3.1. Synthesis and X-ray structure of $[Cu_8(S_2PPh_2)_6][PF_6]_2 \cdot 5CH_2Cl_2$ (1)

In accordance with our recent studies on reactions of elemental chalcogens with phosphines [15–17], reaction of Ph_2PH with 2/8 S_8 in the presence of NEt_3 gave the dithiophosphinate salt $[Ph_2PS_2][HNEt_3]$ in quantitative yields ($^{31}P\{^1H\}$ NMR, d_6-DMSO: $\delta = 60.9$ ppm). Reaction of $[Ph_2PS_2][HNEt_3]$ with $[Cu^I(CH_3CN)_4][PF_6]$ in situ, followed by thorough washing with deoxygenated water to remove the $[PF_6][HNEt_3]$ by-product, and recrystallization from CH_2Cl_2/hexane yielded crystals of the 'empty' cubic cluster $[Cu_8(S_2PPh_2)_6][PF_6]_2 \cdot 5CH_2Cl_2$ (**1**).

Single-crystal X-ray diffraction studies on **1** reveal the octanuclear dication (Fig. 1) to sit on an inversion center and exhibit no significant interactions with either $[PF_6]^-$ or CH_2Cl_2 molecules within the lattice. Each of the faces of the Cu_8 cube in **1** is capped by a μ_4-dithiophosphinate ligand, with Cu–S distances in the range 2.228(2)–2.245(2) Å. The Cu···Cu distances along the edges of the cube are in the range 3.1275(16)–3.2861(14) Å and Cu···Cu···Cu angles lie between 87.82(4)° and 92.97(4)°. Selected unique bond lengths and angles for **1** are given in Table 2.

3.2. Synthesis and X-ray structure of $[Cu_8(\mu_8\text{-}Cl)(S_2PPh_2)_6][PF_6] \cdot 6CH_2Cl_2$ (2)

The analogous mono-cationic chloride centered cluster, $[Cu_8(\mu_8\text{-}Cl)(S_2PPh_2)_6][PF_6] \cdot 6CH_2Cl_2$ (**2**), was also prepared from the reaction of $[Ph_2PS_2][HNEt_3]$ with $[Cu^I(CH_3CN)_4][PF_6]$, but in this case the H_2O-washed product was refluxed in CH_2Cl_2 for 30 min to give a clear solution from which colorless crystals of **2** were grown. These crystals slowly turned blue when exposed to atmospheric oxygen over a period of weeks, presumably due

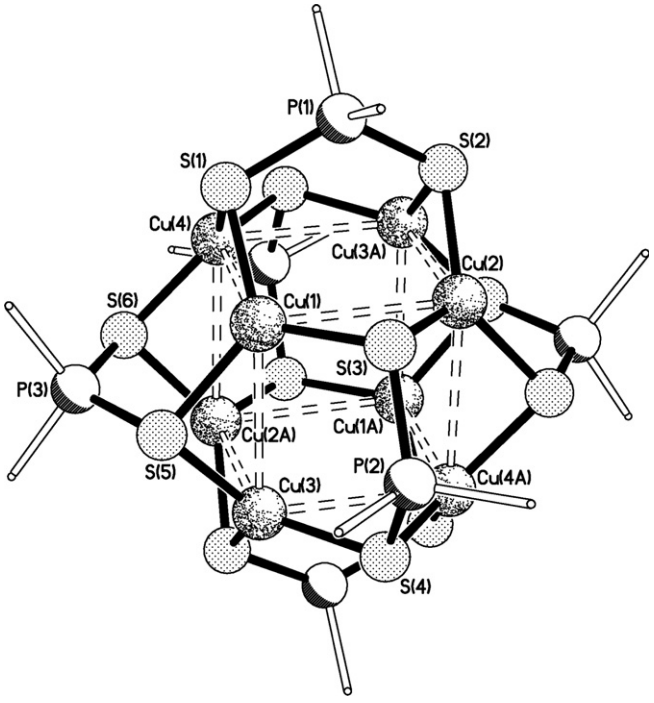

Fig. 1. Molecular structure of the the C_i-symmetric copper(I) cluster dication present in the crystals of **1**. Only the α-carbons of the phenyl rings are shown for clarity.

to oxidation of one or more of the Cu^{I} centers to Cu^{II}. The source of the chloride anion in **2** is thought to be the dichloromethane solvent: similar chloride abstraction from CH_2Cl_2 has been reported for copper(I) alkoxides [18] and dithiophosphates [19], and CH_2 abstraction from CH_2Cl_2 by copper(I) chalcogenophosphinites is also known [20].

The single-crystal X-ray structure of **2** (Fig. 2) shows the cubic cluster to have $\bar{3}$ symmetry, so only one sixth of the cluster is crystallographically unique. As with **1** no significant intermolecular interactions were observed between the copper cluster and the $[PF_6]^-$ or CH_2Cl_2 molecules. Discounting the central anion, the cubic cluster in **2** is topologically equivalent to that in **1** with Cu–S bonds in the range 2.2800(8)–2.2980(10) Å, Cu···Cu distances in the range 3.0770(7)–3.0802(7) Å and Cu···Cu···Cu angles between 89.66(2)° and 90.279(14)°.

The chloride anion resides almost exactly in the middle of the Cu_8 cube, formally coordinating to all eight metal centers with Cu–Cl distances of 2.6804(9) and 2.6613(5) Å. The Cu–Cl–Cu angles lie in the range 70.44(11)–70.63(11)° which is comparable to the value expected (70.53°) for a perfectly centered cube or the anion site in an anti-fluorite lattice. Selected unique bond lengths and angles for **2** are given in Table 2.

Although this is the first example of a halide-centered copper(I) dithiophosphinate cluster, the related copper(I) dithiophosphate clusters $[Cu_8(\mu_8\text{-}Cl)\{S_2P(OR)_2\}_6][PF_6]$ (R = Me [4], *i*Pr [21]) are known, having been prepared using either $[Bu_4N]Cl$ or $[BzEt_3N]Cl$, respectively, as the chloride anion source. The Cu···Cu distances in these dithiophosphate clusters (mean 3.097 and 3.113 Å, respectively) are comparable to those observed in **2**.

3.3. Comparison of the solid-structures $[Cu_8(\mu_8\text{-}X)(S_2PPh)_6]^{z+}$ (X, z = nothing, 2; Cl, 1; S, 0)

Attempts to prepare the neutral sulfide centered cube $[Cu_8(\mu_8\text{-}S)(S_2PPh_2)_6]$ (**3**) from the reaction of $[Ph_2PS_2][HNEt_3]$ with $[Cu^{I}(CH_3CN)_4][PF_6]$ in the presence of S_8 or Na_2S proved unsuccessful. However, **3** has previously been reported from the reaction of $Ph_2P(S)(SSiMe_3)_2$ with CuO*t*Bu [5]. The key bond lengths for clusters **1**–**3**, as determined from the X-ray diffraction data, is given in Table 3.

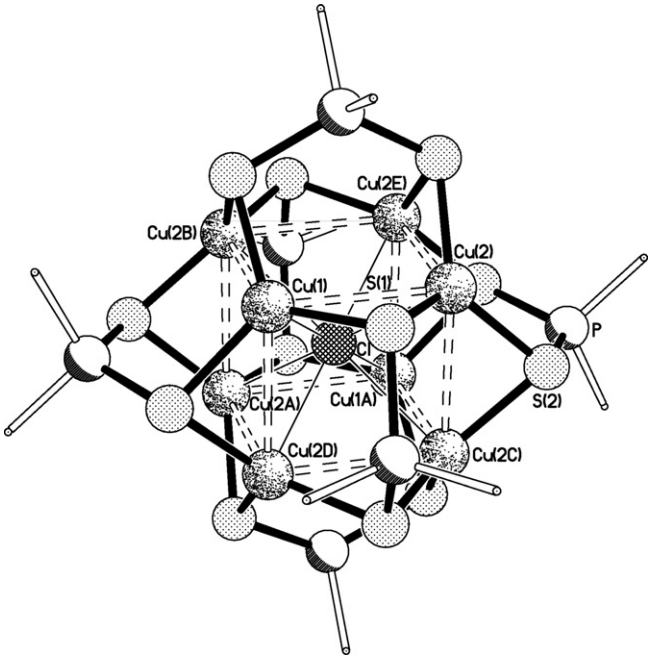

Fig. 2. The molecular structure of the $\bar{3}$-symmetric copper(I) cluster dication present in the crystals of **2** showing the encapsulation of the chloride anion. Only the α-carbons of the phenyl rings are shown for clarity.

The Cu···Cu distances within these clusters increase significantly on going from the sulfide-centered to the chloride-centered to the empty cube. This is also accompanied by a slight decrease in the Cu–S(ligand) distances. Although the large increase in the Cu_8^{I} cube

Table 3
Selected average (mean) bond lengths for the cubic clusters **1**–**3** $[Cu_8(\mu_8\text{-}X)(S_2PPh)_6]^{z+}$

	X	z	Mean bond distance (Å)			Ref.
			Cu···Cu	Cu–S	Cu–X	
1		2	3.197	2.237		
2	Cl	1	3.079	2.289	2.671	
3	S	0	2.824	2.310	2.419	[5]

dimensions for the empty cluster is perhaps at first glance surprising, given that there are no additional steric requirements to fit an anion inside the cube, it can be rationalized by study of the bonding model [22–24]. Each of the copper(I) atoms within the cubic cluster is coordinated in a trigonal planar geometry by three ligand sulfur atoms to give a 16-electron metal center and an overall metal valence electron (MVE) count of 128. This leaves one orbital on each copper not involved in cluster formation – a diffuse $4p_z$ atomic orbital which points towards the center of the cube. Linear combinations of these eight p_z atomic orbitals give a set of $a_{1g} + t_{1u} + t_{2g} + a_{2u}$ orbitals. In the case of the vacant dicationic cube **1** it is expected that these orbitals are empty and lie above the effectively non-bonding Cu···Cu d-orbital overlaps [24].

In the anion centered cubes, the a_{1g} and t_{1u} $Cu(p_z)$ orbital sets overlap with the $3s(a_g)$ and $3p(t_u)$ atomic orbitals of the chloride or sulfide anion to give a 136 MVE cluster with a theoretical $Cu–Cl^-/S^{2-}$ bond order of 0.5 [22,24]. Moreover, the ionic interaction between the negative encapsulated anion and the positive copper cations plays a major role in the overall bonding, and it is this strong ionic interaction that can be used to explain the observed contraction in Cu_8 cube size when the central anion is introduced (**1**–**2**) or when its negative charge is increased (**2**–**3**). It is also likely that the encapsulated anion is responsible for the lengthening of the Cu–S(ligand) distance as a result of its repulsive interaction with the negatively charged dithiophosphinate ligands [24].

3.4. DFT calculations

Theoretical calculations have been carried out by us on the model system $[Cu_8(S_2PMe)_6]^{2+}$ at the B3LYP level of density functional theory to further evaluate the cluster bonding model described above. These calculations reveal the LUMO to contain a strong contribution from the a_{1g} set of $Cu(4p_z)$ orbitals as expected (see Fig. 3). In addition, a small amount of second order mixing between the a_{1g} set and the $Cu(3d_{z^2})$ orbitals is present, which is anticipated to lead to weak net Cu···Cu bonding interactions [24]. This is further backed-up by calculation of the Wiberg bond indexes, which show a small but positive value of 0.027 for the Cu···Cu interaction. However, these Cu···Cu interactions appear too weak to have any significant stabilizing effect on the complex, instead the stability of the dicationic metal cube in the absence of a central 'templating' anion must be attributed almost exclusively to the strength of the metal to dithiophosphinate ligand covalent and ionic interactions.

A comparison of the bonding within dithiophosphinate and dithiophosphate Cu_8 clusters was also undertaken using the optimized model clusters $[Cu_8(\mu_8\text{-}X)(S_2PR_2)_6]^{z+}$ [R = Me, OMe; X(z) = nothing(2), Cl(1), S(0)] – see Table 4. These calculations accurately predict the contraction of Cu···Cu distance and increase in Cu···S(ligand) distance across the series, although all bond lengths are overestimated by approximately 3% when compared to the low-temperature solid-state structural data for the diphenyldithiophosphinate complexes **1**–**3**. Bonding energies were calculated as the difference between the energy of the optimized filled cluster and the sum of the energies of

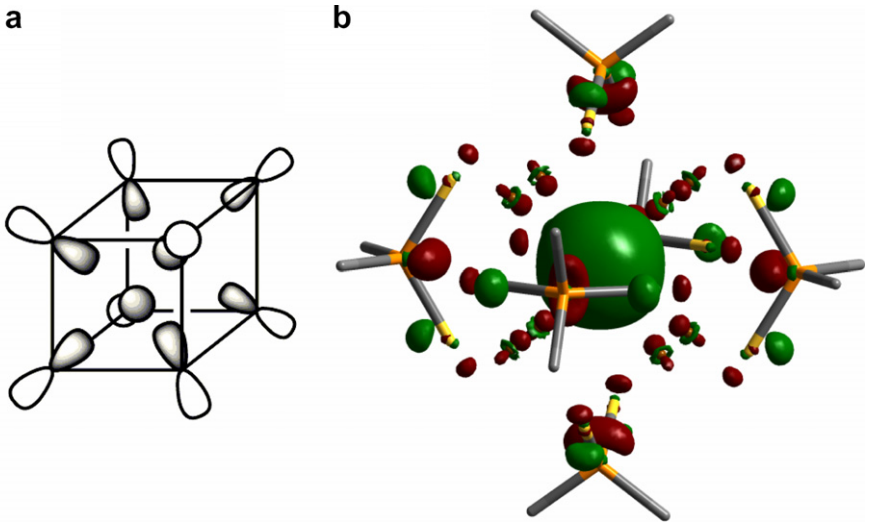

Fig. 3. (a) Schematic diagram of the a_{1g} set of metal orbitals derived from the linear combination of eight $Cu(p_z)$ AOs; (b) calculated surface diagram for the LUMO of $[Cu_8(S_2PMe)_6]^{2+}$.

[a] Bonding energy between $X^{-/2-}$ anion and the $[Cu_8(S_2PR_2)]^{2+}$ empty cage.

Cl^-/S^{2-} and the optimized empty cluster. For all the computed complexes this bonding energy is highly negative, indicating a strong thermodynamic preference for anion encapsulation.

As expected these calculations show dithiophosphinate to be more electron rich than dithiophosphate, with a commensurate increased negative natural charge on the ligand sulfur atoms. Although this gives rise to a somewhat larger positive natural charge on the copper centers, overall there is very little difference between the computed bond lengths or bonding energies of the two cluster types. This suggests that empty dicationic clusters with dithiophosphate ligands should also be accessible. The poor solubility of **1** in most solvents is a potential hindrance to its future applications, and hence attempts to prepare the analogous dithiophosphate Cu^I cluster (with a predicted increased solubility) are currently underway. We are particularly interested in the use of these 'empty' Cu^I_8 clusters as coupling catalysts in organic synthesis, where their dipositive charge, and hence increased electrophilicity, could be expected to yield improvements in reactivity over the previously studied mono-cationic halide-centered Cu^I clusters [4].

4. Conclusions

In summary, we have prepared and crystallographically characterized the first example of an 'empty' Cu^I_8 cationic cage with dithio-phosphorus ligands, hence showing that anion templates are not required for the formation of these species. Theoretical calculations show that the stability of this cluster can be attributed to the strong metal–ligand interactions, with no significant contribution from any Cu···Cu bonding interactions. Comparison of the solid-state structures of the empty Cu^I_8 cluster (**1**) with the analogous chloride and sulfide centered clusters (**2** and **3**, respectively) reveals a considerable contraction of the octanuclear cube both on anion encapsulation and when going from a mono- to di-anion. DFT calculations show that this contraction is predominately due to the ionic interactions between the Cu^I cations and the encapsulated anion. Further DFT calculations indicate that similar dicationic empty Cu^I_8 clusters with dithiophosphate ligands should also be accessible, and attempts to prepare these are underway.

the Opus V3.3X program package. Melting points were determined on a Meltemp apparatus and were uncorrected. Flash column chromatography was performed on Silica Gel (Merck, 230–400 Mesh ASTM). TLC was done using pre-coated plates with a fluorescent indicator (Merck 5735). The stain solutions of permanganate, *p*-anisaldehyde and iodine were used for visualization of the TLC spots.

Thiophene-2-carboxaldehyde oxime, furan-2-carbaldehydeoxime, thiophene-2-hydroximoyl chloride, 5-chloro-thiophene-2-hydroximoyl chloride, 5-chloro-furan-2-hydroximoyl chloride, *N*-(*p*-methoxyphenyl)thiophene-2-carboxamidoxime and *N*-*p*-tolylthiophene-2-carboxamidoxime were prepared by utilizing literature procedures described previously [12–17].

2.2. Synthesis of N-substituted amidoximes

2.2.1. N-Phenyl-5-chloro-thiophene-2-carboxamidoxime (**3a**)

To a solution of 5-chloro-thiophene-2-hydroximoyl chloride (**2a**) (0.98 g, 6.06 mmol) in chloroform (20 mL) was added dropwise aniline (1.13 g, 12.1 mmol) in chloroform with constant stirring at room temperature. The reaction mixture was stirred for 2 d. The precipitate was filtered and the solution was evaporated under reduced pressure. The residual solid was subjected to flash column chromatography (eluant: hexane:ethyl acetate; 1:3) to give *N*-phenyl-5-chloro-thiophene-2-carboxamidoxime (**3a**), 0.78 g, yield: 65%. M.p. 131–133 °C. R_f: 0.42 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3368 (N–H), 3204–3099 (broad, NOH), 1630 (C=N). ^1H NMR (400 MHz, $CDCl_3$ + DMSO-d_6): δ 9.98 (broad s, 1H), 7.20 (broad s, 1H), 6.95 (t, 1H), 6.82 (d, $J = 7.4$ Hz, 2H), 6.65 (d, $J = 3.9$ Hz, 1H), 6.61 (d, $J = 3.9$ Hz, 1H). ^{13}C NMR (100 MHz, $CDCl_3$ + DMSO-d_6): δ 145.13, 140.00, 132.62, 130.00, 128.40, 127.06, 125.93, 122.46, 121.20, 119.92. MS (*m*/*z*,%): 252 (M^+,32), 235 (76), 220 (16), 200 (12), 143 (23), 93 (100), 77 (31), 65 (22), 51 (14).

2.2.2. N-(4-Methylphenyl)-5-chloro-thiophene-2-carboxamidoxime (**3c**)

Colourless needles (hexane–ethyl acetate). Yield: 50%. M.p. 132–134 °C. R_f: 0.54 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3363 (N–H), 3213–3171 (broad, NOH), 1627 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.41 (s, 1H, NOH), 7.29 (s, 1H, NH), 6.98 (d, $J = 7.9$ Hz, 2H), 6.78 (d, $J = 7.6$ Hz, 2H), 6.70 (m, 1H), 6.60 (m, 1H), 2.23 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 146.05, 137.66, 132.98, 130.34, 129.42, 127.46, 126.25, 122.35, 20.83. MS (*m*/*z*,%): M–H_2O, 248 (100), 213 (47), 77 (11).

2.2.3. N-(4-Methoxyphenyl)-5-chloro-thiophene-2-carboxamidoxime (**3e**)

White plates (hexane–ethyl acetate). Yield: 65%. M.p. 140–142 °C. R_f: 0.45 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3344 (N–H), 3234–3111 (broad, NOH), 1631 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.32 (s, 1H, NOH), 7.23 (s, 1H, NH), 6.86 (m, 2H), 6.76 (m, 2H), 6.67 (m, 1H), 6.52 (m, 1H), 3.76 (s, 3H, OCH_3). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 156.37, 146.66, 133.12, 132.87, 130.42, 127.52, 126.21, 124.98, 114.13, 55.49. MS (*m*/*z*,%): M–H_2O, 264 (100), 249 (88), 221 (21).

2.2.4. N-(4-Chlorophenyl)-5-chloro-thiophene-2-carboxamidoxime (**3f**)

Light yellow needles (hexane–ethyl acetate). Yield: 73%. M.p. 97–99 °C. R_f: 0.50 (hexane:ethyl acetate; 3:2). IR (KBr, *v*: cm^{-1}): 3382 (N–H), 3215 (broad, NOH), 1626 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.64 (s, 1H, NOH), 7.66 (s, 1H, NH), 7.14 (d, $J = 9.2$ Hz, 2H), 7.03 (d, $J = 9.2$ Hz, 2H), 6.79 (d, $J = 6.7$ Hz, 1H), 6.73 (d, $J = 4.9$ Hz, 1H), 6.66 (d, $J = 4.1$ Hz, 1H), 6.59 (d, $J = 9.1$ Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 145.80, 145.15, 139.26, 132.74, 130.76, 128.99, 128.78, 127.67, 127.49, 126.41, 122.61, 116.20. MS (*m*/*z*,%): M–H_2O, 268 (100), 233 (40), 198 (5).

2.2.5. N-(4-Bromophenyl)-5-chloro-thiophene-2-carboxamidoxime (**3g**)

Yield: 84%. M.p. 143–145 °C. R_f: 0.61 (hexane:ethyl acetate; 3:2). IR (KBr, *v*: cm^{-1}): 3387 (N–H), 3235 (broad, NOH), 1630 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.60 (s, 1H, NOH), 7.54 (d, $J = 7.0$ Hz, 1H, NH), 7.27 (m, 2H), 6.72 (m, 3H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 145.46, 139.57, 132.35, 131.90, 131.20, 127.74, 126.50, 123.20, 115.73.MS (*m*/*z*,%): M–H_2O, 314 (100), 279 (47), 198 (12).

2.2.6. N-(4-Iodophenyl)-5-chloro-thiophene-2-carboxamidoxime (**3h**)

Yield: 50%. M.p. 141–144 °C. R_f: 0.50 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3394 (N–H), 3217 (broad, NOH), 1636 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.63 (s, 1H, NOH), 7.56 (s, 1H, NH), 7.44 (m, 2H), 6.78–6.61 (m, 4H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 144.84, 140.48, 137.58, 132.74, 130.76, 127.46, 126.43, 123.06, 122.02, 85.40. MS (*m*/*z*,%): M–H_2O, 362 (100), 346 (14), 219 (35), 144 (16).

2.2.7. N-(1-Naphthyl)-5-chloro-thiophene-2-carboxamidoxime (**3i**)

Yield: 65%. M.p. 168–170 °C. R_f: 0.44 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3381 (N–H), 3224–3103 (broad, NOH), 1632 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.61 (s, 1H, NOH), 8.20 (m, 1H), 7.85 (m, 1H), 7.62–7.26 (m, 5H), 6.95 (d, $J = 7.3$ Hz, 1H), 6.60 (d, $J = 1.1$ Hz, 1H), 6.45 (d, $J = 1.1$ Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 146.98, 136.14, 134.22, 133.05, 130.18, 128.94, 128.34, 126.91, 126.39, 126.33, 126.17, 125.47, 124.71, 122.25, 121.06. MS (*m*/*z*,%): M–H_2O, 284 (100), 249 (18), 140 (6).

*2.2.8. N-Phenyl-5-chloro-furan-2-carboxamidoxime (**3j**)*

Yield: 20%. M.p. 147–149 °C. R_f: 0.29 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3384 (N–H), 3119–2945 (broad NOH), 1627 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.52 (s, 1H, NOH), 7.47 (s, 1H, NH), 7.18 (m, 2H), 6.97 (m, 1H), 6.75 (d, $J = 8.2$, 6.48 Hz, 1H), 6.21 (m, 1H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 145.24, 142.39, 140.24, 136.95, 128.85, 122.58, 120.28, 113.44, 107.91. MS (*m*/*z*,%): M–H_2O, 218 (100), 190 (53), 155 (68).

*2.2.9. N-(4-Methylphenyl)-5-chloro-furan-2-carboxamidoxime (**3k**)*

Yield: 40%. M.p. 157–159 °C. R_f: 0.23 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3384 (N–H), 3089–2970 (broad, NOH), 1624 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.31 (s, 1H, NOH), 7.18 (s, 1H, NH), 6.97 (d, $J = 7.9$ Hz, 2H), 6.66 (d, $J = 8.4$ Hz, 2H), 6.40 (d, $J = 1.4$ Hz, 1H), 6.16 (d, $J = 1.6$ Hz, 1H), 2.26 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 145.23, 142.81, 137.59, 136.82, 132.29, 129.39, 120.89, 113.47, 107.82, 20.75. MS (*m*/*z*,%): M–H_2O, 232 (100), 204 (51), 169 (56).

*2.2.10. N-(4-Methoxyphenyl)-5-chloro-furan-2-carboxamidoxime (**3l**)*

Yield: 22%. M.p. 141–143 °C. R_f: 0.32 (hexane:ethyl acetate; 3:2). IR (KBr, *v*: cm^{-1}): 3363 (N–H), 3191–3155 (broad, NOH), 1641 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.34 (s, 1H, NOH), 7.28 (s, 1H, NH), 6.75 (dd, $J = 9.3$ 6.7 Hz, 4H), 6.25 (d, $J = 3.5$ Hz, 1H), 6.16 (d, $J = 3.2$ Hz, 1H), 3.80 (s, 3H, OCH_3). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 155.97, 145.14, 143.39, 136.72, 133.19, 123.56, 114.04, 113.55, 107.74, 55.42. MS (*m*/*z*,%): M–H_2O, 248 (100), 233 (54), 220 (14), 205 (28).

*2.2.11. N-(4-Chlorophenyl)-5-chloro-furan-2-carboxamidoxime (**3m**)*

Yield: 30%. M.p. 142–144 °C. R_f: 0.29 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3382 (N–H), 3127–3094 (broad, NOH), 1622 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.60 (s, br, 1H, NOH), 7.63 (s, 1H, NH), 7.14 (d, $J = 8.7$ Hz, 2H), 6.65 (d, $J = 8.7$ Hz, 2H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 145.00, 141.81, 139.15, 137.11, 128.67, 127.10, 121.26, 113.59, 108.00. MS (*m*/*z*,%): M–H_2O, 254 (100), 183 (22), 155 (31), 127 (75).

*2.2.12. N-(4-Bromophenyl)-5-chloro-furan-2-carboxamidoxime (**3n**)*

Yield: 44%. M.p. 163–164 °C. R_f: 0.66 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3382 (N–H), 3087–2970 (broad, NOH), 1625 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.57 (s, 1H, NOH), 8.20 (s, 1H, NH), 7.20 (d, $J = 6.4$ Hz, 2H), 6.60 (d, $J = 7.3$ Hz, 2H), 6.55 (dd, $J = 3.5$ 1.1 Hz, 1H), 6.30 (dd, $J = 3.2$, 1.1 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 145.10, 141.59, 139.73, 137.06, 131.55, 121.44, 120.21, 114.45, 113.48, 108.00. MS (*m*/*z*,%): M–H_2O, 298 (100), 270 (35), 233 (27), 189 (22).

*2.2.13. N-(4-Iodophenyl)-5-chloro-furan-2-carboxamidoxime (**3o**)*

Yield: 26%. M.p. 165–167 °C. R_f: 0.58 (hexane:ethyl acetate; 3:1). IR (KBr, *v*: cm^{-1}): 3385 (N–H), 3082–2962 (broad, NOH), 1627 (C=N). ^1H NMR (400 MHz, $CDCl_3$ + DMSO-d_6): δ 9.50 (broad s, 1H), 7.48 (d, $J = 8.5$ Hz, 2H), 7.36 (broad s, 1H), 6.50 (d, $J = 8.5$ Hz, 2H), 6.46 (d, $J = 3.3$ Hz, 1H), 6.13 (d, $J = 3.3$ Hz, 1H). ^{13}C NMR (100 MHz, $CDCl_3$ + DMSO-d_6): δ 144.58, 141.56, 140.01, 137.39, 137.17, 121.79, 120.52, 113.61, 107.88, 84.96. MS (*m*/*z*,%): M–H_2O (100), 316 (22), 281 (12), 217 (9), 189 (32), 172 (12), 154 (14), 127 (12).

*2.2.14. N-(1-Naphthyl)-5-chloro-furan-2-carboxamidoxime (**3p**)*

Yield: 30%. M.p. 128–129 °C. R_f: 0.49 (hexane:ethyl acetate; 3:2). IR (KBr, *v*: cm^{-1}): 3365 (N–H), 3143 (broad, NOH), 1636 (C=N). ^1H NMR (300 MHz, $CDCl_3$ + DMSO-d_6): δ 10.56 (s, 1H, NOH), 8.16 (d, $J = 6.7$ Hz, 1H), 7.85 (d, $J = 7.6$ Hz, 1H), 7.60 (d, $J = 8.2$ Hz, 1H), 7.55–7.50 (m, 1H), 7.42 (s, 1H, NH), 7.28 (t, 1H), 6.87 (d, $J = 7.3$ Hz, 1H), 6.21 (d, $J = 3.5$ Hz, 1H), 6.05 (d, $J = 3.5$ Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6):δ 145.10, 141.59, 139.73, 137.06, 131.55, 121.44, 120.21, 114.45, 113.48, 108.00. MS (*m*/*z*,%): M–H_2O, 268 (100), 240 (42), 205 (54), 152 (17).

2.3. Synthesis of oxadiazaboroles

*2.3.1. 4,5-Diphenyl-3-(5-chloro-2-thienyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5a**)*

A mixture of *N*-phenyl-(5-chloro-thiophene)-2-carboxamidoxime (**3a**) (150 mg, 0.68 mmol) and phenylboronic acid (**4**) (92 mg, 0.76 mmol) in toluene (10 mL) was refluxed under an inert atmosphere in the presence of molecular sieves (4 Å) overnight. After extracted with acetone and filtering, the solvent was evaporated under reduced pressure. The crude product was crystallized from hexane–ethylacetate mixture to give **5a** as colorless needles, 140 mg, Yield: 67%. M.p. 164–166 °C. R_f: 0.41 (hexane:ethyl acetate; 3:2). IR (KBr, ν_{max}: cm^{-1}): 1601 (C=N), 1452 (B–N), 1372 (B–O), 1109, 767, 701. ^1H NMR ($CDCl_3$, 300 MHz): δ 7.53–7.49 (m, 5H), 7.40–7.38 (m, 2H), 7.34–7.24 (m, 4H), 6.70 (dd, $J = 4.10$ Hz, 2.05 Hz, 1H), 6.53 (dd, $J = 4.10$ Hz, 2.05 Hz, 1H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 155.51, 136.92, 134.36, 134.01, 131.44, 130.30, 129.64, 129.05, 128.68, 128.29, 126.68, 125.49. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.3. MS (*m*/*z*,%): 338 (M^+,100), 234 (15), 179 (20), 103 (11), 91 (7), 77 (15), 51 (6); HRMS calcd for $C_{17}H_{12}BN_2OSCl$: 338.0452; found: 338.0460.

*2.3.2. 5-Phenyl-3-(2-thienyl)-4-(4-methylphenyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5b**)*

Yield: 45%. M.p. 222–224 °C (hexane:ethyl acetate). R_f: 0.54 (hexane:ethyl acetate; 3:2). IR (KBr, ν_{max}: cm^{-1}): 1604, 1566, 1514 (C=N), 1444 (B–N), 1369 (B–O), 1121, 1024, 822, 724. ^1H NMR ($CDCl_3$, 300 MHz): δ 7.54 (d, $J = 7.91$ Hz, 2H) 7.43–7.17 (m, 8H), 6.92–6.89 (m, 1H), 6.82 (d, $J = 3.51$ Hz, 1H), 2.46 (s, 3H). ^{13}C NMR (100 MHz, $CDCl_3$): δ 156.31, 138.79, 134.36, 134.16, 131.02, 130.40, 129.36, 128.64, 128.23, 127.99, 127.20, 126.73, 21.33. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$):δ 32.4. MS (*m*/*z*,%): 318 (M^+,100), 214 (15), 193 (23), 116 (7), 105 (8), 91 (5), 77 (8); HRMS calcd for $C_{18}H_{15}BN_2OS$: 318.0998; found: 318.1002.

*2.3.3. 4-(4-Methylphenyl)-5-phenyl-3-(5-chloro-2-thienyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5c**)*

Yield: 65%. M.p. 210–212 °C (hexane). R_f: 0.38 (hexane:ethyl acetate; 2:1). IR (KBr, *v*: cm^{-1}): 1600, 1572, 1514 (C=N), 1452 (B–N), 1369 (B–O), 1111, 823, 698. ^1H NMR (300 MHz, $CDCl_3$): δ 7.98–6.55 (m, 11H), 2.20 (s, 3H). ^{13}C NMR ($CDCl_3$, 75 MHz): δ 155.18, 139.08, 134.18, 133.93, 133.71, 133.20, 131.12, 130.64, 129.25, 128.83, 128.01, 127.95, 127.39, 126.59, 125.24, 122.04, 21.27. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.2 MS (*m*/*z*,%): 352 (M^+,100), 248 (11), 193 (25), 116 (11), 105 (8), 77 (11). HRMS calcd for $C_{18}H_{14}BN_2OSCl$: 352.0608; found: 352.0626.

*2.3.4. 4-(4-Methoxyphenyl)-5-phenyl-3-(2-thienyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5d**)*

Yield: 70%. M.p. 161–163 °C (hexane–ethylacetate). R_f: 0.15 (hexane:ethyl acetate; 3:2). IR (KBr, ν_{max}: cm^{-1}): 1610, 1570, 1515 (C=N), 1444 (B–N), 1370 (B–O), 1256, 1030, 841, 705. ^1H NMR (300 MHz, $CDCl_3$): δ 7.55 (d, $J = 7.32$ Hz, 4H), 7.40–7.21 (m, 4H), 7.00–6.86 (m, 4H), 3.89 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$): δ 159.86, 156.70, 134.38, 131.30, 129.79, 129.59, 128.96, 128.26, 127.49, 126.92, 115.15, 55.79. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.2. MS (*m*/*z*,%): 334 (M^+,100), 230 (6), 216 (25), 209 (30), 194 (12), 121 (15), 77 (9). HRMS calcd for $C_{18}H_{15}BN_2O_2S$: 334.0947; found: 334.0978.

*2.3.5. 4-(4-Methoxyphenyl)-5-phenyl-3-(5-chloro-2-thienyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5e**)*

M.p. 169–170 °C (66%) (hexane–ethylacetate). R_f: 0.29 (hexane:ethyl acetate; 2:1). IR (KBr, *v*: cm^{-1}): 1610, 1514 (C=N), 1454 (B–N), 1369 (B–O), 1255, 839, 700. ^1H NMR (300 MHz, $CDCl_3$): δ 7.54–6.60 (m, 11H), 3.84 (s, 3H, OCH_3). ^{13}C NMR (75 MHz, $CDCl_3$): δ 159.82, 155.44, 134.22, 133.99, 134.40, 131.17, 129.38, 128.92, 128.84, 128.07, 127.44, 126.60, 125.28, 115.12, 55.56. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.2. MS (*m*/*z*,%): 368 (M^+,100), 264 (6), 249 (16), 209 (34), 194 (16), 121 (16), 77 (12). HRMS calcd for $C_{18}H_{14}BN_2O_2SCl$: 368.0558; found: 368.0575.

*2.3.6. 4-(4-Chlorophenyl)-5-phenyl-3-(5-chloro-2-thienyl)-4,5-dihydro-1,2,4,5- oxadiazaborole (**5f**)*

M.p. 158–160 °C (hexane) (75%). R_f: 0.50 (hexane:ethyl acetate; 3:2). IR (KBr, ν_{max}: cm^{-1}): 1600, 1571, 1525 (C=N), 1493, 1449 (B–N), 1370 (B–O), 1093, 829, 701. ^1H NMR (300 MHz, $CDCl_3$): δ 7.49–7.40 (m, 6H), 7.31–7.25 (m, 4H), 6.66 (dd, $J = 5.0$, 1.76 Hz, 1H), 6.58 (dd, $J = 3.9$, 1.46 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$): δ 155.23, 135.51, 135.23, 134.31, 131.61, 130.54, 129.96, 129.19, 128.40, 126.81, 125.08. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.2. MS (*m*/*z*,%): 372 (M^+,100), 268 (14), 233 (9), 213 (26), 137 (15), 125 (11), 96 (12), 77 (14), 51 (5). HRMS calcd for $C_{17}H_{11}BN_2OSCl_2$: 372.0062; found: 372.0056.

*2.3.7. 4-(4-Bromophenyl)-5-phenyl-3-(5-chloro-2-thienyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5g**)*

Yield: 75%. M.p. 177–179 °C (hexane–ethyl acetate). R_f: 0.61 (hexane:ethyl acetate; 3:2). IR (KBr, ν_{max}: cm^{-1}): 1602, 1568, 1510 (C=N), 1488, 1455 (B–N), 1366 (B–O), 1105, 1073, 941, 835, 695. ^1H NMR ($CDCl_3$, 300 MHz): δ 7.65 (d, $J = 0.88$ Hz, 1H), 7.63 (m, 1H), 7.49–7.26 (m, 6H), 7.22 (d, $J = 0.88$ Hz, 1H), 7.20 (m, 1H), 6.74 (dd, $J = 2.34$, 1.17 Hz, 1H), 6.56 (dd, $J = 2.34$, 1.17 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$): δ 155.15, 136.04, 134.32, 133.53, 131.62, 130.28, 129.21, 128.41, 126.84, 125.07, 123.23. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.3. MS (*m*/*z*,%): 418 (M^+,100), 314 (12), 257 (14), 181 (8), 169 (8), 143 (12), 102 (18), 90 (12), 77 (15), 63 (8), 51 (8). HRMS calcd for $C_{17}H_{11}BN_2OSBrCl$: 415.9557; found: 415.9567.

*2.3.8. 4-(4-Iodophenyl)-5-phenyl-3-(5-chloro-2-thienyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5h**)*

Yield: 52%. M.p. 184–186 °C (hexane–ethyl acetate). R_f: 0.50 (hexane:ethyl acetate; 3:2). IR (KBr, ν_{max}: cm^{-1}): 1603, 1597, 1508 (C=N), 1485, 1455 (B–N), 1368 (B–O), 1103, 942, 829, 695. ^1H NMR (300 MHz, $CDCl_3$): δ 7.83 (d, $J = 7.6$ Hz, 2H), 7.49–7.25 (m, 6H), 7.07 (d, $J = 7.6$ Hz, 2H), 6.74 (d, $J = 3.5$ Hz, 1H), 6.55 (d, $J = 3.4$ Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$): δ 155.10, 139.49, 136.72, 134.32, 134.27, 131.62, 130.49, 129.23, 128.41, 126.86, 125.05, 94.76. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.2. MS (*m*/*z*,%): 464 (M^+,100), 360 (12), 305 (26), 229 (7), 198 (7), 151 (9), 102 (15), 90 (17), 77 (11), 63 (7). HRMS calcd for $C_{17}H_{11}BN_2OSClI$: 463.9418; found: 463.9409.

*2.3.9. 4-(1-Naphthyl)-5-phenyl-3-(5-chloro-2-thienyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5i**)*

Yield: 46%. M.p. 132–134 °C (hexane–ethyl acetate). R_f: 0.54 (hexane:ethyl acetate; 3:2). IR (KBr, ν_{max}: cm^{-1}): 1599, 1522, 1508 (C=N), 1434 (B–N), 1369 (B–O), 1106, 800, 776, 696. ^1H NMR (300 MHz, $CDCl_3$): δ 8.06 (d, $J = 7.9$ Hz, 1H), 8.00 (d, $J = 7.9$ Hz, 1H), 7.74–7.16 (m, 11H), 6.53 (dd, $J = 1.76$, 0.88 Hz, 1H), 6.39 (dd, $J = 1.76$, 0.88 Hz, 1H). ^{13}C NMR ($CDCl_3$, 75 MHz): δ 156.11,

134.57, 134.22, 133.89, 133.13, 131.48, 131.11, 130.19, 128.90, 128.68, 128.28, 128.24, 127.46, 126.79, 126.62, 125.99, 125.23, 122.52. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.8. MS (*m*/*z*,%): 388 (M^+,100), 249 (26), 229 (69), 153 (25), 140 (18), 126 (11), 115 (12), 77(9), 51 (5). HRMS calcd for $C_{21}H_{14}BN_2OSCl$: 388.0608; found: 388.0607.

2.3.10. 3-(5-Chloro-2-furyl)-4,5-diphenyl-4,5-dihydro-1,2,4,5-oxadiazaborole (**5j**)

Yield: 50%. M.p. 114–116 °C (benzene–petroleum ether). R_f: 0.29 (hexane:ethyl acetate; 3:1). IR (KBr, ν_{max}: cm^{-1}): 1598, 1534 (C=N), 1498, 1484 (B–N), 1375 (B–O), 1138, 1024, 790, 699. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.52–7.23 (m, 11H), 6.07 (dd, $J = 2.34$, 1.17 Hz, 1H), 5.87 (dd, $J = 3.66$, 1.17, 0.88 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$): δ 152.63, 140.20, 139.68, 136.99, 134.40, 131.45, 130.15, 129.20, 128.30, 128.27, 115.70, 108.22. MS (*m*/*z*,%): 322 (M^+,100), 285 (15), 258 (31), 179 (18), 166 (35), 154 (44), 128 (15), 103 (35), 77 (34), 64 (10), 51 (13). HRMS calcd for $C_{17}H_{12}BN_2O_2Cl$: 322.0680; found: 322.0709.

2.3.11. 3-(5-Chloro-2-furyl)-5-phenyl-4-(4-methylphenlyl)-4,5-dihydro-1,2,4,5-oxadiazaborole (**5k**)

Yield: 60%. M.p. 167–168 °C (benzene–petroleum ether). R_f: 0.23 (hexane:ethyl acetate; 3:1). IR (KBr, ν_{max}: cm^{-1}): 1611, 1532, 1515 (C=N), 1485 (B–N), 1376 (B–O), 1138, 1028, 831, 794, 707. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.53 (d, $J = 7.32$ Hz, 2H), 7.41–7.26 (m, 5H), 7.19 (d, $J = 7.32$ Hz, 2H), 7.03 (d, $J = 8.50$ Hz, 1H), 6.77 (d, $J = 8.20$ Hz, 1H) 2.46 (s, 3H). ^{13}C NMR (100 MHz, $CDCl_3$): δ 152.55, 140.15, 139.42, 138.94, 134.19, 134.10, 131.15, 130.49, 129.64, 128.01, 127.79, 122.80, 115.43, 107.93, 21.29. MS (*m*/*z*,%): 336 (M^+,100), 299 (15), 271 (10), 192 (23), 180 (23), 168 (54), 142 (8), 127 (7), 116 (28), 104 (10), 90 (15), 77 (20), 65 (8), 51 (8). HRMS calcd for $C_{18}H_{14}BN_2O_2Cl$: 336.0837; found: 336.0868.

2.3.12. 3-(5-Chloro-2-furyl)-4-(4-methoxyphenyl)-5-phenyl-4,5-dihydro-1,2,4,5-oxadiazaborole (**5l**)

Yield: 65%. M.p. 145–147 °C (hexane–ethyl acetate). R_f: 0.32 (hexane:ethyl acetate; 3:1). IR (KBr, ν_{max}: cm^{-1}): 1612, 1516 (C=N), 1489 (B–N), 1375 (B–O), 1251, 1023, 841, 794, 707. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.45–6.90 (m, 10H), 6.00 (dd, $J = 3.52$, 1.76 Hz, 1H), 5.70 (dd, $J = 3.52$, 1.76 Hz, 1H) 3.81 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$): δ 159.91, 152.92, 140.36, 139.62, 134.40, 131.43, 129.49, 129.34, 128.28, 115.71, 108.26, 55.83. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.0. MS (*m*/*z*,%): 352 (M^+,100), 209 (27), 194 (16), 184 (30), 133 (21), 121 (10), 103 (11), 90 (13), 77 (15). HRMS calcd for $C_{18}H_{14}BN_2O_3Cl$: 352.0786; found: 352.0800.

2.3.13. 4-(4-Chlorophenyl)-3-(5-chloro-2-furyl)-5-phenyl-4,5-dihydro-1,2,4,5- oxadiazaborole (**5m**)

M.p. 131–133 °C (hexane–dichloroethane) (43%). R_f: 0.29 (hexane:ethyl acetate; 3:1). IR (KBr, ν_{max}: cm^{-1}): 1611, 1530 (C=N), 1496 (B–N), 1373 (B–O), 1139, 1092, 1021, 838, 789, 704. ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.49–7.26 (m, 10H), 6.12 (dd, $J = 3.33$ Hz, 1.76 Hz, 1.46,1H), 5.98 (dd, $J = 3.52$ Hz, 1.76 Hz, 1.46 Hz, 1H). ^{13}C NMR ($CDCl_3$, 75 MHz): δ 152.38, 139.88, 135.60, 135.03, 134.36, 131.63, 130.36, 129.65, 128.39, 115.91, 108.33. ^{11}B NMR (160.46 MHz, $CDCl_3$–15% $BF_3 \cdot Et_2O$): δ 32.1. 3. Results and discussion

In a recent paper [11] we described the synthesis and protonation equilibria of 4-unsubstituted 1,2,4,5-oxadiazaboroles in non-aqueous media. In the present work we report here the synthesis of some novel 3,4,5-trisubstituted 1,2,4,5-oxadiazaboroles bearing thiophene, furan and pyridine at the 3-position of the heterocyclic ring. The *N*-substituted amidoximes used as the starting compounds were obtained as described in the literature [12–24] (Scheme 1).

The new oxadiazaboroles **5a**–**v** (Scheme 2) show strong absorptions related to the B–N and B–O stretching vibrations in the 1516–1438 and 1391–1348 cm^{-1} regions in their IR spectra, which are remarkably consistent with the reported values for B–O and B–N stretching frequencies [25]. Iminic carbon chemical shifts of the title oxadiazaboroles in their ^{13}C NMR spectra appeared to resonate in the deshielded region at around 160–149 ppm. When there is a 2-pyridyl group on the number three carbon of the heterocycle, the iminic carbon chemical shifts go to more deshielded lowfield regions. In addition, the ^{11}B NMR spectra of these compounds were measured (the conditions are given in Section 2) and the boron chemical shift frequencies appear between 32.0 and 33.2 ppm, which can be considered as an indication of a trigonal planar sp^2 hybridized boron atom [26,27].

As for the electron impact mass spectra of the oxadiazaboroles; peaks related to the following fragmentations: diaziridine cation in route **a**, nitrilium cation in route **b** and borimide cation in route **c**, would occur (Scheme 3).

Except for compounds **5p** and **5r**, all of the molecular ion peaks have relative abundances of 100%, on account of the following structure which has aromatic stability (Scheme 4).

As a representative view, the X-ray crystal structure and selected atomic parameters are given for compound **5r** (Fig. 1, Tables 1 and 2).

Table 1

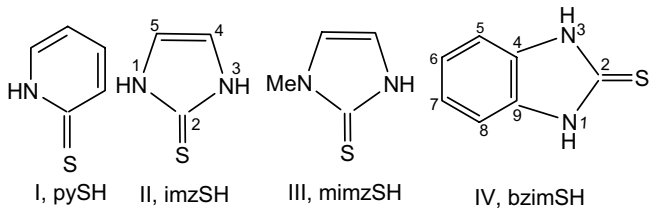

Chart 1.

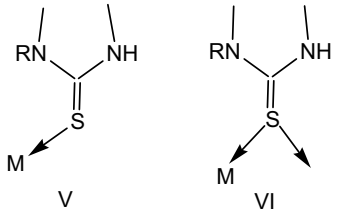

Chart 2. Models of bonding.

neutral ligands, monomers and dimers exhibited modes V (1κS) and VI (μ-1κ^{2}S) modes of bonding (Chart 2).

Recently, we have reported that reaction of 1,3-imidazolidine-2-thione (imzdSH), a saturated analogue of imzSH (II, Chart 1) with copper(I) bromide/iodide (2:1 molar ratio, L:M) has formed novel linear polymers, $\{Cu_6(\mu_3\text{-}1\kappa^3S\text{-imzdSH})_4(\mu\text{-}1\kappa^2S\text{-imzdSH})_2(\mu\text{-}I)_2I_4\}_n$, $\{Cu_6(\mu_3\text{-}1\kappa^3S\text{-imzdSH})_2(\mu\text{-}1\kappa^2S\text{-imzdSH})_4(\mu\text{-}X)_4X_2\}_n$, (X = Br, I), as well as dimers, $\{Cu_2(\mu\text{-}1\kappa^2S\text{-imzdSH})_2(\eta^1\text{-}S\text{-imzdSH})_2Br_2\}$ and $\{Cu_2(\mu\text{-}1\kappa^2S\text{-imzdSH})(1\kappa S\text{-imzdSH})_3Cl_2\}$ [7,8]. It was desired to carry out similar reactions of copper(I) halides with the unsaturated 1,3-imidazoline-2-thione (II, imzSH, Chart 1) and benzimidazoline-2-thione (IV, bzimSH) for obtaining polymeric compounds. The products of these reactions are reported herein.

2. Experimental

2.1. Materials and techniques

Copper(I) halides were prepared by reducing an aqueous solution of $CuSO_4 \cdot 5H_2O$ using SO_2 in the presence of NaX (X = Cl, Br, I) in water [22]. The reagents, 1,3-imidazoline-2-thione, benz-1,3-imidazoline-2-thione and Ph_3P, were procured from Aldrich Chemicals Ltd. and used as such. C, H and N analysis were obtained with Thermoelectron FLASHEA1112 CHNS analyzer. The IR spectra were recorded using KBr pellets in the range 4000–200 cm^{-1} on Pye-Unicam SP-3-300 spectrophotometer. The melting points were determined with a Gallenkamp electrically heated apparatus. ^{1}H NMR spectra were recorded on a JEOL AL-300 FT spectrometer operating at a frequency of 300 MHz in $CDCl_3$ with TMS as the internal reference. The ^{31}P NMR spectra were recorded on a Bruker ACP-300 spectrometer operating at a frequency of 121.5 MHz, using $CDCl_3$ with H_3PO_4 as the external reference.

2.2. Synthesis of complexes

2.2.1. $[Cu_2(1\kappa S\text{-imzSH})(PPh_3)_4Cl_2] \cdot CH_3OH$ (1)

To a solution of copper(I) chloride (0.025 g, 0.25 mmol) in acetonitrile was added a solution of 1,3-imidazoline-2-thione (0.025 g, 0.25 mmol) in acetonitrile, followed by stirring for 1 h at room temperature and to the white precipitates formed was added Ph_3P (0.132 g, 0.50 mmol) and stirred until a clear solution was obtained. The crystalline fibers formed were redissolved in MeOH and a layer of $CHCl_3$ was spread over it. The slow evaporation of solution at room temperature formed colorless crystals of **1**. The complex is soluble in chloroform, dichloromethane and acetonoirile (56%, m.p. 135–138 °C). *Anal.* Calc. for $C_{76}H_{68}Cl_2Cu_2ON_2P_4S$: C, 66.18; H, 4.93; N, 2.03. Found: C, 66.36; H, 4.90; N, 1.63%. Main IR peaks (KBr, cm^{-1}): 3363 s, ν(O–H); 3118–3092 m ν(N–H) + ν(C–H)$_{Ph}$; 2988 w, 2862 m ν(C–H); 1581 s, 1481 s ν(C–N) + δ(C–H); 1217 s ν(C–S); 1093 s ν(P–C$_{Ph}$). ^{1}H NMR data ($CDCl_3$, δ ppm): 7.23 t (C^{4,5}H, imzSH), 7.37 m (*o*-H), 7.33 m (*p*-H), 7.25–7.27 m (*m*-H) (Species **1a**), 7.67 m (*o*-H), 7.55 m (*p*-H), 7.46 m (*m*-H) (Species **1b**). ^{31}P NMR ($CDCl_3$): −3.42 (Species **1a**), 30.74 (Species **1b**) ppm. $\Delta\delta(\delta_{complex} - \delta_{PPh3}) = 1.28$ (Species **1a**); 35.44 (Species **1b**).

Compound **2** was prepared similarly. Here crystals were grown from the reaction solvents (CH_3CN–$CHCl_3$) when allowed to evaporate slowly.

2.2.2. $[CuBr(1\kappa S\text{-imzSH})(PPh_3)_2] \cdot H_2O$ (2)

Complex **2** is soluble in chloroform, dichloromethane and acetonoirile (73%, m.p. 155–157 °C). *Anal.* Calc. for $C_{39}H_{36}BrCuN_2OP_2S$: C, 59.58; H, 4.58; N, 3.56. Found: C, 60.31; H, 4.41; N, 3.12%. Main IR peaks (KBr, cm^{-1}): 3396 s, ν(O–H); 3137 w, 3138 m ν(N–H); 3001–3070 w ν(C–H)$_{Ph}$; 2983 w, 2904 w ν(C–H); 1581 s, 1477 s ν(C–N) + δ(C–H); 1216 s ν(C–S); 1083 s, ν(P–C$_{Ph}$). ^{1}H NMR data ($CDCl_3$, δ ppm): 6.74 t (C^{4,5}H), 10.9 b (NH), 7.66 m (*o*-H), 7.54 m (*p*-H), 7.47 m (*m*-H) [$CuBr(PPh_3)_2$], 7.41 m (*o*-H), 7.33 m (*p*-H), 7.27 m (*m*-H) (**2**). ^{31}P NMR ($CDCl_3$): $\delta = -4.3$, $\Delta\delta(\delta_{complex} - \delta_{PPh3})$, 0.40 (**2**) ppm. Crystals were grown from CH_3CN–$CHCl_3$ mother liquor. Compound **3** was prepared similarly.

2.2.3. $[CuI(1\kappa S\text{-imzSH})(PPh_3)_2]$ (3)

Complex **3** is soluble in chloroform, dichloromethane and chloroform (71%, m.p. 205–207 °C). *Anal.* Calc. for $C_{39}H_{34}ICuN_2P_2S$: C, 57.46; H, 4.17; N, 3.44. Found: C, 57.24; H, 4.15; N, 3.14%. Main IR peaks (KBr, cm^{-1}): 3145 w, ν(N–H); 3070 w, 3051 w ν(C–H)$_{Ph}$; 2981 w, 2958 w ν(C–H); 1577 s, 1473 s ν(C–N) + δ(C–H); 1184 s ν(C–S); 1091 s ν(P–C$_{Ph}$). ^{1}H NMR data ($CDCl_3$, δ ppm): 6.79 t (C^{4,5}H), 7.68 m (*o*-H), 7.64 m (*p*-H), 7.54 m (*m*-H) [$CuI(PPh_3)_2$], 7.47 m (*o*-H), 7.39 m (*p*-H), 7.27 m (*m*-H) (**3**). ^{31}P NMR ($CDCl_3$), −5.1, $\Delta\delta(\delta_{complex} - \delta_{PPh3})$, −0.4 ppm **3**.

2.2.4. *[CuBr(1κS-bzimSH)(PPh$_3$)$_2$] · CH$_3$COCH$_3$ (**4**)*

To a suspension of copper(I) bromide (0.025 g, 0.17 mmol) in acetone was added a solution of benz-1,3-imidazoline-2-thione (0.026 g, 0.17 mmol) in acetone, followed by stirring for 2 h at room temperature and to the white precipitates formed was added PPh_3 (0.091 g, 0.34 mmol) and contents stirred until a clear solution was obtained. The slow evaporation of solution at room temperature formed colorless crystals of **4**. This complex is soluble in chloroform, acetonitrile and dichloromethane (72%, m.p. 228–231 °C). *Anal.* Calc. for $C_{46}H_{42}BrCuN_2OP_2S$: C, 63.05; H, 4.79; N, 3.20. Found: C, 62.97; H, 4.51; N, 2.90%. Main IR peaks (KBr, cm^{-1}): 3110–3041m, ν(N–H) + ν(C–H)$_{Ph}$; 2958 w, 2854 m ν(C–H);1608 w, 1604 w ν(C–N) + δ(C–H); 1155 s ν(C–S); 1091 m ν(P–C$_{Ph}$). ^{1}H NMR data ($CDCl_3$,δ ppm): 11.2 bs (NH) 7.64–7.71 m (*o*-H, *p*-H), 7.55 m (*m*-H) [$CuBr(PPh_3)_2$], 7.47 m (*o*-H), 7.35 m (*p*-H), 7.22–7.30 m (*m*-H, C$^{4-7}$H, bzimzSH) (**4**). ^{31}P NMR ($CDCl_3$), 30.84 [$CuI(PPh_3)_2$], −3.6 (**4**); $\Delta\delta(\delta_{complex} - \delta_{PPh3})$, 35.54 [$CuI(PPh_3)_2$], 1.10 ppm **4**.

2.3. X- ray crystallography

The data for compounds **1**–**4** were collected at 294(1) K on a Siemens P4 diffractometer. The θ-2θ technique was used to measure the intensities up to a maximum of $2\theta = 5°$, with graphite-monochromatised Mo Kα radiator ($\lambda = 0.71073$ Å). Cell parameters were refined in the θ range, 12–20° using XSCANS [23]. The data were corrected for Lorentz and polarization factors. An empirical psi absorption correction was applied. The structure was solved by the direct methods and refined by full matrix least squares methods based on F^2. All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were assigned calculated positions. Scattering factors from the International Tables for X-ray crystallography were used [24]. Data reduction, structure solution, refinement and molecular graphics were performed using SHELXTL-PC [25] and WINGX [26]. For compound **2**, the imidazole ring showed disorder in terms of having unusual bond distances and slightly higher thermal parameters. The disorder could not be resolved and the structure was refined by adding following restraints on bond distances involving the group (C37–N1, C37–N2 1.373(3), C38–N1, C38–N2 1.440(3), C38–C39 1.336(3) and C37–S1 1.703(3) Å, respectively). Hydrogens of water molecule could not be located from the difference Fourier map and have not been included in the model. All other hydrogens were fixed geometrically and were not refined. The cell and refinement parameters are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and infrared spectroscopy

Reactions of 1,3-imidazoline-2-thione (imzSH) with copper(I) halides in 2:1 molar ratio did not yield polymers similar to that formed by 1,3-imidazolidine-2-thione mentioned in introduction [7,8]. There was a change in color from colorless to green (probably due to Cu^{II}) when solution was left in open for several days and no crystalline product could be isolated. The addition of triphenyl phosphine (Ph_3P) yielded crystalline products. Thus the reaction of copper(I) chloride with imzSH in the presence of Ph_3P in 1:2:2 or 1:1:2 (M:L:PPh_3) molar ratios yielded a compound of unusual composition, $[Cu_2(imzSH)(PPh_3)_4Cl_2] \cdot CH_3OH$

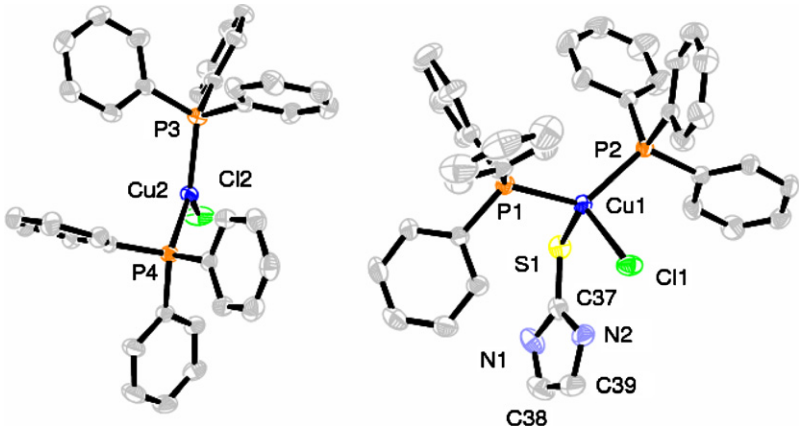

Fig. 1. Two crystallographically independent molecules of $[CuCl(1\kappa S\text{-imzSH})(PPh_3)_2]\cdot[CuCl(PPh_3)_2]$ (**1**) and their partial labeling scheme. Solvent molecule and the hydrogen atoms have been removed for clarity.

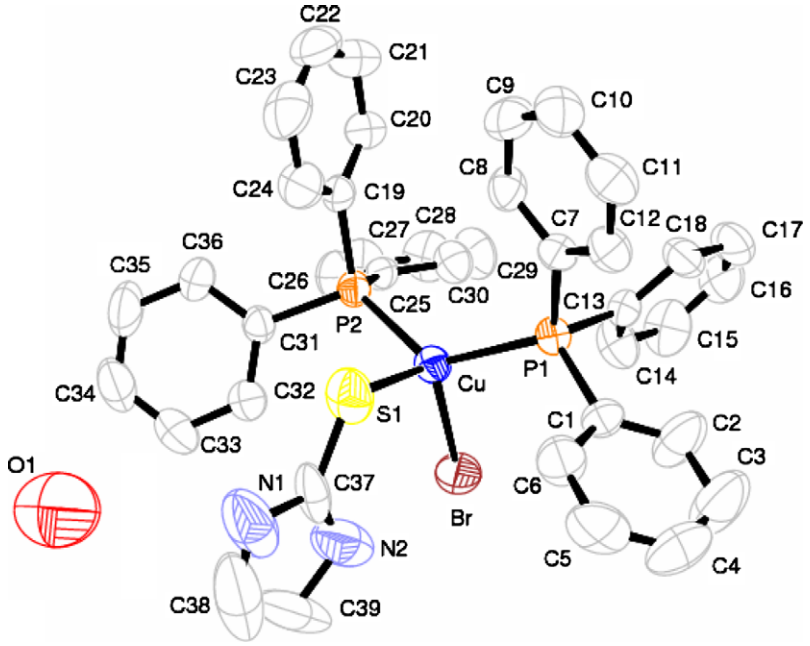

Fig. 2. The structure of $[CuBr(1\kappa S\text{-imzSH})(PPh_3)_2]\cdot H_2O$ (**2**) with numbering scheme.

(**1**), whose X-ray crystallography has shown that its crystals consists of four coordinated $[CuCl(1\kappa S\text{-imzSH})(PPh_3)_2]$ (**1a**) and three coordinated $[Cu(PPh_3)_2Cl]$ (**1b**) independent molecules in the same unit cell (vide infra). In contrast, crystals of complexes of copper(I) bromide/iodide are formed by single molecules of $[CuBr(1\kappa S\text{-imzSH})(PPh_3)_2]\cdot H_2O$ (**2**) and $[CuI(1\kappa S\text{-imzSH})(PPh_3)_2]$ (**3**), respectively, similar to molecule **1a**. A related ligand, 1,3-benzimidazoline-2-thione (bzimSH) formed the complex $[CuBr(1\kappa S\text{-bzimSH})(PPh_3)_2]\cdot CH_3COCH_3$ (**4**), similar to mononuclear complexes, $[Cu(1\kappa S\text{-bzimSH})(PPh_3)_2Cl]\cdot$ acetone and $[Cu(1\kappa S\text{-bzimSH-7-}NO_2)(PPh_3)_2Cl]$ [19a]. In the literature, dealing copper-heterocyclic thioamide chemistry, the only analogous formation of two independent molecules $[Cu(1\kappa S\text{-bztz2SH})_2(PPh_3)_2]$ **A** and][CuCl(1κS-bztz2SH)$(PPh_3)_2$] **B** in the unit cell, resulted from the reaction of $CuCl(PPh_3)_3$ with benzo-1,3-thiazoline-2-thione in 1:2 molar ratio in CH_3CN–MeOH, each having a tetrahedral geometry [27].

The main characteristic IR peaks of complexes of 1,3-imidazoline-2-thione (imzSH) and benz-1,3-imidazoline-2-thione (bzimSH) are listed in the experimental section. The ν(N–H) peak of free imzSH at 3118–3092(m) cm^{-1} undergoes low energy shifts to 3002–3145 cm^{-1} in complexes **1**–**3**. In complex **4**, the ν(N–H) and $\nu(C–H)_{Ph}$ signals merge in the region, 3110–3041 m cm^{-1}. The most significant diagnostic peak due to ν(C=S) in the free imzSH ligand at 1232 cm^{-1} shifts to low energy region 1217–1184 cm^{-1} in its complexes **1**–**3**. Similarly, the ν(C=S) peak of the free bzimSH ligand at 1177 (s) cm^{-1} undergoes low

energy shift to 1155 (s) cm^{-1} in **4**. The shifts in ν(C=S) peaks in all the complexes is attributed to the weakening of C=S bond due to the coordination of thione sulfur to the metal center. In all the complexes, the presence of ν(P–C_{Ph}) occurred in the range, 1083–1093 cm^{-1}. The presence of methanol and water in complexes **1** and **2** has been detected by the presence of ν(O–H) at 3363 (**1**, methanol) and 3396 (**2**, water).

3.2. Crystal structures of complexes 1–4

Complex **1** crystallized in triclinic system with space group $P\bar{1}$, while complexes **2**, **3** and **4** crystallized in monoclinic system with space groups $P2_1/n$ (**2**, **3**) and $P2_1/c$ (**4**). The atomic numbering schemes of complexes **1**, **2**, **3** and **4** are shown in Figs. 1–4, packing diagram in Figs. 5–8 and selected bond lengths and angles are given in Table 2.

3.2.1. Complex [CuCl(1κS-imzSH)(PPh$_3$)$_2$] · [CuCl(PPh$_3$)$_2$] (1)

Complex **1** has four coordinated [CuCl(1κS-imzSH)(PPh$_3$)$_2$] (**1a**) and three coordinated [Cu(PPh$_3$)$_2$Cl] (**1b**) independent molecules in the same unit cell (Fig. 1). In molecule **1a**, Cu is bonded to two P atoms of PPh_3, one S atom of imzSH, and one Cl atom with bond angles around copper in the range, ca. 100–125° (Table 2). It reveals distorted tetrahedral geometry. In molecule **1b**, Cu is bonded to two P atoms of PPh_3, and one Cl atom with bond angles around copper in the range, ca. 114–128° and geometry is distorted trigonal planar. The P–Cu–P angle in **1b** [127.76(3)°] is higher than that in **1a** [124.49(3)°] due to less steric crowding in the trigonal planar geometry. This P–Cu–P angle in **1a** is higher than 122.4° in analogous complex [CuL(PPh$_3$)$_2$Cl] (L = 1, 3- thiazolidine-2-thione) [28]. The Cu–S bond distance, 2.3643(10) Å, in molecule **1a** is comparable with literature values {2.381–2.418 Å} [28,29]. The Cu–Cl bond distance 2.4272(9) Å in complex **1a** is less than sum the of ionic radii of Cu^+ and Cl^-(Cu^+, Cl^-, 2.58 Å) [30]. The Cu–P bond distances, 2.2976(8), 2.2815(9) Å in **1a** are expectedly longer than 2.2695(9), 2.2720(8) Å in three coordinated **1b**, which are similar to Cu–P distances in the analogous complexes [29,31].

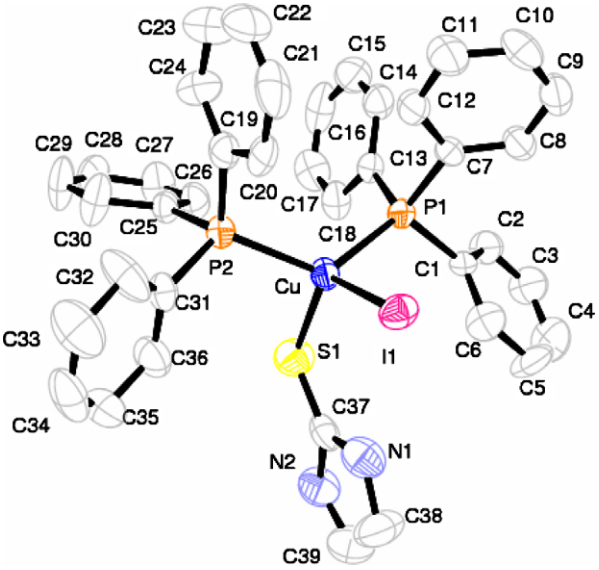

Fig. 3. The structure of [CuI(1κS-imzSH)(PPh$_3$)$_2$] (**3**) with numbering scheme.

3.2.2. Structures of complexes 2–4

In complex **2**, Cu is bonded to two P atoms of Ph_3P ligands, one S atom of the 1,3-imidazoline-2-thione, and one bromine atom. Similar is binding pattern in complexes

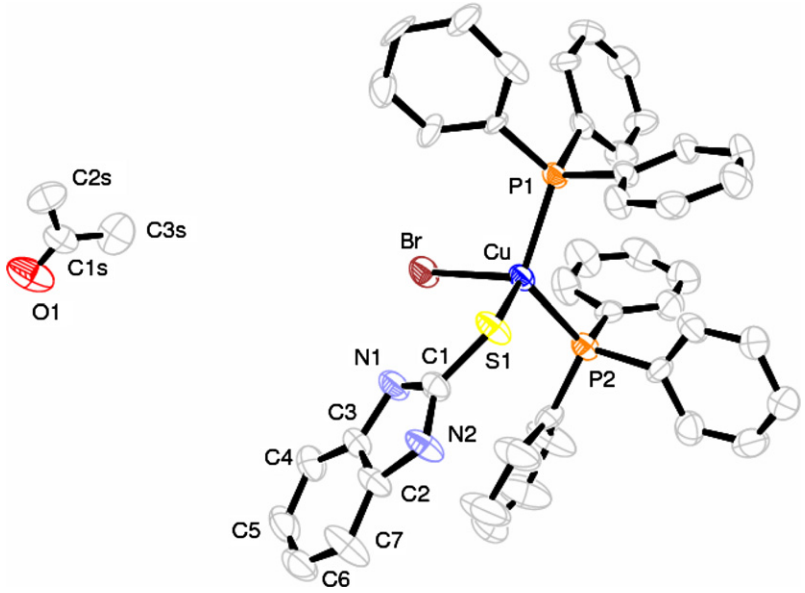

Fig. 4. The structure of [CuBr(1κS-bzimSH)(PPh$_3$)$_2$] · CH_3COCH_3 (**4**) with partial numbering scheme and the solvent.

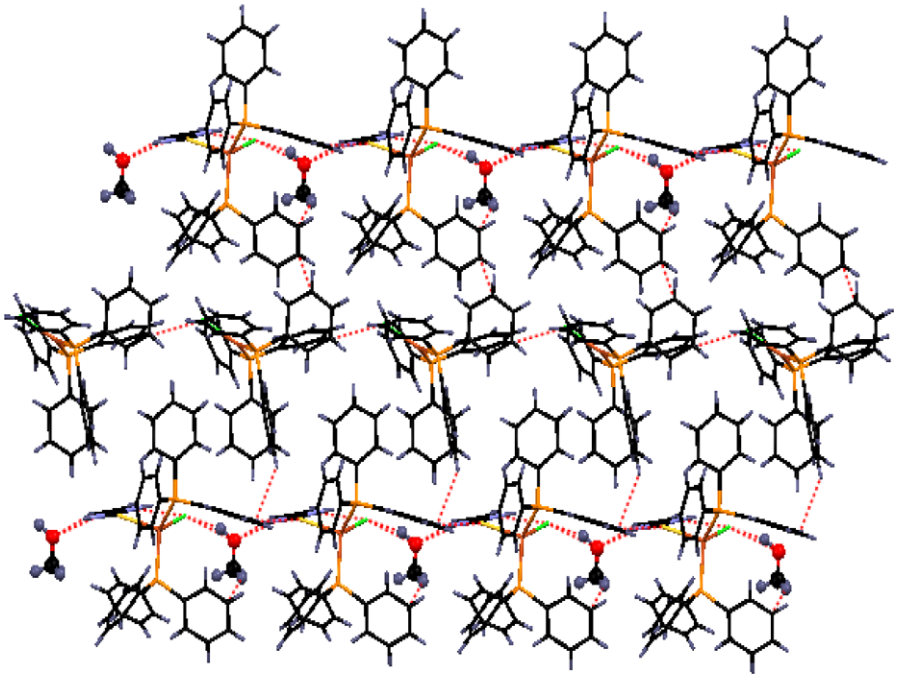

Fig. 5. Crystal structure of complex **1** showing the alternate 1D linear chains of molecule **1a** and molecule **1b**. These two independent chains are further linked to each other due to edge-to-edge π...π and C–H...π interactions forming a 2D network.

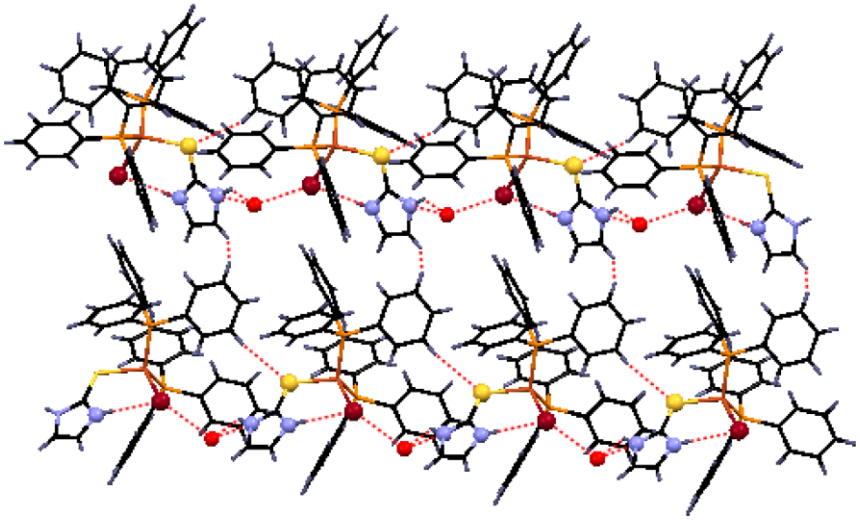

Fig. 6. Packing diagram of compound **2** showing formation 2D structure due to H-bonding and edge-to-edge π...π interactions.

3 and **4** (Figs. 2–4). The angles around Cu lie in the ranges 100.47(7)–128.77(7)°, 102.09(10)–125.06(8)° and 103.64(9)–122.21(8)° in complexes **2**, **3** and **4**, respectively, with P(2)–Cu–P(1) being the largest, and P–Cu–X {X = Br, I} being the smallest. The P–Cu–P angles in complexes **1a**, **2**–**4** are 124.49(3), 128.77(7), 125.06(8) and 122.21(8)°, respectively, and are influenced by the steric and intra- and inter-molecular hydrogen bonding interactions. This reveals a distorted tetrahedral geometry around each copper atom in mononuclear complexes. The Cu–S bond distances lie in close range 2.344(3)–2.373(2) Å in complexes **2**–**4** and are comparable with 2.3643(10) Å in molecule **1a**. The Cu–P distances lie in the range, 2.2819(17)–2.326(3) Å, in complexes **2**–**4**, similar to the distances found in complex **1a**. The Cu–Br and Cu–I bond distances are less than the sum of the ionic radii of Cu^{+} and X^{-} (Cu^{+}, Br^{-}, 2.73; Cu^{+}, I^{-}, 2.97 Å) [30].

3.3. Packing networks of complexes *1–4*

The packing diagram of **1** (Fig. 5) shows alternate 1D linear chains of molecule **1a** and molecule **1b**. Molecule **1a** forms these linear chains due to methanol...chlorine (O1S···Cl 1^{i}) and phenylene C...S (C29...S^{ii}) intermolecu-

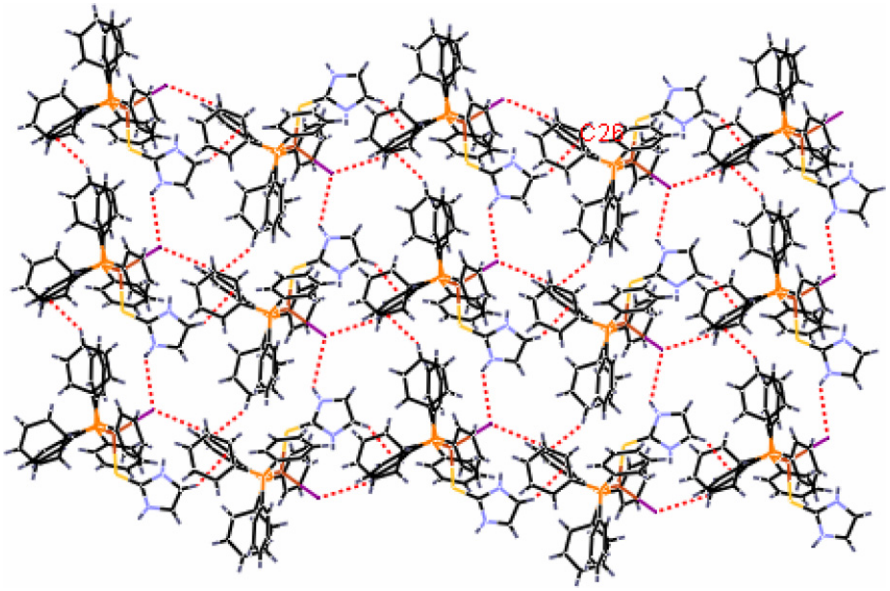

Fig. 7. Crystal structure of compound **3** showing pleated sheet like 2D structure.

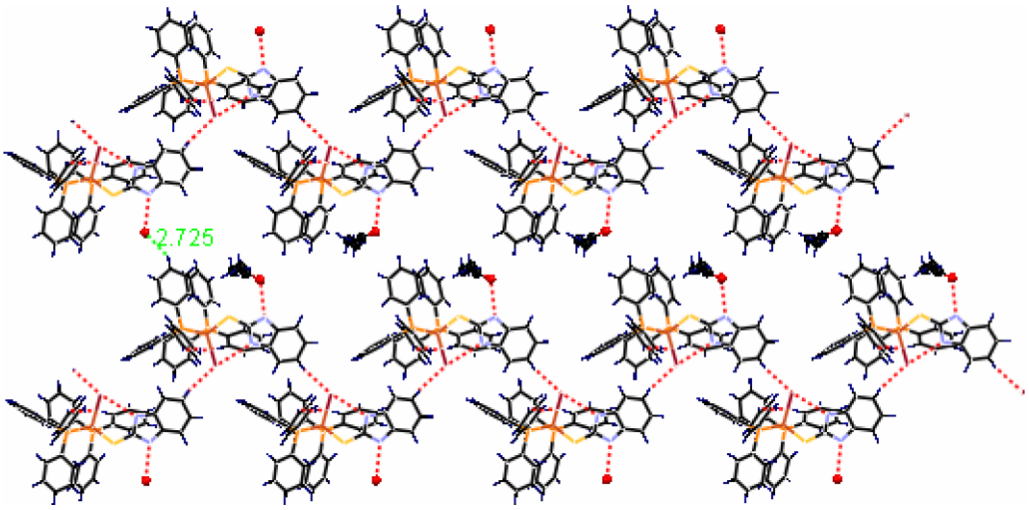

Fig. 8. Packing diagram of compound **4** showing the formation of a 2D H-bonded network in the *bc* plane.

lar and imidazole...methanol (N1···O1S), and imidazole...chlorine (N2···Cl1) intramolecular H-bonding interactions. Molecule 1b is linearly chained due to C74...Cl2 H-bonding interactions. These two independent chains are further linked to each other to form a 2D network due to edge-to-edge π...π interactions between rings **A** (C13–C18) and **I** (C52–C57) and rings **G** (C40–C45) and **E** (C25–C30), with distances of 3.319 and 3.502 Å, respectively, and also due to C–H...π interaction between centroid of ring **C** (C13–C18) and methanol C1S with a distance of 3.688 Å (Table 3).

Complex **2** involves intramolecular H-bonding between imino nitrogen of imidazole and bromine atom (N2···Br) (Fig. 6). Water molecule is present in the crystal lattice and is engaged in intermolecular H-bonding with bromine atom (O1...Br) and with imino nitrogen of imidazole ring (N1···O1) to form the parallel linear chains. These chains are further linked to each other via edge-to-edge π···π interactions (3.582 Å) resulting in 2D structure.

In complex **3**, the terminal iodine atom is engaged in intramolecular H-bonding with imino hydrogen (N1···I1) (Fig. 7). The molecules are linked to each other by means of intermolecular H-bonding, C27···I1^{ii} and C38–H38···ring (C25–C30) (3.858(8) Å) C–H···π interactions to form zig-zag chains. These linear chains are further linked to each other by means of N2···I1^{i} and C–H···π interactions between C22–H22···ring (C25–C30) (3.659(9) Å) to form a pleated sheet like 2D structure.

In complex **4**, there is intramolecular H-bonding between imino hydrogen of imidazole and bromine atom (N1···Br). These molecules are further linked to each other by means of C5–H5···Br H-bonding to form a 1D zig-zag

chain along *c*-axis (Fig. 8). Acetone as a solvent of crystallization is present in crystal lattice and is involved in intermolecular H-bonding N2···O1(solvent) along the chains. C11–H11···O1 weak H-bonds between phenylene C and the solvent helps to form a 2D network in the *bc* plane.

3.4. NMR spectroscopy

The ^{1}H NMR of ligand 1,3-imidazoline-2-thione (imzSH) in DMSO shows a singlet at 6.65 ppm due to equivalent ring ($C^{4}H$, $C^{5}H$) protons. When this ligand coordinates to the metal via its S electrons, ring protons become magnetically inequivalent and thus two expected doublets due to $C^{4}H$, $C^{5}H$ protons merge into an unresolved triplet. Each of complexes **1**–**3** showed a triplet at a low field (7.23, **1**; 6.74, **2**; 6.79 ppm, **3**). Interestingly, NMR spectrum of complex $[CuCl(1\kappa S\text{-imzSH})(PPh_3)_2]\cdot[CuCl(PPh_3)_2]$ (**1**) showed two sets of PPh_3 signals which revealed the formation of $[CuCl(1\kappa S\text{-imzSH})(PPh_3)_2]$ (**1a**) (7.25–7.27 ppm) and $[Cu(PPh_3)_2Cl]$ (**1b**) (7.46–7.67 ppm, PPh_3) in the solution state. Similarly complexes $[CuBr(1\kappa S\text{-imzSH})(PPh_3)_2]\cdot H_2O$ (**2**) and $[CuI(1\kappa S\text{-imzSH})(PPh_3)_2]$ (**3**) showed one set of PPh_3 signals in the regions 7.27–7.41 and 7.27–7.47 ppm, respectively, and another set of weak PPh_3 signals in the regions, 7.47–7.68 ppm showed the formation of compounds, namely, $Cu(PPh_3)_2Br$ and $Cu(PPh_3)_2I$ similar to **1b**. Complex $[CuBr(1\kappa S\text{-bzimSH})(PPh_3)_2]\cdot CH_3COCH_3$ (**4**) showed one set of signals due to PPh_3 in the region, 7.22–7.47 ppm similar to complexes **1a**, **2** and **3** and another set of PPh_3 signals in the region, 7.55–7.64 ppm due to $\{Cu(PPh_3)_2Br\}$. The peaks due to benzimidazoline ring merged with the PPh_3 protons in 7.22–7.64 ppm {cf. peaks due to free bzimSH ligand 7.23 m (2H, $C^{4,7}H$) and 7.15 m (2H, $C^{5,6}H$) in dmso-d_6}. Complexes **2** and **4** showed broad signal due to NH protons (10.2, **2**, 10.4, **4** ppm). The NH proton signals could not be identified in complexes **1** and **3** due to broadening.

The ^{31}P NMR spectra of compounds **1**–**4** showed signals at −3.42 (**1a**), −4.30 (**2**), −5.10 (**3**) and −3.60 ppm (**4**) with coordination shifts ($\Delta\delta$) of 1.28, 0.40, −0.40 and 1.10 3 ppm, respectively. In literature similar shifts in copper(I)–phosphine-heterocyclic thioamide complexes have been observed [29,32]. The signal due to $[CuCl(PPh_3)_2]$ (**1b**) has been identified at 30.74 ppm. Compound **4** showed additional signal at 30.84 ppm, attributed to the formation of species $[Cu(PPh_3)_2Br]$, however, compounds **2** and **3** did not show the formation of similar species $[Cu(PPh_3)_2Br]$ and $[Cu(PPh_3)_2I]$ in solution state.

4. Supplementary material

CCDC 658223, 658224, 658225 and 658226 contain the supplementary crystallographic data for **1**, **2**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. Materials and instrumentation

All reactions were performed under dry deoxygenated nitrogen atmosphere using standard Schlenk techniques. Dichloromethane was dried and distilled over P_2O_5 and acetonitrile was dried over P_2O_5 and stored over molecular sieves. All the catalyst precursors, [{1,3-(3,5-R_2pzCO)$_2$C$_6$H$_4$}Pd$_2$Cl$_2$(μ-Cl)$_2$] (R = ^{t}Bu (**1**) [10], Me (**3**) [10], [{2,6-(3,5-R_2pzCO)$_2$C$_5$H$_3$N)}PdCl$_2$] (R = ^{t}Bu (**4**), Me (**5**)) [11], [(3,5-R_2pz)$_2$PdCl$_2$] (R = H (**6**), Me (**7**), ^{t}Bu (**8**)) [12], [(3,5-^{t}Bu$_2$pz)$_2$PdCl(Me)] (**9**) [12], were prepared by the literature methods, except **2**, which was prepared as described below. Phenylacetylene (98%) was obtained from Merck and used as received. NMR spectra were recorded on a Gemini 2000 instrument at 200 MHz for ^{1}H and 50.3 MHz for ^{13}C. Polymer molecular weights were determined by gel permeation chromatography on a Waters 600E instrument with a Waters 410 differential refractometer detector (THF, at 30 °C, rate = 1.0 mL min^{-1}) and PL-MIXED-C™ columns, using polystyrene as standards.

2.2. Synthesis

2.2.1. 1,3-Bis(3,5-diphenylpyrazolyl-1-carbonyl)benzene (*L1*)

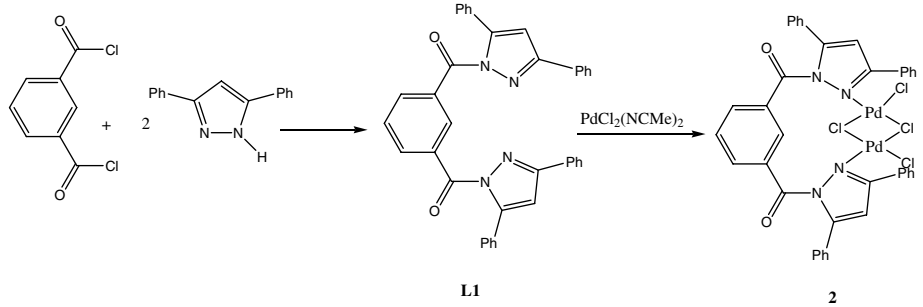
To a solution of isophthaloyl dichloride (0.50 g; 2.46 mmol) in dry toluene (50 mL) was added diphenylpyrazole (1.08 g; 4.92 mmol). The colourless solution turned yellow upon addition of Et_3N (8 mL). The solution was vigorously stirred under nitrogen at room temperature for 24 h. After the specified reaction time, the mixture was filtered and the filtrate evaporated to dryness at reduced pressure to give a yellow solid, which was purified by column chromatography using silica gel and CH_2Cl_2:Et_2O (8:1) as eluent. Yield = 0.64 g, 46%. *Anal.* Calc. for $C_{38}H_{26}N_4O_2$: C, 79.98; H, 4.59; N, 9.82. Found: C, 79.96; H, 4.57; N, 9.65%. ^{1}H NMR ($CDCl_3$): δ 8.95 (s, 1H, Ph); 8.42 (d, 2H, Ph, $^2J_{HH}$ = 10 Hz); 7.69 (t, 1H, Ph); 7.46 (m, 20H, Ph on pz); 6.90 (s, 2H, 4-pz).

2.2.2. Di-μ-chloro-dichloro{1,3-bis(3,5-diphenylpyrazolyl-1-carbonyl)benzene}dipalladium(II) (*2*)

To **L1** (0.33 g, 0.58 mmol) and [PdCl$_2$(NCMe)$_2$] (0.15 g, 0.58 mmol) was added dry dichloromethane (70 mL). The resulting dark red solution was stirred at room temperature under nitrogen for 18 h, turning yellow with formation of small amount of precipitate. The reaction mixture was filtered and the filtrate was evaporated to dryness to give an orange solid. Yield = 0.40 g, 63%. *Anal.* Calc. for $C_{40}H_{30}Cl_8N_4O_2Pd_2$: C, 47.06; H, 2.91; N, 5.78. Found: C, 47.79; H, 2.46; N, 5.78%. ^{1}H NMR ($CDCl_3$): 9.08 (d, 2H, Ph, $^2J_{HH}$ = 4 Hz); 9.05 (d, 2H, Ph, $^2J_{HH}$ = 4 Hz); 8.38 (m, 5H, Ph on pz); 8.31 (t, 1H, Ph); 7.62 (s, 6H, Ph on pz); 7.49 (s, 10H, Ph on pz); 6.79 (s, 2H, 4-pz).

2.3. Polymerization

In a typical experiment a solution of silver triflate (0.078 g, 0.28 mmol) in a 15 mL mixture of CH_2Cl_2 and MeCN (7:1) was added to complex **1** (0.10 g, 0.14 mmol) in 25 mL of CH_2Cl_2 and MeCN (7:1). A white precipitate of AgCl formed immediately and the mixture was stirred for at most 5 min and filtered to give a yellow solution of the active catalyst. To the solution of the active catalyst was added 50 equivalents of phenylacetylene (0.78 mL, 7.0 mmol). The resultant solution changed to dark red immediately. After stirring for 2 min the solution was evaporated to give a dark brown residue, which was dissolved in 10 mL of CH_2Cl_2 followed by the addition of 30 mL of methanol to precipitate a yellowish-orange powder. Yield = (0.58 g, 90%). The product was characterized by a combination of ^{1}H, ^{13}C{^{1}H} NMR spectroscopy and GPC analysis.



2.4. X-ray crystallography

The crystal evaluation and data collection were performed on a Bruker CCD-1000 diffractometer with Mo Kα (λ = 0.71073 Å) radiation and the diffractometer to crystal distance of 4.9 cm. The initial cell constants were obtained from three series of ω scans at different starting angles. The reflections were successfully indexed by an automated indexing routine built in the SMART program [13]. The absorption correction was based on fitting a function to the empirical transmission surface as sampled by multiple equivalent measurements. A successful solution by the direct methods provided most non-hydrogen atoms from the E-map. The remaining non-hydrogen atoms were located in an alternating series of least-squares cycles and difference Fourier maps. All non-hydrogen atoms were refined with anisotropic displacement coefficients. All hydrogen atoms were included in the structure factor calculation at idealized positions and were allowed to ride on the neighboring atoms with relative isotropic displacement coefficients.

3. Result and discussion

3.1. Synthesis of bis(diphenylpyrazolyl-1-carbonyl)benezene ligand and palladium(II) complex (*2*)

The synthesis of both ligand and complex is similar to the other substituted pyrazolyl compounds and their palladium complexes we reported recently [10]. Scheme 1 shows how **L1** and **2** were prepared. The ^{1}H NMR spectrum of the ligand is typical of other 1,3-benzenedicarbonyl pyrazolyl ligands. The C2, C4 and C5 protons on the benzene appear as a triplet (7.69 ppm), a doublet (8.42 ppm) and doublet of a doublet (8.56 ppm) respectively. The ^{1}H NMR spectrum of **2** suggests that the ligand binds to the Pd in a similar fashion as reported for 1,3-benzenedicarbonyl pyrazolyl ligands [10] to form

Scheme 1.

a dinuclear complex. The structures of the ligand and the dinuclear complex were confirmed by X-ray crystallography.

3.2. Descriptions of the structure of *L1* and *2*

Single crystals of **L1** and **2** were obtained from recrystallization of the respective compounds from CH_2Cl_2 and ether at −15 °C. The crystal quality of **2** was poor and the crystals collapsed once it was dry, but X-ray diffraction analysis could be carried out on the crystals if solvent of crystallization was present; although the quality of data from these crystals was not so good. The refinement was therefore only good to establish the connectivity of atoms, and as such we have not discussed any bond parameters. The structure of **2** was found to be isomorphous with the solid-state structures of **1** and **3** [10]. The molecular structures of **L1** and **2** are shown in Figs. 1 and 2 respectively. Crystallographic information is tabulated in Table 1 while selected bond lengths and angles for **L1** are listed as part of the captions for Fig. 1.

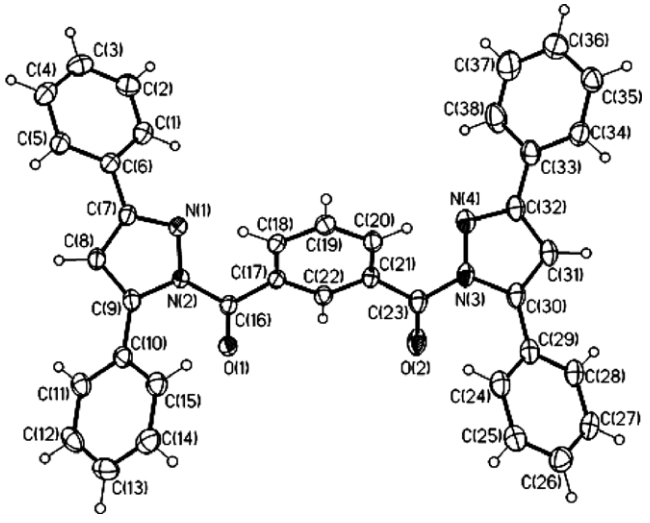


Fig. 1. Molecular structure of 1,3-bis(3,5-diphenylpyrazolyl-1-carbonyl)benzene. Selected bond lengths (Å) and angles (°): N(1)–N(2) 1.374(18), N(2)–C(16) 1.431(19), O(1)–C(16) 1.206(19), C(16)–C(17) 1.485(2). (N91)–N(2)–C(16) 117.31(12), O(1)–C(16)–N(2) 120.03(14), O(1)–C(16)–C(17) 124.22(14).

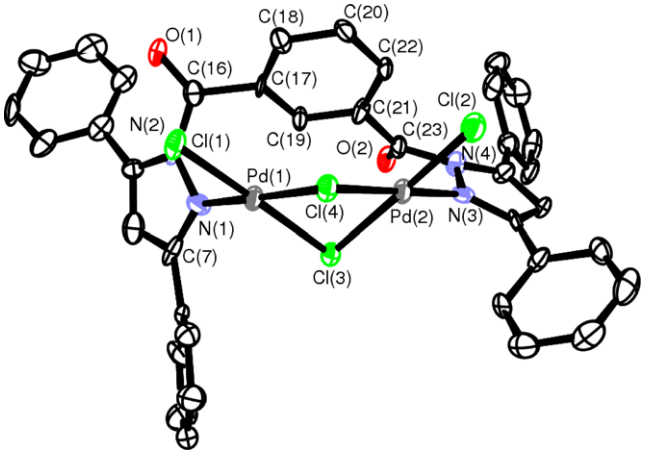

Fig. 2. Molecular structure of **2**. Due to the poor quality of the X-ray data only an ortep drawing is shown to indicate the connectivity of atoms.

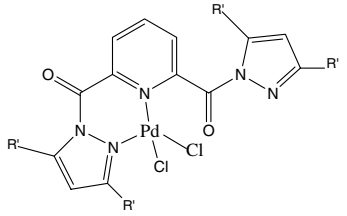
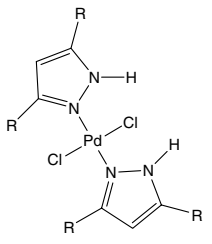
The solid state structure of 1,3-(3,5-R_2pzCO)$_2C_6H_4$ and 1,2-(3,5-R_2pzCO)$_2C_6H_4$ (R = Me, ^{t}Bu) possess either a C_2 or C_s symmetry [10]. These observation can be extended to 1,3-(3,5-Ph_2pzC(O))$_2C_6H_4$. The C_2 symmetry is attained when the pyrazolyl substituents on the benzene ring reside on the opposite sides of its plane. The C_s symmetry is

observed when both substituents are on the same side of the ring with the mirror plane perpendicular to the plane of the ring. Based on the above assessment 1,3-(3,5-$Ph_2pzCO)_2C_6H_4$ has a C_s symmetry. Molecular modeling revealed that the two symmetry conformations are energetically equivalent and are close in energy to a number of calculated energetic minima corresponding to various C_i arrangements. It has also been established that the most energetically favourable conformations are those in which the carbonyl is coplanar with the pyrazole ring.

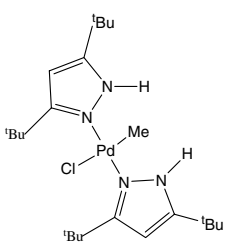


Compound 1,3-$(3,5\text{-}Ph_2pzC(O))_2C_6H_4$ cannot achieve planarity due to either close proximity of the pyrazolyl substituents in the 2-position to the *ortho* hydrogen of the phenyl ring, or due to unfavorable interactions between the nitrogen lone pair and the *ortho* hydrogen. The C=O group can, however, be coplanar with either ring since both pyrazolyl and phenyl groups possess a delocalized π-system, with the preferred ring being the pyrazole. The C–N bond in the O=*C*–*N*–N linkage is shorter than the generic C_{sp2}–N_{sp2} single bond due to electronic resonance. The C–N bond is the shortest when the torsion angle O–C–N–N is 180° and longest when the angle is 90°. The average C–N bond distances in 1,3-$(3,5\text{-}Ph_2pzCO)_2C_6H_4$ averaged 1.4271 Å. This value falls within the range for similar compounds reported by Darkwa et al. [10].

3.3. Polymerization of phenylacetylene



The polymerization of phenylacetylene (PA) was examined with three types of pyrazolyl palladium complexes as catalysts (Scheme 2). These catalysts differ by the nature of the ligand systems, all designed to vary the electron density on the metal centre and the active catalysts were generated *in situ* by reacting each palladium complex with silver triflate in a mixture of CH_2Cl_2 and MeCN. The presence of MeCN is necessary to stabilize the active catalyst, yet the coordination of MeCN has to be weak enough to allow the monomer access to the active centre of the catalysts in order to initiate the polymerization.



(R = ^{t}Bu (**1**), Ph (**2**), Me (**3**))

(R' = ^{t}Bu (**4**), Me(**5**))

(R = H (**6**), Me (**7**), ^{t}Bu (**8**))

(**9**)

Scheme 2.

The stereochemistry of the polyphenylacetylene produced was determined by ^{1}H NMR spectroscopy. Polymers from solvents mixtures were mainly *cis–transoidal* polyphenylacetylene, which showed a sharp singlet at 5.85 ppm for the vinylic protons in the polymer and broad singlets at 6.66 ppm (*ortho*) 6.97 ppm (*meta* and *para*) protons of the phenyl groups in the polymer. In MeCN and THF the ^{1}H NMR spectra of the polymers produced were very broad and centred at 7.25 ppm typical of *trans–cisoidal* polyphenylacetylene.

Polymerization data, showing the effect of catalysts, solvents and ratio of PA:Pd on polymerization, are listed in Tables 2 and 3. All the catalysts showed moderate to high activity and a general trend where substituents on the pyrazolyl unit or pyrazole determined the molecular weight of polyphenylacetylene formed, was observed. Other factors that affected polymer molecular weights are reaction time and nature of solvent. Polymerization with catalyst **1** resulted in very high conversion, with very little variation in polymers molecular weight when monomer to catalyst ratio was kept at 50:1 and CH_2Cl_2:MeCN ratio of 7:1 (Table 2 (entries 1–4)). Increase in MeCN content of the mixture of solvents, as well as monomer to catalyst ratio (Table 2, entries 5–8) resulted in lower conversion and lower polymer molecular weights. The results suggest that with increased concentration of MeCN, the monomer competes with MeCN for the catalyst. The steric bulk of the catalyst also has profound effect on polymer molecular weight. With bulky substituents on the pyrazolyl ligands (i.e. tertiary butyl and phenyl) and at similar polymerization conditions, high-molecular weight polyphenylactylene were formed (Table 2, entries 4 and 9), but the less bulky methyl substituent only produced oligomers (Table 2, entry 10). Steric bulk of catalyst is a well established property that promotes chain propagation in olefin polymerization reactions; a phenomenon that underlies the success of α-diimine late transition metal complexes as catalysts for the polymerization of olefins [7a].

We also observed that when polymerization reactions were run in neat solvents (MeCN and THF) with the active catalyst generated as described, the polymerization was fast but polymer molecular weights were lower than in the solvent mixtures. Both MeCN and THF are donor solvent and would compete with phenylacetylene for the catalytic centre. It therefore comes as no surprise that reactions in these solvents produced lower molecular weight polymers.

Time dependent polymerization experiments with catalyst **1** showed little variation in monomer conversion, (Table 2, entries 1–4). However, there was no increase in activity with time (Fig. 2) as expected if the catalyst is still

Table 2

[a] All reactions were run in 40 mL solvent.
[b] Solvent is a mixture of CH_2Cl_2 and MeCN; [Pd] = 3.5×10^{-3} M; PA:Pd = 50:1.
[c] Reactions run with SO_2; temperature = 25 °C.

active. This is typical of catalyst deactivation, which suggests decomposition of catalyst. Indeed a change in ligand design by using a pyridine linker produced catalysts **4** and **5**; both of which are substantially more stable, albeit less active. Reactions with **4** and **5** took much longer at similar conditions to reach % conversions found for catalysts **1** and **2**; but the steric effect on polymer molecular weight (Table 2, entries 15–18) remained similar to molecular weights observed for catalysts **1**–**3**. It, therefore, appears that upon removal of chloride ligands to give the active catalysts, the uncoordinated pyrazolyl units in **4** and **5** enters the coordination sphere of the palladium and block the coordination site the monomer needs to occupy in order to be polymerized.

In order to establish the full effects of both the carbonyl and pyridine linkers in catalysts **1**–**5**, simple pyrazole palladium complexes (**6**–**9**) were investigated as catalysts for phenylacetylene polymerization. A crucial difference between catalysts **6**–**9** and **1**–**5** is the higher amount of MeCN required to stabilize the active catalysts (i.e. CH_2Cl_2:MeCN = 5:3). Furthermore, % conversion of monomer was generally low with catalysts **6**–**9**, clearly showing that the catalysts centres in **6**–**9** are less electrophilic. Time dependent experiments with **9** showed a gradual increase in % conversion (Table 3, entries 5–9); but never achieved the high conversions observed with **1**–**5**.

We took advantage of the slow kinetics exhibited by catalyst **9** the co-polymerize phenylacetylene and another

monomer. We recently reported the insertion of SO_2 into the Pd–Me bond in **9** [14]. By saturating CH_2Cl_2:MeCN solutions of the active catalyst generated from **9** with SO_2, we could perform time dependent experiments involving the co-polymerization of SO_2 and phenylacetylene. Monomer conversions improved dramatically (Table 3, entries 11–14), but polymer molecular weights decreased with time. Liaw and Lay have co-polymerized CO and phenylacetylene with an *in situ* generated catalyst from 2,2′-bipyridine and $[Pd(MeCN)_4][BF_4]_2$ [15]. The polysulfone formed with catalyst **9** has characteristic ν(SO) peaks at 1259 cm^{-1} in addition to ν(C=C) of the acetylenic functionality at 1550 cm^{-1}.

All the catalysts showed moderate to high activity. The ability of cationic pyrazole palladium catalysts used here to catalyze phenylacetylene polymerization is not surprising. We have observed the formation of linear high density polyethylene catalyzed by bis(pyrazole)nickel(II) [16] and palladium(II) [11] as well as by pyrazolyl palladium(II) [10,12]. This observation confirms the high electrophilicity of these nickel and palladium catalysts, that allows rapid insertion of monomer, gives rise to a much higher rate of chain propagation over chain termination; thus avoiding branching that is common to late transition metal olefin polymerization catalysts. We believe it is this high electrophilicity of the cationic species formed by **1**–**9** that make them active catalysts for phenylacetylene polymerization, when other cationic palladium nitrogen donor compounds [8,7] cannot polymerize acetylenes.

In general complexes **1**, **2** and **4** were the most active, and catalysts with bulky substituents gave high-molecular weight polyphenylacetylene than catalysts that have less bulky substituents. Catalysts with less bulky substituents formed phenylacetylene oligomers. Compared with known Pd(II) catalysts, the (N∧N)Pd(II) catalysts described here are more active, although they produce lower-molecular weight polymers than some of the palladium catalysts reported in the literature. For instance while Pd(II) halide and acetate salts are known to polymerize phenylacetylene to low-molecular weight polymers, the use of Pd(II) acetate is highly exothermic and at times even explosive [3k]. It is also worth noting that the slow conversions by catalyst **9** allowed it to be used as co-polymerization catalyst for SO_2 and phenylacetylene.

4. Conclusions

Pyrazole and pyrazolyl ligands appear to have the right sigma donor ability to produce palladium complexes that catalyze the polymerization of phenylacetylene. This is in contrast to bipyridine and diimine palladium complexes that do not catalyze acetylene polymerization. However, the highly active pyrazolyl palladium catalysts have low stability and gradually deactivates. The lower activity of the pyrazole palladium catalysts allows complexes that have Pd–carbon functionality to be used as co-polymerization catalysts as the slow conversion gives the co-monomer sufficient time to insert to the Pd–C bond, in this case sulfur dioxide, thus enabling chain growth that involves the insertion of sulfur dioxide to produce polyphenylacetylene sulfone.

5. Supplementary material

CCDC 278053 and 275054 contain the supplementary crystallographic data for **L1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

tion metal complexes of Schiff bases containing tetradentate ligands have anti-microbial activity [8]. Transition metal complexes with redox active ligands bearing sterically hindered salicylaldimines are also reported to undergo one- or two-electron transfer. Sterically hindered ligands bearing salicylaldimines are known to be effective antioxidants and are widely used in rancidification of fats and oils [9]. The copper(II) ions play a central role in biological redox metalenzymes like plastocyanin, hemocyanin, azurin, galactose oxidase an others [10]. In most salicylaldimine, the proton is localized at the oxygen atom and in some cases is attached to the nitrogen atom [11]. Proton transfer can occurs both in solid and solution states, in basic and excited states [11,12].

In recent years, considerable interest has developed in copper complexes with mixed donor ligands as structural models for the active site of copper proteins. In the copper proteins a distorted metal ion environment of low symmetry with a mixed donor sets is present [13]. This information prompted us to synthesize copper(II) metal complexes with a mixed donor atoms environment incorporating nitrogen and oxygen as ligands donor. The present manuscript is devoted to the synthesis and spectroscopic characterization of new salicylideneiminate copper(II) metal complexes containing sterically hindered phenol fragment and electron-donating OH and methylsulfanyl (S–CH_3) substituents, attached to the salicylaldehyde moiety. Here, we report synthesis, characterization and electro-spectrochemical properties of three new dissymmetric bidentate salicylaldimine ligands ($\mathbf{L}_n\mathbf{H}$) ($n = 1$, 2, and 3) (L = *N*-[*m*-(methylmercapto)aniline]-3,5-di-*t*-butylsalicylaldimine, $m = 4$, 3, and 2 positions, respectively) and their copper(II) complexes [$\mathbf{Cu}(\mathbf{L}_n)_2$]. A comparative electro-spectrochemical study was provided an understanding the effect of the position of methylsulfanyl groups attached on the phenol fragment on electron transfer mechanism of the ligands and their copper complexes.

2. Experimental

2.1. Materials and measurements

All reagents and solvents were of reagent-grade quality and obtained from commercial suppliers. (Fluka Chemical Company, Taufkirchen, Germany). 3,5-Di-*t*-butyl-2-hydroxybenzaldehyde (3,5-DTB) was synthesized according to the literature procedure [14]. The elemental analyses were carried out in the Laboratory of the Scientific and Technical Research Council of Turkey (TUBITAK). IR spectra were recorded on a Perkin Elmer Spectrum RXI FT-IR Spectrometer as KBr pellets. ^{1}H NMR spectra were recorded on a Bruker-Avence 400 MHz spectrometers. Magnetic Susceptibilities were determined on a Sherwood Scientific Magnetic Susceptibility Balance (Model MK1) at room temperature (20 °C) using Hg[Co(SCN)$_4$] as a calibrant; diamagnetic corrections were calculated from Pascal's constants [15]. Electronic spectral studies were conducted on a Perkin Elmer model Lambda 25 UV–Vis spectrophotometer in the wavelength 200–900 nm. Molar conductivities (Λ_M) were recorded on a Inolab Terminal 740 WTW Series. Cyclic voltammograms (CV) were carried out using CV measurements with Princeton Applied Research Model 2263 potentiostat controlled by an external PC. A three electrode system (BAS model solid cell stand) was used for CV measurements in DMSO and consisted of a 1.6 mm diameter of platinum disc electrode as working electrode, a platinum wire counter electrode, and an Ag/AgCl reference electrode. Tetra-*n*-butylammonium perchlorate (TBAP) was used as a supporting electrolyte. The reference electrode was separated from the bulk solution by a fritted-glass bridge filled with the solvent/supporting electrolyte mixture. The ferrocene/ferrocenium couple (Fc/Fc^+) was used as an internal standard but all potentials in the paper are referenced to the Ag/AgCl reference electrode. Solutions containing ($\mathbf{L}_n\mathbf{H}$) and [$\mathbf{Cu}(\mathbf{L}_n)_2$] were deoxygenated by a stream of high purity nitrogen for at least 5 min before running the experiment and the solution was protected from air by a blanket of nitrogen during the experiment. Controlled potential electrolysis (CPE) was performed with Princeton Applied Research Model 2263 potentiostat/Galvanostat. An BAS model electrolysis cell with a fritted-glass to separate the cathodic and anodic portions of the cell was used for bulk electrolysis. The sample and solvent were placed into the electrolysis cell under nitrogen. UV–Vis spectroelectrochemical experiments were performed with a home-built thin-layer cell that utilized a light transparent platinum gauze working electrode. A platinum wire counter electrode, and Ag/AgCl reference electrode were used for spectroelectrochemical cell. Potentials were applied and monitored with a Princeton Applied Research Model 2263 potentiostat. Time- and applied-resolved UV–Vis spectra were recorded on Agillent Model 8453 diode array spectrophotometer.

2.2. Synthesis of ligands ($\mathbf{L_1H}$, $\mathbf{L_2H}$ and $\mathbf{L_3H}$)

N-[4-(Methylmercapto)aniline]-3,5-di-*t*-butylsalicylaldimine ($\mathbf{L_1H}$), *N*-[3-(methylmercapto)aniline]-3,5-di-*t*-butylsalicylaldimine ($\mathbf{L_2H}$), and *N*-[2-(methylmercapto)aniline]-3,5-di-*t*-butylsalicylaldimine ($\mathbf{L_3H}$) ligands were synthesized by the reaction of 4.20 mmol (0.98 g) 3,5-di-*t*-butyl-2-hydroxybenzaldehyde in 20 ml absolute ethanol and 4.20 mmol (0.58 g) different marcapto aniline derivative in 10 ml ethanol. Also, 3–4 drops of formic acid were added as catalyst. The mixture was refluxed for 2 h, followed by cooling to room temperature. The crystals were filtered in vacuum. Then the products were recrystallized from methanol. The products are soluble in common solvents such as $CHCl_3$, CH_3CH_2OH, DMF and DMSO.

2.2.1. For ($\mathbf{L_1H}$) ligand

^{1}H NMR (400 MHz, $CDCl_3$, Me_4Si, ppm): δ 13.70 (s, 1H, –O*H*, D-exchangeable), δ 8.64 (s, 1H, *H*C=N), δ 7.45–7.25 (m, 6H, Ar-C*H*), δ 2.51 (s, 3H, S–CH_3), δ 1.47 (s, 9H, C–CH_3) and δ 1.33 (s, 9H, C–CH_3). The ^{13}C NMR results:

16.19; 29.43; 31.49; 34.21; 35.15; 118.31; 121.70; 126.76; 127.57; 128.00; 136.76; 136.96; 140.60; 145.86; 158.22 and 162.98 ppm. IR (KBr pellets, ν_{max}/cm^{-1}): 3641–3173 ν(OH), 2958- 2864 ν(Aliph-H), 1615 ν(C=N), 1490–1440 ν(C=C), 1172 ν(C–O).

2.2.2. For (*L₂H*) ligand

^{1}H NMR (400 MHz, $CDCl_3$, Me_4Si, ppm): δ 13.59 (s, 1H, –O*H*, D-exchangeable), δ 8.63 (s, 1H, *H*C=N), δ 7.52–6.99 (m, 6H, Ar-C*H*), δ 2.53 (s, 3H, S–CH_3), δ 1.49 (s, 9H, C–CH_3) and δ 1.34 (s, 9H, C–CH_3). The ^{13}C NMR results: 14.79; 29.46; 31.49; 34.20; 35.18; 117.48; 118.39; 124.75; 125.24; 126.91; 127.06; 128.28; 134.66; 137.13; 140.51; 145.90; 158.39 and 163.28 ppm. IR (KBr pellets, ν_{max}/cm^{-1}): 3643–3172 ν(OH), 2955–2867 ν(Aliph-H), 1615 ν(C=N), 1467–1440 ν(C=C), 1173 ν(C–O).

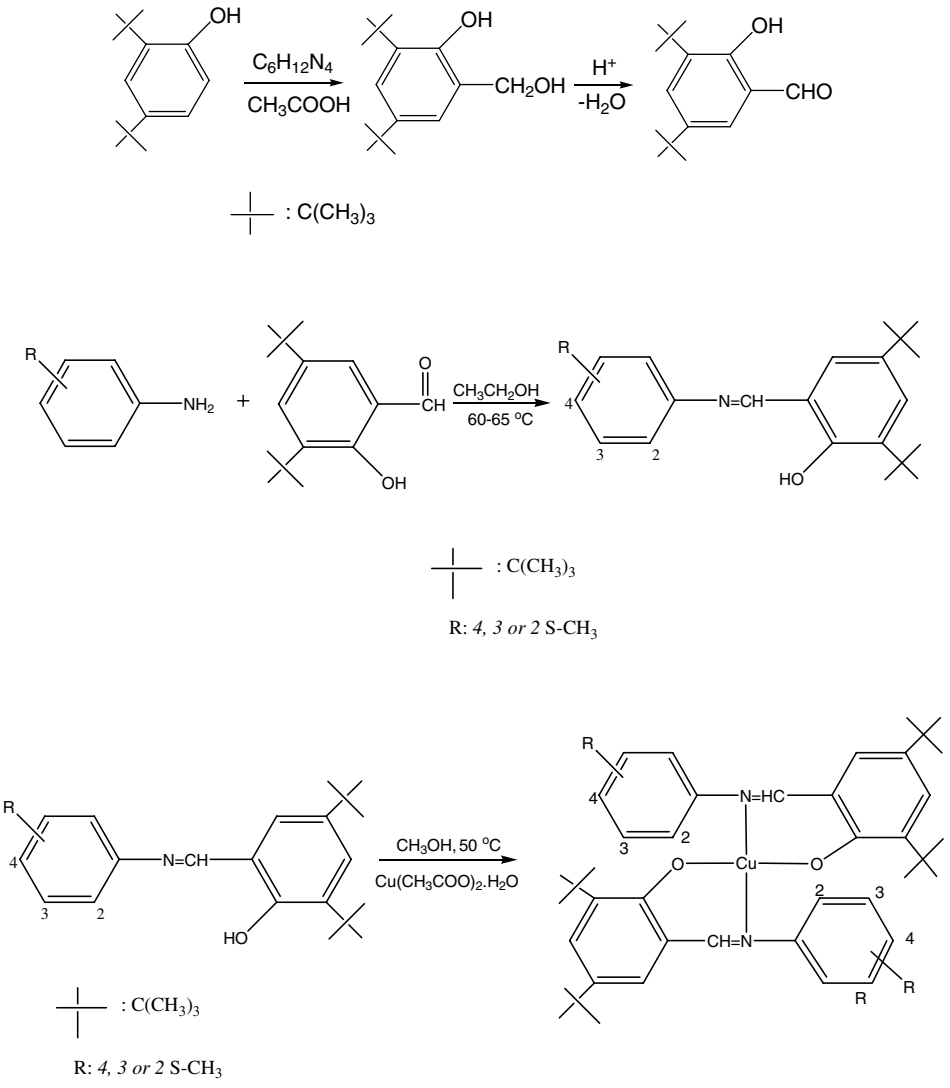
2.2.3. For *L₃H* ligand

^{1}H NMR (400 MHz, $CDCl_3$, Me_4Si, ppm): δ 13.43 (s, 1H, –O*H*, D-exchangeable), δ 8.62 (s, 1H, *H*C=N), δ 7.47–6.86 (m, 6H, Ar-C*H*), δ 2.48 (s, 3H, S–CH_3), δ 1.46 (s, 9H, C–CH_3) and δ 1.32 (s, 9H, C–CH_3). The ^{13}C NMR results: 15.73; 29.42; 31.48; 34.21, 35.12; 117.63; 118.20; 119.11; 124.41; 126.31; 128.23; 129.61; 137.02; 139.92; 140.66; 149.30; 158.28 and 164.18 ppm. IR (KBr pellets, ν_{max}/cm^{-1}): 3650–3170 ν(OH), 2957–2869 ν(Aliph-H), 1613 ν(C=N), 1467–1436 ν(C=C), 1169 ν(C–O).

2.3. Synthesis of the Cu(II) metal complexes

(0.53 g, 1.50 mmol), ligands (**L₁H**), (**L₂H**) or (**L₃H**) was dissolved in absolute methanol (45 cm^3). A solution of 0.75 mmol of the metal salt [$Cu(CH_3COO)_2 \cdot H_2O$ (0.15 g)] in absolute methanol (25 cm^3), was added dropwise under a N_2 atmosphere with continuous stirring. The stirred mixtures were then heated to the reflux temperature for 3 h and were maintained at this temperature. Then, the mixture was evaporated to a volume of 15–20 ml in vacuum and left to cool to room temperature. The compounds were precipitated after adding 5 ml ethanol. The products were filtered in vacuum and washed with a small amount of methanol and water. The products were recrystallized from ethanol. Then they were dried at 100 °C. IR (KBr pellets, ν_{max}/cm^{-1}): 2950–2851 ν(Aliph-H), 1600 ν(C=N), 1488–1456 ν(C=C), 1170 ν(C–O), 522 ν(M–O), 478 ν(M–N) for [**Cu**(**L₁**)$_2$], IR (KBr pellets, ν_{max}/cm^{-1}): 2955–2867 ν(Aliph-H), 1593 ν(C=N), 1471–1460 ν(C=C), 1170 ν(C–O), 537 ν(M–O), 482 ν(M–N). for [**Cu**(**L₂**)$_2$], IR (KBr pellets, ν_{max}/cm^{-1}): 2957–2869 ν(Aliph-H), 1594 ν(C=N), 1460–1430 ν(C=C), 1166 ν(C–O), 532 ν(M–O), 487 ν(M–N) for [**Cu**(**L₃**)$_2$].

3. Results and discussion



The reaction steps for the synthesis of the ligands and their copper complexes are given in Scheme 1. The first step is the synthesis of 3,5-di-*t*-butyl-2-hydroxybenzaldehyde (3,5-DTB) from the reaction of 2,4-di-*t*-butyl phenol with hexamethylene tetramine. In the second step; the ligands (**L₁H**), (**L₂H**) and (**L₃H**) were synthesized by the condensation of 4, 3 or 2-mercapto aniline with 3,5-di-*t*-butyl-2-hydroxybenzaldehyde. For the structural characterization of ligands (**L₁H**), (**L₂H**) and (**L₃H**) and their Cu(II) complexes [**Cu**(**L**$_n$)$_2$], elemental analysis, IR spectra, UV–Vis spectra, ^{1}H and ^{13}C NMR spectra, magnetic susceptibility measurements, molar conductivity were used and the corresponding data are given in experimental section and Tables 1 and 2. The metal to ligand ratios in the Cu(II) complexes were found to be 1:2. The ligands (**L₁H**), (**L₂H**) and (**L₃H**) on interaction with Cu(II) salt yielded complexes corresponding to the general formula [**M**(**L**$_n$)$_2$].

3.1. NMR results

The ^{1}H NMR spectral results obtained for ligands in $CDCl_3$ together the assignments are given in Section 2. The ^{1}H NMR spectra of the (**L₁H**), (**L₂H**) and (**L₃H**) in the $CDCl_3$ do not give any signal corresponding to mercapto aniline groups protons and 3,5-di-*t*-butyl-2-hydroxybenzaldehyde protons. The proton NMR spectra of the free ligands show a peak at 13.70 ppm for (**L₁H**), at 13.59 ppm for (**L₂H**) and at 13.43 ppm for (**L₃H**), characteristic of intramolecular hydrogen bonded OH proton. The peaks at range 7.45–7.25 ppm for (**L₁H**), at range 7.52–6.99 ppm for (**L₂H**) and at range 7.47–6.86 ppm for (**L₃H**) are assignable to the protons of Ar-CH as multiplet peaks. In the ^{1}H NMR spectra of ligands, the chemical shifts observed at δ 8.64 for (**L₁H**), at δ 8.63 for (**L₂H**) ppm and at δ 8.62 for (**L₃H**) is assigned to the proton of azomethine (CH=N) as singlet [16]. The peak at range 2.53–2.48 ppm for ligands are assignable to the protons of S–CH_3 groups as singlet peaks. Also, the protons of the *t*-butyl groups of ligands exhibit singlet peak at δ 1.47 and 1.33 ppm for (**L₁H**), δ 1.49 and 1.34 ppm for (**L₂H**), and δ 1.46 and 1.32 ppm for (**L₃H**), indicating that the *t*-butyl protons of these compounds are magnetically nonequivalent [17]. ^{1}H NMR and ^{13}C NMR data of the ligands are given in Section 2. The Cu(II) metal complexes are paramagnetic, thus their ^{1}H NMR and ^{13}C NMR spectra could not be obtained.

3.2. IR spectra results

The observed peaks may be classified into those originating from the ligand and those arising from the bonds formed between Cu(II) and coordinating sites. The free salicylaldimine ligands (**L₁H**), (**L₂H**) and (**L₃H**) showed strong peaks at 1615–1613 cm^{-1}, which are characteristic of the azomethine ν(C=N) group [18]. Coordination of the salicylaldimine ligands to the metal through the nitrogen atom is expected to reduce the electron density in the azomethine link and lower the ν(C=N) absorption frequency. The peak due to ν(C=N) is shifted to lower frequencies and appears around 1600–1593 cm^{-1}, indicating

Scheme 1. Synthetic route for preparation of ligands ($\mathbf{L}_n\mathbf{H}$) and their copper complexes [$\mathbf{Cu}(\mathbf{L}_n)_2$].

ther supported by the disappearance of the broad ν(OH) peak around 3650–3170 cm^{-1} in the Cu(II) metal complexes, indicating deprotonation of the phenolic proton prior to coordination [18]. The coordination of the azomethine nitrogen and phenolic oxygen are further supported by the appearance of two peaks at 537–522 cm^{-1} and 487–478 cm^{-1} due to ν(Cu–O) and ν(Cu–N) stretching vibrations that are not observed in the infrared spectra of the ligands. Thus, it is clear that the ligands ($\mathbf{L}_1\mathbf{H}$), ($\mathbf{L}_2\mathbf{H}$) and ($\mathbf{L}_3\mathbf{H}$) are bonded to the copper metal ion in a ONNO fashion through the deprotonated phenolate oxygen and salicylaldimine nitrogen.

3.3. UV–Vis spectra results

Electronic spectra of ligands ($\mathbf{L}_1\mathbf{H}$), ($\mathbf{L}_2\mathbf{H}$) and ($\mathbf{L}_3\mathbf{H}$) and their copper complexes [$\mathbf{Cu}(\mathbf{L}_n)_2$] have been recorded in the 200–900 nm range in C_2H_5OH and DMSO solutions, and presented in Fig. 1. The corresponding data are also listed in Table 2. Each ligands and their copper complexes show several intense absorptions in the visible and ultraviolet region. The UV–Vis spectra of the ligands in C_2H_5OH and DMSO showed five absorption bands between 206 and 365 nm, and two or four absorption bands between 253 and 366 nm, respectively. The electronic spectra of the Cu(II) metal complexes in C_2H_5OH and DMSO solutions showed four-seven absorption bands between 216 and 698 nm. In the electronic spectra of the ligands and their copper complexes, the wide range bands seem to be due to both the $\pi\rightarrow\pi^*$ and $n\rightarrow\pi^*$ of C=N chromophore or change-transfer transition arising from π electron interactions between the metal and ligand which involves either a metal-to-ligand or ligand-to-metal electron transfer and d–d transitions [20,21]. In the electronic spectra of ligands and their copper complexes, the absorption bands below 366 nm for ligands and the absorption bands below 426 nm for copper complexes have high extinction coefficients in C_2H_5OH and DMSO solutions and are almost certainly associated with intraligand $\pi\rightarrow\pi^*$ and $n\rightarrow\pi^*$ or charge-transfer transitions [22]. The absorption bands below 276 nm in C_2H_5OH are practically identical and can be attributed to $\pi\rightarrow\pi^*$ transitions in the benzene ring or azomethine (–C=N) groups for ligands. The absorption bands observed within the range of 342–365 nm in C_2H_5OH are most probably due to the transition of $n\rightarrow\pi^*$ of imine group corresponding to the ligands [23]. In the spectra of Cu(II) metal complexes the bands observed within the range of 297–317 nm in C_2H_5OH and DMSO solutions are most probably due to the transition of $n\rightarrow\pi^*$ of imine group corresponding to the metal complexes [23]. For copper complexes, the absorption bands in the range of 413–429 nm are assigned to M→L charge-transfer (MLCT) or L→M charge-transfer (LMCT) [24], respectively. The absorption bands observed at lower energy and in lower intensities between 682 and 803 nm may be attributed to the d–d transitions ($d_{xy} \rightarrow d_{x^2-y^2}$ and $d_{z^2} \rightarrow d_{x^2-y^2}$). On complex formation, the electronic spectra of the copper complexes exhibited significantly different absorption bands compared to those of the ligands in C_2H_5OH and DMSO solutions. As expected, the new bands in the range of 413–429 nm arising from M→L charge-transfer (MLCT) or L→M charge-transfer (LMCT) transitions were observed as a result of coordination of copper metal through azomethine nitrogen. Examples of UV–Vis spectra of the ligands and their copper metal complexes were presented in Fig. 1.

3.4. Magnetic moments

Magnetic susceptibility measurements provide sufficient data to characterize the structure of the metal complexes. Magnetic moments measurements of compounds carried out at 25 °C. The room temperature magnetic moments of Cu(II) metal complexes in the range of 1.82–1.90 B.M which were typical for mononuclear of Cu(II) compounds with a $S = 1/2$ spin state and did not indicate antiferromagnetic coupling of spin at this temperature. These results are comparable to the values reported for slightly distorted tetrahedral geometry [25].

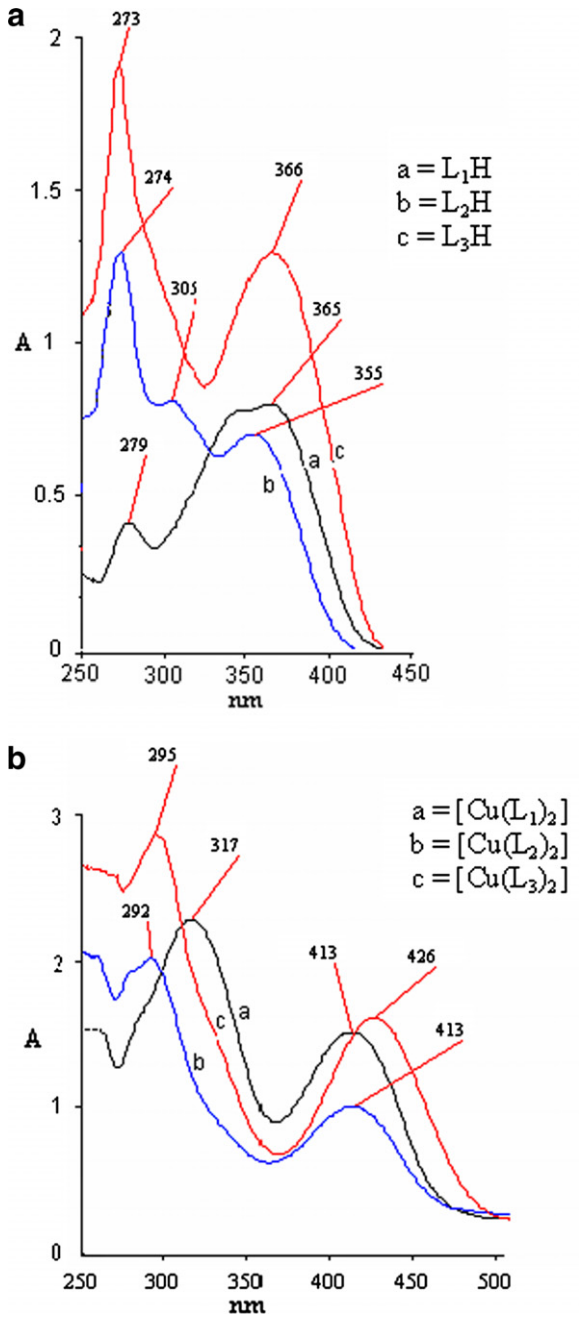

Fig. 1. UV–Vis spectra of ligands ($\mathbf{L}_n\mathbf{H}$) (a); Cu(II) metal complexes $[\mathbf{Cu}(\mathbf{L}_n\mathbf{H})_2]$ in DMSO (b).

3.5. Solubility and molar conductivity

The Ligands ($\mathbf{L}_1\mathbf{H}$), ($\mathbf{L}_2\mathbf{H}$) and ($\mathbf{L}_3\mathbf{H}$), and their Cu(II) metal complexes $[\mathbf{Cu}(\mathbf{L}_n)_2]$ are soluble in C_2H_5OH, CH_3OH, DMSO and DMF solvents. With a view to studying the electrolytic nature of the Cu(II) metal complexes, their molar conductivities were measured in DMF (dimethyl formamide) at 10^{-3} M. The molar conductivities (Λ_M) values of these Cu(II) metal complexes are in the range of 19–26 Ω^{-1} cm^2 mol^{-1} at room temperature [26], indicating their almost non-electrolytic nature. Due to not free ions in Cu(II) metal complexes, the results indicate that Cu(II) metal complexes are very poor in molar conductivity.

3.6. Electrochemistry

The electrochemistry of the ligands ($\mathbf{L}_n\mathbf{H}$) and their copper complexes $[\mathbf{Cu}(\mathbf{L}_n)_2]$ ($n = 1, 2, 3$) were studied by the cyclic voltammetry in the scan rates of 0.025–0.50 V s^{-1} in DMSO solution containing 0.1 M TBAP supporting electrolyte. The cyclic voltammograms (CVs) of the ligands are depicted in Figs. 2 and 3 at 0.025 V s^{-1} scan rate. As seen, all ligands exhibited one irreversible reduction processes without corresponding anodic waves. The redox processes of the ligands are based on the reduction of the azomethine nitrogen in the presence of the phenolic proton in the molecule. Mostly, the process results in the reductive

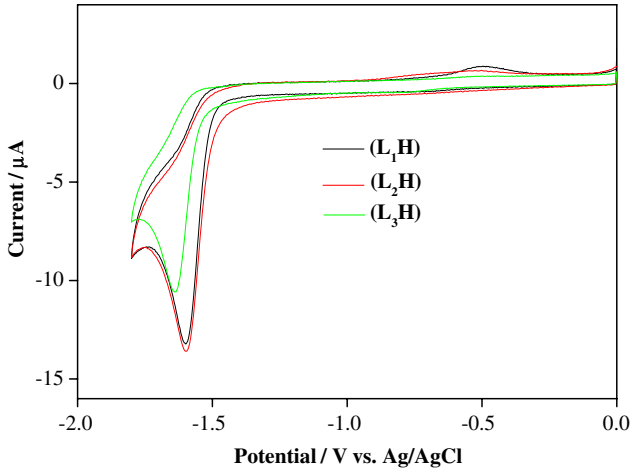

Fig. 2. Cyclic voltammograms (CVs) of the ligands ($\mathbf{L}_n\mathbf{H}$) in DMSO containing 0.1 M TBAP. Scan rates: 0.025 V s^{-1}. Working electrode: a 1.6 mm diameter of platinum disc electrode. $c = 9.4 \times 10^{-3}$ M.

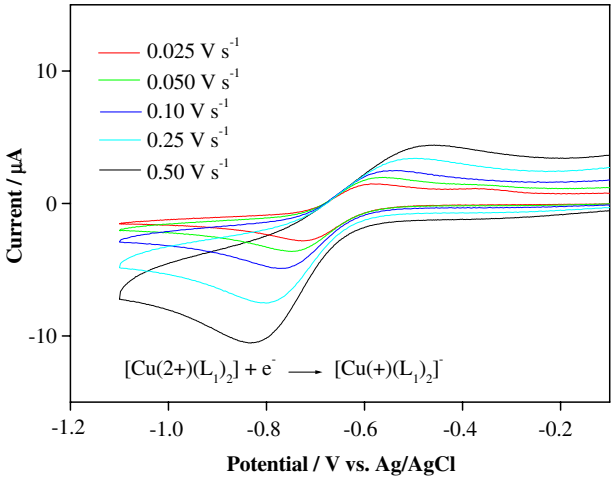

Fig. 3. Cyclic voltammograms (CVs) of the copper complexes $[\mathbf{Cu}(\mathbf{L}_n)_2]$ in DMSO containing 0.1 M TBAP. Scan rates: between 0.025 and 0.50 V s^{-1}. Working electrode: a 1.6 mm diameter of platinum disc electrode. $c = 4.3 \times 10^{-3}$ M.

coupling of the reduced species as previously observed for some Schiff bases such as Salen or its derivatives, indicating irreversible fashion of the processes [27]. However, the reduction process is probably assigned to the electro-deprotonated ligand anion at the platinum surface. The ligands ($\mathbf{L_1H}$), ($\mathbf{L_2H}$), and ($\mathbf{L_3H}$) displayed the cathodic peak potentials at $E_{pc} = -1.60$, -1.60, and -1.64 V versus Ag/AgCl, respectively. It is known that the introduction of electron-donating groups to the electroactive molecules is expected to lead to an increase of electron density in the molecule, thereby making the molecule easier to oxidize and harder to reduce [28–32]. On the other hand, the positions of the substituent on the benzene ring may also effect peak potentials in different extent. This effect was clearly demonstrated by the fact that the cathodic peak potential of ($\mathbf{L_3H}$) was shifted towards more negative potentials compared to those of ($\mathbf{L_1H}$) and ($\mathbf{L_2H}$). It is attributed to the weak-electron-donating methyl sulfanyl group substituted on the *ortho* position of benzene ring. An example of the cyclic voltammograms (CVs) of the copper complexes [$\mathbf{Cu}(\mathbf{L}_n)_2$] in the scan rates of 0.025–0.50 V s^{-1} are exhibited in Fig. 3. The data corresponding to the cyclic voltammograms (CVs) of [$\mathbf{Cu}(\mathbf{L}_n)_2$] are listed in Table 3. All copper complexes showed one quasi-reversible one-electron reduction process in the scan rates of 0.025–0.50 V s^{-1}, which are assigned to simple metal-based one-electron processes; $[Cu(2+)(L_n)_2] + e^- \rightarrow [Cu(1+)(L_n)_2]^-$. The half-wave potentials ($E_{1/2}$) of the reversible Cu(2+)/Cu(1+) redox couples were calculated as the average of the cathodic and anodic peak potentials of the processes. The $E_{1/2}$ of the reduction processes of [$\mathbf{Cu}(\mathbf{L}_1)_2$], [$\mathbf{Cu}(\mathbf{L}_2)_2$], and [$\mathbf{Cu}(\mathbf{L}_3)_2$] are -0.65, -0.65, and -0.68 V versus Ag/AgCl (scan rate 0.025 V s^{-1}), respectively. As seen, $E_{1/2}$ of [$\mathbf{Cu}(\mathbf{L}_3)_2$] was negatively shifted compared to those of [$\mathbf{Cu}(\mathbf{L}_1)_2$], [$\mathbf{Cu}(\mathbf{L}_2)_2$], as observed for the ligands. Although the reduction processes had low ratio of anodic-to-cathodic peak currents (i_{pa}/i_{pc}) (Table 3), the anodic–cathodic peak separations (ΔE) for the Cu(2+)/Cu(1+) couples are 0.100–105 V (scan rate 0.025 V s^{-1}) which assign to the quasi-reversible processes. The slow electron transfer could be associated with a structural rearrangement of the molecule during the reduction process. The reduction processes of ($\mathbf{L}_n\mathbf{H}$) and [$\mathbf{Cu}(\mathbf{L}_n)_2$] are diffusion controlled with the anodic current function ($I_{pa}/v^{1/2}$) independent of the scan rate (v) over the scan range 0.025–0.500 V s^{-1} [33–37].

3.7. In situ UV–Vis behaviors of the electro-reduced ligands and complexes

"The spectroelectrochemical behaviors of ligands ($\mathbf{L}_n\mathbf{H}$) and their copper complexes [$\mathbf{Cu}(\mathbf{L}_n)_2$] were investigated using a thin-layer UV–Vis spectroelectrochemical technique in DMSO solution containing 0.2 M TBAP. The UV–Vis spectral changes for the reduced species of ($\mathbf{L}_n$) and [$\mathbf{Cu}(\mathbf{L}_n)_2$] were obtained in a thin-layer cell during applied potentials. The absorption spectra of electrochemically generated species, $(\mathbf{L_1H})^-$ and $[\mathbf{Cu}(+)(\mathbf{L}_1)_2]^-$, are given in Figs. 4 and 5. The convenient values of applied potentials for in situ spectroelectrochemical experiment were determined for the reduction processes by taking CVs of the complexes in the thin-layer cell.

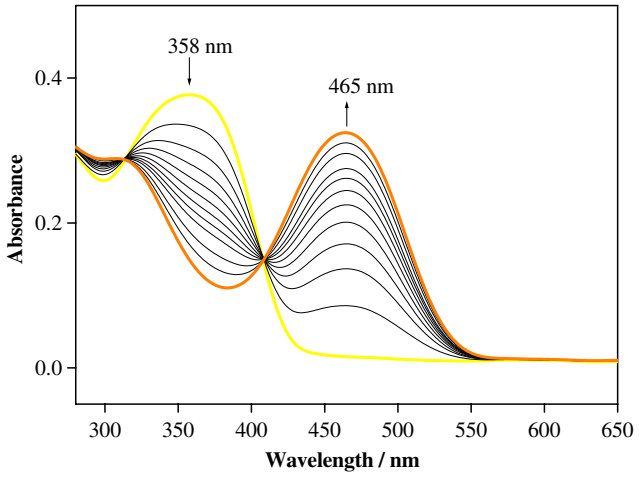

Fig. 4. Time-resolved UV–Vis spectra of ($\mathbf{L_1H}$) during the first reductions at $E_{app} = -1.80$ V in DMSO containing 0.2 M TBAP.

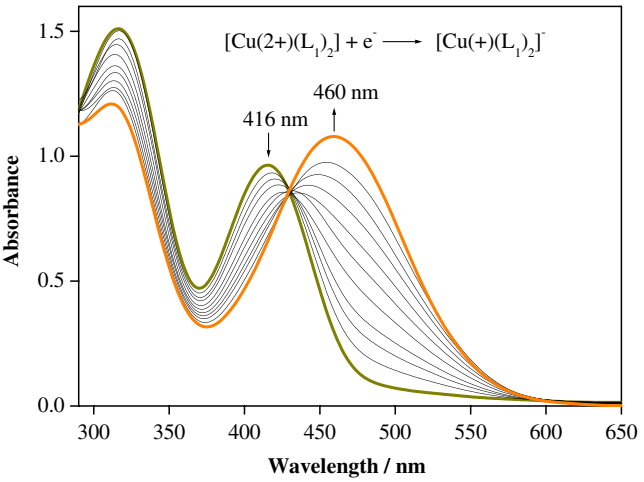

Fig. 5. Time-resolved UV–Vis spectra of [$\mathbf{Cu}(\mathbf{L}_1)_2$] during the first reductions at $E_{app} = -1.00$ V in DMSO containing 0.2 M TBAP.

Fig. 4 shows changes in the electronic spectrum of ($\mathbf{L_1H}$) during reduction process in the thin-layer cell. The well-defined isosbestic point is observed at 408 nm, confirming that the electrode reaction proceeds in a quantitative fashion and therefore the absence of any coupled chemistry [28,29,33,37–39]. When the potential ($E_{app} = -1.80$ V) was applied in the thin-layer cell, the broad band at 358 nm belonging to the $n\rightarrow\pi^*$ transitions of the azomethine (CH=N), disappeared and new bands at 465 and at 315 nm formed during the reduction process. The 465 nm-peak was observed at longer wavelength compared with the neutral ligand, which clearly indicates a reduced product having extended conjugation. The original spectrum corresponding to the neutral ligand was 60% recovered when the potential was applied at $E_{app} = -1.80$ V for the re-oxidation process, indicating decomposition or chemical change of the electro-generated reduced species at the some extent in the time scale of the reduction process. This behavior confirms the irreversible nature of the reduction process observed for the CV of the ligands. Similar spectral changes were observed for ($\mathbf{L_1H}$) and ($\mathbf{L_2H}$) during their reduction processes in the same experimental conditions.

Fig. 5 shows the time-resolved spectra of [$\mathbf{Cu(L_1)_2}$] during the applied potential at $E_{app} = -1.00$ V. The copper complexes showed two main bands at about 316 nm and 416 nm the former of which was referred to the $n\rightarrow\pi^*$ transitions of the azomethine (CH=N) group and the charge-transfer transitions. As expected, the latter band was red-shifted compared to those of the ligands, indicating coordination of the azomethine nitrogen to the copper metal. After reduction, the Cu(II)(d^9)→Cu(I)(d^{10}) process was formed by adding one electron in the metal system. This change resulted in an appearance of the absorption band at 460 nm which was attributed to a metal to ligand charge-transfer transitions (MLCT) in Cu(I) complex. Also, the intensity of the band at 316 nm was decreased during the reduction process. All complexes exhibited similar spectral changes during the reduction processes in the thin-layer cell. The spectral changes were similar to what were observed for a metal-centered reduction Cu(II)→Cu(I) processes in the literature [40–42]. The original spectra of the complexes were obtained upon re-oxidation during spectroelectrochemical measurement. It is concluded that the singly-reduced species remains stable and is not companied by a chemical reaction in the time scale of the spectroelectrochemical measurement. The controlled potential coulometric (CPC) study indicated that the number of electrons transferred for the forward and reverse electrochemical reaction of the complexes was one for the reduction and re-oxidation processes based on the Cu(II)/Cu(I) couples.

4. Conclusion

New sterically constrained Schiff-base ligands ($\mathbf{L_nH}$) ($n = 1$, 2, and 3) (L = *N*-[*m*-(methylmercapto)aniline]-3,5-di-*t*-butylsalicylaldimine, $m = 4$, 3, and 2 positions, respectively) and their copper(II) complexes [$\mathbf{Cu(L_n)_2}$] were synthesized and their electro-spectrochemical properties were investigated using cyclic voltammetric and thin-layer spectroelectrochemical techniques in DMSO. Besides the classical methods such as FT-IR, UV–Vis, ^{1}H and ^{13}C NMR, elemental analysis, magnetic susceptibility, and molar conductivity for structural characterization, the combination of the electrochemical and spectroelectrochemical methods provided a power tool to reveal the complementary nature of the molecular structure and electron-transfer reactions of the reduced species of new electroactive Schiff-bases and their Cu(II) complexes. So the comparative electro-spectrochemical studies revealed that [$\mathbf{Cu(L_n)_2}$] complexes showed four coordination with the ligand ($\mathbf{L_nH}$) having N and O donor sites, and a shift on their half-wave potentials or band positions because of different positions of methylsulfanyl groups attached on benzene ring. The electro-reduced species of [$\mathbf{Cu(L_n)_2}$] complexes remained stable during spectroelectrochemical time scale although the corresponding ligands exhibited an irreversible reduction processes in their CV measurements. Finally, the CVs and the well-defined spectral changes observed during applied potentials in the thin-layer cell spectral data supported the corresponding structures of the copper complexes.

obtain because of its very small interwoven needles which makes the obtainment of single crystal studies difficult [3,7–9]. Harding showed that the positions of Cu in the structure of aurichalcite are octahedrally coordinated [9]. The atom positions occupied by zinc have tetrahedral coordination [9].

Raman spectroscopy has proven very useful for the study of minerals [10–12]. Indeed Raman spectroscopy has proven to be most useful for the study of diagentically related minerals as often occur with carbonate minerals [13–17]. Some previous studies have been undertaken by the authors using Raman spectroscopy to study complex secondary minerals formed by crystallisation from concentrated sulphate solutions [18]. The authors have undertaken some comprehensive studies of selected carbonate minerals [19–23]. The importance of this work rests with the application of Raman spectroscopy to the study of minerals and inorganic compounds which show no or limited symmetry [19,24–31].

As part of our comprehensive research on the molecular structure of secondary minerals, we report the synthesis and characterisation of Ni doped aurichalcite $(Zn^{2+},Cu^{2+},Ni^{2+})_5(CO_3)_2(OH)_6$ using Raman spectroscopy and X-ray diffraction.

2. Experimental

2.1. Synthesis of Ni containing aurichalcite

The mineral $(Cu,Zn,Ni^{2+})_5(CO_3)_2(OH)_6$ was synthesised with a respective metal ratio of 3:16:1. Williams inferred from the studies of natural aurichalcite minerals that the highest ratio of Cu to Zn in aurichalcite is 1:3 [5]. The authors have successfully synthesized aurichalcites with varying Cu/Zn ratios up to Cu:Zn 1:1. A common formula for natural aurichalcite is $Cu_{1.25}Zn_{3.75}(CO_3)_2(OH)_6$. Williams also reported a natural aurichalcite which contained Ni as the dopant ion.

Synthesis of ideal products was modelled on the procedure by Fujita et al. [32]. A solution of metal ions (M^{2+}) was prepared by mixing appropriate concentrations of 1.5 M $Ni(NO_3)_2$, $Cu(NO_3)_2$, and $Zn(NO_3)_2$ that correspond to the desired metal concentrations required in products. Synthesis of the lower nickel concentrations of aurichalcite was carried out by adding dropwise 100 cm^3 of a 1.5 M M^{2+} solution via a peristaltic pump to 1000 cm^3 of 0.2 M HCO_3^- solution at 60 °C. The relatively sensitive nature of aurichalcite to acidic (pH < 6) conditions precluded the use of the depleting methods mentioned in the literature [33] to obtain optimum yields of high phase purity Ni containing aurichalcite. As such, a stream of saturated sodium bicarbonate was added at a quasi-constant rate to maintain a pH ≈7.15. Samples were vacuum filtered and washed with hot, degassed, demineralised water. Samples were then dried overnight at 40 °C. The samples were phase analysed by X-ray diffraction and for chemical composition by EDX measurements.

2.2. X-ray diffraction

Powder X-ray diffraction analyses were performed on a Phillips X-ray diffractometer (radius: 173.0 mm). Incident X-ray radiation was produced from a long fine focused C-Tech PW1050 Co X-ray tube, operating at 40 kV and 32 mA. The incident beam passed through a 1° divergence slit, a 15 mm fixed mask and a 1° fixed anti scatter slit. After interaction with the sample, the diffracted beam was detected by a proportional detector with a 0.2 mm receiving slit fitted to a graphite post-diffraction monochrometer. The detector was set in scanning mode, with an active length of 2.022 mm. Samples were analysed utilising Bragg–Brentano geometry over a range of 3–75° 2θ with a step size of 0.02 ° 2θ, with each step measured for 200 s.

2.3. SEM and EDX

Mineral samples were coated with a thin layer of evaporated carbon and secondary electron images were obtained using an scanning electron microscope (FEI Quanta 200 SEM, FEI Company, Hillsboro, OR, USA). For X-ray microanalysis (EDX), three samples were embedded in Araldite resin and polished with diamond paste on Lamplan 450 polishing cloth using water as a lubricant. The samples were coated with a thin layer of evaporated carbon for conduction and examined in a JEOL 840A analytical SEM (JEOL Ltd., Tokyo, Japan) at 25 kV accelerating voltage. Preliminary analyses of the carbonate mineral samples were carried out on the FEI Quanta SEM using an EDAX X-ray microanalyser, and microanalyses of the clusters of fine crystals were carried out using a full standard quantitative procedure on the JEOL 840 SEM using a JEOL-2300 energy-dispersive X-ray microanalysis system (JEOL Ltd., Tokyo, Japan). Oxygen was not measured directly but was calculated using assumed stoichiometry of the other elements analysed.

2.4. Raman microprobe spectroscopy

The crystals of aurichalcite were placed and oriented on the stage of an Olympus BHSM microscope, equipped with 10× and 50× objectives and part of a Renishaw 1000 Raman microscope system, which also includes a monochromator, a filter system and a Charge Coupled Device (CCD). Raman spectra were excited by a HeNe laser (633 nm) at a resolution of 2 cm^{-1} in the range between 100 and 4000 cm^{-1}. Repeated acquisition using the highest magnification was accumulated to improve the signal to noise ratio. The spectra were calibrated using the 520.5 cm^{-1} line of a silicon wafer. To ensure that the correct spectra are obtained, the incident excitation radiation was scrambled. Details of the technique have been published by the authors.

2.5. Mid-IR spectroscopy

Infrared spectra were obtained using a Nicolet Nexus 870 FTIR spectrometer with a smart endurance single

bounce diamond ATR cell. Spectra over the 4000–525 cm^{-1} range were obtained by the co-addition of 128 scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectra were co-added to improve the signal to noise ratio.

Spectral manipulation such as baseline adjustment, smoothing and normalisation was performed using the Spectracalc software package GRAMS (Galactic Industries Corporation, NH, USA). Band component analysis was undertaken using the Jandel Scientific 'Peakfit' software package, which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done using a Lorentz–Gauss cross-product function with the minimum number of component bands used for the fitting process. The Gauss–Lorentz ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations of r^2 greater than 0.995. The reason for using this type of mathematical function is that this function best fits vibrational spectroscopic data where the central peak is Lorentzian and the wings of the peak are Gaussian. It should be noted that where sharp bands are obtained in the Raman spectra fitting is unique. If one starts with different starting parameters, then the fit will converge to a unique result. When bands are broad the uniqueness of the fit is open to question. Band fitting offers a procedure to determine the exact position of bands.

3. Results and discussion

3.1. X-ray diffraction

The X-ray diffraction patterns of the Ni-aurichalcite together with the reference standard 00-038-0154 are shown in Fig. 1. Clearly, the synthesised mineral is aurichalcite. From the X-ray diffraction data, we can safely assume that the Ni replaces some of the octahedral sites in the crystal structure as the data match so closely with $(Cu_{0.2}Zn_{0.8})_5(CO_3)_2(OH)_6$. At some stage in the future it might be worth another look to see if more nickel can be introduced into the aurichalcite structure by altering the synthesis conditions slightly. The additional peaks in the XRD patterns may be due to the trace of carbonates of zinc and copper.

3.2. Raman spectroscopy

Only a very limited number of Raman studies have been reported on the carbonate anion in hydroxycarbonate type minerals such as hydrozincite and aurichalcite [1,34–39]. When the carbonate species is present as a free ion not involved in any bonding it will exhibit a space group of D_{3h}. In the Raman spectrum, one will observe $\nu_1(A_1')$, $\nu_3(E')$ and $\nu_4(E')$. As a result three bands—the bending non-planar mode $\nu_2(A''2)$, the antisymmetrical stretching mode $\nu_3(E')$ and the bending angular mode $\nu_4(E')$—will be observed in the infrared spectrum around 880, 1415 and 680 cm^{-1}, respectively, while the symmetric stretching mode $\nu_1(A_1')$ is infrared inactive. However, changes can be expected when the carbonate ion is bonded in a mineral structure as it will be affected by interactions with water molecules and OH-groups. In comparison with free CO_3^{2-}, a shift towards lower wavenumbers is generally observed for the carbonate anion in minerals. Interaction between interlayer water molecules and the carbonate ion is reflected by the presence of bands in the OH-stretching region of the infrared spectrum around 3000–3100 cm^{-1}. The shift towards lower wavenumbers indicates a loss of freedom compared to the free CO_3^{2-} and as a consequence, a lowering of the carbonate symmetry from D_{3h} to probably C_{2s} or C_v.

The Raman spectrum of the Ni-aurichalcite is shown in Fig. 2. An intense band at 1070 cm^{-1} is assigned to the ν_1 symmetric stretching mode of the carbonate unit. The band displays some asymmetry on the low wavenumber side of this peak. In the Raman spectrum of natural aurichalcite, two bands were observed at 1060 and 1070 cm^{-1}. The

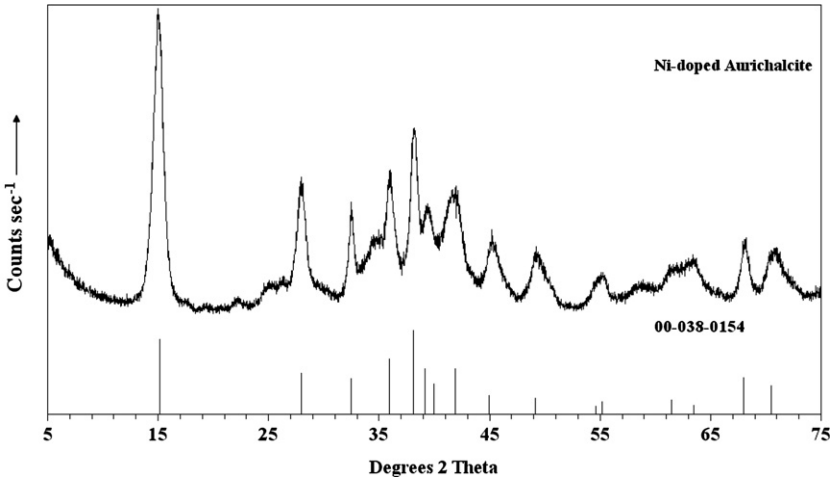

Fig. 1. X-ray diffraction patterns of Ni doped aurichalcite.

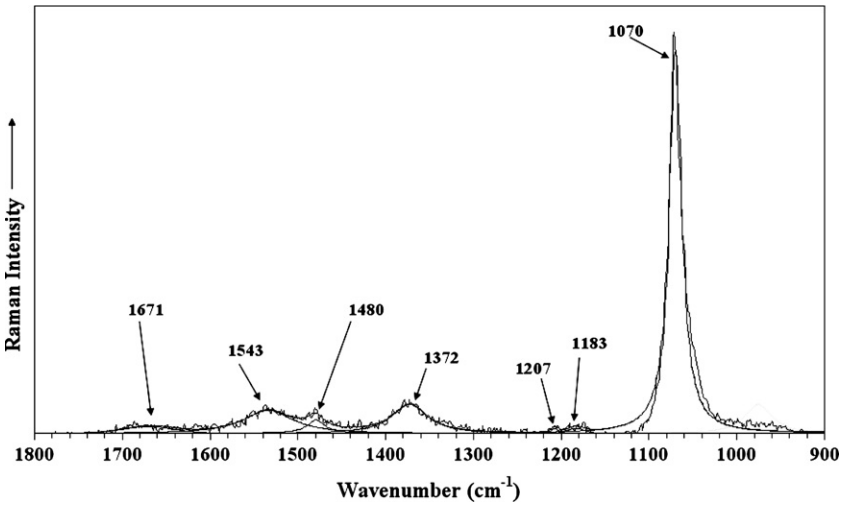

Fig. 2. Raman spectrum of Ni doped aurichalcite in the 900 to 1800 cm^{-1} region.

former band was attributed to the Raman activated δOH deformation mode. It is possible that for the Ni-aurichalcite the two bands overlap and cannot be resolved. Little information on the Raman spectra of aurichalcite is available. Bouchard and Smith published a Raman spectrum of an aurichalcite of unknown origin with an intense peak observed at 1074 cm^{-1} [40]. In the infrared spectrum of the synthesised Ni-aurichalcite (Fig. 3) a low intensity band is resolved at 1049 cm^{-1} whcih may be the infrared activated band equivalent to the Raman v_1 symmetric stretching mode. In the infrared spectrum of natural aurichalcite, a low intensity band is observed at around 1084 cm^{-1} as a shoulder on an infrared spectral profile which is dominated by bands at 1032 cm^{-1} attributed to the δOH deformation mode. The number of bands observed in this spectral region may be attributed to the structural distortion of the mineral. Raman spectra of aurichalcite should be similar to that of the other hydroxy carbonates such as the rosasite mineral group [19,20,28,41]. For rosasite, two intense Raman bands were observed at 1096 and 1056 cm^{-1}. In the infrared spectrum of an aurichalcite from Arizona, two intense bands are observed at 1084 and 1029 cm^{-1} with an additional band at 924 cm^{-1}. The first band at 1084 cm^{-1} is assigned to the v_1 symmetric stretching mode of the carbonate unit. Bands have been observed in the infrared spectra of malachite at 1095 cm^{-1} and for azurite 1090 cm^{-1} [42,43]. The infrared spectrum of hydrocerrusite showed an intense band at 1090 cm^{-1} [44]. Interestingly, the $(CO_3)^{2-}v_1$ band of the aurichalcite mineral should not be infrared active. However, because of symmetry reduction of the carbonate anion the band becomes activated. The intense Raman band observed at 1096 cm^{-1} for rosasite is assigned to the v_1 $(CO_3)^{2-}$ symmetric stretching vibration.

A number of low intensity bands are observed in the 1300–1500 cm^{-1} region (Fig. 2). Bands are observed at 1372, 1480 and 1543 cm^{-1} for the Ni-aurichalcite. These bands may be ascribed to the $v_3(CO_3)^{2-}$ antisymmetric

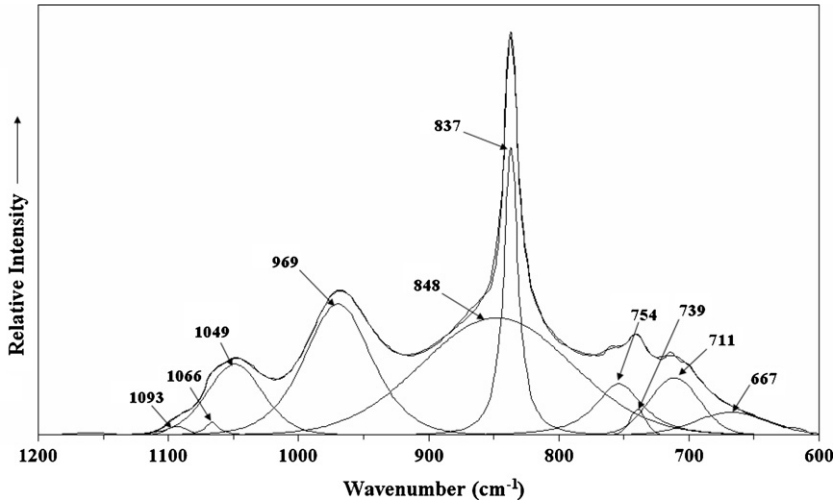

Fig. 3. Infrared spectrum of Ni doped aurichalcite in the 600 to 1200 cm^{-1} region.

stretching modes. Three bands are observed for a natural aurichalcite from Durango at 1506, 1485 and 1337 cm^{-1}. Two very low intensity bands are additionally observed at 1183 and 1207 cm^{-1}. These bands may result from an impurity remaining after the synthesis of the Ni-aurichalcite. The broad band at 1671 cm^{-1} is ascribed to the water bending mode. Such a band for water is found at 1625 cm^{-1}. The observation of the band at 1671 cm^{-1}, a significantly higher wavenumber implies that water is very strongly hydrogen bonded to the aurichalcite surface. In the infrared spectrum in the 1200–1800 cm^{-1} region shown in Fig. 4, intense infrared bands are observed at 1360, 1404, 1482 and 1511 cm^{-1}. These bands are attributed to the v_3 $(CO_3)^{2-}$ antisymmetric stretching modes of the Ni-aurichalcite. The number of bands in this spectral region is attributed to the lack of symmetry of the carbonate anion in the aurichalcite structure. The presence of multiple bands indicates the existence of the carbonate ion in more than one symmetry i.e. two carbonate units exist which are not crystallographically equivalent. In the spectrum reported by Bouchard and Smith, two bands were reported at 1511 and 1479 cm^{-1}. Their spectra showed low signal due to noise, and any low intensity bands would not be observed [40].The observation of multiple sets of bands for the synthetic Ni-aurichalcite suggests that two different carbonate units are in the Ni-aurichalcite structure. A broad band at 1646 cm^{-1} is assigned to the water bending modes. The low intensity of this band suggests that the amount of adsorbed water is low. As for the Raman spectrum the position of the band is higher than that for water. The question arises as to whether water is bonded in the structure of the aurichalcite replacing some of the OH units.

The Raman bands in the low wavenumber region for Ni-aurichalcite are shown in Fig. 5. The v_2 bending modes for carbonates vary from around 890 to 850 cm^{-1}. A single

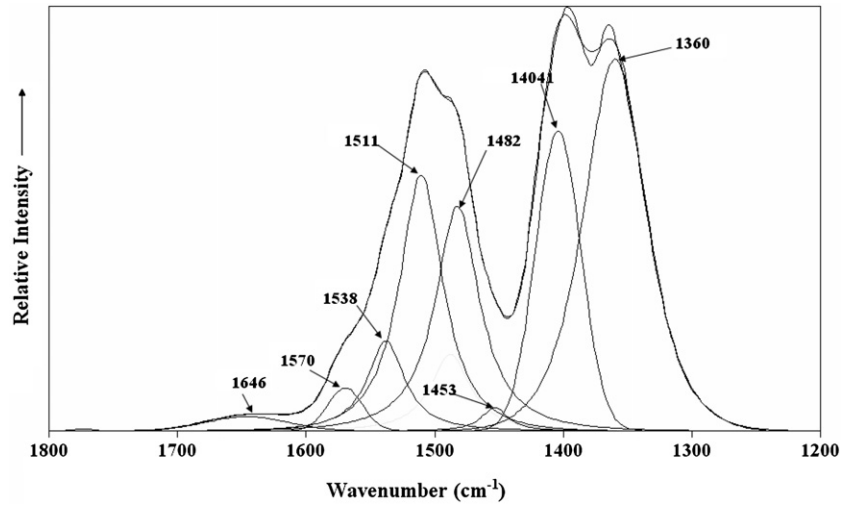

Fig. 4. Infrared spectrum of Ni doped aurichalcite in the 1200 to 1800 cm^{-1} region.

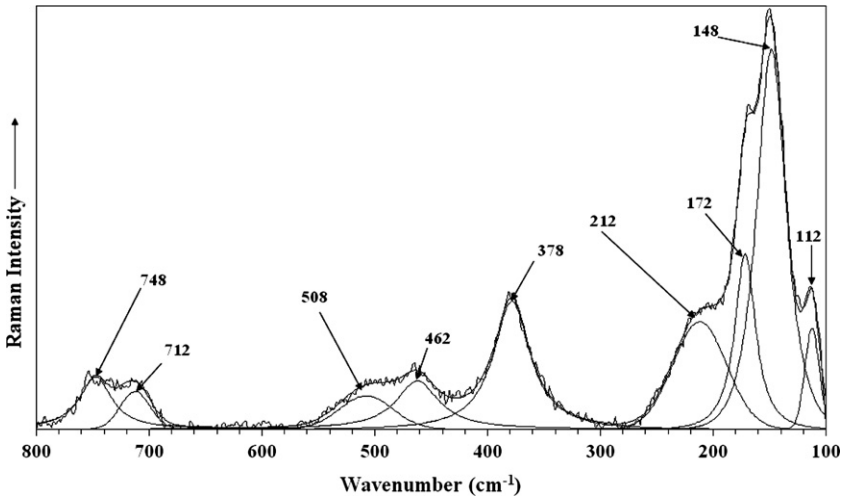

Fig. 5. Raman spectrum of Ni doped aurichalcite in the 100 to 800 cm^{-1} region.

band is observed for Ni-aurichalcite at 855 cm^{-1} assigned to the v_2 bending mode. The band is observed at 860 cm^{-1} for a natural aurichalcite from Arizona. The position of the band for natural aurichalcites appears to vary and probably is a result of crystal strain. It is probable that more than one band is observed in this region; however, the intensity of the band is so low that it makes band fitting difficult. Multiple bands are observed for the carbonate v_4 in phase bending modes in the Raman spectrum of Ni-aurichalcite. Two bands are observed at 712 and 748 cm^{-1}.

A similar result is obtained for natural aurichalcites. For the Durango aurichalcite, three bands are observed at 752, 733 and 708 cm^{-1}; for the Arizona aurichalcite, 748, 737 and 710 cm^{-1}; and for the Chihuahua aurichalcite, 753, 733 and 711 cm^{-1}. The number of bands observed in this spectral region may be attributed to the structural distortion of the mineral. A comparison may be made with other carbonate containing minerals. Only a single band at 817 cm^{-1} is observed in this region for malachite. The infrared spectrum of malachite showed two bands at 879 and 821 cm^{-1} [42]. This infrared spectral region is more complex for azurite with bands observed at 872, 837, 815 and 796 cm^{-1}. This complexity is again ascribed to the loss of degeneracy. The equivalent Raman bands for malachite are observed at 752 and 717 cm^{-1}. In the infrared spectra, bands are observed at 779, 754 and 701 cm^{-1} for azurite and at 780, 750 and 715 cm^{-1} for malachite [42].

The Raman spectra of the low wavenumber region reported in Fig. 5 are expected to show bands associated with CuO and ZnO stretching and bending vibrations. Strong Raman bands for Ni-aurichalcite are observed at 378, 462 and 508 cm^{-1}. Strong bands are observed for auricahlcite at around 498, 460 and 390 cm^{-1}.

In the structure reported by the authors [28], there are three structurally distinct MO stretching vibrations. The M3 site is a solely Zn site. The M1, M2 and M4 sites are shared randomly between Cu and Zn [45]. The above bands are associated with these CuO and ZnO stretching modes. Bouchard and Smith [40] reported the Raman bands at 389, 463 and 503 cm^{-1} which are in agreement with the band positions reported here for Ni-aurchalcite; however no assignments were offered by Bouchard and Smith. The number of bands observed in this spectral region may be attributed to the structural distortion of the mineral. In addition strong Raman bands for Ni-aurichalcite are observed at 112, 148, 172 and 212 cm^{-1}. These bands are attributed to ONiO and OZnO bending vibrations. Two intense bands are observed for natural aurichalcite at around 166 and 142 cm^{-1}. These bands are assigned to the OCuO and OZnO bending vibrations.

The Raman spectra of the OH stretching region of Ni-aurichalcite mineral is shown in Fig. 6. Two broad and quite noisy bands are found at 3362 and 3559 cm^{-1}. The low intensity bands at 2860, 2894 and 2926 cm^{-1} are assigned to CH stretching vibrations of an organic impurity. In the infrared spectrum (Fig. 7) two bands are displayed at 3312 and 3392 cm^{-1}. A comparsion may be made between the spectra of the hydroxyl stretching region of the synthetic Ni-aurichalcite and some selected natural aurichalcites. A single symmetric band is observed for the natural aurichalcite from Durango at 3338 cm^{-1} which may be compared with the value of 3348 cm^{-1} for the Arizona aurichalcite and 3355 cm^{-1} for the aurichalcite from Chihuahua. A comparison can be made with rosasite where two distinct bands are observed at 3387 and 3319 cm^{-1}. The bands are assigned to the OH stretching vibration. Bouchard and Smith reported a noticeably broad band in the Raman spectrum of aurichalcite at 3331 cm^{-1} [40]. This value is in good agreement with the results reported in this work. In the infrared spectra, more complexity is observed. Infrared bands for the Durango aurichalcite are observed at 3491, 3350, 3244 and a broad band at 3173 cm^{-1}. The infrared spectrum of the sample from Chihuahua gave bands at 3359, 3249 and 3106 cm^{-1}. The broad band at around 3002 cm^{-1} may be ascribed to adsorbed water.

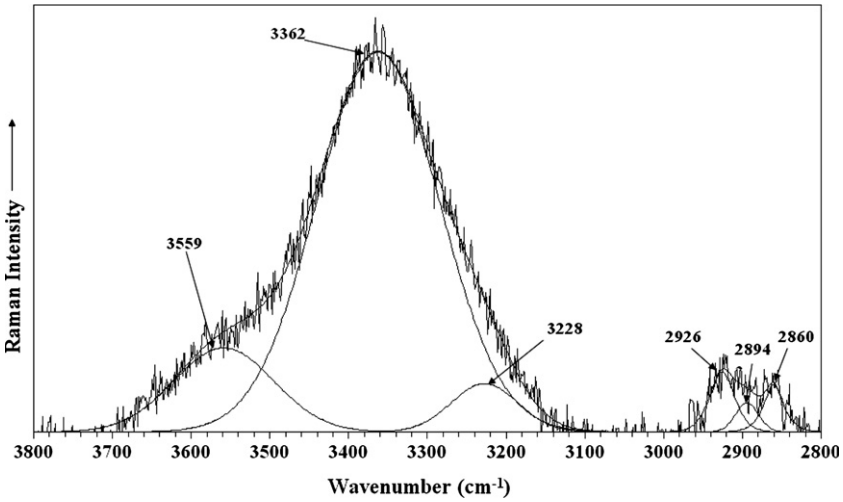

Fig. 6. Raman spectrum of Ni doped aurichalcite in the 2800 to 3800 cm^{-1} region.

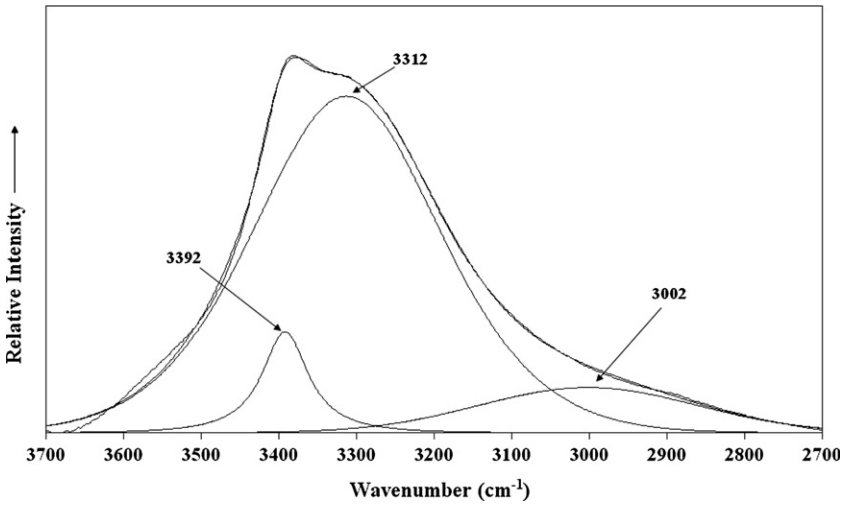

Fig. 7. Infrared spectrum of Ni doped aurichalcite in the 2700 to 3700 cm^{-1} region.

The first two bands are assigned to OH stretching vibrations.

4. Conclusions

Raman spectroscopy complemented with infrared data, X-ray diffraction, electron microscopy and EDAX have been used to characterise the structure and chemical composition of a synthetic aurichalcite. The spectra are correlated with the structure of the mineral. This compositional variation affects the Raman spectral profile. A cation substitution reliance is observed for the hydroxyl stretching vibrational modes. This is related to the hydrogen bond distances of the OH units and the adjacent carbonate units in the aurichalcite structure.

The question arises as to why there are similar Raman spectral patterns for aurichalcite as compared with other hydroxy carbonate minerals such as hydrozincite and members of the rosasite mineral group. The answer must infer that the minerals must have the same structure or at least related structures. Aurichalcite is monoclinic like malachite with point group $2/m$. The rosasite mineral group has spectra similar to that of malcachite. Therefore, it can be suggested that the structure of the rosasite group of minerals is monoclinic, although at this point in time remains unproven. This conclusion is in agreement with the assumptions of Anthony et al. who stated that rosasite and related minerals have monoclinic structure by analogy with malachite [7].

atomic layer deposition (ALD) [8]. Several attempts to prepare MN films from $[M(NEt_2)_4]$ and NH_3 by MOCVD have also been reported, however films of composition M_3N_4 were formed [3,9,10]. Crystalline HfN films have been deposited from the MOCVD (metalorganic chemical vapour deposition) of $Hf(NMe_2)_4$ and *N*,*N*-dimethylhydrazine [11].

We have previously shown that dehalosilylation reactions (i.e. the elimination of Me_3SiX; X = halide) can be employed in the synthesis of TiN and GaN [12,13]. The trimethylsilyl group is labile and can lead to materials with no silicon contamination. Furthermore, decomposition of the adduct $[ZrCl_4\{NH(SiMe_3)_2\}]$ has been shown previously to proceed via elimination of Me_3SiCl and HCl, resulting in the formation of ZrN [5]. We were interested in investigating the synthesis and characterization of adducts, of the type $[MCl_4\{NH(R)(SiR'_3)\}]$ (M = Zr, Hf; R = *t*Bu, R′ = Me; R = SiR'_3 = $SiMe_3$, $SiMe_2H$), all of which have a silyl group attached to the nitrogen atom. The decomposition and pyrolysis of the adducts $[MCl_4\{NH(R)(SiR'_3)\}]$ was investigated in order to evaluate complexes of this type as precursors to metal nitrides, the results of which are described herein. Preliminary low pressure CVD of $[MCl_4\{NH(R)(SiR'_3)\}]$ is also discussed.

2. Results and discussion

The Lewis acid/base adducts $[MCl_4\{NH(R)(SiR'_3)\}]$ (M = Zr, R = SiR'_3 = $SiMe_3$ (**1**), $SiMe_2H$ (**2**), R = *t*Bu, R′ = Me (**3**); M = Hf, R = SiR'_3 = $SiMe_3$ (**4**), $SiMe_2H$ (**5**), R = *t*Bu, R′ = Me (**6**)) were formed by the 1: 1 reaction of MCl_4 with $NH(R)(SiR'_3)$ in dichloromethane at room temperature (Scheme 1).

1: M = Zr, R = SiR'_3 = $SiMe_3$
2: M = Zr, R = SiR'_3 = $SiMe_2H$
3: M = Zr, R = *t*Bu, R' = Me
4: M = Hf, R = SiR'_3 = $SiMe_3$
5: M = Hf, R = SiR'_3 = $SiMe_2H$
6: M = Hf, R = *t*Bu, R' = Me

Scheme 1. Preparation of compounds **1**–**6**.

Compounds **1**–**6** were isolated as white/off-white or yellow solids after work-up of the reaction mixture. All the compounds were stable in the solid state at room temperature. Analytical data obtained for compounds **1**–**6** indicated that complexes of formulation $[MCl_4\{NH(R)(SiR'_3)\}]$ had formed. The compounds were also characterized by ^1H and ^{13}C NMR and mass spectroscopy, which provided further support for the formation of the adducts $[MCl_4\{NH(R)(SiR'_3)\}]$. Unfortunately, X-ray quality crystals of **1**–**6** could not be isolated. Lewis base adducts of zirconium tetrachloride are either monomeric, for example $[ZrCl_4\{N(SiMe_3)PPh_3\}]$ [14], or dimeric via chloride bridges such as in $[ZrCl_3(\mu\text{-}Cl)\{N(C_6H_4Cl)H_2\}]_2$ [15]. Only the presence of monomers was observed in the mass spectral data for the adducts $[MCl_4\{NH(R)(SiR'_3)\}]$ and no higher fragments, such as dimers were observed. The structures of **1**–**6** are therefore thought to be monomeric based on mass spectral evidence and so similar to $[ZrCl_4\{N(SiMe_3)PPh_3\}]$, which consists of a central Zr atom adopting a trigonal bipyramidal coordination geometry.

2.1. Thermal analysis and pyrolysis

The thermogravimetric analysis (TGA) of **1**–**6**, under N_2 at atmospheric pressure, shows that at 580 °C, the precursors had lost between 50% and 77% of weight depending on the sample (Table 1) suggesting that carbon or chlorine is retained in the residue (Figs. 1 and 2).

The observed weight loss for **1**, **2** and **5** are in between the calculated values for formation of $[Cl_2MNH]$ and [ClMN] suggesting that these intermediate compounds have been formed. Precursors of the type $[MCl_4\{NH(SiR'_3)_2\}]$ (compounds **1**, **2**, **4** and **5**) are expected to decompose *via* loss of two equivalents of R'_3SiCl to form an intermediate material of formulation $[Cl_2MNH]_n$, with further heating producing [ClMN] and finally the metal nitride (Scheme 2). In general, the elimination of the second equivalent of trialkylchlorosilane begins before complete elimination of the first equivalent of trialkylchlorosilane. It is possible that the required weight loss for the formation of metal nitride from **1**, **2** and **5** would be attained above 600 °C, although the TGA set-up allows analysis only to 600 °C. Note that TGA at atmospheric pressure only gives an indication of the potential of the precursors to form bulk metal nitrides. Any sublimation of the precursor, a desirable characteristic

Table 1
TGA and pyrolysis results of compounds **1**–**6**

Scheme 2. Proposed decomposition mechanism of $[MCl_4\{NH(SiR_3)_2\}]$.

for low pressure CVD studies would register as a further mass loss, as observed for compounds **3**, **4** and **6**. Nevertheless, the TGA measurements show that all of the complexes decompose at the temperatures of the CVD experiment, probably to form $[Cl_2MNH]$ or [ClMN], but with in some cases sublimation occurring.

The pyrolysis of compounds **1**–**6** was investigated in order to attempt to find the optimum conditions to produce zirconium and hafnium nitride. Based on the TGA results, the compounds were all heated above 600 °C under vacuum to encourage complete decomposition to zirconium or hafnium nitride. Pyrolysis of the zirconium precursors **1**–**3** gave rise to grey–black powders, which were found to contain low levels of carbon (0.65–3.5%) and high levels of chlorine (~30–35%, by elemental analysis). These results support the proposed formation (from the TGA experiments) of the intermediate compound $[Cl_2ZrNH]_n$ (calculated %Cl = 40.03), with the %Cl observed in the pyrolysis products of **1**–**3** suggesting some further decomposition to [ClZrN] (calculated %Cl = 25.20) has occurred. Further support for the proposed decomposition mechanism shown in Scheme 2 was obtained from the ^1H NMR spectrum of the liquid by-products obtained (collected in a liquid N_2 cooled trap) when **1** was thermolysed, which showed resonances assigned to $–SiMe_3$ groups. Compositional analysis by EDAX shows the presence of zirconium and nitrogen in the solids and impurities (Si, Cl by EDAX and C, H and Cl by elemental analysis) were also detected. The grey–black powders did not show any diffraction peaks in their X-ray powder diffraction pattern and are highly sensitive to air/moisture. These results are consistent with those previously reported for **1** [5] and show that compounds **2** and **3** decompose in a similar manner, although %C was higher in the pyrolysed product from **3** probably due to the presence of a *t*Bu group in **3**.

The pyrolysis of **1** and **2** was also carried out under a number of different conditions including vacuum (10^{-3} Torr), under a flow of NH_3 and under N_2. From analytical and XRD data obtained on the powders there was no apparent differences between the products isolated. Compositional analysis by EDAX shows the presence of zirconium and nitrogen in the solids. In addition, significant impurities (Si, Cl by EDAX and C, H and Cl by elemental analysis) were detected and attempts to eliminate these impurities by changing conditions failed.

Pyrolysis of the hafnium nitride precursors **4**–**6** at 650 °C under vacuum, suggest that elimination of the first equivalent of R'_3SiCl has occurred to form $[Cl_2HfNH]$ with some carbon contamination present. These results are in contrast to the TGA of **4**–**6**, which indicated that decomposition to [ClHfN] had occurred. However, the higher weight loss observed in the TGA could be due to sublimation of the precursor. The pyrolysis products from **4**–**6** were also susceptible to oxidation under ambient conditions. Surprisingly, pyrolysis of **5** at 1075 °C under vacuum also produced an air/moisture sensitive solid and did not significantly reduce the %Cl.

2.2. Thin film growth

Low pressure chemical vapour deposition (LPCVD) of **1**–**6** was investigated, the details of which are described in Section 4. Compounds **1**–**3** deposited yellow-coloured films on glass substrates at 620 °C. The films produced were analyzed by EDXA, SEM, powder XRD, XPS and Raman. The films were shown to be amorphous by powder X-ray diffraction. The EDXA data showed the presence of zirconium, nitrogen, carbon and chlorine in the film. Significant breakthrough of the excitation volume through the coating to the underlying glass was observed and so accurate quantitative analysis by EDXA was difficult. By scanning electron microscopy (SEM) the films show the formation of agglomerates of approximately 0.6 μm. All the films were investigated using Raman microscopy. In all cases no

Raman scattering was observed, however, Raman spectroscopy indicated the absence of graphitic carbon in the films. The films passed the Scotch tape test and could not be abraded with a brass stylus but could be marked with a stainless steel scalpel. The films produced showed a maximum transmission in the visible region (450–700 nm) – this behaviour is characteristic of early transition metal nitride films. X-ray photoelectron spectroscopy (XPS) showed the presence of Zr, C, N, O and Cl in the films. The binding energy value for Zr $3d_{5/2}$ for the films deposited from **1**–**3** was measured at 182.1–184.0 eV. These values are close to the Zr $3d_{5/2}$ at 182.2 eV observed in ZrO_2 [16]. However, the Zr $3d_{5/2}$ peak was asymmetrical and the component at 180.3 eV corresponded to zirconium nitride. The N 1s binding energy for the films deposited from **1**–**3** ranged from 396.5–397.5 eV. These values are in agreement with published XPS data for early transition metal nitrides and specifically ZrN_x (396.3–397.5 eV) and Zr_3N_4 (397.2 eV) [3,17]. Thus, XPS indicates that the films comprise of ZrO_2 and ZrN_x, which is supported by the presence of an O 1s peak at 531.0 eV (*cf.* ZrO_2 O 1s 531.1 eV).[18] Significant contamination from chlorine was observed (5–10 atom%), which is consistent with the TGA and pyrolysis experiments. The oxide surface layer was removed by sputtering with the bulk of the films consisting of zirconium nitride and ZrO_2.

Similar results were obtained from the LPCVD of compounds **4**–**6**. Yellow-coloured films were deposited from **4**–**6** on glass substrates at 620 °C. The EDXA data showed the presence of hafnium, nitrogen, carbon and chlorine in the film. Significant breakthrough of the excitation volume through the coating to the underlying glass was observed and so accurate quantitative analysis by EDXA was difficult. By SEM the films show the formation of crystalline-looking agglomerates (Fig. 3). However, the films were shown to be amorphous by powder X-ray diffraction. The films were investigated using Raman microscopy but no Raman scattering was observed. XPS showed the presence of Hf, C, N, O and Cl in the films. Similar to the ZrO_2/Zirconium nitride films, the films produced from **4**–**6** were shown by XPS to comprise of HfO_2 and hafnium nitride. Thus, the N 1s observed at 397.0 eV corresponds well with reported values for Hf_3N_4 (397.8 eV) [3] or HfN_x (397.4 eV) [19] and the O 1s peak at 532.1 eV is close to that expected for HfO_2 (530.7 eV) [20]. The formation of ZrO_2 and HfO_2 indicates that oxidation has occurred either during film deposition or post deposition. Oxidation could occur via diffusion of oxygen from the glass substrates which did not have a barrier layer. However, XPS depth profiling indicated that the amount of zirconium/hafnium and nitrogen increased while oxide decreased with depth in the sample. This suggests that oxidation probably took place after film formation.

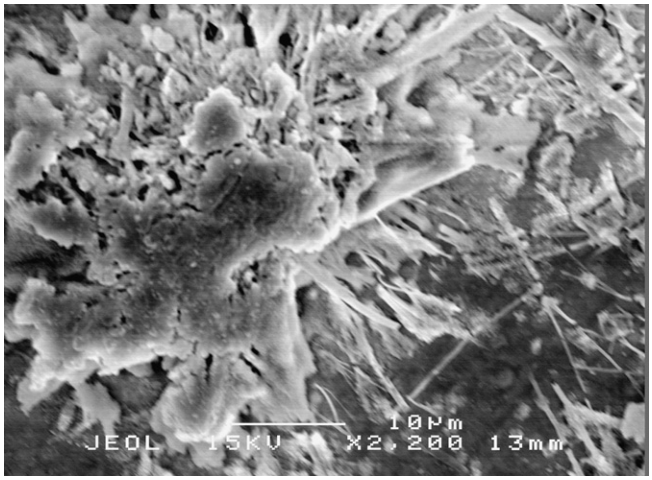

Fig. 3. SEM of a film grown from **6**.

3. Conclusion

The Lewis acid/base adducts $[MCl_4\{NH(R)(SiR'_3)\}]$ (M = Zr, Hf; R = *t*Bu, R′ = Me; R = SiR'_3 = $SiMe_3$, $SiMe_2H$) have been synthesized and characterized. Thermogravimetric analysis and pyrolysis studies showed that $[MCl_4\{NH(R)(SiR'_3)_2\}]$ decomposes via the elimination of R'_3SiCl resulting in the formation of powders of composition [ClMN] or [Cl_2MNH]. Preliminary low pressure CVD studies suggest that $[MCl_4\{NH(R)(SiR'_3)\}]$ is unsuitable as a precursor since amorphous metal oxide/metal nitride films contaminated with carbon and chlorine were obtained.

4. Experimental

4.1. General procedures

All manipulations were performed under a dry, oxygen-free dinitrogen atmosphere using standard Schlenk techniques or in a Mbraun Unilab glove box. Nitrogen (99.99%) was obtained from BOC and used as supplied. Dichloromethane was freshly distilled over CaH_2. The solvents hexane, tetrahydrofuran and toluene were distilled from sodium and benzophenone prior to use. Amines were distilled over 4 Å molecular sieves. All other reagents were procured commercially from Aldrich and used without further purification. Microanalytical data were obtained from University College London (UCL).

4.2. Physical measurements

NMR spectra were recorded on a Bruker AMX400 spectrometer at UCL, referenced to CD_2Cl_2 or $CDCl_3$, which was dried and degassed over molecular sieves prior to use; ^1H and ^{13}C chemical shifts are reported relative to $SiMe_4$ (δ 0.00). Mass spectra (CI) were run on a micromass VG 70-SE spectrometer. IR spectra was collected as nujol and hexachlorobutadiene mulls on a Shimadzu FTIR-8200 instrument. Paraffin oil (nujol) and hexachlorobutadiene was degassed and dried over molecular sieves prior to

use. Melting points were obtained in sealed glass capillaries under nitrogen and are uncorrected. Thermogravimetric analysis (TGA) was performed under a dinitrogen atmosphere with a heating rate of 10 °C min^{-1} and on a Netzsch STA 449C instrument.

X-ray powder diffraction patterns were measured on a Siemens D5000 diffractometer using monochromated Cu $K\alpha_1$ radiation ($\lambda_1 = 1.5406$ Å) with glancing incident radiation (1.5°). EDXA was obtained on a JEOL 35CF and SEM was obtained on a Hitachi S570 instrument using the KEVEX system. X-ray photoelectron spectra were recorded using a VG ESCALAB 220i XL instrument using focused (300 μm spot) monochromatic Al Kα radiation at a pass energy of 20 eV. Scans were acquired with steps of 50 meV. A flood gun was used to control charging and the binding energies were referenced to an adventitious C 1s peak at 284.8 eV. Depth profile measurements were obtained by using argon beam sputtering. Reflectance and transmission spectra were recorded between 300 and 1200 nm by a Zeiss miniature spectrometer. Reflectance measurements were standardized relative to a rhodium mirror and transmission relative to air. Raman spectra were acquired on a Renishaw Raman System 1000 using a helium–neon laser of wavelength 632.8 nm. The Raman system was calibrated against the emission lines of neon.

4.3. Synthesis of [$ZrCl_4${$HN(SiMe_3)_2$}] (1)

$HN(SiMe_3)_2$ (2.2 cm^3, 10 mmol) was added to a suspension of $ZrCl_4$ (2.40 g, 10 mmol) in CH_2Cl_2 (30 cm^3) at room temperature. The reaction mixture was allowed to stir for 72 h to obtain an almost clear solution. The trace amount of insoluble material was filtered out using a filter stick. The filtrate was dried down completely under vacuum yielding a beige coloured powder (1.48 g, 38% yield), m.p. 105 °C. *Anal.* Calc. for $C_6Cl_4H_{19}NSi_2Zr$: C, 18.27; H, 4.86; N, 3.55. IR (cm^{-1}): 2852 s br, 1556 s, 1463 vs, 1340 w, 1265 vs, 819 w, 775 w, 723 s. Mass Spec. (CI) *m/z*: 378, [M]; 307, $ZrCl_2HN^tBuSiMe_3$; 233, $ZrCl(NH_3)_2$; 118, ^{t}BuSiCl.

4.6. Synthesis of [$HfCl_4${$HN(SiMe_3)_2$}] (4)

Compound **4** was prepared in the same manner as **1** but using $HfCl_4$ (8.52 g, 27 mmol), $HN(SiMe_3)_2$ (5.7 cm^3, 27 mmol), yielding a dull yellow/cloudy solution. Removal of the solvent *in vacuo* afforded a white powder (6.73 g, 53% yield), m.p. 120 °C. *Anal.* Calc. for $C_6Cl_4H_{19}HfNSi_2$: C, 14.96; H, 3.98; N, 2.91. Found: C, 14.03; H, 3.78; N, 2.89%. ^{1}H NMR δ/ppm ($CDCl_3$): δ 0.44 (s, SiCH_3), 0.51 (s, SiCH_3), 4.3 (s, br, NH). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 3.26 (s, SiCH_3), 5.43 (s, SiCH_3). IR (cm^{-1}): 3163 s, 2601 w, 1593 m, 1517 s, 1463 s, 1377 s, 1253 s, 1147 s, 1101 s, 1012 m, 920 s, 846 m, 761 w, 719 m, 659 s, 619 w, 607 w, 464 s, 445 w. Mass Spec. (CI) *m/z* 481, [M]; 446, [M]-Cl, 409, [M]-$SiMe_3$; 73, Me_3Si.

4.7. Synthesis of [$HfCl_4${$HN(SiMe_2H)_2$}] (5)

Compound **5** was prepared in the same manner as **1** but using $HfCl_4$ (6.00 g, 19 mmol), $HN(SiMe_2H)_2$ (3.5 cm^3, 19 mmol), yielding a white solution. Removal of the solvent *in vacuo* afforded a white microcrystalline powder (2.22 g, 26% yield), m.p. 91 °C. *Anal.* Calc. for $C_4Cl_4H_{15}HfNSi_2$: C, 10.59; H, 3.33; N, 3.09. Found: C, 10.84; H, 3.71; N, 3.42. ^{1}H NMR δ/ppm (CD_2Cl_2): δ 0.41 (s, SiCH_3) 0.51 (s, SiCH_3), 4.70 (q, SiH) 3.32 (s, br, NH). $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ 1.3 (s, SiCH_3), 3.7 (s, SiCH_3). 4.8. Synthesis of [$HfCl_4${$HN(^tBu)SiMe_3$}] (6)

Compound **6** was prepared in the same manner as **1** but using $HfCl_4$ (0.53 g, 1.66 mmol), $HN(^tBu)SiMe_3$ (0.4 cm^3, 1.6 mmol) yielding a light brown clear solution. Removal of the solvent *in vacuo* yielded a grey coloured powder (0.14 g, 18% yield). *Anal.* Calc. for $C_7Cl_4H_{19}HfNSi$: C, 18.06; H, 4.11; N, 3.01. Found: C, 18.43; H, 4.20; N, 3.28%. ^{1}H NMR δ/ppm (CD_2Cl_2): δ 0.44 (s, SiCH_3), 1.4 (s, C(CH_3)$_3$), 3.69 (s, br, NH). $^{13}C\{^1H\}$ NMR (CD_2Cl_2):

δ 3.3 (s, SiCH_3), 28.3 (s, C(CH_3)$_3$), 30.8 (s, C(CH_3)$_3$). IR (cm^{-1}): 2671 w, 1560 s, 1456 vs, 1344 w, 1263 m, 1161 m, 1028 m, 935 w, 844 w, 723 w.

4.9. Pyrolysis studies

Typically, a sample of precursor (0.30 g) was loaded into a quartz ampoule (30 cm length × 9 mm diameter) in the glove box. The ampoule was then placed in a furnace, which had been pre-heated to the decomposition temperature, such that the sample was in the centre of the furnace. The ampoule was heated for 5 min under a N_2 atmosphere and for a further 4 h under a dynamic vacuum. The furnace was then allowed to cool to room temperature. The powder produced was analyzed by powder XRD and elemental analysis.

4.10. LPCVD studies

The same procedure was followed for all the precursors. Approximately 0.3 g of compound was loaded into the sealed end of a glass tube (400 mm length × 16 mm diameter) in the glovebox. Glass slides (100 mm × 7 mm × 1 mm) were placed carefully along the inside of the tube. The tube was then placed in a furnace such that 30 cm was inside the furnace and the end containing the sample protruded by 4 cm. The tube was heated to a temperature of 620 °C under dynamic vacuum (0.1 Torr, measured by a Hg vacuum gauge). The tube was slowly drawn into the furnace over a period of a few minutes until the sample started to melt. It was then held at that point until all of the precursor had decomposed. Once this had happened, the furnace was allowed to cool to room temperature. The total time taken to complete the whole process was in the region of 120 min. The films deposited on the glass substrates were analyzed by EDAX, SEM, Raman spectroscopy, XPS, and XRD.

measurements, to give ulterior informations about the reactivities of this very important natural compound in the biological processes.

2. Experimental

2.1. Reagents

All chemicals were of analytical-reagent grade and used without further purification. All the solutions were prepared with Milli-Q water. Stock solution of CPI 4.18×10^{-4} mol l^{-1} was prepared by dissolving 76.1 mg of CPI-dihydrochloride in 500 ml of 0.61×10^{-4} mol l^{-1} sodium hydroxide solution. Stock solutions containing 8.90×10^{-3} mol l^{-1} of metal ions were prepared by dissolving weighted suitable quantities of $AgNO_3$ or $AuCl_3$ in water and standardized by Inductively Coupled Plasma (JY24R).

2.2. Methods

For absorbance measurements, all the reactions were studied and monitored, for the required time, by a Hewlett–Packard 8452A diode array spectrophotometer with a 1-cm quartz cell well stoppered and connected to Lauda K2R thermostat. A Metrohm 655 pH meter with a combined electrode (Inlab 413) was used for pH determination.

For the particle size measurements of colloidal metals, transmission electron microscopy (TEM) and electron diffraction studies were carried out on a Philips CM10 instrument operating at 100 kV. The samples were prepared by drying a drop of solution on a carbon-coated Cu grids in air. The film negatives containing the diffraction patterns were scanned at 300 dpi with HP SCANJET 5400C. To eliminate uncertainties in the acceleration voltage and camera length, a standard thallium chloride (TlCl) crystal was used as a reference for the electron diffraction measurements. The morphology of silver and gold colloids was investigated at magnifications up to 73 000.

The diffraction ring in diffraction pattern of TlCl corresponding to the (1 1 1) plane with a lattice spacing $d_{111} = 3.84$ Å, has been obtained according to the ICPDF diffraction data card 06-0486. The camera constant $\lambda \cdot L$ (L in mm and λ in Å) was determined by measuring the radius R of the ring (where R is the distance in mm between the transmitted and diffracted beams), and it was found to be $\lambda \cdot L = 25.92$ Å mm. Provided that diffraction patterns from silver or gold colloids were obtained under the same conditions as the camera constant calibration then the interplanar spacings could be determined using the diffraction relationship: $d_{hkl} = \lambda \cdot L/R$. The particle size distribution in the TEM images was determined using the ImageJ 1.30v Software (The National Institutes of Health, USA) (http://rsb.info.nih.gov/ij).

The scanning electron microscopy (SEM) measurements were carried out on a Leica Cambridge Stereoscan 360 equipped with a backscattered electron detector (4QBSD) at an accelerating voltage of 20 kV. For scanning microscopy, all the samples were prepared by drying 3–5 μl of the solution on aluminum stabs using self-adhesive carbon conductive tabs in a vacuum oven. An X-ray mapping was obtained using an energy dispersive X-ray spectrometer (EDS, Link Analytical) with the SEM. The samples were sputter coated with carbon by Balzers Med 010 to prevent charging when analyzed by the electron beam.

2.3. Gold and silver ions CPI reactions

All the reactions have been carried out from 20 to 60 °C, at pH 6, in the dark because of the photosensitivity of CPI [19]. The value of pH was maintained constant by NaOH addition and determined with a Metrohm 655 pH meter with a combined electrode (Inlab 413).

The reactions of gold ions with CPI were carried out by putting from 100 to 280 μl of the standard solution of CPI and from 104 to 290 μl of the gold stock solution 4.50×10^{-3} mol l^{-1} into 10 ml volumetric flasks.

The reactions of silver ions with CPI were carried out by putting from 100 to 280 μl of the standard solution of CPI and from 50 to 140 μl of the silver(I) 4.68×10^{-3} mol l^{-1} stock solution or from 48 to 135 μl of the silver(II) 4.80×10^{-3} mol l^{-1} stock solution into 10 ml volumetric flasks.

3. Results and discussion

3.1. CPI peculiarity

The CPI is a tetra-anionic porphyrin for the presence of four propionic groups. At pH 6, CPI solution is deep pink with an absorption maximum at 392 nm (Soret band $\varepsilon = 5.98 \pm 0.46 \times 10^4$) and other four weaker bands (Q band) at 500 (IV), 536 (III), 556 (II) and 606 (I) nm (Fig. 1). At this pH, the anionic monomeric form as free-base is prevalent [20].

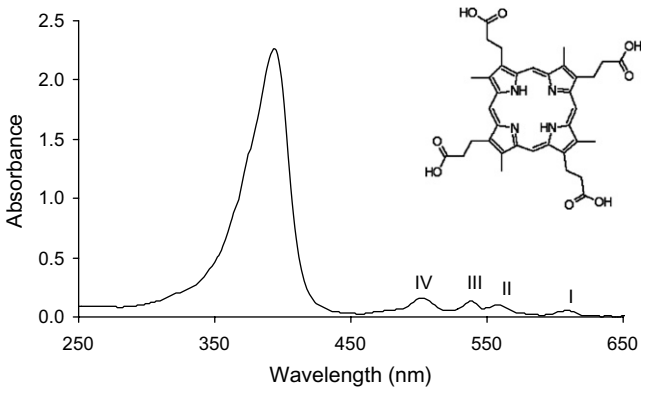

Fig. 1. UV–Vis absorption spectrum of CPI 1.35×10^{-5} mol l^{-1} (pH 6) with inset CPI formula.

3.2. Gold ions reactions

In the reaction of CPI with Au(III), carried out by spectrophotometric measurements, the formation of a plasmon resonance peak at 532 nm attributable of colloidal gold has been previously observed [6].

In this study, the evolution of this reaction has been monitored. At 20 °C, a very slow colour change of the solution was observed: initially it changed from deep pink to grey; after about 2 h it turned to violet and after several days, it changed again from violet to red purple. During this period the UV–Vis absorbance spectra changed in a similar way: the band at 392 nm (corresponding to CPI free-base monomeric form) decreased and the formation of a band at 372 nm (of dimeric form of CPI) that successively reduced with the contemporary increase of a broad band at around 532 nm (red purple solution) was observed (Fig. 2d). Measurements carried out at higher temperatures (up to 50 °C) have immediately shown the formation of the grey colour in the solution that after a week turned to red purple; at temperatures higher than 50 °C, the solution colour changed directly from deep-pink to red purple.

TEM images of the samples of the grey, violet and purple solutions (Fig. 2a–c) showed the initial formation of particles of small sizes (less than 5 nm) in the grey solution, the aggregation of these in the violet solution and the successive increase of particle sizes in purple solution; these particles were of regular distribution, showing several polyhedral structures with sizes ranging from 7 to 60 nm. The change of the colours of the solution (grey, violet and purple) in time was, therefore, due to the coalescence of the colloidal gold particles [21]. The spectrophotometric measurements (Fig. 2d) clearly showed an increase in the plasmon resonance peak at 532 nm with the increase in the particle size. This process involved

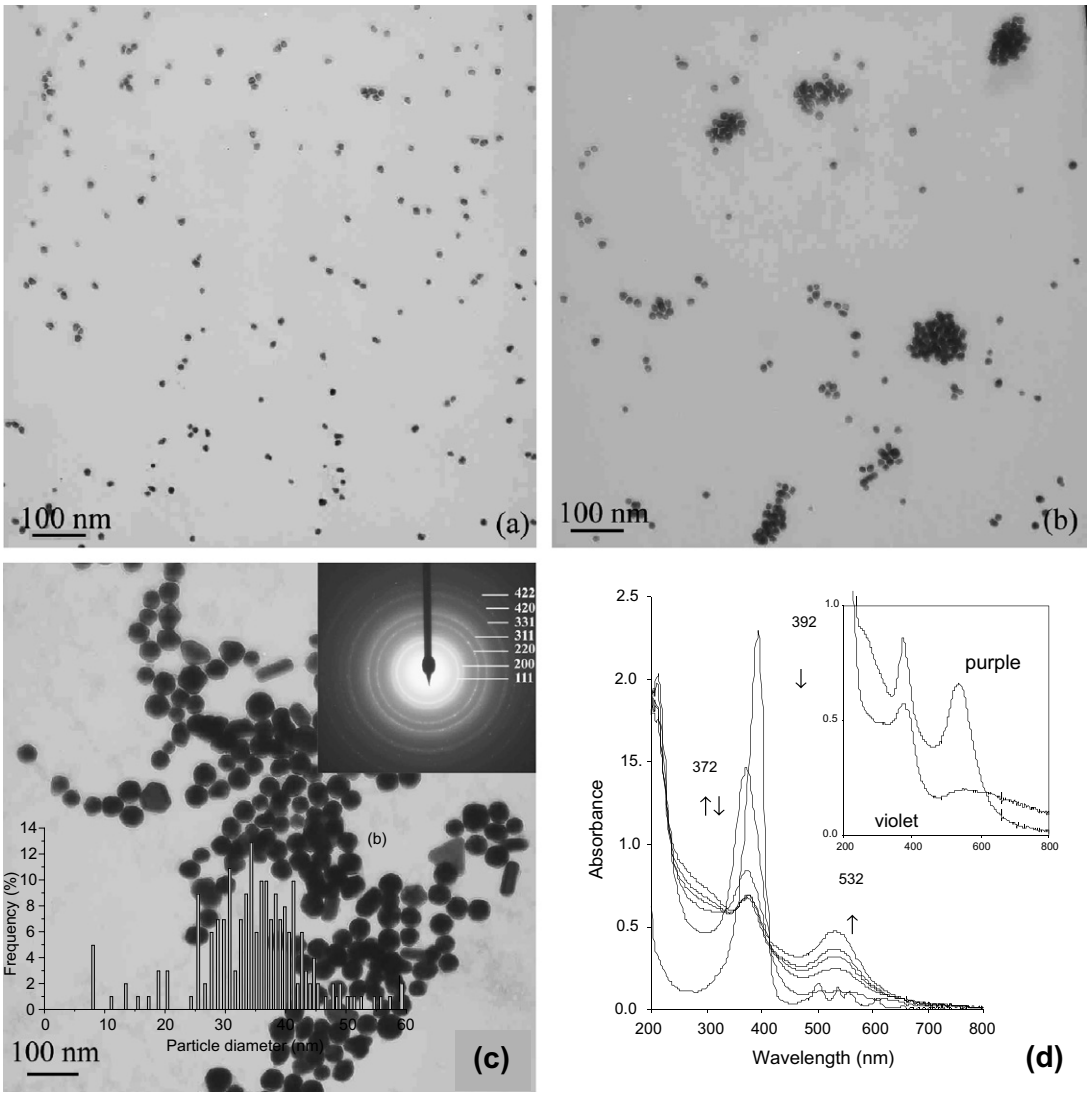

Fig. 2. Reaction at 20 °C of CPI (1.35×10^{-5} mol l^{-1}) with Au(III) (1.35×10^{-4} mol l^{-1}): TEM micrographs (magnification: 73 000×) of gold particles obtained by at once (grey solution) (a), after several days (violet solution) (b) and after several days (purple solution) (c); evolution of UV–Vis spectra during the reaction (up to 120 min) with inset spectra of grey and violet solutions of colloidal gold (d).

three steps: in the first, the metal ions in solution were partially reduced by CPI (Fig. 2a), in the second and third step (Figs. 2b and c), nucleation and successive growth of the particles occurred; the coalescence of atoms leads to the formation of metal clusters and these were stabilized by CPI. In the formation of colloidal gold, the oxidation of CPI occurred by decarboxylation of its propionic groups as previously observed [6]. This provoked the formation of insoluble clotted structure after about one month for the polymerization of neutral decarboxylated CPI. SEM studies of this structure (Fig. 3a) have showed the formation of spheroidal particles of different sizes and twisted into fibrous structures with regular gold distribution as demonstrated by electron backscattered image in Fig. 3c. To explain the nature of these fibrous structures, for comparison, a colloidal gold solution using standard procedure for the reduction with sodium citrate (c.r.) [22] was prepared; this solution was violet and showed an absorption maximum at 548 nm (Fig. 4d). When at pH 6, CPI free-base was added to this solution, a colour intensification was observed and the spectrum showed the presence of the peak at 372 nm (dimeric form of CPI) that decreased in time, and a red shift of the plasmon resonance peak from 548 to 566 nm was observed (Fig. 4d). The red shift arose from the dielectric constant of the CPI capping medium around the gold nanoparticles. This occurred because the negative carboxylic groups of CPI free-base were adsorbed on positive colloidal gold, provoking the initial formation of CPI dimer that decreased in time for gold particles capping proved by the increase of plasmon resonance peak at 566 nm. In fact in Fig. 4a, TEM images showed the gold particles (c.r.) of different sizes and shapes (oval and polygonal structures) that, by CPI addition, changed in agglomerated as well as rodlike fibrous Au-particles, (Fig. 4b and c) indicating the coverage of CPI molecules onto the surface of gold nanoparticles and successive aggregation of these in linear structures.

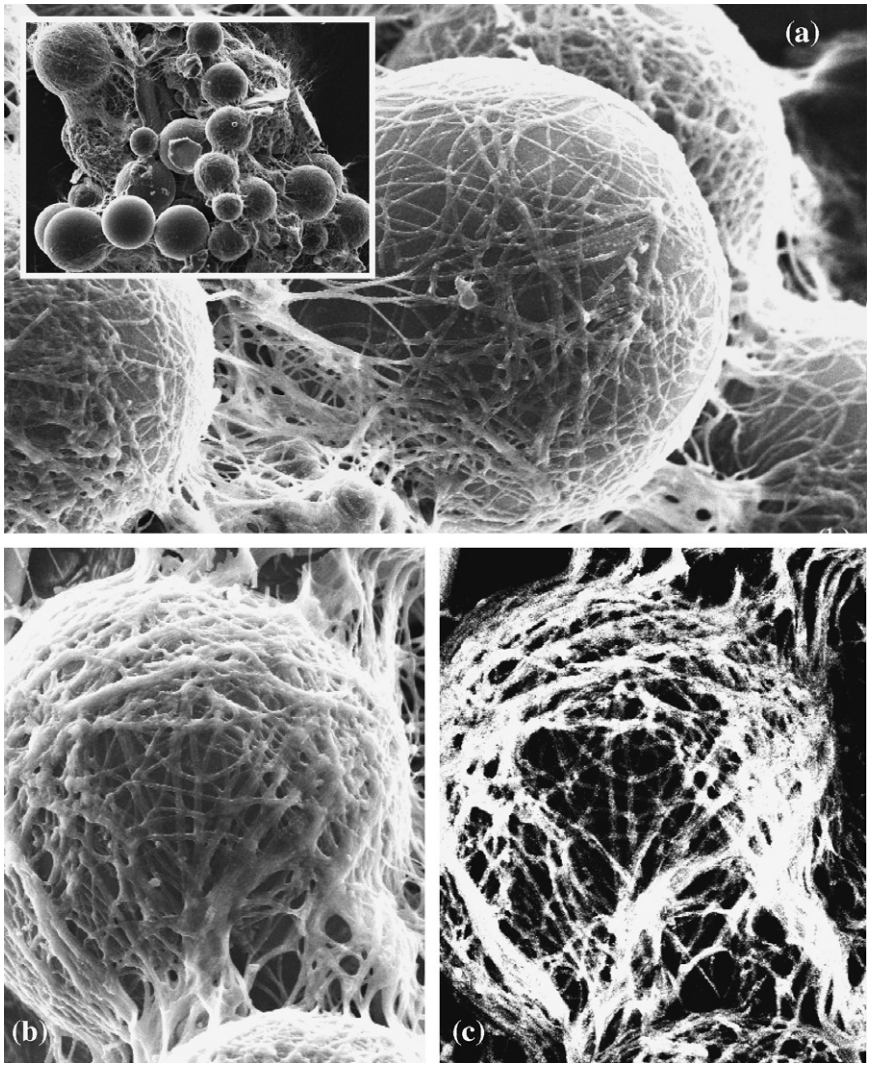

Fig. 3. SEM micrographs of insoluble clotted structure: magnification 809× (a) with inset magnification 205×; magnification 1.00× K (b), electron backscattered image (c).

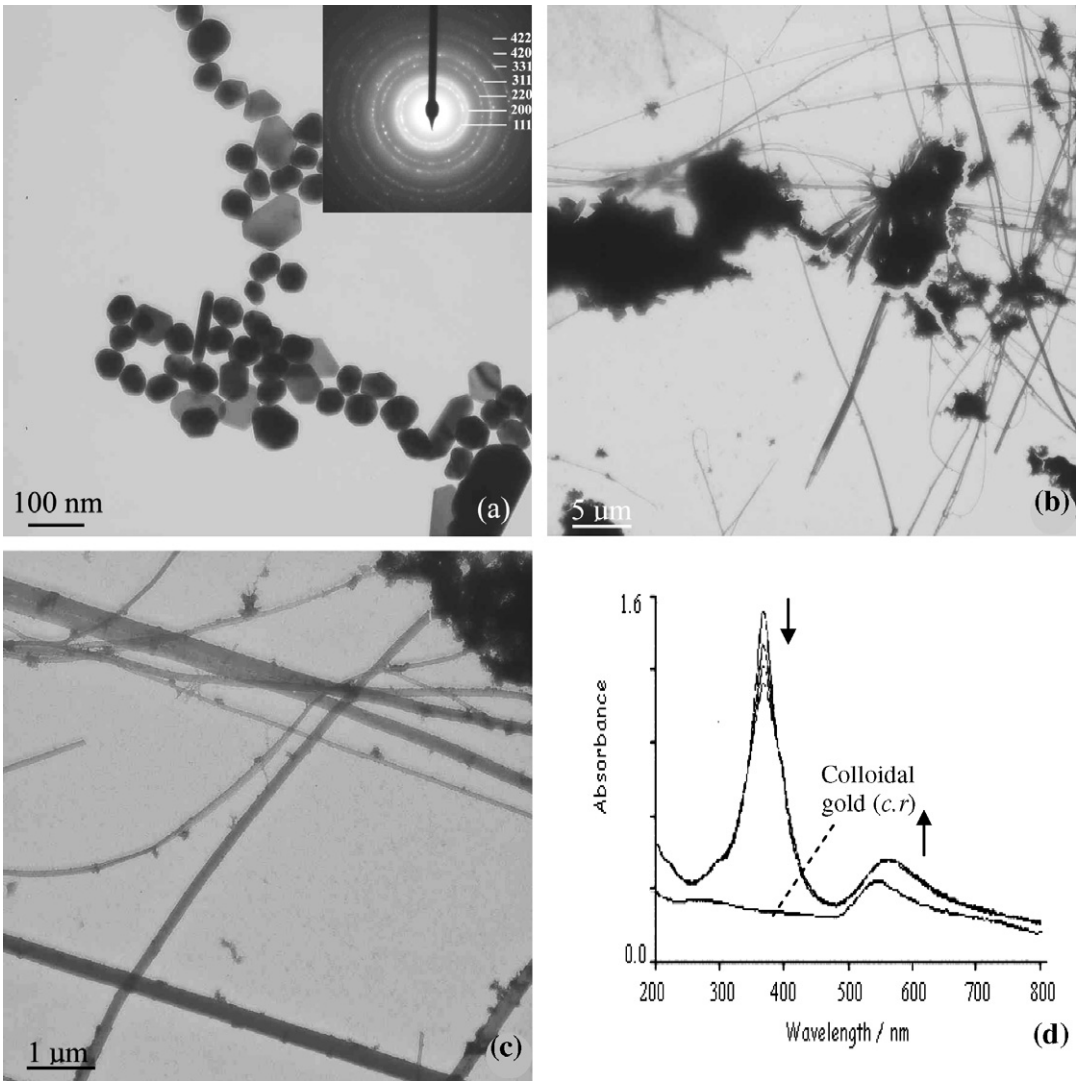

Fig. 4. Reaction at 20 °C of CPI 1.35×10^{-5} mol l^{-1} with gold nanoparticles (c.r.): TEM micrographs and electron diffraction pattern of gold particles (c.r.) at magnification 73000× (a) and in the reaction of CPI at magnifications 1650× (b) and 8900× (c); evolution of UV–Vis spectra during the reaction (d).

3.3. Silver ions reactions

In the reactions of Ag(I) or Ag(II) with CPI, as previously described, Ag^{II}CPI and Ag^{III}CPI complexes with the same absorption maxima (at 260 and 392 nm) were initially formed [6], but the formation of a plasmon resonance peak at 430 nm, with the change of colour solution to deep yellow, attributable to the colloidal silver formation, was observed in time. The spectral evolution of this reaction is reported in Fig. 5a that showed a slight decrease of the absorbance at 260 and 392 nm of silver CPI complexes with a remarkable increase of plasmon resonance peak at 430 nm. The reduction of silver was observed only in the presence of silver CPI complexes, therefore, the formation of colloidal metal must be attributable to the oxidation of Ag^{II}CPI into Ag^{III}CPI. The oxidation of Ag^{II}CPI and the formation of colloidal silver at 20 °C proceeded very slowly and was completed in two days. This reaction was kinetically favoured by higher temperatures, in fact in the same measurements carried out up to 60 °C the formation of the colloid was faster.

TEM images and electron diffraction patterns of these solutions showed silver particles of small sizes (from 4 to 45 nm) and of regular structure, well dispersed and with different spherical shapes (Fig. 5b). In this case, decarboxylated CPI was not formed because the mechanism of silver reduction regarded only the silver CPI complexes.

Neither the spectral change nor the formation of fibrous Ag particles, when CPI was added to colloidal silver solutions prepared by citrate reduction at pH 6, was observed to prove that the adsorption of negative CPI free-base on positive colloidal silver particles did not occur, probably because the surface of colloids was covered by large and strongly attached citrate anions that hindered the absorption of propionic anions of CPI.

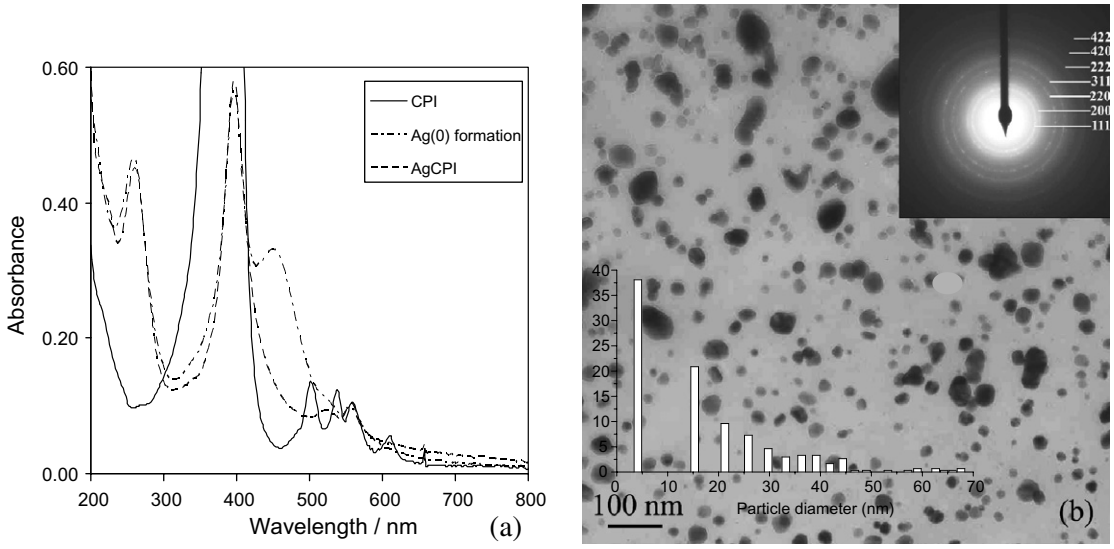

Fig. 5. Reaction at 20 °C of CPI (1.35×10^{-5} mol l^{-1}) with Ag(I) (1.35×10^{-4} mol l^{-1}) after two days: UV–Vis spectrum (a); TEM micrographs (magnification: 73000×) and electron diffraction pattern of silver particles obtained (b).

3.4. Transmission electron diffraction pattern

All samples were examined to determine the structure of the obtained silver and gold nanoparticles. In the insets of Figs. 2c and 4a corresponding to gold nanoparticles obtained by CPI and citrate reduction, respectively, and in Fig. 5b corresponding to silver nanoparticles obtained by CPI reduction, the crystallographic planes for the observed diffraction rings, are identified. The lattice spacing d_{hkl} calculated for silver or gold colloids, compared with theoretical data, according to ICPDF diffraction data, is listed in Tables 1 and 2. The halos of these figures were consistent with cubic-close-packed structure for either silver or gold particles.

4. Conclusions

The investigation on the formation of gold and silver colloidal particles in this research fits into a more general study of the reactions of biological compounds or microorganisms with metallic ions.

This work has allowed the characterization of the nanoparticles obtained in the reaction of CPI with silver and gold ions by spectrophotometric, TEM and SEM techniques.

The reaction of silver ions with CPI to form the metal nanoparticles is slow because it occurred after metal complexation and depended on the reduction of $Ag^{III}CPI$. The deep yellow solution, obtained with absorption maximum at 430 nm, corresponded to the nanoparticles of size between 4 and 45 nm.

In the reaction of gold ions with CPI, the spectra, the sizes and the dimensions of the nanoparticles were depending on the formation kinetic, aggregation and coalescence of colloidal gold particles, stabilized by the negative groups of CPI. Very small particles (sizes less than 5 nm) with regular structures were quickly obtained; the aggregation into several polyhedral structures (sizes up to 60 nm) has been observed in time. In this reaction, the decarboxylation of four propionic groups of CPI provoked the polymerization on the neutral decarboxylate CPI for the formation of spheroidal particles; these were twisted into fibres formed for the coverage of no-decarboxylated CPI molecules onto

the surface of gold nanoparticles and aggregated in linear structures with regular gold distribution. It is in fact well-known that carboxylic acid functional groups, which may be ionized by controlling the pH solution, cap the colloidal particles by electrostatic interactions with their stabilization in solution [23].

This behaviour was not observed in the reaction of CPI with colloidal silver particles because the decarboxylation did not occur and, therefore, the polymerization was not observed.

Because the toxicity of metal nanoparticles is known, this study assumes an important meaning to understand the mechanisms on their probable formation in the human metabolism.

2. Experimental

2.1. Materials and methods

$CuCl_2 \cdot 2H_2O$, KOH, 2-methylimidazole, benzimidazole, CH_3OH, CH_3CN, $C_4H_{10}O$ (S.D. Fine Chem.), 2-ethylimidazole, 2-methylbenzimidazole and $NaClO_4$ (Sigma Aldrich) were used as purchased. The Schiff base ligand was prepared as described in our earlier publication [15]. Elemental analysis was performed on an Elementar vario ELIII Carlo Erba 1108 analyzer. FAB mass spectra were recorded on a Jeol SX-102/DA 6000 mass spectrometer using xenon (6 kV, 10 mA) as the FAB gas. The magnetic susceptibility data were recorded on a Gouy balance at room temperature using mercury(II) tetrathiocyanato cobaltate(II) ($\chi_g = 16.44 \times 10^{-6}$ cgs unit) as the calibrant. The EPR spectra were recorded at room temperature (298 K) and also at liquid nitrogen temperature (77 K) on a Varian E-line Century Series EPR spectrometer operating at 9.4 GHz with TCNE as a calibrant. Electronic spectra were recorded on a Schimadzu UV–Vis 160 spectrophotometer in quartz cells. The IR spectra (400–4000 cm^{-1}) of the complexes were recorded on a Varian 3100 FT IR Excaliber Series spectrophotometer, with samples prepared as KBr pellets. A BAS 100 Epsilon electrochemical analyzer was used for cyclic voltammetric experiments in a DMSO solution of the complex, containing $NaClO_4$ as the supporting electrolyte. The three electrode measurement was carried out at 298 K under a nitrogen atmosphere with a platinum working electrode, a platinum wire auxiliary electrode and a silver/silver chloride reference electrode (Ag/AgCl). The SOD activities were evaluated using alkaline DMSO as a source of superoxide radicals (O_2^-) and nitrobluetetrazolium chloride (NBT) as a scavenger [16].

2.2. Synthesis of the complexes

2.2.1. Synthesis of [Cu(SAA)(H_2O)] (1)

To a methanolic solution (10 mL) of $CuCl_2 \cdot 2H_2O$ (1.0 mmol, 170 mg) a methanolic solution (10 mL) of the potassium salt of the Schiff base (1.0 mmol, 240 mg) was added and the reaction mixture was stirred for 30 min at 25 °C. After completion of the reaction, the dark green precipitate thus formed was collected by filtration and washed with a small amount of methanol and then with diethyl ether successively. The solid was dried in air at room temperature and stored in a $CaCl_2$ desiccator. Yield, 70%. *Anal.* Calc. for $C_{14}H_{11}O_4NCu$ (**1**) C, 52.36; H, 3.42; N, 4.36. Found: C, 51.48; H, 3.94; N, 4.45%. FAB mass (*m*/*z*) Calc.: 321. Found: 320.

2.2.2. Synthesis of [Cu(SAAA)(MeImH)] (2), [Cu(SAA)(EtImH)] (3), [Cu(SAA)(BenzImH)] (4) and [Cu(SAA)(MebenzImH)] (5)

All these ternary complexes were synthesized by following a general procedure. To a methanolic solution (10 mL) of $CuCl_2 \cdot 2H_2O$ (1.0 mmol, 170 mg) a methanolic solution (10 mL) of the potassium salt of the Schiff base (1.0 mmol, 240 mg) was added and the reaction mixture was stirred for 30 min at 25 °C. To the above reaction mixture, a methanolic solution (10 mL) of MeImH (1.0 mmol, 82 mg) was added and the stirring was continued for another 30 min. After completion of the reaction, the light green precipitate thus formed was collected by filtration and washed with a small amount of methanol and then with diethyl ether successively. The solid was dried in air at room temperature and stored in a $CaCl_2$ desiccator. Yield, ~60%. *Anal.* Calc. for $C_{18}H_{15}N_3O_3Cu$ (**2**) C, 56.11; H, 3.89; N, 10.91. Found: C, 56.13; H, 3.75; N, 10.45%. FAB mass (*m*/*z*) Calc.: 385. Found: 384. Complexes **3**, **4** and **5** were synthesized as described above by employing EtImH (1.0 mmol, 96 mg), BenzImH (1.0 mmol, 118 mg) and MeBenzImH (1.0 mmol, 132 mg), respectively, in place of MeImH. *Anal.* Calc. for $C_{19}H_{17}N_3O_3Cu$ (**3**) C, 57.15; H, 4.26; N, 10.53. Found: C, 56.85; H, 4.15; N, 10.50%. FAB mass (*m*/*z*) Calc.: 399. Found: 399. *Anal.* Calc. for $C_{21}H_{15}N_3O_3Cu$ (**4**) C, 59.86; H, 3.56; N, 9.97. Found: C, 59.87; H, 3.50; N, 9.45%. FAB mass (*m*/*z*) Calc.: 421. Found: 420. *Anal.* Calc. for $C_{22}H_{17}N_3O_3Cu$ (**5**) C, 60.69; H, 3.90; N, 9.65. Found: C, 60.56; H, 4.10; N, 9.40%. FAB mass (*m*/*z*) Calc.: 435. Found: 435.

2.3. Crystal structure determination

Crystals suitable for single crystal X-ray analysis for the complexes [Cu(SAA)(MeImH)] (**2**) and [Cu(SAA)(EtImH)] (**3**) were grown by slow evaporation of the CH_3OH:CH_3CN (1:1 V/V) solutions of the complexes at room temperature. The single crystals of **2** and **3** were mounted on a glass fiber and used for data collection. Crystal data were collected on an Oxford Xcalibus-S CCD diffractometer using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). The crystal orientation, cell refinement and intensity measurements were made using the program CAD-4PC, performing psi-scan measurements. The structure was solved by the direct methods using the program SHELXS-97 [17] and refined by full-matrix least-squares techniques against F^2 using SHELXL-97 [18]. All the hydrogen atoms were refined anisotropically. All the hydrogen atoms were geometrically fixed and allowed to refine using a riding model.

3. Results and discussion

The reaction of equimolar ratios of the ligands and metal salt yielded the corresponding metal complexes in good yield. All the present complexes prepared were blue in color. They were found to be soluble in DMF, DMSO and in a mixture of CH_3OH:CH_3CN (1:1 V/V) solution, but were only partially soluble in other organic solvents such as $CHCl_3$ and CH_2Cl_2.

3.1. Magnetic measurements

The magnetic susceptibility measurements in the solid state show that the present complexes are paramagnetic

at ambient temperature. The observed magnetic moment values of the complexes are 1.76 for **1**, 1.78 for **2**, 1.82 for **3**, 1.77 for **4** and 1.83 B.M. for **5**. These values are quite close to the values expected for copper(II) complexes [15,19,20] and is in fair agreement with the spin only system $S = 1/2$.

3.2. Crystal structure

Dark blue crystals of the complexes [Cu(SAA)(MeImH)] (**2**) and [Cu(SAA)(EtImH)] (**3**) suitable for X-ray diffraction studies were grown by slow evaporation of a solution of the complexes in CH_3OH:CH_3CN (1:1 V/V). The ORTEP views of the complexes are shown in Figs. 1 and 2. Crystallographic data and structure refinement parameters are given in Table 1 and selected bond angles and bond distances are given in Tables 2 and 3. The structures of the two complexes [Cu(SAA)(MeImH)] (**2**) and [Cu(SAA)(EtImH)] (**3**) are quite similar. The crystal structures of the complexes reveal the presence of ternary copper(II) structures consisting of a tridendate ONO donor Schiff base, a monodentate ligand (MeImH/EtImH) and a copper(II) center in the discrete monomeric species. The coordination geometry in the complexes is distorted square planar. Complex **2** crystallizes in the orthorhombic system with a space group of $Pna2_1$, $a = 9.3715(3)$ Å, $b = 11.0531(4)$ Å, $c = 15.6391(5)$ Å, $\alpha = 90°$, $\beta = 90°$ and $\gamma = 90°$, whereas complex **3** crystallizes in the monoclinic system with a space group of $P2_1/n$, $a = 11.4066(2)$ Å, $b = 9.4081(2)$ Å, $c = 16.3437(3)$ Å, $\alpha = 90°$, $\beta = 97.960(2)°$ and $\gamma = 90°$. The bond distances of the donor atoms of the Schiff base ligand to the central metal atom for these complexes are in the range 1.883(2) to 1.9637(19) Å and the bond distances of the monodentate ligands to the metal atom are 1.991(2) to 1.9827(19) Å. These values are close to ~1.9 Å, typical of similar of copper(II) complexes [15,21].

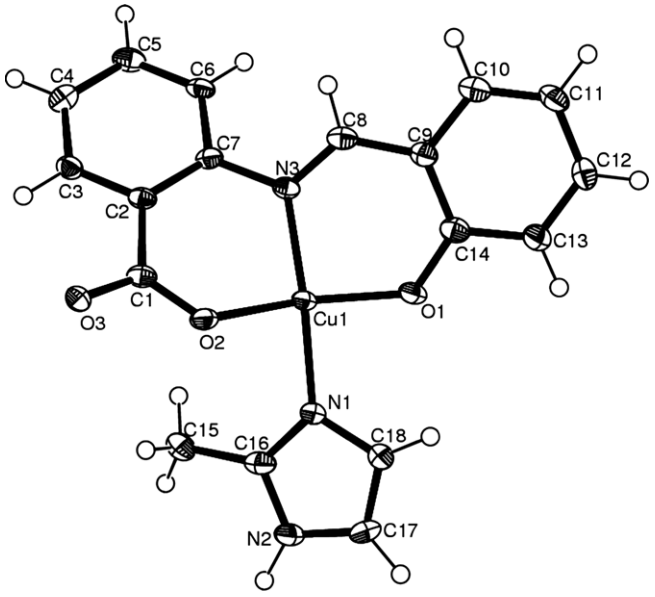

Fig. 1. ORTEP diagram of the complex [Cu(SAA)(MeImH)].

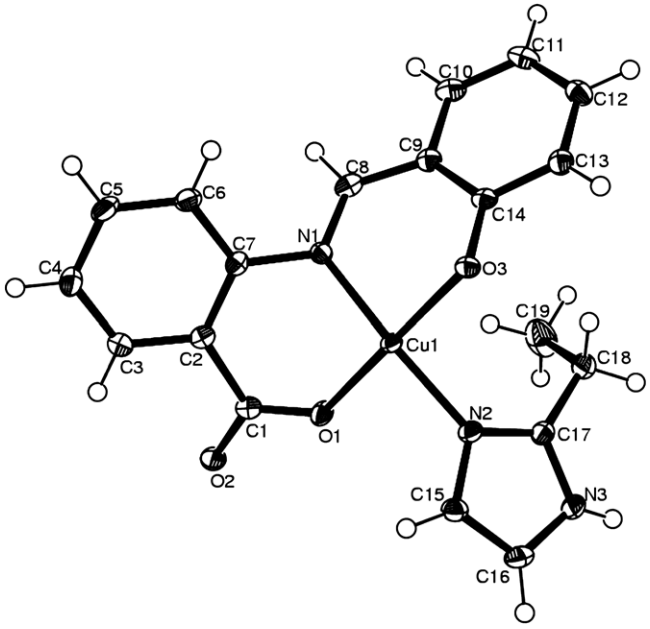

Fig. 2. ORTEP diagram of the complex [Cu(SAA)(EtImH)].

3.3. EPR spectral study

The EPR spectra of the complexes in the polycrystalline state at 298 K and in solution at 77 K were recorded in the X-band region, using 100 KHz field modulation and the g factors were quoted relative to the standard marker TCNE ($g = 2.00277$). EPR spectral assignments of the copper(II) complexes along with the spin Hamiltonian and orbital reduction parameters are given in Table 4. Some representative figures are shown in Figs. 3 and 4.

The EPR spectrum of complex **2** in the polycrystalline state at 298 K shows only one broad signal at $g = 2.110$. Such an isotropic spectrum consisting of a broad signal, and hence only one g value, arises from extensive exchange coupling through misalignment of the local molecular axes between different molecules in the unit cell and enhanced spin lattice relaxation. This type of spectra unfortunately give no information on the electronic ground state of the copper(II) ion present in the complexes. The EPR spectrum of complex **1** in the polycrystalline state at 298 K shows rhombic spectral features with three g values. The EPR spectra of the other complexes in the polycrystalline state at 298 K show axial symmetry with well-defined $g_{\|}$ and $g_{\perp}$ values. The geometric parameter G, which is a measure of the exchange interaction between the copper centers in the polycrystalline compound, is calculated by using the relation [22]: $G = (g_{\|} - 2.0023)/(g_{\perp} - 2.0023)$ for axial spectra and for rhombic spectra $G = (g_3 - 2.0023)/(g_{\perp} - 2.0023)$ and $g_{\perp} = (g_1 + g_2)/2$. The value of G is found to be in the range 2.2–2.9. All the complexes with $g_{\|} > g_{\perp} > 2.0023$ and G values less than 4.0 are consistent

with a $d_{x^2-y^2}$ ground state in a square planar or square pyramidal geometry [23,24].

The solution EPR spectra of the complexes were recorded in DMSO at 77 K. Frozen solution EPR spectra of the complexes have revealed axial features ($g_\| > g_\perp > 2.0023$) and suggest a $d_{x^2-y^2}$ ground state. These spectral features are characteristic of axial symmetry [21,25]. The EPR parameters $g_\|$, $g_\perp$, $A_\|$ and the energies of the d–d transition were used to evaluate the bonding parameters α^2, β^2 and γ^2, which may be regarded as measures of the covalency of the in-plane σ bonds, in-plane π bonds and out-of plane π bonds, respectively, (Table 4). The value of the in-plane sigma bonding parameter α^2 was calculated using the expression [26]:

$$\alpha^2 = (A_\|/0.036) + (g_\| - 2.0023) + 3/7(g_\perp - 2.0023) + 0.04$$

The orbital reduction factors, $K_\| = \alpha^2\beta^2$ and $K_\perp = \alpha^2\gamma^2$ were calculated using the following expression:

$$K_\|^2 = (g_\| - 2.0023)E_{d\text{–}d}/8\lambda_0$$

$$K_\perp^2 = (g_\perp - 2.0023)E_{d\text{–}d}/2\lambda_0$$

where λ_0 is the spin–orbit coupling constant, with a value of $-828\ cm^{-1}$ for a copper(II) d^9 system. According to

f (cm^{-1})	139	145	145	142	138

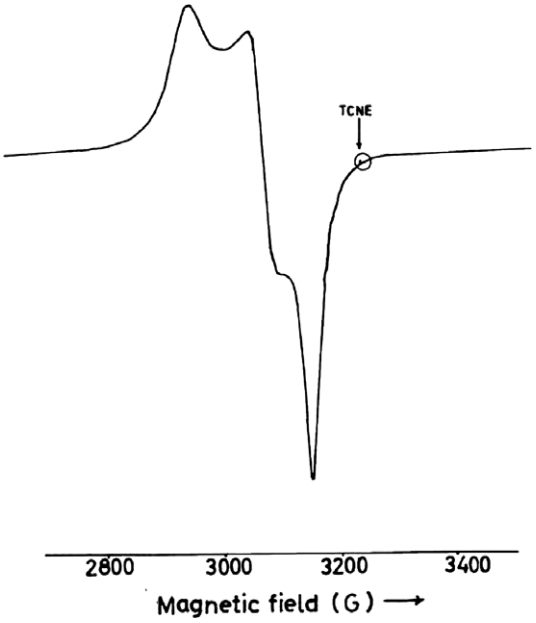

Fig. 3. EPR spectrum of the complex [Cu(SAA)(H_2O)] in powder at 298 K.

Hathaway [23], for pure σ bonding, $K_{\parallel} \approx K_{\perp} \approx 0.77$ and for in-plane π bonding $K_{\parallel} < K_{\perp}$, while for out-of-plane π bonding, $K_{\parallel} > K_{\perp}$.

In all of the present copper(II) complexes, it is observed that $K_{\parallel} > K_{\perp}$, which indicates the presence of significant out-of-plane π bonding. The evaluated values of α^2, β^2 and γ^2 of the complexes are consistent with both strong in-plane σ and out-of-plane π bonding.

The empirical factor $f = g_{\parallel}/A_{\parallel}$ cm^{-1} is an index of tetragonal distortion and its value may vary from 105 to 135 for small to extreme distortions in square planar complexes and it depends on the nature of the coordinated atoms [27]. The f values of these complexes are found to be in the range 138–145, indicating significant distortion from planarity.

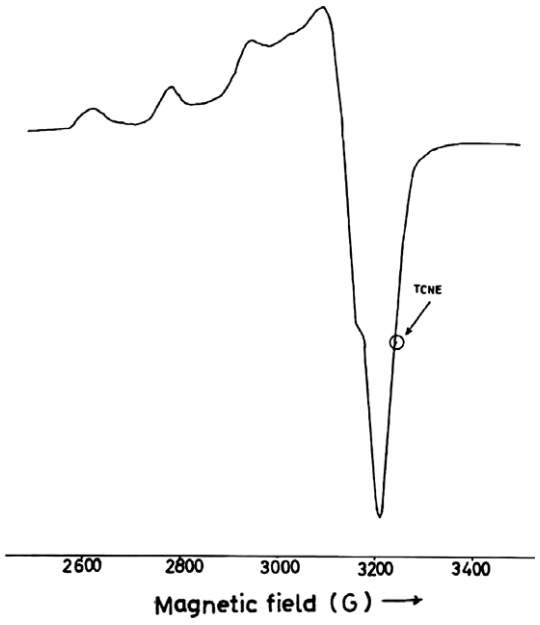

Fig. 4. EPR spectrum of the complex [Cu(SAA)(BenzImH)] (0.003 M) at 77 K in DMSO.

3.4. Electronic spectral study

The significant electronic absorption bands in the spectra of the complexes were recorded in DMSO at 25 °C. For square planar complexes with a $d_{x^2-y^2}$ ground state, three spin allowed transitions are possible, *viz.* $^2B_{1g} \rightarrow {}^2A_{1g}$ $(d_{x^2-y^2} \rightarrow d_z^2)$, $^2B_{1g} \rightarrow {}^2B_{2g}(d_{x^2-y^2} \rightarrow d_{xy})$ and $^2B_{1g} \rightarrow {}^2E_g(d_{x^2-y^2} \rightarrow d_{xz}, d_{yz})$. Since the four d orbitals lie very close together, each transition cannot be distinguished by their energy and hence it is very difficult to resolve the bands into separate components.

The spectra of complexes **1**–**5** each exhibit a broad band centered at 718, 703, 708, 708 and 715 nm, respectively, similar to those reported for copper(II) ions in a square planar environment [28,29]. Due to the broadness of the band, the other expected transitions in this range could not be assigned. The ligand to metal charge transfer band for the complexes appeared at 413–416 nm with a shoulder at 450–461 nm.

3.5. Infrared spectral study

The ν(C=N) band of the ligand at 1621 cm^{-1} is found to be shifted to lower energies (1586–1595 cm^{-1}) in the spectra of the complexes, indicating coordination via the azomethine nitrogen. This is confirmed by bands in the range 459–461 cm^{-1}, which have been assigned to the ν(Cu–N) band [30]. In the IR spectra of the complexes, the replacement of the valence stretching carboxylic vibration $\nu(C{=}O)_{carb}$ of the protonated SAA at 1688 cm^{-1} by the asymmetric, $\nu(CO_2)_{asym}$, at ~1445 cm^{-1} and the asymmetric stretching ν(O–C–O) vibration, $\nu(CO_2)_{syn}$, at ~1381 cm^{-1} as well as the Δ value (~64 cm^{-1}) [$\Delta = \nu(CO_2)_{asym} - \nu(CO_2)_{sym}$] are indicative of a monodentate

coordination mode of the carboxylato group [31]. In the IR spectra of complex **1** a considerable peak observed at 3448 cm^{-1} supports the presence of $\nu(H_2O)$ in the complex. Vibrations at ~460 (weak) (and expected below 400 cm^{-1}, out of our measuring limit) can be attributed to M–O and M–N vibrations [21].

3.6. Cyclic voltammetric measurements

The electrochemical behavior of 1 mM solutions of complexes **1**–**5** have been investigated in DMSO containing 0.1 M $NaClO_4$ as the supporting electrolyte, at a platinum working electrode. The CV results of these complexes are given in Table 5. A representative voltammogram is shown in Fig. 5.

For complexes **1** and **4**, a negative scan initiated at 1000 mV in the potential range 1000 to −1000 mV yielded an irreversible couple corresponding to the Cu(II)/(I) redox process [32]. In these cases the peak potentials difference increases as the scan rate is increased. Constancy of Eo' shows that in all cases both peaks are complementary to each other. The peak current ratio I_{pa}/I_{pc} is less than unity showing that the electron transfer reaction is followed by a chemical reaction (EC mechanism) [33,34].

For complexes **2**, **3** and **5**, a negative scan initiated at 1000 mV in the potential range 1000 to −1000 mV yielded two cathodic peaks at a scan rate 100 mV/s and 200 mV/s (Table 5) but their complementary anodic peaks did not appear, even at higher scan rates. This shows that the Cu(I) state is largely unstable in solution. The E_{pc2} of the corresponding complexes may be due to the Cu(II)/Cu(I) reduction. A perusal of Table 5 shows that the magnitude of the cathodic peak currents I_{pc1} and I_{pc2} differ significantly; I_{pc2} being larger than that of I_{pc1} indicates that the two complex species presumably exist in equilibrium in solution.

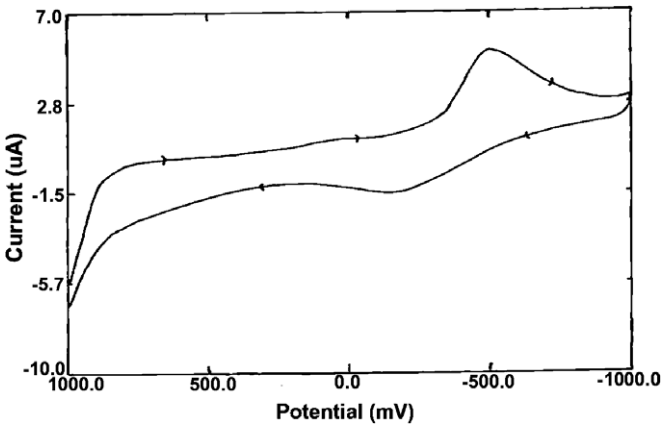

Fig. 5. Cyclic voltammogram of the complex [Cu(SAA)(BenzImH)] in 0.1 M $NaClO_4$ [scan rate: 200 (m V/s)].

3.7. Superoxide dismutase activity

The superoxide dismutase activity (SOD) of the complexes was investigated by the NBT assay method. The SOD activity of the complexes was measured at pH 8.6. The chromophore concentration value required to yield 50% inhibition of the reduction of NBT (IC_{50}) of the present complexes (63 μmol dm^{-3} for **1**, 35 μmol dm^{-3} for **2**, 43 μmol dm^{-3} for **3**, 50 μmol dm^{-3} for **4** and 52 μmol dm^{-3} for **5**) are higher than the value exhibited by the native enzyme ($IC_{50} = 0.04$ μmol dm^{-3}). These higher values may be due to the strong ligand field created by the tridentate Schiff base ligand which opposes the interaction of the complexed copper with the superoxide radical, and another important factor is the ability of the ligand to accommodate the reduced copper(I) center in a tetrahedral-like or linear environment [35].

Table 5

bpm tta tfa

Of the lanthanide metals europium appears to be the most thoroughly studied. This is due in part to the intense luminescence of europium complexes in the visible region of the spectrum. In addition europium complexes display temperature dependent luminescent properties leading to their use as temperature probes. In this report we present the structural and temperature dependent luminescent properties of two homodinuclear europium complexes using tfa and tta as antenna ligands and bridged by bpm, $[Eu(tfa)_3]_2$bpm (**1**) and $[Eu(tta)_3]_2$bpm (**2**).

$[Eu(tfa)_3]_2$bpm (**1**)

$[Eu(tta)_3]_2$bpm (**2**)

2. Experimental

2.1. Materials

All reagents were analytical grade and used without further purification. Europium(III) chloride (Aldrich), 2,2′-bipyrimidine (bpm) (Alfa Aesar), 4,4,4-trifluoro-1-(2-furyl)-1,3-butanedione (tfa), 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione (tta), 2,2′-bipyridine (bpy) (ACROS), toluene, ethyl acetate, hexanes and ethanol (Fisher) were used as received. Elemental analysis was performed by Atlantic Microlabs Inc., Norcross Georgia.

2.2. $[Eu(tfa)_3]_2$bpm (*1*)

Synthesis of this bimetallic complex has been previously reported [27]. A solution of bpm (0.055 g, 0.35 mmol) in absolute ethanol (3.0 mL) was added to a basic (2.1 mL of 1.0 M NaOH) solution of tfa (0.433 g, 2.10 mmol) in absolute ethanol (3.0 mL). The mixture was stirred at room temperature for 30 min. To this solution was added an aqueous (3.5 mL) solution of $EuCl_3 \cdot 6H_2O$ (0.26 g, 0.70 mmol) over a 5 min period. The cream colored precipitate was vacuum filtered, washed 3×10 mL with cold absolute ethanol and allowed to air dry. The resulting powder was recrystallized from an ethyl acetate/hexanes mixture to give a white powder (0.59 g, 76%). *Anal.* Calc. for $Eu_2C_{56}H_{30}N_4O_{18}F_{18}$ (1693): C, 39.74; H, 1.79; N, 3.31. Found: C, 39.94; H, 1.71; N, 3.44%. UV–Vis (toluene): λ_{max} (nm) [log ε] = 337 [5.01].

2.3. $[Eu(tta)_3]_2$bpm (*2*)

Synthesis of this bimetallic complex has been previously reported [27]. A solution of bpm (0.055 g, 0.35 mmol) in absolute ethanol (3.0 mL) was added to a basic (2.1 mL of 1.0 M NaOH) solution of tta (0.476 g, 2.10 mmol) in absolute ethanol (3.0 mL). The mixture was stirred at room temperature for 30 min. To this solution was added an aqueous (3.5 mL) solution of $EuCl_3 \cdot 6H_2O$ (0.26 g, 0.70 mmol) over a 5 min period. The cream colored precipitate was vacuum filtered, washed 3×10 mL with cold absolute ethanol and allowed to air dry. The resulting powder was recrystallized from an ethyl acetate/hexanes mixture to give a white powder (0.46 g, 73%). *Anal.* Calc. for $Eu_2C_{56}H_{30}N_4O_{12}F_{18}S_6$ (1789): C, 37.59; H, 1.69; N, 3.13. Found: C, 37.68; H, 1.73; N, 3.23%. UV–Vis (toluene): λ_{max} (nm) [log ε] = 340 [5.16].

2.4. $Eu(tfa)_3$bpy

For spectroscopic comparisons the monometallic analogs of complex **1** and **2** were synthesized. A solution of 2,2′-bipyridine (bpy, 0.51 g, 3.3 mmol) in absolute ethanol (15 mL) was added to a basic (10 mL of 1.0 M NaOH) solution of tfa (2.1 g, 10 mmol) in absolute ethanol (15 mL). The mixture was stirred at room temperature for 45 min. To this solution was added an aqueous (15 mL) solution of $EuCl_3 \cdot 6H_2O$ (1.2 g, 3.3 mmol) over a 5 min period. The white precipitate was vacuum filtered, washed 3×10 mL with cold absolute ethanol and allowed

to air dry. The resulting white powder was recrystallized from an ethyl acetate/hexanes mixture to give a white powder (2.1 g, 69%). *Anal.* Calc. for $EuC_{34}H_{20}N_2O_9F_9$ (923): C, 44.22; H, 2.18; N, 3.03. Found: C, 43.98; H, 2.16; N, 2.99%.

2.5. *Eu(tta)$_3$bpy*

A solution of 2,2′-bipyridine (bpy, 0.21 g, 1.4 mmol) in absolute ethanol (15 mL) was added to a basic (4.2 mL of 1.0 M NaOH) solution of tta (0.93 g, 4.2 mmol) in absolute ethanol (15 mL). The mixture was stirred at room temperature for 45 min. To this solution was added an aqueous (15 mL) solution of $EuCl_3 \cdot 6H_2O$ (0.50 g, 1.4 mmol) over a 5 min period. The white precipitate was vacuum filtered, washed 3 × 10 mL with cold absolute ethanol and allowed to air dry. The resulting white powder was recrystallized from an ethyl acetate/hexanes mixture to give a white powder (0.45 g, 33%). *Anal.* Calc. for $EuC_{34}H_{20}N_2O_6F_9S_3$ (972): C, 42.03; H, 2.07; N, 2.88. Found: C 41.98; H, 2.19; N, 3.08%.

2.6. Physical measurements

Electronic absorption spectroscopy of the europium(III) complexes was run in toluene solutions with a Shimadzu Multispec-1501 diode array spectrophotometer. Luminescence spectra of the europium(III) complexes in a 1 cm quartz spectrophotometer fluorescence cell (Starna) in toluene were run on a Cary Eclipse fluorescence spectrophotometer. Temperature dependent luminescence of the europium(III) complexes in toluene from 5 °C to 55 °C was controlled using a Cary single cell Peltier temperature controller.

2.7. Crystal structure determination of **1** and **2**

For X-ray examination and data collection, suitable crystals of **1** and **2** were mounted in a loop with paratone-N and transferred immediately to the goniostat bathed in a cold stream. Intensity data were collected on a D8 goniostat equipped with a Bruker Platinum200 CCD detector at Beamline 11.3.1 at the Advanced Light Source (Lawrence Berkeley National Laboratory) using synchrotron radiation (**1**: 196 K, $\lambda = 0.7749$ Å; **2**: 193 K, $\lambda = 0.7758$ Å).[1] A series of data frames measured at 0.2° increments of ω were collected to calculate a unit cell. For data collection, frames were measured at 0.3° intervals of ω. Scan durations for both the unit cell and data collection procedures were 4-s for compound **1** and 3-s for compound **2**. The data frames were collected using the program APEX2 and processed using the program SAINT routine within APEX2.[2] The data were corrected for absorption and beam corrections based on the multi-scan technique as implemented in SADABS.[2]

The structure was solved by a combination of direct methods in SHELXTL[2] and the difference Fourier technique and refined by full-matrix least squares on F^2 (**1**: 0.85 Å; **2**: 0.89 Å resolution). Non-hydrogen atoms were refined with anisotropic displacement parameters with the exception of partial-occupancy F-atoms. All H-atom positions were calculated and treated with a riding model. All H-atom isotropic displacement parameters were defined as $1.2U_{eq}$. In the case of compound **1**, F-atoms of the CF_3 groups show disorder as indicated by the enlarged displacement parameters; multi-component conformations are modeled where possible. The refinements converged with crystallographic agreement factors as summarized in Table 1. The selected bond lengths and bond angles for the complexes are listed in Table 2.

[1] Crystallographic data were collected through the SCrALS (Service Crystallography at Advanced Light Source) program at the Small-Crystal Crystallography Beamline 11.3.1 (developed by the Experimental Systems Group) at the Advanced Light Source (ALS). The ALS is supported by the U.S. Department of Energy, Office of Energy Sciences Materials Sciences Division, under contract DE-AC03-76SF00098 at Lawrence Berkeley National Laboratory.

3. Results and discussion

3.1. Structural analysis

Synthesis of the homodinuclear europium(III) complexes $[Eu(tfa)_3]_2$bpm (**1**) and $[Eu(tta)_3]_2$bpm (**2**) is accomplished in yields greater than 70% by reacting $EuCl_3$ with tfa or tta and bpm in a 2:6:1 ratio as previously described [27].

The structural analysis of compound **1** indicates that it crystallizes as an ethyl acetate solvate in the triclinic space group $P\bar{1}$. Each Eu^{III} ion in **1** (Fig. 1) is eight-coordinate and the complex is neutral. The coordination sphere around each Eu^{III} ion consists of six O atoms from three tfa ligands and two N atoms from the bpm ligand (average distances: Eu–O = 2.354 Å, Eu–N = 2.609 Å). Both Eu centers are in a distorted square-antiprismatic geometry with the approximate square planes defined as O3–O4–O5–O6 and N1–N2–O1–O2 (mean deviation of 0.275(4) and 0.304(4) Å, respectively, with an angle between the planes of 82.8(1)°) about Eu1 and O12–O13–O14–O15 and N3–N4–O10–O11 about Eu2 (mean deviation of 0.067(4) and 0.103(4) Å, respectively, and an angle of 89.9(1)°). The intramolecular Eu···Eu distance across the bridging bpm ligand is 6.8035(8) Å. The individual bpm rings are planar, with a mean deviation of 0.009(6) and 0.008(7) Å for planes defined by N1–N3–C25–C26–C27–C28 and N2–N4–C29–C30–C31–C32, respectively; they are rotated from planarity by 5.7(5)°.

The structural analysis of compound **2** indicates that it crystallizes without solvent in the lattice in the monoclinic space group $P2_1/c$, with the bpm ligand situated about a crystallographic center of symmetry. As with **1**, each Eu^{III} ion in **2** (Fig. 2) is eight-coordinate, bound by six O atoms from three tta and two N atoms from the bpm ligand. The geometry about the Eu centers can also be described as square-antiprismatic with approximate square planes defined as O3–O4–O5–O6 and N1–N2–O1–O2 (mean deviation of 0.158(4) and 0.056(4) Å, respectively, with an angle between the planes of 89.2(1)°). The average Eu–O and Eu–N distances of 2.370 Å and 2.646 Å, respectively,

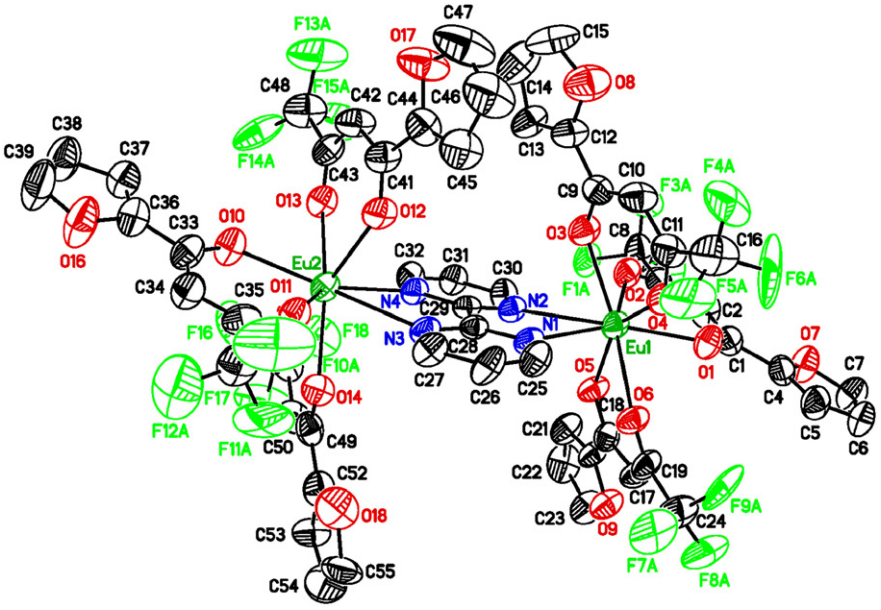

Fig. 1. Molecular structure of $[Eu(tfa)_3]_2$bpm (**1**) showing atomic numbering scheme, 50% thermal ellipsoid probability, only 1 conformation of the disordered CF_3 groups is shown, H-atoms omitted for clarity.

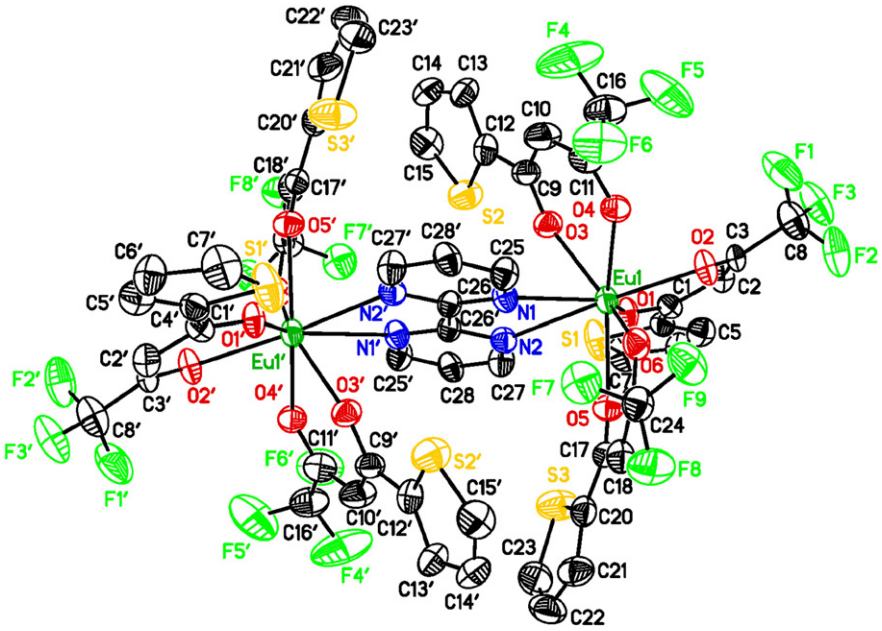

Fig. 2. Molecular structure of $[Eu(tta)_3]_2$bpm (**2**) showing atomic numbering scheme (symmetry-related atoms labeled with a prime), 50% thermal ellipsoid probability, H-atoms omitted for clarity.

are slightly larger than in **1**. The intramolecular Eu···Eu distance (6.9212(15) Å) across the bridging bpm ligand is approximately 0.1 Å longer than that observed in **1**. The individual bpm rings are planar, with a mean deviation of 0.008(6) Å for both rings and a rotation of 0° between the planes.

Simultaneous to our initial report on the synthesis of compound **2**, Shim and co-workers reported an alternate synthetic route to this complex [25]. Their structural analysis of $[Eu(tta)_3]_2$bpm reveals the presence of THF as the solvent of crystallization and a lower overall crystal symmetry of triclinic (space group $P\bar{1}$). They report a 6.3° rotation from planarity for the bpm ligand and a Eu···Eu separation of 6.993 Å. The average Eu–O and Eu–N distances are 2.394 Å and 2.687 Å.

Fernandes and co-workers report the structure of $[Eu(nta)_3]_2$(bpm) (nta = 1-(2-naphthoyl)-3,3,3-trifluoroacetone) [24] where the C_4H_3E (E = O, S) group in compounds **1** and **2** is replaced by a $C_{10}H_7$ group. For this complex, one observes Eu–O and Eu–N distances in the range 2.311(6)–2.384(7) Å and 2.598(8)–2.621(6) Å. The bridging bpm ligand is located on a center of symmetry (rotation from planarity is 0°) and the Eu···Eu distance is 6.856(1) Å.

Replacing both the CF_3 and C_4H_3E (E = O, S) moieties with C_6H_5 groups, Shim and co-workers synthesized and structurally characterized $[Eu(dbm)_3]_2(bpm) \cdot 2Et_2O$ (dbm = dibenzoylmethane) [25]. In this structure, the Eu^{III} sites are eight-coordinate with Eu–O and Eu–N averages distances of 2.343 Å and 2.677 Å. The Eu···Eu separation is 7.011 Å while the bridging bpm ligand is planar and centered about the inversion center.

The metrical details of compounds **1** and **2** also compare favorably with the Tb-containing complex, $[Tb(tta)_3]_2$bpm.EtOAc [26]. The reported Tb···Tb distance across the bridging bpm ligand is 6.7596(5) Å and the bpm ring rotation from planarity is 7.0(2)° (slightly larger than observed in the related structures).

3.2. Electronic and luminescence properties

The UV/Vis spectrum of toluene solutions of $[Eu(tfa)_3]_2$bpm and $[Eu(tta)_3]_2$bpm are dominated by intense broad absorptions associated with the tfa and tta ligands, with the bpm absorption appearing as a weak shoulder near 250 nm. The π–π^* transitions associated with both tfa and tta occur with a $\lambda_{max} = 340$ nm and are responsible for the "antenna" effect leading to the photoluminescence properties of these complexes. The mechanism of energy transfer leading to luminescence is illustrated in Fig. 3. After initial excitation into the ligand singlet excited state intersystem crossing to the ligand triplet state occurs.

This is followed by energy transfer from the ligand triplet state to the ^5D_J manifold of the Eu^{III} ion. All emissions originate from the $^5D_0$ state of the Eu^{III} ion to the ^7F_J manifold, with the $^5D_0 \rightarrow {}^7F_2$ transition being the most intense. This is attributed to the transition becoming allowed due to ligand field effects [29–31]. Due to the symmetry associated with the Eu-bpm-Eu center it is difficult to determine if there is electronic communication between the metal ions via the bpm bridging ligand. The large energy difference between the excited state orbitals associated with the bridging ligand and the metal ions, Fig. 3, suggests that bpm serves only to hold the two Eu(β-diketonate)$_3$ groups together.

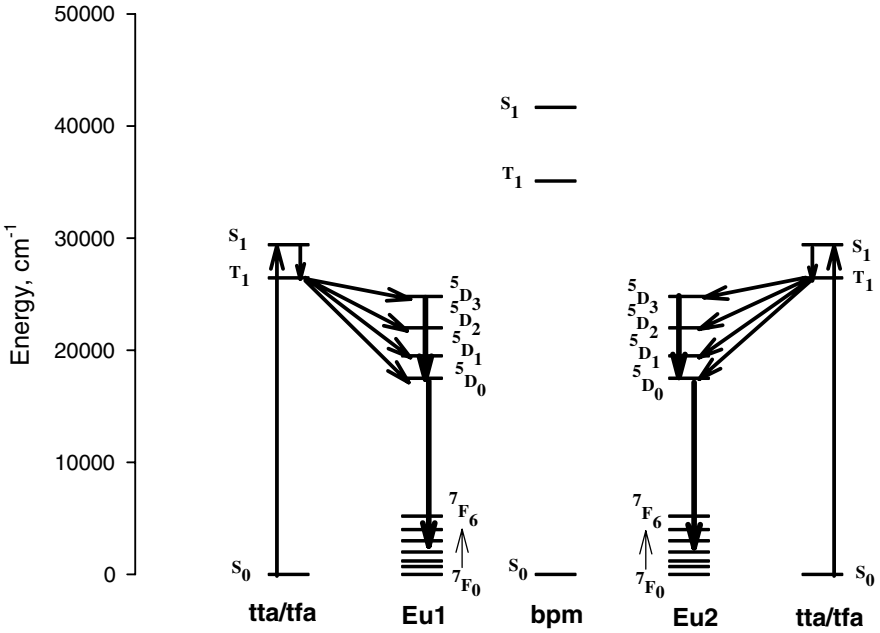

Fig. 3. Schematic energy level diagram and energy transfer process for europium homobimetallic complexes.

The emission spectra of the two europium bimetallic complexes **1** and **2** are very similar, as illustrated in Fig. 4.

The toluene solutions of $[Eu(tta)_3]_2bpm$ (dashed line) and $[Eu(tfa)_3]_2bpm$ (solid line) emit in the visible region when irradiated at 340 nm. The greater intensity observed for $[Eu(tta)_3]_2bpm$ suggests more efficient energy transfer from the triplet state of tta to the europium ^5D_J manifold compared to energy transfer of the triplet state of tfa to the europium ^5D_J manifold. The most intense transition in either complex is $^5D_0 \rightarrow {}^7F_2$ transition at 614 nm due to ligand field effects and the polarizability of the ligand environment around the metal [30].

3.3. Temperature dependent luminescence properties

The use of lanthanide complexes and particularly europium complexes as temperature probes results from the complexes temperature sensitivity. Deactivation of the $^5D_1$ and $^5D_0$ states through thermal quenching is attributed to vibrational interactions with their environment [30]. The

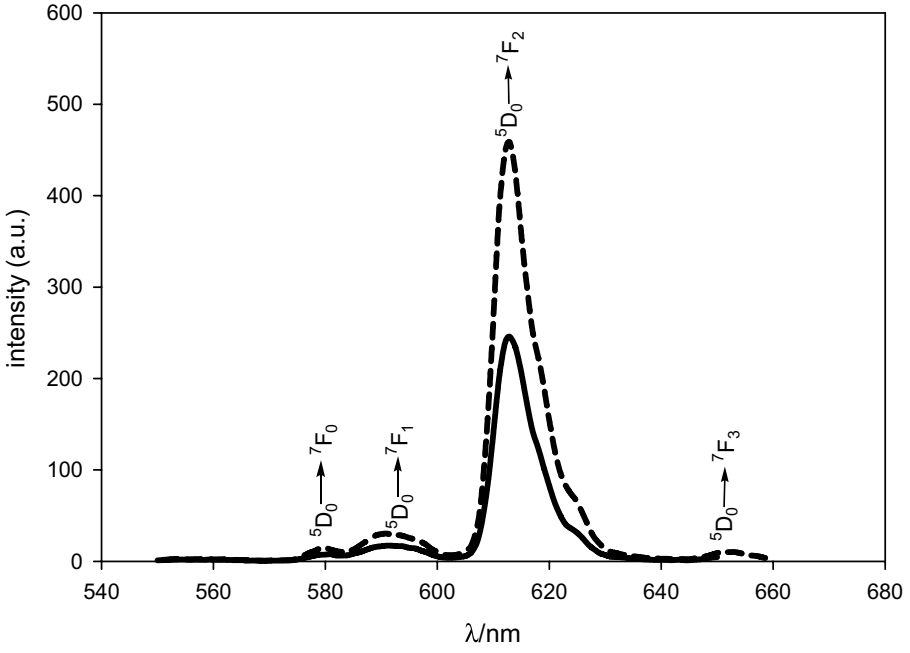

Fig. 4. Emission spectrum of toluene solutions of $[Eu(tta)_3]_2bpm$, dashed line, and $[Eu(tfa)_3]_2bpm$, solid line, at 5 °C. Excitation wavelength was 340 nm.

effect of temperature on the intensity of the emission spectrum and on the lifetime of the emission for $[Eu(tta)_3]_2bpm$ and $[Eu(tfa)_3]_2bpm$ was studied in toluene solutions in the temperature range 5 °C to 55 °C. For comparison similar measurements were made with the monometallic analogs $Eu(tta)_3bpy$ and $Eu(tfa)_3bpy$, where bpy = 2,2′-bipyridine. Fig. 5 illustrates the excitation and emission spectra for toluene solutions of $[Eu(tta)_3]_2bpm$ (Fig. 5A) and $[Eu(tfa)_3]_2bpm$ (Fig. 5B) in the temperature range 5 °C to 55 °C.

As expected the intensity of the $^5D_0 \rightarrow {}^7F_2$ transition at 614 nm decreases with increasing temperature. This is consistent with thermal deactivation of the $^5D_0$ and $^5D_1$ states of the europium [30]. The effect of temperature on the intensity of the 614 nm emission line is similar for the bimetallic ($[Eu(tta)_3]_2bpm$, $[Eu(tfa)_3]_2bpm$) and monometallic ($Eu(tta)_3bpy$, $Eu(tfa)_3bpy$) complexes studied suggesting a similar mechanism of thermal quenching. The monometallic complexes display similar intensity at the 614 nm emission for a given temperature. Intensity of the 614 nm emission for the bimetallic $[Eu(tta)_3]_2bpm$ is similar to that observed for the monometallics but is twice that observed for the tfa bimetallic complex, $[Eu(tfa)_3]_2bpm$.

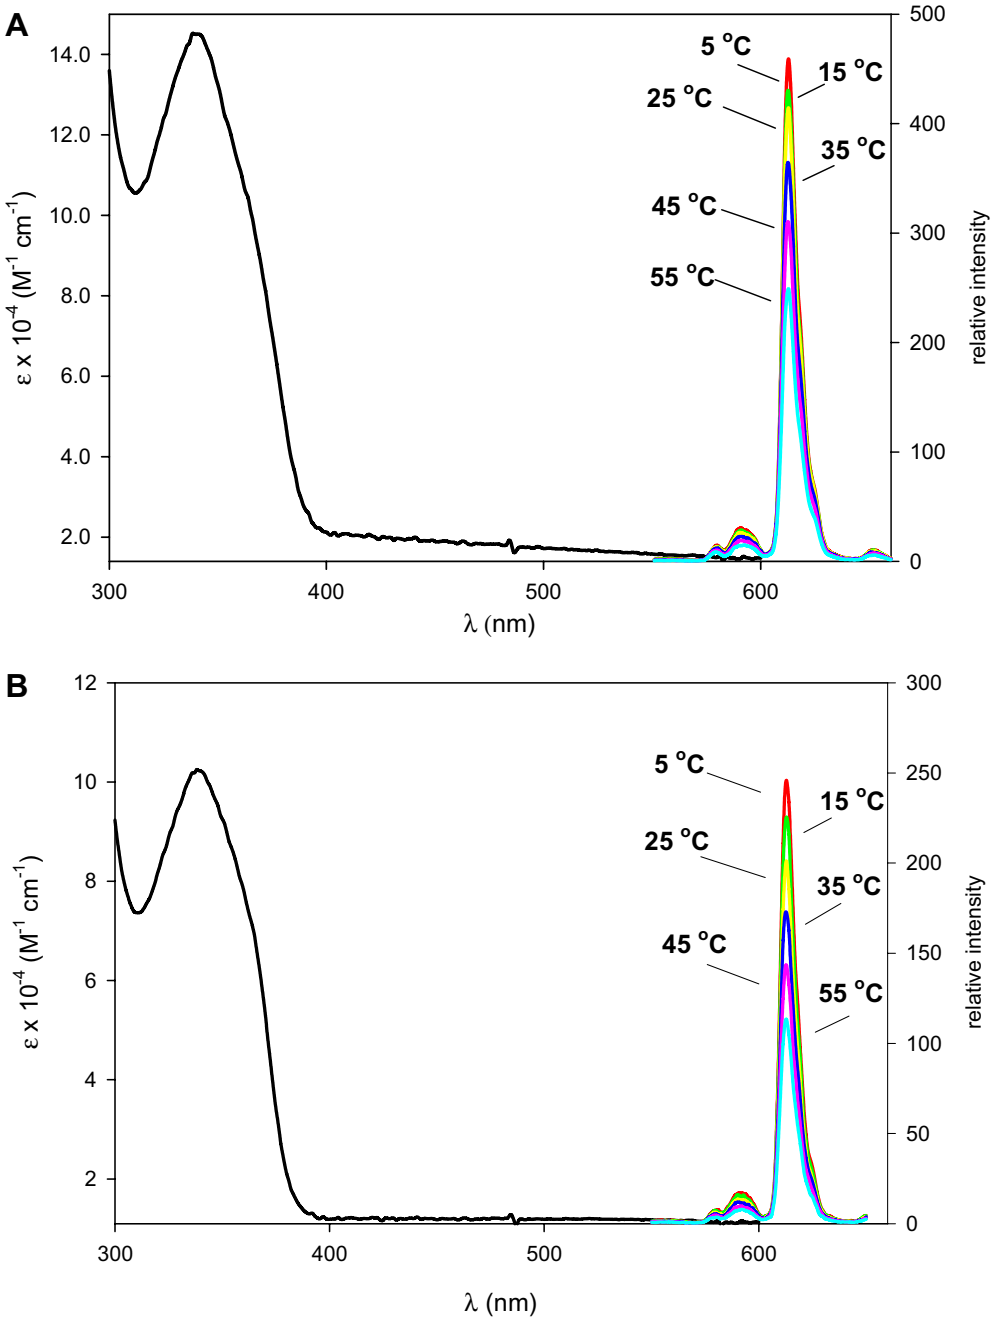

Fig. 5. Absorption and emission spectra in the temperature range 5 °C to 55 °C for toluene solutions of (A) $[Eu(tta)_3]_2bpm$ and (B) $[Eu(tfa)_3]_2bpm$.

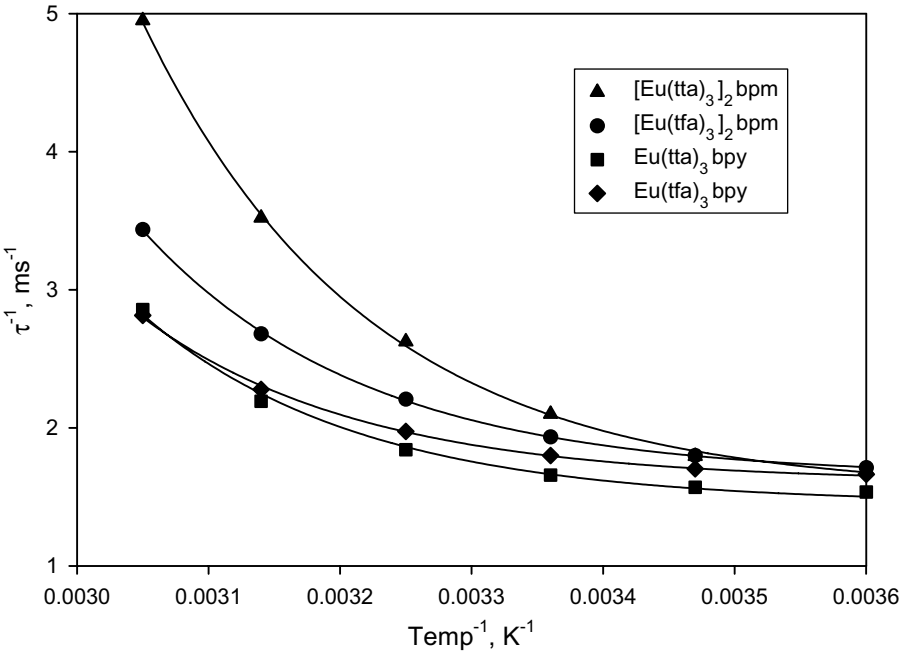

Fig. 6. Arrhenius plots of temperature data.

Table 3
Parameters used to fit the data in Fig. 6 to Eq. (1)

	$[Eu(tta)_3]_2bpm$	$[Eu(tfa)_3]_2bpm$	$Eu(tta)_3bpy$	$Eu(tfa)_3bpy$
k_0 (s^{-1})	1543	1646	1452	1609
k_1 (s^{-1})	2.02×10^{11}	1.10×10^{11}	1.26×10^{11}	9.36×10^{10}
ΔE (kJ mol^{-1})	48.8	48.9	50.0	49.6

Luminescent decay curves of the bimetallic and monometallic europium complexes in toluene fit to a monoexponential. The temperature dependence of the decay times for $[Eu(tta)_3]_2bpm$ (solid triangle), $[Eu(tfa)_3]_2bpm$ (solid circle), $Eu(tta)_3bpy$ (solid square) and $Eu(tfa)_3bpy$ (solid diamond) are illustrated in Fig. 6. These curves can be fit to an Arrhenius-type equation with correlation coefficients $r^2 > 0.9995$ [29–32]

$$1/\tau = k_0 + k_1 \exp(-\Delta E/RT) \quad (1)$$

where k_0 is the temperature independent decay rate, k_1 is the pre-exponential factor, ΔE is the energy gap between the $^5D_0$ state and high energy states and R is the gas constant. Table 3 gives the values for the parameters in equation one used to fit the data for the four europium complexes.

These values are consistent with those observed for $Eu(tta)_3L$, $Eu(fod)_3L$, $Eu(nta)_3L$; where L is a dipyrazolyltriazine derivative, fod is 6,6,7,7,8,8,8-heptafluoro-2,2-dimethyl-3,4-octanedionate and nta is 1-(2-naphthyl)-butane-1,3-dione [7]. From this data it does not appear that the luminescent temperature effects can be related to structural differences in these complexes.

4. Conclusions

The luminescent properties of two new europium homobimetallic complexes, $[Eu(tfa)_3]_2bpm$ (**1**) and $[Eu(tta)_3]_2bpm$ (**2**), and the dependence of the luminescence on temperature were presented. Structural analysis of compound **1**, as an ethyl acetate solvate, was presented for the first time while structural analysis of complex **2**, as a THF solvate, had been previously described in a triclinic space group while our analysis of solvent-free **2** indicates a monoclinic space group. Emission studies of compounds **1** and **2** in toluene solutions are typical of europium complexes containing β-diketonate "antenna" ligands. The intensity of the emission spectra for compounds **1** and **2** is inversely related to temperature. Lifetime measurements in the temperature range of 5 °C to 55 °C fit a monoexponential. Comparison of the luminescence properties and lifetimes of the homodinuclear compounds to their monometallic analogs are very similar. This suggests that there is little electronic communication via the bridging bpm ligand and the two Eu^{III} ions allowing the bimetallic compounds to behave as monometallic compounds in solution. Further studies of heterobimetallic lanthanide complexes bridged by bpm are needed to substantiate this claim.

2,4-hexadiene and L6 = 2,5-bis(4-pyridyl)-3,4-diaza-2,4-hexadiene (Fig. 1)}.

In this series of compounds six nitrogen donor-based ligands have been used. These compounds have been selected as they are capable to act as bridging ligands and thus may form polymeric structures. We will show that subtle changes in the use of conformationally flexible ligands as spacers in the design and construction of coordination polymers may lead to new polymeric networks.

As the counter-ion in these Hg(II) coordination polymers I^- anions have been used, which may also be able to act as bridges between the metal centers. With two types of bridging ligands in one coordination system we anticipated that the complexes will be able to form 1D, 2D or 3D coordination polymers either bridged via the iodide or via the nitrogen donor-based ligands, or via both. With such a multifariousness of possibilities it is a challenge to accurately predict the nature of the compounds one will obtain. Despite these challenges the rational construction of new structurally defined metal–organic frameworks using bridging anions as well as bridging nitrogen donor-based ligands promises to be a versatile approach towards the construction of metal coordination polymers of heavy metal ions.

Recent investigations have addressed the use of the ligands L1–L6 [37–43] for the preparation of coordination polymers with other metal ions [37–43]. These studies have demonstrated that the long conjugated rigid ligands L1–L6 are capable of coordinating transition metal centers with both terminal pyridyl and diaza nitrogen donors and generate novel coordination polymers. The relative orientations of the nitrogen donors on the pyridyl rings towards the zig-zag XC=N–N=CX–, X = H or CH_3, and spacer resulted in unusual building blocks, leading to the construction of polymeric motifs that have not been achieved using normal rigid bidentate organic ligands. The soft acid Hg(II) ion, on the other hand, has a versatile coordination chemistry and can serve to link bridging ligands to form polymeric compounds with novel coordination patterns with the ligands L1–L6.

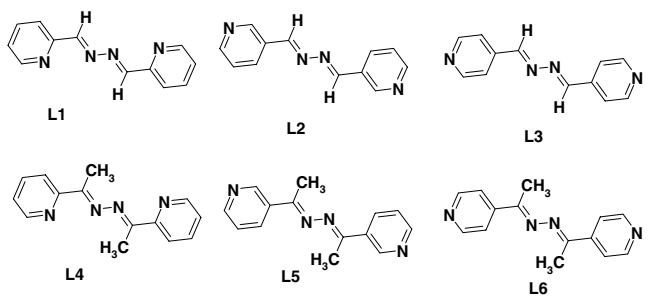

Fig. 1. Organic nitrogen donor-based ligands used in the construction of mercury(II) iodide coordination polymers.

2. Experimental

2.1. Materials and physical techniques

With the exception of the ligands L1–L6 which were prepared according to the literature procedures [44–46], all reagents and solvents for the synthesis and analysis were commercially available and used as received. IR spectra were recorded using Perkin–Elmer 597 and Nicolet 510P spectrophotometers. Microanalyses were carried out using a Heraeus CHN–O– Rapid analyzer. Melting points were measured on an Electrothermal 9100 apparatus and are uncorrected. The thermal behaviour was measured with an PL-STA 1500 apparatus. The luminescent properties were investigated with a Shimadzu RF-5000 spectrofluorophotometer, but the six compounds reported here have not shown luminescent properties.

Crystallographic measurements were made at 293 K for compounds **1**–**6** and 273 K for compound **3** using a Bruker APEX area-detector diffractometer. The intensity data were collected using graphite monochromataed Mo Kα radiation. The structures were solved by direct methods and refined by full-matrix least-squares techniques on F^2. Structure solution and refinement was accomplished using SIR97, SHELXL97 and WINGX [47,48]. The molecular structure plots were prepared using the ORTEPIII [49] and MERCURY [50]. Crystallographic data and details of the data collection and structure refinements are listed in Tables 1 and 2. Bond lengths (Å) and angles (°) for compounds **1**–**6** are reported in Tables 3 and 4. The observed anisotropic thermal parameters, the calculated structure factors, and full lists of bond distances, bond angles and torsion angles are given in the supplementary material.

2.2. Synthesis of $[Hg_2(L1)I_4]_n$ (1)

1,4-Bis(2-pyridyl)-2,3-diaza-1,3-butadiene (L1) (0.5 mmol, 0.105 g) and mercury(II) iodide (0.159 g, 0.5 mmol) were placed in main arm of the branched tube. Methanol was carefully added to fill the arms, the tube was sealed and the ligand-containing arm immersed in an oil bath at 60 °C while the other arm was kept at ambient temperature (Fig. S1). After 2–3 days, yellow crystals (d.p. = 225 °C), had deposited in the cooler arm which were isolated, filtered off, washed with acetone and ether and air dried (0.118 g, yield 85%). *Anal.* Calc. for $C_{12}H_{10}Hg_2I_4N_4$: C, 12.87; H, 0.90; N, 5.00. Found: C, 12.50; H, 0.80; N, 5.10%.

2.3. Synthesis of $[Hg(L2)I_2]_n$ (2), $[Hg(L3)I_2]_n$ (3), $[Hg_2(L4)I_4]_n$ (4), $[Hg(L5)I_2]_n$ (5), $[Hg(L6)I_3](HL6)$ (6)

The compounds **2**–**6** were prepared using the same the method as for compound **1**.

dyl)-3,4-diaza-2,4-hexadiene, L5 = 2,5-bis(3-pyridyl)-3,4-diaza-2,4-hexadiene and L6 = 2,5-bis(4-pyridyl)-3,4-diaza-2,4-hexadiene}. In preparation of all six new compounds the ratio of metal to ligand was same, as 1:1, but the resulted compounds had the different stoichiometry, M_2L in compounds **1** and **4**, ML in the compounds **2**, **3**, **5** and [ML][HL] in the compound **6**. The relatively weak absorption bands around 3025–3035 cm^{-1} in the IR spectra are due to the C–H modes involving the aromatic ring hydrogen atoms. In the compound **4**–**6** the relatively weak absorption bands around 2940–2960 cm^{-1} in the IR spectra are assigned to the C–H modes of groups of ligands L4-L6. The broad absorption band at 3290 cm^{-1} is assigned to the ν(–NH) modes of HL6 component of compound **6**. The absorption bands with variable intensity in the frequency range 1404–1600 cm^{-1} correspond to vibrations of the pyridyl rings.

3.2. Structure descriptions

3.2.1. $[Hg_2(L1)I_4]_n$ (**1**) and $[Hg_2(L_4)I_4]_n$ (**4**)

Single crystal X-ray analysis reveals that the complexes $[Hg_2(L1)I_4]_n$ (**1**) and $[Hg_2(L4)I_4]_n$ (**4**) (Tables 1–3) crystallize in the monoclinic space groups $P2_1/c$ and $C2/c$, respectively. The crystal structures of **1** and **4** consist of two- and one-dimensional polymers (Figs. 2 and 3). In compounds **1** and **4** the ligands L1 and L4 are chelating with each one nitrogen atom of the pyridyl and diaza groups on one side of the molecule coordinating to a mercury(II) ion. The ligand is located on a crystallographic inversion center, thus forming I_2Hg–(L)– HgI_2 moieties. Of the I^- anions one acts as a monodentate ligand with an Hg–I bond length of 2.6418(11) and 2.6683(5) Å in the compounds **1** and **4**, respectively, whereas the other forms a full halogen bridge to a mercury atom of an adjacent I_2HgL moiety. In the compound **1** two I^- anions bridge between three different Hg atoms, thus building Hg–μI–Hg–μI–Hg bridged two-dimensional polymer as shown in Fig. 3a. In the compound **4** two I^- anions bridge between two different Hg atoms, thus building doubly Hg–$(\mu I)_2$–Hg and the Hg_2I_2 rhombs bridged one-dimensional chains as shown in Fig. 3b. The coordination number in compounds **1** and **4** is five and the geometry can be regarded as a distorted tetragonal pyramid

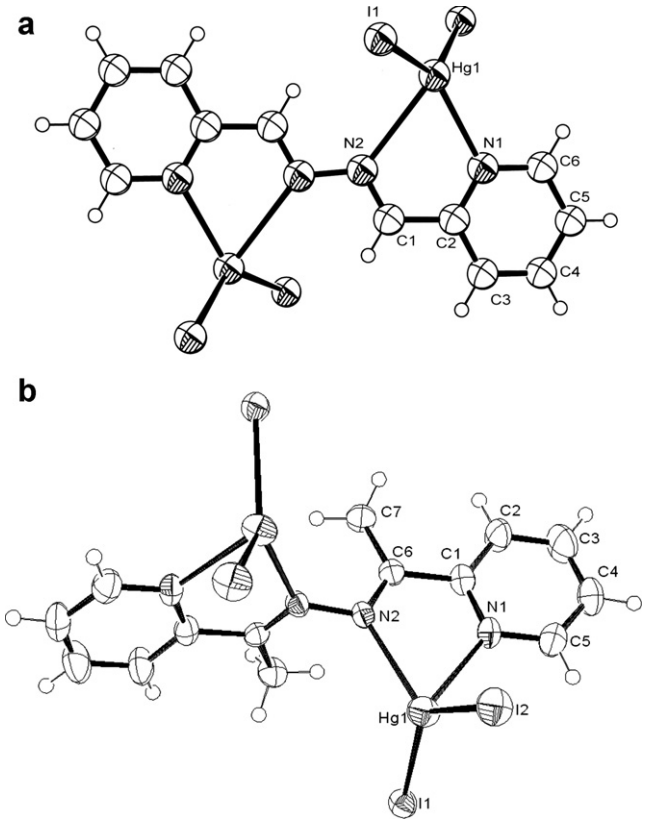

Fig. 2. X-ray crystal structure showing the chelating and bridging coordination of ligands L1 and L4 (a) in compound **1** and (b) in compound **4** (50% thermal displacement ellipsoids).

with two pyridyl nitrogen and two bridging I^- anions in the *basal* positions and one unbridging iodide in the *apical* position. The Hg···Hg distances within the I_2Hg–(L1)–$HgI_2$and I_2Hg–(L4)–HgI_2moieties are 6.372(1) and 5.052(1) Å, those bridged by the I^- anions are 5.039(3) and 4.518(3) Å in the compounds **1** and **4**, respectively. It is interesting that the 2D coordination polymer in compound **1** was changed to 1D one in compound **4** by replacing of methyn hydrogen atoms of ligand L1 with methyl groups in the ligand L4. The main difference of two structure due to the bridging mode of one of I^- anions, as Hg–μI–Hg–μI–Hg in compound **1** and as Hg–$(\mu I)_2$–Hg in compound **4**. However, it seems that the steric effects of methyl groups in the ligand L4 have an effect on

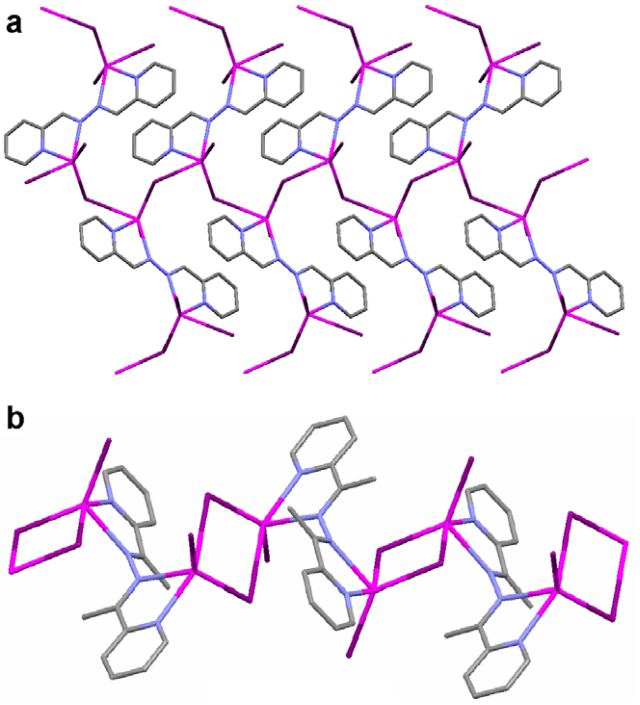

Fig. 3. Showing the 2D and 1D networks (a) in compound **1** and (b) in compound **4**.

the kind of bridging mode of I atoms in the mercury(II) coordination polymers.

3.3. $[Hg(L2)I_2]_n$ (**2**), $[Hg(L3)I_2]_n$ (**3**) and $[Hg(L5)I_2]_n$ (**5**)

Single X-ray crystal analysis reveals that $[Hg(L2)I_2]_n$ (**2**), $[Hg(L3)I_2]_n$ (**3**) and $[Hg(L5)I_2]_n$ (**5**) (Tables 2 and 4) crystallize in orthorhombic, monoclinic and orthorhombic space groups *Pnam*, *P*2/*c* and *Pnma*, respectively. The crystal structures of compounds **2**, **3** and **5** consists of one-dimensional polymeric units of $[Hg(\mu\text{-}L)I_2]$ (L = L2, L3 and L5) (Figs. 4 and 5). The terminal nitrogen atoms of the ligands L2, L3 and L5 are linked to two different mercury atoms, resulting in one-dimensional polymeric units in the solid state. The coordination environments of the Hg ions are distorted tetrahedral with the ligands L2, L3 and L5, thus generating angular nodes at the metal moieties resulting in 1D zig-zag chains. The Hg···Hg distances within the I_2Hg–(L2)–HgI_2, I_2Hg–(L3)–HgI_2 and I_2Hg–(L5)–HgI_2 moieties are 14.90(3), 16.24(2) and 14.90(2) Å in the compounds **2**, **3** and **5**, respectively. The N–Hg1–N and I–Hg1–I angles are 85.0(3) and 148.25(3)° in **2**, 84.2(2) and 148.17(2)° in **3** and 90.61(18) and 145.74(2)° in **5**. The N–Hg1–N angle in the compound **5** is larger than compounds **2** and **3**. This matter may also be related to the presence of methyl groups and increasing of steric effects.

3.4. $[Hg(L6)I_3](HL_6)$ (**6**)

Single X-ray crystal analysis shows that compound **6** (Tables 2 and 4) crystallizes in the triclinic space group $P\bar{1}$. In compounds **1**–**5** the nitrogen of ligands coordinate via both their pyridyl N atoms. In contrast to this the L6 ligand in **6** is linked with only one nitrogen atom of the pyridyl groups on one side of the molecule coordinating to a mercury(II) ion. Determination of the structure of $[Hg(L6)I_3](HL6)$ (**6**) showed the complex in the solid state (Fig. 6) to consists of mononuclear units. The molecular structure of the complex **6** consists of discrete $[Hg(L6)I_3]^-$ anionic and $HL6^+$ cationic compounds. The anionic complex is mononuclear and the mercury atoms are linked by three iodine and one nitrogen atoms and can be considered four-coordinate with I_3N donor atom arrays. The coordination about Hg is distorted tetrahedral and one nitrogen atom of L6 ligands is not coordinated to Hg atoms (Figs. 6 and 7) and thus the L6 acts as a less commonly unidentate ligand.

An interesting point is that the HL_6^+ cations were yielded by resulting in proton–ion transfer between molecular species in the solution. The $HL6^+$ cations are linked by hydrogen bonding (Fig. 7). The hydrogen atom of uncoordinated HL_6^+ cotions are involved in hydrogen bonding, acting as hydrogen-bond donors with N atoms from HL_6^+ cation. The hydrogen bond distances *d*(D–H), *d*(H···A), *d*(D···A), and angle ⟨(DHA)} for N(5)–H(5N)···N(8)[1 + *x*, 1 + *y*, *z*] are 0.86, 1.81, 2.666(6) Å, 177.1°, respectively. As shown in Fig. 6, the hydrogen bonding yields infinite chains of $HL6^+$ relatively perpendicular to mononuclear complex of $[Hg(L6)I_3]^-$ anionic. The other interesting feature complex is that, there are C–H···I interactions, the weak hydrogen bonding, between the hydrogen atoms of $HL6^+$ cations and iodine atoms belonging to adjacent anionic complexes, as shown in Fig. 7. The distance of C–H···I is 4.072 Å and the distances of I···H is 3.167 Å. Indeed, the structure consists an extensive hydrogen-bond network of N–H···N and C–H···I interactions. The reported C–H···I distances range is about 3.20 Å in recent reported species [52,53]. Thus, C–H···I appears to be yet another factor which can make varying contributions to the stability of this complex. Consequently, the two perpendicular anionic and cationic components forms into a two-dimensional network.

4. Thermogravimetric analysis

In order to examine the thermal stabilities of compounds **1**-**6**, thermal gravimetric (TG) and differential thermal analyses (DTA) were carried out between 30 and 700 °C. Compound **1** does not melt and is stable up to 225 °C. The TG curve of compound **1** indicates the decomposition of the compound takes place in one step at 225 °C with two endothermic effects at 250, 304 °C (Fig. S2). The TG curve of compound **2** indicates that this compound does not melt and is stable up to 180 °C at which temperature it begins to decompose. The compound **2** decomposes at 180–600 °C with three exothermic effects at 195, 505 and 610 °C (Fig. S3). The TG curve of compound **3** indicates the release of the L3 molecule to takes place at 175 °C

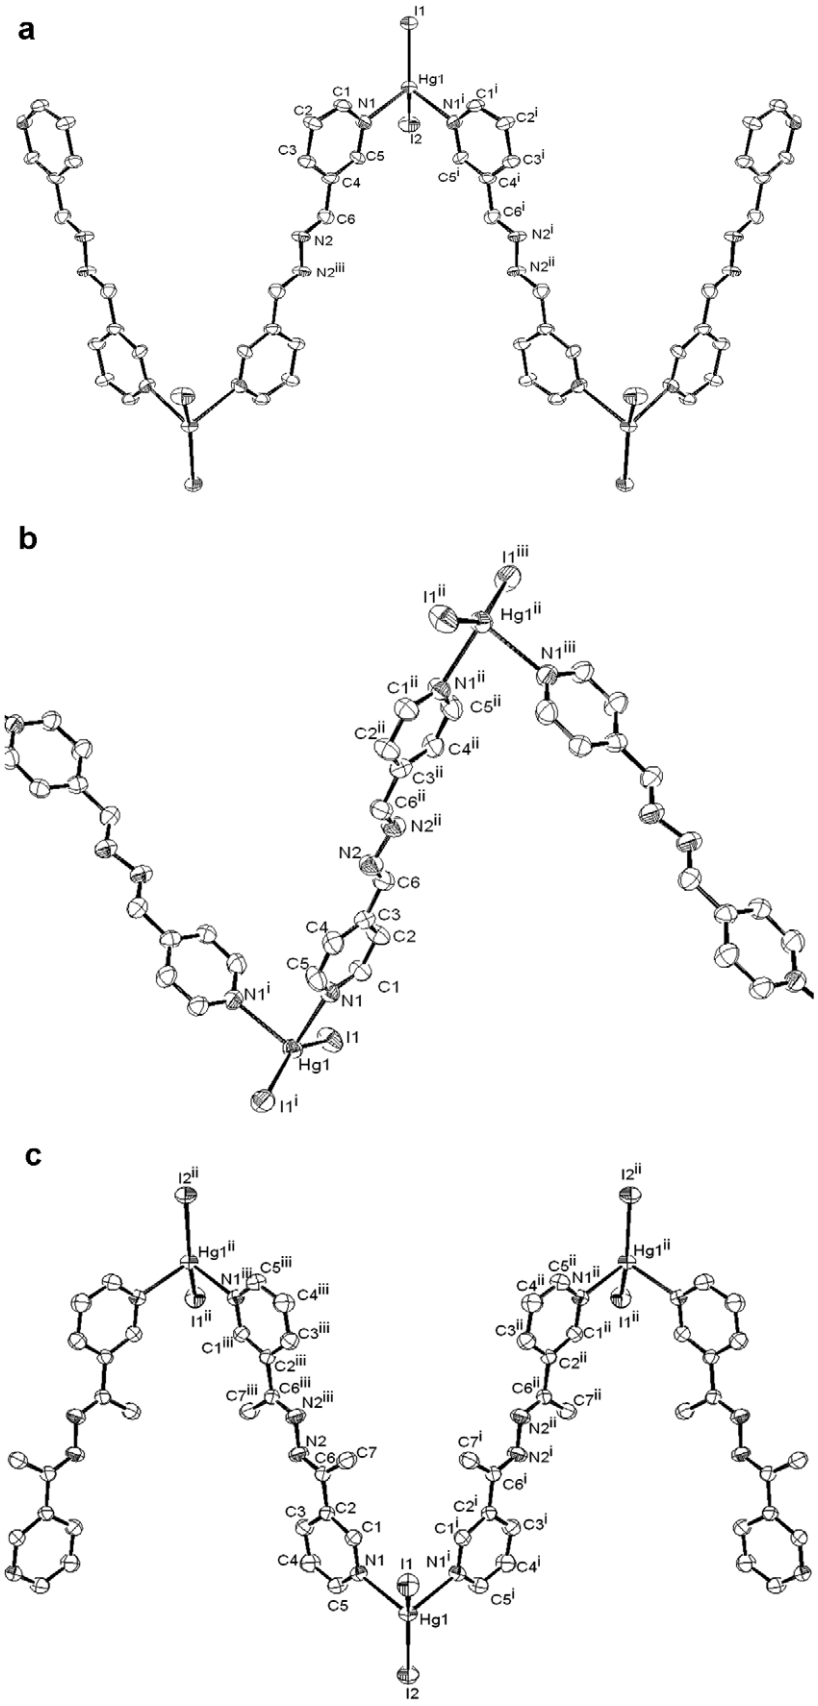

Fig. 4. X-ray crystal structure showing the one-dimensional zig-zag polymer of (a) in compound **2** (i: x, y, $-z+1/2$; ii: $-x$, $-y$, $z+1/2$; iii: $-x$, $-y$, $-z$), (b) in compound **3** (i: $-x$, y, $-z+1/2$; ii: $-x$, y, $-z+1/2$; iii: x, $-y$, $z+1/2$) and (c) in compound **5** (i: $-x$, $y+1/2$, $-z$; ii: x, $-y+1/2$, z; iii: $-x$, $-y$, $-z$). (50% thermal displacement ellipsoids).

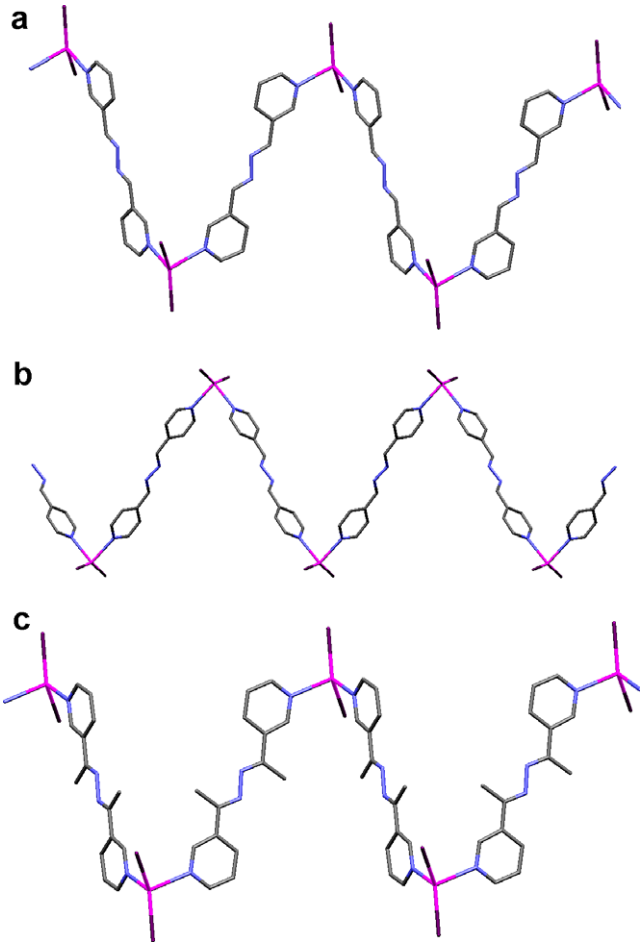

Fig. 5. 1D zig-zag network of the (a) in $[Hg(L2)I_2]_n$ (**2**), (b) in $[Hg(L3)I_2]_n$ (**3**) and (c) in $[Hg(L5)I_2]_n$ (**5**).

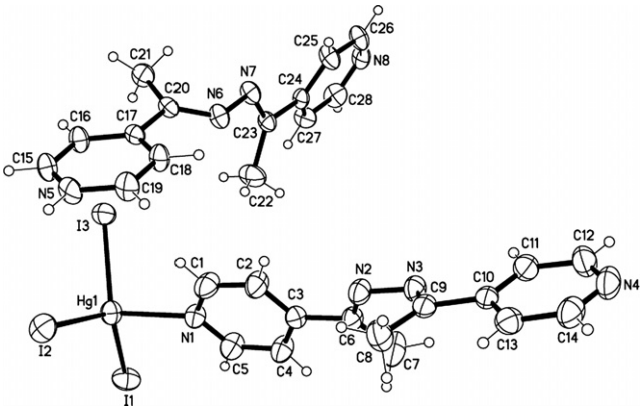

Fig. 6. X-ray crystal structure of compound **6** (50% thermal displacement ellipsoids).

(observed 31.40%, Calc. 31.59%). The solid residue formed at around 180 °C is suggested to be HgI_2. Only at even higher temperatures is it further decomposed, ultimately giving solid that appears to be HgO that under higher temperature is evaporated (Fig. S4). The TG curve of compound **4** indicates the decomposition of compound to

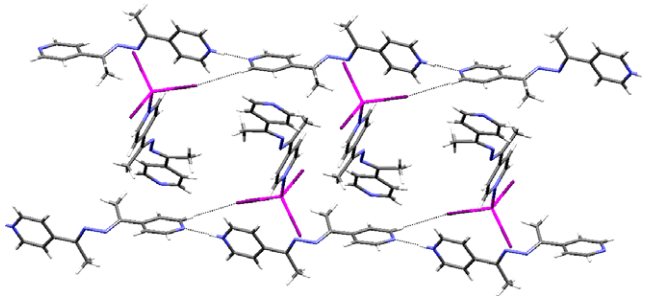

Fig. 7. Depiction of the N···HN hydrogen bonds and weak C–H···I interactions in compound **6**.

take place in the range between 195 and 535 °C with one endothermic effect at 210 and two exothermic effect at 215 and 530 °C (Fig. S5). Compound **5** does not melt and is stable up to 202 °C at which temperature it begins to decompose. The TG curve of compound **5** indicates the decomposition take place between 195 and 540 °C with one endothermic effect at 220 and two exothermic effect at 400 and 535 °C (Fig. S6). The TG curve of compound **6** indicates that the thermal behavior of this compound is different with compounds **1**–**5**. Compound **6** is stable up to 215 °C at which temperature the ligands L6 begins to be removed (Fig. S7). The solid residue formed at around 250 °C is suggested to be the L6-free compound, probability $HHgI_3$ (observed 43.70, Calc. 42.38%), that is stable to 550 °C. In summary, the thermogravimetric analysis shows that all six frameworks have a remarkably thermal stability that they do not melt and only decompose above temperatures of 175–225 °C.

5. Conclusions

Six new mercury(II) coordination polymers with L1 = 1,4-bis(2-pyridyl)-2,3-diaza-1,3-butadiene, L2 = 1,4-bis(3-pyridyl)-2,3-diaza-1,3-butadiene, L3 = 1,4-bis(4-pyridyl)-2,3-diaza-1,3-butadiene, L4 = 2,5-bis(2-pyridyl)-3,4-diaza-2,4-hexadiene, L5 = 2,5-bis(3-pyridyl)-3,4-diaza-2,4-hexadiene and L6 = 2,5-bis(4-pyridyl)-3,4-diaza-2,4-hexadiene, $[Hg_2(L1)I_4]_n$ (**1**), $[Hg(L2)I_2]_n$ (**2**), $[Hg(L3)I_2]_n$ (**3**), $[Hg_2(L4)I_4]_n$ (**4**), $[Hg(L5)I_2]_n$ (**5**), $[Hg(L6)I_3](HL6)$ (**6**), have been synthesized using a thermal gradient approach, the branched tube method. In the assembled processes of compounds **1**–**6**, all factors such as the metal, inorganic anions, solvent medium and metal/ligand ratio are kept constant and the only varied parameter is the ligand, **L1**-**L6** (1,4-bis(X-pyridyl)-2,3-diaza-1,3-butadiene for **1**–**3** and 1,4-bis(X-pyridyl)-2,3-diaza-1,3-hexadiene for **4**–**6**, X = 2, 3 and 4). The compounds are structurally diverse showing three main structural motifs: The coordination polymers obtained from HgI_2 with the ligands L2, L3 and L5 show one-dimensional zig-zag motifs and in these compounds the HgI_2 units are connected to each other by the ligands L2, L3 and L5 through the pyridyl nitrogen atoms. The L1 and L4 ligands in the compounds **1** and **4** act as both a chelating and bridging group by two nitrogen atoms of

the pyridyl groups and two nitrogen atoms of diaza group. The Hg–μI–Hg bridge augments the structures into a two- and one-dimensional coordination polymers, respectively. In the compound **6** the ligand L6 acts as a monodentate ligand, resulting form a discrete compound. This research not only shows the significant influences of the coordination modes and flexibilities of ligands L1–L3 on the structural topology but also illustrates the effect of the substituted methyl on the polymeric components L4–L6, which provides valuable instructions for the rational syntheses of coordination polymers with desired molecular architectures. Also this study demonstrates the capacity of mercury ions as soft lewis acids that are capable to form compounds with coordination numbers of four or five and consequently act in different forms of coordination polymers.

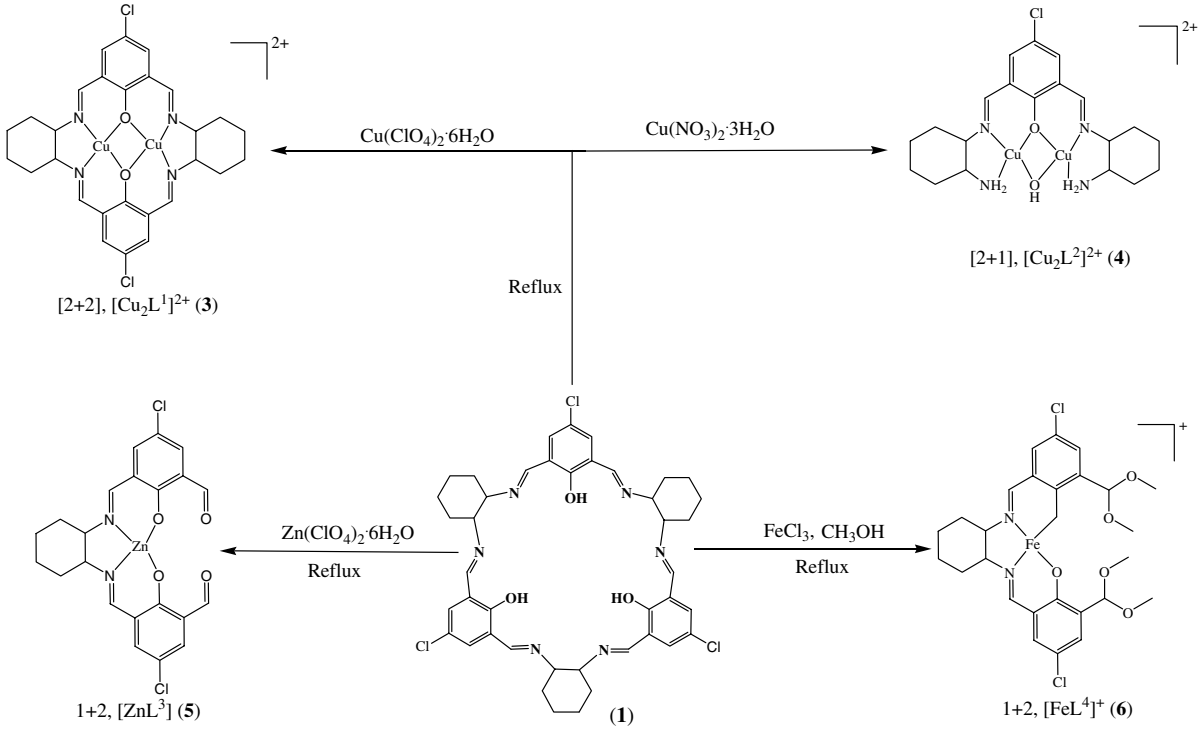
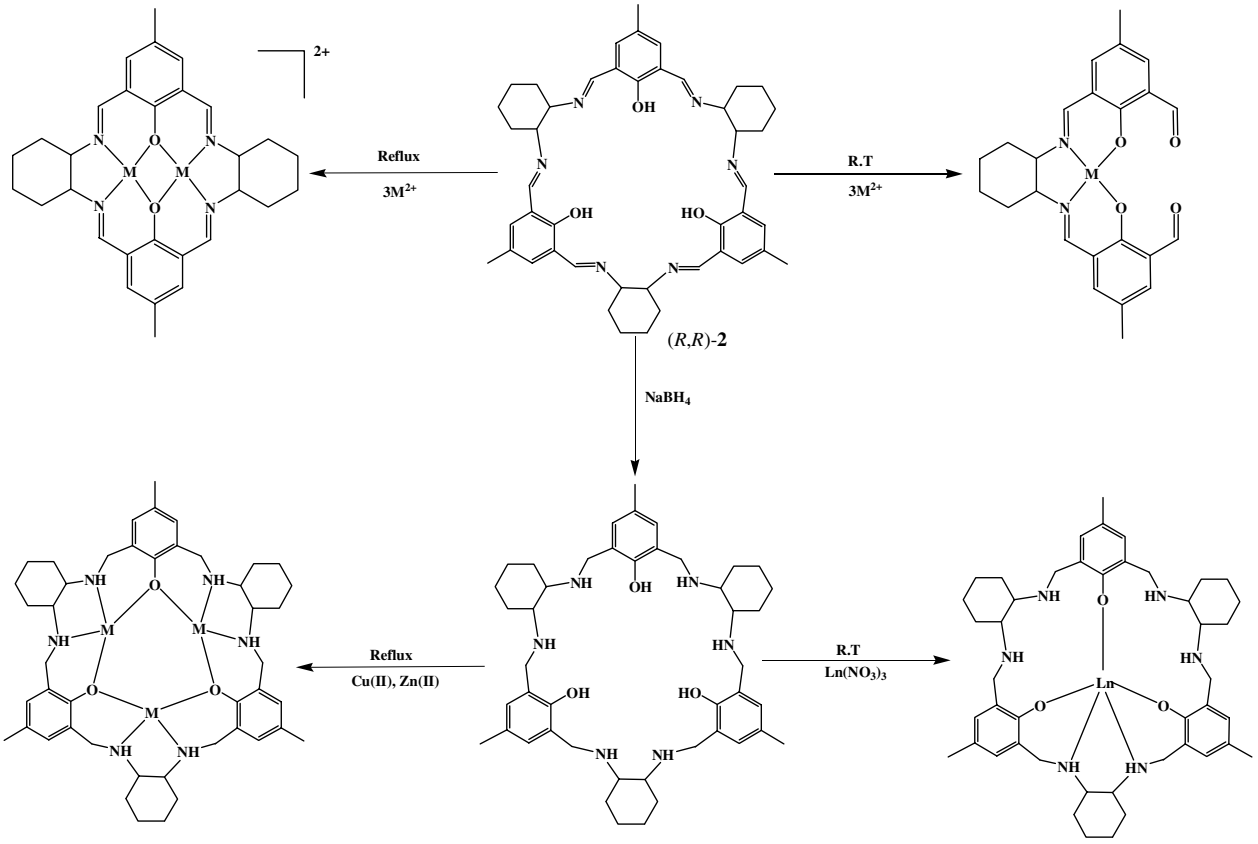
[Cu(II), Zn(II), Ni(II), Mn(II)] produces three [2 + 2] dinuclear [Cu(II), Zn(II), Ni(II)] macrocyclic complexes under reflux condition and one [1 + 2] mononuclear Mn(II) complex at room temperature in which the rearrangement of the backbone occurs [10]. In addition, the reduction of chiral (*R*,*R*)-**2** ligand by $NaBH_4$ leads to the amine macrocycle that is able to form mononuclear or multinuclear complexes [11,12]. Until now, most of the studies are focused on (1*R*,2*R*)-diamine derivatives [8–12], however, (1*S*,2*S*)-diamine involved structures are rarely reported. Herein we use chiral [(1*R*,2*R*) and (1*S*,2*S*)] and racemic *trans*-cyclohexane-1,2-diamines to prepare [3 + 3] macrocycles for the sake of comparison. In order to explore the size matching effect of macrocycles and the stereochemical preferences of metal ions, together with the C–H···Cl hydrogen bonding interactions with chlorine acceptors, we focus our attentions on the coordination chemistry of chlorine substituted [3 + 3] macrocycles **1**. In our previous work, we have succeeded in preparing a series of [2 + 2] Schiff-base macrocyclic ligands and their complexes using a sodium template method [13]. Of special emphasis was placed on the self-assembly of macrocyclic dinuclear zinc(II) moiety with diverse architectures and functions [14,15]. By the same method we prepared [3 + 3] Schiff-base macrocycles **1** and **2** (Scheme 1). The treatment of **1** with certain transitional metal salts [Cu(II), Zn(II), Fe(III)] with different counterions under reflux condition led to the cleavage of Schiff-base C=N double bonds and the rearrangement of the macrocycles (Scheme 2). We acquired [2 + 2], [2 + 1], [1 + 2] kinds of ring-contraction metal complexes in the process of bringing up single crystals. Size effect and coordination geometry of the metal centers, the presence of different counterions and solvents play significant roles on the formation of the final products. Herein, we describe the preparation, spectral and crystallographic characterizations of these ring-contraction complexes, where two new sorts of half-macrocyclic complexes **4** and **6** are included, as well as the comparisons between our contribution in this work and previous reports (Scheme 3).



Scheme 1. General synthetic scheme of macrocycles.



2. Experimental

2.1. Materials and measurements

Chiral [(1*R*,2*R*) and (1*S*,2*S*)] and racemic *trans*-cyclohexane-1,2-diamines were purchased directly from Aldrich. 2,6-Diformyl-4-substituted phenols (R = Cl or CH_3) were pre-

Scheme 2. Schematic illustration for the preparation of complexes **3**–**6**.

Scheme 3. Schematic illustration for Zacharias and Lisowski's work.

pared by an improved oxidation method using active manganese(IV) dioxide [16]. Sodium 2,6-diformyl-4-substituted phenolates were obtained by mixing equimolar amounts of 2,6-diformyl-4-substituted phenols and NaOH in ethanol. The other reagents were of analytical grade from commercial sources and were used without any further purification. Elemental analyses were measured with a Perkin–Elmer 1400C analyzer. Infrared spectra (IR, 4000–400 cm^{-1}) were collected on a Nicolet FTIR 170X spectrophotometer at 25 °C using KBr plates. ^1H NMR spectra were obtained in a Bruker 500 MHz NMR spectrometer. Electrospray ionization (ESI-MS) mass spectra were recorded on a Finnigan MAT SSQ 710 mass spectrometer in a scan range 100–1200 amu. Luminescence spectra were recorded on a Hitachi 850 fluorescence spectrophotometer at room temperature (25 °C). Ultraviolet–Visible (UV–Vis) spectra were recorded on a Shimadzu UV-3100 spectrometer. The circular dichroism spectra were measured with a JASCO J-810 spectopolarimeter using the same solutions as those for the UV–Vis determination. The optical rotation values were determined *via* a WZZ-115 digital auto-polarimeter.

Caution: Perchlorate salts are potentially explosive and should be treated with care and used only in small quantities.

2.2. Synthesis of racemic-*1*

A solution of racemic *trans*-cyclohexane-1,2-diamine (0.57 g, 5 mmol) in ethanol (20 mL) was added dropwise to a suspension of sodium 2,6-diformyl-4-chlorophenolate (1.05 g, 5 mmol) in ethanol (30 mL). The resulting solution was stirred and heated to reflux. As the reaction progressed, the solution became clear quickly. The mixture was kept refluxed for 3 h and concentrated on a rotary evaporator to dry, and then methanol (100 mL) was poured into the residue until yellow microcrystals appeared. The deposits were filtered off and collected in a 70% yield (0.92 g). ESI-MS gave the molecular ion peak at $m/z = 789.2$ (100%), supporting the [3 + 3] condensation. m.p. > 300 °C; ^1H NMR (500 MHz, $CDCl_3$) $\delta =$ 8.68 (3H, s, HC=N), 8.26 (3H, s, HC=N), 7.84 (3H, s, ArH), 7.18 (3H, s, ArH), 3.45 (6H, m, N–CH), 1.93–1.54 (24H, m, CH_2CH_2); UV–Vis (CH_2Cl_2, nm): λ_{max} (ε) = 250, 348; IR data (KBr): $v = 3431$ (w), 2983 (m), 2859 (m), 1637 (s), 1584 (s), 1447 (s), 1374 (m), 1295 (m), 1253 (m), 1143 (w), 1005 (m), 873 (w), 718 cm^{-1} (w). *Anal.* Calc. (%) for $C_{42}H_{45}Cl_3N_6O_3$: C, 64.00; H, 5.75; N, 10.66. Found: C, 63.92; H, 5.83; N, 10.67%. ESI-MS (CH_3OH): m/z 789.2 $[\mathbf{1} + H]^+$.

2.3. Synthesis of (R,R)-*1* and (S,S)-*1*

(*R*,*R*)-**1** and (*S*,*S*)-**1** were prepared by following the procedure similar to that described above. (*R*,*R*)-**1** and (*S*,*S*)-**1** were obtained from the treatment of sodium 2,6-diformyl-4-chlorophenolate (1.05 g, 5 mmol) and (1*R*,2*R*)-cyclohexane-1,2-diamine (0.57 g, 5 mmol) and (1*S*,2*S*)-cyclohex-

ane-1,2-diamine (0.57 g, 5 mmol), respectively. Since (*R*,*R*)-**1**, (*S*,*S*)-**1** and racemic-**1** present identical character of IR, UV–Vis, ESI-MS, only the optical rotation values of these two enantiomers are described simultaneously. (*R*,*R*)-**1**: Yield: 67%, 0.88 g; $[\alpha]_D^{18} = -208$ ($c = 0.1$ g/100 mL in CH_2Cl_2); m.p. > 300 °C; (*S*,*S*)-**1**: Yield: 62%, 0.82 g; $[\alpha]_D^{18} = +210$ ($c = 0.1$ g/100 mL in CH_2Cl_2); m.p. > 300 °C. Single crystals of (*S*,*S*)-**1** suitable for X-ray diffraction were obtained by the diffusion of acetone into a benzene solution of the sample at room temperature.

2.4. Synthesis of (*R*,*R*)-**2** and (*S*,*S*)-**2**

(*R*,*R*)-**2** and (*S*,*S*)-**2** were prepared by following the procedure similar to **1**. (*R*,*R*)-**2**: Yield: 69%, 0.83 g; $[\alpha]_D^{18} = -225$ ($c = 0.1$ g/100 mL in CH_2Cl_2). (*S*,*S*)-**2**: Yield: 71%, 0.86 g; $[\alpha]_D^{18} = +220$ ($c = 0.1$ g/100 mL in CH_2Cl_2); m.p. > 300 °C.

2.5. Synthesis of [(*R*,*R*-L^1)Cu_2(μ-NO_3)] · ClO_4 ((*R*,*R*)-**3**) and [(*S*,*S*-L^1)Cu_2(μ-NO_3)] · ClO_4 ((*S*,*S*)-**3**)

Starting with an ethanol solution (20 mL) of (*R*,*R*)-**1** or (*S*,*S*)-**1** (0.0788 g, 0.1 mmol), $Cu(NO_3)_2 \cdot 3H_2O$ (0.0722 g, 0.3 mmol) in ethanol (10 mL) was added dropwise to the solution. After 2 h′ reflux, an ethanol solution (10 mL) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.1111 g, 0.3 mmol) was added to replace the anions in order to make it possible to grow high-quality single crystals. The resultant solution was filtered and evaporated slowly at room temperature to give the deep green product. Single crystals of (*R*,*R*)-**3** suitable for X-ray structure analysis were grown by slow evaporation of the mother-liquor over two weeks at room temperature. Since (*R*,*R*)-**3** and (*S*,*S*)-**3** present identical character of IR, UV–Vis, ESI-MS, only the optical rotation values of two enantiomers are described simultaneously. (*R*,*R*)-**3**: Yield: ~32%, 0.047 g; $[\alpha]_D^{10} = -486$ ($c = 0.1$ g/100 mL in ethanol); IR data (KBr): $\nu = 3449$ (w), 2935 (w), 2861 (w), 1632 (s), 1543 (m), 1435 (m), 1384 (m), 1320 (m), 1230 (w), 1117 (s), 1087 (s), 1034 (m), 790 (w), 766 (w), 737 (w), 625 cm^{-1} (m); UV–Vis (ethanol, nm): λ_{max} (ε) = 271, 372. *Anal.* Calc. for $C_{28}H_{28}Cl_4Cu_2N_6O_{16}$: C, 34.55; H, 2.90; N, 8.63. Found: C, 34.63; H, 2.96; N, 8.67%. ESI-MS (CH_3OH): *m*/*z*: 325 [$(Cu_2L^1)^{2+}$/2]. (*S*,*S*)-**3**: Yield: ~35%, 0.051 g; $[\alpha]_D^{10} = +479$ ($c = 0.1$ CH_2Cl_2 in ethanol).

2.6. Synthesis of [(*S*,*S*-L^2)$Cu_2(NO_3)_2(OH)(H_2O)$] (**4**)

Starting with a methanol solution (20 mL) of (*S*,*S*)-**1** (0.0788 g, 0.1 mmol), $Cu(NO_3)_2 \cdot 3H_2O$ (0.0722 g, 0.3 mmol) in methanol (10 mL) was added dropwise to the solution. The resulting mixture was reflux for 5 h, cooled, filtered, and evaporated slowly in the air. Blue crystals **4** were obtained firstly from the mother liquid as the primary product. Single crystals suitable for X-ray analysis were obtained by slow evaporation in methanol at room temperature. Yield: ~37%, 0.038 g; $[\alpha]_D^{18} = +354$ ($c = 0.1$ in ethanol); IR data (KBr): $\nu = 3441$ (s), 3225 (m), 2936 (m), 2860 (m), 1649 (s), 1553 (s), 1448 (m), 1384 (s), 1231 (m), 1120 (w), 1052 (m), 1038 (m), 988 (w), 829 (w), 785 (w), 657 cm^{-1} (w); UV–Vis (ethanol, nm): λ_{max} (ε) = 220, 251, 366. *Anal.* Calc. for $C_{20}H_{33}ClCu_2N_6O_{10}$: C, 35.32; H, 4.89; N, 12.36. Found: C, 35.40; H, 4.97; N, 12.44%. ESI-MS (CH_3OH): *m*/*z*: 618.9 [(**4**–NO_3)$^+$].

2.7. Synthesis of [(*R*,*R*-L^3)$Zn(H_2O)$] (**5**)

A solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (0.112 g, 0.3 mmol) in ethanol was added dropwise to an ethanol solution (20 mL) of (*R*,*R*)-**1** (0.0788 g, 0.1 mmol). After refluxing for 1 h, the solvent was removed by vaporization and the residue was dissolved in methanol. Yellow crystals suitable for X-ray analysis were grown by slow evaporation in methanol at room temperature. Yield: ~63%, 0.050 g; $[\alpha]_D^{18} = -417$ ($c = 0.1$ in ethanol); IR data (KBr): $\nu =$ 3449 (m), 2931 (w), 2856 (w), 1655 (s), 1637 (s), 1543 (m), 1433 (m), 1383 (m), 1223 (w), 1028 (m), 778 (w), 735 (w), 524 cm^{-1} (w); UV–Vis (ethanol, nm): λ_{max} (ε) = 267, 390. *Anal.* Calc. for $C_{22}H_{20}Cl_2ZnN_2O_5$: C, 49.98; H, 3.81; N, 5.30. Found: C, 49.84; H, 3.87; N, 5.25%.

2.8. Synthesis of [(racemic-L^4)Fe(Cl)] (**6**)

To a suspension of racemic-**1** (0.157 g, 0.2 mmol) in hot methanol (20 mL) was added a methanol solution (20 mL) of anhydrous $FeCl_3$ (0.097 g, 0.6 mmol). The solution became brown immediately as $FeCl_3$ was added. The resulting mixture was reflux for 2 h, cooled, filtered, and evaporated slowly at room temperature to give the brown product and the pH value of the mother-liquor is *ca.* 5. Brown crystals suitable for X-ray diffraction studies were directly obtained by slow evaporation of the reaction mixture in this case. Yield: ~57%, 0.107 g; IR data (KBr): $\nu = 3428$ (m), 2927 (s), 2858 (s), 1673 (s), 1628 (s), 1543 (s), 1432 (s), 1384 (s), 1219 (m), 998 (w), 828 (w), 733 (w), 674 cm^{-1} (w). UV–Vis (ethanol, nm): λ_{max} (ε) = 269, 387. *Anal.* Calc. for $C_{26}H_{30}Cl_3FeN_2O_6$: C, 49.67; H, 4.81; N, 4.46. Found: C, 49.58; H, 4.77; N, 4.40%. ESI-MS (CH_3OH): *m*/*z* 591.9 [**6**–Cl]$^+$.

2.9. X-ray crystallographic analysis

Single-crystal X-ray diffraction data were measured on a Siemens SMART CCD diffractometer using graphite-monochromatic Mo Kα radiation ($\lambda = 0.71073$ Å). Data collection was performed by using SMART program and cell refinement and data reduction were made with the SAINT program [17]. The structures were solved by directed method and refined on F^2 by using full-matrix least-squares methods with SHELXTL version 6.10 [18]. All non-hydrogen atoms were refined on F^2 by full-matrix least-squares procedure using anisotropic displacement parameters. Hydrogen atoms were inserted in the calculated positions assigned fixed isotropic thermal parameters at 1.2 times

the equivalent isotropic U of the atoms to which they are attached (1.5 times for the methyl groups, nitrogen and oxygen atoms) and allowed to ride on their respective parent atoms. All calculations were carried out on a PC computer with the SHELXTL PC program package and molecular graphics were drawn by using XP, DIAMOND and CHEM3D softwares. Details of the data collection and refinement for (*S*,*S*)-**1** and complexes (*R*,*R*)-**3** and **4**–**6** are given in Table 1, and the selective bond lengths and angles of these complexes are listed in Table 2 (for (*S*,*S*)-**1**), Table 3 (for (*R*,*R*)-**3**, **4**), and Table 4 (for **5**, **6**), respectively.

The absolute configurations of chiral centers are maintained during all metal complexation, which are proved by the determination of their optical rotation values and circular dichroism spectra. In addition, with regard to chloride substituted (*S*,*S*)-**1**, the reasonable Flack value −0.07(5) demonstrates the right specification of chirality [19]. For [3 + 3] macrocycle (*S*,*S*)-**1** and (*R*,*R*)-**2**, they crystallize in the monoclinic chiral space group $P2_1$ in which all six chiral carbon atoms are in *S* configuration for (*S*,*S*)-**1** and *R* configuration for (*R*,*R*)-**2**, which are in agreement with those of the starting material.

However, for complexes (*R*,*R*)-**3** and **4**–**6**, the absolute configurations of chiral carbon atoms cannot be specified from the crystallographic viewpoint because they crystallize in the centrosymmetric space groups (*C*2/*m*, $P\bar{1}$, $P\bar{1}$ or $P2_1/c$) where all the carbon atoms of cyclohexane-1,2-diamine moieties in the macrocyclic backbones are found disordered at two positions. As for the disorder of *trans*-cyclohexane-1,2-diamines in the metal complexes **4**–**6**, we think the disorder is possible because we use racemic starting material where the same amount of (1*R*,2*R*)-cyclohexane-1,2-diamine and (1*S*,2*S*)-cyclohexane-1,2-diamine are present. When the crystals grow from the mother solution, the same amount of (1*R*,2*R*)-cyclohexane-1,2-diamine and (1*S*,2*S*)-cyclohexane-1,2-diamine are believed to be encapsulated. In the refinement of these complexes, free variable are used to give the site occupancy factors for different carbon atoms. In the case of complex **3**, "add symmetry" is suggested by the Platon check program when a chiral space group *C*2 is assigned and very large thermal parameters for the related carbon atoms are generated. As a result, in complex (*R*,*R*)-**3**, the carbon atoms C6–C8, (C6′–C8′) are refined disordered over two sites in 0.545:0.455 occupancies. For complex **4**, the site occupancy factors for C8–C13 (C8′–C13′) and C14–C19 (C14′–C19′) were fixed at 0.443:0.557 and 0.494:0.506, respectively. In complex **5**, the site occupancy factors for C9–C14 (C9′–C14′) and C31–C36 (C31′–C36′) were fixed at 0.466:0.533 and 0.481:0.519, respectively.

3. Results and discussion

3.1. Syntheses and spectral characterizations

One-step synthesis of 27-membered triphenolic Schiff-base macrocycles (*S*,*S*)-**1** and (*R*,*R*)-**2** has been achieved and characterized by EA, IR, NMR, ESI-MS, UV–Vis, CD and fluorescence spectra as well as X-ray single-crystal diffraction. Though sodium 2,6-diformyl-4-substituted phenolate was used as a starting material because we found the presence of Na(I) ion was helpful for the formation of macrocyclic ligands and their respective complexes by in situ

(b) $-x$, $-y+1$, $-z+1$.

metal ion replacement [13], the product turned out to be the protonated compounds **1** and **2** instead of deprotonated sodium phenolates. Our synthesis is different from the method of Zacharias et al., where a room temperature condensation between 2,6-diformyl-4-methyl phenol and (1*R*,2*R*)-cyclohexane-1,2-diamine was performed and higher yields of 80% [9] or 90% [10] were reported. Different from the [2 + 2] condensation in the case of 1,3-propanediamine [13], [3 + 3] condensation was proved to be the main reaction for *trans*-cyclohexane-1,2-diamine [9–11]. However, [3 + 3] cyclohexane-1,2-diamine related macrocycles are not stable when treated with transition metal ions mainly due to the size effect and coordination geometric requirements of the metal centers. In most cases, the ring-degradation took place and the products were complicated and hard to isolate. An alternate way to stabilize this kind of macrocycles is to reduce the C=N double bonds by $NaBH_4$. Till now, two trinuclear (Zn_3 and Zn_2Cu) complexes and one mononuclear Eu(III) complex of reduced (*R*,*R*)-**2** ligand have been documented [11,12].

The products of the reaction of Schiff-base macrocycles **1** with $Cu(NO_3)_2 \cdot 3H_2O$ and $Cu(ClO_4)_2 \cdot 6H_2O$ are mixtures of **3** and **4**. However, they can be gradually isolated according to their different solubility in methanol and ethanol. In our experiment, cyclic [2 + 2] dinuclear Cu(II) complex **3** firstly precipitated from ethanol, and then acyclic [2 + 1] dinuclear Cu(II) complex **4**. The treatment of **1** with $Zn(ClO_4)_2 \cdot 6H_2O$ or $FeCl_3$ under reflux condition gave the primary products **5** and **6**, respectively and the impurities were not separated. Zacharias and co-workers concluded that [2 + 2] macrocyclic dinuclear complexes were the main products under reflux condition (~80%) and [1 + 2] products were obtained at room temperature (~70%) [10]. But our experiments demonstrated that the mixtures of several species typically occurred for this kind of reaction and [1 + 2] and [2 + 1] types of complexes could also be yielded under reflux condition. We have isolated and characterized successfully two new sorts of half-macrocyclic complexes **4** and **6**. In addition, five-coordinate Zn(II) complex **5** exhibited a hydrogen-bonded dimeric structure which differed from the six-coordinate Mn(II) complex reported by Zacharias' group [10]. Interestingly, a new type of [1 + 2] dimethyl acetal complex **6** was produced in methanol where $FeCl_3$ is suggested to be a reactive Lewis acid catalyst [20]. The reaction liquor was in a weak acidic condition (pH 5) originated from the hydrolyzation of $FeCl_3$.

In the UV–Vis spectra, **1** and **2** exhibit similar absorption with two intense bands at *ca.* 250 and 348 nm. The strong absorption band at 250 nm is assigned to the π–π* transition of the benzene rings, whereas the intense absorption at 348 nm is attributed to the π–π* transition of the azomethine chromophore. Compared with the positions in free compounds, these bands in complexes **3**–**6** have undergone bathochromic shifts of 10–30 nm. Such shifts are expected due to the contribution from π–π* ligand-to-metal charge transfer (LMCT).

The sign patterns of the CD spectra in macrocycles suggest the intrinsic chiral difference of enantiomers, which have not been systematically studied in literature. It is found that (*S*,*S*)-**1** gives cotton effects that are mirror images of (*R*,*R*)-**1** (Fig. 1). The first cotton effect of (*S*,*S*)-**1** is positive, but for (*R*,*R*)-**1**, it is negative. Moreover, racemic-**1** does not show any remarkable cotton effect and presents as a line. These results clearly indicate that there is no contribution of the phenyl rings to the cotton effects for the macrocycles **1** and that the chiral cyclohexane-1,2-diamine components control the direction of the twist. In contrast to the corresponding electronic absorption band at 348 nm, their CD bands split into 340 nm and 367 nm, which can be attributed to the split π–π* transition of azomethine. On the other hand, one CD peak appears at 273 nm, corresponded to the UV–Vis absorption at 250 nm. The sign patterns of the CD spectra suggest that conformers of negative chirality predominate in the solutions of (*R*,*R*)-macrocycle, whereas conformers of positive chirality predominate in those of (*S*,*S*)-macrocycle. Compared with **1**, **2** exhibits similar but stronger CD and UV–Vis absorptions.

Comparing the CD spectra of (*S*,*S*)-**3** and (*R*,*R*)-**3** (Fig. 2), the enantiomeric pair shows opposite cotton effects. The broad low-energy absorption band at 450–650 nm of CD spectra is ascribed to the d–d transition of copper(II). The higher energy CD components at 400 and 360 nm for **3**, are assigned to π–π* transition of the azomethine and LMCT transitions. The CD spectrum of **4** shows three cotton peaks: 398 (+), 351 (−) and 298 nm (−) (Fig. 3). The broad low-energy absorption band at 450–

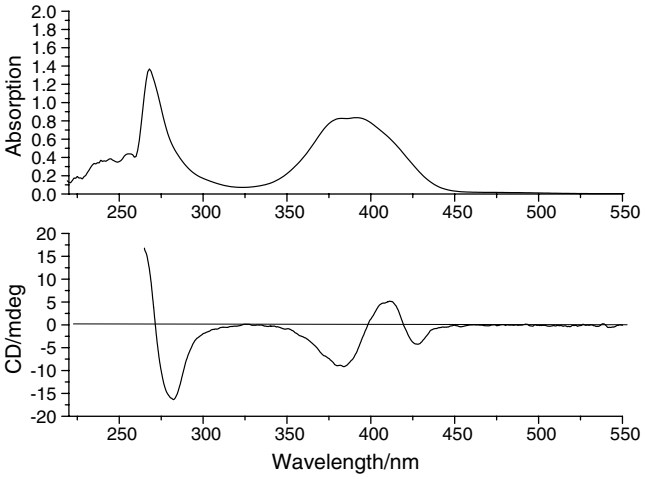

Fig. 4. UV–Vis and CD spectra of (*R*,*R*)-**5** in ethanol.

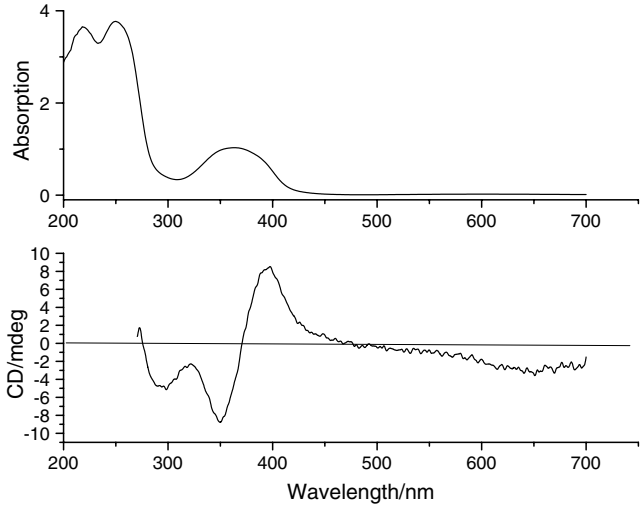

Fig. 3. UV–Vis and CD spectra of **4** in ethanol.

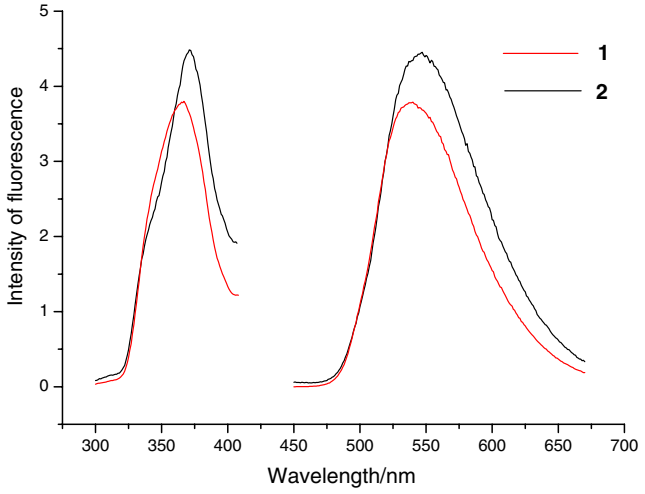

Fig. 5. Fluorescent spectra of **1** and **2** in CH_2Cl_2 solution.

700 nm can be assigned to a d–d transition of metal copper. The CD spectrum of **5** shows four cotton peaks by contrast: 430 (−), 410 (+), 385 (−) and 278 (−) nm (Fig. 4). The studies for the CD spectra of complexes lead us to conclude that the intrinsic chiral difference of the macrocycles can be retained even though the ring-contraction and rearrangement reactions take place.

The fluorescent spectra of **1** and **2** are shown in Fig. 5, with excitation spectra on the left part of the figure and emission spectra on the right part. The maximum excitation bands are located at 371 and 367 nm for **1** and **2**, respectively, whereas the maximum emission bands of them are positioned at 547 and 540 nm, respectively. The yellow fluorescent emission originates from the π–π^* transition of the azomethine chromophore in the compounds. Compare to the macrocycle **1**, metal complexes **3**–**6** quenched the fluorescence in the process of the electron transfer from the chromophore C=N to the metals at the same experimental conditions.

3.2. Crystal structure of (*S*,*S*)-*1* and (*R*,*R*)-*2*

In our experiments, the structures of (*S*,*S*)-**1** and (*R*,*R*)-**2** have been independently determined by X-ray single-crystal diffraction at 298(2) K. However, the crystal structure of (*R*,*R*)-**2** with the data collected at 100(2) K has been newly reported by Lisowski et al. in 2006 [12]. The cell parameters at normal temperature in our case (a = 14.783(1) Å, b = 19.006(1) Å, c = 14.945(1) Å, β = 93.129(1)°, V = 4192.8(4) Å^3) is a little bigger due to the temperature difference (a = 14.650(4) Å, b = 18.789(4) Å, c = 14.803(4) Å, β = 92.56(3)°, V = 4071(2) Å^3). In that paper, the authors simply described the molecular structure of (*R*,*R*)-**2** and did not mention its crystal structure. The CIF of (*R*,*R*)-**2** at 298(2) K, with the final $R_1 = 0.0496$ and $wR_2 = 0.0701$ for intensive data, was attached as the Supporting information of this paper for reference.

(*S*,*S*)-**1** is isomorphous with (*R*,*R*)-**2** although different substituted groups were used. It crystallizes in the chiral

monoclinic space group $P2_1$ with two identical cone-shaped species in each asymmetric unit. The macrocycle contains three tetradentate coordinating sites embedded in a 27-membered cone-like cavity with the dimension of *ca.* 42.36 Å^2 where 21 carbon atoms and six nitrogen atoms are present (Fig. 6). The phenolic hydroxyl groups are positioned at the narrower rim of the cavity, while the chlorine groups form the broader rim. Three phenyl rings in every cavity adopt an analogue equilateral triangle with the corresponding centroid–centroid separations of 6.871, 6.971 and 7.141 Å, and the bite angles between them are 62.1°, 58.3° and 59.6°, respectively.

(*S*,*S*)-**1** and (*R*,*R*)-**2** are stabilized by intramolecular hydrogen bonding interactions (O–H···N and C–H···O) (Table 5). Each hydroxyl group of the phenol unit points to the nitrogen atom of imine moieties with O–H···N distances ranging from 2.57 to 2.62 Å, indicative of strong intramolecular hydrogen-bonding interactions. Hydrogen bonds are also found between the hydrogen atom of CH=N and its neighboring hydroxyl group with the average C–H···O distance of 2.79 Å. In addition, typical intermolecular π–π stacking interactions are observed between the phenyl rings of adjacent macrocycles. As seen in Fig. 7, a vicinal molecule, as a guest by means of π–π stacking interactions with the centroid–centroid separation of 3.599 Å, inserts the triangular hole of the macrocycle forming a dimeric structure. In contrast, π–π stacking interactions between the centroids of contiguous phenyl rings (4.770 Å) of different dimeric pairs are very weak. This kind of packing mode is obviously different from the crystal structure of reduced macrocycle of (*R*,*R*)-**2**, where a channel-like structure governed by the hydrophobic inter-

action and intermolecular N–H···N and C–H···N interactions is generated and π–π stacking interactions are not observed (the shortest separation between the aromatic rings is 5.143 Å) [9].

3.3. Crystal Structure of (*R*,*R*)-3 and 4

The molecular structures of (*R*,*R*)-**3** and **4** with anisotropic displacement ellipsoids and atom-numbering scheme are shown in Figs. 8 and 10, respectively. The distance between Cu(1) and Cu(2) in (*R*,*R*)-**3** is 2.868(1) Å, which is relatively shorter than that in complex **4** (2.937(1) Å) due to the geometric restriction of [2 + 2] macrocyclic ligand. Each Cu(II) center in (*R*,*R*)-**3** and **4** adopts a distorted octahedron geometry. In complex (*R*,*R*)-**3**, the two Cu(II) centers are identical with each being coordinated by two imino nitrogen atoms, two phenoxy bridging oxygen atoms in the basic plane and bridged by two μ_2 bridged nitrate groups above and below the dinuclear skeleton. Perchlorate anion is free from the coordinative bond and is captured in the crystal lattice. To the best of our knowledge, this is the first report on dinuclear Schiff-base complex bridged by two nitrate groups. As for complex **4**, one imine nitrogen atom, one phenol oxygen atom, one amine N-donor from cyclohexanediamine and a μ_2 bridged hydroxyl group form the equatorial plane. Two apical positions are occupied by one μ_2 bridged nitrate ion at one side and one aqua ligand as well as one monodentate nitrate ion at the other side. The slight geometrical differences between Cu(1) and Cu(2) originate from the differences in their axial coordination atoms. That is to say, Cu(1) is bonded to an aqua ligand [Cu(1)–O(1w), 2.508(6) Å], while Cu(2) exhibits a longer bond length with the nitrate donor [Cu(2)–O(6), 2.577(6) Å]. As far as we are aware there is no struc-

ture report on dinuclear metal complex of the [2 + 1] chiral Schiff-base macrocycle.

In the crystal structure of complex (*R*,*R*)-**3**, the perchlorate counterions are intercalated between adjacent layers (Fig. 9) forming hydrogen bonds with C–H proton of the cyclohexyl ring with C–H···O distance of 3.36(1) Å. As for complex **4**, hydrogen bonding interactions and π–π stacking interactions are observed to further stabilize the structure. The oxygen atoms of two water molecules are involved in intramolecular O–H···O H-bonds linking to the nitrate groups. The O···O distances vary from 2.94(1) to 3.05(1) Å in this case. Intermolecular O–H···O hydrogen bonds are also present between H_2O and NO_3^- with the O···O distances in the range from 2.82(1) to 3.08(4) Å. The NH_2 groups also participate in the contact of intermolecular N–H···O hydrogen binding interactions with the acceptors as NO_3^- anion and H_2O molecule. In addition, different kinds of weak C–H···O hydrogen bonds are present between the oxygen atoms of NO_3^- and H_2O and the carbon atoms of the phenyl group, cyclohexyl rings and imine C–H units. These connections generate a 2D layer network as illustrated in Fig. 11.

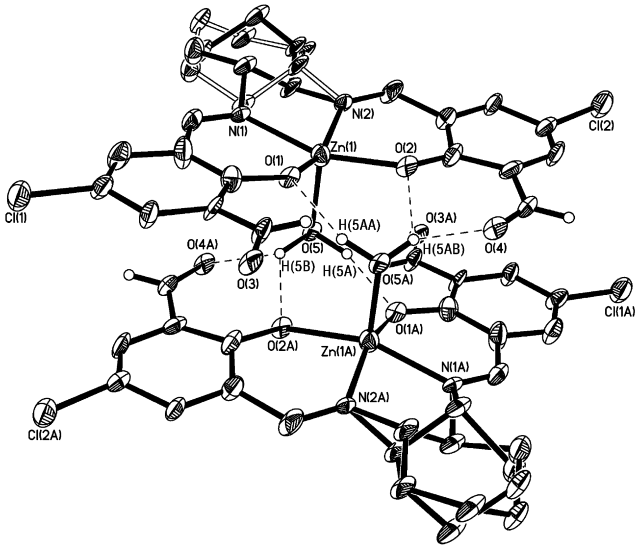

Fig. 12. ORTEP drawing (30% probability displacement ellipsoids) of **5** with the heteroatom-numbering scheme, only molecule **A** related dimeric structure is shown for clarity.

3.4. Crystal Structure of *5*

Complexation of (*R*,*R*)-**1** with $Zn(ClO_4)_2 \cdot 6H_2O$ in a 1:3 ratio in boiling ethanol leads to the formation of [1 + 2] contracted mononuclear complex **5** (Fig. 12). It crystallizes in $P\bar{1}$ space group and the asymmetric unit has two crystallographically independent molecules A and B. The Zn atom has five-coordinate distorted pyramidal geometry supported by a N_2O_3 donor set in molecules A and B. Two phenol oxygen atoms and two C=N nitrogen atoms occupy the equatorial positions and one aqua ligand lies in the axial position. This structure is different from the reported six-coordinate Mn(II) complex packing into a chiral *F*222 space group [10].

It is interesting to mention that hydrogen bonds play a key role in the conformation of a dimeric structure in **5**. As shown in Fig. 13, both of the hydrogen atoms of water

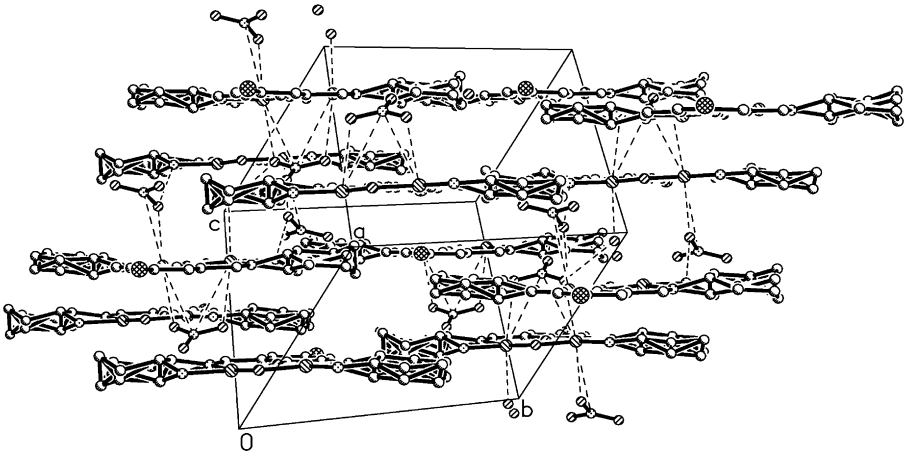

Fig. 11. A crystal packing view of **4** together with the unit cell.

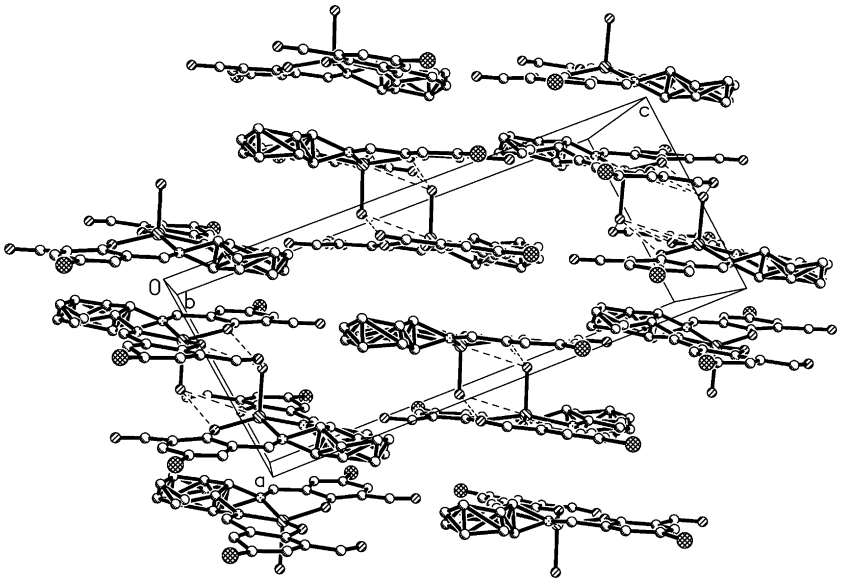

Fig. 13. A crystal packing view of **5** together with the unit cell.

molecule are involved in strong hydrogen bonding interactions with the oxygen atom of phenoxide unit [μ_2 bridging mode: O(5)–H(5A)···O(1) 2.71(1) Å, O(5)–H(5B)···O(2) 2.84(1) Å] and the aldehyde oxygen atom [monodentate mode: O(5)–H(5B)···O(4) 2.60(1) Å] of neighboring molecule. The existence of complementary O–H···O H-contacts stabilizes greatly the half-macrocyclic structure. Furthermore, different kinds of weak C–H···O hydrogen bonding interactions have been observed in the crystal packing. It is noted that intermolecular C–H···Cl interactions are found between the C–H protons of the cyclohexyl ring and the Cl(3) of another molecule with a C···Cl distance of 3.63(1) Å. This non-classical C–H···Cl hydrogen bonding is important in the crystal stacking of **5** [13]. Under the assistance of these above-mentioned weak interactions, a two-dimensional network is constituted.

3.5. Crystal Structure of *6*

It is interesting to find that the reaction of racemic-**1** and anhydrous $FeCl_3$ yields the [1 + 2] type of dimethyl acetal **6** in boiling methanol. Previous reports have demonstrated that Lewis acid $FeCl_3$ can successfully act as a catalyst in organic synthesis especially in strong acidic condition, including a wide range of esterification [21], Friedel–Crafts alkylation and rearrangement reaction [22], and their reaction mechanisms have been fully investigated [23]. In addition, Brooker and co-workers have observed that Fe(III) catalysing changes to [4 + 4] Schiff-base macrocycles where a 1,3-diazacyclopentane ring moiety have been formed [24]. In our reaction, it is suggested that some Schiff-base C=N bonds are broken firstly, coming back to aldehyde, and then the rearrangement intermediate coordinates with

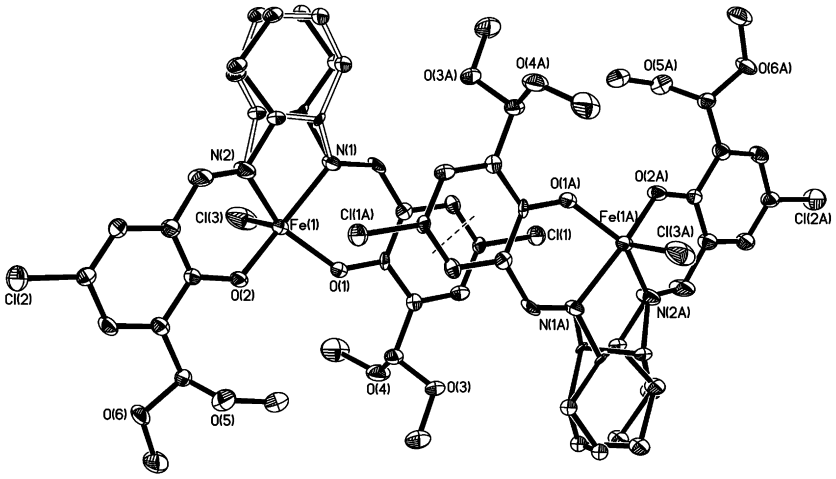

Fig. 14. ORTEP drawing (30% probability displacement ellipsoids) of complex **6** with the heteroatom-numbering scheme.

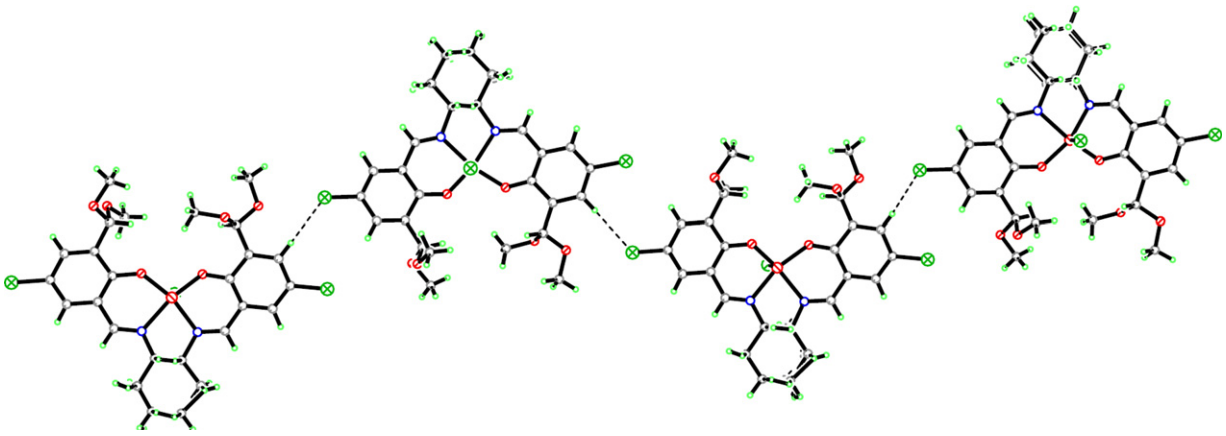

Fig. 15. View of the 1D chain structure of **6** through the C–H···Cl interactions along the *b*-axis.

Fe(III) and the excess $FeCl_3$ as a reactive catalyst and the methanol as nucleophilic reagent to create the acetal **6** simultaneously.

X-ray analyses for **6** indicate that the Fe(III) center adopts the square-pyramidal geometry and is five-coordinated to two imine N-donors, two phenoxy O-donors and one chlorine anion at the axial position (Fig. 14). The dihedral angle between the least-squares plane defined by O(1), Fe(1) and N(1) and the plane defined by O(2), Fe(1) and N(2) is 40.83°. Fe(III) ion deviates from the basal N_2O_2 plane by 0.3888 Å due to the mismatch between the cavity size and the ionic radius of the Fe(III) ion. Complex**6** also consists of dimeric structures stabilized by close intermolecular face-to-face π–π interaction. The centroid–centroid separation between the adjacent parallel aromatic rings is 3.504 Å.

In the crystal packing of **6**, a 1D chain structure along the crystallographic *b*-axis is formed under the assistance of C–H···Cl hydrogen bonds between the chlorine atoms Cl(1) of the aromatic groups and the carbon atoms C(18) of benzene rings (Fig. 15). At the same time, down the direction of the crystallographic *a*-axis, a 1D chain is also observed by the C–H···Cl interactions between the coordinated chlorine atoms Cl(3) and the carbon atoms of methyl C(25) (Fig. 16). The relative H-bond lengths and angles are Cl(1)···C(18) 3.68(1) Å and C(18)–H(18A)···Cl(1) 166.0°, Cl(3)···C(25) 3.69(1) Å and C(25)–H(25A)···Cl(3) 156.0°, respectively. There are two intramolecular C–H···O hydrogen bonds generated between the methyl CH_3 and the oxygen atom of phenol [C(22)–H(22A)···O(1), C(25)–H(25B)···O(2)] and one C–H···O hydrogen bonds formed between C–H of benzene ring and the oxygen atom of dimethyl acetal [C(18)–H(18A)···O(6)].

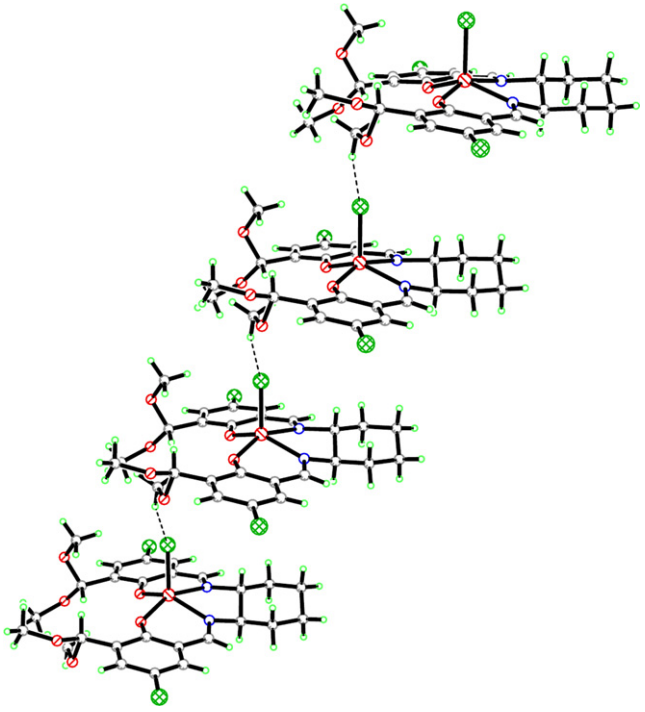

Fig. 16. View of the 1D chain structure of **6** through the C–H···Cl interactions along the *a*-axis.

4. Conclusion

We have reported the syntheses, structural and spectral characterizations of [3 + 3] chiral macrocycles **1** and a series of Cu(II), Zn(II) and Fe(III) ring-contraction complexes. The crystal structures of (*R*,*R*)-**3**, **4**, **5** and **6** demonstrate the formation of corresponding [2 + 2], [2 + 1] and [1 + 2] types of complexes resulting from the cleavage and reorganization of **1** in the course of metal complexation. The reorganization of the macrocycle can be attributed to the planarity and thermodynamic stability of the resulted complexes, namely, the size matching effect of macrocycles as well as the restriction of coordination geometry of the central metals and the counterions used. Specific features of the CD spectra for chiral macrocycles and metal complexes show the asymmetric environment, which will be useful in design of asymmetric catalysis.

2.1. Preparation of $[Sn(CH_2CH_2CN)_3I]$ (1)

A mixture of $[Sn_2(CH_2CH_2CN)_6]$ (0.562 g, 1.0 mmol) and I_2 (0.254 g, 1.0 mmol) in dichloromethane (7 cm^3) was stirred under reflux until the disappearance of iodine was observed. The crystalline solid was filtered off, recrystallized from CH_2Cl_2, washed with cold dichloromethane and dried in vacuo. Yield of the colorless product 0.547 g, 67%. *Anal.* Calc. for $C_9H_{12}N_3ISn$: C, 26.51; H, 2.97; N, 10.30; Sn, 29.11. Found: C, 26.27; H, 2.73; N, 10.15; Sn, 29.40%. IR (KBr, cm^{-1}): 2958 w, 2920 m, 2260 vs (ν_{CN}), 2244 vs (ν_{CN}), 1426 vs, 1417 vs, 1380 w, 1356 vw, 1316 vw, 1283 vw, 1250 vw, 1150 vs, 1140 sh, 1015 m, 1004 s, 912 sh, 890 s, 880 s, 868m, 718 w, 680 vs, 673 vs, 653 s, 632 m, 617 w, 545 vw, 507 vw, 460 m, 440 s, 372 mw. ^{119}Sn NMR (CD_3OD): $\delta = -14.3$ ppm.

Complex $[SnBr(CH_2CH_2CN)_3]$ (**2**) was prepared in a similar manner to $[Sn(CH_2CH_2CN)_3I]$ except for the use 1 mmol of Br_2 instead of I_2. Mass collected 0.527 g, 73%. *Anal.* Calc. for $C_9H_{12}N_3BrSn$: C, 29.96; H, 3.35; N, 11.65; Sn, 32.90. Found: C, 29.79; H, 3.08; N, 11.51; Sn, 32.60%. IR (KBr, cm^{-1}): 2960 w, 2928 m, 2260 vs (ν_{CN}), 2244 vs (ν_{CN}), 1428 vs, 1414 vs, 1382 w, 1310 vw, 1303 vw, 1282 vw, 1268 vw, 1155 vs, 1142 sh, 1015 m, 1003 s, 905 sh, 892 s, 882 s, 870 m, 678 vs, 655 vs, 632 m, 616 w, 508 vw, 460 m, 446 s, 372 mw. ^{119}Sn NMR (CD_3OD): $\delta = -17.5$ ppm.

2.2. Physical measurements

Infrared spectra (KBr pellets and nujol) were recorded on a Bruker IFS 113v, ^{1}H NMR spectra were taken on a Bruker AMX 300 and ^{119}Sn NMR spectra on a Bruker Avance 500. The tin contents were determined using the ICP-AES method on a ARL 3410.

2.3. X-ray crystallographic measurements

All measurements of crystals were performed at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. Accurate cell parameters were determined and refined by a least-squares fit of the 4000 strongest reflections. The data were corrected for Lorentz and polarization effects. Absorption correction based on least-squares fitted against $|F_c| - |F_o|$ differences were also applied [15]. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) (formerly Kuma Diffraction Wrocław, Poland) programs. The structure was solved by direct methods (program SHELXS 97 [16]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL 97 [17] programs. Non-hydrogen atoms were refined with anisotropic vibrational parameters; hydrogen atoms were included from the geometry of the molecules and were refined with isotropic vibrational parameters.

2.4. Computational details

The molecular and electronic structure and IR spectra of the monomer $[SnBr(CH_2CH_2CN)_3]$ and the dimer $[SnBr(CH_2CH_2CN)_3]_2$ of C_1 symmetry have been studied with the GAUSSIAN 03 package of programs [18] using the DFT B3LYP method with the LANL2DZ basis set

3. Results and discussion

Complexes **1** and **2** are colourless, crystalline compounds. An X-ray crystallography study revealed that they are isomorphic and crystallize in the $P2_1/n$ space group. Crystallographic data for complexes **1** and **2** are given in Table 1 and selected bond lengths and angles in Tables 2 and 3. The ORTEP views of the compounds are depicted in Figs. 1 and 2. Both compounds in the solid state consist of zigzag single-strand chains with the bridging 2-cyanoethyl ligand coordinating via the CH_2 group and the N atom (Fig. 3). The tin atoms are in a distorted trigonal bipyramidal environment. In complex **1** axial coordination sites are occupied by the iodo ligand and the N(3) atom of the bridging cyano group; the I(1)–Sn(1)–N(3i) angle is 179.04(5)°. The carbon atoms of the 2-cyanoethyl ligands are coordinated in equatorial positions. The Sn–C distances differ only slightly. The Sn(1)–C(4), Sn(1)–C(1)

C(4)–C(5)	1.534(3)		

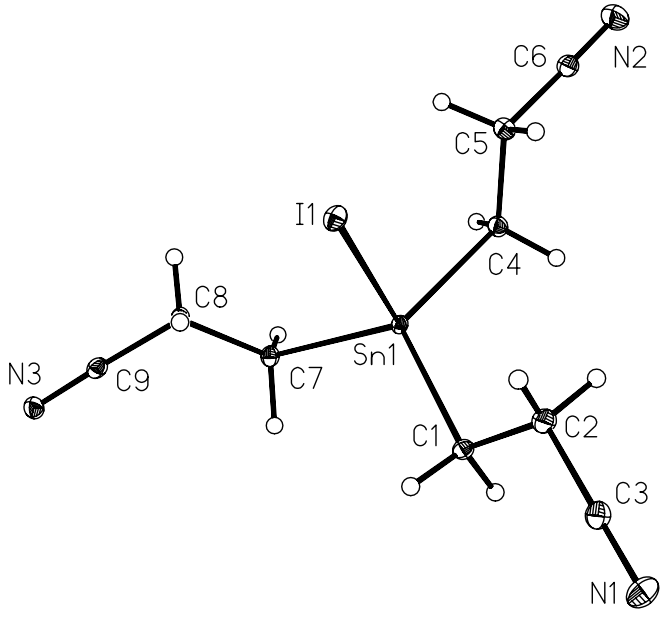

Fig. 1. Molecular structure of complex **1** with crystallographic numbering.

and Sn(1)–C(7) bond lengths are 2.153(2), 2.156(2) and 2.157(2) Å, respectively. The tin-axial ligand bonds are weaker, the Sn(1)–N(3i) (2.5944(19) Å) and Sn(1)–I(1)

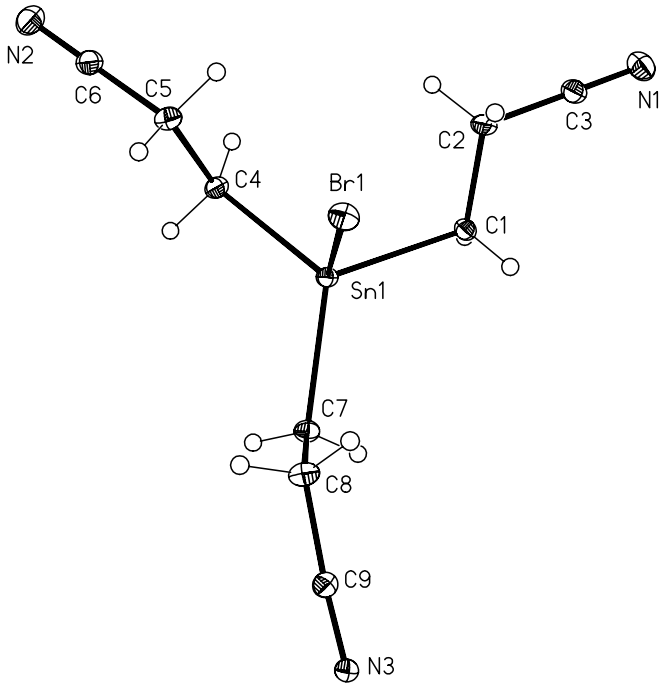

Fig. 2. Molecular structure of complex **2** with crystallographic numbering.

(2.8128(2) Å) distances are considerably longer than those for the equatorial ligands. Considerably weaker bonds of tin with axial ligands in comparison with equatorial ones have been found in many complexes. Thus the Sn–N_{eq} bond in $[Sn(C_4H_9)_2\{OOC(CH_2)_2NCH_2C_6H_5\}]$ is substantially shorter (2.228(3) Å) [19] and in the cationic complex (TBPY-5-12)-$[SnBr_2(C_6H_5)_2(H_2O)]^+$ the Sn–Br_{eq}, Sn–C_{eq}, Sn–Br_{ax} and Sn–O_{ax} bonds are 2.486(1), 2.112(6), 2.599(1) and 2.305(5) Å, respectively [20]. Similarly in the complex with the 2-pyridinecarboxylato ligand, $\{[Bu_2Sn(OOCC_5H_4N)]_2O\}_2$, and in the binuclear pyrazine compound $[Me_2Cl_2Sn(\mu\text{-}NC_4H_4N)SnMe_2Cl_2]$ with the nitrogen ligands coordinated in axial positions, the Sn–N distances are much longer, being 2.550(5) [21] and 2.746(8) Å [22], respectively. It is interesting that there is a weak interaction between iodine atoms of different chains. The I(1)–I(1)#3 distance and Sn(1)–I(1)–I(1)#3 angle are equal to 3.997(1) Å and 159.36(1)°, respectively. Thus, this distance is about 0.3 Å shorter than the sum of the van der Waals radii of iodine atoms. The structure of complex **2** is similar to compound **1**. In the solid state analogous $–(NCCH_2CH_2)_2BrSn(\mu\text{-}NCCH_2CH_2)SnBr(CH_2CH_2CN)_2–$ chains are formed, however, the intermolecular Br–Br distances are larger (4.494 Å) and the Sn–Br–Br angles are smaller (151.66°). Thus in compound **1** there is a weak covalent I–I intermolecular interaction as opposed to complex **2** in which the Br–Br distance is larger than double the van der Waals radius.

The coordination sphere in compound **2** is similar to compound **1**, however in complex **2** there are larger differences between the Sn–C distances. They are equal

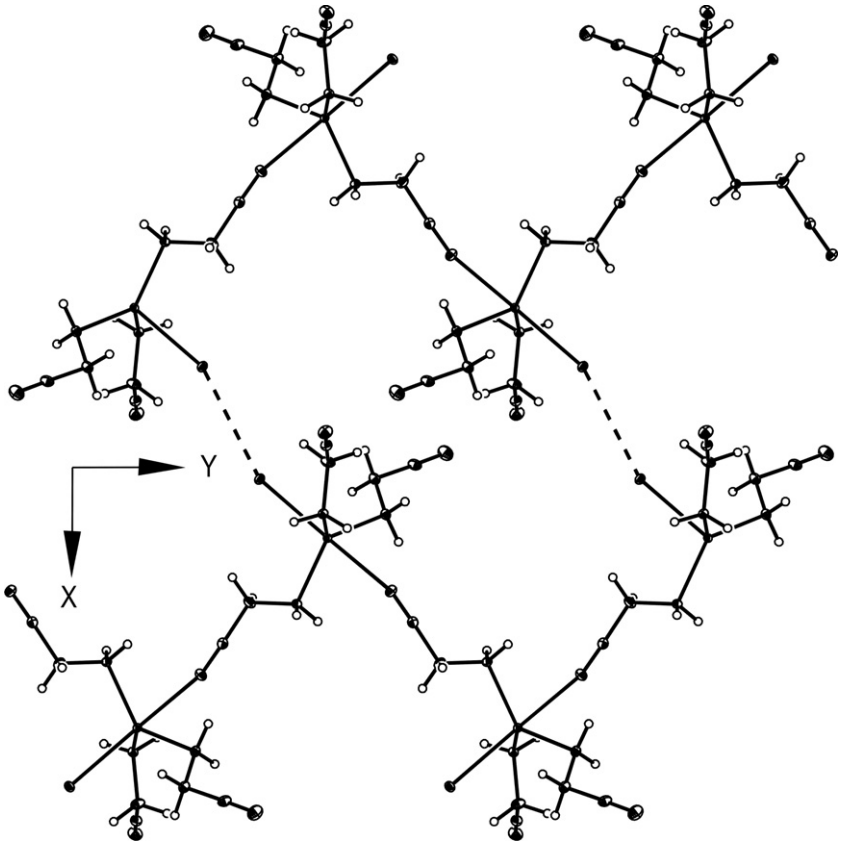

Fig. 3. ORTEP view showing the one-dimensional structure of complex **1**.

to 2.134(2), 2.155(2) and 2.160(2) Å. The Sn(1)–N(3i) bond (2.607(2) Å) is slightly longer than that in complex **1** and the Sn(1)–Br(1) distance (2.5993(4) Å) is almost the same as that in the complex $[SnBr_2(C_6H_5)_2(H_2O)]^+$ [20].

To explain the properties of compounds **1** and **2** and to compare the structures of the isolated $[SnX(CH_2CH_2CN)_3]$ complexes with those in the solid state, the molecular and electronic structure of the $[SnBr(CH_2CH_2CN)_3]$ monomer and $[SnBr(CH_2CH_2CN)_3]_2$ dimer have been studied at the DFT B3LYP level with a LANL2DZ basis set. Calculated interatomic distances and angles agree well with the crystallographic data (Figs. 4 and 5). The calculated coordination sphere of the monomer is pseudotetrahedral with average BrSnC and CSnC angles equal to 105.04° and 113.52°, respectively. As expected, the CSnC angles are smaller and the BrSnC angles are larger than those in compound **2** in the solid state. The calculated interatomic distances and angles for five- and four-coordinated tin atoms are: d(Sn–C) 2.155 and 2.151 Å, ∠CSnC 116.62° and 113.43°, ∠BrSnC 100.72° and 105.13°. Thus the values calculated for a five-coordinated tin atom are similar to those determined for complex **2** (d(SnC) = 2.150 Å, ∠CSnC 117.5° and ∠BrSnC 99.05°). There is a good agreement between the calculated and experimental IR spectra of compound **2** in KBr and nujol as shown in Figs. 6 and 7 and Table 7. The differences between the calculated and experimental values of vibrations are relatively small, especially in the case of bands with great participation of ν(SnBr), ν(SnN), ν(SnC) and ν(CN) stretching vibrations.

Complexes **1** and **2** are soluble in polar organic solvents, e.g. dichloromethane, chloroform, acetone, DMSO and water. The coordination about the tin atom in the complexes in solution can be easily followed using ^{1}H NMR spectroscopy. From the $^2J(^{119}Sn^1H)$ coupling constants calculated from the satellites, it is possible to calculate a value for θ, the C–Sn–C angle in triorganotin compounds, from the following equation [23]:

$$\theta = 0.0161|^2J|^2 - 1.32|^2J| + 133.4$$

The $^2J(^{119}Sn^1H)$ coupling constants for complexes **1** and **2** in $CDCl_3$ are 47.8 and 47.9 Hz, respectively (Table 4). Thus, the θ value for these compounds dissolved in chloroform is 107.1°. Therefore the complexes in chloroform, dichloromethane and other weak coordinating solvents feature four-coordinate Sn atoms with a distorted tetrahedral coordination. However, in solutions of water and other strongly coordinating solvents, substitution of bromo and iodo ligands takes place and five-coordinate complexes are formed:

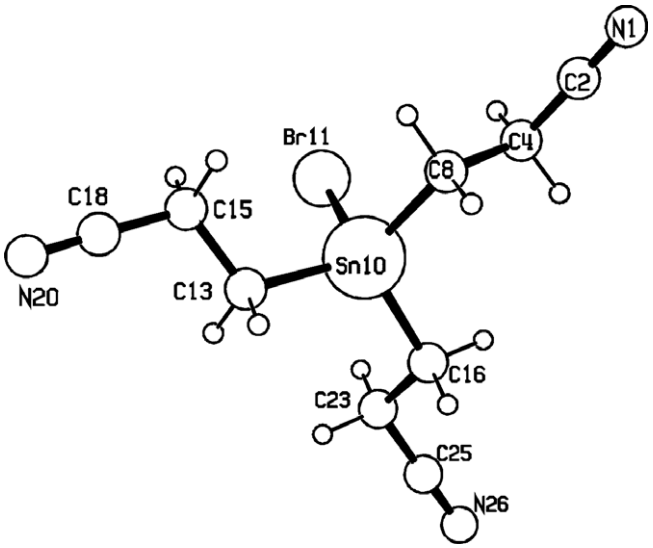

Fig. 4. Molecular structure of $[SnBr(CH_2CH_2CN)_3]$ calculated at the DFT B3LYP level with a LANL2DZ basis set. Selected bond lengths (Å) and angles (°): Sn–C = 2.148–2.149, Sn–Br = 2.602; ⟨CSnC = 113.01–113.95, ⟨CCN = 179.15, ⟨CSnBr = 104.84–105.18.

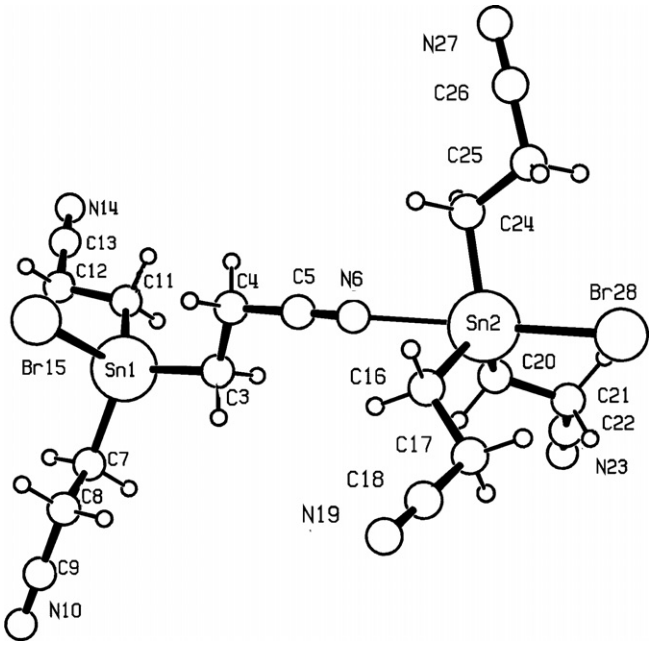

Fig. 5. Molecular structure of $[SnBr(CH_2CH_2CN)_3]_2$ calculated at the DFT B3LYP level with a LANL2DZ basis set. Selected bond lengths (Å) and angles (°): Sn26–C43 = 2.147, Sn26–C16 = 2.148, Sn26–C24 = 2.159, Sn26–Br = 2.601, Sn27–C = 2.154 – 2.157, Sn27–N = 2.682, Sn27–Br = 2.666; ⟨N–Sn27–Br = 178.48, ⟨C–Sn27–C = 116.38–116.99, C–Sn27–Br = 99.71–101.33, ⟨C–Sn26–C = 112.73–114.80, ⟨C–Sn26–Br = 103.73–105.98.

$$[SnBr(CH_2CH_2CN)_3] + 2H_2O \rightarrow [Sn(CH_2CH_2CN)_3(OH)(H_2O)] + H^+ + Br^-$$

Water solutions of these compounds are acidic, the pH of 1 mmol solutions is equal to 3.5. The Br^- and I^- ions are immediately deposited with $AgNO_3$. The $^2J(^{119}Sn^1H)$ coupling constants for complexes **1** and **2** in coordinating solvents are considerably higher than those in $CDCl_3$ (Table 4). In CD_3OD they are equal to 59.2 and 61.4 Hz, respectively, in D_2O 65.9 and 65.8 Hz and in D_2O containing a stoichiometric amount of NaOD 72.4 Hz. Thus the C–Sn–C angles for the complexes in these solutions are about 111.7° and 113.1° in methanol, 116.3° in water and 122.2° in solutions containing sodium hydroxide. In methanol most likely five-coordinate complexes are formed with a relatively strongly distorted trigonal bipyramidal coordination about the tin atoms. Similar C–Sn–C angles (112.7–115.8°) were found for species present in water solutions of $[SnMe_3Cl]$ and for the products of their reactions with glutathione [24]. The presence of the dihydroxo anionic complex $[SnMe_3(OH)_2]^-$ ($\theta = 115.8°$) with a *trans* trigonal pyramidal coordination was suggested for water solutions at a physiological pH value [24]. In acidic water solutions cationic $[Sn(CH_2CH_2CN)_3(H_2O)_2]^+$ or neutral $[Sn(CH_2CH_2CN)_3(OH)(H_2O)]$ complexes are formed with a less distorted trigonal bipyramidal structure, and in slightly basic solutions, obtained by addition of sodium hydroxide (pH 8.0–8.5), the trigonal bipyramidal dihydroxo complex $[Sn(CH_2CH_2CN)_3(OH)_2]^-$ is formed. The interaction of these complexes with adenosine, both in acidic solution obtained by the dissolution of complex **2** in D_2O (pH 3.5) and alkalized with NaOH solution (pH 8–8.5), is weak The ^1H NMR spectra (Tables 4 and 5) of the complexes alone and the complexes in the presence of adenosine are very similar. The chemical shifts as well as the $^2J(^{119}SnH)$ and $^3J(HH)$ coupling constants differ only slightly. However, the interaction of AMP with complex **2**, both in acidic and basic solutions, is relatively strong. The signal of the α-methylene group ($SnCH_2$) is not resolved and the β-methylene groups give two triplets, although the $^2J(^{119}SnH)$ and $^3J(^{119}SnH)$ coupling constants for the **2** + AMP + D_2O and **2** + AMP + D_2O + NaOD systems are similar. The C–Sn–C angles are equal to 115.9° and 122.2°, respectively and differ only slightly from the appropriate values found for solutions of complex **2** without AMP. Two signals were also observed for H^2, H^8 and $H^{1'}$ for the **2** + AMP solution in D_2O. This suggests that in this solution AMP is coordinated via the O atom of the phosphato group, giving two trigonal bipyramidal complexes (Scheme 1), however, the presence of two isomers of one complex cannot be excluded. The ^1H NMR spectra indicate that ATP also interacts with $[Sn(CH_2CH_2CN)_3(OH)(H_2O)]$ and other trigonal bipyramidal complexes, however the changes in the spectra are less pronounced. This results from longer distance of the purine and ribose fragments from the tin atom when ATP is coordinated via the oxygen atom of γ-P.

[a] The average values of $J(^{119/117}SnH)$ coupling constants, ^{119}Sn and ^{117}Sn satellites are not resolved.

Scheme 1.

4. Conclusion

Organotin complexes with 2-cyanoethyl ligands, $[Sn(CH_2CH_2CN)_3I]$ (**1**) and $[SnBr(CH_2CH_2CN)_3]$ (**2**), have been obtained and characterized by NMR and IR spectroscopy methods and X-ray crystallography. Both compounds crystallize in the $P2_1/n$ space group and in the solid state consist of zigzag single-strand chains with bridging 2-cyanoethyl

Table 6

Compounds	Solvent	NMR data, δ (ppm), J (Hz)
1	CD_3OD	15.43 (Cα, $^1J(^{119}Sn–^{13}C) = 472.3$, $^1J(^{117}Sn–^{13}C) = 451.7$); 15.83 (Cβ, $^2J(^{119/117}Sn–^{13}C) = 19.0$); 121.86 (Cγ, $^3J(^{119/117}Sn–^{13}C) = 81.9$)
2	CD_3OD	15.82 (Cα, $^1J(^{119}Sn–^{13}C) = 495.5$, $^1J(^{117}Sn–^{13}C) = 473.5$); 15.19 (Cβ, $^2J(^{119/117}Sn–^{13}C) = 18.8$); 122.67 (Cγ, $^3J(^{119/117}Sn–^{13}C) = 82.0$)
2 + **AMP**	D_2O + NaOD	14.00 (Cα, $^1J(^{119}Sn–^{13}C) = 545.4.3$, $^1J(^{117}Sn–^{13}C) = 521.8$); 13.08 (Cβ, $^2J(^{119/117}Sn–^{13}C) = 19.6$); 64.43 (C5′); 70.07 (C3′); 74.44 (C2′); 83.85 and 83.92 (C4′); 88.05 (C1′); 118.57 (C5); 122.61(Cγ, $^3J(^{119/117}Sn–^{13}C) = 78.4$); 142.21 (C8); 144.47 (C2); 148.29 (C4); 149.99 (C2);

ligands coordinating via the CH_2 group and the N atom. The tin atoms are in a distorted trigonal bipyramidal environment with bromo or iodo ligands and the nitrogen atom occupying axial coordination sites. The Sn(1)–N(3i) distances in complexes **1** and **2** are considerably longer than the Sn–C equatorial bonds. The molecular and electronic structures and IR spectra of $[SnBr(CH_2CH_2CN)_3]$ mononuclear and $[SnBr(CH_2CH_2CN)_3]_2$ dinuclear fragments of the complex have been studied with the DFT B3LYP method. The calculated interatomic distances for the entity containing a five-coordinate tin atom agree well with those found crystallographically. The compounds in water solutions form trigonal bipyramidal complexes containing aqua and hydroxo axial ligands. The ^1H NMR spectra indicate that complexes **1** and **2** interact with 5′-adenosine monophosphate and 5′-adenosine triphosphate via the oxygen atom of the phosphate group Table 6.

to completely enter the central cavity of Pc ring due to its large ionic size. Pb^{2+} has a close shell and is a diamagnetic ion and is expected to enhance intersystem crossing (ISC) and to give Pc complexes with high triplet quantum yields. Lability of lead ion during the work-up of the substituted complex, resulting in regeneration of the starting material, has been reported [22]. Demetallation in PbPc complexes is common [22,28]. There has been less attention paid to non-peripherally [22] substituted compared to peripherally substituted PbPc derivatives. PbPc derivatives have been shown to give good optical limiting properties [29–31] when compared to NiPc and H_2Pc. The study of the photochemical and photophysical behaviour of PbPc complexes has not been fully explored. Polyether peripherally substituted PbPc complex gave a low triplet yield lifetime ($\tau_T = 32$ μs) and about the same triplet quantum ($\Phi_T = 0.30$) compared to the corresponding ZnPc derivative ($\tau_T = 105$ μs, $\Phi_T = 32$) [27]. PbPc derivatives gave large rate constants of intersystem crossing due to the heavy Pb central atom [32]. The lead helicenocyanine derivatives exhibited strong fluorescence when irradiated in the B band region, giving two emission peaks at 500 and 900 nm [33,34].

The development and elucidation of photophysical (triplet yields and lifetimes and fluorescence yields) properties of new phthalocyanine complexes are of fundamental importance, hence this work presents the study of these parameters in different solvents for PbPc derivatives, since solvents affect these parameters.

The complexes studied are: 1,(4)-(tetraphenoxyphthalocyaninato)lead (**7a**), 1,(4)-(tetra-*tert*-butylphenoxyphthalocyaninato)lead (**7b**), 2,(3)-(tetraphenoxyphthalocyaninato) lead (**8a**), 2,(3)-(tetra-*tert*-butylphenoxyphthalocyaninato) lead (**8b**), 2,3-(octaphenoxyphthalocyaninato)lead (**9a**) 2,3-[octakis(4-*t*-butylphenoxyphthalocyaninato)]lead (**9b**), (Scheme 1).

2. Experimental

2.1. Materials

Chloroform ($CHCl_3$), methanol (MeOH), 1-chloronaphthalene (1-CNP), 1-octanol, tetrahydrofuran (THF), dimethylformamide (DMF), hexane and deuterated chloroform ($CDCl_3$) were obtained commercially and dried before use. Potassium carbonate (K_2CO_3), urea, phenol and 4-*tert*-butylphenol were purchased from Aldrich and used as received. Dimethylsulphoxide (DMSO) was purchased from SAARCHEM, and dried in alumina before use. 3-Nitrophthalonitrile (**1**) [11], 4-nitrophthalonitrile (**2**) [35] and 4,5-dichlorophthalonitrile (**3**) [36] were synthesized and purified according to literature procedure. Column chromatography was performed on silica gel 60 (0.04–0.063 mm).

2.2. Equipment

Ground state electronic absorption spectra were performed, on a Varian Cary 500 UV–Vis–NIR spectrophotometer; infra-red spectra (KBr pellets) on Perkin Elmer Spectrum 2000 FT-IR Spectrometer and ^1H nuclear magnetic resonance (^1H NMR) signals on a Bruker EMX 600 NMR spectrometer. Triplet lifetimes (τ_T) and yields were obtained using an Nd-YAG laser providing 400 mJ, 90 ns of laser light at 10 Hz, pumping a Lambda-Physik FL 3002 dye laser. A 300 W xenon arc lamp (Thermo Oriel) provided the analysing light. Kinetic curves were averaged over 256 laser pulses using a Tektronix TDS 360 digital oscilloscope. The τ_T values were obtained by fitting an exponential curve to the kinetic data using ORIGIN Pro 6.0. Elemental analyses were obtained from Carlo Erba 1106 Instrument.

2.3. Photophysical properties

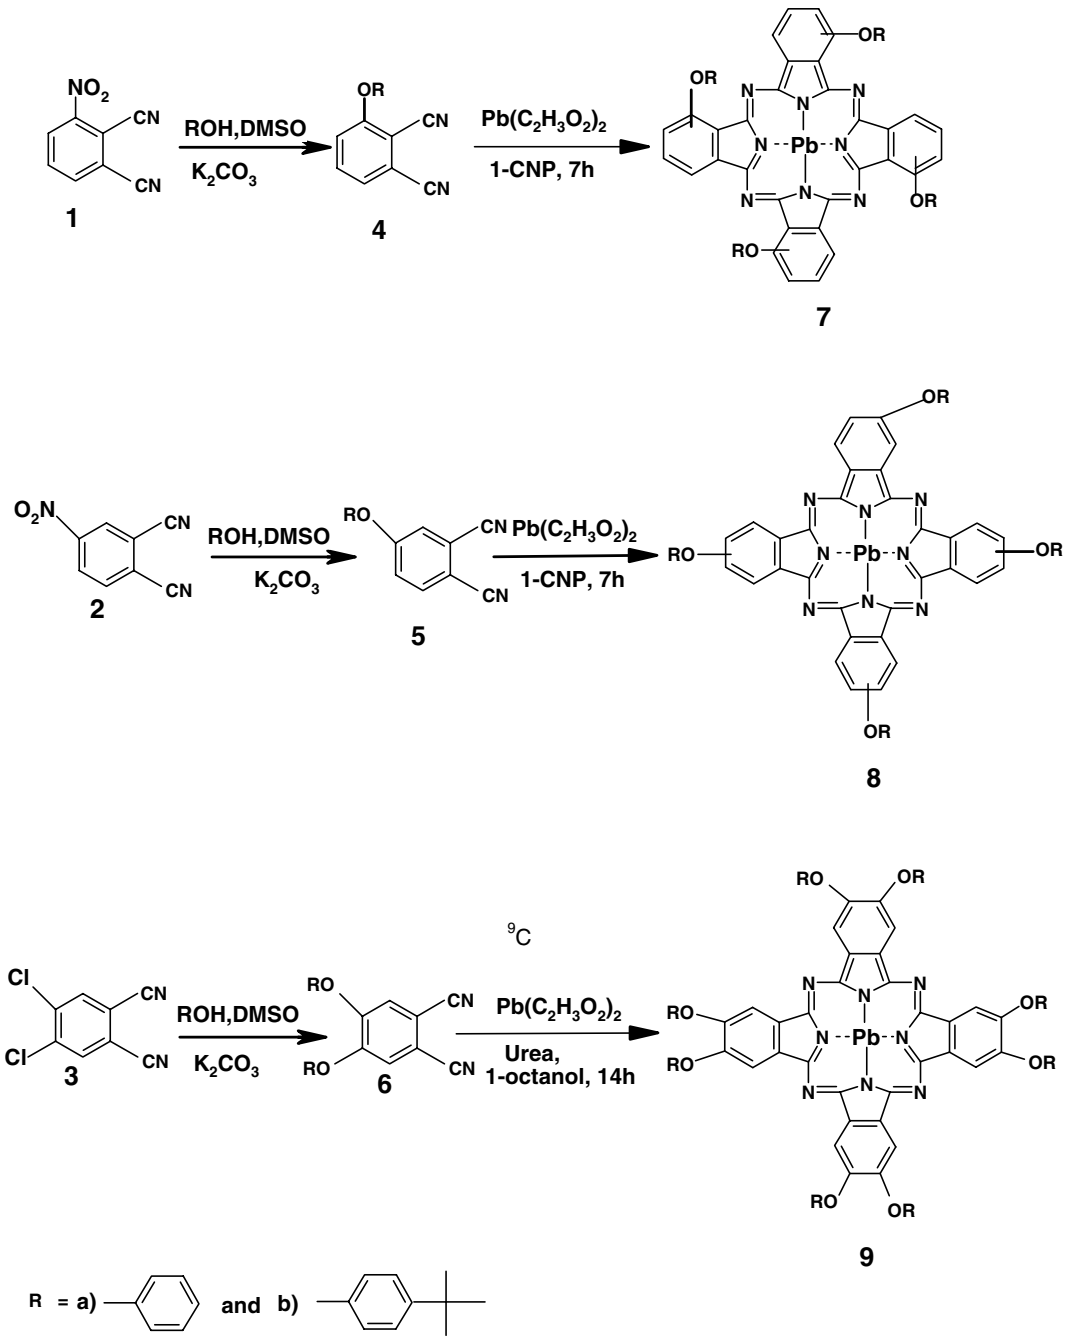
Fluorescence quantum yields (Φ_F) were determined by the comparative method, using Eq. (1) [37,38].

$$\Phi_F = \Phi_F^{std} \frac{F \cdot A_{std} \cdot \eta^2}{F_{std} \cdot A \cdot \eta_{std}^2} \quad (1)$$

where F and F_{std} are the areas under the fluorescence curves of the PbPc derivatives and the standard, respectively. A and A_{std} are the respective absorbances of the sample and standard at the excitation wavelengths (which was ~0.05 in all solvents used), and η and η_{std} are the refractive indices of the solvents used for sample and standard, respectively. ZnPc was employed as a standard in DMSO ($\Phi_F = 0.20$) [37].

The triplet quantum yields were determined using Eq. (2) [39].

$$\Phi_T = \Phi_T^{std} \frac{\Delta A_T \cdot \varepsilon_T^{std}}{\Delta A_T^{std} \cdot \varepsilon_T} \quad (2)$$



where ΔA_T and ΔA_T^{std} are the changes in triplet state absorbance of PbPc derivatives and the standard, respectively. ε_T and ε_T^{std} are the triplet state molar extinction coefficients for the PbPc derivatives and the standard, respectively. Φ_T^{std} is the triplet quantum yield for the standard, ZnPc ($\Phi_T = 0.65$ in DMSO [40], 0.58 in DMF [41] and 0.65 in toluene [42]).

Quantum yields of internal conversion were obtained from Eq. (3), which assumes that only three processes (fluorescence, intersystem crossing and internal conversion), jointly deactivate the excited singlet state of a PbPc molecule.

$$\Phi_{IC} = 1 - (\Phi_F + \Phi_T) \quad (3)$$

2.4. Synthesis

3-Phenoxyphthalonitrile (**4a**), 3-(4-*t*-butylphenoxy)phthalonitrile (**4b**), 4-phenoxyphthalonitrile (**5a**), 4-(4-*t*-butylphenoxy)phthalonitrile (**5b**), 4,5-diphenoxyphthalonitrile (**6a**), and 4,5-bis(4-*t*-butylphenoxy)phthalonitrile (**6b**) were synthesized and characterized according to reported procedures [43–45].

Scheme 1. Synthesis of phenoxy and 4-*t*-butylphenoxy tetra- and octa-substituted lead phthalocyanines.

*2.4.1. 1,(4)-(Tetraphenoxyphthalocyaninato)lead (**7a**)*

Under a blanket of nitrogen, **4a** (1.60 g, 7.30 mmol) was dissolved in 1-CNP (8 ml). Pb acetate (0.91 g, 2.40 mmol) was then added to the solution and the reaction mixture refluxed at 180 °C for 7 h under nitrogen. After cooling, the solution was chromatographed with hexane as eluent to remove 1-CNP. The column was then eluted with $CHCl_3$ which was evaporated off, thus affording **7a**. Yield: 1.27 g (49%). UV–Vis (DMSO): λ_{max} nm ($\log\varepsilon$) 723 (5.33), 652 (4.65), 460 (4.41), 347 (4.77). IR [(KBr) ν_{max}/cm^{-1}]: 1249(C–O–C), 970, 924, 877, 830, 818, 799, 788, 782, 742, 712, 702 (Pc skeletal). ^1H NMR ($CDCl_3$): δ, ppm 9.04–9.06 (4H, d, Pc–H), 8.89–8.92 (4H, m, Pc–H), 8.60–862 (4H, m, Pc–H), 7.78–8.01 (20H, m, phenyl–H). *Anal*. Calc. for $C_{56}H_{32}N_8O_4Pb$: C, 61.87; H, 2.97; N, 10.31. Found: C, 61.81; H, 3.59; N, 10.07%.

*2.4.2. 1,(4)-(Tetra-tert-butylphenoxyphthalocyaninato)lead (**7b**)*

Synthesis and purification was as outlined for **7a** except **4b** instead of **4a** was employed. The amounts of the reagents employed were as follows: **4b** (1.25 g, 4.55 mmol), lead acetate (0.62 g, 1.65 mmol) and 1-CNP (4.5 ml). Yield: 0.80 g (37%). UV–Vis (DMSO): λ_{max} nm ($\log\varepsilon$) 724 (5.22),

652 (4.64), 460 (4.34), 347 (4.67). IR [(KBr) ν_{max}/cm^{-1}]: 1251 (C–O–C), 999, 970, 944, 869, 827, 750 (Pc skeletal), 2960 (*t*-Butyl-H). ^1H NMR ($CDCl_3$): δ, ppm 8.40–9.06 (12H, m, Pc–H), 7.73–8.00 (16H, m, phenyl–H), 1.27–1.32 (36H, m, ^{t}Bu). *Anal*. Calc. for $C_{56}H_{32}N_8O_4Pb$: C, 65.95; H, 4.92; N, 8.55. Found: C, 67.76; H, 6.14; N, 7.14%.

2.4.3. 2,(3)-(Tetraphenoxyphthalocyaninato)lead (**8a**)

Synthesis and purification was as outlined for **7a** except **5a** instead of **4a** was employed. The amounts of the reagents employed were as follows: **5a** (1.25 g, 5.50 mmol), lead acetate (0.7 g, 1.85 mmol) and 1-CNP (6 ml). Yield: 0.92 g (46%). UV–Vis (DMSO): λ_{max} nm ($\log\varepsilon$) 708 (4.95), 638 (4.26), 346 (4.52). IR [(KBr) ν_{max}/cm^{-1}]: 1229 (C–O–C), 960, 942, 928, 904, 886, 869, 856, 781,759,743, 724 (Pc skeletal). ^1H NMR ($CDCl_3$): δ, ppm 8.69–8.78 (4H, m, Pc–H), 8.48–8.61 (4H, m, Pc–H), 8.26–8.31 (4H, m, Pc–H), 7.73–7.97 (20H, m, phenyl–H). *Anal*. Calc. for $C_{56}H_{32}N_8O_4Pb$.2acetate: C, 59.27; H, 3.23; N, 9.54. Found: C, 57.37; H, 3.04; N, 8.85%.

2.4.4. 2,(3)-(Tetra-tert-butylphenoxyphthalocyaninato)lead (**8b**)

Synthesis and purification was as outlined for **7a** except **5b** instead of **4a** was employed. The amounts of the reagents employed were as follows: **5b** (1.05 g, 3.80 mmol), lead acetate (0.57 g, 1.25 mmol) and 1-CNP (4 ml). Yield: 0.75 g (46%). UV–Vis (DMSO): λ_{max} nm ($\log\varepsilon$) 709 (5.00), 638 (4.37), 347 (4.42) IR [(KBr) ν_{max}/cm^{-1}]: 1240 (C–O–C), 978, 963, 943, 930, 879, 855, 843,828,823, 752, 729 (Pc skeletal), 2967 (*t*-butyl-H). ^1H NMR ($CDCl_3$): δ, ppm 8.43–9.01 (12H, m, Pc–H), 7.52–7.55 (16H, m, phenyl–H), 1.33 (36H, s, ^{t}Bu). *Anal*. Calc. for $C_{56}H_{32}N_8O_4Pb$: C, 65.96; H, 4.92; N, 8.55. Found: C, 67.64; H, 5.90; N, 7.19%.

2.4.5. 2,3-Octaphenoxyphthalocyaninatolead (**9a**)

In 1-octanol (8 ml), compound **6a** (2.00 g, 6.40 mmol), lead acetate (0.85 g, 2.12 mmol) and urea (0.50 g, 8.50 mmol) were stirred under a blanket of nitrogen at 150 °C for 14 h. The reaction mixture was allowed to cool, thereafter, methanol (80 ml) was added and the mixture was refluxed for 2 h. After cooling, the mixture was filtered, and the resulting solid sequentially washed with methanol and water and then dried. The crude product was purified by column chromatography, using $CHCl_3$ as the eluting solvent. After evaporation of solvent, the product was further purified by column chromatography (using chloroform as eluent) to afford the title compound as a dark-green solid. Yield: 1.00 g (32%). UV–Vis (DMSO): λ_{max} nm ($\log\varepsilon$) 707 (5.18), 637 (4.41), 348 (4.65). IR [(KBr) ν_{max}/cm^{-1}]: 1269 (C–O–C), 998, 880, 841, 787, 768, 744, 726 (Pc skeletal). ^1H NMR ($CDCl_3$): δ, ppm 8.50–8.58 (8H, s, Pc–H), 7.23–7.44 (40H, m, phenyl–H). *Anal*. Calc. for $C_{80}H_{48}N_8O_8Pb$: C, 65.91; H, 3.32; N, 7.69. Found: C, 65.44; H, 3.73; N, 8.06%.

2.4.6. 2,3-[Octakis(4-t-butylphenoxyphthalocyaninato)] lead (**9b**)

Synthesis and purification was as outlined for **9a** except **6b** instead of **6a** was employed. The amounts of the reagents employed were: **6b** (2.00 g, 4.75 mmol), lead acetate (0.10 g, 1.19 mmol) and urea (0.285 g, 4.75 mmol) in 1-octanol (8.75 ml). Yield: 1.00 g (44%). UV–Vis (DMSO): λ_{max} nm ($\log\varepsilon$) 709 (4.94), 638 (4.17), 358 (4.41). IR [(KBr) ν_{max}/cm^{-1}]: 1269 (C–O–C), 889, 884, 827, 828, 769, 751,744 (Pc skeletal), 2961 (*t*-butyl-H). ^1H NMR ($CDCl_3$): δ, ppm 8.91 (8H, s, Pc–H), 7.13–7.43 (32H, m, phenyl–H), 1.38 (72H, s, ^{t}Bu). *Anal*. Calc. for $C_{112}H_{112}N_8O_8Pb$: C, 70.68; H, 5.93; N, 5.89. Found: C, 69.88; H, 5.92; N, 5.91%.

3. Results and discussion

3.1. Synthesis and characterization

During synthesis the solvents with high boiling point are used to insert the metal in the central cavity. 3-Nitrophthalonitrile (**1**), 4-nitrophthalonitrile (**2**) and 4,5-dichlorophthalonitrile (**3**) may be employed to prepare 3-monosubstituted, 4-monosubstituted and 4,5-disubstituted phthalonitrile derivatives, respectively, through base catalysed nucleophilic aromatic displacement.

The same route employed for **1**, **2** and **3** was used to prepare complexes **4**, **5** and **6** by reacting phenol or 4-*tert*-butylphenol with complexes **1**, **2** and **3**, respectively (Scheme 1). The reactions were carried out in DMSO at room temperature and gave yields of 57% for compound **4a**, 42% for **4b** and **5a**, 35% for **5b**, 63% for **6a** and 72% for **6b**.

Substituted phthalocyanines are prepared by cyclotetramerization of substituted phthalonitriles. 4-Tetra-substituted phthalocyanines can be synthesized from 4-substituted phthalonitriles while 3-tetra-substituted phthalocyanines are obtained from 3-substituted analogues [46]. Octa-substituted phthalocyanines can be synthesized from 4,5-dichlorophthalonitriles [36].

Tetra-substituted phthalocyanines occur as a mixture of four possible structural isomers, differentiated by their molecular symmetry: C_{4h}, C_{2v}, C_s and D_{2h} [47]. Octa-substituted compounds occur as a single isomer and are easy to be purified than the corresponding tetra-substituted compound.

The syntheses of metallophthalocyanine complexes (**7**, **8** and **9**) were achieved by treatment of phthalonitrile **6** with lead acetate in 1-octanol for octa-substituted and **4** and **5** in 1-CNP for tetra-substituted compounds (Scheme 1). Complex **7** is non-peripherally (α) tetra-substituted, complex **8** is peripherally (β) tetra-substituted and complex **9** is peripherally octa-substituted. Column chromatography with silica gel was employed to obtain the purity of products.

The PbPc derivatives were characterized by UV–Vis, IR and NMR spectroscopies, and elemental analyses. The analyses were consistent with the predicted structures as shown in Section 2. The elemental analyses for complexes **7a**, **9a** and **9b** gave excellent percentage carbon values that

were very close to calculated values. For the rest of the complexes, the elemental analysis values were within 2% of the expected values. It has been reported before that for large Pc molecules, elemental analyses often gives unsatisfactory results [48]. However, we are confident of the purity of the complexes since NMR gave excellent results (see below). The sharp peak for the C≡N vibrations in the IR spectra of phthalonitriles **4a**, **4b**, **5a**, **5b**, **6a** and **6b** at ~2233, 2230, 2233, 2231, 2237 and 2224 cm^{-1}, respectively, disappeared after conversion into lead phthalocyanines. All PbPc derivatives showed absorption peaks between 700 and 1000 cm^{-1} which may be assigned to phthalocyanines skeletal vibrations [49]. The characteristic vibrations corresponding to ether groups (C–O–C) at ca. 1200–1247 cm^{-1} and aliphatic CH stretching at ca. 2900–3000 cm^{-1} were observed for the PbPc derivatives.

The ^1H NMR spectra of diamagnetic lead derivatives in $CDCl_3$ were found to be pure with all the substituent and Pc ring protons observed in their respective regions. Tetra-substituted PbPcs (**7** and **8**) show complex patterns due to the presence of mixed isomers. For complex **7a**, ^1H NMR spectra gave multiplets between 8.60–9.06 ppm for three sets of phthalocyanine ring protons, integrating for a total of 12 protons. The phenyl protons were observed as multiplets between 7.78–8.01 ppm integrating 20 protons. Compound **7b** gave multiplets between 8.40–9.06, 7.73–8.00 and 1.27–1.32 ppm integrating 12 protons for Pc ring, 16 protons for phenyl and 36 protons for methyl protons (*t*-Bu), respectively. The ^1H NMR spectra of **8a** and **8b** show similar spectral features as spectra of **7a** and **7b**. Compound **8a**, showed multiplets between 8.26–8.78 ppm integrating 12 protons for Pc ring and peaks at 7.73–7.97 ppm integrating 20 protons for phenyl rings. The ^1H NMR spectrum of **8b** showed a multiplet at 8.43–9.01 ppm intergrating for 12 Pc ring protons, a multiplet at 7.52–7.55 ppm for 16 phenyl protons and a singlet integrating for 36 methyl protons was observed at 1.33 ppm. Although the presence of isomers for tetra-substituted complexes as well as phthalocyanine aggregation at the concentrations used for the NMR measurements may lead to broadening of the aromatic signals [50], the NMR spectra obtained in this work was relatively well-resolved.

The ^1H NMR spectra for octa-substituted complexes **9** show a singlet integrating for 8 Pc ring protons between 8.50–8.58 ppm (**9a**) and at 8.91 ppm (**9b**). Phenyl protons were observed as multiplets between 7.23–7.44 ppm (**9a**) integrating 40H and 7.13–7.43 ppm (**9b**) representing 32H. Complex **9b** also showed a singlet at 1.38 ppm for 72 methyl protons.

UV/Vis spectra of the complexes showed characteristic absorptions in the Q-band and B-band, Figs. 1 and 2. The peaks obtained in the Q-band region in the range 706–742 nm in five different solvents (Table 1) are responsible for the observed green colour of the complexes. The spectra showed monomeric behaviour, evidenced by a single (narrow) Q-band, typical of unaggregated phthalocyanine complexes in DMSO [51]. The B band region was observed around 345–360 nm in DMSO (Figs. 1 and 2).

The Q-band of the non-peripheral tetra-substituted complexes (**7**) is red-shifted when compared to the corresponding peripherally tetra- and octa-substituted complexes. The observed red spectral shift is typical of phthalocyanines with substituents at the non-peripheral positions and has been explained [52,53] to be due to linear combinations of the atomic orbitals (LCAO) coefficients at the non-peripheral positions of the HOMO being greater than those at the peripheral positions. As a result, the HOMO level is destabilized more at the non-peripheral position that it is at the peripheral position. Essentially, the energy gap (ΔE) between the HOMO and LUMO becomes smaller. Generally, OR groups cause a red shift since they can donate electron density from the lone pair into the π system increasing conjugation, hence lowering HOMO–LUMO gap.

Fig. 3 shows the concentration dependence of complex **9a** in DMSO. As the concentration was increased, the intensity of the Q-band also increased and there were no new bands due to the aggregated species for the complex. The Beer–Lambert's law was obeyed for all of these compounds for concentration less than 1×10^{-5} mol dm^{-3}. Aggregation is also dependent on the nature of the solvent. The aggregation behaviour of PbPc complexes were investigated

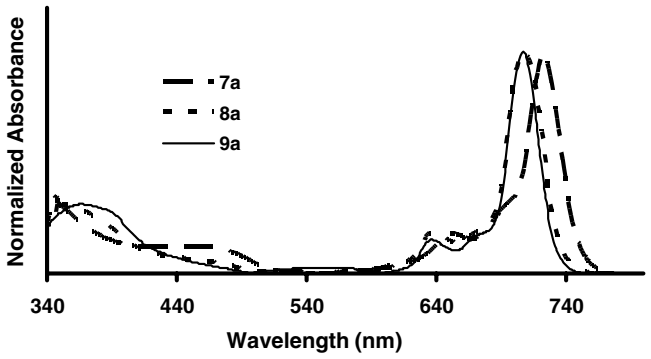


Fig. 1. UV–Vis spectra for tetra- and octa-phenoxy substituted lead phthalocyanines. Solvent = DMSO. Concentration ~2×10^{-6} mol dm^{-3}.

[a] Values of Φ_T and Φ_{ISC} not determined due to lack of standards.

at different solvents (Fig. 4), there were no new band observed in all solvents.

Table 1 shows that the largest red-shift of the Q-band was observed in chloroform. This observation could partly be explained by considering the refractive indices of the solvents. It is known that red-shifting of absorption spectra is a function of the solvent's refractive index [54].

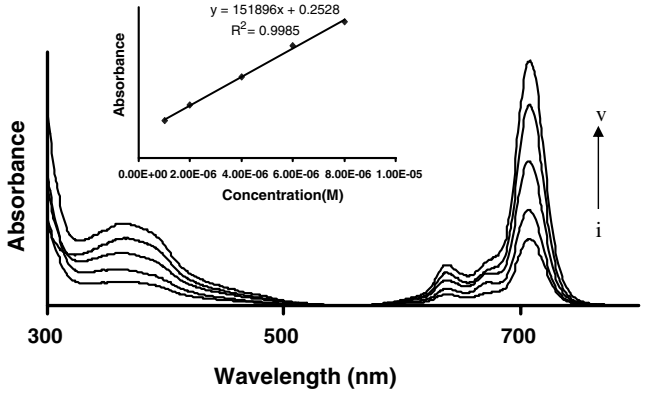

Fig. 3. Absorption spectra of compound **9a** in DMSO at different concentrations: (i) 8×10^{-6}, (ii) 6×10^{-6}, (iii) 4×10^{-6}, (iv) 2×10^{-6}, (v) 1×10^{-6} M.

3.2. Photophysical behaviour

3.2.1. Fluorescence spectra and quantum yields

The values of Φ_F are widely known to be influenced by the factors such as temperature, molecular structure, solvent parameters (polarity, viscosity and refractive index), and the presence of heavy atoms in the solvent and in the molecule itself.

Table 1 shows the Q-band maxima for absorption, emission and excitation spectra. Figs. 5 and 6 show the

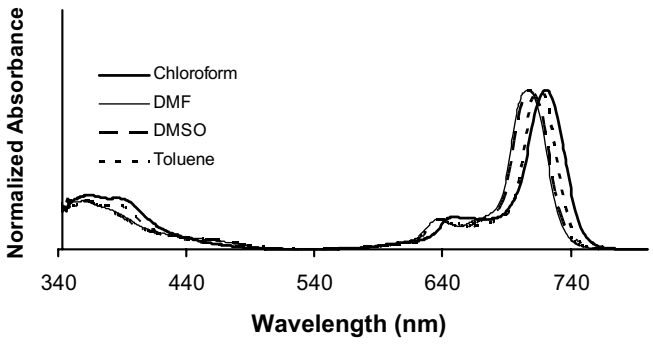

Fig. 4. Absorption spectra of complex **8a** in different solvents. Concentrations ~2×10^{-6} M.

absorption, fluorescence emission and excitation spectra for the complexes in various solvents. The excitation spectra were different from absorption and emission spectra in all solvents shown in Fig. 5 for **7b**. The excitation spectrum shown in Fig. 5a shows demetallation of **7b** in toluene upon excitation, as judged by the blue shifted and split Q band. The excitation spectrum in Fig. 5 was similar to the absorption spectra of the corresponding dematallated H_2Pc derivatives, confirming demetallation upon excitation. Metal free Pcs are known to fluoresce with only one main peak in non-aqueous media which has been assigned as the 0–0 transition of the fluorescence [55]. Complete splitting of the Q band was observed for all complexes in THF, toluene and chloroform. There was broadening in DMSO and partial splitting in DMF of the Q band in the excitation spectra of **7b**. Both DMSO and DMF are basic solvents. It has been documented that in strongly basic solvents, the inner pyrrole hydrogens are acidic enough to dissociate resulting in a charged system (Pc^{-2}) which becomes symmetric and thus possesses an unsplit Q band [51]. This is observed as a partially split Q band in DMF and a broadened Q band in DMSO for **7b**. The lack of split in the Q band in DMSO is more clear in the fluorescence excitation spectra for **9a**, in DMSO (Fig. 5d), which exhibited one band upon excitation. Emission for **9a** was from the demetallated species as evidenced by the red shift observed for emission when compared to the excitation spectra and not the absorption spectra. However, a clear single Q band for the excitation spectra was observed only for complexes **9** in DMSO, Fig. 5d. For other complexes such as **7b** in DMSO, there was broadening of the excitation spectra without showing complete splitting. Thus, the more basic solvents such as DMSO and DMF resulted in a single or broadened excitation spectrum, whereas the less basic solvents (THF, chloroform and toluene) resulted in complete splitting of the Q band of the excitation spectra due to demetallation.

The extent of splitting in the Q band also depended on the nature of the complex considering the same solvent, Fig. 6. For example, the excitation spectrum of **7a** is broadened but not split in DMF (Fig. 6a), while in the same solvent excitation spectrum of **9a** is split. Thus the extent of deprotonation of the ring by the basic solvent depends on the nature of substituents.

The fluorescence quantum yield (Φ_F) values were found to be less than 0.1, hence less than typical values for MPc complexes (e.g. ZnPc in DMSO, $\Phi_F = 0.2$ [37]). Thus, the

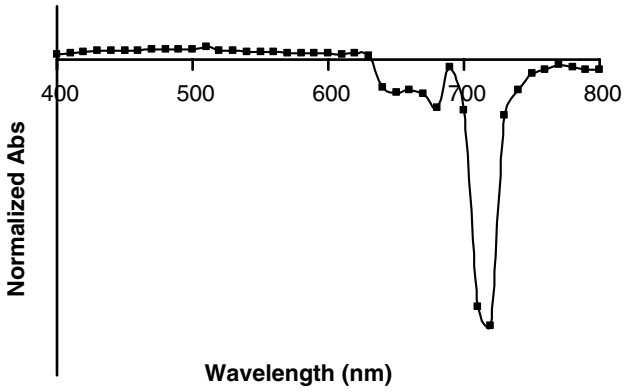

Fig. 7. Transient absorption spectrum for **9a** in DMSO.

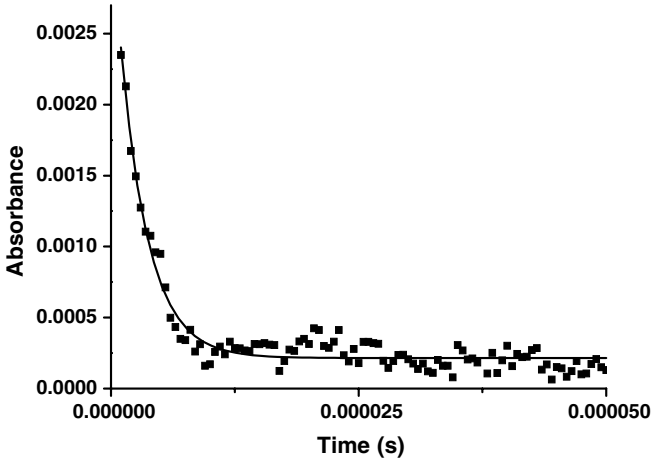

Fig. 8. Triplet decay curve for **9a** in DMF. Excitation wavelength (λ_{exc}) = 706 nm.

Φ_F values are very small due to the presence of heavy atom (Pb) in solution, which enhances intersystem crossing to populate the triplet state, consequently reducing the number of fluorescing molecules. Relatively higher Φ_F values were observed in $CHCl_3$ compared to the rest of the solvents. This contradicts the heavy atom effect of the chlorines in chloroform, which should encourage intersystem crossing resulting in less fluorescence.

The fact that the PbPc complexes become demetallated on excitation suggests that the reported Φ_F values are for the fully or partially dematallated complexes. However the effects of Pb in terms of the heavy atom effect will still influence the values since the Pb is still in solution.

3.2.2. Triplet quantum yields and lifetimes

Both the triplet quantum yield and lifetime were determined by laser photolysis. Transient spectra (Fig. 7) in DMSO showed a single Q band but at a different Q band wavelength from that observed for absorption, thus confirming the changes in the molecule following excitation. As discussed above the molecules demetallate on excitation, but show a single Q band in basic solvents like DMSO. Fig. 8 shows the transient curve for the complexes. Fig. 8 shows a typical triplet decay curve of compound **9a** in DMSO.

Since intersystem crossing and fluorescence are two competing deactivating processes for the excited singlet state, their values for a particular species are expected to be complementary. Thus Table 1 shows high Φ_T values (0.70–0.88) in DMSO, DMF and toluene, corresponding to low Φ_F values of the complexes. These values are high due to the presence of lead. The Φ_T values in $CHCl_3$ and THF could not be determined due to the lack of standard Φ_T values in those solvents. The Φ_T values (Table 1) do not change much with the change of the substituents showing the effect of the phenoxy and *tert*-butylphenoxy substituents on triplet quantum yield was minimal, with Φ_T values ranging between 0.72–0.88 in DMSO, 0.72–0.82 in DMF and 0.70–0.85 in toluene. Thus, the nature of the solvent also has an insignificant effect on the $\Phi_T$values. Again the Φ_T values are for the partially or totally demetallated species since demetallation occurs on excitation, but the Pb is still present in solution.

The triplet curve in Fig. 8 obeyed second order kinetics. This is typical of MPc complexes at high concentrations ($>1 \times 10^{-4}$ M) [56] due to the triplet-triplet recombination. The concentrations employed in this work was in this range hence triplet–triplet recombination is expected.

The triplet lifetime (τ_T) values were found to be low for PbPc complexes compared to ZnPc or AlPc derivatives

[27,57], but are similar to the corresponding InPc derivatives [58], containing a heavy metal, even though the InPc derivatives were not demetallated on excitation. The τ_T values in DMSO were much longer than DMF, chloroform, THF and toluene, which may be attributed to the higher viscosity of DMSO, this has been reported before [45]. Diffusion-like movement that enhance non-radiation deactivation of the excited state are impeded in viscous solvents, resulting in longer excited state lifetimes. The values in DMSO ranged from 20 to 50 μs for PbPc complexes. The triplet lifetimes were very low in the low viscocity solvents DMF, chloroform, THF and toluene, which were less than or equal to 10 μs. Quantum yields of internal conversion (Φ_{IC}) were calculated according to Eq. (3). Table 1 shows that the values of Φ_{IC} were similar.

4. Conclusion

In this study, we synthesized and characterized new non-peripheral and peripheral (phenoxy and 4-*t*-butylphenoxy) tetra-substituted and octa-substituted lead phthalocyanine complexes. The fluorescence spectra were different from absorption spectra due to the loss of symmetry (due to demetallation) upon excitation. The high triplet quantum yields and low triplet lifetimes were observed as the result of heavy atom (Pb).

lines. Generally, cobalt(III) complexes show antitumor activities in vivo [7,8] and, hence recently, the interaction of cobalt complexes with DNA has attracted much attention [9–11]. In a recent report, Shimakoshi et al. have shown that a dicobalt complex was more efficient in cleaving DNA compared to an equivalent monomeric complex [12]. Synthesis of new cobalt(III) complexes enabled chemists to extensively study the ability of these complexes to act as probes in investigating the structure of DNA, when these metal complexes are incorporated with either 1,10-phenanthroline or a modified phenanthroline moiety as one of the ligands.

A polymer–metal complex is composed of a polymeric ligand and metal ion in which the metal ion is attached to the polymer ligand by a coordination bond. In recent years, the chemistry of polymer–metal complexes has been of great interest because these complexes act as excellent models for metalloenzymes [13]. Drug–polymer conjugates are potential candidates for the selective delivery of anticancer agents to tumor tissue and only a very few reports are available for the use of polymer–metal complexes as anticancer drugs [14–16]. Polyethyleneimine (PEI) is a cationic polymer exhibiting the highest positive charge density potential and, recently, PEI has appeared as a possible alternative to viral and liposomal routes of gene delivery [17]. PEI possesses quite a number of advantages as polymer chelating agent, such as good water solubility, high content of functional groups, good physical and chemical stability, and suitable molecular weights [18]. Recently, we have reported our interesting results on the interaction of some polymer–cobalt(III)/copper(II) complexes with DNA [19,20].

In this context, we focused on the development of new water-soluble branched polyethyleneimine–cobalt(III) complex samples with different amounts of cobalt(III) complex (containing 1,10-phenanthroline ligand) moieties bound to the polymer chain and studied the DNA binding properties of these polymer-bound cobalt(III)–phenanthroline complex samples and their antitumor activities on HEp-2 laryngeal cancer cells.

2. Experimental

2.1. Materials and instrumental techniques

Cobalt(II) chloride hexahydrate, 1,10-phenanthroline were purchased from Merck, India. Calf thymus DNA and branched polyethyleneimine (BPEI) (M_w ca. 25000) obtained from Sigma–Aldrich, Germany, were used as such. Plasmid pBR322 DNA was purchased from Genei, India. The spectroscopic titration was carried out in the aqueous buffer solution (50 mM NaCl–5 mM Tris–HCl, pH 7.1) at room temperature. A solution of calf thymus DNA in the buffer gave a ratio of UV absorbance at 260 and 280 nm of (1.8–1.9:1), indicating that the DNA was sufficiently free of protein [21]. Milli-Q water was used to prepare the solutions. The complex, *cis*-$[Co(phen)_2Cl_2]Cl \cdot 3H_2O$, was prepared as reported earlier [22]. Absorption spectra were recorded on a UV–Vis–NIR Cary300 Spectrophotomer using cuvettes of 1-cm path length, and emission spectra were recorded on a JASCO FP 770 spectrofluorimeter. FT-IR spectra were recorded on a FT-IR Perkin–Elmer spectrophotometer with samples prepared as KBr pellets. ^1H NMR spectra were recorded on a BRUKER 400 MHz Spectrometer using D_2O as solvent.

2.2. Synthesis of polymer–cobalt(III) complex samples

A sample of polymer–cobalt(III) complex, *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$, was prepared from *cis*-$[Co(phen)_2Cl_2]Cl \cdot 3H_2O$ by the same method reported earlier for preparing *cis*-$[Co(en)_2(BPEI)Cl]Cl_2$ (en = ethylenediamine) [23] and *cis*-$[Co(en)_2(PVP)Cl]Cl_2 \cdot nH_2O$ [PVP = poly(4-vinylpyridine)] [24]. To a solution of 0.15 g of BPEI dissolved in 15 mL of ethanol, 1.0 g of *cis*-$[Co(phen)_2Cl_2]Cl \cdot 3H_2O$ in 15 mL of water was added slowly with stirring. The mixture was heated between 50 and 60 °C for 12 h in a water bath. The color of the solution changed from violet to reddish brown. After being warmed enough, the dark blue colored mixture was filtered, and the filtrate was dialyzed against cold water for several days. Afterwards, the solvent was evaporated in a rotary evaporator under reduced pressure at room temperature. A dark reddish filmy substance was obtained. It was pulverized and dried. Yield: 0.25 g. *Anal.* Calc.: C, 31.38; H, 7.18; N, 18.85. Found: C, 31.38; H, 7.36; N, 19.13 and $x = 0.245$. (The degree of coordination (x), means the number of moles of cobalt(III) chelate per mole of the repeating unit (imine group) of polymeric ligand. If all the repeating units (imine groups) in the polymer are coordinated to cobalt, then the value of x is 1.) IR (KBr, cm^{-1}): 3433 (ν(N–H), BPEI), 2924, 2853 (C–H asymmetric and symmetric stretching vibration of aliphatic CH_2 of BPEI), 1626 (ν(C=N), phen), 1517 (ν(C=C), phen ring), 849, 725 (ν(C–H), phen). ^1H NMR (D_2O, ppm): δ 8.9 (2H, d, phen), δ 8.3 (2H, s, phen), δ 7.79 (2H, t, phen), δ 7.5 (2H, d, phen), δ 2.5–3.6 (broad, H from N–CH_2–CH_2–N from BPEI).

The polymer–cobalt(III) complex samples with various amounts of cobalt(III) complex units bound to the polymer chain were synthesized by some modifications in the above experimental procedure. That is the amount of *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ in the reaction solution was varied between 0.6 and 1.0 g. Also the reaction duration has been kept between 6 and 10 h.

2.3. DNA-binding experiments

The DNA-binding experiments were performed at 30.0 ± 0.2 °C. The DNA concentration per nucleotide was determined by electronic absorption spectroscopy using the known molar extinction coefficient value of 6600 $M^{-1}\,cm^{-1}$ at 260 nm [25]. Electronic absorption

titration of the polymer–cobalt(III) complex samples in the aqueous buffer solution (50 mM NaCl–5 mM Tris–HCl, pH 7.1) were performed by using a fixed complex concentration (12 μM) with increasing amounts of DNA over a range of 0.5–2 μM.

The binding constant for the interaction of polymer–cobalt(III) complex samples with DNA was obtained from absorption titration data (at 269 nm where only polymer–cobalt(III) complex absorbs in the concentration range used. No absorption could be observed for DNA). The intrinsic binding constant, K_b, has been determined using the equation [26],

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_b - \varepsilon_f) + 1/K_b(\varepsilon_b - \varepsilon_f),$$

where [DNA] is the concentration of DNA in base pairs, ε_a, ε_f and ε_b correspond to A_{obsd}/[total cobalt complex units], the extinction coefficient of the complex in its free form and the extinction coefficient of the complex in the fully bound form, respectively. A plot of [DNA]/($\varepsilon_a - \varepsilon_f$) versus [DNA], gives K_b as the ratio of the slope to the intercept (Our attempts to determine the binding constant for the polymer–cobalt(III) complex samples using the visible region of the spectrum were unsuccessful due to the necessity of using very high concentration of the polymer–cobalt(III) complex at which the complex-DNA adduct precipitates out of the solution).

For fluorescence experiments, DNA was pretreated with ethidium bromide (EB) for 30 min. The polymer–cobalt(III) complexes were then added to this mixture and their effect on the emission intensity was measured. The samples were excited at 450 nm and emission was observed between 500 and 700 nm. These experiments were carried out in 50 mM NaCl–5 mM Tris–HCl at pH 7.1 in aqueous media.

For the gel electrophoresis experiments, super-coiled pBR322 DNA (0.1 μg) was treated with the polymer–cobalt(III) complex in 50 mM Tris–HCl, 18 mM NaCl buffer, pH 7.2. The samples were electrophoresed for 3 h at 50 V on a 0.8% agarose gel in Tris–acetic acid–EDTA buffer. The gel was stained with 0.5 μg/mL of ethidium bromide and photographed in UV light.

2.4. Cell culture

HEp-2 human larynx cancer cells were obtained from King's Institute of Preventive Medicine, Chennai, India. The cells were cultured in RPMI 1640 medium (Sigma–Aldrich, St. Louis, MO, USA), supplemented with 10% fetal bovine serum (Sigma, USA) and 100 μg/mL of penicillin and 100 μg/mL of streptomycin as antibiotics (Himedia, Mumbai, India), in 96 well culture plates, at 37 °C, in a humidified atmosphere of 5% CO_2, in a CO_2 incubator (Heraeus, Hanau, Germany). All experiments were performed using cells from passage 15 or less.

2.5. Cytotoxicity assay [27]

The *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ complex was first dissolved quantitatively in dimethyl sulfoxide (DMSO, Sigma, USA) to make the stock solution. This solution was diluted to get various concentrations of the complex in the range of 25–225 μg/mL. 200 μL of this solution was added to a series of wells containing 5×10^3 HEp-2 cells per well in DMSO medium. DMSO solution was used as the solvent control. After 24 and 48 h of treatment, the gross morphological changes in HEp-2 cells were observed and photographed, using an inverted microscope (Carl Zeiss, Jena, Germany). Immediately thereafter, 20 μL of MTT solution (5 mg/mL in phosphate-buffered saline (PBS)) was added to each well and the plates were wrapped with aluminum foil and incubated for 4 h at 37 °C. The purple formazan product was dissolved by addition of 100 μL of 100% DMSO to each well. The absorbance was monitored at 570 nm (measurement) and 630 nm (reference) using a 96 well plate reader (Bio-Rad, Hercules, CA, USA). Data were collected for four replicates each and used to calculate the respective means. The percentage inhibition was calculated, from this data, using the formula:

$$\frac{\text{Mean absorbance of untreated cells(control)} - \text{Mean absorbance of treated cells} \times 100}{\text{Mean absorbance of untreated cells(control)}}$$

2.6. Hoechst 33258 staining [28]

The cell pathology was detected by staining the nuclear chromatin of trypsinized cells (4.0×10^4/mL) with 1 μL of Hoechst 33258 (1 mg/mL, aqueous) for 10 min at 37 °C. A drop of cell suspension was placed on a glass slide and a cover-slip was laid over to reduce light diffraction. At random 300 cells were observed in a fluorescent microscope (Carl Zeiss, Germany) fitted with a 377–355 nm filter and observed at 400× magnification, and the percentage of cells reflecting pathological changes was calculated. Data were collected for four replicates and used to calculate the mean and the standard deviation.

2.7. Acridine orange (AO) and ethidium bromide (EB) staining

Acridine orange (AO) and ethidium bromide (EB) staining was performed as described by Spector et al. [29]. Cell suspension (25 μL) of each sample (both

attached, released by trypsinization, and floating), containing 5×10^5 cells, was treated with AO and EB solution (1 part of 100 μg/mL AO and 1 part of 100 μg/mL EO in PBS) and examined under a fluorescent microscope (Carl Zeiss, Germany) using an UV filter (450–490 nm). Three hundred cells per sample were counted in tetraplicate for each dose point. Cells were scored as viable, apoptotic or necrotic as judged by the staining, nuclear morphology and membrane integrity, and percentages of apoptotic and necrotic cells were then calculated. Morphological changes were also observed and photographed.

2.8. Leukostat staining

Leukostat staining was performed as described by Spector et al. [29]. Smears of cells (attached, released by trypsinization, and floating were pooled) were fixed by dipping the slide for 10 s in Leukostat fixative solution (2 mg/ml malachite green in 100% methanol). The cytoplasm was stained by dipping for 10 s in Leukostat staining solution 1 (0.1% eosin Y, 0.1% formaldehyde; 0.4% sodium phosphate dibasic, and 0.5% potassium phosphate monobasic) and counterstained by dipping for 10 s in Leukostat staining solution 2 (0.04% azure, 0.04% methylene blue, 0.4% sodium phosphate dibasic, and 0.5% potassium phosphate monobasic). The preparations were examined at 400× magnification in a light microscope (Carl Zeiss, Germany). The cells were scored as normal, apoptotic or necrotic as judged by staining and nuclear/cell morphology. Percentages of apoptotic cells and necrotic cells were then calculated. The morphological changes were also observed and photographed.

3. Results and discussion

3.1. Degree of coordination

The structure of the polymer–cobalt(III) complex is shown in Fig. 1. In this figure 'x' represents degree of coordination. The degree of coordination (x) of the cobalt chelate in the polymer–cobalt(III) complex could be calculated from the carbon content [23,24] or cobalt content [30]. The degree of coordination (x) thus obtained for the polymer–cobalt(III) complexes synthesized were 0.104, 0.125 and 0.245. The x value of the polymer–metal complex was found to reach a constant level of about 0.245. Even if the cobalt chelate was added in large excess or the reaction mixture was warmed for more than 12 h, we could not obtain polymer–cobalt(III) complex samples with degree of coordination more than 0.245. This may be ascribed to the steric hindrance between metal complex units in the polymer chain which prevents further coordination [23].

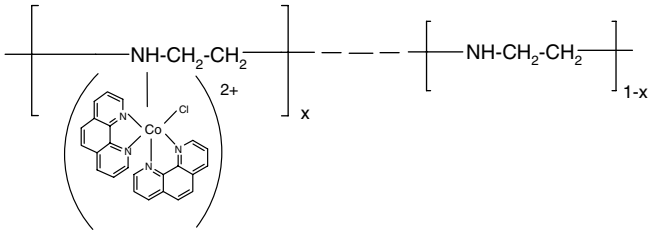

Fig. 1. Structure of *cis*-[Co(phen)$_2$(BPEI)Cl]Cl$_2$ · 4H$_2$O

3.2. Absorption spectroscopic studies

Electronic absorption spectra were initially employed to study the binding of polymer–cobalt(III) complexes with CT-DNA. The absorption spectra in aqueous buffer media of polymer–cobalt(III) complex ($x = 0.245$) in the absence and in the presence of CT DNA are given in Fig. 2. As the concentration of DNA increased, the absorption band of polymer–cobalt(III) complex at 269 nm exhibits hyperchromism and blue shift. A similar hyperchromism has been observed for the soret bands of certain porphyrins when interacted with DNA but has not yet been clearly explained [31].

The polymer–cobalt(III) complex can bind to the double stranded DNA in different binding modes on the basis of their structure and charge and type of ligands. Our polymer–cobalt(III) complex, containing several methylene groups of the branched polyethyleneimine (BPEI) can bind to DNA by van der Waals interactions between these methylene groups and the thymine methyl groups of DNA [32]. On the other hand, since DNA possesses several hydrogen bonding sites which are accessible both in minor and major grooves, it is likely that the amine groups of BPEI forms hydrogen bonds with N-3 of adenine or O-2 of thymine in the DNA, which may contribute to the hyperchromism observed in the absorption spectra. The hyperchromic effect may also be due to the electrostatic interaction between positively charged polymer (BPEI) and the nega-

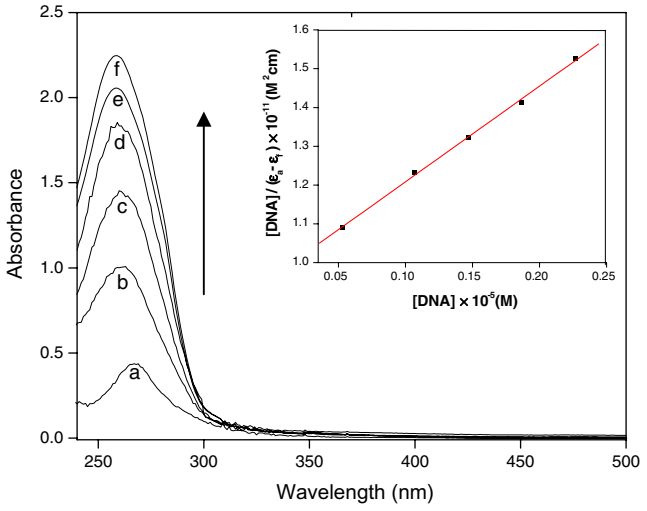

Fig. 2. Absorption spectra of *cis*-[Co(phen)$_2$(BPEI)Cl]Cl$_2$ · 4H$_2$O ($x = 0.245$) in the absence (a) and in the presence of increasing amounts of DNA (b,c,d,e,f), [polymer–cobalt(III) complex] = 12 μM, [DNA] = 0.5–2 μM. Arrow shows the absorbance change upon increasing DNA concentrations. Inset: Plot of [DNA]/($\varepsilon_a - \varepsilon_f$) vs. [DNA].

tively charged phosphate backbone at the periphery of the double helix CT DNA [33]. Structurally, intercalation to DNA may be one of the binding patterns, since our polymer–cobalt(III) complex contains phenanthroline ligands which should provide aromatic moiety extending from the metal center through which overlapping occurs with base pairs of DNA by intercalation. In our complex, the cobalt(III)–phenanthroline chelate moieties are randomly coordinated to the branched polymer, hence complete intercalation of the phenanthroline ligand between a set of adjacent base pairs is sterically impossible, but some type of partial intercalation can be envisioned [34].

Viscosity and circular dichroism measurements could have been helpful to us to confirm the intercalative behaviour. But as our systems are polymeric and DNA being another polymer, we were not able to use viscosity method, because not only changes in the structure of DNA but also the changes in the structure of the polymer–cobalt(III) complex would change the viscosity of the solution. So it will not be possible to resolve the changes in the viscosity behaviour if at all there is a change in the viscosity behaviour. The solubility of polymer–cobalt(III) complex samples are very low, so we could not do circular dichroism measurements also.

The intrinsic binding constant (K_b) values of polymer–cobalt(III) complex with different degrees of cobalt complex content are shown in Table 1 which indicate that complex with higher degree of cobalt complex content has higher K_b value. The significant difference in DNA binding affinity of the three polymer–cobalt(III) complex samples can be understood as a result of the fact that the complex with higher degree of cobalt content shows stronger binding with DNA. Interestingly, the K_b values obtained for our polymer–cobalt(III) complex samples are very much higher than those for the other known ordinary cobalt(III) complexes containing 1,10-phenanthroline and/or modified phenanthroline ligands available in the literature [3–5,35–38]. $[Co(5,6\text{-dmp})_3]^{3+}$ (5,6-dmp = 5,6-dimethyl-1,10-phenanthroline) (K_b, $2.1 \times 10^3\ M^{-1}$), $[Co(phen)_2(bipy)]^{3+}$ (bipy = bipyridine) (K_b, $2.3 \times 10^3\ M^{-1}$), $[Co(phen)_2(imp)]^{3+}$ (imp = imidazo[4,5-*f*][1,10]-phenanthroline) (K_b, $1.2 \times 10^5\ M^{-1}$), $[Co(phen)_2(PIP)]^{3+}$ (PIP = 2-phenylimidazo[4,5-*f*][1,10]-phenanthroline) (K_b, $2.15 \times 10^5\ M^{-1}$), $[Co(phen)_3]^{3+}$ (K_b,$1.6 \times 10^4\ M^{-1}$), $[Co(phen)_2(dicnq)]^{3+}$ (dicnq = dicyanodipyrido quinoxaline) (K_b, $6.0 \times 10^3\ M^{-1}$), $[Co(phen)_2(pdtb)_2]^{3+}$ (pdtb = 3-(pyridine-2-yl)-5,6-diphenyl-as-triazine) (K_b, $8.62 \times 10^3\ M^{-1}$), $[Co(phen)_2(pdta)]^{3+}$ (pdta = 3-(pyridine-2-yl)-as-triazino[5,6-*f*]-acenaphthylene) (K_b, $2.81 \times 10^4\ M^{-1}$), $[Co(phen)_2(HPIP)]^{3+}$ (HPIP = 2-(2-hydroxyphenyl)imidazo[4,5-*f*][1,10]-phenanthroline) (K_b, $4.1 \times 10^5\ M^{-1}$), $[Co(phen)_2(HNAIP)]^{3+}$ (HNAIP = 2-(2-hydroxy-1-naphthyl)imidazo[4,5-*f*][1,10]-phenanthroline) (K_b, $1.8 \times 10^5\ M^{-1}$), $[Co(phen)_2(CNOIP)]^{3+}$ (CNOIP = 2-(2-chloro-5-nitrophenyl)imidazo[4,5-*f*][1,10]-phenanthroline) (K_b, $1.6 \times 10^5\ M^{-1}$), $[Co(en)_2(phen)]^{3+}$ (en = ethylenediamine) (K_b, $1.7 \times 10^3\ M^{-1}$), $[Co(en)_2(dppz)]^{3+}$ (dppz = dipyrido[3,2-*a*:2′,3′-*c*]phenazine) (K_b, $4.3 \times 10^3\ M^{-1}$). Also K_b values for our complex samples are higher than known association constant of PEI to DNA (K_a, $1.2 \times 10^5\ M^{-1}$) [39]. This shows that comparatively our polymer–cobalt(III) complex samples can bind very strongly with DNA.

We have carried out the effect of addition of NaCl salt into the DNA bound polymer–cobalt(III) complex. Fig. 3 shows the changes in the absorption spectra upon addition of increasing amounts of NaCl into the DNA bound polymer–cobalt(III) complex. When increasing the ionic strength of the medium, we observed that the absorbance of the DNA bound polymer–cobalt(III) complex goes on decreasing along with a slight blue shift till the ionic strength reaches sufficiently high value (at 3.2 M). In the case of ordinary cobalt(III)–phenanthroline complex the value is 1.75 M. This implies that electrostatic interaction make significant contribution to the binding between DNA and polymer–cobalt(III) complex.

3.3. Fluorescence studies

No fluorescence was observed for the polymer–cobalt(III) complexes at room temperature in aqueous solution or in any organic solvent examined or in the presence of calf thymus DNA. So the binding of polymer–cobalt(III) complex

Table 1
The intrinsic binding constants (K_b) of polymer–cobalt(III) complex samples with calf thymus DNA

Complex	Degree of coordination (x)	K_b (M^{-1})
cis-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$	0.104	1.13×10^6
	0.125	1.54×10^6
	0.245	2.57×10^6

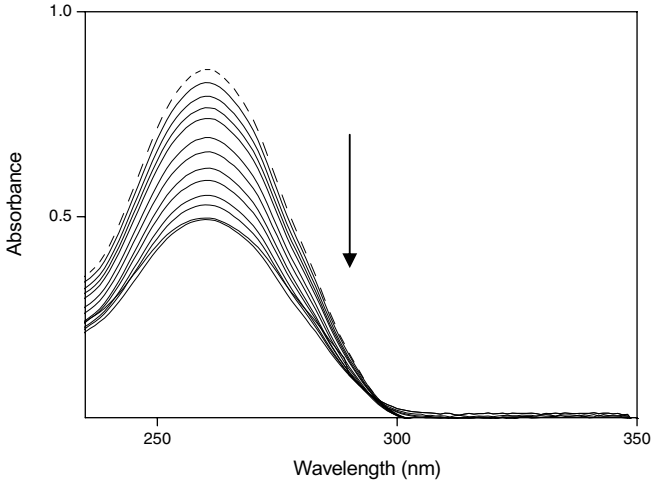

Fig. 3. Influence of the salt concentration on the UV spectra of the DNA bound polymer–cobalt(III) complex ($x = 0.245$) system. Concentrations: [complex] = 12 μM, [DNA] = 0.5 μM. Dashed line: DNA bound polymer–cobalt(III) complex without any salt; solid line: with the addition of 0.1–4 M NaCl.

samples with DNA cannot be directly predicted through the emission spectra. Hence competitive ethidium bromide (EB) binding studies were undertaken to gain support for the extent of binding of polymer–cobalt(III) complex with DNA. The molecular fluorophore, ethidium bromide (EB), emits intense fluorescence light in the presence of CT DNA due to its strong intercalation between the adjacent DNA base pairs [40]. It has been previously reported that the fluorescent light can be reduced by the addition of a second molecule [41], indicating the competition of second molecule with ethidium bromide (EB) in binding to DNA. Recently, Ni et al. [42] found that fluorescence reduction of fluorophore NR (neutral red dye) in the presence of DNA by $Cu(phen)^{2+}$may be due to the replacement of the DNA intercalator, NR. This means that the complex interacts with the same site as NR does. On the other hand, Bronich et al. [43] have reported that the addition of a copolymer (i.e., polyethyleneglycol-polyethyleneimine (PEI)) to ethidium bromide (EB)–DNA complex results in quenching of the fluorescence due to the displacement of ethidium bromide (EB) by the copolymer. Xiao and Zhan [33] have studied the effect of polymeric Schiff base-nickel complexes on the fluorescence of EB-DNA system and they have suggested that a portion of the metal complex, possessing a planar aromatic moiety can intercalate to adjacent base pairs, which can in turn inhibit ethidium bromide (EB) binding to calf thymus DNA competitively. In our studies the addition of the polymer–cobalt(III) complex to DNA pretreated with ethidium bromide (EB) causes appreciable reduction in the emission intensity (Fig. 4), indicating that the replacement of the EB fluorophore by the polymer–cobalt(III) complex, results in decrease in the emission intensity. The polymer–cobalt(III) complex with higher degree of coordination has led to a larger reduction in emission intensity in the presence of DNA. This may be due to the larger number of cobalt(III) chelates (containing phenanthroline ligands) present in the polymer chain which hinders intercalation of ethidium bromide (EB) into DNA and thus decreasing the binding ability between ethidium bromide (EB) and calf thymus DNA.

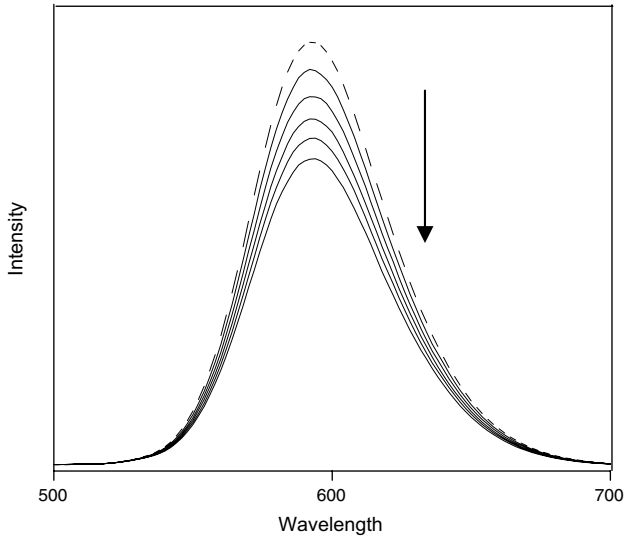

Fig. 4. Emission spectra of EB bound to DNA in the absence (—) and in the presence of *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ (—) ($x = 0.245$), [EB] = 4 μM, [DNA] = 4 μM, [polymer–cobalt(III) complex] = 0–4 μM.

3.4. Gel electrophoresis studies

Preliminary results from the absorption and fluorescence spectral studies show that the polymer–cobalt(III) complex with high cobalt(III) chelate content binds strongly to DNA. Binding of this complex with DNA was also studied by gel electrophoresis using plasmid pBR 322 DNA. This DNA moves on agarose gel under the influence of electrical field. This movement is retarded when they are bound to other molecules. Many polycationic polymer molecules interact with DNA through electrostatic interactions between phosphate groups of the DNA and oppositely charged groups of polymer [44–46]. Forrest et al. [47] and Vinogradov et al. [48] have reported that the polymer, polyethyleneimine (PEI), retards the DNA migration in agarose gel electrophoresis and they suggest that the binding between DNA and polyethyleneimine (PEI) is thought to occur mainly through electrostatic interactions among the participating species. Recently, Annaraj et al. [49] observed that the phenanthroline containing mixed ligand copper(II) complexes retard the mobility of DNA due to the intercalation of the planar phenanthroline groups. Similar retardation in the DNA mobility has also been observed due to the intercalation by ruthenium complexes [50]. In order to substantiate the ionic binding of our polymer–cobalt(III) complex to DNA, gel retardation assay was performed on pBR322 DNA (Fig. 5). Lane 1 is pure DNA not treated with the complex. Lanes 2–9 represent the DNA treated with increasing amounts of the polymer–cobalt(III) complex and lane 10 is for polymer–cobalt(III) complex alone. As seen from Fig. 5 (lanes 2–5), the DNA band migrates completely with increasing the complex concentration from 5 to 30 μM, but at higher complex concentration (40–50 μM), the migration of DNA band diminishes (lanes 6–8) and in lane 9, due to very high concentration (60 μM), complete retardation of the DNA band has been observed. This demonstrates that the cationic segments of the polyethyleneimine might have neu-

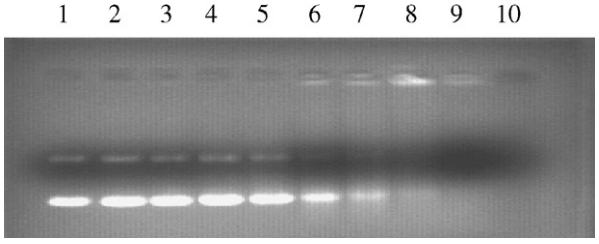

Fig. 5. Gel retardation assay of pBR322 DNA by *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ ($x = 0.245$). Lane 1: DNA alone, lanes 2–9: DNA + polymer–cobalt(III) complex in the concentration of 5, 10, 15, 20, 30, 40, 50, 60 μM. Lane 10: polymer–cobalt(III) complex alone.

tralized the negative charges of DNA which could have facilitated further due to the increased intercalation of the planar phen groups of cobalt(III) complex moieties. The same behaviour in the electrophoresis has been observed earlier by us in the case of some polyethyleneimine–copper(II)/cobalt(III) complexes [19,20].

3.5. Cytotoxicity assay

We examined the effects of the polymer–cobalt(III) complex ($x = 0.245$) on cultured HEp-2 human larynx cancer cells by exposing cells for 24 h and 48 h to the medium containing the complex at 25–225 μg/mL concentration. Bright field microscopic analysis with control and treated cells revealed that the complex produced dose – as well as duration-dependent cytotoxic effect in the cells (Fig. 6). The results of MTT assay (Fig. 7) indicated that the complex inhibited the growth of the larynx cancer cells significantly in a dose- and duration-dependent manner. For 24 h treatment period, higher concentrations of the complex were required to kill the cells whereas for 48 h treatment the cell killing occurred at lower concentrations. As shown in Table 2, the IC_{50} value of the complex was higher for the 24 h treatment groups, i.e., in the range of 100–140 μg/mL, whereas for the 48 h treatment groups the IC_{50} value fell in the range of 45–65 μg/mL.

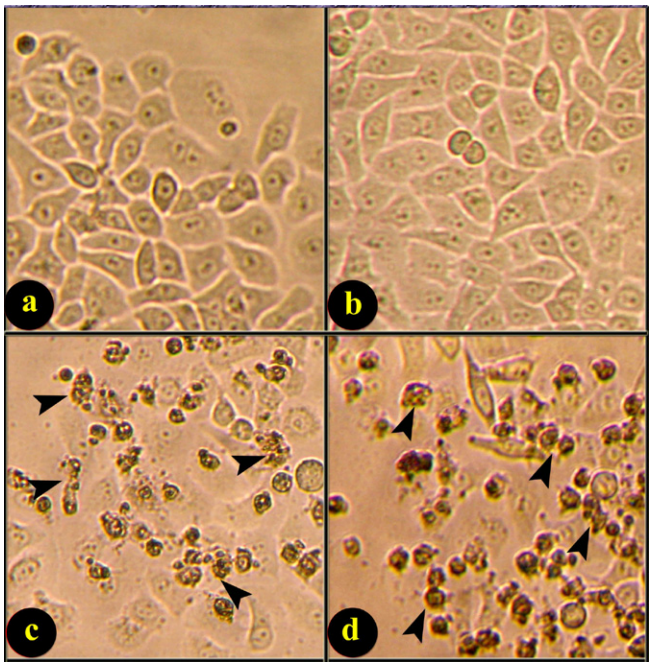

Fig. 6. Bright field microscopic micrographs of HEp-2 cancer cells treated with *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ ($x = 0.245$). 24 and 48 h 400×. (a,b) Control; (c,d) treated. Arrowheads point to detached abnormal cells.

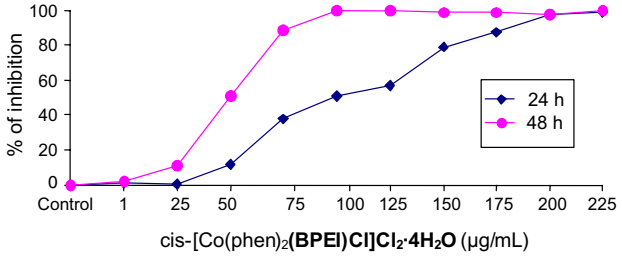

Fig. 7. Graphs showing percentage inhibition vs different concentration for Hep-2 cancer cells exposed to the complex *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ ($x = 0.245$). Treatment with the complex affects viability of cells in dose- as well as duration dependent manner.

3.6. Hoechst 33258 staining

After the cells were treated with IC_{50} concentrations of polymer–cobalt(III) complex ($x = 0.245$) (100,120,140 μg/mL) for 24 and 48 h the cells were observed for cytological changes adopting Hoechst 33258 staining. The observations revealed that the complex brought about cytological changes such as chromatin fragmentation, binucleation, cytoplasmic vacuolation, nuclear swelling, cytoplasmic blebbing and late apoptosis indication of dot-like chromatin and condensation (Fig. 8). These cytological changes indicated that the cells were committed to death. Data collected from the manual counting of cells with normal and abnormal nuclear features are shown in Fig. 11. Both apoptotic and necrotic cells increased in time-dependent manner with both the complexes.

Table 2
IC_{50} range of *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ ($x = 0.245$) for HEp-2 cells

Complex	IC_{50} (μg/mL)	
	24 h	48 h
cis-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ ($x = 0.245$)	90–110	45–65

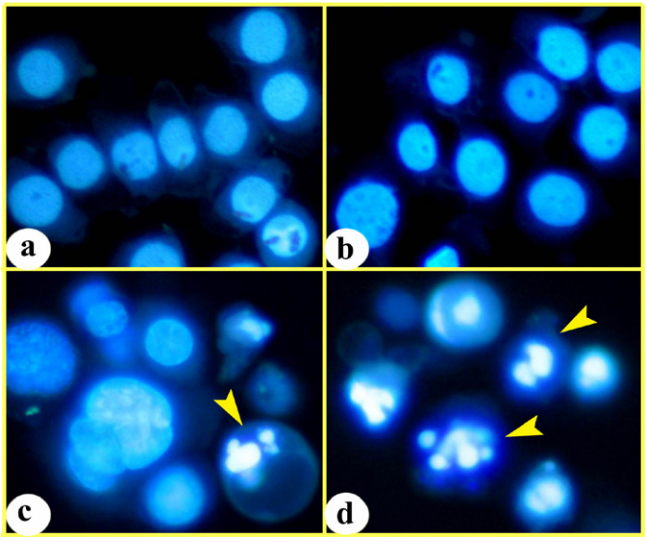

Fig. 8. Hoechst 33258-stained HEp-2 cancer cells treated with *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ ($x = 0.245$) for 24 and 48 h 400×. (a,b) Control; (c,d) *cis*-$[Co(phen)_2(BPEI)Cl]Cl_2 \cdot 4H_2O$ treated. Arrowheads point to the cells with abnormal nuclei, specially indicating fragmentation of nuclei/chromatin.

3.7. Special staining for apoptosis

To quantify apoptosis, we adopted leukostat as well as AO/EB staining. Treatment of cells with polymer–cobalt(III) complex ($x = 0.245$) for 24 and 48 h induced apoptosis. Using Leukostat triple staining, apoptosis was inferred based on the changes in the overall profile of the cell, and with special reference to chromatin condensation and apoptotic body formation. Normal cells were uniformly stained, both in respect of nuclei and cytoplasm (Fig. 9a and b); cells in early apoptosis had normal profile of the cell membrane but the chromatin was condensed and the nuclei were irregularly shaped (Fig. 9c); cells in late apoptosis had intensely stained cell membrane with blebs and darkly stained highly condensed nuclei (Fig. 9c and d); cells undergoing necrosis had lost the nuclear basophilia and, in their final stage, usually appeared as "ghosts" due to cell lysis (Fig. 9d).

AO/EB staining adopting fluorescence microscopy also revealed apoptosis from the perspective of fluorescence. After HEp-2 cells were exposed to various concentrations of polymer–cobalt(III) complex ($x = 0.245$) for 24 and 48 h, the cells were classified into four types according to the fluorescence emission and the morphological feature of chromatin condensation in the stained nuclei. (1) Viable cells had uniformly green fluorescing nuclei with a highly organized structure (Fig. 10a and b). (2) Early apoptotic cells (which still had intact membranes but had started undergoing DNA fragmentation) had green fluorescing nuclei, but peri-nuclear chromatin condensation was visible as bright green patches or fragments (Fig. 11c and d). (3) Late apoptotic cells had orange to red fluorescing nuclei with condensed or fragmented chromatin (Fig. 10c and d). (4) Necrotic cells had uniformly orange to red fluorescing nuclei with no indication of chromatin fragmentation and the cells were swollen to large size (Fig. 10c and d). The results suggest that polymer–cobalt(III) complex ($x = 0.245$) treatment caused more cells to take to apoptosis in 48 h than 24 h in HEp-2 cells.

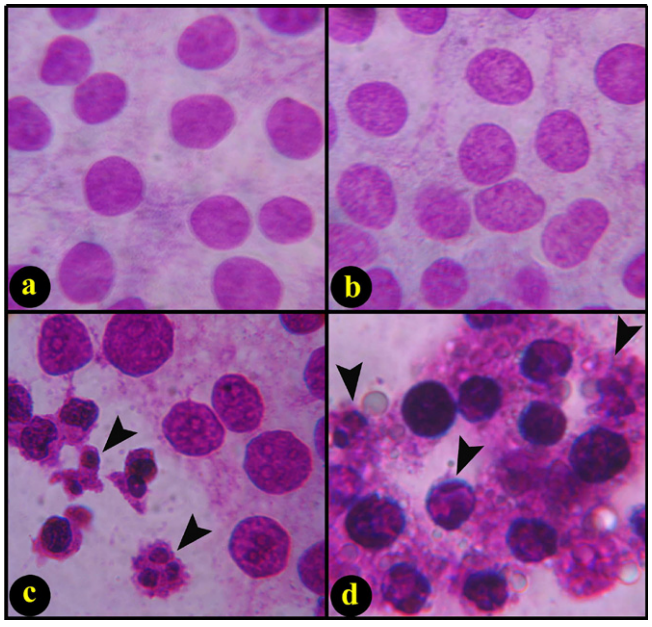

Fig. 9. Leukostat stained HEp-2 cancer cells treated with *cis*-[Co(phen)$_2$(BPEI)Cl]Cl$_2 \cdot 4H_2O$ ($x = 0.245$) 24 and 48 h 400×. (a,b) Control; (c,d) *cis*-[Co(phen)$_2$(BPEI)Cl]Cl$_2 \cdot 4H_2O$ ($x = 0.245$) treated. Arrowheads point to the cells with apoptotic morphologies, specially indicating blebbing.

3.8. Incidence of apoptosis

Data from the three staining methods were compared. Data on cells indicating apoptotic morphologies, induced on treatment with various concentrations of polymer–cobalt(III) complex ($x = 0.245$) for 24 and 48 h, followed by staining with Hoechst 33258, Leukostat and AO/EB, collected from manual counting of cells, are presented in Fig. 10, which indicates that all the three staining methods are efficient in revealing the incidence of apoptosis.

3.9. Efficiency of the complex in killing cancer cells

Thus, polymer–cobalt(III) complex was tested in Hep-2 cancer cell line adopting anti-proliferation and cell morphological assays to find the efficiency in killing the cells and the underlying mechanism. Polymer–cobalt(III) complex has a dose- and duration-dependent relationship in dealing with the cancer cell. Exposing Hep-2 cells to polymer–cobalt(III) complex ($x = 0.245$) led to severe disruption of cellular morphologies such as membrane

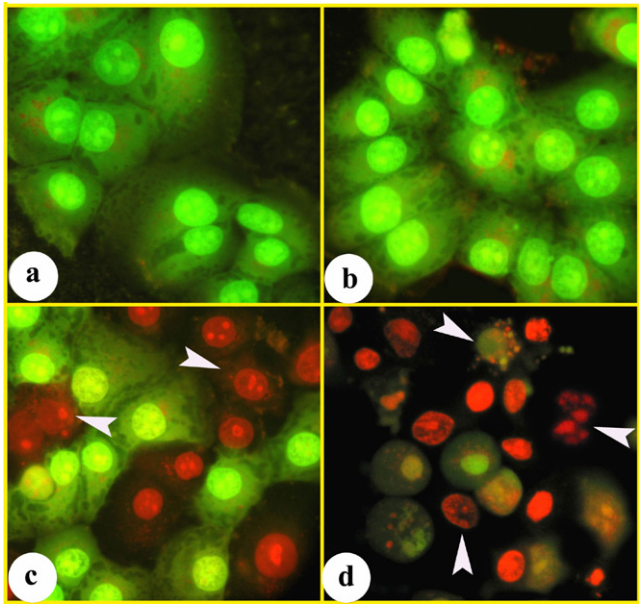

Fig. 10. Photomicrographs of control and AO/EB stained HEp-2 cells incubated for 24 and 48 h, 400×. (a,b) Untreated control cells. The viable cells are uniformly green-fluorescing. (c,d) *cis*-[Co(phen)$_2$(BPEI)Cl]Cl$_2 \cdot 4H_2O$ ($x = 0.245$) treated cells; pre-apoptotic (yellow fluorescing) and apoptotic (red to orange fluorescing) cells were observed. Red to orange fluorescing cells indicate apoptosis. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

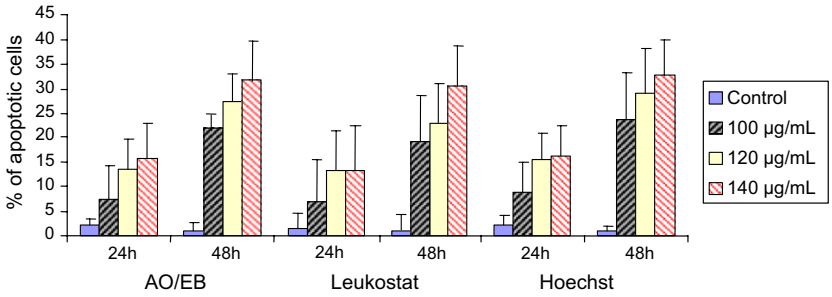

Fig. 11. Bar diagram for comparison of percent cells in apoptosis as revealed by AO/EB, leukostat and Hoechst 33258 staining followed by manual counting. All staining techniques reveal similar data, indicating that all are efficient, though morphological and cytological manifestations differ.

'blebbing' and chromatin fragmentation, which are characteristic of cells dying through apoptotic mechanism. These morphological features were classified based on nuclear as well cytoplasmic features, which reveal that a higher percentage of apoptotic cells is produced in 48 h with a lesser concentration than 24 h.

4. Conclusion

Some new water-soluble polymer–cobalt(III) complexes with different degrees of cobalt(III)–phenanthroline complex moieties on the polymer chain have been synthesized and characterized by Infra-red, UV–Vis, ^{1}H NMR spectral and elemental analysis methods. The DNA binding property of these polymer–cobalt(III) complex samples has been examined by absorption spectroscopy, fluorescence spectroscopy and gel retardation assay. We conclude that many types of interactions like electrostatic interaction, van der Waals interaction, hydrogen bonding and other partial intercalation binding modes exist in this system. The antiproliferative and morphological effects of polymer–cobalt(III) complex sample with high degree of coordination appear to be target-specific killing of cells. In future, this complex might prove to be of application in target-based cancer therapy since the mechanism of cell death appears to be essentially apoptosis but necrosis also is one of the desired endpoints in cancer therapy. From these perspectives, it would be pertinent to confirm the mechanisms of cell killing in the present context by adopting appropriate molecular techniques including expression of pro- and anti-apoptotic genes and caspases in the case of apoptosis, and oxidative damage in the case of necrosis.

the naturally occurring non-radioactive rhenium isotopes are very attractive to clearly establish the molecular structure of ^{99m}Tc- and $^{186/188}$Re-based radiopharmaceuticals. In this context, the design, synthesis and reactivity of novel rhenium oxocomplexes has become the aim of several laboratories, including ours.

Previously, we investigated the reactivity of oxorhenium(V) species – $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)_2]$ (X = Cl or Br) – towards 8-hydroxyquinoline (Hhqn) and quinoline-2-carboxylic acid [8,9]. As an extension of this work, we were keen to examine the reactivity of $[ReOX_3(PPh_3)_2]$ towards quinoline ligands containing both hydroxy and carboxylate fragments. 8-Hydroxyquinoline-7-carboxylic acid (Hhquin-7-COOH) and 8-hydroxy-2-methylquinoline-7-carboxylic acid (Hhmquin-7-COOH) are such ligands. Additionally, presented here and in previous work [8,9] quinoline derivatives are structural fragments of styryloquinolines, which are important class of compounds in the search for the potential inhibitors of HIV-1 integrase [10].

Here we present synthesis of $[ReOCl_2$(hquin-7-COOH)$(PPh_3)] \cdot OPPh_3$ (**1** · $OPPh_3$), $[ReOBr_2$(hquin-7-COOH)$(PPh_3)]$ (**2**), $[ReOCl_2$(hmquin-7-COOH)$(PPh_3)]$ (**3**) and $[ReOBr_2$(hmquin-2-COOH)$(PPh_3)]$ (**4**) complexes. X-ray studies have been performed for **1** · $OPPh_3$, **2** and **3** and they confirm bidentate coordination mode of the quinoline carboxylic acids. The COOH group of the quinoline carboxylic acids in the examined complexes is potentially available for further conjugation.

The electronic structure of **1** has been calculated with the density functional theory (DFT), and TDDFT/PCM calculations have been employed to produce a hundred of singlet excited-states starting from the ground-state geometry optimized in the gas phase.

Currently density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [11]. Recent calculations with TD-DFT method for open- and closed-shell of 5d-metal complexes (including rhenium complexes) have also supported the TD-DFT method to be applicable for such systems giving good assignment of experimental spectra [12,13].

Some theoretical investigations have been carried out on the rhenium compounds. The electronic structures of nitrido, oxo, carbonyl, nitrosyl and nitrile rhenium complexes, as well as their spectroscopic properties, bonding and reactivity have been theoretically studied at the HF, MP2, EHT and DFT levels of theory using various basis sets [14–22]. Gancheff et al. [16] have performed extended tests of the ability of the B3LYP method in LANL2DZ basis set for rhenium compounds in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has shown to be sufficient for the geometry optimization and calculation of spectral properties. The correctness of B3LYP method with LANL2DZ basis set for rhenium complexes has been also proven in this paper. The experimental geometry of $[ReOCl_2$(hquin-7-COOH)$(PPh_3)]$ is well reproduced and the calculated electronic spectrum is in good accordance with the experimental one.

2. Experimental

2.1. General procedure

The $[ReOX_3(PPh_3)_2]$ complexes were prepared as reported previously [23]. 8-Hydroxyquinoline-7-carboxylic acid and 8-hydroxy-2-methylquinoline-7-carboxylic acid were synthesized according to the literature methods [24]. All the other reagents used to the synthesis were commercially available and were used without further purification.

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–180 nm in acetonitrile solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer. The ^{1}H NMR spectrum was recorded with a Bruker AM 400 spectrometer at room temperature using $CDCl_3$ as a solvent.

2.2. Preparation of $[ReOCl_2$(hquin-7-COOH)$(PPh_3)] \cdot OPPh_3$ (**1** · $OPPh_3$)

A mixture of $[ReOCl_3(PPh_3)_2]$ (0.50 g, 0.60 mmol), 8-hydroxyquinoline-7-carboxylic acid (0.13 g, 0.69 mmol) and acetonitrile (50 ml) was stirred at room temperature for 3 h. The resulting red-brown solution was left to slow evaporation and dark red crystals were obtained after few days. Yield 75%.

Anal. Calc. for $C_{46}H_{36}Cl_2NO_5P_2Re$: C, 55.15; H, 3.62; N, 1.40. Found: C, 55.70; H, 3.66; N, 1.45%.

IR (KBr; ν/cm^{-1}): 1707(s) $\nu_{C=O}$(COOH); 1616(m), 1588(m), 1567(m), ν_{CN} and $\nu_{C=C}$; 978(vs) $\nu_{Re=O}$.

2.3. Preparation of $[ReOBr_2$(hquin-7-COOH)$(PPh_3)]$ (**2**)

A procedure similar to that for $[ReOCl_2$(hquin-7-COOH)$(PPh_3)] \cdot OPPh_3$ was used with $[ReOBr_3(PPh_3)_2]$ (0.50 g, 0.52 mmol) and 8-hydroxyquinoline-7-carboxylic acid (0.12 g, 0.63 mmol). Dark red crystals of $[ReOBr_2$(hquin-7-COOH)$(PPh_3)]$ were collected in 80% yield.

Anal. Calc. for $C_{28}H_{21}Br_2NO_4PRe$: C, 41.39; H, 2.61; N, 1.72. Found: C, 40.90; H, 2.68; N, 1.70%.

IR (KBr; ν/cm^{-1}): 1718(s) $\nu_{C=O}$(COOH); 1612(m), 1592(m), 1570(m), ν_{CN} and $\nu_{C=C}$; 981(vs) $\nu_{Re=O}$.

^{1}H NMR (400 MHz; $CDCl_3$) δ = 12.46 (s, 1H, COOH), 8.15 (dd, 1H), 8.04 (d, 1H), 7.93 (dd, 1H), 7.57 (br, 1H), 7.42–7.28 (m, 15H), 7.20 (d, 1H).

2.4. Preparation of [$ReOCl_2$(hmquin-7-COOH)(PPh_3)] (**3**)

A procedure similar to that for [$ReOCl_2$(hquin-7-COOH)(PPh_3)] · $OPPh_3$ was used with [$ReOCl_3(PPh_3)_2$] (0.50 g, 0.60 mmol) and 8-hydroxy-2-methylquinoline-7-carboxylic acid (0.14 g, 0.69 mmol). Crystalline precipitate of [$ReOCl_2$(hmquin-7-COOH)(PPh_3)] was collected in 70% yield.

Anal. Calc. for $C_{29}H_{23}Cl_2NO_4PRe$: C, 47.22; H, 3.14; N, 1.90. Found: C, 47.50; H, 3.10; N, 1.85%.

IR (KBr; ν/cm^{-1}): 1718(s) $\nu_{C=O}$(COOH); 1616(m), 1550(m), 1513(m), ν_{CN} and $\nu_{C=C}$; 983(vs) $\nu_{Re=O}$.

^{1}H NMR (400 MHz; $CDCl_3$) $\delta = 12.42$ (s, 1H, COOH), 7.91 (d, 1H), 7.84 (d, 1H), 7.55 (d, 1H), 7.44–7.26 (m, 15H), 7.15 (d, 1H), 2.89 (s, 3H).

2.5. Preparation of [$ReOBr_2$(hmquin-7-COOH)(PPh_3)] (**4**)

A procedure similar to that for [$ReOCl_2$(hquin-7-COOH)(PPh_3)] · $OPPh_3$ was used with [$ReOBr_3(PPh_3)_2$] (0.50 g, 0.52 mmol) and 8-hydroxy-2-methylquinoline-7-carboxylic acid (0.13 g, 0.64 mmol). Crystalline precipitate of [$ReOBr_2$(hmquin-7-COOH)(PPh_3)] was collected in 65% yield.

Anal. Calc. for $C_{29}H_{23}Br_2NO_4PRe$: C, 42.14; H, 2.80; N, 1.69. Found: C, 42.37; H, 2.73; N, 1.65%.

IR (KBr; ν/cm^{-1}): 1710(s) $\nu_{C=O}$(COOH); 1620(m), 1559(m), 1513(m), ν_{CN} and $\nu_{C=C}$; 982(vs) $\nu_{Re=O}$.

2.6. Crystal structures determination and refinement

The X-ray intensity data of **1** · $OPPh_3$, **2** and **3** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption correction using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [25] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their adjacent atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the aromatic parent atoms and equal 1.5 times the value of equivalent temperature factor of the methyl parent carbon atom and oxygen atom (OH). SHELXS97 [26], SHELXL97 [27] and SHELXTL [28] programs were used for all the calculations.

3. Computational details

The gas phase geometry of **1** was optimized in the singlet ground-state with the DFT method using the hybrid B3LYP [29,30] functional of GAUSSIAN-03 [31]. The LANL2DZ with additional *d* function with exponent $\alpha = 0.3811$ and *f* function with exponent $\alpha = 2.033$ basis set [32,33] was chosen for the rhenium atom and the standard 6-31G basis set for all the other atoms [34,35]. TDDFT calculations were employed to produce a hundred singlet excited-states starting from the ground-state geometry optimized in the gas phase The solvent (acetonitrile) effect was simulated using the polarizable continuum model (PCM) [36].

Natural bond orbital (NBO) calculations were performed with the NBO code [37,38] included in GAUSSIAN03.

4. Results and discussion

4.1. Preparation and infrared data

The $[ReOX_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ and $[ReOX_2(hmquin\text{-}7\text{-}COOH)(PPh_3)]$ (X = Cl, Br) complexes were prepared in good yields by ligand exchange reactions starting from $[ReOX_3(PPh_3)_2]$ complexes and 8-hydroxyquinoline-7-carboxylic acid or 8-hydroxy-2-methylquinoline-7-carboxylic acid.

$$[ReOX_3(PPh_3)_2] + Hhquin\text{-}7\text{-}COOH \rightarrow [ReOX_2(hquin\text{-}7\text{-}COOH)(PPh_3)] + HX + PPh_3$$

X = Cl, Br

$$[ReOX_3(PPh_3)_2] + Hhmquin\text{-}7\text{-}COOH \rightarrow [ReOX_2(hmquin\text{-}7\text{-}COOH)(PPh_3)] + HX + PPh_3$$

The complexes are air stable and soluble in common organic solvents. The $[ReOCl_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ complex crystallizes as the $[ReOCl_2(hquin\text{-}7\text{-}COOH)(PPh_3)] \cdot OPPh_3$ adduct. The starting oxo complexes are synthesized by the reduction of ammonium perrhenate:

$$ReO_4^- + 3X^- + 4H^+ + 3PPh_3 \rightarrow [ReOX_3(PPh_3)_2] + OPPh_3 + 2H_2O$$

and $[ReOX_3(PPh_3)_2]$ compounds can be impure with $OPPh_3$.

The selected frequencies observed in the IR spectra of $[ReOX_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ and $[ReOX_2(hmquin\text{-}7\text{-}COOH)(PPh_3)]$ complexes are given in Section 2. The carboxylic acid group of the *hquin-7-COOH* and *hmquin-7-COOH* ligand is characterized by the $\nu_{C=O}$ absorption observed in the range 1700–1720 cm^{-1} [39,40].

The strong ν(Re=O) stretching bands of $[ReOX_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ and $[ReOX_2(hmquin\text{-}7\text{-}COOH)(PPh_3)]$ compounds are in the higher end of the range observed for $\{ReO\}^{3+}$ core complexes. Similar to the reported previously $[ReOX_2(hqn)(PPh_3)]$ and $[ReOX_2(quin\text{-}2\text{-}c)(PPh_3)]$ complexes, the Re–hydroxy bond *trans* to the oxo ligand does not compete effectively for the d_{Re} orbitals. Moreover,

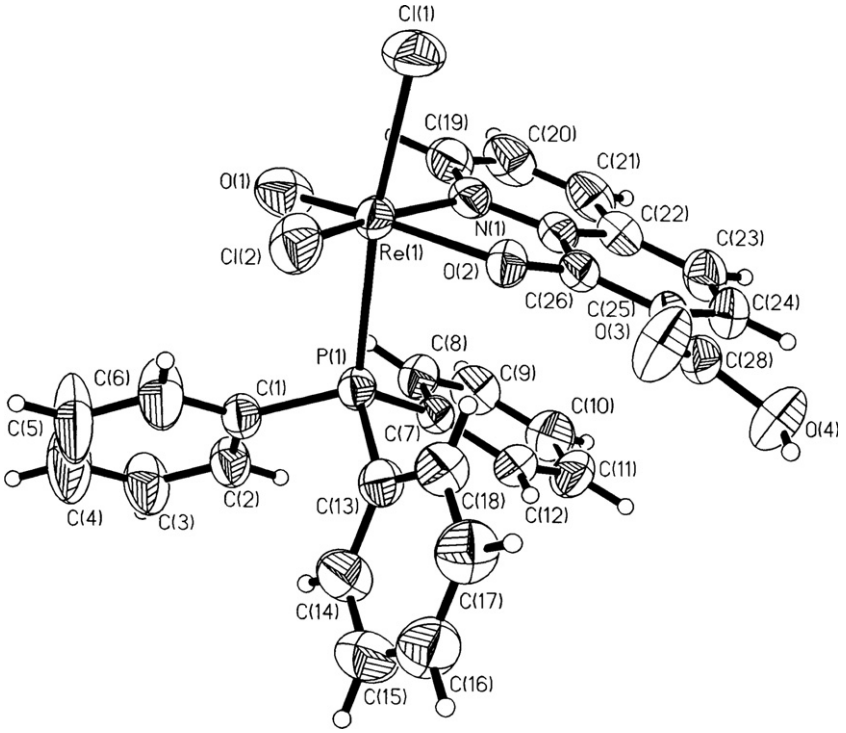

Fig. 1. The molecular structure of **1**. Displacement ellipsoids are drawn at 50% probability.

the narrow range in which the ν(Re=O) bands appear is very similar to those observed for Re(V)-oxo complexes with 8-quinolinolato or quinoline-2-carboxylate ligands [8,9].

4.2. Crystal structures

The crystallographic data for **1** · $OPPh_3$, **2** and **3** are given in Table 1, and molecular structures of the $ReOCl_2$(hquin-7-COOH)(PPh_3)] and [$ReOCl_2$(hmquin-7-COOH)(PPh_3)] complexes are presented in Figs. 1 and 2, respectively. The intermolecular interactions found in the examined structures are shown in Table 2 [41,42]. Additionally in the examined structures exist π···π stacking interactions between the rings of the *hquin-7-COOH* or *hmquin-7-COOH* ligands and one of the triphenylphospine rings. (Table 3) [43]. Presence of the methyl group in the quinoline ring significantly decreases π···π stacking interactions.

The geometry of [$ReOX_2$(hquin-7-COOH)(PPh_3)] and [$ReOX_2$(hmquin-7-COOH)(PPh_3)] compounds reveal typical features of quasi-octahedral oxorhenium(V)complexes with oxygenated bidentate ligands. The deformation of the octahedron is caused by the presence multiple bonding ligand (terminal oxo) and narrow bite angle of the chelating ligand. The high concentration of electronic density along the Re–O_t axis strongly influences the positions of the adjacent halogen atoms, which are pushed away. The presence of the methyl group attached to the quinoline ring in **3** seems to be responsible for significant increase in the Cl(1)–Re(1)–P(1) angle and decrease in the O(1)–Re(1)–P(1) one. In each complex, the rhenium atom is coordinated by a terminal oxygen atom (O_t), two halide ions in *cis* arrangement, the phosphorus atom of PPh_3 molecule, and the bidentate N,O donors of the *hquin-7-COOH* or *hmquin-7-COOH* ligand. The oxygen atom of the quinoline derivative lies in *trans* position to the terminal oxo ion.

Table 2
Hydrogen bonds for **1** · $OPPh_3$, **2** and **3** complexes

D	A	H···A (Å)	D···A (Å)	D—H···A (°)
***1** · OPPh₃*

*Complex **3***				
C(2)	O(2)	2.52	3.067(5)	117.7
C(18)	O(1)	2.40	3.066(4)	129.0

#1 $0.5+x$, $1.5-y$, $-0.5+z$; #2 $-0.5+x$, $1.5-y$, $-0.5+z$; #3: $-x+2$, $-y+1$, $-z+1$.

The selected bond distances and angles of [$ReOX_2$(hquin-7-COOH)(PPh_3)] and [$ReOX_2$(hmquin-7-COOH)(PPh_3)] complexes are collected in Tables 4 and 5.

The Re–O_t bond lengths of [$ReOX_2$(hquin-7-COOH)-(PPh_3)] and [$ReOX_2$(hmquin-7-COOH)(PPh_3)] fall in the range 1.639–1.76 Å, typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicate the presence of a triple bond Re≡O [44]. The elongation of Re–O_t distance in **1** · $OPPh_3$ seems to be results of the crystal packing

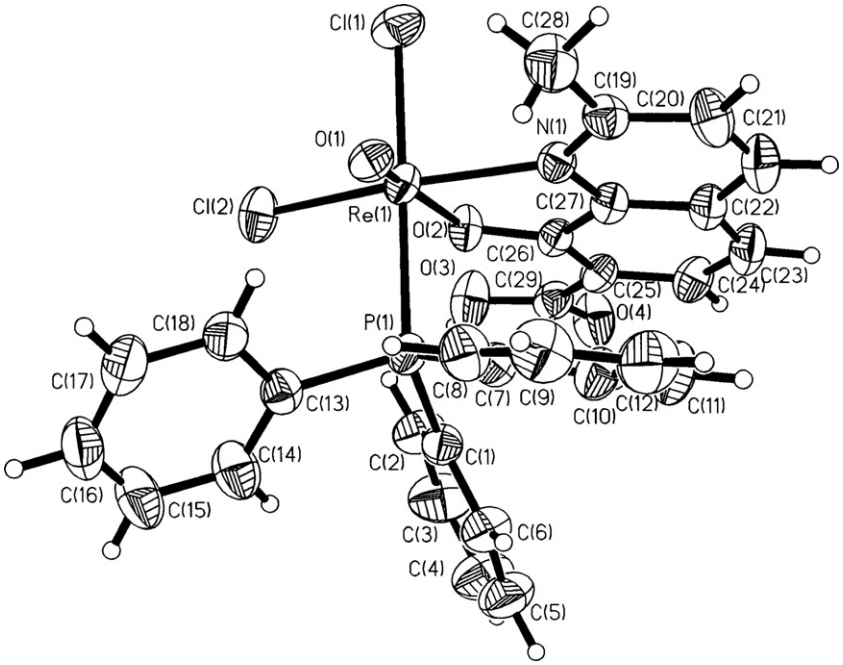

Fig. 2. The molecular structure of **4**. Displacement ellipsoids are drawn at 50% probability.

Table 3
Analysis of short contacts between the *hquin-7-COOH* and *hmquin-7-COOH* rings and triphenylphospine ring (distances in Å and angles in °)

R(I)	R(J)	Cg···Cg	α	β	d_p
1 · *OPPh*$_3$					
Cg(2)	Cg(1)	3.5208	10.74	18.27	3.264
Cg(3)	Cg(1)	3.6021	9.68	21.25	3.385
Complex ***2***					
Cg(2)	Cg(1)	3.6675	16.42	22.00	3.084
Cg(3)	Cg(1)	3.6123	16.19	19.58	3.591
Complex ***3***					
Cg(2)	Cg(1)	4.0621	21.21	24.36	3.075
Cg(3)	Cg(1)	5.3487	17.81	47.74	2.282

R1, R2, R3 indicates the centroids of aromatic rings containing C(7), N(1), C(24) atoms, respectively, α is a dihedral angle between planes *I* and *J*, β is an angle between Cg(I)–Cg(*J*) vector and normal to plane *I* and d_p is a perpendicular distance of Cg(*I*) on ring *J* plane.

caused by the presence of triphenylphosphine oxide in the lattice. The interatomic distances between the rhenium atom and the oxygen atom of bidentate ligand are somewhat shorter than an ideal single Re–O bond length (*ca.* 2.04 Å) [45], and indicates small delocalization in the O(2)–Re(1)–O(1) moiety. The similar trend is observed for many Re(V)-oxo complexes with an monoanionic oxygen *trans* to the oxo group [46].

The Re1–X(1) distances *trans* to the phosphorus atom of PPh_3 molecule are slightly longer than the Re1–X(1) bonds *trans* to the nitrogen atom of the *hquin-7-COOH* or *hmquin-7-COOH* ligand. It is a consequence of *structural trans* effect of the phosphine ligand.

4.3. Geometry optimization, charge distribution, electronic structure and NBO analysis

The geometry of **1** was optimized in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters of **1** are gathered in Table 4. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data (discussed above) are well reproduced in the calculations.

Table 4
The experimental and optimized bond lengths (Å) and angles (°) for **1**

Bond lengths	Experimental	Optimized	Bond angles	Experimental	Optimized
Re(1)–O(1)	1.7197(19)	1.678	O(1)–Re(1)–O(2)	161.91(9)	157.88

Table 6
Atomic charges from the Natural Population Analysis (NPA) for **1**

Atom	Charge
Re(1)	1.012
O(1)	−0.440
O(2)	−0.659
N(1)	−0.466
Cl(1)	−0.391
Cl(2)	−0.337
P(1)	1.270

Table 6 presents the atomic charges from the Natural Population Analysis (NPA) for **1**. The calculated charge on the rhenium atom in **1** is considerable lower than the formal charge +5, corresponding d^2 configuration of the central ion. It results from charge donation from the oxo ligands, halide ions and PPh_3 molecule. The P atom is positively charged, and the charges on the terminal oxo, chloride and oxygen atom of *hquin-7-COOH* are significantly smaller than −2, −1 and −1, respectively. The terminal oxo ions are less negative in comparison with the oxygen atoms of *hquin-7-COOH* ligand. It confirms the higher electron density delocalization from the terminal ligand towards the rhenium center and corresponds to differences in the Re–O(1) and Re–O(2) bond lengths.

The molecular orbital diagram of **1** with several occupied and unoccupied molecular orbital contours is presented in Fig. 3. The local symmetry of the rhenium center has been considered in the discussion: *z* axis goes

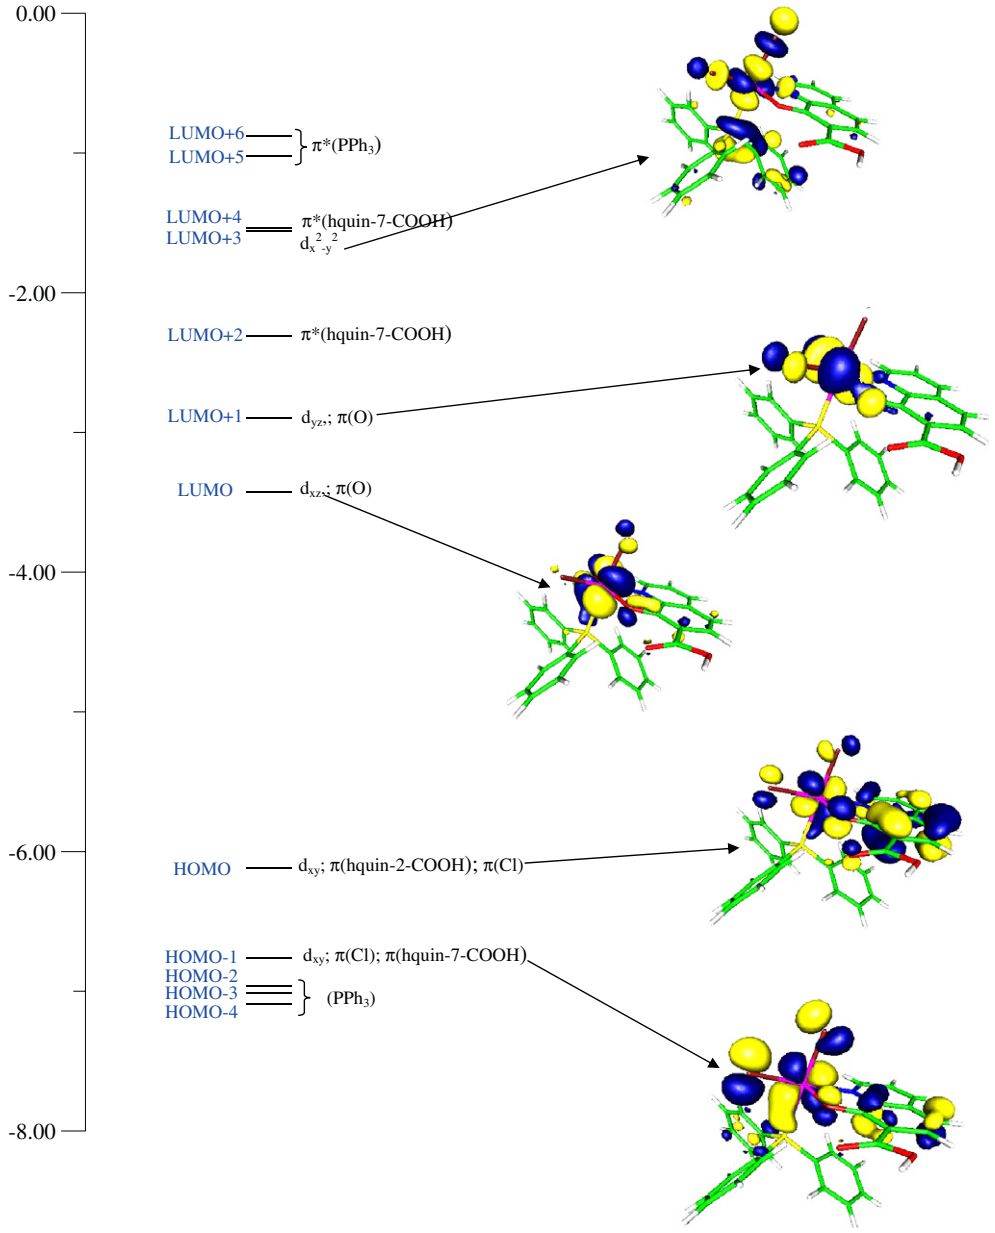

Fig. 3. The energy (eV), character and some contours of the occupied and unoccupied molecular orbitals of **1**. Positive values of the orbital contour are represented in blue (0.04 au) and negative values – in yellow (−0.04 au). (For interpretation of the references in colour in this figure legend, the reader is referred to the web version of this article.)

along the O–Re–O linkage, and *x* axis – through the P–Re–Cl bonds.

The value of the energy separation between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) equals to 2.67 eV. This value is lower in comparison with the HOMO–LUMO gap calculated for the related Re(V)-oxo complexes with 8-quinolinolato or quinoline-2-carboxylate ligands [8,9]. The lower absolute value of the gap energies means lower stability and higher reactivity of the title complex.

Two highest occupied MOs are delocalized among d_{xy} rhenium orbital, chloride and *hquin-7-COOH* orbitals. The LUMO and LUMO + 1 are predominately localized on the rhenium atom (d_{xz} and d_{yz} orbitals) with some contribution of p_π oxygen orbitals. They can be ascribed as π-antibonding rhenium–oxygen molecular orbitals. The LUMO + 3 is of $d_{x^2-y^2}$ character, and d_{z^2} rhenium orbital contributes to the LUMO + 13.

Since the rhenium atom has d^2 electronic configuration, the empty $5d_{xz}$ and $5d_{yz}$ orbitals are available to overlap with $2p_x$ and $2p_y$ orbitals of the terminal oxygen to form an effective triple bond.

The nature of rhenium–terminal oxygen interaction in **1** has been studied by NBO analysis. The occupancy and composition of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 7. Two detected natural Re–O_t bond orbitals of **1** are of π character – they arise from overlap of the two occupied oxygen p_π orbitals with the empty d_{xz} and d_{yz} metal orbitals. Not detected $\sigma_{Re–Ot}$ bond has character of predominant Coulomb-type interactions between the central ion and ligands [47]. The terminal oxo ligand of **1** has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital. Accordingly, NBO analysis confirms a triple bond between the rhenium and the terminal oxygen ligand.

4.4. Electronic spectra

The electronic spectra of [$ReOX_2$(hquin-7-COOH)(PPh_3)] and [$ReOX_2$(hmquin-7-COOH)(PPh_3)] complexes are very similar in terms of the position, intensity and shape of the bands in the whole region 1000–180 nm. The positions and molar absorption coefficients of electronic bands for [$ReOX_2$(hquin-7-COOH)(PPh_3)] and [$ReOX_2$(hmquin-7-COOH)(PPh_3)] complexes are given in Table 8.

The experimental and calculated electronic spectra of **1** are presented in Fig. 4. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and *b* equal to 0.04 nm^{-2}. Table 9 presents the calculated singlet–singlet electronic transitions of **1** and their assignments to the experimental bands. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.015 are listed in Table 9.

The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions the HOMO orbital is described as d_{Re} orbital, whereas the participation of d_{Re} in the H − 1 orbital is omitted.

Table 8
Band position (nm) and molar absorption coefficient [$dm^3\ mol^{-1}\ cm^{-1}$] (in brackets) of [$ReOX_2$(hquin-7-COOH)(PPh_3)] and [$ReOX_2$(hmquin-7-COOH)(PPh_3)] complexes

					209.4 (5.92) 122600

ε – molar absorption coefficient ($dm^3\ mol^{-1}\ cm^{-1}$); f – oscillator strength; H – highest occupied molecular orbital; L – lowest unoccupied molecular orbital.

Two longest wavelength experimental bands at 835.0 and 691.4 nm are attributed to the transitions of d → d character. The *ligand–metal charge transfer* (π(Cl)/π(hquin-7-COOH) → d) transitions make the largest contribution into the experimental band at 481.6 nm.

The intense absorption band with maximum at 402.2 nm results mainly from *metal–ligand charge transfer* (d → π*(hquin-7-COOH)). However the contribution of the *ligand–metal charge transfer* excitations (π(Cl)/π(PPh_3)/π(hquin-7-COOH) → d) into this band is also confirmed by the calculations. The experimental band at 264.8 nm can be asigned the *ligand–metal charge transfer* (π(Cl)/π(hquin-7-COOH) → d) transitions. The absorption bands at 221.8 and 209.4 nm are assigned mainly to *ligand–ligand charge transfer* and interligand (*IL*) transitions. However some contribution of the *ligand–metal charge transfer* from the triphenylphosphine orbitals to the *d* rhenium orbitals in the band at 221.8 nm is also confirmed by the calculations.

As can be seen from Fig. 3 and Table 9, most occupied molecular orbitals are delocalized of the π(Cl)/π(hquin-7-COOH) unit. It seems to explain lack of any differences in the LMCT bands between Cl and Br complexes. Furthermore, the LMCT absorption bands of the examined complexes are broad and overlap.

5. Supplementary material

CCDC 665000, 665001 and 665002 contain the supplementary crystallographic data for $C_{46}H_{36}Cl_2NO_5P_2Re$, $C_{28}H_{21}Br_2NO_4PRe$ and $C_{29}H_{23}Cl_2NO_4PRe$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

The GAUSSIAN03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland.

has been tested for cytotoxicity against HeLa and multidrug resistant CoLo 320DM human cancer cells [18].

In particular, we are interested in the study of metal–metal bonded complexes of non-steroidal anti-inflammatory drugs (NSAIDs) [19,20]. The widely used popular class of NSAID medications is well known due to inflammatory properties but more recently it has attracted great attention mainly because of the chemopreventive effect in a variety of tumors [21].

The mechanism of action for antitumor effects of NSAIDs has not yet been clearly determined [22,23]. The pharmacological properties of individual NSAIDs vary depending on their inhibitory effects in relation to the COX1 and COX2 isoforms [24]. Cyclooxygenase (COX) is the rate-limiting enzyme in the pathway of arachidonic acid metabolism to prostaglandins and thromboxanes [25,26]. The COX1 isoform (chromosome 9) is constitutively expressed while the COX2 isoform (chromosome 1) is induced particularly in inflammatory processes. COX2 expression is up regulated in gliomas and is correlated with increasing histological grade and poor patient prognosis [27–31]. Clinical trials are currently under way to study the COX2 inhibitor effects on tumor progression in patients with glioblastoma multiforme GBM [32,33]. GBM is a malignant brain glioma (WHO grade IV) that has shown little improvement in patient prognosis in recent years despite improvements in surgical techniques and treatment protocols. This is due in part to their highly invasive nature and to the large percentage exhibiting resistance to conventional chemotherapy and radiotherapy [34].

Since epidemological studies have showed up a 50% reduction in the mortality rate from certain cancers in patient consuming NSAIDs, a great interest in the role of cyclooxygenase in neoplasia has been emerged [35,36]. Several studies have demonstrated that certain NSAIDs cause antiproliferative effects independent of cyclooxygenase activity. The effect of some NSAIDs in the proliferation of glioma cell lines have been investigated showing results that may be clinically important for pharmacological intervention in gliomas [36,37].

The present work reports studies on interactions between diruthenium core and NSAIDs and the investigation of antitumor properties of diruthenium–dNSAID complexes (dNSAID = deprotonated NSAID derived from: ibuprofen (Hibp), aspirin (Hasp), naproxen (Hnpx) and indomethacin (Hind) (Fig. 1)). The antitumor effects of the metal compounds were investigated for C6 rat glioma cell line (used as a model for GBM). Two human tumor cell lines (Hep2 larynx and T24/83 bladder) were also tested.

2. Experimental

2.1. Materials

All the chemicals used, unless specifically stated, were reagent grade supplied by Aldrich or Merck and were used as purchased. Aspirin was purchased from Aldrich. The other drugs were purchased from manipulation pharmacies (São Paulo, Brazil): ibuprofen, from Natural Pharma; naproxen, from Purifarma; and indomethacin, from Henrifarma. Elemental analyses and spectroscopic analyses were carried out to confirm their purity. The diruthenium(II, III) precursor compounds, $[Ru_2(O_2CCH_3)_4Cl]$ [38] and $[Ru_2(O_2CCH_3)_4(H_2O)_2]PF_6$ [39], were synthesized starting from $RuCl_3 \cdot nH_2O$ (Aldrich) according to the literature methods.

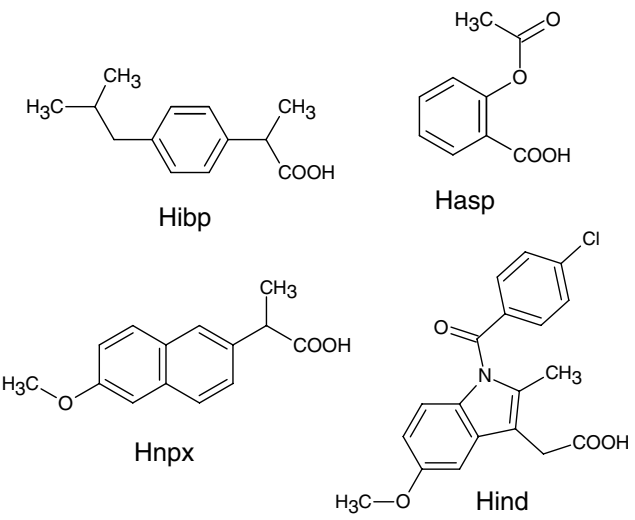

Fig. 1. Structures of Hibp (α-methyl-4-(isobutyl)phenylacetic acid), Hasp (2-(acetyloxy)benzoic acid), Hnpx (2-(6-methoxy-2-naphthyl)propanoic acid), and Hind ([1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-indol-3-yl] acetic acid).

2.2. Physical measurements

Elemental analyses were performed on a Perkin–Elmer CHN 2004 Elemental Analyzer, at Instituto de Química (USP). Electronic absorption spectra of ruthenium compounds in solutions, at 200–700 nm (UV–Vis), were recorded on a Shimadzu UV-1650 PC spectrophotometer. The solid reflectance spectra at 350–1400 nm (UV–Vis/NIR), were measured on a Guided Wave model 260 spectrophotometer equipped with optical fiber. Fourier-Transform Infrared (FTIR) spectra of solid samples dispersed in KBr, at 4000–400 cm^{-1}, were recorded on a Bomen MB-102 spectrophotometer coupled to diffuse reflectance accessory (Pike Technologies Inc.). FTIR transmittance spectra of samples in Nujol mulls between CsI pellets, at 400–200 cm^{-1}, were also recorded on the Bomen MB-102 spectrophotometer. Raman spectra of solid samples were carried out on a Micro-Raman RENISHAW System 3000 (laser line = 632.8 nm). The molar magnetic susceptibilities were measured on powdered samples at room temperature by the Faraday method using an electrobalance Cahn DTL 7500; the diamagnetic corrections were made by Pascal's constants and $Hg[Co(SCN)_4]$ was used for calibration. Molar conductance measurements for $\sim 1 \times 10^{-3}$ mol L^{-1} acetonitrile solutions of the compounds were carried out

with a Digimed DM-31 equipment, at 25.0 ± 0.5 °C; KCl aqueous solution, 146.9 μS cm^{-1} at 25 °C, cell constant = 0.1 cm^{-1}, was used for calibration.

2.3. Syntheses of diruthenium compounds with NSAIDs

2.3.1. Synthesis of $[Ru_2(ibp)_4Cl]$ (1)

The complex was synthesized by modified procedure in relation to that previously reported [19]. $[Ru_2(O_2CCH_3)_4Cl]$ (300 mg, 0.63 mmol) was dissolved in 200 mL of water. After rotary evaporation of the solvent to 40 mL, ibuprofen (660 mg, 3.20 mmol) in 40 mL of ethanol and LiCl (370 mg) in 5 mL of water were, separately, added to this solution. The mixture was stirred under nitrogen for 3 h, at 60 °C. The solid product formed on the bottom of the flask was washed with water and then dissolved in ethanol. After filtration, the resulting solution was allowed to evaporate under nitrogen stream and the dark-brown product was dried in a vacuum desiccator over phosphorus pentoxide. Yield = 74%. *Anal.* Calc. for $C_{52}H_{68}O_8ClRu_2 \cdot \frac{1}{2}H_2O$: C, 58.71; H, 6.16. Found: C, 58.39; H, 6.24%. Electronic absorptions at λ_{max} (nm): 483 and 1125 nm (solid phase); 428 nm (in methanol); μ_{eff} = 3.9 B.M.; FTIR major bands, ν (cm^{-1}): 3053sh ($\nu(CH)_{aromatic}$); 2955ms, 2923sh, 2867m ($\nu(CH)_{aliphatic}$); 1513m ($\nu(CC)_{ring}$); 1465s ($\nu_a(COO^-)$); 1409s ($\nu_s(COO^-)$); 1372m ($\delta_s(CH_3)$); 1286m, 1071m, 1019w (region of $\delta_s(CH_3)$, $\delta_{ring\ in\ plane}$, $\rho(CH_3)$); 849m ($\delta_s(CH_3)$, $\delta_{ring\ out\ plane}$); 740 m ($\delta$(OCO)); 555m, 492m ($\nu$(Ru–O)); molar conductance = 2.6 S cm^2 mol^{-1} in acetonitrile.

2.3.2. Synthesis of $[Ru_2(asp)_4Cl]$ (2)

$[Ru_2(O_2CCH_3)_4Cl]$ (300 mg, 0.63 mmol) was dissolved in 200 mL of water. After reducing the volume of this solution to 65 mL by rotary evaporation, 35 mL of ethanol and solutions of aspirin (640 mg, 3.56 mmol) in 50 mL of ethanol and LiCl (270 mg) in 5 mL of water were separately added to it. The mixture was stirred under nitrogen for 2 h, at 60 °C. Then, it was filtered and, after being washed with water and ethanol, the solid product was dried in a vacuum desiccator over phosphorus pentoxide. Yield = 65%. *Anal.* Calc. for $C_{36}H_{28}O_{16}ClRu_2$: C, 45.31; H, 2.96. Found: C, 45.03; H, 2.96%.

2.3.3. Synthesis of $[Ru_2(npx)_4(H_2O)_2]PF_6$ (3)

$[Ru_2(O_2CCH_3)_4(H_2O)_2]PF_6$ (76 mg, 0.12 mmol) was dissolved in 10 mL of water and, then, ethanol (15 mL) followed by naproxen (140 mg, 0.61 mmol) in 10 mL of ethanol and NH_4PF_6 (230 mg) in 3 mL of water were added. The mixture was stirred under nitrogen for 3 h, at 60 °C, and then kept under stirring and nitrogen atmosphere for 18 h, at room temperature. The solid formed was washed with water and dissolved in ethanol. After filtration, the resulting solution was allowed to evaporate under nitrogen stream and the dark-brown product was dried in a vacuum desiccator over phosphorus pentoxide. Yield = 62%. *Anal.* Calc. for $C_{56}H_{56}F_6O_{14}PRu_2$: C, 51.73; H, 4.34; Found: C, 52.10; H, 4.41%.

2.3.4. Synthesis of $[Ru_2(ind)_4(H_2O)_2]PF_6$ (4)

$[Ru_2(O_2CCH_3)_4(H_2O)_2]PF_6$ (80 mg, 0.13 mmol) was dissolved in 10 mL of water and, then, ethanol (15 mL) followed by indomethacin (240 mg, 0.67 mmol) in 20 mL of ethanol and NH_4PF_6 (240 mg) in 3 mL of water were added. The mixture was stirred under nitrogen for 4 h, at 60 °C, in absence of light. The resulting solution was kept under stirring and nitrogen atmosphere for 18 h, at room temperature. The mixture was centrifuged; the solid product was washed with water and small amounts of ethanol and, then, dried in a vacuum desiccator over phosphorus pentoxide. Yield = 26%. *Anal.* Calc. for $C_{76}H_{64}F_6N_4O_{18}PCl_4Ru_2$: C, 50.41; H, 3.57; N, 3.10. Found: C, 50.54; H, 3.87; N, 2.91%.

2.4. Bioassays in vitro

2.4.1. Cell culture

C6 rat glioma cells were obtained from the ATCC, Hep2 cells and T24/83 cells from the ECACC. Stocks were maintained frozen (liquid nitrogen) in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% foetal calf serum and 20% glycerol. Stock cells were grown in DMEM containing 10% foetal calf serum and antibiotics (penicillin 50 U mL^{-1}, streptomycin 50 μg mL^{-1}). Cells in the exponential phase of growth were used, growing in 75 cm^2 flasks in a humidified atmosphere of 5% CO_2: 95% air at 37 °C.

2.4.2. MTT colorimetric assays

Cells were seeded into 96-well plates at a density of 1–2 × 10^4 cells/well. After overnight incubation the cells were exposed to Ru_2-dNSAID at varying concentrations (1, 10, 100 and 1000 μmol L^{-1}) for 24–72 h, with a change of medium and drug every 24 h. After this growth period, 25 μg of MTT was added to each well and the cells incubated for a further 2–4 h. The medium was removed by aspiration, the cells were re-suspended in 100 μL of 0.04 mol L^{-1} HCl in isopropanol and the reaction product was followed by spectrophotometry at the wavelength of 595 nm. The organic NSAIDs were submitted to the same procedure.

2.4.3. Cell proliferation and viability assay

Cells were seeded into 24-well plates at a density of 1–2 × 10^5 cells/well. After 24, 48 or 72 h cells were harvested by trypsinization (trypsin 0.025%/EDTA 0.02%) before incubating with 0.2% trypan blue solution in PBS for 2 min. Cells were counted using an improved Neubauer counting chamber with cells that did not incorporate the dye considered intact.

2.4.4. mRNA expression analysis of COX-2 by RT-PCR

C6 cells grown *in vitro* and *in vivo* were used for total RNA extraction with Trizol (Life Technologies, USA). The first strand of complementary DNA (cDNA) was generated from 1 μg of RNA, using 2 μL of random

hexamer primer (3 μg μL^{-1}), 1 μL of RNase inhibitor (10 U), 2 μL of deoxynucleoside triphosphate mix (dNTP mix) 10 m mol L^{-1}, and 2 μL moloney murine leukemia virus (M-MLV) reverse transcriptase (200 U μL^{-1}), in a total volume of 20 μL. The reaction was incubated at 21 °C for 10 min, at 42 °C for 50 min and at 99 °C for 10 min in a GeneAmp®PCR System 9700 (PE Applied Biosystems, USA). For amplification of the COX-2 sequence, cDNA was amplified in a 50 μL volume using 0.5 μL (5 U μL^{-1}) platinum Taq DNA polymerase, 1 μL DNTP mix 10 mmol L^{-1}, 1.5 μL $MgCl_2$ 50 mmol L^{-1}, 5 μL PCR buffer 10× and 6 μL of specific primers (3 μL sense + 3 μL antisense). Rat ribosomal L19 (RPL19) gene was amplified as an internal control. The oligonucleotide sequences used for COX-2 and RPL19 were: COX2 sense: 5′-TCAAGACAGATCAGAAG CGA-3′ antisense: 5′-TACCTGAGT GTCTTTGATTG-3′ and RPL19 sense: 5′-TCTCATG GAACACATCCAC AA-3′ antisense: 5′-TGGTCAGCCA GGAGCTTCTT-3′. All reagents used in the reverse transcriptase-polymerase chain reaction (RT-PCR) were purchased from Life Technologies, Brazil. Each cycle of PCR amplification involved denaturing for 1 min at 94 °C, annealing for 1 min at 58 °C and extension for 1 min at 72 °C. To ensure the exponential phase of amplification, the number of PCR cycles was determined and optimized for COX-2 as 38 cycles and RPL19 as 36 cycles. Aliquots of amplified PCR products were fractionated on a 1% agarose gel containing 0.05% ethidium bromide and the image was captured by Foto-Analyst/Archiver^{TM} (Foto-Dyne-Incorporated, USA). Semi-quantitative mRNA expression data was calculated by the ratio of respective mRNA/RPL19 density.

3. Results and discussion

3.1. Diruthenium compounds characterization

Compounds **1** and **2** were prepared by direct reaction between $[Ru_2(O_2CCH_3)_4Cl]$ and the correspondent acidic drug ligands under similar conditions. The $[Ru_2(ibp)_4Cl]$ complex has been obtained by a different method but the characterization data (Section 2) are consistent with those previously reported [19]. Although $[Ru_2(asp)_4Cl]$ has been prepared before [40] no complete characterization of it was found in the literature. Here, the complex was synthesized by a new experimental procedure and its spectroscopic data are presented. The novel compounds, **3** and **4**, were prepared by reactions of $[Ru_2(O_2CCH_3)_4(H_2O)_2]PF_6$with the correspondent acidic drug ligands. Elemental analyses are consistent with complete carboxylate exchange reactions for all the products. The four acetate anions from the precursors chloro-acetate and aqua-acetate are substituted by the deprotonated NSAID (dNSAID) ligands giving the derivatives $[Ru_2(dNSAID)_4Cl]$, with ibp and asp, and $[Ru_2(dNSAID)_4(H_2O)_2]PF_6$, for npx and ind, respectively.

Physicochemical data for compounds **2**, **3** and **4** are shown in Table 1 and they are further discussed along with the data obtained for compound **1** (see Section 2).

Electronic spectra of all diruthenium compounds (in methanol) exhibit absorption bands at about 430 nm which can be ascribed to $\pi(Ru–O, Ru_2) \rightarrow \pi^*(Ru_2)$ electronic transitions. Solid-state λ_{max} shifts to lower energy (470–500 nm) for compounds **1** and **2**, according to observed for analogous diruthenium-tetracarboxylates [41–43]. Broad and low intensity near-IR bands ($\lambda_{max} \sim 1100$ nm) that are characteristics of $\delta(Ru_2) \rightarrow \delta^*(Ru_2)$ electronic transition involving dimetal core δ orbitals were also observed for all solid-state diruthenium compounds. The presence of these UV–Vis and NIR bands is consistent with previously reported spectra for analogous mixed valent diruthenium carboxylates and, consequently, agrees with the existence of metal–metal multiple bonds for the $Ru_2(II,III)$ cores [13,14].

The high effective magnetic moments ($\mu_{eff} = 3.7$–4.1 B.M. per Ru_2 unit) (Table 1) correspond to three unpaired electrons per dinuclear unit according to reported data for analogous complexes and indicate $(\sigma)^2(\pi)^2(\delta)^2(\pi^*\delta^*)^3$ ground state configurations for Ru_2-dNSAIDs complexes [13,14].

Compounds **1** and **2** exhibited low molar conductance values (3.7 S cm^{2}mol^{-1}). The non-electrolyte [44] behavior is consistent with the presence of neutral species in acetonitrile solutions. In contrast, the high values (84 and 65 S cm^2 mol^{-1}, for **3** and **4**, respectively) agree with 1:1 electrolytes according to expected for the presence of $[Ru_2(dNSAID)_4]^+$ cations and PF_6^- anions in solutions of compounds **3** and **4**.

Tentative attributions of most representative FTIR bands for compounds **2**, **3** and **4** are shown in Table 1. No significant spectral changes were observed for the NSAIDs after their coordination to the diruthenium cores, except for the frequencies related to the carboxylic (–COOH) groups [45,46]. The carbonyl stretching, ν(C=O), of the parent acids (1720 cm^{-1}, for Hibp; 1691 cm^{-1}, for Hasp; 1728 cm^{-1}, for Hnpx; 1718 cm^{-1}, for Hind) disappeared in the correspondent metal complexes spectra. Instead, carboxylate (–COO$^-$) typical bands were found at the region of 1480–1400 cm^{-1}. The values for $\Delta\nu$ [ν_a(COO)–ν_s(COO)] are in the range of 40–70 cm^{-1}, corroborating the bridging coordination mode of the carboxylate ligands to the diruthenium cores [14].

The presence of PF_6^- counter-ions in compounds **3** and **4** are confirmed by the bands at ~850 cm^{-1} (ν(PF) stretching, ν_3) and 559 cm^{-1} (δ(FPF), ν_4) [46]. Two relatively intense bands (556 cm^{-1} and 450–490 cm^{-1}), observed for all complexes, might be assigned to ν(Ru–O) stretching modes involving the ruthenium–O(carboxylate) metal-ligand bonds [47].

The Raman bands at 336–357 cm^{-1} can be assigned to ν(Ru–Ru) stretching modes for the two chloro-complexes [47]. The frequencies for compounds **1** (336 cm^{-1}) and **2** (342 cm^{-1}) are shifted to higher energy indicating that

Tentative attributions for major bands observed at the correspondent vibrational FTIR and Raman spectra.
[a] $\delta(CH_3)$ is overlapped with these bands; * not identified, overlapped with $\nu_s(PF_6)$; s = strong; m = medium; mw = medium-weak; ms = medium-strong; w = weak; br = broad; sh = shoulder.

the Ru–Ru bond in Ru_2-dNSAID derivatives are slightly shorter than that observed for Ru_2-acetate precursor (327 cm^{-1}). The ν(Ru–O) band was tentatively ascribed for **1** at 374 cm^{-1} and for **2** at 367 cm^{-1}. The aqua-complexes exhibit broad and overlapped bands, mainly due to the presence of axial water molecules, making difficult the attribution at this region of the spectra. The ν(PF) stretching mode, or ν_1 frequency [46], could be observed around 750 cm^{-1} for both $[Ru_2(dNSAID)_4(H_2O)_2]PF_6$ compounds.

Experimental results corroborate the proposition that $[Ru_2(dNSAID)_4Cl]$ and $[Ru_2(dNSAID)_4(H_2O)_2]PF_6$ exhibit mixed valent Ru_2(II, III) cores with Ru–Ru bonds stabilized by four bridging drug ligands in like-paddle-wheel structures (Fig. 2). The coordination of the large dNSAID anions do not show significant influence on the electronic structure of the novel compounds when compared to the correspondent diruthenium-acetate precursors. Compounds **1** and **2** probably exhibit solid-state polymeric structures like other analogous chloro-complexes. In contrast, compounds **3** and **4** have two axially coordinated water molecules, giving positively charged dimeric units that are charge-balanced by the PF_6^- counter-ions.

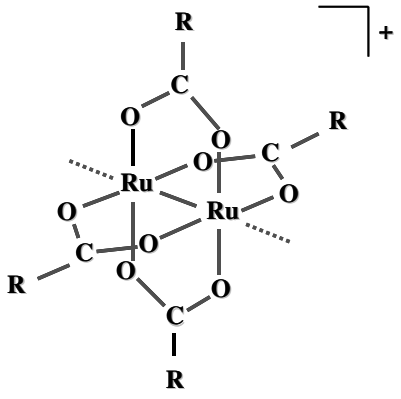

Fig. 2. General structure of the Ru_2-dNSAID compounds.

3.2. In vitro assays

3.2.1. MTT assays

The effects of the four Ru_2–dNSAID complexes and the parent NSAIDs were investigated *in vitro* in the human larynx tumor Hep2, the human bladder tumor T24/83 and the rat glioma C6. Initial experiments found no effects of any drug on the three cell lines at either 1 or 10 μmol L^{-1}, while at 100 μmol L^{-1} the drugs showed some inhibitory effects.

Experiments with 1 mmol L^{-1} complex were discarded as the high concentrations of vehicle (DMSO or ethanol) were cytotoxic to all three cell lines (results not shown). Further experiments were performed at 100 μmol L^{-1}, with no significant effects being found for any of the complexes in the Hep2 human larynx tumor or the T24/83 human bladder tumor (Table 2) after a 24 h incubation period. However, in the C6 rat glioma several drugs were found to inhibit cell proliferation by the MTT assay. The percentages of the control MTT value were: 85.9 ± 6.2 for Hind, 82.7 ± 3.4 for Hnpx, 77.4 ± 5.9 for compound **1** and 72.1 ± 5.5 for compound **3**. Hasp (95.6 ± 4.6) and compound **2** (96.3 ± 7.8) did not exhibit significant values. The high value found for compound **4** (93.1 ± 6.2) could not be explained based on the experiments conducted until the present moment.

3.2.2. Cell proliferation assay

In order to improve the reliability of the MTT data, further experiments for Hibp, Hnpx and their correspondent diruthenium complexes were performed using direct cell counting methods and cell viability analyzed by the trypan blue exclusion method. These experiments were performed on the C6 glioma cell line and involved cell culture in the presence of $[Ru_2(O_2CCH_3)_4Cl]$, Hibp, compound **1**, Hnpx or compound **3** for 24, 48 or 72 h (Table 3). Slight inhibitory effects were found with the Ru_2–dNSAID at 24 h but these were not significant when compared with those obtained by the less accurate MTT assay. Interestingly, inhibition was lost at 48 h but became highly significant at 72 h. In contrast, compound $[Ru_2(O_2CCH_3)_4Cl]$ does not exhibit inhibitory effect at 72 h. These data would suggest that the effects of compounds **1** and **3** are time dependent involving cumulative exposure to the complex to become more anti-proliferative. It is important to note that none of these effects involved direct cytotoxicity as shown by the large percentage of cells which retained their capacity to exclude trypan blue, for example cell viability at 72 h was: 98.5 ± 0.7% for compound **1**; 100 ± 0.1% for compound **3**; and 99.1 ± 0.5% for control (Table 4). Also of note was the inhibitory effect seen after 72 h exposure to the Hibp NSAID alone. Considering that this cell line does not express COX2 under normal culture conditions (Fig. 3) or produce PGE_2 [48] these effects must be through a COX2-independent mechanism.

Compounds **1** and **3** were found to inhibit the proliferation of C6 glioma cells *in vitro* with increasing efficacy correlated to increased time of exposure to the complexes. It is known that the C6 cell line does not express COX2 *in vitro* and therefore any effects of the NSAID component of these complexes must be via either COX1 or non-COX related mechanisms. Coordination of ruthenium to naproxen or ibuprofen, which exhibit antitumor properties alone in C6 cells, had synergistic effects improving their inhibitory properties. Of particular interest is the possibility that these drugs may be even more effective *in vivo* in gliomas where COX2 is expressed by tumor cells, endothelial cells and infiltrating microglial cells. Previous studies with NAMI-A have reported anti-angiogenic and anti-matrix metalloprotease effects [11,12]. The possibility that the complexes

Hnpx	95.6 ± 6.6	81.7 ± 9.5	82.9 ± 2.7[a]

Data are expressed as percentage of control cell number ± SEM. Representative data from three separate experiments with $n = 4$. Drugs were present at a final concentration of 100 μmol L^{-1}. Statistical analysis used 1-way ANOVA with Tukey's post test, $p < 0.05$; [a]versus control; [b]versus ibuprofen; [c]versus naproxen.

Table 4
Cell viability by trypan blue exclusion

	24 h	48 h	72 h
Control	99.5 ± 0.25	99.4 ± 0.39	99.1 ± 0.52
$[Ru_2(O_2CCH_3)_4Cl]$	99.9 ± 0.33	98.5 ± 0.72	98.0 ± 0.41
$[Ru_2(ibp)_4Cl]$	99.8 ± 0.13	98.2 ± 1.10	98.5 ± 0.73
Hibp	99.8 ± 0.11	98.6 ± 0.86	98.4 ± 1.00
$[Ru_2(npx)_4(H_2O)_2]PF_6$	99.8 ± 0.23	98.2 ± 0.84	100 ± 0.10
Hnpx	99.5 ± 0.26	98.3 ± 0.83	99.1 ± 0.45

Viable cell data are expressed as percentage of total cell population ±SEM. Drugs were present at a final concentration of 100 μmol L^{-1}. Cells were incubated with trypan blue prior to counting in a Neubauer chamber. Representative data from three separate experiments with $n = 4$.

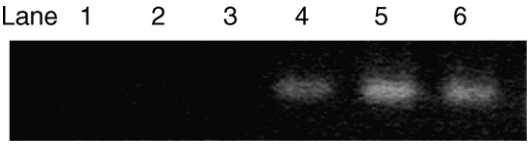

Fig. 3. COX2 mRNA expression in C6 cells *in vitro* lanes 1–3; C6 cells *in vivo* lanes 4–6.

1 and **3** may exert similar effects opens new horizons for studies in the *in vivo* C6 glioma model.

4. Conclusions

Diruthenium compounds of Hipb, Hasp, Hnpx and Hind NSAID drugs exhibited paddlewheel structures with mixed valent $Ru_2(II,III)$ cores containing metal–metal bonds stabilized by four drug-carboxylate bridging ligands. No significant effects were found for the complexes and their parent NSAIDs in the Hep2 human larynx or the T24/83 human bladder tumor. However, the coordination of the $Ru_2(II,III)$ core led to a synergistic effect that increased significantly the C6 rat glioma cell antiproliferative activity of naproxen and ibuprofen drugs. The development of novel drugs with marked effect on glioma cell proliferation, which are also potent inhibitors of COX2, is an important new avenue for future research related to the use of chemotherapy for glioma treatment. The possibility that the diruthenium complexes of ibuprofen and naproxen may exert effects (anti-angiogenic and anti-matrix metalloprotease) that are similar to those exhibited by NAMI-A opens new horizons for *in vivo* C6 glioma model studies.

Investigation about chemical and biological behavior to elucidate the antitumor properties of this kind of compounds is part of our forthcoming work.

Obituary

A tribute to Alfred Geoffrey (Geoff) Sykes FRS (1934–2007)

Professor Alfred Geoffrey Sykes FRS
(1934–2007)

With great pleasure I am honoured to write this tribute in honour of Geoff's life and work, and to help summarise his immense contribution to inorganic chemistry and his support for Polyhedron with his loyal service on the editorial board since the initiation of the journal.

Geoff Sykes was appreciated as a good friend by everyone who knew him. He was a loyal supporter, mentor and teacher to all who worked, studied under and collaborated with him over the years, a person who gave of his time generously.

Geoff obtained his B.Sc. in Chemistry from the University of Manchester in 1955, and his Ph.D. (1958) under Bill Higginson. He then began on the many travels around the world that would epitimise his professional life, setting out for a year of post-doctoral work at Princeton University (1958–1959) before moving to the University of Adelaide for a further year of postdoctoral studies in 1959–60. Geoff's first paper was published in 1960, the work presented at a Faraday Society Discussion meeting in Newcastle that year, organised by Professor Lord Wynne-Jones. This meeting attracted not only a galaxy of physical kineticists, but also many associated with the newly emerging area of inorganic reaction mechanisms including A.W. Adamson, F. Basolo, R.W. Dodson, J. Halpern, N. Hush, E.L. King, R.A. Marcus, L.E. Orgel, R.G. Pearson, D.R. Stranks, N. Sutin, H. Taube, R.J.P. Williams, and W.K. Wilmarth.

Geoff's first academic appointment was to a Lectureship in 1961 at the University of Leeds where he was to remain until 1980. Happy and productive times ensued during those early Leeds years both professionally and personally. Geoff's marriage to Elizabeth (Liz) in 1963 gave rise to three children – Richard, Andrew and Caroline. Geoff quickly established a considerable reputation with a series of pioneering studies on peroxo-dicobalt species and in 1964 gained considerable recognition for his seminal text on the 'Kinetics of Inorganic Reactions' published as one of a series of monographs.

Throughout the 1960s and 1970s the Sykes' group thrived as a result of recruiting many of the best Leeds graduates, post-doctoral fellows, and many top visiting scientists. Geoff's research success resulted in his promotion

doi:10.1016/j.poly.2007.12.009

to a Readership in 1970. That same year he became a founder member of the first discussion group (under the Chemical Society as it was then) devoted to research in Inorganic Reaction Mechanisms. The inaugural IMDG meeting was held in Leeds on 20th January 1970 stimulated by the successful International Meeting held the previous year at Bedford College, London with a plenary by Fred Basolo. Other IMDG founder members prominent in those early days were Martin Tobe (the first chairman), Ted Caldin, Ralph Wilkins, Michael Green, Bill Higginson, Martin Twigg, John Burgess and Geoff Stedman. Geoff was the first secretary/treasurer, later to become Martin Tobe's successor as Chairman. The IMDG still thrives today with a meeting held each year either in Europe or in the UK. The 37th meeting of the Group was held in January 2008 at the University of Barcelona, co-organised, like many have in the past, by another of Geoff's former collaborators, Professor Manuel Martinez.

In 1971 Geoff met Karl Wieghardt (then in Heidelberg) who spent a year in Leeds in what proved to be one of the most productive periods. In 1973 Geoff was awarded his D.Sc. from the University of Manchester. Throughout the 1970s many (now well established) scientists spent time with Geoff at Leeds including: Yoichi Sasaki (now Hokkaido), Andreja Bakac (Ames, Iowa), Takashi Shibahara (Okayama), T. Ramasami (Madras), David Weatherburn (Wellington), Graham Lappin (Notre Dame), Richard Henderson (Geoff's successor to the Chair of Inorganic Chemistry at Newcastle) along with Ph.D. students; Roger Thorneley (Norwich) and Fraser Armstrong (Oxford). This helped to establish Geoff's reputation further in the rapidly developing area of Inorganic Reaction Mechanisms.

Towards the end of the 1970s Geoff developed an interest in mechanistic biological inorganic chemistry performing seminal work on the mechanisms underpinning the action of redox proteins such as plastocyanin (Segal) and the ferredoxins (Armstrong).

In 1980, Geoff was appointed to the Established Chair of Inorganic Chemistry at Newcastle. Studies on iridium aqueous chemistry continued (Richens, Castillo-Blum), but soon became focussed almost entirely on Mo and W aqua ions (Richens, Ooi) which led onto extensive work on the chalcogenide-bridged analogues (Ooi, Fedin. Mederos, Hernandez-Molina). This was a highly productive period. Exchanges with the kinetics group at the University of Bloemfontein (Leipoldt, Lamprecht, Roodt, Swarts), and the inorganic groups at Stellenbosch (Cruywagen, Koch) kept the international flavour going throughout the 1980s and into the 1990s.

At Newcastle the metalloprotein studies continued to thrive even further. Work on blue copper proteins (notably Chapman, McGuinnis, Dennison, Kyritsus) and the ferridoxins (Chapman, Im, Worrall) continued, and the attachment of $[Ru(NH_3)_5(H_2O)]^{2+}$ to surface histidine residues provided an opportunity for studying long range intramolecular electron transfer (Jackman, Lloyd-Raven – JACS, 1998). Seminal studies on hemerythrin (Armstrong), hemocyanin (Andrew), aconitase (Faridoon, Zhuang), and the binuclear Fe-enzymes ribonucleotide reductase (Han, Dobbing) and purple acid phosphatase (Aquino, Twichett) and the Cu-enzyme galactose oxidase (Knowles, Phillips and McPherson) provided further important insights.

In 1985, Geoff hosted one of the Climax/Amax Molybdenum Conferences, and in 1992 the first European Bioinorganic Conference (Eurobic), both of them in Newcastle.

The international flavour of Geoff's group was reflected by 40 different nationalities spending time at various stages over the years providing a friendly and productive atmosphere for research. The group produced 53 Ph.Ds, and amassed over 500 publications. Geoff edited 28 books, including Vols. 32–53 of the highly regarded review series; Advances in Inorganic Chemistry.

Throughout his career Geoff thrived on his many visiting appointments around the world which included time spent at the Argonne National Laboratory, USA; University of Heidelberg; University of Leoben, Austria; Northwestern University, USA; University of Berne, Switzerland; Universities of Sydney, Adelaide and Melbourne, Australia; as a JSPS Fellow in Japan, Kuwait University, Memorial University, Newfoundland; University of the West Indies (Barbados, Trinidad, Jamaica); University of Lausanne, Switzerland; Universities of Stellenbosch and Bloemfontein, South Africa; University of La Laguna, Spain, and the City University of Hong Kong.

In 1999, his immense contribution to our present understanding of the mechanisms of metalloprotein reactions and inorganic coordination complexes was recognised by his election to a Fellowship of the Royal Society, possibly the first for contributions to this area of chemistry.

Geoff was undoubtedly one of the most influential British inorganic chemists of his generation. From my own experience he undoubtedly had a unique ability to attract, enthuse, support and inspire young graduates and researchers into the area of Chemistry that he loved.

We all miss him.

David T. Richens

Available online 28 January 2008

biological activity of these Schiff bases and their metal complexes may come from their interaction with potential donors of biological heterocycles in vivo [13,14]. The efficiency of the Schiff bases as therapeutic agents has often been enhanced upon coordination with a metal [15,16]. In many cases, the pharmacological activity has been found to be highly dependent on the identity of the metal and the donor sequence of the ligands with different ligands showing widely different biological activities although they may vary only slightly in their molecular structure [7,15,16]; however, the mechanism has yet to be determined. To date, no pattern has emerged to enable the activity to be predicted on the basis of the structure of the dithiocarbazate derivatives. Thus, it is worthwhile to carry out the study of additional isomeric dithiocarbazates and their metal complexes to supplement available information with a view of towards elucidation of the selectivity pattern of this class of compounds. We have previously reported the structure of benzyl *N*-[1-(thiophen-2-yl)ethylidene] hydrazine carbodithioate, SB2ATP [17]. Herein, we examine SB2ATP and benzyl *N*-[1-(thiophen-3-yl)ethylidene] hydrazine carbodithioate (SB3ATP) and their metal complexes of cobalt(II), nickel(II), copper(II), zinc(II)and cadmium(II). Since some of the related heterocyclic thiosemicarbazones and their Schiff bases also possess biochemical and pharmacological properties which may afford potential therapeutic applications [18,19] it is anticipated that continuance of this work may provide some basis for comparison and an understanding of structure–reactivity relationships.

2. Experimental

2.1. Materials

All chemicals were analytical grade and, unless otherwise specified, were used as received. The solvents were purified by conventional methods.

2.2. Preparation of S-benzyldithiocarbazate

This compound was synthesized as reported previously [3]. Potassium hydroxide (11.4 g, 0.2 mol) was dissolved completely in 90% ethanol (70 ml) and the mixture was cooled in an ice bath. To the mixture, hydrazine hydrate (10 g, 0.2 mol) was added slowly with stirring. Carbon disulphide (15.2 g, 0.2 mol) was then added drop-wise with vigorous stirring. The temperature of the reaction mixture was not allowed to rise above 5 °C during the period of addition of carbon disulfide. The resulting brown oil was separated by means of a separating funnel and dissolved in 40% ethanol (60 ml) and the solution was cooled in ice. Benzyl chloride (25.3 g, 0.2 mol) was added slowly with vigorous stirring. The white product was separated by filtration, washed with water and dried in air. The crude product was recrystallized from absolute ethanol; yield, 24.5 g (61.9%); the melting point was 124 °C (Lit. 123–125 °C) [1].

2.3. The preparation of benzyl N-[1-(thiophen-2-yl)ethylidene] hydrazine carbodithioate and benzyl N-[1-(thiophen-3-yl)ethylidene] hydrazine carbodithioate (SB2ATP)

The Schiff base, benzyl *N*-[1-(thiophen-2-yl)ethylidene] hydrazine carbodithioate, SB2ATP, was synthesized as reported previously [17]. *S*-Benzyldithiocarbazate, SBDTC (9.9 g, 0.05 mol) was dissolved in absolute ethanol (35 ml). To this solution was added 2-acetylthiophene (6.3 g, 0.05 mol) also in absolute ethanol (30 ml). The mixture was heated while being stirred for 15 min and later allowed to stand for 20 min whereupon a precipitate formed. This precipitate was filtered and dried over silica gel. Crude products were recrystallized from absolute ethanol.

The Schiff base, benzyl *N*-[1-(thiophen-3-yl)ethylidene] hydrazine carbodithioate, SB3ATP, was synthesized by substituting the 2-acetylthiophene with 3-acetylthiophene.

2.4. General method for preparation of the metal complexes

To 0.005 mol of metal salt dissolved in absolute ethanol (20 ml) was added Schiff base (0.01 mol) in 20 ml of absolute ethanol. The mixture was heated while being stirred. The precipitate was filtered, washed with ice-cold ethanol and dried over silica gel. The yield and melting point were recorded for each product. Metal ions used were cobalt, nickel, copper, zinc and cadmium.

2.5. Physical measurements

IR spectra were recorded on a Perkin–Elmer 1650X FTIR spectrometer using KBr pellets, in the 4000–400 cm^{-1} region. Elemental analyses were carried out using a LECO CHNS-932 and a Perkin–Elmer Plasma 1000 Emission Spectrometer. ^1H NMR spectra were obtained on a JOEL JNM 400 MHz spectrometer. The molar conductance of 10^{-3} M solutions of the metal complexes in DMSO were measured at 30 °C using a Jenway 4310 conductivity meter and a dip-cell with platinized electrode. Electronic absorption spectra were obtained on a Shimadzu UV-2501 PC spectrophotometer using DMSO solutions in the 200–900 nm region. An Electrothermal digital melting point apparatus was used to determine the melting points. Room temperature magnetic susceptibility data were collected with a Sherwood Scientific MSB-AUTO magnetic susceptibility balance at 300 K.

2.6. X-ray structure determination

Dark brown crystals of the Ni(II) complex, Ni(SB2ATP)$_2$, were formed when an acetonitrile solution was allowed to slowly evaporate for a couple of weeks. The selected crystal of the Ni(II) complex was mounted on a glass fiber using perfluropolyether oil and cooled rapidly to 150 K in a stream of cold N_2 using an Oxford Cryosystems CRYOSTREAM unit. Diffraction data were mea-

sured using an Enraf-Nonius Kappa CCD diffractometer (graphite-monochromatic Mo Kα radiation, $\lambda = 0.71073$ Å). Intensity data were processed using the DENZO-SMN package [20]. The crystal was found to be monoclinic with $a = 10.5360(3)$ Å, $b = 8.5915(2)$ Å, $c = 17.0856(5)$ Å and $\beta = 103.6699(11)°$. The structure was solved in the space group $P2/c$ using the direct-methods program SIR92 [21] which located all non-hydrogen atoms. Subsequent full-matrix least-squares refinement of F was carried out using CRYSTALS program suite [22]. Coordinates and anisotropic thermal parameters of all non-hydrogen atoms were refined. Hydrogen atoms were positioned geometrically after each cycle of refinement. A five-term Chebychev polynomial weighting scheme was applied. Refinement converged satisfactorily to give $R = 6.01$ and $R_w = 6.13$ with minimum and maximum residual electron density of -0.74 and 1.07 e Å^{-3}.

2.7. Bioactivity

Antimicrobial assays were carried out at the Laboratory of Molecular and Cell Biology, Institute of Biosciences, Universiti Putra Malaysia while cytotoxic assays were done at the Clinical Genetics Unit, Department of Human Growth and Development, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia.

2.7.1. Qualitative antimicrobial assay

Eight pathogenic microbial strains were used to test the biological potential of the compounds: (i) Methicillin resistant *staphylococcus* (MRSA), (ii) *Bacillus subtilis* wild type (B29), (iii) *Bacillus subtilis* mutant defective DNA repair (B28), (iv) *Pseudomonas aeruginosa* (60690), (v) *Candida albicans* (CA), (vi) *Aspergillus ochraceous* (398), (vii) *Saccharomyces cereviceae* (20341) and (viii) *Candida lypolytica* (2075). The antimicrobial activity of each compound was determined qualitatively through the modified disc diffusion method [23]. A lawn of microorganisms was prepared by pipetting and evenly spreading 10 µl of inocula (adjusted turbid metrically to 10^5–10^6 CFU/cm^3 [CFU = colony forming units]) onto agar set in petri dishes. Nutrient agar (NA) was used for bacteria while potato dextrose agar (PDA) was used for fungi. Filter paper discs (Whatman no. 1) measuring 6 mm in diameter were impregnated with dimethylsulphoxide (DMSO) stock solution of the compounds (100 mg/cm^3) and dried under sterile conditions. The dried discs were then placed on the previously inoculated agar surface. The plates were inverted and incubated for 24 h at 37 °C for the bacteria and 30 °C for the fungi. Antimicrobial activity was indicated by the presence of clear inhibition zones around the discs.

2.7.2. Quantitative antimicrobial assay

Compounds that showed positive antimicrobial activity with the disc diffusion assay were subjected to the broth dilution method for the qualitative measurement of micro biostatic (inhibitory) activity as described by Hufford and Clark [24]. The lowest concentration that completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, µg/ml). Streptomycin and nystatin (Sigma, USA) were used as positive controls for bacteria and fungi, respectively.

2.7.3. Cytotoxic assay

2.7.3.1. Cell culture. Five cell lines were used: human myeloid leukemia (HL-60), human ovarian cancer (Caov-3), human cervical cancer (HeLa), human breast carcinoma with positive estrogen receptor (MCF-7) and human breast carcinoma with negative estrogen receptor (MDA-MB-231). All the cell lines were obtained from the National Cancer Institute, USA. HL-60, Caov-3, HeLa and MDA-MB-231 were grown in RPMI-1640 adjusted to contain 0.024 M sodium bicarbonate and 10% fetal calf serum. While MCF-7 was grown in RPMI-1640 containing 0.018 M sodium bicarbonate supplemented with 0.001 M sodium pyruvate, 1 ml of 10 mg/ml bovine insulin and 10% fetal calf serum. All the cells were incubated in an atmosphere of 5% CO_2, 100% relative humidity at 37 °C.

2.7.3.2. Treatments and sample dilutions. Cells from all cell lines were counted, diluted and inoculated on to sterile 96-well microtiter plates. Cells were inoculated in a volume of 100 µl per well at densities between 5000 and 20 000 cells per well (Table 1). The microtiter plates containing the cells were preincubated overnight at 37 °C in an atmosphere of 5% CO_2 and 100% relative humidity to allow stabilization prior to addition of compounds.

Stock solutions of the compounds (10 mg/ml) were prepared using DMSO. The compounds were then diluted with complete medium to concentrations ranging from 100 µg/ml to 0.3 µg/ml. Immediately after preparation of these intermediate dilutions, 100 µl aliquots of each dilution were added to the appropriate microtiter plate wells. The treated cultures were incubated for 4 days in an atmosphere of 5% CO_2 and 100% relative humidity at 37 °C and the end-point was measured using MTT assay as described below.

2.7.3.3. MTT assay. Cytotoxicity was evaluated using MTT (3-[4,5-dimethylthiazo-2-yl]-2,5-diphenyltetrazolium bromide) (Sigma, USA) assay following Mosmann [25] and Monks [26]. The MTT assay was based on metabolic reduction of (3-[4,5-dimethylthiazo-2-yl]-2,5-diphenyltet-

Table 1
Cancer cell lines and inoculation densities used in compound screening

MDA-MB-231	7500

razolium bromide) (MTT). A 40 μl aliquot of MTT solution (2.5 mg MTT in 1 ml of PBS solution) was added directly to all the appropriate microtiter plate wells containing cells, complete growth media and test agents as prepared above. The culture was then incubated for 4 h to allow for MTT metabolism to formazan. After this, the supernatant was pipetted out and 200 μl of DMSO was added to dissolve the formazan. The plates were agitated on a plate shaker to ensure a homogeneous solution and the optical densities were read on an automated spectrophotometric plate reader (model MRX II microplate Elisa reader) at a test wavelength of 570 nm and a reference wavelength of 630 nm. Cytotoxicity is shown as the minimum concentration required to reduce the absorbance of treated cells by 50% with reference to the untreated cells (CD_{50}). Tamoxifen and etoposide were used as cytotoxic standards.

3. Results and discussion

3.1. IR spectroscopy and elemental characterization

Table 2 shows the yield, colour, melting points and elemental analysis of the synthesized compounds. All the compounds were synthesized in reasonable yield. The CHNS values of the compounds were determined to be in agreement with the empirical formulae. These dithiocarbazate substituted esters, SB2ATP and SB3ATP, are capable of exhibiting thione–thiol tautomerism existing in either form or as an equilibrium mixture (Fig. 1).

The IR spectra of the free ligands, SB2ATP and SB3ATP, in KBr do not exhibit a ν(S–H) band at around 2700 cm^{-1}, but show a broad and weak band at 3184 cm^{-1} for SB2ATP and 3188 cm^{-1} for SB3ATP attributable to ν(N–H). This indicates that in the solid state, the ligand remains in the thione form. Although an equilibrium mixture of the thione and thiol tautomeric forms may be expected to exist in solution, the ^{1}H NMR spectra of SB2ATP and SB3ATP in DMSO do not exhibit any signal at approximately 4 ppm due to the S–H proton, however, they display signals at 12.51 ppm (SB2ATP) and 12.43 ppm (SB3ATP) due to N–H protons, indicating that even in solution they exist predominantly as the thione tautomers. In the presence of metal salts, they can quickly convert to the thiol form and coordinate to the metal ion in its deprotonated thiolate form.

Both SB2ATP and SB3ATP display a broad and weak band (3184 cm^{-1} and 3188 cm^{-1}, respectively) attributable to ν(N–H). In the spectra of the complexes, this band was not present. This indicates that the ligands were coordinated in their deprotonated form. In the IR spectra of the complexes, the ν(C=N) band is not shifted but the ν(N–N) band of the free ligands shifted to considerably higher wave numbers suggesting coordination *via* the azomethine nitrogen atom. The shift of the ν(C=S) at 914 cm^{-1} (SB2ATP) and 968 cm^{-1} (SB3ATP) to the higher wave numbers for the metal complexes imply coordination through the thiol sulfur. All the significant IR bands of the Schiff bases and their metal complexes are tabulated (Table 3).

3.2. Molar conductivity and magnetic susceptibility

Molar conductivity data are presented in Table 4. All compounds are non-electrolytes in DMSO indicating covalent bonding in each case. Although some dissociation of the complexes seems to occur, the conductance values are much lower than that expected for 1:1 electrolytes in this solvent. All metal complexes were diamagnetic with the exception of CoSB2ATP with $\mu_{eff} = 2.589 \times 10^{-6}$ BM (unfortunately, data are unavailable for the CoSB3ATP complex).

3.3. Electronic spectra

Electronic spectral data of the synthesized compounds are shown in Table 5. The Schiff bases, SB2ATP and SB3ATP, exhibit $(n \rightarrow \pi^*)_{thiophene}$ bands at 357 nm and 337 nm, respectively [18]. The $(n \rightarrow \pi^*)_{dithiocarbazate}$ band was observed at 392 nm for SB2ATP and 337 nm for SB3ATP. Upon coordination with metal complexes, the $(n \rightarrow \pi^*)_{thiophene}$ and $(n \rightarrow \pi^*)_{dithiocarbazate}$ band shifted.

The UV–vis spectra of Co(II), d^7, complexes indicate that they are distorted tetrahedral structure. The $^4T_1$ (F) $\rightarrow$ $^4A_2$ bands can be seen at 716 nm and 705 nm for SB2ATP and SB3ATP complexes, respectively [27]. The band at 416 nm for both Co(II) complexes can be assigned to the $^4T_1$ (P) $\rightarrow$ $^4A_2$ transition [27]. The bands at 286 nm (SB2ATP) and 262 nm (SB3ATP) are assigned to the LMCT S $\rightarrow$ d. The $Ni(SB2ATP)_2$ complex adopts a distorted square planar structure with the $^4T_1$ (F) $\rightarrow$ $^4A_2$ band observed at 856 nm [27]. $Ni(SB3ATP)_2$ did not exhibit a band in this region. The $^4T_1$ (P) $\rightarrow$ $^4A_2$ transition can be seen at 416 nm for both of the Ni(II) complexes [27]. The LMCT S $\rightarrow$ d absorption for $Ni(SB3ATP)_2$ is at 281 nm but for $Ni(SB2ATP)_2$ this band was hidden by a strong CT transition.

Cu(II) complexes are usually highly distorted [27]. The $^1A_1 \rightarrow {}^1A_2$ and $^1A_1 \rightarrow {}^1B_1$ transitions can be assigned in the 500 nm and 400 nm region, respectively [3]. The absorption at 262 nm in the $Cu(SB3ATP)_2$ spectrum is expected to be the LMCT S $\rightarrow$ d and the 570 nm can be assigned to the $^1A_1 \rightarrow {}^1E$ transition (see Fig. 1).

3.4. The structure of $[Ni(SB2ATP)_2]$

The molecular structure of $Ni(SB2ATP)_2$ is a distorted square planar monomeric entity with twofold axis running through to the metal ion. A perspective view with the atomic numbering scheme of the complex and its packing arrangement are shown in Figs. 2 and 3, respectively. Selected crystallographic data and refinement data are given in Tables 6 and 7. The nickel(II) ion is coordinated through the azomethine nitrogen atom N(2) and the mercapto-sulfur atom S(12) of the Schiff base ligands at 1.949(2) and 2.148(1) Å, respectively. The nickel atom adopts a distorted square planar geometry with N(2)–N(1)–N(2′), N(2)–Ni(1)–S(12) and S(12)–Ni(1)–S(12′) angles of 104.05°, 86.07° and 87.86°. A weak interaction between thiophenyl sulfur to the nickel ion is reflected by the Ni(1)–S(5) distance of 3.22 Å which could be the cause for the distortion from a perfect square planar geometry.

The N(10)–C(11) distance in the complex is 1.292(4) Å, while for the free ligand it is 1.342(2) Å [17]. The decrease in length of this bond upon complexation through the adjacent N(2) atom. The C(11)–S(12) and N(2)–C(3) bond lengths in the complex are 1.737(3) Å and 1.303(3) Å, respectively. These distances are longer than those observed for the free ligand 1.650(2) Å and 1.276(2) Å

Table 5

Log ε (mol^{-1} cm^{-1}) are in parentheses.

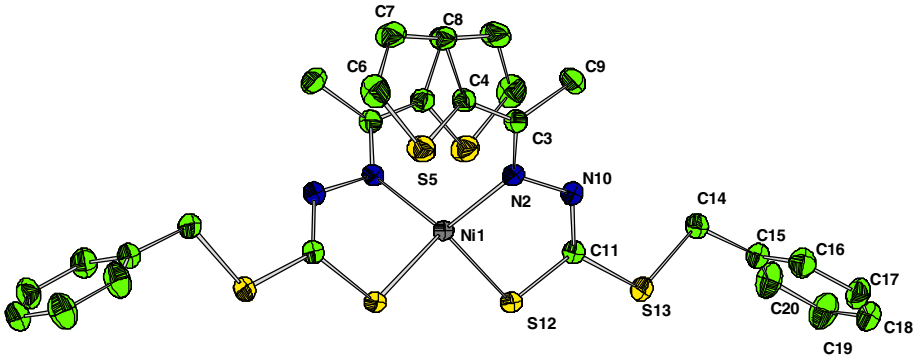

Fig. 2. ORTEP diagram of $Ni(SB2ATP)_2$ with 50% probability displacement ellipsoids showing the distorted square planar arrangement around the metal centre.

[17], as expected and as corroborated by the shifts observed in the infrared spectrum. The C–N bond distances of the complex of the bi-chelated ligands are typical for double bond Schiff base compounds [11]. The C–S bond distances of 1.737(3) Å indicate single bond character which supports the suggestion that the complex formation involves the ligand in its thiol form. The C(3)–N(2)–N(10)–C(11) has a *s*-trans disposition with the benzyl and 1-(thiophene-2-yl)ethylideamine groups nearly orthogonal to each other (79.76°).

3.5. Biological activities

3.5.1. Antimicrobial activity

All compounds were assayed for microbial activity. The disc diffusion technique was employed [23]. The $Cu(SB2ATP)_2$ showed strong activity towards *Candida lypolytica*. SB2ATP, SB3ATP, $Co(SB2ATP)_2$, $Cd(SB2ATP)_2$ and $Cu(SB3ATP)_2$ showed weak microbial activity towards several microbes and fungi while the others showed no activity toward the target microbes and fungi. Quantitative assays were not carried out for these compounds since they showed low activity.

Lead, tin, iron, cobalt and cadmium complexes of *S*-benzyldithiocarbazate Schiff bases formed using 5-methyl-2-furylaldehyde (NS) and 2-furylmethylketone (NS′) did not show not much inhibitory activity against targeted microbes, *Methicillin* resistant *staphylococcus* (MRSA), *Bacillus subtilis*-wild type (B29), *Bacillus subtilis*-mutant defective DNA repair (B28) and *Pseudomonas aeruginosa* (60690) [10]. However, all the compounds showed clear inhibition zones of 10 mm and above against *Aspergillus ochraceous* (398) except the cadmium complex of the 2-furylmethylketone Schiff base [10].

The complexes of the Schiff bases prepared using the same ketone, 2-furylmethylketone, and aldehyde, 5-methyl-2-furylaldehyde, but with different dithiocarbazate moiety, *S*-methyldithiocarbazate, $Cd(NS)_2$, $Sn(NS')_2$ and $Co(NS')_2$ showed clear inhibition of MRSA, B29, B28, 60690, *Candida albicans* (CA), *Aspergillus ochraceous* (398), *Saccharomyces cerevisiae* (20341) and *Candida lypolytica* (2075) with the exceptions that $Cd(NS)_2$ and $Sn(NS')_2$ were inactive towards MRSA and CA, respectively. However, $Cd(NS')_2$, $Fe(NS')Cl_2$ and $Pb(NS')_2$ were inactive towards all target bacteria. $Cd(NS')_2$ was active against CA and 20341, while $Fe(NS')Cl_2$ and $Pb(NS')_2$ showed clear inhibition of 2075 and 398, respectively. $Sn(NS)_2$ showed activity against 60690, MRSA, B29, 2075 and 398. While $Fe(NS)Cl_2$, $Pb(NS)_2$ and $Co(NS)_2$ were inactive towards all target bacteria and fungi [28].

Substitution of the *N* with *S* in the five-membered ring has considerably altered the activity of the compounds towards target microbes and fungi as has substitution of the benzene ring with a methyl group.

3.5.2. Cytotoxic activity

The results of the cytotoxic assays are shown in Table 8. SB2ATP and Cd(SB3ATP)$_2$ showed significant bioactivity towards human myeloid leukemia (HL-60) while Co(SB3ATP)$_2$ showed slight cytotoxic activity towards this cell line. SB2ATP, SB3ATP, Co(SB2ATP)$_2$, Cu(SB2ATP)$_2$, Cu(SB3ATP)$_2$, Zn(SB2ATP)$_2$ and Cd(SB2ATP)$_2$ showed significant chemotherapeutic activity against human breast carcinoma with positive estrogen receptor (MCF-7) while the remainder of the compounds showed significant bioactivity towards this cell line. The Schiff bases show higher cytotoxic activity compared to their metal complexes except for Cu(SB3ATP)$_2$. It can be deduced that metal chelation may slightly inhibit cytotoxic activity. The SB2ATP Schiff bases showed a slightly lower cytotoxic dose concentration than SB3ATP. None of the compounds showed any cytotoxic activity towards human cervical cancer (HeLa) or towards human breast carcinoma with negative estrogen receptors (MDA-MB-231).

Previous studies have shown that bidentate *S*-benzyldithiocarbazate Schiff bases formed using 5-methyl-2-furylaldehyde (NS^a) and 2-furylmethylketone (NS^b) and the Pb(NS^a)$_2$ complex exhibited high cytotoxicity against the Human T-lympho-blastic leukemia (CEM-SS) cell line. The Cd(NS^b)$_2$ complex was inactive towards the CEM-SS cell line in contrast to results reported on other Cd complexes containing similar bidentate ligands [10,11]. *S*-meth-

Table 8
Cytotoxic activity

Compound	IC_{50} (μg/ml)				
	HL-60	Caov-3	HeLa	MCF-7	MDA-MB-231
SB2ATP	13			1.4	
$Co(SB2ATP)_2$				1.8	
$Ni(SB2ATP)_2$					
$Cu(SB2ATP)_2$				4.2	
$Zn(SB2ATP)_2$				3.9	
$Cd(SB2ATP)_2$				4	
SB3ATP				2.8	
$Co(SB3ATP)_2$

Human myeloid leukemia (HL-60); Human ovarian cancer (Caov-3.); Human cervical cancer (HeLa); Human breast carcinoma with positive estrogen receptor (MCF-7); Human breast carcinoma with negative estrogen receptor (MDA-MB-231).
IC_{50} (μg/ml) = inhibition dose at 50%, i.e., the concentration to inhibit growth of cancer cells by 50%.
na, not available.
⩽4 μg/ml = chemotherapeutic significant; 4–30 μg/ml = bioactive significant.
Empty columns indicates ⩾30 μg/ml, i.e. not significant.

yldithiocarbazate Schiff bases prepared using 2-furylmethylketone (NS^c) and 5-methyl-2-furylaldehyde (NS^d), gave complexes, $Cd(NS^c)_2$, $Cd(NS^d)_2$ and $Co(NS^c)_2$, which were very active against CEM-SS and cervical cancer cell (HeLa) lines [28]. The compounds synthesized in this work were not assayed against CEM-SS due to the unavailability of the cell line.

As a general observation, it appears that the complexes of the *S*-benzyldithiocarbazate Schiff base containing the acetylthiophene moiety are not as toxic as the related 2-furylmethylketone and 5-methyl-2-furylaldehyde complexes. It would, therefore, seem that substitution of oxygen by sulfur in the substituent five-membered rings reduces cytotoxicity.

4. Conclusion

The SB2ATP and SB3ATP behave as uninegatively charged bidentate ligands with Co(II), Ni(II), Cu(II), Zn(II) and Cd(II) complexes. The IR spectra of the free ligands indicate that in solid state the ligand remains in the thione form. The thione and thiol tautomeric forms may be expected to exist in solution but the ^1H NMR spectra of SB2ATP and SB3ATP indicates that the ligands, even in solution, exist predominantly as the thione tautomers. All complexes are non-electrolytes in DMSO signifying covalent bonding in each case. The CoSB2ATP complex is paramagnetic with its magnetic moment indicating that it is a square planar structure, the diamagnetic Ni(II) complexes are expected to be in a square planar environment. This has been verified by crystallographic measurements for the NiSB2ATP complex. The diamagnetic Zn(II) and Cd(II) ions are expected to be tetrahedral complexes since they are unlikely to form bridged dimeric square planar structures. The results of magnetic measurements for the Cu complexes may possibly be understood in terms of spin-spin interaction. The thiophenyl substituents displayed lower activity towards target microbes and fungi than the furanyl groups in comparable complexes and also appeared to inhibit the cytotoxicity.

Acknowledgements

We would like to thank the Department of Chemistry, Faculty of Science, Clinical Genetics Unit, Department of Human Growth and Development, Faculty of Medicine and Health Sciences and the Laboratory of Molecular and Cell Biology, Institute of Biosciences, Universiti Putra Malaysia for the provision of laboratory facilities. This research was funded by grants from the Ministry of Science, Technology and Innovation Malaysia, under the Intensification of Research in Priority Areas Scheme (IRPA Grant nos. 09-02-040755 and 09-02-04-0296).

Appendix A. Supplementary material

CCDC 245093 contain the supplementary crystallographic data for complex $Ni(SB2ATP)_2$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.11.035.

W, Si and Ge were determined by ICP-AES. C, H and N analyses were determined using a PE-2400 analyzer. ^{183}W NMR spectra of the Me_4N^+ salts were recorded at 16.64 MHz on a Unity-400 spectrometer (solvent D_2O). Chemical shifts were recorded with respect to 2 mol/L Na_2WO_4 in D_2O for ^{183}W NMR. ^1H NMR spectra were recorded on INOVA 500 NMR spectrometer (solvent D_2O). IR spectra were recorded on an Alpha Centauri FTIR spectrometer (4000–200 cm^{-1} range) as KBr pellets.

2.2. Synthesis

2.2.1. $(Me_4N)_4H_5[(HOOCCH_2CH_2Ge)_3(PW_9O_{34})_2]\cdot 1.5DMSO$ (1)

To a mixture of $Na_8H[PW_9O_{34}]\cdot 12H_2O$ (2.7 g, 1 mmol) and Me_4NBr (1.368 g, 9 mmol) in DMSO (10 mL), $HOOCCH_2CH_2GeCl_3$ (1.875 g, 3 mmol) was added with stirring. The mixture turned clear immediately and some HCl gas was released. The solution was stirred for 10 h at room temperature and then filtered. CH_3CH_2OH (100 mL) was added to the filtrate until no more precipitate formed. The white precipitate was recrystallized from hot DMSO–Et_2O and dried under vacuum, yield 46%. *Anal.* Calc. for $(Me_4N)_4H_5[(HOOCCH_2CH_2Ge)_3(PW_9O_{34})_2]\cdot 1.5DMSO$: P, 1.17; W, 62.26; Ge, 4.13; C, 6.32; H, 1.45; N, 1.05. Found: P, 1.02; W, 62.09; Ge, 3.91; C, 6.50; H, 1.79; N, 1.34%.

2.2.2. $(Me_4N)_4H_5[\{HOOCCH_2(m\text{-}NO_2C_6H_4)CHGe\}_3(PW_9O_{34})_2]\cdot 1.5DMSO$ (2)

Compound **2** was prepared analogously using the same quantities as above, yield 46%. *Anal.* Calc. for $(Me_4N)_4H_5[\{HOOCCH_2(m\text{-}NO_2C_6H_4)CHGe\}_3(PW_9O_{34})_2]\cdot 1.5DMSO$: P, 1.09; W, 58.27; Ge, 3.84; C, 7.81; H, 1.51; N, 1.72. Found: P, 1.12; W, 58.40; Ge, 3.64; C, 7.36; H, 1.87; N, 2.05%.

2.2.3. $(Me_4N)_4H_5[(HOOCCH_2\ CH_2Ge)_3(SbW_9\mathbf{O}_{33})_2]\cdot 1.5DMSO$ (3)

Compound **3** was prepared analogously. To a mixture of $Na_9[SbW_9O_{33}]\cdot 19.5\ H_2O$ (2.7 g, 1 mmol) and Me_4NBr (1.368 g, 9 mmol) in DMSO (10 mL), $HOOCCH_2CH_2GeCl_3$ (1.875 g, 3 mmol) was added with stirring. Then CH_3CH_2OH (100 mL) was added to precipitate out $(Me_4N)_4H_5[(HOOCCH_2CH_2Ge)_3(SbW_9O_{33})_2]$. The white precipitate was recrystallized from hot DMSO–Et_2O and dried under vacuum, yield 48%. *Anal.* Calc. for $(Me_4N)_4H_5[(HOOCCH_2CH_2Ge)_3(SbW_9O_{34})_2]\cdot 1.5DMSO$: Sb, 4.46; W, 60.55; Ge, 3.99; C, 6.14; H, 1.41; N, 1.02. Found: Sb, 4.38; W, 61.04; Ge, 3.70; C, 6.50; H, 1.79; N, 1.34%.

2.2.4. $(Me_4N)_4H_5[\{HOOCCH_2(m\text{-}NO_2C_6H_4)CHGe\}_3(SbW_9O_{33})_2]\cdot 1.5DMSO$ (4)

Compound **4** was prepared analogously using the same quantities as above, yield 49%. *Anal.* Calc. for $(Me_4N)_4H_5[\{HOOCCH_2(m\text{-}NO_2C_6H_4)CHGe\}_3(SbW_9O_{33})_2]\cdot 1.5DMSO$: Sb, 4.18; W, 56.78; Ge, 3.74; C, 7.61; H, 1.47; N, 1.68. Found: Sb, 4.25; W, 56.78; Ge, 3.51; C, 7.36; H, 1.87; N, 2.05%.

2.3. The antitumoral activity of the POMs

The antitumoral activity in vitro of the POMs on two of human cancer cells was tested by the MTT experiment [11]. Samples containing the POMs were treated by the following method: the POMs were dissolved by PBS, then autoclaved and diluted by a RPMI 1640 medium with water to final concentrations of 31.3 μg mL^{-1}, 15.6 μg mL^{-1}, 7.8 μg mL^{-1}, 3.9 μg mL^{-1}, 2 μg mL^{-1} and 1 μg mL^{-1}.

The antitumoral activity in vivo was assayed by the animal tumor implantation method. The C57 rats (18–20 g) were supplied by the Changchun Institute of Biological Manufacture. Animals were randomly divided into four treatment groups: control rats, rats bearing with cancer cell and rats receiving compound **3** $(Me_4N)_4H_5[(HOOCCH_2CH_2Ge)_3(SbW_9O_{33})_2]\cdot 1.5DMSO$ (abbreviated as $(C_3H_5O_2Ge)_3(SbW_9)_2$) and positive control compound treatments. Each experimental group consisted of both male and female animals in a 1:1 ratio. The rats bearing cancer were produced by a single subcutaneous inoculation of 5×10^5 mL^{-1} of S180 cancer cells. The rats receiving drug treatments were administered as a single gavage dose orally on days 1–10 and were sacrificed on day 11, then the weight of the tumor and spleen were measured to assay the inhibitory effect and the effect on the immune organ. The control rats were fed with physiological saline.

3. Results and discussion

3.1. IR spectra

The observed frequencies and tentative assignments of the main IR bands of the title complexes are given in Table 1.

Compared with $PW_{12}O_{40}^{4-}$, the IR spectra of the substituted heteropolyanions still have the four characteristic peaks of $\nu_{as(W\text{–}O_d)}$ (O_d, terminal oxygen), $\nu_{as(W\text{–}O_b\text{–}W)}$, $\nu_{as(W\text{–}O_c\text{–}W)}$ (O_b, O_c, bridging oxygen) and $\nu_{as(X\text{–}O_a)}$ (O_a, central oxygen), indicating that the new complexes still retain the basic frame of a Keggin structure. However, the terminal oxygen vibrations for $[(RGe)_3(PW_9O_{34})_2]^{9-}$ are shifted to a lower energy relative to the terminal oxygen vibration

[a] $R_1 = HOOCCH_2CH_2$, $R_2 = HOOCCH_2(m\text{-}NO_2C_6H_4)CH$.

for $PW_{12}O_{40}^{4-}$. This is due to an increase of negative charge on the polyanion. The P–O_a bond vibrations of $[(RGe)_3(PW_9O_{34})_2]^{9-}$ split. This fact demonstrates that the $[RGe]^{3+}$ group does not occupy the three vacant sites of the PW_9 anions to give $(RGe)_3PW_9$. The IR spectra are similar to that of $Co_3(PW_9)_2$ [12].

The IR spectra display a single, sharp absorption in the 1700–1712 cm^{-1} region. This feature is characteristic of the C=O stretch. This shows the existence of an organogermanium acid group in the complexes.

3.2. ^{1}H NMR and ^{183}W NMR spectra

The ^{1}H NMR and ^{183}W NMR spectra are given in Table 2 and Fig. 1.

The title complexes gave clear ^{1}H spectra. In $HOOCCH_2CH_2GeCl_3$ (the ^{1}H NMR spectrum contains peaks at 2.19 (t, CH_2COOH), 2.86 (t, CH_2GeCl_3) and 9.95 (s, COOH) ppm), the Ge atom links with three chlorine atoms and the H chemical shift of $GeCH_2$ is 2.86 ppm. When $HOOCCH_2CH_2GeCl_3$ was reacted with PW_9 to form $(HOOCCH_2CH_2Ge)_3(PW_9)_2$, for example, the electron density on Ge was affected by the heteropoly anion, the electron density on Ge increased, and thus the H chemical shift of $GeCH_2$ shifted to a higher magnetic field (1.36 ppm). The other H chemical shifts also changed (the ^{1}H NMR shifts are 12.10 (COOH) and 2.49 (t, $2 \times CH_2COOH$) ppm). This demonstrates that the $[RGe]^{3+}$ group is incorporated with the tungstophosphate and the organic group does not separate from the Ge atom.

The ^{1}H NMR spectrum of $[\{HOOCCH_2(m\text{-}NO_2C_6H_4)CHGe\}_3(PW_9O_{34})_2]^{9-}$ is similar to that of $HOOCCH_2(m\text{-}NO_2C_6H_4)CHGeCl_3$, only some shifts occur, similar to that of $[\{HOOCCH_2(m\text{-}NO_2C_6H_4)CHGe\}_3(PW_9O_{34})_2]^{9-}$, indicating that the polyoxometallate anion $[\{HOOCCH_2(m\text{-}NO_2C_6H_4)CHGe\}_3(PW_9O_{34})_2]^{9-}$ contains the organogermanium group.

The ^{183}W NMR spectrum (Fig. 1) for $(HOOCCH_2CH_2Ge)_3(PW_9)_2$ shows two lines of intensity 1:2, indicating

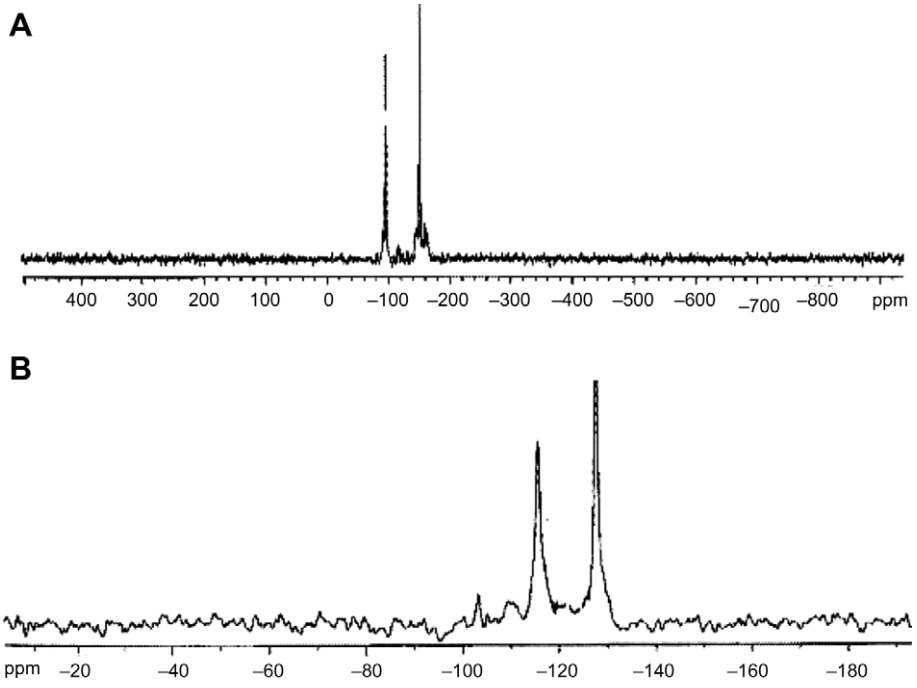

Fig. 1. The ^{183}W NMR spectra of $(HOOCCH_2CH_2Ge)_3(PW_9)_2$ (A) and $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ (B).

Table 3
Inhibitory effect of the title complexes on two human tumor cell lines in vitro

Anions[a]	Dose (μg mL^{-1})	S180 Inhibitory effect (%)	Hela Inhibitory effect (%)
$(PW_9)_2(GeR_1)_3$	0.246	21.97	11.65
	2.46	25.67	23.40
	24.6	96.69	97.09
$(PW_9)_2(GeR_2)_3$	0.433	9.36	10.75
	4.33	30.26	10.88
	43.30	95.15	98.39
$(SbW_9)_2(GeR_1)_3$	0.522	17.87	25.75
	5.220	75.71	94.76
	52.20	99.30	98.81
$(SbW_9)_2(GeR_2)_3$	0.501	2.73	8.97
	5.010	20.29	11.45
	50.10	96.57	59.22

[a] Me_4N salts dissolved in DMSO.

that there are two kinds of coordination environment for tungsten in the $(HOOCCH_2CH_2Ge)_3(PW_9)_2$ anions. According to the ^{183}W NMR patterns of trisubstituted heteropolyanions, summarized by Pope [13], the ^{183}W NMR spectra of sandwich structures show two lines with an intensity ratio of 1:2. This fact supports the stoichiometry of the new heteropolyanion and demonstrates that $(HOOCCH_2CH_2Ge)_3(PW_9)_2$ has a normal D_{3h} symmetry containing three $[HOOCCH_2CH_2Ge]^{3+}$ groups sandwiched between two PW_9 anions.

The ^{183}W NMR spectrum for $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ is similar to that of $(HOOCCH_2CH_2Ge)_3(PW_9)_2$, with two lines of relative intensity 1:2, corresponding to the cap tungsten (3W) and belt tungsten atoms (6W), respectively. This also demonstrates that $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ has a normal D_{3h} symmetry containing three $[HOOCCH_2CH_2Ge]^{3+}$ groups sandwiched between two SbW_9 anions.

3.3. Antitumoral activity

The data summarized in Table 3 show that the title complexes display antiproliferation activity to S180 cancer cells and leucocythemia tumor cells.

From Table 3, we can see that the organogermanium-substituted polyoxotungstates have an inhibitory effect on S180 and leucocythemia tumor cells after being treated for about 4 days. The antitumoral activity increases with the increasing of concentration of the POMs. Compared with the inhibitory effect of $Na_8H[PW_9O_{34}]$, the antitumoral activity of the organogermanium-substituted heteropolyanions $(HOOCCH_2CH_2Ge)_3(PW_9)_2$ was higher at a dose of about 52.20 μg mL^{-1}. This fact shows that the antitumoral activity of the heteropolyanions can be increased by grafting organometallic groups onto the polyoxometallate surface, which can help the POMs cross cell membranes easily. Our experience demonstrates the point of Hill [2]. As for these two kinds of organogermanium substituted heteropolyanion, $(RGe)_3(SbW_9)_2$ exhibits higher antitumoral activity than $(RGe)_3(PW_9)_2$. To investigate the antitumoral activity of $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$, further tests have been carried out and the results are listed in Tables 4 and 5.

Table 4
Inhibitory effect of $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ on the S180 human tumor cell line in vitro

Dose (μg mL^{-1})	Inhibitory effect (%)
1	2.47
2	16.87
3.9	49.56
7.8	77.83
15.6	88.54
31.3	98.69

Table 5
Inhibitory effect of $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ and the influence on the spleen of rats bearing the S180 human tumor cell in vivo

Dose (mg kg^{-1})	Mean tumor weight (g)	Splenic index (mg kg^{-1})
Negative control	2.0614 ± 0.3585	7.9494 ± 1.0660
12.5	1.9102 ± 0.3945	8.5828 ± 1.1056
25.0	$0.9922 \pm 0.1751^*$	9.8604 ± 1.0794
75.0	$0.8966 \pm 0.1947^*$	10.5474 ± 1.0892
Positive control	$0.6631 \pm 0.1040^*$	9.2350 ± 1.1631

* $P < 0.05$.

From Table 4 it can be seen that $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ exhibits a higher inhibitory effect on S180 cancer cell in vitro and the antitumoral activity increases with increasing dosage. The experimental results (Table 5) using the animal tumor implantation method show a decreased tumor weight for the rats bearing S180. It can be seen that $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ remarkably decreased the tumor weights of the rats bearing S180, which for a dose of 25 mg kg^{-1}, resulted in a tumor weight decrease of 51.9%.

From Table 5 it can be seen that when rats bearing S180 were treated by $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ (with doses of 25.0 mg kg^{-1} and 75.0 mg kg^{-1}) for about 10 days, the splenic index increases more than the positive group CYT (cyclophosphamide), which means that $(HOOCCH_2CH_2Ge)_3(SbW_9)_2$ can enhance the immune ability of the rats.

To assess the stability of the complexes, they were treated with the same MTT experimental conditions but without adding cancer cells, and the pH of the solution was about 7.2. After evaporation to dryness, IR and ^1H NMR spectra showed that the complexes retained their Keggin structure and the $[RGe]^{3+}$ group was not eliminated from the XW_9 moiety, demonstrating that they are stable under the evaluation conditions.

4. Conclusions

In summary, we have prepared four new organogermanium substituted heteropolytungstates and all the four complexes have showed quite high activity against two of human tumor cell lines in vitro. Unfortunately, all attempts to obtain crystalline materials for X-ray diffraction analysis using variable mixed solutions (e.g. H_2O, H_2O/DMSO and DMSO/Et_2O) were unsuccessful. In addition, compound **4** has exhibited some certain antitumoral activity in vivo and can increase the splenic index.

[10]. Substitution of various groups on the peripheral positions of porphyrazines has been accomplished either starting with an unsaturated dinitrile precursor with this group attached at the beginning (e.g., dimethylaminoethylthio- [16], tosylaminoethylthio- [17], etc.) or a porphyrazine with reactive functional groups has been prepared at first and then additional groups (e.g., ferrocene [18], benzo-15-crown-5 [19–21], pyridine [13], etc.) have been incorporated by further condensation reactions.

Here in this study, a porphyrazine core with eight 4-*tert*-butylphenyl units attached to the peripheral positions through methylthio bridges was synthesized and metal insertion into the inner core resulted with the corresponding cobalt, zinc, and copper porphyrazines. EPR spectra of paramagnetic Cu–porphyrazine have been investigated in solution and powder form.

2. Experimental

IR spectra were recorded on a Mattson 1000 FT-IR spectrophotometer by using KBr pellets and electronic spectra on an Agile 8453 UV–Vis spectrophotometer. ^{1}H NMR spectra were recorded on Bruker 250 MHz spectrometer using TMS as internal reference. The elemental analyses and mass spectra (LC-MS) were determined in the TUBITAK Laboratory (Center of Science and Technology Research of Turkey). Melting points were obtained with a Gallenkamp CAP MPD-350 apparatus in open capillaries. All reagents and solvents were of reagent grade quality obtained from commercial suppliers. The homogeneity of the products was tested in each step by TLC. Chemicals employed were of the highest grade available. Unless specified other wise, reagent grade reactants and solvents were used as received from chemical suppliers. The solvents were stored over molecular sieves. The disodium salt of dithiomaleonitrile (**1**) was prepared according to the previously reported procedures [24].

Cu^{+2} coordinated metallo-porphyrazine has been investigated by using Electron Paramagnetic Resonance (EPR) technique at room temperature. The EPR spectra of (**3c**) compounds in powder form and in chloroform solution have been recorded by a conventional X-band ($\nu = 9.5$–9.85 GHz) Bruker EMX model spectrometer employing an ac magnetic modulation technique.

2.1. Synthesis of 1,2-bis(4-tert-butylbenzylthio)maleonitrile (2)

Disodium salt of dithiomaleonitrile (**1**) (1.5 g, 8 mmol) and 4-*tert*-butylbenzylbromide (2.94 ml, 10 mmol) in ethanol were mixed under argon at ambient temperature for about 15 min. Then the mixture was heated at 100 °C under argon for about 35 h. The precipitate was settled down from red solution by cooling to room temperature and it was filtered out. The precipitate was dissolved in diethyl ether and filtered to remove any excess disodium salt of dithiomaleonitrile. Finally pale yellow crystals were obtained by evaporation of the solvent under reduced pressure. It was soluble in chloroform, dichloromethane, diethyl ether and acetone. Yield: 2.95 g (85%); m.p. 88 °C. FT-IR (KBr), $\nu_{max}/(cm^{-1})$: 3028 (H–Ar), 2961 C–$(CH_3)_3$, 2209 (C≡N), 1492, 1174, 823, 743, 691. ^{1}H NMR ($CDCl_3$ 250 MHz): $\delta = 7.37$–7.24 (m, 4H, Ar–H), 4.28 (s, 2H, CH_2–S), 1.3 (s, 9H, $(CH_3)_3$–C).

2.2. [2,3,7,8,12,13,17,18-Octakis(4-tert-butylbenzylthio)-porphyrazinato]Mg(II) (3a)

Mg turnings (0.0378 g, 1.575 mmol) and a small I_2 crystal were refluxed in *n*-BuOH (7 ml) for about 20 h to obtain $Mg(BuO)_2$. When 1,2-bis(4-*tert*-butylbenzylthio)maleonitrile (**2**) was added to this suspension and the mixture was refluxed for about 10 h, a dark blue suspension was obtained. The mixture was filtered while hot, washed with *n*-BuOH and the combined filtrates were evaporated under reduced pressure. The remaining oily product was treated with refluxing methanol (30 ml) to dissolve any unreacted maleonitrile and the methanol solution was decanted. The blue–green product was washed with methanol, filtered and dried *in vacuo*. The crude product was purified by column chromatography on silicagel using dichloromethane as the eluent. The pure blue–green porphyrazine was obtained by drying *in vacuo*. Yield: 0.426 g (%81); m.p. >300 °C. FT-IR (KBr), $\nu_{max}/(cm^{-1})$: 3028 (H–Ar), 2978 C–$(CH_3)_3$, 1511, 1462, 1252, 1201, 1105, 1018, 834, 751, 701. ^{1}H NMR ($CDCl_3$ 250 MHz): $\delta = 7.31$–7.10 (m, 4H, Ar–H), 4.91 (s, 2H, CH_2–S), 1.14 (s, 9H, $(CH_3)_3$–C).

2.3. [2,3,7, 8,12,13,17,18-Octakis(4-tert-butylbenzylthio) ^{21}H, ^{23}H porphyrazine] (3b)

Compound **3a** (985 mg, 0.559 mmol) was dissolved in minimum amount of CF_3COOH and stirred overnight at room temperature. The reaction mixture was added into ammonia solution (25%, 7 ml) to neutralize and then cooled overnight at 0 °C. It was treated with chloroform and then the organic phase was washed first with water, then with a solution of 10% Na_2CO_3 and then with water again. The chloroform phase was dried over anhydrous Na_2SO_4 and the solvent was evaporated *in vacuo*. The oily product was treated with a small amount of diethyl ether by cooling in an ice-bath to enhance precipitation. The precipitate formed was filtered when cold. Finally, pure violet colored metal-free porphyrazine was obtained after cooling *in vacuo*. The product was soluble in chloroform, dichloromethane and THF. Yield: 0.341 g (%35). FT-IR (KBr), $\nu_{max}/(cm^{-1})$: 3289 (N–H), 3024 (H–Ar), 2956 C–$(CH_3)_3$, 1513,1461, 1201, 834, 741, 703. ^{1}H NMR ($CDCl_3$ 250 MHz): $\delta = 7.33$–7.17 (m, 4H, Ar–H), 5.18 (s, 2H, CH_2–S), 1.17 (s, 9H, (CH_3)–C), −1.55 (br, 2H, N–H).

2.4. General procedure for metallo-porphyrazines (3c–3e)

To a solution of anhydrous metal salt [$Cu(CH_3COO)_2$ (187 mg, 0.094 mmol), 0.021 g (0.094 mmol) $Zn(CH_3$-

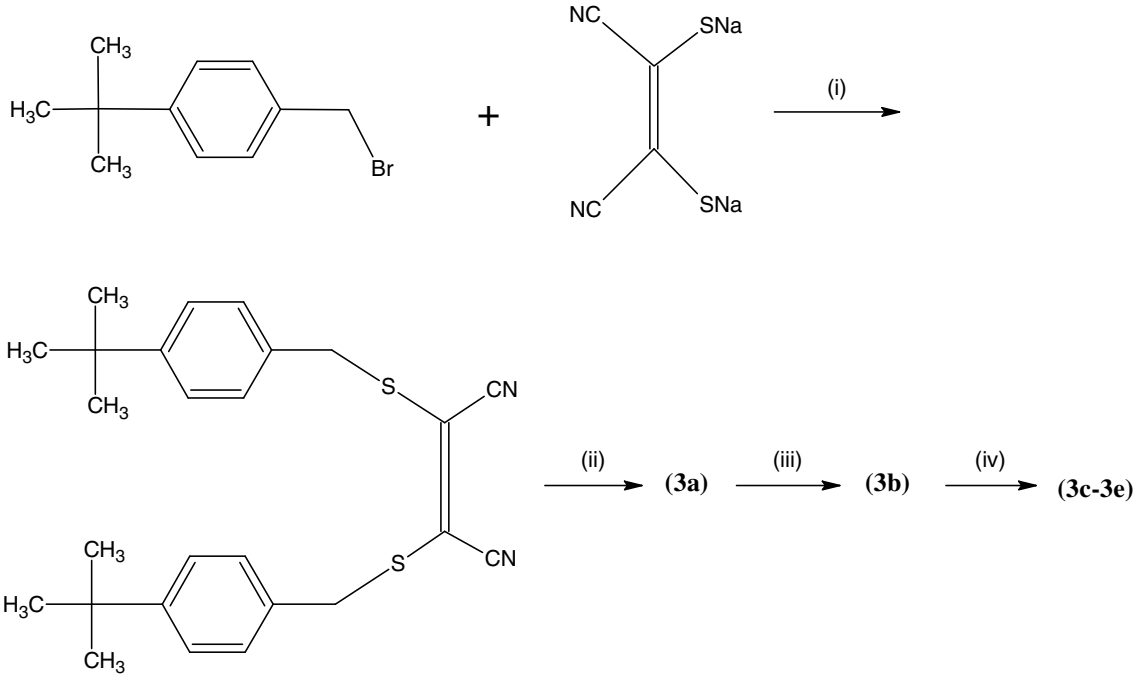
$COO)_2$ or 0.028 g (0.114 mmol) $Co(CH_3COO)_2$] in 10 ml of ethanol was added a solution of **3b** (80 mg, 0.046 mmol) in 10 ml of THF and sealed under Ar. The mixture was stirred and refluxed for 18 h in an oil bath. After cooled to ambient temperature, a precipitate made up of the crude product and the excess metal salt was formed. It was filtered and washed with hot THF. The filtrates were combined and the solvent was evaporated under reduced pressure. The remaining product was first treated with hot water to remove any unreacted metal salt, then washed with methanol and dried *in vacuo*. Finally, pure dark blue porphyrazine derivatives were obtained. The products were very soluble in chloroform, THF and dichloromethane.

*2.4.1. [2,3,7,8,12,13,17,18-Octakis(4-tert-butylbenzylthio)-porphyrazinato]Cu(II) (**3c**)*

Yield: 70 mg (75%). FT-IR (KBr) $\nu_{max}/(cm^{-1})$: 3025 (H–Ar), 2957 C–$(CH_3)_3$, 1511, 1462, 1252, 1201, 1105, 1018, 834, 751, 705.

*2.4.2. [2,3,7,8,12,13,17,18-Octakis(4-tert-butylbenzylthio)-porphyrazinato]Co(II) (**3d**)*

Yield: 96 mg (93%). FT-IR (KBr) $\nu_{max}/(cm^{-1})$: 3025 (H–Ar), 2956 C–$(CH_3)_3$, 1511, 1463, 1253, 1202, 1106, 1025, 835, 752, 705.



*2.4.3. [2,3,7,8,12,13,17,18-Octakis(4-tert-butylbenzylthio)-porphyrazinato]Zn(II) (**3e**)*

Yield: 66 mg (80%). FT-IR (KBr) $\nu_{max}/(cm^{-1})$: 3023 (H–Ar), 2978 C–$(CH_3)_3$, 1513, 1463, 1201, 1106, 1017, 835, 744, 702. ^1H NMR ($CDCl_3$ 250 MHz): $\delta = 7.17$–7.12 (m, 4H, Ar–H), 4.95 (s, 2H, CH_2–S), 1.16 (s, 9H, (CH_3)–C).

3. Results and discussion

3.1. Synthesis and characterization

The starting point of this new porphyrazine structure with eight (4-*tert*-butylbenzylthio) groups bound to the periphery is 1,2-bis-(4-*tert*-butylbenzylthio)maleonitrile (**2**) which was obtained from disodium salt of dithiomaleonitrile (**1**) and 4-*tert*-butylbenzylbromide (Scheme 1). The solid product (**2**) was obtained in relatively high yield (85%). The presence of electron donating S-groups is expected to shift the absorption range of the porphyrazine Q-band to higher wavelength and *tert*-butyl groups to enhance solubility [25–29]. The cyclotetramerization process of dinitrile derivative (**2**) by the template effect of magnesium butanolate in butanol resulted with the blue–green octakis(4-*tert*-butyl-benzylthio)porphyrazinatomagnesium (**3a**) in 81% yield (Fig. 1). It is very soluble in hexane, chloroform, acetone, dichloromethane and DMF, but in soluble in ethanol, benzene and ether. Treatment of this magnesium compound with a strong organic acid (such as triflouroacetic acid) at room temperature for 8 h afforded the metal-free derivatives (**3b**). Thus, the free base porphyrazine were obtained in a reasonable yield of 30–40%. Apparent differences between magnesium and metal-free derivatives are the change of color from the dark blue–green to purplish blue and lowering in the solubility. Insertion of metal ions into (**3b**) with various metal (II) acetates (M = Cu, Co, Zn) at reflux temperature in THF and ethanol afforded derivatives (**3c**–**3e**) in approximately quantitative yield. Elemental analysis results closely follow the values calculated for (**2**, **3a**–**3e**) (Table 1).

Scheme 1. (i) Methanol; (ii) Mg turnings, I_2, *n*-BuOH; (iii) CF_3CO_2H; (iv) EtOH and $Cu(OAc)_2$, $Co(OAc)_2$, or $Zn(OAc)_2$.

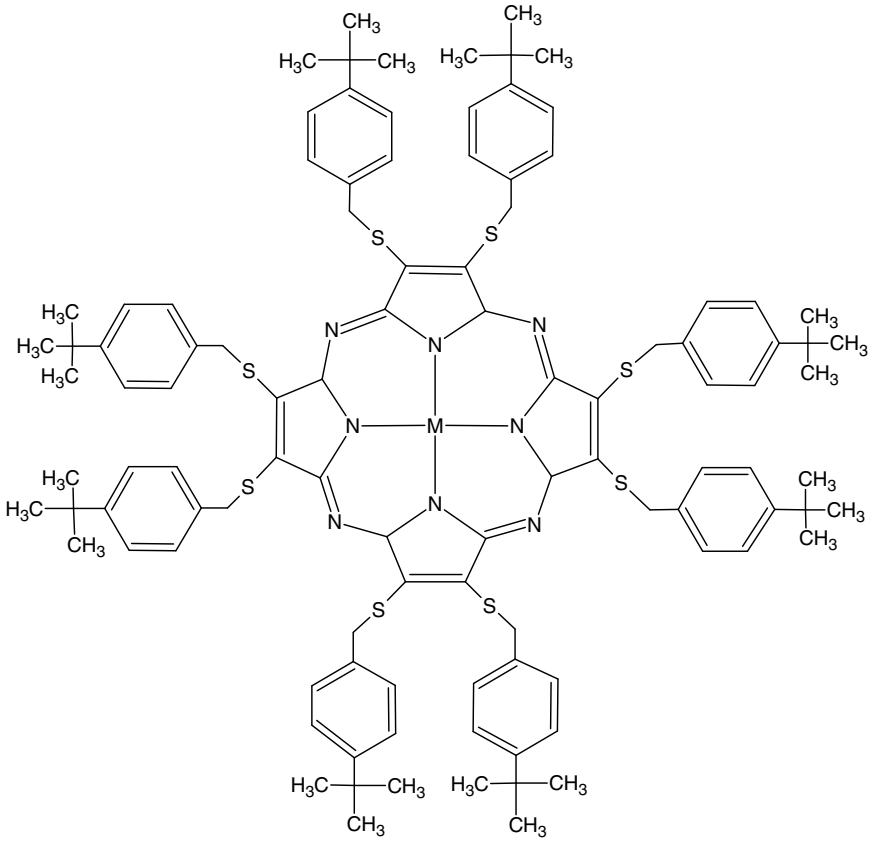


Fig. 1. Octakis(4-*tert*-butylbenzylthio) substituted porphyrazines (M = Mg (**3a**); 2H (**3b**); Cu (**3c**); Co (**3d**); Zn (**3e**)).

Table 1
Elemental analyses results of the porphyrazines[a]

Compound	C	H	N
2	71.84 (71.38)	6.96 (6.98)	6.96 (6.54)
3a	69.55 (69.11)	6.86 (7.13)	6.36 (6.12)
3b	70.48 (70.06)	7.08 (7.57)	6.44 (6.61)
3c	68.61 (68.25)	6.71 (6.57)	6.22 (5.84)
3d	68.49 (68.83)	6.93 (7.44)	6.23 (5.81)
3e	68.94 (68.56)	6.70 (7.12)	6.21 (5.88)

[a] Required values are given in parentheses.

Spectroscopic investigations on the newly synthesized intermediates and porphyrazines are in accordance with the proposed structures. Comparison of the FT-IR spectra of each step gave some hints related to the nature of the product. In the FT-IR spectrum of (**2**) stretching vibration of C≡N is observed at 2213 cm^{-1}, *tert*-butyl peak around 2978 cm^{-1}, S–CH_2 peak around 680 cm^{-1} and aromatic C–H peaks around 3028 cm^{-1}. These values comply with those reported in the literature for similar compounds [30]. The sharp C≡N vibration around 2213 cm^{-1} had disappeared after the formation of porphyrazine (**3a**). After demetalation of (**3a**), the N–H stretching vibration of the inner core of the metal-free porphyrazine (**3b**) was observed around 3289 cm^{-1} as expected [31,32]. The FT-IR spectra of all MPz derivatives (**3a**–**3e**) were very similar (M = Mg, Cu, Co, Zn) as expected [30].

In the ^{1}H NMR spectra of **2**, **3a** and **3b** chemical shifts corresponding to *tert*-butyl protons came out at the expected values: a singlet at 1.3 ppm in (**2**), 1.14 ppm in (**3a**) or 1.17 ppm in (**3b**) corresponding to *tert*-butyl groups. Inner core –NH protons of metal-free porphyrazine (**3b**) appear as a deuterium exchangeable broad chemical shift at −1.55 ppm indicating the typical shielding of inner core protons which is a common feature of the ^{1}H NMR spectra of metal-free porphyrazines [17,31,33,34].

The electronic absorption spectra of all the metallo-porphyrazines (**3a**, **3c**–**3e**) exhibit a strong absorption between 648 and 680 nm which is due to a $\pi \rightarrow \pi^*$ transition and is commonly referred to as Q-band that the first intense bands of porphyrazine core are dominated. A second intense and broad $\pi \rightarrow \pi^*$ transition in the near UV region of the range 343–380 nm which is called soret or B-band is also a characteristic of these tetrapyrole derivatives [16,17]. UV–Vis spectra of metallo-porphyrazines (**3a** in $CHCl_3$, **3c**–**3e** in $CHCl_2$) prepared in the present work exhibited intense single Q-band absorption of the $\pi \rightarrow \pi^*$ transition around 648–679 nm and B-bands in the UV region around 338–382 nm (Fig. 2). As expected the metal-free derivative (**3b**) shows a splitted Q-band at 647 and 714 nm because of the change of symmetry of porphyrazine core from D_{4h} in the case of metallo-species to D_{2h} in the metal-free ones (Table 2) [35–37].

UV–Vis spectra were measured at different levels of concentration to assess whether or not compound **3d** reveals

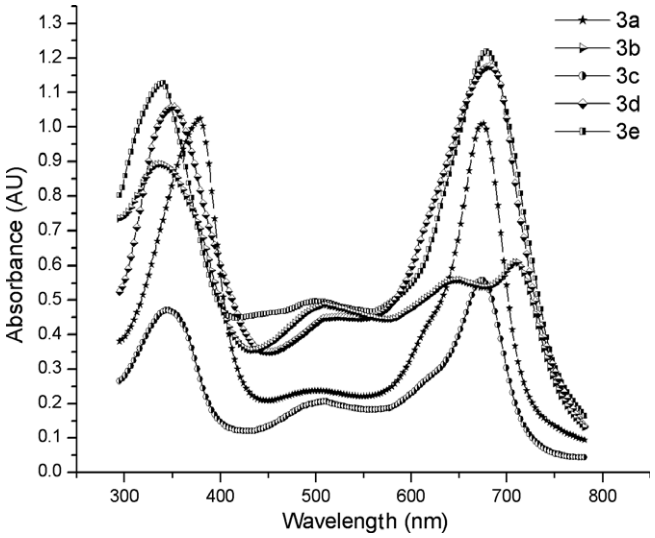

Fig. 2. Electronic spectra of octakis(4-*tert*-butylbenzylthio) substituted porphyrazines **3a**, **3b**, **3c**, **3d** and **3e** as 4×10^{-5} M solutions in dichloromethane.

Table 2
UV–Vis data for the porphyrazines in dichloromethane

Compound	Band λ/nm (log ε/dm^3 mol^{-1} cm^{-1})		
	B	Q	
3a	380 (4.42)	678 (4.38)	
3b	352 (3.97)	653 (3.75)	714 (3.88)
3c	346 (4.24)	674 (4.26)	
3d	352 (4.38)	684 (4.32)	
3e	340 (4.31)	679 (4.35)	

aggregation property. In the light of the results obtained, it was observed that the compound did not show appreciable aggregation in the concentration range of 10^{-3}–10^{-6} M.

3.2. EPR studies for Cu(II) doped porphyrazine

We have tried to measure the room temperature paramagnetic properties of Cu(II) doped porphyrazine sample as powder and solution forms. The first-derivative EPR signals taken from powder and solution forms are shown in Fig. 3. As seen from the figure, the first signal is that of the powder form and it seems to have a single EPR signal with isotropic character and does not contain hyperfine lines. Sometimes, the EPR spectra taken from powder complexes do not exhibit any hyperfine lines at both perpendicular and parallel parts of the spectrum as reported in some Cu(II) complexes [38–40]. The reason must be the exchange-narrowing effect between Cu(II) ions. Therefore, one can expect hyperfine structure in the EPR spectra due to the magnetic interactions between electronic spins ($S = 1/2$) and the nuclear spins ($I = 3/2$). Generally, this interaction can give rise a splitting about a few tens Oersteds which is easily measurable in most of the cases. The absence of hyperfine structure suggests the existence of exchange interactions between electronic spins of Cu(II) ions in the chain. If there is sufficiently strong exchange

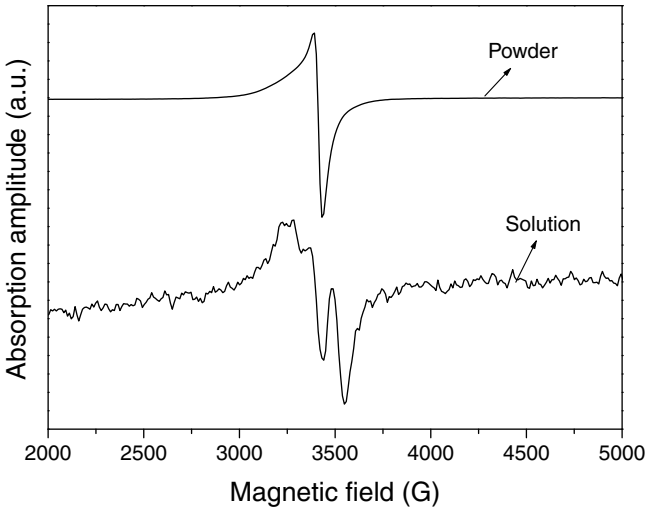

Fig. 3. X-band EPR spectra of (**3c**) as powder form and as chloroform solution at room temperature.

interaction between neighboring electronic spins, then any spin on a particular Cu(II) ion can move around and interact with the nuclear spins of other Cu(II) or nitrogen ions having statistically distributed different nuclear state. The average values of the nuclear spin of different Cu(II) ion cancel out. Thus, the observed EPR spectrum does not exhibit hyperfine features. In this case, the hyperfine structure is completely compressed. That is, the exchange interaction is remarkably strong. The $g_{\|}$ and $g_{\perp}$ values are related by an expression $G = (g_{\|} - 2)/(g_{\perp} - 2)$ and found to be less than 4, which supports the exchange interaction among Cu(II) ions, as well [39].

When we dissolve the powders in chloroform, we can see an EPR spectrum (Fig. 3) for a conventional powdered sample containing a paramagnetic ion with an axially symmetric g factor with $g_{\|} > g_{\perp}$ ($g_{\|} = 2.15$ and $g_{\perp} = 2.04$) and with hyperfine splitting. Namely, the local symmetry of the paramagnetic center giving this signal should be axial. The trend $g_{\|} > g_{\perp} > 2$ indicates that the unpaired electron is located mainly in the $d_{x^2-y^2}$ orbital ($^2B_1$ as ground state) [38]. Here $g_{\|}$ and $g_{\perp}$ denote effective g-values when the applied dc field is parallel ($B_{\|}$) and perpendicular ($B_{\perp}$) to the symmetry axis around the paramagnetic center, respectively. As it is expected, the absorption corresponding to $g_{\perp}$ is more intensive than that of $g_{\|}$ in statistically and randomly oriented solids [40]. Also, the g-value seems to be highly anisotropic.

The Hamiltonian describing an axially symmetric Zeeman interaction can be written as

$$H_{\text{aiso}} = \beta_e(g_{\perp}(B_xS_x + B_yS_y) + g_{II}(B_zS_z)) \quad (1)$$

where β_e and S denote Bohr magneton and the electronic spin angular momentum of the magnetic ion, respectively.

4. Conclusion

In conclusion, we have described the synthesis and spectral characterization of new porphyrazines with bulky

(*tert*-butylphenyl) groups on the periphery. The distinctive property of these compounds is that they have a good solubility in polar organic solvents. The presence of bulky *tert*-butyl groups hindered aggregation at relatively higher concentrations (e.g., 10^{-3} M).

The EPR spectra indicate axial symmetry around paramagnetic Cu^{+2} ion coordinated porphyrazines compounds. Spin Hamiltonian parameters fitted well. Orbital energy levels for magnetic electrons were obtained from Spin Hamiltonian parameters as well. Especially Cu^{+2} coordinated compound shows stronger covalency effects with neighboring N atoms.

HL^2. The mode of coordination of these ligands is determined by the nature of the anion of the parent salt.

2. Experimental

2.1. Materials and instrument

Elemental analyses were performed by atomic absorption spectroscopy (for metals) and with a Perkin–Elmer 2400 CHN Analyzer (for C, H and N). Infrared spectra were recorded as KBr pellets on a UR-20 spectrophotometer in the 4000–400 cm^{-1} region using conventional techniques. Electronic spectra of the compounds in chloroform were recorded on a LOMO MDR-23 spectrophotometer in the 400–800 cm^{-1} region at room temperature. EPR spectra of the powder samples and their solutions in DMF were recorded on a Bruker ESP 300E spectrometer at room temperature and at 77 K. ^1H NMR spectra in DMSO-d^6 solution were recorded on a Varian 400 spectrometer (with Me_4Si as an internal standard) at room temperature.

2.2. X-ray analysis

The crystals of $[CuL_2^1]\cdot H_2O$ are orthorhombic. At 293 K, $a = 13.131(3)$, $b = 14.556(3)$, $c = 13.383(2)$ Å, $V = 2558.4(3)$ Å^3, $M_r = 570.14$, $Z = 8$, space group $Pca2_1$, $d_{calc} = 1.480$ g/m^3, μ(Mo Kα) = 1.060 mm^{-1}, $F(000) = 1172$. Intensities of 25206 reflections (5771 independent, $R_{int} = 0.02$) were measured on an Xcalibur-3 diffractometer (graphite monochromator Mo Kα radiation, CCD detector, ω-scanning, $2\Theta_{max} = 55°$). The absorption correction was made by the semi-empirical method [6] ($T_{min} = 0.475$, $T_{max} = 0.718$). The structure was solved by the direct method using the SHELXTL package [7]. Positions of hydrogen atoms were located from the electron density difference maps and refined by the "riding" model with $U_{iso} = nU_{eq}$ of the non-hydrogen atom bonded with the given hydrogen atom ($n = 1.5$ for methyl and hydroxyl groups and $n = 1.2$ for other hydrogen atoms). Full-matrix least-squares refinement against F^2 in an anisotropic approximation for non-hydrogen atoms using 5753 reflections was converged to $wR_2 = 0.151$ ($R_1 = 0.050$ for 4527 reflections with $F > 4\sigma(F)$, $S = 1.031$).

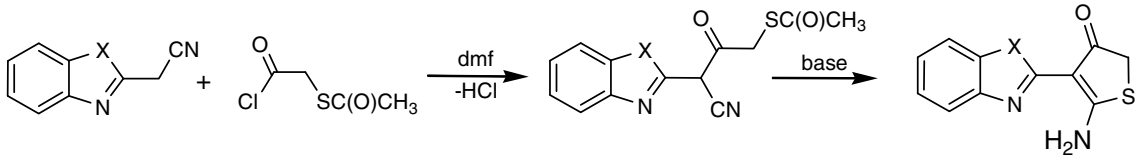
2.3. Preparations

The ligands HL^1 and HL^2 were prepared as described in the literature [8] according to Scheme 1.

2.3.1. Preparation of $[CuL_2^1]\cdot H_2O$ (1)

To a solution of $Cu(CH_3COO)_2\cdot H_2O$ (1.5 mmol) in 5 ml methanol was added a 10 ml methanol solution of HL^1 (3 mmol). The resulting solution was allowed to stand above $CaCl_2$ at room temperature. Dark violet crystals of **1** suitable for X-ray crystallography were formed after 2 days. The crystals were filtered off, washed with methanol and dried in air. The collected mass was 56 mg, yield: 67%. *Anal.* Calc. for $C_{24}H_{22}N_6O_3S_2Cu$: C, 50.56; H, 3.89; N, 14.74; Cu, 11.15. Found: C, 50.66; H, 3.75; N, 14.68; Cu, 11.23%. IR (KBr pellet, cm^{-1}): $\nu = 1630$ (C=O), 1535 (C=N), 3335 (N–H). The compound is soluble in chloroform, toluene, DMSO and DMF.

2.3.2. Preparation of $[ZnL_2^1]$ (2)



This complex was obtained in a similar manner to **1**, except with the use of $Zn(CH_3COO)_2\cdot 2H_2O$ instead of $Cu(CH_3COO)_2\cdot H_2O$. The collected mass was 54 mg, yield: 65%. *Anal.* Calc. for $C_{24}H_{20}N_6O_2S_2Zn$: C, 52.04; H, 3.64; N, 15.17; Zn, 11.80. Found: C, 52.10; H, 3.57; N, 15.22; Zn, 11.75%. IR (KBr pellet, cm^{-1}): $\nu = 1620$ (C=O), 1530 (C=N), 3345 (N–H). The compound is soluble in DMSO and DMF.

2.3.3. Preparation of $[NiL_2^1]\cdot 2H_2O$ (3)

This complex was obtained in a similar manner to **1**, except with the use of $Ni(CH_3COO)_2\cdot 4H_2O$ instead of $Cu(CH_3COO)_2\cdot H_2O$. The collected mass was 49 mg, yield: 60%. *Anal.* Calc. for $C_{24}H_{22}N_6O_4S_2Ni$: C, 49.42; H, 4.15; N, 14.42; Ni, 10.06. Found: C, 49.32; H, 4.17; N, 14.32; Ni, 9.95%. IR (KBr pellet, cm^{-1}): $\nu = 1640$ (C=O), 1540 (C=N), 3340 (N–H). The compound is soluble in chloroform, toluene, DMSO and DMF.

2.3.4. Preparation of $[CuL_2^2]\cdot H_2O$ (4)

To a solution of $Cu(CH_3COO)_2\cdot H_2O$ (1.5 mmol) in 5 ml methanol was added a 10 ml chloroform solution of HL^2 (3 mmol). The resulting solution was allowed to stand above $CaCl_2$ at room temperature. The crystalline product

X = N-CH$_3$ (HL^1)
X = S (HL^2)

Scheme 1.

of **4** was filtered off, washed with methanol and dried in air. The collected mass was 53 mg, yield: 68%. *Anal.* Calc. for $C_{22}H_{16}N_4O_3S_2Cu$: C, 45.86; H, 2.80; N, 9.72; Cu, 11.03. Found: C, 45.91; H, 2.76; N, 9.74; Cu, 11.10%. IR (KBr pellet, cm^{-1}): $\nu = 1620$ (C=O), 1550 (C=N), 3230 (N–H). The compound is soluble in DMSO and DMF.

*2.3.5. Preparation of $[ZnL^2_2]$ (**5**)*

This complex was obtained in a similar manner to **4**, except with the use of $Zn(CH_3COO)_2 \cdot 2H_2O$ instead of $Cu(CH_3COO)_2 \cdot H_2O$. The collected mass was 61 mg, yield: 73%. *Anal.* Calc. for $C_{22}H_{14}N_4O_2S_2Zn$: C, 47.19; H, 2.52; N, 10.0; Zn, 11.67. Found: C, 48.06; H, 2.61; N, 14.74; Zn, 11.55%. IR (KBr pellet, cm^{-1}): $\nu = 1630$ (C=O), 1530 (C=N), 3340 (N–H). The compound is soluble in DMSO and DMF.

*2.3.6. Preparation of $[NiL^2_2]$ (**6**)*

This complex was obtained in a similar manner to **4**, except with the use of $Ni(CH_3COO)_2 \cdot 4H_2O$ instead of $Cu(CH_3COO)_2 \cdot H_2O$. The collected mass was 49 mg, yield: 60%. *Anal.* Calc. for $C_{22}H_{14}N_4O_2S_2Ni$: C, 47.75; H, 2.55; N, 10.14; Ni, 10.61. Found: C, 47.64; H, 2.53; N, 10.08; Ni, 11.58%. IR (KBr pellet, cm^{-1}): $\nu = 1640$ (C=O), 1535 (C=N), 3335 (N–H). The compound is soluble in chloroform, DMSO and DMF.

*2.3.7. Preparation of $[CoL^2_2] \cdot 2H_2O$ (**7**)*

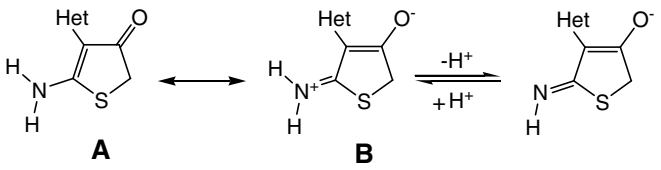
This complex was obtained in a similar manner to **4**, except with the use of $Co(CH_3COO)_2 \cdot 4H_2O$ instead of $Cu(CH_3COO)_2 \cdot H_2O$. The collected mass was 48 mg, yield: 59%. *Anal.* Calc. for $C_{22}H_{18}N_4O_4S_2Co$: C, 44.82; H, 3.08; N, 9.50; Co, 10.00. Found: C, 44.76; H, 3.13; N, 9.46; Co, 10.03%. IR (KBr pellet, cm^{-1}): $\nu = 1630$ (C=O), 1530 (C=N), 3320 (N–H). The compound is soluble in chloroform, DMSO and DMF.

*2.3.8. Preparation of $[Cu(HL^1)_2Cl_2]$ (**8**)*

To a solution of $CuCl_2$ (1.5 mmol) in 5 ml methanol was added a 10 ml methanol solution of HL^1 (3 mmol). The resulting solution was allowed to stand above $CaCl_2$ at room temperature. The crystalline product of **8** was filtered off, washed with methanol and dried in air. The collected mass was 51 mg, yield: 55%. *Anal.* Calc. for $C_{24}H_{22}N_6O_2S_2Cl_2Cu$: C, 46.12; H, 3.55; N, 13.45; Cu, 10.17. Found: C, 45.99; H, 3.51; N, 13.41; Cu, 10.13%. IR (KBr pellet, cm^{-1}): $\nu = 1630$ (C=O), 1560 (C=N), 3330, 3250 (N–H). The compound is soluble in DMSO and DMF.

*2.3.9. Preparation of $[Zn(HL^1)_2Cl_2]$ (**9**)*

This complex was obtained in a similar manner to **8**, except with the use of $ZnCl_2$ instead of $CuCl_2$. The collected mass was 50 mg, yield: 55%. *Anal.* Calc. for $C_{24}H_{22}N_6O_2S_2Cl_2Zn$: C, 45.98; H, 3.54; N, 13.41; Zn, 10.43. Found: C, 46.21; H, 3.49; N, 13.46; Zn, 10.51%. IR (KBr pellet, cm^{-1}): $\nu = 1625$ (C=O), 1550 (C=N), 3325, 3230 (N–H). The compound is soluble in DMSO and DMF.



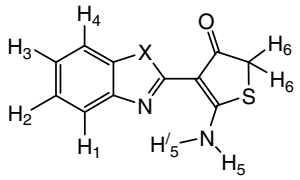
*2.3.10. Preparation of $[Ni(HL^1)_2Cl_2]$ (**10**)*

This complex was obtained in a similar manner to **8**, except with the use of $NiCl_2$ instead of $CuCl_2$. The collected mass was 46 mg, yield: 50%. *Anal.* Calc. for $C_{24}H_{22}N_6O_2S_2Cl_2Ni$: C, 46.48; H, 3.58; N, 13.55; Ni, 9.47. Found: C, 46.51; H, 3.52; N, 13.46; Ni, 9.50%. IR (KBr pellet, cm^{-1}): $\nu = 1640$ (C=O), 1540 (C=N), 3340 (N–H). The compound is soluble in DMSO and DMF.

3. Results and discussions

As was already remarked earlier, 2-amino-4(5H)-ketothiophens can coordinate to metal ions in the neutral and deprotonated forms. The deprotonated form of 2-amino-4(5H)-ketothiophens is realized in those cases where acetate salts are used as a starting reactant. Such behaviour of HL^1 and HL^2 is explained by the acidic nature of the amine hydrogen of these ligands, which is caused by the considerable contribution of the bipolar resonance structure B (see Scheme 2), characteristic for 2-amino-4-keto derivatives of five-membered heterocyclic systems [9]. The complexes with the neutral form of HL^1 are formed on using metal chlorides as the starting salts. These compounds are characterized by considerably less stability on comparison with the complexes with the deprotonated ligand. This behaviour is caused by the low basicity of the amine nitrogen of the ligands. Therefore, coordination compounds with the deprotonated ligand HL^2 cannot be obtained under such conditions.

The structural features of the complexes were determined by IR, electronic, EPR and ^1H NMR spectroscopy and from a single-crystal X-ray study (for **1**). A bidentate coordination of the ligands through the nitrogen atom of the heterocyclic substitute and the amino group of the ketothiophen was proposed based on the IR-spectra. The shift of the absorption band of stretching vibrations ν(C=N) to lower frequencies was used as a criterion of the ligand coordination to the 3d-metal ions. The value of $\Delta\nu$(C=N) for complexes with HL^1 amounted to 60–80 cm^{-1}, while in the case of complexes with HL^2 this value was lower ($\Delta\nu$(C=N) = 50–70 cm^{-1}). The stretching vibrations of the carbonyl group are shifted in the high-frequency region by 5–10 cm^{-1}. This fact can be used as an evidence for the non-participation of the carbonyl oxygen for formation of a coordination bond with the metal ion



Scheme 2.

[10]. The IR spectra of 2-amino-4(5H)-ketothiophens show, in the 3100–3400 cm^{-1} region, two bands due to symmetric and asymmetric stretching vibrations of the NH_2 group, while complexes **1**–**7** show only one band in this region. The disappearance of one band assigned to the stretching vibrations of the N–H bond is related to the substitution of the amine proton by a metal ion. The values of ν(N–H) for all the complexes lie in the range 3310–3350 cm^{-1}, excluding complex **4** – in this case the value of ν(N–H) is 3270 cm^{-1}. Such a difference in the positions of the absorption bands is probably caused by the formation of hydrogen bonds between the amino group of the ligand and molecules of solvent. The IR spectra of coordination compounds **8**–**10** show stretching vibrations of the amino group ν(N–H) around 3320–3330 cm^{-1} (asymmetrical), 3240–3250 cm^{-1} (symmetrical) and an intense band in the 1550–1560 cm^{-1} region corresponds to ν(C=N).

The coordination compounds of zinc, **2** and **5**, were studied using the method of ^1H NMR spectroscopy. As shown in Table 1, the chemical shifts of the protons of the free ligands differ from the ones for the coordination compounds, which are related with the redistribution of electronic density in organic molecule during coordination to the zinc ion. It is necessary to remark that due to the ligand coordination by the metal ion, the biggest shift value (0.5–0.7 ppm) is observed for the aromatic ring proton H(1), located near the coordination centre (see Scheme 3). The existence of ligands in the deprotonated form is confirmed by the disappearance of a signal from one proton of the amino group H(5′) in the NMR spectra of the complexes. Additionally, the signal of the proton H(5) (singlet at 8.23 ppm for **2** and at 9.04 ppm for **5)** is shifted to higher field on comparison with the free ligands, which proves the coordination of the ligands by the zinc ion through the nitrogen atom of the deprotonated amino group. Consequently it is possible to assert that compounds **2** and **5** have similar structures.

The electronic spectrum of a chloroform solution of nickel complex **3** shows two bands at 21 000 and 16 000 cm^{-1}, which can be reasonably assigned to the $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transitions, respectively, suggesting an octahedral geometry of the Ni(II) coordination sphere. In the spectrum of a chloroform solution of complex **6** there is one intensive band at 22 000 cm^{-1}, in contrast to the previous compound. The band in the spectrum of **6** appears due to the electronic transitions typical for a Ni(II) ion in a square-planar surrounding [11]. Such a difference in the structure of coordination compounds **3** and **6** is explained by the different structure of the ligands. It is worth noting that the essential repulsion between the methyl and carbonyl groups induces a significant deviation of the ligand HL^1 from the mean plane passing through the methylbenzoimidazole fragment and thiophene ring. Such a structure of the ligand HL^1 does not provide the possibility of the formation of square-planar complexes. In turn, the ligand HL^2 has a planar structure, which is realized due to the presence of an intramolecular S···O-interaction between the oxygen of the carbonyl group and the sulfur of the benzothiazole substitute. The electronic spectrum of a chloroform solution of complex **7** shows only one band in the visible region at 18 600 cm^{-1}, which can be reasonably assigned to the $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transition, suggesting an octahedral geometry of the cobalt(II) coordination sphere.

X = N-CH_3 (HL^1)
X = S (HL^2)

Scheme 3.

The EPR spectrum of the polycrystalline complex **4** was recorded at room temperature (see Fig. 1). The form of the spectrum is characteristic for mononuclear complexes of Cu(II) with a square-planar surrounding ($g_\perp = 2.067$, $g_\parallel = 2.232$). Also the spectra of compound **4** were recorded in DMF solution at room temperature and at 77 K. Interpretation of the EPR spectrum at 293 K is not possible because of its low quality, which is related to the significant dissociation of the complex. The EPR spectrum of a frozen solution has an axially symmetric form with a divided hyperfine structure in the region of parallel orientation, which is caused by the interaction of an unpaired electron with the nucleus of copper(II) ($I_{Cu} = 3/2$). The EPR spectrum of compound **4** shows three lines in the region of parallel orientation, the fourth line is overlapped by a more intensive line of perpendicular orientation. It displays the following spin-Hamiltonian parameters $g_\parallel = 2.222$; $g_\perp = 2.069$; $A_\parallel = 162 \times 10^{-4}$ cm^{-1}, which are characteristic for copper complexes with N-donor ligands. The EPR

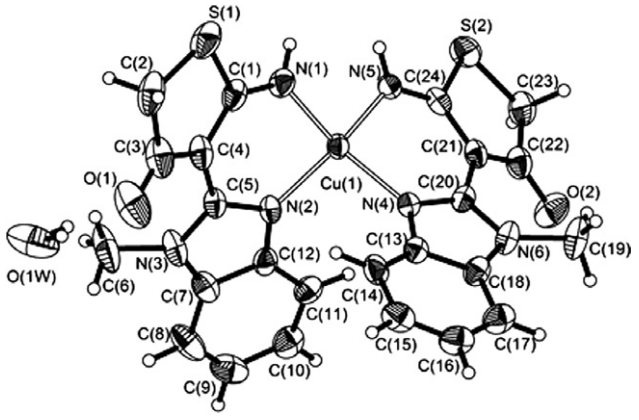
spectrum does not display any superhyperfine features either in the $g_{\|}$ or in the $g_{\perp}$ region, however the large linewidths of the EPR spectra most likely result from the unresolved interaction of the unpaired electron with the nuclear spin of the coordinated nitrogen atoms (^{14}N; $I = 1$), as found for other copper complexes with N-donor ligands [12,13].

An X-ray diffraction study was carried out for compound **1**. In the crystal phase this compound exists as the monohydrate (see Fig. 2). The coordination polyhedron of the Cu(1) atom is formed by four nitrogen atoms of two ligands and the metal has intermediate coordination pattern between tetrahedral and square-planar coordination. The nitrogen atoms of the organic ligands are not coplanar. The angle between the N(1)···N(2) and N(4)···N(5) lines is 38.5°. The nitrogen atoms of the imino group and the heterocyclic substituent of the ligand $(L^1)^-$ are located in *cis*-positions relative to each other. The Cu–N bond lengths (N is the nitrogen of the imino group) are within 1.939–1.959 Å (see Table 2). Such values of the bond lengths are related to the formation of partly covalent bonds, which is typical for amide complexes of copper



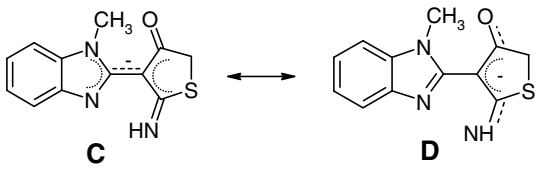


Fig. 2. The molecular structure of the compound $[CuL^1_2] \cdot H_2O$ with 30% probability thermal ellipsoids.

C(5)–N(2)–Cu(1)	125.1(3)	N(5)–C(24)–C(21)	127.9(4)

(with Cu–N bond lengths of 1.91–1.96 Å [14,15]). According to the literature data [16], the length of the Cu···N distance for the coordinated heterocyclic substituent is longer (1.970–1.979 Å). The Cu(1), N(1), C(1), C(4), C(5), N(2) and Cu(1), N(5), C(24), C(21), C(20), N(4) six-membered metallocycles adopt a twist-boat conformation. Deviations of the C(1), N(1) and C(24), N(5) atoms from the mean plane of the remaining atoms of the rings are −0.44, −0.70 and 0.27, 0.54 Å, respectively.

Analysis of the bond lengths within the heterocyclic ligands reveals significant delocalization of the electron density due to the presence of the negative charge. The redistribution of the electron density in the ligands allows the assumption that the structure of these anions can be described as a superposition of two resonance structures C and D (see Scheme 4). The C(1)–N(1) bond (1.275(5) Å) of one of the coordinated ligands is very close to the $C(sp^2)$=N bond length (the mean value is 1.279 Å [17]) and the O(1)–C(3) bond (1.230(8) Å) is close to the C=O bond length (1.210 Å). The C(4)–C(1), C(4)–C(3), C(4)–C(5), N(2)–C(5) and N(3)–C(5) bonds are equalized. Such a distribution of the electron density allows the assumption that the resonance structure C provides the main contribution to the structure of this ligand. In the case of the second ligand, the N(5)–C(24) and O(2)–C(22) bonds

Scheme 4.

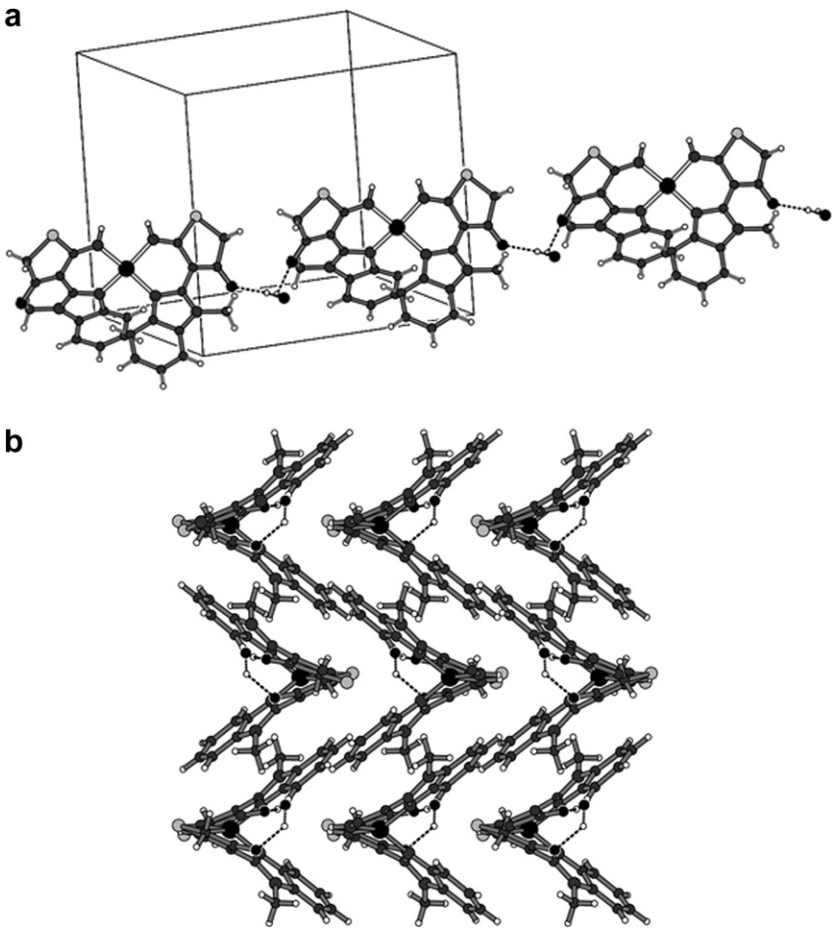

Fig. 3. The infinite chain along the (0 1 0) crystallographic direction (a) and a view of the layer arrangement (b) of complex **1**.

(1.289(5) and 1.259(6) Å) are longer as compared with typical lengths values. The value of the C═O bond length is close to the mean value for a $C(sp^2)$–O^- bond. The C(21)–C(22) and C(21)–C(24) bonds are close enough (1.384(6) and 1.407(6) Å, respectively), but the bond lengths in the imidazole ring are close to their mean value. Therefore the main contribution in the structure of this ligand is provided by the resonance structure D.

The S(1), C(1)···C(4) ring adopts an envelope conformation. Deviation of the C(3) atom from the mean plane of the remaining atoms of the ring is 0.15 Å. The S(2), C(21)···C(24) ring has a twist conformation. Deviations of the S(2) and C(22) atoms from the plane of the remaining atoms of the ring are 0.17 and −0.10 Å, respectively.

The essential repulsion between the methyl and carbonyl groups (shortened intramolecular contacts C(6)···C(3) 3.16 Å (the van der Waals radii sum is 3.42 Å [18]), C(6)···O(1) 2.82 Å (3.00 Å), O(1)···H(6a) 2.13 Å (2.46 Å), C(19)···O(2) 2.85 Å (3.00 Å), C(19)···C(22) 3.21 Å (3.42 Å), O(2)···H(19a) 2.11 Å (2.46 Å)) causes the turn of the methylbenzoimidazole fragment and dihydrothiophene ring relatively to each other (the C(1)–C(4)–C(5)–N(2) and C(24)–C(21)–C(20)–N(4) torsion angles are 24.6(7)° and 22.8(6)°, respectively). The C(6) and C(19) methyl groups are non-coplanar to the plane of the imidazole ring (the C(6)–N(3)–C(7)–C(8) and C(19)–N(6)–C(20)–C(21) torsion angles are −13.3(5)° and 10.3(7)°, respectively). Thus, it is possible to suggest that steric repulsion within the ligands may be responsible for the deformation of the coordination polyhedron of the central atom.

The molecules of **1** form infinite chains along the (0 1 0) crystallographic direction in the crystal (see Fig. 3a) due to intermolecular hydrogen bonds O(1w)–H(1wa)···O(1) (D–H···A = 121°, D–H = 0.91 Å, H···A = 1.90 Å), (x, $1 + y$, z) and O(1w)–H(1wb)···O(2) (D–H···A = 169°, D–H = 0.94 Å, H···A = 2.13 Å). Additionally, an intermolecular association in the structure occurs through π–π stacking interactions (ca. 3.5 Å) between molecules of ligands of adjacent chains. Thereby a layered supramolecular assembly is formed (see Fig. 3b).

4. Conclusions

The present research provides a way of synthesizing 10 novel mononuclear coordination compounds of nickel(II), cobalt(II), zinc(II) and copper(II) with 2-amino-4(5H)-ketothiophens in the neutral and deprotonated forms. Evidently for these compounds, a key difference lies in the nature of the anion in the initial salt and our results

show that complexes of 3d-metal ions with the neutral form of HL^1 were obtained in the case of the usage of metal chlorides as reactants, while complexes with the deprotonated forms of HL^1 and HL^2 were obtained with the use of metal acetates. Thus, the ability of 2-amino-4(5H)-ketothiophens to be deprotonated under soft conditions on coordination by transition metal ions was found. The complexes were unambiguously determined using spectroscopic methods and single crystal X-ray analysis.

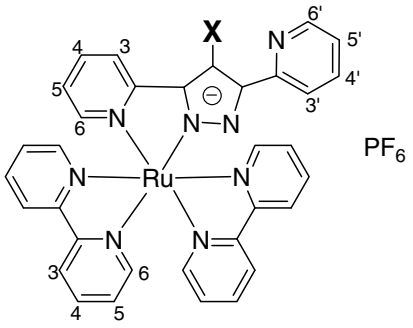

Fig. 1. Structures and labelling scheme for the ^{1}H NMR spectra of complexes **1**–**5**.

research work on functional mimics of the donor side of photosystem II, we have synthesized some new mononuclear ruthenium polypyridyl complexes bearing Hbpp as well as its 4-nitro and 4-halogen substituted analogues. In this paper, we present the synthesis, structure, spectroscopic, electrochemical and acid–base properties of $[Ru(bpy)_2(Xbpp)](PF_6)$. The structures of the mononuclear Ru complexes are showed in Fig. 1.

2. Experimental

2.1. Materials

All chemicals were obtained from commercial sources and were used without further purification. Acetonitrile used in spectroscopic measurements and electrochemistry was of spectroscopy grade. Other solvents were reagent grade. The ligands 3,5-bis(2-pyridyl)-1*H*-pyrazole (Hbpp) [7], 4-chloro-3,5-bis(2-pyridyl)-1*H*-pyrazole (ClHbpp), 4-bromo-3,5-bis(2-pyridyl)-1*H*-pyrazole (BrHbpp), 4-iodo-3,5-bis(2-pyridyl)-1*H*-pyrazole (IHbpp), 4-nitro-3,5-bis (2-pyridyl)-1*H*-pyrazole (NO_2Hbpp) [8] and the complex *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ [9] were prepared according to the reported methods.

2.2. Preparation of the complexes

2.2.1. *[Ru(bpy)$_2$(bpp)](PF$_6$) (**1**) (representative procedure)*

111 mg (0.5 mmol) of Hbpp and 260 mg (0.5 mmol) of *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ were dissolved in 60 mL of ethanol and the mixture was heated under reflux with stirring for 2 h. Then the solution was evaporated to dryness, and the resulting solid was dissolved in a minimum amount of deionized water. A precipitation was formed by adding an excess of aqueous NH_4PF_6 to the solution. After filtration, the compound was purified over neutral alumina using CH_2Cl_2/CH_3OH (40:1, v/v) as the eluent. The major fraction, corresponding to the target complex, was evaporated to dryness to give dark red microcrystals. Yield: 270 mg (70%). ^{13}C NMR (CD_3CN): $\delta = 158.0$, 157.9, 157.8, 157.6, 156.7, 155.0, 153.8, 152.0, 151.8, 151.7, 151.6, 150.4, 150.0, 149.3, 137.1, 136.6, 136.4, 136.21, 136.18, 136.0, 127.31, 127.27, 126.9, 126.3, 124.0, 123.7, 123.4, 123.1, 122.1, 121.1, 119.7, 118.8, 102.6; HRMS ESI, *m*/*z*: $[M-PF_6]^+$. Calc. for $C_{33}H_{25}N_8Ru$: 635.1246. Measured: 635.1261. *Anal.* Calc. for $C_{33}H_{25}F_6N_8PRu\cdot CH_2Cl_2$: C, 47.23; H, 3.15; N, 12.96. Found: C, 47.29; H, 3.51; N, 13.24%.

2.2.2. *[Ru(bpy)$_2$(Clbpp)](PF$_6$) (**2**)*

This complex was prepared in a similar manner to complex **1** from 130 mg (0.25 mmol) of *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ with 64 mg (0.25 mmol) of ClHbpp. Yield: 138 mg (68%). ^{13}C NMR (CD_3CN): $\delta = 157.9$, 157.8, 157.7, 157.5, 155.6, 153.1, 152.0, 151.9, 151.7, 151.6, 150.9, 149.3, 149.0, 144.4, 137.2, 136.8, 136.6, 136.4, 136.3, 136.1, 127.4, 127.3, 127.0, 126.3, 124.0, 123.8, 123.5, 123.2, 122.7, 121.6, 121.3, 119.7, 106.1; HRMS ESI, *m*/*z*: $[M-PF_6]^+$ Calc. for $C_{33}H_{24}ClN_8Ru$: 669.0856. Measured: 669.0879. *Anal.* Calc. for $C_{33}H_{24}ClF_6N_8PRu\cdot CH_3COCH_3$: C, 49.58; H, 3.47; N, 12.85. Found: C, 49.20; H, 3.65; N, 12.75%.

2.2.3. *[Ru(bpy)$_2$(Brbpp)](PF$_6$) (**3**)*

This complex was prepared in a similar manner to complex **1** from 260 mg (0.5 mmol) of *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ with 150 mg (0.5 mmol) of BrHbpp. Yield: 320 mg (75%). ^{13}C NMR (CD_3CN): $\delta = 157.9$, 157.8, 157.7, 157.5, 155.9, 153.3, 152.0, 151.9, 151.64, 151.57, 151.0, 148.9, 145.4, 137.1, 136.8, 136.6, 136.4, 136.3, 136.1, 127.4, 127.3, 127.0, 126.3, 124.0, 123.8, 123.5, 123.2, 122.8, 121.8, 121.7, 119.9, 89.8; HRMS ESI, *m*/*z*: $[M-PF_6]^+$. Calc. for $C_{33}H_{24}BrN_8Ru$: 713.0351. Measured: 713.0371. *Anal.* Calc. for $C_{33}H_{24}BrF_6N_8P\ Ru\cdot CH_3COCH_3$: C, 47.17; H, 3.30; N, 12.22. Found: C, 46.94; H, 3.23; N, 12.29%.

2.2.4. *[Ru(bpy)$_2$(Ibpp)](PF$_6$) (**4**)*

120 mg (0.35 mmol) of IHbpp and 180 mg of (0.35 mmol) *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ were dissolved in 50 mL of ethanol, and the mixture was stirred for 18 h at 50 °C. After an excess aqueous solution of NH_4PF_6 was added, this solution was stirred for a few minutes and the resulting solution was diluted to 200 mL with water. The aqueous phase was extracted with dichloromethane (2 × 50 mL). The organic phase was evaporated to dryness, and the resulting solid was purified over neutral alumina using CH_2Cl_2/CH_3OH (40:1, v/v) as the eluent. The major fraction, corresponding to the target complex, was obtained as a dark red microcrystal after evaporating the solvent. Yield: 144 mg (46%). ^{13}C NMR (CD_3CN): $\delta = 157.8$, 157.74, 157.70, 157.5, 156.2, 154.1, 153.8, 151.9, 151.8, 151.6, 151.5, 151.1, 148.6, 147.6, 136.8, 136.6, 136.34, 136.29, 136.1, 127.39, 127.36, 127.0, 126.3, 124.1, 123.8, 123.5, 123.2, 123.0, 122.2, 121.8, 120.2, 53.7; HRMS ESI, *m*/*z*: $[M-PF_6]^+$. Calc. for $C_{33}H_{24}IN_8Ru$: 761.0212. Measured: 761.0185. *Anal.* Calc. for $C_{33}H_{24}$-

$F_6IN_8P\ Ru \cdot CH_3COCH_3$: C, 44.87; H, 3.14; N, 11.63. Found: C, 45.07; H, 3.29; N, 11.85%.

2.2.5. *[Ru(bpy)$_2$(NO$_2$bpp)](PF$_6$) (**5**)*

This complex was prepared in a similar manner to complex **1** from 130 mg (0.25 mmol) of *cis*-$[Ru(bpy)_2Cl_2] \cdot 2H_2O$ and 66 mg (0.25 mmol) of NO_2Hbpp. Yield: 160 mg (79%). ^{13}C NMR (CD_3CN): $\delta = 157.64$, 157.62, 157.57, 157.4, 154.1, 152.3, 152.1, 151.8, 151.7, 151.6, 151.5, 151.4, 149.2, 144.3, 137.5, 137.2, 137.0, 136.8, 136.7, 136.4, 131.5, 127.6, 127.5, 127.3, 126.5, 124.6, 124.2, 124.0, 123.6, 123.32, 123.31, 123.2, 123.0; HRMS ESI, *m/z*: $[M-PF_6]^+$. Calc. for $C_{33}H_{24}N_9O_2Ru$: 680.1096; Measured: 680.1116. *Anal.* Calc. for $C_{33}H_{24}F_6N_9\ O_2PRu$: C, 48.06; H, 2.93; N, 15.29. Found. C, 47.84; H, 3.02; N, 15.13%.

2.3. Instrumental methods

^1H and $\{^1H–^1H\}$COSY NMR spectra were recorded on a Varian INOVA spectrometer at 400 MHz and ^{13}C NMR spectra were recorded at 100 MHz. Chemical shifts are given in δ units relative to the tetramethylsilane (TMS) signal as an internal reference. High resolution mass spectra (HRMS) were provided by Q-TOF micro (Micromass Int., Manchester, England). Elemental analyses were carried out on a CARLO ERBA MOD-1106 elemental analyzer. UV–Vis absorption spectra were obtained on a HP8453 spectrophotometer with 1 cm quartz cells. Emission spectra were recorded using a FP-6500 spectrofluorometer with 1 cm quartz cells. Emission/excitation slit widths were 10 nm. The spectra were uncorrected for photomultiplier response. The quantum yields of the complexes at 298 K were determined by a relative method using $Ru(bpy)_3^{2+}$ in the same solvent as the standard. The quantum yields were calculated [9] using the following equation:

$$\varphi = \varphi_{std}(A_{std}/A)(I/I_{std})(\eta^2/\eta^2_{std}) \quad (1)$$

where φ and φ_{std} are the quantum yields of unknown and standard samples, A and A_{std} are the absorbances at the excitation wavelength and η and η_{std} are the refractive indices of the solutions. pK_a values were determined in Britton–Robinson buffer (0.04 M boric acid, 0.04 M acetic acid, 0.04 M phosphoric acid). The pH was adjusted by adding conc. NaOH or conc. H_2SO_4 and was measured using a pHS-25 pH meter. The pK_a values were calculated using custom-written non-linear least-squares curve-fitting programs implemented within SigmaPlot 2000 (SPSS Inc.).

Luminescence lifetime measurements were obtained using a LP920 Flash Photolysis Spectrophotometer. Samples were deaerated for 20 min using N_2 gas before the measurements were carried out. Cyclic voltammetric (CV) experiments were performed in a BAS-100W electrochemical potentiostat using a three electrode cell. A glassy carbon disk electrode (3 mm diameter) was used as the working electrode, a platinum wire was used as the auxiliary electrode and a non-aqueous Ag/Ag^+ electrode (0.01 M $AgNO_3$ in CH_3CN) was used as the reference electrode. All cyclic voltammograms presented in this work were recorded at a scan rate of 100 mV/s under an argon atmosphere and the complex concentration was approximately 1 mM. The complexes were dissolved in previously degassed CH_3CN solution containing 0.1 M Bu_4NPF_6 as a supporting electrolyte. The measured potentials in Table 4 were corrected to the value of SCE by adding 0.30 V. Ferrocene was used as an internal standard for the measurement. Under the experimental conditions used, the $E_{1/2}$

value of the ferrocene/ferrocenium couple, which has been corrected, was 0.43 V versus SCE.

2.4. X-ray crystallography

Each of the single crystals was obtained by slow diffusion of *n*-pentane into an acetone solution of the corresponding complexes **2**–**5**. Crystals **2**, **4** and **5** are highly sensitive to losing solvent immediately after removal from their mother liquor, so their measurements were performed at low temperature ($T = 180$ K). Measurements were collected on a Bruker SMART APEXII CCD equipped with Mo Kα radiation. Full-sphere data collection was used with ω and φ scans. Programs used: data collection, Smart V. 5.060 (Bruker AXS 1999); data reduction, Saint+ Version 6.02 (Bruker AXS 1999). Relevant experimental data are presented in Table 1. The structures were solved and refined with the SHELXTL-97 program [10] and the non-hydrogen atoms were refined with anisotropic thermal parameters.

3. Results and discussion

3.1. Preparation

The preparation of these complexes was carried out using standard procedures by the reaction of Hbpp and its derivatives with an equivalent amount of *cis*-$[Ru(bpy)_2Cl_2]$ at reflux [11–13]. In the case of complex **4**, however, the iodine atom on the ligand was found to be partially cleaved producing complex **1**, which was very difficult to separate from the target complex **4**. We optimised the reaction conditions and observed that when the reaction was carried out under mild conditions (at 50 °C for 18 h), no complex **1** was found as a byproduct, and complex **4** was obtained in a 46% yield. All these complexes have been purified by column chromatography. Furthermore, it is worth mentioning that complexes **1**–**5** are all obtained as monocations upon the addition of excess PF_6^-, which has been proved by their HRMS spectra and crystal structures. Therefore, we can conclude that the pyridylpyrazole ligands XHbpp deprotonate easily upon coordination to the metal centre to form $Xbpp^-$ and the valence state of ruthenium is Ru(II).

3.2. ^1H NMR spectra

The ^1H NMR and {H–H}COSY NMR spectra for complexes **1**–**5** have been recorded in CD_3CN solution at room temperature (see supporting information). The numbering scheme used to assign the observed resonances is given in Fig. 1.

Table 2 summarizes the spectral assignments made for complexes **1**–**5**. No complete assignment could be made, but by {H–H}COSY NMR spectra and comparison with the signals of the bipyridine complexes already described [11,14], the major part of the spectrum could be understood. The asymmetric nature of the complexes is evident from the occurrence of a fairly large number of resonances, parts of which are overlapped with each other. The COSY

[a] For ^1H NMR data, respectively: chemical shift (ppm), number of protons.
[b] For proton numbering see Fig. 1.

spectra have been particularly useful in assigning the protons of the pyridine moiety of Xbpp bound to the metal as against the uncoordinated one. The chemical shifts of the protons on the coordinated pyridine ring are noticeably different from those observed for the uncoordinated pyridine of Xbpp, which is mainly caused by the changes in electron density of the ruthenium-bound pyridine ring. But for the H6 proton, the relative higher field shift with respect to the H6′ proton is mainly caused by the maximum diamagnetic shielding by the anisotropic ring current of the adjacent bipyridine rings as can be seen from the structure (see Fig. 1). According to the spectral assignments of complexes **1**–**5**, we can conclude the chemical shifts decrease in the order H3 > H4 > H6 > H5 for the coordinated pyridine ring; H6′ > H3′, H4′ > H5′ for the uncoordinated pyridine ring; H3 > H4, H6 > H5 for the bipyridine ligand. The observation that only H3 of the coordinated pyridine ring among all the protons of Xbpp, at δ 8.37 for **2**, 8.59 for **3**, 8.85 for **4** and 8.65 for **5**, is significantly down field-shifted relative to that of complex **1** (δ 7.84) is of considerable interest. Clearly, the H3 atom is the closest proton to the substituents in the pyrazole ring, which can be confirmed by their crystal structures, so that the electron density around the H3 atom is seriously decreased by their electron-withdrawing effect.

3.3. Crystal structures

ORTEP views of the cationic moieties of complexes **2**–**5** together with the labelling scheme are shown in Fig. 2. All the complexes co-crystallised with acetone molecules. The deprotonation of the pyrazole ring was confirmed by the presence of one PF_6 counter ion per ruthenium centre in the solid-state structures. Selected bond lengths and angles for these complexes are listed in Table 3. The N3–Ru1–N4 bite angles for **2** (78.5(4)°), **3** (77.7(4)°) and **4** (78.28(13)°) correspond well with the bite angle obtained for [Ru(bpy)$_2$(3,5-bis(pyridine-2-yl)-1,2,4-triazole)]PF_6 (78(1)°) [15], [Ru(bpy)$_2$(3-(pyrazin-2′-yl)-5-(pyridine-2″-yl)-1,2,4-triazole)]PF_6 (77.98(6)°) [12] and [Ru(bpy)$_2$(3-(pyrazin-2′-yl)-5-phenyl-1,2,4-triazole)]PF_6 (78.2(4)°) [14]. But for **5** this angle is 76.98(9)°, about 1° smaller than that of the other complexes, attributed to the relatively big steric effect of the nitro group on C7. The bite angles of 78.4(4)° and 78.8(4)° for **2**, 78.9(4)° and 79.0(5)° for **3**, 78.44(13)° and 78.81(14)° for **4**, 78.59(9)° and 78.87(9)°

for **5** for the two bipyridine ligands are typical for this class of complexes. The Ru–N distances 2.037(9)–2.075(1) Å **2**, 2.012(8)–2.083(9) Å **3**, 2.031(3)–2.080(3) Å **4** and 2.024(2)–2.063(2) Å **5** are comparable to those found in other similar complexes [11–14]. Ru1–N4 is the longest and Ru1–N3 is the shortest Ru–N bond in all these complexes. The data show the substituents on the C7 have no obvious effect on the Ru–N distances. The uncoordinated pyridine ring shows a *trans* geometry, i.e., the uncoordinated pyridylic N1 atom is located at the opposite side of the coordinated pyridylic N4 atom, which coincides with the solid-state structure of the ligand Hbpp. The ligand Hbpp is generally planar with two dihedral angles, 3.14° and 9.61°, between one of the two pyridine rings and the central pyrazole pentagon [16]. Due to the existence of the substituents on the C7 in complexes **2–5**, the uncoordinated pyridine rings are twisted out of the plane of the central pyrazole (see Fig. 2). With the increase of the substituents' volume ($NO_2 > I > Br > Cl$), the extent of this twist is bigger, shown by the two dihedral angles: one between the uncoordinated pyridine ring and central pyrazole ring, the other between the coordinated pyridine ring and central pyrazole ring, 56.1° and 7.9° **5**, 38.1° and 8.5° **4**, 25.5° and 4.9° **3**, 15.6° and 1.8° **2**, respectively.

3.4. Electronic properties

The visible absorption and emission data obtained for complexes **1–5**, together with those for $[Ru(bpy)_3]^{2+}$, are listed in Table 4 (also see Fig. 3). The lowest energy absorption feature for these complexes is assigned to several overlapping $d\pi$–π^* transitions due to a series of singlet metal-to-ligand-charge-transfer (^{1}MLCT) transitions ($\log\varepsilon \sim 4$), involving both bpy and Xbpp ligands, by comparison with other ruthenium polypyridyl complexes [11,13,17]. For complex **1**, the absorption and emission maxima are red-shifted with respect to $[Ru(bpy)_3]^{2+}$, which is expected as the π-electron rich pyrazole containing ligand is a stronger σ-donor/weaker π-acceptor than 2,2′-bipyridine and destabilizes the filled metal d-orbitals and hence raises the energy of the ground state of the metal-based orbitals [13,17a]. Additionally, it can be concluded that the introduction of the substituents Cl, Br, I and NO_2 have a blue-shifted effect on the absorption and emission maxima of complex **1**, and among them the influence of NO_2 is the most, whilst Cl, Br and I are similar to each other. Obviously, the greater the electron-withdrawing strength of the substituent, the more the σ-donor ability of the pyrazole ring is reduced.

All the complexes examined are luminescent in the region of 665–715 nm in acetonitrile at room temperature, typical for a ^{3}MLCT emission [11]. The emission lifetimes and quantum yields of these complexes are also listed in Table 4. The emission decay for **1** is double exponential in nature with lifetimes of 44 ns (16%) and 372 ns (84%) (see Fig. 5), but upon the introduction of the Cl, Br, I and NO_2 groups to **1**, an approximate 300 ns decrease in

[a] All the measurements were made in CH_3CN at 298 K.
[b] Lifetimes measured in deaerated CH_3CN at 298 K.
[c] All redox potentials are measured in 0.1 M $TBAPF_6$–CH_3CN, 100 mV s^{-1} scan rate and corrected relative to SCE.
[d] Value obtained from Ref. [9].

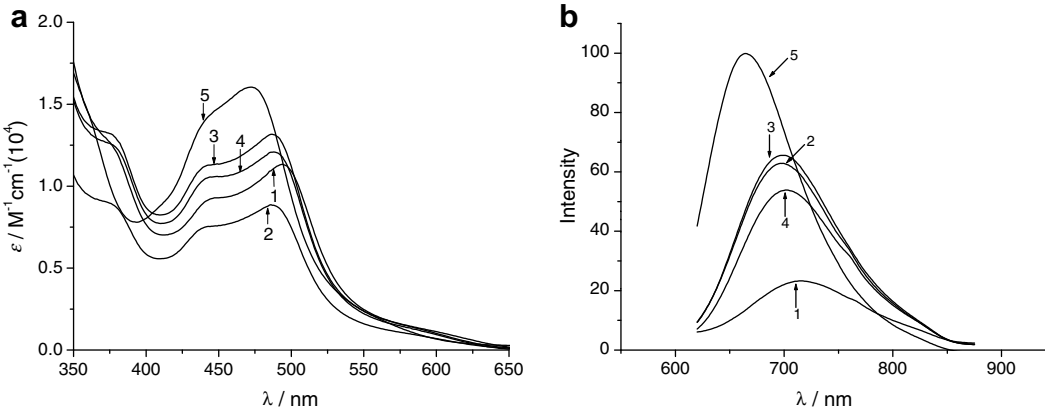

Fig. 3. UV–Vis and emission spectra for complex **1**–**5** (5×10^{-5} M) in CH_3CN at room temperature.

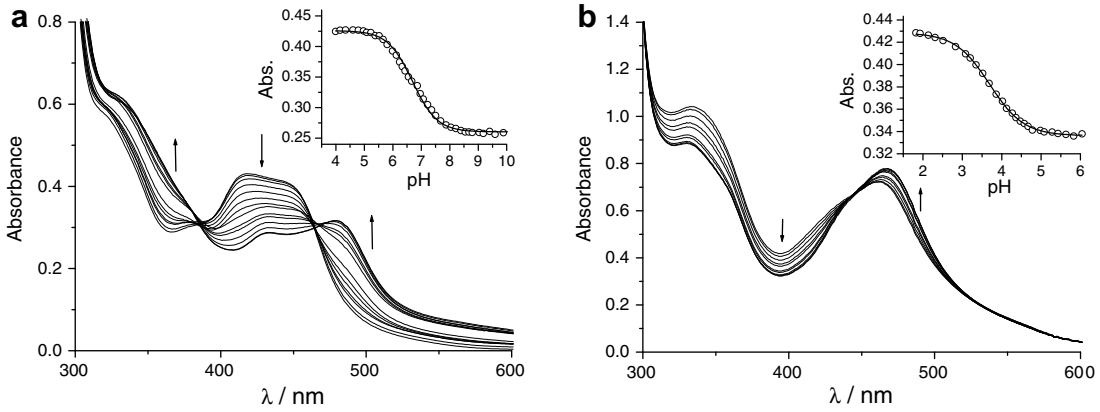

Fig. 4. Changes in the UV–Vis spectra of (a) **1** (5×10^{-5} M) as the pH is varied from 3.99 to 9.88 and (b) **5** (5×10^{-5} M) as the pH is varied from 1.82 to 6.04 in an aqueous Britton–Robinson buffer. The arrows indicate an increase or decrease in band intensity with increasing pH. The insets show the variation of absorbance with pH (418 nm for **1** and 400 nm for **5**).

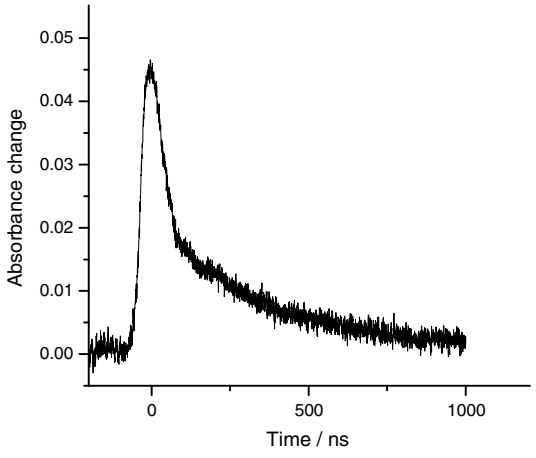

Fig. 5. Kinetic trace for time-resolved emission of complex **1** (50 μM) at 715 nm measured in CH_3CN.

the emission lifetime is observed. This suggests that there is a significant quenching by the substituents Cl, Br, I and NO_2 in the ligands (see Fig. 5).

3.5. Acid–base properties

Complexes **1**–**5** have two sites that can be protonated. One is the uncoordinated pyridylic nitrogen and the other is the pyrazolylic nitrogen on the corresponding $Xbpp^-$ ligand. Therefore, the pK_a values of complexes **1**–**5** can be determined by spectrophotometric acid–base titrations. As expected, the titrations in aqueous Britton–Robinson buffers result in a shift of the lowest energy MLCT band from 418 to 480 nm for **1**, 421 to 474 nm for **2**, 422 to 474 nm for **3**, 422 to 475 nm for **4** and from 460 to 468 nm for **5**. Similar behaviour has been observed for a series of complexes containing imidazole, 1,2,4-triazole and pyrazole moieties and was explained by the increased π-donor capacity of the deprotonated ligand [9,12,17]. According to the pK_a values of those Hbpp containing Ru(II) complexes reported previously [18], the pK_a values at 6.69 ± 0.02 ($R = 0.996$) for **1** (see Fig. 4a, inset), 5.47 ± 0.01 ($R = 0.999$) for **2**, 5.57 ± 0.02 ($R = 0.999$) for **3**, 5.65 ± 0.02 ($R = 0.999$) for **4** (see supporting information) and 3.69 ± 0.01 ($R = 0.999$) for **5** (see Fig. 4b, inset), revealed from the plot of absorbance versus pH, were

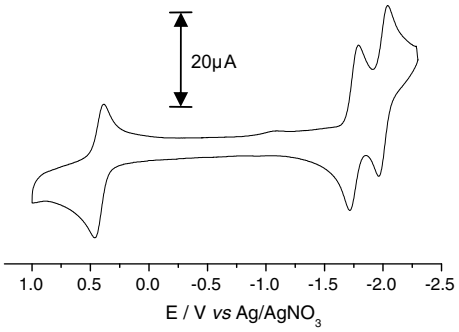

Fig. 6. Cyclic voltammograms of complex **1** (1 mM) in CH_3CN.

assigned to the protonation/deprotonation of the pyrazole moiety as indicated as follows:

$$[Ru(bpy)_2(Xbpp)]^+ \underset{-H^+}{\overset{+H^+}{\rightleftarrows}} [Ru(bpy)_2(XHbpp)]^{2+} \quad (2)$$

With the increase of the electron withdrawing ability of the substituent, the corresponding pK_a value decreased gradually. A comparison of the pK_a values of **5** and **1** showed that the pyrazole ring became more acidic by 3.0 pH units in the presence of the nitro group, which is a strong electron-withdrawing group. As expected, within this framework the pK_a values indicate that the substituents' effect on the acid–base properties of the complexes are substantial. The pK_a values for the protonation/deprotonation of the uncoordinated pyridine moiety in both **1**–**5** were not well determined in the pH range of 1.8–11.

3.6. Electrochemical properties

The redox properties of complexes **1**–**5** have been studied in acetonitrile and the relevant electrochemical data are presented together with $Ru(bpy)_3{}^{2+}$ in Table 4. For each of the complexes a single reversible wave was observed at low oxidation potentials which was assigned to the Ru^{II}/Ru^{III} couple. The metal oxidation potential (0.73 V) for complex **1** (see Fig. 6) is considerably lower than that for $[Ru(bpy)_3]^{2+}$ (1.34 V), owing to the stronger σ-donating pyrazoles. The influences of the substituents Cl, Br and I to the Ru^{II}/Ru^{III} couple are similar and are approximately 50–70 mV higher than that of complex **1**. For **5**, the oxidation wave is observed at a higher potential, 0.96 V (versus SCE), arising from the stronger electron-withdrawing effect of the NO_2 group. All these five complexes undergo two one-electron reversible reductions, similar to those of $[Ru(bpy)_3]^{2+}$, suggesting they are bipyridine-based reductions [11]. In addition, for **5** there is an irreversible reduction peak of the nitro group at −1.58 V (versus SCE).

4. Conclusion

The synthesis, structural, electronic and electrochemical characterization of a new series of $Ru(bpy)_2$ complexes based on the ligand Hbpp are reported. The data presented above indicate that 3,5-bis(2-pyridyl)-1*H*-pyrazole (Hbpp) is a much stronger σ-donor ligand than 2,2′-bipyridine (bpy). On the other hand, the introduction of different substituents such as Cl, Br, I or NO_2 groups to the central pyrazole ring can decrease the ligands σ-donating strength and thereby influence the physico-chemical properties of those complexes to a certain degree. Among them, the effect of the NO_2 group is most obvious and the others complexes with Cl, Br and I show similar properties. The overall effects of these electron-withdrawing groups are in the expected order, making the absorption and emission maxima of complex $[Ru(bpy)_2(bpp)]^+$ (**1**) blue-shifted, the oxidation potential of Ru^{II}/Ru^{III} couple increased and the pK_a value decreased accordingly. In addition, a significant quenching by these groups to the emission of complex $[Ru(bpy)_2(bpp)]^+$ (**1**) was also observed, but the mechanism need to be further investigated. With the relative longer lifetime of 372 ns and the strong absorption in the visible region for complex **1**, it can be potentially used as a photosensitizer to realize light-induced electron transfer to donor–acceptor systems.

state. So far, various ligands, such bipyridine-type and biphenyl cyanide-type ligands, have been used for supramolecular building blocks [12–14]. The affinity of Ag^+ for N-donor ligands is well known. The ligand 1,4-bis(4,5-dihydro-2-oxazolyl)benzene act as bidentate bridging ligand, which may adopts two different forms, namely syn and anti conformation (Fig. 1). The 1,4-bis(4,5-dihydro-2-oxazolyl)benzene ligands in complexes **1**–**4** adopt the different conformations, syn and anti, where syn and anti indicate the relative positions of the nitrogen atoms of the oxazolyl groups. In this paper, the syntheses and structures of Ag(I) complexes of the types $[Ag_2(\mathbf{L})(CH_3COO)_2]_\infty$ (**1**), $[Ag_2(\mathbf{L})_3(ClO_4)_2]_\infty$ (**2**), $[Ag(\mathbf{L})(CF_3SO_3)]_\infty$ (**3**), and $\{[Ag_2(\mathbf{L})_3(H_2O)_3][SO_4]\cdot 9H_2O\}_\infty$ (**4**), form the subject of this report.

2. Experimental

2.1. General procedures

All manipulations were carried out under dry, oxygen-free nitrogen by using Schlenk techniques, unless otherwise noted. Solvents were dried and deoxygenated by refluxing over the appropriate reagents before use. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer. IR spectra (KBr disk) were recorded on a Jasco FT/IR-460 plus spectrometer.

2.2. Materials

The reagent 1,4-bis(4,5-dihydro-2-oxazolyl)benzene was purchased from T.C.I. Chemical Co., silver acetate from Wako Chemical Co., silver sulfate from Aldrich Chemical Co. and silver perchlorate and silver trifluoromethane sulfonate from Strem Chemical Co.

Caution: Perchlorate salts are dangerous (especially if they are dry) and should be handled with care.

2.2.1. Preparation of complex *1*

1,4-Bis(4,5-dihydro-2-oxazolyl)benzene (0.216 g, 1 mmol) in 5 ml MeOH was layered onto a solution of $AgCH_3CO_2$ (0.XX g, 0.10 mmol) in 5 ml H_2O. The resulting solution was slowly diffused for several weeks to give colorless crystal. Yield: 0.407 g (74%). *Anal.* Calc. for $C_{16}H_{18}Ag_2N_2O_6$ (MW = 550.06): C, 34.93; H, 3.29; N, 5.09. Found: C, 34.90; H, 3.29; N, 5.12%. IR (cm^{-1}): 3434(m), 1637(m), 1564(m), 1513(m), 1467(m), 1407(m), 1364(m), 1322(m), 1256(m), 1205(m), 1190(m), 1119(m), 1098(m) 1080(m), 1015(m), 973(m), 938(m), 895(m), 869(m), 688(m).

2.2.5. X-ray crystallography

The diffraction data of **1**–**4** were collected on a Siemens CCD diffractometer, which were equipped with a graphite-monochromated Mo Kα ($\lambda_\alpha = 0.71073$ Å) radiation. Data reduction was carried by standard methods with use of well-established computational procedures [15]. A colorless crystal of **1** was mounted on the top of a glass fiber with epoxy cement. ω data collection method was used to scan the data points at $4.50° \leqslant 2\theta \leqslant 52.24°$. The structure factors were obtained after Lorentz and polarization correction. The positions of some of the heavier atoms, including the silver atom, were located by the direct method. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements [16]. The final residuals of the final refinement were $R_1 = 0.0529$ and $wR_2 = 0.1799$. The crystallographic procedures for the other complexes were similar to those for **1**. Basic information pertaining to crystal parameters and structure refinement are summarized in Table 1. Selected bond distances and angles are listed in Table 2.

3. Results and discussions

3.1. Syntheses

Complexes of the type $[Ag_2(\mathbf{L})(CH_3COO)_2]_\infty$ (**1**), $[Ag_2(\mathbf{L})_3(ClO_4)_2]_\infty$ (**2**), $[Ag(\mathbf{L})(CF_3SO_3)]_\infty$ (**3**), and $\{[Ag_2(\mathbf{L})_3(H_2O)_3][SO_4]\cdot 9H_2O\}_\infty$ (**4**) (**L** = 1,4-bis(4,5-dihydro-2-oxazolyl)benzene) were prepared by reactions of AgX (X = CH_3COO^-, **1**, ClO_4^-, **2**, $CF_3SO_3^-$, **3** and $1/2SO_4^{2-}$, **4**) with 1,4-bis(4,5-dihydro-2-oxazolyl)benzene in

MeOH/H_2O. Crystals suitable for X-ray diffraction studies were obtained by **L** in methanolic solution was layered onto a solution of AgX (X = CH_3COO^-, **1**, ClO_4^-, **2**, $CF_3SO_3^-$, **3** and $1/2SO_4^{2-}$, **4**) in H_2O. All these complexes were structurally characterized by X-ray crystallography. Complexes **1**–**4** were insoluble in most organic solvents, such as methanol, ethanol, chloroform, benzene, toluene, dichloromethane, acetone, acetonitrile, THF but soluble in DMSO or DMF.

3.1.1. Structure of *1*

The structure of complex **1** was solved in the space group $P\bar{1}$ and Fig. 2 shows the local coordination of the silver center atom in **1**. Table 2 list the selected bond distances and angles around Ag for complex **1**. The silver metal center adopts a slightly distorted tetrahedral coordination geometry. The Ag atom is bonded to one 4,5-dihydro-2-oxazolyl nitrogen atoms (Ag–N = 2.329(5) Å) and three acetate oxygen atoms (Ag–O = 2.289(4), 2.297(4) and 2.460(4) Å) from three different bridging acetate anions. The ligands in complex **1** are almost flat with the dihedral angle between two 4,5-dihydro-2-oxazolyl rings is 0°, while the dihedral angle between the 4,5-dihydro-2-oxazolyl and the phenyl rings is 7.4°.

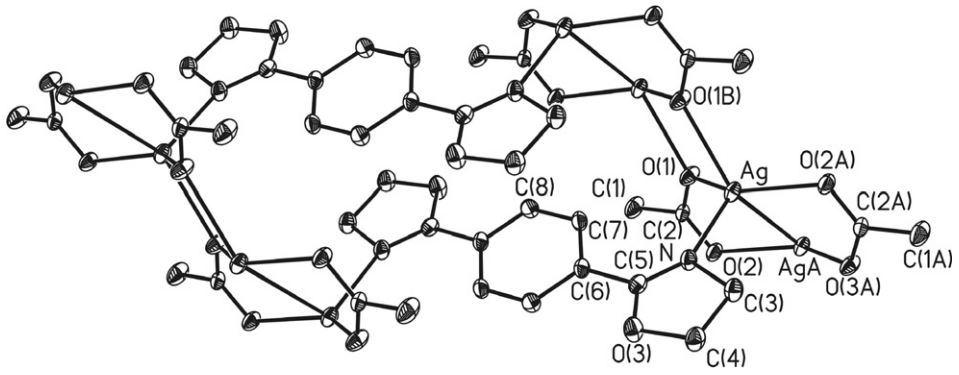

Fig. 2. An ORTEP drawing showing the coordination geometry of the silver metal center of complex **1**.

Complex **1** forms a 2-D pleated coordination polymeric framework, viewing down the *b*-axis (Fig. 3, bottom). Along the *a*-axis, the Ag atoms are linked by the η^1, η^2, μ_3-acetate anions form a 1-D waving $\{Ag_2(OAc)_2\}$ chains which the Ag–Ag separation in the $Ag_2(OAc)_2$ core is 2.985(3) Å and the distance between the cores is 3.698 Å (Fig. 3, top). The acetate anions bridging the silver atoms form an eight-member ring $\{Ag_2O_4C_2\}$, while a four-member ring $\{Ag_2O_2\}$ is formed by two oxygen atoms from the η^2-acetate anions and two silver atoms from two different $Ag_2(OAc)_2$ cores. The dihedral angle between the $\{Ag_2O_4C_2\}$ and $\{Ag_2O_2\}$ rings in 1-D waving chain is

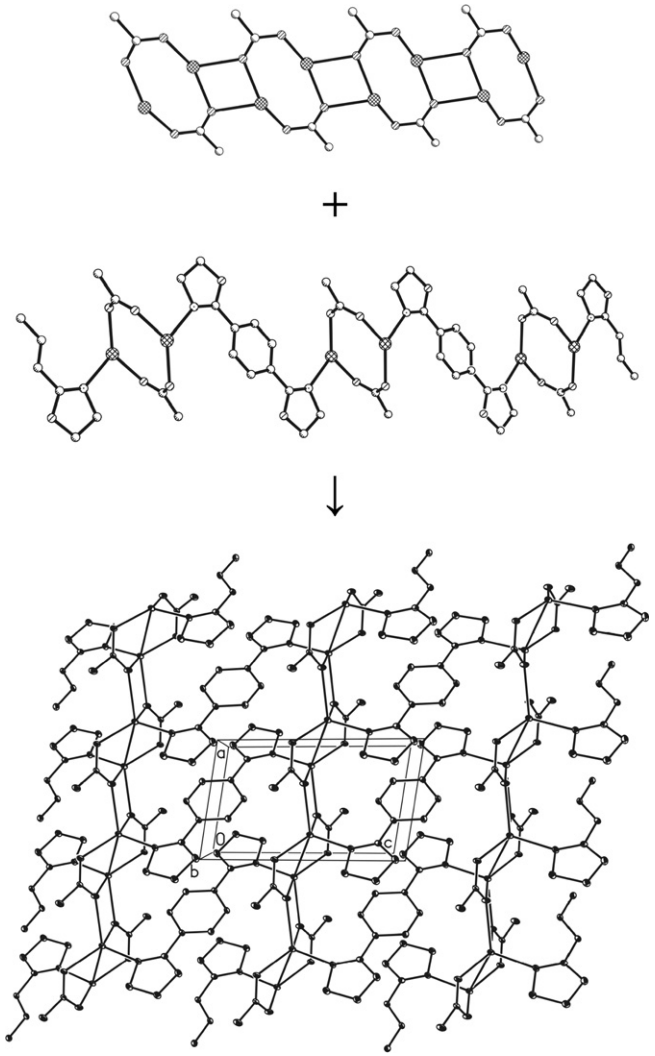

Fig. 3. ORTEP drawings for **1**, showing the waving $\{Ag_2(OAc)_2\}$ chain, top, zig-zag $\{Ag_2(OAc)_2(\mathbf{L})\}$ chain, middle, and the 2-D pleated net, bottom.

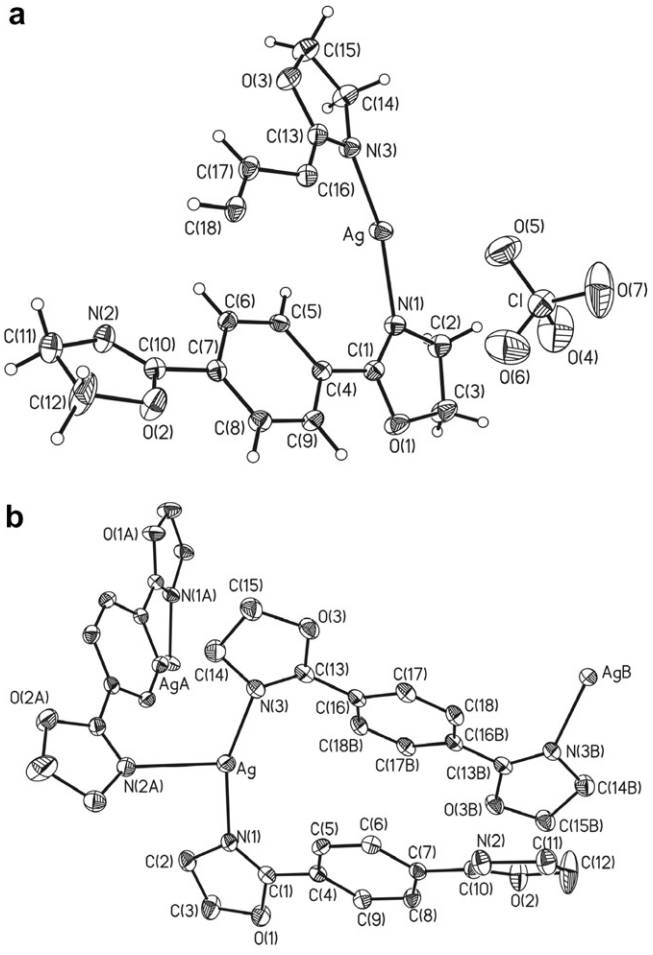

Fig. 4. (a) An ORTEP drawing for the representative asymmetric unit of complexes **2** and **3**. (b) Representative ORTEP diagram showing the coordination arrangement around Ag(I) center of complexes **2** and **3**.

24.0°. Along the *c*-axis, the 1-D zig-zag $\{Ag_2(OAc)_2$ (**L**)$\}$ chains formed by $Ag_2(OAc)_2$ cores and the anti-type bridging ligand, which the Ag–Ag distance in zig-zag chain separated by the bridging **L** is 9.774 Å (Fig. 3, middle) Two anti-type ligands link two $Ag_2(OAc)_2$ cores and two silver atoms into a $\{Ag_6C_{12}N_4O_2\}$ 24-member ring.

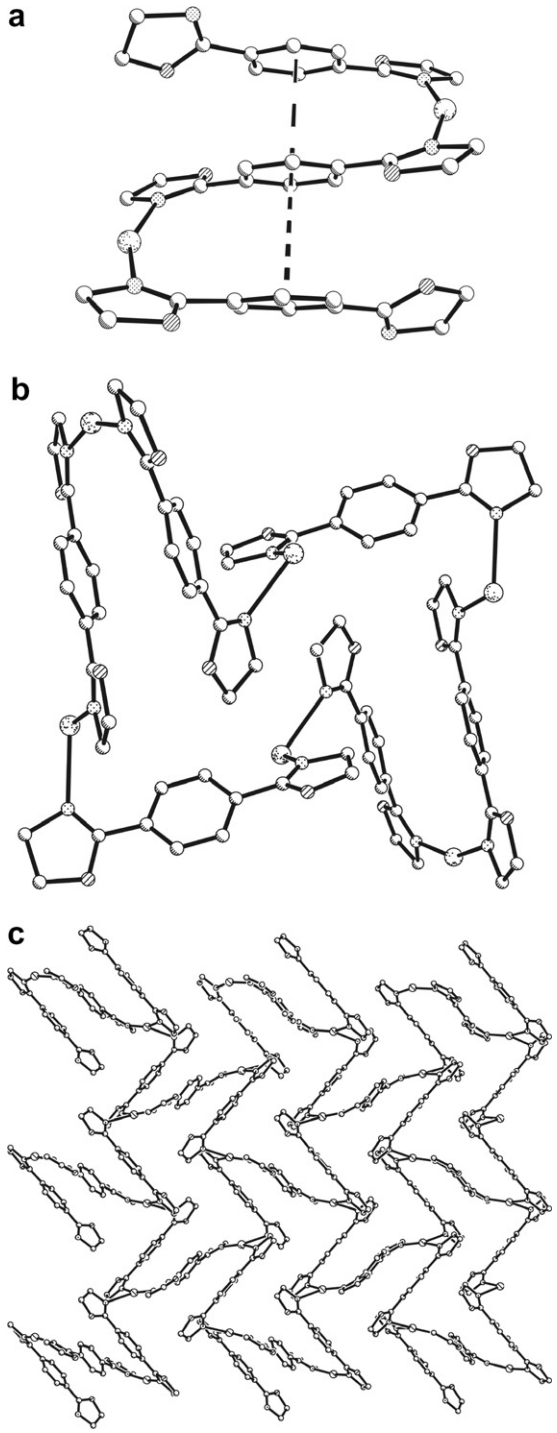

Fig. 5. (a) ORTEP drawing showing the Z-shape building unit in complexes **2** and **3**. (b) Two different conformation ligands form the $\{Ag(L)\}_6$ 54-member ring. (c) Packing diagram showing the cationic 2-D layer for complexes **2** and **3**.

The $\{Ag_6C_{12}N_4O_2\}$ 24-member rings are further extended into a 2-D pleated net, by sharing $Ag_2(OAc)_2$ joints and **L** edges. The complex shows the distorted rectangular pores (5.441×9.774 Å^2), which the length is defined by the distance between Ag(I) atoms linking through **L** ligands and the width is defined by the distance between Ag(I) atoms linking through the η^1, η^2, μ_3-bridging acetate anions.

3.1.2. Structures of 2 and 3

Complexes **2** and **3** are isomorphous and were solved in the same space group $P2_1/c$. Fig. 4a shows a representative asymmetric unit ORTEP diagram for **2**, which containing one silver atom, one and half 1,4-bis(4,5-dihydro-2-oxazol-yl)benzene ligands and an uncoordinated perchlorate anion. The structure of **3** is similar to that of **2** where the ClO_4^- anion is replaced by $CF_3SO_3^-$ anion. Fig. 4b showing the silver metal center is coordinated to three nitrogen atoms from three different 1,4-bis(4,5-dihydro-2-oxazol-yl)benzene ligands (Ag–N(1) = 2.176(3) Å for **2** and 2.175(3) Å for **3**; Ag–N(2A) = 2.466(3) Å for **2** and

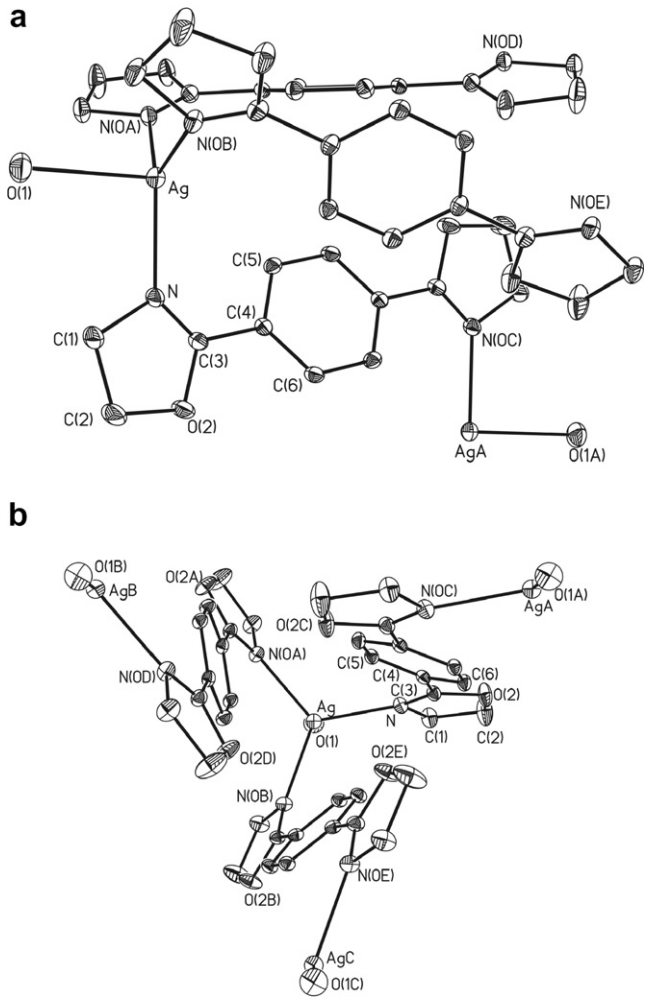

Fig. 6. (a) An ORTEP drawing showing the coordination arrangement around Ag(I) center of complex **4**. (b) An ORTEP drawing showing the three-fold coordination type along the Ag–O axial.

2.492(3) Å for **3**; Ag–N(3) = 2.157(3) Å for **2** and 2.162(3) Å for **3**, respectively) to form a slightly distorted T-shape geometry (∠N(1)–Ag–N(3) = 158.26(11)° for **2** and 154.78(10)° for **3**). Table 2 list the selected bond distances and angles around Ag for complexes **2** and **3**.

In complexes **2** and **3**, three 1,4-bis(4,5-dihydro-2-oxazolyl)benzene ligands link two Ag(I) atoms forming the Z-shape unit as a building block (Fig. 5a). The phenyl groups in the Z-shape building unit interact each through π–π stacking [17], and the distances between the centers of the rings are 3.859 Å for **2** and 3.856 Å for **3**. The bridging ligands in complexes **2** and **3** are not coplanar with the dihedral angels between oxazolyl rings and phenyl rings are 23.2°, 24.4° and 25.7° for complex **2** and 27.8°, 28.0° and 28.5° for complex **3**. The dihedral angles between the oxazolyl rings are 37.4° and 47.5° for complex **2**, and 48.7° and 55.6° for complex **3**, respectively. Fig. 5b showing the six 1,4-bis(4,5-dihydro-2-oxazolyl)benzene ligands link Ag(I) into a $\{Ag(\mathbf{L})\}_6$ 54-member ring. In the $\{Ag(\mathbf{L})\}_6$ ring, the six Ag(I) atoms and six **L** ligands are not coplanar in the chair-form cyclohexane like, which due to the different types of **L** ligands. The Ag–Ag distances separated by the bridging ligands are 6.903 Å and 9.129 Å in complex **2**, and those are 7.202 Å and 9.242 Å in complex **3**, respectively. The $\{Ag(L)\}_6$ rings are further extended into a 2-D layer by sharing Ag(I) joints and **L** edges, Fig. 5c. Complexes **2** and **3** form 3-D supramolecular structures which are interlinked by ClO_4^- and $CF_3SO_3^-$ anions through Ag---O [Ag---O = 3.219(2) Å] interactions and C–H---O [H---O = 2.515–2.547 Å, ∠C–H···O = 133.2 –151.1°] hydrogen bonds for **2**, and through Ag---O [Ag---O = 3.121(3) and 3.546(1) Å] interactions and

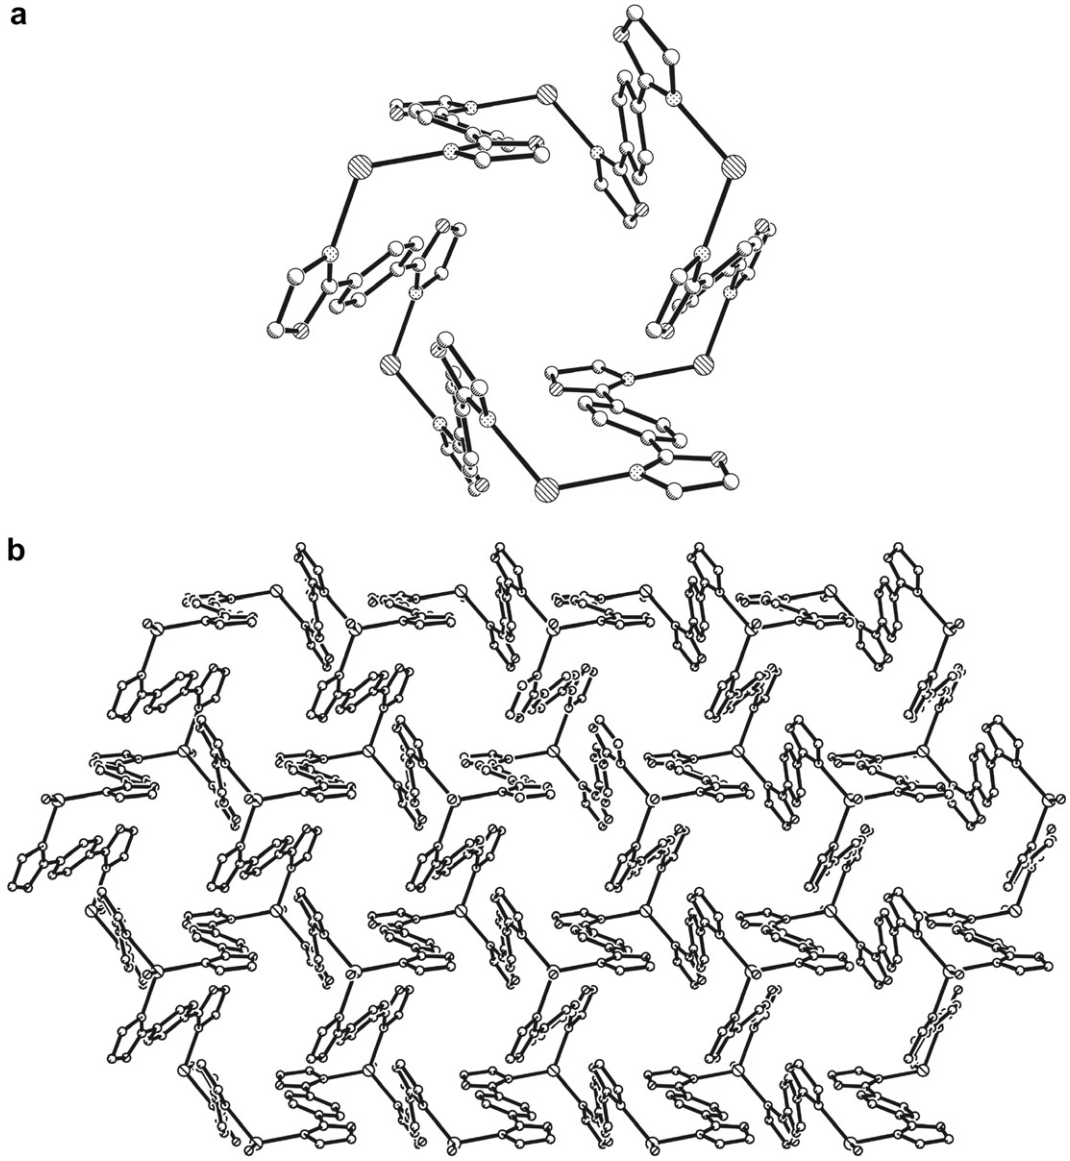

Fig. 7. (a) ORTEP drawing showing the $\{Ag(\mathbf{L})\}_6$ 54-member ring. (b) Packing diagram showing the cationic 2-D layer for complex **4**.

C–H---F [H---F = 2.492 Å, ∠C–H···F = 133.4°] [18] and C–H---O [H---O = 2.524–2.548 Å, ∠C–H···O = 123.9–153.2°] hydrogen bonds for **3**, respectively.

3.1.3. Structures of 4

The structure of complex **4** was solved in the space group *R*-3 and Fig. 6a shows the coordination geometry of the silver metal center. Complex **4** is a four coordinate complex and the coordination geometry of the Ag(I) center adopts a trigonal pyramidal coordination geometry with the bond angles only slightly deviated from 90° and 120° (Table 2). In complex **4**, three 1,4-bis(4,5-dihydro-2-oxazolyl)benzene ligands are each bound via the nitrogen atom of the oxazolyl group (Ag–N = 2.293(2) Å) in the equatorial plane, and the Ag(I) atom also bonded one water molecule (Ag–O(1) = 2.537(4) Å) in a axial position to complete the distorted-trigonal–pyramidal coordination geometry. The silver metal adopts a triangular planar geometry with the bond angles close to 120° (N–Ag–N(A) = 119.411(14)°), and is located only 0.036 Å out of the plane defined by the three nitrogen atoms coordinated the metal atom. Fig. 6b shows the three-fold coordination for Ag(I) center containing 1,4-bis(4,5-dihydro-2-oxazolyl)benzene ligands, viewing along the axial of silver and water bond. The ligands in complex **4** are not flat with the dihedral angle between the oxazolyl group and the phenyl rings is 21.9°.

Fig. 7a showing the six 1,4-bis(4,5-dihydro-2-oxazolyl)benzene ligands link Ag(I) into a $\{Ag(\mathbf{L})\}_6$ 54-member ring, which like as the honey comb pore. The Ag–Ag distance separated by the bridging ligands is 9.347 Å in complex **4**. The $\{Ag(\mathbf{L})\}_6$ rings are further extended into a 2-D layer by sharing Ag(I) joints and **L** edges, Fig. 7b. Complex **4** forms 3-D supramolecular structure which the cationic layers are interlinked by co-crystal water molecules and the sulfate anions through C–H---O [H---O = 2.096–2.558 Å, ∠C–H···O = 105.9–159.4°] hydrogen bonds.

3.1.4. Structural comparisons

The 1,4-bis(4,5-dihydro-2-oxazolyl)benzene ligands in complexes **1**–**4** adopt the different conformations, syn and anti, where syn and anti indicate the relative positions of the nitrogen atoms of the oxazolyl groups. While the **L**'s in **1** and **4** adopt the anti conformation to given the longer Ag–Ag separation, which are 9.774 Å for **1** and 9.347 Å for **4**, those in **2** and **3** adopt both the syn and anti conformations to form coordination polymers with various Ag–Ag distances of 6.903 Å and 9.129 Å in **2** and 7.202 Å and 9.242 Å in **3**, respectively. In complexes **2** and **3**, the ClO_4^- and $CF_3SO_3^-$ anions are not coordinated to the Ag(I) centers, but interact with the Ag(I) metals through the oxygen atom with different Ag–O distances 3.219(2) Å for **2** and 3.121(3) and 3.546(1) Å for **3**, respectively. Fig. 8 shows the schematic drawings for complex **1** (top), **2** and **3** (middle) and **4** (bottom). Complex **1** is a neutral 2-D polymeric layer which formed by Ag(OAc) chains and Ag(**L**)(OAc) chains forming the distorted rectangular net. The cations

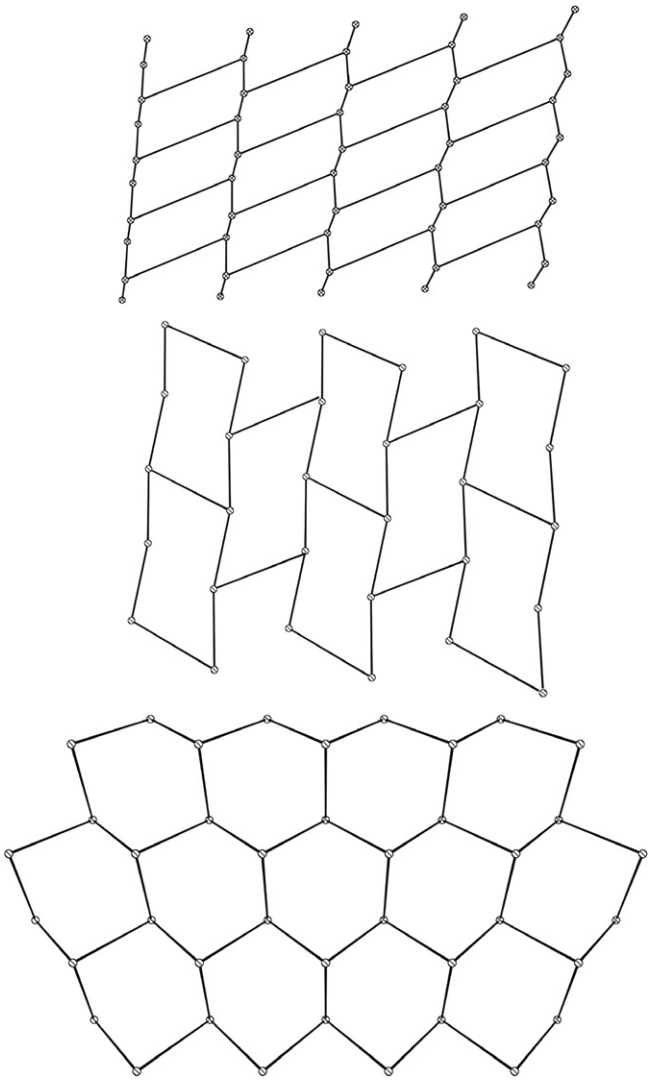

Fig. 8. Schematic drawings for complex **1** (top), **2** and **3** (middle) and **4** (bottom).

of polymeric nets, **2** and **3**, were linking Ag(I) atoms in both syn- and anti-type bridging **L**'s forming the waving 2-D grids, while complex **4** formed 2-D honey comb like framework.

interactions is an important aspect in supramolecular chemistry and crystal engineering. 4-Terpyridone is known to coordinate to the metal ions in its enolic form (LH) [2]. With an expectation that H–O–pyridine–M–pyridine–O–H fragment in $[M(LH)_2]^{n+}$ species may act as hydrogen bond donor/acceptor and thus may be a potential supramolecular synthon, an enolic 4-terpyridone based nickel(II) dicyanamide supramolecule, $[Ni^{II}(LH)_2](dicyanamide)_2 \cdot 2H_2O$ has been previously reported [2b]. Again, if 4-terpyridone forms 1:1 metal complex $[M(LH)(L^1)_x]^{n+}$ (L^1 is another ligand), it will have H–O–pyridine–M moiety which may also act as a hydrogen bond acceptor and donor due to the presence of O–H functionality. In addition to the importance as a supramolecular synthon, 4-terpyridone containing complexes may also exhibit spin-crossover phenomena due to intermediate field strength of this ligand [2a].

Dicyanamide is known as a versatile inorganic bridging ligand to develop coordination polymers. Five types of bridging modes of dicyanamide have been structurally characterized so far; two connecting ($\mu_{1,5}$- or $\mu_{1,3}$-) [4–10], three connecting ($\mu_{1,3,5}$- or $\mu_{1,1,5}$-) [3,10–13], four connecting ($\mu_{1,1,3,5}$-) [14], and even five connecting ($\mu_{1,1,3,5,5}$-) [15]. Although dicyanamide can mediate only weak interactions between the paramagnetic metal centers [4–15], a few multidimensional dicyanamide-bridged compounds exhibit long range magnetic ordering [3]. Evidently, dicyanamide is also a promising building unit to derive magnetic materials.

To explore further 4-terpyridone (LH) containing complexes, we report herein syntheses, molecular and supramolecular structures, and magnetic properties of a mononuclear manganese(II) compound $[Mn^{II}(LH)_2](ClO_4)_2$ (**1**) and a dicyanamide-bridged one-dimensional copper(II) compound $[Cu^{II}(LH)(\mu_{1,5}\text{-dca})]_n(NO_3)_n$ (**2**).

2. Experimental

2.1. Materials and physical methods

All the reagents and solvents were purchased from the commercial sources and used as received. Elemental (C, H, and N) analyses were performed on a Perkin–Elmer 2400 II analyzer. IR spectra were recorded in the region 400–4000 cm^{-1} on a Bio-Rad FTS40 spectrophotometer with samples as KBr disks. Variable-temperature (2–300 K) magnetic susceptibility measurements were carried out with a Quantum Design MPMS SQUID magnetometer.

2.2. Syntheses

2.2.1. $[Mn^{II}(LH)_2](ClO_4)_2$ (**1**)

A methanol solution (10 mL) of $Mn(ClO_4)_2 \cdot 6H_2O$ (0.18 g, 0.5 mmol) was added to a stirred methanol solution (20 mL) of 4-terpyridone (0.249 g, 1 mmol). A yellow precipitate was started to deposit after a few minutes. After stirring for 1 h, the yellow compound was collected by filtration and washed with methanol. Recrystallization from acetonitrile yielded yellow crystalline compound. Yield: 0.3 g (80%). The single crystals suitable for X-ray diffraction were obtained on diffusing diethylether to an acetonitrile solution of yellow crystalline compound. Anal. Calc. for $C_{30}H_{22}Cl_2MnN_6O_{10}$: C, 47.89; H, 2.95; N, 11.17. Found: C, 47.78; H, 3.02; N, 11.26%. IR (KBr/cm^{-1}): perchlorate: 1116s, 637m.

2.2.2. $[Cu^{II}(LH)(\mu_{1,5}\text{-dca})]_n(NO_3)_n$ (**2**)

A methanol solution (25 mL) of $Cu(NO_3)_2 \cdot 3H_2O$ (0.12 g, 0.5 mmol) and 4-terpyridone (0.125 g, 0.5 mmol) was refluxed for 1 h. The resulting blue solution was cooled to room temperature. To this blue solution, an aqueous solution (5 mL) of sodium dicyanamide (0.178 g, 2 mmol) was dropwise added with stirring. After a few minutes blue precipitate started to deposit. After 1 h stirring, the blue compound was collected by filtration and washed with methanol. Recrystallization on diffusing diethylether to a dimethylformamide solution yielded blue crystalline compound containing diffraction quality single crystals. Yield: 0.11 g (50%). Anal. Calc. for $C_{17}H_{11}CuN_7O_4$: C, 46.31; H, 2.51; N, 22.24. Found: C, 46.40; H, 2.42; N, 22.20%. IR (KBr/cm^{-1}): dicyanamide: 2348w (sh), 2315s, 2251s, 2181vs, 2147m (sh); nitrate: 1384s.

2.3. Crystal structure determination of $[Mn^{II}(LH)_2](ClO_4)_2$ (**1**) and $[Cu^{II}(LH)(\mu_{1,5}\text{-dca})]_n(NO_3)_n$ (**2**)

Pertinent crystallographic data of these two complexes are summarized in Table 1. Diffraction data were collected

on a Bruker SMART CCD (for **1**) and a NONIUS Kappa CCD (for **2**) diffractometer in the ω–2ϑ scan mode at 150 K and 295 K, respectively, using graphite monochromated Mo Kα radiation, having $\lambda = 0.71073$ Å. The accurate unit cells were obtained by means of least-squares fittings of 25 centered reflections. The intensity data were corrected for Lorentz and polarization effects, and semiempirical absorption corrections were made from ψ-scans. A total of 27902 reflections were collected for **1** in the range $2\vartheta = 2.06$–$55.0°$ with $-10 \leqslant h \leqslant 11$, $-11 \leqslant k \leqslant 11$, and $-51 \leqslant l \leqslant 51$, of which 7007 independent reflections ($R_{int} = 0.0526$) were used for structure determination. In the case of **2**, among 19403 of the total reflections collected in 2ϑ range of 5.18–55.0° with $-9 \leqslant h \leqslant 9$, $-10 \leqslant k \leqslant 11$, and $-19 \leqslant l \leqslant 19$, 4015 were independent ($R_{int} = 0.0625$). The structures were solved by direct and Fourier methods and refined by full-matrix least-squares methods based on F^2 using the programs SHELXS-97 and SHELXL-97 [16]. All non-hydrogen atoms were readily located and refined by anisotropic thermal parameters. The final least-squares refinements (R_1) based on $I > 2\sigma(I)$ converged to 0.0465 for **1** and 0.0528 for **2**.

3. Results and discussion

3.1. Description of the structure of $[Mn^{II}(LH)_2](ClO_4)_2$ (1)

Molecular structure of $[Mn^{II}(LH)_2](ClO_4)_2$ (**1**) is shown in Fig. 1, while selected bond lengths and angles are listed in Table 2. The structure of **1** contains three independent units: the dication $[Mn^{II}(4\text{-terpyridone})_2]^{2+}$ and two perchlorate anions. The manganese(II) center in **1** is hexacoordinated. Three nitrogens of each of the two enolic 4-terpyridone chelate to the metal ion. The Mn–N distances fall into two ranges; those involving the central pyridine rings are almost the same (Mn–N(2) = 2.197(2) Å and Mn–N(5) = 2.199(2) Å), while those (Mn–N(1) = 2.256(2) Å, Mn–N(3) = 2.252(2) Å, Mn–N(4) = 2.253(2) Å, and Mn–N(6) = 2.275(2) Å) involving the other four rings are little longer. The stereochemistry of the metal ion, due to the rigidity of the donor environment of 4-terpyridone, deviates appreciably from an ideal octahedron. Among fifteen N–Mn–N bond angles, three (N(1)–Mn–N(3), N(2)–Mn–N(5), and N(4)–Mn–N(6)) are *transoid* angles, while the remaining 12 are *cisoid* angles. In addition to the differences in the metal–ligand bond distances, the *transoid* angles (144.58(8)°, 144.37(8)°, and 177.96(8)°) and the wide range of *cisoid* angles (71.82(8)–109.92(8)°) are indicative of high distortion of the coordination environment. The deviations of the metal ion or the donor centers from N(2)N(4)N(5)N(6) and N(1)N(2)N(3)N(5) coordination planes, the later of which is the best least-squares plane, are not very high (<0.05 Å). However, the fact that the atoms N(1), N(3), N(4), and N(6) practically do not define any plane (average deviation of the nitrogens

is 0.68 Å) is in parallel with the large distortion of the coordination environment.

Eight hydrogen bonds, six of C–H···O types and two of O–H···O types, link the individual components in **1** into a three-dimensional network. The analyses of hydrogen bonds and topology resulted therein can be better understood as fragments. Simplified illustration of hydrogen bonds between perchlorate anions, $Cl(1)O_4$ and $Cl(2)O_4$, and 4-terpyridone moieties are shown in Figs. 2 and 3, respectively, while the hydrogen bond geometries are listed in Table 3. As shown in Fig. 2, $Cl(1)O_4$ anion forms hydrogen bonds with four complex dications to result in the creation of a two-dimensional sheet. One perchlorate oxygen, O(3), is a double acceptor and interacts with hydrogens (H(1) and H(13C)) attached with O(1) and C(13C), respectively. The second oxygen, O(4), forms hydrogen bond with H(16A) linked with C(16A). The third oxygen, O(5), interacts with hydrogen H(12B) which is linked with C(12B). The fourth oxygen, O(6), is a bifurcated acceptor and interacts with C(4)–H(4) and C(7)–H(7) hydrogens. Another perchlorate anion, $Cl(2)O_4$, forms two hydrogen bonds, O(2)–H(2)···O(7) and C(15D)–H(15D)···O(7) (Fig. 3). It may be noted that one manganese(II) center (Mn) in Fig. 3 belongs to the two-dimensional sheet represented in Fig. 2, while the second metal center (MnD) belongs to a second two-dimensional sheet. Evidently, the two-dimensional hydrogen bonded sheets formed due to hydrogen bonds involving $Cl(1)O_4$ are interlinked with each other due to the hydrogen bonds involving the second perchlorate anion, $Cl(2)O_4$. Therefore, the overall topology in compound **1** is three-dimensional.

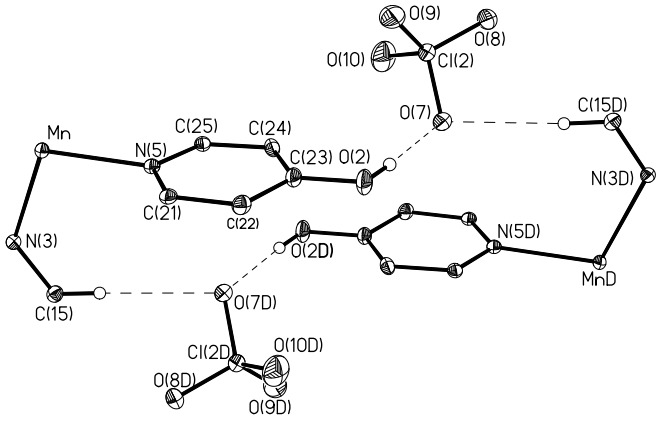

Fig. 3. Perspective view to demonstrate the hydrogen bonds involving one perchlorate anion ($Cl(2)O_4$) and O–H and C–H groups of enolic 4-terpyridones. Except central ring of one 4-terpyridone and except C(15) and N(3) atoms of the second 4-terpyridone, all other atoms have been omitted for clarity. Those hydrogen atoms participating in hydrogen bonds are only shown. Symmetry code: D, $1-x, -1-y, 1-z$.

3.2. Description of the structure of $[Cu^{II}(LH)(\mu_{1,5}\text{-}dca)]_n(NO_3)_n$ (2)

An ORTEP representation of the coordination environment and the formation of one-dimensional infinite chain of **2** is shown in Fig. 4, while the selected bond lengths

Symmetry code: as in Fig. 4.

and angles of this compound are listed in Table 4. As shown in Fig. 4, the metal ion is pentacoordinated by enolic 4-terpyridone, which behaves as a tridented neutral chelating ligand, and nitrile nitrogens of two end-to-end (EE) dicyanamide ligands. The other ends of these two dicyanamides, bonded to a metal ion in *cis* positions (N(4)–Cu–N(6B) = 99.43(13)°), coordinate to two different copper atoms to result in the formation of a one-dimensional chain which propagates along the crystallographic *a* axis.

The coordination geometry around the pentacoordinated metal ion is distorted square pyramidal. The best equatorial plane is defined by three pyridyl nitrogens (N(1), N(2), and N(3)) of 4-terpyridone moiety and one dicyanamide nitrogen (N(6B)), while the axial position is occupied by the second dicyanamide nitrogen (N(4)). The Cu–N distances involving 4-terpyridone fall into two distinct ranges; that (Cu–N(2) = 1.920(3) Å) involving the central pyridine ring is smaller than the bond lengths (Cu–N(1) = 2.038(3) Å and Cu–N(3) = 2.040(3) Å) involving the other two rings. Regarding Cu–N(dicyanamide) bond lengths, while that (Cu–N(6B) = 1.943(3) Å) in the basal plane lie within the range (1.920(3)–2.038(3) Å) of Cu–N(4-terpyridone) distances, the Cu–N(axial) bond length (Cu–N(4) = 2.207(3) Å) is significantly longer due to Jahn–Teller distortion. Among six N–Cu–N bond angles in the equatorial square plane, two (N(1)–Cu–N(3) and N(2)–Cu–N(6B)) are *transoid* angles, while other four are *cisoid* angles. Again, all the four N–Cu–N bond angles involving apical nitrogen (N(4)) are *cisoid* angles. In addition to the differences in the metal–ligand bond distances, the reduction of the *transoid* angles (N(1)–Cu–N(3) = 158.52(13)° and N(2)–Cu–N(6B) = 158.24(14)°) in the basal plane and the wide range of *cisoid* angles (79.65(12)–102.33(12)°) are indicative of high distortion of the coordination environment. The average deviation of the four nitrogen atoms and the displacement of the copper(II) center from the least-squares N(1)N(2)N(3)N(6B) plane are, respectively, 0.096 Å and 0.26 Å, which also

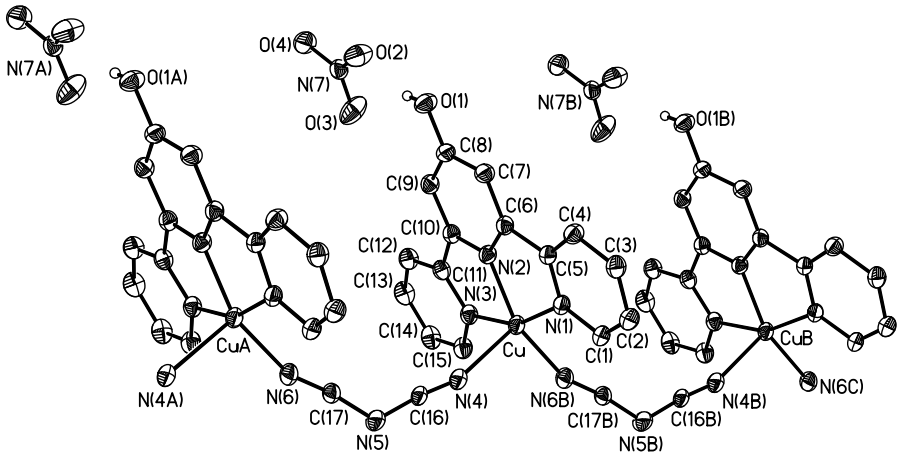

Fig. 4. Crystal structure of $[Cu^{II}(LH)(\mu_{1,5}\text{-dca})]_n(NO_3)_n$ with atom label schemes. C–H hydrogens are omitted for clarity. Symmetry codes: A, $1 + x$, y, z; B, $x - 1$, y, z; C, $x - 2$, y, z.

indicates that the coordination environment around the metal center is highly distorted.

As indicated from the Cu–N–C angles (Cu–N(6B)–C(17B) = 158.5(3)° and Cu–N(4)–C(16) = 161.9(3)°), each EE dca anion coordinates with the metal ion in slightly bent way. The C≡N and C–N distances for the dca anions are in the normal range. In addition, the C–N–C angle of 122.5(4)° indicates the pseudo C_{2v} symmetry of the dicyanamide.

Seven hydrogen bonds, six of C–H···O types and one of O–H···O type, link the dicyanamide-bridged one-dimensional chains into a two-dimensional sheet consisting of interlinked one-dimensional double-chains. A simplified illustration, down the crystallographic *b* axis, of the hydrogen bonds and the topology resulted therein is shown in Fig. 5, while the geometries of hydrogen bonds are listed in Table 5. Parts of four one-dimensional chains (CuA···Cu···CuB, CuD···CuE, CuF···CuG, and CuH···CuI) are shown in Fig. 5. The chains CuA···Cu···CuB and CuF···CuG belong to the same *ac* plane and, in comparison to this *ac* plane, the chains CuD···CuE and CuH···CuI belong to a lower and upper *ac* planes, respectively. Enolic oxygen (O(1)) of CuA···Cu···CuB chain acts as a double acceptor and interacts with two C–H (C(4D)–H(4D) and C(7D)–H(7D)) hydrogens of 4-terpyridone moiety of another chain CuD···CuE. One nitrate oxygen (O(2)) also acts as a double acceptor and interacts with one enolic hydrogen (O(1)–H(1)) and one C–H hydrogen (C(4D)–H(4D)) of two chains, CuA···Cu···CuB and CuD···CuE, respectively. Clearly, these four hydrogen bonds link the one-dimensional chains to result in the generation of one-dimensional double chains. Other two nitrate oxygens (O(3) and O(4)) are hydrogen bonded with two C–H hydrogens, C(13I)–H(13I) and C(14I)–H(14I), of a third one-dimensional chain CuH···CuI to add another dimension in the structure. O(3) acts as a bifurcated acceptor and interacts also with H(9) attached with C(9). In summary, the supramolecular structure in this compound can be considered as a two-dimensional sheet consisting of the hydrogen bonded double chains of interlinked dicyanamide-bridged one-dimensional coordination polymers.

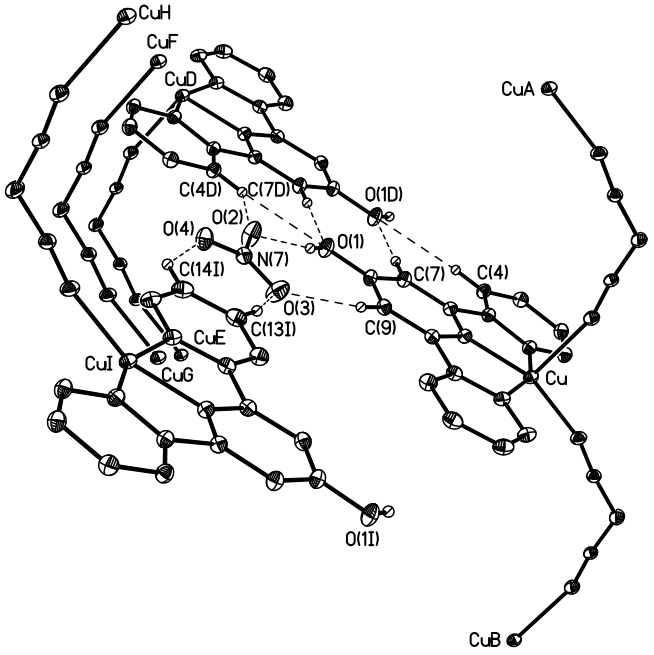

Fig. 5. Perspective view of **1** down the crystallographic *b* axis to show two-dimensional sheet consisting of the hydrogen bonded double chains of interlinked dicyanamide-bridged one-dimensional coordination polymers. C–H hydrogens are omitted for clarity. Symmetry codes: A, $1 + x$, y, z; B, $x - 1$, y, z; C, $x - 2$, y, z; D, $2 - x$, $-y$, $2 - z$; E, $1 - x$, $-y$, $2 - z$; F, $2 - x$, $1 - y$, $2 - z$; G, $1 - x$, $1 - y$, $2 - z$; H, $2 - x$, $2 - y$, $2 - z$; I, $1 - x$, $2 - y$, $2 - z$.

3.3. Magnetic properties

Variable-temperature (2–300 K) magnetic behavior at fixed field strength of 1 T of **1** is shown in Fig. 6 in the form of $\chi_M T$ versus T plots. The $\chi_M T$ value at 300 K is 4.33 $cm^3\ mol^{-1}\ K$, which is almost equal to the spin-only $\chi_M T$ value of high spin Mn^{II}. On lowering of temperature, $\chi_M T$ values remain almost constant upto ~10 K and then decrease rapidly to 2 K where the $\chi_M T$ value is 3.38 $cm^3\ mol^{-1}\ K$. The profile is characteristic of high spin man-

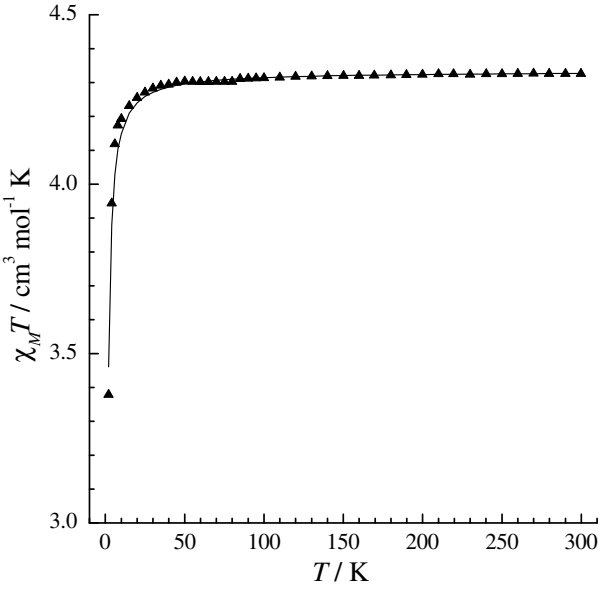

Fig. 6. Experimental (▲) and calculated (—) $\chi_M T$ vs. T plots for **1**.

ganese(II) with zero-field splitting. As shown in Fig. 6, experimental data are well matched with single-ion expression derived from $\mathbf{H} = D(\mathbf{S}_Z^2 - 1/3S(S+1))$ with $g = 1.99$ and $|D| = 0.14\ \mathrm{cm}^{-1}$; the agreement factor ($R$) defined as $\sum\{(\chi_M T)_{obs} - (\chi_M T)_{calc}\}^2/\sum(\chi_M T)^2_{obs}$ being 5.88×10^{-3}. It may be mentioned that, unlike in mononuclear cobalt(II) complexes, $[Co^{II}(LH)_2]X_2 \cdot nH_2O$ (X = Cl, ClO_4) [2a], spin crossover does not occur in the mononuclear manganese(II) compound **1**.

As shown in Fig. 7, $\chi_M T$ values for **2** are almost constant (*ca.* 0.41 $\mathrm{cm^3\ mol^{-1}\ K}$) throughout the temperature range 2–300 K indicating that copper(II) centers in this compound are noninteracting ($J = 0$). It is known from previous studies that copper(II) centers in dicyanamide-bridged compounds are either weakly antiferromagnetic, weakly ferromagnetic or noninteracting and the range of J values is from $-0.35\ \mathrm{cm}^{-1}$ to $0.20\ \mathrm{cm}^{-1}$ [4]. Therefore, $J = 0$ in **2** is in the range observed in reported compounds. Although the interaction in dicyanamide-bridged copper(II) complexes is very weak, the nature of interaction has been explained previously on the basis of equatorial-equatorial (usually short–short) and equatorial-axial (usually short–long) linkage of dicyanamide ligands to copper(II) centers [4a,4b]. According to this hypothesis, if the difference between Cu–N(equatorial) and Cu–N(axial) bond lengths is small and the coordination geometry is less distorted, the interaction should be ferromagnetic for the axial-equatorial case because of accidental orthogonality between the magnetic orbitals. In **2**, the difference between the Cu–N(equatorial) and Cu–N(axial) bond lengths (1.943(3) versus 2.207(3)) is not large. Again, the τ parameter in the square pyramidal coordination geometry is only 0.004, which apparently indicates an almost ideal environment around the metal center in **2**. However, as discussed above, the coordination geometry is actually highly distorted. $J = 0$ in **2** indicates that accidental orthogonality, which is strongly dependent on the structural features, does not take place in **2** probably due to large distortion in the coordination environment.

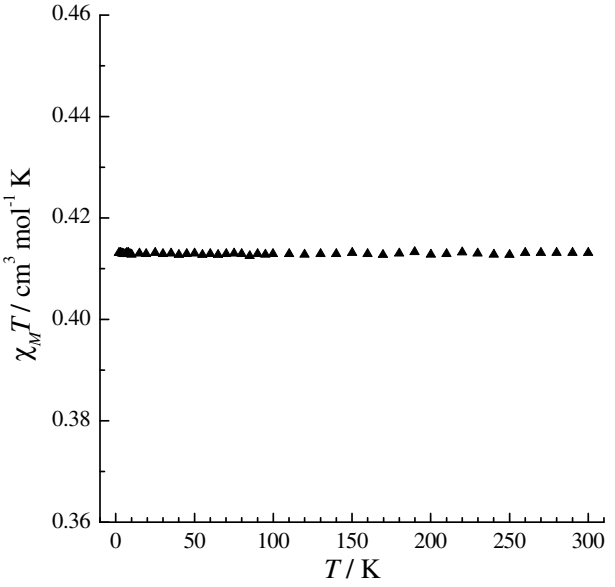

Fig. 7. Experimental (▲) $\chi_M T$ vs. T plots for **2**.

4. Conclusions

The main objective of the present investigation has been isolation and determination of structures of complexes derived from 4-terpyridone with an expectation that 4-terpyridone containing metal compounds may be good building unit to develop hydrogen bonded supramolecular structures. Accordingly, syntheses and structures of two 4-terpyridone containing compounds **1** and **2** have been described in this investigation. In both the compounds, partiticipation of enolic O–H group is observed to generate hydrogen bonded two- or three-dimensional supramolecular structure. Dicyanamide-bridged one-dimensional polymer, **2**, is a new addition in the family of dicyamide-metal systems. Magnetic studies of **1** reveal that, unlike in mononuclear cobalt(II)-4-terpyridone complexes, $[Co^{II}(LH)_2]X_2 \cdot nH_2O$ (X = Cl, ClO_4) [2a], spin-crossover does not take place in the manganese(II) compound **1**. Dicyanamide-bridged copper(II) centers in **2** are practically noninteracting, which is related to the highly distorted coordination environment of the metal centers.

derived from and based upon metal-coordination networks, ranging from simple chains to ladders, sheets, diamondoid nets, and other fascinating architectures [5]. Azide ion is known for its versatility as bridging ligand since it can bind two metal centers in *end-on* and/or *end-to-end* fashions [6,7]. Among the various transition and non-transition metal atoms cadmium is an extremely toxic element that is naturally present in the environment and also as a result of human activities. Recently, in living organisms the concentration of this metal has been increased gradually. The development of chelating agents is essential for the treatment of cadmium intoxication [8]. The practical importance of Cd(II) coordination chemistry results from the mobilization and immobilization of this metal in the environment, in organisms, and in some technical processes which depend significantly on the complexation of the metal center by chelating organic molecules containing nitrogen and/or sulfur donor atoms. Complexes of Cd(II) with nitrogen-containing ligands have also been used successfully in ligand exchange chromatography [9]. Though cadmium has been known as a toxic metal and is often associated with Hg and Pb as one of the biologically harmful metal ions, recently it has been found that Cd(II) ion can serve as the catalytic center in a newly discovered carbonic anhydrase [10]. Cd(II) ion is capable of adopting a wide variety of geometries and coordination numbers permitted by its d^{10} configuration [11]. Most Cd(II) complexes are octahedral [12] while four- and five-coordinated complexes are limited to few cases imposed either by bulkiness of the donor atoms [13–16] or by steric requirements of the ligands [17]. Moreover, the d^{10} center metals like Zn(II) and Cd(II) associated with the conjugated π systems containing aromatic rings favor the development of fluorescent materials [18–20].

Our research group has already reported some mono-, di-, tri- and polynuclear Cd(II) complexes with different Schiff base ligands or various bidentate chelating diamines in presence of pseudohalides [3,8,9,21–25]. Recently, we also reported three new pseudohalide bridged dinuclear Zn(II) complexes [26] of a potentially tetradentate Schiff base ligand which is the condensation product of *o*-vanillin and 2-dimethylaminoethylamine. In continuation, using a N_2O donor tridentate Schiff base ligand **LH** (Scheme 1) obtained by condensing 2-hydroxy-4-methoxybenzaldehyde and 2-diethylaminoethylamine, we have reported synthetic details, spectral characterizations, thermal investigation, along with X-ray crystal structures and fluorescence studies of two new di- and polynuclear Cd(II) complexes, $[Cd_2(L)_2(Cl)_2]$ (**1**) and $[Cd_3(\mu_{1,1}\text{-}N_3)_4(L)_2\{H_2N(CH_2)_2N(C_2H_5)_2\}\cdot H_2O]_n$ (**2**), respectively, in the present paper.

Scheme 1. **LH**.

2. Experimental

2.1. Materials

2-Diethylaminoethylamine, 2-hydroxy-4-methoxybenzaldehyde (Aldrich, Germany), cadmium(II) acetate dihydrate, cadmium(II) chloride dihydrate, sodium azide (E. Merck, India) were used as received. All the solvents were of AR grade and used as received.

Caution! Azido compounds of metal ions are potentially explosive especially in presence of organic ligands. Only a small amount of material should be prepared and it must be handled with care.

2.2. Physical measurements

The infrared spectra of the complexes were recorded on a Perkin–Elmer RX I FT-IR spectrophotometer with KBr discs (4000–300 cm^{-1}). Elemental analyses (C, H, N) were carried out using a Perkin–Elmer 2400 II elemental analyzer. ^1H NMR spectra were recorded on a Bruker 300 MHz FT-NMR spectrometer using trimethylsilane as internal standard in $CDCl_3$ for complexes **1** and **2**. The thermal analysis of **1** was done on a Mettler Toledo TGA/SDTA-851e thermal analyzer system in a dynamic atmosphere of dinitrogen (flow rate: 30 cm^3 min^{-1}) in alumina crucible at a heating rate of 10 °C min^{-1}. Ground state absorptions for the ligand and the complexes were made with a Perkin–Elmer Lambda 40 (UV–Vis) spectrophotometer in methanol. Perkin–Elmer LS50B spectrofluorimeter model was used for the steady state fluorescence measurements of the complexes and Schiff base ligand at room temperature (298 K). The solutions of the ligand and complexes **1** and **2** were prepared in methanol medium.

2.3. Synthesis of the Schiff base ligand and metal complexes

2.3.1. Schiff base $[(C_2H_5)_2NCH_2CH_2N{=}CHC_6H_3(OH)(OMe)]$ (**LH**)

The Schiff base was obtained by refluxing a methanolic solution (50 ml) of 2-hydroxy-4-methoxybenzaldehyde (10 mmol) and 2-diethylaminoethylamine (10 mmol) for 30 min. The resulting orange yellow solution containing the required product was used without further purification.

2.3.2. $[Cd_2(L)_2(Cl)_2]$ (**1**)

To a methanolic solution (20 ml) of cadmium chloride dihydrate (0.200 g, 1 mmol), the solution of Schiff base (1 mmol) was added with constant stirring for 10 min. Colourless, block shaped crystals suitable for X-ray diffraction were obtained after 5 days. Crystals were collected by filtra-

tion and air-dried. Yield: 53%. *Anal.* Calc. for $C_{28}H_{42}N_4O_4Cl_2Cd_2$: C, 42.33; H, 5.33; N, 7.05. Found: C, 42.09; H, 5.25; N, 7.01%.

2.3.3. $[Cd_3(\mu_{1,1}\text{-}N_3)_4(L)_2\{H_2N(CH_2)_2N(C_2H_5)_2\}\cdot H_2O]_n$ (2)

To the aqueous methanolic solution (30 ml) of cadmium acetate dihydrate (0.266 g, 1 mmol), the solution of Schiff base **LH** (1 mmol) was added followed by mixing a solution of sodium azide (0.065 g, 1 mmol) in minimum volume of methanol with constant stirring for 10 min. This mixture was kept at room temperature yielding red, block shaped crystals suitable for X-ray diffraction after 10 days. Crystals were isolated by filtration and air-dried. Yield: 61%. *Anal.* Calc. for $C_{68}H_{120}N_{36}O_9Cd_6$: C, 36.13; H, 5.35; N, 22.31. Found: C, 35.98; H, 5.21; N, 22.25%.

2.4. Crystallographic data collection and structure refinements

Intensity data for crystals of **1** and **2** were collected on Bruker X8 Apex II CCD diffractometer and Bruker SMART Apex CCD diffractometer, respectively. Data were corrected for absorption empirically by means of multi-scans (SADABS) for both **1** and **2**. The structures were solved by direct and difference Fourier methods and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined with anisotropic displacement parameters. The crystallographic computing was performed using SHELXTL [27] programs. Further details have been given in Table 1. Complex **1** crystallises in the non-centrosymmetric space group $P2_1$ and was refined as a racemic twin. No higher symmetry could be found and there are no significant correlation matrix elements to suggest higher molecular symmetry.

Table 1
Experimental, crystallographic and refinement data for complexes **1** and **2**

Complex	1	2
Empirical formula	$C_{28}H_{42}N_4O_4Cl_2Cd_2$	$C_{68}H_{120}N_{36}O_9Cd_6$

Schiff base ligand $\mathbf{L}^-$ bonded through the imine nitrogen, amine nitrogen and phenolato oxygen (N,N,O) atoms. Two phenolato O atoms O(1) and O(3) of two molecules of deprotonated Schiff base ligand bridge the two cadmium(II) centers and link the two halves of the dimer about a pseudo two fold symmetry axis which lies normal to the almost planar Cd_2O_2 ring. The geometry about the five-coordinated cadmium centers is approximately square pyramidal with the chlorine atoms occupying the (off-center) apical sites; the basal planes *e.g.* O(1), O(3), N(1) and N(2) about Cd(1), form good mean-planes from which the Cd atoms are displaced by 0.886(7) and 0.893(7) Å towards the chloride ligands. The bridging oxygen atoms form asymmetric linkages to the Cd atoms with a range of Cd–O distances 2.227(5)–2.294(4) Å and Cd(1)–O–Cd(2) bridging angles of 103.34(18) and 104.13(18)°. The long distance (3.558 Å) between two Cd(II) centers suggests that there is no interaction between these two metal centers. The angles around O(1) and O(3) are 359.44 and 359.33°, respectively (almost equals to 360°) indicating no pyramidal distortion at these atoms.

3.0.2. Description of crystal structure of **2**

The trimeric asymmetric unit of the polymeric complex **2** is shown in Fig. 2 with selected bond distances and bond angles listed in Table 3. This trinuclear asymmetric unit of complex **2** forms a zig-zag ladder shaped one-dimensional polymer (Fig. 3) through the doubly *end-on* azido bridging. The non-bonded Cd(1)...Cd(3), Cd(1)...Cd(2), Cd(2)...Cd(2) and Cd(3)...Cd(3) separations are 3.685, 3.692, 3.972 and 3.847 Å, respectively.

As shown in Fig. 3, the Cd(II) atoms are all six coordinated with distorted octahedral geometry having N_4O_2 donor set for each of the central Cd(1) atom, while N_5O donor set for the adjacent Cd(2) and Cd(3) atoms. The distortion in the geometry from regular octahedron is evidenced from the respective *cis*- and *trans*-angles about Cd(1), Cd(2) and Cd(3) centers (Table 3). Such variations in the bond angles are clearly due to the formation of bridges between the Cd atoms and also due to the formation of chelate by the organic amine. The Cd(1) atom is doubly bound together with both the adjacent Cd(2) and Cd(3) centers by μ_2-phenolato oxygen atoms O(2) and O(4), respectively from the two deprotonated Schiff base moieties $\mathbf{L}^-$ and the $\mu_{1,1}$-azido nitrogen atoms N(4) and N(7), respectively, as depicted in Fig. 2. Again, the Cd(2) or Cd(3) atom of one trimeric asymmetric subunit is bridged with the adjacent cadmium(II) atom of the next subunit via doubly *end-on* azido groups generating one-dimensional ladder shaped zig-zag polynuclear network (Fig. 3). In this complex the chelating diamine is attached with the Cd(1) centers together with the deproto-

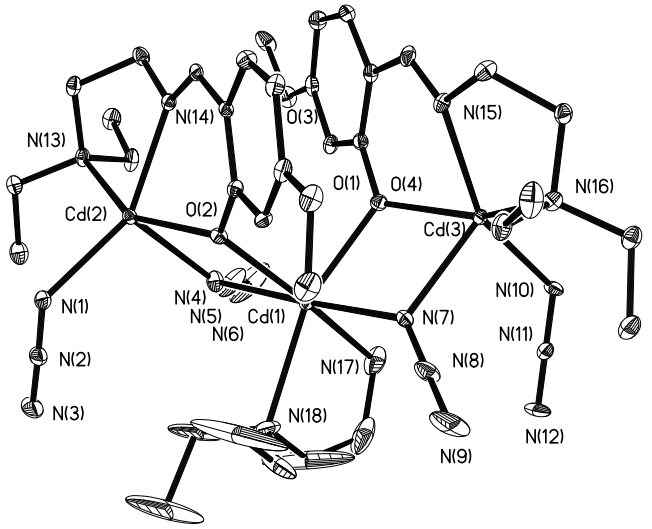

Fig. 2. ORTEP view of the trimeric asymmetric subunit of polymeric complex **2**, with atom labels. Displacement ellipsoids are shown at 50% probability level. The hydrogen atoms are omitted for clarity.

Symmetry transformations used to generate equivalent atoms: #1 $-x$, $-y+1$, $-z$; #2 $-x+1$, $-y+1$, $-z+1$.

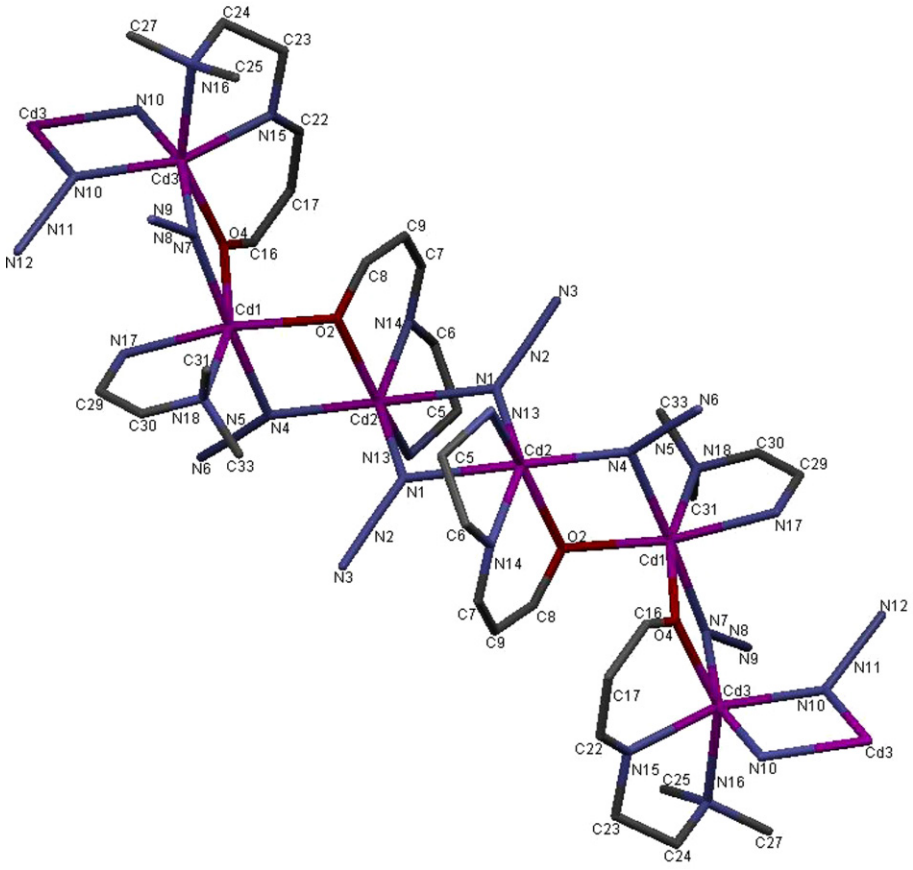

Fig. 3. View of the longer part of zig-zag ladder shaped polymeric chain of the core complex **2** in Mercury, with atom labels (all pendant groups such as the aryl and ethyl moieties are omitted for clarity).

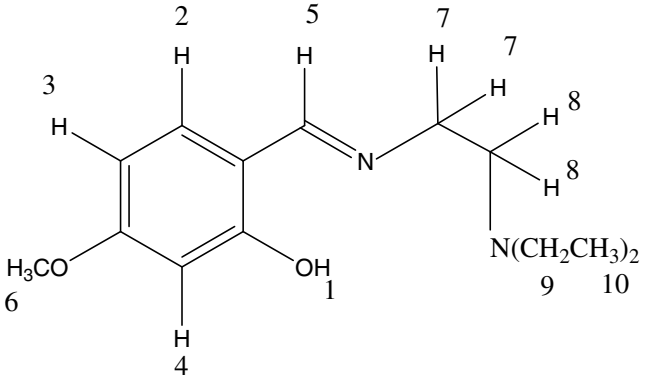
nated bridging Schiff base ligands $\mathbf{L}^-$. The reason behind this may be the partial hydrolysis of the Schiff base ligand in the presence of the azide anion bridged with the metal centers to generate the free amine moiety. The square base around the Cd(1) is formed by phenolato oxygen atoms [O(4) and O(2)] from the two bridging $\mathbf{L}^-$, amino nitrogen atoms N(17) and N(18) from the chelating diamine $H_2N(CH_2)_2N(C_2H_5)_2$, where as the axial sites are occupied by the N(4) and N(7) atoms of the two $\mu_{1,1}$-azido groups with a *trans* angle, N(4)–Cd(1)–N(7), of 177.5(2)°. On the other side the N_2O donor set [imino nitrogen N(14), amino nitrogen N(13) and the bridging phenolato oxygen O(2)] from the bridging $\mathbf{L}^-$ and the *end-on* bridging azido nitrogen N(1) form the square base around Cd(2) and other two $\mu_{1,1}$-azido nitrogen atoms N(4) and N(1)#1 take up two axial positions with respect to the equatorial plane of the pseudooctahedral geometry, with a *trans* angle, N(4)–Cd(2)–N(1)#1, of 167.4(2)°. The environment around the Cd(3) atom is identical with the Cd(2) center. For Cd(3), we define the equatorial plane comprising of imino nitrogen N(15), amino nitrogen N(16), the bridging phenolato oxygen O(4) (coming from the bridging $\mathbf{L}^-$) and the *end-on* bridging azido nitrogen N(10). The N(7) and N(10)#2 are in the axial positions with respect to this plane, with a *trans* angle, N(7)–Cd(3)–N(10)#2, of 159.6(2)°. The bridging angles Cd–O–Cd and Cd–N(azido)–Cd vary from 107.6(2) to 107.66(19)° and 101.6(2)–109.3(3)°, respectively. The N–N–N bond angles in the $\mu_{1,1}$-azido groups are 177.9(13)–178.5(12)°, slightly deviated from the linearity.

3.1. Infrared spectra

The infrared spectra of the complexes are consistent with their structural data given in this paper. The trifurcated bands at 2095, 2067 and 2038 cm^{-1} for **2** are attributed for the bridging azido (N_3^-) groups in **2** [28]. The strong $\nu_{C=N}$ bands occurring at 1625 and 1602 cm^{-1} for **1** and **2**, respectively, are shifted considerably towards lower frequencies compared to that of the free Schiff base ligand (1635 cm^{-1}) indicating the coordination of the imino nitrogen atoms with the metal centers [29]. Ligand coordination to metal centers is substantiated by two bands appearing for ν_{M-N} at 425, 460 cm^{-1} and for ν_{M-O} at 375, 370 cm^{-1} for **1** and **2**, respectively.



3.2. ^1H NMR spectra

The ^1H NMR spectroscopy has been used to extract information regarding the coordination mode of the ligand with metal ions for the complexes **1** and **2**; the NMR data

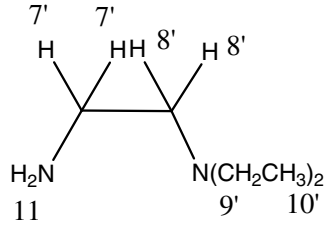


Table 4
^{1}H NMR spectral data with assignments for the Schiff base **LH** and complexes **1** and **2**

Schiff base/ Complex	δ (in ppm)
LH	2.01 (6H, t, $J = 2.1$ Hz, H10); 2.06 (4H, q, $J = 2.4$ Hz, H9); 2.64 (2H, t, $J = 3.4$ Hz, H8); 3.42 (2H, t, $J = 4.5$ Hz, H7); 3.86 (3H, s, H6); 5.26 (1H, s, H1); 6.35 (1H, d, $J = 7.2$ Hz, H2); 6.61 (1H, s, H4); 8.01 (1H, d, $J = 7.8$ Hz, H3); 8.30 (1H, s, H5)
1	2.04 (12H, t, $J = 2.1$ Hz, H10); 2.12 (8H, q, $J = 2.4$ Hz, H9); 2.66 (4H, t, $J = 3.4$ Hz, H8); 3.48 (4H, t, $J = 4.2$ Hz, H7); 3.87 (6H, s, H6); 6.44 (2H, d, $J = 7.2$ Hz, H2); 6.82 (2H, s, H4); 8.05 (2H, d, $J = 7.6$ Hz, H3); 8.33 (2H, s, H5)
2	2.04 (12H, t, $J = 2.1$ Hz, H10); 2.14 (8H, q, $J = 2.4$ Hz, H9); 2.65 (4H, t, $J = 3.2$ Hz, H8); 3.46 (4H, t, $J = 3.9$ Hz, H7); 4.03 (6H, s, H6); 6.51 (2H, d, $J = 6.8$ Hz, H2); 6.83 (2H, s, H4); 8.13 (2H, d, $J = 7.8$ Hz, H3); 8.35 (2H, s, H5); 2.06 (6H, t, $J = 2.1$ Hz, H10′); 2.15 (4H, q, $J = 2.4$ Hz, H9′); 2.63 (4H, t, $J = 3.2$ Hz, H8′); 3.40 (4H, t, $J = 3.9$ Hz, H7′); 5.65 (2H, s, H11)

are summarized in Table 4 showing the proton numbering Schemes 2 and 3. In the ^{1}H NMR spectra of **1** and **2**, the signal due to the phenolic hydrogen (H1) of the free **LH** molecule (5.26 ppm) is absent, indicating the coordination of the deprotonated ligands ($\mathbf{L}^-$) in these complexes. The signals for the amino ethyl groups (H9 and H10) show down-field shifts (0.08 ppm) in their position from those of the free molecule due to the coordination of the amino nitrogen atom with the metal centers. The singlet due to the proton (H5) attached to the imino (–C=N) group shows a down-field shift (0.03–0.05 ppm) compared to its position in the free molecule, reflecting the coordination of the deprtonated Schiff base ligand ($\mathbf{L}^-$) to the metal centers through the imine nitrogen atom. The phenyl hydrogens show significant shifts [0.15–0.16 ppm (H2), 0.22 ppm (H4), 0.12 ppm (H3)] indicating the involvement of phenolato oxygen in coordination with the metal centers. For the complexes, the protons (H7) of the CH_2 group attached to the imine nitrogen and the protons (H8) of the CH_2 group associated with the amine nitrogen atoms show down field shifts from 0.04 ppm and 0.01 ppm, respectively, from that of the free ligand. For complex **2** five additional NMR signals are observed due to the protons (H10′, H9′, H8′, H7′ and H11) of chelating diamine $H_2N(CH_2)_2N(C_2H_5)_2$ attached with the Cd(1) center. Hydrogen atoms attached to the amino nitrogen atoms show increase in the chemical shift value from the free diamine ligand due to the coordination to the Cd(II) ion. The results obtained from the ^{1}H NMR spectra support the structures obtained from X-ray analysis and suggest that the structures of the complexes **1** and **2** are retained in $CDCl_3$ solution.

Scheme 2. Schiff base ligand.

Scheme 3. Free diamine ligand.

3.3. Thermogravimetric analysis

The thermal study of complex **2** was not carried out in order to avoid the explosion of the azide compound. The thermal analysis of complex **1** was performed in the temperature range 28.3–800 °C in dynamic nitrogen atmosphere. It shows a gradual weight loss indicating decomposition in fragment with increasing temperature. The thermogram exhibits the weight loss between 240.5 and 800 °C corresponding to about 76.24% and its stability upto 240.5 °C. The complete decomposition of the complex **1** occurs in three steps. The first step occurs between 240.5 and 487.1 °C, while the second and the third steps take place between 499.1–590.3 °C and 624.3–800 °C, respectively. The mass loss for **1** is due to the elimination of two molecules of the coordinating ligand $\mathbf{L}^-$ and the remaining residue at 800 °C corresponds to cadmium oxide which is confirmed by quantitative estimation.

3.4. Fluorescence spectral studies

The fluorescence properties of the Schiff base ligand (**LH**) and its Cd(II) complexes (**1** and **2**) were studied at room temperature (298 K) in methanol–water solutions (Fig. 4). Complex **1** displays emission spectrum at 410 nm while **2** has a band at 419 nm. Complex **1** shows very weak fluorescence. Complex **2** exhibits strong fluorescence in comparison to **LH** and complex **1**. For Cd(II) complex, no emission originating from metal-centered MLCT/LMCT excited states are expected, since Cd(II) ion is difficult to oxidize or reduce due to its stable d^{10} configuration.

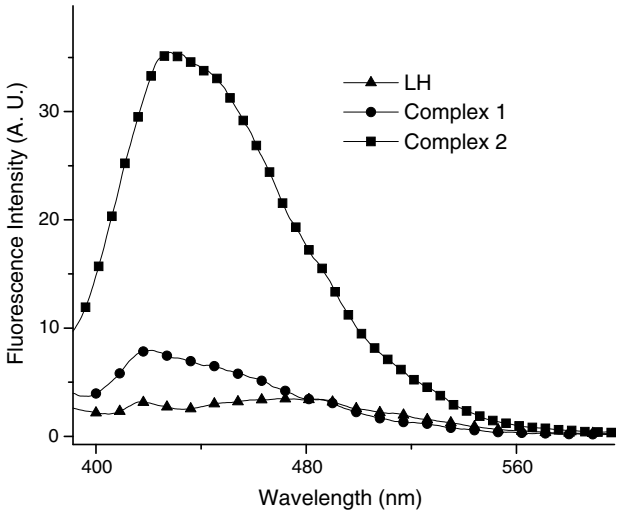

Fig. 4. Fluorescence spectra of LH, complexes **1** and **2** in methanol–water medium ($\lambda_{exc} = 370$ nm).

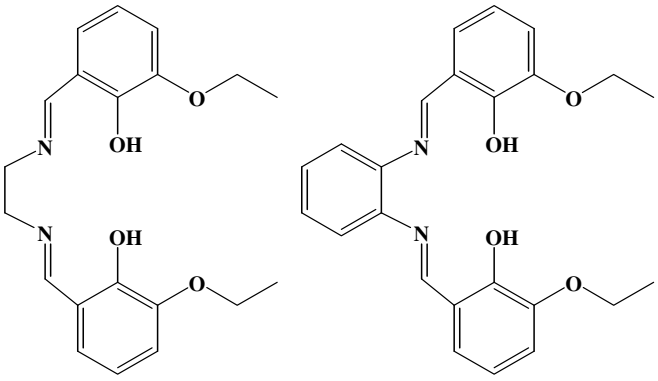
Thus, the emission observed in the complex is tentatively assigned to the $^1(\pi–\pi^*)$ intraligand fluorescence. It is interesting that the Cd(II) complexes show higher intensity than that of the free ligand. Metal ions can enhance or quench the fluorescence emission of some Schiff base ligands containing aromatic ring. Quenching of fluorescence of a ligand by transition metal ions during complexation is a rather common phenomenon which is explained by processes such as magnetic perturbation, redox activity and electronic energy transfer. Enhancement of fluorescence through complexation is, however, of much interest as it opens up the opportunity for photochemical applications of these complexes [30]. In the absence of metal ions the fluorescence of the ligand is probably quenched by the occurrence of a photoinduced electron transfer (PET) process due to the presence of lone pairs of electrons of the donor atoms in the ligand. Such a PET process is prevented by the complexation of **LH** with metal ions; thus the fluorescence intensity may be greatly enhanced by the coordination of Cd(II). This is defined as chelation enhanced fluorescence intensity. The chelation of the ligand to Cd(II) increases the rigidity of the ligand and thus reduces the loss of energy by thermal vibrational decay [31].

4. Conclusion

In this paper it has been shown that the geometry about the Cd(II) centers in the dinuclear complex **1** and polynuclear complex **2** are square pyramidal and distorted octahedral, respectively. The two Cd(II) centers in **1** are held together by two μ_2-phenolato oxygen atoms with the two terminal chlorine atoms occupying the apical sites of the square pyramidal environment of both the metal centers. On the other hand complex **2** is the one-dimensional ladder shaped zig-zag polymer having six-coordinated Cd(II) centers linked via $\mu_{1,1}$-azido and μ_2-phenolato bridges. In this complex also the chelating diamine is attached with the Cd(1) centers together with the deprotonated bridging Schiff base ligands $\mathbf{L}^-$. This may be due to the partial hydrolysis of the Schiff base ligand in presence of the azide anion bridged with the metal centers.

Acknowledgements

We gratefully acknowledge Jadavpur University, Kolkata, India for providing Laboratory facilities. We are thankful to Dr. N. Gucchait and Ms. A. Chakraborty, Department of Chemistry, University College of Science and Technology, Kolkata, India for recording the fluorescence spectra.



Appendix A. Supplementary material

CCDC 649492 and 649491 contain the supplementary crystallographic data for **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.12.005.

H_2L H_2L^1

Chart 1. Chemical structures of H_2L and H_2L^1.

diamines, we have reported that the potential encapsulation of water in the vacant O_4 ligand compartment results in the formation of an inclusion compound $[Cu^{II}L\subset(H_2O)]$ and tetrametallic compounds $[\{Cu^{II}LM^{II}(H_2O)_3\}\{Cu^{II}L\}_2](ClO_4)_2$ (M = Cu, Co, or Mn) consisting of cocrystals of one dinuclear $[Cu^{II}LM^{II}(H_2O)_3]^{2+}$ cationic unit and two mononuclear $[Cu^{II}L]$ moieties (H_2L = *N*,*N*′-ethylenebis(3-ethoxysalicylaldimine); Chart 1) [2]. The reason for cocrystallization in these compounds is clearly understood from the hydrogen bonding interactions. This observation indicates that designed syntheses of dinuclear–mononuclear cocrystals may be possible in similar ligand environments. In order to further explore this possibility, we report here the syntheses, structures, and magnetic properties of an inclusion compound $[Cu^{II}L^1\subset(H_2O)]$ (**1**) as well as self-assembled heptacopper(II) compound $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4\cdot 2CH_3COCH_3$ (**2**), and tetrametallic compounds $[\{Cu^{II}L^1M^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2\cdot H_2O\cdot CH_3COCH_3$ (M = Co (**3**), M = Mn (**4**)) derived from the ligand *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine) (H_2L^1; Chart 1).

2. Experimental

2.1. Materials and physical methods

All the reagents and solvents were purchased from commercial sources and used as received. The Schiff base ligand H_2L^1 was prepared by 2:1 condensation of 3-ethoxysalicylaldehyde and *o*-phenylenediamine in methanol. Elemental (C, H, and N) analyses were performed on a Perkin–Elmer 2400 II analyzer. IR spectra were recorded in the region 400–4000 cm^{-1} on a Perkin–Elmer RXIFT spectrophotometer with samples as KBr disks. Magnetic susceptibility measurements of **1** at 300 K were carried out with a Sherwood Scientific Co., UK magnetic susceptibility balance. Variable-temperature (2–300 K) magnetic susceptibility measurements at a fixed field strength of 1 T were carried out with a Quantum Design MPMS SQUID magnetometer. Diamagnetic corrections were estimated from the Pascal constants [8].

2.2. Syntheses

2.2.1. $[Cu^{II}L^1\subset(H_2O)]$ (**1**) [9]

An aqueous solution (10 mL) of copper(II) acetate monohydrate (1.0 g, 5 mmol) was dropwise added to a suspension of H_2L^1 (2.02 g, 5 mmol) in methanol (30 mL). A reddish brown precipitate started to deposit. After one hour stirring, the compound was collected by filtration and air dried. Dimethylformamide was used for recrystallization. Yield: 1.94 g (80%). Anal. Calc. for $C_{24}H_{24}N_2O_5Cu$: C, 59.56; H, 4.99; N, 5.79. Found: C, 59.65; H, 4.92; N, 5.70%. IR (cm^{-1}, KBr): $\nu_{as}(H_2O)$, 3506w; $\nu_s(H_2O)$, 3468w; ν(C=N), 1606s; $\delta(H_2O)$, 1541m; ν(C–OEt), 1244s. μ_{eff} = 1.71 BM (bohr magneton).

2.2.2. $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4\cdot 2CH_3COCH_3$ (**2**) and $[\{Cu^{II}L^1M^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2\cdot H_2O\cdot CH_3COCH_3$ (M = Co (**3**), M = Mn (**4**))

These three compounds were prepared in the same way as described below for **2** using the appropriate $M(ClO_4)_2\cdot 6H_2O$.

To a suspension of **1** (0.121 g, 0.25 mmol) in acetone (20 mL) was added dropwise with stirring a acetone solution (5 mL) of copper(II) perchlorate hexahydrate (0.093 g, 0.25 mmol). Immediately, a brown solution formed which was filtered after 0.5 h to remove any suspended particles. The filtrate was then kept at room temperature for slow evaporation. After a few days, diffraction quality brown crystals that deposited were collected and washed with cold acetone. Yield: 0.125 g (82%). Anal. Calc. for $C_{126}H_{134}N_{10}O_{44}Cl_4Cu_7$: C, 49.10; H, 4.38; N, 4.55. Found: C, 49.08; H, 4.34; N, 4.47%. IR (KBr/cm^{-1}): $\nu(H_2O)$, 3402w; ν(C=N), 1609s; $\nu(ClO_4)$, 1088vs, 621w.

Data for **3**: Color: brown. Yield: 75%. Anal. Calc. for $C_{75}H_{80}N_6O_{25}Cl_2Cu_3Co$: C, 50.44; H, 4.52; N, 4.71. Found: C, 50.53; H, 4.49; N, 4.76%. IR (KBr/cm^{-1}): $\nu(H_2O)$, 3408w; ν(C=N), 1605s; $\nu(ClO_4)$, 1089vs, 622w.

Data for **4**: Color: red. Yield: 85%. Anal. Calc. for $C_{75}H_{80}N_6O_{25}Cl_2Cu_3Mn$: C, 50.55; H, 4.53; N, 4.72. Found: C, 50.57; H, 4.46; N, 4.66%. IR (KBr/cm^{-1}): $\nu(H_2O)$, 3398w; ν(C=N), 1607vs; $\nu(ClO_4)$, 1094s, 621w.

2.3. Crystal structure determination of $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4\cdot 2CH_3COCH_3$ (**2**) and $[\{Cu^{II}L^1Mn^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2\cdot H_2O\cdot CH_3COCH_3$ (**4**)

The crystallographic data of these two compounds are summarized in Table 1. Diffraction data for **2** were collected on an Enraf-Nonius CAD4 diffractometer at 293 K. The data collection and reduction were carried out with CAD4 Express Enraf-Nonius CAD4 programs package. Data for **4** were collected at 293 K on a XCALI-

BUR diffractometer in the ω/ϕ scan mode using CrysAlis, Oxford Diffraction programs package. All data were corrected for Lorentz-polarization effects and analytical absorption corrections were made for **4**. Both the structures were solved by direct and Fourier methods and refined by full-matrix least-squares methods based on F^2 with the programs SIR92 and SHELXL-97 [10]. The two perchlorates in the asymmetric unit of **2** are statically disordered (occupancy 0.5) situated in O(16), O(17) and O(19), O(20), O(21). Hydrogen atoms were inserted at calculated positions with isotropic parameters constrained to be 1.2 times the U_{eq} of the carrier atoms (1.5 times for hydrogen atoms of methyl groups) and refined except for hydrogen atoms of water molecules which were located from a difference Fourier map. The same isotropic thermal parameters were used for these hydrogen atoms and they were then refined. The final least-squares refinements (R_1) based on $I > 2\sigma(I)$ converged to 0.0576 and 0.0551 for **2** and **4**, respectively.

3. Results and discussion

3.1. Syntheses and characterization

Reaction of copper(II) acetate and H_2L^1 produces the mononuclear copper(II) complex $[Cu^{II}L^1 \subset (H_2O)]$ (**1**). The IR spectrum (Fig. S1) of compound **1** exhibits two weak but sharp bands at 3506 and 3468 cm^{-1} due to the O–H stretching vibration of the water molecule and one medium intensity band at 1541 cm^{-1} due to the bending vibration mode of water. These indicate that the water molecule in **1** is encapsulated in the O_4 compartment of the ligand resulting in the formation of an inclusion product (Chart 2) [2,11]. When **1** is treated with $Cu(ClO_4)_2 \cdot 6H_2O$ in acetone, the heptanuclear compound $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4 \cdot 2CH_3COCH_3$ (**2**) separates from the solution as brown crystals. On the other hand, the reaction of **1** either with $Co(ClO_4)_2 \cdot 6H_2O$ or $Mn(ClO_4)_2 \cdot 6H_2O$ leads to the formation of the heterotetranuclear complexes $[\{Cu^{II}L^1Co^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2 \cdot H_2O \cdot CH_3COCH_3$ (**3**) or $[\{Cu^{II}L^1Mn^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2 \cdot H_2O \cdot CH_3COCH_3$ (**4**), respectively. Surprisingly, no such compound could be isolated with nickel(II) perchlorate. Compared to the $\nu_{C=N}$ vibration observed in the free ligand H_2L^1 at 1615 cm^{-1}, this vibration is shifted slightly to lower frequency at *ca.* 1606 cm^{-1} in complexes **1**–**4**.

3.2. Description of the structures

3.2.1. $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4 \cdot 2CH_3COCH_3$ (2)

One-half of the structure of **2** is symmetry related to the other half because of the presence of a crystallographic twofold axis. The asymmetric unit, $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}](ClO_4)_2 \cdot 1.5[Cu^{II}L^1] \cdot CH_3COCH_3$, in this compound consists of one dinuclear cationic unit $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}]^{2+}$, one and a half mononuclear $[Cu^{II}L^1]$ moieties, two perchlorate anions, and one acetone molecule as solvent of crystallization. Evidently, the overall composition of **2** is $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4 \cdot 2CH_3COCH_3$. In the dicopper(II) core, one copper(II) ion occupies the N_2O_2 cavity, and the second compartment of $[L^1]^{2-}$ is occupied by the second metal ion. As will be discussed below, the dinuclear cation is interlinked with the mononuclear moieties to result in the formation of the heptanuclear assembly in this compound. The structure and interlinking of the dinuclear moiety with the mononuclear fragments are shown in Fig. 1, while the heptanuclear assembly is in Fig. 2.

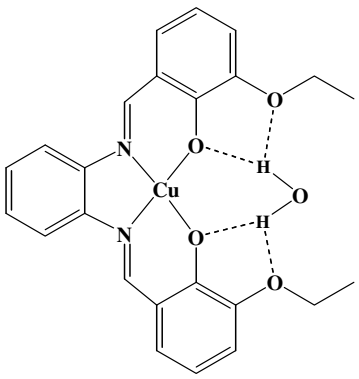

Chart 2. Chemical structure of $[Cu^{II}L^1 \subset (H_2O)]$ (**1**).

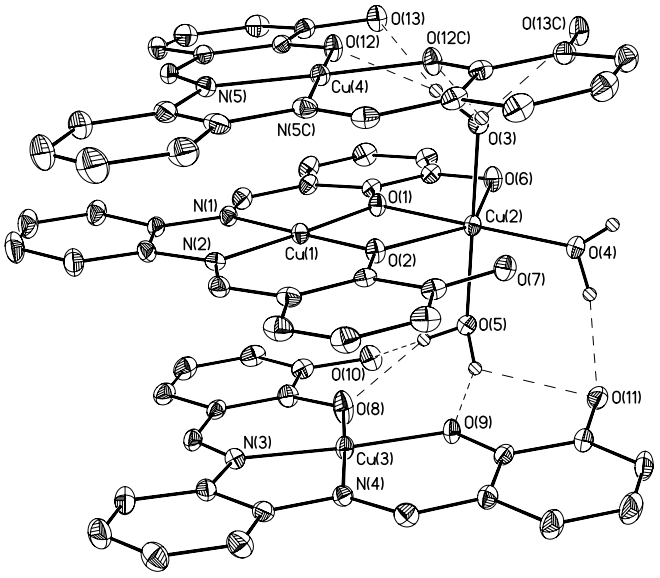

Fig. 1. Structure of **2** representing the dinuclear $\left[Cu^{II}L^{1}Cu^{II}(H_2O)_3\}\right]^{2+}$ cationic unit and two mononuclear $[Cu^{II}L^{1}]$ moieties. Only those hydrogens participating in hydrogen bonds are shown. Except oxygens, other atoms of the ethoxy groups are also omitted for clarity. Cu(2)–O(2) bond is shown to demonstrate an alternate CuO_6 coordination geometry of Cu(2).

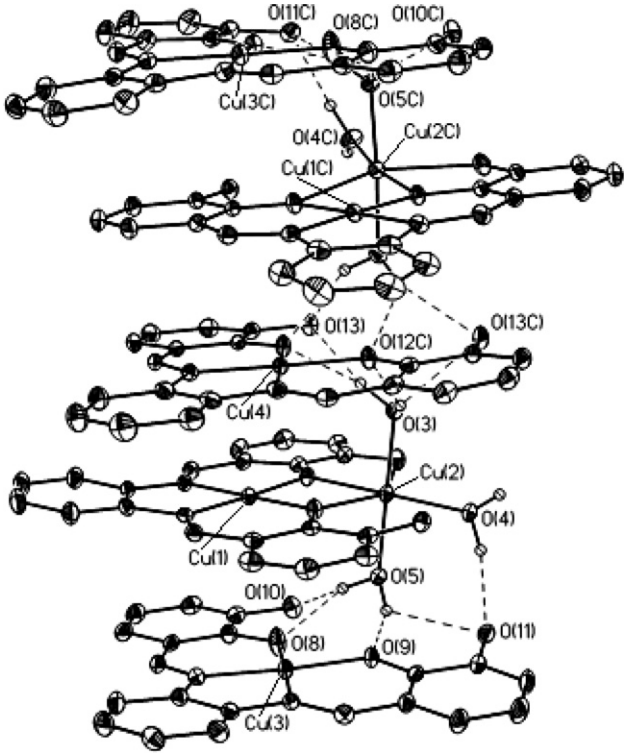

Fig. 2. Structure of **2** representing the interlinking of two dinuclear $[Cu^{II}L^{1}Cu^{II}(H_2O)_3\}]^{2+}$ cationic units and three mononuclear $[Cu^{II}L^{1}]$ moieties to result in the formation of self-assembled heptacopper(II) system. Only those hydrogens participating in hydrogen bonds are shown. Except oxygens, other atoms of the ethoxy groups are also omitted for clarity. Cu(2)–O(2) bond is shown to demonstrate an alternate CuO_6 coordination geometry of Cu(2).

The selected bond lengths and angles of the coordination environments of the three copper(II) centers (Cu(1), Cu(3), and Cu(4)) in the N_2O_2 compartment are in the usual range (Table 2) [2]. The coordination environments of these metal centers are very close to square planar as evidenced by the ranges of the *cisoid* (84.51(18)–95.32(16)°) and *transoid* (175.98(17)–179.40(17)°) angles, the average deviation (0.003–0.043 Å) of the donor atoms, and the displacement (0.000–0.023 Å) of the copper(II) center from the corresponding least-squares N_2O_2 plane.

There are two possibilities regarding the coordination environment of the second metal center (Cu(2)) in the dinuclear core; five-coordinate CuO_5 and six-coordinate CuO_6. In the former case, dinuclear core is monophenoxo-bridged; the second metal center (Cu(2)) is coordinated to one bridging phenoxo oxygen (O(1)), one ethoxy oxygen (O(6)), and three water oxygens (O(3), O(4), and O(5)), while one ethoxy oxygen (O(7)) and one phenoxo oxygen (O(2)) of the ligand remain uncoordinated. The coordination geometry of this pentacoordinated copper(II) is slightly distorted square pyramidal. The bridging phenoxo oxygen (O(1)) and three water oxygens (O(3), O(4), and O(5)) define the basal plane, while the ethoxy oxygen O(6) occupies the apical position. The average deviation

		Cu(1)–O(2)–Cu(2)	91.15(12)

Symmetry: C, $1-x$, y, $0.5-z$.

of the four oxygens and the displacement of the metal center from the least-squares O_4 plane are 0.106 Å and 0.057 Å, respectively. The *transoid* and *cisoid* angles in the O(1)O(3)O(4)O(5) basal plane lie in the ranges 169.81(16)–177.00(15)° and 85.54(15)–93.72(16)°, respectively, while the range of the bond angles involving the apical oxygen is 74.82(13)–95.79(16)°. These values along with the τ [12] value of 0.12 indicate that the coordination geometry of Cu(2) is slightly distorted square pyramidal. In the basal O_4 plane of Cu(2), the Cu–O bond distances lie in the ranges 1.937(4)–1.979(4)Å. By comparison, the apical Cu–O(ethoxy) bond distance is 2.358(4) Å. The Cu···Cu intramolecular distance and Cu–O(phenoxo)–Cu bridge angle are 3.165 Å and 109.73(16)°, respectively. The bridging moiety is appreciably twisted as evidenced by the dihedral angle (90.9°) between the basal planes of the two copper(II) centers.

For the CuO_6 coordination environment, dinuclear core is diphenoxo-bridged (Figs. 1 and 2, Table 2). In addition to the five oxygens in CuO_5 environment, the second phenoxo oxygen (O(2)) is also coordinated in this case. The coordination geometry for this CuO_6 environment is Jahn–Teller distorted tetragonal with the ethoxy oxygen (O(6)) and the second bridging phenoxo oxygen (O(2)) occupying the axial positions. *Transoid* angle and the ranges of *cisoid* angles involving O(2) are 145.89(12)° and 71.46(12)–118.19(15)°, respectively, and the apical Cu(2)–O(2) distance is 2.487(4) Å. If O(2) is considered as a coordinating center, Cu(2)–O(2) bond length should be smaller than the Cu(2)–O(6) bond distance because O(2) and O(6) are anionic and neutral centers, respectively. However, the apical bond length involving anionic center (O(2)) is longer than that involving neutral center (O(6)). Again, in comparison to the *transoid* angles (169.81(16)° and 177.00(15)°) in the O_4 basal plane and the range of all the *cisoid* angles (74.82(13)–95.79(16)°) in CuO_5 environment, the *transoid* angle (O(2)–Cu(2)–O(6) = 145.89(12)°) and the ranges of *cisoid* angles (71.46(12)–118.19(15)°) involving O(2) is significantly deviated from the ideal values. Evidently, coordination of O(2) to Cu(2) results in a tetragonal geometry which is much more distorted than that expected for Jahn–Teller effect, while CuO_5 environment is only slightly distorted from square pyramidal geometry. Therefore, among the two possibilities (CuO_5 and CuO_6), slightly distorted square pyramidal CuO_5 coordination environment is a better choice for Cu(2) center.

As shown in Fig. 1, the hydrogen bonding interactions between coordinated water molecules of the dinuclear $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}]^{2+}$ cation and phenoxo/ethoxy oxygens of the mononuclear $[Cu^{II}L^1]$ moieties result in the dinuclear–mononuclear interlinking in this compound. Among three coordinated water molecules, two ($H_2O(3)$ and $H_2O(5)$) interact and are encapsulated in the O_4 cavity of two $[Cu^{II}L^1]$ species, $[Cu^{II}(4)L^1]$ and $[Cu^{II}(3)L^1]$, respectively. Each of the water hydrogens of these two water molecules form bifurcated hydrogen bonds with two oxygens, one of which is a phenoxo and the second is an ethoxy oxygen. The geometries of these hydrogen bonds are summarized in Table 3. The donor···acceptor contacts for the $H_2O(3)$···phenoxo and $H_2O(5)$···phenoxo hydrogen bonds lie in the ranges 2.921(5)–2.982(5) Å and 2.669(5)–2.762(6) Å, respectively, while the ranges of the donor···acceptor contacts for the $H_2O(3)$···ethoxy and $H_2O(5)$···ethoxy hydrogen bonds are 3.151(5)–3.160(5) Å and 2.913(4)–2.972(5) Å, respectively. Evidently, the hydrogen bonds involving phenoxo oxygens are stronger. Again, the hydrogen bonds involving $H_2O(5)$ are stronger than those involving $H_2O(3)$. In addition to the bifurcated hydrogen bonds between phenoxo/ethoxy oxygens and two coordinated water molecules discussed above, there exists another hydrogen bond between one hydrogen (H(4A)) of the third coordinated water molecule ($H_2O(4)$) and one ethoxy oxygen (O(11)) of the mononuclear $[Cu^{II}(3)L^1]$ unit (Figs. 1 and 2, Table 3). The O(water)···O(ethoxy) contact in this case is 2.751(6) Å.

As already mentioned, one-half of compound **2** is symmetry related to the other half because of the presence of a crystallographic twofold axis. This twofold axis passes through the $[Cu^{II}(4)L^1]$ mononuclear unit. As shown in Fig. 2, the acyclic O_4 compartment of $[Cu^{II}(4)L^1]$ interacts with $H_2O(3)$ and another coordinated water molecule ($H_2O(3C)$; C, $1-x, y, 0.5-z$) of a different dinuclear unit to result in the self-assembled $[2\times2+1\times3]$ heptanuclear Cu^{II}_7 compound containing cocrystallized two dinuclear $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}]^{2+}$ cationic units and three mononuclear $[Cu^{II}L^1]$ moieties.

3.2.2. Description of the structure of $[\{Cu^{II}L^1Mn^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2\cdot H_2O\cdot CH_3COCH_3$ (4)

The structure of **4** consists of the heterotetranuclear $[\{Cu^{II}L^1Mn^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2]^{2+}$ cation (Fig. 3, Table 4),

Table 3

Symmetry: C, $1-x, y, 0.5-z$.

two perchlorate anions, and one water and one acetone molecule as solvent of crystallization. In **4**, as in **2**, the dinuclear $[Cu^{II}L^{1}Mn^{II}(H_2O)_3]^{2+}$ core is interlinked with mononuclear $[Cu^{II}L^{1}]$ moiety by hydrogen bonding interactions. In this case, the interlinking of one dinuclear $[Cu^{II}L^{1}Mn^{II}(H_2O)_3]^{2+}$ core with two mononuclear $[Cu^{II}\ L^{1}]$ moieties generates tetranuclear $Cu^{II}_3Mn^{II}$ assembly. In the dinuclear $[Cu^{II}L^{1}Mn^{II}(H_2O)_3]^{2+}$ core, copper(II) occupies the N_2O_2 compartment, and the second compartment of $[L^{1}]^{2-}$ is occupied by manganese(II). The structural parameters in the planar N_2O_2 coordination environment of the three different copper(II) centers (Cu(1), Cu(2), and Cu(3)) are similar to those in compound **2** (Table 4).

There are two possibilities regarding the coordination environment of manganese(II); five-coordinate MnO_5 involving two phenoxo oxygens (O(1) and O(2)) and three water oxygens (O(3), O(4), and O(5)) and seven-coordinate MnO_7 involving additional coordination by two ethoxy oxygens (O(6) and O(7)). The MnO_5 coordination environment (Fig. 3, Table 4) in **4** is highly distorted. The value of τ [12] in this case is 0.38, indicating that the geometry is highly distorted square pyramidal. In this square pyramidal environment, one phenoxo oxygen (O(1)) and three water oxygens (O(3), O(4), and O(5)) define the basal plane, while the second bridging phenoxo oxygen (O(2)) occupies the apical position. The average deviation of O(1), O(3), O(4), and O(5) from the least-squares O_4 plane is 0.183 Å, and the manganese(II) center is displaced by 0.312 Å from this plane. These deviations and displacement along with the range of *transoid* angles (150.42(10)–173.09(11)°) in the basal O_4 plane and the range of all the 10 *cisoid* angles (69.38(9)–135.97(10)°) indicate significant distortion of the coordination environment of manganese(II). The metal–ligand bond distances in the basal plane (Mn(1)–O(1) = 2.169(2) Å, Mn(1)–O(3) = 2.152(3) Å, Mn(1)–O(4) = 2.171(3) Å, Mn(1)–O(5) = 2.149(3) Å) are slightly shorter than the Mn–O(apical) bond length (Mn(1)–O(2) = 2.249(2) Å). The Cu(1)–O(1)–Mn(1) and Cu(1)–O(2)–Mn(1) bridge angles and the Cu(1)···Mn(1) distance in the dinuclear core are 105.23(10)°, 101.62(10)°, and 3.221 Å, respectively. As in **2**, the bridging moiety in the dinuclear core is highly twisted, as evidenced by the dihedral angles (91.1°) between the N_2O_2 plane of the copper(II) center and the basal O_4 plane of the manganese(II) environment.

If coordination of two ethoxy oxygens are also considered, the coordination environment of manganese(II) is distorted pentagonal bipyramidal; two phenoxo oxygens (O(1) and O(2)), two ethoxy oxygens (O(6) and O(7)), and one water oxygen (O(4)) define the basal pentagonal

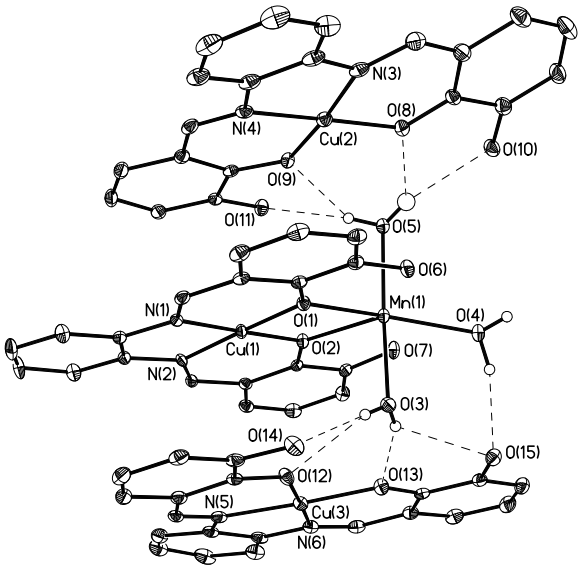

Fig. 3. Structure of the heterotetrametallic unit of composition $[\{Cu^{II}L^{1}Mn^{II}(H_2O)_3\}\{Cu^{II}L^{1}\}_2]^{2+}$ consisting of one dinuclear $[Cu^{II}L^{1}$-$Mn^{II}(H_2O)_3\}]^{2+}$ cationic unit and two mononuclear $[Cu^{II}L^{1}]$ moieties in **4**. Only those hydrogens participating in hydrogen bonds are shown. Except oxygens, other atoms of the ethoxy groups are also omitted for clarity.

plane, while other two water oxygens (O(3) and O(5)) occupy the axial positions. The average deviation of O(1), O(2), O(4), O(6), and O(7) and the displacement of the metal center from the least-squares O_5 plane are 0.17 Å and 0.06 Å, respectively. Mn(1)–O(ethoxy) bond distances (2.511(3) Å and 2.691(3) Å) are much longer than the other five bond lengths (2.169(2)–2.249(2) Å). Due to this difference in bond lengths, the pentagonal plane is significantly distorted as evidenced by the ranges of the apex···apex (O···O) distances (2.515–3.254 Å) and the internal O···O···O angles (91.4–121.5°). Evidently, both the MnO_5 and MnO_7 environments are significantly distorted. However, unlike in copper(II) center, there is no metal-center origin of the difference in bond distances in high spin manganese(II). Due to anionic versus neutral nature of the phenoxo and ethoxy/water oxygens, difference in metal–O(phenoxo) and metal–O(ethoxy/water) bond lengths may take place. However, much longer Mn–O(ethoxy) bond distances in comparison to the Mn–O(water) bond lengths is not usual. Therefore, coordination by two ethoxy oxygens should be discarded and the coordination environment of manganese (II) center should be considered as highly distorted square pyramidal MnO_5.

As in **2**, water encapsulation through bifurcated hydrogen bonds occurs also in **4** to result in the self-assembled $[2 \times 1 + 1 \times 2]$ heterotetranuclear $Cu^{II}_3Mn^{II}$ compound composed of one cocrystallized dinuclear $[\{Cu^{II}L^1Mn^{II}(H_2O)_3\}]^{2+}$ cationic unit and two mononuclear $[Cu^{II}L^1]$ moieties. Among the three coordinated water molecules two are encapsulated in the O_4 cavity of two $[Cu^{II}L^1]$ species. As demonstrated in Fig. 3, $H_2O(3)$ is encapsulated in the O(12)O(13)O(14)O(15) compartment of the $[Cu^{II}(3)L^1]$ moiety, and $H_2O(5)$ is encapsulated in the O(8)O(9)O(10)O(11) compartment of the $[Cu^{II}(2)L^1]$ fragment. The geometries of the hydrogen bonds are summarized in Table 3. The donor···acceptor contacts for the $H_2O(3)$···phenoxo and $H_2O(5)$···phenoxo hydrogen bonds lie in the ranges 2.714(4)–2.795(4) Å and 2.851(4)–2.863(4) Å, respectively, while the ranges of the donor···acceptor contacts for the $H_2O(3)$···ethoxy and $H_2O(5)$···ethoxy hydrogen bonds are 2.943(4)–2.971(4) Å and 3.023(4)–3.030(4) Å, respectively. Evidently, as in **2**, the hydrogen bonds involving phenoxo oxygens are stronger. In this compound also, the third water molecule ($H_2O(4)$) interacts with one ethoxy oxygen with an O(water)···O(ethoxy) distance of 2.822(4) Å (Fig. 3, Table 3).

3.3. Composition of *3*

It has not been possible to grow a diffraction quality crystal of the $Cu^{II}_3Co^{II}$ compound **3**. However, as mentioned in the Section 2, elemental analyses of **3** and **4** are well matched with the similar compositions $C_{75}H_{80}N_6O_{25}Cl_2Cu_3Co$ and $C_{75}H_{80}N_6O_{25}Cl_2Cu_3Mn$, respectively. Again, IR spectra of these two compounds are also similar (Section 2). The similarity in the composition of **3** and **4** as well as the similarity of the structures of the related $Cu^{II}_3Mn^{II}$ and $Cu^{II}_3Co^{II}$ compounds [2] derived from *N*,*N*′ -ethylenebis(3-ethoxysalicylaldimine) (H_2L) suggest that compounds **3** and **4** should have similar structure.

3.4. Comparison of the compositions of *1*–*4* with the related compounds derived from *N*,*N*′-ethylenebis(3-ethoxysalicylaldimine) (H_2L)

The mononuclear copper(II) compounds $[Cu^{II}L^1\subset(H_2O)]$ (**1**) and $[Cu^{II}L\subset(H_2O)]$ (**5**) [2] derived from *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine) (H_2L^1) and *N*,*N*′-ethylenebis(3-ethoxysalicylaldimine) (H_2L), respectively, are inclusion products. The treatment of perchlorate salts of copper(II), cobalt(II), and manganese(II) with **5** results in the self-assembled $[2 \times 1 + 1 \times 2]$ heterotetranuclear $Cu^{II}_3M^{II}$ compounds $[\{Cu^{II}LM^{II}(H_2O)_3\}\{Cu^{II}L\}_2](ClO_4)_2$ (M^{II} = Cu (**6**), Co (**7**), M^{II} = Mn (**8**)) containing self-assembled and cocrystallized single dinuclear $[\{Cu^{II}LM^{II}(H_2O)_3\}]^{2+}$ cationic and two mononuclear $[Cu^{II}L]$ units [2]. Cocrystals of similar composition, $[\{Cu^{II}L^1M^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2 \cdot CH_3COCH_3$ (M^{II} = Co (**3**), M^{II} = Mn (**4**)), are also obtained from the reaction of **1** with the perchlorate salts of cobalt(II) and manganese(II) in the H_2L^1 ligand system. However, the composition of the cocrystal $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4 \cdot 2CH_3COCH_3$ (**2**) produced from the reaction of **1** with copper(II) perchlorate is different. In this case, two dinuclear $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}]^{2+}$ cationic units are self-assembled and cocrystallized with three mononuclear $[Cu^{II}L^1]$ moieties.

As discussed earlier, the second metal center in the dinuclear cores in **2** and **4** adopts slightly distorted square pyramidal CuO_5 and appreciably distorted square pyramidal MnO_5 coordination environment, respectively. The coordination environment of the second metal center in the dinuclear cores in **6**–**8** was also described previously as five-coordinate MO_5 involving coordination by two phenoxo and three water oxygens [2]. However, it may be relevant to discuss other possibilities of coordination environment in **6**–**8**. There are two independent dinuclear units (unit I and unit II) in **6**. The τ [12] values of the CuO_5 environment in these two units are 0.04 and 0.37 indicating almost ideal and appreciably distorted square pyramidal geometry, respectively. The second possibility of coordination environment of the second metal centers in unit I and unit II is Jahn–Teller distorted tetragonal. In these cases, coordination by the ethoxy oxygens O(6) and O(21) to Cu(1) and Cu(5), respectively, should also be considered (Fig. 4). For both the units, two Cu–O(apical) bond distances (Cu(1)–O(5) = 2.37 Å, Cu(1)–O(6) = 2.50 Å, Cu(5)–O(20) = 2.29 Å, Cu(5)–O(21) = 2.55 Å) are significantly different. Again, while the *transoid* angles (174.97° and 177.6°) in the O_4 basal plane of unit I are very close to 180°, the *transoid* angle (145.3°) involving O(6) is deviated significantly from the ideal value indicating significant distortion of the tetragonal geometry. Therefore, as τ is only 0.04 for the CuO_5 environment in unit I, coordina-

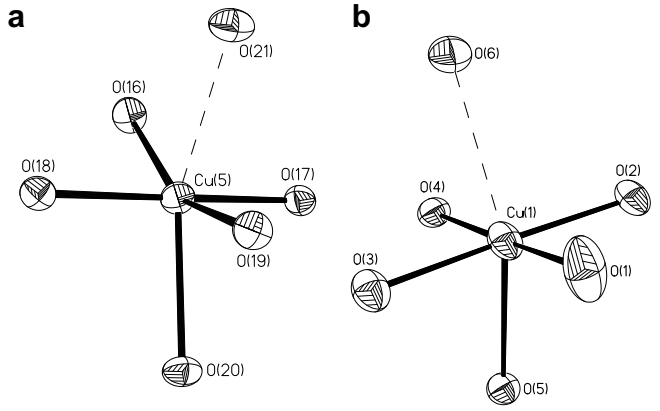

Fig. 4. CuO_5 (solid bonds) and CuO_6 (solid and dotted bonds) coordination environment of copper(II) centers in the O_4 compartment of the two units (a: unit I. b: unit II) in $[\{Cu^{II}LCu^{II}(H_2O)_3\}\{Cu^{II}L\}_2](ClO_4)_2$.

tion geometry of Cu(1) should be better described as slightly distorted square pyramidal. In the case of unit II, both the two possible geometries are significantly distorted as evidenced by the τ value (0.37) in CuO_5 environment, *transoid* angles (153.8° and 176.0°) in the O_4 basal plane, and the *transoid* angle (140.2°) involving O(21). Evidently, it is difficult to judge the nature of coordination environment of Cu(5). However, as the two Cu–O(apical) bond lengths in CuO_6 environment differs significantly (2.29 Å versus 2.55 Å), it may be better to discard the hexacoordinated case and to describe the geometry of Cu(5) as significantly distorted square pyramidal.

The second possibility of the coordination geometry for the cobalt(II) and manganese(II) centers in **7** and **8**, respectively, is pentagonal bipyramidal which involves additional coordination by two ethoxy oxygens (O(2) and O(2A); Fig. 5). However, the bond distances (2.63 Å for **7** and 2.61 Å for **8**) involving the ethoxy oxygens are much longer than the lengths of other five bonds (2.05–2.12 Å for **7** and 2.15–2.20 Å for **8**). As explained earlier, such differences in bond lengths for high spin manganese(II) are not usual. For high spin cobalt(II) also, such differences are not usual because metal-center distortion originates from t_{2g} orbitals. Therefore, five-coordinate MO_5 coordination environment, as described previously [2], should be better choice in these two cases also.

The noteworthy aspect is the remarkable difference between the dinuclear cores in **2** and those of the other compounds **3**–**8**. The dinuclear cores in **3**–**8** are diphenoxo-bridged; the second metal center is coordinated to the two phenoxo oxygens and three water oxygens, while the two ethoxy oxygens are noncoordinated. In contrast, the dinuclear core in **2** is monophenoxo-bridged; the second metal center in this case is coordinated to one phenoxo oxygen, one ethoxy oxygen, and three water oxygens, while one phenoxo and one ethoxy oxygen is noncoordinated to the second metal center. Thus, it appears that the coordination of the ethoxy oxygen to the second metal center is the major factor contributing to the emergence of a new structural motif for **2**.

The relative extent of the encapsulation of water may be understood from the displacement (d_O) of the water oxygen from the least-squares $O(phenoxo)_2O(ethoxy)_2$ plane. In the case of **5**, the oxygen atom of the encapsulated water lies on the least-squares $O(phenoxo)_2O(ethoxy)_2$ plane, and the oxygen atoms of the encapsulated water molecules in **6**–**8** are displaced by 0.92–1.23 Å from the corresponding $O(phenoxo)_2O(ethoxy)_2$ plane, indicating that the extent of encapsulation in **5** is much greater than that in the compounds **6**–**8** [2]. The values of d_O for the two water oxygens O(3) and O(5) in the $Cu^{II}_3Mn^{II}$ compound **4** are 1.10 and 1.16 Å, respectively, indicating that the extent of encapsulation in this compound is similar to that in the compounds **6**–**8**. In the case of the Cu^{II}_7 compound **2**, while the d_O value (1.08 Å) for O(5) is in the range observed in **4**–**8**, the second water oxygen is significantly displaced ($d_O = 1.77$ Å) from the corresponding $O(phenoxo)_2O(ethoxy)_2$ plane indicating that this water molecule is poorly encapsulated.

It should be noted that treatment of compounds **2**–**4** and **6**–**8** with dimethylformamide results in the formation of compound **1** and **5**, respectively, indicating that the O_4

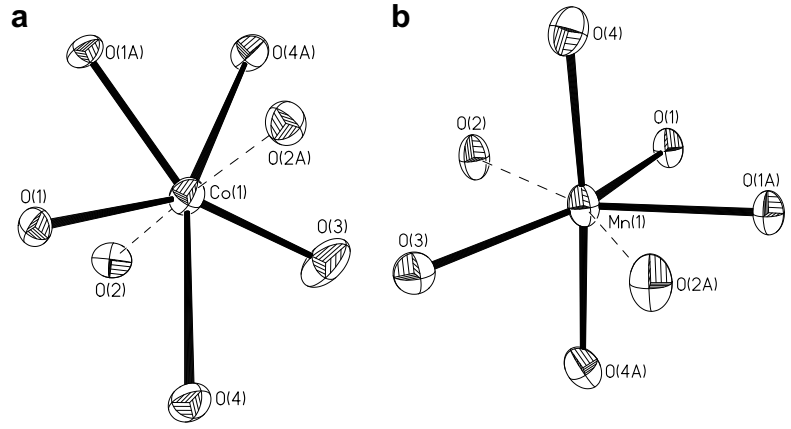

Fig. 5. MO_5 (solid bonds) and MO_7 (solid and dotted bonds) coordination environment of cobalt(II) and manganese(II) centers in $[\{Cu^{II}LM^{II}(H_2O)_3\}\{Cu^{II}L\}_2](ClO_4)_2$ (a: M = Co (**7**). b: M = Mn (**8**)).

compartment is more preferable for water in both the systems [2]. Again, in both the systems, the formation of a 3d–4f or 3d–3d bimetallic core from the mononuclear inclusion product and the decomposition of the former to the latter by dimethylformamide resemble the transmetallation reaction. This behavior can be considered as the resemblance of water with metal ions.

3.5. Magnetic properties

The cryomagnetic behavior of **2** is shown in Fig. 6 in terms of $\chi_M T$ versus T and χ_M versus T plots. The $\chi_M T$ value (2.76 $cm^3\ mol^{-1}\ K$) at 300 K of **2** is slightly greater than the theoretical value (2.62 $cm^3\ mol^{-1}\ K$) for seven isolated copper(II) ions with $g = 2$. On lowering of temperatures, $\chi_M T$ decreases very slowly to 2.43 $cm^3\ mol^{-1}\ K$ at 80 K. On further lowering of temperatures, $\chi_M T$ diminishes rapidly to a narrow plateau (*ca.* 1.13 $cm^3\ mol^{-1}\ K$) in the temperature range 8–6 K. Below 6 K, $\chi_M T$ decreases sharply to reach a value of 0.93 $cm^3\ mol^{-1}\ K$ at 2 K. The profile indicates that there exists a moderate antiferromagnetic interaction in this molecule. The magnetic exchange between the metal ions in the mononuclear species with the pentacoordinated metal center in the dinuclear cores should be very small because these metal ions are separated as Cu(mononuclear)–O(phenoxo)···H–O(water)–Cu(pentacoordinated) and the Cu(pentacoordinated)···Cu(mononuclear) separations lie in the range 4.78–4.91 Å. Therefore, the two copper(II) centers in the $[Cu^{II}L^1]$ moieties should only influence the $\chi_M T$ values as a known amount of paramagnetic impurity. The rapid increase of the χ_M values at lower temperatures (Fig. 6) is indicative of such an assumption. Again, the absence of a maximum in the χ_M versus T plots is also indicative of the influence of the paramagnetic contribution of the two isolated $s = 1/2$ centers. Considering molecular field approximation (zJ') for the possible very weak Cu(mononuclear)–O(phenoxo)···H–O(water)–Cu(pentacoordinated) interaction and the same value for the magnetic moment (μ_{Cu}) of the copper(II) centers in the mononuclear fragments, the theoretical expression for the molar magnetic susceptibility (χ_M) of a system of two exchange-coupled dicopper(II) ($\mathbf{H} = -2J\mathbf{S}_1 \cdot \mathbf{S}_2$) and three mononuclear copper(II) moieties can be derived as [2]

$$\chi_M = \frac{\chi_M^1}{1 - 2zJ'\chi_M^1/N\beta^2 g^2} \quad (1)$$

where

$$\chi_M^1 = \frac{15.995\chi_D T + 3\mu_{Cu}^2}{7.997T}$$

with

$$\chi_D = \frac{N\beta^2 g^2}{kT}\,\frac{2e^{2J/kT}}{1 + 3e^{2J/kT}}$$

Least-squares fitting (Fig. 6) of the experimental data with Eq. (1) leads to $J = -22.2\ cm^{-1}$, $zJ' = -0.12\ cm^{-1}$, $g = 2.146$, and μ_{Cu} (fixed) = 1.73 BM; the agreement factor (R) defined as $[\sum\{(\chi_M T)_{obs} - (\chi_M T)_{calc}\}^2 / \sum(\chi_M T)_{obs}^2]$ is 1.37×10^{-2}. It may be mentioned that simulation (Fig. S2) of almost similar quality is obtained without considering molecular field approximation ($J = -22.7\ cm^{-1}$, $zJ' = 0\ cm^{-1}$ (fixed), $g = 2.143$, μ_{Cu} (fixed) = 1.73 BM, and $R = 1.89 \times 10^{-2}$). In this case divergence between the observed and calculated profiles occurs only for the data below 6 K. Comparison of the simulated curves in Fig. 6 and Fig. S2 indicates that very rapid decrease of $\chi_M T$ below 6 K takes place due to very weak ($zJ' = -0.12\ cm^{-1}$) Cu(mononuclear)–O(phenoxo)···H–O(water)–Cu(pentacoordinated) interaction. Again, it is obvious that sharp decrease of $\chi_M T$ below 80 K is related to moderate antiferromagnetic interaction ($J = -22.2\ cm^{-1}$) because more the extent of antiferromagnetic interaction higher the temperature below which $\chi_M T$ rapidly diminishes and vice versa. For example, if J values are $-40\ cm^{-1}$ and $-5\ cm^{-1}$ for a system like **2**, $\chi_M T$ should rapidly diminish below 120 K and 30 K, respectively.

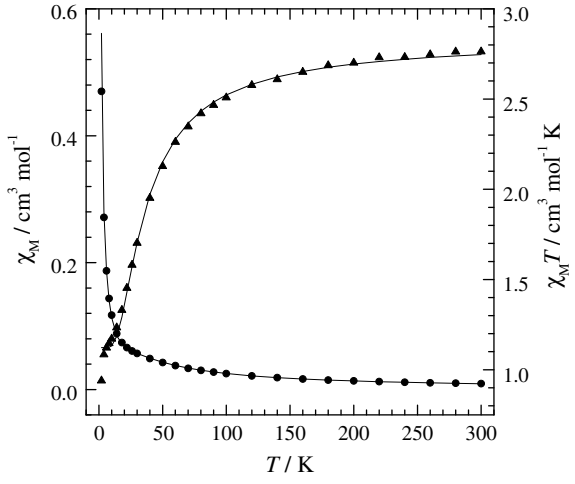

Fig. 6. χ_M (circles) versus T and $\chi_M T$ (triangles) versus T plots for **2**. The solid lines represent the simulated curves with $J = -22.2\ cm^{-1}$, $zJ' = -0.12\ cm^{-1}$, $g = 2.146$, and μ_{Cu} (fixed) = 1.73 BM.

As shown in Fig. 7, the $\chi_M T$ value (5.52 $cm^3\ mol^{-1}\ K$) at 300 K of **4** is almost equal to the theoretical value (5.50 $cm^3\ mol^{-1}\ K$) for the isolated one Mn^{II} ($s = 5/2$) and three Cu^{II} ($s = 1/2$) ions with $g = 2$. In this case, $\chi_M T$ gradually decreases on lowering of temperatures to reach a plateau (3.95 $cm^3\ mol^{-1}\ K$) in the temperature range 22–10 K. Below 10 K, $\chi_M T$ decreases sharply to reach a value of 3.62 $cm^3\ mol^{-1}\ K$ at 2 K. Clearly, the nature of interaction between the copper(II) and manganese(II) centers in the dinuclear core is antiferromagnetic. The absence of a maximum in the χ_M versus T plots as well as the observation of a rapid increase in the χ_M values at lower temperatures (Fig. 7) indicate that the Cu(mononuclear)–O(phenoxo)···H–O(water)–Cu(pentacoordinated) interaction is very weak. Considering molecular field approximation for the possible weak Cu(mononuclear)–O(phenoxo)···H–O(water)–Mn(pentacoordinated) interac-

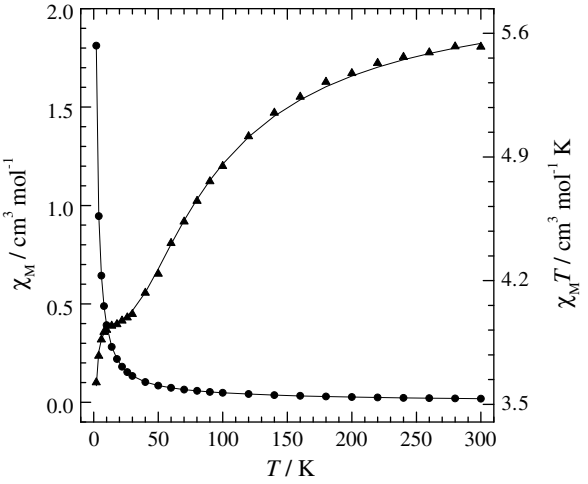

Fig. 7. χ_M (circles) versus T and $\chi_M T$ (triangles) versus T plots for **4**. The solid lines represent the simulated curves with $J = -15.9\ cm^{-1}$, $zJ' = -0.032\ cm^{-1}$, $g = 2.086$, μ_{Cu} (fixed) = 1.73 BM.

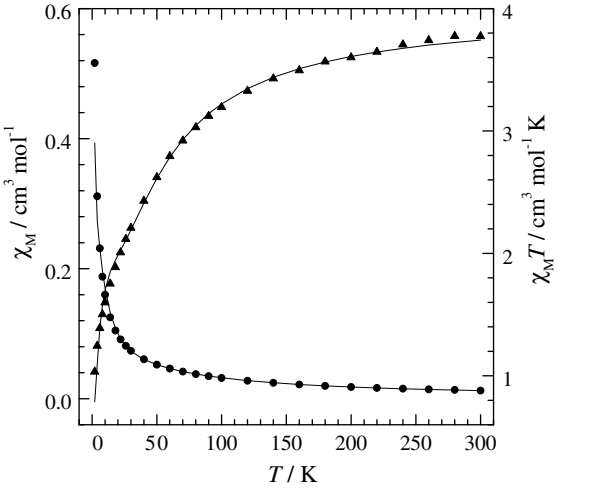

Fig. 8. χ_M (circles) versus T and $\chi_M T$ (triangles) versus T plots for **3**. The solid lines represent the simulated curves with $J = -16.7\ cm^{-1}$, $g = 2.408$, $|D| = 4.53\ cm^{-1}$, μ_{Cu} (fixed) = 1.73 BM.

tion, the theoretical equation of susceptibility one dinuclear $Cu^{II}Mn^{II}$ core and two noninteracting Cu^{II} centers can be derived as [2]

$$\chi_M = \frac{\chi_M^1}{1 - 2zJ'\chi_M^1/N\beta^2 g^2} \quad (2)$$

where

$$\chi_M^1 = \frac{7.997\chi_D T + 2\mu_{Cu}^2}{7.997T}$$

with

$$\chi_D = \frac{N\beta^2 g^2}{kT}\,\frac{10 + 28\,e^{6J/kT}}{5 + 7\,e^{6J/kT}}$$

In this case, global minimization (Fig. 7) takes place with $J = -15.9\ cm^{-1}$, $zJ' = -0.032\ cm^{-1}$, $g = 2.086$, μ_{Cu} (fixed) = 1.73 BM, and $R = 3.15 \times 10^{-3}$. It may be mentioned that slight divergence between the observed and calculated profiles occurs throughout the temperature range for the simulation (Fig. S3) without considering molecular field approximation ($J = -13.6\ cm^{-1}$, $zJ' = 0\ cm^{-1}$ (fixed), $g = 2.057$, μ_{Cu} (fixed) = 1.73 BM, and $R = 1.69 \times 10^{-2}$). Comparison of the simulated curves in Fig. 7 and Fig. S3 indicates that very rapid decrease of $\chi_M T$ below 10 K takes place due to very weak ($zJ' = -0.032\ cm^{-1}$) Cu(mononuclear)–O(phenoxo)···H–O(water)–Mn(pentacoordinated) interaction.

The cryomagnetic behavior of **3** is shown in Fig. 8. In this case, the $\chi_M T$ value (3.77 $cm^3\ mol^{-1}$ K) at 300 K is much greater than the theoretical value for the isolated one Co^{II} ($s = 3/2$) and three Cu^{II} ($s = 1/2$) ions with $g = 2$. On lowering of temperatures, $\chi_M T$ value gradually decreases to 3.12 $cm^3\ mol^{-1}$ K at 90 K. Further lowering of temperatures results in rapid decrease of $\chi_M T$ to 1.03 $cm^3\ mol^{-1}$ K at 2 K. Simulation of the experimental data with Eq. (3) [2], which accounts for the exchange coupling in the dinuclear core, molecular field approximation for the possible weak Cu(mononuclear)–O(phenoxo)···H–O(water)–Co(pentacoordinated) interaction, and magnetic moment for the two mononuclear copper(II) centers, is converged with $J = -15.8\ cm^{-1}$, $zJ' = -1.09\ cm^{-1}$, $g = 2.416$, μ_{Cu} (fixed) = 1.73 BM, and $R = 1.68 \times 10^{-2}$ (Fig. S4). On fixing $zJ' = 0\ cm^{-1}$, simulation (Fig. S5) of very poor quality is obtained with $J = -13.1\ cm^{-1}$, $zJ' = 0\ cm^{-1}$ (fixed), $g = 2.26$, μ_{Cu} (fixed) = 1.73 BM, and $R = 1.21 \times 10^{-1}$. In **2** and **4**, Cu(mononuclear)–O(phenoxo)···H–O(water)–M(pentacoordinated) distances lie in the range 4.78–4.91 Å and 4.85–4.90 Å, respectively, indicating that the similar magnitude of the Cu(mononuclear)–O(phenoxo)···H–O(water)–Co(pentacoordinated) distances in **3**. The similar values of the Cu(mononuclear)–O(phenoxo)···H–O(water)–M(pentacoordinated) distances (Cu_4^{II} (**6**), 4.86–5.04 Å; $Cu_3^{II}Co^{II}$ (**7**), 4.965 Å; $Cu_3^{II}Mn^{II}$ (**8**), 5.034 Å) in the cocrystals derived from H_2L support this assumption. Therefore, as observed for **2** and **4** ($zJ' = -0.12\ cm^{-1}$ and $-0.032\ cm^{-1}$, respectively), the values of zJ' should be small for **3** also. Evidently, the zJ' value of $-1.09\ cm^{-1}$ as well as its significant role in the susceptibility data throughout the temperature range (Fig. S4 versus Fig. S5) should be discarded. It may also be mentioned that the magnetic properties of the systems containing high spin cobalt(II) ion is associated with the first-order orbital angular momentum of the metal center. In **3**, this can be evidenced by the high value of $\chi_M T$ at 300 K. Therefore, the susceptibility data of **3** have been simulated with Eq. (4) [2,13] which considers the exchange coupling between cobalt(II) and copper(II) centers in the dinuclear core, single-ion zero-field parameter (D) of the cobalt(II) ion, and the contribution of the two isolated $s = 1/2$ spins. The simulation (Fig. 8) in this case is converged with $J = -16.7\ cm^{-1}$, $g = 2.408$, $|D| = 4.53\ cm^{-1}$, μ_{Cu} (fixed) = 1.73 BM, and $R = 2.36 \times 10^{-2}$. Comparison of the simulated curves in Fig. 8 and Fig. S5 indicates that rapid decrease of $\chi_M T$

below 90 K is associated with zero-field effect of cobalt(II). It may be noted that g value of 2.408 in **3** is in the usual range (2.2–2.5) of g values in previously reported systems containing cobalt(II) [13–19]. It may also be mentioned that, although simulations of magnetic susceptibility data in some cobalt(II) compounds have been performed without considering D [14], zero-field effect is known to govern the magnetic behavior of many cobalt(II) compounds [13,15–17] and the range of D in reported compounds is much wider; small value of *ca.* 0.1 cm^{-1} [13,15] and large value of *ca.* 10.5 cm^{-1} [16] and even *ca.* 145 cm^{-1} [17] are known. Again, large θ values (*ca.* 30 K or 70 K) taken in the simulation process in some cases [18] might be replaced by large D values (as described above, Fig. 8 versus Fig. S4). It may also be mentioned that magnetic behavior of cobalt(II) containing compounds may be so complicated that even the consideration of zero-field effect results in only poor quality simulation [19].

$$\chi_M = \frac{\chi_M^1}{1 - 2zJ'\chi_M^1/N\beta^2 g^2} \tag{3}$$

where

$$\chi_M^1 = \frac{7.997\chi_D T + 2\mu_{Cu}^2}{7.997T}$$

with

$$\chi_D = \frac{N\beta^2 g^2}{kT}\frac{2 + 10\,e^{4J/kT}}{3 + 5\,e^{4J/kT}}$$

$$\chi_M = \frac{7.997\chi_D T + 2\mu_{Cu}^2}{7.997T} \tag{4}$$

where

$$\chi_D = \frac{2N\beta^2 g^2}{kT}\frac{e^A + 4e^C + e^E}{2e^A + e^B + e^F + e^E}$$

with

$$A = \left[4J + \frac{5}{4}D - (4J^2 - 2DJ + D^2)^{1/2}\right]\Big/kT$$

$$B = \left[2J + \frac{1}{4}D\right]\Big/kT$$

$$C = \left[6J + \frac{9}{4}D\right]\Big/kT$$

$$F = \left[6J + \frac{1}{4}D\right]\Big/kT$$

$$E = \left[\left(4J + \frac{5}{4}D\right) + (4J^2 - 2DJ + D^2)^{1/2}\right]\Big/kT$$

A major emphasis to study the magnetic properties of exchange-coupled complexes is to find out the relationships between structural parameters and magnetic coupling. Based on such correlations one can predict and analyze the magnetic behavior of new systems more easily. Several magneto-structural correlations in different types of systems have been obtained either from experimental results or from theoretical study [13,20–25].

The first and perhaps the most elegant of these correlations was established by Hatfield and Hodgson [20,22] who demonstrated linear dependence of exchange-coupling constant (J) on the Cu–O–Cu bridge angle (θ) in planar dihydroxo-bridged dinuclear copper(II) complexes. Subsequently, similar linear correlations between J and θ have been reported for the alkoxo-bridged tetrameric copper(II) clusters of the cubane type [23] and diphenoxo-bridged macrocyclic dicopper(II) systems [24]. For dihydroxo-bridged and alkoxo-bridged systems, $J = 0$ at bridge angles 97.5° and 95.7°, respectively. These are the angles of accidental orthogonality or cross-over angles below which the interaction is ferromagnetic and above which antiferromagnetic interaction predominates. For diphenoxo-bridged dimmers, $J = 0$ at $\theta \approx 77°$, indicating that antiferromagnetic exchange dominates in these complexes at angles well below the angle for accidental orthogonality established in above two cases. The involvement of an additional exchange pathway through the conjugated double bonds in the phenoxo-bridged systems has been proposed to explain the observed difference in magnetic behavior [24]. Evidently, in dihydroxo, alkoxo, and diphenoxo-bridged copper(II) systems, the range of 95–98° should be considered as cross-over angle. Kahn et al. have examined roof-shaped dihydroxo-bridged copper(II) dimmers [20,25]. Theoretically they have shown that as the dihedral angle (δ) between the two CuO_2 planes decreases from 180°, antiferromagnetic contribution to superexchange decrease and a cross-over is attained at $\delta = 130°$.

The origin of the observed moderate antiferromagnetic interaction ($J = -22.2\ cm^{-1}$) in the dinuclear core in **2** can be understood from the relative orientation of the magnetic orbitals as well as from the above mentioned magneto-structural correlations. In the dinuclear core, two phenoxo oxygens occupy the square plane of the metal ion in the salen-type cavity indicating that the lobes of the $d_{x^2-y^2}$ orbital of this metal ion are directed towards both the bridging atoms. In contrast, for the more probable CuO_5 coordination environment of the second metal center (Cu(2)), one phenoxo oxygen occupies an equatorial position, while the second phenoxo oxygen is noncoordinated. Again, for the less probable CuO_6 coordination environment of Cu(2), two phenoxo oxygens occupy an equatorial and axial positions, respectively. Therefore, the lobes of $d_{x^2-y^2}$ orbital of Cu(2) are directed only towards one phenoxo oxygen. As a matter of fact, only one phenoxo oxygen of the dinuclear core participates in the superexchange interaction, which, in turn, should result in reduced antiferromagnetic interaction. Again, the Cu–O–Cu bridge angle (*ca.* 110°) involving the phenoxo oxygen participating in the exchange pathway is only slightly larger than the cross-over angle (95–98°), proposed in the related systems. Evidently, the moderate antiferromagnetic interaction between the metal centers in the dinuclear core in **2** is related to the participation of only one bridging phenoxo oxygen as well as the value of this bridge angle. It may be noted that the participation of only one phenoxo oxygen

in the exchange interaction as well as the value of Cu–O–Cu bridge angle (*ca.* 105°) are responsible for the similar moderate antiferromagnetic interaction ($-17.4\ cm^{-1}$) in the previously reported compound $[\{Cu^{II}L^{1}Cu^{II}(H_2O)_3\}\{Cu^{II}L^{1}\}_2](ClO_4)_2$ (**6**) [2]. However, slightly greater magnitude ($-22.2\ cm^{-1}$ versus $-17.4\ cm^{-1}$) can be rationalized from the slightly larger value of the Cu–O–Cu bridge angle (110° in **2** versus 105° in **6**).

The exchange interaction between the metal centers in the $Cu^{II}Mn^{II}$ dinuclear core in **4** is also moderately antiferromagnetic ($J = -15.9\ cm^{-1}$). In this case, the extent of interaction is a little less than that between the copper(II) centers in the dinuclear core in **2**. In this compound, all the five d orbitals of manganese(II) are occupied by unpaired electrons. Although the $d_{x^2-y^2} \leftrightarrow d_{x^2-y^2}$ pathway gives rise to an antiferromagnetic interaction, the other four routes provide a ferromagnetic contribution to the overall magnetic coupling. These two opposite effects result in, in comparison to the coupling in the dicopper(II) core in **2**, a reduction in the strength of the net antiferromagnetic interaction between the copper(II) and manganese(II) centers in **4**. It may be mentioned that similar moderate antiferromagnetic interaction ($J = -14\ cm^{-1}$) has been observed in the $Cu^{II}Mn^{II}$ dinuclear core in analogues $Cu^{II}_3Mn^{II}$ compound (**8**) derived from *N*,*N*′ -ethylenebis(3-ethoxysalicylaldimine) (H_2L).

4. Conclusions

The present study is concerned with the designed syntheses of inclusion compound and of dinuclear–mononuclear cocrystals involving the encapsulation of a water molecule. The formation of the inclusion product (**1**) and the dinuclear–mononuclear cocrystals (**2**–**4**) derived from *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine) (H_2L^1) have been the major outcome of the present investigation. The most interesting aspect of this study is the emergence of a heptanuclear copper(II) compound $[\{Cu^{II}L^{1}Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^{1}\}_3](ClO_4)_4 \cdot 2CH_3COCH_3$ (**2**) in which two monophenoxo-bridged dinuclear $[Cu^{II}L^{1}Cu^{II}(H_2O)_3]^{2+}$ cationic units are self-assembled and cocrystallized with three mononuclear $[Cu^{II}L^{1}]$ complex units. The composition of **2** is in sharp contrast to those of the heterotetranuclear complexes $[\{Cu^{II}L^{1}M^{II}(H_2O)_3\}\{Cu^{II}L^{1}\}_2](ClO_4)_2 \cdot H_2O \cdot CH_3COCH_3$ (M = Co (**3**), M = Mn (**4**)) as well as to those of the tetranuclear compounds $[\{Cu^{II}LM^{II}(H_2O)_3\}\{Cu^{II}L\}_2](ClO_4)_2$ (M^{II} = Cu (**6**), Co (**7**), M^{II} = Mn (**8**)) derived from *N*,*N*′-ethylenebis(3-ethoxysalicylaldimine) (H_2L). In these compounds, one diphenoxo-bridged heterodinuclear $[Cu^{II}(L^{1}/L)M^{II}(H_2O)_3]^{2+}$ cationic unit is self-assembled and cocrystallized with two mononuclear $[Cu^{II}(L^{1}/L)]$ moieties. In the $Cu^{II}_3M^{II}$ compounds **3**, **4**, and **6**–**8**, the $Cu^{II}M^{II}$ dinuclear cores are diphenoxo-bridged and the ethoxy oxygens are noncoordinated. In contrast, the dinuclear cores in the heptacopper(II) compound **2** are monophenoxo-bridged and one ethoxy oxygen coordinates to the second metal center. Thus, it appears that the formation of the heptanuclear self-assembly in **2** is related to the coordination of the ethoxy oxygen.

ligands with hydrophilic properties. Among water-soluble phosphanes, particular attention has recently been paid to the cage-like tertiary phosphane 1,3,5-triaza-7-phosphaadamantane (PTA) [7] (Fig. 1) whose high solubility in water has been ascribed to the extensive participation of its three nitrogen atoms in hydrogen bonding interactions with water molecules.

Many PTA metal complexes have been synthesized [8] and utilized in aqueous catalysis, particularly hydrogenation of C=C and C=O bonds, that are useful in fine chemicals synthesis [9]. Ruthenium half-sandwich complexes containing the PTA ligand are also known for their catalytic [10] and biochemical implications [11–13].

In this context, a wide variety of half-sandwich ruthenium(II) complexes with PTA ligands have been reported including cyclopentadienyl (Cp) [11], indenyl [10], and arene [12] complexes; however, despite the similarities between the isoelectronic Cp and Tp (Tp = hydridotris(pyrazolyl)borate) complexes, to the best of our knowledge, no Tp–ruthenium(II) complexes containing PTA ligands have been described to date.

Furthermore, differences in size and electronic properties between Cp and Tp ligands [14] prompted us to explore the synthesis and reactivity of the first water-soluble ruthenium complexes containing a hydridotris(pyrazolyl)borate ligand. Moreover, the presence of nitrogen atoms in the pyrazol groups constitutes a new potential active site for interactions with hydrogen atoms, not only in water but in biological molecules as well.

Recently, we have published a series of ruthenium(II) complexes containing the water-soluble sulfonated phosphane TPPMS [15]. Continuing in line with our interest in the area of water-soluble metal complexes, in this work we report the synthesis of numerous ruthenium(II) complexes containing the cage-like phosphanes PTA or m-PTA and hydridotris(pyrazolyl)borate as ligands. Studies on their DNA binding properties and antimicrobial activity are also reported.

2. Experimental

All manipulations were performed under an atmosphere of dry nitrogen using vacuum-line and standard Schlenk techniques. All reagents were obtained from commercial suppliers and used without further purification. Solvents were dried by standard methods and distilled under nitrogen before use. The compounds [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)$_2$] [16], [RuCl(η^5-C_9H_7)(PPh_3)$_2$] [17] and PTA phosphane [18] were prepared by previously reported methods. Infrared spectra were recorded on a Perkin–Elmer FT-IR Paragon 1000 spectrometer. The C, H, and N analyses were carried out with a Perkin–Elmer 240-B microanalyzer. NMR spectra were recorded on a Bruker 300DPX instrument at 300.1 MHz (^{1}H), 121.5 MHz (^{31}P), or 75.4 MHz (^{13}C) and on a Bruker AC-400 instrument at 400.1 MHz (^{1}H), 161.9 (^{31}P) or 100.6 MHz (^{13}C) using $SiMe_4$ or 85% H_3PO_4 as standards. DEPT experiments were carried out for all the compounds. Coupling constants *J* are given in Hertzs. Resonances due to the Tp ligand are reported by chemical shift and multiplicity only, since all $^3J_{H,H}$ values for pyrazolyl rings are 2 Hz. Abbreviations used: br, broad signal; s, singlet; d, doublet; vt, virtual triplet; sept, septuplet; m, multiplet. For indenyl ligand the atom labels used for the ^{1}H and ^{13}C{^{1}H} are as in previous papers [19].

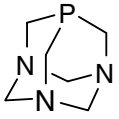

Fig. 1. 1,3,5-Triaza-7-phosphaadamantane (PTA) ligand.

2.1. Synthesis of the complexes

2.1.1. Synthesis of [RuCl{κ^3(*N*,*N*,*N*)-Tp}(*PTA*)$_2$] (*1*)

Method A: To a solution of complex [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)$_2$] (100 mg, 0.11 mmol) in toluene (1.5 mL) was added PTA (53 mg, 0.34 mmol). The reaction mixture was refluxed for 5 h and a yellow precipitate was formed. The solid was filtered off, washed with hexane and dried under vacuum to give compound **1**. Yield: 98% (72 mg).

Method B: To a solution of complex [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(PTA)] (100 mg, 0.13 mmol) in toluene (3 mL) was added PTA (20 mg, 0.13 mmol). The reaction mixture was refluxed for 5 h and a yellow precipitate was formed. The solid was filtered off, washed with hexane and dried under vacuum to give compound **1**. Yield: 99% (85 mg). $S_{20\,°C}$ (H_2O) = 9.0 mg/mL. IR (KBr, cm^{-1}): ν(BH) = 2489. ^{1}H NMR (300.1 MHz, CD_2Cl_2, 20 °C): δ = 7.94 (d, 2H, H^{3,5} (pz)), 7.77 (d, 1H, H^{3,5} (pz)), 7.70 (d, 2H, H^{3,5} (pz)), 7.21 (d, 1H, H^{3,5} (pz)), 6.25 (br, 3H, H^4 (pz)), 4.56 (AB spin system, $J_{HA,HB}$ = 16 Hz, 6H, NCH_2N), 4.47 (AB spin system, $J_{HA,HB}$ = 16 Hz, 6H, NCH_2N), 4.13 (s, 12H, NCH_2P) ppm. ^{13}C{^{1}H} NMR (100.6 MHz, CD_2Cl_2, 20 °C): δ = 147.1 (s, C-3 (pz)), 143.2 (s, 2C, C-3 (pz)), 136.5 (s, C-5 (pz)), 135.1 (s, 2C, C-5 (pz)), 106.1 (s, C-4 (pz)), 105.3 (s, 2C, C-4 (pz)), 73.2 (s, 6C, N*C*H_2N), 53.7 (s, 6C, N*C*H_2P) ppm. ^{31}P{^{1}H} NMR (161.9 MHz, CD_2Cl_2, 20 °C): δ = −29.2 (s, PTA) ppm. *Anal.* Calc. for $C_{21}H_{34}BClN_{12}P_2Ru$: C, 37.99; H, 5.16; N, 25.32. Found: C, 38.05; H, 5.36; N, 25.16%.

2.1.2. Synthesis of [RuCl{κ^3(*N*,*N*,*N*)-Tp}(*PPh*$_3$)(*PTA*)] (*2*)

To a solution of complex [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)$_2$] (1000 mg, 1.14 mmol) in toluene (70 mL) was added PTA (179 mg, 1.14 mmol). The reaction mixture was refluxed for 4 h. After this, volatiles were removed in vacuum. The crude product was recrystallized from dichloromethane/acetone and compound **2** was obtained as a microcrystalline yellow solid. Yield: 96% (842 mg). $S_{20\,°C}$ (H_2O) = 3.0 mg/mL. IR (KBr, cm^{-1}): ν(BH) = 2476. ^{1}H NMR (400.1 MHz, CD_2Cl_2, 20 °C):

2.1.11. Synthesis of [Ru(η⁵-C₉H₇)(PTA)₃][Cl] (11)

To a solution of $[Ru(\eta^5\text{-}C_9H_7)Cl(PPh_3)_2]$ (100 mg, 0.13 mmol) in toluene (3 mL) was added PTA (72 mg, 0.46 mmol). The reaction mixture was heated at reflux during 6 h. The precipitate thus formed was filtered off and dried under vacuum. The solid residue was extracted with water and filtered through kieselguhr. The solvent was evaporated under vacuum and the yellow solid obtained was recrystallized in a mixture dichloromethane/hexane. Yield: 53% (50 mg). $S_{20\,°C}$ (H_2O) = 20.0 mg/mL. ^1H NMR (400.1 MHz, D_2O, 20 °C): $\delta = 7.75$ (d, $J_{H,H} = 8$ Hz, 2H, Ind_6), 7.38 (d, $J_{H,H} = 8$ Hz, 2H, Ind_6), 5.58 (br, 2H, H-1 and H-3 Ind), 5.41 (br, 1H, H-2 Ind), 4.46 (m, 18H, NCH_2N), 3.83 (s, 18H, NCH_2P) ppm. $^{13}C\{^1H\}$ NMR (100.6 MHz, D_2O, 20 °C): $\delta = 128.9$ (s), 124.2 (s) (C-4, C-5, C-6, C-7 Ind), 108.1 (s, 2C, C-3a and C-7a Ind), 91.4 (s, C-2 Ind), 70.5 (s, 9C, NCH_2N), 68.8 (s, 2C, C-1 and C-3 Ind), 55.4 (s, 9C, NCH_2P) ppm. $^{31}P\{^1H\}$ NMR (161.9 MHz, D_2O, 20 °C): $\delta = -26.7$ (s, PTA) ppm. *Anal.* Calc. for $C_{27}H_{43}ClN_9P_3Ru$: C, 44.84; H, 5.99; N, 17.43. Found: C, 44.78; H, 5.91; N, 16.00%.

2.2. DNA mobility shift assays

Reactions between DNA and the ruthenium complexes were performed in 10 mM sodium phosphate buffer at physiological pH 7.0, containing 0.05 μg/μL of the

pBR322 plasmid (4361 base pairs, from Fermentas) and appropriate amounts of freshly prepared solutions of the Ru complexes also dissolved in phosphate buffer. Reaction mixtures were incubated for 14 h at 37 °C. Ten microliters of the reactions were mixed with 1 μL dye (0.025 mg bromophenol blue, 1 mL glycerol and 1 mL distilled water) and they were analyzed by electrophoresis in 0.8% agarose gels in TBE (Tris–Borate–EDTA) buffer. Gel running was conducted at a constant voltage of 3 V/cm. DNA bands were visualized by incubation of the gel with 1 μg/mL ethidium bromide in TBE buffer for 10 min and photographed under UV light.

2.3. Antimicrobial activity

Microbial cytotoxicity of ruthenium compounds was measured against three yeasts (*Candida albicans* ATCC 14053, *Candida parapsilosis* and *Rhodosporidium toruloides*), and different bacteria: *Micrococcus luteus* ATCC 9341, *Bacillus subtilis* ATCC 19659, *Escherichia coli* C600 ATCC 23724, *Streptomyces coelicolor* A3(2), *Streptomyces antibioticus* ATCC 11891, *Streptomyces glaucescens* DSM 40716 and *Pseudomonas aeruginosa* PAO1 ATCC 15692. The antimicrobial activity was tested according to the Kirby Bauer disc diffusion method [20]. The microorganisms were mixed at known concentrations with Mueller Hinton and poured into petri dishes (9 cm in diameter; 10 mL of culture medium per plate). The ruthenium complex was pipetted onto sterile filter paper disks (0.5 cm in diameter) and the solvent evaporated before placing them on the cultures. Plates were maintained at 4 °C during 1 h, and then incubated at 30 °C for the yeasts and *Streptomyces*, and 37 °C for the rest of bacteria. Different amounts per disc were used depending of the compound solubility [450 μg (**1**), 150 μg (**2**), 25 μg (**3**), 100 μg (**4**), 85 μg (**5**), 20 μg (**6**), 125 μg (**7**), 225 μg (**8**), 40 μg (**9**), 20 μg (**10**), 1000 μg (**11**) and 225 μg (**12**)]. For the compounds that were effective against microbes the size of the growth inhibition holes was measured in mm.

2.4. X-ray crystal structure determination of complexes $1 \cdot 2CH_2Cl_2$, $2 \cdot 1.5\ CH_2Cl_2$ and $4 \cdot CH_2Cl_2 \cdot C_6H_{14}$

Crystals suitable for X-ray diffraction analysis were obtained by slow evaporation of a saturated dichloromethane (**1** and **2**) or dichloromethane/ hexane (**4**) solutions. The most relevant crystal and refinement data are collected in Table 1.

Table 1
Crystal data and structure refinement for compounds $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PTA)_2] \cdot 2CH_2Cl_2$, $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)(PTA)] \cdot 1.5CH_2Cl_2$ and $[Ru(NCS)\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)\ (PTA)] \cdot CH_2Cl_2 \cdot C_6H_{14}$

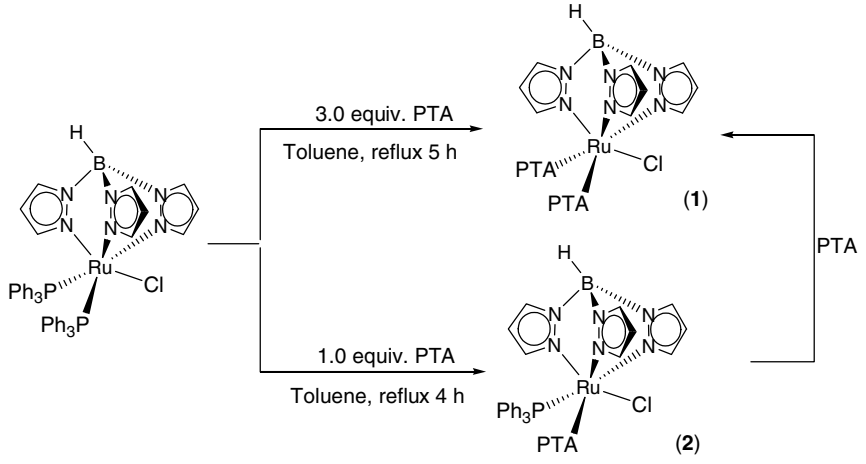
Diffraction data were recorded on a Nonius KappaCCD single crystal diffractometer using Mo Kα radiation, $\lambda = 0.71073$ Å (**1**) and Cu Kα radiation, $\lambda = 1.5418$ Å (**2**). Crystal-detector distance was fixed at 40 mm and using the oscillation method, with 1° oscillation and 30 s exposure time per frame for **1** and crystal-detector distance was fixed at 29 mm and using the oscillation method, with 2° oscillation and 100 s exposure time per frame for **2**. Data collection strategy was calculated with the program COLLECT [21]. Data reduction and cell refinement were performed using the programs HKL DENZO and SCALEPACK [22] and absorption correction was applied by means of Sortav [23]. For **4** data collection was performed at 120(2) K on a Oxford Diffraction Xcalibur Nova single crystal diffractometer, using Cu Kα radiation ($\lambda = 1.5418$ Å). Images were collected at a 65 mm fixed crystal-detector distance, using the oscillation method, with 1° oscillation and variable exposure time per image (7–25 s). Data collection strategy was calculated with the program CRYSALIS PRO CCD [24]. Data reduction and cell refinement was performed with the program CRYSALIS PRO RED [25]. An empirical absorption correction was applied using the Scale3 Abspack algorithm as implemented in the program CRYSALIS PRO RED [25].

The software package WINGX was used for space group determination, structure solution and refinement [26]. The structures were solved by Patterson interpretation and phase expansion using DIRDIF [27]. Isotropic least-squares refinement on F^2 using SHELXL97 was performed [28]. In the crystal of **2** three dichloromethane molecules of solvation per two formula units of the complex were found. A molecule was disordered over two positions, with 0.5 site occupancy factors. All non-hydrogen atoms were anisotropically refined, (except the C atoms of the highly disordered hexane solvent molecule in **4**, which was found and isotropically refined). The coordinates of the H atoms bonded to the boron, in all cases were found from difference Fourier maps and included in the refinement with isotropic parameters. The other hydrogen atoms were geometrically placed riding on their parent atoms with isotropic displacement parameters set to 1.2 times the U_{eq} of the atoms to which they are attached (1.5 for methyl groups). In all cases, the maximum residual electron density is located near the disordered solvent molecules.

The function minimized was $[\Sigma w(F_o^2 - F_c^2)/\Sigma w(F_o^2)]^{1/2}$ where $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$ (a and b values are collected in Table 1) with $\sigma^2(F_o^2)$ from counting statistics and $P = \text{Max}\ (F_o^2 + 2F_c^2)/3$.



Atomic scattering factors were taken from the International Tables for X-ray Crystallography [29]. Geometrical calculations were made with Parst [30]. The crystallographic plots were made with Platon [31].

3. Results and discussion

3.1. Synthesis of half-sandwich ruthenium(II) complexes $[RuCl\{\kappa^3(N,N,N)\text{-}Tp\}(PTA)_2]$ (1) and $[RuCl\{\kappa^3(N,N,N)\text{-}Tp\}(PPh_3)(PTA)]$ (2)

Complex $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)_2]$ undergoes phosphane substitution with adamantane phosphane PTA under different reaction conditions which leads to complexes $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PTA)_2]$ (**1**) and $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)(PTA)]$ (**2**). Thus, the reaction of the complex $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)_2]$ with an excess of PTA (1:3) in refluxing toluene produces the complex $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PTA)_2]$ (**1**), which precipitates from hot, concentrated solutions and can be isolated as a yellow solid with a 98% yield. When the same reaction is carried out using a stoichiometric amount of PTA and more diluted solutions in refluxing toluene, the complex $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)(PTA)]$ (**2**) is isolated as an air-stable, yellow solid with a 96% yield (Scheme 1). Moreover, complex **2** reacts with an excess of PTA, giving rise to complex **1**.

Complexes **1** and **2** are soluble in water (9 and 3 mg/mL, respectively) and in common organic solvents such as methanol, chloroform, and dichloromethane and insoluble

Scheme 1.

in acetone, diethyl ether, and hexane. Both complexes have been analytically and spectroscopically characterized (IR and ^{1}H, ^{13}C{^{1}H} and ^{31}P{^{1}H} NMR). In particular, it must be noted that: (i) the IR spectra (KBr) show the characteristic ν(BH) absorption for the Tp ligand at 2489 (**1**) and 2476 (**2**) cm^{-1}; (ii) ^{31}P{^{1}H} spectrum exhibits a singlet at −29.2 ppm for complex **1** and two doublet resonances at $\delta = 47.1$ and −35.6 ppm ($J_{P,P} = 32$ Hz) for the PPh_3 and the PTA ligands, respectively, for complex **2**; (iii) the ^{1}H NMR spectra show the signals for the two hydrogen atoms of the NCH_2N group of the PTA ligand, which appear as AB spin systems at 4.56 and 4.47 ($J_{HA,HB} = 16$ Hz) for complex **1** and at 4.34 and 4.31 ($J_{HA,HB} = 13$ Hz) for complex **2**. The NCH_2P protons appear as a singlet at 4.13 in complex **1** and as two doublets at 3.90 and 3.86 ($J_{HA,HB} = 16$ Hz) for complex **2**. Assignments of the ^{1}H NMR data were made by comparison with data derived from the literature. The different multiplicity that CH_2 groups of PTA exhibit upon solvent change are noteworthy. These data are consistent with those reported for ruthenium complexes containing the PTA ligand [10–13]; (iv) ^{13}C{^{1}H} NMR spectra reveal the CH_2 groups of the PTA ligand as singlets at 73.2 ppm (NCH_2N) and 53.7 ppm (NCH_2P) for complex **1** and as two doublets at 73.2 ppm ($^3J_{C,P} = 6$ Hz) (NCH_2N) and 51.8 ($J_{C,P} = 14$ Hz) ppm (NCH_2P) for complex **2**.

Slow evaporation of complexes **1** and **2** in CH_2Cl_2 solutions enable crystals to be obtained that are suitable for X-ray diffraction studies of **1** · **2CH$_2$Cl$_2$** and **2** · **1.5 CH$_2$Cl$_2$**. ORTEP type representations are shown in Figs 2 and 3. Selected bonding data are collected in Table 2.

For both complexes, the ruthenium atom exhibits a distorted octahedral coordination geometry bonded $\kappa^3(N,N,N)$ to the hydridotris(pyrazolyl)borate ligand, to

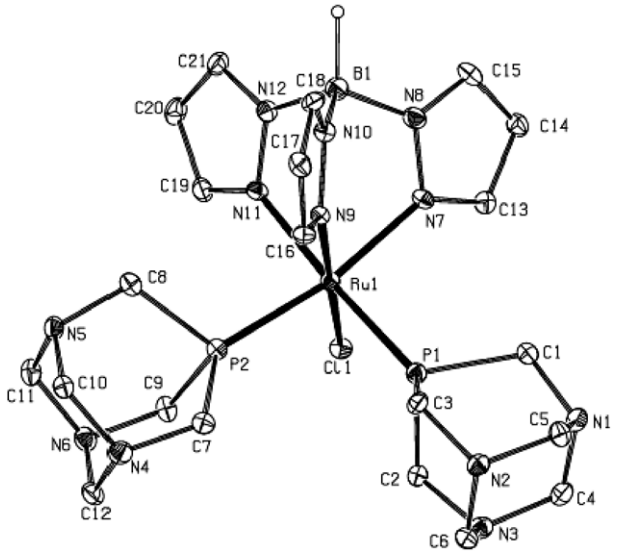


Fig. 2. Molecular structure and atom-labelling scheme for complex **1** · **2CH$_2$Cl$_2$**. Except for B–H, hydrogen atoms have been omitted for clarity as well as solvent molecules. Non-hydrogen atoms are represented by their 10% probability ellipsoids.

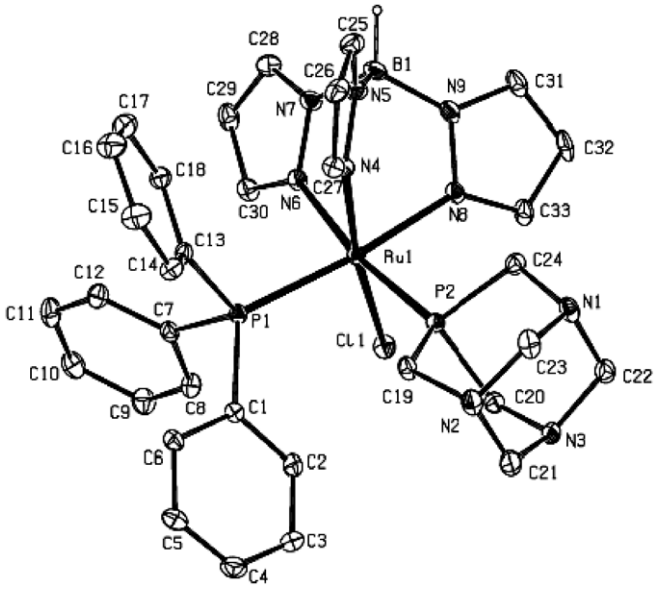

Fig. 3. Molecular structure and atom-labelling scheme for complex **2** · **1.5CH$_2$Cl$_2$**. Except for B–H, hydrogen atoms have been omitted for clarity as well as solvent molecules. Non-hydrogen atoms are represented by their 10% probability ellipsoids.

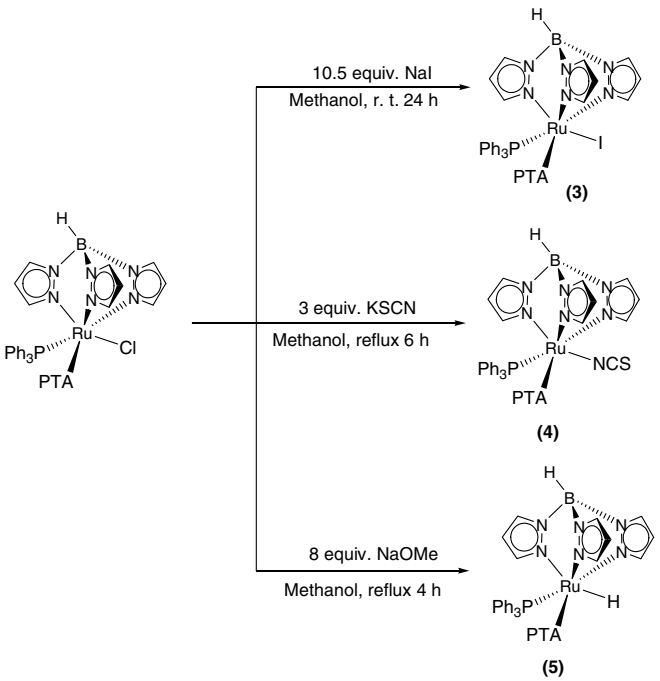
one chlorine atom and to two phosphorous atoms of the PTA ligands in complex **1** and of PTA and PPh_3 in complex **2**. For both complexes, the interligand N–Ru–N angles are in the range of 80.40–88.57 due to the constraints of the chelation of the Tp scorpionate ligand. Ru–N bond distances are typical for divalent ruthenium complexes [RuCl{κ^3(*N*,*N*,*N*)-Tp}(NCMe)(PPh_3)] [32] with Ru–N bond distances in the range of 2.088–2.159. For both complexes, the Ru–N bond distances trans to the phosphane ligands (in the range 2.148(6)–2.159(6)) are significatively longer than those trans to the chlorine atom (Ru(1)–N(9) = 2.088(5) for complex **1** and Ru(1)–N(4) = 2.102(7) for complex **2**) according with the higher trans influence for the phosphane ligands [33,34].



3.2. Chloride metathesis on complex 2: Synthesis of [RuX{κ^3(N,N,N)-Tp}(PPh$_3$)(PTA)] (X = I (3), NCS (4), H (5))

Reaction of complex [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)-(PTA)] (**2**) with an excess of sodium iodide or potassium thiocyanate in methanol leads to the synthesis of the corresponding metathesis complexes [RuX{κ^3(*N*,*N*,*N*)-Tp}-(PPh_3)(PTA)] (X = I (**3**), NCS (**4**)) respectively (Scheme 2). When the reagent was NaMeO, a β-elimination in the intermediate complex [Ru(OMe){κ^3(*N*,*N*,*N*)-Tp}(PPh_3)-(PTA)] produces the hydride complex [RuH{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(PTA)] (**5**).

Complexes **3**–**5** are soluble in water ($S_{20\,°C} = 0.5$ (**3**), 2.0 (**4**) and 1.7 (**5**) mg/mL), alcohols, and dichloromethane and are insoluble in hexane. Elemental analyses corroborate the proposed stoichiometry and ^{1}H, ^{31}P{^{1}H} and ^{13}C{^{1}H} NMR spectra support the proposed structure. The most

Scheme 2.

remarkable features of these complexes are (i) the high field doublet of doublets at −14.71 ppm ($^2J_{H,P} = 31$ Hz and $^2J_{H,P} = 26$ Hz) corresponding to the hydride atom in complex **5**. This datum is consistent with the one reported for recently described PTA hydride complexes [35]; (ii) the IR spectra (KBr) exhibit the characteristic ν(BH) absorption of the Tp ligand at 2466 (**3**), 2485 (**4**), and 2457 (**5**) cm^{-1}, ν(RuH) absorption at 1923 cm^{-1} in complex **5**, and the band at 2113 cm^{-1} due to the NCS ligand in complex **4**. The C–N stretching band of the thiocyanate group appears at a lower frequency for N-bonded than for S-bonded complexes (around 2050 cm^{-1} versus 2100 cm^{-1}, respectively) [36]. However, the ν(CN) frequency is sensitive to other factors and assignments should be applied with caution, as described for iron thiocyanates [37].

To ascertain the coordination mode of the thiocyanate group in complex **4**, an X-ray study was performed. Slow evaporation of the solvent in a CH_2Cl_2/hexane solution of complex **4** allows suitable crystals for X-ray diffraction studies to be obtained. The asymmetric unit consists of a $[Ru(NCS)\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)(PTA)]$ (**4**) molecule, a dichloromethane molecule and a hexane molecule.

An ORTEP type representation is shown in Fig. 4. Selected bonding data are presented in the caption.

As for complexes **1** and **2**, the ruthenium atom exhibits a distorted octahedral coordination geometry bonded $\kappa^3(N,N,N)$ to the hydridotris(pyrazolyl)borate ligand, to two phosphorous atoms of the PTA and PPh_3 ligands and to the nitrogen atom of the NCS group. The Ru–N(Tp) bond distances are in the range of the obtained for complexes **1** and **2**. Again, the Ru–N bond distance trans to the NCS group (Ru(1)–N(8) 2.089(5) Å) is shorter than the other two Ru–N bond distances (2.132(7) and 2.161(6)) in accord with the similar trans influence of Cl and NCS ligands [38].

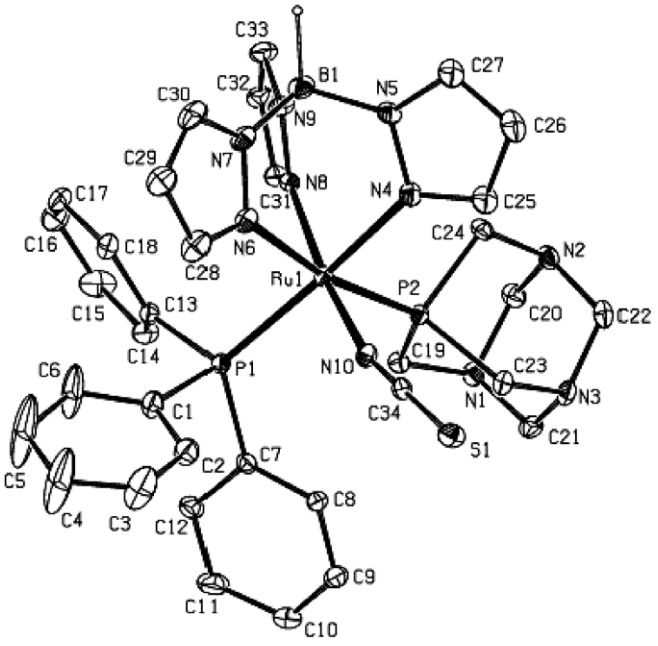

Fig. 4. Molecular structure and atom-labelling scheme for complex $\mathbf{4}\cdot\mathbf{CH_2Cl_2}\cdot\mathbf{C_6H_{14}}$. Except for B–H, hydrogen atoms have been omitted for clarity as well as solvent molecules. Non-hydrogen atoms are represented by their 10% probability ellipsoids. Selected bond lengths (Å): Ru(1)–N(4) = 2.132(7), Ru(1)–N(6) = 2.161(6), Ru(1)–N(8) = 2.089(5), Ru(1)–N(10) = 2.033(6), Ru(1)–P(1) = 2.3294(18), Ru(1)–P(2) = 2.2894(15), N(10)–C(34) = 1.161(9), C(34)–S(1) = 1.631(7). Selected bond angles (°): N(4)–Ru(1)–N(6) = 81.9(3), N(6)–Ru(1)–N(8) = 87.2(2), N(4)–Ru(1)–N(8) = 87.1(3), N(4)–Ru(1)–N(10) = 84.9(3), N(6)–Ru(1)–N(10) = 90.1(2), N(8)–Ru(1)–N(10) = 171.8(3), N(4)–Ru(1)–P(1) = 174.10(17), N(4)–Ru(1)–P(2) = 88.66(16), N(6)–Ru(1)–P(1) = 92.4(2), N(6)–Ru(1)–P(2) = 169.9(2), N(8)–Ru(1)–P(1) = 94.21(18), N(8)–Ru(1)–P(2) = 88.72(16), P(1)–Ru(1)–N(10) = 93.64(19), P(2)–Ru(1)–N(10) = 92.64(16), P(1)–Ru(1)-P(2) = 97.12(6), Ru(1)–N(10)–C(34) = 166.9(6), N(10)–C(34)–S(1) = 179.1(8).

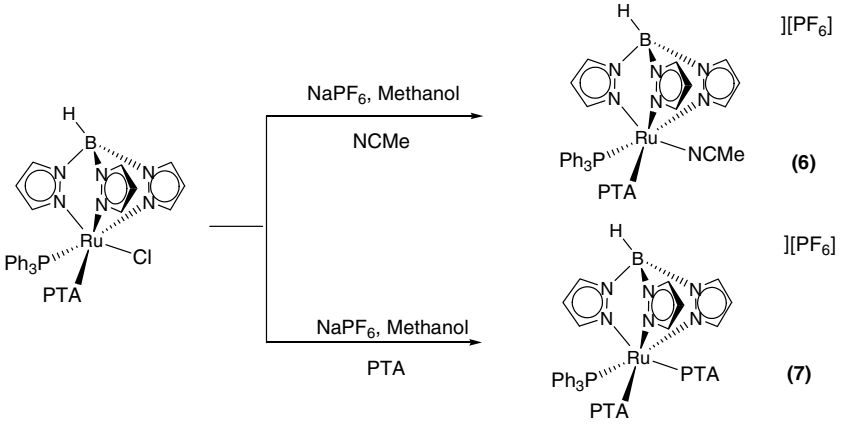
The thiocyanate group is N-bonded and displays a linear NCS arrangement (Ru–N–C and N–C–S angles 166.9(6)° and 179.1(8)°, respectively) as found for analogous ruthenium N-bonded derivatives [39]. The Ru–N(10) bond distance of 2.033(6) Å is consistent with a donation of d_π electron density from ruthenium to the π-accepting thiocyanate group.

3.3. Synthesis of the cationic complexes $[Ru\{\kappa^3(N,N,N)\text{-}Tp\}(NCMe)(PPh_3)(PTA)][PF_6]$ (6) and $[Ru\{\kappa^3(N,N,N)\text{-}Tp\}(PPh_3)(PTA)_2][PF_6]$ (7)



Reaction of complex $[RuCl\{\kappa^3(N,N,N)\text{-}Tp\}(PPh_3)(PTA)]$ (**2**) with an appropriate chloride abstractor such as $NaPF_6$ in the presence of acetonitrile, allows the cationic complex $[Ru\{\kappa^3(N,N,N)\text{-}Tp\}(NCMe)(PPh_3)(PTA)][PF_6]$ (**6**) to be synthesized. When the reaction is carried out in the presence of PTA, the complex $[Ru\{\kappa^3(N,N,N)\text{-}Tp\}(PPh_3)(PTA)_2][PF_6]$ (**7**) is obtained (Scheme 3).

Complexes **6** and **7** are soluble in water (0.4 and 2.5 mg/mL, respectively), alcohols, and dichloromethane and insoluble in diethyl ether and hexane. Analytical and spectroscopic data are consistent with the proposed structure. Thus, the IR spectra for complexes **6** and **7** are characterized by ν(BH) at 2491 and 2488 cm^{-1} and by $\nu(PF_6)$ at 840 and 842 cm^{-1}, respectively. $^{31}P\{^1H\}$ spectra show two doublets at $\delta = 43.9$ (PPh_3) and −42.4 (PTA) ($J_{P,P} = 29$ Hz) for complex **6** and one triplet $\delta = 48.6$ (PPh_3) and one doublet at $\delta = -49.1$ (PTA) ($J_{P,P} = 31$ Hz) for complex **7**. For complex **6,** the methyl group of the NCMe ligand appears as a singlet at 2.19 ppm in the ^1H NMR and at 4.0 ppm in the $^{13}C\{^1H\}$ spectra.

Attempts to synthesize complexes $[Ru\{\kappa^3(N,N,N)\text{-}Tp\}(NCMe)(PTA)_2][PF_6]$ and $[Ru\{\kappa^3(N,N,N)\text{-}Tp\}(PTA)_3][PF_6]$ from $[RuCl\{\kappa^3(N,N,N)\text{-}Tp\}(PTA)_2]$ (**1**) failed and the starting material was recovered.

3.4. Methylation reactions: Synthesis of $[RuCl\{\kappa^3(N,N,N)\text{-}Tp\}(m\text{-}PTA)_2][CF_3SO_3]_2$ (8) and $[RuX\{\kappa^3(N,N,N)\text{-}Tp\}(PPh_3)(m\text{-}PTA)][CF_3SO_3]$ (X = Cl (9), H (10))

Treatment of complexes **1**, **2**, and **5** at −30 °C with MeOTf in CH_2Cl_2 leads to the methylation of one of the nitrogen atoms of the PTA ligand resulting in the

Scheme 3.

complexes containing the 1-methyl-3,5-diaza-1-azonia-7-phosphaadamantane (m-PTA) triflate ligand. Thus, the complexes $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(\text{m-PTA})_2][CF_3SO_3]_2$ (**8**), $[RuCl\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)(\text{m-PTA})][CF_3SO_3]$ (**9**), and $[RuH\{\kappa^3(N,N,N)\text{-Tp}\}(PPh_3)(\text{m-PTA})][CF_3SO_3]$ (**10**) have been isolated as yellow solids (Scheme 4).

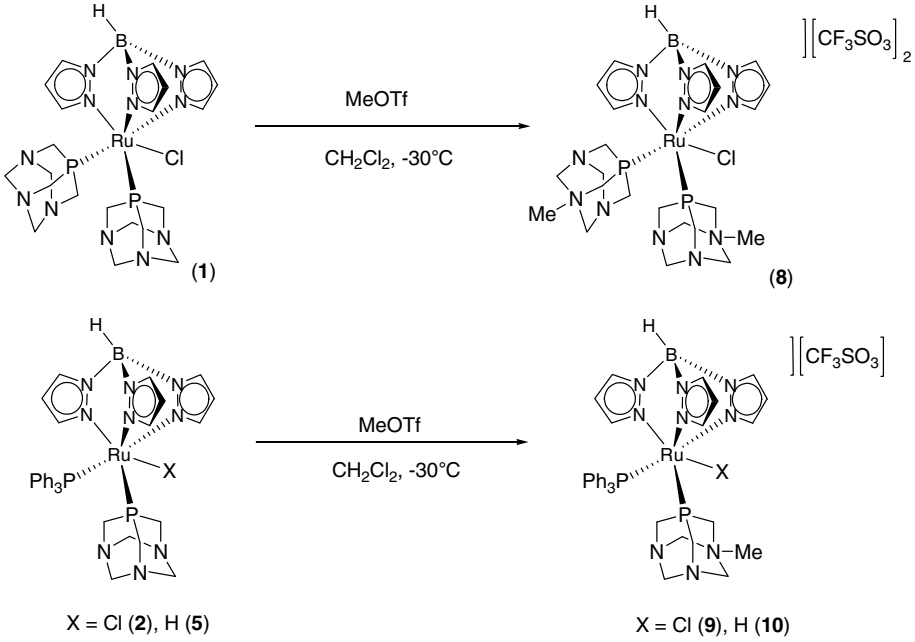
Water solubility decreases with respect to the parent compounds (4.5 mg/mL (**8**), 0.8 mg/mL (**9**), 0.4 mg/mL (**10**) versus 9 mg/mL (**1**), 3 mg/mL (**2**), and 1.7 mg/mL (**5**)).

Elemental analysis and spectroscopic data agree with the proposed formulations. Thus, the chemical shift of the phosphorous atom of the m-PTA ligand in the $^{31}P\{^1H\}$ NMR spectra ($\delta = -9.8$ (**8**), -13.6 (**9**), -4.7 (**10**)) appears in all cases at lower fields than the PTA ligand in the former complexes spectra ($\delta = -29.2$ (**1**), -35.6 (**9**), -23.4 (**10**)). The typical AB spin system for the NCH_2N groups observed in the ^1H NMR spectra of complexes **1**, **2**, and **5** disappears and a large number of doublets and triplets in the range of 4.12–5.12 ppm appear for complexes **8**–**10**. The methyl group of the m-PTA ligand for complexes **8**–**10** appears as a singlet in the range of 2.43–2.80 in the ^1H NMR spectra and 48.9–49.2 in the $^{13}C\{^1H\}$ NMR spectra.

3.5. Synthesis of $[Ru(\eta^5\text{-}C_9H_7)(PTA)_3][Cl]$

For comparative purposes, the synthesis of complex $[Ru(\eta^5\text{-}C_9H_7)(PTA)_3][Cl]$ (**11**) was carried out. Hence, the treatment of $[RuCl(\eta^5\text{-}C_9H_7)(PPh_3)_2]$ with PTA ligand in refluxing toluene allows the synthesis of complex **11** as a yellow solid with a 53% yield. It has been analytically and spectroscopically characterized and its water solubility has been quantified as 20 mg/mL.

The indenyl complex $[Ru(\eta^5\text{-}C_9H_7)(PTA)_3][Cl]$ (**11**) exhibits a single resonance in the $^{31}P\{^1H\}$ NMR spectrum at $\delta = -26.7$ ppm. The ^1H NMR spectrum reveals the presence of the indenyl group and the PTA ligands. Accordingly, the spectrum shows a NCH_2N multiplet at 4.46 ppm and a singlet at 3.83 ppm for the NCH_2P protons of the PTA ligand. Complex $[RuCl(\eta^5\text{-}C_9H_7)(PPh_3)(PTA)]$ (**12**) has also been used in this work and has been synthesized as previously reported [10a].



3.6. Chemical behavior in aqueous solution

Stability of complexes **2**, **5**, **6**, **9**, and **10** under physiological conditions was tested by heating samples of complexes in phosphate buffer solutions at pH 7 to 37 °C. After 14 h, no appreciable decomposition was observed in any of the complexes tested. The experiments were conducted both in the presence and in absence of oxygen and no significant differences were found.

Conductivity measurements in water (5×10^{-4} M) for complexes **1**–**3** confirm that these complexes are neutral in aqueous solution, ruling out potential halide dissociation.

3.7. DNA binding properties and cytotoxicity of ruthenium complexes

The reported complexes **1**–**10** present in their structures a hydridotris(pyrazolyl)borate ligand which contain three pyrazol groups and PTA or m-PTA ligands conferring water solubility to the complexes by virtue of hydrogen bonding to the tertiary amine nitrogen atoms. The new synthesized complexes are appealing for the study of their

Scheme 4.

DNA binding properties, since it is well known that the most advanced as antitumoral ruthenium complexes are those with N-donor ligands [40]. Furthermore, the hydride ligand in complexes **5** and **10** constitutes an additional site for hydrogen bonding.

The interaction of new ruthenium complexes with supercoiled DNA (SC) was tested by shift mobility assay on agarose gels. Alteration of the mobility of SC DNA and/ or open circular DNA (OC) indicates a disturbance of the DNA structure by the ruthenium compounds. Retardation of SC DNA was observed for complexes containing the PTA ligand, namely [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(PTA)] (**2**), [RuH{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(PTA)] (**5**), [Ru{κ^3(*N*,*N*,*N*)-Tp}(NCMe)(PPh_3)(PTA)][PF_6] (**6**), and [Ru{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)$(PTA)_2$][PF_6] (**7**), and with m-PTA [RuCl{κ^3(*N*,*N*,*N*)-Tp}$(m\text{-}PTA)_2$][CF_3SO_3]$_2$ (**8**), [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(m-PTA)][CF_3SO_3] (**9**), and [RuH{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(m-PTA)][CF_3SO_3] (**10**). The indenyl complexes [Ru(η^5-C_9H_7)$(PTA)_3$][Cl] (**11**) and [RuCl(η^5-C_9H_7)-(PTA)(PPh_3)] (**12**) were also found to be active (Fig. 5).

No interaction with the plasmid was detected for complexes [RuCl{κ^3(*N*,*N*,*N*)-Tp}$(PTA)_2$] (**1**), [RuI{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(PTA)] (**3**), and [Ru(NCS){κ^3(*N*,*N*,*N*)-Tp}-(PPh_3)(PTA)] (**4**). Given that complex **1**, which does not exhibit any effect, is the most soluble of the pyrazolyl borate complexes described, we can state that solubility of the complex is not the only important factor. On the other hand, even though complex **2** binds to DNA, the replacement of chloride by iodide or NCS in complexes **3** and **4**, respectively, results in the loss of DNA binding and biological activity (see below), probably due to a stronger Ru–I or Ru–N–C–S bonding which prevents the coordination of nucleophiles from the DNA bases to the ruthenium atom.

To perform an initial analysis of the *in vivo* activity of the novel ruthenium complexes, we have used the Kirby Bauer disc diffusion method described by Biemer [20]. This classical assay has been widely used for screening new antimicrobial compounds, as well as for their quantification by using logarithmic calibration curves [20]. Seven different bacteria (*M. luteus*, *B. subtilis*, *E. coli* C600, *S. coelicolor*, *S. antibioticus*, *S. glaucescens,* and *P. aeruginosa*) and three eukaryotic microorganisms (*C. albicans*, *C. parapsilosis,* and *R. toruloides*) were used (see Section 2 and Fig. 6). Complexes [Ru{κ^3(*N*,*N*,*N*)-Tp}(NCMe)(PPh_3)(PTA)][PF_6] (**6**), [RuCl{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(m-PTA)][CF_3SO_3] (**9**), and [RuH{κ^3(*N*,*N*,*N*)-Tp}(PPh_3)(m-PTA)][CF_3SO_3] (**10**) proved to be the most biologically active compounds. They were active against most of the microorganisms tested and showed the largest inhibition halos (for *M. luteus*, inhibition growth halo of 15 mm (**6**), 21 mm (**9**) and 17 mm (**10**), for *S. antibioticus* inhibition growth halo of 11 mm for each one, *S. coelicolor* inhibition growth halos of 14 (**6**), 13 (**9**) and 10 mm (**10**), and for *S. glaucescens* inhibition

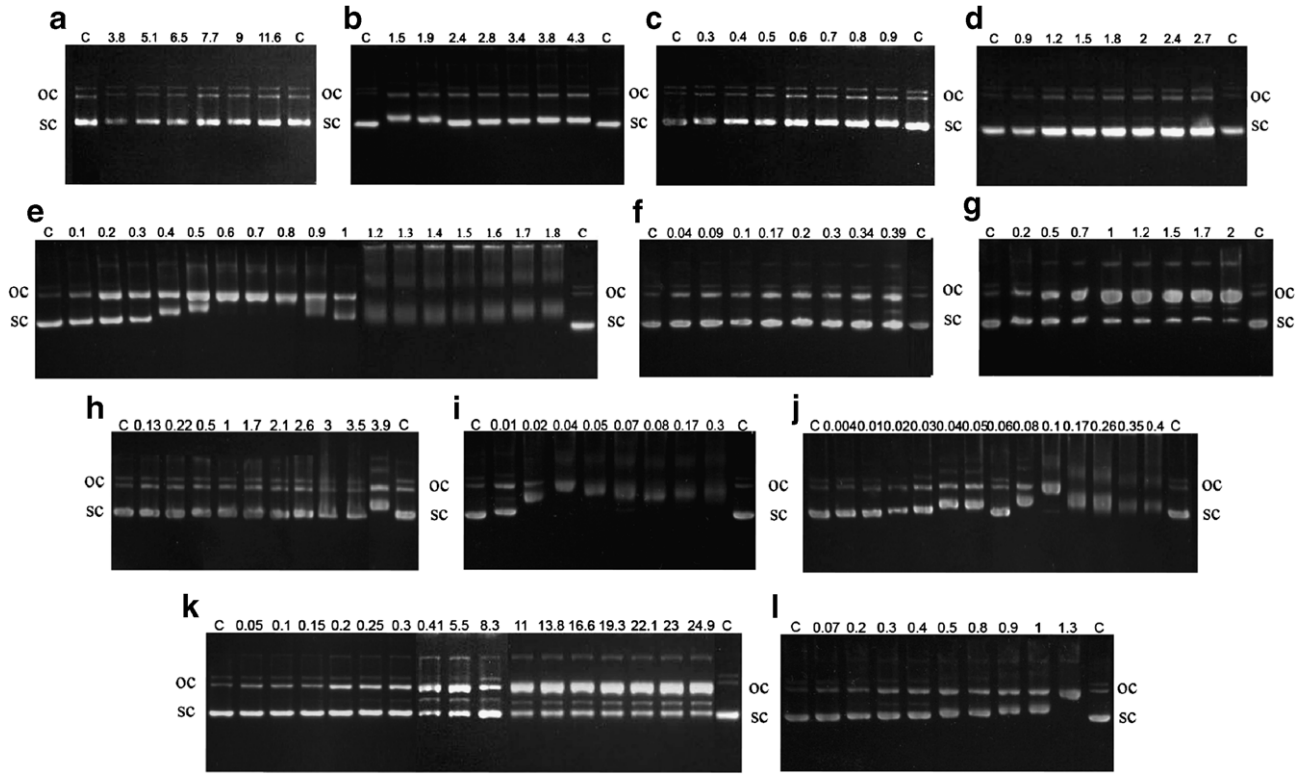


Fig. 5. DNA mobility shift assay for the water-soluble ruthenium complexes: (a) **1**, (b) **2**, (c) **3**, (d) **4**, (e) **5**, (f) **6**, (g) **7**, (h) **8**, (i) **9**, (j) **10**, (k) **11**, (l) **12**. The range of ruthenium complex concentrations used were (top of the panels, mM): **1** (3.8–11.6), **2** (1.5–4.3), **3** (0.3–0.9), **4** (0.9–2.7), **5** (0.1–1.8), **6** (0.04–0.39), **7** (0.2–2), **8** (0.13–3.9), **9** (0.01–0.3), **10** (0.004–0.4), **11** (0.05–24.9), **12** (0.07–1.3). C is the control lane without the ruthenium complex. OC, open circular plasmidic DNA; SC, supercoiled DNA.

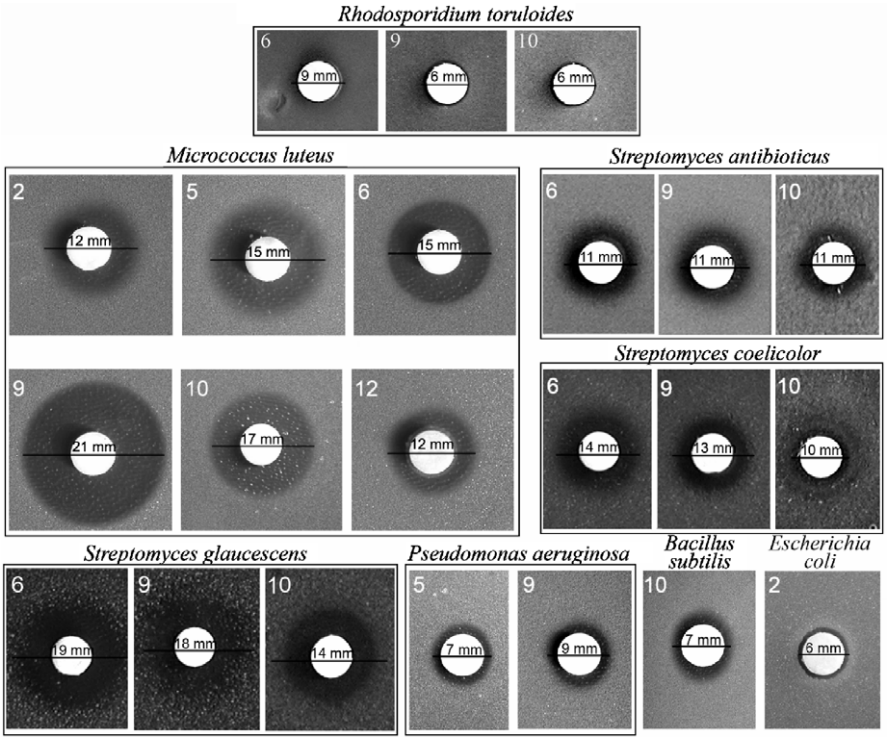

Fig. 6. DNA antimicrobial activity of the ruthenium complexes. The compounds (numbers), inhibition halos (mm), and the microorganism tested are indicated. Ruthenium complex used per disc: 450 μg (**1**), 150 μg (**2**), 25 μg (**3**), 100 μg (**4**), 85 μg (**5**), 20 μg (**6**), 125 μg (**7**), 225 μg (**8**), 40 μg (**9**), 20 μg (**10**), 1000 μg (**11**), and 225 μg (**12**).

growth halos of 19 (**6**), 18 (**9**) and 14 mm (**10**)) (Fig. 6). Their antimicrobial activity, however, is relatively low when compared to that of antibiotic compounds: for example, erythromycin A (0.6 μg) or mitramycin (1 μg) give inhibition halos against *M. luteus* of 21 mm in diameter (not shown), whereas the most active ruthenium compound **9** displayed the same inhibition growth halo diameter at 20 μg concentration.

The activity results revealed important differences among the microorganisms tested. *M. luteus* and *Streptomyces* species were the most sensitive microorganisms (Fig. 6). These two genera have high guanine and cytosine content in their genomes [41] (60–70%), which could explain their high sensitivity to the complexes analyzed, since guanine residues have been described as preferential binding sites when DNA is modified with ruthenium(II) [42]. In accordance with this hypothesis, the other less sensitive bacteria assayed have lower guanine and cytosine percentages [41]. On the other hand, *M. luteus* and *Streptomyces* differ in their sensitivity to ruthenium complexes; also, differences in sensitivity were observed among the three *Streptomyces* species analyzed (Fig. 6). This suggests that additional factors other than guanine and cytosine content affect the biological activity of the ruthenium complexes, and the cellular permeability could be one of them. The assayed yeasts were strongly resistant to the ruthenium complexes: only *R. toruloides* was sensible to complexes **6**, **9** and **10**, while *C. albicans* and *C. parapsilosis* were resistant to the twelve tested compounds (not shown), stressing again the importance of the particular microorganism with respect to the cytotoxicity results. Complexes **6**, **9**, and **10** were the most biologically active compounds. Interestingly, they correspond to the lower water-soluble compounds (see Section 2), suggesting that the solubility could be an important factor determining cellular activity. An underlying explanation for this might be related to the hydrophobic nature of the biological cell membranes, which are more permeable to the less water-soluble complexes. This would explain also the high resistance of yeasts, since in this case chromosomal DNA is additionally protected by the nuclear membrane.

In summary, we have described the first examples of hydridotris(pyrazolyl)borate ruthenium complexes containing the water-soluble PTA phosphane, their interaction with plasmidic DNA, and also their antimicrobial activity. Future experiments will be necessary to test the putative effect of these compounds against tumoral eukaryotic cells, their primary targets and the mechanism involved, including those hypothetically related with their DNA binding properties.

4. Conclusion

The ruthenium(II) complexes reported here constitute the first examples of water-soluble hydridotris(pyrazolyl)borate complexes. The presence of 1,3,5-triaza-7-phosphaadamantane (PTA) and 1-methyl-3,5-diaza-1-azonia-7-phosphaadamantane (m-PTA) triflate induce hydrophilicity in the complexes. Compounds with the m-PTA ligand have been

selectively synthesized by direct methylation of PTA complexes with methyl triflate in mild conditions. Moreover, hydride complexes **5** and **10** are interesting for their potential use in synthesis, either catalytic or stoichiometric processes that are currently under research.

Several of the ruthenium(II) complexes tested show DNA binding and antimicrobial activity. Among the compounds used, complexes with the methylated PTA phosphane ligand **9** and **10** were the most active against prokaryotic microorganisms, in spite of the low water solubility found in these derivatives. On the other hand, derivatives **5** and **10** showed a high interaction capability with DNA, probably due to their ability for establish hydrogen bonding. Although they have not been tested yet against mammalian cells, they constitute an interesting subject for research as potential antitumor agents.

The precise mechanisms involved in DNA coordination of these complexes remain unclear. Current development of new metal complexes and subsequent analysis of DNA coordination will undoubtedly clarify this point, thereby facilitating the synthesis of more active drugs.

Appendix A. Supplementary material

CCDC 649219, 649220 and 649221 contain the supplementary crystallographic data for ($\mathbf{1 \cdot 2CH_2Cl_2}$), ($\mathbf{2 \cdot 1.5CH_2Cl_2}$) and ($\mathbf{4 \cdot CH_2Cl_2 \cdot C_6H_{14}}$). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.12.013.

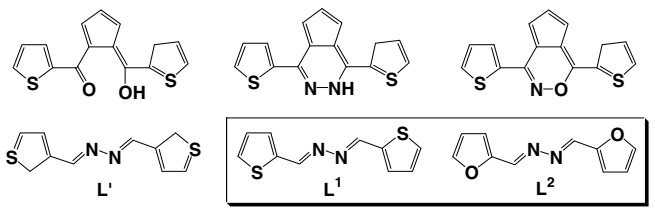

Chart 1.

terminal heterocyclic rings with sulfurs and oxygens, respectively, with an emphasis to investigate the variation in topology of the resulting compounds with the counterions used. We report herein the preparation and structures of five silver compounds, $[AgL^1_2](PF_6)$ (**1**), $[Ag_2L^2_3](PF_6)_2$ (**2**), $[Ag_2L^2_3](ClO_4)_2$ (**3**), $[Ag_2L^2_2](BF_4)_2$ (**4**), and $[Ag_2L^2(NO_3)_2]$ (**5**). X-ray structure analysis of these compounds revealed that compound **1** is a discrete molecule, whereas compounds **2**–**5** are coordination polymers or networks constructed by either covalent bonds or van der Waals contacts.

2. Experimental

All solid chemicals were purified by recrystallization, and all solvents were distilled and stored over molecular sieves. Ligands L^1 (1,2-bis(thiophen-2-ylmethylene)hydrazine) [19] and L^2 (1,2-bis(furan-2-ylmethylene)hydrazine) [33] were prepared by the literature methods. IR spectra were recorded with a Nicolet 320 FTIR spectrophotometer. Elemental analyses were performed with EA1110 (CE instrument, Italy) at the Korea Basic Science Institute. Photoluminescence (PL) experiments were performed with an AB2 spectrophotometer (Amico Bowmann).

2.1. Preparation of $[AgL^1_2](PF_6)$ (1)

A dichloromethane solution (4 ml) of L^1 (61.0 mg, 0.280 mmol) was allowed to diffuse slowly into a methanol solution (3 ml) of $AgPF_6$ (35.0 mg, 0.139 mmol). Yellow crystals of compound **1** formed in 5 days (62 mg, 0.089 mmol, 64%). *Anal.* Calc. for $C_{20}H_{16}F_6N_4PS_4Ag$ ($M_r = 693.45$): C, 34.64; H, 2.31; N, 8.08. Found: C, 33.89; H, 2.51; N, 7.85%. IR (KBr, cm^{-1}): 1603 (s), 1420 (m), 1212 (m), 1050 (m), 838 (s), 714 (m).

2.2. Preparation of $[Ag_2L^2_3](PF_6)_2$ (2), $[Ag_2L^2_3](ClO_4)_2$ (3), $[Ag_2L^2_2](BF_4)_2$ (4), and $[Ag_2L^2(NO_3)_2]$ (5)

Polymers **2**–**5** were prepared in the same way. A dichloromethane solution (4 ml) of L^2 (46.0 mg, 0.250 mmol) was layered on the top of a methanol solution (6 ml) of $AgPF_6$ (43.0 mg, 0.169 mmol). Yellow crystals of compound **2** formed in 5 days (70 mg, 0.065 mmol, 76%). *Anal.* Calc. for $C_{30}H_{24}F_{12}N_6O_6P_2Ag_2$ ($M_r = 1070.23$): C, 33.67; H, 2.24; N, 7.85. Found: C, 33.96; H, 2.52; N, 7.67%. IR (KBr, cm^{-1}): 1637 (s), 1465 (m), 1289 (m), 1021 (m), 842 (s), 756 (m).

Data for polymer **3**: 68% yield. *Anal.* Calc. for $C_{30}H_{24}N_6O_{14}Cl_2Ag_2$ ($M_r = 979.19$): C, 36.80; H, 2.45; N, 8.58. Found: C, 37.05; H, 2.39; N, 7.85%. IR (KBr, cm^{-1}): 1637 (s), 1465 (m), 1288 (m), 1093 (s), 1016 (m), 935 (m), 756 (m).

Data for polymer **4**: 80% yield. *Anal.* Calc. for $C_{20}H_{16}B_2F_8N_4Ag_2$ ($M_r = 765.73$): C, 31.37; H, 2.09; N, 7.31. Found: C, 31.10; H, 2.18; N, 7.38. IR (KBr, cm^{-1}): 1636 (s), 1461 (m), 1391 (m), 1294 (m), 1054 (s), 935 (m), 769 (m).

Data for polymer **5**: 72% yield. *Anal.* Calc. for $C_{10}H_8N_4O_8Ag_2$ ($M_r = 527.94$): C, 22.75; H, 1.52; N, 7.58. Found: C, 22.46; H, 1.55; N, 7.58. IR (KBr, cm^{-1}): 1634 (s), 1447 (m), 1357 (s), 1273 (s), 1014 (m), 936 (m), 761 (m).

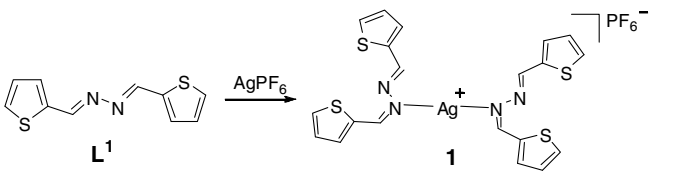
2.3. X-ray structure determination

X-ray data were collected with a Siemens P4 diffractometer (**1**) or a Bruker Smart APEX2 diffractometer (**2**–**5**) equipped with a Mo X-ray tube. Absorption corrections were made with ψ-scan data (**1**) or SADABS (**2**–**5**) [34]. All calculations were carried out with SHELXTL programs [35]. All structures were solved by direct methods. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were generated in idealized positions and refined in a riding model. Details on crystal data, intensity collection, and refinement details are given in Table 1.

3. Results and discussion

3.1. Preparation

In this study, all compounds $[AgL^1_2](PF_6)$ (**1**), $[Ag_2L^2_3](PF_6)_2$ (**2**), $[Ag_2L^2_3](ClO_4)_2$ (**3**), $[Ag_2L^2_2](BF_4)_2$ (**4**), and $[Ag_2L^2(NO_3)_2]$ (**5**) were prepared by layer diffusion, in which a dichloromethane solution containing a ligand was layered on the top of a methanol solution containing a silver salt. All products were characterized by elemental analysis, IR spectroscopy, and X-ray diffraction, and their IR spectra display the C=N stretches in the range 1603–1636 cm^{-1}, which is consistent with the fact that C=N stretches of Schiff bases appear in the range 1603–1680 cm^{-1} [36–38].



Our initial goal was to prepare silver coordination polymers by treating silver salts (AgX) with ligand L^1, which contains terminal thiophene rings (sulfur donors). For this purpose, $AgPF_6$ was selected, because it possesses a labile PF_6^- ion and a soft Ag metal. Inconsistent with our expectation, however, an ionic Ag compound $[AgL^1_2](PF_6)$ (**1**) was produced from the reaction (Eq. (1)). In the cationic part of compound **1**, the Ag metal is bonded to the harder imine nitrogen atoms in the Schiff-base fragments in the ligand (L^1), not to the softer sulfur atoms in the terminal thiophene rings, which are *cisoid* to each other. In the free form of ligand L^1, the terminal thiophene rings are in a *transoid* conformation [19]. It would be meaningful to compare compound **1** with $[AgL'_2](PF_6)$, which contains an iso-

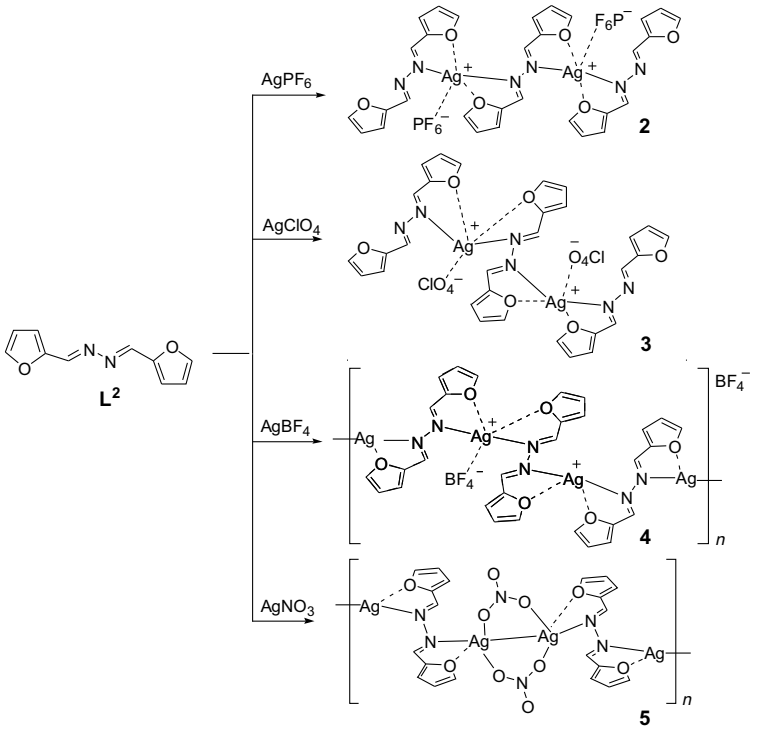
meric ligand of $\mathbf{L}^1$. Unlike polymer **1**, $[Ag\mathbf{L}'_2](PF_6)$ formed a 2D network in which the sulfur donors participated in the Ag···S contacts and two F atoms of the counterion PF_6^- participated in the Ag···F contacts [20]. It should be pointed out that we previously obtained silver coordination polymers $\{[Ag\mathbf{L}^1_{0.5}(NO_3)]$ and $[Ag\mathbf{L}^1_2](ClO_4)\}$ by treating $AgNO_3$ and $AgClO_4$ with ligand $\mathbf{L}^1$ [19]. We believe that the different reactivity between these two silver salts and $AgPF_6$ is primarily due to the different counterions in the starting silver salts.



(1)

In contrast with the above results, the corresponding reactions of silver salts (AgX: X = PF_6^-, ClO_4^-, BF_4^-, NO_3^-) with ligand $\mathbf{L}^2$, which contains terminal furan rings (oxygen donors), produced silver coordination networks based on covalent bonds or van der Waals contacts: $[Ag_2\mathbf{L}^2_3](PF_6)_2$ (**2**), $[Ag_2\mathbf{L}^2_3](ClO_4)_2$ (**3**), $[Ag_2\mathbf{L}^2_2](BF_4)_2$ (**4**), and $[Ag_2\mathbf{L}^2(NO_3)_2]$ (**5**) (Scheme 1, where intermolecular van der Waals contacts are omitted for clarity). In all these polymers or networks, the imine nitrogen atoms are bonded to the Ag ions, and the furan rings in each $\mathbf{L}^2$ are *transoid*. Interestingly, all the furan oxygen atoms are in van der Waals contacts with the silver ions to form five-membered pseudo-chelates in these coordination polymers.

3.2. Structures

The structure of compound **1** with the atom-numbering scheme is shown in Fig. 1. This ionic compound consists of one Ag(I) metal, two $\mathbf{L}^1$ ligands, and one PF_6^- ion that is not bound to the Ag metal and simply behaves as a counterion. The central silver atom is covalently bonded to two nitrogen atoms of two different $\mathbf{L}^1$ ligands.

A monomer unit of compound **2** is given in Fig. 2, which shows an asymmetric unit consisting of one Ag, one and half $\mathbf{L}^2$, and one PF_6^-. The Ag–N bond lengths (2.200(3) and 2.244(3) Å) indicate normal covalent bonds, and therefore the Ag metal is 2-coordinate. The Ag metal is further bound to three oxygen (O1–O3) and two fluorine (F3 and F6) atoms via van der Waals contacts: Ag···O (2.705(3)–3.091(3) Å) and Ag···F (3.049(3)–3.144(4) Å). Considering

Scheme 1.

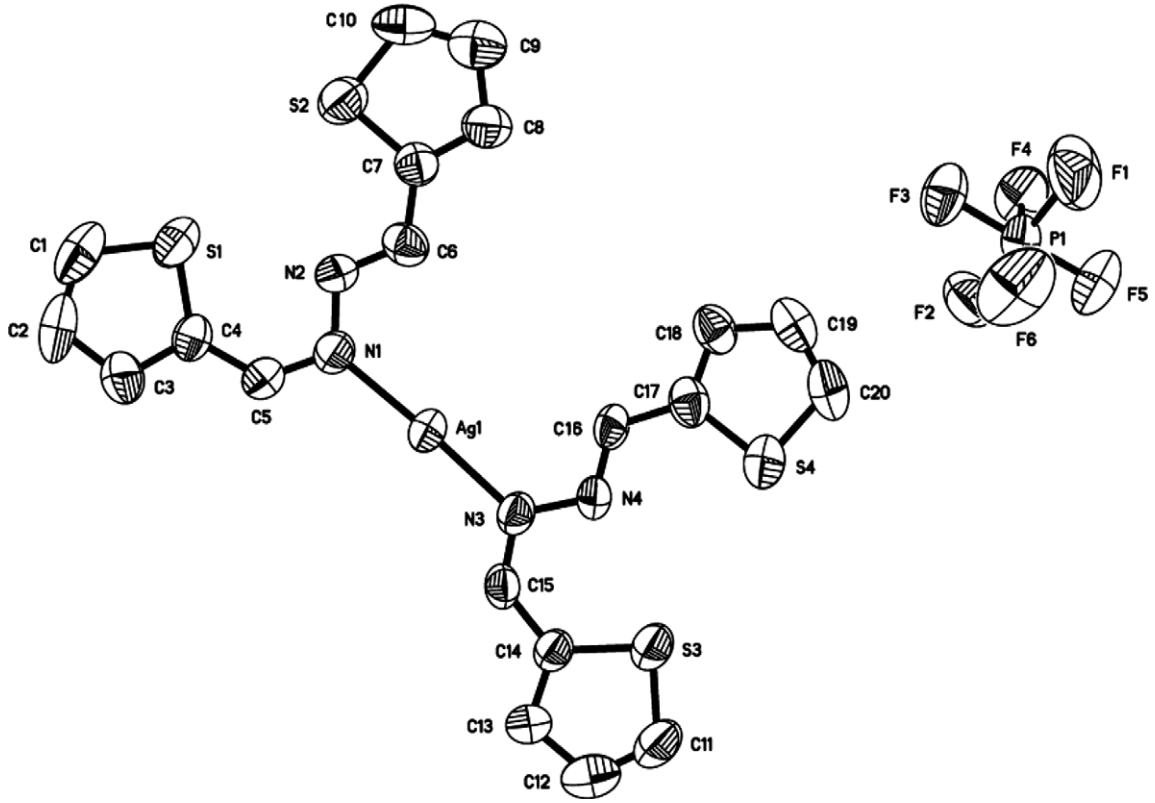


Fig. 1. ORTEP drawing of compound **1** with 50% probability thermal ellipsoids. Selected bond distances (Å) and angles (°): Ag1–N1 2.141(7), Ag1–N3 2.141(6), N1–N2 1.386(9), N3–N4 1.405(9); N1–Ag1–N3 176.6(3), C5–N1–Ag 1119.7(6), N4–N3–Ag1, 125.2(5).

these van der Waals contacts, the Ag metal may now be thought of as being 7-coordinate. For comparison, the van der Waals radii of Ag, O, and F atoms are 1.72, 1.50, and 1.55 Å, respectively. Fig. 3 demonstrates a 2D

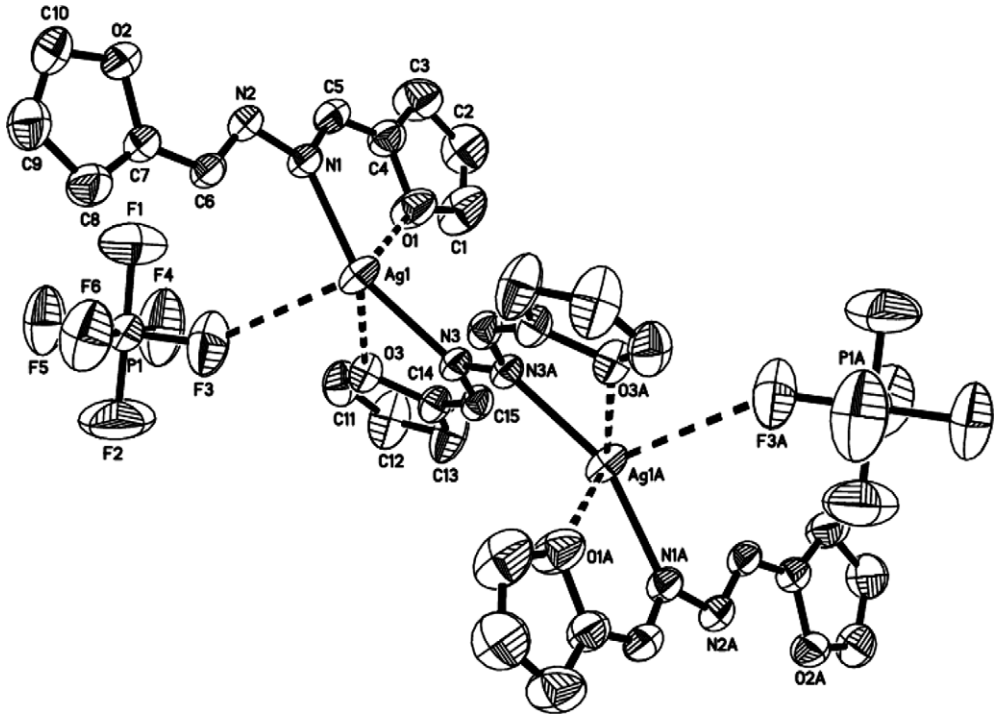

Fig. 2. Monomer unit of compound **2** showing van der Waals contacts (dashed lines). Selected bond distances (Å) and angles (°): Ag1–N1 2.200(3), Ag1–N3 2.244(3), N1–N2 1.401(4); N1–Ag1–N3 158.2(1), C5–N1–Ag1 122.5(2), N2–N1–Ag1 124.3(2).

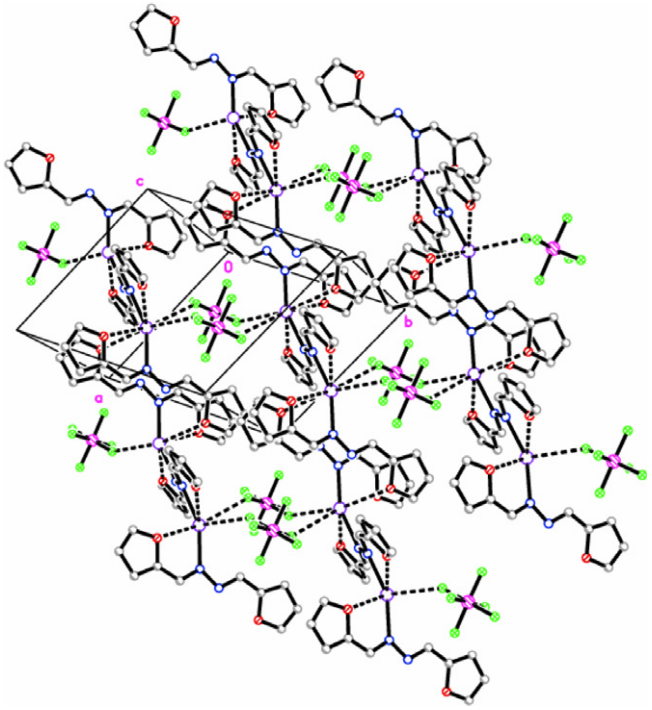

Fig. 3. Packing diagram of compound **2** along the *c*-axis showing a 2D network.

network of compound **2**, in which the Ag_2L_3 repeating units are connected by the PF_6^- ions (in the [0 1 1] direction) as well as by the ligands (in the diagonal direction of the unit cell). In other words, the 2D network is constructed by two types of intermolecular van der Waals contacts of Ag···F (PF_6^-; Ag···F–P–F···Ag connectivity) and Ag···O (furan). The Ag···F interactions lead to the formation of cyclohexane-like connectors between arrays forms by the Ag···O interactions.

A monomer unit of compound **3** is presented in Fig. 4, which is isostructural with compound **2**, except for the counterion (PF_6^- versus ClO_4^-). The Ag metal is also 2-coordinate. Each Ag metal is in van der Waals contacts (Ag···O = 2.680(2)–3.200(2) Å) with five oxygen atoms (O1–O3 (furan); O4 and O6) (ClO_4^-), and therefore its coordination sphere may also be considered as 7-coordinate. As consistent with our expectation, like compound **2**, compound **3** has a 2D network form, in which the ClO_4^- counterions play the same role as the PF_6^- counterions in compound **2** (Fig. 5).

A dinuclear monomer unit of compound **4** is given in Fig. 6, which shows two Ag metals, two $\mathbf{L}^2$ ligands, and two BF_4^- ions. Two Ag metals have distinct coordination environments due to van der Waals contacts, explaining a dimeric chemical formula $[Ag_2\mathbf{L}^2_2](BF_4)_2$, not $[Ag\mathbf{L}^2](BF_4)$. The Ag1 atom is bound to two oxygen (O2 and O3) and one fluorine (F7) atoms via van der Waals contacts: Ag···O (2.713(5) and 2.787(6) Å) and Ag···F (2.931(9) Å). On the other hand, the Ag2 atom is in van der Waals contacts with two oxygen (O1 and O4) atoms only: Ag···O (2.613(5) and 2.700(5) Å). Considering these van der Waals contacts, the Ag1 metal may be regarded as 5-coordinate and the Ag2 metal as 4-coordinate. Fig. 7 is a packing diagram of compound

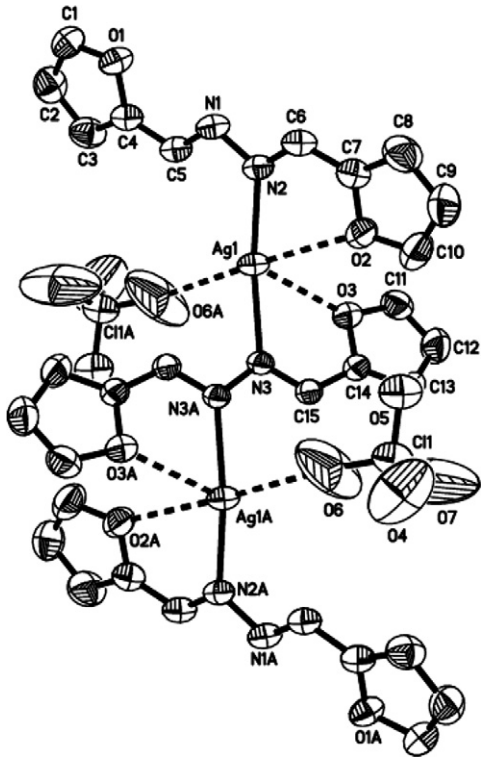

Fig. 4. Monomer unit of compound **3** showing van der Waals contacts. Selected bond distances (Å) and angles (°): Ag1–N2 2.217(2), Ag1–N3 2.268(2), N1–N2 1.401(3); N2–Ag1–N3 151.4(1), C6–N2–Ag1 124.0(2), N1–N2–Ag1 123.5(2).

4, which shows a 1D chain. The monomer units are covalently connected in the atom-connectivity manner of –N–N–Ag–N–N–Ag–N–N– to give a 1D chain. It is worth noting that only one (F7) out of eight F atoms participates in the van der Waals contacts.

Compound **5** also has a dinuclear monomer unit consisting of two Ag metals, one $\mathbf{L}^2$, and two NO_3^- ligands (Fig. 8). The Ag–N (2.288(2) and 2.359(2) Å) and Ag–O (NO_3^-) bond lengths (2.419(2) and 2.472(2) Å) indicate normal covalent bonds. Two Ag metals are distinct. Besides the Ag1–N1, Ag1–O3, and Ag1–O6#1 bonds, the Ag1 metal is further bound to three oxygen atoms (O1, O4#2, and O7#1) via van der Waals contacts (Ag···O = 2.668(2)–2.716(3) Å). On the other hand, the Ag2 metal is covalently bonded to the N2, O5#3, O6, and O4#4 atoms, and it is further in van der Waals contacts with two oxygen atoms (O2 and O6#5; Ag···O = 2.745(2) and 2.845(2) Å) and another Ag2 metal (Ag···Ag = 3.3510(4) Å) In this manner, the Ag2 metal can now be thought of having a 7-coordinate environment. Fig. 9 shows a packing diagram of compound **5**. The $Ag_2\mathbf{L}^2$ units are connected by the NO_3^- ions along the *a*-axis and by the ligands along [110] direction to form a 2D network, in which two NO_3^- ions are distinct. One NO_3^- ion (N3, O3–O5) links four Ag metals via four Ag–O covalent bonds (Ag1–O3, Ag1#7–O4, Ag2#1–O4, Ag2#8–O5) and one Ag···O van der Waals contact (Ag1···O5). The other NO_3^- ion (N4, O6–O8) links three Ag metals via two Ag–O covalent bonds (Ag1#3–O6, Ag2–O6) as well as two Ag···O van der Waals contact (Ag1#3–O7, Ag2#10···O6). The ligands are oriented approximately along the *c*-axis, and the $Ag_2(NO_3)_2$ fragments along the *a*-axis.

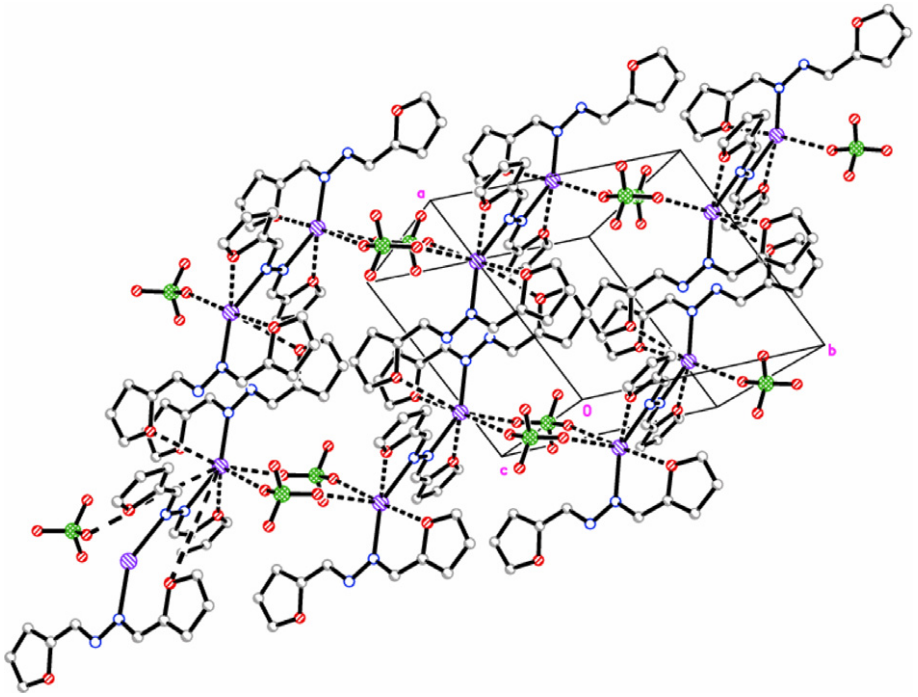

Fig. 5. Packing diagram of compound **3** showing a 2D network.

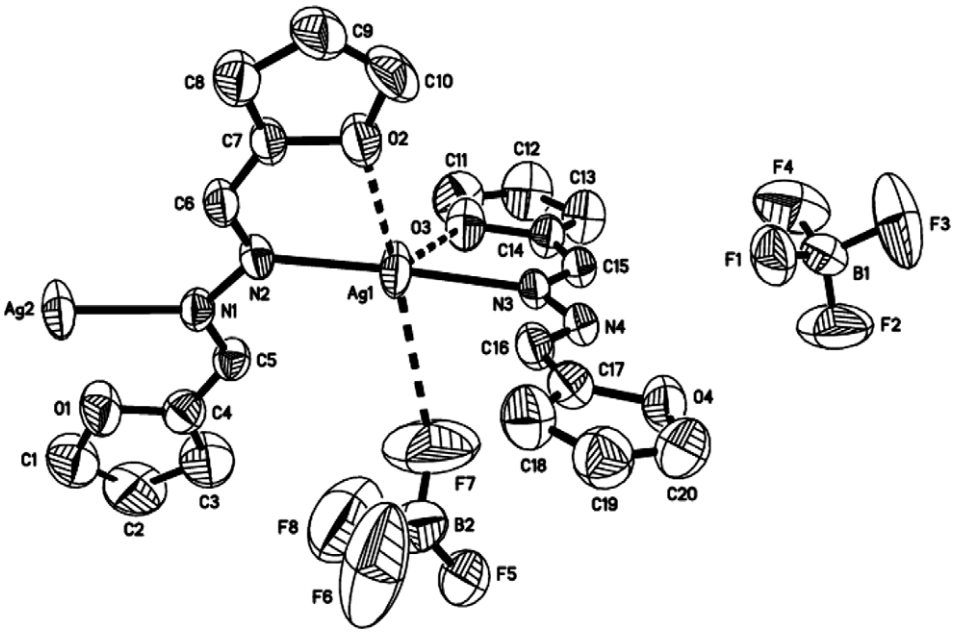

Fig. 6. Monomer unit of compound **4** showing van der Waals contacts (dashed lines). Selected bond distances (Å) and angles (°): Ag1–N2 2.177(5), Ag1–N3 2.187(5), Ag2–N1 2.168(5); Ag2–N4#1 2.181(5), N2–Ag1–N3 170.8(2), N1–Ag2–N4#1 175.8(2). Symmetry transformations used to generate equivalent atoms: #1 $-x+1/2$, $y-1/2$, $z+1/2$.

3.3. Photoluminescence (PL) property of compound 5

Recently, much research has been focused on coordination polymers exhibiting photoluminescence due to their potential application as light emitting diodes [5,39–41]. Of five compounds in this study, only compound **5** exhibits green photoluminescence in the solid state at room temperature. Fig. 10 shows its photoluminescence emission spectrum, which displays a single well-defined maximum at 480 nm ($\lambda_{excitation} = 290$ nm). Photoluminescent silver coordination polymers commonly exhibit weak blue emission at low temperature that depends on the nature of ligands [18,19,26,29,31], and therefore the room-temperature photoluminescence of compound **5** is somewhat interesting, considering the lack of photoluminescence of ligand $\mathbf{L}^2$.

In summary, we prepared five silver compounds, $[Ag\mathbf{L}^1_2](PF_6)$ (**1**), $[Ag_2\mathbf{L}^2_3](PF_6)_2$ (**2**), $[Ag_2\mathbf{L}^2_3](ClO_4)_2$ (**3**), $[Ag_2\mathbf{L}^2_2](BF_4)_2$ (**4**), and $[Ag_2\mathbf{L}^2(NO_3)_2]$ (**5**) by layer diffusion (dichloromethane–methanol). All compounds were structurally characterized by X-ray diffraction. Compound **1** is a discrete compound. Whereas compounds **2** and **3** form 2D networks by van der Waals contacts, compounds **4** and **5** are a 1D and a 2D coordination polymer, respectively, formed by covalent bonds. The structural variation in the polymeric compounds **2**–**5** depended on the counter-ion used. Compound **5** exhibited blue-green photoluminescence at room temperature in the solid state.

4. Supplementary material

CCDC 654198, 654199, 654200, 654201, and 654202 contain the supplementary crystallographic data for **1**, **2**, **3**, **4**, and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from

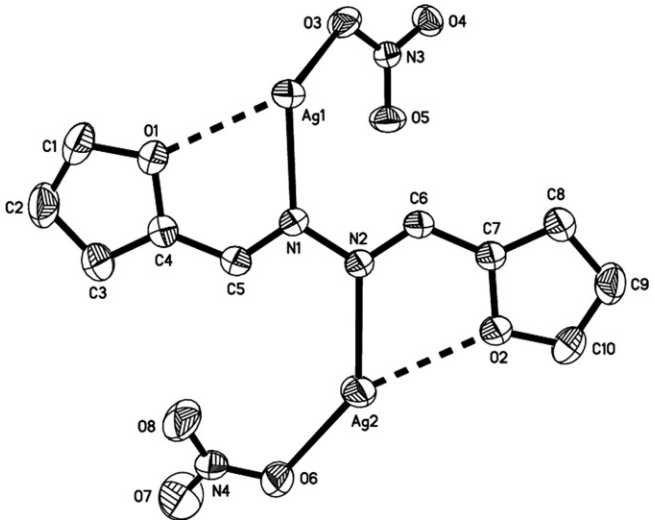

Fig. 8. Monomer unit of compound **5** showing van der Waals contacts. Mn^{II}–Mn^{II} → Mn^{III}–Mn^{III} redox cycle similar to the catalase enzyme. X-ray structure diffraction shows that in *Thermus thermophilus* catalase the Mn···Mn separation is 3.18 Å in the reduced Mn^{II}–Mn^{II} form and 3.14 Å in the oxidized Mn^{III}–Mn^{III} form [18]. The *T. thermophilus* catalase contains a $\mu_{1,3}$-carboxylate ligand as a bridge. During hydrogen peroxide dismutation, it is believed that these bridges undergo changes, but their functional significance remains unidentified. In the literature, there are three systems based on a series of dinuclear complexes; the first system, the functionalized Schiff base $[Mn(2\text{-}OHsalpn)]_2$, is an excellent peroxide disproportionation catalyst in acetonitrile [19–21]. The second system, that shows moderate activity, contains a septadentate ligand with a benzimidazole group and a single bridging alkoxide [22–25]. The third model complexes (only three in the literature), using dicarboxylic acid as a bridge, have been reported as efficient catalysts [26,27]. Some mononuclear manganese(II) complexes are also reported to show catalase activity. However, the best chemical mimics of manganese catalase are 10^3–10^5 times slower than the enzymes.

In this work, as part of our continuing interest to synthesize and structurally characterize cobalt(III) [28] and zinc(II) complexes [29] of mixed ligands, long chain α,ω-dicarboxylic acid and 1,10-phenanthroline, we report here the preparation and characterization of a manganese(II) complex of perfluorosebacic acid ($HO_2C(CF)_8CO_2H$) and 1,10-phenanthroline. Besides, we examined its catalytic activity on H_2O_2 disproportionation. It is known that manganese(II) carboxylate complexes with added phenanthroline are particularly active catalysts for the disproportionation of hydrogen peroxide in the presence of the added base imidazoyl [30]. Here, we will report on the catalytic activity of the polymeric Mn(II) complex with a dicarboxylate bridge and a long Mn–Mn distance.

2. Experimental

All chemicals were commercially available in p.a. grade and were used without further purification. Elemental analysis was performed on a VARIO EL*III* CHNOS Elemental Analyzer. FT-IR spectra were recorded on a JASSCO FT/IR-300E spectrophotometer using the KBr pellet technique in the range 4000–400 cm^{-1}. The electronic spectra were recorded on a SHIMADZU UV-2450 spectrophotometer. Conductometric measurement was carried out on a Thermo-Orion Aplus 145A with an Orion electrode 011510. Thermogravimetric Analysis (TG) was taken on a SETERAM LabsysDTA 1600:amb 1600 °C unit at a heating rate of 5 °C/min under an argon atmosphere.

2.1. Synthesis of the catalyst

Addition of 0.5 ml (1M) Na_2CO_3 to a stirred solution of $MnSO_4 \cdot H_2O$ (200 mg, 0.985 mmol) in 10 ml of H_2O yielded a precipitate, which was separated by filtration, washed with distilled water several times and finally added to a stirred solution of phenanthroline monohydrate (195 mg, 0.985 mmol) and perfluorosebacic acid (483 mg, 0.985 mmol) dissolved in 20 ml of EtOH/H_2O (1:1 v/v). The mixture was stirred for *ca.* 2 h. The colorless solution was allowed to stand at room temperature. Slow evaporation for 2 days afforded light green crystals. Decomp. point 225–227 °C, yield 436 mg (49%). *Anal.* Calc. for $C_{34}H_{18}N_4O_5F_{16}Mn$ (921.45): C, 44.32; H, 1.97; N, 6.08. Found: C, 44.13; H, 1.74; N, 5.93%. FT-IR (KBr): 3434, 3066, 1705, 1693, 1592, 1518, 1496, 1428, 1381, 1345, 1304, 1213, 1148, 847, 807, 727, 655, 639, 555 cm^{-1}.

2.2. Crystallography

A light green color crystal of the manganese complex, $\{[Mn(O_2C(CF_2)_8CO_2)(phen)_2]H_2O\}_n$, suitable for data collection was mounted on a glass fiber and data collection was performed on a STOE IPDS IIdiffractometer with graphite monochromated Mo Kα radiation at 296 K. Details of crystal data, data collection and refinement are given in Table 2.

The structure was solved by direct-methods using SHELXS-97 [31] and refined by full-matrix least-squares methods on F^2 using SHELXL-97 from within the WINGX [32,33] suite of software. All non-hydrogen atoms were refined with anisotropic parameters. Hydrogen atoms bonded to carbon were placed in calculated positions (C–H = 0.93 Å) and refined using a riding model with U = 1.2U of the parent atom for C–H. The H atoms of the water oxygen atom were located in difference maps and refined subject to a DFIX restraint of O–H = 0.83 Å (U = 1.5U of the parent atom). The large s.u. values and displacement parameters of some F atoms in the molecule are caused by disorder of the perfluorosebacate group. The refinement of the disordered perfluorosebacate group was made anisotropically using PART and EADP restrictions. This disorder was modelled as two different orientations as Fa and Fb groups [hereafter Fa = F1a, F2a, F3a, F4a, F5a, F6a, F9a, F10a and Fb = F1b, F2b, F3b, F4b, F5b, F6b F9b, F10b], seen in Fig. 1, with occupancy factors of 0.267(6) and 0.733(6), respectively. The molecular drawing was obtained using ORTEP-III [34] and MERCURY [35]. Geometric calculations were performed on PLATON [36].

2.3. Hydrogen peroxide disproportionation studies

Volumetric measurements of evolved dioxygen during the reaction of the manganese(II) complex with H_2O_2 were carried out as follows: A 50 ml two-necked round-bottom flask containing a solution of the complex in organic solvents was placed in a water bath (±0.2 °C). One of the necks was connected to a graduated burette filled with water and the other was stoppered by a rubber septum. The solution was stirred for 20 min to reach a stable temperature. While the solution was stirring, a chosen volume of H_2O_2 stock solution was injected into it through the rubber septum using a syringe, and the volume of evolved

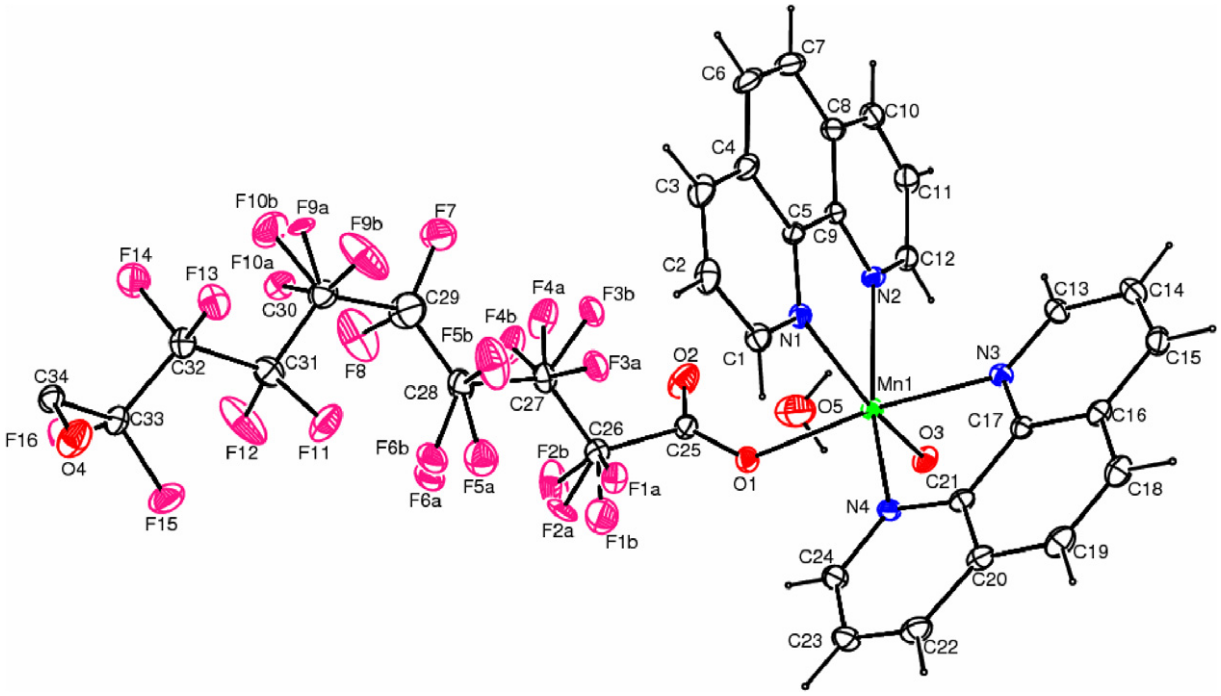

Fig. 1. Molecular structure of $\{[Mn(O_2C(CF_2)_8CO_2)(phen)_2]H_2O\}_n$, asymmetric unit.

dioxygen was measured with a burette as a function of time.

3. Results and discussion

$\{[Mn(O_2C(CF_2)_8CO_2)(phen)_2]H_2O\}_n$ was prepared in high yield reacting $MnCO_3 \cdot H_2O$ with perfluorosebacic acid and 1,10-phenanthroline in a water–ethanol mixture. Crystallization was done by evaporation at room temperature. The complex is soluble in methanol and insoluble in acetone, toluene and hexane. The molar conductivity of the complex is 20 S cm^2 mol^{-1} in methanol.

The ORTEP view of the manganese(II) complex with an asymmetric unit is shown in Fig. 1 and important interatomic data are listed in Table 1. The crystallographic data are summarized in Table 2. The structure of the complex consists of a one-dimensional neutral coordination chain $\{[Mn(O_2C(CF_2)_8CO_2)(phen)_2]H_2O\}_n$ with one guest H_2O molecule. The manganese atom is six-coordinate by two bidentate phen ligands via N1–N2 and N3–N4, and half of the two dicarboxylate ligands, both of them monodentate via O1 and O3 atoms. The manganese ion has an irregular six-coordinate geometry, principally due to the acute bite binding angle required by the phenanthroline ligands ((N4–Mn1–N3) 72.39(18)° to (N2–Mn1–N1) 72.52(2)°). The largest single deviation from octahedral geometry, however, is 158.04(19)° (O1–Mn1–N3), this may be due to steric interference between the perfluorosebacate ion and the phenanthroline ring. As would be expected, the non-coordinating oxygens of the perfluorosebacate ligand are involved in extensive hydrogen-bonding (Table 3). It can be seen from Fig. 2 that the uncoordinated oxygen (O4) is involved in hydrogen-bonding with the atoms C15 and C18, resulting in $R_1^2(6)R_2^2(62)R_1^2(6)R_2^2(18)$ motifs parallel to the ab plane. In the extended structure, the water oxygen (O5) is involved in interchain hydrogen-bonding; the one-dimensional polymer chains are connected by interchain O5–H5A···F14 ($x-1$, $-y+1/2+1$, $z-1/2$),

O5–H5B···O2 and C7–H7···O5 ($-x+1$, $-y+1$, $-z$) interactions (Fig. 2), which forms a $R_4^4(63)$ motif parallel to the ab plane. The ring atom C13 in the reference molecule at (x, y, z) acts as a hydrogen-bond donor, via atom H13, to atom F12 ($-x+1$, $y-1/2$, $-z+1/2$), thus forming a C(14) chain running parallel to the [0 1 0] direction. At the same time, atom C10 in the reference molecule at (x, y, z) acts as a hydrogen-bond donor, via atom H10, to atom O2 ($-x+1$, $-y+1$, $-z$), thus forming $R_2^2(18)$ rings running parallel to the [0 0 1] direction and centrosymmetric $R_2^2(18)$ rings centred at (1/2, 1/2, n) (n = zero or integer). The structure also contains two intermolecular C–H···π interactions. The first is from C6 in the phenyl ring of the reference molecule to the centroid of the Cg(7) ($1-x$, $-y$, $-z$) ring [C6···Cg(7) = 3.67(3) Å, H6···Cg(7) = 2.7701 Å, C6–H6···Cg(7) = 164.75°]. The second C–H···π contact is between C3 in the phenanthroline ring to the centroid of the Cg(4) ($1-x$, $-y$, $-z$) ring [C3···Cg(4) = 3.50(3) Å, H3···Cg(4) = 2.6049 Å, C3–H3···Cg(4) = 164.14°]. The C–H···π interactions produce a chain running parallel to the [1 0 0] direction. There are also π···π interactions [Cg(4)–Cg(7) ($2-x$, $-y$, $-z$), Cg(6-)-Cg(6) ($1-x$, $-y$, $-z$) and Cg(7)–Cg(4) ($2-x$, $-y$, $-z$)] with the geometric parameters as given in Table 3. The intrachain Mn1···Mn1 ($1+x$, $3/2-y$, $1/2+z$) distance is 15.830(5) Å, whereas the shortest interchain distance is 21.475(4) Å for Mn1···Mn1 ($1+x$, $1/2-y$, $-1/2+z$). The Mn–N bond lengths in apical positions are slightly shorter, Mn1–N4 = 2.26(5) Å, Mn1–N2 = 2.284(5) Å, than the Mn–N bond lengths in the equatorial plane, Mn1–N3 = 2.325(5) Å, Mn1–N1 = 2.306(5) Å. The equatorial plane is constituted by two nitrogen atoms (Mn1–N3 and Mn1–N1), belonging to two different phen ligands, while the other positions are occupied by two oxygen atoms (Mn1–O1 = 2.139(5) Å and Mn1–O3 = 2.122(5) Å) of two coordinated perfluorosebacate ligands.

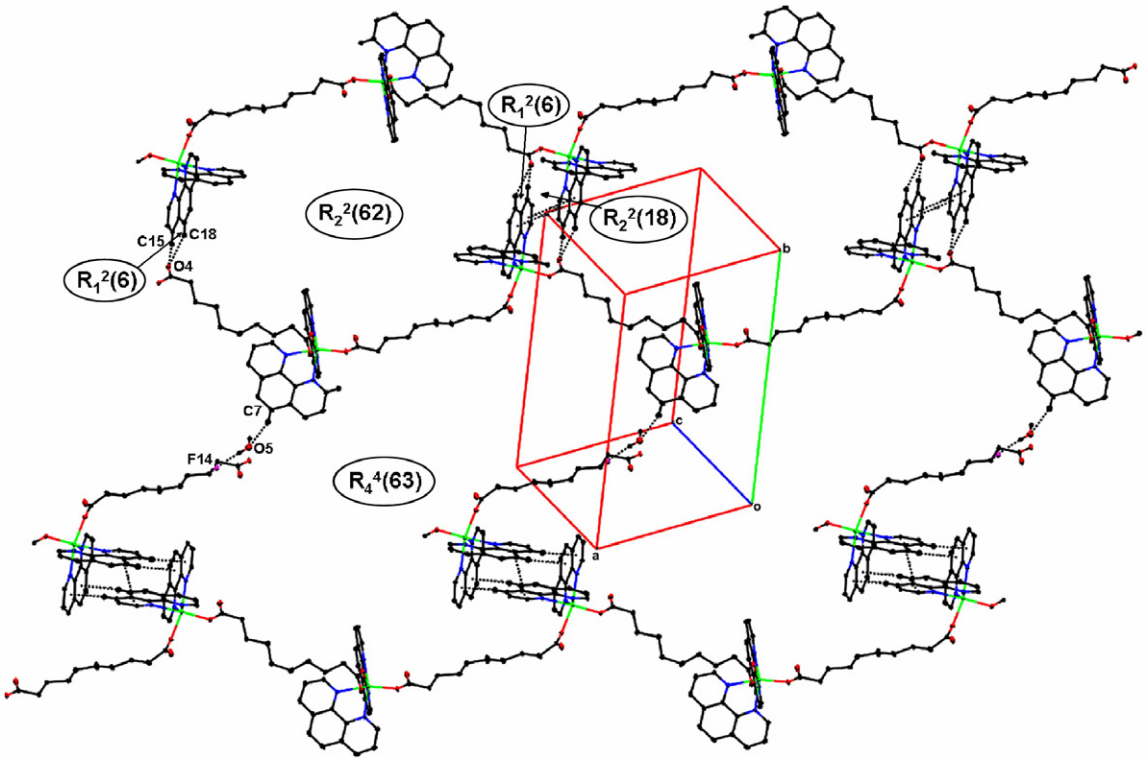

Fig. 2. Supramolecular assembly of the $\{[Mn(O_2C(CF_2)_8CO_2)(phen)_2]H_2O\}_n$ complex into a 2D layer based on intermolecular hydrogen bonds, π–π and π-ring interactions.

The unique structural feature of complex focuses on the role of the perfluorosebacate ligands which directly bridges manganese atoms forming an infinite linear coordination chain along the a axis (Fig. 2). The packing diagram of the complex is also shown in Fig 3.

3.1. IR and UV–Vis spectroscopic studies

The FT-IR spectrum of the title compound show characteristic bands of C–F stretching in the 1213–1148 cm^{-1} region. Bands due to vibrations of the carboxylate ligand are broad strong peaks at 1693 cm^{-1} for antisymmetric and 1381 cm^{-1} for symmetric stretching. These values are quite a bit higher than the literature values because of the high electronegativity of the fluorine atoms in the long chain. The separation (Δ) between $\nu_{as}(COO^-)$ and $\nu_s(COO^-)$ is 312 cm^{-1}, indicating a monodentate coordination mode for the coordinated carboxylate group [37,38]. The absorption at 1760 cm^{-1}, assigned to the asymmetrical stretching of free carboxyl groups, shows a shift towards a relatively low frequency when compared to $\nu_{as}(COO^-)$ (1693 cm^{-1}) of coordinated carboxylic acid in which intermolecular hydrogen-bonding possibly weakens the C=O bond in the carboxyl group. The stretching vibrations corresponding to those typical of coordinated 1,10-phenanthroline occur at 727, 847 and 1518 cm^{-1}.

The ground state term of the high spin octahedrally coordinated Mn(II) ion is $^6A_{1g}$. It is known that all d–d transitions in high spin d^5 complexes have extremely low intensity and in the presence of organic ligands they can rarely be detected not only because they are Laporte forbidden but also spin forbidden. This is also case of the title Mn(II) complex. Nevertheless, the electronic spectrum of the manganese complex exhibits three weak intensity absorption bands at ca. 322, 447 and 597 nm, which could be tentatively assigned to $^6A_{1g} \rightarrow {}^4T_{1g}(^4P)$, $^6A_{1g} \rightarrow {}^4E_g$, $^4A_{1g}(^4G)$ and $^6A_{1g} \rightarrow {}^4T_{1g}$ (^4G), respectively [39]. In the high energy region, very intense multiple absorption bands (204, 223 and 264 nm) are observed for $\pi \rightarrow \pi^*$ and/or $n \rightarrow \pi^*$ charge transitions of the coordinated groups.

3.2. Thermal analysis of the complex

The thermal decomposition of the Mn(II) complex was studied by thermogravimetry (TG) under argon atmosphere from 50 to 800 °C (Fig. 4). The manganese complex decomposes via an endothermic solid state reaction. The TG data shows that the decomposition mainly occurs in two steps. The complex does not decompose up to 200 °C. In the first step, a sharp drop corresponds to the lost of phenanthroline ligands at 198–219 °C (weight loss 39.87%, calculated 39.94%). The second decomposition step corresponds to release of the coordinated perfluorosebacate ligands (weight loss 54.1%, calculated 54.02%).

3.3. Catalysis studies

All the reactions were carried out in a 50 ml round-bottom flask which was thermostatically controlled. To methanol (5 ml) was added the manganese(II) complex and the

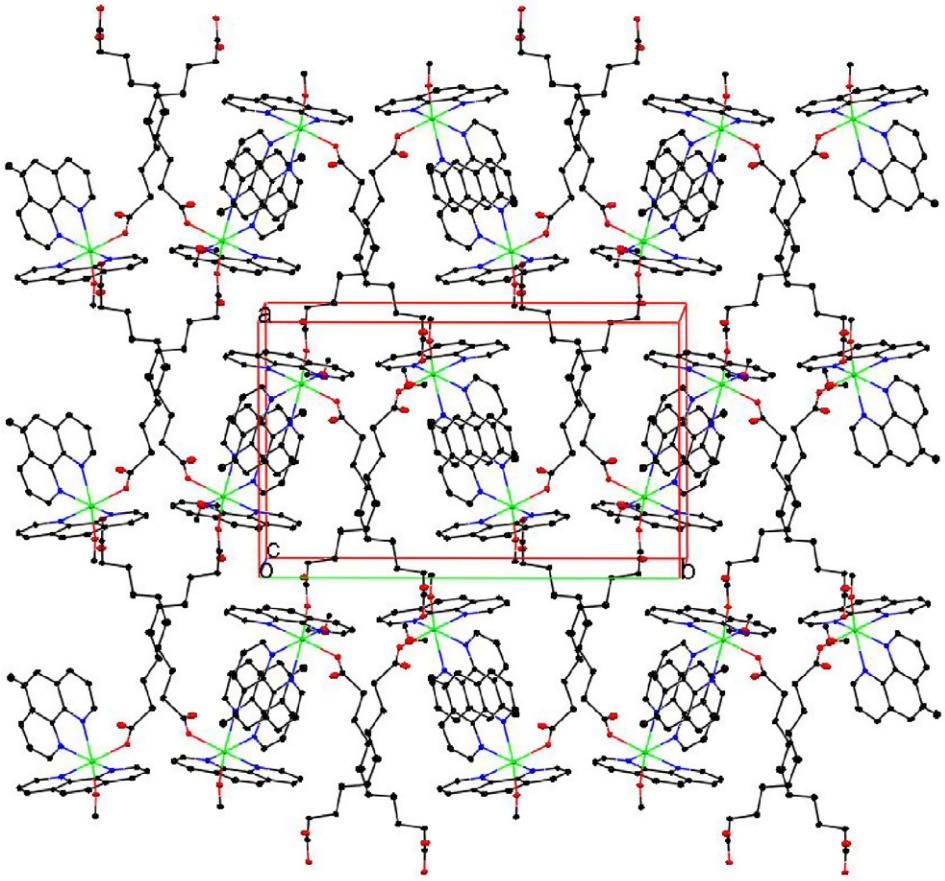

Fig. 3. Packing arrangement of the molecules in the unit cell.

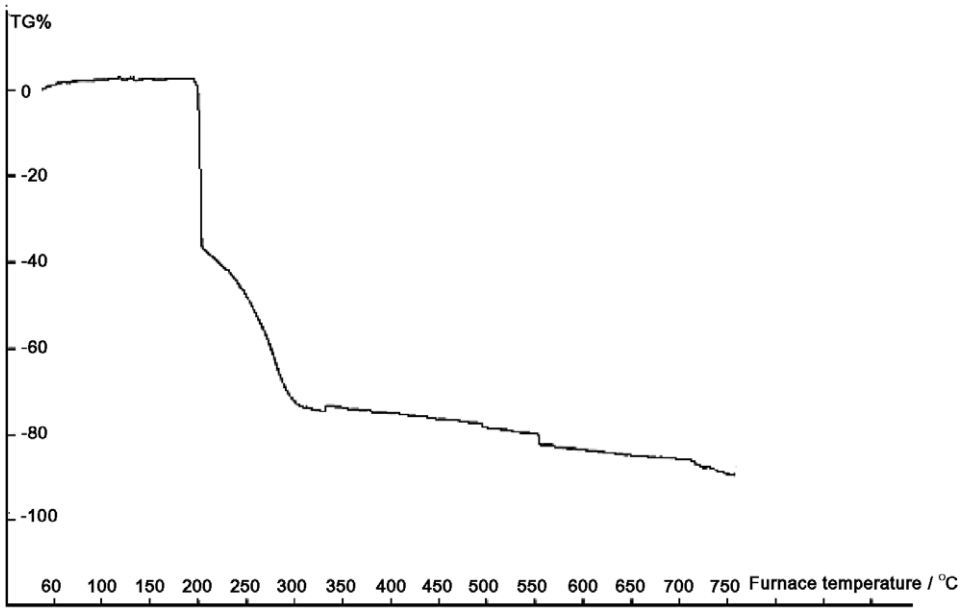

Fig. 4. The TG curve for the manganese complex in the range 50–800 °C (weight taken = 12.0 mg).

flask closed with a rubber septum. After hydrogen peroxide addition, dioxygen evolution was measured at time intervals, volumetrically. The observed initial rates were expressed in M s^{-1} and were calculated from the maximum slope of curve describing evolution of O_2 versus time. We did not observe a brown precipitate that is insoluble in

many solvents, characteristic of MnO_2, at the end of the reaction.

3.3.1. Solvent influence

Many different solvents have been used in previous studies on the catalase-like reaction. It was reported that the mechanism of the reaction can change between DMF and acetonitrile [7,10]. In our studies we also observed that the decomposition rate of H_2O_2 by the manganese complex has been found to depend strongly on the solvents used. Fig. 5 illustrates the data obtained in methanol, acetonitrile, DMF and water. In the inset of Fig. 5, an induction period to reach rigorous evolution of dioxygen was observed in DMF and in water, but no induction period has been observed in methanol and acetonitrile. The reaction rate was the slowest (2.27×10^{-5} M s^{-1}) and only a small part (4.3% at 150 min) of hydrogen peroxide was disproportionated in water. The reaction in methanol has the best results (22.1×10^{-5} M s^{-1}, ten times faster than in water, 46% disproportionation at 150 min). For this reason all subsequent measurements were performed in methanol. The experimental initial rates were calculated as 9.19×10^{-5} and 4.13×10^{-5} M s^{-1} for acetonitrile and DMF, respectively.

3.3.2. Kinetics

The dependence of the initial rates of dioxygen evolution was examined with varying concentrations of H_2O_2 and the manganese(II) complex. In the first experimental series, the hydrogen peroxide concentration was kept constant and the concentration of the complex was varied ($2.21–17.7 \times 10^{-4}$ M). Fig. 6 shows the first-order dependence of the H_2O_2 disproportionation rate with respect to catalyst concentration. The order of reaction calculated from the plot of $\ln(v_0)$ versus ln[catalyst] was found to be unity ($-\ln v_0 = 1.39 \ln[\text{catalyst}] - 1.231$; $R^2 = 0.956$) (Fig. 6b). Under the conditions studied in this set of kinetic measurements, the linear dependence of the rate is also evidence that the reaction is first order with respect to the catalyst concentration (Fig. 6c), and the rate constant ($k_{cat} = 0.214$ s^{-1}) was obtained from the slope of this line. In the second experimental series, the catalyst concentration was kept constant and the H_2O_2 concentration was varied (0.09–3.14 M). For the a constant initial concentration of Mn(II) (0.26×10^{-4} M), Fig. 7 demonstrates the effect of the initial concentration of H_2O_2 on the initial rate, v_0. For $[H_2O_2]$ lower than 0.357 M, which corresponds to $[H_2O_2]/Mn(II) = 74.5$, the initial rate increased with increasing $[H_2O_2]$. During this period, depending on the extent of electron transfer within the complex, the resulting active intermediate species can be regarded as Mn(II) coordinated with H_2O_2 and Mn(III) coordinated with peroxo, hydroperoxo or hydroxo complexes. All these intermediate complexes decompose with an excess amount of H_2O_2 by cycling their oxidation states, probably between Mn(II) and Mn(III), without any significant decomposition of the complexes themselves. On further addition of H_2O_2 after this point, the initial rate decreased rapidly with increasing $[H_2O_2]$. The exact reason for the non-linear catalytic behavior with the further addition of

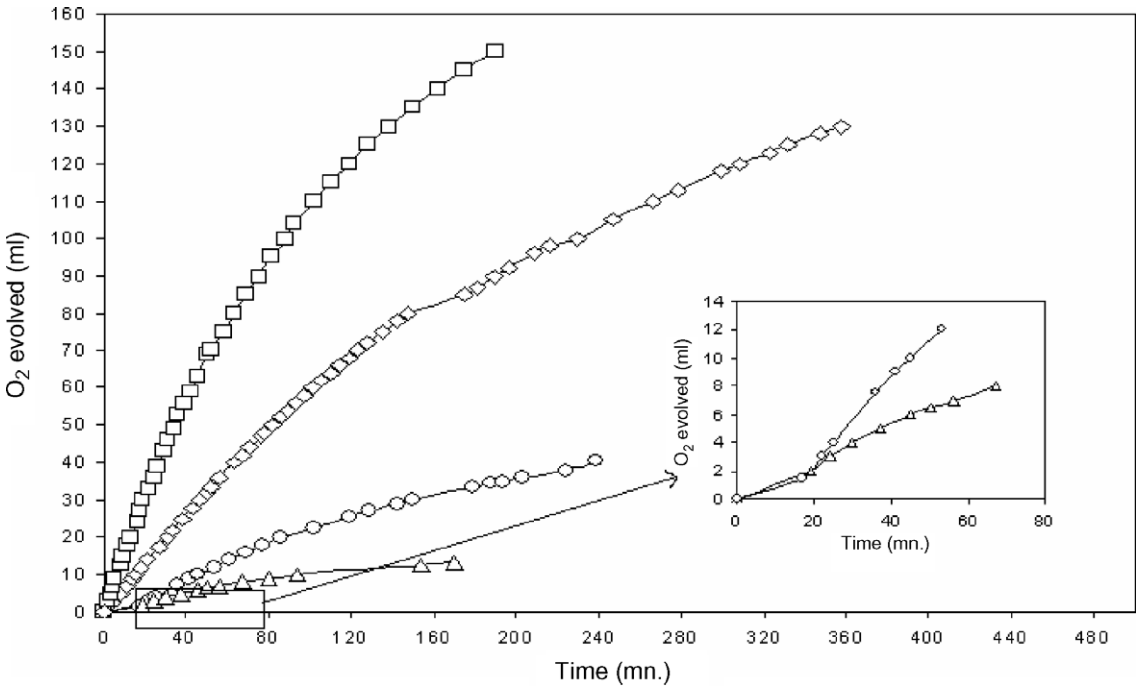

Fig. 5. Time dependence of dioxygen evolution upon reaction of the manganese complex with H_2O_2 in different solvents: methanol (□), acetonitrile (♦), DMF (○) and water (△). Conditions; [catalyst] = 0.886 M, $[H_2O_2]$ = 4.850 M at 295 K. The inset shows the induction time for disproportionation of H_2O_2 in DMF and water.

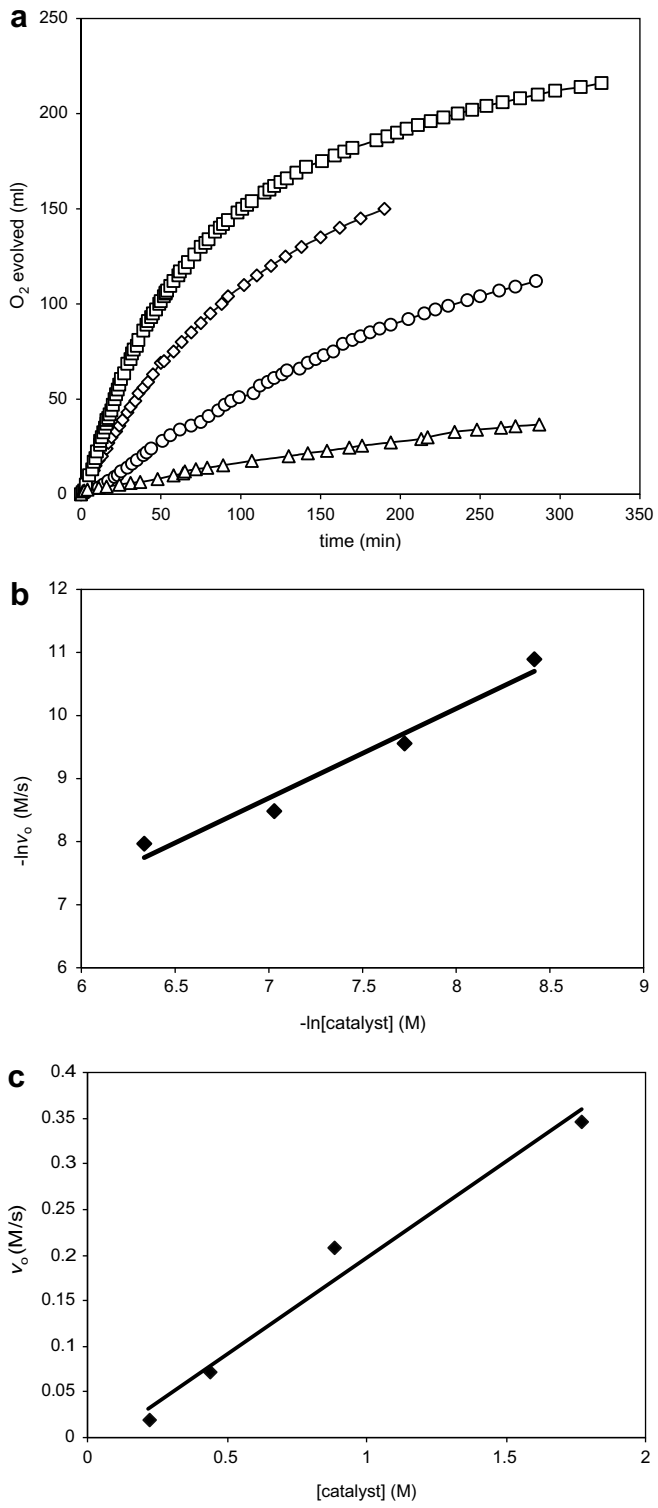

Fig. 6. Effect of catalyst concentration on the initial rate of H_2O_2 disproportionation: (a) Evolution of O_2 formation at constant H_2O_2 ($[H_2O_2] = 4.85$ M) concentrations with different concentrations of catalyst in methanol at 298 K: 2.21×10^{-4} (□), 4.42×10^{-4} (♦), 8.84×10^{-4} (○) and 17.70×10^{-4} (△). (b) $-\ln v_0$ vs. $-\ln$[catalyst]. (c) v_0 vs. [catalyst].

H_2O_2 is difficult to assess without detailed mechanistic studies. The decrease of the initial rate is probably attributed to the decomposition of the active intermediate species, being reduced to an inactive Mn(II) complex, or the decrease of the molar fraction of the active intermediate complex with increasing H_2O_2 concentration.

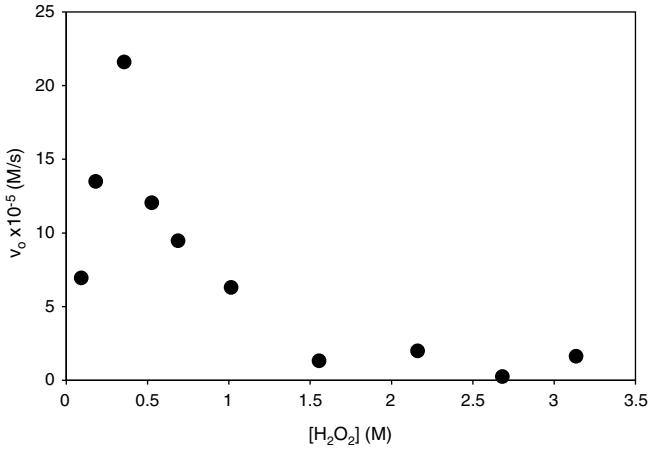

Fig. 7. Effect of H_2O_2 concentration on the initial rate of H_2O_2disproportionation at 299 K and [catalyst] $= 0.26 \times 10^{-4}$ M in methanol.

At constant catalyst concentration, Michaelis–Menten parameters could not be determined since it does not give saturation kinetics. This result shows that the catalytic activity of the present compound is not similar to related dinuclear model compounds with Mn–Mn distances similar with that of catalase enzyme [40], since the Mn–Mn distance of about 15.8 Å in the solid state may be different in the solution phase and the chain structure probably does not allow a similar mechanism for the disproportionation of H_2O_2.

The calculated initial rate constant ($k_{cat} = 0.214\ s^{-1}$) is within the range of values, $k_{cat} = 0.18$–$0.40\ s^{-1}$, obtained for dinuclear Mn complexes having (μ-AcO)(μ-MeO) bridges (reaction cond.: solvent = methanol, acetonitrile at 25 °C) [11]. The present model system gives higher catalytic activity than that of $k_{cat} = 0.027\ s^{-1}$ for [(tol)Mn(bbml)$_2$Mn(tol)](ClO$_4$)$_2 \cdot H_2O \cdot 0.5$EtOH (bbml = 2-[bis(2-benzimidazoylmethyl)-amino]ethanol; tol = toluic acid; reaction cond.: solvent = acetonitrile, at 13 °C) [41] and $k_{cat} = 0.013\ s^{-1}$ for [Mn(III)(TTP)] (TTP = meso-tetraphenylporphyrin; reaction cond.: solvent = methanol, acetonitrile at 25 °C) [19]. Additionally, we tested the activity of manganese(II) nitrate, manganese(II) perchlorate and manganese(II) carbonate under identical conditions as in the case of the present compound. As shown in Fig. 8, 25% of H_2O_2 decomposed using the present polymeric compound whereas 0.2% of H_2O_2 decomposed using the other manganese(II) compounds.

3.3.3. Temperature dependence

The determination of thermodynamic parameters of the hydrogen peroxide disproportionation reaction with the manganese complex was carried out by investigating the rate of oxygen evolution with [catalyst]=48.5×10^{-4} M, $[H_2O_2] =$ 0.34 M at different temperatures over the range 285–328 K. The plot of $-\ln v_0$ versus $1/T$ yields straight line

($-\ln v_0 = 6015/T - 12.365$; $R^2 = 0.966$) (Fig. 9). The value of the enthalpy, entropy and free energy of activation have been calculated from the known equations $\Delta H = E_a - RT$, $\Delta S = Rln(hA/e^2K_BT)$ and $\Delta G = \Delta H - T\Delta S$, respectively. The Arrhenius plot, constructed from the obtained kinetic data, yielded the following activation parameters at 301 K; $E_a = 50.0$ kJ mol^{-1}; $\Delta H^{\ddagger} = 47.5$ kJ mol^{-1}; $\Delta S^{\ddagger} = -153.8$ J K^{-1} mol^{-1}; $\Delta G^{\ddagger} = 96.3$ kJ mol^{-1}.

3.3.4. Effect of base addition

The rate of H_2O_2 disproportionation in our studies was significantly affected by addition of a strong base (NaOH). Such an enhancement of the rate of hydrogen peroxide disproportionation by added base has also been reported by other workers [17,25]. In control experiments, we observed a very slow disproportionation of H_2O_2 on the addition of NaOH to H_2O_2 in the absence of catalyst. No lag phase was observed for the reaction with or without addition of NaOH. The initial rates of H_2O_2 disproportionation in the presence and absence of NaOH are compared in Fig. 10. The maximum effect was observed upon addition of 2 eqiuv. of NaOH (per complex) at which point the rate of dioxygen evolution (1.25×10^{-3} M s^{-1}) was *ca.* 4 times higher than in the absence of NaOH under identical conditions. Further addition of NaOH caused a decrease of the initial rate. When 7 equiv. of NaOH were added, the initial rate was 22 times slower (5.07×10^{-4} M s^{-1}) than 2 equiv. of NaOH, but the catalyst was still active for a long time. The role of NaOH is not clear in the catalytic cycle with the Mn(II) complex at this moment, but the function of the hydroxide is probably related to its ability to bind to the Mn(II) ion. Stability of the one electron oxidized mixed-valence state Mn_2(II,III) is probably caused by binding of the hydroxide ligand on addition of 2 equiv. of NaOH. Upon addition of more than 2 equiv. of base, it is possible that the coordination around the manganese ion may change and produce inactive intermediate species.

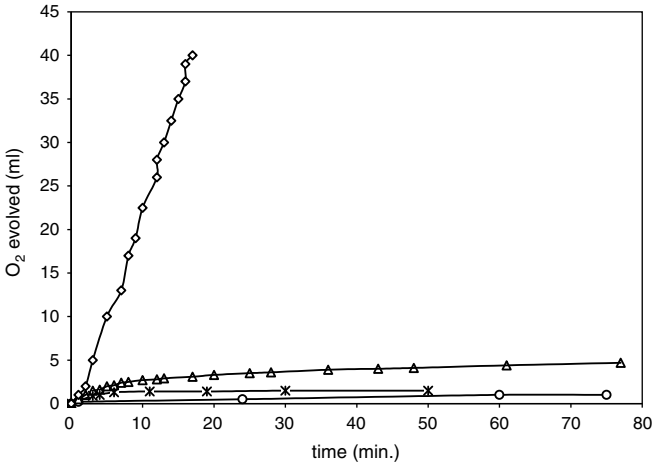

Fig. 8. Time dependence of dioxygen evolution upon reaction of different manganese compounds with H_2O_2 in methanol: {[$Mn(O_2C(CF_2)_8CO_2)$-$(phen)_2$]H_2O}$_n$ (♦), $MnCO_3$ (△), $Mn(ClO_4)_2 \cdot 6H_2O$ (∗) and $Mn(NO_3)_2$ (○). Reaction conditions: Substrate/catalyst = 2750 at 298 K.

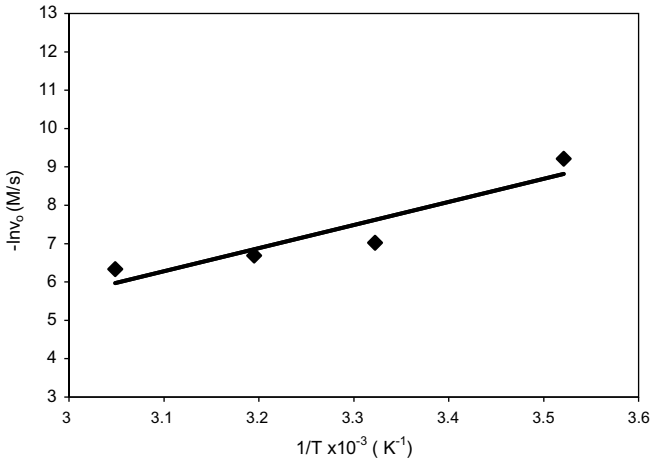

Fig. 9. The rate of O_2 formation at constant [catalyst] (48.5×10^{-4} M) and [H_2O_2] (0.34 M) at different temperatures in methanol.

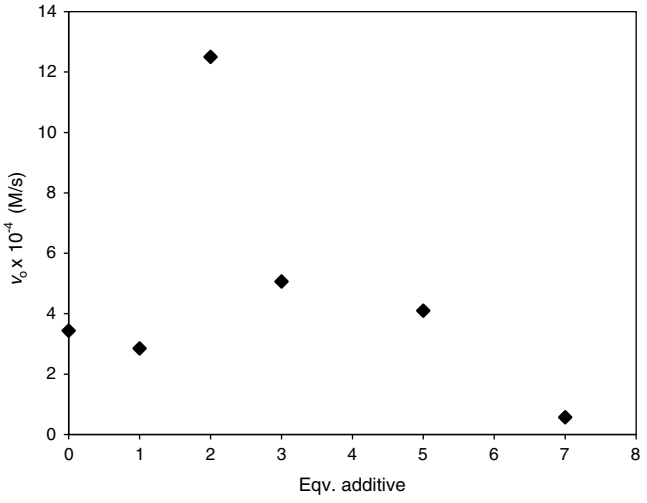

Fig. 10. Effect of base addition on the initial rate of H_2O_2 disproportionation at 300 K. Conditions: catalyst = 5.53×10^{-7} mol, H_2O_2 = 5.48×10^{-3} mol in methanol (5 ml).

3.3.5. UV–Vis monitoring of the catalase reaction

UV–Vis absorption spectra were taken during the progress of the reaction of the manganese complex with H_2O_2 in the presence of NaOH in methanol at room temperature. After addition of the substrate and base, the spectra reveal four weak absorption bands at 487, 622, 745 and 890 nm, which may be accounted for by the formation of a catalyst–substrate intermediate complex. The optical transitions are consistent with d–d transitions of Mn(III) or Mn_2(III,III) species, as previously reported [42,43].

4. Conclusion

In this study, the synthesis, full characterization and the catalytic activity of a one-dimensional polymeric manganese(II) complex with a long Mn–Mn distance have

been presented. The disproportionation of H_2O_2 by the present compound does not exhibit saturation kinetics with the substrate, but there is first-order dependence of the reaction rate on the catalyst and it proceeds without an initial time-lag in methanol. The turnover and the rate of reaction increase remarkably with the addition of two equivalents of NaOH to the catalyst solution, but the initial rate of O_2 evolution gradually decreases as more than two equivalents of NaOH are added. The kinetic and spectroscopic evidence suggest that the catalytic activity of the compound is not similar to catalase enzyme. The exact nature of the active species participating during the turnover could not be confirmed at the present moment.

Scheme 1. Exo bidentate ligands with a bis(amido)alkane spacer; β-sheet.

1–**5**. The crystal structures of these complexes reveal that **1**–**3** exhibit a 1D-coordination network, **4** is a 0D-complex and **5** exhibits a doubly interpenetrated 2D-network containing 4,4-topology. The crystallographic parameters are given in Table 1, bond lengths around Cu(II) in complexes **1**–**5** are given in Table 2 and parameters for hydrogen bonding are given in Table 3.

$Cu(L_1)(NBA)_2(H_2O)_2 \cdot (HNBA) \cdot 2H_2O$ (**1**)
$Cu(L_2)(NBA)_2(H_2O)_2 \cdot (HNBA) \cdot EtOH$ (**2**)
$Cu(L_3)(NBA)_2(H_2O)_2 \cdot 2H_2O$ (**3**)
$Cu(L_1)_2(HIPA)_2 \cdot 6H_2O$ (**4**)
$Cu(L_1)(SA)(H_2O)_2 \cdot H_2O$ (**5**)

2.1. Coordination geometry around the Cu(II) ions

In all the complexes the Cu(II) ions have an octahedral coordination geometry with two pyridine N atoms of the ligands, two water molecules and two O atoms of carboxylates, and it also sits on an inversion center. The Cu–O (carboxylate) distances are somewhat shorter (1.954(3)–1.980(3) Å) than the Cu–N(pyridine) distances (2.020(4)–2.052(4) Å). The Cu–O(aqua) distances (2.466(2)–2.680(5) Å) are much longer than those of Cu–O(carboxylate) and Cu–N(pyridine). Therefore, the coordination geometry around Cu(II) can be best described as a "Jahn–Teller" distorted octahedron with elongated axial distances. Only one O-atom of the carboxylates coordinates to Cu(II) in a monodentate fashion while the other uncoordinated O-atom of the carboxylates is involve in intramolecular

Table 2

Scheme 2. Coordination geometry around Cu(II) and intramolecular hydrogen bonding observed in the crystal structures of **1**–**5**.

hydrogen bonds with coordinated water molecules to form a cyclic ring containing Cu(II) (Scheme 2). In these six membered rings the O···O distances of intramolecular hydrogen bonds are 2.676(4), 2.694(3), 2.705(7), 2.688(5) and 2.614(6) Å in the structures of **1**–**5**, respectively.

2.2. One-dimensional networks in complexes *1*–*3*

In the crystal structures of **1**–**3**, the ligands L_1, L_2 and L_3 exhibit the lengths of 12.850, 14.146 and 16.629 Å, respectively.[1] However, the separation of the Cu(II) atoms by the ligand in the crystal structures does not follow a similar trend; the separation distances are 16.227, 15.839 and 19.153 Å in **1**–**3**, respectively (Fig. 1). In all the three structures, the interplanar angles between the amide and pyridine are quite similar (22–25°). However, the interplanar angles between the pyridine and alkyl chain (3.4°) and the amide and alkyl chain (19.7°) of **2** differ significantly from those of **1** (81.3° and 86°) and **3** (97.8° and 58.2°).

Moreover, complexes **1** and **2** include HNBA and water or EtOH as guest molecules. The available guest volume in the structures of **1** and **2** accounts for 31.5% and 39.5% of the crystal volume respectively. In contrast, complex **3** includes water but not HNBA. In all the three structures the 1D-chains are assembled into two-dimensional layers. However, the compositions of the layers differ significantly from each other (Fig. 2). In **1**, hydrogen bonding between coordinated water molecules and N–H groups and also between CO groups and uncoordinated water molecules join the chains. Two water molecules indeed form an eight membered ring with amide CO groups, which comprises of four O-atoms and four H-atoms. The shortest interchain separation of Cu(II) atoms in the layer is 8.653 Å. The nitro benzoate groups are positioned above and below the layer in a perpendicular fashion.

In complex **2** the chains are joined together by hydrogen bonding between coordinated water and CO groups. The NBA moieties are positioned above and below the layer with some inclination towards plane of the layer. The shortest interchain separation of the Cu(II) atoms in the layers is 8.731 Å. Within the layer there exist rectangular cavities which are occupied by EtOH molecules (not located).

The 1D-chains in complex **3** also form a layer via O–H···O hydrogen bonds between water molecules and benzoates. Further, the joining of these chains occurs through the formation of a cyclic hydrogen bond aggregate comprising of six O-atoms and six H-atoms. The amide CO is also involved in O–H···O hydrogen bonding with a free water molecule.

In complexes **1** and **2**, the layers pack on each other such that channels are formed parallel to the layers. These channels are occupied by HNBA molecules which have a disorder in both the complexes. In both cases each moiety of HNBA (guest) is surrounded by the six coordinated NBA moieties (Fig. 3). In short, these structures can be described as bilayer architectures in which the layer of metal ion and ligand alternates with the layer of coordinated and uncoordinated NBA moieties.

2.3. 0D and interpenetrated 2D networks containing dicarboxylate moieties (*4* and *5*)

As the usage of monocarboxylic acid in **1**–**3** resulted in 1D-chains, we considered dicarboxylic acids (H_2IPA and H_2SA) in anticipation of forming higher dimensional coordination networks. As anticipated, complex **5** formed a 2D network whereas complex **4** differed from our expectations and formed a 0D species. The 0D complex results as only one carboxylate of HIPA and one pyridine moiety of L_1 coordinates with Cu(II). The second –COOH of H_2IPA does not lose a proton and exhibits C–O and C=O bond lengths of 1.309(5) and 1.216(5) Å, respectively, while the deprotonated –COOH has C–O bond lengths of 1.273(5) and 1.248(5) Å.[2]

The –COOH of HIPA and the uncoordinated pyridine group of L_1 interact with each other via an O–H···N hydrogen bond (Fig. 4). Differing from all the structures reported here, the metal to ligand ratio in this complex is 1:2. The O–H···N hydrogen bond between the pyridine and COOH group assembles the aggregates into 1D-chains which are further linked into a 2D layer *via* hydrogen bonds between water molecules and amide functional groups.

In complex **5**, the coordination environment is similar to the above complex but both the carboxylates of SA and both the pyridines of L_1 coordinates to Cu(II) to form a (4,4)-layer containing rectangular cavities of the dimension 9.67×16.46 Å^2 (see Fig. 5). The diagonal-to-diagonal distances are 17.25 and 20.77 Å, which confirm the rectangular nature of the cavities. The layers are interpenetrated in a 2-fold fashion with an inclined orientation in the diagonal-to-diagonal mode, the Cu(II) planes of these layers exhibit an interplanar angle of 48.8°. The $Cu(OH_2)_2$ moieties of

[1] The length of the ligand has been considered as the distance between the two pyridine N-atoms of the ligand.

[2] The deprotonation might have occurred by the ligand which is present in excess or by the presence of counter anions of the Cu(II) salts ClO_4^-.

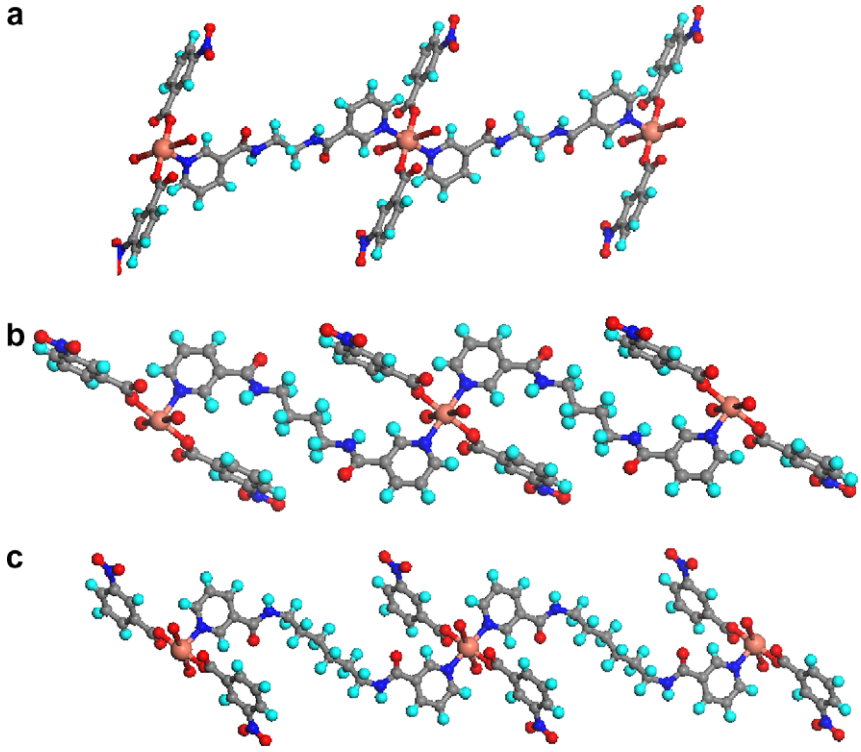

Fig. 1. One-dimensional coordination networks exhibited by crystal structures: (a) **1**, (b) **2**; and (c) **3**. Compare the network in **1** with those in **2** and **3**.

one network fit into the cavities of the other network by the formation of N–H···O hydrogen bonding between amide N–H and coordinated water molecules. Also the CO of the amide forms a hydrogen bond with a free water molecule.

2.4. Thermogravometric analysis for complexes *1* and *2*

The TGA of complexes **1** and **2** were analyzed, and both complexes show differences in the loss of solvent molecules. Complex **1** loses all four water molecules (two loosely coordinated and two uncoordinated) at 78 °C (weight loss: expt. 7.94% and calc.7.96%) and loses guest HNBA by 239 °C (weight loss: expt. 17.85% and calc.18.46%). Whereas complex **2** loses EtOH at room temperature as the crystals were taken out of the mother liquor and kept at room temperature for a week. Complex **2** without EtOH loses coordinated water molecules by 179 °C.

3. Conclusion

The ligands L_1, L_2 and L_3 were shown to form coordination networks in the presence of carboxylic acids HNBA, H_2IPA and H_2SA. The presence of HNBA resulted in 1D networks with the inclusion of HNBA itself as guest molecules in complexes **1** and **2**. Although H_2IPA is a diacid under the given conditions, it exhibits mono deprotonation and forms discrete species as one of the pyridine groups of the ligand is occupied by the –COOH group of HIPA. In contrast, H_2SA forms a dianion and acts as a spacer between Cu(II) ions to form a higher dimensional coordination network. The resultant network contains rectangular grids of dimension 9.7×16.5 Å^2 and doubly interpenetrates in an inclined mode. In all the complexes, due to the presence of coordinated and free water molecules, amide-to-amide hydrogen bonds were not observed.

4. Experimental

4.1. Synthesis of complex *1*

An ethanolic solution (10.0 mL) of $Cu(ClO_4)_2$ (370.15 mg, 1.0 mmol) was added to a solution of 3-nitrobenzoic acid (668.0 mg, 4.0 mmol) in EtOH (10.0 mL). The resultant solution was added to a stirred solution of the ligand L_1 (540 mg, 2.0 mmol) in 30 mL of EtOH, which resulted in the formation of a blue precipitate. The precipitate was dissolved by adding 20.0 mL of water and the clear solution was kept for slow evaporation. Complexes **2**–**5** were synthesized in a similar way by taking the corresponding ligand and carboxylic acids.

4.2. Elemental analysis

1 *Anal.* Calc. for $C_{35}H_{35}CuN_7O_{18}$: C, 46.43; H, 3.87; N, 10.83. Found: C, 45.95; H, 4.05; N, 11.24%.

3 *Anal.* Calc. for $C_{32}H_{38}CuN_6O_{14}$: C, 48.51; H, 4.80; N, 10.61. Found: C, 47.90; H, 4.52; N, 10.34%.

4 *Anal.* Calc. for $C_{44}H_{50}CuN_8O_{18}$: C, 50.69; H, 4.80; N, 10.75. Found: C, 51.12; H, 4.64; N, 10.63%.

5 *Anal.* Calc. for $C_{18}H_{24}CuN_4O_9$: C, 42.90; H, 4.77; N, 11.12. Found: C, 43.40; H, 4.88; N, 10.99%.

4.3. X-ray crystal structure determination

The single crystal data were collected on a Bruker-Nonius Mach3 CAD4 X-ray diffractometer using graphite monochromated Mo Kα radiation ($\mu = 0.71073$ Å) by the ω-scan method. The structures were solved by direct methods and refined by least square methods on F^2 using SHELX-97 [7]. Non-hydrogen atoms were refined anisotropically and hydrogen atoms were fixed at calculated positions and refined using a riding model. The hydrogen atoms of water molecules were located and refined with afix-2 instruction in the complexes of **3** and **4**. PLATON was used for the calculation of available guest volumes [8]. The HNBA moieties were disordered in both complexes **1** and **2** and were modelled as shown in Scheme 3.

2. Experimental

All solvents were HPLC grade and used without further purification. Melting points were determined using Kofler hot stage melting point apparatus. IR spectra were recorded on Shimadzu Fourier Transform Infrared Spectrometer FTIR-400 using KBr disks. ^{1}H NMR spectra were recorded on a Bruker AVANCE 400 MHz in the deuterated solvents specified, and are reported in parts per million (ppm, δ).

The films were deposited onto standard microscope slide substrates of thickness 1 mm at room temperature. The slide substrates were cleaned ultrasonically in acetone and then rinsed with deionized water. The films were deposited using spin coating technique (Specialty Coating Systems G3P-8 Spin Coater) under nitrogen flow at 2000 rpm for 2 min. The surface microstructure was measured by atomic force microscopy (AFM; Veeco CP-II) in non-contact mode with Si tips at a scan rate of 1 Hz. The film thickness of 45–50 nm was estimated from AFM measurements. Transmittance $T(\lambda)$, and reflectance, $R(\lambda)$ spectra of the films were measured at normal incidence and at an incident angle of 5°. The measurements were acquired at room temperature in the spectral range 190–3000 nm by using a computer-aided double-beam spectrophotometer Shimadzu 3150 UV–VIS–NIR with a resolution of 0.1 nm. Phthalocyanine diffraction pattern was examined using Shimadzu XRD-6000 X-ray diffractometer using Cu Kα radiation ($\lambda = 1.5418$ Å). The X-ray tube voltage and current were 40 kV and 30 mA, respectively.

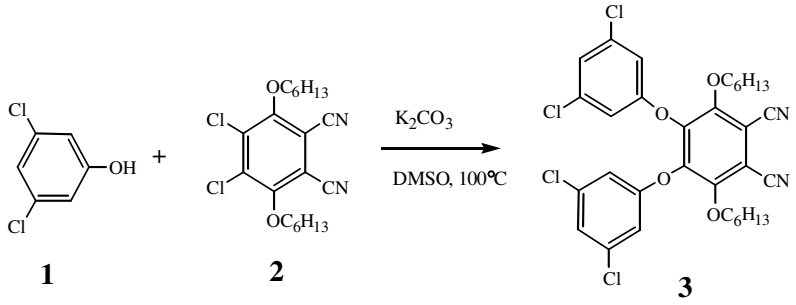
2.1. Preparation of 4,5-dichloro-3,6-dihexyloxyphthalonitrile (2)

The compound was synthesized as reported before [13].

2.2. Preparation of 4,5-bis(3,5-dichlorophenoxy)-3,6-bis(hexyloxy)phthalonitrile (3)

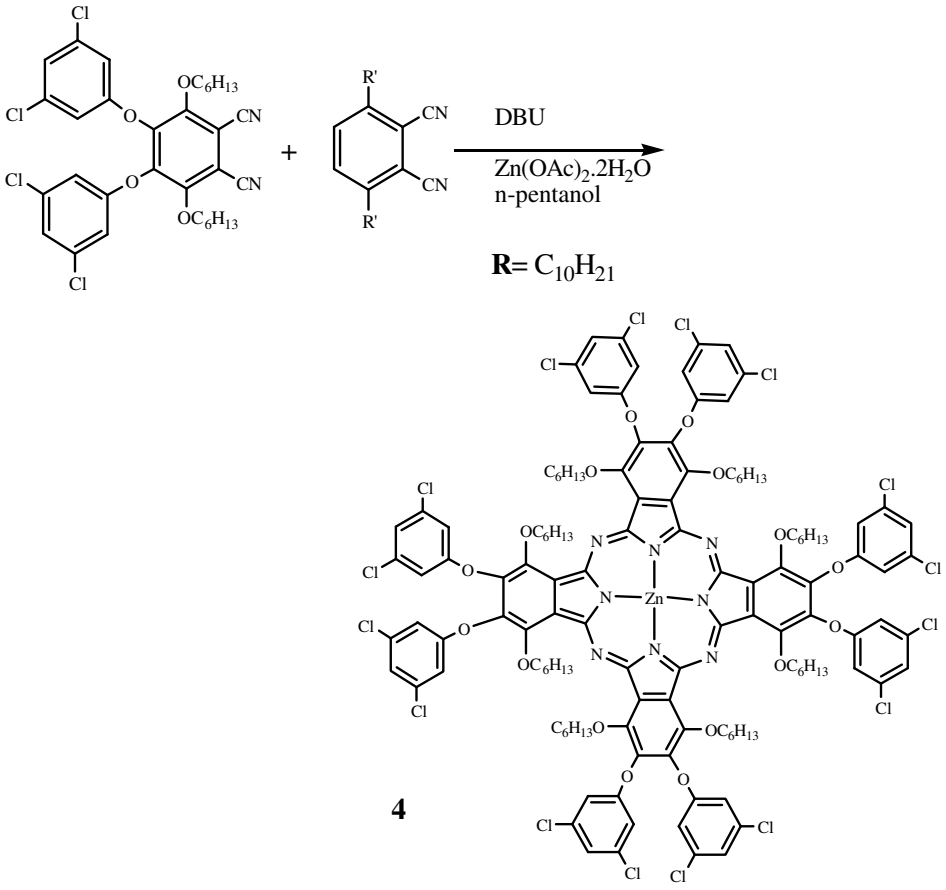
The compound was synthesized following the procedure reported before [13]. The resulting product was purified by column chromatography (silica gel, eluent: *n*-hexane:THF, 5:1) to yield 4,5-bis(3,5-dichlorophenoxy)-3,6-bis(hexyloxy)phthalonitrile (**3**) as a white solid (280 mg, Yield 85 %). IR (KBr): ν_{max} cm^{-1} 2933, 2851, 1596, 2220 (C≡N), 1604 (C=C), 1468, 1315, 1263, 1125 (C–O–C), 963, 832. MS (GC–MS): *m*/*z* (CI) 650. δ_H (400 MHz; $CDCl_3$): δ_H, ppm 7.09 (2H, t, Ar–**H**), 6.71 (4H, d, Ar–**H**), 4.16 (4H, t, **OCH**$_2$), 1.67 (4H, quint, –CH$_2$**CH**$_2$(CH$_2$)$_3$CH$_3$), 1.2–1.48 (12H, m, –CH$_2$CH$_2$(**CH**$_2$)$_3$CH$_3$), 0.82 (6H, t, 2 × **CH**$_3$).

2.3. Preparation of 1,4,8,11,15,18,22,25-octahexyloxy-2,3,9,10,16,17,23,24-octa-(3,5-dichlorophenoxy)phthalocyaninato zinc(II) (4)



A mixture of 3,6-didecylphthalonitrile (40 mg 0.095 mmol), 4,5-bis(3,5-dichlorophenoxy)-3,6-bis(hexyloxy)phthalonitrile (127 mg, 0.196 mmol), zinc acetate dihydrate 99.999% (excess) and two drops of 1,8-diazabicyclo[5,4,0]undec-7-ene (DBU) in dry n-pentanol (10 mL) was heated to reflux for 12 h under an argon atmosphere. The reaction mixture was cooled down to room temperature and the solvent was rotaevaporated under reduced pressure. The resulting dark green compound was separated by silica gel column chromatography using the appropriate eluent. Column chromatography on silica gel with *n*-hexane/DCM 4:1 gave five bands. The required 1,4,8,11,15,18,22,25-octahexyloxy-2,3,9,10,16,17,23,24-octa-(*3,5-dichloro*phenoxy)phthalocyaninato zinc(II) (**4**) was collected as the final fraction by changing the eluent to (*n*-hexane/DCM 3:2) and it was further purified by column chromatography (silica gel, eluent: petroleum ether (bp 40–60 °C)/THF 10:1) to afford a waxy green product (70 mg, Yield 9%). IR(KBr): ν, cm^{-1}, 3052 (Ar–CH), 2940 and 2850 (CH_2). δ_H (400 MHz, $CDCl_3$): δ_H, ppm 6.90 (8H, t, Ar–H), 6.65 (16H, d, Ar–H), 4.17 (16H, t, 8 × OC**H**$_2$), 1.02–1.60 (64H, m), 0.81 (24H, t, 8 × –C**H**$_3$). δ_C (400 MHz, $CDCl_3$) ppm 14.0 (**C**H$_3$), 22.5 (CH_2), 25.3 (**C**H$_2$), 29.9 (**C**H$_2$), 31.4 (**C**H$_2$), 76.6 (O**C**H$_2$), 114.4 (2 × **C**H), 120.4 (C), 123.6 (**C**H), 135.6 (**C**), 146.1 (**C**), 146.9 (**C**), 157.8 (**C**), 164.3 (**C**). MS (GC–FAB): *m*/*z* (%) 2668 $[M+H]^+$, MS (GC–FAB): *m*/*z* (%) 2668 $[M+H]^+$.

3. Results and discussion



3.1. Synthesis

Preparation of the phthalonitrile derivative with the desired substituents is a critical step in phthalocyanine synthesis. In the key intermediate, aryloxy groups substituted with chlorine atoms were incorporated to increase the solubility of the resulting phthalocyanine. The oxygen atoms in the non-peripheral and peripheral positions cause a bathochromic shift of the long wavelength absorption maximum which helps to widen the visible window of the target ZnPc. Therefore, 4,5-bis(3,5-dichlorophenoxy)-3,6-bis(hexyloxy)phthalonitrile was prepared by the treatment of 4,5-dichloro-3,6-dihexyloxyphthalonitrile with 3,5-dichlorophenol, **1**, and K_2CO_3 in DMSO, Scheme 1.

It is difficult to synthesize the target ZnPc complex by direct cylotetramerization of 4,5-bis(dichlorophenoxy)-3,6-dihexyloxyphthalonitrile in the presence of a catalytic amount of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) [14]. The steric effect of the bulky substituents on the phthalonitrile probably is the reason for the slow reaction progress. The target ZnPc complex was synthesized according to the statistical condensation of two different phthalonitriles procedure [13,15]. The procedure involves the reaction of 4,5-bis(3,5-dichlordphenoxy)-3,6-dihexyloxyphthalonitrile (**3**) and 3,6-didecylphthalonitrile (2:1 ratio) in *n*-pentanol in the presence of $Zn(OAc)_2 \cdot 2H_2O$ and a catalytic amount of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) at 140 °C under argon atmosphere for 12 h (Scheme 2). The resulting crude product was subjected to TLC using *n*-hexane/DCM (3:2)

Scheme 1. Synthesis of 4,5-bis(dichlorophenoxy)-3,6-dihexyloxyphthalonitrile (**3**).

Scheme 2. Synthesis of 1,4,8,11,15,18,22,25-octahexyloxy-2,3,9,10,16,17,23,24-octa-(3,5-dichlorophenoxy)phthalocyaninato zinc(II) (**4**).

as eluent and showed five bands. The first fraction contained the undesired symmetrical octadecylphthalocyanine (AAAA) compound. The following three bands were possibly AAAB, AABB and ABBB which can be isolated in a very small quantity. The final separable green fraction was the symmetrical phthalocyanine derivative (BBBB), **4**, which was further purified by a new column using petroleum ether (bp 40–60 °C)/THF 10:1 as eluent to yield 60 mg (8.4%) as green waxy product. The aromatic region showed two broad signals integrated for 24 protons and assigned to the phenoxy ring protons. A triplet at 4.17 ppm was assigned to the 16 methylenoxy protons. The FAB–MS showed an isotopic cluster at 2668 m/e corresponding to the expected structure.

Attaching the chlorinated pheneoxy groups to the peripheral position and hexyloxy groups to the non-peripheral position of phthalocyanines enhanced the solubility in organic solvents [16]. The increased solubility might be due to that the steric hindrance of peripheral 3,5-dichlorophenoxy substituents makes it harder to form dimers of **4**. The prepared ZnPcs show high solubility in various organic solvents such as acetone, benzene, toluene, dichloromethane, ethyl acetate and tetrahydrofuran.

3.2. Electronic absorption spectrometry

The UV–Vis spectrum of **4** in THF solution is typical of phthalocyanine compound, having a soret and Q-bands

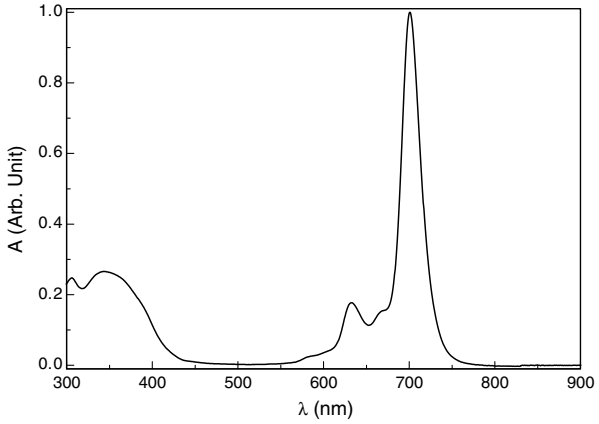


Fig. 1. UV–Vis absorption spectrum of **4** in THF solution at room temperature.

(Fig. 1). The introduction of dichlorphenoxy groups onto the phthalocynine periphary increases the Q-band absorption wavelength of these molecules. The absorption spectrum of **4** is characterized by a strong absorption in the red region and a weaker absorption in the blue region. It is clear that the absorption bands of the chlorinated phenoxy phthalocyanine **4** are shifted to a longer wavelength compared with the unsubstituted Pc. The spectral shift is attributed to the distortion of the ZnPc macrocycle and the electron withdrawing chlorine substituents on the phenyl rings. It is possible that the high electron withdrawing character of chlorine atoms tends to depopulate the π-systems, which would lead from a highly symmetrical planar state to low symmetry state molecule. However, there is no apparent change in the spectral features by comparing the chlorinated-phenoxy with the fluorine substituted phthalocyanines [13].

3.3. Structural studies

The structure and morphology of phthalocyanine thin film was examined by using AFM. Many investigations on the morphology of metal–phthalocyanine have been reported especially CuPc complexes [17–19]. The molecular orientation strongly depends on the growth conditions and substrates. The regular structure of phthalocyanine thin films is described as a stack of needle-like molecules with alternating tilt angles so that the molecules are arranged in zig-zag chains. The growth direction of the molecule columns (*b*-axis) is normally found either with the *b*-axis parallel to the surface or standing up from the substrate face with an angle of about 32° from the surface plane [17–19].

Fig. 2a and b shows 5 × 5 μm 2D and 3D AFM images of the thin film surface. The molecular arrangement of the ZnPc crystallites is visible. The phthalocyanine molecules are growing in aggregation rows rather in the parallel or in the zig-zag arrangement. The roughness of the films was estimated to be about 4.2 nm.

The XRD results of the as-deposited ZnPc film are shown in Fig. 3. The film showed a low degree of crystallinity as indicated by the small intensity of the diffraction peak at $2\theta = 5.08°$. The pattern shows the α form because it does not show the characteristic double intense peak that is observed with the β form. The individual crystallite grain size was determined using Scherrer's relation [20] and was found in the order of 16.56 nm.

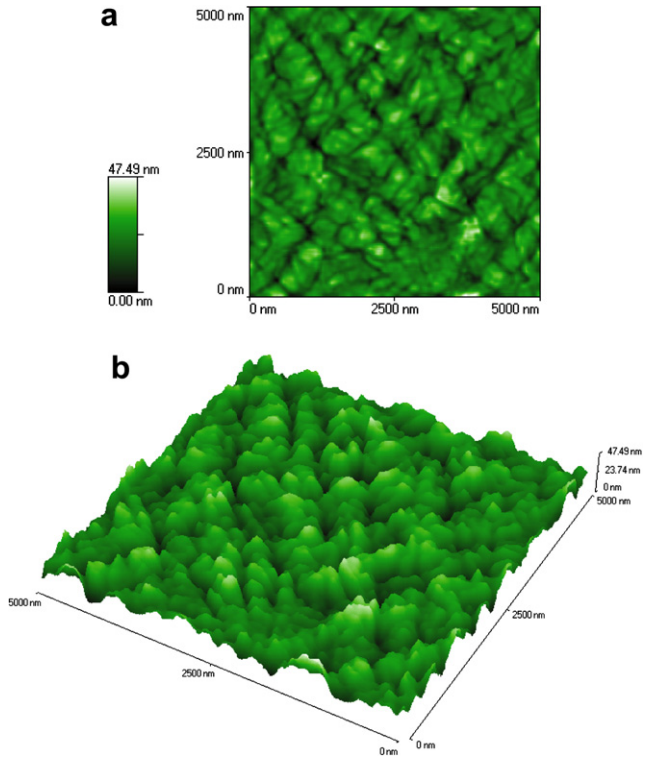

Fig. 2. 5 μm × 5 μm AFM surface pattern of thin film of **4**: (a) 2-D as-deposited and (b) 3-D as-deposited.

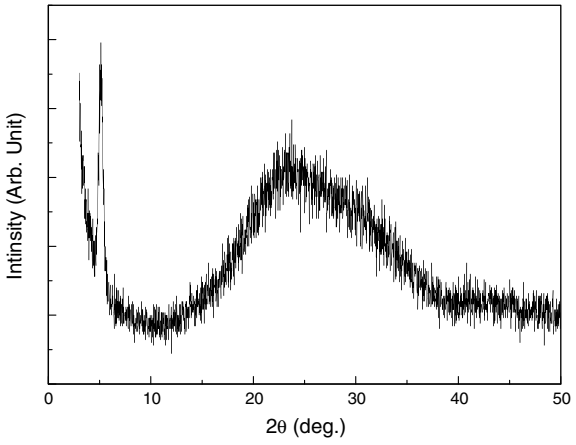

Fig. 3. X-ray diffraction pattern of as-deposited thin film of **4**.

3.4. Optical studies

Fig. 4 shows the UV-near infrared spectral behavior of transmittance $T(\lambda)$ and reflectance $R(\lambda)$ of the as-deposited ZnPc thin film. In Fig. 5, we report the absorption spectra

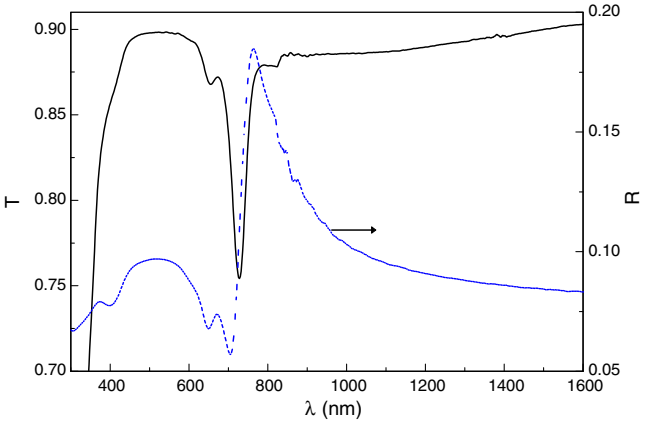

Fig. 4. Spectral behavior of transmittance $T(\lambda)$ and reflectance $R(\lambda)$ of thin film of **4**.

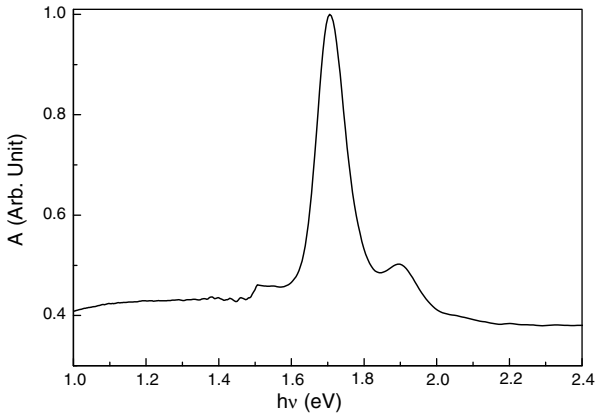

Fig. 5. Spectral distribution of absorbance A (v) of thin film of **4**.

of ZnPc thin film as a function of photon energy, hv. There are two main absorption bands: Q_I at about 728 and Q_{II} at about 655 nm and identified as the Q-band and attributed to the monomer and dimer, respectively [21].

The optical parameters were calculated from the transmission, absorption, and reflectivity data. The average transmission of a thin film on a substrate is given by [20]:

$$T = \frac{(1-R)^2(1+k^2/n^2)}{\exp(\alpha d) - R^2\exp(-\alpha d)} \tag{1}$$

where

$$k = \frac{\alpha\lambda}{4\pi} \tag{2}$$

The parameters α, k, d, n, and λ are the absorption coefficient, absorption index, thin-film thickness, refractive index, and wavelength of the incident light in air, respectively. In any practical experiments, where $k^2 \ll n^2$, the average transmission is simplified as

$$T = \frac{(1-R)^2\exp(-\alpha d)}{1 - R^2\exp(-2\alpha d)} \tag{3}$$

The reflectivity of an absorbing medium of indices n and k in air for normal incidence is given by:

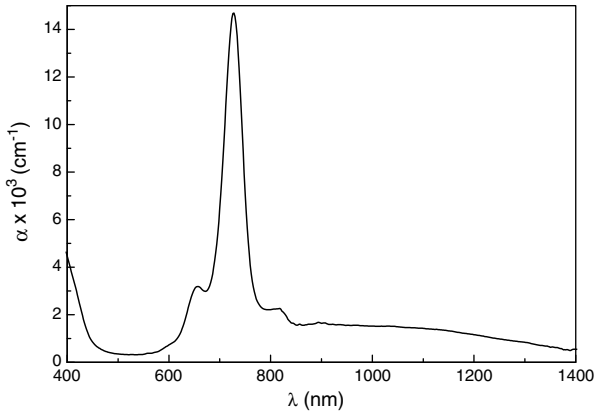

Fig. 6. The variation of absorption coefficient α as a function of wavelength of thin film of **4**.

$$R = \frac{(n-1)^2 + k^2}{(n+1)^2 + k^2} \tag{4}$$

where n is the refractive index.

Using Eqs. (2) and (3), the variation of absorption coefficient, α, with the wavelength was calculated as shown in Fig. 6.

The spectral distribution of refractive index $n(\lambda)$ for **4** in the range 200–2800 nm is shown in Fig. 7. The spectrum shows an anomalous scattering in the range 300–760 nm with various peaks and a normal dispersion in the wavelength range 760–2700 nm. A very high rate of decrease is seen the refractive index in the range of wavelength 760–1400 nm followed by a very low rate of decrease until about 2550 nm whereas the refractive index becomes wavelength-independent. Finally a sudden drop around ~2700 nm occurs.

The variation of absorption coefficient α with photon energy hv and the optical energy gap E_g is obtained from the following formula [20]:

$$\alpha = \alpha_0(hv - E_g)^S \tag{5}$$

where α_0 is a constant

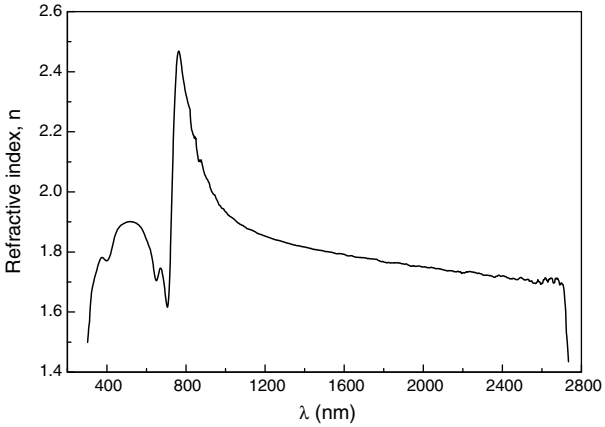

Fig. 7. Spectral distribution of refractive index $n(\lambda)$ of thin film of **4** in the range 200–2800 nm.

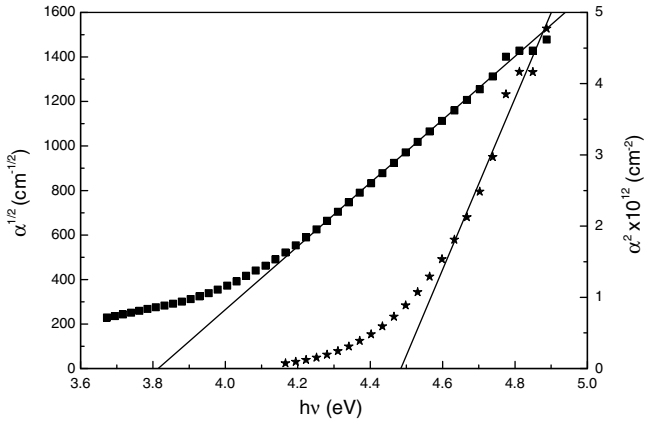

Fig. 8. Variation of $\alpha^{1/2}$ and α^2 with photon energy $h\nu$ of as-deposited thin film of **4**.

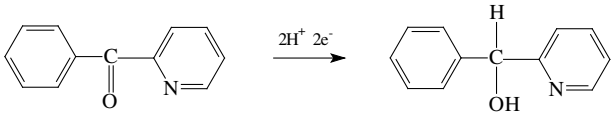
The exponent S determines the type of transition and can take the values 1/2, 2, or 3/2 for direct, indirect, and forbidden transitions, respectively [20]. A satisfactory fit was obtained for $\alpha^{1/2}$ and α^2 as a function of $h\nu$, Fig. 8. This indicates that the absorption mechanism is due to both the indirect and direct transitions. The optical band gap of the indirect and direct transitions (E_{gi}, E_{gd}) can be obtained from the intercept of $\alpha^{1/2}$ versus $h\nu$ plots with the energy axis and α^2 versus $h\nu$, respectively (Fig. 8). The results obtained for indirect and direct optical band gaps for the as-deposited **4** thin film were determined as 3.81 and 4.48 eV, respectively.

4. Conclusions

The present work describes the preparation, characterization and spin coated film of novel hexadecachlorinatedphthalocyaninato zinc(II), which have been peripherally substituted with eight chlorinated-phenoxy groups and non-peripherally substituted with eight hexyloxy groups. The synthesized complex possesses excellent solubility in various organic solvents such as CH_2Cl_2, THF, acetone and ethyl acetate.



The structure and optical properties of the spin coated ZnPc thin films of thickness about 45–50 nm have been studied. X-ray studies revealed the typical structure of phthalocyanines with the diffraction peak at $2\theta = 5.08°$. Studies using AFM showed that the phthalocyanine molecules are growing in aggregation rows.

The optical properties of the ZnPc thin film were studied in the range 200–2800 nm. The absorption spectra recorded show two main Q-bands: Q_I at about 728 and Q_{II} at about 655 nm. The spectral distribution of refractive index $n(\lambda)$, was obtained. The optical band gap of the indirect and direct transitions were found to be equal to 3.81 and 4.48 eV, respectively.

through the N–O chelating site. This coordination produces a five-membered ring containing an unsaturated α-iminoketo function which can act as a π acceptor towards a bound π electron-rich metal center. The α-iminoketo chelation plays an important role in the biosynthesis of the pterins, lumazines, and flavins coenzymes [9,10]. This type coordination has been confirmed for $[ReCl(CO)_3(bopy)]$ complex [11], whereas in the examined structures two-electron reduced form is coordinated to the central ion.

Here we present synthesis, spectroscopic data and X-ray structures of $[ReOCl_2(bopyH)(PPh_3)]$ (**1**) and $[ReOBr_2(bopyH)(PPh_3)]$ (**2**). In addition, the paper includes density functional theory (DFT) and time-dependent DFT (TD-DFT) calculations for chloride complex. Recently, the electronic structures of nitrido, oxo, carbonyl, nitrosyl and nitrile rhenium complexes, as well as their spectroscopic properties, bonding and reactivity have been theoretically studied at the HF, MP2, EHT and DFT levels of theory using various basis sets [12–20]. Gancheff and co-workers [14] have performed extended tests of the ability of the B3LYP method in LANL2DZ basis set for rhenium compounds in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has shown to be sufficient for the geometry optimization and calculation of spectral properties. The correctness of B3LYP method with LANL2DZ basis set for rhenium complexes has been also proven in this paper. The experimental geometry of **1** is well reproduced and the calculated electronic spectrum is in good accordance with the experimental one.

2. Experimental

2.1. General procedure

All the reagents used to the synthesis were commercially available and were used without further purification. The $[ReOX_3(PPh_3)_2]$ (X = Cl, Br) complexes were prepared according to the literature methods [21].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in acetonirile solution. ^1H NMR spectrum was obtained in $CDCl_3$ using Bruker Avance 400 spectrometer. Elemental analyses (CHN) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOCl_2(bopyH)(PPh_3)]$

A mixture of $[ReOCl_3(PPh_3)_2]$ (0.50 g, 0.6 mmol), benzoylpyridine (0.15 g, 0.8 mmol), ethanol (80 ml) and two drops of concentrated HCl was refluxed for 5 h. The blue-violet solution was cooled and left to slow evaporation. The violet crystals that formed were filtered and recrystallized from slow evaporation of an acetonitrile solution. Yield 75%.

IR (KBr; ν/cm^{-1}): 1600 (m), 1567 (w) ν_{CN} and $\nu_{C=C}$; 945 (vs) $\nu_{Re=O}$.

^1H NMR (400 MHz; $CDCl_3$) $\delta = 4.72$ (s, 1H), 6.70 (d, 1H), 7.22–752 (m, 20H), 7.69 (br, 2H), 8.25 (d, 1H).

Anal. Calc. for $C_{30}H_{25}Cl_2NO_2PRe$: C, 50.07; H, 3.50; N, 1.95. Found: C, 50.85; H, 3.73; N, 1.77%.

2.3. Preparation of $[ReOBr_2(bopyH)(PPh_3)]$

A procedure similar to that for $[ReOCl_2(bopyH)(PPh_3)]$ was used with $[ReOBr_3(PPh_3)_2]$ (0.5 g, 0.52 mmol), benzoylpyridine (0.14 g, 0.76 mmol) and two drops of HBr. Crystalline violet precipitate of $[ReOBr_2(bopyH)(PPh_3)]$ was collected in 80% yield.

IR (KBr; ν/cm^{-1}): 1599 (m), 1571 (w) ν_{CN} and $\nu_{C=C}$; 945 (vs) $\nu_{Re=O}$.

Anal. Calc. for $C_{30}H_{25}Br_2NO_2PRe$: C, 44.57; H, 3.12; N, 1.73. Found: C, 44.18; H, 3.25; N, 1.89%.

2.4. Crystal structures determination and refinement

The X-ray intensity data of $[ReOX_2(bopyH)(PPh_3)]$ (X = Cl, Br) were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and absorption correction [22,22] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent atom. SHELXS97 [23], SHELXL97 [24] and SHELXTL [25] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.5. Magnetic measurements

The magnetic measurements of the powdered samples were measured over the temperature range 1,8–300 K using a quantum design SQUID-based MPMSXL-5-type magnetometer. The superconducting magnet was generally operated at a field strength ranging from 0 to 5 T. Measurements of a sample of the compound were made at a magnetic field of 0.5 T.

The SQUID magnetometer was calibrated with the palladium rod sample (Materials research corporation, measured purity 99.9985%). Corrections are based on subtracting the sample-holder signal.

2.6. Computational details

The gas phase geometry of **1** was optimized without any symmetry restrictions in the singlet ground-state with the DFT method using the hybrid B3LYP functional of GAUSSIAN-03 [26–28]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+G** basis for chlorine, phosphorous, oxygen and nitrogen, 6-31G* for carbon and 6-31G for hydrogen atoms [29,30]. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [31] was used for the valence electrons. Additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ on the rhenium atom were added [32]. All vibrations in the calculated vibrational spectrum of **1** were real thus the geometry structure was a true energy minimum.

The electronic spectrum of **1** was calculated with the TDDFT method, and the solvent effect was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM) [33].

Natural bond orbital (NBO) calculations were performed with the NBO code [34,35] included in GAUSSIAN03.

3. Results and discussion

3.1. Preparation and infrared data

The $[ReOX_2(bopyH)(PPh_3)]$ (X = Cl, Br) complexes were prepared by refluxing of $[ReOX_3(PPh_3)_2]$ with a small excess of benzoylpyridine in ethanol. In the both structures two-electron reduced form of benzoylpyridine is coordinated to the central ion. Addition of two drops of HX acid allows obtaining the title complexes in higher yield.

The strong ν(Re=O) stretching bands of the $[ReOX_2(bopyH)(PPh_3)]$ compounds are found in at ~945 cm^{-1}, at a relatively high wavenumber, which suggests that the Re–hydroxy bond *trans* to the oxo ligand does not compete effectively for the Re_d orbitals and indicates the presence of the {O=Re–O} structural subunit in the examined structures.

3.2. Crystal structures

The both complexes are isostructural, they crystallise in the monoclinic space group $P2_1/n$ and their structures consist of discrete and well-separated monomers.

The molecular structure of **1** is presented in Fig. 1 and the selected bond distances and angles of $[ReOX_2(bopyH)(PPh_3)]$ (X = Cl, Br) complexes are collected in Tables 2 and 3, respectively.

The geometry of $[ReOX_2(bopyH)(PPh_3)]$ compounds reveals typical features of quasi-octahedral oxorhenium(V)complexes with oxygenated bidentate ligands. In the both complexes, the rhenium atom is coordinated by a terminal oxygen atom (O_t), two halide ions in *cis* arrangement, the phosphorus atom from PPh_3 molecule, and the bidentate N, O donors of the reduced form of benzoylpyridine. The oxygen atom of the bopyH occupies *trans* position to the terminal oxo ion. The deformation of the octahedron is caused by the presence multiple bonding ligand (terminal oxo) and narrow bite angle of the chelating ligand. The high concentration of electronic density along the Re–O_t axis strongly influences the positions of the adjacent halogen atoms, which are pushed away.

For complex **1** the rhenium atom is displaced 0.1804(16) Å from the equatorial plane formed by the two chlorine, one nitrogen and one phosphorous atoms (plane A) and 0.0001(23) and 0.1222(19) Å from the axial planes formed respectively by the two oxygen, one chlorine and one nitrogen atoms (plane B) and two oxygen, one chlorine and one phosphorous atoms (plane C). Least squares plane A is inclined at 88.10(13)° to plane B and at 89.89(13)° to plane C. Planes B and C are inclined at 88.24(9)°. These values for bromide analogue are,

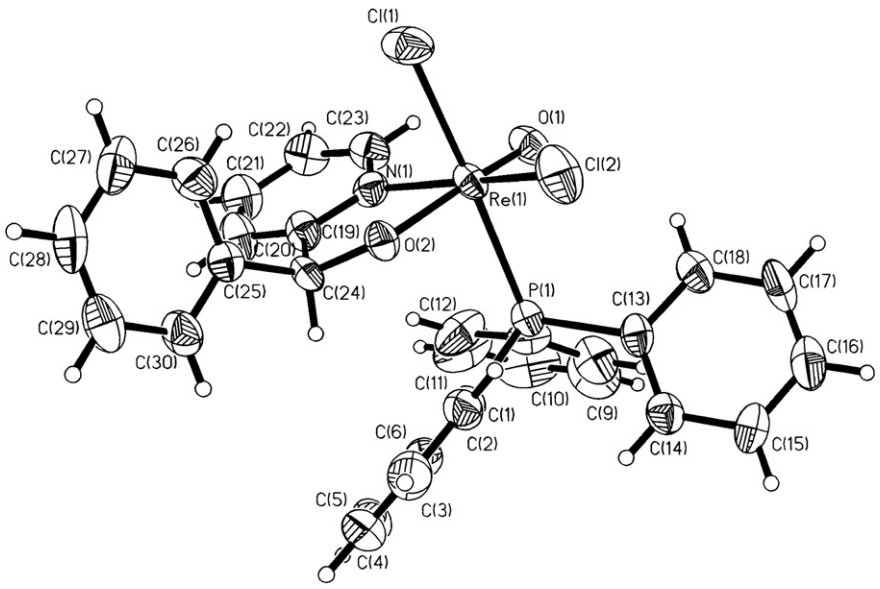

Fig. 1. The molecular structure of **1**. Displacement ellipsoids are drawn at 50% probability.

respectively, 0.1787(9), 0.0101(12) and 0.1299(9) Å, 88.35(7)°, 89.90(6)° and 89.90(4)°.

In compound **1**, the planar in the experimental error pyridine and phenyl rings are inclined at 81.1(2)° and the spacer C(24) atom derive 0.054(11) and 0.052(12) Å, respectively, from these planes. These values in **2** are, respectively, 82.26(12)°, 0.025(6) and 0.069(6) Å.

The Re–O_t bond lengths fall in the range 1.639–1.76 Å, which is typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicates the presence of a triple bond Re≡O [36]. The interatomic distance between the rhenium atom and the oxygen atom of bopyH in *trans* position to the terminal oxo ion, is only somewhat shorter than an ideal single Re–O bond length (*ca.* 2.04 Å) [37]. It indicates small delocalization in the O(2)–Re(1)–O(1) moiety. The similar trend is observed for many Re(V)-oxo complexes with an monoanionic oxygen *trans* to the oxo

			Cl(1)–Re(1)–P(1)	176.54(6)	177.14

group [38]. The Re1–X(1) distances *trans* to the phosphorus atom of the triphenylphosphine molecule are slightly longer than the Re1–X(2) bonds *trans* to the nitrogen atom of the bopyH ligand. It is a consequence of structural *trans* effect of the PPh_3 ligands.

3.3. Geometry optimisation, charge distribution and NBO analysis

Complex **1** indicated diamagnetic properties in the whole measuring temperature range from values $-0.60 \times 10^{-6}\,cm^3\,g^{-1}$ at 1.8 K to $-0.32 \times 10^{-6}\,cm^3\,g^{-1}$ at 300 K. The geometry of **1** was optimised in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters of **1** are gathered in Table 2. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

Table 4 presents the atomic charges from the Natural Population Analysis (NPA) for **1**. The calculated charge on the rhenium atom is considerable lower than the formal charge +5, corresponding d^2 configuration of the central ion. It results from significant charge donation from the ligands. The charges on the terminal oxo, chloride and oxygen atom of bopyH are significantly smaller than −2, −1 and −1, respectively. The terminal oxo ion is less negative in comparison with the oxygen atom of bopyH ligand. It indicates the higher electron density delocalization from the O_t ligand towards the central ion and corresponds to differences in the Re–O_{hydoxy} and Re–$O_{terminal}$ bonds lengths.

The nature of rhenium–terminal oxygen interaction in **1** has been studied by NBO analysis. The occupancy and composition of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 5. Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [34,35].

The detected natural Re–O_t bond orbitals of **1** are π orbitals – the p_x and p_y oxygen orbitals and d_{xz} and d_{yz} rhenium orbitals are involved in their formation. Not detected $\sigma_{Re–Ot}$ bond has character of predominant Coulomb-type interactions between the central ion and ligands [39]. The

Table 4
Atomic charges from the Natural Population Analysis (NPA) for **1**

Atom	Charge

Table 5
The occupancy of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligand for **1**

BD	Occupancy	Composition of NBO	BD[a]	Occupancy
Re–O_t	1.988	$0.564(d)_{Re} + 0.826(p)_O$	$0.826(d)_{Re} - 0.564(p)_O$	0.294
Re–O_t	1.986	$0.573(d)_{Re} + 0.819(p)_O$	$0.819(d)_{Re} - 0.573(p)_O$	0.317

BD denotes 2-center bond.
[a] Antibond NBO.

terminal oxo ligand of **1** has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital. Accordingly, NBO analysis confirms a triple bond between the rhenium and the terminal oxygen ligand.

3.4. Electronic spectra

The experimental and calculated electronic spectra of **1** are presented in Fig. 2. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. In general, the electronic spectrum of **1** is well reproduced by the calculations. Some shifts between the experimental and calculated absorption bands may come from the basis sets which are approximated to a certain extent.

The shape of the UV–Vis spectrum of **2** is the same as for the chloride analogue; the absorption bands of the bromide complex were recorded at 746.0, 607.0, 332.5, 249.5 and 208.0 nm.

Table 6 presents the most important electronic transitions calculated with the TDDFT method assigned to the observed absorption bands of **1**. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy to the orbitals HOMO and LUMO involved in the electronic transitions. Contour plots and energy of the selected HOMO and LUMO orbitals active in the electronic transitions are depicted in Fig. 3.

The TDDFT/PCM calculations show that the two longest wavelength experimental bands of **1** at 767.0 and 589.5 nm originate in the HOMO → LUMO and HOMO → LUMO + 1 transitions, respectively. As d_{Re} orbitals take main part in the HOMO, LUMO and LUMO + 1 orbitals, the HOMO → LUMO and HOMO → LUMO + 1 transitions may be attributed to the transitions of d → d character. However, as it can be seen from Fig. 3, the HOMO, LUMO and LUMO + 1 orbitals are delocalized among rhenium ion, chloride, oxo and bopyH ligands so a delocalized MLLCT (metal–ligand-to-ligand CT) description also can be used.

The absorption band at 330.5 nm can be related to a metal-to-bopyH ligand charge transfer (MLCT) with a certain contribution of ligand–metal charge transfer (π_{PPh3}/π_{bopyH}/π_{Cl} → d) transitions.

The experimental bands below 300 nm result mainly from ligand–ligand charge transfer and interligand (IL) transitions.

Table 6
The energy and molar absorption coefficients of experimental absorption bands and the electronic transitions calculated with the TDDFT method for **1**

The most important orbital excitations	Character	λ (nm)	E (eV)	f	Experimental Λ (nm) (E (eV)) ε

Scheme 1.

ferrocenyl) the latter reaction's yields suffer significantly and long reaction times are required. The former method produces, in most cases, yields in excess of 80% in 2–3 h [9]. The disassembly of a tetrathiophenecarboxylate derivative would be a prime candidate for such a reaction, as both the di- and mononuclear thiophene containing complexes would have the potential to be electrochemically polymerized.

Herein we report the synthesis and characterization as well as electrochemical behaviour of both diruthenium(II,III) and monoruthenium(II) complexes incorporating the thiophene-containing ligands 3-thiophene carboxylate, 3-thiophene acetate, *trans*-3-(3-thienyl)acrylate and 2,2′-bithiophene-5-carboxylate (Scheme 1).

2. Experimental

2.1. Equipment

Cyclic voltammetry studies were performed on dry dichloromethane solutions (approx. 1 mM) containing 0.1 M tetrabutylammonium hexafluorophosphate ($TBAPF_6$) that were placed in a standard three-neck cell with Luggin-Haber capillary, with an Analytical Sensors Inc. Pt button working electrode, a saturated calomel reference electrode (SCE) and a platinum wire counter electrode. The potential applied to the working electrode was controlled by a Pine Instruments bipotentiostat (model AFCBP1) interfaced to a PC through a PINECHEM 2.7.9 software package. Cyclic voltammetry scans were conducted at a scan rate of 0.100 V/s. The working electrode was polished prior to each scan using Buehler Alpha Micropolish I alumina (5.0 μm) followed by Buehler Gamma Micropolish II deagglomerated alumina (0.05 μm) on a Buehler microcloth. Infrared spectra were performed on KBr discs using a Bio-Rad FTS-175 spectrophotometer. NMR measurements were carried out on a Bruker Avance II 400 MHz spectrophotometer using Norell sample tubes. Elemental analysis was performed by Canadian MicroAnalytical Services Ltd., Delta, BC.

2.2. Materials

Most of the reagents and solvents were purchased from commercial sources and used as received. $Ru_2(\mu\text{-}O_2CCH_3)_4Cl$ was prepared by the method of Mitchell et al. [12]. Dichloromethane was distilled over CaH_2 and stored under argon prior to use. Tetrabutylammonium hexafluorophosphate ($TBAPF_6$) was recrystallized three times from ethanol and thoroughly dried before use. All of the synthetic procedures were carried out under an atmosphere of argon.

2.3. Syntheses

2.3.1. Preparation of $[Ru_2(\mu\text{-}O_2CR)_4(MeOH)_2]PF_6$ complexes, O_2CR^- = thiophene-3-carboxylato **1**, thiophene-3-acetato **2**, and trans-3-(3-thienyl)acrylato **3**

$Ru_2(\mu\text{-}O_2CCH_3)_4Cl$ (0.100 g, 0.21 mmol) and a 6-fold molar excess (1.26 mmol) of the appropriate thiophene-3-carboxylic acid were dissolved in 50 ml of a 1:1 water/methanol solution. The brown solution was then refluxed under argon for 8 h over which time it lightened somewhat to an orange or yellow-brown. The solution was placed in the fridge overnight, the resulting brown solid of $Ru_2(\mu\text{-}O_2CR)_4Cl$ collected, washed with methanol and diethyl ether and dried in vacuo. Further purification of these $Ru_2(\mu\text{-}O_2CR)_4Cl$ derivatives was not carried not. Subsequent dechlorination was typically carried out by dissolving 0.100 g (0.13 mmol) of the $Ru_2(\mu\text{-}O_2CR)_4Cl$ in 50 ml of methanol (0.080 g (0.010 mmol) of the acrylato derivative in 90 ml of methanol). To this solution was added a solution of 0.033 g (0.13 mmol) of silver hexafluorophosphate in 10 ml of methanol (0.025 g (0.10 mmol) in 10 ml for the acrylato derivative). These solutions were heated in the dark, with stirring, at 40–50 °C for 1 h. The AgCl that formed was then filtered off over a bed of Celite. The orange/brown filtrate was collected and concentrated under vacuum to precipitate a dark brown solid which was collected and washed with a small amount of cold methanol. Yields: **1**: 0.063 g (51%); **2**: 0.060 g (46%); **3**: 0.062 g (60%). Elem. *Anal.* Calc. for **1**, $C_{22}H_{20}O_{10}S_4Ru_2PF_6$: C, 28.73; H, 2.19. Found: C, 28.62; H, 2.29%. Elem. *Anal.* Calc. for **2**, $C_{26}H_{28}O_{10}S_4Ru_2PF_6$: C, 32.00; H, 2.89. Found: C, 32.11; H, 2.71%. Elem. *Anal.* Calc. for **3**, $C_{30}H_{28}O_{10}S_4Ru_2PF_6$: C, 36.04; H, 2.82. Found: C, 35.88; H, 2.99%. IR (cm^{-1}) for **1**: 3448 (m), 3115 (w), 1526 (s), 1441 (s), 1393 (m), 1349 (s), 1045 (w), 865 (s). For **2**: 3498 (m), 3109 (w), 2923 (m), 2859 (w), 1465 (s), 1436 (s), 1394 (s), 1292 (s), 1043 (w), 839 (s). For **3**: 3448 (m), 3101 (w), 3023 (w), 1628 (s), 1426 (s), 1384 (s), 1294 (m), 1248 (m), 990 (m), 845 (s).

*2.3.2. Preparation of $[Ru_2(\mu\text{-}O_2CC_8H_5S_2)_4(EtOH)_2](PF_6)$, $O_2CC_8H_5S_2^- = 2,2'$-bithiophene-5-carboxylato **4***

$Ru_2(\mu\text{-}O_2CCH_3)_4Cl$ (0.100 g, 0.21 mmol) and 6-fold molar excess of 2,2′-bithiophene-5-carboxylic acid (0.266 g, 1.26 mmol) were dissolved into 25 ml of argon-purged methanol. This brown solution was then refluxed under argon for 8 h, over which time the solution lightened slightly. Upon completion of the reflux, the solution was placed in the fridge overnight. The resulting brown solid was collected via suction filtration, and washed successively with methanol and diethyl ether. Dechlorination of the product was then carried out by dissolving 0.100 g of the product into 50 ml of argon-purged ethanol. To this, a solution of silver hexafluorophosphate (0.030 g, 0.11 mmol) in 10 ml of argon purged ethanol was added. The combined solution was heated to 40–50 °C and stirred for 1 h in the dark. The solution was then filtered through a bed of Celite to remove the precipitated AgCl, and washed with 20 ml of ethanol. The red-brown filtrate was collected and reduced in volume, precipitating a dark brown solid. This solid was collected via suction filtration. Yield: **4**: 0.107 g (91%). Elem. *Anal.* Calc. for **4**, $C_{40}H_{32}O_{10}S_8Ru_2PF_6$: C, 37.64; H, 2.53. Found: C, 37.39; H, 2.54%. *2.3.3. Preparation of $[Ru(\eta^2\text{-}O_2CR)(dppe)_2]PF_6$ complexes, O_2CR^- = thiophene-3-carboxylato **5**, thiophene-3-acetato **6**, and trans-3-(3-thienyl)acrylato 7*

About 0.050 g of the appropriate $[Ru_2(\mu\text{-}O_2CR)_4(MeOH)_2]PF_6$ derivative was dissolved under argon in 100 ml of methanol. To this was added four molar equivalents of 1,2-bis(diphenylphosphino)ethane (dppe) and the resulting solution refluxed for 8 h during which time the solution changed colour from red-brown to bright yellow. The solution was cooled, reduced in volume to 30 ml and placed in the fridge overnight. The resulting yellow crystalline solid was collected by suction filtration and dried in vacuo. Yields: **5**: 0.095 g (67%); **6**: 0.129 g (89%); **7**: 0.105 g (72%). Elem. *Anal.* Calc. for $\mathbf{5}\cdot CH_3OH$, $C_{58}H_{55}O_3F_6P_5RuS$: C, 57.95; H, 4.61. Found: C, 58.29; H, 4.50%. For **7**: (^1H): 5.92–7.82 (m, 40H, dppe phenyl protons); 6.90 (m, 1H, thiophene proton); 7.15 (m, 2H, thiophene proton); 4.91 (d, 1H, acrylic proton); 6.51 (d, 1H, acrylic proton); 1.53, 2.09, 2.30, 2.93 (m, 8H, methylene protons). (^{31}P): 58.02 (t, 2P) and 58.72 (t, 2P).

*2.3.4. Preparation of $[Ru(\eta^2\text{-}O_2CC_8H_5S_2)(dppe)_2](PF_6)$, $O_2CC_8H_5S_2^- = 2,2'$-bithiophene-5-carboxylato **8***

About 0.125 g, (0.1 mmol) of $[Ru_2(\mu\text{-}O_2CC_8H_5S_2)_4(EtOH)_2](PF_6)$ and four molar equivalents of bis-1,2-(diphenylphosphino)ethane (160 mg, 0.4 mmol) were dissolved in 150 ml of argon-purged ethanol. The dark brown solution was refluxed for 8 h, during which time the solution changed to a cloudy yellow. The solution was removed from heat and allowed to cool to room temperature. Potassium hexafluorophosphate (20 mg, 1.1 mmol) was added to the solution with stirring. The volume of the solution was then reduced using rotary evaporation to approximately 40 ml. The solution was then placed in the fridge overnight. The resulting orange-yellow crystalline solid that precipitated from solution was collected using suction filtration and dried under vacuum. Yield: **8**: 0.160 g (79%). Elem. *Anal.* Calc. for **8**: C, 58.51; H, 4.27; P, 12.37. Found: C, 58.29; H, 4.32; P, 12.51%. IR (cm^{-1}): 3430 (m), 3064 (w), 1518 (m), 1432 (s), 1414 (s), 1384 (m), 1097 (m), 841 (s), 747 (m), 695 (s). ^1H NMR (400 MHz, $CDCl_3$) δ (ppm): 5.91–7.78 (m, 40H, dppe phenyl protons); 7.65 (d, 1H, bithiophene proton); 7.34 (d, 2H, bithiophene protons); 7.22 (d, 1H, bithiophene proton); 7.05 (m, 1H, bithiophene proton); 1.53, 2.11, 2.35, 2.91 (m, 8H, methylene protons). ^{31}P NMR (400 MHz, $CDCl_3$) δ (ppm): 58.15 (t, 2P) and 58.48 (t, 2P).

2.4. X-ray crystallography

Crystals were mounted on a glass fiber and all measurements were made on a Rigaku AFC5R diffractometer (or Rigaku RAXIS RAPID imaging plate area detector for **8**) with either graphite monochromated Mo Kα (complexes **5** and **8**) or Cu Kα (complexes **6** and **7**) radiation and a rotating anode generator. The structures were solved by direct methods [13,14] and expanded using Fourier techniques [15]. For complexes **5**, **6** and **8** the non-hydrogen atoms were refined anisotropically and some of the hydrogen atoms were refined isotropically with the rest included in fixed positions. For complex **7** some non-hydrogen atoms were refined anisotropically, while the rest were refined isotropically. Hydrogen atoms were included but not refined. Neutral atom scattering factors were taken from Cromer and Waber [16]. Anomalous dispersion effects were included in F_{calc} [17]; the values of $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley [18]. The values for the mass attenuation coefficients are those of Creagh and Hubbell [19]. All calculations were performed using the CRYSTALSTRUCTURE [20,21] crystallographic software package. A full listing of crystal parameters is given in Table 1.

3. Results and discussion

3.1. Synthesis

The synthesis of the tetracarboxylate derivatives (**1**–**4**) was carried using a standard carboxylate exchange reaction in 1:1 (v/v) methanol/water, using an excess of the desired carboxylic acid (HO_2CR), followed by dechlorination of the $Ru_2(\mu\text{-}O_2CR)_4Cl$ intermediate in methanol or ethanol to get the desired solvent diadducts as PF_6^- salts (Eqs. (1) and (2)) [5]. The diadducts are easier to work with than the chloride derivatives as they are soluble in a wider variety of solvents.

$$Ru_2(\mu\text{-}O_2CCH_3)_4Cl + \text{excess } HO_2CR \rightarrow Ru_2(\mu\text{-}O_2CR)_4Cl + \text{free } HO_2CCH_3 \quad (1)$$

$$Ru_2(\mu\text{-}O_2CR)_4Cl + AgPF_6 \xrightarrow{MeOH} [Ru_2(\mu\text{-}O_2CR)_4(MeOH)_2]PF_6 + AgCl \quad (2)$$

The "disassembly" of complexes **1**–**4** to form the mononuclear ruthenium derivatives of the form $[Ru(\eta^2\text{-}O_2CR)(dppe)_2]PF_6$ (complexes **5**–**8**) was achieved by a method we [9–11] and others [22] have used in which the dimer is reacted with a π-acid ligand such as a phosphine; bis(1,3-diphenylphophino)ethane (dppe) in our case (Eq. (3)). The advantage of using this method, as was mentioned in the Introduction, is the ability to synthesize complexes containing relatively bulky R groups in good yields.

$$[Ru_2(\mu\text{-}O_2CR)_4(MeOH)_2]PF_6 + 4dppe \xrightarrow{PF_6^-} 2[Ru(\eta^2\text{-}O_2CR)(dppe)_2]PF_6 + \text{free } {}^-O_2CR \text{ and oxidation products} \quad (3)$$

All complexes gave satisfactory elemental analyses.

3.2. Infrared and NMR properties

Complexes **1**–**4** show infrared spectra typical of this class of compounds with C–H stretching modes at 2850–3150 cm^{-1}, symmetric and asymmetric O–C–O stretches in the range 1384–1441 cm^{-1}, thiophene ring modes at 1000–1300 cm^{-1} and a strong P–F stretching mode around 840 cm^{-1} [23]. In addition, the O–H stretching mode due to the axially coordinated methanol or ethanol is seen around 3450 cm^{-1}. Similar infrared bands are seen for the mononuclear complexes **5**–**8**. The only difference of note is that the separation between the symmetric and asymmetric O–C–O stretching modes is somewhat smaller due to the η^2 versus μ_2 coordination of the carboxylate.

^{1}H NMR (400 MHz) was performed on complexes **5**–**8** (complexes **1**–**4** are paramagnetic with three unpaired elec-

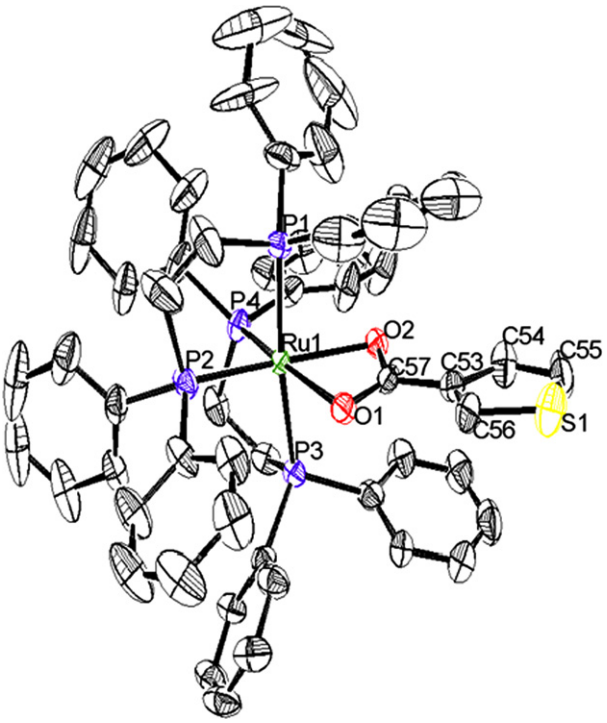

Fig. 1. Molecular structure of the $[Ru(\eta^2\text{-}O_2CC_4H_3S)(dppe)_2]^+$ cation, **5**. Hydrogen atoms, the hexafluorophosphate anion and the methanol molecule of solvation have been omitted for clarity.

trons per dimer) and gave limited information. The phenyl and thiophene protons are seen in the 5.9–7.9 ppm range with the methylene protons at 1.5–3.0 ppm which is similar to what we have seen previously for $[Ru(\eta^2\text{-}O_2CCH_3)(dppe)_2]PF_6$ [9]. In complex **7** the *trans* –HC=CH– protons are clearly discernible as a pair of doublets at 4.91 and 6.51 ppm. The ^{31}P NMR spectra for all three complexes show the characteristic doublet of triplets around 58 ppm which have been reported in an earlier study [9]. The splitting between the triplets in all three cases is very small which is consistent with the A_2B_2 splitting pattern seen in $[Ru(\eta^2\text{-}O_2CCH_3)(dppe)_2]PF_6$ [9].

3.3. X-ray structures

Complexes **5**–**8** were also characterized by X-ray diffraction and the relevant crystal data is reported in Table 1. Complex **5** crystallizes in the $C2/c$ space group with a molecule of methanol in the unit cell. An ORTEP diagram is shown in Fig. 1 and selected bond lengths and angles are given in Table 2. The three bidentate ligands (two dppe's and a carboxylate) assume a distorted octahedral geometry about the Ru center with P–Ru–P and P–Ru–O bond angles in the range 82.4–106.6° and the O–P–O bond angle a more restrictive 60.0°. The Ru–P bond lengths are 2.290(2) and 2.303(1) Å for those *trans* to a carboxylate oxygen and 2.360(1) and 2.372(1) Å for those *trans* to another phosphorous, a clear illustration of the greater *trans*-influence of P versus O. The Ru–O bond lengths

Ru(1)–O(2)–C(57)	90.1(3)	O(1)–C(57)–O(2)	118.9(5)

are 2.180(4) and 2.192(3) Å showing relatively symmetrical binding to the Ru. All of the bond lengths and angles are similar to those of the previously reported structures of $[Ru(\eta^2\text{-}O_2CR)(dppe)_2]PF_6$ with $R = CH_3$ and ferrocenyl [9].

Complex **6** crystallized in the $P2_1$ space group and displays very similar bond lengths and angles to those in complex **5** except that the carboxylate group binds less symmetrically with Ru–O bonds of 2.138(8) and 2.202(8) Å. As well, the thiophene ring is significantly bent out of plane with respect to the Ru–O–C–O plane with an angle of 79(1)°! Fig. 2 gives an ORTEP diagram of complex **5** and Table 3 summarizes the bond lengths and angles.

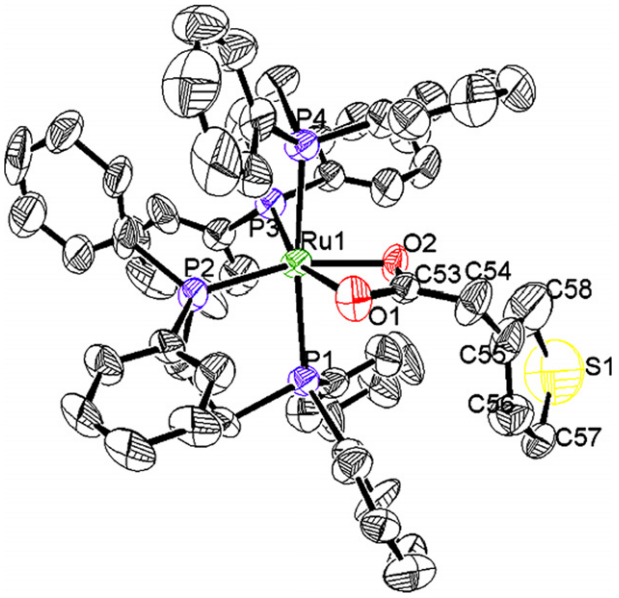

Fig. 2. Molecular structure of the $[Ru(\eta^2\text{-}O_2CCH_2C_4H_3S)(dppe)_2]^+$ cation, **6**. Hydrogen atoms and the hexafluorophosphate anion have been omitted for clarity.

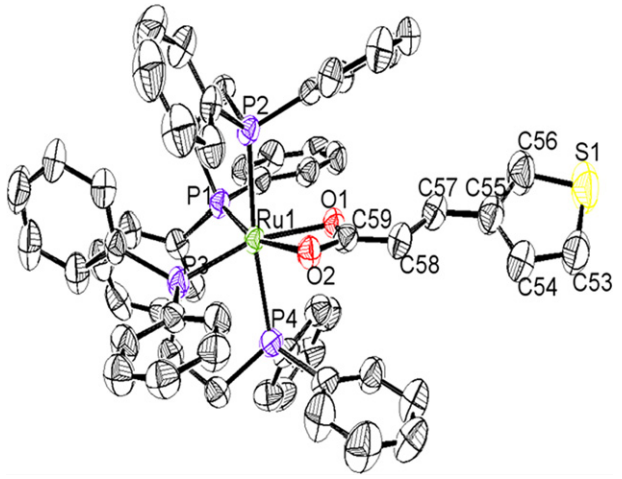

Fig. 3. Molecular structure of the $[Ru(\eta^2\text{-}O_2CCH{=}CHC_4H_3S)(dppe)_2]^+$ cation, **7**. Hydrogen atoms, the hexafluorophosphate anion and the methanol molecule of solvation have been omitted for clarity.

Complex **7** crystallized in the *Pbca* space group with a half molecule of methanol in the unit cell. An ORTEP diagram is seen in Fig. 3 and bond lengths and angles given in Table 4. The corresponding bond lengths and angles are, again, similar to those in complexes **5** and **6** and to those previously reported [9]. The asymmetry of the carboxylate binding is somewhere between that seen in complexes **5** and **6** with Ru–O bond lengths of 2.166(3) and 2.211(3) Å. The thiophene–CH=CH– moiety extends relatively straight out from the Ru core with an *anti* arrangement about the double bond. The dihedral angle between the Ru–O(1)–C(59)–O(2) plane and the thiophene ring is 33°. The C(55)–C(57), C(57)–C(58) and C(58)–C(59) bond lengths are 1.454(8), 1.320(8) and 1.455(8) Å, respectively, indicating limited, if any, conjugation.

Complex **8** also crystallized in the orthorhombic Pbca space group and an ORTEP diagram is shown in Fig. 4 with selected bond lengths and angles listed in Table 5. The key bond lengths and angles are again similar to those of complexes **5**–**7**. The two thiophene rings are close to being coplanar with a dihedral angle of 9.1(2)°.

3.4. Electrochemistry

3.4.1. Diruthenium(II,III) tetra-(3-thiophencarboxylates) and tetra-(2,2′-bithiophene-5-carboxylate), *1*–*4*

The cyclic voltammetry of the diruthenium(II,III) tetra-(3-thiophenecarboxylates) and tetra-(2,2′-bithiophene-5-carboxylate), **1**–**4**, were performed on 1mM solutions in the presence of 0.1 M $TBAPF_6$ in dry dichloromethane. Full details are given in Section 2. A typical experiment consisted of 6–10 consecutive scans run at 100 mV/s. It should be noted that thiophene-3-carboxylates were employed, rather than the thiophene-2-carboxylates such as those synthesized by Jimenez-Aparicio and coworkers [8], since they are better candidates for polymerization as the position of the carboxylate at the 3-position leaves both α sites on the ring available for coupling. The scans for diruthenium(II,III) tetra-3-thiophenecarboxylate, **1**, are shown in Fig. 5. Similar scans are seen for complexes **2** and **3** with E_{pa} values greater than 1.5 V. In fact, there are no clearly distinguishable oxidation waves in most cases, only shoulders on the more intense solvent oxidation wave.

Estimates of the E_{pa} values from these shoulders are given in Table 6. There is no evidence of oxidative polymerization of the thiophene rings in any of the three single ring thiophene carboxylates as the scans *diminish* somewhat in intensity (rather than increasing as a polymer film grows) which is likely due to passivation of the electrode surface which deposits an electronically insulating film. The high oxidation potential of these complexes reflects the electron-withdrawing nature of the carboxylate group attached

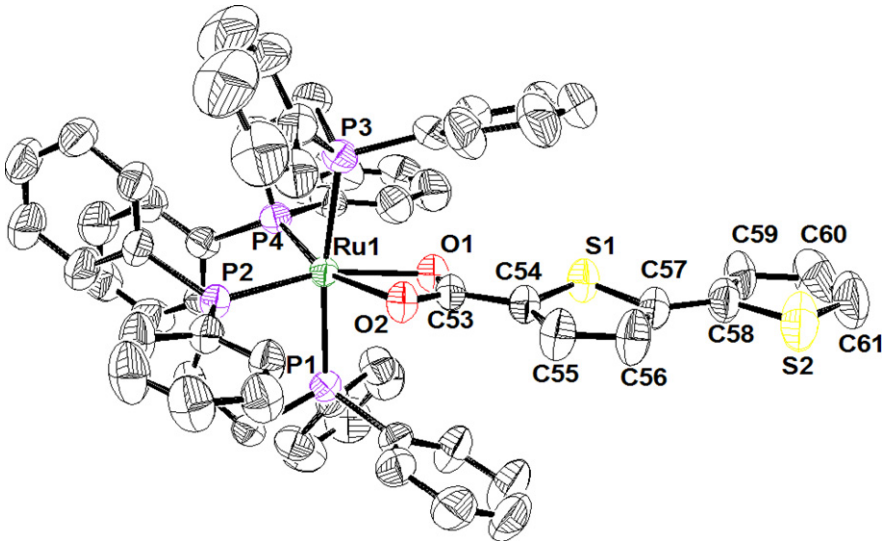

Fig. 4. Molecular structure of the $[Ru(\eta^2\text{-}O_2CC_8H_5S_2)(dppe)_2]^+$ cation, **8**. Hydrogen atoms and the hexafluorophosphate anion have been omitted for clarity.

[c] Most likely due to a small amount of impurity.

to the thiophene ring which serves to destabilize any radical cation intermediate and thus inhibit oxidative polymerization. It should be noted that the oxidation is unlikely to be due to the $Ru_2^{6+/5+}$ couple as this couple has never been seen inside the solvent front in any diruthenium(II,III) tetracarboxylate adducts with modest axial Lewis base donors (such as methanol in these cases) [5,6]. Only in strong axial donor adducts, such as phosphines, does this wave become accessible [24].

The behaviour of the bithiophene complex, **4**, is, on the other hand, distinctly different. Inspection of the voltammogram (see Fig. 6) shows an E_{pa} value for the initial scan at 1.55 V. This clear oxidation wave is much lower than those of the mono-thiophene systems, which indicates that the radical cation intermediate is more accessible. For this compound, the terminal thiophene ring is presumably far enough removed from the carboxylate group to permit cation formation and subsequent coupling. This value lowers somewhat with each subsequent scan, indicative of poly-

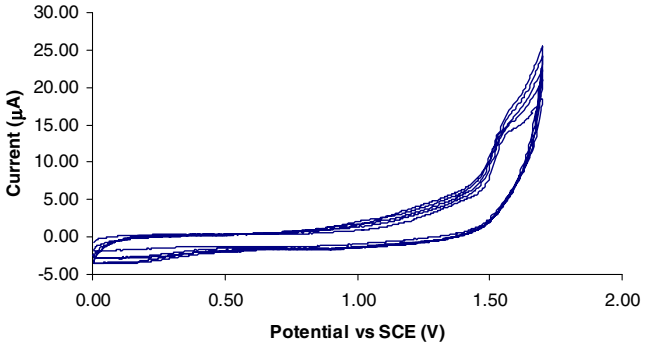

Fig. 6. Consecutive cyclic voltammetry scans for complex **4** in dichloromethane (scan rate = 100 mV/s).

merization. In addition, a distinct *growth* in the current is seen on successive scans, which again is strong evidence for the occurrence of oxidative polymerization. This was further confirmed by the appearance of a transparent yellow film on the platinum surface of the working electrode.

It should be noted here that in all cases the free ligands (see Scheme 1) do not show any evidence of polymerization, only a large oxidation wave, E_{pa}, at greater than 1.5 V for the single-ring thiophenes and an $E_{pa} = 1.45$ V for the 2,2′-bithiophene-5-carboxylic acid. The latter case shows a dramatic drop and deterioration in current on the second scan that indicates potential dimerization and precipitation from solution. On subsequent scans dimerization is inhibited by the newly-deposited film, and the observed current drops off noticeably (see Fig. S1). This suggests that 2,2′-bithiophene-5-carboxylic acid is also not capable of polymerizing in its free acid form.

3.4.2. Mononuclear ruthenium(II) 3-thiophenecarboxylates and 2,2′-bithiophene-5-carboxylate, 5–8

The "diphosphine-disassembled" mononuclear ruthenium(II) 3-thiophene-carboxylate and 2,2′-bithiophene-5-carboxylate derivatives, **5**–**8**, were studied under identical conditions to their dinuclear precursors. Fig. 7 shows a set of consecutive cyclic voltammetry scans on complex **6** and while the oxidation potentials, E_{pa}, seem somewhat better resolved and lie at slightly lower potentials, than in the dinuclear derivatives, there does not appear to be any polymerization taking place.

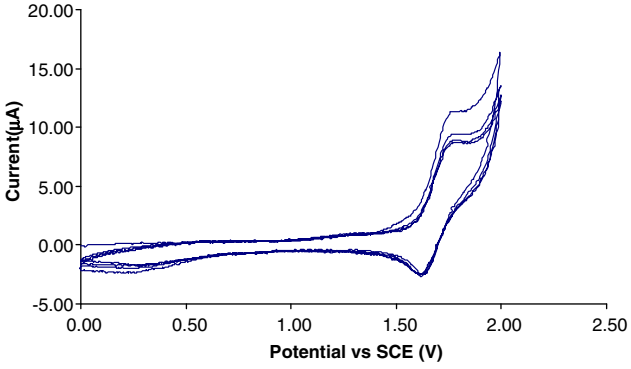

Fig. 7. Consecutive cyclic voltammetry scans for complex **6** in dichloromethane (scan rate = 100 mV/s).

A $Ru^{3+/2+}$ process is evident, centered around 1.65 V. This potential is somewhat high due to the presence of the two π-acidic diphosphine ligands. A thiophene oxidation process is not observed before the upper potential limit (~2 V) is reached. Repeated potential cycling of complexes **5** and **7** also yielded no evidence of polymerization. Presumably, the inductive nature of the carboxylate group is sufficient to elevate thiophene's oxidation potential beyond the point at which it can effectively undergo coupling. It is also possible, particularly for complexes **5** and **6**, that the degree of steric crowding imparted by the diphosphines inhibits access to the thiophene thereby preventing any possible coupling reaction.

Contrary to the behaviour of complex **4**, the "disassembled" 2,2′-bithiophene-5-carboxylato derivative, **8**, shows no evidence of polymerization either and its profile looks similar to those of complexes **5**–**7** (see Fig. S2). The inability of complex **8** to polymerize was not a surprise. The dinuclear ruthenium complex, **4**, has four available thiophene groups for coupling reactions. In the disassembled monoruthenium product, there is only one available carboxylate ligand but because of the substituents in the 2-position with respect to the sulfur (as in 2-thiophenecarboxylate), the structure allows for, at most, dimerization. The potential values for **5**–**8** are summarized in Table 6 and compare well with those previously measured in our lab for the complex $[Ru(\eta^2\text{-}O_2CCH_3)\text{-}(dppe)_2]PF_6$ which displays $E_{pa} = 1.70$ V versus SCE and $E_{pc} = 1.60$ V ($E_{1/2} = 1.65$ V) [9].

3.5. Further polymer characterization

Due to the aforementioned polymerization of complex **4**, further electrochemical and spectral studies were performed. Additional polymer films were synthesized *via* electrochemical polymerization of the complex in boron trifluoride diethyl etherate ($BF_3 \cdot OEt_2$) without added electrolyte. The use of this solvent has been reported in the preparation of several different metallopolymers involving thiophene-substituted transition metal complexes, in part due to its ability to stabilize radical cation intermediates formed during oxidation, as evidenced by lower E_{pa} potentials [25–27]. A cyclic voltammogram showing the electropolymerization of complex **4** in $BF_3 \cdot OEt_2$ is shown in Fig. 8 (top). The polymer was also grown on an indium tin oxide (ITO) transparent electrode from this same solution in order to perform UV–Vis spectroscopy on the film. This can be seen in Fig. 8 (bottom) where the much larger current is due to this electrodes' substantially larger surface area. In both figures, a growth in current with increasing scan number is evident, reflecting the deposition of a thicker electroactive polymer film onto the electrode surface with each scan [28].

The polymer-coated electrode was then removed from the polymerization medium and placed into a fresh solution of 0.10 M Bu_4NPF_6 in dichloromethane. A series of potential scans was performed in order to probe the elec-

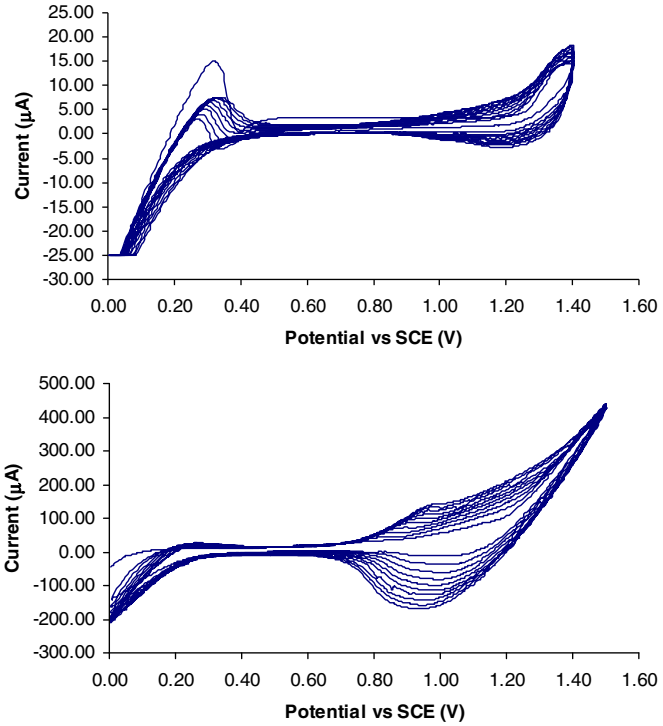

Fig. 8. Consecutive cyclic voltammetry scans for complex **4** in $BF_3 \cdot OEt_3$ on a (top) Pt electrode and (bottom) ITO electrode.

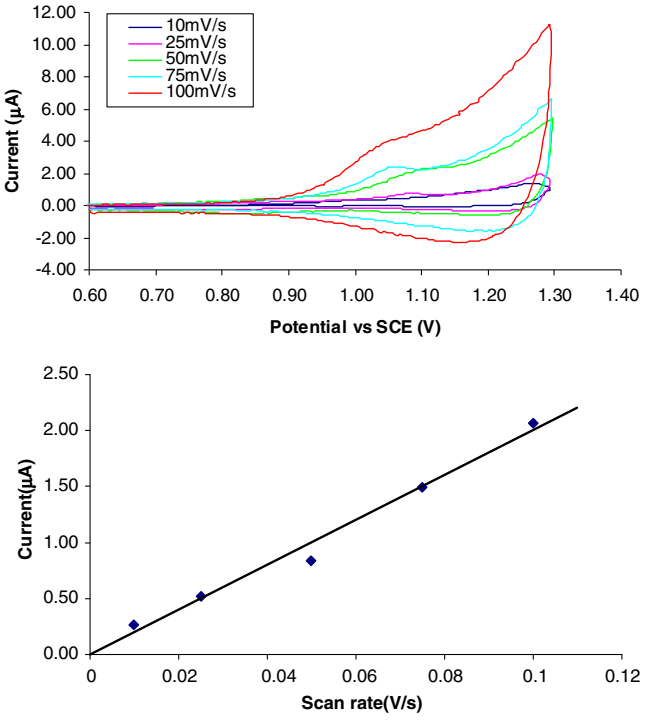

Fig. 9. (Top) Cyclic voltammograms for a "poly[Ru_2(μ-2,2′-bithiophene-5-carboxylate)$_4$(EtOH)$_2$]"-coated Pt electrode at varying scan rates in dichloromethane. (Bottom) Plot of peak current vs. scan rate for the system above.

trochemistry of the newly-formed polymer. Studies carried out over a range of scans speeds (Fig. 9, top) demonstrate a linear relationship between current and scan rate, confirming that the observed electrochemistry results from surface-confined sites [29,30]. The Randles–Sevcik equation describes diffusional behaviour for a species in solution ($i_p = 2.69 \times 10^5 n^{3/2} A D^{1/2} C \upsilon^{1/2}$, where n is the number of electrons transferred, A is the area of electrode, D is the diffusion coefficient, C is the concentration and υ is the scan rate). Since this is clearly not the case for our system (Fig. 9, bottom) this result, in conjunction with the results of the above polymerization experiment, suggest an electroactive polymer coating. Visual inspection of the electrode revealed a dark, insoluble film on its surface.

Fig. 10 shows the UV–Vis spectra for complex **4** and its polymer. The peak at 354 nm arises from what is likely a π–π* charge-transfer transition within the bithiophene ring system. The molar absorptivity (ε) for this transition is $4.0 \times 10^4\ M^{-1}\ cm^{-1}$. The two smaller peaks at 237 and 255 nm are also most likely due to weaker π–π* charge transfer processes occurring within the bithiophene ring with absorptivities of 1.45×10^4 and $1.42 \times 10^4\ M^{-1}\ cm^{-1}$, respectively. The spectrum of the polymer (Fig. 10, bottom) was performed using a transparent ITO coated glass electrode, upon which the polymer was grown. In this spectrum the primary charge-transfer band is shifted to 393 nm. The red shift is attributed to the longer conjugation path in the polymerized form. As the monomer units link together, the π orbital system becomes further delocalized, lowering the energy of the system, and thus lowering

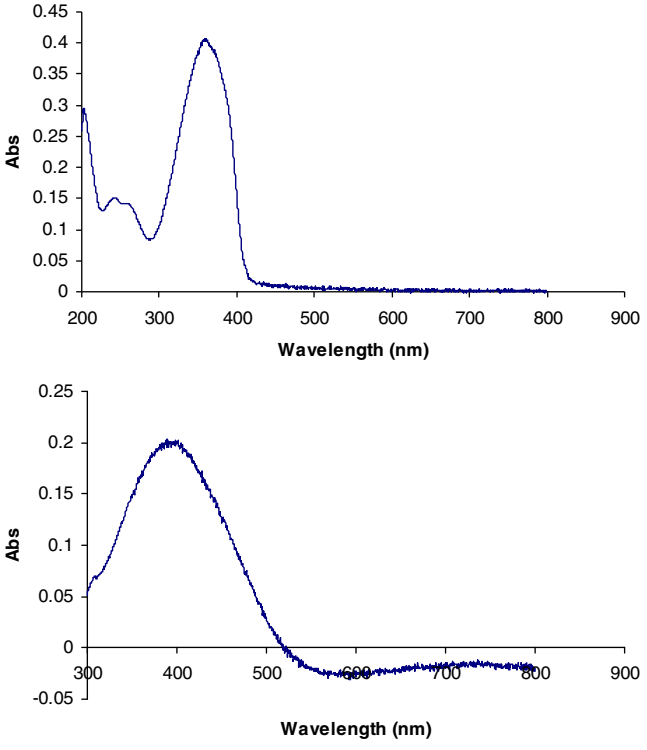

Fig. 10. (Top) UV–Vis spectrum of [Ru_2(μ-2,2′-bithiophene-5-carboxylate)$_4$-(EtOH)$_2$](PF$_6$), **4**, in ethanol (1.00×10^{-5} M, 20 °C). (Bottom) UV–Vis spectrum of "poly[Ru_2(μ-2,2′-bithiophene-5-carboxylate)$_4$(EtOH)$_2$]" on an ITO electrode at 20 °C.

the energy of the absorption process. The broadening of the peak can be explained by cross-linking reactions. The molar absorptivities for the polymer could not be determined as the spectrum was taken of a transparent solid of unknown concentration. The wavelength of this transition is close to the data reported for a solution-phase study for tetrathiophene (394 nm) [31]. It is expected that tetrathiophene linkages will be formed during anodic polymerization. It is acknowledged here that comparisons between solution-phase data and solid-state data must be made with caution, due to differences in solvent-chromophore interactions and the presence of counterions in the polymer film.

4. Conclusion

We have synthesized and characterized eight thiophene-carboxylate-containing complexes; four dimers of the form $[Ru_2(\mu\text{-}O_2CR)_4(alcohol)_2]PF_6$ which were made via a facile carboxylate exchange reaction and four monomers of the form $[Ru(\eta^2\text{-}O_2CR)(dppe)_2]PF_6$ which can be synthesized in moderate to high yield by a disassembly process (R = $-C_4H_3S$, $-CH_2C_4H_3S$, $-CH{=}CHC_4H_3S$ and $-C_8H_5S_2$). All complexes were characterized by IR and elemental analysis and the four monomers were also characterized by NMR and X-ray crystallography. In the six compounds containing mono-thiophene ring systems, cyclic voltammetry scans showed no evidence of oxidative polymerization of the attached thiophene groups possibly due to the very high thiophene oxidation potential in the dinuclear derivatives and a combination of high oxidation potential and steric hindrance in the mononuclear disassembled products. Interestingly, the dimer complex containing the bithiophene ring system, 2,2′-bithiophen-5-carboxylate, was able to be polymerized by anodic polymerization and thin films were produced in both dichloromethane and $BF_3 \cdot OEt_2$. The ability of **4** to undergo polymerization is presumably due to the lower oxidation potential of its bithiophene substituents compared to those present in **1**–**3**. The availability of four polymerization sites in the lantern complex, **4**, permits multiple linking reactions, contrary to its mono-ruthenium analogue, **8**.

clear species with four pendent SCN^- and two ppz coordinating Co(II) center through N atoms resulting an octahedral coordination environment, to the contrary of our expectation. Interestingly here ppz gets protonated owing to charge neutrality and debars SCN^- bridging resulting a supramolecular network. Assuming the source of the proton as NH_4^+ ions in the solution we have planned to prevent the protonation using NaSCN instead of NH_4SCN. A similar reaction in the identical condition leads **II**, a polymorph of **I** (Fig. 1).

2. Experimental

2.1. Materials

All the chemicals used were of AR grade.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were measured from KBr pellets on a Nicolet 520 FT-IR spectrometer. Thermal analyses were carried out on SDT Q600 TA instrument.

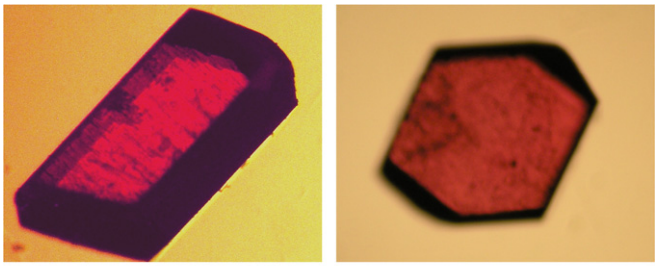

Fig. 1. Polymorphs **I** and **II** with distinct morphology.

2.3. Synthesis

Polymorph **I** was prepared using diffusion technique. A methanolic solution (10 mL) of ppz (1 mmol, 0.086 g) was diffused on an aqueous layer (10 mL) of $Co(NO_3)_2 \cdot 6H_2O$ (1 mol, 0.291 g) and NH_4SCN (2 mmol, 0.152 g) in a tube. Pink crystals suitable for X-ray analysis were obtained at the junction of the two solutions after a few days. Polymorph **II** was synthesized adopting the same reaction procedure as in **I** using NaSCN instead of NH_4SCN. Yield: 75% for **I** and 72% for **II**. *Anal.* Calc. for $C_{12}H_{22}CoN_8S_4$: C, 30.93; H, 4.72; N, 24.05. Found: C, 30.44; H, 4.63; N, 24.39% for **I** and C, 30.42; H, 4.62; N, 24.37% for **II**.

2.4. Crystallographic data collection and refinement

Single crystals of the polymorphs were mounted on a Bruker Smart and Crysalis (Oxford Diffraction) diffractometer for polymorphs **I** and **II**, respectively, equipped with a graphite monochromator and Mo Kα ($\lambda = 0.71073$ Å) radiation. The structure was solved using Patterson method with the help of SHELXL software package. The correct position for the cobalt atom was deduced from an E-map. Subsequent difference Fourier synthesis and least-square refinement revealed the positions of the remaining non-hydrogen atoms. At this point, a calculation by PLATON showed that there was no missed crystallographic symmetry. Non-hydrogen atoms were refined with independent anisotropic displacement parameters. Hydrogen atoms were placed in "idealized positions" and their

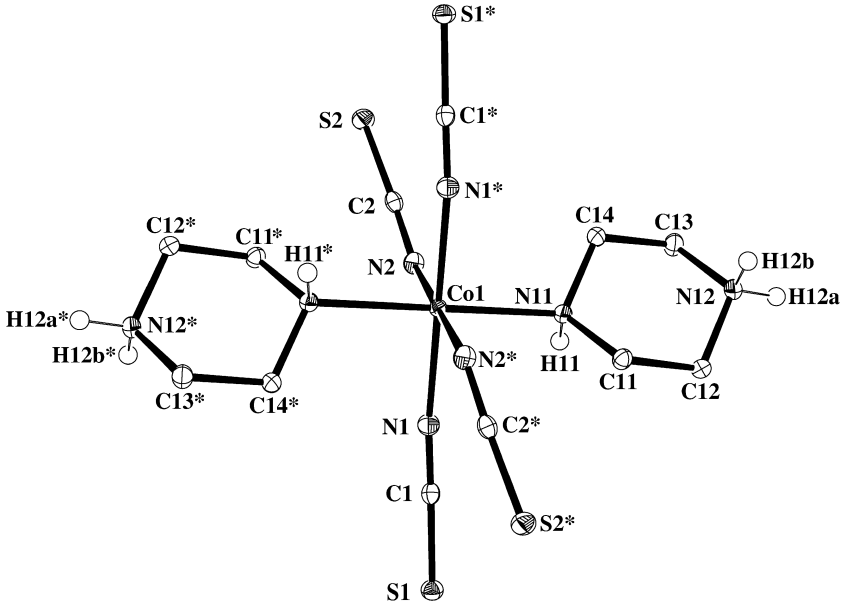

Fig. 2. The ORTEP diagram with 50% ellipsoidal probability for **I**.

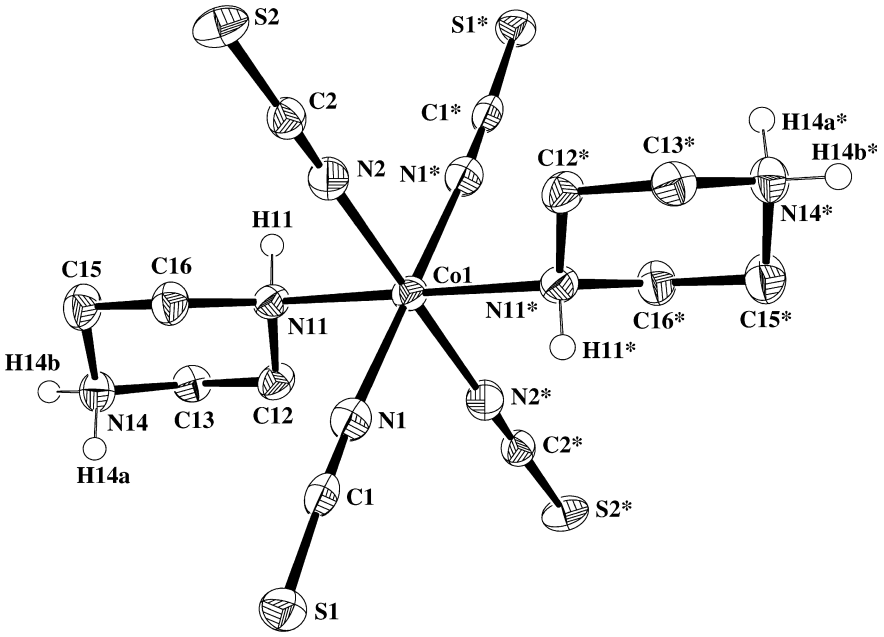

Fig. 3. The ORTEP diagram with 50% ellipsoidal probability for **II**.

displacement parameters were fixed to be 25% larger than those of the attached non-hydrogen atom. Successful convergence was indicated by the maximum shift/error of 0.001 for the last cycle of the least-squares refinement. All calculations were carried out using SHELXL 97 [12], SHELXS 97 [13], PLATON 99 [14], ORTEP-32 [15] and WINGX system Ver-1.64 [16].

3. Results and discussion

3.1. Structural description

ORTEP diagrams for the two polymorphs have been depicted in Figs. 2 and 3. Co(II) centers assume octahedral coordination environments with Co(II) atoms occupying the inversion center in both of them. Interestingly they have the same space group but the unit cell dimensions are slightly different (Table 1) from each other. Four SCN^- molecules and two ppz molecules bind the Co(II) center through their N terminals. SCN^- molecules form the equatorial plane of the Co(II) octahedron and ppz molecules occupy the *trans* axial positions. It is to note that ppz molecules get protonated in both the cases to maintain charge neutrality and this helps in building the supramolecular networks. In **I**, Co(II)–N distances for the equatorial plane are 2.08 Å and 2.18 Å whereas the axial Co(II)–N distance is 2.21 Å. In case of **II**, Co(II)–N distances of the equatorial plane are 2.11 Å and 2.14 Å whereas the axial Co(II)–N distance is 2.25 Å (Table 2). Octahedral geometry of **I** is observed to be more distorted than that of **II**, reflected from the bond angles (Table 2). The angles, N–Co–N′ vary in the range 86.33–92.15° for **I** and 88.76–90.56° for **II**. Most prominent distinction between **I** and **II** is the angle of SCN^- alignment with respect to the *trans* equatorial line passing through N–Co–N′ (Scheme 1) of the Co(II) octahedral coordination environment. Two SCN^- ions make 15.41° and 50.39° angles with this direction in **I** but these

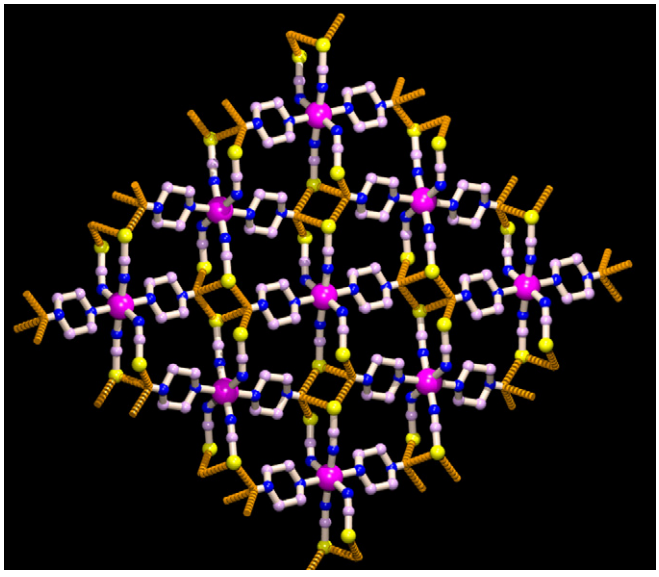

Fig. 4. Trifurcated N–H···S hydrogen bonds form 2D layers (1 0 1) in **I**.

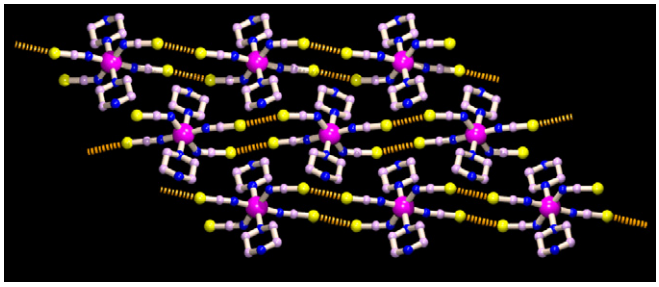

Fig. 5. 2D layers (1 0 1) of **I** viewed as side-by-side alignment of S···S interaction mediated supramolecular 1D ribbons.

are very small, i.e. 3.51° and 8.67° in **II** (Table 2). The angular differences produce a near parallel alignment of coordinated SCN^- ions in **I**, and nearly perpendicular alignment in **II**.

Occurrence of two supramolecular assemblies in case of polymorphs **I** and **II** are due to difference of SCN^- alignment in the outer coordination sphere. In **I** the monomer fragments interact with each other through rarely observed trifurcated hydrogen bonding (N12–H12A···S1; N12–H12A···S2; N12–H12A···S1; Table 3) leading to 2D supramolecular sheet (Fig. 4). The sheets are in (1 0 1) planes. This hydrogen bonding cooperation has been reinforced by S···S interactions, operating between SCN^- ions of adjacent Co(II) centers. The 2D sheet can be viewed as the parallel alignment of 1D supramolecular chains, generated through S···S weak forces (Fig. 5). The S···S distances are 3.6032(4) Å for S1···S2* (* = x, $-1 + y$, z) and 3.6033(4) for S2···S1** (** = x, $1 + y$, z) which are less than the sum of the van der Waals radii of S atoms [17]. Due to the relative angular alignment of successive Co(II) centers, the 2D sheet is actually a thick layer with the

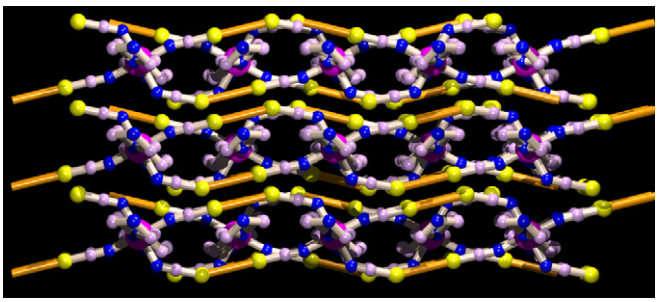

Fig. 6. Stacking of 2D layers in **I** along [1 0 1] (S atoms lie on the edges of the layers with boundaries demarcated by S···S interaction).

SCN^- ligands from adjacent units interacting through S···S interactions and remains nearly parallelly aligned on the two faces of this layer (Fig. 6). The thick layers are stacked along [1 0 1] direction facilitated by inter layer N–H···S and N–H···N hydrogen bonding (Table 3, Fig. S1).

Nearly perpendicular alignment of SCN^- in the outer coordination sphere generates a distinctly different supramolecular assembly in case of **II**. N–H···S hydrogen bonds between adjacent monomers lead to a (4, 4) net topology of the supramolecular 2D sheets (in 1 1 0 plane) parallelly linked through N–H···S hydrogen bond resulting a 3D supramolecular network (Table 3, Figs. 7 and 8).

3.2. Thermal analysis

The thermogravimetric analyses of **I** and **II** (Figs. 9 and 10) reveal that both the polymorphs have identical

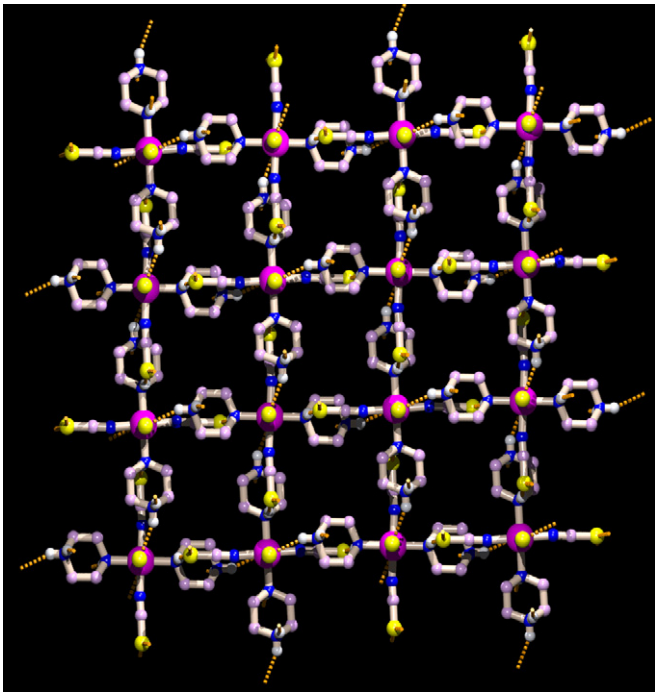

Fig. 7. Supramolecular arrangement leading to assembly in (1 1 0) plane with (4, 4) net topology through N–H···S hydrogen bonding in **I**.

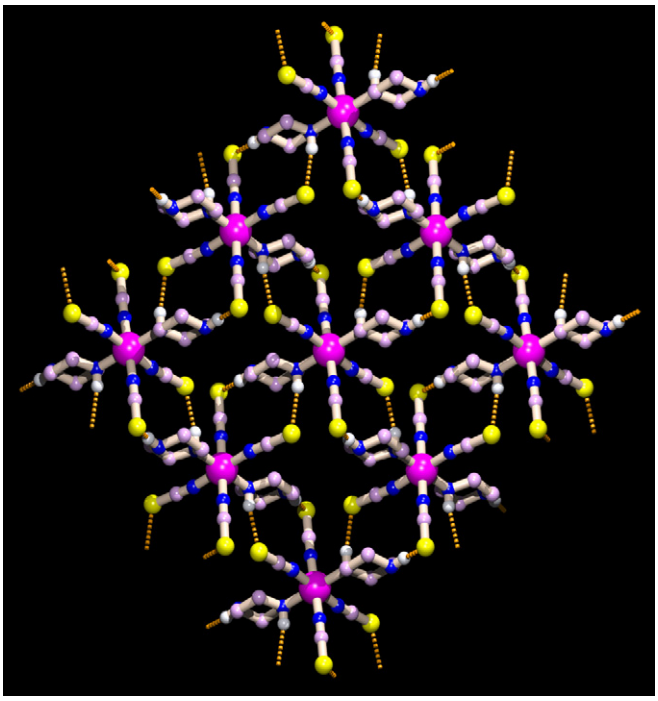

Fig. 8. Details of N–H···S hydrogen bonding between adjacent monomers in **II** (viewed along *a* axis).

decomposition pattern but **I** has slightly higher decomposition temperature (~260 °C) than that of **II** (~282 °C). The DSC curve of **I** does not show any phase transition before decomposition whereas, **II** shows small endothermic pick ($\Delta H = 5.228\ J\ g^{-1}$) in the temperature range, 208–228 °C indicating **II** → **I** transformation. We have run the cooling curve which does not show any phase transition. The room temperature IR spectra of **I** and **II** (Figs. S2 and S3) show a noticeable difference in the ν_{CN} band of SCN^-. There is only one band at 2100.34 cm^{-1} in **I** but **II** shows two bands at 2086.84 cm^{-1} and 2021.26 cm^{-1}. The thermally induced transition [**II** → **I**] is also corroborated by the IR spectra. The room temperature IR spectra immediately after heating **II** at 222 °C show (Fig. S4) only one band at 2108.05 cm^{-1} in the 1900–2300 cm^{-1} region, which is nearly identical to that of **I**. We have also recorded the same spectrum at room temperature after storing the above heated sample at open atmosphere for ~50 days, which shows the reappearance of the IR band at 2023.19 cm^{-1} (Fig. S5) close to the original band at 2021.26 cm^{-1}, showing time dependent reversibility. The foregoing facts suggests polymorph (II) reverts slowly. Thereby we can assume that the polymorphs are enantiotropically related and polymorph **II** is the thermodynamicly stable form at temperatures below the phase transition. This is a counter intuitive considering the higher decomposition temperature and higher density of **I** with respect to **II**, but this kind of anomaly is not uncommon [18] and deserves further investigation.

4. Conclusion

The study shows that for coordination complexes, flexible alignment of pendant ligands is an important fact that needs to be considered which is often overlooked. In the present case the flexible alignment of pendant SCN ligands in the outer coordination sphere is probably the root for the appearance of two polymorphs. The polymorphism phenomenon shows how relatively weaker forces, i.e. S···S interactions cooperate with rare trifurcated hydrogen bond and produce distinctly different packing pattern indicating the urgency of understanding as well as controlling

such weak forces in any successful crystal engineering endeavor.

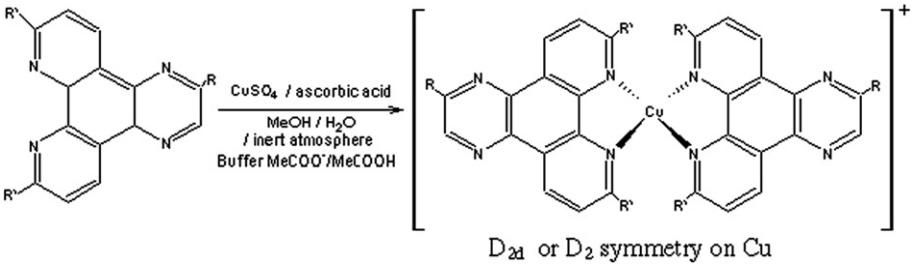
copper(I)–polypyridine type complexes, the absorption characteristics of the MLCT band depends on the symmetry of the ground state, whereas the properties of the excited state strongly depend on the structural distortions following the change in the formal oxidation state after excitation. Different structural and chemical properties, and the coordination ability of the solvents, have been used to modulate the geometry distortions of the ground and excited state [2–6]. This line of research on the Cu–polypyridine family has been reviewed by Meyer et al. up to 1999 [7]. More recently, the dynamics of the distortion process on the photo excited MLCT state of the $[Cu(I)(dmp)_2]^+$, dmp = dimethylphenanthroline, has been investigated both experimentally and theoretically [8]. Using pulsed X-Ray, a transient five-coordinated MLCT state was proposed to have the coordination geometry of a distorted trigonal bipyramid [8a].

The plasticity of the coordination sphere in copper complexes has also been used to investigate specific changes in the microenvironments of electroactive and/or photoactive cores, by studying the size effect of the dendritic core in Cu(I)–polypyridine dendrimers [9].

Coppens et al. [10] with the aim to quantify the Cu coordination environment distortion, defined a distortion parameter ξ_{CD} and found an inverse correlation between the ξ_{CD} value for the ground-state geometry of $[Cu(bfp)_2]^+$ complex, bfp = 2,9-bis(trifluoromethyl)-1,10-phenanthroline, and its ^{3}MLCT excited-state lifetime. A more quantified relationship between structural changes and oxidation state has also been established [11]. Very recently, in order to further elucidate the role of the ligand structure in defining the photophysical properties of $[Cu(NN)_2]^+$ type complexes, Armaroli et al. [12], synthesized two novel phenanthroline ligands characterized by the presence of bulky aryl substituents in the 2,9-positions. The Cu(I) homoleptic complex with the most bulky substituent, shows an unusual absorption spectrum since the intensities of the characteristic band in the range 440–470 nm and the low lying shoulder (500–600 nm) are inverted, so the most prominent band is centered at 560 nm while that at 444 nm appears as a weak shoulder. This spectrum is similar to that of a Cu(I)–catenate complex, which presents a low symmetry, that is, a strongly distorted tetrahedral geometry.

In this context, the present work reports the synthesis, and the spectroscopic and electrochemical characterization of homoleptic copper(I) complexes with substituted pyrazino[2,3-*f*]-1,10-phenanthroline, RpplR′ (R = H, Me, COOMe, and R′ = H, Me) as ligand (Scheme 1).

The ligand ppl (which can be seen as a "fusion" of a bipyridine and a quinoxaline moiety or a phenanthroline and a pyrazino moiety) has been formerly reported by our research group and others [13]. It works as an acceptor of electronic density, which is delocalized mainly on the quinoxaline ring of its structure [13]. This fact should improve the directionality of the electron transfer of the MLCT excited state in the copper complexes. The use of a substituent (R) in the quinoxaline moiety was in order to evaluate its effect on the ground and excited state properties; in the case of R = COOH, the group was envisioned as an anchoring group to a semiconductor oxide electrode, in a potential application of the complex as dye in a solar conversion cell. On the other hand, R′ = Me in the phenanthroline moiety of the ligand is used in order to evaluate comparatively the steric effect on the symmetry of the metal center and to avoid the possibility of exciplex quenching of the excited state [7].



2. Experimental

2.1. Materials

1,10-Phenantroline (hydrate), 2,9-dimethyl-1,10-phenantroline and NH_4PF_6 were p.a. Sigma–Aldrich. The rest of the solids were Merck p.a. chemicals; all of them were used as purchased. All solvents were Merck p.a.; when needed, they were purified and dried by standard methods [13]. The precursors 1,10-phenanthroline-5,6-dione and 2,9-dimethyl-1,10-phenantroline-5,6-dione were synthesized following reported procedures. The corresponding elemental analysis and ^{1}H NMR spectra were in agreement with the published results [14].

2.2. Physical measurements

Elemental analyses were performed on a Fisons Instruments Analyzer, model EA 1108/CHNS-O with PC NCR system 3225. UV–Vis spectra were recorded on a Shimadzu, UV-3101 PC Spectrophotometer, IR Spectra on Bruker Vector-22FTIR spectrometer using KBr pellets and ^{1}H NMR Spectra on a Bruker AC/200 (200 MHz) or Bruker

Scheme 1.

Aspect 400 MHz spectrometer, using CD_3CN or CD_3Cl as solvent and TMS as reference. ESR spectra were recorded in the X band (9.7 GHz) using a Bruker ECS 106 spectrometer with a rectangular cavity and 50 kHz field modulation.

Cyclic voltammetry experiments were carried out using a Bas CV-50W-2,3-MF-9093 equipment with a three-electrode arrangement with a platinum wire, a platinum coil and a Ag/AgCl electrode (in a tetra butyl ammonium chloride solution and adjusted to SCE) as working, auxiliary and reference electrodes, respectively. Experiments were carried out under argon atmosphere, with (TFBTBA) 0.1 M as supporting electrolyte and a scan speed of 200 mV s^{-1}. Emission measurements were carried out in an Aminco SLM-C spectrofluorimeter, at room temperature in Ar atmosphere.

2.3. Synthesis

2.3.1. Ligands

The synthesis of the pyrazino[2,3-*f*]-1,10-phenanthroline (ppl), 2-methylpyrazino[2,3-*f*]-1,10-phenanthroline (Meppl) and 2-carboxylic acid methyl ester pyrazino[2,3-*f*]-1,10-phenanthroline (COOMeppl) were carried out according to Ref. [13]. The pyrazino[2,3-*f*]-2,9-dimethyl-1,10-phenantroline ($pplMe_2$) was synthesized following the same procedure as for the ppl ligand but using 2,9-dimethyl-1,10-phenantroline as starting material. 2-Carboxylic acid pyrazino[2,3-*f*]-1,10-phenanthroline was synthesized as described in Ref. [13], but with the following modifications: after the green solution was poured over ice, the green solid obtained was filtered off and thoroughly washed with water. KOH (1 M) was added to a suspension of the green solid in water until complete dissolution. The solution was filtered and HCl (1:1) added to the supernatant. The white precipitate was filtered off, washed and dried in vacuum. Elemental analysis and ^1H NMR spectra for all the ligands were in agreement with the published results [13]. For pyrazino[2,3-*f*]-2,9-dimethyl-1,10-phenantroline ($pplMe_2$) the results are: Yield: 26.9% *Anal*. Calc. for $C_{16}H_{12}N_4$: C, 73.83; H, 4.65; N, 21.52. Found: C, 72.70; H, 4.67; N, 21.00%. IR (ν_{max}/cm^{-1}): 750, 1391, 1362, 1362. ^1H NMR ($CDCl_3$ as solvent, δ in ppm, J in Hz): 7.64 (d, 2H, H_2, $H_{2''}$, $J_{2,3} = 8.32$), 9.35 (d, 2H, H_3, H_3', $J_{3,2} = 8.32$), 8.90 (s, 2H, H_4, H_4), 2.98 (s, 6H; methyl).

2.3.2. *[Cu(RpplR′)$_2$] PF$_6$ type copper complexes*

General method: The syntheses were carried out following the McMillin general procedure [15]. In a typical synthesis, two degassed solutions, one contains 0.64 mmol of the ligand in 20 ml of methanol and the other one containing 80 mg (0.32 mmol) of $CuSO_4 \cdot 5H_2O$ and 52 mg (0.32 mmol) of NH_4PF_6 dissolved in 10 ml of acetate/acetic acid buffer (0.05 M) were mixed. A green solution was obtained. The solution was degassed and the system maintained in Ar atmosphere. Excess of ascorbic acid (0.48 mmol) was added to the mixture and a reddish-violet solid suddenly precipitated. The solid was collected by vacuum filtration, washed with degassed water, methanol and finally with ethyl ether. The solid was then dried in vacuum and kept under nitrogen or argon. All the steps were carried out under an inert atmosphere.

Bis(pyrazino[2,3-*f*]-1,10-phenanthroline)copper(I) hexafluorophosphate, $[Cu(I)(ppl)_2]$ PF_6 (**1**) Yield: 96.5%. *Anal*. Calc. for $[Cu(I)(C_{14}H_8N_4)_2]PF_6$: C, 49.92; H, 2.39; N, 16.64. Found: C, 49.96; H, 2.16; N, 16.96%. IR (ν_{max}/cm^{-1}): 740, 841, 1391, 1467, 1581.

3. Results and discussion

Following McMillin's general procedure [15], it was possible to synthesize four new homoleptic complexes of Cu(I) with substituted pyrazino[2,3-*f*]-1,10-phenanthroline, RpplR′, as ligand. Elemental analysis results were in good agreement with the proposed formula for the complexes giving therefore evidence of their purity. The IR spectra of the complexes exhibit the characteristic bands of the corresponding free ligands, except for showing the effect of coordination to the metal. All the metal-complexes display a strong band at 841 cm^{-1} characteristic of the PF_6^- ion.

The ^1H NMR spectra of the complexes display signals at the same region than that for the corresponding free ligands; nevertheless, since the signals are wide, no unambiguous assignment was possible. Initially we supposed that, although the species were manipulated under inert atmosphere, it was not possible to discard the presence of paramagnetic Cu(II) species as an explanation of the low resolution of the spectra; *nevertheless, a silent EPR*[1] for the complexes (not shown) indicated the definitive absence of Cu(II) species. This result was in agreement with the fact that on the NMR spectra, although the signals corresponding to the complexes are wide, the ones corresponding to the solvent were not. A fluxional process as the reason for the observed NMR behavior was postulated. To prove

[1] EPR spectra conditions: Center field: 3250.500 G; sweep width: 1000.000 G; frequency: 9.750 GHz; receiver gain: 74 dB; modulation amplitude: 0.87 G; sweep time: 41.943 s.

this possibility, a VT NMR study was accomplished. Fig. 1 shows the results for the [Cu(I)(Meppl)] PF_6 compound.

The figure shows that at low temperature the signals sharpen, some of them resolve given support to the fluxionally hypothesis. Added to this fact (or maybe related with it) and considering that the RpplR′ ligands have an acceptor character, and that the experimental evidence indicates that even in the ground state (at room temperature) the Cu(I) geometry is distorted towards the Cu(II) preferred geometry, our interpretation is that it is possible to think that the complex presents a type of "internal paramagnetism" due to the presence of a more deshielded Cu(I) as consequence of the displacement of the electronic density towards the acceptor RpplR′ ligand.

Fig. 2 shows the electronic absorption spectra of the complexes. All of them display bands in the 400–650 nm range, which are of MLCT character.

According to the analysis of McMillin et al. [16] for similar complexes of $Cu(NN)_2^+$ type, the shoulder around 500 nm should be assigned to the band named as band I. The assignment of this electronic transition is still controversial [17], but it is related to either a static or dynamic flattening distortion ($D_{2d} \rightarrow D_2$ symmetry). The band centered around 450 nm, named as band II, is associated to an $e(xz, yz) \rightarrow e(\pi^*L)$ excitation on a D_{2d} symmetry or $b(yz) \rightarrow b_2(\pi^*L)$ on D_2 symmetry. The band named as band III, which appears around 380 nm in other polypyridine systems, seems to be, in our case, overlapped with a LC band in the proximity of 350 nm. The UV zone shows ligand centered $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ bands around 250, 300 and 350 nm. Table 1 summarizes the λ_m absorption data for band II.

As in the case of homoleptic and heteroleptic complexes of Ru (II) with Rppl as ligand, the λ_{max} of the MLCT band around 450 nm and the LC bands in the copper complexes, do not change significantly with the R substituent [13]; the tendency of the small changes observed cannot be explained in terms of its donor/acceptor character. The changes are minor also at the shoulder around 350 nm, but the red or blue shift is in agreement with the acceptor or donor properties of the substituents respect to the ppl

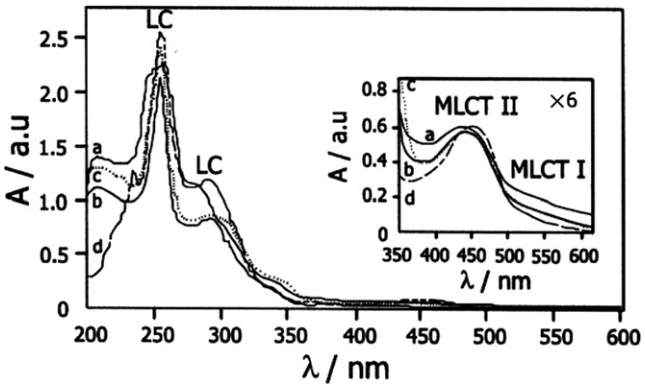

Fig. 2. Electronic absorption spectra of 1.7×10^{-5} M copper complexes solution in CH_3CN as solvent: [Cu(I) (ppl)] PF_6 (a), [Cu(I)(Meppl)] PF_6, (b), [Cu(I)(COOMeppl)]PF_6 (c), [Cu(I)(pplMe)]PF_6 (d); LC ligand centered, MLCT ligand to metal charge transfer.

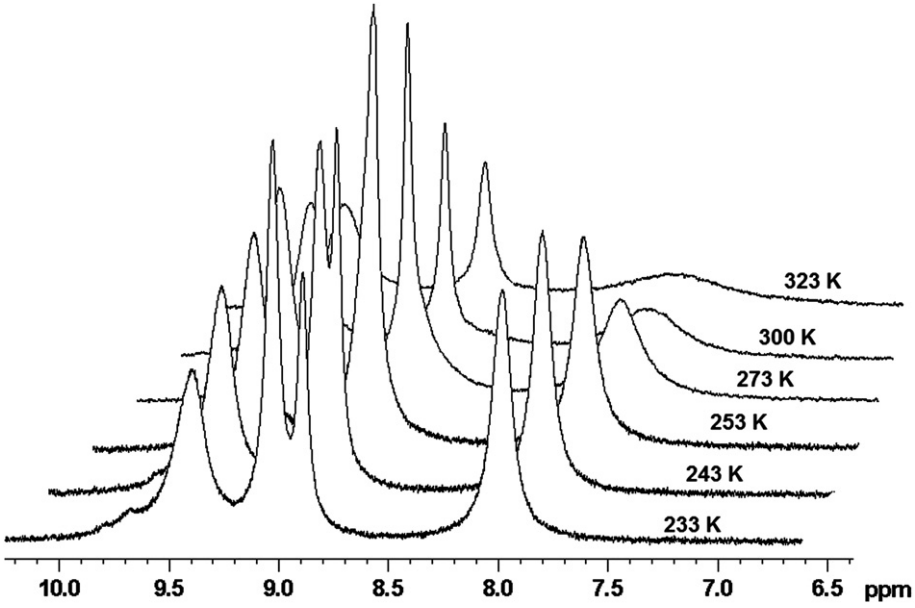

Fig. 1. NMR spectra as a function of the temperature of a [Cu(I)(Meppl)] PF_6, solution in CH_3CN as solvent.

ligand. Changes in the R′ substituents produce a more significant change in the λ_{max} of band II, although not in the way expected for the donor character of the methyl group.

The spectral characteristics of the complexes in Fig. 1, point to a certain degree of D_2 flattened symmetry distortion on the metal center [7,9,12]. If the intensity of the shoulder around 500 nm is taken as a measure of such distortion in the ground state, the observed order for the degree of distortion is $[Cu(I)(ppl)_2]PF_6 > [Cu(I)(Meppl)_2]PF_6 \cong [Cu(I)(COOMeppl)_2]PF_6 > [Cu(I)(pplMe_2)_2]PF_6$.

The above mentioned similar tendency in the electronic absorption spectra of copper complexes and ruthenium complexes with ppl type ligands is less evident when the redox properties are analyzed, since the redox potential of the copper center on the complexes reported herein is affected by the electronic character of R and R′, although the corresponding Ru(II) complexes do not show this behavior [13]; Table 2 shows the electrochemical potentials for the series of complexes.

The redox potentials values do not show the expected correlation with the acceptor or donor electronic character of the substituents on the ligands, *e.g.* the Cu(I)/Cu(II) potential for $[Cu(I)(Meppl)_2]PF_6$ shows a more positive value than that for $[Cu(I)(ppl)_2]PF_6$ or, more surprising, the oxidation process for $[Cu(I)(ppl(Me)_2)_2]PF_6$ is energetically much more disfavored than the same process for $[Cu(I)(COOMeppl)_2]PF_6$. These results, as well as the irreversibility of the redox couples, are not unexpected taking into account the inner-sphere geometric change associated with the change in oxidation state. The relation of the irreversibility of the redox process with the distortion had also been observed electrochemically for some Cu(II) complexes [18]. Karpishin et al. [5a] reported that the absorption spectra of $[Cu(II)(dpp)]^{2+}$ ion, dpp = 2,9-diphenyl-1,10-phenanthroline, shows a low energy shoulder at 750 nm, assigned to a d–d transition and a 575 nm band, assigned to a LMCT. They concluded that $[Cu(II)(dpp)]^{2+}$ remains four-coordinated in solution as it was in the solid states indicated by the X-ray structure. In our case, the electronic absorption spectra of the Cu(II) complexes (not shown)[2] show a visible band centered at ~680 nm with a low extinction coefficient (≈70 cm^{-1} M^{-1}). Although it is difficult to establish the coordination symmetry around copper using visible absorption spectra, the characteristics of this band resembles the band for five or six-coordinated species of Cu(II), giving support to a distortion following the oxidation state change [19,20].

In order to model the solvent dependence of the redox potentials of $[Cu(I)(dmp)_2](PF_6)$, Meyer et al. [7] consider solvent binding equilibrium, following the flattened distortion after the Cu(I)/Cu(II) oxidation. This effect lowers the free energy, making the overall redox process (electron transfer process, distortion of the metal center and coordination of the solvent) more favorable. Therefore, the redox potential values must reflect the balance of the energies associated to all factors affecting the redox process. Consequently, the greater distortion of the Cu(I) site in $[Cu(I)(ppl)_2]PF_6$ ground state relative to $[Cu(I)(Meppl)_2]PF_6$, as seen by absorption spectroscopy, reduces the positive ΔG value associated to the distortion process in the excited state, but not the negative ΔG of the solvent coordination. The effect of both facts favoring the oxidation process, could exceed the effect of the good donor character of the methyl in $[Cu(I)(Meppl)_2]PF_6$, explaining the less positive oxidation potential in the first complex. Otherwise, in the case of $[Cu(I)(ppl(Me)_2)_2]PF_6$ the distortion in the ground state of the Cu(I) center is partially hindered, as well as the distortion after the oxidation process. Consequently the good solvent coordination process and the donor character of the methyl group would not be compensated, explaining its more positive oxidation potential. On the other hand, as expected, the presence of an attractor group produces a change on the redox potentials disfavoring the copper oxidation process and favoring the reduction of the ligand, $E_{pc_{(1)}}$, (*e.g.*: free ppl < -1.5 V; $pplCH_3 < -1.5$ V and COOMeppl $= -1.1$ V). In the same solvent, the Cu(II)/Cu(I) processes for $[Cu(I)(phen)_2]^+$ and $[Cu(I)(dmp)_2]^+$ have a potential of 0.04 V and 0.68 V, respectively [21], as compared with E_{pa} (V) values 0.03 V and 0.4 V values for $[Cu(I)(ppl)_2]^+$ and $[Cu(I)(ppl(Me)_2)_2]^+$, respectively. Therefore, Cu(I) is more unstable with the ppl and $ppl(Me)_2$ ligand. This fact cannot be explained by the acceptor character of the ppl ligand; thus structural effects that would favor Cu(II) type geometry in the ground state should be responsible for this result.

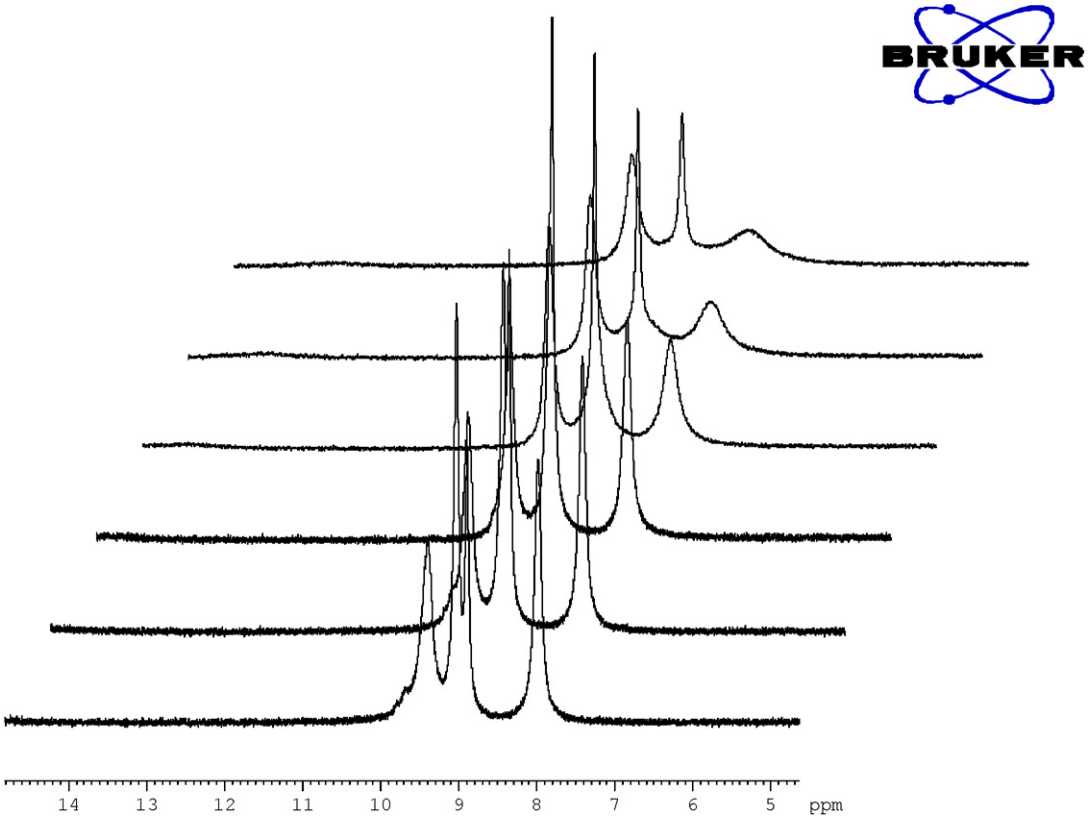
The effect of the solvent on the redox potential values can be seen by comparing the values in two different solvents for the complex with ppl as ligand; as expected from the model described above, the oxidation is more favored in DMSO than in CH_3CN, in accordance with the greater coordination power of the latter solvent.

All complexes studied in this work showed no emission in acetonitrile at room temperature. Although starting

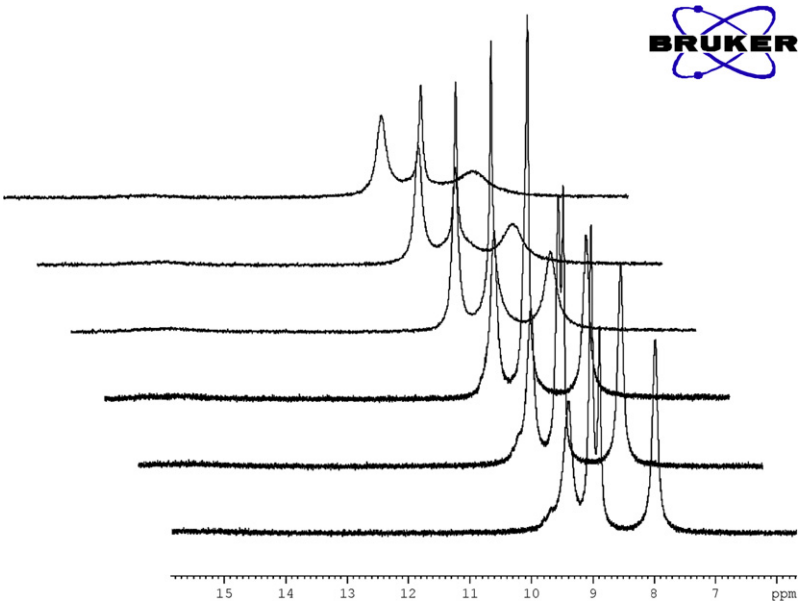
Table 2
Electrochemical properties of $[Cu(I)(RpplR)_2]PF_6$ complexes, vs. SCE in CH_3CN as solvent

Compounds	E_{pa} (V)	E_{pc} (V)	$E_{pc_{(1)}}$ (V)
$[Cu(I)(ppl)]_2PF_6$	0.14	0.03	$\geqslant -1.5$
	0.10[a]	0.05[a]	
$[Cu(I)(Meppl)_2]PF_6$	0.18	0.07	$\geqslant -1.5$
$[Cu(I)(COOMeppl)_2]PF_6$	0.31	0.15	−1.1
$[Cu(I)(ppl(Me)_2)_2]PF_6$	0.59	0.40	$\geqslant -1.5$

[a] In DMSO as solvent; −1.5 is the cathodic limit of the solvent. E_{pa} is assigned to Cu(I)/Cu(II) oxidation. E_{pc} is the corresponding Cu(II)/Cu(I) back process. $E_{pc_{(1)}}$ corresponds to ligand reduction.



[2] $[Cu(II)(ppl)_2](PF_6)_2$ copper complex: the synthesis was carried out following the same procedure as synthesis (b) in Section 2, except for the addition of the ascorbic acid reductor; the solid was precipitated by the addition of NH_4PF_6.



from a distorted ground state, the geometrical change to a more flattened coordination geometry in going to the Franck–Condon state, produced after light absorption (MLTC band), allows the exciplexes quenching process [22]; this explains the non emissive character of the complexes. In this context it was expected that this excited state distortion should be avoided by the steric effect produced by the dimethyl substitution in the 2 and 9 positions in the phenanthroline moiety of the ppl ligand, permitting in this way the $[Cu(I)(ppl(Me)_2)_2]PF_6$ complex to photoluminesce. Nevertheless, no emission was observed even in a less coordinant solvent such as dichloromethane. The excited state behaviour of $[Cu(I)(Meppl)_2]PF_6$ can be compared with the observed for $[Cu(I)(dmp)_2]^+$. In the latter, emission is observed, although with a low quantum yield even in rigid media at low temperature [23]. In spite of the fact that ligand delocalization arguments would predict longer lifetimes and a better excited emissive state [24], the absence of emission in $[Cu(I)(Meppl)_2]PF_6$ is not unreasonable because, as shown above, even in the ground state the geometry of the Cu(I) center in $[Cu(I)(Meppl)_2]PF_6$ is distorted toward the Cu(II) geometry. In general, the photophysical properties of the excited state of some metal polypyridinic type complexes [5b,24,25] reflect the mixture of a variety of electronic (basicity of the donor, electron delocalization) and structural factors (changes in metal-ligand distances, distortion on the metal geometry, change of the coordination number, fluxionally of the ligands). In contrast to ruthenium complexes, structural factors are predominant in the case of copper complexes, influencing even properties related to the ground state, as shown in this work.

Scheme 1. Structural formulae of the ligands.

Scheme 2. Most common coordination modes of picolinato and 3-hydroxypicolinato ligands.

X-ray diffraction in the solid state [17,18]. In accordance with this expectation, two of the picolinate derivatives prepared in present work were isolated as crystalline solids and were studied by diffractometry. Attempts to recrystallize the complex of **3** unexpectedly gave rise to a new derivative containing both $TlMe_2^+$ and Na^+. This new product is, as far as we know, the first heterobimetallic compound of H6hpic$^-$ to be prepared and identified by X-ray diffraction.

2. Experimental

2.1. Materials

Hpic, $H_2$3hpic and $H_2$6hpic were commercial products (Merck, Fluka, Aldrich). $TlMe_2I$ and $TlMe_2(OH)$ were obtained according to the methods reported in the literature [19,20]. All other chemicals were AR grade and were used without further purification.

2.2. Measurements

Elemental analysis (C, H, N) was performed using Fisons 1108 and Perkin-Elmer analyzers. Melting points were determined with a Büchi apparatus and were not corrected. IR [KBr pellets (4000–500 cm^{-1}) and Nujol mulls between polyethylene pellets (500–100 cm^{-1})] and Raman (polycrystalline samples) spectra were recorded on a Bruker IFS-66V spectrometer equipped with an FRA 106 module. ^{1}H and ^{13}C NMR spectra were measured at room temperature on Bruker AMX 300 (operating at 300.14 and 75.48 MHz, respectively) and AMX 500 (operating at 500.14 and 125.77 MHz, respectively) spectrometers using sample solutions in DMSO-d_6. Chemical shifts are reported in ppm and referred to TMS using the solvent signal for ^{1}H and ^{13}C spectra (^{1}H: 2.50 ppm, ^{13}C: 39.50 ppm). Chemical shifts were considered positive at lower applied field.

2.3. Synthesis and characterization

2.3.1. *[$TlMe_2$(pic)]* ***(1)***

An aqueous solution of dimethylthallium hydroxide, prepared from $TlMe_2I$ (0.462 g, 1.28 mmol), was added dropwise to a stirred solution of picolinic acid (0.156 g, 1.28 mmol) in methanol (20 mL). The mixture was stirred for about 8 h and then concentrated with a rotary evaporator until a solid product was formed. Yield: 79%. M.p. 230 °C. *Anal.* Calc. for $C_8H_{10}NO_2Tl$ (356.56): C, 26.95; H, 2.83; N, 3.93. Found: C, 27.02; H, 2.79; N, 3.93%. IR (cm^{-1}): $\nu_s(CO_2)$ 1364 s, ν_{ring}(Py) 1608 m, 1587 m, 1563 m, 1469 w, ν(Tl–C) 525 w, ν(Tl–O) 411 s, ν(Tl–N) 208 w. Raman (cm^{-1}): ν(Tl–C) 497 s, ν(Tl–O) 411 w. ^{1}H NMR $\delta = 0.73$ (d, 6H, $TlMe_2^+$, $^2J_{H-Tl} = 429.5$ Hz), 7.58 (dd, 1H, H^5, $^3J_{H-H} = 7.12$ Hz, $^4J_{H-H} = 1.23$ Hz), 7.95 (td, 1H, H^4, $^3J_{H-H} = 7.64$ Hz, $^4J_{H-H} = 1.64$ Hz), 8.04 (d, 1H, H^3, $^3J_{H-H} = 7.70$ Hz), 8.66 (d, 1H, H^6, $^3J_{H-H} = 4.49$ Hz). ^{13}C NMR $\delta = 124.4$ (C^3), 124.7 (C^5), 137.4 (C^4), 147.6 (C^6), 155.0 (C^2), 167.8 (C^7). The carbon signal of the $TlMe_2^+$ moiety was not observed.

Crystals suitable for single-crystal X-ray diffraction studies were obtained by recrystallization from the methanol solution of the crude product.

2.3.2. *[$TlMe_2$(H3hpic)]* ***(2)***

An aqueous solution of dimethylthallium hydroxide, prepared from $TlMe_2I$ (0.460 g, 1.30 mmol), was added dropwise to a stirred solution of 3-hydroxypicolinic acid (0.180 g, 1.30 mmol) in methanol (25 mL). The final mixture was stirred for about 8 h and then concentrated with a rotary evaporator until a solid product was formed. Yield: 70%. M.p. 270 °C. *Anal.* Calc. for $C_8H_{10}NO_3Tl$ (372.56): C, 25.79; H, 2.71; N, 3.76. Found: C, 25.78; H, 2.66; N, 3.71%. Crystals suitable for X-ray diffraction studies were obtained by recrystallization of the crude product from methanol.

2.3.3. *[$TlMe_2$(H6hpic)]* ***(3)***

An aqueous solution of dimethylthallium hydroxide, prepared from $TlMe_2I$ (0.469 g, 1.27 mmol), was added dropwise to a stirred solution of 6-hydroxypicolinic acid (0.177 g, 1.27 mmol) in methanol (30 mL). The final mixture was stirred for about 8 h and then concentrated with a rotary evaporator until a solid product was formed. Yield: 63%. M.p. 241°C. *Anal.* Calc. for $C_8H_{10}NO_3Tl$

(372.56): C, 25.79; H, 2.71; N, 3.76%. Found: C, 26.24; H, 2.58; N, 4.07%. IR (cm^{-1}): $\nu_s(CO_2)$ 1385s, ν_{ring}(Py) 1592 m, 1556 m, 1520 m, $\nu(C_{Py}–OH)$ 1240 m, ν(Tl–C) 520 sh, ν(Tl–O) 342 m. Raman (cm^{-1}): ν(Tl–C) 487 s. The poor solubility of this complex in DMSO prevented the measurement of its NMR spectra.

When the crude product was recrystallized from methanol, a few single crystals of $[NaTlMe_2(H6hpic)_2]$ (**3′**) were obtained after a very slow solvent evaporation of almost a year being one of which suitable for X-ray diffraction studies. It is plausible that the Na^+ cation present in the compound comes from the NaOH solution used in the preparation of Me_2TlOH.

2.4. Crystallographic data collection and structure determination

Data collection and processing were carried out using an Enraf-Nonius CAD 4 diffractometer with a graphite-monochromated Mo Kα radiation source ($\lambda = 0.71073$ Å). Details of the crystal structure determination and refinement for all three compounds are given in Table 1. The intensities were corrected for Lorentz polarization factors. The structures were solved using a Patterson method for heavy atoms and refined by full matrix least-squares methods for the location of the remaining non-hydrogen atoms (SHELX 97 [21]). All of the non-hydrogen atoms were treated anisotropically. All hydrogen atoms were included in the model at geometrically calculated positions. The maximum height around Tl atom in the final ΔF map was 6.4 e $Å^{-3}$ at a distance of 0.30 Å of the heavy atom. The drawings were obtained using the ORTEP [22] and MERCURY [23] programs.

3. Results and discussion

3.1. Crystal structures

The crystal structures of compounds **1** and **2** are shown in Fig. 1 and their bond distances and angles are listed in Table 2.

The asymmetric unit of compound **1** consists of two independent molecules associated as a dimer. In the asymmetric unit of compound **2** there is only one molecule but this is also associated with a neighbouring one (i = $-x$, $-y$, $-z$). In both compounds the ligands are N,O-chelated with the monodentate deprotonated carboxylate groups bridging two dimethylthallium(III) units. In this way, each ligand coordinates one $TlMe_2^+$ unit through a pyridine nitrogen (N11/N21 in **1**, N in **2**) and one carboxylate

oxygen (O12/O22 in **1**, O1 in **2**), with the latter also binding to a second $TlMe_2^+$ unit.

These two complexes exhibit some common features: (a) the structural parameters of the $[TlMe_2]^+$ unit [Tl–C = 2.105(6)–2.127(13) Å, C–Tl–C = 171.4(2)–173.0(6)°] are similar to those found in other $[TlMe_2]^+$ complexes with N,O or O,O donor ligands [17,24,25]; (b) the Tl–N distances [2.567(11), 2.586(10) and 2.678(5) Å] are close to or shorter than those found in $[TlMe_2(phen)](ClO_4)$ [2.75(2) Å] [26] and $[TlMe_2(Py)_2CH_2]NO_3$ [2.658(9), 2.666(9) Å] [27] although they are longer than those in $TlMe_2^+$ complexes with other hydroxy pyridine carboxylic acids [11,18]; (c) the Tl–O bond lengths in the dimers, in the range 2.501(9)–2.665(8) Å, are comparable with those in other $TlMe_2^+$ carboxylate complexes [17,18]; (d) the weak interactions between the metal and the second atom of the $-COO^-$ group (O11/O21 in **1** and O2 in **2**) associate the dimers to give a polymeric chain along the *x*-axis (see Fig. 2 for compound **1**). The distance between Tl and O(2)^{i} [3.462(5) Å] in **2** is too close to the sum of the van der Waals radii {Tl–O = 3.50 Å [28]} to be considered a significant bonding interaction. The resulting $[C_2NO_3]$ coordination sphere can be described as a very distorted octahedron with the methyl groups in the apical positions (Fig. 2).

In **2** there are also intramolecular hydrogen bonds formed between the hydroxyl O(3)–H(3) group and the oxygen O(2) of the COO^- (Fig. 1b, Table 3).

Despite the structural similarity between the complexes, some small differences between the two compounds are

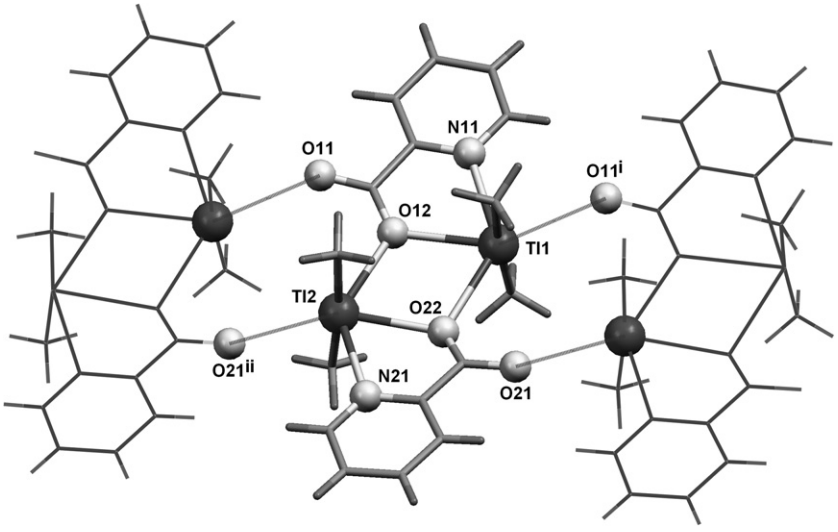

Fig. 2. Fragment of the polymeric chain in **1**.

	N–H···O(3)^{iv}	0.8800	1.9711	2.8148	160.20

(iv) $= -y + 1/2, -x + 1, -z + 1/2$.

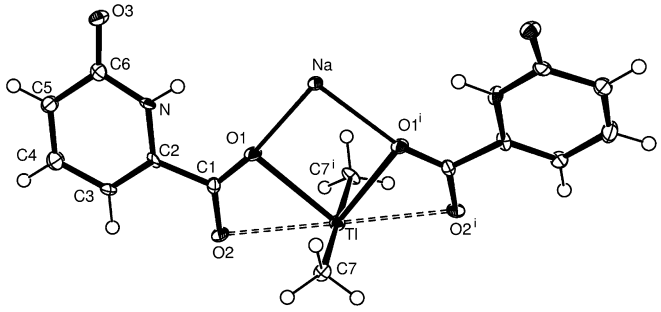

Fig. 3. Asymmetric unit and numbering scheme used for **3′**.

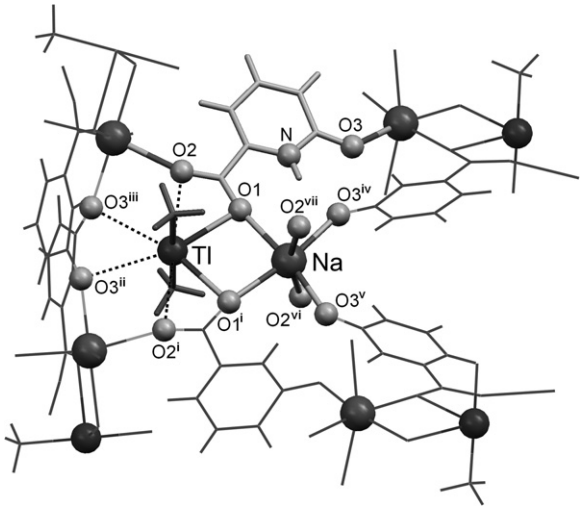

Fig. 4. MERCURY plot showing a fragment of the 3D polymeric arrangement and all the metal–ligand interactions in **3′**.

evident concerning the strength of the primary and secondary M–L bonds. For example, while the Tl–N interaction is significantly shorter in **1**, the intramolecular and intradimer Tl–O bonds are longer. These differences are highlighted in Fig. 1a and b. It is also worth noting that the interdimer secondary Tl···O interactions are shorter in **1**.

The X-ray crystal structure of **3′** is presented in Fig. 3. The asymmetric unit of this compound consists of an H6hpic$^-$ anion (occupation 1) and dimethylthallium(III) and Na^+ cations (occupation 0.5 each). The derivative is a three-dimensional polymer in which the H6hpic$^-$ anions interact with cations through bonding forces that probably have a significant ionic character, at least in the Na^+ case. The picolinate anion with the deprotonated carboxylate group is in the keto form and the presence of a proton on the N atom rules out its involvement in the coordination. As in **1** and **2**, O1 oxygens from the carboxylate groups of two ligands bridge between the two, in this case, heterobimetallic cations to give a four-membered Tl–O1–Na–O1 ring (see Figs. 3 and 4), which in turn leads to a Tl···Na distance [3.70585(11) Å] shorter than the sum of the van der Waals radii (Tl–Na = 4.30 Å) [29,30]. Additionally, the O2 (carboxylate) and O3 (carbonyl) oxygen atoms both interact with Na^+ and, more weakly, with Me_2Tl^+, so all three oxygens of the picolinate ligand are simultaneously in close, and probably ionic, contact with both metallic cations (see Fig. 4). The C_2O_6 atoms around the thallium form a distorted hexagonal bipyramid with the apical methyl groups [C–Tl–C = 179.0(6)°], while the six oxygen atoms surrounding the sodium ion form a distorted octahedron [O(1)^i–Na–O(3)^{iv} = 170.5(3)°].

Comparison of the ligand moiety with free $H_2$6hpic [31] highlights the following structural changes: (i) deprotonation of the –COOH group leads to the expected modification in the carbon–oxygen bond distances (two unequal distances belonging to the C=O and C–OH fragments in the free acid become two almost equal C–O distances in the complex); (ii) the distances in the N–C(6)–O(3) fragment evolve in the complex to the "normal" distances for the keto form [N–C(6) distance increases with respect to the free ligand, which is in an intermediate keto-enol form, while C–O(3) diminishes].

In the lattice, adjacent units of **3′** are also connected through NH···O(1) and NH···O(3)^{iv} hydrogen bonding interactions (see Table 3), which reinforce the three-dimensional network.

3.2. IR and Raman spectra

The main IR (1800–100 cm^{-1}) and Raman (600–100 cm^{-1}) frequencies for complexes **1**–**3** are listed in the Section 2. Assignments were made by comparison with the IR spectra of the free acids and literature data [12,32,33]. The spectra of the complexes lack a band that can be ascribed to the stretching vibration of the C=O bond, an observation consistent with deprotonation of the COOH group and the presence of the enolic form of both H3hpic$^-$ and H6hpic$^-$ ligands. Note that this means that the latter adopts a different tautomeric form in **3** than in **3′**, suggesting that the coordination mode of H6hpic$^-$ in **3** may be similar to that of H3hpic$^-$ in **2** (see Fig. 1). The absorption bands in the 1620–1460 cm^{-1} range in the spectra of the complexes correspond to the strongly mixed [ν(C=N), δ(CN), δ(NH) and ν_{ring}(Py)] modes and these are labelled in Section 2 as ν_{ring}(Py). The difference $\Delta\nu = [\nu(CO_2)_{asym} - \nu(CO_2)_{symm}]$, which correlates with the coordination pattern of the carboxylate group, could not be determined due to overlap of $\nu(CO_2)_{asym}$ with ν_{ring}(Py) in the spectra of the complexes.

Stretching vibrations for the Tl–C, Tl–O and Tl–N bonds in the IR and Raman spectra of all three complexes (see Section 2) are within the range for the $[TlMe_2]^+$ complexes with (N,O)/(O,O) donor ligands [33].

3.3. NMR study

Due to its low solubility in non polar solvents, the NMR spectra of compounds **1** and **2** were recorded in DMSO-d_6. Compound **3**, which is not soluble in this solvent, was not investigated. The assignment of the ^{1}H and ^{13}C resonances listed in Section 2 was carried out with the aid of the ligand spectra, ^{1}H–^{13}C heteronuclear correlations (HMQC and HMBC) and literature data [12]. For the atomic numbering used see Scheme 1.

In the proton spectra of the compounds, the presence of a broad doublet at high field centred at 0.74 ppm for compounds **1** and **2** indicates the presence of the organometallic moiety and the expected 1:1 (ligand/Me_2Tl) molar ratio.

In compound **1**, the absence of a broad signal at 12.40 ppm indicates deprotonation of the ligand. The singlet observed at 15.53 ppm in the spectrum of compound **2**, which accounts for one proton, is displaced 2 ppm downfield with respect to that in the free ligand. The observed connectivity of this signal with C^4, C^2 and C^3 in a HMBC experiment shows that, as in the solid state (see Fig. 1b), in DMSO solution the ligand in **2** is in the enol form.

Analysis of the ^{13}C data and comparison with those of the free acids [34] shows that C^2 experiences a deshielding effect (+6.6 ppm) in **1** and the same occurs with C^7 (+1.6 ppm). Other carbons are shielded (C^6 −1.8, C^5 −2.3 ppm) or are unchanged (C^4 and C^3). In complex **2** the changes observed in the spectrum of the ligand are similar but are more marked than those observed in previously studied complexes of H3hpic$^-$ with the same coordination mode [12]: C^7, C^6 and C^2 are strongly deshielded (+5.9, +3.9 and +5.6 ppm, respectively) and the other carbons, particularly C^4, are shielded (C^4 −6.5, C^5 −2.1, C^3 −0.7 ppm) with respect to those in the acid.

The ^{1}H and ^{13}C chemical shifts of the organometallic moiety, together with the values of the coupling constants $^1J(^{13}C–^{205}Tl)$ and $^2J(^1H–^{205}Tl)$, are in the range found for other dimethylthallium compounds with (N,O)/(O,O) donor atoms [18,33–36].

4. Conclusion

The work described here concerns the synthesis and characterization of dimethylthallium(III) complexes with picolinic, 3-hydroxypicolinic and 6-hydroxypicolinic acids. The compounds were characterized by elemental analysis and vibrational spectroscopy in the solid state. X-ray diffraction studies of compounds **1** and **2** show a distorted octahedral environment, with the metal atom coordinated to the methyl groups and the N and O atoms of the monodeprotonated acid. The thallium coordination is completed by the O atom of a neighbouring ligand, leading to the formation of a polymeric chain in compound **1** and a dimeric association in compound **2**. The latter complex contains intramolecular hydrogen bonds between the remaining hydroxylic hydrogen and one of the oxygen atoms of the carboxylate group.

The solubility of compounds **1** and **2** in DMSO facilitated its study in solution by ^{1}H and ^{13}C NMR spectroscopy. In complex **2** the singlet observed at 15.53 ppm indicates that the enol form of the ligand is present in the solid state remains in solution.

When we attempted to recrystallize compound **3**, only a few crystals of **3′** were serendipitously obtained after very slow evaporation of the solvent. This derivative is a three-dimensional polymer in which the monodeprotonated ligand interacts with the cations through bonding forces that probably have significant ionic character. The coordination sphere around the thallium atom is a distorted hexagonal bipyramid with the methyl groups apical and six

oxygen atoms of four different ligands equatorial. The distorted octahedron that surrounds the sodium ions is formed by six oxygen atoms of six different ligands.

is necessary for the synthesis of the later complexes. As a result, coordination of the carbonate anion is not reversible and decomposition of the complexes takes place by loss of it. These complexes are similar to the previously reported $[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(OCe^{IV}OH_2)_3]^{12-}$[16]. The carbonate anion makes a well-defined bonding interaction with the internal cavity of the sandwich-type complex and on this basis Pope and Müller define these complexes as *cryptates* [3].

2. Experimental

2.1. Chemical and apparatus

All reagents were commercially obtained and were used without further purification. $Na_8H[A\text{-}\alpha\text{-}AsW_9O_{34}]\cdot xH_2O$ was prepared according to the literature [17,18]. Infrared spectra were recorded in KBr disks on a Thermo Nicolet FT-IR model Nexus-670 and NMR spectra were recorded on a BRX-500 AVANCE spectrometer. The resonance frequency is 125.75 MHz for ^{13}C and the chemical shift is given with respect to chloroform as an external standard.

Thermogravimetric Analysis (TGA) and Differential Scanning Calorimetry were carried out using PL-1500 TGA and NETZSCH DSC 200 F3 apparatus, respectively. The electronic spectra were recorded on a Varian, CARY 1E UV–Vis spectrophotometer.

2.2. Complex preparation

2.2.1. $K_{10}Na[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(YOH_2)_3(CO_3)]\cdot 19H_2O$ (**1**)

A 0.45 g (1.5 mmol) sample of $YCl_3\cdot 6H_2O$ was dissolved in 20 mL of twice distilled water, and 2 mL of 1 M Na_2CO_3 was slowly added to the solution with stirring. The slurry was heated to 80 °C, and then solid $Na_8H[A\text{-}\alpha\text{-}AsW_9O_{34}]\cdot xH_2O$ (2.1 g, 0.8 mmol) was quickly added with vigorous stirring. The solution was maintained at 80 °C for 30 min and then cooled to room temperature. Any insoluble material was removed by centrifugation and then solid KCl (3 g) was added to the solution. The solution was cooled in an ice water bath and then filtered off. The crude product was dissolved in a minimal amount of hot water and cooled to 5 °C. This procedure was repeated at least twice (yield: 1.2 g, 37%). Single crystals suitable for X-ray crystallography were obtained from the filtrate of the second recrystallization at 5 °C by slow evaporation. *Anal.* Calc. for $K_{10}Na[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(YOH_2)_3(CO_3)]\cdot 19H_2O$: C, 0.20; K, 6.66; Na, 0.39; As, 2.55; W, 56.4; Y, 4.54; H_2O, 6.96. Found: C, 0.22; K, 6.50; Na, 0.35; As, 2.40; W, 57.0; Y, 4.63; H_2O, 6.80%.

2.2.2. $K_{10}Na[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(YbOH_2)_3(CO_3)]\cdot 17H_2O$ (**2**)

The procedure for **1** was repeated, but $YbCl_3\cdot 6H_2O$ (0.57 g) was used instead of $YCl_3.H_2O$ (yield: 1.3 g, 38%). *Anal.* Calc. for $K_{10}Na[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(YbOH_2)_3(CO_3)]\cdot 17H_2O$: C, 0.2; K, 6.63; Na, 0.39; As, 2.54; W, 56.1; Yb, 8.80; H_2O, 6.10. Found: C, 0.22; K, 6.56; Na, 0.35; As, 2.38; W, 55.1; Yb, 9.54; H_2O, 6.00%.

2.2.3. $K_{10}Na[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(SmOH_2)_3(CO_3)]\cdot 18H_2O$ (**3**)

A 0.55 g (1.5 mmol) sample of $SmCl_3\cdot 6H_2O$ was dissolved in 20 mL of twice distilled water, and 2 mL of 1 M Na_2CO_3 was slowly added to the solution with stirring. Solid $Na_8H[A\text{-}\alpha\text{-}AsW_9O_{34}]\cdot xH_2O$ (2.1 g, 0.8 mmol) was quickly added with vigorous stirring. The solution was maintained at room temperature (30 °C) for 60 min. Any insoluble material was removed by centrifugation and then solid KCl (3 g) was added to the solution. The solution was cooled in an ice water bath and then filtered off. The crude product was dissolved in a minimal amount of warm water and cooled to 5 °C. This procedure was repeated at least twice (yield: 1.1 g, 35%). Single crystals suitable for X-ray crystallography were obtained from the filtrate of the second recrystallization at 5 °C by slow evaporation. *Anal.* Calc. For $K_{10}Na[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(SmOH_2)_3(CO_3)]\cdot 18H_2O$: C, 0.21; K, 6.68; Na, 0.39; As, 2.56; W, 56.6; Sm, 7.71; H_2O, 6.46. Found: C, 0.19; K, 6.59; Na, 0.36; As, 2.37; W, 56.2; Sm, 7.78; H_2O, 6.40%.

2.3. X-ray crystallographic structure determination

Crystal data collection and refinement parameters for **1** and **3** are given in Table 1. The data were collected at 100 K on a Bruker APEX 1000 CCD area detector single crystal diffractometer with graphite-monochoromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data collection, indexing and initial cell refinements were all handled using APEX2 software [19]. The final cell parameters were determined from least-squares refinement on 8521 and 8889 reflections for **1** and **3**, respectively. The multi-scan method was used to carry out absorption corrections. The structures were solved using direct methods and difference Maps techniques (SHELXTL, V5.1) [20]. All metal atoms were refined anisotropically. Scattering factors and anomalous dispersion corrections were taken from the International Tables for X-ray Crystallography [21]. Structure solution, refinement and generation of publication materials were performed by using SHELXTL V5.1 software. Selected bond lengths and bonds angles of **1** and **3** are given in Table 2.

3. Result and discussion

3.1. Syntheses and stabilities

$A\text{-}\alpha\text{-}[AsW_9O_{34}]^{9-}$ reacts with MCl_3 (M = Y, Yb and Sm) in an aqueous Na_2CO_3 solution (0.09 M) to form **1**, **2** and **3** in modest yields, respectively. Monitoring of the reaction solution by pH shows that the pH of the carbonate solution decreases (5.5) with addition of MCl_3 (M = Y,

Yb and Sm) and increases with addition of A-α-$[AsW_9O_{34}]^{9-}$. The trivalent metals react with the carbonate ion to form the corresponding insoluble metal carbonate (the solution becomes turbid) and then A-α-$[AsW_9O_{34}]^{9-}$ reacts with metal carbonate (the solution becomes clearer). In order to establish the compositions of the complexes in

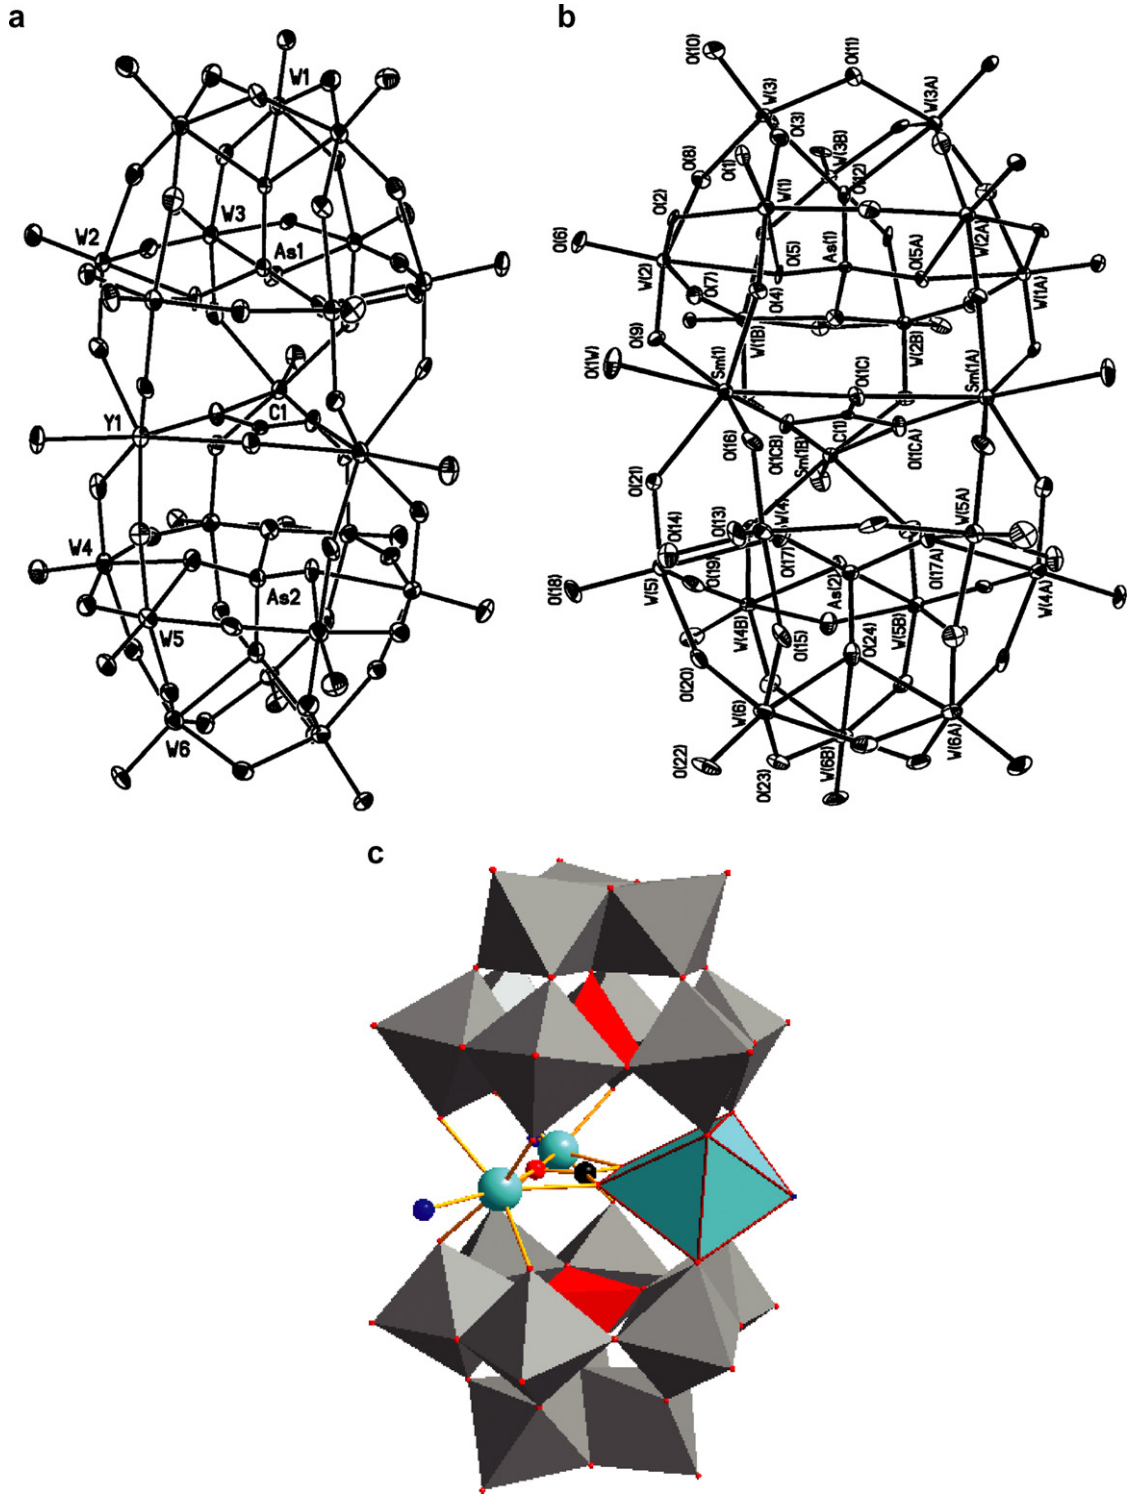

Fig. 1. Thermal ellipsoid plot of: (a) $[(A\text{-}\alpha\text{-}sW_9O_{34})_2(YOH_2)_3(CO_3)]^{11-}$ (**1**), (b) $[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(SmOH_2)_3(CO_3)]^{11-}$ (**3**) set at the 50% probability level and (c) combination ball-and-stick/polyhedral representation of **1** and **3**. The W, As, M (Y, Sm), C, O atoms and water molecule are shown in grey, orange, aqua, black, red and blue, respectively. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

solution, turbidity variation of the solution as a function of addition of A-α-$[AsW_9O_{34}]^{9-}$, which is due to the formation of the complexes in solution, were performed. The titration results show a breakpoint near to the 2:3 L:M^{III} (L = A-α-$[AsW_9O_{34}]^{9-}$) ratio. The syntheses of **1**, **2** and **3** require the presence of CO_3^{2-}. **1**, **2** and **3** are also synthesized in the presence of HCO_3^-. It has been demonstrated that the starting material A-α-$[AsW_9O_{34}]^{9-}$ can be transformed to B-α-$[AsW_9O_{34}]^{9-}$ simply by heating the solid. The reaction of 2 mmol of B-$[AsW_9O_{34}]^{9-}$ prepared in this way with an aqueous carbonate solution of 3 mmol of YCl_3 generated anion **1** directly. The crystal structure (see below) reveals that anion **1** contains two A-α-$[AsW_9O_{34}]^{9-}$ units, which indicates that the synthesis involves a structural rearrangement of the starting material B-α-$[AsW_9O_{34}]^{9-}$. Preparation of the samarium derivative at 80 °C is not favored because of the formation of an unknown suspended solid on recrystallization, which is followed by a decrease of the product yield.

Unlike the A-type sandwiches based on divalent d-block metals [14,17,18,22,23], the complexes of **1**, **2** and **3** are stable in unbuffered H_2O. The experimental results suggest that**1** and **2** are stable in the pH range of 5–10 for long time. **3** is not stable in the above conditions. The best stability condition for **3** is the pH range 6–9. When complexes **1**, **2** and **3** are passed through a strongly acidic ion exchange (Dowex-50W-X8) column, the product is the Dawson anion, $[As_2W_{18}O_{68}]^{6-}$, which is isolated as $H_6[As_2W_{18}O_{68}]$. This observation confirms that the $AsW_9O_{34}^{9-}$ units in the complexes are the A-isomer [24–26].

3.2. Structures

Single crystal analysis was carried out on **1** and **3**, which are isostructural with **2**. The complexes crystallize in the cubic space group $P2_13$, with a total number of 37 atoms in the anion part containing 6W (W1–W6), 2As (As1–As2), 1Y (Y1), 26O (O1–O26), 1C (C1) and 1H_2O (O1W) atoms for **1** and 36 atoms containing 6W (W1–W6), 2As (As1–As2), 1Sm (Sm1), 25O (O1–O26, O1C), 1C (C1) and 1H_2O (O1W) atoms for **3** in the asymmetric unit. The structures of **1**and**3** consist of two lacunary A-α-$[AsW_9O_{34}]^{9-}$ Keggin moieties which are linked by an equatorial M_3CO_3 (M = Y^{III} or Sm^{III}) belt into an assembly of virtual C_{3v} symmetry (Fig. 1). The metal ions (M^{III}) form a regular triangle and are fixed together by oxygen atoms of a carbonate anion lying in the center and coplanar to the metal ions (Fig. 2). The C_3 axis of the anionic complexes is perpendicular to the equatorial belt and involves the carbon atom of the carbonate anion. The oxygen atoms of the carbonate anion lie on the midpoint of the side of the regular triangle. On the basis of valance bond sum (VBS) calculations, derived by Brown and Altermatt [27,28], the oxygen atoms of the belt are oxides and not hydroxides (Table 2).The encapsulated CO_3^{2-} still displays D_{3h} symmetry and as a special feature

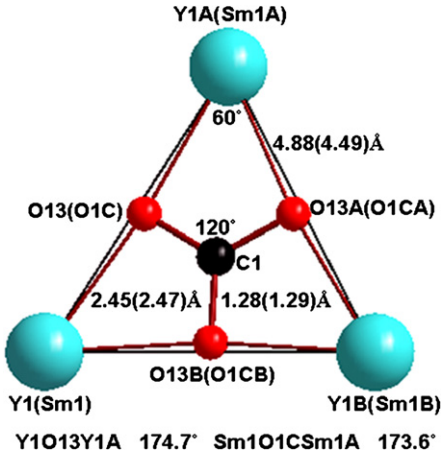

Fig. 2. The relevant distances (Å) and angles (°) for the M_3CO_3 belt arrangement in **1** and **3**.

acts as a tridentate ligand, which is unusual in metallocarbonate complexes. The VBS for the carbon and oxygen atoms is 4.02(3) and 1.98(1), respectively. Each M^{III} ion adopts a mono-capped trigonal-prismatic coordination, the local 3-fold axis of the MO_6 group lying in the regular triangular M_3CO_3 plane. The trigonal prismatic geometry is achieved by two terminal oxygen atoms of an edge shared pair of WO_6 octahedra to each A-α-$[AsW_9O_{34}]^{9-}$ moiety and two oxygen from the belt. The cap is achieved by one external water ligand. The M–O bond lengths in the MO_6 group and M–O(nW) are in the range 2.265(7)–2.452(6) Å, average 2.335(8) Å, and 2.369(6) Å for **1** and 2.335(10)–2.473(10) Å, average 2.388(6) Å, and 2.426(10) Å for **3**, respectively (Table 2). The VBS for the yttrium, samarium, tungsten and arsenic atoms is 2.96, 2.90, 6.08(6) and 4.96(15), respectively.

3.3. IR and NMR spectroscopy

As expected, the IR spectra of the A-type sandwich complex anions are very similar to that of the trivalant lacunary A-$[XW_9O_{34}]^{9-}$. The IR spectra of **1**, **2** and **3** are very similar and are also similar to that of A-$[AsW_9O_{34}]^{9-}$, except for the splitting of the asymmetry stretching vibration of W–Oc–W (Oc is the edge sharing oxygen) (Fig. 3). This splitting is attributed to the presence of the trivalent cations (directly bound to the terminal oxygen of an edge shared pair of WO_6) [29,30]. The IR spectra of **1**, **2** and **3** show bands in the region 1491–1465 cm^{-1}, which is assigned to the doubly degenerate ν_3 vibrational mode of CO_3^{2-} with a small splitting of 10 cm^{-1} [31]. This splitting is attributed to distortion of the CO_3^{2-} group (Fig. 3). The other two infrared active modes, ν_2 and ν_4, overlap with the W–O stretching bands.

The ^{13}C NMR spectrum of **1** (0.1 mM) shows one peak at 171.32 ppm which is attributed to the encapsulated CO_3^{2-} anion (Fig. 4). In order to obtain a solution of **1** that was concentrated enough for ^{13}C NMR spectroscopy it

Fig. 3. IR spectra of **1** (upper), **2** (inner) and **3** (lower).

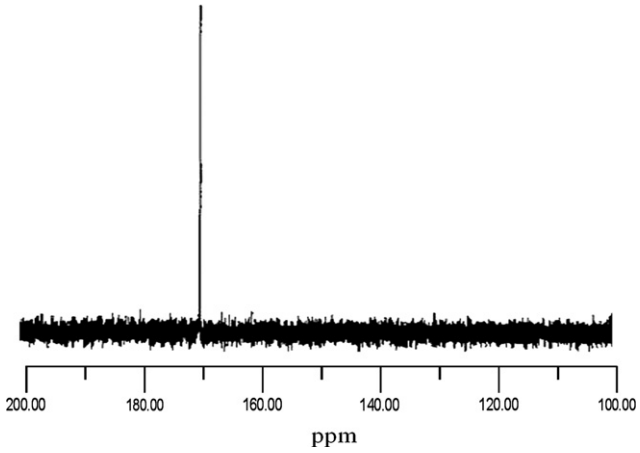

Fig. 4. ^{13}C NMR spectrum of **1**.

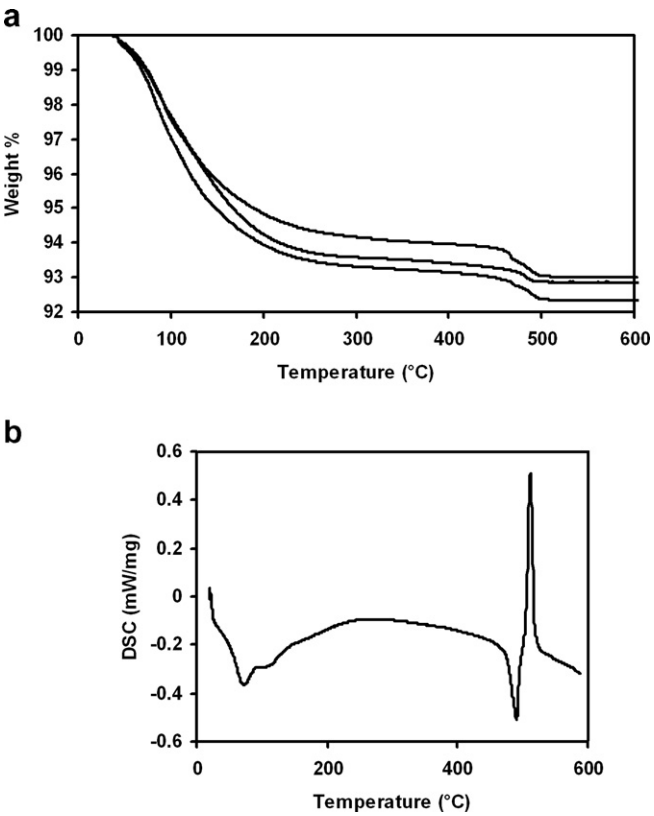

Fig. 5. (a) Thermogravimetric curve of **1** (lower), **2** (upper) and **3** (inner) and (b) differential scanning calorimetric curve of **2**.

was necessary to convert the potassium salt to the lithium salt by addition of $LiCLO_4$. The lithium salt of **1** is stable for several months and its solution (during NMR scanning) is stable.

3.4. Thermal properties TGA and DSC

Thermogravimetric analysis (TGA) curves of **1**, **2** and **3** show two mass loss regions below 500 °C. The first, 30–300 °C with 6.8%, 6.0% and 6.4% weight loss, is assigned to lattice and coordinated water (bonded to $M^{(III)}$) loss, equal to 22 (19 + 3), 20 (17 + 3) and 21 (18 + 3) molecules for **1**, **2** and **3**, respectively. The second region, 430–500 °C, with approximately 0.8%, 0.8% and 0.71% weight loss for **1**, **2** and **3**, respectively, are assigned to the loss of one molecule of CO_2 from the decomposition of CO_3^{2-} (Fig. 5a). Differential scanning calorimetry (DSC) curves of **2** show two endothermal and one exothermal process. The endothermal processes at 80–120 °C and 491 °C are attributed to exit of the water contents of the complex and CO_2, respectively, and the exothermal process at 510 °C is attributed to the decomposition of the structure (Fig. 5b). On the basis of the TGA and DSC studies it can be thus concluded that **1** and **2** are thermally stable up to 490 °C but, **3** decomposes from 440 °C.

3.5. Electronic spectroscopy

The UV-electronic spectra of the complexes **1**, **2** and **3** exhibit two characteristic bands at/200 and/257 nm ($\varepsilon = 55200$), assigned to W-/Od and W-/Ob-/W transitions, respectively (Od is a terminal oxygen and Ob is a bridging oxygen [1]) (Fig. 6a). These bands are shifted to lower frequencies on comparison with the A-$[AsW_9O_{34}]^{9-}$ ligand, due to the coordination of the lanthanide cations.

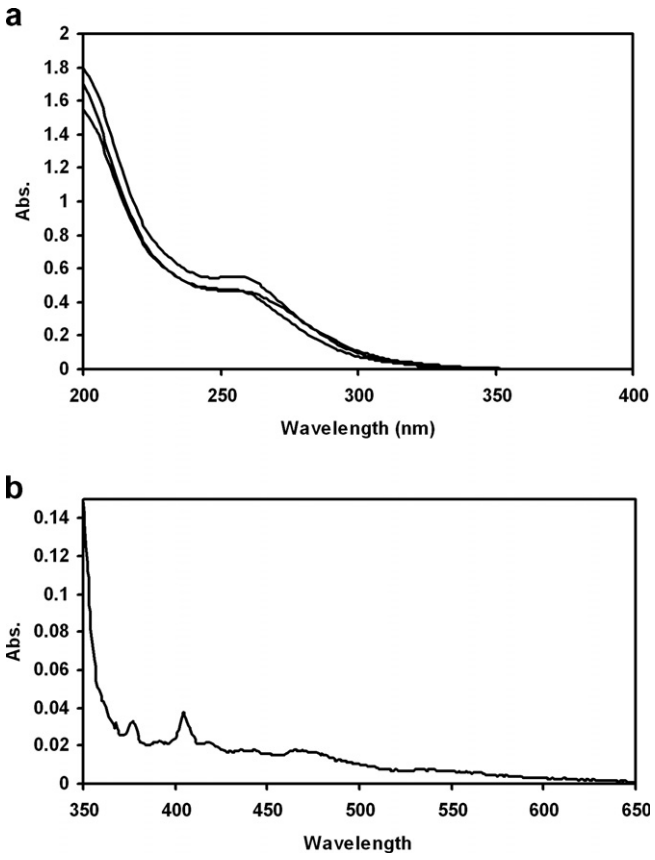

Fig. 6. (a) UV spectra of (1×10^{-5}M) **1** (lower), **2** (upper) and **3** (inner) and (b) visible spectrum of (5×10^{-3} M) **3**.

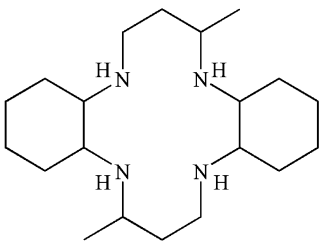
Complex **3** exhibits an additional metal-to-ligand charge transfer band at 350–400 nm ($\varepsilon_{max} = 7$) (Fig. 6b).

4. Conclusion

Three new sandwich-type polyoxometallate complexes $[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(MOH_2)_3(CO_3)]^{11-}$ ($M = Y^{(III)}$, $Yb^{(III)}$ and $Sm^{(III)}$) were synthesized by the reaction of $M^{(III)}$ ions with $A\text{-}\alpha\text{-}[AsW_9O_{34}]^{9-}$ in carbonate solution. The experimental results show that the synthesis of the complexes requires the presence of the carbonate anion. The crystal structure of complexes consist of two lacunary $A\text{-}\alpha\text{-}[AsW_9O_{34}]^{9-}$ Keggin moieties which are linked by a M_3CO_3 belt into an assembly of virtual C_{3v} symmetry. The complexes are stable up to ~490 °C, and the decomposition of the complexes is followed by the loss of a carbonate anion. Other tools such as IR, ^{13}C NMR, UV–Vis spectroscopy, TGA and DSC confirm the structures.

5. Supplementary material



Crystallographic data (CIF file) for the structural analysis have been deposited with the Fachinformationszentium Karlsruhe (FIZ), CSD-number 391424 and 391425. These data can be obtained free of charge via E-mail: crysdata@FIZ-Karsruhe.de.

L

2. Experimental

2.1. Materials and physical methods

All chemicals used in syntheses were of reagent grade and were used without further purification. The macrocycle 3,14-dimethyl-2,6,13,17-tetraazatricyclo[14,4,$0^{1.18}$,$0^{7.12}$] docosane (L) and $[Ni(L)]Cl_2 \cdot 2H_2O$ were prepared according to the literature methods [19,20]. Infrared spectra were recorded as KBr pellets on a Perkin–Elmer Paragon 1000 FT-IR spectrometer. The solution electronic and diffuse reflectance spectra were obtained on a Jasco V-550 spectrophotometer. Magnetic susceptibility data were collected in the temperature range 5.0–300 K in an applied field of 1.0 T with the use of a Quantum Design MPMS7 SQUID magnetometer. The diamagnetic corrections were calculated from Pascal's constants. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Synthesis of $\{[Ni(L)(isoph)] \cdot 3H_2O\}_n$ (1)

An aqueous solution (10 ml) of $[Ni(L)]Cl_2 \cdot 2H_2O$ (251 mg, 0.5 mmol) was added to an aqueous solution (10 ml) of sodium isophthalate (105 mg, 0.5 mmol) and the mixture was stirred for 30 min at room temperature. The solution was filtered and left at room temperature until the violet crystals formed. The product was recrystallized from a hot water/acetonitrile (1:1 v/v, 10 ml) mixture. Yield: 65%. *Anal.* Calc. for $C_{28}H_{50}N_4NiO_7$: C, 54.82; H, 8.22; N, 9.13. Found: C, 54.93; H, 8.31; N, 9.04%. IR (KBr, cm^{-1}): ν(NH) 3210, ν_{as}(COO) 1717, 1606, 1560, ν_{sym}(COO) 1425, 1381.

2.3. Syntheses of $\{[Ni(L)(H\text{-}chtc)] \cdot H_2O\}_n$ (2)

This compound was prepared as violet crystals in a reaction similar to that of **1**, using sodium 1,3,5-cyclohexanetricarboxylate (140 mg, 0.5 mmol) instead of sodium isophthalate. Yield: 68%. *Anal.* Calc. for $C_{29}H_{52}N_4NiO_7$: C, 55.51; H, 8.35; N, 8.93. Found: C, 55.42; H, 8.43; N, 8.86%. IR (KBr, cm^{-1}): ν(OH) 3405, ν(NH) 3205, ν_{as}(COO) 1690, 1560, ν_{sym}(COO) 1449, 1394.

2.4. X-ray crystal structure analysis

Intensity data collected on a Bruker SMART 1000 CCD (**1**) and an Enraf-Nonius CAD4 (**2**) diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Accurate cell parameters and an orientation matrix were determined by the least-squares fit of 25 reflections. The intensity data were collected by the ω-2θ technique and corrected for Lorentz and polarization effects. An empirical absorption correction was applied with the SADABS program [21] for **1** and φ-scan [22] for **2**. The structure was solved by direct methods [23] and the least-squares refinement of the structure was performed by the SHELXL-97 program [24]. All atoms except for all hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions, allowing them to ride on their parent C or N atoms with $U_{iso}(H) = 1.2U_{eq}$(C or N). For **1**, the

hydrogen atoms of Ow(3) were not found. Crystal parameters and details of the data collections and refinement are summarized in Table 1.

3. Results and discussion

3.1. Crystal structures

An ORTEP drawing of $\{[Ni(L)(isoph)]\cdot 3H_2O\}_n$ (**1**) with the atomic numbering scheme is shown in Fig. 1 and the selected bond lengths and angles are listed in Table 2. The ligand skeleton of the present compound takes the *trans*-III(*R,R,S,S*) configuration with two chair six-membered and two gauche five-membered chelate rings. The crystal structure of **1** has cationic $[Ni(L)]^{2+}$ units, $isoph^{2-}$ anion, and water molecules. An inversion center exists on the central nickel(II) ion. In the chain structure, the nickel(II) reveals a distorted octahedral coordination environment in which the macrocycle and carboxylate oxygen atoms of the two $isoph^{2-}$ ligands have assembled around the nickel(II) center. Thus, one-dimensional coordination polymers have formed. The Ni···Ni distance across the polymer backbone is 11.327(1) Å, whereas the closest Ni···Ni distance between neighboring stands is 8.032(1) Å. The Ni–N (secondary amine) distances vary from 2.057(3) to 2.091(3) Å and the Ni–O (carboxylate oxygen) distances vary from 2.128(2) to 2.140(2) Å, giving an axially elongated octahedron in the 1D chain direction. The average Ni–N distance of 2.075(3) Å is significantly longer than in the square-planar geometry of $[Ni(L)]Cl_2\cdot 2H_2O$ [1.948(4) Å] [20], but is similar to that observed for high-spin octahedral nickel(II) complexes with 14-membered tetraaza macrocyclic ligands [25–27]. The average Ni–O distance of 2.134(2) Å is comparable to the previously reported values in the related systems $\{[Ni(L)(tp)]\cdot 2H_2O$ [17]: Ni–O = 2.116(3) Å; $[Ni(L)(pdc)]\cdot H_2O$ [17]: Ni–O = 2.121(9) and 2.137(10) Å; $[Ni(cyclam)(tp)]\cdot 4H_2O$ [28]: Ni–O = 2.129(5) Å}, which have a tetragonally distorted octahedral geometry. The N–Ni–N angles of the six-membered chelate rings are larger than those of the five-membered chelate rings. The axial Ni(1)–O(1) and Ni(2)–O(3) linkages are bent slightly off the perpendicular

Symmetry codes: (i) $x, y-1, z-1$; (ii) $x, y-1, z$; (iii) $-x+1, -y-1, -z$; (iv) $-x+1, -y, -z+1$.

C(22) and Ni(2)–O(3)–C(27) angles and C(22)–O(1) and C(27)–O(3) distances relative to the isoph^{2-} ligand are 135.6(2)–136.5(2)° and 1.267(4)–1.255(4) Å, respectively. Interestingly, the secondary amines of the macrocycle are hydrogen bonded to the carboxylate oxygen atoms of the isoph^{2-} ligand [N(1)···O(2)^{ii} 2.886(4) Å, 160(4)°; N(3)···O(4)^{iii} 2.930(4) Å, 154(4)°; symmetry codes: (ii) $-x+1, -y+1, -z+1$; (iii) $-x, -y+1, -z-1$]. Furthermore, the water molecules found in the lattice also form hydrogen bonds with other water inclusions [Ow(1)···Ow(2)^{iv} 2.839(8) Å, 89(2)°; Ow(1)···Ow(2) 2.969(8) Å, 95(2)°; Ow(1)···Ow(3)^{v} 3.087(11) Å, 122(2)°; Ow(2)···Ow(1) 2.969(8) Å, 94(2)°; symmetry codes: (iv) $x, -y+3/2, z+1/2$; (v) $x, y, z-1$] (Fig. 3).

An ORTEP drawing of $\{[Ni(L)(H\text{-}chtc)]\cdot H_2O\}_n$ (**2**) with the atomic numbering scheme is shown in Fig. 2 and the selected bond lengths and angles are listed in Table 3. The structure of **2** consists of $[Ni(L)]^{2+}$ units, H-chtc^{2-} anion, and water molecule. The nickel(II) ion occupies a distorted octahedral coordination environment in which the macrocycle, two H-chtc^{2-} ions, and water molecule have assembled around each nickel center. Consequently, a 1D coordination polymer has formed. The intramolecular Ni···Ni distance is 8.800(1) Å, whereas the shorter intermolecular Ni···Ni distance is 9.273(2) Å. The two average Ni–N (secondary amine) distances [Ni(1)–N_4 = 2.057(8) and Ni(2)–N_4 = 2.066(7) Å] are shorter than the two Ni–O (carboxylate oxygen) distances [Ni(1)-O(1) = 2.176(6) and Ni(2)–O(3) = 2.152(6) Å], which is similar to that observed for complex **1**. The axial Ni(1)–

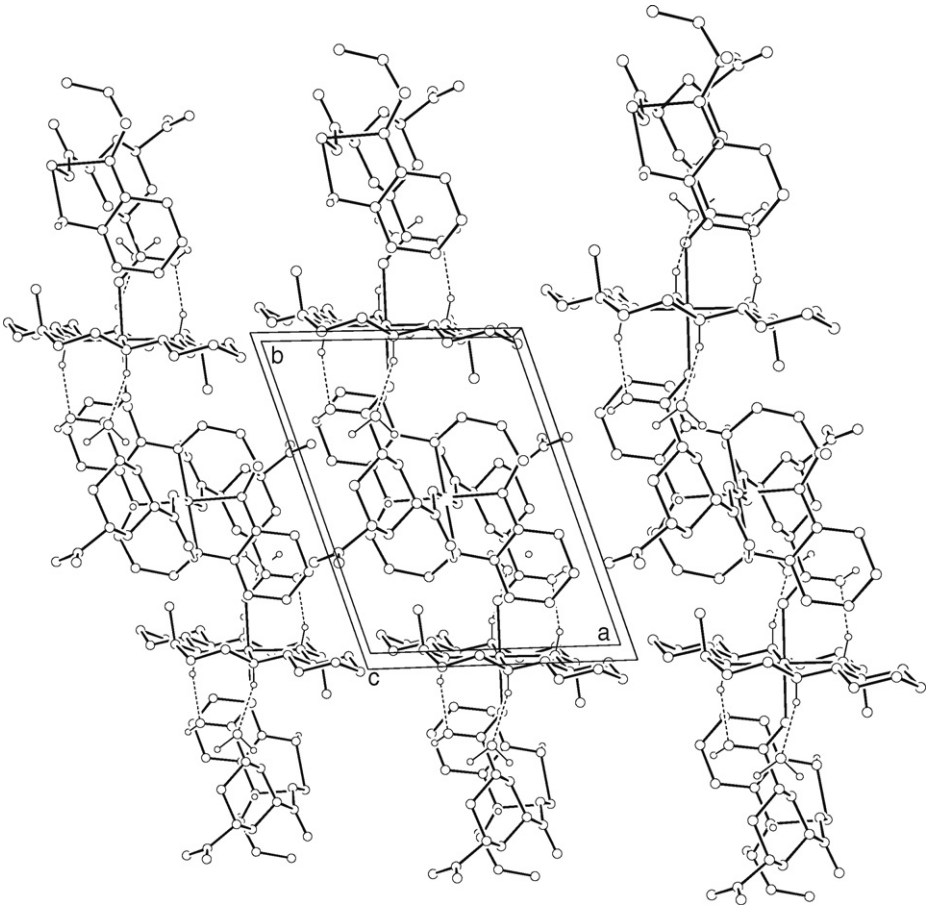

Fig. 4. Crystal packing of $\{[Ni(L)(H\text{-}chtc)]\cdot H_2O\}_n$ (**2**), showing the hydrogen bonds as dotted lines.

O(1) and Ni(2)–O(3) bonds are bent slightly off the perpendicular to the NiN_4 plane by 3.8–9.6° and 0.8–1.6°, respectively. The dihedral angles (β) between the plane of the carboxylate group and NiN_2O_2 plane involving Ni(1) and Ni(2) are 70.0(5) and 19.0(2)°. The coordination of the H-chtc^{2-} bridge is slightly asymmetrical; the two Ni(1)–O(1)–C(21) and Ni(2)–O(3)–C(25) angles are 130.6(6) and 133.7(6)°, the larger angle corresponding to the shorter bond distance. In contrast to complex **1**, the COO^- and COOH groups of the H-chtc^{2-} ligand coordinate to the nickel(II) ion but the other COO^- group is not coordinated to the metal ion. Interestingly, the protonated carboxylate oxygen atom of the H-chtc^{2-} ligand is hydrogen-bonded to the carboxylate oxygen atom [O(4)···O(6)^{viii} 2.577(9) Å, 104(9)°; symmetry code: (viii) $-x, -y-1, -z+1$]. Furthermore, the secondary amines of the macrocycle are hydrogen bonded to the carboxylic and carboxylate oxygen atoms of the H-chtc^{2-} ligand and water molecule [N(1)···O(2)^{v} 2.870(10) Å, 152.9°; N(4)···O(4)^{vii} 2.862(10) Å, 159.7°; N(3)···Ow(1)^{vi} 2.941(10) Å, 143(7)°; symmetry codes: (v) $-x+1, -y-1, -z$; (vi) $-x+1, -y, -z-1$; (vii) x, y, z]. Similar result was observed for the related macrocyclic complex *trans*-[Ni(*O*-benzoato)$_2$(cyclam)] [29]. The water molecules found in the lattice also form hydrogen bonds with the carboxylate oxygen atoms of the H-chtc^{2-} ligand [Ow(1)···O(5)^{viii} 2.857 (10) Å, 142(8)°; Ow(1)···O(2)^{viii} 2.721(10) Å, 155(10)°; symmetry code: (viii) $-x+1, -y-1, -z+1$] (Fig. 4).

3.2. Characterization of the complexes

The spectroscopic data of the complexes are listed in Table 4. The solid reflectance and MeCN solution spectra of **1** and **2** show an absorption maximum in the region 268–270 and 270–272 nm attributed to ligand–metal charge-transfer transitions associated with the nitrogen and oxygen donors [30]. The visible absorption spectra of the complexes in the solid and solution show that d–d transition $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ [31] occurs at 523–532 (solid), 520–524 nm (MeCN), which are ca. 60–70 nm longer than that of the square-planar complex $[Ni(L)](ClO_4)_2 \cdot 2H_2O$ (459–465 nm) [19]. This fact indicates that the nickel(II) ion has a high-spin octahedral coordination environment [32]. However, all compounds dissolve in water and decompose into the original building block $[Ni(L)]Cl_2 \cdot 2H_2O$ ($\lambda_{max} = 463$ nm) [20], indicating that the square-planar species is predominant over octahedral species in aqueous solution.

[a] Solution = CH_3CN and H_2O at 20 ± 0.1 °C; Solid = diffuse reflectance.
[b] Ref. [19].

The magnetic susceptibilities (χ_m) of **1** and **2** were measured in the range of 5.0–300 K. The χ_m and effective magnetic moment (μ_{eff}) versus temperature plots for the compounds **1** and **2** are shown in Figs. 5 and 6. The room temperature magnetic moments (μ_B) are 2.89 for **1** and 3.19 for **2**, respectively. For all compounds the μ_{eff} values gradually decrease with decreasing temperature, indicating the presence of an antiferromagnetic interaction between the nickel(II) centers. The magnetic susceptibility data are interpreted with Fisher's model for the classical-spin chain system ($S = 1$ and $H_{chain} = -J \sum S_i \cdot S_{i+1}$) [33,34]. The χ_m data can be expressed as

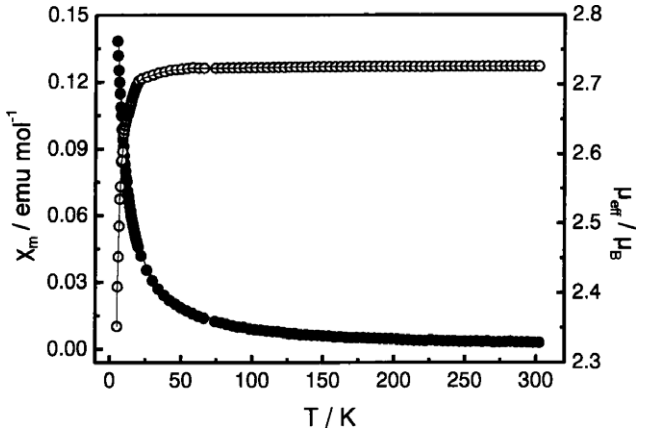

Fig. 5. Plots of χ_m vs. T (●) and μ_{eff} vs. T (○) for $\{[Ni(L)(isoph)] \cdot 3H_2O\}_n$ (**1**). The solid line represents the best fit of the experimental data to Eq. (1).

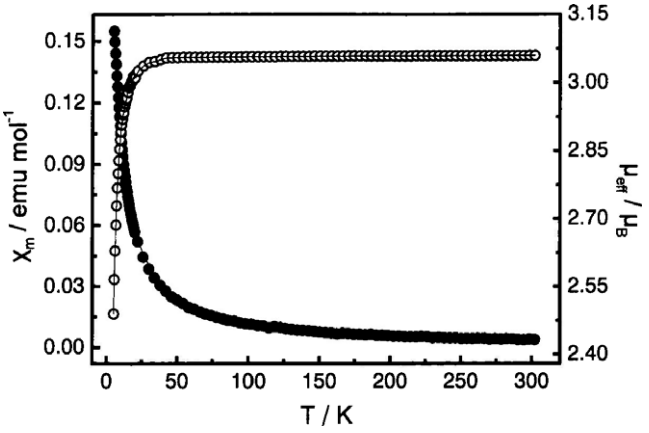

Fig. 6. Plots of χ_m vs. T (●) and μ_{eff} vs. T (○) for $\{[Ni(L)(H\text{-}chtc)] \cdot H_2O\}_n$ (**2**). The solid line represents the best fit of the experimental data to Eq. (1).

Table 5
Structural and magnetic data of nickel(II) complexes

Complex	g	J (cm^{-1})	α (°)	β (°)	d_{intra} (Å)	d_{inter} (Å)
{[Ni(Me_4cyclam)(pdc)] · H_2O}$_n$[a]	2.26	−1.04	4.0, 4.5	3.7, 38.5	11.2	7.9
{[Ni(L)(isoph)] · $3H_2O$}$_n$ (**1**)	2.02	−0.93	4.0, 7.1	11.2, 78.1	11.3	8.0
{[Ni(L)(H-chtc)] · H_2O}$_n$ (**2**)	2.28	−1.28		19.0, 70.5	8.8	9.3

Me_4cyclam = 2,5,9,12-tetramethyl-1,4,8,-11-tetraazacyclotetradecane; pdc = 2,6-pyridinedicarboxylate.
[a] Ref. [35].

$$\chi_m = \frac{N\beta^2 g^2 S(S+1)}{3kT}\frac{(1+\mu)}{(1-\mu)} \quad (1)$$

$$\text{with} \quad \mu = \coth\left[\frac{JS(S+1)}{kT}\right] - \left[\frac{kT}{JS(S+1)}\right]$$

The best fitting of the variable-temperature data to Eq. (1) gives $J = -0.93\ cm^{-1}$ with $g = 2.02$ for **1** and $J = -1.28\ cm^{-1}$ with $g = 2.28$ for **2**, suggesting the existence of very weak antiferromagnetic interactions between the nickel(II) ions. The structural and magnetic data for complexes **1** and **2** are given in Table 5 along with the other carboxylate-bridged nickel(II) complexes. The value of J for **1** is smaller than that of **2**, but is similar to that observed in {[Ni(Me_4cyclam)(pdc)] · H_2O}$_n$ (Me_4cyclam = 2,5,9,12-tetramethyl-1,4,8,-11-tetraazacyclotetradecane; pdc = 2,6-pyridinedicarboxylate) [35], which reveals 1D coordination polymer with the distorted octahedral geometry. An increase in the intramolecular distances slightly leads to a decrease in the antiferromagnetic coupling constant with carboxylate-bridged nickel(II) complexes. However, the intermolecular distances and dihedral angles do not follow the expected trend, which may not play a significant role.

4. Supplementary material

CCDC 668949 and 668950 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

overcome by introduction of the bulky heterocyclic ligands. As a result, some palladium complexes with aromatic N-containing ligands, e.g. derivatives of pyridine, quinoline, pyrazole and 1,10-phenanthroline, have shown very promising antitumor characteristics [4–9]. As the biological activity of a complex strongly depends on the nature of the ligands and on the metal coordination pattern, the recent research has been directed to synthesis and evaluation of complexes with biologically interesting ligands with the aim of widening spectrum of complex activity. The combination of metallic and organic activity may reveal new modes of action. These findings have stimulated investigation of complexes with the aminophosphonate derivatives because of their relevance to the natural systems and important biological and pharmacological properties [10,11]. Our research in this area is focused on complexes with the aromatic aminophosphonates and we have designed and structurally characterized a series of palladium and platinum complexes which demonstrated notable *in vitro* cytostatic activity against various tumor cell lines [7–9,12,13]. It is interesting to note that in some cases palladium complexes were more active than their platinum analogues [13].

As a continuation of our study on this class of organophosphorus compounds which might be of interest as antitumor agents, in the present work we describe the synthesis as well as spectroscopic properties and thermal analysis of palladium(II) complexes with monoethyl 8-quinolylmethylphosphonate. The antitumor activity *in vitro* of complexes was investigated against the epidermoid human KB and murine leukemia L1210 cell lines. In the course of investigations, the obtained results were compared with those previously reported for the palladium complexes of the corresponding diethyl 8-quinolylmethylphosphonate and the monoethyl 2-quinolylmethylphosphonate [7,8], and are discussed in terms of their coordination behaviour and structure–activity relationships.

2. Experimental

2.1. Materials and methods

Monoethyl 8-quinolylmethylphosphonate hydrochloride monohydrate (8-Hmqmp · HCl · H_2O) and sodium 8-quinolylmethylphosphonate dihydrate (Na(8-mqmp) · $2H_2O$), prepared as previously described [14], were purified prior to use by recrystallization from absolute ethanol. Palladium reagents (Aldrich) were high purity products and used as received. Solvents were purified and dried according to standard procedures.

Melting points were determined on a hot stage microscope and are uncorrected. Infrared spectra were recorded on an ABB Bomen MB102 spectrometer using KBr (4000–250 cm^{-1}) and polyethylene (400–200 cm^{-1}) pellets. Mass spectrometric measurements were performed on a double-focusing reverse-geometry VG ZAB 2F instrument operating under FAB conditions using the 8 keV Xe atoms. Glycerol or 3-nitrobenzyl alcohol were employed as the matrix for recording the positive-ion mass spectra. Negative-ion spectra were obtained with the 3-nitrobenzyl alcohol liquid matrix. The UV–Vis spectra were obtained in DMF solution with a Perkin–Elmer 124-spectrophotometer in the 250–600 nm range. The ^1H NMR spectra were recorded with Varian Gemini 300 Fourier-transform spectrometer in DMF-d_7 at 300 K with $SiMe_4$ as an internal reference. The two-dimensional experiments were performed by standard pulse sequences, using GEMINI DATA SYSTEM software Version 6.3 Revision A. The ^1H–^1H COSY spectra were obtained in the magnitude mode, while NOESY spectra in the phase-sensitive mode. Conductance measurements were carried out at room temperature using a CD 7A Tacussel conductance bridge for 10^{-3} mol^{-1} solutions in DMF and methanol. Magnetic susceptibilities were determined at the room temperature by the standard Gauy method using a Cahn-Ventron RM-2 balance and $CuSO_4 \cdot 5H_2O$ as the susceptibility standard. The thermogravimetric analyses (TG) were carried out on a Cahn RG electromicrobalance in an air atmosphere at a heating rate of 4 °C min^{-1} up to 850 °C. Differential thermal analyses (DTA) were performed with a Netzsch 406 differential thermal analyzer applying a heating rate of 5 °C min^{-1} in static air atmosphere. The reference substance was pure alumina. The samples were diluted with the reference substance in the ratio 1:1 by weight. The X-ray powder diffraction patterns were taken with a Philips counter diffractometer (monochromatized Cu Kα radiation). Elemental analyses (C, H and N) were performed on a Perkin–Elmer Analyser PE 2400 Series 2 in the Ruđer Bošković Institute. The chlorine and bromine content was determined by the Schöninger method, phosphorus by the vanadomolybdatophosphoric acid spectrophotometric method, and water by the thermogravimetric analysis.

2.2. Synthesis of the complexes

The complexes of 8-Hmqmp were prepared either by reaction of 8-Hmqmp · HCl · H_2O or Na(8-mqmp) · $2H_2O$ with palladium(II) halide compounds.

2.2.1. [8-H_2mqmp]$_2$[$PdCl_4$] (**1**)

(a) A concentrated aqueous solution of $K_2[PdCl_4]$ (0.146 g, 0.45 mmol) was added dropwise to a stirred solution of 8-Hmqmp · HCl · H_2O (0.255 g, 0.84 mmol) in water (3 ml). The reaction mixture was continuously stirred for 24 h at room temperature. The hazel precipitate that gradually formed was filtered off, washed with ice-cold water and methanol, and dried *in vacuo* over P_2O_5. Yield 0.205 g, 65%.

(b) $PdCl_2$ (0.090 g, 0.48 mmol) was dissolved in water (3 ml) by addition of 1:1 HCl (0.5 ml) and heating for 30 min at 50 °C. After filtration to remove any impurities, the cooled solution was added dropwise to a concentrated solution of Na(8-mqmp) · $2H_2O$ (0.240 g, 0.877 mmol) in water (3 ml). An additional constant stirring for 12 h at 4 °C yielded precipitate which was separated, washed and

dried as described. Yield 0.203 g, 64%; m.p. 182–183 °C. *Anal*. Calc. for $C_{24}H_{30}Cl_4N_2O_6P_2Pd$: C, 38.30; H, 4.02; N, 3.72; Cl, 18.84; P, 8.23; Pd, 14.19. Found: C, 38.12; H, 4.14; N, 3.58; Cl, 18.51; P, 8.54; Pd, 14.14%. Molar conductance Λ_M (DMF; MeOH, 22 °C) 72.4; 209.2 S cm^2 mol^{-1}. UV–Vis (λ_{max}, nm (ε, dm^3 mol^{-1} cm^{-1}), DMF): 276 (33 110); 300 (sh); 314 (6310); 332 (1660); 426 (210).

2.2.2. [8-H_2mqmp]$_2$[$PdBr_4$] · 2H_2O (2)

(a) A mixture of $PdBr_2$ (0.146 g, 0.55 mmol) and 1:1 HBr (1.3 ml) in water (3 ml) was stirred for 1 h, filtered and then was slowly added to a solution of Na(8-mqmp) · 2H_2O (0.249 g, 0.912 mmol) in water (3 ml). After vigorous stirring for 4 h, the reddish brown precipitate that formed was separated, washed with cold water and dried under vacuum. Yield 0.347 g, 80%.

(b) A mixture of $K_2[PdBr_4]$ (0.216 g, 0.43 mmol) and 1:1 HBr (0.9 ml) in water (4 ml) was added to a concentrated aqueous solution of 8-Hmqmp · HCl · H_2O (0.255 g, 0.84 mmol). The reaction mixture was stirred for 24 h at room temperature, the formed precipitate was isolated, washed and dried as described. Yield 0.292 g, 72%; m.p. 171–173 °C. *Anal*. Calc. for $C_{24}H_{34}Br_4N_2O_8P_2Pd$: C, 29.82; H, 3.55; N, 2.90; Br, 33.07; P, 6.41; Pd, 11.01; H_2O, 3.72. Found: C, 29.59; H, 3.81; N, 2.78; Br, 32.82; P, 6.36; Pd, 10.96; H_2O, 3.78%. Molar conductance Λ_M (DMF, MeOH, 22 °C) 70.1, 206.8 S cm^2 mol^{-1}. UV–Vis (λ_{max}, nm (ε, dm^3 mol^{-1} cm^{-1}), DMF): 278 (13 180); 300 (sh); 315 (7760); 412 (1990); 510 (320).

2.2.3. [8-H_2mqmp]$_2$[Pd_2Cl_6] (3)

A mixture of $K_2[PdCl_4]$ (0.247 g, 0.76 mmol) and 1:1 HCl (0.5 ml) in water (4 ml) was added to a concentrated aqueous solution of Na(8-mqmp) · 2H_2O (0.202 g, 0.74 mmol). The hazel precipitate that formed after stirring the reaction mixture for 24 h at room temperature was filtered off, washed with cold water and acetone, and dried under vacuum over P_2O_5. Yield 0.220 g, 64%; m.p. >180 °C (decomp.). *Anal*. Calc. for $C_{24}H_{30}Cl_6N_2O_6P_2Pd_2$: C, 31.00; H, 3.25; N, 3.01; Cl, 22.87; P, 6.66; Pd, 22.88. Found: C, 30.91; H, 3.12; N, 2.96; Cl, 22.75; P, 6.42; Pd, 22.69%. Molar conductance Λ_M (DMF, MeOH, 22 °C) 81.4, 175.2 S cm^2 mol^{-1}. UV–Vis (λ_{max}, nm (ε, dm^3 mol^{-1} cm^{-1}), DMF): 280 (17 920); 312 (sh); 338 (2820); 436 (340).

2.2.4. [8-H_2mqmp]$_2$[Pd_2Br_6] · 2H_2O (4)

A mixture of $K_2[PdBr_4]$ (0.418 g, 0.83 mmol) and 1:1 HBr (1.3 ml) in water (5 ml) was added dropwise to a stirred solution of Na(8-mqmp) · 2H_2O (0.221 g, 0.81 mmol) in water (3 ml). The reaction mixture was stirred for 4 h at 4 °C. The reddish brown precipitate that formed was filtered off, washed with minimum ice-cold water and dried under vacuum overnight at ambient temperature. Yield 0.345 g, 70%; m.p. >160 °C (decomp.). *Anal*. Calc. for $C_{24}H_{34}Br_6N_2O_8P_2Pd_2$: C, 23.38; H, 2.78; N, 2.27; Br, 38.90; P, 5.03; Pd, 17.26; H_2O, 2.92. Found: C, 23.02; H, 2.72; N, 2.18; Br, 38.71; P, 5.18; Pd, 16.98; H_2O, 3.15%. Molar conductance Λ_M (DMF, MeOH, 22 °C) 79.8, 171.1 S cm^2 mol^{-1}. UV–Vis (λ_{max}, nm (ε, dm^3 mol^{-1} cm^{-1}), DMF): 283 (19 950); 314 (sh); 419 (3310); 514 (490).

2.2.5. [8-H_2mqmp] [Pd(8-Hmqmp)Cl_3] (5)

This complex could be prepared either by heating the tetrachloropalladium complex **1** or hexachlorodipalladium complex **3** in methanol at reflux temperature for 30 min under a stream of nitrogen. The hot solution was filtered to remove some black decomposition products. The brown precipitate that gradually formed on cooling was isolated, washed with cold methanol and dried under vacuum at room temperature. M.p. 170–172 °C. *Anal*. Calc. for $C_{24}H_{29}Cl_3N_2O_6P_2Pd$: C, 40.25; H, 4.08; N, 3.91; Cl, 14.85; P, 8.65; Pd, 14.86. Found: C, 40.01; H, 3.96; N, 3.75; Cl, 14.62; P, 8.72; Pd, 14.75%. Molar conductance Λ_M (DMF, MeOH, 22 °C) 49.2, 126.1 S cm^2 mol^{-1}. UV–Vis (λ_{max}, nm (ε, dm^3 mol^{-1} cm^{-1}), DMF): 275 (11 120); 292 (9890); 314 (5980); 334 (1590); 428 (190).

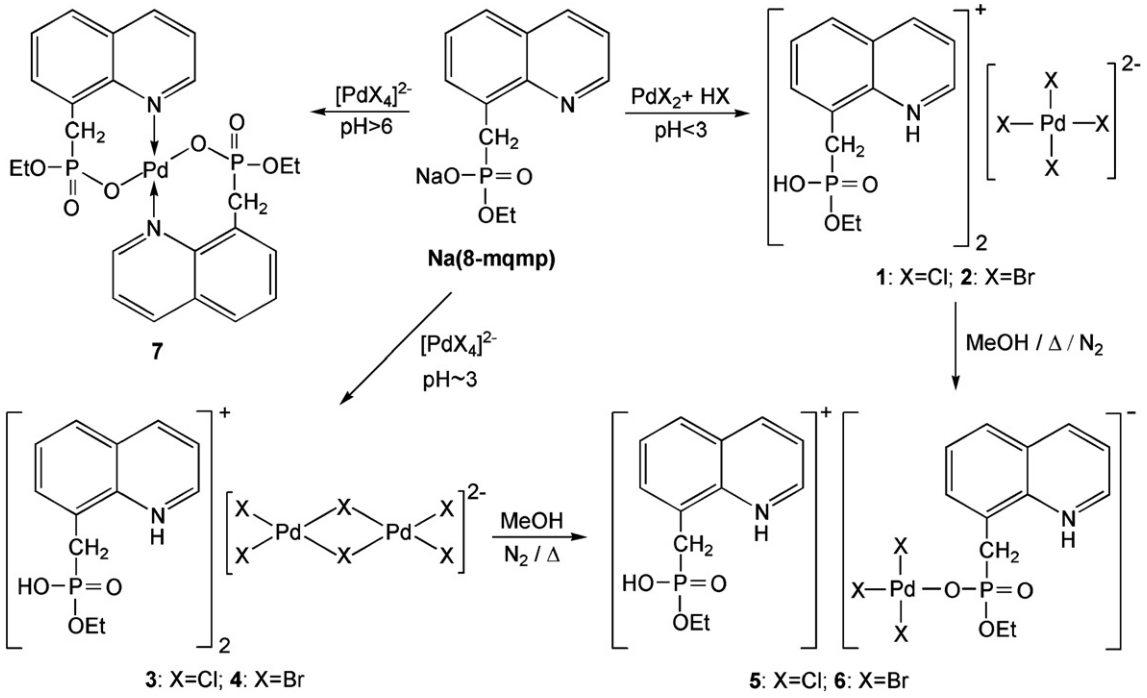
2.2.6. [8-H_2mqmp] [Pd(8-Hmqmp)Br_3] (6)

This complex was prepared as a dark brown compound by the similar procedure as its chloro analogue **5**, by heating the tetrabromopalladium complex **2** or hexabromodipalladium complex **4** in methanol at reflux temperature under an inert atmosphere. M.p. 162–164 °C. *Anal*. Calc. for $C_{24}H_{29}Br_3N_2O_6P_2Pd$: C, 33.93; H, 3.44; N, 3.30; Br, 28.22; P, 7.29; Pd, 12.52. Found: C, 33.69; H, 3.52; N, 3.18; Br, 28.35; P, 7.18; Pd, 12.64%. Molar conductance Λ_M (DMF, MeOH, 22 °C) 48.7, 124.0 S cm^2 mol^{-1}. UV–Vis (λ_{max}, nm (ε, dm^3 mol^{-1} cm^{-1}), DMF): 277 (13 420); 290 (10 230); 303 (sh); 316 (6610); 419 (1740); 520 (260).

2.2.7. [Pd(8-mqmp)$_2$] · 2H_2O (7)

(a) A concentrated aqueous solution of $K_2[PdCl_4]$ (0.130 g, 0.40 mmol) was added to a stirred solution of 8-Hmqmp · HCl · H_2O (0.240 g, 0.79 mmol) in water (2 ml) adjusted to pH 6 by addition of dilute sodium hydroxide. An additional stirring of 48 h yielded pale yellow precipitate which was filtered off, washed with minimum cold water and absolute ethanol, and dried under vacuum over P_2O_5. Yield 0.172 g, 68%.

(b) A concentrated aqueous solution of $K_2[PdCl_4]$ (0.163 g, 0.50 mmol) was added dropwise to a stirred solution of Na(8-mqmp) · 2H_2O (0.256 g, 0.94 mmol) in water (3 ml). The reaction mixture was continuously stirred for 48 h at room temperature. The precipitate that formed was separated, washed and dried as described. Because of its hygroscopity, the handling of this complex was performed under nitrogen in a dry-box. Yield 0.213 g, 70%; m.p. >200 °C (decomp.). *Anal*. Calc. for $C_{24}H_{30}N_2O_8P_2Pd$: C, 44.84; H, 4.70; N, 4.36; P, 9.64; Pd, 16.55; H_2O, 5.61. Found: C, 44.72; H, 4.59; N, 4.16; P, 9.38; Pd, 16.42; H_2O, 5.99%. Molar conductance Λ_M (DMF, 22 °C) 0.6 S cm^2 mol^{-1}. UV–Vis (λ_{max}, nm (ε, dm^3 mol^{-1} cm^{-1}), DMF): 311 (13 070); 317 (13 490).



2.3. In vitro antitumor assays

In vitro antitumor activity of the complexes was evaluated against KB cell line derived from an oral epidermoid human carcinoma and murine leukemia L1210 cell line according to previously described methods [9]. The KB cells were maintained in Eagle's Minimum Essential Medium (MEM) supplemented with 10% newborn calf serum and 1% non-essential amino acids. The cell population doubling time was ca. 24 h. The L1210 cells were maintained in RPMI 1640 medium, supplemented by 10% fetal calf serum. Under these conditions the doubling time was 12 h. The complexes were dissolved immediately before use in sterile DMSO, and these solutions were diluted with the growth medium to the desired concentrations. The final DMSO concentration in the culture medium, 0.5%, showed no cytostatic effect in preliminary tests. At least five concentrations of each compound were used and each concentration was tested in triplicate on at least two separate occasions. Cytostatic activity was valued as percentage of the cellular growth inhibition in culture treated with complex compounds with respect to the growth observed in the control culture. Data were analyzed using Student unpaired *t*-test and significance was accepted at which tumor cell growth showed 50% inhibition (IC_{50}), and was calculated by linear regression analysis [15].

3. Results and discussion

3.1. Synthesis and properties

The complex-forming behaviour of monoethyl 8-quinolylmethylphosphonate towards palladium(II) ion has been investigated by reactions of the hydrochloride, 8-Hmqmp · $HCl \cdot H_2O$, and sodium salt, Na(8-mqmp) · $2H_2O$, of this monoester with palladium(II) halide compounds in aqueous solution over a wide pH range. It is interesting to note that while preparing monoalkyl esters of the aniline- and quinoline-based phosphonic acids under the same experimental conditions, by acidification of the corresponding sodium salts with diluted hydrochloric acid, the obtained monoesters exhibit great differences in their structural properties. Thus, it was shown that the monoalkyl (α-anilinobenzyl)phosphonates have inner-salt character, with the aniline group being protonated and the phosphonic acid group being ionized, which was confirmed by the spectroscopic and X-ray crystallographic studies [16,17]. In the case of benzeneazoanilino derivatives in which the basicity of the aniline N atom is reduced by participation of its electron pair in resonance with the adjacent azobenzene π-system, the isolated monoesters have a neutral molecular form [17–19]. Monoethyl ester of 2-quinolylmethylphosphonic acid exhibits also a zwitterion structure [20] similar to a large number of various alkyl α-aminophosphonic acids and their monoesters [21,22]. On the other hand, the corresponding monoethyl 8-quinolylmethylphosphonate was isolated as the hydrochloride with a water of crystallization [14]. For this reason, comparing the complex forming ability of these two monoesters with respect to the Pd(II) ion, the great differences could be observed. The former ligand depending on pH exhibits either the molecular, zwitterion or the anionic form, and therefore according to the acidity of the reaction solution forms three types of palladium(II) complexes; dihalide adducts *trans*-$[Pd(2\text{-}Hmqmp)_2X_2]$ ($pH \sim 3.5$), ion-pair salt complexes $[2\text{-}H_2mqmp][Pd(2\text{-}$

Scheme 1. Synthesis of the complexes by reaction of sodium 8-quinolylmethylphosphonate with palladium(II) halide compounds.

Hmqmp)X_3] (pH < 3) (X = Cl, Br) and chelate complex [Pd(2-mqmp)$_2$] (pH > 6) [9,20]. Monoethyl 8-quinolylmethylphosphonate at various reaction conditions could form four types of palladium complexes (see Section 2). Reactions of sodium salt are presented in Scheme 1. Generally, under acidic solution were isolated the ion-pair salt complexes [8-H_2mqmp]$_2$[PdX_4] (**1** and **2**, pH < 3) and [8-H_2mqmp]$_2$[Pd_2X_6] (**3** and **4**, pH ~ 3), containing the protonated quinoline ligand as cation and tetrahalopalladate or hexahalodipalladate complex as anion. By heating in methanol the chloro complexes **1** and **3** as well as bromo complexes **2** and **4** were converted into the quinolinium salt complexes [8-H_2mqmp][Pd(8-Hmqmp)X_3] (**5** and **6**), containing as anion the quinoliniummethylphosphonatetrihalopalladate complex with palladium bonded at the phosphonic acid moiety while the quinoline nitrogen is protonated. In neutral and basic media 8-Hmqmp acts as a bidentate chelate ligand through the quinoline nitrogen and the deprotonated phosphonic acid group giving complex **7**, [Pd(8-mqmp)$_2$] · $2H_2O$, with two seven-membered {N,O} chelate rings [23]. All attempts to prepare dihalide adducts with ligand bonded only through the quinoline nitrogen were unsuccessful.

The prepared complexes are microcrystalline or powder like diamagnetic compounds, coloured yellow to brown, and are stable in the solid state under normal laboratory conditions. The molar conductance data in DMF and methanol are consistent with the proposed structure of complexes; complexes **1**, **2**, **3** and **4** exhibit conductivities comparable to those of 2:1 electrolytes (Λ_M = 70–82 in DMF and 171–209 in methanol), **5** and **6** to those of 1:1 electrolytes ($\Lambda_M \approx 49$ in DMF and 125 in methanol), while the very low conductance of complex **7** ($\Lambda_M < 1$ in DMF) confirms the presence of deprotonated phosphonic acid group in this chelate complex. In general, complexes are only slightly soluble or insoluble in all common solvents, and slightly soluble or soluble in DMF and DMSO. The structure of the complexes, as well as their stability and mode of decomposition, were deduced mainly from their spectral and thermal studies. The relevant spectral data are summarized in Tables 1–4, while results of antitumor assays are listed in Table 5.

3.2. IR spectra

The IR spectra of the complexes are very complicated due to extensive vibrational coupling and overlapping of the absorption bands, so the proposed assignments given in Table 1 must be regarded as approximate description of the vibrations.

All the ionic complexes **1**–**6**, which contain the protonated quinoline nitrogen, show the characteristic bands attributed to the $\nu(NH^+)$ vibration, similarly as the hydro-

chloride salt of the 8-mqmp, but their position is a bit different [14,24]. In the complexes a very broad complex progression of absorptions mostly of medium intensity is between 2900 and 2400 cm^{-1}, less intense absorption is centered within 2380 and 2320 cm^{-1}, and a medium to strong sharp band is at about 1635 cm^{-1} (see Fig. 1a). The variation in their position may arise from the weak hydrogen bonding between the NH^+ and the phosphoryl oxygen or that of the lattice water present in some of the complexes. In addition, in these regions also occur the less intense absorptions characteristic for the hydrogen bonded phosphonic acidic P(O)OH group [19,25]. The absorption over 1600 cm^{-1} contributes to deformation modes of the lattice water present in the hydrated complexes. It is worth noting that in the non-hydrated phosphonic acid compounds there is no evidence of band at about 3500 cm^{-1} normally ascribed to the absorption of the OH group alone. The hydrated complexes **2** and **4** in the ν(OH) region show two rather intense bands in the range 3550–3400 cm^{-1}, while in the hydrochloride salt is present only one broad ν(OH) absorption around 3250 cm^{-1}, indicating a strong hydrogen bonding in this salt. All complexes show also a great complexity of the spectra in the region of 1250–950 cm^{-1} where bands arising from the stretching modes of the P=O, P–O–C and PO–H vibrations, along with those of the ionized PO_2^- group, give a series of medium to very strong absorption bands. The variation in position and complexity of these absorptions is arising from their sensitivity to the hydrogen bonding, as well as to the nature of the metal ion [19,26]. Coordination of single oxygen of a PO_2^- group would result in considerably different P–O bond orders arising from a combination of bond polarization and covalence effects.

The far-IR spectra of the ionic complexes are consistent with the spectral data obtained for complexes containing the square-planar monomeric $[PdX_4]^{2-}$, dimeric halobrid-

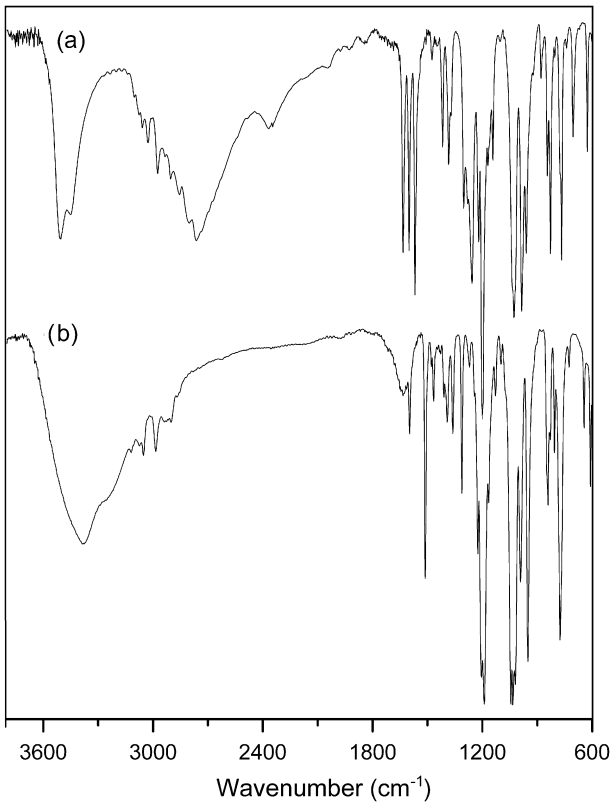

Fig. 1. Infrared spectra of complexes (a) **4** and (b) **7**.

ged $[Pd_2X_6]^{2-}$ anions as well as complexes having the form $[PdLX_3]^-$ for which the C_{2v} symmetry is a reasonable approximation [8,27]. Thus, one ν(Pd–X) band is visible in the complexes **1** and **2**, two bands in the chloride complex **3**, while complicated absorption is present in complex **5** in the examined region. In the case of bromo complexes **4** and **6** only one band is found in the examined range, as the other bands are expected to be at the lower frequencies [27,28].

In the spectrum of complex **7** there is no evidence of the bands associated with the NH^+ and P–O–H absorptions (see Fig. 1b), since in this complex the deprotonated phosphonate ligand acts as a N,O-bidentate ligand in the ionic form. Its spectrum is characterized by a series of complex bands of medium to very strong intensity between 1230 and 1190 cm^{-1} for the antisymmetric and between 1045 and 1015 cm^{-1} for the symmetric mode of the PO_2^- vibration. In the latter frequency region also occurs a strong ν(PO–C) absorption. One ν(Pd–N) band at 260 cm^{-1} confirms palladium coordination through the quinoline nitrogen in a *trans*-orientation. The presence of the lattice water in this complex is confirmed by a very broad ν(OH) absorption around 3400 cm^{-1}.

3.3. ^1H NMR spectra

While all bromopalladium complexes are sufficiently soluble in DMF for the ^1H NMR spectral analysis, among the chloro complexes only for the tetrachloropalladium complex **1** a satisfactory spectrum could be obtained. The spectral data are given in Table 2 and the numbering scheme is shown in Scheme 1.

In the spectra of complexes the resonances of most of protons show a certain downfield shift with respect to the sodium salt of the quinoline ligand. These changes could be explained by decrease in the electron density in the heterocyclic aromatic ring caused by the protonation of the quinoline nitrogen in the ionic complexes or by its coordination to palladium atom in the chelate complex, as well as by the proximity of the palladium atom which is known to be magnetically anisotropic bringing about deshielding effects [29]. In general, the magnitude of the shift changes decreases with the distance from the protonation or coordination site. Therefore, in the ionic complexes the most pronounced downfield shift could be observed for the aromatic protons and there are no significant differences in the spectra between three types of palladium complexes. The signal of OH and NH^+ protons gives a broad singlet between 6 and 7.5 ppm. The situation is more complicated in the chelate complex **7**, which spectrum shows a great complexity arising from the existence of more isomeric species with different magnetic environment in dynamic equilibrium. This can be interpreted by the restricted rotation around the metal–ligand bond due to the proximity of the bulky phosphonate ligand group and the formation of the asymmetric center on the phosphorus atom as a result of the N,O-ligand bonding to palladium. As a consequence either the broadening or the presence of few sets of signals could be observed. The connectivities from 2D NMR experiments corroborate the tentative assignments of all protons in the major isomer, which are given in Table 2 along with the tentative spectral range covering absorption of all isomers of each proton. The greatest downfield shift was observed for the aromatic H-2 proton (0.52 ppm) and for the PCH_2 protons (2.64–2.98 ppm). The similar spectroscopic feature has been reported for some palladium(II) and platinum(II) complexes of various quinoline derivatives [13,16,30], which was confirmed by variable temperature measurements.

3.4. UV–Vis spectra

All palladium(II) complexes are diamagnetic with a square-planar geometry, for which three spin-allowed d–d transitions corresponding to transitions from the three lower lying d levels to the empty $d_{x^2-y^2}$ orbitals, are expected [31]. The ground state is $^1A_{2g}$ and the excited states related to these transitions are $^1A_{2g}$, $^1B_{1g}$ and ^1E_g in order of increased energy. Overlapping of the strong absorptions from the charge-transfer or intraligand transitions (π–π^* transitions in quinoline) prevents the observation and detection of the expected bands [32]. The relatively dark colour of the ionic complexes (**1**–**6**) indicates strong charge-transfer absorptions originating in the ultraviolet and trailing off into the visible region. The most prominent absorption in all three types of ionic complexes

is in the visible region around 430 nm for the chloro and about 515 nm for the corresponding bromo complexes, which could be ascribed to the metal-to-ligand charge-transfer transitions. The absorption at lower energies in bromide complexes than in their chloride analogues is due to the lower position of bromide in the spectrochemical series, and their various optical electronegativity [33]. In addition, the intensity of absorption bands is generally higher for the bromide complexes, which could be ascribed to the increased ligand participation in the occupied MO-levels, derived mainly from the metal d-levels. The relatively pale colour of the chelate complex **7** indicates that the quinoline ligand has a low ligand field strength in forming this complex.

3.5. Mass spectra

All palladium complexes have been investigated by positive/negative FAB mass spectrometric measurements, giving valuable structural information of these compounds. The fragment ions containing palladium and halide atoms are identified by the presence of the characteristic clusters of isotopic peaks corresponding to the relative abundances of the palladium and halide isotopes. The major structurally informative fragment ions in the positive-ion mode of all the complexes are given in Table 3, while those obtained in the negative-ion mode of the ionic complexes **1**–**6** are summarized in Table 4.

In the positive-ion mass spectra of all the palladium complexes, the protonated ligand molecule [8-Hmqmp+H]$^+$ as the intact cation is the base peak (*m*/*z* 252). The loss of the C_2H_4 according to six-membered McLafferty-type rearrangement yields the $[QCH_2PO\text{-}(OH)_3]^+$ ion at *m*/*z* 224 [34]. This fragment ion is dominant in the spectra of the free ligand, both, in the form of hydrochloride and sodium salt. In addition, all compounds show ions obtained by loss of a water molecule as well as the ethanol loss from the protonated ligand, which is often observed in the mass spectrometry of the ethyl esters [35,36], and ions obtained by FAB-induced dimerization of the organophosphorus ligand at *m*/*z* 503. In the complexes the first point to be noted is that only complex **7** exhibits the protonated molecular ion. Its intensity (6%) is much lower than that obtained for the corresponding chelate complex of 2-Hmqmp (37%), indicating less stability of the former complex with bidentate N,O-bonded ligand forming seven-membered chelate ring with respect to the second one with the six-membered chelate ring [20]. Complexes **5** and **6** contain structurally relevant fragment ions that allow also the anion characterization by the small abundant fragment ions formed by the successive loss of the three halide ions from the anionic trihalide palladium complex. The predominant peaks corresponding to ions containing palladium in the complexes are those with metal bonded to one or two ligand molecules at *m*/*z* 357 and *m*/*z* 607, respectively, as well as to those with palladium bonded to some ligand fragments $[Pd(QCH_2)PO_2OH]^+$, $[Pd(QCH_2)]^+$ and $[PdQ]^+$ at *m*/*z* 328, *m*/*z* 248 and *m*/*z* 236, respectively. It may be presumed that these ions contain the bidentate N,O-bonded organophosphorus ligand while in the ion at *m*/*z* 248 the quinolylmethyl fragment may undergo palladation at the quinoline nitrogen and the quinolylmethyl carbon atom. It is worth noting that the spectra show also some sodium adduct ions based on addition of sodium ion presumably either to halides or to phosphonate oxygen atoms as well as are present NBA matrix ions and their sodium adducts.

In the negative-ion mass spectrometry the palladium halide fragment ions are more stable and abundant than in the positive-ion mode [37], giving more structural information of the anionic part of the ionic complexes. The spectra of all the complexes show the palladium halide $[PdX_n]^-$, $n = 2$, 3 and dipalladium halide adduct ions $[Pd_2X_n]^-$, $n = 2$–6. As expected, the latter fragment ions are much more abundant in hexahalodipalladium complexes **3** and **4**, which show also the structure specific $[LPd_2X_6]^-$ ion at *m*/*z* 673 and *m*/*z* 935, respectively. Palladium trihalide and dihalide adduct ions are the most abundant palladium-containing peaks in tetrahalopalladium complexes **1** and **2**, and a spectrum of bromide complex with fragment ion assignation is presented in Fig. 2. In trihalide palladium complexes **5** and **6**, the important diagnostic fragment ions are those of small abundance obtained by sequential loss of halide radicals from the deprotonated molecular ion as well as those related to the intact complex anion $[PdLX_3]^-$ at *m*/*z* 462 and *m*/*z*

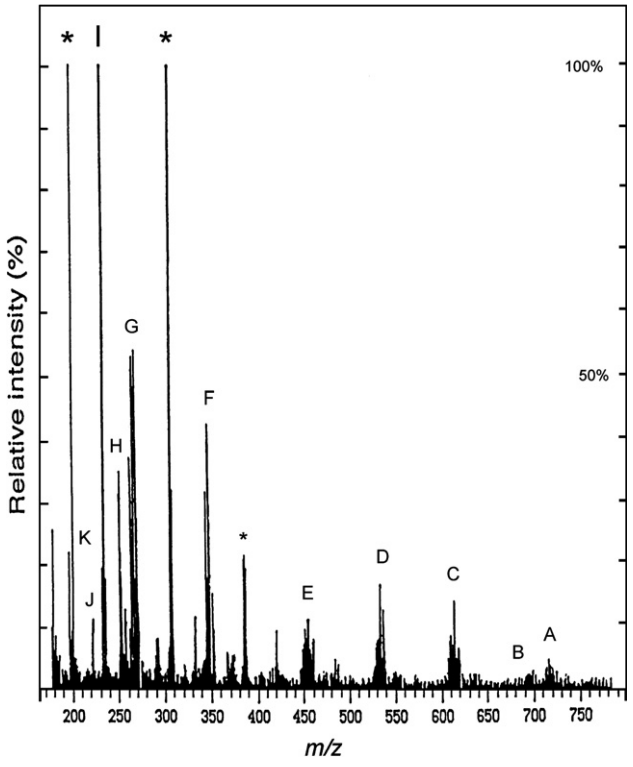

Fig. 2. Negative-ion FAB mass spectrum of complex **2** with NBA matrix. Matrix ions are indicated by an asterisk.

594, respectively, and those obtained by subtracting one and two halide radicals from these ionic species. The fragmentation pattern of the ligand molecule is similar to that obtained in the positive-ion mode including C_2H_4, H_2O and EtOH loss from the deprotonated ligand molecular ion.

3.6. Thermal data

Decomposition behaviour of the complexes was investigated also by thermal analyses, and examples of the appropriate TG-DTA plots for complexes **1**, **4** and **7**, are presented in Fig. 3. Although no stable intermediate products, except the corresponding anhydrous compounds in the case of the hydrated complexes **2** and **4**, were found owing to the complexity and the overlap of the degradation processes, thermal analysis subsequently followed by the IR study provides valuable information about decomposition properties of the complexes. IR spectra were recorded every 50 °C and are compared with the corresponding spectra at room temperature. The hydrated complexes **2** and **4** exhibit a single dehydration step between 80–140 °C with the mass loss close to evolution of two molecules of water. Degradation of the ionic halide complexes begins by a dehalogenation process overlapped with the ligand deesterification, and is influenced by the type of complex. Dehalogenation occurs in two steps, as revealed by the very distinct inflections in the TG curves, although well-defined

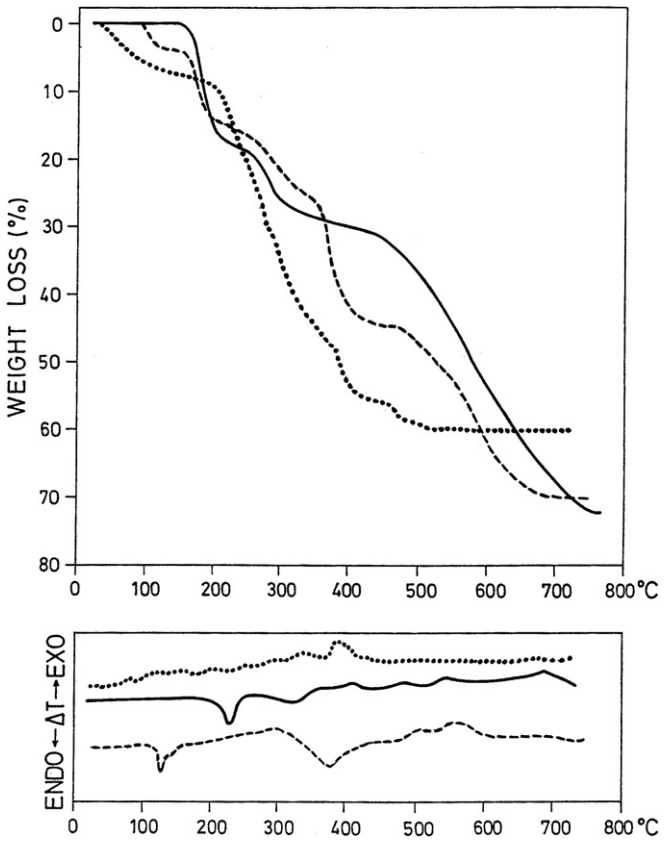

Fig. 3. TG-DTA curves for complexes: **1** (___); **4** (– – – –) and **7** (· · · · · ·).

TG plateaus are not reached. In tetrahalopalladium and hexahalodipalladium complexes, the first step ranged up to 220–240 °C and 210–220 °C, respectively, corresponds to the loss of two halogens and two ethyl ester groups (found mass loss: 19.1, 24.4, 19.2 and 21.7%; calc. 21.4, 25.9, 17.3 and 20.3% for **1**, **2**, **3** and **4**, respectively). The mass loss in the second step which ranged up to ca. 300–320 °C corresponds approximately to the release of two and four, respectively, remaining halogens (found mass loss: 10.7, 15.3, 13.5 and 20.8%; calc. 9.4, 16.5, 15.3 and 25.9%). In the quinolinium trihalopalladium complexes the first step between 165 °C and 185 °C for the chloride and between 190 °C and 210 °C for the bromide complex corresponds approximately to the loss of one halide ion (found mass loss: 5.4 and 10.6%; calc. 4.9 and 9.4%, respectively). The mass loss in the second step, which ends at ca. 300 °C, of ca. 20% (calc. 22.5) for **5** and ca. 27% (calc. 29.4) for **6** corresponds approximately to two halide ions and two ethyl ester groups. In the DTA curves these processes are visible as two endothermic peaks between 210 °C and 290 °C. The complete dehalogenation and deesterification of the complexes is confirmed by the absence of the *ν*(Pd–Cl/Br), P–O–Et and C–C ethyl absorptions in the IR spectra. The pyrolytic decomposition of the ligand is followed by a continuous mass loss with several mostly endothermic or unclear peaks in the DTA curves. In the chelate complex **7** a broad dehydration step between 40 and 160 °C, which indicates that two water molecules are lattice-held [38], is followed by decomposition of the complex including deesterification and other ligand degradation processes in the 200–500 °C region. The pyrolytic residue in all the complexes is a mixture of Pd and P_2O_5, which was confirmed by the IR and X-ray data. Difference obtained between the calculated and found residue value could be ascribed to partial sublimation of P_2O_5, which takes place at higher temperatures [39].

It was shown that dehalogenation of the complexes is the main process in the course of decomposition of the halide complexes, what is in agreement with the FAB-mass spectroscopy data, in which the main fragment ions are those obtained by the sequential loss of halide ions.

3.7. Antitumor activity

The antitumor activity of the complexes **1**–**7** was assayed *in vitro* on the human epidermoid KB and the murine leukemia L1210 cell lines as a preliminary screening for their biological activity. The results, expressed as concentration of the complex required to inhibit the tumor cell growth by 50% (IC_{50}), are summarized in Table 5. Reported data of the molecular and ionic palladium complexes with diethyl 8-quinolylmethylphosphonate (8-dqmp) and monoethyl 2-quinolylmethylphosphonate (2-Hmqmp) are given for comparative purposes [8,9]. In general, it was shown that the L1210 line was more responsive than the KB cell line and that the bromo complexes were slightly more effective than their chloro analogues in the case of monoester 8-

Hmqmp derivatives. However, for complexes of diester 8-dqmp there is no significant difference in response between the two cell lines, neither between the chloro and bromo complexes. Complexes of diester were a bit more effective than those of monoesters, especially against the KB cell line, which may be partly ascribed to the greater solubility and lypophilicity of the former complexes. Fairly good relationship generally could be seen between activity and solubility of the complexes. The lypophilicity of the complexes increases with increasing bulkiness from monoester to diester derivatives and may facilitate transport through the cellular membranes [40]. On the other hand, the presence of the acidic phosphonate group in monoester may cause the opposite effect. It is interesting to note that there are no significant differences in antitumor activity between various types of complexes with 8-Hmqmp (ca. 18–50 in KB and 10–18 μM in L1210 cells) and 2-Hmqmp (ca. 18–44 in KB and 16–22 μM in L1210 cells), as well as between neutral and ionic complexes of 8-dqmp (ca. 7–18 in KB and 8–16 μM in L1210 cells), in spite of their different structural properties and presumably different properties in hydrolysis, transport mechanism inside the cells and different mode of DNA binding and nicking ability [41]. Cytotoxicity in the case of ionic complexes most probably reflects the combined activity of the protonated ligand and the anionic metal complex. Further studies on the potential mechanism of antitumor action of complexes are needed for a better understanding how chemical properties of complexes impact their biological activity.

4. Conclusion

With the aim of preparing new complexes which might be of interest as antitumor agents, a series of palladium(II) complexes of monoethyl 8-quinolylmethylphosphonate has been prepared and studied. Depending on the reaction conditions (pH and initial quinolinium and palladium salts) four types of complexes were isolated, which structure as well as stability and mode of decomposition were determined by spectral and thermal studies. The biological properties of the complexes were investigated by evaluation of their antitumor activity. In general, it may be concluded that the quinoline-based aminophoshonates and their palladium(II) complexes represent an interesting family of compounds with regard to their physicochemical, structural and biological properties. Although none of the complexes were found to exhibit cytostatic activity with potential therapeutic applicability, the present results obtained by studying the chemical characteristics that mold biological activity of the complexes could help in design of the novel compounds with potent biological activity.

Acknowledgement

The financial support of the Croatian Ministry of Science, Education and Sports (Grant No. 098-0982915-2950) is gratefully acknowledged. The authors would like to thank Mr. Ž. Marinić for recording the NMR spectra and Dr. R. Trojko for some TG/DTA measurements.

Scheme 1. Formation of self-assembled macrocycles **3a** and **3b**.

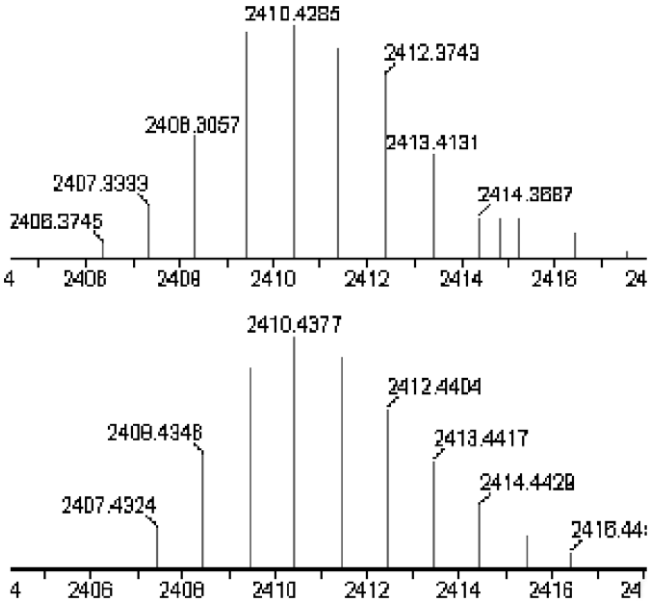

Figure 2. ESI-MS spectrum of **3a**–**3b**, in acetonitrile. Isotopic distribution for $[M_2L_2]^+$, found (top) and calculated (bottom).

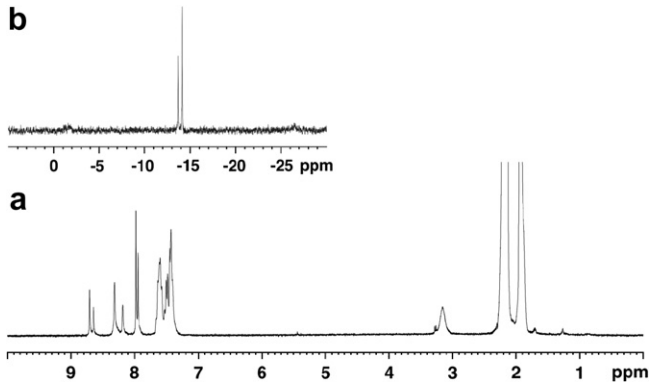

Figure 1. (a) ^{1}H NMR (CD_3CN, 25 °C), and (b) ^{31}P NMR (CD_3CN, 25 °C) of macrocycles **3a**–**3b.**

changes that make pyridil groups non-equivalents. The ^{31}P NMR spectrum also contains two singlets, at −13.72 and −14.16 ppm indicative of the presence of two isomers with equivalent corners and phosphine ligands. The presence of a *syn*/*anti* isomer due to two inequivalent phosphorus centres, coordinated to platinum in cis position must show an AB pattern with a J_{P1-P2} coupling constant in the ^{31}P NMR spectrum. No P–P coupling was observed, in ^{31}P NMR spectrum, that means that the two phosphorus atoms remained equivalents for the isomer presents *syn*/*syn* **3b** and *anti*/*anti* **3a**.

The integration ratio of the ^{31}P NMR signals was found to be temperature-dependent, changing from 1:2 at room temperature over 2.5:1 at 258 K, and 1:5 at 338 K. This, strongly supports the presence of two different conformers in equilibrium (Fig. 3). As suitable X-ray quality crystals for **3** could not be obtained, MM2 force field simulation

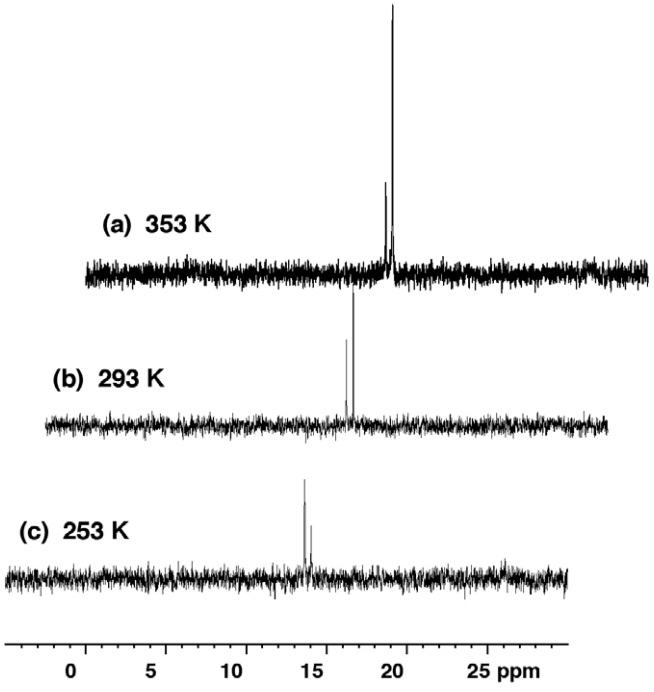

Figure 3. ^{31}P NMR (81 MHz) spectrum of isomers **3a** and **3b**. Variable temperature ^{31}P NMR spectra recorded in CD_3CN at (a) 353 K; (b) 293 K; (c) 253 K.

was employed to visualize the shape and size of **3a**–3b [5]. A view of the molecules is shown in Fig. 4.

The structure establishes the formation of a 34-membered macrocycles, containing two identical platinum atoms, separated by 17.16 and 17.27 Å, respectively. Size estimation using MM2 simulations shows the assemblies are almost 25 Å in length and 8 Å wide. N–Pt–N angle values for **3a**–b are given in Table 1.

Simulation studies are in agreement with the experimental NMR data (Table 1) showing an upfield displacement of the ^{31}P NMR signal when N–Pt–N angle close to 90° increase, while the opposite behavior is found for ^{1}H NMR shifts corresponding to protons orto to the pyridyl–nitrogen atom. In order to corroborate this, the bipyridin Pt complex $[Pt(dppp)(Py)_2][OTf]_2$ (**4**) [6] (Fig. 5) was prepared and the upfield shift of the ^{31}P NMR signals $\partial = -14.86$ ppm was found to be in accordance with the N–Pt–N angle value 90.73° obtained from the theoretical simulation (Table 1).

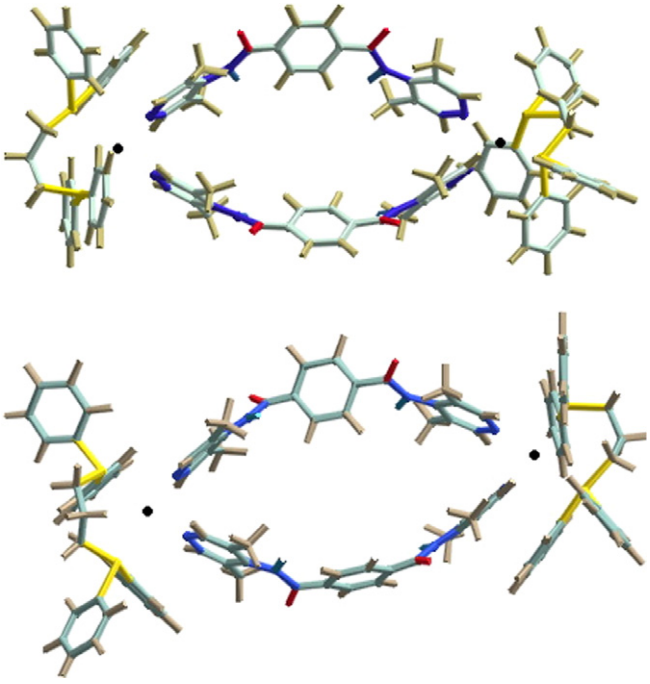

Figure 4. Optimized structures corresponding to the **3a** *anti* and **3b** *syn* compounds obtained from CAChe.

Table 1
Experimental ^{31}P NMR coordination shifts in $[Pt(dppp)(L)_2][OTf]_2$ and calculated N–Pt–N angle values

Solvent	Ligand $(L)_2$	$[Pt(dppp)(L)_2][OTf]_2$ ∂^{31}P (ppm)	N–Pt–N (°)	Pt1–Pt2 (Å)
$CDCl_3$	H_2O	−12.60		
$CDCl_3$	CD_3CN	−16.12		
CD_3CN	CD_3CN	−15.10		
CD_3CN	Py	−14.86	90.73	
CD_3CN	2B (3b)	−14.16	83.77	17.16
CD_3CN	2A (3a)	−13.72	83.28	17.27

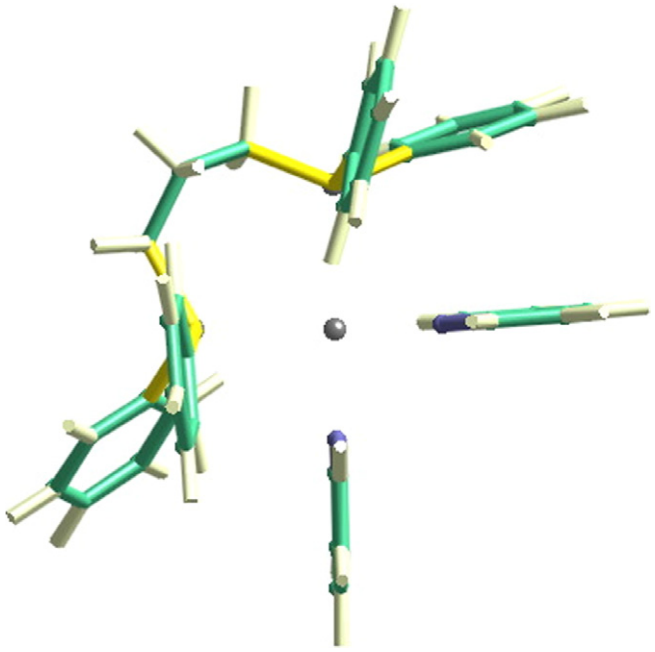

Figure 5. $[Pt(dppp)(Py)_2][OTf]_2$ (**4**) optimized structure obtained from CAChe.

Based on the results summarized in Table 1, that an upfield displacement of the ^{31}P NMR signals correspond to an increase of the N–Pt–N angle values, the signal at $\partial = -13.72$ ppm on the ^{31}P NMR spectra was assigned to the *anti* arrangement **3a** with a N–Pt–N angle of 83.28°, while the signal at $\partial = -14.16$ ppm correspond to the *syn* arrangement **3b** with a N–Pt–N angle of 83.77°.

3. Conclusions

The bis(amidopyridine) ligands combine easily with *cis*-protected square planar platinum (II) corners to form M_2L_2 macrocycles. The bridging coordination of the bis(amidopyridine) ligand **2** can occur with different ligand conformations **A** or **B** in witch the NH groups have a *syn* or an *anti* arrangement. The distinctive $\Delta\partial$ values, 0.22 ppm for the alfa pyridil hydrogens, and 0.44 ppm for the diphosphine ligand (^{31}P NMR shifts) produced from differences in the chemical environment of the **3a**–**b** isomers, have been found to be closely related with the N–Pt–N angle aperture of the complexes, and used to the assignment.

In summary, a new rhomboid was isolated, as two different geometric isomers **3a** *anti* and **3b** *syn*.

4. Experimental

^{1}H NMR and ^{31}P NMR spectra were obtained using a Bruker AMX 300 NMR and were recorded at 300 and 81 MHz, respectively. All reagents and chemicals were obtained from the Aldrich Chemical Company and were used as received unless otherwise noted.

Syntheses of [Pt(dppp)(O_3SCF_3)$_2$] (**1**) was prepared according to literature procedures [3e]. ^{1}H NMR (300 MHz, CD_3Cl) $\delta = 7.72$–7.65 (m, 8H), 7.49–7.40 (m, 12H), 2.93 (m, 4H), 2.17 (m, 2H); ^{31}P {^{1}H NMR} (CD_3Cl, 81 MHz) $\delta = -12.6$ (s, ^{195}Pt satellite, $J_{Pt-P} = 3789.8$ Hz); ^{19}F NMR (188.6 MHz, CD_3Cl) $\delta = -77.0$ ppm. ^{1}H NMR (300 MHz, CD_3CN) $\delta = 7.62$–7.50 (m, 8H), 7.49–7.39 (m, 12H), 2.85–2.60 (m, 6H); ^{31}P {^{1}H NMR} (CD_3CN, 81 MHz) $\delta = -15.1$ (s, ^{195}Pt satellite, $J_{Pt-P} = 3789.8$ Hz).

4.1. *N,N′-Bis(3,5-dimethyl-4-pyridinyl)-1,4-benzene-dicarboxamide (**2**)*

To a CH_2Cl_2 (10 ml) solution of 1,4 benzene-dicarbonyl dichloride (235 mg, 1 mmol) at 0 °C was added 4-amino-3,5-lutidine (285 mg, 2.1 mmol) and N,N-diisopropylethylamine (420 μl, 2.5 mmol). The solution was stirred at room temperature for 2 h and subsequently heated at reflux for 2 h. The reaction mixture was diluted with CH_2Cl_2(10 mL), washed with saturated $NaHCO_3$ and brine, dried over anhydrous $MgSO_4$, and evaporated. The solid residue was washed with diethyl ether and recrystallized in CH_2Cl_2/EtOAc solvent to provide **2** as a white solid (190 mg, 50%). ^{1}H NMR (300 MHz, CD_3CN) $\delta = 9.78$(s, NH, 2H), 8.25 (s, 4H), 8.16 (s, 4H), 2.26 (s, 12H); ESI-MS *m/z* 375.1814 $[M+H]^+$ (calc. mass), Found (375.1821).

4.2. *Macrocycles **3a**–**3b***

To a solution of **2** (3.7 mg, 1 mmol) in CD_3CN 500 μl was slowly added [Pt(dppp)(O_3SCF_3)$_2$] (**1**) (9.1 mg, 1 mmol) and heated at 45 °C for 2 h. **3a** *anti* ^{1}H NMR (300 MHz, CD_3CN) $\delta = 8.71$ (s, NH, 4H), 8.31 (s, 8H), 7.98 (s, 4H), 7.61 (brs, 8H), 7.98 (brs, 16H), 3.16 (brs, 8H), 2.17(brs, 4H), 1,89 (s, 24H); ^{31}P {^{1}H NMR} (CD_3CN, 81 MHz) $\delta = -14.16$ (s, ^{195}Pt satellite, $J_{Pt-P} = 1508$ Hz); **3b***syn*; ^{1}H NMR (300 MHz, CD_3CN) $\delta = 8.64$ (s, NH, 4H), 8.19 (s, 8H), 7.95 (s, 4H), 7.61 (brs, 8H), 7.44 (brs, 16H), 3.16 (brs, 8H), 2.17 (brs, 4H), 1,89 (s, 24H); ^{31}P {^{1}H NMR} (CD_3CN, 81 MHz) $\delta = -13.72$ (s, ^{195}Pt satellite, $J_{Pt-P} = 1510$ Hz). ESI/MS: *m/z* 2410.4766 (M-OTf) found; 2410.4377 (M-OTf) calc. Elemental analysis Found: C, 47.32; H, 3.74; N,4.48. Calculated for $C_{102}H_{96}F_{12}O_{16}P_4Pt_2S_4$: C, 47.85; H, 3.78; N,4.38. stoichiometry is found for the acetate type $[Cu_2(RCOO)_4(denia)_2]$ dimeric complexes [3–7]. The 1:2 stoichiometry can be found in monomeric complexes of $Cu(RCOO)_2(denia)_2(H_2O)_x$, where $x = 0$, [8–10], $x = 2$ [11–15], $x = 4$ [16] or in $Cu(RCOO)_2(denia)_2(CH_3OH)$ [17], and in all those complexes the denia molecules are unidentate N donor ligands. Recently the first polymeric complex with bridging denia molecules, of the composition $[Cu_2(ClCH_2COO)_4(denia)_1]_n$, has been structurally characterized [18]. In this paper we report on the preparation, spectral and magnetic properties, and X-ray structures of two new copper(II) complexes containing the denia ligand – one is a polymeric complex of an unusual stoichiometry containing denia bridges, $[Cu_2(2\text{-}NO_2Bz)_4(denia)_1]_n$ (**1**), and its molecular counterpart with the same 2-nitrobenzoato-ligand showing the usual and most frequent stoichiometry, $[Cu(2\text{-}NO_2Bz)_2(denia)_2(H_2O)_2]$ (**2**), together with the complex $[Cu_2(2\text{-}NO_2Bz)_4(DMF)_2]$ (**3**), that was obtained as a byproduct by recrystallization of (**1**) using dimethylformamide solvent.

2. Experimental

2.1. Synthesis

Both complexes (**1**) and (**2**) could be obtained from the same reaction mixture at different temperatures.

2.1.1. Preparation of $[Cu_2(2\text{-}NO_2Bz)_4(denia)_1]_n$ (1)

An ethanolic solution of copper(II) acetate (1 mmol in cca 20 mL of ethanol) was stirred with *N*,*N*-diethylnicotinamide (2 mmol), then 2-nitrobenzoic acid (2 mmol) was added and the reaction mixture was stirred until the precipitation of the green product finished (about 20 min). The microcrystalline green product (**1**) was filtered off, washed with a small portion of ethanol and dried at ambient temperature. The light blue mother liquid obtained after filtration was left for crystallization. Blue crystals of complex (**2**) were obtained from mother liquid. Crystals of (**1**) suitable for X-ray structure determination were obtained by recrystallization of (**1**) from an ethanolic solution.

Calc. for $C_{38}H_{30}N_6O_{17}Cu_2$ Cu, 13.10; C, 47.06; H, 3.12; N, 8.67. Found: Cu, 13.37; C, 46.86; H, 3.21; N, 9.41%.

2.1.2. Preparation of $[Cu(2\text{-}NO_2Bz)_2(denia)_2(H_2O)_2]$ (2)

An ethanolic solution of copper(II) acetate (1 mmol in cca 20 mL of ethanol) was stirred with *N*,*N*-diethylnicotinamide (2 mmol), then 2-nitrobenzoic acid (2 mmol) was added and the reaction mixture was stirred under heating until the green microcrystalline solid dissolved and a dark blue solution was obtained. The obtained solution was left to stand for slow crystallization and the obtained blue crystalline product (including crystals suitable for X-ray structure determination) was filtered off, washed with a small amount of ethanol and dried at ambient temperature.

Calc. for $C_{34}H_{44}N_6O_{12}Cu$: Cu, 8.06; C, 51.81; H, 5.12; N, 10.66. Found: Cu, 8.82; C, 51.99; H, 5.24; N, 11.71%.

2.1.3. Preparation of $[Cu_2(2\text{-}NO_2Bz)_4(DMF)_2]$ (3)

Crystals for X-ray structure determination were obtained by recrystallization of (**1**) from dimethylformamide.

Calc. for $C_{34}H_{30}N_6O_{18}Cu_2$: Cu, 13.22; C, 44.96; H, 3.14; N, 8.74. Found: Cu, 13.00; C, 44.90; H, 3.20; N, 8.95%.

2.2. Analytical measurements

Carbon, hydrogen and nitrogen analysis were carried out on a CHNSO FlashEA 1112 (ThermoFinnigan) elemental analyzer. Copper was determined by electrolysis of a water solution obtained by sample mineralization with a mixture of sulfuric acid and potassium peroxodisulfate.

2.3. Physical measurements

Electronic spectra (190–1100 nm) of the complexes were measured in Nujol suspensions with a SPECORD 200 (Carl Zeiss Jena) spectrophotometer, and infrared spectra in the region 4000–100 cm^{-1} were measured with a Nicolet MAGNA 750 IR spectrometer using both KBr pellet and Nujol suspension techniques for the 4000–400 cm^{-1} region and polyethylene pellets for the 400–100 cm^{-1} region.

EPR spectra of powdered samples were recorded at room temperature and at 77 K, on a Bruker ESP 300 spectrometer, operating at the X-band and equipped with an ER 035M Bruker NMR gaussmeter and a HP 5350B Hewlett Packard microwave frequency counter.

Data collection and cell refinement of complex (**1**) were carried out using a Siemens P4 diffractometer [19], data for complex (**2**) were collected using a Nonius kappaCCD diffractometer [20], and for complex (**3**) using an Xcalibur PX kappa-geometry diffractometer with a CCD Onyx camera with graphite monochromated Mo Kα radiation, using the CRYSALIS software package [21]. Intensity data were corrected for Lorenz and polarization factors and absorption corrections of (**1**) were made [22]. The structures were solved by the direct atom method with SHELXS-97 [23], and refined by the full-matrix least squares procedure with SHELXL-97 [24]. Geometrical analyses were performed using SHELXL-97 [24] and the structures were drawn using the ORTEP-3 for Windows program [25]. Final crystal data and structure refinement parameters are given in Table 1.

Magnetization measurements of all the samples in the temperature range 1.8–300 K were carried out on powdered samples of the complexes, at a magnetic field of 5 kG, using a Quantum Design SQUID Magnetometer (type MPMS-XL5). Corrections for diamagnetism of the constituent atoms were calculated using Pascal constants [26], the value of 60×10^{-6} cm^3 mol^{-1} was used as the temperature-independent paramagnetism of the Cu^{2+} ion. The effective magnetic moments were calculated from the expression:

$$\mu_{eff} = 2.83\sqrt{\chi_m^{corr} \cdot T}\ (\text{B.M.})$$

3. Results and discussion

3.1. Complex preparation

The present study of *N*,*N*-diethylnicotinamidecopper(II) complexes with 2-nitrobenzoate anions is based on a knowledge that the 2-nitrobenzoate anion in comparison to other isomeric nitrobenzoate anions exhibits variable bonding modes, due to the presence of a nitro-substituent in the *ortho*-position. The formation of a dimeric complex, $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2]\cdot 2H_2O$, has been observed [27]. On the other hand, $[Cu(2\text{-}NO_2bz)_2(3\text{-pyme})_2(H_2O)_2]$ (where 3-pyme=3-pyridylmethanol) is the first complex with the 3-pyme ligand that exhibits a molecular monomeric structure [28], while all other carboxylatocopper(II) complexes with the 3-pyme ligand have a polymeric structure with 3-pyme as a bridging ligand. A monomeric structure was also observed in the $[Cu(2\text{-}NO_2bz)_2(nia)_2(H_2O)_2]$ complex [29]. However, the reaction conditions (solvent used, stoichiometry and temperature) can play a significant role in such syntheses, and therefore we performed the syntheses under different conditions. The reactions done in water solutions gave $[Cu_2(2\text{-}NO_2Bz)_4(denia)_1]_n$ (**1**) only at lower copper(II):denia molar ratios (1:0.5 or 1:1), whilst with copper(II):denia ratios higher than 1:1 blue solutions were obtained and blue crystals of $[Cu(2\text{-}NO_2Bz)_2(denia)_2(H_2O)_2]$ (**2**) crystallized after solvent evaporation. Less polar solvents that shift equilibria towards dimeric species

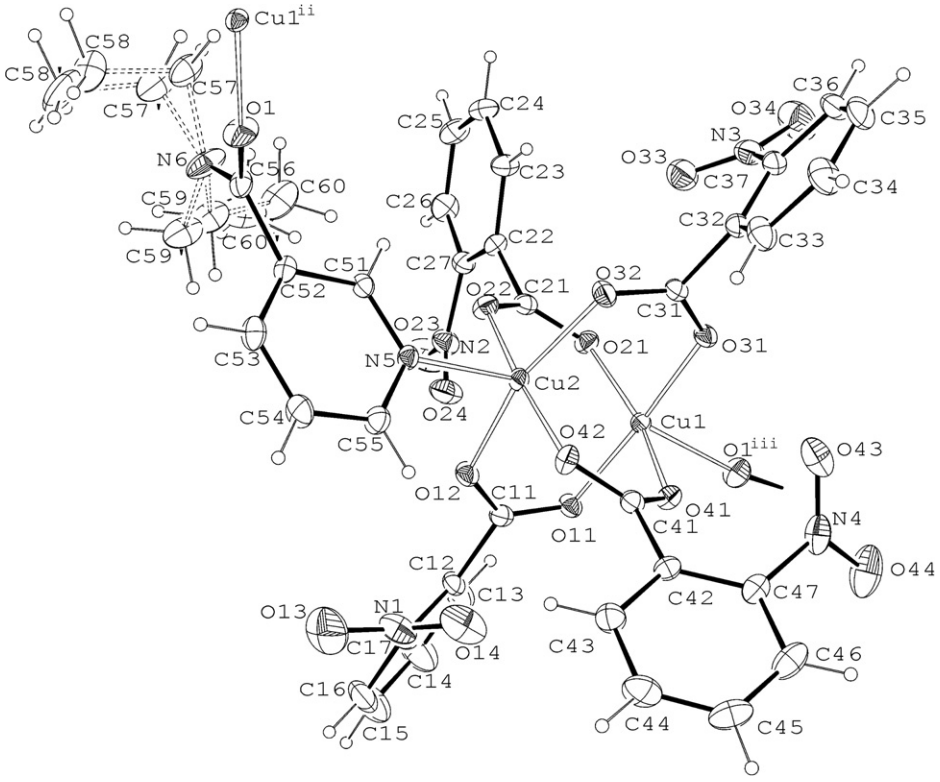

Fig. 1. Perspective view of $[Cu_2(2\text{-}NO_2bz)_4(denia)_1]_n$ (**1**) with the non-hydrogen atom numbering scheme. The disordered ethyl groups of the complex are drawn in open dashed lines.

in solution (acetone and/or toluene) give preferential complex (**1**) formation even at copper(II):denia molar ratios of 1:2 or 1:4. However, recrystallizations from different solvents have shown that the acidity of the reaction mixture (presence of acetic acid) after the reaction probably plays a significant role in transformation of $[Cu_2(2\text{-}NO_2Bz)_4(denia)_1]_n$ (**1**) to $[Cu(2\text{-}NO_2Bz)_2(denia)_2(H_2O)_2]$ (**2**) during heating of the reaction mixture.

3.2. Structure, spectral and magnetic properties of $[Cu_2(2\text{-}NO_2Bz)_4(denia)_1]_n$ (1)

The principal structural features and atom numbering scheme of complex (**1**) are depicted in Fig. 1 and selected bond distances and angles are listed in Table 2. The independent part of the structure consists of the dimeric $Cu_2(2\text{-}NO_2Bz)_4$ unit and one molecule of a denia ligand that is bonded to the Cu2 atom of the dimeric unit *via* the pyridine N5 nitrogen atom (with a Cu2–N5 distance of 2.145(4) Å) and bonded *via* the carbonyl O1 oxygen atom to the Cu1^{ii} [(ii) $= x + 0.5, -y + 0.5, z - 0.5$] atom of a neighbouring dimeric unit (with a Cu1–O1 distance of 2.137(4) Å), thus forming a *zig-zag* chain parallel to the *ac* plane. The square-pyramidal coordination polyhedron of the Cu1 atom has the base formed by the O11, O21, O31 and O41 atoms of carboxylate groups (average Cu1–O_{base} distance 1.968 Å) and the O1 atom of the bridging denia molecule in the apical position. Similarly, the square pyramid of the Cu2 atom consists of O12, O22, O32 and O42 oxygen atoms (average Cu2–O_{base} distance 1.972 Å) within the basal plane and the N5 nitrogen atom in the apical position. The Cu1···Cu2 distance within the dimeric $Cu_2(2\text{-}NO_2bz)_4$ unit is 2.6990(9) Å and both copper atoms are shifted from the basal planes towards the apical position, showing a Cu1–O_4(basal plane) distance of 0.209 Å and Cu2–O_4(basal plane) distance of 0.238 Å, confirming the greater shift of the copper atom from the basal plane towards the apical nitrogen atom in comparison to that towards the apical O-donor [30]. The distance between the Cu atoms bridged by the denia molecule, Cu2···Cu1^{ii} [(ii) $= x + 0.5, -y + 0.5, z - 0.5$], is 7.980(3) Å.

An interesting feature of this structure is that all four 2-nitrobenzoato anions are crystallographically independent, thus all of them exhibit different space orientations. The dihedral angles between the Cu_2O_2C plane (bridging carboxylato group with both copper atoms) and the corresponding phenyl ring plane are 40.4° for the C12–C17 ring, 69.1° for the C22–C27 ring, 61.6° in the case of the C32–C37 ring and finally 35.2 for the C42–C47 ring. Consequently these different space orientations of the phenyl rings lead to the conclusion that to name this structure as a "paddle-wheel" like structure is inadequate because the C12–C17 phenyl ring shows an opposite space orientation in comparison to the three other rings. Similarly different values were found for the "nitro group-to-benzene ring" with a dihedral angle of 49.4° for the C12–C17 ring, 14.3° for the C22–C27 ring, 26.0° for the C32–C37 ring and 52.2° for the C42–C47 ring.

The published structure of $[Cu_2(ClCH_2COO)_4(denia)]_n$, the only one containing a bridging denia ligand [18], differs from our one by having an "antiparallel denia bridge orientation" which results in alternation of two different dimeric units $\{-[Cu_2(RCOO)_4]-N(\mu\text{-denia})O-[Cu_2(RCOO)_4]-O(\mu\text{-denia})N-\}_n$, while the "similar denia bridge orientation" in our case leads to the formation of dimeric units with two different apical donor atoms. It should be stressed that this is the second example in which two Cu(II) atoms within one dimeric unit are different from each other by their coordination polyhedra (Cu^1O_4O' and Cu^2O_4N). The first one was the $[Cu_2(Cl_3CCOO)_4(caf)]_n \cdot 2n(CH_3C_6H_5)$ polymeric complex [31] with a caffeine molecule as the bridging ligand between the dimeric units. Similarly, different chromophores were observed [32] for the molecular complex $[Cu_2(fluf)_4(caf)(H_2O)]$ where caf = caffeine and fluf = flufenamate. On the other hand, the alternation of two different dimeric units were found for the $[Cu_2(CH_3COO)_4(nia)]$ [33] (where nia = nicotinamide) and $[Cu_2(Me_3CCOO)_4(NITpPY)]_n$ complexes [34] (where NITpPY = 2-(3-pyridyl)-4,4,5,5-tetramethyl-1*H*-imidazolyl-1-oxyl-3-oxide). The polymeric chains of complexes $[Cu_2(2\text{-}O_2Nbz)_4(denia)]_n$ (a) and $[Cu_2(ClCH_2COO)_4(denia)]_n$ (b) are given in Fig. S1 in the Supplementary material.

Both magnetic susceptibility measurements, Fig. 2, and EPR spectra, Fig. 3, have proved the presence of a dimeric moiety within the crystal structure of $[Cu_2(2\text{-}NO_2Bz)_4(denia)_1]_n$ (**1**). Magnetic susceptibility, measured in the temperature range 1.8–300 K, has shown that complex (**1**) is diamagnetic in the temperature region 1.8–75 K, then the magnetic susceptibility increases systematically with increasing temperature, from 80 K to 300 K, and a reaches maximum at about room temperature. At 300 K the observed value of the effective magnetic moment is equal to 1.33 B.M. and at a temperature of 80 K $\mu_{eff} \cong 0.08$ B.M. This trend indicates an exchange antiferromagnetic interac-

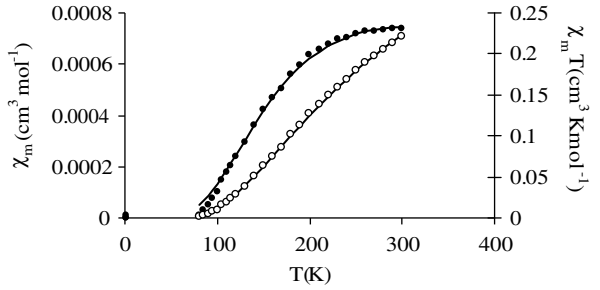

Fig. 2. The plot of χ_m (•) and the $\chi_m T$ (○) product vs. temperature for complex (**1**) (χ_m – the molar magnetic susceptibility calculated per one copper(II) center). The solid line was generated from the best-fit magnetic parameters, $g = 2.20$, $2J = -340\ cm^{-1}$ $zJ' = -0.10\ cm^{-1}$, $R = 2.00 \times 10^{-4}$.

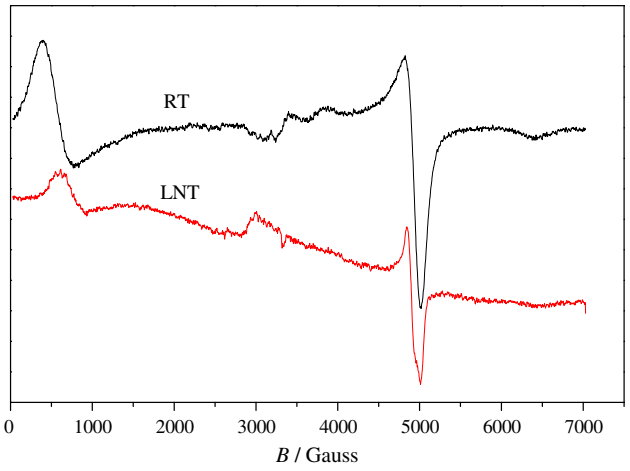

Fig. 3. EPR spectra of a powdered sample of complex (**1**) at room (RT) and at liquid nitrogen temperature (LNT). Parameters obtained from the spectra: $g_\perp = 2.07$, $g_\parallel = 2.35$, $D = 0.380\ cm^{-1}$.

tion between the copper(II) magnetic centers like in the other dimeric Cu^{II} tetracarboxylates [35,36]. Similar magnetic properties were observed in the dihydrate tetrakis(2-nitrobenzoato)di(aqua)dicopper(II) complex [27]. The magnetic data of the complex were fitted to a susceptibility equation derived from the spin Hamiltonian $H = -2JS_1S_2$, with the Bleaney–Bowers equation [37], to characterize the intradimer interaction:

$$\chi_{Cu} = \frac{N\beta^2 g^2}{3kT}\left[1 + \frac{1}{3}\exp\left(\frac{-2J}{kT}\right)\right]^{-1} + N\alpha$$

(where N is the Avogadro number, g – the spectroscopic splitting factor, β – the Bohr magneton, k – the Boltzmann constant and J – the exchange parameter), together with the application of a molecular field model for the calculation of the present magnetic data of complex (**1**) to obtain characteristics of the interdimer magnetic interactions, the zJ' parameter (z is the number of nearest neighbours) [42].

$$\chi_m^{corr} = \frac{\chi_m}{1 - \frac{2zJ'\chi_m}{Ng^2\beta^2}}$$

The best fitting parameters: singlet–triplet energy gap $2J = -340\ cm^{-1}$, $zJ' = -0.1\ cm^{-1}$, $g = 2.20$, were obtained with a good agreement factor $R = 1.99\ 10^{-4}$, R is the agreement factor, defined by

$$R = \frac{\sum_{i=1}^{n}(\chi_i^{exp}T - \chi_i^{calc}T)^2}{\sum_{i=1}^{n}(\chi_i^{exp}T)^2}$$

The results are presented in Fig. 2. The calculation procedure shows that the main factor determining the magnetic properties of the polymeric complex **1** is the antiferromagnetic coupling between the Cu^{2+} ions in the dimeric subunits. The magnetic interactions through diethylnicotinamide are very weak ($zJ' = -0.1\ cm^{-1}$), comparable to nicotinamide bridges [38]. The $2J$ value exceeding $300\ cm^{-1}$ is in good relation [39] to the coplanarity of all four carboxylato groups with the corresponding Cu_2O_2 planes. The greatest deviation from coplanarity was found between the O11–C11–O12 plane and the corresponding O11–Cu1–Cu2–O12 plane, where the φ_{bend} dihedral angle is 2.90°.

The EPR spectra, Fig. 3, of complex (**1**) shows the typical features of dimeric "acetate type" copper(II) complexes. The signal of complex (**1**) is very weak at liquid nitrogen temperature and that is consistent with the magnetic susceptibility measurements and raising a singlet state population with decreasing temperature. It is worth noting that no signal of a paramagnetic monomeric impurity is observed in this case, thus the dimeric units are connected and form a polymeric structure.

This structural observation is also supported by the IR spectrum data. The spectrum of complex (**1**) contains peaks of COO^- vibrations at 1579 (ν_{as}) and 1411 cm^{-1} (ν_s). The $\Delta\nu$ value ($\Delta\nu = \nu_{as} - \nu_s$) of 168 cm^{-1} is consistent with a bridging mode of bonding of the 2-NO_2-benzoate anion [40] and our previous results [27]. The electronic spectrum of (**1**) exhibits a broad asymmetric band with a maximum at 733 nm, that could be assigned to a d ← d transition, and a shoulder at about 375 nm, which is typical for a dimeric "acetate type" structure.

3.3. Structure, spectral and magnetic properties of [Cu(2-NO_2Bz)$_2$(denia)$_2$(H_2O)$_2$] (2)

The structure of (**2**) consists of centrosymmetric molecules, Figs. 4 and 5, with an elongated tetragonal-bipyramidal coordination polyhedron around the Cu atom (Table 3). The coordination sphere of the copper(II) atom in the *trans*-basal plane is formed by two 2-nitrobenzoate anions bonded *via* O1 atoms (the Cu–O1 distance is 1.958(2) Å) and two denia molecules bonded *via* N2 atoms (the Cu–N2 distance is 2.042(2) Å), and in the apical positions are two water molecules (the Cu–O1W distance is 2.462(2) Å). The water molecules, due to an intramolecular hydrogen bond (O1W–H2W···O2^{iii} with O1W···O2^{iii} [symmetry code: (iii) $-x+1$, $-y$, $-z$] at a distance of 2.770(2) Å) are slightly shifted from a precise apical posi-

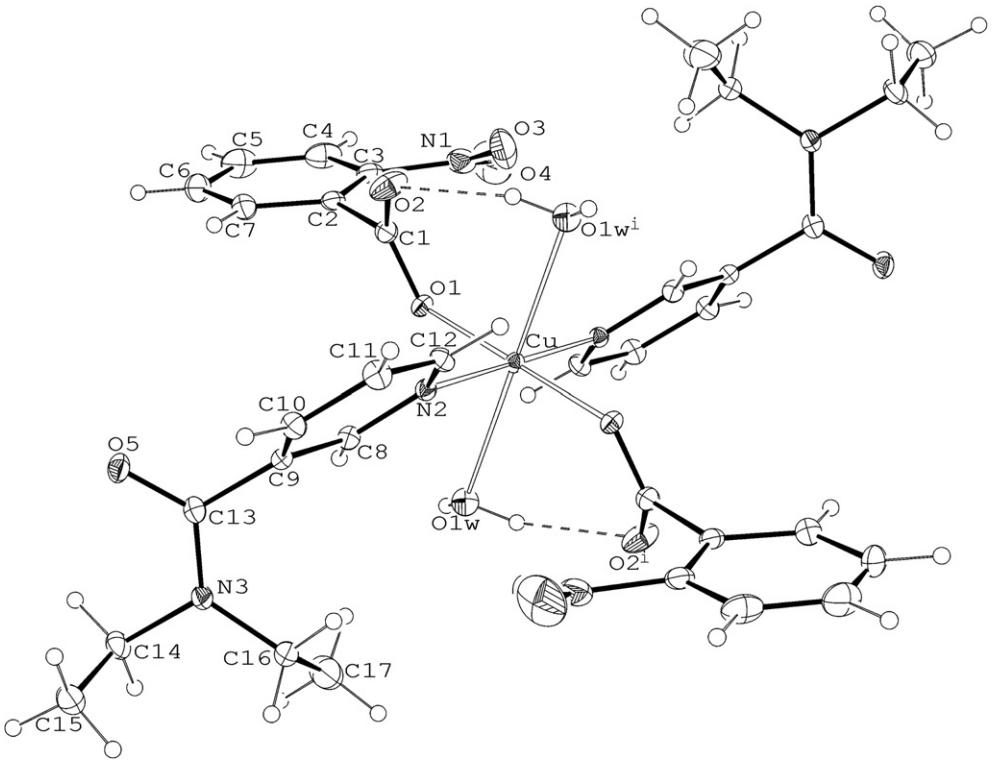

Fig. 4. Perspective view of $[Cu(2\text{-}NO_2bz)_2(denia)_2(H_2O)_2]$ (**2**) with the non-hydrogen atom numbering scheme.

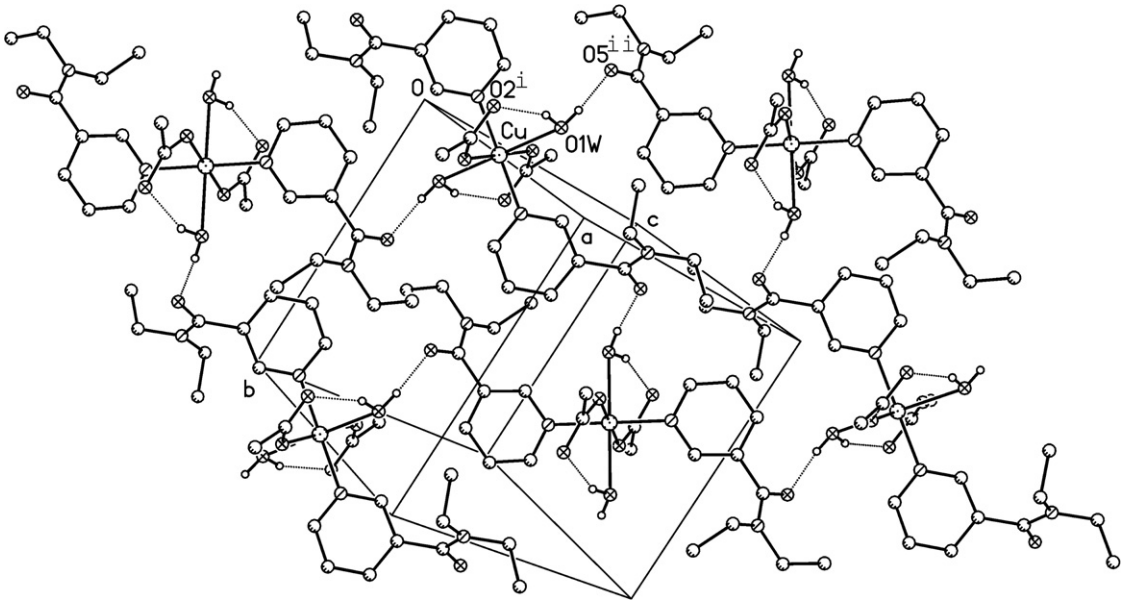

Fig. 5. View of the two-dimensional sheet of complex (**2**). Dashed lines indicate O–H···O hydrogen bonds. The 2-nitrophenyl groups are omitted for clarity.

Table 3
Selected distances (Å) and angles (°) for complex **2**

Cu–O1	1.9579(13)	O1–Cu–O1W	86.52(6)
Cu–N2	2.0415(16)	O1–Cu–N2	92.17(6)
Cu–O1W	2.4622(16)	N2–Cu–O1W	87.46(6)

tion towards the uncoordinated O2 carboxylato oxygen atom and the O1–Cu–O1W angle is 86.52(6)° (Table 4). The molecules of (**2**) are linked to adjacent molecules by O1W–H1W···O5^{iv} [symmetry code: (iv) $x+3/2$, $y1/2$, $z+1/2$] hydrogen bonds with a O1W···O5^{iv} distance of 2.810(2) Å into 2-D hydrogen bonding sheets with a Cu···Cu distance of 9.403(3) Å (Fig. 5).

The structure of (**2**) can be compared to other complexes of the general formula $[Cu(RCOO)_2(denia)_2(H_2O)_2]$ [11–15]. The Cu–O distances (Cu–O_{eq} where O_{eq} is the oxygen of a carboxylate group, and Cu–O_{ax} where O_{ax} stands for water oxygen) for complex (**2**) were found within the range

Table 4
Parameters in (Å) and (°) of hydrogen bonds within the structure of complex **2**

D–H···O	d(D···O)	∠(DHO)	Symmetry code
O1W–H1W···O5^{iv}	2.810 (2)	168 (4)	$-x+3/2$, $y-1/2$, $-z+1/2$
O1W–H2W···O2^{iii}	2.770 (2)	155 (4)	$-x+1$, $-y$, $-z$

of those distances for other known complexes 1.936(3) and 2.557(3) Å for RCOO = mefenamate [11], 1.961(2) and 2.449(2) Å for RCOO = flufenamate [12], 1.959(2) and 2.485(2) Å for RCOO = 4-nitrobenzoate [13], 1.965(2) and 2.503(2) Å for RCOO = 2-chloronicotinate [14] and 1.960(1) and 2.440(2) Å for RCOO = 2-chlorobenzoate [15]. On the other hand, the Cu–N_{eq} distance (N_{eq} is the pyridine nitrogen atom of the denia ligand) for complex (**2**) is the longest one in comparison to 2.027(3) Å for RCOO = mefenamate [11], 2.001(2) Å for RCOO = flufenamate [12], 2.019(2) Å for RCOO = 4-nitrobenzoate [13], 2.015(2) Å for RCOO = 2-chloronicotinate [14] and 2.031(2) for RCOO = 2-chlorobenzoate [15]. The value of the τ parameter ($\tau = R_S/R_L$), indicating [41] the degree of tetragonal elongation of the octahedron, increases in the order 0.775 (mefenamate) [11] <0.795 (2-chloronicotinate) [14] <0.800 (4-nitrobenzoate) [13] <0.809 (flufenamate) [12] <0.813 for complex (**2**) <0.818 (2-chlorobenzoate) [15]. All the complexes $[Cu(RCOO)_2(denia)_2(H_2O)_2]$ have a similar molecular structure, but only $[Cu(2\text{-}ClBz)_2(denia)_2(H_2O)_2]$ [15] is isostructural with complex (**2**).

The magnetic data of $Cu(2\text{-}NO_2bz)_2(denia)_2(H_2O)_2$ are shown in Fig. 6. At 300 K $\chi_m T$ is equal to 0.417 cm^3 K mol^{-1} ($\mu_{eff} = 1.83$ B.M.) and it is characteristic for non-coupled, $S = 1/2$ Cu^{II} centers. With a lowering of a temperature, the $\chi_m T$ value and the magnetic moment smoothly, but systematically, increase to $\chi_m T = 0.431$ cm^3 K mol^{-1} ($\mu_{eff} = 1.86$ B.M.) at 1.8 K. It suggests a very weak ferromagnetic interaction between the Cu^{II} centers, similar to those observed for the polymeric, $[Cu\{3,5\text{-}(NO_2)_2bz\}_2(ron)_2]_n$ complex [28]. Very weak but antiferromagnetic interactions were also observed in the similar monomeric complex $[Cu(2\text{-}NO_2Bz)_2(nia)_2(H_2O)_2]$ [29]. This similarity is probably based on similar weak intermolecular hydrogen bonds (Table 4) in the crystal lattice. The π–π stacking between the aromatic rings of complex **1** molecules was not observed in the crystal structure. In order to obtain a value of the exchange interactions parameter, the present magnetic data of (**2**) have been fitted using magnetic centers ($S = 1/2$) in the molecular field model of magnetic interactions [42]:

$$\chi_m = \frac{N\beta^2 g^2}{3kT} S(S+1), \quad \chi_m^{corr} = \frac{\chi_m}{1 - \frac{2zJ'\chi_m}{Ng^2\beta^2}}$$

where zJ' is the molecular exchange parameter, z is number of the nearest neighbours. The R is the agreement factor defined as

$$R = \sum_{i=1}^{n} \frac{(\chi_i^{exp} T - \chi_i^{calc} T)^2}{(\chi_i^{exp} T)^2}.$$

The magnitude of the magnetic exchange between the ions obtained from these calculations, $zJ' = 0.05$ cm^{-1}, $R = 4.99 \cdot 10^{-5}$ confirm only very weak ferromagnetic interactions in the crystal lattice of complex **2**.

The EPR spectrum, Fig. 7, of complex (**2**) is different from the previous one and is of the axial type with hyperfine splitting in the parallel area that was detected at room and even at liquid nitrogen temperature. Hyperfine splitting of polycrystalline samples of Cu(II) complexes is observed when the copper centers are isolated in the crystal lattice [29], in this case by 2-nitrobenzoate anions and denia molecules.

This conclusion is supported by the IR spectrum of $Cu(2\text{-}NO_2Bz)_2(denia)_2(H_2O)_2$ where the COO^- vibrations at 1607 (ν_{as}), and 1375 cm^{-1} (ν_s), giving a difference between asymmetric and symmetric vibration of 232 cm^{-1}, confirms the monodentate bonding mode of the 2-NO_2-benzoate anion [40]. The electronic spectrum of this monomeric complex also differs from the dimeric

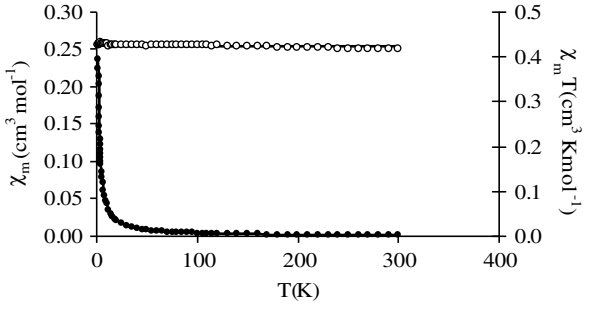

Fig. 6. Plots of the magnetic data versus temperature; χ_m (●), $\chi_m \cdot T$ (○) for complex (**2**). Solid lines present calculated curves using magnetic centers ($S = 1/2$) in the molecular field model of the magnetic interactions (parameters in the text).

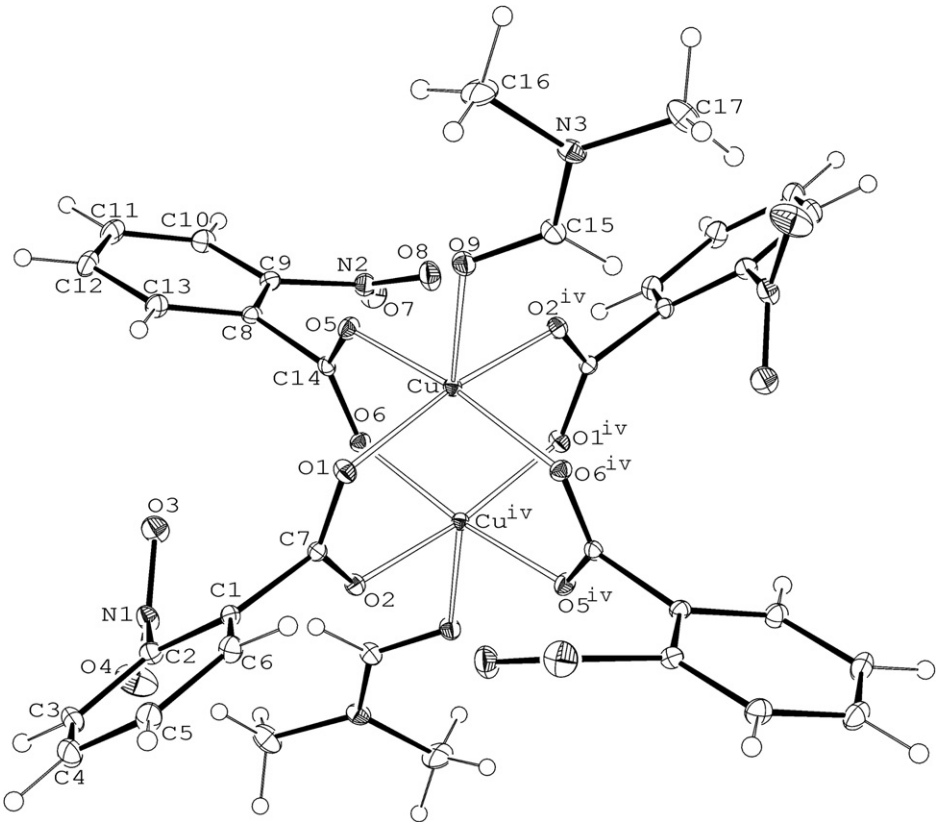

Fig. 8. Perspective view of $[Cu_2(2\text{-}NO_2bz)_4(DMF)_2]$ (**3**) with the non-hydrogen atom numbering scheme.

ones and the d ← d transition for complex (**2**) was found at 634 nm as a broad asymmetric band.

3.4. Structure, spectral and magnetic properties of $[Cu_2(2\text{-}NO_2Bz)_4(DMF)_2]$ (3)

The molecular structure and the numbering scheme are shown in Fig. 8. The structure consists of the centrosymmetric dimeric molecule $[Cu_2(2\text{-}NO_2bz)_4(DMF)_2]$, in which two copper(II) atoms are bridged *via* four carboxylato anions thus forming a square base of four oxygen atoms (Table 5) around each copper (the average Cu–O distance is 1.97(2) Å). The apical position of the square-pyramidal coordination polyhedron is occupied by the oxygen atom O9 of a DMF molecule (the Cu–O9 distance is 2.127(2) Å). The copper atoms are displaced from the respective basal planes towards the apical oxygen atoms by 0.19(1) Å, and the Cu–Cu separation within the dimer was found to be 2.633(1) Å. The crystal structure of (**3**) can be compared with the other dimeric copper(II) aromatic carboxylates with DMF ligands in apical positions [43–53]. It is interesting that the Cu···Cu intradimer distances vary within a narrow region from 2.598 to 2.641 Å, and this variation is caused mainly by moving the copper atom from the basal plane towards the apical ligand (correlation coefficient $R = 0.90$, Table S1 and Fig. S2), and this movement must be related to the anionic bridging ligand nature[1], because the apical ligands are DMF. Similarly, the Cu–DMF distances vary from 2.097 to 2.207 Å and there is a very weak relationship between this distance and the displacement of the copper atom from the basal plane. Comparison of similar complexes containing the moiety $[Cu_2(2\text{-}NO_2bz)_4(L)_2]$ (where $L = H_2O$ [27] or L = DMSO [54]) with complex (**3**) shows that the nature of the apical ligand exhibits a greater influence on all the Cu···Cu, the Cu–basal plane and $Cu\text{–}O_{apic}$ distances.

The magnetic properties of complex (**3**) (Fig. 9) are shown as plots of χ_m and the $\chi_m T$ product versus T (χ_m – the molar magnetic susceptibility calculated per one copper(II) center). The magnetic susceptibility reaches a maximum at room temperature and the value of $\chi_m T$ continuously decreases on lowering of the temperature. At 300 K the observed value of $\chi_m T$ is 0.238 cm^3 K mol^{-1} and the effective magnetic moment is equal to 1.38 B.M. At the temperature 50 K, $\chi_m T$ reaches a minimum (about 0.002 cm^3 K mol^{-1}, which corresponds to $\mu_{eff} \cong 0.13$ B.M). This trend indicates an antiferromagnetic exchange interaction between the two copper(II) magnetic centers of the dimeric unit and depopulation of the excited triplet ($S = 1$) state. Further temperature decreasing results in an increase of $\chi_m T$, probably due to the presence of mono-

[1] For data see Supplementary material Table S1.

Symmetry codes: (v) $-x+1, -y+1, -z+1$.

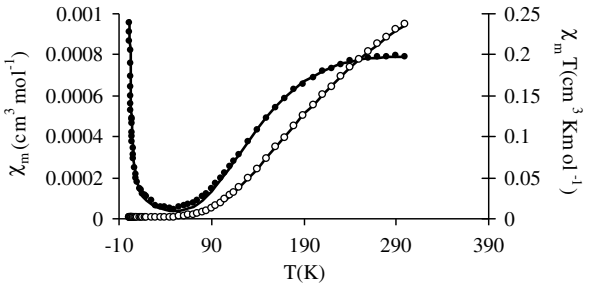

Fig. 9. The plot of χ_m and the $\chi_m T$ product vs. temperature for complex (**3**) (χ_m – the molar magnetic susceptibility calculated per one copper(II) center). The solid line was generated from the best-fit parameters $g_{dim} = 2.20$, $g_{mon} = 2.16$, $2J = -320\ cm^{-1}$, $R = 9.97 \times 10^{-6}$.

meric impurities present in this sample. The magnetic data of the complex were fitting using the modified Bleaney–Bower's equation [42]:

$$\chi_m = \left\{ \frac{Ng_{dim}^2\beta^2}{3kT}\left[1 + \frac{1}{3}(e^{-2J/kT})\right]^{-1} \right\}(1-x) + \left(\frac{Ng_{mon}^2\beta^2}{4kT}\right)x$$

where x is the mole fraction of the monomeric form, and g_{mon} and g_{dim} are spectroscopic splitting factors of the monomer and dimer forms, respectively, and the other symbols have their usual meaning. The magnetic parameters: $g_{dim} = 2.20$, $g_{mon} = 2.16$, $2J = -320\ cm^{-1}$ and monomeric impurities at the 0.38% level were obtained, $R = 9.97 \times 10^{-6}$

$$R = \sum_{i=1}^{n} \frac{(\chi_i^{exp}T - \chi_i^{calc}T)^2}{(\chi_i^{exp}T)^2}$$

The "normal" $-2J$ value for complex (**3**) is a proof of the mutual relation between the $-2J$ value and the φ_{bend} angle. Both structurally independent bridges are nearly planar and exhibit small values of the φ_{bend} angle 1.1(2)° and 3.2(2)°. The orientation of the benzene rings with respect to the carboxylate bridge probably has no influence on the magnetic interaction between the copper centers.

The EPR spectra of the powdered sample of complex (**3**) were measured at room temperature and liquid nitrogen temperature (Fig. 10). The spectra exhibit features typical of those for dimeric carboxylatocopper(II) complexes, absorptions at low and high field (at room temperature $H_{z1} \approx 415$ G and $H_{z2} \approx 6280$ G, respectively) and the line $H_{\perp 2} \approx 4900$ G. At liquid nitrogen temperature the signal of the dimeric species becomes weaker, but hyperfine splitting was observed in the H_{z1} region (Fig. 10). At room temperature as well as at liquid nitrogen temperature a monomeric impurity was observed at about 3380 G.

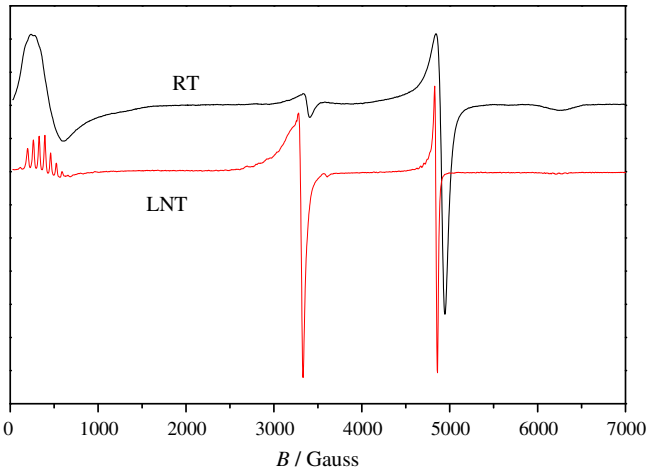

Fig. 10. EPR spectra of a powdered sample of complex (**3**) at room (RT) and at liquid nitrogen temperature (LNT). The amount of monomeric impurity, calculated from magnetic measurements equal ~0.4%, and 7 lines observed at H_{z1} lines correspond to $A = 65$ G. Remaining EPR parameters are: $g_{\perp} = 2.06$, $g_{\parallel} = 2.28$, $D = 0{,}346\ cm^{-1}$, $g_{mon} = 2.06$.

The spectrum of (**3**) contains peaks of COO^{-} vibrations at 1577 (ν_{as}) and 1412 cm^{-1} (ν_s), and the $\Delta\nu$ value ($\Delta\nu = \nu_{as} - \nu_s$) of 168 cm^{-1} is similar to that for complex (**1**). Similarly the electronic spectrum of (**3**) exhibits a broad asymmetric band with a maximum at 718 nm (d ← d transition) and a shoulder at about 400 nm.

generate fragments those could be subsequently relegated. Zn(II), being a strong Lewis acid, exchanges ligands very rapidly. Several Zn(II) complexes are well-known for their hydrolase activity [7c]. Hydrolytic cleavage active species mimic restriction enzymes. The oxidative DNA cleavage involves either oxidation of the deoxyribose moiety by abstraction of sugar hydrogen or oxidation of nucleobases. Oxidative DNA cleavage by redox-active metal complexes, like $[Fe(edta)]^{2-}$ or Cu(1,10-phenanthroline)$_2$Cl$_2$, is mediated by the production of reactive oxygen species, like HO$^{\cdot}$, through a Fenton-type mechanism [10]. These free radicals abstract the most accessible and exposed sugar hydrogens and initiate the oxidative cleavage, leading to DNA-cleavage products. The purine base guanine is most susceptible for oxidation among the four nucleobases. The role of ternary copper(II) complexes in biological systems is well known [11]. Among the transition metal based DNA cleaving agents, copper phenanthroline complexes are particularly primarily sugar directed. They are responsible for direct strand scission by hydrogen atom abstraction from the deoxyribose moiety. Sigman and coworkers have reported that the bis-(1,10-phenanthroline)copper(I) complex in the presence of H_2O_2 act as a 'chemical nuclease' that efficiently nicks DNA [1,2]. Recently there have been several reports of copper(II) complexes showing efficient chemical nuclease activity [12–17]. Recent reports have shown that amino acid/peptide based copper(II) complexes show efficient DNA cleavage activity by oxidative and hydrolytic pathways [17–22]. Such complexes may show DNA cleavage both in the presence (chemical nuclease) or absence (hydrolytic) of a reducing agent. The favored pathway depends on several factors, viz. Lewis acidity, accessible redox potential and rate of ligand exchange.

The present work stems from our interest to explore the structural and functional properties of redox active ternary copper(II) complexes having bioessential α-amino acids L-leucine or L-isoleucine and *N*,*N*-donor heterocyclic bases as a DNA groove binder. The efficiency of the DNA strand scission can be enhanced by increasing the binding affinity of the metal complex for DNA. Typically such coordination complexes contain a DNA-binding moiety that binds either at a groove, or act as an intercalator, thereby increasing the DNA-targeting ability of the metal complex. Our choice of 2,2′-bipyridine (bpy), 1,10-phenanthroline (phen) and dipyridoquinoxaline (dpq) are based on their differences in DNA binding ability. Both L-leucine and L-isoleucine are essential for development of skeletal muscle tissue and preserve muscle glycogen levels [24].

Herein, we report the syntheses, structure, DNA binding and oxidative DNA cleavage properties of ternary copper(II) complexes of the general formula [Cu(L-leu/ile)(B)(H$_2$O)](X) (**1**–**6**) where B is a *N*,*N*-donor heterocyclic base, viz. 2,2′ -bipyridine (bpy, **1**, **4**); 1,10-phenanthroline (phen, **2**, **5**) and dipyrido[3,2-*d*:2′,3′-*f*]quinoxaline (dpq, **3**, **6**), L-leu = L-leucine and L-ile = L-isoleucine (Scheme 1). The bpy and dpq complexes of L-ile (**4**, **6**) have been structurally characterized by X-ray crystallography. Studies have been made to explore the role of DNA binder and amino acid along with mechanistic pathways involved in the 'chemical nuclease' activity.

Scheme 1. Complexes **1**–**6** and the heterocyclic bases.

2. Experimental

2.1. Materials

All products were obtained from commercial sources and were used without further purification. Solvents used for electrochemical and spectroscopic studies were purified by standard procedures [25]. The supercoiled pUC19 DNA (CsCl purified) was purchased from Bangalore Genei (India). Calf thymus (CT) DNA, agarose (molecular biology grade), distamycin-A, catalase, superoxide dismutase (SOD) and ethidium bromide (EB) were obtained from Sigma (USA). Tris(hydroxymethyl)aminomethane–HCl (Tris–HCl) buffer solution was prepared by using deionized, sonicated triple distilled water. The *N*,*N*-donor heterocyclic base dipyrido[3,2-*d*:2′,3′-*f*]quinoxaline (dpq) was prepared by the literature procedure using 1,10-phenanthroline-5,6-dione as a precursor and reacting it with ethylenediamine [26]. The complexes **2** and **5** were prepared by literature procedures [27].

2.2. Preparation of [Cu(AA)(B)(H$_2$O)](X) (1–6) (AA = L-leu (1–3) or L-ile (4–6); B = bpy, phen, dpq); X = NO$_3^-$ (2, 4, 5); ClO$_4^-$ (1, 3, 6)

The complexes were prepared by following a modified reported [27] synthetic procedure in which a 10 ml aqueous solution of Cu(NO$_3$)$_2$ · 3H$_2$O (0.48 g) or Cu(ClO$_4$) · 6H$_2$O (0.75 g) (2.0 mmol) was reacted with L-leucine or L-isoleucine (0.27 g, 2.1 mmol) treated with NaOH (0.08 g, 2.0 mmol) in water (10 ml) under magnetic stirring at room temperature. Slow evaporation of the solution at room temperature yielded a crystalline material. Crystals of complexes **4** and **6** were suitable for X-ray diffraction studies. After 30 min, a 20 ml methanolic solution of the heterocyclic base [bpy (0.28 g), phen (0.35 g), dpq (0.42 g) (1.8 mmol)] was added to the solution and the resulting

mixture was stirred for 2 h at room temperature. On cooling the solution to an ambient temperature, it was filtered and the filtrate on slow concentration yielded a crystalline solid of the product. The solid was isolated and washed with cold aqueous methanol and finally dried over P_4O_{10} (Yield: ~75%). *Anal*. Calc. for $C_{16}H_{22}CuN_3O_7Cl$ (**1**): C, 41.12; H, 4.74; N, 8.99. Solubility and stability. The complexes showed high solubility in water, methanol, dimethylformamide (DMF) and dimethyl sulfoxide (DMSO) and are insoluble in hydrocarbons. They are stable in the solid and in solution phases.

Caution! Perchlorate salts are potentially explosive and only small quantities were handled with care.

2.3. General methods

The elemental analysis was done using a Thermo Finnigan FLASH EA 1112 CHNS analyzer. The infrared and electronic spectra were recorded on Perkin–Elmer Lambda 35 and Perkin–Elmer spectrum one 55 spectrophotometers, respectively. DNA melting experiments were carried out on a Varian Cary 300 Bio UV–Vis spectrophotometer attached to a Cary Peltier temperature controller. Molar conductivity measurements were done using a Control Dynamics (India) conductivity meter. Electrochemical measurements were made at 25 °C on an EG&G PAR model 253 VersaStat potentiostat/galvanostat with electrochemical analysis software 270 using a three electrode setup consisting of a glassy carbon working, platinum wire auxiliary and a saturated calomel reference electrode (SCE) in DMF containing 0.1 M TBAP. The electrochemical data were uncorrected for junction potentials. Magnetic susceptibility data at 298 K were obtained using Model 300 Lewis-coil-force magnetometer of George Associates Inc. (Berkley, USA) make.

2.4. X-ray crystallographic procedures

Single crystals of [Cu(L-ile)(bpy)(H_2O)](NO_3) · H_2O (**4** · H_2O) and [Cu(L-ile)(dpq)(H_2O)](ClO_4) (**6**) were obtained by slow evaporation of an aqueous-methanolic solution of the complexes. A rectangular single crystal was mounted on a glass fiber and used for data collection. All geometric and intensity data were collected at 293 K using an automated Bruker SMART APEX CCD diffractometer equipped with a fine focus 1.75 kW sealed tube Mo Kα X-ray source ($\lambda = 0.71073$ Å), with increasing ω (width of 0.3°/frame) at a scan speed of 5 and 2 s/frame for complexes **4** and **6**, respectively. Intensity data, collected using the ω–2θ scan mode, were corrected for Lorentz-polarization effects and for absorption [28]. SMART software was used for data acquisition and SAINT software for data extraction [29]. Absorption corrections were made using SADABS [30]. The structures were solved and refined by the full-matrix least-squares method using the SHELX system of programs [31]. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms attached to the heteroatoms were in their calculated positions and refined using a riding model. Perspective views of the complexes were obtained by ORTEP [32].

2.5. DNA binding experiments

The UV absorbance at 260 and 280 nm of the CT-DNA solution in 5 mM Tris–HCl buffer (pH 7.2) gave a ratio of 1.9, indicating the DNA was free of protein [33]. The

concentration of CT DNA was measured from the band intensity at 260 nm with a known ε value (6600 M^{-1} cm^{-1}) [34]. Absorption titration measurements were done by varying the concentration of CT DNA, keeping the metal complex concentration constant in 5 mM Tris–HCl/5 mM NaCl buffer (pH 7.2). Samples were kept for equilibrium before recording each spectrum. The intrinsic binding constant (K_b) for the interaction of the complexes with CT-DNA were determined from a plot of [DNA]/($\varepsilon_a - \varepsilon_f$) vs. [DNA] using absorption spectral titration data and the following equation:

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_b - \varepsilon_f) + [K_b(\varepsilon_b - \varepsilon_f)]^{-1},$$

where [DNA] is the concentration of DNA in base pairs. The apparent absorption coefficients ε_a, ε_f and ε_b correspond to $A_{obsd.}$/[Cu], the extinction coefficient for the free copper(II) complex and extinction coefficient for the copper(II) complex in the fully bound form, respectively [35]. K_b is given by the ratio of the slope to the intercept.

The apparent binding constant (K_{app}) values of the complexes were determined by a fluorescence spectral technique using ethidium bromide (EB) bound CT DNA solution in Tris–HCl/NaCl buffer (pH, 7.2). The emission intensities of EB at 600 nm (546 nm excitation) with an increasing amount of the ternary complex concentration were recorded. Ethidium bromide was non-emissive in Tris–buffer medium due to fluorescence quenching of the free EB by the solvent molecules [36]. In the presence of DNA, EB showed enhanced emission intensity due to its intercalative binding to DNA. A competitive binding of the copper complexes to CT DNA could result in the displacement of EB or quenching of the bound EB by the paramagnetic copper(II) species, decreasing its emission intensity.

DNA-melting experiments were carried out by monitoring the absorbance of CT-DNA (200 μM NP) at 260 nm with varying temperature in the absence and presence of the complexes in a 2:1 ratio of DNA to complex with a ramp rate of 0.5 °C min^{-1} in phosphate buffer (pH 6.85) using a Peltier system attached to the UV–Vis spectrophotometer.

Viscometric titrations were performed with a Schott Gerate AVS 310 Automated Viscometer. The viscometer was thermostated at 37 °C in a constant temperature bath. The concentration of DNA was 200 μM in NP and the flow times were measured with an automated timer, each sample was measured three times and an average flow time was calculated. Data were presented as $(\eta/\eta_0)^{1/3}$ vs. [complex]/[DNA], where η is the viscosity of DNA in the presence of complex and η_0 was the viscosity of DNA alone. Viscosity values were calculated from the observed flowing time of DNA-containing solutions (t) corrected for that of buffer alone (t_0), $\eta = (t - t_0)$ [37].

2.6. DNA cleavage experiments

The extent of cleavage of supercoiled (SC) DNA in the presence of the complex and reducing agent MPA was determined by agarose gel electrophoresis. In a typical reaction, supercoiled pUC19 DNA (0.2 μg), taken in 50 mM Tris–HCl buffer (pH 7.2) containing 50 mM NaCl, was treated with the complex. The extent of cleavage was measured from the intensities of the bands using the UVITEC Gel Documentation System.

For mechanistic investigations, inhibition reactions were carried out by adding the reagents prior to the addition of the complex. The solutions were incubated for 1 h in a dark chamber at 37 °C, followed by addition to the loading buffer containing 25% bromophenol blue, 0.25% xylene cyanol and 30% glycerol (2 μL), and the solution was finally loaded on 1.0% agarose gel containing 1.0 μg/ml ethidium bromide (EB). Electrophoresis was carried out for 2 h at 60 V in tris–acetate–EDTA (TAE) buffer. Bands were visualized by UV light and photographed for analysis. Due corrections were made to the observed intensities for the low level of NC form present in the original sample of SC DNA and for the low affinity of EB binding to SC in comparison to nicked circular (NC) and linear forms of DNA [38]. The concentration of the complexes or the additives mentioned corresponded to the quantity of the sample in 2 μL stock solution prior to dilution to the 20 μL final volume by Tris–HCl buffer.

3. Results and discussion

3.1. Synthesis and general aspects

The ternary copper(II) complexes are prepared in high yield from the reaction of $Cu(NO_3)_2 \cdot 3H_2O$ or $Cu(ClO_4)_2 \cdot 6H_2O$ with L-leucine/L-isoleucine and heterocyclic bases. The complexes are stable and soluble in water and common polar organic solvents. They are characterized from the analytical and physicochemical data (Table 1). The complexes display an intense charge transfer (CT) band in the range 200–310 nm, that can be attributed to the $\pi \rightarrow \pi^*$ transition of the coordinated *N*,*N*-donor heterocyclic base. The d–d band is observed at ~600 nm in aqueous medium and is in agreement with a square-pyramidal geometry (Fig. 1). The complexes are redox active and display a cyclic voltammetric response near −0.1 V vs. SCE in DMF-0.1 M TBAP. The redox process is assignable to the Cu(II)/Cu(I) couple. The complexes show 1:1 electrolytic behavior in solution.

3.2. Crystal structures

The bpy and dpq complexes of L-isoleucine (**4** · H_2O, **6**) are structurally characterized using the single-crystal X-ray diffraction technique. Selected crystallographic data are summarized in Table 2. The ORTEP views of the complexes are shown in Figs. 2 and 3. Selected bond distances and angles are given in Table 3. The crystal structures of [Cu(L-leu)(phen)(H_2O)](NO_3) (**2**) and [Cu(L-ile)(phen)(H_2O)](NO_3) (**5**) are known [27]. Both the complexes show distorted (4 + 1) square-pyramidal geometry, in which Cu^{2+} coordinates with two nitrogen atoms of 1,10-phenanthroline, the amino nitrogen atom and one carboxylate oxygen atom of

L-Leu/Ile in equatorial positions, and an oxygen atom of water in the elongated axial position. Complexes **4** and **6** crystallize in the non-centrosymmetric $P2_1$ (monoclinic) and $P\bar{1}$ (triclinic) space groups, having one and two independent molecules in the crystallographic asymmetric unit respectively. The copper(II) ion is coordinated in a distorted square-pyramidal (4 + 1) coordination geometry through the carboxylate oxygen atom O(1) and the amino nitrogen atom N(3) of L-isoleucine and two N-atoms of 2,2′-bipyridine/dpq and a weakly bound apical water molecule (average trigonal distortion parameter, τ (**4** · H_2O) = 0.268; τ_{av} (**6**) = 0.087) [39]. Both the structures resemble the corresponding known structure of [Cu(L-leu/L-ile)(phen)(H_2O)](NO_3) [27]. The configuration at the isoleucine chiral α-carbon is *S* in both complexes. The copper atom is displaced by ~0.15 and ~0.19 Å from the mean plane through its basal atoms in the direction towards the apical water molecule for complexes **4** and **6**, respectively.

Table 2
Selected crystallographic data for **4** · H_2O and **6**

	4 · H_2O	**6**

$w = 1/[\sigma^2(F_o^2) + (AP)^2 + (BP)]$	$A = 0.0595$; $B = 0.1680$	$A = 0.0640$; $B = 0.0000$

[a] $R = \sum||F_o| - |F_c||/\sum|F_o|$.
[b] $wR = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o)^2]\}^{1/2}$; $w = [\sigma^2(F_o)^2 + (AP)^2 + BP]^{-1}$, $P = (F_o^2 + 2F_c^2)/3$.

Both the bpy (**4**) and dpq (**6**) structures show extensive intermolecular non-covalent interactions. While one hydrogen atom of the axial water ligand is hydrogen-bonded to the carboxylate oxygen atom belonging to the neighbouring molecule (distances: 2.678 and 2.819 Å), the other hydrogen atom is H-bonded with the oxygen atom of the lattice NO_3^-/ClO_4^- anion (distances: 2.776 and 2.851 Å). The unit cell packing diagrams and intermolecular hydrogen bonding interactions present in **4** · H_2O and **6** are shown in Figs. S1–S4 (see supporting information).

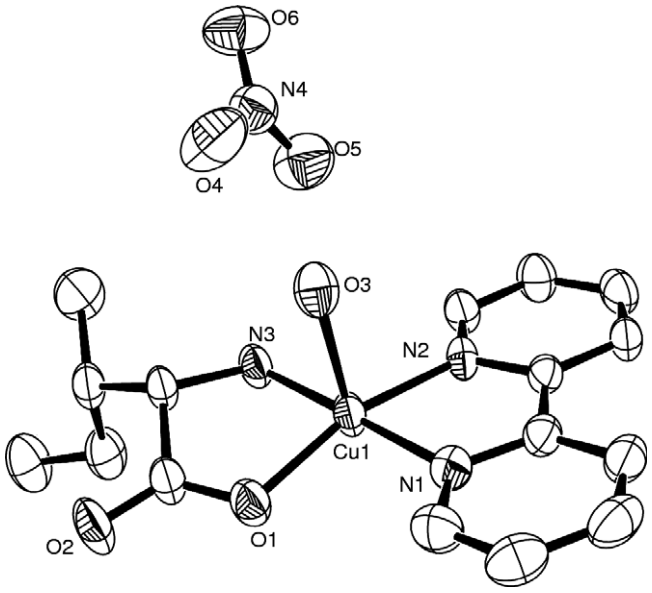

Fig. 2. ORTEP diagram of complex **4** showing 50% probability thermal ellipsoids with the atom labelling scheme for the metal and heteroatoms.

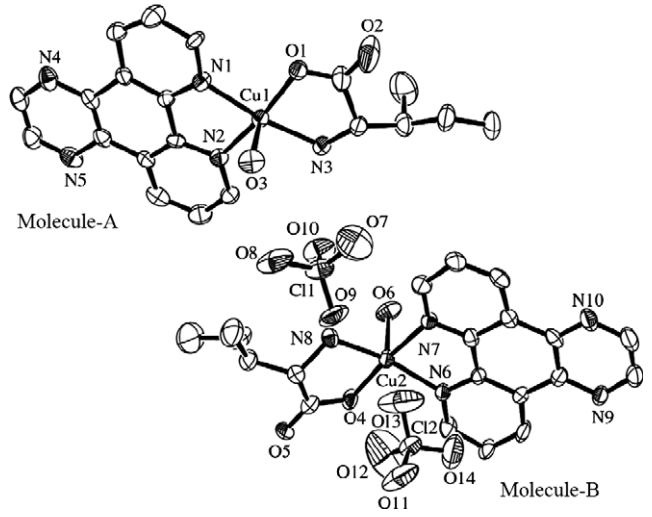

Fig. 3. ORTEP diagram of two independent molecules of complex **6** showing 30% probability thermal ellipsoids with the atom labelling scheme for the metal and heteroatoms.

3.3. DNA binding properties

The binding of complexes **1**–**6** to calf thymus (CT) DNA has been studied by electronic absorption spectral techniques. The interaction of complex **5** with DNA had been reported earlier [27d]. We have studied this complex for comparison with the other analogous complexes here. The absorption spectral traces of complex **3** with increasing concentration of CT DNA are shown in Fig. 4. We have observed a minor bathochromic shift of ~3 nm along with significant hypochromicity for the phen and dpq complexes. The intrinsic DNA binding constants (K_b) of the complexes to CT DNA are obtained by monitoring the change of the absorption intensity of the spectral bands with increasing concentration of CT DNA, keeping the complex concentration constant. The bpy complexes show weak binding to the DNA due to less extended planarity compared to phen or dpq, which is consistent with the observed trend in hypochromism. The K_b values for complexes **2** and **3** are 5.1×10^3 and 1.05×10^4 M^{-1}, respectively. The higher binding propensity of the phen and dpq complexes in comparison to their bpy analogues could be due to the presence of extended planar aromatic rings facilitating non-covalent interactions with the DNA molecule. Earlier studies on bis-phen copper complex have shown that this complex binds to DNA either by partial intercalation or by binding of one phen ligand to the minor groove while the other phen making favourable contacts within the groove [40–43]. The nature of binding of the phen complex is proposed to be similar as observed for the bis-phen species.

The emission spectral method is used to study the relative binding of the complexes to calf thymus-DNA. The emission intensity of ethidium bromide (EB) is used as a spectral probe as EB shows no apparent emission intensity in buffer solution because of solvent quenching and shows an enhancement of the emission intensity when intercalatively bound to DNA [44]. The binding of the complexes to DNA decreases the emission intensity of EB. The relative binding propensity of the complexes to DNA is measured from the extent of reduction of the emission intensity (Fig. 5, Table 1). The reduction of the emission intensity of EB on increasing the complex concentration could be caused due to displacement of the DNA bound EB by the ternary copper(II) complexes.

The denaturation of DNA from double-strand to single strand results in absorption hyperchromism at 260 nm. The binding of metal complexes to the double-stranded DNA usually stabilizes the duplex structure to some extent, depending on the strength of the interaction with the nucleic acid [45]. The binding should lead to an increase in the melting temperature (T_m) of DNA as compared to DNA itself. The binding of the phen and dpq complexes results in a moderate increase (~2 °C) in the melting temperatures (ΔT_m) of CT-DNA suggesting primarily an electrostatic and/or groove binding nature of the complexes (Table 1, Fig. 6a).

To investigate further the binding modes of the complexes viscosity measurements on solutions of calf thymus DNA incubated with the complexes were carried out. Because the viscosity of a DNA solution is sensitive to the addition of organic drugs and metal complexes bound by intercalation, we examined the effect on the specific relative viscosity of DNA upon addition of complexes. The relative specific viscosity (η/η_0), (η and η_0 are the specific viscosities of DNA in the presence and absence of a complex, respectively) of DNA reflects the increase in contour length associated with the separation of DNA base pairs caused by intercalation. The relative viscosity of DNA and contour length follows the equation: $(\eta/\eta_0) = (L/L_0)^{1/3}$,

Table 3
Selected bond distances (Å) and angles (°) for [Cu(L-ile)(bpy)(H_2O)](NO_3) · H_2O (**4** · H_2O) and for the two molecules of [Cu(L-ile)(dpq)(H_2O)](ClO_4) (**6**)

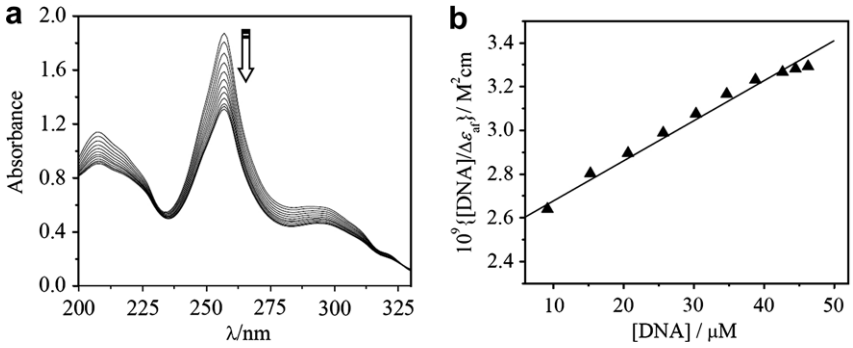

Fig. 4. (a) Absorption spectral traces on addition of CT DNA to a solution of **3** (shown by arrow). (b) Plot of $[DNA]/(\varepsilon_a - \varepsilon_f)$ vs. [DNA] for the absorption titration of CT-DNA with complex **3**.

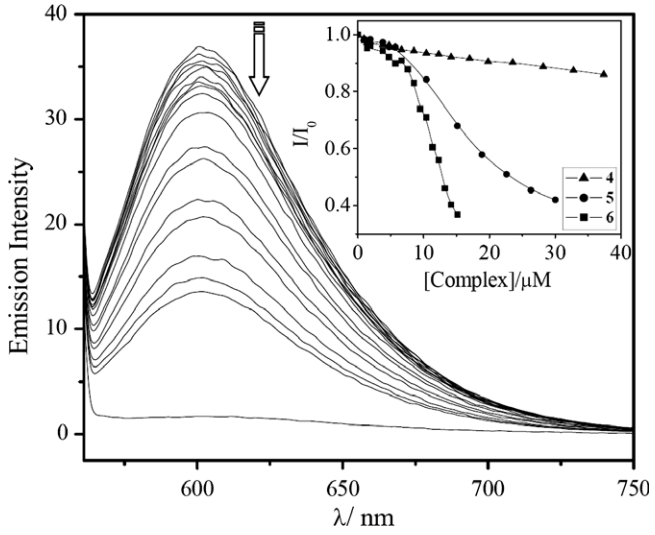

Fig. 5. Emission spectral changes on addition of [Cu(L-ile)(dpq)(H_2O)](ClO_4) (**6**) to CT-DNA bound to ethidium bromide (shown by arrow). Inset: Effect of addition of [Cu(L-ile)(B)(H_2O)](X) [B = bpy (**4**, ▲); phen (**5**, ●); dpq (**6**, ■)] to the emission intensity CT DNA-bound ethidium bromide in a 5 mM Tris–HCl/5 mM NaCl buffer (pH 7.2) at 25 °C.

where L and L_0 are the contour length of DNA in the presence and absence of complex respectively [37]. A classical intercalator such as EtBr could cause a significant increase in the viscosity of DNA solutions, in contrast, a partial and/or non-classical intercalation of the ligand could bend or kink DNA resulting in a decrease in its effective length with a concomitant increase in its viscosity [46,47]. The plots of relative viscosities with R = [Cu]/[DNA] are shown in Fig. 6(b). The change in relative viscosity for the dpq complexes are more than that for the phen or bpy analogues suggesting greater DNA binding propensity of the dpq complexes in comparison to the phen or bpy analogues, but this change is less compared to that of potential classical intercalators, e.g. ethidium bromide. This is consistent with the observed trend shown by other optical methods and suggests primarily an electrostatic and/or groove binding nature of the complex.

3.4. DNA cleavage studies

The oxidative DNA cleavage activity of the complexes in the presence of the reducing agent 3-mercaptopropionic acid (MPA, 5 mM) was studied by agarose gel electrophoresis

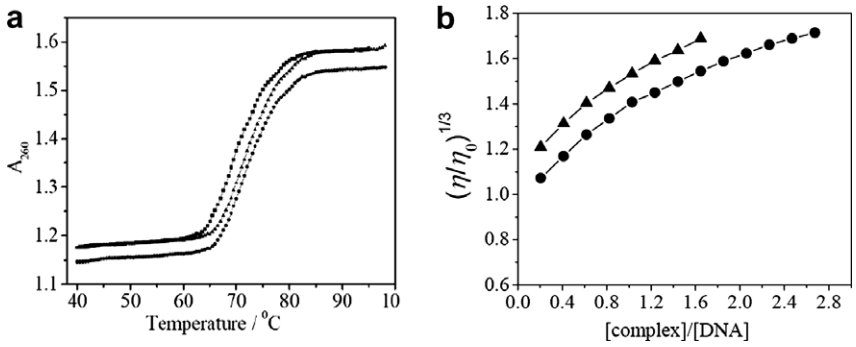

Fig. 6. (a) Effect of addition of complexes **3** (●) and (**6**) (▲) (50 μM) on the melting temperature of CT- DNA (■) (200 μM) in 5 mM Phosphate buffer (pH 6.85) with a ramp rate of 0.5 °C/min. (b) Change in relative specific viscosity of CT-DNA (150 μM) with addition complexes **2** (●) and **3** (▲) in 5 mM Tris–Cl buffer medium at 37 ± 0.1 °C.

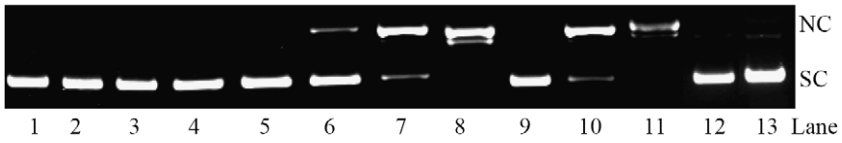

Fig. 7. Gel electrophoresis diagram showing the cleavage of SC pUC19 DNA (0.2 μg, 30 μM) by complexes **1**–**6** (30 μM) in 50 mM Tris–HCl/50 mM NaCl buffer (pH 7.2) in the presence of MPA (5 mM): Lane 1, DNA + MPA; Lane 2, DNA + L-leu (30 μM) + MPA; Lane 3, DNA + L-ile (30 μM) + MPA; Lane 4, DNA + **2**; Lane 5, DNA + **5** + MPA; Lane 6, DNA + **1** + MPA; Lane 7, DNA + **2** + MPA; Lane 8, DNA + **3** + MPA; Lane 9, DNA + **4** + MPA; Lane 10, DNA + **5**; Lane 11, DNA + **6** + MPA; Lane 12, DNA + distamycin-A (100 μM) + **2** + MPA; Lane 13, DNA + distamycin-A (100 μM) + **6** + MPA.

using supercoiled (SC) plasmid pUC19 DNA (0.2 μg, 30 μM NP) in 50 mM Tris–HCl/50 mM NaCl buffer (pH, 7.2) and the copper(II) complexes (Fig. 7). Selected DNA cleavage data are given in Table 4. The phen and dpq complexes show significant "chemical nuclease" activity. 30 μM of complexes **3** and **6** show almost complete conversion of the SC (form I) to its nicked circular form (NC, form II) of DNA. Control experiments using only MPA or the ternary complexes alone do not show any apparent conversion of SC to its nicked-circular (NC) form. The DNA cleavage activity order for the complexes follows the relative binding propensities of the complexes to DNA. The bpy complexes are cleavage inactive due to their poor binding ability to ds-DNA. This may be attributed to ROS forms which may not be able to reach the SC-DNA by diffusion and consequently are quenched by solvent molecules. To determine the groove binding preference of the complexes, control experiments have been carried out in the presence of the minor groove binder distamycin-A [48]. Inhibition of cleavage in the presence of distamycin-A for both the phen and dpq complexes suggest their minor groove binding nature.

Mechanistic aspects of the chemical nuclease reactions were investigated using various control experiments (Fig. 8). The addition of hydroxyl radical scavengers, [49] like DMSO, catalase and KI, shows significant inhibition of the DNA cleavage activity of the complexes, indicating the possibility of the involvement of the hydroxyl radical and/or a "copper-oxo" intermediate as the reactive species. Addition of superoxide dismutase (SOD) does not show any apparent effect on the DNA cleavage activity, suggesting the non-involvement of $O_2^{\cdot -}$ in the cleavage reaction

Table 4
Selected cleavage data of SC pUC19 (0.2 μg, 30 μM NP) by complexes **1**–**6**[a]

Sl. no	Reaction condition	[Complex]/μM	% SC	% NC
1	DNA + MPA		97	3
2	DNA + L-leucine (30 μM) + MPA		95	5
3	DNA + L-isoleucine (30 μM) + MPA		96	4
4	DNA + **2**	30	92	8
5	DNA + **5**	30	94	6
6	DNA + **1** + MPA	30	86	14
7	DNA + **2** + MPA	30	24	76
8	DNA + **3** + MPA	30	10	90[b]
9	DNA + **4** + MPA	30	88	12
10	DNA + **5** + MPA	30	28	72
11	DNA + **6** + MPA	30	11	89[b]
12	DNA + distamycin-A[c] + **2** + MPA	30	74	26

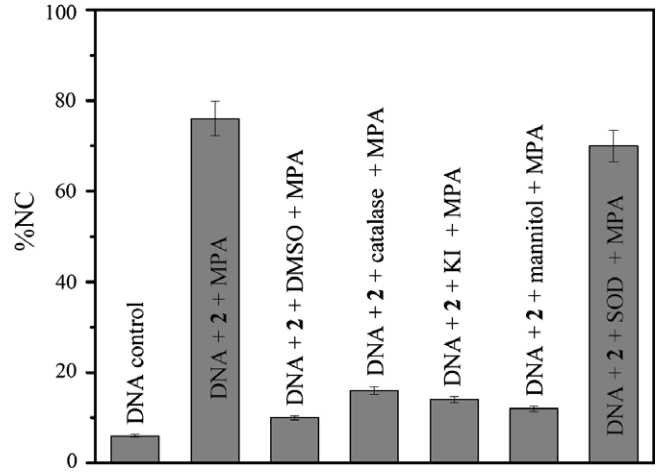
[e] 4 units.
[f] 1 mM.
[g] 1 mM.
[h] 4 units.



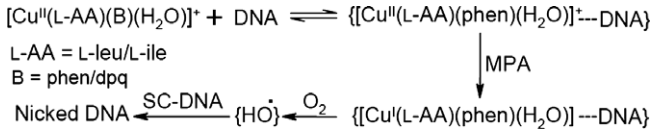


Fig. 8. Cleavage of SC pUC19 DNA (30 μM) by [Cu(L-leu)(phen)(H_2O)](NO_3) (**2**) in the presence of MPA (5 mM) with various additives in Tris buffer (pH 7.2) medium. The additive concentrations/quantity are: DMSO (4 μL), catalase (4 U), KI (1 mM), mannitol (1 mM), SOD (4 U).

Scheme 2. Proposed mechanistic pathway for the chemical nuclease activity of the complexes in Tris–buffer medium.

[50]. The pathways involved in the DNA cleavage reactions are believed to be analogous to those proposed by Sigman and coworkers for the chemical nuclease activity of bis(phen)copper species (Scheme 2) [1,43,44].

4. Conclusions

Ternary redox active copper(II) complexes having N,O-donor α-amino acid L-leucine or L-isoleucine and *N*,*N*-donor heterocyclic bases have been prepared and characterized. The copper(II) complexes with planar phenanthroline bases, with a CuN_3O_2 coordination geometry, show efficient DNA binding ability. The phen and dpq complexes were shown to be DNA minor groove binders. The study also confirms that the binding ability of the complexes is an important precondition to show efficient DNA cleavage activity. Efficient chemical nuclease activity is observed for the redox active phen and dpq complexes under physiological reaction conditions via a mechanistic pathway involving formation of hydroxyl radicals in the presence of the reducing agent MPA.

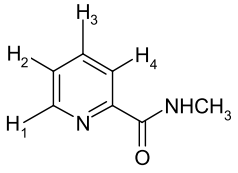

Scheme 1. Labeling of biomolecules with rhenium tricarbonyl complex [9].

The presented work is involved in a series of studies on coordination chemistry of rhenium(I) tricarbonyl complexes with the goal of searching new ^{186}Re and ^{188}Re radiopharmaceuticals. Data, Publisher already, on coordination chemistry of numerous monovalent rhenium tricarbonyl compounds allow the preparation of a number of water-soluble carbonyl complexes with various donor-active species. These complexes have attracted interest as precursors for the labeling of the tumor cells targeting biomolecules [7], because such labeling requires existence of a bifunctional chelator [8]. This can be presented in Scheme 1.

2. Experimental

The work was performed with macroamounts of natural, non-radioactive rhenium. To synthesize the complex, we adopted procedure described by Schöster and Zeisler [10]. Because it had originally been established for obtaining the technetium compounds, detailed experimental conditions were slightly changed. To characterize the obtained compounds, we used conventional analytical methods: elemental analysis, X-ray diffraction, IR spectroscopy, NMR and HPLC.

2.1. Synthesis

N-Methylpyridine-2-carboxyamide (ligand, **1**) was obtained according to the general procedure [11]: 4 g (0.0325 mol) of the 2-picolinic acid was dissolved in 100 cm^3 of toluene and 10 cm^3 of oxalyl chloride was added. A reaction mixture was heated under reflux for 10 h, the solvents and the unreacted substrates were then evaporated. The solid product was washed with hexane, dissolved in 20 cm^3 of 25% solution methylamine in methanol and stirred overnight in a RT. The crude product was purified on a silica gel column (chloroform–methanol; 98:2 vol/vol). 2.1 g of pure product was obtained. (Yield: 43.7%).

Calc.: C, 64.86; H, 5.40; N, 20.05. Found: C, 64.75; H, 5.50; N, 19.89%. ^{1}H NMR ($CDCl_3$, 200 MHz, δ [Hz]): 8.51 (1H, dd, $J_1 = 0.8$, $J_2 = 7.8$, H-1), 8.20 (1H, d, $J = 8.0$, H-4); 7.82 (1H, dt, $J_1 = 1.8$, $J_2 = 7.8$, H-2), 7.40 (1H, dq, $J_1 = 1.4$, $J_2 = 5.0$, $J_3 = 7.3$, H-3), 3.05, 3.021 (3H, 2 × s, HNCH_3) ^{13}C NMR ($CDCl_3$, 50 MHz): 164.55, 149.40, 147.52, 186.76, 124.54, 212.43, 25.55. IR (film): 3050, 2944, 1590, 1530, 1470, 1405, 1398, 1300, 1150, 792.

[Re(CO)$_3$L]Cl (complex, **2**) was obtained as follows: Re(CO)$_5$Cl (170 mg, 0.470 mmol) was dissolved in 13 mL THF. On addition of **1** (62 mg, 0.455 mmol) the solution turned yellow and intensity of the color gradually increased. After 16 h of stirring under Ar at ambient temperature, a light yellow substance started to precipitate. Progress of the reaction was checked by TLC analysis. The reaction was completed after 48 h, the solvent was evaporated and the residue extracted with pentane. Then, the solution was separated, solvent evaporated and solid residue was isolated as an air-stable, microcrystalline phase, soluble in common organic solvents. Its IR spectrum (KBr pellets) displays three bands in the carbonyl stretching region: a sharp intense band at 2085 cm^{-1} and two lower-energy bands closely spaced (1998 and 1879 cm^{-1}), typical for the tricarbonyl Re^{I} complexes. Single crystals of the title complex [Re^{I}(CO)$_3$L]Cl suitable for the X-ray studies were grown from the dichloromethane/hexane (vol:vol = 2:1). Yield: ca. 25%.

[1] Bold letters mean fingerprint positions of the Re-(CO) vibrations in the IR spectra.

2.2. X-ray studies

Data were collected on the KUMA KM4 four-circle diffractometer operating in the ω–2θ mode. Structure was solved by direct method [12] and refined by full-matrix least-squares method [13]. The reflections were processed using profile analysis and corrected for the Lorentz factor and polarization effect. The heavy atom i.e. Re was located by applying Patterson's method and the positions of other non-hydrogen atoms were determined in the course of successive refinement using SHELXLS program. Final refinement on F^2 by full-matrix least-squares method was performed on positional parameters of all atoms, anisotropic temperature factors of all non-hydrogen atoms and isotropic temperature factors of hydrogen atoms. Weighting scheme was used in the following form: $w = 1/[\sigma^2(F_o^2) + (A \cdot P)^2 + B \cdot P]$, where $P = [\mathrm{Max}(F_o^2, 0) + 2F_c^2]/3$. Values of the parameters A and B are given in Table 1. Calculations were carried out using the SHELXL97 program [12,13]. A summary of the experimental details is presented in Table 1.

IR spectra of **1** or **2** in solid KBr pellets (investigated species being about 1% of the pellet; 4000–600 cm^{-1}) were recorded using Bruker Equinox 55 FT-IR spectrophotometer. FIR spectra (600–200 cm^{-1}) were recorded in the solid CsI pellets. All spectra were registered for at least three pellets with 50 scans each and with spectral resolution of 1 cm^{-1}.

Method of structure solution	Patterson method
Method of structure refinement	full-matrix least-squares on F^2
Number of parameters refined	164
Goodness-of-fit on F^2	1.142

2.3. ^1H NMR

^{1}H NMR spectra were recorded on the Varian Unity Plus Spectrometer operating at 500 MHz. Tetramethylsilane was used as an internal standard. Chemical shifts are reported in ppm.

2.4. HPLC

HPLC analyses were performed on the Merck L7100 system equipped with the Supelcosil LC-C_{18} HPLC column and Shimadzu UV–Vis SPD-10AVP detector. HPLC solvents were TEAP buffer, 25 mM, pH 2.25 (solvent A) and MeOH (HPLC grade; solvent B). Elutions were made in the gradients: 0–3 min: 100% A, 3–6 min: to 75% A; 6–9 min: to 66% A; 9–20 min to 0% A; 20–25 min: 0% A; 25–30 min: to 100% A. Flow rate: 1 mL/min.

2.5. Quantum chemical investigation

Initial three-dimensional structure of the compound was built using the SPARTANPRO 5.0 software [14] and as the first step, semiempirical geometry optimization was performed at the PM3 level.

It has already been demonstrated that quantum chemical investigations using the MPW1PW/LanL2DZ method within the density functional theory (DFT) framework yielded the geometry and vibrational frequencies for heavy metal complexes in good agreement with the experimental data [15]. Taking this into consideration, final calculations of the **2** structural parameters and vibrational frequencies have been performed by two independent DFT methods: MPW1PW/LanL2DZ and B3LYP/LanL2DZ using the GAUSSIAN 98 program package [16], running on the Silicon Graphics IRIS Indigo workstation with the processor RISC 10000.

3. Results and discussion

All analytical methods (elemental analysis, NMR spectra, sharp melting of the complex) demonstrate that both **1** and **2** were obtained and purified properly. Integration of the peaks area in ^{1}H NMR spectra gives result adequate to the numbers of protons, both in **1** and **2**. The most distinct difference between the ^{1}H NMR spectra of **1** and **2** is the absence of the H–N–CH_3 peak in the spectrum of ligand, which is present in the spectrum of complex at 10.60 ppm. This can be attributed to the analytical conditions – possible presence of small amount of the $CDCl_3$ hydrolysis products and the isotopic exchange appearing on the aforementioned group.

It is well known fact that Re^I complexes are easily oxidized in aerated aqueous solutions, i.e. under real conditions. So, stability of **2** towards oxidation was checked in aqueous solution by registering UV–Vis spectra and by performing the HPLC analyses as a function of time. A slight decrease in the absorption was observed in the region

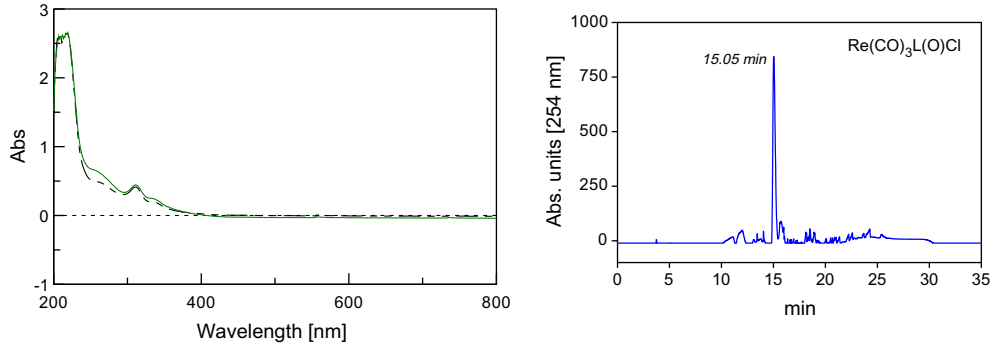

Fig. 1. Left: UV–Vis spectra of the title complex **2** registered in the beginning of the experiment (solid line) and after a week (dotted line); right: HPLC of **2**.

of 250 nm (generally assigned to the d → π^*_{CO} transitions in the Re^I complexes [17]) after a few days only. Nevertheless, within time required for preparing and medical application of the ^{188}Re-radiopharmaceuticals, i.e. several hours, no distinct change in the spectrum was detected (see, left part of Fig. 1). Also, area of the HPLC peak characteristic for **2** (retention time $R_t = 15.05$ min) remained constant.

An essential point in structural considerations was checking the chemical form of the free ligand. It is a textbook knowledge that amides and thioamides may exist in the keto- or enol-forms. Quantum chemical calculations have shown that energy of *N*-methylpyridine-2-carboxyamide in the keto-form is about 15.62 kcal/mol lower than the enol-. For *N*-methyl-2-pyridinethioamide the difference is 10.99 kcal/mol. These large values suggest that both ligands exist predominantly in the keto-form and the thio compound may be more easily converted into the enol-form. Unfortunately ligand **1** is an oily species and its X-ray diffraction studies appeared to be impossible.

Luckily in order to compare molecular structure of **2** with its thio-analogue studied already [18], both X-ray diffraction studies and quantum chemical calculations appeared to be possible to realize. In the first step using semiempirical calculations on the PM3 level we optimized structure of **2** containing ligand in the conformation proposed by Mueller as the most probable [20]. Next, the conformer exhibiting the lowest PM3 energy was optimized using the DFT procedure. Both experimental and theoretical results show that **2** exhibits similar structure to this with *N*-methylpyridine-2-thiocarboxyamide [18].

Molecular structure of the title complex together with atom labeling is shown in Fig. 2. Selected bond lengths and bond angles (both experimental values and found theoretically) are listed in Table 2.

The main results obtained in the structural investigations may be summarized as follows:

- We expected that three CO molecules form a Re^I octahedron together with donor nitrogen and oxygen atoms from the bidentate ligand (**1**), and one chloride anion. However, we have found that Re^I cation adopts a slightly distorted octahedral geometry with C(1)–Re–O(11) = 170.7(2)°, C(2)–Re–N(11) = 172.4(2)° and Cl–Re–C(3) 177.7(23)°. The N–Re^I–O angle of 75.25° (bite angle) is smaller than 90° in the regular octahedron. This small bite angle is, however, typical for 5-membered chelate rings. The bond distances of Re–C 1.881(7)–1.912(7) Å are in the range of these in numerous known $Re^I(CO)_3^+$ complexes [20]. Finally, the Re–N and Re–O bond distances in **2** are 2.176(5) and 2.163(4) Å, respectively. Summarizing – planar 5-membered ring as well as picoline ring are nearly perpendicular to the Cl–Re^I–C(3) axis. The corresponding dihedrals are inserted into Table 1.
- The MPW1PW/LanL2DZ and B3LYP/LanL2DZ procedures result in very similar structures of **2**. What is more, the parameters calculated at the initial PM3 level were also very similar to those DFT ones and also to the experimental values.
- In spite of the fact that several possible rotamers of free ligand may exist (in the case of picolinamide, see [19]), because of their stabilization by the intramolecular hydrogen bonds, only one complex structure has been

confirmed crystallographically. Also quantum chemical calculations have not shown the existence of other structures with comparable energies.

- All the intramolecular Cl···H distances, both placed in the pyridine ring and in the –HN–CH_3 group are too long to suggest formation of the hydrogen bonds. The experimental nearest C–H···Cl^- distance is equal to 4.02 Å, while the respective value calculated from the literature data is equal to [21] −3.77 Å. On the other hand, the experimental Cl···H–C(15) distance between the neighboring molecules, equal to 2.82 Å, does not exclude the existence of intramolecular hydrogen bonds which stabilize the molecular packing (see, Fig. 3).

Infrared spectra of the species are shown in Fig. 4. Detailed assignment of the peaks was made according to our previous paper [14], the references cited therein and to [22]. The most important IR bands of **1** and **2**, are listed in Table 3 together the proposition of their assignment. As one can see, all main bands of the pyridinecarboxyamide vibrations can be found in both spectra. Also three characteristic peaks of the Re^I–(CO) vibrations (≈2000 cm^{-1}), which appear only in the spectrum of the complex, confirm the existence of the typical rhenium-tricarbonyl core. It has been shown that a region of 2000 cm^{-1} can be treated as a fingerprint region for the $Re(CO)_3^+$ core [23]. For some complexes, however, only two peaks are observed. It can be seen that their frequencies, $\nu_{CO(Re)}$, are lower than the corresponding values for the pyridinethiocarboxyamide complex [18]. Therefore we may deduce that the ionicity

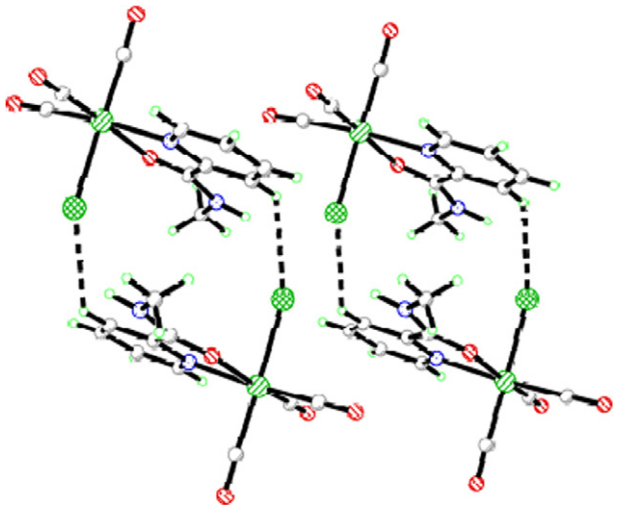

Fig. 3. A part of the molecular packing of **2** showing intermolecular hydrogen bonds creating a dimer structure. Hydrogen bonds are indicated by dashed lines.

of the Re^I-pyridinecarboxyamide bond is greater than that of its thio-analogue. Mullikan charges on the atoms in the analogous Tc^I N,O- and N,S-chelates, reported by Narbutt [24] are consistent this observation. Theoretical calculations of the molecular vibrations also generate bands situated in the region of 2000 cm^{-1}, close to the experimental peaks. Furthermore, the region of 520 cm^{-1} spectra of **2** exhibit three distinct peaks (namely, at 530, 510 and 482 cm^{-1}), which can be attributed to the Re–C vibrations. Appearance of three separate peaks in both regions (2000 and 520 cm^{-1}) may be interpreted in terms of the inequality of the CO groups forming the $Re(CO)_3^+$ core.

The comparison of the calculated and experimental frequencies found for the three $\nu_{CO(Re)}$ and the $\nu_{C=O,(amide)}$ vibrations (see, Table 3) shows that the mean ratio of the calculated to experimental values is 0.9928 ± 0.0180. This agreement correlates well with the similarity of the experimental and calculated structures (Table 3).

The experimental value for the Re^I–O bond in (**2**), of 2.16 Å, is by 0.28 Å shorter than that for Re^I–S (2.44 Å [18]) and nearly equal to that of Re^I–N in the Re^I tricarbonyl *N*-(2-pyridinylmethylene)phenylamine complex (2.19 Å [25]). Therefore, if we assume that the radius of the Re^I cation is the same in all the three complexes, we could have suggested that the oxygen radius is also smaller than that of sulfur by about 0.28 Å. However, both differences between the ionic radii of the dinegative oxygen and sulfur ions and between the radii of the *2p* and *3p* orbitals in the oxygen and sulfur atoms (responsible for the covalent bonds) are close to 0.45 Å [27]. Let us discuss the different values of 0.28 and 0.45 Å in terms of different contributions from ionicity and covalency in the Re^I–X bonds (Fig. 5):

- It is well known, that coordination bonds are formed by electron pairs which come from the donor atoms of ligands. The difference in Pauling electronegativity

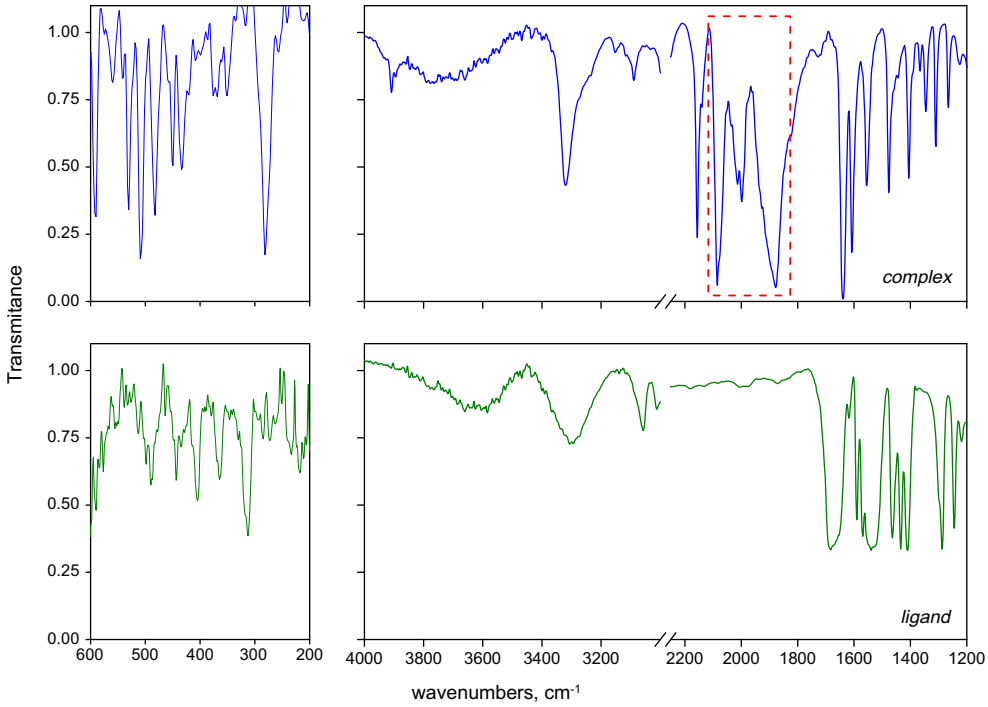

Fig. 4. FT-MIR (right, KBr pellets) and FT-FIR (left, CsI pellets) spectra of ligand **1** and complex **2**.

between two atoms in a chemical bond, e.g. Re^{I}–X, is the measure of its ionic/covalent character: $\Delta\chi \leqslant 1$, for mainly covalent bond [26]. The increase in the difference ($\Delta\chi = \chi_X - \chi_{Re}$) makes the ionic character of the bond stronger. The plot of the length of the Re^{I}–X against $\Delta\chi_{Re-X}$ is nearly linear (Fig. 5, left). Assuming that the radius of the Re^{I} cation in the N,O and N,S complexes is constant ($\chi_{(Re)} \sim 1.9$ [26]), a greater shift of electron density towards electronegative atom (O,S: ~3.5 and ~2.5, respectively [26]) takes place in the Re^{I}–O bond. Therefore, the ionicity of the Re^{I}–O bond is greater than that of the Re^{I}–S one (Fig. 5, right part).

- The ratio of the ionic/covalent bond character can also be discussed in terms of the "hard and soft acids and bases" concept [28]. In the complex studied, Re^{I} cation acts as a soft acid because of low positive charge and relatively large size. Comparing the electronegativity of the S and O donor atoms ($\chi_{(O)} > \chi_{(S)}$) and their radii (oxygen being smaller than sulfur, i.e. $\langle r_{cov} \rangle$ are ~0.65 and ~1.10 Å, respectively) we may assume that pyridinethioamide is softer base than pyridineamide. Because soft–soft combinations form mainly covalent and hard–hard combinations mainly ionic bonding [28], based on the HSAB concept, we may conclude that the covalent character of the Re^{I}–S bond is greater than that of the Re^{I}–O bond.
- To finish, the length of Re–O/S bonds length can be discussed in terms of the free ligands basicity (defined as a propensity to donate an electron pair and forming new bond, which acts in the opposite sense to electronegativity). Because the oxygen and sulfur donor atoms in the pyridineamide and pyridinethioamide are in the same chemical environment, the ligands basicity depends mainly on the properties of the oxygen and sulfur donor atoms (the only two atoms which differentiate both ligands). Based on the experimentally obtained crystallographic data for the $Re^{I}(CO)_3$-pyridine(thio)amides, we may suggest that for the pyridineamide complex electronegativity effect plays a greater role and for pyridinethioamide complex a greater role plays the basicity of the donor atom.

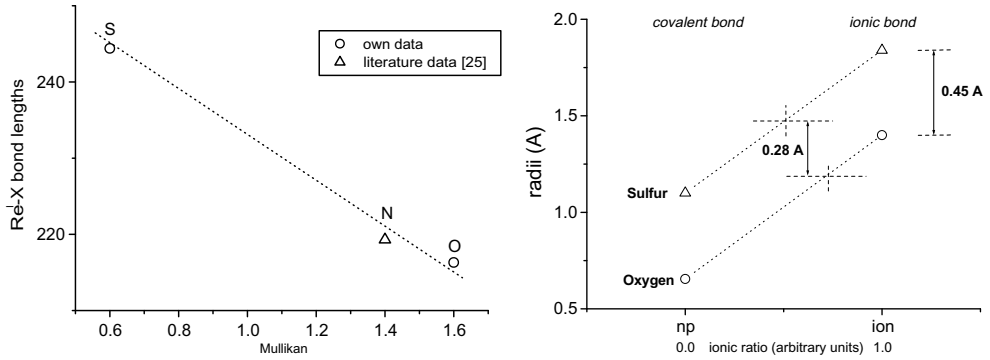

Fig. 5. Re^{I}–X distances found for (**2**) and structurally similar complexes [18,25] (left) and clarification of the distance shortening (right).

Recapitulating, we can conclude that difference in the Re–X bonds length in the $Re(CO)_3$–pyridineamide and –pyridinethioamide (0.28 Å), smaller than expected value (0.45 Å), is caused by higher covalent shortening of the Re–S bond than of the Re^{I}–O one.

Our observation of the ionic/covalent character of the Re^{I}–*N*-methyl-2-pyridine(thio)carboxyamide bonds seems to be consistent with this drawn by Czerwinski and Narbutt from their theoretical calculation of the Mullikan charge distribution in the Tc^{I} complexes formed with the same ligands [24].

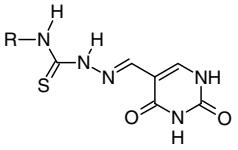
4. Conclusions

A novel bidentate ligand with N,O donor atoms, L = *N*-methyl-2-pyridinecarboxyamide (**1**) and the tricarbonyl-chloro-rhenium(I) complex, $[Re(CO)_3L]Cl$ (**2**), have been synthesized. Structural studies of **2** confirm that ligand **1** coordinates the Re^{I} cation bidentatly by O and N atoms. The same can be seen in the most stable structure obtained from the quantum chemical calculations. The investigated complex **2** is not oxidized in aerated solutions within sufficient time for it to be applied in nuclear medicine. As a result of different covalent shortenings of the Re^{I}–S and Re^{I}–O bonds (reflecting their different covalent/ionic contribution) difference in the bond lengths decreases from the theoretical value of 0.45 Å to the value of 0.28 Å.

Acknowledgements

The work was undertaken within the Maria Curie Transfer of Knowledge training contract MTKD-CT-2004-509224 (POL-RAD-PHARM: *Chemical studies for design and production of new radiopharmaceuticals*).

We thank Dr. W. Starosta (INCT) for help in the X-ray studies and Prof. S. Siekierski (INCT) for valuable discussions on structural features of the complexes.



Appendix A. Supplementary material

CCDC 270202 contains the supplementary crystallographic data for $C_{10}H_8ClN_2O_4Re$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.12.031.

Scheme 1. Chemical drawing of the R-H_3ut ligands.

Moreover, uracil provides oxygens as additional potential coordinating sites to the thiosemicarbazidic chain.

The present paper deals with the syntheses and characterization of four 5-formyluracil thiosemicarbazones (H_3ut) with substituents on the aminic nitrogen of the thiosemicarbazide chain. The introduction of the different groups: ethyl-, allyl-, phenyl-, methylphenyl-groups (Scheme 1) is made in order to vary the hydrophilic–lipophilic character of the compounds with the aim of increasing the absorption of the drugs in cells.

Substitutions on the terminal N position can also affect the coordination and biological properties [5,6,10,11,24–29]. Moreover, as small molecules, they could react at specific sites along a DNA strand through a series of weak interactions [30]. Many anticancer drugs exert their antitumor effects through binding to DNA in one way or another, thereby blocking the replication of DNA and inhibiting the growth of tumor cells. The understanding of DNA binding and cleavage is the basis for the design of new, efficient antitumor drugs, their effectiveness depending on the binding mode and affinity towards DNA [31,32]. The biological action mechanism of thiosemicarbazone complexes is not clear or well defined so far. One of the proposed pathways is DNA oxidative damage induced by the copper ion [1]. In this view the presence of a moiety with a potential high DNA affinity could act as a Trojan horse in order to anchor the active metal complex to the target site. Copper complexes are also synthesized and identified by means of different spectroscopic and analytical techniques.

To quantify the DNA binding capability in aqueous solution, a spectroscopic investigation with calf thymus DNA has been carried out. Nuclease activity has been verified on plasmid DNA pBR 322 by electrophoresis.

2. Experimental

2.1. Materials and physical measurements

5-Formyluracil (Aldrich, 98%), 4-ethylthiosemicarbazide (Janssen), 4-allylthiosemicarbazide (Janssen), 4-(3-methyl)-phenylthiosemicarbazide (Janssen), 4-phenylthiosemicarbazide (Janssen), $Cu(NO_3)_2 \cdot 3H_2O$ (Carlo-Erba) and $CuCl_2 \cdot 2H_2O$ (Carlo-Erba) were commercially available and were used without further purification. C, H, N and S analyses were obtained with a Carlo-Erba 1108 instrument. IR spectra were recorded using KBr pellets in the 4000–400 cm^{-1} range and using CsI pellets in the 650–150 cm^{-1} range on a Nicolet 5PC FTIR spectrophotometer. Calf thymus (CT) DNA was obtained from Serva and was used as received. DNA samples were dissolved in 50 mM NaCl/5 mM Tris, pH 7.2. A stock solution of CT-DNA was prepared by dissolving the nucleic acid in this buffer in order to obtain a *ca.* 10^{-5} M in base-pair, [bp] solution that gave ratios of UV absorbance at 260 and 280 nm, A_{260}/A_{280}, of *ca.* 1.8, indicating that the CT-DNA was sufficiently protein free. The concentration of the nucleic acid solutions was determined by UV absorbance at 260 nm after 1:100 dilution of the stock solution. The extinction coefficient ε_{260} was taken as 13100 $M^{-1}\,cm^{-1}$ [33]. Stock solutions were stored at 4 °C and used after no more than 4 days. TRIS and TRIS–acetate–EDTA 10× buffers and agarose were purchased from Sigma. pBR322 DNA plasmid (Roche), DirectLoad Wide-Range DNA marker, ethidium bromide and gel loading solution type I 6× concentrate were from Sigma. Chemical ionization-mass (*m*/*z*, 70 eV) fragmentation patterns were obtained, using samples dissolved in methanol, with a Finnegan 1020 6c mass spectrometer equipped with a quadrupole mass selector MATSSQ 710. Melting points were determined with a Gallenkamp instrument. UV measurements were performed on a Perkin–Elmer UV/Vis Lambda 25 spectrometer with quartz cuvettes. Thermogravimetric analyses were performed on a Perkin–Elmer TGA 7 from 30 °C to 450 °C with a 20 °C/min gradient in N_2 atmosphere. Conductivity measurements were performed on a Mayo International Srl digital conductimeter with samples dissolved in absolute EtOH. NMR spectra were recorded on a Bruker AC300 Spectrometer.

2.2. Synthesis of the ligands

5-Formyluracil thiosemicarbazones (**1**), (**3**) and (**4**) (R-H_3ut, Scheme 1) were synthesized by dissolving ca. 0.80 mmol of aldehyde in 20 mL of water at reflux temperature and adding dropwise an equimolar amount of thiosemicarbazide previously dissolved by refluxing in 20 mL of the same solvent. To the 5-formyluracil solution a couple of drops of HCl were added as a catalyst. The mixture was left under magnetic stirring at reflux temperature for 3 h. All compounds afforded shining yellow powders with cooling, which were filtered on Buchner funnel, washed several times with H_2O and allowed to dry in air. The same method has already been used to synthesize ligand **2** [18,34].

2.2.1. Et-H_3ut (*1*)

Yield: 129 mg (67%). *Anal.* Calc. for $C_8H_{11}N_5O_2S$: C, 39.83; H, 4.59; N, 29.03; S, 13.29. Found: C, 40.15; H, 4.46; N, 28.47; S, 13.43%. Main IR peaks (KBr, cm^{-1}): ν(N–H) 3434 m and 3169 w; ν(C–$H_{aliphatic}$) 2973 w;

ν(C=O) 1711 vs and 1675 vs; ν(C=N) 1631 s; ν(C=S) 772 m. UV–Vis (DMF, nm, M^{-1} cm^{-1}) 270 (18900), 334 (21000). MS (*m*/*z*, %) MH^+ (242, 85%); ^{1}H NMR ($CDCl_3$, ppm): 11.55 (CSN*H*, 1H, br s), 9.95 (N3H_{ur}, 1H, s), 9.55 (N1H_{ur}, 1H, s), 8.51 (CH_{ur}, 1H, s), 8.03 (CH_2N*H*, 1H, t), 7.86 (C*H* = N, 1H, s), 3.05 (CH_2, 2H, m), 1.14 (CH_3, 3H, t). ^{13}C NMR ($CDCl_3$, ppm): 178.3 (*C*S), 175.9 (*C*H_2N) 164.0 (*C*4$_{ur}$), 151.4 (*C*2$_{ur}$), 146.5 (*C*6$_{ur}$), 113.7 (*C*5$_{ur}$), 132.2 (*C*HN), 38.1 (*C*H_3). 2.2.3. Ph-H_3ut (**3**)

Yield: 162 mg (68%). *Anal.* Calc. for $C_{12}H_{11}N_5O_2S$: C, 49.82; H, 3.83; N, 24.21; S, 11.08. Found: C, 50.02; H, 4.03; N, 24.33; S, 10.98%. Main IR peaks (KBr, cm^{-1}): ν(N–H) 3391 s and 3204 w; ν(C–H$_{aromatic}$) 3045; ν(C=O) 1726 mw and 1668 vs; ν(C=N) 1621 m; ν(C=S) 784 m. UV–Vis (DMF, nm, M^{-1} cm^{-1}) 270 (23900), 351 (26010). MS (*m*/*z*, %) MH^+ (290, 78%); ^{1}H NMR ($CDCl_3$, ppm): 11.60 (CSN*H*, 1H, br s), 10.10 (N3H_{ur}, 1H, s), 9.52 (N1H_{ur}, 1H, s), 8.54 (CH_{ur}, 1H, s), 8.10 (Ph-N*H*, 1H, s), 7.85 (C*H* = N, 1H, s), 7.54–7.00 (CH_{ar}, 5H, m). ^{13}C NMR ($CDCl_3$, ppm): 178.8 (*C*S), 165.1 (*C*4$_{ur}$), 151.8 (*C*2$_{ur}$), 146.4 (*C*6$_{ur}$), 114.2 (*C*5$_{ur}$), 126.7–124.8 (*C*$_{ar}$), 134.2 (*C*HN). M.p. 201 °C.

2.2.4. MePh-H_3ut · H_2O (**4**)

Yield: 195 mg (74%). *Anal.* Calc. for $C_{13}H_{15}N_5O_3S$: C, 48.59; H, 4.70; N, 21.79; S, 9.98. Found: C, 48.49; H, 4.68; N, 21.61; S, 10.19%. Main IR peaks (KBr, cm^{-1}): ν(O–H) 3429 bs; ν(N–H) 3251 m and 3200 w; ν(C–H$_{aromatic}$) 3039; ν(C–H$_{aliphatic}$) 2999 w; ν(C=O) 1718 s and 1676 vs; ν(C=N) 1632 m; ν(C=S) 773 m. UV–Vis (DMF, nm, M^{-1} cm^{-1}) 272 (21800), 359 (24300). MS (*m*/*z*, %) $MH^+ - H_2O$ (304, 85%); ^{1}H NMR ($CDCl_3$, ppm): 11.58 (CSN*H*, 1H, br s), 10.10 (N3H_{ur}, 1H, s), 9.54 (N1H_{ur}, 1H, s), 8.54 (CH_{ur}, 1H, s), 8.08 (Ph-N*H*, 1H, s), 7.84 (C*H* = N, 1H, s), 7.55–7.00 (CH_{ar}, 4H, m), 2.31 (CH_3, 3H, s). ^{13}C NMR ($CDCl_3$, ppm): 178.6 (*C*S), 165.4 (*C*4$_{ur}$), 152.0 (*C*2$_{ur}$), 146.5 (*C*6$_{ur}$), 114.2 (*C*5$_{ur}$), 128.0–124.2 (*C*$_{ar}$), 134.2 (*C*HN), 17.9 (*C*H_3). M.p. 210 °C.

2.3. Synthesis of the Cu(II) complexes

The Cu(II) complexes were synthesised following this general procedure: *ca.* 0.30 mmol of the ligands were dissolved in EtOH (40 mL) with gentle heating. An equimolar amount of $Cu(NO_3) \cdot 3H_2O$ or $CuCl_2 \cdot 2H_2O$ was dissolved in the minimum quantity of the same solvent and added dropwise to the pale yellow ligand solutions. All the resulting mixtures slowly became light green coloured and were left under magnetic stirring at reflux temperature for 1 h. By slow solvent evaporation dark green powders were afforded and characterized.

2.3.1. [Cu(Et-H_3ut)$NO_3(OH_2)_2$]$NO_3 \cdot 2H_2O$ (**5**)

2.4. DNA interaction studies

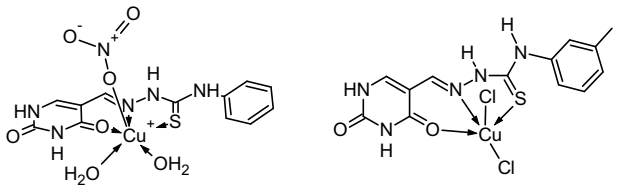
Binding constants for the interaction of the studied compounds with nucleic acid were determined as described in [35]. These studies were carried out on the ligands and their nitrate complexes because with their ionic character they are expected to show more interactions towards DNA than the neutral chloro complexes. The intrinsic binding constant K_b for the interaction of the studied compounds with CT-DNA was calculated by absorption spectral titration data using the following equation: $1/\Delta\varepsilon_{ap} = 1/(\Delta\varepsilon K_b D) + 1/\Delta\varepsilon$ where $\Delta\varepsilon_{ap} = |\varepsilon_A - \varepsilon_f|$, $\Delta\varepsilon = |\varepsilon_B - \varepsilon_f|$, $D = [DNA]$, and ε_A, ε_B and ε_f are the apparent, bound and free extinction coefficients of the compound, respectively. K_b is given by the ratio of the slope to intercept from the plot of $[DNA]/(\varepsilon_A - \varepsilon_f)$ versus [DNA] and it is expressed in M^{-1}. The previous equation, originally used to calculate the binding constants for hydrophobic derivatives, is now broadly used to investigate a wide variety of metal complexes containing phenanthroline and its derivatives and it has been adopted to obtain binding constant values from metal complexes with different ligands [23,30,36–39]. Fixed amounts of the ligands and of the complexes were dissolved in DMSO because the high solubility of the compounds in this solvent allowed us to prepare concentrated solutions and therefore to utilize reduced volumes (5 μL) for titrations. It was also verified that the DMSO percentage (0.7%) added to the DNA solution did not interfere with the nucleic acid; in fact, the 260 nm absorption band is not subjected to modifications in intensity and position. Concentrated solutions of NaCl, Tris–HCl (pH 7.2) buffer and DNA were prepared. Calculated amounts of the described stock solutions were taken to final concentration values of 50 mM NaCl, 5 mM Tris–HCl and increasing amounts of DNA over a range of DNA concentrations from 10^{-5} to 10^{-3} M. These solutions were then added to the 5 μL solution of the considered compounds in order to maintain the final volume of the solutions as fixed to 700 μL. The compounds were titrated at room temperature. The changes in absorbance of DNA of an intraligand (IL) band upon each addition were monitored at the maximum wavelengths 334, 335, 351 and 359 nm for **1**, **2**, **3** and **4**, respectively for the ligands, and at the maximum wavelengths 336, 339, 356 and 360 nm for complexes **5**, **7**, **9** and **11**, respectively.

2.5. Nuclease activity

The DNA cleavage was carried out on double stranded plasmid DNA pBR 322 by electrophoresis. Buffers were prepared using sterile distilled water. Solutions composed of 1.6 μL of plasmid (40 μg/mL), 4 μL of the studied compounds dissolved in DMSO (0.1 mM) and 8.4 μL Tris buffer solution (10 mM) were incubated for 1 h at 37 °C. This was followed by addition of a gel loading solution, and each sample was loaded directly into different wells on a 1.5% agarose gel for analysis by electrophoresis at 75 V for 3 h. The gel was stained with ethidium bromide and photographed under UV light in a transilluminator.

3. Results and discussion

3.1. Synthesis and spectroscopy



The ligands were synthesised in water in good yields. The products absorbed water giving rise to a gel-like texture and therefore it was necessary to pay attention to the drying step on the Buchner funnel and in air.

The copper complexes were synthesised by the direct reaction of the inorganic salt solutions with the ligand solutions. Under the experimental conditions used both monovalent anions are always present and therefore no ligand deprotonation is observed. The synthesis of the complexes is reproducible and the thiosemicarbazones coordinate as tridentate ligands in their neutral form (H_3ut). The elemental analyses are in agreement with the general formula $M(R\text{-}H_3ut)X_2 \cdot nH_2O$, where X is the counterion. Conductivity measurements show that complexes bearing nitrate as counterions behave as 1:1 electrolyte type compounds and therefore are monocationic [40], while complexes bearing chlorine as counterions behave as neutral molecular complexes. Thermogravimetric analyses show that two water molecules are directly bound to the metal center in the nitrate derivatives. Therefore, as a consequence of the inorganic anionic nature, two types of stoichiometries are exhibited, namely $[Cu(R\text{-}H_3ut)NO_3(OH_2)_2]NO_3$ and $[Cu(R\text{-}H_3ut)Cl_2]$ (see Scheme 2).

These observations agree with previous results [23].

3.2. IR and electronic spectra

The infrared spectral data of the ligands and their metal complexes are reported in Section 2 with their tentative assignments. It is interesting to note that the uracyl moiety owns two carboxyl groups but only the one whose ν(C=O) is assigned at *ca.* 1670 cm^{-1} is involved in coordination. Upon metal binding this carboxyl stretching is shifted downwards by 20–30 cm^{-1} while ν(C=O) not directly linked to the metal is shifted to higher frequencies because of inductive effects arising from the metal coordination. On coordination of the azomethine nitrogen, ν(C=N) shifts to lower wavenumbers by 15–25 cm^{-1}, as the band shifts from *ca.* 1630 cm^{-1} in the uncomplexed thiosemicarbazone spectra to *ca.* 1600 cm^{-1} in the spectra of the complexes. Coordination of the azomethine nitrogen is confirmed with the presence of bands at *ca.* 450 cm^{-1} (at 465 cm^{-1} for complex **12**) assignable to ν(Cu–N) for these complexes. The decrease in the stretching frequency of the C=S bond from *ca.* 770–790 cm^{-1} in the thiosemicarbazones upon complexation indicates coordination *via* the sulfur atom. The presence of a new band in the 345–355 cm^{-1} range assignable to ν(Cu–S), is another indication of the involvement of sulfur coordination. The presence of an absorption at *ca.* 420 cm^{-1} in the spectra of the complexes is assignable to ν(Cu–O). The IR spectra of the chloro complexes also display bands at *ca.* 315 and 300 cm^{-1}, characteristic of coordinated ν(Cu–Cl).

Scheme 2. Hypothesized structure for complex **9** (left) and **10** (right) deduced from spectroscopic data.

The electronic spectra of the complexes in DMF solution are presented in Section 2. Each thiosemicarbazone and its copper(II) complexes have ring $\pi \rightarrow \pi^*$ bands in the range 260–312 nm and $n \rightarrow \pi^*$ bands in the range 312–357 nm. The ligand field strength of the sulfur atom has been found to vary more than that of any other donor atom, with variations of up to 50% being known [40]. This is probably due to the variation in π-bonding effects according to whether the sulfur atom has two or three lone pairs, as in thioketones (>C=S) or mercaptide ions (≡C–S^-), which allows ample scope for M-S π-bonding. The complex spectra have bands in the range 330-357 nm which must be due to L → M transfer from sulfur to copper [41].

3.3. Absorption spectral features of DNA binding

The binding constants obtained for ligands **1**, **2**, **3** and **4** are 2.1×10^3, 1.0×10^3, 2.9×10^2 and 5.6×10^3, respectively. The binding constants obtained for complexes **5**, **7**, **9** and **11** are 2.5×10^2, 5.9×10^2, 2.3×10^1 and 2.3×10^3, respectively. In Fig. 1 the plot of $[DNA]/(\varepsilon_A - \varepsilon_f)$ versus [DNA] for absorption titration of the studied complexes is reported, useful for obtaining K_b by the ratio of the slope to intercept.

Our experimental K_b values are lower than those observed for classical intercalators (ethidium-DNA, 1.4×10^6 in 25 mM Tris–HCl/40 mM NaCl buffer, pH 7.8 [42]; 3.0×10^6 in 5 mM Tris–HCl/50 mM NaCl buffer, pH 7.2 [this work]), indicating that the compounds bind DNA with less affinity, as already noticed for copper(II) complexes with macrocyclic ligands [36]. It is interesting to note that the metal complexes reported in this work bind to DNA with less affinity than copper complexes with aliphatic thiosemicarbazones [37], complexes synthesised with formyluracil thiosemicarbazones bearing less bulky substituents on the side chain [23] and copper complexes with thiosemicarbazide [43]. Since upon complexation no significant increase of K_b was observed, the constant values can probably be related to the role played by the ligand in the binding to DNA. The terminal NH group seems to play an important function in the binding process: as the access to the NH becomes more difficult with the presence of bulky substituents, the association to the nucleic acid becomes weaker. Compounds **4** and **11**, having the bulkier methylphenyl substituent, show a major affinity towards the nucleic acid with respect to the phenyl analogues **3** and **9** (K_b 5.6×10^3 (**4**) versus 2.9×10^2 (**3**) and K_b

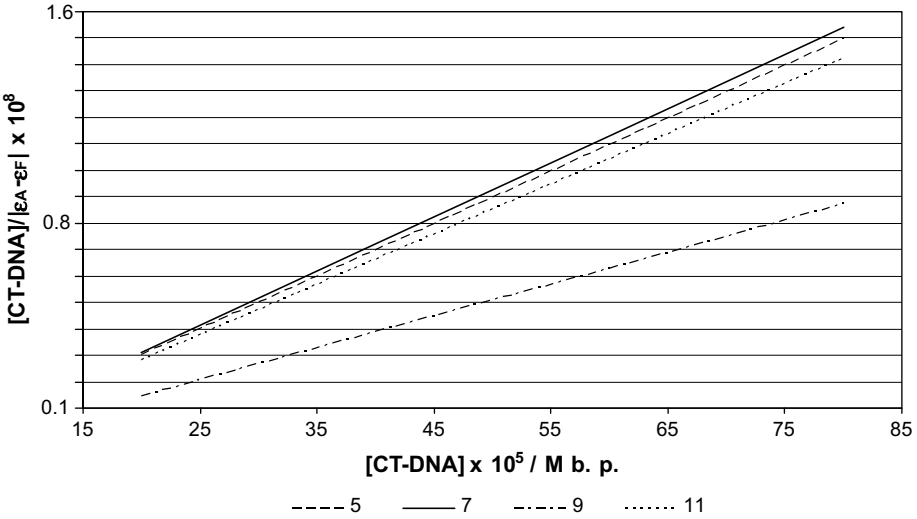


Fig. 1. Typical plots of $[DNA]/(\varepsilon_A - \varepsilon_f)$ vs [CT-DNA] for absorption titration with CT-DNA in 50 mM NaCl/5 mM Tris buffer, pH 7.2 at 25 °C.

2.3×10^3 (**11**) versus 2.3×10^1 (**9**)). This effect can probably be ascribed to the major deviation from planarity of the overall thiosemicarbazonic system due to the methyl substituent on the aromatic ring, as observed in N terminal substituted thiosemicarbazones [28] that decreases the steric hindrance on increasing the accessibility to the aminic group. The weak interactions between our compounds and the nucleic acid are also confirmed by a negligible hypochromism and bathochromism in the electronic absorption spectra of DNA bound to different compounds. These phenomena are generally attributed to intercalation, involving a strong stacking interaction between the aromatic chromophores and the base pairs of DNA. The ratio r ($r = [CT\text{-}DNA]/[complex]$) varied between 0 and 15 in 5 mM Tris–HCl buffer (pH 7.2), 50 mM NaCl at 25 °C. Our results are in agreement with the fact that the glycosidic bond of a formyluracil residue derivative in DNA is about 3 orders of magnitude more labile than that of the parent pyrimidine, thymine and is assignable to the electron-withdrawing effect of the 5-formyl substituent [44]. Additionally, the electron-withdrawing substituent destabilizes the *N*-glycosidic bond, rendering oligonucleotides containing formyluracil, highly susceptible to hydrolysis. The thiosemicarbazidic chain in the five position of the uracil moiety could additionally form potentially irreversible covalent cross-links with an amino group of DNA-binding proteins, resulting in locking the binding instead of blocking binding [44]. The presence of substituents on the terminal nitrogen seems to weaken the capability of bonding towards DNA.

3.4. Nuclease activity

In addition to the studies carried out with CT-DNA, a gel electrophoresis experiment using pBR322, a circular plasmid DNA, was performed with all our compounds. From the results (data not shown) it was verified that at millimolar concentrations for all tested compounds the supercoiled was the predominant form of DNA followed by a slight amount of the open circular form, indicating that there is no significant breaking of plasmid-DNA due to oxidative stress or phosphodiester hydrolysis.

4. Conclusions

As hypothesized in the introduction, the presence of a substituent on the thiosemicarbazidic chain strongly affects the DNA interactions of thiosemicarbazones and their metal complexes. The variation of the hydrophilic/lipophilic character due to the different alkylic or aromatic groups could vary the uptake by the cells but this feature has no consequence on the direct effects of the compounds towards DNA; on the contrary, with respect to the unsubstituted analogous compounds, the free NH_2 thiosemicarbazone moiety seems to play an important role in DNA binding. The presence of the substituents, on the other hand, has no consequence on the coordination mode that, on the contrary, seems to be more influenced by the counterion.

Another characteristic of an efficient photosensitizer is a Q-band absorption close to 700 nm. The Q-band of octa(thiophen-2-yl) ZnAzaPc was found at 673 nm, whereas unsubstituted AzaPc has a Q-band at 635 nm [5] and both octaphenylZnAzaPc and octa(pyridin-2-yl)ZnAzaPc absorb at 657 nm [4]. In other words, thiophen-2-yl peripheral substituents induce substantially red shifted Q-bands for these macrocycles.

We have reported several investigations on the synthesis [6–8] and photodynamic properties [9–12] of alkylheteroatom (N, O, S) substituted AzaPcs. AzaPcs substituted peripherally with pyridin-2-yl were also investigated by another group from the UV–Vis spectral and electrochemical point of view [13–16]. However, as far as we know, there has been no systematic study of how mixed types of substituents (heteroaromatic and alkylheteroatom) on the AzaPcs influence the Q-band positions, singlet oxygen and fluorescence quantum yields.

Our aim for the present investigation is to extend our knowledge about how various types of substituents on ZnAzaPc influence the three characteristics: Q-band positions, singlet oxygen and fluorescence quantum yields of the complexes. The most interesting substituent among the carbon attached heterocycles, the thiophen-2-yl group, will be compared to thiophen-3-yl and benzo[*b*]thiophen-3-yl groups. However, good solubility and low tendency to aggregate are important for efficient PDT sensitizers as well. Both characteristics are expected to improve for octasubstituted AzaPcs with two different types of peripheral substituents instead of one. Therefore, ZnAzaPcs with a combination of thiophen-2-yl and either sulfur or nitrogen attached substituents, will be synthesized and studied. We have not considered substituents attached through oxygen, since the carbon–oxygen bond is labile during normal reaction conditions for cyclotetramerisations [8,11]. However, an interesting and successful approach to the synthesis of AzaPcs with ether linked substituents has been reported recently [2]. The choice of sulfur attached substituents was made among alkylsulfanyl groups, since arylsulfanyl groups are somewhat labile and may be replaced by nucleophiles. The two nitrogen attached substituents were chosen so that one is electron donating (thiomorpholine), and the other is electron withdrawing (a substituted maleimide). Both the sulfur and nitrogen attached substituents are relatively bulky in order to prevent aggregation.

2. Experimental

2.1. Materials and methods

Electron impact (EI) mass spectra of compounds **2**–**5** were obtained on a Finnigan MAT 95XL spectrometer at 70 eV electron energy and 1.0 mA electron current. MALDI-TOF mass spectra of compounds **6** and **7** were recorded in the negative reflectron mode on a mass spectrometer Voyager-DE STR (Applied Biosystems, Framingham, MA, USA). For each sample, 0.5 μl of the mixture was spotted onto the target plate, air-dried and covered with 0.5 μl of matrix solution consisting of 10 mg of α-cyano-4-hydroxycinnamic acid in 100 μl of 50% ACN in 0.1% TFA. The instrument was calibrated externally with a five-point calibration using Peptide Calibration Mix1 (LaserBio Labs, Sophia-Antipolis, France). IR spectra were obtained on a Nicolet 20-SXC FT IR spectrometer. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker Avance DPX 400 NMR spectrometer or on a Bruker Avance Digital 600 NMR spectrometer at 100.4, 399.65 or 600.18 MHz, respectively. Chemical shifts are given relative to internal tetramethyl silane (TMS). UV–Vis spectra were recorded on a Cary 50 UV–Vis spectrophotometer or a UV-2401PC spectrophotometer from Shimadzu. Fluorescence data were obtained on an AMINCO-Bowman Series 2 luminescence spectrometer. Melting points were obtained on a Büchi 530 melting point apparatus and are uncorrected. The elemental analyses were carried out on an Automatic Microanalyser EA1110CE (Fisons Instruments S.p.A., Milano, Italy). Merck Kieselgel 60F 254 was used for thin layer chromatography (TLC) and Merck silica 63–200 μm was used for column chromatography. Zinc phthalocyanine (ZnPc) was purchased from Eastman Organic Chemicals (New York, USA). 1,3-Diphenylisobenzofuran (DPBF) was obtained from Aldrich.

2.2. Synthesis

The following compounds have been prepared previously in our laboratories and published: **2c** and **6c** [4], **5a** and **7a** [17], **7c** [18] and **7d** [22]. Compound **3** was prepared according to a published procedure [19].

2.2.1. Compounds *2*

*2.2.1.1. General procedure for the synthesis of compounds **2**.* A solution of 3,3′-thenil (**1a**) [20] or 3,3′-benzo[*b*]thenil (**1b**) [21] (10 mmol) and diaminomaleonitrile (15 mmol) in glacial acetic acid (30 ml) was heated under reflux for **2a** 24 h, and for **2b** 3 h. The solvent was removed under reduced pressure and the residue was extracted with dichloromethane (DCM) and chromatographed on silica with DCM.

*2.2.1.2. 5,6-Di(thiophen-3-yl)pyrazine-2,3-dicarbonitrile (**2a**).* Yield: 2.38 g (81%) of a pale yellow powder, m.p. 218–220 °C. EIMS: *m*/*z* (% rel. int.) 295 (22.9), 294 (M, 100), 293 (50.0), 261 (44.3), 250 (15.6). Found 294.00338, calcd. for $C_{14}H_6N_4S_2$ 294.00339. UV–Vis (DCM): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 280 (16000), 350 (17000). ^{1}H NMR ($CDCl_3$): δ, ppm 7.25 (2H, dd, $J_{4,5} = 5$ Hz, $J_{4,2} = 1.3$ Hz), 7.38 (2H, dd, $J_{5,2} = 3$ Hz, $J_{5,4} = 5$ Hz), 7.83 (2H, dd, $J_{2,5} = 3$ Hz, $J_{2,4} = 1.3$ Hz). ^{13}C NMR ($CDCl_3$): δ, ppm 113.17 (CN), 126.94, 127.73, 129.18, 130.61, 136.63, 149.81. IR (KBr): ν, cm^{-1} 3105, 2239 (CN), 1651, 1503, 1387, 1218, 1162, 806, 701.

*2.2.1.3. 5,6-Di(benzo[b]thiophen-3-yl)pyrazine-2,3-dicarbonitrile (**2b**).* Yield: 1.65 g (42%) of a yellow powder, m.p. 254–258 °C (decomp). EIMS: *m/z* (% rel. int.) 395 (21.3), 394 (M, 15.2), 393 (21.2), 362 (26.9), 159 (67.2). Found 394.03447, calc. for $C_{22}H_{10}N_4S_2$ 394.03462. UV–Vis (DCM): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 265 (22000), 362 (15300), 395 (15800). ^1H NMR ($CDCl_3$): δ, ppm 7.36, *H5* (2H, dd, $J_{5,4} = 8$ Hz, $J_{5,6} = 7$ Hz), 7.42, *H6* (2H, dd, $J_{6,7} = 8$ Hz, $J_{6,5} = 7$ Hz), 7.67, *H2* (2H, s), 7.87, *H7* (2H, ddd, $J_{7,6} = 8$ Hz, $J_{7,5} = 2$ Hz, $J_{7,4} = 0.7$ Hz), 7.93, *H4* (2H, ddd, $J_{4,5} = 8$ Hz, $J_{4,6} = 2$ Hz, $J_{4,7} = 0.7$ Hz). ^{13}C NMR ($CDCl_3$): δ, ppm 113 (CN), 122.91, 123.61, 125.60, 125.61, 129.48, 130.96, 132.98, 135.72, 140.08, 151.21 (after 24 h, an orange precipitate separates from the $CDCl_3$ solution). IR (KBr): ν, cm^{-1} 3109(w), 2238 (w, CN), 1500, 1429, 1382, 1246, 1182, 1063, 856, 803, 758, 735.

*2.2.2. Compounds **5***

*2.2.2.1. 5-(tert-Butylsulfanyl)-6-(thiophen-2-yl)pyrazine-2,3-dicarbonitrile (**5b**).* A solution of *tert*-butanethiol (3 mmol, 0.78 g) in 0.1 M NaOH (3.3 mmol, 3.3 ml) was stirred at ambient temperature for 0.5 h. A solution of **3** (3 mmol, 0.74 g) in THF (6 ml) was added with stirring. The reaction mixture was stirred for 15 min, water (25 ml) was added, and the precipitate was collected by filtration and was washed thoroughly with water. Yield: 0.87 g (97%) of a yellow powder, m.p. 184–186 °C (decomp). EIMS: *m/z* (% rel. int.) 300 (M, 4.5), 246 (9.6), 245 (33.5), 244 (84.0), 243 (100). Found 300.04949, calc for $C_{14}H_{12}N_4S_2$ 300.05034. UV–Vis (DCM): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 390 (14100), 345 (16300), 285 (14600). ^1H NMR ($CDCl_3$): δ, ppm 1.69 (9H, s), 7.23, *H4* (1H, dd, $J_{4,3} = 4$ Hz, $J_{4,5} = 5$ Hz), 7.71, *H5* (1H, dd, $J_{5,4} = 5$ Hz, $J_{5,3} = 1$ Hz), 8.22, *H3* (1H, dd, $J_{3,4} = 4$ Hz, $J_{3,5} = 1$ Hz). The pulse techniques HSQC and HMBC were used for identification of the ^{13}C signals. ^{13}C NMR ($CDCl_3$): δ, ppm 29.63 (*CH*$_3$), 52.39 (*C*Me$_3$), 113.33 (*CN*), 113.42 (*CN*), 125.66 (*C2*-pyrazine), 126.74 (*C3*-pyrazine), 128.71 (*C4*-thiophene), 133.03 (*C3*-thiophene), 133.95 (*C5*-thiophene), 138.44 (*C2*-thiophenyl), 148.06 (*C6*-pyrazine), 159.73 (*C5*-pyrazine). IR (KBr): ν, cm^{-1} 2998, 2959, 2232 (w, CN), 1488, 1423, 1326, 1264, 1138, 1092, 1049, 909, 850, 728.

*2.2.3. Compounds **6***

*2.2.3.1. General procedure for the synthesis of compounds **6**.* Compound **2** (1 mmol) and dry zinc(II) acetate (1 mmol) were ground together in a mortar, transferred to a round bottomed flask, quinoline (0.5 ml) was added, and nitrogen was passed over the reaction mixture for 20 min at ambient temperature. The mixture was heated to 155–160 °C for 50 min (**2a**) and 15 min (**2b**). The dark solid that formed was thoroughly washed, using sonification, with water, acetone and a mixture of DCM and acetone.

*2.2.3.2. [Octa(thiophen-3-yl)-(octazaphthalocyaninato)]-zinc(II) (**6a**).* Yield: 0.2 g (64%) of a black powder. UV–Vis (pyridine): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 661 (224000), 599 (26000), 385 (113000). MALDI-TOF MS *m/z* 1240.08 [M+H$^+$]. *Anal.* Calc. for $C_{56}H_{24}N_{16}S_8Zn + 5H_2O$: C, 50.46; H, 2.57; N, 16.81. Found: C, 50.49; H, 2.33; N, 16.74%.

*2.2.3.3. [Octa(benzo[b]thiophen-3-yl)-(octazaphthalocyaninato)]zinc(II) (**6b**).* Yield: 0.18 g (44%) of a black powder. UV–Vis (pyridine): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 664 (187000), 600 (37000), 390 (91000). The DQF-COSY pulse technique was used for identifications of ^1H NMR signals. ^1H NMR (pyridine-d_5): δ, ppm 7.24 *H5* (4H, partly superimposed on the pyridine signal), 7.37, *H6* (4H, m), 8.01, *H7* (4H, d, $J = 7.8$ Hz), 8.17, *H2* (4H, s), 8.53 *H4* (4H, d, $J = 7.8$). The use of the HSQC pulse technique allowed identification of the following ^{13}C NMR signals: ^{13}C NMR (pyridine-d_5): δ, ppm *C7* 123.3, *C4* 124.5, *C5* 125.3, *C6* 125.3, *C2* 131.2. MALDI-TOF MS *m/z* 1641.03 [M+H$^+$]. *Anal.* Calc. for $C_{88}H_{40}N_{16}S_8Zn + 5H_2O$: C, 60.98; H, 2.91; N, 12.93. Found: C, 57.86; H, 2.61; N, 12.33%.

*2.2.4. Compounds **7***

*2.2.4.1. [Tetra(tert-butylsulfanyl)-tetra(thiophen-2-yl)-(octazaphthalocyaninato)]zinc(II) (**7b**).* Compound **7b** was prepared from **5b** and $Zn(OAc)_2$ in quinoline as described for compounds **6**. The crude product was purified as for compounds **6**. The crude product was then chromatographed on silica with pyridine. Yield 40% of a black, shiny solid. UV–Vis (pyridine): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 671 (234000), 605 (47000), 395 (160000). *NMR*: Four different signals were found for each of the three thiophene protons, apparent due to isomers. The corresponding ^{13}C signals were found by HSQC and HMBC pulse techniques. Each isomer is listed separately with the corresponding $^1H/^{13}C$ NMR signals (pyridine-d_5): δ, ppm: *Isomer 1*: *H5*/*C5*, 8.08 (d, $J = 5$ Hz)/131.8, *H4*/*C4*, 7.49 (m)/129.0, *H3*/*C3*, 8,77 (m)/131.5, *C2*, 143.7, *C6-pyrazine*, 147.6. *Isomer 2*: *H5*/*C5*, 8.06 (d, $J = 5$ Hz)/131.8, *H4*/*C4*, 7.48 (m)/129.0, *H3*/*C3*, 8,74 (m)/131.6, *C2*, 143.7, *C6-pyrazine*, covered by the pyridine signal. *Isomer 3*: *H5*/*C5*, 7.87 (d, $J = 5$ Hz)/131.2, *H4*/*C4*, 7.41 (m)/128.6, *H3*/*C3*, 8,66 (m)/131.5, *C2*, 142.8, *C6-pyrazine*, 147.6. *Isomer 4*: *H5*/*C5*, 7.85 (d, $J = 5$ Hz)/131.2, *H4*/*C4*, 7.39 (m)/128.6, *H3*/*C3*, 8,62 (m)/131.6, *C2*, 143.0, *C6-pyrazine*, 147.7. *tert-butyl groups*: ^1H NMR (pyridine-d_5): δ, ppm 2.23–2.32 (broad singlets, several signals). MALDI-TOF MS *m/z* 1265.08 [M+H$^+$]. *Anal.* Calc. for $C_{56}H_{48}N_{16}S_8Zn + 2H_2O$: C, 51.62; H, 4.02; N, 17.20. Found: C, 51.70; H, 3.89; N, 17.05%.

*2.2.5. (Tetra{1-[3-chloro-4-(4-thiomorpholinyl) maleimidyl]}-tetra(thiophen-2-yl)-(octazaphthalocyaninato))zinc(II) (**7d**)*

The previously reported product [22] was further purified by absorbing a DCM solution of the compound on a silica column. Impurities were eluted with DCM, and compound **7d** was eluted with pyridine, which was removed

under reduced pressure. The dark solid residue was triturated with diethyl ether and filtered to give a dark blue to black shiny solid. UV–Vis (pyridine): λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$) 675 (208 000), 615 (49 000), 390 (172 000), 315 (191 000). *NMR*: Two different signals were found for each of the three thiophene protons, apparently due to isomers. The corresponding ^{13}C signals were found by DQF-COSY, HSQC and HMBC pulse techniques. Each isomer is listed separately with the corresponding $^{1}H/^{13}C$ NMR signals (pyridine-d_5): δ, ppm: *Isomer 1*: *H5*/*C5*, 7.84/132.3, *H4*/*C4*, 7.27/129.4, *H3*/*C3*, 8.61/132.2, *C2*, 139.3. *Isomer 2*: *H5*/*C5*, 7.79/132.4, *H4*/*C4*, 7.21/129.3, *H3*/*C3*, 8.48/132.2, *C2*, 139.3. Two isomers were found for thiomorpholine, and they are listed as above. *Isomer 1*: *H2*/*C2*, 2.92/28.4, *H3*/*C3*, 4.33/51.8, *C3-maleimide*, 143.2. *Isomer 2*: *H2*/*C2*, 2.89/28.4, *H3*/*C3*, 4.30/51.8, *C3-maleimide*, 143.3. MALDI-TOF MS *m*/*z* 1832.94 [M+H$^+$]. *Anal*. Calc. for $C_{72}H_{44}Cl_4N_{24}O_8S_8Zn + 5H_2O$: C, 44.78; H, 2.82; N, 17.44. Found: C, 47.25; H, 3.06; N, 17.74%.

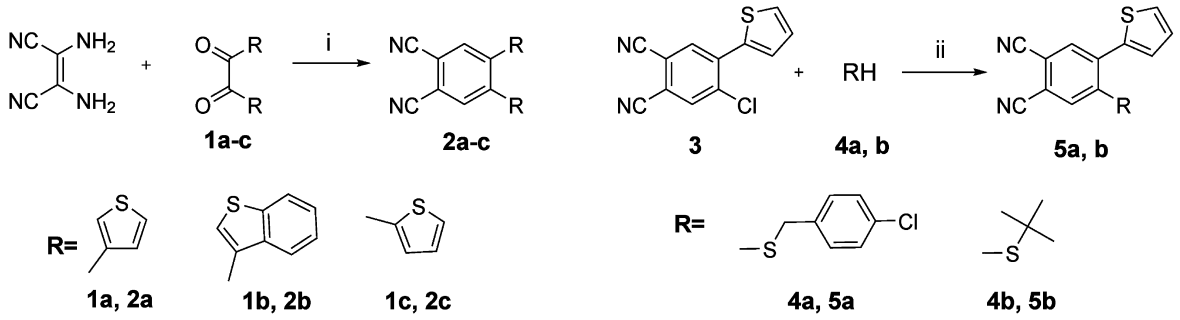
2.3. Singlet oxygen measurements

Singlet oxygen production was monitored as DPBF (1,3-diphenylisobenzofuran) decomposition reactions, as reported by us previously [10], but with a slight modification. Pyridine solutions of the metal complexes **6a**–**c** and **7a**–**d** were heated at approximately 115 °C for a few minutes to ensure complete dissolution and monomerisation of possible dimers. The pyridine solutions were cooled to ambient temperature, diluted until the Q-band λ_{max} absorption became 0.1 and then kept strictly in the dark. A 2.4 ml sample of these solutions was transferred into a 10 × 10 mm quartz optical cell, 24 μl of a 5 mM stock solution of DPBF in pyridine was added, and the resulting solution was purged with oxygen for 1 min. A Tip 200 W halogen lamp was used for irradiation of the oxygen purged solution, and exact time intervals were used. The decomposition of DPBF was monitored at 417 nm, and irradiation was stopped before the decomposition of DPBF had reached 15%. Other conditions (filters, etc.) as well as the calculations of Φ_Δ have been described previously [10]. ZnPc in pyridine was used as the standard ($\Phi_\Delta = 0.61$ [23]).

2.4. Fluorescence measurements

Fluorescence quantum yields of the dyes were determined in pyridine and calculated according to following equation (Eq. (1)):

$$\Phi_F^S = \Phi_F^R \frac{AUC^S}{AUC^R} \frac{1 - 10^{-A^R}}{1 - 10^{-A^S}} \quad (1)$$



where Φ_F is the fluorescence quantum yield, AUC is the integrated area under the emission spectrum and A is absorbance at the excitation wavelength. Superscripts R and S correspond to reference and sample, respectively. ZnPc in pyridine was used as a reference ($\Phi_F = 0.20$ in pyridine [23]). The dye solutions prepared as mentioned above were used for measurements after the appropriate dilution. In all cases the absorbance at λ_{max} of the Q-band was below 0.04 in order to minimize reabsorption of the emitted light. Fluorescence emission spectra were recorded after excitation at 606 nm. Fluorescence excitation spectra were recorded observing the fluorescence signal at 720 nm.

3. Results and discussion

3.1. Syntheses and characterisation

The syntheses of pyrazine-2,3-dicarbonitriles **2a**–**c**, **3** and **5a**,**b** are shown in Scheme 1. The macrocycles ZnAzaPcs **6a**–**c** and **7a**–**b** were obtained from monomers **2**, **3** and **5** and their structures are shown in Fig. 1. Compounds **2a**, **b** were obtained from a condensation between diaminomaleonitrile and 3,3′-thenil (**1a**) or 3,3′-benzo[*b*]thenil (**1b**) dissolved in acetic acid. The extended conjugation of the benzo[*b*]thiophene group is reflected in the UV–Vis absorption at 395 nm for compound **2b** compared to 350 nm for **2a**. Compound **3** was used for syntheses of the sulfanyl substituted monomers **5a,b**. The zinc complexes **6a**–**c** and **7a**–**d** were obtained from cyclotetramerization with zinc(II) acetate and quinoline. Attempts to tetramerize compound **3** by the same procedure gave an AzaPc macrocycle ($\lambda_{max}(\varepsilon) = 670$ (81 000)) of low solubility. Neither MALDI-TOF nor elemental analyses confirmed the expected structure. The chlorine atom of **3** is most likely labile and was exchanged either during cyclisation or work up procedures.

The thiophen-3-yl substituted compound **6a** has very low solubility in most organic solvents, including pyridine, and therefore NMR spectra could not be properly measured for **6a**. Compounds **6b**–**c** and **7a**–**d** are somewhat more soluble and pyridine-d_5 solutions were used for NMR studies of these substances. ^{1}H NMR spectra of **6b**–**c** and **7a**–**d** were recorded, and the pulse techniques DQF-COSY, HSQC and HMBC were used to correlate proton and carbon signals. NMR spectra of compound **6b**, dissolved in pyridine-d_5, show all the aromatic protons, including the thiophen-2-yl protons, at a higher field than for the corresponding protons of monomer **2b**. Complexation with zinc is expected to have, and indeed it has, the same effect on all these macrocycles. It was noted that the pyridine-d_5 solution of **6b** deposited a dark precipitate after about 24 hours, apparently due to slow aggregation. Complexes **7a**–**d** are expected to be mixtures of four constitutional isomers due to the unsymmetrically substituted monomers. Compound **7b**, with equal numbers of thiophen-2-yl and *tert*-butylsulfanyl groups, gave four different proton signals for each of the three thiophen-2-yl hydrogens. We interpret these as signals from four isomers. The tendency of aggregation plays an important role in the interpretation of NMR spectra. The *tert*-butylsulfanyl groups may cause more steric strain than the 4-chlorobenzylsulfanyl group of **7a** and consequently **7b** is less

Scheme 1. Scheme of the synthesis of the precursors. Reaction conditions: (i) acetic acid, reflux; (ii) pyridine, acetone (for **4a**) or NaOH, water, THF (for **4b**).

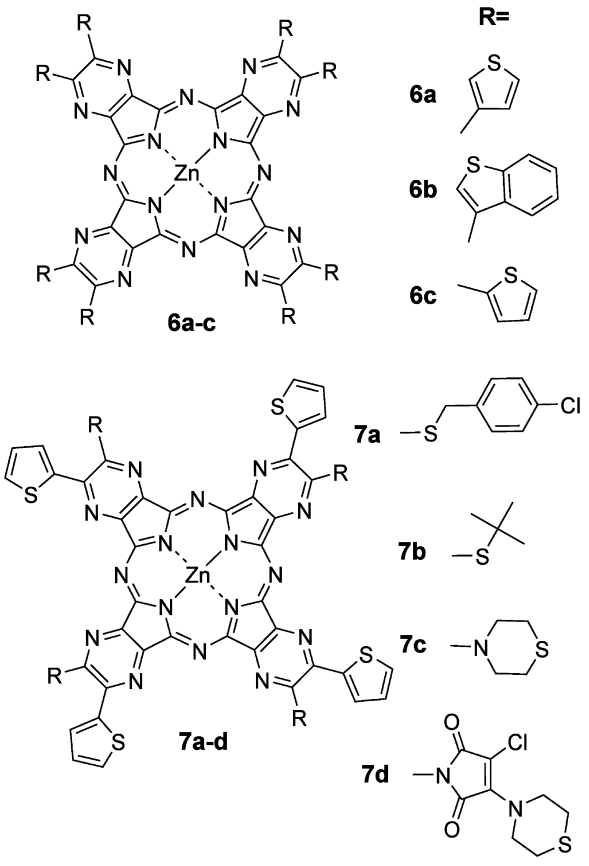


Fig. 1. Structures of the substituted ZnAzaPc systems examined in the study.

aggregated. Only one set of ^{1}H NMR signals were observed for the thiophen-2-yl groups of **7a** [17], indicating one isomer only. However, the presence of other isomers could have been masked by aggregation. Compound **7d**, with a large substituted maleimide group, shows two sets of proton signals for each of the three thiophen-2-yl hydrogen atoms and also for each of the two different kinds of thiomorpholine hydrogen atoms. This indicates that there are at least two different isomers of **7d**. Similarly to the previous compound, the presence of two other isomers may be masked by aggregation.

The mass spectra of the dyes were measured by MALDI-TOF spectrometry. The mass $M+H^+$, as well as the adducts with Na^+ and K^+, were detected for all the new macrocycles, i.e. for compounds **6a**–**b**, **7b** and **7d.** Due to ionisation, a stepwise removal of isobutenes from the *tert*-butylsulfanyl substituents of **7b** was observed in accordance with previous observations [10]. These observations confirm the expected structure of **7b**. No other than the expected molecular ions were detected in the mass spectra of compounds **6a**–**b**, **7b** and **7d**.

Elemental analyses of the dyes were satisfactory for compounds **6a** and **7b**. However the elemental analyses of **6b** and **7d** are not quite satisfactory, and we conclude that these compounds are slightly contaminated. Due to the low solubilities of compounds **6b** and **7d**, further purifications were not successful.

Table 1 summarizes the spectral, photophysical and photochemical data for compounds **6a**–**c** and **7a**–**d**. Complex **6a** with thiophen-3-yl substituents has a Q-band at 661 nm, whereas **6c**, with thiophen-2-yl substituents, has a Q-band at 673 nm. The 12 nm red shift for **6c** is most likely caused by better conjugation, i.e. more resonance forms, between the macrocycle and thiophen-2-yl groups. Compound **6b** shows a 3 nm red shifted Q-band compared to **6a** and this probably reflects the higher aromaticity of benzo[*b*]thiophene compared to thiophene. Compounds **7a**–**d** are substituted with four thiophen-2-yl groups and either four sulfanyl, amino or imido groups. The following Q-band positions were measured for these compounds: 669 (**7a**), 671 (**7b**), 669 (**7c**) and 675 nm (**7d**). Compound **6c** is substituted with eight peripheral thiophen-2-yl groups, and its Q-band position is 673 nm. Therefore it appears that four peripheral thiophen-2-yl substituents will induce almost the same red shift of a Q-band as eight thiophen-2-yl groups. Except for the substituted maleimide group of compound **7d**, the other sulfanyl or amino groups of **7a**–**7c** have negligible effects on the Q-band positions of these compounds. Incidentally, maleimide substituents were originally used in order to facilitate cyclotetramerisations since imido-nitrogens would be electron withdrawing [22]. Electron donating substituents make the cyclization procedure complicated [7] while electron withdrawing groups facilitate macrocycle formation [2,12].

Table 1
Spectral, photophysical and photochemical data of the substituted ZnAzaPc systems in pyridine

	Peripheral substitution		Q-band λ_{max} (nm)	Fluorescence λ_{max} (nm)	Φ_Δ	Φ_F
ZnPc	H	H	674	680	0.61[a]	0.20[a]
6a	thiophen-3-yl	thiophen-3-yl	661	668	0.581	0.235
6b	benzo[*b*]thiophen-3-yl	benzo[*b*]thiophen-3-yl	664	672	0.416	0.102
6c	thiophen-2-yl	thiophen-2-yl	673	680	0.635[b]	0.176[b]
7a	thiophen-2-yl	4-chlorobenzylsulfanyl	669	678	0.695	0.177
7b	thiophen-2-yl	*tert*-butylsulfanyl	671	680	0.672	0.162
7c	thiophen-2-yl	thiomorpholine	669	678	0.107	0.019
7d	thiophen-2-yl	substituted maleimide	675	682	0.103	0.036

[b] From Ref. [4].

3.2. Fluorescence and singlet oxygen quantum yields

The quantum yields were measured in pyridine and with zinc phthalocyanine (ZnPc) as the reference. The data obtained are summarized in Table 1. Singlet oxygen quantum yields were determined using a specific chemical trap for singlet oxygen, 1,3-diphenylisobenzofuran (DPBF)[3]. Several other dyes, previously synthesized by us but not characterized from the point of view of quantum yields, were introduced into this study in order to clarify the influence of peripheral substituents on the photophysical and photochemical properties of AzaPc macrocycles. Fluorescence spectra were of a typical shape for AzaPc, with only a small Stokes shift in the range of 7–9 nm (see Table 1). The calculations of quantum yields were based on the absorption of light in the Q-band area. The presence of low mass impurities, without absorption in the Q-band area, will not influence the results obtained for compounds **6b** and **7d**. This was confirmed also by a perfect fit between the absorption and fluorescence excitation spectra (for example see Fig. 2). The possible impurities would modify the absorption spectra but not the fluorescence excitation spectra. The aggregation of the dyes did not influence the results either, because the measurements were performed in very dilute pyridine solutions (below 0.5 μM for Φ_Δ and below 0.2 μM for Φ_F) where the dyes stay almost exclusively in the monomeric form. Also perfect agreement of absorption and excitation spectra (Fig. 2) confirmed the presence of only the monomeric form during measurements.

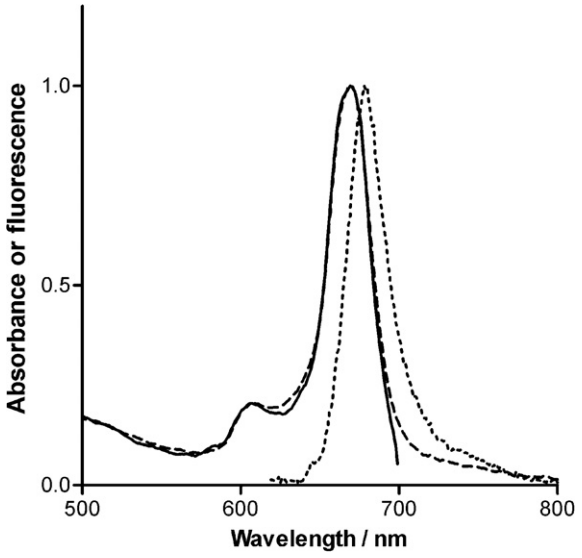

Fig. 2. Normalized absorption (dashed line), fluorescence excitation (full line) and fluorescence emission (dotted line) spectra of compound **7c**.

The sum of the quantum yields ($\Phi_\Delta + \Phi_F$) of the macrocycles with octathiophene substitution (**6c**) and (**6a**) was the same. The change of position of the thiophene substitution (thiophen-2-yl or thiophen-3-yl) led only to differences in the distribution of released energy between fluorescence and photoprocess type II (higher Φ_Δ for **6c** and reversely higher Φ_F for **6a**). An extended conjugation of the benzo[*b*]thiophene group in compound **6b** decreases the overall quantum yields. This is probably due to the larger molecular size, which increases the possibility to release absorbed energy in the form of heat through collision with surrounding molecules. Similarly, larger naphthalocyanines have lower quantum yields compared to Pc [24]. Compounds **7** are unsymmetrically substituted and the influence of the second substituent was also investigated. We have shown previously [11] that alkylsulfanyl substituents have positive effect on Φ_Δ, while the presence of nitrogen connecting peripheral chains with the macrocycle strongly decreases the overall quantum yields [10]. The obtained results confirmed further such formulated structure-activity relationships. Compounds **7a** and **7b** with alkylsulfanyl substituents exerted the highest Φ_Δ value amongst the studied compounds. Their values of Φ_Δ were very close to each other because both substituents (*tert*-butylsulfanyl and 4-chlorobenzylsulfanyl) should influence the macrocycle in the same way. Compounds **7c** and **7d**, with nitrogen atoms connecting the substituents to the macrocycle, showed far lower quantum yields. This is also in good agreement with previously postulated relationships.

4. Conclusion

The present studies have shown that ZnAzaPcs substituted with thiophen-2-yl groups in combination with other

substituents may be of interest for the development of new photosensitizers. The thiophen-2-yl group will, regardless of the presence of other groups, cause a red shift of the Q-band to 670 nm or higher. A combination of imide substituents, attached to the macrocycle through nitrogen atoms, and thiophen-2-yl substituents, is expected to increase the Q-band red shift further, as seen for compound **7d**. However, imide substituents in general are expected to decrease the singlet oxygen quantum yields of ZnAzaPcs, and will be of little interest in our future search for efficient photosensitizers. The thiophen-3-yl substituents are less efficient than thiophen-2-yl groups for inducing red shifted Q-bands, and therefore are less interesting for a future search for photosensitisers. However, the thiophen-3-yl substituents induce a relatively high production of singlet oxygen, which may be of interest for other purposes. The best combination of substituents for the prepared ZnAzaPcs is a mixture of thiophen-2-yl substituents with bulky sulfanyl groups. This combination gives good solubility and little aggregation due to more disorder in these compounds. The bulky *tert*-butylsulfanyl substituents of **7b** inhibit efficiently the aggregation, and together with its high Φ_Δ and absorbance at 671 nm, this compound is promising for future tests as a potential photosensitizer in PDT. The $\Phi_\Delta = 0.67$ of this AzaPc is more than sufficient for efficient sensitization. For comparison, the sulfonated AlPc approved for various cancer treatments under the name Photosens (developed in NIOPIK, Russia) has $\Phi_\Delta = 0.42$ [25].

While several dimeric complexes of copper(I) halides with heterocyclic thioamides are reported [12], there are only two dimeric complexes of heterocyclic thioamides with silver(I), namely, $[Ag_2Br_2(pymSH)_2(PPh_3)_2]$ (pymSH = pyrimidine-2-thione) [10a] and $[Ag_2(\mu\text{-S-pySH})_2\text{-}(\mu\text{-P,P-dppb})_2](NO_3)_2$ (dppb = $Ph_2P\text{-}(CH_2)_4\text{-}PPh_2$) [10b]. In this paper, dimeric complexes of silver(I) halides with pyridine-2-thione are reported and characterized using analytical data, NMR spectroscopy and single crystal X-ray crystallography.

2. Experimental

2.1. Materials and techniques

Pyridine-2-thione and triphenyl phosphine were procured from Aldrich–Sigma Ltd. Silver(I) halides were freshly prepared from $AgNO_3$ and NaBr, or KCl and dried *in vacuo*. Elemental analysis for C, H and N were carried out using a thermoelectron FLASHEA1112 analyser. The melting points were determined with a Gallenkamp electrically heated apparatus. The IR spectra of the ligands and the complexes were recorded on the FTIR-SHIMADZU 8400 Fourier Transform spectrophotometer in the range, 4000–500 cm^{-1} (using KBr pellets). ^1H NMR spectra were recorded on a JEOL AL300 FT spectrometer at 300 MHz in $CDCl_3$ with TMS as the internal reference. The ^{31}P NMR spectra were recorded at 121.5 MHz with $(CH_3O)_3P$ as the external reference taken as zero position.

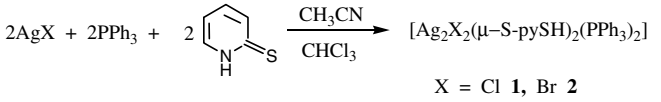
2.2. Synthesis of $[Ag_2(\mu\text{-S-pySH})_2(PPh_3)_2Cl_2]$ (1)

To AgCl (0.025 g, 0.17 mmol) suspended in 20 mL of acetonitrile was added solid PPh_3 (0.045 g, 0.17 mmol) and stirring was carried out for 24 h. Acetonitrile was removed from the white colored precipitates and chloroform (15 mL) was added. To these precipitates suspended in chloroform, solid pyridine-2-thione (0.019 g, 0.17 mmol) was added, and the contents stirred for 1 h until clear solution was obtained. Slow evaporation of the solution at room temperature formed a solid mass which was crystallized from methanol–dichloromethane mixture (20 mL, 1:3 v/v). The yellow colored crystals were formed. Yield: 60%; m.p. 155–57 °C. *Anal.* Calc. for $AgClC_{23}H_{20}NSP$: C, 53.43; H, 3.87; N, 2.71. Found: C, 53.78; H, 3.70; N, 3.01%. Main IR peaks (KBr, cm^{-1}), υ(N–H), 3178(m); υ(C–H), 3035–2920(m); υ(C=N) + υ(C–C); 1608(m)–1571(s); δ(N–H) + δ(C–H), 1500(s)–1363(s); υ(C=S), 1130(s); υ(P–C_{Ph}) 1093(m). ^1H NMR (δ, $CDCl_3$), δ = 7.81(d, H^6), 7.26–7.63m (Ph_3P + $C^{3,4}H$); 6.89(t, H^5). ^{31}P NMR ($CDCl_3$), δ = −98.4 ppm, $\Delta\delta(\delta_{complex} - \delta_{PPh_3})$ = 14.8 ppm. δP, –78.63, $\Delta\delta$ = 34.80 ppm.

2.3. Synthesis of $[Ag_2(\mu\text{-S-pySH})_2(PPh_3)_2Br_2]$ (2)

To AgBr (0.025 g, 0.13 mmol) suspended in 20 mL of acetonitrile was added solid PPh_3 (0.070 g, 0.26 mmol) and stirring was carried out for 24 h. Acetonitrile was removed from the white colored precipitates and chloroform (15 mL) was added. To the precipitates suspended in $CHCl_3$ solid pyridine-2-thione (0.019 g, 0.17 mmol) was added and the contents were stirred for 1 h until a clear solution was obtained. Slow evaporation of solution at room temperature formed a solid mass which was treated with diethyl ether to remove any unreacted PPh_3 and then crystallized from methanol–dichloromethane mixture (25:75:v/v). The yellow colored crystals were formed. Yield: 65%; m.p. 190–195 °C. *Anal.* Calc. for $AgBrC_{23}H_{20}NSP$: C, 49.22; H, 3.55; N, 2.49. Found: C, 49.50; H, 3.91; N, 2.49%. Main IR peaks (KBr, cm^{-1}); ν(N–H), 3170(m); υ(C–H) 3058(m)–3035(m); ν(C=N) + υ(C=C); 1608(m)–1569(s); δ(N–H) + δ(C–H) 1498(s)–1361(s); ν(C=N), 1608(w); ν(C=S), 1128(s); ν(P–C_{Ph}), 1093(m). ^1H NMR data (δ, $CDCl_3$): 7.78 (d, H^6); 7.67 (m, H^4); 7.57(d, H^3); 6.91(t, H^5); 7.32–7.53 (PPh_3). ^{31}P NMR ($CDCl_3$), δ = − 100.6, $\Delta\delta(\delta_{complex} - \delta_{PPh_3})$ = 12.6 ppm. δP, −78.29, $\Delta\delta$ = 34.86 ppm.

2.4. Crystallography



Single crystals of compounds **1** and **2** were mounted on CCD area detector diffractometer, equipped with a graphite monochromator and Mo Kα radiator (λ = 0.71073 Å). The unit cell dimensions and intensity data were measured at 93(2) K. The structures were solved by the direct methods, and refined by the full matrix least square based on F^2 with anisotropic thermal parameters for the non-hydrogen atoms using Bruker SMART (data collection and cell refinement), Bruker SAINT (data reduction) SHELXS-97 (structure solution), and SHELXL-97 (structure refinement) and Bruker SHELXTL (molecular graphics) [13–16]. A multi-scan absorption correction (SADABS) was applied.

3. Results and discussion

3.1. Synthesis and IR spectroscopy

Reaction of silver(I) chloride with PPh_3 in acetonitirile and then with pyridine-2-thione chloroform (1:1:1 molar ratio) yielded compound of stoichiometry, {AgCl(pySH)(PPh_3)} and similar reaction with silver(I) bromide yielded, {AgBr(pySH)(PPh_3)}. The X-ray crystallography has shown both compounds to be dimers, $[Ag_2Cl_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ **1** and $[Ag_2Br_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ **2** (Scheme 1).

Complexes showed ν(N–H) peaks at 3178 cm^{-1} in **1** and at 3170 cm^{-1} in **2**, and it revealed that there is no deprotonation of NH proton of pySH ligand. The diagnostic

Scheme 1.

ν(C=S) peak in free pySH ligand occurs at 1138 cm^{-1} [12], which is shifted to lower energy region in complexes, at 1130 cm^{-1} **1** and 1128 cm^{-1} **2**. These trends in ν(C=S) and ν(N–H) peaks suggest coordination by thione sulfur donor atom. The ν(C–H) peaks fall in the regions 3055–2920 cm^{-1}; while other peaks due to ν(C–C) + ν(C=N) + δ(N–H) + δ(C–H) fall in the region, 1332–1608 cm^{-1}. A characteristic peak due to $\nu(P–C_{Ph})$ at 1093 cm^{-1} indicated the presence of PPh_3 in the complexes.

3.2. Crystal structures of the complexes

Compounds $[Ag_2(\mu\text{-S-pySH})_2Cl_2(PPh_3)_2]$ **1** and $[Ag_2(\mu\text{-S-pySH})_2Br_2(PPh_3)_2]$ **2** crystallized as triclinic crystals in space group $P\bar{1}$. The atomic numbering schemes of complexes **1** and **2** are shown in Figs. 1 and 2, respectively. Crystal data are given in Table 1 and bond lengths and angles are given in Table 2.

In complex **1**, Ag is bonded to one Cl atom, one P atom of Ph_3P and one S atom of pySH forming three coordinate unit, {AgCl(Ph_3P)(pySH)}, and two such units dimerize via the bonded S atoms to yield sulfur-bridged dimer $[Ag_2Cl_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ **(1)** (Fig. 1). The formation of $[Ag_2Br_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ **(2)** (Fig. 2) is similar with Br as the anion. The central Ag_2S_2 core forms a parallelogram with two unequal Ag–S bond distances (2.5832(8), 2.7208(11) Å) in **1** and (2.6306(4), 2.6950(7) Å) in **2**, respectively. These bridging Ag–S bond distances are in the range of terminal Ag–S bond distance, 2.625 Å in [AgCl(pySH)(PPh_3)$_2$] [9a]. The S–Ag–S and Ag–S–Ag bond angles within the {Ag(μ-S)$_2$Ag} core of **1** are 87.190(15)° and, 92.810(15)° **1**, respectively. The similar angles are 87.814(18)° and 92.187(18)° in **2**. The angles around Ag vary in the range 87.19(2)–121.71(2)° in **1**, and 87.81(2)–121.53(2)° in **2**, which indicate highly distorted tetrahedral geometries. Finally the Ag–S–C bond angles are 105.10(6)°,

2			
Ag–P	2.441(1)	Ag–Br	2.631(1)
Ag–S	2.608(1)	Ag–S$^{\#1}$	2.695(1)
S–C(1)	1.717(2)	Ag···Ag	3.8211(4)
P–Ag–Br	121.53(2)	P–Ag–S	121.16(2)
S–Ag–Br	109.47(2)	P–Ag–S$^{\#1}$	102.44(2)
Br–Ag–S$^{\#1}$	106.98(1)	Ag–S–Ag	92.19(2)
Ag–S–C(1)	103.79(8)	S–Ag–S$^{\#1}$	87.81(2)
Ag$^{\#1}$–S–C(1)	111.62(1)		

109.93(6)° in **1** and 103.79(8)°, 111.62(1)° in **2** and are similar to that reported for $[Ag(pySH)(PPh_3)_2Cl]$ [9a].

The Ag–Cl bond is strong as the bond distance in complex **1**, 2.530(1) Å is less than the sum of the ionic radii of Ag^+ and Cl^-, 2.7501 Å [17]. The Ag–Br bond distance in complex **2**, 2.631(1) Å, is shorter than the Ag–Br bridging bond distance [2.7350(6), 2.8241(5) Å] observed in $[Ag_2Br_2(\mu\text{-S-pymSH})_2(PPh_3)_2]$ [10a]. The S–C bond distance 1.722(2) Å in **1** is slightly larger than 1.717(2) Å in complex **2**. This is due to high electronegativity of Cl^- versus Br^- which weakens C–S bond in the former. The Ag–P bond distances are, 2.4346(10) Å in **1** and 2.4414(6) Å in **2**, which are nearly same. The Ag···Ag contacts of compounds **1** and **2** of 3.8425(8) and 3.8211(4) Å, respectively, are higher than twice the sum of van der Waals radius of Ag atom, 3.40 Å.

There are inter dimer π–π stacking interactions between pyridyl rings. The inter ring distances are 3.498 and 3.510 Å in complexes **1** and **2**, respectively. Packing diagrams are shown in Figs. 3 and 4.

3.3. NMR spectroscopy

Proton NMR spectra of sparingly soluble complexes, $[AgCl(pySH)(PPh_3)]_2$ **1** and $[AgBr(pySH)(PPh_3)]_2$ **2**, in $CDCl_3$ has been recorded. Complexes **1** and **2** show peaks due to H^6 proton at low field, δ 7.81 and 7.78 ppm, respectively, vis-à-vis the free ligand (pySH) at δ 7.56 ppm [12]. Likewise, H^5 proton signals at δ 6.89 (**1**) and 6.91 (**2**) ppm are downfield (free pySH, δ 6.73 ppm). The H^3 and H^4 proton signals for **1** merged with the PPh_3 signals in the region, δ 7.26–7.63 ppm; while in complex **2**, these signals were clearly visible (see Section 2). The ^{31}P NMR spectra showed two peaks for each complex with coordination shifts, 14.8, 34.80 ppm (**1**) and 12.6, 34.86 (**2**) ppm. These data reveal that dimers (δ 34.80, 34.86 ppm **1** and **2**) probably set an equilibrium with monomers (14.8, 12.6 ppm,**1a**, **2a**, respectively) in solution. The monomers are suggested as $AgX(pySH)(PPh_3)_2$ (X = Cl, **1a**; Br, **2a**) formed by rearrangement of dimers in solution, a phenomenon observed in copper(I) halide-thiosemicarbazone chemistry [18].

3.4. Electronic absorption spectroscopy

The electronic absorption spectrum of complex **1** in dichloromethane showed three peaks at λ_{max} values of 238, 270 and 359 nm. Similarly complex **2** has shown two peaks at λ_{max} values of 239, 271 and 359 nm. The peaks

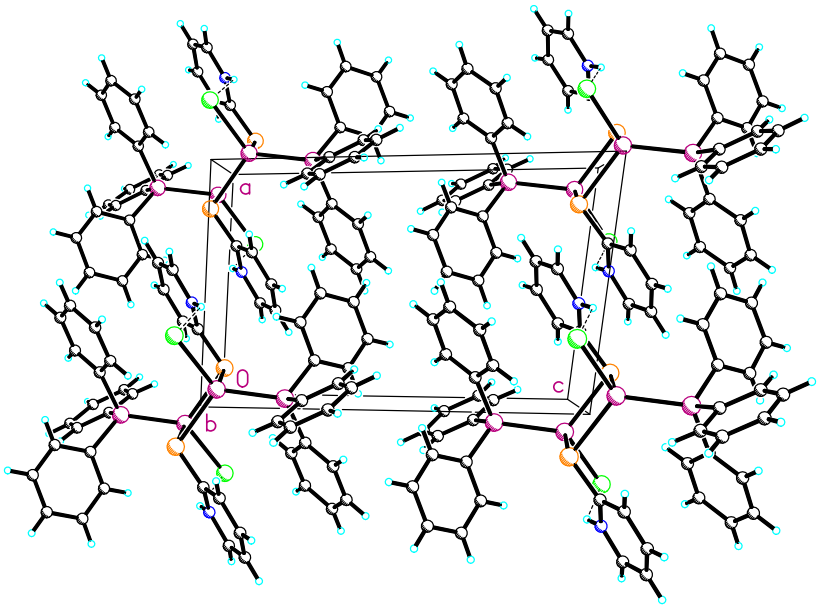

Fig. 3. Packing diagram of complex **1**.

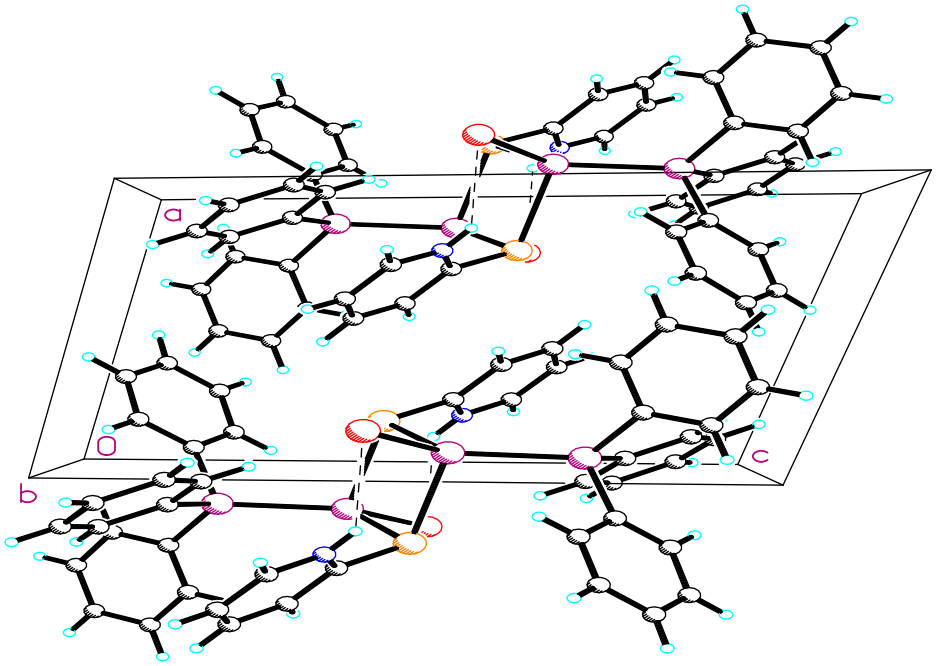

Fig. 4. Packing diagram of complex **2**.

at 359 nm are attributed to –C═S groups due to n → π* transitions while other beaks are due to π → π* transitions based on pyridyl and phenyl rings. Neither of the two compounds exhibited any fluorescence properties.

3.5. Conclusion

Pyridine-2-thione has formed hitherto unknown dimers **1** and **2**. It may be noted that AgCl has formed both previously known monomer, $[Ag(pySH)(PPh_3)_2Cl]$ [9a], and the newly formed dimer $[Ag_2Cl_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ **1**; while for copper(I) chloride only monomer, $[CuCl(pySH)(PPh_3)_2]$ is known to date as all efforts to get a dimer $[Cu_2Cl_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ ended in the formation of only monomer $[CuCl(pySH)(PPh_3)_2]$ due to strong intramolecular –NH···Cl hydrogen bonding in the latter [12].

stackings responsible for the extended networks are also discussed.

2. Experimental

2.1. Materials and measurements

All reagents were purchased from commercial sources and used as supplied. The elemental analyses (C, H and N) were performed on a Vario EL Elemental Analyser. IR spectra were recorded on a MATTSON 1000 FT/IR spectrophotometer as KBr pellets in the frequency range 4000–400 cm^{-1}. ESR spectra were run on a Varian E-109C model X Band EPR spectrophotometer. Room temperature magnetic susceptibility measurements were carried out using a Sherwood Scientific MXI model Evans magnetic balance. Thermal analysis curves (TG and DTA) were obtained from a Rigaku TG8110 thermal analyzer in a static air atmosphere using a sample size of 5–10 mg.

2.2. Synthesis of the copper(II) complexes

Complexes **1** and **2** were prepared using the same synthesis procedure. Ten millilitres of methanol solution of saccharin (2 mmol, 0.37 g) was mixed with a warm methanol solution of $Cu(OAc)_2 \cdot H_2O$ (1 mmol, 0.20 g) with stirring. To the solution, 2 mmol (0.17 g) ppz or 2 mmol (0.26 g) aeppz dissolved in 10 ml methanol was added drop-wise and the reaction mixtures were stirred for 1 h at room temperature. The resulting solutions were allowed to stand at room temperature and X-ray quality green prisms of **1** and **2** were formed after a day.

$[Cu(sac)_2(ppz)(H_2O)]_n$ (**1**): Yield 70%. *Anal.* Calc. for $C_{18}H_{20}N_4O_7S_2Cu$ (%) C, 40.64; H, 3.79; N, 10.53. Found C, 40.67; H, 3.65; N, 10.63%. (Solid KBr pellet): ν (cm^{-1}) 3417sb, 3342s, 3276m, 3053w, 2927w, 1656vs, 1572vs, 1456m, 1336m, 1288vs, 1153vs, 1103sh, 1034s, 958vs, 748s, 677s, 604s, 521m, 453m.

$[Cu(sac)_2(aeppz)_2]$ (**2**): Yield 90%. *Anal.* Calc. for $C_{26}H_{38}N_8O_6S_2Cu$ (%) C, 40.50; H, 5.58; N, 16.33. Found C, 40.59; H, 5.46; N, 16.44%. 2.3. X-ray crystallography

Intensity data for the title complexes were collected using a Stoe-IPDS-2 diffractometer equipped with a graphite monochromated (Mo Kα radiation, $\lambda = 0.71073$ Å) at 293 K. The structure was solved by direct methods using SHELXS-97 [7] and refined by a full-matrix least-squares procedure using the program SHELXL-97 [7]. The value of R_{int} for the structure of **2** is slightly high due to the crystal quality. All non-hydrogen atoms were easily found from the difference Fourier map and refined anisotropically. All carbon and amine hydrogen atoms were included using a riding model, while the water H atoms were refined freely. Details of crystal data, data collection, structure solution and refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

The new complexes were prepared by the direct reaction of the ppz or aeppz ligands with a mixture of copper(II) acetate and saccharin in solution. Both complexes were obtained in high yields (over 70%) and the analytical data are consistent with the proposed formulation of the complexes, and also confirmed by X-ray crystallography as reported in this paper. All the complexes are non-hygroscopic and stable in air, and soluble in water, methanol and ethanol.

The FT-IR spectra of all the complexes were recorded in the frequency range 4000–400 cm^{-1}. In the IR spectra of **1**, the strong and broad absorption band centered at around 3417 cm^{-1} are attributed to the ν(OH) vibrations of the aqua ligand. The bands at 3342 and 3276 cm^{-1} are assigned to the ν(NH) vibrations of the ppz ligand. The corresponding vibrations were observed at 3300 and 3245 cm^{-1} for **2**. The weak bands in the range 3115–2835 cm^{-1} are due to the aromatic and aliphatic ν(CH) vibrations. The bands for the carbonyl group of sac appear at *ca.* 1655 and 1620 cm^{-1}, respectively. The carbonyl bands at around 1650 cm^{-1} usually correspond to the monodentate coordination of sac through the deprotonated N-atom [8]. In the

Table 1

Index range (h,k,l)	−8/9, −14/14, −17/17	−9/10, −12/12, −14/14
Reflections collected	15685	12245
Data/parameters	4322/297	3383/188
Goodness-of-fit on F^2	1.047	1.005
R_1 [$I > 2\sigma$]	0.0284	0.0419
wR_2	0.0755	0.1050

case of the coordination *via* the carbonyl group, a significant shift to lower frequencies occurs due to a weakening of the carbon–oxygen bond. Therefore, the sharp bands at 1655 and 1620 cm^{-1} for complexes **1** and **2**, respectively, clearly indicate that the sac is N-bonded in **1**, but O-bonded in **2**. The stretching vibrations of $\nu_{asym.}(SO_2)$ and $\nu_{sym.}(SO_2)$ were observed as very strong bands at *ca.*1285 and 1155 cm^{-1}, respectively.

The electronic spectra of methanol solutions of **1** and **2** display broad absorption bands at 632 ($\varepsilon = 54$ dm^3 mol^{-1} cm^{-1}) and 623 nm ($\varepsilon = 53$ dm^3 mol^{-1} cm^{-1}), respectively, which are assigned to d–d transitions. The strong absorption bands below 300 nm are due to intra-ligand transitions of ppz, aeppz and sac ligands.

The powder ESR spectra of complexes **1** and **2** were measured at the room temperature. Both complexes display intense spectra with no hyperfine structure. Complex **1** exhibits a broad signal with three g values ($g_z = 2.244$, $g_x = 2.139$ and $g_y = 2.008$). The R factor for complex **1** [defined as $R = (g_x - g_y)/(g_z - g_y)$], is 1.24, which suggests that the 3d unpaired electron of the copper(II) ion occupied the d_{z^2} orbital [9,10]. The ESR spectrum of complex **2** shows a sharp signal with a g value of 2.162. Compared to that of the free electron value ($g = 2.0023$), it can be concluded that in both complexes, the interactions between copper(II) centers in the solid state are negligible.

The room temperature magnetic moments are 1.76 and 1.74 B.M. for complexes **1** and **2**, respectively, and consistent with the calculated value (1.73 B.M.) of the spin-only magnetic moment of the d^9 configuration. As well as ESR spectra, magnetic susceptibility measurements also indicate that the polymeric complex **1** does not exhibit any anti-ferromagnetic interaction at the room temperature.

3.2. Description of the crystal structures

Complex **1** is a 1D helical coordination polymer and the ORTEP view of the building unit with atom labeling is shown in Fig. 1. Selected bond lengths and angles are listed in Table 2. The copper(II) ion is coordinated to an aqua O atom, two imine nitrogen atoms from two sac ions and two N atoms of two symmetry related ppz ligands. The coordination geometry around the Cu^{II} center is described as a trigonal-bipyramidal generated by N1–N2–N3–N4–OW1 atoms with τ value of 0. 61, which is used to describe the degree of distortion for penta-coordinated complexes ($\tau = 0$ for an ideal square-pyramid and $\tau = 1$ for an ideal trigonal-bipyramid) [11]. The sac anions are N-coordinated and their nitrogen atoms act as the axis of trigonal-bipyramid with the mean Cu–N distance of 2.057(2) Å. Two N atoms from two ppz rings together with an aqua O atom are composed of the basal plane and the copper(II) ion is deviated from this coordination plane by 0.068(1) Å. The ppz rings are in normal chair conformation with the puckering parameters $q = 0.550(2)$–$0.561(2)$ Å and $\theta = 0.00(1)$–$3.06(1)°$, and the ring torsion angles lying in the range of 54.1–56.2°. On the other hand, the sac ring system is essentially planar and the dihedral angles between the adjacent sac rings is 14.64(5)°.

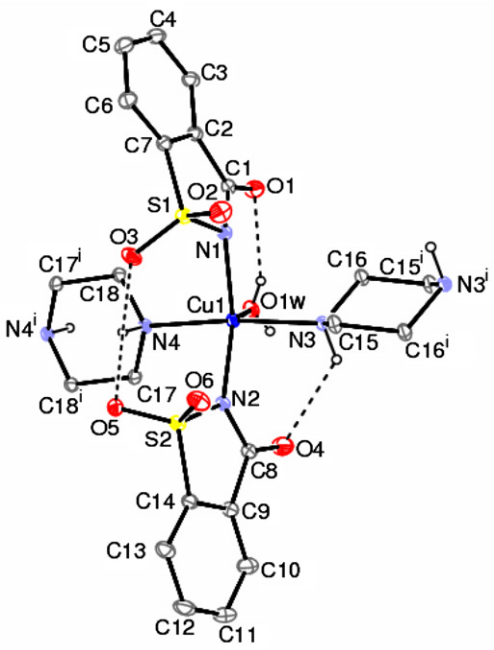

Fig. 1. The building block unit and coordination environment of Cu^{II} in **1** with the atom labeling scheme. CH hydrogen atoms are omitted for clarity. The intramolecular hydrogen bonds are indicated by dashed lines. Symmetry code (i) = $-x + 2$, $-y + 1$, $-z + 1$.

N3–Cu1–O1	92.22(6)	N3–Cu1–$O1^i$	87.78(6)

Symmetry operations: (i) $-x$, $-y + 1$, $-z$.

The copper(II) centers are bridged by both nitrogen atoms of ppz ligands leading to a 1D helical chain (Fig. 2). The closest Cu–Cu^i contact is only 6.915 Å (i = $-x + 2$, $-y + 1$, $-z + 1$). Analysis of the crystal packing of complex **1** in the unit cell shows that there exist multiple intra- and intermolecular hydrogen-bonding interactions as listed in Table 3. The individual chains running parallel to the crystallographic axis c are connected by OW–H···O hydrogen bonds into 2D layers running in the

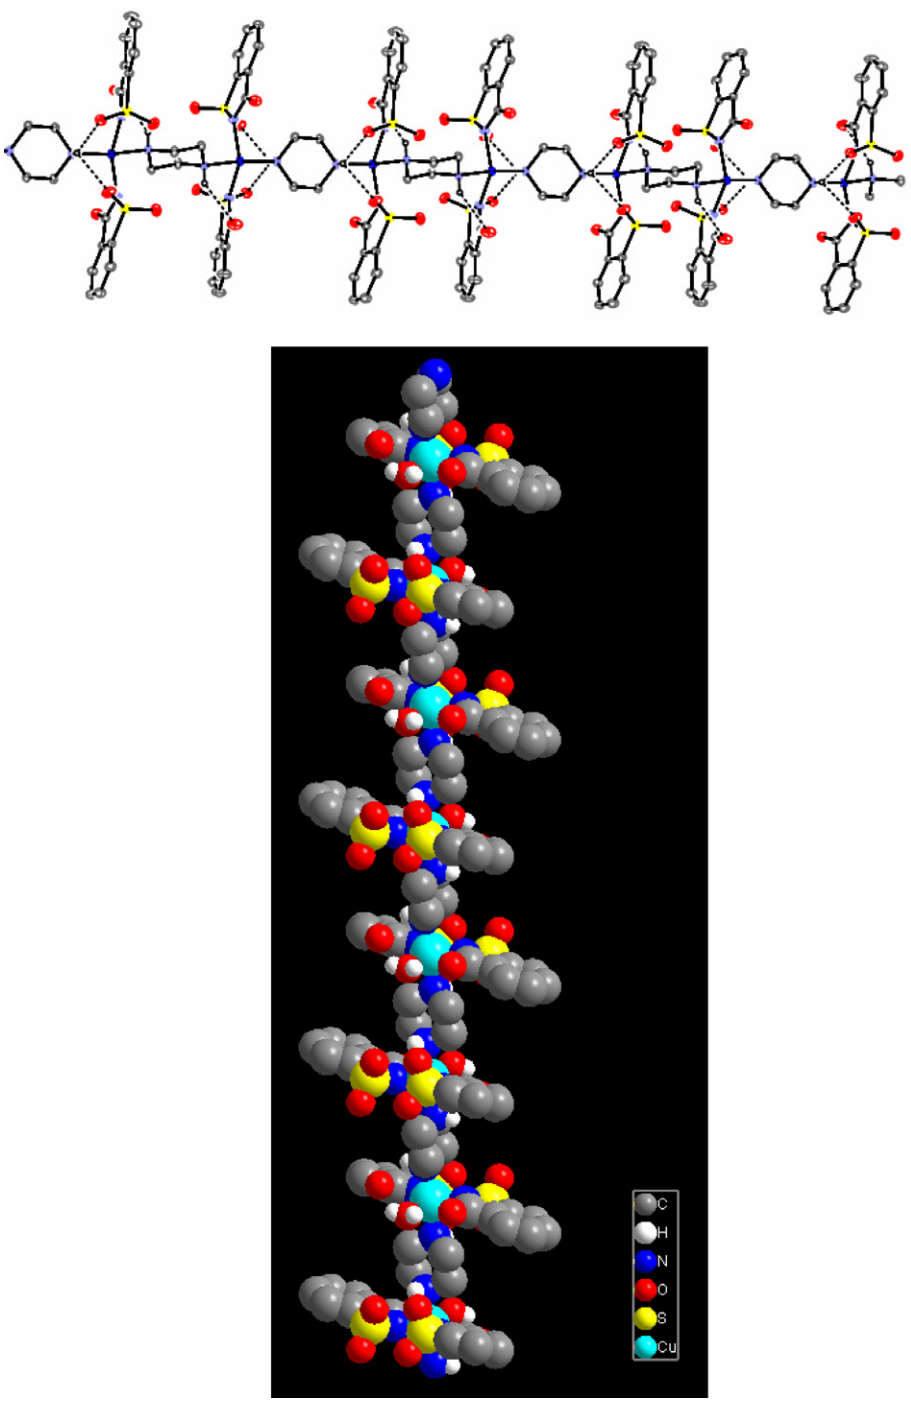

Fig. 2. ORTEP and space-filling views of a fragment of a one-dimensional helical chain in **1**.

ab plane and these layers are further associated by weak π(sac)–π(sac) stacking interactions with the Cg–Cg^{i} separation of 3.923(2) Å (i = $-x$, $-y$, $-z$) to give a 3D network as shown in Fig. 3.

The molecular view of complex **2** is illustrated in Fig. 4. The selected bond lengths and angles are given in Table 2. The crystal structure of **2** consists of isolated centrosymmetric $[Cu(sac)_2(aeppz)_2]$ molecules, in which the Cu^{II} ion lies on a center of inversion and displays a distorted octahedral coordination geometry with two aeppz and two sac ligands at the *trans* positions. In contrast to complex **1**, the sac ion in **2** coordinates to Cu^{II} through to carbonyl O atom, while aeppz acts as an *N*,*N*′-bidentate chelating ligand, creating a five-membered ring around Cu^{II}.

Complex **2** is isostructural with the cobalt(II), nickel(II), zinc(II) and cadmium(II) complexes of sac containing aeppz ligands [12–14]. All complexes show similar structural characteristics and the most interesting feature in these metal complexes is the elongation of the octahedral geometry even in the case of Ni^{II}, Zn^{II} and Cd^{II}. The elon-

Table 3

O1W–H1W···O5^{i}	0.78(4)	2.06(4)	2.839(3)	172(3)
Complex ***2***				
N2–H2A···N1	0.90	2.25	2.955(3)	135
N2–H2B···N4^{ii}	0.90	2.38	3.189(3)	150
N4–H4A···O3^{iii}	0.82(4)	2.27(4)	3.083(4)	169(3)

Symmetry operations: (i) $x+1$, y, z; (ii) $x-1$, y, z; (iii) $-x+1$, $-y+2$, $-z$.

gation occurs along the M–$N_{ppz\ ring}$ bonds and is possibly due to a poor overlap between the orbitals of the metal ions and the sp^3 lone pair of the $N_{ppz\ ring}$ atom. In the series of the isostructural cobalt(II), nickel(II), copper(II) and zinc(II)-sac complexes of aeppz, the elongation is the most pronounced in the case of copper(II) with a Cu–N3 bond distance of 2.469(2) Å. This is clearly as a result of the additional effect of the Jahn–Teller distortion.

Another interesting feature of complex **2** is the O-coordination of the sac ligands *via* the carbonyl oxygen atom, since sac commonly exhibits the N-coordination mode and the O-coordination is rare. In complex **2**, both sac ligands are O-coordinated and it appears that the steric hindrance of the aminoethyl group impedes the coordination of sac through the negatively charged N atom. The Cu–O_{sac} bond distance of 2.103(2) Å is slightly longer than those found in [Cu(dipyr)(sac)$_2$(H_2O)] [15], [Cu(sac)$_2$(py)$_3$] [16], [Cu(pypr)$_2$(sac)$_2$] [17] and ApyH[Cu(sac)$_3$(H_2O)$_2$] [18], where dipyr, py, pypr and ApyH are dipyridylamine, pyridine, 2-pyridinepropanol and 2–aminopyridinium, respectively. Again, as in complex **1**, the sac ring system in **2** is essentially planar. The puckering parameters of the ppz ring system in **2** are $q = 0.535(2)$ Å and $\theta = 174.18(12)°$, and the torsion angles are in the range 52.1–58.2°, suggesting that the ppz rings exhibit an essentially cyclohexane-like chair conformation.

The molecules of **2** in the unit cell are doubly bridged by N–H···N and N–H···O hydrogen bonds, forming a hydrogen bonded chain running along the *a* axis (Fig. 5). These hydrogen bonded chains are extended to a 2D layer by π(sac)–π(sac) stacking interactions with the *Cg*–*Cg*^{i} separation of 3.886(1) Å (i = 2 − *x*, 1 − *y*, 1 − *z*).

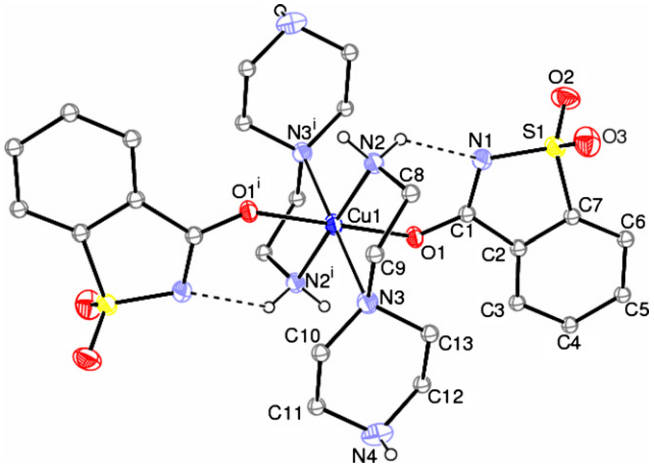

Fig. 4. The molecular structure of **2** with the atom labeling scheme. CH hydrogen atoms are omitted for clarity. The intramolecular hydrogen bonds are indicated by dashed lines. Symmetry code (i) = − *x*, −*y* + 1, −*z*.

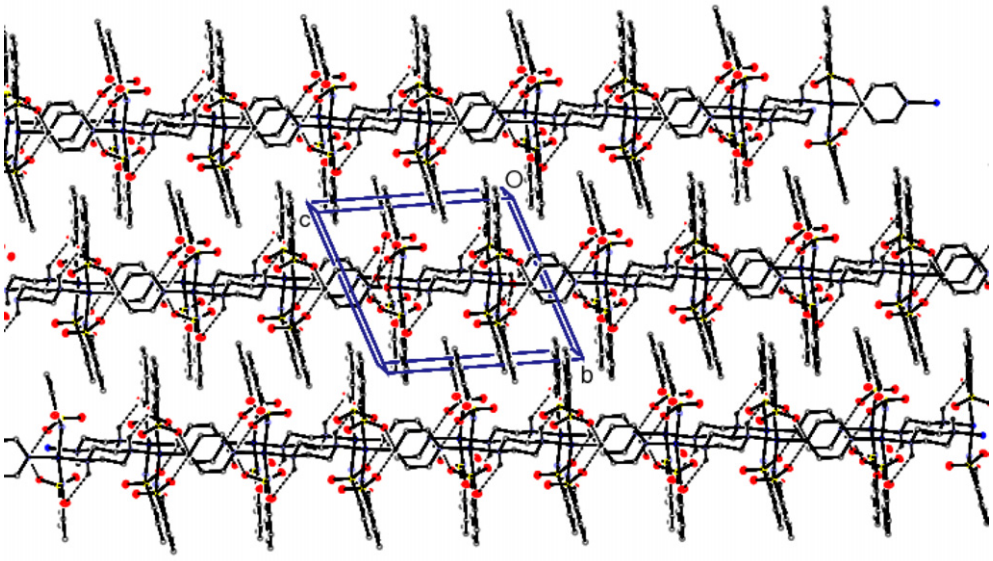

Fig. 3. Packing of 1D chains into 3D network in **1** viewed down the *a* axis, showing aromatic π···π stacking interactions between sac ligands.

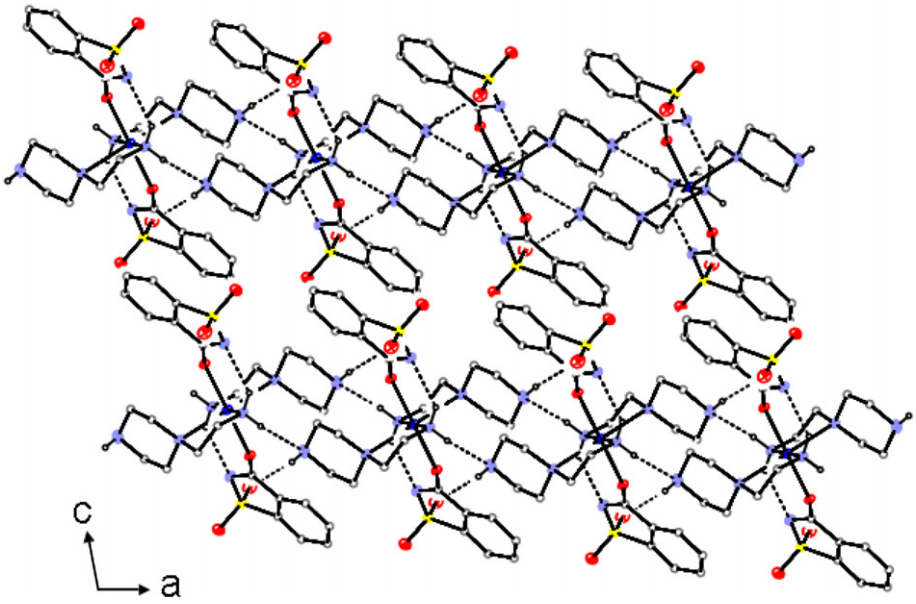

Fig. 5. Packing of hydrogen bonded chains of **2**, viewed down the *b* axis.

3.3. Thermal analysis

Thermal behavior of the complexes was studied by DTA and TG in the temperature range 20–800 °C in the static atmosphere of air. Complex **1** dehydrates between 35 and 103 °C with a mass loss of 3.6% (calc. 3.4%). The elimination of the ppz ligand takes place in the temperature range 162–259 °C, accompanied by a mass loss of 16.0% (calc. 16.2%). The decomposition of the sac moiety occurs between 270 and 474 °C with two extremely exothermic DTA peaks at 401 and 509 °C to give an end product CuO.

Complex **2** is thermally stable up to 143 °C and then begins to decompose. The TGA curve shows that complex **2** exhibits a continuous mass in the temperature range 143–540 °C and therefore, it is difficult to calculate mass loss values. However, the endothermic DTA peaks at 153, 226 and 247 °C correspond to removal of two aeppz molecules, while the highly exothermic peak at 489 °C is characteristic for the degradation of the sac anion [19]. The decomposition ends at 540 °C to give a decomposition product CuO. The total experimental mass loss of 89.0% agrees well with the calculated value of 90.7%.

Acknowledgements

We thank Dr. O. Z. Yesilel and Dr. B. Karabulut for their assistance in obtaining DTA-TG curves and ESR spectra, respectively.

Appendix A. Supplementary material

CCDC 670731 and 670732 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.01.009.

butyl-hydroperoxide (*t*-BuOOH in dacane, 78%), were purchased from Aldrich Chemical Co. and were used without further purification. HPLC grade acetonitrile obtained from Qualigens Chemicals (Glaxo, India); extra pure dichloromethane (99%) obtained from Merck. All sodium and potassium phosphates (anhydrous) were obtained from Pfizer Chemicals (India) and were further dehydrated by heating at 200 °C under vacuum 6 h and were stored under argon.

Dichloromethane and acetonitrile were dried over $CaCl_2$ and were freshly distilled from P_4O_{10}. Acetonitrile was further distilled, once more from 1:1 mixture of $KMnO_4$ and $LiCO_3$. Cyclohexene was purified by passing through silica gel (120 mesh) column until it was nearly 100% pure (as analyzed by GC) prior to use.

Iron(III) [tetrakis(pentafluorophenyl)] porphyrin triflate was synthesized by stirring silver triflate (9 mg) and iron(III) [tetrakis(pentafluorophenyl)] porphyrin chloride (7 mg) in acetonitrile (CD_3CN, 1.5 mL) for several days. A change from chloride to triflate coordination was evidenced from the expected shift in the β-pyrrole ^1H NMR resonance from 80 to 58 ppm.

2.2. Experimental setup

Each reaction was conducted in 4.0 mL vial fitted with silicone septa. A flow meter (with an outlet) was connected with a 5 mm polyethylene tube with an oxygen cylinder. A sensitive stopper and a needle (0.16 mm, o.d.) were attached between the flow meter and the cylinder. The outlet is first closed with silicone septa and then pierced with the same sized needle to ensure a laminar flow and a pressure of 1 atm of oxygen. To maintain constant temperature the vial was dipped into a paraffin oil bath with a heating coil connected to a dimmerstat. All the reactions were performed at 32 ± 1 °C unless mentioned otherwise.

A Perkin–Elmer (Auto system XL) gas chromatograph fitted with an Carbo Wax (30 m × 0.32 mm × 0.5 μm) capillary column and an FID detector was used to detect the production of oxidation products. Oxidation products were quantified relative to internal standard (C_6F_5I). The identification and quantitation of the products were done from the response factors of standard samples.

Some reactions are strictly maintained in argon atmosphere where the oxygen was removed from solvents and substrates by bubbling with argon. Reaction mixtures of solvent, internal standard, catalyst and substrate were prepared in air-tight, sealed 5.0 mL reaction vials with septa caps. Oxidant was added to the reaction mixture via a gas-tight microsyringe through the septa cap. Samples for GC analysis were removed via a gas-tight microsyringe to prevent exposure to oxygen.

2.3. Spectroscopic measurements

All the electronic spectra were recorded on a Perkin–Elmer UV–Vis spectrophotometer(Model Lambda 2S) interfaced with a computer using PECSS software. The spectrophotometer cell holder was equipped with the outer water-circulating jacket to maintain constant temperature. Constant temperature of 25 °C was maintained by using a Julabo F-30 circulator. Most of the samples were taken in acetonitrile (1 mL) in a 1 cm path-length long-necked cell with air-tight silicon septa. Some samples containing catalyst in acetonitrile (1 mL) were analyzed in presence of solid anhydrous phosphates (5 mg) after shaking.

The ^1H NMR spectra were obtained using a Bruker DPX-300 (300 MHz) spectrometer in acetonitrile (d_3). (i) The ^1H NMR of β-pyrrole protons of catalyst were done in precision NMR tubes by addition of 6.0 mM iron[tetrakis(pentafluorophenyl)] porphyrin chloride in 0.5 mL acetonitrile (d_3). (ii) The same were recorded for iron[tetrakis(pentafluorophenyl)] porphyrin triflate. (iii) In sample (i) 100 μL of D_2O was added and analyzed. (iv) Forth sample was prepared by stirring iron[tetrakis(pentafluorophenyl)] porphyrin triflate (6 mM) and anhydrous K_2HPO_4 (10 mg) in acetonitrile (1.5 mL) in a vial for 5–6 h. After stirring 0.5 mL of the decanted solution were taken for analysis.

3. Result and discussion

3.1. Role of phosphate

The oxidation of cyclohexene with dioxygen in presence of small quantities of *t*-BuOOH and various phosphate salts has been studied. In a typical reaction a mixture of cyclohexene (3.25 M), *t*-BuOOH (5.5 mM), $F_{20}TPPFeCl$ (9.0 ± 1 μM, $F_{20}TPPH_2$ = *meso*tetrakis(pentafluorophenyl)porphyrin) and solid phosphate salt (25 mg) in acetonitrile (1 mL) was stirred at 32 ± 1 °C for 20 min under 1 atm of dioxygen. The organic products formed were analyzed by GC and the results are given in Table 1. The results support the following conclusions: (i) phosphate salts are assisting the dioxygen activation process, (ii) potassium phosphates

Table 1
$F_{20}TPPFe(III)Cl$ catalyzed oxidation of cyclohexene in presence of various phosphates at 32 ± 1 °C where 2-cyclohexen-1-one (**1**) and 2-cyclohexen −1-ol (**2**) were the major products[a]

Entry no.	Phosphate	Product profile (mM)		Total yield (mM)	TOF (min^{-1})	(**1**)/(**2**) ratio
		(**1**)	(**2**)			
1	K_2HPO_4	52.7	27.6	80.3	446	1.9
2	Na_2HPO_4	26.6	11.3	37.9	210	2.3
3	KH_2PO_4	5.4	2.0	7.4	41	2.7
4	NaH_2PO_4	4.6	1.8	6.4	35	2.5
5	K_3PO_4	51.1	29.0	80.1	445	1.8
6	Na_3PO_4	34.5	14.3	48.9	271	2.4

[a] All the reactions were performed at 32 ± 1 °C for 20 min in acetonitrile (1.0 mL) containing cyclohexene (3.25 M) at 1 atm of oxygen. Average results of duplicate sets of experiments are given. Concentrations of catalyst: 9.0–11μM; *tert*-butyl hydroperoxide: 5.5 mM; and phosphate: 25 mg. In all these reactions the yield of cyclohexe oxide was less than 0.5 mM and are not reported here.

are more efficient than the corresponding sodium phosphates (entry: 1 versus 2, 3 versus 4 and 5 versus 6), (iii) among the potassium phosphate salts the order of efficiency is $K_3PO_4 \approx K_2HPO_4 \gg KH_2PO_4$ (entries 1, 3 and 5). In these experiments it has been noted that the variation in the phosphate particle size has no effect on the reaction yield. The phosphate salts were grind into powder so that it can be stirred well. The results have demonstrated that almost all the phosphates included in this study, especially K_2HPO_4 and K_3PO_4 play significant role in dioxygen activation. Secondly, the presence of small quantities of hydroperoxide initiates the oxygenation more efficiently. Similar role of K_2HPO_4 has also been noted in the oxygenation of cyclohexane and cyclooctene. In the following however we present details of the reactions conducted with K_2HPO_4 only.

3.2. Role of catalyst and t-BuOOH

The above noted reaction was when conducted with two different catalyst concentrations and the reactions were monitored for 1 h, 2-cyclohexen-1-one (**1**) and 2-cyclohexen-1-ol (**2**) were the major products and epoxide formation was always very low (below 0.5 mM). The products were formed linearly till about 20 min, and afterwards catalyst decay was noticed, and the non-linear product formation has also been observed. These results are given in Fig. 1A. These reactions were then conducted in absence of *t*-BuOOH and Fig. 1B clearly demonstrates that the presence of *t*-BuOOH initiates the oxygenation process. In order to realize the role of various reagents, the control experiments were then carried out for only 20 min and the results are given in Table 2. The first data set (entries 1–6, Table 2) clearly indicated that: in absence of catalyst there is no reaction (entry 6), dioxygen activation is definitively there (entries 1 and 5), in absence of the hydroperoxide dioxygen activation is quite appreciable (entries 1 and 2), and its presence makes dioxygen activation more efficient. Notable feature in these two reactions is that the product ratio remains the same (1.9), which is indicative of the probable operation of similar mechanism in presence and in absence of *t*-BuOOH in the oxygenation of cyclohexene. The rest of the data reported in Table 2 (entries 7–16) and their comparative analysis support the conclusion that F_{20}TPPFeCl is the best catalyst among the series used in this study. The data also indicate that the role of phosphate in dioxygen activation is not special for only one catalyst, it seems to be a general phenomenon. In fact similar effect has also been observed in TPP and TMP derivatives too, but we have not reported those data here. It has also been noted that among dichloromethane and acetonitrile the latter one is the solvent of better choice (entries 1 and 4).

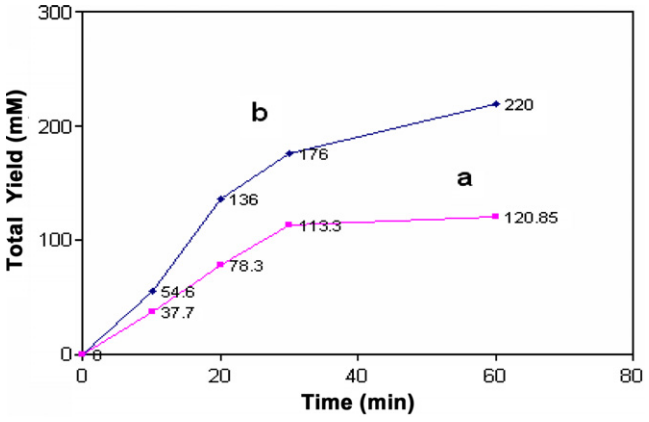

Fig. 1A. Plot of the total yield of cyclohexene oxidation products vs. time, catalyzed by $F_{20}TPPFe^{III}Cl$ in acetonitrile under 1 atm of O_2 at 32 ± 1 °C. Catalyst concentrations were (a) 9 ± 1 μM and (b) 27 ± 1 μM. *tert*-Butyl hydroperoxide: 5.5 mM and phosphate: 25 mg in acetonitrile. Average values of duplicate sets of experiments are used in the plots.

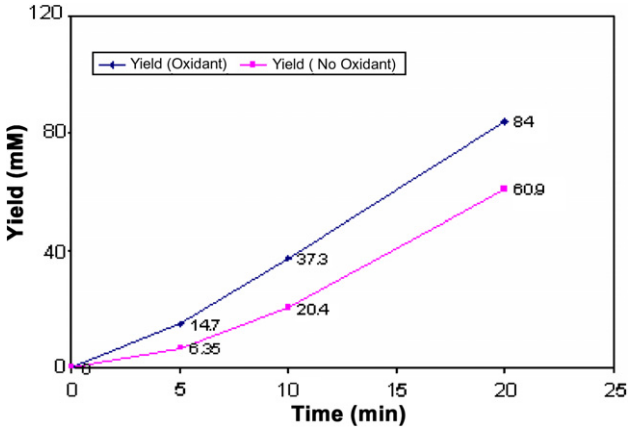

Fig. 1B. Plot of the total yield of cyclohexene oxidation products vs. time, catalyzed by $F_{20}TPPFe^{III}Cl$ in acetonitrile under 1 atm of O_2 at 32 ± 1 °C in presence and absence of oxidant (*t*-BuOOH). Catalyst concentrations being 9 ± 1 μM. *tert*-Butyl hydroperoxide: 5.5 mM and phosphate: 25 mg in acetonitrile.

3.3. Spectral analysis

In presence of only K_2HPO_4 the spectrum of the catalyst was changed continuously till 3.6 h, this is shown in Fig. 2. In presence of K_3PO_4, which is more basic, the spectrum of the catalyst was changed exactly similarly but faster (in 30 min). Such spectral change was not observed in case of KH_2PO_4 up to 4 h. The addition of *t*-BuOOH to a solution of the catalyst already having K_2HPO_4 for 3.6 h evolves another spectrum (Fig. 3). There is also a clear change of the catalyst spectrum in acetonitrile containing excess of cyclohexene (Fig. 4) and this is not the case for either cyclohexane or cyclooctene. This change shown in Fig. 4 has an induction period of 17 min, which shortens to 4 min in presence of K_2HPO_4.

Careful analysis of the spectral changes support that all the four transitions (highest occupied $a_2u(\pi)$ and $a_1u(\pi) \rightarrow$ two degenerate lowest unoccupied $e_g(\pi^*)$) of the catalyst remained intact in all the spectra presented in Figs. 2 and 4, and these bands are only shifted by few

[b] In this reaction medium *t*-BuOOH was absent.
[c] These reactions were conducted in absence of phosphate.
[d] This reaction was conducted in dichloromethane.
[e] This reaction was conducted under argon atmosphere.
[f] This reaction was conducted without any catalyst.

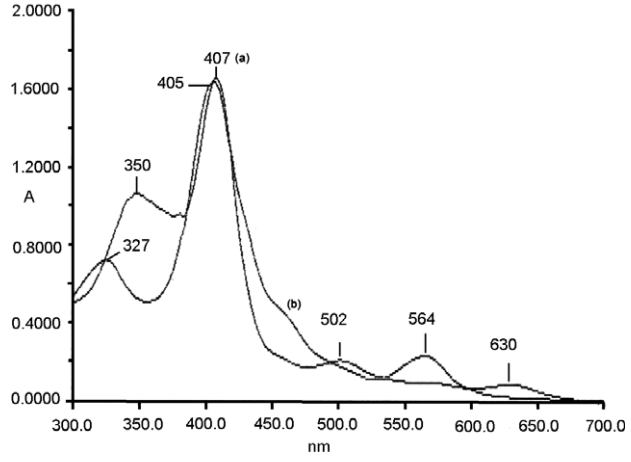

Fig. 2. UV–Vis spectra of (a) $F_{20}TPPFe^{III}Cl$ (16 μM) in acetonitrile and (b) $F_{20}TPPFe^{III}Cl$ (16 μM) in acetonitrile in presence of K_2HPO_4.

nanometers with some changes in the intensities of the transitions only [14]. The most rational proposition for this observation could be the possible exchange of the axial ligand rather than any major change of the spin state of the central metal ion or any modification on the porphyrin periphery during these catalytic reactions. It has been noted that this kind of spectral change is very strongly dependant on the solvent system used. For example the change is very slow in dichloromethane than in acetonitrile.

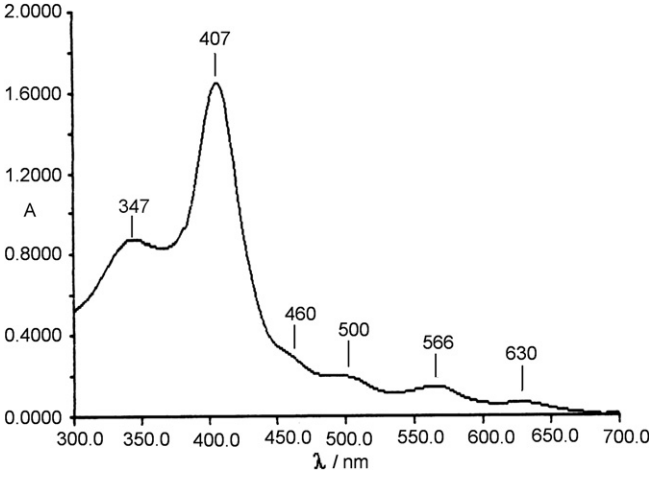

Fig. 3. UV–Vis spectrum of $F_{20}TPPFe^{III}Cl$ (15 μM) on addition of *t*-BuOOH (5.5 mM) to a solution of catalyst solution in acetonitrile containing K_2HPO_4.

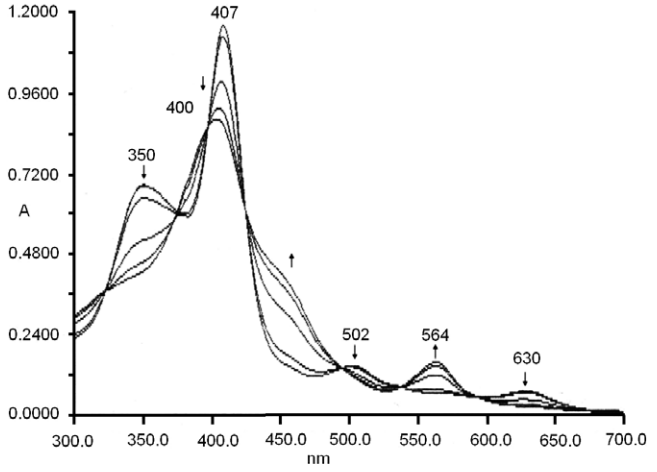

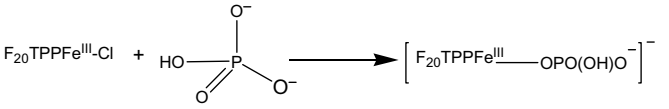

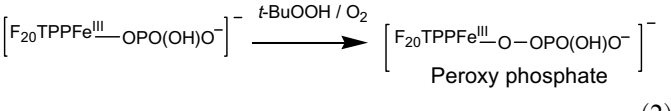

Fig. 4. UV–Vis spectra of $F_{20}TPPFe^{III}Cl$ (9 μM) in acetonitrile in presence of cyclohexene (0.65 M).

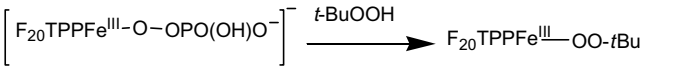

We believe that the change observable in Fig. 2 is due to the exchange of iron(III) bound chloride by HPO_4^{2-} ions (Eq. (1)). Presence of the band at 350 nm in $F_{20}TPPFeCl$ is diagnoistic of the presence of the bound chloride ion to the ferric ion of the catalyst. Addition of phosphate shifts this band to 327 nm. This could be due to the probable displacement of the chloride ligand by the phosphate ion. Among CH_3CN and CH_2Cl_2 the former solvent facilitated this process and this may be owing to the higher polarity and better solubility of the phosphate in CH_3CN.

In an ^{1}H NMR experiment, the catalyst was stirred with silver triflate (trifluoromethanesulfonic acid silver salt, CF_3SO_3Ag) in acetonitrile for several days to remove the chloride ion. The β-pyrrole proton peak of the corresponding catalyst with triflate axial ligand was observed at 58 ppm (Supplementary Figure S1). The β-pyrrole proton peak then shift to 83.03 ppm when the solution was stirred with dry K_2HPO_4 after filtration(Supplementary Figure S2), indicates the phosphate ligation to Fe(III). The salt used is highly anhydrous and ligation through any water molecule may be discarded by the fact that in that case the peak would have shifted to 70 ppm. These results probably indicate the HPO_4^{2-} ion participation in these reactions. Furthermore, the use of KH_2PO_4 and NaH_2PO_4 (Table 1, entries 1–4) decreases the product yields signifying the importance of Eq. (1) and it seems to be expected form the fact that coordination ability of KH_2PO_4 is less than that of K_2HPO_4 and K_3PO_4 and may be due to the dissociation differences. This is again supported by the fact that time taken for the spectral change due to removal of Cl^- ion may be given in order $KH_2PO_4 >> K_2HPO_4 > K_3PO_4$.

The coordinated phosphate must be more electrophilic, so its possible oxidation by *t*-BuOOH/O_2 to give the coordinated peroxy phosphate as represented by Eq. (2) is possible. In presence of excess of *t*-BuOOH with respect to the catalyst the possible replacement (at least partial) of peroxy phosphate by *tert*-butyl hydroperoxide may be anticipated (Eq. (3)) and this could explain the extra peaks (more than four) observed in Fig. 3. We believe that the reaction is going through a radical pathway as indicated by the fact that presence of even 10 mM of 2,4,6-tri-*tertiary*butylphenol ceases the reaction completely.

Here peroxy phosphate probably cleaves homolytically to evolve PFe(IV) = O and the cyclohexene radical (Eq. (4)). The evolution of such oxoiron(IV) species through Eq. (5) cannot also be ignored. Subsequent reaction of oxoiron(IV) and alkoxy radical to evolve the cyclohexene radical (Eq. (6)) will certainly be the next important step for dioxygen activation [6]. This will be followed by the proposed Eqs. (7)–(14). Epoxide is the major product where oxoiron(IV) porphyrin cation radical is the major reactive intermediate [1]. In our system epoxide is not the major product in cyclohexene oxidation, so we do not think heterolytic cleavage of the peroxy phosphate is important here. Slow epoxidation could be possible from the hydroperoxy or peroxy phosphate adduct as has been anticipated recently from the theoretical studies [15]. The homolytic cleavage of peroxy linkage proposed in this study seems to be more appropriate for cyclohexene in particular, because it has the ability to coordinate to iron(III) (Fig. 4).

The above reaction was then tested on cyclohexane and cyclooctene and the results are given in Tables 3 and 4, respectively. In case of cyclohexane oxidation a mixed solvent (acetonitrile:dichloromethane) was used and the reactions were monitored for 2 h. In this reaction cyclohexanol and cyclohexanone were the major products. Secondly in the cyclohexane oxygenation, F_{20}TPPMnCl seems to be the better catalyst than the corresponding iron analogue. The cyclooctene oxidation was carried out in acetonitrile:dichloromethane (2:1) and the reactions were monitored for 4–8 h. It has been established from the independent studies that 2-cyclohexen-1-one and cyclohexanone were not formed from the over oxidation of 2-cyclohexen-1-ol and cyclohexanol, respectively, under our catalytic reaction conditions. The oxygenation reactions of both cyclohexane and cyclooctene were found to be very slow and less efficient with respect to that of cyclohexene. This may be rationalized from the fact that cyclohexene acts as a ligand to Fe(III) center of the catalyst (Fig. 4), which can encourage homolytic cleavage of the peroxyphosphate to

Table 3
Catalytic oxidation of cyclohexane to cyclohexanone (**3**) and cyclohexanol (**4**)[a]

[a] All the reactions were performed at 32 ± 1 °C for 2 h in acetonitrile:dichloromethane (1:1) solvent (0.5 mL), containing cyclohexane (6.5 M), catalyst (16 ± 1 μM for $F_{20}TPPFeCl$ and 11 ± 1 μM for $F_{20}TPPMnCl$), *tert*-butyl hydroperoxide (5.5 mM) and K_2HPO_4 (25 mg) in 1 atm of oxygen. Average values of duplicate sets of experiments are given in the table.
[b] No oxidant (*t*-BuOOH) used.
[c] Argon atmosphere, but in presence of 5.5 mM of *t*-BuOOH.
[d] No phosphate.

Table 4
Catalytic oxidation of cyclooctene to cyclooctene oxide[a]

Entry no.	Catalyst (μM)	Product profile (mM) cyclooctene oxide	TOF (min^{-1})
1	$F_{20}TPPFe^{III}Cl$	12	5.5
2[b]	$F_{20}TPPFe^{III}Cl$	28	6.5
3[c]	$F_{20}TPPFe^{III}Cl$		
4[d]	$F_{20}TPPFe^{III}Cl$	1.4	0.6
5	$F_{20}TPPMn^{III}Cl$	8.0	3.7
6[d]	$F_{20}TPPMn^{III}Cl$	0.06	

[a] All the reactions were performed at 32 ± 1 °C for 4 h in acetonitrile:dichloromethane (2:1) solvent (0.5 mL), containing cyclooctene (4.5 M), catalyst (30 ± 2 μM for $F_{20}TPPFeCl$ and 09 ± 1 μM for $F_{20}TPPMnCl$), *tert*-butyl hydroperoxide (5.5 mM) and K_2HPO_4 (25 mg) in 1atmosphere of oxygen. Average values of duplicate sets of experiments are given in the table.
[b] Reaction was performed for 8 h.
[c] No oxidant (*t*-BuOOH) used.
[d] No phosphate.

oxoiron(IV) species, secondly low dissociation of the co-catalyst used for cyclohexane and cyclooctene reaction medium could be the reason for such low yield. It has also been noted that absence of *t*-BuOOH in the oxidation reaction of cyclohexane no product was formed. Thus it is clear from the fact that R· radical formation from R–H is very important for this radical reaction to occur (Eq. (4)). Since cyclohexene radical is stable enough due to conjugation, formation R· radical is easier even in absence of hydroperoxide in such reaction condition which is not possible in case of cyclohexane. Absence of hydroperoxide in cyclohexene thus slows down the product yield (Table 2, entry 2[b]; Fig. 1B) and results no product formation in the oxidation of cyclohexane. Thus simultaneous presence of small *t*-BuOOH is required along with K_2HPO_4 for the oxidation of cyclohexane. In this oxidation possibly the formation of *t*-BuOOH adduct with iron(III) (Eq. (3)) is most important.

We have also observed that presence of even 10 μL/1.5 mL of the anhydrous acetonitrile solvent inhibits the dioxygen activation in presence of phosphate and *t*-BuOOH and the total yield of the oxidized product was noticeably reduced.

4. Conclusions

We have convincingly demonstrated that in the metalloporphyrin catalyzed dioxygen activation anhydrous phosphates play a very significant role. Presence of a small quantity of a hydroperoxide enhances the process appreciably. It has been shown that by appropriate tuning of the reaction medium, the dioxygen activation under ambient conditions is certainly possible. In the oxygenation of cyclohexane manganese porphyrins seem to be more promising. We are in the process of further tuning the solvent, catalyst and co-catalyst to achieve selective products with higher turnovers so that the results could be more useful.

which TTF ligands act as substituted groups. However, these TTF molecules were excluded from the helices for their rigid backbones, just like that previously reported by Munakata et al. [13d]. It is a challenge to involve TTF motifs into a helix, there is no effective method to predict the final network topology of a self-assembly process for it was highly effected by several factors such as metal centers [19], ligands [20], solvents [21], counterions [22], and so on. Recently, the use of Ag(I) cation was of growing interest for its various coordination modes such as linear, trigonal, tetrahedral, triangle pyramid and T-shaped [23–27]. Although many Ag-coordinated helical structures have been synthesized [28], to our best knowledge, no Ag(I)–TTF helical coordination polymer was reported before. In this paper, two novel 3D coordination polymeric networks $[Ag_4(tces\text{-}TTF)_2(CF_3SO_3)_2](CF_3SO_3)_2$(tces = 2,3,6,7-tetra(cyanoethylsulfanyl)) (**1**) and $[Ag_2(bmdt)_2](SbF_6)_2 \cdot$ acetone(bmdt = 4,5-bis(methylsulfanyl)-1,3-dithiole-2-thione) (**2**) were synthesized, both of them formed 3D networks constructed from coordinate bonds only, axially chiral helical frames were found in **1** and **2**. Details of the preparations, crystal structures, conductive behavior and S···S contacts are discussed.

tces-TTF

bmdt

2. Experimental

2.1. Materials and instrumentation

All the chemicals and solvents used in the syntheses were bought commercially as analytical grade. The tces-TTF and bmdt ligands were prepared according to literature methods [29,30]. Elemental analysis (for C, H, and N) was performed using a ThermoQuest Flash EA1112 elemental analyzer. The IR spectra (400–4000 cm^{-1}) were recorded on a JASCO FT/IR-460 plus spectrometer with the samples prepared as KBr pellets. The UV–Vis spectra were recorded on UV–VIS8500 UV spectrometer with the crystalline samples dissolved in CH_3CN. The conductivities were measured by conventional two-probe technique with compacted pellets.

2.2. Synthesis of the compounds

2.2.1. Synthesis of $[Ag_4(tces\text{-}TTF)_2(CF_3SO_3)_2](CF_3SO_3)_2$ (1)

An acetone solution (2 mL) of $AgCF_3SO_3$ (11.6 mg, 0.045 mmol) was added into an acetone solution (10 mL) in which tces-TTF (12.3 mg, 0.023 mmol) was dissolved. The mixture was stirred at 40 °C for 6 hours and filtered, then the filtrate was introduced into a glass tube and layed with *n*-hexane as a diffusion solvent. The glass tube was sealed, after standing at room temperature for 15 days, orange block crystals of **1** were obtained. *Anal.* Calc. for $C_{40}H_{32}Ag_4F_{12}N_8O_{12}S_{20}$: C, 22.68; H, 1.52; N, 5.29. Found: C, 23.16; H, 1.71; N, 5.42%. IR data (KBr pellet, cm^{-1}): 2953.07(w), 2926.15(w), 2249.56(m), 1625.70(m), 1416.46(s), 1259.29(s), 1033.66(s), 1175.40(s), 647(s) cm^{-1}; UV–Vis: λmax = 390 nm.

2.2.2. Synthesis of $[Ag_2(bmdt)_2](SbF_6)_2 \cdot$ acetone (2)

Bmdt (0.2 mmol, 45.2 mg) was dissolved in the mixture of acetone and CH_3CN (5 mL), $AgSbF_6$ (0.2 mmol, 68.7 mg) was dissolved in acetone (3 mL), these two solutions were mixed together and stirred at 20 °C for 2 h and filtered, the filtrate was introduced into a glass tube and layed with diethyl ether as a diffusion solvent. The glass tube was sealed and made to stand at room temperature for 1 week, then brown block crystals of **2** were obtained. *Anal.* Calc. for $C_{13}H_{18}Ag_2F_{12}OS_{10}Sb_2$: C, 13.03; H, 1.51. Found: C, 12.83; H, 1.45%. IR data (KBr pellet, cm^{-1}): 2911.02(w), 1469.49(m), 1420.32(m), 1315.21(m), 1058.73(s), 1035.59(m), 967.13(w), 900.59(w), 663.30(s). UV–Vis: λmax = 408 nm.

2.3. Crystal structure determination

For complex **1**, data collection ($6.4 < 2\theta < 55.0°$) was performed at 150 K on a Rigaku/MSC Mercury CCD diffractometer ($\lambda = 0.71070$ Å); For complex **2**, data collection ($3.4 < 2\theta < 50.0°$) was performed at 180 K on a Bruker Smart APEX CCD diffractometer ($\lambda = 0.7107$). The two structures were solved using direct methods and refined with full-matrix least-squares (SHELX-97). The crystal data and details of the structure determinations of **1** and **2** are summarized in Table 1, selected bond lengths and angles are listed in Table 2.

3. Results and discussions

3.1. Crystal structure of complex *1*

The coordination geometry of silver(I) and partial atom numbering of **1** are shown in Fig. 1. There are three crystallographically independent silver(I) atoms in this network all of which feature a 4-coordinate mode. Ag(3) is coordinated by four N atoms from three different tces-TTF ligands (two are from the same ligand in the diagonal direction). Connected by one Ag(3) atom and C=C bonds on the terminal side of TTF skeleton, these flexible cyanoethylsulfanyl arms form a right-handed helix (Fig. 1). As Ag(3) atoms are located on a infinite wavy line (along *b*-axis) and tces-TTF ligands are alternately arranged on both sides of the line (Fig. 2), the helix is infinitely prolonged on both sides of the wavy line, thus a 1D column is formed by the two orderly arranged helices with the Ag(3) wavy line functioning as a "hinge". This 1D column can also be described as a sandwich structure with extended TTF shells and helical stuffing.

Since all the long flexible nitrile chains of tces-TTF are sandwiched inside the 1D columns, the S atoms of the cyanoethylsulfanyl arms are exposed to each other between adjacent columns. Therefore, Ag(1) and Ag(2) atoms can easily bridge them together to result in a 2D layer extending along *a*-axis. The S–Ag–S angles are 135.14° of S(5)–Ag(1)–S(5) and 123.62(7)° of S(6)–Ag(2)–S(6), respectively. As 4-coordinate metal centers, Ag(1) (or Ag(2)) atom also connects two $CF_3SO_3^-$ anions by O atoms. Two adjacent Ag(1) (or Ag(2)) atoms are double-bridged by $CF_3SO_3^-$ anion through Ag–O bonds (Fig. 3, free $CF_3SO_3^-$ anions are omitted for clarity), therefore these anions stick the 2D layers together to extend infinitely along *c*-axis and

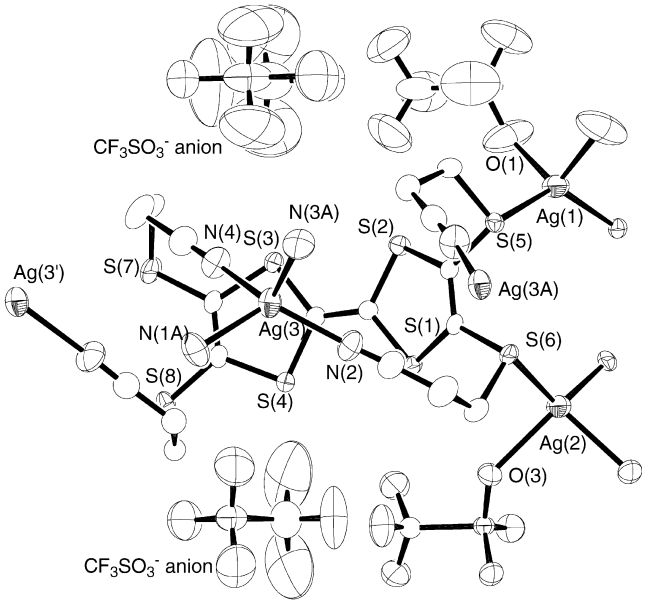

Fig. 1. Coordination geometry of Ag(3) and partial atom numbering of **1**.

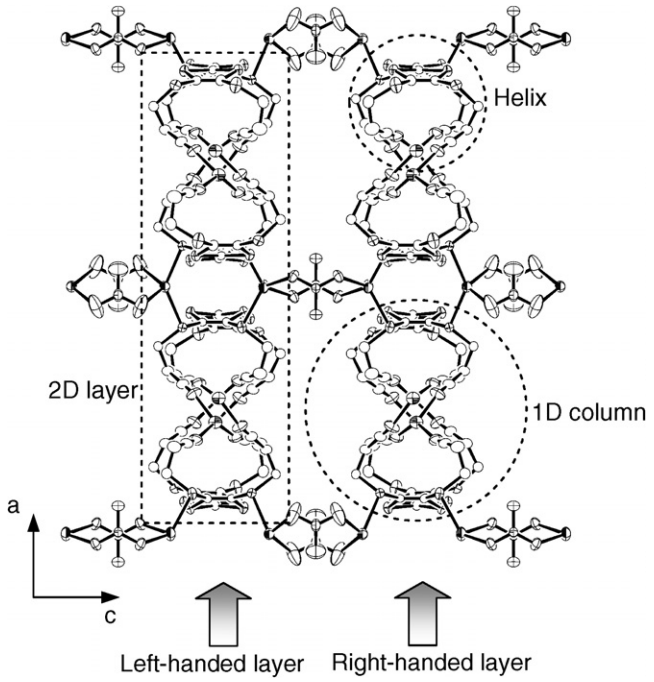

Fig. 3. "8"-shaped channels and axially chiral motifs in polymer **1**.

finally form a 3D network. It is noteworthy that polymer **1** is completely constructed by coordinate bonds, this phenomenon is rare for metal-TTF polymers and gives rise to a stable construction of the polymer. Viewed along *b*-axis, an obvious "8"-shaped channel is found. The vacuities between the "8"-shaped channels are smaller ones which have S···S contacts due to the close face-to-face arrangement of two TTF molecules. The canals between the 2D sheets are separated by $CF_3SO_3^-$ anions to result in the largest channels which are occupied by free $CF_3SO_3^-$ anions. Another coordination polymer with 1D linear structure based on Ag(I) and a TTF derivative bearing two cyanoethylsulfanyl and two methylsulfanyl groups is known [13c], however, for polymer **1**, more flexible cyanoethyl groups help to form helical motifs; various coordination modes of Ag(I) and $CF_3SO_3^-$ anions involved in the coordination system lead to a 3D network.

3.2. Crystal structure of complex *2*

The crystallographic study revealed that complex **2** is also a 3D network with crisscrossed grids assembled orderly by bmdt ligands. Fig. 4 gives the coordination geometry and atom numbering of Ag(I) and bmdt ligands. There are two crystallographically independent silver(I) atoms in the network and both of them are connected with four S atoms from three bmdt ligands. The bond lengths of Ag(1)–S range from 2.456 to 2.881 Å and those of Ag(2)–S from 2.534 to 2.632 Å, while the angles of S–Ag(1)–S and S–Ag(2)–S are within the ranges of 83.81–148.22° and 81.56–135.77°, respectively. Therefore, both Ag(1) and Ag(2) adopt a distorted tetrahedral coordination sphere. Fig. 5 gives the top view of complex **2** (along *b*-axis), Ag(1) and Ag(2) atoms form two kinds of Ag_2S_2 rhombohedra units which connect bmdt ligands regularly and spiral up along *b* axis infinitely, thus a 3D network with helices along *b*-axis is obtained. The SbF_6^- anions were included between the 2D gridding layers.

To better understand the structure conformation of **2**, we simplified the Ag_2S_2 rhombohedra as a 4-connected node. For both $Ag(1)_2S_2$ and $Ag(2)_2S_2$ nodes, the shortest circuits starting and ending on each center are five hexagons and one octagon. Thus the topology type of **2** can be classified as $6^5.8$, and the connection mode of the network can be described as "cds" which is similar to the structure of $CdSO_4$ [31].

3.3. Helical structures of *1* and *2*

Both **1** and **2** formed unusual helical structures albeit complexes **1** and **2** are synthesized from different ligands

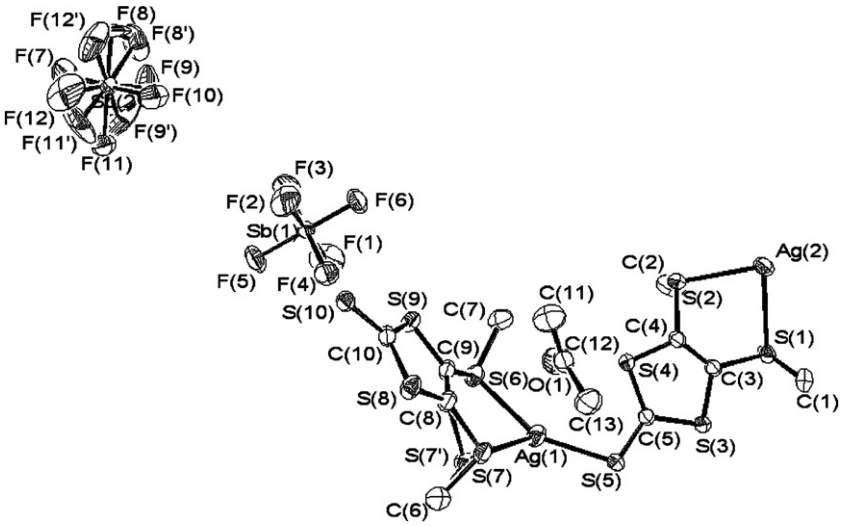

Fig. 4. Structure and labeling of **2** (ORTEP, 50% probability).

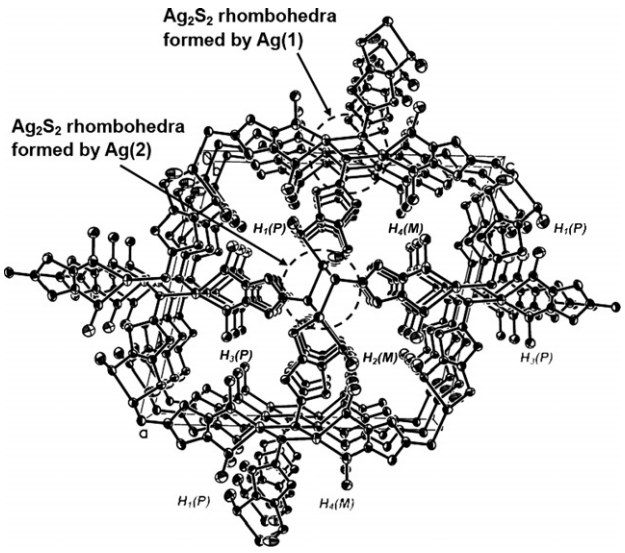

Fig. 5. Overall 3D supramolecular structure with axially chiral griddings for **2** (SbF_6^- anions and acetone were omitted for clarity).

and silver(I) salts. Fig. 6 exhibits the striking feature of polymer **1** with infinite axially chiral double-stranded helix in a space-filling mode. 1D columns on *ab* plane are connected by Ag(1) and Ag(2) atoms to result in a homo-chiral 2D layers, however, the chirality alternates between the layers. In Fig. 6a (left-handed case), the left helix spirals up by sharing the downside C=C bonds of the TTF skeletons, while the right one sharing the upside; It undergoes the same way for the right-handed one (Fig. 6b) except the helix was marked with black and gray. The double-helices feature a twisted geometry because Ag(3) atoms from the wavy lines were arranged on one plane, this was consistent with the formation of "8"-shaped channels which extended infinitely along *b*-axis. The formation of unusual double-stranded helices in complex **1** can be ascribed to the four long flexible arms of ligand tces-TTF and the coordination feature of silver(I). Although some coordination polymers with double-helical frames were reported before [32], it is rare for the case of TTF derivatives, and also, for using coordinate bonds to construct double-helical structures [33].

An overall 3D network structure of **2** is shown in Fig. 5. Four types of helices were found in **2** (Fig. 7), named as H_1, H_2, H_3 and H_4, respectively. These bmdt ligands are connected head to tail by Ag(1) or Ag(2) atoms and spiral up along *b*-axis. A further observation of these helices shows that when they were assembled along *a*-axis, the chirality does not change, while along *c*-axis, it alternates.

Helices with partially shared hinges formed by metal atoms or organic ligands are not rare [34], similar structures with parallel helices were also reported before [35]. To our surprise, complex **2** has entirely shared sides formed by bmdt ligands only, adjacent griddings are not penetrated and feature an approximately identical construction mode. Besides, this 3D network is built up through coordinate bonds only and result in a $6^5.8$ topology, to the best of our knowledge, suchlike TTF-based helical structure was never reported before.

Additionally, the double helix in **1** can also be described as two single stranded helices hinged by the Ag(3) wavy line which have the same chirality, and were enclosed between two rows of TTF skeletons to result in a sandwich structure. In **2**, the shorter skeleton and three coordination sites (S1, S2, S5) of bmdt provide tri-connected assemblies, they were regularly linked by Ag_2S_2 rhombohedra units in a head-to-tail fashion and this made it possible to form an infinite helix.

In this paper, two different types of ligands tces-TTF and bmdt were used for the following reasons: (a) rigid TTF π-backbone (whole for tces-TTF and half for bmdt) may bring potential properties like other TTF polymers; (b) feasible bonding sites (four N atoms on tces-TTF and three S atoms on bmdt) may provide rich coordination modes; (c) tces-TTF possesses flexible cyanoethylsulfanyl arms which are possible to form a helical structure [15e].

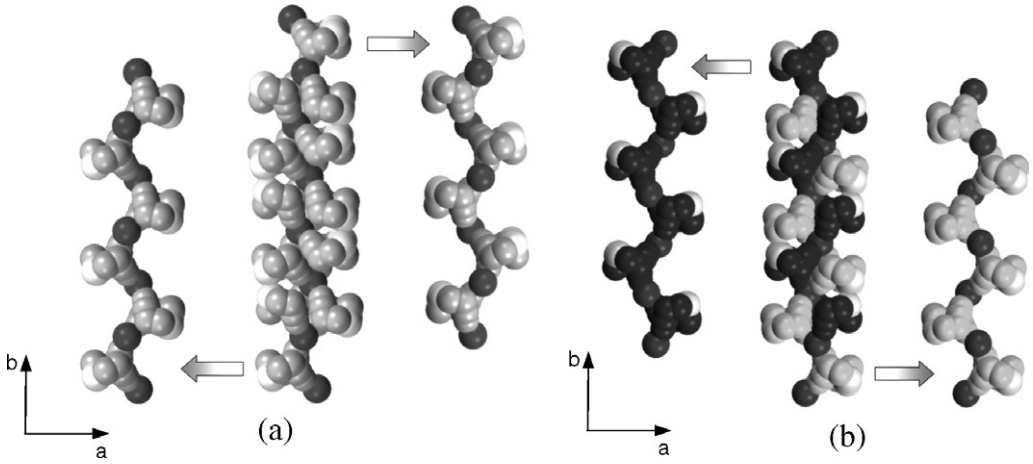

Fig. 6. Space-filling representation of the 1D column in **1** (atoms not involved in the double-stranded helix were omitted for clarity). (a) Left-handed. Ag: black; C: dark gray; S: gray; (b) Right-handed. Black and gray represent the two strands of helices, respectively.

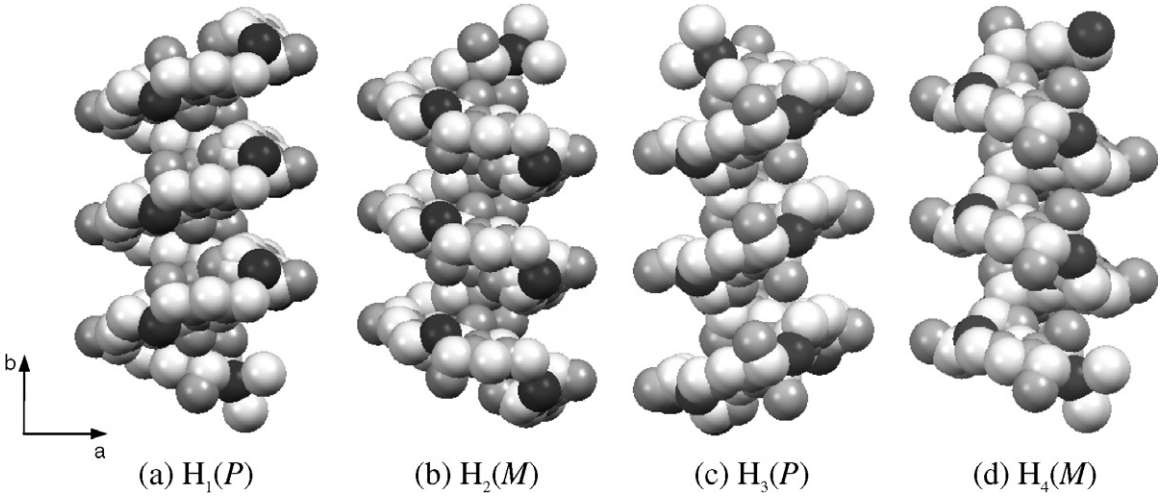

Fig. 7. Four types of axially chiral griddings in **2**. H_1 (a) and H_2 (b) are enantiomorphous as well as H_3 (c) and H_4 (c). Ag: black; C: dark gray; S: gray. (a) $H_1(P)$ (b) $H_2(M)$ (c) $H_3(P)$ (d) $H_4(M)$.

3.4. Spectroscopic properties and conductivity

The IR spectrum of **1** reveals a sharp band at 1416 cm^{-1} which indicates neutral tces-TTF molecules. The UV–Vis spectra of **1** and **2** show a range of absorption from 380 to 430 nm which may be ascribed to local excitations of tces-TTF and bmdt molecules. No spectral information indicating radical cations was found, σ value of polymer **1** is $3.47 \times 10^{-6} S \cdot cm^{-1}$ (measured by conventional two-probe technique under room temperature). It is S···S contacts that contribute to this weak conductive property, Fig. 2 shows the S···S contacts in polymer **1**: 3.397(2) Å of S(5)···S(7) and 3.434(2) Å of S(6)···S(8) which extend infinitely along the 1D column; 3.588(3) Å of S(3)···S(3′) and 3.517(3) Å of S(4)···S(4′) which are approximately perpendicular to the former ones. For complex **2**, it is an insulator, no S···S contact within 3.70 Å (van der Waals radii of two sulfur atoms) was found.

4. Conclusion

Two 3D coordination polymeric networks with axially chiral motifs were synthesized and crystallographically characterized. Complex **1** has novel "8"-shaped channels and twisted double-helical structure. Although the center TTF skeleton of tces-TTF is rigid, those flexible cyanoethylsulfanyl arms contribute to the formation of the helical structure. **1** also exhibits semi-conductive behavior ($\sigma = 3.47 \times 10^{-6} S\ cm^{-1}$) because of extensive intramolecular S ··· S contacts. In polymer **2**, bmdt ligands are linked by Ag_2S_2 analogues and result in an infinite helix which shares its sides with adjacent ones. A tailored building block with multi-coordinate sites helps the formation of this helical structure. In addition, complex **2** is also a "cds" network with a $6^5.8$ topology. It is an insulator for it has not effective S···S contacts. These two 3D polymeric networks are formed by coordinate bonds only, and therefore their stabilities are higher.

Scheme 1. Schematic view of the macrocyclic copper(II) complex.

macrocyclic copper(II) complex $Cu(cyclam)^{2+}$ in order to obtain a heterometallic system $\{[Cu(cyclam)][Co(NCS)_4]\}_n$ bridged by a thiocyanate group. Square-planar macrocyclic complexes of Cu(II) and Ni(II) with two free coordination places at the metal atom can play here the role of the so-called "building blocks". Considering the fact that in unsaturated complexes of the type [14]dieneN$_4$, the N-configuration of the macrocyclic ring influences its conformation, and thus the arrangement of substituents in it [15], an attempt was undertaken to study the relation between the N-configuration and the crystal structure and magnetic properties of the compounds obtained [9]. Previously, we obtained a heterometallic compound of the type $[(CuL_3)[Co(NCS)_4]$ (L_3 = *N-meso*-5,12-Me$_2$-7,14-Et$_2$-[14]-4,11-dieneN$_4$) [9], in which the macrocyclic complexes of Cu(II) forms a linear polymer with the $[Co(NCS)_4]^{2-}$ anion. There are also two known complexes of the general formula $[ML_3]_2[Mn(NCS)_4](ClO_4)_2$ (where M = Cu(II), Ni(II); L_3 = N-dl-5,7,7,12,14,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene), whose crystal structures are built up by isostructural, trinuclear complex-cations $\{[ML_3]_2[Mn(NCS)_4]\}^{2+}$ (M = Ni^{II}, Cu^{II}) and perchlorate anions [16]. It is shown that the number and size of the substituents in the macrocyclic rings influence the crystal structure and magnetic properties of the compounds. In this paper, we present results concerning a new such system, containing the non-saturated substituted complex CuL_1^{2+} (where L_1 = *N-rac*-5,12-Me$_2$-[14]-4,11-dieneN$_4$) (Scheme 1), as well as the simple ion of the $[Co(NCS)_4]^{2-}$complex.

2. Experimental

2.1. Materials

All materials used in this work were of reagent grade purity and were used as commercially obtained. $[CuL_1](ClO_4)_2$ was prepared as previously reported [17].

2.2. Synthesis of the complex

A solution of $[CuL_1](ClO_4)_2$ (73.02 mg, 0.15 mmol) in CH_3CN (10 mL) was added, dropwise, to a solution containing an aqueous solution of KSCN (58.31 mg, 0.6 mmol) and $CoCl_2 \cdot 6H_2O$ (35.69 mg, 0.15 mmol). The mixture was subsequently stirred. After a few days a dark-blue crystalline solid was formed from the violet solution by slow evaporation. It was filtered and washed using diethyl ether (2 × 10 mL). Yield: 82.53 mg (95%). A blue needle crystal of the compound suitable for X-ray diffraction studies was obtained by slow evaporation of a solution of all the reagents in CH_3CN–H_2O (1:1) at room temperature. *Anal.* Calc. for $C_{16}H_{24}N_8S_4CoCu$ (579.14): C, 33.18; H, 4.18; N, 19.35; S, 22.15. Found: C, 33.20; H, 4.27; N, 19.48; S, 21.78. The copper and cobalt content was determined by the ICP method: Calcd Co, 10.18; Cu, 10.97. Found: Co, 9.88; Cu, 10.12.

2.3. Infrared spectra

The FIR spectrum was measured in Nujoll mulls (500–50 cm^{-1}) and the MIR spectrum in KBr pellets (4000–500 cm^{-1}) with a Brucker IFS 66 spectrophotometer.

The infrared spectrum of the complex exhibits three bands near 2000 cm^{-1} (2121 and 2088 cm^{-1}), which are associated with the ν_{as}(NCS) stretching mode, resulting from a combinations of four effects: (i) the presence of bridging thiocyanate ligands (Co–NCS–Cu); (ii) the presence of non-bridging thiocyanate ligands (Co–NCS); (iii) the distorted octahedral copper(II) environment and (iv) the tetrahedral environment of cobalt(II).

2.4. Magnetic measurements

Magnetic measurements in the temperature range 1.8–300 K were performed using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The SQUID magnetometer was calibrated with a palladium rod sample (Materials Research Corporation, measured purity 99.9985%). Magnetization measurements of a polycrystalline sample were carried out at a magnetic field of 0.5 T over the temperature range 1.8–300 K and versus a magnetic field from 0 to 5 T at a temperature of 2 K. Corrections are based on subtracting the sample holder signal and the contribution χD estimated from Pascal constants [18].

2.5. EPR spectra

EPR spectra were recorded at room temperature and 77 K on a Bruker ESP 300 spectrometer operating at the X-band frequency, equipped with an ER 035M Bruker NMR gaussmeter and HP 5350B Hewlett–Packard microwave frequency counter. The spectra at 4.5 K temperature were measured with an X-band Radiopan SE/X 2543 spectrometer.

2.6. X-ray crystallographic analysis

A blue needle crystal was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector,

and was used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation with the ω scan mode. A 42 s exposure time was used. The unit cell parameters were determined from 7689 strongest reflections. Details concerning crystal data and refinement are given in Table 1. Examination of reflections on six reference frames monitored after each 10 frames measured showed 9.8% loss of the intensity. During the data reduction the above decay correction coefficient was taken into account. Lorentz, polarization and numerical absorption [19] corrections were applied. The structure was solved by the partial structure expansion procedure. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique on F^2. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent atom with geometric idealisation after each cycle of refinement and with individual isotropic displacement factors equal to 1.2 times the value of the equivalent displacement factor of the parent non-methyl atom and 1.5 times of the parent methyl group carbon atom. The methyl groups were allowed to rotate about their local threefold axis. The SHELXS97 [20], SHELXL97 [21] and SHELXTL [22] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs. Selected interatomic bond distances and angles are listed in Table 2.

3. Results

3.1. Structural description

A perspective view of the structure occupying the asymmetric unit of the unit cell together with the atom numbering scheme is shown in Fig. 1, displacement ellipsoids are plotted with 50% probability. All atoms lie in general positions. The macrocyclic chiral nitrogen atoms have the

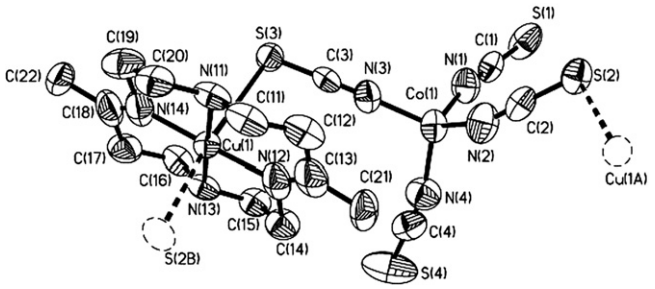

Fig. 1. The molecular conformation of $\{(CuL_1)[Co(NCS)_4]\}$ with the atom numbering, plotted with 50% probability of displacement ellipsoids. The hydrogen atoms are omitted for clarity. Atoms belonging to the asymmetric unit are indicated by full lines. The symmetry generated atoms Cu(1A) and S(2B) are indicated by dashed lines.

configuration R and S for the N(11) and N(13) atoms, respectively, thus the macrocycle does not posses chirality. Despite this fact, the title compound crystallises in the chiral space group $P2_12_12_1$. The copper atom is six coordinated by four macrocyclic nitrogen atoms and two sulfur atoms of bridging thiocyanate groups. The coordination polyhedra of the copper atoms can be described as distorted tetragonal bipyramid with the sulfur atoms in axial positions. The copper atom deviates 0.043(2) Å from the macrocyclic N_4 least squares plane. Adopting a slightly distorted tetrahedral coordination (Table 2), the cobalt atom is four coordinated by the nitrogen atoms of the thiocyanate groups. The bridging thiocyanate groups are located in a facial arrangement. One of the Cu–S distances (Table 2) is distinctly larger than the most common values (2.33–2.95 Å), but still lies in the typical range of 2.2–3.2 Å observed for Cu–SCN bonds in coordination compounds. The macrocycle conformation can be described as sc^-, sc^+, ap^-, ap^-, sc^-, ap^+, ap^+, sc^+, sc^-, ap^-, ap^+, sc^+, ap^-, ap^-. The existence of a twofold screw axis around the copper atom expands the molecules to a one-dimensional zig-zag coordination polymer along the crystallographic *c* axis (Fig. 2). In the structure can be found medium strength N–H···S hydrogen bonds (Table 3) [23] of which one (N(11)–H(11)···S(3)) provides additional stabilisation to the polymer chain and a second (N(13)–H(13)···S(1)) expands the polymer chain to a two-dimensional net along

the crystallographic *ac* plane. Besides those mentioned above, there are no unusual intermolecular short contacts in the structure. The polymer chain nearest Cu(1)···Co(1) distances are 6.4152(9) and 6.0988(9) Å, and the nearest Cu(1)···Co(1) interchain distances are 6.8609(9), 6.9628(9) and 6.0336(10) Å.

3.2. Magnetic properties

The magnetic behavior of the complex is shown in Fig. 3 in the form of χ_M and $\chi_M T$ versus T plots, where χ_M is the magnetic susceptibility per Cu(II)Co(II). The value of $\chi_M T$ at room temperature for the compound equals 2.78 $cm^3\ mol^{-1}\ K$ (4.72 B.M.), which is larger than the expected value for a magnetically non-interacting Cu(II)-Co(II) entity with local spins $S_{Cu} = 1/2$ and $S_{Co} = 3/2$ (2.25 $cm^3\ mol^{-1}\ K$, $g = 2.0$). This may be due to the contribution of the spin–orbit coupling of the Co^{II} ion. It is also likely that at room temperature we already have ferromagnetic coupling occurring. In this way, the value of $\chi_M T$ is greater than the calculated value. Upon cooling, the $\chi_M T$ value is practically independent of temperature in the temperature range 100–300 K and then increases as the temperature is lowered further to $T_{max} = 10$ K. The $\chi_M T$ values at T_{max} is equal to 2.97 $cm^3\ mol^{-1}\ K$ (4.87 B.M.). The interaction of cobalt(II) with copper(II) gives rise to spin triplet ($S = 1$) and spin quartet ($S = 2$) low lying states, separated by *J*. The increase of $\chi_M T$ upon cooling

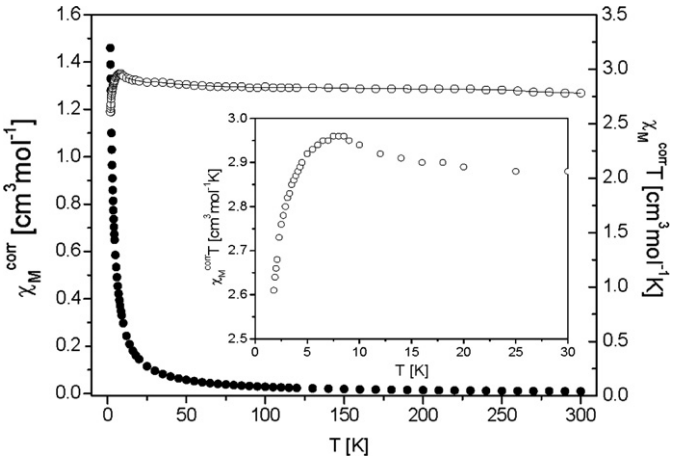

Fig. 3. Thermal dependence of χ_M (●) and $\chi_M T$ (○) for $\{(CuL_1)[Co(NCS)_4]\}$. The solid line is the calculated curve.

indicates that the quartet is the ground state, the interactions between the Cu(II) and Co(II) ions through the thiocyanate bridge being ferromagnetic in the temperature range 10–300 K. Below 10 K, $\chi_M T$ rapidly decreases at the lowest temperatures to 2.61 $cm^3\,mol^{-1}$ K (4.57 B.M.). The lowered $\chi_M T$ value below 10 K indicates the contribution of an antiferromagnetic interaction between the ferromagnetic chains and/or the zero-field splitting effect of Co^{II}.

The values of C and θ, determined from the relation $1/\chi_M = f(T)$ over the 50–300 K range of temperatures, are equal to 2.80 $cm^3\,mol^{-1}$ K and 1.4 K, respectively. The positive value of the Weiss constant confirms that ferromagnetic coupling occurs.

As mentioned in the structural discussion, this complex can be viewed as a heterobimetallic one-dimensional zigzag chain. The problem is why in the examined compound there is no minimum on the $\chi_M T$ versus T curve, which is typical for ferrimagnetic behaviour.

According to Kahn's theory [2b], for a ferrimagnetic chain, $\chi_M T$ first decreases on cooling, reaches a minimum for finite temperatures, then diverges as T approaches zero. The minimum on $\chi_M T$ corresponds to a short range order state where spins S_A and S_B of adjacent magnetic center are antiparallel, but where there is no correlation between the neighboring AB units. Below the temperature of the minimum $\chi_M T$ value, the magnetic behavior is qualitatively equivalent for a chain of n spins $|S_A - S_B|$ which are ferromagnetically coupled. If the intrachain interaction is ferromagnetic ($J > 0$), no extremum of the $\chi_M T$ versus T plot can be observed and $\chi_M T$ increases in the low temperature range. This situation is occured in the examined complex.

The J_{CuCo} parameter can be related to contributions from pairs of magnetic orbitals for copper(II) in octahedral symmetry and cobalt(II) tetrahedral symmetry and is given by

$$J_{CuCo} = \frac{1}{3}(J_{a_1b_1} + J_{a_2b_1} + J_{b_2b_1})$$

which contains only positive terms, of which $J_{a_1b_1}$ is the most important. For the reason of strict orthogonality of the magnetic orbital, the interaction is certainly ferromagnetic with an $S = 2$ ground state well separated in energy from an $S = 1$ excited state.

For magnetic interactions occurring over the whole temperature range, the following equation describing the behavior of a heterometallic chain with F/AF interactions was used [2b]:

$$\chi_{chain} = \frac{N\beta^2}{3kT}\left[g^2\frac{1+u}{1-u} + \delta^2\frac{1-u}{1+u}\right]$$

$$g = (g^e_{Cu} + g^e_{Co})/2$$

$$\delta = (g^e_{Cu} - g^e_{Co})/2$$

$$u = \coth\left(\frac{J^c}{kT}\right) - \left(\frac{kT}{J^c}\right)$$

where:

$$g^c_{Cu} = g_{Cu}[S_{Cu}(S_{Cu}+1)]^{1/2}$$

$$g^c_{Co} = g_{Co}[S_{Co}(S_{Co}+1)]^{1/2}$$

$$J^c = J[S_{Cu}(S_{Cu}+1)S_{Co}(S_{Co}+1)]^{1/2}$$

Taking into consideration the possibility of interchain interactions occurring in the crystal lattice, a correction for a molecular field was also taken into account [24]:

$$\chi_M = \frac{\chi_i}{1 - [(2zJ'/Ng_i^2\mu_B)\chi_i]}$$

The following parameters were obtained from the calculations: $g_{Co} = 2.28$, $g_{Cu} = 2.08$, $J = 1.42\ cm^{-1}$, $zJ' = -0.26\ cm^{-1}$, as indicated by the solid curve in Fig. 3. The agreement factor R, defined as $R = \sum(\chi_{exp}T - \chi_{calc}T)^2/\sum(\chi_{exp}T)^2$, is 2.76×10^{-5}. A positive value of the integral J_{CuCo} witnesses the occurrence of a ferromagnetic interaction between the Co^{II} and Cu^{II} ions. The small value of J_{CuCo} obtained from the calculations follows from the large distances between those ions, amounting to 6.4152(9) and 6.0988(9) Å. The decrease of the value of $\chi_M T$ in the low-temperature range (below 10 K) is thus caused by the occurrence of interchain antiferromagnetic interactions, as well as the parameter D originating from the Co(II) ion, which was not resolved, however, because of too complex mathematical calculations. Interchain interactions in this compound are very weak, of antiferromagnetic character ($zJ' = -0.26\ cm^{-1}$), which is the result of large distances between the metallic ions in the neighboring chains. The nearest Cu(1)···Co(1) interchain distances are 6.8609(9), 6.9628(9) and 6.0336(10) Å.

This suggestion fully confirms the magnetization versus field curve at 2 K. The results are shown in Fig. 4, where the molar magnetization M is expressed in B.M. units and M is expected to have the saturation value M_s, when M/kT becomes very large, according to the equation of $M_s = Ng\mu_B S$. In such a case the ground state

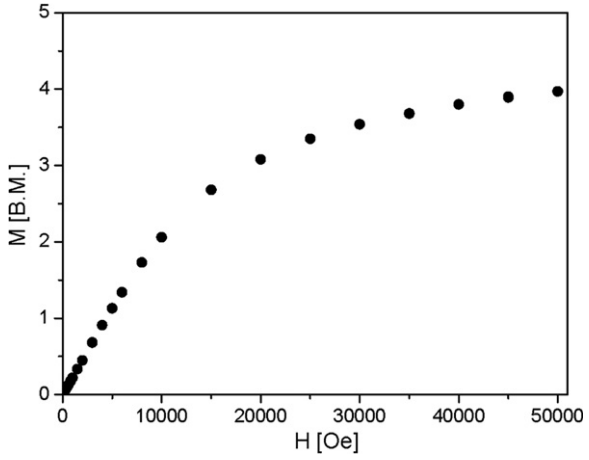

Fig. 4. Field dependence of the magnetization for complex {(CuL$_1$)-[Co(NCS)$_4$]}.

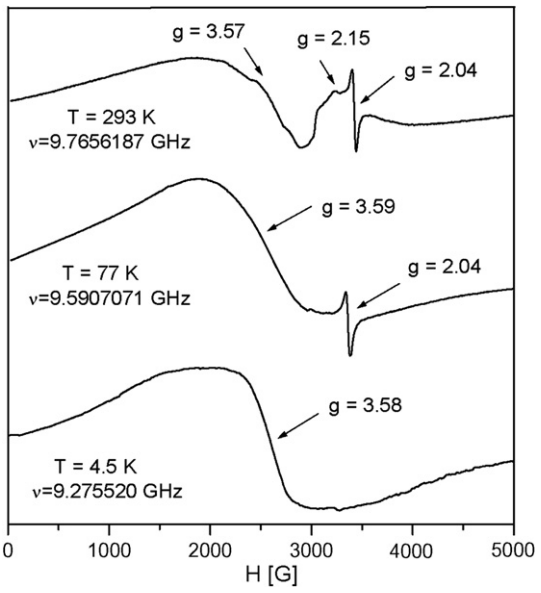

Fig. 5. EPR spectra for $\{(CuL_1)[Co(NCS)_4]\}$ at room temperature, 77 K and 4.5 K.

is $S_{max} = 1/2 + 3/2 = 2$ and the magnetization (per Cu–Co unit) should saturate to the value of $M = 4$ B.M. Experimental data have shown that at the magnetic field $B = 5$ T and with the temperature as low as $T = 2.0$ K the magnetization adopts a value of $M = 3.97\mu_B$, very close to the theoretical value. This fact evidences a very small or absence role of the zero-field splitting effect for the Co(II) ions.

3.3. EPR spectra

X-band EPR spectrum of a powdered sample of the complex $\{(CuL_1)[Co(NCS)_4]\}$ exhibits a broad low-field signal at $g \sim 3.58(10)$ at 293 K. This signal is assigned to a transition within the lowest $|\pm 3/2\rangle$ doublet of the spin state of Co^{II} magnetic center. The spectrum shows also an anisotropic line at $g = 2.04$ (Fig. 5), which is connected only with the electronic configuration ($S = 1/2$) of the copper centers in the octahedral ligand field. The EPR signal of the complex at higher temperatures can indicate superimposing copper(II) and cobalt(II) ground state doublet signals (lines at $g = 2.04$ and 2.15). At 77 and 4.5 K, the spectra display the same isotropic line at $g = 2.04$ ($\delta_{Hpp} = 50$ G) and a more intensive and broad signal at $g \sim 3.59$. The EPR spectrum consists of a few lines, because the investigated complex contains two magnetic centers Cu^{2+} ($S = 1/2$) in a distorted octahedral environment and Co^{II} ($S = 3/2$) with nearly tetrahedral coordination.

4. Discussion

The examined complex has a similar crystalline structure to $(CuL_2)[Co(NCS)_4]$ (L_2 = *N-meso*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$) [9], however the macrocyclic complexes of Cu(II) used for the synthesis differ in the number and size of substituents in the macrocyclic rings. Taking into account the substituents in the macrocyclic rings, the central ion is accessible for the bridging ligands from both sides, due to which it forms a linear polymer with the $[Co(NCS)_4]^{2-}$ anion. For the above reason, the magnetic properties of both complexes are similar, with characteristic weak ferromagnetic interactions. The magnetic properties mainly depend upon the nature of the magnetic orbitals of the metals interacting with each other and the bridge angle [2b]. The bond lengths and the angles of the Cu–S–C bridge in the CuCo unit differ slightly. The bridge angles are equal to 97.86(14)° and 97.92(14)° for $(CuL_2)[Co(NCS)_4]$ (L_2 = *N-meso*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$) [9] and 97.76(15)° and 104.65(18)° for the examined complex. The Cu–S distances are equal to 2.9845(11) and 2.9830(11) Å for the compound investigated earlier and the same distances in the obtained compound are unequivalent and are equal to 2.8761(13) and 3.1704(13) Å. Additionally, the polymer chain nearest Cu(1)···Co(1) distances are 6.4152(9) and 6.0988(9) Å and are larger than in the literature complex (5.93(2) and 5.94(5) Å) [9]. These results suggest that when the distance between the metal ions increase, the magnitude of the exchange coupling constant decreases, as expected for poor overlap of magnetic orbitals, which is a reason for the occurrence of a higher value of the parameter J for compound $(CuL_2)[Co(NCS)_4]$ (L_2 = *N-meso*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$) ($J = 3.07$ cm^{-1}) [9].

On the other hand, by comparing the results obtained for complex $\{(CuL_1)[Co(NCS)_4]\}$ (L_1 = *N-rac*-5,12-Me_2-[14]-4,11-dieneN$_4$) with an appropriate system $\{[Cu(cyclam)][Co(NCS)_4]\}_n$ [13], in which cyclam, being a macrocyclic saturated non-substituted tetra-azo ligand, has greater freedom in adapting itself to the spatial requirements of the anion, it can be seen that substituents that occur at the peripheries of a macrocyclic ligand have significant influence on the properties of the complex obtained. The compound $\{[Cu(cyclam)][Co(NCS)_4]\}_n$, similarly to the examined complex, forms a 1-D polymeric chain, but its magnetic properties are different. Complex $\{(CuL_1)[Co(NCS)_4]\}$ shows the occurrence of weak ferromagnetic interactions between the magnetic centres, while the compound $\{[Cu(cyclam)][Co(NCS)_4]\}_n$ was treated as a ferrimagnetic chain [13], for which there was the occurrence of weak antiferromagnetic interactions in the chain, probably together with an antiferromagnetic coupling between the chains. The authors suggest that the ferrimagnetic character of this compound will likely show itself below 1.7 K. The reason for the differences in the magnetic properties should be looked for in the crystalline structure. Both compounds crystallize with the same crystallographic structure, but in different point groups, which was caused by a different packing in the crystal lattice and a different mutual arrangement of the magnetic centres. In the compound $\{[Cu(cyclam)][Co(NCS)_4]\}_n$, the Cu–S bonds occurring are unequivalent (2.891(3) and 3.160(3) Å) while the bridging angles are equal (111.81(15)° and 111.97(12)°).

Additionally, the Cu···Co distance within the chain is equal to 6.909(3) Å and the same distance between chains is equal to 6.361(2) Å. The intrinsic structural features and larger distance between the copper(II) and cobalt(II) centers leads to a poor overlap of magnetic orbitals. This is probably the main reason for the different magnetic properties. In both compounds the heterogeneous-core character suggests the possibility of the occurrence of both ferro- (F) and antiferromagnetic (AF) interactions. It may be thus supposed that in the complex $\{(CuL_1)[Co(NCS)_4]\}$ that we obtained, the contribution coming from the F interactions is bigger than the contribution from AF interactions, in contrast with the compound $\{[Cu(cyclam)][Co(NCS)_4]\}_n$.

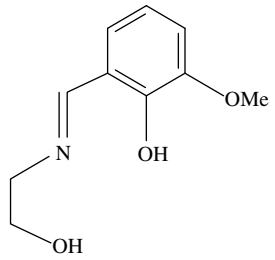

Chart 1. Chemical structure of H_2L.

A few Schiff base ligands have been previously utilized to derive uranium compounds. Salmon et al. have reported a number of mono-, tri-, tetra- and hexanuclear uranium(IV) complexes derived from compartmental Schiff base ligands obtained by the condensation of salicylaldehyde or substituted salicylaldehydes with diamines [14–16]. A mononuclear uranyl(VI) compound in a similar ligand environment has been reported by Ikeda et al. [8]. Using a tridentate ligand obtained by the condensation of 3-methoxysalicylaldehyde and *o*-aminophenol, a diphenoxo-bridged diuranyl(VI) compound has been reported by Reedijk and coworkers [17]. A series of dialkoxo-bridged diuranyl(VI) compounds derived from tridentate ligands obtained by the condensation of salicylaldehyde or substituted salicylaldehydes and substituted 2-aminoethanol have been reported by Rao and coworkers [18]. Herein, we report the synthesis, molecular and supramolecular structure, spectroscopy and electrochemistry of a dialkoxo-bridged diuranyl(VI) compound $[(UO_2)_2(L)_2(dimethylformamide)_2]$ (**1**) derived from the Schiff base ligand (H_2L; Chart 1) obtained by the condensation of 3-methoxysalicylaldehyde with 2-aminoethanol.

2. Experimental

2.1. Materials and physical methods

All the reagents and solvents were purchased from commercial sources and were used as received. The Schiff base ligand H_2L was prepared by condensing 3-methoxysalicylaldehyde with 2-aminoethanol in methanol. The syntheses of the ligand and title compound were performed in open atmosphere. Elemental (C, H and N) analyses were performed on a Perkin–Elmer 2400 II analyzer. IR spectra were recorded in the region 400–4000 cm^{-1} on a Perkin–Elmer RXIFT spectrophotometer with the samples as KBr disks. Electronic spectra were obtained with a Hitachi U-3501 spectrophotometer. The electrospray ionization mass spectra were recorded on a Micromass Qtof YA 263 mass spectrometer. The ^1H NMR (300 MHz) spectra were recorded on a Bruker Avance DPX-300 spectrometer. Cyclic voltammetric (CV) measurement was done using a Bioanalytical System BAS 100B electrochemical analyzer. The concentration of the supporting electrolyte, tetrabutylammonium perchlorate (TBAP), was 0.1 M, while that of the complex was 1 mM. Cyclic voltammetric measurement in dimethylsulfoxide solution was carried out with a three-electrode assembly comprising a glassy carbon disk working electrode, a platinum auxiliary electrode and an aqueous Ag/AgCl reference electrode. The reference electrode was separated from the bulk solution using a TBAP salt bridge in acetonitrile. Under the experimental conditions, the $E_{1/2}$ value of the ferrocene/ferrocenium couple was 400 mV.

[a] $R_1 = [\sum||F_o| - |F_c||/\sum|F_o|]$.
[b] $wR_2 = [\sum w(F_o^2 - F_c^2)^2/\sum wF_o^4]^{1/2}$.

2.2. Synthesis of $[(UO_2)_2(L)_2(dmf)_2]$ (**1**)

To a stirred dimethylformamide (dmf) solution (40 ml) containing H_2L (0.098 g, 0.5 mmol) and uranyl nitrate hexahydrate (0.251 g, 0.5 mmol) was added a dmf solution (10 mL) of triethylamine (0.101 g, 1 mmol). The resulting red solution was filtered to remove any suspended particles and the filtrate was kept at room temperature. After a few hours a red crystalline compound containing diffractable single crystals were deposited, then collected by filtration and washed with methanol. Yield: 0.24 g (90%). *Anal.* Calc. for $C_{26}H_{36}N_4O_{12}U_2$: C, 29.11; H, 3.38; N, 5.22. Found: C, 29.20; H, 3.46; N, 5.31%. IR (KBr/cm^{-1}): υ(C=N), 1636 vs; υ(O=U=O), 891 m.

2.3. Structure determination and refinement of $[(UO_2)_2(L)_2(dmf)_2]$ (1)

Single-crystal X-ray intensity data of the title compound were collected at 293 K on a Nonius Kappa diffractometer with a CCD area detector, using Mo K_α radiation having $\lambda = 0.71073$ Å. The intensity data were processed with the Nonius program suites DENZO-SMN [39] and corrected for Lorentz, polarisation, background and absorption effects [40]. The crystal structure was determined by direct methods and subsequent Fourier and difference Fourier syntheses, followed by full-matrix least-squares refinements on F^2 [41,42]. All H atoms could be located in the difference Fourier map and refined without constraints, except for the methyl hydrogen atoms, which were treated as "riding". Using anisotropic treatment of the non-H atoms and unrestrained isotropic treatment of the H atoms, the refinement converged at an R value of 2.9%. Crystal data, details of the measurement and refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis

The title compound $[(UO_2)_2(L)_2(dmf)_2]$ (**1**) is readily formed on reacting uranyl nitrate hexahydrate, H_2L, and triethylamine in dimethylformamide. Deprotonation of both the phenolic and alcoholic hydrogens takes place in the reaction mixture. As will be discussed below, two uranyl(VI) species are bridged by two alkoxo oxygen atoms of two deprotonated ligands, while the phenoxo oxygen acts as a terminal donor center. Each of the two uranyl(VI) species are further coordinated to one dmf molecule, resulting in the formation of the title compound.

3.2. IR, UV–Vis, mass and NMR spectra

The IR spectrum of H_2L exhibits one strong absorption at 1644 cm^{-1} due to the stretching vibration of the imine moiety. In the diuranyl(VI) compound **1**, the imine stretching is observed at a slightly lower frequency (1636 cm^{-1}). A medium intensity band at 891 cm^{-1} in the IR spectrum of **1** can be assigned to the stretching vibration of the O=U=O moiety. This assignment is supported by the results of Cattalini et al. and Ikeda and coworkers [19,20].

The UV–Vis spectrum of H_2L exhibits two bands at 261 nm ($\varepsilon = 2497$ L mol^{-1} cm^{-1}) and 418 nm ($\varepsilon = 209$ L mol^{-1} cm^{-1}) and a shoulder at 294 nm ($\varepsilon = 540$ L mol^{-1} cm^{-1}). In the spectrum of **1**, one band at 256 nm ($\varepsilon = 7686$ L mol^{-1} cm^{-1}) and two shoulders at 346 nm ($\varepsilon = 1935$ L mol^{-1} cm^{-1}) and 402 nm ($\varepsilon = 1059$ L mol^{-1} cm^{-1}) appear due to an internal ligand transition. An additional band at 475 nm ($\varepsilon = 349$ L mol^{-1} cm^{-1}) in the spectrum of **1** appears due to a charge transfer from the uranyl oxygens to the uranium (VI) center.

The composition of **1** was further verified by electrospray ionization mass spectroscopy (ESI-MS positive). The ESI-MS spectrum of **1** in dimethylsulfoxide exhibits two peaks at $m/z = 464.17$ and 927.26, which are assignable to $[(UO_2)_2L_2H]^+$ (60%) and $[(UO_2)_2LH]^+$ (100%) cations, respectively. As shown in Fig. 1, the isotopic distribution patterns of the observed peaks and the simulated spectral patterns are in excellent agreement with each other.

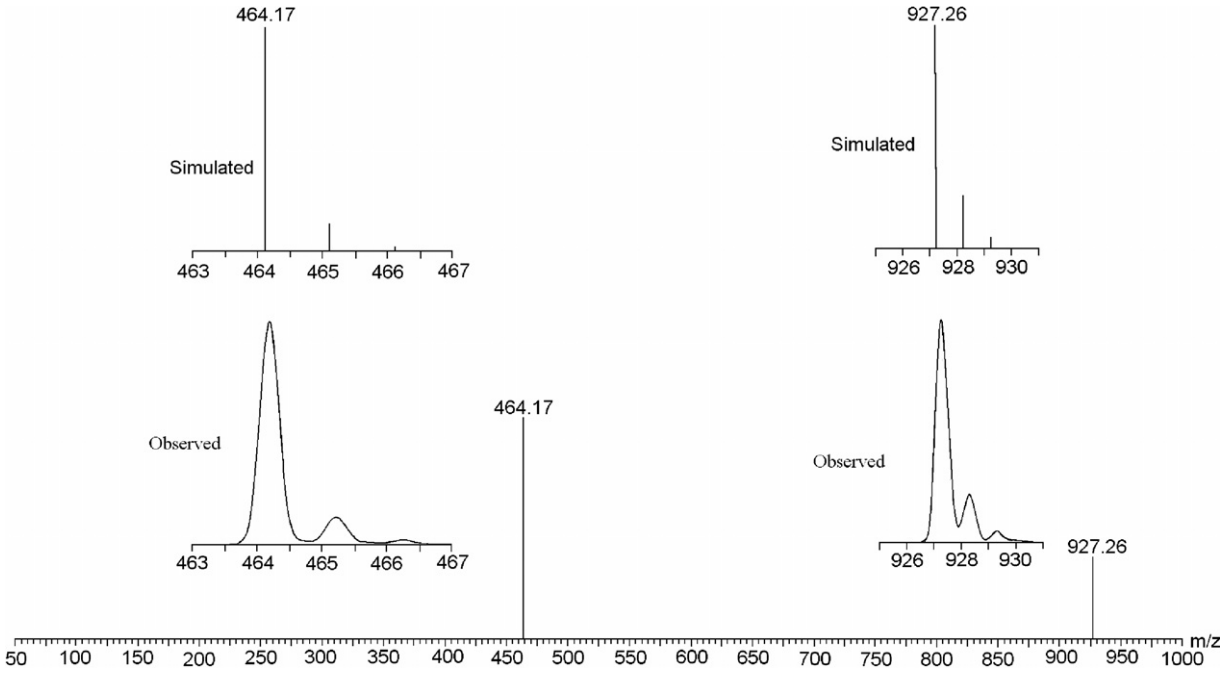

Fig. 1. ESI-MS spectrum of $[(UO_2)_2(L)_2(dmf)_2]$ (**1**) in DMSO.

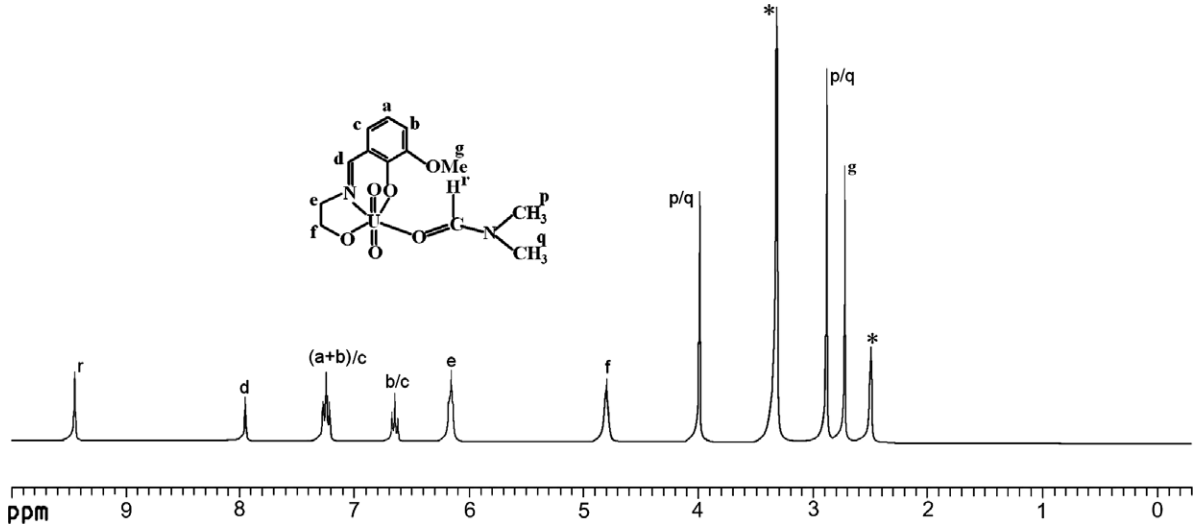

Fig. 2. ^{1}H NMR spectrum of $[(UO_2)_2(L)_2(dmf)_2]$ (**1**) in DMSO-d_6. * marked signals are due to solvent.

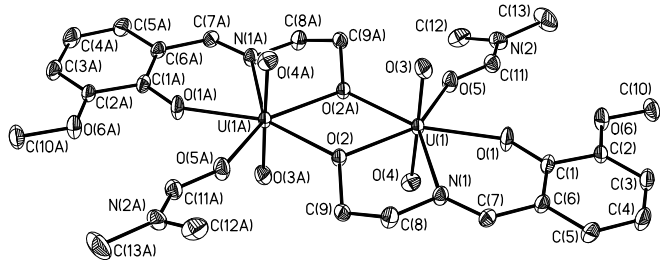

Fig. 3. Crystal structure of $[(UO_2)_2(L)_2(dmf)_2]$ (**1**) with the atom labelling scheme. Hydrogen atoms are omitted for clarity. Symmetry code: A, $1-x$, $1-y$, $-z$.

The proton NMR spectrum (Fig. S1 in supplementary informations) of the ligand H_2L in $CDCl_3$ exhibits six peaks at 13.67 (br, 2H, phenolic OH and alcoholic OH), 8.38 (s, 1H, imine), 6.77–6.96 (m, 3H, aromatic), 3.89–3.93 (t, 2H, CH_2 of $CH_2N{=}CH$), 3.74–3.77 (t, 2H, CH_2 of CH_2OH) and 3.89 ppm (s, 3H, OCH_3). On the other hand, the spectrum of complex **1** in DMSO-d_6 (Fig. 2) is comprised of nine peaks. In comparison to those in H_2L, the methoxy hydrogens (2.73 ppm (s, 3H, OMe)) and imine hydrogen (7.95 ppm (s, 1H, imine)) are a little shielded. Again, splitting of three aromatic hydrogen atoms (6.62–6.67 (t, 1H, aromatic) and 7.21–7.27 ppm (t, 2H, aromatic)) takes place. The presence of the dmf ligand in this complex is evidenced by two singlets (2.88 (s, 3H, CH_3 (DMF)) and 3.99 ppm (s, 3H, CH_3 (DMF))) due to the methyl groups and one singlet at 9.45 ppm (s, 1H, CHO (DMF)) due to the amide moiety. It may be mentioned that both ^{1}H and ^{13}C NMR spectra have been used to characterize uranium(IV) and uranium(VI) compounds [1,8,13,15–19].

3.3. Description of the structure

The crystal structure of **1** is shown in Fig. 3, while selected bond lengths and angles are listed in Table 2.

Table 2
Selected bond lengths (Å) and angles (°) of **1**

U(1)–O(2)–U(1A)	110.14(11)

Symmetry code: A, $1-x$, $1-y$, $-z$.

The structure of **1** reveals that it is a dialkoxo-bridged dinuclear compound of uranyl(VI) containing two deprotonated ligands, $[L]^{2-}$, two dimethylformamide (dmf) molecules and two UO_2^{2+} centers. One half of the molecule is symmetry related to the other half due to the presence of a center of inversion. The uranium(VI) center in this

compound is heptacoordinated by the phenoxo oxygen and imine nitrogen of a $[L]^{2-}$, two uranyl oxygens, two bridging alkoxo oxygens of two $[L]^{2-}$, and one oxygen atom of a dmf molecule. The coordination geometry around the uranium(VI) center is distorted pentagonal bipyramidal; two uranyl oxygens (O(3) and O(4)) occupy the axial positions, while the basal pentagonal plane is defined by the phenoxo oxygen (O(1)), bridging alkoxo oxygens (O(2) and O(2A)), imine nitrogen (N(1)) and dmf oxygen (O(5)). As expected, due to π-back bonding, the U–O bond lengths (U(1)–O(3) = 1.790(4); U(1)–O(4) = 1.786(3) Å) involving uranyl oxygens are much shorter than the U–O(phenoxo), U–O(alkoxo), U–O(dmf) and U–N(imine) bond distances in the basal plane, which lie in the range 2.254(4)–2.564(4) Å. The U–O(phenoxo, terminal), U–O(alkoxo, bridging), U–N(imine) and U–O(dmf) distances in **1** lie in the ranges observed in the previously reported related compounds [17,18,28–30].

The *transoid* angle (178.68(11)°) involving the axial uranyl oxygens as well as the *cisoid* angles (89.56(11)–93.58(11)° for O(3) and 85.89(11)–90.73(14)° for O(4)) involving the axial oxygens and the five donor atoms in the basal plane are close to the ideal values. Again, from the least-squares NO_4 basal plane, the nitrogen or oxygen atoms defining the plane are deviated by only *ca.* 0.06 Å and the metal center is displaced by only 0.07 Å. However, the ranges of apex···apex (O···O or O···N) distances and internal angles (O···O···O, O···N···O or N···O···O) inside the basal pentagonal plane are 2.696–2.952 Å and 100.0–114.7°, respectively, indicating distortion of the coordination geometry from the ideal case. In the dinuclear unit, the metal centers are separated by 3.861(4) Å with a U(1)–O(2)–U(1A) bridge angle of 110.14(11)°.

Three C–H···O type hydrogen bonds involving one uranyl oxygen (O(4)), two dmf hydrogens (H(12B), H(13C)) and the imine hydrogen (H(7)) link the dinuclear units into a two-dimensional network. A simplified illustration of the hydrogen bonded two-dimensional sheet is demonstrated in Fig. 4. As shown in this figure, one uranyl oxygen (O(4)) of a dinuclear unit U(1)···U(1A) acts as a triple acceptor and interacts with the dmf hydrogens H(12BD) and H(13CD) of the dinuclear unit U(1D)···U(1E) as well as with the imine hydrogen H(7F) of the dinuclear unit U(1F)···U(1G). Similarly, another uranyl oxygen O(4A), which is symmetry related to O(4), of the dinuclear unit U(1)···U(1A) interacts with the hydrogens of two other dinuclear units U(1H)···U(1I) and U(1J)···U(1K). Clearly, one dinuclear unit is interlinked with four other units to result in the creation of a two-dimensional sheet (Fig. 4). The geometries of the hydrogen bonds are given in Table 3.

3.4. Electrochemistry

The cyclic voltammetric measurement of complex **1** was carried out in dimethylsulfoxide at 25 °C under a nitrogen

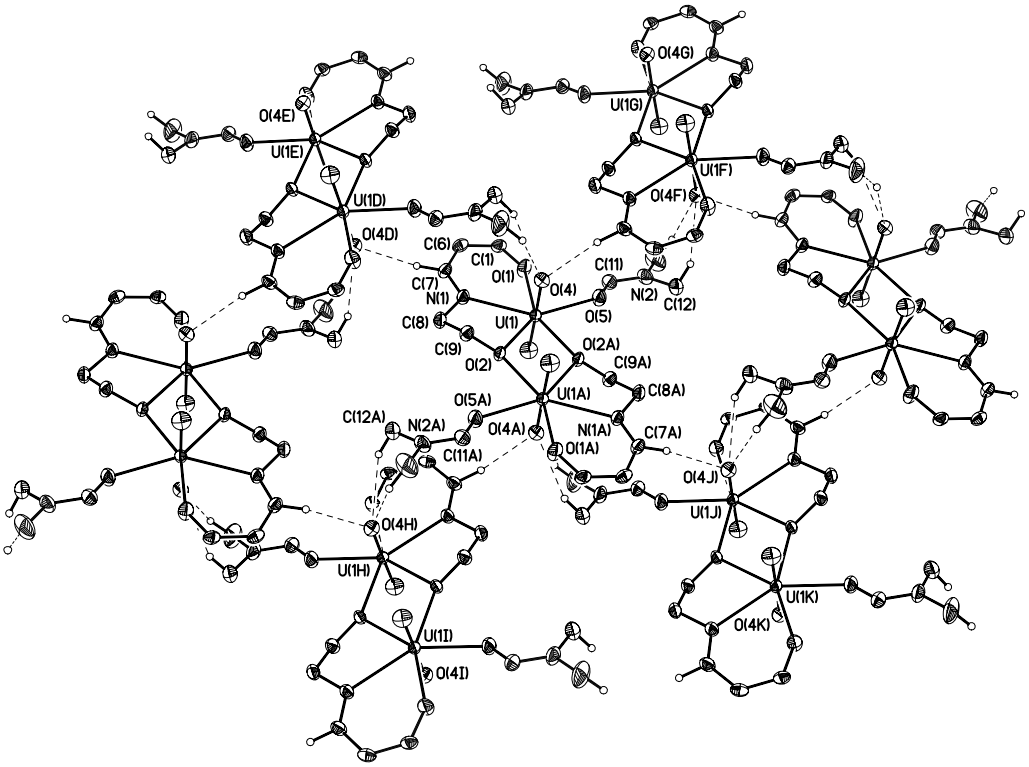

Fig. 4. Perspective view to demonstrate the hydrogen bonding interactions and the resultant two-dimensional topology in $[(UO_2)_2(L)_2(dmf)_2]$ (**1**). The atoms C(2), C(3), C(4), C(5), C(10) and O(6) are omitted for clarity. Among the hydrogen atoms, only three participating in hydrogen bonds are shown. Symmetry codes: D, $1.5 - x$, $y - 0.5$, $0.5 - z$; E, $0.5 + x$, $0.5 - y$, $0.5 + z$; F, $1.5 - x$, $0.5 + y$, $0.5 - z$; G, $0.5 + x$, $1.5 - y$, $0.5 + z$; H, $x - 0.5$, $0.5 - y$, $z - 0.5$; I, $0.5 - x$, $y - 0.5$, $-0.5 - z$; J, $x - 0.5$, $1.5 - y$, $z - 0.5$; K, $0.5 - x$, $0.5 + y$, $-0.5 - z$.

Table 3
Geometries (distances in (Å) and angles in (°)) of the hydrogen bonds in **1**

D–H···A	D···A	H···A	D–H···A

Symmetry codes: as in Fig. 4.

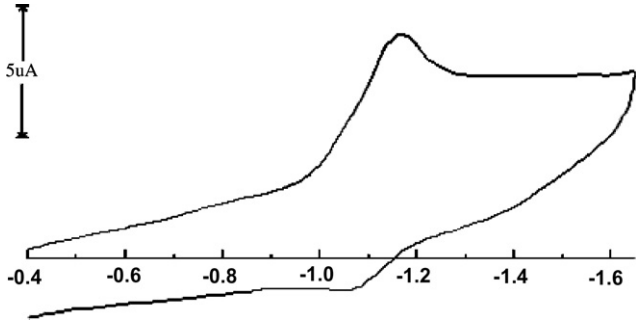

Fig. 5. Part (−400 to −1650 mV) of the cyclic voltammogram of complex **1** in dimethylsulfoxide in the scan range 0 to −1800 mV at a scan rate of 50 mV s^{-1}.

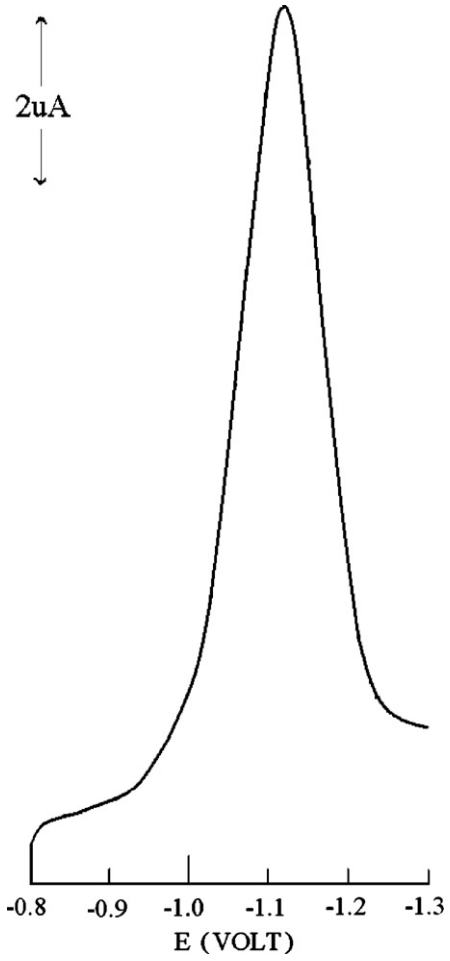

Fig. 6. Square wave voltammogram (−800 to −1300 mV) of complex **1** in dimethylsulfoxide at a scan rate of 50 mV s^{-1}.

atmosphere using glassy carbon as the working electrode and at a scan rate of 50 mV/s. In the potential range of 0 to −1800 mV, one cathodic response at −1160 mV and, in the return sweep, one anodic peak at −1063 mV are observed. The part (*ca.* −400 to −1650 mV) containing the peaks of the cyclic voltammogram for the 0 to −1800 mV scan range is shown in Fig. 5, while the square wave voltammogram (SWV) related to this couple is shown in Fig. 6. The $E_{1/2}$ value of this couple is −1112 mV. It may be noted that the peak position (−1120 mV) in SWV (Fig. 6) is very close to the $E_{1/2}$ value obtained from cyclic voltammogram. Again, the value of the difference (ΔE_P) of the cathodic and anodic peak potentials is 97 mV, indicating the quasireversible nature of the reduction–oxidation process. The observation of only one couple clearly indicates that the 2 equiv. uranium(VI) centers in **1** are reduced (U(VI)U(VI) → U(V)U(V)) at −1160 mV and the reduced uranium(V) centers are oxidized (U(V)U(V) → U(VI)U(VI)) at −1063 mV.

It may be relevant to discuss the electrochemical properties of only a few previously reported results. Ikeda et al. have reported that the quasireversible U(VI) → U(V) reduction of uranium compounds derived from *N*,*N*′-disalicylidene-*o*-phenylenediaminate, dibenzoylmethanate and carbonato ligands takes place at −1550 mV, −1362 mV and *ca.* −751 mV, respectively [12]. Kiplinger and his group have shown that uranium(IV) compounds may exhibit a single reversible reduction (U(IV) → U(III)), a reversible reduction (U(IV) → U(III)) and oxidation (U(IV) → U(V)), as well as two reversible reductions and one reversible oxidation (U(IV) → U(V)). The $E_{1/2}$ values for these reduction and oxidation processes lie in the ranges −1830 mV to −2790 mV and +180 mV to −480 mV, respectively [9–11].

4. Conclusions

The dialkoxo-bridged diuranyl(VI) compound described here is an addition to the family of uranium chemistry and actinide chemistry. The compound has been characterized by elemental analysis and its X-ray single crystal structure, as well as by IR, NMR and mass spectra. The participation of uranyl oxygens in the hydrogen bonding interactions and in developing a two-dimensional supramolecular structure have been enlightened in the present investigation. A cyclic voltammetric study of the title compound has been performed and compared with the electrochemical properties of previously reported uranium compounds.

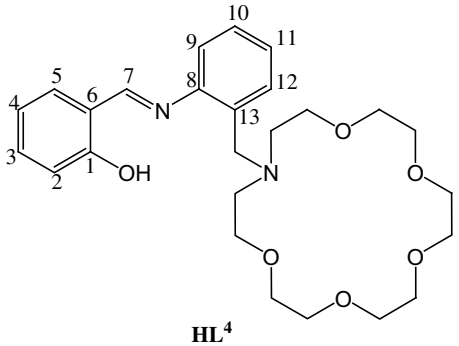
($\mathbf{L}^1$) [10], 1,10-diaza-15-crown-5 ($\mathbf{L}^2$) [11] and 4,10-diaza-12-crown-4 ($\mathbf{L}^3$) [12] (see Scheme 1).

As a continuation of our works, herein we present the corresponding synthesis and structural characterization of the lanthanide(III) complexes of the related monobracchial receptor *N*-(2-salicylaldiminatobenzyl)-1-aza-18-crown-6 ($\mathbf{L}^4$) shown in Scheme 1. The study of Ln(III) complexes of this receptor allows to evaluate the effect that the absence of one arm may have on the coordination ability of the receptor. From the structural point of view this receptor derives from $\mathbf{L}^1$ by loss of one 2-salicylaldiminato-benzyl pendant and replacement of the corresponding pivotal nitrogen atom by an oxygen donor. The complexes have been also characterized by *ab initio* calculations at the HF/3-21G* level. The crystal structures of the corresponding praseodymium and samarium compounds were determined by X-ray crystallography.



2. Experimental

2.1. Reagents

Lanthanide(III) perchlorates hydrates (La–Lu, excluding Pm) were purchased from Alfa laboratories, either as solid samples (La and Ce) or as 50% w/w aqueous solutions. All other chemicals were purchased from commercial sources and used without further purification. Solvents were of reagent grade and were purified by the usual methods. Acetonitrile-d_3 for NMR measurements (Merck, 99% D) was used as received. *Caution!* Although we have experienced no difficulties with the perchlorate salts, they are potentially explosive when combined with organic ligands and should be handled in small quantity and with the necessary precautions [13].

2.2. Synthesis

2.2.1. *N*-(2-Aminobenzyl)-1-aza-18-crown-6 ($\mathbf{pL}^4$)

2-Nitrobenzyl chloride (0.65 g, 3.79 mmol), 1-aza-18-crown-6 (1.00 g, 3.79 mmol) and Na_2CO_3 (1.20 g, 20 mmol) in acetonitrile (40 mL) were stirred and refluxed for 24 h. The mixture was filtered, the filtrate concentrated to dryness, and the yellow oily residue extracted with CH_2Cl_2/water. The organic phase was dried over anhydrous $MgSO_4$ and concentrated under reduced pressure. The resulting yellow oil was dissolved in absolute ethanol (60 mL) and Pd/C added. Hydrazine hydrate (0.7 mL) was slowly added and the reaction mixture was heated and stirred for 1 h. After filtration and evaporation of the solvent, the resulting crude product was purified by column chromatography (basic aluminium oxide, CH_2Cl_2) to afford the desired product as a pale yellow oil. ^{1}H NMR (500 MHz, CD_3Cl; δ, ppm): 7.0 (t, 1H, arH), 6.9 (d, 1H, arH), 6.6 (m, 2H, arH), 4.7 (b, 2H, –NH_2), 3.6 (m, 20 H, –CH_2–), 2.7 (m, 6H, –CH_2–). MS FAB: $m/z = 369$ ($pL^4 + H$). IR (KBr): $\nu = \nu(NH_2)$ 3432, 3353 cm^{-1}.

2.2.2. Preparation of the complexes

A stoichiometric amount (1:1) of *N*-(2-aminobenzyl)-1-aza-18-crown-6 ($\mathbf{pL}^4$) and salicylaldehyde was dissolved in 2-propanol (30 mL) and heated to reflux. After 1 h, a solution of equimolar quantity of triethylamine in 10 mL of 2-propanol was added, and the reflux was maintained for 30 min. A solution of the corresponding hydrated lanthanide(III) perchlorate (equimolar) in 25 mL of the same solvent was then added and the resultant solution was refluxed for 3 h, filtered while hot and the filtrate left to evaporate slowly at room temperature to yield yellow solids that were collected by filtration and dried under vacuum over $CaCl_2$.

2.3. Measurements

Elemental analyses were carried out on a Carlo Erba 1108 elemental analyzer. FAB-mass spectra were recorded using a FISONS QUATRO mass spectrometer with Cs ion-gun and 3-nitrobenzylalcohol as a matrix. ^1H and ^{13}C NMR spectra were run at 25 °C with Bruker AC200 F and Bruker WM-500 spectrometers. Chemical shifts are reported in parts per million with respect to TMS. Spectral assignments were based in part on two-dimensional COSY and NOESY experiments. IR-spectra were recorded, from KBr discs, using a Bruker Vector 22 spectrophotometer. Conductivity measurements were carried out at 20 °C with a Crison Micro CM 2201 conductimeter using 10^{-3} M solutions of the complexes in acetonitrile.

2.4. X-ray crystallography

Three-dimensional X-ray data were collected on a Bruker Smart 1000 CCD for compound **3** and on a Bruker X8 APEXII CCD for compound **5**. Data were corrected for Lorentz and polarization effects and for absorption by semiempirical methods [14] based on symmetry-equivalent reflections. Complex scattering factors were taken from the program SHELX97 [15] included in the WINGX program system [16] as implemented on a Pentium® computer. The structure was solved by Patterson methods (DIRDIF99) [17] and refined by full-matrix least-squares on F^2. Hydrogen atoms were included in calculated positions and refined in a riding mode, except the hydrogen atoms of the coordinated water molecule, which were first located in a difference electron-density map, fixed to the oxygen atom O(7), and then left to refine freely in the final stages of refinement in both cases. In **5** the position of the hydrogen atom of the –OH group of the 2-propanol molecule was fixed. Refinement converged with anisotropic displacement parameters for all non-hydrogen atoms. The crystal of **3** presents disorders in one perchlorate ion and in some atoms of the crown moiety. These disorders have been solved, and two atomic sites for O(20), O(22), O(23), C(17), C(18), C(19), C(20), O(3) have been observed and refined. The sites occupancy factors were 0.70(3) for O(20A), O(22A), O(23A), and 0.537(10) for C(17A), C(18A), C(19A), C(20A), O(3A). The crystal of **5** present a disordered perchlorate group and 34 least-squares restraints had to be imposed to resolve the disorder. The site occupancy factor was 0.82 for

2.5. Computational methods

Full geometry optimizations of the $[Ln(L^4)(H_2O)]^{2+}$ systems (Ln = La, Pr, Sm, Ho, Lu) were performed *in vacuo* at the RHF level. For these calculations the effective core potential (ECP) of Dolg et al. and the related [5s4p3d]-GTO valence basis set were used for the lanthanides [18], while the 3-21G* basis set was used for the ligand atoms. The X-ray structure of compound **3** was used as input geometry for each geometry optimization. The two conformations observed in the solid state for compound **3** were considered. The relative free energies of the two conformers of $[Ln(L^4)(H_2O)]^{2+}$ complexes were calculated in vacuo at the same computational level, and they include non-potential energy contributions (that is, zero point energy an thermal terms) obtained by frequency analysis. The nature of the calculated stationary points as true minima was checked by frequency analysis. All HF calculations were performed by using the GAUSSIAN 98 package (Revision A.11.3) [19].

3. Results and discussion

Reaction of HL^4 [prepared *in situ* by the condensation of *N*-2-aminobenzyl-1-aza-18-crown-6 and salicylaldehyde] with triethylamine and the corresponding hydrated lanthanide perchlorate in 2-propanol led to complexes of formula $[Ln(L^4)(H_2O)](ClO_4)_2 \cdot x$solv (Ln = La–Tb, excluding Pm). Attempts to prepare the corresponding complexes of the heaviest Ln(III) ions (Ln = Dy–Lu) under analogous conditions were unsuccessful. The IR and FAB mass spectra of the complexes confirmed the formation of the Schiff-base armed macrocycle as well as its presence in the complexes. The IR spectra (KBr discs) feature a band attributable to $\nu(C{=}N)_{imine}$ stretching mode at *ca.* 1610 cm^{-1} which, together with the absence of bands due to carbonyl and/or amine vibration modes, confirms the formation of the imine bond. Bands corresponding to the ν_{as}(Cl–O) stretching and δ_{as}(O–Cl–O) bending modes of the perchlorate groups appear at *ca.* 1090 and 623 cm^{-1}. The absorption at 623 cm^{-1} clearly shows up without splitting, as befit uncoordinated anions [20]. The FAB-mass spectrum of each complex displays a very intense peak (100% BPI) corresponding to the $[Ln(L^4)(ClO_4)]^+$ fragment. The ^{1}H NMR spectrum of the La(III) diamagnetic complex **1** recorded in acetonitrile-d_3 solution shows broad signals for the protons of the macrocyclic unit, while the signals corresponding to protons of the pendant arm are well resolved. The later signals could be assigned with the aid of the 2D COSY and NOESY spectra (see scheme 1 for labelling): δ 8.28 (s, 1H, H7), 7.57 (m, 1H, H12), 7.55 (m, 1H, H10), 7.47 (m, 2H, H5 and H3), 7.35 (ddd, 1H, H11), 7.28 (dd, 1H, H9), 7.78 (m, 2H, H2 and H4). The NOESY spectrum gives a strong cross-peak relating H7 and H5 (H7···H5 = 2.37 Å in the X-ray structure of **5**) and a weaker signal relating H7 and H9 (H7···H9 = 2.52 Å in the X-ray structure of **5**). The spectrum does not show signals attributable to the carbonyl and amine precursors, in agreement with the formation of the expected complex. The broad signals observed for the proton nuclei of the crown moiety indicate the presence of a conformational equilibrium in solution due to the flexibility of the macrocyclic unit.

The solid state structures of the praseodymium and samarium complexes have been determined by X-ray diffraction studies. Crystals consist of the $[Ln(L^4)(H_2O)]^{2+}$ cations (Ln = Pr or Sm), two well-separated perchlorate anions, and solvent molecules (2-propanol in both crystals, and also water in the praseodymium complex) hydrogen bonded to the coordinated water molecule. Fig. 1 displays a view of the structures of the cations. In the case of the $[Pr(L^4)(H_2O)]^{2+}$ complex the carbon atoms C(17), C(18), C(19) and C(20), as well as the oxygen atom of the crown moiety O(3) are disordered. It is well known that crown and aza-crown ethers may take several slightly different conformations in the solid state [21]. These different conformations are not always resolved by X-ray determinations, which often yield an average representation of the unit cell. In the Pr(III) complex two different conformations of the crown moiety are well resolved by the X-ray determination [10,11]. By contrast, only one conformation of the crown moiety is observed in the Sm(III) complex. This conformation corresponds to that observed for the Pr(III) complex taking into account the sites labeled as **A** in Fig. 1.

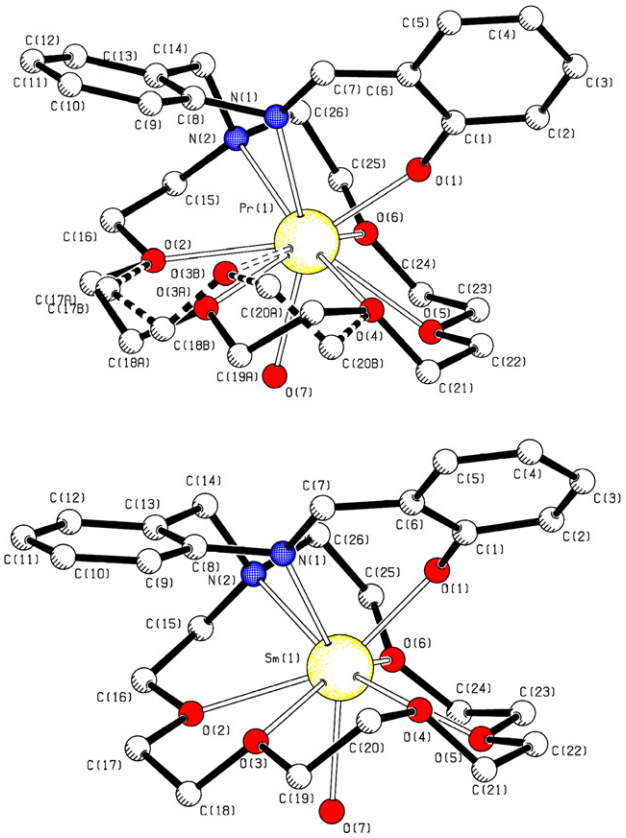

Fig. 1. X-ray crystal structures of the $[Pr(L^4)(H_2O)]^{2+}$ and $[Sm(L^4)(H_2O)]^{2+}$ cations present in **3** (top) and **5** (bottom). Hydrogen atoms are omitted for simplicity.

Bond distances of the metal coordination environment in $[Ln(L^4)(H_2O)]^{2+}$ complexes (Ln = Pr or Sm) are given in Table 2, while bond angles of the metal coordination environment are given in Table S1 (Supporting Information). The lanthanide ion is coordinated to the eight available donor atoms of the ligand and to the oxygen atom of an inner-sphere water molecule. The coordinated water molecule is located on the opposite side of the crown moiety with respect to the pendant arm. The metal ion is almost symmetrically positioned with respect to the crown cavity. The Ln-crown donors distances (Table 2) fall in the range between 2.505–2.679 (Pr) and 2.435–2.634 Å (Sm), and they are similar to the distance between the Ln(III) ion and the oxygen atom of the coordinated water molecule [2.503(5) (Pr) and 2.446(2) Å (Sm)] and Ln-imine nitrogen [2.567(3) (Pr) and 2.519(2) Å (Sm)] bond lengths. The distance to the phenolate oxygen donor atom is clearly shorter than the remaining bond distances of the Ln(III) coordination sphere [Pr(1)–O(1) 2.257(3) Å; Sm(1)–O(1) 2.2461(19) Å]. The bond distances of the metal coordination environment in $[Pr(L^4)(H_2O)]^{2+}$ are slightly shorter than those found in the related complex with the bibracchial receptor $\mathbf{L}^1$, $[Pr(L^1)]^+$ [10]. However, this is expected because the Pr(III) ion is 10-coordinate in $[Pr(L^1)]^+$, while in $[Pr(L^4)(H_2O)]^{2+}$ the metal ion is only nine-coordinate. The Sm-donor distances observed in **5** are very similar to those reported for the Sm(III) complex of $\mathbf{L}^2$ (Scheme 1), in which the metal ion is also nine-coordinate. In both $[Ln(L^4)(H_2O)]^{2+}$ complexes (Ln = Pr or Sm) the oxygen atoms O(2), O(3A), O(4) and O(6) are essentially coplanar, with a mean deviation from planarity of 0.032 (**3**) and 0.0405 Å (**5**). The pivotal nitrogen donor N(2) is located 1.664(3) (**3**) and 1.830(2) Å (**5**) above this plane, and the oxygen atom O(5) is placed 1.040(3) (**3**) and 1.098(2) Å (**5**) below it. The coordination polyhedron around the metal ion is so severely distorted that it may be viewed both as a monocapped distorted dodecahedron, where atom O(2) is capping a triangular face of the dodecahedron, or as a monocapped square antiprism comprised of two pseudoplanes defined by N(1), N(2), O(2), O(3) (lower plane) and O(1), O(4), O(6), O(7) (upper plane), with the oxygen atom O(5) capping the latter. On the other hand, the benzene and phenol rings are not coplanar, and they intersect at 56.89(11)° (**3**) and 42.42° (**5**). Thus, the coordination of the pendant arm to the Ln(III) ion provokes a loss of planarity of both aromatic rings.

In previous works, we have found that in the $[Ln(L^1)]^+$ complexes [10] the lanthanide ion is 10-coordinate and deeply buried in the receptor cavity, so that additional ligands such as water molecules are excluded from the metal coordination environment. In spite of their lower denticity, a similar situation occurs for the lanthanide complexes of the bibracchial lariat ethers *N*,*N*′-bis(2-salicylaldiminatobenzyl)-1,10-diaza-15-crown-5 ($\mathbf{L}^2$) and *N*, *N*′-bis(2-salicylaldiminato benzyl)-4,10-diaza-12-crown-4 ($\mathbf{L}^3$) [11,12], in which the metal ion is nine- or eight-coordinate. However, the X-ray crystal structures of the $[Ln(L^4)(H_2O)]^{2+}$ complexes reported here (Ln = Pr or Sm) demonstrate that the monobracchial receptor $\mathbf{L}^4$ is not able to protect the lanthanide ion from the interaction with water molecules. The inner-sphere water molecule coordinates to the Ln(III) ion in *trans* position with respect to the donor atoms of the pendant arm. As a consequence the metal ion is placed inside the crown hole, in contrast to the Ln(III) complexes of the bibracchial lariat ethers $\mathbf{L}^1$–$\mathbf{L}^3$ where the metal ion is placed over the plane of the crown moiety [10–12].

The $[Ln(L^4)(H_2O)]^{2+}$ systems (Ln = La, Pr, Sm, Ho, Lu) were investigated *in vacuo* by means of *ab initio* calculations at the HF/3-21G* level. It has been demonstrated that the use of a more extended basis sets for the ligand atoms or a higher level of theory (B3LYP, MP2) does not result in an improvement of the agreement between experimental (X-ray) and calculated structures [22,23]. As there is not a good all-electron basis set for lanthanides, the effective core potential (ECP) of Dolg et al. and the related [5s4p3d]-GTO valence basis set was applied in these calculations [18]. This ECP includes $46 + 4f^n$ electrons in the core, leaving the outermost 11 electrons to be treated explicitly, and it has been demonstrated to provide reliable results for the lanthanide aqua-ions [22], several lanthanide chelates with polyamino carboxylate ligands [24] and lanthanide dipicolinates [25]. Recently, we have proved to give excellent results also for lanthanide complexes with pendant-armed

[a] From single-crystal X-ray diffraction analyses.
[b] From *ab initio* calculations at the HF/3-21G* level. Two different geometries labelled as **A** and **B** were calculated.
[c] $AF_i = [\sum(\exp - \mathrm{calcd})^2 / \sum(\exp)^2]^{1/2}$, where exp and calcd denote experimental and calculated values, respectively.
[d] $\Delta G^{\circ}_{298K} = G^{\circ}_{298\ K}(\mathbf{B}) - G^{\circ}_{298\ K}(\mathbf{A})$.

crowns [12] or azacrowns [26] and chelates containing pyridine units [27]. Compared to all-electron basis sets, ECPs account to some extent for relativistic effects, which are believed to become important for the elements from the fourth row of the periodic table. Two geometries of the complexes showing the two different conformations of the crown moiety observed in the X-ray structure of the Pr(III) complex were considered. The conformation denoted as **A** corresponds to that observed for the Pr(III) complex in the solid state taking into account the sites labelled as C(17A), C(18A), C(19A), C(20A), O(3A) in Fig. 1, while the conformation denoted as **B** is generated by the occupation of sites C(17B), C(18B), C(19B), C(20B), O(3B). *In vacuo* optimized Cartesian coordinates obtained for the different $[Ln(L^4)(H_2O)]^{2+}$ systems are given in Supporting Information. The optimized geometries obtained for the $[Pr(L^4)(H_2O)]^{2+}$ system are shown in Fig. 2.

The **A** and **B** conformations calculated for the $[Pr(L^4)(H_2O)]^{2+}$ system are in good agreement with the experimental geometrical parameters obtained from the X-ray single crystal analysis of compound **3**. According to Table 2, the calculated distances between the praseodymium ion and the donor atoms are in reasonably good agreement with those observed experimentally (within 0.07 Å, except Pr–O(5) that deviates 0.11 Å), as evidenced by the excellent agreement factors obtained [$AF_i = 0.022$ (**A**) and 0.019 (**B**); $AF_i = [\sum(\exp - \mathrm{calcd})^2 / \sum(\exp)^2]^{1/2}$, where exp and calcd denote experimental and calculated values, respectively) [28]. The Sm-donor distances calculated for conformation **A** also show a good agreement with the experimental bond lengths observed in the solid state (within 0.10 Å, $AF_i = 0.019$). The calculated structures for the remaining $[Ln(L^4)(H_2O)]^{2+}$ systems investigated (Ln = La, Ho, Lu) are very similar to the experimental and calculated structures found for the Pr(III) and Sm(III) analogues, with a water molecule in the first coordination

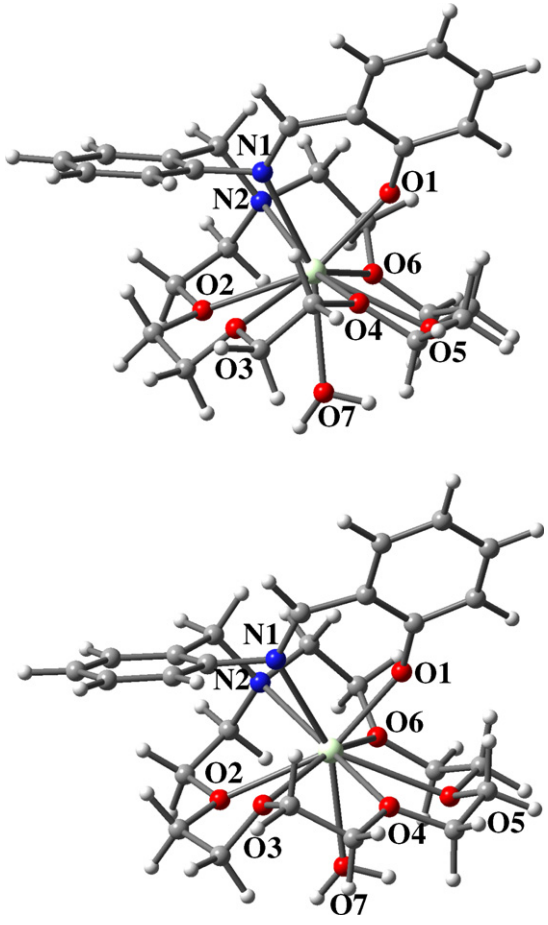

Fig. 2. Calculated structures for the $[Pr(L^4)(H_2O)]^{2+}$ system as optimised in vacuo at the HF/3-21G* level (top: conformation **A**; bottom: conformation **B**).

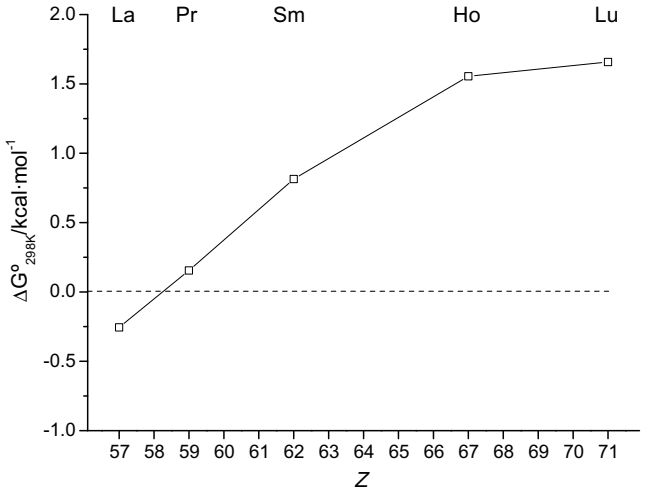

Fig. 3. In vacuo relative free energy of the **B** conformation ($\Delta G^{\circ}_{298\ K} = G^{\circ}_{\mathbf{B}} - G^{\circ}_{\mathbf{A}}$) in $[Ln(L^4)(H_2O)]^{2+}$ complexes.

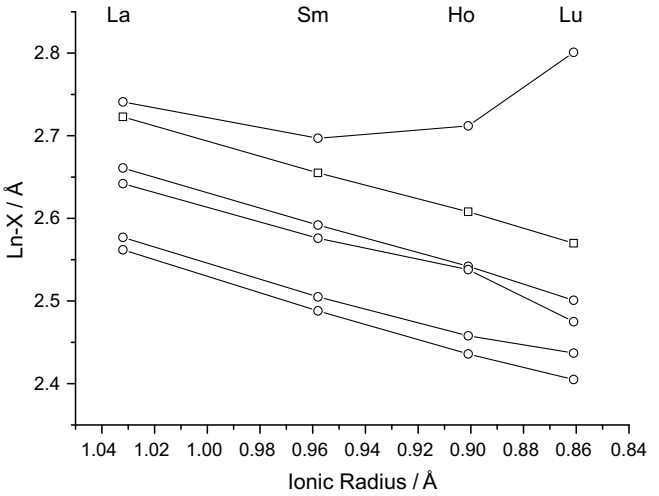

Fig. 4. Ln–O_C (-○-) and Ln–N_A (–□–) bond distances calculated at the HF/3-21G* computational level for the $[Ln(L^4)(H_2O)]^{2+}$ complexes showing conformation **A** [N_A = amine nitrogen atoms; O_C = crown ether oxygen atoms].

sphere. The calculated La-donor bond lengths (Table 2) are similar to those found experimentally in the lanthanum complex with the related receptor $\mathbf{L}^1$ [10].

The relative free energies of the **A** and **B** conformations of $[Ln(L^4)(H_2O)]^{2+}$ complexes were calculated in vacuo at the HF/3-21G* level, and the results are reported in Table 2 and Fig. 3. Relative free energies were calculated as $\Delta G^{\circ}_{298\ K} = G^{\circ}_{298\ K}(\mathbf{B}) - G^{\circ}_{298\ K}(\mathbf{A})$, and therefore a positive relative energy indicates that the **A** conformation is more stable than the **B** one. Our calculations indicate that the relative energy of conformation **B** increases along the lanthanide series. The **A** conformation is the most stable one in the case of the La(III) complex, while for the Pr(III), Sm(III), Ho(III) and Lu(III) complexes the minimum energy conformation corresponds to the **A** form. Both **A** and **B** conformations are observed in the solid state structure of the Pr(III) complex, while for Sm(III) only the **A** form is found, which suggests a stabilization of conformation **A** on decreasing the ionic radius of the Ln(III) ion, as predicted by our quantum mechanical calculations. The relative free energies reported in Table 2 for $[Pr(L^4)(H_2O)]^{2+}$ predict a small energy difference between the **A** and **B** conformations (0.15 kcal · mol^{-1}), in agreement with the fact that both conformations are observed in the solid state.

On the other hand, the calculated structures of the $[Ln(L^4)(H_2O)]^{2+}$ systems (**A** conformation) show that, with the exception of Ln–O(5), the calculated Ln-donor bond lengths decrease along the lanthanide series (Table 2, Fig. 4), as usually observed for Ln(III) complexes. However, the Ln–O(5) distance decreases from La (2.741 Å) to Sm (2.697 Å), but then increases in the Ho (2.712 Å) and Lu (2.801 Å) complexes (Fig. 4). A similar situation is found for conformation **B**, in which the Lu–O(5) distance amounts to 2.935 Å (Table 2). Although these results should be taken with care, since no geometry optimizations have been attempted for other conformations of the macrocyclic receptor in the complexes (the **A** and **B** conformations observed in the X-ray crystal structure of the Pr(III) complex were used as input geometries), the lengthening of the Ln–O(5) distance at the end of the series suggests that the macrocyclic cavity size of $\mathbf{L}^4$ provides the best fit with the lightest Ln(III) ions along the lanthanide series.

4. Concluding remarks

The mono-armed azacrown *N*-(2-salicylaldiminatobenzyl)-1-aza-18-crown-6 ($\mathbf{L}^4$) forms complexes of formula $[Ln(L^4)(H_2O)](ClO_4)_2 \cdot x$solv with lanthanides from La to Tb, excluding Pm. The solid state structures of the Pr(III) and Sm(III) complexes, as well as theoretical calculations performed at the HF level indicate that the $[Ln(L^4)(H_2O)]^{2+}$ complexes adopt at least two different conformations along the lanthanide series. Moreover, calculated relative free energies of the two isomers along the lanthanide series are in agreement with the structures observed in the solid state. These results suggest that the energetics of these complexes can be appropriately calculated at the HF level. It is well known that the conformation adopted by a macrocyclic ligand in Ln(III) complexes can affect drastically some properties such as the exchange rate of inner-sphere water molecules [29]. Thus, the prediction of the structure of lanthanide complexes by using theoretical methods is important to help on the design of systems with the desired properties.

A comparison of the coordinative properties of the monobracchial lariat ether $\mathbf{L}^4$ with those of the bibracchial receptor $\mathbf{L}^1$ shows that removing a pendant arm results in a lower encapsulating capability of the ligand, which allows additional ligands such as water molecules to enter the inner coordination sphere of the Ln(III) ion in the complexes of $\mathbf{L}^4$, a condition required for the application of Ln(III) complexes as contrast agents in MRI [1]. We are

currently investigating structural modifications in the ligand backbone to improve the solubility of the complexes in aqueous media.

Scheme 1.

we synthesized coordination polymers of Zn(II) containing these ligands. The ligand (L1) in the scheme in fact was prepared through the reaction between 2-chloropyridine and azide ion, forming tetrazolo[1,5-*a*]pyridine (abbreviated as py-tetrazole). This ligand is a potentially multi-dentate ligand, however, it acts in the synthesized complex $[Zn_2(N_3)_4(\text{py-tetrazolate})_2](\text{py-tetrazole})$ (**1**) as a monodentate and links zinc center not through the pyridinic nitrogen but through a nitrogen atom of the other three tetrazole nitrogens. This complex crystallizes with uncoordinated py-tetrazole molecule. The second ligand L2 in the scheme: 3-hydroxypyridine (3-OHpy), behaves as *O*,*O*-bridging, i.e. in the tautomeric keto-form (pyridone) in the prepared zinc(II) complex, $[Zn_2(N_3)_4(3\text{-OHpy})]\cdot 2H_2O$ (**2**) which crystallizes with two lattice water molecules. L3 is pyrimidine (pym) which is potentially bidentate and has the ability to bridge metal centers, afforded $[Zn(N_3)_2(pym)]$ (**3**). The structural motifs of these complexes are variable from ladder (1D), to rings (2D) and cubes (3D). Complexes **1** and **2** are unprecedented in all known metal azide complexes. These three new complexes are studied by spectroscopic methods and X-ray crystal diffraction. The room temperature photoluminescence of complex **2** is measured. The results of this study are reported here.

2. Experimental

2.1. Materials and instrumentation

Elemental analyses were carried out using a Perkin–Elmer analyzer and infrared spectra were recorded on a Perkin–Elmer FTIR Series 1600 spectrophotometer as KBr pellets [18]. Luminescence spectra were recorded on a Yobin Yvon SPEX Fluoromax 2 instrument. Starting ligands have been purchased from Aldrich Company, other chemicals were of analytical grade quality and used without further purification. Aqueous hydrazoic acid is obtained with a modified Kipp's generator by decomposition of NaN_3 in H_2SO_4/H_2O (1:3, v:v) and subsequent transfer of HN_3 into H_2O with aid of an inert gas stream. Stock solutions of aqueous ZnN_6 (0.89 mmol Zn/mL H_2O) are obtained in a similar manner by the reaction of HN_3 with a suspension of basic zinc carbonate (0.10 g/mL) H_2O [19].

Caution: Azide compounds and hydrazoic acid (HN_3) are potentially explosive! Only a small amount of material should be prepared and handled with care.

2.2. Synthesis

2.2.1. $\{[Zn_2(N_3)_4(\text{py-tetrazole})_2](\text{py-tetrazole})\}_n$ (1)

Complex **1** was prepared by mixing an aqueous solution of ZnN_6 saturated with hydrazoic acid (10 mL, 8.9 mmol Zn) with 2-chloropyridine (0.50 g, 4.4 mmol) in MeOH (10 mL). The mixture was heated to 95 °C for 30 min with subsequent step-wise cooling to 4 °C. Needle-shaped colorless crystals of the complex were deposited after approx.12 weeks. Yield: approx. 55%. *Anal*. Calc. for $C_{15}H_{12}N_{24}Zn_2$:

2.3. X-ray crystallography

Single crystal X-ray data for complexes **1** and **3** were measured on a modified STOE four circle diffractometer, and for **2** on a Bruker-AXS SMART APEX CCD diffractometer using graphite crystal-monochromatized Mo Kα; radiation ($\lambda = 0.7107$ Å). The intensities were corrected for Lorentz-polarisation effects and for absorption. Crystallographic data and processing parameters are given in Table 1. The structures were solved by direct methods and subsequent Fourier analyses. Anisotropic displacement parameters were applied to non-hydrogen atoms in full-matrix least-squares refinements based on F^2. The hydrogen atoms were assigned with isotropic displacement factors and included in the final refinement cycles by use of geometrical restraints. Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated. The programs DIFABS, SADABS and SHELXTL/PC program package [20] were used for computations. Selected bond distances and bond angles are given in Tables 2, 4 and 6, for complexes **1**–**3**, respectively. Hydrogen bonds of complex **2** are summarized in Table 5.

3. Results and discussion

3.1. Crystal structures

3.1.1. Crystal structure of $\{[Zn_2(N_3)_4(py\text{-}tetrazole)_2](py\text{-}tetrazole)\}_n$ (1)

The X-ray structure determination for complex **1** revealed that the five coordinate Zn(II) atoms are bridged

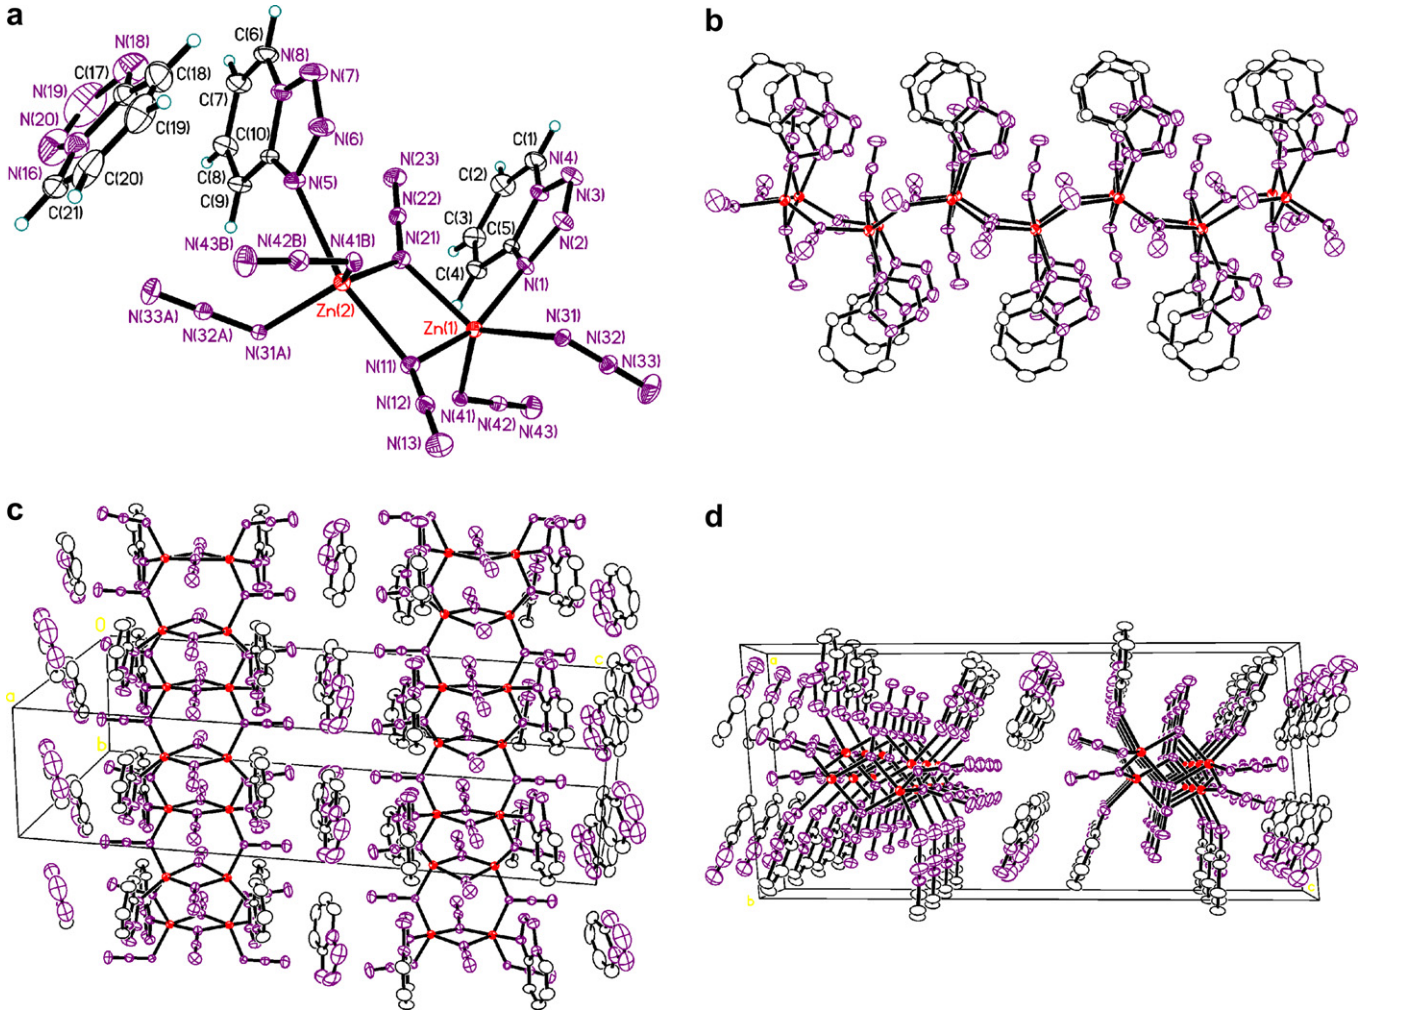

Fig. 1. (a) Perspective view with atom labeling scheme of **1**. Symmetry codes according Table 2. (b) Part of the "ladder-like" arrangement of Zn(II) azide double chains of **1**. (c) Packing view of **1** along the *a*-axis of unit cell. (d) Packing view of **1** along the *b*-axis of unit cell.

by four azido bridges in the EO fashion with a ladder-like arrangement of the 1D zinc(II) azide double chain. A drawing of the asymmetric unit with atom labeling scheme is shown in Figs. 1a–d, show the ladder-like arrangement of the double chain propagated along the crystallographic *b*-axis, and packing plots of the unit cell. Selected bond lengths and bond angles are collected in Table 2. In the coordination chain each zinc(II) ion is coordinated to di-EO azido bridges [Zn(1)–N(11) = 2.087(3), Zn(1)–N(21) = 2.085(3) Å] connecting other Zn(II) ion in the opposite chain forming four-membered Zn_2N_2 cyclic unit [maximum deviation = 0.075(3) Å] crossing the double chain, and two EO bridging azides each on one side of the Zn(II) center [Zn(1)–N(31) = 2.063(3), Zn(1)–N(41). = 2.047(3) Å]. The fifth position is occupied by the nitrogen atom N(1) [Zn(1)–N(1) = 2.252(3) Å] of the tetrazole ring, leading to the formation of a ZnN_5 chromophore. The stereochemistry around Zn(1) center is intermediate between SP and TBP (τ-value = 0.51), whereas Zn(2) is in a TBP environment (τ-value = 0.56) with N(21), N(31A) and N(41B) in the equatorial positions and N(5) and N(11) are the axial atoms. As seen from Fig. 1c and d, 4 Zn atoms are interlinked through EO bridging azides giving tetranuclear Zn(II) rings or eight-membered ring and these rings are connected successively to form a ladder of 1D double chain along the *b*-axis. The Zn···Zn distances within the four-membered Zn_2N_2 cyclic units are Zn(1)–Zn(2) = 3.2256(11) Å, whereas the Zn–Zn distances within the eight-membered rings Zn_4N_4 are Zn(1)–Zn(2A) = 3.6003(13) Å and Zn(1)–Zn(2B) = 3.5929(13) Å. In the channels between parallel ladders the py-tetrazole molecules are located Fig. 1c and d. The four bridging azido ligands are asymmetric and almost linear with N–N–N angles from 178.3(4)° to 179.7(4)°, whereas the N(1)–N(2)–N(3) and N(2)–N(3)–N(4) angles of the bonded py-tetrazolate molecule are 111.9(3)° and 105.2(3)°, respectively. The four azido groups show pronounced deviations from linearity in the connection with Zn(II) [Zn–N–N angles from 102.23(12)° to 130.1(3)°]. π–π ring–ring interactions are observed between the five- and six-membered rings of adjacent bicyclic $C_5H_{14}N_4$ molecules (Table 3).

3.1.2. Crystal structure of $\{[Zn_2(N_3)_4(3\text{-}OHpy)]\cdot 2H_2O\}_n$ (**2**)

The principle structure features for complex **2** are illustrated in Fig. 2a, along with a labeling scheme, and selected bond lengths and bond angles are collected in Table 4. The X-ray structure determination of **2** revealed that the Zn(II) atoms are linked by four azido groups all behave in the μ-1,1-EO mode and an oxygen atom from the 3-OH-py ligand which means that this hydroxypyridine molecule acts in the tautomeric keto-form, i.e. as pyridone, in the present complex and bridges two Zn(II) atoms, thus behaving as an *O,O*-bidentate bridging ligand, leading to a 2D system, further carrying into a 3D supramolecular network with the help of several hydrogen bonding interactions. Fig. 2b and c, show the 2D system extented along the *b*- and *c*-axes, and a view of the 2D sheet along the *b*-axis of the unit cell. In the coordination chain each Zn(II) center links another Zn(II) center through a bridging EO azide group and O atom of an *O,O*-pyridone bridge giving rise to a four-membered Zn_2NO ring [Zn(1)–N(11) = 1.996(5) Å and Zn(1)–O(1) = 2.107(4) Å], and links a second Zn center via di-EO bridging azides [Zn(1)–N(21) = 2.054(5) Å] forming a four membered Zn_2N_2 unit [Zn(1)–Zn(2) = 3.2097(11) Å] and finally connects a third Zn(II) atom through an EO azide group. Thus, the zinc center is in a five coordinated environment with a ZnN_4O chromophore. The four-membered ring Zn_2NO deviates from planarity with a max. deviation = 0.063(6) Å for [Zn(1)/O(1)/Zn(2)/N(11)] and a maximum deviation = 0.090(6) Å for [Zn(1)/O(1)/Zn(2D)/N(11)]. The stereochemistry of both Zn centers can be best described as distorted TBP with τ-values of 0.67 and 0.61 for Zn(1) and Zn(2), respectively. Around Zn(1) and Zn(2) the equatorial atoms are N(11), N(31), N(21) and N(11), N(21B), N(41A) and the axial atoms are O(1), N(41) and O(1), N(31A), respectively. As

Symmetry codes: (A) $1-x, -1/2+y, 3/2-z$. (B) $1-x, -y, 2-z$. (C) $x, 1/2-y, 1/2+z$. (D) $1-x, 1/2+y, 3/2-z$. (E) $x, 1/2-y, -1/2+z$. (F) $1+x, 1/2-y, 1/2+z$.

can be seen from Fig. 2b, four zinc(II) centers are interconnected by EO azides to afford a tetranuclear ring and eight zinc centers are interconnected to form an octanuclear ring. These two types of rings are the bases for the formation of the 2D sheet. The Zn···Zn distances within the tetranuclear zinc(II) rings are: 3.2097(11) and 3.6318(12) Å; the Zn···Zn separations between opposite pairs of metal centers within the octanuclear zinc(II) rings are in the range from 7.625(2) to 9.714(3) Å. The azide groups are asymmetric and linear [N–N–N angles are from 178.1(7)° to 179.3(7)°], and all of them deviate from linearity in connection with Zn atoms [Zn–N–N angles from 116.1(4)° to 131.6(4)°]. Hydrogen bonds of different types: [O–H···N] between O atom of a lattice water molecule and the end nitrogen atom of an EO azide, or between an oxygen atom of a lattice water and the nitrogen atom of pyridone ligand [N–H···O], and O–H···O between oxygen atoms of lattice water molecules are formed (Table 5). These hydrogen bonds consolidate the structure and lead to the formation of 3D supramolecular network.

3.1.3. Crystal structure of $[Zn(N_3)_2(pym)]_n$ (3)

The principle structural features of complex **3** are shown in Fig. 3a, along with a labeling scheme, and selected bond lengths and bond angles are collected in Table 6. The structure features six coordinate Zn(II) atoms, EE bridging azido ligands and *N*,*N*′-bidentate bridging pym ligand forming a 3D network. In the asymmetric unit, each Zn(II) center is surrounded by four EE azide bridges [Zn(1)–N(2) = 2.151(3) Å, Zn(1)–N(4) = 2.148(3) Å], and two nitrogen atoms from bidentate *N*,*N*′-pyrimidine bridging ligands [Zn(1)–N(1) = 2.188(3) Å] to adopt ZnN_6 chromophore. The 3D system can be seen as zinc-pym chains placed in parallel planes, zinc atoms lie on inversion centers, pym ligands lie across mirror planes and azido ligands lie about 2-fold axes. The four EE azido bridges link each zinc center to two similar chains placed in the upper plane and two similar chains placed in the lower plane. The Zn–N–N bond angles lie around 122.5°. The azido ligands are symmetric [N(2)–N(3) = 1.176(2), N(3)–N(2B) = 1.176(2) Å and N(4)–N(5) = 1.179(2), N(5)–N(4C) = 1.179(2) Å] and linear [N–N–N angles = 178.1(4)° and 179.2(5)°] (Fig. 3b).

3.2. IR and luminescence spectra

The IR spectra of the title complexes in the solid state exhibit the following very strong band associated with the $\nu_{as}(N_3)$ vibration mode: 2012, 2098 cm^{-1}; 2121, 2091 cm^{-1}, and 2078 cm^{-1}, for complexes **1**, **2**, and **3**, respectively. The positions of these bands for **1** and **2** with EO azide bridges only are higher than expected [around 2090, 2070 cm^{-1}, and 2100, 2065 cm^{-1} for **1** and **2**, respectively] if the relationship $\nu_{as}(N_3)$ versus Δd [Δd the difference between the two N–N distances in an azide group] reported earlier [21,22] is valid. The existence of hydrogen bonded lattice water in complex **2** is confirmed by the appearance of broad bands in the range of 3600–2500 cm^{-1}.

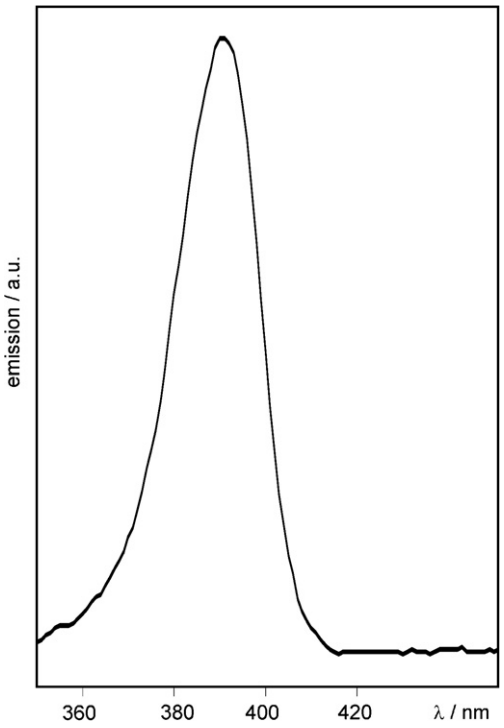

Fig. 4. Luminescence spectrum of **2**.

The photoluminescence properties of the solid zinc(II) complexes have been studied at room temperature. Complexes **1** and **3** do not flouresce, whereas complex **2** exhibits photoluminescence. 3-Hydroxypyridine shows photoluminescence at room temperature with an emission maximum at ca. 390 nm upon excitation at 300 nm. The zinc complex derived from 3-OHpy, **2** exhibits also a strong emission at 390 nm (FWHM: 22 nm) upon excitation at 300 nm (Fig. 4). As Zn(II), Cd(II) and Hg(II) are not easily oxidize or reduce due to their electronic d^{10} configuration, no emission originated from metal centers excited states are expected in case of such cations. Thus the flourescence observed in case of complex **2** is assigned to the intra-ligand flourescence [23,24]. The complexation of the ligands may also increase the rigidity and reduces the loss of energy by thermal vibrational decay. However, 3-OHpy from which complex **2** is derived, in the solid state exist in the keto and enol tautomers, and its flourescence is due to both tautomeric forms. In complex **2**, the 3-OHpy exists only in the keto form, in which the pair of electron remain as in the free ligand. This may explain why both 3-OHpy and its Zn(II) azide complex fluoresce almost at the same wavelength maximum, except that the intensity of the flouresence of the complex is more than twice the intensity of the free 3-OHpy ligand.

4. Discussion

Three zinc(II) azido complexes of three different ligands have been synthesized. In fact the ligand tetrazolo[1,5-*a*]pyridine (py-tetrazole) was prepared through the interac-

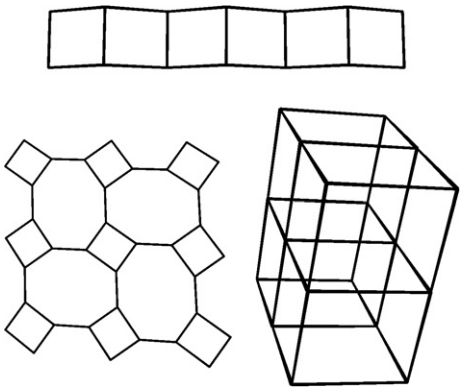

Fig. 5. Simplified representation of the structural motifs observed in complexes **1** (ladder, 1D), **2** (rings, 2D) and **3** (cubes, 3D).

tion of 2-chloropyridine with azide N_3^- ion under hydrothermal conditions, as given in Scheme 1; the py-tetrazole then interacts with zinc(II) azide affording complex **1**. In the case of complex **2**, we started with 3-hydroxypyridine, under reaction condition this ligand seems to prefer to be in the tautomeric keto-form, and we obtained a complex containing the pyridone which behaves as an *O*,*O*-bidentate bridging ligand. As we have seen the structure of complex **1** consists of a ladder-like arrangement in which four zinc centers interconnect through EO bridging azide forming tetranuclear rings and the uncoordinated py-tetrazole molecules are located in the channels between the parallel ladders. This structure is unprecedented in metal azido complexes. The structure of complex **2**, on the other hand, consists of tetranuclear zinc(II) rings fused with octanuclear zinc(II) rings forming 2D sheets, which is carrying into 3D network through the hydrogen bonding interaction. This structure too is unprecedented in known metal azido complexes (Fig. 5). In both complexes **1** and **2** with EO azide bridges only, the Zn–Zn distances within the Zn_2N_2 cyclic units fall well within the range of 3.03–3.31 Å found for other zinc(II) azido complexes containing such units [25]. All EO bridging azides in both complexes are asymmetric [the two N–N lengths within the azide group are different] and linear as reported earlier [26]. Complex **3** contains only EE bridging azido ligands which are symmetrical and linear as usual [26], and its structure resembles that of manganese(II) azide with pyrimidine [27]. In terms of network analysis [28] the topology of **2** may be described as a distorted "4.8^2" 2D net [the lengths of the edges within the tetranuclear rings are 3.210 and 3.632 Å, respectively, and additionally 3.280 Å in the octanuclear rings (Fig. 5, bottom left)]; the topology of **3** as distorted "α-Po" 3D net [the lengths of the edges of the cubes are 5.588, 5.752 and 6.042 Å, respectively (Fig. 5, bottom right)].

5. Conclusions

We isolated three zinc(II) azide complexes with some pyridines and pyrimidine by hydrothermal technique. Although we started with 2-chloropyridine which interacts with the azide ion forming py-tetrazole ligand and the isolated complex found to be $\{[Zn(N_3)_4(\text{py-tetrazole})_2](\text{py-tetrazole})\}_n$ (**1**) which links the zinc ion not through the pyridine nitrogen atom but via a nitrogen atom from the tetrazole part. The ladder-like structure of this complex contains tetranuclear zinc(II) rings. This structure is unprecedented. In complex **2**, the 3-Ohpy, starting reactant found to behave in the tautomeric keto-form and ligated zinc atoms as *O*,*O*-bidentate bridging ligand, in addition to the existence of tetranuclear zinc(II) and octanuclear zinc(II) rings fused together to generate 2D sheets which carrying into 3D supramolecular network with the help of hydrogen bonding. This complex exhibits photoluminescence at room temperature, and is unprecedented too in the metal azide complexes. Complex **3** consists of three-dimensional network. These results prompted us to explore the synthesis of zinc and other metal complexes with 2-, and 4-hydroxypyridines as well as other 2-X-pyridines in presence of azide ion and to explore the photoluminescence of the isolated complexes. Such reactions are under current investigation.

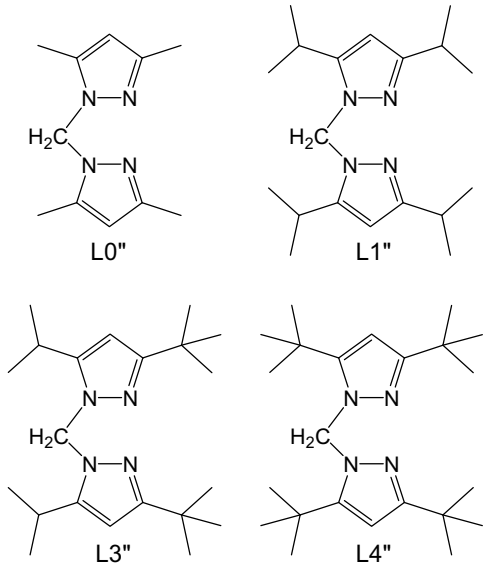

Fig. 1. Structures of N2 bidentate ligands discussed in this work: bis(3,5-dimethyl-1-pyrazolyl)methane (L0″), bis(3,5-diisopropyl-1-pyrazolyl)methane (L1″), bis(3-tertiary-butyl-5-isopropyl-1-pyrazolyl)methane (L3″), bis(3,5-ditertiary-butyl-1-pyrazolyl)methane (L4″).

and many copper(II) complexes with these ligands have been reported. For example, for $[Cu(bipy)X_2]$ ($X = NO_3$ [16], ONO [17], and Cl [18]), $[Cu(en)X'_2]$ ($X' = Cl$ [19] and $N(NO_2)CH_3$ [20]), and $[Cu(phen)(X'')_2]$ ($X'' = NO_3$ [21] and ONO [22]), and $[Cu(napy)(NO_3)_2]$ [23]. Some of the structures of these complexes were clarified by X-ray crystallography. In particular, nitrate and nitrite ions can coordinate to the central copper atom, in a unidentate or bidentate coordination mode. Differences in coordination modes of both nitrate and nitrite ions have been reported by Brill et al. for $[Cu(en)\{N(NO_2)CH_3\}_2]$ [20].

In this work, the copper(II) nitrato complexes $[Cu(L0'')_2(NO_3)]NO_3$ (**1NO$_3$**), $[Cu(L0'')(NO_3)_2]$ (**2**), $[Cu(L1'')(NO_3)_2]$ (**3**), $[Cu(L3'')(NO_3)_2]$ (**4**), and $[Cu(L4'')(NO_3)_2]$ (**5**), the chloro complexes $[Cu(L0'')_2Cl]_2(CuCl_4)$ (**6CuCl$_4$**), $[Cu(L0'')_2Cl]_2(Cu_2Cl_6)$ (**6Cu$_2$Cl$_6$**), $[Cu(L1'')Cl_2]$ (**7**), and $[Cu(L3'')Cl_2]$ (**8**), the nitrito complexes $[Cu(L0'')(ONO)_2]$ (**9**) and $[Cu(L1'')(ONO)_2]$ (**10**), and the complexes with perchlorate ions $[Cu(L0'')_2(CH_3OH)](ClO_4)_2$ (**11ClO$_4$**) and $[Cu(L1'')_2(H_2O)](ClO_4)_2$ (**12ClO$_4$**) were systematically synthesized using four different bpzm ligands that show a difference in bulkiness at the pyrazolyl rings. The complexes $[Cu(L1'')(NO_3)_2]$ (**3**), $[Cu(L1'')Cl_2]$ (**7**), and $[Cu(L1'')(ONO)_2]$ (**10**) with L1″ have been reported before [13,14]. All the complexes were characterized by X-ray crystallography and by IR, far-IR, UV–Vis absorption, and ESR spectroscopy. The influences of the second coordination sphere effects of the ligands on the complexes are examined. The structures and properties of the obtained complexes are also compared with those of the copper(II) complexes having tpzm as an N3 tridentate ligand.

2. Experimental

2.1. Materials

Preparation and handling of all of the complexes was performed under an argon atmosphere using standard Schlenk tube techniques. Dichloromethane were purified by refluxing and distilling under an argon atmosphere over phosphorous pentoxide. Diethyl ether, toluene, and heptane were purified by refluxing and distilling under an argon atmosphere over sodium benzophenone ketyl [24]. Chloroform, methanol, acetone, 2-propanol, and octane were spectroscopic grade and were used after bubbling with an argon gas. NMR solvents were obtained from Cambridge Isotope Laboratories, Inc. Silica gel for ligand purification was obtained from Merck KGaA. Other reagents are commercially available. The syntheses of ligands (L0″ [25], L1″ [13], and L4″ [26]) and complex $(Ph_4P)_2[Cu_2Cl_6]$ [27] and copper(II) complexes using L1″ ($[Cu(L1'')(NO_3)_2]$ (**3**), $[Cu(L1'')Cl_2]$ (**7**), and $[Cu(L1'')(ONO)_2]$ (**10**) [13,14]) were prepared by publish methods.

2.2. Measurements

IR and far-IR spectra were recorded on KBr pellets in the 4000–400 cm^{-1} region and Nujol mull in the 650–150 cm^{-1} region, respectively, using a JASCO FT/IR-550 spectrophotometer. ^1H NMR (600 MHz) and ^{13}C NMR (150 MHz) spectra were obtained on a Bruker AVANCE-600 NMR spectrometer in chloroform at room temperature. UV–Vis absorption spectra in dichloromethane at room temperature in the 240–1840 nm range were recorded with a JASCO V-570 spectrophotometer unless stated otherwise. ESR spectra as frozen solutions (dichloromethane/1,2-dichloroethane (1/1) or methanol/ethanol (9/1)) were recorded on a Bruker EMX-T ESR spectrometer at 140 K in quartz tubes (diameter 5 nm) with liquid nitrogen temperature controller BVT 3000. The elemental analyses (C, H, N) were performed by the Department of Chemistry at the University of Tsukuba.

2.3. Preparation of ligands

2.3.1. $H_2C(3\text{-}tBu\text{-}5\text{-}iPrpz)_2$ L3″

Dichloromethane (130 cm^3) was added to a mixture of 3-tertiary-butyl-5-isopropylpyrazole [28] (6.16 g, 37.1 mmol), potassium carbonate (7.76 g, 56.2 mmol), and tetrabutylammonium hydrogensulfate (2.00 g, 5.89 mmol). This solution was bubbled with an argon gas for 15 min. This solution was then heated and gently refluxed for 2 weeks at ~110 °C (inner temperature of autoclave). During the reaction time, the color of the solution became dark brown. The mixture was allowed to cool to room temperature, and then the insoluble material was filtered off and washed with acetone. The filtrate was evaporated under reduced pressure. The remaining dark brown solid was dissolved in toluene (50 cm^3). The solution was

refluxed for 1 day after addition of a catalytic amount of predried of *p*-toluenesulfonic acid monohydrate (0.11 g, 0.58 mmol). The mixture was allowed to cool to room temperature, and then the solvent was removed under reduced pressure. The obtained solid was dissolved in a 2:1 mixture of dichloromethane/acetone. The solution was chromatographed on a silica gel column using the 2:1 dichloromethane/acetone mixed solvent as eluent. After collection of the corresponding fractions, the solvent was removed under reduced pressure to yield a pale-yellow solid. Crystallization from heptane at −30 °C gave colorless crystals. Yield: 73% (4.70 g, 13.6 mmol). *Anal.* Calc. for $C_{21}H_{36}N_4$: C, 73.21; H, 10.53; N, 16.26. Found: C, 73.30; H, 10.72; N, 16.24%. IR (cm^{-1}): 2962vs, 2866s, 1545s, 1469s, 1384w, 1359s, 1316s, 1234s, 1094m, 1066m, 970m, 801s, 785m, 638w, 415w. ^1H NMR (δ): 1.02 (d, $J_{HH} = 6.8$ Hz, 12H, $CH(CH_3)_2$), 1.25 (s, 18H, $C(CH_3)_3$), 3.40 (sept, $J_{HH} = 6.8$ Hz, 2H, $CH(CH_3)_2$), 5.85 (s, 2H, 4-*H*(pz)), 6.23 (s, 2H, H_2C). ^{13}C NMR (δ): 23.26 ($CH(CH_3)_2$), 24.90 ($CH(CH_3)_2$), 30.50 ($C(CH_3)_3$), 31.99 ($C(CH_3)_3$), 62.29 (H_2C), 99.34 (4-*C*(pz)), 151.3 (3-*C*(pz)), 161.0 (5-*C*(pz)).

2.3.2. $H_2C(3,5\text{-}tBu_2pz)_2$ L4″

An alternative synthetic procedure of L4″ was previously reported [26]. Our synthetic procedure was carried out in the same manner as that of L3″, using 3,5-ditertiary-butylpyrazole [29] (8.00 g, 44.4 mmol), potassium carbonate (8.00 g, 58.0 mmol), and tetrabutylammonium hydrogensulfate (2.30 g, 6.77 mmol) in dichloromethane (120 cm^3). This solution was then heated and gently refluxed for 2 weeks at ~110 °C (inner temperature of autoclave). The chloroform solution was chromatographed on a silica gel column. The desired fractions were eluted using chloroform. Crystallization from heptane at −30 °C gave colorless crystals. Yield: 53% (4.36 g, 11.7 mmol). *Anal.* Calc. for $C_{23}H_{40}N_4$: C, 74.14; H, 10.82; N, 15.04. Found: C, 74.17; H, 10.86; N, 15.07%. IR (cm^{-1}): 2962vs, 1542s, 1461s, 1397m, 1362s, 1312s, 1261s, 1229s, 1093m, 795vs, 774m, 685w, 404m. ^1H NMR (δ): 1.20 (s, 18H, $C(CH_3)_3$), 1.24 (s, 18H, $C(CH_3)_3$), 5.90 (s, 2H, 4-*H*(pz)), 6.51 (s, 2H, H_2C). ^{13}C NMR (δ): 28.66 ($CH(CH_3)_3$), 29.37 ($CH(CH_3)_3$), 30.86 ($C(CH_3)_3$), 30.89 ($C(CH_3)_3$), 65.83 (H_2C), 101.0 (pz-4*C*), 151.9 (pz-3*C*), 157.9 (pz-5*C*).

2.4. Preparations of complexes

2.4.1. $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2(NO_3)]NO_3$, $[Cu(L0'')_2(NO_3)]NO_3$ (**1NO$_3$**)

To a solution of L0″ (0.30 g, 1.47 mmol) in dichloromethane (20 cm^3) was added a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.20 g, 0.81 mmol) in acetone (20 cm^3). After stirring for 1 h, the solvent was removed under reduced pressure, and a light blue solid was obtained. Slow crystallization from methanol/acetone (4/1) solution at room temperature gave light blue crystals. Yield: 19% (104 mg, 0.174 mmol). *Anal.* Calc. for $C_{22}H_{32}CuN_{10}O_6$: C, 44.33; H, 5.41; N, 23.50. Found: C, 44.11; H, 5.46; N, 23.08%. IR (cm^{-1}): 3428w, 3131w, 3018w, 1557vs, 1480s, 1383s, 1285s, 1040m, 1017m, 833m, 808m, 681m. far-IR (cm^{-1}): 646w, 640w, 628w, 495m, 479m, 440w, 418w, 365m, 351m, 341m, 301vs, 269vs, 254s, 208w, 192m. UV–Vis λ/nm (ε/mol^{-1} dm^3 cm^{-1}) (CH_3OH): 696 (70). ESR (CH_3OH/CH_3CH_2OH (9/1) 140 K): $g_{\|}$, 2.30 ($A_{\|}$, 153 G); $g_{\perp}$, 2.07.

2.4.2. $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}(NO_3)_2]$, $[Cu(L0'')(NO_3)_2]$ (**2**)

The synthetic procedure was the same as **1NO$_3$**, except the ratio of the raw substrates and crystallization solvents. To a solution of L0″ (0.20 g, 0.98 mmol) in dichloromethane (20 cm^3) was added a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.237 g, 0.98 mmol) in acetone (20 cm^3). After stirring for 2 h, the solvent was removed under reduced pressure, and a light blue solid was obtained. After extracting with dichloromethane, crystallization from dichloromethane/heptane (1/1) at −30 °C gave light blue crystals. Yield: 11% (42.5 mg, 0.108 mmol). *Anal.* Calc. for $C_{11}H_{16}CuN_6O_6 \cdot 0.25(CH_2Cl_2)$: C, 32.71; H, 4.03; N, 20.35. Found: C, 32.88; H, 4.22; N, 20.36%. IR (cm^{-1}): 3447m, 3045w, 1556m, 1517m, 1469m, 1383vs, 1273vs, 1052w, 1024w, 1006s, 806s, 795s, 678m. far-IR (cm^{-1}): 642w, 629m, 496m, 479w, 416w, 363m, 332vs, 301vs, 277vs, 245m, 175m. UV–Vis λ/nm (ε/mol^{-1} dm^3 cm^{-1}): 739 (100), 295 (2820). ESR (CH_2Cl_2/CH_2ClCH_2Cl (1/1) 140 K): $g_{\|}$, 2.29 ($A_{\|}$, 158 G); $g_{\perp}$, 2.06.

2.4.3. $[Cu\{H_2C(3\text{-}tBu\text{-}5\text{-}iPrpz)_2\}(NO_3)_2]$, $[Cu(L3'')(NO_3)_2]$ (**4**)

To a solution of L3″ (0.20 g, 0.58 mmol) in dichloromethane (15 cm^3) was added a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.154 g, 0.64 mmol) in acetone (20 cm^3). After stirring for 1 h, the solvent was removed under reduced pressure, and a purple solid was obtained. Slow crystallization from dichloromethane/heptane (1/1) gave purple crystals. Yield: 63% (193 mg, 0.36 mmol). *Anal.* Calc. for $C_{21}H_{36}CuN_6O_6$: C, 47.40; H, 6.82; N, 15.79. Found: C, 47.24; H, 6.73; N, 15.48%. IR (cm^{-1}): 3474m, 3028m, 2969s, 2935m, 2869m, 1550s, 1502vs, 1483s, 1439s, 1384vs, 1364s, 1306s, 1267s, 1232s, 1069m, 1020s, 1004s, 990m, 807s, 768m far-IR (cm^{-1}): 633m, 543w, 505w, 475w, 433w, 409w, 392w, 373w, 348vs, 324m, 308vs, 301m, 276w, 244w, 200w, 171m. UV–Vis λ/nm (ε/mol^{-1} dm^3 cm^{-1}): 634 (90), 307 (2790). ESR (CH_2Cl_2/CH_2ClCH_2Cl (1/1) 140 K): $g_{\|}$, 2.28 ($A_{\|}$, 169 G); $g_{\perp}$, 2.06.

2.4.4. $[Cu\{H_2C(3,5\text{-}tBu_2pz)_2\}(NO_3)_2]$, $[Cu(L4'')(NO_3)_2]$ (**5**)

To a solution of L4″ (0.40 g, 1.07 mmol) in dichloromethane (20 cm^3) was added a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.285 g, 1.18 mmol) in acetone (20 cm^3). After stirring for 1 h, the solvent was removed under reduced pressure, and a deep blue solid was obtained. Crystallization from dichloromethane/heptane (1/1) at −30 °C gave

deep blue crystals. Yield: 64% (389 mg, 0.69 mmol). *Anal.* Calc. for $C_{23}H_{40}CuN_6O_6 \cdot 0.5H_2O$: C, 48.54; H, 7.26; N, 14.77. Found: C, 48.23; H, 7.17; N, 14.68%. IR (cm^{-1}): 3463m, 2965vs, 1542m, 1500vs, 1383vs, 1283vs, 1225w, 1018m, 1001m, 805s, 755w, 419m. far-IR (cm^{-1}): 638w, 614w, 566w, 472w, 395w, 381w, 373w, 339s, 322m, 312s, 300m, 277w, 180w, 158w. UV–Vis λ/nm (ε/mol^{-1} dm^3 cm^{-1}): 589 (120), 301 (2290). ESR (CH_2Cl_2/CH_2ClCH_2Cl (1/1) 140 K): $g_{\|}$, 2.28 ($A_{\|}$, 172 G); $g_{\perp}$, 2.06.

2.4.5. *[Cu{H$_2$C(3,5-Me$_2$ pz)$_2$}$_2$Cl]$_2$(CuCl$_4$), [Cu(L0″)$_2$Cl]$_2$(CuCl$_4$) (**6CuCl$_4$**)*

To a solution of L0″ (0.30 g, 1.47 mmol) in dichloromethane (15 cm^3) was added a solution of $CuCl_2 \cdot 2H_2O$ (0.14 g, 0.81 mmol) in acetone (20 cm^3). After stirring for 1 h, the solvent was removed under reduced pressure, and a green solid was obtained. Crystallization from acetone/toluene (6/1) at −15 °C gave green crystals. Yield: 57% (260 mg, 0.21 mmol). *Anal.* Calc. for $C_{44}H_{64}Cl_6Cu_3N_{16} \cdot 3H_2O \cdot (CH_3)_2CO$: C, 42.36; H, 5.74; N, 16.82. Found: C, 42.36; H, 5.58; N, 16.92%. IR (cm^{-1}): 3504m, 3129w, 3012m, 2962w, 2922w, 1708s, 1557s, 1465m, 1419m, 1368m, 1282vs, 1219m, 1056w, 1042m, 1001w, 834w, 814w, 786w, 678m. far-IR (cm^{-1}): 627w, 528w, 495w, 476w, 434w, 391w, 349m, 296vs, 263w, 251w, 244w, 223w, 186w, 176w. UV–Vis λ/nm (ε/Cu^{-1} mol^{-1} dm^3 cm^{-1}): 908 (130), 287 (3980). ESR (CH_2Cl_2/CH_2ClCH_2Cl (1/1) 140 K): $g_{\|}$, 2.27 ($A_{\|}$, 148 G); $g_{\perp}$, 2.09.

2.4.6. *[Cu{H$_2$C(3,5-Me$_2$ pz)$_2$}$_2$Cl]$_2$(Cu$_2$Cl$_6$), [Cu(L0″)$_2$Cl]$_2$(Cu$_2$Cl$_6$) (**6Cu$_2$Cl$_6$**)*

A synthetic procedure is the same as **6CuCl$_4$**, except the ratio of the raw substrates and crystallization solvents. To a solution of L0″ (0.40 g, 1.96 mmol) in dichloromethane (15 cm^3) was added a solution of $CuCl_2 \cdot 2H_2O$ (0.37 g, 2.15 mmol) in acetone (20 cm^3). After stirring for 1 h, the solvent was removed under reduced pressure, and a deep green solid was obtained. Crystallization from dichloromethane/octane (2/1) at −15 °C gave deep green crystals. Yield: 84% (565 mg, 0.41 mmol). *Anal.* Calc. for $C_{44}H_{76}Cl_8Cu_4N_{16} \cdot 2CH_2Cl_2$: C, 36.23; H, 4.50; N, 14.70. Found: C, 36.66; H, 4.77; N, 14.39%. IR (cm^{-1}): 3467m, 3126w, 3024w, 2923w, 1626w, 1557vs, 1465s, 1388m, 1284vs, 1153w, 1043s, 824s, 677m. far-IR (cm^{-1}): 644m, 627s, 591w, 497w, 475m, 419w, 398w, 333s, 302s, 276m, 267m, 251s, 225s, 186s. UV–Vis λ/nm (ε/Cu^{-1} mol^{-1} dm^3 cm^{-1}): 893 (130), 287 (3840). ESR (CH_2Cl_2/CH_2ClCH_2Cl (1/1) 140 K): $g_{\|}$, 2.32 ($A_{\|}$, 146 G); $g_{\perp}$, 2.11.

2.4.7. *[Cu{H$_2$C(3-tBu-5-iPrpz)$_2$}Cl$_2$], [Cu(L3″)Cl$_2$] (**8**)*

To a solution of L3″ (0.40 g, 1.16 mmol) in dichloromethane (15 cm^3) was added a solution of $CuCl_2 \cdot 2H_2O$ (0.22 g, 1.29 mmol) in acetone (20 cm^3). After stirring for 1 h, the solvent was removed under reduced pressure, and a dark brown solid was obtained. Crystallization from chloroform/heptane (3/2) at −50 °C gave orange crystals. Yield: 47% (263 mg, 0.55 mmol). *Anal.* Calc. for $C_{21}H_{36}Cl_2CuN_4$: C, 52.66; H, 7.58; N, 11.70. Found: C, 52.22; H, 7.47; N, 11.52%. IR (cm^{-1}): 3445m, 2963s, 2867w, 1616w, 1545m, 1459m, 1360m, 1316m, 1234s, 1094, 801s, 409s. far-IR (cm^{-1}): 641m, 622w, 307m, 300vs, 244m, 183s. UV–Vis λ/nm (ε/mol^{-1} dm^3 cm^{-1}): 848 (150), 387 (940), 287 (3330). ESR (CH_2Cl_2/CH_2ClCH_2Cl (1/1) 140 K): $g_{\|}$, 2.27 ($A_{\|}$, 140 G); $g_{\perp}$, 2.08.

2.4.8. *[Cu{H$_2$C(3,5-Me$_2$pz)$_2$}(ONO)$_2$], [Cu(L0″)(ONO)$_2$] (**9**)*

To a solution of [Cu(L0″)$_2$Cl]$_2$(Cu$_2$Cl$_6$) **6Cu$_2$Cl$_6$** (0.56 g, 0.41 mmol) in dichloromethane (25 cm^3) was added a solution of $NaNO_2$ (0.23 g, 3.33 mmol) in methanol (15 cm^3). After stirring for 1 h, the solvent was removed under reduced pressure, and a deep green solid was obtained. Crystallization from dichloromethane/diethyl ether (2/1) at −15 °C gave green crystals. Yield: 34% (217 mg, 0.60 mmol). *Anal.* Calc. for $C_{11}H_{16}CuN_6O_4 \cdot 0.25(C_2H_5)_2O$: C, 38.09; H, 4.93; N, 22.21. Found: C, 38.77; H, 4.76; N, 22.30%. IR (cm^{-1}): 3460w, 2963m, 1556m, 1467w, 1371w, 1262s, 1199w, 1096w, 1024w, 798vs, 677w, 525w. far-IR (cm^{-1}): 635w, 615w, 604w, 590w, 494m, 478m, 374vs, 342m, 313m, 288w, 260w, 210w, 197w, 153m. 2.5. X-ray data collections and structural determinations

Crystal data and refinement parameters for the investigated ligands (L3″ and L4″) and the copper(II) complexes (**1NO$_3$**, **2**, **4**, **5**, **6CuCl$_4$**, **6Cu$_2$Cl$_6$**, **8**, **9**, **11ClO$_4$**, **12ClO$_4$**) are given in Tables 1, 2. The diffraction data were measured on a Rigaku/MSC Mercury CCD system with graphite monochromated Mo Kα ($\lambda = 0.71069$ Å) radiation at low temperature. Each crystal was mounted on the tip of a glass fiber by heavy-weight oil. The unit cell parameters of each crystal from six image frames were retrieved using Rigaku Daemon software and refined using CrystalClear on all observed reflection [30]. Data using 0.5° intervals in ϕ and ω for 20 s/frame (L3″ and **9**), for 40 s/frame (L4″ and **1NO$_3$**), for 45 s/frame (**2**), for 60 s/frame (**5** and **8**), for 30 s/frame (**6CuCl$_4$**, **6Cu$_2$Cl$_6$**, and **12ClO$_4$**), and for 35 s/frame (**4** and **11ClO$_4$**) were collected with a maximum two theta value of 55° (744 oscillation images). The highly redundant data sets were reduced using CrystalClear and corrected for Lorentz and polarization effects. An empirical absorption correction was applied for each complex [30–32]. Structures were solved by direct-methods (SIR92 [33] or SIR97 [34]). The position of the metal atoms and their first coordination sphere were located from the *E*-map; other non-hydrogen atoms were found in alternating difference Fourier syntheses (DIRDIF99 [35]) and least-squares refinement cycles were refined anisotropically during the final cycles (CrystalStructure) [31,32]. Hydrogen atoms were refined using the riding model. A Sheldick weighting scheme was employed except for **1NO$_3$** and **6CuCl$_4$**. Strong remaining peaks of **6Cu$_2$Cl$_6$**, and **9** are due to the disordered solvents and nitrite ions, respectively. The low qualities of crystalline of **1NO$_3$** and **6CuCl$_4$** were observed. The absolute structure of **1NO$_3$** was deduced based on Flack parameter, 0.024(18), refined using 2569 Friedel pairs [36].

3. Results and discussion

3.1. Synthesis

The synthetic methods for various bpzm ligands were reported by Trofimenko [37] and were modified by Elguero et al. [25]. Referring to the reported methods, the reaction of pyrazole with dichloromethane in an autoclave was carried out, and this way, the desired bpzm ligands could be obtained in high yield. The desired isomer of L3″ could be selectively synthesized by the reported method [38].

To avoid reactions with atmospheric moisture, all complexes were synthesized under an argon atmosphere. Schematic drawings of all complex preparations performed in this work are summarized in Scheme 1. Copper(II) nitrato complexes were synthesized with all four bpzm ligands presented here. In the case of L0″, two kinds of complexes, **1NO$_3$** and **2**, were obtained. They differ in the ligand to copper(II) ratio: Cu:L0″=1:2 in **1NO$_3$** versus Cu:L0″ = 1:1 in **2**. Both complexes **1NO$_3$** and **2** can be separated due to their different solubility in dichloromethane. Complexes **4** and **5** were synthesized by the method reported for **3** [13]. By the reaction of L0″ with $CuCl_2 \cdot 2H_2O$, two kinds of chloro complexes were obtained. The ratio of $CuCl_2$ to L0″ is different in these compounds: $CuCl_2$:L0″ = 3:4 in **6CuCl$_4$**, and $CuCl_2$:L0″ = 1:1 in **6Cu$_2$Cl$_6$**. Structures of the anions ($CuCl_4^{2-}$ in **6CuCl$_4$** and $Cu_2Cl_6^{2-}$ in **6Cu$_2$Cl$_6$**) have already been reported [27,39]. These complexes were selectively obtained by changing the ratio of the substrates

Scheme 1. Schematic drawing of each reaction for this work.

in the reaction, and the solvent used for crystallization. In the case of L1″ and L3″, the copper(II) to ligand ratio in the chloro complexes **7** [14] and **8** is 1:1. On the other hand, in the case of L4″, the chloro complex could not be synthesized, since this complex is very unstable due to the steric repulsion with the ligand. The nitrito complexes **9** and **10** were obtained from the corresponding chloro complexes $\mathbf{6Cu_2Cl_6}$ and **7**. In the case of L3″, the corresponding nitrito complex could not be obtained due to the low stability of **8** in methanol. The complexes with perchlorate ions, $\mathbf{11ClO_4}$ and $\mathbf{12ClO_4}$, contain two molecules of bpzm. Despite the preparation under the same conditions, different solvates were found in these cases (methanol in $\mathbf{11ClO_4}$ and water in $\mathbf{12ClO_4}$). Methanol cannot coordinate to the copper ion because of the bulkier pyrazolyl substituents in $\mathbf{12ClO_4}$. In the case of L3″ and L4″, the complexes with the perchlorate ions could not be isolated.

3.2. Crystal structures

The novel N2 bidentate ligand L3″ and the most hindered N2 bidentate ligand L4″ in this work were obtained as suitable crystals and their structures were determined by X-ray crystallography. ORTEP drawings of L3″ and L4″ are shown in Figs. S1 and S2, respectively. Selected bond distances and angles are listed in Tables S1 and S2, respectively. In the case of L3″, the substituent at the 3rd position of the pyrazolyl rings is the tertiary-butyl group. The increase in steric repulsion in L4″ is evident from the slightly larger C(methylene)–N bond lengths (1.462 Å in L4″ versus 1.450 Å in L3″) and more obtuse N–C(methylene)–N angles (115.5(1)° in L4″ versus 113.4(2)° in L3″). Moreover, differences in bond lengths and angles are found in the complexes derived from each of the ligands, showing the second coordination sphere effects.

Complexes $\mathbf{1NO_3}$, **2**, **4**, **5**, $\mathbf{6CuCl_4}$, $\mathbf{6Cu_2Cl_6}$, **8**, **9**, $\mathbf{11ClO_4}$, and $\mathbf{12ClO_4}$ were obtained as suitable crystals and their structures were determined by X-ray crystallography. All the complexes have a mononuclear structure. ORTEP drawings of these complexes are shown in Figs. 2, 3 and S3. Crystal structures of **3**, **7**, and **10** have been reported previously [13,14]. Selected structural parameters for the nitrato and nitrito complexes $\mathbf{1NO_3}$–**5** and **9**–**10** (Table 3), the chloro complexes **6**–**8** (Tables 4 and S3), and the solvate complexes $\mathbf{11ClO_4}$ and $\mathbf{12ClO_4}$ (Table 5) are listed as indicated.

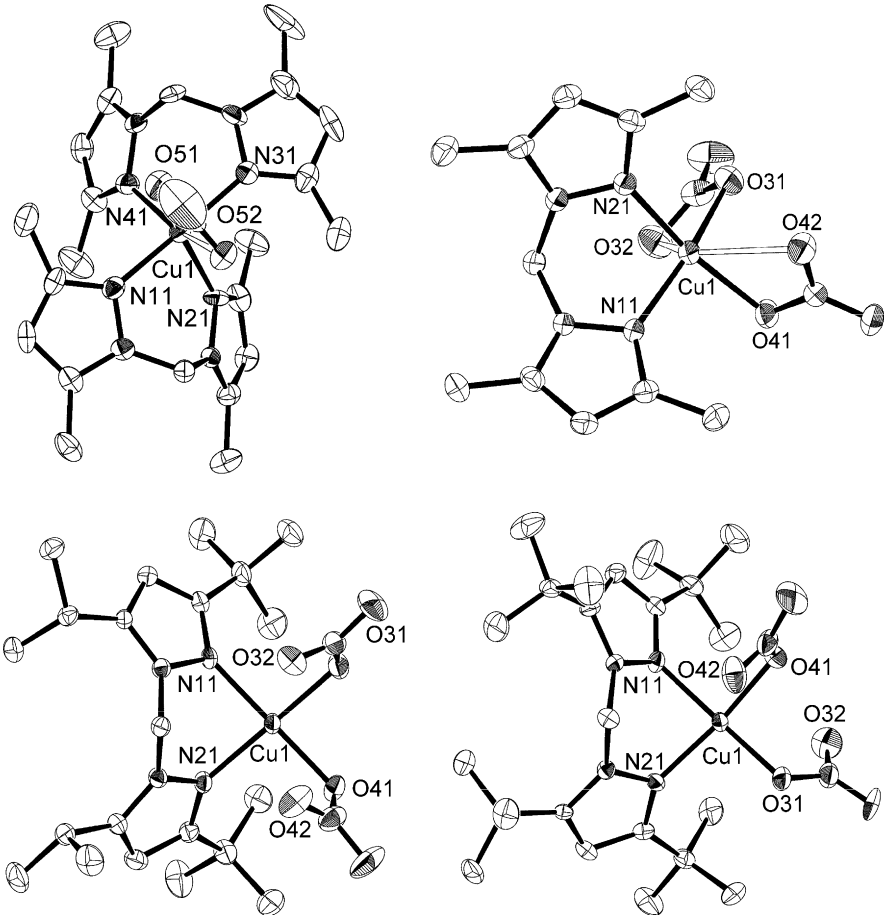

Fig. 2. Crystal structures of $[Cu(L0'')_2(NO_3)]^+$ (the cation portion of $\mathbf{1NO_3}$) (top left), $[Cu(L0'')(NO_3)_2]$ (**2**) (top right), $[Cu(L3'')(NO_3)_2]$ (**4**) (bottom left), and $[Cu(L4'')(NO_3)_2]$ (**5**) (bottom right).

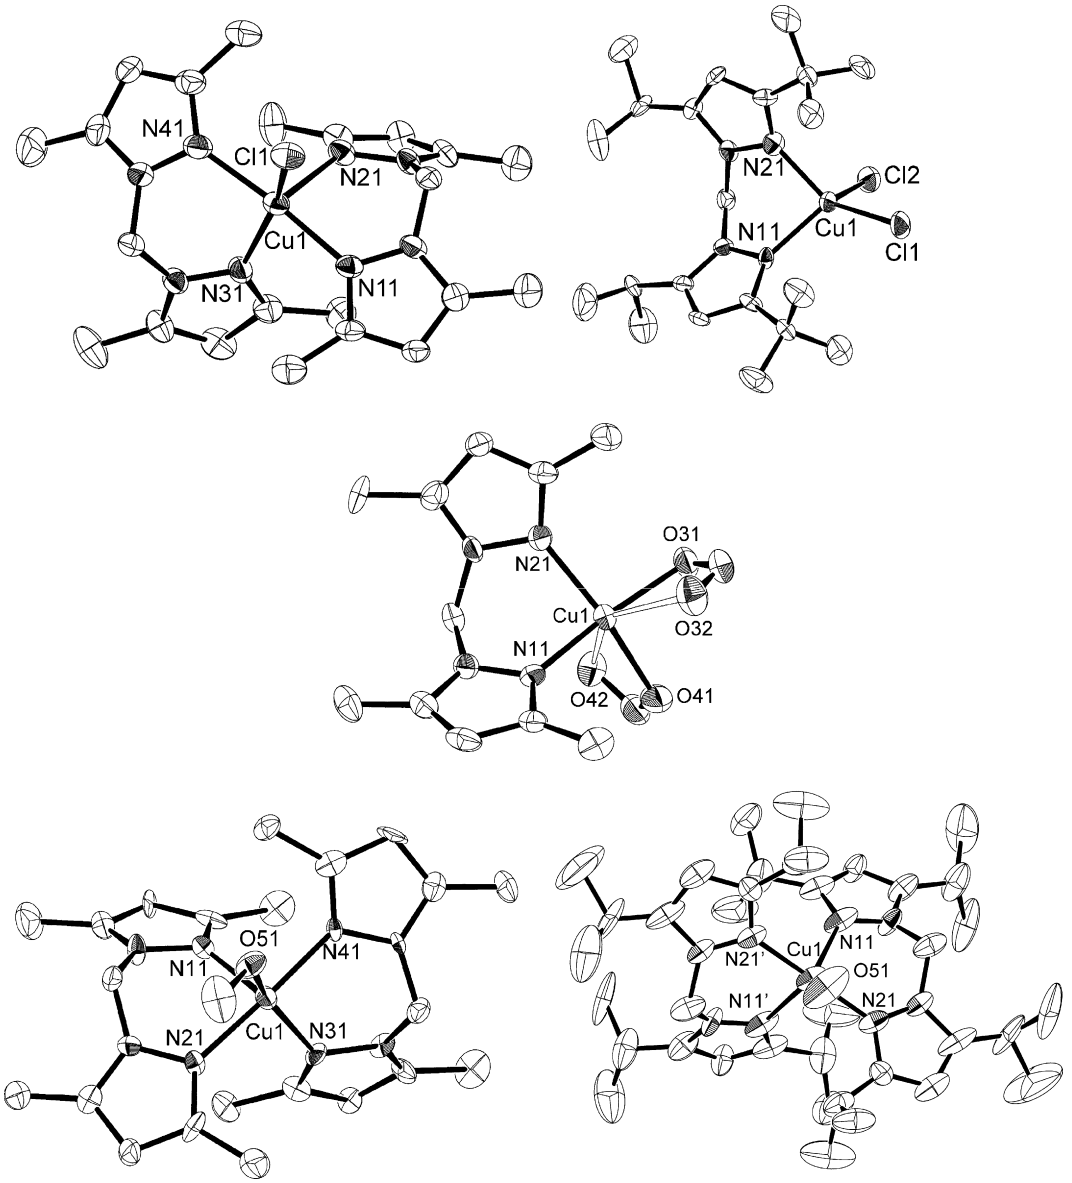

Fig. 3. Crystal structures of $[Cu(L0'')_2Cl]^+$ (the cation portion of **6CuCl$_4$**) (top left), $[Cu(L3'')Cl_2]$ (**8**) (top right), $[Cu(L0'')(ONO)_2]$ (**9**) (center), $[Cu(L0'')_2(CH_3OH)]^{2+}$ (the cation portion of **11ClO$_4$**) (bottom left), and $[Cu(L1'')_2(H_2O)]^{2+}$ (the cation portion of **12ClO$_4$**) (bottom right) (symmetry codes: $-X+2,\ Y,\ -Z+1/2$).

In this study, a distance of less than 2.25 Å between copper and an oxygen atom is identified as a Cu–O bond. In addition, Brill et al. regard an atomic distance of less than 2.50 Å as an indicator for the presence of a distinct Cu–O′ interaction [20]. All copper(II) nitrato and nitrito complexes exhibit a plane around the copper atom. The structures of these complexes are categorized as three types:

(a) Complexes where the copper atom is coordinated by two bpzm ligands and one nitrate (or nitrite) ion, showing a (close to) bidentate coordination mode of the nitrate (or nitrite) ion;
(b) Complexes where the copper atom is coordinated by one bpzm ligand and two nitrate (or nitrite) ions, showing a (close to) bidentate coordination mode of the nitrate (or nitrite) ions;
(c) Complexes that contain the same ligand to ion ratio as (b), but the coordination mode of the nitrate ion(s) is close to monodentate.

The coordination mode of the nitrate (or nitrite) ions is also judged by three additional indicators: equivalence of Cu–O and Cu–O′ bond lengths, equivalence of Cu–O–N and Cu–O′–N bond angles, and the O′–N–O bond angle. When these bond lengths and angles are equivalent, the coordination mode of the nitrate (or nitrite) ions is close to bidentate. When the O′–N–O bond angle is small, the coordination mode of these ions is almost symmetric bidentate. In Table 3, **1NO$_3$**, $[Cu(bipy)_2(ONO)]NO_3$ [40], and $[Ni(L0'')_2(NO_3)]NO_3$ [42] are included as type (a). Owing to the small bulkiness of the substituents in L0″, the steric repulsion between ligands is the smallest in **1NO$_3$**. Since

bond lengths of Cu–O and Cu–O′ are within 2.25 and 2.50 Å, respectively, the coordination mode of the nitrate ion is close to asymmetric bidentate in this case. **1NO$_3$** shows a distorted octahedral structure. These structures are clearly different from $[Ni(L0'')_2(NO_3)]NO_3$, in the case of which the coordination mode of the nitrate ion is close to symmetric bidentate [42]. Complexes **2**, **3**, **9**, **10**, $[Cu(bipy)(NO_3)_2]$ [16], $[Cu(bipy)(ONO)_2]$ [17], and $[Cu(phen)(ONO)_2]$ [22] belong to the type (b); the bond lengths of Cu–O and Cu–O′ are within 2.01 and 2.50 Å, respectively. Therefore, the coordination mode of the two ions is asymmetric bidentate. For the nitrato complexes of type (b), the Cu–O′–N angles (82.6° in **2** and 82.7° in **3**) are reduced, whereas the Cu–O–N angles (103.3° in **2** and 102.9° in **3**) are enlarged, as compared to **1NO$_3$** (Cu–O′–N angle: 85.9(3)° and Cu–O–N angle: 102.6(3)°). In addition, the O′–N–O angles (118.0° in **2** and 117.0° in **3**) are enlarged compared to the O′–N–O angle of **1NO$_3$** (116.4(4)°). Therefore, the coordination mode of the nitrate ions in **2** and **3** is close to monodentate compared to that of **1NO$_3$**. Owing to nonequivalent Cu–O and Cu–O′ bond lengths in **2**, **3**, **9**, **10**, $[Cu(bipy)(NO_3)_2]$ [16], $[Cu(bipy)(ONO)_2]$ [17], and $[Cu(phen)(ONO)_2]$ [22], these complexes show a highly distorted octahedral structure. Complexes **4**, **5**, and $[Cu(phen)(NO_3)_2]$ [21] correspond to type (c). The Cu–O and Cu–O′ bond lengths of type (c) become more nonequivalent compared to type (b), due to the increased steric repulsion related to the larger bulkiness of the pyrazolyl substituents. The Cu–O′ bond lengths of type (c) are extended to 2.6 Å. Therefore, the coordination mode of two nitrate ions is almost monodentate. As compared to type (b), the Cu–O′–N angles (78.0° in **4** and 77.8° in **5**) and the N–Cu–N angles (86.82(16)° in **4** and 89.37(19)° in **5**) of type (c) are reduced, while the Cu–O–N angles

(111.0° in **4** and 110.4° in **5**) are enlarged. On the other hand, when an N3 tridentate ligand like tris(3,5-diisopropyl-1-pyrazolyl)methane (L1′) is used, the five-coordinate complex $[Cu(L1')(NO_3)_2]$ is obtained [10]. This complex shows a square pyramidal geometry. In addition, the tris(3,5-ditertiary-butyl-1-pyrazolyl)methane (L4′) ligand could not even be synthesized. As described above, in the case of L4″, the nitrato complex **5** could be prepared. This result proves the difference in the properties of the two ligand systems (N2 bidentate versus N3 tridentate).

In the copper(II) chloro complexes, the cation $[Cu(L0'')_2Cl]^+$ (cation of **6CuCl$_4$** or **6Cu$_2$Cl$_6$**) contains the copper(II) ion and the ligand L0″ in the ratio of 1:2. This cationic complex forms an N4 plane around the copper ion. As listed in Table 4, the structures of these cation complexes are very close to $[Cu(phen)_2Cl]Cl$ [43], $[Cu(phen)_2Cl]ClO_4$ [44], $[Cu(bipy)_2Cl]PF_6$ [45], and $[Cu(bipy)_2Cl]BF_4$ [46]. The structures of the copper ions in **7** and **8** are tetrahedral due to the larger bulkiness of the pyrazolyl rings compared to L0″. The Cl–Cu–Cl angle (98.75(13)°) in **8** is more acute than that (103.67(6)°) in **7**, and the average Cu–Cl distance (2.026 Å) in **8** is longer than that (1.990 Å) in **7** because of the steric repulsion resulting from the larger bulkiness of the substituents in **8**. In our previous study, the five-coordinate chloro complex $[Cu(L1')Cl_2]$ was obtained [10]. This complex $[Cu(L1')Cl_2]$ has a square pyramidal structure with two chloride ions and three nitrogen atoms bound to copper. Therefore, the coordination number and the structure of this complex are also clearly different from those of **7** and **8**. Moreover, the average Cu–N distance (2.140 Å) in $[Cu(L1')Cl_2]$ is the largest of all complexes included in Table 4. In the case of L3′, the corresponding chloro complex could not be isolated. This result also relates to the difference in the number of donor atoms between the N2 bidentate and N3 tridentate ligands.

Two complexes with perchlorate ions show a copper atom to ligand ratio of 1:2. The two perchlorate anions exist only as counter anions due to the lower coordination ability compared to nitrate, nitrite, and chloride anions. In **11ClO$_4$**, the copper(II) ion is coordinated by two bpzm ligands and one molecule of methanol. The τ value of **11ClO$_4$** is 0.37, showing a distorted square pyramidal structure [47], where the structural parameter τ is defined as $\tau = (\alpha - \beta)/60°$, where α and β are the largest angles ($\alpha > \beta$) around a five-coordinate metal center (τ is equal to 0 for an ideal square pyramidal geometry, while for a perfect trigonal bipyramidal geometry it becomes 1). Moreover, the coordinated methanol remains bound under reduced pressure. Although two L1″ ligands coordinate to the copper(II) ion in **12ClO$_4$**, one molecule of water is coordinated instead of methanol. Despite of the same crystallization conditions, the copper(II) ion is coordinated by different solvents in **11ClO$_4$** and **12ClO$_4$**, because of the steric repulsion around the copper atom. Nevertheless, the Cu–O bond length of **11ClO$_4$** (2.039(8) Å) is almost the same as that of **12ClO$_4$** (2.044(8) Å). The τ value of **12ClO$_4$** is 0.64, showing a distorted trigonal bipyramidal structure [47]. In addition, the color of **12ClO$_4$** changed from green to red under reduced pressure. This change suggests the dissociation of water from **12ClO$_4$**, and the IR peak corresponding to the stretching vibration of ν(O–H) disappeared in the red solid. As shown in Table 5, many copper(II) aqua complexes with other N2 bidentate ligands have been reported [48–57]. However, compared to **11ClO$_4$**, there are only a few reports of complexes containing coordinated methanol [51–54].

3.3. IR spectra

In the middle-IR region, characteristic absorptions for $\nu_{as}(NO_2)$, $\nu_s(NO_2)$, ν(NO), and $\delta(NO_2)$ for the bidentate and monodentate nitrate ions are predicted [13,58–66]. Since **1NO$_3$**–**5** exhibit asymmetric bidentate or almost asymmetric bidentate or monodentate binding modes of the nitrate ions, they showed four bands; $\nu_{as}(NO_2)$: 1500–1557 cm^{-1}, $\nu_s(NO_2)$: 1267–1285 cm^{-1}, ν(NO): 1001–1020 cm^{-1}, and $\delta(NO_2)$: 805–808 cm^{-1} [58–61] (Fig. 4). Because the N–O bond lengths of the nitrate ions are almost the same in **2**–**5**, these peaks are observed at almost the same positions in the IR spectra, and no effect of the coordination mode of the nitrate ions on the IR spectroscopic property was observed. Furthermore, because the NO_3 groups do not extend themselves on the same side in **4**, one more peak at 1306 cm^{-1} is observed on the higher energy side. Moreover, **1NO$_3$** exhibits more complicated vibrational spectra compared to **2**–**5**, since **1NO$_3$** has a nitrate counter anion and an asymmetrically bidentate coordinated nitrate ion that exhibits different Cu–O bond lengths. The peaks at 833 cm^{-1} and around 1480 cm^{-1} come from the counter nitrate anion. The peak of $\nu_{as}(NO_2)$ (1557 cm^{-1}) in **1NO$_3$** is shifted to higher energy compared to **2**–**5**.

[a] Ref. [47].
[b] Six-coordinate complexes.

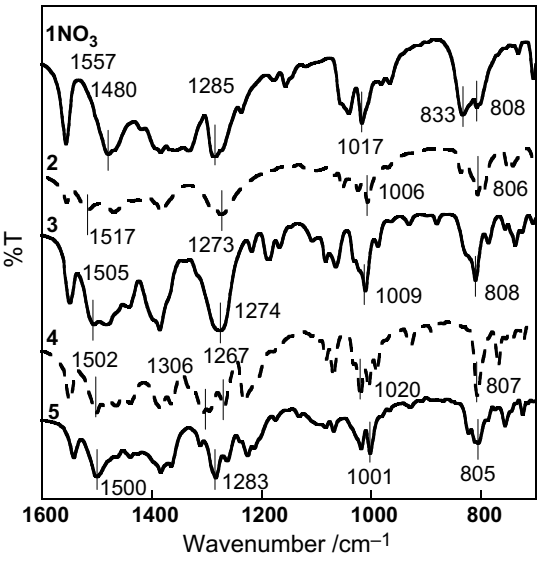

Fig. 4. IR spectra of copper(II) nitrato complexes **1NO$_3$**–**5**.

In the case of the chloro complexes, no characteristic absorptions are observed in the middle-IR region. The N–O stretching bands of the nitrito complexes **9** and **10** are indicated in the IR spectra in Fig. S4. In this case, three characteristic peaks are in observed: ν_s(N–O), ν_{as}(N–O), and δ(O–N–O) [13,58,63]. In **10**, the features at 1346, 1181, and 849 cm^{-1} have been assigned to ν_s(N–O), ν_{as}(N–O), and δ(O–N–O), respectively, by using [Cu(L1″)(O^{15}NO)$_2$] [13]. The N–O stretching bands in **9** are also assigned with respect to those of **10** as ν_s(N–O) at 1371, ν_{as}(N–O) at 1199, and δ(O–N–O) around 850 cm^{-1}. Moreover, no influence of the Cu–O′ bond on these vibrational properties was observed for the nitrito complexes. As shown in Fig. S5, two peaks resulting from the perchlorate ions are observed for **11ClO$_4$** and **12ClO$_4$**. The perchlorate ions show intense stretching vibrations at 1101 cm^{-1} and around 622 cm^{-1}. Both peaks are observed in all the complexes having perchlorate counter ions [58,61]. The ν(O–H) peak due to the coordinated methanol in **11ClO$_4$** is not observed. This lack of ν(O–H) in the IR spectrum is also observed for [Mn(L1′)Br(CH$_3$OH)$_2$]Br [12]. On the other hand, the ν(O–H) peak of the coordinated water is in fact observed at 3674 cm^{-1} in **12ClO$_4$**. After the color of **12ClO$_4$** turned from green to red under reduced pressure, this peak corresponding to ν(O–H) disappeared. This proves a dissociation of the coordinated water from **12ClO$_4$** under reduced pressure.

3.4. Far-IR spectra

In the far-IR region, the coordinated nitrate ion shows the characteristic absorptions of ν_s(Cu–O) and ν_{as}(Cu–O) in **1NO$_3$**–**5** (Fig. 5). Since the bond length of Cu–O is almost the same, the bands of ν_s(Cu–O) and ν_{as}(Cu–O) in **1NO$_3$**–**5** should be observed in 332–348 and 301–323 cm^{-1}, respectively [58,66–69]. The peaks of ν(Cu–O′) in **1NO$_3$**–**3** were observed in the lower energy side. The peak of ν(Cu–O′) depends on the coordination mode of the nitrate ions to copper atom, and this result is different from those of ν(NO$_2$) in middle-IR region. The reason of this different behavior is unclear. On the other hand, only one peak of ν(Cu–O′) was observed in 269–280 cm^{-1}, since the Cu–O′ bond is much weaker than Cu–O. The spectral shape of **4** is slightly different from the natures of other nitrato complexes due to the different geometry.

The assignments of stretching vibration bands (ν(Cu–Cl)) of the chloro complexes **6CuCl$_4$**–**8** were performed (Fig. S6) [13,66,70–72]. Complexes **6CuCl$_4$**, **6Cu$_2$Cl$_6$**, **7**, and **8** having terminal Cu–Cl bond(s) show the peaks of ν(Cu–Cl$_t$) around 300 and 280 cm^{-1} (Table 6). Because the counter anions of **6CuCl$_4$** and **6Cu$_2$Cl$_6$** also have some bridging Cu–Cl$_b$ bonds, more complicated ν(Cu–Cl) bands were observed in the 200–300 cm^{-1} region. The assignments of stretching vibration bands of these anions were referred with those of (NEt$_4$)[CuCl$_4$], (PPh$_4$)$_2$[Cu$_2$Cl$_6$], and (C$_3$N$_3$H$_2$(NH$_2$)$_3$)[Cu$_2$Cl$_6$]. Some peaks of ν(Cu–Cl$_b$) were observed in the lowest energy side from ν(Cu–Cl$_t$) region. As same as IR measurement, the stretching vibration bands in **9** have already been assigned by using

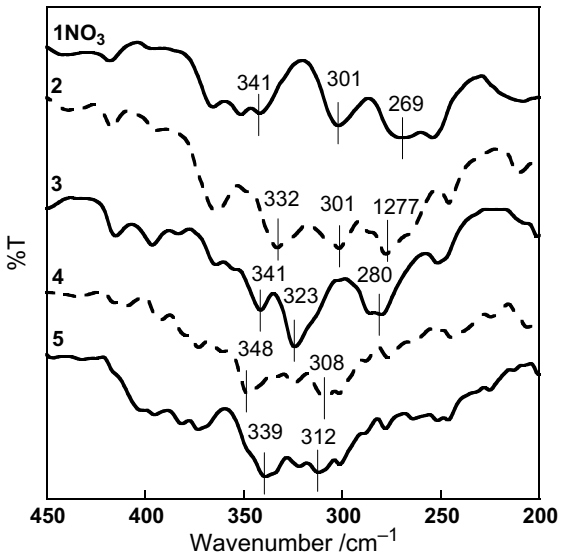

Fig. 5. Far-IR spectra of copper(II) nitrato complexes **1NO$_3$**–**5**.

Table 6
Cu–Cl stretching vibrations of copper(II) chloro complexes

ν(Cu–Cl) (cm^{-1})					Reference

$[Cu(L1'')(O^{15}NO)_2]$ [13]. From this assignment, the stretching vibration bands at 374 and 349 cm^{-1} in **10** are assigned to ν_s(Cu–O) and ν_{as}(Cu–O), respectively (Fig. S7). As same as **1NO$_3$–3**, the peaks of ν(Cu–O′) in **9** and **10** were observed at 319 and 330 cm^{-1}, respectively. Only the ν(Cu–O) in **11ClO$_4$** and **12ClO$_4$** due to the bond between the copper(II) ion and oxygen atom of the coordinated solvates was observed at 349 and 348 cm^{-1}, respectively (Fig. S8).

3.5. Electronic absorption spectra

The absorption maxima (λ_{max}) of all the complexes are summarized in Table 7. The d–d transition bands in **1NO$_3$–5** are almost the same as the reported nitrato complexes containing N2 bidentate ligands [63]. As shown in Fig. 6, the d–d transition bands of **4** and **5** were shifted to the higher energy side compared with those of **2** and **3**. Because of the structural distortions in **4** and **5**, the energy gap between the d orbitals should be enlarged. Additionally, in **1NO$_3$** and **2** having the same ligand, the d–d transition bands of **1NO$_3$** were shifted to the higher energy side compared with those of **2**, because of higher steric repulsion between the substituents of the ligands in **1NO$_3$**. In **2**, **3**, and **5**, the LMCT transition bands from nitrate to the copper(II) ions were observed around 300 nm. However, the CT transition bands of **4** were shifted to the lower energy sides compared with those of **2**, **3**, and **5** due to the different coordination mode. In **1NO$_3$**, only one nitrate ion coordinates to the copper(II) ion. Therefore, the CT transition absorptivity was weak as a shoulder around 300 nm.

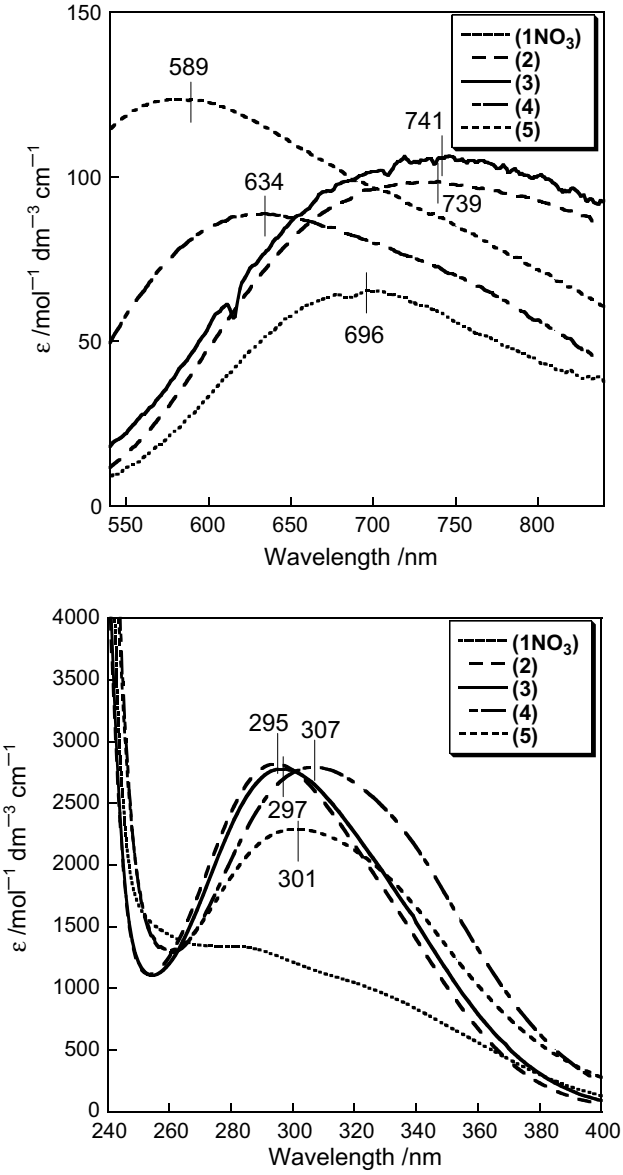

Fig. 6. Electronic absorption spectra of nitrato complexes in **1NO$_3$–5** in d–d transitions region (top) and in CT transitions region (bottom).

In **6CuCl$_4$**, **6Cu$_2$Cl$_6$**, and **7–12**, the LMCT transition bands were observed in the region of 350–450 nm (Figs. S9–S11). Complexes **6CuCl$_4$** and **6Cu$_2$Cl$_6$** containing the same cation showed almost the same absorption behavior. As listed in Table 7, these absorptions in **6CuCl$_4$** and **6Cu$_2$Cl$_6$** are very close to **7** and **8**. In $(Ph_4P)[Cu_2Cl_6]$, the LMCT transition bands were observed at 325 and 475 nm. Furthermore, the π–π* transition bands were observed around 270 nm. On the other hand, the LMCT transition bands in **6CuCl$_4$**, **6Cu$_2$Cl$_6$**, **7**, and **8** were observed around 290 nm, since the coordination modes

of the chloride ions are almost the same in these chloro complexes. As compared with **7**, the d–d transition bands in **8** were shifted to the higher energy side due to higher steric repulsion between the ligand and the chloride ions. On the other hand, the d–d transition bands in [Cu(bipy)Cl_2] and [Cu(en)Cl_2] [28] in the higher energy side than those in **8** and **9** are found [63a], since this energy gap between the d orbitals of tetrahedral type is smaller than those of square planar type. Two nitrito complexes showed almost the same absorption behavior due to almost the same coordination mode of the nitrite ions and the complex structure. The d–d transition bands in **10** were shifted to the higher energy side than those in **9** due to larger steric repulsion between the ligand and the nitrite ions. The d–d transition bands of the synthesized nitrito complexes are almost the same as those of the reported nitrito complexes containing N2 bidentate ligand [63a]. In addition, the absorption bands around 280 nm in these complexes were assigned to the LMCT transition bands from nitrite to the copper(II) ion [13]. In **11**ClO_4 and **12**ClO_4, only the LMCT transition bands was observed in the CT transitions region, since two perchlorate ions does not coordinate to copper(II) ion. The d–d transition bands in **12**ClO_4 were shifted to the higher energy side compared with those in **11**ClO_4, because of larger steric repulsion between the substituents of the ligand.

3.6. ESR spectra

The $A_{\parallel}$ and g values of the synthesized complexes are summarized in Table S4, together with the reported complexes. Two kinds of mixture solvents were used for ESR measurements. The mixture solvent α (methanol/ethanol = 9:1) was used for **1**NO_3, because **1**NO_3 was insoluble in dichloromethane. In addition, when **12**ClO_4 dissolved in the mixture solvent β (dichloromethane/1,2-dichloroethane = 1:1), the solution color turned from green to brown, accompanied by the dissociation of water. In the case of chloro complexes **6**$CuCl_4$, **6**Cu_2Cl_6, **7**, and **8** and the complexes with perchlorate ions **11**ClO_4 and **12**ClO_4, the solution colors of these complexes were changed at 140 K, since some water in solvents would coordinate to the copper atom. The spectra of **1**–**5** and **9**–**10** are shown in Figs. 7 and S12, respectively [20,63,74,75]. The order of $g_{\parallel} > g_{\perp} > 2.0023$ is satisfied in all the complexes except **8** and **9** having a tetrahedral structure, it was confirmed that the unpaired electron of the copper(II) ion exists in $d_{x^2-y^2}$ orbital. In the results of UV–Vis absorption measurements, the Δ value order is $\Delta(\mathrm{ONO}) \geqslant \Delta(\mathrm{NO_3}) > \Delta(\mathrm{Cl})$, so that the $g_{\perp}$ values are expected; $g_{\perp}(\mathrm{Cl}) > g_{\perp}(\mathrm{NO_3}) \geqslant g_{\perp}(\mathrm{ONO})$, where Δ is energy gap between the d orbitals (cm^{-1}). In general, $A_{\parallel}$ value of the complex having a tetrahedral structure is smaller than that having a square plane. However, this tendency was not observed in **7** and **8** owing to the different structures at 140 K. The ^{14}N superhyperfine coupling appeared clearly in **4** and **5**, and their $A_{\parallel}$ values were much larger than those of **1**NO_3–**3** (Fig. 7). These

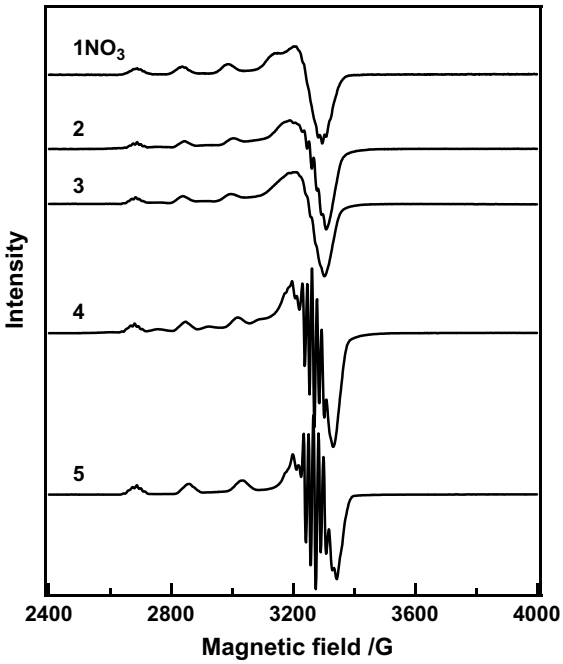

Fig. 7. ESR spectra of nitrato complexes **1**NO_3–**5**.

results prove their square planar structure [76]. On the other hand, this ^{14}N superhyperfine coupling was slightly observed in **2** and **9**, and that the ^{14}N superhyperfine coupling depends on the structures for the coordinated nitrogens. If the coordination mode of the nitrate (or nitrite) ion would be almost unidentate, the influence of the coordinated nitrogen become strong, and the ^{14}N superhyperfine coupling could appear clearly. As shown in Fig. S12, the spectra of the nitrito complexes **9** and **10** are different from those of **2** and **3**.

4. Conclusion

In this work, novel nine copper(II) complexes ligated by various bpzm ligands were systematically synthesized and characterized. As for the structures of the synthesized nitrato and nitrito complexes, the coordination mode of the nitrate or nitrite ions affected on their complex structures. In **1**NO_3, the coordination mode of the nitrate ion is almost asymmetric bidentate, taking a distorted octahedral structure. Complexes **2**, **3**, **9**, and **10** have almost asymmetric bidentate nitrate or nitrite ions, and take a highly distorted octahedral structure. On the other hand, **4** and **5** have almost unidentate nitrate ions because of the higher bulkiness of the ligands, and have a square planar structure. Further, the structural differences caused by the bulkiness of the ligands are also confirmed in the synthesized chloro complexes and the complexes with perchlorate ions. In IR measurements, three $\nu(NO_2)$ and one $\delta(NO_2)$ are observed in the nitrato complexes. However, those of **1**NO_3 and **4** were shifted because of the different coordination number and coordination mode of two nitrate ions for the copper plane. In far-IR spectra, the

peak of ν(Cu–O′) was observed when the coordination mode of the nitrate (or nitrite) ions would be bidentate. In UV–Vis spectra, the d–d transition bands were shifted to higher energy side by the distortion of the complex structure. In ESR spectra, by the effect of the nitrogen atoms of the ligand, the ^{14}N hyperfine coupling is clearly observed in **4** and **5**, and this proves their square planar structure.

From these systematic researches by using several ligands L0″, L1″, L3″, and L4″ with different steric bulkiness, we obtained many structural effects and different observations in their physicochemical properties. As for the counter anion, NO_3^-, NO_2^-, Cl^-, and ClO_4^-, different coordination ability towards copper(II) ion was observed. In particular, we can prepare all complexes with NO_3^- as $[Cu(Ln'')(NO_3)]$ ($n = 0$, 1, 3, and 4) type. However, we cannot make the following complexes even different experimental conditions; $[Cu(L0'')Cl_2]$, $[Cu(L4'')Cl_2]$, $[Cu(L3'')(NO_2)_2]$, $[Cu(L4'')(NO_2)_2]$, and $[Cu(Ln'')(ClO_4)_2]$. From this research, we also demonstrate the influences on the differences in second coordination sphere effects on the ligands and nitrogen numbers (bpzm versus tpzm). We are now underway to identify these ligand effects on their structures, reactivities, and physicochemical properties with copper(I) ion.

Acknowledgements

This research was supported by grants for Grant-in-Aid for Scientific Research (B) (14350471 and 17350043) from JSPS and for Scientific Research on Priority Areas "Advanced Molecular Transformations of Carbon Resources" (19020011) from MEXT. We appreciate the kind editing of this manuscript by Dr. Nicolai Lehnert of University of Michigan.

substitution reaction and containing the 2,2′-biimidazole ($biimH_2$), 2-(2′-pyridyl)imidazole (pyim) and 2,2′-bipyridine (bipy) chelating ligands (Scheme 1).

With rhenium and $biimH_2$, a few crystal structures involving only Re(III) and Re(V) metal ions have been reported [30–32]. Beauchamp et al. observed that the Re(V) precursors $[ReOX_3(PPh_3)_2]$ and $[ReO(OEt)X_2(PPh_3)_2]$ are reduced by PPh_3 in the presence of $biimH_2$ affording the Re(III) compounds *cis*,*trans*-$[ReX_2(PPh_3)_2(biimH_2)]X$, X being Cl^-, Br^- and I^- halide counterions [31]. Other similar Re(III) compounds of general formula $[ReX_2(PMe_3)_2(biimH_2)]X$ (X = Cl, Br and I) were further obtained [32]. In addition, the Re(V) mononuclear compound $[ReOCl_2(OPPh_3)(biimH_2)]Cl$ was prepared, by refluxing $[ReOCl_3(OPPh_3)(Me_2S)]$ and $biimH_2$ in $CHCl_3$, and characterized by X-ray diffraction. Another Re(V) mononuclear complex, $[ReOCl_3(biimH_2)]$, was also obtained by the same authors but its crystal structure was not solved [30].

As far as we know, there is only one crystal structure described with rhenium and pyim ligand, that of the Re(III) compound $[ReCl_2(PPh_3)_2(pyim)]^+$ recently reported [33]. This complex is obtained when *trans*-$[ReOCl_3(PPh_3)_2]$ is allowed to react with pyim in methanol. In the same reaction conditions but by using 2-(2′-pyridyl)-1-methylimidazole (pyimMe) instead pyim a Re(V) complex, $[ReCl_3(PPh_3)(pyimMe)]$, was also synthesized [33]. By using other derivative ligand, the 2-(2′-pyridyl)benzimidazole, one Re(III) complex and another one of Re(IV) were prepared and also characterized by X-ray diffraction [24].

Rhenium with the bipy diimine ligand present in its sphere of coordination has been much more explored with Re(I) than with other oxidation states [Re(II)–Re(V)]. Concerning rhenium(IV), in 1984 the $[ReCl_4(bipy)]$ complex was prepared, by pyrolysis reaction from $[bipyH_2][ReCl_6]$ [34]. However, its crystal structure was not solved until 1990 [18], when it was obtained unexpectedly in the reaction of $ReCl_5$ and bipy in the presence of hexamethyldisiloxane. More recently, the analogous bromo-complex, $[ReBr_4(bipy)]$, has been described [35]. It is worth noting that although two different methods of synthesis and also the X-ray structure of $[ReCl_4(bipy)]$ complex are found in the literature [18,34], to date its magnetism study has been not reported.

Scheme 1.

We report here the synthesis of two new Re(IV) solvated mononuclear complexes of formula $[ReCl_4(biimH_2)]\cdot 2DMF$ (**1**) and $[ReCl_4(pyim)]\cdot DMF$ (**2**) where $biimH_2$ = 2,2′-biimidazole, pyim = 2-(2′-pyridyl)imidazole and DMF = *N*,*N*-dimethylformamide and, moreover, an alternative method to prepare the previously reported $[ReCl_4(bipy)]$ (**3**) complex (bipy = 2,2′-bipyridine), together with the X-ray structure of **2** and the magnetic properties of all of them **1**–**3**.

2. Experimental

2.1. Materials

N,*N*-dimethylformamide (max. 0.03% water) and 2-propanol solvents, and 2,2′-bipyridine ligand employed for synthesis were purchased from commercial sources and used as received. $BiimH_2$ and pyim ligands as well as ammonium hexachlororhenate(IV), $(NH_4)_2[ReCl_6]$, were prepared by following the literature procedures of Refs. [36–38], respectively.

2.2. Synthesis of the complexes

2.2.1. $[ReCl_4(biimH_2)]\cdot 2DMF$ (1)

A mixture of $(NH_4)_2[ReCl_6]$ (0.60 g, 1.38 mmol) and 2,2′-biimidazole ($biimH_2$) (0.22 g, 1.64 mmol) in 15 mL of DMF was heated at 110 °C during 6 h leading to a dark red-orangish solution together with a white solid. After cooling at room temperature, the solid was removed by filtration and the filtrate was transferred into a flask. Then, 50 mL of 2-propanol were added very slowly by means of a Pasteur pipette, the flask was closed and left to diffuse. Red-orangish crystals of **1** were grown in a month, which were not suitable for X-ray diffraction studies and numerous attempts to grow better ones were unsuccessful. Yield: *ca.* 25–30%. *Anal.* Calc. for $C_{12}H_{20}N_6Cl_4O_2Re$ (**1**): C, 23.69; H, 3.31; N, 13.81. Found: C, 23.30; H, 3.22; N, 13.75%. IR peaks associated to $biimH_2$ ligand appear at (cm^{-1}) 3155m, 3129s, 2927m, 1906w, 1514m, 1493m, 1424s, 767s and 669m, and the peaks assigned to DMF at (cm^{-1}) 1655vs, 1380s and 705m.

2.2.2. $[ReCl_4(pyim)]\cdot DMF$ (2)

This compound was obtained by following a very similar procedure to that described above for **1**. A mixture of $(NH_4)_2[ReCl_6]$ (0.30 g, 0.69 mmol) and 2-(2′-pyridyl)imidazole (pyim) (0.30 g, 2.07 mmol) in 10 mL of DMF was heated during 3–4 h leading to a brown solution. After cooling at room temperature, any solid present was removed by filtration and discarded. **2** was separated as red-orangish crystals after slow diffusion performed in 2-propanol as in **1**. These red-orangish crystals were suitable for X-ray diffraction studies. Yield: *ca.* 35%. *Anal.* Calc. for $C_{11}H_{14}N_4Cl_4ORe$ (**1**): C, 24.19; H, 2.58; N, 10.26. Found: C, 23.98; H, 2.49; N, 10.21%. IR peaks associated to pyim ligand appear at (cm^{-1}) 3135m, 3094w, 3065m, 2926m,

1908m, 1576s, 1473s, 1256m, 790s and 674m, and those assigned to DMF at (cm^{-1}) 1639vs, 1384s and 701m.

2.2.3. [$ReCl_4$(bipy)] (3)

A mixture of ammonium hexachlororhenate(IV) (0.60 g, 1.38 mmol) and bipy (0.50 g, 3.20 mmol) in 5 mL of DMF was refluxed under argon atmosphere during 2–3 h leading to a dark green solution. After cooling at room temperature, the solution was filtered and heated at 60 °C to eliminate fully the solvent. 50 mL of acetone were added to the residue obtained stirring for 20 min. Then, the insoluble solid was removed by filtration and discarded. Finally, 4–5 drops from a 0.5 M HCl solution were added (to avoid any possible hydrolysis) and by slow evaporation at room temperature brown-yellowish needles were formed in two weeks. Yield: *ca.* 35–40%. *Anal.* Calc. for $C_{10}H_8N_2Cl_4Re$ (**1**): C, 24.81; H, 1.67; N, 5.79. Found: C, 24.56; H, 1.63; N, 5.80%. IR peaks associated to bipy ligand appear at (cm^{-1}) 3080m, 1602vs, 1563m, 1465s, 1445vs, 950m, 770s and 722m.

2.3. Physical measurements

Infrared spectra of **1**–**3** were recorded with a Nicolet 320 FTIR spectrophotometer as KBr pellets in the 4000–400 cm^{-1} region. Magnetic susceptibility measurements of **1**–**3** were carried out with a Quantum Design SQUID magnetometer in the temperature range 1.9–300 K and under an applied magnetic field of 1 T in the high-temperature range, and 250 G at low temperatures to avoid any problem of magnetic saturation. The device was calibrated with $(NH_4)_2Mn(SO_4)_2 \cdot 6H_2O$. Diamagnetic corrections of the constituent atoms were estimated from Pascal constants [39].

2.4. Crystallographic data collection and structure determination

A crystal of dimensions 0.08 × 0.18 × 0.10 mm of **2** was mounted on a Bruker-Nonius X8APEXII CCD area detector system and used for data collection. Diffraction data were collected at room temperature by using graphite-monochromated Mo K_α radiation ($\lambda = 0.71073$ Å). A total of 1938 frames of data were collected using a narrow-frame method with scan widths of 0.3° in ϕ and ω, exposure time of 5 s per frame using a crystal-to-detector distance of 50 mm. These data were processed through the SAINT [40] reduction and SADABS [41] absorption software to yield a total of 20861 reflections.

The unit cell parameters, which are listed in Table 1 together with a summary of the structure refinement data, were based upon least-squares refinement of 4467 reflections. Of the total collected reflections, 6125 were independent [$R_{int} = 0.0347$, with 4405 having $I > 2\sigma(I)$] and used to solve the structure with the SHELXTL software package [42]. The structure was solved by standard direct methods and subsequently completed by Fourier recycling. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were placed in geometrically suitable positions and were refined as riding atoms. The final full-matrix least-squares refinements on F^2, minimizing the function $\sum w(|F_o| - |F_c|)^2$, reached convergence with values of the discrepancy indices given in Table 1. The final geometrical calculations were carried out with the PARST program [43]. The graphical manipulations were performed using the XP utility of the SHELXTL system. Main interatomic bond lengths and angles for **2** are given in Table 2.

3. Results and discussion

3.1. Crystal structure of [$ReCl_4$(pyim)] · DMF (2)

The crystal structure of compound **2** is made up of discrete molecules of [$ReCl_4$(pyim)] and *N,N*-dimethylformamide (DMF) which are held together by means of van der Waals interactions and hydrogen bonds. A perspective drawing of the molecular structure of the [$ReCl_4$(pyim)] unit along with the atom numbering is depicted in Fig. 1, while selected bonds lengths and angles are listed in Table 1. Each [$ReCl_4$(pyim)] unit contains a six-coordinated rhenium atom in a distorted octahedral environment constituted by four chloride anions and one bidentate pyim molecule. The main distortion of the ideal octahedral geometry is due to the short bite angle of the bidentate pyim ligand [76.4(2)° for N(1)–Re(1)–N(2)]. The average values of Re–Cl and Re–N bond lengths [2.330 and 2.117 Å, respectively] are in agreement with those found in the literature for similar Re(IV) mononuclear complexes [15,24–28]. The N(1), N(2), Cl(1), Cl(3) set of atoms define the best equatorial plane around the Re atom, which is placed practically in this plane. The pyim rings are planar and they show C–C and C–N bonds lengths values as expected [29]. The pyrimidyl and imidazole rings form a dihedral angle of 7(1)°, while the dihedral angle between the pyim and main equatorial planes is 6.5(1)°. In the crystal packing, [$ReCl_4$(pyim)] molecules are linked through weak van der Waals forces, moreover, hydrogen bonding interactions take place between O(1) atom from carbonyl of the DMF molecule and N–H group from pyim ligand [N(3)···O(1a) distance is 2.673(6) Å, (a) = $1-x$, $1-y$, $2-z$]. On the other hand, π–π stacking interactions are also observed in the lattice of **2** with an interplanar distance of 3.45 Å and an overlap efficiency of *ca.* 50%. The shortest intermolecular Cl···Cl distance was found to be 3.621(1) Å [Cl(4)···Cl(4b), (b) = $2-x$, $2-y$, $2-z$, distances visualized as broken lines in Fig. 2] and the value of the shortest intermolecular Re···Re separation being 7.697(1) Å [Re(1)···Re(1c); (c) = $1-x$, $-0.5+y$, $1.5-z$].

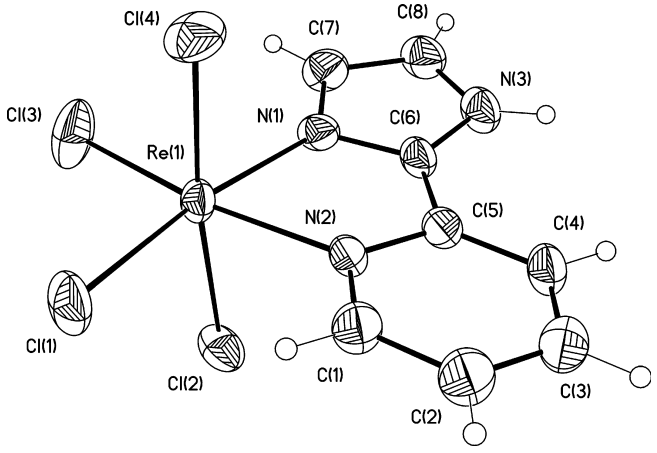

Fig. 1. Perspective drawing of the molecular structure of **2** showing the atom numbering scheme. Thermal ellipsoids are drawn at 30 % of probability level.

3.2. Magnetic properties

The magnetic properties of the compounds **1** and **2**, under the form of both $\chi_M T$ and χ_M versus T plots (χ_M being the molar magnetic susceptibility), are shown in Figs. 3 and 4, respectively. At room temperature, $\chi_M T$ values are 1.68 (**1**) and 1.60 $cm^3\ mol^{-1}$ K (**2**). These values are as expected for magnetically isolated Re(IV) ($S_{Re} = 3/2$) mononuclear complexes with $g = 1.8$–1.9 [27,29]. Upon cooling, $\chi_M T$ values for both compounds decrease very slowly until 70 (**1**) and 80 K (**2**), then they decrease quickly and vanishing practically at lower temperatures. The fact that $\chi_M T$ attains values even lower than 1 $cm^3\ mol^{-1}$ K, in low temperature range, indicates the occurrence of intermolecular antiferromagnetic interactions, as discussed in previous works [27,44]. Indeed, the susceptibility curves (χ_M versus T) exhibit small maxima at 2.8 K in both compounds (**1** and **2**), this last feature being also characteristic of antiferromagnetically coupled systems. The decrease of $\chi_M T$ values observed at higher temperatures can be attributed exclusively to the zero-field splitting ($2D$), which is very large for Re(IV) in a distorted octahedral environment, because of the high value of the spin-orbit coupling constant (λ *ca.* 1000 cm^{-1} in the free $5d^3$ ion). In fact, for six-coordinated Re(IV), the first excited term which arises from the ^4F free-ion ground term is $^4T_{2g}$ and under a tetragonal distortion, this excited state is split into $^4B_2$ and ^4E terms. Under this pattern, the interaction of these two excited terms with the quartet ground spin state, leads to two Kramers doublets, $|\pm 3/2>$ and $|\pm 1/2>$, which are separated by an energy gap of $|2D|$ (zero-field splitting resulting from the combined action of second-order spin–orbit interaction and the tetragonal crystal field). A detailed inspection of the crystal packing of **2** reveals intermolecular interactions between adjacent [$ReCl_4$(pyim)] units through space *via* Re–Cl···Cl–Re contacts. The shortest Cl···Cl separation is 3.621(1) Å and, therefore, very close to the van der Waals distance.

Taking into consideration these facts, we have used the theoretical expression for the magnetic susceptibility [Eq. (2)] derived from the Hamiltonian [Eq. (1)] to analyze the magnetic behaviour of **1** and **2**. Due to the intermolecular interactions that take place, a θ parameter was included in the expression (2) in attempt to fit the experimental data and to analyze the magnetic coupling between the mononuclear units.

$$\widehat{H} = D[(\widehat{S}_Z)^2 - S(S+1)/3] + g_{\parallel}\beta H_Z \widehat{S}_Z + g_{\perp}\beta(H_X \widehat{S}_X + H_Y \widehat{S}_Y) \quad (1)$$

$$\chi_M = \frac{\chi_{\parallel} + 2\chi_{\perp}}{3} \quad (2)$$

where

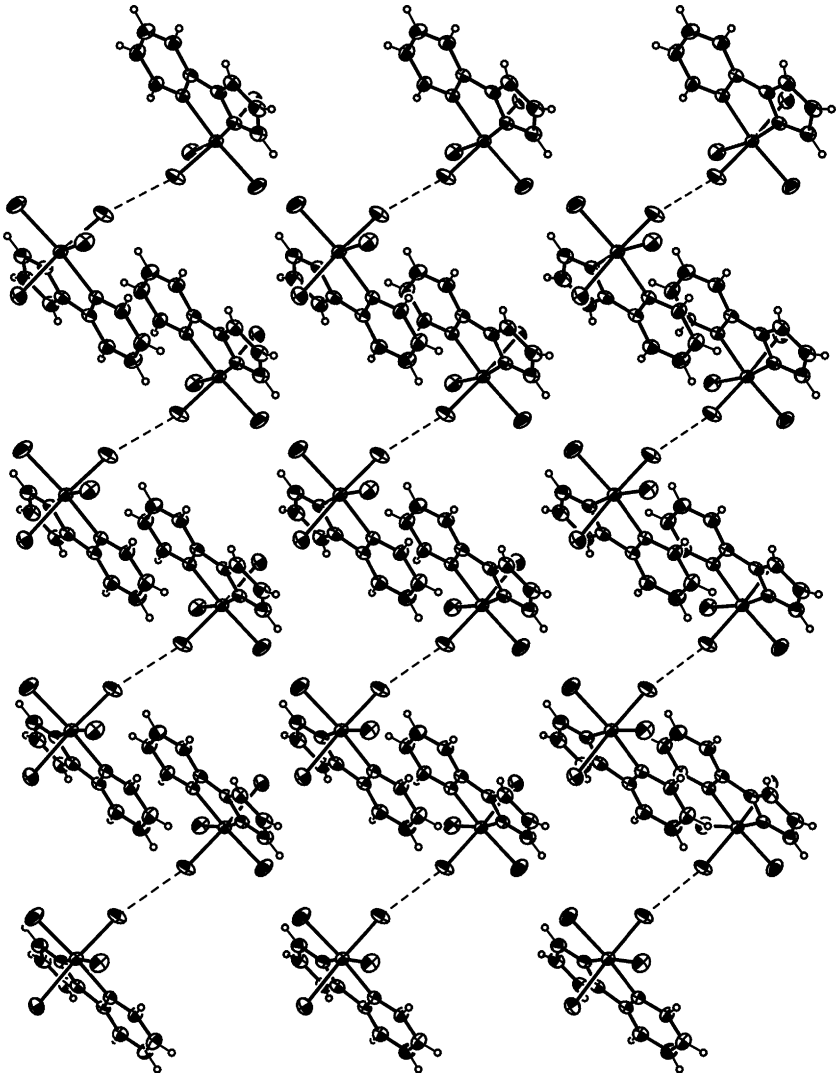

Fig. 2. View along z-axis of a crystal packing fragment in **2** showing the shortest interionic Cl···Cl contacts (broken lines) between adjacent [$ReCl_4$(pyim)] units. Solvent molecules have been omitted for clarity.

$$\chi_{\parallel} = \frac{N\beta^2 g_{\parallel}^2}{4k(T-\theta)} \frac{1+9\exp(-2D/kT)}{1+\exp(-2D/kT)}$$

$$\chi_{\perp} = \frac{N\beta^2 g_{\perp}}{k(T-\theta)} \frac{1+(3kT/4D)[1-\exp(-2D/kT)]}{1+\exp(-2D/kT)}$$

The large axial anisotropy from Re(IV) accounts for a great value of D together with different values for $g_{\parallel}$ and $g_{\perp}$. However, we have measured the magnetic susceptibility on microcrystalline powder samples of both compounds and from these measurements it is not possible to define reliable and unique values for $g_{\parallel}$ and $g_{\perp}$ or the sign of D. The fit of experimental data considering all of these parameters results in several (mathematically) possible solutions. However, in all of them the absolute value of D and the main value of g remain practically constants. Best least-squares fit parameters are: $\theta = -5.5$ K, $g = 1.90$ and $R = 2.3 \times 10^{-4}$ for **1** and $\theta = -9.6$ K, $g = 1.88$ and $R = 8.7 \times 10^{-5}$ for **2** [R being the agreement factor defined as $\sum i[(\chi_M T)_{obs}(i) - (\chi_M T)_{calc}(i)]^2/\sum i[(\chi_M T)_{obs}(i)]^2$]. As one can see, the calculated curves for **1** and **2** reproduce very well the experimental magnetic data in the whole temperature range. These results support also the formula that we propose for compound **1**, given that **1** exhibits very close magnetic curves and therefore the same magnetic behaviour that **2**. The negative θ values obtained show the occurrence of a significant antiferromagnetic coupling because of intermolecular Cl···Cl interactions, θ being for **2** almost twice the value found in compound **1**. The presence of more solvent molecules in **1**, generating a possible longer Re–Cl···Cl–Re separation and leading to a lower intensity of the magnetic coupling, would account for the larger θ value observed in **2**.

The magnetic properties of the complex **3** as $\chi_M T$ and χ_M versus T plots are shown in Fig. 5. The $\chi_M T$ value at room temperature is 1.27 $cm^3\,mol^{-1}\,K$, which is smaller than that expected for a magnetically isolated Re(IV) centre (see above), suggesting that a significant antiferromagnetic interaction occurs in this compound. Upon

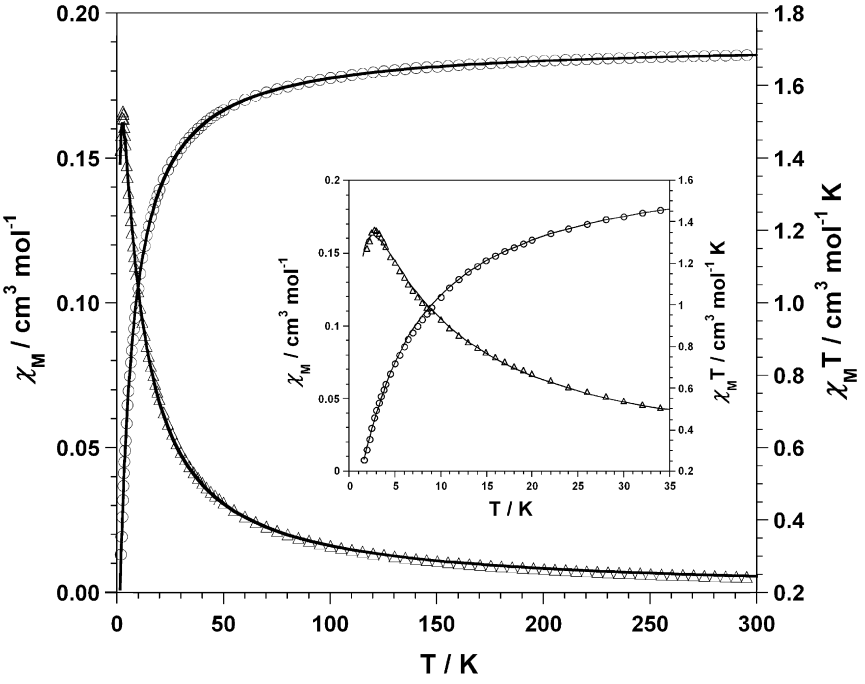

Fig. 3. Thermal variation of χ_M (Δ) and $\chi_M T$ (○) for **1**: (—) best-fit curve (see text).

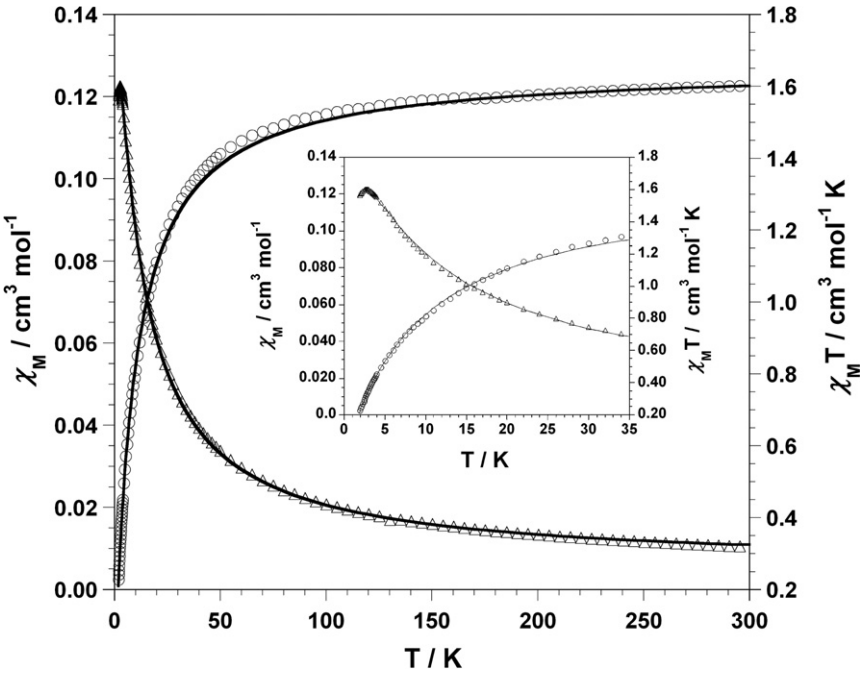

Fig. 4. Thermal variation of χ_M (Δ) and $\chi_M T$ (○) for **2**: (—) best-fit curve (see text).

cooling, $\chi_M T$ values quickly decrease to reach a value of 0.031 $cm^3\,mol^{-1}$ K at 1.9 K. The susceptibility curve (χ_M versus T) shows a maximum at 5.6 K with $\chi_{M\ (max)} = 0.052\ cm^3\,mol^{-1}$. The extrapolated value of χ_M at $T = 0$ is 0.036 $cm^3\,mol^{-1}$, that is about 2/3 its value at the temperature at which it is a maximum. This fact indicates that we are dealing with a three-dimensional antiferromagnetic ordering [45], a magnetic behaviour that also we have observed recently in a two-dimensional $Re^{IV}Ag^{I}$ species [46], however heat capacity measurements would be needed to verify this magnetic ordering.

Due to the lack of an adequate theoretical model to analyze these magnetic experimental data, the evaluation of the magnitude of the exchange coupling in **3** is precluded. Nevertheless, the $\chi_M{}^{-1}$ versus T plot in the temperature range 80–300 K exhibits a linear behaviour, and fitting the experimental data by means of a simple Curie–Weiss expression we got the following magnetic parameters:

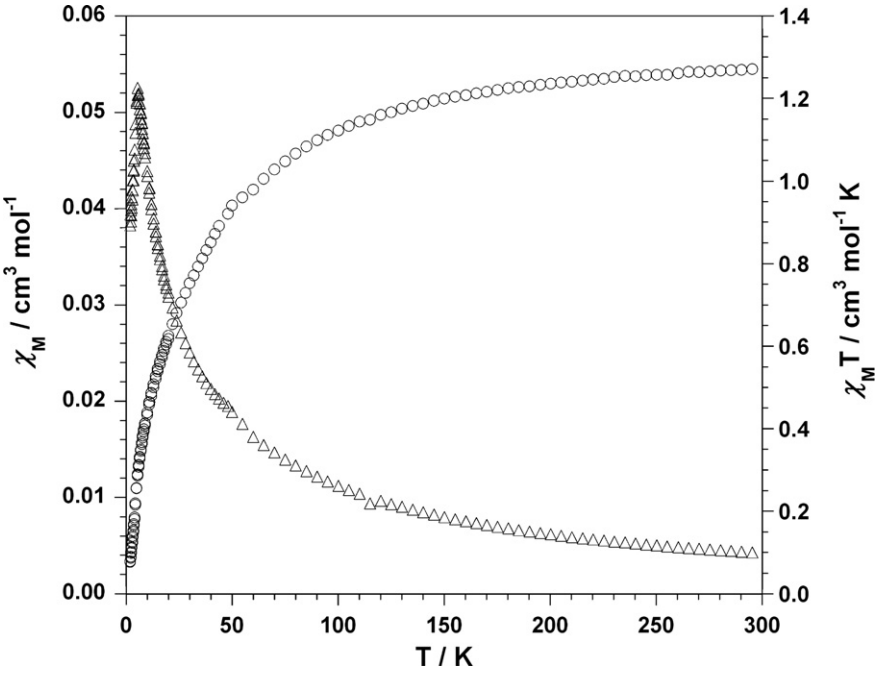

Fig. 5. Thermal variation of χ_M (Δ) and $\chi_M T$ (○) for **3**.

$C = 1.36\ \text{cm}^3\ \text{mol}^{-1}$, $\theta = -21.2$ K and $g = 1.87$. This negative θ value supports that a significant antiferromagnetic interaction takes place in **3**. As one can see, θ value in **3** is larger than those obtained for **1** and **2**. However, it deserves to be noted that in the latter fit the θ parameter includes both intermolecular interactions and the zero-field splitting and, aiming at comparing the θ parameter from **1**–**3**, it must be carefully considered. In fact, the shortest Cl···Cl distance found in **3** is somewhat longer than that of **2**, in spite of the presence of solvent molecules in **2** [3.620(1) (**2**) and 3.787(1) Å (**3**)]. So that, the magnetic coupling intensity due to intermolecular interactions between paramagnetic Re(IV) centers in **3** should not be much larger than that of **2**.

4. Conclusions

By reacting $[ReCl_6]^{2-}$ and L (L = $biimH_2$, pyim and bipy chelating ligands) in DMF we have prepared the three Re(IV) compounds namely $[ReCl_4(biimH_2)] \cdot 2DMF$ (**1**), $[ReCl_4(pyim)] \cdot DMF$ (**2**) and $[ReCl_4(bipy)]$ (**3**), and solved the crystal structure of **2** by X-ray diffraction. Magnetic susceptibility measurements reveal that **1**–**3** exhibit significant antiferromagnetic couplings, which take place by means of Re–Cl···Cl–Re type intermolecular interactions. In **3**, such interactions lead to an antiferromagnet behaviour.

Supplementary material

CCDC 669709 contains the supplementary crystallographic data for **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Heterocyclic bases *viz.* 2,2′-bipyridine (bipy) and 1,10-phenanthroline (phen) were used as auxiliary ligands for coordination.

2. Experimental

2.1. Materials

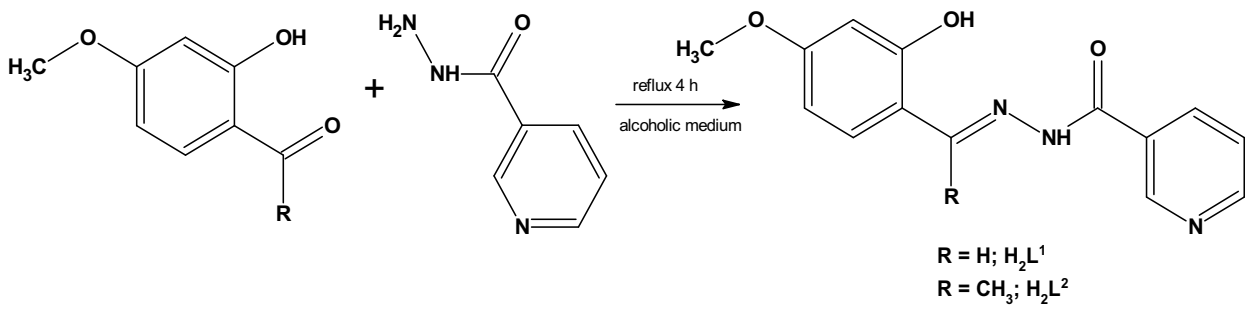
2-Hydroxy-4-methoxyacetophenone (Aldrich), 2-hydroxy-4-methoxybenzaldehyde (Aldrich), nicotinic acid hydrazide (Aldrich), vanadyl sulphate (Aldrich), 2,2′-bipyridine (Qualigen), 1,10-phenanthroline (Ranchem) were of analar grade and used without further purification. Solvents used were ethanol, methanol and water.

2.2. Synthesis of the ligands

The synthesis of 2-hydroxy-4-methoxybenzaldehyde nicotinic acid hydrazone (H_2L^1) has been reported by us earlier [11]. 2-Hydroxy-4-methoxyacetophenone nicotinic acid hydrazone (H_2L^2) was synthesized by the following method. An equimolar mixture of the nicotinic acid hydrazide and 2-hydroxy-4-methoxyacetophenone was refluxed in ethanol/methanol for 4 h (Scheme 1).

H_2L^2: Elemental *Anal.* Calc.: C, 63.15; H, 5.30; N, 14.73. Found: C, 62.94; H, 5.39; N, 14.46%.

2.3. Synthesis of complexes



The complexes $[VOL^1]_2 \cdot H_2O$ (**1**) and $[VOL^2]_2 \cdot H_2O$ (**4**) were prepared by refluxing 1 mmol of $VOSO_4 \cdot H_2O$ in aqueous solution and 1 mmol of the corresponding ligand (H_2L^1 in ethanol or H_2L^2 in methanol) for 4 h. The complexes $[VOL^1bipy]$ (**2**), $[VOL^1phen] \cdot 1.5H_2O$ (**3**), $[VOL^2(OCH_3)]_2$(**5**) and $[VOL^2phen] \cdot 2H_2O$ (**6**) were prepared by refluxing 1 mmol each of $VOSO_4 \cdot H_2O$ in aqueous solution, heterocyclic base (bipy/ phen) in solid form and the corresponding ligand (H_2L^1 ethanol or H_2L^2 in methanol) for 4 h. In complex **5**, the base added was not incorporated and oxovanadium(IV) is oxidized to oxovanadium(V) to form a dimeric product. The structure has been determined by single crystal X-ray diffraction studies. But the yield was too low to do the remaining studies.

2.4. Physical measurements

Elemental analysis of the ligands and complexes were carried out using a Vario EL III CHNS analyzer at SAIF, Kochi, India. Infrared spectra were recorded on a JASCO FT/IR-4100 type A spectrometer in the range 4000–400 cm^{-1} using KBr pellets. Electronic spectra were recorded on a Cary 5000 version 1.09 UV–Vis–NIR spectrophotometer using DMF as the solvent. The EPR spectra of the complexes in the solid state at 298 K and in DMF at 77 K were recorded on a Varian E-112 spectrometer using TCNE as the standard, with 100 kHz modulation fre-

quency and 9.1 GHz microwave frequency at the SAIF, IIT Bombay, India.

2.5. X-ray crystallography

A dark green crystal of the compound **5** having approximate dimensions of 0.33 × 0.18 × 0.16 mm^3 was sealed in glass capillary. The crystallographic data and structure refinement parameters for the complex **5** are given in Table 1.

The X-ray diffraction data for the compound was measured at 150(2) K, data acquisition, cell refinement and data reduction were done using the CRYSALIS CCD, Oxford Diffraction Ltd. [12]. The structure was solved by direct methods and full-matrix least-squares refinement using SHELX97 [13] package. The positions of all the non-hydrogen atoms were included in the full-matrix least-squares refinement using SHELX97 program and all the hydrogen atoms were fixed in calculated positions for compound **5**.

3. Results and discussion

After double deprotonation, hydrazones coordinate as tridentate ligands in the enolate form (L^{2-}) in all the complexes. The colors and partial elemental analyses of the complexes are presented in Table 2. The elemental analyses of the complexes are in agreement with the general formula $[(VOL)_2]$ (for complexes **1** and **4**); [VOLB] (for complexes **2**, **3** and **6**) and $[VOLX]_2$ (for complex **5**). X-ray quality single crystals of the compound **5** were obtained by slow evaporation of its solution in CH_3OH/ H_2O mixture over a period of one week.

3.1. Crystal structure of the compound $[VOL^2(OCH_3)]_2$(5)

The molecular structure of the compound **5** along with atom numbering scheme is given in Fig. 1. The selected bond lengths and bond angles of the molecule is summarized in Table 3. Compound **5** crystallizes in the triclinic crystal system with a space group $P\bar{1}$. This is a centrosymmetric bis(μ-methoxy) bridged vanadium(V) dimer consists of one vanadium atom (V1), one terminal oxo group (O3), one methoxy oxygen (O5), tridentate hydrazone ligand binding to the metal center *via* phenoxy oxygen (O2), azomethine nitrogen (N1), enolic oxygen (O3) atoms. The vanadium(V) ions in the dimer exhibit distorted octahedral geometry with O3, N1, O2, O5 atoms defining the equatorial plane and O4 and O5a atoms at the apical positions;

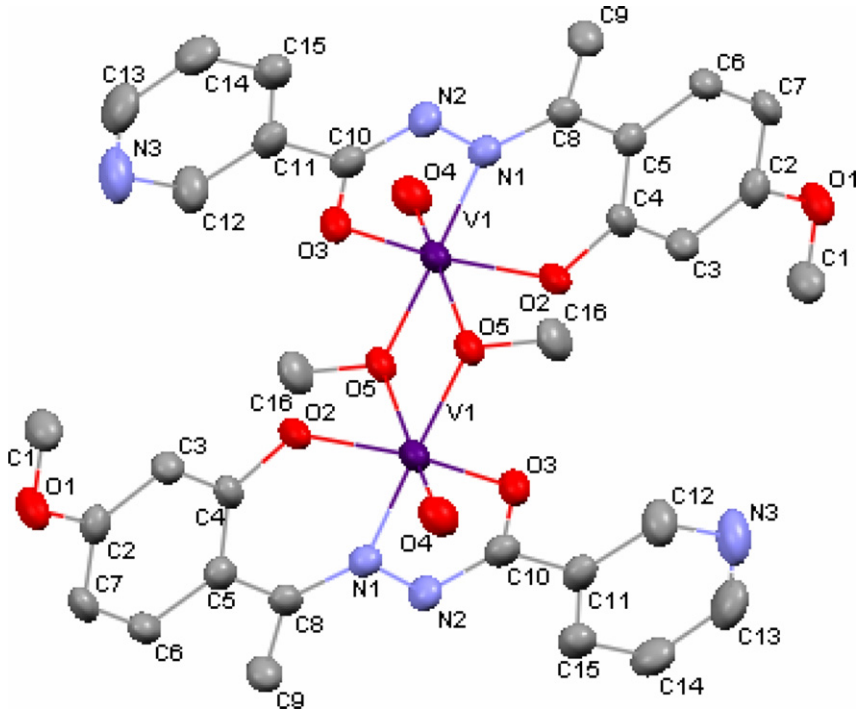

Fig. 1. Structure and labeling scheme for $[VOL^2(OCH_3)]_2$ (**5**).

the metal atom is displaced towards the axial oxo atom (O4) by 0.3548 Å from the equatorial plane.

The terminal V1–O4 (oxo) distance is 1.5896 Å, V1–O5a (bridging) is 2.3655 Å, V1–O2 (phenoxy) is 1.8215 Å and V1–O3 (ketoxy) is 1.9258 Å, these agree well with the corresponding values reported for related systems. The trans influence of the oxo (O4) ligand in one apical position of the vanadium octahedron manifests itself by elongation of the bond distance for the apically bonded bridging methoxy oxygen atom [V1–O5a = 2.3655 Å] when compared to the distance for the other methoxy oxygen atom [V1–O5 = 1.8208 Å]. The intramolecular V1–V1a distance is found to be 3.338 Å and falls within the range of known V–V distances in double bridged vanadium polynuclear systems. The centrosymmetric dimer is formed *via* the bridging oxygens connecting two vanadium atoms. Hence the vanadium atom adopts a distorted octahedral geometry [14,15].

The mean plane deviation calculations show that the atoms in the basal plane O3, N1, O2 and O5 are nearly planar with a maximum mean plane deviation of 0.007 Å and V1 is slightly deviated from planarity with a distance of 0.3548 Å. Ring puckering analyses and least-square plane

3.2. Infrared and electronic spectral studies

Selected vibrational bands of the free ligands and their vanadium complexes, which are useful for determining the mode of coordination of the ligands, are given in Table 5. The ligands exhibit bands in the regions 1638–1643, 3023–3182 and 3222–3421 cm^{-1} due to C=O, N–H and O–H stretches, respectively. These bands disappear on complexation, indicating the transformation of carbonyl moiety to enolic moiety and consequent replacement of the phenolic and enolic hydrogens [7]. A new band appearing in the 1232–1255 cm^{-1} region in the metal complexes was assigned to the ν(C–O) (enolato) mode [17]. The shifting of ν(C=N)

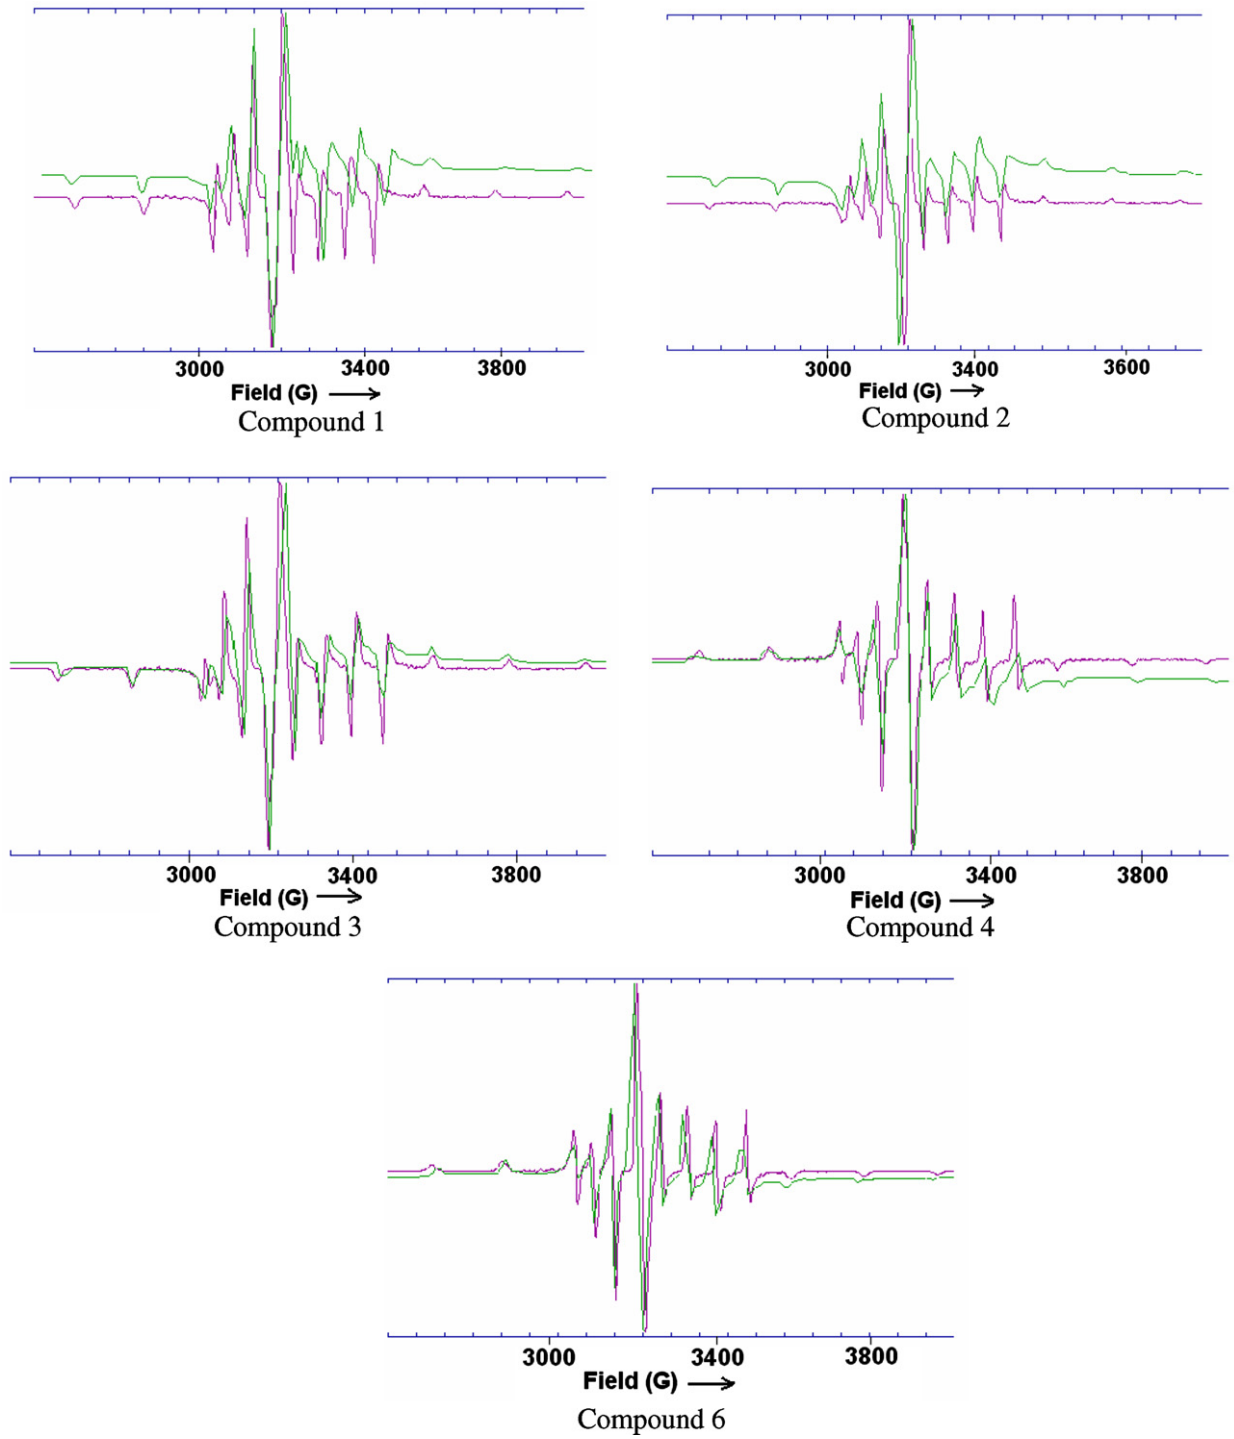

Fig. 5. Experimental (green) and simulated best fit (purple) of the EPR spectra of complexes **1**, **2**, **3**, **4** and **6** in DMF at 77 K. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

(azomethine) of the ligands (1602–1604 cm^{-1}) to lower wavenumbers in the metal complexes (1587–1600 cm^{-1}) indicates the coordination of azomethine nitrogen to the metal. A ligand characteristic band at *ca.* 1025 cm^{-1} due to ν(N–N) stretch undergoes a shift to a higher wavenumbers upon complexation due to diminished repulsion between the lone pairs of adjacent nitrogen atoms [18]. Furthermore, the bands in the regions 548–562 and 422–428 cm^{-1} can be assigned to the stretching modes of the metal to ligand bonds, ν(V–O) and ν(V–N), respectively [19]. In addition, the compounds exhibit a strong band in the 940–977 cm^{-1} range due to the terminal V=O stretching, indicates hexacoordinated environment around the metal center. Complexes **1** and **4** have a band in the region 833–845 cm^{-1} indicating V–O–V bridge vibrations [20]. Tentative structure of compound **1** is shown in Fig. 3.

The electronic spectra of the complexes in DMF solution are presented in the Table 6. The hydrazone ligands and their vanadium(IV) complexes have bands in the range 33 000–36 000 cm^{-1} corresponding to $\pi \rightarrow \pi^*$ of the azomethine group and bands in the range 29 500–32 000 cm^{-1} due to $n \rightarrow \pi^*$ of the carbonyl group. In all the complexes an intense band at *ca.* 24 740 cm^{-1} is assignable to the phenolic oxygen$\rightarrow V_{(d\pi)}$ ligand to metal charge transfer (LMCT) band [21,22]. The d–d bands expected at higher energy regions are probably obscured by the tail of the LMCT absorption. Representative spectra of the complexes along with the simulations are presented in Fig. 4.

3.3. EPR spectra

EPR spectra of all the oxovanadium(IV) complexes (**1**–**4** and **6**) were recorded in polycrystalline state at 298 K and in DMF solution at 77 K. In polycrystalline state at 298 K, the compound **1** is axial with $g_{\parallel} = 1.985$ and $g_{\perp} = 2.072$ G and the other complexes are isotropic with $g_{iso} \sim 1.988$ G.

In frozen DMF solution at 77 K, two sets of eight line spectra showing hyperfine splitting due to the ^{51}V nucleus ($I = 7/2$) are obtained in all the complexes. The spectral parameters are given in Table 7 and the experimental and simulated best fits[1] of EPR spectra of all the complexes are given in Fig. 5. All the compounds show well-resolved axial anisotropy with two sets of eight line pattern with $g_{\parallel} < g_{\perp}$ and $A_{\parallel} \gg A_{\perp}$ relationship characteristic of an axially compressed d^1_{xy} configuration [23]. Ligand nitrogen or hydrogen superhyperfine splittings are not observed on the vanadium line. This indicates that the unpaired electron to be in b_{2g} (d_{xy}, $^2B_2$ ground state) orbital localized on metal, thus excluding the possibility of its direct interaction with the ligand [24,25]. The EPR data of Table 7 reveals that phen slightly increases $A_{\parallel}$ and decreases $g_{\parallel}$, compared to bipy for an identical primary ligand. For an identical auxiliary ligand, the complexes with $(L^2)^{2-}$ species have slightly higher $A_{\parallel}$ values compared to the complexes associated with $(L^1)^{2-}$ species. For complexes with different principal ligand and without auxiliary ligand, $(L^2)^{2-}$ species have slightly higher $A_{\parallel}$ values compared to $(L^1)^{2-}$ species.

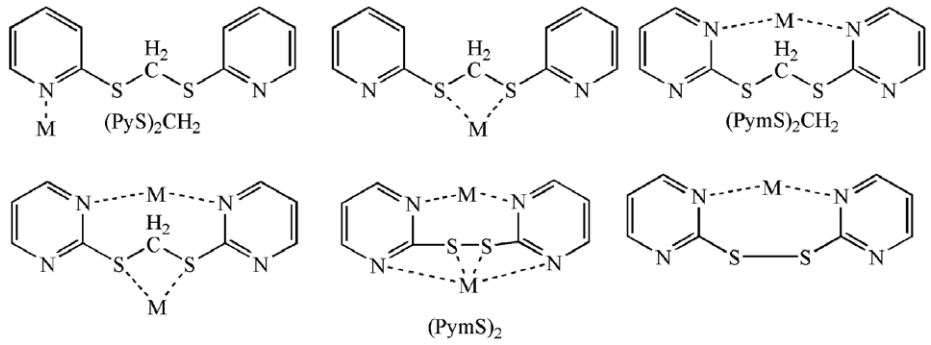

Fig. 1. Coordination modes of $(PyS)_2CH_2$, $(PymS)_2CH_2$ and $(PymS)_2$.

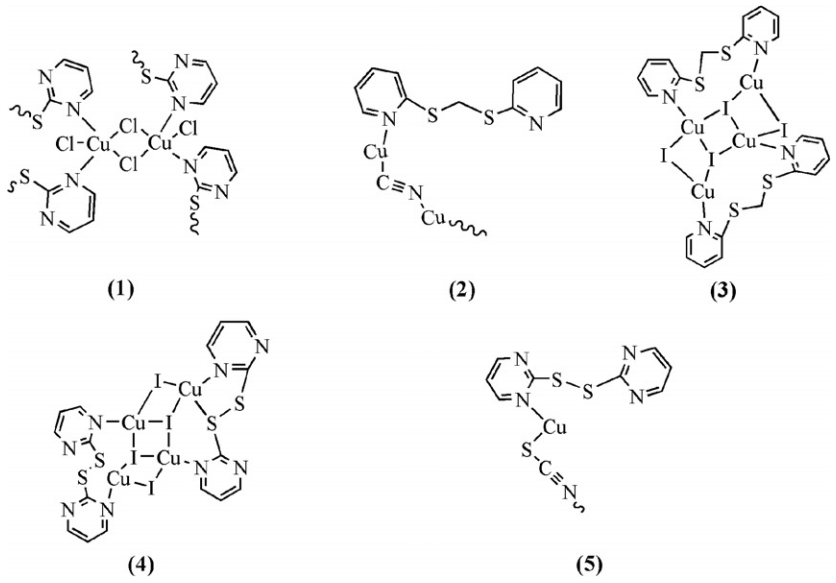

Fig. 2. Products **1**–**5** from the reactions of $(PyS)_2CH_2$, $(PymS)_2CH_2$ and $(PymS)_2$ with copper halides and pseudo halides.

advantage of these precursors is that they provide the opportunity for anion incorporation, which promotes the isolation of uncharged motifs that have accessible channels for possible small molecule adsorption. Traditionally, the synthesis of copper polymers has involved high temperature reactions as it was believed this was required to form metastable phases that would not be accessible at lower temperatures [2b,12]. For example, the reaction of CuSCN with 1,2,-bis(4pyridyl)bipyridylethane (bpa), to form the infinite polymer $[Cu(SCN)_2bpa]_\infty$, involves vacuum synthesis at 180 °C [11c]. On the other hand, slow diffusion or co-crystallization techniques have yielded polymeric chains, but usually in low yields [11a,13]. Instead of these typical methods, we wished to investigate synthetic routes that employ mild conditions and result in air stable products that can be isolated in moderate yields, thus allowing exploration of their further chemistry. Experimentally it was determined that reaction of the copper precursor and ligand in acetonitrile, followed by over night heating to 70–100 °C, afforded a series of copper complexes that vary structurally depending on the copper precursor selected. Compounds **1**–**5**, Fig. 2, were isolated at ambient conditions as thermally stable crystalline materials, in moderate to high yield. Here in we report the results of the investigation of $(PyS)_2CH_2$, $(PymS)_2CH_2$ and $(PymS)_2$ with copper halides and pseudo halides.

2. Experimental

The synthesis of $(PyS)_2CH_2$ [14] and $(PymS)_2CH_2$ [15] were performed according to the published procedure. $(PymS)_2$ was prepared through modification of the literature procedure[1].

[1] 2-Mercaptopyrimidine (1.68 g, 15 mmol) was added to a stirred solution of potassium hydroxide (0.84 g, 15 mmol) in ethanol (60 mL). The mixture was warmed to reflux and then bromoform (1.3 mL, 15 mmol) was added drop-wise. The resultant mixture was refluxed for 24 h. After adding water (90 mL), the mixture was left to stand overnight. The yellow precipitate was filtered off and washed with cold ethanol and cold water giving a brown solid that was recrystallized from hot ethanol and water (1.30 g).

All chemicals were purchased from Aldrich or Acros and used as received. Melting points were preformed on a Meltemp apparatus under ambient conditions. In a typical experiment, the ligand and copper salt in a 1:1 mol ratio were dissolved in acetonitrile and heated to between 80 and 90 °C for 12 h. Grease free Teflon sealed Schlenk flasks were employed to avoid grease contamination and to allow heating of a sealed system. All crystals were obtained from slow evaporation of the solution at room temperature. Crystal data were collected with a Bruker SMART 1000 diffractometer using graphite monochromated molybdenum radiation ($\lambda = 0.7107$ Å). Crystals were attached to glass fibers using paratone oil and data were collected at −60 °C. The data were corrected for absorption. Structures were solved by direct methods using the SHELXS-97 [16,17] program and refined via full-matrix least squares [16,17]. Crystal data for all compounds are given in Table 1.

2.1. Synthesis of 1: $[(PymS)_2CH_2Cu(\mu Cl)Cl]_\infty$

In a grease free Schlenk flask, 5 mL of acetonitrile, $CuCl_2 \cdot 2H_2O$ (0.04 g, 0.23 mmol) and $(PymS)_2CH_2$ (0.05 g, 0.21 mmol) were added together. The reaction mixture was heated at ~100 °C for 14 h. After 14 h, the green colored reaction mixture was gravity filtered to remove insoluble impurities. The solution was kept at room temperature for 2 days, during which time large, teal green crystals, suitable for single crystal analysis were isolated. M.Pt. decomposes at 150–152 °C, yield: 0.045 g (51% with respect to $CuCl_2 \cdot 2H_2O$) IR (KBr pellet, υ cm^{-1}): 2956.1 (s), 2923.8 (s), 2855.3 (s), 1614.9 (m), 1578.7 (m), 1461.9 (m), 1449.8 (m), 1386.0 (m), 1181.4 (m), 817.5 (m), UV–Vis (CH_3CN): λ max (nm) = 254, 311, 462.

2.2. Synthesis of 2: $[(PyS)_2CH_2CuCN]_\infty$

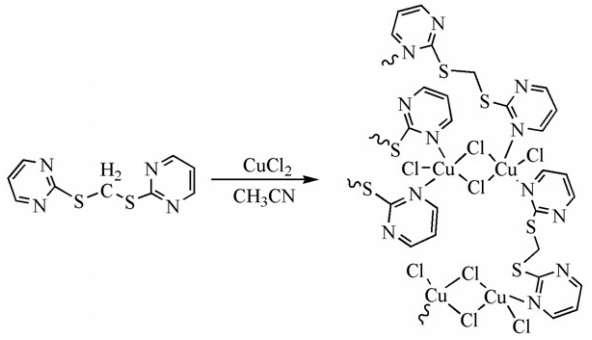
In a grease free Schlenk flask, 5 mL of acetonitrile, CuCN (0.035 g, 0.391 mmol) and $(PymS)_2CH_2$ (0.1 g, 0.391 mmol) were mixed. The reaction mixture was stirred at 80–100 °C for 14 h. After cooling to room temperature the colorless solution was gravity filtered to remove insoluble particles. The solution was stored overnight at room temperature, yielding colorless single crystals of **2**. M.Pt. 72–74 °C, yield: 0.049 g (39% with respect to CuCN), IR (KBr pellet, υ cm^{-1}): 2361.0 (s), 1578.2 (s), 1554.7 (s), 1465.4 (m), 1455.1 (m), 1411.7 (m), 1337.3 (m), 1285.9 (m), 1214.1 (m), 1143.4 (m), 1123.5 (m), 1040.8 (m), 986.5 (m), 755.0 (m), 740.0 (m), 714.0 (m), ^{1}H NMR (300 MHz, CD_3CN, 25 °C): 5.01 (s, 2H), 7.13 (t, 2H), 7.26 (d, 2H), 7.62 (t, 2H), 8.49 (d, 2H). UV–Vis (CH_3CN): λ max (nm) = 250, 290.

2.3. Synthesis of 3: $[(PyS)_2CH_2Cu_2I_2]_2$

CuI (0.1 g, 0.53 mmol) and $(PyS)_2CH_2$ (0.03 g, 0.12 mmol) were dissolved in ~5 mL of acetonitrile. The solution was stirred for 14 h at 80–90 °C. Following filtration, storage of the solution at room temperature afforded pale yellow crystals of **3** suitable for X-ray diffraction. M.Pt. decomposes at 145–147 °C, yield: 0.30 g (45% with respect to CuI), IR (KBr pellet, υ cm^{-1}): 2960.0 (s), 2927.8 (s), 2854.2 (m), 1449.8 (m), 1413.5 (m), 1373.3 (m), 1260.5 (m), 797.4 (s), 765.2 (s), 749.1 (m), ^{1}H NMR

(300 MHz, CD_3CN, 25 °C): 5.02 (s, 2H), 7.14 (t, 2H), 7.28 (d, 2H), 7.63 (t, 2H), 8.49 (d, 2H). UV–Vis (CH_3CN): λ max (nm): 209, 245, 360.

2.4. Synthesis of 4: $[(PymS)_2Cu_2I_2]_2$



CuI (0.1 g, 0.52 mmol) and $(PymS)_2$ (0.18 g, 0.52 mmol) were dissolved in ~5 mL CH_3CN and heated to 70–80 °C for 14 h. After filtration of the yellow solution and storage at room temperature for 5 days, suitable X-ray quality yellow crystals of compound **4** were isolated. M.Pt. 175–177 °C, yield: 0.34 g (50% with respect to CuI) IR (KBr pellet, υ cm^{-1}): 2359.3 (s), 1640.2 (s), 1425.6 (m), 1376.0 (m), 1196.4 (m), 1167.2 (m), 822.6 (m), 804.9 (s), 774.1 (m), 766.9 (m), 744.4 (m), 629.0 (m), 448.5 (m), ^1H NMR (300 MHz, CD_3CN, 25 °C): 7.25 (t, 2H), 8.61 (d, 4H). UV–Vis (CH_3CN): λ max (nm) = 209, 242, 359.

2.5. Synthesis of 5: $[(PymS)_2CuSCN]_\infty$

~5 mL of acetonitrile, CuSCN (0.04 g, 0.33 mmol) and $(PymS)_2$ (0.1 g, 0.29 mmol) were added together in a grease free Schlenk flask. The reaction mixture was stirred for 14 h at 90–100 °C. The colorless solution was filtered to remove a cloudy precipitate. Slow evaporation of the colorless solution at room temperature afforded colorless crystals of **5**. M.Pt. 112–115 °C, yield: 0.037 g (30% with respect to CuSCN), IR (KBr pellet, υ cm^{-1}): 2110.1 (s), 2066.9 (s), 1550.9 (m), 1427.2 (m), 1375.6 (m), 1196.6 (m), 1169.4 (m), 817.6 (m), 767.1 (w), 743.6 (m), 629.1 (m), ^1H NMR (300 MHz, CD_3CN, 25 °C): 6.91 (t, 2H), 6.94 (t, 2H), 8.10 (d, H), 8.30 (d, 4H). UV–Vis (CH_3CN): λ max = 236 nm.

3. Results and discussion

The reaction of (bispyrimidylthio)methane with $CuCl_2$ afforded teal paramagnetic crystals of the complex $[(PymS)_2CH_2CuCl_2]_\infty$ as shown in Scheme 1. Experimentally it was determined that the choice of solvent is important. Attempts using tetrahydrofuran, benzonitrile, ethanol, water or toluene were all unsuccessful and no coordination of the ligand to the metal was observed. For all reactions acetonitrile was used as the solvent.

Scheme 1. Synthesis of $[(PymS)_2CH_2Cu(\mu Cl)Cl]_n$.

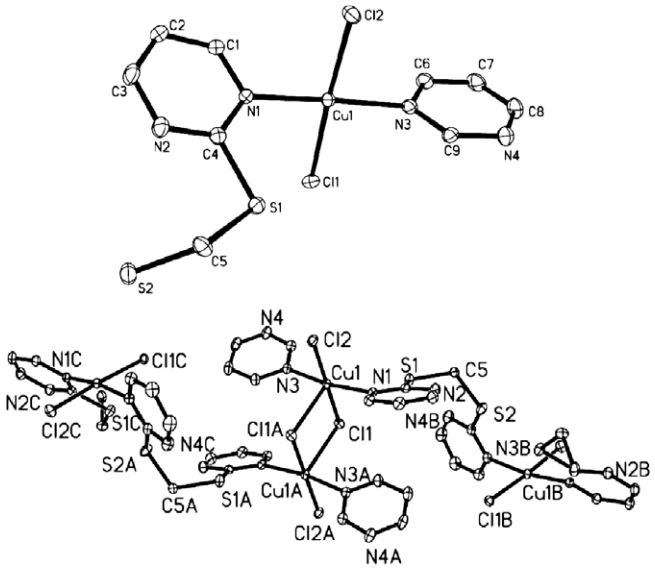


Fig. 3. Diagram of the asymmetric crystallographic unit and the polymeric structural motif. Thermal ellipsoids shown at 30% probability level, hydrogen atoms are omitted for clarity. Selected bond lengths (Å) and angles (°): Cu(1)–N(1) 2.049(2), Cl(1)–Cu(1)–N(1) 93.04(6), N(3)–Cu(1)–Cl(2) 88.11(7), Cl(1)–Cu(1)–Cl(1a) 85.97(3).

The overall structural motif can be described as two-dimensional sheet with the interchain linkage provided by the organic ligand. The X-ray crystal structure of **1** is exhibited in Fig. 3.

The geometry around each copper atom is five coordinate corresponding to distorted trigonal bypyrimidal geometry. The ligand bridges the copper centers. Every copper atom is coordinated to two nitrogen atoms, N(1) and N(3), from pyrimidine groups provided by two different ligand molecules. Making up the remaining two coordination sites on copper are chloride atoms, Cl(1) bridges two copper centers (μ2) while the other remains terminal. The bond lengths of the chlorides vary only slightly, the terminal chloride has a Cu–Cl distance of 2.2468(8) Å compared to the bridged Cu–Cl distance of 2.2822(7) Å. Compound **1** can be compared to a previously reported structure $[CuCl_2(\mu\text{-dpds})]$ (dpds = dipyridyl disulfide) (**A**) [18], Fig. 4, that was isolated from the similar reaction of bis(2pyridylthio)methane with $CuCl_2$.

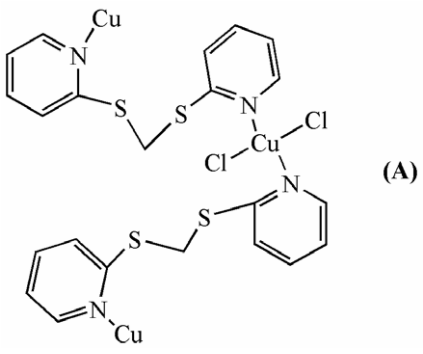

Fig. 4. Structurally similar molecule to (1), from the reaction of $CuCl_2$ with bptm [18].

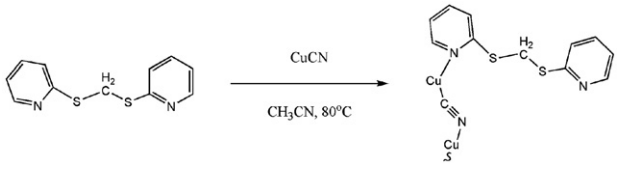
Comparison of the structures of $[CuCl_2(\mu\text{-dpds})]$ with $[(PymS)_2CH_2Cu(\mu Cl)Cl]_\infty$ (**1**) reveals distinct differences that likely arise from the different experimental procedures. $[CuCl_2(\mu\text{-dpds})]$ was formed from the slow diffusion of methanol solution of copper(II) chloride and the ligand. The main difference between the two structures is that in **A** the chloride atoms do not bridge, instead they retain their trans geometry yielding an infinite helical chain. The bridging halides in complex **1** help minimize the distance between the pyridyl layers, by constraining the geometry. The Pym–Pym distance is 3.697 Å (between corresponding aromatic carbons), which is relatively short and so should allow π–π stacking, however the arrangement of the pyrimidyl rings are slightly twisted. Comparison of the bond lengths and angles between $[CuCl_2(\mu\text{-dpds})]$ and **1** show good similarity, and are detailed in Table 2.



Polymer **1** is soluble in common organic solvents and is relatively thermally stable, melting to a green liquid at 150–152 °C. The UV–Vis spectrum of **1** showed broad adsorptions between 250 and 470 nm which are assigned as Cu–ligand charge transfer transitions. Luminescence measurements were attempted in acetonitrile at room temperature, but no meaningful data could be obtained.

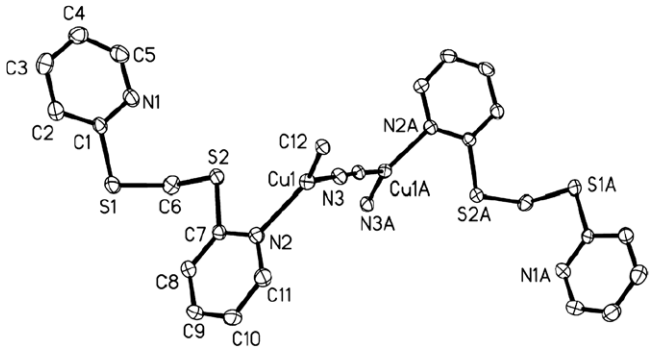
In an attempt to further develop polymeric networks, the reaction of $(PyS)_2CH_2$ with CuCN was performed, Scheme 2. CuCN has limited solubility in acetonitrile, but the reaction proceeds as a suspension, however the lower yield of the product (39%) is due to the lower solubility of the metal salt.

Colorless crystals of **2** (Fig. 5) were isolated at room temperature and crystallize in the orthorhombic, chiral space group, $P2(1)2(1)2(1)$. Solid-state X-ray analysis revealed the ambidentate CN ligand bridges each copper center and is coordinated to a nitrogen atom of the pyridyl group from bis(bipyridylthio)methane. This results in each copper center having two cyanide groups, giving rise to distorted trigonal planar geometry. The C–N distance of

Table 2
Comparison of the bond lengths (Å) between complexes $[CuCl_2(\mu\text{-dpds})]$ [18] and (**1**)

	$[CuCl_2$ $(\mu\text{-dpds})]$ (**A**)	$[(PymS)_2CH_2$ $Cu(\mu Cl)Cl]_\infty$ (**1**)
Cu–N(1)	2.047(3)	2.049(2)
Cu–N(2) for **A**, N(3) for **1**	2.045(1)	2.038(2)
Cu–Cl(1)	2.2840(9)	2.2822(7)
Cu–Cl(2)	2.261(1)	2.2468(8)

Scheme 2. Synthesis of **2**, $[(PyS)_2CH_2CuCN]_\infty$.



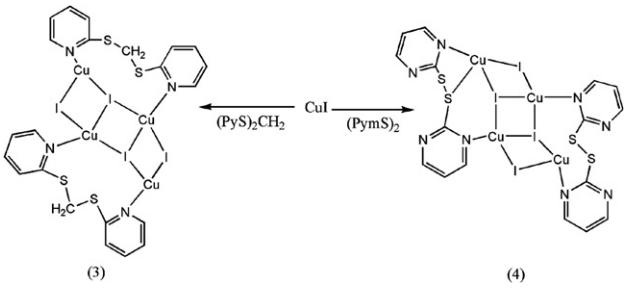


Fig. 5. Crystallographic analysis of **2** $[CuCN(PyS)_2CH_2]_\infty$. Ellipsoids are shown at 30% probability level with hydrogen atoms omitted for clarity. Selected bond lengths (Å) and angles (°) of **2**: Cu(1)–N(2) 2.034(2), Cu(1)–C(12) 1.872(3), C(12)–N(3) 1.154(3), N(2)–Cu(1)–C(12) 120.93(10), N(3)–C(12)– Cu(1) 174.9(2), Cu(1)–Cu(1a) 4.933.

1.154(3) Å is typical of the C–N bond in cyanide [11,19]. The distance between Cu centers is 4.933 Å. Each Cu(I) atom has distorted trigonal planar geometry with angles of 125.43(10)°, 113.25(9)° and 120.93(10)°. Three coordinate distorted trigonal planar geometry is a characteristic of Cu(I) cyanide structures, for example in $KCu(CN)_2$ [20]. The geometry around the Cu(1)–C(12)–N(3) ligand is close to linear, with an angle of 174.9(2). Infrared spectroscopy exhibited the distinctive CN stretch at 2361 cm^{-1} that is within the range expected for a bridged CN ligand [11f,19,20]. Proton NMR on **2** showed the proton signals shifted downfield when compared with the free ligand [10]. This was observed in the spectra of complexes **2**–**5** suggesting that the structure is retained in solution when the crystalline material is redissolved.

Bond lengths and angles of **2** show good agreement with other Py–CuCN complexes, for example $[(CuCN)_2[CuCN]_2(\mu\text{-}4\text{-}4'bipy)]$ has a Cu–CN bond length of 1.862(3) Å and a Cu–N(Py) bond length of 2.069(2) Å [21]. Within the polymeric network of **2** the distance between the aromatic layers (i.e. from C(1)–C(1a) or S(1)–S(1a)) is ~8.702 Å [22].

Having successfully isolated polymeric chains from copper(II) chloride and copper(I) cyanide, we wished to extend the series and examine if polymeric chains would be isolated using copper(I) iodide. Using similar reaction conditions as were used for the formation of **1** and **2** $(PyS)_2CH_2$ and $(PymS)_2$ were reacted with CuI (Scheme 3).

Complexes **3** and **4** show structural similarity, both feature the Cu_4I_4 core which can be described as a 'ladder type' arrangement that is well documented common for copper halides [3]. The four copper atoms and four iodine atoms form parallelograms, with Cu–Cu distances of 2.849 Å and 2.862 Å between the two copper atoms in **3** and 3.038 and 2.657 Å in **4**. This can be compared with the Cu–Cu distance in metallic copper of 2.556 Å and the Van der Waals radius of copper at 2.80 Å [23] and is a typical value for discrete Cu–I ladder structures [24]. Complex **3** is analogous to the Cu(I) bromide compound isolated by

Scheme 3. Reactions of copper(I) iodide with $(PyS)_2CH_2$ and $(PymS)_2$.

García-Martínez and co-workers [10] from the reaction of $(PyS)_2CH_2$ with Cu(I)Br, however, unlike their copper cluster, complex **3** was the major reaction product and was isolated in 67% yield.

Complex **3** crystallizes as yellow triclinic crystals (Fig. 6) space group $P\bar{1}$, while complex **4** crystallizes as yellow monoclinic crystals, space group, $P2_1/c$ (Fig. 7).

Single crystal X-ray analysis of complex **3** reveals that two different bonding arrangements occur around the copper centers, but both adopt distorted tetrahedral geometries. Cu(1) is coordinated to the pyridyl nitrogen (N1) and two bridging iodides, I(1) and I(2). The second copper center, Cu(2), has coordination to a pyridyl nitrogen atom N(2), a sulfur atom from the ligand, S(1) and two bridging iodides, I(1) and I(2). Thus, the ligand bridges two copper centers. The iodide atoms bridge the copper atoms in μ3 and μ2 modes. The two copper centers have distorted tetrahedral geometry with angles ranging from 102.43(2)° to 118.11(11)° for Cu(1) and 100.48(12)° to 116.68(4)° around Cu(2). The Cu–I bridges are found to be slightly asymmetric, Cu(1)–I(1) = 2.7257 Å, Cu(1)–Cu(I2A) = 2.6776(8) Å, but this is not uncommon for bridged halides and can be compared to $[Cu_4(L^1)_2I_4]$ (L^1 = bis(6-methyl-2 pyridyl methyl sulfide)) that has bond lengths of 2.586(1)–2.652(1) Å for the bridged iodides, a Cu–N distance of 2.031(3) Å and a Cu–S distance of 2.570(1) Å [25,26].

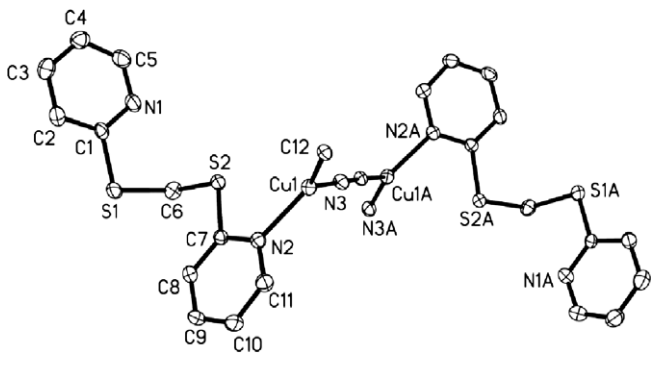

Fig. 6. Crystal structure of complex **3**, thermal ellipsoids at 30% probability level, hydrogen atoms are omitted for clarity. Key bond lengths (Å) and angles (°): Cu(1)–I(1) 2.7257(7), Cu(1)–I(2) 2.6776(8), Cu(2)–N(2) 2.079(4), Cu(2)–I(2) 2.5693(8), Cu(1)–N(1) 2.071(4), Cu(2)–S(1) 2.3010(14), N(1)–Cu(1)–I(2) 107.67(11), N(1)–Cu(1)–I(1) 104.82(11), I(1)–Cu(1)–I(2a) 106.91(2), S(1)–Cu(2)–I(2) 116.68(4), N(2)–Cu(2)–I(1a) 100.48(12).

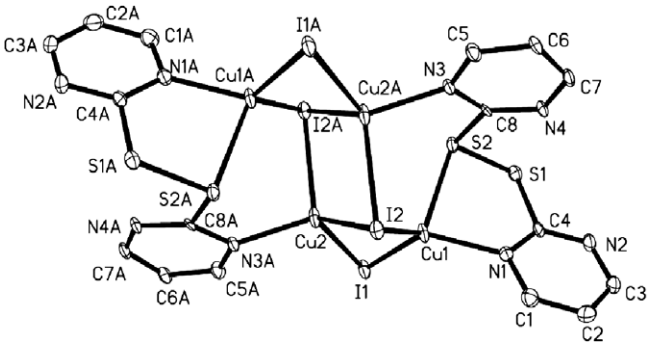

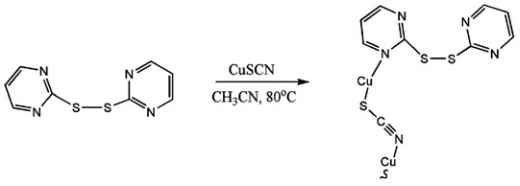

Fig. 7. X-ray crystal structure of $[(PymS)_2Cu_2I_2]_2$, complex **4**, thermal ellipsoids at 30% probability level. Hydrogen atoms are omitted for clarity. Key bond lengths (Å) and angles (°): Cu(1)–N(1) 2.053(7), Cu(2)–N(3a) 2.061(7), Cu(1)–S(2) 2.421(2), Cu(1)–I(1) 2.5612(11), N(1)–Cu(1)–I(2) 114.1(2), I(1)–Cu(1)–S(2) 106.20(6), N(1)–Cu(1)–Cu(2) 172.1(2), N(1)–Cu(1)–S(2) 85.97(19).

Unlike the analogous bromide compound, complex **3** has no hydrogen bonding existing between the CH_2 group and the iodides [10]. This is possibly due to the lower electronegativity of the iodine versus bromine, and the larger size between the atoms, therefore a polymeric chain of clusters does not form. Solution luminescent measurements in acetonitrile were performed on **3** and **4** but no luminescence was recorded, it is possible that low temperature solid-state measurements are required.

PymS–SPym was prepared serendipitously in high yield from the attempted synthesis of $(PymS)_3CH$. Despite this not being the desired product, it could be reproducibly prepared in high yield[1]. The reaction of $(PymS)_2$ with CuI (Scheme 3) afforded monoclinic yellow crystals of compound **4** in high yield, Fig. 7.

The solid-state analysis reveals a dimeric structure that features a tetrameric core of copper atoms. Each ligand chelates one copper atom through S(1) and N(1) atoms and coordinates to another Cu(2) through another nitrogen atom, thus bridging between the two. An average Cu–S bond is reported to be around 2.67 Å [26], the Cu–S distance of 2.421(2) Å is significantly shorter than this distance, and is attributed to the steric constraints of the ligand. It is noteworthy to mention that complex **4** appears to be thermally robust in the solid-state and in solution, however, attempts to use the similar system, PyS–SPy, for framework synthesis resulted in cleavage of the S–C aromatic bond and formation of elemental sulfur.

To continue the series the reaction of CuCN with $(PymS)_2$ was performed, however no crystalline product could be isolated. Exchange of copper cyanide for copper

Scheme 4. Synthesis of **5** from the reaction of $(PymS)_2$ with CuSCN.

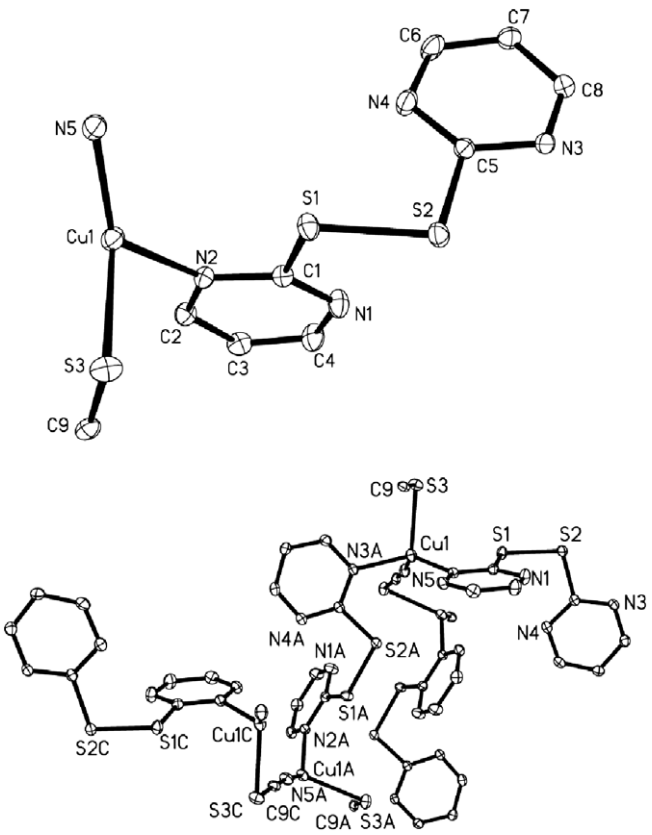

Fig. 8. Crystal structure of $[(PymS)_2CuSCN]_\infty$ (**5**) asymmetric unit and polymeric network. Thermal ellipsoids at 30% probability and hydrogen atoms are omitted for clarity. Selected bond lengths (Å) and angles (°): Cu(1)–N(3) 2.1580(19), Cu(1)–S(3) 2.3957(7), Cu(1)–N(2) 2.036(2), Cu(1)–N(5) 1.918(2), S(1)–C(1) 1.785(2), S(3)–C(9) 1.656(3), N(2)–Cu(1)–S(3) 96.95(6), N(5)–Cu(1)–S(3) 115.80(7), N(2)–Cu(1)–N(3) 105.77(8).

thiocyanate, afforded colorless crystals of an infinite two-dimensional polymeric material **5**, Scheme 4 and Fig. 8.

Use of copper(I) thiocyanate has not been well explored for use in metal organic framework construction, in part because of its limited solubility in organic solvents [11]. We were drawn to this precursor, given our success with copper cyanide, and because this copper salt exists as polymeric $[Cu(SCN)]_\infty$ [27].

Polymer **5** crystallizes in the monoclinic space group $P2_1/c$ and the X-ray analysis shows that each copper is tetrahedrally coordinated to two nitrogen atoms from two different ligands, sulfur and nitrogen atoms from the thiocyanate group. Complex **5** forms a two-dimensional network. The geometry around the thiocyanate group is nearly linear, with the S–C≡N angle of 178.3(2)°, and a Cu–Cu separation of 5.559 Å. The bond lengths and angles in **5** compare well with that of $[Cu(SCN)(pyz)]_\infty$, that has Cu–S and Cu–N bonds of 2.349(2) Å and 1.940(4) Å, respectively [11g]. Infrared spectroscopy of polymer **5** exhibited CN stretches at 2110.1 and 2066.9 cm^{-1} and at 767.1 cm^{-1}, associated with the S–C stretch and these values compare well with other reported polymeric structures [11].

4. Conclusion

We have shown that copper(II) chloride, copper(I) iodide and copper pseudo halides can be used in conjunction with flexible heteroelemental organic linkers to form polymers that can incorporate the anion into the framework. This type of preparation is a versatile useful approach for construction of neutral polymeric frameworks that offer potential for further reactions and framework growth, because of the availability of uncoordinated donor atoms present.

Future work will explore the further chemistry of these polymers and will focus on expanding the chemistry of the dipodal ligands for further polymeric materials.

ligand in the coordination sphere makes possible a charge transfer, LLCT type, in the form of an electronic transition directed to the diimine ligand, the origin of the excited electron depends strongly on the actual complex composition, mainly on the nature of the axial ligand. Thus, the formation of MLCT and/or LLCT excited states involves processes which may be described in terms of the redox couples Re^{I}/Re^{II}, $L_2/L_2^{\cdot -}$ and $L'/L'^{\cdot +}$.

When the axial ligand and the Re^{I} moiety are linked through a carboxylate bridge, as in the complexes $(RCO_2)Re^{I}(CO)_3(2,2'\text{-bpy})$ (R = methyl, 1-pyrenyl, 9-anthranyl, 2-naphthyl) the luminescent LLCT excited state induces photodecarboxylation [5] after the optical excitation of the Re^{I} complexes at wavelengths of the ligand-centered transitions (Eq. (1)):

$$(RCO_2)Re^{I}(CO)_3(2,2'\text{-bpy}) \xrightarrow{h\nu} \text{LLCT} \rightarrow R^{\cdot} + CO_2 + Re^{I}(CO)_3(2,2'\text{-bpy})^{\cdot} \quad (1)$$

However, this decarboxylation is inhibited [11] when R has a strong donating character as in $(RCO_2)Re^{I}(CO)_3L$ (R = 4-dimethylaminobenzyl (4-DMAB), ferrocene; L = phen, 2,2′-bpy). The photophysical and photochemical processes of (RCO_2) $Re^{I}(CO)_3L$ (R = ferrocene, 4-DMAB) are significantly different from the processes undergone by the complexes $(RCO_2)Re^{I}(CO)_3(2,2'\text{-bpy})$ (R = methyl, 1-pyrenyl, 9-anthranyl, 2-naphthyl). Differences in the quantum yields of photodecarboxylation and in the kinetics of the charge transfer excited-state relaxation are associated with the higher energies of the LLCT (RCO_2– to L) charge-transfer excited states in the latter complexes [11] and with the presence of a different excited state from the LLCT (RCO_2– to L) and MLCT (Re-to-L). This excited state was identified as having chemical properties and spectroscopic features consistent with those of a charge transfer from Re to RCO_2 [11].

The UV–Vis/IR spectroelectrochemistry of AQ-2-CO_2–$Re^{I}(CO)_3(2,2'\text{-bpy})$, (AQ = anthraquinone) was looked upon in our lab [12]. The in-situ spectra of the electrochemically reduced radical anions, $AQ^{\cdot -}$ and $2,2'\text{-bpy}^{\cdot -}$, were in excellent agreement with those obtained from the products of reductive quenching of the corresponding photochemically-excited states. In this work, the spectroelectrochemical behavior of DMAB–CO_2–$Re^{I}(CO)_3$(phen) and DMAB–COOH acid, was investigated with a view to establishing comparisons among species formed electrochemically and those arising by electron transfer quenching of excited states of the complex or its ligands. The study deals, in addition, with the nature of products and intermediates generated in the reduction and/or oxidation of DMAB–CO_2–$Re^{I}(CO)_3$(phen) and DMAB–COOH obtained through flash photolysis and pulse radiolytic techniques. A comparison is made between the nature of the radical species produced after the reduction/oxidation of DMAB–CO_2–$Re^{I}(CO)_3$(phen) and DMAB–COOH using electrochemical, flash photolytical and pulse radiolytical methods.

2. Experimental

2.1. Electrochemical procedures

The cells for voltammetry and spectroelectrochemistry experiments have been described elsewhere [13]. In addition, ac voltammograms were recorded with an exciting amplitude of 1.6 mV rms at 11 Hz with a slow sweep rate of 3 mV s^{-1}. DC voltammograms were obtained with a conventional computerized set-up. Acetonitrile, ACN, Merck "SeccoSolv", was further dried over activated alumina for several days. The procedure was found to be suitable for electrochemistry in the −2.0/+1.8 V (versus Ag/AgCl, KCl_{sat}) potential range. $(Bu_4N)PF_6$ was dried in vacuum at 60 °C for at least 24 h. Pt discs (6 mm dia) were used as working electrodes. Potentials were measured against a Ag/AgCl, KCl_{sat} reference electrode. Oxygen was removed from the solutions by bubbling purified nitrogen for at least 30 min prior to each experiment. A Pt mesh, separated from the working compartment by a porous disc, was used as a counter electrode. A fresh surface was generated before each experiment by polishing the working electrode to a mirror finish with alumina, sonicated, rinsed with Millipore-Milli-Q water and dried before being placed in the solution. The quality of the surface was tested by inspecting the response to cycling the working electrode in the supporting electrolyte. Solutions were prepared with analytical-grade reagents.

2.2. Spectroelectrochemical measurements

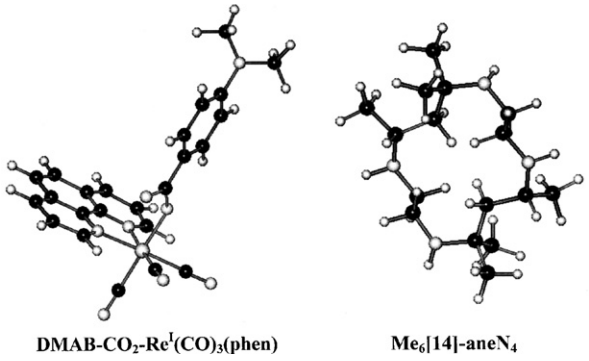
Potential modulated spectra were obtained in situ with a home-made, UV–Vis spectrometer [12,14,15]. In the technique, the light is focused onto the electrode at an angle of 45° while the electrode potential, and therefore the reflected light, is modulated at 11 Hz (square wave). The reflected intensity, an ac signal, ΔR, was sensed with a photomultiplier and rectified by a lock-in amplifier. The spectra are, unless stated otherwise, the normalized difference between the optical response at a given potential against that at a potential taken as reference, R_{ref}, i.e., $\Delta R/R_{ref} = (R - R_{ref})/R_{ref}$ versus wavelength (integral measurements, i.e. large modulations). Differential spectra $\delta R/R$ are taken with a small amplitude modulation as a function of potential at a set wavelength (reflectogrammes). The set-up has been described in more detail elsewhere [16–18].

2.3. Flash-photochemical procedures

Optical density changes occurring on a time scale longer than 10 ns were investigated with a flash photolysis apparatus described elsewhere [19–21]. In these experiments, 25 ns flashes of 351 nm light were generated with a Lambda Physik SLL-200 excimer laser. The energy of the laser flash was attenuated to values equal to or less than 20 mJ/pulse by absorbing some of the laser light

by solutions of $Ni(ClO_4)_2$ with appropriate optical transmittances, $T = I_t/I_0$, where I_0 and I_t are, respectively, the intensities of the light arriving to and transmitted from the photolysis cell. The transmittance, $T = 10^{-A}$, was routinely calculated by using the spectrophotometrically measured absorbance, A, of the solution. A right angle configuration was used for the pump and the probe beams. Concentrations of the complexes were adjusted to provide homogeneous profiles of photogenerated intermediates over the optical path, $l = 1$ cm, of the probe beam. To satisfy this optical condition, solutions were prepared with an absorbance equal to or less than 0.4 over the 0.2 cm optical path of the pump. Concentrations of the complexes were adjusted to give optical densities equal to or less than 0.05 for a 1 cm optical path at 350 nm. All solutions used in the photochemical work were deaerated with streams of ultrahigh-purity N_2 before and during the irradiations.

2.4. Pulse radiolysis



Pulse radiolysis experiments were carried out with a model TB-8/16-1S electron linear accelerator. The instrument and computerized data collection for time-resolved UV–Vis spectroscopy and reaction kinetics have been described elsewhere in the literature [22,23]. Thiocyanate dosimetry was carried out at the beginning of each experimental session. Details of the dosimetry have been reported elsewhere [22,24]. The procedure is based on the concentration of $(SCN)_2^{\bullet -}$ radicals generated by the electron pulse in a N_2O-saturated 10^{-2} M SCN^- solution. In the procedure, the calculations were made with $G = 6.13$ and an extinction coefficient $\varepsilon = 7.58 \times 10^3\ M^{-1}\ cm^{-1}$ at 472 nm [22,24] for the $(SCN)_2^{\bullet -}$ radicals In general, the experiments were carried out with doses that in N_2-saturated aqueous solutions resulted in $(2.0 \pm 0.1) \times 10^{-6}$ M to $(6.0 \pm 0.3) \times 10^{-6}$ M concentrations of e^-_{aq}. In these experiments, solutions were deaerated with streams of the O_2-free N_2 or N_2O gasses. In order to irradiate a fresh sample with each pulse, an appropriate flow of the solution through the reaction cell was maintained during the experiment.

The radiolysis of CH_3OH and CH_3OH/H_2O mixtures with ionizing radiation has been reported elsewhere in the literature [25–27]. These studies have shown that pulse radiolysis can be used as a convenient source of e^-_{sol} and $C^{\bullet}H_2OH$ radicals.

Since e^-_{sol} and $C^{\bullet}H_2OH$ have large reduction potentials, i.e., −2.8 V versus NHE for e^-_{sol} and −0.92 V versus NHE for $C^{\bullet}H_2OH$, they have been used for the reduction of coordination complexes and for the study of electron transfer reactions. The yield of e^-_{sol} in CH_3OH ($G \approx 1.1$) is about a third of the G-value in the radiolysis of H_2O ($G \approx 2.8$) [25]. In solutions where e^-_{sol} was scavenged with N_2O [27] the $C^{\bullet}H_2OH$ radical appears to be the predominant product (yield > 90%) of the reaction between CH_3OH and $O^{\bullet -}$.

2.5. Materials

4-(Dimethylamino)benzoic acid (DMAB–COOH) was obtained from Aldrich and used as received. The complex DMAB–CO_2–$Re^I(CO)_3$(phen) and the macrocycle $[Ni(Me_6[14]\text{–}aneN_4)](ClO_4)_2$ were available from previous works [11,28] (Scheme 1).

Scheme 1.

3. Results and discussion

3.1. Electrochemistry

AC voltammetry experiments conducted on DMAB–COOH (1×10^{-3} M) in Pt/ACN/Bu_4NPF_6 solutions at 11 Hz, Fig. 1, show a reversible wave at 1.00 V versus Ag/AgCl, the background being featureless. The electrochemical behavior of DMAB–COOH can be compared to that of dimethylaniline (DMA). The anodic oxidation of DMA occurs irreversibly to form $DMA^{\bullet +}$ at a potential

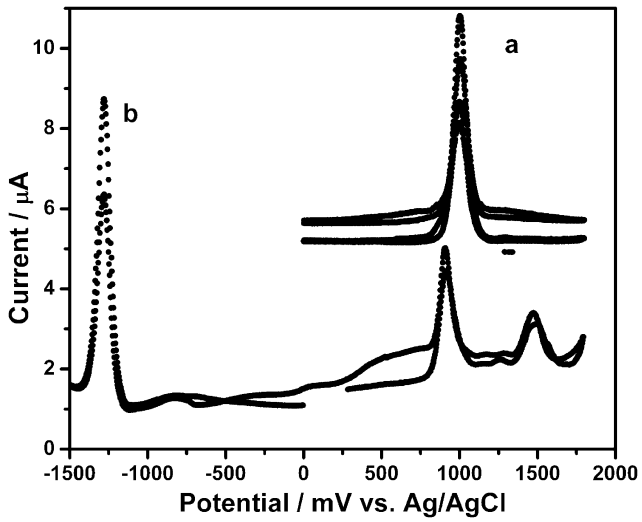


Fig. 1. (a) Alternating current voltammogram (ACV) between 0 and 1.75 V of the Pt/ACN + 0.1 M Bu_4NPF_6/1×10^{-3} M DMAB–COOH interface. (b) ACV between −1.5 and 1.75 V of the Pt/ACN + 0.1 M Bu_4NPF_6/2×10^{-4} M DMAB–CO_2–$Re^I(CO)_3$(phen). Frequency 11 Hz, amplitude 1.6 mV_{rms}, $v = 3.0\ mV\ s^{-1}$ (one cycle). Electrode area: 0.28 cm^2. Forward and back scans.

of about 0.76 V versus SCE [29]. In our case the reversible current response, corresponds to the couple of the amine in DMAB–COOH, i.e. DMAB–COOH/DMAB$^{\cdot+}$–COOH. The fact that the oxidation potential of the amine lies at more positive values in DMAB–COOH than in DMA can be rationalized in terms of the properties of the electron attracting group –CO_2 which makes the amine oxidation less facile. The electrochemical oxidation of DMA and other p-substituted dialkylanilines leads to the formation of *N*,*N*,*N*′,*N*′-tetraalkylbenzidine as the major oxidation product [29,30]. However, our electrochemical results did not show the generation of oxidation products derived from the radical cation DMAB$^{\cdot+}$–COOH. It seems that the formation of coupled compounds as products of the primary radical cation DMAB$^{\cdot+}$–COOH cannot be observed on the timescale set by the ac voltammetry modulation.

AC voltammetry experiments were conducted on DMAB–CO_2–$Re^{I}(CO)_3$(phen) (2×10^{-4} M) in Pt/ACN/Bu_4NPF_6 solutions at 11 Hz. The current response for DMAB–CO_2–$Re^{I}(CO)_3$(phen), Fig. 1, shows three reversible waves at −1.28 V, +0.91 and +1.47 V versus Ag/AgCl. Based on published reports [11,31] the reversible reduction wave at −1.28 V can be ascribed to a reduction on the phen ligand of the Re^{I} complex. The anodic wave at +0.91 V can be assigned to the amine oxidation in the Re^{I} complex. The potential (+0.91 V) lies between those corresponding to DMA and DMAB–COOH as the effect of the electron attracting group –CO_2 on the amine redox potential is less pronounced in the Re^{I} complex than in DMAB–COOH since the carboxylate group is also withdrawing electron density from the Re^{I} center and its moiety. The anodic wave at +1.47 V can be related to the Re^{I}/Re^{II} couple [11,12,31].

With a view to identifying the species electrochemically generated, associated to the waves observed on ac voltammetry, spectroelectrochemical experiments were designed to study the species generated in the redox processes of DMAB–COOH and DMAB–CO_2–$Re^{I}(CO)_3$(phen). The in situ reflectance spectrum, integral (large modulation), inset to Fig. 2, recorded in DMAB–COOH 1×10^{-3} M in Pt/ACN/Bu_4NPF_6 0.1 M solutions with a potential modulation between +0.9 and +1.5 V, shows a band peaking at 475 nm. The spectrum of the inset to Fig. 2 is in good agreement with the absorption of DMAB$^{\cdot+}$–COOH obtained in flash photolysis experiments [32] as well as with the data reported for DMA$^{\cdot+}$ ($\lambda_{max} \sim 490$ nm [33]) and *p*-bromo-*N*,*N*-dimethylaniline ($\lambda_{max} \sim 490$ nm in ACN [34]) radical cations. Therefore, the spectrum of Fig. 2 (inset) can be assigned to the amine radical cation DMAB$^{\cdot+}$–COOH detected reversibly under our experimental conditions. The detection of the spectra of the amine radical cations by spectroelectrochemistry has been considered difficult due to their high reactivity [35,36], therefore this is probably the first time the absorption of DMAB$^{\cdot+}$–COOH can be observed by using this technique.

A similar spectrum was obtained (Fig. 2) when the in situ reflectance was recorded with DMAB–CO_2–$Re^{I}(CO)_3$(phen) 2×10^{-4} M in Pt/ACN/Bu_4NPF_6 0.1 M solutions with a potential modulation between +0.9 and +1.2 V, showing the absorption spectrum ($\lambda_{max} = 475$ nm) of the amine radical cation in the Re^{I} complex.

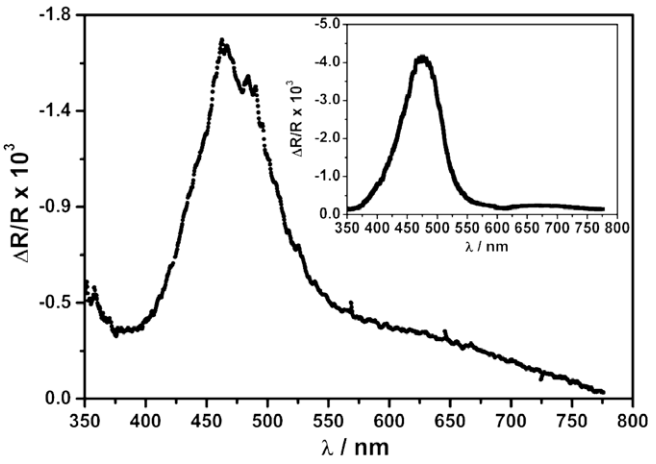

Fig. 2. Modulated reflectance spectra of the Pt/ACN + 0.1 M Bu_4NPF_6/2×10^{-4} M DMAB–CO_2–$Re^{I}(CO)_3$(phen) system between 0.9 and 1.2 V, 11 Hz. Angle of incidence $\phi = 45°$. The inset shows the modulated reflectance spectra of the Pt/ACN + 0.1 M Bu_4NPF_6/1×10^{-3} M DMAB–COOH system between 0.9 and 1.2 V.

When the in situ reflectance was recorded in DMAB–CO_2–$Re^{I}(CO)_3$(phen) with a modulation applied between −1.00 and −1.50 V under the same experimental conditions, the absorption spectrum observed is that of Fig. 3 (λ_{max} at 420 and 560 nm), which can be attributed, according to literature [11,37], as arising from the spectrum of the reduced phen radical in the Re^{I} complex.

Fig. 4 shows the spectrum observed when the potential modulation applied to the DMAB–CO_2–$Re^{I}(CO)_3$(phen) complex was set between 1.20 and 1.70 V, i.e. covering the voltammetric wave of Re^{II} in the complex. The negative lobe arises from the absorption at 1.70 V. This spectrum,

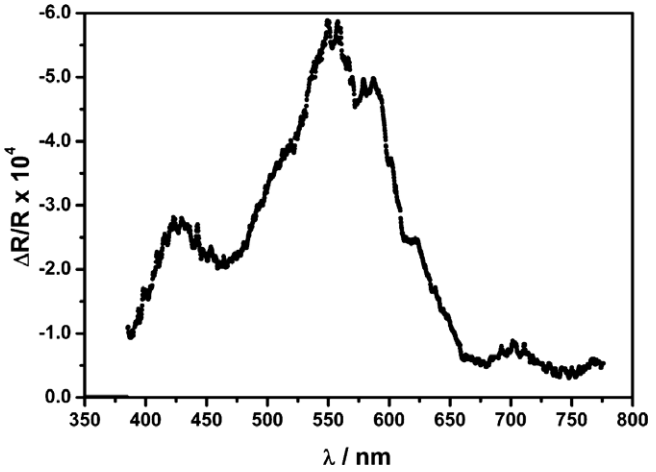

Fig. 3. Modulated reflectance spectra of the Pt/ACN + 0.1 M Bu_4NPF_6/2×10^{-4} M DMAB–CO_2–$Re^{I}(CO)_3$(phen) system between −1.00 and −1.50 V, 11 Hz.

$\lambda_{max} \sim 400$ nm (maximum is partially clipped because of the band bipolar nature), is characteristic of Re^{II} complexes [38–40] in good agreement with the spectrum of pulse radiolytically generated $(L')Re^{II}(CO)_3(L)^z$ complexes ($L' = 4,4'$-bpy; L = dipyridil [3,2-a:2′3′-c] phenazine and $z = +2$ or $L' = Cl$; L = bathocuproinedisulfonate and $z = -1$) [41]. The absorption indicated in Fig. 4 as positive, should arise from the amine oxidation, partially sensed by the modulation lower limit, at 1.20 V. In order to discard the possibility of contributions to the spectrum in Fig. 4 (to the negative lobe) from impurities generated if the amine group was oxidized at potentials higher than +1.00 V, a reflectogramme, (differential reflectance versus potential) was recorded at the absorption wavelength of Re^{II} species ($\lambda = 418$ nm) [40,42]. The comparison between the optical response ($\delta R/R$) versus potential (unfolded format), in the inset to Fig. 4, top frame, and the ac voltammogramme, bottom frame, clearly indicates the coincidence of the absorption of the Re^{II} species at the same potential of the Re^{I} oxidation.

3.2. Pulse radiolysis redox products

The spectra of the transient species produced by one-electron oxidation of DMAB–COOH was investigated by pulse radiolysis of their water solutions in the presence of NaCl 0.1 M under a N_2O atmosphere. The spectrum of the transient species, Fig. 5, corresponds to the absorptions of the oxidized amine radical cation. The absorption turned out to be in good agreement with that observed spectroelectrochemically (compare to Fig. 2). The cation radical $DMAB^{\cdot+}$–COOH is formed by the reaction of $Cl_2^{\cdot-}$ and DMAB–COOH within the first 2 μs after the radiolytic pulse and decays by first order kinetic on a 100 μs-1 ms timescale. Eqs. (2)–(5) summarize the sequence of events

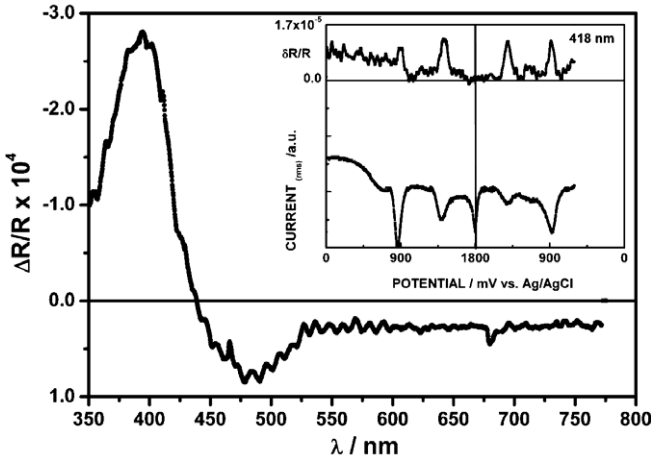

Fig. 4. Modulated reflectance spectra of the Pt/ACN + 0.1 M Bu_4NPF_6/ 2×10^{-4} M DMAB–CO_2–$Re^{I}(CO)_3$(phen) system between 1.20 and 1.70 V, 11 Hz. The inset shows in the top frame a reflectogramme (differential reflectance versus potential, unfolded format) carried out at the absorption wavelength of Re^{II} species ($\lambda = 418$ nm). The bottom frame displays the corresponding ACV.

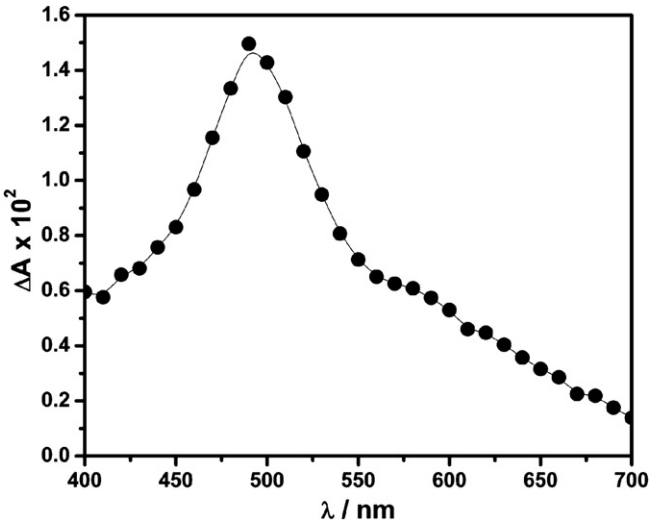

Fig. 5. Transient spectrum recorded at a delay of 7.5 μs after the radiolytic pulse in pulse radiolysis experiments conducted on DMAB–COOH 1×10^{-4} M water solutions in the presence of NaCl 0.1 M under N_2O atmosphere.

that lead to the formation of $DMAB^{\cdot+}$–COOH after the radiolytic pulse in aqueous solutions of DMAB–COOH:

$$N_2O + e^-_{sol} + H_2O \rightarrow OH^{\cdot} + OH^- + N_2 \quad (2)$$

$$OH^{\cdot} + Cl^- \rightarrow Cl^{\cdot} + OH^- \quad (3)$$

$$Cl^{\cdot} + Cl^- \rightleftarrows Cl_2^{\cdot-} \quad (4)$$

$$Cl_2^{\cdot-} + DMAB\text{–}COOH \rightarrow 2Cl^- + DMAB^{\cdot+}\text{–}COOH \quad (5)$$

The sequence of events in the radiolysis of N_2 deaereated methanolic solutions is shown in the kinetic scheme of Eqs. (6)–(8):

$$CH_3OH \rightsquigarrow CH_3OH^+, e^-_{sol} \quad (6)$$

$$CH_3OH^+ \rightarrow CH_3O^{\cdot} + H^+ \quad (7)$$

$$CH_3O^{\cdot} + CH_3OH \rightarrow CH_3OH + C^{\cdot}H_2OH \quad (8)$$

Thus, the main reducing species in pulse radiolysis of methanolic solutions under a N_2 atmosphere are e^-_{sol} and $C^{\cdot}H_2OH$.

However, when methanolic solutions are deareated with N_2O, e^-_{sol} are consumed through Eq. (9) and the main radical product of the reaction between e^-_{sol} and N_2O is $C^{\cdot}H_2OH$:

$$N_2O + e^-_{sol} + CH_3OH \rightarrow C^{\cdot}H_2OH + OH^- + N_2 \quad (9)$$

Pulse radiolytically generated e^-_{sol} reacted with 1×10^{-4} M DMAB–CO_2–$Re^{I}(CO)_3$(phen) complex in N_2-saturated methanolic solutions with a rate constant $k \sim 1.3 \times 10^{10}$ M^{-1} s^{-1}. The spectra of the transient species, Fig. 6, were recorded 29 μs after the radiolytic pulse. They correspond to Re^{I} complexes, [DMAB–CO_2–$Re^{I}(CO)_3(phen^{\cdot-})$] with coordinated $phen^{\cdot-}$ ligand radicals. The [DMAB–CO_2–$Re^{I}(CO)_3(phen^{\cdot-})$] products were stable for a time longer than 0.5 ms at the concentrations, $\sim 10^{-6}$ M, reached in the radiolysis experiments. Moreover, the spectra of the products produced by pulse radiolysis, which

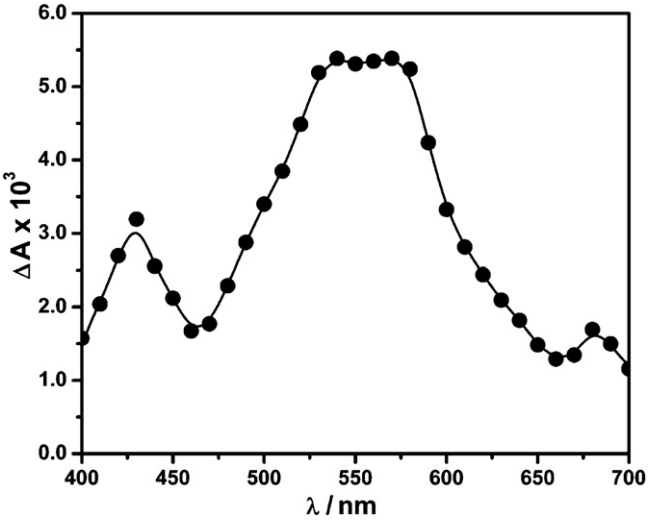

Fig. 6. Transient spectrum recorded at a delay of 29 μs after the radiolytic pulse in pulse radiolysis experiments conducted on 1×10^{-4} M DMAB–CO_2–$Re^I(CO)_3$(phen) complex in N_2-saturated methanolic solutions.

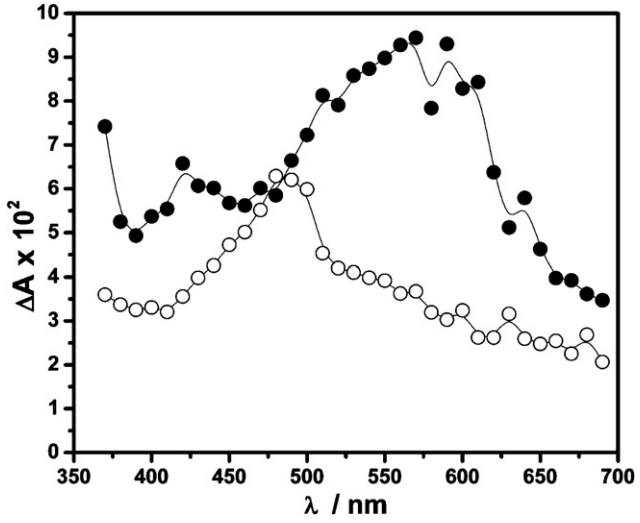

Fig. 7. Transient spectra generated after 351 nm excitation of DMAB–CO_2–$Re^I(CO)_3$(phen) in different experimental conditions: (●) DMAB–CO_2–$Re^I(CO)_3$(phen) 1×10^{-4} M in the presence of TEA 0.1 M in ACN at a time delay of 900 ns after the laser pulse and (○) DMAB–CO_2–$Re^I(CO)_3$(phen) 1×10^{-4} M in the presence of [Ni^{II}(Me_6[14]–aneN_4)] 0.1 M in ACN at a time delay of 900 ns after the laser pulse.

show the spectrum of phen$^{\bullet -}$ in the Re^I complex, are in agreement with the spectroelectrochemistry (Fig. 3).

In N_2O-saturated methanolic solutions of 1×10^{-4} M DMAB–CO_2–$Re^I(CO)_3$(phen) the reaction of $C^{\bullet}H_2OH$ radicals with the Re^I complexes did not generate detectable concentrations of [DMAB–CO_2–$Re^I(CO)_3$(phen$^{\bullet -}$)].

The standard potential of the $C^{\bullet}H_2OH$, H^+/CH_3OH couple, ~−0.92 V versus NHE, is lower than the reduction potential of the phen ligand in the Re^I complex (i.e. −1.08 V versus NHE). As a result $C^{\bullet}H_2OH$ radicals were unable to reduce the phen ligand of the DMAB–CO_2–$Re^I(CO)_3$(phen) complex.

The extinction coefficient of the transients (ε_R) were calculated using the relationship

$$\varepsilon_R = \varepsilon_P + [\Delta A_R \times (G \times \varepsilon)(SCN)_2^{\bullet -}]/[\Delta A(SCN)_2^{\bullet -} \times G_R] \quad (10)$$

where ε_P is the extinction coefficient of the parent molecule, $\Delta A(SCN)_2^{\bullet -}$ is the absorbance of the thiocyanate radical at 472 nm and G_R is the radiation chemical yield of the radical. On this basis, $\varepsilon_{560\ nm} = 3.0 \times 10^3\ M^{-1}\ cm^{-1}$ and $\varepsilon_{490\ nm} = 1.4 \times 10^3\ M^{-1}\ cm^{-1}$ were calculated for [DMAB–CO_2–$Re^I(CO)_3$(phen$^{\bullet -}$)] and DMAB$^{\bullet +}$–COOH, respectively.

3.3. Redox reactions of excited states

In order to establish a comparison between spectroelectrochemistry, pulse radiolysis and flash photolysis experiments, the reduction of the phen ligand in DMAB–CO_2–$Re^I(CO)_3$(phen) was carried out through the luminescence quenching of the complex DMAB–CO_2–$Re^I(CO)_3$(phen) with the reductant triethylamine (TEA). Fig. 7 shows the spectrum of the transient, generated after excitation with a 351 nm laser, of DMAB–CO_2–$Re^I(CO)_3$(phen) solutions in ACN in the presence of TEA at a time delay of 900 ns after the laser pulse. The spectrum observed, with λ_{max} at 420 and 560 nm, is similar to that of the phen$^{\bullet -}$ in the Re^I complex. However, a close inspection of Fig. 7 shows that the absorption peaks at 420 and 560 nm are broader and less well defined than those in the spectra of phen$^{\bullet -}$ in the Re^I complex obtained by spectroelectrochemistry and pulse radiolysis techniques. This disparate behavior can be rationalized in terms of the different quenching reactions of accessible excited states responsible of the photophysical properties of the DMAB–CO_2–$Re^I(CO)_3$(phen) complex [11] with TEA, Eqs. (11)–(16):

$$\text{DMAB–}CO_2\text{–}Re^I(CO)_3(\text{phen}) \xrightarrow{h\nu} [\text{DMAB–}CO_2\text{–}Re^{II}(CO)_3(\text{phen}^{\bullet -})]^* \quad (11)$$

$$\text{DMAB–}CO_2\text{–}Re^I(CO)_3(\text{phen}) \xrightarrow{h\nu} [(\text{DMAB}^{\bullet +} - CO_2)\text{–}Re^I(CO)_3(\text{phen}^{\bullet -})]^* \quad (12)$$

$$\text{DMAB–}CO_2\text{–}Re^I(CO)_3(\text{phen}) \xrightarrow{h\nu} [(\text{DMAB–}CO_2^{\bullet -})\text{–}Re^{II}(CO)_3(\text{phen})]^* \quad (13)$$

$$[\text{DMAB–}CO_2\text{–}Re^{II}(CO)_3(\text{phen}^{\bullet -})]^* + \text{TEA} \xrightarrow{k_{q1}} [\text{DMAB–}CO_2\text{–}Re^I(CO)_3(\text{phen}^{\bullet -})] + \text{TEA}^{\bullet +} \quad (14)$$

$$[(\text{DMAB}^{\bullet +}\text{–}CO_2)\text{–}Re^I(CO)_3(\text{phen}^{\bullet -})]^* + \text{TEA} \xrightarrow{k_{q2}} [\text{DMAB–}CO_2\text{–}Re^I(CO)_3(\text{phen}^{\bullet -})] + \text{TEA}^{\bullet +} \quad (15)$$

$$[(\text{DMAB–}CO_2^{\bullet -})\text{–}Re^{II}(CO)_3(\text{phen})]^* + \text{TEA} \xrightarrow{k_{q3}} [(\text{DMAB–}CO_2^{\bullet -})\text{–}Re^I(CO)_3(\text{phen})] + \text{TEA}^{\bullet +} \quad (16)$$

Eqs. (11)–(13) account for the formation of the excited states $MLCT_{Re\rightarrow phen}$ and $MLCT_{Re\rightarrow(DMAB–CO_2)}$ (i.e. Re^I

to phen and Re^I to $–CO_2–$DMAB in character) and the excited state $LLCT_{(DMAB–CO_2)\rightarrow phen}$ ($–CO_2–$DMAB to phen in character) after light absorption by the DMAB–CO_2–$Re^I(CO)_3$(phen) complex. The reduction of the $MLCT_{Re\rightarrow phen}$ excited state of the complex DMAB–CO_2–$Re^I(CO)_3$(phen) by TEA, represented by Eq. (14), has been previously observed with similar Re^I complexes [37,42,43], and occurs on a timescale within the excimer laser lifetime (~25 ns) to form the radical cation $TEA^{\cdot+}$ and the reduced $phen^{\cdot-}$ radical anion in the Re^I complex. The reduction of the $LLCT_{(DMAB–CO_2)\rightarrow phen}$ by TEA, Eq. (15), is a feasible process since the oxidation potentials of TEA [42] and DMAB are close together and the energy of the $LLCT_{(DMAB–CO_2)\rightarrow phen}$, as estimated from the redox potentials of DMAB/$DMAB^{\cdot+}$ and phen/$phen^{\cdot-}$ in the Re^I complex is $E_{00} \sim 2.19$ eV. As the $MLCT_{Re\rightarrow(DMAB–CO_2)}$ is higher in energy than the $MLCT_{Re\rightarrow phen}$, the reduction of $MLCT_{Re\rightarrow(DMAB–CO_2)}$ by TEA, Eq. (16), is also a possible process from a thermochemical standpoint. Therefore, [DMAB–CO_2–$Re^I(CO)_3(phen^{\cdot-})$] and [(DMAB–$CO_2^{\cdot-}$)-$Re^I(CO)_3$(phen)] species may be contributing to the spectral features of the transient generated after the reduction of the excited states of the Re^I complex by TEA. These properties may explain the spectral differences between the $phen^{\cdot-}$ spectrum obtained in flash photolysis experiments and the $phen^{\cdot-}$ spectrum obtained by spectroelectrochemical and pulse radiolysis techniques.

The oxidative quenching of the $MLCT_{Re\rightarrow phen}$ and $MLCT_{Re\rightarrow(DMAB–CO_2)}$ and $LLCT_{(DMAB–CO_2)\rightarrow phen}$ excited states of DMAB–CO_2–$Re^I(CO)_3$(phen) was carried out in laser flash photolysis experiments ($\lambda_{exc} = 351$ nm) of a 10^{-4} M solution of the Re^I complex in the presence of [Ni^{II}(Me_6[14]–$aneN_4$)]. The spectrum of the transient generated under oxidative conditions is shown in Fig. 7. This spectrum is similar to that of the oxidized amine in the Re^I complex (compare to Fig. 2), suggesting that the [Ni^{II}(Me_6[14]–$aneN_4$)] oxidant quenches the accessible excited states of the Re^I complex producing mainly [($DMAB^{\cdot+}$–CO_2)–$Re^I(CO)_3$(phen)] and Re^{II} species, according to Eqs. (17)–(19):

$$[DMAB–CO_2–Re^{II}(CO)_3(phen^{\cdot-})]^* + [Ni^{II}(Me_6[14]–aneN_4)] \xrightarrow{k_{q4}} [DMAB–CO_2–Re^{II}(CO)_3(phen)] + [Ni^{I}(Me_6[14]–aneN_4)] \quad (17)$$

$$[(DMAB^{\cdot+}–CO_2)–Re^{I}(CO)_3(phen^{\cdot-})]^* + [Ni^{II}(Me_6[14]–aneN_4)] \xrightarrow{k_{q5}} [(DMAB^{\cdot+}–CO_2)–Re^{I}(CO)_3(phen)] + [Ni^{I}(Me_6[14]–aneN_4)] \quad (18)$$

$$[(DMAB–CO_2^{\cdot-})–Re^{II}(CO)_3(phen)]^* + [Ni^{II}(Me_6[14]–aneN_4)] \xrightarrow{k_{q6}} [DMAB–CO_2–Re^{II}(CO)_3(phen)] + [Ni^{I}(Me_6[14]–aneN_4)] \quad (19)$$

A comparison of the spectra in Figs. 4 and 7 shows that the Re^{II} species formed in Eqs. (17) and (19) must contribute to the spectral features at wavelengths equal to or shorter than 400 nm. The presence of the [($DMAB^{\cdot+}$–CO_2)–$Re^I(CO)_3$(phen)] species, Eq. (18), accounts for the features between 400 and 700 nm in Fig. 7. In addition, absorptions near 380 nm can be assigned to the Ni^I macrocycle [28] produced in Eqs. (17)–(19).

In this regard, the spectrum of the excited state of DMAB–CO_2–$Re^I(CO)_3$(phen) ($\lambda_{max} \sim 475$ nm and a broad shoulder between 500 and 600 nm [11]), could be viewed as having mainly the spectral features of the $LLCT_{(DMAB–CO_2)\rightarrow phen}$ excited state [i.e. having spectral features of both $phen^{\cdot-}$ ($\lambda_{max} \sim 420$ and 550 nm) and $DMAB^{\cdot+}$–CO_2 ($\lambda_{max} \sim 475$ nm)] with smaller spectral contributions from $MLCT_{Re\rightarrow phen}$ and $MLCT_{Re\rightarrow(DMAB–CO_2)}$. However, a close comparison between the spectra of the excited states (MLCTs and LLCT) and the spectra of the species generated under pulse radiolysis/spectroelectrochemistry experiments is more dubious since in the $MLCT_{Re\rightarrow phen}$ and $MLCT_{Re\rightarrow(DMAB–CO_2)}$ excited states the $phen^{\cdot-}$ and/or $DMAB–CO_2^{\cdot-}$ ligands are coordinated to a Re^{II}, a low spin d^5, while in the latter species the reduced/oxidized ligands are coordinated to a Re^I, a low spin d^6. Therefore, differences in coulomb and exchange integrals may be making important contributions to the shapes and positions of electronic bands and the comparison may not be valid.

4. Concluding remarks

AC voltammetry experiments conducted on DMAB–COOH and DMAB–CO_2–Re(CO)$_3$(phen) in ACN solutions showed reversible anodic waves corresponding to the oxidation of DMAB in the parent compound DMAB–COOH, and the Re^I complex. The spectrum of the radical cation, $DMAB^{\cdot+}$, was detected using both spectroelectrochemistry and pulse radiolysis techniques applied to DMAB–COOH and/or DMAB–CO_2–$Re^I(CO)_3$(phen). An excellent agreement was observed between the spectrum of the radical cation $DMAB^{\cdot+}$ obtained electrochemically or radiolytically. Besides, the reduction of the phen ligand in the DMAB–CO_2–$Re^I(CO)_3$(phen) complex was also reversible as observed by ac voltammetry. The spectrum of the radical anion $phen^{\cdot-}$ in the Re^I complex was gathered by spectroelectrochemistry in good agreement with that obtained by the reaction of solvated electrons with phen ligands in the DMAB–CO_2–$Re^I(CO)_3$(phen) complex in pulse radiolysis experiments. Extinction coefficients of $\varepsilon_{560\,nm} = 3.0 \times 10^3\ M^{-1}\,cm^{-1}$ and $\varepsilon_{490\,nm} = 1.4 \times 10^3\ M^{-1}\,cm^{-1}$ were calculated for [DMAB–CO_2–$Re^I(CO)_3(phen^{\cdot-})$] and $DMAB^{\cdot+}$–COOH, respectively from pulse radiolysis experiments. The in situ UV–Vis spectra of the electrochemically reduced radical anions, $phen^{\cdot-}$, was compared with those obtained from the products of the reductive quenching of the corresponding photochemically excited states. Differences between the $phen^{\cdot-}$ spectrum obtained by spectrolectrochemistry and flash photolysis techniques were rationalized in terms of the reduction products of the excited states $MLCT_{Re\rightarrow phen}$, $MLCT_{Re\rightarrow\ (DMAB–CO_2)}$ and $LLCT_{(DMAB–CO_2)\rightarrow phen}$ of the

Re^{I} complex by TEA. The oxidative quenching of the Re^{I} complex excited states by $[Ni^{II}(Me_6[14]\text{-ane}N_4)]$ showed the formation of $[(DMAB^{\cdot+}\text{–}CO_2)\text{-}Re^{I}(CO)_3(phen)]$ as the main primary product.

communities in terms of their composition and function and, in order to understand their responding strategy, we must fully characterize the complexes in hands.

This paper describes three new cadmium(II) complexes with 3-hydroxypicolinic acid which have been prepared, identified by chemical analysis, characterized by the appropriate spectroscopic methods, both in solution and in the solid state, and their crystal structures were determined by X-ray diffraction method.

2. Experimental

2.1. Materials and physical measurements

All chemicals were used as received without further purification. Cadmium(II) iodide and cadmium(II) acetate dihydrate were purchased from Aldrich, while 3-hydroxypicolinic acid was purchased from Fluka.

CHN analyses were performed in the Analytical Services Laboratories of the Ruđer Bošković Institute.

The IR spectra were obtained from KBr pellets in the range 4000–450 cm^{-1} with a Perkin–Elmer Spectrum RXI FT-spectrometer.

The one- and two-dimensional homo- and heteronuclear ^{1}H, ^{13}C, ^{15}N and ^{113}Cd NMR spectra were recorded with a Bruker AV 600 spectrometer, operating at 600.133 MHz for the ^{1}H nucleus, 150.917 MHz for the ^{13}C nucleus, 60.796 MHz for the ^{15}N nucleus and 133.096 MHz for the ^{113}Cd nucleus. Samples were measured from DMF-d_7 solutions at 25 °C (298 K) in 5 mm NMR tubes. Chemical shifts, in ppm, are referred to TMS (^{1}H and ^{13}C NMR spectra), to NH_4NO_3 (^{15}N NMR spectra) and to $Cd(NO_3)_2 \cdot 4H_2O$ (^{113}Cd NMR spectra). FID resolution in ^{1}H, ^{13}C, ^{15}N and ^{113}Cd NMR spectra was 0.29, 0.54, 0.93 and 3.05 Hz per point, respectively. The following measurement techniques were used: standard ^{1}H and ^{13}C gated proton decoupling, ^{15}N and ^{113}Cd power gated decoupling, APT, COSY, HMQC and HMBC. The 2D NMR spectra were measured in pulsed field gradient mode (z-gradient).

2.2. [CdI(3-OHpic)(3-OHpicH)(H_2O)]$_2$ (**1**)

A solution of 3-hydroxypicolinic acid (0.11 g, 0.8 mmol) in 10 mL of water was added to a solution of cadmium(II) iodide (0.14 g, 0.4 mmol) in 10 mL of water. The pH value of the resulting colourless solution was 2. The solution was left to stand at room temperature for several days. The colourless crystals were then filtered off, washed with water and dried in air. Yield: 0.08 g (40.0%). *Anal.* Calc. for $C_{24}H_{22}Cd_2I_2N_4O_{14}$: C, 26.96; H, 2.08; N, 5.24. Found: C, 27.01; H, 2.16; N, 5.12%. IR data (KBr pellet, cm^{-1}): 3245(m), 2924(m), 2853(m), 1659(s), 1617(s), 1594(m), 1570(m), 1534(s), 1526(s), 1478(s), 1447(s), 1390(m), 1356(m), 1333(m), 1314(m), 1297(s), 1264(s), 1244(s), 1225(m), 1211(m), 1149(m), 870(m), 815(m), 788(m), 678(m), 663(m).

2.3. [Cd(3-OHpic)$_2$(H_2O)$_2$] (**2**)

A solution of 3-hydroxypicolinic acid (0.20 g, 1.4 mmol) in 15 mL of water was added to a solution of cadmium(II) acetate dihydrate (0.19 g, 0.7 mmol) in 5 mL of water. The pH value of the resulting colourless solution was 4. The colourless crystals were formed immediately and filtered off the next day, washed with water and dried in a desiccator over NaOH. The crystals suitable for X-ray crystal structure analysis were obtained by slow evaporation of the mother liquor solution, remained after filtration of the product, at room temperature. Yield: 0.26 g (86.7%). *Anal.* Calc. for $C_{12}H_{12}CdN_2O_8$: C, 33.94; H, 2.85; N, 6.60%. Found: C, 34.32; H, 2.90; N, 6.93%. IR data (KBr pellet, cm^{-1}): 3317(m), 2852(m), 2359(m), 1684(m), 1653(s), 1647(s), 1635(s), 1594(m), 1576(m), 1559(m), 1482(m), 1452(s), 1392(s), 1339(s), 1303(s), 1232(s), 890(m), 855(m), 821(m), 809(m), 699(m), 688(m), 668(m).

2.4. [Cd(3-OHpic)$_2$]$_n$ (**3**)

A solution of **2** (0.15 g, 0.4 mmol) in 6 ml of *N*,*N*-dimethylformamide was left to stand at room temperature for 2 weeks to give colourless crystals. The crystals were filtered off, washed with small amount of DMF and dried in air. Yield: 0.09 g (64.3%). *Anal.* Calc. for $C_{12}H_8CdN_2O_6$: C, 37.09; H, 2.08; N, 7.21. Found: C, 37.16; H, 2.13; N, 6.98%. IR data (KBr pellet, cm^{-1}): 1634(s), 1601(s), 1578(m), 1455(s), 1407(s), 1392(s), 1328(s), 1311(s), 1261(m), 1245(s), 1226(s), 1114(m), 889(m), 824(s), 813(m), 701(m), 683(s).

2.5. X-ray crystal structure analysis

The data collection was carried out on Oxford Diffraction Xcalibur four-circle kappa geometry single-crystal diffractometer with Xcalibur Sapphire 3 CCD detector by applying the CrysAlis Software system, Version 171.31.5 at room temperature [6]. Data reduction has been applied by the same programme [6]. Seven runs containing 759 data collection frames for **1**, 9 runs containing 1196 data collection frames for **2** and 11 runs containing 1382 data collection frames for **3** were collected at the crystal-detector distance of 60 mm with the exposure time of 15, 5 and 20 s for **1**, **2** and **3**, respectively, and with ω scan type for all three structures.

The data have been corrected for Lorentz-polarization factor and scaled for absorption effects by multi-scan for all structures. The structures were solved by direct methods. Refinement procedure by full-matrix least squares methods based on F^2 values against all reflections has been performed including anisotropic displacement parameters for all non-H atoms.

In **3**, the anisotropic displacement parameters for all atoms are large and the bond precision is small due to the lower quality of crystal and the data collected. All our attempts to obtain crystals of better quality of **3** have

failed so far. Atoms N1 and C11 (having anisotropic displacement parameters non-positive defined) were refined only isotropically in order to refine well the structure of this compound. The Flack parameter for the structure of **3** could also not be refined.

The positions of hydrogen atoms belonging to the carbon atoms Csp^2 for all structures were geometrically optimized applying the riding model [Csp^2–H, 0.93 Å; $U_{iso}(H) = 1.2U_{eq}(C)$]. The positions of hydrogen atoms belonging to the hydroxyl O atoms for the structures of **1** and **3** were geometrically optimized applying the riding model [O–H, 0.82 Å; $U_{iso}(H) = 1.5U_{eq}(O)$]. The hydrogen atoms belonging to water molecule O7 atom and pyridine N2 atom in the structure of **1** have been found in the electron-density Fourier maps. The distances between N2 and H12N atoms and between O7 and H27O atoms were restrained to average value of 0.90(5) Å using SHELXL97 DFIX instruction while H17O atom was refined freely. The hydrogen atoms belonging to the water molecule O4 and hydroxyl O3 atom in the structure of **2** have been found in the electron-density Fourier maps and refined freely. The distance between O1 and O4 atoms in the structure of **3** was restrained to the average value of 2.000(5) Å using SHELXL97 DFIX instruction.

Calculations were performed with SHELXS97 [7] and SHELXL97 [8]. The molecular graphics were done with ORTEP-3 [9] and MERCURY (Version 1.4.2) [10].

3. Results and discussion

3.1. Preparation of complexes

Both cadmium(II) complexes **1** and **2** were obtained under the similar reaction conditions using different cadmium(II) salts as starting materials, while **3** was obtained by recrystallization of **2** from *N*,*N*-dimethylformamide solution. All isolated compounds are air-stable, colourless and soluble in solvents with pronounced donor properties (such as *N*,*N*-dimethylformamide, *N*,*N*-dimethylsulphoxide, pyridine and 4-picoline).

All prepared compounds were characterized by IR spectroscopy and ^1H, ^{13}C, ^{15}N and ^{113}Cd NMR spectroscopy.

3.2. Vibrational spectroscopy

Infrared spectroscopy data confirm the coordination of 3-OHpic ligand to cadmium(II) ion *via* the carboxylate group in all three compounds. In the spectra of **1** and **2** the band associated to the asymmetric stretching vibrational mode, $\nu_{asym}(-COO^-)$ is shifted for 41 cm^{-1} (**1**) and 47 cm^{-1} (**2**) to lower wave numbers, while the $\nu_{sym}(-COO^-)$ band is shifted for 11 cm^{-1} (**1**) and 17 cm^{-1} (**2**) to higher wave numbers compared with the values registered for the free ligand [3,4]. The measured values of $\Delta(\nu_{asym}(-COO^-) - \nu_{sym}(-COO^-))$ amounts 326 cm^{-1} and 314 cm^{-1} for **1** and **2**, respectively, indicating the presence of carboxylate groups coordinated to cadmium(II) ion in unidentate mode [11] which is in agreement with the crystal structure of both compounds. The typical stretching ν(C–N) vibrational mode of substituted pyridines appears for the uncoordinated ligand at 1609 cm^{-1}, but there are two bands at 1617 and 1594 cm^{-1} in the spectra of **1** corresponding to this vibrational mode. This is in a good agreement with two coordination modes of 3-OHpicH in **1**: *N*,*O*-chelation involving the endocyclic nitrogen atom of 3-OHpic ligand and monodentate binding of 3-OHpicH through carboxylic oxygen atom [4]. The typical stretching ν(C–N) vibrational mode of substituted pyridines for **2** shifts to lower wave number (for 15 cm^{-1}) in comparison with the free ligand. This is in a good agreement with *N*,*O*-chelation, involving the endocyclic nitrogen atom of 3-OHpic ligand, confirmed by the X-ray crystal structure analysis. The broad absorption band of medium intensity at 3245 cm^{-1} indicates hydrogen bonding in the structure of **1**, while the broad absorption band of medium intensity at 3317 cm^{-1} in **2** indicates hydrogen bonds involving water molecules bound to cadmium(II) ion.

Unfortunately, due to the overlapping of maxima and vibrational coupling in the spectrum of **3**, the observed shifts of absorption bands, sensitive to metal coordination relatively to those of the free ligand, could not be unambiguously assigned.

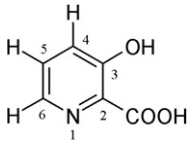
3.3. NMR spectroscopy

The assignments of NMR spectra of the ligand (3-OHpicH) and its cadmium(II) complexes were shown in Table 1. The numbering of atoms is consistent with IUPAC nomenclature and it is shown in Scheme 1.

NMR measurements were performed in DMF-d_7 solution. Cadmium induced ^1H and ^{13}C NMR shifts are defined as the difference between proton or carbon chemical shifts in the complexes and the free ligand molecule.

The ^1H and ^{13}C NMR spectra of **1** suggest that Cd(OHpic)$_2$ exists in DMF-d_7 solution, similar to previously reported spectra of [CdCl(3-OHpic)(3-OHpicH)(H_2O)]$_2$ and [CdBr(3-OHpic)(3-OHpicH)(H_2O)]$_2$ [4].

The ^1H NMR spectra of the compounds **2** and **3** revealed the largest complexation shift ($\Delta\delta$) for the H-6 proton in both complexes. Complexation with cadmium induces shielding effects for all H-atoms (−0.211 to −0.311 ppm) of the ligand molecule. The signal of the hydroxyl group of the compound **2** was not observed due to large broadening, while that of compound **3** has downfield shift. Water protons of compound **2** were not observed. This fact could be attributed to the establishing of strong hydrogen bonds between the hydroxyl and the coordinated water molecules.



In the ^{13}C NMR spectra the greatest change upon complexation with cadmium was observed for the chemical shift of C-6. Deshielding effects were observed for C-2, C-6 and the carboxylic carbon (3.31–3.79 ppm) and shielding effects for C-3, C-4 and C-5 (−0.23 to −2.84 ppm).

In order to characterize the possible binding site for Cd^{2+} cation, ^{15}N NMR has been determined. As it can

Sign (+) denotes deshielding effect, while (−) denotes shielding effect of cadmium.
[a] Recorded in DMF-d_7 solutions. Reffered to TMS. Number of protons in brackets.
[b] Reffered to saturated aqueous NH_4NO_3 (20.8 ppm for NH_4^+).
[c] Reffered to saturated aqueous $Cd(NO_3)_2 \cdot 4H_2O$ (0 ppm).
[d] Cadmium induced chemical shifts ($\Delta\delta$/ppm) are obtained by subtracting the chemical shifts of parent compound (3-OHpicH) from the chemical shifts of Cd-complex.
[e] n denotes the number of bonds between nuclei in spin–spin coupling; (s) singlet, (d) doublet.

Scheme 1. Numbering scheme of the atoms in 3-hydroxypicolinic acid.

be seen from the Table 1, chemical shifts of the nitrogen atom for both compounds **2** (104.27) and **3** (104.30) are quite close to the corresponding chemical shift of the ligand (103.39).

Accordingly, chemical shifts and coupling constants are almost the same in both compounds **2** and **3**, so we have recorded ^{113}Cd NMR to clarify whether complexes exist in solution. ^{113}Cd chemical shifts of the compounds **2** and **3** were 258.99 ppm and 375.39 ppm, respectively. Highly coordinated cadmium(II) sphere of the compound **3** induces a subtle electron redistribution throughout the molecule, causing deshielding effect on ^{113}Cd chemical shift. Therefore, ^{113}Cd NMR opens a direct route to probe the environment of the bound cation itself [12].

3.4. Structural description of *1*

Crystal data and details of the structure determination for **1** are given in Table 2. ORTEP-3 view of the molecular structure of compound **1** is depicted in Fig. 1a and its crystal structure in Fig. 2a. Some selected interatomic bond distances and angles are listed in Table 3, as well as hydrogen bond geometry in Table 4.

Compound **1** is isostructural with [CdX(3-OHpic)(3-OHpicH)$(H_2O)]_2$ (X = Cl, Br) [4]. Its molecular structure reveals centrosymmetric dimmers containing two cadmium(II) ions with distorted octahedral coordination geometries, bridged with two iodine atoms (Cd1–I1 2.947(1) Å, Cd1–$I1^i$ 2.922(1) Å) (symmetry code (i) $1-x$, $-y$, $2-z$). The coordination environment of each cadmium(II) ion also consists of 3-hydroxypyridine-2-carboxylate ligand coordinated through *N*,*O* donor set of atoms (forming five-membered chelate ring, Cd1–N1 2.348(3) Å, Cd1–O1 2.327(2) Å), 3-hydroxypyridinium-2-carboxylate ligand coordinated monodentately through carboxylate O4 atom (Cd1–O4 2.339(2) Å) and water molecule (Cd1–O7 2.305(3) Å) (Table 3 and Fig. 1a). Monodentate 3-hydroxypyridinium-2-carboxylate ligand, bound to Cd1 as a zwitter ion with protonated N2 atom, is required to be in a neutral form by the charge balance of the molecular formula.

The bond distance Cd1–N1 is larger than the analogous one in [CdX(3-OHpic)(3-OHpicH)$(H_2O)]_2$ (X = Cl, 2.328(2) Å; X = Br, 2.334(4) Å) [4] but the bond distance Cd1–O1 is shorter (X = Cl, 2.344(2) Å; X = Br, 2.340(3) Å). The Cd1–O4 bond distance (carboxylate O4 atom from monodentate 3-hydroxypicolinate ligand) is larger than the corresponding ones in [CdX(3-OHpic)(3-OHpicH)$(H_2O)]_2$ (X = Cl, 2.314(2) Å; X = Br, 2.324(3) Å) [4] and the Cd1–O7 bond distance (water molecule O7 atom) corresponds to the ones in the latter complexes (X = Cl, 2.305(2) Å; X = Br, 2.307(4) Å) [4].

The bond angles around Cd centre are in the range of 165–175° for the formally *trans* pairs of the ligating atoms and in the range of 72–107° for the formally *cis* pairs, indicating the distortion of the octahedron. The angles indicating the largest distortion from the ideal octahedral geometry are the bite angle O1–Cd1–N1 with value equal to 71.5(1)° and angle O1–Cd1–O4 with value of 106.9(1)°.

The dihedral angle between the least squares calculated planes through the atoms of pyridine ring (N1/C1/C2/C3/C4/C5) and the corresponding five-membered chelate ring (Cd1/N1/C1/C6/O1) is 3.1(1)° while the dihedral angle

There are three intramolecular hydrogen bonds in the crystal structure of **1** (Table 4 and Fig. 2a), two of the type O–H···O and one of the type N–H···O. The first intramolecular O–H···O hydrogen bond (in anionic 3-OHpic ligand) is formed by the hydroxyl O3 atom and uncoordinated carboxylic O2 atom (2.573(4) Å) while the second one (in zwitterionic 3-OHpic ligand), formed by the hydroxyl O6 atom and coordinated carboxylate O4 atom, is slightly longer (2.600(4) Å) than the first one. The intramolecular N–H···O hydrogen bond is formed by endocyclic N2 atom and uncoordinated carboxylate O5 atom (2.683(4) Å) and is longer than the latter O–H···O hydrogen bonds. There are also two intermolecular hydrogen bonds of O–H···O type, the first is formed by water molecule O7 atom and coordinated carboxylate O1 atom (2.708(4) Å) and the second by the same O7 atom and uncoordinated carboxylate O5 atom (2.726(4) Å). Thus, water molecule O7 atom acts as a double proton donor (O7···O1 and O7···O5 intermolecular hydrogen bonds). Intermolecular hydrogen bond of N–H···O type is formed

by the endocyclic N2 atom and uncoordinated carboxylate O2 atom (2.752(4) Å). Endocyclic N2 atom is a double proton donor, forming both intramolecular (N2···O5) and intermolecular (N2···O2) hydrogen bonds while both carboxylate O5 and O2 atoms act as double proton acceptors, forming intramolecular (N2···O5 and O3···O2) and intermolecular (O7···O5 and N2···O2) hydrogen bonds. Intermolecular hydrogen bonds link molecules of **1** into a three-dimensional supramolecular structure. There is also one weak intermolecular hydrogen bond (3.317(5) Å) of type C–H···O in the crystal structure of **1** (Table 4).

3.5. Structural description of *2*

Crystal data and details of the structure determination for **2** are given in Table 2. ORTEP-3 view of the molecular structure of compound **2** is depicted in Fig. 1b and its crystal structure in Fig. 2b. Some selected interatomic bond distances and angles are listed in Table 3, as well as hydrogen bond geometry in Table 4.

The molecular structure of **2** consists of cadmium(II) ion with the distorted octahedral coordination geometry. Cadmium(II) ion is situated on a crystallographic inversion centre. The coordination environment contains two 3-hydroxypyridine-2-carboxylate ligands in the equatorial plane (Cd1–N1 2.299(1) Å, Cd1–O1 2.301(1) Å) and two water molecules in axial position (Cd1–O4 2.309(1) Å) (Table 3 and Fig. 1b). 3-OHpic ligands are bound to cadmium(II) ion in a bidentate *N*,*O*-chelated mode forming a five-membered chelate ring.

Complex **2** is isomorphous with zinc(II) [1,2] and manganese(II) [1] complexes with 3-hydroxypicolinic acid. The bond distance Cd1–N1 in **2** is shorter than the corresponding ones in $[Cd(pic)_2]_n$ (Cd–N1 2.35(1) Å, Cd–N2 2.34(2) Å) [13], $[Cd(6\text{-Mepic})_2]_n$ (Cd1–N1 2.374(2) Å, Cd1–N2 2.341(2) Å) [5] and in $[CdX(3\text{-OHpic})(3\text{-OHpicH})(H_2O)]_2$ (X = Cl, 2.328(2) Å; X = Br, 2.334(4) Å) [4]. The bond distance Cd1–O1 in **2** is also shorter than the analogous ones in $[Cd(pic)_2]_n$ (Cd–O2 2.35(2) Å, Cd–O4 2.36(2) Å) [13], $[Cd(6\text{-Mepic})_2]_n$ (Cd1–O1 2.332(2) Å, Cd1–O3 2.325(2) Å) [5] and in $[CdX(3\text{-OHpic})(3\text{-OHpicH})(H_2O)]_2$ (X = Cl, 2.344(2) Å; X = Br, 2.340(3) Å) [4]. However, Cd–O bond distance (carboxylate O atom from 3-OHpicH ligand bound monodentately to Cd(II) ion) in the latter compound (X = Cl, 2.314(2) Å; X = Br, 2.324(3) Å) is comparable with Cd1–O1 bond distance in **2**.

Two water molecules are bound to cadmium(II) ion in *trans* position with the angle O4–Cd1–O4^{ii} (symmetry code (ii) $-x, -y, 1-z$) of 180.0°. The bond distance Cd1–O4 (O atom from water molecule) is very similar to the ones in $[CdX(3\text{-OHpic})(3\text{-OHpicH})(H_2O)]_2$ (X = Cl, 2.304(2) Å; X = Br, 2.307(4) Å) [4].

The bond angles around Cd centre are about 180° for the formally *trans* pairs of the ligating atoms, but the distortion of the octahedron is indicated by the bond angles around Cd centre for the formally *cis* pairs lying within the range of 73–107°. The angles indicating the largest distortion from the ideal octahedral geometry are the bite angle O1–Cd1–N1 with value 73.3(1)° and angle N1–Cd1–O1^{ii} (symmetry code (ii) $-x, -y, 1-z$) with value 106.7(1)°.

The dihedral angle between the least squares calculated planes through the atoms of pyridine ring (N1/C1/C2/C3/C4/C5) and the corresponding five-membered chelate ring (Cd1/N1/C1/C6/O1) is 2.7(1)°.

There are three hydrogen bonds of the type O–H···O in the crystal structure of **2** (Table 4 and Fig. 2b). One of them is intramolecular hydrogen bond (2.537(3) Å) formed by the hydroxyl O3 atom and uncoordinated carboxylate O2 atom while the other two are intermolecular hydrogen bonds formed between water molecule O4 atom and coordinated carboxylate O1 atom (2.694(2) Å) and between water molecule O4 atom and uncoordinated carboxylate O2 atom (2.727(2) Å) (Table 4). The water molecule O4 atom acts as a double proton donor forming the latter intermolecular hydrogen bonds. On the contrary, uncoordinated O2 atom acts as double proton acceptor forming both intramolecular (O3···O2) and intermolecular (O4···O2) hydrogen bonds. Intermolecular hydrogen bonds (O4···O1 and O4···O2) link molecules of **2** into two-dimensional network in *ac* plane. There are also two weak intermolecular hydrogen bonds (3.312(3) Å and 3.410(3) Å) of type C–H···O in the crystal structure of **2** (Table 4).

3.6. Structural description of *3*

Crystal data and details of the structure determination for **3** are given in Table 2. ORTEP-3 view of the molecular structure of compound **3** is depicted in Fig. 1c and its crystal structure in Fig. 2c. Some selected interatomic bond distances and angles are listed in Table 3, as well as hydrogen bond geometry in Table 4.

In **3**, the cadmium(II) ion is octahedrally coordinated by two 3-hydroxypyridine-2-carboxylate ligands perpendicular to one another (Fig. 2c). 3-OHpic ligands are bound to cadmium(II) ion in a bidentate *N*,*O*-chelated mode forming a five-membered chelate ring (Cd1–N1 2.285(7) Å, Cd1–O1 2.510(8) Å; Cd1–N2 2.290(7) Å, Cd1–O4 2.486(8) Å) (Table 3). Two carboxylate O atoms from another two symmetry-related ligand molecules are also coordinated to the cadmium(II) ion (Cd1–O1 2.340(8) Å, Cd1–O4^{iii} 2.344(9) Å) (symmetry code (iii) $1/2-x, y-1/2, 2-z$), expanding its coordination to a distorted octahedron. Each carboxylate O atom in **3** bridges cadmium(II) ions, forming one-dimensional chain which extends in the [0 1 0] direction (Fig. 2c). The coordination mode of 3-OHpic in **3** is the same as the coordination modes of picolinic acid in $[Cd(pic)_2]_n$ [13] and 6-methypicolinic acid in $[Cd(6\text{-Mepic})_2]_n$ [5], resulting in one-dimensional polymeric chains. However, the structure of **3** is non-centrosymmetric and there are hydrogen bonds between the polymeric chains of **3** (*vide infra*), explaining good solubility of **3** in organic solvents with donor properties in comparison with $[Cd(6\text{-Mepic})_2]_n$ [5].

The bond distances Cd1–N1 and Cd1–N2 in **3** are shorter than the analogous ones in $[Cd(pic)_2]_n$ (2.35(1)

and 2.34(2) Å) [13] and in $[Cd(6\text{-Mepic})_2]_n$ (2.374(2) and 2.342(2) Å) [5]. On the contrary, the bond distances Cd1–O1 and Cd1–O4 are larger than the corresponding ones in $[Cd(pic)_2]_n$ (2.35(2) and 2.36(2) Å) [13] and in $[Cd(6\text{-Mepic})_2]_n$ (2.332(2) and 2.325(2) Å) [5], as well as the bond distances Cd1–O^{iii} and Cd1–$O4^{iii}$ (symmetry code (iii) $1/2 - x, y - 1/2, 2 - z$) are also larger than in $[Cd(pic)_2]_n$ (2.23(2) and 2.25(1) Å) [13] and in $[Cd(6\text{-Mepic})_2]_n$ (2.272(2) and 2.279(2) Å) [5].

The bond angles around Cd centre are in the range of 105–157° for the formally *trans* pairs of the ligating atoms and in the range of 46–133° for the formally *cis* pairs, indicating the large distortion of the octahedron. The angles indicating the large distortion from the ideal octahedral geometry are the bite angles N1–Cd1–O1 with value of 65.0(6)° and N2–Cd1–O4 with value equal to 63.0(5)°.

The dihedral angle between the least squares calculated planes through the atoms of pyridine ring (N1/C1/C2/C3/C4/C5) and the corresponding five-membered chelate ring (Cd1/N1/C1/C6/O1) is 1.7(7)° while the analogous angle (between planes defined by atoms N2/C7/C8/C9/C10/C11 and Cd1/N2/C7/C12/O4) is 7.3(8)°.

There are two hydrogen bonds of the type O–H···O in the crystal structure of **3** (Table 4 and Fig. 2c). One of them is intramolecular hydrogen bond (2.54(2) Å) formed by the hydroxyl O3 atom and uncoordinated carboxylate O2 atom while the other is intermolecular hydrogen bond (3.04(2) Å) formed by hydroxyl O6 atom and uncoordinated carboxylate O5 atom. The latter hydrogen bond links one-dimensional polymeric chains of **3** in [1 0 0] direction, resulting in a two-dimensional network in *ab* plane (Fig. 2c). There are also two weak intermolecular hydrogen bonds (3.18(2) Å and 3.30(2) Å) of type C–H···O in the crystal structure of **3** (Table 4). Thus, uncoordinated carboxylate O2 atom acts as triple proton acceptor, forming intramolecular (O3···O2) and two intermolecular hydrogen bonds (C5···O2 and C9···O2).

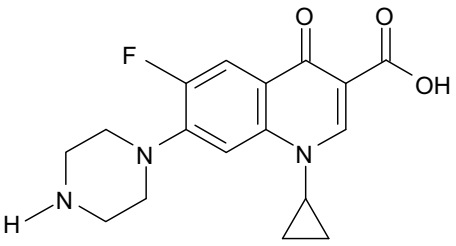
4. Conclusion

By using 3-hydroxypicolinic acid as pyridinecarboxylate ligand, we have synthesized three novel cadmium(II) complexes: diaqua-bis(3-hydroxypyridine-2-carboxylato-*N*,*O*)-bis(3-hydroxypyridinium-2-carboxylato-*O*)-diiododicadmium(II) (**1**), *trans*-diaqua-bis(3-hydroxypyridine-2-carboxylato-*N*,*O*)cadmium(II) (**2**) and *catena*-poly[bis(3-hydroxypyridine-2-carboxylato-*N*,*O*)cadmium(II)] (**3**). Synthesis of **1** and **2** were done in water solution, using different starting cadmium(II) salts, iodide and acetate, respectively. Complex **3** was obtained by recrystallization of **2** from DMF solution. All compounds were characterized by elemental analysis, IR and ^{1}H, ^{13}C, ^{15}N, ^{113}Cd NMR spectroscopy while their crystal structures were determined by X-ray single-crystal diffractometry method.

Three different coordination modes of 3-hydroxypicolinic acid in prepared complexes were established in the solid state. Bidentate *N, O*-chelated mode was found in the structure of **1** and **2**, monodentate mode through carboxylate O atom belonging to zwitterionic ligand was found only in **1**, while bidentate *N*,*O*-chelated and bridging mode were revealed in the structure of **3**. Thus, complex **1** is dimmer, **2** is monomer while **3** has polymeric structure. In all prepared complexes cadmium(II) ion has a distorted octahedral coordination.

^{15}N NMR spectroscopy confirmed that 3-OHpic ligand is not bound to cadmium(II) ion through endocyclic nitrogen atom due to the similar chemical shift of nitrogen atom in complexes in comparison with the free ligand. Thus, the ligand is apparently bound to cadmium(II) ion monodentately through carboxylate oxygen atom in DMF solution of the related complexes.

5. Supplementary data



CCDC 662949, 662950 and 662951 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

Highly sensitive analytical methods for the determination of antibacterial drugs can be designed on the basis of specific luminescent properties of some lanthanide ions [8], such as Eu(III) and Tb(III). Spectra of such complexes have "linear" Stark structure that are specific [9,10].

Lanthanide–quinolone complexes could also be useful for therapeutic and diagnostic applications in medicine (fluorescence microscopy bioimaging, DNA hybridization assay, etc.) [11,12]. Labeling of DNA could be especially promising due to the fact that quinolones interact with DNA and this interaction is important for the mode of action of these drugs [13].

Luminescence spectra of Eu(III) are characterized by a narrow resonance line of $^5D_0$–$^7F_0$ transition and sufficiently informative picture of the Stark splitting. The anion charges, the distance between ligands and rare-earth metal, as well as the symmetry of the environment of the central lanthanide ion can influence the Stark splitting magnitude of the $^5D_0$–$^7F_1$ and $^5D_0$–$^7F_2$ transitions [14]. Intensification of the electrostatic interaction between a rare-earth metal and coordinated ligand and the reduction of the environmental symmetry around the central lanthanide ion result in the increase of splitting of energy levels.

There are few papers dealing with the composition, structure and spectral luminescent properties of the lanthanide complexes with fluoroquinolones [7,9,10,15,16]. Li et al. [16] described compounds with general formula $Ln(cfq)_2Cl(H_2O)_n$ (Ln–Pr, Nd, Sm, Gd, Tb, Dy, Ho, Er, Tm, Yb, $n = 7$–9) and analyzed their spectroscopic data (IR, electronic spectra). However, the crystallographic data were reported only for the cerium complex $[Ce(cf)_2(H_2O)_4]Cl \cdot (H_2O)_{3.25}(C_2H_5OH)_{0.25}$ (**2**). It was also reported that the europium(III) complex of quinolone family member ofloxacin and terbium(III) complex of ciprofloxacin could be used as fluorescent markers for histological staining [17]. This procedure is much faster than traditional hematoxylin and eosin histologic stain method but the authors have only proposed the structures of rare-earth metal–quinolone complexes whereas no crystal structures were available.

In this paper, the crystal structure and spectral luminescent properties of compound $[Eu(cfqH)(cfq)(H_2O)_4]Cl_2 \cdot 4.55H_2O$ (**1**) in the solid state have been thoroughly analyzed and its stability in aqueous and DMSO solutions evaluated by ^1H and ^{19}F NMR measurements.

2. Experimental

2.1. Synthesis of $[Eu(cfqH)(cfq)(H_2O)_4]Cl_2 \cdot 4.55H_2O$ (1)

The synthesis was carried out solvothermally in a Teflon container. Europium(III) chloride hexahydrate (0.0451 g, 0.123 mmol), ciprofloxacin hydrochloride hydrate (0.142 g, 0.369 mmol) and 1,3-bis(dimethylamino)-2-propanol ligand (bdmapH, 0.0180 g, 0.123 mmol) were added to a mixture of water (2.0 mL) and ethanol (2.0 mL). The mixture was stirred and the suspension placed in a stainless steel autoclave followed by heating at 150 °C for 48 h. Cooled orange solution was evaporated isothermally in air. After one week, a few pale yellow crystals suitable for structure determination had grown on the top of the bulk of the microcrystalline material. Yield: 0.0588 g (47.2%). $\lambda_{max}(\varepsilon)$ in water: 224 nm (9610 L mol^{-1} cm^{-1}), 272 (29 600 L mol^{-1} cm^{-1}), 321 (11 700 L mol^{-1} cm^{-1}). The results of the elemental analysis are in agreement with the formula $[Eu(cfqH)(cfq)(H_2O)_4]Cl_2 \cdot 8H_2O$ (*Anal.* Calc. for $C_{34}H_{59}Cl_2EuF_2N_6O_{18}$: C, 37.10; H, 5.40; N, 7.63. Found: C, 36.73; H, 5.16; N, 7.40%).

2.2. X-ray crystallography

collected at 150(2) K on a Nonius Kappa CCD diffractometer equipped with a cooling device (Oxford Cryosystems, Cryostream Cooler 700), a Mo Kα anode ($\lambda = 0.71073$ Å) and a graphite monochromator, and the multiscan absorption correction [18] was performed. The structure was solved by direct methods (SHELXS-97) and refined by a full-matrix, least-squares procedure based on F^2 (SHELXL-97) [19]. Hydrogen atoms attached to water oxygen atoms coordinated to europium were found from difference Fourier maps and were subjected to the constrained refinement. A check using the PLATON program [20] revealed voids of approximately 200 Å^3 in the crystal packing due to the specific shape of the coordination compound (Fig. 1). Additional solvent water molecules were found in these voids and they were taken in the refinement with the anti-bumping constraints and the atomic occupation parameters were also refined. Positions of the hydrogens of these solvent water were not located. The hydrogen atoms (apart from the terminal piperazinyl hydrogens) of the ciprofloxacin moieties were placed at calculated positions and treated using appropriate riding models.

2.3. Spectroscopy and elemental analysis

The emission spectra of the europium and gadolinium complexes were obtained on the SDL-1 (LOMO) spectrometer (the frequency measurement error is ±3 cm^{-1}) with DRSh-250 mercury lamp and "Tungsram" used as an excitation sources and monochromatic light from the xenon lamp using the KSVU monochromator. The scale of the spectrometer wavelengths was verified using lines of the helium–neon sources and mercury lines, including duplicate 5769.6–5790.6 Å. Measurements were conducted at 300 and 77 K.

A Cary Eclipse Fluorescence Spectrophotometer (Varian) was used to measure excitation spectra and fluorescence lifetimes. All measurements were performed at 300 K. Emission and excitation slit widths were 5 nm and rates of 600 nm min^{-1} were used. The metal luminescence excitation was acquired by monitoring the emission at 613 nm for Eu(III). Quoted lifetime is the average value of at least three independent measurements, each of which being obtained by monitoring the emission intensity at 613 nm after 6–8 different delay times with a gate time of 0.4 ms. Decay curves were fitted with OriginLab using built-in least-square-goodness-of-fit Levenberg–Marquardt algorithm (LMA).

NMR spectra were recorded at 9.4 T (^{1}H resonating at 400 MHz) using a Bruker Avance NMR spectrometer equipped with a 5 mm normal configuration broadband tuneable probe applying conditions previously described [21]. ^{19}F NMR spectra (resonating at 376 MHz) were acquired at 25 °C unless stated otherwise using an acquisition time of 7 s, post-acquisition delay of 2 s and a flip angle of 30°. ^{19}F NMR spectra were referenced externally to 1% CF_3CO_2H in $CDCl_3$ at 25 °C (−78.5 ppm); ^{1}H NMR spectra were referenced internally to TMS (0 ppm). Saturation transfer measurements utilized an acquisition time of 1.7 s, post-acquisition delay of 6 s for saturation, flip angle of 30° and a power level for irradiation of 57 dB relative to the full power pulse. The concentration of the NMR solutions was ca. 2 mg mL^{-1}.

UV–Vis spectrum of an aqueous solution was acquired on a Perkin–Elmer Lambda 19 spectrometer.

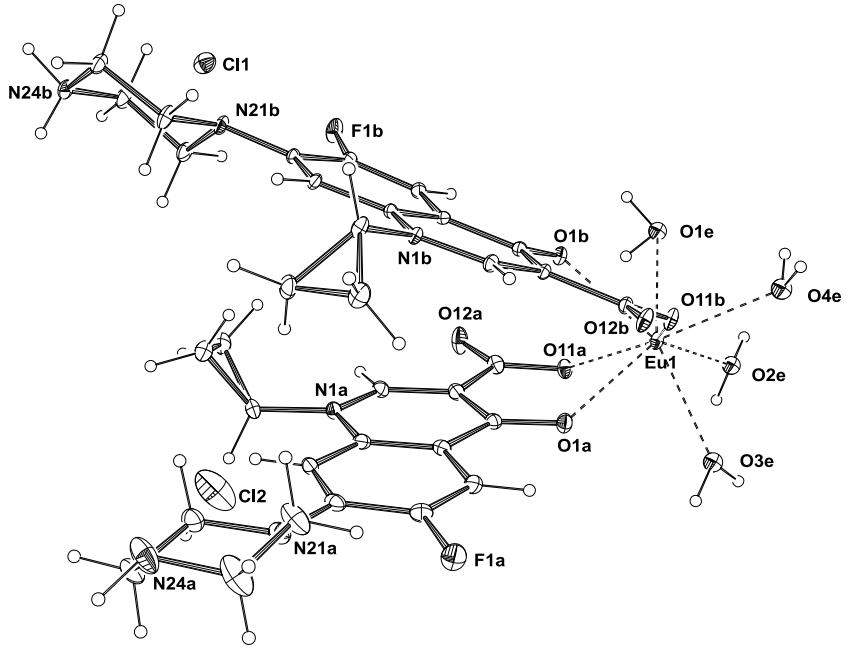

Fig. 1. ORTEP view of $[Eu(cfqH)(cfq)(H_2O)_4]Cl_2 \cdot 4.55H_2O$ showing the coordination around the europium ion.

IR spectra were recorded on a Shimadzu IRPrestige-21 infrared spectrophotometer using KBr pellets. Raman spectra were recorded on a Bruker RFS 100/s spectrophotometer.

Elemental analyzes were performed on a Perkin–Elmer 204C microanalyzer.

3. Results and discussion

3.1. Synthesis

It is interesting to note that it was necessary to use an excess of ligand in the mixture of europium salt and ciprofloxacin to obtain crystals of **1**. It was previously reported that the presence of histidine in the preparation of quinolone metal complexes could result in the isolation of new crystalline products which are different from those obtained without using this compound [22,23]. In the present case, the addition of either bdmapH or histidine provoked the formation of crystals of **1**. As reported before, we believe the additional ligand may serve to fine tune the protolytic equilibria to reach the correct species distribution for crystallization [22,23].

The crystals of the title complex are stable in solution but are not very stable in air which was already observed for other metal–quinolone complexes [24]. It was also shown before [25–27] that weakly bonded lattice water molecules could easily be lost from metal–quinolone complexes already at room temperature.

3.2. Crystal structure analysis

The crystal structure of compound **1** is shown in Fig. 1. The drawing was prepared with the aid of ORTEPII [28] program. Selected bond lengths and angles within the complex together with hydrogen bond distances around the terminal piperazinyl nitrogens are presented in Table 2.

All bond distances and angles (given in CIF Supplementary material) in **1** are in an agreement with corresponding data cited in the literature [29,30]. The asymmetric unit of **1** consists of $[Eu(cfqH)(cfq)(H_2O)_4]^{2+}$ cation, two chloride ions and six partially disordered, solvent water molecules. Both quinolone molecules are bidentately O,O-bonded to europium through the ring carbonyl (O1) and carboxylate (O11) oxygen atoms. Additionally, four water molecules are also coordinated to the metal center. The bond lengths between europium and carboxylate oxygen atoms (Eu–O11) are slightly shorter than the bond lengths between europium and ring carbonyl oxygen atoms (Eu–O1) in the same quinolone molecule (see Table 2). This is in agreement with our observation in a recent experimental charge density study where this effect was explained as a consequence of the asymmetry of C–O bond lengths of the carboxylate group [31]. One of the molecules of ciprofloxacin is in a zwitterionic form (the carboxylic hydrogen from O11 atom is bonded to a terminal nitrogen atom N24 of the piperazine ring) [6], the second one seems to appear with only one hydrogen attached to N24. This was indicated not only from the peaks in a difference electron density map, but also from the inspection of the possible hydrogen bonds around piperazinyl nitrogens (Table 2).

It is interesting to compare the structure of the title complex **1** with that of compound **2** [16]. In the latter, both ciprofloxacin molecules are anionic and thus only one chloride ion is needed to compensate the charge of Ce^{3+}. Most probably the medium used in the synthesis of cerium complex was slightly more basic due to the presence of pyridine. In complex **1**, the coordination number of the metal center is 8, which is common for europium [32]. Coordination polyhedron around europium is formed by 8 oxygen atoms and could be described as a distorted square antiprism, O11b, O1b, O4e, and O1e atoms forming nearly planar quadratic arrangement (the largest deviation from the mean plane is 0.047(3) Å), whilst the opposite part of the polyhedron is closer to the dodecahedral arrangement (O3e and O11a being out of plane of the four oxygens O1a, O3e, O2e, and O11a), as depicted in Fig. 2. The Eu–O bond lengths range from 2.354(4) to 2.463(4) Å whilst the corresponding O–Eu–O angles span from 69.91(18) to 149.6(2)°. In the cerium complex **2**, the coordination number of the metal center is also 8 and the coordination polyhedron could be described as a square antiprism with the angles O–Ce–O lying in the range 68.8–140.9°.

A very complex network of hydrogen bonds involving quinolone heteroatoms, chloride ions and numerous water molecules is present in the crystal structure of **1**. However, the complete determination is not possible due to disorder of the solvent water molecules mentioned above.

3.3. IR, Raman spectroscopy studies

IR and Raman spectra have been assigned. The assignment was based on the comparison of title compound spec-

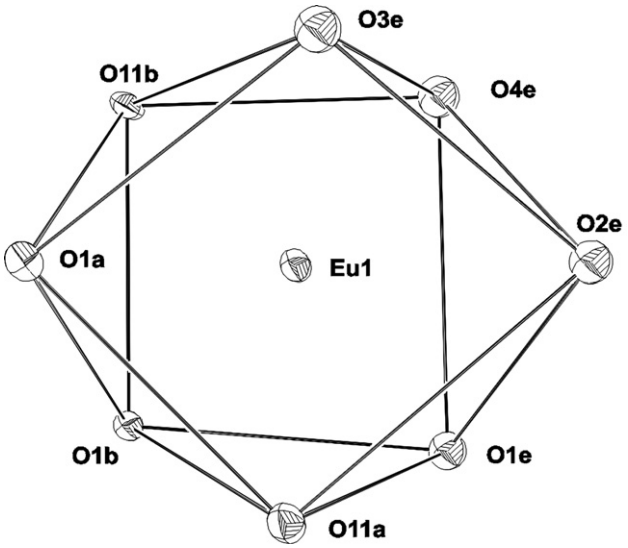

Fig. 2. Coordination polyhedron around europium atom in **1**: distorted square antiprismatic arrangement.

tra and the available literature data of quinolones and their metal complexes [33–35]. The crystallographic data, especially the interatomic distances were also taken into account (Table 2).

The most significant data from IR and Raman spectra of the complex are discussed below and selected bands are given in Table 3.

Bands in the region 3400–3200 cm^{-1} could be assigned to the symmetric and asymmetric stretching vibrations of the OH groups of the inner- and outer-sphere water molecules. The difference between vibration frequencies of $\nu_{as}(H_2O)$ and $\nu_s(H_2O)$ depends on the symmetry of the formed complexes. The shift of the characteristic bands of the IR spectra, changes of their intensity and half-width result from the increasing of bond energy of water molecules with the environment. Two types of water molecules (coordinated and crystal) are present in compound **1**. This leads to the appearance of several absorbance bands of the symmetric, asymmetric stretching vibrations and the overtone of the deformation vibrations in the region 3200–3400 cm^{-1} (Table 3).

Table 3
Selected bands of IR and Raman spectra of $[Eu(cfqH)(cfq)(H_2O)_4]Cl_2 \cdot 4.55H_2O$ with assignments

IR, cm^{-1} (I_{arb})	Raman, cm^{-1}(I_{arb})	assignment
	328(s)	ν(Eu–I)

1616(s), 1633(s)	1627(m)	ν(C=O)
2498(m)		$\nu(NH_2^+)$
	2982(m)	ν(C=C), ν(C–H)
3396(s)		
3404(s)		$\nu_s(H_2O)$, $\nu_{as}(H_2O)$

Abbreviations: s – strong, m – medium, w – weak, sh – shoulder, I_{arb} – intensity in arbitrary units.

The absorbance band at 2498 cm^{-1} in the IR spectrum of the compound ascribed to $\nu(NH_2^+)$ results from the existence of the zwitterionic form of cfqH. There are such bands in the IR spectra of all fluoroquinolone hydrochlorides and these have been assigned to the stretching vibrations $\nu(NH_2^+)$ of the protonated secondary aliphatic nitrogen atom (2900–2300 cm^{-1}) [33].

As could be realized from the crystallographic results, both quinolone molecules are not equivalent; one ciprofloxacin molecule is zwitterionic, the other is anionic. In zwitterionic ciprofloxacin, the bond length C4B–O1B is 1.268(8) Å whereas the corresponding distance for C4A–O1A in the anionic molecule is 1.256(8) Å. Two characteristic bands observed in the IR spectrum of **1** at 1616 and 1633 cm^{-1} could be ascribed to ν(C=O) vibrations of the carbonyl group. We assume that the first corresponds to the ν(C=O) vibration in the zwitterionic molecule of quinolone, whereas the latter corresponds to the ν(C=O) vibration in the anionic molecule of quinolone.

We can assign the title compound's bands at 1487 cm^{-1} and 1386 cm^{-1} to ν_{as}(O–C–O) and ν_s(O–C–O), respectively. The corresponding bands in cfqH are found at 1451 and 1377 cm^{-1}. This shift could be explained by coordination of cfqH to Eu(III) ion. This is further supported by the Raman spectrum of the title compound where we can see that the intensity of bands assigned to ν_s(O–C–O) is twice as much as the intensity of bands ν_{as}(O–C–O) (Table 3).

3.4. Luminescence spectroscopy

It is known that the luminescence observed for aqueous solutions of Eu(III) salts is very weak as a result of a facile de-excitation pathway. Efficient luminescence requires that the lanthanide ion is well separated from any high frequency oscillators such as the overtone of the ν(OH) vibration of coordinated water molecules. Sensitized lanthanide emission can occur via energy transfer from organic ligands with excited triplet states of appropriate energy, which was first observed for lanthanide tris (β-diketonates) [36].

Under UV irradiation, the title compound **1** emits a red light, which is characteristic for Eu(III) ions. Excitation of the complex into the lowest energy ligand-centered absorption band ($\lambda_{ex} = 340$ nm according to the measured excitation spectrum) gives rise to the well-known structured emission of the Eu(III) ion.

The characteristic splitting of the bands and intensities of ^5D_j–^7F_j transitions ($j = 1$–3) of the emission spectrum of the compound **1** are typical for mononuclear compounds of Eu(III). The spectrum consists of the single line of the $^5D_0$–$^7F_0$ transition, three bands of the $^5D_0$–$^7F_1$ transition, and five components of the $^5D_0$–$^7F_2$ transition

(Fig. 3a). The spectrum is dominated by the $^5D_0$–$^7F_2$ transition; more than 50% of the total emission is centered on the 613 nm peak.

The strong deformation of the coordination sphere of the Eu(III) ion resulting from the different interatomic distances of Eu–OcfqH (2.354–2.396 Å) is reflected in the emission spectrum. The lack of the inversion centrum leads to the relieving of the prohibition so the peak intensity of the $^5D_0$–$^7F_0$ transition is almost equal to the one of the $^5D_0$–$^7F_1$ transition peaks.

The emission decay kinetics of the solid state complex **1** for the most intense emission (613 nm) is monoexponential (Fig. 4), which reveals that all Eu(III) ions lie in the same average environment. This result is in agreement with the results of the crystal structure determination. The decay curves are fitted into a single-exponential equation as $I = I_0\exp(-t/\tau)$, where I and I_0 are the luminescent intensities at times t and 0 and τ is defined as the luminescence lifetime. A value of 0.99996 for the correlation coefficient R^2 was obtained. The fitted value of τ for the complex **1** is 920 μs.

In Fig. 3b, the positional relationship of the levels of the ground and electronically excited states of the cfqH molecule and complex **1** are shown. The position of the S_1 ππ* level has been estimated according to fluorescence and absorbance spectra. The value of the energy of the Tππ* state of cfqH is 20,500 cm^{-1} and was obtained from the phosphorescence spectrum of the Gd(III) chelate of cfqH. This value is close to the value of the norfloxacin (another quinolone family member) triplet state energy (20 000 cm^{-1}) [37].

The compounds of Eu(III) with cfqH emit an intensive red luminescence under UV irradiation due to effective transfer of excitation energy from ππ and nπ – levels of cfqH to metastable $^5D_0$ level of Eu(III) which is the result of direct interatomic contacts of central ion Eu(III) with ciprofloxacin molecules linked with metal ion through oxygen heteroatoms.

3.5. NMR spectroscopy

To evaluate the stability and structure of complex **1** in aqueous solution, both ^1H and ^{19}F NMR measurements were performed on a D_2O solution of **1** whereby the complex was found to be stable without change over the course of several days. Both nuclei indicated the presence of only one species but due to the paramagnetism of the Eu^{3+} cation and dynamic exchange, all signals in both spectra were quite broad. In the ^1H NMR spectrum, only a single set of peaks appeared to be present, though disentanglement of the signals and assignment was prohibitive given the large chemical shift translations brought about by the presence of the Eu^{3+} cation. In the ^{19}F NMR spectrum, a clear single signal at −124.96 ppm, however, was present [thus also implying the equivalence of the distinct complexed cfq(H) units by rapid unit or proton exchange].

In an attempt to observe distinct ligands, e.g. by observing amine and ammonium signals in the ^1H NMR or by slowing the exchange rate of the proton transfer and thus rendering the cfq units inequivalent, complex **1** was also examined in DMSO-d_6 solution. However, this led to displacement of the cfq(H) ligand, presumably by DMSO, leading to a stable equilibrium that did not change over the course of several days and which consisted of three species: complex **1**, a complex containing only one cfq unit and

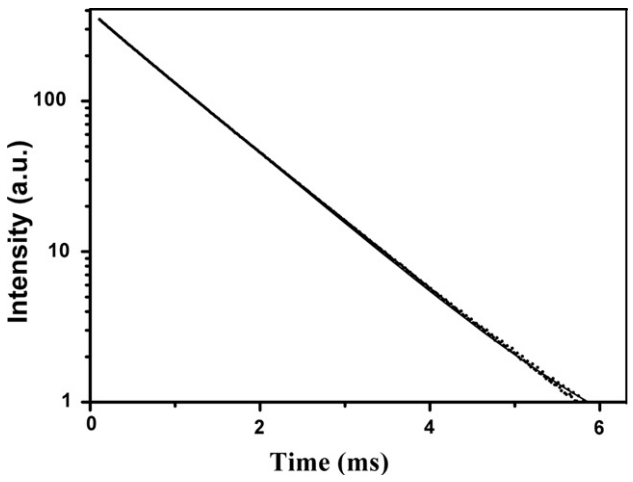

Fig. 4. The decay curve of the luminescent $^5D_0$ state for the compound **1** (···) and its fitting into a single-exponential function (—).

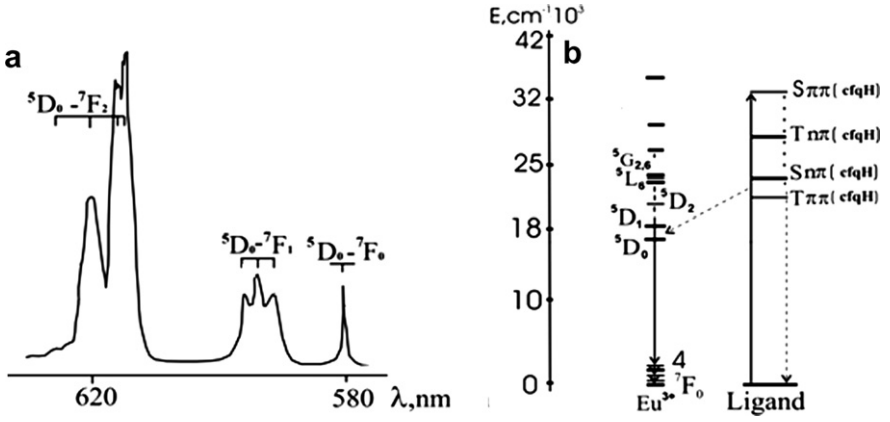

Fig. 3. Luminescence spectra of compound **1** (solid state) (a), scheme of the electronically excited states and photophysical processes of compound **1** (b). Abbreviations: S – singlet state; T – triplet state.

a complex free of any cfq moiety. This conclusion was based on the presence of three signals in the ^{19}F NMR, one of which was assigned to free cfqH due to its relatively sharp lines constituting a dd and its chemical shift which, at −124.59 ppm, was akin to a prepared sample of cfqH in DMSO-d_6 ($\delta = -124.29$ ppm). The observation of free cfqH means that at least two signals in addition are likely to be observed, one for **1** and the other for cfq-dissociated complex (thus, by default, the exchange of the distinct cfq(H) units in **1** is also rapid). The other two signals were both broad and were assigned to complex **1** ($\delta = -126.18$ ppm) and the monoligand complex ($\delta = -125.60$ ppm). The assignment of these two signals was based on ^{19}F NMR saturation transfer experiments and the relative rates of exchange between the three species as all three species readily exchanged the cfqH unit. From the integration of the ^{19}F NMR signals, the three species were present in a ratio of 11:40:49 for a complex free of any cfq moiety, a complex containing only one cfq unit and complex **1**, respectively, after consideration that the excess of free cfqH over a complex containing only one cfq unit must represent a complex free of any cfq moiety (and taking into account that this excess signal intensity must be proportioned by a factor of 2).

Interpretation of the ^{1}H NMR spectrum was complicated by the aforementioned aspects, particularly for the aliphatic region. However, sharp signals for the Hs *ortho* and *meta* ($\delta = 7.957$ ppm, d; and 7.599 ppm, d; respectively) to the F were observed and were thus assigned to free cfqH in solution. These chemical shifts are in accord with those observed for a prepared sample of cfqH in DMSO-d_6 ($\delta = 7.899$ and 7.542 ppm, respectively). By a 2D EXSY spectrum, the set of three signals comprising the exchanging spins of each species for each of these two Hs were identified and then assigned based on their integration in accordance with the ^{19}F NMR results. For complex **1**, the *ortho* and *meta* Hs resonated at 9.262 (br) and 6.544 (br d) ppm, respectively. For the complex containing only one cfq unit, the *ortho* and *meta* Hs resonated at 6.279 (br) and 5.899 (br d) ppm, respectively. That the system was a stable equilibrium was evident not only by these saturation transfer and 2D EXSY experiments, but also by ^{19}F spectra acquired at higher temperature (45 °C) which led to the perturbation of the signal intensities by a shift towards greater dissociation; upon returning to 25 °C, the original signal intensities were duly resumed. These results clearly establish the efficacy of complex **1** in solution.

4. Conclusions

In conclusion, the complex of Eu(III) ions with fluoroquinolone ciprofloxacin has unique fluorescent properties. The strong emission of complex originates from an intrachelate energy transfer from the triplet state of the ligand to the excited energy levels of the lanthanide ion, in other words, fluoroquinolone serves as an energy donor to lanthanides. Moreover, the Stark structure of the spectrum for the tested europium–ciprofloxacin complex is very specific. According to our results, we believe that the methods for the selective and sensitive determination of fluoroquinolones (in biological matrices, pharmaceutical samples, environment, etc.), can be developed on the basis of the specific luminescent properties of europium–quinolone complexes. The complex **1** was stable in aqueous solution based on ^{1}H and ^{19}F NMR measurements whilst in DMSO solution it formed a stable equilibrium with dissociated species.

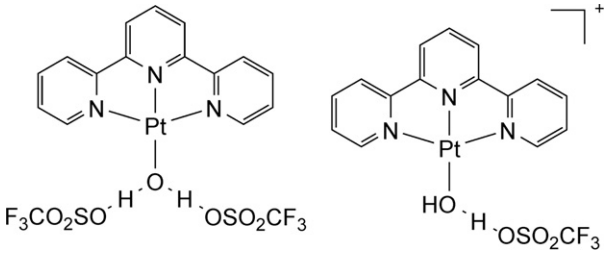
1.1. Computational details

The computational geometry optimisations of the species considered in this paper were performed *in vacuo* using the hybrid DFT B3PW91 method [8] without symmetry constrains. The "restricted" formalism was applied in all calculations. The basis sets considered were CEP-121G {CEP-31G on the Pt atom} (BS1), D95V {SDD on the S, Cl and Pt atoms} (BS2), D95** {LANL2DZ on the Pt atom, D95* with diffuse sp functions on the O atoms} (BS3) [9]. Geometry convergence was accelerated using the GDIIS algorithm and a first refinement of the structures was obtained using the restricted semi-empirical PM3 method [10]. All of the resultant stationary points were characterized as true minima (i.e., no imaginary frequencies). Atomic charges derive from Mulliken population analysis [11]. After the geometry optimisations, the Onsager solvation model [12] was added (nitromethane, $\varepsilon = 39.4$) to improve B3PW91/BS1 calculations (BS1s) for the platinum-terpy-aqua-anion systems. Solute volumes were computed from the previously gas-phase optimised geometries.

PM3 calculations were carried out with computers equipped with IBM PowerPC G5 processors operating at 2.1 GHz frequency. The software used was the SPARTAN 02 Macintosh version [13]. DFT calculations were carried out at CINECA (Centro Italiano di Supercalcolo, Bologna, Italy) using IBM p5-575 computers with 64-bit IBM Power5 processors operating at 1.9 GHz frequency. The software used was the GAUSSIAN '03 [14].

2. Results and discussion

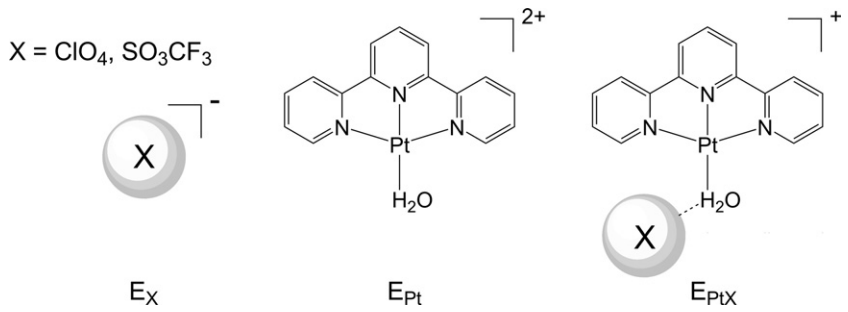
The reported X-ray structural data on $[Pt(H_2O)(terpy)](SO_3CF_3)_2$ [1] show two hydrogen-bond interactions between the coordinated water and two triflate ions, while in the optimised $[(terpy)Pt(OH_2\cdots OSO_2CF_3)]^+$ cation here reported only one triflate ion is present. This difference should not, however, greatly affect the inner Pt(II) coordination sphere, thus in Table 1 a direct comparison between experimental and computed structural data is made. Even if longer bonds are well known artefacts of pure and, to a lesser extent, hybrid DFT methods [15], the calculated Pt–L lengths and L_1–Pt–L_2 angles can be considered comparable with the experimental data: the greatest difference between DFT and X-ray data is about 1.5% for Pt–L bond lengths and less than 0.5% for L_1–Pt–L_2 angles. The computed bond length between the $[Pt(terpy)(H_2O)]$ and the $[SO_3CF_3]$ fragments can not, instead, be directly compared with the experimental data for the $[Pt(terpy)(H_2O)](SO_3CF_3)_2$, owing to the different globally positive charge of the model used, which results, as expected, in a shortening of the bond distances between cation and counter-anion.



DFT calculations were mainly performed to evaluate the relative interaction energies between the $[Pt(H_2O)(terpy)]^{2+}$ cation and the triflate and perchlorate anions. The energy of the *in vacuo* interaction between the $[Pt(H_2O)(terpy)]^{2+}$ cation and the counter-anions (ΔE_X) was calculated from Eq. (1):

$$\Delta E_X = E_X + E_{Pt} - E_{PtX} \quad (1)$$

where E_X is the energy of the free counter-anion X^- {ClO_4^- or $SO_3CF_3^-$}, E_{Pt} is the energy of the $[Pt(H_2O)(terpy)]^{2+}$ cation and E_{PtX} is the energy of the adduct between one molecule of the counter-anion and the $[Pt(H_2O)(terpy)]^{2+}$ cation, as depicted in Scheme 1. The energy values E_X, E_{Pt} and E_{PtX} derive from the geometry optimisations described in the previous section and are summarized in Table 2.



In Fig. 1 the ΔE_{ClO_4} and $\Delta E_{SO_3CF_3}$ values, expressed in kcal/mol, are compared. Absolute values of ΔE_{ClO_4} and $\Delta E_{SO_3CF_3}$ are not particularly meaningful, since they cover also the electrostatic interaction between the $[Pt(H_2O)(terpy)]^{2+}$ and the counter-anion. What is striking is that on the same basis set the $\Delta E_{SO_3CF_3}$ values is always about 5 kcal/mol higher than ΔE_{ClO_4}. This result has been confirmed also using an implicit solvation model like the Onsager one [12]: in the BS1s column of Table 2 are in fact reported the energy values obtained at the B3PW91/BS1 level of theory on considering nitromethane ($\varepsilon = 39.4$) as solvent, which is the NMR solvent of reference [1]. Data in Table 2 and Fig. 1 highlight that the interaction between the $[Pt(H_2O)(terpy)]^{2+}$ cation and the triflate anion is stronger than the one with the perchlorate anion, as expected from the previously reported NMR data [1].

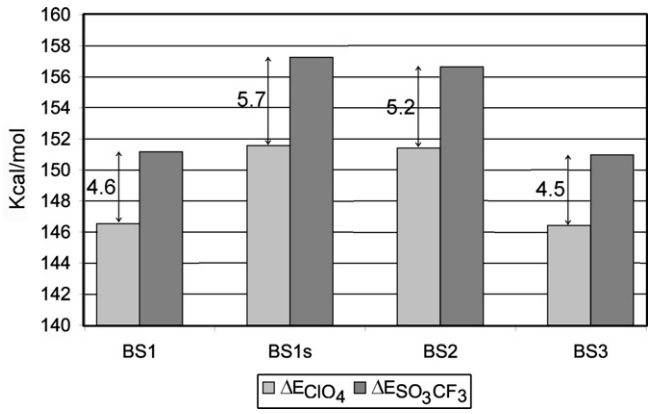

Fig. 1. Comparison between the ΔE_{ClO_4} and $\Delta E_{SO_3CF_3}$ values at different levels of theory.

The use of Eq. (1) can potentially lead to over-evaluate the molecular interactions, because of basis set superposition error (BSSE) [15]. Happily enough, for the systems described BSSE does not seem to have any important effect. In fact, we considered three different basis sets (namely BS1, BS2 and BS3) with different sizes: the number of basis functions for the Pt-terpy-aqua-triflate system is 397 with BS1, 343 with BS2 and 477 with BS3, while for the Pt-terpy-aqua-perchlorate is 361 with BS1, 313 with BS2 and 475 with BS3. The calculated interaction energy differences between perchlorate and triflate are, as already described, very similar for all the three basis sets and there does not seem to exist any meaningful correlation between energy values and the number of basis functions.

It is known that the perchlorate ion has a much less hydrogen-bond acceptor ability than triflate, therefore the $(\Delta E_{SO_3CF_3}–\Delta E_{ClO_4})$ values can be tentatively considered as an estimate of the water–triflate $[(terpy)Pt(OH_2\cdots OSO_2CF_3)]^+$ hydrogen-bond energy without the electrostatic contribution [4,16].

The greater strength of the interaction between the $[Pt(H_2O)(terpy)]^{2+}$ cation and the triflate anion, if compared to the one with the perchlorate anion, is confirmed by the $[(terpy)Pt(OH_2\cdots OClO_3)]^+$ and $[(terpy)Pt(OH_2\cdots OSO_2CF_3)]^+$ oxygen–oxygen hydrogen bond lengths, summarized in Table 3. On the same basis set the $[(terpy)Pt(OH_2\cdots OSO_2CF_3)]^+$ oxygen–oxygen bond length is always shorter (about 0.08 Å) than the $[(terpy)Pt(OH_2\cdots OClO_3)]^+$ one, in agreement with both the experimental NMR observations [1] and the computed energy values. These results confirm the relatively poor interacting ability usually attributed to the perchlorate anion [1,5,16]. The DFT B3PW91/BS3 optimised geometries of the two platinum derivatives are shown in Fig. 2.

A further confirmation of the lower hydrogen-bond character of the $[(terpy)Pt(OH_2\cdots OClO_3)]^+$ interaction, if compared to the $[(terpy)Pt(OH_2\cdots OSO_2CF_3)]^+$ one, comes from the comparison of the Mulliken charges on the H atom involved in the O···H···O bridge in the two adducts. To a lower electron density of the H atom usually corresponds a stronger hydrogen-bond [4]: as observable in Table 4, on the same basis the Mulliken charge of the H atom in the triflate derivative is always more positive than the one in the corresponding perchlorate model, this highlighting the greater hydrogen-bond character of the coordinated water–triflate interaction.

Finally, to better understand the NMR behaviour of the Pt-terpy aqua species, we considered in an explicit way also the role of the solvent (CH_3NO_2). The DFT B3PW91/BS1 energy results for the free $[Pt(H_2O)(terpy)]^{2+}$ cation, the

	$[(terpy)Pt(OH_2\cdots OClO_3)]^+$	$[(terpy)Pt(OH_2\cdots OSO_2CF_3)]^+$
BS1	0.413	0.424
BS2	0.476	0.518
BS3	0.475	0.485

free nitromethane molecule, the adduct of two nitromethane molecules and the $[(terpy)Pt(H_2O\cdots ONOCH_3)]^{2+}$ cation are reported in Table 5. The same table also reports the interaction energy between nitromethane and $[Pt(H_2O)(terpy)]^{2+}$ (ΔE_{PtS}) and between two nitromethane molecules (ΔE_{SS}), calculated on the basis of Eqs. (2) and (3):

$$\Delta E_{PtS} = E_S + E_{Pt} - E_{PtS} \quad (2)$$

$$\Delta E_{SS} = 2E_S - E_{SS} \quad (3)$$

The estimated energy of the interaction between one molecule of nitromethane and the $[Pt(H_2O)(terpy)]^{2+}$ cation is about 25.8 kcal/mol, relatively high if compared with the one existing between two solvent molecules, which is about 4.9 kcal/mol. Moreover, the computed oxygen–oxygen hydrogen-bond length in $[(terpy)Pt(OH_2\cdots ONOCH_3)]^{2+}$ is relatively short, 2.598 Å [4]. This means that the $[Pt(H_2O)(terpy)]^{2+}$ cation in solution can be better described with almost one molecule of solvent hydrogen-bonded to the aqua ligand, as in the geometry-optimised model in Fig. 3.

The ^1H NMR spectrum of the complex $[Pt(H_2O)(terpy)](SO_3CF_3)_2$ in CD_3NO_2 solution showed the presence of two species, while in the $[Pt(H_2O)(terpy)](ClO_4)_2$ ^1H NMR spectrum only one derivative was present. Moreover, both the spectra were strongly affected by the addition of salts like lithium triflate and lithium perchlorate [1]. A possible explanation to the NMR experimental results, supported by the DFT results here reported, is the presence in the case of $[Pt(H_2O)(terpy)](SO_3CF_3)_2$ of an equilibrium between a solvent-adduct like $[Pt(terpy)(OH_2\cdots ONOCD_3)](SO_3CF_3)_2$ and a hydrogen-bonded adduct of the type $[Pt(terpy)(OH_2\cdots OSO_2CF_3)](SO_3CF_3)$, as summarized in Scheme 2. The weaker interaction of perchlorate ion with coordinated water, instead, causes the

presence in solution of only a solvent-adduct species of the type $[Pt(OH_2\cdots ONOCD_3)](ClO_4)_2$.

3. Conclusions

The ^1H NMR spectra of the $[Pt(H_2O)(terpy)]X_2$ $\{X = ClO_4, SO_3CF_3\}$ complexes in CD_3NO_2 showed differences which were ascribed to different hydrogen-bond interactions between the coordinated water molecule and the counter-anions [1]. Even if quite simplified, the DFT calculations described in this paper strongly confirmed the proposed explanation and allowed to estimate the energy difference between the $[(terpy)Pt(OH_2\cdots OSO_2CF_3)]^+$ and the $[(terpy)Pt(OH_2\cdots OClO_3)]^+$ hydrogen-bond adducts. The proposed model for the interaction between the Pt(II) acqua-complex and the counter-anions was also supported by the computed oxygen–oxygen hydrogen-bond lengths of the triflate and perchlorate adducts and by the Mulliken charges on the hydrogen atoms of the O···H···O bridges.

Finally, from the studies on the $[(terpy)Pt(OH_2\cdots ONOCH_3)]^{2+}$ model and from the comparison of the interaction between CH_3NO_2 and $[Pt(H_2O)$- $(terpy)]^{2+}$ and that between two solvent molecules, it was highlighted that also nitromethane is able to strongly interact with the aqua ligand of the considered complex.

4. Supplementary material

CCDC 654357 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk.

containing perfluoroaryl groups are being exploited in organic semiconductors [12]. It has been predicted that Er^{3+} complexes of fully halogenated ligands may eventually show emission quantum yields close to 100% [13]. An additional requirement for efficient photosensitization of Er^{3+} is the ability to absorb visible light. Since the existing fully halogenated ligands do not possess this feature, we are now investigating new ligand systems that combine the absence of hydrogen atoms with the provision of a chromophore.

Potassium 2-nitrophenoxide is known to combine with lanthanide ions to give a range of chains, layers and clusters [14]. We now report the synthesis, structures and luminescence properties for the first metal complexes to be prepared using the orange-coloured salts of 3,4,5,6-tetrafluoro-2-nitrophenol (**1**) (Scheme 1), a compound which is easily made by hydrolysis of commercially available pentafluoronitrobenzene, following the literature procedure [15]. We show that it is able to exclude hydrogen from the environs of lanthanide ions as well as absorbing visible light. We chose to introduce this ligand as its caesium salt, in the hope of preparing analogues of the volatile, anhydrous salts such as $Cs[Er(HFA)_4]$, where HFA = 1,1,1,5,5,5-hexafluoroacetylacetonate. However, even when the caesium salt of **1** was mixed with erbium chloride in a 4:1 molar ratio, a crystalline complex with the stoichiometry Cs_2ErL_5 (L = tetrafluoro-2-nitrophenoxide) was isolated. Our investigations have therefore focused on complexes of this type.

2. Experimental

2.1. Instrumentation and general procedures

^{19}F NMR spectra were obtained on a Bruker AMX400 and the chemical shifts were referenced to external $CFCl_3$. MALDI mass spectra were recorded using a Bruker Daltonics Autoflex. CI mass spectra were obtained by the EPSRC National Mass Spectrometry Service Centre, Swansea using a Finnigan MAT 95XP. CHN elemental analyses were performed by MEDAC Ltd., Egham, Surrey. All photoluminescence experiments were conducted using solid samples of the metal complexes. Excitation was by ~7 ns pulses from a Continuum Panther optical parametric oscillator (OPO) pumped with a Surelite I laser. The luminescence was dispersed in a Triax 550 spectrometer and detected using a Hamamatsu R5509-72 infrared photomultiplier tube.

1

Scheme 1. Chemical structure of 3,4,5,6-tetrafluoro-2-nitrophenol.

2.2. X-ray crystallography

Data for **2**, **3** and **7** were collected at 120 K using a Nonius Kappa CCD area detector diffractometer mounted at the window of a molybdenum rotating anode (50 kV, 90 mA, $\lambda = 0.71069$ Å). The crystal-to-detector distance was 30 mm and ϕ and ω scans were carried out to fill the Ewald sphere. Data collection and processing were carried out using COLLECT [16], DENZO [17] and MAXUS [18] and empirical absorption correction was applied using SORTAV [19]. Data for **5** were collected on a CAD-4 diffractometer using $\lambda = 0.71069$ Å with ω–2θ scans at 160 K. The unit cell parameters were determined by least-squares refinement on diffractometer angles for 25 automatically centred reflections [20]. Data for **5** were corrected for absorption by empirical methods (ψ scan) [21] and for Lorentz-polarization effects by XCAD4 [22].

The structures were solved by heavy-atom methods using SHELXS-97 and DIRDIF-99 programs [23,24], and were refined anisotropically (non-hydrogen atoms) by full-matrix least-squares on F^2 using SHELXL-97. The H atoms were calculated geometrically and refined using the riding model facility in the SHELXL-97 program. Solvent molecules were located in the crystal structures of **3**, **5** and **7**. All showed relatively high anisotropic thermal parameters, reflecting not only a high degree of thermal motion, but also a degree of positional disorder. In the case of **5**, two unique solvent molecules were located in the asymmetric unit. One was found to be fully occupied, however the second which lies close to the twofold axis was fixed at half occupancy as indicated by a refinement of the fractional site occupancies for the atoms in this molecule. Interatomic distances in the solvent molecules in the structure of **5** were restrained to lie within the accepted ranges. The programs ORTEP-3 [25] and PLATON [26] were used for diagrams and WINGX [27] was used to prepare material for publication.

2.3. Synthesis

2.3.1. $Cs_2Er(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**2**)

o-O_2N–C_6F_4–OH (0.422 g, 2.0 mmol) and Cs_2CO_3 (0.326 g, 1.0 mmol) were dissolved in a mixture of MeCN (10 mL) and H_2O (3 mL) with stirring at room temperature. A solution of $ErCl_3 \cdot 6H_2O$ (0.153 g, 0.40 mmol) in water (3 mL) was then added dropwise. After 2 h the solvent was evaporated to dryness under reduced pressure and the residue was extracted with Et_2O (3 × 10 mL). The Et_2O extract was filtered, concentrated and the residue recrystallized from Et_2O–hexane to give $Cs_2Er(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**2**) (0.338 g, 57%) as orange blocks. *Anal.* Calc. for $C_{30}Cs_2ErF_{20}N_5O_{15}$: C, 24.29; H, 0.00; N, 4.72. Found: C, 24.55; H, 0.10; N, 5.01%. λ_{max} (nm) (MeCN) 223 ($\varepsilon = 64000$), 266 (17700), 406 (11000); ν_{max} (cm^{-1}) (KBr)

Calc. for $C_{24}CsF_{16}N_4O_{16}Yb$ (M^-−*o*-O_2N–C_6F_4–OCs): 1150 (10), 1149 (40), 1148 (26), 1147 (100), 1146 (50), 1145 (69), 1144 (44). Found: 1150 (8), 1149 (42), 1148 (29), 1147 (100), 1146 (59), 1145 (67), 1144 (32).

2.3.6. $Cs_2(Et_2O)_{0.5}Yb(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (7)

By analogy with the preparation of **3**, recrystallization by layering ether with hexane at room temperature gave crystals of **7** as orange blocks that were suitable for X-ray analysis.

3. Results and discussion

3.1. Crystal growth and X-ray crystallography

The rare earth complexes were prepared in aqueous acetonitrile, which was then evaporated and the residue was extracted with boiling diethyl ether. Concentration of the ether extracts and the addition of pentane, hexane or carbon tetrachloride led to the formation of crystals. Samples used for X-ray diffraction were obtained by layering of solvents at room temperature and were dried only briefly, since prolonged drying under vacuum caused some of the crystals to lose their transparency. Two crystalline erbium complexes were characterized: orange blocks **2** (stoichiometry Cs_2ErL_5) and yellow blades **3** (an etherate, $Cs_2ErL_5\cdot Et_2O$). Formation of the unsolvated product **2** was favoured when solvent was allowed to evaporate from a boiling solution of the complex in Et_2O–hexane, whereas the etherate **3** crystallized following slow diffusion of CCl_4 or pentane into an ethereal solution of the complex at *ca.* 18 °C. Ether of crystallization was also present in the other two complexes that were used for X-ray diffraction [$Cs_2YL_5\cdot 1.5Et_2O$ (**5**) and $Cs_2YbL_5\cdot Et_2O$ (**7**)].

The structure of the unsolvated erbium complex **2** is shown in Fig. 1; crystallographic details, metal–ligand bond lengths and selected bond angles are provided in Tables 1–3. In the crystal structure of $Cs_2YL_5\cdot 1.5Et_2O$

(**5**) the space group $I2/a$ was used as a non-standard setting of $C2/c$ in order to give a smaller β angle. The coordination of the tetrafluoronitrophenoxide ligands to the rare earth ions in the four crystal structures is very similar. Each M^{3+} ion is bound to five aryloxide ligands, of which three are monodentate; the remaining two ligands are additionally coordinated to the rare earth through one oxygen atom of the nitro group, making them bidentate and giving a coordination number of seven. Similar coordination about the rare earth has been reported for $K_2Ln(o\text{-}O_2NC_6H_4O)_5$ (Ln = Sm, Eu) [14], but the structures of these two potassium salts incorporate pentane of crystallization within the distinct channels that are present. The possibility that 2-nitrophenoxide units can be both monodentate and bidentate has also been established in the chemistry of lanthanide picrates [28]. The Et_2O molecules in our solvated complexes are somewhat disordered, particularly so in the case of the yttrium derivative **5**, but it is clear that none of this solvent coordinates to the rare earth metals. The geometry about the rare earth ions in complexes **2**, **3**, **5** and **7** is irregular. The bidentate nitrophenoxide ligands have narrow O–M–O bite angles, in the range 68–72°. The M ions are significantly closer to the phenoxide oxygen atoms than to the oxygen atoms of the coordinating nitro groups; for example the Er–O contacts range between 2.18 and 2.24 Å (phenoxide) and 2.37 and 2.53 Å (NO_2).

The two crystallographically distinct Cs^+ ions in the solvent-free form of **2** make contacts with the phenoxide and nitro groups, so that each caesium atom has eight oxygen atoms within 3.4 Å. In addition some close Cs–F contacts are present, so that Cs (1) is only 3.13 Å from F(17), which is thus its closest neighbour, and 3.34 Å from F(19). Plenio

Table 3

has noted that the distribution of $CF\cdots Cs^+$ contacts in the literature shows a clear maximum in the range 3.2–3.4 Å, providing evidence for an attractive Cs–F interaction [29]. The structures of the etherates again show contact of Cs^+ with both fluorine and oxygen atoms, including those of Et_2O.

3.2. Spectroscopic and analytical characterization

Analytical samples were dried for several days at *ca.* 20 °C and 1 mm Hg, after which CHN combustion analysis indicated that materials with the compositions Cs_2ErL_5 (**2**), $Cs_2ErL_5 \cdot Et_2O$ (**3**), Cs_2YL_5 (**4**) and $Cs_2YbL_5 \cdot 0.5Et_2O$ (**6**) had been obtained. Weak IR absorptions close to 2970 cm^{-1} and small amounts of hydrogen found by combustion analysis indicate that some solvent is present at low levels (<20 mol%) in bulk samples of the 'unsolvated' materials. Removal of the remaining Et_2O from $Cs_2YbL_5 \cdot 0.5Et_2O$ (**6**) was attempted by heating under reduced pressure; significant loss in mass occurred only on heating above 120 °C and under these conditions the darkening of the sample indicated decomposition. Attempts to sublime the complexes *in vacuo* also led to decomposition.

Compounds **2**, **4** and **6** were further characterized by ^{19}F NMR, IR, UV and mass spectrometry. Despite the considerable peak broadening in the ^{19}F NMR spectra (376 MHz, DMSO-d_6, $T = 27$ °C) of the paramagnetic Er^{3+} and Yb^{3+} derivatives **2** and **6**, four fluorine environments were clearly resolved in each case. The ^{19}F NMR spectrum of the Y^{3+} salt **4** also showed some broadening, particularly in the case of the most upfield peak (assigned as F-6). This suggested that the complex might be fluxional and the spectrum was therefore recorded at a higher temperature (60 °C). The peaks became much sharper, but they then remained sharp after cooling the sample back to 27 °C, which is consistent with an irreversible ligand displacement by DMSO. Mass spectra in chemical ionization mode showed strong $[CsML_4]^-$ negative ions with the expected isotopic distribution patterns. UV–Vis spectra were recorded in acetonitrile solution and all the compounds showed similar spectra, which were dominated by three strong absorption bands of the ligand. The longest wavelength absorptions occurred at λ_{max} between 402 and 406 nm in acetonitrile solutions of concentrations of *ca.* 10^{-4} M. Fivefold dilution with acetonitrile caused the λ_{max} of the longest wavelength band to increase to 415–428 nm; this shift was accompanied by an increase in the ε value and again suggests the occurrence of solvolysis.

3.3. Photoluminescence studies

Fig. 2 shows the photoluminescence spectra for the $Cs_2(Et_2O)_{0.5}Yb(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**6**) and $Cs_2Er(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**2**) samples. Both materials show luminescence characteristic of the central ion with emission for the $^2F_{5/2} \rightarrow {}^2F_{7/2}$ transition for ytterbium and for the $^4I_{13/2} \rightarrow {}^4I_{15/2}$ transition for the erbium ion. For ytterbium an excitation wavelength of 460 nm was used. In the case of erbium an excitation wavelength of 520 nm was chosen to provide direct excitation into the $^2H_{11/2}$ level of the Er^{3+} ion, which rapidly decays to the $^4I_{13/2}$ level. The shapes of the photoluminescence spectra for both materials are independent of excitation wavelength. The rise time of the $^4I_{13/2} \rightarrow {}^4I_{15/2}$ transition gives a direct measurement of the decay time from the initially excited state into the $^4I_{13/2}$ level and was measured to be of the order of 25 ns. Photoluminescence excitation (PLE) spectroscopy of both samples (Fig. 3) was recorded by monitoring the output from the peak of the ion-related photoluminescence whilst changing the excitation wavelength over the range 410–680 nm. For the ytterbium complex **6** the PLE spectrum shows a broad feature peaking at ~520 nm and a second feature extending to shorter wavelengths (<410 nm). Also shown in Fig. 3 is the absorption spectrum of this complex which is a broad band with a peak at ~400 nm. This feature in the absorption spectra can be assumed to be the absorption into the singlet state of the ligand. The majority of the absorption that results in ytterbium emission therefore appears to come from another band at longer wavelengths than the singlet absorption. We suggest that this may be direct absorption into the triplet state, the long lifetime of which encourages transfer into the ytterbium ion. This absorption is weak, so is not seen in the visible absorption spectrum where it is masked by the tail of the singlet absorption. Also shown in Fig. 3 is the PLE spectrum of $Cs_2Er(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ **2**. This has the same shape as that for $Cs_2Yb(Et_2O)_{0.5}(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ **6** but with additional peaks due to direct absorption into the Er^{3+} ions. To illus-

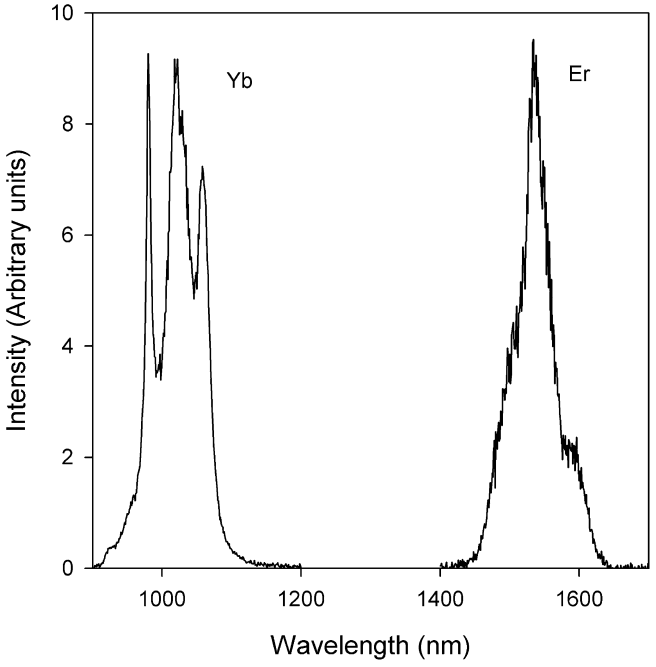

Fig. 2. Near-infrared photoluminescence spectra for $Cs_2Yb(Et_2O)_{0.5}(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**6**) and $Cs_2Er(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**2**).

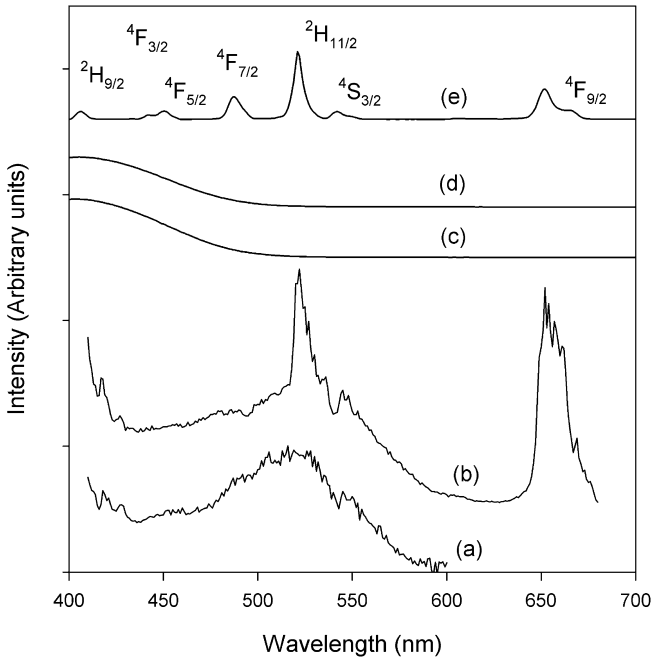

Fig. 3. Photoluminescence excitation spectrum of (a) $Cs_2Yb(Et_2O)_{0.5}(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**6**) and (b) $Cs_2Er(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**2**). Also shown for comparison are the visible absorption data for $Cs_2Yb(Et_2O)_{0.5}(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**6**) in MeCN (spectrum c: λ_{max} 403 nm, ε 10400), $Cs_2Er(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ (**2**) in MeCN (spectrum d: λ_{max} 406 nm, ε 11000) and for a solution of $ErCl_3 \cdot 6H_2O$ in MeOH (spectrum e: λ_{max} 520 nm, ε 3.9).

trate this the absorption spectrum of a solution of erbium chloride in methanol is also given which shows the narrow absorption into erbium ions. The fact that these lines are superimposed upon the same broad feature that was observed for the $Cs_2Yb(Et_2O)_{0.5}(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ **6** shows that the ligand is acting as a weak sensitizer for erbium as well as for ytterbium. The rise time for the $^4I_{13/2} \rightarrow {}^4I_{15/2}$ transition was found to be independent of the excitation wavelength used. This suggests that energy transfer from the ligand to the erbium ion is not the rate-limiting step in the energy migration. For the $Cs_2Yb(Et_2O)_{0.5}$ $(o\text{-}O_2N\text{–}C_6F_4\text{–}O)_5$ **6** the rise time was found to be identical to the laser response (~7 ns) which supports this observation.

Lifetime data were recorded at the peak of the photoluminescence spectra at a temperature of 300 K. For erbium this corresponded to the $^4I_{13/2} \rightarrow {}^4I_{15/2}$ transition (1545 nm) and for ytterbium the $^2F_{5/2} \rightarrow {}^2F_{7/2}$ transition (1032 nm). Lifetime data were fitted with either a one or two exponential decay model using a Marquardt–Levenberg algorithm to find the best fit.

The luminescence decay of the erbium complex **2** could be fitted by a single exponential function, giving a lifetime of 20.2 μs. As we have noted, it is very difficult to remove all traces of hydrogen-containing solvents from these materials. From recent work on deuterated Cs[Er(HFA)$_4$] [7], it has been demonstrated that any C–H oscillators within 20 Å of an erbium ion can quench the lifetime to <100 μs, so the low levels of solvent detected in these samples would be sufficient to limit the lifetime to the observed value of 20.2 μs. Compared with the 1.8 μs lifetime observed for Cs[Er(HFA)$_4$], where the hexafluoroacetylacetonate (HFA) ligands each contain a single C–H bond, there is a considerable extension in lifetime associated with exclusion of hydrogen from the environs of the erbium ion. The luminescence lifetime of the etherate **3** was 22.9 μs. Given that reproducibility of the lifetime measurements is of the order of ±5%, there does not appear to be a significant difference in lifetime between the two samples.

The luminescence decay of the ytterbium complex **6** was best described using two lifetimes: 142 μs (92%) and 351 μs (8%), both of which greatly exceed the value of 21.6 μs observed for Cs[Yb(HFA)$_4$]. It has been previously noted by Faulkner that the luminescence in crystalline samples does not always undergo a simple exponential decay [3d], and that this may be due to surface effects. In the case of compound **6** the relative proximity of Yb^{3+} ions to residual solvent molecules could significantly affect their lifetimes.

Photoluminescence of the yttrium complex **4** was excited using wavelengths of 355 nm and 410 nm to investigate the ligand luminescence in the absence of an optically active ion. The luminescence spectra are shown in Fig. 4. For the 355 nm excitation a peak at ~430 nm can be seen which extends towards 700 nm. At 410 nm excitation there is some evidence of the short wavelength peak being present, modified by the presence of a 435 nm high pass filter in the beam path to remove the pump laser, but the spectrum is dominated by a longer wavelength peak at *ca.* 650 nm. Both of these emission bands overlap the main absorption bands of erbium in the visible region of the spectra and this probably accounts for the fast coupling observed between the ligand and the erbium ion. It can be seen that the longer

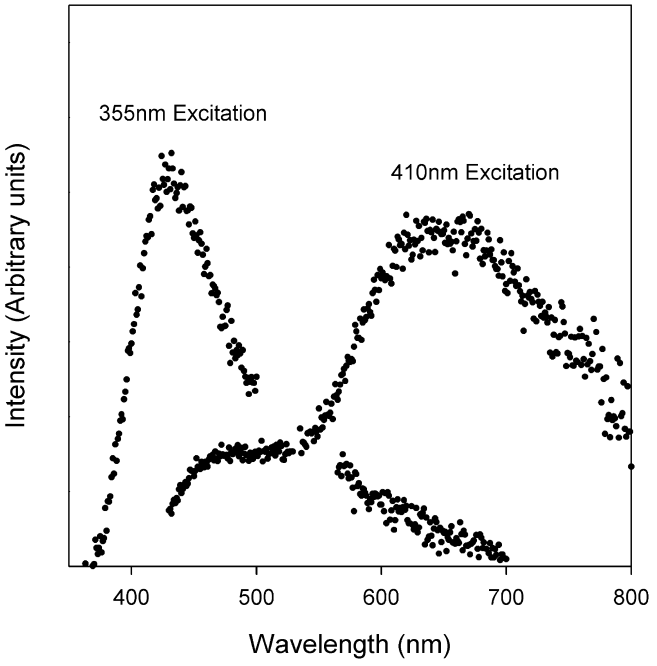

Fig. 4. Photoluminescence spectra of $Cs_2Y(o\text{-}O_2NC_6F_4O)_5$ **4** at two excitation wavelengths.

wavelength emission extends to >800 nm which just brings it within the energy of the absorption into the $^2F_{5/2}$ level for ytterbium. This may therefore account for the ability of the ligand to act as a sensitizer for ytterbium. It is possible that the longer wavelength peak observed with 410 nm excitation is radiative recombination of the triplet state. A similar change in the ligand luminescence from singlet to triplet state as the excitation wavelength is increased was observed in aluminium tris(8-hydroxyquinolinate) [30].

4. Conclusions

We have structurally characterized the first examples of rare earth pentakis(3,4,5,6-tetrafluoro-2-nitrophenoxide) complexes and have shown that this ligand can form chelates with tripositive rare earth ions in a similar way to the non-fluorinated 2-nitrophenoxide. It can completely displace water from the coordination sphere of the rare earth, thus allowing synthesis to be performed in aqueous solution. The erbium and ytterbium complexes **2** and **6** luminesce in the infrared and have luminescence lifetimes far exceeding those of typical hydrogen-containing ligands. The tetrafluoro-2-nitrophenoxide ligand absorbs blue and ultraviolet light quite strongly and shows a small antenna effect for photoexcitation of Er^{3+} and Yb^{3+} ions by visible light. Whereas the complexes are unsuitable for vacuum deposition, they are soluble in organic solvents and capable of being processed in solution.

B	DAHQERMDVSETHLHWHT
C	Ac-DAHQERMDVSETHLHWHT-NH_2

Substitution of F → D, L → A, C → S is supposed to prevent peptide precipitation in the solution.

the three His residues and Cu-induced oxidation, or Cu(II) reduction to Cu(I) [3]. The presence of only one or zero His residues between the two cysteines (Cys144 and Cys158) does not induce Cu(II) reduction and the oxidative reactions [9].

To evaluate the binding of Cu(II) by the three histidyl region we synthesized the protected and unprotected octadecapeptide (DAHQERMDVSETHLHWHT and Ac-DAHQERMDVSETHLHWHT-NH_2) having two distinct metal-binding-domains, the albumin-like N-terminal (DAH) and APP cysteine-rich three His domain at the C-terminal. The N-terminal albumin-like motif is also present in the APP cysteine-rich region (FLH) at positions 135–137 (Table 1). This is a strongly conserved sequence in APP proteins.

2. Experimental

2.1. Chemical synthesis, purification and analysis of the synthetic peptide

Both peptides were synthesized according to published methods using standard solid phase synthesis techniques with a manual methodology [10,11].

The protected amino acids and other chemicals were purchased from Peptide International, Fluka, Sigma–Aldrich. The protected peptide was synthesized on TentaGel R RAM resin (Rapp Polymers; capacity 0.18 mmol/g, 1 g). The resin was treated with piperidine (20%) in dimethylformamide and all amino acids were linked with the use of the DIPCI/HOBt methodology. The coupling reaction time was 1 h. Piperidine (20%) in dimethylformamide was used to remove the *Fmoc* group at all steps. After deprotection of the last N^{α}-*Fmoc* group, the peptide resin was washed and treated with *N*-acetylimidazole in dimethylformamide for 24 h. After washing with methanol the protected peptide resin was dried *in vacuo*. The resin was then treated with trifluoroacetic acid/H_2O/phenol/triisopropylsilane (reagent B, 8.8/0.5/0.5/0.2) 10 ml per 1 g of the resin at room temperature for 2 h. After filtration of the exhausted resin, the solvent was concentrated in vacuo and the residue triturated with diethyl ether. The crude peptide was checked by RP-HPLC (0–100% B in 60 min ($A = 0.1\%$ TFA/H_2O, $B = 80\%$ CH_3CN/H_2O + 0.08% TFA), 1 ml/min, Kromasil C_{18} analytical column (4.6 × 250 mm, 5 μm), UV detection at 223 nm, $R_t = 21.05$ min) and MS ($M_{theoretical} = 2270.4$, $[M+H^+]_{experimental} = 2271.2$). The peptide was purified with HPLC using a Vydac C_{18} semi-preparative column (10 × 250 mm, 5 mm) with a gradient of 10–50% B in 120 min (A and B solvents as described before), flow 10 ml/min, UV detection at 223 nm. The fraction containing the pure peptide was liophylized twice and the purity assessed by analytical RP-HPLC (0–100% B in 60 min, 1 ml/min, Kromasil C_{18} analytical column (4.6 × 250 mm, 5 μm), UV detection at 223 nm, $R_t = 22.6$ min, purity 99%), and MS ($[M+H^+]_{experimental} = 2271.0$) using a Bruker Biflex III Maldi-Tof Mass Spectrometer (Bruker Daltonics).

The unprotected version of the peptide was synthesized on TentaGel PHB resin (Rapp Polymer; capacity 0.22 mmol/g, 1 g). The first amino acid was attached manually to the resin with the use of an esterification reaction of an underivatised support (6 time excess of the symmetrical anhydride in dimethylforamide, DIPCI/DMAP). The symmetrical anhydride was gently agitated with the resin for 2 h. Next the resin was washed with DMF and used for the synthesis as described above. After the peptide synthesis, the resin was washed with methanol and the free peptide resin was dried *in vacuo*. The resin was then treated with trifluoroacetic acid/H_2O/phenol/triisopropylsilane (reagent B, 8.8/0.5/0.5/0.2) 10 ml per 1 g of the resin at room temperature for 2 h. After filtration of the exhausted resin, the solvent was concentrated *in vacuo* and the residue triturated with diethyl ether. The crude peptide was checked by HPLC (0–100% B in 60 min, Kromasil C_{18} analytical column, 1 ml/min, C_{18} analytical column (4.6 × 250 mm, 5 μm), UV detection at 223 nm, $R_t = 20.05$ min) and MS ($M_{theoretical} = 2229.4$, $[M+H^+]_{experimental} = 2230.2$). The peptide was purified with RP-HPLC using a Vydac C_{18} semi-preparative column (10 × 250 mm, 5 μm), flow 10 ml/min, UV detection at 223 nm, with a gradient of 5–50% B in 120 min (A and B as described above). The fraction containing the pure peptide was lyophilized twice and the purity assessed by analytical HPLC (0–100% B in 60 min, Kromasil C_{18} analytical column, flow 1 ml/min, C_{18} analytical column (4.6 × 250 mm, 5 μm), UV detection at 223 nm, $R_t = 20.6$ min, purity 99%), and MS ($[M+H^+]_{experimental} = 2230.0$).

2.2. Potentiometric measurements

Stability constants for both the proton and Cu(II) complexes were calculated from three titrations carried out over the range pH 3–11 at 25 °C using a total volume of 1.5 cm^3. The purities and exact concentration of the solutions of the ligands were determined by the method of Gran [12]. NaOH was added from a 0.250 cm^3 micrometer syringe which was calibrated by both weight titration and titration of standard materials. The metal ion concentration was 1×10^{-3} M and the metal to ligand ratio was 1:1.1 and 0.5:1.0. The pH-metric titrations were performed at 25 °C in 0.1 M KCl on a MOLSPIN pH-meter system using a Russel CMAW 711 semi-combined electrode calibrated in hydrogen concentration using HCl [13]. The

SUPERQUAD and HYPERQUAD programs were used for stability constant calculations [14,15]. Protonation constants and stability constants were determined independently. Standard deviations were computed by SUPERQUAD and HYPERQUAD and refer to random errors only. They are, however, a good indication of the importance of a particular species in the equilibrium.

2.3. Spectroscopic measurements

Solutions for the spectroscopic measurements were of similar concentrations to those used in the potentiometric studies. Electron paramagnetic resonance (EPR) spectra were recorded on a Brucker ESP 300E spectrometer at X-band frequency (9.3 GHz) at 120 K. Circular dichroism (CD) spectra were recorded on a Jasco J-715 spectropolarimeter in the 800–235 nm range. The values of $\Delta\varepsilon$ (*i.e.* $\varepsilon_1 - \varepsilon_2$) and ε were calculated at the maximum concentration of the particular species obtained from the potentiometric data.

3. Results and discussion

3.1. Unprotected peptide

The octadecapeptide, DAHQERMDVSETHLHWHT, has 10 potential protonation sites and it behaves as a $H_{10}L$ ligand with protonation constants collected in Table 2. The protonation sites include the N-terminal amino group, four histidyl imidazoles, two glutamic and two aspartic side chain carboxylates and the carboxylate of the C-terminal Thr. The differences between the pK values of the four His are within statistical range (0.4–0.6). The same relations are observed for the pairs of Asp and Glu carboxylates, respectively, indicating no distinct interactions between the protonation sites.

The calculations based on the potentiometric titration data show formation of 9 coordination species (Table 3, Fig. 1). The coordination begins around pH 2.5 and the first clear spectroscopic evidence for metal ion binding to peptide is seen around pH 4, in which the d–d transitions centered around 620 nm indicate two nitrogen (2N) coordination [6].

The hypothetical plot calculated with use of the stability constants obtained for binary systems, showing the competition between two binding sites of the albumin N-terminal tripeptide Asp-Ala-His-NH_2 fragment [16] and the three

Metal to ligand ratio = 1.0:1.1; [Cu(II)] = 0.001 M.

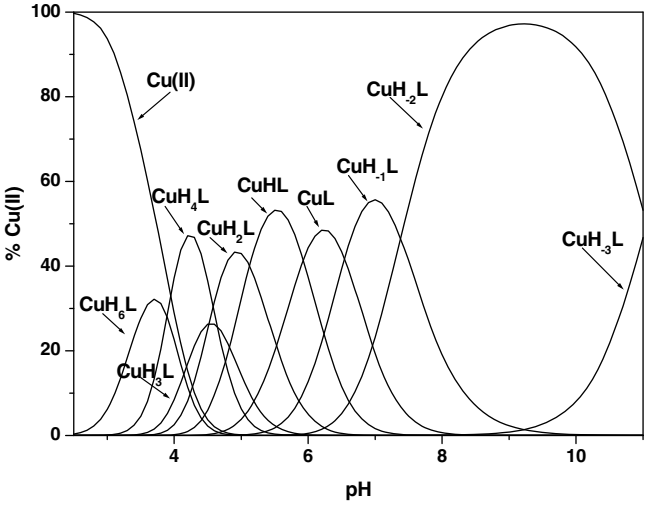

Fig. 1. Species distribution profile for the Cu(II) complexes of DAH-QERMDVSETHLHWHT. Metal to peptide molar ratio = 1:1; [Cu(II)] = 0.001 M.

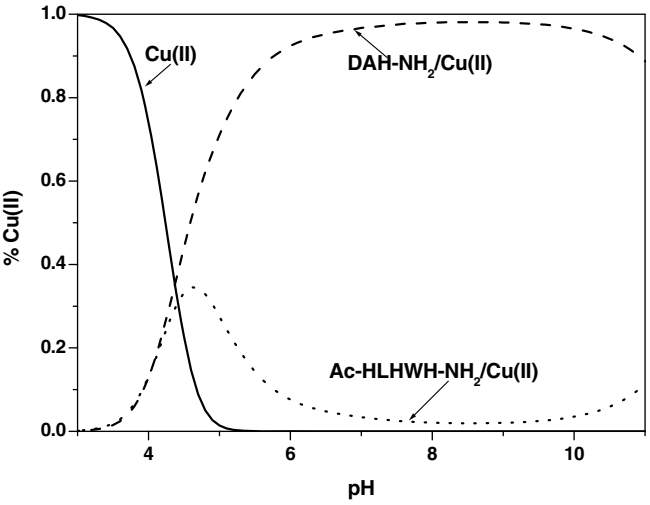

Fig. 2. Competition diagram between Ac-HLHWH-NH$_2$/Cu(II) [6] and DAH–NH$_2$/Cu(II) [16] complexes. Metal to peptide molar ratio = 1:1:1; [Cu(II)] = 0.001 M.

His region Ac-HLHWH-NH$_2$ [6] (Fig. 2) clearly indicates that the albumin-like site is more effective in coordinating the Cu(II) ion, especially above pH 6. Within the pH range 4–5 both sites are comparable in binding, but around pH 7 the "three His" APP site binds less than 5% of the copper. The CD, UV–Vis and EPR spectra for the unprotected octadecapeptide indicate that 4N {NH$_2$, 2 × N$^-$, N$_{imid}$} coordination at N-terminal begins around pH 5. This follows the formation of the CuHL species. The CuHL complex with albumin-like binding undergoes deprotonation at the three His residues within the APP-like region with a pK_a value very close to those observed for the metal-free peptide (Table 3). The spectroscopic parameters above pH 5.5 (CuHL, CuL, CuH$_{-1}$L and CuH$_{-2}$L complexes) are exactly the same, supporting the same coordination mode in all these species. The formation of CuH$_{-3}$L may result from the deprotonation of the metal-bound imidazole [16]. A comparison of the CD spectra for solutions in the physiological pH range (Fig. 4) for the considered systems, DAHQERMDVSETHLHWHT/Cu(II), Ac-HLHWH-NH$_2$/Cu(II) [6] and DAH–NH$_2$/Cu(II) [16] complexes, clearly shows that the coordination mode of DAHQERMDVSETHLHWHT/Cu(II) is similar to that found for the DAH-NH$_2$/Cu(II) system. Thus, even if the APP three His region binds Cu(II) ions in the physiological pH range very effectively *via* the five-nitrogen donor system {3 × N$_{imid}$, 2 × N$^-$} [6,7], it is poorly competitive to the

Table 4

Metal to ligand ratio = 0.5:1.0; [Cu(II)] = 0.001 M.

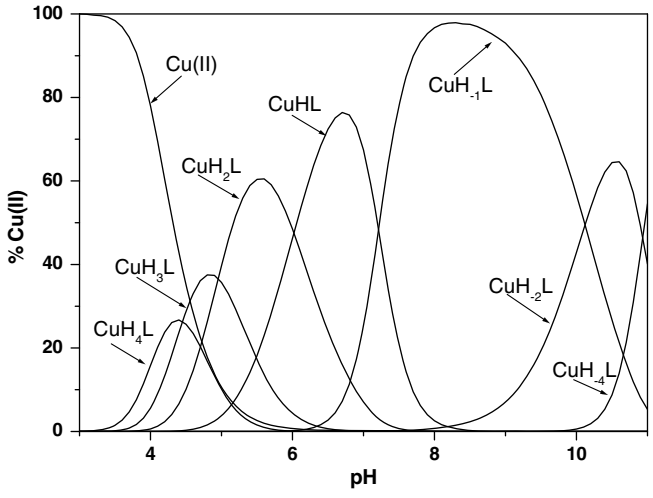

Fig. 3. Species distribution profile for the Cu(II) complexes of Ac-DAHQERMDVSETHLHWHT-NH$_2$. Metal to peptide molar ratio = 0.5:1; [Cu(II)] = 0.001 M.

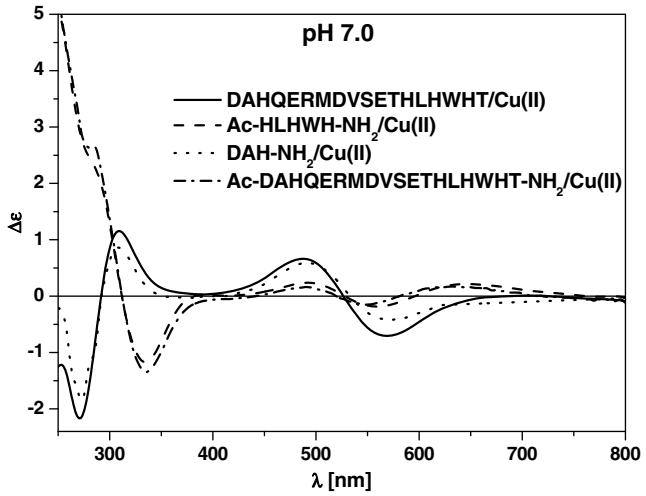

Fig. 4. Comparison of the CD spectra of DAHQERMDVSETHLHWHT/Cu(II), Ac-HLHWH-NH_2/Cu(II) [6], Ac-DAHQERMDVSETHLHWHT-NH_2/Cu(II) and DAH–NH_2/Cu(II), [16] complexes at pH 7. Metal to peptide molar ratio = 1:1:1; [Cu(II)] = 0.001 M.

albumin-like coordination (Figs. 2 and 5B). However, the presence of the second binding site, –HLHWH–, in the unprotected peptide increases the stability of the complexes formed and DAHQERMDVSETHLHWHT becomes more effective than the DAH–NH_2 ligand (Fig. 5A).

3.2. N- and C-protected peptide

The N- and C-protected peptide, Ac-DAHQERMDVSETHLHWHT-NH_2, behaves as a H_8L acid. The protonation constants corresponding to the Arg side chain (pK 10.11), 4 His imidazoles and three carboxylates are collected in Table 4. Calculations based on the potentiometric data related to titrations in the presence of Cu(II) (range pH 3–10.5) indicate the formation of six complex species; all of them are mono-complexes with different degrees of protonation. The distribution diagram reported in Fig. 3 shows that the coordination starts at a pH lower than 4. Coordination of the Cu(II) ion in CuH_4L starts at the imidazole nitrogen of the His residue, which is an anchoring site for the metal ion (a band present at 723 nm in UV–Vis and $A_{II} = 163 \times 10^{-4}\,cm^{-1}$, $g_{II} = 2.33$ in the EPR spectrum). Within the physiological pH range, the CuHL and $CuH_{-1}L$ complexes dominate. The CuHL complex at pH 7.0 involves most likely the $\{3N_{im}, N^-\}$ binding mode, supported by a d–d transition at 588 nm. Spectroscopic parameters obtained above pH 8.0 for the $CuH_{-1}L$ complex are similar to those observed for Cu(II)/APP(145–157) with the $\{3N_{im}, 2N^-\}$ coordination [7]. The potentiometric data obtained clearly show that the behavior of its binding to Cu(II) is very similar to that observed for the three histidine peptide, Ac-ETHLHWHTVAKET-NH_2 [7]. Thus, the major complexes present in the physiological pH range for protected the octadecapeptide fragment have a coordination mode as those observed earlier for the APP peptide, indicating that the basic binding site involves the three His domain when the albumin terminal is N-protected. The splitting of the d–d transitions indicates a lowering of the geometry around the metal ion in the $CuH_{-1}L$ species. Formation of $CuH_{-2}L$ results in the distinct reorganization of the coordination sphere around the Cu(II) ion, probably related to the coordination of an additional amide nitrogen. Above pH 10 two protons dissociate from $CuH_{-2}L$ to give a $CuH_{-4}L$ species derived from the deprotonation of the Arg side chain and the metal bound imidazole. CD spectra at about pH 7 (Fig. 4) for the systems Ac-DAHQERMDVSETHLHWHT-NH_2/Cu(II), Ac-HLHWH-NH_2/Cu(II) [6] and DAH–NH_2/Cu(II), [16] show that the coordination mode of

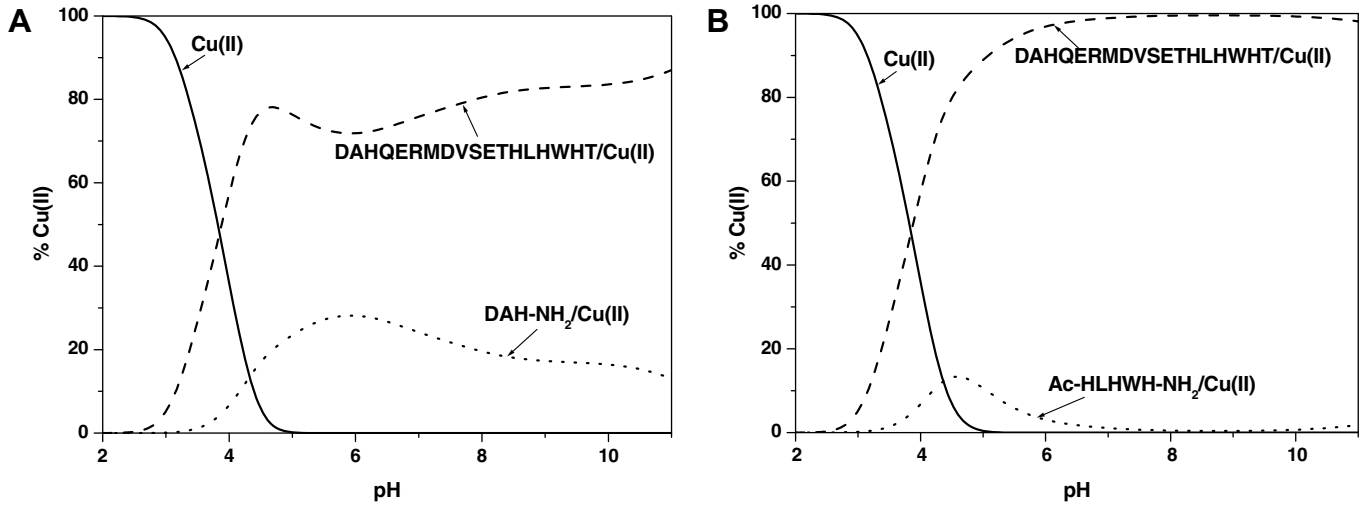

Fig. 5. Competition diagrams between the DAHQERMDVSETHLHWHT/Cu(II) and Ac-HLHWH-NH_2/Cu(II) [6] complexes, (A); DAHQERMDVSETHLHWHT/Cu(II) and DAH-NH_2/Cu(II) [16] complexes, (B). Metal to peptide molar ratio = 1:1:1; [Cu(II)] = 0.001 M.

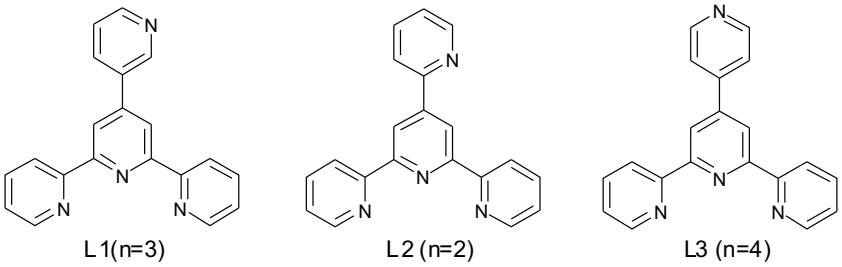
the protected peptide is similar to that found for Ac-HLHWH-NH_2/Cu(II) (see Table 5).

4. Conclusion



The –HXHYH– motif is very effective in binding Cu(II) although it is unable to compete with the albumin-like coordination. This could be a critical factor when both peptides are inserted into a protein sequence. This strong multi-histidine and amide binding could be responsible for the protection of Cu(II) reduction to Cu(I) reported recently for some variants of APP protein [3].

and extend the structure into higher dimensionality [5a,7]. To our knowledge, among the three isomers, L3 is better studied than the other two. It has been found to form macrocyclic oligomers [8], 1D linear [5d,9] and grid-like [10] polymers, 3D chiral self-catenated network [11] and supramolecular motifs [12]. Studies based on the other two pytpy ligands are rare [5b,6,13]. We noticed that the angles between mono- and tridentate N-donor sites in L1 and L2 are different and we believe this subtle structural difference may affect the metal–ligand coordination environment, as well as the overall dimensionality of the architecture [6,13c].

With this understanding, one crucial aim of this work is to explore the intrinsic factors of these positional isomeric ligands for tuning the structural assembly, which may provide further insights in designing new hybrid crystalline materials, four compounds, namely, $\{[Cd_3(L1)_2(SCN)_6](THF)_2\}_n$ (**1**), $[Cd_2(L1)(CH_3OH)Cl_4]_n$ (**2**), $[Cd_2(L2)_2(N_3)_4]$ (**3**), $[Cd_2(L2)_2(SCN)_4]$ (**4**), were synthesized based on the use of L1 and L2 as ligands and Cd^{II} halides (pseudohalides) as metal salts.

2. Experimental

2.1. Materials and methods

Ligands 4′-(3-pyridyl)-2,2′:6′,2″-terpyridine (L1) and 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine (L2) were prepared according to the literature method [14]. All the other chemicals were used as obtained from commercial sources without further purification. Elemental analyses (C, H and N) were performed with Elementar Vario EL III elemental analyzer. Infrared spectra were recorded on a Bruker EQUINOX55 spectrometer as KBr pellets in the range of 4000–400 cm^{-1}. Luminescent spectra were measured at room temperature on a Hitachi F4500 fluorescence spectrophotometer.

2.2. Syntheses and characterization

2.2.1. $\{[Cd_3(L1)_2(SCN)_6](THF)_2\}_n$ (*1*)

NH_4SCN (0.030 g, 0.4 mmol) was added to methanol solution (10 mL) of $Cd(NO_3)_2 \cdot 4H_2O$ (0.031 g, 0.2 mmol) with stirring. The resulting solution was carefully layered on solution of L1 (0.031 g, 0.1 mmol) in THF (10 mL). Colorless crystals formed at the methanol/THF interface and were collected by filtration to give a yield of 65% (based on Cd). *Anal.* Calc. for $C_{54}H_{44}Cd_3N_{14}O_2S_6$ (**1**): C, 44.71; H, 3.06; N, 13.52. Found: C, 44.73; H, 3.03; N, 13.53%. IR (cm^{-1}, KBr): 3422(w), 3052(w), 2967(w), 2857(w), 2113(s), 2076(s), 1597(m), 1546(m), 1472(m), 1434(w), 1394(m), 1244(w), 1056(w), 1012(w), 791(m).

2.2.2. $[Cd_2(L1)(CH_3OH)Cl_4]_n$ (*2*)

Compound **2** was obtained upon carefully layering a solution of $CdCl_2 \cdot 2.5H_2O$ (0.046 g, 0.2 mmol) in methanol (10 mL) onto the solution of L1 (0.031 g, 0.1 mmol) in THF (10 mL). The solution was left for 3 weeks at room temperature. X-ray quality transparent crystals were collected by filtration to give a yield of 52% (based on Cd). *Anal.* Calc. for $C_{21}H_{18}Cd_2Cl_4N_4O$ (**2**): C, 35.57; H, 2.56; N, 7.90. Found: C, 35.55; H, 2.57; N, 7.91%. IR (cm^{-1}, KBr): 3402(s), 3077(m), 1607(m), 1546(m), 1473(m), 1247(w), 1010(w), 797(m).

2.2.3. $[Cd_2(L2)_2(N_3)_4]$ (*3*)

Compound **3** was obtained using a procedure similar to that for **1** except that NaN_3 and L2 were used instead of NH_4SCN and L1. Colorless crystals were collected by filtration to give a yield of 73% (based on Cd). *Anal.* Calc. for $C_{40}H_{28}Cd_2N_{20}$ (**3**): C, 47.40; H, 2.78; N, 27.64. Found: C, 47.36; H, 2.80; N, 27.66%. IR (cm^{-1}, KBr): 3345(w), 2032(s), 1591(m), 1550(m), 1469(m), 1406(m), 1278(w), 1011(m), 784(m).

2.2.4. $[Cd_2(L2)_2(SCN)_4]$ (*4*)

Compound **4** was obtained using a procedure similar to that for **1** except that L2 was used instead of L1. Colorless crystals were collected by filtration to give a yield of 79% (based on Cd). *Anal.* Calc. for $C_{44}H_{28}Cd_2N_{12}S_4$ (**4**): C, 49.03; H, 2.62; N, 15.59. Found: C, 49.06; H, 2.63; N, 15.55%. IR (cm^{-1}, KBr): 3444(w), 2110(s), 2024(s), 1600(m), 1550(m), 1466(m), 1404(m), 1243(w), 1013(m), 781(m).

2.3. X-ray crystallography

Single crystal X-ray diffraction studies of complexes **1**–**4** were performed on a Bruker Smart Apex II CCD diffractometer equipped with a graphite crystal monochromator

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum|F_o|$, $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

situated in the incident beam. The data collections were performed with Mo Kα radiation ($\lambda = 0.7107$ Å) by ω scan mode in the range of $1.82 < \theta < 25.10°$ (for **1**), $2.29 < \theta < 25.10°$ (for **2**), $2.32 < \theta < 25.10°$ (for **3**), $1.63 < \theta < 25.09°$ (for **4**) at 296(2) K. The crystal parameters and experimental details of the data collection are summarized in Table 1. All structures were solved by the direct methods using SHELXS program of the SHELXTL-97 package and refined with SHELXL [15]. Metal atoms in all complexes were located from the E-maps and other non-hydrogen atoms were located in successive difference Fourier syntheses. The final refinements were performed by full-matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. All hydrogen atoms were included in calculated positions and refined with isotropic thermal parameters riding on those of the parent atoms. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. IR spectra

The IR spectra for compounds **1**–**4** contain characteristic C=N and C=C vibrational frequencies for free ligands L1 and L2 at 1600–1450 cm^{-1}. The strong ν_{as}(SCN) absorption peaks at 2113 cm^{-1} for **1** and 2110 cm^{-1} for **4** show the presence of 1,3-μ-thiocyanate ligands and that at 2076 cm^{-1} for **1** and 2024 cm^{-1} for **4** are indicative of N-terminal coordination [16]. In **2**, a broad band centered around 3402 cm^{-1} can be assignable to the O–H stretch of the coordinated MeOH molecule. In **3**, $\nu_{as}(N_3)$ appears as a very strong splitting band at 2044 cm^{-1} and 2032 cm^{-1} is assigned to the existence of both end-on bridging and terminal azide ligand [17].

3.2. Description of the structures

3.2.1. $\{[Cd_3(L1)_2(SCN)_6](THF)_2\}_n$ (**1**)

Single crystal X-ray diffraction shows that **1** consists of a 1D grid-like chain. The asymmetric unit contains one and a half crystallographically independent Cd^{II} atoms (Fig. 1). Cd1 adopts a distorted octahedral geometry in a CdN_5S fashion, in which three nitrogen atoms from the tridentate sites of one L1 and one nitrogen atom from SCN^- ligand comprise the equatorial plane, and one nitrogen atom and one sulfur atom from different SCN^- ligands occupy the axial positions. The hexa-coordinated Cd2 atom coordinates to four SCN^- ligands at the equatorial plane and two pendant pyridyl rings from two L1 at the axial positions. The Cd–N and Cd–S distances falling in the range of 2.181(3)–2.383(3) Å, and 2.720(2)–3.018(2) Å, respectively, are all within the normal range. The SCN^- groups are nearly linear with the N–C–S bond angles in the range 176.83–179.38°, C–N–Cd and C–S–Cd linkages are bent and the related bond angles are in accordance with similar types of reported complexes [16].

An interesting feature is that three cadmium atoms (Cd1, Cd2 and Cd1A) locate in a line and are bridged by four μ-1,3-SCN^- ligands with the distances of Cd1···Cd1A and Cd1···Cd2 being 11.767 Å and 5.884 Å, respectively. L1 as a bridging ligand links Cd1 and Cd2 with nitrogen atoms from tridentate and mono-dentate domains, leading to the formation of 1D chain as shown in Fig. 2. The resulting chain can be considered as a series of [2 × 2] parallelo-

Symmetry operation: #1: $-x+2$, $-y$, $-z$; #2: $-x+2$, $-y$, $-z+1$; #3 x, y, $z-1$; #4: x, y, $z+1$ for **1**. #1: $x+1/2$, $-y+3/2$, $z+1/2$ for **2**.

gram grids interconnected through sharing Cd2 atoms at diagonally opposite corners, which is significantly different from the reported 1D grid-type structures formed by L3 [10], in which the grids are interconnected through halide atoms.

Within the grid, the length of the long edge measured by Cd1···Cd2 distance across L1 bridge is 10.478 Å, while the long diagonal distance measured by Cd2···Cd2 distance is 14.214 Å and the angle Cd1···Cd2···Cd1B is 62.13°. The dihedral angle of 32.35° between the pendant and central pyridines of L1 is largely a consequence of the geometric requirement imposed by metal atoms and no intra-unit face-to-face π–π interactions are observed.

The chains pack together through short face–face aromatic–aromatic interactions between the terminal and central terpyridyl rings (3.904 Å centroid–centroid), giving rise to 2D sheets (Fig. 2). THF solvent molecules are located in the lattice and form short contacts with protons of pyridyl rings and nitrogen atoms from bridging SCN^- anions, respectively (C1–H1···O1^{i}, 3.408 Å, 135.4°; C25–H25B···N6^{ii}, 3.517 Å, 150.5°; symmetry code i: ($x-1$, y, z), ii: ($-x+1$, $-y+1$, $-z$)).

3.2.2. $[Cd_2(L1)(CH_3OH)Cl_4]_n$ (**2**)

Compound **2** is a 2D wave-like structure formed through L1 bridging tetranuclear cadmium building units. As shown in Fig. 3, the asymmetric unit contains one L1, two crystallographically independent cadmium atoms, four chloride anions and one methanol molecule. Cd1 atom adopts octahedral geometry with the equatorial plane defined by three nitrogen atoms [Cd1–N1 = 2.339(3), Cd1–N2 = 2.305(3) and Cd1–N3 = 2.337(3) Å] from the tridentate sites of one L1 and one bridging chloride atom. The axial positions are occupied by one terminal and one bridging chloride atoms. The Cd1–Cl distances fall in the range of 2.459(1)–2.931(1) Å similar to those found in other Cd chloride coordination polymers [18]. Cd2 atom also adopts octahedral geometry with the equatorial plane defined by one nitrogen atom from the pendant pyridine of L1, three bridging chloride atoms. The axial positions are occupied by one bridging chloride and one methanol molecule. The Cd2–N, Cd2–S and Cd2–O distances are all within the normal range.

One of the outstanding features in **2** is the tetranuclear Cd units are formed and bridged by L1 resulting in an infinite 2D non-interpenetrating architecture (Fig. 4). Four cadmium atoms locate in a zig-zag shape, bridged by three double chloride bridges into Cd1–Cl_2–Cd2–Cl_2–Cd2A–Cl_2–Cd1A subunit with the distances of Cd1···Cd2, Cd1···Cd1A and Cd2···Cd2A being 3.938, 10.068 and 3.750 Å, respectively. Within the tetranuclear unit, each Cd_2Cl_2 is nearly coplanar and adjacent Cd_2Cl_2 planes are nearly perpendicular to each other. Each Cd_4 unit is bridged by four L1 and each L1 as a mono-tridentate bridging ligand links two Cd^{II} atoms into a 2D structure with $\{Cd_{10}C_{48}Cl_6\}$ macrocycles (Fig. 4). Within the macrocycles, it is interesting that L1 selectively links metal atoms with its tri- and mono-dentate sites. The tpy domain of L1 is nearly coplanar and coordinates to Cd1 atom, while the pendant pyridine rotates 17.80° relative to the central pyridyl ring to coordinate to Cd2. Adjacent L1 ligands which, respectively, link Cd1 and Cd2 atoms in the same Cd_4 unit are approximately anti-parallel and offset. Two face-to-face interactions between the central and terminal pyridyl rings are observed with centroid–centroid distance 3.664 and 3.773 Å, respectively, which stabilized the overall structure.

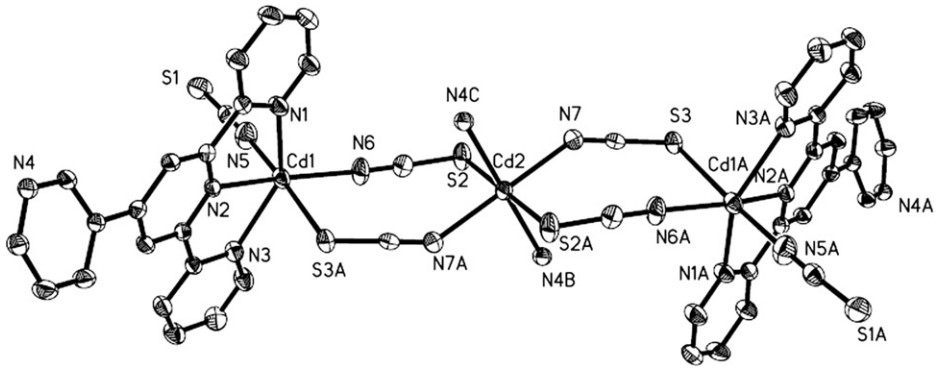

Fig. 1. ORTEP diagram of $\{[Cd_3(L1)_2(SCN)_6](THF)_2\}_n$, **1** with atom numbering scheme. Ellipsoids are drawn at 30% probability. H atoms and solvent molecules are not present for clarity.

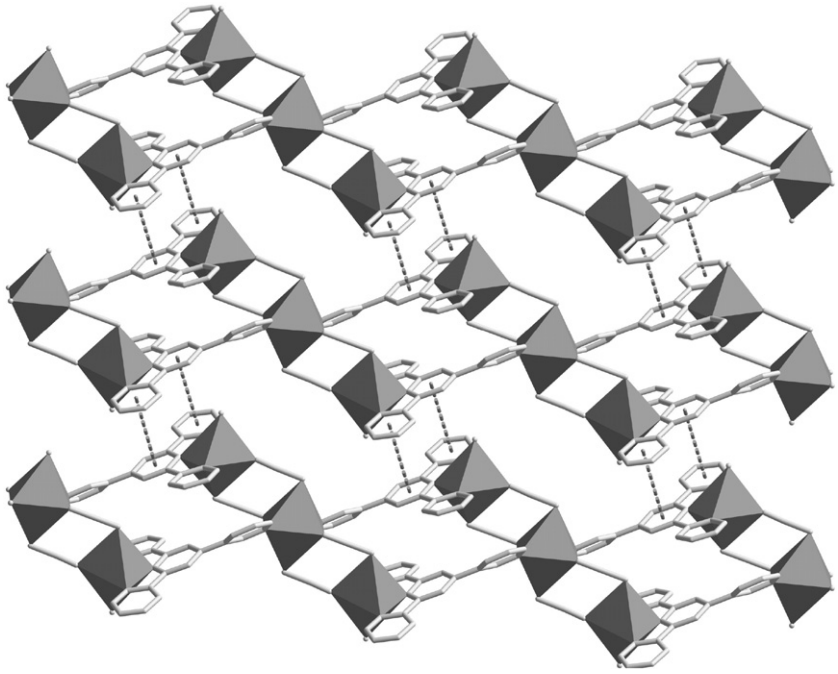

Fig. 2. View of the 1D grid-like structure of **1** packed into 2D supramolecular layer through $\pi\cdots\pi$ interactions. H atoms and solvent molecules are not present for clarity.

It should be noted that the actual structure of the 2D layer is wave-like, adjacent layers get a tightly packed structure without any guest molecules, the interlayer H-bonds *via* the interaction of terminal chloride atoms with hydrogen atoms of coordination methanol molecules [O1–H1A$\cdots$Cl1^{iii}, 3.158 Å, 162.7°, symmetry code iii: (*x*,

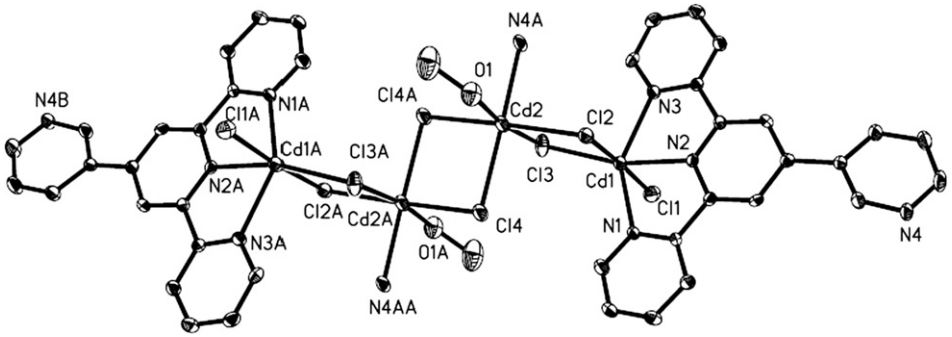

Fig. 3. ORTEP diagram of $[Cd_2(L1)(CH_3OH)Cl_4]_n$, **2** with atom numbering scheme. Ellipsoids are drawn at 30% probability.

y, *z* + 1)] connect the 2D structure into 3D framework (Fig. 5).

3.2.3. $[Cd_2(L2)_2(N_3)_4]$ (**3**)

Compound **3** is a dimeric structure (Fig. 6). Each centrosymmetric dimer consists of Cd^{II} ions linked by two end-on bridging azide groups. The other two azides act as terminal ligands. The Cd_2N_2 core is planar with a Cd···Cd distance of 3.727 Å and a Cd–N–Cd bridging angle is 103.62°. The local coordination environment of each Cd^{II} ion is a distorted octahedron with the equatorial plane defined by three nitrogen atoms from the tridentate sites of one L2 and one nitrogen atom from the intra-dimer end-on azide bridge. The axial positions are occupied by two nitrogen atom from the intra-dimer end-on azide bridge and monocoordinate azide ligand, respectively. The bridging and terminal azide ligands are nearly linear and bond to Cd^{II} atoms with bent angle of Cd1–N5–N6 122.11° and Cd1–N8–N9 118.79°. Different from L1, L2 functions as a chelating ligand with the pendant uncoordinated pyridyl ring. A similar dimeric structure based on tpy and Mn-azide has been reported [19]. The pendant and central pyridines of L2 are twisted with a lower dihedral angle 4.79° than the value

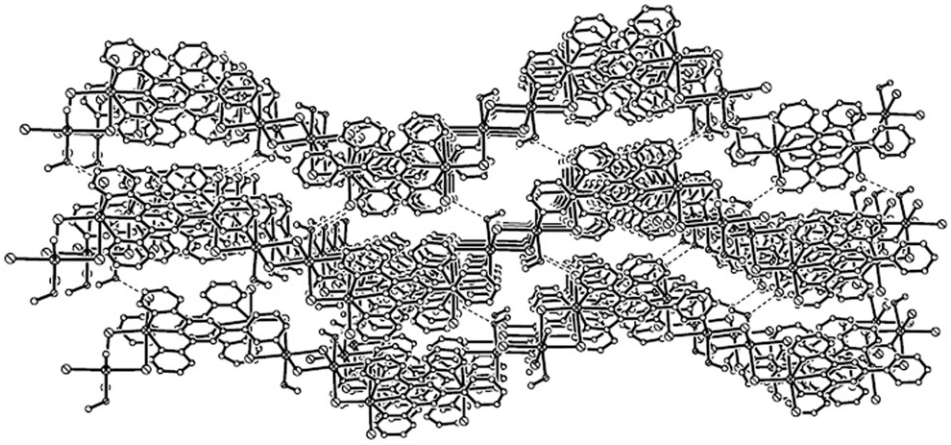

Fig. 5. Sideview of the 2D wave-like structure connected into 3D structure *via* interlayer H-bonding interactions.

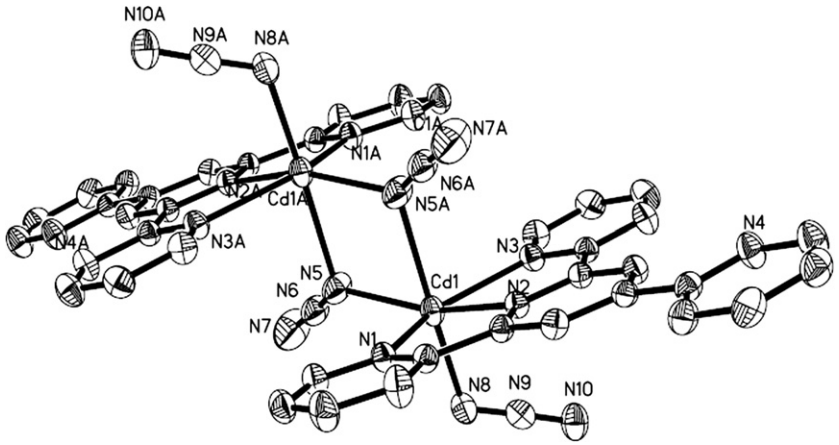

Fig. 6. ORTEP diagram of $[Cd_2(L2)_2(N_3)_4]$, **3** with atom numbering scheme. Ellipsoids are drawn at 30% probability.

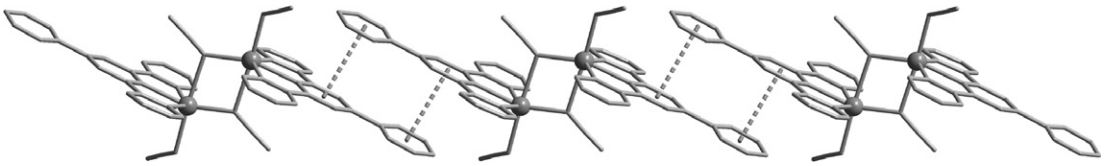

Fig. 7. Structure of the 1D chain in **3** supported by π···π interactions. All H atoms are omitted for clarity.

of L1 in compound **1**. Strikingly, the pendant rings stack with central pyridine on an adjacent molecule (3.724 Å of centroid–centroid), each pair of rings is approximately coplanar and offset. This type of intermolecular face–face aryl interactions links the dimeric units into infinite 1D chain (Fig. 7). The chains are packed together into a 2D plane, however, no short π···π interactions are observed between the chains.

3.2.4. $[Cd_2(L2)_2(SCN)_4]$ (**4**)

Compound **4** is also a dimeric structure (Fig. 8). Each centrosymmetric dimer consists of Cd^{II} ions bridged by double μ-1,3-SCN^- bridges, forming a nearly planar eight-member ring, $Cd(SCN)_2Cd$, with a Cd···Cd separation of 5.898 Å. The coordination environment of each Cd^{II} ion is a distorted octahedron with the equatorial plane defined by three nitrogen atoms from the tridentate sites of one L2 and one S atom from the intra-dimer SCN^- bridge. The axial positions are occupied by two nitrogen atoms from the intra-dimer SCN^- bridges and monocoordinate SCN^- ligand, respectively. The bridging SCN^- ligands are nearly linear with angle of S–C–N 178.92° and bond to Cd^{II} atoms with bent angle of Cd1–N5–C21 152.35° and Cd1–S1–C21 162.09°. The terminal SCN^- ligands themselves bent with angle of S–C–N 174.71° bond to Cd^{II} atoms with bent angle of Cd1–N6–C22 119.34°. Similar to compound **3**, the nitrogen atom at the 2-position from the pendant pyridyl ring does not participant in the coordination. The pendant and central pyridines of L2 are twisted with a dihedral angle 10.03°, two terminal pyridyl rings are twisted with dihedral angles 8.26°, 9.77° respect to the central pyridyl ring. The intermolecular face–face aryl interactions between the terminal terpyridyl rings and the pendant pyridyl rings from adjacent molecules link the dimeric structures into 1D chain (Fig. 9). This kind of stacking way is significantly different from above mentioned structure **3** and no short aryl–aryl interactions are observed between chains.

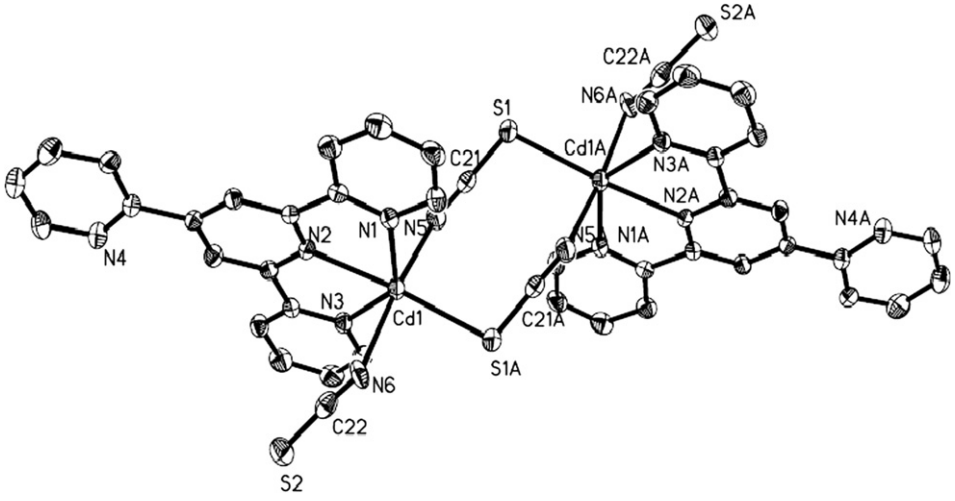

Fig. 8. ORTEP diagram of $[Cd_2(L2)_2(SCN)_4]$, **4** with atom numbering scheme. Ellipsoids are drawn at 30% probability.

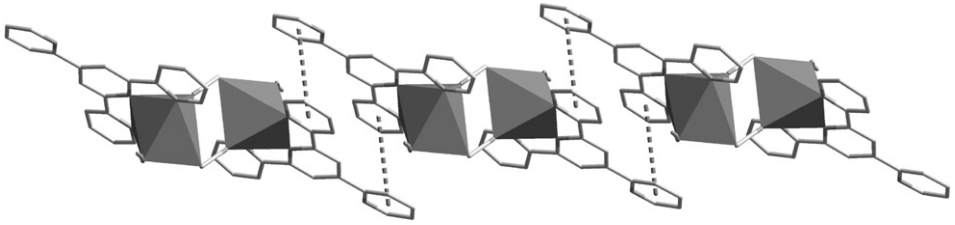

Fig. 9. Structure of the 1D chain in complex **4** supported by π···π interactions. H atoms are omitted for clarity.

3.3. Structural comparison

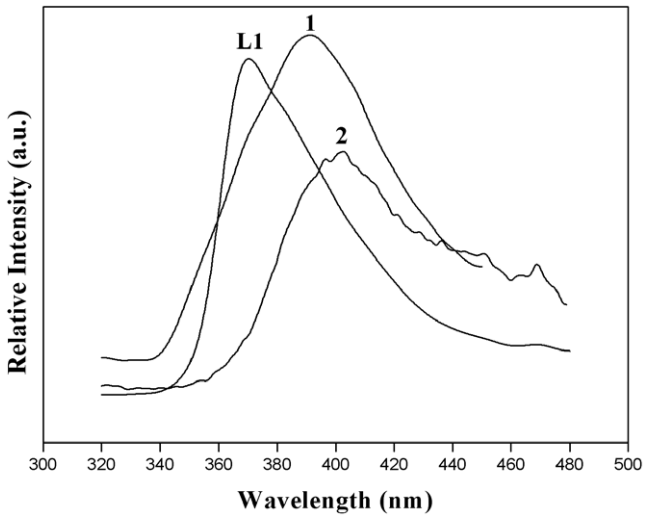
L1 and L2 are pyridyl substituted terpyridine isomers which are only differ in the position of nitrogen atom at substituted pyridyl ring. However, subtle structural difference may influence the overall metal–organic frameworks. L1 has a bite angle of 120° between mono-dentate and tridentate motifs while L2 has a bite angle of 60°. L1 itself rotates a larger angle between tpy domain and pendant pyridyl ring than L2 because of the repulsion force arising from the central and pendant pyridyl β-hydrogen atoms and thus enjoy less space-crowding than L2. As a result, it is easier for L1 to coordinate a second metal with covalent bond. The pendant pyridyl ring of L2 prefers to be involved in the non-covalent bond unless a serious rotation [20]. Consistent to the above analysis, in compounds **1** and **2**, L1 as mono-tridentate bridging ligand with the corresponding twist angles of 32.35° and 17.80° between central and pendant pyridines, respectively, and links metal atoms into 1D and 2D structures. While in compounds **3** and **4**, L2 as chelating ligand forms the dimeric structures with the corresponding twist angles of 4.79° and 10.03° between central and pendant pyridines, respectively.

Unsubstituted tpy as an excellent chelating ligand has been widely used, which can easily form mononuclear complexes $[M(tpy)_2]^{n+}$[21]. Dance et al. have reported the packing modes of the unsubstituted terpyridyl complexes [22]. Compared to unsubstituted tpy, more types of short $\pi\cdots\pi$ contacts could be observed. Constable and others have discussed the role of aromatic stacking of substituents in the crystal engineering of tpy complexes [5a,5f,7,9,23]. The aromatic stacking interactions were observed in the four compounds (Scheme 2). In compound **1** and **2**, type A interactions exist, in which two adjacent ligands anti-orientation arranged and the central pyridyl ring packs on the adjacent terminal pyridyl ring form tpy unit with centroid–centroid distance 3.904 Å and 3.664 Å, respectively. In compound **3**, dimmers packed together though the pendant rings stack with central pyridine on an adjacent molecule with centroid–centroid distance 3.724 Å as shown in type B. Type C can be found in compound **4**, in which the terminal pyridine contact with pendant pyridyl rings from adjacent molecules with centroid–centroid distance 3.774 Å.

3.4. UV–Vis and luminescent spectra

The UV–Vis absorption of ligands L1, L2 and compounds **1**, **3** and **4** were examined. Compound **2** is insoluble in common organic solvent, so, its UV–Vis spectrum could not be carried out. The UV–Vis absorption bands for L1 in DMF are at ca. 278 and 308 nm while that for L2 at ca. 280 and 318 nm, these two bands are assigned to intraligand π–π^* or n–π^* transition [24]. The absorption bands for compounds **1**, **3** and **4** shift to 284 and 325 nm for **1**, 284 and 327 for **3**, 286 and 328 for **4**, respectively. This kind of shift in the energy may be related to the π orbital being perturbed by the coordination effect of Cd^{II} ion.

Metal–organic polymeric compounds with d^{10} configuration have been found to exhibit photoluminescent properties [25]. The photoluminescent spectra of L1, L2 and complexes **1**–**4** in the solid state at room temperature were examined. The fluorescence emission band for L1 is at ca. 368 nm in the solid state upon excitation at 255 nm, while that for L2 is at ca. 373 nm, which correspond to π–π^* transition [26]. Compounds **1** and **2** exhibit emission peaks at 391 and 402 nm upon excitation at 255 nm, respectively. The emission bands are compared to that of the free L1



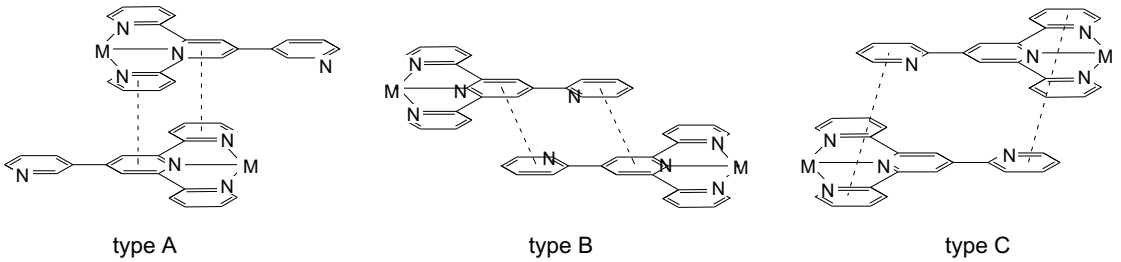


Fig. 10. Emission spectra of L1, **1** and **2** in the solid state at room temperature.

Scheme 2. Stacking motifs observed in the four compounds.

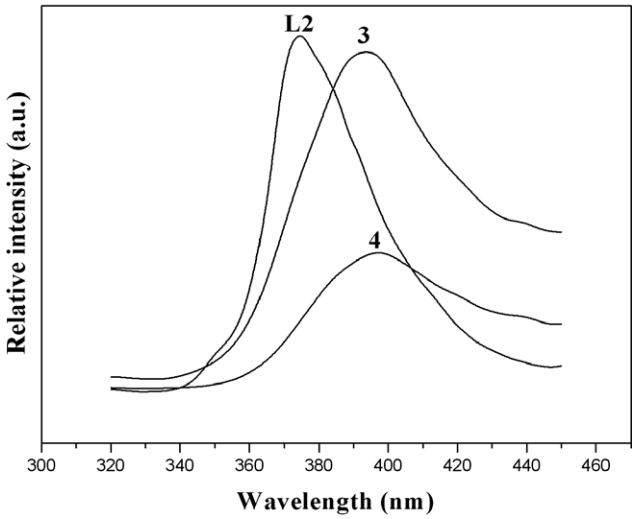

Fig. 11. Emission spectra of L2, **3** and **4** in the solid state at room temperature.

and exhibit red-shift of ca. 23 and 34 nm, suggesting that the emissions of **1** and **2** originated from the intraligand transition (Fig. 10) [27]. Similarly, compounds **3** and **4** exhibit emission peaks at 393 and 397 nm, respectively, which are ca. 20 and 24 nm red-shift to L2. These emissions may also be attributed to the intraligand transition (Fig. 11).

4. Conclusion

In summary, the reaction of Cd^{II} halide or pseudohalide with two terpyridine derived isomers resulted in four novel Cd^{II} coordination compounds. Compound **1** shows a 1D grid-like structure constructed from Cd_3 units with L1 bridges. Compound **2** is a 2D wave-like structure consisting of Cd_4 unit bridged by L1. Compound **3** and **4** are dimeric structures and extends into 1D chains by different types of $\pi\cdots\pi$ stacking interactions. Compared the four structures, we found that two isomers exhibit different coordination behavior under the same reaction conditions and extend structures into diverse dimensionalities. This result undoubtedly indicates that the isomers with different disposition of the coordination atoms do play a dominating role in the construction of crystalline materials. The successful synthesis of these compounds may provide some new information on the selection of suitable organic building blocks for controllable synthesis of desired species with predictable structures and properties.

2. Experimental

2.1. General procedures

Melting points were determined using an Electrothermal melting point apparatus and are uncorrected. Elemental analyses were performed by the Campbell microanalytical laboratory at the University of Otago. Ligands **1**–**3** were prepared by literature procedures [7,9b]. Solvents were purified according to standard procedures. Other reagents were obtained from commercial sources and used as supplied.

2.2. Complexes of 2,2′-biquinazoline (*1*)

2.2.1. Preparation of silver(I) nitrate complex *4*

Reaction of **1** (12.6 mg, 0.049 mmol) in methanol with silver nitrate (17.0 mg, 0.10 mmol) in methanol gave a yellow precipitate. Yield 15.1 mg (48%), m.p. >250 °C (dec.). *Anal.* Calc. for $C_{16}H_{10}N_4Ag_2(NO_3)_2 \cdot H_2O \cdot MeOH$ C, 31.51; H, 2.49; N, 12.97. Found: C, 31.39; H, 2.47; N, 13.08%.

2.2.2. Preparation of palladium(II) chloride complex *5*

Reaction of **1** (13.0 mg, 0.05 mmol) dissolved in hot acetone and a methanolic solution of 0.151 M Li_2PdCl_4 (0.7 ml, 0.10 mmol) gave a yellow crystalline solid. Yield 19.0 mg (95%), m.p. > 300 °C (dec.). *Anal.* Calc. for $C_{16}H_{10}N_4PdCl_2 \cdot 1/2MeOH$: C, 43.88; H, 2.68; N, 12.41. Found: C, 43.69; H, 2.40; N, 12.17%. ^1H NMR (500 MHz, DMSO): δ 10.30 (2H, s, H4), 8.73 (2H, d), 8.51 (4H, m), 8.16 (2H, t, H). Single crystals were grown by immersion of a Li_2PdCl_4 solution in a solution of **1**.

2.2.3. Preparation of copper(II) chloride complex *6*

Reaction of **1** (12.8 mg, 0.05 mmol) in methanol with copper(II) chloride (17.1 mg, 0.10 mmol) in methanol gave a green precipitate. Crystals suitable for X-ray structure analysis were grown from diffusion of acetonitrile into a DMF solution of the complex. Yield 20.7 mg (95%), m.p. 279 °C. *Anal.* Calc. for $C_{16}H_{10}N_4CuCl_2 \cdot 2/3DMF$: C, 48.98; H, 3.35; N, 14.81. Found: C, 48.67; H, 3.13; N, 15.18%.

2.2.4. Preparation of copper(I) iodide complex *7*

Reaction of **1** (12.9 mg, 0.05 mmol) in methanol with copper(I) iodide (19.7 mg, 0.10 mmol) in acetonitrile gave a black precipitate. Yield 21.0 mg (66%), m.p. >280 °C. *Anal.* Calc. for $C_{16}H_{10}N_4Cu_2I_2 \cdot 1/2MeOH$ C, 30.26 H, 1.45; N, 8.55. Found: C, 30.54; H, 1.45; N, 8.26%.

2.2.5. Preparation of cadmium(II) nitrate complex *8*

Reaction of **1** (12.8 mg, 0.05 mmol) dissolved in dichloromethane with cadmium nitrate (31.4 mg, 0.10 mmol) dissolved in hot methanol gave a colourless solution. A colourless crystalline solid appeared on cooling. Yield 24.1 mg (71%). *Anal.* Calc. for $C_{16}H_{10}N_8O_{12}Cd_2 \cdot H_2O$: C, 25.55; H, 1.67; N, 14.96. Found: C, 25.50; H, 1.67; N, 14.87%. Crystals suitable for X-ray diffraction were obtained by recrystallisation from 1:1 $MeOH/H_2O$.

2.3. Complexes of 4,4′-biquinazoline (*2*)

2.3.1. Preparation of silver(I) nitrate complex *9*

Reaction of **2** (12.8 mg, 0.05 mmol) in acetone with silver(I) nitrate (17.2 mg, 0.10 mmol) in methanol gave a white precipitate. Yield 8.1 mg (34%), m.p. >250 °C (dec.). *Anal.* Calc. for $C_{32}H_{20}N_{11}O_9Ag_3 \cdot 1/2(CH_3)_2CO$: C, 38.13; H, 2.20; N, 14.60. Found: C, 38.03; H, 2.27; N, 14.61%.

2.3.2. Preparation of palladium(II) chloride complex *10*

Reaction of **2** (12.8 mg, 0.050 mmol) in acetonitrile with a methanolic solution of 0.151 M Li_2PdCl_4 (0.7 ml, 0.10 mmol) gave a yellow solid. Yield 17.4 mg (72%), m.p. >330 °C. *Anal.* Calc. for $C_{16}H_{10}N_4PdCl_2 \cdot MeOH$: C, 43.66; H, 3.02; N, 11.98. Found: C, 43.31; H, 3.31; N, 12.25%.

2.3.3. Preparation of copper(II) chloride complex *11*

Reaction of **2** (12.8 mg, 0.05 mmol) in acetone with copper(II) chloride (17.4 mg, 0.10 mmol) in acetonitrile gave a green solution. Small green crystals appeared on standing overnight. Yield 11.1 mg (53%), m.p. >200 °C (dec.). *Anal.* Calc. for $C_{16}H_{10}N_4CuCl_2 \cdot 1/2CH_3CN \cdot 1/3(CH_3)_2CO$: C, 49.95; H, 3.22; N, 14.56. Found: C, 49.91; H, 2.90; N, 14.68%.

2.4. Complexes of 2,2′-biquinoxaline (*3*)

2.4.1. Preparation of silver(I) nitrate complex *12*

Reaction of **3** (13.3 mg, 0.051 mmol) in dichloromethane (10 ml) with silver(I) nitrate (17.4 mg, 0.10 mmol) in methanol (10 ml) gave an orange solution. Orange crystals suitable for X-ray structure analysis were obtained from this solution on standing. Yield 16.2 mg (74%), m.p. 199–201 °C. *Anal.* Calc for $C_{16}H_{10}N_5O_3Ag$: C, 44.88; H, 2.39; N, 16.36. Found: C, 44.75; H, 2.47; N, 15.99%.

2.4.2. Preparation of copper(II) chloride complex *13*

Reaction of **3** (13.3 mg, 0.052 mmol) with copper(II) chloride (18.5 mg, 0.107 mmol) in methanol gave a dark green crystalline solid. Yield 18.5 mg (84.6%), m.p. >350 °C. *Anal.* Calc. for $C_{16}H_{10}N_4CuCl_2 \cdot MeOH \cdot 1/2H_2O$: C, 47.08; H, 3.59; N, 12.92. Found: C, 46.94; H, 3.27; N, 12.65%. Crystals suitable for X-ray crystal structure analysis were obtained by layering a methanol solution of copper(II) chloride onto a dichloromethane solution of **3**.

2.4.3. Preparation of copper(I) iodide complex *14*

Reaction of **3** (12.9 mg, 0.05 mmol) in acetone with copper(I) iodide (19.7 mg, 0.10 mmol) in acetonitrile gave a black precipitate. Yield 19.4 mg (65%), m.p. >300 °C. *Anal.*

Calc. for $C_{32}H_{20}N_8Cu_5I_5 \cdot 1/2(CH_3)_2CO$: C, 26.87; H, 1.55; N, 7.57. Found: C, 27.14; H, 1.34; N, 7.57%. Recrystallisation of this black solid from DMSO gave deep red square plates.

2.4.4. Preparation of bistriphenylphosphinecopper(I) nitrate complex *15*

Reaction of **3** (12.7 mg, 0.049 mmol) in methanol (10 ml) with bis(triphenylphosphine)copper(I) nitrate (65.0 mg, 0.10 mmol) in methanol (10 ml) gave a red solution, which on slow evaporation furnished large red crystals. Yield 32.6 mg (73%), m.p. 210–212 °C. *Anal.* Calc. for $C_{52}H_{40}N_5O_3P_2Cu \cdot 1/2MeOH$: C, 68.22; H, 4.58; N, 7.58. Found: C, 68.19; H, 4.61; N, 7.46%.

2.4.5. Preparation of cadmium(II) chloride complex *16*

Reaction of **3** (13.3 mg, 0.05 mmol) dissolved in hot dichloromethane with cadmium chloride (17.4 mg, 0.10 mmol) dissolved in hot methanol gave a white precipitate immediately. The precipitate was filtered off and washed (2 × 2 ml MeOH). Yield 15.3 mg (69%), m.p. 278–280 °C. *Anal.* Calc. for $C_{16}H_{10}N_4CdCl_2$: C, 43.52; H, 2.28; N, 12.69. Found: C, 43.59; H, 2.51; N, 12.61%.

2.5. X-ray crystallography

The crystal data and details of the data collections and refinements for the X-ray structures are listed in Table 1. Measurements were made with a SMART CCD area detector using graphite-monochromatized Mo Kα ($\lambda =$ 0.71073 Å) radiation. The structures were solved by direct methods using SHELXS [13] and refined on F^2 using all data by full-matrix least-squares procedures with SHELXL-97 [14]. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in calculated positions with isotropic displacement parameters 1.2 times the isotropic equivalent of their carrier atoms. The functions minimised were $\sum w(F_o^2 - F_c^2)$, with $w = [\sigma_2(F_o^2) + aP_2 + bP]^{-1}$, where $P = [\max(F_o)^2 + 2F_c^2]/3$.

3. Results and discussion

We decided to explore the coordination chemistry of ligands **1**–**3** by examining their reactions with a selection of late transition metals. For this purpose we chose silver(I), palladium(II), copper(II), copper(I) and cadmium(II) reagents, since we have previously found that these metals lead to a diverse array of interesting metallosupramolecular assemblies [4]. In each case, the ligand was reacted with 2 equiv. of the metal reactant, in an attempt to induce the highest nuclearity of the resulting assemblies.

2,2′-Biquinazoline (**1**) is structurally related to 2,2′-bipyrimidine, which is well known to form binuclear complexes in which two metals are held together with a separation of *ca* 5.5 Å [15]. However, ligand **1** differs in that not all the nitrogens are symmetrically equivalent, there being two more hindered nitrogens adjacent to the fused benzo rings. As a consequence of this reduced symmetry there are three possible chelating modes of coordination in a mononuclear complex (Fig. 1) depending on which nitrogens are coordinated. Similarly, there are two possible coordination modes for a homobinuclear complex. Such unsymmetrical derivatives of 2,2′-bipyrimidine have been surprisingly ignored by coordination chemists [16].

Reaction of **1** with silver nitrate led to a complex **4** in moderate yield that was shown by elemental analysis to have a 2:1 M:L ratio. Despite numerous attempts to grow

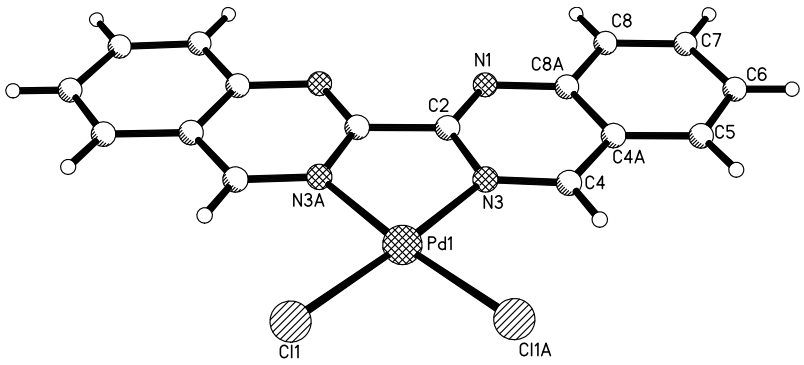

Fig. 2. Perspective view of **5**. Selected bond lengths (Å) and angles (°): Pd1–N3 2.027(2), Pd1–Cl1 2.2925(9), N3–Pd1–N3A 80.72(13), N3–Pd1–Cl1A 94.34(7), N3–Pd1–Cl1 174.85(7), Cl1–Pd1–Cl1A 90.63(5).

crystals of this complex, none were formed and the complex was shown by NMR to dissociate in donating solvents, such as acetonitrile. Reaction of **1** with lithium tetrachloropalladate gave, in high yield, a palladium complex **5** that was soluble in DMSO and showed a significant downfield shift of the H4 singlet in the ^{1}H NMR spectrum, relative to the free ligand. This suggested that this proton lies close to the chlorine atoms and hence that the ligand chelates in mode (a) of Fig. 1. In order to confirm this, a single crystal X-ray structure determination was carried out.

The palladium complex **5** crystallises in the orthorhombic space group *Pbcn*, with half a molecule in the asymmetric unit, the other half being generated by a twofold rotation axis. A perspective view of the structure is shown in Fig. 2, which reveals that the ligand binds to the metal

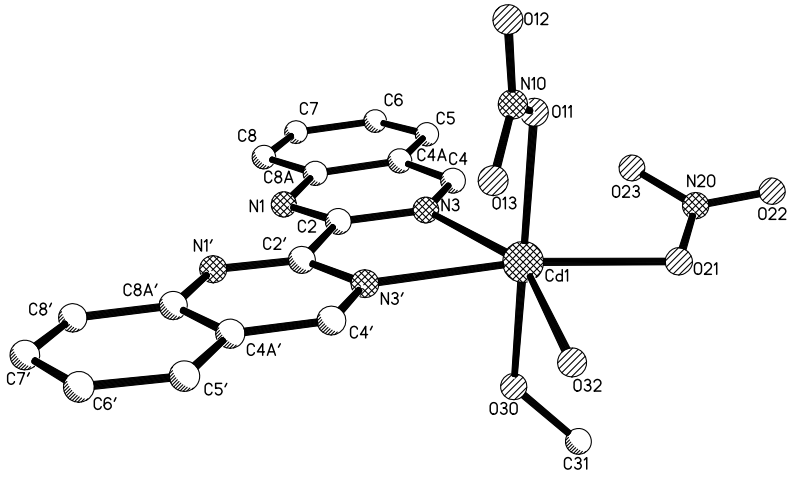

Fig. 5. Perspective view of the asymmetric unit of **8**; hydrogen atoms have been removed for clarity. Selected bond lengths (Å) and angles (°): Cd1–N3′ 2.394 (2), Cd1–N3 2.398(2), Cd1–O30 2.306(2), Cd1–O21 2.309(2), Cd1–O11 2.311(2), Cd1–O32 2.328(2), N3′–Cd1–N3 69.54(6), O30–Cd1–O21 89.64(6), O30–Cd1–O11 168.30(7), O30–Cd1–O32 87.12(8), O30–Cd1–N3′ 89.73(6), O30–Cd1–N3 80.89(7).

through the least hindered nitrogens, as suggested by the NMR results. The bond lengths to the palladium atom are similar to those in the palladium chloride complex of 2,2′-bipyridine [17]. The molecules of **1** are planar (mean deviation from plane: 0.018(5) Å), and the molecules pack in alternating columns.

A 1:1 copper(II) chloride complex **6** was obtained by reaction of **1** with $CuCl_2$ in methanol. Recrystallisation by diffusion of acetonitrile into a DMF solution of this compound furnished crystals suitable for X-ray structure determination. Fig. 3 shows the structure of **6**, which crystallises in the monoclinic space group $C2/c$. The asymmetric unit contains one molecule of **1**, one $CuCl_2$, one-third of a water molecule, and disordered DMF molecules with occupancies of one-half and two-thirds. The complex has a 1:1 M:L ratio but is binuclear, with two chlorine atoms bridging two copper atoms, having a Cu···Cu separation of 3.521(2) Å. The two halves of the complex are related by a crystallographic centre of inversion. Again ligand **1** chelates the metal using the least hindered nitrogens. The copper atom has square-pyramidal geometry with two nitrogens, monodentate and bridging chlorides in the basal plane, and a bridging chloride at the apex. The copper atom is positioned 0.263(6) Å out of the basal plane towards the apical chlorine. The Cu–Cl bond lengths for the bridging and non-bridging chlorines are both within the normal range for structures of this type [18].

The binuclear copper units pack in strips, shown in Fig. 4, with the edges of the coplanar aromatic rings adjacent and 3.269(4) Å apart. A partially occupied DMF solvate molecule shares the space between the binuclear units of the strips with a water molecule, the DMF occurring two-thirds of the time. The strips organize in layers with the centroid of one of the fused pyrimidine rings of the ligand lying 3.471(4) Å above the midpoint of the C4A–C8A bond of another, indicating a weaker π–π interaction than occurs within the strips. Another DMF molecule lies on a mirror plane in the space between the strips.

Reaction of **1** with copper(I) iodide gave a product **7** with a 2:1 M:L ratio, which was extremely insoluble and probably polymeric. Reaction with cadmium(II) nitrate gave a product that was also shown to have a 2:1 M:L ratio. However, recrystallisation of this from a methanol/water mixture furnished crystals with a 1:1 ratio, the structure of which is shown in Fig. 5.

This mononuclear complex **8** crystallises in the monoclinic space group $P2_1/n$. Once again the ligand chelates the metal through the least hindered nitrogens. The cadmium is hexacoordinate with the remaining sites occupied by oxygen atoms of two monodentate nitrates and coordinated water and methanol molecules. Compared to the two previous structures the bite angle subtended by the ligand is considerably reduced, due to the much longer M–N bond lengths.

In the solid state, the mononuclear cadmium units assemble into hydrogen bonded dimers about a centre of inversion, as shown in Fig. 6. The non-coordinated nitrogens of **1** interact with the hydroxyl hydrogen of the coordinated methanol of the adjacent unit. The bifurcated hydrogen is slightly closer to one of the two nitrogens, with H30A lying 2.30(3) Å from N1 and 2.55(3) Å from N1′. These hydrogen bonds distort the coordination geometry of the cadmium by pulling the methanol towards the hindered nitrogens of the adjacent molecule, which results in an O30–Cd1–O11 angle of 168.28(7)°. The dimers are also held together by π–π stacking between the coplanar rings of **1**, which are separated by 3.369(6) Å. Within the crystal further intermolecular aggregation occurs through more conventional [19,20] hydrogen bonds from each of the coordinated water hydrogen atoms to nitrate oxygens of adjacent units.

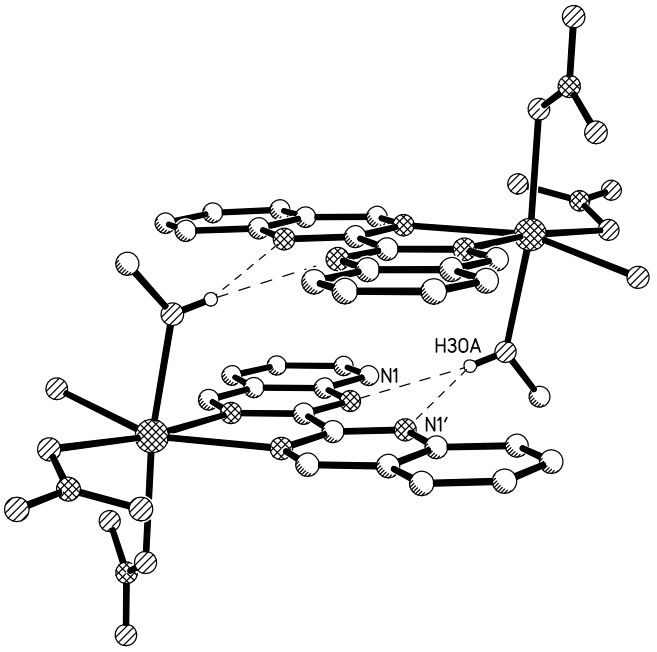

Fig. 6. Perspective view of a dimer of **8**, with the hydrogen bonding of H30A shown.

Having established that 2,2′-biquinazoline (**1**) prefers to form mononuclear complexes through chelation using the less hindered nitrogens, we next turned our attention to the coordination chemistry of the regioisomer 4,4′-biquinazoline (**2**). As shown in Fig. 7, this ambivergent ligand can be viewed as having the combined features of the divergent ligand 4,4′-biquinoline (**a**) and the convergent ligand 1,1′-biisoquinoline (**b**). 4,4′-Biquinoline is a linear bridging ligand, similar to the well studied 4,4′-bipyridine [15]. 1,1′-Biisoquinoline exists in a non-planar form due to the steric

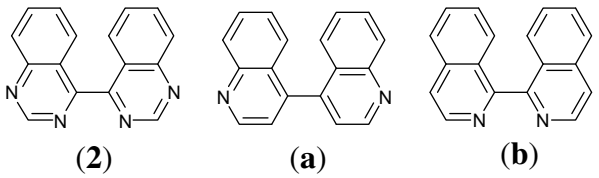

Fig. 7. Relationship of **2** to 4,4′-biquinoline (**a**) and 1,1′-biisoquinoline (**b**).

interaction between H8 and H8′, which leads to the formation of an atropisomeric mixture. The coordination chemistry of 1,1′-biisoquinoline is dominated by this non-planarity, which also distorts the chelate ring of the complexes formed [21] and allows 1,1′-biisoquinoline to bridge two metals [22]. The crystal structure of **2** has shown that
