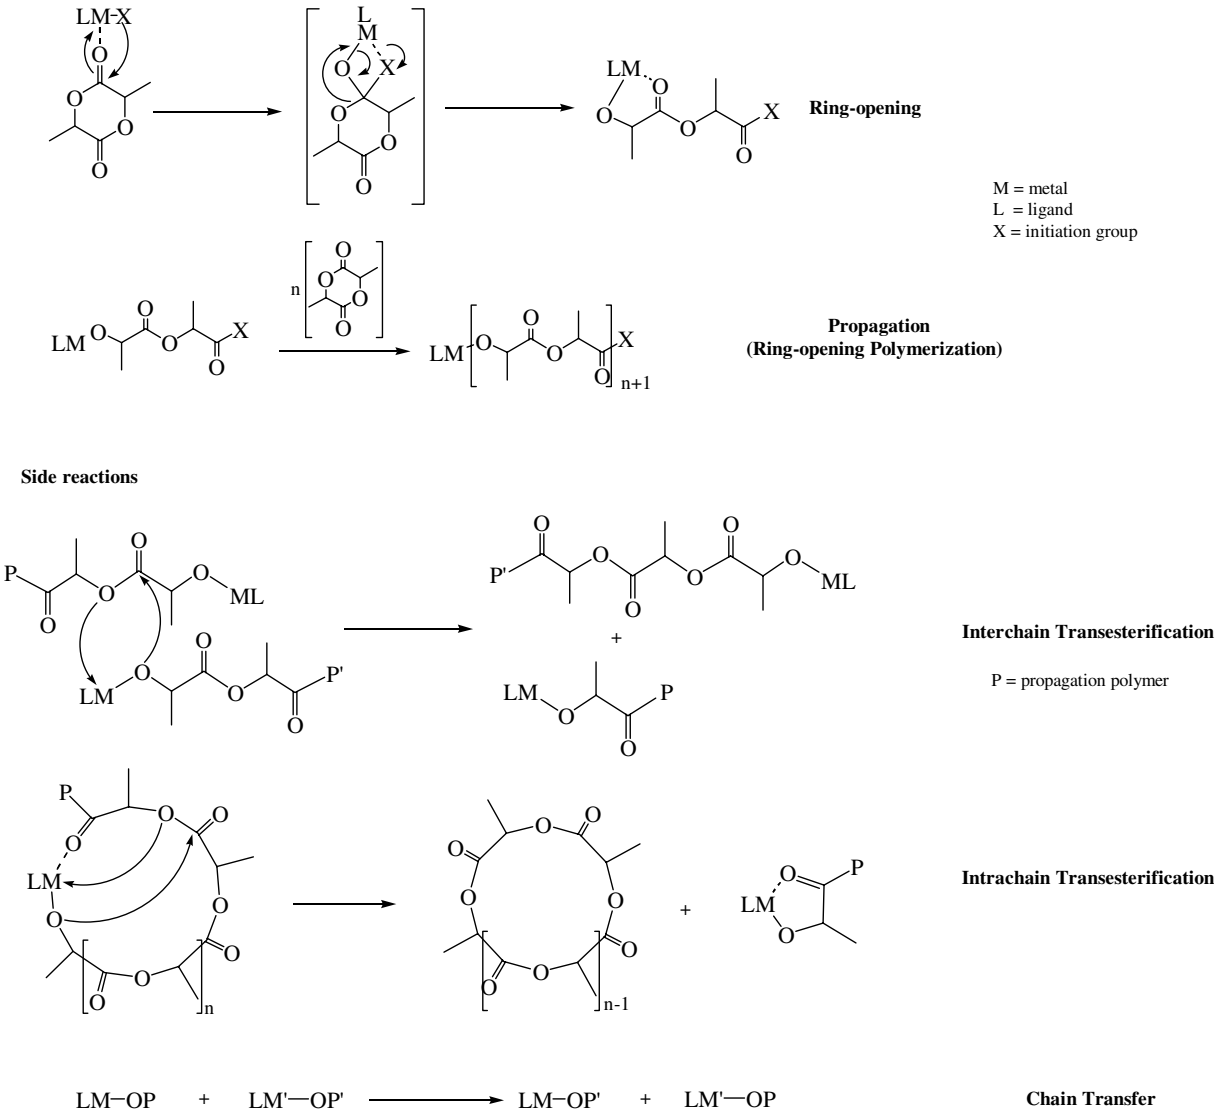
magnetic anomaly and below 14 K the value of χ_M product increases with temperature lowering. This behavior is characteristic of mononuclear complexes with d^4 low-spin octahedral Re(III) complexes ($^3T_{1g}$ ground state) [30–38] and arise because of the large spin–orbit coupling ($\zeta = 2500\ cm^{-1}$ [39]), which gives diamagnetic ground state. It seems that in room temperature, in accordance Boltzmann's distribution, it is populated higher magnetic state, which is depopulated with temperature lowering and decreasing of the magnetic moment is observed.

The variation of the magnetization M versus the magnetic field H for complex **1** at 2 K is shown in Fig. 6. The M versus H curve for complex very slowly increases and indicates value of the magnetization near zero (0.014 BM) at 5 T. Magnetization of the sample confirms that the ground state is diamagnetic.

4. Supplementary material



CCDC 640907 and 640908 contain the supplementary crystallographic data for $C_{39}H_{31}Cl_5N_4OPRe$ and $C_{38}H_{29}Cl_3N_4Pr$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Reactions involved in ring-opening polymerization employing a coordination catalyst.

One advantage of studying a slow catalytic system is that one may judge the relative importance of subtle changes at the metal center on the rate of the reaction and in this regard we were attracted to the study of organotin(IV) complexes in the ring-opening and ROP of lactide. We found previously that the rate of initial ring-opening of LA by Ph_3SnX complexes was very sensitive to the nature of the X group and followed the order $X = NMe_2 > OMe > OPr^i > OBu^t > N(SiMe_3)_2 > OPh$ which indicated the importance of both steric and electronic factors, namely the nucleophilicity of the X group [15]. In the ROP of LA by Ph_3SnX initiators it was also noted that the tin(IV) complexes were subject to ligand redistribution reactions yielding Ph_4Sn and $Ph_2Sn(OP)_2$ species and furthermore that when the initiating group $X = NMe_2$ intrachain *trans*-esterification was favored yielding cyclic-oligoesters and $Ph_2Sn(OCHMeC(O)NMe_2)_2$ [16,17]. In contrast the $Ph_2Sn(OPr^i)_2$ initiators produced a much "better behaved" catalytic system for the ROP of LA and this prompted us to evaluate the influence of various aryl substitutents *p*-XC_6H_4, where $X = CF_3$, F, H, OMe and NMe_2, on the kinetics of the ROP by bisaryltin(IV) complexes $(C_6H_4)_2Sn(OPr^i)_2$ and to compare these with the dialkyltin(IV) complex $(Bu^n)_2Sn(OPr^i)_2$. These considerations provide the basis for the work described herein.

2. Experimental

2.1. General

The manipulation of air-sensitive compounds involved standard Schlenk line and dry box techniques. All solvents were distilled under nitrogen from alkali metals and stored over 4 A molecular sieves. L-Lactide was purified by sublimation under vacuum three times. Benzene-D_6 was dried over activated molecular sieves and stored in the glove

box. The tin dichlorides of general formula (p-$XC_6H_4)_2SnCl_2$ (where X = CF_3, F, H, Me, MeO, NMe_2) were synthesized via the Kochesnikov redistribution reaction involving the tin tetrachloride with (p-$XC_6H_4)_4Sn$ and isolated by re-crystallization from toluene as described previously [18,19]. Samples of high purity were obtained by a distillation under vacuum using a Kugelrohr apparatus, except for (p-$Me_2NC_6H_4)_2SnCl_2$ which was recrystallized twice from toluene. Tin chlorides of formula (p-$XC_6H_4)_3SnCl$ (where X = CF_3, F, Me) were synthesized via the Kochesnikov redistribution reaction involving (p-$XC_6H_4)_2SnCl_2$ with (p-$XC_6H_4)_4Sn$ in the neat at 170 °C and purified by distillation under vacuum (Kugelrohr apparatus) [20]. Ph_3SnNMe_2 was synthesized by the reaction of $LiNMe_2$ with Ph_3SnCl in benzene according to the literature procedure [4]. ^1H, ^{13}C and ^{118}Sn NMR spectra were obtained from either Bruker DPX-400 or DPX-250 spectrometers using benzene-D_6 as solvent and elemental analyses were performed by the Atlantic Microlab, Inc. All kinetic data were obtained from NMR scale reactions. Standard solutions of (p-$XC_6H_4)_2Sn(O^iPr)_2$ and L-lactide were made in benzene-D_6 and stored in the dry box. Appropriate aliquots of both reagents (molar ratio = 1:50) were transferred to a J. Young NMR tube. The reaction temperatures were regulated via a thermostatically controlled oil bath. For lactide polymerizations reaction rates of polymerization were determined from ^1H NMR data (400 MHz) where the sum of the area of monomer and polymer peaks (CH and Me) was assumed to be 100% and rates of disappearance of monomer were calculated by the substraction of the polymer peaks from the monomer peaks and dividing by the concentration of monomer at $t = 0$ to give a ratio. Equilibrium monomer concentrations were determined by polymerizing L-lactide using the (p-$XC_6H_4)_2Sn(O^iPr)_2$ catalyst precursors in benzene-D_6 (1:25 O^iPr: L-lactide; $[LA]_{init} = 0.1229$ M]) at various temperatures. The natural log of the equilibrium monomer concentration was then plotted against $1/T$ to give a straight line. These data were used in the various polymerization reactions as indicated in Fig. 4. The value of k_{prop} was determined from the gradient a plot of $-\ln[(A - A_{eq})/(A_0 - A_{eq})]$ versus time (Fig. 6), where $A = [LA]$, A_{eq} = the equilibrium [LA] for a given temperature and $A_0 = [LA]$ at $t = 0$.

2.2. Synthesis

2.2.1. (p-$Me_2NC_6H_4)_2SnCl_2$

Following the procedure given in the literature [20], (p-$Me_2NC_6H_4)_4Sn$ (11.62 g, 19.4 mmol) and $SnCl_4$ (2.27 ml, 19.4 mmol) were dissolved in toluene (100 ml) and heated up to 110 °C. Cooling down slowly to room temperature gave crystals of the title compound, which were isolated by filtration. Yield 15.04 g, 90%. ^1H NMR (C_6D_6, 400 MHz): δ 7.57 (d, $^3J_{H-H} = 8.8$ Hz, m-CH aryl, 4 H), 6.43 (d, $^3J_{H-H} = 8.8$ Hz, d, o-CH aryl, 4 H), 2.35 (s, $N(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 152.5 (C–$N(CH_3)_2$), 136.7 (m-CH), 122.5 (ipso-C–Sn), 112.7 (o-CH), 39.1 ($N(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −3.3 ppm.

2.3. General procedure for the synthesis of (p-$XC_6H_4)_2Sn(O^iPr)_2$ (X = CF_3, F, H, Me, MeO) and (p-$Me_2NAr)_3SnO^iPr$

Typically, a solution of (p-$XC_6H_4)_2SnCl_2$ (1 equiv) in benzene was added via a syringe to a vigorously stirred and ice cooled suspension of $LiNMe_2$ (2.2 equiv) in benzene. After stirring at room temperature for 2 days, the suspension was separated by centrifugation or filtration. All volatiles were removed under high vacuum to quantitatively leave (p-$XC_6H_4)_2Sn(NMe_2)_2$ (as shown by NMR spectroscopy) as colorless oils or solids. The compounds were redissolved in hexanes and a ten-fold excess of isopropanol was added at room temperature. After stirring for ca. 4 h all volatiles were removed under vacuum and the solid residues were recrystallized from hexanes at −40 °C to yield analytically pure samples of the title compounds.

2.3.1. (p-$CF_3C_6H_4)_2Sn(O^iPr)_2$

(p-$CF_3C_6H_4)_2SnCl_2$ (1105 mg, 2.30 mmol) and $LiNMe_2$ (260 mg, 5.10 mmol). Yield 450 mg, 37%. M.p. 83–85 °C; ^1H NMR (C_6D_6, 400 MHz): δ 7.50 (d, $^3J_{H-H} = 7.6$ Hz, o-CH aryl, 4 H), 7.37 (d, $^3J_{H-H} = 8.0$ Hz, m-CH aryl, 4 H), 4.28 (sept, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 2 H), 1.24 (d, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 142.8 (ipso-C–Sn), 136.6 (o-CH), 132.8 (d, $^2J_{C-F} = 40.2$ Hz, C–CF_3), 125.6 (d, $^3J_{C-F} = 4.0$ Hz, m-CH), 124.5 (d, $^1J_{C-F} = 272.6$ Hz, C–CF_3), 68.2 ($OCH(CH_3)_2$), 27.6 ($OCH(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −173.7 ppm; *Anal.* Calc. for $C_{20}H_{22}F_6O_2Sn$ (527.088): C, 45.57; H, 4.21. Found: C, 45.43; H, 4.02%.

2.3.2. (p-$CF_3C_6H_4)_2Sn(NMe_2)_2$

^1H NMR (C_6D_6, MHz): δ 7.4–7.5 (m, CH aryl, 8 H), 2.81 (s, $N(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, MHz): δ 142.4 (ipso-C–Sn), 137.2 (o-CH), 132.2 (d, $^2J_{C-F} = 32.2$ Hz, C–CF_3), 125.4 (d, $^3J_{C-F} = 3$ Hz, m-CH), 124.7 (d, $^1J_{C-F} = 271.6$ Hz, CF_3), 43.6 ($N(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −83.7 ppm.

2.3.3. (p-$FC_6H_4)_2Sn(O^iPr)_2$

(p-$FC_6H_4)_2SnCl_2$ (1270 mg, 3.38 mmol) and $LiNMe_2$ (362 mg, 7.10 mmol). Yield 910 mg, 63%. M.p. 85–87 °C; ^1H NMR (C_6D_6, 400 MHz): δ 7.43 (dd, $^3J_{H-H} = 8.4$ Hz, $^3J_{H-F} = 6$ Hz, m-CH aryl, 4 H), 6.82 (tr, $^3J_{H-H} = 8.4$ Hz, o-CH aryl, 4 H), 4.33 (sept, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 2 H), 1.28 (d, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 164.9 (d, $^1J_{C-F} = 250.5$ Hz, C–F), 138.2 (d, $^3J_{C-F} = 7$ Hz, m-CH), 133.1 (d, $^4J_{C-F} = 4$ Hz, ipso-C–Sn), 116.6 (d, $^2J_{C-F} = 20.1$ Hz, o-CH), 67.9 ($OCH(CH_3)_2$), 27.8 ($OCH(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −152.6 ppm; *Anal.* Calc. for

$C_{18}H_{22}F_2O_2Sn$ (427.073): C, 50.62; H, 5.19. Found: C, 50.34; H, 5.08%.

2.3.4. $(p\text{-}FC_6H_4)_2Sn(NMe_2)_2$

^{1}H NMR (C_6D_6, 250 MHz): δ 7.35 (dd, $^3J_{H-H} = 8.5$ Hz, $^3J_{H-F} = 6.3$ Hz *m*-CH aryl, 4 H), 6.88 (dd, $^3J_{H-H} = 8.5$ Hz, $^4J_{H-F} = 8.6$ Hz *o*-CH aryl, 4 H), 2.84 (s, $N(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 62.9 MHz): δ 164.6 (d, $^1J_{C-F} =$ 245 Hz, C–F), 138.7 (d, $^3J_{C-F} = 7.1$ Hz, *m*-CH), 132.7 (d, $^4J_{C-F} = 4.4$ Hz, ipso-C–Sn), 116.4 (d, $^2J_{C-F} = 19.7$ Hz, *o*-CH), 43.6 ($N(CH_3)_2$) ppm.

2.3.5. $Ph_2Sn(O^iPr)_2$

Ph_2SnCl_2 (2057 mg, 5.98 mmol) and $LiNMe_2$ (670 mg, 13.14 mmol). Yield 1610 mg, 69%. M.p. 83–84 °C (dec.). The analytical data obtained were in agreement with those previously reported [4].

2.3.6. $(p\text{-}MeC_6H_4)_2Sn(O^iPr)_2$

(p-$MeC_6H_4)_2SnCl_2$ (974 mg, 2.62 mmol) and $LiNMe_2$ (280 mg, 5.49 mmol). Yield 330 mg, 30%. M.p. 77-78 °C (dec.); ^{1}H NMR (C_6D_6, 400 MHz): δ 7.64 (d, $^3J_{H-H} =$ 8 Hz, *m*-CH aryl, 4 H), 7.02 (d, $^3J_{H-H} = 8$ Hz, *o*-CH aryl, 4 H), 4.47 (sept, $^3J_{H-H} = 6$ Hz, OC*H*$(CH_3)_2$, 2 H), 2.04 (s, CH_3, 6 H), 1.35 (d, $^3J_{H-H} = 6$ Hz, OCH(C*H*$_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 140.6 (*C*–CH_3), 136.5 (*m*-CH), 134.7 (ipso-C–Sn), 130.1 (*o*-CH), 67.7 (O*C*H$(CH_3)_2$), 28.0 (C–*C*H_3), 21.4 (OCH(*C*$H_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): $\delta -$ 147.1 ppm; *Anal.* Calc. for $C_{20}H_{28}O_2Sn$ (419.145): C, 57.31; H, 6.73. Found: C, 57.19; H, 6.65%.

2.3.7. $(p\text{-}MeC_6H_4)_2Sn(NMe_2)_2$

^{1}H NMR (C_6D_6, 250 MHz): δ 7.60 (d, $^3J_{H-H} = 7.9$ Hz, *m*-CH aryl, 4 H), 7.07 (d, $^3J_{H-H} = 7.9$ Hz, *o*-CH aryl, 4 H), 2.99 (s, $N(CH_3)_2$, 12 H), 2.08 (s, CH_3, 6 H) ppm; ^{13}C NMR (C_6D_6, 62.9 MHz): δ 139.7 (*C*–CH_3), 137.1 (*m*-CH), 134.3 (ipso-C–Sn), 129.9 (*o*-CH), 43.9 ($N(CH_3)_2$), 21.4 (C–*C*H_3) ppm.

2.3.8. $(p\text{-}MeOC_6H_4)_2Sn(O^iPr)_2$

(p-$MeOC_6H_4)_2SnCl_2$ (1031 mg, 2.56 mmol) and $LiNMe_2$ (274 mg, 5.37 mmol). Yield 750 mg, 65%. ^{1}H NMR (C_6D_6, 250 MHz): δ 7.66 (d, $^3J_{H-H} = 8.8$ Hz, *m*-CH aryl, 4 H), 6.83 (d, $^3J_{H-H} = 8.8$ Hz, *o*-CH aryl, 4 H), 4.52 (sept, $^3J_{H-H} = 6$ Hz, OC*H*$(CH_3)_2$, 2 H), 3.21 (s, CH_3O, 6 H), 1.40 (d, $^3J_{H-H} = 6$ Hz, OCH(C*H*$_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 162.1 (*C*–OMe), 138.0 (*m*-CH), 128.1 (ipso-C–Sn), 115.2 (*o*-CH), 67.7 (O*C*H$(CH_3)_2$), 54.4 (CH_3O), 28.3 (OCH(*C*$H_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −133.7 ppm; *Anal.* Calc. for $C_{20}H_{28}O_4Sn$ (451.144): C, 53.25; H, 6.26. Found: C, 52.98; H, 6.14%.

2.3.9. $(p\text{-}MeOC_6H_4)_2Sn(NMe_2)_2$

^{1}H NMR (C_6D_6, 400 MHz): δ 7.58 (d, $^3J_{H-H} = 8.4$ Hz, *m*-CH aryl, 4 H), 6.87 (d, $^3J_{H-H} = 8.4$ Hz, *o*-CH aryl, 4 H), 3.29 (s, OCH_3, 6 H); 3.00 (s, $N(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 161.6 (*C*-OCH_3), 138.3 (*m*-CH), 128.3 (ipso-C–Sn), 115.1 (*o*-CH), 54.5 (C–O*C*H_3), 43.9 ($N(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −7.4 ppm.

2.3.10. $(p\text{-}Me_2NC_6H_4)_3SnO^iPr$

(p-$Me_2NC_6H_4)_2SnCl_2$ (858 mg, 1.99 mmol) and $LiNMe_2$ (224 mg, 4.39 mmol). Yield 170 mg, 32%. M.p. 125–126 °C (dec.); ^{1}H NMR (C_6D_6, 250 MHz): δ 7.86 (d, $^3J_{H-H} =$ 8.4 Hz, *m*-CH aryl, 6 H), 6.68 (d, $^3J_{H-H} = 8.4$ Hz, *o*-CH aryl, 6 H), 4.59 (sept, $^3J_{H-H} = 6$ Hz, OC*H*$(CH_3)_2$, 1 H), 2.48 (s, $N(CH_3)_2$, 18 H), 1.48 (d, $^3J_{H-H} = 6$ Hz, OCH(C*H*$_3)_2$, 6 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 151.7 (*C*–NMe_2), 138.0 (*m*-CH), 125.3 (ipso-C–Sn), 113.4 (*o*-CH), 67.5 (O*C*H$(CH_3)_2$), 39.8 ($N(CH_3)_2$), 28.4 (OCH(*C*$H_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −66.6 ppm; *Anal.* Calc. for $C_{27}H_{37}ON_3Sn$ (538.312): C, 60.24; H, 6.93. Found: C, 60.12; H, 6.78%.

2.3.11. $(p\text{-}Me_2NC_6H_4)_2Sn(NMe_2)_2$

(p-$Me_2NC_6H_4)_2SnCl_2$ (2094 mg, 4.87 mmol) and $LiNMe_2$ (550 mg, 10.78 mmol). Yield 1900 mg, 87%. M.p. 75–76 °C (dec.); ^{1}H NMR (C_6D_6, 400 MHz): δ 7.69 (d, $^3J_{H-H} = 8.4$ Hz, *m*-CH aryl, 4 H), 6.66 (d, $^3J_{H-H} =$ 8.4 Hz, *o*-CH aryl, 4 H), 3.11 (s, Sn–$N(CH_3)_2$, 12 H), 2.49 (s, *p*-$N(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 100.6 MHz): δ 151.7 (*C*–$N(CH_3)_2$), 138.0 (*m*-CH), 123.1 (ipso-C–Sn), 113.4 (*o*-CH), 44.1, (Sn–$N(CH_3)_2$), 39.7 (*p*-$N(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −60.8 ppm; *Anal.* Calc. for $C_{20}H_{32}N_4Sn$ (447.205): C, 53.71; H, 7.21. Found: C, 53.44; H, 7.03%.

2.4. General procedure for the synthesis of $(p\text{-}XC_6H_4)_3SnO^iPr$ ($X = CF_3$, F, Me)

Typically, a suspension of (p-$XC_6H_4)_3SnCl$ (1 equiv) and LiO^iPr (1.1 equiv) in benzene was vigorously stirred for two days at room temperature and for ca 4 h at 60 °C. After centrifugation and filtration of the mixture all volatiles were removed under vacuum and the residues were either recrystallized from hexanes at −40 °C or distilled under vacuum (Kugelrohr apparatus) to yield analytically pure samples of the title compounds.

2.4.1. $(p\text{-}MeC_6H_4)_3SnO^iPr$

(p-$MeC_6H_4)_3SnCl$ (1735 mg, 4.06 mmol) and LiO^iPr (280 mg, 4.24 mmol). Yield 1340 mg, 73%. Bp. 135 °C (4×10^{-2} mbar); ^{1}H NMR (C_6D_6, 400 MHz): δ 7.7 (d, $^3J_{H-H} = 7.6$ Hz, *m*-CH aryl, 6 H), 7.06 (d, $^3J_{H-H} =$ 7.6 Hz, *o*-CH aryl, 6 H), 4.42 (sept, $^3J_{H-H} = 6$ Hz, OC*H*$(CH_3)_2$, 1 H), 2.07 (s, CH_3, 9 H), 1.36 (d, $^3J_{H-H} =$ 6 Hz, OCH(C*H*$_3)_2$, 6 H) ppm; ^{13}C NMR (C_6D_6, 62.9 MHz): δ 139.8 (*C*–CH_3), 137.0 (*m*-CH), 135.7 (ipso-C–Sn), 129.9 (*o*-CH), 67.9 (O*C*H$(CH_3)_2$), 28.2 (C–*C*H_3), 21.4 (OCH(*C*$H_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −85.9 ppm; *Anal.* Calc. for $C_{24}H_{28}OSn$ (451.189): C, 63.89; H, 6.26. Found: C, 63.67; H, 6.05%.

2.4.2. $(p\text{-}FC_6H_4)_3SnO^iPr$

(p-$FC_6H_4)_3SnCl$ (1336 mg, 3.04 mmol) and LiO^iPr (220 mg, 3.33 mmol). Yield 880 mg, 63%. M.p. 53–54 °C; ^1H NMR (C_6D_6, 400 MHz): δ 7.36 (dd, $^3J_{H-H} = 8.4$ Hz, d, $^3J_{H-F} = 6$ Hz, *m*-CH aryl, 4 H), 6.87 (tr, $^3J_{H-H} = 8.4$ Hz, *o*-CH aryl, 4 H), 4.18 (sept, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 1 H), 1.23 (d, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 6 H) ppm; ^{13}C NMR (C_6D_6, 62.9 MHz): δ 164.7 (d, $^1J_{C-F} = 249.7$ Hz, C–F), 138.5 (d, $^3J_{C-F} = 6.9$ Hz, *m*-CH), 133.5 (d, $^4J_{C-F} = 3.8$ Hz, ipso-C–Sn), 116.5 (d, $^2J = 20.1$ Hz, *o*-CH), 68.0 ($OCH(CH_3)_2$), 28.0 ($OCH(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −89.1 ppm; *Anal.* Calc. for $C_{21}H_{19}F_3OSn$ (463.080): C, 54.47; H, 4.14. Found: C, 54.21; H, 4.07%.

2.4.3. $(p\text{-}CF_3C_6H_4)_3SnO^iPr$

(p-$CF_3C_6H_4)_3SnCl$ (967 mg, 1.64 mmol) and LiO^iPr (120 mg, 1.82 mmol). Yield 840 mg, 84%. M.p. 92–93 °C; ^1H NMR (C_6D_6, 400 MHz): δ 7.41 (d, $^3J_{H-H} = 8$ Hz, *o*-CH aryl, 6 H), 7.37 (d, $^3J_{H-H} = 8$ Hz, *m*-CH aryl, 6 H), 4.14 (sept, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 2 H), 1.20 (d, $^3J_{H-H} = 6$ Hz, $OCH(CH_3)_2$, 12 H) ppm; ^{13}C NMR (C_6D_6, 62.9 MHz): δ 142.5 (ipso-C–Sn), 137.0 (*o*-CH), 132.6 (d, $^2J_{C-F} = 32.7$ Hz, *C*–CF_3), 125.7 (d, $^3J_{C-F} = 3.8$ Hz, *m*-CH), 124.6 (d, $^1J_{C-F} = 272.4$ Hz, C–CF_3), 68.5 ($OCH(CH_3)_2$), 27.9 ($OCH(CH_3)_2$) ppm; ^{118}Sn NMR (C_6D_6, 149.2 MHz): δ −106.0 ppm; *Anal.* Calc. for $C_{24}H_{19}F_9OSn$ (613.103): C, 47.02; H, 3.12. Found: C, 46.89; H, 2.98%.

2.5. Competitive studies on the ring-opening of lactide with $(p\text{-}X\text{-}C_6H_4)_3SnOiPr$ where X = F, Me, NMe_2

(1) 11.8 mg of (p-$FC_6H_4)_3SnOiPr$ and 11.6 mg of (p-$MeC_6H_4)_3SnOiPr$ and 3.7 mg of L-lactide (1:1:1 ratio) were dissolved in benzene-D_6 (0.5 mL) and the reaction was monitored after ca. 13 h at r.t. by ^1H NMR spectroscopy (ratio: 1.0:0.7 for X = F:Me).

(2) 6.8 mg of (p-$MeC_6H_4)_3SnOiPr$ and 8.1 mg of (p-$Me_2NC_6H_4)_3SnOiPr$ and 2.5 mg of L-lactide (1:1:1 ratio) were dissolved in benezene-D_6 (0.5 mL) and the reaction was monitored after ca. 130 min at r.t. by ^1H NMR spectroscopy (ratio: 0.9:1.0 for X = Me:NMe_2). In competitive experiments the initial loss of the triaryltin complex was monitored. At longer time the ^1H NMR spectra are complicated by other reactions including further LA insertion and *trans* esterification.

2.6. Crystallography

A summary of crystal data collection and refinement details for compounds (p-$Me_2NC_6H_4)_3SnO^iPr$, $Ph_2Sn(O^iPr)_2$ and (p-$FC_6H_4)_2Sn(O^iPr)_2$ is given in Table 1. The data collection crystals for (p-$Me_2NC_6H_4)_3SnO^iPr$ were colorless rectangular plates, $Ph_2Sn(O^iPr)_2$ was a colorless plate, and (p-$FC_6H_4)_2Sn(O^iPr)_2$ was a colorless triangular chunk. Single crystal data sets were collected on a Nonius Kappa CCD diffractometer with Mo Kα radiation at low temperature using an Oxford Cryosystems Cryostream Cooler. All sets were measured out to 2θ of 55°. Data integration was done with Denzo [18]. Scaling and merging of the data was done with Scalepack [18]. All structures were solved by the direct methods procedure or the Patterson method in SHELXS-86[19a] or SHELXS-97 [19b]. Full-matrix least-squares refinements based on F^2 were done SHELXL-97 [20], as incorporated in the WINGX package [21].

The methyl group hydrogen atoms were added at calculated positions using a riding model with U(H) = 1.5*Ueq-(bonded C atom). For each methyl group, the torsion angle, which defines its orientation about the C–C bond was refined. The other hydrogen atoms were included in

Table 1

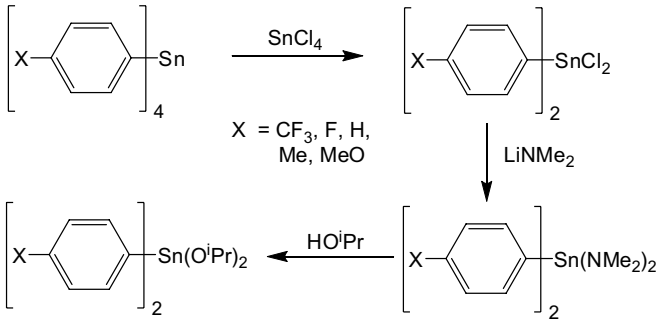
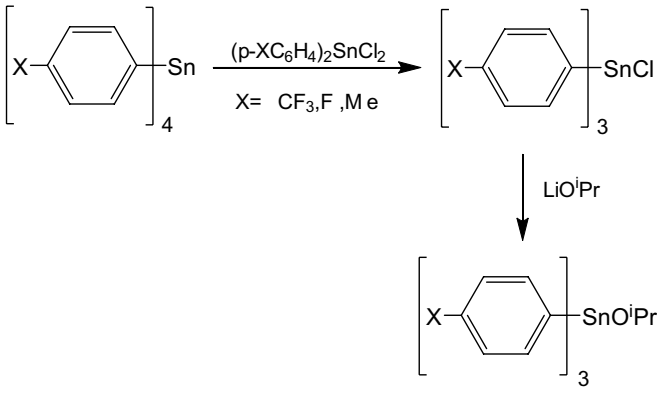
the model at calculated positions using a riding model with U(H) = 1.2*Ueq(bonded C atom). Neutral atom scattering factors were used and include terms for anomalous dispersion [22].

3. Results and discussion



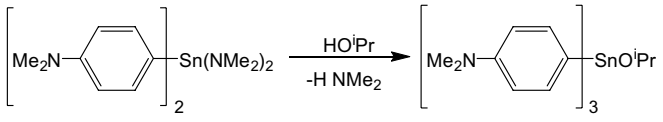
3.1. Preparations

The new compounds described in this work were prepared via the Kochesnikov redistribution reactions as shown in Schemes 2–4.



3.2. Structures

The $(p\text{-}XC_6H)_3Sn(OPr^i)$ compounds are monomeric in benzene solution and in the solid state and the molecular structure of the complex $(p\text{-}Me_2NC_6H_4)_3Sn(OPr^i)$ is shown in Fig. 1.



In contrast the bisaryltin(IV) isopropxides are loosely associated dimeric species in the solid state. The molecular structure of the $[(Ph)_2Sn(OPr^i)_2]_2$ dimer is shown in Fig. 2.

Scheme 2. Synthesis of $(p\text{-}XC_6H_4)_2Sn(O^iPr)_2$ (X = CF_3, F, H, Me, MeO).

Scheme 3. Synthesis of $(p\text{-}XC_6H_4)_3SnO^iPr$ (X = CF_3, F, Me).

Scheme 4. Synthesis of $(p\text{-}Me_2NAr)_3SnO^iPr$.

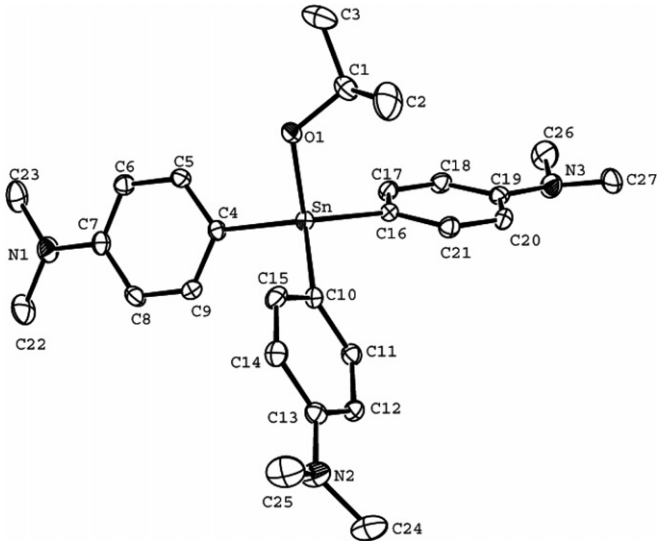


Fig. 1. Molecular structure of $(p\text{-}Me_2NC_6H_4)_3SnO^iPr$ in the crystal. The thermal ellipsoids correspond to 30% probability. Hydrogen atoms are omitted for clarity. Selected bond lengths (Å) and angles (°): Sn–O1 2.0007(15), Sn–C4 2.110(2), Sn–C10 2.121(2), Sn–C16 2.120(2), C1–O1 1.423(3), C1–C2 1.501(3), C1–C3 1.514(3), O1–C1–C2 110.2(2), O1–C1–C3 108.61(19), Sn–O1–C1 119.79(13), O1–Sn–C4 100.38(7), O1–Sn–C16 105.84(7), O1–Sn–C10 110.09(8), C4–Sn–C16 119.09(8), C4–Sn–C10 109.64(8), C16–Sn–C10 111.00(8).

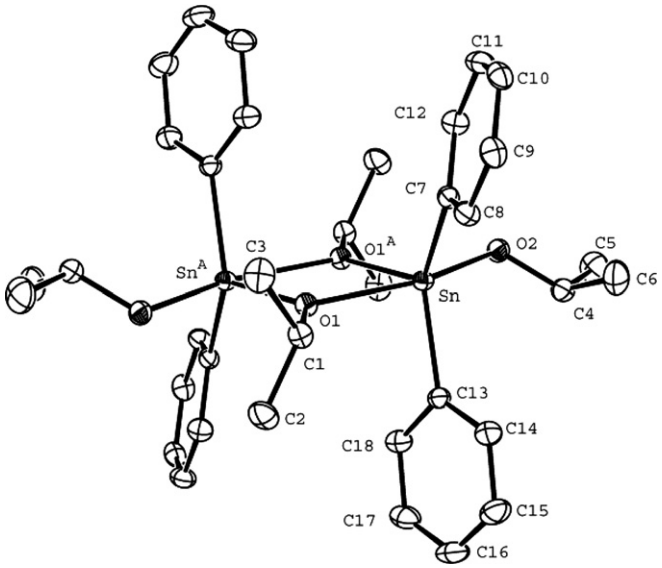

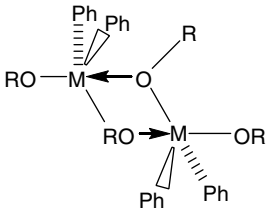

Fig. 2. Molecular structure of $[Ph_2Sn(O^iPr)_2]_2$ in the crystal. The thermal ellipsoids correspond to 30% probability. Hydrogen atoms are omitted for clarity.

The molecule has a crystallographically imposed center of inversion. The coordination geometry about the Sn(IV) center can be described as that of a highly distorted trigonal bipyramid with the terminal Sn–O2 and bridging Sn–O1 bonds being mutually *trans*, O2–Sn–O1 = 162.71(5)°. The bridging Sn–O bonds are very asymmetric with one being short, Sn–O1A = 2.020(1) and one long Sn–O1 = 2.356(1) Å. Another way to view the geometry is to consider that the structure is the result of two pseudo tetrahedral SnO_2C_2

centers weakly associating via the formation of a Sn–O dative bond as depicted below.

The molecular structure of the related complex $[(p\text{-}FC_6H_4)_2Sn(OPr^i)_2]_2$ is shown in Fig. 3 and a comparison of structural data is given in Table 2.

3.3. Solution NMR studies

In order to interrogate the nature of the bis-aryl tin alkoxides in solution we undertook NMR studies that imply that the weakly associated dimers observed in the solid state dissociated to monomers in solution. (1) Only one type of alkoxide group is seen by NMR spectroscopy, (2) the ^{119}Sn NMR signals are sharp and their chemical shifts appear in the range of other known monomeric triarylstannalkoxides and (3) the DOSY NMR spectra for these two compounds yield diffusion coefficients and estimated radii that are comparable to the known monomeric compounds Ph_2SnCl_2 and Ph_3SnCl.

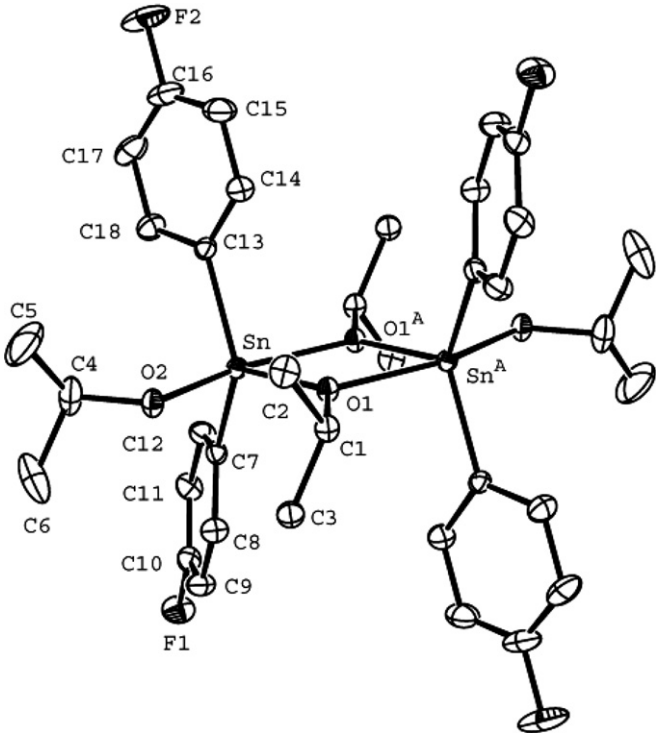

Fig. 3. Molecular structure of $[(p\text{-}FC_6H_4)_2Sn(O^iPr)_2]_2$ in the crystal. The thermal ellipsoids correspond to 30% probability. Hydrogen atoms are omitted for clarity.

3.4. Studies of kinetics

As described in the Experimental Section the reactions were monitored by ^1H NMR spectroscopy in benzene-d_6 over various temperatures with the catalyst to monomer L-LA ratio of 1:50. The conversion of monomer LA to polymer PLA was determined by integration as was the equilibrium concentration of monomer as a function of temperature. The natural log of the equilibrium monomer concentration was then plotted against $1/T$ to give a straight line. These data are shown in Fig. 4 and were used in the various polymerization reactions.

The values of k_{obs} were determined from the gradient of a plot of $-\ln\{[A]-[A]_{eq}/[A]_0-[A]_{eq}\}$ versus time as shown in Fig. 5.

The activation parameters, $\Delta H^{\neq}$ and $\Delta S^{\neq}$, were extracted from the Arrhenius plots of $-\ln k/T$ versus $1/T$ (see Fig. 6). The activation parameters are summarized in Table 3.

We also examined the order of the reaction in [Sn] under pseudo-first-order conditions where [LA]/[Sn] > 45. The plot of k_{obs} versus [Sn] for the five samples examined when [Sn] represents the concentration of $Ph_2Sn(OPr^i)_2$

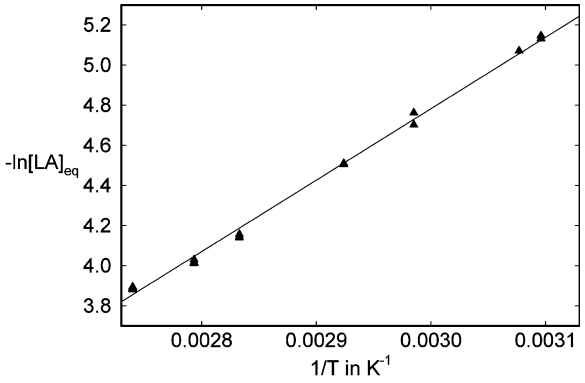

Fig. 4. Plots of $-\ln[LA]_{eq}$ vs. $1/T$ giving a straight line, which allows for the determination of the equilibrium monomer concentration of L-lactide (LA) at various temperatures.

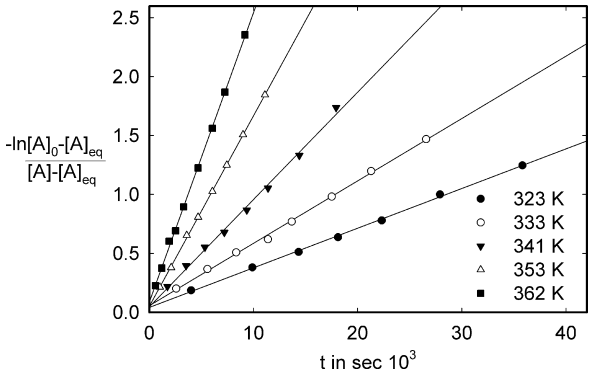

Fig. 5. Typical plot of $-\ln[[A_0] - [A_{eq}]/[A] - [A_{eq}]]$ vs. time in the ROP of L-lactide by $Ph_2Sn(O^iPr)$ at various temperatures.

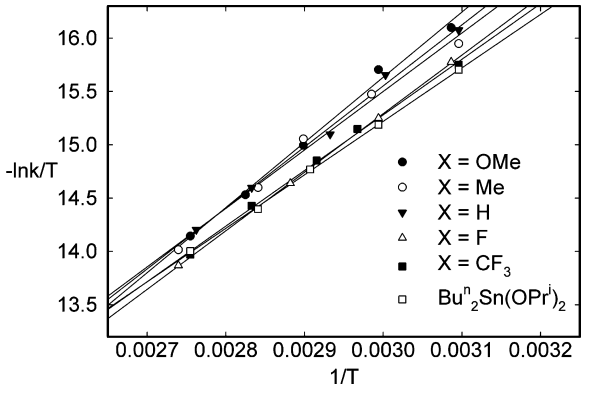

Fig. 6. Plots of $-\ln k/T$ vs. $1/T$, giving a straight line, which allows for the determination of the activation parameters ΔH^* and ΔS^*.

Table 3
Calculated activation parameters for the polymerization of lactide with (p-$XC_6H_4)_2Sn(O^iPr)_2$ and $Bu^n_2Sn(OPr^i)_2$ as catalysts

Catalysts	ΔH^*(kcal/mol)	ΔS^* (e.u.)
(p-$MeOC_6H_4)_2Sn(O^iPr)_2$	12.1(5)	−53(5)
$(Ph)_2Sn(O^iPr)_2$	11.4(5)	−50(5)
(p-$MeC_6H_4)_2Sn(O^iPr)_2$	10.9(5)	−49(5)
(p-$FC_6H_4)_2Sn(O^iPr)_2$	11.2(5)	−44(5)
(p-$CF_3C_6H_4)_2Sn(O^iPr)_2$	10.4(5)	−48(5)
(n-$Bu)_2Sn(O^iPr)_2$	10.0(5)	−47(5)

employed in the polymerization at 70 °C is shown in Fig. 7a. As can be seen the plot yields a straight line with a non-zero intercept in [Sn]. The only reasonable explanation for this is that in each case studied an equivalent amount of the catalyst is inactive and is presumably removed from the system by hydrolysis or some other reaction that leads to its inactivity. This situation is not uncommon and was specifically noted by Hillmyer et al. [23] in a related study of the polymerization of LA by a monomeric zinc alkoxide complex.

The plot of $\ln k$ versus $-\ln[Sn]$ from which the order of the reaction in tin can be deduced is shown in Fig. 7b (order in [Sn] 1.41). In constructing this plot we have assumed the correlation for the concentration of [Sn] by its intercept in Fig. 7a. From this we obtain an order in [Sn] of 0.93., which we take to imply first order reactivity. Once again this situation is similar to that described by Hillmyer [23].

As can be seen from Table 3 there is a very small range of $\Delta H^{\neq}$ values and for the p-XC_6H_4 groups it appears that the electron withdrawing substituents lower that activation enthalpy when compared with the electron donating OMe group. However, the range is very small. A plausible interpretation of this would be that the more electrophilic the metal center exhibits greater Lewis acidity toward the LA monomer thus favoring a larger K_{eq} for the reversible binding of LA. The reactivity of $(Bu^n)_2Sn(OPr^i)_2$ which is comparable to the (p-$CF_3C_6H_4)_2Sn(OPr^i)_2$ complex is an outrigger in as much as its steric factors are not the same.

Irrespective of the interpretation that may be placed on the subtle factors influencing $\Delta H^{\neq}$, one point that emerges unequivocally from this study is that the entropy of activation is large in magnitude and negative, $\Delta S^{\neq} \sim -50 \pm 5$ eu. This is quite a bit larger than typically seen for a bimolecular reaction for which $\Delta S^{\neq}$ values fall in the range of −25 to −35 eu. Values of ~ -50 eu imply a very highly ordered transition state as is sometimes found for constrained cyclic transition states. For example, 2 + 2 cycloadditions in organic chemistry generally have $\Delta S^{\neq}$ values of 35 ± 5 eu [24]. Recent computations by Gibson et al. [25,26] on the ROP of LA by Mg and Sn alkoxides would seem to sup-

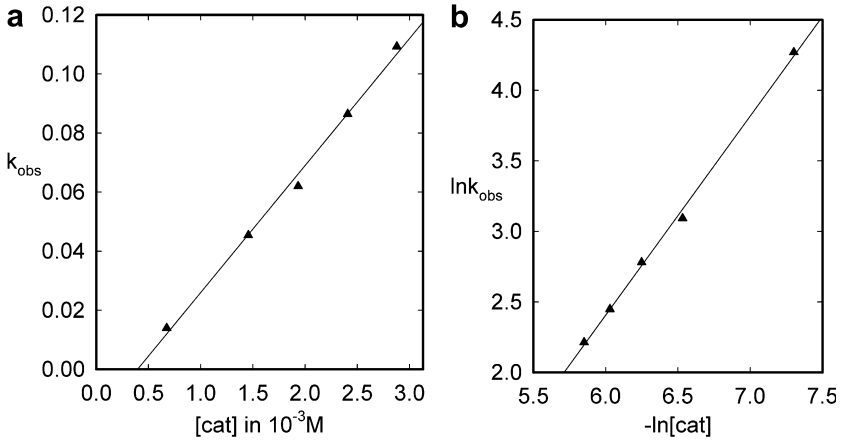

Fig. 7. Plots of k_{obs} vs. [cat] (a) and $\ln k_{obs}$ vs. $-\ln$[cat] (b) in the ROP of L-lactide by different concentrations of $Ph_2Sn(OPr^i)_2$ at 70 °C.

port this view but in our present study we have not evaluated the influence of solvent.

4. Supplementary material

CCDC 637509, 637508 and 637510 contain the supplementary crystallographic data for $(p\text{-}Me_2NC_6H_4)_3SnO^iPr$, $Ph_2Sn(O^iPr)_2$ and $(p\text{-}FC_6H_4)_2Sn(O^iPr)_2$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Results and discussion

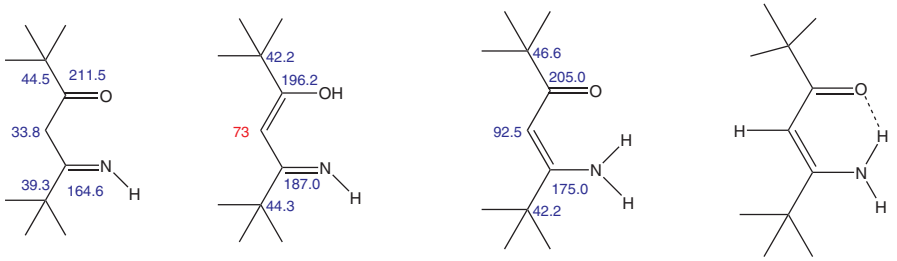
2.1. Ligand synthesis and structural characterization

The transformation of 2,2,6,6-tetramethylheptane-3,5-dione (Htmhd) into 2,2,6,6-tetramethyl-3-amino-4-hepten-5-one (Htmha or **1**) may be presented as Eq. (1)

$$\mathrm{Htmhd} + \mathrm{NH_3} \rightarrow \mathrm{Htmha} + \mathrm{H_2O} \quad (1)$$

This reaction is quite possible if water is removed from the reaction mixture by a physical method (distillation or binding with molecular sieves) or by chemical methods (the reaction with $TiCl_4$, $SiCl_4$, $Si(CH_3)_3Cl$, $AlCl_3$, PCl_5, etc.). We have chosen $TiCl_4$ as the water acceptor. $TiCl_4$ is supposed to react with water in the organic solvent in two stages (Eqs. (2) and (3)) [17]

$$TiCl_4 + H_2O \rightarrow TiOCl_2 + 2HCl \quad (2)$$



$$TiOCl_2 + H_2O \rightarrow TiO_2 + 2HCl \quad (3)$$

Our investigation shows that these two stages are suitable for the synthesis of Htmha from Htmhd under an excess of dry ammonia, but the best yield of the product was obtained for the combination of reactions (1) + (3). Therefore we added for the synthesis technique proposed an appropriate amount of water to $TiCl_4$ to produce $TiOCl_2$ before the addition of Htmhd. At the final stage of the synthesis we used an adequate amount of aqueous ammonia to hydrolyze the intermediate. Our technique allowed us to obtain only the N,O substituted product **1**, the product with a higher amination degree (N,N substituted diimine) being not isolated. Nevertheless, the formation of diimine products has been demonstrated in the literature [12,16], though it was established for compounds without bulky *tert*-butyl substituents. Hence, we cannot exclude the diimine product formation in our case, but it might have been destroyed by water. The IR spectra of the compound obtained show two bands at 3405 and 3346 cm^{-1}, assigned to ν(N–H) [18] vibrations. The chemical analysis results evidence the presence of only one imino group in the molecule. In combination, the whole data collection on the compound identification confirms the preparation of Htmha. It should be noted that our synthesis technique is easily monitored and is guided by the color change during the procedure, due to the specific colors of each titanium intermediate.

It is possible to present the synthesized 2,2,6,6-tetramethyl-3-amino-4-hepten-5-one (**1**) as three tautomeric structures with the oxygen atom in the ketone or enol form (Fig. 1a–c, numbers in Fig. 1 represent ^{13}C chemical shifts estimated with the help of ChemDraw Ultra 8.0). The observed ^{13}C NMR spectrum unambiguously reveals that the ketone form **1a** does not exist in the investigated solution, because there is a signal for the =CH– group and no signal of a $–CH_2–$ group. The unresolved triplet of the =CH– group exists in the ^1H NMR spectrum and, moreover, there are two broad signals which can be referred to protons of HNH– or –NH– and OH– groups.

The chemical shifts of 205.5 and 173.3 ppm in the ^{13}C NMR spectrum fit well to the results computed for carbons bonded to heteroatoms in structure **1c** (205 and 175 ppm respectively). This agrees with commonly accepted views that enaminoketones of all types exist predominantly in the carbonyl form [19]. However, the noticeable deviation of the computed chemical shifts for **1c** from the observed ones for γ-carbon and quaternary carbons of the $–C(CH_3)$ groups makes us assume that compound **1** exists in solution as a form close to **1d**, that arises from **1c** due to a hydrogen bond forming between one of the protons of the $–NH_2$ group and an oxygen atom. In the ^1H NMR spectrum the broad signal at 10.4 ppm corresponds to the hydrogen atom of the –HN–*H*–O– moiety, and the second broad signal at 5 ppm is assigned to another proton of the amino group, not connected with an oxygen atom.

A single-crystal X-ray diffraction study reveals that there are two crystallographically independent molecules in the crystal structure of Htmha, which are shown with atom numbering in Fig. 2. The structure and the conformation of the molecules are very close, the average lengths of the C=N and C=O bonds being 1.326 and 1.254 ($\Delta = 0.074$) Å respectively (Table 2). The length difference for the C–Cγ bonds does not exceed 0.04 Å. In the *tert*-butyl substituents the $C–CH_3$ distances are the same, 1.530 Å. In the amino group, one of the N–H bonds is elongated by ~0.1 Å to the oxygen atom of the ketone group, while the HNH···O distance is two times longer than the N–H bonds, suggesting some certain intramolecu-

1a 1b 1c 1d

Fig. 1. Possible tautomeric forms of Htmha in solution.

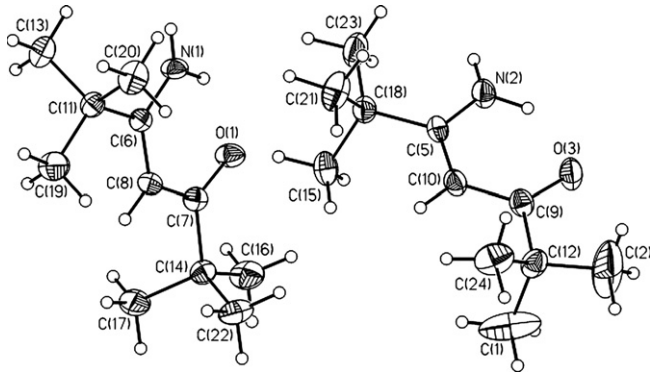


Fig. 2. ORTEP drawing of enaminoketone (**1**) molecules.

lar hydrogen bonding in the molecule (H···O 1.85 and 1.93 Å). Another hydrogen bond between the molecules occurs in the crystal with a H···O distance of 2.09 Å. A distinctive feature of the amino- group is that it is planar, and the C–NH_2 bond is much shorter than that in amines, indicating the unshared electron pair (UEP) of the nitrogen atom participates in conjugate chemical bonding. Judging from the length of the adjacent chemical bonds, a π-conjugated electron system forms at least over the N–C–C atoms in the molecule. As to the delocalization of electrons down to the ketone group, π-conjugation over the C–C–O atoms is less pronounced. Thus in the solid state, the pure ligand also appears to be rather an enaminoketone than an enol. Our data on the structure of Htmha are in good agreement with those obtained by other authors (P.-L. Franceschini, H.W. Schmalle, H. Berke, private communication, 2004, CCDC No. 249230).

2.2. Synthesis and structural characterization of $Cu[(CH_3)_3CC(NH)CHC(O)C(CH_3)_3]_2$ (**2**)

For the synthesis of the copper complex **2** we used a technique based on the reaction between the ligand and $CuCl_2 \cdot 2H_2O$ in aqueous ammonia. The reaction performance in alkaline media prevented ligand hydrolysis and raised the product yield. There is a band at 3374 cm^{-1} in the IR spectrum of **2** that indicates N–H chemical bond vibrations [18]. This data and elemental analysis results confirm the successful preparation of $Cu[(CH_3)_3CC(NH)CHC(O)C(CH_3)_3]_2$.

The crystal structure of the copper complex is molecular, built of a separate *trans*-complexes. Fig. 3 depicts the structure of compound **2**. The copper atom is located at the centre of symmetry and displays square planar coordination by two nitrogen and two oxygen atoms, giving CuO_2N_2 coordination. The difference between the Cu–O and Cu–N bond lengths is negligible, being only 0.003 Å. The distinction between C=N, C=O and symmetrical C–Cγ bonds in the chelate rings is also minimal (Table 3), i.e. the chemical bonds are leveled in the chelate ring comparing to the free ligand. For the Bu^t substituents the average C–CH_3 distance is 1.534 Å, and the C–C–C angles are close to tetrahedral within the ±5° error. The chelate rings are slightly bent along the O···N line by 1.5°. The revealed geometric parameters of this compound are in agreement with the data obtained for other copper ketoiminates [2]. Fig. 4 illustrates the package of molecules along the *x*-axis. All the intermolecular contacts are Van-der-Waals. The shortest Cu···CH_3 distance is 3.74 Å. Each molecule is surrounded by six others, and four Cu···Cu distances are

Symmetry transformations used to generate equivalent atoms: #1 $-x+2$, $-y$, $-z+2$.

8.486 Å whilst the other two are 9.775 Å. On the whole, the structure of $Cu(tmha)_2$ is close to that of $Cu(tmhd)_2$ [20]. The X-ray powder diffraction study and preliminary single-crystal experiments for $Ni[(CH_3)_3CC(NH)CHC(O)C(CH_3)_3]_2$ show that compounds **2** and **3** are isostructural.

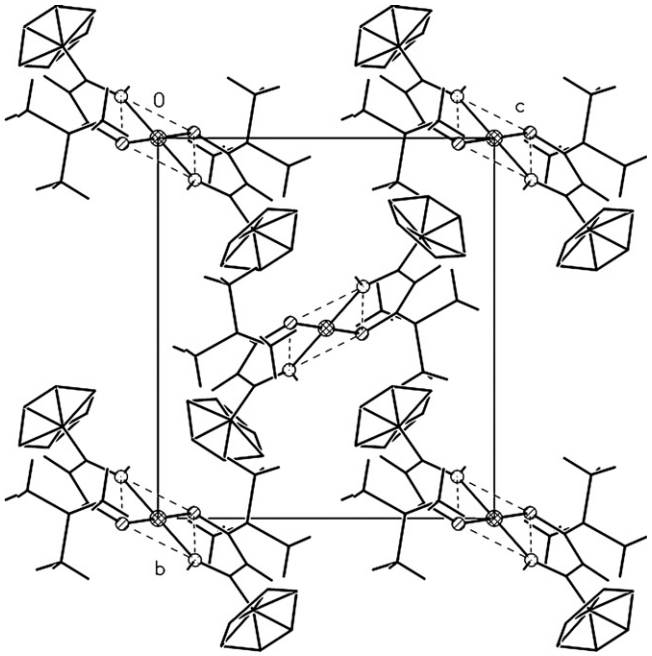

Fig. 4. Projection of the crystal packing of compound (**2**) onto the *a* plane.

2.3. Thermogravimetry study of $Cu[(CH_3)_3CC(NH)CHC(O)C(CH_3)_3]_2$ (**2**) and $Ni[(CH_3)_3CC(NH)CHC(O)C(CH_3)_3]_2$ (**3**)

A TG study, performed under a helium flow up to a final temperature of 400 °C, was carried out to compare the thermal stability of the related ketoiminate and diketonate derivatives of copper and nickel (Fig. 5). The TG curves show that the evaporation rate of **2** becomes noticeable after the melting point and is higher than that of $Cu(tmhd)_2$. The decomposition rate of compound **2** during

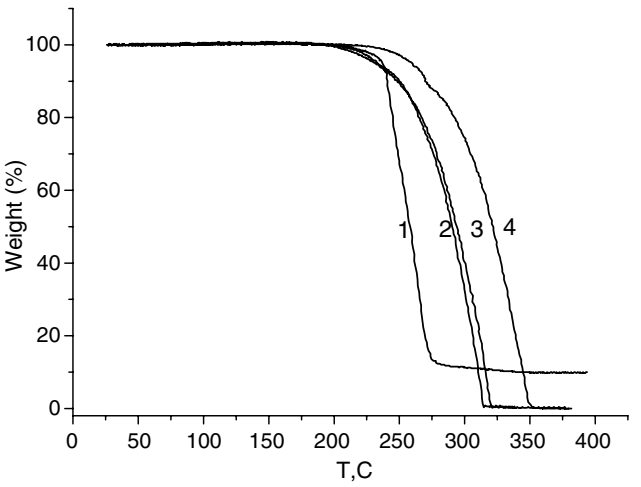

Fig. 5. TGA profiles for 1 – $Cu(tmha)_2$; 2 – $Cu(tmhd)_2$; 3 – $Ni(tmhd)_2$; 4 – $Ni(tmha)_2$.

heating also increases resulting in 9% of a solid residue. At the same time, $Cu(tmhd)_2$ evaporates slower and without decomposition at higher temperatures. Thus, compound **2** seems to be more volatile but less stable under heating than $Cu(tmhd)_2$. Surprisingly, $Ni(tmha)_2$ appeared to be less volatile than $Ni(tmhd)_2$. Even though compound **3** is less volatile than **2**, its stability to heating is obvious.

3. Concluding remarks

The ligand $(CH_3)_3CC(NH)CHC(O)C(CH_3)_3$ (**1**) was synthesized from 2,2,6,6- tetramethylheptane-3,5-dione by amination with dry ammonia in the presence of $TiCl_4$ in benzene at room temperature. The Cu(II) complex $Cu[(CH_3)_3CC(NH)CHC(O)C(CH_3)_3]_2$ (**2**) and the Ni(II) complex $Ni[(CH_3)_3CC(NH)CHC(O)C(CH_3)_3]_2$ (**3**) were synthesized in water/alcohol alkaline solutions. The compounds obtained were identified by elemental analysis, ^1H and ^{13}C NMR, IR-spectroscopy and characterized by TGA, X-ray powder diffraction and single-crystal X-ray diffraction studies. A crystallographic analysis shows that the metal complexes (**2**) and (**3**) are isostructural to each other and related β-diketonate complexes.

4. Experimental

4.1. General considerations

The solvents used in the preparation were dried and distilled from sodium benzophenone ketyl. Htmhd (2,2,6,6-tetramethylheptane-3,5-dione = dipivaloylmethane) of 99% purity (Merck) was used without pretreatment. Commercially available $TiCl_4$, $CuCl_2 \cdot 2H_2O$, $NiCl_2 \cdot 6H_2O$, NaOH, and aqueous ammonia of adequate purity were used. The synthesis of $Cu(tmhd)_2$ and $Ni(tmhd)_2$ was carried according to [21,22] respectively.

Compounds **1**, **2** ($Cu(tmha)_2$), **3** ($Ni(tmha)_2$), $Cu(tmhd)_2$ and $Ni(tmhd)_2$ were purified by vacuum sublimation in a gradient tube oven ($P \sim 10^{-3}$ Torr, $T = 50$–300 °C). The elemental analysis was performed on a Carlo-Erba 1106 device (Italy). The infrared spectra were measured in KBr pellets on a Scimitar FTS2000 spectrometer. The NMR spectra were recorded on a Bruker MSL300 spectrometer; chemical shifts were referenced to the protio impurity of the NMR solvent (^1H) or to the NMR solvent (^{13}C). The thermal analysis was performed in a He flow at the heating rate 10°/min (~150 mg samples) using a Q-1000 (F. Paulik, J. Paulik, L. Erdey) device.

The X-ray powder diffraction analysis was performed with a DRON-3M diffractometer. Ni-filtered Cu Kα radiation was used. The diffraction pattern was scanned in an angular range from 5° to 45° 2θ at room temperature.

X-ray intensity data were collected on a Bruker X8Apex CCD diffractometer at 150 K using the standard technique (ω- and φ-scans of narrow frames) and corrected for absorption effects (SADABS). The structures were solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELX97 program set (Sheldrick 1998) [23]. The crystallographic data and details of single-crystal diffraction experiments for compounds **1** and **2** are given in Table 1. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms of CH_3 groups were calculated by geometrical methods. In the copper complex, the Bu^t-groups from the side of the nitrogen atoms are disordered at low temperature. Selected bond lengths and angles are given in Tables 2 and 3.

4.2. Synthesis of the $(CH_3)_3CC(NH_2)CHC(O)C(CH_3)_3$ ligand (*1*)

The synthesis of $(CH_3)_3CC(NH_2)CHCOC(CH_3)_3$ (**1**) was carried out under an inert atmosphere of dry nitrogen. Htmhd (1:10 in benzene) was added dropwise to a suspension of $TiOCl_2$ ($TiCl_4 + H_2O$) in benzene under vigorous stirring in a three-neck flask. The reactants were taken in a molar ratio of 1:1 producing a red-brown mixture. A slow flow of dry nitrogen was purged above the mixture overnight. Gaseous ammonia was obtained from the reaction of NaOH with aqueous ammonia. Then NH_3, dried over NaOH, was bubbled through the mixture under stirring for a day until the reaction mixture became hazel colored. After that, a stoichiometric amount of aqueous ammonia was added by pipette under stirring over 2 h. The mixture was settled for 30 min, producing a white precipitate and a colorless solution. The solution was decanted, and the precipitate was washed with a portion of benzene and decanted again. The crude product was separated on a rotary evaporator and recrystallized from heptane after cooling in the refrigerator. The pure ligand in the form of white crystals was obtained after sublimation in a vacuum ($T = 100$ °C, $P = 10^{-3}$ Torr). Yield ~80%. *Anal.* Calc. for $C_{11}H_{21}NO$: C, 72.08; H, 11.55; N, 7.64. Found: C, 72.24; H, 11.55; N, 7.64%.

^1H and ^{13}C NMR spectra in $CDCl_3$ and $CDCl_3/CCl_4$ solutions indicate that the compound exists in the ketone form, revealing the structure with an intramolecular hydrogen bond as in Fig. 1d. ^1H NMR (300 MHz, 25 °C, ppm): 1.14 [s, $(CH_3)_3CCN$]; 1.21 [s, $(CH_3)_3CC(O)$]; 5.0 (br s, *H*NH–O); 5.32 (unresolved triplet, CH); 10.44 (br s, HN*H*–O,). ^{13}C NMR{^1H} (75.4 MHz, 25 °C, ppm): 28.5 (s, CH_3); 29.5 (s, CH_3); 36.5 (s, *C*–C=N); 42.6 (s, *C*–C=O); 87.0 (s, CH); 173.3 (s, C–N); 205.5 (s, C=O).

IR (cm^{-1}): 3405 (vs), 3347 (s), 3176 (m), 2967 (vs), 2907 (m), 2869 (m), 1633 (m), 1596 (s), 1525 (vs), 1500 (m), 1387 (m), 1363 (m), 1300 (m), 1216 (m), 1151 (vs), 1065 (vw), 1014 (m), 937 (vw), 868 (s), 798 (vw), 774 (m), 728 (w), 690 (m), 634 (m), 531 (vw), 472 (m), 406 (vw). M.p.: 131–132 °C.

4.3. Synthesis of $Cu(CH_3)_3CC(NH)CHCOC(CH_3)_3]_2$ (*2*)

0.366 g (2.0 mmol) of **1** was dissolved in 10 ml of ethanol and 2 ml of aqueous ammonia. Then a solution of 0.170 g (1.0 mmol) $CuCl_2 \cdot 2H_2O$ in 5 ml of ethanol was added

under stirring. The mixture was transferred to an evaporation dish and left for evaporation in air. 10 ml of benzene was added to the solid residue in the dish. The obtained solution was filtered and dark-violet crystals of **2** appeared after the solvent was removed. The product was purified by vacuum sublimation ($T = 180$ °C, $P = 10^{-3}$ Torr). Yield 0.3 g (70%). *Anal.* Calc. for $C_{22}H_{40}CuN_2O_2$: C, 61.72; H, 9.42; N, 6.54. Found: C, 61.95; H, 9.52; N, 6.44%.

IR (cm^{-1}): 3374 (s), 2960 (vs), 2907 (m), 2867 (m), 1579 (vs), 1524 (s), 1483 (s), 1427 (vs), 1357 (m), 1330 (s), 1237 (s), 1178 (s), 1025 (vw), 958 (w), 931 (vw), 875 (m), 777 (s), 742 (vw), 657 (vw), 627 (m), 523 (vm), 499 (m), 438 (vw), 396 (vw). M.p.: 209–210 °C.

4.4. Synthesis of $Ni(CH_3)_3CC(NH)CHCOC(CH_3)_3]_2$ (3)

0.238 g (1.0 mmol) of $NiCl_2 \cdot 6H_2O$ dissolved in 20 ml of ethanol was added under stirring to a solution of 0.366 g (2.0 mmol) of ligand **1** and 0.112 g (2.0 mmol) of KOH in 20 ml of ethanol. The mixture was heated at 60–80 °C for 1 h and then left in air until it dried. The solid residue was treated with chloroform. The extract was filtered, and red crystals of the product were isolated after the solvent evaporated. The product was purified by vacuum sublimation ($T = 190$ °C, $P = 10^{-3}$ Torr). Yield: 0.34 g (80%). *Anal.* Calc. for $C_{22}H_{40}NiN_2O_2$: C, 62.43; H, 9.53; N, 6.62. Found: C, 62.55; H, 9.41; N, 6.50.

^1H and $^{13}C\{^1H\}$ NMR spectra in $CDCl_3/CCl_4$ solution indicate that only one isomer exists in solution. It seems to us that it is the *trans*-isomer. ^1H NMR (300 MHz, 25 °C, ppm, Hz): 0.99 [s, $(CH_3)_3C$]; 1.27 [s, $(CH_3)_3C$]; 5.082 (d, CH, 2.8); 5.37 (br s, HN). $^{13}C\{^1H\}$ NMR (75.4 MHz, 25 °C, ppm): 29.0 (s, CH_3); 29.3 (s, CH_3); 38.0 (s, *C*–$C(H_3)_3$); 38.8 (s, *C*–$C(H_3)_3$); 89.0 (s, CH); 176.7 (s, C–N); 185.8 (s, C=O).

IR (cm^{-1}): 3366 (s), 3175 (vw), 2959 (vs), 2867 (s), 1587 (vs), 1497 (vs), 1431 (s), 1357 (m), 1326 (s), 1241 (m), 1222 (s), 1173 (s), 1113 (w), 1026 (w), 969 (w), 931 (vw), 880 (m), 823 (vw), 782 (vs), 701 (vw), 666 (m), 532 (w), 515 (w), 443 (vw), 408 (vw). M.p.: 267–268 °C.

5. Supplementary material

CCDC 634189 and 634188 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

self-assembled molecular squares of multidentate ligands [5]. Recently we have reported the first molecular square grid of a carbohydrazone ligand with Zn(II) ions [6]. Here we report magnetically coupled Ni(II) molecular squares of two carbohydrazone building blocks along with that of two thiocarbohydrazone building blocks.

2. Experimental

Quinoline-2-carbaldehyde (Aldrich), di-2-pyridyl ketone (Aldrich), 2-benzoylpyridine (Aldrich), thiocarbohydrazide (Aldrich) and carbohydrazide (Fluka) were used as received. Nickel(II) chloride hexahydrate (Merck) and ammonium hexafluorophosphate (Fluka) were used as supplied and solvents were purified by standard procedures before use.

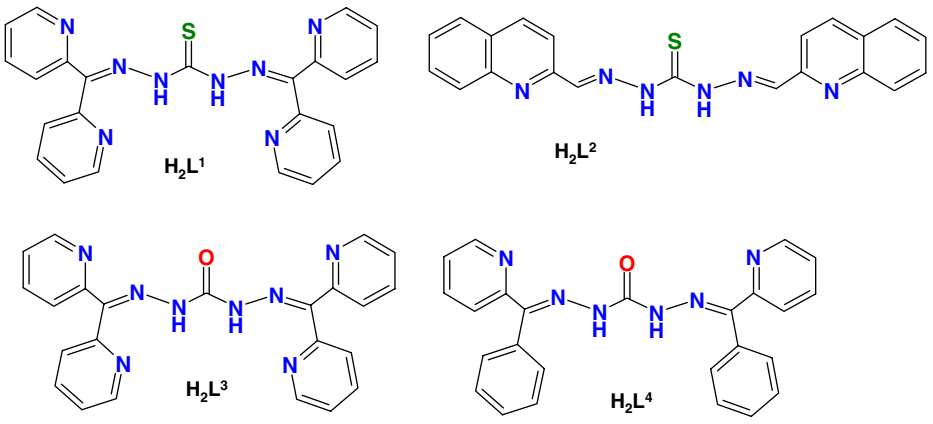
2.1. Synthesis of ligands

The synthesis of H_2L^1 was reported [7] meagerly, without any spectral studies. The other three ligands were synthesized as already reported by us [6,8,9]. The structures of these ligands are given in Scheme 1.

2.1.1. H_2L^1

Dipyridyl ketone (0.391 g, 2.1 mmol) in 10 ml methanol was added to thiocarbohydrazide (0.011 g, 1 mmol) dissolved in hot methanol (30 ml). After adding a drop of HCl, the solution was refluxed for 1 h and on cooling a yellow mass precipitated. It was then washed with methanol and ether and dried over P_4O_{10} *in vacuo*. Yield 80%. M.p. 188 °C. Elemental *Anal.* Calc. C, 63.00; H, 4.14; N, 25.55; S, 7.31. Found: C, 62.30; H, 4.32; N, 25.19; S, 7.27%. IR (KBr pellet, cm^{-1}): 3340br (νN–H), 3049m (νC–H), 1581m, 1483s, 1456vs, 1423s (νC=N+ νC=C), 1303m, 1282m (νC–N/νheterocyclic), 1223s (νC=S), 1118s (νN–N), 872m, 802s, 741m (δC–H), 646m (δpy). UV–Vis [methanol, λ_{max} cm^{-1} (ε $M^{-1}\,cm^{-1}$)]: 43480 (12270), 36230 (11390), 28250 (18300). ^1H NMR ($CDCl_3$, δ ppm): 15.45 (1H, s), 14.56 (1H, s), 8.73 (1H, d), 8.62 (1H, d), 8.50 (1H, d), 8.21 (1H, d), 7.92 (1H, d), 7.84 (1H, t), 7.75 (3H, m), 7.55 (1H, d), 7.51 (1H, d), 7.38 (1H, t), 7.31 (1H, t), 7.25 (1H, t), 7.20 (2H, d).

2.2. Synthesis of the complexes



All the complexes were prepared by a general procedure. To a hot solution of the respective ligand (1 mmol) in 50 ml methanol was added an equivalent amount of nickel(II) chloride hexahydrate (0.240 g) dissolved in 10 ml hot methanol. The mixture was refluxed for an hour and NH_4PF_6 (2 mmol, 0.3326 g) was added in 20 ml methanol. The resulting solution was refluxed for 2 more hours and allowed to stand at room temperature. The compound precipitated was filtered, washed with methanol and ether and recrystallized in acetonitrile/ethanol (1:1 v/v) mixture and dried *in vacuo* over P_4O_{10}.

2.2.1. $[Ni(HL^1)]_4(PF_6)_4 \cdot 11H_2O$ (**1**)

Yield: 0.440 g (63%). Elemental *Anal.* Calc. C, 40.00; H, 3.28; N, 16.22; S, 4.64. Found: C, 39.72; H, 2.98; N, 16.76; S, 4.99%. It was found to be very difficult to get good quality single crystals for X-ray diffraction. However crystals suitable for X-ray analysis were obtained by slow evaporation of a solution of the compound in an ethanol–methanol mixture. The complex $[Ni(HL^1)]_4[PF_6]_4 \cdot 11H_2O$ (**1**) crystallized as $[Ni(HL^1)]_4(PF_6)_4 \cdot 0.5\ CH_3CH_2OH \cdot 2.8H_2O$ (**1a**) and the relatively high R-factors of **1a** are due to the bad quality of the crystal. All attempts to get better quality crystals failed. IR (KBr pellet, cm^{-1}): 3422br (νN–H), 3065m, 3012m (νC–H), 1588s, 1547s, 1493s, 1462s, 1427s, 1393s (νC=N+νC=C), 1328m, 1267s (νC–N/νheterocyclic), 1094s (νC–S), 1161m, 1116m (νN–N), 998m, 978m, 789m, 742m, 710m (δC–H), 842vs (νP–F), 352m (νNi–S), 429m (νNi–N_{azo}), 280s (νNi–N_{py}). UV–Vis [DMF, λ_{max} cm^{-1} (ε $M^{-1}\,cm^{-1}$)]: 17700 (64800), 18940 (113800), 29590 (36300).

2.2.2. $[Ni_2(HL^2)L^2]_2(PF_6)_2 \cdot 7H_2O$ (**2**)

Yield: 0.430 g (78%). Elemental *Anal.* Calc. C, 46.22; H, 3.33; N, 15.40; S, 5.88. Found: C, 46.57; H, 3.15; N, 15.09; S, 6.00%. IR (KBr pellet, cm^{-1}): 3414br, 3114w (νN–H),

2.3. Physical measurements

Elemental analyses were carried out using a Vario EL III CHNS analyzer at SAIF, Kochi, India. Infrared spectra were recorded on a Thermo Nicolet, AVATAR 370 DTGS model FT-IR spectrophotometer with KBr pellets and the ATR technique at SAIF, Kochi, India. The far IR spectra were recorded using polyethylene pellets in the 500–100 cm^{-1} region on a Nicolet Magna 550 FTIR instrument at the Regional Sophisticated Instrumentation Facility, Indian Institute of Technology, Bombay, India. Electronic spectra were recorded on a Cary 5000 version 1.09 UV–vis spectrophotometer. High-resolution MALDI spectra were measured by the MS-service (Laboratorium für Organische Chemie, ETH Zürich, Switzerland) on an IonSpec HiResM-ALDI apparatus in a DCTB matrix and dichloromethane solvent. The magnetic susceptibility measurements were carried out at the Department of Physics, Boise State University, Boise, USA in the polycrystalline state on a Quantum Design PPMS superconducting magnetometer at 500 Oe field strength. The molar conductances of the complexes in DMF solutions at room temperature were measured using a direct reading conductivity meter.

2.4. X-ray crystallography

The crystallographic data and structure refinement parameters for compound **1a** are given in Table 1. The data were collected using a Bruker Apex2 CCD diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation on a triclinic single crystal of dimensions $0.37 \times 0.15 \times 0.04$ mm^3 with $P\bar{1}$ symmetry at the X-ray Crystallography Unit, School of Physics, Universiti Sains Malaysia. The unit cell dimensions and intensity data were measured at 100 K. The trial structure was solved using SHELXS-97 [10] and refinement was carried out by full-matrix least squares on F^2 (SHELXTL). One of the pyridyl groups is disordered over two sites and the rings have been constrained to be regular hexagons. Hydrogen atoms were placed at calculated positions and allowed to ride on their parent atoms. The hydrogen atoms of the water molecules could not be located from the difference map, which was obtained by WINGX [11]. The molecular graphics employed were ORTEP-III [12], MERCURY [13], DIAMOND version 3.0 [14] and PLATON [15].

Data/restraints/parameters	10136/0/1387
Goodness-of-fit on F^2	1.043
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0849$, $wR_2 = 0.2282$
R indices (all data)	$R_1 = 0.1296$, $wR_2 = 0.2809$
Largest difference in peak and hole (e Å^{-3})	1.427 and −1.317

3. Results and discussion

Carbohydrazones and thiocarbohydrazones can exist in keto/thioketo and enol/thioenol tautomeric forms [16]. The absence of a ν(SH) band at ~2600 cm^{-1} in the IR spectra

of H_2L^1, H_2L^2, **1** and **2** is a clear indication of the absence of thiol tautomers in the free or coordinated form in these compounds. Molar conductivity measurement in a 10^{-3} M DMF solution of **2** shows it to be a 2:1 electrolyte ($147\ \Omega^{-1}\ cm^2\ mol^{-1}$) [17]. For all the other three compounds the conductance values obtained are $\sim 30\ \Omega^{-1}\ cm^2\ mol^{-1}$ in 10^{-4} M DMF solution. Complex **2** was assigned the formula $[Ni_2(HL^2)L^2]_2\ (PF_6)_2 \cdot 7H_2O$ and **1**, **3** and **4** were assigned the general formula $[Ni(HL)]_4[PF_6]_4 \cdot nH_2O$. The variable temperature magnetic studies reveal intramolecular antiferromagnetic couplings for all molecular square grids. The MALDI-MS spectra reveal the formation of tetra-nuclear molecular square structures for all the four compounds. The theoretical simulation of isotropic distribution patterns of all molecular ion peaks and their fragmentation peaks could be achieved well, confirming the proposed structural formulae. The structure of **1** has been confirmed by a single crystal X-ray study and is in good agreement with the mass structural study.

3.1. Mass spectral studies

For the unequivocal characterization of large molecules, mass spectrometry was found useful as a complementary tool. The structure and stability of coordination complexes under ionization conditions are dependent on various factors like the ligand itself, metal ions, counter ions, solvent, temperature, concentration, etc. MALDI mass spectra as a DCTB mix on the positive ion mode is found to give excellent results for stable Ni(II) square grids of both thiocarbohydrazones and carbohydrazones.

The MALDI-MS spectrum of compound **1** in dichloromethane shows the presence of three main peaks at *m*/*z* 495.0602, 991.1073 and 1981.2342. The peak centered at 1981.2342 is assigned to the molecular ion peak expected for $[Ni_4(HL^1)L^1_3]^+$ (calc. 1981), with good agreement with the simulated spectrum (Fig. 1). The base peak at *m*/*z* 495.0602 is assigned to $[Ni(HL^1)]^+$ (calc. *m*/*z* 495) and the other major peak at 991.1073 is assigned to $[Ni_2(HL^1)L^1]^+$ (calc. 991). In the case of compound **2**, two major peaks are obtained at *m*/*z* 1827.1019 and 1765.1557. Here the peak at 1765.1557 is assigned to the $[Ni_4(HL^2)L^2_3]^+$ ion (calc. 1765), with a well matching simulation (Fig. 2). The base peak at 1827.1019 is assigned to the molecular ion peak with two methanol molecules (calc. 1827). Another peak at 1323.1211 is assigned to $[Ni_3(HL^2)L^2_2]^+$ (calc. 1323).

Considering the carbohydrazone compounds, the MALDI MS spectrum of compound **3** displays only two main peaks centered at *m*/*z* 479.0873, as the base peak, and at 1917.4364, the molecular ion peak. The former peak is assigned to $[Ni(HL^3)]^+$ (calc. *m*/*z* 479) and the latter to the $[Ni_4(HL^3)L^3_3]^+$ ion (calc. 1917) (Fig. 3), agreeing well with the calculated isotropic distribution pattern of the

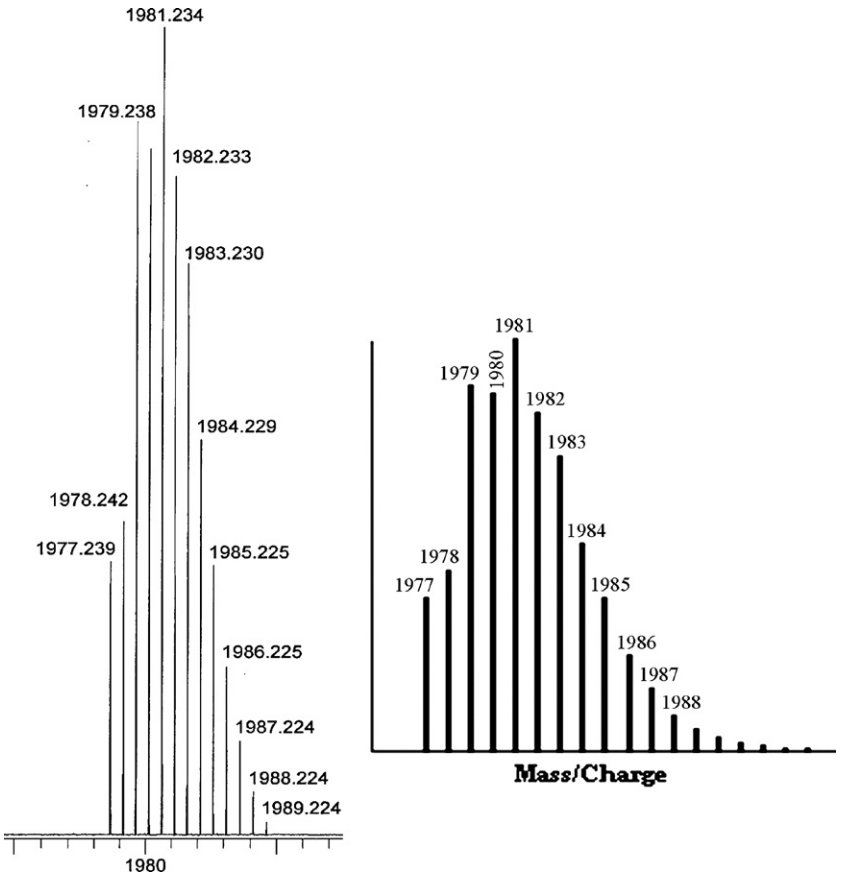

Fig. 1. The isotropic distribution pattern of the molecular ion peak $[Ni_4(HL^1)L^1_3]^+$ of **1** and its theoretical simulation on the right.

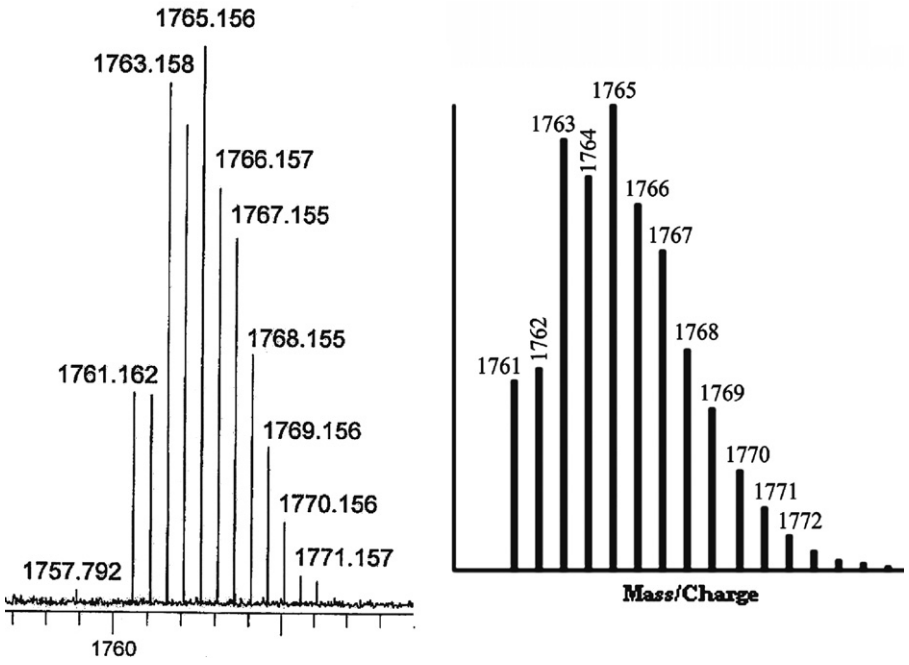

Fig. 2. The isotropic distribution pattern of peak corresponding to $[Ni_4(HL^2)L^2_3]^+$ of complex **2** and its theoretical simulation.

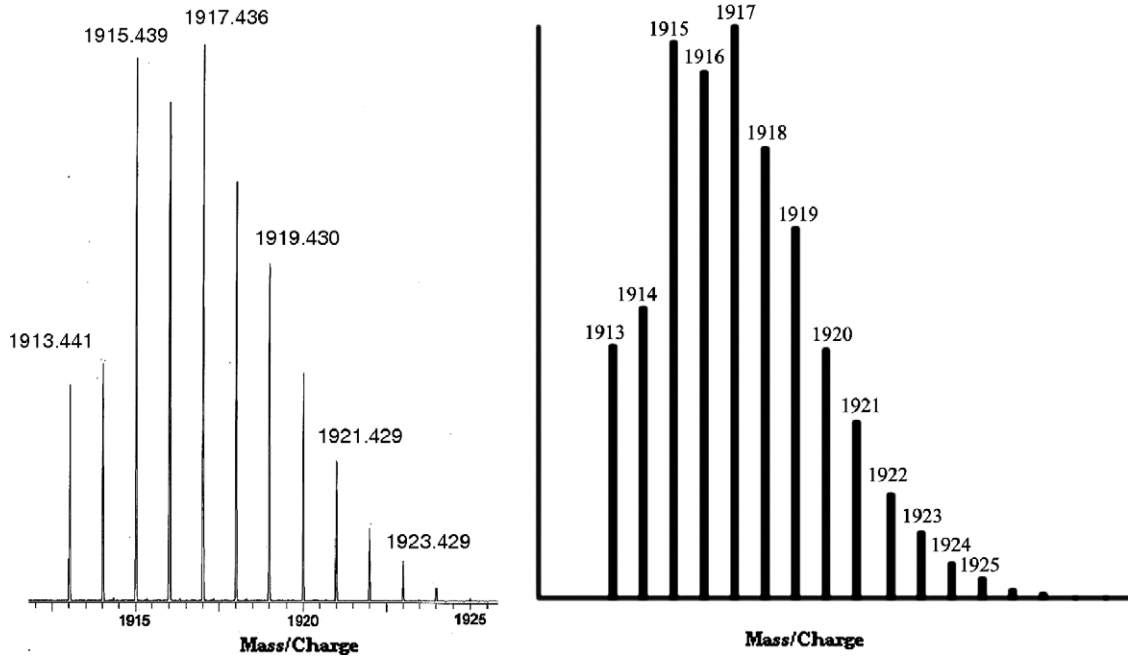

Fig. 3. The isotropic distribution pattern of $[Ni_4(HL^3)L^3_3]^+$ of complex **3** and its theoretical simulation.

molecular square structure and being characteristic results. Small peaks centered at *m*/*z* 536 and 958 are assigned as $[Ni_2(L^3)–H]^+$ (calc. 535) and $[Ni_2(HL^3)L^3]^+$ (calc. 957) respectively, also agreeing well with the calculated isotropic pattern. Complex **4**, however, exhibits many peaks centered at *m*/*z* 477.0968, 702.1126, 760.0297, 953.1987, 1011.1215, 1068.0470, 1100.0369, 1264.1392, 1487.2386, and a base peak at 1909.4594. Of these, the peaks at 477.0968 and 1909.4594 are assigned to the $[Ni(HL^4)]^+$ (calc. 477) and $[Ni_4(HL^4)L^4_3]^+$ ions (calc. 1909), with agreeing simulations. The latter peak (Fig. 4) is characteristic of a molecular square structure and the former is its monomer, usually obtained under MALDI ionization. The two other major peaks at 1011.1215 and 1487.2386, assigned to $[Ni_3(L^4)_2–H]^+$ (calc. 1011) and $[Ni_4(L^4)_3–H]^+$ (calc. 1487) respectively, also support the expected molecular square structure $[Ni(HL^4)]_4(PF_6)_4 \cdot 9H_2O$. Another peak centered at 2443.5110 is assigned to $[Ni_4(HL^4)_3L^4(PF_6)_2 \cdot 2CHCl_2 \cdot 4H_2O]^+$ (calc. 2443). However some weaker peaks at 1100.0369 and 1264.1392 are assigned to $[Ni_3(L^4)_2Cl \cdot$

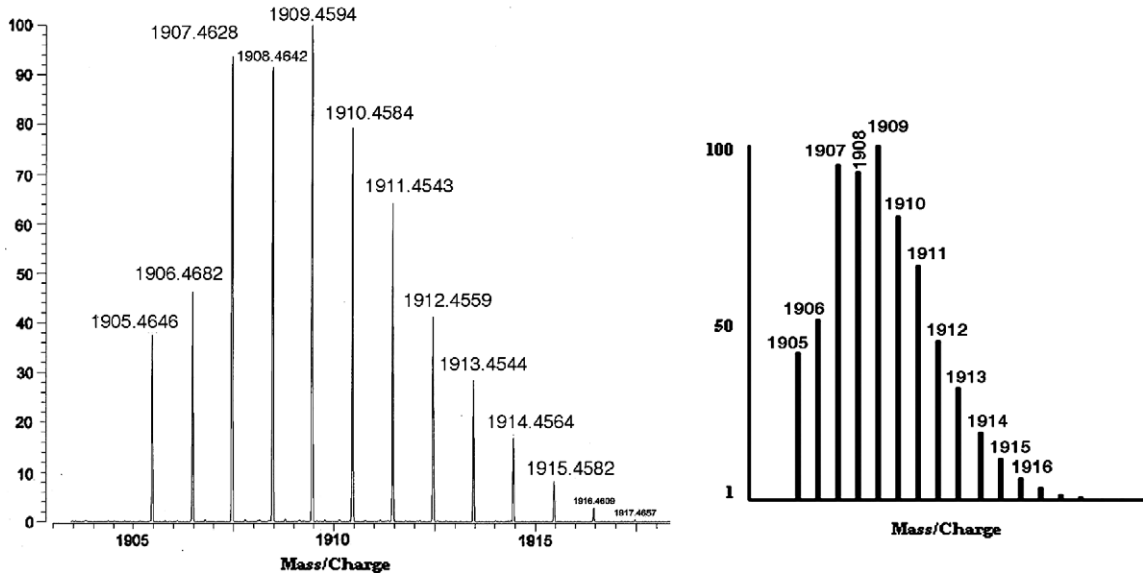

Fig. 4. The isotropic distribution patterns of $[Ni_4(HL^4)L_3^4]^+$ of complex **4** and its simulation.

$3H_2O]^+$ (calc. 1101) and $[Ni_3(L^4)_2Cl \cdot H_2O$+benzoylpyridine hydrazone$]^+$ (calc. 1262) respectively, due to the presence of the impurity of the chloride complex. These results are indicative of the stability of Ni(II) molecular squares in the solution phase.

3.2. Crystal structure of compound *1a*

The molecular structure of **1a** is given in Fig. 5 and the coordination core about the Ni(II) centers and their atom numbering scheme are given in Fig. 6. Selected bond lengths and bond angles are summarized in Table 2. The tetranuclear $[Ni(HL^1)]_4^{4+}$ cation has four Ni(II) centers, organized by four monodeprotonated ligands HL^1, as a molecular square. Each metal center is octahedrally coordinated by making use of atoms like one of the pyridyl nitrogen atoms, its nearby azomethine nitrogen and thiolate sulfur atoms of two perpendicular HL^{1-} ligands. These two HL^{1-} ligands bind to Ni(II) in the *mer* configuration, with pairs of sulfur atoms and pyridyl N atoms each bearing a *cis* relationship and the azomethine N atoms keep a *trans* configuration, as found in related octahedral Ni(II) thiocarbohydrazone [5,18] and thiosemicarbazone complexes [19,20]. As a result four fused five membered chelate

		Ni(4)–S(1)–Ni(1)	168.71(17)

rings share each metal center. The sulfur atoms share a position of adjacent Ni(II) octahedra (Fig. 6) and thus connect the centers to build a symmetrical molecular square (Fig. 7). The adjacent Ni–Ni distances are ~4.7 Å {they vary from 4.679(2) Å for Ni(1)–Ni(2) to 4.797(2) Å for Ni(2)–Ni(3)} and the angles subtended at the sulfur atoms Ni–S–Ni varies from 165.30(17)° for Ni(3)–S(4)–N(4) to 168.71(17)° for Ni(1)–S(3)–Ni(4). The Ni–Ni distances across the diagonals of the square are 6.749(2) Å for Ni(1)–Ni(3) and 6.692(2) Å for Ni(2)–Ni(4) and the Ni–Ni–Ni angles are ~90° {these vary from 88.73(4)° for Ni(2)–Ni(3)–Ni(4) to 90.82(4)° for Ni(1)–Ni(2)–Ni(3)}. The four Ni atoms are in a plane with a maximum mean plane deviation of 0.0525(17) Å for Ni(1). The sulfur atoms S(2) and S(4) are above and S(1) and S(3) are below this plane by ~0.2 Å.

The bond parameters (Table 2) show that the geometry around the Ni(II) centers are distorted significantly from perfect octahedra. For example, considering the octahedron around the Ni(1) atom, the mean plane of the bicyclic chelate ring Ni(1), N(1), C(5), C(6), N(3), N(4), C(12), S(2) {having a maximum deviation of 0.020(11) Å for the N(1) atom} makes a dihedral angle of 86.8(2)° with that of its counterpart chelate ring defined by Ni(1), N(25), C(74), C(75), N(27), N(28), C(81), S(1) {having a maximum deviation of -0.125(13) Å for the C(74) atom}. The bond lengths Ni–$N_{azomethine}$, Ni–N_{py} and Ni–S around the Ni(1) atom increase in that order, as in similar compounds [5,18] and as in mononuclear Ni(II) octahedral thiosemicarbazone complexes [19–23]. Also, the trans angles N(1)–Ni(1)–S(2), N(25)–Ni(1)–S(1) and N(3)–Ni(1)–N(27) are 161.9(3)°, 161.3(3)° and 175.0(4)° respectively. These factors suggest considerable distortion from a perfect octahedral geometry around the Ni(1) center.

The C–S bond lengths of ~1.73 Å are within the normal range of a C–S single bond. The hydrogen atoms were

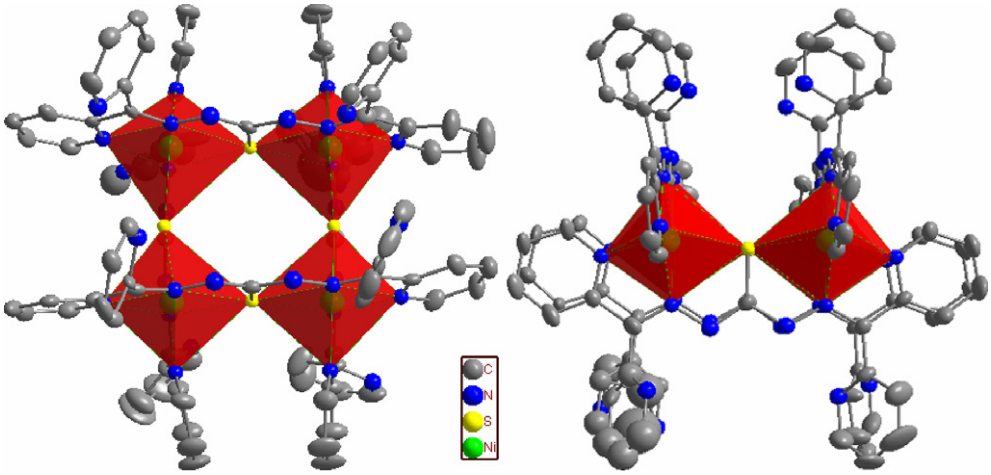

Fig. 7. Top view and side view of the cationic part of the molecule with octahedral polyhedra around the Ni(II) centers, showing the symmetrical nature of **1a**. Hydrogen atoms are removed for clarity.

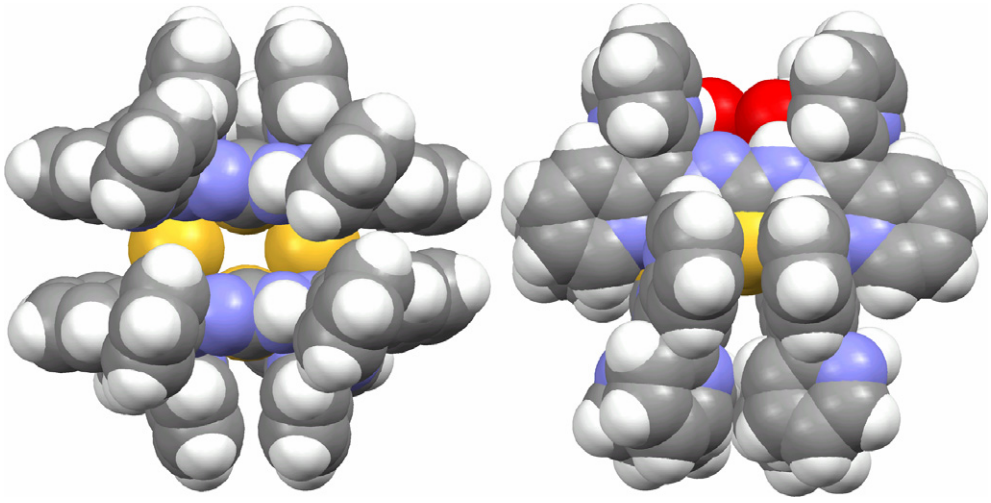

Fig. 8. Spacefill models of complex **1a**, showing the cavity inside the square grid $[Ni(HL^1)]_4^{4+}$ (left, top view) and side view showing the trapped water molecules inside the four uncoordinated pyridyl groups of it (right).

located at N(5), N(12), N(20) and N(28). The N(13)–C(35), N(21)–C(58) and N(29)–C(81) bond distances are smaller compared to their counterparts {by 0.030(23), 0.030(21) and 0.060(23) Å respectively}, confirming the deprotonation of the thiol tautomeric form to form the square grid by four monoanionic ligands. The molecules are connected by various intermolecular interactions involving water and PF_6^- anions. Two of the water molecules are trapped inside the four uncoordinated pyridyl groups (Fig. 8). Some C–H···π and very weak π···π interactions are involved in the packing of the molecules in the lattice (Fig. 9). Relevant hydrogen bonding and other interactions are summarized in Table 3.

3.3. Magnetic studies

For all four compounds, the temperature dependence of the molar magnetic susceptibility χ_m was investigated over the temperature range 5–325 K. All compounds show common features. The effective magnetic moments μ_{eff} at room temperature of **2** and **3** are found to be low compared to that expected for four independent Ni(II) ions and also decrease with decreasing temperature, suggesting antiferromagnetic interactions between the Ni(II) ions. The temperature dependence curves of **1** and **4** are similar to that of **2** and **3**, but with slightly higher μ_{eff} values at room temperature. These features indicate a dominant antiferromagnetic interaction in these compounds.

The room temperature effective magnetic moments μ_{eff} of the sulfur-bridged squares are found to be 6.05 μ_B for **1** and 4.01 μ_B for **2**. As the temperature is lowered μ_{eff} of both **1** and **2** decreases gradually and reaches a minimum of 0.51 μ_B for **2** and 0.45 μ_B for **1** at 5 K. The variable temperature magnetic behaviour of both compounds are indicative of antiferromagnetic coupling between the Ni(II) ions, and this is greater in **2**. The room temperature μ_{eff} of 4.50 μ_B shown by complex **3** is low compared to its sulfur bridged counterpart compound **1**. The thermal dependence curve of **3** implies strong antiferromagnetic interactions between the Ni(II) centers. The μ_{eff} values show a regular decrease upon decreasing the temperature and reach a minimum value of 0.66 μ_B at 5 K. The antiferromagnetic coupling in complex **4** is found to be low compared to that of **3**, as evidenced by the room temperature magnetic moment of 5.80 μ_B. On cooling, μ_{eff} decreases and reaches a minimum value of 0.83 μ_B at 5 K.

To fit and interpret the magnetic susceptibility data of the complexes, first it is necessary to find all possible magnetic

pathways in the complicated but regular structures. Assuming all the four Ni(II)–X–Ni(II) couplings are equal, ie using a single coupling constant J that takes into account all the exchange pathways to be equal, is a reasonable assumption in light of the X-ray crystallographic study of **1a** which reveals a similar nature of the M–S–M angles (~167°), there is probably a super exchange mechanism through the intervening sulfur atoms. Therefore, for a square arrangement of four metal centers, a D_{4h} [2 × 2] grid, a suitable exchange Hamiltonian [24] is used.

$$\hat{H} = -2J(\hat{S}_1 \cdot \hat{S}_2 + \hat{S}_2 \cdot \hat{S}_3 + \hat{S}_3 \cdot \hat{S}_4 + \hat{S}_1 \cdot \hat{S}_4)$$

The allowed eigenvalues were then substituted in to the modified van Vleck equation,

$$\chi_M = \frac{N\beta^2 g^2}{3k(T-\Theta)} \frac{\sum S'(S'+1)(2S'+1)e^{-E(S')/kT}}{\sum (2S'+1)e^{-E(S')/kT}}(1-\rho) + \frac{N\beta^2 g^2 S(S+1)\rho}{3kT} + \mathrm{TIP}$$

where $E(S')$ refers to the energy of each spin state defined by S'. For Ni(II) molecular squares $S' = S_1 + S_2 + S_3 + S_4$. The best-fit results using the program MAGMUN4.1 [25] for **2** and **3** are given in Figs. 10 and 11 along with the fitting parameters. Relatively high J (negative) values are consistent with strong intramolecular antiferromagnetic coupling interactions in the Ni(II) complexes. TIP was assumed as 6×10^{-4} emu mol^{-1}, a typical value for Ni_4 complexes [26]. However, we could not get a reasonable fit for

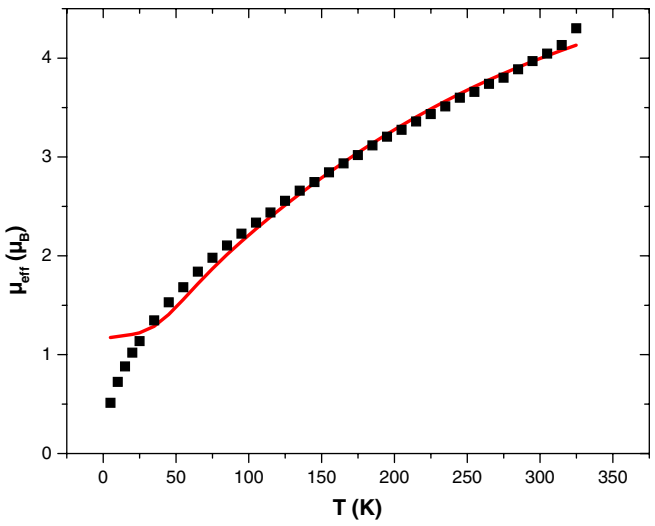

Fig. 10. Temperature dependence of the effective magnetic moment μ_{eff} (solid squares) for the thiocarbohydrazone Ni(II) square complex **2**. The solid line represents the best fit obtained with $g = 2.047 \pm 0.067$, $J = -126.24 \pm 8.88\ cm^{-1}$, $\Theta = -0.0385$ K, $\rho = 0.0405$, $R = 4.57 \times 10^{-2}$.

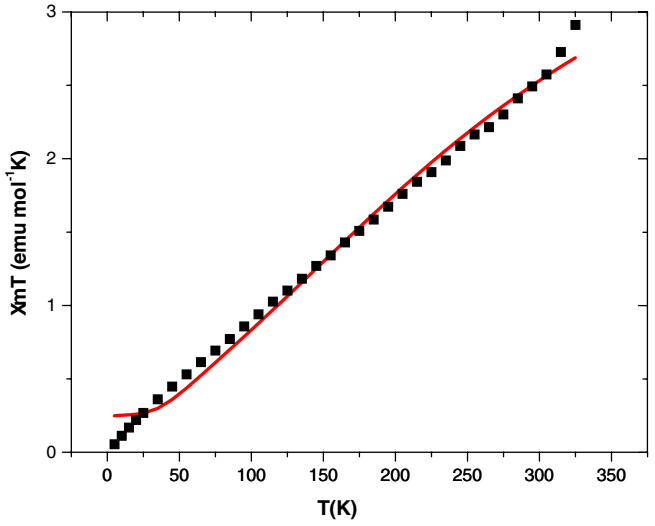

Fig. 11. $\chi_m T$ data (solid squares) as a function of temperature for the carbohydrazone Ni(II) square complex **3**. The solid line represents the best fit obtained with $g = 2.221 \pm 0.064$, $J = -113.85 \pm 7.57\ cm^{-1}$, $\Theta = -0.016$ K, $\rho = 0.05$, $R = 4.90 \times 10^{-2}$.

complexes **1** and **4**, which may be associated with zero-field splitting (D), especially at lower temperatures and/or due to slight variations in the M–X–M angles, so that more J values need to be considered. The M–O–M arrangement of 180° is known as an ideal structure for strong antiferromagnetism [27]. This linearity as the origin of strong AF coupling is in accordance with VB [28–30] and MO [31] studies. Logically, Kahn also explained this feature in his book [32].

procedure [11], therefore, it is still necessary to design, synthesize and characterize structurally new families of transition metal complexes, investigate the self-assembly features of the specific molecular architectures, and further understand the magnetostructural relationship. Herein we reported on the syntheses and characterizations of the crystal structure for four new complexes which are based on the molecular architecture CuL^+ (L = *N*-(8-quinolyl)salicylaldimine), from dimeric entities to one-dimensional (1D) chain systems, and further investigated their magnetic behaviors.

2. Experimental

2.1. Materials and measurements

The reagents and solvents employed were commercially available and were used as received. *N*-(8-quinolyl)salicylaldimine (HL) was prepared from 8-aminoquinoline and salicylaldehyde in MeOH according to the literature [12]. C, H and N microanalyses were carried out with a Perkin–Elmer 240 elemental analyzer. IR spectra were recorded using KBr discs on a Bruker Vector 22 spectrophotometer in the range 4000–400 cm^{-1}. Magnetic susceptibilities of polycrystalline samples were measured over the range 2–350 K using a Quantum Design MPMS-5S superconducting quantum interference device (SQUID) magnetometer, and diamagnetic corrections were made using Pascal's constants. EPR spectra were recorded on a Bruker 2000-D-SRC spectrometer at 293 K and the microwave frequency is near to 9.7 GHz.

2.2. Preparation of compounds *1*–*4*

N-(8-quinolyl)salicylaldimine and $Cu(ClO_4)_2$ were mixed in a molar ratio of 1:1 in a minimum amount of

DMF, the mixture was stirred at room temperature until all the solid dissolved, and then it was filtered. The filtrate was stood in a refrigerator at ca. 4 °C for 3 days, and the formed brown crystals of CuL(DMF)(ClO_4) (**1**) were collected by filtration, washed with Me_2CO and dried in air. Yield ca. 50% based on Cu. Elemental analysis Calc. for $C_{19}H_{18}ClCuN_3O_6$: C, 47.2; H, 3.75; N, 8.70. Found: C, 46.9; H, 3.87; N, 8.64%. IR spectrum (cm^{-1}): 2934.9m (ν_{C-H} of DMF), 1644.4m ($\nu_{C=N}$ of DMF), 1086.2s (ν_{Cl-O} of ClO_4^-).

The syntheses of CuL(Ac) (**2**), CuL(N_3) (**3**) and CuL(SCN) (**4**) were similar to that of **1** except for using the corresponding anion instead of ClO_4^-. Brown crystals of **2** were obtained (yield ca. 53% based on Cu). Elemental analysis Calc. for $C_{18}H_{14}CuN_2O_3$: C, 58.5; H, 3.82; N, 7.57. Found: C, 58.2; H, 3.90; N, 7.36%. IR spectrum (cm^{-1}): 2924.6m (ν_{C-H} of CH_3COO^-), 1613.7m ($\nu_{as(C=O)}$ of CH_3COO^-). Brown crystals of **3** were obtained (yield ca. 47% based on Cu). Elemental analysis Calc. for $C_{16}H_{11}CuN_5O$: C, 54.5; H, 3.14; N, 19.9. Found: C, 54.4; H, 3.66; N, 19.7%. IR spectrum (cm^{-1}): 2048.9s ($\nu_{as}(N{=}N{\equiv}N)^-$ of N_3^-). Brown crystals of **4** were obtained (yield 49% based on Cu). Elemental analysis Calc. for $C_{17}H_{11}CuN_3OS$: C, 55.4; H, 3.01; N, 11.4. Found: C, 55.5; H, 3.24; N, 11.3%. IR spectrum (cm^{-1}): 2100.1s ($\nu_{(CN)}$ of SCN^-), 758.5m ($\nu_{(CS)}$ of SCN^-).

2.3. X-ray single crystal structures

Suitable single crystals of **1**–**4** were selected and mounted onto thin glass fibers. X-ray intensity data were measured at 293 K on a Bruker SMART APEX CCD-based diffractometer with graphite-monochromatic Mo Kα radiation ($\lambda = 0.71073$ Å). Data reductions and absorption corrections were performed with the SAINT and SADABS software packages, respectively [13]. All structures were solved by a combination of direct methods and difference Fourier syntheses and refined against F^2 by the full-matrix least-squares technique [14]. Anisotropic displacement parameters were refined for all non-hydrogen atoms except for the disordered atoms. Hydrogen atoms were added theoretically and were riding on their parent atoms. In the crystal of **1**, the ClO_4^- anion is disordered, in which three atoms, O(4), O(5) and O(6), occupy two positions and the occupancy factors for each position are fixed as 0.5 in the refinement procedure. Crystallographic

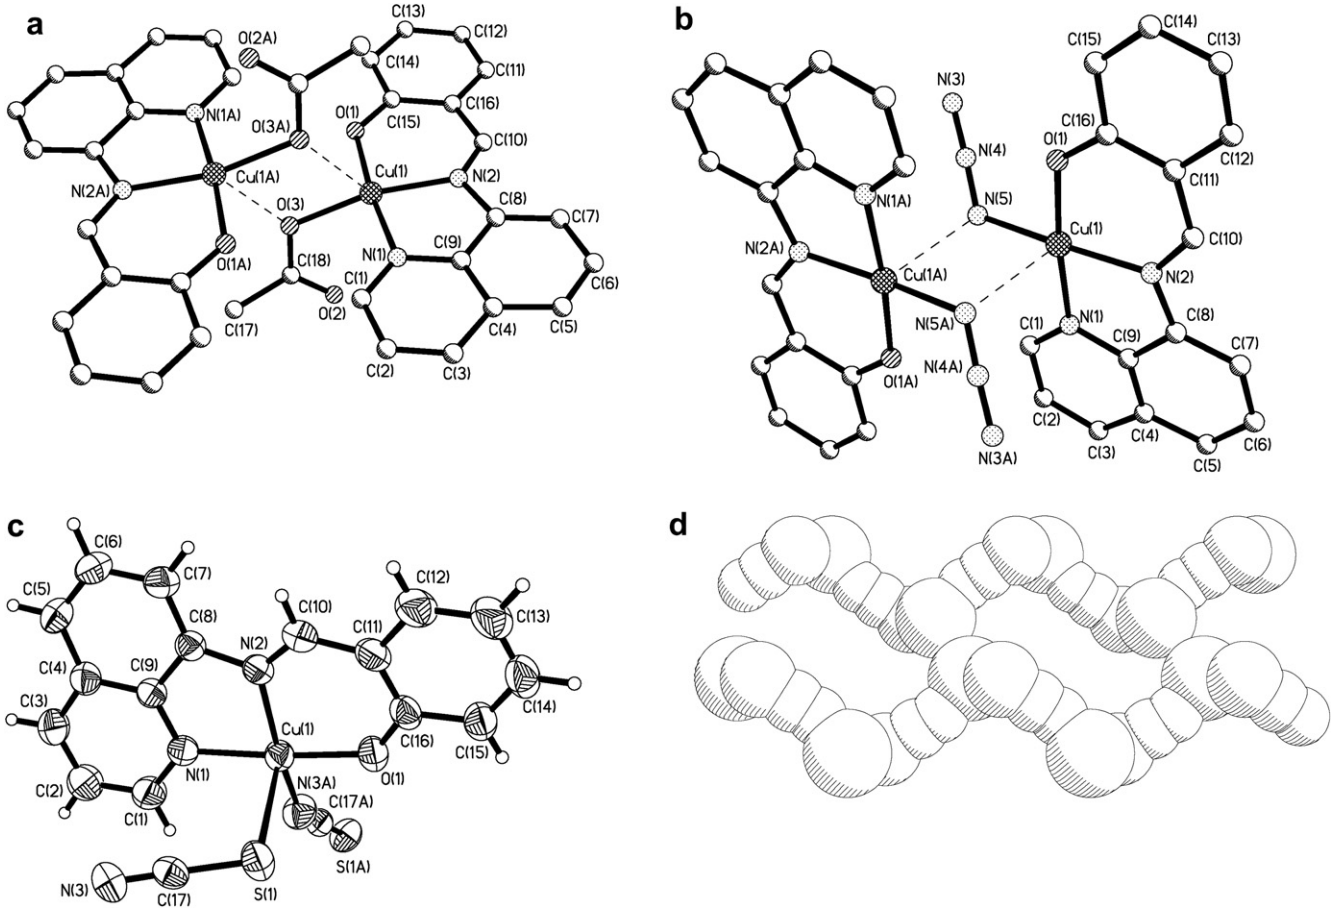

Fig. 2. Molecular structures of a dimer with H-atoms omitted for clarity (a) for **2** (symmetric code $A = -x, -y, -z$) and (b) for **3** (symmetric code $A = 0.5 - x, 1.5 - y, -z$); (c) ORTEP view of **4** with 50% thermal possibility (symmetric code $A = 1.5 - x, 0.5 + y, 0.5 - z$); (d) 1D helical chain in **4** constructed from ···SCN–Cu–SCN–Cu··· (space fill graph in which only Cu and SCN remain and other atoms are omitted for clarity).

data and other pertinent information for **1**–**4** are summarized in Table 1. Selected bond lengths and angles are listed in Table S1.

3. Results and discussion

3.1. Structure description

The asymmetric unit of **1** contains one $CuL(DMF)^+$ cation together with one ClO_4^- anion, and Fig. 1a shows a portion of the structure of $CuL(DMF)^+$. The Cu^{2+} center in **1** is chelated by one deprotonated tridentate *N*-(8-quinolyl)salicylaldimine anionic ligand and coordinated by one solvent ligand (DMF) to furnish a square-planar coordination environment. The Cu–N bond lengths are 1.952(5) and 1.980(5) Å, and the Cu–O bond lengths are 1.889(4) (from phenolate), 1.956(4) (from DMF) Å. Two neighboring $CuL(DMF)^+$ cations stack face-to-face and form a dimer via the μ_2-O atoms of the phenolate (Fig. 1b) with a Cu···O distance of 2.604 Å. Therefore, the actual coordination geometry of the Cu^{2+} center might be considered as a square-pyramid. Within a dimer the Cu···Cu separation is 3.274 Å, the O(1)–Cu(1)···O(1A) and Cu(1)–O(1)···Cu(1A) (symmetric code $A = 1 - x, -y, -z$) angles are 87.9° and 92.2°, respectively. Between neighboring dimers the Cu···Cu distance is more than 5.716 Å.

Replacement of $Cu(ClO_4)_2$ with $Cu(Ac)_2$ and $Cu(N_3)_2$ lead to compounds **2** and **3**, respectively. Both complexes are isostructural with each other, in which two CuL^+ cations form a dimer through two bridged μ_2-O from $-COO^-$ (for **2**) or μ_2-N from N_3^- (for **3**) atoms. For such two compounds, not only are the binding fashions in the coordination sphere around the Cu^{2+} ion very similar but also the packing diagrams are nearly identical to each other (cf. Figs. S2 and S3), thus just the structure of **2** is described.

As shown in Fig. 2a, in the dimeric **2**, each Cu^{2+} center is pentacoordinated and adopts a slightly distorted square-pyramidal geometry (the τ value of the Cu^{2+} center is ~0.11, and the geometry about the pentacoordinate metal ion is analyzed with the formalism in which internal angles are combined into a single parameter, τ, which ranges from 0 for square pyramidal to 1 for trigonal bipyramidal [15]) with one O and two N atoms from the tridentate ligand and one O atom from the acetate anion forming the base plane. The bond distances and angles around the Cu^{2+} center are within the normal range. The O atom from another moiety of the dimer occupies the vertex position with angles of O(3A)–Cu(1)–O(3) = 71.7°, O(3A)–Cu(1)–O(1) = 91.4°, O(3A)–Cu(1)–N(1) = 88.3° and O(3A)–Cu(1)–O(1) = 120.4°, and the O(3A)–Cu(1) distance is 2.680Å. The Cu···Cu separation is 3.788 Å within a dimer, and is more than 7.360 Å between neighboring dimers.

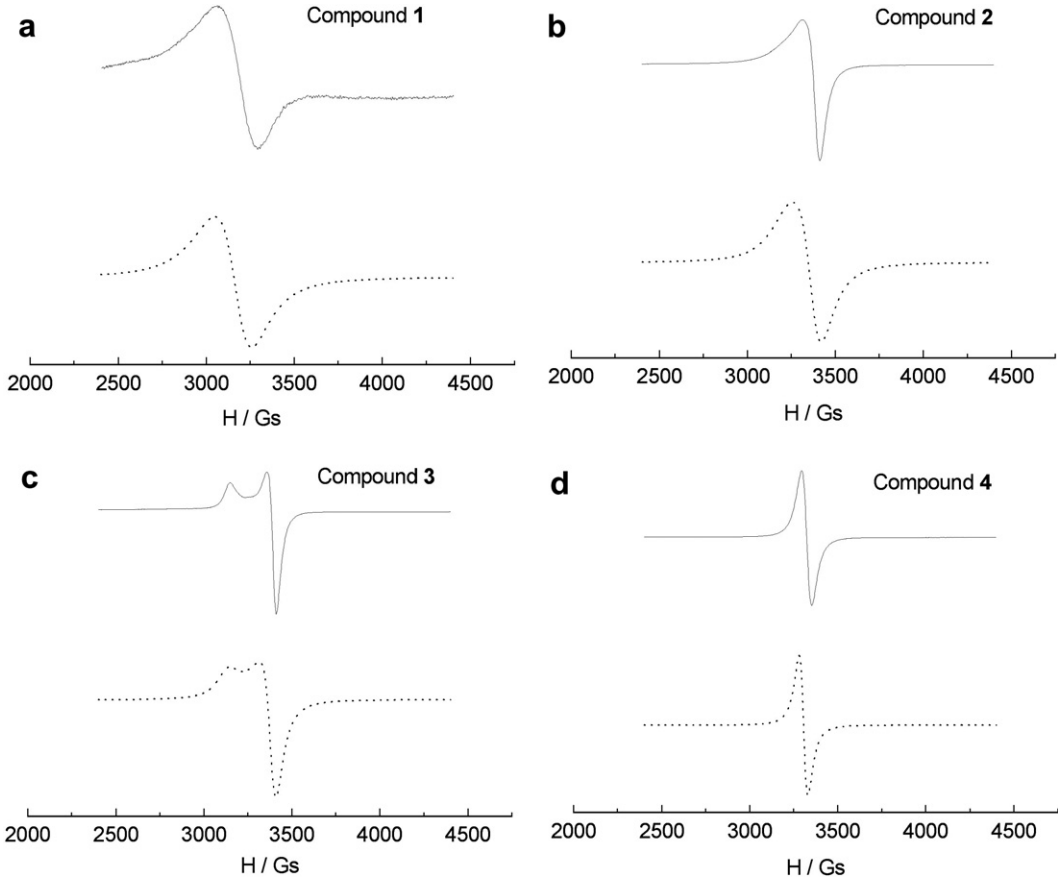

Fig. 3. EPR spectra of **1**–**4** at room temperature (solid lines: experimental data; dot lines: simulated plots).

In the crystal of **4**, the binding fashions in the coordination sphere around the Cu^{2+} ion are similar to those in **2** and **3**, namely the Cu^{2+} center in **4** is surrounded by one deprotonated tridentate ligand and two SCN^- anions to form a distorted square-pyramidal coordination environment (the τ value of the Cu^{2+} center is ~0.29), as illustrated in Fig. 2c, and the bonding parameters in the coordination sphere around the Cu^{2+} ion, summarized in Table S1, are comparable with those in **2** and **3**. However, there is a distinct difference from **2** and **3** in that the neighboring Cu^{2+} ions are bridged by SCN^- anions in a fashion ···SCN–Cu–SCN–Cu··· to extend a helix and uniform chain along the *b*-axis direction (cf. Fig. 2d). The Cu···Cu separation is 6.185 Å in the chain, and more than 4.605 Å between neighboring chains.

For **1**–**4**, in the presence of different anions under similar experimental conditions, the Cu^{2+} centers adopt a square-pyramidal geometry, but the crystal packing structures are distinct. Due to the ClO_4^- anion possessing a weak binding interaction with the metal ion, the Cu^{2+} center completes its coordination requirement via a solvent ligand (DMF) in **1**, and this is why the crystals of **1** are only facilitated from DMF solution. In crystals of both **2** and **3**, the $-COO^-$ and N_3^- anions are, respectively, bound to the Cu^{2+} ion in the manner of μ_2-O ($-COO^-$) and μ_2-N (N_3^-), even if the ligand can serve as a bifunctional ligand. The CuL^+ tectons form discrete dimers through a μ_2-bridging atom in **1**–**3**, and a 1D helical chain linked through the SCN^- anion, which serves as a bifunctional ligand, in **4**. The results reveal that the counter ion, solvent and metal ion features as well as weak intermolecular interactions cooperatively affect the formation of the supramolecular architecture, and finally control the crystal packing manner of the coordination compound.

3.2. EPR spectra and magnetic properties

Fig. 3 displays typical X-band EPR spectra of **1**–**4** that were carried out on polycrystalline samples at 293 K. From the viewpoint of the crystal structure, the coordination environments around the Cu^{2+} ion in **1**–**4** are similar to each other, however the spectral features are distinct. The EPR spectra of **1**–**3** show axial symmetrical signals and smaller linewidths, even if $g_{\parallel}$ and $g_{\perp}$ are not well resolved in the spectra of **1** and **2**, and the EPR spectrum of **4** displays an isotropic feature. If we take into consideration

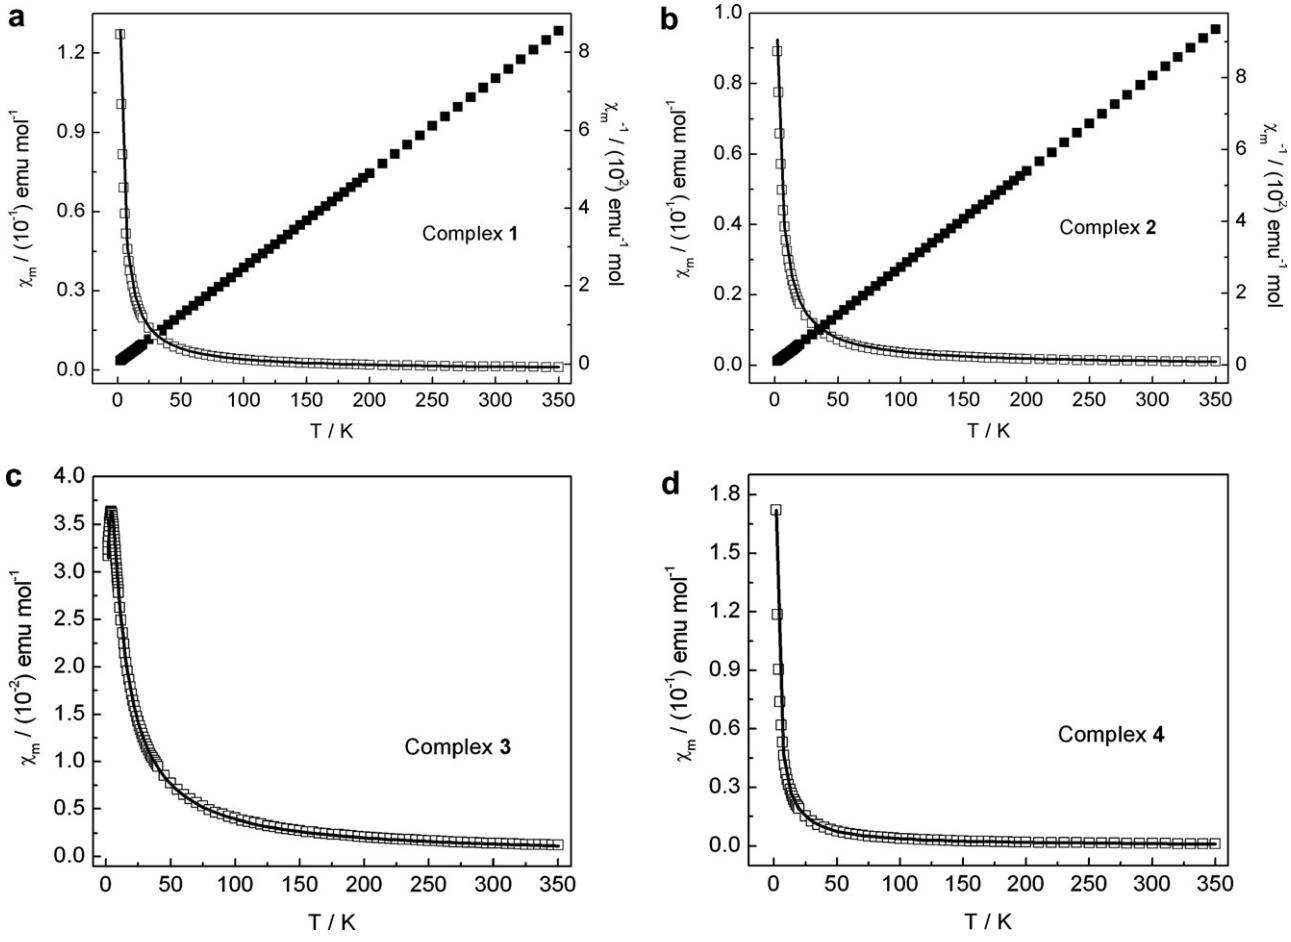

Fig. 4. Plots of χ_m (calculated per mole Cu^{2+} ion) vs. *T* for **1**–**4** (open squares: experimental data; solid lines: theoretical reproduction and details, see the text).

the field derivative of the absorption signal and Lorentzian line shape to simulate the EPR spectra of **1**–**4** and the corresponding parameters, the *g*-factor and the half-width at half-height, the best fits are given below: $g_x = g_y = 2.196$ with a half-width of 175 Gs, and $g_z = 2.285$ with a half-width of 270 Gs for **1**; $g_x = g_y = 2.071$ with a half-width of 120 Gs, and $g_z = 2.165$ with a half-width of 170 Gs for **2**; $g_x = g_y = 2.063$ with a half-width of 70 Gs, and $g_z = 2.228$ with a half-width of 90 Gs for **3**; $g_x = g_y = g_z = 2.113$ with a half-width of 50 Gs for **4**.

Temperature dependences of the magnetic susceptibilities for **1**–**4** are presented in Fig. 4. Owing to the structural findings, it is reasonable to consider **1**–**3** as isolated spin dimer systems and **4** as a uniform spin chain with $S = 1/2$. From the plots of $\chi_m - T$, it was found that the variations of magnetic susceptibility with temperature for **1**, **2** and **4** follow the simple Curie–Weiss behavior, so we fitted the magnetic susceptibility data to Eq. (1) to yield the parameters $C = 0.429(2)$ emu K mol^{-1} and $\theta = -1.33(2)$ K for **1**, $C = 0.406(4)$ emu K mol^{-1} and $\theta = -2.39(6)$ K for **2**, and $C = 0.383(0)$ emu K mol^{-1} and $\theta = -0.23(0)$ K for **4**. The *g*-factors deduced from the *C* constants are 2.14 for **1**, 2.08 for **2** and 2.02 for **4**

$$\chi_m = \frac{C}{T - \theta}. \quad (1)$$

Structurally, the magnetic behavior of **3** should obey an isolated spin dimer system with $S = 1/2$. In fact, a maximum is observed in its plot of $\chi_m - T$ which means the magnetic coupling feature within the dimer is AFM. In a dimmer, the function of magnetic susceptibility as temperature is described by Eq. (2) which is based on the spin Hamiltonian $H = -2JS_1S_2$:

$$\chi_m = \frac{Ng^2\mu_B^2}{k_BT} \cdot \frac{1}{3 + \exp(-2J/k_BT)}. \quad (2)$$

The best fit for the magnetic susceptibility of **3** in the temperature range 6–350 K gives a *g*-factor = 2.021(5) and $J/k_B = -4.32(1)$ K. The *g*-factor values for **1**–**4** obtained from the fits are comparable with the experimental values from EPR measurements.

4. Conclusion

In summary, we have synthesized four new complexes utilizing the deprotonated tridentate *N*-(8-quinolyl)salicylaldimine anionic ligand (L) by reaction with CuX_2 ($X = ClO_4^-$, Ac^-, N_3^- and SCN^-), and investigated their crystal structures and magnetic properties. Although the coordination geometries of the Cu^{2+} centers are similar to each other in the four complexes, their EPR spectra are totally different, which discloses their distinct electronic structures. The tectons of CuL^+ form discrete dimers [$(CuL(DMF))_2$ in **1** and $(CuLX)_2$ in **2** and **3**] and a 1D helical chain of $\cdots$CuL(SCN)$\cdots$ in **4**. These findings demonstrate that the binding ability and structural features of the counter anion play an important role in controlling the final packing structure of the complex. As we addressed in the Section 1, the issue of the assembly of novel supramolecular entities with desired structures and properties is still one of the great challenges in the supramolecular field.

Scheme 1. Hydrogen bond network for $[M(sac)_2(H_2O)_4]\cdot 2H_2O$ complexes.

which is in chemical equilibrium with the dimeric compound $[Cr_2(sac)_4(py)_2]$.

Another relevant feature is that the saccharinate ion is a multifunctional ligand. This molecule has three coordination centers: the carbonyl and the sulphonyl oxygen atoms and the nitrogen atom, see Scheme 2. It can bind to a metal ion as a monodentate ligand, as is observed in the isostructural set of compounds of general formula $[M(C_7H_4NO_3S)_2(H_2O)_4]\cdot 2H_2O$, or as a bidentate ligand as in $[Cr_2(sac)_4]$, $[Cu_2(sac)_4(Himid)_4]$, (Himid = imidazole) and $[Cd_2(sac)_4(Himid)_4]$ [7–9].

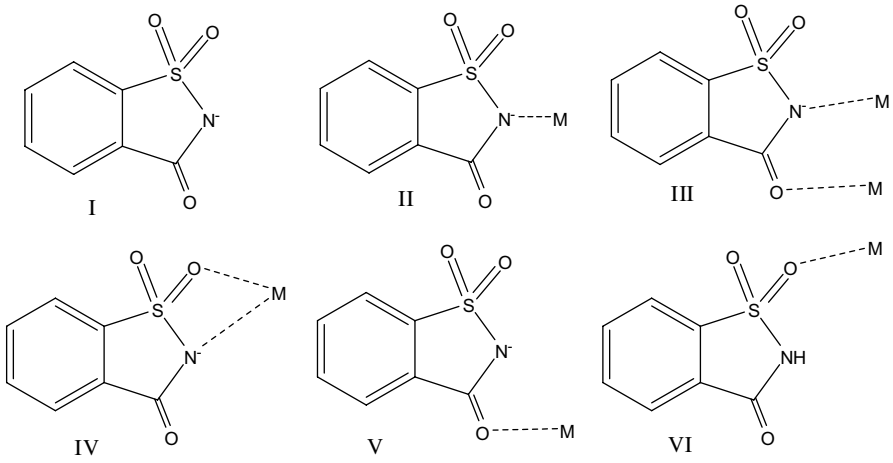
This feature has attracted interest on the use of saccharinate compounds as starting materials to prepare mixed-ligand complexes, using monodentate or bidentate ligands such as pyridine [3,5,6], imidazole [10] phosphine [11], or 2,2-bipyridine [12].

The aim of this work was to study the effect of the pyrazole, (Hpz), molecule as co-ligand in mixed-ligand saccharinate complexes. Pyrazole molecule has the dual capability of to act as a monodentate or as a bridging ligand when deprotonated or using the N–H group to participated in hydrogen bond formation with available hydrogen bond acceptor and/or hydrogen donor sites [13,14]. We were successful in preparing and characterizing complexes with the formula $[M(sac)_2(Hpz)_2(H_2O)_2]$, M = Co(II), Ni(II) and Cu (II); with zinc(II) the product was $[Zn(sac)_2(Hpz)_2]$. We describe here the crystal structures, spectroscopic and thermogravimetric properties of the products obtained.

2. Experimental

2.1. Methods and materials

Solvents, methanol, ethanol, pyrazole (Hpz), nickel(II) nitrate, cobalt(II) nitrate, copper(II) nitrate, zinc(II) nitrate and sodium saccharinate were used as purchased. The transition metal saccharinates, $[M(sac)_2(H_2O)_4]\cdot 2H_2O$, where M = Ni(II), Co(II), Cu(II) and Zn(II), were prepared as described in the literature [15] and isolated as crystalline materials.



2.2. Synthesis of the complexes

2.2.1. $[Co(sac)_2(Hpz)_2(H_2O)_2]$

A sample of pyrazole, 0.27 g, (4.0 mmol) was added to a solution of 0.53 g (1.0 mmol) of cobalt(II) saccharinate in 25.0 mL of water. The reaction mixture was refluxed for 40 min. The solution was cooled to room temperature and after two days red crystals were obtained. They were filtered off and washed with cold water. Yield: 0.48 g (81%). Crystals suitable for X-ray measurements were obtained by slow evaporation of the mother liquid over a few days. *Anal.* Calc. for $C_{20}H_{20}N_6O_8S_2Co$: C, 40.3; H, 3.4; N, 14.1; Co, 9.9. Found: C, 40.9; H, 3.4; N, 13.8; Co, 9.9%. IR (KBr pellet, cm^{-1}): 3513(s), 3310 (s), 1635(vs), 1586(m), 1344(m), 1264(m), 1150(m), 1054(m), 953(m), 895(m), 754(m), 721(m), 681(m). μ_{eff} (298 K): 4.87 B.M. λ_{max} (H_2O) (ε M^{-1} cm^{-1}): 470sh, 490sh, 524(22).

2.2.2. $[Ni(sac)_2(Hpz)_2(H_2O)_2]$

Pyrazole, 0.27 g (4.0 mmol) was added to a solution of 0.53 g (1.0 mmol) of nickel saccharinate in 25.0 mL of

Scheme 2. Coordination modes of saccharinate ion I.

water. The reaction mixture was refluxed for 1 h. The hot solution was filtered, and the resulting solution was left standing overnight. A light blue microcrystalline solid was obtained. It was filtered and washed with cold water. Yield was 0.42 g (71%). Crystals suitable for X-ray measurements were obtained by slow evaporation of a water solution of the compound. *Anal.* Calc. for $C_{20}H_{20}N_6O_8S_2Ni$: C, 40.3; H, 3.3; N, 14.1; Ni, 9.8. Found: C, 40.6; H, 3.6; N, 13.7; Ni, 9.6%. IR (KBr pellet, cm^{-1}): 3519(m), 3312 (s), 3005(s), 1636(vs), 1586(vs), 1344(m), 1266(vs), 1151(vs), 1055(m), 953(s), 859(m), 754(m), 682(m). μ_{eff} (299 K): 3.2 B.M. λ_{max} (H_2O) (ε M^{-1} cm^{-1}): 380(15), 630(7) 1031(5) nm.

2.2.3. *[Cu(sac)$_2$(Hpz)$_2$(H$_2$O)$_2$]*

A sample of pyrazole, 0.27 g (4.0 mmol) was added to a solution of 0.53 g (1.0 mmol) of copper saccharinate in 75 mL of water. The reaction mixture was refluxed for 20 min while stirring. The resulting solution was cooled and allowed to evaporate slowly few days at room temperature. The resulting deep blue crystals were collected by suction filtration and dried in air. The crystals obtained in this way were suitable for X-ray analysis. Yield was 0.31 g (50%). *Anal.* Calc. for $C_{20}H_{20}N_6O_8S_2Cu$: C, 39.9; H, 3.0; N, 14.0; Cu, 10.6. Found: C, 39.9; H, 2.9; N, 13.9; Cu, 10.6%. IR (KBr pellet, cm^{-1}): 3543(m), 3334 (m), 3141(s), 3089(m), 3068(m), 1611(vs), 1579(vs), 1347(m), 1298(vs), 1263(s), 1171(s), 1158(m), 1070(m), 1059(m), 950(s), 859(m), 783(m), 754(s), 680(m), 594(m), 539(m). μ_{eff}: 1.90 B.M. UV–Vis (λ, nm (ε, M^{-1} cm^{-1})): 670(81).

2.2.4. *[Zn(sac)$_2$(Hpz)$_2$]*

Pyrazole, 0.27 g (4.0 mmol) was added to a solution of 0.53 g (1.0 mmol) of zinc saccharinate in 50.0 mL of water. The reaction mixture was refluxed for 45 min. The resulting solution was cooled and allowed to evaporate slowly over a few days at room temperature and a crop of crystals was obtained. The colorless crystals were collected by suction filtration and dried in air. The crystals obtained in this way were suitable for X-ray analysis. Yield was 0.35 g (62%). *Anal.* Calc. for $C_{20}H_{16}N_6O_6S_2Zn$: C, 42.4; H, 4.7; N, 16.6; Zn, 11.6. Found: C, 42.6; H, 4.6; N, 16.9; Zn, 11.6%. IR (KBr pellet, cm^{-1}): 3108(s), 1656(vs), 1591(vs), 1528(m), 1456(m), 1359(m), 1308(s), 1256(s), 1171(s), 1071(m), 947(s), 784(m), 751(s), 677(m), 594(m).

2.3. Physical measurements

FT-IR spectra were recorded for KBr pellets with a Perkin–Elmer Spectrum 1000. Thermal analyses were performed on a Texas Instruments Thermal Advantage

Universal Analysis 2000, under a dynamic nitrogen atmosphere with the sample kept in aluminum crucibles (aluminum oxide a standard; constant heating rate 10 K min^{-1}). Magnetic susceptibility was measured using a Johnson Matthey MSB-1 balance at 25 °C. Electronic spectra of freshly prepared DMF solutions of the complexes were recorded on a Shimadzu spectrophotometer UV-1601 PC, using 10 mm quartz cells.

2.4. X-ray crystallography

Single-crystal X-ray diffraction data for compounds **1** and **2** were gathered at room temperature, while data for compound **3** were collected at 100 K using a Siemens SMART CCD-based diffractometer. The reflections were integrated using the commercial program SAINT, and corrected for systematic errors with the public-domain program SADABS [16–18]. Compound **4** was measured on a Nonius Kappa-CCD diffractometer equipped with a nitrogen cold stream operating at 100 K and a Mo-target rotating-anode X-ray source. Final cell constants were obtained from least squares fits of all integrated reflections. Structures were solved by direct methods [17] and refined to F^2 by full-matrix least-squares [18]. The refinements converged with the residuals given in Table 1, which summarizes the most important crystal data and refinement parameters.

3. Results and discussion

3.1. Synthesis

The aim of this work was to study the effects of a pyrazole co-ligand on the coordination mode of saccharinate in mixed-ligand complexes. Previous observations showed that a second ligand in the coordination sphere of saccharinate complexes could produce N- or O-coordination of the saccharinate ion, as observed in $[Cu_2(sac)_4(Himid)_4]$, $[V(sac)_2(py)_4]$ and $[Ni(sac)_2(py)_4]$ and recently in $[Cu(sac)_2(Hpz)_4]$ [19]. The reaction with pyrazole in water solution yields compounds of the formula $M(sac)_2(Hpz)_2(H_2O)_2$ for M = Co(II), Ni(II), Cu(II), and $Zn(sac)_2(Hpz)_2$, all with saccharinate ions N-coordinated. Their compositions were checked by analysis of their C, H and N content. The values are in good agreement with the above formulas.

3.2. Description of the crystal structures

Figs. 1–4 give the thermal ellipsoid drawings of the structures of the Ni, Co, Cu and Zn compounds, indicating the atom numbering schemes. Bond lengths and angles are given in Table 2. The complexes **1**, **2** and **3** have the general molecular formula $[M(sac)_2(HPz)_2(H_2O)_2]$ and **4** is Zn(sac)2(Hpz)$_2$. The metal atoms in **1**, **2** and **3** are located on crystallographic inversion centers and have distorted pseudo-octahedral geometry. The coordination environment of each metal center is made up of two pyrazole molecules, two water molecules and two saccharinate ligands, all in the *trans* configurations. It can be affirmed that the saccharinate and the two non-substituted water molecules of the original saccharinate complexes are retained. In the original series of saccharinate complexes, two different orientations were found for the coordinated water molecules – the so called *flat* and *pyramidal* cases [2]. In the idealized flat case, the M–O bond lies in the plane of the water molecule; all four atoms are coplanar. In the pyramidal case the M–O and two H–O bonds point roughly at three of the four vertices of a tetrahedron. In the structures considered in this work, only the pyramidal case is present; the other water molecules were substituted by a nitrogen atom

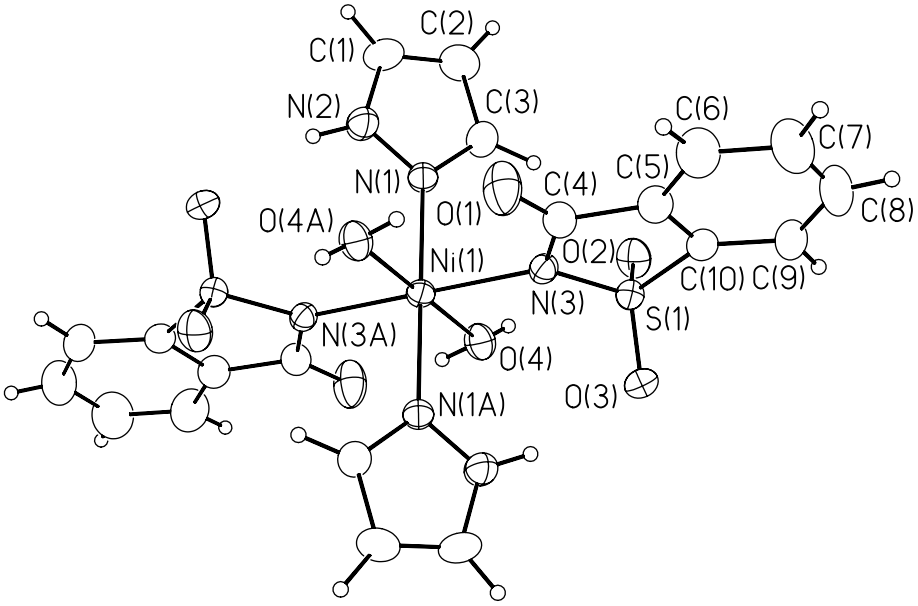

Fig. 1. Drawing of the compound **1** showing 50% probability displacement ellipsoids.

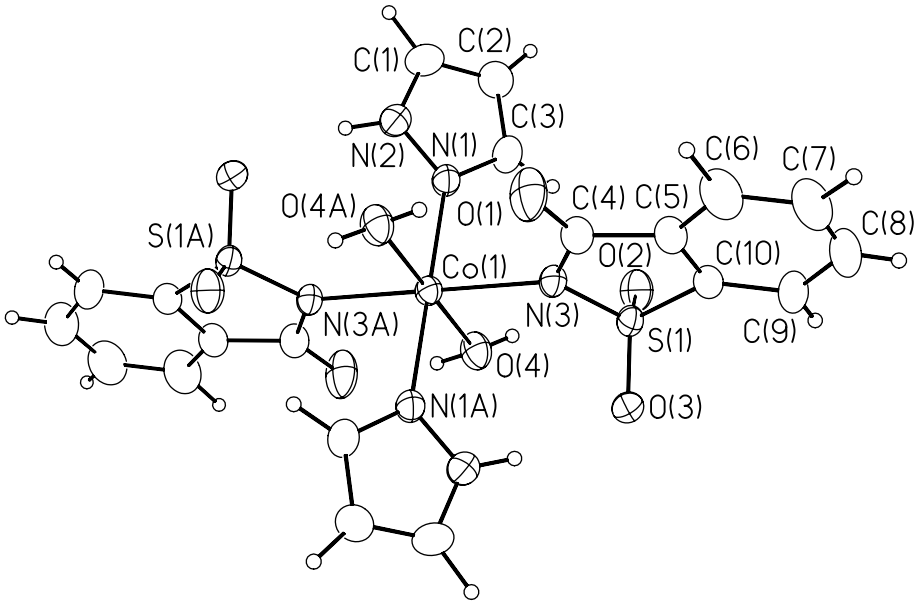

Fig. 2. Drawing of the compound **2** showing 50% probability displacement ellipsoids.

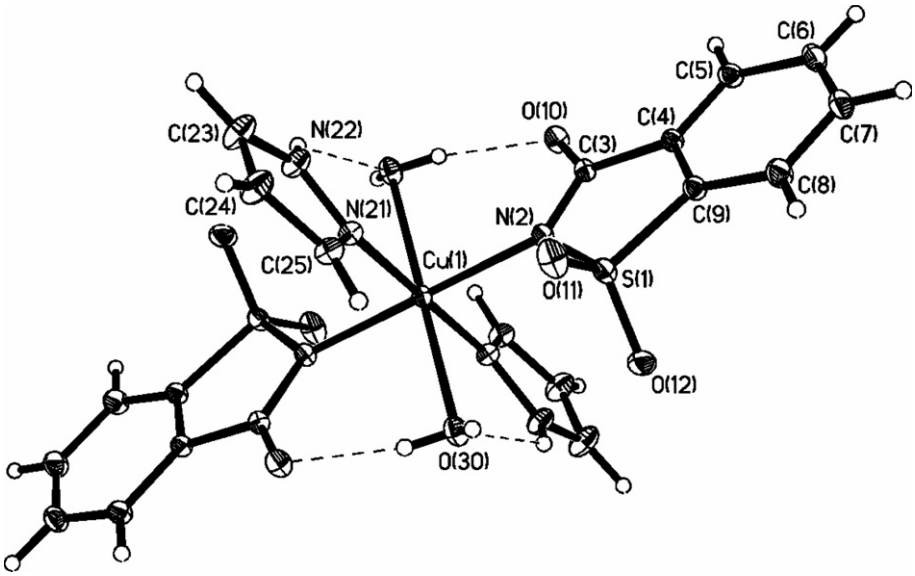

Fig. 3. Drawing of the compound **3** showing 50% probability displacement ellipsoids.

of the pyrazole ring. It is likely that the water molecules are pyramidal here in conjunction with the formation of strong intramolecular hydrogen bonds with the carbonyl oxygen of the saccharinate ligand. The N–H group forms hydrogen bonds with the saccharinate sulfonyl oxygen atoms in the cobalt and nickel complexes. In the copper complex, the hydrogen bonding is formed with the coordinate water molecule oxygen atom, see Table 3. As expected for a metal ion with a d^9 electronic configuration, the copper complex shows an elongated axis along the O–Cu–O bonds 2.4266(11) Å. In spite of the mixed ligand set (4N and 2O) there is not a rigorously, octahedral coordination sphere, and hence, no rigorous electronic degeneracy is possible. It would appear, however, that the structure comes close enough to the ideal case that the vibronic problem envisioned in the work by Jahn and Teller plays a role in the structures of this work. The distortion causes the arrangement around the metal ion to change with respect to the cobalt(II) and nickel(II) complexes, as shown in Fig. 5. In the Ni(II) and Co(II)-complexes, the saccharinate and water molecules are on the same plane but, in the copper compound they are not. The bond distances M–Nsac and M–Ow are longer than in the former saccharinate complexes [4], the M–NHpz distances are shorter than the M–Nsac for the Co(II), Ni(II) and Cu(II)-complexes. The zinc complex shows a pseudo-tetrahedral coordination around the metal ion. There is no difference between the Zn–N bonds, and the N–Zn–N angles are around 112°.

The final difference-Fourier maps for **1** and **2** show, respectively, two peaks and one peak greater than 1.0 e/Å^3. The peaks can be explained in both cases by the presence of intergrowths, as detailed below.

Evidence for polymorphic intergrowths in the structures of compounds **1** and **2.** Both structures, **1** and **2**, have larger than normal residual peaks in their final difference-Fourier maps. An explanation for these peaks, in terms of polymorphic intergrowths, can be understood through an examination of the packing patterns of the two structures. The two crystal structures, which are based on almost isostructural molecules, are nevertheless quite distinct, but related crystal structure types. Beginning with the unit cell of **2**, the nickel complex, the following

Symmetry transformations for **1**, #1 $(1-x, 1-y, -z)$; for **2**, #1 $(-x, -y, -z)$.
Symmetry transformations for **3**: #1 $(-x, -y, -z)$.
Symmetry transformations for **4**: #1 $(1-x+1, -y+1, -z+1)$ #2 $(-x, -y+1, -z+1)$.

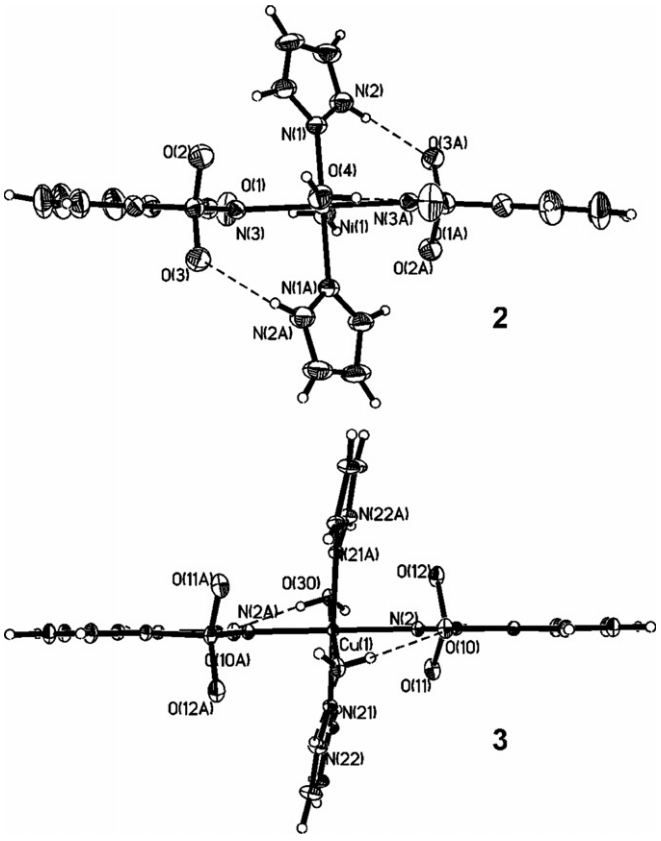

Fig. 5. Ligand orientation around the metal ion and hydrogen bonds interactions in compounds **2** and **3**.

transformation, if valid, would give a unit cell almost identical to that of the cobalt complex: $a' = a + 0.5c$; $b' = b$; $c' = -a + 0.5c$. $a' = 12.247$, $b' = 8.332$, $c' = 12.914$ Å, $\beta' = 110.36°$. These values can be compared to the cell parameters of **1**, (Table 1.) The transformation is not, in fact, valid, as it involves non-integral lattice translations that are not present in the structure of **2**. Thus, while the two cells have a geometrical relationship, the structures are not the same; detailed examination of the packing patterns indeed establishes that the structure types are different, see Fig. 6.

In the final difference-Fourier map for the nickel complex, **2**, there is a peak of 1.68 e/Å^3, located at $(0, 0.5, 0)$. Taking due account of symmetry and cell transformations, these coordinates represent the difference between the principal M–M Patterson vector in **1** and that in **2**. (It is one of several possibilities, all related by symmetry.) This difference peak could arise if a small component of a polymorph, with the same structure type as **1** was present in the sample of **2** from which the X-ray data were gathered. In a similar fashion, the final difference map for the cobalt complex, **1**, shows two residual peaks with densities greater than 1.0 e/Å^3 – one of 3.34 e/Å^3 at $(0.5, 0, 0)$ and a second, 1.85 e/Å^3 at $(0.2164, 0.8707, -0.1139)$. Again, taking appropriate account of cell transformations and symmetry, the relationship of the first peak to the cobalt atom, and of the second peak to the sulfur atom, represent the differences between the relative locations of these atoms in the two structures. Taken together with what is observed in the difference map for the nickel complex, this provides strong evidence that both of these structures are affected, albeit to different degrees, by minor intergrowths of a second polymorph with the structure of the nickel complex representing the polymorphic type for the cobalt compound and vice versa.

A more detailed analysis of this structural feature will be published elsewhere.

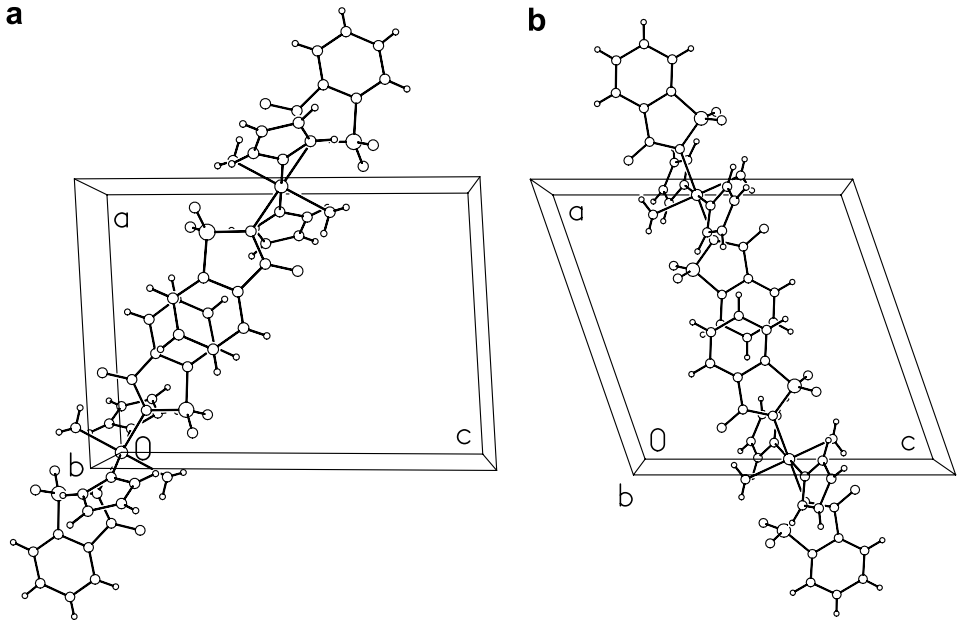

Fig. 6. Packing diagram of the compounds **1, a** and **2, b**, shown as the a-b face.

Table 4
Assignment of the most characteristic IR bands of **1**, **2**, **3** and **4**

Modes	1	2	3	4
ν(O–H) with intramolecular hydrogen bonds	3513/ 3310	3519/ 3312 f	3546/ 3337 f	
ν(N–H)	3066	3063	3141/3089/3068	3187/3108
ν(C=O)	1635	1636	1611	1656
$\nu_{as}(SO_2)$	1264	1266	1285	1298
$\nu_{s}(SO_2)$	1151	1151	1158	1171

3.3. Spectroscopic and magnetic properties

The most significant frequencies in the IR spectra of the metal complexes are given in Table 4. The IR spectra of the Ni(II), Co(II) and, Cu(II)-complexes resemble each other indicating a similar structural pattern. The strong and sharp bands in the range 3546–3310 cm^{-1} are attributed to the ν(OH) vibrations of water molecules with intramolecular hydrogen bond interactions [20]. As shown in Figs. 1 and 2, the water molecules form hydrogen bonds with the carbonyl oxygen atom and intermolecular interactions with the sulfonyl groups for **1** and **2**, and with the carbonyl group in **3**, the O···O distance being ca. 2.9 Å. The Zn(II) compound shows no O–H bands. The N–H stretching vibrations for the pyrazole moiety appear in the range 3066–3187 cm^{-1} as sharp bands. The copper compound displays three bands, with a splitting pattern that can be attributed to the hydrogen bonding interactions. The ν(CO) bands of the sac ligands appear at 1635 in **1** and **2**, 1656 in **3** and 1611 cm^{-1} in **4**. The low frequency in the latter compound could be attributed to the intra- and intermolecular hydrogen bonds; this is in agreement with the higher frequency of the carbonyl stretching vibration in the zinc(II) complex where there are no hydrogen bonds. The $\nu_{asym}(SO_2)$ sac absorptions appear as strong bands between 1264 and 1285 cm^{-1}, while $\nu_{sym}(SO_2)$ bands occur as strong bands at ca. 1150 cm^{-1}. The SO_2 vibration frequencies in these complexes are similar to those for the sodium saccharinate monohydrate; the sulfonyl groups are less susceptible to changes in the vibration frequency as a result of hydrogen bonding interactions.

The spectroscopic data are consistent with octahedral coordination geometry and indicate that the structure showed in solid state is preserved in solution. The λ_{max} values are blue-shifted, respect to tetra-hydrated sacharinate complexes, as expected for pyrazole as stronger ligand than water [21]. The effective magnetic moments at room temperature are in the range for high-spin complexes with octahedral coordination geometry, as observed in the crystal structures [22].

3.4. Thermal analysis

The thermal behavior of the compounds was investigated by means of thermogravimetric (TG) and differentia-thermal analysis (DTA) measurements in a flowing nitrogen atmosphere (temperature range 25–512 °C). Thermo-analytical data (decomposition stages, temperature ranges, peak maxima and mass losses) for the metal complexes are summarized in Table 5. The degradation of compounds **1**, **2** and **3** occurs in four or five successive TG steps. In the first two steps the mass loss corresponds to the release of two water molecules for **1** and **3**. For the case of compound **2**, two steps correspond to two water molecules and one pyrazole. It is accompanied by two endothermic DTA signals. The next step involves the loss of two pyrazole molecules, with an endothermic DTA signal. In the last step, an exothermic process takes place, which corresponds to the elimination of a saccharinate molecule.

Table 5
Thermoanalytical data for the metal complexes **1**, **2**, **3** and **4**

Compound/ Stage[a]	Temperature range, °C	DTG^{b}_{max}, °C	Removed group[a]	Mass loss (%)	
				Calculated	Found
[Co(sac)$_2$(pz)$_2$(H$_2$O)$_2$]					
1	40–148	129(−)	H_2O	3.53	3.02
2	148–197	176(−)	H_2O	3.8	3.05

4	375–512	408(+)	Hsac	31.02	30.6
[Ni(sac)$_2$(pz)$_2$(H$_2$O)$_2$]					
1	46–198	167(−)	Hpz	10.95	11.42
2	198–260	207(−)	$2H_2O$	6.42	6.02
3	260–373	337(−)	Hpz	14.37	11.42
4	374–512	425(+)	Hsac	35.95	30.06
[Cu(sac)$_2$(pz)$_2$(H$_2$O)$_2$]					
1	79–145	110(−)	$2H_2O$	6.48	6.00
2	145–239	219(−)	Hpz	11.46	11.33
3	239–304	281(−)	Hpz	18.29	11.33
4	383–790	344(−)	Hsac	23.88	30.34
5	404–512	468(+)		20.11	
[Zn(sac)$_2$(pz)$_2$]					
1	28–225	192(−)		2.1	
2	225–375	355(−)	2Hpz	21.98	24.07
3	275–512	441	Hsac	33.51	32.2

[a] pz: pyrazole, sac: saccharinate ion.
[b] (+) and (−) donate endothermic and exothermic processes, respectively.

The degradation of the zinc complex, **4** takes place with a smoothly continuous loss of mass, with one medium endothermic DTA signal, and two small DTA signals – one endothermic and one exothermic at 355 and 441 °C, respectively. This behavior is different from the other three compounds that show clear and defined step wise degradation. Probably, the absence of hydrogen bond in the zinc compound could be the determinant factor for the observed continuous degradation.

4. Conclusion

The results of this work show how hydrogen bonds between the ligands in the complex favored the arrangement around the central ion, for the Ni, Co and Cu compounds. This can be better observed, if it is compared with reported saccharinate–imidazole complexes, which show the following formula: $[M(Himid)_4(H_2O)_2]\cdot 2sac$ for

M = Co, Ni, [23,24], $[Cu_2(sac)_4(Himid)_4]$, [8], Here, the position of the second nitrogen atom in the imidazole ring, does not favor hydrogen bonding with the water molecules in the complex. The Zn compound in both cases, has the formula $[Zn(sac)_2(am)_2]$, am = Hpz or Himid, [25]. In this case, probably as a d^{10} complex, the tetrahedral compound is kinetically favored.

Scheme 1. Some possibilities for metal carboxylate complex formation by ring opening reactions of pyromellitic dianhydride by alcohols.

opening, as illustrated in Scheme 1 and also to use the ring opening reactions for formation of metal complexes of first row transition metals.

2. Experimental

2.1. General

The reagents used here were purchased from commercial sources (Sigma–Aldrich or Fluka) and were used as received unless otherwise stated. The X-ray diffraction data were collected at 296 K with Mo Kα radiation ($\lambda = 0.71073$ Å) using a Bruker Nonius SMART CCD diffractometer equipped with a graphite monochromator. SMART software was used for data collection and also for indexing the reflections and determining the unit cell parameters; the collected data were integrated using SAINT software. The structures were solved by direct methods and refined by full-matrix least-squares calculations using SHELXTL software. All the non-H atoms were refined in the anisotropic approximation. The crystallographic parameters of the compounds studied are given in Table 1.

2.2. Synthetic procedures for the complexes

2.2.1. Synthesis of (2,2′-bipyridyl)dibenzoato nickel(II) [A]

Benzoic acid (733 mg, 6 mmol) and potassium hydroxide (337 mg, 6 mmol) were mixed together with nickel(II) chloride hexahydrate (710 mg, 3 mmol) in a mortar. The whole content was heated at 100 °C for 30 min. The mixture was cooled and transferred to a solution of 2,2′-bipyridine (234 mg, 3 mmol) in 10 ml of methanol. The mixture was stirred for half an hour, after which time a green colored solution was obtained and filtered. The filtrate was kept undisturbed for crystallization to give crystals of **A** (isolated yield 87%). Elemental *Anal.* Calc. for $C_{24}H_{18}N_2NiO_4$: C, 63.01; H, 3.94. Found C, 63.03; H, 3.96%. IR (KBr, cm^{-1}): 3434(b), 1593(m), 1523(s), 1426(s), 1073(w), 1026(w), 857(m), 726(m), 734(m), 685(m). Visible λ_{max}, 645 nm ($\varepsilon_{ethanol} = 9.11\ M^{-1}\ cm^{-1}$).

2.3. The ring opening reactions of pyromellitic dianhydride

The complexes with different compositions are prepared by reactions of *in situ* generated 2,5-dicarbomethoxy benzene 1,4-dicarboxylic acid or its isomer 2,4-dicarbomethoxy benzene 1,5-dicarboxylic acid (abbreviated as LH_2) with different metal salts and nitrogen containing heterocycles such 1,10-phenanthroline (phen) or 2,2′-bipyridine (bpy) as follows:

2.3.1. Synthesis of dicarboxylate complexes

$[Ni_2L_2(phen)_2(CH_3OH)_2(H_2O)_2]\cdot 2CH_3OH$ [**B**]: To a solution of pyromellitic dianhydride (218 mg, 1 mmol) in methanol (15 ml) a solution of nickel(II) acetate tetrahydrate (248 mg, 1 mmol in 5 ml methanol) was added, giving a green cloudy solution. To this solution a solution of 1,10-phenanthroline (200 mg, 1 mmol in 5 ml methanol) was added, followed by stirring at room temperature for 1 h. The solution was refluxed for 8 h and filtered, the filtrate on standing gave complex **B** (isolated yield of pure crystals 14%). Elemental *Anal.* Calc. for $C_{54}H_{60}N_4Ni_2O_{24}$: C, 51.21;

3. Results and discussion

In order to prepare different first row transition metal carboxylates, as depicted in Scheme 1, we have tested the feasibility of a basic one-pot reaction of a nitrogen donor ligand and carboxylic acid with a first row transition metal acetate. For this purpose the reaction of benzoic acid with nickel(II) acetate in the presence of 2,2′-bipyridine was carried out in an one pot reaction. The complex (2,2′-bipyridyl)dibenzoato nickel(II) [**A**] could be easily prepared in this reaction. Alternatively the same complex also could be prepared by reaction of nickel(II) chloride with potassium benzoate followed by treatment with 2,2′-bipyridine. This complex has an IR absorption at 1593 cm^{-1} (ν_{COO^-}) corresponding to stretching of a coordinated carboxylate group; this absorption is lower in frequency than in free benzoic acid (ν_{COO^-} 1680 cm^{-1}). The synthetic procedure for complex **A** reported here is much simpler than the earlier reported procedure [6]. The complex was further characterised by determining its crystal structure. It has a distorted octahedral geometry around the nickel with benzoate groups acting as chelating ligands and one bipyridine ligand occupying the remainder of the coordination sites, as shown in Fig. 1. The carboxylate chelates are unsymmetrical, for example, the Ni1–O1 and Ni1–O2 bond distances are not equal; same is true for the Ni1–O3 and Ni1–O4 pair. Although the structure of the complex **A** is very simple, it serves as a starting point to design the synthesis for low dimensional coordination polymers or cyclic complexes.

The reaction of pyromellitic dianhydride with nickel(II) acetate tetrahydrate in methanol followed by treatment with 1,10-phenanthroline gave the metallacycle [**B**] (Scheme 2). By directly using 1,3-benzene dicarboxylic acid as a precursor, we could not prepare such cyclic complexes. However, adopting the ring opening methodology of pyromellitic dianhydride, as illustrated in Scheme 2, we could prepare novel metallacycles of nickel(II). The product has a characteristic ester frequency at 1726 cm^{-1}, showing that the pyromellitic dianhydride ring has opened to form the corresponding ester. The identity of the cyclic product has been established by crystallography (Fig. 2). In this complex each nickel(II) ion is attached to two mono-dentate

carboxylate groups from the dicarboxylic acids; these groups occupy *cis*-positions around the nickel ion. Additional to these, the six coordinations positions around the nickel(II) ion are completed by 1,10-phenanthroline, water and methanol molecules. The carboxylate groups attached at the 1,3-position of the aromatic rings facilitate the formation of the cyclic metallacarboxylato complex. The coordinated water molecules on two metals are *trans* to each other and the same is the case with the methanol molecules. Fig. 3.

In this particular case the other complex from the 1,4-dicarboxylate isomer could not be obtained and insolubility of the products has prevented further characterization of open chain compounds, if any, formed in the reaction. However, from the room temperature reaction of nickel(II) acetate tetrahydrate with pyromelletic dianhydride and 2,2′-bipyridine in methanol we could obtain the mononuclear nickel complex **C** (Scheme 3). Formation of the 1,4-dicarboxylato complex occurs due to the synthetic procedure, as we have carried out the reaction at room temperature which prefers to form thermodynamically stable products. In general such ring opening reactions of pyromellitic dianhydride by alcohol (without any other reagent being added) leads to equimolar amounts of the 1,3- and 1,4-dicarboxylic acids [5a]. Formation of **C** provides a clue that under adequate reaction conditions the 1,4-dicarboxylato anion should act as ligand by replacing the labile aqua ligand, leading to polymeric materials. The TGA of the compound **C** shows a weight loss at 129 °C due to the loss of four water molecules (experimental wt. loss 13.4%; theoretical 12.7%). When the IR spectrum of compound **C** is compared with the spectrum after heating **C** at 130 °C for 15 min, the absorption at 3525 cm^{-1} disappears and also the carboxylate frequency is shifted from 1567 cm^{-1} to 1578 cm^{-1}, showing coordination of carboxylate group/s (Fig. 4a). On heating at 130 °C compound **C** becomes very insoluble in all common solvents. The process is attributed to the dehydration of the aqua ligands. The dehydration may lead to dinuclear species as observed. However, the poor solubility of the product prevented us from further study in this direction. On prolonged heating of compound **C** at 200 °C, a profound effect on the carbonyl frequency of the ester group could

Scheme 3.

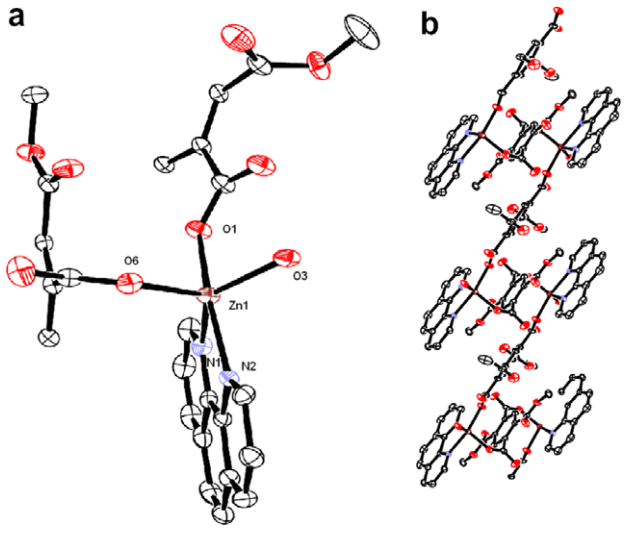

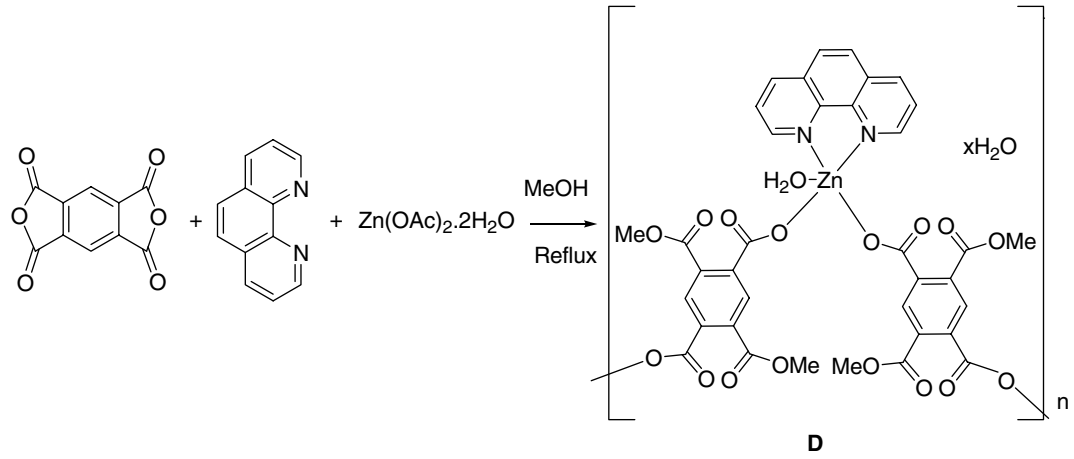

Fig. 4b. (a) The asymmetric unit of the zinc complex **D** showing the coordination environment. Some important bond distances (Å) Zn1–N1, 2.17; Zn1–N2, 2.10; Zn1–O1, 2.05; Zn1–O3, 2.00; Zn1–O6, 2.22; and bond angles (°) ∠N1–Zn1–N2, 78.13; ∠O1–Zn1–O3, 90.13; ∠O3–Zn–O6, 105.91. (b) The polymeric structure of **D** (all hydrogen atoms and water of crystallisation are omitted for clarity; drawn with 20% thermal ellipsoids).

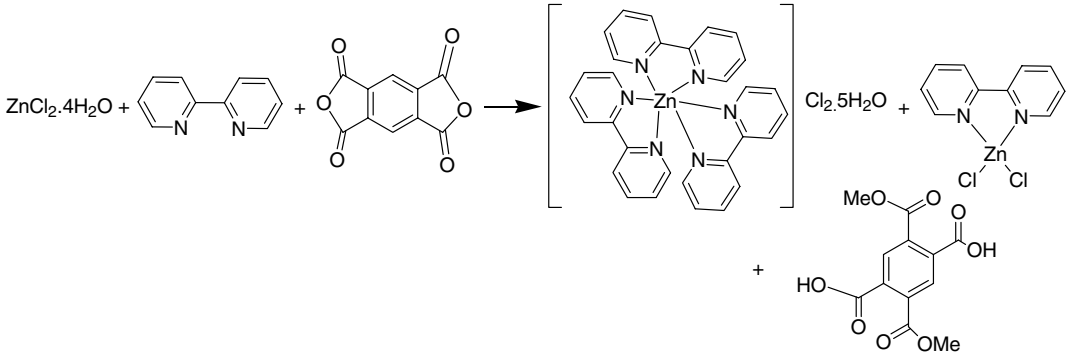
be seen. A new absorption at 1778 cm^{-1} appeared, in addition to an absorption at 1717 cm^{-1} (Fig. 4a), and the remaining peaks became slightly broadened without much shift being observed. The OH group absorption peak at 3105 cm^{-1} of the parent compound was shifted to 3368 cm^{-1} on heating at 200 °C. This suggests that the complex formed on heating at 200 °C absorbs moisture. We have tried making the anhydrous derivative, but the attempts were not successful.

Although we could not succeed in characterising the polymeric product/s from the reactions with nickel, from a similar reaction of pyromellitic dianhydride with zinc(II) acetate and 1,10-phenanthroline in methanol, a crystalline compound **D** having a polymeric structure (Scheme 4) could be characterised. This dicarboxylate complex **D** has five coordination around the zinc ions (Fig. 4b). In the polymer, each zinc ion has a distorted square-pyramidal geometry. The five coordination positions are completed by a water molecule, 1,10-phenanthroline and two monodentate carboxylate groups. The crystals qualities of the polymer were not very good for crystallography, but the available data are good enough to describe the polymeric chain. Since all these reactions gave a low yield of polymeric product in the pure form, we looked into the other possible products in these reactions.



Due to limited solubility of the products we looked carefully for a reaction from which we could obtain different types of crystals. From the reaction of zinc(II) chloride with pyromellitic dianhydride in methanol with 2,2′-bipyridine (1:1:2 molar ratio); we got two crystalline compounds and a white solid. The crystal structures of the crystalline compounds were determined and they were found to be $[Zn(bpy)_3Cl_2]\cdot 5H_2O$ and $Zn(bpy)Cl_2$. The compound $[Zn(bpy)_3Cl_2]\cdot 5H_2O$ has an analogous structure to that already reported [8]. The white solid compound has characteristic features of 2,5-dicarbomethoxy benzene1,4-dicarboxylic acid as well as bipyridine, suggesting it to be a zinc complex, but lack of crystal structure and limited solubility limits our further discussion on this issue. However, it is clear that in these reactions metal bipyridine complexes are formed as side products, lowering the yield of the polymeric product, which may be attributed to such side reactions which compete with metal–oxygen bond formation by metal–nitrogen bond formation. It may also be noted

Scheme 4.

that the use of a 1:3 stoichiometric ratio of zinc to bidentate ligand, namely 2,2'-bipyridine, led to the formation of $[Zn(bpy)_3]Cl_2 \cdot 5H_2O$ along with formation of 2,5-dicarbomethoxy benzene 1,4-dicarboxylic acid (the free acid is characterised by recording its IR and ^1H NMR spectra and comparing them with those of an authentic sample). This suggests that the anhydride ring opening and the complex formation both occur in a competitive manner and the reaction can be represented by Scheme 5. This shows that the competitive reaction between the nitrogen donating ligands and carboxylic acid groups to occupy the maximum coordination sites makes the yield of the carboxylate complexes less. Nevertheless it provides a better method to obtain characterisable metal dicarboxylate complexes having optimum solubility.

Recently it has been shown that zinc complexes of phenylene diacrylic acid form clusters leading to hydrogen storage material [7]. However, complex **D** presented here has a much simpler structure with a five coordination geometry around the zinc ions. From the available data, use of a 2:1 stoichiometry of the chelating ligand with respect to the metal acetate, along with one equivalent of pyromellitic dianhydride, has not been fruitful for polymeric product formation. For example, we have observed a self-assembled structure from such a reaction with cobalt(II), in which one of the carboxylato groups remains free and participates in hydrogen bonding in the self-assembled structure. The structure of the cobalt complex **E** obtained from the reaction of cobalt(II) acetate with pyromellitic dianhydride in the presence of 2,2′-bipyridine is illustrated in Fig. 5. The complex has a distorted octahedral structure with a monodentate carboxylate group and the other carboxaylate group at the 4-position remains as the carboxylato anion. Besides the two 2,2′-bipyridine ligands, the complex has one water molecule in the coordination sphere. In addition to the one aqua ligand the complex has four water of crystallisation molecules in the lattice and has the composition $[Co(bpy)_2(H_2O)L] \cdot 4H_2O$ (where $LH_2 = 2,5$-dicarbomethoxy benzene 1,4-dicarboxylic acid). From the crystallographic study we could not locate the positions of the six hydrogen atoms around the three lattice water molecules. However, thermogravimetric analysis confirmed the loss of water molecules corresponding to the four molecules of water of crystallisation. The presence of ester group absorptions at 1738 cm^{-1} and 1717 cm^{-1} suggests that the two ester groups have slightly different environments and supports the results obtained from the crystallographic study. The complex has a visible absorption at 482 nm in methanol due to a d–d transition of the d^7-electronic configuration. It has magnetic moment of 6.51 BM corresponding to a

Scheme 5. Products from the reaction of zinc(II) chloride with pyromellitic dianhydride in methanol in the presence of 1,10-phenanthroline.

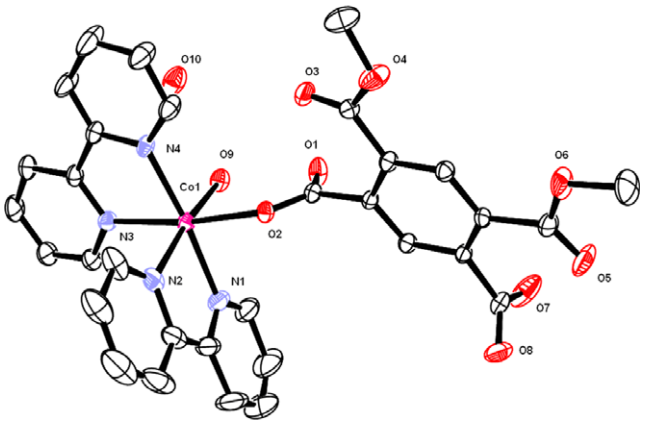


Fig. 5. The ORTEP (20% thermal ellipsoids) diagram of the cobalt(II) complex obtained from the reaction of pyromellitic dianhydride, cobalt(II) acetate and 2, 2′-bipyridine in a 1:1:2 molar ratio in methanol (hydrogen atoms are omitted for clarity). Some important bond distances (Å) Co1–O9, 2.09; Co1–N3, 2.10; Co1–N2, 2.14; Co1–N1, 2.11; Co1–O2, 2.13 and bond angles (°) ∠O1–Co1–O2, 91.75; ∠N1–Co1–N2, 76.35; ∠N2–Co2–N3, 92.34; ∠N1–Co1–O2, 86.87.

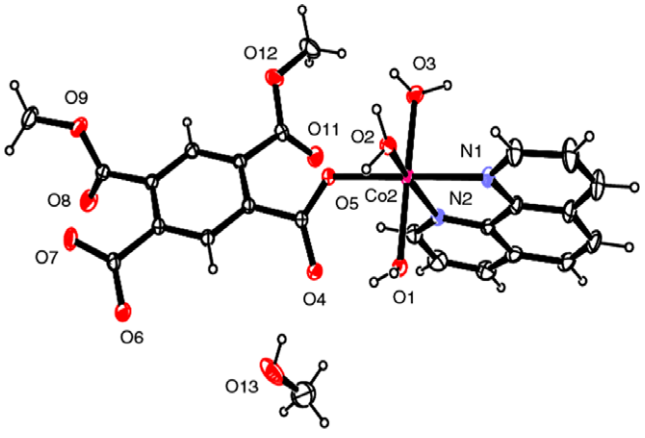
d^7-octahedral cobalt(II) complex. The reaction of pyromellitic dianhydride, cobalt(II) acetate and 1,10-phenanthroline in a 1:1:1 molar ratio in methanol gave a complex having the composition $[Co(phen)(L)(H_2O)_3]\cdot CH_3OH$, [**F**] and its crystal structure is shown in Fig. 6. This compound has a distorted octahedral geometry with one monodentate carboxylate.

The compound has a weak absorption at 487 nm corresponding to the d–d transition of an octahedral d^7 cobalt(II) system. The TGA shows that three coordinated water molecules are released on heating up to 250 °C, and they are lost in three steps.



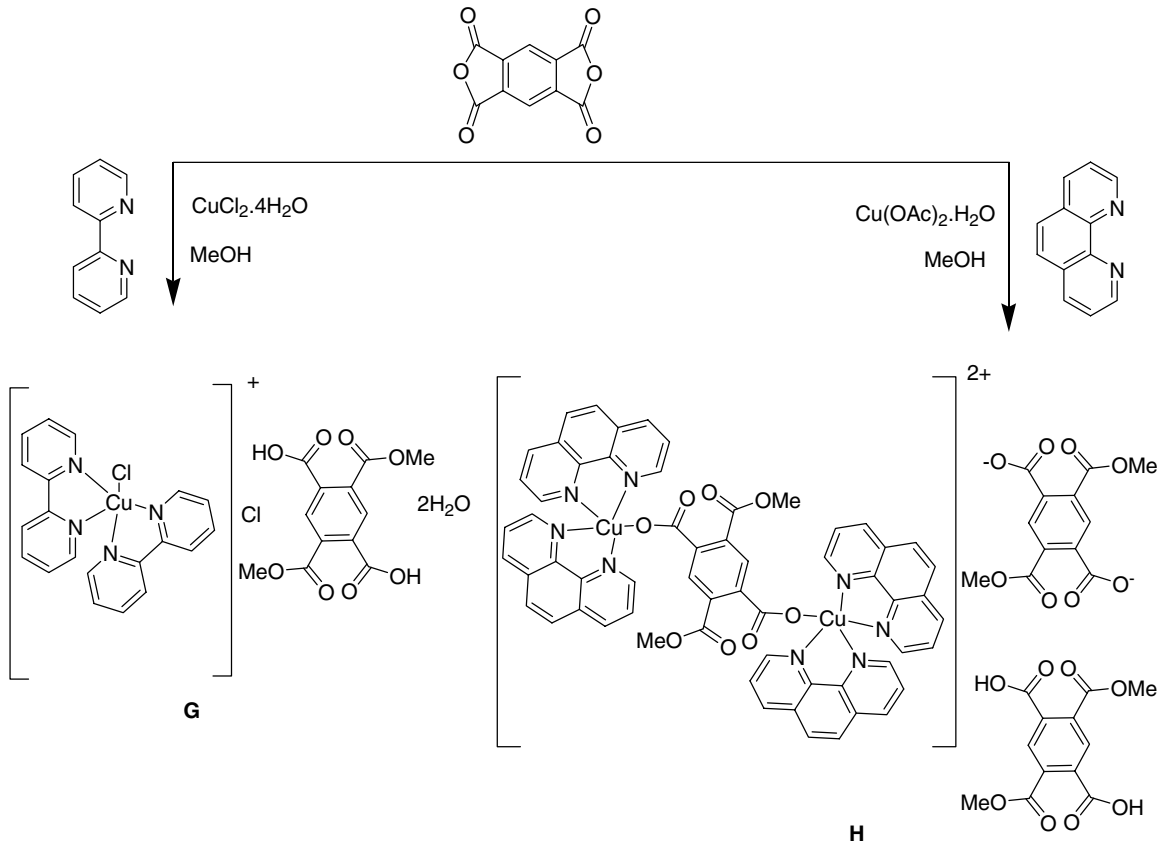


Fig. 6. The ORTEP (20% thermal ellipsoids) diagram of the cobalt(II) complex obtained from the reaction of pyromellitic dianhydride, cobalt(II) acetate and 1,10-phenathroline in a 1:1:1 molar ratio in methanol. Some important bond distances (Å) Co2–O1, 2.16; Co2–N1, 2.10; Co2–N2, 2.14; Co2–O2, 2.10; Co2–O3, 2.06; Co2–O5, 2.11 and bond angles (°) ∠O1–Co2–O2, 88.29; ∠N1–Co2–N2, 77.80; ∠N2–Co2–O1, 84.20; ∠N1–Co1–O2, 92.18.

We have also carried out independent reactions of pyromellitic dianhydride with methanol and copper(II) chloride, as well as with copper(II) acetate in the presence of bidentate aromatic heterocyclic ligands. Two different products obtained from such reactions are illustrated in Scheme 6. The reaction of copper(II) chloride with pyromellitic dianhydride in methanol with 2,2′-bipyridine led to the formation of a dinuclear complex. The complex has two 2,2′-bipyridine ligands attached to each copper and is bridged by two monodentate carboxylato groups at the 1,4-positions of 2,5-dicarbomethoxy benzene 1,4-dicarboxylic acid. The complex has the composition $[CuCl(bpy)_2]Cl\cdot 2H_2O\cdot LH_2$; where LH_2 is 2,5-dicarbomethoxy benzene 1,4-dicarboxylic acid and bpy = 2,2′-bipyridine. The ionic chloride is estimated by treatment of **G** with dilute silver nitrate and weighing the chloride as the silver chloride. An interesting feature of the complex is that in the lattice the chloride ion is hydrogen bonded to form a layered structure. The water molecules occur in pairs and each pair are hydrogen bonded to each other and are further hydrogen bonded to the chloride anion as depicted in Fig. 7c. The hydrogen bonding forms alternate four and six member rings and these rings are repeated along the crystallographic *a*-axis. The chloride ions are in T-shape three coordination environments in the hydrogen bonding scheme. Such a T-shaped hydrogen bonding environment in anion binding is important in anion recognition by amides and related compounds [9].

On the other hand, at room temperature the reaction of copper(II) acetate with pyromellitic dinahydride at room temperature followed by treatment with 1,10-phenanthroline (Scheme 6) led to a dinuclear complex having the composition $[Cu_2(phen)_4\mu\text{-}(L)]L\cdot LH_2$; (phen = 1,10-phenanthroline). In the complex two copper(II) ions are bridged by the 2,5-dicarbomethoxy benzene 1,4-dicarboxylato dianion. The charges on the metal ions are further neutralised by a dianion of an uncoordinated dicarboxylic acid. The structures of complexes **G** and **H** are shown in Fig. 7a and b. The complex has also a neutral dicarboxylic acid included as a co-crystal. In addition to the characteristic IR absorptions of 1,10-phenanthroline, the complex has the characteristic IR frequency for the ester groups at 1718 cm^{-1}.

The bond distances in the two copper(II) complexes are shown in Table 2. It clearly depicts that the compounds have five coordinated square-pyramidal geometries around the copper(II) centre. Complex **G** has a visible absorption at 737 nm due to a d–d transition. The complex shows a molar conductance of 67.5 $ohm^{-1}\,cm^2\,mol^{-1}$ in methanol which suggests it is a 1:1 electrolyte. Complex **H**, being highly insoluble in common solvents, prevented us from comparing their visible spectra in solution.

In conclusion, we have demonstrated a simple yet very useful synthetic methodology for the synthesis of first row transition metal carboxylate complexes through esterification of pyromellitic dianhydride. The ring opening

Scheme 6.

reactions of pyromellitic dianhydride with methanol can lead to either 1,4-dicarboxylic acid or 1,5-dicarboxylic acid depending on the metal salts and ancillary ligands used. Several such metal complexes are characterised by crystallography. In order to establish the selectivity in product formation, a greater understanding of the ring opening reactions by first row transition metal ions is needed. The limited solubility of the products and formation of multiple products made us take up selective cases where crystals suitable for X-ray diffraction were obtained. Present results suggest that the synergic competition between the nitrogen donor and carboxylato ligand leads to the formation of different compositions of dicarboxylate complexes. The reaction of chloride and acetate salts of copper in ring opening reactions of pyromellitic dianhydride suggested that the chloride occupies one of the coordination sites, yielding a mononuclear carboxylate complex, whereas using copper(II) acetate the product prefers coordination of the dicarboxylic acid as a bridging ligand through the two distal ends to give a dinuclear copper complex. From the

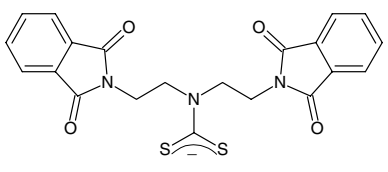
is a well-documented phenomenon [10–12]. In our efforts to correlate structure and fluorescent properties of main group metal dithiocarbamates and their adducts, in this paper we report the synthesis and spectral characterization of six new adducts along with the single crystal X-ray structural analysis of $[Zn(4\text{-mpzdtc})_2(1,10\text{-phen})]\cdot H_2O$ (**1**).

2. Experimental

All the reagents and solvents employed were commercially available analytical grade materials and were used as supplied, without further purification. IR spectra were recorded on an ABB Bomem MB 104 spectrometer (range 4000–400 cm^{-1}) as KBr pellets. The UV–Vis spectra were recorded in CH_2Cl_2 on a HITACHI U-2001 spectrophotometer. NMR spectra were recorded on a Bruker 400 MHz spectrometer at room temperature, using $CDCl_3$ as the solvent. ^{13}C NMR spectra were recorded in the proton decoupled mode. Fluorescence spectra of the free ligands, parent complexes and adduct were recorded in $CHCl_3$. To prevent any non-linearity of the fluorescent intensity, 400 nm was chosen as the excitation wavelength.

2.1. Preparation of the complexes

2.1.1. Preparation of padtc and 4-mpzdtc



N,*N*′-(iminodiethylene)bisphthalimide 'pa' was prepared by the method reported earlier [13]. Twenty millimoles of the amines pa and mpz were converted into padtc and 4-mpzdtc (Fig. 1) by mixing with 20 mmols of carbondisulfide under ice-cold conditions.

2.1.2. Preparation of the parent complexes

The parent complexes, $[M(dtc)_2]$ [M = Zn or Cd and dtc = 4-mpzdtc or padtc], were prepared by mixing the corresponding amine (20 mmol) and carbondisulfide (20 mmol) in ethanol under ice cold conditions (5 °C). To the yellow dithiocarbamic acid solutions, aqueous solutions of the metal salts ($ZnSO_4$ or $Cd(NO_3)_2$) were added with constant stirring. Pale yellow solids separated from the solution, which were filtered, washed with water, alcohol and then dried in air.

2.1.3. Preparation of adducts ***1–6***

In general, adducts were prepared by adding a hot solution of 1,10-phenanthroline (200 mg, 1 mmol) or

2,2′-bipyridine (155 mg, 1 mmol) in benzene to a hot suspension of the parent dithiocarbamate (1 mmol) in a benzene:chloroform (1:1) mixture. The resulting pale yellow solution was filtered and cooled. The yellow adduct separated out, which was filtered and recrystallised from a benzene:chloroform (1:1) solvent mixture. All the above complexes were analysed for carbon, hydrogen and nitrogen content and the results are shown in Table 1 along with the IR spectral data.

2.2. X-ray crystallography

Intensity data were collected at ambient temperature (295 K) on a Philips PW 1100 diffractometer [14] using graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). All the non-hydrogen atoms were refined anisotropically. The hydrogen atoms of the water molecule were located in the Fourier map and were subsequently constrained. The other remaining hydrogen atoms were fixed geometrically. The absorption correction was performed with the psi-scan technique [15]. The ORTEP diagram was drawn with the ORTEP-3 program [16].

3. Results and discussion

3.1. Infrared spectral studies

For the present set of compounds **1–6**, the ν_{C-N} (thioureide) band appears in the region 1380–1490 cm^{-1}. The reduction in ν_{C-N} (thioureide) for the adducts is attributed to the change in coordination number from 4 to 6 and the steric effect exerted by 1,10-phenanthroline or 2,2′-bipyridine. The ν_{C-S} bands are observed in the region 1000 cm^{-1} (**1–6**) without any splitting, supporting the bidentate coordination of the dithiocarbamate to the metal centre. For the padtc complexes, an intense band due to ≻C═O stretching appears in the region 1696–1772 cm^{-1}, which is due to the asymmetrical and symmetrical ≻C═O stretching modes. The carbonyl group absorption remains unaffected in the complexes indicating its non-involvement in the complexation. The characteristic bands due to 1,10-phenanthroline and 2,2′-bipyridine appear around 1600, 1510 cm^{-1} (1,10-phen) and 1595 cm^{-1} (2,2′-bipy) in the adducts **1–6** [17]. Other bands due to 1,10-phenanthroline and 2,2′-bipyridine are masked by those due to the dithiocarbamate ligands.

3.2. NMR spectral studies

NMR spectral data of all the synthesized compounds are given in Table 2 along with the splitting patterns.

3.2.1. ^1H NMR

Signals observed around 4.20 ppm for the complexes **1–4** are due to α-CH_2 protons present in the dithiocarbamate. The observed deshielding of the α-protons in all the cases [18] is attributed to the release of electrons on the nitrogen of the NR_2 groups, forcing high electron density towards the sulfur (or the metal) *via* the thioureide π-system. Although the magnitude of the deshielding decreases with the increase in distance from the metal centre or the thioureide bond, the β-CH_2 and N–CH_3 proton signals are also slightly deshielded on complexation. A change of the central metal atom [Zn/Cd] does not affect the position of the signals very much in the ^1H NMR spectra of **1–4** as the interaction is mainly electrostatic in nature. Apart from these signals, the signals observed in the downfield region of 7.36–9.21 ppm are assigned to the protons present in the nitrogenous ligands, 1,10-phenanthroline and 2,2′-bipyridine.

For complexes **5** and **6**, a triplet observed around 4.20 ppm is assigned to the α-CH_2 protons and the β-CH_2 protons appeared at around 4.06 ppm as triplets. In complexes **1–4**, the α-CH_2 protons are deshielded to a greater magnitude than the β-CH_2 protons. In complexes **5** and **6**, both α- and β-protons are deshielded to a

[a] Chemical shift due to a, e protons.
[b] Aromatic proton signals from padtc$^-$ also merged with the 1,10-phenanthroline ring proton signals.
[c] Signals for aromatic carbons in padtc$^-$ merged with the 1,10-phenanthroline ring signals.

comparable extent because of the presence of the electron withdrawing –(O=C)$_2$–N group in the adjacent position to β-CH$_2$. The shift of electron density towards the metal centre through the thioureide bond is more pronounced than the movement of electrons towards the carbonyl groups, which leads to the very minimal deshielding of the α-CH$_2$ protons.

3.2.2. ^{13}C NMR

The signals observed around 207 ppm for complexes **1**–**6** are assigned to the thioureide carbon $\delta(N^{13}CS_2)$. A downfield shift of the α-carbon signals (to the thioureide π-system) in the case of complexes **1**–**4** is an indication of the important consequence of the complexation process, viz. a significant thioureide $N^{\delta+}\cdots C^{\cdot\delta-}$ contribution to the stability of the complexes and a resultant reduction in the electron density.

The β-CH$_2$ carbons of the complexes **1**–**4** resonate around 55 ppm and are not greatly affected on complexation, similar to the N–CH$_3$ carbon signals, which are observed around 46 ppm, because of the relative distance from the thioureide π-system and the metal centre. A small difference observed in the chemical shifts of the α- and β-carbons of **5** and **6** is mainly attributed to the presence of the electron withdrawing (O=C)$_2$N– and –NCS$_2$ π-system adjacent to the β- and α-carbons, respectively. The assignment of the deshielded signal to the α-carbon is accomplished by considering the pronounced electron withdrawing effect of the NCS$_2$ π-system and the closer proximity of the α-carbons to the metal centre.

The carbonyl carbon in complexes **5** and **6** resonates at 168.7 and 168.8 ppm, respectively. The observed small differences in chemical shifts for the 1,10-phenanthroline and 2,2′-bipyridine fragments in adducts **1**–**6** compared to the free 1,10-phenanthroline and 2,2′-bipyridine signals can be attributed to charge delocalization, which prevents the movement of electron density from the adjacent carbons. Generally, the extent of deshielding for the thioureide $N^{13}CS_2$ signal in main group metal dithiocarbamates is greater in magnitude than those of normal valence state transition metal dithiocarbamates, which is in line with the observed thioureide carbon chemical shifts of the synthesized compounds [19].

3.3. Fluorescence spectral studies

M(dtc)$_2$ (where M = Zn and Cd and dtc = general notation for the dithiocarbamate anion) complexes show less intense or no fluorescence in the visible region. It may be attributed to the absence of effective fluorophores in the parent complexes or a less effective MLCT (metal to ligand charge transfer) [20] between the metal centre and dithiocarbamate ligands. On excitation, for complexes with a MS$_4$N$_2$ chromophore (**1**–**6**), fluorescence maxima are observed in the region 440–460 nm, which may be due to a possible metal ligand charge transfer (MLCT) or the brief masking of the lone pair of electrons of nitrogen through a photoinduced electron transfer (PET) [21]. Complexes **5** and **6** show fluorescence bands with comparatively high intensity compared to the other octahedral complexes, which is attributed to the presence of the phthalimide group (where the carbonyl group is in conjugation with the aromatic π-system) along with 1,10-phenonthroline in the metal chelates.

3.4. Structural analysis

[Zn(4-mpzdtc)$_2$(1,10-phen)]·H$_2$O (**1**) is monomeric and discrete. The ORTEP diagram of **1** is shown in Fig. 2 together with the atom-numbering scheme. Four formula units are present in the unit cell. One molecule of water is co-crystallized along with the complex molecule. The molecule sits on a two fold axis. From the crystal structure of **1**, it is clear that zinc is hexacoordinated with four sulfur atoms from the dithiocarbamate ligands and two nitrogen atoms from the chelating 1,10-phenanthroline. The short thioureide C–N distance, 1.347(14) Å indicates that the π electron density is delocalized over the S$_2$CN moiety and that this bond has a strong double bond character. Because of the small bite angle [S–Zn–S = 70.26(7)°] of the dithiocarbamate and the steric influence of 1,10-phenanthroline, the central metal atom is in a highly distorted octahedral coordination environment.

The distinct asymmetry in Zn–S distances [Zn(1)–S(2) = 2.459(3) and Zn(1)–S(3) = 2.6192(16) Å] is due to the steric effect exerted by 1,10-phenanthroline, as observed for similar adducts [18]. The C–S distances [C(4)–S(3) = 1.700(9) and C(4)–S(2) = 1.712(5) Å] are symmetric, indicating that the presence of an additional neutral ligand affects the S–Zn–S bite angle and Zn–S distances. The Zn–N distance is found to be 2.195(6) Å. The C–C and C–N bond distances associated with the piperazine ring are normal. To avoid 1,3-diaxial steric interactions with the axial hydrogens, the methyl group in the terminal position (C(11) in the ORTEP diagram) is equatorially bonded to the nitrogen. The piperazine ring is in a normal chair conformation. The nitrogen, N(8) of the methyl piperazine ring shows a short contact with the hydrogen atom of the water molecule (O(1)W ··· N(8) 2.936(0.008) Å), indicating a hydrogen bonded interaction. However, the interaction involving O(1)W ··· S3 through H(2)W is less significant,

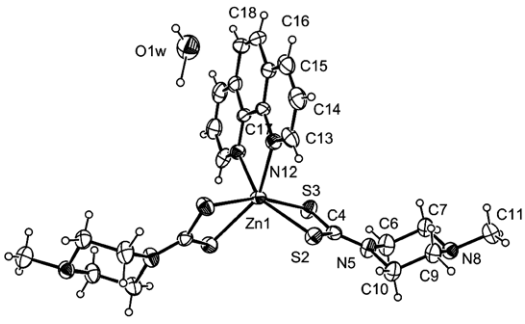

Fig. 2. ORTEP diagram of [Zn(4-mpzdtc)$_2$(1,10-phen)]·H$_2$O (**1**).

relatively (3.506(0.005) Å). The 1,10-phenanthroline ring shows normal bond parameters.

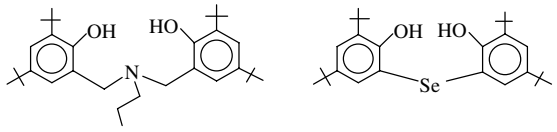
3.5. VBS analysis

Valence bond sum (VBS) analysis can be applied to estimate the bond lengths; vice-versa the sum of the bond lengths should give information about the valence of the central metal ion. Hence, VBS studies indirectly prove the correctness of the crystal structures determined. For complex **1**, VBS values were calculated by two procedures [22,23]. The values are 1.8098 (OK/B) and 1.8420 (B/OK), and among the two values V_i(B/OK) is closer to the expected formal oxidation state of 2. It has been already reported [17] that in the case of the parent bisdithiocabamates of Zn(II), VBS values are almost 2 and generally the values are greater than the sum for the adducts. The decrease in BVS values in the case of the adducts can be ascribed to the increase in Zn–S distances (which are longer than those observed in $Zn(dtc)_2$ complexes), due to the presence of an additional neutral ligand.

Appendix A. Supplementary material



CCDC 263876 contain the supplementary crystallographic data for **1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.06.008.

oxygen species and UV/visible light [7–11]. At the same time, several studies have shown that vitamin C sometimes increases DNA damage in humans, acting as a pro-oxidant [7,12,13].

For some time we have been engaged in exploring the chemistry of bis(phenolate) ligands of transtion metal ions in a mixed ligand environment [14]. Here, we describe the synthesis, crystal structure, cyclic voltammetric and kinetic studies on the oxidation of ascorbic acid by a vanadium(V) complex, viz. $[VO(L^1)(acac)]$ ($H_2L^1 = N,N$-bis(2-hydroxy-3,5-di-*tert*-butylbenzyl)propylamine) and $[VO(L^2)(acac)]$ ($H_2L^2 = 2,2'$-selenobis(4,6-di-*tert*-butylphenol)). We hope to delineate the mechanism of the oxidation of ascorbic acid and to find relations between the kinetic parameters and pH. The results may contribute to an understanding of the behavior of vanadium complexes in human tissue and blood.

H_2L^1 H_2L^2

2. Experimental

2.1. Physical measurements

Elemental analyses were carried out using a Perkin–Elmer 240 elemental analyzer. Infrared spectra (400–4000 cm^{-1}) were recorded from KBr pellets on a Nickolet Magna IR 750 series-II FTIR spectrophotometer. Electronic spectra were recorded on an Agilent 8453 UV–Vis diode array spectrophotometer. ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ on a Bruker 300 MHz NMR spectrometer using TMS ($\delta = 0$) as an internal standard. Room temperature ^{51}V NMR spectra were obtained with a Bruker 7 tesla magnet and MSL100 pulsed NMR spectrometer. Electrochemical measurements were carried out using a computer controlled PAR model 263A VERSASTAT electrochemical instrument with a glassy carbon disk (4 mm diameter, EG&G) working electrode. Conductance measurements were carried out with a JENCONS 4010 conductivity meter.

2.2. Materials

$[VO(acac)_2]$ and the starting materials for the synthesis of ligands (H_2L^1) and (H_2L^2), namely, 2,4 di-*tert*-butylphenol, (Lancaster), formaldehyde (Merck India), *n*-butylamine (Loba Chemie, India), *n*-propylamine (Loba Chemie, India) and selenium dioxide (Loba Chemie, India) are of reagent grade and were used as received. Tetrabutyl ammonium perchlorate (TBAP) was purchased from Aldrich Chemicals. Solvents like methanol, dichloro methane, *n*-hexane and acetonitrile (Merck, India) were of reagent grade and were dried by standard methods before use. $CDCl_3$ (Aldrich) was used as received.

2.3. Synthesis

2.3.1. Synthesis of ligands

The ligands (H_2L^1 and H_2L^2) have been synthesized according to the published procedure [15] and characterized further by CHN and NMR spectroscopic analyses.

2.3.2. General methods for the synthesis of $[V^VO(L^1)(acac)]$ (**1**) and $[V^VO(L^2)(acac)]$ (**2**)

Equimolar quantities of $[VO(acac)_2]$ and the appropriate ligand were stirred in air in acetonitrile for a few hours. The resulting dark colored solution was kept at −5 °C after filtration. Diffraction quality crystals were obtained after a few days.

2.3.2.1. $[V^VO(L^1)(acac)]$ (**1**). Yield: 80%. *Anal.* Calc. for $C_{38}H_{58}NO_5V$ (659.79): C, 69.42; H, 9.26; N, 2.31. Found: C, 69.25; H, 9.20; N, 2.35%. FTIR (KBr, cm^{-1}): ν(V=O) 964. ^1H NMR ($CDCl_3$): δ 7.27 (d, 2H, Ar-H), 6.96 (d, 2H, Ar-H), 5.68 (s, 1H, acac), 3.49 (s, 4H, Ar-CH_2), 2.05 (s, 3H, –$COCH_3$), 1.7 (m, N-CH_2), 1.46 (s, 3H, CH_3), 1.57 (s, 18H), 1.29(s, 18H), 0.64 (t, 3H, CH_3); ^{13}C NMR ($CDCl_3$): δ 191.08 ($C_{carbonyl}$, acac), 188.3 ($C_{enolate}$, acac), 144.31, 136.05, 129.15, 124.97, 122.38, 103.37, 77.84 (=C, acac), 77.41 (CH_3, acac), 76.99 (CH_3, acac), 54.17 (N-CH_2), 40.56 (Ar-CH_2), 35.8 ($C(CH_3)_3$), 34.88 ($C(CH_3)_3$), 32.16 ($C(CH_3)_3$), 32.12 ($C(CH_3)_3$), 32.04 ($C(CH_3)_3$), 30.7 ($C(CH_3)_3$), 30.63 ($C(CH_3)_3$), 30.09 ($C(CH_3)_3$), 26.64($C(CH_3)_3$), 13.02 (CH_2), 12.3 (CH_3).

2.3.2.2. $[V^VO(L^2)(acac)]$ (**2**). Yield: 81%. *Anal.* Calc. for $C_{33}H_{47}O_5SeV$ (653.63): C, 60.64; H, 7.20. Found: C, 60.25; H, 7.30%. FTIR (KBr, cm^{-1}): ν(V=O) 981. ^1H NMR ($CDCl_3$): δ 7.45 (d, 2H, Ar-H), 7.28 (t, 2H, Ar-H), 5.86 (s, 1H, acac), 2.09 (s, 3H, –$COCH_3$), 1.56 (s, 3H, CH_3), 1.5 (s, 18H), 1.27(s, 18H); ^{13}C NMR ($CDCl_3$): δ 192.26 ($C_{carbonyl}$, acac), 189.2 ($C_{enolate}$, acac), 146.02, 131.01, 128.83, 125.34, 123.71, 104.33, 77.84 (=C, acac), 77.41 (CH_3, acac), 76.99 (CH_3, acac), 33.35 ($C(CH_3)_3$), 35.21 ($C(CH_3)_3$), 31.86 ($C(CH_3)_3$), 30.29 ($C(CH_3)_3$), 26.66($C(CH_3)_3$).

2.4. X-ray crystallography

Crystal data and structure refinement details for both crystals are given in Table 1. The diffraction data for both complexes were collected using Mo Kα radiation. Data for **1** were collected with a KM4CCD diffractometer with a four-circle area-detector (KUMA Diffraction, Poland), and equipped with an Oxford Cryostream Cooler (Oxford Cryosystems, UK). The ω scan technique with different κ and φ offsets for covering an independent part of the reflections in the 3.3°–25.0° θ range was performed. The cell parameters were refined from all strong reflections. Data

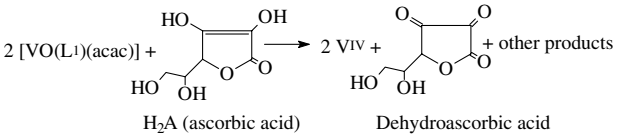
reduction was carried out using the CrysAlis RED (Oxford Diffraction, UK) program, an analytical absorption correction was applied. The structures were determined by direct methods and SHELXS-97 [16]. H atoms attached to C atoms were positioned geometrically, with C–H = 0.95–0.98 Å, and with U_{iso}(H) values of 1.2 U_{eq} (C) [1.5 U_{eq} (C) for methyl atoms].



The diffraction data for complex **2** were collected using the MAR research image plate system. The structure was determined using SHELXL [16]. An empirical absorption correction was carried out using DIFABS [17]. The non-hydrogen atoms were refined anisotropically and H atoms isotropically. H atoms attached to C atoms were positioned geometrically and given thermal parameters equivalent to 1.2 times that of the atom to which they were attached. Both structures were refined to convergence on F^2 using the full matrix least-squares procedure by SHELXL-97 [18]. Data for publication were prepared by SHELXL and PARST [19], and figures by ORTEP-III [20].

2.5. Kinetic measurements

The oxidation of ascorbic acid by [VO(L^1)(acac)] (**1**) was studied in 50% MeCN–50% H_2O (v/v) at 25 °C at an ionic strength $I = 0.10$ M (KCl). The decomposition of complexes **1** and **2** in the presence of HCl was followed kinetically under identical conditions but devoid of ascorbic acid. Stock solutions were prepared freshly prior to kinetic study and saturated with dry N_2, purging for at least 15 min. All kinetic experiments were conducted under pseudo-first-order conditions with the complexes as the minor component and were followed by monitoring the disappearance of the substrate. Typical substrate concentrations were $(5.0–9.0) \times 10^{-5}$ M. The pH in self-buffered media was measured with a Systronics digital pH meter model-335 (Systronics, India), equipped with a glass electrode, and the actual pH of the solution was calculated according to Allen and Tidwell as: $pH_{actual} = pH_{observed} + 0.18$ [21]. The absorbance, over specified time intervals, was recorded for at least 5 half-lives. The absorbance-time data thus obtained were fitted with the HP-8453 system program to get the pseudo-first-order rate constants. The data for triplicate runs were found to fall within the error limit ±5%.

2.6. Stoichiometry and reaction products

To determine the stoichiometry of the reaction, a measured excess (0.003 M) of complex **1** was reacted with variable known concentrations of ascorbic acid (0.0005, 0.00075 and 0.001 M). The unreacted complex was determined spectrophotometrically in each case and a 2:1 [complex]:[ascorbic acid] stoichiometry prevailed, as depicted in Eq. (1). Parallel blank solutions were also prepared to account for the auto-decomposition of the complex.

(1)

The dehydroascorbic acid product was identified by Roe's method [22]. It was not possible to characterize or identify the reduced vanadium(IV) species due to its ready decomposition under the kinetic conditions.

3. Results and discussion

Complexes **1** and **2** were prepared by the reaction of equimolar quantities of [VO(acac)$_2$] with H_2L^1 and H_2L^2 respectively in MeCN. The conductance measurements in MeCN showed very low conductivity (3 S for **1** and 5.7 S for **2**), indicating that both the complexes are electrically neutral.

3.1. Description of the crystal structures

The unit cells consists of discrete molecules of complexes **1** and **2**, and both molecules crystallize in the P21/c (No. 14) space group. The ORTEP diagrams of the complexes, with the atom-labelling schemes, are shown in Figs. 1 and 2. Crystal data and selected inter atomic parameters are listed in Tables 1 and 2, respectively.

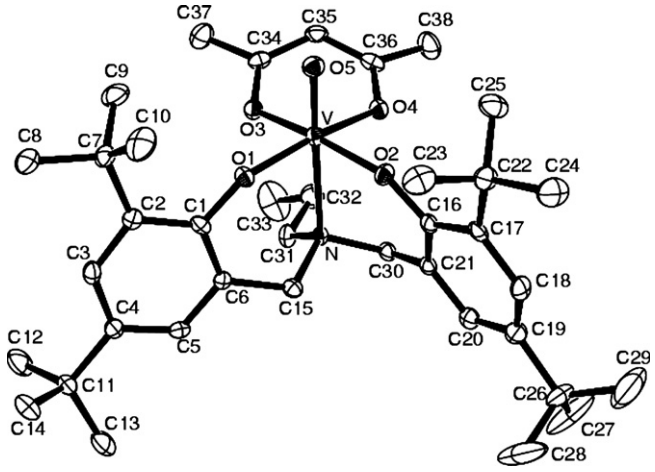


Fig. 1. ORTEP representation of $[V^{V}O(L^{1})(acac)]$ (**1**).

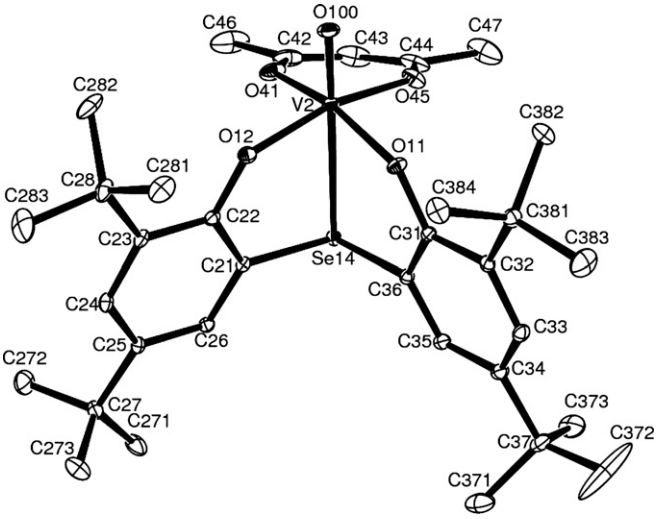

Fig. 2. ORTEP representation of $[V^{V}O(L^{2})(acac)]$ (**2**).

In complex **1** the vanadium atom in each molecule is octahedrally coordinated in an O_5N donor environment. A terminal V=O oxygen atom occupies an axial position. The ONO donor set of one ligand moiety coordinates facially with the nitrogen atom *trans* to the terminal oxygen atom. The two oxygen atoms of the bidentate acetylacetone ligand occupy the remaining two sites. The equatorial VO_4 unit is far from planar. The deviation of the vanadium atom is 0.2285(5) Å from the mean plane comprised by the two independent phenolate oxygen atoms O1, O2 and two acetylacetone oxygen atoms, O3 and O4. The two diagonal angles O1–V–O4 and O2–V–O3, 163.19(8) and 164.30(8)°, respectively, are significantly less than 180°. This deviation from the ideal geometry may be caused by the small bite angles made by two phenolate oxygen atoms and tripodal nitrogen atom with vanadium (O1–V–N = 83.34(8)° and O2–V–N = 81.19(8)°). This is again due to a remarkably longer V–N distance (2.446(2) Å) in comparison with the average length of 2.08 Å for this bond in related VNO_5 complexes reported earlier and in the

Table 2
Selected bond lengths (Å) and bond angles (°) in complexes **1** and **2**

Complex **1**		Complex **2**	
Bond lengths

		O45–V2–Se14	83.2(1)
		O41–V2–Se14	81.8(1)

Cambridge Structural Database [14a,15]. The phenomena may be explained in terms of a *trans* labilizing effect of the oxo group, which occupies another axial position at a normal distance of 1.588 (2) Å [14a,23].

In complex **2** the geometry around the vanadium center is the same as in **1** but with a SeO_5 donor environment. The basal plane is defined by the O(11), O(12), O(41) and O(45) atoms, and the axial coordinates are occupied by the oxo group (O(100)) and sole Se(14) atom. The vanadium atom is shifted by 0.349 Å from the equatorial plane towards the apical O(100) atom, rendering a shortening in the diagonal angles O11–V2–O41 (157.74°) and O12–V2–O45 (158.9°).

The V–Se distance is 2.954(2) Å, a distance comparable to the 2.886(1) Å found by Wieghardt et al. [23b] in a dinuclear vanadium(V) complex with the same selenobis(phenolate) ligand. This could represent a weak interaction, but such an interpretation is complicated by the fact that the rigidity of the ligand forces the Se atom into occupying an octahedral position. A search of the Cambridge Crystallographic Database established 71 instances of V–Se bonds, with a mean bond length of 2.48 Å. However, these structures are from a variety of oxidation states and do not include any examples with V(V). This V–Se distance can be compared to the V–N distance of 2.446(2) Å found in **1**. This distance is also considerably higher than the norm for V–N bonds and is a reflection not only of the steric constraints of the ligand, but also of the position of the atoms *trans* to the terminal oxygen atom.

In both the complexes the two ligands H_2L^1 and H_2L^2 behave in almost a similar way. The vanadium atom is distorted more from the equatorial plane in **2** (0.349 Å) than in **1** (0.228 Å) and this may be due to the longer

V–Se coordinate bond. The axial and equatorial V–O bond distances are in rather good agreement with similar reported complexes [23]. The V–O(phenoxo) bond distances are in the range 1.96–2.00 Å. The equatorial acetylacetonate oxygen atoms shows slightly longer V–O bond distances [24]. All the aromatic rings in the two complexes retain aromaticity. The two mean planes formed by the respective aromatic rings intersect at an angle of about 64.68 and 74.59° in complexes **1** and **2**, respectively.

3.2. ^{51}V nuclear magnetic resonance (NMR) study

^{51}V NMR spectra at room temperature of complexes **1** and **2** were obtained with a Bruker MSL100 pulsed NMR spectrometer. At the calibrated magnetic field of 7.0452 Tesla, the reference frequency for ^{51}V is 78.851 MHz. The spectra of both the samples could be theoretically simulated with the consideration of anisotropic chemical shift and a lorentzian line shape. Complex **1** has a line width of about 100 kHz and chemical shift values $\sigma1 = -480$ ppm and $\sigma2 = \sigma3 = 300$ ppm. For complex **2**, the line width is about 400 kHz and $\sigma1 = -490$ ppm and $\sigma2 = \sigma3 = 380$ ppm.

In solution, the rigidity of the molecular structure breaks down due to the weakening of the bonds, giving rise to various kinds of intra-molecular motions. In NMR experiments, such mobilities are reflected in the narrowing of the resonance spectrum. Fig. 3 shows the spectra of **1** (Fig. 3a) and **2** in acetonitrile at room temperature. Complex **1** yields a narrow line at −300 ppm, indicating complete disappearance of the chemical shift anisotropy. Complex **2** (Fig. 3b) also shows a strong narrow peak in the same position, but also a peak of smaller amplitude is obtained at about 115 ppm together with a broad structure, indicating that the chemical shift anisotropy is only partially averaged out and that the structural rigidity of this compound is not entirely lost under these conditions.

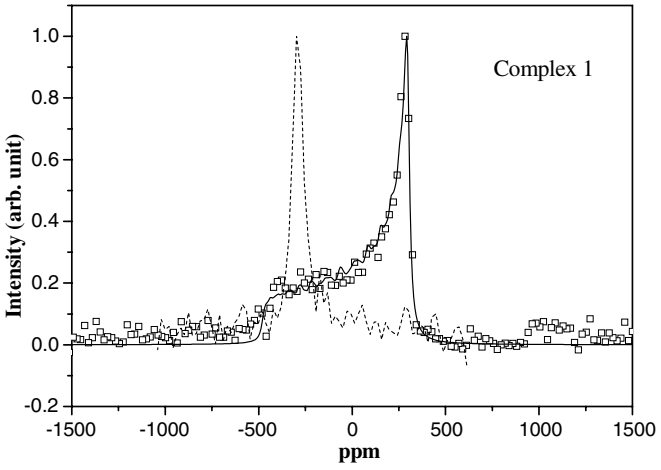

Fig. 3a. ^{51}V NMR spectra of complex **1**. The discreet points are data experimentally obtained. The solid line is a theoretical simulation, and the dashed lines represent a spectrum obtained from solution.

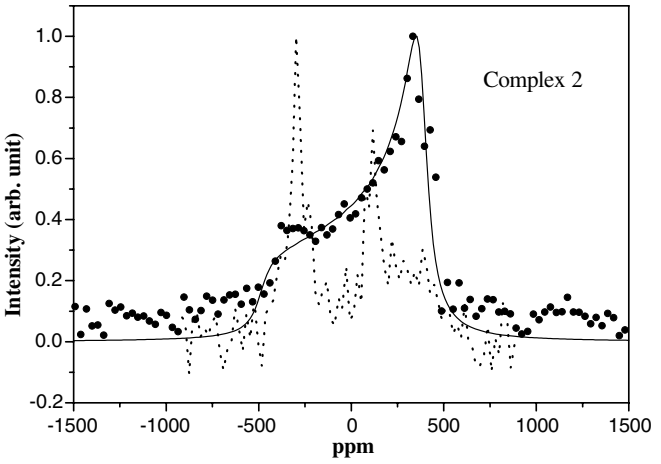

Fig. 3b. ^{51}V NMR spectra of complex **2**. The discreet points are data experimentally obtained. The solid line is a theoretical simulation, and the dashed lines represent a spectrum obtained from solution.

3.3. Electrochemical study

The electrochemical behaviors of complexes **1** and **2** were studied by cyclic voltammetric techniques in the range +1.00 to −0.6 V in acetonitrile at a glassy carbon electrode and Ag/AgC1 reference electrode using tetrabutylammonium perchlorate (TBAP) as the supporting electrolyte. Both the complexes showed reversible cyclic voltameric responses and $E_{1/2}$ appears at −0.38 and −0.10 V (−0.18 and 0.10 V versus NHE) for complexes **1** and **2**, respectively (Fig. 4). Coulometric experiments show that the waves are due to one-electron transfer processes. Since both the phenolato and acetylacetonato ligands are not reduced in the experimental potential range we propose that these potentials are metal centered and appear due to the VO^{3+}/VO^{2+} couple [25].

Complex **2** shows reduction at a less negative potential than complex **1** and indicates the nature and influence of

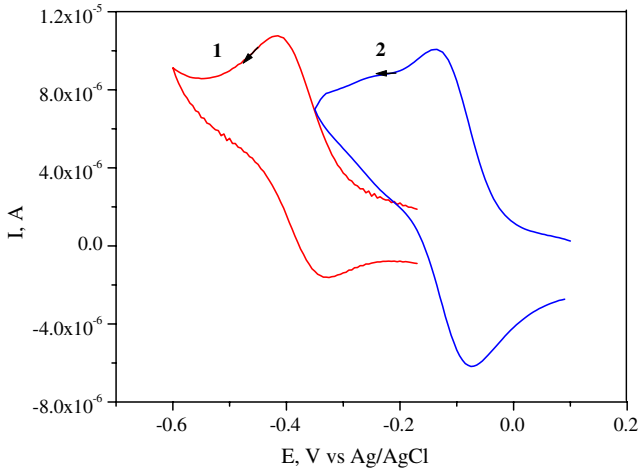

Fig. 4. Cyclic voltammograms of complexes **1** and **2** in acetonitrile solution containing 1 mM complex and 0.1 M n-Bu_4NClO_4 (scan rate = 0.1 V/s).

the bound ligands on the redox behavior of vanadium. This study strongly suggests that the stability of the VO^{3+} center is much higher in the presence of the H_2L^1 ligand than in presence of H_2L^2. A reasonable explanation comes from the hard-soft acid base principle. In complex **1**, the V(V)–N bond is a hard-hard interaction which is stable. Vanadium(V) is harder than vanadium(IV) and so reduction leads to a V(IV)–N bond, which is a soft-hard mismatch. On the other hand, the V(V)–Se bond in complex **2** is a hard-soft mismatch. Reduction to vanadium(IV) produces a V(IV)–Se bond which is a soft-soft match, making the reduction easier.

3.4. Kinetics of the oxidation of ascorbic acid

The kinetics of oxidation of ascorbic acid by complex **1** was conducted under pseudo-first-order conditions by monitoring the disappearance of the vanadium(V) species at 671 and 503 nm. The deep blue (**1**) and purple (**2**) colours of the complexes with high ε values [λ (nm) (ε, $M^{-1}\,cm^{-1}$): 330(8000), 510(5940) and 670 (8380) for **1** and 335(4400), 503(8400) and 781(4980)] for **2**] are presumably due to phenolate to vanadium(V) charge transfer transitions, and are comparable to other oxovanadium(V) complexes of phenolate derived ligands [26].

The gradual disappearance of these bands may be attributed to the fact that on reduction to vanadium(IV), complex **1** undergoes rapid decomposition in mixed aqueous solution (Fig. 5), and this is evidenced from the steady disappearance of the bands shown in the time resolved spectra for its acid catalyzed decomposition (SUP Fig. 1). The reactions were followed for more than 5 half lives and pseudo-first-order rate constants were extracted by fitting the kinetic traces to the HP-8453 system program. The kinetic conditions adopted are: $[H_2A]_t$ (where H_2A is fully protonated ascorbic acid) = 0.001–0.09 M, [Complex] ~ 1×10^{-4} M, pH 3.25–5.15, $I = 0.10$ M (KCl) and temperature 25 °C.

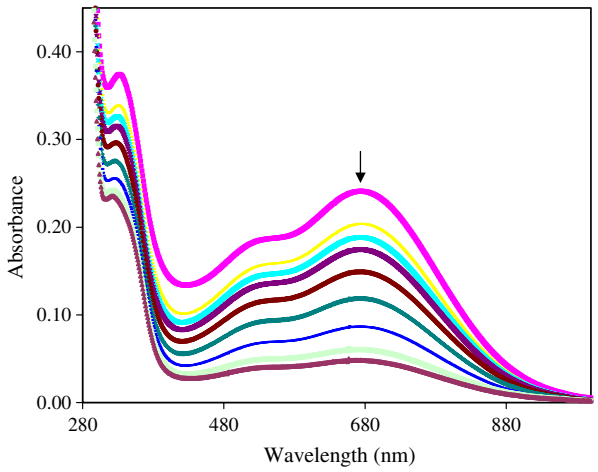

Fig. 5. Time resolved spectra for the oxidation of ascorbic acid by complex **1** at 25 °C. Conditions are: $[H_2A]$ 0.09 M, pH 4.5, $I = 0.10$ M (KCl). The first and second spectra were recorded immediately after mixing and at 200 s, respectively. Successive spectra were taken at 100 s time interval.

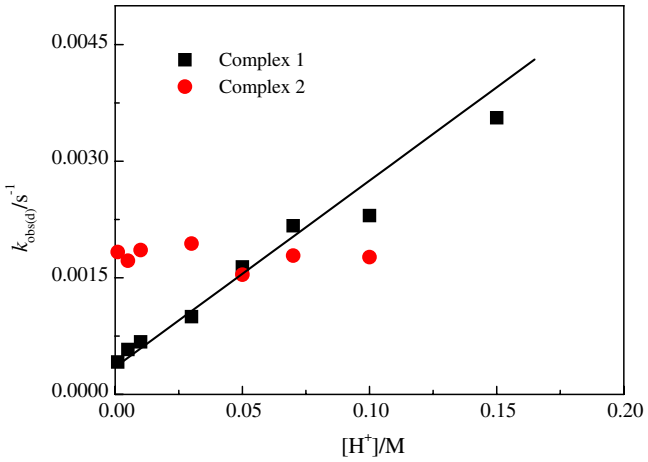

Fig. 6. Acid catalyzed decomposition of complex **1** in 50% MeCN–50% H_2O at 25 °C.

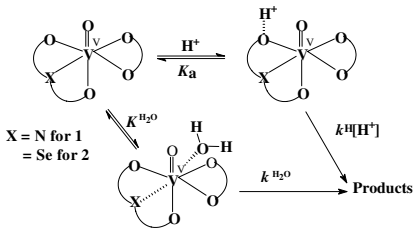

3.4.1. Decomposition of *1* and *2*

In the experimental range pH 3.25–5.15 there might be the possibility of protonation on the coordinated ligands, thereby causing the decomposition of the complexes. To explore this aspect, the acid catalyzed decomposition of the complexes was studied in the range $[H^+]$ 0.001–0.20 M in 50% MeCN–50% H_2O without ascorbic acid. For complex **1**, a plot of $k_{obs(d)}$ versus $[H^+]$ yields a straight line (Fig. 6) with a positive intercept on the rate axis, as given by Eq. (2) with k_0 as solvent mediated and k_1 as proton assisted decomposition paths, with $k_0 = (3.51 \pm 1.42) \times 10^{-4}\ s^{-1}$ and $k_1 = (2.40 \pm 0.15) \times 10^{-2}\ M^{-1}\ s^{-1}$.

$$k_{obs}(d) = k_o + k_1[H^+] \quad (2)$$

In the case of complex **2** it was surprisingly noticed that the decomposition rate is independent of $[H^+]$ and is solely mediated by the hydrolytic path with $k_0 = (4.0 \pm 0.05) \times 10^{-3}\ s^{-1}$. Based on these kinetic data a plausible overview of decomposition paths can be predicted, as shown in Scheme 1. Here, $k_0 = K^{H_2O} \cdot k^{H_2O}$ and $k_1 = K_a k^H$. Single protonation of the coordinated ligand is indicated by the first-order dependence of rate on $[H^+]$. Now the question arises whether protonation occurs on the bis-phenolate or acetylacetonate ligand. Based on pK_a values[1] it is more likely that the protonation should occur on the phenolate-oxygen atom. For the aqua-mediated decomposition path the coordination of H_2O to the metal center may take place in two ways. One is direct coordination to give a seven coordinated intermediate and another is the partial rupture of the V–X (X = N or Se) bond to facilitate the

[1] The pK_a of acetylacetone is 8.8 and that of *p*-methylphenol is 10.26 in water [27]. 2,4-Di-*tert*-butylphenol is insoluble in water but it is expected to have a higher pK_a value than alkyl-substituted phenols.

Scheme 1.

approach of H_2O towards the metal center. In the case of complex **1**, k_0 is lower than that of complex **2** and indicates the possibility of the second type of water coordination as the very weak V–Se bond facilitates this approach in the case of complex **2**. Another reason for a lower k_0 value for complex **1** may be due to the presence of the propyl group attach to the coordinated N atom of the ligand, imposing some kind of steric congestion around the metal center. As complex **2** undergoes only the hydrolytic decomposition, an attempt was taken to study the dependence of the rate on the water percentage present in the reaction medium. So, at 30%, 50%, 60% and 70% of H_2O (v/v), the decomposition rates 1.3×10^{-04}, 9.5×10^{-04}, 1.80×10^{-03}, 1.9×10^{-03} and 1.9×10^{-03}, respectively, were found, increasing with the increase in water % and becoming constant at $H_2O > 50\%$.

3.4.2. Oxidation of ascorbic acid by *1*

As the hydrolytic decomposition rate for **2** is high, probably higher than its rate of reduction by ascorbic acid; kinetics of oxidation of ascorbic acid was followed only for **1**. At pH 4.50, a variation of H_2A concentration was carried out and a plot of k'_{obs} versus $[H_2A]_t$ yielded a non-linear curve with a decreasing slope (Fig. 7) and this curve is best described by Eq. (3). As complex **1** undergoes acid catalyzed decomposition, the respective decomposition rates at the experimental pHs, $k_{obs(d)}$, were calculated with the knowledge of k_0 and k_1. Thus the pseudo-first-order rate constants (k'_{obs}) corresponding to the electron transfer process were calculated as $k'_{obs} = k_{obs(t)} - k_{obs(d)}$, where, $k_{obs(t)}$ is the total rate constant, $k_{obs(d)}$ = decomposition rate constant.

$$k'_{obs} = \frac{2kQ[H_2A]}{1+Q[H_2A]} \tag{3}$$

Here, 2 is the stoichiometric factor manifesting that ascorbic acid acts as a $2e^-$ reducing agent. Such a dependence of rate on ascorbic acid concentration indicates that the reactions proceed through a rapid pre-equilibrium formation of an intermediate (inner- or outer-sphere type) followed by slower decomposition, and can best be represented, in general, by Eq. (4).

$$A + B \overset{Q}{\rightleftharpoons} C \overset{k}{\rightarrow} \text{products} \tag{4}$$

$$k_{obs} = \frac{kQ[B]}{1+Q[B]} \tag{4a}$$

Non-linear computer fitting of the experimental data to Eq. (4a) yields $k = (1.12\pm0.04)\times10^{-3}\ M^{-1}\ s^{-1}$ and $Q = 63\pm7\ M^{-1}$ for **1**.

The oxidation of ascorbic acid has been found to depend on the pH of the medium. pH variation experiments were carried out in the range pH 3.25–5.15 at $[H_2A]_t = 0.005$ M, where a strict first-order dependence of rate on H_2A is prevailing. The pK_a of ascorbic acid (Eq. (5)) is reported to be 3.91 in H_2O at 25 °C[1] and at pH 4.5 both H_2A and HA^- species are relevant in the reaction solutions.

$$H_2A \overset{K_a}{\rightleftharpoons} HA^- + H^+ \tag{5}$$

As we did not get any saturation of decomposition rate on $[H^+]$, even at ~0.20 M, it can safely be assumed that at pH ⩾ 3.0 the protonated species of **1** would be very low in concentration at our experimental pH range. The *p*H–rate profile thus is mainly governed by Eq. (5). Plots of pH versus $\log(k')(k' = k'_{obs}/2[\ H_2A]_t)$ are S-shaped curves (Fig. 8). It is interesting to note that such a plot for complex **1** follows the normal reactivity trend, i.e., k'_{obs} increases with an increase in pH, rendering HA^- as a more reactive species than H_2A. Considering all these facts a general reaction scheme applicable for complex **1** could be framed as:

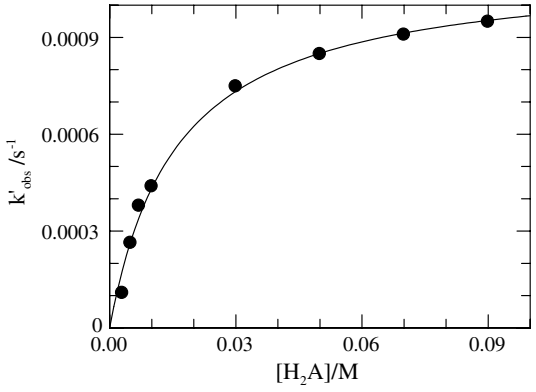

Fig. 7. Plots of k_{obs} vs. $[ascorbic\ acid]_t$ for the oxidation of ascorbic acid by complex **1** at pH 4.50 and 25 °C.

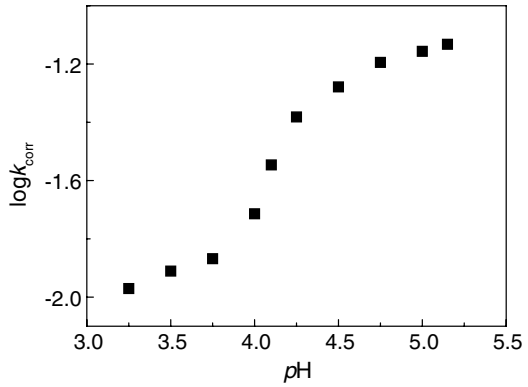

Fig. 8. Plots of $\log k_{corr}$ vs. pH for the oxidation of ascorbic acid by complex **1** at $[H_2A] = 0.005$ M.

$$[V^{V}(L^{1})(acac)] + H_2A \overset{Q_1}{\rightleftharpoons} \{[V^{V}(L^{1})(acac)], H_2A\} \overset{k_1}{\rightarrow} \{[V^{IV}(L^{1})(acac)], H_2A^{\cdot+}\} \overset{fast}{\rightarrow} HA^{\cdot} + \text{decomposition products} \quad (6)$$

$$[V^{V}(L^{1})(acac)] + H_2\ A^{-} \overset{Q_2}{\rightleftharpoons} \{[V^{V}(L^{1})(acac)], H_2A\}^{-} \overset{k_2}{\rightarrow} \{[V^{IV}(L^{1})(acac)], H_2A\} \overset{fast}{\rightarrow} HA^{\cdot} + \text{decomposition products} \quad (7)$$

$$[V^{V}(L^{1})(acac)] + HA^{\cdot} \overset{fast}{\rightarrow} \text{dehydroascorbic acid} + \text{decompostion products} \quad (8)$$

From the above reaction sequence (Eqs. (6)–(8)) the rate law (Eq. (9)) can be derived

$$k = \frac{k_1Q_1[H^+] + k_2Q_2K_{a^1}}{[H^+] + K_{a^1}} \quad (9)$$

A non-linear computer-fit program was used to fit the experimental data to Eq. (9) and the parameters thereby derived are:

$k_1Q_1 = (7.63 \pm 0.8) \times 10^{-3}$ $M^{-1}\,s^{-1}$, $k_2Q_2 = (1.02 \pm 0.03) \times 10^{-1}\,M^{-1}\,s^{-1}$ and $K_a{}^1 = (1.77 \pm 0.20) \times 10^{-5}$ M. ($pK_a{}^1 = 4.75$) for complex **1**. The pK_a value thus obtained is slightly higher than that of the reported value and this slight elevation in the pK_a value may be attributed to the H-bonding interaction of the dissociable proton with the vanadyl oxygen atom as well as with one of the phenolate oxygen atoms of the coordinated ligand. A similar elevation of the pK_a value in the ascorbic acid oxidation reactions was observed previously.

For complex **1**, the ratio $k_2Q_2/k_1Q_1 = 13.37$, which is very low compared to other reactions. In the absence of other factors like H-bonding, the $k(HA^-)/k(H_2A)$ ratio generally varies between 10^4 and 10^5 [28]. Such a low reactivity ratio implies that there is H-bonding between the OH proton of the ascorbic acid and the vanadyl oxygen atom, which provides a low energy pathway for the electron transfer process. This probability of H-bonding is more pronounced in the case of H_2A than HA^- i.e., $Q_1 > Q_2$ and thereby HA^- has a lower overall reactivity (k_2Q_2), and hence the observed reactivity trend. Similar observations were also encountered in the oxidation of ascorbic acid by several nickel(III) and nickel(IV) complexes of oxime-imine ligands [29]. One point that needs to be clarified in this study is the mechanistic route. Vanadium(IV/V) species generally react both by inner- and outer-sphere mechanisms [30]. However, no evidence for the formation of a stable intermediate was encountered during the spectral scanning of these reactions to support the inner-sphere route. Based on the higher Q values ($Q = 63$ for **1**), it can be concluded that these reactions probably proceed via an inner-sphere route, particularly through the formation of a hydrogen bonded adduct. Due to the lack of a self-exchange rate constant (k_{11}) for these complexes, it was not possible to calculate the theoretical outer-sphere rate constants by the application of the Marcus theory [31] to support or contradict this proposition.

4. Conclusion

(1) Complexes **1** and **2** were prepared by the reaction of equimolar quantities of $[VO(acac)_2]$ with H_2L^1 and H_2L^2 respectively in acetonitrile medium.
(2) The conductance measurements in acetonitrile showed very low conductivity (3 S for **1** and 5.7 S for **2**) indicating that both the complexes are electrically neutral.
(3) ^{51}V NMR both in solid and solution phases proved the presence of vanadium(V) species.
(4) Both complexes **1** and **2** showed reversible cyclic voltammeric responses with $E_{1/2} - 0.18$ and 0.10 V versus NHE, respectively.
(5) The kinetics of oxidation of ascorbic acid by complex **1** in 50% MeCN–50% H_2O (v/v) at 25 °C proceeds through pre-equilibrium formation of a H-bonded adduct and is manifested by high formation constant values ($Q = 63$), and is further supported by low k_2Q_2/k_1Q_1 ratios (13.37).

no splitting of the v_3 mode. Johan et al. published the position of the infrared bands of tunisite at 1155 cm^{-1} (v_1), 850 cm^{-1} (v_2), 1530 cm^{-1} (v_3) [7]. No band position was given for the (v_4) mode. For these minerals the position as determined by infrared spectroscopy of the water bands was not forthcoming.

Raman spectroscopy has proven very useful for the study of minerals [10–12]. Indeed Raman spectroscopy has proven most useful for the study of diagentically related minerals as often occurs with carbonate minerals [13–17]. Some previous studies have been undertaken by the authors using Raman spectroscopy to study complex secondary minerals formed by crystallisation from concentrated sulfate solutions [18]. Very few spectroscopic studies of the hydrated double carbonates have been forthcoming and what studies that are available are not new. Few Raman studies of any note are available [19,20]. The aim of this paper is to present Raman and infrared spectra of natural hydrated double carbonates including pirssonite, gaylussite and tunisite. The paper is a part of systematic studies of vibrational spectra of minerals of secondary origin in the oxide supergene zone and their synthetic analogs.

2. Experimental

2.1. Minerals

Selected minerals were obtained from the Mineralogical Research Company and other sources including Museum Victoria. The samples were phase analysed by X-ray diffraction and for chemical composition by EDX measurements.

The origin of the minerals are as follows:

Pirssonite – Green River, Sweetwater Co., Wyoming labelled as pirssonite 1.
Pirssonite – Searles Lake, San Bernardino Co., California labelled as pirssonite 3.
The mineral pirssonite 3 is a type mineral [21] and is used as a standard or reference mineral (please go to p. 552 of Ref. [21]).
Gaylussite – Teels Marsh, Esmeralda County, Nevada. Gaylussite is listed on p. 241 of Ref. [21].
Tunisite – near Condorcet, Drome, France (p. 716 of Ref. [21]).

2.2. Raman microprobe spectroscopy

The crystals of halogenated carbonates were placed and oriented on the stage of an Olympus BHSM microscope, equipped with 10× and 50× objectives and part of a Renishaw 1000 Raman microscope system, which also includes a monochromator, a filter system and a Charge Coupled Device (CCD). Raman spectra were excited by a HeNe laser (633 nm) at a resolution of 2 cm^{-1} in the range between 100 and 4000 cm^{-1}. Repeated acquisition using the highest magnification was accumulated to improve the signal to noise ratio. Spectra were calibrated using the 520.5 cm^{-1} line of a silicon wafer. In order to ensure that the correct spectra are obtained, the incident excitation radiation was scrambled. Previous studies by the authors provide more details of the experimental technique. Details of the technique have been published by the authors [22–25].

2.2.1. Mid-IR spectroscopy

Infrared spectra were obtained using a Nicolet Nexus 870 FTIR spectrometer with a smart endurance single bounce diamond ATR cell. Spectra over the 4000–525 cm^{-1} range were obtained by the co-addition of 64 scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectra were co-added to improve the signal to noise ratio.

Spectral manipulation such as baseline adjustment, smoothing and normalisation were performed using the Spectracalc software package GRAMS (Galactic Industries Corporation, NH, USA). Band component analysis was undertaken using the Jandel 'PEAKFIT' software package which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done using a Lorentz–Gauss cross-product function with the minimum number of component bands used for the fitting process. The Gauss–Lorentz ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations of r^2 greater than 0.995.

3. Results and discussion

The Raman spectra of two pirssonite minerals and gaylussite, shortite and quintinite in the 950–1450 cm^{-1} region are shown in Fig. 1. Adler and Kerr predicted from their infrared data that the carbonate units were crystallographically single units in the structure of pirssonite [8]. This was later confirmed by crytsallographic studies of synthetic pirssonite and gaylussite [26]. The Raman spectra of pirssonite as shown in Fig. 1a and b show a single intense band at around 1080 cm^{-1}. The position of this band is sample dependent. The band is observed at 1074 cm^{-1} for the second pirssonite mineral sample. A low intensity band at 1050 cm^{-1} is observed in the Raman spectrum and it is considered this band is a hot band. Adler and Kerr reported based on infrared spectra the position of the v_1 band as 1068 cm^{-1} [8]. The carbonate unit in galylussite is on a C_1 site and is crystallographically distinct. Thus no splitting of the carbonate bands should be observed. This is confirmed by a single Raman band for galylussite at 1078 cm^{-1}. Adler and Kerr did not report an infrared band for gaylussite in the v_1 position. In contrast the Raman spectrum of shortite (Fig. 1d) shows two Raman bands at 1070 and 1090 cm^{-1}. Adler and Kerr reported two infrared bands at 1069 and 1089 cm^{-1} in excellent agreement with the Raman data reported in this work [8].

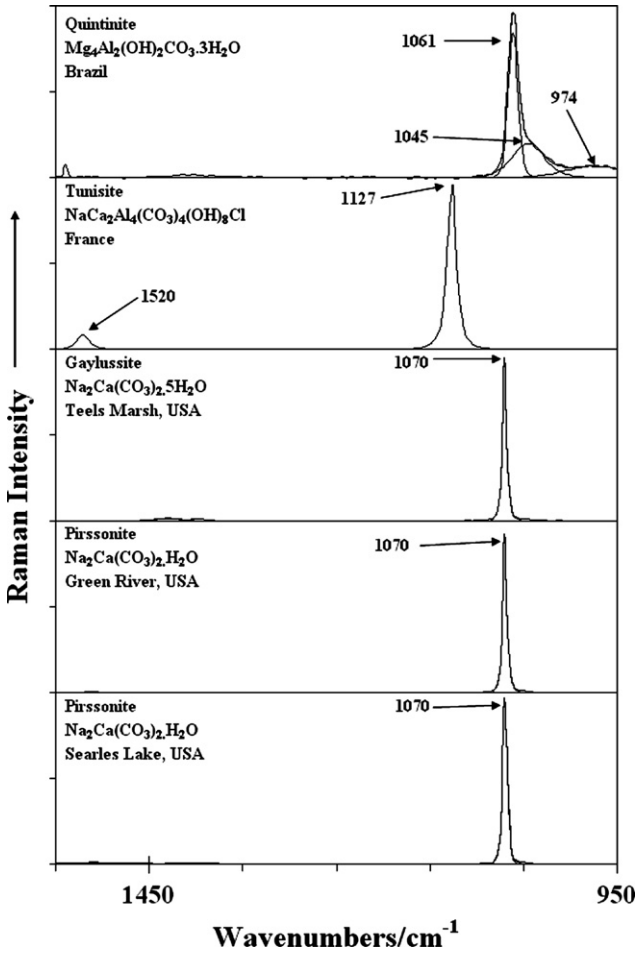

Fig. 1. Raman spectra of pirssonite (sample 1), pirssonite (sample 2), gaylussite, shortite, quintinite in the 950–1450 cm^{-1} region.

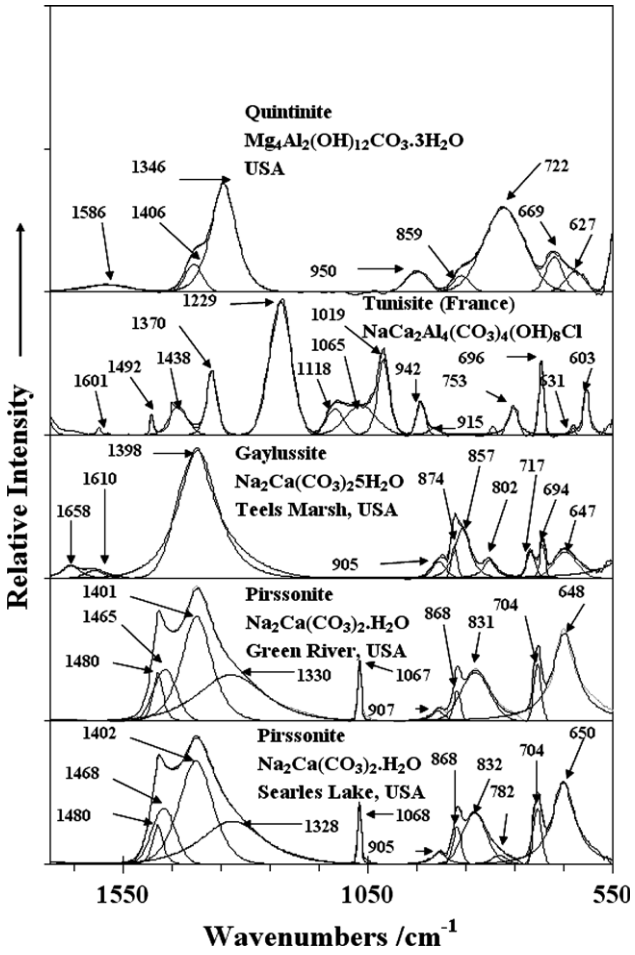

Fig. 2. Infrared spectra of pirssonite, gaylussite, tunisite, shortite and quintinite in the 550–1600 cm^{-1} region.

The Raman spectra of quintinite (a hydrotalcite) shows two bands at 1062 and 1050 cm^{-1} which may be attributed to $(CO_3)^{2-}$ symmetric stretching modes. Often the Raman spectra of carbonate in the interlayer of hydrotalcites show two or more bands for the symmetric stretching mode.

The infrared spectra of the minerals pirssonite, gaylussite, tunisite and quintite are reported in Fig. 2. The infrared spectra of pirssonite shows a low intensity band at 1067–8 cm^{-1} in close agreement with the results published by Adler and Kerr [8]. The observation of the Raman band supports the concept of distortion of the carbonate unit in pirsonite. No infrared band was observed in this position for gaylussite. In tunisite two bands are observed at 1065 and 1118 cm^{-1}. An infrared band was reported by Johan et al. for tunisite at 1155 cm^{-1} [7]. No infrared bands were observed for quintinite in this spectral region confirming the lack of distortion of the carbonate units in quintinite. This is expected since the carbonate units are held in the interlayer of the quintinite structure.

In the Raman spectrum of pirssonite three bands are observed at 1406, 1468 and 1511 cm^{-1}. These bands are assigned to the v_3 antisymmetric stretching modes. In the infrared spectra of pirssonite three bands are observed at 1402, 1465 and 1480 cm^{-1}. Adler and Kerr reported two infrared bands at 1414 and 1488 cm^{-1} [8]. Although the crystallographic data show there is only one crystallographically distinct carbonate unit in the structure of pirssonite, the observation of three antisymmetric stretching modes supports the concept that some carbonate units are distorted in the pirssonite structure. In contrast two Raman bands for gaylussite are observed for gaylussite at 1398 and 1429 cm^{-1}. In the infrared spectrum of gaylussite only a single broad band is observed at 1398 cm^{-1}. These results differ from that found by Adler and Kerr who found only a single infrared band at 1414 cm^{-1} for gaylussite. The low site symmetry of the carbonate unit in shortite results in the splitting of the v_3 antisymmetric stretching modes. Four Raman bands are observed at 1410, 1445, 1476 and 1511 cm^{-1}. Adler and Kerr found four infrared bands at 1410, 1453, 1481 and 1522 cm^{-1} [8]. For the mineral quintinite a very low intensity broad band at 1414 cm^{-1} is observed. In the infrared spectrum of quintinite three bands are observed at 1346, 1406 and 1586 cm^{-1}. The first two bands are assigned to the v_3 antisymmetric stretching modes whilst the intense band at 1346 cm^{-1} is ascribed to an OH deformation mode.

The Raman spectra of two pirssonite minerals and gaylussite, shortite and quintinite in the 100–950 cm^{-1} region are shown in Fig. 3. Further confirmation of the distortion of carbonate units in the pirssonite structure is obtained through the observation of the v_2 bending mode at around 879 cm^{-1}. Adler and Kerr reported an infrared band in this position in the infrared spectra [7]. For gaylussite a Raman band is observed at 898 cm^{-1} and is attributed to this assignment. This band for shortite is of very low intensity and is only observed through scale expansion. For quintinite low intensity bands are observed at 801 and 852 cm^{-1}. In contrast in the infrared spectra the band should show considerable intensity as may be observed in the infrared spectra of the double carbonates. The infrared spectra of pirssonite displays two bands at 832 and 868 cm^{-1}. Three bands for gaylussite are observed at 802, 857 and 874 cm^{-1}. The infrared spectrum of quintinite shows a broad band at 859 cm^{-1}.

The Raman spectrum of pirssonite shows two bands at 644 and 719 cm^{-1}. These bands are assigned to the v_4 $(CO_3)^{2-}$ bending modes. Adler and Kerr reported two infrared bands at 699 and 712 cm^{-1}. In the infrared spectra of pirssonite (Fig. 2) two bands are observed at 650 and 704 cm^{-1} in harmony with the position of the Raman results. For gaylussite three Raman bands are observed in this v_4 spectral region at 664, 699 and 719 cm^{-1}. Adler and Kerr reported only two bands in the infrared spectrum at 692 and 720 cm^{-1} [8]. Four Raman bands are observed for shortite at 695, 715, 719 and 730 cm^{-1}. Adler and Kerr reported four infrared bands at 693, 709, 719 and 730 cm^{-1} [8]. The observation of two symmetric stretching modes with different wavenumbers for shortite offers the distinction between two crystallographic different carbonate units. The low site symmetry of the carbonate unit in shortite results in the splitting of the v_4 bending modes. According to Farmer [1], the shortite structure is complex with the Ca^{2+} is 9 coordinated, one Na^{+} 8 coordinated and one Na^{+} 6 coordinated. In the structure of shortite there are two distinct $(CO_3)^{2-}$ units one on site symmetry C_{2v} and a second on a site C_s symmetry. This complexity is reflected in the Raman spectrum of shortite as shown in Fig. 1d. For the carbonate quintinite only a single low intensity band at 700 cm^{-1} is observed.

The Raman spectra of two pirssonite minerals and gaylussite, shortite and quintinite in the 3100–3800 cm^{-1} region are shown in Fig. 4. No Raman spectrum was

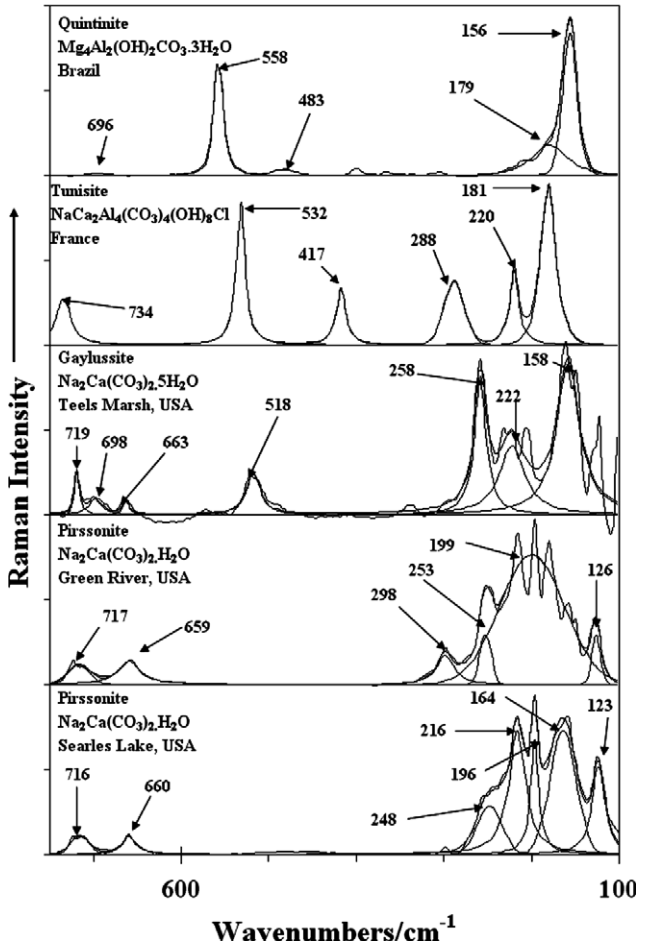

Fig. 3. Raman spectra of pirssonite (sample 1), pirssonite (sample 2), gaylussite, shortite, quintinite in the 100–950 cm^{-1} region.

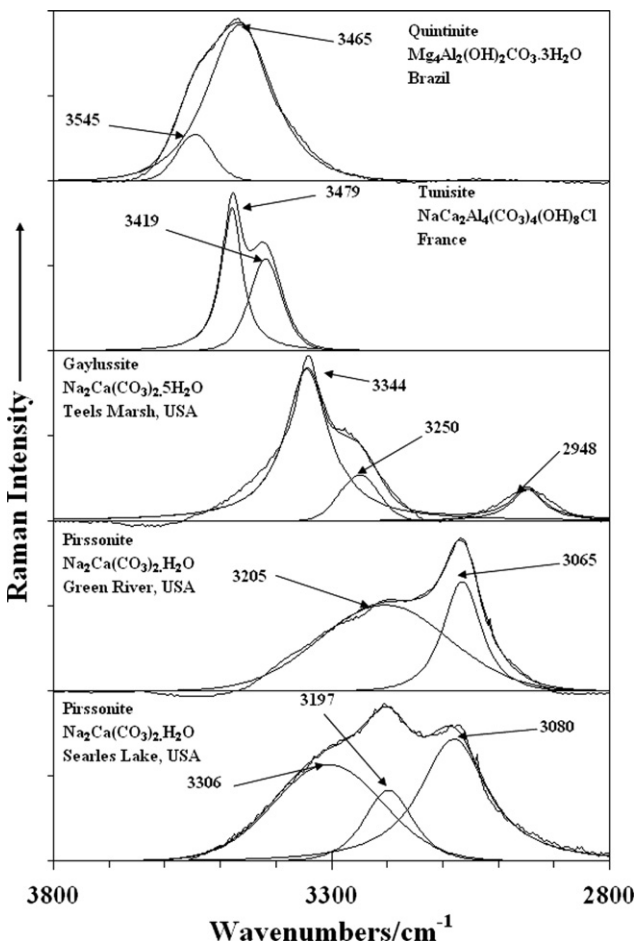

Fig. 4. Raman spectra of pirssonite (sample 1), pirssonite (sample 2), gaylussite, shortite, quintinite in the 3100–3800 cm^{-1} region.

observed for shortite in this spectral region as is expected. This confirms the shortite mineral is anhydrous. The Raman spectrum of pirssonite (sample 1) in the 2500–3700 cm^{-1} region show three bands at 3085, 3202, 3307 cm^{-1}. For the second pirssonite mineral three bands are observed at 3065, 3302 and 3284 cm^{-1}. In the infrared spectrum of pirssonite a complex system of overlapping bands is observed. This spectral region may be resolved into band components at 2954, 3058, 3188 and 3326 cm^{-1}. Adler and Kerr did not provide any information on the IR bands of the OH units for pirssonite or gaylussite in the OH stretching region. The Raman spectrum of gaylussite in the OH stretching region shows three bands at 2950, 3250 and 3347 cm^{-1}. In the infrared spectrum three bands at 2944, 3268 and 3334 cm^{-1} are observed (Fig. 5). For quintinite the Raman spectrum shows two bands at 3464 and 3546 cm^{-1}. In the infrared spectrum two bands at 3167 and 3373 cm^{-1} are observed.

Studies have shown a strong correlation between OH stretching frequencies and both O···O bond distances and H···O hydrogen bond distances [27–30]. Libowitzky (1999) showed that a regression function can be employed relating the hydroxyl stretching frequencies with regression coefficients better than 0.96 using infrared spectroscopy [31]. The function is described as: $v_1 = (3592 - 304) \times 109^{\frac{-d(O-O)}{0.1321}}$ cm^{-1}. Thus OH···O hydrogen bond distances may be calculated using the Libowitzky empirical function. Thus for pirssonite hydrogen bond distances from the infrared data of 2.639 Å (2954 cm^{-1}), 2.663 Å (3058 cm^{-1}), 2.699 Å (3188 cm^{-1}) and 2.755 Å (3326 cm^{-1}) are calculated. The Raman bands at 3085, 3202 and 3307 cm^{-1} provide values of 2.669, 2.75 and 2.746 Å. From the infrared bands of gaylussite at 2950, 3250 and 3347 cm^{-1} hydrogen bond distances of 2.639, 2.721 and 2.766 cm^{-1} are estimated. For the mineral quintinite, the IR bands at 3167 and 3373 cm^{-1} provide hydrogen bond distances of 2.693 and 2.780 Å. The Raman OH stretching band give slightly longer distances of 2.851 and 2.986 Å. The large variation hydrogen bond distances which are present in pirssonite and gaylussite can also be seen in other mixed anion minerals such as peisleyite where the distances ranging between 3.052 and 2.683 Å. Such hydrogen bond distances are typical of secondary minerals. For pirssonite and gaylussite hydrogen bond distances from 2.669 to 2.766 Å are observed. A range of hydrogen bond distances are observed from reasonably strong to weak hydrogen bonding. This range of hydrogen bonding contributes to the stability of the mineral.

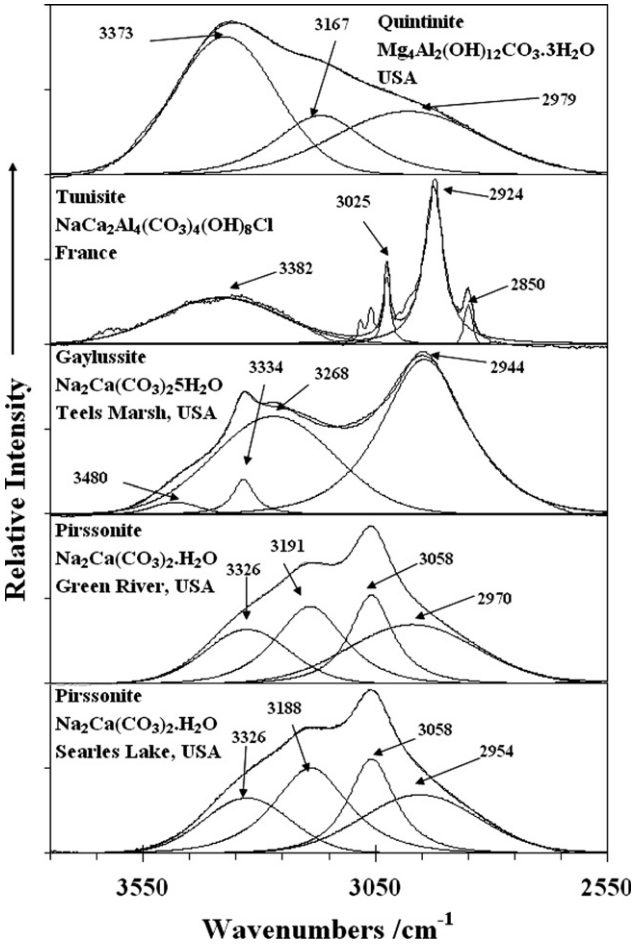

Fig. 5. Infrared spectra of pirssonite, gaylussite, tunisite and quintinite in the 2550–4000 cm^{-1} region.

4. Conclusions

The double carbonates pirssonite, gaylussite, tunisite and shortite were characterised by both Raman and infrared spectroscopy. These double carbonates are characterised by v_1 stretching bands around 1060–1080 cm^{-1}. The position of the band appears to be dependent on the symmetry of the carbonate units in the structure. For pirssonite and gaylussite only a single band is observed whilst for shortite and for comparison quintinite two bands are observed in the symmetric stretching region. This confirms the concept of more than one crystallographically distinct carbonate unit in the crystal. Multiple antisymmetric stretching modes are, however, observed for pirssonite indicating distortion of the carbonate unit in the crystal. This distortion is also observed by the number of bands in the v_4 in phase bending region where multiple bands are observed for pirssonite, gaylussite and shortite.

Acknowledgements

The financial and infra-structure support of the Queensland University of Technology, Inorganic Materials Research Program is gratefully acknowledged. The Australian Research Council (ARC) is thanked for funding the instrumentation. Mr. Dermot Henry of Museum Victoria is thanked for the loan of some of the carbonate minerals.

nucleases over enzymatic ones are well delineated: the former are smaller in size, rendering a fast stretching in the hindered sites of macromolecules. The redox properties of the metal and dioxygen as well are utilized for direct strand scission or base modification [33,34]. Multinuclear copper complexes seem to serve an important role [35–40].

Recently we have synthesized and characterized an octanuclear copper(II) complex of a N_2O_3-donor Schiff base which shows effective oxidative cleavage of plasmid DNA [35]. Herein, we report the synthesis, crystal structure and magnetic property of a tetranuclear copper(II) complex, $[Cu_4(L)_2(tp)(dmf)_2]$ (**1**) [H_3L = 1,3-bis(salicylideneamino)-propan-2-ol, tp = terephthalate, dmf = *N*,*N*′-dimethylformamide]. The variable temperature-dependent susceptibility measurement (2–300 K) of **1** reveals a dominant ferromagnetic coupling, $2J = 18.70\ cm^{-1}$. Complex **1** binds to double-stranded CT (calf-thymus) DNA giving a K_{app} value of $1.25 \times 10^7\ M^{-1}$ and displays efficient cleavage of supercoiled pUC19 DNA in the presence of H_2O_2 following a hydroxyl radical pathway.

2. Experimental

2.1. Materials and physical methods

All reagents and chemicals were purchased from commercial sources and were used without further purification. The ligand 1,3-bis(salicylideneamino)propan-2-ol (H_3L, Scheme 1) was prepared by a reported method [41]. The supercoiled (SC) pUC19 DNA (caesium chloride purified) was purchased from Bangalore Genie (India). The calf thymus (CT) DNA, agarose (molecular biology grade), distamycin and ethidium bromide (EB) were obtained from Sigma. Tris(hydroxymethyl)-aminomethane–HCl (Tris–HCl) buffer was prepared using deionized and sonicated triple distilled water. Solvents used for spectroscopic studies were purified and dried by standard procedures before use [42]. FT-IR spectra were obtained on a Nicolet MAGNA-IR 750 spectrometer with samples prepared as KBr pellets. Elemental analysis was carried out in a 2400 Series-II CHN Analyzer, Perkin–Elmer, USA. Variable temperature magnetic susceptibility and field dependence of magnetization measurements were performed on a Quantum Design MPMS XL-5 SQUID magnetometer. Absorption and luminescence spectra were studied on Shimadzu UV2100 UV–VIS recording spectrophotometer and Perkin–Elmer LS 55 luminescence spectrometer, respectively. Circular dichroic spectra of DNA were obtained by using JASCO J-815 automatic recording spectropolarimeter operating at 25 °C. The region between 220 and 320 nm was scanned for each sample.

Scheme 1. Schematic structure of H_3L.

CAUTION: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only a small amount of material should be prepared and handled with caution.

2.2. Synthesis of $[Cu_4(L)_2(tp)(dmf)_2]$ (1)

25 mL of a methanolic solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.29 g, 0.8 mmol) was added to a magnetically stirred 25 mL methanolic solution of the ligand (H_3L) (0.12 g, 0.4 mmol). The mixture was stirred for 15 min with addition of NEt_3 (0.11 mL, 0.8 mmol), whereby a deep green solution was formed. The disodium salt of terephthalate acid (Na_2tp) (0.04 g, 0.2 mmol) dissolved in 5 mL of water was then added slowly to the above mixture, the green solution was stirred for another 30 min, and after that the resulting solution was refluxed for 2 h. A precipitate appeared, which was filtered. The precipitate was washed with methanol and dried at room temperature. This was dissolved in DMF and the solution was gently warmed. The solution was again filtered and the filtrate was left at room temperature. Dark green colored prismatic single crystals of **1** for X-ray crystallography were obtained on slow evaporation of the filtrate after a few days. (Yield: 65%, 0.15 g). *Anal.* Calc. for $C_{48}H_{48}Cu_4N_6O_{12}$: C, 49.87; H, 4.15; N, 7.27. Found: C, 49.65; H, 3.97; N, 7.07%. FT-IR (KBr phase) (cm^{-1}): 3432 br, 2939 br, 1665 vs, 1640 vs, 1578 vs, 1451 s, 1386 vs, 1193 w, 1149 w, 754 m, 681 w, 576 w (br, broad; w, weak; m, medium; s, strong; vs, very strong).

2.3. X-ray crystallography

Crystal data for **1**, $C_{48}H_{48}Cu_4N_6O_{12}$, $M = 1155.11$, monoclinic, space group $P2_1/c$ (No. 14), $a = 12.123(1)$, $b = 17.823(2)$, $c = 11.737(1)$ Å, $\beta = 108.82(1)°$, $V = 2400.4(4)$ Å^3, $Z = 2$, $D_c = 1.598\ g\ cm^{-3}$, $F(000) = 1180$. Reflections measured 33 793, independent 5810 with $R_{int} = 0.047$. Empirical absorption correction, SADABS ($T_{max} = 1.00$, $T_{min} = 0.755$). Final R_2 (F^2, all reflections) = 0.056, $R_{2w} = 0.084$, conventional $R_1 = 0.035$ for 334 parameters, GoF = 1.01. Bruker SMART CCD area-detector, Mo Kα radiation ($\lambda = 0.71073$ Å), $T = 150$ K, ω scan mode, $\theta_{min} = 3°$, $\theta_{max} = 28.00°$. The structure was solved by direct methods (SHELXS) and refined by full-matrix least squares with anisotropic thermal parameters for non-hydrogen atoms. Hydrogen atoms were partly refined with fixed isotropic thermal parameters, and partly placed in calculated positions. Atoms H1–H6 cannot be placed in ideal positions because carbon atoms C23 and C24 are bonded to an sp^2 nitrogen atom. Atoms H1–H6 can be placed in staggered positions in two ways, and there is no manner to predict which one is correct. Therefore, it is necessary to find them in the Fourier map and at this point there is no indication that they cannot be refined isotropi-

cally, as we have done. The program used was Personal SDP on a Pentium III PC.

2.4. DNA-binding and cleavage experiments

The concentration of CT DNA was determined from the absorption intensity at 260 nm with a known ε value of 6600 M^{-1} cm^{-1} [43]. The binding of **1** to CT DNA has been studied by the fluorescence spectral method using the emission intensity of EB. The apparent binding constant, K_{app}, for **1** was estimated by the equation: $K_{EB}[EB] = K_{app}[complex]$ where K_{EB} is 1.0×10^7 M^{-1} [44].

The DNA cleavage experiment was done by agarose gel electrophoresis. Supercoiled (SC) pUC19 DNA (2.5 μL, 0.5 μg) in Tris–HCl buffer (50 mM, pH 7.2) containing NaCl (50 mM) was treated with complex **1** in the presence or absence of additives. The DNA cleavage by **1** (10–35 μM) was studied in the presence of H_2O_2 (60–80 μM). The experimental samples were incubated first for 60 min at 37 °C and after that loading buffer (25% bromophenol, 30% glycerol (3 μL), 0.25% xylene cyanol) was added. It was finally loaded on 1% agarose gel containing 1.0 μg mL^{-1} EB. Electrophoresis was carried out at 40 V for 2.0 h in tris-acetate EDTA (TAE) buffer. The cleavage activity was measured by determining the ability of **1** in relaxing the SC DNA to its nicked circular (NC) form. Bands were visualized by UV light and photographed. The proportion of DNA in the SC and NC forms after electrophoresis was estimated quantitatively from the intensities of the bands by using a UVITEC Gel Documentation System with due correction of the low level of NC present in the original sample and the low affinity of EB binding to SC compared to NC forms of DNA [45]. Control experiments were done using different reagents such as DMSO (4 μL), distamycin (100 μM), NaN_3 (5 mM), 3-mercaptopropionic acid (MPA, 5 mM) and dithiothreitol (DTT, 5 mM) added to SC DNA prior to the addition of **1**.

3. Results and discussion

3.1. Crystal structure of *1*

Complex **1** is centrosymmetric and crystallizes from *N*,*N*-dimethylformamide in the monoclinic system, space group $P2_1/c$ (No. 14). The dinucleating pentadentate character of the ligand (H_3L) and the desired pair-of-dimers arrangement, through the incorporation of the bridging terephthalate moiety, is clearly evident and shown in Fig. 1. The copper atoms are coordinated in a slightly distorted square pyramidal arrangement within each dinucleating half of the complex and bridged mono-atomically by the secondary alkoxo oxygen of the ligand and di-atomically by the terephthalate moiety. The apical position is occupied by the oxygen atom (O(6)) of the dmf (*N*,*N*′-dimethylformamide). The dmf molecule bridges two copper atoms (Cu(1) and Cu(2)) of each dinucleating half by a μ_2-oxygen atom in an unsymmetrical manner. The distances between Cu(1)–O(6) and Cu(2)–O(6) are 2.345(2) and 2.565(2) Å, respectively. This is comparable to the Cu–O distances in some of the reported DMF coordinated complexes [46–50]. The dihedral angle between the [$CuNO_3$] moieties is 115.2(1)°, and a consequent bending of the molecule from coplanarity is evident. The intramolecular distance between Cu(1) and Cu(2) of each dinucleating half is 3.076(1) Å. This is comparable to the Cu–Cu distances in some of the terephthalate bridged complexes [51,52]. The Cu(1)–O(2)–Cu(2) bridging angle is 104.3(1)° and the angle at which the plane of the terephthalate moiety intersects the plane encompassing the Cu(1)–O(2)–Cu(2) bridge is 103.2(1)°. The pertinent across-terephthalate intramolecular copper-to-copper separations are Cu(1)–Cu(1A) 11.187(1) Å, Cu(2)–Cu(2A) 11.204(1) Å and Cu(1)–Cu(2A) 10.765(1) Å. Further important bond lengths and angles are given in Table 1.

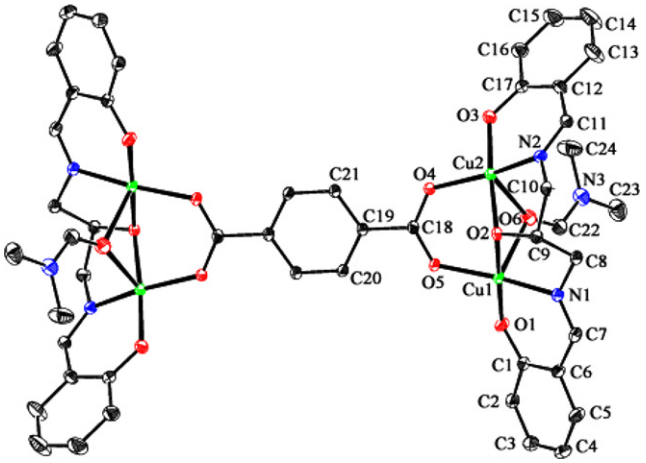

Fig. 1. ORTEP drawing and atom numbering scheme for $[Cu_4(L)_2(tp)(dmf)_2]$ (**1**), (H atoms are omitted for clarity).

The concept that C–H–O interactions exist as significant secondary interactions, and occasionally assumes the dominant interaction [53] in molecular solids is now well established [54,55]. Fig. 2 shows the molecular packing for **1** in

3.2. Magnetic property

The magnetic susceptibility of complex **1** has been measured in the temperature range 300–2 K under an external field of 1000 Oe. The temperature dependence of χ_M of the $[Cu_2L]$ unit is shown in Fig. 3a. Upon cooling, χ_M increases reaching a maximum of 68.16×10^{-2} cm^3 mol^{-1} at around 2 K. The observed $\chi_M T$ product at room temperature (300 K), 1.04 cm^3 mol^{-1} K, is larger than the spin-only values of 0.75 cm^3 mol^{-1} K expected for two isolated copper(II) ions ($S = 1/2$) assuming $g = 2.00$. As the temperature is lowered, the $\chi_M T$ value continuously increases and reaches a value of 1.04 cm^3 mol^{-1} K at 2 K. Such behavior is characteristic of a dominant ferromagnetic interaction in complex **1**. This ferromagnetic interaction between the Cu^{2+} ions is probably due to the lower Cu1–O6–Cu2 angle (77.44(5)°), quite far from 90°, of the DMF bridged copper ions.

$$\chi = \frac{Ng^2\beta^2}{kT}\left[3 + \exp\left(\frac{-2J}{kT}\right)\right]^{-1}(1-P) + \frac{Ng^2\beta^2 P}{4kT} + N_\alpha \quad (1)$$

The data were first treated by applying a modified Bleaney and Bowers [58] Eq. (1), calculated for two $S = 1/2$ centers under a $-2JS_1S_2$ spin Hamiltonian, using a non-linear least-squares fitting routine which assumes that the two dinuclear moieties have no cross-ligand (H_3L) coupling, as would be expected. All the symbols in Eq. (1) have their usual meaning and P is the fraction of monomeric impu-

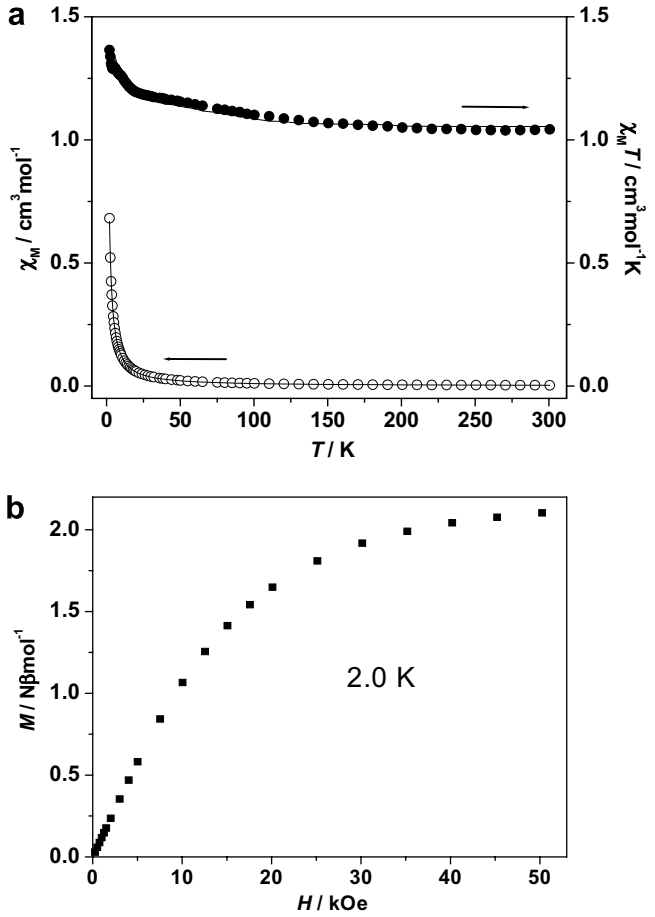

Fig. 3. (a) χ_M and $\chi_M T$ vs. T (□) under an applied magnetic field of 1000 Oe for **1** from 2 to 300 K. (b) The field dependent magnetization (■) at 2 K up to 50 KOe.

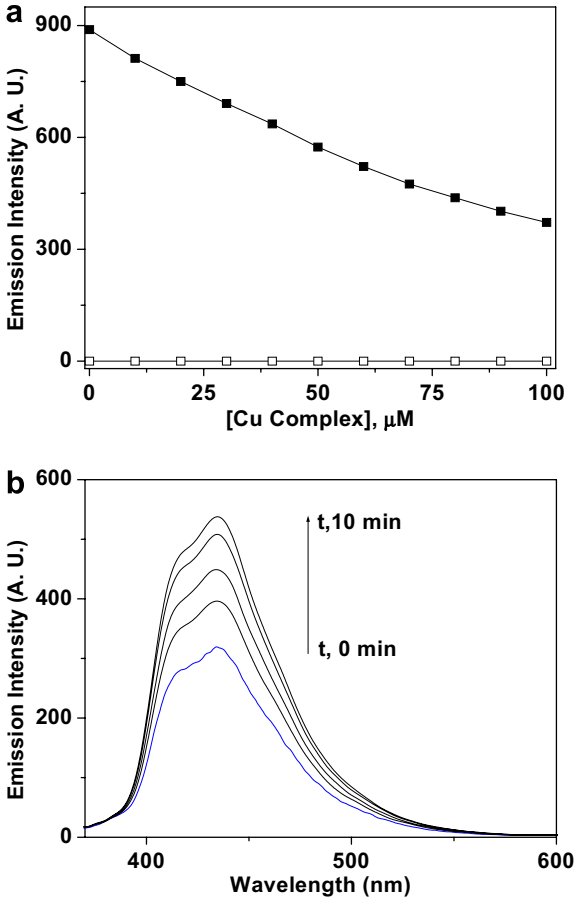

Fig. 4. (a) The effect of addition of complex **1** (■) on the emission intensity of 50 μM CT DNA-bound ethidium bromide in Tris–HCl/NaCl buffer (50 mM, pH 7.2) at 25 °C; (□) on the emission intensity of the ethidium bromide in absence of CT DNA but at different concentrations of **1**. (b) Emission spectra of complex **1** (10 μM) in the presence of CT DNA (397 μM) showing enhancement of intensity at 435 nm (excitation wavelength: 340 nm) with time in Tris–HCl/NaCl buffer (50 mM, pH 7.2). Blue line indicates the emission of **1**. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

rity. An excellent fit was obtained (Fig. 3a) using the parameter values $g = 2.24$, $2J = 18.70\ \text{cm}^{-1}$, $P = 0.012$ and $N_\alpha = 20 \times 10^{-6}\ \text{cm}^3\ \text{mol}^{-1}$. The field dependent magnetization at 2 K up to 50 KOe was also measured (Fig. 3b) with $M = 2.1\ \mu_B$ at 50 KOe, slightly larger than the $M_S = 2\ \mu_B$ for two isolated Cu^{2+} ions, confirming the dominant ferromagnetic coupling.

3.3. DNA-binding and cleavage studies

The binding of **1** to CT DNA has been studied by the fluorescence spectral method using the emission intensity of EB. EB does not show any emission in buffer medium due to fluorescence quenching by solvent molecules [59]. In the presence of CT DNA, it shows emission due to its intercalative binding to DNA. Addition of **1** results in the competitive binding to DNA, causing a reduction of the emission intensity. This is due to the displacement of EB from the DNA bound state to the free state, and the copper(II) complex from the free state to the DNA bound state. We have measured the reduction of emission intensity of EB at different concentrations of **1**, as shown in Fig. 4a. The apparent binding constant (K_{app}) has been calculated from the equation: $K_{EB}[EB] = K_{app}[complex]$, ($Kapp(EB) = 1.0 \times 10^7\ M^{-1}$) and the concentration of EB is 50 μM. The concentration of the complex is taken for observing 50% reduction of the emission intensity of EB [44]. The K_{app} value for complex **1** is estimated as $1.25 \times 10^7\ M^{-1}$ and is comparable to reported values [35,36].

Complex **1** is emissive at 435 nm (340 nm excitation) in Tris–HCl/NaCl buffer (50 mM, pH 7.2). The emission spectral changes of **1** in the presence of CT DNA have been studied. The emission intensity is found to increase with time until it reaches a constant value after *ca.* 10 min (Fig. 4b). The corresponding enhancement (at 435 nm) with longer times is due to significant intercalative binding [35].

Fig. 5 displays the CD spectra of CT DNA treated with **1** with the ratio of 0.1, 0.3, 0.5 and 0.7 (complex/DNA). Both the positive (~275 nm) and negative (~245 nm)

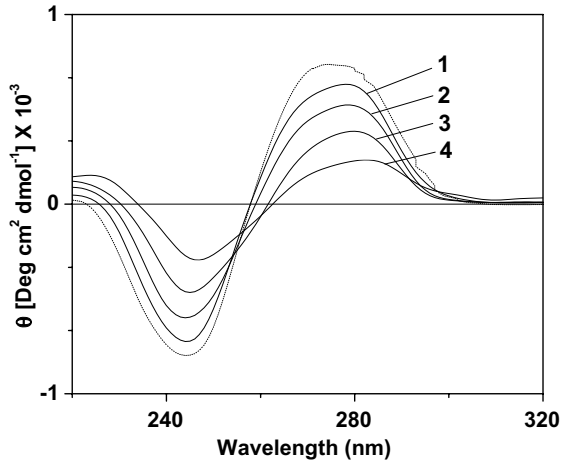

Fig. 5. CD spectra of CT DNA (100 μM) in the absence (·····) and presence (—) of complex **1** at the ratio [Cu complex]/[DNA] = 1:0.1, 2:0.3, 3:0.5 and 4:0.7.

bands decreased in intensity with the increase of the complex concentration. This suggests the Cu complex can unwind the DNA helix and lead to loss of helicity [60]. From the results of fluorescence and CD spectroscopic studies, one can conclude that **1** effectively binds to CT DNA.

A question may hang about the exact nature of the complex species involved in binding. The diffuse reflectance spectrum of **1** at 694 nm shows the characteristics of a CuO_4N core with the copper ion in a square pyramidal environment. In the working buffer medium, the electronic spectrum shows a blue shift of *ca.* 24 nm (Fig. 6). This is quite significant and indicates a modification of the coordination sphere of the metal ion during the intercalative interaction. In order to confirm that the complex remains in the solvent, the electron spray mass spectrum of **1** was obtained in water. The spectrum (Fig. 7) shows a peak at 1008.8 that can be assigned to the tetranuclear species $[Cu_4(L)_2(tp)]$ which corroborates the presence of the tetra-

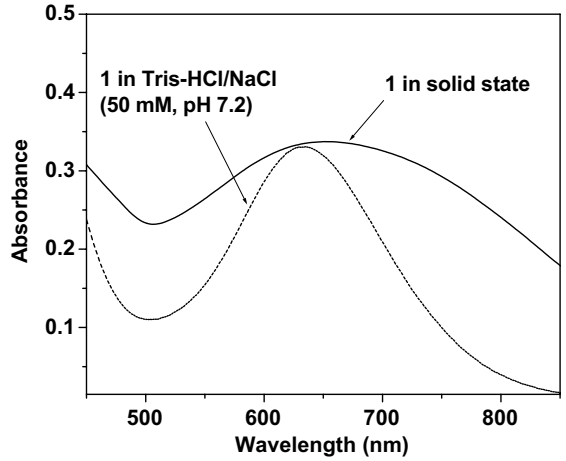

Fig. 6. Absorption spectra of **1** in the solid state and in Tris–HCl/NaCl buffer (50 mM, pH 7.2).

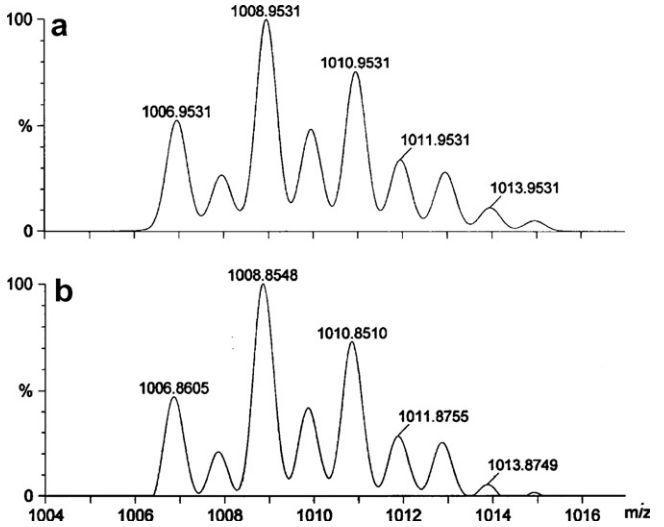

Fig. 7. Electron spray mass spectrum of **1** shows a peak at 1008.8 that can be assigned to the tetranuclear species $[Cu_4(L)_2(tp)]$. The isotopic distributions for the above molecular species in water obtained experimentally (a) correspond to the simulated patterns (b).

nuclear complex entity in solution with a modification of the coordination sphere of the metal ion. The isotopic distributions for the above molecular species in water obtained experimentally correspond to the simulated patterns (Fig. 7).

The ability of complex **1** to perform DNA cleavage has been studied by gel electrophoresis using supercoiled (SC) pUC19 DNA in Tris–HCl/NaCl buffer (50 mM, pH 7.2). The tetranuclear copper(II) complex on reaction with DNA in the presence of H_2O_2 as an oxidizing agent presents high nuclease activity (Fig. 8). In the presence of MPA (3-mercaptopropionic acid) and DTT (dithiothreitol), the compound is inactive towards any cleavage. A 35 μM solution of **1** cleaves SC DNA (0.5 μg) to the extent of ~94% on treatment with 60 μM H_2O_2. A significant cleavage (~83%) is also observed at 30 μM complex concentration using 60 μM H_2O_2. **1** could mediate the conversion of most of the supercoiled DNA to the nicked form at 35 μM, and it could not induce the conversion of SC to the

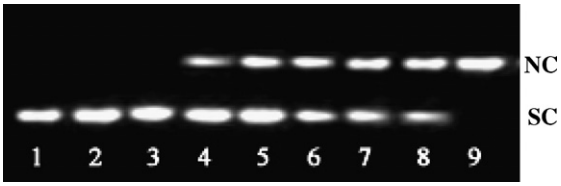

Fig. 8. Agarose gel electrophoresis diagram showing the cleavage of SC pUC19 DNA (0.5 μg) by complex **1**treated with various concentrations of H_2O_2in Tris–HCl/NaCl buffer (50 mM, pH 7.2). Incubation time: 1 h (37 °C). Lane 1: DNA control; lane 2: DNA + H_2O_2 (80 μM); lane 3: DNA + **1** (35 μM); lane 4: DNA + H_2O_2 (80 μM) + **1** (5 μM); lane 5: DNA + H_2O_2 (80 μM) + **1** (10 μM); lane 6: DNA + H_2O_2 (80 μM) + **1** (20 μM); lane 7: DNA + H_2O_2 (60 μM) + **1** (20 μM); lane 8: DNA + H_2O_2 (60 μM) + **1** (30 μM). lane 9: DNA + H_2O_2 (60 μM) + **1** (35 μM).

linear form at the tested concentrations DNA cleavage data of SC pUC19 DNA by **1** on treatment with hydrogen peroxide are given in Table 3. In fact a comparison of lanes 3 and 4 [DNA + H_2O_2 (60 μM) + $CuCl_2 \cdot 2H_2O$ (30 μM); DNA + H_2O_2 (60 μM) + $CuCl_2 \cdot 2H_2O$ (40 μM), respectively] with lane 6 [DNA + H_2O_2 (60 μM) + **1** (35 μM)] shows that **1** cleaves completely the SC DNA to NC (nicked circular) DNA while the Cu(II) salt shows only ~4–8% cleavage (Fig. 9). The control experiments, under aerobic conditions, show that H_2O_2 (80 μM) or **1** (35 μM) alone is cleavage inactive. DNA cleavage data by **1** in the presence of potential inhibitors and the copper(II) salt are given in Table 4. Control experiments also show that the addition of distamycin completely inhibits the cleavage of SC DNA which indirectly supports the minor groove binding of **1** (lane 5, Fig. 9).

Experiments with different scavenging agents were carried out to identify the intermediate reactive oxygen species (ROS) that might be formed in the DNA cleavage reaction (Fig. 10). The addition of NaN_3 to the system was found to have little effect on DNA cleavage, suggesting that singlet oxygen and H_2O_2 are not the effective ROS for the cleavage. The addition of 4 μL and 6 μL DMSO could inhibit

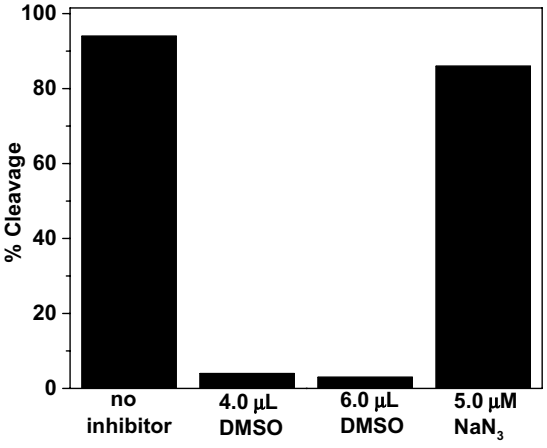

Fig. 10. Histogram representing overall strand scission (nicked form) of pUC19 plasmid DNA by **1** (35 μM) and H_2O_2 (60 μM) in the presence of standard radical scavengers.

completely the cleavage process mediated by **1**. This suggests the possible involvement of diffusible hydroxyl radicals (HO•) as the reactive species. Moreover, since the complex is not able per se to induce any effect on double-stranded DNA (Fig. 8), it appears that an oxidizing agent is required for producing the cleavage process.

To better understand the mechanism of the cleavage reaction we studied the visible spectral changes on addition of H_2O_2 to an aqueous solution of **1**. The absorption maximum ($\lambda_{max} = 635$ nm) due to the d–d transition decreased with increasing concentration of H_2O_2 (Fig. 11). This result suggests that the Cu(II) in the complex is reduced to Cu(I) by H_2O_2. For this reduction process we propose the following mechanism: [61]

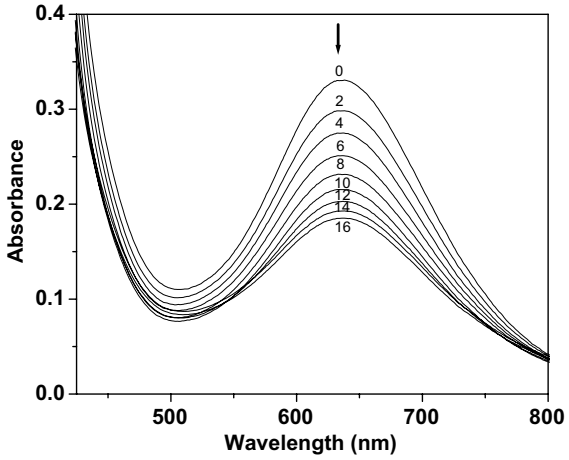

Fig. 11. Visible spectral changes of **1** (1.3 mM) in aqueous solution by addition of different amounts of H_2O_2. 2, 4, 6, 8, 10, 12, 14 and 16 μL of H_2O_2 35%.

$$Cu^{II}(L) + H_2O_2 \rightarrow Cu^{I}(L) + 2H^+ + O_2^-$$

The hydroxyl radicals involved in the cleavage process can be generated from the Cu(I) compound by a Fenton or a Haber–Weiss mechanism:

$$Cu^{I}(L) + H_2O_2 \rightarrow Cu^{II}(L) + HO^{\cdot} + OH^-$$

$$Cu^{I}(L) + O_2 \rightarrow Cu^{II}(L) + O_2^-$$

$$O_2^- + H_2O_2 \rightarrow O_2 + HO^{\cdot} + OH^-$$

On comparison of the cleavage property with some reported results [35,62,63] of Cu(II) complexes, we note that a lesser amount of oxidizing agents (here hydrogen peroxide) and complex are required in our case for maximum cleavage of DNA. The cleavage data clearly show that more than 90% cleavage occurs with a very small amount of complex concentration (35 μM).

4. Conclusions

A new terephthalate-bridged tetranuclear copper(II) metallointercalator (**1**) derived from a N_2O_3-donor Schiff base ligand H_3L has been synthesized and structurally characterized by X-ray crystallography. The copper atoms are coordinated in a slightly distorted square pyramidal arrangement within each dinucleating half of the complex, and bridged mono-atomically by the secondary alkoxo oxygen of the ligand and di-atomically by the terephthalate moiety. The apical position is occupied by the oxygen atom of dmf. The structure of **1** reveals a short intramolecular Cu–Cu separation (*ca.* 3.1 Å), in combination with long intramolecular copper separations (*ca.* 11 Å). The variable temperature-dependent susceptibility measurement (2–300 K) of **1** reveals a dominant ferromagnetic coupling, $2J = 18.70\ cm^{-1}$. Complex **1** binds to double-stranded CT (calf-thymus) DNA with a K_{app} value of $1.25 \times 10^7\ M^{-1}$ and displays efficient cleavage of supercoiled pUC19 DNA in the presence of H_2O_2 following a hydroxyl radical pathway. The results are of significance in designing a new transition metal complex based on a simple Schiff base ligand as an inorganic complex nuclease.

Scheme 1.

3. Synthesis and spectroscopic data for compounds III–VII

The complexes of 2,3-pyridine dicarboxylic acid (LH_2) **III–V** and of pyromellitic acid (L_1H_4) were prepared by the reaction procedure given below. All the compounds **III–VII** gave satisfactory elemental analysis when analyzed in the crystalline form; however, for compounds **V–VII** in bulk, a deviation was observed probably due to solvent of crystallization.

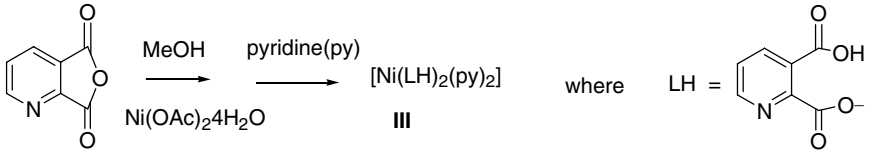
$[Ni(LH)_2(H_2O)_2(py)_2]$ (py = pyridine) (**III**): To a solution of 2,3-pyridine dicarboxylic anhydride (0.3 g, 2 mmol) dissolved in methanol (10 ml, at 60 °C) a solution of nickel(II) acetate tetrahydrate (0.248 g, 1 mmol) in methanol (10 ml) was added. The reaction mixture was stirred at room temperature for half an hour and to this mixture pyridine (abbreviated as py) (0.16 g, 2 mmol) was added. The resulting solution on standing gave pink crystals after 4 days (yield 35%). IR (KBr, cm^{-1}): 3414(bs), 1712(m), 1599(m), 1559(s), 1480(s), 1441(s), 1418(m), 1369(s), 1275(s), 1210(s), 1152(m), 1135(m), 1101(s), 1062(m), 871(m), 847(m), 823(m), 754(s), 703(s), 665(s), 629(s), 499(s). Elemental *Anal*. Calc. for $C_{24}H_{18}N_4NiO_8$: C, 52.45; H, 3.28. Found: C, 52.46; H, 3.32%.

$[Co(LH)_2(H_2O)_2$ (**IV**): Compound **IV** was prepared in an analogous manner to **III** by the reaction of 2,3-pyridine dicarboxylic anhydride with cobalt(II)acetate tetrahydrate, but without treatment with pyridine. Yield 86%. IR (KBr, cm^{-1}): 3411(bs), 1675(s), 1562(s), 1440(s), 1373(s), 1265(m), 1178(m), 1102(s), 871(w), 758(m), 661(s), 513(m). Elemental *Anal*. Calc. for $C_{14}H_{12}CoN_2O_{10}$: C, 39.33; H, 2.81. Found: C, 39.41; H, 2.84%.

$[\{Zn_2(L)_3\}bpyH_2.3H_2O]_n$ (bpy = 4, 4′-bipyridine) (**V**): A solution of 2,3-pyridine dicarboxylic anhydride (0.3 g, 2 mmol) was prepared in methanol (10 ml, at 60 °C). To this solution a solution of zinc(II) acetate dihydrate (0.22 g, 1 mmol) in methanol (5 ml) was added. The reaction mixture was stirred at room temperature for half an hour and to this mixture 4,4′-bipyridine (abbreviated as bpy) (0.16 g, 2 mmol) was added. A white precipitate appeared. The precipitate dissolved on addition of water (10 ml) and a white crystalline zinc complex was obtained after 7 days (yield 64%). ^{1}HNMR (DMSO-d_6): 8.67 (t, 4H, $J = 12$ Hz), 8.39 (m, 1H), 8.23 (m, 2H), 8.10 (m, 1H), 7.86 (m, 1H), 7.6 (dm, 4H, $J = 12$ Hz). IR (KBr, cm^{-1}): 3375(bs), 3055(w), 1626(s), 1579(s), 1450(w), 1374(s), 1270(w), 1111(m), 964(m), 813(s), 750(w), 708(m), 678(m), 504(w).

$[Cu(phen)_2Cl]L_1H_3$ (phen = 1,10-phenathroline) (**VI**): Pyromellitic dianhydride (0.218 g, 1 mmol) was dissolved in methanol (10 ml) by stirring for 10 min. A solution of copper (II) chloride dihydrate (0.170 g, 1 mmol) in methanol (5 ml) was added to this solution and stirred further for 10 min. The solution turned green. To this a solution of 1,10-phenanthroline (0.396 g, 2 mmol) in methanol (2 ml) was added and stirred for 1 h. The solution became intense bluish green, with slight turbidity. The solution was left standing for crystallization. After three days green crystals appeared (yield 40%). IR (KBr, cm^{-1}): 3445(w), 3071(w), 1738(s), 1705(s), 1583(s), 1520(s), 1447(s), 1431(s), 1367(s), 1347(s), 1267(s), 11489(m), 1120(s), 1107(s), 995(s), 945(s), 852(s), 721(s), 632(s). UV–Vis λ_{max} (methanol): 735 nm ($\varepsilon = 155\ M^{-1}\ cm^2$) (see Table 1).

$[Cu_2(phen)_4L_1]4H_2O$ (**VII**): To a solution of pyromellitic dianhydride (0.218 g, 1 mmol) dissolved in methanol (10 ml) a solution of cupric acetate monohydrate (0.199 g, 1 mmol) in methanol (5 ml) was added and stirred for 15 min. A blue colored turbid solution appeared. To this a solution of 1,10-phenanthroline (0.396 g, 2 mmol) in methanol (2 ml) was added. The solution became slightly turbid. The solution was stirred overnight, filtered and was allowed to crystallize. After four days blue colored crystals appeared (yield 34%). IR (KBr, cm^{-1}): 3391(bs), 1738(w), 1717(s), 1590(s), 1518(m), 1427(m), 1394(m), 1360(s), 1345(s), 1251(s), 1241(s), 1107(s), 851(s), 811(m), 722(s). UV–Vis λ_{max} (methanol): 737 nm ($\varepsilon = 172.8\ M^{-1}\ cm^2$).



4. Results and discussions

The reaction of 2,3-pyridine dicarboxylic anhydride with first row transition metal acetates of cobalt, nickel and zinc in methanol leads to metal dicarboxylate complexes. These reactions are found to be metal dependent and in none of the cases studied here we could obtain methyl ester containing metal complexes. However, in the absence of metal salts we observed the formation of methyl ester from the reaction of methanol with 2,3-pyridine dicarboxylic anhydride. The reaction of nickel (II) acetate tetrahydrate with 2,3-pyridine dicarboxylic anhydride in methanol followed by treatment with pyridine gave the mono-nuclear nickel complex (**III**), as illustrated in Scheme 2. The structure of the complex is shown in Fig. 1. It has a six coordination environment around the nickel ion with two chelating ligands derived from the 2,3-pyridine dicarboxylato mono anion and two pyridine ligands. The pyridine molecules occupy *trans* positions in the distorted octahedral geometry.

It was observed earlier [5a] that the reaction of phthalic anhydride with nickel acetate along with pyridine in

Scheme 2.

methanol gives the corresponding nickel carboxylato complex of the mono-esterified dicarboxylic acid. These results and the present observations on only the hydrolytic product formation from 2,3-pyridine dicarboxylic anhydride clearly support the coordination effect of the pyridine nitrogen atom in the reaction of nickel(II) acetate tetrahydrate with 2,3-pyridine dicarboxylic anhydride. Complex **III** shows strong intramolecular hydrogen bonding between the OH group of the neutral carboxylic acid and the carbonyl oxygen of another coordinating carboxylato group. The intramolecular hydrogen bonding parameters are d_{D-A} 2.413 Å, d_{D-H} 0.927 Å and ∠D–H···A 173.14 °.

A similar reaction of cobalt(II) acetate tetrahydrate with 2,3-pyridine dicarboxylic anhydride gave a chelated complex with the composition $[Co(LH)_2(H_2O)_2]$ (**IV**). The complex has a six coordination geometry, with the two water molecules occupying *trans*-positions with respect to each other. The structure of the complex is shown in Fig. 2. The complex has intra-molecular hydrogen bonding, O3–H···O2 (d_{D-A} 2.399 Å and ∠D–H···A 179.35°).

The reaction between zinc(II) acetate with 2,3-pyridine dicarboxylic anhydride in methanol followed by treatment with 4,4′-bipyridine gave a polymeric zinc complex (**V**) having the composition $[\{Zn_2(L)_3\}bpyH_2 \cdot 3H_2O]_n$, where L = the 2,3-pyridine dicarboxylato dianion and $bpyH_2$ = the 4,4′-bipyridinium dication, n is an integer. In this case also no methyl-ester was observed. The backbone of the polymer is shown in Fig. 3b. In this complex each zinc

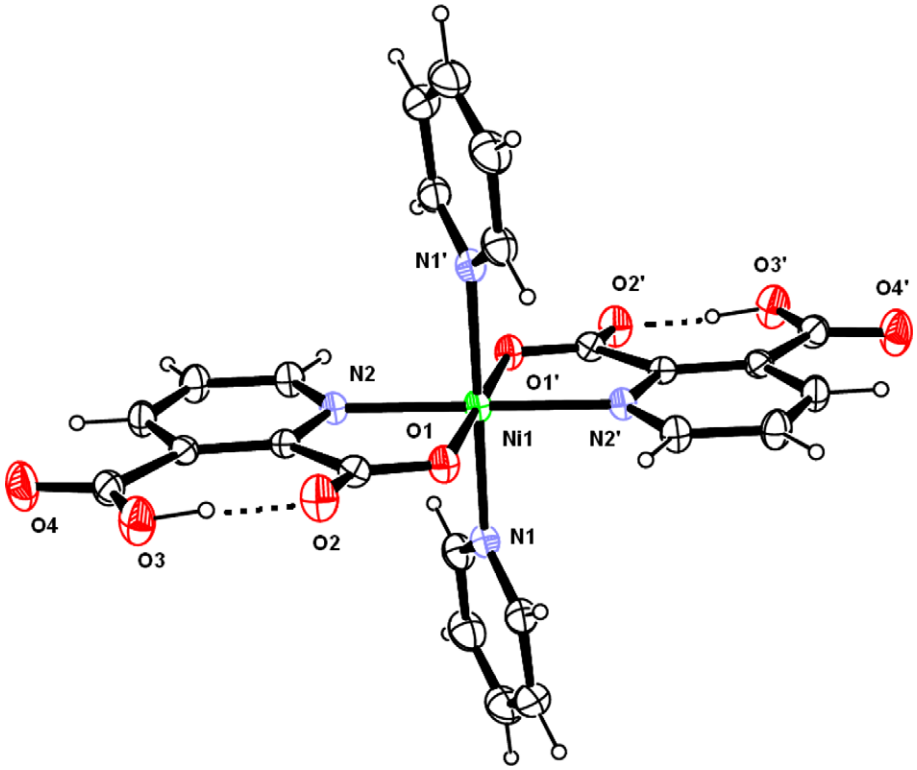

Fig. 1. Structure of complex (**III**) (Drawn with 20% thermal ellipsoids). Some selected bond distances (Å) and angles (°) are Ni1–N2, 2.05; Ni1–N1, 2.13; Ni1–O1, 2.03; ∠N1–Ni1–O1, 89.21; ∠N2–Ni1–O1, 100.89; ∠N1–Ni1–N2, 90.80.

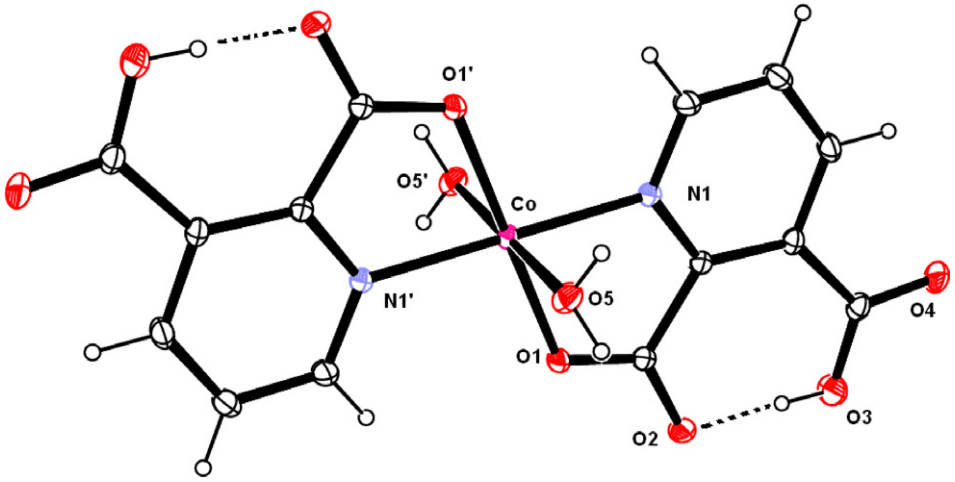

Fig. 2. The structure of $[Co(LH)_2(H_2O)_2]$ (**IV**).

ion has a six coordination number and has a N2O4 type of environment. The two Zn–O bonds along the *z*-axis are longer than the other Zn–O and Zn–N bond distances, showing distortion in the octahedral geometry. In order to compensate the negative charge on each of the zinc ions, the 4,4′-bipyridine molecules are found to be protonated and act as counter cations. In this case the polymeric chains (Fig. 3b) are formed from the coordinated carboxylato groups by opening of the anhydride rings. The coordination geometry around the zinc ions is shown in Fig. 3a. We anticipated the formation of assembled structures of dimeric units by a bridging 4,4′-bipyridine ligand, as this ligand generally acts as a bridging ligand which leads to grid like structures [7a,7b]. In contrast this ligand was found to be outside the coordination sphere, in the protonated form. In the polymeric structure of **V** each of the binuclear repeat units has three molecules of water of crystallization each and also a 4,4′-bipyridinium dication each. It may be interesting to note that in the lattice, the planarity of the bipyridine rings is lost. The two pyridine rings in the dication have a dihedral angle of 38.42° between the two rings. The protonated species of

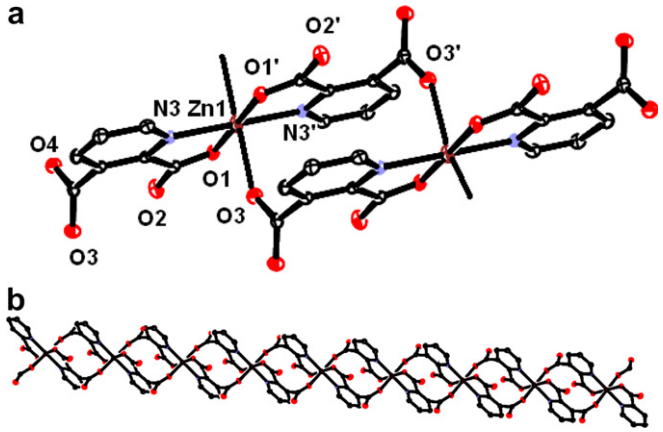

Fig. 3. (a) A part of the dimeric repeated units of (**V**) (Drawn with 20% thermal ellipsoids, hydrogen atoms are omitted for clarity). Some bond distances (Å) and angles (°) are Zn1–N3, 2.08; Zn1–O1, 2.07; Zn1–O3, 2.25; ∠N3–Zn1–O1, 79.48; ∠N3–Ni1–O3, 100.52; ∠O1–Zn1–O3, 84.09; atoms O5, O6, O7 are from water of crystallization. (b) One-dimensional chain in the coordination polymer (**V**).

analogous compounds, such as methyl-viologen, are used as cations in designing metallo-organic frameworks; where these cations assist in the inclusion of electron-rich substrates through charge transfer interactions [7c]. In these cases the planarity of the bications of methyl-viologen was also lost and a definite twisting of the pyridine rings was observed [7c]. It may be mentioned that functionalized pyromellitic diimides [8] were used for the syntheses of coordination polymers, in which dinuclear units formed by bridging ligands hold another bridging ligand, but our zinc polymer is structurally different from them. In our case the zinc centers are anionic, whereas in the earlier reported polymers the zinc centers were cationic. Moreover, the chelating nature of the ligand in the polymeric structure of **V** forces it to have repeated chain units having equal strength throughout the chain. The reaction of 2,3-pyridine dicarboxylic anhydride with zinc(II)acetate dihydrate was monitored by ^{1}H NMR spectroscopy. The 2,3-pyridine dicarboxylic anhydride has three multiplets at 7.62–7.66, 8.31–8.36 and 8.69–8.73 ppm in deuterated methanol, due to the three aromatic protons in it. On addition of zinc(II) acetate dihydrate to a solution of 2,3-pyridine dicarboxylic anhydride (1:2 molar ratio) in deuterated methanol at room temperature, besides the signals for 2,3-pyridine dicarboxylic anhydride, three additional aromatic multiplet signals with equal integration at 7.83–7.89, 8.15–8.18, 8.44–8.47 ppm appear. There is also a methyl signal at 2.0 ppm arising from liberated acetic acid. In this reaction precipitation of a white solid on addition of zinc acetate was observed. To make the solution homogeneous we added deuterated dimethylsulfoxide in order to record the ^{1}H NMR spectra. Observation of simple spectra for the reaction mixture, with only three new aromatic protons of equal integration clearly tells us there is the formation of only one type of complex in solution.

It is clear that the ester of the carboxylic acid is not formed in these reactions between the hydrated salts of cobalt, nickel and zinc acetate and 2,3-pyridine dicarboxylic anhydride in methanol. Thus, it may be imagined that the metal is allowing hydrolysis of a methyl ester formed in these reactions. Thus, we performed a control experiment between preformed methyl ester with zinc(II) chloride in methanol and observed no hydrolysis of the methyl-ester under similar conditions. From this experiment we have ruled out the possibility of hydrolysis of an ester that might have formed during the reaction. However, while carrying out reaction between copper(II) chloride and 1,10-phenanthroline with pyromellitic dianhydride, we observed that the nature of the product formed from this reaction is dependent on the reaction conditions [5b]. For example, a reaction carried out with a 1:1 ratio of cupric chloride to 1,10-phenanthroline gave methyl ester, whereas a reaction carried out with a 1:2 cupric chloride to 1,10-phenanthroline ratio gave a metal complex having the composition $[Cu(phen)_2Cl]L_1H3$ (**VI**). In this complex (**VI**), the carboxylate anion formed does not coordinate to the metal. The structure of the complex is shown in Fig. 4. The complex cation has a distorted square pyramidal geometry, in which the 1,10-phenanthroline rings do not remain in one plane but are disposed in a twisted manner. It is interesting to note that the mono-anion of 1,2,4,5-benzene tetracarboxylic acid, which neutralizes the charge, has strong intramolecular hydrogen bonding between the carboxylato and carboxylic acid groups at the 1 and 2 positions through O2–H···O3 (d_{D-A} 2.38 Å; d_{D-H} 1.22 Å; ∠D–H···A = 172.96°). The other carboxylic acids are involved in intermolecular hydrogen bonding.

The reaction of copper(II) acetate dihydrate and 1,10-phenanthroline (1:2 ratio) with pyromellitic dianhydride gave an interesting dinuclear product (**VII**) having the composition $[Cu_2(phen)_4L_1]\cdot 4H_2O$ (where L_1 = tetra-anion of 1,2,4,5-benzene tetracarboxylic acid, phen = 1,10-phenanthroline), as illustrated in Scheme 3. This reaction also did not lead to the formation of an ester complex, however changing the ratio from 1:2 between copper(II) acetate and 1,10-phenanthroline to 1:1 led to the formation of the corresponding methyl ester, namely 1,4 di-carbomethoxy 2,5-benzene dicarboxylic acid [5b]. Thus, on increase of the amount of nitrogen donor ligands (such as 1,10-phenanthroline), the esterification of pyromellitic dianhydride is inhibited. Complex **VII** has two copper ions held by two carboxylic acid groups at 1,4-positions and each copper has two 1,10-phenanthroline bidentate ligands (Fig. 5). The rest of the charge on the copper ions is balanced by the two carboxylato groups that are present on the ring as dianions. This compound has four molecules of water of crystallization. It may be mentioned that the use of polydentate ligands with dicarboxylates led to flexible structures [9] and it was also observed that the polymerization reactions leading to high molecular weight metal carboxylate polymers were inhibited by the use of bigger nitrogen donor ligands [10]. Isolation and characterization

of the copper complexes **VI** and **VII** provides evidence to these facts. The complex formation with dicarboxylic acids with metal salts is generally very sensitive to the reaction conditions and type of ligand under consideration [11].

In conclusion we have demonstrated preferential hydrolysis over esterification in cyclic anhydrides by hydrated first row transition metal salts to prepare metal carboxylate complexes having diverse coordination possibilities. This study

also provides methods to synthesize dinuclear and mononuclear metal complexes by using chelating ligands. In the case of copper it is observed that the chloride ion blocks the coordination of the carboxylato group; leading to a mononuclear complex having a chloride ion in the coordination sphere. The hydrolytic cleavage of anhydride in alcoholic medium is also dependent on the reaction conditions.

strategy to produce appropriated building blocks is to use ancillary bidentate nitrogen ligands that can give rise to $[M(NN)]^{2+}$ metal corners [6].

The non-planar ligand di(2-pyridyl)sulfide (DPS) can act as an assistant ligand in coordination compounds joining two nitrogen atoms in a chelating fashion [7] or bridging two metal ions [8]. A more rare coordination mode can occur, in which nitrogen and sulphur atoms are involved [7,9]. On the other hand, the planar ligand 4,4′-dimethyl-2,2′-bipyridine (Mebpy) possesses two more basics nitrogen atoms than 2,2′-bipyridine analogous and assumes the bidentate chelating coordination mode [10]. These two nitrogen ligands can be applied in the formation of the mentioned molecular building subunits.

In this work, we report the preparation and structural characterization of four copper(II) complexes namely [μ-(ox){Cu(Mebpy)(NO_3)(H_2O)}$_2$] (**1**), [μ-(ox){Cu(Mebpy)-(ClO_4)(H_2O)}$_2$] (**2**), [μ-(ox){Cu(DPS)(H_2O)}$_2$](ClO_4)$_2$ (**3**) and [Cu(DPS)(ox)(H_2O)] · 2H_2O (**4**) that contain both oxalate dianion and the ancillary nitrogen ligands (Mebpy or DPS). These compounds can be used as novel molecular building blocks for coordination polymers construction.

2. Experimental

2.1. Materials and physical measurements

Di(2-pyridyl)sulfide (DPS) ligand was obtained according to the published method [11], however, it was purified through a chromatographic column using (hexane:ethyl acetate/7:3) solvent mixture as eluent. Yield: 5.53 g, 55%. All other reagents were purchased from Aldrich Chemical Co. and used without further purification.

Elemental analyses for C, H and N were carried out with a Perkin–Elmer 2400 analyzer. IR spectra were recorded with a Bomem Michelson 102 FTIR spectrophotometer using NaCl pellets in the wavenumber range of 4000–600 cm^{-1} with an average of 128 scans and 4 cm^{-1} of spectral resolution. Fourier-Transform Raman spectroscopy was carried out using a Bruker RFS 100 instrument, Nd^{3+}/YAG laser operating at 1064 nm in the near infrared and CCD detector cooled with liquid N_2 with an average of 500 scans and 4 cm^{-1} of spectral resolution. Thermogravimetric analysis (TG/DTG) data were collected with a TG-50 Mettler STARe using 1.0 mg packed in alumina crucible. Samples were heated at 10 °C/min from room temperature to 800 °C in a dynamic nitrogen atmosphere (flow rate = 200 mL/min). Differential scanning calorimetry (DSC) measurements were carried out with a Shimadzu DSC50, using 1.0 mg samples packed in aluminum crucible, with a heating rate of 10 °C/mim in the range of 25–480 °C. Dynamic nitrogen atmosphere (flow rate = 50 mL/mim) was used.

2.2. Synthesis of [μ-(ox){Cu(Mebpy)(NO_3)(H_2O)}$_2$] (1)

By slow diffusion, 10 mL of an aqueous solution of $Na_2C_2O_4$ (18 mg, 0.13 mmol) were added to 20 mL of methanolic solution containing Mebpy (50 mg, 0.27 mmol) and $Cu(NO_3)_2 \cdot 3H_2O$ (65 mg, 0.27 mmol) at room temperature. After few days, blue crystals suitable for X-ray analysis were obtained. Yield: 88%. *Anal*. Calc. for $C_{26}H_{28}O_{12}N_6Cu_2$: C, 41.99; H, 3.79; N, 11.30. Found: C, 41.93; H, 3.58; N, 11.37%. IR (NaCl, cm^{-1}): ν(OH), 3574 (m), 3403 (m); ν(CH), 3064 (w); $\nu(CH_3)$, 2924 (w), 2852 (w); ν_{asym}(COO), 1649 (s), 1626 (sh); ν(CC/CN), 1617 (sh), 1560 (w), 1496 (w), 1447 (w); ν_{sym}(COO, NO_3^-), 1356 (s); δ_{oop}(CH), 842 (w); δ(O–C–O), 795 (w). Raman (1064 nm, cm^{-1}): ν(CH), 3079 (m), 2928 (m); ν(CC/CN), 1617 (s), 1561 (s), 1496 (m).

2.3. Synthesis of [μ-(ox){Cu(Mebpy)(ClO_4)(H_2O)}$_2$] (2)

Caution! Perchlorate salts with organic solvents are potentially explosive. A small amount of material only should be prepared and it should be handled with care.

Complex **2** was prepared through a similar procedure used for compound **1**. 10 mL of an aqueous solution of $Na_2C_2O_4$ (18 mg, 0.13 mmol) were layered on to 20 mL of acetonitrile solution containing Mebpy (50 mg, 0.27 mmol) and $Cu(ClO_4)_2 \cdot 6H_2O$ (100 mg, 0.27 mmol) at room temperature. After 15 min, blue needle crystals suitable for X-ray analysis were obtained. Yield: 48%. *Anal*. Calc. for $C_{26}H_{28}O_{14}N_4Cl_2Cu_2$: C, 38.15; H, 3.45; N, 6.84. Raman (1064 nm, cm^{-1}): ν(CH), 3085 (m), 2932 (m); ν(CC/CN), 1617 (s), 1561 (s), 1497 (m).

2.4. Synthesis of [μ-(ox){Cu(DPS)(H_2O)}$_2$](ClO_4)$_2$ (3)

To 10 mL of an ethanolic solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (118 mg, 0.32 mmol), 10 mL of an ethanolic solution of DPS (60 mg, 0.32 mmol) were added. A solid precipitated immediately. By slow diffusion, $Na_2C_2O_4$ (21 mg, 0.16 mmol) dissolved in 20 mL of water was added. The blue solution turned limpid and was allowed to stand. After a few days, dark blue crystals suitable for X-ray analysis were filtered. Yield: 63%. *Anal*. Calc. for $C_{22}H_{20}O_{14}N_4S_2Cu_2Cl_2$: C, 31.97; H, 2.44; N, 6.78. 2.6. X-ray diffraction measurements

Single crystal X-ray data were collected using a Bruker Kappa CCD diffractometer with Mo Kα ($\lambda = 0.71073$ Å) at room temperature. Data collection, reduction and cell refinement were performed by COLLECT, EVALCCD and DIRAX programs, respectively [12]. The structures were solved and refined using SHELXL-97 [13]. An empirical isotropic extinction parameter x was refined, according to the method described by Larson [14a]. A multiscan absorption correction was applied [14b]. The structures were drawn by ORTEP-3 for Windows [15]. Hydrogen atoms were located from Fourier difference maps. Anisotropic displacement parameters were assigned to all non-hydrogen atoms (see Table 1).

3. Results and discussion

3.1. Crystal structures of [μ-(ox){Cu(Mebpy)(NO_3)(H_2O)}$_2$] (1), [μ-(ox){Cu(Mebpy)(ClO_4)(H_2O)}$_2$] (2), [μ-(ox){Cu(DPS)(H_2O)}$_2$](ClO_4)$_2$ (3), [Cu(DPS)(ox)(H_2O)] · 2H_2O (4)

All compounds studied in this work crystallize in monoclinic systems. Figs. 1 and 2 show the ORTEP [15] views of compounds **1**, **2**, **3** and **4** molecular structures and mainly geometric parameters are displayed in Table 2.

Compounds **1** and **2** are isostructural and crystallize in $P2_1/n$ space group, forming binuclear structures, as shown in Fig. 1. Each Cu(II) center adopts a distorted octahedral geometry, in which the basal plane is formed by two nitrogen atoms of MeBpy (N1 and N2) and two oxygen atoms of oxalate ion (O1 and O2) and the axial positions are occupied by an one water molecule (O3) and oxygen atom (O4) of nitrate ion in compound (**1**) and of perchlorate ion in compound (**2**). In compound (**1**), Cu–N1, Cu–N2, Cu–O1 and Cu–O2 bond distances are 1.992(2), 1.989(2), 1.990(1) and 1.981(1) Å, respectively, while Cu–O3 and Cu–O4 bond lengths are much longer (2.410(2) and 2.472(2) Å), characterizing a tetragonally elongated octahedron (4+2 environment) due to a very pronounced Jahn–Teller effect. Similar geometry is observed in compound (**2**) where Cu–N1, Cu–N2, Cu–O1 and Cu–O2 bond distances are 1.988(3), 1.987(3), 1.990(2) and 1.986(2) Å respectively, while Cu–O3 and Cu–O4 bond lengths are also much longer (2.405(3) and 2.559(4) Å). In despite of Cu–O4 bond length is bigger in **2** than in **1**, the

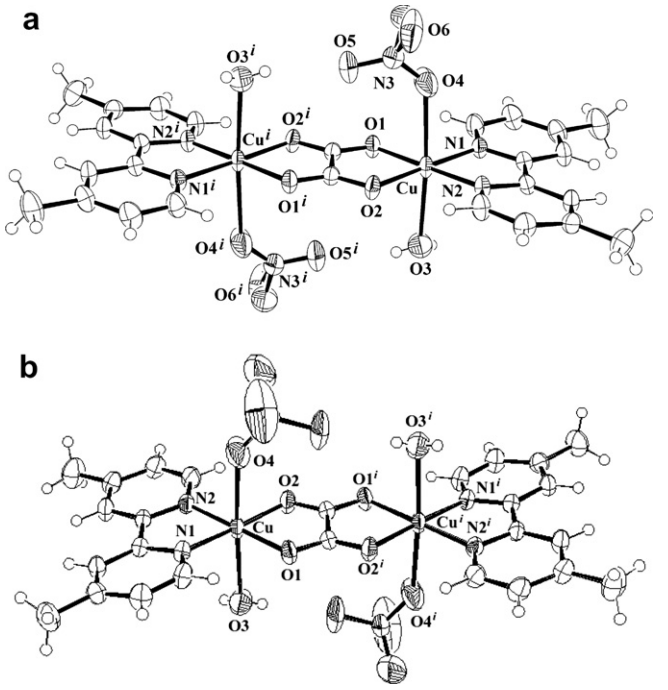

Fig. 1. Crystal structure of (a) [μ-(ox){Cu(Mebpy)(NO_3)(H_2O)}$_2$] (**1**) and (b) [μ-(ox){Cu(Mebpy)(ClO_4)(H_2O)}$_2$] (**2**). *Symmetry code:* (a) i: $-x$, $2-y$, $1-z$; (b) i: $-x$, $2-y$, $2-z$.

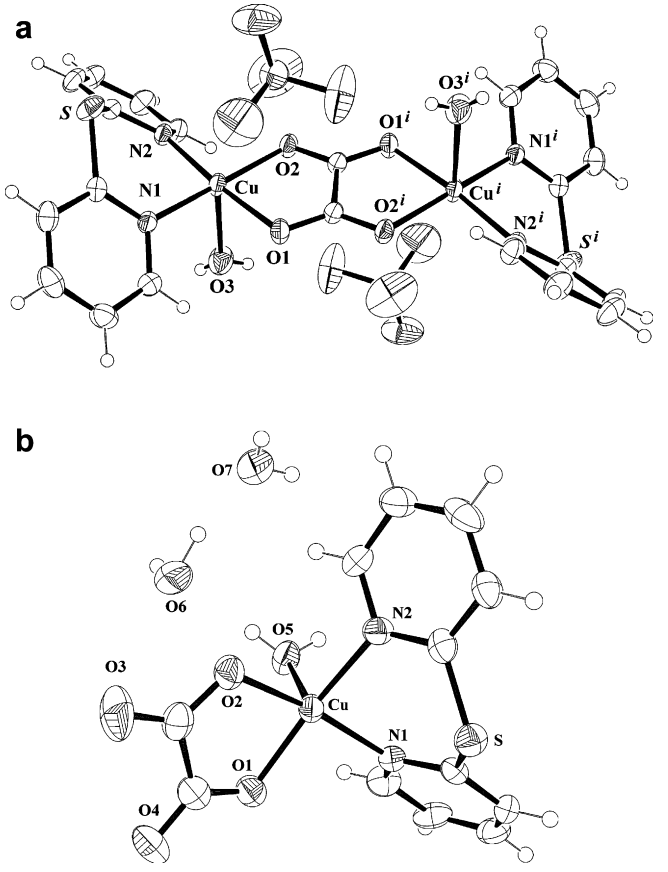

Fig. 2. Crystal structure of (a) [μ-(ox){Cu(DPS)(H_2O)}$_2$](ClO_4)$_2$ (**3**) and (b) [Cu(DPS)(ox)(H_2O)]· $2H_2O$ (**4**). *Symmetry code:* (a) i: $-x$, $2-y$, $1-z$; (b) i: $-x$, $2-y$, $-z$.

environment around Cu site is characterized in the same way (4+2). The oxalate ion acts in bis(bidentate) coordination mode bridging two Cu(II) sites with Cu···Cu distance very similar in both compounds (5.16 Å in (**1**) and 5.17 Å in **2**). There is an inversion center in the middle of oxalate C–C bond, as indicated by the analysis of IR and Raman vibrational spectra. In both compounds, the coordination water molecules of a binuclear unit are involved in medium hydrogen bonds (average distance of O···O is 2.875(4) Å) with nitrate in **1** and perchlorate in **2** anions of the adjacent unit giving rise to a one-dimensional arrangement parallel to crystallographic axis *a*, as can be seen in Fig. 3. Hydrogen bond geometric parameters of **1** are displayed in Table 3. Additionally, the pyridyl rings of neighbor molecules from two one-dimensional chains present average of centroid–centroid and interplanar distances of 3.81 and 3.70 Å, respectively, indicating the existence of π-stacking interaction, extending the dimensionality to a 2-D array, shown in Fig. 3. In compound **1** is observed a disorder in one of the oxygen atoms of nitrate anion (O6 and O6A), as can be seen in Fig. 1a. O6 and O6A are located at two different sites and the occupational distribution is not equivalent; one site presents occupational factor around 0.65.

The literature [4i] describes the crystal structure of the analogous compound [{Cu(NO_3)(H_2O)(bipy)}$_2$(ox)], which is very similar to compound **1**. In this case, the equatorial Cu–O and Cu–N distances vary from 1.96 to 1.99 Å, being in the same range to that observed in **1**. However, Cu–O distances of axial sites (2.351 and 2.755 Å) are significantly different from each other and from those observed in **1** and the authors describe the polyhedron coordination as 4+1+1 environment. Also, the crystal packing presents the same hydrogen bonds between the coordinated water molecules and nitrate groups and π-stacking interaction between pyridyl rings. Curiously, the crystal structure of the same compound, namely [Cu_2(μ-C_2O_4)(bpy)$_2$-(H_2O)$_2$(NO_3)$_2$], has been described a year later [16], but no comparison to the first description was made.

Similarly to **1** and **2**, compound **3** is also binuclear, as can be seen in Fig. 2a, and crystallizes in a monoclinic space group $P2_1/n$. In this case, however, each Cu(II) center is pentacoordinated, being surrounded by two nitrogen atoms of DPS ligand (N1 and N2), two oxygen atoms of oxalate anion (O1 and O2) and one water molecule (O3). According to the trigonality index $\tau = 0.04$ ($\tau = (\beta - \alpha)/60$, where β is the greatest basal angle and α is the second in magnitude; $\tau = 0$ and 1 for perfect square-pyramidal and trigonal-bipyramidal geometries, respectively) [17], Cu(II) ions exhibit a slightly distorted square pyramidal geometry. The basal plane is formed by N1, N2, O1 and O2 atoms and the metal ion sits at 0.078 Å above this plane. The apical positions are occupied by O3 atoms and the Jahn–Teller distortion can be observed (d(Cu–O3) = 2.294(2) Å). DPS ligands assume the bidentate chelating fashion, wherein the six-membered chelate rings adopt a boat conformation, with the angle between pyridyl

rings of 51.4°. As observed in compounds **1** and **2**, the binuclear structure is achieved through the bridging oxalate anion wherein the Cu···Cu distance is 5.19 Å and there is an inversion center in the middle of oxalate C–C bond, as indicated by the vibrational spectra. The complex structure is cationic and the neutral compound is formed by the presence of two perchlorate anions (Fig. 2a), which are involved in very weak interactions with the metal centers (d(O6–Cu) = 3.155(7) Å). The oxygen atoms of perchlorate anions are all disordered in two sites. They were refined in groups and the occupational factor of main group is around 0.69.

Crystal packing view along crystallographic axis *a* shows two orientations for oxalate ligands (Fig. 4) where the angle between oxalate planes is 80.5°. Perchlorate anions link binuclear units through O···S and O···O van der Waals

interactions. As can be seen in Fig. 4a, water molecules are involved in weak hydrogen bond interactions with perchlorate anions with average of O···O distance of 2.968(6) Å, forming a two-dimensional arrangement (2D). Geometric parameters of hydrogen bond in (**3**) are displayed in Table 3. The compound [Cu_2(bdpm)$_2$(H_2O)$_2$(μ-ox)](ClO_4)$_2$ · H_2O (bdpm = bis(3,5-dimethylpyrazol-1-yl)methane) described in the literature [18] presents a very similar structure in comparison to **3**. The Cu(II) centers show the same distorted square-pyramidal geometry with basal Cu–O and Cu–N and apical Cu–O (water) distances equivalent to those observed in compound (**3**).

Compound (**4**) crystallizes in a non-centrosymmetric orthorhombic space group $P2_1cn$ and, differently from

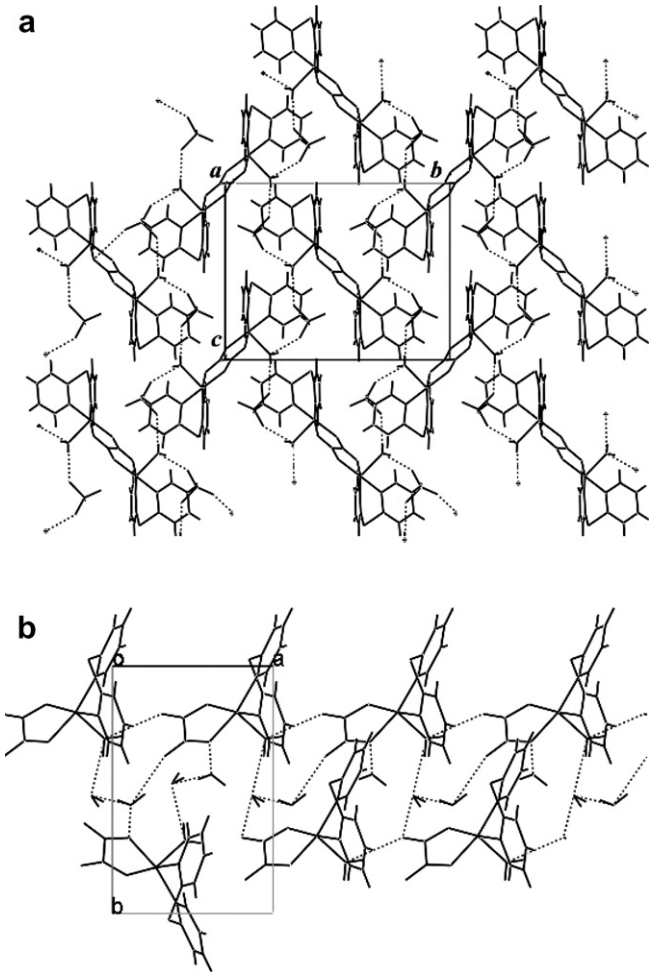

Fig. 4. (a) Crystal packing of **3** viewed along crystallographic *a* axis. (b) Hydrogen bond arrangement in **4** viewed along crystallographic *c* axis.

the others this compound is mononuclear (Fig. 2b). Cu(II) center is coordinated by two nitrogen atoms (N1 and N2) from DPS ligand in a bidentate chelating coordination mode, two oxygen atoms (O1 and O2) from oxalate dianion in a terminal bidentate chelating fashion and one oxygen atom (O5) from a water molecule, exhibiting a slightly distorted square pyramidal geometry with trigonality index $\tau = 0.04$. The metal site is located at 0.185 Å above the basal plane formed by N1, N2, O1 and O2 atoms. The angle between pyridyl rings in DPS ligand is 52.2°, similar to that observed in compound **3**. DPS pyridyl rings of adjacent complexes show average of centroid–centroid and interplanar distances of 4.42 and 3.35 Å, respectively. In despite of short interplanar distance, the centroid–centroid distance is longer than 4.0 Å, suggesting that the aromatic rings are not involved in π-stacking interaction, due to horizontal translation in crystal packing (average of 2.44 Å). In addition, two lattice water molecules are observed in crystal structure. All water molecules are involved in weak hydrogen bond to coordinated and non-coordinated oxygen atoms of oxalate ligand and medium between them in a three-dimensional arrangement (Fig. 4b). The average of O···O separation in medium and weak hydrogen bonding is 2.742(7) and 2.889(6) Å, respectively. Geometric parameters of hydrogen bond in **4** are displayed in Table 3.

There are other related compounds described in the literature, like the analogous namely $[Cu(bipy)(C_2O_4)(H_2O)]\cdot 2H_2O$ (bipy = 2,2′-bipyridine) [19a] and $[Cu(C_3H_2O_4)(C_{12}H_{12}N_2)(H_2O)]\cdot 2H_2O$ ($C_3H_2O_4$ = malonate ion and $C_{12}H_{12}N_2$ = 4,4′-dimethyl-2,2′-bipyridine) [19c]. In both cases, the metal center is five-coordinated and adopts the distorted square-pyramidal geometry in which the dicarboxylate group acts in the bidentate coordination mode and the Cu–O and Cu–N bond distances are very similar to those observed in compound **4**.

3.2. General characterization

All studied compounds were obtained by diffusion in situ of an aqueous solution of $Na_2C_2O_4$ to solutions in different solvents of respective copper(II) salts ($Cu(NO_3)_2\cdot 3H_2O$ for **1** and **4** and $Cu(ClO_4)_2\cdot 6H_2O$ for **2** and **3**) and nitrogen ligands Mebpy (for **1** and **2**) and DPS (for **3** and **4**). The analytical data indicated the formation of binuclear compounds **1**–**3** with (Cu^{2+}:Mebpy:ox/1:1:1/2) in **1** and **2** and (Cu^{2+}:DPS:ox/1:1:1/2) in **3** stoichiometric ratio, and mononuclear compound **4** in (Cu^{2+}:DPS:ox/1:1:1) proportion.

Thermogravimetric curves for compounds **1**–**4** are shown in Figure S1 in the supplementary material. For **1** and **3** it can be noticed the first weight loss in the temperature ranges of 120–180 °C and 80–160 °C, respectively, in both cases corresponding to two coordination water molecules (obsd. 4.83%, calcd. 4.83% for **1** and obsd. 4.04%, calcd. 4.36% for **3**). Differently from **1** and **3**, for compound **4** the dehydration step occurs at lower temperature range (40–60 °C) indicating the presence of two crystallization water molecules (obsd. 9.21%, calcd. 9.15%). In addition for **4**, it can be observed a second mass loss around 110 °C consistent with a coordination water molecule. Curiously, in compound **2** the dehydration temperature range is also low (40–80 °C), but in this case these two water molecules (obsd. 3.78%, calcd. 3.55%) are coordinated to the metal centers, as confirmed by X-ray diffraction analysis. In all cases, the complete thermal decomposition can be identified above 190 °C in one or two steps. The final residues at 800 °C agree with two mols of CuO for compound **1** (obsd. 22.8%, calcd. 21.3%) and one mol of CuO for compound **4** (obsd. 22.5%, calcd. 20.2%). For compounds **2** and **3**, it was not possible to calculate the final mass residue due to the presence of ClO_4^- anion that causes an explosive behavior leading to a great error in the calculations. The literature [4i] describes the thermal behavior of a compound analogous to **1**, namely $[\{Cu(NO_3)(H_2O)(bipy)\}_2(ox)]$, where bipy = 2,2′-bipyridine. In this case, the thermogravimetric curve presents the same pattern exhibited by compound **1**.

DSC curves for the four complexes are exhibited in Figure S2 in the supplementary material. In the curve of compound **1** it can be noticed two exothermic events around 264 and 306 °C, while for compounds **2** and **3** there

is only one exothermic path at 291 and 284 °C, respectively, all of them corresponding to complexes thermal decomposition. Especially for the two latter compounds, the endothermic events attributed to the dehydration process are not observable due to the high intensity of the exothermic ones mentioned above. On the other hand, for compound **4**, it is noteworthy the presence of two different endothermic events at 59 and 123 °C assigned to the lattice and coordination water molecules losses, respectively.

The infrared spectra of complexes **1**–**4** show medium to strong and broad absorption bands in the 3574–3403 cm^{-1} wavenumber range assigned to ν(OH) stretching mode indicating the presence of water molecules in all complexes, in agreement to the thermal analysis results. Pyridine rings vibrational bands shift from 1592 cm^{-1} in free Mebpy to 1617 cm^{-1} in **1** and to 1615 cm^{-1} in **2** and from 1572 cm^{-1} in free DPS to 1591 and 1589 cm^{-1} in complexes (**3**) and (**4**), respectively. In fact, the presence of ν(CC/CN) at higher wavenumbers in complexes is indicative of metal coordination to pyridine nitrogen atoms, as observed for other compounds containing pyridine derivative ligands described in the literature [7,8,20].

One of the most relevant features of IR spectra concerns the carbon–oxygen stretching frequencies of oxalate group because they can provide important information about the coordination modes of this ligand. Compounds **1**–**3** spectra display characteristics bands of the oxalate bridging ligand [4c,18] around 1650 cm^{-1} (ν_{asym}(COO)), 1356 cm^{-1} (ν_{sym}-(COO)) and 800–760 cm^{-1} (δ(O–C–O)). On the other hand, in compound **4** spectrum it can be observed a medium intensity band at 1708 cm^{-1} assigned to non-coordinated CO moiety of oxalate anion and absorptions at 1670s cm^{-1} (ν_{asym}(COO)), 1403s and 1263s cm^{-1} (ν_{sym}-(COO)) and 778m cm^{-1} (δ(O–C–O)), indicating the bidentate coordination mode, in accordance to other reported bidentate oxalate-containing copper(II) complexes [21]. Additionally, in compounds **2** and **3** spectra, strong bands at 1142–1032 cm^{-1} frequency range, confirm the presence of ClO_4^- anion.

In the Raman spectra of compounds **1**–**3** the bands related to the asymmetric and symmetric stretching modes of COO^- groups are absent due to the presence of the inversion center in the molecules structures. Differently from **1**–**3**, the Raman spectrum of compound **4** shows bands at 1709, 1669 cm^{-1} and 1402, 1266 cm^{-1} assigned to asymmetric and symmetric stretching modes of COO^- groups, respectively, reinforcing the terminal bidentate chelating coordination mode of oxalate anion toward the Cu(II) site. All the Raman spectra can be seen in Figure S3 in the supplementary materials.

4. Conclusions

In summary, this work describes the preparation, crystal structures and spectroscopic characterization of four oxalate copper(II) complexes containing the 4,4′-dimethyl-2,2′-bipyridine (Mebpy) or di(2-pyridyl)sulfide (DPS) nitrogen ligands namely [μ-(ox){Cu(Mebpy)(NO_3)(H_2O)}$_2$] (**1**), [μ-(ox){Cu(Mebpy)(ClO_4)(H_2O)}$_2$] (**2**), [μ-(ox){Cu(DPS)(H_2O)}$_2$](ClO_4)$_2$ (**3**) and [Cu(DPS)(ox)(H_2O)]·2H_2O (**4**).

X-ray diffraction measurements have shown that complexes **1**–**3** are binuclear, in which the oxalate anion bridges two Cu(II) centers, while the complex **4** is mononuclear and the oxalate anion adopts the terminal bidentate chelating coordination mode. In **1** and **2** the Cu(II) sites display a distorted octahedral geometry (4+2 environment) in which the base is formed by two oxygen atoms of oxalate anion (O1 and O2) and two nitrogen atoms of Mebpy ligand (N1 and N2). The axial positions are occupied by one *aqua* ligand and one nitrate anion in compound **1** and one perchlorate anion in coumpound **2**, both exhibiting a very pronounced Jahn–Teller distortion. For both compounds, the coordination water molecules of a binuclear unit are involved in hydrogen bonds with the anions (NO_3^- for (**1**) and ClO_4^- for **2**) of the adjacent unit giving rise to a one-dimensional arrangement parallel to crystallographic axis *a*. The dimensionality is extended to a 2-D array through π-stacking interaction between the pyridyl rings of neighbor molecules.

Differently from **1** and **2**, in compounds **3** and **4** the Cu(II) centers exhibit a slightly distorted square pyramidal geometry. In both cases, the basal plane is constituted by two oxygen atoms from oxalate anion (O1 and O2) and two nitrogen atoms from DPS ligand (N1 and N2) and, the apical position is occupied by a water molecule.

Table 1
Table of the pyromorphite minerals used in this work and their origin

Code	Mineral	Formula	Arsenate substitution	%PbO	$\%P_2O_5$	$\%As_2O_5$	%Cl	Origin
Pyro 1	pyromorphite	$Pb_5(PO_4)_3Cl$		82.3	16.1	0.1	2.7	Mount Isa, QLD
Pyro 2	pyromorphite	$Pb_5(PO_4)_3Cl$	AsO_4	Not measured				Brown's Prospect, Rum Jungle, NT
Pyro 3	pyromorphite	$Pb_5(PO_4)_3Cl$		82.2	14.7		2.6	Tennant Creek, NT
Pyro 4	pyromorphite	$Pb_5(PO_4)_3Cl$		82.8	15.7	trace	2.6	Broken Hill, NSW
Pyro 5	pyromorphite	$Pb_5(PO_4)_3Cl$	AsO_4	82.9	12.6	4.5	2.7	Broken Hill, NSW
Pyro 6	pyromorphite	$Pb_5(PO_4)_3Cl$		82.8	15.4	0.3	2.6	Kintore Open Cut, Broken Hill, NSW
Pyro 7	calcian pyromorphite	$(Ca,Pb)_5(PO_4)_3Cl$	Not determined					Block 14 Mine, Broken Hill, NSW
Pyro 8	arsenian pyromorphite	$Pb_5(AsO_4,PO_4)_3Cl$	AsO_4	82.9	10.6	5.5	2.8	Bunker Hill Mine, Kellogg, Idaho, USA

two minerals difficult, but usually pyromorphite is green and mimetite is yellow. Such colourations lend the minerals to NIR spectroscopy. Vanadinite is usually red. Pyromorphite's main characteristic is its unique crystal habit of stacked branching barrel-shaped crystals.

Farmer reported the vibrational spectra of minerals with a fluoroapatite structure [11]. The infrared spectra of pyromorphite showed bands at 1030 and 970 cm^{-1} attributed to phosphate v_3 antisymmetric stretching vibrations and at 572 and 542 cm^{-1} assigned to phosphate v_4 bending modes [11]. The infrared spectra of mimetite showed bands at 815, 803 and 783 cm^{-1} attributed to arsenate v_3 antisymmetric stretching vibrations and at 415 and 383 cm^{-1} assigned to arsenate v_4 bending modes [11]. The vibrational spectra of lead apatites were reported by Levitt and Condrate [12,13]. Crystal structure and factor group analysis have

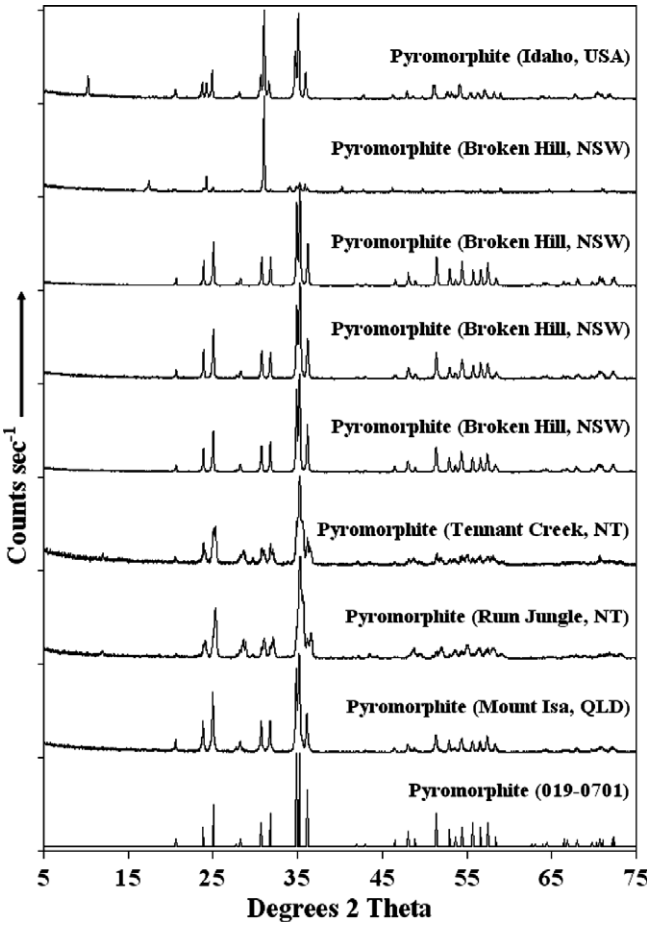

Fig. 1. XRD patterns of a selection of pyromorphite minerals.

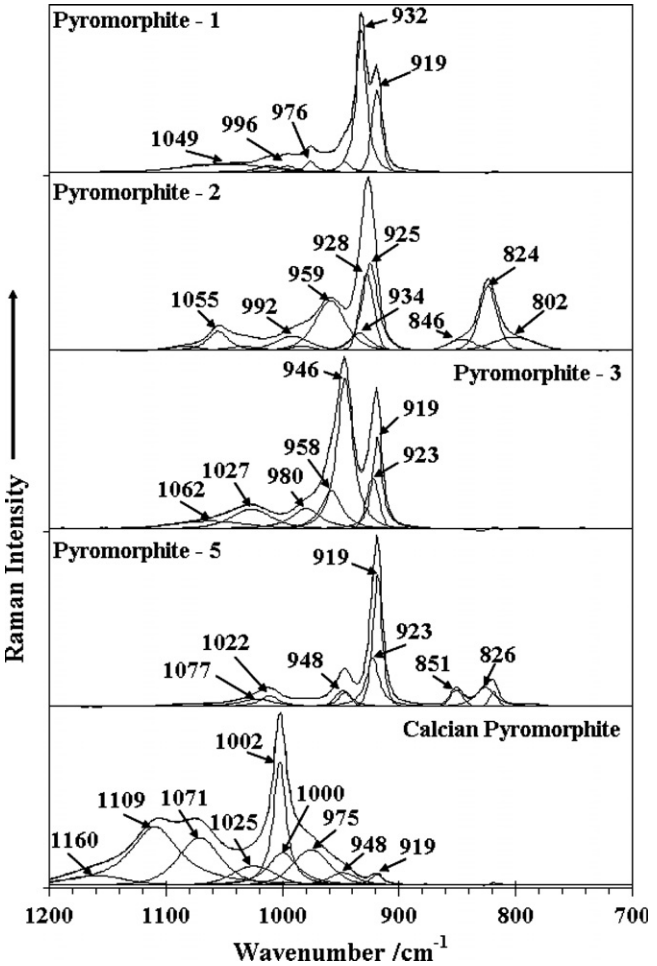

Fig. 2. Raman spectra of pyromorphite in the high wavenumber region.

been undertaken [14]. Bartholomai and Klee reported the vibrational spectra of single crystals of pyromorphite, vanadinite and mimetite [15].

Raman spectroscopy has proven very useful for the study of minerals [16–18]. Indeed Raman spectroscopy has proven most useful for the study of diagentically related minerals as often occurs with carbonate minerals [19–23]. Some previous studies have been undertaken by the authors using Raman spectroscopy to study complex secondary minerals formed by crystallisation from concentrated

sulphate solutions [24]. Very few recent spectroscopic studies of natural pyromorphite minerals have been forthcoming and what studies that are available are not new. Some Raman studies are available [25,26]. In this work we have obtained Raman and infrared spectra of selected pyromorphites, arsenianpyromorphite and phosphohedyphane and relate the spectra to the structure of the minerals.

2. Experimental

2.1. Minerals

The pyromorphite minerals were supplied by The Mineralogical Research Company. A selection of pyromorphite minerals were also provided by The South Australian Museum (Adelaide, Australia). Table 1 reports the pyromorphite minerals together with their origin. All of the minerals except for the arsenian pyromorphite are from Australian mineral deposits. The minerals were analysed by EDX measurements for chemical composition and by powder X-ray diffraction for phase purity. Some EDX measurements are given in Table 1. The XRD patterns of a selection of pyromorphite minerals from Australia and international origins are shown in Fig. 1. Also shown is the reference pattern for pyromorphite.

2.2. Raman spectroscopy

The crystals of pyromorphite were placed and oriented on the stage of an Olympus BHSM microscope, equipped with 10× and 50× objectives and part of a Renishaw 1000 Raman microscope system, which also includes a monochromator, a filter system and a charge coupled device (CCD). Raman spectra were excited by a HeNe laser (633 nm) at a resolution of 2 cm^{-1} in the range between 100 and 4000 cm^{-1}. Repeated acquisition using the highest magnification was accumulated to improve the signal to noise ratio. Spectra were calibrated using the 520.5 cm^{-1} line of a silicon wafer. Previous studies by the authors provide more details of the experimental technique [27–30]. Some minimal background is observed in the spectra of pyromorphites. This background is removed by using performed using the Spectracalc software package GRAMS (Galactic Industries Corporation, NH, USA) by using a multipoint fitting function (Go to Grams, select arithmetic, select baseline, select multipoint fitting, select fit points to line).

Band intensities in the Raman spectroscopy of crystals including minerals are very much dependent upon the orientation. Such studies have been undertaken by the authors [31–35]. The intensity will depend upon the orientation of the crystal relative to the incident beam. Such orientation effects were not explored in this research as it is beyond the scope of this research as the objective of the research was to study the isomorphous substitution especially looking for substitution by arsenate, hydroxyl and water in the pyromorphite structure.

2.3. Mid-IR spectroscopy

Infrared spectra of the pyromorphites were obtained using a Nicolet Nexus 870 FTIR spectrometer with a smart endurance single bounce diamond ATR cell. Spectra over the 4000–525 cm^{-1} range were obtained by the co-addition of 64 scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectra were co-added to improve the signal to noise ratio.

Spectral manipulation such as baseline adjustment, smoothing and normalisation were performed using the Spectracalc software package GRAMS (Galactic Industries Corporation, NH, USA). Band component analysis was undertaken using the Jandel 'Peakfit' software package which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done using a Lorentz–Gauss cross-product function with the minimum number of component bands used for the fitting process. The Gauss–Lorentz ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations of r^2 greater than 0.995.

3. Results and discussion

3.1. Raman spectroscopy

The Raman spectra of selected pyromorphite minerals in the 700–1200 cm^{-1} region are shown in Fig. 2. The results of the band component analyses of the Raman spectra are reported in Table 2. The Raman spectra show intense bands in the 920–950 cm^{-1} region. Two bands are observed for pyromorphite 1 (origin Mt Isa, Queensland) at 919 and 932 cm^{-1}. A single band is observed for pyromorphite 2 (Rum Jungle, Northern Territory) at 925 cm^{-1}. This band is asymmetric and additional bands at 928 and 934 cm^{-1} may be resolved. In the spectra of pyromorphite 2, two bands are observed at 802 and 824 cm^{-1}. These bands are assigned to the $(AsO_4)^{3-}$ v_1 symmetric stretching mode. The band at 925 cm^{-1} is attributed to the $(PO_4)^{3-}$ v_1 symmetric stretching mode. Farmer based upon infrared spectra, also reported this band at 925 cm^{-1} [11]. Two bands are also observed for pyromorphite 3 (Tennant Creek, Northern territory, Australia) at 919 and 946 cm^{-1}. For pyromorphite 5 (Broken Hill, New South Wales, Australia) a single band is observed at 919 cm^{-1}. This Raman band also shows some asymmetry and an additional component at 923 cm^{-1} may be resolved. Two additional bands at 826 and 851 cm^{-1} are observed in the spectrum of pyromorphite 5. These bands are also assigned to the $(AsO_4)^{3-}$ symmetric stretching modes.

The infrared spectra are shown in Fig. 3. The results of the band component analysis of the infrared spectra are reported in Table 3. The spectra appear complex with a number of overlapping bands. An infrared band of low intensity is observed at around 916 cm^{-1}. This band is the infrared equivalent of the Raman band observed at 925 cm^{-1}. Levitt and Condrate reported the symmetric stretching mode of $(PO_4)^{3-}$ in pyromorphite at 920 cm^{-1} [12,13]. Adler and Kerr found the infrared band to occur at 926 cm^{-1} [36]. Bartholomai and Klee published the sin-

gle crystal spectra of pyromorphite [15]. Two bands were observed at 920 and 919 cm^{-1} ascribed to the A_g and E_{2g} vibrational modes. The latter band was very intense and the former intense. Two bands are resolved for pyromorphite 5 at 919 and 923 cm^{-1} and these bands may be attributed to these vibrational modes.

The infrared spectra of the studied minerals are shown in Fig. 3. A series of bands for pyromorphite sample 1 were band resolved at 1049, 996 and 976 cm^{-1}. The first band may be simply part of the background. These bands are attributed to the $(PO_4)^{3-}$ antisymmetric stretching mode of pyromorphite. Typically these bands are expected to show greater intensity in the infrared spectrum as compared with the Raman spectrum. Levitt and Condrate reported three Raman bands at 1014, 980 and 947 cm^{-1} and attributed these modes to the antisymmetric stretching vibration [12]. Bartholomai and Klee assigned bands at 1025 (weak), 1011 (weak) and 949 cm^{-1} (strong) [15]. For pyromorphite 2, Raman bands are observed at 1055, 992, 959 cm^{-1} and correspond at least in part to the observations of Bartholomai and Klee. For pyromorphite 3 an intense Raman band at 946 cm^{-1} is observed which is within spectral resolution and is in agreement with the intense Raman band as published by Bartholomai and Klee. In the infrared spectra (Fig. 3) two bands are observed at around 1017 and 950 cm^{-1} and are attributed to the antisymmetric stretching modes of $(PO_4^{3-}$. Levitt and Condrate reported infrared bands for pyromorphite in similar positions [12,13].

The Raman spectra in the 500–700 cm^{-1} region for the selected pyromorphites are reported in Fig. 4. The simplest spectrum of pyromorphite 3 shows two bands at 553 and 579 cm^{-1}. Farmer based upon the work of Bhatnagar and Levitt and Condrate [13,37] reported two bands for pyromorphite at 542 and 572 cm^{-1} [11]. These bands are assigned to the v_4 phosphate bending modes. The Raman spectrum of pyromorphite 2, is more complex with a significant number of bands at 547, 554, 586 and 592 cm^{-1}. Any reduction in symmetry of the phosphate anion because of isomorphous substitution will result in the loss of degeneracy and additional bands may be observed. Such degeneracy is also observed for pyromorphite 1 where bands are observed at 543, 555, 575, 591 and 595 cm^{-1}. Unsubstituted pyromorphite 1 has one less band that substituted pyromorphite 5. This difference can be explained by crystal orientation effects.

For the calcian pyromorphite, two bands which are quite broad in comparison to the pure pyromorphites are observed at 552 and 573 cm^{-1}. These two bands, although of low intensity in the Raman spectrum, are also observed in the infrared spectra at around 540 and 575 cm^{-1} (Fig. 3).

The Raman spectra in the 100–500 cm^{-1} region of pyromorphite are displayed in Fig. 5. Bands are observed around 400–500 cm^{-1} and between 100 and 250 cm^{-1}. The first region is attributed to the v_2 bending modes of the phosphate units. For pyromorphite 3, two Raman bands are observed at 393 and 409 cm^{-1}. These bands are

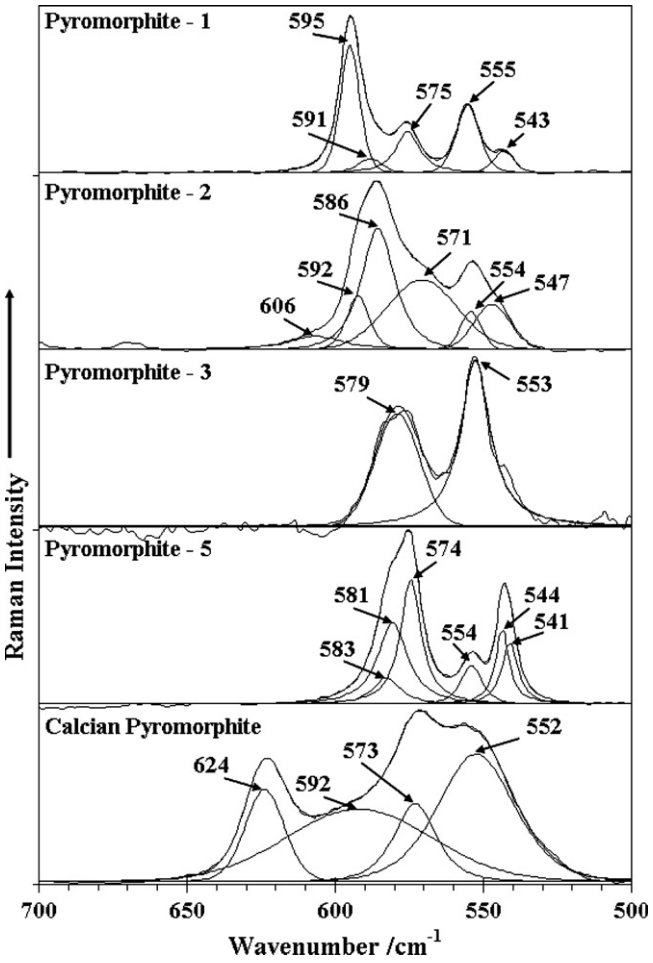

Fig. 4. Raman spectra of pyromorphite in the low wavenumber cm^{-1} region.

non-symmetric and other bands may be resolved. Additional bands are observed at 390, 419 and 436 cm^{-1}. For pyromorphite 2, Raman bands are observed at 396, 424 and 430 cm^{-1}. The additional complexity is accounted for by the reduced symmetry of phosphate anion in pyromorphite 2. In addition two bands are observed at 331 and 354 cm^{-1}. These Raman bands are attributed to the v_2 bending modes of the arsenate anion [38–45] and in effect provides evidence for some arsenate substitution of phosphate in this mineral. The Raman spectrum in pyromorphite 5 shows an even more complex profile. Two Raman bands for pyromorphite 5 at 347 and 375 cm^{-1} are attributed to the v_2 bending modes arsenate anion. Pyromorphite 2 and 5 are arsenian pyromorphite, indicated by the two additional bands. Two Raman bands at 347 and 375 cm^{-1} are attributed to the v_2 bending modes arsenate anion and the bands at 392 and 418 cm^{-1} to the v_2 bending modes of the phosphate anion. Pyromorphites 1, 2, 3 and 5 show exactly five bands after deconvolution in the range 390–451 cm^{-1}. The only difference is the additional bands 331–375 cm^{-1}, which can be accounted for arsenate substitution. It is noted that the position of these bands have not been previously reported. Farmer (page 390) simply state

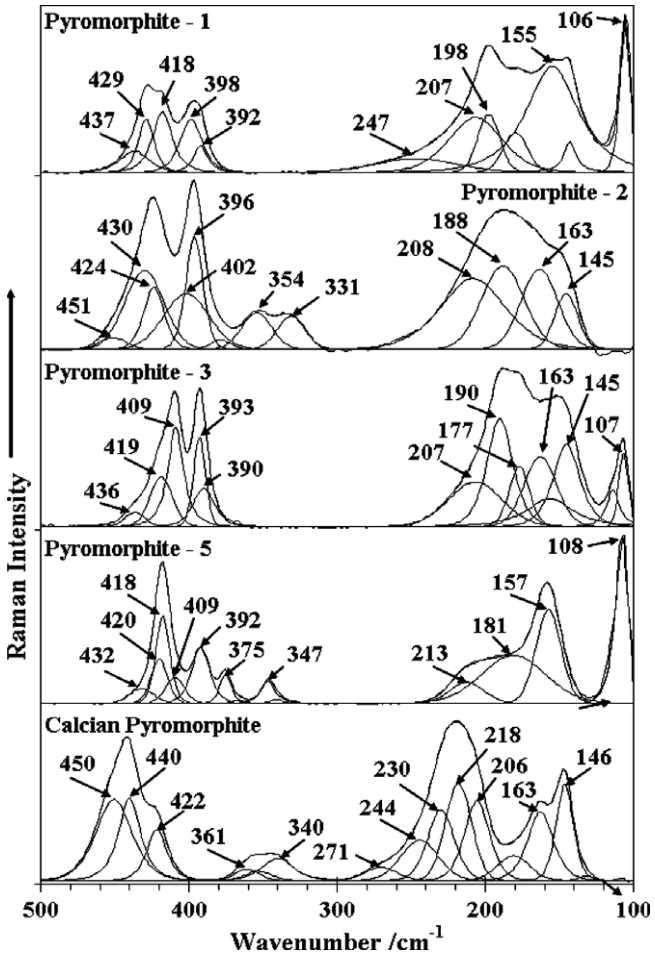

Fig. 5. Raman spectra of pyromorphite in the low wavenumber region.

that the bands occurred at <400 cm^{-1} [11]. No recent vibrational spectroscopic studies of these types of apatite minerals have been forthcoming [46–48]. Botto et al. showed that by using vibrational spectroscopic techniques the Cl in pyromorphite can be replaced by OH units [49]. These workers also showed that some carbonate anions were present in a pyromorphite mineral and replaced the phosphate in the minerals [49]. In the calcian pyromorphite, two broad low intensity Raman bands at 340 and 361 cm^{-1} are attributed to the presence of arsenate and the Raman bands at 422, 440 to the phosphate v_2 bending modes. This study has shown that several of the so called pyromorphite minerals contain arsenate as a substitute for phosphate. It is apparent that arsenate can readily replace phosphate in the structure. The study of this spectral region goes a long way to proving the solid solution formation of the mimetite–pyromorphite series [50]. A broad profile in the Raman spectra from 100 to 250 cm^{-1} is observed. It is difficult to define the attribution of bands in this spectral region other than to define the bands as lattice modes. The intense band at 107 cm^{-1} is present in pyromorphite 1, 3 and 5 spectra but is absent in the spectra of pyromorphite 2 and the calcian pyromorphite. Such a presence or absence of a band may be due to orientation effects.

The Raman spectra of selected pyromorphite minerals in the 3000–4000 cm^{-1} are shown in Fig. 6. Infrared spectra were also obtained but the quality of the spectra were lacking and were not reported. The spectra suffered from a poor signal to noise ratio and the spectrum of water vapour contributed to this noise. It is interesting that significant Raman intensity is observed in this spectral region. There are a number of possibilities for the assignment of these bands (a) OH stretching vibrations as an isomorphic substitution of OH units for Cl^- ions in the pyromorphite structure (b) the bands are due to OH vibrations of adsorbed water (c) the bands are due to OH vibrations of bonded water. The Raman spectra of pyromorphite samples 1–3 show strong similarities in the 2500–4000 cm^{-1} region. One possible interpretation is that the bands in the 3000–3450 cm^{-1} region are ascribable to water OH stretching bands; the higher wavenumber bands at for example 3508 and 3642 cm^{-1} for pyromorphite 1 may be attributed to OH stretching vibrations resulting from the OH substitution for Cl^- ions in the pyromorphite structure. The higher wavenumber bands in the OH stretching region are not observed for the calcian pyromorphite. Instead a band at 3383 cm^{-1} is found and is assigned to the OH stretching vibration of water. In other words some

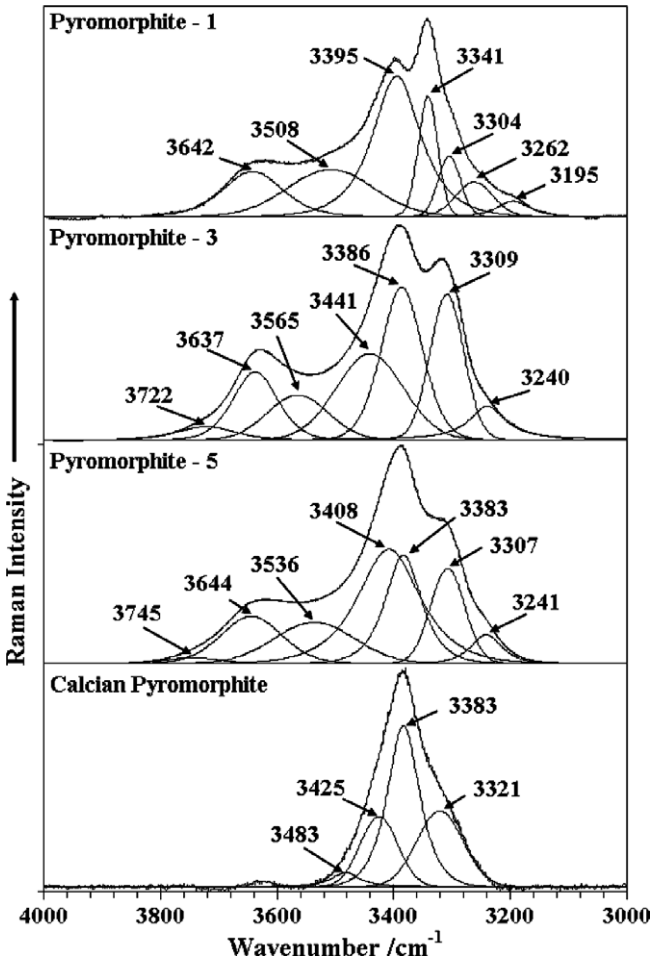

Fig. 6. Raman spectra of pyromorphite in the OH stretching region.

water is involved in the structure of natural pyromorphite. Further research would need to be undertaken to prove this concept. Botto et al. also found that Cl–OH substitution occurred for pyromorphite [49]. A previous study by the principal author on the Raman spectra of vanadinite also proved that substitution of vanadinite by phosphate and the partial replacement of chloride by hydroxyl units can occur [51].

4. Conclusions

This research has found the following results:

(a) Raman spectroscopy can be used to characterise pyromorphite and arsenian substituted pyromorphites.
(b) For most pyromorphite minerals splitting of the v_1 $(PO_4)^{3-}$ symmetric stretching mode is observed, implying the phosphate units in the structure are not equivalent.
(c) The implication is that the phosphate units are not all equivalent in the structure of pyromorphite.
(d) In selected pyromorphite minerals some replacement of phosphate by arsenate occurs as is observed in the Raman spectra.
(e) Similarly replacement of the Cl^- ion by OH^- units is confirmed by the Raman spectra in the OH stretching region.
(f) Multiple bands in both the v_4 and v_2 bending regions support the concept of the reduction in symmetry of the phosphate anion in pyromorphite.
(g) The true formula of pyromorphites in practice is significantly different from that commonly accepted. A more appropriate formula is $Pb_5(PO_4, AsO_4)_3(Cl,OH) \cdot xH_2O$. Such a formula is supported by the work of Botto et al. who showed that substitution of Pb, $(PO_4)^{3-}$, and Cl by Ca, Ba, $(CO_3)^{2-}$ and OH can readily occur [49].
(h) This research has also shown that pyromorphite contains chemically bonded water.

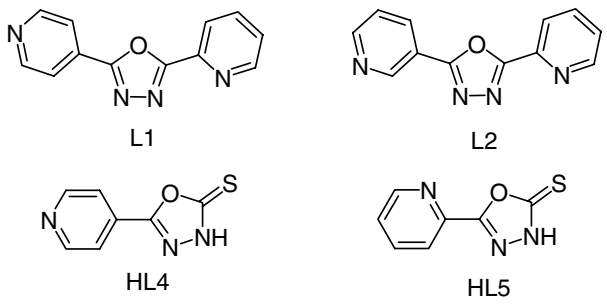

Chart 1.

discrete complexes generated from unsymmetric oxadiazole-containing organic ligands and inorganic salts. So far, a variety of products resulting from the assembly of metal salts with unsymmetric oxadiazole-bridged ligands (**L1** and **L2**, Chart 1) have been synthesized and characterized by us, which possess some specific features of tunable achiral/chiral helix and NLO-active properties [16]. Meanwhile, only few polymeric compounds containing **HL4** (Chart 1) have been reported by us and other groups [17]. Up until now, the coordination polymers or supramolecular complexes based on oxadiazole-bridged organic ligands, such as 5-(2-pyridyl)-1,3,4-oxadiazole-2-thione (**HL5**), are in general undeveloped. This encouraged us to undertake further studies on unsymmetric oxadiazole-containing ligands of this type and explore their interesting coordination chemistry. Following this approach, we now expand the coordination chemistry with **HL5**. As we all know, d^{10} transition-metal ions, such as Zn(II), Cd(II) and Hg(II), can produce a variety of complexes that not only exhibit appealing structures but also possess photoluminescence properties. In this contribution, three new divalent d^{10} transition-metal coordination polymers and discrete coordination complexes, namely, $[Zn(\mathbf{L5})_2(H_2O)_2]$ (**2**), $[Cd(\mathbf{L5})_2]_n$ (**3**) and $[Hg_2(\mathbf{L5})_4]$ (**4**), were successfully isolated, which shows the effect of metal radii on the formation of different coordination complexes. In addition, thermal stabilities, room-temperature solid state luminescent and SHG (second-harmonic generation) properties of **HL5** and **2**, **3** and **4** were investigated in detail.

2. Experimental

2.1. Materials and general methods

The reagents and solvents employed were commercially available and were used as received without further purification. Elemental analyses were performed on a Perkin–Elmer 240 elemental analyzer. The FT-IR spectra were recorded from KBr pellets in the range 400–4000 cm^{-1} on a Bruker Tensor27 spectrometer. ^1H and ^{13}C NMR spectra were recorded on a Bruker AV-400 NMR spectrometer at 400 and 100 MHz using DMSO-d_6 solution at room temperature; the DMSO-d_6 signal was used to lock the field and all chemical shifts are given relative to tetramethylsilane (TMS). Thermogravimetric analysis (TGA) data were collected with a Perkin–Elmer TGS-2 analyzer in N_2 at a heating rate of 10 °C min^{-1}. The emission/excitation spectra were recorded on an Edinburgh FLS920 spectrometer equipped with a continuous Xe900 Xenon lamp and an nF900 ns flash lamp. Kurtz powder SHG measurements were performed on ground samples of crystalline **2**–**4** with a synchroscan streak camera (Hamamatsu Model C1587, 8 ps resolution) connected to a polychromator as the detector system, and an optical parametric generator (Spectra Physics, Model:OPA-800C) pumped by a mode-locked Ti:sapphire laser oscillator–amplifier system (Spectra Physics, Model: Hurricane) as the pump source. The powder second-harmonic signals were compared to that of urea to determine the relative SHG efficiencies of **2**–**4**.

2.2. Synthesis of the ligand 5-(2-pyridyl)-1,3,4-oxadiazole-2-thione (*HL5*, *1*)

To a solution containing 95% ethanol (80 ml) and potassium hydroxide solution (1.12 g, 20 mmol) was added picolinohydrazide (2.74 g, 20 mmol). After the solution was mixed, slightly more than 1 equiv. of carbon disulfide was added and the mixture was refluxed for 4 h. After concentration of the solution to a small volume, the residue was dissolved in water. A precipitate was obtained by adding the solution to ice containing hydrochloric acid. The solid was filtered off and dried. The crude production was recrystallized from alcohol to give block pale-yellow crystals **1**. Yield 70% (2.50 g). Mp: 209–210 °C. ^1H NMR (400 MHz, DMSO-d_6) δ: 8.8 (s, 1H), 8.0 (s, 1H), 7.5 (s, 2H), 3.3 (b, 1H). IR (KBr, cm^{-1}) v: 3127 (w), 3050 (w), 2855 (m), 2664 (br), 2586 (br), 1870 (w), 1802 (br), 1727(w), 1594 (s), 1566 (m), 1522 (s), 1472 (m), 1438 (s), 1349 (m), 1315 (s), 1256 (w), 1165 (m), 1145 (m), 1072 (m), 1046 (s), 1015 (w), 1002 (s), 975 (w), 957 (m), 937 (s), 881(m), 788 (s), 739 (s), 719 (w), 692 (s), 628 (m), 561 (s), 510 (m), 486 (w). ESI-MS (ESITOF N_2): m/z 180 (M+1). *Anal.* Calc. for $C_7H_5N_3OS$: C, 46.92; H, 2.81; N, 23.45. Found: C, 46.81; H, 2.80; N, 23.54%.

2.3. Synthesis of $[Zn(L5)_2(H_2O)_2]$ (*2*)

A water solution (5 ml) containing **HL5** (0.035 g, 0.2 mmol) was placed at the bottom of a straight glass test tube of 150 mm length and 15 mm diameter. In the middle of the tube was placed a buffer layer of 1:1 methanol–water (5 ml). $ZnSO_4 \cdot 7H_2O$ (0.029 g, 0.1 mmol) in a methanol solution (4 ml) was then added above the buffer layer. After two weeks, good pale-yellow bar-shaped crystals suitable for X-ray diffraction were obtained in a yield of 75%. *Anal.* Calc. for $C_{14}H_{12}N_6O_4S_2Zn$: C, 36.73; H, 2.64; N, 18.36. Found: C, 36.63; H, 2.62; N, 18.40%. IR (KBr, cm^{-1}) v: 3239 (br, w), 3058 (w), 1616 (m), 1572 (w), 1550 (m), 1490 (m), 1442 (w), 1405 (w), 1393 (m), 1372 (s), 1301 (w), 1266 (w), 1174 (w), 1162 (m), 1102 (m), 1084 (s), 1049 (s), 1019 (m), 892 (s), 798 (s), 749 (w), 724 (m), 700 (s), 644 (m), 536 (br, m), 490 (w), 412 (m).

2.4. Synthesis of $[Cd(L5)_2]_n$ (3)

A water solution (5 ml) containing **HL5** (0.035 g, 0.2 mmol) was placed at the bottom of a straight glass test tube of 150 mm length and 15 mm diameter. In the middle of the tube was placed a buffer layer of 1:1 methanol–water (4 ml). $CdSO_4 \cdot 8/3H_2O$ (0.026 g, 0.1 mmol) in a methanol solution (5 ml) was then added above the buffer layer. After three days, pale-yellow black-shaped crystals suitable for X-ray diffraction were obtained in a yield of 65%. *Anal.* Calc. for $C_{14}H_8CdN_6O_2S_2$: C, 35.87; H, 1.72; N, 17.93. Found: C, 35.75; H, 1.70; N, 17.99%. IR (KBr, cm^{-1}) *v*: 3055 (m), 2039 (w), 1958 (w), 1606 (m), 1574 (w), 1540 (s), 1477 (s), 1418 (s), 1394 (w), 1371 (m), 1291 (w), 1266 (w), 1157 (m), 1096 (m), 1070 (s), 1035 (m), 1008 (w), 892 (s), 795 (s), 745 (m), 720 (w), 706 (m), 685 (w), 632 (m), 540 (w), 497 (w), 405 (s).

2.5. Synthesis of $[Hg_2(L5)_2]_n$ (4)

A water solution (5 ml) containing **HL5** (0.035 g, 0.2 mmol) was placed at the bottom of a straight glass test tube of 150 mm length and 15 mm diameter. In the middle of the tube was placed a buffer layer of 1:1 methanol–water (4 ml). $HgBr_2$ (0.036 g, 0.1 mmol) in a methanol solution (5 ml) was then added above the buffer layer. Well-shaped plate crystals of **4** suitable for X-ray diffraction were obtained within one week in 70% yield. *Anal.* Calc. for $C_{28}H_{16}Hg_2N_{12}O_4S_4$: C, 30.19; H, 1.45; N, 15.09. Found: C, 30.30; H, 1.44; N, 15.17%. IR (cm^{-1}) *v*: 3052 (m), 2038 (w), 1960 (w), 1607 (m), 1542 (s), 1478 (s), 1416 (s), 1370 (m), 1293 (w), 1268 (w), 1158 (m), 1094 (m), 1068 (s), 1037 (m), 1010 (w), 895 (s), 795 (s), 744 (m), 721 (w), 706 (m), 684 (w), 630 (m), 494 (w), 405 (s).

2.6. X-ray crystallography

Single-crystal X-ray diffraction measurements of **1**–**4** were carried out with a Bruker APEX II CCD diffractometer equipped with a graphite crystal monochromator situated in the incident beam for data collection at 293(2) K. The lattice parameters were obtained by least-squares refinement of the diffraction data of 567 (for **1**), 774 (for **2**), 798 (for **3**) and 668 (for **4**) reflections, and data collections were performed with Mo Kα radiation ($\lambda = 0.71073$ Å). All the measured independent reflections were used in the structural analysis, and semi-empirical absorption corrections were applied using the SADABS program. The program SAINT [18] was used for integration of the diffraction profiles. All the structures were solved by direct methods using the SHELXS program of the SHELXTL package and refined with SHELXL [19]. Metal atoms were located from the *E*-maps and other non-hydrogen atoms were located in successive difference Fourier syntheses. The final refinement was performed by full-matrix least-squares methods with anisotropic thermal parameters for

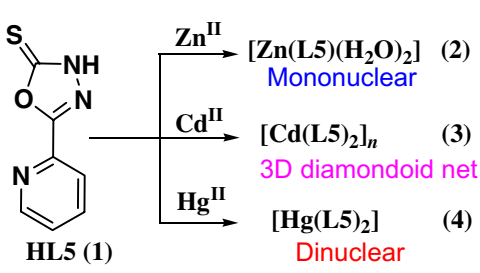
all the non-hydrogen atoms based on F^2. All the hydrogen atoms were first found in difference electron density maps, and then placed in the calculated sites and included in the final refinement with the riding model approximation with displacement parameters derived from the parent atoms to which they were bonded. A summary of the crystallographic data and structure refinements are listed in Table 1.



3. Results and discussion

3.1. Syntheses of complexes 2–4

All the complexes **2**–**4** were obtained as neutral complexes from a mixture of water and methanol solution by the reaction of **HL5** with three d^{10} transition-metal salts (Scheme 1). Compound **2** could also be isolated by using $Zn(NO_3)_2$ as the Zn(II) source, as confirmed by X-ray diffraction, IR spectra and elemental analyses. Similar cases were also observed for Cd(II) and Hg(II) complexes, which indicates that the final products are independent of the counter-anions in the metal salts. Furthermore, although **2**–**4** have the exact 2:1 ligand/metal compositions, our trials showed that the products do not significantly depend on the ligand-to-metal ratio (when the ligand/metal ratio is increased or decreased, complexes **2**–**4** still have 2:1 ligand/metal compositions).

3.2. Description of 1

Single X-ray analysis for compound **1** reveals that there is one molecule of **HL5** in the asymmetric unit (Fig. 1a). The pyridyl and oxadiazole plane is not co-planar (its dihedral angle is 4.47°), which is distinctively different from that of the free ligand **HL4** [17b]. It is surprisingly observed that **HL5** exists in the *cis*-conformation (Chart 2), partly because of being propitious to form hydrogen bonds. A pair of **HL5** molecules, each using the oxadiazole and pyridyl nitrogen atoms, forms one kind of hydrogen bond (N(3)–H(3A)···N(1) 2.732(2) Å) in the head-tail form. Additionally, each **HL5** molecule, using the pyridyl carbon atom and oxadiaozle sulfur atom, forms another kind of hydrogen bond (C(1)–H(1)···S(1) 3.830(1) Å) in the same head-tail form. These hydrogen bonds result in one-dimensional hydrogen-bonded chains [20]. Between the adjacent hydrogen-bonded chains, each **HL5** molecule further forms two donor-accept hydrogen bonds (C(2)–H(2)···S(1) 3.06 and 3.296 Å) with the thione sulfur of the adjacent oxadiazole ring from another pyridyl group; these chains align parallel but right about to each other, resulting in a wave-like two-dimensional hydrogen-bonded layer along the (0 1 1) plane (Fig. 1c). It is obvious that the layer structures in **HL5** are different from that in its analogue compound **HL4** [17b]. The layers are further extended into a three-dimensional supramolecular array via offset π–π aromatic stacking interactions with a face-to-face distance of ca. 3.50 Å between the oxadiazole and pyridyl rings (Fig. 1c and Figure S1). Two types of hydrogen-bonded patterns A–D, notated as

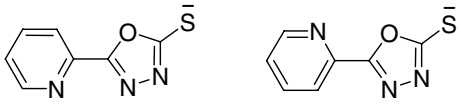

Chart 2.

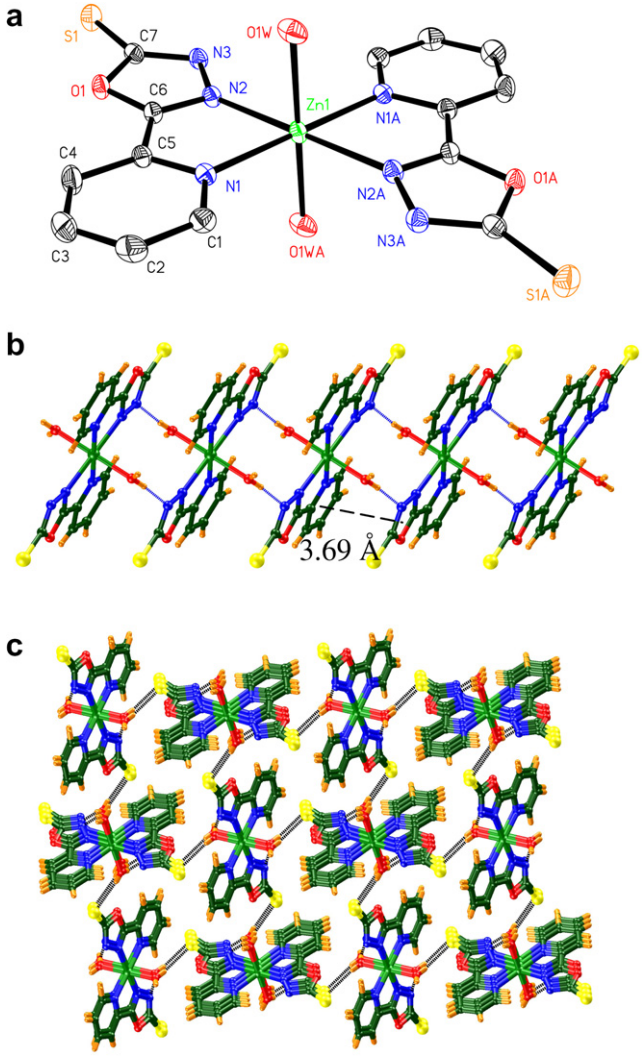
$R_4^3(20)$ (Fig. 1b(A)) and $R_2^2(7)$ (Fig. 1b(B)), are interestingly observed in this 2-D array (Fig. 1b).

3.3. Description of 2

In the centrosymmetric mononuclear compound **2**, each Zn^{II} ion is located at the inversion center. Each zinc ion coordinates to two pyridyl and two oxadiazole nitrogen atoms from two distinct **L5** moieties (Zn–N distance: 2.137(2) and 2.193 (2) Å, respectively) and two distinct water molecules (Zn–O lengths: 2.111(2) Å), as shown in Fig. 2a, adopting an approximate octahedral geometry (ZnN4O2). Ligand **L5** behaves as a bidentate chelating ligand (Scheme 2a), coordinating to the Zn^{II} center with only the N_{ox} (ox = oxadiazole) and N_{py} atom, thus resulting in this mononuclear structure.



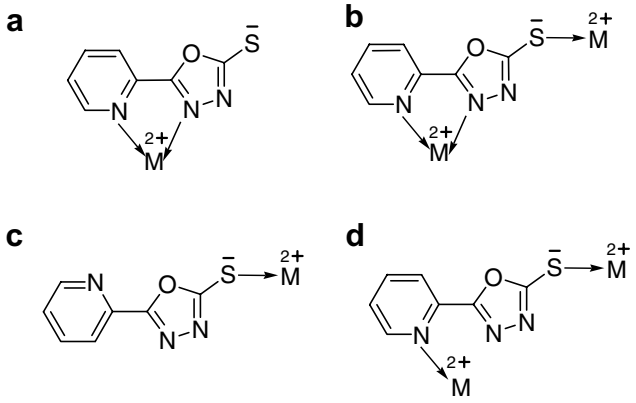


Fig. 2. (a) View of the mononuclear structure of **2** (hydrogen atoms are omitted for clarity). (b) View of the 1-D supramolecular chain along [0 1 1] plane. Thin blue lines stand for hydrogen bonds. (c) The stacking diagram of the parallel coordination sheets along the *a* axis. Thin blue lines stand for hydrogen bonds. (For interpretation of the references in color in this figure legend, the reader is referred to the web version of this article.)

Scheme 2. Coordination modes of **L5**.

Analysis of the crystal packing of **2** reveals the existence of intermolecular O–H···N hydrogen bonds, O(1w)–H(1wB)···N(3)^{i} (i = 1 + *x*, *y*, *z*), between the oxygen atom from water O(1w) ligands and the nitrogen atom from the oxadidazole group of ligand **L5** (Fig. 2b). In addition, there are intermolecular O–H···S hydrogen bonds, O(1W)–H(1WA)···S1^{ii} (ii = 1/2 + *x*, 3/2 − *y*, − 1/2 + *z*), between the sulfur atoms and one of the O(1w) water ligands from an adjacent complex molecule [20]. The O···N separation is 2.874 Å with a H···O distance of 2.09 Å, and a bond angle of 167°. Additionally, the O···S separation is 3.269 Å with a H···S distance of 2.52 Å, and a bond angle of 176°, being in the normal range of such non-covalent interactions [20].

Therefore, these mononuclear subunits are connected through these hydrogen bonds and π···π stacking interactions (3.69 Å) to form a three-dimensional supramolecular network (Fig. 2b and c).

It is very interesting that the S–C bond (the bond length is 1.674(2) Å) in **L5** is longer than that in free **HL5**, whereas the N3–C7 bond (1.319(3) Å) of **L5** anion is shorter than that of free **L5** (Table 2). These results are in agreement with its uncoordinated structural geometry. In complex **2**, the dihedral angle between the oxadiazole and pyridyl plane of **L5** (5.36°) is bigger than that of the free ligand **HL5**. It is noteworthy that the conformation of **L5** is *trans*-in complex **2**, obviously distinguished from that of the free ligand **HL5** (Chart 2 and Fig. 1a).

3.4. Description of 3

When the place of the Zn^{II} ion has been taken by the large Cd^{II} ion, a different structure is formed for **3** under similar reaction conditions. Compound **3** crystallizes in the acentric space group *Fdd2*. Each asymmetric unit of **3** contains one Cd atom and one **L5** ligand. As shown in Fig. 3a, the local coordination geometry around the Cd1 center can be described as a distorted octahedral geometry. The Cd1 center coordinates to four nitrogen atoms and two sulfur atoms from four distinct **L5** moieties (Fig. 3a).

The Cd1 center is connected to four adjacent Cd centers through the **L5** bridges resulting in a neutral 3D

diamondoid coordination polymer (Fig. 3b) with adjacent Cd···Cd separations of 7.69(1) Å and Cd–Cd–Cd angles of 73.8–151.5°. These angles are significantly deviated from 109.45°, the expected value for an idealized diamond network [21], thus the diamondoid network in **3** is distorted (Figure S2). Although there are long Cd···Cd separations in **3**, no cavities are formed within each diamondoid net (Fig. 3b). The crystal structure of **3** is very similar to those reported previously [6c]. However, it is noted that no interpenetration was formed in the diamondoid net **3**, which is obviously different from those reported previously [6b,21], probably because of **L5** possessing a rigid structure and a short distance between the donor atoms.

Ligand **L5** acts in the bis-monodentate or chelating-tridentate mode (Scheme 2b) in **3**, which is different from that in **2**. However, it is noteworthy that **L5** in both **2** and **3** only exists in the *trans*-conformation (Chart 2).

3.5. Description of *4*

When the larger Hg^{II} ions were used instead of Zn^{II} and Cd^{II} ions, another different structure is generated, in the form of **4**, under similar reaction conditions. The structure of complex **4** is shown in Fig. 4a. The molecules of **4** exist

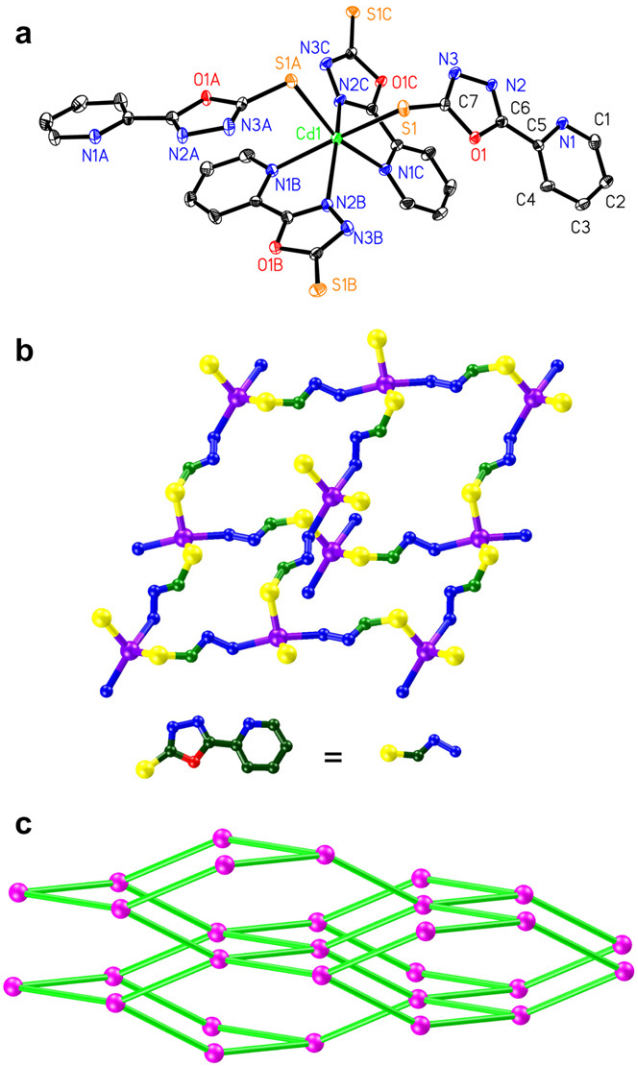

Fig. 3. (a) Coordination environment of the metal atom in **3** (hydrogen atoms are omitted for clarity). (b) The simplied presentations of the diamondoid net of **3**. (c) The schematic presentations of the uninterpenetrated diamondoid network in **3**.

as a centrosymmetric 14-membered metallacyclic ring formed by two **L5** ligands that bridge two Hg^{II} ions with the pyridine nitrogen and oxadiazole sulfur in the *trans*-form. However, the metallacyclic ring in **4** is non-planar. The dihedral angle between the pyridyl and oxadiazole rings is 6.77°. The opposite oxadiazolyl rings and pyridyl rings are parallel to each other. It is interestingly observed that intermolecular π···π stacking interactions exist between the oxadiazole rings (the distance is 3.38 Å) in the metallacycle (Fig. 4a). In this complex, the **L5** ligand has two coordination modes, a monodentate mode (Scheme 2c) and bidentate bridging mode (Scheme 2d), and each Hg^{II} center is coordinated by one pyridine nitrogen atom and two oxadizole sulfur atoms from three different **L5** ligands, showing a distorted "T" shaped geometry with a N–Hg–S average bond angle in the range 87.7(1)–170.6(1)°. The bond lengths of Hg–N of 2.39 Å and Hg–S_{av} of 2.84 Å fall within the

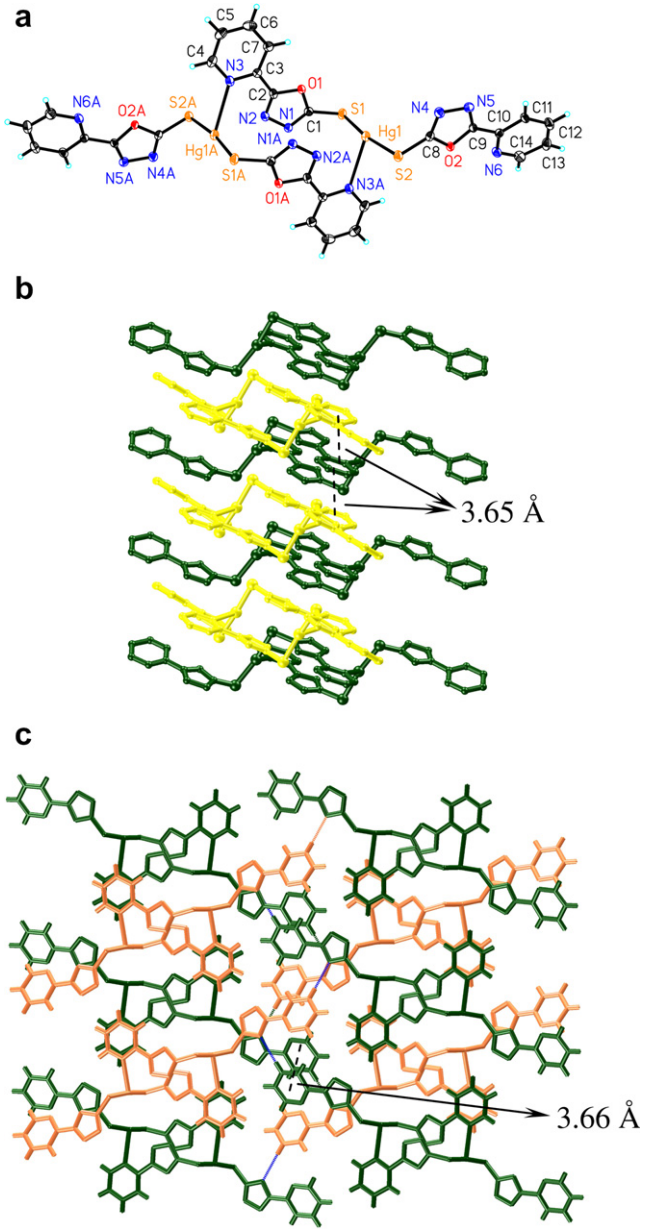

Fig. 4. (a) Coordination environment of the metal atoms in **4**. (b) View of the 1-D supramolecular chain from the side. (c) The stacking diagram of the parallel coordination sheets along the *c* axis.

range of expected values (Table 2). The binuclear structures are connected to each other through π···π stacking interactions (the distance between two macrocycles is 3.65 Å) [20] to form an infinite chain of macrocycles like a stair structure along the *c* axis (Fig. 4b and Figure S3). These 1-D chains further result in the formation of an infinite 2-D supramolecular layer along the *ab* plane through π···π stacking interactions and weak C–H···π interactions (the distance is 3.65 Å, C–H···π 2.94 Å) (Fig. 4c). These 2-D supramolecular layers are further constructed into a 3-D supramolecular structure by weak intermolecular hydrogen-bonds [C(12)–H(12A)···O1^{i} (3.33(1) Å)] ($i = -x, -1/2 + y, 1/2 - z$) and π···π stacking interactions (3.66 Å) (Fig. 4c).

It is noteworthy that **L5** in **4** exists not only in the *trans*-conformation but also in the *cis*-conformation, which is different from both **2** and **3** (Chart 2).

3.6. Thermogravimetric analysis (TGA)

To study the thermal stability of compounds **2**–**4**, thermal gravimetric analyses (TGA) were performed on the single-crystal samples. For complex **2**, the first weight loss occurred in stages starting at 155 °C and completing at 218 °C, corresponding to the loss of two coordinated water molecules. The anhydrous complex suffered serious mass loss upon heating to 275 °C, attributable to decomposition of the organic ligand. For complex **3**, there is no weight loss below 335 °C. The main structure decomposed at 405 °C, exhibiting high thermal stability. Complex **4** began to decompose at 289 °C, then there was one obvious weight-loss stage in the range 289–420 °C, corresponding to decomposition of the ligand.

3.7. Luminescent properties

Construction of coordination polymers and discrete complexes by the judicious choice of organic spacers and transition-metal ions can be an efficient method for obtaining new electroluminescent materials, due to the higher thermal stability of coordination polymers and discrete complexes, and the ability to enhance, shift and quench luminescent emission of organic ligands [4]. The luminescent spectra of free ligand **HL5** and its metal complexes **2**–**4** were investigated in the solid state at room temperature (Fig. 5). The solid state luminescent analyses show that complexes exhibit different properties. As shown in Fig. 5, the free **HL5** ligand displays weak luminescence in the solid state at room temperature; the emission for free ligand **HL5** (**1**) is at 444 nm ($\lambda_{ex} = 395$ nm), which can be assigned to the $\pi^{*}\rightarrow\pi$ transition of the oxadiazole moiety [22]. However, its complexes **2** and **3** exhibit intense greenish-blue radiative emission maxima at ca. 524 and 502 nm

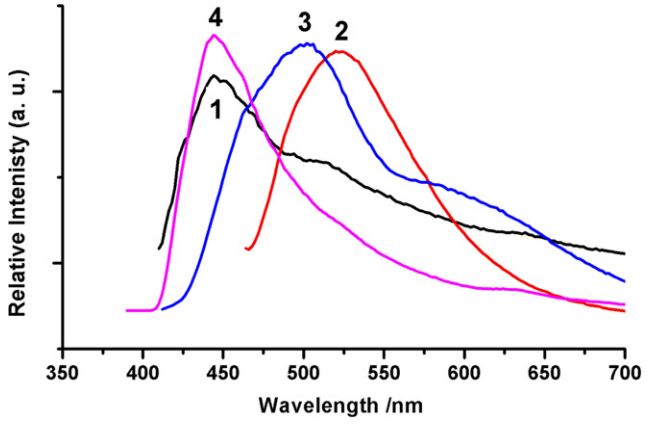

Fig. 5. Photoinduced emission spectra of free ligand **1** (**HL5**) and its complexes **2**–**4** in the solid state at room temperature.

($\lambda_{ex} = 405$ nm), which are red-shifted by 80 and 58 nm compared to the free ligand, respectively. These can be assigned tentatively to ligand-to-metal charge transfers (LMCT) [4]. However, complex **4** exhibits a strong emission at 444 nm ($\lambda_{ex} = 380$ nm), which can be tentatively assigned to the intraligand emission of the **L5** ligand. It is observed that compared to the spectra of the free ligand **HL5**, there was neither a blue-shift nor a red-shift phenomena in the spectrum of **4**. In other words, the emission color and intensity of the free ligand **HL5** is significantly affected by its incorporation into the complexes containing metal ions. Thus the difference in the intensity of emission results from the different d^{10} transition-metals, which suggests that the change of radius and coordination geometries has an important effect on the fluorescent properties.

3.8. SHG efficiency

According to the principles proposed by Kurtz and Perry [23] the strength of the second harmonic generation (SHG) efficiency of the compounds can be estimated by measuring powder samples. Only complex **3** is SHG-active (0.6 U, U = SHG intensity of urea), which confirms that it crystallizes in a polar space group and is in agreement with the structural analyses.

4. Conclusions

Three new inorganic–organic coordination polymer and discrete complexes are generated from a versatile organic ligand 5-(2-pyridyl)-1,3,4-oxadiazole-2-thione and d^{10} transition-metal salts. This work demonstrates that the rigid and unsymmetric **L5** anion adopts different coordination modes along with the variation of the metal radii, which plays a very important role in the construction and the properties of these new materials. In addition, the coordination geometry of the metal ions is very important for the formation of acentric crystal structures. We are currently extending this result by preparing other new multifunctional ligands of this type with different coordination groups. It is anticipated that this new type of organic ligands will result in a variety of coordination polymers or supramolecules with unique structural features and interesting properties.

Our previous studies have focused on the synthesis of new pcs exhibiting liquid crystal and gas sensor properties [27–29,33–39]. The films of the pcs showing mesomorphic properties at room temperature have been proven to be used as photoconductors and gas sensors in molecular electronic devices. The ordered pc films obtained from liquid crystalline pc compounds are more sensitive than disordered pc films [28,39]. Recently, we have reported the synthesis of peripherally symmetrical substituted octa *p*-tolyl-sulfonyl (tosyl) amido pcs and their NMR and UV spectra investigations in different solvents and pH [40]. We have found that the hydrogen bonding capacity and deprotonation of the tosylamido groups causes interesting spectroscopic properties. Their potential application as chemical gas sensor is being investigated. However, only tosylamido substitution of the pc ring was not enough to exhibit mesogenic properties. Therefore, we designed electron-with-drawing tosylamido and donor alkylthia substituted novel unsymmetrical pcs which are liquid crystals owing to the alkyl chains. The synthesis, characterization and investigation of mesogenic properties are reported here. Also, the influence of the presence of the tosylamido unit on the phthalocyanine core on the mesomorphic properties was determined.

2. Experimental methods

2.1. Materials

The 4,5-dicyano-*N*,*N*′-ditosyl-*o*-phenylenediamine (**1**) [40] and 1,2-di(alkylthio)-4,5-dicyanobenzene derivatives (**2a**–**2c**) [41,42] were synthesized according to published procedures. All other reagents and solvents were reagent-grade quality, obtained from commercial suppliers and dried before use as described by Perrin and Armarego [43].

3. Measurements

Elemental analyses were obtained from Thermo Finnigan Flash 1112. Infrared spectra in KBr pellets were recorded on a Bio-Rad FTS 175C FT IR spectrophotometer. Optical spectra in the UV–Vis region were recorded with a Shimadzu 2001 UV PC spectrophotometer using a 1 cm pathlength cuvette at room temperature The mass spectra were recorded on a LCQ-ion trap (Thermofinnigan, San Jose, CA,USA), equipped with an Electrospray (ES) source. ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ solutions on a Varian 500 MHz spectrometer. Thermogravimetric analyses were carried out on Mettler Toledo Star^e Thermal Analysis System at a rate of 10 °C min^{-1}in a nitrogen flow (50 ml min^{-1}). The phase transition behaviour of these compounds was observed by means of a polarizing microscope (Leitz Wetzler Orthoplan-pol.) equipped with a hot stage (Linkam TMS 93) and temperature-controller (Linkam LNP). Transition temperatures were determined with a scan rate of 10 °C min^{-1} using a Mettler Toledo Star^e Thermal Analysis System/DSC 822^e. The differential scanning calorimeter system was calibrated with indium from 3 to 4 mg samples under nitrogen atmosphere.

3.1. Synthesis of asymmetric phthalocyanines

3.1.1. 2,3,9,10,16,17-Hexakis(hexylthio)-23,24-bis(tosilamido)phthalocyaninato nickel(II) (**3a**)

A mixture of 1,2-di(hexylthio)-4,5-dicyanobenzene (**2a**) (2 mmol), 4,5-dicyano-*N*,*N*′-ditosyl-*o*-phenylenediamine (**1**) (1 mmol), anhydrous $NiCl_2$ (1.5 mmol), 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU, 3 mmol) and 4 ml dried *n*-hexanol were heated to reflux for 18 h under an argon atmosphere. After cooling to room temperature the mixture was treated with ethanol (10 ml), filtered off and washed several times with ethanol. The dark green product was purified by preparative thin layer chromatography (TLC) using a 5:2 CH_2Cl_2/*n*-hexane solvent system. Yield: 8%. Elemental *Anal*. Calc. for $C_{82}H_{102}N_{10}NiO_4S_8$ (1605): C, 61.29; H, 6.40; N, 8.72. Found: C, 61.10; H, 6.35; N, 8.70%. IR (KBr) ν_{max} (cm^{-1}): 3258 (NH), 2956–2856 (CH_2, CH_3), 1599 (C_{ar}=N), 1350, 1163 (SO_2), 560 (CS). MS (ES–MS), *m*/*z* (%): 1606 (100) $[M+H]^+$, 1607 (50) $[M+2H]^+$. ^{1}H NMR ($CDCl_3$) δ: 0.94–1.18 (m, 18H, CH_3), 1.43–2.00 (m, 36H, CH_2), 2.21 (t, 6H, Ar–CH_3), 3.05–3.58 (m, 24H, CH_2), 7.9–8.42 (m, 18H, NH, CH_{ar}). ^{13}C NMR ($CDCl_3$, Decoupled) δ: 13.09 (CH_3), 13.16 (CH_3), 20.59 (CH_2), 21.59 ($C_{ar}CH_3$), 27.72–28.16 (CH_2), 30.50–33.07 (CH_2), 118.5 ($C_{ar}H$), 124.10 ($C_{ar}H$), 127.08 ($C_{ar}H$), 128.8 (C_{ar}), 129.85 ($C_{ar}H$), 132.05 (C_{ar}), 132.72 (C_{ar}), 134.7 (C_{ar}), 138.71 (C_{ar}), 139.11 (C_{ar}), 141.00 (C_{ar}), 143.01 (CN), 143.50 (CN).

3.1.2. 2,3,9,10,16,17-Hexakis(dodecylthio)-23,24-bis(tosilamido) phthalocyaninato nickel(II) (**3b**)

A mixture of 1,2-di(dodecylthio)-4,5-dicyanobenzene (**2b**) (2 mmol), 4,5-dicyano-*N*,*N*′-ditosyl-*o*-phenylenediamine (**1**) (1 mmol), anhydrous $NiCl_2$ (1.5 mmol), 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU, 3 mmol) and 4 ml dried *n*-hexanol were heated to reflux for 18 h under an argon atmosphere. After cooling to room temperature the mixture was treated with ethanol (10 ml), filtered off and washed several times with ethanol. The dark green product was purified by preparative thin layer chromatography (TLC) using a 5:1 CH_2Cl_2/*n*-hexane solvent system. Yield: 7%. Elemental *Anal*. Calc. for $C_{118}H_{174}N_{10}Ni\ O_4S_8$ (2110): C, 67.11; H, 8.30; N, 6.63. Found: C, 67.00; H, 8.31; N, 6.70%. IR (KBr) ν_{max} (cm^{-1}): 3263 (NH), 2957–2856 (CH_2, CH_3), 1598 (C_{ar}=N), 1348, 1164 (SO_2), 559 (CS). 4. Result and discussions

4.1. Synthesis and characterization

The synthetic route of the pcs is shown in Scheme 1. 1,2-Di(alkylthio)-4,5-dicyanobenzenes (**2a**–**2c**) and 4,5-dicyano-*N*,*N*′-ditosyl-*o*-phenylenediamin (**1**) were synthesized according to the published procedures [40–42]. For the preparation of the pcs, we tried two different methods: ring expansion of corresponding sub-pc and statistical condensation of the phthalonitriles. For the first method, the diiminoisondoline derivative of **1** is required. Probably due to hydrolysis of the tosyl groups, it could not be obtained according to the literature [45–47]. Therefore, we adopted the second method (the statistical condensation method) for the preparation of the asymmetric pcs (**3a**–**3c**). Mixed condensation of 1,2-di(alkylthio)-4,5-dicyanobenzene (**2a**–**2c**) and 4,5-dicyano-*N*,*N*′-ditosyl-*o*-phenylenediamin (**1**) in the presence of anhydrous nickel (II) chloride, DBU as a strong nitrogen base and *n*-hexanol as the solvent afforded the asymmetric pcs (**3a–3c**). Generally, this method predicts that the reaction of two different phthalonitriles of the same reactivity in a 3:1 ratio will afford a mixture of products in the following percentages: A_4 33%, A_3B 44%, other cross-condensation products 23% [44]. In our case, the 1,2-di(alkylthio)-4,5-dicyanobenzene derivatives (**2a**–**2c**) are much more reactive than 4,5-dicyano-*N*,*N*′-ditosyl-*o*-phenylenediamine (**1**), therefore the symmetric octaalkylthio phthalocyanine (A_4) derivatives were found to be more preferable than the asymmetric **3a**–**3c** pcs (A_3B). To increase the yield of the asymmetric pcs (**3a**–**3c**) we tried several experiments with different molar ratios, and a 2:1 ratio of two dinitrile derivatives **2a**–**2c** and **1** was found to be the most appropriate. The asymmetric pcs (**3a**–**3c**) were separated by preparative thin layer chromatography from the corresponding symmetric octaalkylthio substituted Ni(II) pc derivatives [$NiPc(SR)_8$] and the other products.

Elemental analysis results and the spectral data (^{1}H NMR, ^{13}C NMR, FT IR, UV–Vis and MS) for the newly synthesized pcs (**3a**–**3c**) were consistent with the assigned formulations. The results are given in the experimental section.

The IR spectral results of the pcs (**3a**–**3c**) are different from the precursors **1** and **2a**–**2c**, so the sharp peak for the C≡N vibrations around 2220–2240 cm^{-1}, associated

Scheme 1. Synthesis of phthalocyanines **3a**–**3c** (i) metal salt, DBU, *n*-hexanol, reflux.

with the nitrile groups, disappeared after conversion into the pcs. The NH groups gave absorption bands at around 3260 cm^{-1} and the characteristic vibration of SO_2 groups appeared at around 1340 and 1160 cm^{-1} in the spectra of all the pcs, and confirmed the presence of the tosylamido groups. In addition, a group of intense absorption bands was also seen in the range 2856–2957 cm^{-1} in the IR spectra of **3a**–**3c**. These can be attributed to the C-H stretching vibrations of the substituted alkyl chains.

A close investigation of the mass spectra of **3a**–**3c** confirmed the proposed structures. The mass spectra of these compounds were obtained by the electron spray (ES) technique. We observed the molecular ion peaks of the pcs at *m/z*: 1606 for **3a**, *m/z*: 2111 for **3b** and *m/z*: 2446 for **3c.**

A common feature of the ^1H NMR spectra of the pcs (**3a**–**3c**) is the broad absorptions probably caused by the aggregation of the pc, which is frequently encountered at the concentrations used for NMR measurements. The ^1H NMR spectra of **3b** and **3c** are similar to that of **3a**. The ^1H NMR spectrum of **3a** exhibits the aromatic and NH protons at 7.90–8.42 ppm as multiplets, the aliphatic CH_2 protons between 1.43 and 3.58 ppm as multiplets, CH_3 protons at δ 0.94–1.18 and ArC–CH_3 protons at around 2.21 ppm. The ratio of aromatic to aliphatic protons appears to show that the benzo groups with two different substituents are present in a 3:1 ratio. The ^{13}C NMR spectral data of **3a**–**3c** given in experimental section are also in accord with the expected structures.

The blue-green pcs show typical electronic spectra with two strong absorption bands: a Soret (B) band at around 300–350 nm and a Q band at around 600–700 nm. The UV–Vis. spectra of **3a**–**c** were obtained in chloroform and the results are given in Table 1. All of these pcs gave very similar spectra; they show the Q band at 697 nm and the B band at 323 nm. Increasing the length of the alkyl chain caused a decrease of the intensity of the Q band as expected. The electronic spectrum is given for compound **3a** (Fig. 1). In addition to this octatosylamido Ni(II) and octahexilthia Ni(II) phthalocyanines are given in Fig. 1 to compare the absorption bands. The electronic absorption spectrum of octatosylamido Ni(II) phthalocyanine gave two Q bands in chloroform: a monomeric Q band around 680 nm together with a blue-shifted intense band around 640 nm corresponding to aggregated species. No additional band around 640 nm corresponding to aggregated species was observed in the electronic spectra of the asymmetric species (**3a**–**3c**). Octahexylthia substituted Ni(II) phthalocyanine also a gave different electronic spectrum from its

asymmetric derivative (**3a**), with a Q band around 702 nm and a higher extinction coefficient than **3a**.

4.2. Mesomorphic properties

The phase transition behaviours of the compounds **3a**–**3c** were determined by differential scanning calorimetry (DSC) and polarizing microscopic observations. Phase transition temperatures and enthalpy changes of these products are presented in Table 2. The DSC-measurement of compounds **3a**–**3c** show a significant sharp peak in the vicinity of 150 °C, which relates to the melting transition. Furthermore the DSC diagram of **3b** and **3c** depict a weak peak at about 227 °C and 205 °C, respectively that belongs to the clearing point. These investigations indicate that the compounds exhibit a thermotropic liquid crystalline phase between the melting and clearing point [25–28,32–34]. No such additional peak is observed for compound **3a**, which excludes further phase transitions. Only the melting to the mesophase is present. The phthalocyanine derivative **3a** did not give any isotropic transition until 280 °C. Therefore the heating cycles were interrupted before reaching any clearing point to avoid decomposition for **3a**. The thermal stability of the phthalocyanines (**3a**–**3c**) has been investigated by thermal gravimetric analysis (TGA). The initial decomposition of the compounds **3a**, **3b** and **3c** determined

Table 2
Phase transition temperatures and enthalpies for the compound **3a**–**3c** as determined by DSC[a]

Compound	Heating		Cooling	
	C → Col_h → I		I → Col_h → C	
3a	165 (3.90)	not observed	not observed	120 (4.06)
3b	161 (32.54)	227 (1.19)	218 (2.96)	91 (21.11)
3c	144 (42.53)	205 (6.17)	198 (5.52)	23 (50.59)

Heating and cooling rates: 10 °C, heating range: 0–280 °C.
[a] Phase nomenclature: Col_h = discotic hexagonal columnar phase, I = isotropic phase.

Fig. 2. Optical texture of **3b** observed at 170 °C (Magnification ×16).

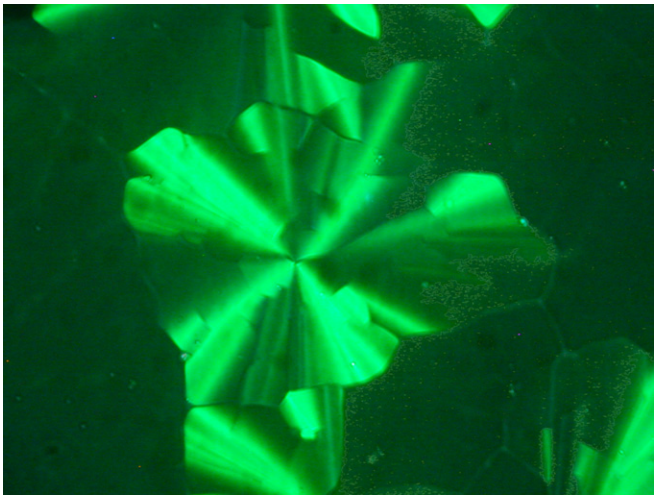

Fig. 3. Optical texture of **3c** observed at 170 °C (Magnification ×50).

by thermogravimetry occur above 298, 290 and 295 °C, respectively, and show negligible differences according to the length of the alkyl-chains. The main decomposition points are 325, 335 and 330 °C, respectively.

Also, the phase transition temperatures of the complexes (**3a**–**3c**) have been surveyed by polarization microscopy. The birefringence textures of the samples were obtained by slow cooling (5 °C min^{-1}) from the isotropic melt. The microscopic observation gave magnificent results for these complexes (**3a**–**3c**). Figs. 2 and 3 shows the photomicrograph of the mesophase of **3b** and **3c**, respectively at 170 °C. For this typical fan-shaped texture, often observed for Col_h, these mesophases could be thus confirmed as the Col_h phases [27–29,33,34].

According to the literature, the mesophase transition temperature of the symmetric hexylthia and dodecylylthia substituted Ni(II) Pcs were 36 and 20 °C [28]. When compared with their asymmetric derivatives (**3a**–**3c**), it could be seen that addition of tosylamido groups to the phthalocyanine core increases the liquid crystal phase transition temperatures but decreases the clearing temperature. The isotropic liquid phase was not observed for hexylthia and dodecylthia substituted Ni(II) Pcs until 300 °C in the literature [28], though isotropic transitions were observed for the asymmetric derivatives (**3b**, **3c**) at 227 and 205 °C respectively. Furthermore, increasing the length of the alkyl chain decreases the melting and isotropic phase transition temperatures of compounds **3a**–**3c**.

5. Conclusions

Asymmetric mesogenic phthalocyanines are rather few. In the present work, the synthesis of new asymmetric Ni(II) phthalocyanines are described and characterized by standard methods (^1H and ^{13}C NMR, elemental analysis, IR, UV/Vis and mass spectrometry). The asymmetric Ni(II) phthalocyanine derivatives **(3a–3c)** exhibit a hexagonal columnar (Col_h) structure. The influence of nature of the side chains upon the mesomorphic properties was compared for the asymmetric pcs (**3a**–**3c**) and also with their symmetric analogous without the tosylamido group [$NiPc(SR)_8$]. It could be seen that addition of the tosylamido group to the phthalocyanine core increases liquid crystal phase transition temperatures but decreases clearing temperatures. In addition to this, increasing the length of alkyl chain decreases the melting and isotropic phase transition temperatures of the compounds **3a**–**3c**.

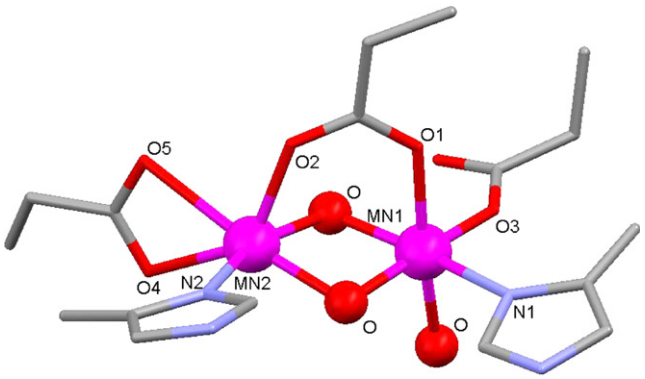

Fig. 1. The dimanganese active site of Mn catalase from *L. plantarum*. The coordinates were obtained from PDB 1JKU and rendered using Mercury 1.4.1 software. Mn(1)–Mn(2), 3.03 Å; Mn(1)–N(1), 2.17 Å; Mn(1)–O(1), 2.11 Å; Mn(1)–O(3), 1.85 Å; Mn(1)-μ-O, 1.92 Å and 2.01 Å; Mn(2)–N(2), 2.16 Å; Mn(2)–O(2), 2.10 Å; Mn(2)–O(4), 2.38 Å; Mn(2)–O5, 2.42 Å; Mn(2)-μ-O, 1.98 Å and 2.23 Å.

The dimanganese redox center of Mn catalase can have at most five oxidation states and four of them have been characterized structurally or spectroscopically. The enzyme isolated under reducing conditions shows the $Mn^{II}Mn^{II}$ oxidation state and is eventually autoxidized to the $Mn^{III}Mn^{III}$ oxidation state through the $Mn^{II}Mn^{III}$ state under air [12]. The autoxidation is more effective under basic conditions. Periodate oxidation of the enzyme results in the superoxidized $Mn^{III}Mn^{IV}$ oxidation state, and the superoxidized Mn catalase is catalytically inactive. It has been suggested that catalytically active manganese catalase utilizes the $Mn^{II}Mn^{II} \leftrightarrow Mn^{III}Mn^{III}$ catalytic cycle [13]. The catalytic activity of Mn catalase in the $Mn^{II}Mn^{II}$ oxidation state is also inhibited in the presence of the chloride ion by the formation of the $Mn^{II}_2(\mu\text{-Cl})(\mu\text{-OH})$ or $Mn^{II}_2(\mu\text{-Cl})$ core [10]. The chloride ion inhibits only the $Mn^{II}Mn^{II}$ oxidation state of the enzyme and the inhibitory effect is reversible [14], but the reactivation mechanism of the inhibited enzyme is not known yet. It has also been reported that the formation of autoxidized Mn catalase is retarded by a high concentration of chloride ion [15].

Due to its easy preparation and versatile coordination chemistry, TPA (tris(2-pyridylmethyl)amine) has been used as a popular biomimetic ligand. Various alkali metal and transition metal complexes of TPA have been synthesized and used for biological model systems such as dioxygen activation by iron non-heme oxygenases [16]. Although many TPA manganese complexes have been reported [17–20], few TPA complexes of $MnCl_2$ have been reported. Although the preparation of $TPAMnCl_2$ has been reported [21], its physical properties and reactivity were not reported. Especially, the synthesis of dinuclear $[TPA_2Mn_2(\mu\text{-Cl})_2]^{2+}$ has never been reported to our knowledge.

Here we report the synthesis, X-ray crystallographic structure, physical properties and catalytic activity of the $[TPA_2Mn^{II}_2(\mu\text{-Cl})_2]^{2+}$ complex. The H_2O_2 dismutation activity of the $[TPA_2Mn^{II}_2(\mu\text{-Cl})_2]^{2+}$ complex was compared with the complexes $TPAMn^{II}Cl_2$ and $[TPA_2Mn^{III}Mn^{IV}(\mu\text{-O})_2]^{3+}$. The $[TPA_2Mn^{II}_2(\mu\text{-Cl})_2]^{2+}$ and $[TPA_2Mn^{III}Mn^{IV}(\mu\text{-O})_2]^{3+}$ complexes are relevant to chloride-inhibited and superoxidized Mn catalase, respectively.

2. Experimental

2.1. General

All experiments and reactions were carried out under a dinitrogen atmosphere using standard Schlenk line techniques or in an inert atmosphere glove box, unless otherwise noted. All solvents were distilled under dinitrogen and nitrogen gas was bubbled through them before each use in the glove box. $MnCl_2$ and $Mn(NO_3)_2 \cdot 4H_2O$ were purchased from Aldrich and were used without further purification. $H_3TPA(ClO_4)_3$ was prepared by the published method [22].

FT-IR spectra were collected on a Nicolet DX V. 4.56 FT-IR spectrometer in KBr pellets and the spectra were corrected for background effects. Elemental analyses were performed in the Microanalytical Laboratory at the University of Michigan. The data were corrected using acetanilide as a standard. ESI-Mass spectra were obtained on a Finnigan LCQ-DECA mass spectrometer by direct injection. Cyclic voltammetry (CV) was performed on a Princeton Applied Research model 263A potentiostat with a K0264 microcell kit. Three electrodes, consisting of a glassy carbon working electrode, a Pt auxiliary electrode and a saturated calomel electrode (SCE) as a reference electrode, were used for the measurements. The complexes of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-Cl})_2](ClO_4)_4$ (**I**), $TPAMnCl_2$ (**II**) and $[TPA_2Mn_2(\mu\text{-O})_2](ClO_4)_3$ (**III**) were dissolved in MeCN (for **I** and **III**) or CH_2Cl_2 (for **II**), together with 0.1 M $^nBuNPF_6$ as a supporting electrolyte. The scanning rate was 50 mV/s and $E_{1/2}$ of the ferrocene oxidation in MeCN was observed at +0.67 V under these conditions. Magnetic susceptibilities of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-Cl})_2](ClO_4)_4$ (**I**), $TPAMnCl_2$ (**II**), and $[TPA_2Mn_2(\mu\text{-O})_2](ClO_4)_3$ (**III**) were measured in the temperature range 4–300 K with a Quantum Design MPMS SQUID. The magnetic field of the measurements was 5000 G over the temperature range. The crystalline sample was put into a cellophane capsule under a dinitrogen atmosphere. The magnetic susceptibility of the holder was determined separately for background corrections. Diamagnetic corrections were estimated from Pascal's constants [23]. The temperature-dependent magnetic susceptibility data were fitted using the Origin program. The EPR spectrum of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-Cl})_2](ClO_4)_4$ (**I**) was obtained at 100 K in the X-band region using a Bruker EMS 4102-ST ESR spectrometer with PC data acquisition.

2.2. Catalytic study

In a 20 ml vial with a stirring bar, the Mn complex was dissolved in 3.0 mL of MeCN under dinitrogen to make a

0.1 mM solution. The vial was sealed with a septum, and connected to the gas volume measurement apparatus through a double-ended needle. The catalysis was initiated by introducing 20% H_2O_2 solution using a syringe. The amount of product formation was calculated from the volume of oxygen gas generated using the ideal-gas equation. The substrate concentration vs. initial velocity graphs were obtained from the triplicate measurements at each substrate concentration.

2.3. $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**)

$MnCl_2$ (0.43 g, 3.43 mmol) in MeOH (10 mL) was added to 10 mL of a methanol solution of $H_3TPA(ClO_4)_3$ (2.03 g, 3.43 mmol) and NEt_3 (1.43 mL, 10.28 mmol). The reaction mixture was stirred for 2 h at room temperature. The reaction was stopped by filtration and diethyl ether was layered over the filtrate. A pale yellow oil product was isolated by decanting the supernatant. It was dissolved in acetone (10 mL) and filtered to remove insoluble impurities. Diethyl ether was layered over the filtrate to induce incipient crystallization. Greenish yellow rhombic crystals were formed in a few days and isolated by filtration. $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (870 mg, 0.638 mmol, 37%). FT-IR (KBr, cm^{-1}): 2935(w), 2754(w), 2677(m), 2489(w), 1600(s), 1475(m), 1442(m), 1145(vs), 1108(vs), 1091(vs), 1014(m), 773(m), 763(w), 626(m). *Anal.* Calc. for $C_{48}H_{68}Cl_6Mn_2N_{10}O_{16}$ (MW 1363.72): C, 42.28; H, 5.03; N, 10.27. Found: C, 42.02; H, 5.37; N, 10.21%. ESI-MS^+ (MeOH, *m/z*) 380.4 ($[TPAMnCl]^+$), 444.3 ($[TPAMn(ClO_4)]^+$), 517.2 ($[TPAMnCl_2(Et_3NH)]^+$), 581.1 ($[TPAMnCl(Et_3NH)(ClO_4)]^+$), 795.1 ($[TPA_2Mn_2Cl_3]^+$), 861.1 ($[TPA_2Mn_2Cl_2(ClO_4)]^+$), 925.1 ($[TPA_2Mn_2Cl_2(ClO_4)(MeOH)_2]^+$), 989.0 ($[TPA_2Mn_2Cl_2(ClO_4)(MeOH)_4]^+$). 2.4. $TPAMnCl_2$ (**II**)

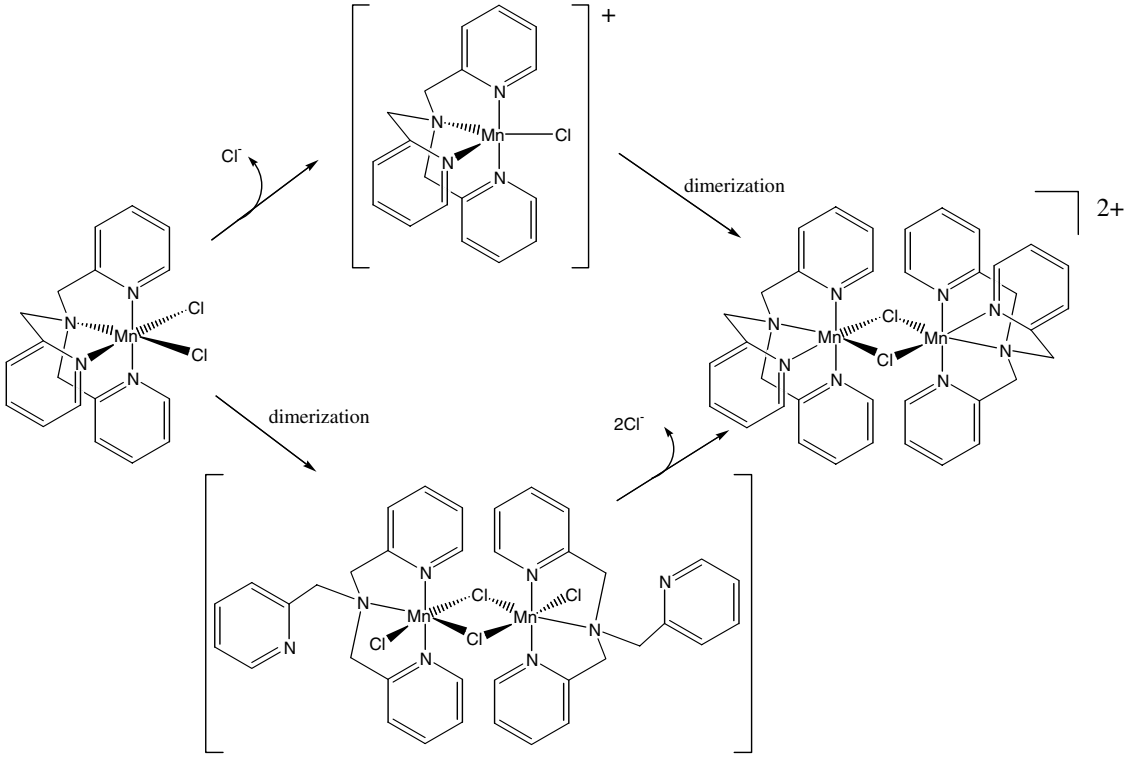
Complex **II** was prepared from the perchlorate salt of TPA according to the published method [21], with a slight modification. $MnCl_2$ (0.25 g, 2.01 mmol) in MeOH (20 mL) was added to 20 mL of a methanol solution of $H_3TPA(ClO_4)_3$ (1.19 g, 2.01 mmol) and NEt_3 (0.84 mL, 6.03 mmol). The reaction mixture was stirred for an hour at 50 °C. The solvent was removed under vacuum and the resulting yellow oil was redissolved in MeOH. Solvent diffusion by diethyl ether produced transparent crystals in a day. $TPAMnCl_2$ (290 mg, 0.697 mmol, 35%). FT-IR (KBr, cm^{-1}): 3065(w), 2904(w), 1602(vs), 1442(m), 1423(m), 1014(m), 773(s), 763(m), 638(m). *Anal.* Calc. for $C_{18}H_{18}Cl_2MnN_4$ (MW 416.20): C, 51.94; H, 4.36; N, 13.46. Found: C, 51.54; H, 4.11; N, 13.87%. ESI-MS^+ (MeOH, *m/z*) 380.3 ($[TPAMnCl]^+$), 794.9 ($[TPA_2Mn_2Cl_3]^+$). Cyclic voltammetry (CH_2Cl_2, versus SCE, V) 1.17(rev), 2.04(qr). Magnetic susceptibility: 5.64 μ_B (300 K), 5.54 μ_B (4 K).

2.5. $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**)

The synthesis of the complex $[TPA_2Mn_2(\mu\text{-}O)_2](S_2O_6)_{3/2} \cdot 7H_2O$ has been reported before [17], and here complex **III** has been prepared by a different method. $H_3TPA(ClO_4)_3$ (355 mg, 0.6 mmol) in 3 mL of MeOH was dissolved by adding NEt_3 (250 μL, 1.8 mmol). To this, $Mn(NO_3)_2 \cdot 4H_2O$ (150 mg, 0.6 mmol) in MeOH (2 mL) was added. The reaction mixture was stirred for 2 h at room temperature, and a few drops of H_2O_2 was added into the reaction mixture until it turned into a black solution. The solvent was removed by N_2 purging, resulting in a black residue. The residue was redissolved in MeCN and slow solvent diffusion by diethyl ether produced a black precipitate. The black precipitate was filtered, washed with diethyl ether several times, and extracted with a minimal amount of MeCN. The solution was kept under air and black plate-type crystals were isolated from the MeCN extract in a day. $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (120 mg, 0.113 mmol, 37.7%). FT-IR (KBr, cm^{-1}): 3070(w), 2955(w), 2250(w), 1606(s), 1485(m), 1445(m), 1383(m), 1289(m), 1088(vs), 765(s), 623(m). *Anal.* Calc. for $C_{38}H_{39}Cl_3Mn_2N_9O_{14}$ (MW 1062.00): C, 42.98; H, 3.70; N, 11.87. Found: C, 42.17; H, 3.69; N, 11.45%. UV–Vis (green in MeCN): λ_{max} (ε) = 439 nm (2040 $M^{-1}\,cm^{-1}$), 558 nm (1060 $M^{-1}\,cm^{-1}$), 658 nm (890 $M^{-1}\,cm^{-1}$). Cyclic voltammetry (MeCN, versus SCE, V) 0.40(rev), 1.35(rev). Magnetic susceptibility: 1.38 μ_B (300 K), 1.97 μ_B (4 K).

2.6. X-ray crystallography



Greenish yellow rhombic crystals of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) and transparent needle-shaped crystals of $TPAMnCl_2$ (**II**) were obtained from the mother liquor after several days. Black plate-shaped crystals of $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**) were isolated by slow evaporation of MeCN solvent under air. The diffraction data for **I** was collected at 293(2) K and the data for **II** and **III** were collected at 123(2) K using a Bruker SMART area diffractometer equipped with a monochromator in the Mo Kα ($\lambda = 0.71073$ Å) incident beam. The CCD data were integrated and scaled using the Bruker-SAINT software package [24], and the structures were solved and refined using SHEXTL V5.10 [25]. The crystal data and structural parameters are shown in Tables 1 and 2. The structures for compounds **I**, **II** and **III** were solved by direct methods to locate heavy atoms, and the non-hydrogen atoms were located through subsequent difference Fourier syntheses. Structural refinement was carried out by full-matrix least squares on F^2. All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were located in the calculated positions.

Scheme 1. Proposed reaction pathways for the formation of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) from $TPAMnCl_2$ (**II**).

3. Results and discussion

3.1. Syntheses

The iron analog of **I**, $[TPA_2Fe_2(\mu\text{-}Cl)_2](BPh_4)_2$, has been reported as a model compound of diferrous enzyme active centers [26], but the synthesis of the complex $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) has never been reported to our knowledge. The synthetic method for **I** is very similar to that for $[TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$, and $H_3TPA(ClO_4)_3$ with triethylamine was used in both syntheses for the chelation of the metal ion. When the metallation was tried with free TPA at room temperature, only complex **II** was obtained. In the case of $TPAFeCl_2$, the formation of penta-coordinated $[TPAFeCl]^+$ was observed in the presence of trialkylphosphine and this was suggested as an intermediate during the formation of $[TPA_2Fe_2(\mu\text{-}Cl)_2]^{2+}$ [27]. Likewise, different reaction conditions and crystallization solvent systems would have facilitated the formation of a penta-coordinated $[TPAMnCl]^+$ intermediate, which results in the $[TPA_2Mn_2(\mu\text{-}Cl)_2]^{2+}$ complex. The other possibility of $[TPA_2Mn^{II}_2(\mu\text{-}Cl)_2]^{2+}$ formation is elimination of the terminal chloride ligands from the $TPA_2Mn_2Cl_2(\mu\text{-}Cl)_2$ dimer which could be formed during the reaction (Scheme 1).

The synthesis of $[TPA_2Mn^{III}Mn^{IV}(\mu\text{-}O)_2]^{3+}$ with dithionate counter anions by H_2O_2 oxidation of the Mn(II) complex was first reported by Towle, et al. [17] and the one-electron less oxidized $[TPA_2Mn^{III}Mn^{III}(\mu\text{-}O)_2]^{3+}$ complex was achieved by air-oxidation of $[TPAMn^{II}(DTBSQ)]BPh_4$ [21],[1] The reaction conditions for **III** were different from the published methods. $Mn(NO_3)_2$ was used as a metal reagent and MeOH, instead of water, was used as the reaction solvent. Upon H_2O_2 oxidation, the solution-generated $TPAMn^{II}(\eta^2\text{-}NO_3)(\eta\text{-}ClO_4)$ complex [20] was oxidized and dimerized to complex **III**, which was monitored by color changes of the reaction mixture.

3.2. Structural description

The complex $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) crystallized with four perchlorate and two triethylammonium ions in the monoclinic $P2_1/c$ space group (Table 1). The dinuclear manganese core formed a rhombic structure with two distorted octahedral Mn centers (Fig. 2, Table 2). This crystallized with four perchlorate and two triethylammonium counter ions in the unit cell (Fig. 3). The average $Mn–N_{pyr}$ distance is 2.24(1) Å,[2] which is slightly shorter than that of $TPAMnCl_2$ (**II**). The $Mn–N_{amine}$ distance is 2.283(2) Å and is significantly shorter than the corresponding bond of **II**. The average $Mn(1)–N_{pyr}$ distance and $Mn(1)–N_{amine}$ distance are 2.26(2) and 2.3643(15) Å, respectively. The two Mn–Cl bond distances of **I** are

[1] DTBSQ = 3,5-di-tert-butyl-1,2-semiquinonate.

[2] The number in the parenthesis of average bond distances represents the larger of the individual standard deviations or the standard deviation from the mean, $\sigma = \mathrm{SQRT}[\Sigma_{i=1}^{n}(x_i - x)^2/n(n-1)]$, where x_i is an individual standard deviation, x is the average of individual standard deviations.

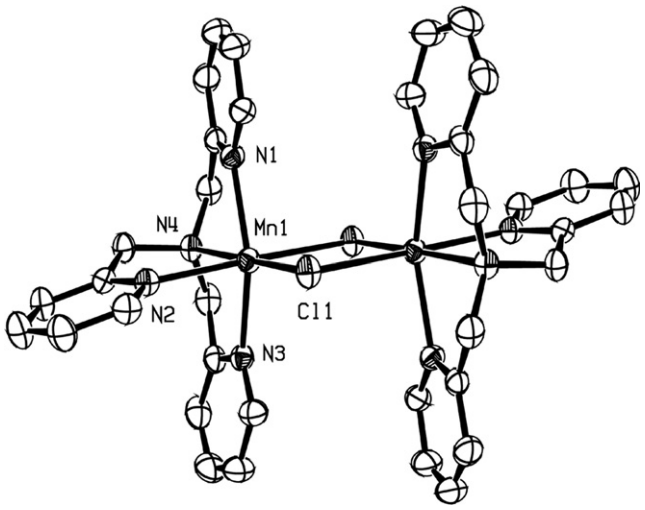

Fig. 2. Crystallographic structure of $[TPA_2Mn_2(\mu\text{-}Cl)_2]^{2+}$ with thermal ellipsoids (50% probability); counter ions and hydrogen atoms are omitted for clarity. The Mn(1)–Mn(1)#1 distance is 3.521(2) Å.

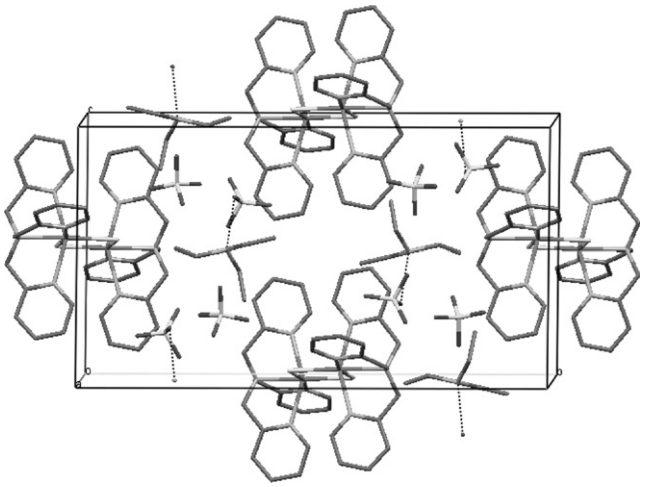

Fig. 3. Packing plot of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**). Broken lines indicate hydrogen bonds.

2.4056(9) and 2.6286(10) Å, respectively. Compared to **II**, one of Mn–Cl bonds is elongated by more than 0.1 Å, which is the most distinct bond distance difference between complexes **I** and **II**. The angles between the two axial ligands in **I** and **II** are 166.20(4)° and 176.00(6)°, respectively, and complex **I** shows a more axially-distorted geometry. The distance between the two Mn centers of **I** is 3.521(2) Å, which is much longer than that of the native manganese catalase because it has two chloride bridging ligands instead of water/hydroxide ligands. The protein structure of chloride-inhibited Mn catalase has been reported and a dimanganese center with two bridging chloride ligands was suggested [10]. The distances of the Mn–Mn separation of the chloride-inhibited Mn catalase were obtained from X-ray protein crystallography (3.30 Å) and EPR spectroscopy (3.51 Å) [28]. These values are comparable to the Mn–Mn distance of complex **I**.

The crystallographic structure of $TPAMnCl_2$ (**II**) without a MeOH molecule has been deposited before by others, but the structure was not discussed [29]. The solid state structure of $TPAMnCl_2 \cdot MeOH$ (**II** · MeOH) has been characterized in the monoclinic $P2_1/n$ space group by single crystal X-ray crystallography at 123(2) K (Table 1). The mononuclear Mn complex, **II**, is a six-coordinate Mn^{II} complex with a distorted octahedral coordination geometry (Fig. 4, Table 2). In the coordination sphere of the Mn atom, two chloride ligands are located in a *cis*-configuration at distances of 2.5180(6) and 2.3996(7) Å for Mn(1)–Cl(1) and Mn(1)–Cl(2), respectively. The average Mn(1)–N_{pyr} distance is 2.26(2) Å and the Mn(1)–N_{amine} distance is 2.3643(15) Å, which suggests a high spin configuration of **II** [30]. The average N_{pyr}–Mn(1)–N_{amine} angle and the N(4)–Mn(1)–Cl(1) angle are 73.2(4)° and 93.65(4)°, respectively.

Black crystals of the complex $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**) were isolated upon solvent evaporation and were stable under air. It crystallized in the triclinic $P\bar{1}$ space group with two unique $[TPA_2Mn_2(\mu\text{-}O)_2]^{3+}$ cations (Table 1). The structure of the same core with dithionate counter anions and water molecules in the unit cell has been reported before [17], but the solved structure showed significantly different structural parameters.

The $[TPA_2Mn_2(\mu\text{-}O)_2]^{3+}$ cation of **III** showed a similar structure to the $[TPA_2Mn_2(\mu\text{-}Cl)_2]^{2+}$ cation of complex **I**. The dimanganese core formed a rhombic structure with distorted octahedral Mn centers (Fig. 5, Table 2). Two different Mn–O bond distances were found from two unique $[TPA_2Mn_2(\mu\text{-}O)_2]^{3+}$ complexes in the unit cell of **III**. The average distance of the short Mn–O bonds is 1.799(3) Å and the average distance of the long Mn–O bonds is 1.817(3) Å. The difference of 0.018 Å is significant but much smaller than the reported value of 0.06 Å in the charge-localized structure [17].

The average distance of the equatorial Mn–N bonds is 2.066(16) Å and the average distance between the Mn

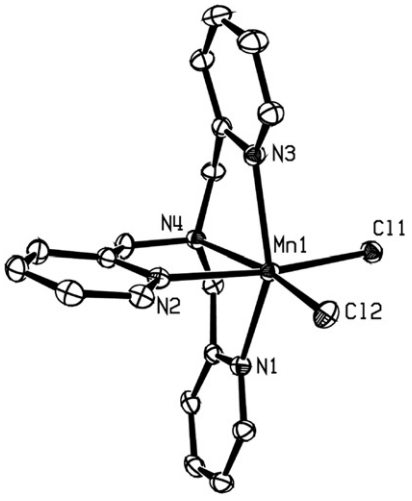

Fig. 4. Crystallographic structure of $TPAMnCl_2$ (**II**) with thermal ellipsoids (50% probability); hydrogen atoms are omitted for clarity.

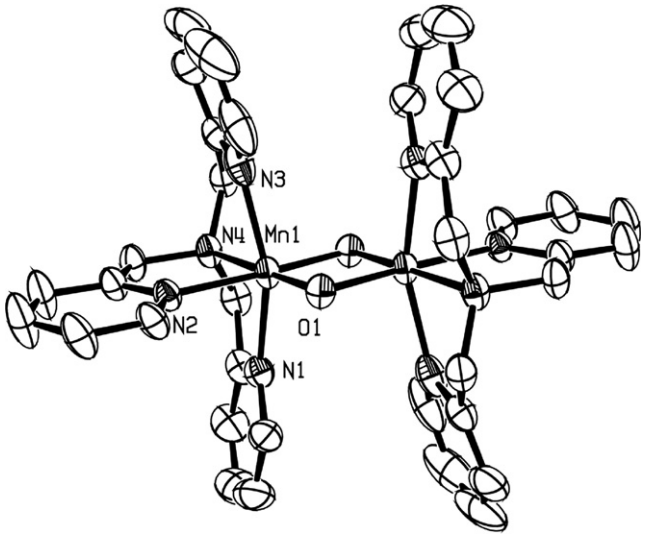

Fig. 5. Crystallographic structure of $[TPA_2Mn_2(\mu\text{-}O)_2]^{3+}$ with thermal ellipsoids (50% probability); counter ions and hydrogen atoms are omitted for clarity.

and axial N atoms is 2.119(9) Å. The average distance of the Mn–N bonds which are *trans* to the longer Mn–O bond is 2.038(3) Å and that of the Mn–N bonds which are *trans* to the shorter Mn–O bond is 2.095(3) Å. It is believed that the Mn–N bonds that are in a *trans*-position to the μ-O ligands (equatorial Mn–N's) are shorter than the other axial Mn–N bonds due to axial Jahn–Teller distortion. The average distance of the Mn–N bonds is 2.092(13) Å, which suggests a high spin configuration of each Mn center in the $Mn^{III}Mn^{IV}$ dinuclear complex [30]. The angles of the two unique Mn–O–Mn bridges are 92.92(11)° and 93.28(11)°, which are much smaller than the reported values, ranging from 94.0° to 94.7° in other complexes with the same $[Mn_2(\mu\text{-}O)_2]^{3+}$ core. Accordingly, the Mn–Mn distances are shorter than the reported values, being 2.6244(12) and 2.6256(13) Å, with an average of 2.6250(13) Å [17]. The Mn–Mn distance of **III** is shorter than 2.70 Å, the distance found from the active site of superoxidized Mn catalase [31]. The angles of the two axial ligands of **III** are 156.48(15)° and 155.53(16)° for N(1)–Mn(1)–N(3) and N(5)–Mn(2)–N(7), respectively.

3.3. Physical properties

FT-IR spectra of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) and $TPAMnCl_2$ (**II**) are almost identical, except that the peaks from the $(Et_3NH)^+$ and $(ClO_4)^-$ ions are found for complex **I**. The peaks from $(Et_3NH)^+$ were found at 2754, 2677 and 2489 cm^{-1}, and the $(ClO_4)^-$ ion showed very strong absorptions at 1200 cm^{-1} and 1050 cm^{-1}. MeCN in the crystal unit cell of $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**) was observed at 2250 cm^{-1} for the C≡N stretching, and the C=O stretchings of perchlorate in **III** were found at 1088 cm^{-1} [32].

Cyclic voltammetry of complexes **I** and **II** was carried out to see if the two Mn centers in $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) communicate electrochemically. $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) in MeCN showed multiple oxidation waves, among which the first two oxidation waves at $E_{1/2} = 1.09$ V and $E_{1/2} = 1.30$ V versus SCE were quasireversible (Fig. 5). These oxidations were assigned to the $Mn^{II}Mn^{II}/Mn^{II}Mn^{III}$ and $Mn^{II}Mn^{III}/Mn^{III}Mn^{III}$ oxidation, respectively. The indistinct E_{pa} of the first oxidation ($E_{1/2} = 1.09$ V) and E_{pc} of the second oxidation ($E_{1/2} = 1.30$ V) are probably due to the instability of the $Mn^{II}Mn^{III}$ species. The third reversible oxidation wave found at $E_{1/2} = 1.75$ V can be assigned to the reversible two-electron redox pair of $Mn^{III}Mn^{III}/Mn^{IV}Mn^{IV}$, based on the oxidation current. $TPAMnCl_2$ (**II**) in CH_2Cl_2 showed a reversible oxidation wave at $E_{1/2} = 1.17$ V, corresponding to Mn^{II}/Mn^{III} oxidation (Fig. 5). The next quasi-reversible oxidation wave found at $E_{1/2} = 2.04$ V was assigned to the Mn^{III}/Mn^{IV} redox pair. Experiments at different scan rates confirmed no dimerization of **II** to **I** under the electrochemical conditions. Therefore, the electrochemical property of the dinuclear Mn complex **II** is different from the mononuclear complex **I**. The electrochemical property, as well as the magnetic susceptibility and an EPR study, of $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**) has been reported before [33]. Complex **III** showed two oxidation potentials at $E_{1/2} = 0.24$ and $E_{1/2} = 1.04$ versus SCE, which are the same as the reported values.

Temperature-dependent magnetic susceptibility data were obtained to study the spin configuration of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) and $TPAMnCl_2$ (**II**). For complex **III**, the magnetic exchange parameter $J = -159$ cm^{-1} was reported [33].

From $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**), the magnetic moment of 7.89 μ_B at 300 K was much smaller than the spin-only magnetic moment expected for a $S = 5$ spin system (10.95 μ_B) (Fig. 6). The effective magnetic moment decreased as the temperature was lowered and a magnetic susceptibility of 2.02 μ_B was observed at 4 K. The magnetic susceptibility was fitted based on the isotropic Heisenberg

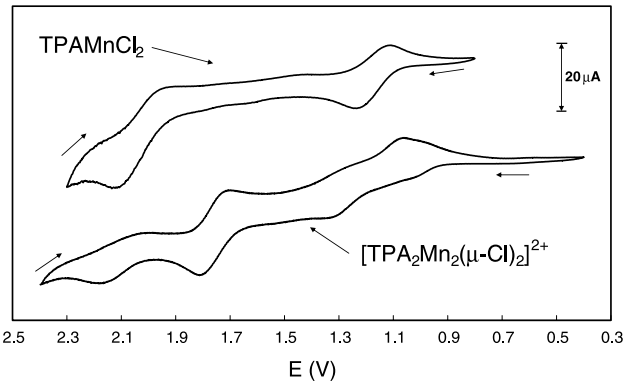

Fig. 6. Cyclic voltammograms of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) and $TPAMnCl_2$ (**II**) at a scan rate of 50 mV/s. Supporting electrolyte: 0.1 M $^nBu_4NPF_6$.

model, $\boldsymbol{H} = -2J\boldsymbol{S}_1 \cdot \boldsymbol{S}_2$ ($\boldsymbol{S}_1 = \boldsymbol{S}_2 = 5/2$), given as follows [34]:

$$\chi = \frac{2Ng^2\beta^2}{kT}\,\frac{e^x + 5e^{3x} + 14e^{6x} + 30e^{10x} + 55e^{15x}}{1 + 3e^x + 7e^{6x} + 9e^{10x} + 11e^{15x}}$$

where $x = J/kT$, and the other symbols have their usual meaning. With $g = 2.0$, the magnetic exchange parameter $J = -8.8\ \mathrm{cm}^{-1}$ was obtained from a fit of experimental data. Thus, complex **I** was characterized as a high spin system with an antiferromagnetic coupling. Although the exchange parameter for chloride-inhibited Mn catalase was not reported, fluoride-inhibited Mn catalase from *L. plantarum* was reported as $J = -1.3\ \mathrm{cm}^{-1}$ [35]. The mononuclear Mn complex of **I** showed a magnetic susceptibility of 5.64 μ_B at 300 K and 5.54 μ_B at 4 K. The calculated spin-only magnetic moment of high spin Mn^{2+} was 5.92 μ_B, which is close to the experimental value. The magnetic moment measurements confirmed the $S = 5/2$ state for $TPAMnCl_2$ (**II**).

Because $TPAMnCl_2$ (**II**) was characterized as a typical high spin Mn^{II} complex and the EPR spectrum of $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**) was reported before [33], he frozen solution EPR spectrum of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) was only obtained at 100 K (Fig. 7). Complex **I** showed very complicate hyperfine signals at around 1600 G and seven hyperfine signals at 3200 G. It was assigned as a spin-coupled $Mn^{II}Mn^{II}$ core [36]. Mn catalase with a $Mn^{II}Mn^{II}$ core shows very complex signals between 2500 G and 4000 G and is characterized by two 11-line hyperfine signals at 3300 G and 3800 G. The overall spectral shapes of the spectra for complex **I** and the reported chloride-inhibited Mn catalase were similar [15], but the resonances were observed at different magnetic fields, probably due to the different coordination environments of the $Mn^{II}Mn^{II}$ centers.

3.4. Catalytic study

Catalytic dismutation of H_2O_2 by $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**), $TPAMnCl_2$ (**II**) and $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**) was studied by volumetric O_2 measurement. All the complexes produced O_2 catalytically. The substrate versus initial velocity plots of the complexes are shown in Fig. 8. Because the catalysis followed sigmoidal kinetics, they were fitted with Hill equation to obtain kinetic parameters.[3] In general, sigmoidal kinetics are observed from multi-subunit enzyme catalysis or from substrate-dependent enzyme activation [37]. In the case of the TPAMn complexes, substrate-activation of the catalysts seems to be the reason for the observed sigmoidal kinetics, and all the complexes seem to act as precatalysts.

The kinetic parameters for complexes **I**, **II** and **III** are shown in Table 3. Catalytic H_2O_2 dismutation by **I** and **II** is reported first here, although preliminary catalytic activity of complex **III** without kinetic parameters has been reported before by others [38]. The kinetic parameters of the K_M and Hill constants for complexes **I** and **II** are very similar, which implies the same reactive species may be involved in the catalysis. Different k_{cat} values result from different relative concentrations of the catalyst formed from complexes **I** and **II**. It seems that $TPAMnCl_2$ (**II**) can be dimerized to $[TPA_2Mn_2(\mu\text{-}Cl)_2]^{2+}$ under the catalytic conditions, so that it exhibits similar catalytic properties to **I** (see Fig. 9).

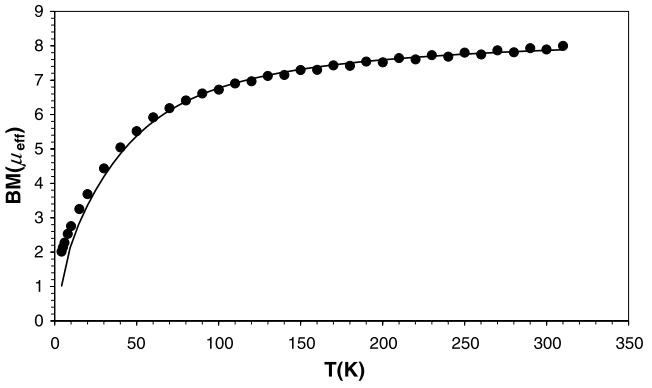

Fig. 7. Molar magnetic susceptibility of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) plotted μ_{eff} vs. temperature. Closed circles represent measured data and the solid line represents the simulated fitting.

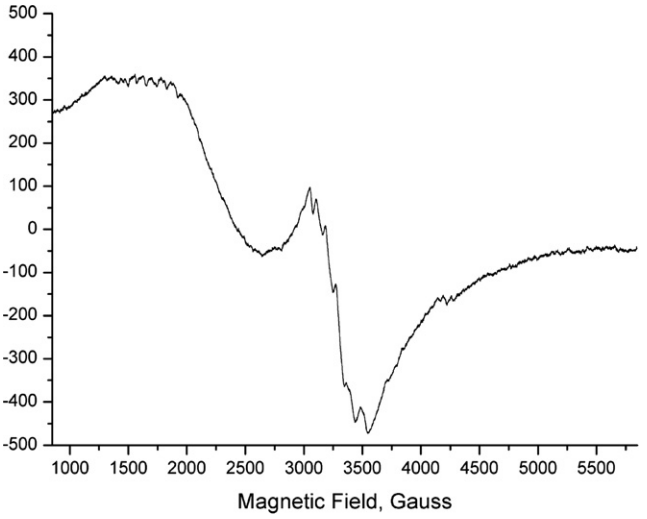

Fig. 8. EPR spectrum of the complex $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) at 100 K.

Table 3
Kinetic parameters for $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**), $TPAMnCl_2$ (**II**) and $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**)

	I	II	III
k_{cat} (s^{-1})	1.96 ± 0.05	1.28 ± 0.05	3.27 ± 0.05
K_M (M)	1.47 ± 0.04	1.42 ± 0.07	1.09 ± 0.03
Hill constant (n)	4.2 ± 0.4	3.4 ± 0.5	2.7 ± 0.2

[3] Hill equation, $v_i = V_{max}\cdot[H_2O^2]^n/(K_M{}^n + [H_2O^2]^n)$, where v_i is the initial velocity, V_{max} is the maximum velocity, $[H_2O_2]$ is the concentration of substrate, n is the Hill constant, K_M is the Michaelis constant.

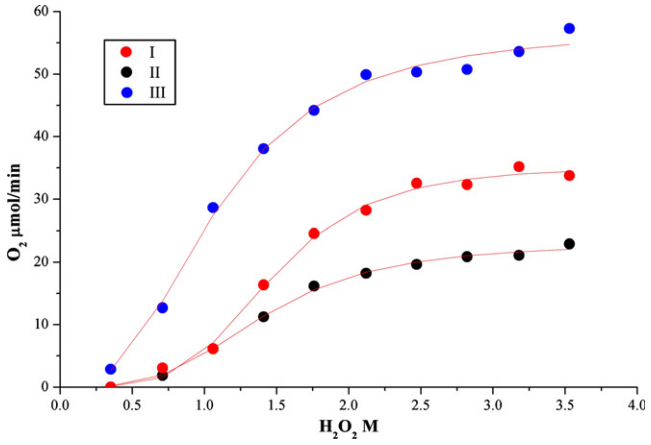

Fig. 9. Reaction rate of O_2 generation by $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**), $TPAMnCl_2$ (**II**) and $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**). The plots were simulated with the Hill equation.

The structure of $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) with a $Mn^{II}Mn^{II}$ center is similar to the chloride-inhibited active center of Mn catalase (*vide supra*). It was reported that the inhibition is reversible [14], and the catalytic activity of **I** may be relevant to the reactivation of the chloride-inhibited enzyme. Although there is no physical evidence, it is possible that H_2O_2 can act as an acid to protonate the bridging chloride atoms.[4] Chloride ion was also reported to prevent autooxidation of the enzyme, which is fast under basic conditions [15]. During the activation process, all the chloride ligands can be substituted sequentially by H_2O_2 or water to generate active species. The generated catalyst can follow the catalytic cycle which might be relevant to Mn catalase.

4. Conclusion

As a model system of chloride-inhibited manganese catalase, the complex $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) has been synthesized. The complex was characterized physically and structurally. Structural features between complex **I** and $TPAMnCl_2$ (**II**) showed little difference, except one of the Mn–Cl bonds was changed. However, the electrochemical properties of **I** and **II** were significantly different, and the dinuclear complex **I** showed multiple redox waves. Both complexes were characterized to have high spin d^5 Mn centers, and complex **I**, with two $S = 5/2$ Mn centers, showed an antiferromagnetic coupling. Catalytic dismutation of H_2O_2 by $(Et_3NH)_2[TPA_2Mn_2(\mu\text{-}Cl)_2](ClO_4)_4$ (**I**) was studied and compared to the related $TPAMnCl_2$ (**II**) and $[TPA_2Mn_2(\mu\text{-}O)_2](ClO_4)_3$ (**III**) complexes. A ctalytic study of **I** suggested that reactivation of chloride-inhibited Mn catalase could require acid-catalyzed bridging ligand substitution.

[4] H_2O_2 is a weak acid with pK_a 11.65.

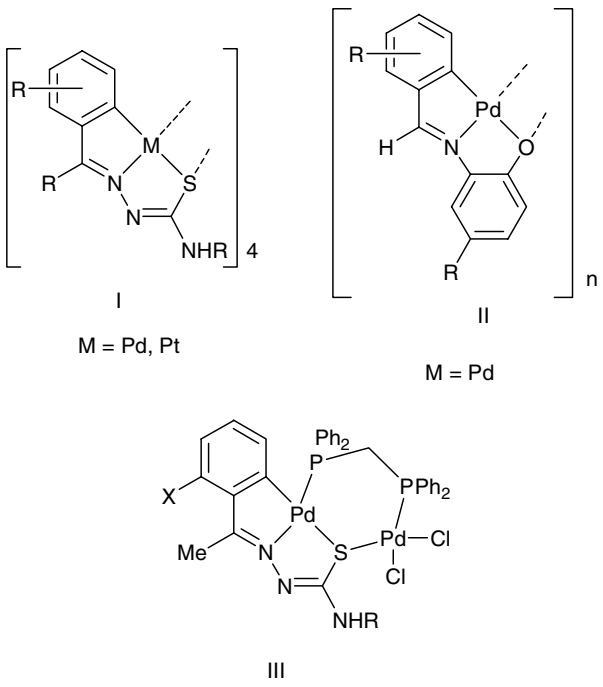

Fig. 1. Cyclometallated complexes with [C, N, X] (X = O, S) ligands.

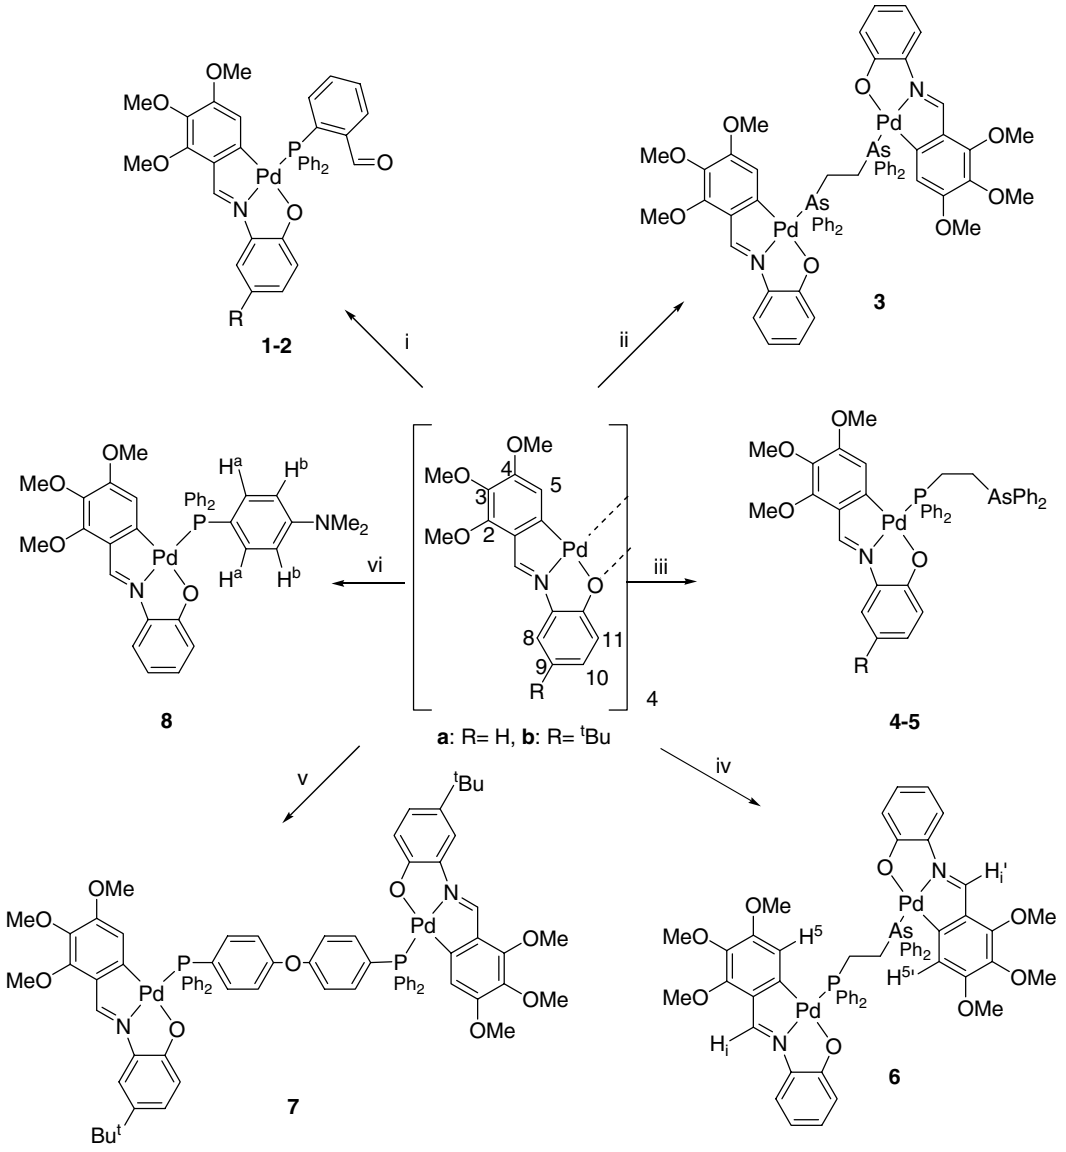
brings about opening of the tetranuclear structure due to the P–$X_{bridging}$ bond cleavage, whereas the P–$X_{chelating}$ bond persists, even when large excess of the phosphine was used, putting forward its unusual strength. More recently, we have shown that reaction of the tetranuclear tetramers derived from thiosemicarbazones (X = S) with bis(diphenylphosphino)methane caused cleavage of the tetranuclear structure to give new mononuclear complexes, in which the phosphine is monodentate, where one phosphorus atom is uncoordinated. These complexes represent a new class of bidentate [P, S] chelating metalloligands capable of coordinating a second metal centre and, therefore, may be used as building blocks in the construction of polynuclear structures **III** (Fig. 1) [23].

We reasoned that the similar behavior of terdentate [C, N, O] Schiff base species towards nucleophiles, in terms of a strong P–$O_{chelating}$ bond, could be used to explore a new range of compounds upon reaction of the former with phosphines, arsines, and mixed phosphorus/arsenic ligands. Therefore, herein, we report the reactivity of complexes $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)\text{-}5\text{-}RC_6H_3]\}]_4$ (**1a**: R = H, **1b**: R = ^{t}Bu) with bidentate [P, O], [P, As], [P, P], [As, As] and [P, N] ligands.



2. Results and discussion

The compounds and reactions are shown in Scheme 1. The compounds were characterised by IR and by ^{1}H, ^{31}P–{^{1}H} spectroscopy and, in part, FAB mass spectrometry; the elemental analysis (C, H, N) supports the expected elemental composition (data in Section 4).

Treatment of **1a** and **1b** with $PPh_2[2\text{-}(COH)C_6H_4]$ in 1:4 molar ratio or with $Ph_2P[4\text{-}(NMe_2)C_6H_4]$ in 1:2 or 1:4 molar ratios, afforded the mononuclear complexes $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)C_6H_4\}\{PPh_2[2\text{-}HOC)C_6H_4]\}]$ (**2a**) $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)\text{-}5\text{-}^tBuC_6H_3\}\{PPh_2[2\text{-}(HOC)C_6H_4]\}]$ (**2b**) and $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)C_6H_4]\}\{PPh_2[4\text{-}(NMe_2)C_6H_4]\}]$ (**7a**), respectively, as air stable solids, in which the tetrameric structure was cleaved after P–$O_{bridging}$ bond cleavage. Coordination of the palladium atom to the C=N moiety was confirmed by the shift to lower wavenumbers of the ν(C=N) band, as compared to the free ligand [21,24,25]. Absence of the ν(OH) band was in agreement with the presence of a phenolate oxygen bonded to the palladium atom [21,22]. These findings were observed for the remaining compounds and shall not be discussed further (see Section 4). The proton resonances were unequivocally assigned (see Section 4); those ascribed to *H*5 and *H*C=N appeared as doublets due to coupling with the ^{31}P nucleus with *J* values of *ca.* 4 and 10 Hz, respectively. In the ^{31}P–{^{1}H} spectra the phosphorus resonance signal appeared as a singlet *ca.* δ 33.0 ppm; these findings were in agreement with a phosphorus *trans* to nitrogen arrangement [21,26–30]. The signals assigned to the *H*5 and 4-O*Me* protons were shifted to lower frequency, as compared to the cyclometallated complexes **1a** and **1b**, due to shielding of phosphine phenyl rings. We have previously observed similar shifts in related complexes, confirming the relative *trans* disposition of the nitrogen atom and the phosphine ligand [17,31]. The FAB mass spectra showed the cluster of peaks characteristic of the $[M]^+$ fragment at 680, **2a**, 738, **2b**, and 697, **7a** uma.

Reaction of **1a** with $AsPh_2(CH_2)_2Ph_2As$ (dppae) in a 1:2 ratio in acetone, gave the dinuclear cyclometallated complex $[\{Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)C_6H_4]\}\}_2\{\mu\text{-}AsPh_2(CH_2)_2Ph_2As\}]$ (**3a**) as an air stable solid. In the ^{1}H NMR spectrum the *H*C=N and H^5 proton resonances appeared as singlets at δ 7.57 and 5.51 ppm, respectively. The H5 and 4-O*Me* resonances were shifted towards lower frequency by *ca.* 0.2 and 1.2 ppm, respectively, due to the shielding effects of the diarsine phenyl rings. Only one set of signals was observed for the proton resonances, indicative of the symmetrical nature of the compounds. The FAB mass spectrum showed two clusters of peaks centred at 1271 and 878 uma, assigned to the molecular ion and to loss of one cyclometallated unit, respectively. Compound **3a** was also isolated when excess dppa was used, establishing the strength of the Pd–$O_{chelating}$ bond, which was not cleaved even under these reaction conditions.

Treatment of **1a** or **1b** with $Ph_2P(CH_2)_2Ph_2As$ (arphos) in the appropriate molar ratio afforded compounds $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)C_6H_4]\}\{PPh_2(CH_2)_2Ph_2As\text{-}P\}]$ (**4a**), $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)\text{-}5\text{-}^tBuC_6H_3]\}\{PPh_2(CH_2)_2Ph_2As\text{-}P\}]$ (**4b**), and $[\{Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N[2\text{-}(O)C_6H_4]\}\}_2\{\mu\text{-}PPh_2(CH_2)_2Ph_2As\}]$ (**5a**). Coordination of the ligand through the phosphorus atom was confirmed by: (a) the multiplicity of the *H*5 and *H*C=N

Scheme 1. (i) Phosphine (acetone, 1:4 molar ratio), (ii) dppae (acetone, 1:2 or 1:4 molar ratio), (iii) arphos (acetone, 1:4 molar ratio), (iv) arphos (acetone, 1:2 molar ratio), (v) diphosphine (acetone, 1:2 or 1:4 molar ratio), (vi) phosphine (dichloromethane, 1:2 or 1:4 molar ratio).

resonances, which were observed as doublets by coupling to the ^{31}P nucleus; (b) the chemical shift of the phosphorus resonance signal at δ 32.5 (**4a**), δ 33.4 (**4b**) and δ 34.0 (**5a**), downfield shifted from its position in the spectrum of the free phosphine, and also in agreement with a phosphorus *trans* to nitrogen coordination to the metal center [21,26–30]. The asymmetric nature of compound **5a** was evidenced by the two distinct sets of proton signals observed for both cyclometallated moieties. Accordingly, two doublet resonances at δ 8.14 and δ 5.42, were assigned to the *H*5 and *HC*=N protons, respectively, coupled to the ^{31}P nucleus with [$^4J(H_iP) = 10.5$ Hz, $^4J(H^5P) = 3.9$ Hz], and two singlets were ascribed to the *H*5′ and *H*′C=N protons at δ 7.58 and δ 5.56, respectively.

In the FAB mass spectra the set of peaks at 834 and 890 uma, for **4a** and **4b**, respectively, were assigned to the $[MH]^+$ ions; their isotopic pattern confirmed the mononuclear formula of the complexes. For compound **5a** a cluster of peaks at 1226 uma was consistent with a dinuclear formula.

Treatment of **2b** with $Ph_2P(C_6H_4)O(C_6H_4)Ph_2P$ in a 1:2 or 1:4 molar ratio at room temperature in acetone gave the dinuclear compound [{Pd{2,3,4-$(MeO)_3C_6HC(H)$=N[2-(O)-^{t}BuC_6H_3]}}$_2${μ-$PPh_2(C_6H_4)O(C_6H_4)Ph_2P$}] (**6b**) (the use of excess phosphine only gave **6b** and unreacted **2b**), after column chromatography (see Section 4). Therefore, the diphosphine could not behave as monodentate through only one phosphorus atom. Thus, both sets of *HC*=N and H5 resonances showed coupling to the phosphorus nuclei [$^4J(HP) = 10.7$ and $^4J(HP) = 3.7$ Hz], and the ^{31}P–{^1H} NMR spectrum revealed a singlet at δ 28.2, in agreement with equivalent phosphorus nuclei.

3. Conclusions

We have shown that Schiff base ligands derived from 2-aminophenols secure three metal coordination sites in cyclometallated palladium(II) compounds and leave but one bonding site for further reaction with nucleophiles, such as tertiary phosphines or arsines. Consequently, the $P–O_{chelating}$ bond remained throughout all the processes in this study, and it was not cleaved upon reaction with the nucleophiles tested. Additional coordinating atoms on the phosphine ligand, such as nitrogen or oxygen, did not show any relevant bonding properties. However, diphosphines or diarsines could bridge two cyclometallated moieties, rendering dinuclear species.

In the case of arphos, this ligand showed to be versatile in its coordination to the cyclometallated complexes **1a** and **1b**. Thus, by adjusting the relative molar ratio, mono- or dinuclear complexes could be prepared, with the ligand behaving as mono- or bidentate, respectively. Still, arphos did not act as a chelating ligand, regardless of the reaction conditions employed.

4. Experimental

4.1. General procedures

Solvents were purified by standard methods [32]. Chemicals were reagent grade. The phosphines PPh_2[2-(HOC)C_6H_4], $PPh_2(CH_2)_2Ph_2As$ (arphos), $Ph_2P(C_6H_4)O(C_6H_4)Ph_2P$ and Ph_2P[4-$(NMe_2)C_6H_4$] were purchased from Aldrich-Chemie. $Ph_2As(CH_2)_2Ph_2As$ (dppae) were purchased from ALFA. Microanalyses were carried out using a Carlo Erba Elemental Analyzer, Model 1108. The cyclometallated complexes **1a** and **1b** were synthesized using the procedure reported recently by us [21]. IR spectra were recorded as KBr discs on a Perkin–Elmer 1330 and on Mattson spectrophotometers. NMR spectra were obtained in $CDCl_3$ and referenced to $CHCl_3$ (^1H and $^{13}C–\{^1H\}$) or 85% H_3PO_4 ($^{31}P–\{^1H\}$) and were recorded on Bruker AC-2005 or Bruker AVANCE 300 spectrometers. All chemical shifts were reported downfield from standards. The FAB mass spectra were recorded using a Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix.

Analytical and spectroscopic data for the cyclometallated starting complexes **1a** and **1b**.

4.2. [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)C$_6$H$_4$]}]$_4$ (**1a**)

Anal. Calc. for $C_{64}H_{60}N_4O_{16}Pd_4$: C, 49.1; H, 3.8; N, 3.6. Found: C, 48.9; H, 3.8; N, 3.5%. IR: ν(C=N), 1589sh, m cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$, δ ppm, *J* Hz): 3.51 [s, 3H, OMe]; 3.82 [s, 3H, OMe]; 4.02 [s, 3H, OMe]; 5.67 [s, 1H, H^5]; 7.57 [s, 1H, HC=N]; 6.62 [dd, 1H, H^8, $^3J(H^8H^9) = 7.6$, $^4J(H^8H^{10}) = 1.5$]; 6.37 [dt, 1H, H^9, $^3J(H^9H^{10}) = 7.5$, $^4J(H^9H^{11}) = 1.5$]; 6.91 [dt, 1H, H^{10}, $^3J(H^{10}H^{11}) = 7.5$, $^4J(H^8H^{10}) = 1.5$]; 7.44 [d, 1H, H^{11}, $^3J(H^{11}H^{10}) = 7.6$, $^4J(H^9H^{11}) = 1.5$]. FAB-MS: $m/z = 1566$ $[M]^+$; 391 $[M/4]^+$.

4.3. [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)-5-^{t}BuC$_6$H$_3$]}]$_4$ (**1b**)

Anal. Calc for $C_{68}H_{68}N_4O_{16}Pd_4$: C, 50.3; H, 4.2; N, 3.5. Found: C, 50.1; H, 4.1; N, 3.5%. IR: ν(C=N), 1571sh, m cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 1.24 [s, 9H, ^{t}Bu]; 3.38, 3.81, 4.03 [s, 9H, MeO]; 5.81 [s, 1H, H^5]; 6.75 [d, 1H, H^8, $^4J(H^8H^{10}) = 2.2$]; 6.99 [dd, 1H, H^{10}, $^3J(H^{10}H^{11}) = 8.8$, $^4J(H^8H^{10}) = 2.2$]; 7.35 [d, 1H, H^{11}]; 7.54 [s, 1H, HC=N]. FAB-MS: $m/z = 1792$ $[MH]^+$; 896 $[M/2]^+$.

4.4. [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)C$_6$H$_4$]}{PPh$_2$[2-(HOC)C$_6$H$_4$]}] (**2a**)

PPh_2(4-(HOC)C_6H_4) (49.8 mg, 0.31 mmol) was added to a suspension of [Pd{2,3,4-$(MeO)_3C_6HC(H)$=N(2-(O)-C_6H_4)] (36.9 mg, 0.31 mmol) in acetone (15 cm^3). The mixture was stirred for 12 h and the solvent removed to give a violet solid which was recrystallized from dichloromethane/hexane. Yield 56%. *Anal.* Calc. for $C_{35}H_{29}NO_5PPd$: C, 61.7; H, 4.3; N, 2.0. Found: C, 61.5; H, 4.3; N, 1.9%. IR: ν(C=O), 1697s cm^{-1}, ν(C=N), 1572s cm^{-1}. FAB-MS: $m/z = 680$ $[M]^+$. ^1H NMR (300 MHz, $CDCl_3$, δ ppm, *J* Hz): 10.37 [d, 1H, *H*C=O, $^4J(HP) = 2.4$], 8.14 [d, 1H, HC=N, $^4J(HP) = 10.8$], 7.59 [t, 1H,$^3J(HH) = 7.6$], 7.10 [d, 1H, H^8, $^3J(H^8H^9) = 7.1$], 6.89 [m, 2H, H^{10}, H^{11}], 6.30 [m, 2H, H^9, H^{11}], 5.54 [s, 1H, H^5, $^4J(H^5P) = 4.9$], 3.94 (s, 3H, MeO), 3.72 (s, 3H, MeO), 2.95 (s, 3H, MeO). $^{31}P–\{^1H\}$ NMR (121.44 MHz, $CDCl_3$, δ ppm): 33.3 s.

Compound **2b** was obtained following a similar procedure as a violet solid.

4.5. [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)-5-^{t}BuC$_6$H$_3$]}{PPh$_2$[2-(HOC)C$_6$H$_4$]}] (**2b**)

Yield 66%. *Anal.* Calc. for $C_{39}H_{38}NO_5PPd$: C, 63.4; H, 5.2; N, 1.9. Found: C, 63.4; H, 5.1; N, 1.8%. IR: ν(C=O), 1697s cm^{-1}, ν(C=N), 1571s cm^{-1}. FAB-MS: $m/z = 738$ $[M]^+$. ^1H NMR (200 MHz, $CDCl_3$, δ ppm, *J* Hz): 10.34 [d, 1H, *H*C=O, $^4J(HP) = 2.4$], 8.11 [d, 1H, HC=N, ^4J (HP) = 10.7], 7.02 [d, 1H, H^8, $^4J(H^8H^{10}) = 2.3$], 6.92 [dd, 1H, H^{10}, $^3J(H^{10}H^{11}) = 8.6$, $^4J(H^8H^{10}) = 2.3$], 6.22 [d, 1H, H^{11}, $^3J(H^{10}H^{11}) = 8.6$], 5.52 [s, 1H, H^5, $^4J(H^5P) = 3.9$], 3.98 (s, 3H, MeO), 3.74 (s, 3H, MeO), 2.95 (s, 3H, MeO), 1.24 (s, 9H, ^{t}Bu). $^{31}P–\{^1H\}$ NMR (80.96 MHz, $CDCl_3$, δ ppm) 33.3 s.

Compound **3a** was obtained following a similar procedure, as a red solid, but using a complex cyclometallated/diarsine 1:4 or 1:2 molar ratio.

4.6. [{Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)C$_6$H$_4$]}}$_2$-{μ-AsPh$_2$(CH$_2$)$_2$Ph$_2$As}] (**3a**)

Yield 49%, using 1:2 molar ratio and 21% using 1:4 molar ratio. *Anal.* Calc. for $C_{58}H_{54}N_2O_8Pd_2As_2$: C, 54.8;

H, 4.3; N, 2.2. Found: C, 54.7; H, 4.2; N, 2.1%. IR: ν(C=N), 1572s cm^{-1}.

FAB-MS: $m/z = 1271$ $[MH]^+$; 878, $[LPd(AsPh_2(CH_2)_2Ph_2As)]^+$. ^1H NMR (200 MHz, $CDCl_3$, δ ppm, J Hz): 7.57 [s, 1H, HC=N], 6.9 [m, 2H, H^8,H^{10}], 6.59 [d, 1H, H^{11}, $^3J(H^{10}H^{11}) = 7.8$], 6.35 [t, 1H, H^9, $J(H^8H^9) = 7.1$], 5.51 [s, 1H, H^5], 3.01 (s, br, 2H, $AsCH_2$), 3.93 (s, 3H, MeO), 3.71 (s, 3H, MeO), 2.63 (s, 3H, MeO).

Compounds **4a**, **4b** were prepared similarly, as violet solids, using a cyclometallated complex/arsinophosphine 1:4 molar ratio.

*4.7. [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)C$_6$H$_4$]}-{PPh$_2$(CH$_2$)$_2$Ph$_2$As-P}] (**4a**)*

Yield 64%. *Anal.* Calc. for $C_{42}H_{39}NO_4PPdAs$: C, 60.5; H, 4.7; N, 1.7. Found: C, 60.4; H, 4.6; N, 1.6%. IR: ν(C=N), 1569s cm^{-1}. FAB-MS: $m/z = 834$ $[MH]^+$. ^1H NMR (200 MHz, $CDCl_3$, δ ppm, J Hz): 8.15 [d, 1H, HC=N, $^4J(HP) = 9.7$], 7.13 [dd, 1H, H^8, $^3J(H^8H^9) = 8.0$, $^4J(H^8H^{10}) = 1.4$], 6.96 [dt, 1H, H^{10}, $^3J(H^9H^{10}) = 8.0$, $^4J(H^8H^{10}) = 1.4$], 6.63 [d, 1H, H^{11}, $^3J(H^{10}H^{11}) = 8.0$], 6.39 [t, 1H, H^9, $^3J(H^9H^{10}) = 8.0$], 5.47 [d, 1H, H^5, $^4J(H^5P) = 2.4$], 3.94 (s, 3H, MeO), 3.72 (s, 3H, MeO), 2.95 (s, 3H, MeO), 2.48 (br, 4H, PCH_2CH_2As). ^{31}P–{^1H} NMR (80.96 MHz, $CDCl_3$, δ ppm): 32.5 s.

*4.8. [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)-5-^{t}BuC$_6$H$_3$]}{PPh$_2$(CH$_2$)$_2$Ph$_2$As-P}] (**4b**)*

Yield 56%. *Anal.* Calc. for $C_{46}H_{47}NO_4PPdAs$: C, 62.1; H, 5.3; N, 1.6. Found: C, 62.2; H, 5.1; N, 1.5%. IR: ν(C=N), 1571s cm^{-1}. FAB-MS: $m/z = 890$ $[MH]^+$. ^1H NMR (200 MHz, $CDCl_3$, δ ppm, J Hz): 8.13 [d, 1H, H_i,$^4J(H_iP) = 10.2$], 7.08 [d, 1H, H^8, $^4J(H^8H^{10}) = 2.4$], 7.03 [dd, 1H, H^{10}, $^3J(H^{10}H^{11}) = 8.5$, $^4J(H^8H^{10}) = 2.4$], 6.57 [d, 1H, H^{11}, $^3J(H^{10}H^{11}) = 8.5$], 5.48 [s, 1H, H^5, $^4J(H^5P) = 3.4$], 3.97 (s, 3H, MeO), 3.72 (s, 3H, MeO), 2.95 (s, 3H, MeO), 2.47 (br, 4H, PCH_2CH_2As), 1.29 (s, 9H, ^{t}Bu). ^{31}P–{^1H} NMR (80.96 MHz, $CDCl_3$, δ ppm): 33.4 s.

Compound **5a** was obtained following a similar procedure as violet solid but using a complex cyclometallated/arphos 1:2 molar ratio.

*4.9. [{Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)C$_6$H$_4$]}}$_2$-{μ-PPh$_2$(CH$_2$)$_2$Ph$_2$As}] (**5a**)*

Yield 64%. *Anal.* Calc. for $C_{42}H_{39}NO_4PPdAs$: C, 60.5; H, 4.7; N, 1.7. Found: C, 60.4; H, 4.6; N, 1.6%. IR: ν(C=N), 1572s cm^{-1}. FAB-MS: $m/z = 1226$ $[M]^+$; 834 $[LPd(arphos)]^+$. ^1H NMR (200 MHz, $CDCl_3$, δ ppm, J Hz): 8.14 [d, 1H, HC=N, $^4J(HP) = 10.5$], 7.58 [s, 1H, H′C=N], 7.12 [d, br, 1H, H^8], 6.95 [t, br, 1H, H^{10}], 6.59 [dd, 1H, H^{11}, $^3J(H^{10}H^{11}) = 8.5$, $^4J(H^9H^{11}) = 2.4$], 6.38 [t, br, 1H, H^9], 5.56 [s, 1H, $H^{5\prime}$], 5.42 [d, 1H, H^5, $^4J(H^5P) = 3.9$], 3.95 (s, 6H, MeO), 3.71 (s, 6H, MeO), 2.84 (s, 3H, MeO), 2.81 (s, 3H, MeO), 3.01 (br, 4H, PCH_2CH_2As). ^{31}P–{^1H} NMR (80.96 MHz, $CDCl_3$, δ ppm): 34.0 s.

*4.10. [{Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)-^{t}BuC$_6$H$_3$]}}$_2${μ-PPh$_2$(C$_6$H$_4$)O(C$_6$H$_4$)Ph$_2$P}] (**6b**)*

A suspension of complex **1b** in acetone was treated with $PPh_2(C_6H_4)O(C_6H_4)Ph_2P$ (cyclometallated complex/diphosphine 1:4 or 1:2 molar ratio) in acetone and the resulting mixture was stirred for 24 h. The solvent was then removed under vacuum to give a violet solid which was chromatographed on a column packed with silica gel. Elution with CH_2Cl_2–C_2H_5OH (99:1) afforded a violet oil after solvent removal, which was recrystallized from dichloromethane–hexane to give the desired product as a violet solid. Yield 27%. *Anal.* Calc. for $C_{76}H_{74}N_2O_9P_2Pd_2$: C, 68.2; H, 5.2; N, 1.4. Found: C, 68.1; H, 5.1; N, 1.3%. IR: ν(C=N), 1565s cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$, δ ppm, J Hz): 8.00 [d, 1H, HC=N, $^4J(HP) = 10.7$], 5.59 [d, 1H, H^5, $^4J(H^5P) = 3.7$], 4.00 (s, 3H, MeO), 3.77 (s, 3H, MeO), 3.02 (s, 3H, MeO), 1.27 (s, 9H, ^{t}Bu). ^{31}P–{^1H} NMR (121.44 MHz, $CDCl_3$, δ ppm): 28.2 s.

Compound **7a** was obtained as a violet solid following a similar procedure to the one used for **6b** but using dichloromethane as solvent.

*4.11. [Pd{2,3,4-(MeO)$_3$C$_6$HC(H)=N[2-(O)C$_6$H$_4$]}-{PPh$_2$[4-(NMe$_2$)C$_6$H$_4$]}] (**7a**)*

Yield 67%, using 1:4 molar ratio, and 36% using 1:2 molar ratio. *Anal.* Calc. for $C_{36}H_{35}N_2PdO_4P$: C, 62.0; H, 5.1; N, 4.0. Found: C, 62.1; H, 5.1; N, 4.1%. IR: ν(C=N), 1572s cm^{-1}. FAB-MS: $m/z = 697$ $[M]^+$. ^1H NMR (300 MHz, $CDCl_3$, δ ppm, J Hz): 8.17 [d, 1H, HC=N, $^4J(HP) = 10.4$], 7.11 [dd, 1H, H^8, $^3J(H^8H^9) = 7.5$, $^4J(H^8H^{10}) = 1.9$], 6.89 [dt, 1H, H^{10}, $^3J(H^{10}H^{11}) = 8.4$, $^4J(H^8H^{10}) = 1.9$], 6.68 [dd, H^b, $^3J(H^aH^b) = 8.0$, $^4J(H^bP) = 1.6$], 6.44 [d, 1H, H^{11}, $^3J(H^{10}H^{11}) = 8.4$], 6.34 [t, 1H, H^9, $^3J(H^9H^{10}) = 7.5$], 5.61 [d, 1H, H^5, $^4J(H^5P) = 4.9$], 3.95 [s, 3H, MeO], 3.73 [s, 3H, MeO], 2.97 [s, 3H, MeO], 2.98 [s, 6H, Me_2]. ^{31}P–{^1H} NMR (121.44 MHz, $CDCl_3$, δ ppm): 32.3 s.

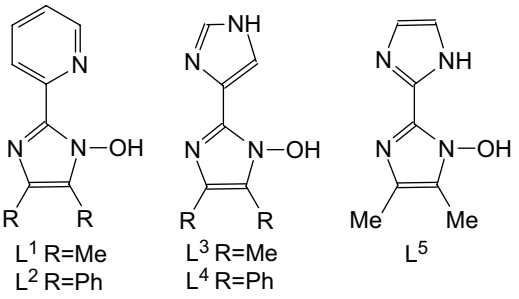

Fig. 1. *N*-hydroxyimidazole ligands.

rate salt with the imidazole ligand in alcohol. The complexes were soluble in a variety of organic solvents and insoluble in water. The complexes formulated with a metal:ligand ratio of 1:2 and were characterised by spectroscopy {IR and NMR (where appropriate)}, microanalysis and X-ray crystallography.

The X-ray crystal structure of $[Cu(L^1)_2](ClO_4)_2 \cdot H_2O$ (Figs. 2a–2c, Tables 1 and 2) shows the Cu(II) ion sitting at a centre of symmetry and with tetragonal geometry. The two L^1 ligands form six-membered, chelate rings with the metal and are *trans* to each other. Both of the NO chelating, neutral *N*-hydroxyimidazole ligands have tautomerised and are in the zwitterion form (Fig. 3), with the uncoordinated imidazole imine N atom being protonated and the oxime O atom deprotonated. There are also long axial bonds to the two perchlorate anions and the solvate water molecule makes three hydrogen bonds to the protonated amine, the oxime O atom and to a perchlorate O atom. The two heterocyclic rings within each ligand are titled at 13.8(1)° to one another. There is π–π stacking (Fig. 2b) creating an infinite two-dimensional network sheet structure. The sheets are linked through the hydrogen bonds between the water molecules and the ligands resulting in the formation of channels which host the water molecules (Fig. 2c).

The three other Cu(II) complexes and one Zn(II) complex all contain two NO chelating zwitterionic *N*-hydroxy-

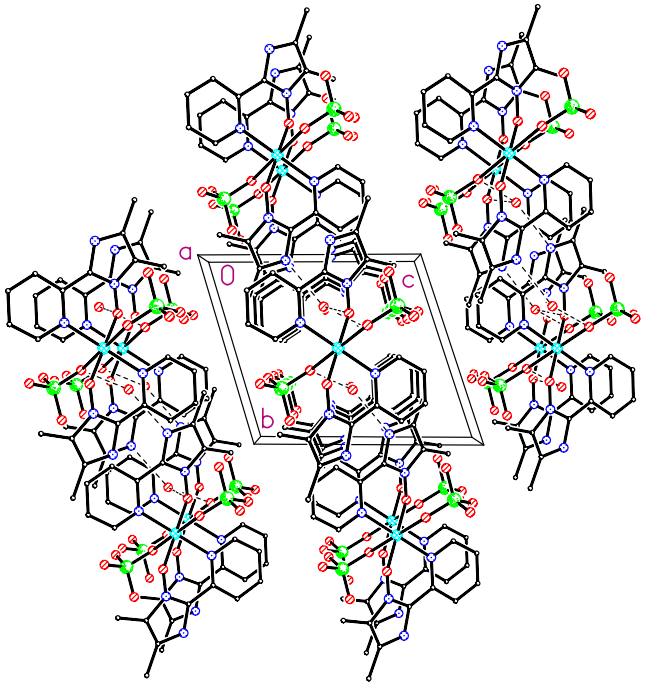

Fig. 2b. π–π stacking in $[Cu(L^1)_2](ClO_4)_2 \cdot H_2O$.

imidazole ligands (Figs. 4–7, Tables 1 and 2) and have core structures similar to $[Cu(L^1)_2](ClO_4)_2 \cdot H_2O$. The three anhydrous Cu(II) complexes have approximate square planar coordination geometry. In the case of $[Cu(L^2)_2](ClO_4)_2$ there are additional hydrogen bonding interactions between the protonated imine N atoms and the perchlorate oxygen atoms stitching neighbouring complexes into infinite chains (for example see Fig. 4). Intermolecular bridging perchlorates and π–π stacking orders the $[Cu(L^3)_2](ClO_4)_2$ units complexes into a supramolecular array (Fig. 5). In the case of $[Cu(L^5)_2](ClO_4)_2$, weak 'Cu–perchlorate–protonated imine' interactions create chains of complex dications (Fig. 7b).

In $[Zn(L^4)_2MeOH](ClO_4)_2 \cdot MeOH$ the cation is a centrosymmetric dimer (Fig. 6a) where the two halves (Fig. 6b) are linked by two bridging deprotonated hydroxyl

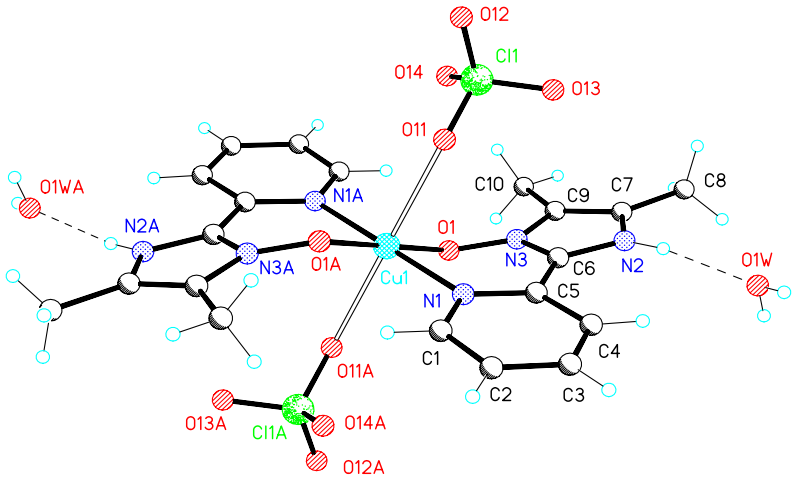

Fig. 2a. X-ray structure of $[Cu(L^1)_2](ClO_4)_2 \cdot H_2O$.

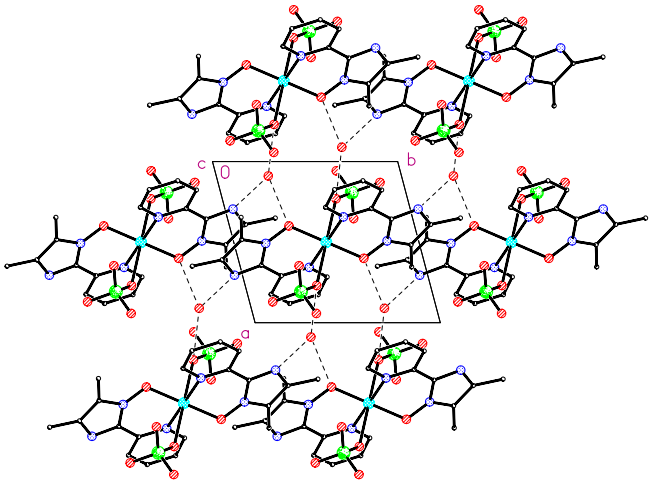

Fig. 2c. Hydrogen-bonded water molecules in the channels formed in $[Cu(L^1)_2](ClO_4)_2 \cdot H_2O$.

O^- atoms (O2). The Zn(II) ions are six-coordinate, the sixth ligand being a methanol solvate molecule. There is extensive hydrogen bonding network involving the coordinated methanol, the methanol of solvation, the perchlorate anion and the hydrogen of the protonated amine N atom. This three-dimensional coordination polymer structure is shown in Fig. 6c.

To our knowledge, the above five complexes are the first documented examples of *N*-hydroxyimidazoles tautomerising to form zwitterions upon complexation to a metal ion and, as such, represent a novel class of ligand.

3. Experimental

Chemicals were purchased from commercial sources and, unless specified, were used without further purification. *N*-Hydroxyimidazoles were prepared by reacting monoximes with aldehydes and ammonia [10,11]. Infrared spectra of solids (in a KBr matrix) were recorded in the region 4000–400 cm^{-1} on a Nicolet FT-IR Impact 400D infrared spectrometer. ^1H NMR spectra were run as solutions in DMSO-d_6 on a Bruker Avance 300 MHz instrument. Microanalytical data were provided by the Microanalytical Laboratory, National University of Ireland, Cork, Ireland. X-ray crystallographic data (Table 3) were collected at 150 K on a Bruker SMART 1000 diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and refined by full-matrix least-squares on F^2 using all the reflections. All the non-hydrogen atoms were refined anisotropically and hydrogen atoms bonded to carbon were inserted at calculated positions using a riding model. Hydrogen atoms bonded to O or N were located from difference maps and refined with fixed, isotropic thermal parameters,

except for $[Zn(L^4)_2MeOH](ClO_4)_2 \cdot MeOH$ (where all the H atoms were inserted at calculated positions) and $[Cu(L^5)_2](ClO_4)_2$ (where they were located and not further refined).

3.1. $[Cu(L^1)_2](ClO_4)_2 \cdot H_2O$

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ and L^1 (1:2 mol ratio) in acetonitrile was refluxed for 4 h and then left to stand overnight. The precipitated green complex was recrystallised from a mixture of acetonitrile and ethanol. Yield = 81%. The complex was soluble in hot acetonitrile and insoluble in water. *Anal.* Calc. for $C_{20}H_{24}N_6O_{11}Cl_2Cu$: C, 36.46; H, 3.67; N, 12.76. Found: C, 36.50; H, 3.29; N, 12.32%. Scheme 1. The ligands H_6ipa-hyhb ($n = 2$) and H_6ipa-hyhh ($n = 4$).

this context we have recently established an excess to homochiral helical arrays and porous 3D coordination frameworks based on metal complexes containing nucleoside-based salen-type ligands [4] and trinucleating triaminoguanidine-based Schiff-base ligands [5], respectively.

To generate dinuclear *meta*-phenylene-bridged building blocks we synthesized the new Schiff-base ligands H_6ipa-hyhb and H_6ipa-hyhh shown in Scheme 1 providing two [ONO] *N*-salicylidenehydrazide binding pockets bridged through a central resorcinol moiety, which is additionally functionalized by hydroxyl side chains. To date only a scarce number of dinuclear copper(II) complexes with the 1,3-dihydroxybenzene bridging motif have been synthesized which utilize double Schiff-base ligands of 4,6-diacetylresorcinol [6,7], but no crystal structure is reported as yet. In contrast the momonuclear metal complexes of the analogous *N*-salicylidenehydrazide ligands with a variety of different side chain functionalities providing only one binding pocket are well documented [8,9]. In particular, the use of such ligands with hydroxyalkyl side chains leads to supramolecular interactions via hydrogen bonding networks as was shown for vanadium(V) complexes [10]. Moreover, it is interesting to note that in the case of copper(II) complexes of such mononucleating *N*-salicylidenehydrazide ligands the side chain functionality provides a coordinative cross-linking of the phenolate-bridged dinuclear units generating a 2D coordination polymer [11].

In this paper, we report the synthesis and chemical characterization of three novel copper(II) coordination polymers based on the new ω-hydroxyalkyl functionalized double Schiff-base ligands H_6ipa-hyhb and H_6ipa-hyhh (see Scheme 1). The crystal structures of these complexes and their magnetic properties are presented.

2. Experimental

2.1. Materials

4-Hydroxybutanoic acid hydrazide and 6-hydroxyhexanoic acid hydrazide were synthesised by hydrazinolysis of the corresponding lactone. All the other starting materials are commercially available and were used without further purification. Abbreviations used throughout the text: ipa = 4,6-dihydroxy-5-methyl-benzene-1,3-dicarbaldehyde, H_6ipa-hyhb = 4-hydroxy-butanoic acid [1-2,4-dihydroxy-5-[(4-hydroxy-butyryl)-hydrazonomethyl]-3-methyl-phenyl-methylidene]-hydrazide, H_6ipa-hyhh = 6-hydroxy-hexanoic acid [1-2,4-dihydroxy-5-[(6-hydroxy-hexanoyl)-hydrazonomethyl]-3-methyl- phenyl-methylidene]-hydrazide.

2.2. Physical measurement

Melting points were determined via a VEB Analytik Dresden HMK 72/41555. NMR spectra were recorded on Bruker AVANCE 200 and 400 MHz spectrometers at ambient temperatures. The chemical shifts were referenced to tetramethylsilane and are reported in ppm. The infrared spectra were recorded on a Bruker IFS55/EQUINOX spectrometer. Elemental analyses were determined on a Leco CHNS/932 and a VARIO EL III elemental analyzer. Magnetic susceptibilities were obtained from polycrystalline samples using a Quantum-Design MPMSR-5S SQUID magnetometer, measurements were conducted with an applied magnetic field of 2 and 5 kOe in the temperature range from 2 to 300 K. The measured values of χ_M were corrected for their diamagnetic contributions.

2.3. Synthesis of the ligands

2.3.1. 2-Methyl-4,6-diformylresorcinol (ipa)

2-Methylresorcinol (10.0 g, 80 mmol) was mixed with hexamethylenetetramine (22.5 g, 160 mmol) in trifluoroacetic acid (100 mL). Trifluoroacetic acid anhydride (7 mL) was added to the resulting brown reaction solution. This solution was heated at 80 °C for five days under argon atmosphere. The reaction mixture was poured into 4 M HCl (350 mL), stirred for 10 min and extracted with CH_2Cl_2 (7 × 100 mL). The combined organic layers were dried over Na_2SO_4 and the solvent removed under vacuum. The crude product obtained as brown needles was pure enough for the following ligand syntheses (Yield: 5.2 g, 35%). The aqueous layer was allowed to stand in the refrigerator at 8 °C for three days and another fraction of ipa could be isolated as pale pink needles. These were separated by filtration and dried under vacuum (Yield: 2.7 g, 19%). NMR- and IR-spectroscopic measurements revealed that both fractions are identical (overall yield: 7.9 g, 54%). Colorless needles of ipa can be obtained by steam distillation of the combined fractions. M.p. 187 °C. ^{1}H NMR (200 MHz, $CDCl_3$): $\delta = 2.09$ (s, 3H, C*H*$_3$); 7.66 (s, 1H, arom. C*H*); 9.74 (s, 2H, C*H*O); 11.99 ppm (s, 2H, O*H*). ^{13}C NMR (100 MHz, $CDCl_3$): $\delta = 6.5$ (*C*H$_3$); 113.5 (arom. C^2); 115.2 (arom. $C^{4,6}$); 139.9 (arom. C^5); 166.3 (arom. $C^{1,3}$); 194.0 ppm (*C*HO). IR (KBr, cm^{-1}): 2866 vw, 1648 vs, 1610 vs, 1378 m, 1339 m, 1306 s, 1224 w, 1166 vs, 1008 m, 777 m, 726 m, 647 m, 533 m.

2.3.2. H_6ipa-hyhb

4-Hydroxybutanoic acid hydrazide (1.9 g, 16 mmol) was added to a suspension of ipa (1.5 g, 8 mmol) in ethanol (100 mL) and the resulting yellow solution was stirred over night at room temperature. The volume of the reaction mixture was reduced to approximately 30 mL resulting in the precipitation of a pale yellow solid which was filtered off, washed with a small amount of ethanol

and dried under vacuum (Yield: 2.8 g, 96%). M.p. 190 °C (decomposition). As can be seen in the NMR spectra, the ligand is a mixture of two isomers at the ratio of 4:1. *Anal.* Calc. for $C_{17}H_{24}N_4O_6 \cdot H_2O$: C, 51.25; H, 6.58; N, 14.06; Found: C, 51.21; H, 6.73; N, 14.28%. ^{1}H NMR (400 MHz, DMSO-d_6): $\delta = 1.72$ (tt, 4H, $^3J = 7.4$ Hz, CH_2 CH_2OH); 2.06 and 2.07 (s, 3H, CH_3); 2.25 and 2.55 (t, 4H, $^3J = 7.4$ Hz, CH_2C=O); 3.33 (s, 2H, H_2O); 3.42 (dt, 4H, $^3J_t = 6.0$ Hz, $^3J_d = 5.0$ Hz, CH_2OH); 4.51 (t, 2H, $^3J = 5.0$ Hz, CH_2O*H*); 7.36 and 7.37 (s, 1H, arom. C*H*); 8.09 and 8.22 (s, 2H, C*H*=N); 11.18, 11.31, 11.61, 11.62 and 12.43 ppm (s, 4H, arom. O*H* and N*H*). ^{13}C NMR (50 MHz, DMSO-d_6): $\delta = 7.6$ (*C*H_3); 27.1, 28.2, 28.4 and 30.6 (*C*H_2); 60.1 (*C*H_2OH), 110.5, 110.8 and 111.2 (arom. C^2, $C^{4,6}$); 130.8 and 131.1 (arom. C^5); 145.2 and 147.7 (*C*H=N); 157.7 and 158.6 (arom. $C^{1,3}$); 168.3 and 172.9 ppm (*C*=O). 2.4. Synthesis of the complexes

2.4.1. $\{[Cu_2(H_4ipa\text{-}hyhb)(Hpz)_2](ClO_4)_2\}_n$ (1)

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (209 mg, 0.6 mmol) in methanol (3 mL) was added to a suspension of H_6ipa-hyhb (107 mg, 0.3 mmol) in methanol (4 mL). To the resulting dark green solution pyrazole (39 mg, 0.6 mmol) was added and the reaction solution was stirred for 20 min. Aqueous ammonia (2 equiv.) was added generating a green precipitate within 10 min, which redissolves by addition of further methanol (15 mL). Slow evaporation of the solvent afforded after about one week green prisms of $\mathbf{1} \cdot n$MeOH suitable for X-ray diffraction. The crystals were separated by filtration and dried under vacuum, which leads to the loss of the solvent of crystallization (Yield: 126.2 mg, 51%). M.p. > 280 °C (decomposition). *Anal.* Calc. for $C_{23}H_{30}Cl_2Cu_2N_8O_{14}$ (**1**): C, 32.87; H, 3.60; N, 13.33. Found: C, 33.08; H, 3.55; N, 13.33%. IR (KBr, cm^{-1}): 3379 s, 3138 w, 2959 m, 2885 m, 2799 w, 1592 vs, 1565 vs, 1396 m, 1358 m, 1276 m, 1203 s, 1121 vs, 1091 vs, 1047 s, 771 m, 627 m.

2.4.2. $\{[Cu_2(H_4ipa\text{-}hyhb)(Him)_2](ClO_4)_2\}_n$ (2)

The synthesis is analogous to what is described for complex **1**. The use of imidazole (38 mg, 0.6 mmol) instead of pyrazole afforded green prisms of the desired complex as its solvate $\mathbf{2} \cdot \frac{n}{2}H_2O$ (Yield: 170.1 mg, 73%). M.p. > 260 °C (decomposition). *Anal.* Calc. for $C_{23}H_{31}Cl_2Cu_2N_8O_{14.5}$ ($\mathbf{2} \cdot \frac{n}{2}H_2O$): C, 32.52; H, 3.68; N, 13.19. Found: C, 31.78; H, 3.52; N 12.39%. IR (KBr, cm^{-1}): 3330 vs, 3144 w, 2959 m, 2885 w, 1593 vs, 1555 vs, 1425 w, 1396 m, 1366 w, 1277 m, 1201 s, 1141 m, 1121 vs, 1091 vs, 1068 s, 771 w, 626 m.

2.4.3. $\{[Cu_2(H_4ipa\text{-}hyhh)(Hpz)_2](ClO_4)_2\}_n$ (3)

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (286 mg, 0.8 mmol) in methanol (2 mL) was added to a suspension of H_6ipa-hyhh (168.3 mg, 0.4 mmol) in methanol (8 mL). After stirring for 15 min a clear dark green solution was obtained. Pyrazole (53 mg, 0.8 mmol) and aqueous ammonia (2 equiv.) were added and the solution was stirred for further 20 min. Slow diffusion of diethylether into this solution afforded within three days green prisms of $\mathbf{3} \cdot n$MeOH suitable for X-ray diffraction. The crystals were filtered off and dried under vacuum, which leads to the loss of the solvent of crystallization (Yield: 195.8 mg, 57%). M.p. > 280 °C (decomposition). *Anal.* Calc. for $C_{27}H_{38}Cl_2Cu_2N_8O_{14}$ (**3**): C, 36.17; H, 4.27; N, 12.50. Found: C, 36.11; H, 4.03; N, 12.37%. IR (KBr, cm^{-1}): 3430 s, 3136 w, 2935 m, 2860 w, 1594 vs, 1569 vs, 1391 m, 1362 m, 1278 m, 1208 s, 1121 vs, 1062 s, 768 m, 625 m.

2.5. X-ray crystallographic studies

X-ray measurements were carried out on a Nonius Kappa CCD diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 71.073$ pm) at 183(2) K. The crystallographic data are summarized in Table 1. Data were corrected for Lorentz and polarization effects, but not for absorption effects [12]. The structures were solved by direct methods with SHELXS-97 and refined by full-matrix least-squares techniques against F_0^2 using SHELXL-97 [13]. The hydrogen atoms were included at calculated positions with fixed thermal parameters. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Synthesis and characterization

The two new ligands H_6ipa-hyhb and H_6ipa-hyhh were synthesized by Schiff base condensation of 2-methyl-4,6-diformylresorcinol (ipa) with two equivalents of the appropriate hydrazides in methanol (Scheme 2). The isophthalaldehyde derivative (ipa) was prepared by a new route with a modified Duff formylation [14] through *ortho*-formylation of 2-methylresorcinol with two equivalents of hexamethylenetetramine (HMTA) in trifluoroacetic acid (TFA). The isophthalaldehyde was isolated analytical pure in 54% overall yield. Reported synthetic routes obtained the aldehyde in lower overall yields of 9% [15] and 36% [16] in time-consuming multi-step-synthesis. Our synthesis is an efficient alternative to the reported literature procedures.

Scheme 2. Synthesis of the ligands H_6ipa-hyhb ($n = 2$) and H_6ipa-hyhh ($n = 4$); HMTA = hexamethylenetetramine.

Each ligand provides two tridentate [ONO] binding pockets with the phenolate oxygen atom, the imine nitrogen atom, and the carbonyl oxygen atom as potential donors. Furthermore, the hydroxyl groups of the alkyl side chains provide additional donors. Depending on the pH value of the solution the phenol groups, the amide groups, and the side chain hydroxyl groups can be deprotonated and therefore the ligands can adopt a variable di-, tetra- or hexaanionic protonation state. The reaction with two equivalents of $Cu(ClO_4)_2 \cdot 6\ H_2O$ in methanol in the presence of two equivalents of aqueous ammonia afforded dark green solutions. Subsequent addition of two equivalents of pyrazole results in the formation of $\{[Cu_2(H_4ipa\text{-}hyhb)(Hpz)_2](ClO_4)_2\}_n$ (**1**) and $\{[Cu_2(H_4ipa\text{-}hyhh)(Hpz)_2](ClO_4)_2\}_n$ (**3**) which can be isolated as green crystals of the corresponding solvent containing compounds **1** · *n*MeOH and **3** · *n*MeOH, respectively. The use of imidazole instead of pyrazole leads to complex $\{[Cu_2(H_4ipa\text{-}hyhb)(Him)_2](ClO_4)_2\}_n$ (**2**) isolated as green crystals of **2** · $\frac{n}{2}H_2O$. In all three complexes the ligands act in their dianionic form. Both phenolate groups are deprotonated, whereas the amide and the hydroxyl groups are still protonated.

The complexes were characterized by X-ray structural analysis, elemental analysis, and IR spectroscopy. The crystals of **1** · *n*MeOH and **3** · *n*MeOH lost the co-crystallized methanol molecules upon drying. The IR-spectra of both ligands exhibit two strong characteristic bands at 1667

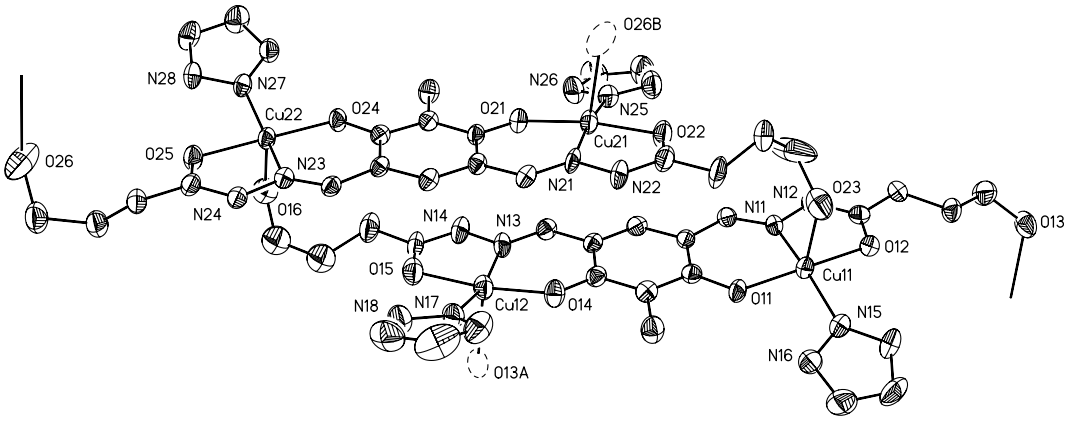

Fig. 1. Structure of the asymmetric unit of compound $\mathbf{1}\cdot n$MeOH. Symmetry-related atoms are labeled with index A and B. The perchlorate ions, methanol molecules and hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at the 50% probability level.

and 1629 cm^{-1} (H_6ipa-hyhb) and 1663 and 1628 cm^{-1} (H_6ipa-hyhh), which can be attributed to amide I ($\nu_{C=O}$) and the imine stretching vibration ($\nu_{C=N}$). Both bands were shifted in all three complexes to approximately 1593 and 1565 cm^{-1} due to the coordination of the imine nitrogen atoms and the carbonyl oxygen atoms to the copper ions. In the spectra of the complexes a new strong characteristic broad band can be detected at 1121 cm^{-1} which is attributed to the stretching vibration of the perchlorate ions.

3.2. Description of the structures

3.2.1. $\{[Cu_2(H_4ipa\text{-}hyhb)(Hpz)_2](ClO_4)_2\}_n\cdot nMeOH$ ($\mathbf{1}\cdot n$MeOH)

The compound $\mathbf{1}\cdot n$MeOH crystallizes in the monoclinic space group $P2_1/n$ forming an one-dimensional coordination polymer built up by the dinuclear dicationic complex entities $[Cu_2(H_4ipa\text{-}hyhb)(Hpz)_2]^{2+}$ linked via apical coordination of the hydroxyl groups of both ligand side chains to two adjacent dinuclear complex units.

The molecular structure of the asymmetric unit as well as the atom numbering scheme of the heteroatoms is illustrated in Fig. 1. The asymmetric unit contains four crystallographically independent copper atoms embedded in two ligands. The two binding sites of each ligand are occupied by the copper ions Cu*i*1 and Cu*i*2 ($i = 1, 2$; running number assigned to the independent ligand moieties). The copper atoms are in a distorted square pyramidal coordination environment. The basal square planes are formed by the phenolate oxygen atoms O*i*1/O*i*4, the Schiff base nitrogen atoms N*i*1/N*i*3, the carbonyl oxygen atoms O*i*2/O*i*5, and the nitrogen atoms N*i*5/N*i*7 of the pyrazole co-ligands. The latter are coplanar with the bridging aromatic ligand. The apical positions at the copper ions are occupied by hydroxyl groups O*i*3/O*i*6 of the neighboring complex units. Each dinuclear unit is bound to two adjacent units, this coordination mode leads to the formation of a double hydroxyalkyl-bridged infinite chain structure.

Selected bond lengths and angles are summarized in Table 2. The donor-copper distances within the basal plane are similar for both complex entities and with 189–201 pm in the expected range [17]. The apical bond lengths vary from 225 to 241 pm and are significantly longer due to the weaker coordination of the hydroxyl oxygen atoms and the typical Jahn–Teller distortion of the copper(II) ion. These distances show significant differences for the two independent complex units with values of about 225–229 pm for Cu11–O23 and Cu12–O13A and a considerable elongation for the second moiety with values of about 240 pm (Cu21–O26B and Cu22–O16). Consequently, somewhat different coordination geometries are observed for the copper centers of the two ligand moieties within the asymmetric unit, which reflects in the variation of the τ parameters ($\tau = 0$ for an ideal tetragonal pyramid; $\tau = 1$ for an ideal trigonal bipyramid [18]) of the corresponding polyhedra ($\tau_{Cu11} = 0.11$, $\tau_{Cu12} = 0.14$, $\tau_{Cu21} = 0.03$, $\tau_{Cu22} = 0.02$).

The distance between the copper centers within the dinuclear complex entities across the resorcinol bridge is 827 pm, whereas the shortest non-covalent distances within the coordination chains are found at 465 (Cu11···Cu11A) and 491 pm (Cu22···Cu22A). For the separation between

Table 2

Symmetry transformations used to generate equivalent atoms: A = $x + 1$, y, z; B = $x + 1$, $y + 1$, z.

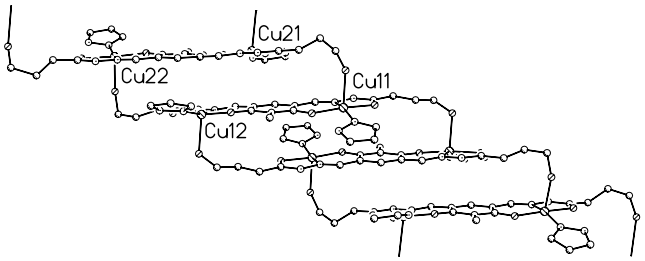

Fig. 2. Polymer structure of complex $\mathbf{1}\cdot n$MeOH. The perchlorate ions and methanol molecules as well as hydrogen atoms are omitted for clarity.

copper centers of adjacent coordination polymer chains distances of at least 706 pm are found. The two ligand molecules are nearly planar with a mean deviation of 5.2 pm for $i = 1$ and 6.0 pm for $i = 2$ from the best least square plane including the ligand atoms except the alkyl side chains. Moreover, the two distinct complex moieties assemble nearly coplanar with a distance of approximately 300 pm and an angle of about 3° between their normal vectors. Due to the coordination of the hydroxyl side chains to adjacent dinuclear complex entities the building blocks assemble to one-dimensional chains along the [0 1 0] direction of the unit cell, which is illustrated in Fig. 2. This results in the formation of a distorted ladder like cationic coordination polymer.

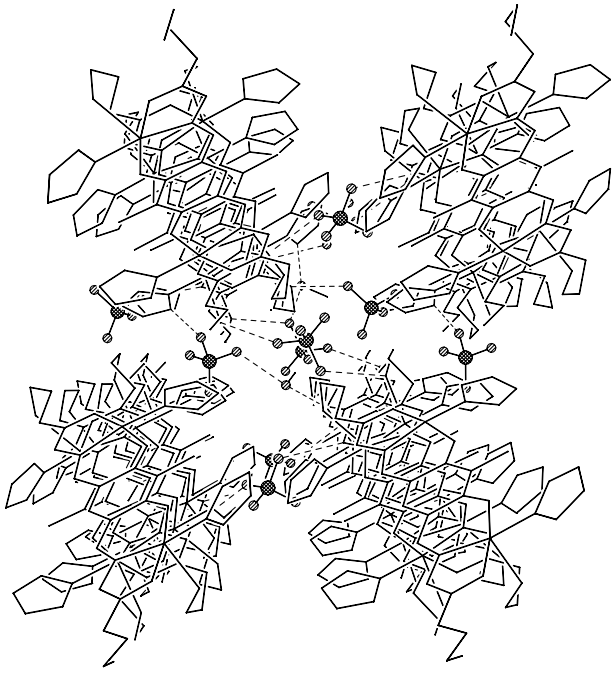

Fig. 3. Assembly of the coordination chains of compound $\mathbf{1}\cdot n$MeOH. View along the coordination chains in [0 1 0] direction. Hydrogen atoms are omitted for clarity. Dashed lines indicate the hydrogen bonds.

In the crystal packing the cationic chains assemble parallel as depicted in Fig. 3. The perchlorate ions located between the chains are cross-linking them by hydrogen bond interactions forming a 3D supramolecular assembly. The perchlorate ions interact through their oxygen atoms via O13–H···O–Cl–O···H–O26 with the protonated hydroxyl groups of the ligand side chains of two adjacent coordination chains. Additional hydrogen bonding links are established through the perchlorate ions by interaction with the amide groups N*i*2–H, N*i*4–H and the uncoordinated pyrazole amine N18–H via O16–H···O–Cl–O···H–N24, N22–H···O–Cl–O···H–N14 and N18–H···O–Cl–O···H–N12.

3.2.2. $\{[Cu_2(H_4ipa\text{-}hyhb)(Him)_2](ClO_4)_2\}_n\cdot\frac{n}{2}H_2O$-($\mathbf{2}\cdot\frac{n}{2}H_2O$)

Reaction of ligand H_6ipa-hyhb with $Cu(ClO_4)_2\cdot 6H_2O$ using imidazole instead of pyrazole results in the formation of a distorted ladder like polymer structure analogous to complex **1**. Complex **2** crystallizes together with one molecule of water per two building block units in the orthorhombic space group *Pbcn*. Again the asymmetric unit contains two independent dinuclear complex fragments, double linked over the hydroxyl oxygen atoms of the side chains as shown in Fig. 4.

Each copper ion is coordinated in the basal plane by the [ONO] ligand binding pocket and the nitrogen atom of the imidazole co-ligand. The apical position is occupied by a hydroxyl oxygen atom. The bond lengths, angles, and dis-

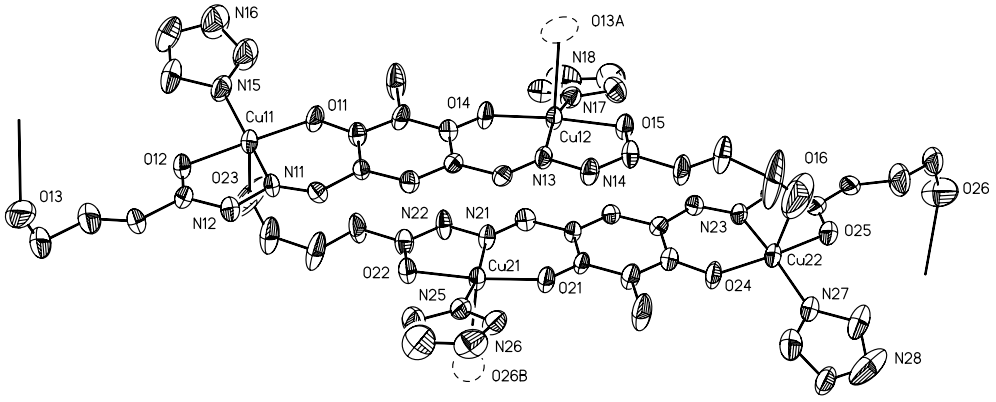

Fig. 4. Structure of the asymmetric unit of compound $\mathbf{2}\cdot\frac{n}{2}H_2O$. Symmetry-related atoms are labeled with index A and B. The perchlorate ions, water molecules and hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at the 50% probability level.

tances within the dinuclear complex units are comparable with those of complex **1** (see supporting information). The distances between the axial hydroxyl oxygen atoms and the copper ions (Cu11–O23 247.7, Cu12–O13 246.6, Cu21–O26 261.9, and Cu22–O16 245.0 pm) are significant longer than those to the donor atoms within the basal plane. Therefore, the coordination environment of the copper ions can be best described as (4 + 1) square pyramidal with a weak apical coordination of the hydroxyl oxygen atoms of adjacent dinuclear complex units ($\tau_{Cu11} = 0.12$, $\tau_{Cu12} = 0.15$, $\tau_{Cu21} = 0.08$, $\tau_{Cu22} = 0.10$). All copper centers exhibit small displacements from the best fit mean planes given by the corresponding four basal donor atoms of 16.5 (Cu11), 14.3 (Cu12), 11.9 (Cu21), and 14.2 pm (Cu22) towards the apical position. Within the dinuclear units one copper center is situated above and one below the ligand mean plane defined by all ligand atoms except the hydroxyalkyl side chains. The related absolute displacements of the copper centers from this plane are larger for Cu12 and Cu22 (about 11 pm) as compared to Cu11 (3.9 pm) and Cu21 (0.6 pm), which approximately lie within this plane. In analogy to complex **1** the cationic dinuclear complex units generating the 1D coordination polymer are nearly coplanar (see Fig. 5).

The perchlorate counterions are involved in a hydrogen bonding network which is somewhat different to what is observed for compound **1** · *n*MeOH due to the replacement of the co-ligand by imidazole. Nevertheless, also in this case the 1D coordination chains running along the [1 0 0] direction assemble parallel as depicted in Fig. 6.

3.2.3. {[Cu_2(H_4ipa-hyhh)(Hpz)$_2$](ClO_4)$_2$}$_n$ · *n*MeOH (**3** · *n*MeOH)

The complex cation within the asymmetric unit of the polymeric compound {[Cu_2(H_4ipa- hyhh)(Hpz)$_2$](ClO_4)$_2$}$_n$ · *n*MeOH (**3** · *n*MeOH) is illustrated in Fig. 7. The corresponding bond lengths and angles are given in Table 3. In analogy to compounds **1** and **2** two copper ions are coordinated by one doubly deprotonated ligand molecule, but in contrast to **1** and **2** only one ligand moiety is present in the asymmetric unit.

Both copper centers are coordinated by the phenolate oxygen atoms O1/O4, the Schiff base nitrogen atoms N1/N3, and the carbonyl oxygen atoms O2/O5 of the ligand. The fourth position in the basal plane is occupied by the nitrogen atoms N5/N7 of the pyrazole co-ligands. In the apical position at Cu1 a perchlorate ion is weakly bound through the oxygen atom O14 at a distance of 252 pm, whereas the apical position at Cu2 is occupied by the

N1–Cu1–N5	174.8(1)	N3–Cu2–O7	167.9(1)

Symmetry transformations used to generate equivalent atoms: B = $x - 1$, y, $z - 1$.

hydroxyl oxygen atom O3 of an adjacent building block with a bond distance of 240 pm. The copper ions Cu1 and Cu2 lie approximately within the basal plane of their square-pyramidal coordination polyhedra with a displacement of 6.6 ($\tau = 0.07$) and 12.9 pm towards the apical position ($\tau = 0.04$), respectively.

The dinuclear copper complex cations $[Cu_2(H_4ipahyhh)(Hpz)_2]^{2+}$ assemble to 1D coordination chains linked through the hydroxyl group O3 of one of the two ligand side chains. The 1D coordination polymers are arranged along the [1 0 1] direction of the unit cell. As depicted in Fig. 8 two such chains are cross-linked via hydrogen bonds between the hydroxyl oxygen atom O6 and the amid nitrogen atom N2 of two adjacent chains (O6···N2 278 pm).

The individual dinuclear building blocks of adjacent double chains are stacked through π–π interactions at a distance of about 350 pm as shown in Fig. 9. This leads to a interlaced zipper-like arrangement of the hydrogen bonded double chains. The stacked double chains are further linked by hydrogen bonding interactions between the oxygen atoms of the weakly bound perchlorate ion and the pyrazole nitrogen atom N8 as well as the hydroxyl oxygen atom O6 (O11···N8 282 and O13···O6 283 pm). The second perchlorate counterion is not involved in this network and shows a disorder of all oxygen atoms typical for non-bounded perchlorate ions.

3.3. Magnetochemistry

The magnetization of polycrystalline samples of the compounds **1**, $\mathbf{2}\cdot\frac{n}{2}H_2O$, and **3** were measured in the temperature range between 2 and 300 K. For **1** the temperature dependence of the paramagnetic molar susceptibility χ_M, which is based on the constituting dinuclear building block, and its product with temperature $\chi_M T$ are depicted in Fig. 10. A similar magnetic behavior is observed for the compounds $\mathbf{2}\cdot\frac{n}{2}H_2O$ and **3**. The experimental $\chi_M T$ values at 300 K of 0.88 $cm^3\,K\,mol^{-1}$ for **1**, 0.93 $cm^3\,K\,mol^{-1}$ for $\mathbf{2}\cdot\frac{n}{2}H_2O$, and 0.86 $cm^3\,K\,mol^{-1}$ for **3** are characteristic for the spin-only value of two independent copper(II) ions. Upon lowering the temperature $\chi_M T$ slightly decreases down to 0.75 $cm^3\,K\,mol^{-1}$ at 50 K. Further lowering the temperature leads to a rapid decreases of $\chi_M T$ approaching values close to zero. This behavior is characteristic for an antiferromagnetic coupling between the copper centers with an $S = 0$ ground state.

In order to explain the magnetic properties the experimental $\chi_M T$ data were first analyzed with the alternating chain model derived from the spin Hamiltonian given in Eq. (1) [19,20].

$$\hat{H} = -J\sum_{i=1}^{n/2}[\hat{S}_{A_{2i}}\cdot\hat{S}_{A_{2i-1}} + \alpha\hat{S}_{A_{2i}}\cdot\hat{S}_{A_{2i+1}}]. \quad (1)$$

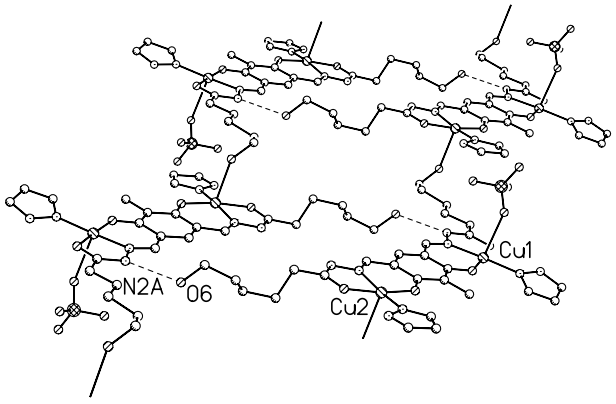

Fig. 8. Double chain structure of compound $\mathbf{3}\cdot n$MeOH. The perchlorate ions as well as the methanol molecules and hydrogen atoms are omitted for clarity. Dashed lines indicate the hydrogen bond O6···N2 (278 pm). The chains run along the [1 0 1] direction of the unit cell.

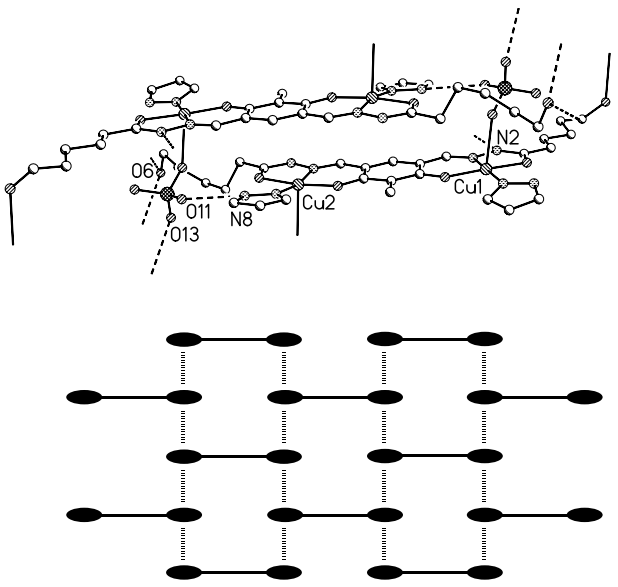

Fig. 9. Top: π–π Stacking and hydrogen bonding interactions between building block units of adjacent double chains of compound $\mathbf{3}\cdot n$MeOH (cf. Fig. 8); dashed lines indicate hydrogen bonds. Bottom: Schematic representation of the arrangement of the hydrogen bonded double chains; the dumb bells represent the 1D coordination polymers linked to double chains; depicted with view along the chains.

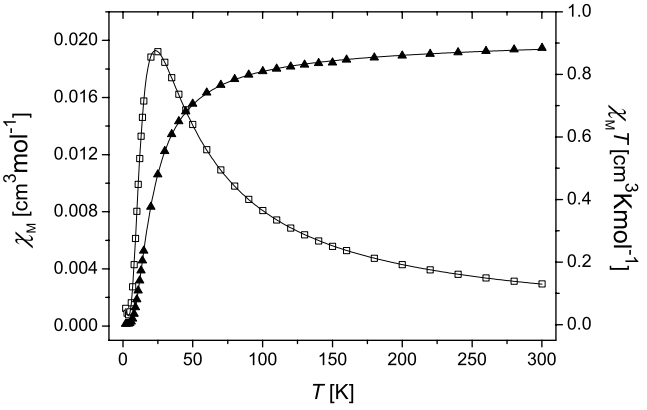

Fig. 10. Plots of χ_M (□) and $\chi_M T$ (▲) vs. T for compound **1**. The corresponding fit functions according to Eq. (2) are drawn as solid lines (for parameters see text and Table 4).

Using the numerical expression reported by Hatfield et al. ($n = 10$ and $S = 1/2$ for data with $T > 9.4$ K) [20] the best fit for compound **1** leads to $J = -26.2\ \mathrm{cm}^{-1}$, $\alpha J = -0.4\ \mathrm{cm}^{-1}$ ($\alpha = 0.016$), $g = 2.20$, and $\chi_{tip} = 2 \times 10^{-5}\ \mathrm{cm}^3\ \mathrm{mol}^{-1}$ with a coefficient of determination of $r^2 = 0.99991$. Herein the J value is assumed to represent the exchange interaction between two copper(II) ions via the resorcinol bridge, whereas the αJ value can be assigned to exchange interaction with adjacent building blocks linked through the hydroxyalkyl side chains of the ligand. The very small values of αJ are consistent with the fact that no efficient exchange pathway (e.g. superexchange or spinpolarisation) is possible along the bridging hydroxyalkyl side chains. Moreover, any kind of through space interaction within the examined temperature range is prohibited by the interatomic distances between non-covalently linked copper centers within and across polymeric chains.

Therefore, the magnetic data were analyzed with the Bleaney–Bowers equation for isolated dinuclear copper(II) complexes ($\hat{H} = -J \cdot \hat{S}_1 \cdot \hat{S}_2$ with $S_1 = S_2 = 1/2$) [21]. The contribution of the paramagnetic impurity (ρ) with $S = 1/2$ as well as the temperature independent paramagnetism (χ_{tip}) were also taken into account according to Eq. (2).

$$\chi_M T = \frac{2N_A g_{eff}^2 \beta^2}{k_B} \left[\frac{(1-\rho)}{\left[3 + e^{\frac{-J}{k_B T}}\right]} + \frac{\rho}{4} \right] + \chi_{tip} T. \qquad (2)$$

The best fit obtained for compound **1** resulted in $J = -26.1\ \mathrm{cm}^{-1}$, $g = 2.18$, $\chi_{tip} = 4 \times 10^{-5}\ \mathrm{cm}^3\ \mathrm{mol}^{-1}$, and $\rho = 0.0026$ with $r^2 = 0.99998$. These values are in very good agreement with those obtained by the fit for the alternating chain model, even leading to a somewhat better coefficient of determination. Therefore, the latter analysis, which is solely based on interactions within the building blocks, was also adopted for compounds $\mathbf{2} \cdot \frac{n}{2}H_2O$ and **3** for which the fit parameters are listed in Table 4.

The exchange coupling constants J are the same for the two dinuclear building blocks with coordinated pyrazole present in **1** and **3**, whereas the coupling is slightly more antiferromagnetic in the case of imidazole as co-ligand as found in compound $\mathbf{2} \cdot \frac{n}{2}H_2O$. To the best of our knowledge there is only one report describing magnetic properties of similarly bridged dinuclear copper(II) complexes with double Schiff-base ligands of 4,6-diacetylresorcinol [6]. These complexes also show antiferromagnetic exchange interactions with a Weiss constants θ ranging from -10 to -20 K depending on the utilized amine ligand side chains.

Table 4
Fit parameters for the magnetic data of the complexes **1**–**3** according to the Bleaney–Bowers equation

Compound	J (cm^{-1})	g_{eff}	ρ	χ_{tip} (cm^3/mol)	r^2
1	−26.12(6)	2.186(1)	0.0026(7)	4×10^{-5}	0.99998
$\mathbf{2} \cdot \frac{n}{2}H_2O$	−28.25(4)	2.193(1)	0.0020(5)	21×10^{-5}	0.99998
3	−26.50(5)	2.171(1)	0.0065(6)	2×10^{-5}	0.99998

Regression of the Curie plots of the compounds **1**–**3** resulted in θ values of about -17 K in all three cases, which is clearly within the reported range. The observed antiferromagnetic behavior can be explained by an intramolecular spin-exchange interaction within the dinuclear complex moieties through the π-pathway of the resorcinol bridge without significant magnetic exchange interactions between adjacent building blocks of the coordination polymer chains.

4. Conclusions

Three polymeric copper(II) complexes were synthesized with two novel double Schiff-base ligands providing two equal [ONO] binding pockets. The dinuclear building blocks, in which the copper ions are linked through a resorcinol bridge, possess additional ω-hydroxyalkyl groups. With pyrazole or imidazole as co-ligands at the copper(II) ions 1D cationic chains are formed, which are linked through an apical coordination of the hydroxyl groups of adjacent building blocks at the copper centers. Depending on the length of the ligand side chains the dinuclear building blocks are assembled to coordination chains of different topology. Due to their cationic nature, the resulting infinite 1D coordination chains are cross-linked by hydrogen bonding interaction with their perchlorate counterions. For **3** additional π–π interactions lead to a stacking of the building block units. The complexes are the first examples exhibiting these types of polymeric 1D topologies. Further studies regarding supramolecular network structures with ligands providing other side chains are under investigation. Temperature-dependent magnetic measurements show antiferromagnetic exchange interactions between the copper(II) centers within the dinuclear building blocks through the π-system of the central resorcinol moiety.

polymers are synthesized. The results of single-crystal X-ray diffraction reveal that $[Pr(mal)(OH)(bipy)\cdot 2H_2O]_n$ (**1**) is a 1-D helical chain with seven-coordinated Pr centers, which is the first sample with a seven coordination number in light lanthanide ionic complexes with carboxylic acids. $\{[Dy^1(SBA)_3(H_2O)_2][Dy^2(SBA)_3(H_2O)_2]\cdot 4H_2O\}_n$ (**2**) forms a 1-D chain-like molecular structure containing two crystallographically unique dysprosium centers, the Dy^1 center is seven-coordinated while Dy^2 is eight-coordinated, which is the first example with a seven coordination number in lanthanide benzene–carboxylate complex systems. Both of $\{[Tb(OHnic)(Onic)(H_2O)_5\cdot(OHnicH)]\cdot H_2O\}_n$ (**3**) and $\{[Sm(OHnic)(Onic)(H_2O)_5\cdot(OHnicH)]\cdot H_2O\}_n$ (**4**) exhibit an interesting 1-D chain-like polymeric structure in which there exist three types of 6-OHnicH ligands, which is rare for lanthanide carboxylate complexes.

Moreover, the photophysical properties of these complexes were studied with ultraviolet absorption spectra, fluorescence excitation and emission spectra. Since hydrothermal products are usually stable and insoluble in common solvents arising from their polymeric structures, both complexes **1** and **2** may be potential candidates for photoactive materials. Especially, for all four complexes, their molecules contain modifiable functional groups such as hydroxyl and sulfo, so they may be used as precursors to synthesize luminescent lanthanide organic-inorganic hybrid materials [42–44].

2. Experimental

2.1. Preparation of complexes

$Ln(NO_3)_3\cdot 6H_2O$ (Ln = Pr, Sm, Tb, Dy) were prepared by dissolving their respective oxides in concentrated nitric acid followed by drying. Maleic acid, 4-sulfobenzoic acid, 6-hydroxynicotinic acid and 2,2′-bipyridine were purchased from Aldrich and were used without further purification. All the other reagents were commercially available and were used as received.

2.1.1. $[Pr(mal)(OH)(bipy)\cdot 2H_2O]_n$ (**1**)

$Pr(NO_3)_3\cdot 6H_2O$ (0.3 mmol), maleic acid (0.45 mmol) and 2,2′-bipyridine (0.3 mmol) were mixed in 15 mL deionized water, and the pH value of the resulting solution was adjusted to be about 6.5 with 0.2 M NaOH solution. After stirring for half an hour, the mixture was placed in a 25 mL Teflon-lined reactor and heated at 160 °C in an oven for 3 days and then slowly cooled to room temperature by air cooling, and well-shaped light colorless single crystals of complex **1** suitable for X-ray single crystal diffraction analysis were obtained. *Anal.* Calc. for $C_{28}H_{30}N_4O_{14}Pr_2$ (928.38): C, 36.19; H, 3.23; N, 6.03. Found: C, 36.01; H, 3.28; N, 5.98%. The IR spectrum exhibits a pattern of bands in the range 4000–400 cm^{-1}: 1423 cm^{-1} ($\nu_s(COO^-)$), 1562 cm^{-1} ($\nu_{as}(COO^-)$).

2.1.2. $\{[Dy^1(SBA)_3(H_2O)_2][Dy^2(SBA)_3(H_2O)_2]\cdot 4H_2O\}_n$ (**2**)

$Dy(NO_3)_3\cdot 6H_2O$ (0.3 mmol) and 4-sulfobenzoic acid (0.9 mmol) were mixed in 15 mL deionized water, and the pH value of the resulting solution was adjusted to be about 6.5 with 0.2 M NaOH solution. After stirring for half an hour, the mixture was placed in a 25 mL Teflon-lined reactor and heated at 160 °C in an oven for 3 days and then slowly cooled to room temperature by air cooling, and well-shaped light colorless single crystals of complex **2** suitable for X-ray single crystal diffraction analysis were obtained. *Anal.* Calc. for $C_{42}H_{46}Dy_2O_{38}S_6$ (1116.15): C, 45.16; H, 4.12. Found: C, 44.96; H, 4.18%. The IR spectrum exhibits a pattern of bands in the range 4000–400 cm^{-1}: 1409 cm^{-1} ($\nu_s(COO^-)$), 1554 cm^{-1} ($\nu_{as}(COO^-)$).

2.1.3. $\{[Ln(OHnic)(Onic)(H_2O)_5\cdot(OHnicH)]\cdot H_2O\}_n$ [Ln = Tb (**3**), Sm (**4**)]

The corresponding lanthanide complexes with 6-OHnicH were prepared by homogeneous precipitation. A stoichiometric amount of lanthanide nitrate $Ln(NO_3)_3\cdot 6H_2O$ (0.5 mmol) and 6-OHnicH acid (1.5 mmol) were dissolved in deionized water and 95% C_2H_5OH, respectively. The pH value of the 6-OHnicH ethanol solution was adjusted to be about 6.5 with 0.2 M NaOH solution. Then the 6-OHnicH acid ethanol solution was added dropwise to the $Ln(NO_3)_3$ aqueous solution and the mixed solution was stirred for 4 h. The resulting solution was filtered and the filtrate was allowed to stand at room temperature. After three weeks, well-shaped light colorless single crystals suitable for analysis were obtained. Data of the Tb complex (**3**): *Anal.* Calc. for $C_{18}H_{24}N_3O_{15}Tb$ (678.30): C, 31.63; H, 3.51; N, 6.15. Found: C, 31.94; H, 3.39; N, 6.08%. The IR spectrum exhibits a pattern of bands in the range 4000–400 cm^{-1}: 1411 cm^{-1} ($\nu_s(COO^-)$), 1544 cm^{-1} ($\nu_{as}(COO^-)$). Data of the Sm complex (**4**): *Anal.* Calc. for $C_{18}H_{24}N_3O_{15}Sm$ (672.75): C, 32.11; H, 3.57; N, 6.24. Found: C 32.31; H, 3.52; N, 6.18%. The IR spectrum exhibits a pattern of bands in the range 4000–400 cm^{-1}: 1411 cm^{-1} ($\nu_s(COO^-)$), 1544 cm^{-1} ($\nu_{as}(COO^-)$).

2.2. Measurements and apparatus

Elemental analyses (C, H, N) were determined with an Elementar Cario EL elemental analyzer. IR spectra were recorded with a Nicolet Nexus 912 AO446 spectrophotometer (KBr pellet), in the 4000–400 cm^{-1} region. Ultraviolet absorption spectra were measured using an Agilent 8453 spectrophotometer. The luminescence (excitation and emission) spectra for the solid complex samples at room temperature and low temperature (77 K) were determined with a Perkin–Elmer LS-55 spectrophotometer, the whole excitation and emission slit widths were 10 and 5 nm, respectively. The phosphorescence spectrum was determined with a Perkin–Elmer LS-55 spectrophotometer.

2.3. Measurement of emission efficiencies

The relative emission quantum efficiencies were calculated according to the previous works by Shinkai and coworkers [45,46]. Using rhodamine B as the standard sample, the calculation equation can be described as $\Phi = \Phi_S \cdot (n^2 \cdot A_S \cdot I / n_S^2 \cdot A \cdot I_S)$, in which I and I_S are absorbency for sample materials and standards, A and A_S are integrated areas under the curves of the lanthanide ions strongest emission lines ($^4F_{9/2} \rightarrow {}^6H_{15/2}$ transition for Dy^{3+} ions, $^5D_4 \rightarrow {}^7F_5$ transition for Tb^{3+} ions and $^4G_{5/2} \rightarrow {}^6H_{7/2}$ transition for Sm^{3+} ions) with regard to sample materials and standards, respectively. In addition, n and n_S are the refractive index of the sample materials and standards. Since the solution concentration is very low (10^{-4} mol dm^{-3}), the refractive index of the solution can be regarded as that of the solvent. At room temperature, the refractive index of ethanol is 1.361. Through the above equation, the relative emission quantum efficiencies of complexes **2**, **3** and **4** were calculated.

2.4. Crystal structure determination

X-ray single crystal diffraction data for complexes **1**–**4** were performed with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The reflections were collected with a Bruker SMART APEX detector. The structures were solved by direct methods. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares methods. The hydrogen atoms were added geometrically and were not refined. All calculations were performed using SHELXS-97 and SHELXL-97 [47,48]. A summary of the crystallographic data and refinement parameters are given in Table 1.

Notes: The packing unit cell diagram for complex **2**, the 1-D chain drawing for complexes **3** and **4**, the absorption and excitation spectra of complexes **3** and **4** and the phosphorescence spectra of the ligands can be seen in Supplementary material.

3. Results and discussion

3.1. Crystal structure of $[Pr(mal)(OH)(bipy)\cdot 2H_2O]_n$ (1)

The complex $[Pr(mal)(OH)(bipy)\cdot 2H_2O]_n$ (**1**) crystallizes in the monoclinic system, with the space group $P2_1/c$. X-ray crystallographic analysis shows that it exhibits a one-dimensional helical chain structure. Fig. 1 shows the structural unit of complex **1**, which contains one praseodymium center, one mal ligand, one OH ligand and one chelating bipy ligand. Each praseodymium center is seven-coordinated by five oxygen atoms and two nitrogen atoms, and the coordination geometry of the praseodymium center can be described as a monocapped octahedral. Among the above-mentioned five oxygen atoms, four

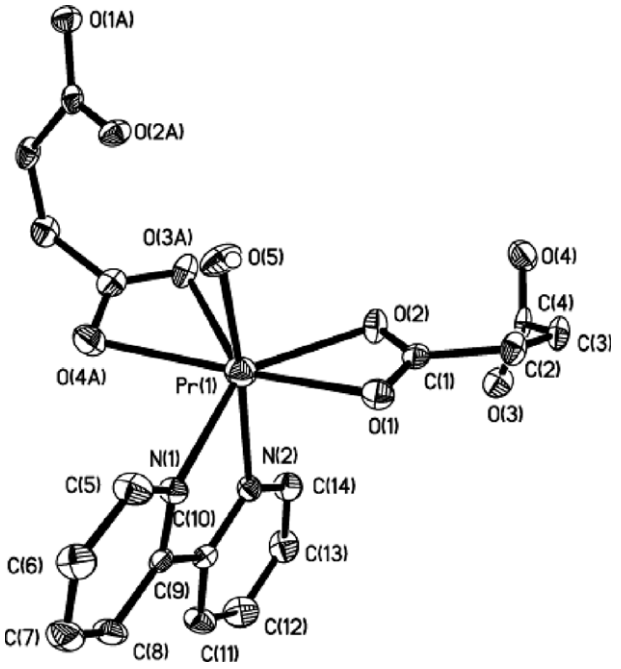

Fig. 1. The ORTEP drawing for complex **1** with the atom labelling scheme.

(O1, O2, O3, O4) are from two different mal ligands and the remaining one (O5) is from one-coordinated OH ligand. The average Pr–O bond distance is 2.336 Å. In addition, the two nitrogen atoms (N1, N2) are from one chelating bipy ligand. Selected bond lengths and angles for complexes **1** and **2** are listed in Table 2, and for complexes **3** and **4** in Table 3.

The important feature of complex **1** is that the coordination number of the praseodymium centers is seven. As is well known, lanthanide ions have high coordination numbers (>6). Especially, the light lanthanide ions (La–Gd) have larger ionic radii than the heavy lanthanide ions (Tb–Lu) due to the lanthanide contraction phenomenon, so the coordination numbers of light lanthanide ions are usually bigger than those of heavy lanthanide ions. For lanthanide aromatic carboxylate complexes, coordination number 8 and 9 are typical, and the number 7 has only been found once previously, in the heavy lanthanide ion complex $[Er(OHCH_2COO)(OCH_2COO)(H_2O)]_n$ [49]. Complex **1** therefore is the first example with a seven coordination number in light lanthanide ionic complexes with carboxylic acids.

In the structure of complex **1**, all the mal anions are deprotonated completely, and they act as tetradentate-bridging ligands towards the seven-coordinated praseodymium centers. For one mal anion, four oxygen atoms from two different carboxyls are coordinated to two praseodymium centers, and the praseodymium centers are connected by mal anions to form a 1-D helical polymeric chain along the *b* axis with a Pr···Pr distance of 5.8661 Å, as shown in Fig. 2. In addition, the bipy planes are on two sides of the zigzag chain alternately and parallel to each other.

Symmetry transformations used to generate equivalent atoms: (a) $-x$, $y+1$, z; (b) x, $y-1$, z.

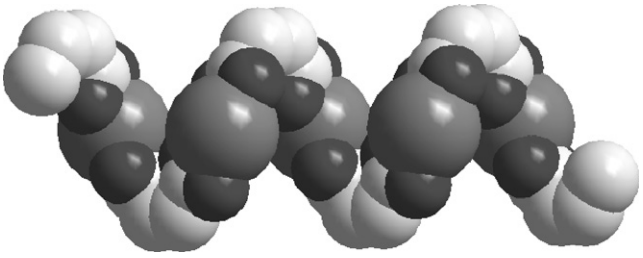

Fig. 2. The 1-D helical chain drawing for complex **1**. For clarity, phen and water molecules are deleted.

range indicating aromatic π–π stacking interactions. The offset angle of the π–π stacking interactions is 33.56°. The interchain hydrogen bonds and π–π stacking interactions are in a novel alternate fashion, and consolidate the stacked arrangement leading to a 3-D supramolecular architecture.

3.2. Crystal structure of $\{[Dy^1(SBA)_3(H_2O)_2]$-$[Dy^2(SBA)_3(H_2O)_2]\cdot 4H_2O\}_n$ (**2**)

The complex $\{[Dy^1(SBA)_3(H_2O)_2][Dy^2(SBA)_3(H_2O)_2]\cdot 4H_2O\}_n$ (**2**) crystallizes in the triclinic system, with the space group $P\bar{1}$. X-ray crystallographic analysis shows that it exhibits a 1-D chain-like structure. As shown in Fig. 4, there are two crystallographically unique dysprosium centers in the crystal structure. The Dy^1 center is seven-coordinated, completed by seven oxygen atoms from five SBA anions and two-coordinated water molecules, and the coordination geometry of the Dy^1 center can be described as a distorted monocapped trigonal prism. Among the above-mentioned seven oxygen atoms, four (O6, O7, O13, O18) are from four bridging SBA ligands, another one (O1) is from a chelating SBA ligand and the remaining two (O11, O12) are from two-coordinated water molecules. The average Dy^1–O bond distance is 2.225 Å. The Dy^2 center is eight-coordinated completely by eight oxygen atoms from five SBA anions and two-coordinated water molecules, the coordination geometry of Dy^2 can be described as a distorted square antiprism. Among the above-mentioned eight oxygen atoms, four (O14, O19, O23, O24) are from four bridging SBA ligands, two (O28, O29) are from a chelating SBA ligand and the remaining two (O33, O34) are from two-coordinated water molecules. The average Dy^2–O bond distance is 2.366 Å. All the Dy^2–O bond distances are much longer than the corresponding Dy^1–O distances.

All the SBA molecules are protonated and take part in the coordination to the dysprosium centers. There are three coordination modes of SBA in the structure: (a) the SBA anion acts as a monodentate ligand towards the Dy^1 center, which causes the coordination number of Dy^1 to be 7, and this coordination mode of carboxyl is seldom seen in the structures of lanthanide aromatic complexes; (b) the SBA anion acts as a bidentate chelating ligand towards the Dy^2 center; (c) the SBA anion acts as a bidentate bridging ligand towards the Dy^1 and Dy^2 centers. Two different typical dysprosium centers are connected by the bridging SBA ligands to form a dimeric fundamental unit with a $Dy^1\cdots Dy^2$ distance of 5.2604(17) Å; then the dimeric units are linked by SBA(c) linking two Dy^1 and Dy^2 centers of neighboring units with a $Dy^1\cdots Dy^1$ distance of 4.4639(14) Å and a $Dy^2\cdots Dy^2$ distance of 4.9355(16) Å; the chains are further linked by interchain hydrogen bonds with both the lattice water molecules and coordinated water molecules as donors and both oxygen atoms of the sulfo group and oxygen atoms of the carboxylate group as acceptors.

To the best of our knowledge, only two lanthanide 4-sulfobenzoic acid complexes $[Ln_2(1,4\text{-BDS})(SBA)_2\cdot 3H_2O]_n$ (Ln = Eu or Gd, 1,4-BDS = benzene-1,4-disulfonic acid) have been reported, and both of them are 3-D networks [50]. In the structures of the two complexes, the sulfonate and carboxyl groups are coordinated to lanthanide centers together, and the coordination number of the lanthanide centers is 9. For complex **2**, only carboxyl groups are coordinated to the lanthanide centers while the sulfonate groups are idle, indicating that the carboxyl groups have a stronger tendency to coordinate to the lanthanide ions than the sulfonate groups in aqueous solution. In addition, the coordination number of the Dy^1 center is seven causing complex **2** to be the first example with a seven coordination number in lanthanide benzene–carboxylate complex systems.

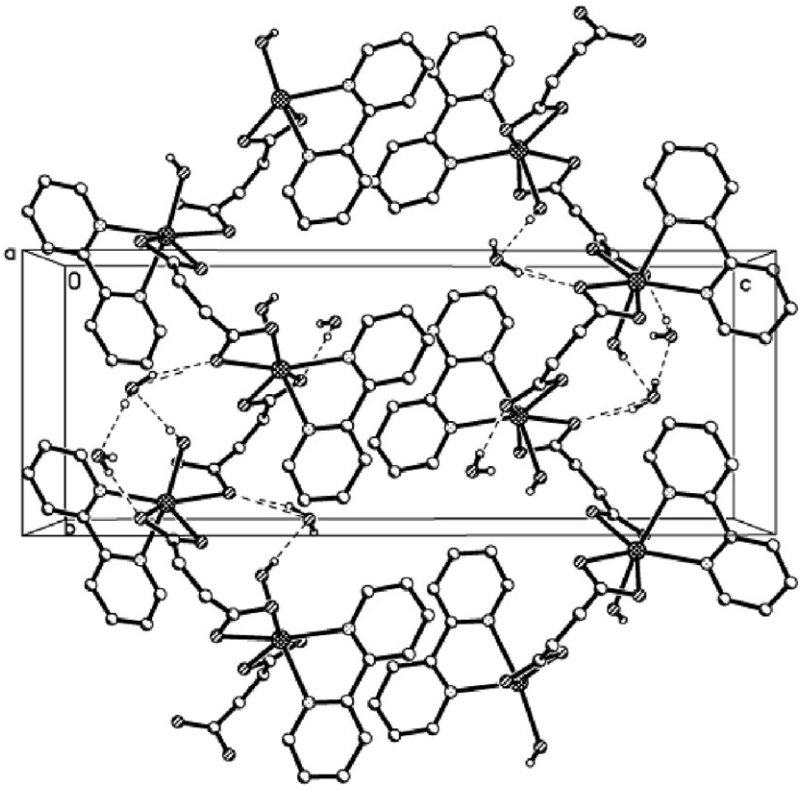

Fig. 3. The packing unit cell diagram for complex **1**.

3.3. Crystal structure of $\{[Ln(OHnic)(Onic)(H_2O)_5 \cdot (OHnicH)] \cdot H_2O\}_n$ [Ln = Tb (3), Sm (4)]

The isomorphous complexes $\{[Tb(OHnic)(Onic)(H_2O)_5 \cdot (OHnicH)] \cdot H_2O\}_n$ (**3**) and $\{[Sm(OHnic)(Onic)(H_2O)_5 \cdot (OHnicH)] \cdot H_2O\}_n$ (**4**) crystallize in the triclinic space group $P\bar{1}$. Fig. 5 shows the crystal structure of complex **3**, whose asymmetric unit contains one terbium center, three 6-OHnic ions, five-coordinated water molecules and one lattice water molecule. Each terbium center is nine-coordinated completely by nine oxygen atoms, and the coordination geometry of terbium center can be described as a distorted monocapped square antiprism. Among the above-mentioned nine atoms, four (O1, O4, O5, O6) are from one bridged $Onic^{2-}$ anion and one monodentate $OHnic^{-}$ anion with a $Tb–O_{hydroxyl}6$ distance of 2.361(3) Å; and the other five are from five-coordinated water molecules with bond distances of 2.394(3)–2.503(3) Å between the terbium center and the oxygen atoms. The average Tb–O distance is 2.433 Å. For complex **4**, the bond distance between the samarium center and the hydroxyl oxygen atom is 2.390(5) Å (Sm–O6) and the average Sm–O distance is 2.474 Å. All the Sm–O bonds are longer than the Tb–O bonds, and the reason for that is the radius of the Sm ion is greater than the Tb ion.

An important feature of complexes **3** and **4**, which does not occur in other lanthanide carboxylate structures to our best knowledge, is that there exist three types of 6-OHnicH ligands in this polymeric structure: (1) the $Onic^{2-}$ anion acts as tridentate-bridging tridentate ligand towards two terbium centers, the Tb centers are connected into a chain-like structure by this coordination mode with the hydroxyl oxygen atoms connecting the terbium center of a neighboring unit; (2) the $OHnic^{-}$ anion acts as a monodentate ligand towards the terbium center; and (3) very interestingly, one neutral OHnicH molecule is not coordinated to a terbium center, but it exists in the structure mostly depending on hydrogen bonding and intermolecular bonding. In the structure of complex **4**, the 6-OHnicH ligands show the same coordination modes.

It is desirable to mention that the $Ln–O_{hydroxyl}$ distances are 2.361(3) Å (Tb-complex) and 2.390(5) Å (Sm-complex), indicating that the hydroxyl groups of the bridging ligands are protonated. Numerous examples of lanthanide–calixarene structures point in this direction, showing phenolate-lanthanide distances of 2.3–2.4 Å [51–55] while protonated phenols are at least 0.2 Å longer [56,57], so it can be determined that the bridging ligand is dianionic and the uncoordinated ligand is neutral. This can be easily understood as the coordination of the carboxylate moiety of the bridging ligand may lead to electron withdrawing effects that decrease the pK of the hydroxyl function, allowing its deprotonation.

Previously, Burns and Baldwin have discussed the structure of $Sm(o\text{-}HOC_6H_4COO)_3 \cdot H_2O$ [56], in which the carboxyl oxygen atoms and the hydroxyl oxygen atoms are coordinated to samarium centers together, and samarium centers are connected to a 1-D chain structure depending on the carboxyl groups linking up the central metal ions completely. In addition, Ni and co-workers have discussed the structures of $Ce(o\text{-}HOC_6H_4COO)_3 \cdot H_2O$ and $Tb(o\text{-}HOC_6H_4COO)_3 \cdot 4H_2O$ [57]. The complex $Ce(o\text{-}HOC_6H_4COO)_3 \cdot H_2O$ shows a similar structure to $Sm(o\text{-}HOC_6H_4COO)_3 \cdot H_2O$, however, in the structure of the Tb complex only carboxyl oxygen atoms are coordinated to Tb ions. These show that the hydroxyl oxygen atom of *o*-hydroxybenzoic acid is coordinated to the central metal ions in the light-lanthanide complexes but not in the heavy-lanthanide complexes. In contrast to *o*-hydroxybenzoic acid, the 6-OHnicH ligand shows some new coordination behaviors: the hydroxyl oxygen atom is coordinated to both light- and heavy-lanthanide ions; especially, lanthanide

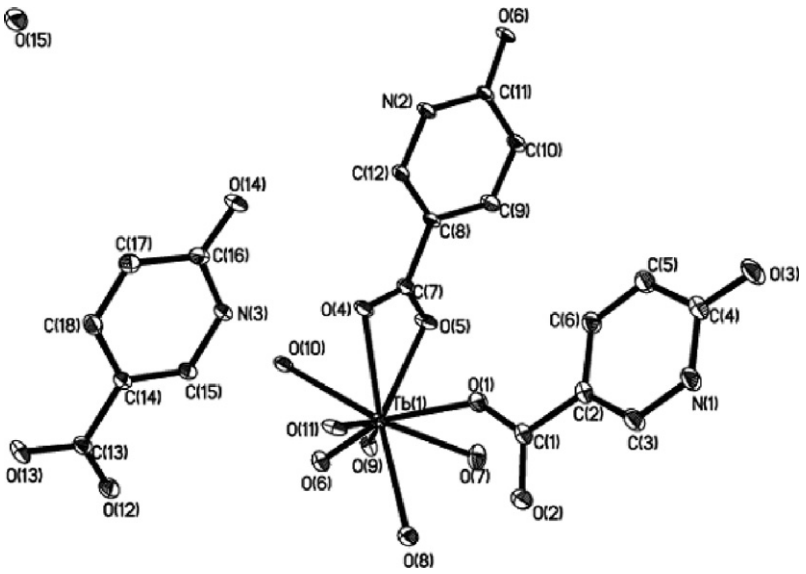

Fig. 5. The ORTEP drawing for complex **3** with the atom labelling scheme, complex **4** shows a very similar structure.

ions are connected into a chain-like structure depending on the hydroxyl oxygen atoms linking up the central metal ion of a neighboring unit.

Fig. 6 shows the packing view of a unit cell for complex **3**, comprising of an infinite chain in which the molecules in the crystal are held together by a system of hydrogen bonding. There exist six types of O–H···O intermolecular hydrogen bonds in the structure of complex **3**: one is the O–H···O intermolecular hydrogen bonding between the oxygen atoms of the lattice water molecules and the hydroxyl oxygen atoms of the monodentate OHnic ions (O(15)–H(15B)···O(3)[c]); the second is the O–H···O intermolecular hydrogen bonding between the oxygen atoms of the coordinated water molecules and the carboxyl oxygen atoms of the uncoordinated 6-OHnicH molecules (O(8)–H(8A)···O(13)[d], O(9)–H(9B)···O(13)[f], O(10)–H(10A)···O(12)[f] and O(11)–H(11B)···O(13)[d]); the third is the O–H···O intermolecular hydrogen bonding between the oxygen atoms of the coordinated water molecules and the hydroxyl oxygen atoms of the uncoordinated 6-OHnicH molecules (O(10)–H(10B)···O(14)[e] and O(11)–H(11A)···O(14)[g]); the fourth is the O–H···O intermolecular hydrogen bonding between the oxygen atoms of the coordinated water molecules and the carboxyl oxygen atoms of the monodentate OHnic ions (O(9)–H(9A)··· O(2)[i]); the fifth is the O–H···O intermolecular hydrogen bonding between the oxygen atoms of the lattice water molecules and the carboxyl oxygen atoms of the monodentate OHnic ions (O(15)–H(15A)···O(2)[g]); the last one is the O–H···O intermolecular hydrogen bonding between the oxygen atoms of the coordinated water molecules and the oxygen atoms of the lattice water molecules (O(7)–H(7A)···O(15)[e] and O(7)–H(7B)···O(15)[h]). In addition, there exists one type of O–H···O intramolecular hydrogen bond: the O–H···O intramolecular hydrogen bonding between the oxygen atoms of the coordinated water molecules and the carboxylic oxygen atoms of the monodentate OHnic ions (O(8)–H(8B)···O(1) and O(8)–H(8B)···O(2)). In the structure of complex **4**, the hydrogen bonds are analogous with these of complex **3**. The interchain hydrogen bonds are in a novel alternate fashion, and consolidate the stacked arrangement leading to a 3-D supramolecular architecture.

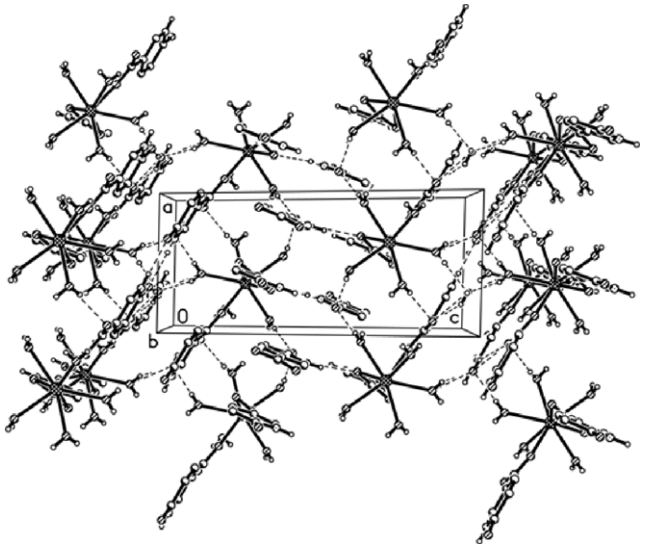

Fig. 6. The packing unit cell diagram for complex **3**, complex **4** shows a very similar unit cell.

3.4. Luminescent properties of complexes *2*, *3* and *4*

The ultraviolet absorption spectrum of $\{[Dy^1(SBA)_3(H_2O)_2][Dy^2(SBA)_3(H_2O)_2]\cdot 4H_2O\}_n$ (10^{-4} mol dm^{-3} ethanol solution) shows a domain absorption band at 212 nm (Fig. 7a), which is attributed to the characteristic absorption of the SBA ligand and the coordination interaction between lanthanide ions and SBA anions to form the more extensive $\pi \rightarrow \pi^*$ conjugated system. The excitation spectrum of complex **2** exhibits that the effective energy absorption (solid state samples) mainly takes place in the spectral range 200–440 nm, and the excitation bands consist of five main peaks at 208, 294, 351, 389 and 417 nm (Fig. 7b). The excitation band at 208 nm is attributed to the absorption of the SBA ligand, indicating that SBA is the energy donor for the luminescence of the Dy^{3+} ion. In addition, the excitation band at 351 nm is due to the own characteristic absorption of the Dy^{3+} ion, which is the direct absorption of the Dy^{3+} excited state. The facts indicate that besides the intramolecular energy transfer mechanism [58,59], there is also a directly excitation mechanism for the Dy^{3+} ions in complex **2**, as follows:

$$Dy^{3+} \xrightarrow{h\nu} Dy^{3+**}(^4F_{9/2}) \xrightarrow{\text{radiative}} {}^6H_J + h\nu' \quad (J = 15/2, 13/2)$$

The emission spectrum shows two apparent emission peaks on excitation at 208 nm: one is at 478 nm and the other is at 572 nm (Fig. 7c), which corresponds to the characteristic emission $^4F_{9/2} \rightarrow H_J$ ($J = 15/2$, 13/2) transition of the Dy^{3+} ion. It is worth pointing out that the blue emission intensity of the $^4F_{9/2} \rightarrow {}^6H_{15/2}$ transition is much stronger than the yellow emission of $^4F_{9/2} \rightarrow {}^6H_{13/2}$. As a result, the title complex exhibits an intense blue photoluminescence upon radiation of UV light in the solid state at room temperature. We further measured the low temperature luminescence spectrum of complex **1** at 77 K, and it still showed the two emissions of the dysprosium ion, at around 482 and 572 nm, the blue emission intensity is also much stronger than the yellow emission (Fig. 7d). The relative emission quantum efficiencies of complexes **2**, **3** and **4** were calculated according to the previous works by Shinkai and co-workers. For complex **2**, the quantum yield value is calculated to be 0.91%, which indicates a good luminescence performance of complex **2**.

The ultraviolet absorption spectra of $\{[Ln(OHnic)(Onic)(H_2O)_5\cdot(OHnicH)]\cdot H_2O\}_n$ (Ln = Tb, Sm) (10^{-4} mol dm^{-3} ethanol solution) exhibit domain absorption peaks in the narrow ultraviolet region in the range of 200–330 nm, and the maximum absorption peaks are located at around 253 and 300 nm, which can be attributed to the characteristic absorption of the 6-OHnicH ligand and

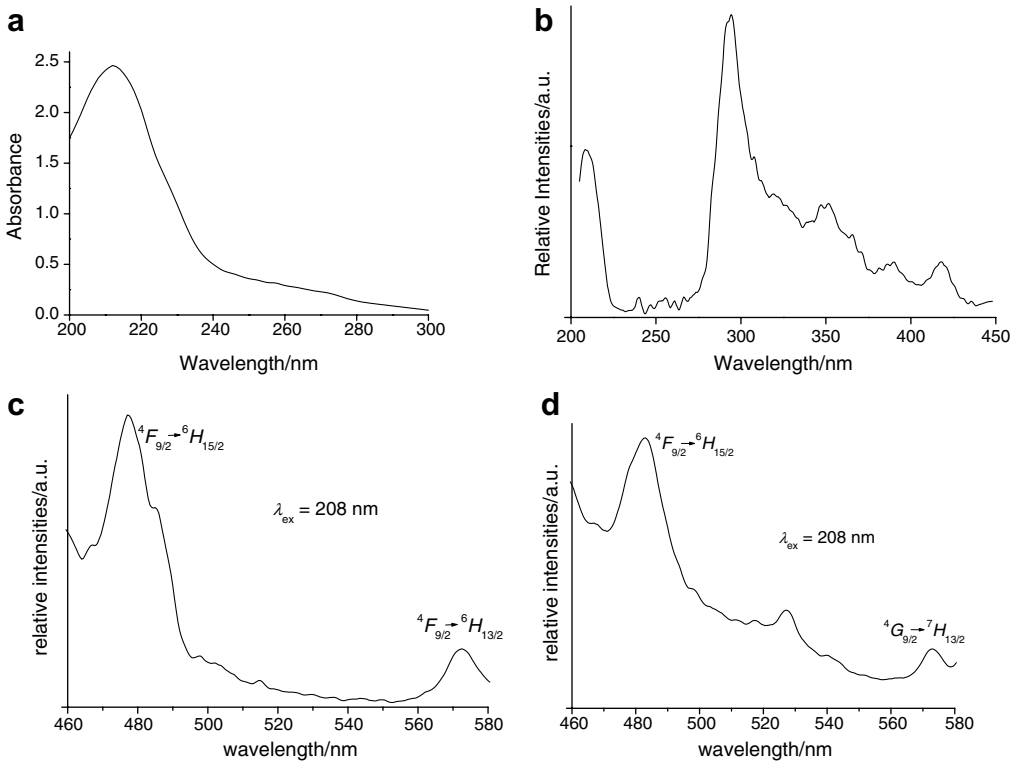

Fig. 7. The absorption, excitation and emission spectra of complex **2**.

the coordination interaction between lanthanide ions and 6-OHnicH anions to form a more extensive $\pi \rightarrow \pi^*$ conjugated system. The excitation spectra of complexes **3** and **4** (solid state samples) show that the effective energy absorption mainly takes place in the long ultraviolet region of 300–400 nm: the excitation bands for complex **3** under the green emission of 543 nm shows two main peaks: 351 nm and 371 nm; the excitation band for complex **4** under the orange emission of 600 nm shows five main peaks: 300 nm, 333 nm, 340 nm, 345 nm and 400 nm. The emission spectrum of complex **3** show two emission peaks on excitation at 371 nm: 488 nm and 543 nm, attributed to the characteristic emission $^5D_4 \rightarrow {}^7F_J$ ($J = 6$, 5) transition of the Tb^{3+} ion. The emission spectrum of complex **4** show two emission peaks on excitation at 400 nm: 560 nm and 594 nm, attributed to the characteristic emission $^4G_{5/2} \rightarrow {}^6H_J$ ($J = 5/2$, 7/2) transition of the Sm^{3+} ion. We further measured the low temperature luminescence spectra of complexes **3** and **4** at 77 K, and both of them show stronger emission luminescence than at room temperature (Figs. 8 and 9). It is worth pointing out that in the structure there are so many water molecules which can decrease the luminescence intensity of a rare earth complex, because the thermal vibration of the water molecules would consume partially the energy absorbed by the ligand; therefore, both complexes **3** and **4** exhibit weak luminescence. In addition, one 6-OHnic ligand is not coor-

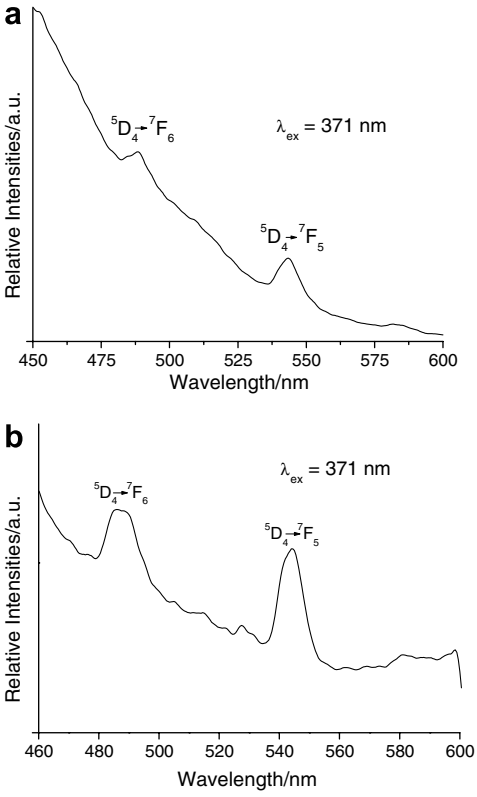

Fig. 8. Luminescence spectra of complex **3** ((a): room temperature; (b): low temperature).

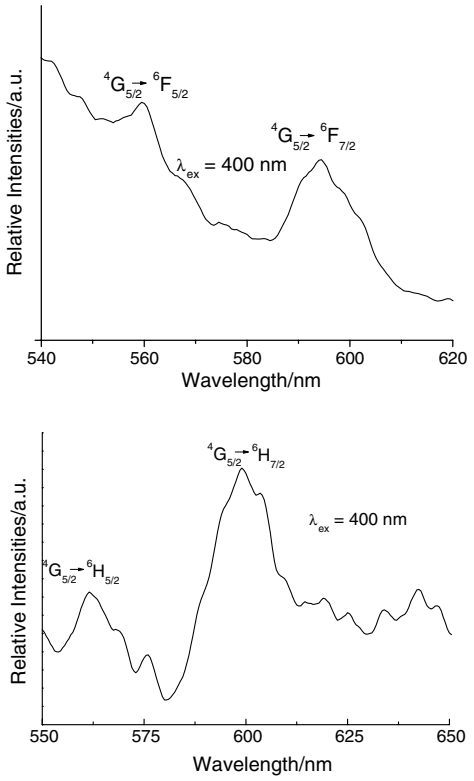

Fig. 9. Luminescence spectra of complex **4** ((a): room temperature; (b): low temperature).

dinated to the central lanthanide ion, and it cannot have a very efficient energy transfer to the central lanthanide metal. So the emission quantum yields for complexes **3** and **4** are not high, and are calculated to be 0.54% and 0.46%, respectively.

4. Conclusion

Four new lanthanide coordination polymers $[Pr(mal)(OH)(bipy)\cdot 2H_2O]_n$ (**1**), $\{[Dy^1(SBA)_3(H_2O)_2][Dy^2(SBA)_3(H_2O)_2]\cdot 4H_2O\}_n$ (**2**), $\{[Tb(OHnic)(Onic)(H_2O)_5\cdot(OHnicH)]\cdot H_2O\}_n$ (**3**) and $\{[Sm(OHnic)(Onic)(H_2O)_5\cdot(OHnicH)]\cdot H_2O\}_n$ (**4**) have been synthesized. Complex **1** is a 1-D helical chain with seven-coordinated praseodymium centers, which is the first example with a seven coordination number in light lanthanide ionic complexes with carboxylic acids. Complex **2** forms a 1-D chain-like molecular structure containing two crystallographically unique dysprosium centers, the Dy^1 center is seven-coordinated while Dy^2 is eight-coordinated, which is the first example with a seven coordination number in lanthanide benzene–carboxylate complex systems. The isomorphous complexes **3** and **4** exhibit an unprecedented 1-D chain-like polymeric structure, and there exist three types of 6-OHnicH ligands in the structural unit, which is rare for lanthanide carboxylate complexes. The photophysical properties of these complexes were studied with ultraviolet absorption spectra, fluorescence excitation and emission spectra.

Scheme 1.

of **11**. The lack of study on metal complexes of ligand **11** prompted us to undertake the synthesis and structural investigations of the zinc(II) complexes. Zn(II) is a diamagnetic ion and maintains the d^{10} electron configuration which minimizes intrinsic coordination geometry preferences whilst favoring coordination by ligands of intermediate basicity. In this paper, we describe the X-ray structural investigation on the metallation of **11** leading to the mononuclear zinc(II) complex (*N*-*o*-chlorobenzimido-*meso*-tetraphenylporphyrinato)(methanol)zinc(II) methanol solvate [Zn(*N*-NCO(*o*-Cl)C_6H_4-tpp)(MeOH) · MeOH; **12** · MeOH]. Tsurumaki et al. have reported the electronic structures of oxidized metalloporphyrin complexes by acid-induced cleaveage of Ni(II) complexes of tetraarylporphyrin *N*-oxides at −25 °C [6]. A similar kind of acid hydrolysis was reported by Latos-Grazynski and co-workers for the cleavage of the Ni–O bond in nickel-(II)-6,11,16,21-tetraphenyl-22-hydroxy-*m*-benziporphyrin (TPBPO)Ni^{II}, leading to (TPBPOH)$Ni^{II}Cl$, and for the cleavage of the Ni–C bond in nickel(II)-6,11,16,21-tetraphenyl-*m*-benziporphyrin, leading to chloronickel(II)-22-*H*-6,11,16,21-tetraphenyl-*m*-benziporphyrin [7,8]. We tried to apply acid-hydrolysis to Zn–N bond cleavage in **12** · MeOH. The Zn–N bond in **12** · MeOH is cleaved by addition of aqueous HCl (2%) to a CH_2Cl_2 solution of the complex leading to the desired complex chloro(*N*-*o*-chlorobenzamido-*meso*-tetraphenylporphyrinato)zinc(II) methylene chloride solvate [Zn(*N*-NHCO(*o*-Cl)C_6H_4-tpp)Cl · CH_2Cl_2; **13** · CH_2Cl_2]. Intramolecular hydrogen bonding between the *ortho* chlorine and (*o*-Cl)benzamido hydrogen might enhance the formation of complex **13**. Collectively, we describe the two-stage formation of **13** and the spectroscopic properties of complexes **12** and **13**.

2. Experimental

2.1. *N*-NHCO(*o*-Cl)C_6H_4-Htpp (**11**)

Compound **11** was prepared in 32% yield in the same way as described for *N*-NHCOC_6H_5-Htpp using 2-chlorobenzoyl azide [2]. Compound **11** was dissolved in CH_2Cl_2 and layered with MeOH to give a purple solid. ^{1}H NMR (559.95 MHz, $CDCl_3$, 20 °C) δ: 9.10 [d, 2H, H_β, ^3J(H–H) = 4.2 Hz]; 8.86 [d, 2H, H_β, ^3J(H–H) = 4.8 Hz]; 8.57 [s, 2H, H_β]; 8.15 [s, 2H, H_β]; 8.20 [d, 2H, *ortho* protons *o*-H, ^3J(H–H) = 6.0 Hz]; 8.10 [d, 2H, *o*-H, ^3J(H–H) = 6.6 Hz]; 7.76–7.85 (m, 12H, *meta* and *para* protons); 5.94 [t, 1H, (*o*-Cl)BA-Ph-H_4 (where (*o*-Cl)BA = the *o*-chlorobenzamido ligand), ^3J(H–H) = 7.5 Hz]; 5.70 [d, 1H, (*o*-Cl)BA-Ph-H_3, ^3J(H–H) = 7.8 Hz]; 5.34 [t, 1H, (*o*-Cl)BA-Ph-H_5, ^3J(H–H) = 7.5 Hz]; 2.13 [d, 1H, (*o*-Cl)BA-Ph-H_6, ^3J(H–H) = 7.8 Hz]; −0.26 [bs, 2H, NH]. *Anal.* Calc. for $C_{51}H_{34}ClN_5O$: C, 79.73; H, 4.46; N, 9.12. Found: C, 79.29; H, 4.29; N, 9.05%. MS(FAB): $(M)^+$ 768 (calc. for $C_{51}H_{34}ClN_5O$: 768). UV–Vis spectrum, λ (nm) [$\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})] in CH_2Cl_2: 429 (213.9), 540 (10.8), 579 (9.7), 637 (7.4). IR (KBr) cm^{-1}: 3052 [ν(CH)], 1624 (amide I band), 1548 (amide II band), 1307 (amide III band), 1594 and 1462 (phenyl ring), 1439 [ν(CN)], 754 [ν(CCl)].

2.2. Zn(*N*-NCO(*o*-Cl)C_6H_4-tpp)(MeOH) · MeOH (**12** · MeOH)

Compound **12** was prepared in 75% yield in the same way as described for Zn(*N*-NCOC_6H_5-tpp)(MeOH) · MeOH using *N*-NHCO(*o*-Cl)C_6H_4-Htpp [2], with a reaction temperature of 30 °C and a reaction time of 30 min.

Compound **12** was dissolved in CH_2Cl_2 and layered with MeOH to obtain purple crystals for single-crystal X-ray analysis. ^{1}H NMR (559.95 MHz, $CDCl_3$, 20 °C) δ: 9.12 [d, 2H, H_β(2,13), ^3J(H–H) = 4.2 Hz]; 8.88 [d, 2H, H_β(3,12), ^3J(H–H) = 4.2 Hz]; 8.78 [s, 2H, H_β(7,8)]; 7.76 [s, 2H, H_β(17,18)]; 8.36 [d, 2H, *ortho* protons *o*-H(26,28), ^3J(H–H) = 7.8 Hz]; 8.09 [d, 2H, *o*-H(22,32), ^3J(H–H) = 6.6 Hz]; 8.84 [bs, 2H, *ortho* protons *o′*-H(38,40)]; 8.21 [bs, 2H, *o′*-H(34,44)]; 7.72–7.87 (m, 12H, *meta* and *para* protons); 6.10 [t, 1H, (*o*-Cl)BA-Ph-H_4, ^3J(H–H) = 7.2 Hz]; 5.91 [d, 1H, (*o*-Cl)BA-Ph-H_3, ^3J(H–H) = 7.8 Hz]; 5.69 [t, 1H, (*o*-Cl)BA-Ph-H_5, ^3J(H–H) = 7.8 Hz]; 3.61 [d, 1H, (*o*-Cl)BA-Ph-H_6, ^3J(H–H) = 7.8 Hz]. *Anal.* Calc. for $C_{53}H_{40}ClN_5O_3Zn$: C, 71.06; H, 4.50; N, 7.82. Found: C, 71.03; H, 4.19; N, 7.47%. MS(FAB): $(M)^+$ 832 (calc. for $C_{51}H_{32}ClN_5OZn$: 832). 2.3. Zn(*N*-NHCO(*o*-Cl)C_6H_4-tpp)Cl · CH_2Cl_2 (**13** · CH_2Cl_2)

Compound **12** (0.06 g, 0.069 mmol) in CH_2Cl_2 (50 ml) was extracted with 2% HCl (50 ml). After the CH_2Cl_2 layer was concentrated to dryness, the residue was redissolved in a minimum of CH_2Cl_2. Removal of the solvent and recrystallization from CH_2Cl_2–CH_3CN [1:1 (v/v)] gave the blue solid **13** (0.059 g, 0.062 mmol, 90%). Compound **13** was dissolved in CH_2Cl_2 and layered with CH_3CN to obtain blue crystals for single-crystal X-ray analysis. ^{1}H NMR (559.95 MHz, $CDCl_3$, 20 °C) δ: 9.03 [d, 2H, H_β(2,13), ^3J(H–H) = 4.8 Hz]; 8.89 [s, 2H, H_β(7, 8)]; 8.89 [d, 2H, H_β(3,12), ^3J(H–H) = 4.2 Hz]; 8.38 [s, 2H, H_β(17,18)]; 8.34 [s, 2H, *ortho* protons *o*-H(26,28)]; 8.12 [s, 2H, *o*-H(22,32)]; 8.77 [s, 2H, *o′*-H(38,40)]; 8.42 [s, 2H, *o′*-H(34,44)]; 7.77–7.94 (m, 12H, *meta* and *para* protons); 6.45 [t, 1H, (*o*-Cl)BA-Ph-H_4, ^3J(H–H) = 7.2 Hz]; 6.23 [t, 1H, (*o*-Cl)BA-Ph-H_5, ^3J(H–H) = 7.8 Hz]; 6.13 [d, 1H, (*o*-Cl)BA-Ph-H_3, ^3J(H–H) = 8.4 Hz]; 5.29 [d, 1H, (*o*-Cl)-BA-Ph-H_6, ^3J(H–H) = 8.1 Hz]; −0.56 [s, 1H, NH]. *Anal.* Calc. for $C_{51}H_{33}Cl_2N_5OZn$: C, 70.56; H, 3.83; N, 8.07. Found: C, 69.99; H, 3.28; N, 8.09%. MS(FAB): $(M - H)^+$ 867 (calc. for $C_{51}H_{33}Cl_2N_5OZn$: 868). UV–Vis spectrum, λ (nm) [$\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})] in CH_2Cl_2: 440 (306.8), 455 (208.6), 617 (22.2). IR (KBr) cm^{-1}: 3350 [ν(NH)], 3053 [ν(CH)], 1690 (amide I band), 1574 (amide II band), 1274 (amide III band), 1596 and 1480 (phenyl ring), 1441 [ν(CN)], 751 [ν(CCl)].

2.4. Spectroscopy

^{1}H and ^{13}C NMR spectra were recorded at 599.95 and 150.87 MHz, respectively, on Varian Unity Inova-600 spectrometers locked on deuterated solvent, and referenced to the solvent peak. The ^{1}H NMR is relative to $CDCl_3$ at $\delta = 7.24$ and ^{13}C NMR to the center line of $CDCl_3$ at $\delta = 77.0$. HMQC (heteronuclear multiple quantum coherence) was used to correlate protons and carbon through one–bond coupling and HMBC (heteronuclear multiple bond coherence) for two- and three-bond proton–carbon coupling. Nuclear Overhauser effect (NOE) difference spectroscopy was employed to determine the ^{1}H–^{1}H proximity through space over a distance of up to about 4 Å.

The positive-ion fast atom bombardment mass spectrum (FAB MS) was obtained in a nitrobenzyl alcohol (NBA) matrix using a JEOL JMS-SX/SX 102A mass spectrometer. UV–Vis spectra were recorded at 20 °C on a HITACHI U-3210 spectrophotometer. IR spectra were measured at 20 °C in KBr discs on a Bomem, DA8.3 spectrometer. Elemental analyses were obtained using a Heraeus CHN-O-S-Rapid elemental analyzer.

2.5. X-ray crystallography

Table 1 presents the crystal data as well as other information for **12** · MeOH and **13** · CH_2Cl_2. Measurements were taken on a Bruker AXS SMART-1000 diffractometer using monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at a temperature of 100(2) K for **12** · MeOH and 297(2) K for **13** · CH_2Cl_2. Empirical absorption corrections were made for both complexes. The structures were solved by direct methods (SHELXL-97) [9] and refined by the full-matrix least-squares method. The (*o*-Cl)BA group within **12** · MeOH is disordered with an occupancy factor of 0.55 for Cl, C(46), C(47), C(48), C(49), C(50), C(51) and

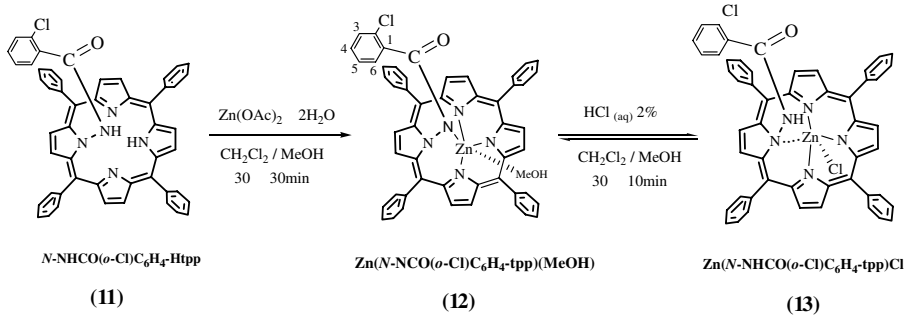
0.45 for Cl′, C(46′), C(47′), C(48′), C(49′), C(50′), C(51′). The phenyl group within **12** · MeOH is disordered with an occupancy factor of 0.5 for C(43), C(44) and 0.5 for C(43′), C(44′). O(1) within **12** · MeOH is disordered with an occupancy factor of 0.9 for O(1) and 0.1 for O(1′). All non–hydrogen atoms were refined with anisotropic thermal parameters, whereas all hydrogen atoms were placed in calculated positions and refined with a riding model. Table 2 lists selected bond distances and angles for complexes **12** · MeOH and **13** · CH_2Cl_2.

3. Results and discussion

3.1. Formation and characterization of *12*

Insertion of $Zn(OAc)_2$ into **11** in a methylene/methanol solution results in the formation of a five-coordinate diamagnetic complex **12** in 75% yield (Scheme 2).

3.2. Crystal structure of *12* · *MeOH*



The structure of **12** · MeOH, determined in an X-ray diffraction study, is shown in Fig. 1a. The geometry around Zn in **12** · MeOH is described as a distorted trigonal bipyramid with N(2), N(5) and O(2) lying in the equatorial plane. The Zn–O(2) bond distance is 2.107(2) Å and the mean Zn-4N distance is 2.024(3) Å for **12** · MeOH. The Zn–O(2) (MeOH) distance of 2.107(2) Å is slightly longer than the sum of the covalent radii of Zn and O (1.92 Å) but is significantly shorter than the sum of the van der Waals radii of Zn and O (2.90 Å) [10]. This Zn–O(2) contact may be described as a weak covalent bond. The distortion in five-coordinate complexes can be quantified by the "degree of trigonality" which is defined as $\tau = (\beta - \alpha)/60$, where "$\beta$" is the largest and "$\alpha$" the second largest of the L_{basal}–M–L_{basal} angles [11]. In **12**, we find $\beta = 169.22(9)°$ [N(3)–Zn–N(1)] and $\alpha = 131.45(10)°$ [N(2)–Zn–N(5)] for **12** · MeOH (Table 2) and thus a τ value of 0.63 is obtained for **12** · MeOH. Hence, the geometry around Zn(II) in **12** · MeOH is best described as a distorted trigonal bipyramid. In **12** · MeOH (Fig. 1a), the observed H(3)···O(1) and O(3)···O(1) distances are 1.821(2) and 2.609(2) Å (Table 2), respectively, which fall below those values expected from van der Waals distances (2.60 and 2.80 Å, respectively). The O(3)–H(3)–O(1) angle is 173.65(9)°, and its deviation from linearity is small. Therefore, this intermolecular hydrogen bonding causes an increased polarization of the carbonyl bond in **12** · MeOH. Consequently, the carbonyl carbon C(45) in **12** · MeOH becomes more positive, thereby accounting for its NMR downfield shift of 2.8 ppm observed at 20 °C, i.e. from 161.5 ppm for C(45) in **13** to 164.3 ppm for the same carbonyl carbon in **12** · MeOH (Tables S1 and S2).

3.3. Formation and characterization of *13*

When a solution of **12** in CH_2Cl_2 is treated with aqueous hydrogen chloride (2%), a new species is formed that can be formulated as **13** (Scheme 2). The reaction is reversed by heating the products in CH_2Cl_2/MeOH at 30 °C for 10 min (Scheme 2).

3.4. Crystal structure of *13* · CH_2Cl_2

The structure of **13** · CH_2Cl_2, determined by an X-ray diffraction study, is shown in Fig. 1b. The (*o*-Cl)BA group lies on the side opposite to the chloride Cl(1) in **13** · CH_2Cl_2. The coordination bond lengths Zn–N(1) 2.131(2) Å, Zn–N(2) 2.007(2) Å, Zn–N(3) 2.138(2) Å and Zn–Cl(1) 2.090(9) Å are within the limit found for zinc(II) porphyrins. The (*o*-Cl)BA nitrogen N(5) in **13** · CH_2Cl_2 is no longer bonded to zinc as indicated by its longer internuclear distance, 2.935(2) Å for Zn···N(5). Moreover, the Zn···N(4) distance of 2.557(2) Å for **13** · CH_2Cl_2 is longer than 2.138(2) Å for Zn–N(3) but is significantly shorter than the sum of the van der Waals radii of Zn and N (2.95 Å) [10]. This longer Zn···N(4) contact in **13** · CH_2Cl_2 may be viewed as a secondary intramolecular interaction. This kind of secondary interaction was earlier observed for Zn(*N*-Me-tpp)Cl with Zn···N1 = 2.530(7) Å [12,13]. Most chemists seem to consider this secondary interaction between the metal ion and the fourth N as a weak bond in *N*-substituted porphyrin metal complexes. In the present case, we find $\beta = 138.30(9)°$ [N(2)–Zn–N(4)] and $\alpha = 136.98(9)°$ [N(1)–Zn–N(3)] for **13** · CH_2Cl_2 and thus a τ value of 0.02 is obtained for **13** · CH_2Cl_2. Hence, the

N-NHCO(*o*-Cl)C_6H_4-Htpp (**11**)

Zn(*N*-NCO(*o*-Cl)C_6H_4-tpp)(MeOH) (**12**)

Zn(*N*-NHCO(*o*-Cl)C_6H_4-tpp)Cl (**13**)

Scheme 2.

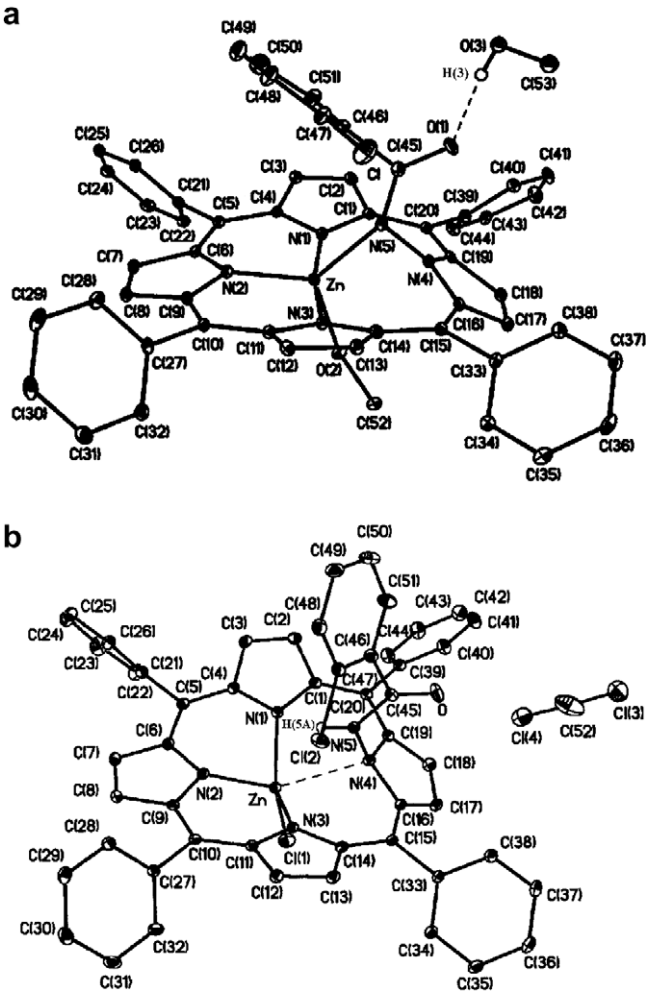


Fig. 1. Molecular configuration and atom-labelling scheme for (a) **12** · MeOH and (b) **13** · CH_2Cl_2, with ellipsoids drawn at 30% probability for both complexes. Hydrogen atoms except H(3) in **12** · MeOH and H(5A) in **13** · CH_2Cl_2 are omitted for clarity.

geometry around Zn(II) in **13** · CH_2Cl_2 is best described as a square-based pyramid with Cl(1) as the apical atom. The τ value of 0.02 obtained for **13** · CH_2Cl_2 is quite close to the value of 0.05 for Zn(*N*-Me-tpp)Cl [12,13]. Hence compounds **13** · CH_2Cl_2 and Zn(*N*-Me-tpp)Cl have a similar coordination geometry around the Zn^{2+} ion. We adopt the plane of three strongly bound pyrrole nitrogen atoms [i.e. N(1), N(2) and N(3)] as a reference plane 3N for **12** · MeOH and **13** · CH_2Cl_2. The zinc ion in **13** · CH_2Cl_2 (or **12** · MeOH) is displaced from the 3N plane by 0.75 Å (or 0.09 Å) toward the chloride [Cl(1)] [or O(2)(MeOH)] (Fig. S1). The occurrence of weak intramolecular hydrogen bonding between the (*o*-Cl)benzamido hydrogen [H(5A)] and the chlorine Cl(2) in **13** is reflected in the long N(5)–H(5A)···Cl(2) bond distance of 2.768(2) Å and acute N(5)–H(5A)···Cl(2) angle of 107.68(9)° (Table 2). This weak intramolecular hydrogen bonding might strengthen the formation of complex **13**.

3.5. ^1H NMR spectroscopy data of 12 and 13 in $CDCl_3$

In solution, the molecule has an effective C_s symmetry with a mirror plane running through the N(2)–Zn–N(5)–N(4) unit for **12** or the N(2)–Zn–N(4)–N(5) unit for **13**. As a result, the ^1H NMR spectra will exhibit four pyrrole resonances [H_β(7,8), H_β(17,18), H_β(3,12), H_β(2,13)] for these two complexes (Fig. 2). Non-equivalence of the two sides of the macrocycle will cause each phenyl ring to have two distinct *ortho* resonances with one set of *ortho* protons, *o*-H(22,32) and *o*-H(26,28), for phenyl C(24) and C(30) and the other set of *ortho* protons, *o′*-H(34,42) and *o′*-H(38,40), for phenyl C(36) and C(42), unless the rotation around the C_{meso}–C_1 [C(5)–C(21), C(10)–C(27) or C(15)–C(33), C(20)–C(39)] bond is sufficiently fast in these two complexes (Fig. 2).

The tautomerism exchange between the two NH protons of **11** in CD_2Cl_2 is fast on the ^1H NMR timescale at both 20 and −90 °C. Hence only one type of N–H proton signal was observed for **11** in CD_2Cl_2 at 20 and −90 °C. At −90 °C, traces of water were frozen from the solution of **11** and **13** in CD_2Cl_2. Thus, the frozen water inhibits intermolecular proton exchange between water and NH protons of **11** and **13**, and allows the observation of a broad singlet for the NH proton at $\delta = -0.51$ ppm ($\Delta\nu_{1/2} = 11.8$ Hz) for **11** and $\delta = -0.69$ ppm ($\Delta\nu_{1/2} = 9.1$ Hz) for **13** at −90 °C. In this case, the NH proton signal for **11** and **13** at −90 °C is broadened by the quadrupolar interaction of the ^{14}N nucleus. The signal arising from the NH proton of **11** in CD_2Cl_2 was observed as a broad singlet at $\delta = -0.29$ ppm ($\Delta\nu_{1/2} = 23$ Hz) at 20 °C. These NMR data suggest that the NH protons of **11** undergo intermediate intermolecular proton exchange with water at 20 °C.

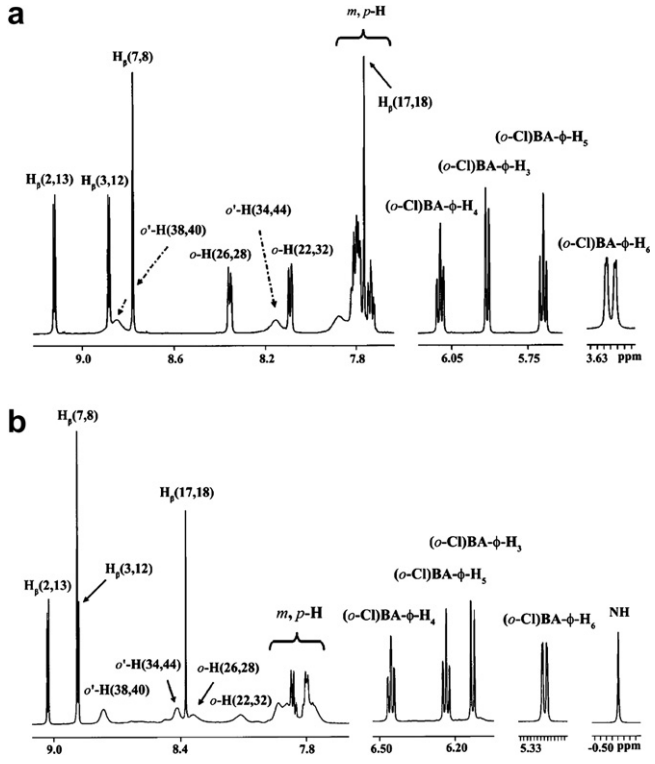

Fig. 2. The 599.95 MHz ^{1}H NMR spectra in $CDCl_3$ at 20 °C for (a) **12** and (b) **13**, where ϕ = Ph (phenyl group).

Moreover, the ^{1}H NMR spectrum of **13** in CD_2Cl_2 showed a sharp singlet at $\delta = -0.58$ ppm ($\Delta\nu_{1/2} = 2.1$ Hz) for the NH proton at 20 °C (see a similar spectrum shown in Fig. 2b). This sharp signal ($\Delta\nu_{1/2} = 2.1$ Hz) is not in agreement with that of $\Delta\nu_{1/2} = 9.1$ Hz found for **13** in the absence of any exchange. Hence, these NMR data for **13** indicate that the NH proton [i.e., H(5A)] bound to N(5) undergoes rapid intermolecular proton exchange with water at 20 °C. Due to the ring current effect, upfield shifts for the ^{1}H resonances of (*o*-Cl)BA-Ph-H_6, (*o*-Cl)BA-Ph-H_3, (*o*-Cl)BA-Ph-H_5 and (*o*-Cl)BA-Ph-H_4 for **13** in $CDCl_3$ at 20 °C are $\Delta\delta = -2.48$ [from 7.77 (obtained from *o*-chlorobenzamide) to 5.29 ppm], −1.29 (from 7.42 to 6.13 ppm), −1.12 (from 7.35 to 6.23 ppm) and −0.95 (from 7.40 to 6.45 ppm), respectively (Fig. 2b). As the distance between the geometrical center (C_t) of the 4N plane and axial protons gets smaller qualitatively, the shielding effect becomes larger [14]. In **13**, the distance for $C_t\cdots$(*o*-Cl)BA-Ph-H_6, $C_t\cdots$(*o*-Cl)BA-Ph-H_3, $C_t\cdots$(*o*-Cl)BA-Ph-H_5 and $C_t\cdots$(*o*-Cl)-BA-Ph-H_4, increases from 5.615, 6.119, 7.138 to 7.312 Å. As the (*o*-Cl)BA-Ph-H_6 proton of **13** is closer to C_t, the shielding gets larger for this (*o*-Cl)BA-Ph-H_6 proton. A similar ring current effect is also observed for **12**. The average distance between $C_t\cdots$(*o*-Cl)BA-Ph-H_6, $C_t\cdots$(*o*-Cl)-BA-Ph-H_5, $C_t\cdots$(*o*-Cl)BA-Ph-H_3 and $C_t\cdots$(*o*-Cl)BA-Ph-H_4 for **12** increases from 3.934, 5.438, 5.684 to 6.166 Å. The fact that all four distances between C_t and (*o*-Cl)BA-Ph protons in **12** are shorter than those distances in **13** indicates that the ring current effect of (*o*-Cl)BA protons in **12** would be larger and in turn the ^{1}H upfield shifts for those protons in the same compound would be still higher. This observation is corroborated by the doublet at 3.61 ppm for (*o*-Cl)BA-Ph-H_6 in **12** and the doublet at 5.29 ppm for the same Ph-H_6 proton in **13**, the triplet at 5.69 ppm for (*o*-Cl)BA-Ph-H_5 in **12** and the triplet at 6.23 ppm for the same Ph-H_5 proton in **13**, the doublet at 5.91 ppm for (*o*-Cl)BA-Ph-H_3 in **12** and the doublet at 6.13 ppm for the same Ph-H_3 proton in **13**, the triplet at 6.10 ppm for (*o*-Cl)BA-Ph-H_4 in **12** and the triplet at 6.45 ppm for the same Ph-H_4 proton in **13** (Fig. 2).

3.6. Solid state IR spectroscopy data of 11, 12 and 13

Compound **12** could be viewed as a tertiary amide and it displayed a unique amide I band at 1597 cm^{-1} in the IR spectrum in the solid state. The two interactions due to a strong intermolecular hydrogen bond between O(1) and H(3) and the covalent bond Zn–N(5) reduces the C=O stretching frequency by 53 cm^{-1} from 1650 cm^{-1} for tertiary amides to 1597 cm^{-1} for **12** [15]. The O–H stretching and methyl bending bands of MeOH in **12** occur near 3643 and 1384 cm^{-1}, respectively. Moreover, compounds **11** and **13** are classified as secondary amides with bands at 1624, 1548 and 1307 cm^{-1} (or 1690, 1574 and 1274 cm^{-1}) being assigned as amide I, II and III bands of **11** (or **13**). These data are quite close to those frequencies of 1680–1630, 1570–1515 and 1300 cm^{-1} reported for amide I, II and III bands of secondary amides [15,16]. The band at 3350 cm^{-1} results from the N(5)–H(5A) stretch of **13**.

4. Conclusion

Two distinct types of zinc complexes, hitherto unreported, have been obtained from *N*-*o*-chlorobenzamido-*meso*-tetraphenylporphyrin (*N*-NHCO(*o*-Cl)C_6H_4-Htpp; **11**). In Zn(*N*-NCO(*o*-Cl)C_6H_4-tpp)(MeOH) (**12**), the N–H bond of the *o*-chlorobenzamido ligand is cleaved and the *o*-chlorobenzamido nitrogen participates in bonding to the zinc ion. In Zn(*N*-NHCO(*o*-Cl)C_6H_4-tpp)Cl (**13**), the *o*-chlorobenzamido [(*o*-Cl)BA] substituent is left intact and the zinc(II) ion is coordinated to the three nitrogens of the macrocycle core. Compound **13** can be synthesized in the reaction of **12** with aqueous HCl (2%).

Scheme 1. Different neutral and anionic forms.

in the resulting complexes, which opens a multiplicity of bonding schemes. The different donor atoms as well as the various structures of thiourea derivatives result in a variety of complexes [3–5,7,18,20].

In recent years various studies have been reported on a derivative group of thiourea with antifungal activity [7], namely *N*-2-pyridine-*N*′-arylthioureas, showing different substitution patterns on either only one or on both rings [22–25]. These different chemical structures create specific properties for each compound, for example a methoxy-substituent can add to the intermolecular hydrogen bonding scheme [26]. In some cases, these intermolecular interactions can form centrosymmetric dimers [27].

In the current study we tried to synthesize derivatives of the *N*-2-pyridine-*N*′-arylthioureas group. The fact that the copper complexes of thiourea derivatives show an antioxidant effect in biological systems [28] encouraged us to produce copper complexes using our synthesized ligands.

Three new ligand types were prepared **L1**: *N*-2-(4-picolyl)-*N*′-(4-methoxyphenyl)thiourea (4PicTu4OMePh), **L2**: *N*-2-(6-picolyl)-*N*′-(4-methoxyphenyl)thiourea (6PicTu4OMePh) and **L3**: *N*-2-(4-picolyl)-*N*′-(4-nitrophenyl)thiourea (4PicTu4NO_2Ph) (Scheme 2).

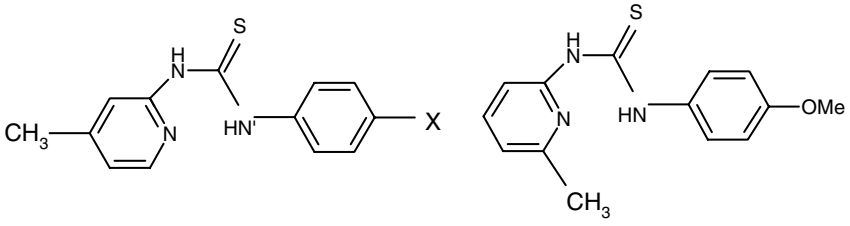
All these three ligands were reacted with copper(II) acetate. Coordination of ligand **L1** resulted in complex **C1**, [Cu(4PicTz4OMePh)(OAC)(EtOH)], which was obtained as suitable crystals for single crystal X-ray structure analysis.

Also, we report for the first time new compounds that were the product of an oxidation of some reported ligands by copper(II), for example compound **P1**, (PyHTz4OMePh), was isolated and characterized, and was the result of the reaction of the ligand **L4**, *N*-(2-pyridyl)-*N*′-(4-methoxyphenyl)thiourea, [29,30] with copper(II) as we tried to prepare complex **C2**.

2. Experimental

2.1. General procedure

4-Methyl and 6-methyl-2-aminopyridines, 4-methoxy and 4-nitrophenyl isothiocyanates were purchased from Aldrich. Copper(II) acetate monohydrate and solvents were supplied by Merck. All chemicals were used without further purification.



Melting points were determined with the Electro Thermal IA 9000 Series apparatus. FT-IR spectra were obtained with a Nicolet 5SXC spectrometer and using KBr (4000–400 cm^{-1}) pellets. ^1H and ^{13}C NMR spectra in DMSO-d_6 were recorded on a Bruker AVANCE 500 spectrometer at room temperature and with TMS as the internal reference. Elemental analyses for C, H and N were performed on an O-Rapid elemental analyzer.

2.2. Synthesis of the ligands, complexes and precursor

The new ligands, **L1** (4PicTu4OMePh), **L2** (6PicTu4OMePh) and **L3** (4PicTu4NO2Ph) were synthesized using modified protocols from the literature [29,31]. The already reported ligand **L4** (PyTu4OMePh) was prepared as described [29]. The crystals of ligands **L1** and **L2** for X-ray analysis were obtained from recrystallization of an ethanol solution. Percentage yields, melting point, elemental analyses and spectroscopic studies for the ligands **L1**, **L2** and **L3** are as follows.

2.2.1. Ligand *L1* (*4PicTu4OMePh*)

Yield: 0.22 g white powder (82%). Mp: 181–183 °C. FT-IR data (KBr, cm^{-1}): 3490w, 3195m, 3040m, 2920m, 1606s, 1581s, 1524s, 1471s, 1399m, 1346s, 1321s, 1242vs, 1176vs, 1117w, 1095w, 1026s, 824m, 734s, 645m, 603m. ^1H NMR (DMSO-d_6, ppm): 2.29 (s, 3H, H7A, 7B and 7C), 3.75 (s,3H, H19A, 19B and 19C), 6.92 (d, 2H, H14 and 16), 6.93 (d, 1H, H3), 7.05 (s, 1H, H5), 7.51 (d, 2H, H13 and 17), 8.15 (d, 1H, H6), 10.72 (s, 1H, NH), 13.66 (s, 1H, N′H). ^{13}C NMR (DMSO-d_6, ppm): 21.38 (CH_3), 55.74 (OCH_3), 113.12 (C3), 114.12 (C14 and 16), 119.83 (C5), 126.51 (C13 and 17), 132.21 (C12), 145.64 (C6), 150.63 (C4), 154.23 (C2), 157.43 (C15), 179.08 (C=S). *Anal.* Calc.

L1: X = OCH_3 (4PicTu4OMePh)

L3: X = NO_2 (4PicTu4NO_2Ph)

L2: (6PicTu4OMePh)

Scheme 2. Representation of *N*-2-(4-picolyl)-*N*′-(4-methoxyphenyl)thiourea (4PicTu4OMePh), *N*-2-(6-picolyl)-*N*′-(4-methoxyphenyl)thiourea (6PicTu4OMePh) and *N*-2-(4-picolyl)-*N*′-(4-nitrophenyl)thiourea (4PicTu4NO_2Ph).

for $C_{14}H_{15}N_3OS$: C, 58.60; H, 5.49; N, 15.38. Found: C, 58.72; H, 5.60; N, 15.41%. (The numbers have been clarified in Fig. 1.)

2.2.2. Ligand *L2* (*6PicTu4OMePh*)

Yield: 0.23 g white powder (85%). Mp: 189–190 °C. FT-IR data (KBr, cm^{-1}): 3585vw, 3223m, 3196m, 3030m, 2833w, 1608s, 1562s, 1535m, 1509m, 1451s, 1374m, 1341s, 1299m, 1242vs, 1181s, 1154s, 1111w, 104s, 833s, 795s, 728s, 648m, 624m. ^{1}H NMR (DMSO-d_6, ppm): 2.46 (s, 3H) (H7A, 7B and 7C), 3.75 (s,3H) (H19A, 19B and 19C), 6.94 (d, 3H) (H3, 14 and 16), 7.04 (d, 1H) (H5), 7.59 (d, 2H) (H13 and 17), 7.69 (t, 1H) (H4), 10.73 (s, 1H, NH), 13.92 (s, 1H, N′H). ^{13}C NMR (DMSO-d_6, ppm): 23.69 (CH_3), 55.78 (OCH_3), 110.17 (C3), 114.20 (C14 and 16), 117.63 (C5), 125.65 (C13 and C17), 132.29 (C12), 139.99 (C4), 153.65 (C2), 154.82 (C6), 157.27 (C15), 178.50 (C=S). *Anal.* Calc. for $C_{14}H_{15}N_3OS$: C, 58.60; H, 5.49; N, 15.38. Found: C, 58.48; H, 5.48; N, 15.49%. (The numbers have been clarified in Fig. 2.)

2.2.3. Ligand *L3* (*4PicTu4NO$_2$Ph*)

Yield: 0.18 g pale yellow (62.5%). Mp: 164 °C. FT-IR data (KBr, cm^{-1}): 3285m, 3070w, 2915s, 1592m, 1540s, 1496s, 1377w, 1328vs, 1200s, 1099m, 1031m, 857m, 741m, 676m, 650w. ^{1}H NMR (DMSO-d_6, ppm): 2.30 (s, 3H, H7A, B and C), 6.98 (d, 1H, H3), 7.07 (s, 1H, H5), 8.14 (d, 2H, H13 and 17), 8.21 (d, 2H, H14 and 16), 8.23 (d, 1H, H6), 11.08 (s, 1H, NH), 14.58 (s, 1H, N′H). ^{13}C NMR (DMSO-d_6, ppm): 21.40 (CH_3), 113.45 (C3), 120.40 (C5), 123.20 (C13 and 17), 124.70 (C14, C15 and 16), 143.89 (C12), 145.49 (C6), 151.13 (C4), 153.76 (C2), 178.49 (C=S). *Anal.* Calc. for $C_{13}H_{12}N_4O_2S$: C, 54.17; H, 4.17; N, 19.44. Found: C, 54.12; H, 4.23; N, 19.55%. (The numbers are similar with the numbers in Fig. 1.)

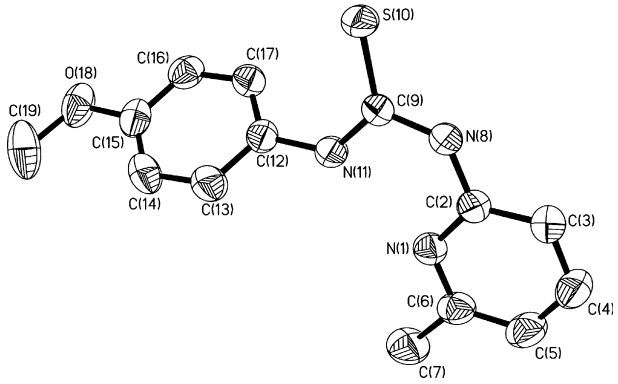

Fig. 2. Molecular structure of **L2** (H atoms are omitted for the clarity; 50% probability level).

2.2.4. Complex *C1*

Complex **C1** [Cu(4PicTz4OMePh)(OAC)(EtOH)] was synthesized from ligand **L1** and copper(II) acetate monohydrate. Copper(II) acetate monohydrate (0.1 g, 0.5 mmol) in 3 mL ethanol was added gradually to the solution of ligand **L1** (0.14 g, 0.5 mmol) in 35 mL ethanol, heated under reflux for 3 h and stirred for 15 h at room temperature. The reaction mixture was filtered off and a slight dark green powder was separated. Dark crystals of the filtrate were obtained after ten days at room temperature. It decomposed at 235 °C. Yield: 0.19 g dark green powder (87%). FT-IR data (KBr, cm^{-1}): 3525w, 2945w, 1616m, 1594m, 1525s, 1459s, 1330m, 1244s, 1159m, 1086w, 1061m, 1027m, 850m, 794m, 630m. *Anal.* Calc. for $C_{18}H_{21}CuN_3O_4S$: C, 49.20; H, 4.78; N, 9.5. Found: C, 48.80; H, 4.80; N, 8.80%.

2.2.5. Complex *C2*

Complex **C2** was synthesized from ligand **L2** and copper(II) acetate monohydrate, using the method as for complex **C1**. The reaction mixture was filtered off and a slight dark olive green powder was separated. It did not melt up to 380 °C. Yield: 0.18 g dark green powder (81%). FT-IR data (KBr, cm^{-1}): 3442w, 2995w, 15869, 1570m, 15462s, 1439s, 1329m, 1259m, 1228m, 1155w, 1047w, 850w, 780m, 680m. *Anal.* Calc. for $C_{16}H_{18}CuN_3O_4S$: C, 48.97; H, 4.59; N, 10.71. Found: C, 47.90; H, 4.30; N, 8.95%.

2.2.6. Complex *C3*

Complex **C3** was also synthesized from ligand **L3** and copper(II) acetate monohydrate, like complexes **C1** and **C2**. An olive green powder as the product was filtered and washed with ethanol and ether, dried in an oven at 80 °C. This compound decomposed at 260 °C. Yield: 0.19 g olive green powder (80%). FT-IR data (KBr, cm^{-1}): 3410vw, 2955w, 1579m, 1521s, 1495s, 1339s, 1290m, 1248s, 1181m, 1084m, 1030m, 841m, 543w. *Anal.* Calc. for $C_{17}H_{20}CuN_4O_5S$: C, 44.80; H, 4.20; N, 12.30. Found: C, 45.11; H, 4.11; N, 12.40%.

2.2.7. Complex *C4*

Complex **C4** was prepared using ligand **L4** and copper(II) acetate monohydrate. 3 mL of an ethanolic solution of copper(II) acetate monohydrate (0.10 g, 0.05 mmol) was added slowly to the ligand **L4** (0.26 g, 0.1 mmol) in 20 mL ethanol, and stirred for 4 h at room temperature. The resulting olive green powder was filtered and washed with

ethanol and ether, dried in an oven at 80 °C. This compound decomposed at 190 °C. Yield: 0.20 g olive green powder (70%). FT-IR data (KBr, cm^{-1}): 3460vw, 2965w, 1553s, 1525m, 1494s, 1443m, 1412s, 1342s, 1289w, 1239s, 1141m, 1024m, 819m, 773m, 722m, 612w. *Anal.* Calc. for $C_{26}H_{20}CuN_6O_2S_2$: C, 54.31; H, 3.50; N, 14.61. Found: C, 54.62; H, 3.27; N, 14.83%.

2.2.8. Precursor *P1* (*PyHTz4OMePh*)

Opaque crystals were obtained from the filtrate of complex **C2** by slow evaporation after three weeks at room temperature. 0.039 g. Mp: 184–186 °C. ^{1}H NMR (DMSO-d_6, ppm): 3.71 (s, 3H, H11A, B and C), 6.85 (s, 1H, H12), 6.9 8 (dd, 1H, H16), 6.95 (s, 1, H6), 7.3 5 (d, 1H, H4), 7.85 (dd, 1H, H17), 7.59 (d, 1H, H3), 7.8 3 (d, 1H, H18), 8.29 (s, 1H, H15). ^{13}C NMR (DMSO-d_6, ppm): 57 (CH_3), 107.24 (C6), 113.16 (C18), 114.85 (C4), 120.15 (C3), 119.81 (C16), 133.58 (C1), 138.38 (C17), 146.94 (C15), 148.96 (C2) 149.15 (C13), 156.69 (C5), 177.78 (C8). *Anal.* Calc. for $C_{13}H_{11}N_3OS$: C, 60.7; H, 4.13; N, 16.34. Found: C, 60.59; H, 4.28; N, 16.18%. (The numbers have been clarified in Fig. 7.)

2.3. X-ray crystallography

Selected crystals of the ligands **L1** and **L2** and the precursor **P1** were mounted on a Bruker-AXS SMART diffractometer with an APEX CCD area detector. Graphite-monochromated Mo Kα radiation (71.073 pm) was used for all measurements. The nominal crystal-to-detector distance was 5.00 cm. A hemisphere of data was collected by a combination of three sets of exposures. Each set had a different ϕ angle for the crystal, and each exposure took 20 s and covered 0.3° in ω. The data were corrected for polarization and Lorentz effects, and an empirical absorption correction (SADABS) [32] was applied. The cell dimensions were refined with all unique reflections. The structures were solved by direct methods (SHELXS-97) [33]. Refinement was carried out with the full-matrix least-squares method based on F^2 (SHELXL-97) with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were inserted in calculated positions and refined riding with the corresponding atom.

Complex **C1** was mounted on a Bruker SMART [34] diffractometer with a 1000 CCD area detector. Graphite-monochromated Mo Kα radiation (71.073 pm) was used for measurement. The data were corrected for polarization and Lorentz effects, and an empirical absorption correction (SADABS) [35] was applied. The cell dimensions were refined with SAINTPLUS [36]. The structure was solved first by the direct method and second by the difmap method. Refinement was carried out with the full-matrix least-squares method based on F^2 (SHELXTL-98) [37] with anisotropic thermal parameters for all non-hydrogen atoms. Relevant crystallographic information for the ligands **L1** and **L2**, complex **C1** and precursor **P1** are summarized in Table 1.

3. Results and discussion

3.1. Spectroscopic studies

The solid-state properties of these new compounds were examined by infrared spectroscopy. Selected absorption bands of ligands **L1**, **L2** and **L3**, and complexes **C1**, **C2**, **C3** and **C4** are given in Table 2. The thiourea derivatives can be in the thione or thiol forms. The absence of the ν (S–H) band at about 2570 cm^{-1} and the presence of the ν (N–H) bands in the range of 3000–3300 cm^{-1} in the IR spectra revealed the evidence for thione tautomer formation in the solid state of these compounds. In some cases these bands can be broad as the result of hydrogen bonding. The absorbance bands for different bonds and func-

[c] COO.
[d] OH.

tional groups in prepared ligands and complexes have been inserted in Table 2 [10,31,38–42].

^1H and ^{13}C NMR spectroscopy were applied to characterize and define the structural properties, particularly the intra- and intermolecular hydrogen bonding of the ligands **L1**, **L2**, **L3** and **L4** in solution. The presence of NH and N′H resonances in the ^1H NMR (Table 3) and the absence of SH resonances indicate the thione tautomeric form as the stable form in the solutions of the synthesized ligands. The resonance for C=S, shown by the ^{13}C NMR spectra, is an additional evidence for the thione tautomeric form of the ligands.

Corresponding to the literature, the ^1H NMR spectrum of PyTuPh indicates that the N′H and NH resonances appear at 13.86 and 10.90 ppm, but these resonances vary with different parameters, such as the substituted groups on the rings, which release and withdraw electron density in each ring, their positions and intra- and inter-hydrogen bondings [26,27,29,30,43].

[a] Similar positions are located in each column.
[b] N′H, thiourea connects to the phenyl ring.
[c] NH, thiourea connects to the pyridine ring.
[d] This work.

For example, exchange of a methoxy group in **L1** for a nitro group in **L3** causes that the N′H and NH resonances are shifted further downfield to 14.58 and 11.08 ppm, respectively [31]. The methoxy group in different positions has a small effect on intra-hydrogen interactions and the chemical shift of N′H, but inter-hydrogen bonding and subsequently the chemical shift of NH are influenced by ortho- and meta-substitution positions in comparison to a para-substitution position in the phenyl ring.

In contrast, the different positions of the methyl group in the pyridine ring in ligands **L1** (para-position), **L2** (ortho-position) and PyTu4OMePh (without any substitution) have the same effect on the intermolecular hydrogen bonding and the chemical shifts of NH. On the other hand this position in the phenyl ring has no effect on the chemical shift of NH [29]. The different positions of the methyl group in the pyridine ring affect the intramolecular hydrogen bonding and the chemical shift of N′H (Table 4) [10,43].

^{13}C NMR spectra data reveals (Table 5) no significant differences of the chemical shifts in ligands **L1** and **L2** containing methyl and methoxy groups. In comparison, the nitro group in ligand **L3** causes variations of chemical shifts for C2, C4 and C15 to those of **L1** and **L2**. The chemical shifts of carbon of the C=S bond in all three ligands was about 179 ppm. This similar chemical shift could be due to the isolated position of the thione group in these ligands [44–46].

3.2. Crystal structures of *L1*, *L2*, *C1* and *P1*

Comparison of the molecular structures of ligands **L1**, **L2** (Figs. 1 and 2) and related compounds such as PyTu4OMe [29,30], 4PicTuPh [31], 6PicTuPh [31], 4PicTu2OMePh [43] and 6PicTu2OMePh [43] indicate that the bond distances and angles are similar and are not affected by the substitution patterns on the phenyl or pyridine rings (Table 6).

In the crystal packing of ligand **L1**, weak intermolecular hydrogen bonding interactions were identified between N8–H8···S29 as well as N27–H27···S10, connecting two molecules to each other and forming centrosymmetric dimers in the solid state (Fig. 3). Two strong intramolecular hydrogen bonds, N11–H11···N1 and N30–H30···N20, are formed between NH from thiourea and N from the pyridine ring in each molecule. The centrosymmetric dimer of ligand **L2** (Fig. 4) is also formed by a weak intermolecular hydrogen bonding interaction, N8–H8···S10.

The ligand **L2** contains two strong intramolecular hydrogen bonds, N11–H11···N1 too (Table 8).

The synthesis of complex **C1** starts with the polarization of the C=S bond in ligand **L1** by the copper(II) ion. The transfer of electron density to the sulfur atom results in

the polarization and oxidation of the C=S bond [47–49]. The reaction of the sulfur atom with C17 in the phenyl ring eliminates two hydrogen atoms, which are connected to N8 and C17, and a new five-membered ring is formed. The N8–C9 bond length is decreased and the S10–C9 bond length is increased in the complex **C1** [49].

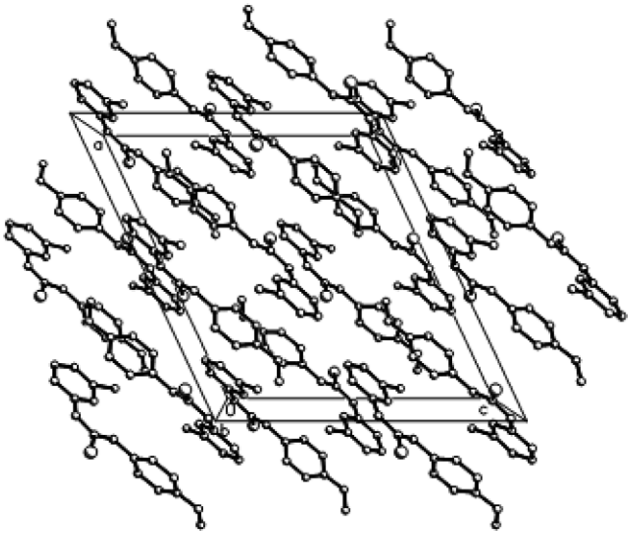

Fig. 4. View of the unit cell **L2**.

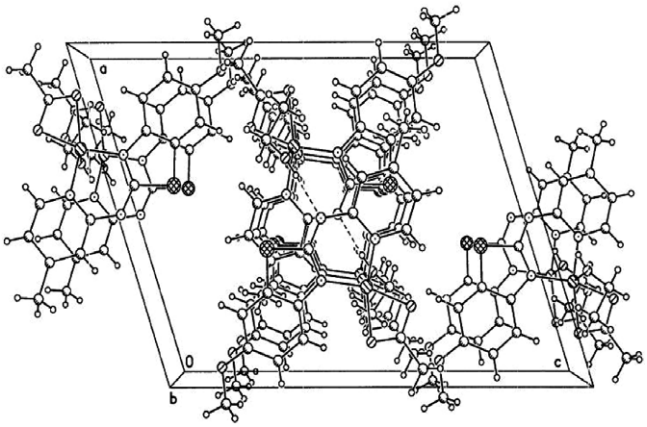

Fig. 6. View of the unit cell of complex **C1** with hydrogen bonding.

The oxidized cyclization form of ligand **L1** communicates with the copper(II) ion as a bidentate chelating agent, via the nitrogens of pyridine and thiourea (Fig. 5).

According to the Pearson principle, the nitrogen atoms of the ligands as a hard base are bound to copper(II) as a hard acid in these complexes [50]. These connections make a six-membered chelate ring around the central ion. This ligand appears as a uninegatively charged form in the complex. In addition, the acetate anion is coordinated to the copper ion in the same plane as **L1**. One solvent molecule occupies the axial position of the complex **C1** via its

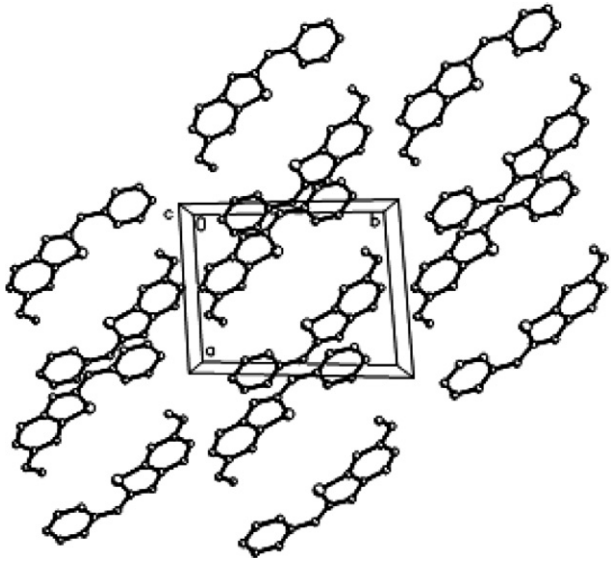

Fig. 8. View of the unit cell of **P1** (H atoms are omitted for clarity).

oxygen atom. Finally, the copper ion is in a five-coordinated environment.

The oxidation of **L1** requires the reduction of another compound in the solution, which is most likely copper(II) [47–49]. The neutral form of complex **C1** containing two negative ligands can be due to the existence of a copper(II) ion that is the result of oxidation of copper(I). The most probable oxidant for the oxidation of the copper(I) ion is dissolved oxygen in the solution.

A five-coordinated complex can be as a trigonal-bipyramid (TBPY), a square-pyramid (SPY) or, an intermediate between these two forms. The structural index parameter ($\tau = (\beta - \alpha)/60$) can be used to determine the structure of the five-coordinated complex [51]. Complex **C1** has a τ value of 0.16, which indicates that the structure of **C1** is very close to SPY [52–62]. Complex **C1** possesses two equal strong intermolecular hydrogen bonds (Fig. 6 and Table 8).

Precursor **P1** is obtained by the oxidative cyclization of ligand **L4** during the preparation of complex **C4** ($C_{26}H_{20}CuN_6O_2S_2$) (Fig. 7). The changes in the bond lengths of **P1** correspond to those of **L1** in complex **C1**. For example, the C–S bond length in precursor **P1** is increased in comparison to that in **L4** (Tables 6 and 7). Two strong hydrogen bonds N12–H12···N27 and N30–H30···N9 form centrosymmetric dimers of **P1** (Fig. 8, Table 8).

4. Conclusion

Characterization of three new pyridyl thiourea derivatives 4PicTu4OMePh, 4PicTu4NO_2Ph and 6PicTu4OMePh and their structures show the existence of hydrogen bonding interactions. The electron withdrawing nitro group has more an effect than the electron donating methoxy group on intra- and intermolecular hydrogen bonding. The position of the methoxy group in the phenyl ring has no effect on intermolecular hydrogen bonding, but the location of the methyl group influences intramolecular hydrogen bonding and the chemical shift of the proton

Table 8

(NH′). The different positions of the methyl group in the pyridine ring can affect the intramolecular hydrogen bonding and the chemical shift of the proton (NH′).

The reactions of $Cu(OAC)_2$ with the ligands, **L1**, **L2**, **L3** and **L4** result in the new complexes [Cu(4PicTz4OMeTu4NO2Ph)(OAC)], [$Cu(PyHTz4OMePh)_2$] respectively, and a precursor PyHTz4OMePh of **L4**. Oxidative cyclizations of the ligands **L1**, **L2** and **L4** occur during these reactions. The oxidative cyclization in **L1** and **L4** are observed clearly in the molecular structures of **C1** and **P1**. The result of the oxidative cyclization is the appearance of new absorption bands for C–S in the IR spectra of the complexes **C1** and **C4**. The similarity between **L1** and **L2**, and the existence of identical electron donating groups in these ligands, cause oxidative cyclization to be expected in complex **C2**. Also, the new absorbance band in the IR spectrum of this complex shows the formation of a C–S bond. But in complex **C3**, the nitro electron withdrawing group decreases the electron density around the sulfur atom and prevents oxidative cyclization in this complex. Its IR spectrum confirms this point.

In complex **C1**, the copper(II) ion has a square-pyramidal structure and is surrounded by the anionic bidentate oxidative cyclization ligand (4PicTu4OMePh), an acetate anion and ethanol as a solvent. The presence of the precursor (PyHTz4OMePh) in the second reaction shows that first the oxidative cyclizations of the ligands occur and then the complexes are formed.

5. Supplementary material

CCDC 612985, 612986, 285594 and 612987 contain the supplementary crystallographic data for **L1**, **L2**, **C1** and **P1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Foreword

Polyhedron Symposia-in-Print, number 28 transition metal chemistry of NO, N_2O and related molecules

Nitric oxide (NO) is an unusual example of a stable diatomic molecule that possesses an odd-electron configuration, the chemistry of which has been extensively studied. In particular, the transition metal chemistry of NO has been studied for many decades, thereby demonstrating that the NO ligand can exhibit a variety of coordination modes. By comparison to NO, the transition metal chemistry of derivatives such as nitroxyl (HNO) and nitrous oxide (N_2O) have been little explored.

This Symposium-in-Print provides a forum that describes not only the transition metal chemistry of NO, but also derivatives such as hyponitrite $[N_2O_2]^{2-}$, nitrite $[NO_2]^-$ nitroxyl (HNO) and other species that share common bonding similarities (e.g. diazenido compounds).

doi:10.1016/j.poly.2007.07.001

lable manner, as well as limiting NO exposure to selected sites within the body, we have entrapped [Ru(terpy)(L)-NO](PF$_6$)$_3$ complexes (where terpy = 2,2′:6′,2″-terpyridine and L = 2,2′-bipyridine (bpy) and 3,4-diiminebenzoic acid (NH · NHq) into sol–gel processed polysiloxane and silicone matrices. Recently some physico-chemical properties of nitrosyl complexes entrapped in a silicate sol–gel matrix have been described [19,20]. Although the authors have suggested its use in therapeutic applications due to the controlled NO release, there is no experimental indication that kind of system will work in biological experiments.

In this study, NO measurements were carried out and we have found that [Ru(terpy)(L)NO](PF$_6$)$_3$ complexes can also promote NO-release from the sol–gel and silicone membranes by ultraviolet and visible light irradiation. Some pharmacological properties of the entrapped [Ru(terpy)(NH · NHq)NO](PF$_6$)$_3$ complexes have also been described based on the photolysis at 532 nm showing the versatility of these materials for therapeutic applications.

2. Experimental

2.1. Chemicals and reagents

$RuCl_3 \cdot nH_2O$, terpyridine (terpy) and bipyridine (bpy) were purchased as high purity reagents from Aldrich Chemicals and were used as supplied. Doubly distilled water was used for all experiments. All preparations and measurements were carried out under an argon atmosphere and protected from light.

2.2. Synthesis of ruthenium complexes

The recrystallized complex salt [RuCl(bpy)(terpy)]Cl, [Ru(bpy)(terpy)(NO)](PF$_6$)$_3$, [RuCl(NH · NHq)(terpy)]Cl and [Ru(NH · NHq)(terpy)NO](PF$_6$)$_3$ were prepared as previously published [22–24].

2.3. Preparation of the membranes

The hybrid composite was synthesized by preparing a mixture of 24 mL tetraethoxysilane (Aldrich, Milwaukee, WI, USA) and 19 mL of bidistilled water. The reagents were carefully added and three drops of concentrated HCl were added in order to catalyze the reaction. The nitrosyl ruthenium complexes (*ca*. 0.001 g) were added with constant stirring into 4.5 mL of hydrolyzed. The solution was stirred for 5 min at 60 °C and aliquots (2.0 mL) of the mixture were then transferred to a Petri dish (58 mm diameter) to complete the reaction. The molds remained opened for 3 days until they no longer exhibited weight loss due to evaporation of residual water and solvent.

The silicone resin was prepared by mixing polydimethylsiloxane (PDMS Dow Corning) (2.000 g) with tetraethoxysilane (TEOS, Fluka) (0.500 g) in 2.5 cm^3 of isopropylic alcohol. To this mixture we add the nitrosyl ruthenium compound (0.001 g), previously dissolved in the 0.5 cm^3 of acetonitrile, and five drops of di-*n*-butyltin–dilaurate complex, 5% in hexane (Gelest) as catalyst. The final mixture was stirred for 5 min. The wet gels were air-dried at room temperature for 24 h.

2.4. Apparatus

Ultraviolet-visible (UV–Vis) spectra were recorded on a Hitachi U-3501 and a Hewlett Packard HP8452A diode array spectrophotometer. Infrared (IR) spectra were recorded on either a Protegé 460 series or a MB Bomem 102 FTIR spectrometer. Scanning electron microscopy was performed using a LEO 440 microscope equipped with an Oxford EDS detector. The pH measurements were made using a 430 pH meter from Corning. NO release was measured with an ISO-NOP NO meter from Word Precision Instruments. Continuous photolysis with monochromatic irradiations at 355 and 436 nm was carried out using a 150 W Xenon lamp in a model 6253, Oriel Universal Arc Lamp Source. The irradiation wavelength was selected with an Oriel interference filter, with 10 nm band path, for photolysis at the appropriate wavelengths. The progress of the photoreactions was monitored spectrophotometrically.

2.5. Nitric oxide release measurement

The experiment was performed using a photo-reactor (0.18 m^3) containing 250 W fluorescent lamps (Philips), which were used as a visible light source. The 450–800 nm wavelength range was achieved using a filter. A total of 0.200 g of membrane containing incorporated nitrosyl ruthenium complexes were added to a quartz UV–Vis reservoir containing 10 mL of 0.01 M phosphate buffer solution pH 7.4. This reservoir was connected by a polyethylene tube (20 cm; 1 mm diameter) to another chamber containing 10 mL of phosphate buffer solution where the NO-sensor (amino-700 from Innovative Instruments, Inc) was adapted. Argon flux was bubbling in both reservoirs during the experiment.

The reservoir containing the membrane was submitted to light irradiation and the NO was detected by measuring the current.

2.6. Vessel preparation

Male *Wistar* rats (180–200 g) were killed by decapitation and the thoracic aorta was quickly removed and dissected free and cut into rings 4 mm long. The endothelium was mechanically removed by gently rolling the lumen of the vessel on a thin wire. The aortic rings were placed between two stainless-steel stirrups, and connected to an isometric force transducer (50630-45, Harward Bioscience, South Natick, MA, USA) and the other was connected to a fixed support in the chamber in order to record the tension on a Harward Bioscience Oscillograph polygraph. The rings were placed in a 10 mL organ chamber containing Krebs

solution with the following composition (mmol/L): NaCl 130, KCl 4.7, KH_2PO_4 1.2, $MgSO_4$ 1.2, $NaHCO_3$ 14.9, Glucose 5.5, $CaCl_2$ 1.6. The solution was maintained at pH 7.4 gassed with 95% O_2 and 5% CO_2, at 37 °C. The rings were initially stretched to a basal tension of 1.5 g, before allowing to equilibrate for 60 min in the bath fluid that was changed every 15–20 min. Endothelial integrity was qualitatively assessed by the degree of relaxation caused by acetylcholine (ACh,1 μmol/L) in the presence of contractile tone induced by phenylephrine (0.1 μmol/L). Because our studies require endothelium-denuded aortas, the rings were discharged if there was any degree of relaxation to ACh, in order to avoid possible influence of endothelial factors. The tissues were washed, pre-contracted with the EC_{50} of phenylephrine (0.1 μmol/L). On top of the contraction, the chamber was loaded with $0.134\ g \pm 0.004$ $(n = 7)$ of the membrane containing entrapped $[Ru(NH \cdot NHq)(terpy)NO]^{3+}$, which was added in a dialysis bag to avoid any adverse physiological effect due the organic reagents. Similar experiment was run with the control (membrane without ruthenium complex -0.129 ± 0.004 $(n = 7)$). After addition of the membrane, the light was activated and time-course for relaxation induction was evaluated. Relaxation was calculated as a percentage of the maximal contraction induced by phenylephrine.

Light irradiation for the pharmacological assays was performed using a photo-reactor. The reactor consists of a 0.5 m^3 box inside which aluminum was placed to increase light reflection. Three 250 W fluorescent lamps (Philips) were used as a visible light source with 450–800 nm wavelength range achieved with a filter (7.05 cm^2 area) positioned in front of each channel on the chamber.

2.7. Statistical analysis

Relaxant responses to the NO donor were measured from the plateau of the phenylephrine contraction and were expressed as percent reversal of the phenylephrine pre-contraction. Data are expressed as mean ± SEM. In each set of experiments,*n* indicates the number of rats studied. We considered the maximal relaxing effect for compounds when the concentration used reached the baseline. Statistical significance was tested by one-way ANOVA (Bonferroni's Multiple Comparison Test) and values of $p > 0.05$ were considered to be significant.

3. Results and discussion

The nitrosyl ruthenium complexes, $[Ru(terpy)(L)NO]^{3+}$ (L = bpy; NH · NHq), used in the present study have been proposed as a NO donor agents in aqueous acidic solution by external stimulation [24].

These species react very rapidly in aqueous medium with hydroxide ion to give deep yellow solutions (Eq. (1)).

$$[RuL_5(NO)]^{3+} + 2OH^- \overset{K_{eq}}{\rightleftharpoons} [RuL_5(NO_2)]^{+} + H_2O \qquad (1)$$

Spectral changes accompanying this reaction for $[Ru(bpy)(terpy)NO]^{3+}$ are shown in Fig. 1. The product was characterized as $[Ru(NO_2)(L)(terpy)]^{+}$ (nitro form) based mainly on the similarity of the analogous ruthenium complexes [24]. The spectral profiles show that, above pH 3.00 for $[Ru(bpy)(terpy)NO]^{3+}$ and pH 6.00 for $[Ru(NH \cdot NHq)terpy)NO]^{3+}$, the nitro form exists in significant amounts at equilibrium. Low pH is somehow crucial for both nitrosyl ruthenium species generate NO release by light irradiation. In this regard, novel strategies to preserve the properties of $[Ru(terpy)(L)NO]^{3+}$ should be developed for biomedical applications. We found that silicone and sol–gel matrices could allow stabilizing the nitrosyl species as well be a convenient target delivery system for NO release.

The physico-chemical properties of $[Ru(terpy)(L)NO]^{3+}$ seems to be unaffected by the entrapping process with sol–gel or silicone membranes as judged by the UV–Vis and FTIR analysis. The solid sate absorbance spectra for sol–gel and silicone samples doped with nitrosyl ruthenium complexes show some similarities to those obtained in aqueous solution. Fig. 2 shows the electronic spectrum of $[Ru(bpy)(terpy)NO]^{3+}$, as an example of a [Ru(ter-

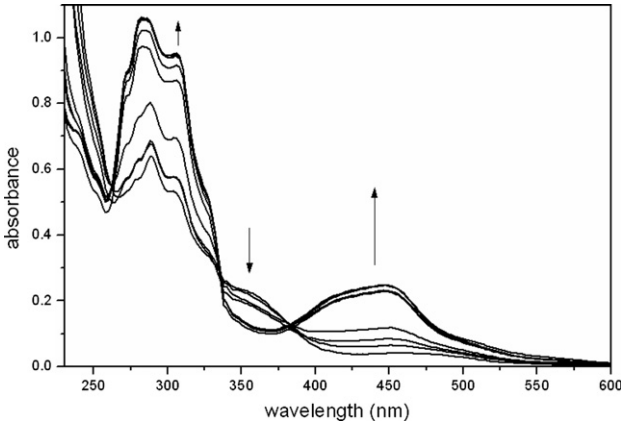

Fig. 1. Spectral profile change with pH for the conversion of $[Ru(NH \cdot NHq)(terpy)NO]^{3+}$ in $[Ru(NH \cdot NHq)(terpy)(NO_2)]^{+}$. Concentration of the complex = 2.6×10^{-5} M. pH 2.02, 2.40, 3.20, 3.58, 6.30, 7.40.

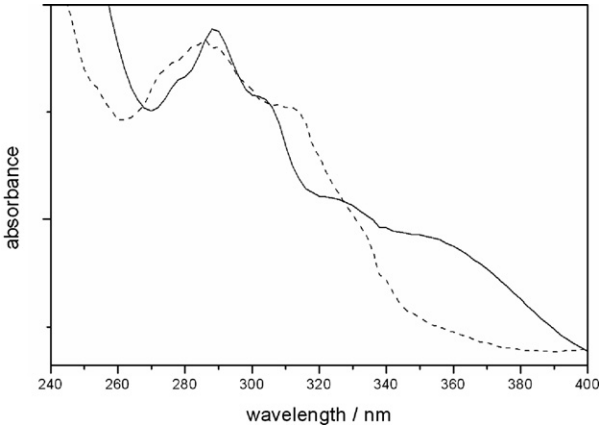

Fig. 2. Electronic spectrum of $[Ru(bpy)(terpy)NO]^{3+}$ in solution pH 2.03 (solid line) and in silicone matrix (dashed line).

py)LNO]$^{3+}$ species in solid state (dashed line) and in aqueous solution (solid line) performed at room temperature. A series of three bands were observed in both spectra in the region of 250–300 nm attributed to intra-ligand transition. However, the electronic spectrum in solution shows a shoulder at 360 nm, attributed to a metal ligand charge transfer band [24], which was not observed in the solid state, probably due the medium effect.

Scanning electron microscopy (SEM) of the studied membranes in this study was applied to determine the distribution pattern and size of particles in the solid matrices. All matrices obtained were found to be amorphous materials (Figure S1: Supporting Material). The SEM micrographs revealed irregularly shaped particles with broad size of 1000 μm for both membranes as well as a homogenous distribution. The samples of [Ru(bpy)(terpy)-NO](PF$_6$)$_3$ complex doped in sol–gel and silicone matrices formed three-dimensional networks while the samples of [Ru(NH · NHq)(terpy)NO](PF$_6$)$_3$ complex showed edges and conchoidal fractures, as well as globular particle shapes with low-dimensional structures.

The entrapped [Ru(terpy)LNO]$^{3+}$ complex on the matrices was submitted to light irradiation at 355 nm, while the [Ru(NH · NHq)(terpy)NO]$^{3+}$ complex was also irradiated at 532 nm. NO monitoring of these photochemical processes in aqueous solution, as observed for [Ru(NH · NHq)-(terpy)NO]$^{3+}$ as an example of nitrosyl ruthenium complex entrapped in silicone matrix, showed NO release (Fig. 3) although in the absence of light no current increase was recorded. The amount of available NO *per* volume of the matrices can be controlled by the amount of [Ru(bpy)(terpy)LNO]$^{3+}$. It implies that tissue exposure to such materials could be convenient because it provides different dosages of NO. After exhaustive photolysis, the UV–Vis spectrum of the entrapped [Ru(terpy)LNO]$^{3+}$ showed [Ru(terpy)-L(H$_2$O)]$^{2+}$ characteristics (Figure S2: Supporting Material).

The stability of the solid matrices to entrap the nitrosyl compounds was tested by rinsing the samples in 0.1 mol L^{-1} HCl and also in phosphate buffer solution at pH 7.40 for 30 min. The electronic spectra of these dispel aliquots showed insignificant absorption, which was considered as a qualitative indicator of the efficiency of the entrapment of ruthenium nitrosyl complexes in sol–gel and silicone matrices.

Due the spectroscopic and photochemical characteristics of [Ru(NH · NHq)(terpy)NO]$^{3+}$ complex in aqueous solution [24] as well encapsulated in a solid matrix, some pharmacological assays was performed. In a vasodilator test, denuded rat aortic rings were previously contracted with phenylephrine and vasorelaxation was verified in the presence of doped matrix. In this experiment, we used the sol–gel matrix (*ca.* 0.200 g), which was kept in a cellulose dialysis tubing to avoid any other side reaction. The addition of the membrane without entrapped compound in the absence of light did not produce vasodilation response. However, as shown in Fig. 4, in the presence of visible light irradiation and after depletion of endogenous photoactivable NO stores, NO release caused relaxation of denuded pre-contracted aorta with maximum within about 100 s. In pre-contracted aortic rings, pre-incubation with oxyhaemoglobin 10 μmol/L for 30 min, a known NO scavenger [25], completely abolished the relaxation induced by the matrix indicating that NO is released in the extracellular medium.

Vasodilation using sol–gel or silicone as target delivery system shows similar vasorelaxation effects observed for [Ru(NH · NHq)(terpy)NO]$^{3+}$ in physiological solution [7]. The entrapped ruthenium complexes induced E_{max}: 29.9 ± 3.6% for sol–gel matrix. It seems to be less effective when compared to the [Ru(NH · NHq)(terpy)NO]$^{3+}$ in physiological solution, which is possibly explained by the fact that activation of guanylyl-cyclase is nitric oxide concentration dependent. In addition, the membrane releases NO extracellularly and some NO amount can be lost outside the cells. In this way, less NO could be available inside the cell to promote the guanylyl-cyclase activation and

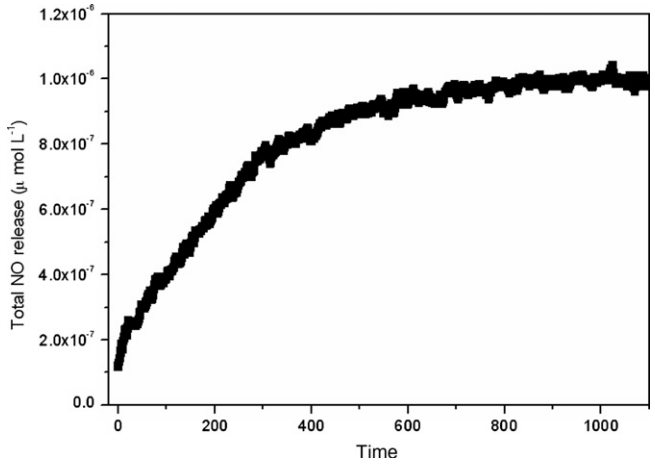

Fig. 3. Time course of NO release from [Ru(NH · NHq)(terpy)NO]$^{3+}$ complex in silicone matrix under 532 nm light irradiation. Mass membrane = 0.200 g.

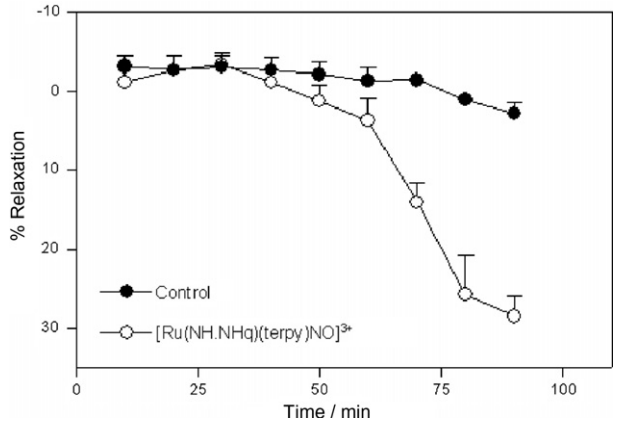

Fig. 4. Time-course for [Ru(NH · NHq)(terpy)NO]$^{3+}$-induced relaxation. Denuded aortic rings were pre-contracted with 100 nmol L^{-1} phenylephrine and [Ru(NH · NHq)(terpy)NO]$^{3+}$ doped in sol–gel matrix (○, $n = 7$) and control (sol–gel matrix) (●, $n = 7$) were added. Data are means ± SEM of n experiments performed on preparations obtained from different animals.

aorta relaxation. Apparently, the observed vasodilation using the target delivery system suggests that local delivery of NO may help increasing the local potency.

4. Conclusions

In the present study, we showed for the first time that the NO released from entrapped $[Ru(NH \cdot NHq)(terpy)\text{-}NO]^{3+}$ by light irradiation induces rat aorta relaxation, as demonstrated by its vasodilatory effect. This NO-release ability might represent an effective mechanism for some therapeutic applications because NO has been shown to prevent biofilm formation. Studies are being conducted at our laboratory to quantify NO optimal amount required to prevent, for example, bacterial adhesion, which may be useful in the development of patch-based topical therapies.

under an Ar atmosphere. NMR spectra were recorded in $CDCl_3$ at 22 °C on a 300 MHz Varian instrument and chemical shifts are expressed in ppm relative to residual $CHCl_3$. Air- and/or water-sensitive manipulations were carried out under a dry nitrogen atmosphere using standard Schlenk or glovebox techniques. Nitric oxide gas was purified following a reported procedure [23].

2.1.2. CP1

Compounds **M1** (30 mg, 0.07 mmol), **M2** (50 mg, 0.04 mmol), 5,5′-dibromo-2,2′-bithiophene (10 mg, 0.04 mmol), 4-bromobenzaldehyde (1 mg, 0.007 mmol), $[Pd(PPh_3)_4]$ (8.2 mg, 0.007 mmol), and CuI (1 mg, 0.007 mmol) were combined with morpholine (5 mL) in a pressure tube inside a glove box. The tube was sealed with a Teflon screw cap and removed from the glove box. The reaction mixture was stirred and heated at 70 °C for 25 h. The orange mixture was added to a solution of ethyl acetate to give a precipitate. Isolation of the precipitate and washing with diethyl ether gave an orange solid. The orange solid was purified by using a Chelex column with water as the solvent, and the eluant was removed under reduced pressure to afford the final product (29 mg, 37%). ^{1}H NMR (DMSO): δ 8.0–6.8 (br m, 38 H); 5.4–4.1 (br m, 46 H); 4.0–2.0 (br, overlaps with water and DMSO). $M_n = 9700$ g/mol. Spectroscopic parameters are presented in Table 1.

Table 1
Selected physical properties of **CP1** in various solvents

Property	H_2O	MeCN/H_2O (90:10)	pH 7.4 HEPES/KCl
$\lambda_{\pi\rightarrow\pi^*}$ (nm)	446	425	446
$\log\varepsilon$	3.52	3.46	3.52
λ_{em} (nm)	483	490	483
I_{Cu}/I_0	0.24	0.10	0.10
K_{SV} (M^{-1})	6.1×10^4	4.3×10^5	1.4×10^4
I_{NO}/I_{Cu}	2.1	4.9	0.88
$I_{Angeli's\ Salt}/I_{Cu}$	6.6	3.2	2.1

2.2. Spectrophotometric measurements

2.2.1. General considerations

Absorption spectra were recorded on a Cary 50 spectrophotometer. Fluorescence spectra were acquired on a Photon Technology International Quanta Master 4L fluorimeter. Circulating water baths were used to maintain all samples at 25 ± 1 °C. Samples for fluorescence had a path length of 1 cm in Spectrosil quartz (6Q) or polystyrene cuvettes from Starna, with optical densities <0.05 and 3.0 mL sample solution volumes. Quantum yields (Φ) were determined by averaging the results of at least three trials. Values were referenced to NIST-issued quinine bisulfate (in 0.105 M perchloric acid in Millipore water, $\Phi = 0.546$).

2.2.2. Metal ion selectivity

A 3.0 mL aliquot of a 7.9 μM **CP1** working solution in H_2O was added to each of 17 polystyrene cuvettes. Basal fluorescence spectra were acquired for each sample, and then 2.5 equiv. of each metal salt were introduced by addition of a 10 μL aliquot of a 6.0 mM aqueous stock solution of metal salt to each cuvette. The salts used were NaCl, KNO_3, $MgSO_4$, $CaCl_2$, $BaCl_2$, $EuCl_3$, $Mn(OAc)_2$, $NiSO_4\cdot6H_2O$, K_2PtCl_4, $CuSO_4\cdot5H_2O$, $ZnCl_2$, $CdSO_4$, $Hg(OAc)_2$, $Al_2(SO_4)_3$, and $Pb(OAc)_2\cdot3H_2O$. Fluorescent spectra were recorded within 1 min following addition and again after 10 min. No differences were observed between spectra acquired after 1 or 10 min. The relative quenching efficiency of each metal ion is summarized in Fig. 1 and individual spectra are presented in Fig. S1.

2.2.3. Titration of CP1 with $CuSO_4\cdot5H_2O$

A 3.0 mL aliquot of a 7.9 μM **CP1** solution (in H_2O, 90:10 MeCN/H_2O, or 50 mM HEPES, 100 mM KCl buffer) was added to a polystyrene cuvette. Small aliquots (4.0–20 μL) of 0.60 mM or 6.0 mM $CuSO_4\cdot5H_2O$(aq) were added to the cuvette, where 4.0 μL represents 0.10 or 1.0 equiv. of Cu(II) and 20 μL represents 5.0 equiv. of Cu(II) per mol bithiophene unit in the polymer backbone,

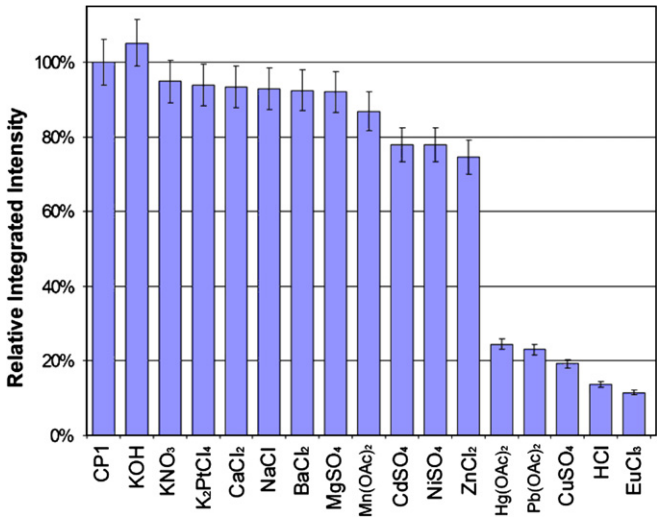

Fig. 1. Relative quenching of **CP1** emission by various species in aqueous solution.

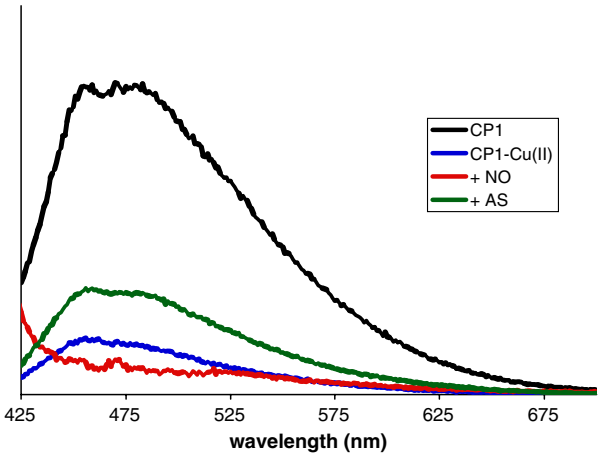

Fig. 2. Emission response of **CP1**–Cu(II) (blue trace) to NO (red trace) and to Angeli's Salt (AS, green trace) in pH 7.4 HEPES/KCl buffer. The fluorescence spectrum of **CP1** (black trace) is given for comparison. (For interpretation of the references to color in the figure legend, the reader is referred to the web version of this article.)

respectively. A total of 42 μL of $CuSO_4 \cdot 5H_2O$ solution was added to the solutions of **CP1** in water and 90:10 MeCN/H_2O, and 118 μL was added to the solutions of **CP1** in pH 7.4, 50 mM HEPES, 100 mM KCl (pH 7.4 HEPES/KCl) buffer. The fluorescence spectra and Stern–Volmer plots are presented in Figs. S2–S4. Relevant photoluminescent parameters are summarized in Table 1.

2.2.4. Response to nitric oxide

2.2.4.1. Response of CP1–Cu(II) complex to excess NO(g) in unbuffered solution. A 3.0 mL aliquot of a 7.9 μM **CP1** solution (in H_2O or 90:10 MeCN/H_2O) was added to a quartz cuvette. A 20 μL aliquot of a 6.0 mM $CuSO_4 \cdot 5H_2O$ solution in H_2O was added to form the **CP1**–Cu(II) complex. The cuvette was sealed with a gastight screw cap equipped with a septum. A 250 μL aliquot of NO(g) (86 equiv. NO per Cu(II) ion) was bubbled through the solution via a gastight syringe inserted through the septum, the solution was vigorously shaken for 3 s, and the fluorescence response was measured. Fluorescence spectra are presented in Figs. S5 and S6 and the fluorescent response is summarized in Table 1.

2.2.4.2. Response of CP1–Cu(II) complex to excess NO(g) in buffered solution. A 3.0 mL aliquot of a 7.9 μM **CP1** solution in pH 7.4 HEPES/KCl buffer was added to a quartz cuvette. A 100 μL aliquot of a 6.0 mM $CuSO_4 \cdot 5H_2O$ solution in H_2O was added to form the **CP1**–Cu(II) complex. The cuvette was sealed with a gastight screw cap equipped with a septum. A 250 μL aliquot of NO(g) (17 equiv. NO per Cu(II) ion) was bubbled through the solution via a gastight syringe inserted through the septum, the solution was vigorously shaken for 3 s, and the fluorescence response was measured. The fluorescence spectrum is presented in Fig. 2 and the fluorescent response is summarized in Table 1.

2.2.5. Selectivity studies

2.2.5.1. Response of CP1–Cu(II) complex to excess SIN-1-Cl in H_2O. A 3.0 mL aliquot of a 7.9 μM **CP1** solution in H_2O was added to a polystyrene cuvette. A 20 μL aliquot of 6.0 mM $CuSO_4 \cdot 5H_2O$ in H_2O was added to form the **CP1**–Cu(II) complex and a basal fluorescence scan was acquired. This solution was transferred to a polystyrene cuvette containing 1.5 mg of SIN-1-Cl (62 equiv. SIN-1-Cl per Cu(II) ion), the cuvette was shaken for 3 s, and the fluorescence was measured. No change in integrated emission was observed.

2.2.5.2. Response of CP1–Cu(II) complex to excess Angeli's Salt in unbuffered solution. A 3.0 mL aliquot of a 7.9 μM **CP1** solution (in H_2O or 90:10 MeCN/H_2O) was added to a polystyrene cuvette. A 20 μL aliquot of a 6.0 mM $CuSO_4 \cdot 5H_2O$ solution in H_2O was added to form the **CP1**–Cu(II) complex and a basal fluorescence scan was acquired. This solution was transferred to a polystyrene cuvette containing 2.4 mg Angeli's Salt (170 equiv. Angeli's Salt per Cu(II) ion), the cuvette was vigorously shaken for 3 s, and the fluorescence was measured. Fluorescence spectra are presented in Figs. S7 and S8 and the fluorescent response is summarized in Table 1.

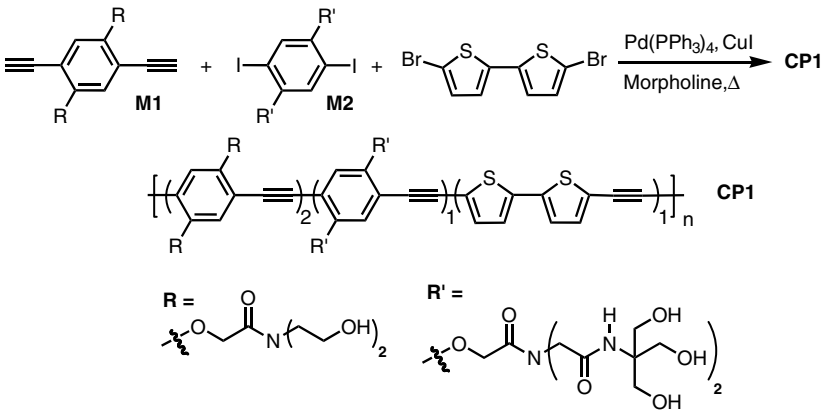
2.2.5.3. Response of CP1–Cu(II) complex to excess Angeli's Salt in buffered solution. A 3.0 mL aliquot of a 7.9 μM **CP1** solution in pH 7.4 HEPES/KCl buffer was added to a polystyrene cuvette. A 100 μL aliquot of a 6.0 mM $CuSO_4 \cdot 5H_2O$ solution in H_2O was added to form the **CP1**–Cu(II) complex and a basal fluorescence scan was acquired. This solution was transferred to a polystyrene cuvette containing 2.4 mg Angeli's Salt (34 equiv. Angeli's Salt per Cu(II) ion), the cuvette was vigorously shaken for 3 s, and the fluorescence was measured. The fluorescence spectrum is presented in Fig. 2 and the fluorescent response is summarized in Table 1.

3. Results and discussion

3.1. Design and synthesis

We had previously reported water-soluble poly(*p*-phenyleneethynylene) derivatives **A** and **B** with main chain bipyridyl units for metal ion binding, and the Cu(II) CMPs derived from these CPs showed promise for fluorescence turn-on detection of NO [15]. Unfortunately, the Stern–Volmer quenching constant was rather low in water for CPs with bipyridyl ligating groups. In the current study, the reporter module of the CP scaffold comprises the same poly(*p*-phenyleneethynylene) building blocks previously described, but the bipyridyl ligating units have been replaced by bithiophene units. CPs featuring non-ionic water-solubilizing side chains are less sensitive to ionic strength and pH than are CPs with ionic variants [21,22]. Furthermore, CPs with ionic side chains can interact with charged biomolecules such as proteins or DNA to form polyelectrolyte complexes that perturb CP emission [24–28]. Although a number of creative biosensor applications have taken advantage of this feature [25,29,30], emission changes resulting from such 'nonspecific interactions' [24] will yield spurious results for detecting neutral molecules such as NO or HNO. Non-ionic side chains can also interact nonspecifically with biomolecules, but these interactions will be much weaker than for ionic–ionic interactions.

In our previous study [15], we attributed the weak binding of metal ions to the bipyridyl units therein to competition among the side chains, water, and bipyridyl groups for metal binding. One possible strategy to perturb this competitive balance would be to decrease the metal-binding affinity of the water-solubilizing side chains, but this tactic can be synthetically prohibitive and might negatively affect the solubility/biocompatibility of the polymer. An alternative would be to decrease the metal-binding affinity of the main chain receptors. A transition metal could perturb the photoluminescent properties of the polymer without forming a substitutionally inert bond to donor atoms in the main chain.



The red-shifted emission of thiophene relative to simple arenes confers upon **CP1** an emission profile that is red-shifted to a range more amenable for biological sensing applications. Thiophene is a poor ligand for metal ions, and the few structurally characterized complexes that exhibit direct M–$S_{thiophene}$ bonds [31,32] reveal that the thiophene can be displaced by coordinating solvents such as MeCN or weakly-coordinating solvents such as CH_2Cl_2. Presumably, this kinetic lability can be attenuated by incorporating the thiophene moiety into a multidentate ligand framework or by supramolecular preorganization that holds the thiophene in proximity to the metal. Although the thiophene–metal bond may be readily broken, a fast kinetic exchange rate will allow a transition metal to quench the main chain emission through transient coordination. Because thiophene red-shifts CP emission similar to pyridine and has much poorer metal-binding affinity, we employed bithiophene as the metal ion receptor for our CP scaffold.

CP1 (Scheme 1) was prepared by Sonogashira coupling of **M1**, **M2**, and 5,5′-dibromo-2,2′-bithiophene under conditions described by others [21,22] and adapted by us [15]. To limit the molecular weight of **CP1**, 4-bromobenzaldehyde was added as an end-capping group. Purification of the material involved precipitation from ethyl acetate and subsequent rinsing with ethyl ether. To ensure full removal of Cu(I) added during the Sonogashira coupling, aqueous CP solutions were passed through a column loaded with Chelex 100 resin [15].

3.2. Spectroscopic properties and emission response to metal ions

CP1 is an orange solid with $\lambda_{max} = 446$ nm and $\lambda_{em} = 483$ nm in water. In a less polar MeCN/H_2O (90:10) mixture, the absorption maximum shifts hypsochromically to 429 nm. The emission maximum does not change as dramatically as the absorption maximum, with only a 7 nm bathochromic shift in MeCN/H_2O (90:10) versus water. Key spectroscopic parameters are summarized in Table 1.

We first examined the response of **CP1** emission to various metal ions and pH values in water. Fig. 1 shows the

Scheme 1. Preparation of **CP1**.

relative integrated emission afforded by the addition of 2.5 equiv. of various metal salts or Brønsted acid/base. Of the metals tested, only Hg(II), Pb(II), Cu(II), and Eu(III) lead to >75% quenching. Hg(II) and Cu(II) also efficiently quenched emission of **A** and **B** (Chart 1), while Eu(III) did not quench the emission of these materials (Pb(II) was not explored).

Fluorescent CP-based NO sensors operating via the reductive nitrosylation mechanism have primarily been Cu(II)–CMPs. Thus, we studied the quenching efficiency of Cu(II) for **CP1** in a more detailed and quantitative fashion. In water, adding 5 equiv. of Cu(II) to **CP1** leads to a 76% quenching of **CP1** emission. The corresponding Stern–Volmer quenching constant (K_{SV}) was measured to be $6.1 \times 10^4\ M^{-1}$, approximately the same value observed for Cu(II) quenching of bipyridyl-functionalized CP **A** in water ($K_{SV} = 5.2 \times 10^4\ M^{-1}$). However, the emission quenching efficiency of **CP1** in MeCN/H_2O ($K_{SV} = 4.3 \times 10^5\ M^{-1}$) was approximately seven times greater than in water. Quenching is somewhat less efficient in buffer ($K_{SV} = 1.4 \times 10^4\ M^{-1}$) than in water. Quenching data and K_{SV} values are listed in Table 1 and Stern–Volmer plots are provided in Figs. S2–S4. In both water and MeCN/H_2O (90:10), the Stern–Volmer plots behave linearly at low [Cu(II)] and begin to level off after 0.5 equiv. Cu(II) per bithiophene unit, suggesting that each Cu(II) center can only access *one* thiophene moiety, consistent with a mixed side chain/main chain coordination environment for copper.

3.3. Emission response to nitric oxide

Addition of 86 equiv. of NO to a 7.9 μM **CP1**–Cu(II) solution in MeCN/H_2O (90:10) afforded an immediate 4.9-fold increase in integrated emission. By comparison, the same experiment in water produced only a 2.1-fold fluorescence turn-on relative to **CP1**–Cu(II). This difference can be rationalized by the difference in **CP1** quenching by Cu(II) in these two solvents. Because the integrated emission of **CP1**–Cu(II) relative to **CP1** is greater in water than MeCN/H_2O (90:10) and is thus less quenched, we would expect the NO-induced turn-on in MeCN/H_2O (90:10) to be greater than in water by the same amount. Indeed, the **CP1**–Cu(II) complex is 2.3 times more quenched in MeCN/H_2O (90:10) compared to water, and the NO-induced turn-on is 2.3 times greater in MeCN/H_2O (90:10) than in water.

Ultimately, we are interested in developing CMPs for sensing NO *in vivo*. Surprisingly, exposure of a 7.9 μM **CP1**–Cu(II) solution in pH 7.4 HEPES/KCl buffer to 17 equiv. NO (relative to Cu) led to a 12% decrease in integrated emission (Fig. 2). Because this decrease was accompanied by an increase in Rayleigh scattering and visual turbidity, it would appear that CMP precipitation is occurring on a small scale and *not* genuine quenching of fluorescence. The same experiment, when performed in pH 7.0 100 mM NH_4OAc, displays no change in integrated emission and no precipitation.

3.4. Emission response to reactive nitrogen species

Despite considerable interest in developing sensors for detecting nitric oxide [13–16,33–40], there has been a surprising lack of progress in sensing other reactive nitrogen species. Only recently has a platform capable of discriminating HNO from NO been disclosed [41]. Our first CMP-based NO sensor employed a bipyridyl-substituted poly(*p*-phenylenevinylene) derivative, and the corresponding Cu(II)–CP complex exhibited a 2.8-fold increase in integrated emission upon addition of excess NO(g) or Angeli's Salt [14]. In this and subsequent work, we have been interested to explore the response of our CMP-based sensors to reactive nitrogen species other than NO.

Addition of 62 equiv. of SIN-1-Cl to a 7.9 μM **CP1**–Cu(II) solution in water produced no change in fluorescence. However, when the same experiment was performed using 170 equiv. of Angeli's Salt, an immediate 5.7-fold turn-on in fluorescence was observed, ultimately leveling off after 20 min at 6.6 times the **CP1**–Cu(II) integrated emission. This result is surprising, given that the integrated emission of **CP1** in water is quenched by 76% with Cu(II), whereby a full restoration in fluorescence can only result in a 4.2-fold enhancement. However, in unbuffered aqueous media Angeli's Salt will dramatically increase the alkalinity of the solution. In the course of our metal selectivity measurements, we observed that increasing the pH of an aqueous solution of **CP1** leads to an increase in integrated emission. Indeed, the pH increases from 6 to 9 upon addition of Angeli's Salt, accounting for 'restored' fluorescence that is higher than the initial fluorescence of **CP1**.

In contrast, when a 7.9 μM **CP1**–Cu(II) solution in MeCN/H_2O (90:10) was exposed to 170 equiv. of Angeli's Salt, an immediate 3.3-fold increase in integrated emission was observed. No restoration beyond initial **CP1** fluorescence occurs in this experiment, presumably because MeCN/H_2O (90:10) undergoes a smaller pH change than pure water. Freshly collected Millipore water has a pH ~ 6 and would quench **CP1** emission relative to biologically relevant milieu. However, MeCN/H_2O (90:10) has only one-tenth the water and therefore one-tenth the available protons for quenching **CP1** emission compared to pure water; thus, the integrated emission of metal-free **CP1** in MeCN/H_2O (90:10) would be greater than in pure water. Furthermore, the large relative MeCN composition of the solvent will substantially influence pK_a values. The pH values for many buffers increase by nearly two log units in going from pure water to MeCN/H_2O (1:1) [42]. This deviation becomes more pronounced for simpler, non-buffering molecules as the percentage of MeCN increases. In the case of ammonia, the pK_a shifts up by more than 7 log units from pure water to pure MeCN [43]. Consequently, the pK_a of water in MeCN/H_2O (90:10) will be substantially higher and thus less susceptible to deprotonation with attendant alkalinity-induced fluorescence enhancement. Because MeCN/H_2O (90:10) is less sensitive to alkalinization, the pH-dependent emissive behavior in

MeCN/H_2O (90:10) is greatly diminished and thus the fluorescence does not increase beyond the initial **CP1** value.

To mimic biological milieu more faithfully and to avoid pH-dependent emission responses, we performed the HNO sensing experiments in pH 7.4 HEPES/KCl buffer. Upon addition of 34 equiv. Angeli's Salt to a 7.9 μM **CP1**–Cu(II) solution in buffer, the integrated emission immediately increased 2.1-fold (Fig. 2). Because the pH is buffered at 7.4, this change in fluorescence is a genuine response to HNO uncomplicated by pH variations.

4. Conclusions

A CMP incorporating bithiophene-based metal binding units, **CP1**, forms a Cu(II) complex that displays good emission enhancement upon exposure to NO(g) in H_2O and MeCN/H_2O (90:10). The fluorescence of **CP1**–Cu(II) shows a 12% decrease in emission upon treatment with NO in pH 7.4 HEPES/KCl buffer, probably a consequence of precipitation, and no change in ammonium acetate solution. Remarkably, a 2.1-fold increase in **CP1**–Cu(II) integrated emission occurs upon exposure to Angeli's Salt in the HEPES buffer, indicating that **CP1**–Cu(II) can sense HNO selectively over NO in buffered aqueous solutions. Because **CP1**–Cu(II) displays greater fluorescence enhancement with Angeli's Salt in MeCN/H_2O (90:10) and water, the selectivity of **CP1**–Cu(II) for HNO over NO in buffer arises not from unique sensitivity to HNO, but rather from an insensitivity to NO. The ability of **CP1**–Cu(II) to react with HNO under conditions in buffered aqueous solution where NO does not represents a significant step towards developing sensors to explore the separate roles of HNO and NO *in vivo*.

2. Experimental

All manipulations were carried out under nitrogen by standard Schlenk techniques unless otherwise stated. Solvents were purified, distilled and degassed prior to use. NMR spectra were recorded on a Varian Mercury 300 spectrometer operating at 300, 121.5, and 282.5 MHz for ^{1}H, ^{31}P, and ^{19}F, respectively. Chemical shifts (δ, ppm) were reported with reference to $SiMe_4$ (^{1}H), H_3PO_4 (^{31}P), and $CF_3C_6H_5$ (^{19}F). Infrared spectra (KBr) were recorded on a Perkin–Elmer 16 PC FT-IR spectrophotometer. Elemental analyses were performed by Medac Ltd, Surrey, UK. The ligands $K[N(R_2PQ)_2]$ (R = Ph, Q = O, S, or Se; R = Pr^i, Q = S or Se) [18–21] and $[Ru(NO)Cl_3(PPh_3)_2]$ [22] and $[Rh(NO)Cl_2(PPh_3)_2]$ [23] were prepared according to literature methods. $Ru(NO)Cl_3 \cdot xH_2O$ was purchased from Strem Ltd and used as received.

2.1. Preparation of trans-[Ru(NO)(Cl){N(R$_2$PS)$_2$}$_2$] (R = Ph (1), Pr^i (2))

A suspension of $[Ru(NO)Cl_3(PPh_3)_2]$ (200 mg, 0.26 mmol) and 2 equiv. of $K[N(Ph_2PS)_2]$ (256 mg, 0.53 mmol) in dmf (20 ml) was heated at reflux for 2–3 h, during which the color changed from dark green to orange. The solvent was pumped off, and the residue was washed with Et_2O and then extracted with CH_2Cl_2. Recrystallization from CH_2Cl_2–Et_2O–hexane afforded orange crystals.

Compound **1**: Yield: 83 mg (30%). *Anal.* Calc. for $C_{48}H_{40}ClN_3OP_4RuS_4 \cdot CH_2Cl_2$: C, 51.2; H, 3.7; N, 3.7. Found: C, 51.1; H, 3.9; N, 3.5%. ^{1}H NMR ($CDCl_3$): δ 6.94–7.96 (m, C_6H_5). $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): δ 38.20 (s). IR (KBr, cm^{-1}): 1834 [ν(N≡O)].

Compound **2**: Yield: 28 mg (42%). ^{1}H NMR ($CDCl_3$): δ 2.46–2.60 (m, 4H, C*H*(CH_3)$_2$), 2.10–2.23 (m, 4H, C*H*(CH_3)$_2$), 1.21–1.34 (m, 48H, CH(C*H*$_3$)$_2$). $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): δ 60.84 (s). IR (KBr, cm^{-1}): 1841, 1826 [ν(N≡O)].

2.2. Preparations of trans-[Ru(NO)(Cl){N(Ph$_2$PSe)$_2$}$_2$] (3) and trans-[Ru(NO)(Cl){N(Ph$_2$PSe)$_2$}{Ph$_2$P(Se)NPPh$_2$}] (4)

A mixture of $[Ru(NO)Cl_3(PPh_3)_2]$ (200 mg, 0.26 mmol) and 2 equiv. of $K[N(Ph_2PSe)_2]$ (305 mg, 0.53 mmol) was heated in dmf (20 ml) at reflux for 3 h, during which the color changed from dark green to orange. The solvent was pumped off, and the residue was purified by column chromatography (silica gel) using CH_2Cl_2–hexane (1:1) as eluant. Complexes **3** and **4** were isolated as orange and reddish orange crystals, respectively.

Compound **3**: $R_f = 0.11$. Yield: 125 mg (38%). *Anal.* Calc. for $C_{48}H_{40}ClN_3OP_4RuSe_4 \cdot CH_2Cl_2$: C, 44.1, H, 3.2; N, 3.2. Found: 44.5; H, 3.1; N, 3.1%. ^{1}H NMR ($CDCl_3$): δ 7.20–7.94 (m, 40H, C_6H_5). $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): δ 28.98 (s). IR (KBr, cm^{-1}): 1834 [ν(N≡O)].

Compound **4**: $R_f = 0.23$. Yield: 40 mg (13%). *Anal.* Calc. for $C_{48}H_{40}ClN_3OP_4RuSe_3 \cdot 1.5CH_2Cl_2$: 45.8; H, 3.3; N, 3.2. Found: C, 45.9; H, 3.3; N, 3.4%. ^{1}H NMR ($CDCl_3$): δ 6.89–8.10 (m, 40H, C_6H_5). $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): δ 71.49 (ddd, $J_{PP} = 40.0$ Hz, $J_{PP} = 9.8$ Hz, $J_{PP} = 6.2$ Hz, PPh_2), 55.66 (d, $J_{PP} = 40.0$ Hz, P(Se)Ph_2 *trans* to PPh_2), 31.88 (dd, $J_{PP} = 3.5$ Hz, $J_{PP} = 9.8$ Hz), 26.91 (dd, $J_{PP} = 3.5$ Hz, $J_{PP} = 6.2$ Hz). IR (KBr, cm^{-1}): 1837 [ν(N≡O)].

2.3. Preparation of cis-[Ru(NO)Cl{N(Ph$_2$PO)$_2$}$_2$] (5)

A suspension of $Ru(NO)Cl_3 \cdot xH_2O$ (25 mg, 0.098 mmol) and 2 equiv. of $K[N(Ph_2PO)_2]$ (89 mg, 0.20 mmol) in acetone (15 ml) was heated at reflux for overnight. The solvent was removed, and the residue was extracted with CH_2Cl_2. Recrystallization from CH_2Cl_2–Et_2O–hexane afforded pale reddish brown crystals. Yield: 47 mg (48%). *Anal.* Calc. for $C_{48}H_{40}ClN_3O_5P_4Ru \cdot CH_2Cl_2$: C, 54.3; H, 3.9; N, 3.9. Found: C, 54.1; 3.9; N, 3.8%. ^{1}H NMR ($CDCl_3$): δ 6.85–7.93 (m, 40H, C_6H_5). $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): δ 38.94 (d, $J_{PP} = 4.0$ Hz), 34.74 (d, $J_{PP} = 3.3$ Hz), 34.64 (d, $J_{PP} = 3.7$ Hz), 31.52 (d, $J_{PP} = 3.7$ Hz). IR (KBr, cm^{-1}): 1863 [ν(N≡O)].

2.4. Preparation of [Rh(NO){N(Ph$_2$PQ)$_2$}$_2$] (R = Ph, Q = S (6) or Se (7); R = Pr^i, Q = S (8))

A mixture of $[Rh(NO)Cl_2(PPh_3)_2]$ (50 mg, 0.069 mmol) and $K[N(Ph_2PQ)_2]$ (0.14 mmol) in THF (10 ml) was heated at reflux for 1 h. The solvent was pumped off and the residue was washed with hexane. Recrystallization from CH_2Cl_2–hexane (**6** and **7**) or Et_2O–hexane (**8**) afforded red crystals.

Compound **6**: Yield: 45 mg (63%). *Anal.* Calc. for $C_{48}H_{40}N_3OP_4RhS_4$: C, 56.0; H, 3.9; N, 4.1. Found: C, 55.7; H, 3.9; N, 3.0%. ^{1}H NMR ($CDCl_3$): δ 7.77–7.84 (m, 16H, C_6H_5), δ 7.26–7.37 (m, 24H, C_6H_5). $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): δ 37.85 (d, $J_{RhP} = 3.5$ Hz). IR (KBr, cm^{-1}): 1655 [ν(N≡O)].

Compound **7**: Yield: 46 mg (65%). *Anal.* Calc. for $C_{48}H_{40}N_3OP_4RhSe_4$: C, 47.4; H, 3.3; N, 3.5. Found: C, 47.4; H, 3.3; N, 3.4%. ^{1}H NMR ($CDCl_3$): δ 7.77–7.83 (m, 16H, C_6H_5), 7.26–7.39 (m, 24H, C_6H_5). $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): δ 27.97 (d, $J_{RhP} = 4.1$ Hz). IR (KBr, cm^{-1}): 1629 [ν(N≡O)].

IR (KBr, cm^{-1}): 1618 [ν(N≡O)].

2.6. Preparation of [Rh(NO){NH(Pr^i_2PS)$_2$}$_2$][BF_4]$_2$ (10)

To a solution of **8** (40 mg, 0.053 mmol) in Et_2O (10 ml) was added 2 equiv. of HBF_4 (54% in Et_2O, 15 μl, 0.11 mmol) at 0 °C. The orange solid was collected and washed with Et_2O. Recrystallization from CH_2Cl_2-Et_2O afforded orange crystalline solid. Yield: 31 mg (62%). *Anal*. Calc. for $C_{24}H_{58}B_2F_8N_3OP_4RhS_4 \cdot 0.5CH_2Cl_2$: C, 30.2; H, 6.1; N, 4.3. Found: C, 30.1; H, 6.6; N, 4.2%. ^{1}H NMR (CDCl$_3$): δ 6.80 (s, 2H, N*H*), 2.74–2.88 (m, 8H, C*H*(CH$_3$)$_2$), 1.20–1.46 (m, 48H, CH(C*H*$_3$)$_2$). ^{31}P{^{1}H} NMR (CDCl$_3$): δ 89.45 (s). ^{19}F{^{1}H} NMR (CDCl$_3$): δ −148.96 (s). IR (KBr, cm^{-1}): 1650, 1677 [ν(N≡O)].

2.7. X-ray diffraction analysis

A summary of crystallographic data and experimental details for **2**, **4**, and **9** are summarized in Table 1. Intensity data were collected on a Bruker SMART APEX 1000 CCD diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 100(2) K. The collected frames were processed with the software SAINT. Structures were solved by the direct methods and refined by full-matrix least-squares on F^2 using the SHELXTL software package [24]. Non-hydrogen atoms were refined anisotropically. Selected bond lengths and angles for complexes **2**, **4** and **9** are listed in Tables 2–4, respectively.

3. Results and discussion

3.1. Ruthenium nitrosyl compounds

Treatment of [Ru(NO)Cl$_3$(PPh_3)$_2$] with 2 equiv. of K[N(R_2PS)$_2$] in refluxing dmf afforded the nitrosyl compounds *trans*-[Ru(NO)Cl{N(R_2PS)$_2$}$_2$] (R = Ph (**1**), Pr^i (**2**)) (Scheme 2), isolated as air-stable orange solids. The ^{31}P {^{1}H} NMR spectra for both **1** and **2** exhibit a single resonance (at δ 38.2 (s) and 60.84 (s) ppm, respectively),

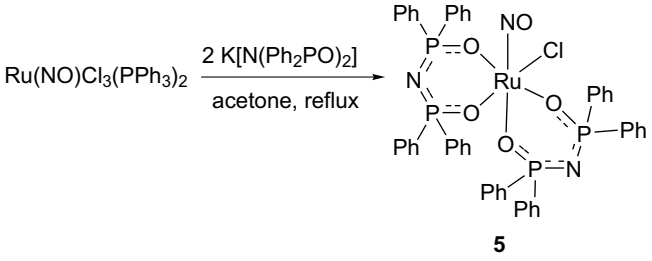
Scheme 2.

consistent with the *trans* geometry of the compounds. The IR spectrum of **1** shows a strong N–O band at 1834 cm^{-1}, which is similar to that for *trans*-[Ru(NO)Cl(S_2CNEt_2)$_2$] (1840 cm^{-1}) [25]. The splitting for the *v*(NO) band (1826 and 1841 cm^{-1}) for **2** is probably due to a solid-state effect. Photolysis of **2** in THF led to a green species that did not exhibit any *v*(NO) bands in the IR spectrum, indicating that the loss of the nitrosyl ligand. Unfortunately, we have not been able to crystallize this green complex.

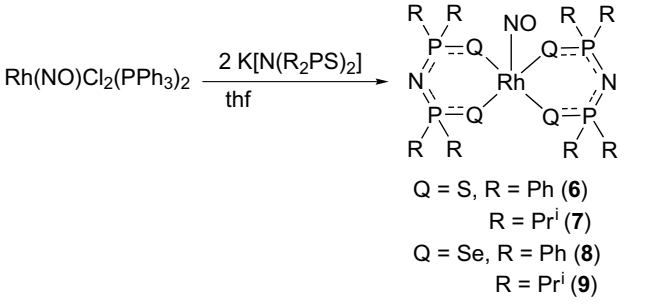
Reaction of [Ru(NO)Cl_3(PPh_3)$_2$] with 2 equiv. of K[N($Ph_2PSe)_2$] in refluxing dmf led to a mixture of *trans*-[Ru(NO)Cl{N($Ph_2PSe)_2$}$_2$] (**3**) and *trans*-Ru(NO)Cl{N($Ph_2PSe)_2$}{Ph_2P(Se)NPPh_2}] (**4**) (Scheme 3), which could be separated by column chromatography using CH_2Cl_2–hexane as eluant. Apparently, the formation of **4** involved the Ru-assisted selenium atom abstraction of one [N($Ph_2PSe)_2$]$^-$ ligand in **3**, possibly by PPh_3. It may be noted that in a previous paper, we reported that interaction of [Ru(=CHPh)Cl_2(PCy_3)$_2$] (Cy = cyclohexyl) with K[N($Ph_2PSe)_2$] resulted in selenium atom abstraction from the [N($Ph_2PSe)_2$]$^-$ ligand and the formation of *trans*-[Ru(=CHPh){Ph_2P(Se)NPPh_2}$_2$] along with *trans*-[Ru(=CHPh){N($Ph_2PSe)_2$}$_2$] [26]. Chalcogen atom abstraction occurred for the [N($Ph_2PSe)_2$]$^-$ ligand but not in the sulfide analogue presumably because of the weaker P=Se bond strength compared with that of P=S. The IR N–O stretching frequency of **3** (1834 cm^{-1}) is similar to that of **1**. The ^{31}P {H} NMR spectrum of **3** displays at singlet at δ 28.98 ppm, indicative of the *trans* geometry of the molecule. In the ^{31}P {^{1}H} NMR spectrum of **4**, the doublet



Scheme 3.

of doublets of doublets at δ 71.49 ppm ($^3J_{PP} = 40$, $^2J_{PP} = 9.8$ and $^3J_{PP} = 6.2$ Hz) is assigned to the PPh_2 group, whereas the doublet at δ 55.66 ppm ($^3J_{PP} = 40$ Hz) is assigned to the $P(Se)Ph_2$ group opposite to the PPh_2 group. The remaining two $P(Se)Ph_2$ groups appear as two doublets of doublets at δ 26.91 ($^4J_{PP} = 3.5$, $^3J_{PP} = 6.2$ Hz) and 31.88 ppm ($^4J_{PP} = 3.5$, $^3J_{PP} = 9.8$ Hz) ppm, respectively.

No reaction was found between $[Ru(NO)Cl_3(PPh_3)_2]$ and $K[N(Ph_2PO)_2]$. Refluxing $Ru(NO)Cl_3 \cdot xH_2O$ with $K[N(PPh_2PO)_2]$ in acetone gave *cis*-$[Ru(NO)Cl\{N(Ph_2PO)_2\}_2]$ (**5**) (Scheme 4), isolated as air-stable brown crystals. Unlike the sulfide and selenide analogues, the NO and Cl ligands in **5** are *cis* to each other, as evidenced by the $^{31}P\{^1H\}$ NMR spectrum that displays four doublets at δ 38.94, 34.74, 34.64 and 31.52 ppm ($J \sim 3$–4 Hz). The IR NO stretching frequency for **5** (1863 cm^{-1}) is higher than those of **1** and **3**, suggesting that the P=O group is less electron-releasing than chloride.



3.2. Rhodium nitrosyl compounds

Treatment of $[Rh(NO)Cl_2(PPh_3)_2]$ with $K[N(R_2PQ)_2]$ in THF afforded $[Rh(NO)\{N(R_2PQ)_2\}_2]$ (R = Ph, Q = S (**6**) or Se (**7**); R = Pr^i, Q = S (**8**) or Se (**9**)) (Scheme 5), isolated as air-stable red crystals. The $^{31}P\{^1H\}$ NMR spectra of **6**, **7**, and **9** display doublets at δ 37.85, 27.97, and 54.38 ppm, respectively, with J_{RhP} values of 3–4 Hz, whereas a singlet at δ 63.17 ppm was found for **8**. The IR N–O stretching frequencies for **6**–**9** of 1618–1655 cm^{-1} are within the range expected for bent nitrosyl compounds [2], although they are higher than that for $[Rh(NO)Cl_2(PPh_3)_2]$ (1559 cm^{-1}) [23]. The ν(NO) for $[Rh(NO)\{N(R_2PQ)_2\}_2]$ was found to

Scheme 4.

Scheme 5.

decrease in the order R: Pr^i > Ph, Q: Se > S. This suggests that the selenium ligand is a stronger donor than the sulfur counterpart.

Unlike **1**, no reaction was found when **6** in THF was irradiated with UV light. Attempts have been made to activate the nitrosyl ligand of the Rh nitrosyl compounds by treatment with nucleophiles and electrophiles. No reactions were found when **6** was reacted with MeLi or $LiBEt_3H$. Treatment of **6** with PMe_3 in $CDCl_3$ gave $OPMe_3$ identified by ^{31}P NMR spectroscopy along with an uncharacterized Rh species that showed the absence of ν(NO) in the IR spectrum. We have not been able to crystallize this Rh-containing product. Reaction of **7** with HBF_4 in Et_2O afforded an orange precipitate **10** analyzed as dicationic $[H_2\mathbf{7}][BF_4]_2$. The IR spectrum of **10** shows ν(NO) at 1650 and 1677 cm^{-1}, indicating that the bent nitrosyl ligand remained intact. The $^{31}P\{^1H\}$ NMR spectrum of **10** displays a singlet at δ 89.45 ppm that is considerably more downfield than that for **7**, but similar to that for $HN(Pr^i_2PS)_2$ (δ 91.2 ppm). The observation of a single ^{31}P signal suggests that **10** has a square pyramidal geometry with 2 equivalent $[N(Pr^i_2S)_2]^-$ ligands at the equatorial positions. In addition to the resonances due to the isopropyl protons, the ^1H NMR spectrum displays a broad NH resonance at δ 6.80 ppm that underwent deuterium exchange upon treatment with D_2O. On the basis of the spectroscopic data, **10** is formulated as a dicationic Rh nitrosyl compound containing two protonated dithioimidodiphosphinate ligands, $[Rh(NO)\{HN(Pr^i_2PS)_2\}][BF_4]_2$.

3.3. Crystal structures

The solid-state structure of **2** is shown in Fig. 1; selected bond lengths and angles are listed in Table 2. The geometry about Ru is pseudo octahedral with the nitrosyl ligand opposite to the chloride. The Ru–N–O linkage is linear (177.3(5)°) as expected for the $\{MNO\}^6$ configuration using the Enemark–Feltman notation [27]. The Ru–N distance of 1.810(5) Å is rather long compared with those of reported Ru(II) nitrosyl compounds (e.g. 1.643(8) and 1.687(8) Å for $[Ru(NO)(bdt)_2]^-$ (bdt = 1,2-benzenethiolate) [28] and 1.751(5) Å for *trans*-[Ru(TPP)(NO)(OH)] (TPP = tetraphenylporphyrin dianion [29]). The Ru–S distances (av. 2.4387 Å) are comparable to those in $[Ru\{N(Pr^i_2PS)_2\}_2(PPh_3)]$ (av. 2.405 Å) [16]. Similar to other M–$[N(R_2PS)_2]$ complexes, the P–S distances (2.026(2)–2.049(2) Å) in **2** are longer than those in $HN(Pr^i_2PS)_2$ (1.941(1) and 1.949(1) Å) [20] whereas the P–N distances (1.586(5)–1.594(4) Å) are shorter than those in the latter (1.682(3) and 1.684(2) Å). The P–N–P angles in **2** (134.4(3)° and 136.4(3)°) are slightly larger than that in $HN(Pr^i_2PS)_2$ 131.6(1)°) [20].

The solid-state structure of **4** is shown in Fig. 2; selected bond lengths and angles are listed in Table 3. The geometry around Ru is pseudo octahedral with the nitrosyl group opposite to the chloride. The nitrosyl ligand is linear with the Ru–N–O angle of 175.9(3)°. The Ru–N distance in **4**

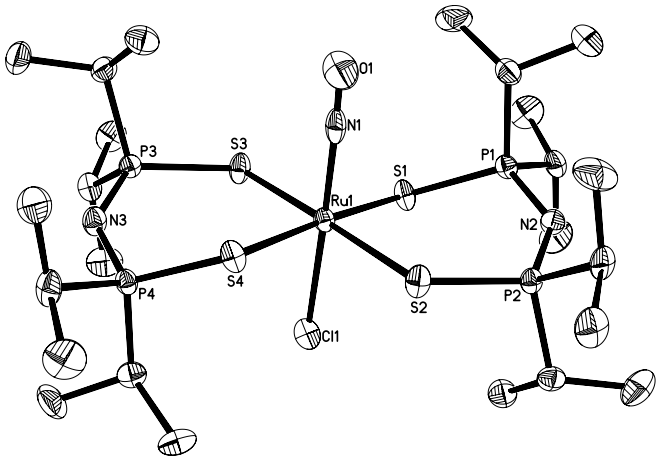

Fig. 1. Molecular structure of *trans*-[Ru(NO)Cl{N(Pr^i_2PS)$_2$}$_2$] (**2**). The ellipsoids are drawn at 30% probability level.

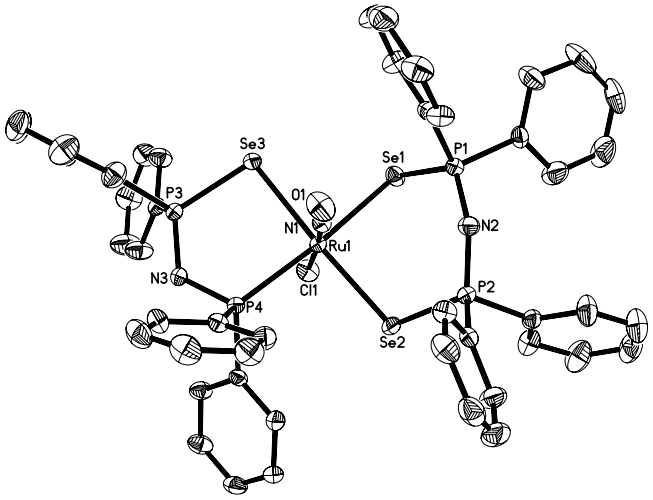

Fig. 2. Molecular structure of *trans*-[Ru(NO)(Cl){N(Ph$_2$PSe)$_2$}{Ph$_2$P(Se)NPPh$_2$}] (**4**). The ellipsoids are drawn at 30% probability level.

(1.719(3) Å) is typical of Ru(II) nitrosyl compounds [7]. The Ru–P distance (2.372(1) Å) is comparable to that in [Ru(=CHPh){Ph$_2$P(Se)NPPh$_2$}$_2$] (av. 2.383 Å) [25]. The Ru–Se (*trans* to P) (2.5765(7) Å) is longer than the Ru–Se (*trans* to Se) (2.5060(6) and 2.5321(7) Å) due to the *trans* influence of the PPh$_2$ group. The N–P distance in the [Pr^i_2P(Se)NPPr^i_2]$^-$ ligand (1.616(2) Å) is slightly longer than the N–P(Se) distances (1.573(2)–1.593(2) Å). The P–N–P angle in the [Pr^i_2P(Se)NPPr^i_2]$^-$ ligand (123.9(2)°) is obviously smaller than that in the [N(Pr^i_2PSe)$_2$]$^-$ ligand (135.9(2)°).

The solid-state structure of **9** is shown in Fig. 3; selected bond lengths and angles are listed in Table 4. The geometry around Rh is pseudo square pyramidal with the nitrosyl ligand occupying the apical position. The Rh–N–O angle is 125.7(3)° that is characteristic for bent nitrosyl compounds [1,2]. A similar bond angle was found for [Rh(NO)Cl$_2$(PPh$_3$)$_2$] (125(1)°) [30]. The bending of the Rh–N–O linkage is in accordance with the {RhNO}^{7} electron configuration [27]. It may be noted that the isoelectronic Co compound [Co(NO)(S$_2$CNEt$_2$)$_2$] also has square pyramidal geometry with an apical bent nitrosyl ligand [31]. The Rh–N distance of 1.905(3) Å is comparable to that in [Rh(NO)Cl$_2$(PPh$_3$)$_2$] (1.91(1) Å) [30]. The Rh atom is displaced above the Se$_4$ mean plane by ca. 0.317 Å. The average Rh–Se distance is 2.5099 Å. The P–Se (2.1848(9)–2.210(1) Å) and P–N (1.593(3) and 1.605(3) Å) distances and P–N–P angles (134.4(3)° and 136.4(3)°) compare well with those in **4**.

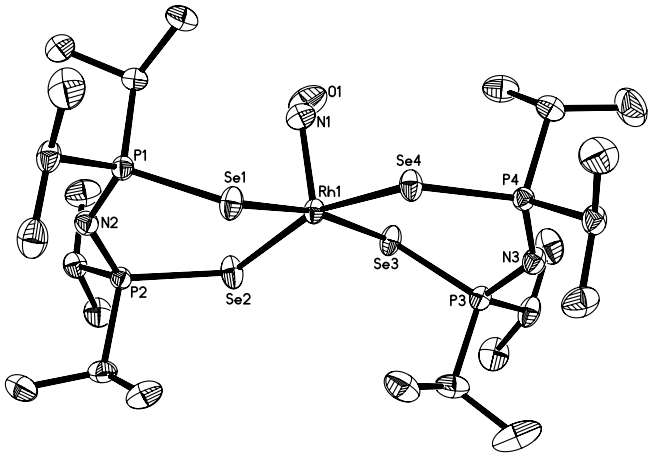

Fig. 3. Molecular structure of [Rh(NO){N(Pr^i_2PSe)$_2$}$_2$] (**9**). The ellipsoids are drawn at 30% probability level.

4. Conclusion

In summary we have synthesized and structurally characterized Ru and Rh nitrosyl compounds with [N(R$_2$PQ)$_2$]$^-$ (Q = O, S, Se) ligands. X-ray crystallography revealed that the nitrosyl ligand in the Ru compounds is linear whereas that in the Rh analogue is bent. Interaction of [Ru(NO)Cl$_3$(PPh$_3$)$_2$] with K[N(Ph$_2$PSe)$_2$] resulted in selenium atom abstraction of the ligand and formation of *trans*-[Ru(NO)(Cl){N(Ph$_2$PSe)$_2$}{Ph$_2$P(Se)NPPh$_2$}]. Treatment of [Rh(NO){N(Pr^i_2PS)$_2$}$_2$] with HBF$_4$ led to protonation of the dithioimidodiphosphinate ligands and formation of dicationic [Rh(NO){HN(Pr^i_2PS)$_2$}$_2$][BF$_4$]$_2$.

detection of N_2O is an indirect indicator for the formation of HNO [3], although there are other sources of N_2O in the chemistry of nitric oxide, for example as a product of NO disproportionation mediated by transition metal complexes [12]

$$2HNO \rightarrow N_2O + H_2O \quad (1)$$

2. Experimental

2.1. General

Infrared spectra were obtained using a Nicolet 4700 FTIR and a 0.5 mm-pathlength sealed IR cell. UV–Vis spectra were collected on an HP 8453 diode array spectrophotometer. GC–MS data were obtained using a Hewlett–Packard 6890 Series GC System and a 5973 Mass Selective Detector. Data manipulation was performed using Igor Pro software. Irradiation of samples in IR cells was performed using the 365 nm output of a Mineralight handheld UV lamp. Irradiation in UV–Vis cells was performed using Starna airtight cuvettes equipped with septum caps.

Samples for spectroscopic studies were prepared under a nitrogen atmosphere in the glovebox. Anhydrous chloroform (Aldrich, SureSeal) was transferred via cannula to a Schlenk flask, deaerated, and brought into the glovebox. Solutions of **1** were then prepared and, for studies under nitrogen, loaded into IR cells and removed from the glovebox. For studies performed under CO, samples were placed in airtight flasks equipped with rubber septa and removed from the glovebox, and then CO was bubbled through the solution. These samples were then transferred to IR cells via syringe. Molar concentrations of N_2O in solution were calculated from FTIR data using absorbance values at 2220 cm^{-1}, an extinction coefficient of 910 $M^{-1}\,cm^{-1}$ [13], and a pathlength of 0.05 cm. Molar concentrations of **1** in solution were estimated from FTIR data using absorbance values at 1415 cm^{-1} (a frequency at which there appeared to be little overlap with any other species in solution), an extinction coefficient of 420 $M^{-1}\,cm^{-1}$, and a pathlength of 0.05 cm.

2.2. Synthesis of $Os(N(O)H)(CO)Cl_2(PPh_3)_2$ (1)

Except where noted, all syntheses were carried out under nitrogen. Reagents were used without additional purification. Solvents were deaerated prior to use.

$Os(N(O)H)(CO)Cl_2(PPh_3)_2$ (**1**) was synthesized in a three-step process. First, $Os(H)(CO)Cl(PPh_3)_3$ was synthesized from $OsCl_6^{2-}$ according to a literature method [14]. To a refluxing mixture of triphenylphosphine (1 g) and 2-methoxyethanol (20 mL) was added a slurry of K_2OsCl_6 (330 mg) in 2-methoxyethanol. Then a 10 mL portion of formaldehyde solution (37% in water/methanol) was cannulated into this mixture. The color changed from brownish red to yellowish green, and the mixture was allowed to reflux for 30 min. After cooling, the off-white solid that had settled to the bottom of the flask was isolated and used without further purification.

In the second step, the crude $Os(H)(CO)Cl(PPh_3)_3$ was used for the synthesis of $Os(NO)(CO)Cl(PPh_3)_2$, following literature methods [5,6]. To a mixture of 300 mg $Os(NO)(CO)Cl(PPh_3)_2$ and 100 mg *N*-methyl-*N*-nitrosyl-*p*-toluenesulfonamide (Aldrich, "Diazald") was added 100 mL ethanol. The mixture was allowed to reflux for 3 h, during which time the color changed from yellow to brownish orange. Upon cooling, a brownish orange powder settled to the bottom. The ethanol was removed by cannula, and the solid was washed repeatedly with pentane. The product, $Os(NO)(CO)Cl(PPh_3)_2$, was characterized by its IR spectrum, which was in good agreement with the literature [5].

$Os(N(O)H)(CO)Cl_2(PPh_3)_2$ (**1**) was formed by the reaction of $Os(NO)(CO)Cl(PPh_3)_2$ with gaseous HCl. The synthesis and isolation followed the general method of Wilson and Ibers [5]. To produce gaseous HCl, H_2SO_4 was added to NaCl. In the glovebox, crystals of $Os(NO)(CO)Cl(PPh_3)_2$ (~50 mg) were partially dissolved in dry, deaerated benzene (4 mL) in a test tube with a stir bar. This test tube was placed in a 500 mL three-neck round-bottom flask. HCl gas was flushed through the flask while the benzene solution was stirred. It was then allowed to stand for ~15 min, and then the whole system was flushed with N_2. The flask was then disconnected from the HCl set-up, brought into the glovebox, and allowed to stand for an hour to let the particles settle. The benzene solution was transferred into a separate test tube, leaving behind a yellow/orange powder. Dry, degassed pentane (50 mL) was allowed to slowly effuse into the benzene solution, producing red crystals. The product was characterized by its IR spectrum ($\nu_{CO} = 1980\ cm^{-1}$ and $\nu_{NO} = 1415\ cm^{-1}$ in $CHCl_3$).

3. Results and discussion

The FTIR spectrum of $Os(N(O)H)(CO)Cl_2(PPh_3)_2$ (**1**) shows a strong ν_{CO} absorbance at 1980 cm^{-1}, as well as an absorbance at 1415 cm^{-1}, assigned to the ν_{NO} of coordinated HNO by comparison to the literature data [5]. The peaks at 1435 cm^{-1} and 1483 cm^{-1} are assigned to vibrational modes of the PPh_3 ligands since these peaks are observed for free PPh_3 and other PPh_3-containing osmium species. The UV–Vis spectrum of **1** in $CHCl_3$ shows an absorption maximum at 364 nm (Fig. S1).

3.1. Photochemical reactivity of $Os(N(O)H)(CO)Cl_2(PPh_3)_2$ under nitrogen

When a solution of **1** in $CHCl_3$ under nitrogen was subjected to continuous photolysis at 365 nm, the FTIR absorbance changes shown in Fig. 1 were observed. The peaks at 1415 cm^{-1} and 1980 cm^{-1} decreased in intensity, while a new band grew in at 1925 cm^{-1}. The bands at 1435 cm^{-1} and 1483 cm^{-1} attributed to PPh_3 were nearly unchanged

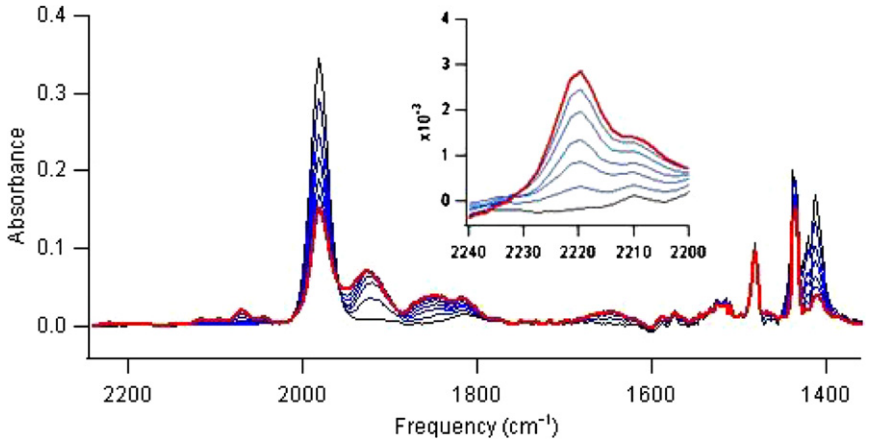

Fig. 1. Infrared spectral changes observed upon 365 nm continuous photolysis of a $CHCl_3$ solution of **1** under nitrogen. The total time of photolysis between the first and last spectrum was 30 min. The spectrum of **1** before photolysis is shown in black. The final spectrum is shown in red. Inset: an enlargement of the spectral region 2200–2240 cm^{-1} showing the growth of a peak indicating the formation of N_2O. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

by photolysis. The spectral changes at other frequencies are consistent with photochemical loss of HNO. The decrease in intensity of the bands at 1415 cm^{-1} and 1980 cm^{-1} indicates disappearance of **1**, while the growth of a peak at 1925 cm^{-1} suggests that the product of the photochemical reaction contains a carbonyl ligand. A weak peak was also observed to grow in at 2220 cm^{-1} (inset in Fig. 1), consistent with the appearance of N_2O, which is known to form rapidly from HNO [11]. For comparison, an FTIR spectrum of N_2O-saturated $CHCl_3$ was obtained, and it displayed an analogous peak at the same frequency (2220 cm^{-1}) as the purported N_2O peaks observed in these photochemical studies (Fig. S2). To further confirm the photochemical production of N_2O, a solution of **1** in $CHCl_3$ was irradiated in an air-tight cuvette, and a small sample of this solution was withdrawn and analyzed by GC–MS. A peak with $m/z = 44$ (consistent with N_2O) was observed, overlapping with $m/z = 32$ (O_2) and $m/z = 28$ (N_2) peaks. (The sample had been exposed to air in the transfer and injection process.) The elution time matched well with an authentic sample of N_2O in $CHCl_3$, and this peak was absent in analogous samples not subjected to photolysis.

The disappearance of the HNO peak of **1**, the observation of N_2O formation and the appearance of a new peak attributed to a metal–carbonyl stretch all point to the possible operation of a primary photoreaction involving dissociation of **1** to HNO plus $Os(CO)Cl_2(PPh_3)_2$. A five-coordinate species $OsCl_2(PPh_3)_3$ similar to the proposed osmium product has been reported [15]. The photochemically released HNO would form N_2O through the known dimerization pathway, although a competing pathway might be the reaction of HNO with **1** considering that this is present in greater concentration.

In addition to the peaks attributed to N_2O and the osmium carbonyl product, a broad absorption centered at ~1840 cm^{-1} appeared, possibly due to the ν_{NO} stretching vibration of a linear nitrosyl, and weak peaks appeared above 2000 cm^{-1}, which is an appropriate range for metal-hydride or carbonyl stretches.

Longer term (2 h) photolysis demonstrated that the initial species formed are themselves subject to secondary photolysis (Fig. 2). After 30 min (blue spectrum in Fig. 2), **1** was nearly depleted, as indicated by the relatively small absorbance at 1415 cm^{-1}, and the largest product peak appeared at 1925 cm^{-1}. Upon further photolysis (red spectrum in Fig. 2), the peak at 1925 cm^{-1} decreased in intensity, while peaks grew in at 1973 cm^{-1} and 2040 cm^{-1}. The latter are consistent with the formation of $Os(CO)_2Cl_2(PPh_3)_2$ (**2**), the infrared spectrum of which has been reported [16]. After 60 min of photolysis, the peak at 1415 cm^{-1} is gone, and the peak at 2220 cm^{-1} has stopped growing. Thus appearance of N_2O correlates well with the disappearance of **1**.

3.2. Thermal reactivity of *1* under nitrogen

A portion of the solution of **1** used for photolysis experiments was stored under nitrogen in the dark at room temperature for ~3 h (the duration of the photolysis experiments). During this time, no significant decomposition of **1** occurred, as indicated by the lack of spectral changes (Fig. S3).

3.3. Photochemical reactivity of *1* under CO

When a solution of **1** in $CHCl_3$ was equilibrated with 1 atm CO and subjected to 365 nm irradiation, the major products were **2** and N_2O, according to the changes in the FTIR spectrum (Fig. 3). The evidence for the formation of N_2O is the growth of the peak at 2220 cm^{-1}, coinciding with the disappearance of the peak at 1415 cm^{-1} characteristic of **1**. At the same time, peaks at 2043 cm^{-1} and ~1975 cm^{-1}, corresponding to $Os(CO)_2Cl_2(PPh_3)_2$ [16],

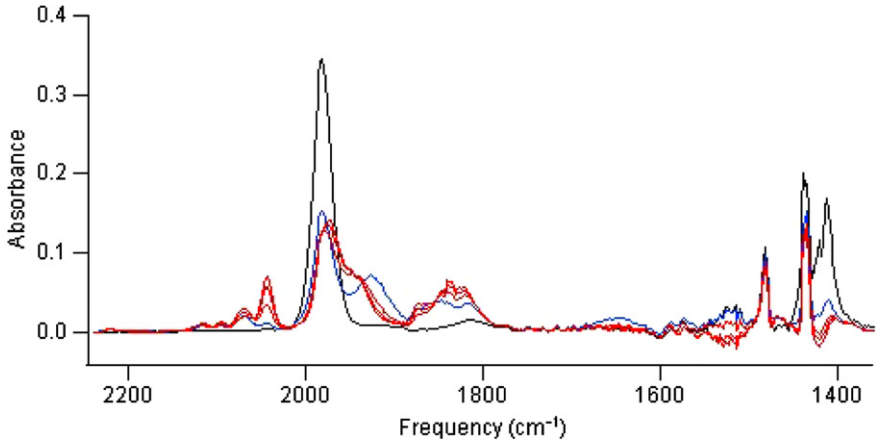

Fig. 2. Spectral changes observed when a $CHCl_3$ solution of **1** under nitrogen in an IR cell was subjected to 365 nm photolysis. Spectra were obtained every 30 min, and the total time of photolysis between the first and last spectrum was 2 h. The spectrum before photolysis is shown in black. The spectrum after 30 min of photolysis is shown in blue. The spectra after 60, 90, and 120 min of photolysis are shown in red. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

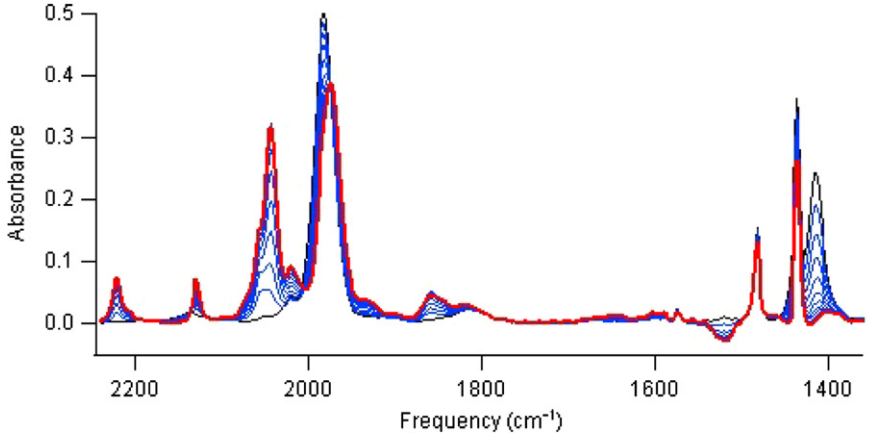

Fig. 3. Infrared spectral changes observed upon 365 nm continuous photolysis of a $CHCl_3$ solution of **1** under ~1 atm CO. The total time of photolysis between the first and last spectrum was 60 min. The initial spectrum is shown in black. The final spectrum is shown in red. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

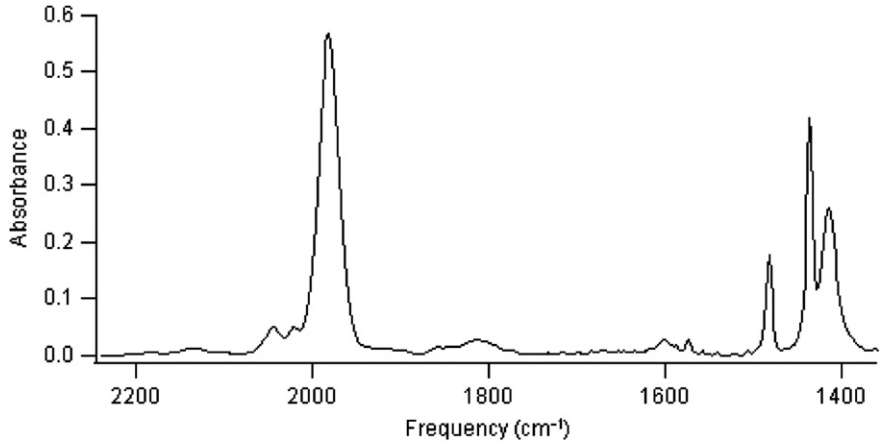
appeared. (The band at 1975 cm^{-1} overlaps with the starting material's strong absorbance at 1980 cm^{-1}, but its presence can be inferred from the fact that the peak at 1980 cm^{-1}, which is stronger than the peak at 1415 cm^{-1}, does not decrease in intensity as quickly as the latter. Also, the final spectrum obtained after exhaustive photolysis clearly shows a peak at 1975 cm^{-1}.) In addition to peaks corresponding to N_2O and **2**, weaker peaks appeared in the 1800–1900 cm^{-1} range and in the 2000–2150 cm^{-1} range, as was observed in reactions under dinitrogen.

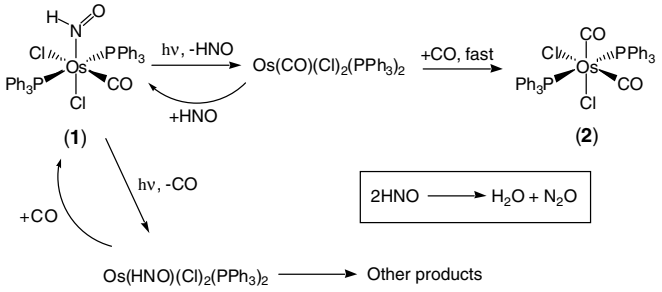
3.4. Thermal reactivity of *1* under CO

A portion of the same sample of **1**, equilibrated under 1 atm CO, was allowed to sit in the dark for 80 min, the result being the modest spectral changes shown in Fig. 4. Consistent with the literature reports [8], a small amount of **2** was formed, as indicated by the peak at 2040 cm^{-1}. However, $Os(CO)_2Cl_2(PPh_3)_2$ is formed much faster under irradiation than in the dark. After 60 min of photolysis, **2** was the major product and **1** was almost completely gone, but under analogous conditions in the dark, very little conversion of **1** to **2** took place in a similar time frame.

The accelerated formation of N_2O and $Os(CO)_2Cl_2(PPh_3)_2$ is further evidence that HNO is photochemically liberated from **1**. The dicarbonyl **2** should be formed more rapidly by reaction of CO with the five-coordinate HNO-loss photoreaction intermediate $Os(CO)Cl_2(PPh_3)_2$ than by direct reaction of CO with **1**, the mechanism of which is unknown. The likely pathway is irradiation-induced HNO labilization followed by trapping of the resulting five-coordinate osmium intermediate, as depicted in Scheme 1. The additional FTIR absorbances that appear at 1840 cm^{-1} and in the 2000–2100 cm^{-1} range suggest that other products are formed under photochemical conditions, very likely as the result of CO photodissociation.

The observation that the relative product yields varied with reaction conditions is consistent with this model.





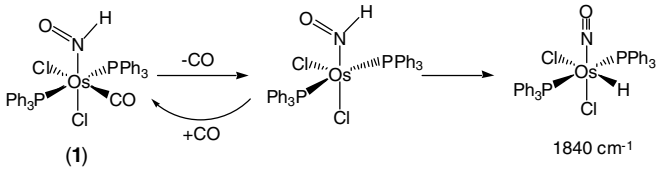


Fig. 4. Infrared spectrum of a sample of **1** under ~1 atm CO after 80 min reaction in the dark at room temperature.

Scheme 1.

The yield of N_2O relative to the amount of **1** consumed is significantly greater under CO than under N_2, as shown in Fig. 5, where the concentration of N_2O generated is plotted against the concentration of **1**. The yield of N_2O relative to disappearance of **1** is given by the negative of the slope of this line. Under N_2, the yield is 0.012, whereas under CO, it is 0.14, more than an order of magnitude larger. (Note that since two HNO are necessary to generate N_2O, the latter number implies that at least 28% of **1** decayed to give nitrous oxide under these conditions. This analysis, however, does not account for other possible fates of nitroxyl.)

According to Scheme 1, the presence of excess CO in the system would affect the net photochemistry in two ways. First, CO could back-react with the five-coordinate intermediate, $Os(N(O)H)Cl_2(PPh_3)_2$, to re-form **1**, thus reducing the net photochemistry along the CO-loss pathway. This would increase the relative importance of the HNO-loss pathway, thus increasing the yield of N_2O relative to disappearance of **1**. The second impact of solution CO would be to trap the HNO-loss photoreaction intermediate, $Os(CO)Cl_2(PPh_3)_2$, to form **2**. This would minimize

Scheme 2.

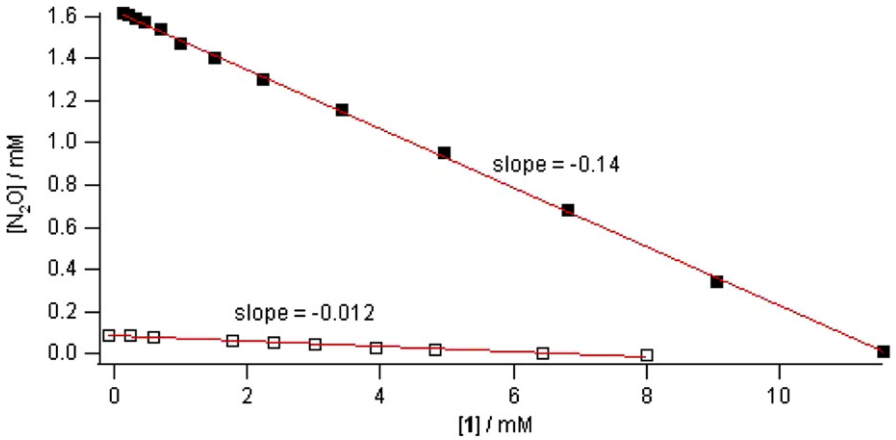

Fig. 5. Molar concentration of N_2O vs. molar concentration of **1**, calculated from the data shown in Figs. 1 and 3. Open squares represent data collected when samples of **1** were irradiated under N_2. Filled squares represent data collected when samples of **1** were irradiated under CO.

back reaction of $Os(CO)Cl_2(PPh_3)_2$ with the HNO generated, thus allowing the latter to react along the N_2O formation pathway. In either case, Scheme 2 predicts that the presence of CO will increase the yield of N_2O relative to depletion of **1**, as was observed. Notably, the reaction of HNO with a metal center to form an HNO complex has a precedent in the reported trapping of nitroxyl with deoxymyoglobin [5].

Although net quantum yields were not measured for this system, the first scenario would lead to a decrease in the overall rate of conversion of **1** to the products, while the second would lead to an increased rate *if* the experiments with and without added CO were carried out under analogous conditions of light intensity, etc. The qualitative experiments illustrated in Fig. S4 show that there is no great difference in the photoinduced decay of **1** regardless of whether or not CO is present although that there was a modest *increase* under CO. In the context of Scheme 1 and the data presented in Fig. 5, this would imply that the major pathway(s) for the depletion of **1** is relatively unaffected by CO but that the pathway generating N_2O is strongly enhanced. Thus, if CO photodissociation is followed by an irreversible unimolecular reaction leading to rapid depletion of the initially formed intermediate $Os(N(O)H)Cl_2(PPh_3)_2$, then the effect of CO on the CO-loss pathway may be small while trapping of $Os(CO)Cl_2(PPh_3)_2$ to form **2**, would enhance the formation of N_2O by inhibiting the back reaction of HNO with that unsaturated intermediate.

What might be a fast irreversible pathway depleting the intermediate $Os(N(O)H)Cl_2(PPh_3)_2$ of the CO-loss pathway? Although the ''other products'' observed were not conclusively elucidated, the appearance of an IR band at 1840 cm^{-1} (Fig. 1) is consistent with the formation of linearly coordinated NO. Furthermore, the absence of a corresponding carbonyl stretch for this species suggests that it was formed via the CO-loss pathway. Hydride migration from the N-coordinated HNO to the vacant coordination site left by CO would give the nitrosyl hydride complex $Os(NO)(H)Cl_2(PPh_3)_2$, as proposed in Scheme 2. An analogous compound, $Os(NO)(H)(O_2CCF_3)_2(PPh_3)_2$, has been reported to have $\nu_{NO} = 1820\ cm^{-1}$ [17], a value similar to that observed in this work (1840 cm^{-1}). While it might be expected that the formation of the nitrosyl product would be inhibited by excess CO owing to back reaction of the intermediate to reform **1**, the effect on the 1840 cm^{-1} band was relatively modest even when the photolysis is carried out under a CO atmosphere. This would be consistent with the unimolecular decay of the intermediate $Os(N(O)H)Cl_2(PPh_3)_2$ (via hydride migration?) being sufficiently fast to compete with the bimolecular back-reaction under the conditions of this study.

4. Summary

Studies of the photochemical and thermal reactivity of **1** indicate that HNO is photochemically liberated from **1**. This conclusion is supported by the detection of N_2O, the product of HNO dimerization, as well as by the spectral characterization of the organometallic products and comparison of reactivities under various conditions. A model for the overall thermal and photochemical reactivity of **1** in $CHCl_3$ is presented in Scheme 1.

2. Experimental

2.1. Synthesis

All chemicals were purchased and were used as received. *cis*-[Ru(NO)(CH_3O)(pyca)$_2$], *trans*-[Ru(NO)(CH_3O)(pyca)$_2$]-[30], and *cis*-[Ru(NO)(H_2O)(pyca)$_2$]ClO_4 [31] were prepared according to the methods in the literature.

2.1.1. *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4

A suspension of *cis*-[Ru(NO)(H_2O)(pyca)$_2$]ClO_4 (100 mg, 0.20 mmol) in CH_3CN (20 cm^3) was refluxed for 7 h to give a yellow solution. This yellow solution was concentrated to 5 cm^3 using a rotary evaporator, and diethyl ether (2 cm^3) was added to give a yellow precipitate. The product was collected by filtration, washed with diethyl ether and dried in vacuum. Yield: 78 mg (75%). *Anal.* Calc. for $C_{14}H_{11}N_4O_9ClRu$: C, 32.60; H, 2.15; N, 10.86. Found: C, 32.70; H, 2.16; N, 10.68%. IR ν(NO) = 1899 cm^{-1}. ^1H NMR (CD_3CN): δ 2.54 (3H, s, CH_3), 8.00 (1H, t, 5-py), 8.02 (1H, t, 5-py), 8.26 (2H, d, 3-py), 8.40 (1H, t, 4-py), 8.48 (1H, t, 4-py), 8.79 (1H, d, 6-py), 8.87 (1H, d, 6-py). ^{13}C NMR (CD_3CN): δ 118.4 (–CN), 129.5(5-py), 129.6 (5-py), 131.2(3-py), 131.8(3-py), 144.2(4-py), 145.2(4-py), 149.8(6-py), 150.6(6-py), 152.8(2-py), 153.0(2-py), 170.1 (–COO–), 172.2(–COO–).

2.1.2. *trans*-[Ru(NO)(OH)(pyca)$_2$]

$RuCl_3 \cdot nH_2O$ (content of Ru: 41%) (200 mg, 0.81 mmol) and Hpyca (200 mg, 1.62 mmol) were dissolved in C_2H_5OH (50 cm^3). The solution was refluxed for 3 h to give a yellow solution. After 1 day standing and removal of the yellow solid, $(C_2H_5)_4NCl$ (200 mg, 1.21 mmol) was added to the yellow solution to give a yellow solid. The yellow solid, whose main constituent was $(C_2H_5)_4N$[$RuCl_2$(pyca)$_2$], was collected by filtration. Yield: 118 mg (28%). The collected solid, $(C_2H_5)_4N$[$RuCl_2$(pyca)$_2$] (100 mg, 0.18 mmol), was added to an aqueous solution (30 cm^3) of pH 6.22 containing $NaNO_2$ (500 mg, 7.25 mmol). The resultant solution of pH 8.38 was refluxed for 10 h, and then concentrated to dryness using a rotary evaporator to give a yellow solid. This yellow solid was dissolved in CH_3CN (10 cm^3) and the resulted solution was filtrated to remove insoluble matters. The solution was concentrated and allowed to stand till a yellow solid appeared. The product was collected by filtration, washed with diethyl ether and dried in vacuum. Yield: 53 mg (75%). *Anal.* Calc. for $C_{12}H_9N_3O_6Ru$: C, 36.74; H, 2.31; N, 10.71. Found: C, 36.90; H, 2.24; N, 11.05%. IR ν(NO) = 1852 cm^{-1}. ^1H NMR (D_2O): δ 2.07 (1H, s, OH), 8.04 (2H, t, 5-py), 8.30 (2H, t, 4-py), 8.46 (2H, d, 3-py), 8.85 (2H, d, 6-py). ^{13}C NMR (D_2O): δ 128.6 (3-py), 130.8 (5-py), 143.8 (4-py), 149.7 (6-py), 151.1 (2-py), 175.2($-COO^-$).

2.2. Physical measurements

IR spectra were recorded on a Perkin–Elmer FT-1650 FTIR spectrophotometer using samples prepared as KBr disks. Elemental analyses were performed by the Sophia University Analytical Facility. ^1H NMR and ^{13}C NMR spectra were obtained with a JEOL JML-LA500 spectrometer.

2.3. X-ray crystallography

Single crystals of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 and *trans*-[Ru(NO)(OH)(pyca)$_2$] were obtained by recrystallization from the acetonitrile solutions and then vapor diffusion of ether into those solutions. The intensity data were collected on a Rigaku Mercury CCD diffractometer, using graphic monochromatized Mo Kα radiation (0.71069 Å). All the calculations were carried out using the Crystal Structure software package [34]. Structures were solved by a direct method, expanded using Fourier techniques and refined using full-matrix least-squares techniques.

2.4. Electrochemical measurements and reduction of ruthenium complexes

Cyclic voltammograms (CVs), normal pulse voltammograms (NPVs), and differential pulse voltammograms (DPVs) of nitrosylruthenium complexes (1.00 mmol dm^{-3}) were made on acetonitrile or dimethylformamide solutions containing 0.1 mol dm^{-3} tetraethylammonium perchlorate, TEAP (Nakarai Tesque. Ltd.), as supporting electrolyte, or on methanol solutions containing 0.1 mol dm^{-3} tetra(*n*-butyl)ammonium hexafluorophosphate, TBAH, (Nakarai Tesque. Ltd.) as supporting electrolyte, with a platinum disk working electrode (ϕ = 1.6 mm) and an Ag|0.01 mol dm^{-3} $AgNO_3$ reference electrode using a BAS 100B/W electrochemical analyzer. Hydrodynamic voltammograms (HDVs) were made with a rotating platinum disk working electrode (ϕ = 3.0 mm) using a BAS RDE-2 rotating electrode. At the end of each measurement, ferrocene was added as an internal standard to correct redox potentials.

Electrochemical reduction of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 and *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] in CH_3CN containing 0.1 mol dm^{-3} TEAP and in CH_3OH–CH_3CN (1:4, v/v) containing 0.1 mol dm^{-3} TBAH were performed by the controlled potential electrolysis (CPE) technique. CPE was carried out in a three-compartment cell with a platinum gauze working electrode in the first-compartment, an auxiliary electrode in the second-compartment, and an reference electrode in the third-compartment using a Huso polarograph Model 312 and 343B digital coulometer. After the electrolyses, changes of the reduced species were monitored by CV and HDV.

2.4.1. Isolation of ruthenium complexes from the electrolyzed solution

The CPE experiments of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] in CH_3CN–CH_3OH (1:4, v/v) containing 0.1 mol dm^{-3} TBAH was performed at the potential of the first reduction

wave (−0.9 V). The CPE consumed 0.05 mol of electrons per mole of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$]. The volume of the electrolyzed solution was reduced by solvent evaporation. The solid material was recrystallized from CH_2Cl_2 and ether for several times. The ruthenium complex was obtained in 65% yield. IR (in CH_3CN) ν(NO) = 1843 cm^{-1}. $E_{1/2} = -1.12$, $E_{pa} = -1.71$ V.

3. Results

3.1. Syntheses and characterization

cis-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 was synthesized by a simple substitution reaction of the H_2O ligand of *cis*-[Ru(NO)(H_2O)(pyca)$_2$]ClO_4 with a CH_3CN solvent under refluxing conditions. *trans*-[Ru(NO)(OH)(pyca)$_2$] was formed by a reaction of *cis*-[$Ru^{III}Cl_2$(pyca)$_2$]$^-$ with NO_2^- in H_2O. The pH value of the reaction mixture changed from 6.22 to 8.38 during this reaction.

Wave numbers of the characteristic N–O stretching mode (ν(NO)) and redox potentials based on reductions of the $(RuNO)^{3+}$ moiety of synthesized and related nitrosylruthenium complexes are presented in Table 1. Each nitrosylruthenium complex having pyca ligands shows a strong NO stretching vibration in the range of 1838–1940 cm^{-1} and CO stretching vibrations(s) of the pyca ligand(s) in 1650–1700 cm^{-1}. Two reduction potentials of the present and previous nitrosyl ruthenium complexes, which can be assigned to the ligand-based reductions of the (RuNO) moiety, $(RuNO)^{3+/2+}$ and $(RuNO)^{2+/+}$, respectively, are summarized in Table 1. The observed values of wave number of the ν(NO) band and redox potetials of the (RuNO) moiety are reasonable, compared with those of similar nitrosylruthenium complexes previously reported [8–33].

In ^{1}H NMR spectra of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 and *trans*-[Ru(NO)(OH)(pyca)$_2$], proton signals of the pyca ligands were clearly obtained in the normal aromatic region, indicating these nitrosyl complexes had the diamagnetic property. A ^{1}H NMR spectrum of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 showed 8 signals assignable to the methyl group of the acetonitrile ligand and pyridyl protons of the pyca ligands, and the ^{13}C NMR spectrum 14 signals to two carbon atoms of the acetonitrile ligand and 10 of the pyridyl and two of the carboxylate groups of the pyca ligands. These spectra revealed the two pyca ligands were unequivalent to each other and, thus, coordinates in a *cis*-form. A ^{1}H NMR spectrum of *trans*-[Ru(NO)(OH)(pyca)$_2$] showed 5 signals assignable to a hydroxy and pyridyl protons of the hydroxo and the pyca ligands, and a ^{13}C NMR one 6 signals to five of the pyridyl and one carboxylate groups of the pyca ligands. The simpler spectral profile indicated two pyca ligands of *trans*-[Ru(NO)(OH)(pyca)$_2$] symmetrically coordinated to the metal center in a *trans*-form.

3.2. Crystal structures

The crystallographic data are summarized in Table 2. The selected bond distances and angles are summarized in Table 3. *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 and *trans*-[Ru(NO)(OH)(pyca)$_2$] show pseudo-octahedral coordination with three nitrogen atoms of the nitrosyl and two pyca ligands, two oxygen atoms of two pyca ligands, and one nitrogen of the acetonitrile ligand or one oxygen of the hydroxo ligand, as shown in Figs. 1 and 2.

The geometries around the ruthenium center of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 and *trans*-[Ru(NO)(OH)(pyca)$_2$] are consistent with the results of NMR spectroscopy. The nitrosyl ligands are essentially linearly coordinated to the ruthenium centers with Ru–N–O angles 173.4(2) and 171.1(2)°. The Ru–N and N–O bond lengths, 1.759(2) and 1.124(4) Å for *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 and 1.766(2) and 1.153(2) Å for *trans*-[Ru(NO)(OH)(pyca)$_2$], of the (RuNO) moieties are similar to those of previously reported {RuNO}^{6}-type complexes [8–20,30,31]. The Ru–N(pyca) bond lengths, 2.078(2) and 2.062(2) Å of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 and 2.076(1) and 2.059(1) Å of *trans*-[Ru(NO)(OH)(pyca)$_2$] are similar to each other. The Ru–O(pyca) bond lengths

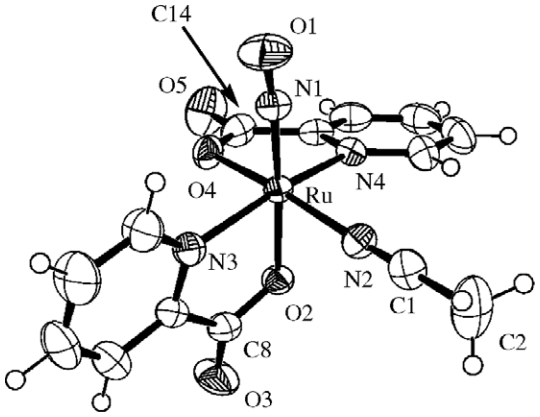

Fig. 1. Structure of *cis*-[Ru(NO)(CH_3CN)($pyca)_2$]$^+$.

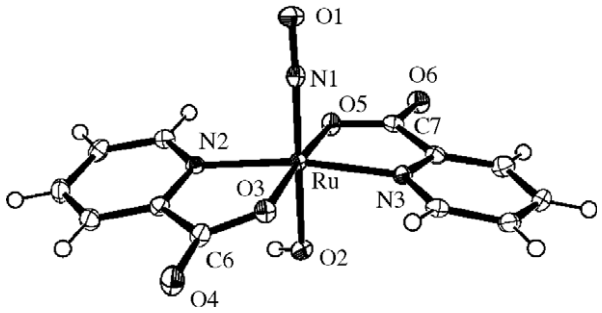

Fig. 2. Structure of *trans*-[Ru(NO)(OH)($pyca)_2$].

[Ru(NO)(CH_3CN)($pyca)_2$]ClO_4 and 1.293(2) and 1.296(2) Å of *trans*-[Ru(NO)(OH)($pyca)_2$], are found between the carboxylate carbon atoms and the oxygen atoms that coordinate to the ruthenium center, and the shorter bond lengths, 1.198(4) and 1.201(3) Å and 1.223(2) and 1.224(2) Å, between the carbon atoms and the non-coordinating ones. The difference in the bond length between the two for *cis*-[Ru(NO)(CH_3CN)($pyca)_2$]-ClO_4, 0.12 Å, is bigger than that for *trans*-[Ru(NO)(OH)-($pyca)_2$], 0.07 Å, while the O–C–O angles are not significantly different between the two.

3.3. Electrochemical properties

Electrochemical properties of this series of nitrosylruthenium complexes having two pyca ligands were studied by cyclic and normal pulse voltammetry. Redox potentials of two new complexes and related complexes are shown in Table 1. CVs of *cis*-[Ru(NO)(CH_3CN)($pyca)_2$]ClO_4 and *trans*-[Ru(NO)(OH)($pyca)_2$] in CH_3CN are shown in Fig. 3. CVs of all the complexes in Table 1 showed a reversible redox couple and an irreversible reduction wave in the potential window of CH_3CN or DMF. The profiles of these CVs were similar to those of {RuNO}^{6}-type complexes. The reversible redox couples of all the complexes were of Nernstian one-electron process, confirmed by the ratio of I_{pa} and I_{pc} of the CVs (the dotted lines in Fig. 3) and the analysis of NPVs.

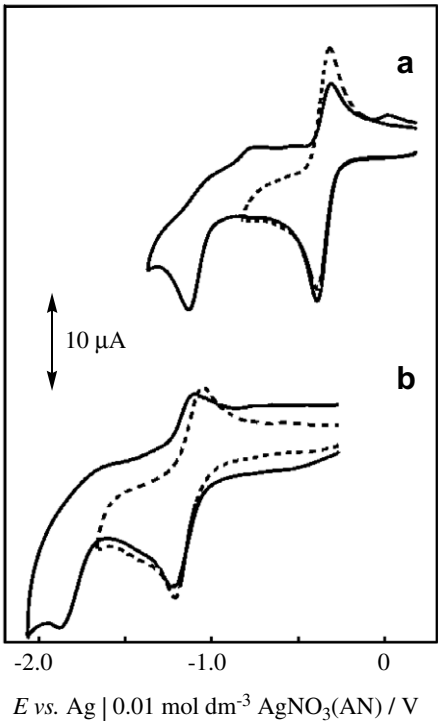

Fig. 3. Cyclic voltammograms in CH_3CN containing 0.10 mol dm^{-3} TEAP at 25 °C (scan rate = 200 mV s^{-1}); (a) *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4, and (b) *trans*-[Ru(NO)(OH)(pyca)$_2$].

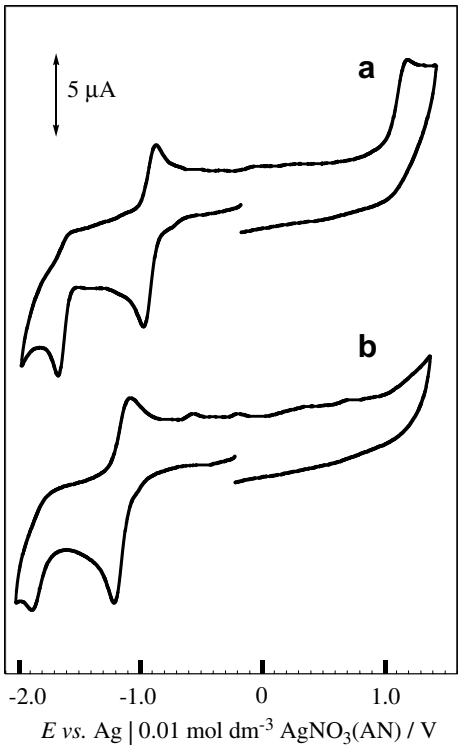

Fig. 4. Cyclic voltammograms in CH_3CN containing 0.10 mol dm^{-3} TEAP (scan rate = 200 mV s^{-1}); (a) *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] and (b) *trans*-[Ru(NO)(CH_3O)(pyca)$_2$].

3.4. Electrochemical reductions based on (RuNO)-moiety

Electrochemical reductions of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4, *cis*-[Ru(NO)(CH_3O)(pyca)$_2$], and *trans*-[Ru(NO)(CH_3O)(pyca)$_2$] were performed by CPE to determine the number of electrons that participated in a redox reaction and to observe the reaction that followed. CVs of *cis*- and *trans*-[Ru(NO)(CH_3O)(pyca)$_2$] are shown in Fig. 4a and b, respectively.

The CPE for these nitrosylruthenium complexes in CH_3CN containing 0.1 mol dm^{-3} TEAP were performed at the potential of the first reduction wave, −0.40, −1.00, and −1.15 V for *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4, *cis*-[Ru(NO)(CH_3O)(pyca)$_2$], and *trans*-[Ru(NO)(CH_3O)(pyca)$_2$], respectively. The number of electrons was determined by the relation of the change in wave height of HDV (a diffusion current) with the quantity of electricity consumed during electrolysis. The results revealed these waves corresponded to one-electron reduction processes. For the oxidation wave of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] shown in Fig. 4a, the result of the CPE at 1.50 V revealed the number of electrons was 1.0. The reduction products of *cis*- and *trans*-[Ru(NO)(CH_3O)(pyca)$_2$] in CH_3CN at 25 °C were both stable during the experiments of the CPE at −1.10 V, where the number of electrons was 1.0. Profiles of the first waves of the CVs for *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] in CH_3CN and CH_3OH–CH_3CN (1:4, v/v) are different as shown in Figs. 5a and b. The first wave in CH_3CN was observed as a reversible couple at $E_{1/2} = -0.90$ V,

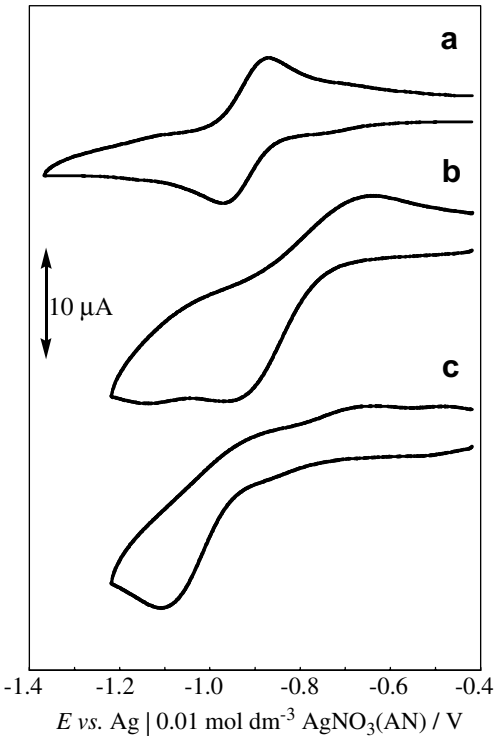

Fig. 5. Cyclic voltammograms of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$]: (a) in CH_3CN, (b) in CH_3OH–CH_3CN (1:4, v/v) before the electrolysis, and (c) after the electrolysis.

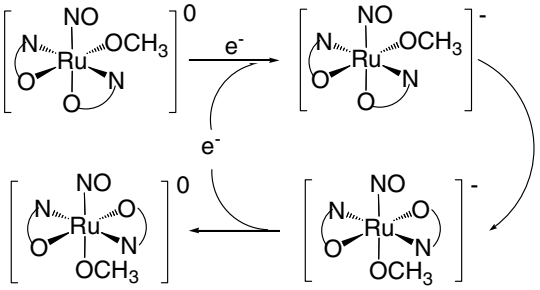
while that in CH_3OH–CH_3CN as a quasi-reversible one ($E_{pc} = -0.91$ V) and a small wave appeared in the negative potential region ($E_{pc} = -1.11$ V). The CPE in CH_3OH–CH_3CN at −0.95 V was performed at 25 °C until 0.1 mol of electrons were added per mole of *cis*-[Ru(NO)(CH_3O)-(pyca)$_2$]. The first reduction wave of *cis*-[Ru(NO)(CH_3O)-(pyca)$_2$] at −0.91 V decreased and a new wave at −1.1 V appeared as shown in Fig. 5c.

The reaction product was isolated from the electrolyzed solution in 65% yields as a solid under atmosphere. The isolated ruthenium complex showed ν(NO) at 1843 cm^{-1} in CH_3CN solution and a reversible and irreversible reduction waves at −1.12 and −1.71 V, respectively. Thus, the isolated complex was identified as *trans*-[Ru(CH_3O)-(NO)(pyca)].

4. Discussion

Synthesis of *trans*-[Ru(NO)(OH)(pyca)$_2$] was carried out by using $RuCl_3 \cdot nH_2O$ as a starting material with a pyca ligand in C_2H_5OH under refluxing conditions to afford *cis*-[$Ru^{III}Cl_2$(pyca)$_2$]$^-$, and $NaNO_2$ was used as a nitorsylating and reducing agent in H_2O. The formation reaction of the nitrosyl complex did not proceed only in alcohol such as CH_3OH and C_2H_5OH, because the nitrosylation reaction using the nitrite ion is known to require protic conditions [33]. The geometry around the ruthenium center changed from the *cis*-form to the *trans*-form during the reaction. This geometrical change is explained by the stability of the *trans*-form due to coordination of a strong π-accepter nitrosyl and a π-donor hydroxo ligands in the *trans* position as the same way described in the previous report [30]. The values of ν(NO), the CV profiles showing two one-electron reduction waves in CH_3CN, and the linearly coordinated nitrosyl ligand of *cis*-[Ru(NO)(CH_3CN)-(pyca)$_2$]ClO_4 and *trans*-[Ru(NO)(CH_3O)(pyca)$_2$] indicate that these nitrosyl complexes are classified into the {RuNO}^{6} configuration. The ν(NO) and reduction waves (ν(NO) = 1899 cm^{-1}, $E_{1/2} = -0.35$ V and $E_{pc} = -1.13$ V) of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 were, respectively, observed at a higher wave number and in a higher potential region than those of *trans*-[Ru(NO)(OH)(pyca)$_2$] (ν(NO) = 1852 cm^{-1}, $E_{1/2} = -1.13$ V and $E_{pc} = -1.86$ V). These results indicate that the hydroxo ligand of *trans*-[Ru(NO)(OH)(pyca)$_2$] functions as an electronic donating group and the acetonitrile of *cis*-[Ru(NO)(CH_3CN)-(pyca)$_2$]ClO_4 as an electronic accepting group.



The nitrosyl ligand linearly coordinates to the ruthenium center as would be expected from the results of IR spectroscopy and cyclic voltammetry. The effect of the nitrosyl ligand on the structural parameters of the pyca ligands is observed. The shorter Ru–O(pyca) bond lengths of *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4 than those of *trans*-[Ru(NO)(OH)(pyca)$_2$] are explained by electronic difference between an electronic accepting acetonitrile ligand and an electronic donating hydroxo ligand. For *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]ClO_4, the Ru–O(pyca) bond length between the ruthenium center and the oxygen atom that in located at the *trans*-position toward the nitrosyl ligand is the shortest due to the strong nitrosyl *trans*-influence. The C–O bond lengths between the carboxylic carbon atom and oxygen atoms in the pyca ligands are also found to show a similar *trans*-influence owing to the existence of an electronic attracting group such as NO and CH_3CN. The lengths of the C–O bonds, where the oxygen atoms coordinate to the ruthenium center, are longer than those of the non-coordinating oxygen atom for *cis*-[Ru(NO)-(CH_3CN)(pyca)$_2$]ClO_4, indicating they are categorized as single and double bonds, respectively, while there is a less significant difference between those for *trans*-[Ru(NO)-(OH)(pyca)$_2$].

Cyclic voltammograms of nitrosylruthenium complexes in CH_3CN generally show a reversible and an irreversible wave that are based on reduction of (RuNO)-moiety as shown in:

$$(RuNO)^{3+} + e^- \rightleftarrows (RuNO)^{2+} \quad (1)$$

$$(RuNO)^{2+} + e^- \rightarrow (RuNO)^{+} \quad (2)$$

The first waves of all nitrosylruthenium complexes in Table 1 are confirmed to be reversible and of one-electron process by analyses of CVs and NPVs and the CPE at the peak potential of the first wave in CH_3CN. The reduction potential of a nitrosylruthenium complex is a good indicator of chemical reactivity of the nitrosyl ligands like the frequency of ν(NO), indicating both *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]-ClO_4 and *trans*-[Ru(NO)(OH)(pyca)$_2$] belong to the unreactive group. The CV profile of the *cis*-form shows an oxidation wave in CH_3CN, although such is rare. This irreversible oxidation wave is of a Ru(III)/Ru(II) one-electron oxidation process, which is confirmed by changing the diffusion current of the HDV during the CPE in CH_3CN [30]. On the other hand, electrochemical reduction behaviors of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] in CH_3CN are usual, showing one reversible and one irreversible wave in the normal potential region. The CPE in CH_3CN at −1.15 V reveals that the one-electron reduced complex, *cis*-[Ru(NO)(CH_3O)-(pyca)$_2$]$^-$, is stable within the experimental time, which is consistent with the CV profile. The one-electron reduced complex changes in CH_3OH–CH_3CN (1:4, v/v) within the CV's time scale as shown in Fig. 5b. In fact, the CV after the CPE in CH_3OH–CH_3CN at −0.95 V to generate the one-electron reduced complex shows only a wave at −1.10 V as shown in Fig. 5c. This wave is assigned to *trans*-[Ru(NO)(CH_3O)(pyca)$_2$] by addition of an authentic sample to the electrolyzed solution and confirmed by a DPV (Fig. S2). The formation of *trans*-[Ru(NO)(CH_3O)-(pyca)$_2$] is also confirmed by the CV and IR data for the isolated complex from the electrolyzed solution (Figs. S3 and S4). Thus, *trans*-[Ru(NO)(CH_3O)(pyca)$_2$]$^-$ is generated by an isomerization reaction of the one-electron reduced complex of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] in CH_3OH–CH_3CN. These results are interpreted by *cis–trans* geometrical isomerization accompanying the electochemical one-

Scheme 1. Possible mechanism for isomerization accompanying one-electron reduction of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] in CH_3OH–CH_3CN.

electron reduction of *cis*-[Ru(NO)(CH_3O)(pyca)$_2$] as shown in Scheme 1. The second electron transfer step is explained by potential difference between *cis*- and *trans*-[Ru(NO)-(CH_3O)(pyca)$_2$]. The reduction potential of the *cis*-complex is more positive than that of the *trans*-one. Thus, the *cis*-complex is easily reduced by the one-electron reduced form of the *trans*-one.

5. Conclusions

The bis(pyridinecaroboxylato)nitrosylruthenium complexes with a variety of coexisting ligands have been synthesized and characterized. Reactions of these nitrosyl complexes under basic aqueous conditions afforded the nitrosyl complex, $[\{Ru(NO)(pyca)_2\}(H_3O_2)]^+$, which had been characterized in the previous paper [31]. Thus, the nitrosyl ligand of these series of complexes can be classified into unreactive category. The stabilities of the nitrosyl complexes have been explained by considering the electronic interaction between ligands through the ruthenium center. The present *cis–trans* isomerization reaction of [Ru(NO)(CH_3O)(pyca)$_2$] via the one-electron reduction reaction is important for regulating the geometries of these complexes where the electronic interaction occurs between the nitrosyl ligand and other co-existing ligands. It is worthy to note that electrostatic change of the (RuNO)-moiety induces the geometrical isomerization reaction in connection with a photo-induced isomerization of the metal complexes having a nitrosyl ligand.

Appendix A. Supplementary material

CCDC 633232 and 633233 contain the supplementary crystallographic data for *cis*-[Ru(NO)(CH_3CN)(pyca)$_2$]-ClO_4 and *cis*-[Ru(NO)(CH_3O)(pyca)$_2$]. These data can be obtained free of charge via http://www.ccdc.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.04.018.

compounds have been described recently and their electronic structure elucidated [12–14], there is a lack concerning the investigation of capability of these compounds as NO-carrier, as well as about studies of the photochemical NO release. More recently, Siri and coworkers [15] have performed theoretical studies by exploring the reactivity of nitrosyl iron complexes of cyclam, and concluded that only the *cis* isomer is able to release NO, while the *trans*-[Fe(cyclam)(NO)Cl]Cl is stable under the same conditions, and can be further oxidized under oxygen atmosphere [15]. Aiming to understand the reactivity of the nitrosyl iron cyclam complexes concerning the NO release, this article presents a new synthetic route for the *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex, its characterization and a photochemical study.

2. Experimental

Doubly distilled water was used throughout. Cyclam (1,4,8,11-tetraazacyclotetradecane) was obtained from Aldrich and used without further purification. The *cis*-[Fe(cyclam)Cl_2]Cl complex was prepared according to the literature procedure [16].

2.1. Preparation of trans-[Fe(cyclam)(NO)Cl]Cl_2

The complex *trans*-[Fe(cyclam)(NO)Cl]Cl_2 was prepared by dissolving 0.100 g (0.263 mmol) of *cis*-[Fe(cyclam)Cl_2]Cl in 100 mL of water, under argon atmosphere. A nitric oxide gas flow was passed through the solution for 1 h. The solution was then rotary-evaporated to 2 mL, and the *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex was precipitated by the addition of 5 mL of ethanol and 10 mL of diethyl ether solution. Recrystallization of *trans*-[Fe(cyclam)-(NO)Cl]Cl_2 in aqueous solution yielded yellow crystals suitable for single crystal X-ray analysis. Crystal data and structure refinement for this complex are summarized in Table 1. The IR spectrum obtained for both crystalline and powder isolated materials in different solvents medium is identical. Elemental analysis: Calc.: C, 30.6; H, 5.1; N, 17.8. Found: C, 30.5; H, 5.0; N, 17.5%.

The characterization of *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex was carried out by electrochemical techniques, electronic UV–Vis and infrared spectroscopy and X-ray crystallography.

2.2. Quantum yield

Quantum yield was determined from initial spectral changes and was plotted versus reaction percentage and extrapolated back to 0% reaction to minimize inner filter effects. The reported quantum yield is the average of, at least, three independent experiments.

2.3. Apparatus

Single crystals were used for data collection and cell parameter determination on an Enraf–Nonius Kappa-CCD diffractometer, using Mo Kα radiation ($k = 0.71073$ Å). Data collection was made by using the COLLECT program [17]; integration and scaling of the reflections were performed with the HKL Denzo-Scalepack system of programs [18]. Absorption corrections were carried out by using the multi-scan method [19]. The structure was solved by direct methods with SHELXS-97 [20]. The models were refined by full-matrix least-squares on F^2 with SHELXL-97 [20]. All the hydrogen atoms were stereochemically positioned and refined with the riding model [21].

[a] Data collection, data processing, structure solution and structure refinement respectively.

Electrochemical experiments were performed with an electrochemical analyzer BAS 100W from Bioanalytical Systems at 25.0 ± 0.2 °C. These were generally performed on millimolar solutions of the complexes in 0.10 M CF_3CO_2Na (pH 7.0) aqueous solution by using a conventional three-electrode glass cell with a glassy carbon (ca. 0.13 cm^2 of geometrical area) and Pt foil and Ag/AgCl as the working, auxiliary and reference electrodes, respectively. The electrochemical experiments were performed at room temperature. The reversibility of the electrochemical processes was checked by the linearity of the peak

height for the reduction process as a function of the square root of the scan rate, and the separation between the anodic (E_a) and cathodic potential peaks in the range of 50–80 mV at 25 °C [22]. Elemental analyses were performed with a Perkin–Elmer CHN 2400 analyzer. Electronic spectra were acquired with a HP-8453 diode-array spectrophotometer. IR spectra were obtained in KBr pellets with a Shimadzu IR Prestige-21 spectrophotometer. Monochromatic irradiation at 330 nm was carried out using an Oriel 200-W universal arc lamp source in model 68805. The irradiation wavelength was selected with an Oriel interference filter for photolysis at the appropriate wavelength. The interference filter had an average band pass of 10 nm and the collimated beam intensities ranged from 4×10^{-8} to 1×10^{-9} einstein^{-1} cm^{-2} as determined by ferrioxalate actinometry. The progress of the photoreactions was monitored spectrophotometrically with an HP-8453 diode-array spectrophotometer.

3. Results and discussion

The infrared spectrum of the title complex showed peaks in the range 3190–2856 cm^{-1} that are characteristic of νNH and those in the range 1460–1430 cm^{-1} characteristic of νCH and νCN stretching modes of the cyclam ligand [23,24]. The geometrical configuration assignments are based on the IR fingerprint pattern. Indeed, the IR spectra, in the 800–900 cm^{-1} region, are characteristic of the conformation of the cyclam ligand and can define the coordination scheme of the central metal ion [25,26]. The complexes in the *trans* configuration showed two groups of peaks separated by 80 cm^{-1}. The main peak at lower wavenumber that appears close to 811 cm^{-1} is due to the methylene group, while the absorption peaks close to 891 cm^{-1} can be attributed to the secondary amine vibrations [15]. Also, the IR spectrum exhibits a strong peak at 1888 cm^{-1} assigned to the νNO, which is consistent with the presence of nitrosyl group in the NO^+, $\{FeNO\}^6$ oxidation form [14,27]. The presence of the nitrosyl group in linear form (NO^+) was confirmed by X-ray diffraction studies. The compound crystallizes in the monoclinic space group $P2_1/c$. ORTEP projections are shown in Fig. 1. Bond lengths and angles are given in Table 2. The coordinated nitric oxide forms a linear Fe–NO moiety with a bond angle of 177.4°, and N–O bond length (1.091 Å) are comparable to the angle and distance (177.8° and 1.131 Å) found in *trans*- K{[Fe(cyclam)(NO^0)-Cl] · [FeCl(cyclam)(NO^+)]$_2$}(PF_6)$_6$ complex [14] attributed by oxidation state NO^+. The Fe–N(1) bond length (1.682 Å) is comparable to that of portion $[FeCl(cyclam)(NO^+)]^{2+}$ complex (1.648 Å) [14], which is $\{FeNO\}^6$ type, and shorter than *trans*-[Fe(cyclam)(NO)Cl](ClO_4) (1.820 Å) [12], which is $\{FeNO\}^7$ type. The presence of the two Cl^- ions disordered gives the correct charge balance for the structure. This requires that iron atom is present in the Fe^{2+} oxidation state.

The electronic spectrum of complex presented three bands at 230 nm ($\varepsilon = 1.4 \times 10^4$ M^{-1} cm^{-1}), 315 nm ($\varepsilon = 1.3 \times 10^3$ M^{-1} cm^{-1}) and 335 nm ($\varepsilon = 1.2 \times 10^3$ M^{-1} cm^{-1}). Since the complex is structurally and electronically similar to the *trans*-[Ru(cyclam)(NO^+)Cl]$^{2+}$ species, it is likely that their UV–Vis spectra would be similar [27]. Based on this analogy, the relatively intense band at 230 nm was assigned to the LMCT charge transfer band

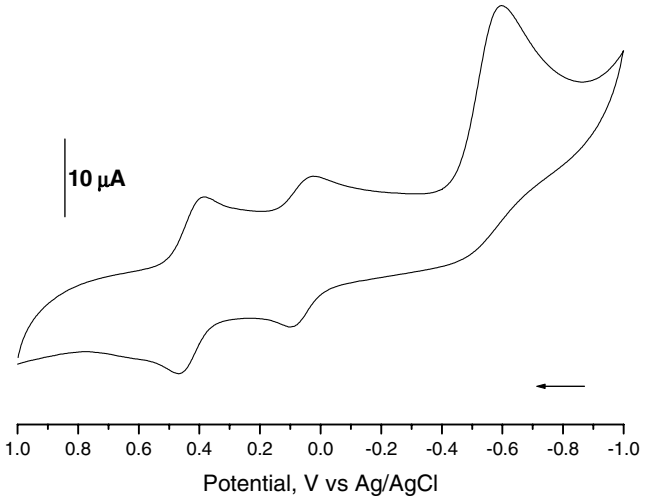

Fig. 2. Cyclic voltammograms for the *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex in a 0.10 mol L^{-1} CF_3COONa aqueous solution. $E_{initial} = -1.00$ V, $T = 25$ °C, pH 5, $v = 0.10$ V/s.

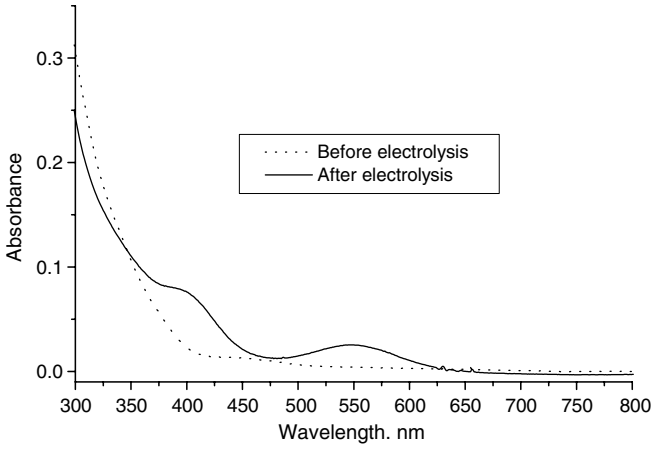

Fig. 3. Electronic spectra of an aqueous solution of *trans*-[Fe(cyclam)(NO)Cl]Cl_2 (dotted line) and the product of electrolysis at 0.2 V.

$[\pi_p(Cl^-) \rightarrow e_g(Fe)]$ and the band at 335 nm was assigned to a spin-allowed d–d transition $^1A_1 \rightarrow {}^1T_1$ [27,28]. The band at 315 nm was assigned to the MLCT $t_{2g} \rightarrow \pi^*(NO^+)$ because upon reduction with zinc amalgam these maxima disappear. Consistent with this assignment, this band shifted to lower energy with increase solvent polarity.

The cyclic voltammetric behavior of complex *trans*-[Fe(cyclam)(NO)Cl]Cl_2 is similar to the *trans*- K{[FeCl-(NO^0)(cyclam)] · [FeCl(NO^+)(cyclam)]$_2$}$(PF_6)_6$ [14] and presented a strong dependence on the potential range investigated, as well as on the initial sweep direction. Fig. 2 shows the cyclic voltammogram for a scan starting at −1.0 V with initial anodic sweep, in which three electrochemical processes are evidenced at −0.70, 0.08 and 0.40 V versus Ag/AgCl.

In harmony with an electrochemical chemical electrochemical (ECE) mechanism, the process centered at 0.08 V is not observed until the potential scan reach the more cathodic potential (Fig. 2).

A reasonable interpretation of the electrochemical results is supported by the electronic, FTIR and EPR spectra obtained for the *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex acquired after the electrolysis experiments in which the potential was controlled at two different values: −0.7 V and 0.2 V. Upon electrolysis under controlled potential at 0.2 V, the electronic spectrum (Fig. 3) presented two new absorption bands at 398 and 560 nm characteristic of the *trans*-[Fe(cyclam)(NO^0)Cl]$^+$ species formed after the first reduction process. The bands in the visible region of the spectrum are transitions predominantly of d–d character indicating that the *trans*-{Fe–NO}^{6} and *trans*-{Fe–NO}^{7} species must then have different d^n electron configurations, and also suggesting that the one-electron reduction process is centered at the nitric oxide ligand [12].

Furthermore, the IR spectrum of formed species after irradiation, in the solid state, does not present the characteristic of the $\nu(NO^+)$ stretching mode at 1888 cm^{-1}. However, a new peak characteristic of the $\nu(NO^0)$ vibrational stretching mode appeared at 1635 cm^{-1}, [29]. The EPR spectrum (Fig. 4) of formed species in solution at 77 K displays a broad isotropic signal at $g_{iso} = 2.00$. The g value is consistent with an unpaired electron occupying a NO π^* orbital in the {FeNO}^{7} moiety with significant NO^0 character [14,30]. Likewise, the high potential waves ($E_{1/2} = 0.40$ V versus Ag/AgCl) observed in the cyclic voltammogram of the *trans*-[Fe(cyclam)(NO)-Cl]Cl_2 complex are attributed to the *trans*-{FeNO}$^{6/7}$ redox process centered at the nitric oxide ligand.

Upon electrolysis, in which the potential was controlled at −0.7 V, the current intensity of the processes centered at −0.70 and 0.40 V decrease at the expense of the increase in the current intensity for the process centered at 0.08 V. It is reasonable to attribute the process centered at approximately 0.08 V to the $Fe^{III/II}$ redox couple in the

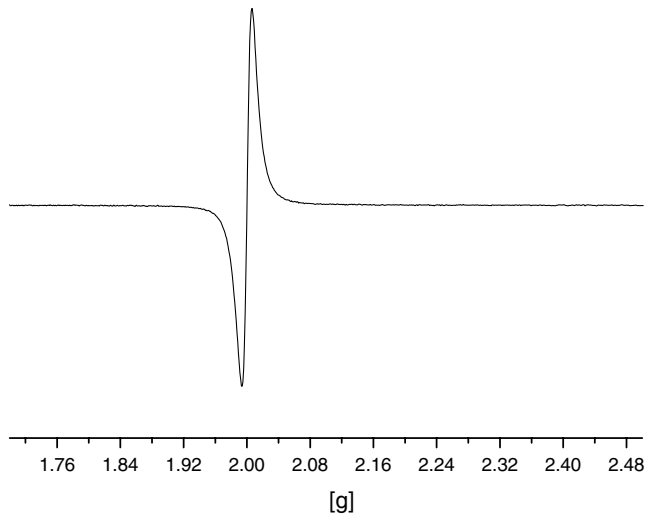

Fig. 4. EPR spectrum, in solid state, of the isolated product of the electrolysis of *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex at 0.20 V. $T = 77$ K.

trans-[Fe(cyclam)Cl(H_2O)]$^{2+/+}$ generated species after the reduction at −0.70 V. To confirm this assignment, the solution was gently rotary-evaporated and the compound was isolated in the solid state. The IR spectrum of the resulting compound showed no NO peaks (1888 and 1635 cm^{-1}), indicating that the NO dissociation occurred upon the second reduction followed by concomitant generation of the *trans*-[Fe(cyclam)Cl(H_2O)]$^{2+}$ complex. The electronic spectrum of this isolated species in aqueous medium showed two bands at 220 nm and 330 nm. These bands are characteristic of the *trans*-[Fe(cyclam)Cl(H_2O)]$^{2+}$ complex ion [23], reinforcing the assignment for the infrared spectrum discussed above. The following scheme of reactions (Eqs. (1)–(4)) accounts for the voltammetric behavior of the *trans*-[Fe(cyclam)(NO)Cl]$^{2+}$ complex ion, in aqueous media:

$$\textit{trans}\text{-}[Fe^{II}(cyclam)(NO^{+})Cl]^{3+} + e^{-} \overset{E_{1/2}=0.40\ V}{\rightleftharpoons} \textit{trans}\text{-}[Fe^{II}(cyclam)(NO^{0})Cl]^{2+} \quad (1)$$

$$\textit{trans}\text{-}[Fe^{II}(cyclam)(NO^{0})Cl]^{2+} + e^{-} \overset{E_{p}=-0.70\ V}{\rightarrow} \textit{trans}\text{-}[Fe^{II}(cyclam)(NO^{-})Cl]^{+} \quad (2)$$

$$\textit{trans}\text{-}[Fe^{II}(cyclam)(NO^{-})Cl^{2+} + H_2O \rightarrow \textit{trans}\text{-}[Fe^{II}(cyclam)(H_2O)Cl]^{2+} + NO^{-} \quad (3)$$

$$\textit{trans}\text{-}[Fe^{II}(cyclam)(H_2O)Cl]^{2+} \overset{E_{1/2}=0.08\ V}{\rightleftharpoons} \textit{trans}\text{-}[Fe^{III}(cyclam)(H_2O)Cl]^{3+} + e^{-} \quad (4)$$

3.1. Photochemical study

The title complex is stable in solution and in the solid state and only undergoes NO release upon electrolysis and photolysis. In a preliminary investigation, it was observed that photolysis at longer wavelengths (400–600 nm) does not induce photochemical reactivity. Conversely, the irradiation of the complex in aqueous solution, pH 3.4, with light $\lambda_{irradiation} = 330$ nm showed that FeNO moiety undergoes labilization according to Eq. (5)

$$\textit{trans}\text{-}[Fe(cyclam)(NO)Cl^{3+} \xrightarrow{h\nu\ pH\ 3.4} \textit{trans}\text{-}[Fe(cyclam)(H_2O)Cl]^{3+} + NO^{0} \quad (5)$$

Similar photochemical behavior is found for other metal nitrosyl complexes [7].

The aqua complex was identified by comparing the UV–Vis spectrum, electrochemical and infrared data with those of authentic samples of previously characterized *trans*-[Fe(cyclam)Cl(H_2O)]Cl_2. In the electronic spectra changes during the photolysis of the *trans*-[Fe(cyclam)(NO)Cl]Cl_2 complex in 0.1 M NaCl aqueous solution, pH 3.4, it was observed an increase of the LMCT band [$\pi_p(Cl^-) \rightarrow e_g(Fe)$] at 230 nm. This band is characteristic of the *trans*-[Fe(cyclam)Cl(H_2O)]Cl which was generated after NO release according to Eq. (5). Table 3 presents the quantum yield for the photoreaction depicted in Eq. (5) determined from the changes in the electronic spectra, at pH 3.4–6.4 range.

Table 3
Dependence of the ϕ_{NO} with pH

pH	ϕ_{NO}
3.4	0.28 ± 0.05
4.2	0.19 ± 0.03
5.4	0.16 ± 0.03
6.4	0.08 ± 0.02

From these data, it is clearly observed the decreasing in the quantum yield at the expense of the increasing of the pH values. This effect can be explained by the equilibrium illustrated in (Eq. (6)), which favors the *trans*-[Fe(cyclam)-(NO_2)Cl]$^{+}$ formation at high pH values, and the major product is therefore the nitrite species.

$$\textit{trans}\text{-}[Fe(cyclam)(NO)Cl]^{3+} + 2OH^{-} \rightleftharpoons \textit{trans}\text{-}[Fe(cyclam)(NO_2)Cl]^{+} + H_2O \quad (6)$$

In addition, the photolysis of *trans*-[Fe(cyclam)(NO)Cl]Cl_2 dispersed in KBr was performed, and monitored by IR spectroscopy (Fig. 5). The successively acquired IR spectra showed the decrease in the intensity of the νNO^{+} peak at 1888 cm^{-1} at the expense of the appearance of a new peak at 2229 cm^{-1}, which can be assigned to stretching mode of the NO^{+} free of coordination [31].

The photoreaction also was monitored by cyclic voltammetry (Fig. 6). The formation of NO as a photoproduct is confirmed by the increase of the current intensity of the process at 0.85 V, which is attributed to the free $NO^{0/+}$ oxidation. Also, the process centered at approximately 0.40 V versus Ag/AgCl, assigned to the redox process *trans*-$\{FeNO\}^{6/7}$ centered at the NO ligand, is not observed at the first cycle. By performing successive scans, after reduction of the Fe^{III} to Fe^{II} in the aqua species ($E = 0.02$ V), the Fe^{II} complex reacts with free NO regenerating the starting compound which explains the lack of the anodic wave at

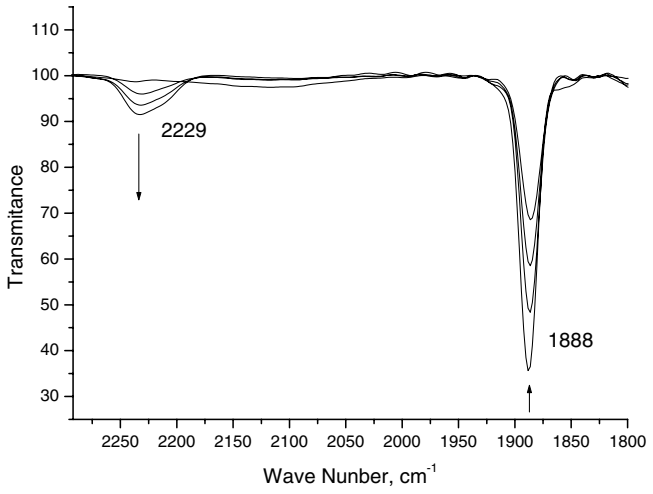

Fig. 5. Infrared spectra of the *trans*-[Fe(cyclam)(NO)Cl]Cl_2 compound dispersed in KBr as function of the irradiation process under 330 nm light.

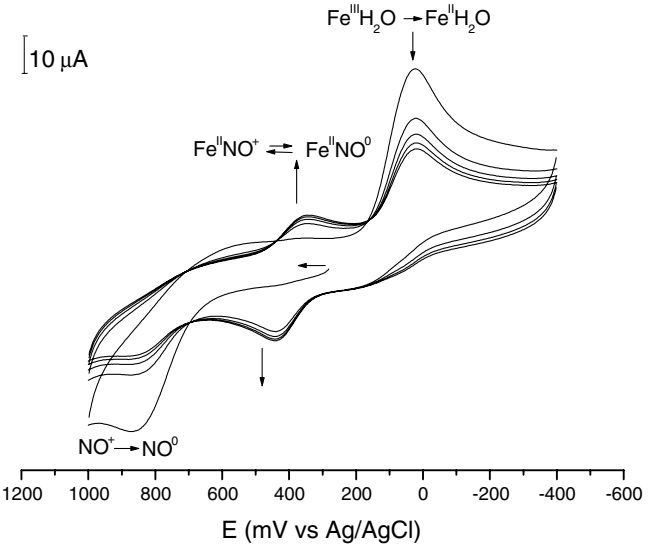

Fig. 6. Changes observed in the cyclic voltammogram of the *trans*-$[Fe(cyclam)(NO)Cl]^{2+}$ complex ion during photolysis at 330 nm, pH 3.4.

0.09 V and the appearance of the process centered at 0.40 V.

A particularly interesting observation is the pH dependence of the photoreaction. When the title compound was irradiated in 0.1 M NaCl aqueous solution, pH 7.0, instead of the release of NO, it was observed the reaction of photoreduction and production of the *trans*-$[Fe (cyclam)(NO^0)Cl]^{+}$ species. The progress of the photoreaction was monitored spectrophotometrically, and it was observed an increase in absorbance at 450 and 550 nm. These spectral changes are consistent with the formation of *trans*-$[Fe(cyclam)(NO^0)Cl]^{+}$ [12]. Hauser and coworkers [12] have observed that the spectra of *trans*-$\{FeNO\}^6$ and *trans*-$\{FeNO\}^7$ are completely different in nature whereas the spectra of *trans*-$\{FeNO\}^8$ are nearly the same.

4. Conclusion

The data collected in this work suggest that, upon irradiation at 330 nm, the *trans*-$[Fe(cyclam)(NO)Cl]Cl_2$ complex releases NO moiety. Since this energy is considered relatively high to indicate this complex as a suitable NO donor model for phototherapy purposes, further experiments are currently under investigation at our laboratories concerning the substitution of the Cl^- ligand in order to obtain a similar complex in which NO releasing could occur at lower energy.

5. Supplementary material

CCDC 633369 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. General remarks

All manipulations were performed under an atmosphere of argon using standard Schlenk techniques unless otherwise specified. Solvents were dried by refluxing over Na/benzophenone ketyl (THF, toluene, diethyl ether, hexane) or P_2O_5 (dichloromethane), and distilled just before use. Pentane, DMF, CH_3OH, and C_2H_5OH (anhydrous) were purchased from Kanto Chemical and used as received. Cyclohexene were purified by trap-to-trap distillation and stored under argon. IR spectra were recorded on a JASCO FT/IR-610 spectrometer, whereas ^1H (300 MHz) and $^{13}C\{^1H\}$ (75.5 MHz) NMR spectra were obtained on a JEOL JNM-LA300 spectrometer. GC analyses were performed on a GL-Sciences GC353B gas chromatograph equipped with a DB1 J&W capillary column. Elemental analyses were performed by the Analytical Facility at the Research Laboratory of Resources Utilization, Tokyo Institute of Technology.

2.2. Catalytic hydrogenation of cyclohexene

To a stainless steel autoclave containing the catalyst (7.0 μmol) was added cyclohexene (575 mg, 7.0 mmol) and the solvent (4 mL) by a syringe. After hydrogen gas was introduced into the autoclave, the mixture was stirred at 90 °C for 13 h. The amount of cyclohexane was determined by gas chromatography using heptane as an internal standard.

2.3. Preparation of [$Cp^*Ru(NO)(\eta^2$-$C_6H_{10})$] (3)

A mixture of $[Cp^*Ru(NO)(C_6H_5)_2]$ (**1**; 127.1 mg, 0.302 mmol) [5] and cyclohexene (0.62 mL, 6.11 mmol) in toluene (15 mL) was heated at 45 °C for 12 h. After removal of the solvent, the resultant dark red oil was dissolved in hexane and chromatographed on a column of silica gel under argon. After a faint yellow band eluted with hexane was discarded, the second band eluted with toluene/hexane (1:2) was collected and evaporated to dryness. Recrystallization from pentane at −30 °C afforded **3** as red crystals (34.9 mg, 33%). ^1H NMR (C_6D_6): δ 1.59 (m, 4H, $-CH_2(CH_2)_2CH_2-$), 1.66 (s, 15H, Cp^*), 2.56, 2.79, 3.05 (m, 2H each, vinyl and allyl). $^{13}C\{^1H\}$ NMR (C_6D_6): δ 10.1 ($C_5(CH_3)_5$), 23.2 ($-CH_2(CH_2)_2CH_2-$), 31.0 ($=CHCH_2$), 57.6 (=CH), 97.4 ($C_5(CH_3)_5$). IR (KBr): 1673 cm^{-1} (ν_{NO}). *Anal.* Calc. for $C_{16}H_{25}NORu$: C, 55.15; H, 7.23; N, 4.02. Found: C, 54.68; H, 7.34; N, 4.05%.

2.4. X-ray diffraction study

Complex **2** was prepared according to the literature [5], and single crystals suitable for X-ray analysis were obtained from recrystallization from benzene. The crystals of **2** and **3** are mounted on glass fibers. Diffraction experiments were performed on a Rigaku Saturn CCD area detector with graphite-monochromated Mo Kα radiation ($\lambda = 0.710\ 70$ Å). Intensity data were corrected for Lorentz-polarization effects and for absorption. Details of crystal and data collection parameters are summarized in Table 1.

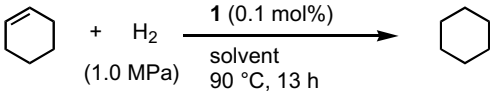
Structure solution and refinements were carried out by using the CRYSTALSTRUCTURE program package [6]. The heavy-atom positions were determined by a direct methods program (SIR-92) [7], and remaining non-hydrogen atoms were found by subsequent Fourier syntheses. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares techniques based on F^2, whereas all hydrogen atoms were placed at calculated positions.

3. Results and discussion

3.1. Catalytic hydrogenation of cyclohexene



When the (nitrosyl)ruthenium complex **1** was stirred in cyclohexene under 1.0 MPa of H_2 at 90 °C for 13 h, catalytic hydrogenation of cyclohexene took place to afford cyclohexane in moderate yield (Eq. (1), entry 1 in Table 2). Screening of the solvent revealed that use of water gave the best result; the yield of cyclohexane reached to 94% in the reaction with a cyclohexene:**1** ratio of 1000:1 (entry 8). Addition of only 100 equiv. of water per **1** caused a significant decrease in the yield of cyclohexane (entry 9). These results indicate that water seems to serve not only as a simple additive but an efficient reaction media. In the related hydrogenation of alkenes catalyzed by a (nitrosyl)rhodium complex $[Rh(NO)\{P(C_6H_5)_3\}_2$(*p*-benzoquinone)], heterogeneous rhodium(0) metal particles generated by the decom-

position of the complex are proposed to be the true catalyst [8]. In contrast, the mercury poisoning experiment in the present hydrogenation suggests that the catalysis proceeds essentially in the homogeneous phase (entry 10) [9].

(1)

The ^1H NMR spectrum indicated the product mixture contains the dinuclear nitrosyl complex [$Cp^*Ru(\mu_2\text{-}NO)_2RuCp^*$] (**2**), which is a thermolysis product of **1** [5], and a novel (nitrosyl)(cyclohexene)ruthenium complex [$Cp^*Ru(NO)(\eta^2\text{-}C_6H_{10})$] (**3**) as the detectable organometallic species. Complex **3** could be obtained in a pure form by the reaction of **1** with an excess of cyclohexene followed by a chromatographic workup as shown in Eq. (2). The ^1H and $^{13}C\{^1H\}$ NMR spectra of **3** closely resemble to those of the propylene complex [$Cp^*Ru(NO)(\eta^2\text{-}CH_2{=}CHCH_3)$], which has been prepared by the thermolysis of the methyl–vinyl complex [$Cp^*Ru(NO)(CH_3)(CH{=}CH_2)$] [5]. The NO stretching band of **3** at 1673 cm^{-1} is comparable with that of the related η^2-naphthalene complex [$Cp^*Ru(NO)(\eta^2\text{-}C_{10}H_8)$] (1713 cm^{-1}) [10].

(2)

1 **3**

Both **2** and **3** have proved to catalyze the hydrogenation as shown in Table 3. The catalytic activity of the cyclohexene complex **3** was almost equal to that of **1**, whereas the efficiency of the dinuclear catalyst **2** was slightly lower. It is of interest that the ruthenium complex [$Cp^*Ru(CH_3CN)_3$][OSO_2CF_3] [11] without a nitrosyl ligand was less effective for this hydrogenation.

The detailed mechanism of the catalytic hydrogenation is still unclear. Bergman and co-workers have demonstrated that reductive elimination of biphenyl from **1** takes

Table 3
Hydrogenation of cyclohexene catalyzed by ruthenium complexes[a]

Entry	Complex	Yield (%)[b]
1	[$Cp^*Ru(NO)(C_6H_5)_2$] (**1**)	94
2	[$Cp^*Ru(\mu_2\text{-}NO)_2RuCp^*$] (**2**)[c]	82
3	[$Cp^*Ru(NO)(\eta^2\text{-}C_6H_{10})$] (**3**)	94
4	[$Cp^*Ru(CH_3CN)_3$][OSO_2CF_3]	53

place at 45 °C to afford a coordinatively unsaturated species [$Cp^*Ru(NO)$] (**A**), which subsequently reacts with a variety of trapping reagents [5,10]. For example, thermolysis of **1** in the presence of triphenylsilane gives rise to the formation of the oxidative addition product [$Cp^*Ru(NO)H\{Si(C_6H_5)_3\}$] [10]. In the catalytic hydrogenation, similar oxidative addition of H_2 to the thermally produced **A** may take place to give the dihydrido species [$Cp^*Ru(NO)H_2$] (**B**). The osmium analogue of **B**, [$Cp^*Os(NO)H_2$], has been isolated from the reaction of [$Cp^*Os(NO)Br_2$] with $NaBH_4$ [12]. The reaction of the dihydride **B** with cyclohexene would lead to the formation of cyclohexane and regeneration of the coordinatively unsaturated species **A**. In this step, bending of the nitrosyl ligand or ring slippage of the Cp^* ligand may take place to facilitate insertion of cyclohexene into the Ru–H bond in **B**. The cyclohexene complex **3** does not seem to be involved in the turnover cycle, because the hydrogenation was much slower in neat cyclohexene, which would be a more favorable condition for the formation of **3**. It is to be noted that **3** could not be observed when isolated **2** was used as the catalyst. This observation indicates that an alternative mechanism without rapture of the dinuclear core of **2** is also possible.

Acceleration of the reaction in water also remains to be clarified. The high polarity of water does not seem to be essential, because the hydrogenation in the less polar organic solvents proceeds faster than that in the polar ones (Table 1). A possible explanation is that the organic substrate/product–water biphasic conditions may cause the local dilution of cyclohexene, which would promote the dissociation of cyclohexene from **3** in the resting state [13]. Further investigation into the mechanism is under way.

3.2. Crystal structures of 2 and 3

The dinuclear complex **2** has previously been characterized only by spectroscopic methods [5]. An X-ray analysis was thus carried out to determine the solid state structure of **2** (Fig. 1). The approximately D_{2h} symmetric structure of **2** with two bridging nitrosyl ligands is almost isostructural with the iron and osmium analogues [$Cp'Fe(\mu_2\text{-}NO)_2FeCp'$] ($Cp' = \eta^5\text{-}C_5H_5$ [14], $\eta^5\text{-}C_5H_4CH_3$ [15]) and [$Cp^*Os(\mu_2\text{-}NO)_2OsCp^*$] [12]. The short metal–metal distance of 2.5366(5) Å is consistent with a formal Ru–Ru double bond as observed in, e.g., [$Cp^*Ru\{Si(CH_3)_3\}(\mu_2$-

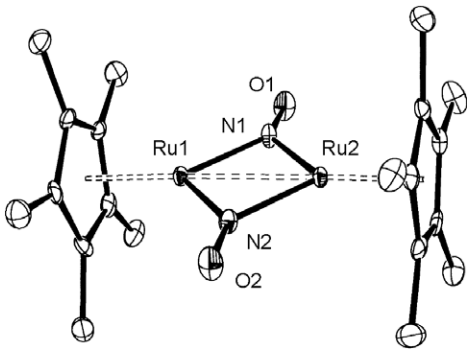

Fig. 1. Crystal structure of **2**. Hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at 30% probability level. Selected bond distances (Å) and angles (°): Ru1–Ru2, 2.5366(5); Ru1–N1, 1.924(5); Ru1–N2, 1.915(5); Ru2–N1, 1.933(5); Ru2–N2, 1.918(5); N1–O1, 1.217(7); N2–O2, 1.219(7); Ru1–N1–O1, 139.0(4); Ru1–N2–O2, 140.1(3); Ru2–N1–O1, 138.7(3); Ru2–N2–O2, 137.1(4).

Cl)(μ_2-CH_2)RuCp*] (2.527(1) Å) [16]. The Ru_2N_2 face is almost planar with the dihedral angle of 0.4(2)° around the Ru–Ru vector. The two Cp* ligands are in an almost eclipsed position to each other.

Fig. 2 depicts the molecular structure of the cyclohexene complex **3**. The nitrosyl ligand is essentially linear with the Ru–N–O angle of 175.8(4)°. The cyclohexene ligand adopts an *endo* form to avoid the steric repulsion with the Cp* ligand. The angle defined by the Ru–C11–C12 and C16–C11–C12–C13 planes (ca. 115°) suggests the significant π back donation from the Cp*Ru(NO) moiety to the coordinated alkene. The distance of the coordinated C═C bond is 1.390(9) Å. These structural characteristics are common with the closely related η^2-naphthalene complex [Cp*Ru(NO)(η^2-$C_{10}H_8$)]; the corresponding angle and distance are 115° and 1.418(8) Å, respectively [10].

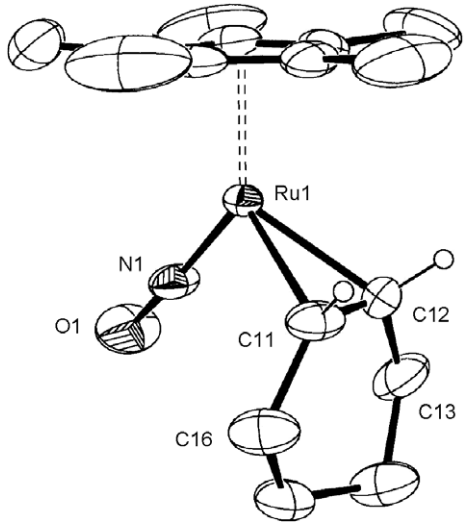

Fig. 2. Crystal structure of **3**. Hydrogen atoms except for the vinyl hydrogens are omitted for clarity. Thermal ellipsoids are drawn at 30% probability level. Selected bond distances (Å) and angles (°): Ru1–N1, 1.732(5); Ru1–C11, 2.161(5); Ru1–C12, 2.163(5); N1–O1, 1.187(7); C11–C12, 1.390(9); Ru1–N1–O1, 175.8(4); Ru1–C11–C16, 122.5(5); Ru1–C12–C13, 120.4(4).

4. Conclusion

We have demonstrated that the (nitrosyl)diphenyl complex **1** serves as a good catalyst precursor for hydrogenation of cyclohexene. Although the mechanistic details have not yet been understood completely, the possible role of the nitrosyl ligand in the catalysis is suggested. In addition, the crystal structures of two catalysts, the nitrosyl-bridged dinuclear complex **2** and mononuclear cyclohexene complex **3** bearing a linear nitrosyl ligand, have been determined.

Scheme 1.

observed by Parkin and co-workers [12] in the study of model complexes of the enzyme carbonic anhydrase. Once again, the identity of the metal ion in a tripodal ligand frameworks determines the coordination geometry of the nitrate ligand.

Yet, in these examples, comparing the electronic properties of the coordinated ligand across such a series of complexes is complicated by the change in metal identity. In order to accurately investigate the effects on the electronic structure of the complexes upon changes in coordination geometry would require a series of related ligand frameworks (excluding the nitrate), all containing the same central metal, but which still allows variations in nitrate geometry. To our knowledge, the ferric porphyrinate complexes [Fe(por)(NO_3)] provide the only example of such a series. Hence we undertook a study of the electronic structure for such a series of complexes aiming to correlate changes in both the Mössbauer and EPR spectra with changes in ligand geometry.

A number of porphyrinate complex structures containing a coordinated nitrate ligand have been reported [13] with a range of coordination modes reported therein. Characterization of a five-coordinate monodentate ferrous complex [Fe(TpivPP)(NO_3)]$^-$ has been published [14]. The structures of the ferric porphyrinate complexes [Fe(por)(NO_3)] based upon the porphyrinates OEP, [15] TPP, [16] and TpivPP [17] demonstrate the geometries illustrated in Scheme 1. Initial attempts at forming a nitrite-coordinated heme complex had resulted in formation of free nitrate as determined by IR spectroscopy following an oxygen atom transfer reaction [18]. A related reaction utilizing picket fence porphyrin (TpivPP) with a protected ligand binding site resulted in nitrate formation with nitrate coordinated to the heme [17]. The crystal structure of [Fe(TpivPP)(NO_3)] [17] displays a symmetrically coordinated bidentate nitrate ligand with the projected plane of the nitrate eclipsing a trans pair of porphyrin nitrogen atoms. Asymmetric bidentate coordination has been reported for [Fe(TPP)(NO_3)] [16] with the projected plane of the nitrate bisecting adjacent pairs of porphyrin nitrogen atoms. The triclinic [Fe(OEP)(NO_3)] [15] exhibits a monodentate nitrate ligand. We have subsequently determined the crystal structure of a monoclinic form of [Fe(OEP)(NO_3)] (reported herein) which also possess a monodentate nitrate ligand.

Initially we undertook to investigate the effects of nitrate coordination mode upon the electronic structure of the ferric porphyrinates. Based upon the reported variations in coordination geometry, the complexes [Fe(por)(NO_3)] provide a means of studying systematic changes in the electronic environment of the iron as the coordination geometry changes. However, seemingly contradictory EPR results were obtained, and led us to reexamine the structure of the asymmetric bidentate coordinated species [Fe(TPP)(NO_3)] [16]. The structure was redetermined at 100 K with crystals having comparable cell constants to those reported previously. Our new structure demonstrates that, rather than a single asymmetric bidentate coordination mode, the nitrate ligand is in fact disordered over two positions. This new structure is discussed particularly in relation to the previous room temperature example [16]. We also present a second crystalline form of [Fe(OEP)(NO_3)], which like the previously reported structure, [15] contains a monodentate nitrate ligand. In addition to the two new crystal structures, we provide electronic characterization of all three [Fe(por)(NO_3)] complexes both in solution and solid state. These reveal marked differences in nitrate coordination geometry between the solid and solution coordination modes for both of the bidentate systems.

2. Experimental

2.1. General information

All reactions were carried out using standard Schlenkware techniques unless otherwise noted. Tetrahydrofuran and hexanes were distilled over sodium and benzophenone prior to use. Methylene chloride was distilled over calcium hydride. H_2OEP was purchased from Midcentury Chemicals. H_2TPP was synthesized according to the method of Adler et al. [19] Metallation reactions to yield [Fe(OEP)(Cl)] and [Fe(TPP)(Cl)] were carried out according to Adler et al. [20] H_2TpivPP was prepared according to a local modification of the reported synthesis [21]. [Fe(TpivPP)(Cl)] was obtained by stirring 150 mg of the free-base overnight with 100 mg of $FeCl_2$ in 25 mL of THF and 0.2 mL of 2,6-lutidine.

Solution UV–Vis spectra were measured on a Perkin–Elmer Lambda 19 UV–Vis–near-IR spectrometer. IR spectra were collected on single crystals ground between two sodium chloride plates with a small amount of Nujol. Spectra were collected on a Nicolet Nexus 870 FT-IR spectrometer. EPR measurements on ground single crystals of [Fe(TpivPP)(NO_3)] were made at 77 K on a Bruker ER 100E spectrometer calibrated with a dpph standard. All other EPR measurements were made on a Bruker EMX-EPR spectrometer. Measurements were made on either frozen methylene chloride solutions or finely ground crystalline solids. Samples were prepared for Mössbauer spectroscopy by grinding approximately 40 mg of crystals, immobilizing in Apiezon M grease to form a mull which was subsequently sealed in an airtight Mössbauer cup.

2.2. Synthesis of [Fe(OEP)(NO$_3$)]

[Fe(OEP)(Cl)] (109.5 mg, 0.176 mmol) was placed in a Schlenk flask with finely ground $AgNO_3$ (35.8 mg, 0.211 mmol). THF (25 mL) was added and the solution stirred overnight. The solvent was removed in vacuo and the reddish-brown solid redissolved in methylene chloride, filtered to remove the inorganic salts and layered with hexanes. X-ray quality crystals were obtained after 7 days.

2.3. Synthesis of [Fe(TPP)(NO$_3$)]

Large single crystals of [Fe(TPP)(NO_3)] were obtained using a similar metathesis pathway. [Fe(TPP)(Cl)] (150 mg, 0.24 mmol) was stirred overnight in 15 mL of THF with 48 mg (0.29 mmol) of $AgNO_3$. Subsequent solvent removal, dissolution in methylene chloride and filtration was carried out prior to layering with hexanes. Large single crystals of up to 2.5 mm length were obtained after 5 days.

Table 1
Crystallographic details for [Fe(OEP)(NO_3)] and [Fe(TPP)(NO_3)]

	[Fe(OEP)(NO_3)]	[Fe(TPP)(NO_3)]
Formula	$C_{36}H_{44}FeN_5O_3$	$C_{44}H_{28}FeN_5O_3$
FW (amu)	650.61	730.56
a (Å)	13.209(3)	10.0271(3)
b (Å)	13.774(3)	16.1341(5)
c (Å)	19.258(4)	16.1341(5)
β (°)	105.50(3)	90.330(2)
V (Å^3)	3376.2(12)	3399.24(17)
Space group	$P2_1/c$	$P2_1/n$
Z	4	4
μ (mm^{-1})	0.489	0.495
Radiation	Mo Kα, $\bar{\lambda} = 0.71073$	Mo Kα, $\bar{\lambda} = 0.71073$
Temperature (K)	293	100(2)
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0502$, $wR_2 = 0.1140$	$R_1 = 0.0447$, $wR_2 = 0.1167$
Final R indices (all data)	$R_1 = 0.0802$, $wR_2 = 0.1311$	$R_1 = 0.0704$, $wR_2 = 0.1405$

Determination of the cell constants of the crystals revealed comparable values to those previously reported [16].

2.4. Synthesis of [Fe(TpivPP)(NO$_3$)]

[Fe(TpivPP)(Cl)] (150 mg, 0.14 mmol) was placed in a Schlenk flask with 27 mg (0.16 mmol) of $AgNO_3$ and 15 mL of THF. The mixture was stirred overnight and the solvent evaporated prior to redissolving in CH_2Cl_2 and filtration. UV–Vis spectroscopy of both the THF and CH_2Cl_2 solutions confirmed the formation of [Fe(TpivPP)(NO_3)] yet attempts to obtain a crystalline product were unsuccessful in spite of multiple attempts using variations in crystallization conditions.

2.5. X-ray structure determination

Structures of [Fe(OEP)(NO_3)] and [Fe(TPP)(NO_3)] were solved using the direct methods program SHELXS [22]. All heavy atoms were located using subsequent difference Fourier syntheses. The structures were refined against F^2 with the program SHELXL [23], in which all data collected were used including negative intensities. All nonhydrogen atoms were refined anisotropically. All hydrogen atoms were idealized using the standard SHELXL idealization method. Complete crystallographic details, atomic coordinates, anisotropic thermal parameters and fixed hydrogen coordinates for both are included in the Supplementary material. Table 1 gives brief crystallographic details.

A single crystal of [Fe(OEP)(NO_3)] was mounted on a glass fiber with the long axis approximately collinear with the axis of the fiber. All measurements were performed with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) on an Enraf-Nonius FAST area detector diffractometer at 127 K as previously described [24]. Intensities of all reflections were reduced using Lorentz and polarization correction factors; the data were also corrected for absorption by an empirical (ψ scans) absorption correction ($\mu = 0.489$ mm^{-1}). Two positions of the methyl carbons of ethyl groups 6 and 7 were observed with this

disorder arising from rotation about the Cm–C(6) and Cm–C(7) bonds. This was resolved by allowing the two possible methyl group positions to refine giving relative occupancies of 65% and 35%. Relevant bond lengths and angles for [Fe(OEP)(NO_3)] are summarized in Table 2.

A single crystal of [Fe(TPP)(NO_3)] was placed in inert oil, mounted on a glass fiber attached to a brass mounting pin and transferred to the cold stream of the diffractometer. Crystal data were collected and integrated using a Bruker Apex system with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Data collection was carried out at 100 K. [Fe(TPP)(NO_3)] was found to possess a disordered nitrate ligand with two orientations. The two nitrate orientations were refined and determined to have relative occupancies of 60% and 40%. Oxygen atoms of the major orientation are labelled O1A and O2A whilst the minor orientation is labelled O1B and O2B. The central nitrogen atom and the uncoordinated oxygen of the nitrate ligand did not display any disorder. Relevant bond lengths and angles for [Fe(TPP)(NO_3)] are summarized in Table 2.

3. Results

The crystal structures of two five-coordinate nitrate-ligated iron(III) porphyrinate complexes have been obtained. The first of these, monoclinic [Fe(OEP)(NO_3)], represents a second crystalline example of a monodentate nitrate coordinated system in an iron(III) porphyrinate [15]. The second structure, [Fe(TPP)(NO_3)], is a redetermination of a previously reported room temperature structure [16]. Here, we report a revised structure from data collected at 100 K.

Fig. 1 shows the ORTEP diagram and a partial labelling scheme for the monoclinic form of [Fe(OEP)(NO_3)] clearly illustrating the monodentate coordination geometry of the nitrate ligand. Fig. 2a is a schematic representation of the porphyrin core showing the perpendicular displacements

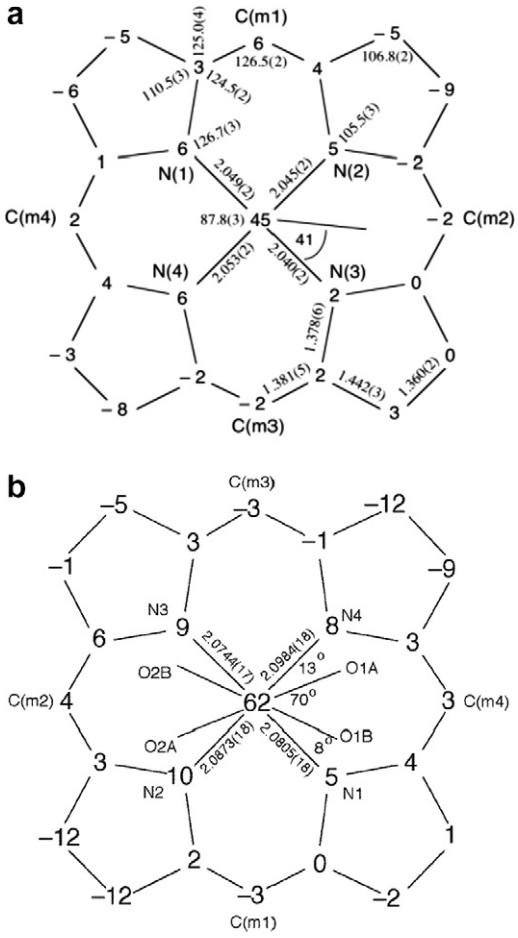

Fig. 2. Formal diagram of the porphyrinato core of (a) [Fe(OEP)(NO_3)] and (b) [Fe(TPP)(NO_3)] displaying perpendicular displacement (in units of 0.01 Å) of the core atoms from the 24-atom mean porphyrin plane. Positive displacements are towards the nitrate coordinated face of the porphyrin. The projections of the nitrate ligand upon the porphyrin plane are also shown. For [Fe(TPP)(NO_3)], the two orientations of the nitrate ligand are shown. (O1A and O2A represent the oxygen atom positions of the major orientation.)

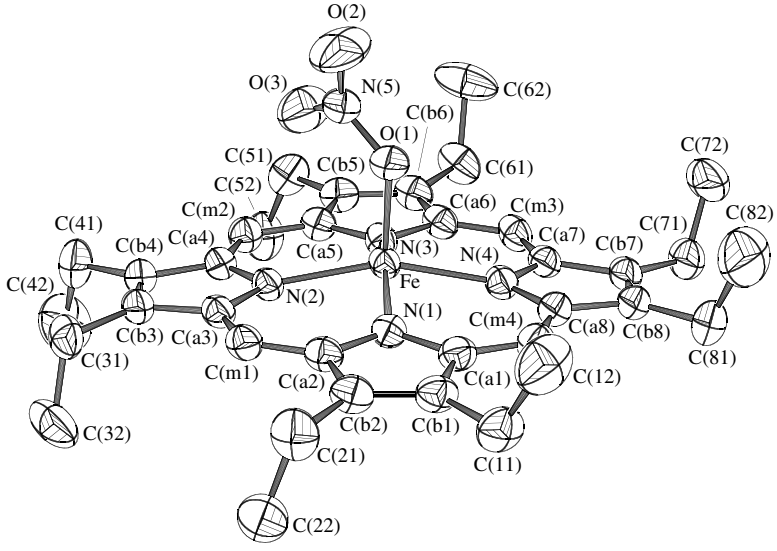

Fig. 1. ORTEP diagram of the monoclinic form of [Fe(OEP)(NO_3)] with 50% probability ellipsoids. The atom labeling scheme is also shown.

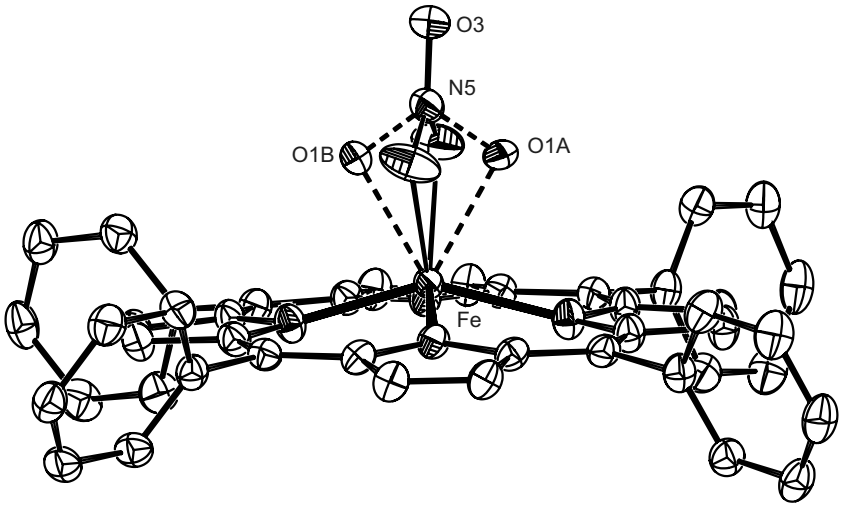

Fig. 3. ORTEP diagram of [Fe(TPP)(NO_3)] with 50% probability ellipsoids. Both orientations of the nitrate ligand is shown with the major orientation labelled O1A, O1B.

[a] Measured on CH_2Cl_2 solution.
[b] Measured as KBr disk.

from the 24-atom mean plane. The iron is significantly shifted out of the plane in the direction of the nitrate ligand while the porphyrin core shows a modest combined doming/tenting distortion. An ORTEP diagram for [Fe(TPP)(NO_3)] illustrating both orientations of the nitrate ligand is shown as Fig. 3. The bidentate coordination mode of the nitrate is clearly evident. Fig. 2b shows the porphyrin core of [Fe(TPP)(NO_3)] which also shows a large displacement of the iron in the direction of the nitrate ligand. Projections of both orientations of the nitrate ligand are illustrated with the coordinating oxygens of the major orientation being labeled O1A, O2A. The minor orientation is rotated approximately 70° from the major with both lying close to a pair of opposite Fe–N_p bonds. The dihedral angles (ϕ) which represent the relative orientation of the nitrate ligand with respect to the closest Fe–N_p vector are 13° and 8° for the major and minor orientations respectively. In contrast, for monoclinic [Fe(OEP)(NO_3)] structure, ϕ is 41° with the nitrate ligand lying almost midway between a pair of Fe–N_p bonds. For both the OEP and TPP systems, the nitrate plane lies perpendicular to the plane of the porphyrin. Selected bond lengths for these complexes and related systems are given in Table 2.

Table 3 reports UV–Vis and IR spectroscopic data for the [Fe(por)(NO_3)] complexes. EPR measurements for both ground crystalline solids and solutions were made on all three systems. These data are summarized in Table 4. Solution measurements on all three porphyrin systems made at 4 K are clearly axial with the major feature $g_\perp = 5.7$–6.0 and the minor feature, $g_\parallel \sim 2$. Powder mea-

	RT	1.07	0.37

surements on the monodentate [Fe(OEP)(NO_3)] also reveal an axial spectrum with $g = 5.8$, 2. By contrast, rhombic spectra are observed for the crystalline bidentate TPP and TpivPP complexes with g values as reported in Table 4. Mössbauer spectra were collected at 4.2 K in zero field for ground crystalline samples of all three porphyrinates. These are fit to a $S = 5/2$ model and data for this fit are given in Table 5. Spectra are illustrated in Fig. 6.

4. Discussion

4.1. Synthetic aspects

We report a straightforward synthetic route for obtaining ferric iron porphyrinate complexes containing a coordinated nitrate ligand. A simple metathesis reaction yields the desired [Fe(por)(NO_3)] complex with the undesirable side-products being removed by a simple filtration. The ease of this synthetic pathway is emphasized when compared with the previous reported methods which either proceeded via an oxygen atom transfer [17], NO attack of a bridged μ-oxo-dimer [15] or in the case of the TPP derivative, reaction of the μ-oxo-dimer with aqueous nitric acid followed by a three-week crystallization [16]. In the latter case, we are able to successfully obtain large crystals in under one week. The only problem encountered with the new reaction system lay in the inability to obtain crystals of the picket-fence porphyrin complex [Fe(TpivPP)(NO_3)]. We were able to show spectroscopically that the species could be obtained in solution yet were unable to prepare a solid crystalline sample. UV–Vis and IR spectroscopic data for all three systems are given in Table 3. In all cases, IR bands associated with the free nitrate ligand were not found, confirming the coordinated nature of the nitrate in all three cases.

4.2. Molecular structures

We report here a new crystalline form and a redetermined structure for two high-spin ferric (nitrato)-porphyrinates. Schematic representations of the porphyrin core for these systems and all other [Fe(por)(NO_3)] complexes are shown in Fig. 4. At the onset of the project, it was thought, based on the reported structures [15–17] that the series of complexes [Fe(por)(NO_3)] exhibited distinct examples of three coordination geometries (Scheme 1). However after evaluation of the EPR data, we decided to redetermine the structure of the asymmetric bidentate coordinated system [Fe(TPP)(NO_3)] [16]. The reported structure [16] showed a nitrate ligand lying midway between a pair of Fe–N_p bonds with two very different Fe–O bond lengths of 2.019(4) and 2.323(8) Å and δ, the difference between the Fe–O bond lengths, of 0.304 Å. The porphyrin core displays a characteristic saddling distortion and the iron is significantly displaced from the mean porphyrin plane in the direction of the nitrate ligand. A similar saddling distortion and iron out-of-plane displacement is observed in the porphyrin core of our redetermined structure at 100 K Fig. 2b. In fact, if we overlay the porphyrin cores of the RT structure and our newly redetermined structure so as to align the saddling patterns, we observe that the originally reported nitrate ligand orientation lies midway between the two orientations found in the 100 K structure. This is consistent with the very large thermal ellipsoids observed for the two *coordinated* oxygen atoms of the nitrate. Based upon

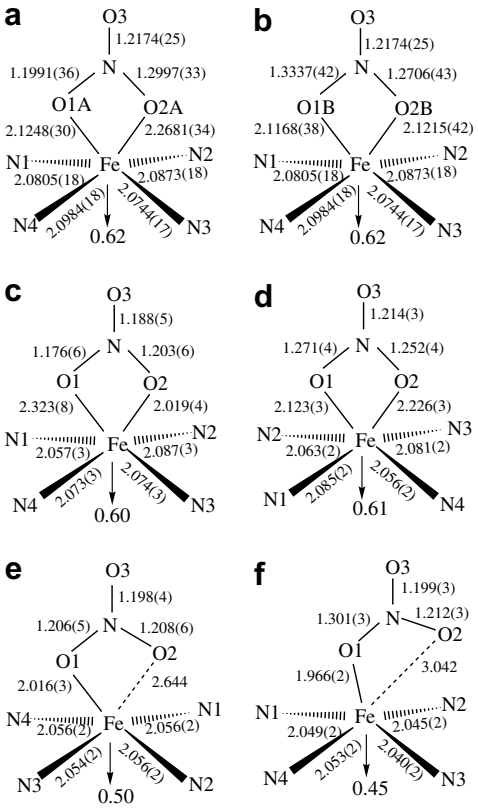

Fig. 4. Schematic representations of the N_4FeNO_3 geometry for all [Fe(por)(NO_3)] complexes. Structures represented are (a) [Fe(TPP)(NO_3)] 100 K, major orientation; (b) [Fe(TPP)(NO_3)] 100 K, minor orientation; (c) [Fe(TPP)(NO_3)]. Room temperature structure (Ref. [16]); (d) [Fe(TpivPP)(NO_3)] (Ref. [17]); (e) [Fe(OEP)(NO_3)] triclinic form (Ref. [15]); (f) [Fe(OEP)(NO_3)] monoclinic form.

this observation, we conclude the previously reported nitrate ligand orientation is in fact an averaging of the two orientations we observe in our 100 K structure. These two orientations present a more eclipsed nitrate position both lying approximately 10° from a Fe–N_p vector. A similar orientation is observed in the other bidentate system [Fe(TpivPP)(NO_3)] [17] where the bidentate nitrate lies 10° from the closest Fe–N_p vector. However, neither of the two new nitrate orientations in the 100 K structure of [Fe(TPP)(NO_3)] display anywhere near the same extent of asymmetric coordination as reported in the RT structure. The major orientation shows the greatest disparity in the two Fe–O bond length ($\delta = 0.1433$ Å) whereas the bond lengths in the minor orientation are practically equivalent ($\delta = 0.0047$ Å). Based upon these results, we reclassify the [Fe(TPP)(NO_3)] system as containing a symmetrically coordinated bidentate nitrate ligand.

We also observe some disparity in the Fe–O distances in the two structures of [Fe(OEP)(NO_3)]. This is most evident in the nonbonded distance between the iron center and the noncoordinating oxygen, O2, in Fig. 4e and f. Although the Fe–O bond length for both of the monodentate nitrates are very similar, the nitrate position with respect to the porphyrin core is significantly different. In the previously reported triclinic form [15], the nitrate adopts an orientation similar to the bidentate systems with the Fe–O2 vector perpendicular to the porphyrin plane and passing through the core center where the iron sits. In the monoclinic form, the Fe–O bond lies more perpendicular to porphyrin plane with the N–O(2) bond shifted significantly from the centered normal to the porphyrin plane. This is reflected in a marked increase in the distance between the iron center and the noncoordinated O(3) from 2.644 Å in the triclinic system to 3.042 Å for the monoclinic system. In both cases, the nitrate ligand still lies close to midway between a pair of Fe–N_p vectors and equivalent iron out-of-plane displacements are observed.

Fig. 4 illustrates the core geometry for all ferric [Fe(por)(NO_3)] systems reported to date. There are a number of features common to all the systems. Each system displays a significant out-of-plane displacement of the iron in the direction of the nitrate ligand. large out-of-plane displacements are common in five-coordinate ferric porphyrinates [25]. No significant differences are observed in the Fe–N_p distances for each system although the distances for the two monodentate OEP derivatives are slightly shorter than the meso-substituted porphyrinates.

The variation in the projection of the nitrate plane onto the plane of the porphyrin has already been discussed briefly. Comparing the data from all systems reveals when the nitrate coordinates in a bidentate fashion, the projection of the ligand plane is close to a Fe–N_p vector with a dihedral angle (ϕ) of ~10°. When the nitrate coordinates in a monodentate fashion, the orientation changes such that it lies midway between the two Fe–N_p vectors, possibly to minimize steric interactions between the pyrrolic nitrogens and the uncoordinated oxygen of the nitrate ligand.

4.3. EPR spectroscopy

EPR spectra on both the powder and solutions of all three nitrate complexes were collected at 77 and 4 K. These data are summarized in Table 4 and displayed in Fig. 5. For the OEP complexes, the EPR spectra for both solid and solution at both temperatures are axial. At 77 K however, the minor $g_\parallel$ feature was too weak to be detected. When the temperature is reduced to 4 K, both $g_\perp$ and $g_\parallel$ features are evident. The observation of axial spectra for both the solid and the solution is consistent with a monodentate coordination mode in both states. Similar axial spectra are observed in other five-coordinate high-spin systems such as [Fe(por)(Cl)] [26]. We have already discussed the differences in coordination mode of the nitrate ligand in the TPP and picket-fence derivatives and we would expect the EPR spectra for these to differ from the simple axial spectra observed for the OEP derivative. Had the previously reported coordination mode of the nitrate in [Fe(TPP)(NO_3)], the highly asymmetric bidentate geometry, been representative of the nitrate geometry at lower temperatures, we would perhaps have expected to see EPR spectra for this system that differ from both that of the OEP and TpivPP systems. Instead, following our new crystallographic determination, we now expect the EPR spectra of the TPP and TpivPP derivatives to be somewhat similar. Indeed, this is true with the EPR of the ground crystalline material displaying rhombic spectra for both of the bidentate coordinated systems. [Fe(TPP)(NO_3)] at 77 K exhibits a complex spectrum from which we identify a major rhombic component has $g = 7.71$, 4.04 and 1.78

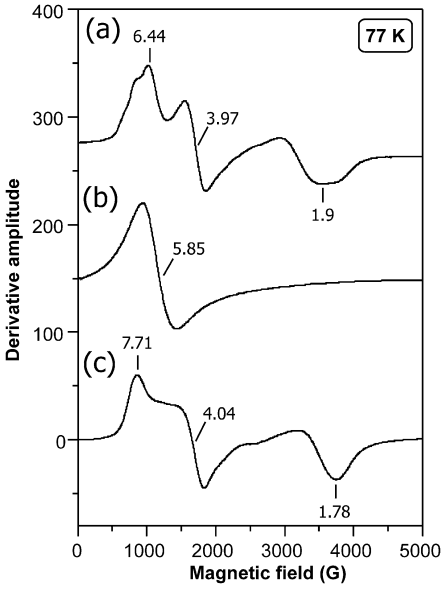

Fig. 5. EPR spectra at 77 K of ground single crystals of (a) [Fe(TpivPP)(NO_3)], (b) [Fe(OEP)(NO_3)], and (c) [Fe(TPP)(NO_3)].

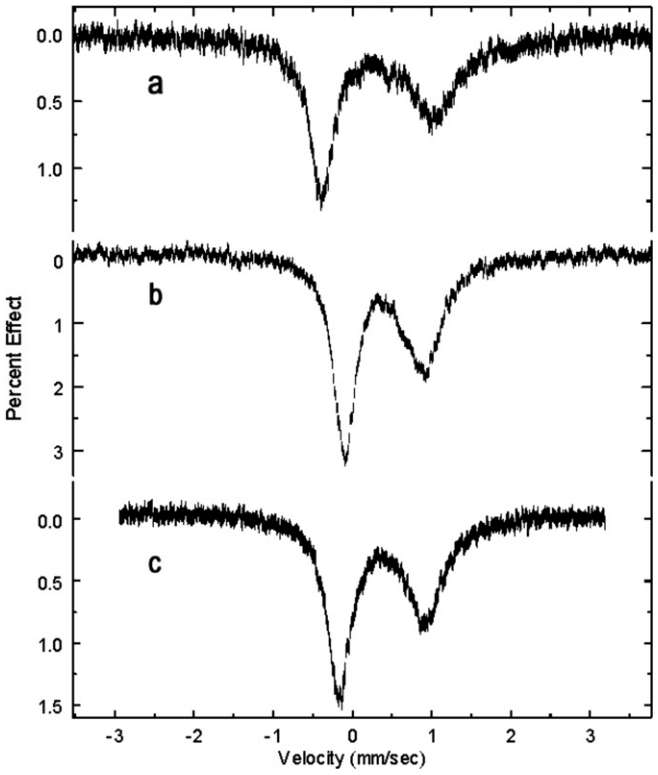

Fig. 6. Mössbauer spectra of (a) [Fe(OEP)(NO_3)], (b) [Fe(TPP)(NO_3)], and (c) [Fe(TpivPP)(NO_3)]. Spectra taken at room temperature.

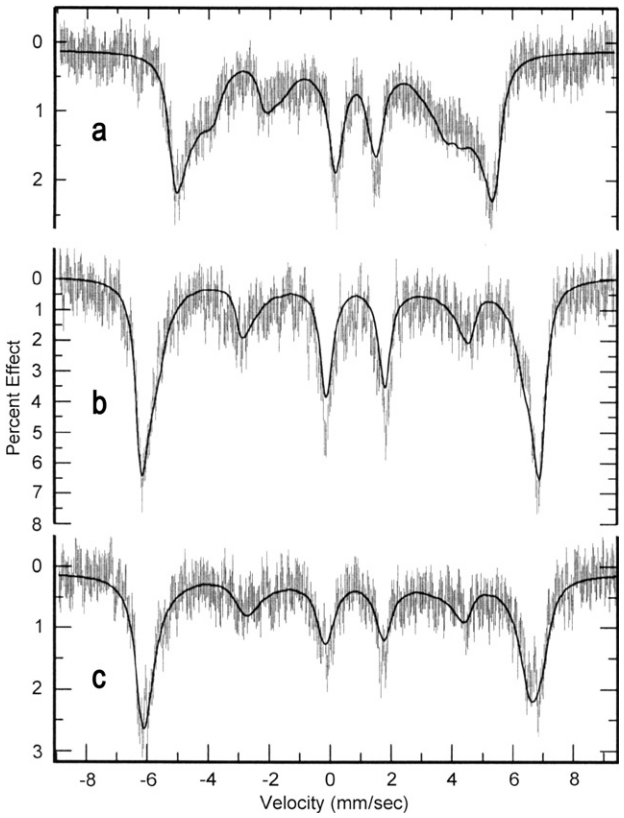

Fig. 7. Mössbauer spectra and calculated fits of the spectra of (a) [Fe(OEP)(NO_3)], (b) [Fe(TPP)(NO_3)], and (c) [Fe(TpivPP)(NO_3)]. Spectra taken at 4.2 K and an applied 4.5 T field parallel to the gamma ray beam.

with the largest g-tensor shifting to 8.5 at 4 K. Correspondingly, the largest g-tensor in the EPR spectrum of the ground crystalline [Fe(TpivPP)(NO_3)] is smaller than that of the TPP derivative ($g = 6.44, 3.97, 1.9$). EPR data from a powder sample of [Fe(TpivPP)(NO_3)] of unknown phase which was prepared using a crude precipitation technique exhibits a characteristic axial spectrum with $g = 5.5, 2$ pattern. Based upon our observations from the OEP system, this likely contains a monodentate nitrate ligand. Similarly, axial EPR spectra are observed for solutions of the TPP and picket fence derivatives. This suggests that the coordination mode of the nitrate ligand in both these systems changes to monodentate upon solvation.

4.4. Mössbauer spectroscopy

Table 5 summarizes the Mössbauer measurements carried out on each of the nitrate complexes collected over a range of temperatures. All three systems were studied at 4 K in an applied magnetic field and the spectra could be satisfactorily fit to a $S = 5/2$ model (Table 6 and Fig. 7). All three systems displayed asymmetric quadrupole doublets at room temperature. Linewidths broadened such that quadrupole splitting fits were inaccessible in the temperature range from 150 K to below 18 K for the TPP and TpivPP derivatives; the OEP derivative did not show the same broadening behavior. The values for the quadrupole splitting are somewhat larger than other high-spin ferric systems such as [Fe(por)(Cl)] ($\Delta E_q \sim 0.9$ mm/s). Since the quadrupole splitting is dependent upon the symmetry of the metal center and we have already observed significant differences in the nature of the g tensors in the ground crystalline samples, we expect here to observe substantial differences in the values of ΔE_q for all three systems. Although differences are observed, the fact that the OEP derivative has the largest value of ΔE_q is unexpected. Moreover, there remains some uncertainty about the exact phase for the picket fence porphyrin measurement.

Table 6
Data from $S = 5/2$ fit to 4.2 K Mössbauer spectra of [Fe(por)(NO_3)] derivatives

Complex	ΔE_q (mm/s)	δ (mm/s)	η	Γ (mm/s)	D (cm^{-1})	E (cm^{-1})	$A_{ii}/g_N\beta_N$ (T)
[Fe(OEP)(NO_3)]	1.44	0.53	0.06	0.52	5.7	0.37	−14.9, −17.3, −2.7
[Fe(TPP)(NO_3)]	0.97	0.61	0.0	0.42	6.9	0.6	−21.8, −20.0, −10.4
[Fe(TpivPP)(NO_3)]	1.0	0.56	0.4	0.57	10	0.2	−23.1, −20.9, −2.0

5. Summary

Nitrate can bind to the iron center in the iron(III) porphyrinates in either a symmetric bidentate or monodentate mode. An earlier report of an asymmetric binding mode is probably not correct. EPR spectra display sensitivity to the coordination mode. An axial high-spin signal is seen for monodentate coordination, whereas a rhombic high-spin spectrum is observed for the bidentate species. Mössbauer spectra do not appear to be as sensitive to the coordination mode.

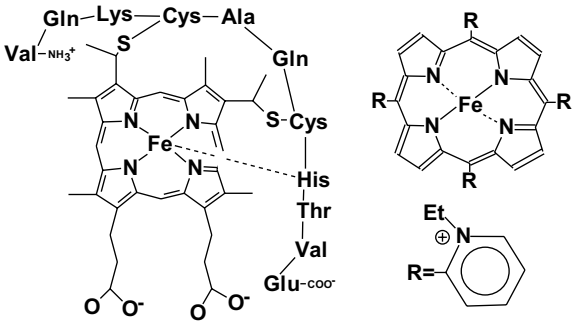
relevance of the reaction of nitroxyl with thiol compounds probably lies in its oxidative character leading to disulfides, or in the irreversible formation of sulfinamide adducts [14]. While these reactions are specifically associated with the biochemical activity of HNO when critical metals or thiols are involved, the spin forbidden reaction of HNO with molecular oxygen can be regarded as a sink reaction generating a cytotoxic two electron oxidant which is also a hydroxylating agent [15,16]. A comparative study of the reactivity of HNO from the nitroxyl donor Angeli's salt showed that HNO will preferentially react with proteins containing ferric centres or thiols rather than with O_2 or with itself forming N_2O [16].



Heme model compounds offer the opportunity to study the reaction kinetics without the complexity arising from ligand interactions with the protein matrix. For example, the heme peptide microperoxidase-11 (MP11) provides a Fe^{III}-histidine pentacoordinated centre that allows the study of the influence of the axial histidine on the reaction. Another perspective of analysis is offered by cationic Mn^{III} porphyrins. The reactions of these porphyrins with HNO donors have been studied by our group and we reported an assisted decomposition of HNO donors leading to the formation of $Mn^{II}NO$ compounds [17]. In this context, we have looked into the reaction between the commonly used nitroxyl donors sodium trioxodinitrate ($Na_2N_2O_3$, Angeli's salt, AS) [18,19] and toluene sulfohydroxamic acid (TSHA), an analogue of Piloty's acid [20,21], with the ferric model compounds Fe^{III}MP11 and the cationic ferric tetrakis *N*-ethylpyridinium-2yl porphyne $[Fe^{III}TEPyP]^{5+}$ (Scheme 1).

2. Materials and methods

2.1. Experimental methods

2.1.1. Reagents

AS and TSHA were synthesized according to published literature [22]. $[Fe^{III}TEPyP]^{5+}$ and MP11 were purchased from Frontier Scientific and Sigma–Aldrich Argentina, respectively, and used as received.

Scheme 1. Structure of Fe^{III}MP11 and $[Fe^{III}TEPyP]^{5+}$.

2.1.2. Reactions of heme models with AS and TSHA

All experiments were done at 25 °C in 0.1 M phosphate buffer, containing EDTA 10^{-4} M to avoid HNO catalytic decomposition by Cu^{II} and other divalent ions. Porphyrin concentration was 5×10^{-6} M, unless otherwise noted. UV–Vis spectra were recorded with a HP 8453 spectrometer in a septum sealed 1 cm path quartz cell. All manipulations were performed under argon atmosphere using septa; solutions were purged for at least 20 min with Ar. All reactions were unaffected by the irradiation of the sample with the light source of the spectrometer. AS and TSHA solutions were freshly prepared for each set of measurements and kept on ice. The donor concentration was checked before each measurement by following its absorbance [21,23]. TSHA was dissolved in ethanol 96%, and added to the porphyrin solutions to a final ethanol/water ratio minor than 1%. The reaction rate was measured by following the absorbance of the porphyrins at the peak position of the Soret and/or Q bands. All reactions were pursued until no more spectroscopic changes were observed, unless otherwise stated. Reaction times ranged from 60 s to 2 h.

Previous studies by our group showed that the reaction is always first order on both reactants, the metalloporphyrin and either the HNO or the donor [17]. To compute the corresponding bimolecular rate constants (k_{on}), the observed first order rate constants (k_{obs}), for several donor or HNO concentrations were obtained for the reactions with $[Fe^{III}TEPyP]^{5+}$ and with MP11 by the initial rate method using the equation:

$$k_{obs} = \frac{v_{on}}{[P]_0} = k_{on}[HNO/Donor]_0$$

where v_{on} is the initial rate of the metalloporphyrin decay, $[P]_0$ is the initial concentration of $[Fe^{III}TEPyP]^{5+}$ or MP11, k_{on} is the second order rate constant and $[HNO/Donor]_0$ is the concentration of the free HNO or of the nitroxyl donor. The HNO concentration was estimated by the following kinetic analysis:

$$\text{Donor(TSHA/ AS)} \xrightarrow{k_d, v_d} \text{HNO} \quad (1)$$

$$\text{HNO} + Fe^{III}P \xrightarrow{k_{on}, v_{on}} Fe^{II}P\text{–NO} \quad (2)$$

$$\text{HNO} \xrightarrow{k_h, v_h} 1\frac{1}{2}N_2O + 1\frac{1}{2}H_2O \quad (3)$$

where the reaction (1) represents the donor decomposition, (2) represents HNO reaction with the metalloporphyrin ($Fe^{III}P$) and (3) represents HNO dimerization. The reaction (1) was considered as an irreversible reaction because its inverse rate is negligible with respect to reactions (2) and (3) at the initial rate condition. Applying the steady state approximation for [HNO], all the HNO produced through reaction (1) must be consumed in reactions (2) and (3), therefore $v_d = v_{on} + v_h$. The donor decomposition first order rate constant k_d [18,20,23,24] ($k_{d(TSHA)} = 3.5 \times 10^{-4}\ s^{-1}$, $k_{d(AS)} = 8 \times 10^{-4}\ s^{-1}$; determined in this work) and the dimerization second order rate constant [15,23,25] k_h ($k_h = 8 \times 10^6\ M^{-1}\ s^{-1}$) [15] are known data. There-

fore, by measuring the initial v_{on} and the donor concentration, [HNO] can be estimated as

$$[\mathrm{HNO}] = \sqrt{\frac{k_d[\mathrm{Donor}] - v_{on}}{k_h}}$$

From the k_{obs} versus [HNO] or [Donor] plots, an estimated $k_{on(HNO)}$ or $k_{on(Donor)}$ can be obtained from the slope. This type of analysis has already been done for studying HNO reaction kinetics [16,17]. Each point showed in the plots corresponds to the mean of at least three independent measurements.

2.2. Computational methods

All computations were performed at the DFT level with the SIESTA code [26,27], which consists on a very efficient DFT implementation which uses pseudopotentials and numerical basis sets. The use of standard norm-conserving pseudopotentials [28] avoids the computation of core electrons, smoothing at the same time the valence charge density. In our study, the nonlinear partial-core correction was applied to the iron atom [29]. Basis functions consist of localized (numerical) pseudoatomic orbitals, projected on a real space grid to compute the Hartree potential and exchange correlation potentials matrix elements. For all atoms, basis sets of double ξ plus polarization quality were employed, with a pseudoatomic orbital energy shift of 25 meV and a grid cutoff of 150 Ry. Calculations were performed using the generalized gradient approximation functional proposed by Perdew et al. [30]. The SIESTA method has shown an excellent performance for medium and large systems and has also proved to be appropriate for heme models with this combination of functional, basis sets, and grid parameters [31,32]. The model used consisted of a porphyrin saturated with hydrogen atoms in all side chains ($Fe^{III}P$) plus the corresponding ligand (5-methylimidazole, NO or AS) optimized in vacuum. We have performed the geometry optimizations of the $[Fe^{III}P(AS)]^{-1}$ complex at the low spin state, which has been found to be the ground state of the system.

3. Results and discussion

3.1. Reaction of $[Fe^{III}TEPyP]^{5+}$ with AS

When AS is added to $[Fe^{III}TEPyP]^{5+}$ solutions under inert atmosphere in equimolar ratio, total conversion of $[Fe^{III}TEPyP]^{5+}$ to $[Fe^{II}TEPyP(NO)]^{4+}$ is observed in less than a minute verifying that the stoichiometry of the reaction is 1:1 in reagent and product (Fig. 1). Although AS decomposes spontaneously with a half life of 866 s, measured under the same reaction conditions at pH 7, as mentioned in Section 2, the equimolar reaction exhibits a half life for AS of just about 5 s, indicating that the decomposition rate is noticeably faster in the presence of the metalloporphyrin. In this scenario, the direct reaction of AS with

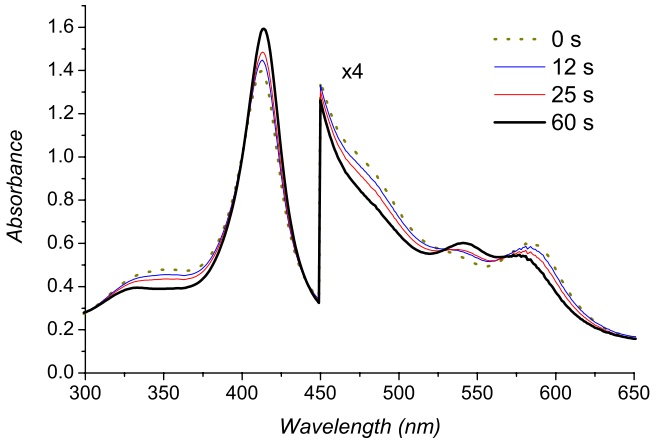


Fig. 1. Spectral changes observed for the addition of AS to a solution $[Fe^{III}TEPyP]^{5+}$ (2×10^{-5} M) (phosphate buffer pH 7, 25 °C). $[Fe^{III}TEPyP]^{5+}$: dotted line, $[Fe^{II}TEPyP\text{-}NO]^{4+}$: thick solid line.

the porphyrin is expected to be the main reaction pathway for AS decomposition. Therefore, the second order rate constant for the reaction ($k_{on(AS)}$) was determined (Table 1) from the slope of the k_{obs} versus [AS] plot (Fig. 2). This results find a precedent in our previous work with Mn^{III} porphyrins, where we demonstrated that the positively charged porphyrin $[Mn^{III}TEPyP]^{5+}$ assists the decomposition of both nitroxyl donors AS and TSHA [17].

3.2. Reaction of $[Fe^{III}TEPyP]^{5+}$ with TSHA

The half life of the spontaneous decomposition of TSHA at pH 10, measured under the experimental conditions described in Section 2.1.2, is 33 min while the half life for the reaction with $[Fe^{III}TEPyP]^{5+}$ is about 10 s, indicating once more that the metalloporphyrin is reacting directly with TSHA. In Fig. 3 is depicted the k_{obs} versus [TSHA]. From the slope of this plot a value for the bimolecular binding constant rate $k_{on(TSHA)}$ is obtained (Table 1).

3.3. Reaction of MP11 with AS

When excess of AS is added to $Fe^{III}MP11$ aqueous solutions under inert atmosphere at pH 7, spectral changes corresponding to the conversion of $Fe^{III}MP11$ to $Fe^{II}MP11(NO)$ are observed (Fig. 4). This product was identified by comparison with the one obtained from the same starting material, sodium dithionite, and nitric oxide (data not shown). The absence of an isosbestic point in Fig. 4 suggests the presence of more than two species. A Principal Factor Analysis predicts the presence of three spectral components in the kinetics which indicates the formation of an intermediate. The rate of HNO production (calculated from known AS concentrations and the decomposition rate constant) and of the reaction of HNO with $Fe^{III}MP11$ are plotted in Fig. 5. As it can be seen in Fig. 5, in all cases HNO production exceeds its consumption by the heme compound indicating that the metalloporphy-

Table 1
Bimolecular reaction rate constants for the binding of nitroxyl donors and HNO to Fe and Mn porphyrins

Porphyrin	pH	Donor	$k_{on(Donor)}$ (M^{-1} s^{-1})	$k_{on(HNO)}$ (M^{-1} s^{-1})
$[Mn^{III}TEPyP]^{5+}$ [17]	7/10	AS/TSHA	$0.8–3.6 \times 10^4$	
$[Fe^{III}TEPyP]^{5+}$	7	AS	$5.4 \pm 0.2 \times 10^3$	
$[Fe^{III}TEPyP]^{5+}$	10	TSHA	$1.1 \pm 0.3 \times 10^4$	
$[Mn^{III}TPPS]^{3-}$ [17]	7/10	AS/TSHA		$\sim 4–9 \times 10^4$
$[Fe^{III}TPPS]^{3-}$ [13]	7	AS	0.5	$\sim 1 \times 10^6$
Fe^{III}MP11	7	AS		$6.4 \pm 0.5 \times 10^4$
Fe^{III}MP11	10	TSHA		$3.1 \pm 0.4 \times 10^4$

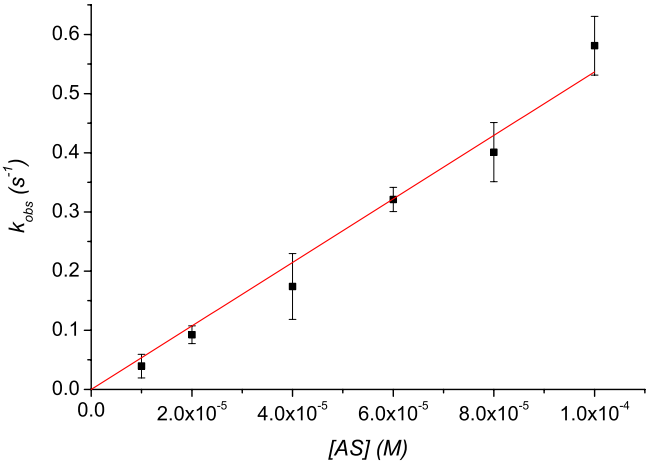

Fig. 2. Initial observed constant rates vs. [AS] (pH 7 phosphate buffer, 25 °C), for the reaction of $[Fe^{III}TEPyP]^{5+}$ (2×10^{-5} M) with AS.

rin may be reacting directly with the species HNO. Under these circumstances from the plot of the observed rate constant versus [HNO] (Fig. 6) is obtained a value for the bimolecular HNO binding rate constant at pH 7 (Table 1).

3.4. Reaction of MP11 with TSHA

When excess of TSHA is added to Fe^{III}MP11 aqueous solutions under inert atmosphere at pH 10, the spectral changes and kinetics were similar to those observed when AS was the donor (Fig. 7). From the plot of the observed rate constants versus [HNO] (Fig. 8) the rate constant for the bimolecular reaction of HNO at pH 10 is derived (Table 1).

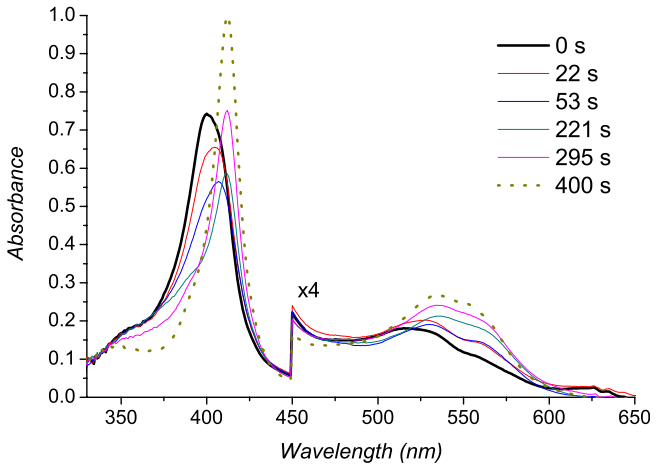

Fig. 4. Spectral changes observed at successive times for the reaction of AS with Fe^{III}MP11 (pH 7 phosphate buffer, 25 °C). Fe^{III}MP11: thick solid line, Fe^{II}MP11-NO: dotted line.

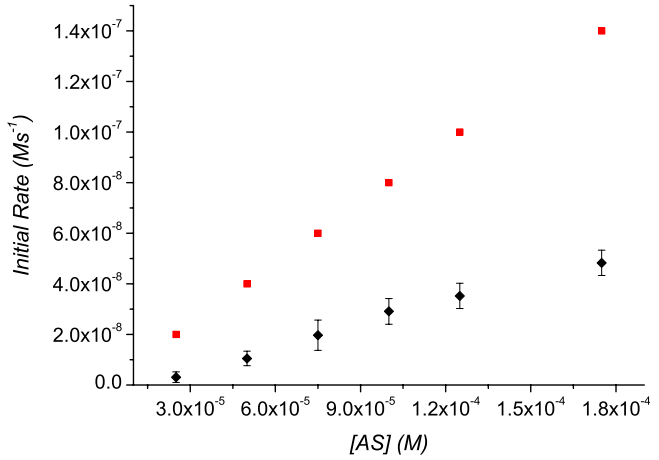

Fig. 5. Calculated initial HNO production rates (squares) and initial reaction rates (diamonds) vs. initial AS concentration (phosphate buffer, 25 °C), for the reaction of Fe^{III}MP11 (5.0×10^{-6} M) with AS (0.2–2.0×10^{-4} M).

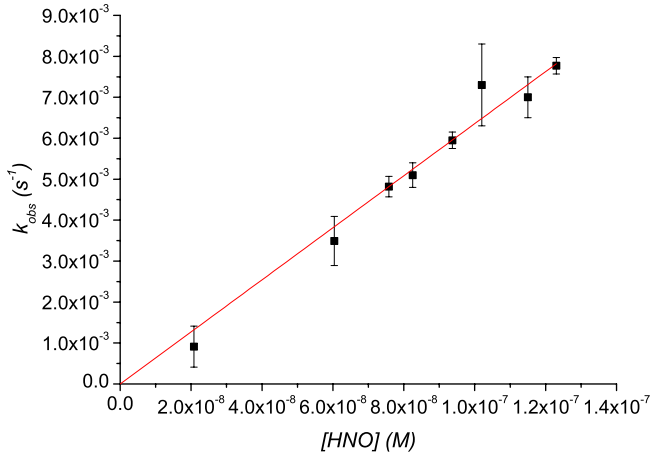

Fig. 6. Initial observed constant rates vs. estimated [HNO] (pH 7 phosphate buffer, 25 °C), for the reaction of Fe^{III}MP11 (5.0×10^{-6} M) with AS (0.2–2.0×10^{-4} M).

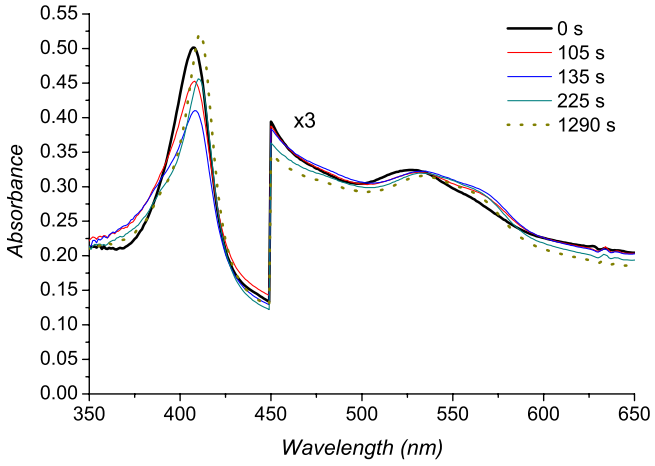

Fig. 7. Spectral changes observed at successive times for the reaction of TSHA with Fe^{III}MP11 (pH 10 phosphate buffer, 25 °C). Fe^{III}MP11: thick solid line, Fe^{II}MP11-NO: dotted line.

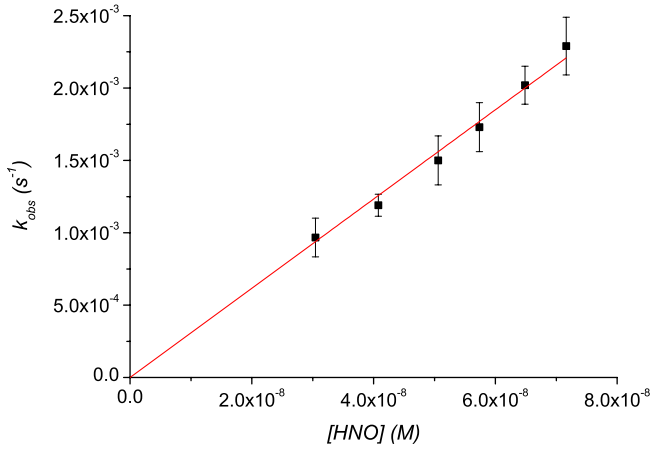

Fig. 8. Initial observed constant rates vs. estimated [HNO] (pH 10 phosphate buffer, 25 °C), for the reaction of Fe^{III}MP11 (5×10^{-6} M) with TSHA (0.3–1.5×10^{-4} M).

In order to gain some insight into the possible nature of the reaction intermediate we followed the reaction by ^{1}H NMR using AS. Fig. 9 shows the ^{1}H NMR spectrum of the starting material, and exhibits the characteristic α-CH_3 chemical displacements between 75 and 55 ppm, attributable to a high spin species [33]. This supports the fact that MP11 is initially pentacoordinated with the proximal histidine as the sole axial ligand or hexacoordinated with water and histidine. The low spin final product is characterized by the α-CH_3 signals between 15 and 30 ppm, suggesting that the product may be the ferrous heme hexacoordinated with NO and histidine as axial ligands [33]. The ^{1}H NMR spectrum scanned during the evolution of the reaction (reaction time: 304 s) shows the α-CH_3 signals in the 30–15 ppm region and an additional signal in this range (pointed in Fig. 9 with an arrow) not observed in the initial and final spectra that indicates the intermediacy of a low spin adduct. The same pattern is observed with both HNO donors and the hemepeptide MP11, while no intermediate is observed for the reaction with free metalloporphyrins. The reaction rate suggest that HNO initially reacts with MP11 in a similar manner to that observed with others negatively charged metalloporphyrins [13,17], but now leading to a low spin reaction intermediate due to the proximal histidine. Subsequently, it is likely that a change occurs in the conformation of the peptide chain,

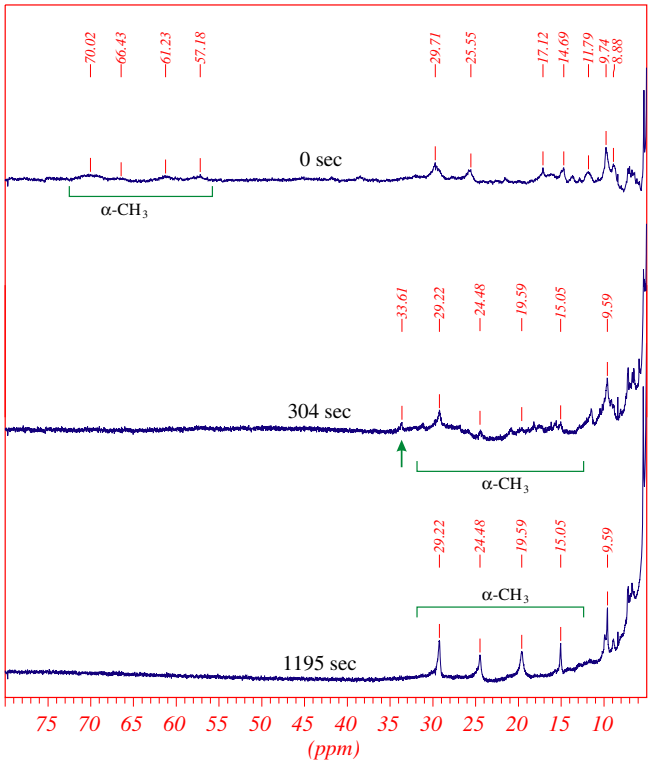

Fig. 9. ^{1}H NMR spectra of the kinetic between MP11 and AS in D_2O at 30 °C under inert atmosphere recorded using a 500 MHz Bruker AM500 spectrometer ($[MP11]_{initial} = 4 \times 10^{-3}$ M and $[AS]_{initial} = 1$ M). 1st spectrum (0 s): MP11; 2nd spectrum (304 s): MP11 (Fe^{III}) + intermediate + Fe^{II}MP11-NO; 3rd spectrum (1195 s): Fe^{II}MP11-NO.

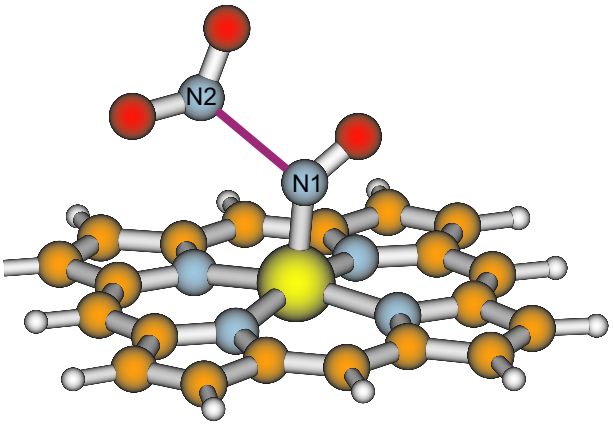
reflected by the UV–Vis and ^{1}H NMR spectroscopic changes, giving rise to the final product.

To obtain additional insight on the intermediate complex between $[Fe^{III}TEPyP]^{5+}$ with AS ($N_2O_3^{2-}$), we have characterized by means of DFT calculations the possible complexes with different coordination patterns (through the N or O atoms) by using a model system of metalloporphyrin, $[Fe^{III}P]^+$. The complex proposed in Scheme 2 and depicted in Fig. 10, coordinated through the N atom, has been found to be the most stable minimum in the potential energy surface. This complex has been found to be more stable than the complexes with AS bound to the metal centre through any of the oxygen atoms. The results also show that the N1–N2(AS) bond length is significantly longer in the $[Fe^{III}P(AS)]^-$ complex than in free AS (2.319 versus 1.371 Å). Furthermore, the N1–N2(AS) bond dissociation energy in the $[Fe^{III}P(AS)]^-$ complex (28.2 kcal/mol), a process which yields as products the $Fe^{II}P$-NO complex and nitrite, is significantly reduced compared to free AS (44.3 kcal/mol). These data support the cleavage of AS assisted by coordination to the metalloporphyrin. The same model system with Mn instead of Fe results in a weaker N1–N2(AS) bond (distance: 2.620 Å, dissociation energy: 19.5 kcal/mol) [17].

The energy of the same process was also calculated for the iron model compound with 5-methylimidazole as sixth ligand, mimicking the coordinated histidine in MP11. Despite the shorter N1–N2 distance in this complex (2.106 Å), the dissociation energy is lower (22.7 kcal/mol) than without the sixth ligand indicating that this intermediate is even less stable than the previous one and probably more difficult to be kinetically detected if formed.

Table 1 summarizes the reported values of k_{on} for nitroxyl donors or nitroxyl and different metalloporphyrins. The data is consistent with two alternative pathways for the reactivity of nitroxyl donors (AS, TSHA) with prophyrin centres in aqueous solutions (Scheme 2). The first one comprises the stepwise assisted decomposition of the donor, enhancing its decomposition rate more than 100 times (through reactions (3) and (4)). Despite the k_{on} for HNO binding are higher than for the donors, the concentration of the donors is four orders of magnitude higher than of the former, leading to a faster pathway for the direct reaction with the donor. This kind of interaction was first observed by our group with Mn^{III} cationic porphyrins [17] and in the present work is also observed with the ferric analogue.



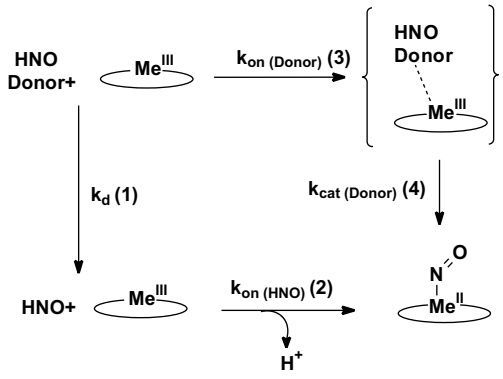


Fig. 10. Optimized DFT structure of the putative intermediate formed by Fe^{III}-Porphyrin and AS.

An interesting point concerning the direct reaction between the donor and the metalloporphyrin is the fact that a possible redox mechanism could be operative for TSHA. Piloty's acid, has been shown to be oxidized by several iron complexes yielding the corresponding radical, which decomposes yielding NO and the reduced metal complex [34]. In our scenario, this mechanism would imply that the reaction proceeds through an intermediate state with the reduced porphyrin (Fe^{II}), radical TSHA and free NO. Afterwards, NO reacts very fast with the reduced iron porphyrin yielding the corresponding nitrosyl complex as the final product, as observed here. However, we cannot discard a mechanism involving an intermediate formed by TSHA and the metalloporphyrin, followed by the NO^- transfer to the porphyrin. Both mechanisms are compatible with our results.

It can be noticed in Table 1 that Fe^{III}MP11 reacts faster with HNO at pH 7 than at pH 10. This is probably due to the fact that in alkaline media the hydroxyl is bound instead of a water molecule, lowering the reaction rate due to the stronger binding.

It is also noteworthy that a positively charged environment seems to be a prerequisite for direct HNO donor–target interaction. Moreover, we found just one study where assisted decomposition of AS by a heme protein (cytochrome P450) is reported [35]. With this picture in mind, direct interaction of HNO donors with biological targets in *in vivo* studies seems to be likely. Furthermore, interpretation of kinetic data from *in vitro* studies under high HNO donor concentrations should be made cautiously. On the other hand, the negatively charged Fe^{III} and Mn^{III} porphyrins and Fe^{III}MP11 react mainly with free HNO. It is not surprising that Fe^{III}MP11 behaves like the anionic porphy-

Scheme 2. Proposed reaction mechanism for HNO donors with metalloporphyrins.

Table 2
Bimolecular rate constants for HNO and NO binding to metalloporphyrins and heme proteins

Target	Reactant	k_{on} (M^{-1} s^{-1})	Ref.
Fe^{III}MP11	HNO	$3.1–6.4 \times 10^4$	this work
Fe^{III}MP11	NO	1.1×10^6	[36]
$[Fe^{III}TPPS]^{3-}$	NO	4.5×10^5	[37]
metMb (Fe^{III})	HNO	8×10^5	[16]
Catalase (Fe^{III})	HNO	3×10^5	[16]
$[Fe^{II}TPPS]^{4-}$	NO	1.5×10^9	[37]
Mb (Fe^{II})	HNO	1.4×10^4	[12]
O_2	HNO	3×10^3	[16]

rins given the proximity of two propionate side chains to the heme pocket. It is also relevant to note that as previously shown [13] free NO possible evolves due to homolytic decomposition of the nitrosyl complexes.

The bimolecular rate constants for HNO binding to the Fe^{III} heme models presented here are quite fast and comparable to the observed reactions rates for NO and HNO reactions with ferric heme systems (Table 2).

It is clear from the data presented in Table 2, that although lacking the protein scaffold, the soluble porphyrins and MP11 display reactivity properties against HNO comparable with the observed reactivity of HNO with heme proteins, which are the main biological targets [16]. The bimolecular rate constants for HNO binding to ferric heme systems are in the order of 10^5–10^6 M^{-1} s^{-1}, similar to the values obtained for NO and probably represent an upper limit for the reaction with ferric hemes. However, these rates are more than 1000 times lower than the corresponding values for NO or CO binding to ferrous hemes [37]. This trend can be explained due to the fact that, for ferric hemes, the ligand binding kinetic is dependent on the lability of the leaving water ligand in contrast with ferrous hemes where the water ligand is weakly bounded [37]. This fact has been shown to play a key role in ligand binding rates in heme proteins [38], therefore it is also expected to be determining towards the reactivity of HNO.

2. Computation details

DFT calculations with the hybrid exchange-correlation functional B3LYP [11] were carried out using the GAUSSIAN03 [12] package. Unless otherwise noted, the geometry of the compounds of interest was optimized in the LanL2DZ [13,14] basis set. The spin-unrestricted UB3LYP method was used for the open-shell systems, and the Kohn–Sham orbital diagrams for these compounds were obtained using the restricted open-shell B3LYP method. Partial atomic charges and orbitals occupations were computed according to the natural atomic orbital (NAO) schemes.[1] Molecular orbitals were plotted using MOLEKEL 4.3 [15].

For the closed-shell systems the Mayer's bond orders [8,9] are calculated as

$$B_{AB} = \sum_{\mu\in A}\sum_{\nu\in B}(\mathbf{DS})_{\mu\nu}(\mathbf{DS})_{\nu\mu}. \quad (1)$$

Here **S** is the overlap matrix and **D** is the spinless density matrix, $\mathbf{D} = \mathbf{P}^{\alpha} + \mathbf{P}^{\beta}$:

$$D_{\mu\nu} = 2\sum_{i}^{occ.} C_{\mu i}C^{*}_{\nu i}; \quad P^{\alpha}_{\mu\nu} = \sum_{i\in\alpha}^{occ.} C_{\mu i}C^{*}_{\nu i}; \quad P^{\beta}_{\mu\nu} = \sum_{i\in\beta}^{occ.} C_{\mu i}C^{*}_{\nu i}, \quad (2)$$

where **C** is the matrix of MO coefficients. In the case of the open-shell systems the Mayer's bond orders are calculated as [8,9]

$$\begin{aligned} B_{AB} &= \sum_{\mu\in A}\sum_{\nu\in B}[(\mathbf{DS})_{\mu\nu}(\mathbf{DS})_{\nu\mu} + (\mathbf{QS})_{\mu\nu}(\mathbf{QS})_{\nu\mu}] \\ &= 2\sum_{\mu\in A}\sum_{\nu\in B}[(\mathbf{P}^{\alpha}\mathbf{S})_{\mu\nu}(\mathbf{P}^{\alpha}\mathbf{S})_{\nu\mu} + (\mathbf{P}^{\beta}\mathbf{S})_{\mu\nu}(\mathbf{P}^{\beta}\mathbf{S})_{\nu\mu}], \end{aligned} \quad (3)$$

where **Q** is the spin density matrix, $\mathbf{Q} = \mathbf{P}^{\alpha} - \mathbf{P}^{\beta}$. For the closed shell systems the Wiberg's bond order indices are calculated in the NAO[2] [18,19] basis as

$$W_{AB} = \sum_{\mu\in A}\sum_{\nu\in B}(D^{NAO}_{\mu\nu})^2 \quad (4)$$

and for the open shell systems [8,9] as

$$\begin{aligned} W_{AB} &= 2\sum_{\mu\in A}\sum_{\nu\in B}[(P^{\alpha,NAO}_{\mu\nu})^2 + (P^{\beta,NAO}_{\mu\nu})^2] \\ &= 2(W^{\alpha}_{AB} + W^{\beta}_{AB}). \end{aligned} \quad (5)$$

We use the local cylindrical symmetry model to break down the A–B bond order index into σ-, π-, and δ-contributions, i.e. $C_{\infty v}$ local symmetry is assumed for each bond. For any given pair of atoms A and B the coordinate system is transformed so, that the *z*-axis would coincide with the bonding line between these two atoms. Depending on the orientation of orbitals μ and ν in respect to the *z*-axis the corresponding term in Eqs. (1), (3), (4), (5) is assigned to σ-, π- or δ-contribution, as illustrated by the Mayer index for the closed shell systems:

$$\begin{aligned} B_{AB} &= \sum_{\substack{\mu\in A\\ \mu\in\sigma}}\sum_{\substack{\nu\in B\\ \nu\in\sigma}}((PS)_{\mu\nu}(PS)_{\nu\mu}) + \sum_{\substack{\mu\in A\\ \mu\in\pi}}\sum_{\substack{\nu\in B\\ \nu\in\pi}}((PS)_{\mu\nu}(PS)_{\nu\mu}) \\ &\quad + \sum_{\substack{\mu\in A\\ \mu\in\delta}}\sum_{\substack{\nu\in B\\ \nu\in\delta}}((PS)_{\mu\nu}(PS)_{\nu\mu}) + \text{residual} \\ &= (B_{AB})_{\sigma} + (B_{AB})_{\pi} + (B_{AB})_{\delta} + (B_{AB})_{res}. \end{aligned} \quad (6)$$

The last term, B_{res}, covers all cases, for which the μ and ν orbitals do not belong to the same type (σ, π or δ). A similar procedure is used for the calculation of W_{AB}. For the open-shell systems the technique is modified appropriately. The method was tested for a set of compounds with various types of chemical bonds, including a number of molecules with cyclic structures.[3] The largest "residual" contributions were found for molecules with small cycles. The validity of this procedure for each bond can be monitored through the B_{res} (or W_{res}) value: if the 'residual component' is not negligible then $B \neq B_{\sigma} + B_{\pi} + B_{\delta}$ and the bond indices analysis discussed above is impossible. Detailed description of the method will be given elsewhere (work in progress).

3. Results and discussion

3.1. Free NO molecule, NO^+ and NO^- ions

Nitric oxide is a stable free radical, the unpaired electron in this molecule resides on a π^* molecular orbital. According to the qualitative molecular orbitals theory, the "classical" bond order in a diatomic molecule is

$$BO = \frac{N_{bond} - N_{antibond}}{2}, \quad (7)$$

where N_{bond} and $N_{antibond}$ are the number of electrons on the bonding and antibonding MO's, respectively. These bond orders can be easily separated into σ, π, and δ-contributions by sorting the MO's according to their symmetry. For the free nitric oxide and its ions the classical bond orders are:

	NO^+	NO^0	NO^-
	$(\sigma)^{10}(\pi)^4(\pi^*)^0$	$(\sigma)^{10}(\pi)^4(\pi^*)^1$	$(\sigma)^{10}(\pi)^4(\pi^*)^2$
BO	3	2.5	2
BO_{σ}	1	1	1
BO_{π}	2	1.5	1

[1] For all dimetal complexes, except $Ru_2(dpf)_4$ and $Ru_2(dpf)_4(NO)_2$, the structural information, MO and NBO analysis are obtained from earlier DFT calculations described in Refs. [16,17].

[2] The possibility of Wiberg indices calculation using the Lowdin orbitals, $W^{(L)}$, has also been considered.

[3] From the B3LYP/cc-pvdz calculation for benzene molecule we found $B_{CC} = 1.46$, $B_{\sigma} = 0.92$, $B_{\pi} = 0.54$, $W_{CC} = 1.44$, $W_{\sigma} = 0.96$, $W_{\pi} = 0.47$, and $B_{res} = W_{res} = 0$. This is in good agreement with the values of $B_{\sigma} = 1.00$ and $B_{\pi} = 0.45$ obtained in Ref. [20] for B3LYP/cc-pvdz using a different scheme of analysis.

The population of the π^* orbital in the row NO^+, NO^0, NO^- leads to the increase in the bond length (experimental values: 1.06 Å, 1.154 Å, 1.26 Å respectively) and to the decrease in the IR stretching frequencies ν(NO) from 2377 (NO^+) through 1875 (NO) to 1470 cm^{-1} (NO^-) [3,21]. The calculated bond lengths, vibrational frequencies, bond orders and their components for these species are given in Table 1.

As a rule the Wiberg bond indices, computed using the Lowdin orbitals, $W^{(L)}$, are overestimated,[4] especially their σ-component. The quantum chemical bond orders B, B_σ, B_π, W, W_σ, and W_π (Table 1) correlate well with the classical BO values and reliably discriminate between different oxidation states of nitric oxide. The σ-bond order is close to 1 and is almost constant in the series NO^+, NO^0, NO^-. The difference between oxidation states is reflected by B_π or W_π indices. The basis set dependence is more pronounced for the Mayer indices than for the Wiberg indices.

3.2. Ruthenium six-coordinate nitrosyl complexes

The well-known robustness of the linear $\{RuNO\}^n$ group in six-coordinate ruthenium nitrosyls is the obvious explanation of the fact that ruthenium forms more nitrosyls than any other metal [2]. Therefore, we shall start from the analysis of the bonding in these compounds. The calculated values of NO charge (q(NO)), σ- and π-electron population (n_σ and n_π), bond lengths (r) and bond orders for the $[Ru(NO)Cl_5]^{2-}$ complex (symmetry C_{4v}) are given in Table 2. Preferring the NAO-based results to the Mulliken/Mayer scheme, we took into account that: (i) Mulliken populations and Mayer bond orders (q_{Mull}, B_{AB}) are much more dependent on the basis set than corresponding values based on the NAO approach (q_{NAO}, W_{AB}); (ii) the high B(Ru–Cl) indices are not realistic; (iii) negative values of B_{AB} were obtained for some compounds. For these reasons we choose the NAO-based technique for further analysis and discussion. Due to the weak basis set dependence of the bond indices obtained via this approach, the following calculations were performed at the B3LYP/L an L2DZ level.

Since the residual contributions were not found for B and W indices, the analysis of their σ- and π-components is valid. In Fig. 1 the W_{AB} indices for the anionic, neutral, and cationic complexes with linear $\{RuNO\}^6$ group: $[Ru(NO)(CN)_5]^{2-}$, [Ru(NO)hedta] (hedta is the triple-charged anion *N*-(hydroxyethyl)ethylenediaminetriacetate), $[Ru(NO)(NH_3)_5]^{3+}$ are presented. In all cases the N–O σ-bond orders are almost the same as in the free NO, NO^+, and NO^- species. The N–O π-bond orders are close to that for NO^-(Tables 1 and 2; Fig. 1). The prevailing contribution to the Ru–N bonding is brought by the π-component with a bond index of about 1. Note that according to the EDA analysis [27] for the $[Ru(NO)(CN)_5]^{2-}$ complex also there is a significant (ca. 70 %) contribution of the π-orbital interaction to the M–NO covalent bonding [28]. A comparison of Ru–C bond orders in $[Ru(CN)_6]^{4-}$, $[Ru(CN)_6]^{3-}$ ($W_\sigma = 0.43-0.44$, $W_\pi = 0.08-0.09$), and $[Ru(NO)(CN)_5]^{2-}$ complexes (Fig. 1) shows that *cis*- and *trans*-influence of nitric oxide is relatively small, the most noticeable effect being the slight increase of W_σ(Ru–C_{trans}).

For all complexes, regardless of the computational method and basis set used, unusually large values of through-atom indices (TAI) B_{RuO} and W_{RuO} were obtained (see Scheme 1).

The emergence of TAI(Ru–O) is due to the d_π(Ru) and π^*(NO) orbital mixing and, consequently, to large values of $D_{\mu\nu}$ and $(\mathbf{DS})_{\mu\nu}$ for $\mu = d_{xz}$(Ru) and $\nu = p_x$(O), and for $\mu = d_{yz}$(Ru) and $\nu = p_y$(O). Thus, the non-zero TAI suggests delocalization of the π-electron density over the linear fragment and is not likely to be an artefact. It is worth

[4] This effect was also noted in a recent work [24], devoted to the analysis of bond orders in the iso-nitrous acid complexes.

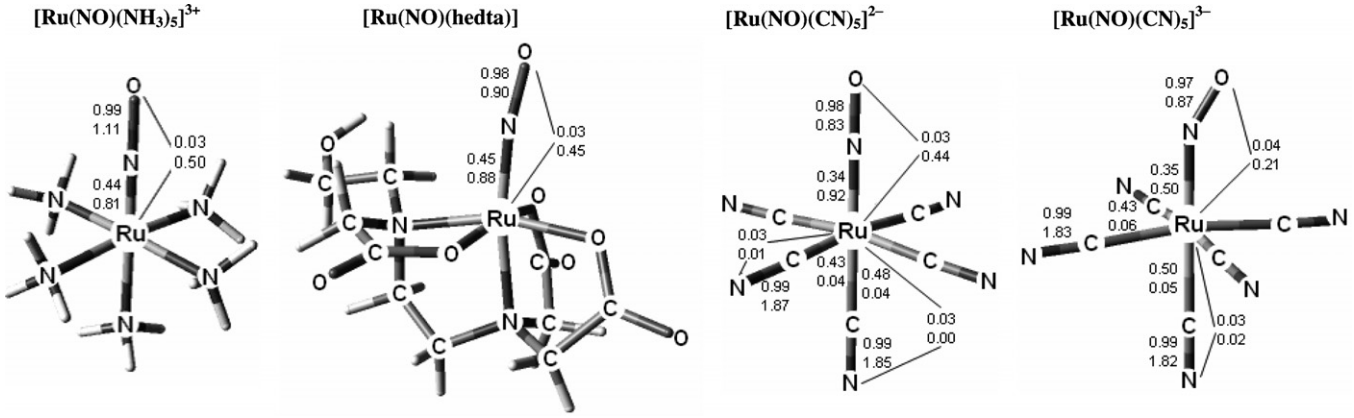
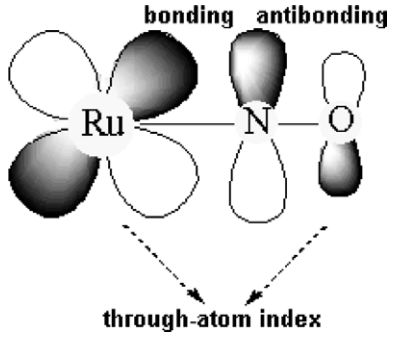
[a] Experimental values (Å): r(Ru–N) = 1.738; 1.747; r(N–O) = 1.131; 1.112; r(Ru–Cl_{trans}) = 2.357; r(Ru–Cl_{cis}) = 2.375 [22,23].

mentioning that significant TAI's were found for a number of linear organic and inorganic molecules with multiple bonds, such as CO_2, N_2O, HCNO, $H_2C{=}C{=}C{=}CH_2$, $HC{\equiv}C{-}C{\equiv}CH$, $N{\equiv}C{-}C{\equiv}N$, etc., as well as for carbonyl complexes, though in the latter case the TAI-values are only about a half of those for $\{RuNO\}^6$. The predominant contribution to the TAI is always due to the π-component. For the {RuCN} fragments the Ru–N TAI's are negligibly small (Fig. 1), including those for the bridging CN group in $[(NO)Ru(py)_4{-}N{-}C{-}Ru(py)_4(CN)]^{3-}$ (Scheme 2).

In the $\{RuNO\}^6$ complexes the charge on NO is close to zero, the triple-charged $[Ru(NO)(NH_3)_5]^{3+}$ cation being the only exception to this rule. The total number of electrons on the π-orbitals, n_π(NO), is higher than for the free NO molecule, while for the σ-orbitals n_σ(NO) is lower by approximately the same value. The natural occupancies of ruthenium d-orbitals (Table 4) in octahedral nitrosyl complexes correspond to Ru^{III} oxidation state and d^5 electronic configuration: the $n(d_\pi) = n(d_{xz}) + n(d_{yz})$ values reflect the oxidation state of the metal, at the same time $n(d_{z^2})$ and $n(d_{x^2-y^2})$ values reflect the σ-donor properties of the ligands. In the bridged $[(NO)Ru(py)_4NCRu(py)_4(CN)]^{3-}$ complex both of the Ru atoms are surrounded by π-acceptor ligands, therefore the d_π occupancies (3.12





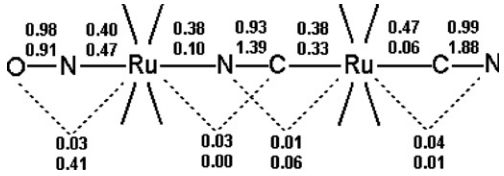


Fig. 1. W_σ (upper value) and W_π (lower value) indices for the six-coordinate nitrosyl complexes of ruthenium.

Scheme 1.

Scheme 2.

and 3.57) are significantly lower than 4, at that binuclear compound exhibits some features of a mixed-valence complex.

Taking into account the calculated charges on the NO ligand, the interpretation of the nitrosyl complexes as compounds of Ru^{III} and NO^0 appears reasonable[5] despite the fact that the N–O bond order is lower than that for the free molecule, and is closer to the value characteristic for NO^-. The latter phenomenon can be explained by the high degree of delocalization in the three-center M–N–O fragment. The unique π-bond order index for Ru–N, which is almost as high as 1, provides sufficient basis to treat Ru–N as a polar covalent bond. Since nitric oxide is a radical with the unpaired electron on a π^* orbital, the optimal conditions for the formation of the covalent M–NO bond are achieved when the d_{xz} and d_{yz} AO of the metal atom are occupied by 1.5 electrons each. In this case the electron pairs $1.5e(d_{xz}) + 0.5e(\pi_x^*)$ and $1.5e(d_{yz}) + 0.5e(\pi_y^*)$ occupy the {MNO}-delocalized orbitals, which are bonding in respect to M–N and antibonding in respect to N–O. Analyzing the M–NO linkage in terms of Green's covalent bond classification [30], Landry et al. [31] conclude that the metal atom is required to contribute three electrons to the metal–nitrosyl bonding interaction, which is in complete agreement with our results. The Ru–N σ-bond is a typical donor acceptor $d_{z^2} \leftarrow \sigma$ (N) bond with $W_\sigma \sim 0.4$, and is localized in the interatomic region.

The increase of the number of electrons in the $\{MNO\}^n$ group to $n = 7$ prohibits the covalent bond formation scheme discussed above. The reasons of M–N–O group bending in complexes with $n > 6$ were discussed in detail in [5,32,33]. We address this issue from the point of view of bond order analysis. Two examples are considered: (i) $[Ru(NO)(CN)_5]^{2-}$ ($n = 6$) and $[Ru(NO)(CN)_5]^{3-}$ ($n = 7$; angle $RuNO = 146^0$ [25]) complexes, and (ii) [Ru(NO)(hedta)] ($n = 6$), $[Ru(NO)(hedta)]^-$ ($n = 7$), $[Ru(NO)(hedta)]^{2-}$ ($n = 8$) series. The N–O bond orders in $[Ru(NO)(hedta)]^q$ were analyzed in Ref. [26] in conjunction with experimental IR stretching frequencies ν(NO). From the Fig. 1 it follows that the π-bond order in $[Ru(NO)(CN)_5]^{3-}$ is almost twice less than $[Ru(NO)(CN)_5]^{2-}$. For the former complex the primary contribution (0.38–0.50) to W_π(Ru–N) is delivered by the π_y component, which is orthogonal to the Ru–N–O plane. This component of the π-bond does not change significantly as compared with the $[Ru(NO)(CN)_5]^{2-}$ complex, which is also true for d_{yz} and π_y^*(NO) orbital occupancies. The in-plane contribution is drastically diminished due to the decrease of the π^*(NO) contribution into the bonding MO (Fig. 2b) and the occupation of the antibonding orbital (Fig. 2c) with

[5] This is in agreement with the calculated bond lengths and the IR stretching frequencies ν(NO). The preferential interpretation of the coordinated nitric oxide as NO^0 is also confirmed by the energy decomposition analysis (EDA) and by the representation of the multiconfigurational wave function in the form of linear combinations of the valence bond structures [28,29].

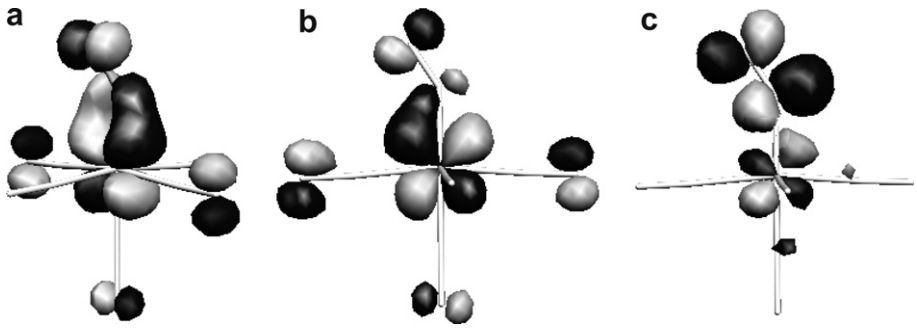

Fig. 2. Molecular π-orbitals of the complex $[Ru(NO)(CN)_5]^{3-}$ with the main contributions of {RuNO} group: orthogonal to the Ru–N–O plane (a), in the Ru–N–O plane (b) and singly occupied molecular orbital (SOMO) in the Ru–N–O plane (c).

consequent compensation of the bonding and antibonding $d_\pi - \pi^*(NO)$ interactions. The TAI(Ru–O) decreases as well. The unpaired electron in the $\{MNO\}^7$complex is distributed between d_{xz} and $\pi_x^*(NO)$, leading to a negative charge on the NO ligand (−0.22).

Similar trends can be observed for the changes of structural parameters and bond orders as we go from $\{RuNO\}^6$ to $\{RuNO\}^7$ in the $[Ru(NO)(hedta)]^q$ (Table 3) series. The further addition of one more electron to $\{RuNO\}^7$ leads to the almost complete destruction of the in-plane Ru–NO π-bond. The out-of-plane π_y-components of the Ru–NO and N–O bonds still remain unchanged. The contribution of s(Ru) into W_σ(Ru–N) is almost the same for these three compounds (0.11–0.12), while the d_{z^2}(Ru) contribution increases from 0.31 ($q = 0$) through 0.36 ($q = -1$) to 0.51 ($q = -2$) due to the mixing of d_{z^2} and π_x^* orbitals in the complexes with the bent {RuNO} group. The increase of π_x^*(NO) population leads to a noticeable negative charge on NO, and is accompanied by the destruction of the intraligand π_x-bond. So, the bond order indices and their components demonstrated sufficient sensitivity to the changes in the {RuNO} group ligand environment and the metal oxidation state and therefore can be used to describe the specific features of MNO bonding.

Table 3

[a] Experimental values are 1848, 1858, and 1383 cm^{-1} for $[Ru(NO)(hedta)]$, $[Ru(NO)(hedta)]^-$, and $[Ru(NO)(hedta)]^{-2}$, respectively [26].

3.3. Paddlewheel dimetal $M_2(BL)_4$ and $M_2(BL)_4(L)_2$ complexes

The geometrical parameters of the dimetal carboxylates $M_2(O_2CR)_4$ and $M_2(O_2CR)_4(NO)_2$ (M = Rh and Ru) optimized by the B3LYP method with two basis sets and the results of the NBO analysis were presented earlier [16,17]. In this work the geometries of $Ru_2(dpf)_4$ and $Ru_2(dpf)_4(NO)_2$ were fully optimized without symmetry constraints, and the minimum energy structures were verified by vibration frequencies calculations. We also considered a possibility of replacement of the phenyl fragments in dpf by hydrogen atoms (model complexes $Ru_2(dHf)_4$ and $Ru_2(dHf)_4(NO)_2$). It was found that this model reproduces the main distinctive features of N,N-bridging ligands (electronic configuration of the diruthenium core, Ru–Ru bond length and bond order, etc.), although the values of Ru–N–O and Ru–Ru–$N_{(NO)}$ angles are noticeably underestimated (Table 5).

Paddlewheel dimetal $M_2(BL)_4$ complexes belong to the relatively few polyatomic compounds, for which Eq. (7) is in use. If both metal atoms are placed on the z axis, their d_{z^2}-orbitals are responsible for the σ-bonding, d_{xz} and d_{yz} – for the π-bonding, d_{xy} and $d_{x^2-y^2}$ – for the δ-bonding.[6] The metal–metal bond order is determined by the electron number and consecution of MO's occupation. In the dimetal cores under consideration all bonding MO's $\{\sigma^2\pi^4\delta^2\}$ are

[6] The $d_{x^2-y^2}$ orbitals form the σ-bonds with the bridging ligands, usually they are regarded as unoccupied and so are excluded from consideration at the estimation of the bond order by Eq. (7).

occupied. In the case of $\{Ru_2\}^{4+}$ core there are four electrons on the antibonding π*- and δ*-orbitals (double metal–metal bond; spin-triplet ground state); in the case of $\{Rh_2\}^{4+}$ there are six electrons on these orbitals (single metal–metal bond; closed-shell ground state) (Table 5).

Norman, Renzoni, and Case showed that the highest occupied orbitals of $\{Ru_2\}^{4+}$ compounds, π* and δ*, were likely to be close in energy, and pointed out that the δ*-orbital interacts significantly with the lower lying carboxylate orbitals, while the π* does not [38]. Cotton and Matusz noticed that N,N-ligands may differ a lot from carboxyl groups in their influence on the relative energies of the Ru–Ru bonding and antibonding orbitals [39]. Indeed, the replacement of $BL = O_2CH^-$ by the stronger electron donor dpf^- leads to the increase of the $d_{x^2-y^2}$ population and to the increase of energy splitting for the MO's δ* ($d_{xy} - d_{xy}$) ± π(X) (X = O or N in bridging ligands). As a result, energy of the antibonding MO with dominant δ* contribution is higher than the π*(Ru–Ru) energy level (Fig. 3), therefore the electronic configurations of these complexes are different: $(\pi^*)^2(\delta^*)^2$ ($Ru_2(O_2CR)_4$) and $(\pi^*)^3(\delta^*)^1$ ($Ru_2(dpf)_4$). For the second of these complexes the greater metal–metal distance reflects the smaller strength of δ-bonding in comparison with π-bonding. The calculated W_{MM}, W_σ, W_π, and W_δ values (Table 6) correctly describe the above mentioned distinctions in the bonds between the metal atoms in three complexes. The low (~0.2) values of B_δ(Ru–Ru) and W_δ(Ru–Ru) as compared with the classical bond order $BO_\delta(Ru–Ru) = 0.5$ for the $Ru_2(dpf)_4$ complex can be explained by the participation of δ-orbitals in the bonds with bridging ligands.

Complexes $M_2(BL)_4(NO)_2$ are a remarkable example of compounds in which the NO molecule is in *trans*-position to the covalent metal–metal bond. All dinitrosyl complexes considered here have closed-shell ground states, though for $Ru_2(dpf)_4(NO)_2$ the singlet and triplet states are nearly degenerate. As a result of NO coordination, the orbital diagrams change essentially (Figs. 3 and 4). In the series $Rh_2(O_2CR)_4(NO)_2$, $Ru_2(O_2CR)_4(NO)_2$, and $Ru_2(dpf)_4(NO)_2$ with the increase of the M–N–O angle the M–N bond order approaches the value typical for mononuclear complexes with a linear {MNO} group. The value of TAI(M–$O_{(NO)}$) is growing in the same series. The value of W_π(N–O) is close to that for the free NO^- anion. The residual component for M–M and N–O bonds is equal to zero; for M–N and, especially, for M–$O_{(NO)}$ bonds W_{res} are not negligible (Table 7). Nevertheless, for the paddle-wheel nitrosyl compounds the decomposition of bond indices into σ-, π- and δ-contributions is acceptable for all bonds except M–$O_{(NO)}$. The computed indices are consistent with the following bonding model for these compounds. The NO group may be considered as a neutral

molecule with unpaired electron on π^* MO, in this case the formal configurations of the metal ions are d^6(Ru) and d^7(Rh). The formation of the M–NO bonds occurs according to the same pattern as for mononuclear complexes with a bent {MNO} group: the out-of-plane π_y-component is constructed according to the "1.5e + 0.5e" rule (vide supra) and has the bond index of ca. 0.45; the index for the in-plane π_x-component is reduced as compared to π_y; the σ-bond index is equal to 0.3–0.5 (Table 7).

In the $Rh_2(O_2CH)_4$ complex there are two electrons on each of the antibonding π_{xz}^* and π_{yz}^* orbitals, so these MO's take almost no part in the bond (Tables 7 and 8). Therefore, the axial coordination of nitric oxide is realized by the formation of σ-bond through the interaction between LUMO σ_{dz2}^*(Rh–Rh) of {Rh_2} core and π_x^*(NO) SOMO's of both NO molecules. Such interaction is possible only for the bent {RhNO} group. The occupation of the resulting $\pi_x^*(NO) + \sigma^*(Rh–Rh) + \pi_x^*(NO)$ MO by two electrons leads to the drastic decrease of the metal–metal bond order. These data are consistent with the NBO analysis of the Rh–Rh bond breaking upon the coordination of nitric oxide to $Rh_2(O_2CR)_4$ [16].

In $Ru_2(O_2CH)_4$ π_{xz}^* and π_{yz}^* MO's of the metal core are occupied by a total of two electrons. In $Ru_2(O_2CH)_4(NO)_2$ these electrons together with the electrons on π^* MO's of two NO molecules occupy the $\pi^*(NO) + \pi^*(Ru–Ru) + \pi^*(NO)$ orbitals linking the Ru atoms with NO (Figs. 4 and 5). The increase of π^*(Ru–Ru) population causes diminution of the metal–metal bond order (Table 7). In the case of linear {RuNO} group the donation from σ(NO) to the doubly occupied $d_{z^2}(Ru1) + d_{z^2}(Ru2)$ MO is impossible, therefore the bent structure of this fragment is preferable. The electron density is transferred from NO to the partially occupied $d_{\pi x}$-orbitals, leading to the decrease of π_x^*(Ru–Ru) orbital contribution to the covalent bond with

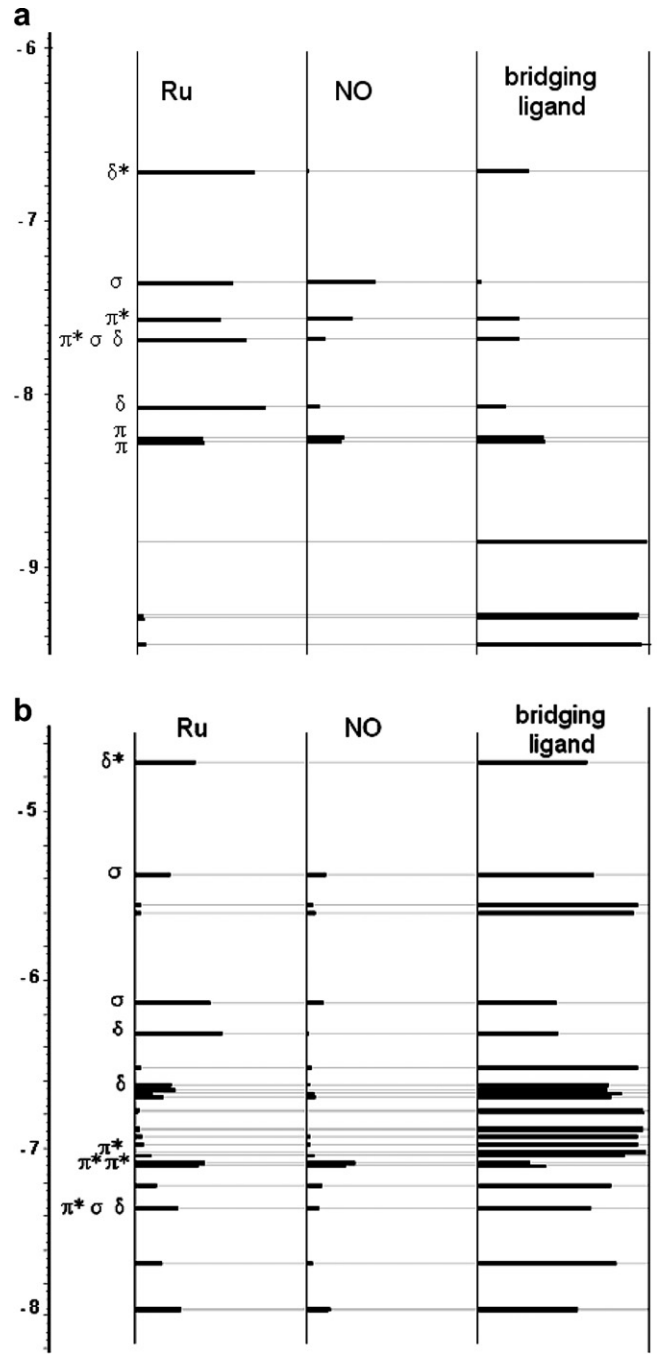

Fig. 4. The molecular orbital diagrams (energies are given in eV) and fragment contributions (percent) for the complexes $Ru_2(O_2CH)_4(NO)_2$ (a) and $Ru_2(dPf)_4(NO)_2$ (b).

NO: the in-plane $W_{\pi x}$(Ru–N) is noticeably less than the out-of plane $W_{\pi y}$(Ru–N), 0.27 and 0.41 respectively. The populations of ruthenium d-AO's remain almost unchanged upon coordination of NO to $Ru_2(O_2CH)_4$ (Table 8). In the case of $Ru_2(dpf)_4$ the addition of two NO molecules changes the electron configuration of the metal atoms (Table 8, Fig. 5). The mechanism of the Ru–Ru π-bond destruction is the same as for the $Ru_2(O_2CH)_4$ complex; the absence of the δ(Ru–Ru) bond

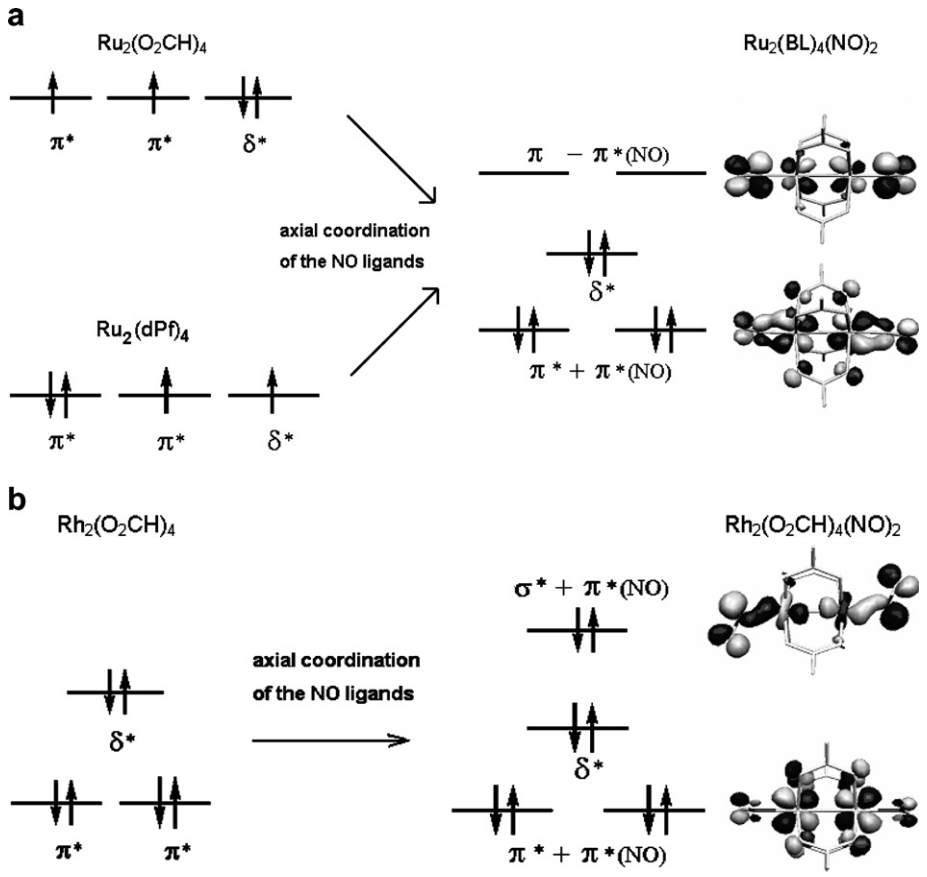
is a result of δ^* MO population. So, despite the different electron configurations of $\{Ru_2\}^{4+}$ in $Ru_2(BL)_4$ the d-electron configurations for the $Ru_2(BL)_4(NO)_2$ complexes are the same (Table 8). The *cis*-influence of NO on the bonds of metal atoms with the bridging ligands is relatively small (Tables 6 and 7).

The sharp decrease of σ-, π-, and δ- metal–metal bond orders for all paddlewheel complexes is the evidence of the destruction of the bond between the metal atoms in the presence of the axially coordinated nitric oxide molecules (Scheme 3).

The loosening of the direct interaction between the metal atoms and the covalent nature of the M–NO bond explain the long M–M and short M–N distances in the paddlewheel dimetal complexes with nitric oxide molecules as axial ligands.



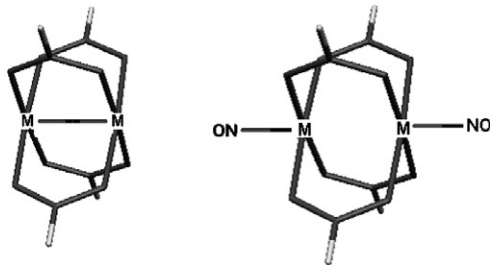


Fig. 5. Scheme of the interaction between the antibonding orbitals of the $\{M_2\}$ core and π^*(NO) orbitals: (a) M = Ru, (b) M = Rh.

3.4. Conclusions

In this work, we investigated the electronic structure of transition-metal nitrosyl complexes using Mayer and Wiberg bond order indices, and the proposed novel technique of bond order decomposition into σ-, π-, and δ-contributions. The important advantage of the bond order indices is their independence from any presupposed scheme of bonding in molecules or assumption of metal and NO oxidation states, so the calculated values can be used to derive an unbiased model of the chemical bond. The remarkable property of nitric oxide as a ligand is the ability to form metal–NO bonds with extraordinarily high π-bond order indices, and this gives the basis to treat these bonds as covalent. The noticeable through-atom M–(N)–O indices obtained for the linear {RuNO} group reflect the significant degree of π-electron density delocalization over the triatomic fragment. The analysis of bond orders and their components for the paddlewheel dimetal $M_2(BL)_4(NO)_2$ complexes provides a compact representation of the metal–metal bond destruction caused by the coordination of nitric oxide.

Acknowledgments

The GAUSSIAN03 calculations were carried out using the computational facilities of the Peterhof Telecommunication Center (St. Petersburg State University). Financial support from the Russian Foundation for Basic Research (Project No. 05-03-32463) is gratefully acknowledged.

vacuum line, and distilled into vacuum-tight storage flasks. Metallic rhenium was a Chempur (Germany) product, used as received. Phenylhydrazine ($PhNHNH_2$) was an Aldrich product, used as received; *p*-tolylhydrazine (*p*-tolyl-$NHNH_2$) was prepared by treating, under nitrogen, the corresponding *p*-tolyl$NHNH_2 \cdot HCl$ salt with a slight excess of NaOH in aqueous solution. A solid separated out which, after 15 min of stirring, was filtered, washed with water and dried over P_2O_5 under vacuum for 24 h. $PPh(OEt)_2$ and PPh_2OEt were prepared by the method of Rabinowitz and Pellon [10]. Other reagents were purchased from commercial sources in the highest available purity and used as received. Infrared spectra were recorded on a Perkin–Elmer Spectrum One or Nicolet Magna 750 FT-IR spectrophotometer. NMR spectra (^1H, ^{31}P) were obtained on Bruker AC200 or AVANCE 300 spectrometers at temperatures varying between −90 and +30 °C, unless otherwise noted. ^1H spectra are referred to internal tetramethylsilane; $^{31}P\{^1H\}$ chemical shifts are reported with respect to 85% H_3PO_4, with downfield shifts considered positive. COSY NMR experiments were performed using standard programs. The SwaN-MR software package [11] was used to treat NMR data. The conductivity of 10^{-3} M solutions of the complexes in CH_3NO_2 at 25 °C were measured on a Radiometer CDM 83 instrument. Elemental analyses were determined in the Microanalytical Laboratory of the Department of Pharmaceutical Sciences, University of Padova, Italy.

2.1.1. *[$ReBr(ArN_2)_2(PPh_2OEt)_3$] ($BPh_4$)$_2$ (**1**) [Ar = Ph (**a**), p-tolyl (**b**)]*

An equimolar amount of Br_2 (0.16 mmol, 0.42 mL of a 0.38 M solution in CH_2Cl_2) was added to a solution of the appropriate bis(aryldiazenido) [$Re(ArN_2)_2(PPh_2OEt)_3$]-BPh_4 complex (0.16 mmol) in 10 mL of CH_2Cl_2 cooled to −196 °C. The reaction mixture was brought to 0 °C, stirred for 10 min and then evaporated to dryness under reduced pressure. The oil obtained was triturated at 0 °C with ethanol (2 mL) containing an excess of $NaBPh_4$ (0.48 mmol, 0.164 g). A red-brown solid slowly separated out which was filtered and twice crystallised from CH_2Cl_2 and diethyl ether; yield ⩾40% .

Anal. Calc. for $C_{104}H_{99}B_2BrN_4O_3P_3Re$ (**1b**): C, 68.13; H, 5.44; N, 3.06; Br, 4.36. Found: C, 67.97; H, 5.30; N, 3.17; Br, 4.13%. $\Lambda_M = 126.5$ S cm^2 mol^{-1}.

2.1.2. *[$ReBr_2(PhN_2)_2(PPh_2OEt)_2$]$BPh_4$ (**2a**)*

The complex was prepared following the method used for compounds **1**, starting from the [$Re(PhN_2)_2$-$(PPh_2OEt)_3$]BPh_4 derivative and using a reaction time, at room temperature, of 8 h; yield ⩾55%.

Anal. Calc. for $C_{64}H_{60}BBr_2N_4O_2P_2Re$: C, 57.54; H, 4.53; N, 4.19; Br, 11.96. Found: C, 57.40; H, 4.64; N, 4.11; Br, 12.16%. $\Lambda_M = 53.8$ S cm^2 mol^{-1}.

2.1.3. *[$ReBr_2(ArN_2)_2\{PPh(OEt)_2\}_2$]$BPh_4$ (**3**) [Ar = Ph (**a**), p-tolyl (**b**)]*

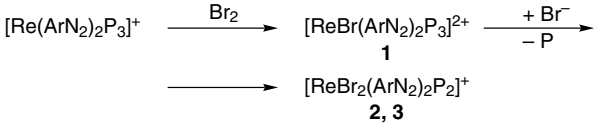
An equimolar amount of Br_2 (0.16 mmol, 0.42 mL of a 0.38 M solution in CH_2Cl_2) was added to a solution of the appropriate bis(aryldiazenido) [$Re(ArN_2)_2\{PPh$-$(OEt)_2\}_3$]BPh_4 complex (0.16 mmol) in 10 mL of CH_2Cl_2 cooled to −196 °C. The reaction mixture was brought to 0 °C, stirred for 1 h and then left to reach room temperature. After two hours of stirring, the solvent was removed under reduced pressure to give an oil which was triturated with diethyl ether (5 mL). A red-brown solid slowly separated out which was filtered and crystallised from CH_2Cl_2 and diethyl ether; yield ⩾70% .

Anal. Calc. for $C_{56}H_{60}BBr_2N_4O_4P_2Re$ (**3a**): C, 52.88; H, 4.75; N, 4.41; Br, 12.56. Found: C, 52.69; H, 4.64; N, 4.50; Br, 12.37%. $\Lambda_M = 55.0$ S cm^2 mol^{-1}.

Anal. Calc. for $C_{58}H_{64}BBr_2N_4O_4P_2Re$ (**3b**): C, 53.59; H, 4.96; N, 4.31; Br, 12.29. Found: C, 53.72; H, 4.83; N, 4.42; Br, 12.48%. $\Lambda_M = 54.2$ S cm^2 mol^{-1}.

2.1.4. *$ReBr_2(ArN_2)(ArN{=}NH)(PPh_2OEt)_2$ (**4**) [Ar = Ph (**a**), p-tolyl (**b**)]*

Method A: an equimolar amount of Br_2 (0.20 mmol, 0.53 mL of a 0.38 M solution in CH_2Cl_2) was added to a solution of the appropriate [$Re(ArN_2)_2(PPh_2OEt)_3$]BPh_4 complex (0.20 mmol) in 10 mL of CH_2Cl_2 cooled to −196 °C. The reaction mixture was brought to 0 °C, stirred for 1 h and then left to reach room temperature. The solution was stirred for 8 h until the [$ReBr_2(ArN_2)_2$(P-$Ph_2OEt)_2$]$^+$ (**2**) cations were completely formed. The solvent was removed under reduced pressure to give an oil which was triturated with ethanol (2 mL). After 2–3 h of stirring, a red-brown solid of **4** began to separate out from the resulting solution, which was cooled to −25 °C to complete the precipitation. The solid was filtered and crystallised from ethanol; yield ⩾65%.



Method B: an equimolar amount of $Li(BHEt_3)$ (0.1 mmol, 100 μL of a 1 M solution in THF) was added to a solution of the appropriate aryldiazenido [$ReBr_2(ArN_2)_2(PPh_2OEt)_2$]$BPh_4$ (**2**) complex (0.1 mmol) in 10 mL of CH_2Cl_2 cooled to −196 °C. The reaction mixture was brought to 0 °C and stirred for 1 h. The solvent was removed under reduced pressure to give an oil which was treated with ethanol (2 mL). A red-brown solid separated out from the resulting solution which was filtered and crystallised from ethanol; yield ⩾75%.

Anal. Calc. for $C_{40}H_{41}Br_2N_4O_2P_2Re$ (**4a**): C, 47.21; H, 4.06; N, 5.50; Br, 15.70. Found: C, 47.38; H, 4.16; N, 5.38; Br, 15.92%.

Anal. Calc. for $C_{42}H_{45}Br_2N_4O_2P_2Re$ (**4b**): C, 48.24; H, 4.34; N, 5.36; Br, 15.28. Found: C, 48.07; H, 4.30; N, 5.48; Br, 15.43%.

3. Results and discussion

Pentacoordinate bis(aryldiazenido) [$Re(ArN_2)_2P_3$]BPh_4 complexes react with equimolar amounts of Br_2 to give first

Scheme 1. P = PPh_2OEt (**1**, **2**), $PPh(OEt)_2$ (**3**); Ar = Ph (**a**) and *p*-tolyl (**b**).

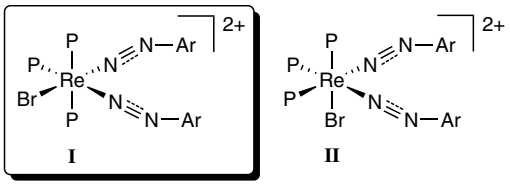


Chart 1.

the tris(phosphine) $[ReBr(ArN_2)_2P_3]^{2+}$ (**1**) species and then the $[ReBr_2(ArN_2)_2P_2]^{+}$ (**2**, **3**) derivatives, as shown in Scheme 1.

The reaction was studied between −80 and +20 °C by ^1H and ^{31}P NMR. Results showed that the addition of an equimolar amount of Br_2 to the $[Re(ArN_2)_2(PPh_2OEt)_3]^{+}$ cation at −80 °C caused the disappearance of precursor signals and the appearance of new signals attributable to the (mono)bromide tris(phosphine) complex cation **1**. Increase in the sample temperature caused a further spectral change, with the appearance of the signals of bis(bromide) complex **2** and free phosphine. The first product of bromination was therefore the dicationic $[ReBr(ArN_2)_2P_3]^{2+}$ (**1**) species and the free Br^- anion, which further reacted with complex **1** to give the final derivative **2**. It may be noted that, with the $PPh(OEt)_2$ ligand, the substitution of one phosphine in the first formed $[ReBr(ArN_2)_2\{PPh(OEt)_2\}_3]^{2+}$ cation is very fast even at low temperature, preventing separation of the complex in pure form. Instead, the final bis(bromide) compounds **2** and **3** were separated with both PPh_2OEt and $PPh(OEt)_2$ phosphines and fully characterised.

Crucial for the successful synthesis of the new bis(aryldiazenido) complexes **1**–**3** was the use of equimolar amounts of Br_2 and beginning the reaction in frozen solutions. Otherwise, large amounts of decomposition products resulted, which prevented purification of the compounds.

Complexes **1**, **2** and **3** were obtained as reddish-brown solids, stable in air and in solution of polar organic solvents, where they behave like 1:2 (**1**) or 1:1 (**2**, **3**) electrolytes [12]. The analytical and spectroscopic data (IR and NMR; Table 1) support the proposed formulations. The IR spectra of the $[ReBr(ArN_2)_2(PPh_2OEt)_3](BPh_4)_2$ (**1a, 1b**) complexes show two bands of medium intensity at 1695 and 1662 cm^{-1} (**1a**), or 1690 and 1659 cm^{-1} (**1b**), attributed to the ν_{N_2} of two aryldiazenido groups in a mutually *cis* position. The ν_{N_2} values, falling above 1600 cm^{-1}, also indicate [4a] singly-bent coordination for both aryldiazenido ligands, which are therefore formally bonded as ArN_2^+ to the central metal, resulting in formal oxidation state I [Re(+1)]. The reaction of $[Re(ArN_2)_2P_3]^{+}$ cations with Br_2 therefore proceeds with the $2e^-$ oxidation of rhenium (from −1 to +1) and formation of one bonded and one free Br^- anion (Scheme 1).

In the temperature range +20 to −80 °C, $^{31}P\{^1H\}$ NMR spectra appear as an AB_2 multiplet, which can be simulated with the parameters listed in Table 1.

These data do not allow us to assign a geometry to the complexes unambiguously, i.e., to decide between geometries **I** and **II** (Chart 1). However, as the ^1H NMR spectra of the $[ReBr(p\text{-tolylN}_2)_2P_3](BPh_4)_2$ (**1b**) complex (Table 1) show two singlets at 2.38 and 2.35 ppm of the methyl substituents of the *p*-tolylN_2 ligands, geometry **I** may tentatively be proposed for both complexes.

The IR spectra of the bis(bromide) bis(aryldiazenido) $[ReBr_2(ArN_2)P_2]BPh_4$ (**2**, **3**) complexes show two bands between 1655 and 1626 cm^{-1} (Table 1), attributed to ν_{N_2} of two aryldiazenido in a mutually *cis* position. The ν_{N_2} values suggest, in this case too, a singly-bent aryldiazenido ligand, formally bonded as ArN_2^+ to a Re(I) central metal [4]. In addition, in the far-IR region the spectrum of the $[ReBr_2(p\text{-tolylN}_2)\{PPh(OEt)_2\}_2]BPh_4$ (**3b**) complex also shows two bands of medium intensity at 185 and 150 cm^{-1}, attributable to ν_{ReBr} of the two Br^- ligands in a mutually *cis* position.

The ^1H NMR spectra of complexes **2** and **3** exhibit the signals of the phosphine and aryldiazenido ligands and of the BPh_4 anion. Only one singlet for the methyl substituent of the *p*-tolylN_2 ligands is observed in the spectra of **3b**, suggesting the magnetic equivalence of the two aryldiazenido ligands. Furthermore, in the temperature range between +20 and −80 °C, the $^{31}P\{^1H\}$ NMR spectra of bis(bromide) complexes **2**, **3** appear as sharp singlets, in agreement with the magnetic equivalence of the two phosphine ligands. On the basis of these data, a *cis–trans* geometry of type **III** (Chart 2) may be proposed for our bis(aryldiazenido) derivatives **2**, **3**.

The $[ReBr_2(ArN_2)_2P_2]^{+}$ (**2**, **3**) cations slowly react in ethanol to give a new complex which, in the case of P = PPh_2OEt, was isolated in pure form and characterised as the aryldiazenido-aryldiazene $ReBr_2(ArN_2)(ArN{=}NH)P_2$ (**4**) derivative (Scheme 2).

The formation of the aryldiazene ArN=NH ligand from the aryldiazenido may be explained by the addition of one H^- species to the ArN_2 group, a hydride which presumably arises from hydrogen abstraction from the ethanol solvent. In order to confirm this reaction and shed light on the properties of bis(aryldiazenido) complexes **2**, **3**, we reacted the $[ReBr_2(ArN_2)_2P_2]^{+}$ cations with an equimolar amount of $LiBHEt_3$, and found that the reaction proceeded to give the same aryldiazene–aryldiazenido complexes **4**, **5**, as shown in Scheme 3. This result therefore shows that the coordinated aryldiazene ArN=NH group is formed by the addition of a hydride to the Nα nitrogen atom of a coordinated aryldiazenido, and consequently supports the reaction of Scheme 2, with the abstraction of one hydride from ethanol to give the aryldiazene species.

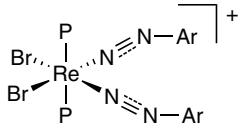
[d] Positive shifts downfield from 85% H_3PO_4.

The addition of a hydride to the ArN_2 group may also take place to the Nβ nitrogen atom to give an arylhydrazide(2−) $ReBr_2(ArN_2)[ArN(H)N]P_2$ derivative. However, although the spectroscopic data alone do not allow us to distinguish between a diazene or a hydrazide species, the known precedents [8b,13] seem to suggest as more probable the formation of the aryldiazene derivatives **4**, **5**.



The easy synthesis of aryldiazene complexes **4**, **5** prompted us to prepare bis(aryldiazene) complexes by reacting $[ReBr_2(ArN_2)_2P_2]^+$ with an excess of $LiBHEt_3$. However, although the reaction was carried out at low temperature and proceeded with a color change in the solution from reddish-brown to orange, no stable complex was separated. In addition, the further reaction of $ReBr_2(ArN_2)$-$(ArN{=}NH)P_2$ (**4**, **5**) with $LiBHEt_3$ gave intractable

$$[ReBr_2(ArN_2)_2P_2]^+ \xrightarrow{EtOH} ReBr_2(ArN_2)(ArN{=}NH)P_2$$
2, 3 → **4, 5**

Scheme 2. P = PPh_2OEt (**4**), $PPh(OEt)_2$ (**5**); Ar = Ph (**a**) *p*-tolyl (**b**).

$$[ReBr_2(ArN_2)_2P_2]^+ \xrightarrow[0\ ^\circ C]{LiBHEt_3} ReBr_2(ArN_2)(ArN{=}NH)P_2$$
2, 3 → **4, 5**

Scheme 3. P = PPh_2OEt (**4**), $PPh(OEt)_2$ (**5**); Ar = Ph (**a**) *p*-tolyl (**b**).

III

Chart 2.

mixtures of products, suggesting that only mono-diazene mono-diazenido complexes **4**, **5** are stable and may be isolated. Lastly, it was also noted that the formation of $ReBr_2(ArN_2)(ArN{=}NH)P_2$ from the reaction of **2** and **3** with equimolar amounts of $LiBHEt_3$ proceeded with both PPh_2OEt and $PPh(OEt)_2$ phosphine ligands, but only with PPh_2OEt was a solid obtained (**4**); with $PPh(OEt)_2$, only an oily product was separated.

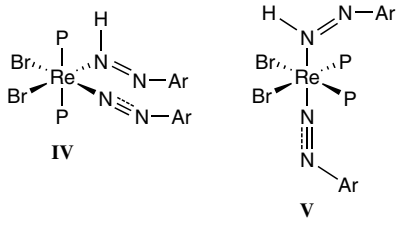
Aryldiazene complexes were often prepared from coordinated aryldiazenido by means of protonation reaction with Brønsted acid [4,5]. However, the reaction results in $2e^-$ oxidation of the metal center. Direct reaction of the aryldiazenido with a hydride-donor agent is rather rare [8b,13] but does not involve any change in the oxidation number of the metal center. The addition of a hydride anion to the Nα of the aryldiazenido ligand of a Re(I) complex allows easy synthesis of aryldiazene–aryldiazenido complexes **4**, **5**, with the metal in the same oxidation state [Re(I)].

Good analytical data were obtained for aryldiazene complexes **4**, which appear as reddish-orange solids, stable in air and in solution of polar organic solvents, where they behave as non-electrolytes. Spectroscopic data (IR and NMR; Table 1) support the proposed formulation.

The infrared spectra of the aryldiazene–aryldiazenido $ReBr_2(ArN_2)(ArN{=}NH)P_2$ (**4**) complexes show one medium-intensity band at 1622 cm^{-1} (**4a**) and 1628 cm^{-1} (**4b**), attributed to ν_{N_2} of the aryldiazenido ligand. No bands attributable to ν_{NH} or $\nu_{N=N}$ of the aryldiazene group were observed. However, the presence of the ArN=NH ligand was confirmed by the ^1H NMR spectra of the complexes, which show the characteristic [1,4–6], slightly broad, high-frequency signal (15–12 ppm) of the diazene hydrogen atom. The two signals at 12.73 and 12.70 (**4a**) and 12.58 and 12.57 ppm (**4b**) observed in our complexes also suggested the presence of two isomers. This was confirmed by the $^{31}P\{^1H\}$ NMR spectra which, in the temperature range between +20 and −80 °C, show two singlets at 89–85 ppm for both complexes **4a** and **4b**. Lastly, the presence of three singlets at 2.40, 2.37 and 2.35 ppm for the methyl substituents of the 4-$CH_3C_6H_4N_2$ and 4-$CH_3C_6H_4N{=}NH$ ligands in complex **4b** further support the existence of two isomers.

Taking into account the fact that, in the far-region of the IR spectrum, complex **4a** shows two medium-intensity bands at 177 and 150 cm^{-1}, attributable to ν_{ReBr} of the two bromide ligands in a mutually *cis* position, two geometries of type **IV** and **V** (Chart 3) may be proposed for our aryldiazene–aryldiazenido derivatives **4**.

$ReBr_2(ArN_2)(ArN{=}NH)(PPh_2OEt)_2$ (**4**) complexes react with NEt_3 to give, after addition of $NaBPh_4$ and work-up, reddish-orange solids which turned out to be the Re(-1) bis(aryldiazenido) $[Re(ArN_2)_2P_3]BPh_4$ derivatives, used as precursors (see Scheme 1). The yield was rather low, but addition of free phosphine (PPh_2OEt) greatly increased the obtained amount of bis(aryldiazenido) derivatives. Triethylammonium $[NHEt_3]BPh_4$ salt was also separated from the reaction mixture.



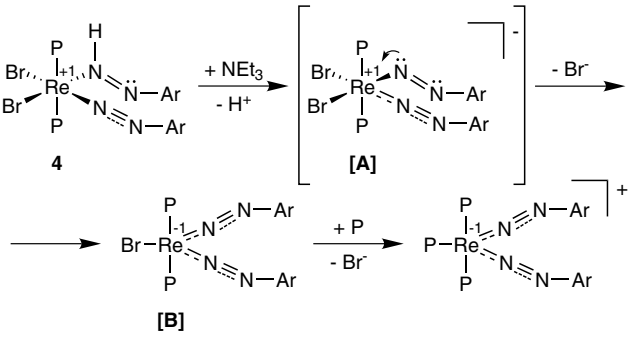


Chart 3.

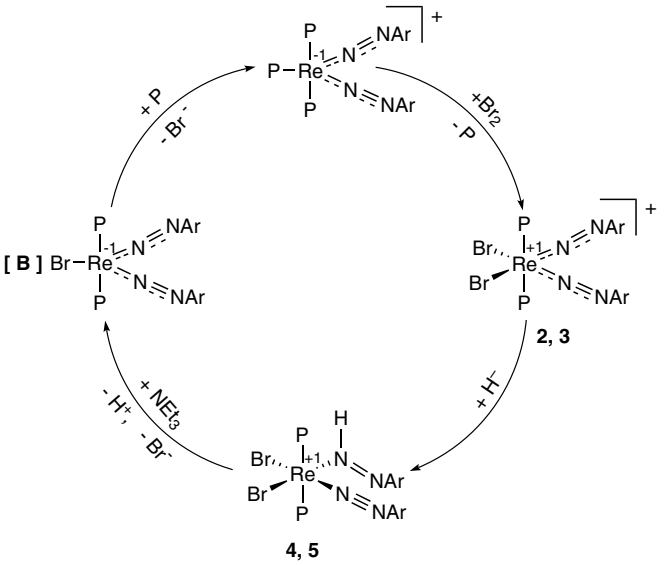
Scheme 4. P = PPh_2OEt.



These results may be explained by the fact that the aryldiazene is acidic [1,4–6] and may be deprotonated [1] to give a doubly-bent aryldiazenido ArN_2^- ligand (intermediate **[A]**, Scheme 4).

Upon rearrangement of ArN_2^- to ArN_2^+ and concurrent formal reduction of the central metal to Re(−1), the bis(aryldiazenido) complex **[B]** is formed by the loss of one Br^- ligand, to reach the more stable 18-electron configuration. Substitution of the bromide ligand with PPh_2OEt, through either ligand exchange between the molecules of the complexes, or addition of free phosphite, gives the more stable bis(aryldiazenido)tris(phosphite) $[Re(ArN_2)_2P_3]BPh_4$ species.

These results highlight the interesting properties shown by the bis(aryldiazenido) complexes of rhenium stabilised by phosphite ligands, as shown in Scheme 5.

The starting bis(aryldiazenido) $[Re(ArN_2)_2P_3]^+$ complexes of Re(−1) undergo $2e^-$ oxidation with Br_2 to give the $[ReBr_2(ArN_2)_2P_2]^+$ (**2**, **3**) derivatives, which can add one hydride anion to the aryldiazenido Nα nitrogen atom to give the aryldiazene–aryldiazenido $ReBr_2(ArN_2)(ArN{=}NH)P_2$ (**4**, **5**) complexes. Deprotonation of the aryldiazene ligand in **4** and **5** results in $2e^-$ reduction of the central metal, affording, after dissociation of one bromide ligand, the pentacoordinated Re(−1) $ReBr(ArN_2)_2P_2$ derivatives **[B]**. Substitution of the Br^- ligand with phosphite yields the starting bis(aryldiazenido) $[Re(ArN_2)_2P_3]BPh_4$ complexes.

[1] Separation of $[NHEt_3]BPh_4$ strongly supports the proposed deprotonation reaction.

Scheme 5.

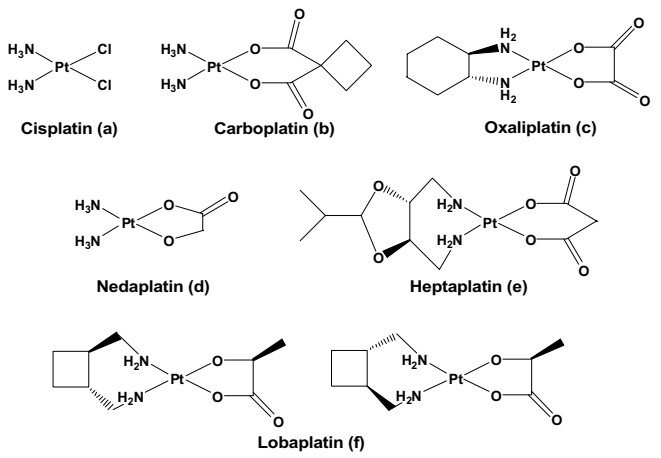

Fig. 1. Structures of cisplatin, carboplatin, oxaliplatin, nedaplatin, heptaplatin and lobaplatin.

of the problems associated with clinically used Pt drugs. They break the cisplatin paradigm by binding to DNA in other ways and may therefore be active against cisplatin-resistant cancer cell lines. Pt^{IV} complexes are also under investigation [7] where they are thought to be activated by reduction in the more reducing environment of cancer cells, thereby acting as prodrugs of the corresponding anti-tumour active Pt^{II} derivatives. An additional strategy to overcome the drawbacks associated with clinically used Pt drugs is to tether biologically-active ligands to the Pt which have, in themselves, inherent anti-tumour properties [1,3].

Nitric oxide (NO) has emerged as one of the most versatile and ubiquitous molecules in the human body with a diverse range of physiological functions including, amongst others, gene regulation, cytostasis, platelet function, vascular smooth muscle relaxation and proliferation, memory, immune stimulation and apoptosis [8–10]. It is derived from L-arginine *via* the catalytic action of a remarkable class of haem-containing metalloenzymes, the NO synthases (NOS), of which three different isoforms are known to exist; endothelial NOS (eNOS), neuronal NOS (nNOS) and inducible NOS (iNOS) [9,10].

Expression of NOS has been demonstrated in a variety of human and murine tumour types including gynecological, breast, head and neck, prostate, bladder and colon cancers and central nervous system tumours such as glioblastomas [11]. The toxic properties of NO are harnessed, within the immune system, in order to facilitate the control of infections and tumour cell growth [11,12]. Generated by iNOS, at high μmol/L concentrations at the site of infection, NO is thought to attack cancer cells by binding to metal centres involved in their respiration, thereby disrupting their function [10,13]. Additionally, NO has been demonstrated to upregulate p53, the tumour suppressor gene [10]. NO-mediated inhibition of DNA synthesis may also be an important mechanism by which macrophages induce cytotoxicity. NO can induce DNA damage by generating reactive nitrogen oxide species (RNOS) such as peroxynitrite and $ONOO^-$, which can oxidise and nitrate DNA and potentially cause single-strand DNA breaks *via* attack on the sugar–phosphate backbone [10,14]. Dinitrogen trioxide, another RNOS derived from NO, can nitrosate amines to form carcinogenic *N*-nitrosamines, which can then alkylate DNA [10,15].

Conflicting reports of pro- and anti-cancer activity associated with NO clearly illustrate the need for further research in this area in order to fully elucidate and understand the precise role of NO in cancer biology. High concentrations of NO, for example, can promote tumour cell death by apoptosis whereas lower concentrations of NO can promote tumour cell proliferation, vascularisation or even resistance to apoptosis [10,11]. In addition to concentration, the cellular effects of NO also depend on its source, latency, cell type and phenotype [10].

NO donors are currently under investigation as therapeutic agents for the treatment of a variety of disease states including cancer [16,17]. We recently reported that hydroxamic acids (RC(O)NHOH), a class of organic bioligands with a diverse range of biological functions [18,19], can act as effective NO donors by virtue of the fact that they readily transfer NO to ruthenium(III) (Ru^{III}) to form stable Ru^{II} nitrosyls. Moreover, in recent years, although there has been a surge of interest in developing novel Ru^{II} nitrosyl complexes, capable of releasing cytotoxic NO [20–23], as yet there is little or no evidence in the literature of NO-releasing Pt-based chemotherapeutics. The potential of NO delivery systems in the enhancement of platinum cytotoxicity has however been demonstrated, by pretreating Chinese hamster V79 lung fibroblast cells with bolus NO or NO delivered from NONOate NO donors. The tumour cells were markedly sensitized to subsequent cisplatin treatment [24]. It was on this premise that we wished to employ a novel synergistic approach, exploiting the well-established anti-cancer properties of Pt and the NO-releasing ability of hydroxamic acids and, in so doing, advance a new class of bifunctional metallodrug with dual DNA-binding and NO-releasing properties. 3- and 4-pyridinehydroxamic acids were specifically chosen with a view to synthesising Pt pyridinehydroxamic acid complexes where the pyridine nitrogen would selectively coordinate Pt^{II} or Pt^{IV} thereby leaving the hydroxamic acid moiety uncoordinated and potentially free to release cytotoxic NO.

Herein, we describe the synthesis, characterisation and NO-releasing ability of a novel class of 3- and 4-pyridinehydroxamic acid (3- and 4-pyhaH) complexes of Pt^{II} and Pt^{IV}. The crystal structure of the Pt^{IV} derivative, *cis*-$[PtCl_4(4\text{-pyhaH})_2]\cdot 2CH_3OH$ is reported. The corresponding 3- and 4-pyridinecarboxylic acid (3- and 4-pycaH) Pt^{II} and Pt^{IV} complexes, together with the Pt^{II} pyridine analogue were also synthesised and characterised to serve as reference standards in biological testing.

2. Experimental

2.1. General

3-Pyridinecarboxylic acid (nicotinic acid) **3**, 4-pyridinecarboxylic acid (isonicotinic acid) **4**, benzohydroxamic acid **5**, methylnicotinate, ethylisonicotinate and pyridine, were all purchased from Aldrich and used without further purification. $K_2[Pt^{II}Cl_4]$ and $K_2[Pt^{IV}Cl_6]$ were used as received from Johnson Matthey. $K[Ru^{III}(Hedta)Cl]\cdot 2H_2O$ was synthesised as previously reported [25].

IR and far-IR spectroscopic measurements were obtained using a Mattson Genesis II CSI FTIR spectrometer. The spectra were analysed using WINFIRST software. Between 4000 and 400 cm^{-1}, KBr discs were employed while between 600 and 200 cm^{-1}, polythene discs (Nujol mull) were used. FTIR grade KBr and nujol were purchased from Aldrich. ^1H NMR spectra were recorded on a Bruker Avance 400 NMR spectrometer and the spectra analysed using TopSpin 1 software. Chemical shifts were measured relative to the undeuterated solvent peak. Elemental analysis was performed by the Microanalytical Laboratory, School of Chemistry & Chemical Biology, University College Dublin, Belfield, Dublin. Electrospray ionisation mass spectroscopy (ESI-MS) experiments were performed on a Quattro Micro quadrupole electrospray mass spectrometer (Micromass, Waters Corp., USA): 10 μL of the samples was injected in 300 μL of acetonitrile:water (60:40, v/v).

2.1.1. Synthesis of 3-pyridinehydroxamic acid (3-pyhaH) (*1*)

Hydroxylamine hydrochloride (5.1 g, 72 mmol) was added to sodium hydroxide (5.8 g, 146 mmol) in deionised water (37 ml). The resulting solution was then added dropwise to methylnicotinate (5.0 g, 36 mmol) in methanol (55 ml). The solution was stirred at room temperature for 72 h, after which the solution was acidified to pH 5.5 using 5% HCl. The solvent was removed *in vacuo* yielding a yellow solid. Methanol (60 ml) was added and sodium chloride filtered. The solvent was removed *in vacuo* yielding a light pink solid, which was recrystallised from water. Yield: 3.0 g, 22 mmol, 66%. *Anal.* Calc. for $C_6H_6N_2O_2$: C, 52.17; H, 4.38; N, 20.28. Found: C, 52.11; H, 4.24; N, 20.14%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 11.25$ (s, 1H, OH), 9.13 (s, 1H, NH), 8.77 (s, 1H, aromatic H), 8.55 (d, 1H, aromatic H), 7.93 (d, 1H, aromatic H), 7.33 (dd, 1H, aromatic H).

2.1.2. Synthesis of 4-pyridinehydroxamic acid (4-pyhaH) (*2*)

4-pyhaH was synthesised from ethylisonicotinate in line with the procedure for 3-pyhaH described in Section 2.1.1 above. Yield: 74%. Anal. Calc. for $C_6H_6N_2O_2$: C, 52.17; H, 4.38; N, 20.28. Found: C, 52.20; H, 4.26; N, 20.18%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 11.42$ (s, 1H, OH), 9.25 (s, 1H, NH), 8.57 (dd, 2H, aromatic H), 7.54 (dd, 2H, aromatic H).

2.1.3. Synthesis of cis-$[Pt^{II}Cl_2(3\text{-pyhaH})_2]\cdot 2H_2O$ (*6*)

3-Pyridinehydroxamic acid (3-pyhaH) (0.146 g, 1.06 mmol) in methanol (7 ml) was added to $K_2[Pt^{II}Cl_4]$ (0.20 g, 0.48 mmol) in deionised water (7 ml). The resulting solution was stirred without protection from light at room temperature for 24 h turning yellow in colour. A yellow precipitate was filtered and dried over P_2O_5. Yield: 0.18 g, 0.31 mmol, 65%. *Anal.* Calc. for $PtC_{12}H_{16}N_4O_6Cl_2$: C, 24.92; H, 2.79; N, 9.69; Cl, 12.26. Found: C, 24.88; H, 2.65; N, 9.64; Cl, 12.35%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 11.48$ (s, 2H, OH), 9.31 (s, 2H, NH), 8.98 (s, 2H, aromatic H), 8.76 (d, 2H, aromatic H), 8.14 (d, 2H, aromatic H), 7.47 (dd, 2H, aromatic H).

The Pt^{II} and Pt^{IV} compounds, **7**–**14**, were synthesised by reaction of the appropriate pyridine derivative or pyridine with either $K_2[Pt^{II}Cl_4]$ or $K_2[Pt^{IV}Cl_6]$, respectively, by the method described in Section 2.1.3 above.

2.1.4. cis-$[Pt^{II}Cl_2(4\text{-pyhaH})_2]\cdot H_2O$ (*7*)

Yield: 70%. *Anal.* Calc. for $PtC_{12}H_{14}N_4O_5Cl_2$: C, 25.73; H, 2.52; N, 10.00; Cl, 12.66. Found: C, 25.94; H, 2.34; N, 9.74; Cl, 12.49%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 11.53$ (s, 2H, OH), 9.43 (s, 2H, NH), 8.78 (dd, 4H, aromatic H), 7.59 (dd, 4H, aromatic H).

2.1.5. cis-$[Pt^{II}Cl_2(3\text{-pycaH})_2]$ (*8*)

Yield: 69%. *Anal.* Calc. for $PtC_{12}H_{10}N_2O_4Cl_2$: C, 28.14; H, 1.97; N, 5.47; Cl, 13.84. Found: C, 28.01; H, 1.90; N, 5.25; Cl, 13.56%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 9.19$ (s, 2H, aromatic H), 8.84 (d, 2H, aromatic H), 8.33 (d, 2H, aromatic H), 7.45 (dd, 2H, aromatic H).

Yield: 77%. *Anal.* Calc. for $PtC_{12}H_{10}N_2O_4Cl_2$: C, 28.14; H, 1.97; N, 5.47; Cl, 13.84. Found: C, 28.11; H, 1.91; N, 5.27; Cl, 13.96%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 8.79$ (dd, 4H, aromatic H), 7.70 (dd, 4H, aromatic H).

2.1.7. cis-$[Pt^{II}Cl_2(py)_2]$ (*10*)

Yield: 75%. *Anal.* Calc. for $PtC_{10}H_{10}N_2Cl_2$: C, 28.31; H, 2.38; N, 6.60. Found: C, 28.21; H, 2.15; N, 6.38%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 8.47$ (d, 4H, aromatic H), 7.49 (t, 4H, aromatic H), 7.32 (m, 2H, aromatic H).

2.1.8. cis-$[Pt^{IV}Cl_4(3\text{-pyhaH})_2]\cdot 2H_2O$ (*11*)

Yield: 63%. *Anal.* Calc. for $PtC_{12}H_{16}N_4O_6Cl_4$: C, 22.20; H, 2.48; N, 8.63; Cl, 21.85. Found: C, 22.47; H, 2.41; N, 8.48; Cl, 21.69%. ^1H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 11.79$ (s, 2H, OH), 9.51 (s, 2H, NH), 9.13 (s, 2H, aromatic H), 8.88 (d, 2H, aromatic H), 8.26 (d, 2H, aromatic H), 7.48 (dd, 2H, aromatic H).

2.1.9. cis-$[Pt^{IV}Cl_4(4\text{-pyhaH})_2]\cdot 2CH_3OH$ (*12*)

Yield: 63%. *Anal.* Calc. for $PtC_{14}H_{20}N_4O_6Cl_4$: C, 24.83; H, 2.98; N, 8.27; Cl, 20.94. Found: C, 24.77; H, 2.91; N,

8.22; Cl, 20.78%. ^{1}H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 11.88$ (s, 2H, OH), 9.64 (s, 2H, NH), 8.85 (dd, 4H, aromatic H), 7.97 (dd, 4H, aromatic H).

2.1.10. *cis*-[$Pt^{IV}Cl_4$(3-pycaH)$_2$] (**13**)

Yield: 61%. *Anal.* Calc. for $PtC_{12}H_{10}N_2O_4Cl_4$: C, 24.72; H, 1.73; N, 4.80; Cl, 24.32. Found: C, 24.70; H, 1.69; N, 4.63; Cl, 24.11%. ^{1}H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 9.23$ (s, 2H, aromatic H), 8.61 (m, 4H, aromatic H), 7.66 (dd, 2H, aromatic H).

2.1.11. *cis*-[$Pt^{IV}Cl_4$(4-pycaH)$_2$] (**14**)

Yield: 67%. *Anal.* Calc. for $PtC_{12}H_{10}N_2O_4Cl_4$: C, 24.72; H, 1.73; N, 4.80; Cl, 24.32. Found: C, 24.56; H, 1.91; N, 4.55; Cl, 24.17%. ^{1}H NMR (400 MHz, [d_6]-DMSO, 25 °C): $\delta = 8.79$ (dd, 4H, aromatic H), 7.98 (dd, 4H, aromatic H).

2.1.12. K[Ru^{II}(Hedta)(NO)Cl] · H_2O (**15**)

cis-[$Pt^{II}Cl_2$(3-pyhaH)$_2$] · $2H_2O$ (**6**) (0.29 g, 0.50 mmol) was added to a yellow aqueous solution (15 ml) of K[Ru^{III}(Hedta)Cl] · $2H_2O$ (0.25 g, 0.50 mmol), resulting in a reddish solution. The reaction was refluxed for 3 h whereupon it turned brown in colour. The reaction was concentrated in vacuo (~5 ml), purified on a sephadex column LH20 using water as eluent to give K[Ru(Hedta)(NO)Cl] · H_2O as a brown solid. Yield: 58%. *Anal.* Calc. for $RuC_{10}H_{15}N_3ClKO_{10}$: C, 23.42; H, 2.95; N, 8.19; Cl, 6.91; K, 7.62. Found: C, 23.45; H, 2.91; N, 8.42; Cl, 6.97; K, 7.46%. ^{1}H NMR (400 MHz, D_2O, 25 °C): $\delta = 4.43$ (d, 2H, CH_2 glycine), 4.34 (s, 2H, CH_2 glycine), 4.09 (2H, s, CH_2 glycine), 3.84 (2H, s, CH_2 glycine) 3.61 (4H, m, CH_2 ethylenediamine); ^{13}C NMR (400 MHz; D_2O; 25 °C): $\delta = 181.8$, 178.5 (CO bound glycinate), 177.7, 168.8 (CO free glycinate), 65.45, 65.4, 64.7, 64.3 (CH_2 glycinate), 62.8, 60.4 (CH_2 ethylenediamine); ν_{max}/cm^{-1} 3345s (OH), 2986s, 2947s (CH, H_2edta), 1894vs (NO), 1726s (CO free glycine arms) and 1649b (CO bound glycine arms); ESI-MS m/z: 456 ([M−H]$^-$).

K[Ru^{II}(Hedta)(NO)Cl] · H_2O (**15**) was likewise obtained by reacting *cis*-[$Pt^{II}Cl_2$(4-pyhaH)$_2$] · H_2O (**7**) with K[Ru^{III}(Hedta)Cl] · $2H_2O$ in line with the procedure described above.

2.2. Structural characterisation of *cis*-[$Pt^{IV}Cl_4$(4-pyhaH)$_2$] · $2CH_3OH$ (**12**)

Crystal data and experimental details for **12** are summarised in Table 1. The structure of **12** was refined in the *Pbcn* space group. Crystal data were collected on a Bruker Smart Apex CCD diffractometer at 100 K using monochromated Mo Kα radiation, ($\lambda = 0.71073$ Å) and the $\phi - \omega$ scan method. The structure was solved by direct method (SHELXS-97) [26] and refined by full-matrix least squares using SHELXL 97-2 package [26]. All hydrogen atoms were localised in the difference fourier map and allowed to refine freely.

Table 1
Summary of crystal data for **12**

Empirical formula	$C_{14}H_{20}N_4O_6Cl_4Pt$
Formula weight	677.23
Temperature (K)	100(2)
Wavelength (Å)	0.71073
Crystal system	orthorhombic
Space group	*Pbcn*
Unit cell parameters	
a (Å)	7.3794(5)
b (Å)	11.9791(8)
c (Å)	24.8071(17)
α (°)	90
β (°)	90
γ (°)	90
Volume (Å^3), Z	2192.9(3), 4
D_{calc} (Mg/m^3)	2.051
Absorption coefficient (mm^{-1})	6.924
F(000)	1304
Crystal size (mm)	0.30 × 0.20 × 0.20
θ Range for data (°)	3.21–29.46
Index ranges	$-9 \leqslant h \leqslant 9$, $-16 \leqslant k \leqslant 16$, $-33 \leqslant l \leqslant 32$
Reflections collected	18484
Independent reflections (R_{int})	2891 (0.0289)
Completeness to $\theta = 29.46°$ (%)	94.8
Absorption correction	semi-empirical from equivalents
Maximum and minimum transmission	0.3381 and 0.2305
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	2891/0/172
Goodness-of-fit on F^2	1.049
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0217$, $wR_2 = 0.0453$
R indices (all data)	$R_1 = 0.0277$, $wR_2 = 0.0471$
Largest difference in peak and hole (e Å^{-3})	1.713 and −0.904

$R_1 = \sum\|F_o| - |F_c\|/\sum|F_o|$, $wR_2 = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{1/2}$.

2.3. Pharmacological tests

The NO-releasing properties of the test compounds were investigated using an isolated organ bath experiment as follows. Thoracic aorta rings were prepared from male Wistar Hannover rats weighing about 250–400 g purchased from the animal facility of the University of Trieste. The animals were maintained according to the guidelines in force in Italy (DDL 116, 21/02/92 and subsequent addenda) and in compliance with the "Guide for the care and use of laboratory animals" DHIIS Publ. No (NHI) 86-23, Bethesda, MD, NHI (1985). Rat thoracic aortas were carefully removed, after killing of the animals by CO_2 overdose, put into a Petri dish containing Krebs solution (containing 118.3 mM NaCl, 25 mM $NaHCO_3$, 4.8 mM KCl, 2.5 mM $CaCl_2$, 1.2 mM $MgSO_4$, 1.2 mM KH_2PO_4, 11.1 mM glucose, at pH 7.4), and cleaned of fat and of connective tissue. Aorta rings, cut at about 2 mm, were put into a 20 mL organ bath (model 4050, Ugo Basile, Padova Italy) with constant gas flow (95% O_2 + 5% CO_2) at 37 ± 0.5 °C. Two stainless steel hooks were inserted into the aortic lumen to fix the test sample to the bath bottom and to connect it to a force transducer. Aortic rings were equilibrated with Krebs solution and maintained under an optimal ten-

sion of 2 g for 40 min before experiments. Rings were stimulated with 30 mM KCl to assess the integrity of the strips (rings with abnormal contraction were discarded), and responsive rings were rinsed with Krebs solution and allowed to equilibrate for a further 30 min. Contraction was elicited by adding phenylephrine (dissolved in ultrapure water) to the bath (final concentration 3×10^{-7} M). Once sample contraction reached a plateau, the relaxation–response curve was obtained by cumulative additions of acetylcholine (dissolved in ultrapure water) to the organ bath (final concentrations ranging between 10^{-9} M and 10^{-4} M). After their maximal relaxation, aorta rings were rinsed with Krebs solution and allowed to re-equilibrate for 30 min. Contraction was elicited again by phenylephrine, and compounds **1**–**10** were tested in the concentration interval between 10^{-9} and 10^{-4} M (stock solutions were prepared in DMSO with subsequent dilutions in ultra-pure water in order to keep DMSO in the bath to less than 0.1%); cisplatin was used as control, at the same concentrations and conditions.

The vehicle used for dissolving the test complexes was also tested for relaxation. Contraction or relaxation were recorded isometrically *via* a force–displacement transducer (model 7003, Ugo Basile, Padova, Italy) connected to a Unirecord Microdynamometer recorder (model 7050, Ugo Basile, Padova, Italy). Experiments with compounds **6** and **8** were repeated in the presence of 10 μM methylene blue (dissolved in ultrapure water), a guanylate cyclase inhibitor [27]. In this case, methylene blue was added to the organ bath, for 10 min, every time before inducing contraction with phenylephrine. For each compound, experiments were replicated at least three times.

2.4. Statistical analysis

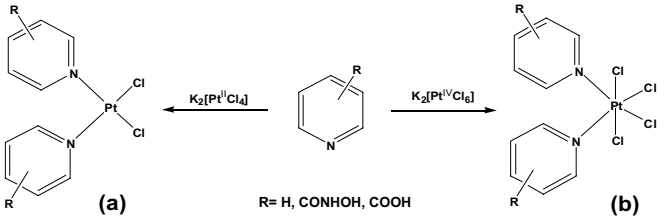
Data were submitted to computer-assisted statistical analysis using ANOVA analysis of variance and Tukey–Kramer multiple comparison post-test or Student *t*-test.

3. Results and discussion

3.1. Synthesis and spectroscopic characterisation of ligands *1–4*

3- and 4-pyridinecarboxylic acid (3- and 4-pycaH) were used as purchased and a selection of IR spectral data are provided in Supplementary data.

The hydroxamic acids were synthesised by reacting the corresponding carboxylic methyl or ethylesters with hydroxylamine in aqueous methanol in line with literature methods [28]. They were obtained in good yields (55–85%) and excellent purity and were characterised by elemental analysis, IR and ^{1}H NMR spectroscopy. The IR spectra of 3-pyhaH **1** and 4-pyhaH **2** contain stretches between 3180–3190 cm^{-1}, 2800–2850 cm^{-1} and 1640–1660 cm^{-1} which may be assigned to ν_{O-H}, ν_{N-H} and $\nu_{C=O}$, respectively. The symmetric and asymmetric stretches corresponding to $\nu_{C=O}$ are found as only one stretch due to intramolecular hydrogen bonding, while the broad ν_{O-H} of the hydroxamato may be attributed to intermolecular hydrogen bonding. These values concur with those previously reported in the literature [29,30]. Selected IR spectral data for **1** and **2** are provided in Supplementary data.



The ^{1}H NMR spectra of the hydroxamic acids **1** and **2** in d_6-DMSO show N–H and O–H resonances at *ca.* 9.2 ppm and 11.3 ppm, respectively, both of which are concentration-dependent due to extensive intermolecular hydrogen bonding at high concentrations. The ^{1}H NMR spectrum of **1** exhibits 4 resonances at 8.77, 8.55, 7.93 and 7.33 ppm corresponding to the four protons of the *meta*-substituted pyridine ring, while that of **2** has two resonances at 8.57 and 7.54 ppm corresponding to the four protons of the *para*-substituted derivative.

3.2. Synthesis and characterisation of Pt^{II} and Pt^{IV} complexes *6–14*

The dichlorido Pt^{II} complexes, **6**–**10** and their Pt^{IV} analogues, **11**–**14** were prepared by reaction of $K_2[Pt^{II}Cl_4]$ or $K_2[Pt^{IV}Cl_6]$, respectively, with the appropriate pyridine derivative (pyd) in aqueous or aqueous/methanolic solutions (Scheme 1).

The previously reported Pt^{II} pyridine analogue, *cis*-$[Pt^{II}Cl_2(py)_2]$ **10** [31], was also synthesised to serve as a reference standard in biological testing. In all cases the yellow Pt^{II} and Pt^{IV} products were obtained in good yield (60–80%) and excellent purity and were further characterised by IR and ^{1}H NMR spectroscopy. The *cis*-configurations of the Pt^{II} complexes, **6**–**10** (Fig. 2), were confirmed by the classic Kurnakov test [32].

The spectroscopic data for the Pt^{II} and Pt^{IV} pyhaH and pycaH complexes are consistent with coordination *via* the pyridine nitrogen and reveal the free nature of the uncoordinated hydroxamic or carboxylic acid moiety as expected. Selected IR and far-IR spectral data for the free ligands and Pt^{II} and Pt^{IV} complexes are provided in Supplementary data (Table 1). Briefly the $\nu_{C=O}$ of the Pt pyhaH and pycaH complexes are found at *ca.* 1660 and 1705 cm^{-1}, respectively, and as expected are comparable to those of the corresponding free ligands. The hydroxamic acid complexes, in addition, display sharp ν_{N-H} and broad ν_{O-H} stretches, again comparable to those of the corresponding free ligands. Far-IR data can also be particularly useful in determining the stereochemistry of the complexes

Scheme 1. Synthesis of (a) *cis*-$[Pt^{II}Cl_2(pyd)_2]$ and (b) *cis*-$[Pt^{IV}Cl_4(pyd)_2]$.

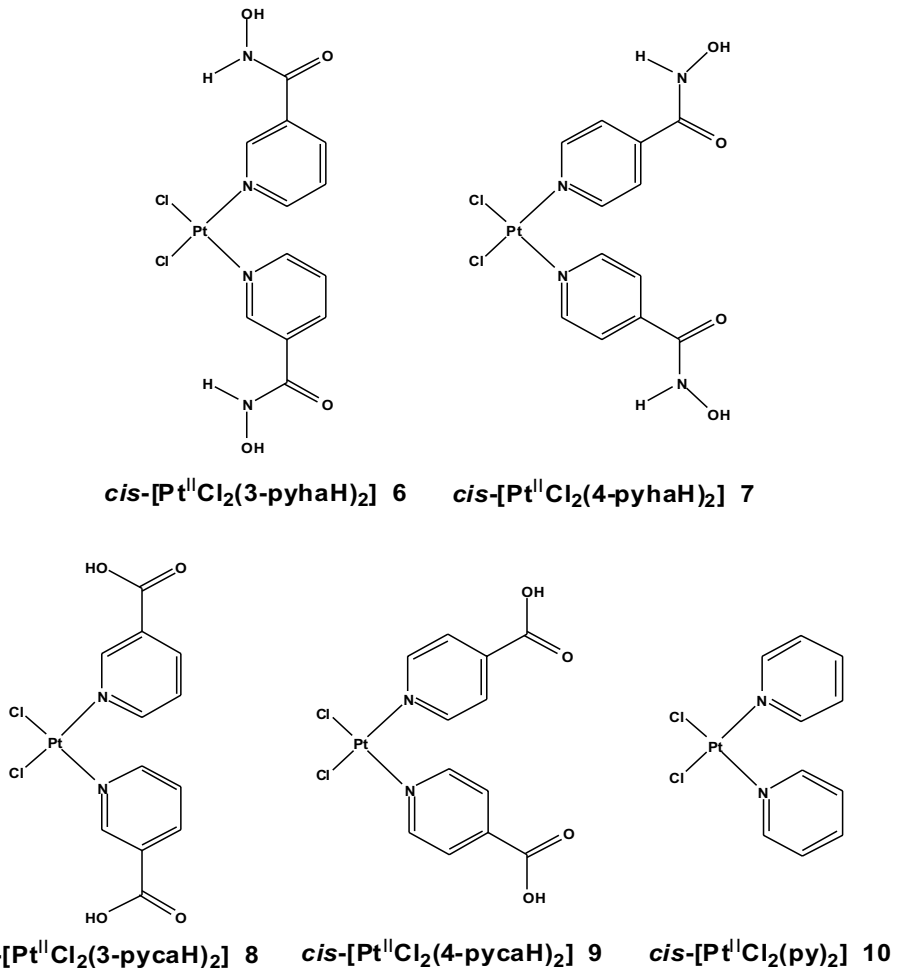


Fig. 2. Structures of the dichlorido Pt^{II} complexes.

synthesised. For a square planar Pt^{II} complex of general formula $PtCl_2L_2$, where L is a monodentate ligand, the *trans*-isomer (D_{2h}) exhibits only one ν_{Pt-Cl} whereas the *cis*-isomer (C_{2v}) exhibits two stretches. For Pt^{IV} complexes of type $PtCl_4L_2$, the *trans*-isomer (D_{4h}) exhibits one ν_{Pt-Cl} and the *cis*-isomer (C_{2v}) exhibits four [33]. The far-IR data support the *cis* configuration for **6** and **8**–**14**. Occasionally the ν_{Pt-Cl} merge as is the case with *cis*-$[Pt^{II}Cl_2(4\text{-pyhaH})_2]$ **7** and the configuration of the complex cannot be accurately determined from far-IR data alone.

The ^1H NMR spectra for all the Pt complexes support the presence of one isomer only. For the pyhaH complexes **6**, **7**, **11** and **12** in d^6-DMSO, N–H and O–H resonances are observed at *ca.* 9.3 ppm and *ca.*11.5 ppm, respectively, and are, as expected, comparable to those of the free ligands. The ^1H NMR spectrum of *cis*-$[Pt^{II}Cl_2(3\text{-pyhaH})_2]$ contains 4 resonances at 8.98, 8.76, 8.14 and 7.47 ppm corresponding to the eight protons of the *meta*-substituted pyridine rings. A similar overall pattern is observed in the ^1H NMR spectra of the Pt^{II} and Pt^{IV} complexes with 4 and 2 resonances integrating well for the complexes with coordinated *meta* and *para*-substituted pyridine rings, respectively, and a shift consistent with complexation.

*3.3. Structural characterisation of cis-[$Pt^{IV}Cl_4$(4-pyhaH)$_2$] · 2CH_3OH (**12**)*

Yellow crystals of **12** suitable for a single crystal X-ray diffraction experiment were obtained by slow evaporation from a methanol solution. The atomic numbering scheme and atom connectivity for **12** are shown in Fig. 3 and a selection of bond lengths and angles reported in Table 2. In **12**, the Pt^{IV} complex displays a near perfect octahedral geometry, not surprisingly given its symmetric nature. The N(1)–Pt–N(1) and the Cl(2)#1–Pt–Cl(2) bond angles are 178.42(6)° and 179.86(4)°, respectively. The N(1)–Pt–Cl(1)#1 and N(1)–Pt–Cl(2)#1 bond angles are 89.91(6)° and 89.21(7)°, respectively. The Pt–Cl bond lengths range from 2.295(1) to 2.308(1) Å and the shorter Pt–N bond lengths are 2.062(2) Å. The two pyhaH ligands lie in the *cis*-configuration where each is present as a monodentate ligand coordinated *via* the pyridine nitrogen only with an uncoordinated hydroxamic acid functional group.

In addition, hydroxamic acids are known to adopt one of two tautomeric forms, the enol and the keto, each of which can exist as *E* or *Z* conformers [19], where the stereodescriptors *E* and *Z* are used to describe the *trans* and *cis*

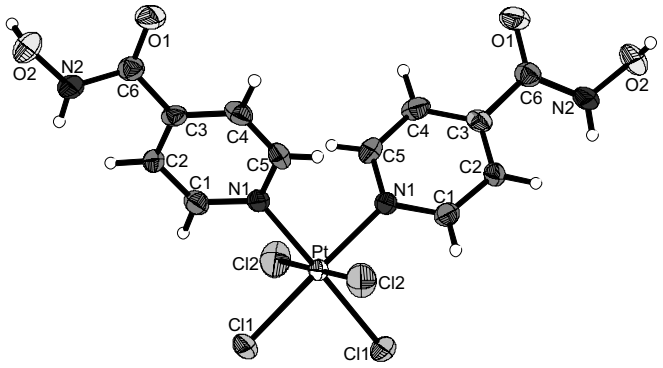

Fig. 3. ORTEP diagram of **12** with solvent molecules omitted. The atomic numbering scheme is displayed (thermal ellipsoids at 80% probability level).

Table 2
Selected bond lengths (Å) and angles (°) with estimated standard deviations for **12**

Bond atoms	Distance (Å)	Angle atoms	Angle (°)
Pt–N(1)	2.062(2)	N(1)–Pt–N(1)#1	91.66(12)
Pt–N(1)#1	2.062(2)	N(1)–Pt–Cl(1)#1	89.91(6)
Pt–Cl(1)#1	2.2951(7)	N(1)#1–Pt–Cl(1)#1	178.42(6)
Pt–Cl(1)	2.2951(7)	N(1)–Pt–Cl(1)	178.42(6)
Pt–Cl(2)#1	2.3084(7)	N(1)#1–Pt–Cl(1)	89.91(6)
Pt–Cl(2)	2.3084(7)	Cl(1)#1–Pt–Cl(1)	88.51(4)

C(6)–N(2)	1.330(3)	Cl(1)#1–Pt–Cl(2)#1	89.18(3)
N(2)–O(2)	1.394(3)	Cl(1)–Pt–Cl(2)#1	90.93(3)
		N(1)–Pt–Cl(2)	90.69(7)
		N(1)#1–Pt–Cl(2)	89.21(7)
		Cl(1)#1–Pt–Cl(2)	90.93(3)
		Cl(1)–Pt–Cl(2)	89.18(3)
		Cl(2)#1–Pt–Cl(2)	179.86(4)

orientation of the OH and C=O groups of the hydroxamic acid. The X-ray structural determination of **12** evidenced the free hydroxamic acid moieties in the keto form, adopting *Z* conformation. The hydroxamic acid NH and OH each hydrogen-bond to the oxygen acceptor atoms of different methanol solvent molecules with NH···O and OH···O bond length of approximately 2.00 and 1.81 Å, respectively, while the hydroxamic acid carbonyl oxygen hydrogen-bonds to a third methanol solvent molecule with an O···HO bond length of approximately 1.86 Å (Supplementary data, Fig. 1 and Table 2). With the complex situated on a twofold axis, a three-dimensional hydrogen-bonded lattice results (Fig. 4). The hydrogen-bond distances and angles are presented in Supplementary data (Table 2).

The crystal structure of **12**, together with a comparison of the far-IR spectral data for **12** with those of **11**, **13** and **14**, assist in the definitive assignment of the *cis*-configuration for each of the Pt^{IV} pyhaH and pycaH complexes synthesised (Fig. 5). Selected IR and far-IR spectral data are provided in Supplementary data (Table 1).

3.4. Synthesis and characterisation of $K[Ru^{II}(Hedta)(NO)Cl]\cdot H_2O$ (**15**)

To establish that the free hydroxamic acid moieties in *cis*-$[Pt^{II}Cl_2(x\text{-pyhaH})_2]$ ($x = 3$, 4) are sources of NO, we reacted *cis*-$[Pt^{II}Cl_2(x\text{-pyhaH})_2]$ with the well-known ruthenium (Ru) NO scavenger, $K[Ru^{III}(Hedta)Cl]\cdot 2H_2O$, which resulted in the facile formation of the Ru^{II}-nitrosyl, $K[Ru^{II}(Hedta)(NO)Cl]\cdot H_2O$. Reaction of *cis*-$[PtCl_2(py)_2]$ with $K[Ru^{III}(Hedta)Cl]\cdot 2H_2O$ did not yield a Ru^{II}-nitrosyl product.

The Ru^{II}–NO^+ complex, $K[Ru^{II}(Hedta)(NO)Cl]\cdot H_2O$ (**15**) was obtained upon reaction of *cis*-$[Pt^{II}Cl_2(x\text{-pyhaH})_2]$ ($x = 3$, 4) i.e. **6** or **7** with the well-known NO scavenger, $K[Ru^{III}(Hedta)Cl]\cdot 2H_2O$. Elemental analysis, IR, ^1H and ^{13}C NMR and ESI-mass spectra are consistent with the formulation, $K[Ru^{II}(Hedta)(NO)Cl]\cdot H_2O$ and concur with previously reported examples of Ru^{II}-edta-NO

Fig. 5. Structures of tetrachlorido Pt^{IV} complexes.

complexes in the literature [34]. The IR spectra of **15** contains a distinctive ν_{NO} at 1894 cm^{-1}. ESI-MS in the negative mode was used to unequivocally identify the Ru^{II}–NO$^+$ complex, [Ru^{II}(Hedta)(NO)Cl]$^-$; a mass peak at 456 amu with the correct isotopic abundances was observed. Previous reported reactions of K[Ru^{III}(Hedta)Cl] · 2H$_2$O with hydroxamic acids such as benzohydroxamic acid gave the Ru^{II}–NO$^+$ complex, K$_2$[Ru^{II}(edta)(NO)Cl] [18]. The doubly protonated edta complex Ru(H$_2$edta)(NO)Cl was previously isolated by reacting K[Ru(Hedta)Cl] · 2H$_2$O with *N*-methyl-*N*-nitroso-*p*-toluenesulfonamide or NO gas under argon [34]. Depending on pH, the Ru^{II}-NO$^+$ complexes can be isolated with the free arm of the ethylenediaminetetraacetate in the protonated or the anionic form.

3.5. Pharmacological tests

The free ligands **1**–**4**, benzohydroxamic acid **5** and the Pt^{II} compounds **6**–**10** and their corresponding reference numbers are listed in Table 3.

The effects on vasorelaxation of Pt^{II} compounds **6**–**9**, the hydroxamic acid ligands **1** and **2**, the carboxylic acid ligands **3** and **4** and the control compounds, benzohydroxamic acid **5**, *cis*-[Pt^{II}Cl$_2$(py)$_2$] (**10**), and cisplatin were studied using thoracic aorta rings isolated from rats. Given the fact that Pt^{IV} compounds are thought to be activated by reduction to their corresponding Pt^{II} analogues, the NO-releasing properties of the Pt^{IV} compounds herein described were not investigated.

Table 3
The free ligands, benzohydroxamic acid and the Pt^{II} compounds and their corresponding reference numbers

3-Pyridinehydroxamic acid (3-pyhaH)	**1**
4-Pyridinehydroxamic acid (4-pyhaH)	**2**
3-Pyridinecarboxylic acid (nicotinic acid) (3-pycaH)	**3**
4-Pyridinecarboxylic acid (isonicotinic acid) (4-pycaH)	**4**
Benzohydroxamic acid (bhaH)	**5**
cis-[Pt^{II}Cl$_2$(3-pyhaH)$_2$] · 2H$_2$O	**6**
cis-[Pt^{II}Cl$_2$(4-pyhaH)$_2$] · H$_2$O	**7**
cis-[Pt^{II}Cl$_2$(3-pycaH)$_2$]	**8**
cis-[Pt^{II}Cl$_2$(4-pycaH)$_2$]	**9**
cis-[Pt^{II}Cl$_2$(py)$_2$]	**10**

Compounds **6** and **7**, as well as their ligands **1** and **2**, induce the same extent (~80% at the highest concentration used) of vasorelaxation of aortic rings pre-contracted with phenylephrine, irrespective of the position in the pyridine ring of the hydroxamic acid moiety (Fig. 6). Benzohydroxamic acid, used as a positive control [18], induces vasorelaxation to a lesser extent (Fig. 8). Ligands characterised by the presence of a carboxylic acid group, i.e. compounds **3** and **4**, induce mild relaxation of aorta rings, comparable to that induced by water (the solvent used to dissolve these compounds), that reaches approximately 30% at concentrations $\geqslant 10^{-7}$ M (Fig. 7). In contrast, the corresponding Pt derivatives **8** and **9** cause vasorelaxation statistically (**3** versus **8** $p < 0.02$ for concentrations $\geqslant 10^{-7}$ M) greater than that of the free ligands, with a maximum of approximately 60%, at the highest concentration used (Fig. 7).

Cisplatin and *cis*-[Pt^{II}Cl$_2$(py)$_2$] **10**, studied in the same experimental model (Fig. 8), do not induce relaxation of the aorta rings (relaxation comparable to that induced by

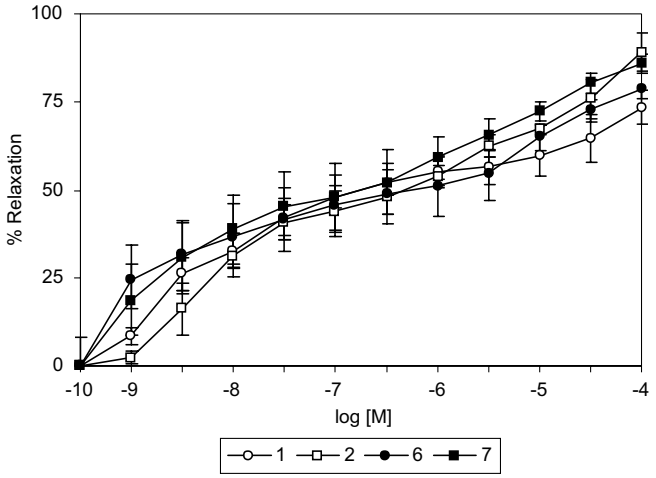

Fig. 6. Effects of compounds 3-pyhaH **1**, 4-pyhaH **2** and of respective platinum compounds *cis*-[Pt^{II}Cl$_2$(3-pyhaH)$_2$] (**6**) and *cis*-[Pt^{II}Cl$_2$(4-pyhaH)$_2$] (**7**) on aortic ring relaxation.

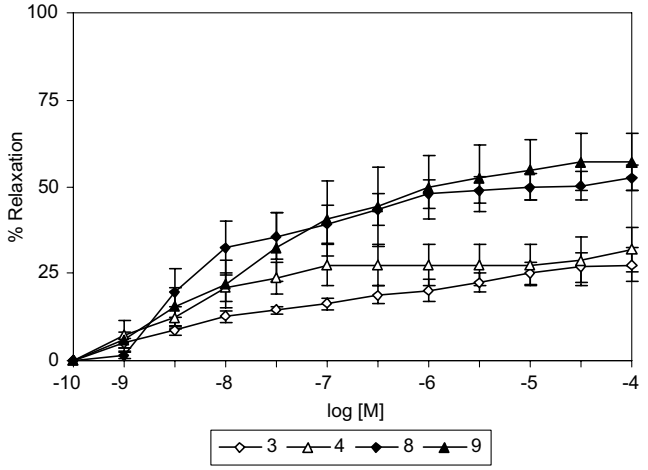

Fig. 7. Effects of compounds 3-pycaH **3**, 4-pycaH **4** and of respective platinum compounds *cis*-[$Pt^{II}Cl_2$(3-pycaH)$_2$] (**8**) and *cis*-[$Pt^{II}Cl_2$-(4-pycaH)$_2$] (**9**) on aortic rings relaxation.

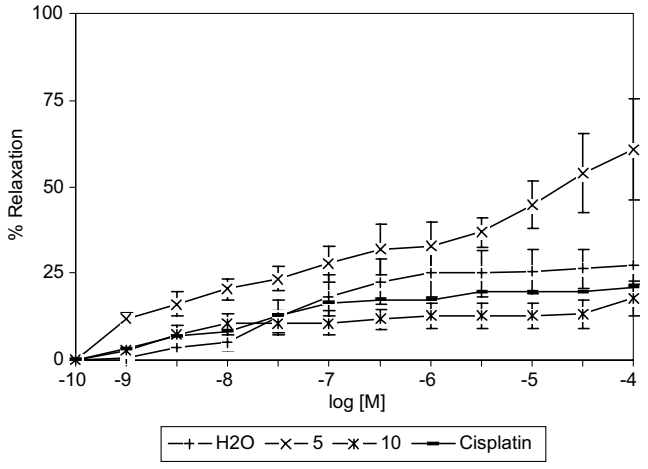

Fig. 8. Effects of water, benzohydroxamic acid **5**, *cis*-[$Pt^{II}Cl_2(py)_2$] (**10**) and cisplatin on aortic rings relaxation.

water) suggesting the lack of any role of the Pt ion *per se* in this phenomenon.

The involvement of NO in the induced vasorelaxation of compounds **6** and **8** was further investigated in the presence and absence of the guanylate cyclase inhibitor methylene blue (Fig. 9). Methylene blue completely abolished the vasorelaxation induced by both compounds **6** and **8**, indicating the involvement of the NO signaling pathway, likewise in the case of compound **8**, a derivative free of the hydroxamic acid moiety.

This data show that both hydroxamic acid and carboxylic acid derivatives in the rat aortic ring model cause NO-dependent releasing properties through a mechanism involving the NO signaling pathway, as supported by the inhibitory effects of the guanylate cyclase inhibitor methylene blue. The former exhibited enhanced NO-dependent releasing properties relative to the latter. It should be stressed that only hydroxamic acid derivatives, *via* the hydroxamic acid functional group, have the potential to

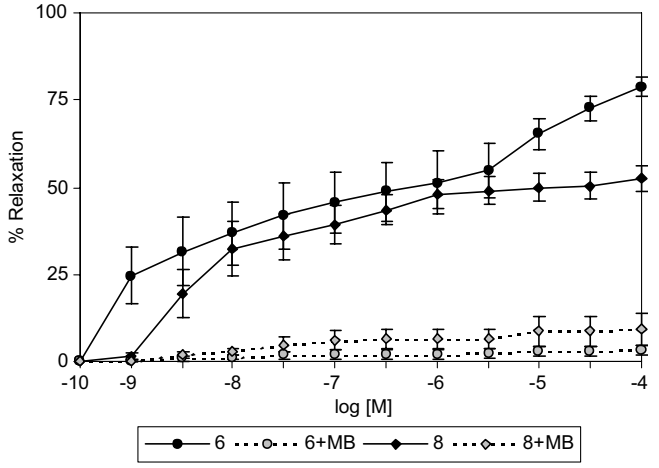

Fig. 9. Effects of *cis*-[$Pt^{II}Cl_2$(3-pyhaH)$_2$] (**6**) and *cis*-[$Pt^{II}Cl_2$(3-pycaH)$_2$] (**8**) in the presence or absence of methylene blue (MB).

release NO. It may therefore be hypothesised that the mechanism of vasorelaxation of aortic rings is probably due to stimulation of NOS activity of the aorta endothelial cells, to which NO-release from compounds **6** and **7** might also contribute, at least at concentrations higher than 3×10^{-5} M.

4. Conclusions

A series of novel Pt^{II} and Pt^{IV} pyridinehydroxamic acid complexes were synthesised with a view to advancing a new class of metallodrug with dual DNA-binding and NO-releasing properties. We can conclude from our investigation that the Pt^{II} pyridinehydroxamic acid derivatives induce potent *in vitro* effects attributable to either NO-release from the hydroxamic acid moiety and/or stimulation of iNOS of the endothelial cells. Considering the role of NO and iNOS activation in the process of proliferation and metastases, the data of the present work suggest further *in vitro* and *in vivo* testing of these compounds on cell proliferation and solid metastasising tumours, respectively. The complexes herein described are not however sufficiently soluble for a full biological investigation. We are currently in the process of developing analogues with superior aqueous solubility.

fundamental roles in biochemical processes, including cardiovascular control, neuronal signaling and as an agent for defense mechanisms against microorganisms and tumors [16,17]. It has been demonstrated that NO is involved as a mediator in one tumor-induced angiogenic process, which is a key step in the formation of metastasis [18]. The possibility of usage of nitrosyl ruthenium complexes as novel antitumor agents which might release cytotoxic NO within tumor cells, leading to cell death, was suggested for the complexes *cis,fac*-$[RuCl_2(NO)(DMSO\text{-}O)_3]BF_4$, *cis,mer*-$[RuCl_2(NO)(py)_3(NO)]BF_4$ and *cis*-$[RuCl_2(NO)$-(terpy)]Cl [19–21]. Additionally it has been claimed that the activity of NAMI-A against disseminated tumors might be related with NO metabolism *in vivo* [20]. Phosphine complexes, including dppf ones (dppf = 1,1′-bis(diphenylphosphino)ferrocene), of various transition metals (Au, Ag, Cu, Ru, Rh, Pt, Pd) have been evaluated as potential antitumor agents in various human tumor cell lines [22–24]. For the Au complexes, for instance, the observed activity has been attributed to the presence of the phosphine ligands, since similar complexes without them had a very low activity [25]. In this sense the metallic center act as carrier of the real drug, protecting it of oxidation or other reactions in the cellular media [26]. The work presented in this paper describes the synthesis, structure, spectroscopic, electrochemical and preliminary *in vitro* antitumor activity of the nitrosyl *fac*-$[RuCl_3(NO)(dppf)]$.

2. Experimental

2.1. Materials for synthesis

Solvents utilized were purified by standard methods. All chemicals used were of reagent grade or comparable purity. The $RuCl_3 \cdot 3H_2O$ was purchased from Aldrich and the dppf ligand was purchased from Strem. The $RuCl_3NO \cdot 2H_2O$, was prepared according to the literature method [27].

2.2. Instrumentation

The infrared spectra were measured from powder samples diluted in KBr or in CH_2Cl_2 solutions using CaF_2 windows on an FTIR Bomem-Michelson 102 spectrometer in the 4000–200 cm^{-1} region for KBr sample and 4000–1000 cm^{-1} for CH_2Cl_2 solution. UV–Vis spectrum was recorded in a HP8452A (diode array) spectrophotometer. All the NMR experiments were recorded on a BRUKER equipment 9.4 T (400 MHz for hydrogen frequency). The $^{31}P\{^1H\}$, ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded in CD_2Cl_2. TMS (^1H, $^{13}C\{^1H\}$) and H_3PO_4 85% ($^{31}P\{^1H\}$) were used for internal and external reference. Cyclic voltammetry (CV) experiments were carried out at room temperature in CH_2Cl_2 and CH_3CN containing 0.10 M $Bu_4N^+ClO_4$ (TBAP) (Fluka Purum) using a BAS-100B/W Bioanalytical Systems Instrument; the working and auxiliary electrodes were stationary Pt foils; a Luggin capillary probe was used and the reference electrode was Ag/AgCl. In these conditions the ferrocene is oxidized at 0.43 V (Fc^+/Fc) in CH_2Cl_2 or in CH_3CN. The microanalyses were performed by Microanalytical Laboratory of Universidade Federal de São Carlos, São Carlos (SP), using a FISIONS CHNS, mod. EA 1108 micro analyser.

2.3. X-ray crystallography

Red crystals of the *fac*-$[RuCl_3(NO)(dppf)]$ complex were grown by slow evaporation of dichloromethane/diethyl ether solution. The crystal was mounted on an Enraf-Nonius Kappa-CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The final unit cell parameters were based on all reflections. Data collections were made using the COLLECT program [28]; integration and scaling of the reflections were performed with the HKL DENZO-SCALEPACK system of programs [29]. Absorption correction was carried out using the gaussian method [30]. The structure was solved by direct methods with SHELXS-97 [31]. The model was refined by full-matrix least squares on F2 by means of SHELXL-97 [32]. All hydrogen atoms were stereochemically positioned and refined with the ridging model. The ORTEP showed in Fig. 3 was prepared using ORTEP-3 for windows [33]. Hydrogen atoms of the aromatic rings were set isotropic with a thermal parameter 20% greater than the equivalent isotropic displacement parameter of the atom to which each one is bonded. The data collections and experimental details are summarized in Table 1, and selected bond distances and angles are given in Table 2.

2.4. Synthesis

To a deoxygenated methanolic solution (25 mL) of the $RuCl_3NO \cdot 2H_2O$ precursor (200 mg; 0.72 mmol) was added stoichiometric amount of the dppf ligand (396 mg; 0.72 mmol). The mixture was refluxed under Ar atmosphere for 6 h, leading to the formation of a red suspension. The resultant suspension was concentrated until ca. 5 mL and filtered off. The obtained solid was washed with cold methanol (1 × 5 mL) followed by diethyl ether (2 × 5 mL) and dried *in vacuo*. Yield: 338 mg (60%). ^1H NMR (400.21 MHz, CD_2Cl_2, 298 K): 4.54, 4.66, 4.70, 5.35[1] (s, 2H each, C_5H_4), 7.36 (m, 4H, Ph), 7.44 (t, 6H, Ph), 7.52 (m, 2H, Ph), 7.94 (m, 8H, Ph). $^{13}C\{^1H\}$ NMR (100.64 MHz, CD_2Cl_2, 298 K): 73.8 (t_{AB}, $^3J_{C-P} = 3.3$ Hz, CH of C_5H_4), 74.1 (t_{AB}, $^3J_{C-P} = 3.3$ Hz, CH of C_5H_4), 76.3 (t_{AB}, $^2J_{C-P} = 4.3$ Hz, CH of C_5H_4), 76.9 (t_{AB}, $^2J_{C-P} = 4.3$ Hz, CH of C_5H_4), 78.3 (d, $^1J_{C-P} = 57$ Hz, C of C_5H_4), 127.6 (t_{AB}, $^3J_{C-P} = 5.5$ Hz, C_m of Ph), 128.9 (t_{AB}, $^3J_{C-P} = 5.1$ Hz, C_o of Ph), 131.2 (dd, $^1J_{C-P} = 63$ Hz, $^3J_{C-P} = 3.5$ Hz, C_i of Ph), 131.4 (s, C_p of Ph), 131.9 (dd,

[1] Signal observed in $CDCl_3$. This singlet signal is coincident with the residual CH_2Cl_2 of the CD_2Cl_2 solvent.

2.5. Cell culture and cytotoxicity assay

In vitro cytotoxicity assays on cultured human tumor cell lines still represent the standard method for the initial screening of antitumoral agents. Thus, as a first step to assess its pharmacological properties, the new ruthenium complex was assayed toward a human breast tumor cell line MDA-MB-231 (ATCC No. HTB-26). The cells were routinely maintained with Dulbecco's Modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum (FBS), at 37 °C in a humidified 5% CO_2 atmosphere. After reach confluence, the cells were detached by tripsinization and counted. For the cytotoxicity assay, 4×10^4 cells well^{-1} were seeded in 200 μL of complete medium in 96-well plates (Corning Costar). The plates were incubated at 37 °C in 5% CO_2 for 24 h to allow cell adhesion prior to drug testing. The complex was dissolved in sterile DMSO (stock solution with maximum concentration of 2 mM) and diluted to 1.5, 1.0, 0.5, 0.2, 0.1, 0.05 and 0.02 mM. Two microliters of each complex sample were added to 200 μL medium (without FBS) in such a way that the final concentration of DMSO in each well was approximately 1% and the final concentration of the complex was diluted approximately 100 times. The others compounds evaluated (free dppf, $RuCl_3NO \cdot 2H_2O$ and cisplatin) were also dissolved in sterile DMSO. Cells were exposed to the complex for a 48 h-period. Cell respiration, as an indicator of cell viability, was determined by the mitochondrial-dependent reduction of MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) to formazan [34]. MTT solution (0.5 mg/mL) was added to cell cultures and incubated for a 3-h period. Thereafter, 100 μL of isopropanol was added in order to dissolve the formazan crystals. The conversion of MTT to formazan by metabolically viable cells was monitored by an automated microplate reader at 570 nm. The percentage of cell viability was calculated by dividing the average absorbance of the cells treated with the ruthenium complex by that of the control; % cell viability versus drug concentration (logarithmic scale) was plotted to determine the IC_{50} (drug concentration at which 50% of the cells are viable relative to the control), with its estimated error derived from the average of 3 trials.

Table 2
Selected bond distances (Å) and angles (°) for *fac*-[$RuCl_3$(NO)(dppf)]

3. Results and discussion

3.1. Characterization

The infrared spectrum of a pure sample of *fac*-[$RuCl_3$(NO)(dppf)] in KBr showed a split nitrosyl stretch with one peak at 1837 cm^{-1} and other at 1830 cm^{-1}. Additionally there was a shoulder at 1852 cm^{-1}. Splitting of NO peaks in solid state IR spectra have been observed for complexes such as *cis*-[RuCl(NO)(en)$_2$]Cl$_2$ [35], *mer*-[RuX_3(NO)(en)] where X = Cl, Br, and I [36] and [RuCl(NO)(bpe) $\cdot$ $2H_2O$] [bpe = *N*,*N*′-bis(2-pyridinecarboxamide)-1,2-ethane dianion [37]. To verify the possibility of some interaction with KBr as the cause of the extra NO stretch, a spectrum was obtained using a NaCl pellet. In this condition only one NO stretch at 1875 cm^{-1} and a shoulder at 1845 cm^{-1} were observed (see Fig. 1). Thus, it might be concluded from these data that bromide might displace chloride when the sample is prepared in KBr, because the

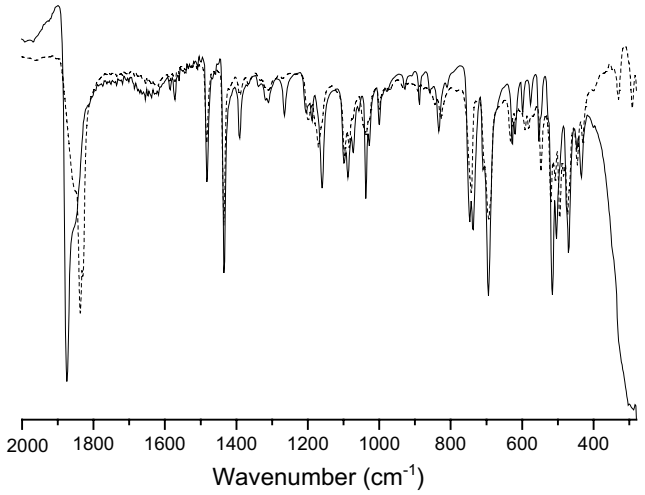

Fig. 1. IR spectra of *fac*-[$RuCl_3$(NO)(dppf)] in KBr (dashed) and NaCl pellets.

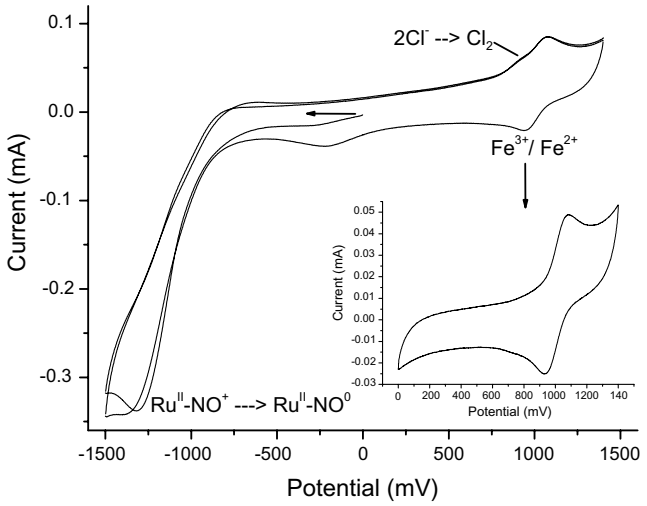

Fig. 2. Cyclic voltammetric response for *fac*-[$RuCl_3$(NO)(dppf)] in CH_2Cl_2 at 100 mV s^{-1}. Inset: same experiment but utilizing a smaller range of potentials (0–1400 mV).

observed peak in NaCl was at higher stretching frequency than that observed in KBr. To avoid this effect the IR spectrum was obtained in CH_2Cl_2 solution and just a single band for the νNO at 1860 cm^{-1} was observed, being another evidence of the solid state effect in the NO stretch split. Other important bands are also those involving the Ru center and the chloride ligands in the low energy region [38]. In the *fac*-[$RuCl_3$(NO)(dppf)] the Ru-Cl bands appeared at 331 and 290 cm^{-1} in KBr pellet as previously observed for the series *fac*-[$RuCl_3$(NO)(P–P)], P–P = dppm, dppe, c-dppen, dppp, dppb and dcpe [27,39,40].

In the $^{31}P\{^1H\}$ NMR spectrum the new complex showed a singlet signal at 28.0 ppm, indicating the magnetic equivalence of the phosphorus atoms, and consequently the *fac* arrangement for the chlorides. The free dppf ligand showed a resonance signal at −16.5 ppm, so the great shift observed indicates the coordination of the ligand to the ruthenium center. The ^1H NMR spectrum of the *fac*-[$RuCl_3$(NO)(dppf)] showed signals for the phenyl groups of the phosphine as multiplets at δ 7.34–7.94 ppm. The ferrocenyl protons show resonances in the region δ 4.50–5.35, appearing as four singlets with relative integrals 1:1:1:1. This is in contrast with the observed in other related 1,1′-disubstituted ferrocene compounds where the ferrocenyl signals usually appear as two triplets corresponding to the AA′BB′ spin system with a coupling constant of ca. 2 Hz for an eclipsed arrangement of the C_5H_4 rings [41]. This is indicative of a staggered arrangement for the two C_5H_4 rings, which has not been confirmed by X-ray crystallographic studies. So, for the title complex there is a difference in the C_5H_4 rings conformation when in solution or in solid state as shown by X-ray structure. Examples of dppf complexes with four singlets for the Cp rings are $[Ru(bipy)_2(dppf)]^{2+}$ [42] and *fac*-[$Re(CO)_3Cl$(dppf)] [43], as indicated by their X-ray analysis where staggered conformations were found. The cyclic voltammetric experiments of *fac*-[$RuCl_3$(NO)(dppf)] were carried out in CH_2Cl_2 and also in CH_3CN solutions. The CV response is dominated by an irreversible reduction, assigned to the reduction of the NO^+ group coordinated to Ru(II) [40,44–46] and a reversible pair corresponding to the pair Fe^{3+}/Fe^{2+} of the dppf ligand as showed in Fig. 2. The reduction of the coordinated NO^+ group is accompanied by a rapid chemical reaction, hence, there is no sign of a return wave even at low temperature (0 °C) and at scan rates up to 5 V s^{-1}. No additional studies were done to determine if NO is released after NO^+ reduction. After the irreversible NO^+ reduction, scanning to positive potential, a new dependent irreversible wave is observed as a shoulder at 0.95 V. This process can be ascribed to the oxidation of free chloride present in the solution indicating that reduction is accompanied by loss of chloride [20,40]. At slightly more positive potentials a reversible wave appeared corresponding to the Fe^{3+}/Fe^{2+} redox pair of the coordinated dppf ligand. In general when coordinated the $E_{1/2}$ of the dppf ligand increases due to the electronic delocalization that stabilizes de Fe^{2+}. This is observed in our complex and the redox potential for the free dppf of 0.74 V [47] is lower than the observed for *fac*-[$RuCl_3$-(NO)(dppf)], 1.0 V. Utilizing CH_3CN as solvent was possible to observe in addition to the previously mentioned waves, an irreversible anodic peak at 2.35 V due the oxidation of the very stable Ru^{II} center, this wave is independent of the NO^+ reduction. The high value for the Ru^{3+}/Ru^{2+}potential is explained by the presence of the NO^+ (strong π acceptor) [48] and it's irreversible character is indicative of instability of the Ru^{III}–NO^+ fragment. Comparing with other species in which the peak potential for the pair Ru^{3+}/Ru^{2+} is not observed, such as the *trans*-$[RuCl(NO)(dppe)_2]^{2+}$ and $[RuCl(NO)(dcpe)(bipy)]^{2+}$ [49,50], the [$RuCl_3$(NO)(dppf)] as well the previously studied [$RuCl_3$(NO)(P–P)] [39,40] complexes show a higher electron density on the metal center because of the presence of two additional chlorides.

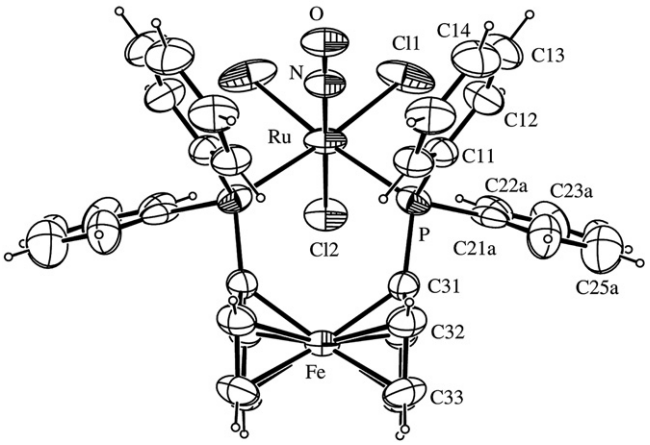

Fig. 3. ORTEP view of *fac*-[$RuCl_3(NO)(dppf)$] showing the atoms labeling and the 50% probability ellipsoids.

3.2. Structural studies

In the structure of the *fac*-[$RuCl_3(NO)(dppf)$] the metal adopts a distorted octahedral geometry as can be seen in the ORTEP (Fig. 3). The nitrosyl group is essentially linear, *trans* positioned to the Cl^-, consistent with the NO stretching vibration band in the IR spectra, both indicating that the NO group is formally bound to the metal as NO^+ [13]. The N–O bond lengths of 1.149(6) Å is consistent with other reported data [27,39,40,51]. The Ru–Cl(1) and Ru-Cl(3) bond lengths 2.4535(12) Å are longer than the Ru–Cl(2) one (*trans* NO; 2.3475(14)) by 0.106 Å, consistent with the *trans* strengthening effect of the NO, also know as 'inverse structural *trans* effect' [52]. The Ru–Cl distances in the range 2.35–2.45 Å are very similar to the related *fac*-[$RuCl_3(NO)(P–P)$] complexes [39,40]. The Ru–P distances of 2.40 Å are similar to the observed in the *fac*-[$RuCl_3$-(NO)(dppb)], but very different from that found in the [$Ru(RCOO)_2(dppf)$] complexes that are close to 2.26 Å [53]. Distances and angles involving the NO group are very similar from that found in the other members of the *fac*-[$RuCl_3(NO)(P–P)$] series [27,39,40,54]. The P(1)–Ru–P(2) angle is 98.90(4)°, which is in the ordinary range for ruthenium compounds with chelated dppf, for example, in the series [$Ru(RCOO)_2(dppf)$], $R = CH_3–CH_3CH_2–C_6H_5$ this angle is in the range 96.53(13)–99.58(5)° [53]. In addition, a variety of bonding parameters typically reported for dppf-containing compounds [55] are presented for some Ru complexes in Table 3. The new *fac*-[$RuCl_3(NO)(dppf)$] and the [$RuCl(dppf)(\eta^6$-*p*-cimeno)]PF_6 [56] present the cyclopentadienyl rings of the dppf ligand in the "synperiplanar eclipsed" conformation while in the [RuClH(dppf)-(CO)(PPh_3)] [57] such rings are in the "synclinal staggered" conformation.

Table 4
IC_{50} values in MDA-MB-231 cell line of *fac*-[$RuCl_3(NO)(dppf)$], $RuCl_3NO \cdot 2H_2O$, free dppf and cisplatin measured in DMSO solutions

Compound	IC_{50} (μM)
fac-[$RuCl_3(NO)(dppf)$]	10 ± 3
$RuCl_3NO \cdot 2H_2O$[a]	>200
dppf	97 ± 8
cisplatin	63 ± 5

[a] The maximum utilized concentration was 200 μM.

3.3. Cytotoxicity results

The cells were exposed to the compound for a relatively long period (2 days), to allow the compound to be able to reach DNA, or another unknown biological target. The complex *fac*-[$RuCl_3(NO)(dppf)$], the uncoordinated dppf and the $RuCl_3NO \cdot 2H_2O$ precursor complex were tested against the MDA-MB-231 cells. For comparison purposes, the cytotoxicity of cisplatin was evaluated under the same experimental conditions. The IC_{50} values, calculated from the dose–survival curves obtained after 48 h drug treatment from MTT assay, are shown in Table 4. The $RuCl_3$-$NO \cdot 2H_2O$ complex proved to be completely ineffective against the tested cell line. The free dppf ligand showed a low activity with an IC_{50} value of 97 ± 8 μM, approximately 10-fold higher than that of the new nitrosyl complex *fac*-[$RuCl_3(NO)(dppf)$]. Even compared with cisplatin (reference metallodrug) our complex is six times more active indicating its potentiality as an antitumor agent. Considering the lack of activity of the $RuCl_3(NO) \cdot 2H_2O$ species seems reasonable to suggest that the activity of *fac*-[$RuCl_3(NO)(dppf)$] is due to the presence of the dppf in its structure which is the real cytotoxic agent and its activity is increased when coordinated to the "$RuCl_3NO$" unity. Studies are been developed in our laboratory to check this possibility.

4. Conclusions

In this work the synthesis and full characterization of the new ruthenium nitrosyl complex *fac*-[$RuCl_3$-(NO)(dppf)] was showed. Spectroscopical, electrochemical and X-ray data indicated a complex of the type {Ru^{II}–

$NO^+\}^6$. Preliminary *in vitro* antitumor activity of this complex showed a moderate to good citotoxicity to the MDA-MB-231 tumor cell line with an IC_{50} of 10 ± 3 μM, a value that is lower than those observed for the $RuCl_3NO \cdot 2H_2O$ precursor, free dppf and cisplatin.

$PaPy_3H$ $PaPy_2QH$

The $\{Ru–NO\}^6$ nitrosyl $[(PaPy_3)Ru(NO)](BF_4)_2$ exhibits great stability in aqueous solution over a wide range of pH (3–11) for long periods of time. We have employed this nitrosyl to successfully deliver NO to biological targets such as myoglobin, cytochrome c oxidase and soluble guanylate cyclase under *controlled conditions of illumination* [18,21,22]. In order to further improve the NO donating capacity of this NO donor, we recently decided to increase the extent of conjugation in the carboxamide arm of the ligand. We hypothesized that the greater light-harvesting properties of the quinoline moiety (versus pyridine) might enhance the photolability of the Ru–NO unit. In such attempt, we have now synthesized the ligand *N*,*N*-bis (2-pyridylmethyl)amine-*N*-ethyl-2-quinaldine-2-carboxamide ($PaPy_2QH$) that contains a quinoline group in place of pyridine [23]. In this paper we report the synthesis, structure and properties of the $\{Ru–NO\}^6$ nitrosyl $[(PaPy_2Q)Ru(NO)](BF_4)_2$. This nitrosyl indeed exhibits improved photoefficiency when exposed to low-intensity (mW) UV light.

2. Experimental

2.1. Materials and methods

2.1.1. General procedures

The starting Ru(II) salt $[Ru(DMSO)_4Cl_2]$ was prepared from $RuCl_3 \cdot 3H_2O$ as described elsewhere [24]. NO gas was supplied by Spectra Gases, Inc. and purified as described previously [16]. All other reagents were procured from Aldrich Chemical Co. The solvents used in this work were dried according to standard procedures: EtOH and MeOH were distilled from Mg/I_2; MeCN and CH_2Cl_2 from CaH_2; Et_2O from Na; and DMF from BaO. The two ligands $PaPy_3H$ and $PaPy_2QH$ were synthesized by following published procedures [20,23]. $[(PaPy_3)Ru(NO)](BF_4)_2$ was synthesized according to procedures published by us in a previous account [19].

2.1.2. Synthesis of $[(PaPy_2Q)Ru(NO)](BF_4)_2$

A slurry of the yellow starting salt $[Ru(DMSO)_4Cl_2]$ (0.180 g, 0.38 mmol) in 15 ml of EtOH was heated to reflux temperature to generate a clear orange solution. Separately, 0.150 g (0.38 mmol) of the ligand $PaPy_2QH$ was dissolved in 5 ml of EtOH and deprotonated with NaOEt (generated in situ with 10 mg (0.42 mmol) of NaH). The two solutions were then mixed at reflux temperature to generate a dark orange solution. After 35 min of heating, 1 equiv. of solid $NaNO_2$ (0.030 g, 0.42 mmol) was added to the hot solution and the heating was continued for 45 min. A dilute solution of HBF_4 in 3 ml of EtOH was then added to the hot solution and the resulting precipitate was collected by filtration through glass frit under N_2 atmosphere. The reddish-orange solid was washed several times with cold EtOH, then Et_2O and dried under high vacuum. This crude complex was finally stirred in CH_2Cl_2 containing 5% MeOH for several hours. This step provided pure $[(PaPy_2Q)Ru(NO)](BF_4)_2$ (not soluble in CH_2Cl_2/MeOH) as a yellow solid (170 mg) in 65% yield. *Anal*. Calc. for $C_{24}H_{22}B_2F_8N_6O_2Ru$: C, 41.11; H, 3.16; N, 11.99. Found: C, 40.95; H, 3.26; N, 12.07%. Selected IR frequencies (KBr disk, cm^{-1}): 1868 (s, ν_{NO}), 1633 (vs, ν_{CO}), 1457 (w), 1378 (m), 1083 (s), 1035 (s), 767 (m), 533 (w), 521 (w). Electronic spectrum in MeCN, λ_{max} in nm (ε in $M^{-1}\,cm^{-1}$): 245 (19460), 308 (4280), 335 (sh, 3480), 420 (1040). ^1H NMR (CD_3CN) δ: 9.07 d (1H), 8.38 m (2H), 8.23 t (2H), 8.17 m (2H), 8.03 t (1H), 7.90 d (2H), 7.55 d (2H), 7.47 t (2H), 5.31 m (4H), 3.86 (2H), 3.42 t (2H).

2.2. Physical measurements

2.2.1. Spectroscopy

The ^1H NMR spectra were recorded at 298 K on a Varian 500 MHz instrument. A Perkin–Elmer Spectrum-One FT-IR spectrometer was used to monitor the IR spectra. The electronic absorption spectra were obtained with a Carey 50 spectrophotometer (Varian).

2.2.2. Photolysis experiments

Release of NO in solution under aerobic condition was monitored with an *in* NO Nitric Oxide Measuring System (Innovative Instruments, Inc.) using the *ami*NO-2000 electrode. The rates of NO release upon exposure to UV light were measured with a ~0.1 mM solution of the complex in 1 cm× 1 cm quartz cuvette. The light sources employed in this study include (a) an UV Transilluminator (UVP, Inc.) with peak intensity of 5 mW/cm^2 at 300 nm and (b) monochromatic light generated from an Apex Illuminator (150 W Xenon lamp) equipped with a Cornerstone 130 1/8M monochromator (measured intensity of 10 mW at 410 nm). The cuvettes (placed at a distance of 3 cm) were exposed to UV light for no more than 40 s per interval to prevent heating the solution and the electronic spectra were recorded. The apparent rates of NO release were followed at an appropriate wavelength for each compound and the absorbance versus time plots generated in SigmaPlot, and fitted to the 3-parameter exponential equation: $y = y_o + a^*(1 - \exp(-k^*x))$ as done previously. For quantum yield (ϕ) measurements, a ~0.3 mM solution was used to ensure sufficient absorbance ($\geqslant$99%) at the incident wavelength; no more than 20% photolysis occurred in each measurement. Standard actinometry using ferrioxalate was employed to calibrate the light source.

Table 1
Summary of crystal data for $[(PaPy_2Q)Ru(NO)](BF_4)_2 \cdot MeCN$

Empirical formula	$C_{26}H_{25}B_2F_8N_7O_2Ru$
Formula weight	742.22
Crystal color and habit	dichroic yellow needle
Crystal size (mm)	$0.45 \times 0.06 \times 0.05$
Crystal system	triclinic
Space group	$P\bar{1}$
Temperature (K)	90(2)
a (Å)	7.5961(8)
b (Å)	12.4837(13)
c (Å)	15.7711(17)
α (°)	72.844(2)
β (°)	85.539(2)
γ (°)	80.816(2)
Volume (Å^3)	1409.9(3)
Z	2
D_{calc} (Mg/m^3)	1.748
Absorbance coefficient, μ (mm^{-1})	0.650
Reflections collected	18 500
Independent reflections [R_{int}]	8121 [0.0441]
Observed reflections ($I > 2\sigma(I)$)	6629
Maximum and minimum transmission	0.968 and 0.759
Goodness-of-fit on F^2	1.017
Final R indices [$I > 2\sigma(I)$]	$R_1^a = 0.0425$, $wR_2^b = 0.1045$
R indices (all data)	$R_1 = 0.0580$, $wR_2 = 0.1129$

[a] $R_1 = \sum\|F_o| - |F_c\|/\sum|F_o|$.
[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$ and $w = 1/[\sigma^2(F_o^2) + (aP)^2 + (bP)]$, where $P = (2F_c^2 + F_o^2)/3$.

Table 2
Selected bond lengths (Å) and bond angles (°) for $[(PaPy_2Q)Ru(NO)](BF_4)_2$ and $[(PaPy_3)Ru(NO)](BF_4)_2$

	$[(PaPy_2Q)Ru(NO)](BF_4)_2$	$[(PaPy_3)Ru(NO)](BF_4)_2$
Ru–N(6)	1.779(2)	1.779(2)
N(6)–O(2)	1.147(3)	1.142(3)

2.2.3. X-ray crystallography

Long yellow needles of $[(PaPy_2Q)Ru(NO)](BF_4)_2 \cdot MeCN$ were grown via vapor diffusion of Et_2O into an MeCN solution of the complex at room temperature. Diffraction data were collected at 90 K on a Bruker SMART ApexII instrument using Mo Kα radiation ($\lambda = 0.71073$ Å) and the data were corrected for absorption. The structures were solved using the standard SHELXS-97 package. Additional refinement details are contained in the CIF files (Supplementary material). Instrument parameters, crystal data, and data collection parameters are summarized in Table 1. A comparison of selected bond distances and bond angles for $[(PaPy_2Q)Ru(NO)](BF_4)_2$ and $[(PaPy_3)Ru(NO)](BF_4)_2$ are listed in Table 2.

3. Results and discussion

3.1. Synthesis

The nitrosyl $[(PaPy_2Q)Ru(NO)](BF_4)_2$ was synthesized via acidification of the corresponding Ru(II)–NO_2 precursor in a one-pot reaction (Eq. (1)) [25–27]. The reaction of the deprotonated ligand $PaPy_2Q^-$ with the Ru(II) starting salt $[Ru(DMSO)_4Cl_2]$ followed by the addition of $NaNO_2$ leads to the formation of the Ru(II)–NO_2 precursor (not yet successfully isolated). Acidification of this species, generated *in situ*, with HBF_4 finally affords the nitrosyl in good yield. Coordination of the deprotonated carboxamido nitrogen to the ruthenium center is not affected in this acidification step. Although addition of dilute $HClO_4$

$$Ru^{II}\text{–}NO_2 + 2H^+ \rightarrow \{Ru\text{–}NO\}^6 + H_2O \quad (1)$$

in place of HBF_4 results in formation of the perchlorate salt of the nitrosyl, acids like HCl afford an intractable mixture of species. $[(PaPy_2Q)Ru(NO)](BF_4)_2$ is soluble in a wide variety of polar solvents including H_2O, MeCN, DMF and MeOH.

3.2. Structure of $[(PaPy_2Q)Ru(NO)](BF_4)_2 \cdot MeCN$

The structure of the cation $[(PaPy_2Q)Ru(NO)]^{2+}$ is shown in Fig. 1. The pentadentate $PaPy_2Q^-$ ligand is coordinated to the ruthenium center via three ring nitrogens, the tertiary amine nitrogen and the carboxamido nitrogen. The sixth coordination site, *trans* to the carboxamido nitrogen, is occupied by NO and the overall geometry is pseudo octahedral. Similar binding by the analogous ligand $PaPy_3^-$ to ruthenium has been observed in $[(PaPy_3)$-

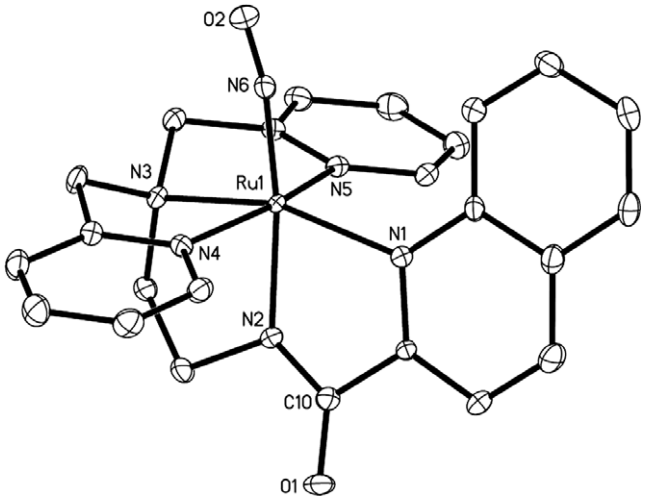

Fig. 1. Thermal ellipsoid (probability level 50%) plot of $[(PaPy_2Q)$-$Ru(NO)]^{2+}$ with the atom-labeling scheme. H atoms are not shown for the sake of clarity.

$Ru(NO)]^{2+}$ [19]. Although the metric parameters of $[(PaPy_2Q)Ru(NO)]^{2+}$ are very similar to those of $[(PaPy_3)Ru(NO)]^{2+}$, there are some differences. For example, the Ru–N(O) bond length of $[(PaPy_2Q)Ru(NO)]^{2+}$ is identical to that of $[(PaPy_3)Ru(NO)]^{2+}$ (both 1.779(2) Å long). Similarly, the N(6)–O(2) bond distances are very close to each other (1.142(3) Å and 1.147(3) Å). In both cases, the shortest bond between the ligand ($PaPy_3^-$ or $PaPy_2Q^-$) and the ruthenium center is the $Ru–N_{amido}$ bond (1.997(2) Å and 1.988(2) Å, respectively). However, the $Ru–N_{quin}$ distance of $[(PaPy_2Q)Ru(NO)]^{2+}$ is longer (2.133(2) Å) than the corresponding $Ru–N_{py}$ distance of $[(PaPy_3)Ru(NO)]^{2+}$ (2.097(2) Å). In addition, the quinoline moiety is slightly tilted away from the coordinated NO (Table 2). The latter difference most possibly arises from the steric bulk of the quinoline unit. The larger quinoline moiety also causes more bending of the Ru–N–O unit in $[(PaPy_2Q)Ru(NO)]^{2+}$ (168.8(2)°) compared to 170.9(2)° in $[(PaPy_3)Ru(NO)]^{2+}$. No π–π stacking has been noted in the structure of $[(PaPy_2Q)Ru(NO)](BF_4)_2 \cdot MeCN$.

3.3. Spectroscopic characterization

$[(PaPy_2Q)Ru(NO)]^{2+}$ exhibits sharp ^1H NMR spectrum in CD_3CN solution at 298 K (Fig. 2), typical of low-spin diamagnetic $\{Ru–NO\}^6$ complexes. The N–O stretching frequency (ν_{NO}) of $[(PaPy_2Q)Ru(NO)]^{2+}$ (1868 cm^{-1}) also falls within the generally accepted range (1800–1950 cm^{-1}) for such nitrosyls. Coordination of the deprotonated carboxamido nitrogen to the metal center is evident in the red-shift of the ν_{CO} value of the complex compared to that of the free ligand (1633 cm^{-1} versus 1667 cm^{-1}).

The electronic absorption spectrum of $[(PaPy_2Q)Ru(NO)]^{2+}$ (Fig. 3) consists of a prominent band at 420 nm ($\varepsilon = 1040\ M^{-1}\ cm^{-1}$) arising from the $d(Ru) \rightarrow \pi^*(NO)$ transition. Similar bands are also observed in other $\{Ru–NO\}^6$ nitrosyls such as [(salen)Ru(NO)(Cl)] ($\lambda_{max} = 376$ nm) and [(bpb)Ru(NO)(Cl)] ($\lambda_{max} = 380$ nm) [28,29]. The small red-shift of the absorption band of $[(PaPy_2Q)Ru(NO)]^{2+}$ compared to that of $[(PaPy_3)Ru(NO)]^{2+}$ ($\lambda_{max} = 410$ nm, Fig. 3) most possibly arises from the extended conjugation of the quinoline moiety [29]. Close inspection of the absorption spectra of $[(PaPy_2Q)Ru(NO)]^{2+}$ and $[(PaPy_3)Ru(NO)]^{2+}$ reveals that introduction of the quinoline moiety in the ligand frame enhances the overall absorption in the UV range of 350–380 nm to a significant extent. As discussed below, this additional absorption due to quinoline has a strong effect on the photoreactivity of $[(PaPy_2Q)Ru(NO)]^{2+}$ compared to $[(PaPy_3)Ru(NO)]^{2+}$.

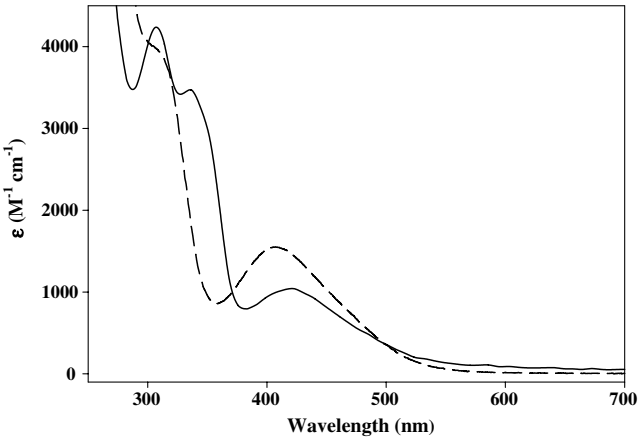

Fig. 3. Electronic absorption spectra of $[(PaPy_2Q)Ru(NO)](BF_4)_2$ (solid line) and $[(PaPy_3)Ru(NO)](BF_4)_2$ (dashed line) in MeCN.

3.4. Photolability of NO

In recent years, we and others have reported a number of $\{Ru–NO\}^6$ nitrosyls that exhibit photolability of the bound NO ligand [19,28–31]. Most of these nitrosyls afford Ru(III) species as the photoproduct (Eq. (2)) in solvents like water. For example, photorelease of NO from $[(PaPy_3)Ru(NO)]^{2+}$ generates $[(PaPy_3)Ru(H_2O)]^{2+}$ that has been characterized by EPR spectroscopy. In the present work, we have studied the photorelease of NO from $[(PaPy_2Q)Ru(NO)]^{2+}$ in both protic and aprotic solvents. As shown in Fig. 4, exposure of a solution of $[(PaPy_2Q)Ru(NO)](BF_4)_2$ in MeCN to low-intensity UV light

$$\{Ru–NO\}^6 + h\nu + solv \rightarrow Ru^{III}–(solv) + NO \quad (2)$$

results in changes in its electronic spectrum consistent with the photorelease of NO. Upon illumination, new peaks are generated at 385 nm and 470 nm and isosbestic points at 360 nm and 305 nm clearly indicate clean conversion of $[(PaPy_2Q)Ru(NO)]^{2+}$ to the solvato species. Release of NO upon illumination can be detected easily by the use of NO-electrode. The resulting NO amperogram (Fig. 4, inset) indicates that NO is released rapidly upon illumina-

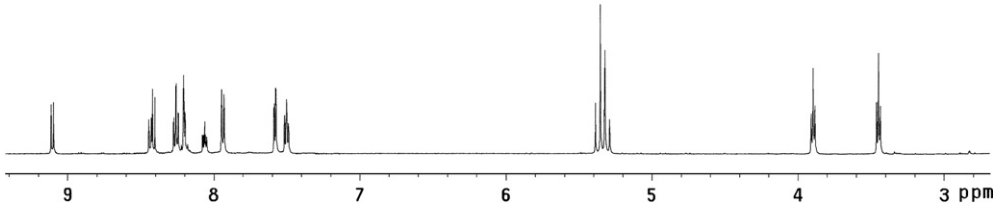

Fig. 2. ^1H NMR spectrum (500 MHz) of $[(PaPy_2Q)Ru(NO)](BF_4)_2$ in CD_3CN at 298 K.

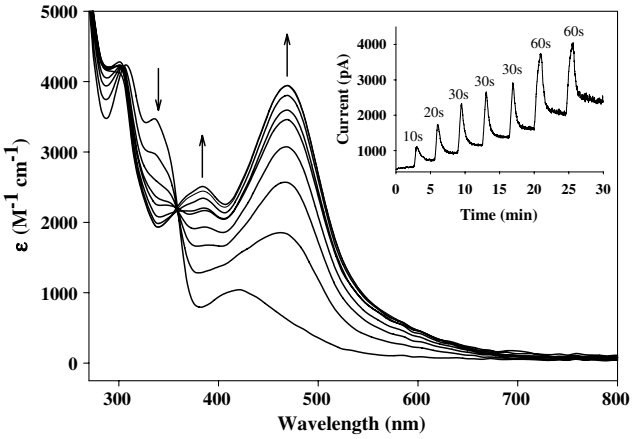

Fig. 4. Changes in electronic spectrum of $[(PaPy_2Q)Ru(NO)](BF_4)_2$ in MeCN observed upon photolysis with low-intensity UV light ($\lambda_{irr} = 300$ nm, 5 mW/cm^2). Inset: NO amperogram indicating release of NO in aqueous solution (pH 7) upon exposure to short pulses of UV light.

tion of an aqueous solution (pH 7) of $[(PaPy_2Q)Ru(NO)]^{2+}$ with low-intensity UV light.

In order to explore the effect(s) of the quinoline moiety on the capacity of NO release by $[(PaPy_2Q)Ru(NO)]^{2+}$, we have compared its photochemical efficiency with that of $[(PaPy_3)Ru(NO)]^{2+}$. The quantum yield value at 300 nm (ϕ_{300}) of $[(PaPy_2Q)Ru(NO)]^{2+}$ in MeCN solution (0.14) is significantly higher than that of $[(PaPy_3)Ru(NO)]^{2+}$ (0.06). Under physiological conditions (H_2O, pH 7), $[(PaPy_2Q)Ru(NO)]^{2+}$ also exhibits a higher quantum efficiency ($\phi_{355} = 0.20$) compared to its pyridine congener $[(PaPy_3)Ru(NO)]^{2+}$ ($\phi_{355} = 0.12$). When the ϕ value of $[(PaPy_2Q)Ru(NO)]^{2+}$ is compared with the ϕ values of other photoactive ruthenium nitrosyls (Table 3), it becomes evident that $[(PaPy_2Q)Ru(NO)]^{2+}$ exhibits sufficient photoactivity for biological purposes.

Close examination of Fig. 3 reveals that ligation of the quinoline-based ligand in $[(PaPy_2Q)Ru(NO)]^{2+}$ shifts the $d(Ru) \rightarrow \pi^*(NO)$ transition (photoactive band) to 420 nm. $[(PaPy_3)Ru(NO)]^{2+}$ exhibits its λ_{max} at 410 nm. In order to examine the effect(s) of irradiation at ~400 nm, we have also determined the quantum yields of both nitrosyls at 410 nm. Interestingly, $[(PaPy_2Q)Ru(NO)]^{2+}$ retains its high level of photoactivity at this wavelength ($\phi_{410} = 0.17$) compared to $[(PaPy_3)Ru(NO)]^{2+}$($\phi_{410} = 0.05$). It is therefore evident that the coordinated quinoline moiety not only increases absorption in the 350–380 nm region (thus acting as a light harvestor) but also enhances the $d(Ru) \rightarrow \pi^*(NO)$ transition and increases the photoactivity at ~400 nm.

Measurements on the time-dependent release of NO from $[(PaPy_3)Ru(NO)]^{2+}$ and $[(PaPy_2Q)Ru(NO)]^{2+}$ (under 300 nm UV light, 5 mW/cm^2) indicate that $[(PaPy_2Q)Ru(NO)]^{2+}$ releases NO faster ($t_{1/2} \approx 0.6$ min) than $[(PaPy_3)Ru(NO)]^{2+}$ ($t_{1/2} \approx 1.4$ min). This fact in conjunction with high ϕ value and greater stability in water makes $[(PaPy_2Q)Ru(NO)]^{2+}$ a very good candidate for the delivery of NO to biological targets.

Ford and co-workers have synthesized several chromium-nitro complexes that include peripheral ''UV antennae'', like pyrene, to increase the overall photochemical efficiency of NO generation [34]. In this work, a *directly coordinated* light-harvesting quinoline unit (Fig. 3) enhances the photoefficiency of $[(PaPy_2Q)Ru(NO)](BF_4)_2$ compared to its pyridine analogue $[(PaPy_3)Ru(NO)](BF_4)_2$. We believe that other photoactive ruthenium nitrosyls could be similarly modified to improve (a) their photoefficiencies and (b) their potential as NO donors in PDT.

We are currently interested in studying the reaction of $\{MNO\}^7$ complexes with dioxygen in aqueous medium, a study with both fundamental and bioinorganic relevance. Recent reports [11,15] suggest that the rate constant of this process (k_{ox}) might be significantly influenced by the redox potential of the $E_{MNO^+/MNO}$ couple, leading to a linear free-energy relation (LFER) between ln k_{ox} and $E_{NO^+/NO}$ with a negative slope value close to the one predicted by the Marcus model. This result has been rationalized in terms of an associative mechanism that involves the formation of a covalent bond between molecular oxygen and the $\{MNO\}^7$ moiety [15]. Complementary, this same study suggests that six-coordination is crucial to achieve fast oxidation of bound $NO^{\cdot}$ and NO^- complexes, but certainly a more systematic investigation of the autoxidation reaction of hexacoordinated $\{MNO\}^6$ species appears as necessary.

In spite of the large amount of well-described species of this kind, it is not an easy task to find literature examples of water-soluble nitrosyl species with robust coordination spheres that remain unaffected upon redox changes [16]. Examples with the appropriate redox potential to explore their reactions with dioxygen are even scarcer. We explore here one possible alternative to obtain such a species, namely the use of pendant-arm derivatized *N*-macrocyclic ligands. We report the preparation, isolation and characterization of the $\{RuNO\}^6$ species *cis*-$[Ru(L^{py})NO](PF_6)_3$ (**I**) (L^{py} = *N*-(2-methylpyridyl) 1,4,8,11-tetraazacyclotetradecane), focusing on its electronic structure an the possibility of redox interconversion to the one-electron reduced $\{RuNO\}^7$ species.
