Abstract

The reactions of $PbPh_2(OAc)_2$ with alkylglyoxylate thiosemicarbazones (HRGTSC, R = Et, Bu) afforded complexes of the type $[PbPh_2(GTSC)]\cdot H_2O$, $[PbPh_2(RGTSC)_2]$ and $[PbPh_2Cl(BuGTSC)]$. The structures of HRGTSC (R = Me, Et, Bu), $[PbPh_2(OAc)(RGTSC)]$(R = Me, Et, Bu), $[PbPh_2Cl(BuGTSC)]$ and $[PbPh_2(GTSC)]\cdot H_2O$ have been studied by X-ray diffraction. $[PbPh_2(OAc)(RGTSC)]$ and $[PbPh_2(GTSC)]\cdot H_2O$ have $[PbC_2NO_3S]$ kernels and the coordination sphere of the metal is pentagonal bipyramidal. $[PbPh_2Cl(BuGTSC)]$ has a $[PbC_2NOSCl]$ kernel and the coordination geometry around lead is pentagonal bipyramidal with one vacant site. Analysis of the bond distances in $[PbPh_2(GTSC)]\cdot H_2O$ suggests a significant affinity between diphenyllead(IV) and carboxylate donor groups, supporting a borderline acidic character for this organometallic cation. ^1H and ^{13}C NMR spectra in DMSO-d_6 suggest the partial dissociation of the acetate in $[PbPh_2(OAc)(RGTSC)]$ solutions and indicate some differences in the coordination mode of the two $RGTSC^-$ ligands in $[PbPh_2(RGTSC)_2]$ complexes.

Keywords: Diphenyllead(IV) complexes; Thiosemicarbazone ligands; X-ray crystal structures; ^1H and ^{13}C NMR spectra

1. Introduction

Lead is a very toxic metal and occupies second place after arsenic in the priority list of hazardous substances published by the Agency for Toxic Substances and Disease Registry [1]. Since the ban on the use of tetraethyllead as an antiknock additive in gasoline in western countries, the main social concern has been focused on lead(II) compounds. However, organolead(IV) derivatives still represent a significant danger because they have not been prohibited everywhere and because they are more toxic than Pb(II) derivatives to mammals, a fact established a long time ago [2]. Moreover, there is no specific therapy for intoxication by this type of compound [3]. At present, chelation is the first option for the treatment of lead(II) poisoning but the chelating agents in clinical use do not seem to be effective against organolead(IV) intoxication [3]. In an effort to contribute to a solution for this problem, we are currently investigating the coordination chemistry of the $R_nPb^{(4-n)+}$ cations in a search for new chelate ligands that are able to fulfil the coordinative demand of these ions and are capable of playing an effective role in a detoxifying mechanism. For our studies we selected $PbPh_2^{2+}$ as a model organolead(IV) cation for two main reasons: it is fairly stable in solution and it is also less toxic than its aliphatic counterparts [2,4] helping to maintain a reasonable safety during the experimental work. On the other hand, it seems that the coordination behaviour of aromatic and non-aromatic organolead(IV) cations is analogous (e.g. [5]).

A search of the Cambridge Structural Database (CSD) [6] shows that complexes of the $PbPh_2^{2+}$ cation have

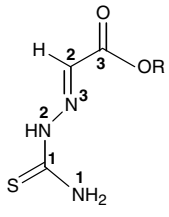
doi:10.1016/j.poly.2007.08.027

coordination numbers from 4 to 8 and the choice of donor atoms is rather flexible. Thus, O, N, S or Cl donor atoms are common in $PbPh_2^{2+}$ coordination spheres and give rise to a large variety of kernels, a situation that also occurs in Pb(II) complexes [7].

In this work, we report the structural characterization of several complexes of diphenyllead(IV) with thiosemicarbazones derived from glyoxylic acid (see Scheme 1). According to our results, $PbPh_2^{2+}$ shows a significant affinity for deprotonated –SH and –C(O)OH donor groups, suggesting that this cation may have a borderline acidic character according to the HSAB principle of Pearson [8] – as does the Pb(II) cation [7].

2. Experimental

2.1. Materials and methods



Di-*n*-butyl D-tartrate (Aldrich), diethyl L-tartrate (Aldrich), diphenyllead(IV) dichloride (Avocado), silver acetate (Fluka) and thiosemicarbazide (Merck) were used as received. Diphenyllead(IV) diacetate was prepared [*caution!* organolead(IV) compounds are very toxic; see Section 1] by reaction of diphenyllead(IV) dichloride and silver acetate in methanol. The AgCl was filtered off and the solution containing organolead(IV) acetate was used immediately in the preparation of the complexes.

Elemental analyses were performed with a FISONS 1108 analyser. Melting points were determined with a Büchi apparatus. The electrospray mass spectra of the complexes were measured on a Hewlett–Packard model LC-MSD 1100 instrument (positive ion mode, 98:2 MeOH/HCOOH as mobile phase, 20–100 V). The ^1H and ^{13}C NMR spectra of DMSO-d_6 solutions were recorded at room temperature using Bruker AMX 300 or AMX 500 spectrometers; chemical shifts in ppm were referred to TMS using the solvent signal.

2.2. Synthesis of the thiosemicarbazone ligands

Ethyl glyoxylate thiosemicarbazone (HEtGTSC) and *n*-butyl glyoxylate thiosemicarbazone (HBuGTSC) were both prepared in a similar way according to a previously described method [9]. The synthesis of HMeGTSC and the physical, analytical and spectroscopic properties for HBuGTSC and HMeGTSC will be reported elsewhere [10]. Physical, analytical and spectroscopic properties for HEtGTSC are as follows: mp 155 °C. *Anal.* Calc. for $C_5H_9N_3O_2S$: C, 34.3; H 5.1, N, 24.0; S, 18.3. Found: C, 34.3; H 5.2; N, 23.5; S, 17.8%. 2.3.2. Reaction of HBuGTSC/PbPh$_2$(OAc)$_2$

A solution of HBuGTSC (0.1 g, 0.49 mmol) in methanol (5 ml) was slowly added to a solution of freshly prepared diphenyllead(IV) diacetate (0.49 mmol in 20 ml of methanol). This 1:1 molar ratio mixture was stirred for 6 h and the solvent was slowly evaporated until yellow crystals precipitated. Mp 180 °C. *Anal.* Calc. for $C_{21}H_{25}N_3O_4SPb$ ([PbPh$_2$(OAc)(BuGTSC)]): C, 40.2; H 4.0; N, 6.7; S, 5.1. Found: C, 40.2; H 4.0; N, 6.6; S, 5.0%. MS (electrospray), *m*/*z* (%): 564 (56) [M−OAc]. ^{1}H NMR (DMSO): *0.74t*, 0.87t, 0.90t [3H, C(7)H$_3$]; *1.06sext*, 1.40 m [2H, C(6)H$_2$]; *1.40m*, 1.58q [q, 2H, C(5)H$_2$]; *1.72sb*, 1.81sb [3H, CH_3COO^-]; *4.04t*, 4.10t, 4.17t [2H, C(4)H$_2$]; 7.37 [t, 2H, H$_p$]; 7.50 [t, 4H, H$_m$]; *7.77d*, 7.84d [d, 4H, H$_o$], *7.54s*, 8.04s, 8.13s [1H, C(2)H], 8.45s vb [N(1)H$_2$]. ^{13}C NMR (DMSO): 13.4 [C(7)H$_3$], 13.6 [C(7)H$_3$], 18.2 [C(6)H$_2$], 18.7 [C(6)H$_2$], 23.2 [C(8)H$_3$COO$^-$], 30.0 [C(5)H$_2$], 30.1 [C(5)H$_2$], 63.9 [C(4)H$_2$], 65.3 [C(4)H$_2$], 129.4 [C$_p$], 129.9 [C$_m$], 132.2 [C(2)], 132.6 [C$_o$], 165.2 [C(3)], 168.9 [C$_{ipso}$], 179.6 [C(1)]. Crystals suitable for the X-ray study were obtained from the mother liquor.

When the reaction was carried out under similar conditions, but using a 1:2 (M:L) molar ratio, the suspension was stirred for 6 h and kept at low temperature for 12 h. The resulting yellow solid was filtered off and dried under vacuum. Mp 171 °C. *Anal.* Calc. for $C_{26}H_{34}N_6O_4S_2Pb$ ([PbPh$_2$(BuGTSC)$_2$]): C, 40.7; H 4.4; N, 10.9; S, 8.3. Found: C, 39.6; H 4.4; N, 10.4; S, 8.0%. ^{1}H NMR (DMSO): 0.74t, 0.89t [3H, C(7)H$_3$]; 1.06sext, 1.36m [2H, C(6)H$_2$]; 1.36m, 1.61q [q, 2H, C(5)H$_2$]; 4.11t, 4.17t [2H, C(4)H$_2$]; 7.32 [t, 2H, H$_p$]; 7.43 [t, 4H, H$_m$]; 7.73d [d, 4H, H$_o$]; 7.42s, 8.13s [1H, C(2)H]; 8.08sb, 8.22sb [2H,

N(1)H_2]. ^{13}C NMR (DMSO): 13.4, 13.7 [C(7)H_3]; 18.2, 18.6 [C(6)H_2]; 30.2 [C(5)H_2]; 64.8, 64.0 [C(4)H_2]; 129.0 [C_p], 130.0 [C_m], 131.0, 131.6 [C_o], 135.3 [C(2)], 164.0, 166.2 [C(3)], 169.2 [C_{ipso}], 177.5, 179.6 [C(1)]. As a second fraction, a small amount of crystals suitable for an X-ray study were also obtained, showing the formation of a new complex [$PbPh_2Cl$(BuGTSC)]. When the reactions were carried out under reflux only unidentified products were obtained.

2.4. X-ray crystallography

Crystal data, experimental details and refinement results are listed in Table 1. Data were collected on Bruker Smart CCD 1000 or Enraf-Nonius CAD-4 diffractometers and were corrected for absorption by multi-scan [12] or SADABS [13]. The structures were solved using direct (ligands) or Patterson (complexes) methods, followed by conventional difference Fourier techniques. All of the H atoms were introduced in calculated positions except those in HEt-GTSC, which were all located in the Fourier difference map and refined isotropically, and the water protons in [$PbPh_2$(GTSC)]·H_2O (H1W and H2W), which were located and refined as a rigid model. The crystal of [$PbPh_2$(OAc)(MeGTSC)] shows disorder in regard to one of the phenyl rings (C21–C26), with two atomic sites observed for each of the atoms in this fragment. The site occupancy factors were determined as 0.65 and 0.35 and only the lengths of bonds and angles involving the atoms with the higher occupancy have been included in the Tables. The program used was SHELX-97 [14]. Molecular graphics were obtained with ORTEP [15] and PLATON [16].

3. Results and discussion

3.1. Synthesis

The reactions of the ligands HEtGTSC and HBuGTSC at room temperature with freshly prepared methanolic solutions of $PbPh_2(OAc)_2$ afforded complexes of the type $[PbPh_2(OAc)(RGTSC)]$ and $[PbPh_2(RGTSC)_2]$ (R = Et, Bu) when 1:1 and 1:2 M:L molar ratios were used, respectively. Furthermore, the reaction of HBuGTSC in the 1:2 molar ratio also afforded $[PbPh_2Cl(BuGTSC)]$ as a minor product, which probably results from the incomplete displacement of the Cl^- anions from $PbPh_2Cl_2$ during the $PbPh_2(OAc)_2$ synthesis (vide supra). All of the reactions with HBuGTSC, when heated under reflux, afforded unidentified products, while reactions with HEtGTSC rendered $[PbPh_2(OAc)(MeGTSC)]$ and $[PbPh_2(GTSC)]\cdot H_2O$, with the former produced through a transesterification process and the latter formed by hydrolysis of the initial ligand.

3.2. Crystal structures of the ligands

The molecular structures of the ligands HEtGTSC, HBuGTSC and HMeGTSC are shown in Fig. 1 together with the numbering scheme used. Selected bond distances and angles are shown in Table 2.

As can be seen from Fig. 1a and b, HEtGTSC and HBuGTSC both crystallize in a similar way with two slightly different molecules (molecules 1 and 2) in the asymmetric unit. The bond distances and bond angles in both molecules, as well as in HMeGTSC, are similar and within the values found for this class of compounds [17]. In all of these ligands the thiosemicarbazone chains adopt an *E*-configuration with respect to the C=N aldimine bonds and the C–S bonds are *trans* to the N–N bonds. As one would expect in this type of ligand, the E conformation is stabilized by the formation of intramolecular hydrogen bonds involving NH_2 groups and the aldimine nitrogen (see Table 4 and Fig. 2). Besides these hydrogen bonds, intermolecular $N(1)H_2\cdots S$ and $N(2)H\cdots O(1)$ hydrogen bonds link molecules to form a polymeric chain along the *z* (for HEtGTSC) or *x* (for HBuGTSC and HMeGTSC) axis. Furthermore, additional $N(1)H_2\cdots S$ intermolecular hydrogen bonds between two of these chains give rise to a double chain (see Fig. 2 for HEtGTSC).

3.3. Crystal structures of the complexes

The crystal structures of the three analogous compounds $[PbPh_2(OAc)(RGTSC)]$ (R = Me, Et, Bu) are similar and are represented in Fig. 3 and Figs. 1S and 2S. Selected bond distances and angles are given in Table 3. In all of these compounds – which have $[PbC_2NO_3S]$ kernels – the metal is bonded to the two carbon atoms from the phenyl groups, to the S, N(3) and O(1) atoms from a tridentate thiosemicarbazone ligand and to the two oxygen atoms, O(3) and O(4), from an anisobidentate acetate ($d_{Pb-O(3)} = 2.31$–2.32 Å; $d_{Pb-O(4)} = 2.64$–2.75 Å). These seven atoms adopt a very distorted pentagonal bipyramid around the metal, with the C(11) and C(21) atoms from the phenyl groups at the apexes and the S, N(3), O(1), O(3) and O(4) atoms in the equatorial plane, which also includes the Pb atom [Pb,S,N(3),O(1),O(3),O(4) plane; rms: 0.0326, 0.0493, 0.0304 for R = Me, Et and Bu, respectively]. The main distortion from the ideal bipyramid arises due to the narrow C–Pb–C angle [149.9(3)–159.79(19)°] and the short bite of the equatorial ligands.

The coordination of the three thiosemicarbazonates is roughly the same in the three complexes. The TSC^- ligands

Symmetry transformations used to generate equivalent atoms: [a] i = $-x$, $-y$, $-z$; ii = x, y, $z+1$; iii = x, y, $z-1$; [b] i = $-x-1$, $-y+2$, $-z+2$; ii = $x+1$, $y-1$, $z-1$; iii = $-x$, $-y+2$, $-z+2$; iv = $x-1$, $y+1$, $z+1$; [c] i = $x+1$, y, z; ii = $-x$, $-y$, $-z+2$; iii = $x-1$, y, z; [d] i = x, $-y+1$, $z+1/2$; [e] i = $x-1$, y, z; [f] i = $x+1/2$, $-y+1/2$, $z+1/2$; [g] i = $-x+2$, $-y$, $-z+1$; ii = $-x+1$, $-y$, $-z+1$; [h] ii = $-x$, $1+y$, z.

form the strongest bond with the metal through the sulphur atom {d(Pb–S) ~ 2.60 Å; sum of the covalent radii Pb + S = 2.58 Å [18]} and also form a medium strength Pb–N(3) bond ($d_{Pb-N(3)}$ = 2.55–2.61 Å; sum of the covalent radii Pb + N = 2.24 Å [18]) and a Pb···O(1) secondary interaction {$d_{Pb-O(1)}$ = 2.80–2.82 Å; sum of the covalent radii Pb + O = 2.20 Å [18]}. It is worth noting that this close approach between lead and the carbonyl oxygen atom can be imposed simply by the stereochemistry of the ligand. The Pb–S bond distances are very similar in the three complexes. The Pb–N(3) and Pb–O(1) bond distances are also analogous in [$PbPh_2$(OAc)(MeTSC)] and [$PbPh_2$(OAc)(BuTSC)] but slightly longer in [$PbPh_2$(OAc)(EtTSC)]. This could be the reason why the acetate ligand is more strongly bound to the metal atom in the ethyl derivative.

The deprotonation and coordination of the HRGTSC ligands to the lead atom causes changes in its conformation, placing the C(1)–S bonds *cis* to the N(2)–N(3) bonds. Nevertheless, the *E*-conformation around C(2)–N(3), which has been observed in the free ligands, is retained in the complexes and allows the simultaneous coordination of the S, N(3) and O(1) atoms to the metal.

The strong Pb–S bond promotes a significant evolution of the ligands from the thione to the thiol form (the average value for the C–S bond distance is 1.685 Å in the ligands and this becomes 1.737 Å in the complexes).

In [$PbPh_2$(OAc)(MeTSC)] and [$PbPh_2$(OAc)(BuTSC)] an intermolecular hydrogen bond involving one hydrogen atom of the NH_2 group and the oxygen atom O(4) (see Table 4) associates the molecules in chains parallel to the *z*-axis in the methyl derivative (see Fig. 4) but bisecting the *xz*-plane in the butyl derivative. In [$PbPh_2$(OAc)(EtTSC)], in addition to the bond described above, there is another link between the same two molecules, in this case involving the second hydrogen atom of the NH_2 group and O(1). This gives rise to a polymeric chain (see Fig. 5) with more strongly associated molecules that extends along the *x*-axis.

The molecular structure of [$PbPh_2$Cl(BuGTSC)] is shown in Fig. 6 together with the numbering scheme used. Selected bond distances and angles are shown in Table 3.

In this complex the lead atom is coordinated to a monodeprotonated S,N(3),O(1)-donor thiosemicarbazone, to a chloro ligand and to two phenyl groups. The phenyl groups are in the axial positions and the S, N(3), O(1) and Cl atoms are in the equatorial plane of a distorted pentagonal bipyramid with a vacant position [Cl–Pb–O(1) = 145.93(7)°]. The C–Pb–C angle bends towards the unoccupied position of the polyhedron and it seems that there is no intermolecular interaction apart from the hydrogen bonds (the closest donor atom to lead, apart from those mentioned above, is an S atom located 4.9 Å away).

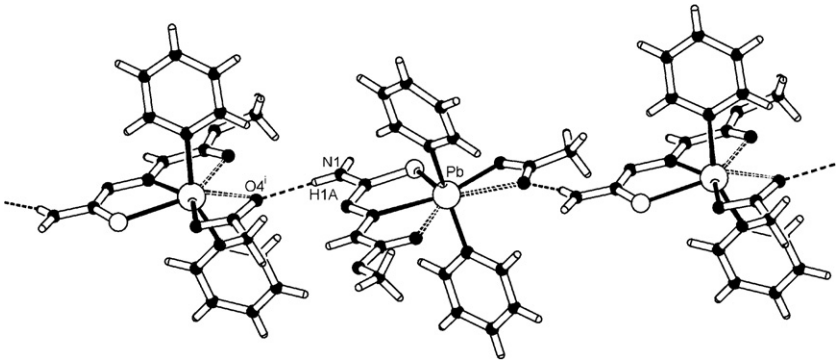

Fig. 4. Hydrogen bond in [$PbPh_2$(OAc)(MeGTSC)].

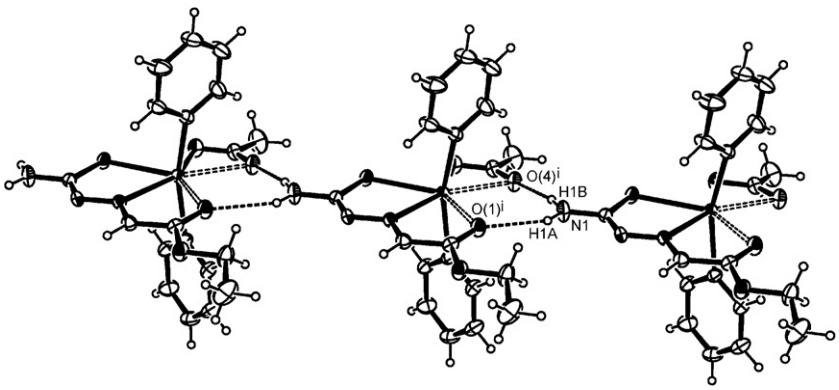

Fig. 5. Hydrogen bonds in [$PbPh_2$(OAc)(EtGTSC)].

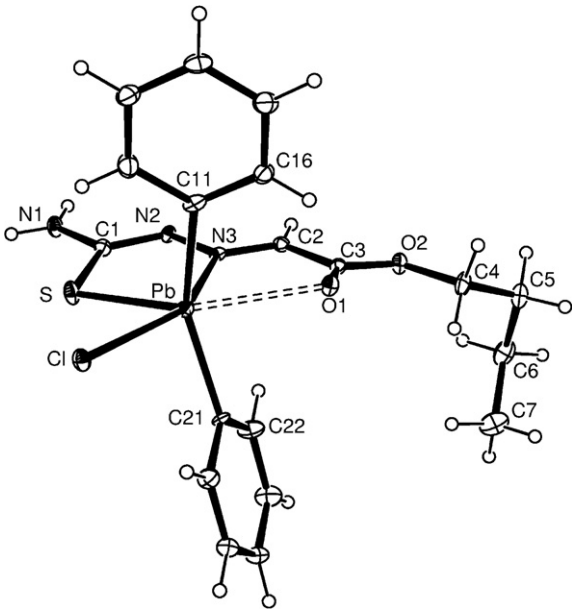

Fig. 6. Molecular structure of $[PbPh_2Cl(BuGTSC)]$.

The thiosemicarbazone ligand retains the *E*-conformation around the C=N bond (as in the free ligand) and the C–S bond length increases in accordance with the ligand evolution to the thiol form after deprotonation and coordination to the metal.

There are two intermolecular hydrogen bonds in the lattice and these involve the $N(1)H_2$ group and the Cl and N(2) atoms. These two weak interactions (see Table 4, Fig. 7) give rise to a polymeric chain parallel to the *x*-axis.

The asymmetric unit of $[PbPh_2(GTSC)] \cdot H_2O$ is represented in Fig. 8 and selected bond distances and angles are given in Table 3. In this compound, which also has a $[PbC_2NO_3S]$ kernel, the metal atom is bonded to the two C atoms from the phenyl groups, to the S, N(3) and O(1) atoms of a bideprotonated thiosemicarbazone and to the two oxygen atoms, $O(1)^i$ and $O(2)^i$, from the $-COO^-$ terminal group of a neighbouring molecule. These last two atoms occupy the sites of the acetate oxygen atoms in the $[PbPh_2(OAc)(RGTSC)]$ complexes described above. Thus, the ligand bridges two lead atoms and is tridentate with respect to one of them – through the S, N(3) and O(1) atoms – and bidentate with respect to the other (Pb^{ii}, ii = 0.5 − *x*, −0.5 + y, 0.5 − *z*) through the O(1) and O(2) atoms. Once again, the seven atoms in the coordination sphere adopt a very distorted pentagonal bipyramidal geometry around the metal, with the phenyl groups axial and the S, N(3), O(1), $O(1)^i$ and $O(2)^i$ atoms equatorial (rms = 0.0688 or 0.0732 if the Pb atom is also included). This arrangement gives rise to the polymeric chain parallel to the *y*-axis, as represented in Fig. 9.

In this complex the Pb–S bond can also be considered as a strong bond, although the bond distance is slightly longer than those in the $[PbPh_2(OAc)(RGTSC)]$ complexes. At the same time, the Pb–O(1) distance [and also the Pb–N(3) distance] diminishes. The reason for these changes is the higher donor capacity of the $-COO^-$ group in $[PbPh_2(GTSC)] \cdot H_2O$ with respect to the C=O group in $[PbPh_2(OAc)(RGTSC)]$. The consequent shortening of the Pb–O(1) bond displaces the carbamide group away from the metal. This stronger Pb–O bond supports the idea that diphenyllead(IV) has a good affinity for the carboxylate group and suggests a borderline Lewis acid character [8] for the diorganolead cations similar to that of Pb(II) [10].

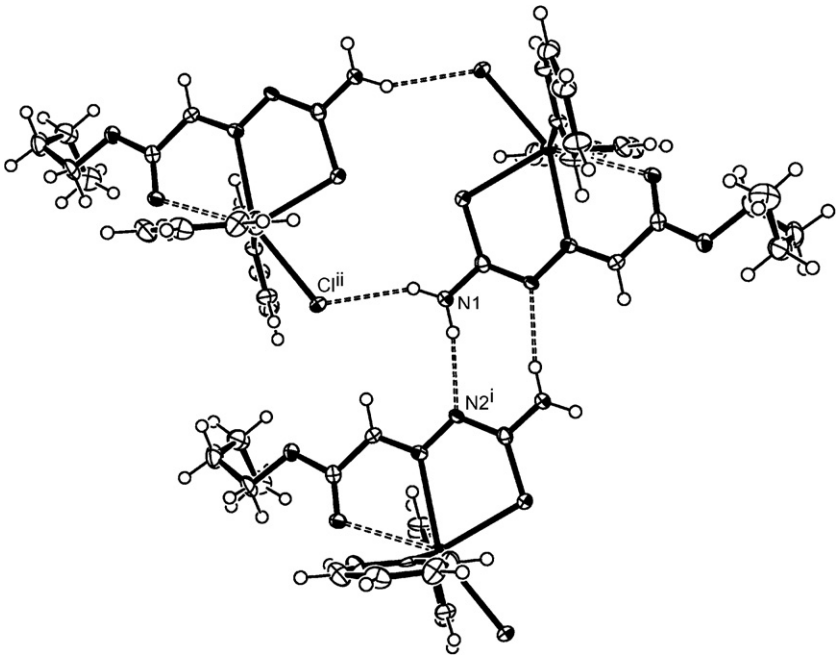

Fig. 7. Hydrogen bonds in $[PbPh_2Cl(BuGTSC)]$.

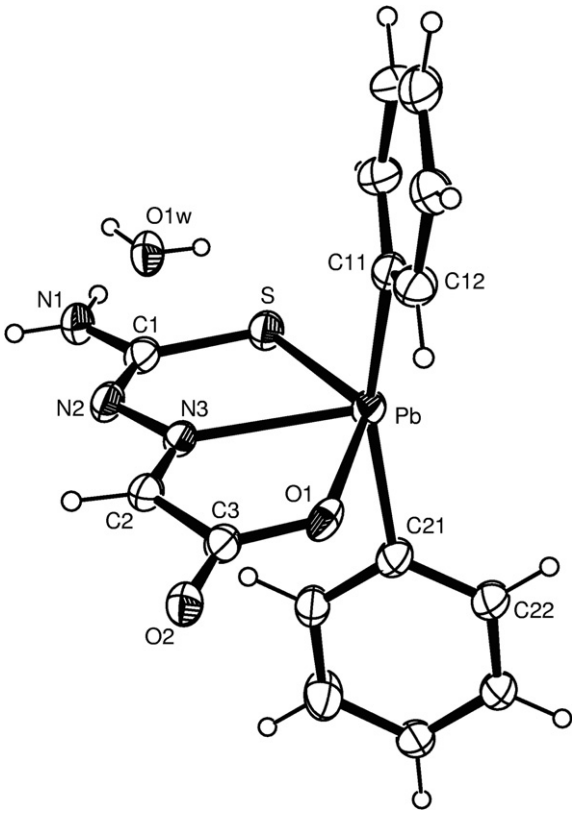

Fig. 8. Asymmetric unit in $[PbPh_2(GTSC)]\cdot H_2O$.

The water molecule in the lattice bridges, through hydrogen bonding, two molecules belonging to the polymeric chain described above (see Fig. 10 and Table 4).

3.4. Solution studies

The ^1H and ^{13}C NMR data from DMSO-d_6 solutions of the complexes are included in Section 2. Only the spectra of $[PbPh_2(GTSC)]\cdot H_2O$ allow a straightforward assignment, because this complex shows the expected signals for each hydrogen and carbon nucleus, suggesting the presence of only one species in solution. The spectra of the other complexes are more complicated and contain, e.g., two or more signals for the C(2)H, R and acetate groups and, in some cases, even for the organometallic fragment.

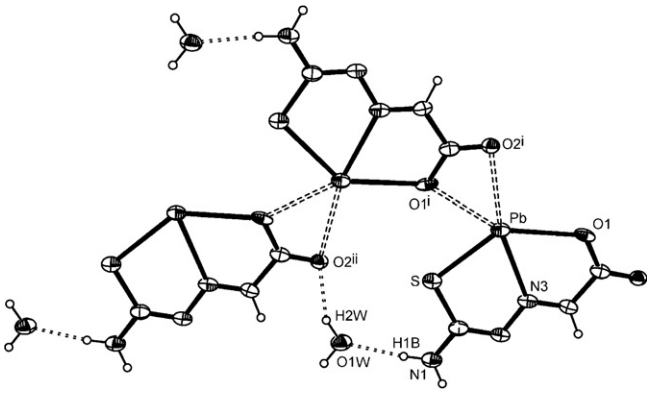

Fig. 10. Hydrogen bonds in $[PbPh_2(GTSC)]\cdot H_2O$.

In the heteroleptic derivatives, $[PbPh_2(OAc)(RTSC)]$, the complexity of the spectra may be due to the partial displacement of the acetate ligand from the coordination sphere of the metal in response to the donor competition of the solvent. This hypothesis is supported by the importance of the [M−OAc] species in the ESI spectra (methanolic solutions, see Section 2) and also by the presence of two signals associated with the methyl group of the acetate in the NMR spectra.

The complex spectral behaviour of the $[PbPh_2(RGTSC)_2]$ compounds (see Section 2) could be related to the versatile coordination mode of this type of thiosemicarbazone [11]. The presence of N^2,S- and N^3,S-coordinated $RGTSC^-$ ligands, as observed for the ethyl derivative in the solid state [11], should probably lead to perceptible spectral differences between the two non-equivalent thiosemicarbazonates.

Syntheses, characterization and crystal structures of mixed-ligand Cu(II), Ni(II) and Mn(II) complexes of *N*-(1-phenyl-3-methyl-4-propenylidene-5-pyrazolone)-salicylidene hydrazide containing ethanol or pyridine as a co-ligand

Abstract

Five new mixed-ligand complexes [CuL(EtOH)] (**1**), [NiL(EtOH)$_3$] (**2**), [$Mn_2L_2(\mu_2$-EtOH)$_2$(EtOH)$_2$] (**3**), [CuL(Py)] · MeOH (**4**) and [NiL(Py)$_3$] (**5**) (L^{2-} = *N*-(1-phenyl-3-methyl-4-propenylidene-5-pyrazolone)-salicylidene hydrazide anion, Py = pyridine) have been synthesized and characterized by elemental analyses, IR spectra, thermal analyses and single crystal X-ray diffraction. The crystallographic structural analyses of these complexes reveal that the ligand (H_2L) itself undergoes isomerization from the keto form to the enol form in the reaction, then loses two protons and acts as a double negatively charged tridentate chelating agent coordinated to the metal ion in the solution. The final results show that when a co-ligand was present in the synthetic reaction, other coordination sites around the metal ions Cu^{2+} and Ni^{2+} were completed either by the ethanol or pyridine molecules under the common solvent reaction or solvothermal syntheses conditions, respectively. In the case of the Mn^{2+} ion, it was still coordinated with the solvent molecules regardless of whether it was synthesized under the common solvent reaction or solvothermal syntheses with pyridine. The reason for this difference might be attributed to the fact that the coordination modes and bonding effect of the co-ligand with the metal ions are different, the final complexes tend to form the most stable compound.

1. Introduction

Pyrazolone-5 derivatives, especially 4-acyl pyrazolone, form an important class of organic compounds and represent a big scientific and applied interest in biological, analytical applications, catalysis, dye and extraction metallurgy, etc. [1–6]. Furthermore, 4-acyl pyrazolone derivatives have the potential to form different types of coordination compounds due to the several electron-rich donor centers [7–9] and tautomeric effect of the enol form and keto form [10–12]. Complexes containing these ligands are known for almost every transition and main group metal, often showing unusual structural and chemical properties [13,14]. Meanwhile, compounds containing hydrazide moieties and their complexes also possess biological activities, especially serving as potential inhibitors for many enzymes [15].

During the course of our research, we have synthesized a series of 4-acyl pyrazolone derivatives [16–18] and reported some transition metal complexes [19–21]. In order to further investigate the coordination abilities and complexation behaviors of pyrazolone-based ligands, we extended the study to the syntheses of new 4-acyl pyrazolone derivatives and their transition metal complexes. This paper presents the syntheses, characterization and crystal structures of the Cu(II), Ni(II) and Mn(II) mixed-ligand complexes of

N-(1-phenyl-3-methyl-4-propenylidene-5-pyrazolone)-salicylidene hydrazide containing ethanol or pyridine as a co-ligand.

2. Experimental

2.1. Materials and general physical measurements

1-Phenyl-3-methyl-4-propionyl-5-pyrazolone and salicylic hydrazide were synthesized according to the Refs. [22,23]. Other chemicals and solvents were analytical grade and commercially available.

Elemental analyses of C, H and N were performed using a PE-240C analyzer. IR spectra were recorded on a BRUKER EQUINOX-55 spectrophotometer within the range 400–4000 cm^{-1}. The crystal structures were determined by a BRUKER SMART 1000 CCD detector and the SHELXTL-97 crystallographic software package. The simultaneous TG–DTA curves were obtained using a NETZSCH STA 449C model instrument, the experiments were carried out in dynamic air atmosphere with a flow rate of 30 cm^3 min^{-1}. Solvothermal syntheses experiments were performed in a Teflon-lined stainless steel autoclave with an inner volume of 40 mL.

2.2. Synthesis of the ligand H_2L

The ligand was synthesized by the same method described in the literature [26]. The yield was 72.6%. Molecular formula: $C_{20}H_{20}N_4O_3$. F.w.: 364.40. m.p.: 198–199 °C.

2.3. Syntheses of the complexes containing ethanol as a co-ligand

The synthesis procedure for [CuL(EtOH)] (**1**) was as follows: The ligand H_2L (1.5 mmol) was dissolved in 25 mL of hot anhydrous ethanol. To this solution was added dropwise an ethanolic solution of $Cu(CH_3COO)_2 \cdot H_2O$ (1.5 mmol) with constant stirring. The mixture was further refluxed for 3 h, then the green solution was filtered and the filtrate, as a clear solution, was slowly evaporated at room temperature and green block single crystals of **1** suitable for X-ray diffraction analysis were obtained.

The complexes [NiL(EtOH)$_3$] (**2**) and [$Mn_2L_2(\mu_2$-EtOH)$_2$(EtOH)$_2$] (**3**) were synthesized by the same procedure as for **1** with the corresponding metal acetate and ligand. Single crystals of **2** were obtained by slow evaporation of its ethanol solution. Single crystals of **3** were grown by slow evaporation of its ethanol and dichloromethane solution (volume rate 2:1) at room temperature.

2.4. Solvothermal syntheses of the complexes containing pyridine as a co-ligand

The synthesis procedure for [CuL(Py)] · MeOH (**4**) was as follows: The ligand H_2L (1 mmol) was dissolved by the addition of an aqueous solution of 1 M NaOH in 15 mL methanol. To this 8 mL of a methanolic solution of $Cu(CH_3COO)_2 \cdot H_2O$ (1 mmol) and 1.6 mL of a mixture of pyridine and acetonitrile with volume ratio of 1:1 were added in turn, then the mixture was stirred and loaded into a Teflon-lined stainless steel autoclave. The sealed autoclave was heated to 120 °C and kept isothermal for 48 h. After cooling to room temperature, brown crystals were collected by filtration and dried in air. Yield: 0.42 g (78.2% based on copper).

The complex [NiL(Py)$_3$] (**5**) was synthesized in a similar way, using $Ni(CH_3COO)_2 \cdot 4H_2O$ instead of $Cu(CH_3COO)_2 \cdot H_2O$. Yield: 0.55 g (83.5% based on nickel).

2.5. X-ray crystallography

The single crystal X-ray diffraction data collections for the complexes were performed on a BRUKER SMART 1000 CCD diffractometer, using graphite-monochromated MoKα radiation ($\lambda = 0.71073$ Å) at 293 K. Semi-empirical absorption corrections were applied using the SADABS program [24]. The structures were solved by direct methods and refined by full-matrix least squares on F^2 using the SHELXTL-97 program [25]. In complex **1**, the C21 and C22 atoms of the coordinated ethanol molecule are disordered into two positions, with site occupancy factors of 0.783 and 0.217. In complex **2**, the C1, C2, C3, C4, C5, C6 atoms of the phenyl group are disordered and have two positions with site occupation factors of 0.605 and 0.395. The C21 and C22, C23 and C24, C25 and C26 atoms of the three coordinated ethanol molecules are also disordered into two positions with site occupation factors of 0.292 and 0.708, 0.226 and 0.774, 0.568 and 0.432, respectively. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were generated geometrically and treated by a mixture of independent and constrained refinement. A summary of the crystal data, data collection parameters and convergence results are compiled in Table 1.

3. Results and discussion

3.1. Syntheses

Elemental analyses of the synthesized compounds are summarized in Table 2. The analytical data agree well with the proposed formula of the compounds. The synthetic mechanism of the principal ligand is shown in Scheme 1. The ligand can exist either in the enol form I or II or keto form III. However, the IR and X-ray crystallographic structural analyses of the ligand H_2L indicate that in the solid state it exists in keto form III. The molecular structure of the ligand [26] is depicted in Fig. 1.

The physical analyses results indicate that the complexes synthesized under the common solvent reaction have a 1:1 metal to ligand stoichiometry, in which the ligand H_2L converts to the enol form II, then loses two hydrogen atoms and functions as a doubly negatively charged tridentate chelating agent coordinated to the metal ion, while

other coordination sites around the metal ion are completed by the ethanol molecules. When the same reactions were carried out in methanol solvent in the presence of pyridine by solvothermal syntheses, the pyridine molecules were coordinated to the metal ions in the prepared Cu(II) and Ni(II) complexes. However, when the Mn(II) complex was synthesized under the same conditions, the product $[Mn_2L_2(\mu_2\text{-MeOH})_2(MeOH)_2]$, which was confirmed by element analysis and TG analysis, was obtained. We guess its structure is similar to $[Mn_2L_2(\mu_2\text{-EtOH})_2(EtOH)_2]$ (**3**).

Scheme 1.

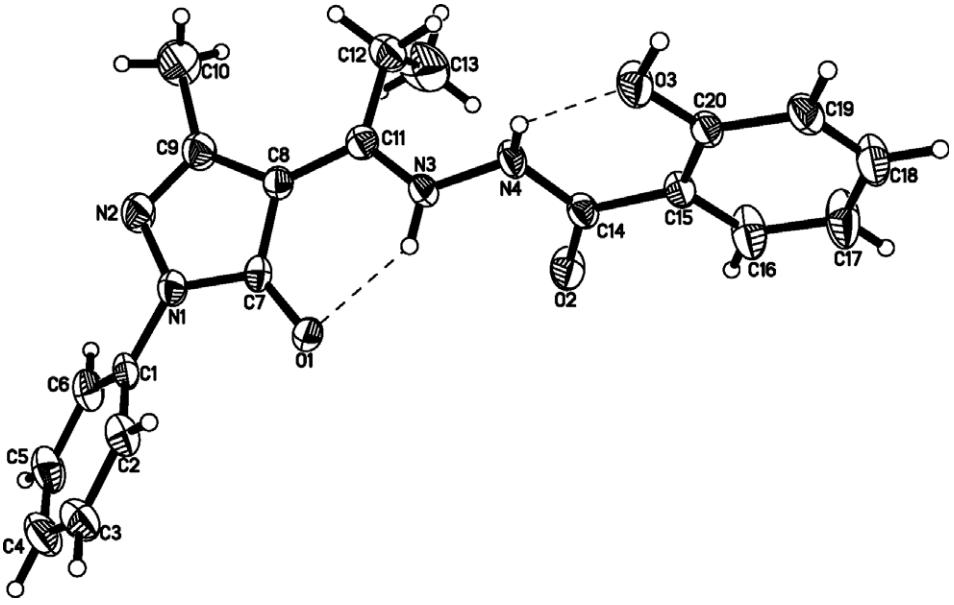

Fig. 1. Molecular structure and crystallographic numbering scheme for the ligand H_2L.

These complexes are stable in air and soluble in most common organic solvents and are readily soluble in DMF and DMSO.

3.2. Structural description

Selected bond lengths (Å) and bond angles (°) of the complexes are listed in Table 3. Hydrogen bonding interactions in the structures are listed in Table 4.

3.2.1. The structure of [CuL(EtOH)] (1)

A perspective view of **1** with the labelling scheme is given in Fig. 2. The Cu(II) ion is coordinated by an ONO tridentate ligand (pyrazolone oxygen atom O1, azomethine nitrogen N3 and enolate oxygen O2) and one oxygen atom (O4) from an ethanol molecule to form a $CuNO_3$ coordination environment with a square-planar geometry. The bond angles show that the complex is distorted from a regular square-planar structure, with O1–Cu1–O2 and O4–Cu1–N3 bond angles of 178.5(6) and 172.1(1)°, respectively, which are deviated from the ideal value of 180°. The deviation of the atom Cu1 from the plane defined by O1, N3, O2 and O4 (the mean deviation from the plane is 0.0278 Å) is 0.0430 Å, which indicates that the five atoms are almost coplanar.

The ligand H_2L itself undergoes isomerization from the keto form to the enol form (form II) in the reaction and acts as a tridentate chelating agent L^{2-}, coordinating to the Cu(II) ion in the solution. The fourth coordination site around the Cu(II) center is completed by the oxygen atom of an ethanol molecule.

Furthermore, it can be found that the hydrazone skeleton [C11=N3–N4=C14] and a certain degree of

O3–H3···N4	0.82	1.81	2.54(5)	147.2

Symmetry labels: (a) $x+1/2, -y+1/2, z+1/2$; (b) $-x, -y+2, -z$; (c) $-x+1/2, y-1/2, -z+1/2$; (d) $-x+3/2, y+1/2, -z+1/2$; (e) $-x+1, -y, -z+1$.

delocalized π-electrons of the pyrazolone ring appear in the complex, which results in coplanarity of plane I {N1N2C7C8C9}, plane II {O1C7C8C11N3Cu1} and plane III {N3N4C14O2Cu1}, of which the interplanar angles of plane I and III with II are 1.3° and 0.7°, respectively.

There are both intra- and intermolecular hydrogen bonds in the structure (Fig. 3). The amido N4 atom forms an intramolecular H-bond with HO3 of the phenolic hydroxyl group [O3···N4, 2.56(5) Å, 144(5)°], which links N4–C14–C15–C20–O3H30 to form a pseudo-six membered ring. Furthermore, the oxygen atom O4 of the coordinated ethanol molecule is intermolecularly hydrogen-bonded to the N2 atom of the pyrazolone ring of the adjacent unit, with an O4···N2 contact of 2.75(5) Å. Through the intermolecular hydrogen bonds, the complex units are linked into a supramolecule with a 1D chain structure.

3.2.2. The structure of $[NiL(EtOH)_3]$ (2)

The view of complex **2** as a monomeric unit is depicted in Fig. 4. The Ni(II) ion is in a distorted octahedral geometry, being hexa-coordinated by two oxygen atoms (O1, O2) and one nitrogen atom (N3) from the tridentate ligand and three oxygen atoms (O4, O5 and O6) from three ethanol molecules to form a NiNO5 coordination environment. The equatorial plane is made up of O1, O2, N3 and O5. The Ni1–O1, Ni1–O2, Ni1–O5 and Ni1–N3 bond lengths are 1.983(2), 2.050(2), 2.062(2) and 2.011(2) Å, respectively. While the axial positions of the distorted octahedral geometry are occupied by the O4 and O6 atoms of two other ethanol molecules, with two long Ni1–O distances of 2.104(2) and 2.111(2) Å. The average deviation of O1, O2, N3 and O5 with regard to the mean basal plane is 0.0076 Å. The Ni1 ion is displaced by −0.0137 Å from the equatorial plane. The ligand–metal–ligand bite angles differ from the ideal value of 90°, varying between 81.1(1)° [N3–Ni1–O2] and 94.9(9)° [O1–Ni1–O5]. The bond angles of O1–Ni1–O2, N3–Ni1–O5 and O4–Ni1–O6 are 172.6(6)°, 173.5(6)° and 177.6(6)°, respectively, which are slightly deviated from the theoretical value of 180°, these information indicate that the coordination sphere of Ni1 is best described as a slightly distorted octahedron. The longer Ni1–O(ethanol) bond lengths indicate that the oxygen atoms of the ethanol molecules coordinate less strongly than the donor atoms of the ligand.

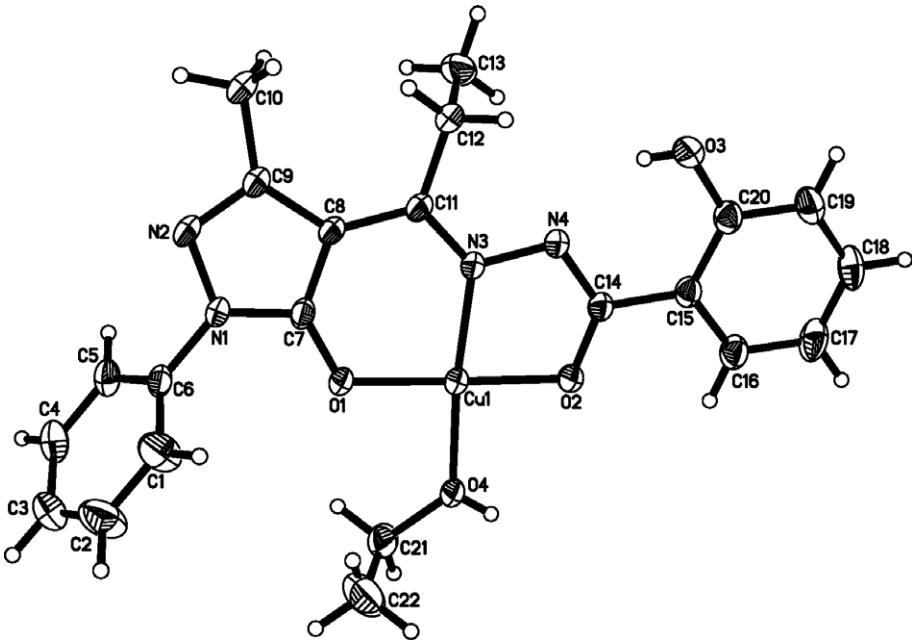

Fig. 2. A perspective view of **1** with the atom numbering scheme, thermal ellipsoids are at the 30% probability level.

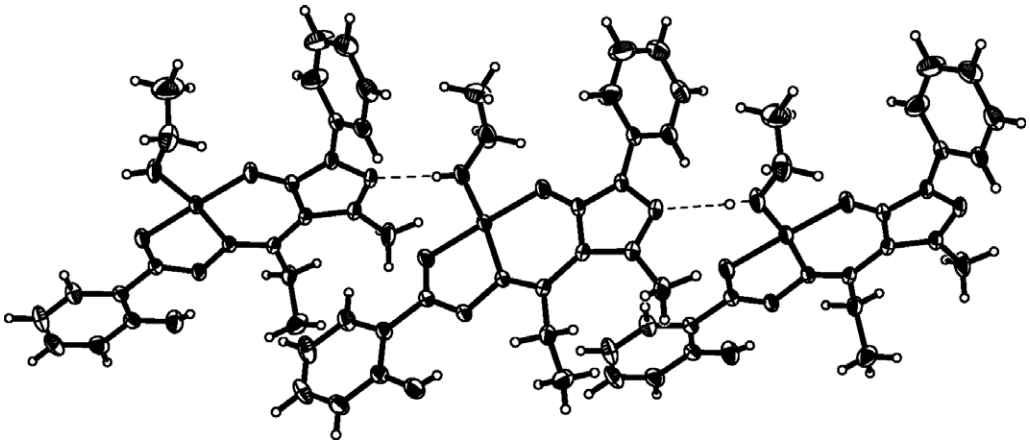

Fig. 3. The packing view of the unit cell for **1**.

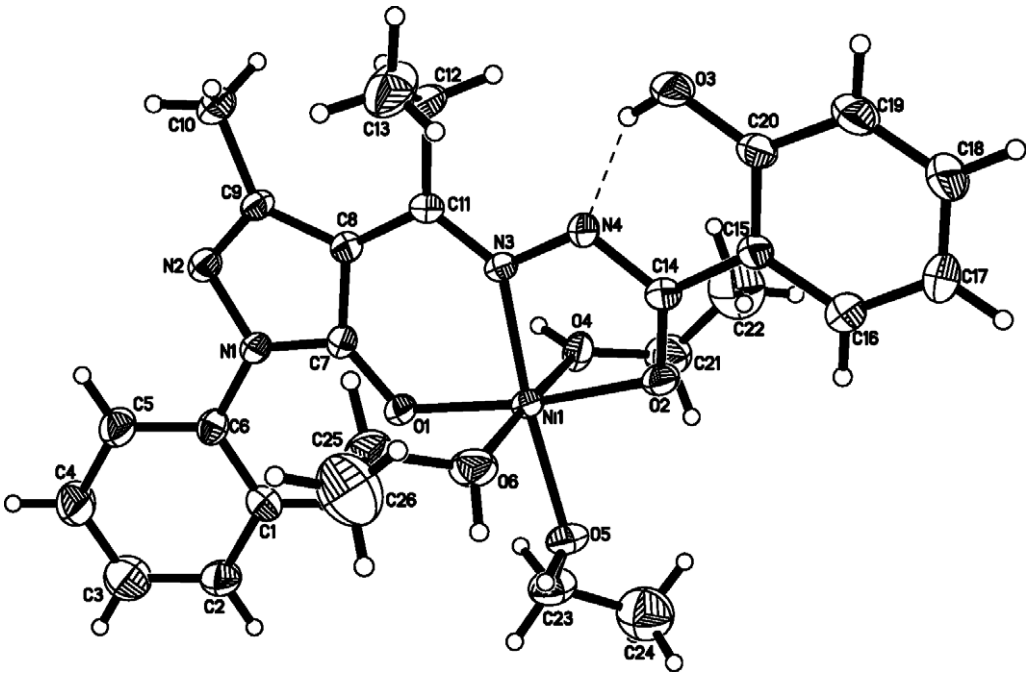

Fig. 4. The crystal structure of **2**, the thermal ellipsoids are drawn at the 30% probability level.

In the complex, the six-membered chelate ring {C7C8C11N3O1Ni1} and the five-membered chelate ring {N3N4C14O2Ni1} are coplanar with the pyrazolone ring. The dihedral angles are 2.7° and 4.0°, respectively. The plane defined by the {N4, C14, C15, C20, O3} atoms is also coplanar with the phenyl ring of {C15–C20}, the dihedral angle is 2.4°. These show that the ligand has favorable coplanarity.

Fig. 5 illustrates the packing diagram of **2**. The most interesting feature in the complex is that the intermolecular hydrogen bonds play an important role in the crystal packing and the stability of the complex. Adjacent units are cross-linked by two types of intermolecular hydrogen bonds (O–H···N and O–H···O), which stabilize the conformation. The oxygen atom (O4) of one ethanol molecule of a mononuclear unit is hydrogen bonded to a nitrogen atom (N2) of the pyrazolone ring of an adjacent complex unit (O4···N2 = 2.85(5) Å). The oxygen atoms (O5 and O6) of two other ethanol molecules are further hydrogen bonded to the hydroxyl oxygen atom (O3) of the third complex unit (O5···O3 = 2.60(0) Å, O6···O3 = 2.65(5) Å). Through the intermolecular hydrogen bonds, the units are linked into supramolecular 2D layers.

3.2.3. The structure of $[Mn_2L_2(\mu_2\text{-}EtOH)_2(EtOH)_2]$ (3)

The molecular structure of complex **3** is shown in Fig. 6. The crystal structure is built up of dinuclear centrosymmetric complex molecules, $[Mn_2L_2(\mu_2\text{-}EtOH)_2(EtOH)_2]$. Each Mn(II) is hexa-coordinated by one tridentate ligand, two bridging ethanol molecules and a coordinated ethanol

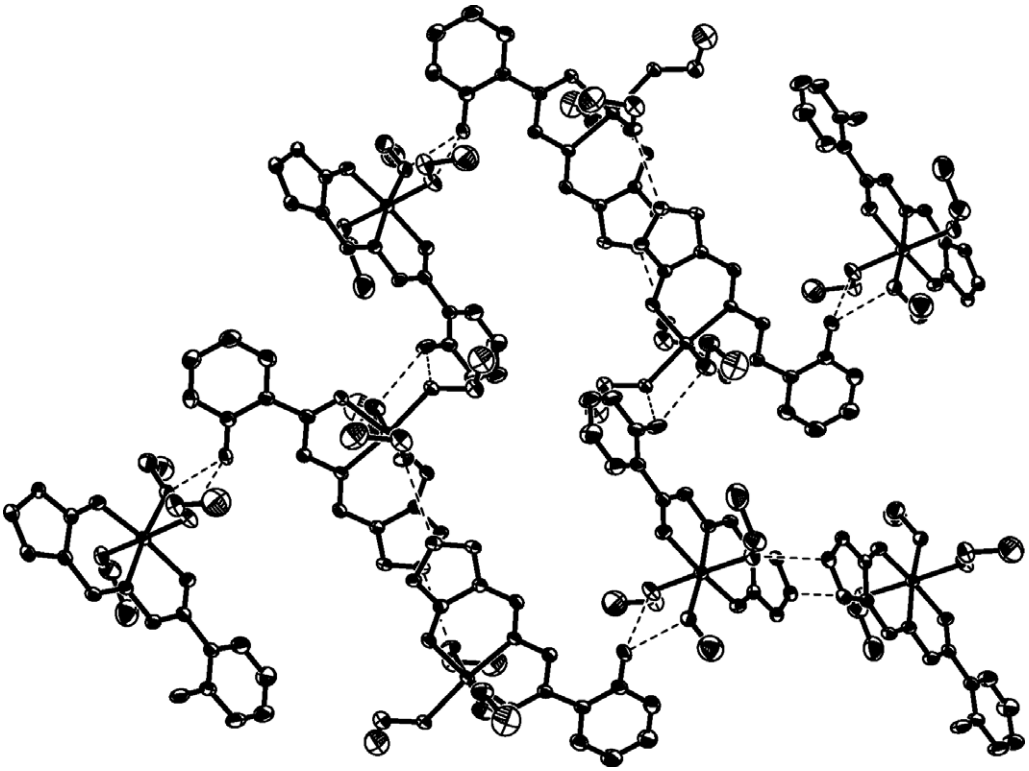

Fig. 5. The two-dimensional network structure of **2** formed by hydrogen-bonding interactions.

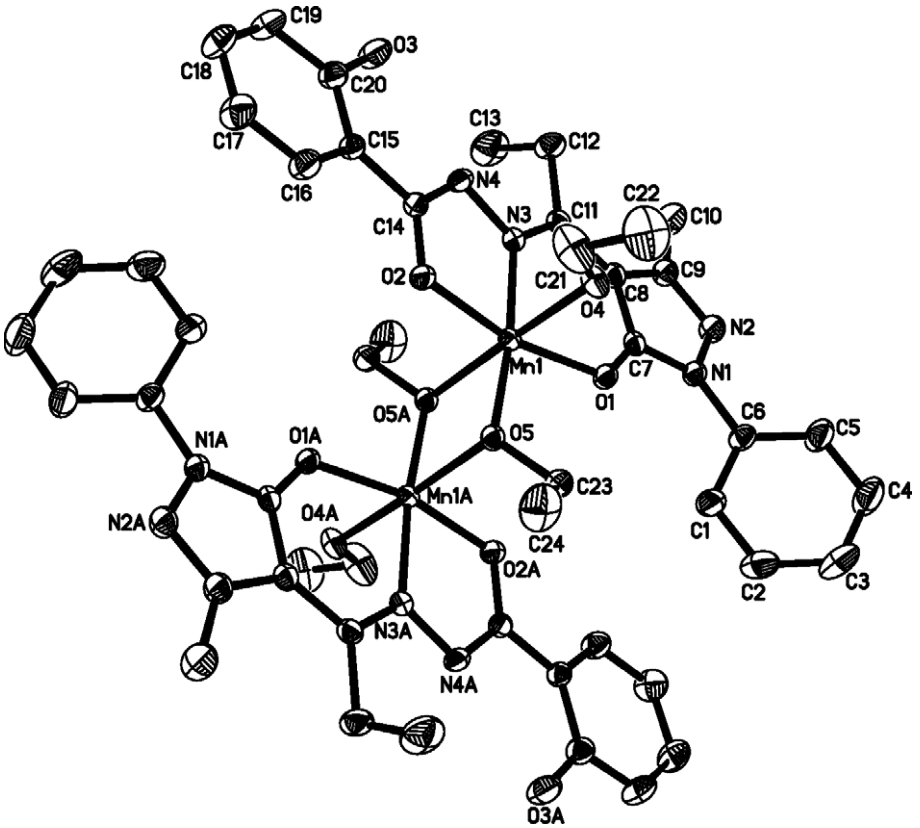

Fig. 6. Perspective view of **3** with 30% probability displacement ellipsoids.

molecule to form a MnNO5 coordination environment. The Mn1 ion has an octahedral geometry with the basal plane consisting of two oxygen atoms from the ligands (O1, O2), with Mn1–O distances of 1.923(2) and 1.947(2) Å, and two oxygen atoms of the ethanol molecules (O4, O5A), with Mn1–O distances of 2.283(2) and 2.202(2) Å. The axial positions are occupied by the azomethine nitrogen (N3) and ethoxo atom (O5). The average deviation of O1, O2, O4 and O5A with regard to the mean basal plane is 0.1367 Å. Mn1 is displaced by −0.0071 Å from the equatorial plane. The bond angles of O1–Mn1–O2, O4–Mn1–O5A and N3–Mn1–O5 are 167.0(1), 172.6(7) and 173.5(5)°, respectively. This indicates that the coordination sphere of the Mn1 ion is a slightly distorted octahedron.

In the binuclear unit, the two Mn(II) ions are connected by two oxygen atoms from two bridging ethanol molecules to define a centrosymmetric dimeric unit, in such a way a planar asymmetric bridge between the Mn ions is formed. Each bridging oxygen atom is more closely associated with a single Mn(II), with the bond lengths Mn1–O5 of 1.883(2) Å and Mn1–O5A of 2.202(2) Å (which are shorter than the bond length to the terminal oxygen, Mn1–O4 of 2.283(2) Å). The Mn1–O5–Mn1A bond angle of 100.8(9)°, and a Mn···Mn distance of 3.155 Å is observed in the complex. The formation of an oxygen bridged binuclear complex with high stability might be the reason for solvent molecule coordination regardless of whether the complex was synthesized under the common solvent reaction or by solvothermal synthesis with pyridine.

In the crystal structure, the complex molecules are interconnected through intermolecular O4–H4···N2 hydrogen bonds formed between O4 of the coordinated ethanol molecule and the N2 atom of the pyrazolone ring of a neighboring molecule (O4···N2 = 2.82(1) Å). Thus sheets of molecules parallel to the crystallographic *bc*-plane are formed (Fig. 7).

For the three complexes with ethanol as the co-ligand, the coordination number (CN) should be expected to be of the same order as for the ionic radii, i.e., Mn > Ni > Cu. However, the coordination number is Mn = Ni > Cu and the coordination geometry around Ni(II) and Mn(II) is a distorted octahedron while Cu(II) displays a square plane, which can be explained by the ionic radii of the cations and the well-known tetragonal Jahn-Teller distortion for Cu(II) [27]. The results also show that the interactions in the equatorial plane of Cu(II) were strengthened, as the in-plane Cu(II)–N and Cu(II)–O(ligand) distances are significantly shorter than those observed for the nickel(II) and manganese(II) complexes. On the other hand, it is found that the Mn(II) complex assumes a dimeric structure bridged by two ethanol molecules. It appears that Mn(II), with an ionic radius (0.84 Å) larger than the ionic radius of Ni(II) (0.69 Å), allows dimerization of the mononuclear units in **3** [28].

3.2.4. The structure of [CuL(Py)] · MeOH (4)

A perspective view of [CuL(Py)] · MeOH (**4**) with the labelling scheme is given in Fig. 8. The structure of **4** consists of an electroneutral Cu(II) mixed-ligand complex and one uncoordinated crystal methanol molecule. The Cu1 ion is tetra-coordinated with two oxygen atoms (O2, O3) and one nitrogen atom (N2) from the tridentate ligand and one nitrogen atom (N5) from a pyridine molecule to form a CuN2O2 coordination environment with a slightly distorted square-planar geometry. The derivations of the four donor atoms (O2, O3, N2 and N5) from their least-squares plane are 0.0027 Å, 0.0026 Å, −0.0022 Å and −0.0020 Å, respectively, and the Cu1 ion is displaced by −0.0012 Å out of the plane; all these figures show that the five atoms are almost coplanar. The bond angles show that the complex is distorted from a regular square-planar structure, with N2–Cu1–N5 and O2–Cu1–O3 bond angles of

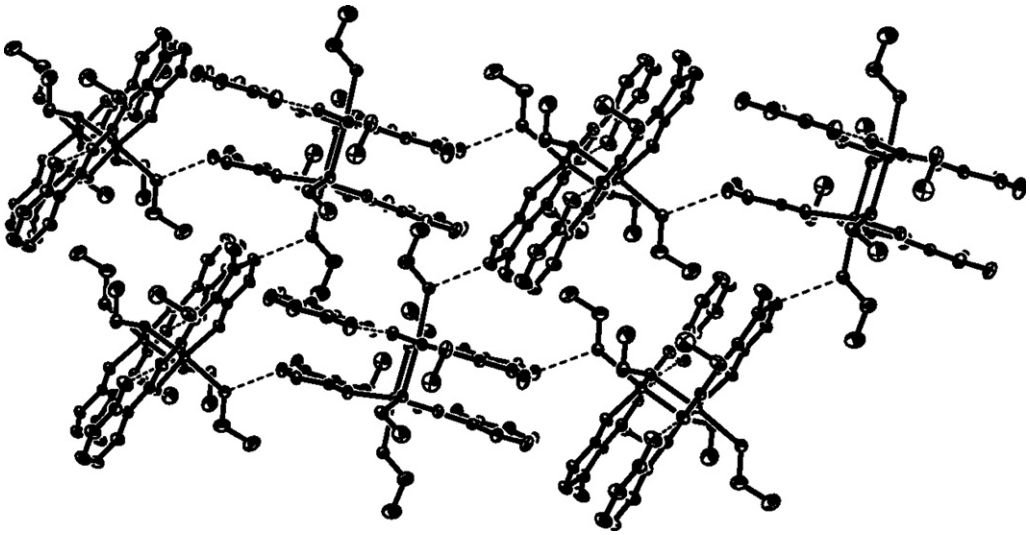

Fig. 7. 2-D network structure of **3** formed by hydrogen-bonding interactions.

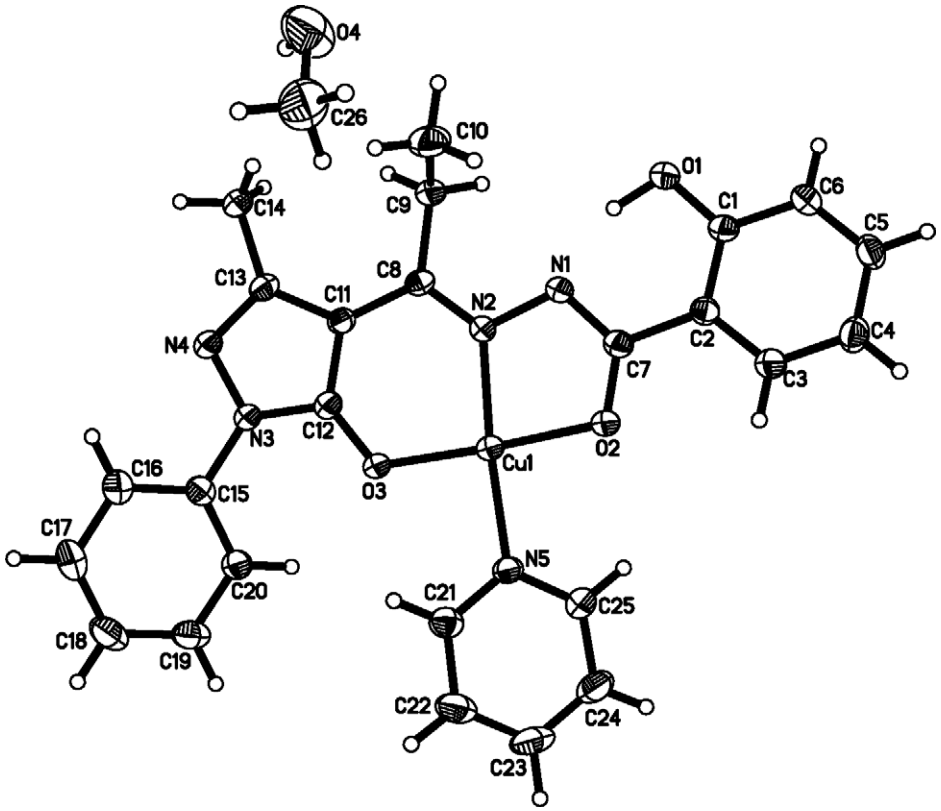

Fig. 8. The molecular structure of **4** with thermal ellipsoids shown at 30%.

175.1(2)° and 177.1(1)°, respectively, which are deviated from the ideal value of 180°.

In this complex, the ligand L^{2-} also adopts the enolic form II bonded to the Cu1 ion. The dihedral angle between the six-member chelating plane {O3C12C11C8N2Cu1} (mean derivation 0.0132 Å) and the pyrazolone ring (mean derivation 0.0027 Å) is 1.4°. The five-member chelating plane {O2C7N1N2Cu1} (mean derivation 0.0076 Å) is almost coplanar with the six-member chelating ring (dihedral angle 1.1°). It is concluded that there is considerable conjugation in the complex.

As shown in the packing diagram of **4** (Fig. 9), the O4 atom of the uncoordinated methanol molecule and the N4 atom of the pyrazolone ring provide the hydrogen bonding donor and acceptor, respectively. Atom O4 is hydrogen bonded to N4 at a N4···H(O4) distance of 2.13 Å, the

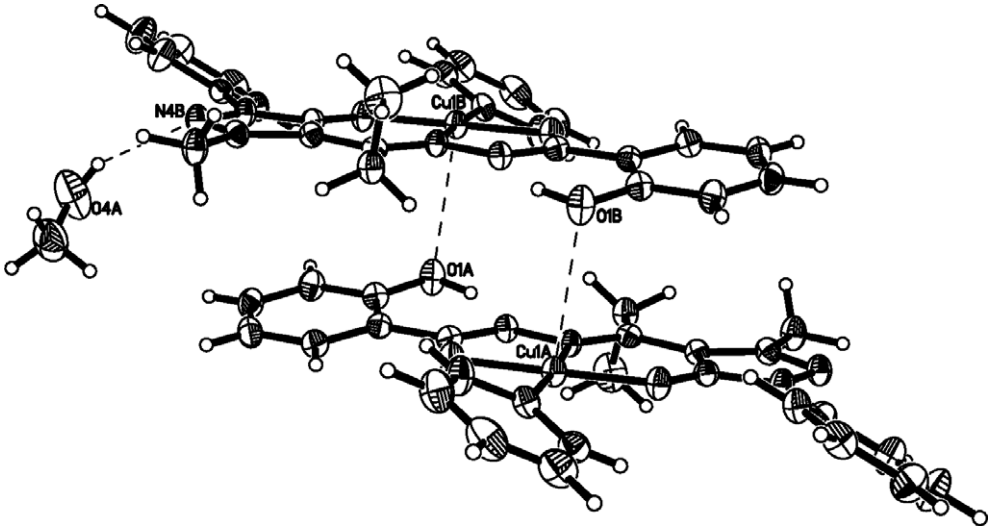

Fig. 9. Illustration of weak interactions between the phenolic oxygen atoms and central metal ions, broken lines indicate weak interactions and hydrogen bonds.

O4···N4 distance is 2.89(9) Å. The two complex units link to each other through a weak contact between the phenolic oxygen atoms and central metal ions (O1A···Cu1B, O1B···Cu1A) with a long distance (3.023 Å) to form a dimer. These O···Cu contacts suggest that there are π–π stacking interactions between the primary ligands.

3.2.5. The structure of [NiL(Py)$_3$] (5)

The molecular structure of **5**, together with the atom-numbering scheme is illustrated in Fig. 10. Selected bond lengths (Å) and bond angles (°) are listed in Table 3.

In the mixed-ligand complex **5**, the coordination geometry around the hexa-coordinated Ni(II) ion is described by a slight distorted octahedron, the Ni1 ion being coordinated by two oxygen atoms (O1 and O2) and one nitrogen atom (N3) of L^{2-} and three nitrogen atoms (N5, N6 and N7) from three pyridine molecules. The O1, O2, N3 and N6 atoms constitute the equatorial plane, while the axial positions are occupied by the N5 and N7 atoms. The average deviation of O1, O2, N3 and N6 with regard to the mean basal plane is 0.0051 Å. The Ni1 ion is displaced by 0.0099 Å from the equatorial plane. The bond angles of O1–Ni1–O2, N3–Ni1–N6 and N5–Ni1–N7 are 173.8(9)°, 173.6(6)° and 175.4(5)°, respectively, which are slightly deviated from the theoretical value of 180°. This indicates that the coordination geometry of the Ni1 ion is a slightly distorted octahedron. The average bond length of Ni1–N(pyridine) is 2.121 Å, in which the bond length Ni1–N6 (2.082(3) Å) is shorter than Ni1–N5 (2.132(3) Å) and Ni1–N7 (2.148(3) Å). The C7–O1 and C14–O2 bond distances are 1.279(3) and 1.274(3) Å, respectively, which are shorter than 1.43 Å for a C–O single bond and longer than 1.22 Å for a C=O double bond length. The C11–N3 (1.300(3) Å) and C14–N4 (1.322(3) Å) bond lengths are close to a C=N double bond (C=N, 1.28 Å), which confirms that the keto form III of the ligand isomerizes to the enol form II and then participates in bonding. Furthermore, after the coordination complex is formed, a hydrazone skeleton [C11=N3–N4=C14] appears with a certain degree of delocalization of the π-electrons of the pyrazolone ring and the hydrazone skeleton. This conjugation results in coplanarity of plane I {N1N2C7C8C9}, plane II {O1C7C8C11N3Ni1}, plane III {N3N4C14O2Ni1} and plane IV {C15–C20}, of which the interplanar angles of plane I and III with II are 8.7° and 5.8°, respectively; plane IV with II is 7.6°.

It is noteworthy that when the reactions of the ligand H_2L and the respective metal acetate were carried out in methanol solvent in the presence of pyridine, the pyridine molecule replaced methanol and coordinated to the metal ions Cu(II) and Ni(II) to complete the coordination requirement. However for Mn(II), the product [Mn_2L2-(μ_2-MeOH)$_2$(MeOH)$_2$], similar to [Mn_2L_2(μ_2-EtOH)$_2$-(EtOH)$_2$], was obtained. The preference for either pyridine or methanol is in fair agreement with Pearson's theory of hard and soft acids and bases, preferring bases of the same quality: the 'harder' Mn(II) binds intermediate base pyridine ligands much less compared to the 'intermediate' acid Ni(II), which prefers to bind with the 'harder' methanol molecule [29].

3.3. Comparison of the free ligand H_2L and these complexes

Useful information can be derived by comparing the structure of the ligand in free state and in the complexes. A comparison of the bond lengths of H_2L and the mixed-

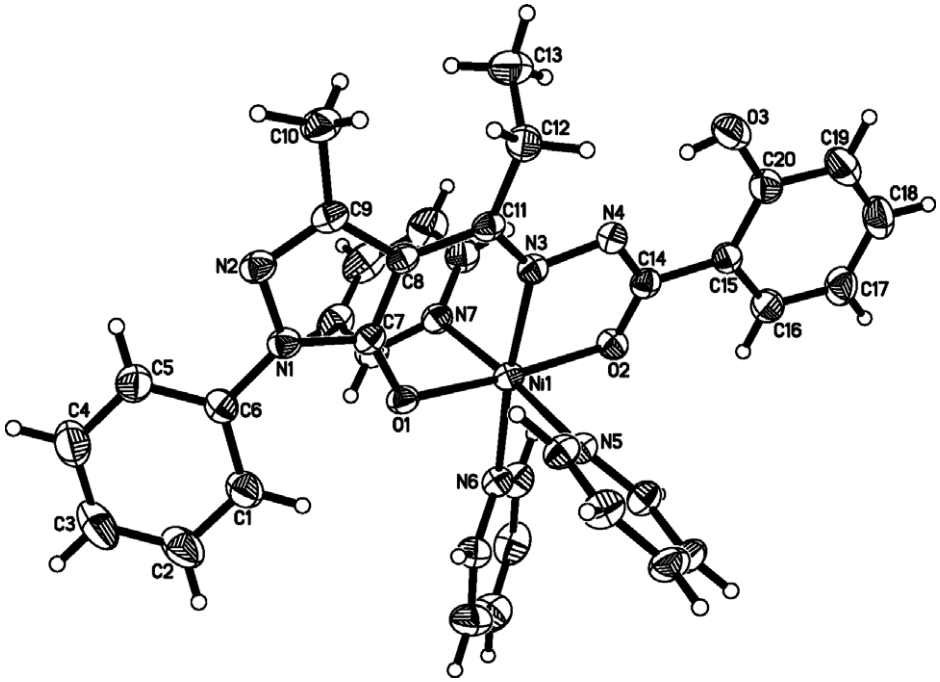

Fig. 10. The molecular structure of **5** with thermal ellipsoids shown at 30%.

ligand complexes are listed in Table 5. Some bond lengths are changed. As far as bond distances around the coordination atoms O1, O2 and N3 are concerned, the changes are the most obvious. In the free ligand, the bond distances of O1-C7 and O2–C14 are 1.266(3) and 1.218(3) Å, respectively, which is in good agreement with a C=O double bond. The bond length of C8–C11 is 1.400(4) Å, which is indicative of significant conjugate double bond character. While the C11–N3 bond distance is 1.311(4) Å, slightly shorter than a normal C–N bond distance. All of these demonstrate that the keto tautomer (form (III) in Scheme 1) is favored over the enol form (I) or (II) for the ligand. In the complexes, however, bonds O1–C7 and O2–C14 are lengthened, having values close to the value of a C–O single bond. While the bond lengths of N3–C11 and N4–C14 in the complexes are shorter than the corresponding C–N distance in the ligand. All these changes indicate that the ligand exists in the enol form II (in Scheme 1) in the reaction and acts as a tridentate ligand coordinated to the metal ion, with the other coordination sites around the metal ions being completed by the co-ligand.

In the free ligand, the pyrazolone ring (plane I) is coplanar with plane II defined by the C7, C8, C11, N3 and O1 atoms, the dihedral angle between them is only 0.8°. Plane III (N4, C14, C15, C20, O3) is also almost coplanar with plane IV (C15–C20), the dihedral angel between them is 8.9°. Moreover, the dihedral angle between plane II and plane III is 69.3°. These data indicate that the whole molecule is non-planar. However, in the structures of these complexes, the hydrazone skeleton [C11=N3–N4=C14] appears and there is a certain degree of delocalization of the π-electrons of the pyrazolone ring. This conjugation results in coplanarity of the pyrazolone ring, six-member chelating plane, five-member chelating plane and the plane defined by (C15–C20). Namely, the main body of the ligand is in a plane. These data reveal that the configuration of the ligand changed to planar in solution to facilitate the coordination of the enolic oxygen O2 to the metal ion.

3.4. IR spectra

The assignments of IR bands are observed to be in good agreement with the X-ray structural data. The main stretching frequencies of the IR spectra of the ligand H_2L and its mixed-ligand complexes are tabulated in Table 6.

Table 5
Comparison of bond lengths of H_2L and the complexes

Bond	H_2L	1	2	3	4	5
C7–O1	1.266(3)	1.290(3)	1.268(3)	1.295(3)	1.287(3)	1.279(3)
C14–O2	1.218(3)	1.290(3)	1.249(3)	1.303(3)	1.292(3)	1.274(3)

Table 6
IR band assignments for the ligand and the complexes

Compound	υ_{O-H}	υ_{N-H}	$\upsilon_{C=O}$	υ_{C-O^-}	$\upsilon_{C=N}$	$\upsilon_{C=N\ Py}$	υ_{C-OH}	υ_{M-O}	υ_{M-N}
H_2L	3249	3249	1663, 1614				1308		
1	3444			1453	1604		1305	512	472
2	3445			1450	1603		1304	517	459
3	3482			1454	1597		1304	514	461
4	3313			1453	1602	1576	1301	511	464
5	3176			1445	1599	1576	1305	506	457

The ligand spectrum shows a medium intensity band at around 3249 cm^{-1}, assigned to the hydrogen bond NH and OH stretching vibrations [30], the strong bands at 1663 and 1614 cm^{-1} are respectively allocated as υ(C=O) of the hydrazide and υ(C=O) of the pyrazolone-ring [4,31]. From the above analyses, it is concluded that the ligand exists in the keto form in the solid state. However, in the spectra of the complexes, the υ(C=O) bands are both absent. Meanwhile, a new band is observed at around 1450 cm^{-1} due to υ(C–O^-). The band at around 510 cm^{-1} is assigned to υ(M–O) [32]. From these observations, it is concluded that the ligand reacts in the enol form when coordinated to the metal ion in the solvent and the two enolic protons are replaced by M(II) in the complexes. The results are also confirmed by the crystal structure analyses above.

In the spectra of the complexes, the NH stretching vibration disappears and new bands at about 1600 and 1576 cm^{-1} appear, which are respectively allocated as υ(–C=N–N=C–) of the hydrazone and the coordinated pyridine nitrogen [30,33]. All of these demonstrate that the nitrogen atoms of the imino-group and the pyridine are coordinated to M(II). The new bands at 460 cm^{-1} for the complexes are assigned to υ(M–N), which further confirms the results [34].

In the ligand spectra, the strong band observed at 1308 cm^{-1} is assigned to the υ(C–OH) stretching vibration of the phenolic oxygen. This band shifts very feebly in the spectra of all the metal complexes, indicating the non-coordination of the phenolic oxygen to the central metal.

3.5. Thermal analyses

The thermal analyses results of these complexes are represented in Table 7. The results show that the complexes have very similar thermal behavior. In all cases the ethanol or pyridine moiety is removed first followed by the ligand moiety, leaving the respective metal oxide as the decomposition residue. The thermal decomposition behaviors of these complexes reflected the structural information as well. Only the thermal decomposition of complexes **3** and **5** are discussed here in detail.

3.5.1. Thermal analysis of $[Mn_2L_2(\mu_2\text{-}EtOH)_2(EtOH)_2]$ (3)

The simultaneous TG–DTG–DTA curves of complex $[Mn_2L_2(\mu_2\text{-}EtOH)_2(EtOH)_2]$ is shown in Fig. S1 and it

Table 7
Thermal analyses data for these mixed-ligand complexes

Complex	Stage	TG temperature range (°C)	DTG peak temperature (°C)	Removed group	TG mass loss%		Residue compound	Residue found (Calc.)%
					Found	Calculated		
1	I	115–165	140	EtOH	9.67	9.76	[CuL]

	III	340–580	370	L	64.37	64.50	CuO	15.90 (14.81)
5	I	110–177	155	2Py	23.93	24.02	[NiL(Py)]	
	II	177–225	212	Py	11.95	12.01	[NiL]	
	III	368–485	403	L	52.30	52.20	NiO	11.75 (11.34)

indicates that the thermal decomposition takes place in three stages. In the first stage from 105 to 175 °C, two moles of ethanol molecules degrade, shown as one maximum in the DTG curve at 155 °C with a 10.13% mass loss (Calc.: 9.04%). The second stage starts at 175 °C and ends at 259 °C, the corresponding mass loss (8.11%) is due to the degradation of another two moles of ethanol molecules, which is in agreement with the calculated value (9.04%). The DTG curve shows two peaks at 215 and 236 °C for this stage. The third stage is related to the decomposition of the L^{2-} anion in the temperature range of 259–450 °C and shows a strong exothermic process with a DTA peak at 394 °C, the observed mass loss (66.36%) coincides with the theoretical value (67.99%). The decomposition completes at 450 °C and the final residue is qualitatively proved to be Mn_2O_3, with an observed mass of 15.30% as against the calculated value of 15.49%.

3.5.2. Thermal decomposition of [NiL(Py)$_3$] (5)

The simultaneous TG–DTG–DTA curves of the mixed-ligand complex [NiL(Py)$_3$] are shown in Fig. S2. The thermal decomposition of complex **5** is in three stages. The endothermic degradation of two moles of pyridine molecules takes place in the first stage between 110 and 177 °C with a mass loss of 23.93% (Calc.: 24.02%). The maximum rate of mass loss is indicated by the DTG peak at 155 °C. The residue at the first stage was found to be [NiL(Py)], and the second stage between 177 and 225 °C corresponds to decomposition of the remaining pyridine molecule, and one endotherm is observed in the DTA trace. The observed mass loss is 11.95% which is consistent with the theoretical value of 12.01%. With heating, the decomposition of the ligand followed. The third stage, which occurs in the temperature range 368–485 °C with a DTG peak at 403 °C, corresponds to the decomposition of the ligand, the observed mass loss (52.30%) is roughly coincident with the calculated value (52.20%). This step appears in the DTA curve as a broad exotherm with $T_{max} = 447$ °C and $\Delta H = 11$ kJ g^{-1}. The final residue, estimated as nickel oxide, has the observed mass 11.75% as against the calculated value of 11.34%.

4. Conclusion

A series of five new mixed-ligand complexes of the pyrazolone derivative ligand *N*-(1-phenyl-3-methyl-4-propenylidene-5-pyrazolone)-salicylidene hydrazide (H_2L) have been synthesized and characterized. X-ray crystallographic structural analyses of these complexes reveal that the ligand (H_2L) undergoes isomerization from the keto form to the enol form in the reaction and acts as a double negatively charged tridentate chelating agent coordinated to the metal ion in solution. Comparing with the reported results in this field, the strategy to design and utilize a pyrazolone derivative as a versatile ligand goes further. The final results also show that when a co-ligand was presented in the synthetic reaction, other coordination sites around the metal ions Cu^{2+} and Ni^{2+} were completed either by ethanol or pyridine molecules under the common solvent reaction or solvothermal syntheses conditions, respectively, this was not the case for the Mn^{2+} ion which was still coordinated with the solvent molecules. The different effects of the co-ligand on the structure of the compounds are also discussed.

Abstract

The organic ammonium tetrathiomolybdates *N*-methylethylenediammonium tetrathiomolybdate (*N*-Me-enH$_2$)[MoS$_4$] (**1**), *N*-(3-aminopropyl)propane-1,3-diaminium tetrathiomolybdate (dipnH$_2$)[MoS$_4$] (**2**), 4-(2-ammonioethyl)piperazin-1-ium tetrathiomolybdate hemihydrate (2-pipH-1-EtNH$_3$)[MoS$_4$]$\cdot$ 1/2H$_2$O (**3**) and 2,2′-iminodiethanaminium tetrathiomolybdate (dienH$_2$)[MoS$_4$] (**4**), were synthesized by an aqueous reaction of ammonium tetrathiomolybdate with the organic amines *N*-methylethylenediamine (*N*-Me-en), bis(3-aminopropyl)amine (dipn), 2-piperazin-1-ylethanamine (2-pip-1-EtNH$_2$) and bis(2-aminoethyl)amine (dien), respectively. All compounds were characterized by elemental analysis, ^{1}H NMR, IR, Raman and UV–Vis spectra, and the crystal structures of compounds **1**–**3** were determined. The structures of **1**–**3** consist of diprotonated organic cations, which are linked to the tetrahedral $[MoS_4]^{2-}$ anions with the aid of several weak H-bonding interactions. The MoS$_4$ tetrahedron in all compounds is slightly distorted with one or more Mo–S bonds being elongated, which can be attributed to the H-bonding interactions. The difference Δ between the longest and the shortest Mo–S bond lengths for **1**–**3** are 0.0379, 0.0186 and 0.0302 Å, respectively. Unlike **1** and **2**, which are anhydrous, compound **3** is a hemihydrate. The water molecule in **3** occupies the pores between alternating layers of the cations and anions in the crystallographic *bc*-plane. Compound **3** exhibits four types of weak H-bonding interactions namely N–H$\cdots$S, N–H$\cdots$O, O–H$\cdots$S and C–H$\cdots$S. All four tetrathiomolybdates decompose endothermically forming amorphous disulfides containing C and N. A comparative structural description of 28 tetrathiomolybdates is presented.

1. Introduction

The chemistry of tetrathiomolybdate is an area of current research interest in view of its usefulness as a precursor for the preparation of catalytically active metal sulfide materials [1]. A very important application is the routine use as a starting material in synthetic inorganic chemistry for the preparation of several Mo–S compounds [2,3]. In organic syntheses, tetrathiomolybdate has been used as a S-transfer reagent for the synthesis of several organo sulfur compounds [4]. The reactivity of tetrathiomolybdate has been investigated with several organic agents like alkyl halides [5], organic trisulfide [6] organic disulfide [7], thiophenol [8], 1,1-dithiolate disulfide [9], and more recently with organic amines [10–17]. Unlike the reactions of tetrathiomolybdate with other organic reagents like organic disulfides or thiophenol where the tetrathiomolybdate undergoes changes like for example the reduction of Mo(VI) to Mo(V), with organic amines the tetrahedral tetrathiomolybdate(VI) core is retained intact and the organic amines function as cations for charge balance [10–16]. From a structural point of view the acentric tetrahedral $[MoS_4]^{2-}$ unit can be used as a building block

to create non-centrosymmetric materials by an appropriate choice of counter cations, which can also be used as cationic handles to distort the MoS_4 tetrahedron by suitably altering the cation–anion interactions. In this context we are investigating the structural chemistry of group VI tetrathiometalates, and for tetrathiotungstates we have demonstrated that the reaction of $[WS_4]^{2-}$ with organic amines leads to the facile formation of organic ammonium tetrathiotungstates [15,18–24]. In many of these structurally characterized compounds, the WS_4 tetrahedron is slightly distorted with one or two of the W–S bonds elongated, which has been attributed to the S···H interactions between $[WS_4]^{2-}$ and the organic cation [21–25]. The importance of H-bonding interactions in the structural chemistry of tetrathiotungstates can also be evidenced by the fact that in some compounds the organic amines are only partially protonated. In view of this, it is of interest to investigate the reactions of tetrathiometalates with tri- or polyamines and alkyl substituted amines. In the present work, we have studied the reaction of $[MoS_4]^{2-}$ with the methyl substituted organic amine *N*-methylethylenediamine (*N*-Me-en) and three triamines bis(3-aminopropyl)amine (dipn), 2-piperazin-1-ylethanamine (2-pip-1-EtNH_2) and bis(2-aminoethyl)amine (dien). Herein we describe the synthesis, spectroscopic, and thermal characterization of the organic tetrathiomolybdates obtained by the above reaction. The structures of compounds **1**–**3** are reported here, while the structure of **4** has been reported by Pokrel et al. earlier [26]. Compounds **1**–**3** constitute new additions to the growing list of structurally characterized tetrathiomolybdates. The availability of structural information for several tetrathiomolybdates permits us to make a comparative study of the structural features, the details of which are described in this paper.

2. Experimental

2.1. Materials and physical measurements

The amines *N*-methylethylenediamine (*N*-Me-en), bis-(3-aminopropyl)amine (dipn), 2-piperazinyl-1-ethylamine (2-pip-1-EtNH_2), bis(2-aminoethyl)amine (dien), and the solvents were used as obtained from commercial sources with analytical purity. $(NH_4)_2[MoS_4]$ (ATM) was prepared by a literature method [27]. The details of the instrumentation used for the elemental analysis, IR, Raman and UV–Vis spectroscopy, thermal analysis were the same as described in our previous reports [11,12]. X-ray powder patterns were recorded in transmission geometry using a STOE STADI P diffractometer (Cu Kα = 1.54056 Å).

2.2. Preparation of compounds *1*–*4*

Freshly prepared ATM (260 mg, 1 mmol) was dissolved in 15 mL of distilled water containing 2 drops of 25% aqueous ammonia, and filtered. To the deep red coloured filtrate, *N*-Me-en (0.3 mL, 3.4 mmol) was added in drops at room temperature and the reaction mixture was left aside for crystallisation. After 1–2 days, red blocks of compound **1** slowly crystallized from the solution. The crystals were isolated by filtration, washed with a little ice-cold water (2 mL) followed by isopropanol (10 mL) and ether (10 mL) and dried under vacuum. Yield 75%. The use of dipn, 2-pip-1-EtNH_2 and dien instead of *N*-Me-en in above synthesis afforded the complexes **2**–**4** in 70% yield. All complexes are quite stable in air and dissolve in aqueous alkali solution, DMSO and DMF.

for Lorentz, polarization effects and a numerical absorption correction was applied for all compounds. The structures of the compounds **1**–**3** were solved with direct methods using SHELXS-97 [28] and refinement was done against F^2 using SHELXL-97 [28]. All non-hydrogen atoms were refined using anisotropic displacement parameters. The hydrogen atoms were located in difference map but in most cases were positioned with idealized geometry (ammonium hydrogen atoms in **2** and **3** allowed to rotate but not to tip) and refined isotropically using a riding model. The H atom of the water in **3** was located in difference map, its bond lengths set to ideal values and afterwards it was refined using a riding model. The absolute structure for **1** and **2** was determined and is in agreement with selected setting. The technical details of data acquisition and some selected refinement results for **1**–**3** are summarised in Table 1.

3. Results and discussion

3.1. Synthesis

Compounds **1**–**4** were synthesized by a direct aqueous reaction of ATM with the corresponding organic amine. In this reaction the stronger organic bases displace the weaker ammonia from ATM and no change is observed with respect to the tetrathiomolybdate. This observation is in accordance with the known stability of $[MoS_4]^{2-}$ in alkaline medium [29,30]. The compounds analysed satisfactorily for the proposed formula containing $[MoS_4]^{2-}$ in association with the diprotonated cations of *N*-Me-en, dipn, 2-pip-1-EtNH_2 and dien in **1**–**4**, respectively. The presence of the organic amine and $[MoS_4]^{2-}$ could be inferred based on the NMR and UV–Vis spectral data, respectively. In earlier reports we have shown that the use of the cyclic diamine (±)*trans*-1,2-diaminocyclohexane (*trans*-1,2-cn) results in the formation of (*trans*-1,2-cnH)$_2$[MoS_4] containing the monoprotonated amine [14] while the use of the polyamine tris(2-aminoethylamine) (tren) leads to the formation of (trenH_2)[MoS_4]·H_2O [11]. The synthesis of compound **4** containing the diprotonated triamine dien has been reported earlier by an alternate method which involves passing of H_2S gas into an aqueous molybdate solution containing dien [26]. It is interesting to note that the central secondary amine functionality and one of the terminal N atoms of the triamine bis(3-aminopropyl)amine (dipn) are protonated in **2** unlike in the related triamine dien in **4** where the protonation of the terminal primary amine groups has been reported [26]. In **3** only two of the N atoms are protonated. It has been reported that MoO_3 dissolves in aqueous dien resulting in the formation of the hexacoordinated neutral complex [MoO_3(dien)] where dien functions as a neutral tridentate ligand [31,32]. The neutral compound is freely soluble in water and forms (dienH_2)[MoO_4] in solution [33]. While (dienH_2)[MoO_4] exists only in solution, the corresponding tetrathio analogue **4** can be crystallised as a stable solid indicating the difference in the chemistry of

oxo- and thiomolybdates. Our several efforts to prepare the neutral trithio complex [MoS_3(dien)] by the reaction of MoS_3 with dien were not successful as MoS_3 does not dissolve in aqueous dien unlike MoO_3. Furthermore, our attempts to obtain a 2:3 $[MoS_4]^{2-}$ complex of the fully protonated dipn and dien by changing the reaction stoichiometries were not successful. In all cases only the diprotonated ammonium compounds were obtained. As observed earlier [12] for other organic thiomolybdates, the aqueous reaction of **1**–**4** with $[Ni(en)_3]^{2+}$ resulted in a cation exchange leading to the quantitative formation of the known metal–organic tetrathiomolybdate $[Ni(en)_3][MoS_4]$ [34].

3.2. Crystal structure description of *1*–*3*

Compound **1** (*N*-Me-enH_2)[MoS_4] crystallises in the non-centrosymmetric orthorhombic space group $P2_12_12_1$ with all atoms located in general positions and its structure consists of tetrahedral $[MoS_4]^{2-}$ dianions and *N*-methylethylenediammonium cations (Fig. 1). Compound **1** is isostructural with the corresponding W analogue [22] in accordance with our earlier observation wherein a pair of $[MS_4]^{2-}$ (M = Mo, W) compounds linked to the same cation are isostructural. The MoS_4 tetrahedron is slightly distorted and the S–Mo–S bond angles range between 108.36(6)° and 110.65(5)° (average: 109.47°) (Table 2). The Mo–S distances vary from 2.1635(14) to 2.2014(12) Å with a mean Mo–S bond length of 2.1861 Å. An analysis of the crystal structure reveals that

the each $[MoS_4]^{2-}$ anion is linked to four different cations with the aid of several weak N–H···S and C–H···S interactions (Table 3). A total of seven N–H···S interactions ranging from 2.362 to 2.868 Å and four C–H···S interactions between 2.825 and 2.953 Å are observed and all S···H contacts are shorter than the sum of their van der Waals radii [35]. The two longer Mo–S(3) and Mo–S(1) bonds at 2.2014(12) and 2. 1997(13) Å are involved in shorter N–H···S contacts accompanied by larger N–H–S angles while the other two shorter Mo–S bonds are involved in longer S···H contacts. Thus the strength and number of the S···H interactions can account for the observed distinct Mo–S bond distances. The three-dimensional H-bonded network is shown in Fig. 1. The difference Δ between the longest and shortest Mo–S bond lengths in **1** is 0.0379 Å and is quite larger than the Δ value of 0.0111 Å observed earlier (enH_2)[MoS_4] [10] (enH_2 is ethylenediammonium).

Compound **2** (dipnH_2)[MoS_4], crystallises in the non-centrosymmetric orthorhombic space group $Pca2_1$ with all atoms located in general positions. The structure consists of diprotonated $(dipnH_2)^{2+}$ cations and $[MoS_4]^{2-}$ anions (Fig. 2). The geometric parameters of the cation are in the normal range. Compound **2** is isostructural to its corresponding W analogue [23] and one of the primary N atoms and the central secondary N atoms are protonated. The MoS_4 tetrahedron is slightly distorted (S–Mo–S angles: 108.97 (5)–110.33 (4)°; average: 109.47°) with Mo–S bond distances ranging from 2.1717 (13) to 2.1903 (9) Å (average: 2.1818 Å) (Table 2). The observed Δ value of 0.0186 Å, is less than that for compound **1**. Cations and anions are involved in three varieties of H-bonding interactions, which include eight N–H···S, one N–H···N and four C–H···S bonds (Table 4). The resulting three-dimensional crystal-packing diagram is displayed in Fig. 2. $(dipnH_2)^{2+}$ and $[MoS_4]^{2-}$ are stacked in rods along

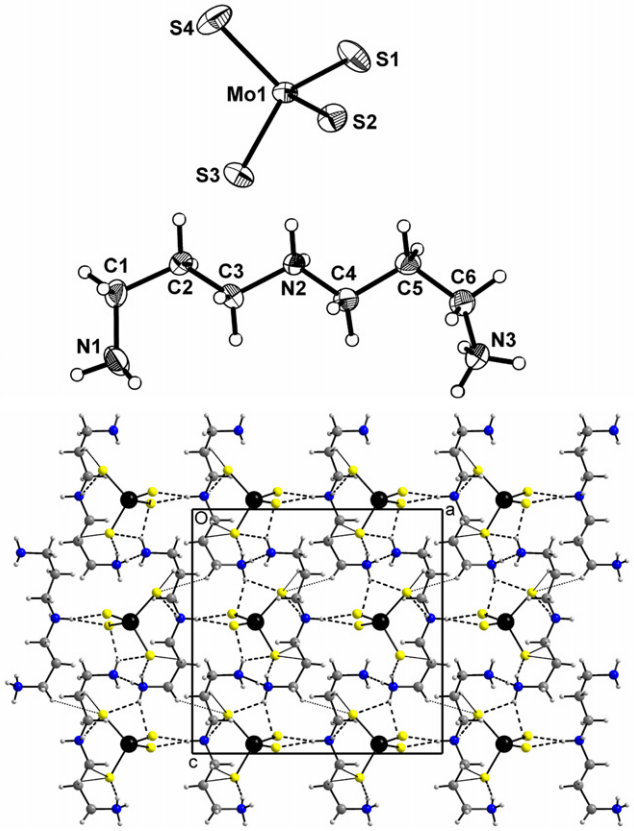

Fig. 2. The crystal structure of (dipnH$_2$)[MoS$_4$] (**2**) showing the atom-labelling scheme. Displacement ellipsoids are drawn at 50% probability level except for the H atoms, which are shown as circles of arbitrary radius (top). The three-dimensional extended network with view along *b*-axis (bottom). H-bonding is shown as dashed lines.

[0 0 1] to form a pseudo-hexagonal array. The cations and anions alternate along [1 0 0] and [0 1 0]. In the (0 1 0) plane a layer like arrangement is found with the anions being located in the pockets formed by three neighboring cations. A very short N3–H···N1 contact at 1.864 Å links the cations into a chain along the '*c*'-axis and each anion is surrounded by four cations and vice versa.

Compound **3** (2-pipH-1-EtNH$_3$)[MoS$_4$]·1/2H$_2$O (**3**), crystallises in the monoclinic space group *C*2/*c* and its structure consists of (2-pipH-1-EtNH$_3$)$^{2+}$, [MoS$_4$]$^{2-}$ located in general position and a crystal water with the oxygen located on a twofold axis (Fig. 3). The cyclic amine adopts the chair conformation with the ethylammonium group occupying equatorial position and the tertiary N remains unprotonated. The geometric parameters of the organic cation are in the normal range. Like for the other two compounds, the [MoS$_4$] tetrahedron is slightly distorted (S–Mo–S: 108.51 (3)–110.34 (3)°; Mo–S bond lengths: 2.1703 (7)–2.2005 (8) Å; average Mo–S distance: 2.1835 Å) (Table 2). The difference between the longest and shortest Mo–S distance Δ is 0.0302 Å and is comparatively larger than that for **2** but less than that observed in **1**. (2-pipH-1-EtNH$_3$)$^{2+}$, [MoS$_4$]$^{2-}$, and H$_2$O are linked via four varieties of H-bonding interactions consisting of five N–H···S, one N–H···O, one O–H···S and one C–H···S bonds (Table 5). It is interesting to note that the crystal water is H-bonded to two symmetry related [MoS$_4$]$^{2-}$ anions via O–H···S bonds while O11 forms H-acceptor bonds (N–H···O) with the organic cation leading to a tetrahedral coordination around the oxygen of water (Fig. 4). This unit linked via H$_2$O can be considered as a synthon to describe the extended supramolecular structure which consists of alternating layers of organic cations and anions with the water molecules occupying the pores between the alternating layers. The N–H···S and C–H···S interactions serve to link the layers of cations and anions (Fig. 4).

3.3. Spectral studies

Compounds **1**–**4** were characterised by using a combination of ^{1}H NMR, UV–Vis, infrared and Raman spectroscopic techniques. The observed chemical shifts (see Section 2) are in the normal range confirming the presence of the organic moieties in **1**–**4**. The electronic spectra of **1**–**4** recorded in dilute ammonia exhibit intense signals at around 468, 317 and 241 nm and the peak positions are identical within experimental error to ammonium tetrathiomolybdate [27]. These bands can be assigned to the charge transfer transitions of the [MoS$_4$]$^{2-}$ anion. The signals in the mid IR (up to 500 cm^{-1}) originate from the organic cations, while the vibrations of the [MoS$_4$]$^{2-}$ unit are observed at lower energies below 500 cm^{-1}. As expected the IR spectra of compounds **1**, **2** and **4** are

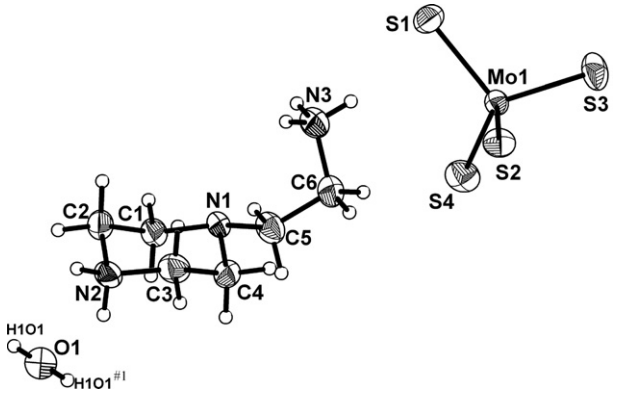

Fig. 3. Crystal structure of $(2\text{-pipH-1-EtNH}_3)[MoS_4]\cdot 1/2H_2O$ (**3**) showing the atom-labelling scheme. Displacement ellipsoids are drawn at 50% probability level except for the H atoms, which are shown as circles of arbitrary radius. Symmetry code: #1 $1-x, y, 1.5-z$.

identical with that of their W counterparts [22,23] with the signals due to the vibrations of $[MoS_4]^{2-}$ unit occurring at slightly higher energies. The strong band at 3434 cm^{-1}, which can be assigned to the O–H stretching vibration indicates the presence of water in the hemihydrate compound **3**. For all compounds the N–H region appears broad and shifted to lower wave numbers as compared to the free amines. This can be attributed to the change of amine group into the ammonium cation and the hydrogen bonding interactions between the organic cation and $[MoS_4]^{2-}$ anion. A broad signal due to the N–H vibration occurs at around 3046 cm^{-1} for **1** while for **2**–**4**, this vibration occurs at 2998, 3081 and 3054 cm^{-1}, respectively. However, the N–H region of **2** and **4** is quite different from that of **1**, as extra bands at 3272, 3228 cm^{-1} in **2** and 3257 cm^{-1} in **4**, are observed. These signals can be attributed to the N–H vibrations of the free amine part of the organic cations in **2**–**4**, indicating that the amines are partially protonated in **2**–**4**. Such signals have been earlier observed for the free amine functionality in $(trenH_2)[MoS_4]\cdot H_2O$ [11]. For the free tetrahedral $[MoS_4]^{2-}$ anion four characteristic bands $\nu_1(A_1)$, $\nu_2(E)$, $\nu_3(F_2)$, and $\nu_4(F_2)$ are expected [36,37]. All four bands are Raman active while only ν_3 and ν_4 are infrared active. When the T_d symmetry of MoS_4 is lowered to C_{2v} as in $[Ni(MoS_4)_2]^{2-}$ where $[MoS_4]^{2-}$ functions as a bidentate ligand, a splitting of the triply degenerate $\nu_3(F_2)$ vibration of the M–S bond occurs [36,37]. In $[Ni(MoS_4)_2]^{2-}$ the Mo–S bond to the bridging S atom is long (Mo–S–Ni) and the Mo–S bond to terminal S atom is short (2.151 Å). In our compounds the longer Mo–S bonds are always observed when strong S···H bonding interactions are present, and the Mo–S bond length distribution indicates a slight distortion of the tetrahedra. In **1** the asymmetric stretching vibration ν_3 appears as a split signal at 463 and 448 with a further shoulder at 433 cm^{-1}. The observed extra signals can be attributed to the distortion of MoS_4 tetrahedron and lowering of symmetry. All compounds exhibit a strong signal

in their Raman spectrum at around 455 cm^{-1}, which can be assigned to the $\nu_1(A_1)$ vibration. The bands at around 200 and 190 cm^{-1} in the IR–Raman spectra of **1**–**4** can be assigned to the ν_4.

3.4. Comparative structural chemistry of tetrathiomolybdates

In addition to the tetrathiomolybdates **1**–**3** reported herein, several others have been structurally characterized [10–16,38–48]. The isolation of $[MoS_4]^{2-}$ anions with a variety of cations like ammonium, K^+, metal complex cations like $[Co_2(tren)_3]^{2+}$, $[Mn(dien)_2]^{2+}$, $[Ni(en)_3]^{2+}$, several organic ammonium cations like $(enH_2)^{2+}$, $(N\text{-Me-enH}_2)^{2+}$, $(dipnH_2)^{2+}$, $(1,3\text{-pnH}_2)^{2+}$, $(1,4\text{-bnH}_2)^{2+}$, $(trenH_2)^{2+}$, $(pipH_2)^{2+}$ (for the explanation of abbreviations see Table 6) tetralkylammonium cations, etc. indicates the flexibility of the MoS_4 tetrahedron to exist in different structural environments. The structural parameters of 28 tetrathiomolybdates are listed in Table 6 of which $(trenH_2)[MoS_4]\cdot H_2O$ and $(2\text{-pipH-1-EtNH}_3)[MoS_4]\cdot 1/2H_2O$ (**3**) are the only known structurally characterised hydrates and both exhibit more varieties of H-bonding interactions. A comparison reveals that the ammonium, K^+, Rb^+, Cs^+ and methylammonium tetrathiomolybdates are isostructural and crystallise in the centrosymmetric *Pnma* space group while three of the four known $[MoS_4]^{2-}$ compounds with metal complex cations crystallise in non-centrosymmetric space groups. The use of chiral amines like $[PhCH(CH_3)NH_2]$ results in tetrathiomolybdates crystallising in chiral space groups [15]. Interestingly the use of tetralkylammonium cations like $(NR_4)^+$ (R = methyl or butyl) results in non-centrosymmetric solids. It is to be noted that for the $(NEt_4)^+$ salt of $[MoS_4]^{2-}$ in addition to the reported triclinic $P\bar{1}$ form, a polymorphic $P2_12_12_1$ has been identified [41]. As observed recently for $[WS_4]^{2-}$ compounds, the $[MoS_4]^{2-}$ compounds derived from en, *N*-Me-en and dipn crystallise in non-centrosymmetric groups [22,23]. In all compounds the MoS_4 tetrahedron is slightly distorted (Table 6), which can be attributed to the cation–anion interactions. In an earlier report we had shown that the Δ value in tetrathiotungstates can be taken as a useful measure of the distortion of the WS_4 tetrahedron and a threshold value of 0.03 was estimated. A very high Δ value of 0.1541 Å was observed for $[Co(dien)]_2[MoS_4][MoOS_3]$ [42], where one of the S atoms is disordered and its position partially occupied by O resulting in a structure consisting of superimposed $[MoS_4]^{2-}$ and $[MoOS_3]^{2-}$ ions, being responsible for the unusually short Mo–S bond length. When the analysis is done keeping aside such compounds, it is observed that $(pipH_2)[MoS_4]$ [11] shows the longest Mo–S distance of 2.2114 Å as well as the maximum Δ value of 0.0431 Å, in analogy to the corresponding W compound. The average value of the Mo–S distance ranges from 2.1765 Å in $[Mn(dien)_2][MoS_4]$ [39] to 2.1921 Å in $[(n\text{-Bu})_4N]_2[MoS_4]$ [34]. In general the average Mo–S bond distance for all compounds scatters in a small range and the Δ value is around 0.02 Å. The Δ value for compound **1** is 0.0379 indicative of a distortion of the tetrahedron as evidenced by a comparison of the IR spectral bands in the Mo–S region (Fig. 5). In this analysis, a noticeable difference as compared to tetrathiotungstates is that more examples of non-centrosymmetric $[MoS_4]^{2-}$ compounds are observed.

3.5. Thermal investigations

It is well documented that ammonium tetrathiomolybdate undergoes a two-step decomposition to form MoS_2 [2,49] as shown below:

$$(NH_4)_2[MoS_4] \overset{\text{endo}}{\rightarrow} NH_3\uparrow + H_2S\uparrow + MoS_3 \overset{\text{exo}}{\rightarrow} MoS_2 + S\uparrow$$

In contrast, organic ammonium tetrathiomolybdates decompose endothermically in a single step in most cases [11,12] and the final amorphous residue always contains considerable amounts of C [50]. In a recent report we have shown that tetralkylammonium tetrathiomolybdates exhibit a complex thermal behaviour involving structural phase transitions as well as emissions of different organic fragments like disulfides and amines [50]. For the decomposition of **1**–**4** (argon atmosphere; heating rate of 4 K) no exothermic events were observed. Although the exact nature of the intermediates formed cannot be described in the absence of mass spectral data of the emitted fragments,

it is interesting to note that the thermal patterns exhibit a common trend. The decomposition temperatures and the composition of the final sulfide residues are collected in Table 7. The composition of the residues is in good agreement with that derived from EDX analysis. The X-ray powder patterns of the final C and N containing molybdenum sulfide residues of **1**–**4** showed only broad humps indicating their amorphous nature.

Compound **1** exhibits two endothermic events at 124 and 153 °C, assignable to the decomposition of the organic cation as well as tetrathiomolybdate. The total mass loss up to 600 °C is 37.6%. The elemental analysis of the final product showed the presence of C and N and can be formulated as $MoS_{2.3}C_{1.3}N_{0.4}$. For **2** the endothermic signal at 73 °C can be attributed to a phase transition and a similar behaviour was observed recently for tetralkylammonium thiomolybdates [50]. Compound **2** is thermally stable up to 116 °C and its decomposition is evidenced by the two endothermic events at 136 and 194 °C. The total mass loss up to 600 °C is 50.5% and is higher than expected for the loss of dipn and H_2S only (46.3%). The analysis of the residue is indicative of incomplete removal of organics.

In the TG–DTA curve of **3** (Fig. 6), the first mass loss around 100 °C, is accompanied by an endothermic peak at 107 °C. The mass loss of 2.68% and is in very good agreement for the loss of half mole of water (expected is 2.47%). The anhydrous compound thus formed starts

Table 7
Thermal characterization data for **1**–**4**

Complex	DTA temp (°C)	TG mass loss (%)	Elemental analysis of residue (%)	Final residue
(N-Me-enH_2)[MoS_4] (**1**)	124 endo 153 endo	37.60	C 8.15 H 0.25 N 3.19 S 37.97	$MoS_{2..3}C_{1.3}N_{0.4}$
(dipnH_2)[MoS_4] (**2**)	136 endo 183 endo	50.51	C 6.79 H 0.27 N 1.69 S 37.66	$MoS_{2.1}C_{1.01}N_{0.2}$
(2-pipH-1-EtNH_3)[MoS_4] · 1/2H_2O (**3**)	107 endo 160 endo	2.68 41.75	C 14.79 H 0.47 N 5.07 S 29.45	$MoS_{1.7}C_{2.4}N_{0.7}$
(dienH_2)[MoS_4] (**4**)	153 endo 187 endo	37.68	C 13.03 H 0.61 N 4.67 S 34.32	$MoS_{2.2}C_{2.2}N_{0.7}$

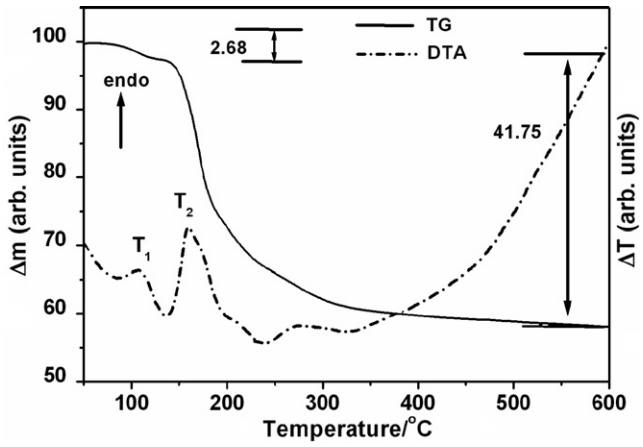

Fig. 6. TG and DTA curves for (2-pipH-1-EtNH_3)[MoS_4] · 1/2H_2O (**3**) (heating rate 4 K/min; Ar atmosphere; $T_1 = 107$ and $T_2 = 160$ °C are peak temperatures).

decomposing endothermically as evidenced by the signal at 160 °C and a sharp mass drop in the TG curve. A total mass loss of 44.43% up to 600 °C is quite less than expected for the removal of water, amine and H_2S (47.27%). Based on analytical data the residue can be formulated as $MoS_{1.7}C_{2.3}N_{0.7}$. The Mo:S ratio is 1:1.7 instead of 1:2 indicating the presence of some structural C. Compound **4**, which exhibits two endothermic events at 153 and 187 °C, is stable up to about 130 °C and decomposes with a total mass loss of 37.68% up to 500 °C, which is lower than expected for the emission of dien and H_2S (41.66%). The elemental analysis of the residue indicates $MoS_{2.2}C_{2.2}N_{0.7}$ as composition.

4. Conclusions

The organic ammonium tetrathiomolybdates **1**–**4** were synthesized by an aqueous reaction of $(NH_4)_2[MoS_4]$ with the corresponding organic amines. All the compounds were characterised by elemental analysis, spectroscopy methods, and the structures of **1**–**3** were determined. In compounds **2**–**4** the triamines are partially protonated forming dications. The characterization of such compounds demonstrates the ability of $[MoS_4]^{2-}$ to stabilise partially protonated organic ammonium cations. A comparative study of structural data of several tetrathiomolybdates highlights, that in most of the compounds the average Mo–S bond length scatters in a relatively narrow range, i.e. this structural parameter cannot be regarded as a good measure of the actual distortion of the anions. A more sensitive parameter is the difference Δ between the longest and shortest Mo–S bonds. Above a critical value for Δ the symmetry of the MoS_4 tetrahedron is reduced which is reflected by the appearance of extra signals in the Mo–S region of the infrared spectrum. The compounds **1**–**4** decompose endothermically and the resulting decomposition products are amorphous carbon contaminated metal sulfides with compositions $MoS_{2.3}C_{1.3}N_{0.4}$, $MoS_{2.1}C_{1.01}N_{0.2}$, Mo- $S_{1.7}C_{2.4}N_{0.7}$ and $MoS_{2.2}C_{2..2}N_{0.7}$, respectively.

Abstract

Mononuclear nickel(II) complexes with two ONS donor thiosemicarbazone ligands {salicylaldehyde 3-hexamethyleneiminyl thiosemicarbazone [H_2L^1] and salicylaldehyde 3-tetramethyleneiminyl thiosemicarbazone [H_2L^2]} have been prepared and physico-chemically characterized. IR and electronic spectra of the complexes have been obtained. The thiosemicarbazones bind to the metal as dianionic ONS donor ligands in all the complexes except in $[Ni(HL^1)_2]$ (**1**). In compound **1**, the ligand is coordinated as a monoanionic (HL^-) one. The magnetic susceptibility measurements indicate that all the complexes are mononuclear and are diamagnetic. The complexes were given the formulae $[Ni(HL^1)_2]$ (**1**), $[NiL^1py]$ (**2**), $[NiL^1\alpha\text{-pic}]$ (**3**), $[NiL^1\gamma\text{-pic}]\cdot H_2O$ (**4**), $[NiL^2py]$ (**5**) and $[NiL^2\gamma\text{-pic}]$ (**6**). The structures of compounds **2** and **3** have been solved by single crystal X-ray crystallography and were found to be distorted square planar in geometry with coordination of azomethine nitrogen, thiolato sulfur, phenolato oxygen and pyridyl nitrogen atoms.

Keywords: Thiosemicarbazone; Nickel(II) complex; Salicylaldehyde; Crystal structure

1. Introduction

The coordination chemistry of thiosemicarbazones with transition metals [1–4], which began with Jensen's work [5], has been more intensively investigated as compared to that of main group elements [6,7]. Thiosemicarbazones are an important group of multidentate ligands with potential binding sites available for a wide variety of metal ions [8–10]. These thiourea derivatives find substantial applications in different facets of contemporary scientific research. Thiosemicarbazones and their metal complexes are a broad class of biologically active compounds [4]. Due to this biological activity, there is considerable interest in metal complexes of heterocyclic thiosemicarbazones [4]. Nickel(II) complexes containing sulfur donors have received considerable attention due to the identification of a sulfur rich coordination environment in biological nickel centres, such as the active sites of certain ureases, methyl-*S*-coenzyme-M-methyl reductase and hydrogenases [11].

Spectral and, in some complexes, structural investigations of a series of nickel(II) complexes of ONS donor thiosemicarbazones [12–16] have been reported earlier. The thiosemicarbazone ligand usually coordinates with the metal through the imine nitrogen and sulfur atom. The ligands feature more than two covalent sites, the number of which depends on the aldehyde and on the tautomeric equilibrium of the thiosemicarbazone, although the most common way to coordinate is through the thiolate form [17]. We have reported Cu(II) [18] and Zn(II) [19] complexes of the present thiosemicarbazone ligands recently. Here, we report six mononuclear nickel (II) complexes of salicylaldehyde 3-hexamethyleneiminyl and 3-tetramethyleneiminyl thiosemicarbazones. These complexes were characterized by IR, electronic and magnetic data.

2. Experimental

2.1. Materials

All the solvents used for the synthesis of the thiosemicarbazone ligands and their complexes were purified by distillation. Pyridine, α/β/γ-picoline, $Ni(OAc)_2 \cdot 4H_2O$ (Central drug house) were used as received. 4-Methyl-4-phenyl-3-thiosemicarbazide was prepared as reported previously [20].

2.2. Synthesis of the ligands

H_2L^1 was prepared using a reported procedure [21]. H_2L^2 was prepared as described by adapting the reported procedure [20,21]. A solution of 4-methyl-4-phenyl thiosemicarbazide (1 g, 5.52 mmol) in acetonitrile (5 ml) was treated with salicylaldehyde (0.60 ml, 5.52 mmol) and pyrrolidine (0.50 ml, 5.52 mmol) and refluxed for 20 min. The solution was allowed to cool and the fine colorless needles of the compound separated out. It was filtered off, washed with cold acetonitrile and dried *in vacuo* over P_4O_{10}. The compound was recrystallized from methanol. The structures of the two ligands are given in Scheme 1.

2.3. Synthesis of complexes

Complex **1** was prepared by refluxing an ethanolic solution of H_2L^1 with a methanolic solution of $Ni(OAc)_2 \cdot 4H_2O$ in a 2:1 molar ratio for 4 h. The brown colored complex that formed was filtered, washed with ethanol and then with ether and dried over P_4O_{10} *in vacuo*. The complexes **2**–**6** were prepared by refluxing an ethanolic solution of the corresponding ligands and heterocyclic bases with a methanolic solution of $Ni(OAc)_2 \cdot 4H_2O$ in a 1:1:1 molar ratio. The complexes that separated were filtered, washed with ethanol and finally with ether and dried over P_4O_{10} *in vacuo*. Crystals suitable for X-ray analysis for compounds **2** and **3** were obtained by slow evaporation of solutions of the compounds from an ethanol methanol mixture (1:1 v/v) over 10 days.

The colors and analytical data of the complexes, elemental analysis and magnetic susceptibilities are presented in Table 1.

2.4. Physical measurements

Elemental analyses were carried out using a Vario EL III CHN analyzer at SAIF, Kochi, India. Magnetic susceptibility measurements were carried out at IIT, Roorkee, India, at 298 K in the polycrystalline state on a PAR model 155 Vibrating sample magnetometer at 5 kOe field strength using $Hg[Co(SCN)_4]$ as a calibrant. The FT-IR spectra were recorded on a Thermo Nicolet AVATAR 370 DTGS FTIR spectrometer using KBr pellets in the range 400–4000 cm^{-1} at SAIF, Cochin University of Science and Technology, Kochi 22, India, and far IR spectra were recorded in the range 50–500 cm^{-1} on a Nicolet Magna 550 FT-IR spectrophotometer using polyethylene pellets at SAIF, IIT, Bombay, India. Electronic spectra were recorded on a UVD-3500 UV–VIS-Double beam Spectrophotometer from solutions in DMF. ^1H NMR spectra were recorded on a Bruker AMX 300 in $CDCl_3$ with TMS as an internal standard.

2.5. X-ray crystallography

Reddish brown crystals of compounds **2** and **3**, having approximate dimensions of $0.26 \times 0.21 \times 0.17$ and $0.35 \times 0.30 \times 0.20$ mm^3, respectively, were selected. The crystal data for compounds **2** and **3** were collected by CrysAlis CCD, Oxford Diffraction Ltd. with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. In compound **2**, the atom C10 in the ring containing N3 is disordered as this carbon splits over two sets of positions. Restraints were applied to assist the geometry of the disordered atom. The ratio of major to minor disorder components for the C10 atom is 54:46. Compound **3** similarly has some disorder in the 7-membered ring. Even though refinement with restraints was applied to the 7-membered ring, the problems of the weak data could not be improved further. In spite of several attempts, we were unable to isolate single crystals of good quality.

In both of these compounds restraints were applied to assist the geometry of the disordered atoms. The trial structure was solved using SHELXS-97 [22] and refinement was

carried out by full-matrix least squares on F^2 (SHELXL) [22]. The molecular and crystal structures are illustrated by DIAMOND version 3.1d [23] and MERCURY [24]. All non-hydrogen atoms were refined anisotropically and hydrogen atoms were geometrically fixed at calculated positions. The crystallographic data and structure refinement parameters for the complexes are given in Table 2.

3. Results and discussion

The elemental analyses data are consistent with the general empirical formula $[M(HL)_2]$ for **1**, MLB for **2**, **3**, **4**, **5** and **6** where M is the nickel metal atom, L is the doubly deprotonated thiosemicarbazone ligand and B is the heterocyclic bases *viz.* py and α/β/γ pic. All the nickel complexes are reddish brown in color, which is common for complexes involving thiosemicarbazone coordination, resulting from the sulfur to metal charge transfer bands [25]. The complexes are insoluble in most common solvents. They are however soluble in DMF and DMSO.

The room temperature magnetic moments of the Ni(II) complexes suggest that they are all essentially diamagnetic. For the d^8 electronic configuration, diamagnetism generally implies that the metal ion has a square-planar configuration. The electronic spectra of the complexes in DMF solution are not well resolved owing to very intense charge transfer bands extending into the visible portion of the spectra.

3.1. Crystal structure of the compound [NiL^{1}py] and [NiL^{1}α-pic]

The molecular structures of [NiL^{1}py] (**2**) and [NiL^{1}α-pic] (**3**) along with the atom labelling schemes are shown in Figs. 1 and 2, and selected bond lengths and bond angles are summarized in Table 3. The ligand H_2L^1 gets doubly deprotonated to behave as an ONS tridentate ligand, coordinating *via* its phenolato oxygen, azomethine nitrogen and thiolate sulfur atom in the deprotonated form after thiol formation, giving a distorted square planar geometry around the nickel atom. The fourth coordination site is occupied by the nitrogen atom from the heterocyclic bases. The *E* configuration of the thiosemicarbazone chain about the C7–N1 bond is retained to facilitate the coordination of the thiolate sulfur to Ni in the two complexes. This reveals that no rotation has occurred about the azomethine bond for coordination. The coordination results in one 5-membered and one 6-membered chelate ring in the two complexes.

Compound **2** crystallizes with two monomers per asymmetric unit in the orthorhombic crystal system. The two molecules in the asymmetric unit are almost identical. So the discussion can be limited to one of the molecules. The Ni1 coordination is almost square planar with a maximum mean deviation of the coordinating atoms (phenolic oxygen O1, azomethine nitrogen N1, thiolate sulfur S1 and

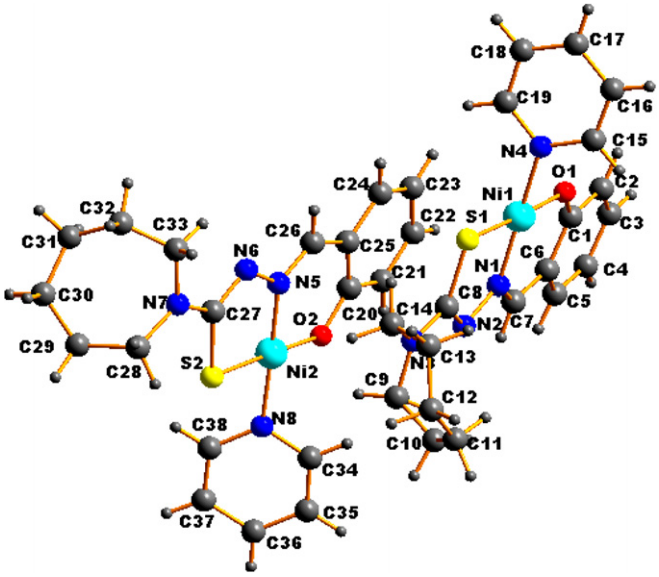

Fig. 1. Molecular structure of compound **2**.

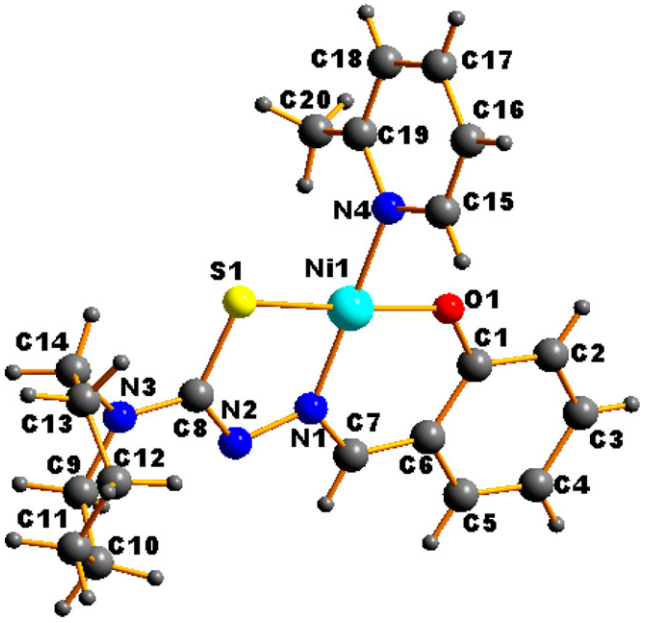

Fig. 2. Molecular structure of compound **3**.

pyridyl nitrogen N4) from their own plane of 0.0103 Å for N4. The thiosemicarbazonato moiety, C7–N1–N2–C8–S1–N3, also is almost planar and has a maximum mean plane deviation of 0.037(4) Å and an angle of 2.86(6)° to the plane of the four donor atoms, while the phenyl ring has an angle of 6.29(10)° to the donor plane of compound **2** indicating that the thiosemicarbazone moieties are close to coplanar with the nickel's coordination plane. Ring puckering analysis and least-square plane calculations show that the Cg(5) ring comprising of atoms N3, C9, C10, C11, C12, C13 and C14, and the Cg(10) ring comprising of atoms N7, C28, C29, C30, C31, C32 and C33 adopt a chair conformation [$Q_T = 0.696(6)$ Å (Cg(5)) and $Q_T = 0.650(6)$ Å (Cg(10))].

The bond angles O1–Ni1–N1 [96.16(12)°], O1–Ni1–N4 [85.35(11)°] and N1–Ni1–S1 [87.08(10)°] also reveal the distortion of the square plane comprising of Ni1, O1, S1, N1 and N4. The dihedral angle formed by the least square planes Cg(1) comprising of atoms Ni1, S1, N1, N2 and C8, and Cg(2) comprising of atoms Ni1, O1, N1, C1, C6 and C7 is 3.47(12)°. The C7–N1 bond distance of 1.305(4) Å lengthens compared to the corresponding C7–N1 bond distance (1.269(3) Å) in the ligand. The delocalization of electron density from the coordinating nitrogen onto the central metal atom gives rise to an elongated N1–N2 bond length (1.406(3) Å) compared to the uncomplexed thiosemicarbazone (1.356(3) Å). Also, the C7–N1–N2 bond angle decreases considerably compared to the ligand H_2L^1. The loss of the proton bound to N2 in H_2L^1 produces a negative charge which is delocalized on the N1–N2–C8 system. This is indicated by the lengthening of the bond C8–S1, 1.753(4) Å, compared to the value of 1.684(3) Å in the ligand. This thiolate formation is also supported by the decrease in bond length of N2–C8, 1.304(4) Å from the value of 1.362(3) Å found in the uncomplexed thiosemicarbazone. The bond angles O1–Ni1–N4 [85.35(11)°] and S1–Ni1–N1 [87.08(10)°] are also analogous, as expected on the basis of the similar square planar nature for all the complexes. Coordination of O1 results in O1–C1 decreasing by approximately 0.04–0.05 Å.

Compound **3** crystallizes with only one monomer per asymmetric unit in the monoclinic crystal system. The bond angles N1–Ni1–O1 [96.5(2)°], O1–Ni1–N4 [87.56(19)°] and N1–Ni1–S1 [86.77(19)°] reveal the distortion of the square planar geometry. The dihedral angle formed by the least square planes Cg(1) comprising of atoms Ni1, S1, N1, N2 and C8, and Cg(2) comprising of atoms Ni1, O1, N1, C1, C6 and C7 is 0.6(2)°. Similar to compound **2**, the

[a] Ref. [17].

C7–N1 bond length increases compared to the ligand. Thus on complexation, the azomethine C–N bond lengthens because of coordination of the azomethine nitrogen. Coordination lengthens the thiosemicarbazone moiety's C8–S1 bond length to 1.759(6) Å and shortens the N2–C8 bond length to 1.302(7) Å. The maximum deviation from the least square planes around the Ni(II) ion is 0.0626(5) Å for N1. The thiosemicarbazonato moiety, C7–N1–N2–C8–S1–N3, is almost planar with a maximum mean deviation of 0.028(6) for N2 and is at an angle of 1.46(9)° to the plane of the four donor atoms, while the dihedral angle formed by the phenyl ring is 1.95(2)° to the donor plane. The hexamethyleneiminyl ring adopts a chair conformation [$Q_T = 0.7269$ Å].

The dihedral angles formed by the least square planes Cg(1) and Cg(2) for the compounds support the distorted square planar conformation for these complexes, where greater distortion is observed for compound **2**. This small deviation from coplanarity would certainly not hinder the delocalization of electrons in the coordination sphere, and the stability of the complex is sustained.

The Ni–$N_{azomethine}$ bond lengths are shorter compared to the Ni–N_{base} bond lengths, indicating greater strength of the former bonds compared to the latter in the two complexes. The O1–Ni1–N1 bond angles are slightly greater compared to the similar Ni(II) ONS donor complexes [Ni(PTSC)(PPh_3)] 95.32(9)°, [Ni(PTSC)(PPh_3)].$CHCl_3$, 95.4(1)° [12] and [Ni($C_{18}H_{18}N_6O_2S_2$)](ClO_4)$_2 \cdot 2CH_4O$, 83.64(12)° [26], and the N1–Ni1–S1 bond angles are comparable. The N1–Ni1–S1 bond angles are greater compared to [Ni(Et-fbt)$_2$], 85.35(11)°, [Ni(fbt)$_2$], 84.90(10)° [27] and [Ni(NQTS)$_2$] · 2DMSO 81.47(16)° [28]. The C–$N_{azomethine}$ bond length is shorter compared to other C–N_{py} bond lengths in the complexes. This indicates that the bonding is dominated by the thiosemicarbazone moiety.

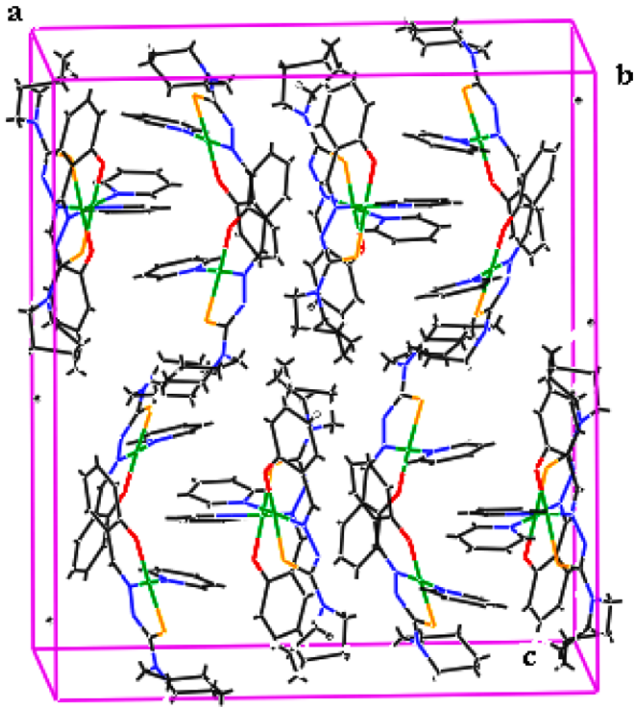

Fig. 3. Unit cell packing diagram of compound **2**.

In compound **2**, adjacent molecules are arranged in an offset manner within the unit cell when viewed along the *a* axis, as seen in Fig. 3, as a result of diverse π–π stacking, CH–π and hydrogen bonding interactions (Table 4).

The molecules of **3** are connected by various hydrogen bonding interactions and are arranged parallel along the *a* axis (Fig. 4). Though π–π interactions exist in the lattice of compound **3**, they are observed at distances greater than 4.0 Å, also there are no effective CH–π interactions (Table 5). adjacent molecules are arranged opposing directions within the unit cell.

3.2. Infrared spectra

The characteristic IR bands (50–4000 cm^{-1}) for the four free ligands differ from those of their complexes and pro-

vide significant indications regarding the bonding sites of the ligands. IR spectral assignments of the ligands and the complexes are listed in Table 6. A medium band in the range 3070–3160 cm^{-1} in the free ligands, due to the $\nu(^2NH)$ vibration, disappears in the spectra of the complexes, providing strong evidence for ligand coordination around the Ni(II) ion in its deprotonated form.

The IR spectra of the ligands H_2L^1 and H_2L^2 exhibit intermolecular hydrogen bonded ν(OH) vibrations at 3315 and 3232 cm^{-1}, respectively, which disappear in the spectra of the complexes except for **1**. It is further corroborated with the decrease in stretching frequency by 60–80 cm^{-1} for ν(CO) as well as the appearance of a band in the 410–430 cm^{-1} region due to a ν(Ni–O) stretch in the spectra of the complexes [29]. It indicates coordination *via* the phenolic oxygen. In complex **1**, the phenolic group is not coordinated to the metal. The non-involvement of the phenolic group of the same thiosemicarbazone ligand in a zinc complex [19] has been proven by us. However, there is X-ray crystal structure evidence for the existence of the phenol rather than the phenolate form in a closely related salicylaldehyde thiosemicarbazone [30], with the ligand acting as an ONS donor.

On coordination of the azomethine nitrogen, $\nu(C{=}N_{azo})$ shifts to lower wavenumbers by 10–20 cm^{-1}, as the band shifts from 1613 cm^{-1} in the uncomplexed thiosemicarbazone spectrum to ~1596 cm^{-1} in the spectra of the complexes. Coordination of the azomethine nitrogen is confirmed by the presence of a new band in the range 450–490 cm^{-1}, assignable to ν(Ni–N) for these complexes [31]. The ν(N–N) band of the thiosemicarbazone is found in the 1030–1075 cm^{-1} range. The increase in the frequency of this band in the spectra of the complexes, due to the increase in the bond strength, again confirms coordination *via* the azomethine nitrogen [19].

The bands in the ranges 1320–1340 and 835–865 cm^{-1} due to thioamide {which is partly $\nu(C{=}S)$} stretching and bending vibrations, respectively, of the free ligands are shifted to lower values, indicating coordination of the thiolate sulfur to the Ni(II) ion. This negative shift of ν(CS) in the complexes has already been indicated by Campbell [1]. Coordination *via* the thiolato sulfur is confirmed with the presence of a new band in the range 320–350 cm^{-1}, assignable to ν(Ni–S) for these complexes [32]. In all the Ni(II) complexes, another strong band is found in the range 1530–1540 cm^{-1}, which may be due to the newly formed $\nu(C{=}^2N)$ bond formed as a result of enolization. The IR spectra of the complexes, except **1**, display bands characteristic of coordinated heterocyclic bases [33].

3.3. Electronic spectra

The electronic spectral assignments of the ligands and their complexes are given in Table 7. The thiosemicarbazones show a ring $\pi \rightarrow \pi^*$ band at ~36000 cm^{-1} and an

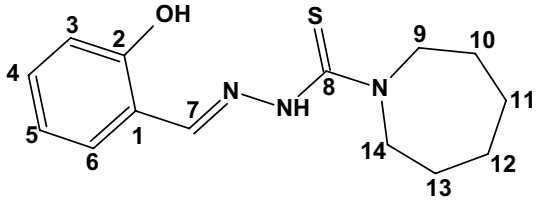

Fig. 5. The structure of the ligand H_2L^1 along with atom labelling scheme.

$n \rightarrow \pi^*$ band (involving transitions within the thiosemicarbazone moiety, mainly C(7)=N(1) and C(8)–S groups [16]) at ~30000 cm^{-1}. These bands are slightly shifted upon complexation. The shift of the $\pi \rightarrow \pi^*$ bands to a longer wavelength region in the complexes is the result of the C–S bond being weakened and the conjugation system being enhanced on complexation [34,35]. The $n \rightarrow \pi^*$ bands in the complexes show a blue shift due to donation of the lone pair of electrons to the metal and hence the coordination of the azomethine with a reduction of intensity.

In the case of complexes having ONS donor ligands, two ligand to metal charge transfer bands are found in the 25000–28000 and 23000–24500 cm^{-1} ranges. Their positions are dependent on the steric requirements of the N(4) substituents. That is, thiosemicarbazones with bulkier N(4)-substituents have these bands at somewhat higher energies. In most of the dianionic complexes, LMCT maxima of the phenolate complexes show line broadening with a tail running into the visible part of the spectrum. This may result from a phenolate to Ni(II) LMCT band being superimposed on the low energy side of the S → Ni(II) LMCT. Each complex has a broad d–d combination band that appears as a shoulder on the intraligand and charge-transfer bands. These nickel complexes show a trend of increasing size of the N(4)-substituent and lower energy of the d–d band maximum, presumably due to weakening of the coordinate bonding with increased bulkiness of the ligands. The absence of bands below 10000 cm^{-1} confirms the square planar nature of the complexes [36,37].

3.4. ^1H NMR spectra

The numbering scheme used in the ^1H NMR spectrum of the ligand H_2L^1 is given in Fig. 5 and the spectra of the complexes **1** and **4** are given in Figs. 6 and 7. The ^1H NMR spectrum of the ligand H_2L^1 has been discussed earlier [19]. ^1H NMR spectral assignments of the ligand and its Ni(II) complexes **1** and **4** are given in Table 8. The signals for ^2NH are absent from the spectra of these complexes, as expected, and the phenolic OH is absent in the spectrum of complex **4** because of its loss on complex formation, which is an evidence for the coordination of the ligand as a doubly deprotonated anion. The spectra of complexes **1** and **4** show a sharp singlet which integrates as one hydrogen at δ 7.44 and 7.83 ppm,

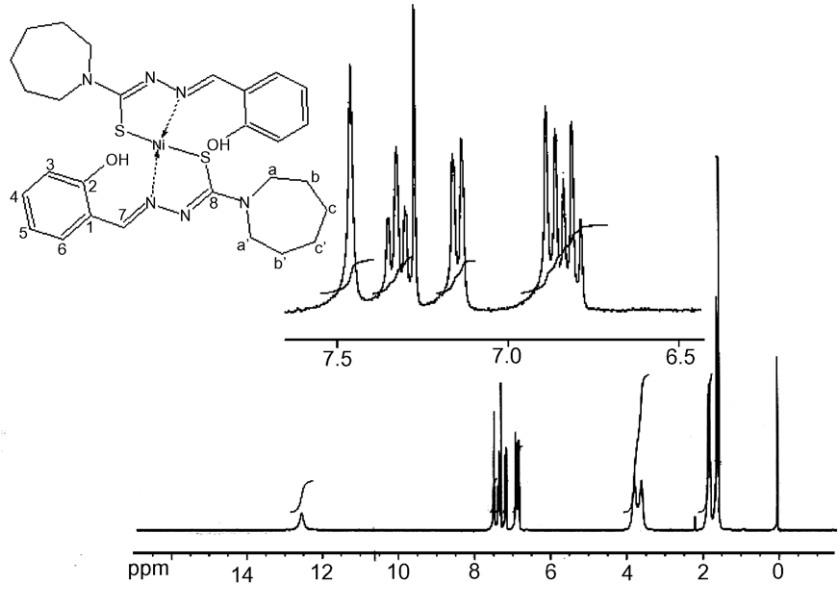

Fig. 6. ^1H NMR spectrum of compound **1**.

Table 8
^{1}H NMR ($CDCl_3$) assignments of the ligand H_2L^1 and its Ni(II) complexes (δ in ppm)

Compound	OH	Aromatic protons				^{8}CH=	^{a}CH$_2$	^{b}CH$_2$	^{c}CH$_2$
		H^6Ph	H^4Ph	H^3Ph	H^5Ph				
H_2L^1	11.3	7.09	6.97	6.80	6.67	7.99	3.63	1.66	1.42
$[Ni(HL^1)_2]$ (**1**)	12.51	7.45	7.31	7.13	6.82	7.45	3.67	1.79	1.56
$[NiL^1\gamma\text{-pic}]\cdot H_2O$ (**4**)		7.25	7.18	7.14	6.80	7.83	3.61	1.74	1.55

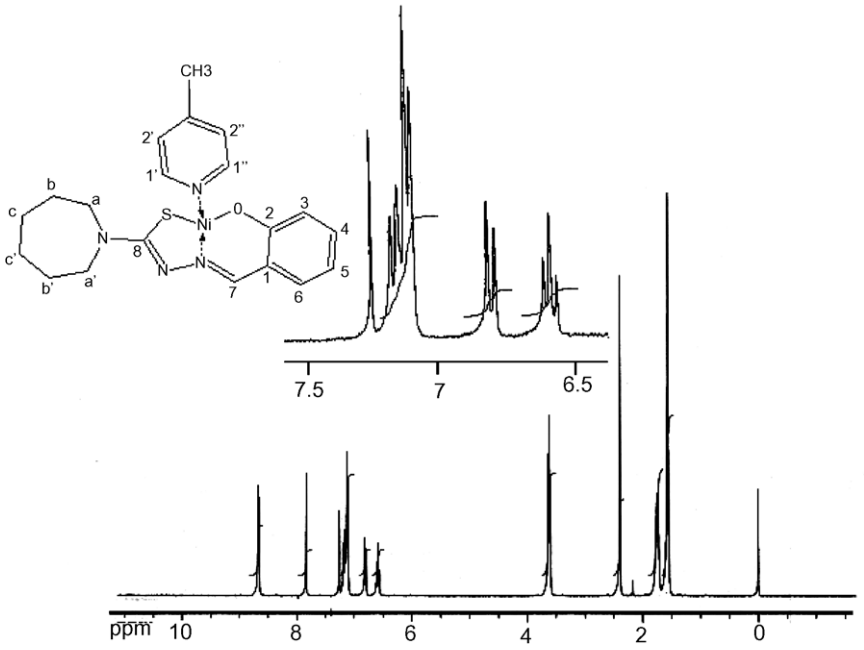

Fig. 7. ^{1}H NMR spectrum of compound **4**.

respectively, corresponding to ^{7}CH= present in the thiosemicarbazone moiety. Complex **1** shows a peak at δ 12.51 ppm due to the presence of the uncoordinated hydroxyl group. The more downfield shift of the OH protons compared to the uncomplexed thiosemicarbazone may be due to the overall loss of electron density and hydrogen bonding interactions. The ^{1}H NMR spectrum of **1** shows a multiplet which integrates as two hydrogens at δ *ca.* 6.82 ppm and is assigned to the protons attached to ^{3}C and ^{5}C of the phenyl ring. ^{4}CH and ^{6}CH protons of the phenyl ring appear at δ 7.13 and 7.31 ppm, respectively. In complex **4**, the protons of the aromatic ring ^{3}CH and ^{5}CH appear at δ 6.58 and 6.80 ppm. The spectrum also shows a multiplet which integrates as four hydrogens at δ *ca.* 7.15 ppm, corresponding to ^{4}CH, ^{6}CH and the base protons $H^{2'}$ and $H^{2''}$. The upfield shift of these base protons may be due to the presence of the electron releasing methyl group present in the pyridine ring. The heterocyclic base protons ($H^{1'}$ and $H^{1''}$) are present as a doublet, which integrates as two hydrogens at δ 8.66 ppm. The downfield shift of these protons may be the result of the withdrawal of electron density from the thiosemicarbazone moiety and the heterocyclic base, due to coordination with the metal atom [38]. Methyl protons appear as a singlet at δ 2.38 ppm (see Fig. 7).

Abstract

The synthesis and characterization of several new bis(1-alkenyl)platinum(II) complexes have been carried out. The structure of *cis*-[Pt(dppp)($(CH_2)_6CH{=}CH_2)_2$] has been determined by X-ray crystallography. The stability and reactivity of the compounds, *cis*-[$PtL_2((CH_2)_nCH{=}CH_2)_2$] ($n = 3$ or 4 and L_2 = 1,3-bis(diphenylphosphino)propane (dppp), 1,2-bis(diphenylphosphino)ethane (dppe), L = PPh_3) is strongly dependent on the nature of ligand systems. It is found that the insertion of carbon monoxide into the metal–carbon bonds of the platinum alkenyl complexes is possible. Other reactions including transmetalation, intermolecular alkenyl migrations, oxidative addition of methyl iodide are described and the thermal decomposition of the bis(alkenyl) complexes are also reported.

Keywords: Bis(alkenyl) complexes; Structure; Reactivity; Insertion reactions; Oxidative addition; Transmetalation

1. Introduction

Metal–alkenyl complexes are an important class of compounds. These compounds have been implicated as potential model compounds for intermediates in a number of catalytic cycles as well as other applications [1]. Metal–alkenyl complexes have been shown to act as precursors for the preparation of thin metal films, which can in turn be applied in the micro-electronics and catalysis industries [2]. Recently we have shown that bis(1-alkenyl)platinum complexes undergo a novel ring closing metathesis (RCM) reaction to give medium to large metallacycles [3–5]. Selective and quantitative isomerization of *cis*-[PtL_2(1-alkenyl)$_2$] to *cis*-[PtL_2(2-alkenyl)$_2$] complexes has also been observed [6]. In order to explore the reactivity pathways for these complexes, we have investigated some novel reactions of platinum alkenyl complexes. The present paper also explores the influence of the nature of phosphine ligands on the reactivity aspects of the title compounds.

2. Experimental

2.1. Materials and methods

All manipulations were carried out under a nitrogen atmosphere unless otherwise stated. Commercially available solvents were distilled from Na metal/benzophenone ketyl before use.

2.1.1. Nuclear magnetic resonance spectroscopy

^1H, ^{13}C and ^{31}P NMR spectra were recorded on a Bruker DMX-400 spectrometer and all ^1H chemical shifts are reported relative to the residual proton resonance in deuterated solvents (all at 298 K, C_6D_6).

2.1.2. Elemental analysis

Microanalyses were conducted with a Thermo Flash 1112 Series CHNS-O Elemental Analyzer instrument.

2.1.3. GC–MS analysis

GC analyses were carried out using a Varian 3900 gas chromatograph equipped with an FID and a 30 m × 0.32 mm CP-Wax 52 CB column (0.25 μm film

thickness). The carrier gas used was helium at 5.0 psi. The oven was programmed to hold at 32 °C for 4 min and then to ramp to 200 °C at 10 °C/min and then hold for 5 min. GC–MS analyses for peak identification were performed using an Agilent 5973 gas chromatograph equipped with MSD and a 60 m × 0.25 mm Rtx-1 column (0.5 μm film thickness). The carrier gas was helium at a flow rate of 0.9 ml/min. The oven was programmed to hold at 50 °C for 2 min and then ramp to 250 °C at 10 °C/min and then hold for 8 min.

2.1.4. Infrared spectroscopy

Infrared spectra were recorded on a Perkin–Elmer Spectrum One FT-IR Spectrometer.

2.1.5. Materials

All chemicals were obtained commercially and unless otherwise stated, were used as received without further purification. 1-Alkenyl Grignard reagents ($BrMgCH_2CH_2(CH_2)_nCH{=}CH_2$; $n = 1, 3, 4, 6$) [7], $Pt(COD)Cl_2$ [8], $Pt(dppe)Cl_2$, [9] $Pt(dppp)Cl_2$, [9] and $Pt(PPh_3)_2Cl_2$ [9] were prepared according to the literature procedures. Bis(1-octenyl)(dppp)platinum(II) (**1**), bis(1-hexenyl) *cis*- bis(triphenylphosphine)platinum(II) (**2**), bis(1-hexenyl)(dppp)platinum(II) (**3**), bis(1-pentenyl)*cis*-bis(triphenylphosphine)platinum(II) (**4**) and bis(1-pentenyl)(dppp)-platinum(II) (**5**) were prepared as reported earlier [4].

2.1.6. Crystallographic data for compound *1*

Single crystals of compound **1** were obtained by recrystallization and slow evaporation from Et_2O at room temperature. Intensity data for the compound **1** was collected at 113 K on a Nonius Kappa CCD diffractometer using graphite- monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). $C_{43}H_{56}P_2Pt$, $M = 829.91$, triclinic, $P\bar{1}$, $a = 12.59740(10)$, $b = 12.98700(10)$, $c = 14.5363(2)$ Å, $\alpha = 110.3300(10)°$, $\beta = 90.6480(10)°$, $\gamma = 117.1230(10)°$, $V = 1943.33(3)$ Å^{-3}, $Z = 2$, $\mu = 3.720$ mm^{-1}, unique reflections = 55 624/7391 [R(int) = 0.0467], $R_1 = 0.0210$, $wR_2 = 0.0433$ [$I > 2\sigma(I)$].

2.2. Synthesis of the metal complexes

2.2.1. Preparation of bis(1-pentenyl)(dppe)platinum(II) (*6*)

$Pt(COD)Cl_2$ (506 mg, 1.352 mmol) in diethyl ether (20 ml) was cooled to −78 °C and of 1-pentenyl Grignard reagent (2.8 ml, 1.34 M, 3.75 mmol) was added. The solution was warmed to 0 °C and then stirred until the solution became clear. To this, solution dppe (539 mg, 1.353 mmol) was added and stirred for 30 h until a clear solution was formed. The excess Grignard reagent was removed by hydrolyzing the reaction mixture with saturated aqueous NH_4Cl (5 ml) at −78 °C. The aqueous layer was washed with dichloromethane (2 × 5 ml), dried with anhydrous magnesium sulfate and filtered. The solvent was removed under reduced pressure and the residue recrystallized from a CH_2Cl_2/hexane mixture (3 ml: 5 ml) at −10 °C for 48 h. The pale yellow crystalline solid was separated by decanting the mother liquor and dried under vacuum for 3 h. For compound **6**. Yield: 96%. M.p. 84–85 °C. *Anal*. Calc. for $C_{36}H_{42}P_2Pt$: C, 59.09; H, 5.79. Found: C, 58.98; H, 5.69%. IR (ν_{max}/cm^{-1}) in CH_2Cl_2: 1605(m), 1636(s); ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.36–7.91 (m, 20H, Ph); 5.55–5.72 (m, 2H, =CH); 4.68–4.82 (m, 4H, $=CH_2$); 1.96–2.22 (m, 4H, P-CH_2); 1.21–1.88 (m, 12H, –CH_2);^{13}C NMR (100 MHz, $CDCl_3$) δ: 141.01 (s, 2C);133.16–133.29 (m, 12C); 129.98 (s, 8C) 127.55–128.32 (m, 4C); 112.40 (s, 2C); 32.08–32.56 (m, 2C); 30.88 (s 2C); 29.03–29.79 (m, 2C); 22.57 (d, $J = 6.67$ Hz 2C) 21.60 (d, $J = 6.58$ Hz), $^{31}P\{^1H\}$ 45.76 (s) ($J_{Pt-P} = 1641$ Hz).

2.2.2. Carbonylation of compound 6

Compound **6** (262 mg, 0.358 mmol) was dissolved in toluene (25 ml) of. After bubbling CO through the contents of the flask for 5–6 min, the solution was stirred at room temperature under ambient pressure of carbon monoxide (balloon). After 72 h, the solvent was removed under the reduced pressure. The residue was filtered and recrystallized from a CH_2Cl_2/hexane mixture (2:1 v/v) to give compound **10a**. Yield: 62%. M.p. 118–126 °C. *Anal*. Calc. for $C_{38}H_{42}O_2P_2Pt$: C, 57.94; H, 5.37. Found: C, 58.16; H, 5.42%. IR (ν_{max}/cm^{-1}) in CH_2Cl_2: 1608(m), 1680(s). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.24–7.91 (m, 20H, Ph); 5.54–5.69 (m, 2H, CH); 4.61–4.80 (m, 4H, $=CH_2$); 1.98–2.40 (m, 4H, P–CH_2); 1.16–1.86 (m, 12H, CH_2); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 206.78 (s, 2C); 140.92 (s, 2C); 133.21–133.58 (m, 12C); 129 (s, 8C); 126.71–128.37 (m, 4C); 112.30 (s, 2C); 31.55 (m, 2C); 30.87 (s, 2C) 25.10 (d, $J = 8.66$ Hz); 24.14 (d, $J = 8.71$ Hz) $^{31}P\{^1H\}$ 46.00 (s) ($J_{Pt-P} = 2320$ Hz).

2.2.3. Carbonylation of compound *1*

A similar procedure was followed by taking compound **1** (61 mg, 0.073 mmol) in a round bottom flask containing toluene (15 ml). The reaction was carried out and worked-up as described above to give compound **10b** as colourless crystals. Yield: 86%. M.p. 104–105 °C. *Anal*. Calc. for $C_{45}H_{56}O_2P_2Pt$: C, 61.01; H, 6.37. Found: C, 61.16; H, 6.42%. IR (ν_{max}/cm^{-1}) in CH_2Cl_2: 1605(m), 1676(s). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.21–7.97 (m. 20H, Ph); 5.40–5.70 (m, 2H, =CH); 4.63–4.73 (m, 4H $=CH_2$); 1.99–2.15 (m, 6H, P–CH_2); 1.23–1.92 (m, 24H, CH_2).

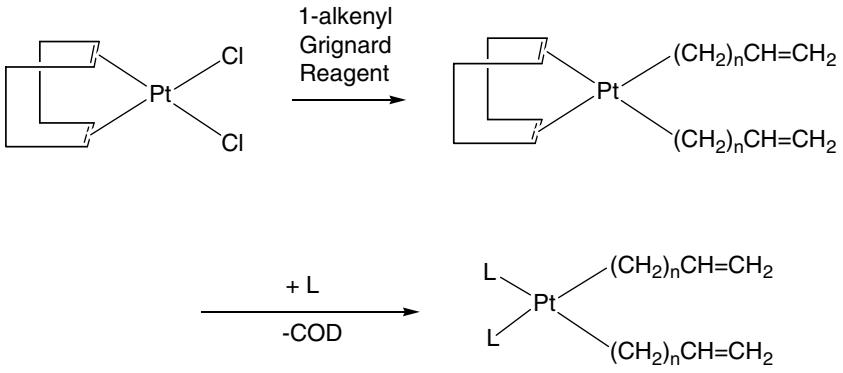
2.2.4. Reaction of $Pt(1\text{-pentenyl})_2(PPh_3)_2$ (*4*) with $[Cp^*IrCl_2]_2$

Compound **4** (232 mg, 0.271 mmol) and $[Cp^*IrCl_2]_2$ (0.104 mg, 0.135 mmol) were transferred into a Schlenk flask containing toluene (5 ml). The mixture was heated for 3 h at 85–90 °C. A colourless precipitate was formed during the reaction. The solvent was removed in vacuo. The mixture was treated with diethylether (5 ml). The insoluble crystalline solid was found to be a mixture of $[Pt(PPh_3)_2Cl_2]$ and $[IrCp^*(PPh_3)Cl_2]$. The products **13** and

14 from the solution were separated by using a *p*-TLC with CH_2Cl_2 as an eluent. The pale yellow band was extracted and compound **13** was obtained as a yellow oily substance (48 mg). The oil was treated with *n*-hexane (3 ml) and on cooling a yellow solid resulted which was shown to be compound **13**, bis(1-pentenyl)(tetramethylcyclopentadienyl)iridium(III)- (triphenylphosphine) Yield: 50%. M.p. 66–68 °C. *Anal.* Calc. for $C_{37}H_{46}IrP$: C, 62.24; H, 6.49. Found: C, 62.43; H, 6.59%. ^1H NMR (300 MHz, $CDCl_3$) δ: 6.99–8.10 (m, 15H, Ph); 5.63–5.94 (m, 2H, =CH); 4.88–5.13 (m, 4H, $=CH_2$); 4.19 (s, 1H, Cp^*–H); 0.76–2.12 (m, 12H, CH_2); $^{31}P\{^1H\}$ 25.88 (s).

2.2.5. Reaction of Pt(1-pentenyl)$_2$ (dppp) (5) with $[Cp^*IrCl_2]_2$

Compound **5** (202 mg, 0.272 mmol) and $[Cp^*IrCl_2]_2$ (0.105 mg, 0.136 mmol) were taken in to a Schlenk flask containing toluene (15 ml). The mixture was heated for 13 h at 85–90 °C. The colourless precipitate that formed during the reaction was found to be compound **11**, (η^3-dimethylallyl)[1,3-bis(diphenyl phosphino)propane]-platinum(II)chloride. Yield: 68%. M.p. 144–146 °C. *Anal.* Calc. for $C_{32}H_{35}P_2PtCl$: C, 53.97; H, 4.95. Found: C, 54.16; H, 4.88%. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.23–7.78 (m, 20H, Ph); 3.30–3.87 (m, 3H, allylic-H); 2.17–2.67 (m, 4H, P–CH_2); 1.09–1.17 (m, 6H, CH_2); $^{31}P\{^1H\}$ −1.32 (s) (J_{Pt-P} = 3828 Hz). All the solvent was removed from the solution and the obtained pale yellow solid was recrystallized from 1:1 *n*-hexane-diethylether mixture to yield the compound **12**. Yield: 75%. M.p. 108–112 °C. *Anal.* Calc. for $C_{14}H_{22}IrCl$: C, 40.23; H, 5.31. Found: C, 40.46; H, 5.36%. ^1H NMR (300 MHz, $CDCl_3$) δ: 4.43 (s, 1H, Cp–H); 3.95 (m, 1H, CH); 2.95 (m, 1H, **CH**–CH_3); 2.20 (m, 2H, –CH_2), 1.81 (s, 12H, Cp–CH_3), 1.52–1.61 (m, 2H, CH_2); 0.92–1.06 (m, 3H, CH_3).



2.2.6. Reaction of Pt(1-pentenyl)$_2$ (dppp) (6) with MeI

Compound **6** (304 mg, 0.415 mmol) and 118 mg of MeI (0.832 mmol) were taken in to of CH_2Cl_2 (5 ml). After stirring at room temperature for 72 h, a pale yellow precipitate was formed. The precipitate was washed with diethylether (5 ml) and recrystallized from CH_2Cl_2–hexane mixture (1:1). The product was found to be compound **9b**. The product **9a** was isolated from the solution. After removing the solvent, the compound was recrystallized from a mixture of toluene (2 ml) and hexane (1 ml). The liquid product was found to be 5-iodo-1-pentene. For compound **9a**, (1-pentenyl)(methyl)[1,2-bis-(diphenylphosphino)ethane] platinum(II). Yield: 52%. M.p. 110–112 °C. *Anal.* Calc. for $C_{32}H_{36}P_2Pt$: C, 56.72; H, 5.35. Found: C, 56.66; H, 5.62%. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.18–7.92 (m, 20H, Ph); 5.69–5.86 (m, 1H, =CH); 4.77–4.98 (m, 2H, $=CH_2$); 1.85–2.29 (m, 4H, P–CH_2); 1.15–1.67 (m, 6H, CH_2); $^{31}P\{^1H\}$ δ 45.96, 45.91 (d), 45.76, 45.70 (d) (1685 and 1635 Hz).

3. Results and discussion

3.1. Synthesis and characterization of compounds

The bis(alkenyl)–platinum complexes were prepared in high yields by reacting the appropriate Grignard reagents with $Pt(COD)Cl_2$. Several derivatives of these compounds were synthesized using various ligand systems, mainly, PPh_3, dppe and dppp (Scheme 1). All the data gathered for compounds (**1–6**) are consistent with the proposed formulations. The ^1H NMR spectra exhibit signals which are characteristic of species containing a vinylic functionality, while the ^{31}P NMR spectra showed sharp singlets with their respective platinum satellites. Single crystals of compound **1** were obtained by recrystallization from Et_2O at room temperature. Crystallographic data are listed

1, L_2 = dppp, n = 6;
2, L = PPh_3, n = 4;
3, L_2 = dppp, n = 4;
4, L = PPh_3, n = 3;
5, L_2 = dppp, n = 3;
6, L_2 = dppe, n = 3.

Scheme 1.

Table 1
Selected bond distances (Å) and angles (°) of compound **1**

Bond distances			
Pt(1)–C(61)	2.119 (3)	C(56)–C(55)	1.526 (4)
Pt(1)–C(51)	2.120 (3)	C(65)–C(66A)	1.5207 (7)
Pt(1)–P(1)	2.2766 (7)	C(57)–C(58)	1.292 (5)
Pt(1)–P(2)	2.2873 (7)	C(68A)–C(67A)	1.211 (7)
Bond angles			
C(61)–Pt(1)–C(51)	85.05 (10)	C(51)–Pt(1)–P(1)	89.86 (8)
C(61)–Pt(1)–P(2)	91.98 (7)	C(61)–Pt(1)–P(1)	174.78 (7)
P(1)–Pt(1)–P(2)	92.97 (2)	C(51)–Pt(1)–P(2)	173.58 (7)

in Section 2, and selected bond distances and angles are given in Table 1.

The molecular structure of compound **1** (Fig. 1) shows square-planar coordination geometry around the platinum. The Pt–C and Pt–P bonds of compound **1** are similar and comparable with the literature reports of similar compounds [10](2.119(3)–2.120(3) Å and 2.2766(7)–2.2873(7) Å, respectively), while the C=C distances range from 1.211(7) to 1.292(5) Å. The P–Pt–P, P–Pt–C and C–Pt–C bond angles in compound **1** are observed as 92.97(2), 89.86(8) to 91.98(7) and 85.05(10), respectively.

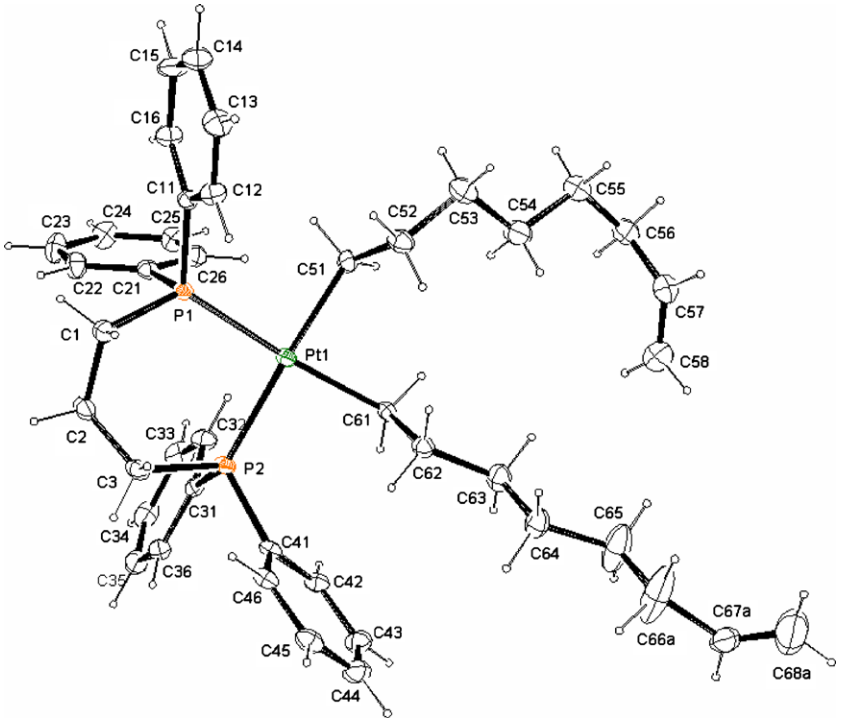
3.2. Reactivity of metal–alkenyl complexes

Generally, metal alkenyl complexes can show two distinct reaction pathways: (i) reaction at the M–C bond (ii) coordination of the pendant alkene. It is interesting to note that these special features impart novel chemistry to these compounds [1a].

The interaction of metal–alkenyls with electrophilic reagents such as acids and halogens gives the corresponding hydrocarbons or 1-haloalkenes resulting from the cleavage of metal–carbon bonds and the hydrogenation and hydroformylation reactions of some metal alkenyl compounds have been reported with the Lewis acid $TiCl_4$ [1b], we explored other novel reactions with various substrates. The group 10 metal-catalyzed cross-coupling reactions are very important in organic synthesis through oxidative addition, transmetallation, and reductive elimination steps [11]. Some of these reactions may have considerable potential in chemical synthesis, since they provide a method for the formation of new C–C bonds by reductive elimination or formation of C–X bonds. The effect of the length of the alkenyl chains, the influence of the solvent as well as the nature of ligand systems on the reactivity of the title compounds will be discussed.

3.3. Thermal decomposition and rearrangement reactions

Although thermal decomposition pathways of metal–alkenyl complexes may be similar to those of metallacycles or metal alkyl complexes, the products formed can differ considerably because of the pendant alkene functionality. The thermal stability of the metal–alkenyl complexes is dependent on the solvent system, thus halogenated solvents readily cleave the M–C bond to form metal halides irrespective of the ligand system. Bis(alkenyl) metal complexes can give various products on decomposition (Scheme 2).



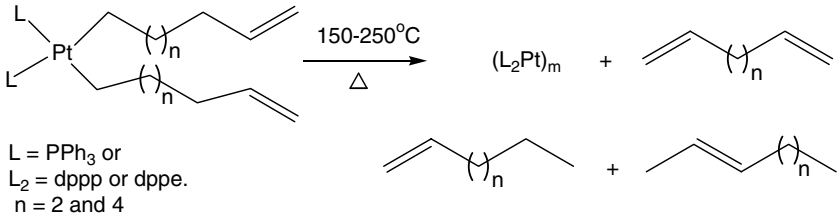


Fig. 1. Molecular structure and atom labeling scheme for compound **1**. Displacement ellipsoids are drawn at the 40% probability level and H atoms are shown as small spheres of arbitrary radii. Atom C67 was disordered over two positions: C67A with Site Occupancy 0.535 and C67B with Site Occupancy 0.465.

Scheme 2.

Our present experiments show that the organic products depend on the nature of the ligands, and this may relate to the stability and reactivity of the metal–alkenyl compounds in solution. Thus the triphenylphosphine complexes, $Pt(PPh_3)_2\{(CH_2)_nCH{=}CH_2\}_2$ were found to yield an intense red colour on decomposition which we believe to be due to $[(PPh_3)2Pt]_m$ clusters. In contrast, the $PtL_2[(CH_2)_3CH{=}CH_2]_2$ complexes (where $L_2 = $ dppp or dppe) were found to be quite stable up to 100 °C [6]. The diphosphine ligands have generally been found to increase the thermal stability of the complexes significantly. It is also believed that metal alkenyl species may be important intermediates in the decomposition of metallacycloalkanes through β-hydride elimination [12,13].

Several interesting trends were noted in the products isolated from the thermolysis reactions. First, all the decomposition reactions showed the presence of 2-alkene and cycloalkane as major components. Second, the organic product distributions are quite dependent on the time of heating as well as the medium of reaction whether in the solid state or in solution (Table 2). It can be seen that there is a significant decrease in the quantities of 1-alkene species with increasing the time of heating, with the exception of PPh_3 derivatives, which is in agreement with earlier reports [6]. Further thermal studies will be carried out to try and understand the mechanistic aspects for the formation of the organic products in these reactions.

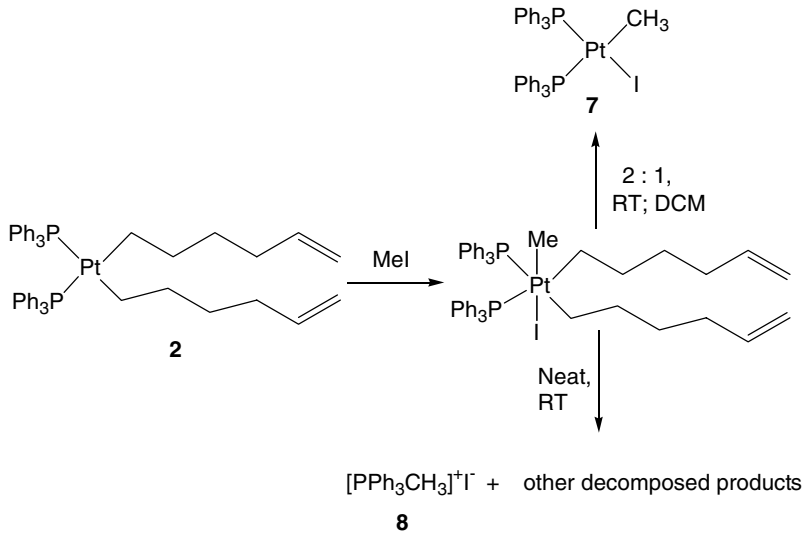

Table 2
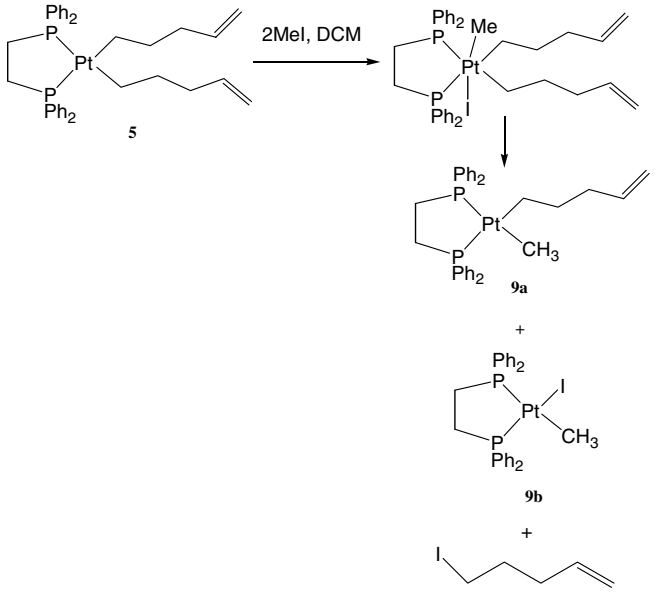
Thermal decomposition of bis(1-hexenyl)(dppp)platinum(II) (**3**), at 175 °C

Medium	Observed products (%)*				
	n-Hexane	1-Hexene	2-Hexene (*cis*- + *trans*-isomers)	Cyclohexane	1,5-Hexadiene
Solid					
1 h	25	8	41	14	11
3 h	2	0	63	22	12
10 h	1	0	63	18	8
24 h	0	0	71	21	8
CH_2Cl_2	14	0	83	3	1



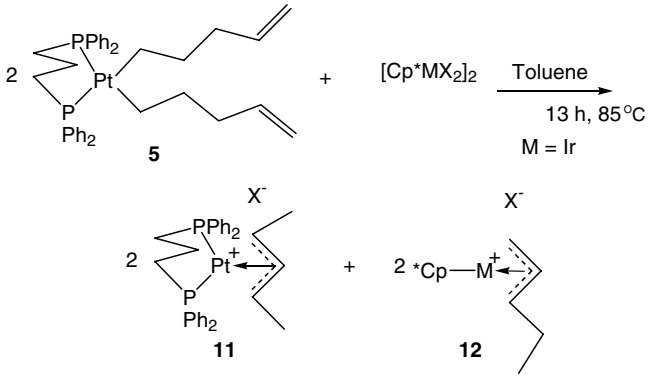
By GC–MS analysis.

3.4. Oxidative addition

The oxidative addition of organic molecules to unsaturated transition metal complexes is a fundamental process in organometallic chemistry and catalytic reactions [14]. It was found that the bis(alkenyl)platinum(II) complexes undergo oxidative addition reactions with methyl iodide to yield different products, depending on the experimental conditions (Schemes 3 and 4). It is presumed that the reaction proceeds via the formation of hexacoordinate platinum(IV) species by oxidative addition as reported earlier

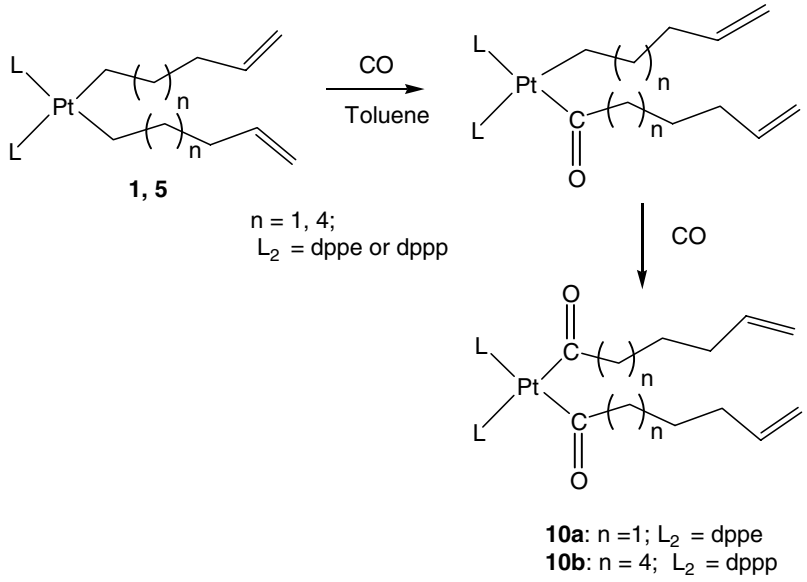
Scheme 3.

Scheme 4.



products. In contrast, the presence of excess MeI showed the quantitative formation of the known methylphosphonium iodide salt (**8**). The decomposed products could not be identified or isolated. The formation of the new compound **9a** (15%) and known compound **9b** (41%) [16] were evident when the ligand was dppe in the presence of 1:2 MeI (Scheme 4). The formation of 5-iodo-1-pentene (32%) was also confirmed. It is of interest to note that the addition of MeI allowed the formation of a new metal–carbon bond and breaking of already existing metal–carbon bond simultaneously, this is significant. The nature of ligand systems show a marked effect in oxidative addition reactions, which may be due to differences in steric, electronic and chelating effects in the ligands.

3.5. Carbonylation



Carbon monoxide insertion into M-alkyl as well as M-acyl bonds to form M-acyl as well as α-ketoacyl complexes

[15]. The organic products were found to be 1-alkenes, 2-alkenes and α,ω-dienes. Attempts to isolate these intermediate hexacoordinate platinum(IV) species were unsuccessful.

Surprisingly, the oxidative addition of MeI to compound **2** afforded different products depending on the experimental conditions and ligand systems (Scheme 3). It is of interest to note that when MeI was allowed to react with **2** in 2:1 molar ratio, a 70% of known compound $Pt(PPh_3)_2MeI$ (**7**) [16] was isolated. The major organic products were found to be 1-hexene (56%), 2-hexene (23%), 1,5-hexadiene (5%) as well as other unidentified

Scheme 6.

Scheme 5.

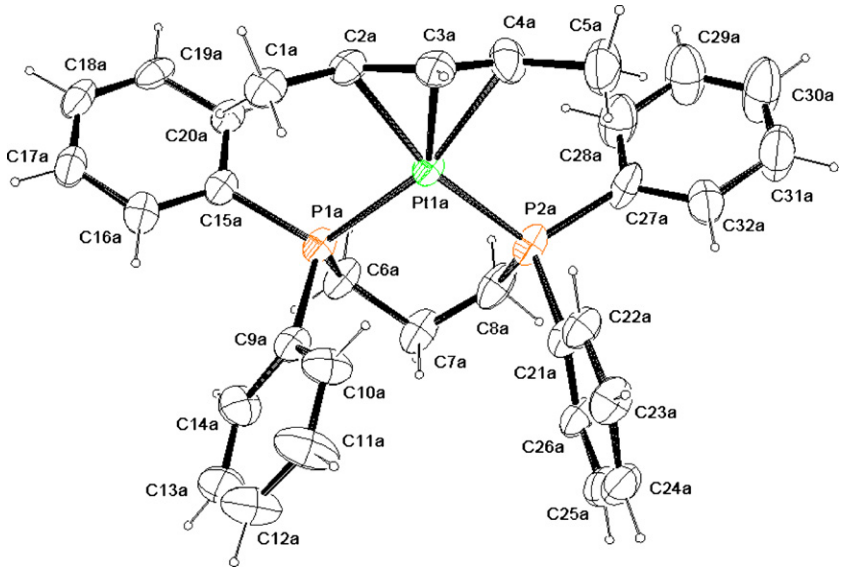


Fig. 2. Molecular structure and atom labeling scheme for the cationic part of the compound **11**, showing one of the two unique molecules (A and B) with the atom-numbering scheme; the suffix a denotes the crystallographically independent molecule A. Displacement ellipsoids are drawn at the 25% probability level and H atoms are shown as small spheres of arbitrary radii.

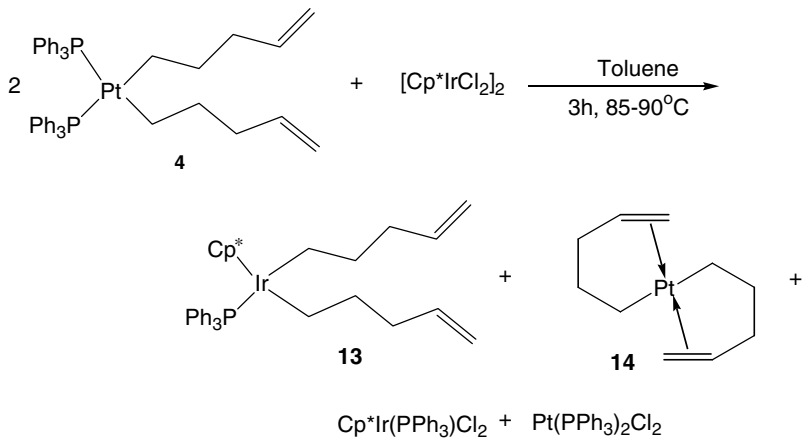
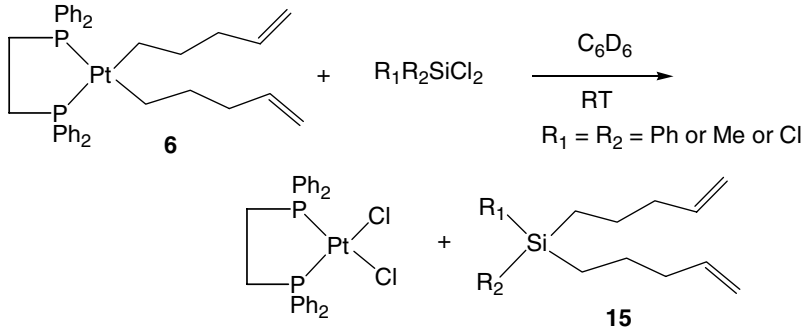
is well known in the literature [14,17]. It was found that the reaction of carbon monoxide with the bis(pentenyl)platinum(II) complex $L_2Pt[(CH_2)_3CH{=}CH_2]_2$ ($L_2 = dppe$) afforded the expected di(acyl) inserted products **10a** while the reactions with other bis(pentenyl) complexes gave unidentified products ($L_2 = COD$). The ^1H NMR spectra of the reaction mixture ($L = PPh_3$ and $L_2 = dppp$) showed very complex signals indicating the presence of the monoacyl intermediate, which was identified by the characteristic ^{31}P NMR spectrum. However, the reaction smoothly proceeds to the formation of compound **10a** over time. This was evidenced by the ^{13}C NMR which shows a signal in the region of δ 206.8 ppm for the carbonyl carbon as well as a signal at δ 31.5 ppm corresponding to the carbon α to the carbonyl carbon. The IR spectral analysis of the reaction mixture also indicated the presence of bands corresponding to the coordinated CO, which may be due to the replacement of PPh_3 with CO ligands, when $L = PPh_3$. A solution of compound **1** in toluene was subjected to carbonylation with carbon monoxide gas at room temperature. This resulted in the insertion of CO into the Pt–C σ bond to afford the di-acyl product as a colourless crystalline solid after 48 h (Scheme 5). Two strong IR bands at 1605 cm^{-1} (C=C) and 1676 cm^{-1} (C=O) were observed in the spectrum of compound **10b**.

3.6. Transmetalation reactions



Transmetalation is a fundamental step in cross-coupling chemistry [11]. Various transmetalation reactions of group 10 metal halide complexes with organoboronic acid or organometallic reagents have received recent attention [18,19]. Clarke and Heydt have reported the importance of ligand steric effects on transmetalation reactions of some organometallic complexes [20].

The diphosphine ligand system allowed the quantitative formation of allylic metal complexes after reaction of compound **5** with the dimeric sandwich compounds of iridium (Scheme 6). Products **11** and **12** were isolated from diethylether solution and characterized by spectroscopically. Compound **11** was also characterized by X-ray analysis, but the structure was not fully refined.[1]



The Pt–P bonds of compound **11** are found to be 2.261(2) and 2.265(2) Å, while the Pt–C bond distances range from 2.156(10)–1.266(3) Å (Fig. 2). Strikingly, the distance between central allylic carbon (C_3) and metal is the shortest. The allylic carbon–carbon distances (C_2–C_3 and C_3–C_4), ranging from 1.349(18) to 1.427(16), showed the nature of double bond and the other C_1–C_2 and C_4–C_5 distances are found to be single bonds. The P–Pt–P, P_1–Pt–C_2 and C–Pt–C bond angles in compound **11** are observed as 94.69(11), 98.0(3) and 66.9(5), respectively.

In contrast, the PPh_3 ligand system shows a different trend in the reactivity by forming unexpected compounds **13** and **14** (Scheme 7). The compound can be easily assigned in the ^{31}P NMR, showing a signal at 26.4 ppm

[1] The cationic part of the structure was completely solved, but we failed to solve the counter anion because there were unidentified discrete solvent molecules in this structure. However, the positions for the atoms of cationic part of the compound 11 molecules were unambiguously placed and refined with reasonable anisotropic displacement parameters. The final *R* factor of 0.0591 is acceptable. We therefore report this structure here. The parameters for crystal data collection and structure refinements are in Table 1. The bond lengths, angles, torsion angles and other molecular parameters are in Table 2–6 (see supporting information for the tables and other details about the data collection).

Scheme 7.

Scheme 8.

without any satellites. $Pt(PPh_3)_2Cl_2$ and $Cp*Ir(PPh_3)Cl_2$ were also recovered from the reaction mixture as insoluble solids from a benzene solution. All these products were isolated and characterized. Data for compound **14** was in agreement with the literature [21].

3.7. Alkenyl group migration reactions

The reaction of platinum(II)-alkenyls with halosilanes yielded the corresponding alkenyl silane products (Scheme 8), with quantitative migration of the alkenyl chains from the platinum to the silicon center. In all the reactions, the products were isolated and identified. The characterization of compound **15** is in agreement with previously reported data [22].

4. Conclusions

Various reactions of bis(alkenyl) platinum complexes have been carried out and shown to yield interesting products. The chelating effect of diphosphine ligands is shown to affect the stability as well as the reactivity aspects of these title compounds significantly. It was also found that these compounds decomposed in the presence of halogenated solvents under light or heat. The length of alkenyl chains did not influence the reactivity of the alkenyl complexes. Studies are in progress which should yield information regarding further reactivity aspects and mechanisms of reactions of these platinum(II) alkenyls and other metal alkenyl compounds. Furthermore the scope of other insertion reactions in the presence of, oxygen, sulphur dioxide, carbon dioxide and elemental sulphur will be explored which may lead to produce some interesting organic products.

Abstract

New tetraruthenated manganese (III) porphyrins were synthesized and characterized (^{31}P NMR, cyclic voltammetry, UV–Vis). This new system presents four units of cationic "[RuCl(dppb)(X-bipy)]$^{+}$". The electrochemical and catalytic properties of the central manganese (III) show dependence on the characteristics of the peripheral ruthenium complexes as evidenced by the $Mn^{(III)}/Mn^{(II)}$ reduction potential.

The catalytic oxidation reactions of olefins, cyclohexene and cyclohexane, were carried out in the presence of tetrapyridyl manganese (III) porphyrins containing cationic ruthenium complex and using iodosylbenzene as oxygen donor. The performance of these new tetraruthenated porphyrins systems were evaluated and compared with the manganese porphyrin.

Keywords: Tetraruthenated porphyrins; Manganese porphyrins; Oxidation catalysis

1. Introduction

The metalloporphyrins are widely studied due to their participation in biological systems promoting, for example, oxygen transport, electron transferences and of note are the studies on mimetic catalytic oxidation reactions [1,2]. The primordial factor of these reactions is related to the formation of high valence Mn^{IV}=O and Mn^{V}=O species [3–6] via oxygen-donor agent, usually H_2O_2 and PhIO.

Usually, one way to introduce electronic and/or steric modifications on porphyrins is through *meso*-functionalization of the porphyrin rings leading to different properties [7–12].

Thus, tetrapyridyl substituted porphyrins are widely employed as building blocks for supramolecular systems construction [13–17]. The functionalization of the pyridyl group by linking ruthenium complexes can afford both electronic and steric changes on porphyrins making them very attractives and a fascinating way to manipulate the structure of such systems [13–17].

Some works on oxidation of organic substrates applying tetraruthenated manganese porphyrins can be found in the literature [16,18,19] and their activities are related to the electronic and steric effects of the peripheral ruthenium complexes.

In this paper is presented the synthesis, characterization and catalytic evaluation of new supra-molecular manganese (III) porphyrins $\{Mn^{(III)}TPyP[RuCl(dppb)(X\text{-}bipy)]_4\}(PF_6)_5$, where dppb = 1,4-bis(diphenylphosphino)butane; X-bipy = 4,4′-substituted-2,2′-bipyridine; *X* = –Cl, –Me and –OMe). In addition, oxidation reactions were conducted using the porphyrin $[Mn^{(III)}TPyP]^+$ without any peripheral ruthenium complexes. X-ray structure of $[RuCl(dppb)(bipy)(4\text{-}Mepy)]PF_6$ is presented for understanding and visualization of how are the ruthenium peripherals in the manganese–porphyrin system.

2. Experimental

2.1. Materials and instrumentation

All manipulations were carried out under purified argon using standard Schlenk technique. Reagent grade solvents were appropriately distilled and dried before use. The $RuCl_3 \cdot 3H_2O$ was supplied by Johnson Matthey Ltd. or purchased from Aldrich. Methylenechloride (Baker) (DCM) HPLC grade was degassed prior to use. Cyclohexane (Aldrich) and cyclohexene (Aldrich) were distilled prior to use. The *cis*-$[RuCl_2(dppb)(X\text{-}bipy)]$ (X = –H, $–CH_3$, CH_3O–, –Cl) were synthesized as described in the literature [20,21]. The UV–Vis spectra were recorded on a Hewlett–Packard 8453A diode-array spectrophotometer. Cyclic voltammetry (CV) experiments were carried out at room temperature in CH_2Cl_2 using a BAS-100B/W Bioanalytical Systems Instruments; the working and auxiliary electrodes were stationary Pt foils, and the reference electrode was Ag/AgCl, 0.10 M $Bu_4N^+ClO_4^-$ (TBAP) (Fluka Purum), a medium in which ferrocene is oxidized at 0.43 V (Fc^+/Fc). Elemental analyses were performed in the Chemistry Department at Universidade Federal de São Carlos. The NMR data of the compounds were acquired using a Bruker DRX-400 spectrometers using D_2O/CH_2Cl_2 or $CDCl_3$ as deuterated solvent. Chemical shifts are reported with respect to the phosphorus signal of phosphoric acid (85%) for ^{31}P and residual solvent proton for ^1H. The *cis*- and *trans*- used in the text refer to the position of chlorides related to each other.

2.2. Iodosylbenzene (PhIO)

Iodosylbenzene was prepared from iodobenzene diacetate and NaOH [22,23], and its purity (>98%) was confirmed by the iodometric method. Samples were stored in freezer.

2.3. Oxidation reactions

The reactions were carried out in a 3 mL vial with screw cap containing a silicone teflon-coated septum. In a standard reaction, the solvent and cyclohexane were added to the vial containing the pre-catalyst and iodosylbenzene under argon atmosphere, and the flask was adapted in a dark chamber. The mixtures were magnetic stirred at room temperature (25 °C).

2.4. Product analysis

The oxidation products of the catalytic reactions were analyzed by gas-chromatography using hexadecane as internal standard. A Shimadzu 17A chromatograph with FID ($N_2 = 30$ mL min^{-1}: $H_2 = 40$ mL min^{-1}; compressed air = 500 mL min^{-1}) detector and Silica (25 m long and 0.5 mm inner diameter with 1 mm thick Silica as stationary phase) column were used. The yields of the reactions are referred to the amount of PhIO consumed in each reaction. The products of the reactions were analyzed by a comparison of their retention times with authentic samples. Control of all reactions was carried out under the same experimental conditions, but in the absence of pre-catalysts for all runs. The stability of the catalysts was checked by UV–Vis spectroscopy.

3. Synthesis

3.1. [RuCl(dppb)(bipy)(4-Mepy)]PF_6

To a methylenechloride (5.0 mL) solution of *cis*-$[RuCl_2(dppb)(bipy)]$ (100 mg; 0.132 mmols) the 4-methylpyridine ligand (12.3 mg; 0.132 mmols) and NH_4PF_6 (215 mg; 1.32 mmols) were added. The reaction was stirred at room temperature for 2 h. The solution was concentrated and addition of *n*-hexanes yielded a yellow solid, which was collected by filtration, washed well with deionized water and diethyl ether and dried under vacuum. Yield: 93%. Elemental *Anal.* Calc. for $C_{44}H_{43}ClN_3P_3F_6Ru \cdot CH_2Cl_2$: C, 51.86; H, 4.35; N, 4.03. Found: C, 51.78; H, 4.42; N, 4.20%. $^{31}P\{^1H\}$ NMR, r.t., δ 37.87 (s); 0 °C, 38.83 (d), 38.37 (d) ($^2J = 34.0$ Hz). The recrystallization of the complex from CH_2Cl_2/MeOH/ether gave yellow crystals suitable for X-ray analysis. The structure of the $[RuCl(dppb)(bipy)(4\text{-}Mepy)]PF_6$ complex can be used as a model for the structures of the porphyrin derivatives obtained in this work.

4. Porphyrins and porphyrins derivatives

4.1. Meso-tetra(4-pyridyl)porphynatemanganese(III) acetate, [$Mn^{(III)}$ TPyP](OAc) (MnP) where TPyP = meso-tetra(4-pyridyl)porphyrin

TPyP = meso-tetra(4-pyridyl)porphyrin, was done by adapting the method describe in the literature [24] refluxing the free-base (H_2TPyP, Aldrich, 97%) and manganese (II) acetate (Fluka) in glacial acetic acid during 4 h. The acid was removed in a rotary evaporator; the solid was dissolved in methylenechloride and filtered, the solvent was pumped out and manganese–porphyrin (MnP) was obtained.

A representative synthesis of {$Mn^{(III)}$-TPyP[RuCl(dppb)(X-bipy)]$_4$}$(PF_6)_5$ is as follow:

{$Mn^{(III)}$-TPyP[RuCl(dppb)(CH_3O-bipy)]$_4$}$(PF_6)_5$ (MeO–MnP). To a methylenechloride (5.0 mL) solution of [$Mn^{(III)}$TPyP](OAc) (3.0 mg; 4.2 μmols) a methylenechloride solution of *cis*-[$RuCl_2$(dppb)(CH_3O-bipy)] (14.0 mg; 17.4 μmol), and NH_4PF_6 (10.0 mg; 61.0 μmols) were added. The reaction was stirred at room temperature for 4 h. The solution was concentrated and addition of *n*-hexanes yielded a black solid, which was collected by filtration, washed well with deionized water and diethyl ether and dried under vacuum.

Yield: 93%. Elemental *Anal.* Calc. for $C_{200}H_{184}Cl_4F_{30}MnN_{16}O_8P_{13}Ru_4$: C, 53.22; H, 4.11; N, 4.97; Ru, 8.96; Mn, 1.22. Found: C, 53.35; H, 4.05; N, 4.62; Ru, 8.42; Mn, 1.08%.

4.2. X-ray diffraction data

Yellow single crystals of *cis*-[RuCl(dppb)(bipy)-(4-Mepy)]PF_6 suitable for X-ray structure analysis were obtained by recrystallization from dichloromethane solution. The X-ray data were performed on graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation on an Enraf-Nonius Kappa CCD diffractometer. Data were collected up to 50° in 2θ, with a redundancy of 4. The final unit cell parameters were based on all reflections. Data collections were done using the COLLECT program [25]; integration and scaling of the reflections were performed with the HKL Denzo–Scalepack system of programs [26]. Absorption corrections were carried out using the multi-scan method [27]. The structure was solved by direct methods with SHELXS-97 [28]. The model was refined by full-matrix least-squares on F^2 by means of SHELXL-97 [29]. All the hydrogen atoms were stereochemically positioned and refined with the riding model. All H atoms were located on stereochemical grounds. The data collections and experimental details for the complex are summarized in Table 1.

Largest differences in peak and hole (e Å^{-3})	1.486 and −0.863

5. Results and discussion

The ORTEP [30] molecular structure of the [RuCl(dppb)-(bipy)(4-Mepy)]PF_6 complex and selected bond length and angles are in Fig. 2.

The X-ray single crystal structure of the [RuCl(dppb)-(bipy)(4-Mepy)]PF_6 complex revealed that the Ru(II) ion is in a distorted octahedral geometry. The Ru–Cl, Ru–N, Ru–P distances found for the [RuCl(dppb)(bipy)-(4-Mepy)]PF_6 are in the expected range reported in the literature [31]. The Ru–N bond length is longer for those *trans* to P- atom than the one *trans* to chloride (see caption in Fig. 2). The stronger structural *trans* effect of the phosphines than the chloride can account for these differences in bond length [32,33].

The $^{31}P\{^1H\}$ NMR spectra of the precursors *cis*-[$RuCl_2$(dppb)(X-bipy)] show two doublets in the range 46 and 31 ppm ($^2J_{PP} \sim 36$ Hz) in CH_2Cl_2 (see Table 2) which is characteristic of a AX spin system. The formation of tetraruthenated porphyrins involves the dissociation of one chloride of the *cis*-[$RuCl_2$(dppb)(X-bipy)] complex and its coordination to the pyridyl groups leading to the formation of "[RuCl(dppb)(L)(X-bipy)]$^+$" unities (L = pyridyl group of the porphyrin ring). The substitution reaction is accompanied by a change in the spin system, the initial AX changes to an AB system. This change is indicative of the formation of such isomer where the pyridyl group is *trans* to P of the dppb ligand. The same behavior is observed in the reaction of *cis*-[$RuCl_2$(dppb)(X-bipy)] [34] with

[a] $^{31}P\{^{1}H\}$ acquired at 0 °C.

N-donor ligands. As can be seen is Fig. 2, the 4-Mepy is in *trans* position with one P-atom of the diphosphine. In this way it is easy to attribute the formation of the tetraruthenated porphyrin and the isomer of the peripheral ruthenium complexes as proposed in Fig. 1.

It is worth of mention that the multiplicity of the phosphorus atoms of the dppb ligand is solvent and temperature dependent. This accidental degeneracy was observed before by James and by us [35,36]. For example, the complex $\{Mn^{(III)}$-TPyP[RuCl(dppb)(Me-bipy)]$_4\}(PF_6)_5$ in methylenechloride the ^{31}P NMR spectrum show a singlet, but in chloroform the AB quadruplet is resolved. The signals are broader than the analogues containing zinc metallated porphyrins due to the presence of a paramagnetic Mn(III) [36].

The cyclic voltammograms of the manganese complexes prepared consist of a pair of reversible peaks ($Ia/Ic \cong 1$), attributed to the one electron $Ru^{(III)}/Ru^{(II)}$ couple (Table 2) and another for $Mn^{(II)}/Mn^{(III)}$ couple. The higher potentials for Ru^{III}/Ru^{II} for the $\{Mn^{(III)}$-TPyP[RuCl(dppb)-(X-bipy)]$_4\}(PF_6)_5$ complex when compared with the starting ruthenium complexes, *cis*-[$RuCl_2$(dppb)(X-bipy)], can be explained by the dissociation of one donor (chloride), reducing the electron density on metal center and enormously increasing the potential.

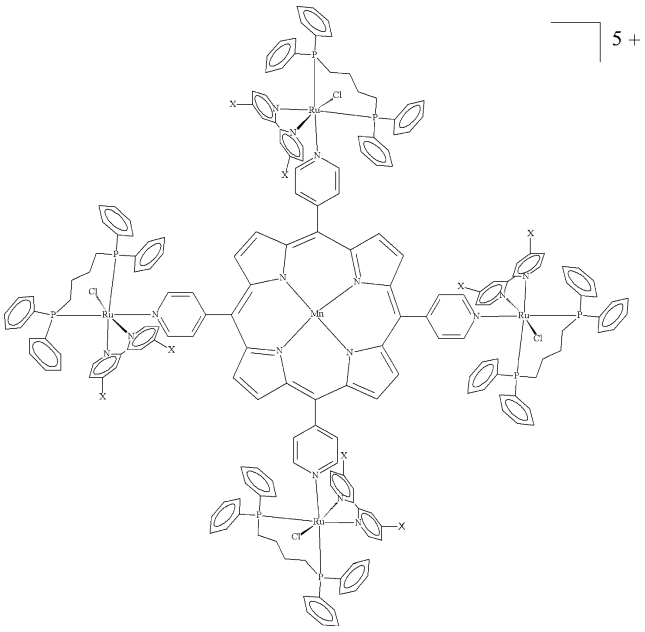

Fig. 1. Structure of $\{MnTPyP[RuCl(dppb)(X\text{-}bipy)]_4(PF_6)_5$, (X = –$CH_3$, –OMe, –Cl).

The manganese reduction potentials are higher for the tetraruthenated porphyrins than $Mn^{(III)}$-TPyP (−80 mV) which is in agreement with previously reported data [37]. The reduction potential variation for the peripheral ruthenium is inversely related to the manganese (see Table 2). This clearly shows that the electron density on $Mn^{(III)}$ can be tuned just changing the characteristics of the peripheral ruthenium complexes.

Typical bands in the UV/Vis spectra of $Mn^{(III)}$-TPyP porphyrin complex [38] are observed at 621, 584, 475 and 370 nm. The $\{Mn^{(III)}$-TPyP[RuCl(dppb)(X-bipy)]$_4\}(PF_6)_5$ complexes, besides the typical bands for the manganese porphyrin they show other arising from the ruthenium peripheral complex, such as $\pi \rightarrow \pi^*$ from the bipyridine ligand, in the UV region [21].

6. Catalytic activity

The catalytic mechanism involving manganese porphyrins is mentioned in the literature and is based on the formation of Mn^{IV}=O and Mn^{V}=O species [3–6,16]. One strategy to modulate the bulkiness environment or the electronic characteristics of the metalloporphyrin center is binding selected metal complexes in the peripheral nitrogens of the tetrapyridylporphyrin.

The oxidation of cyclohexane with PhIO in the presence of the $[Mn^{(III)}$-TPyP]OAc or of the supramolecular $\{Mn^{(III)}$-TPyP[RuCl(dppb)(X-bipy)]$_4\}(PF_6)_5$ species, at 25 °C, was found to yield cyclohexanol and cyclohexanone as major products. None of these products could be found in the absence of the porphyrins species, showing that they are, in fact, promoting the oxygen atom transfer to the substrate. The catalytic activity of $[Mn^{(III)}$-TPyP]OAc and $\{Mn^{(III)}$-TPyP[RuCl(dppb)(X-bipy)]$_4\}(PF_6)_5$ species for the epoxidation of cyclohexene by iodosylbenzene, in methylenechloride, was evaluated under identical experimental conditions [24].

The conversion of the oxidation reactions of cyclohexene and cyclohexane, based on iodosylbenzene, was up to 97%. For the epoxidation reactions the yields in epoxide were around 60% to MnP, 11% to MeO–MnP, 13% to Me–MnP and 10% Cl–MnP (reaction time = 1.5 h,

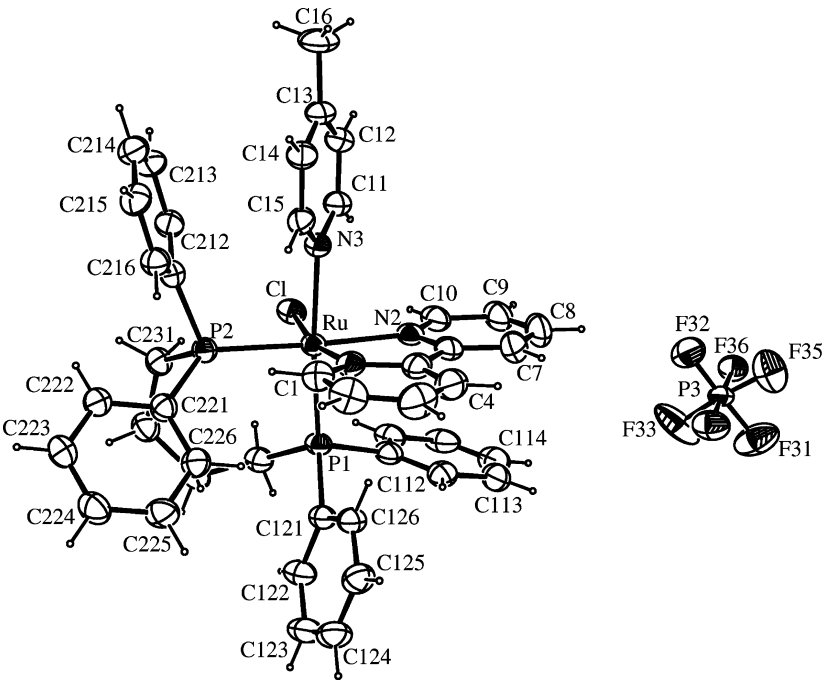

Fig. 2. X-ray structure of [RuCl(dppb)(bipy)(4-Mepy)]PF_6 (ORTEP plot with ellipsoids at the 50% probability). Bond lengths (Å): Ru–N(1) 2.096(4), Ru–N(2) 2.140(4), Ru–N(3) 2.203(4), Ru–P(1) 2.3571(12), Ru–P(2) 2.3645(13), Ru–Cl 2.4560(13). Bond angles (°): P(1)–Ru–P(2) 93.38(4), N(1)–Ru–Cl 168.25(12), N(2)–Ru–Cl 91.55(12), N(3)–Ru–Cl 87.47(11), P(1)–Ru–Cl 86.35(4), P(2)–Ru–Cl 87.94(4), N(1)–Ru–N(2) 77.74(17), N(1)–Ru–N(3) 86.60(15), N(2)–Ru–N(3) 83.93(14), N(1)–Ru–P(1) 98.29(11), N(2)–Ru–P(1) 89.74(10), N(3)–Ru–P(1) 171.03(11), N(1)–Ru–P(2) 102.48(12), N(2)–Ru–P(2) 176.80(10), N(3)–Ru–P(2) 92.89(11).

$[cat] = 4 \times 10^{-7}$ mol L^{-1}, cat:PhIO:cyclohexene molar ratio 1:30:2000) for both systems.

The [$Mn^{(III)}$-TPyP]OAc catalyst leds to the formation of cyclohexanol (14%) and cyclohexanone (6%) in a ratio C-ol:C-one of 2.3, but MeO–MnP, Me–MnP and Cl–MnP generated cyclohexanol (35%, 30% and 28%) and cyclohexanone (9%, 4% and 5%). However, the PhIO yields were 96%, 70%, 77% and 65% for MnP, MeO–MnP, Me–MnP and Cl–MnP, respectively. No detectable degradation of MnP catalyst (evaluated by the presence of the Soret band) was observed by UV–Vis spectroscopy. The high values on the total conversion based on the consumption of PhIO can be explained by the occurrence of parallel reactions in the systems as previously reported [4] especially reactions that involve allylic oxidations of the cyclohexene. Others species was formed during the reaction but it was not measured, but this justify the small yield for the epoxide formation Table 3.

Comparison of our system with the closest found in the literature [19] using the supramolecular {MnT4PyP[RuCl-(bipy)$_2$]$_4$}$^{5+}$, for the epoxidation reactions our system presents lower yield in epoxide, but for cyclohexane oxidation the ratio C-ol:C-one is higher, showing that our system has higher selectivity on cyclohexanol Table 4.

Very recently was shown that electron-rich manganese porphyrins decay faster than electron-deficient ones [39]. In this study this was not observed, probably because the electron density of the manganese centers are not too different when the highly reactive Mn^{V}=O site is formed in solution or because the peripheral groups prevent the degradation of the molecule under highly oxidizing conditions.

Table 3
Oxidation of cyclohexene by PhIO in CH_2Cl_2

7. Conclusions

New tetraruthenated porphyrins were synthesized, characterized and their catalytic properties on oxidation of cyclohexanone and cyclohexane were evaluated. The properties of the porphyrins are practically not dependent on the characteristics of peripheral ruthenium complexes containing substituted bipyridines. The catalytic results obtained in this work allows to suggest that the yield and the selectivity of the products are modulated better by the presence or absence of steric effect than by the electronic effect induced by the peripheral ruthenium complexes on the central metal. The yield on epoxide is decreased comparing the non-tetraruthenated porphyrin with the tetraruthenated, but for cyclohexane the presence of peripheral ruthenium complexes increase the yield on cyclohexanol. The electron density of the manganese center does not affect significantly the yield and selectivity of the products of the catalytic reactions. Probably this difference on electron density of the metal center is not significant after the formation of the real catalytic Mn^{V}=O site, in solution.

Abstract

The crystal structure, spectroscopic properties and catalytic property of the copper(II) complex, prepared by the reaction between copper(II) diacetate with the bidentate Schiff base, SalAHE (SalAHE = salicylaldehydeimine-1-hydroxyethane), are reported. This complex is able to oxidize 3,5-di-*tert*-butylcatechol to the respective *o*-quinone. The oxidation reaction was studied in CH_3CN with molecular oxygen at 0, 5, 15 and 25 °C. The progress of the catalytic reaction was followed by gas chromatographic analyses (GC).

1. Introduction

Copper has been known as an essential bioelement for some time but its biological role(s) has been recognized only in the last decades due to the rapid development of bioinorganic chemistry, a successful interaction between model complexes and protein biochemistry [1–8].

The environment around the metal center and its conformational flexibility are the key factors for a metalloprotein to carry out a specific physiological function, e.g. dioxygen binding, oxygen utilization, etc. In order to emulate the biological activity of metalloproteins, particularly their active sites, various model metal complexes containing Schiff base ligands have been synthesized and studied for their dioxygen uptake [9–15] and oxidative catalysis [16–20].

The oxidation of organic substrates with molecular oxygen under mild conditions is of great interest for industrial and synthetic processes both from an economical and environmental point of view. The synthesis and investigation of functional model complexes for metalloenzymes with catechol oxygenase or catechol oxidase activity is therefore of great promise for the development of new and efficient catalysts for oxidation reactions [21]. Two major enzymes play the key role in these reactions, catechol dioxygenases and catechol oxidases. Most functional mimics of catechol oxidase are mono- or dinuclear Cu(II) complexes [22–27].

As part of the ongoing investigations by our group for spectroscopic studies [28–31] and metal-salen catalyzed oxidations [32], we describe in this work the preparation, characterization, crystal structure and catalytic activity of [Cu(SalAHE)$_2$] for oxidation of catechol. The catalytic oxidation of 3,5-di-*tert*-butylcatechol by copper(II) complex in acetonitrile (CH_3CN) saturated with molecular oxygen was studied in a homogenous system.

2. Experimental

2.1. Reagents

Ethanolamine, 99% (Riedel-de-Haën Inc.); salicylaldehyde, 98%; copper(II) acetate, 99% (Alfa Morton Thiokol Inc.); chloroform-*d* 99.8 at.% D, $CDCl_3$ (Aldrich Chemical Co.); acetonitrile, 99.9%; 3,5-di-*tert*-butylcatechol, 99%; 3,5-di-*tert*-1,2-benzoquinone, 98%. All other solvents and reagents were obtained commercially and were used without further purification.

2.2. Preparation of the copper(II) complex

The complex was prepared in a manner similar to that described [33]. Salicylaldehyde (3.0 mmol, 0.320 ml) and ethanolamine (3.0 mmol, 0.181 ml) were dissolved in 15 ml of methanol. The solution was stirred for 1 h at 60 °C, and then $Cu(CH_3COO)_2 \cdot H_2O$ (1.5 mmol, 0.2995 g) was added to the reaction mixture with continuous stirring for 4 h at 60 °C. The solution was then cooled to room temperature, filtered and the solid was purified with cold ethanol (5 ml at 5 °C) and dried over silica.

Green powder. Yield: 0.326 g, 55.6%. M.p. 178.2–178.7 °C (uncorrected). *Anal.* Calc. for $C_{18}H_{24}N_2O_6Cu$: C, 50.5; H, 5.65; N, 6.55. Found: C, 50.9; H, 5.75; N, 6.7%. Selected IR bands (KBr, cm^{-1}): 1636s, ν(C=N); 1396m, ν(C–N); 1327m, ν(Ph–O); 429w, ν(Cu–O). UV–Vis spectrum in CH_3CN [λ_{max} (nm), ε ($dm^3\,cm^{-1}\,mol^{-1}$)]: $268_{shoulder}$ (18650), 366 (7580), 631 (157).

2.3. Crystallography

Suitable single crystal of the [Cu(SalAHE)$_2$] complex was formed by slow evaporation of an ethanolic solution at room temperature. Diffraction data were acquired using a single crystal mounted on an Enraf-Nonius CAD4 diffractometer. Intensity data were obtained using Mo Kα radiation ($\lambda = 0.71073$ Å) monochromated with graphite using ω–2θ scan mode. The details of the X-ray data collection, structure solution and structure refinements were given in Table 1.

Unit-cell parameters were obtained by the least-squares fit of the setting angles of 25 reflections. Three standard reflections, checked every 2 h, showed no significant variations (±0.1%). The intensity data were corrected for Lorentz polarization and absorption effects on the basis of PSISCAN [34].

The structure was solved on the WinGX system with the localization of the position of the copper atom using the Patterson method with the program SIR97 [35]. The refinement was effected through SHELXL97 [36], with the simultaneous analysis of the geometric parameters of the structure made through system PLATON [37], incorporated the WinGX. Non-hydrogen atoms were refined anisotropically. The hydrogen atoms had been located geometrically, assuming thermal displacement as being equal the 1.3 times the Beq of the atom to which it is bonded.

Table 1
Crystal data and details of the structure determination for [Cu(SalAHE)$_2$]

Empirical formula	$CuC_{18}H_{20}N_2O_4$
Formula weight	391.91
Temperature (K)	293
Radiation (Å)	Mo Kα 0.71073
Crystal system	Monoclinic

Index ranges	$-25 \leqslant h \leqslant 25$; $-6 \leqslant k \leqslant 0$; $0 \leqslant l \leqslant 27$
Total reflections collected	5145
Independent reflections	5003 [$R_{int} = 0.026$]
Observed reflections $I \geqslant 2\sigma(I)$	2678
Number of parameters	229
R observations	0.0388
wR observations	0.1253
Goodness-of-fit	1.00
Maximum/minimum $\Delta\rho$ (e Å^3)	0.61/−0.57

The graphic representations of the molecules were done using the program ORTEP3 for Windows [38] with 50% probability displacement ellipsoids.

2.4. Physical measurements

Elemental microanalyses (C, H, N) were performed by the Microanalytical Laboratory of the Departamento de Química of the Universidade Federal de São Carlos, São Carlos, São Paulo with a Faison EA 1108 CHNS-O instrument. IR spectroscopy on KBr, dried and stored at 110 °C, pressed discs (1% by weight) with a Bomem Michelson 102 FT-IR instrument. Electronic spectra were recorded in the 190–1100 nm range using a Shimadzu MultSpec-1501 instrument. These spectra of the CH_3CN solutions were obtained at room temperature using matched 1.0 cm quartz cells.

2.5. Blank reactions without any catalyst

Reactions were run in a round-bottom flask at 25, 15, 5 and 0 °C by mixing 0.0222 g (1.0 mmol) of 3,5-di-*tert*-butylcatechol and 10.0 ml of CH_3CN as solvent, saturated with molecular oxygen, each reaction was monitored at 30 min for the first four hours and at 24 h by GC. The quantitative GC analysis of the catechol products was carried out using a SHIMADZU GC-2010 Chromatograph equipped with an FID detector and a J&W DB-5 capillary column (29 m × 0.25 mm × 0.25 μm). Hydrogen was used as carrier gas. The oxidation products yields were calcu-

lated from the chromatogram area, GC error for the determination was within ±3%. The products were characterized by ^{1}H NMR obtained using a Bruker ARX 200 MHz 4.7 T spectrometer with $CDCl_3$ as solvent and TMS with internal standard, and IR spectroscopy on KBr pressed discs (1% by weight) with a Bomem Michelson 102 FT-IR instrument.

2.6. Oxidation of 3,5-di-tert-butylcatechol with catalyst

The conditions of the oxidation reactions in the presence of the catalyst are the same as the blanks except that 0.0039 g, 0.01 mmol of the catalyst was added. The final substrate to catalyst ratio is 100:1.

3. Results and discussion

3.1. IR spectrum

The IR spectrum of the complex exhibits various bands in the 300–4000 cm^{-1} region. In the 3400–3100 cm^{-1} region, were observed two bands in 3329 and 3232 cm^{-1} attributed to O–H stretching. These O–H stretchings are due to the OH of the ligand and with water associated with the solid formed in the reaction since the KBr is stored at 110 °C until use. The microanalysis is consistent with the presence of two waters in the molecular formula. The characteristic C=N stretching frequencies are in the 1592–1640 cm^{-1} region as reported for similar ligands [28,39], the complex exhibits this band at 1636 cm^{-1}. The C–N stretching frequency has been reported in the 1350–1410 cm^{-1} region [41–43], for the complex the band is attributed in 1396 cm^{-1}. A band at 1327 cm^{-1} is attributed to ν(Ph–O) stretching, for similar ligands this band appears as a weak band within the 1290–1340 cm^{-1} range [40–45].

3.2. Molecular structure of [Cu(SalAHE)$_2$]

The structure of [Cu(SalAHE)$_2$] determined by X-ray crystallography consist of two independent half molecules in the asymmetric unit. The Cu atoms are located on the crystallographic inversion centers, giving rise (by $\bar{1}$ symmetry operation) to two independent molecules with different conformation as shown in Fig. 1, with label scheme of the atoms. As shown in Fig. 1, the central copper(II) atom is coordinated with two imine nitrogen atoms and two phenolate oxygen atoms of the two Schiff base ligands. The Schiff base SalAHE (salicylaldehydeimine-1-hydroxyethane) is a bidentate and monoanionic ligand, which results in a neutral copper complex. The X-ray crystallography symmetry imposes that the two ligands be oriented in a *trans* configuration, in which the hydroxyl groups are involved in hydrogen bonds. Contrary to the solid isolated from the reaction mixture that has two water molecules, the isolated crystal does not present either coordinated water or hydration water. In Table 2 selected bond lengths and angles for [Cu(SalAHE)$_2$] are presented. The angles O–Cu–N are 91.92(8)° and 88.08(8)° for the Cu1, and 91.33(9)° and 88.67(9)° for Cu_2. These bond angles are all close to 90°. The distorted square planar coordination is reinforced by the strictly planar arrangement around the Cu atoms. The bond length Cu–N is longer than that of Cu–O and is in agreement with others found in the literature [33,49]. The central copper atom and the ligands form two six-member rings which increase the stability of the complex. Table 3 shows the hydrogen interactions. The presence of hydrogen bonds O–H···O in the solid state makes a bidimensional supramolecular polymer, in the (1 0 0) crystallographic plane depicted in Fig. 2. The interactions C–H···O (Fig. 2) shows that the crystal packing is a very complex three-dimensional polymer, but the interactions are not negligible.

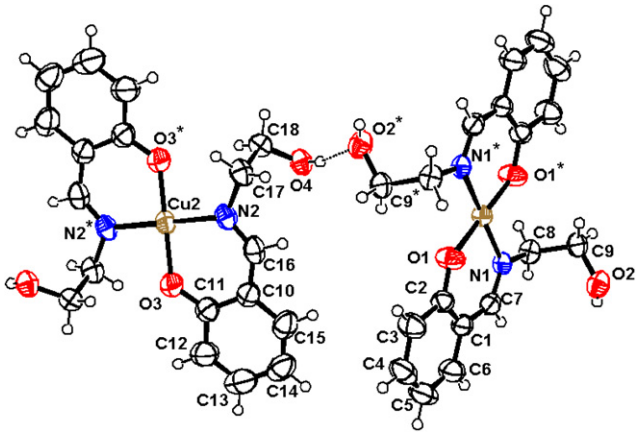

Fig. 1. An ORTEP drawing of [Cu(SalAHE)$_2$] and the atom numbering.

Table 2
Selected bonds and angles for the [Cu(SalAHE)$_2$]

Bonds lengths (Å)			
Cu(1)–O(1)	1.876(2)	Cu(2)–O(3)	1.885(2)
Cu(1)–N(1)	2.013(2)	Cu(2)–N(2)	1.999(2)
Bonds angles (°)			
O(1)–Cu(1)–N(1)	91.92(8)	O(3)–Cu(2)–N(2)	91.33(9)
O(1)–Cu(1)–O(1a)	180	O(3)–Cu(2)–O(3b)	180
O(1)–Cu(1)–N(1a)	88.08(8)	O(3)–Cu(2)–N(2b)	88.67(9)
N(1)–Cu(1)–N(1a)	180	N(2)–Cu(2)–N(2b)	180

3.3. Catalytic oxidation of 3,5-di-tert-butylcatechol

In general, 3,5-di-*tert*-butylcatechol is used as substrate to investigate the oxidation capability of copper complexes, due to its low redox potential, which makes it easy to oxidize to 3,5-di-*tert*butylquinone (DTBQ), and the presence of bulky, non-polar substituents, which prevent further oxidation reactions, such as ring opening reactions, and cyclization/tautomerization reactions [26].

Among the mononuclear copper(II) complexes, compounds possessing intermediate geometry between trigonal bipyramidal and square pyramidal [45] are considered to be

Table 3
Hydrogen bonds distances and angles for the [Cu(SalAHE)$_2$]

A	H	B	A–H (Å)	H···B (Å)	A···B (Å)	Angle (°)	Symmetry operation
O2	OH2	O4	0.82	2.00	2.742(3)	151	$3-x, -y, 2-z$
O4	OH4	O2	0.82	1.92	2.723(3)	165	$3-x, -1-y, 2-z$
C8	H8A	O1	0.97	2.37	2.763(3)	104	$3-x, -1-y, 2-z$
C9	H9B	O1	0.97	2.49	3.051(4)	116	$3-x, -1-y, 2-z$
C17	H17B	O3	0.97	2.33	2.755(4)	105	$2-x, -y, 2-z$
C18	H18A	O3	0.97	2.53	3.061(4)	115	$2-x, -y, 2-z$

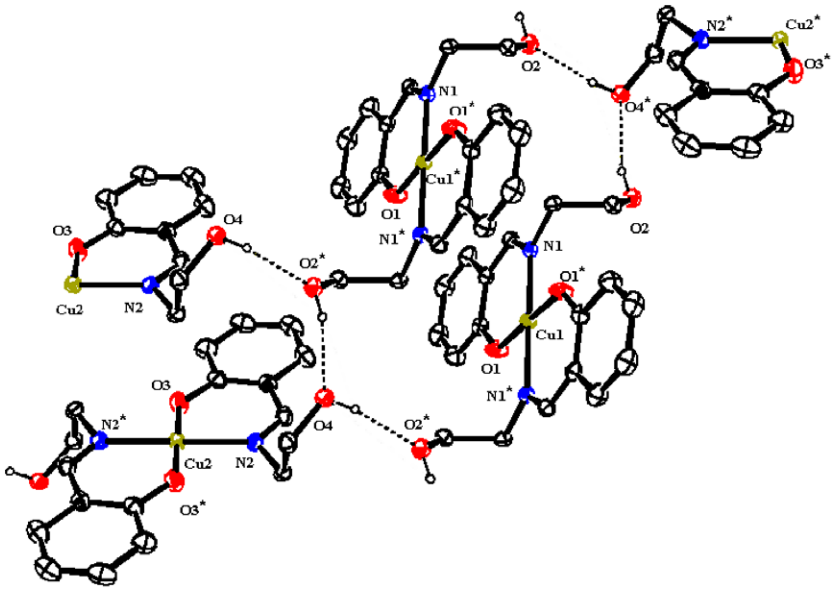

Fig. 2. Supramolecular bidimensional polymer of [Cu(SalAHE)$_2$].

potential models, due to its biological relevance in the geometrical rearrangement [46] during the tyrosinase substrate binding reaction. Kida and co-workers have studied a number of copper(II) complexes and have shown that dinuclear complexes catalyze the reaction while the mononuclear species are either not as efficient or inactive depending on the steric demands of the ligands [47]. Neves and co-workers studied the mononuclear and binuclear copper(II) complexes of the unsymmetrical, binucleating ligand, *N*,*N*,*N*-tris-(2-pyridylmethyl)-1,3-diaminopropan-2-ol, as models for the active site of catechol oxidase [48]. The mononuclear complex was inactive in this oxidation reaction while the binuclear complex is a potential model for the dinuclear copper site in catechol oxidase.

We have examined the catalytic activity of the mononuclear copper(II) complex, [Cu(SalAHE)$_2$], for oxidation of 3,5-di-*tert*-butylcatechol by molecular oxygen in oxygen saturated acetonitrile solutions. The initial rate for the catechol oxidation was determined by monitoring the appearance of the quinone peak in CG chromatogram. For reactions without catalyst at different temperatures the yields after 24 h were below 5%. The progress of the oxidation reactions of 3,5-di-*tert*-butylcatechol in presence of the copper(II) complex at four different temperatures, 0, 5, 15 and 25 °C, and without catalyst at 25 °C are shown in Fig. 3. The results of the catalytic oxidation of 3,5-di-*tert*-butylcatechol for the systems studied are given in Table 4.

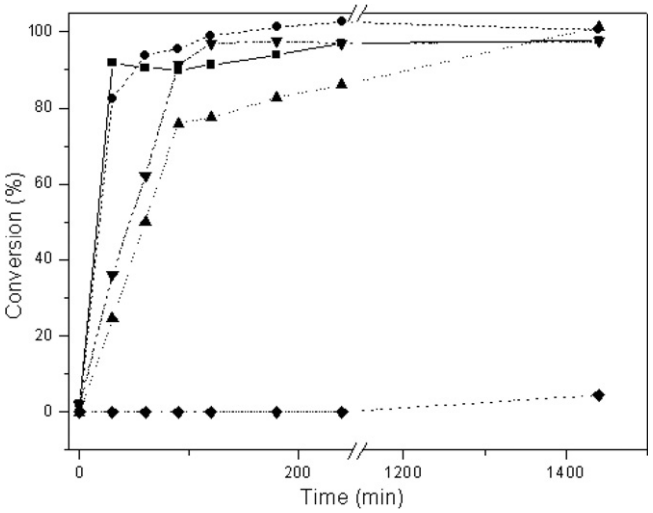

Fig. 3. Effect of temperature on the oxidation of 3,5-di-*tert*-butylcatechol; ■ 25 °C; ● 15 °C; ▼ 5 °C; ▲ 0 °C and ♦ for 25 °C without catalyst.

Table 4
3,5-Di-*tert*-butylcatechol conversion (mol%) at four different temperatures with $[Cu(SalAHE)_2]$ as catalyst and without the catalyst at 25 °C

Time (min)	25 °C	15 °C	5 °C	0 °C	25 °C (without catalyst)
30	92	82	36	24.5	0
60	91	94	62	50	0
90	90	96	91	76	0
120	91	99	97	77	0
180	94	100	98	83	0
240	97	100	97	86	0
1440	98	100	98	100	4.5

Table 5
Comparison of the kinetic parameters for different temperatures

Temperature (°C)	k_{cat} (s^{-1})	Yields (%)
0	0.76 ± 0.10	100
5	1.13 ± 0.19	98
15	3.35 ± 0.29	100
25	8.03 ± 0.43	98

The values of k_{cat}, determined considering a first order reaction for oxidation of catechol with the copper(II) complex as catalyst, at 0, 5, 15 and 25 °C are given in Table 5. The values of $\Delta H^{\neq}$ and $\Delta S^{\neq}$ for 25 °C, determined from temperature dependence studies, are 62.2 ± 4.1 kJ mol^{-1} and -10 ± 1 J K^{-1} mol^{-1}, respectively. The negative value of $\Delta S^{\neq}$ indicates the operation of an associative mode of activation.

The product of the catalytic oxidation of 3,5-di-*tert*-butylcatechol was characterized by IR and ^1H NMR. For the ^1H NMR spectra, a change for two of the hydrogen peaks on the aromatic ring was observed. For the substrate, 3,5-di-*tert*-butylcatechol, peaks appear at 6.78 and 6.91 ppm with $J = 2.1$ and for the reaction product, 3,5-di-*tert*-1,2-benzoquinone, these two peaks are shifted to 6.21 and 6.93 ppm respectively with $J = 2.2$. This is in accordance with a ^1H NMR spectra of commercial 3,5-di-*tert*-1,2-benzoquinone. In the IR spectra, the absence of bands at 3460 and 3260 cm^{-1} attributed to ν(O–H) present in substrate and the appearance of a band at 1680 cm^{-1} attributed to ν(C=O) of the product are the main changes observed.

4. Conclusions

A new Schiff base copper(II) complex $[Cu(SalAHE)_2]$ was synthesized and characterized. The crystal structure of this complex shows that the central part of the molecule strictly coplanar with the two ligands in the *trans* configuration. The crystal packing makes an infinite supramolecular polymer, using conventional and non-conventional H-bonds This mononuclear complex is able to oxidize 3,5-di-*tert*-butylcatechol to the respective *o*-quinone with molecular oxygen.

Abstract

The synthesis and characterization of the ligands R_3PAu(**1**–H) (R = ^{n}Bu, Ph) and (**1**–H)Au(μ-dppe)Au(**1**–H) (**1** = HC≡CCH$_2$Otpy, tpy = 2,2′:6′,2″-terpyridine) are reported. The single crystal structures of $^n Bu_3PAu$(**1**–H) and (**1**–H)Au(μ-dppe)Au(**1**–H) have been determined, and weak hydrogen bonding rather than aurophilic interactions operate between the molecules in the solid state.

Keywords: Gold(I); 2,2′:6′,2″-Terpyridine; Phosphine; Alkyne; Ligand

1. Introduction

The use of terminal C≡CH groups to produce organometallic complexes through M–C σ-bond formation is well documented, with platinum(II) and gold(I) derivatives being especially important [1–4]. Current interest is these derivatives arises from possible applications in advanced materials based upon their luminescent [5–9] and nonlinear optical [3,10–13] properties. We have recently reported a family of platinum(II)-centred ditopic 2,2′:6′,2″-terpyridine (tpy) ligands which are synthesized by coupling 4′-(2-propyn-1-oxy)-2,2′:6′,2″-terpyridine (HC≡CCH$_2$Otpy (**1**)) with *trans*-[PtI$_2$(PR$_3$)$_2$] (R = Et, ^{n}Bu, Ph) [14,15] or 4′-(4,7,10-trioxadec-1-yn-10-yl)-2,2′:6′,2″-terpyridine with *trans*-[PtI$_2$(PEt$_3$)$_2$] [16]. Metal binding by the tpy domains leads to the formation of [n + n] metallomacrocyclic products with n = 2, 3 or 4 for M = Fe(II). Mixtures of these products convert in solution to the thermodynamically favoured $[Fe_2L_2]^{4+}$ [15]. We have now turned our attention to gold(I) alkynyl derivatives [17], and report here a series of new ligands in which tpy domains are linked to C≡CAuPR$_3$ (R = ^{n}Bu, Ph) or C≡CAu(μ-dppe)AuC≡C units (dppe = bis(diphenylphosphino)ethane). Previous examples of gold(I) σ-acetylide-functionalized polypyridine ligands have been based upon 1,10-phenanthroline [18–21].

2. Experimental

2.1. General procedures

Infrared spectra were recorded on a Shimadzu FTIR-8400S spectrophotometer with samples as solids using a Golden Gate ATR accessory. ^{1}H, ^{13}C and ^{31}P NMR spectra were recorded on a Bruker Avance DRX 400 spectrometer; the numbering scheme adopted for the ligands are shown in the reaction schemes. Chemical shifts for ^{1}H and ^{13}C NMR spectra are referenced with respect to residual solvent peaks and TMS = δ 0 ppm; ^{31}P NMR signals are referenced with respect to 85% aqueous H_3PO_4. MALDI-TOF mass spectra were recorded using a PerSeptive Biosystems Voyager mass spectrometer with α-cyano-4-hydroxycinnamic acid matrix. Electronic absorption spectra were recorded on a Varian-Cary 5000 spectrophotometer.

Compound **1** [22] $^n Bu_3PAuCl$ [23] and ClAu(μ-dppe)AuCl [24–26] were prepared by literature methods. Ph_3PAuCl was purchased from ChemPur.

2.2. Compound 2

Compound **1** (0.219 g, 0.763 mmol), $^{n}Bu_3PAuCl$ (0.330 g, 0.759 mmol) and CuI (14.7 mg, 77.2 μmol) were added to Et_3N (10 ml). The reaction mixture was stirred at room temperature for 4 h. Solvent was then removed and the product was separated by column chromatography (alumina, CH_2Cl_2–acetone 99:1). There was a single fraction, from which **2** was isolated as a white oil (0.233 g, 0.340 mmol, 44.8%). Crystals of **2** could be obtained by slow evaporation of the crude reaction mixture. Compound **2**: ^{1}H NMR (400 MHz, $CDCl_3$) δ (ppm) 8.65 (ddd, *J* 4.7, 1.8, 0.8 Hz, 2H, H^{A6}), 8.54 (dt, *J* 7.9, 0.9 Hz, 2H, H^{A3}), 8.04 (s, 2H, H^{B3}), 7.79 (dt, *J* 7.6, 2.0 Hz, 2H, H^{A4}), 7.26 (ddd, *J* 7.6, 5.1, 1.0 Hz, 2H, H^{A5}), 5.01 (s, 2H, OCH_2), 1.67 (m, 6H, PCH_2), 1.48 (m, 6H, PCH_2CH_2), 1.38 (sextet, *J* 7.6 Hz, 6H, CH_2CH_3), 0.87 (t, *J* 7.6 Hz, 9H, CH_3); $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$) δ (ppm) 166.4 (C^{B4}), 156.9 ($C^{B2/A2}$), 156.1 ($C^{B2/A2}$), 148.9 (C^{A6}), 136.5 (C^{A4}), 123.5 (C^{A5}), 121.2 (C^{A3}), 107.7 (C^{B3}), 96.6 ($C{\equiv}CAu$), 57.2 (OCH_2), 27.1 (s, CH_2CH_3), 25.4 (d, J_{PC} 33.0 Hz, PCH_2), 24.1 (d, J_{PC} 14.0 Hz, PCH_2CH_2), 13.5 (s, CH_3), signal for $C{\equiv}CAu$ not resolved; $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$) δ (ppm) 25.7. MALDI-MS *m*/*z* 686 $[M]^+$, 288 $[M-AuPBu_3]^+$. IR (ν, cm^{-1}) 2955 w, 2924 w, 2862 w, 2361 w, 2130 w, 1736 w, 1558 m, 1450 m, 1404 m, 1335 m, 1188 m, 1088 m, 1018 s, 879 w, 795 m, 741 m, 617 w, 563 w, 525 w. UV/Vis λ_{max}/nm 247, 277.

2.3. Compound 3

Compound **1** (0.0820 g, 0.285 mmol), Ph_3PAuCl (0.148 g, 0.299 mmol) and CuI (10.9 mg, 57.3 μmol) were added to Et_3N (12 ml) and CH_2Cl_2 (12 ml). The reaction mixture was stirred at room temperature for 2 h. The precipitate that formed was separated by filtration, and then solvent was then removed from the filtrate to give a yellow-green oil. Purification by column chromatography (alumina, CH_2Cl_2–acetone 99:1) gave one fraction yielding **3** as a white oil (0.145 g, 0.194 mmol, 68.1%). **2**: ^{1}H NMR (400 MHz, $CDCl_3$) δ (ppm) 8.67 (ddd, *J* 4.5, 2.0, 1.2 Hz, 2H, H^{A6}), 8.57 (dt, *J* 8.0, 1.2 Hz, 2H, H^{A3}), 8.09 (s, 2H, H^{B3}), 7.81 (dt, *J* 7.6, 1.6 Hz, 2H, H^{A4}), 7.47 (m, 9H, $H^{Ph3,4}$), 7.41 (m, 6H, H^{Ph2}), 7.28 (ddd, *J* 7.2, 4.8, 1.2 Hz, 2H, H^{A5}), 5.08 (s, 2H, OCH_2); $^{13}C\{^1H\}$ NMR (125 MHz, $CDCl_3$) δ (ppm) 166.5 (C^{B4}), 157.0 ($C^{B2/A2}$), 156.2 ($C^{B2/A2}$), 149.0 (C^{A6}), 136.6 (C^{A4}), 134.2 (d, J_{PC} 13.8 Hz, $C^{Ph2/3}$), 131.5 (s, C^{Ph4}), 129.9 (d, J_{PC} 140 Hz, $C{\equiv}CAu$), 129.5 (d, J_{PC} 55.0 Hz, C^{Ph1}), 129.1 (d, J_{PC} 11.3 Hz, $C^{Ph2/3}$), 123.6 (C^{A5}), 121.3(C^{A3}), 107.8 (C^{B3}), 96.8 (d, J_{PC} 26 Hz, $C{\equiv}CAu$), 57.2 (OCH_2); $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$) δ (ppm) 38.8. MALDI-MS *m*/*z* 748 $[M]^+$, 289 $[M-Ph_3PAu]^+$ (base peak). IR (ν, cm^{-1}) 3066 w, 2963 w, 2921 w, 2863 w, 2350 w, 2130 w, 1581 s, 1563 s, 1469 m, 1436 m, 1406 m, 1345 m, 1334 m, 1186 m, 1101 m, 1020 s, 795 m, 745 m, 692 s. UV/Vis λ_{max}/nm (2.39×10^{-5} mol dm^{-3}, CH_2Cl_2) 249 (ε/dm^3 mol^{-1} cm^{-1} 106,000), 278 (72,700).

2.4. Compound 4

Compound **1** (0.270 g, 0.941 mmol), ClAu(dppe)AuCl (0.405 g, 0.469 mmol) and CuI (9.4 mg, 49.4 μmol) were added to Et_3N (12 ml) and CH_2Cl_2 (12 ml). The reaction mixture was stirred at room temperature for 4 d. The crude product formed as a precipitate and was removed by filtration. It was purified by column chromatography (alumina, CH_2Cl_2–acetone 90:10). One fraction was eluted and from this, **4** was isolated as a white oil (0.253 g, 0.185 mmol, 39.4%). Crystalline 4 was obtained from a $CHCl_3$ solution left standing at room temperature. ^{1}H NMR (400 MHz, $CDCl_3$) δ (ppm) 8.63 (ddd, *J* 4.8, 1.8, 0.8 Hz, 4H, H^{A6}), 8.55 (dt, *J* 8.0, 0.8 Hz, 4H, H^{A3}), 8.06 (s, 4H, H^{B3}), 7.78 (dt, *J* 7.6, 1.8 Hz, 4H, H^{A4}), 7.56 (m, 8H, Ph), 7.7–7.3 (overlapping m, 12H, Ph), 7.25 (ddd, *J* 7.6, 4.8, 1.0 Hz, 4H, H^{A5}), 5.00 (s, 4H, OCH_2), 2.56 (br s, 4H, PCH_2); $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$) δ (ppm) 166.4 (C^{B4}), 157.0 ($C^{B2/A2}$), 156.1 ($C^{B2/A2}$), 149.0 (C^{A6}), 136.6 (C^{A4}), 134.9 (C^{Phipso}), 133.2 (t, J_{PC} 7 Hz, $C^{Ph2/3}$), 132.1 (C^{Ph4}), 129.5 (t, J_{PC} 5 Hz, $C^{Ph2/3}$), 123.7 (C^{A5}), 121.3 (C^{A3}), 107.7 (C^{B3}), 97.0 ($C{\equiv}CAu$), 57.1 (OCH_2), 23.7 (PCH_2), signal for $C{\equiv}CAu$ not resolved; $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$) δ (ppm) 36.5. MALDI-MS *m*/*z* 1388 $[M+Na]^+$. IR (ν, cm^{-1}) 3055 w, 2924 m, 2854 m, 1697 w, 1558 s, 1435 s, 1404 s, 1335 s, 1258 m, 1188 s, 1103 m, 1018 s, 879 s, 795 m, 725 s, 687 s. UV/Vis λ_{max}/nm (4.62×10^{-5} mol dm^{-3}, CH_2Cl_2) 233 (ε/dm^3 mol^{-1} cm^{-1} 55,500), 253 sh (37,900), 277 (30,400).

2.5. Crystal structure determinations: general

Data were collected on an Enraf Nonius Kappa CCD instrument; data reduction, solution and refinement used the programmes COLLECT [27], SIR92 [28], DENZO/SCALEPACK [29] and CRYSTALS [30].

2.6. Crystal data for 2

$C_{30}H_{39}AuN_3OP$, $M = 685.60$, triclinic, space group $P\bar{1}$, $a = 11.1882(2)$, $b = 11.3401(2)$, $c = 14.3037(2)$ Å, $\alpha = 92.6970(9)$, $\beta = 110.5440(7)$, $\gamma = 116.1495(8)°$, $U = 1480.86(5)$ $Å^3$, $Z = 2$, $D_{calc} = 1.537$ Mg m^{-3}, μ(Mo-Kα) = 5.047 mm^{-1}, $T = 173$ K, 8610 reflections collected. Refinement of 8555 reflections (325 parameters) with $I > 2.0\sigma I$) converged at final $R_1 = 0.0315$ (R_1 all data = 0.0498), $wR_2 = 0.0491$ (wR_2 all data = 0.0592), goodness-of-fit = 0.968.

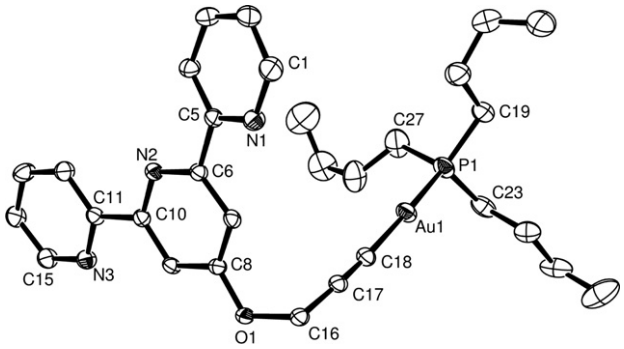
2.7. Crystal data for 4 · 4CHCl3

$C_{66}H_{52}Au_2Cl_{12}N_6O_2P_2$, $M = 1842.49$, triclinic, space group $P\bar{1}$, $a = 8.7136(3)$, $b = 13.3106(4)$, $c = 15.9758(4)$ Å, $\alpha = 110.037(2)$, $\beta = 91.133(2)$, $\gamma = 95.801(2)°$, $U = 1728.92(9)$ $Å^3$, $Z = 1$, $D_{calc} = 1.770$ Mg m^{-3}, μ(Mo-Kα) = 4.797 mm^{-1}, $T = 173$ K, 7916 reflections collected. Refinement of 5094 reflections (442 parameters) with $I > 3.0\sigma$ *I*) converged at final $R_1 = 0.0325$ (R_1 all data = 0.0626),

$wR_2 = 0.0359$ (wR_2 all data = 0.0574), goodness-of-fit = 1.112.

3. Results and discussion

The reactions of alkyne **1** with $^{n}Bu_3PAuCl$ and Ph_3PAuCl were carried out using standard conditions [31] (Scheme 1). The yields of products **2** and **3** were affected by the choice of Et_3N or a mixture of Et_3N and CH_2Cl_2 as solvent. The MALDI mass spectra of **2** and **3** showed parent ions at m/z 686 and 748, respectively. Fragmentation by loss of the $AuPR_3$ unit was observed for both compounds. The $^{31}P\{^1H\}$ NMR spectrum of solutions of each of **2** and **3** exhibited one singlet (δ 25.7 ppm for **2**, δ 38.8 ppm for **3**). Both compounds were characterized by ^1H and ^{13}C NMR spectroscopies. In the ^1H NMR spectra, the signals assigned to the tpy protons of **2** and **3** were characteristic of a non-coordinated ligand, confirming that there had been no competition between alkyne and tpy domains for interaction with the gold(I) centre. The loss of the signal for the C≡CH proton in **1** was evidence for the formation of a C–Au bond. On going from **1** to **3**, the signals in the ^{13}C NMR spectrum assigned to the C≡C units shifted to higher frequency, from δ 77.6 and 76.3 ppm in **1** [22] to δ 129.9 and 96.8 ppm in **3**. Each of these signals was a doublet with coupling of the ^{31}P *trans* to the alkyne unit (J_{PC} 140 Hz, for C≡*C*Au and J_{PC} 26 Hz for *C*≡CAu). These chemical shifts and coupling constants are similar to data reported for other $RC{\equiv}CAuPR'_3$ species [32–36]. For compound **2**, the ^{13}C NMR signal for the *C*≡CAu carbon was observed at δ 96.6 ppm, but the resonance for the metal-bonded C atom could not be resolved. Single crystals of **2** suitable for X-ray crystallography were serendipitously grown by slow evaporation of the crude reaction mixture (CH_2Cl_2–Et_3N 1:1 solvent). Crystals of **2** (colourless plates) were separated from crystals of **1** (large blocks) by hand. The molecular structure of **2** is shown in Fig. 1 and selected bond parameters are listed in the caption. The tpy unit is in the *trans*,*trans*-conformation that is expected for a non-coordinated ligand. The terpy unit deviates slightly from planarity, with the angles between the least squares planes of the rings being 14.0(2)° (for rings containing N1 and N2) and 3.6(2)° (for rings containing N2 and N3). The fact that bond C8–O1 is shorter (1.367(4) Å) than O1–C16 (1.443(4) Å) is consistent with the O atom being sp^2 hybridized, and there being a degree of π-delocalization between the central pyridine ring and oxygen atom. The structural determination confirms the presence of a linear C–C≡C–Au–P unit. All other structural parameters are as expected. In the crystal lattice, molecules of **2** form dimeric motifs, supported by non-classical C–H···N hydrogen bonds (Fig. 2). Rows of dimers assemble along the *a*-axis, with weak C–H···π-alkyne interactions [37–42] operating between dimers (C15H151···C18 = 2.72 Å, C15H151···C17 = 3.00 Å). These rows are aligned so as to produce alternating domains of alkyl and tpy groups (Fig. 3). Interestingly, the weak C–H···N and C–H···π-alkyne interactions dictate the molecular packing, and there are no aurophilic [43,44] or π-stacking interactions.



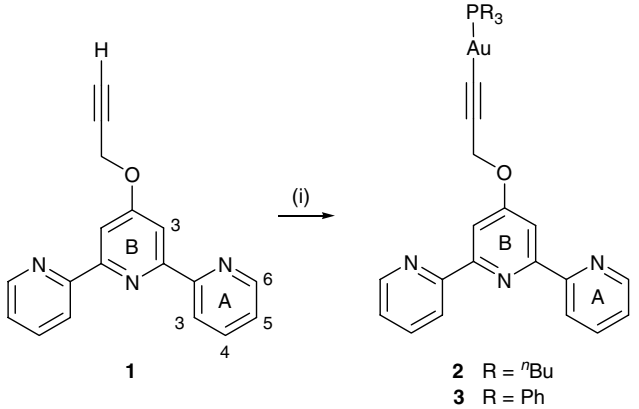


Fig. 1. The structure of **2** with displacement ellipsoids drawn at the 30% probability level; H atoms omitted for clarity. Selected bond lengths and angles: Au1–P1=2.279(1), Au1–C18 = 2.018(4), C17—C18 = 1.186(5), C16–C17 = 1.467(5), C16–O1 = 1.443(4), C8–O1 = 1.367(4), C5–C6 = 1.491(4), C10–C11 = 1.493(4) Å; P1–Au1–C18 = 175.1(1), Au1–C18–C17 = 175.3(3), C18–C17—C16 = 176.7(4), C17—C16–O1 = 111.5(3), C16–O1–C8 = 117.4(3)°.

Scheme 1. Reaction scheme for the formation of **2** and **3**: (i) R_3PAuCl, CuI in Et_3N (for **2**) or Et_3N/CH_2Cl_2 (for **3**). The ring labelling is used for NMR assignments.

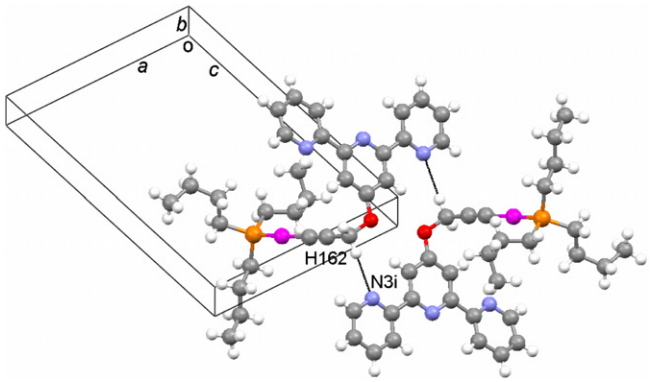

Fig. 2. Dimeric motif in the packing of **2**; symmetry code i = 2 − *x*, 2 − *y*, −*z*. C16H162···N3i=2.53, C16···N3i = 3.433(5) Å; C16–H162···N3i = 158.0°.

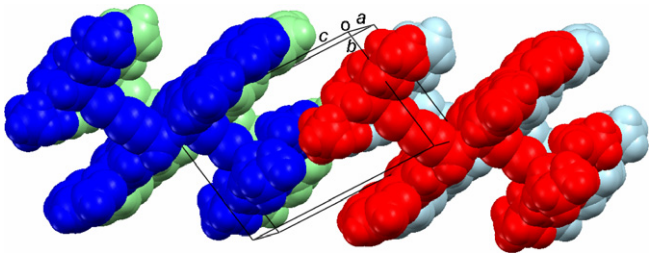

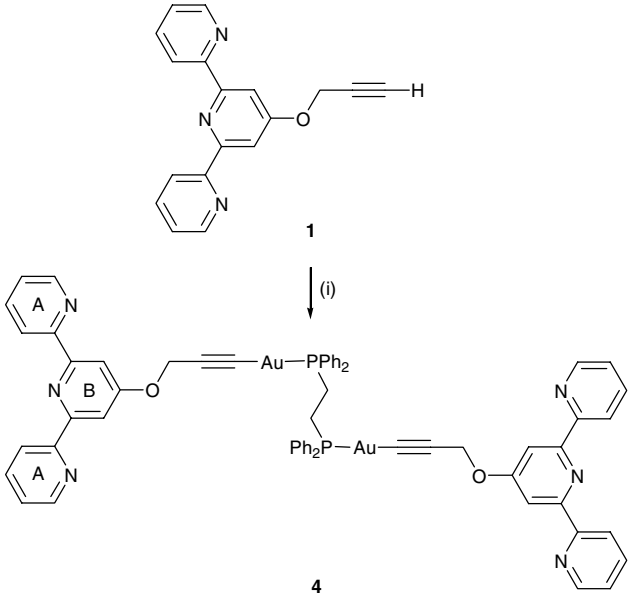

Fig. 3. Four dimers of **2** showing their assembly into rows along the *a*-axis, and the resulting domains of alkyl chains (centre of unit cell) and tpy groups.

Compounds **2** and **3** illustrate the success of the methodology of functionalizing a tpy metal-binding domain in the 4′-position with a gold(I) phosphine. However, in order to develop these systems further towards their use as building blocks in metallomacrocyclic or polymeric systems, it is necessary to incorporate a bridging bis(phosphine) ligand. For initial studies, we chose dppe. Ligand **1** reacts with ClAu(μ-dppe)AuCl in Et_3N/CH_2Cl_2 in the presence of CuI (Scheme 2) to yield **4** in moderate yield. In the MALDI mass spectrum, a peak at *m*/*z* 1388 was assigned to $[M + Na]^+$. The solution $^{31}P\{^1H\}$ NMR spectrum exhibited one signal (δ 36.5 ppm), consistent with the formation of a symmetrical product. The ^1H and $^{13}C\{^1H\}$ NMR spectra were also consistent with the presence of 2 equiv tpy units and a symmetrical dppe ligand. In **4**, the ^{13}C NMR signal for the $C{\equiv}CAu$ carbon was observed at δ 97.0 ppm, consistent with the chemical shifts observed for the analogous C centres in **2** and **3**. As in **2**, the signal for the gold-bonded C atom in **4** was not resolved.

Crystals of $\mathbf{4} \cdot 4CHCl_3$ suitable for an X-ray diffraction study were grown from a $CHCl_3$ solution. The structure of **4** is shown in Fig. 4. The molecule is centrosymmetric, with

Scheme 2. Reaction scheme for the formation of **4**: (i) ClAu(dppe)AuCl, CuI in Et_3N/CH_2Cl_2. The ring labelling is used for NMR assignments.

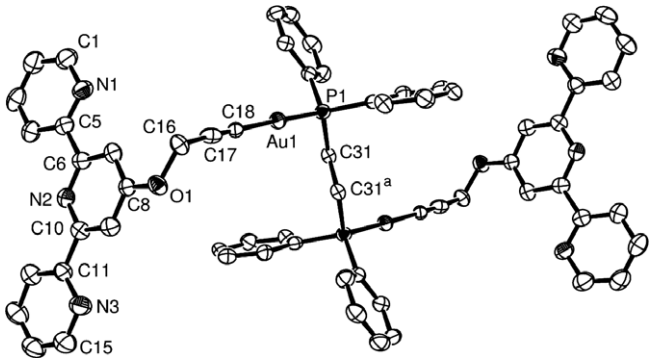

Fig. 4. The structure of **4** in $\mathbf{4} \cdot 4CHCl_3$ with displacement ellipsoids drawn at the 30% probability level; H atoms omitted for clarity. Selected bond lengths and angles: Au1–P1 = 2.275(1), Au1–C18 = 2.062(6), C17—C18 = 1.117(8), C16–C17 = 1.481(8), C16–O1 = 1.449(7), O1–C8 = 1.361(7) Å; P1–Au1–C18 = 178.8(2), Au1–C18–C17 = 177.6(5), C18–C17—C16 = 176.2(6), C17—C16–O1 = 112.3(5), C16–O1–C8 = 119.0(4)°.

the tpy groups adopting a *transoid* arrangement. As a result, there is no intramolecular Au···Au close contact. A search of the CSD [45] shows that in XAu(μ-dppe)AuX derivatives with relatively simple X substituents, a *transoid* arrangment of the Au(μ-dppe)Au unit is usually favoured [46–53], and the formation of an intramolecular Au···Au interaction appears not to drive the molecule towards adopting a *cisoid* arrangement. In several cases, intermolecular aurophilic interactions lead to the formation of polymeric chains [48,54,55]. The structure of ClAu(μ-dppe)AuCl is noteworthy. In both the unsolvated complex and ClAu(μ-dppe)AuCl · $0.4CH_2Cl_2$ [56,57], the Au(dppe)Au unit adopts a conformation between *cisoid* and *transoid*. Inspection of these structures using Mercury v. 1.4.2 [58] shows that in ClAu(μ-dppe)AuCl, intermolecular aurophilic interactions lead to the formation of cyclic dimers, while polymeric chains are present in ClAu(μ-dppe)AuCl · $0.4CH_2Cl_2$. In $\mathbf{4} \cdot 4CHCl_3$, one of the crystallographically independent solvate molecules is ordered, and the second is disordered over two sites (65:35%). The supramolecular interactions that dominate the packing of molecules of **4** are non-classical hydrogen bonds. The C–H···N and O···H–C interactions shown in Fig. 5a, along with those that are symmetry related to the latter, result in the assembly of hydrogen-bonded chains. Significantly, there are no intermolecular Au···Au or π-stacking interactions, and packing of the hydrogen-bonded chains (Fig. 5b) involves only very weak C–H···π-alkyne and C–H···π-aryl contacts along with hydrogen bonds between N2 and one $CHCl_3$ molecule (N2···H321C32 = 2.28 Å, N2···H321–C32 = 162°). Additional factors which may oppose the formation of Au···Au interactions are the steric demands of the substituents and the overall length of the molecule [59].

The isolation of compounds **2**–**4** illustrates the viability of attaching a gold(I) phosphine unit to an alkynyl-functionalized tpy to produce either a gold(I)-decorated monotopic ligand or a gold(I) phosphine bridged ditopic ligand. We now plan to undertake investigations of the coordination behaviour of these ligands.

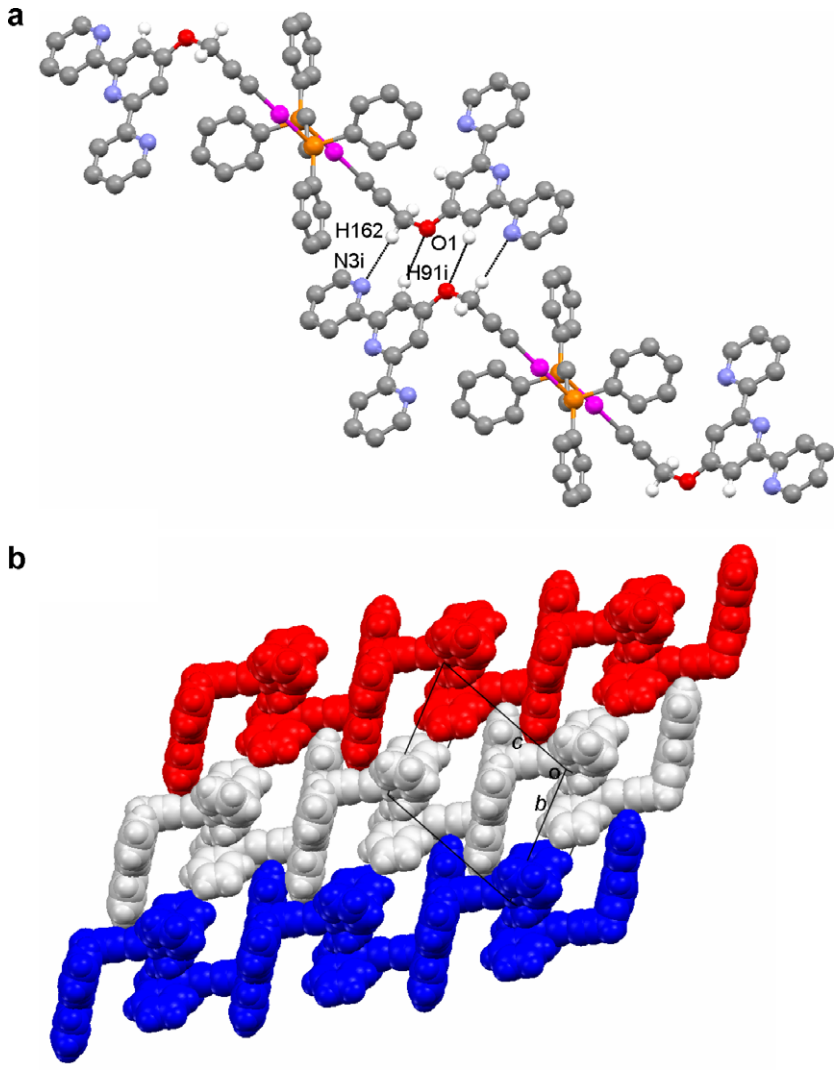

Fig. 5. (a) Non-classical hydrogen bonding interactions between molecules of **4**; symmetry code i = 1 − *x*, −1 − *y*, 1 − *z*. C16H162···N3i = 2.54, C16···N3i = 3.445(8) Å, C16–H162···N3i = 158°, O1···H91iC9i = 2.64, O1···C9i = 3.569(8) Å, O1···H91i–C9i = 162°. Hydrogen atoms other than those of the CH and CH_2 groups involved in hydrogen bonding are omitted for clarity. (b) Packing of hydrogen-bonded chains of **4**.

Abstract

Complexes of general formula, $[M(isa\text{-}sme)_2]\cdot n(solvate)$ [$M = Ni^{2+}$, Cu^{2+}, Zn^{2+}, Cd^{2+}; isa-sme = monoanionic form of the Schiff base formed by condensation of isatin with *S*-methyldithiocarbazate; $n = 1$ or 1.5; solvate = MeCN, DMSO, MeOH or H_2O] have been synthesized and characterized by a variety of physicochemical techniques. An X-ray crystallographic structure determination of the $[Ni(isa\text{-}sme)_2]\cdot MeCN$ complex reveals a six-coordinate, distorted octahedral geometry. The two uninegatively charged, tridentate, Schiff base ligands are coordinated to the nickel(II) ion meridionally *via* the amide O-atoms, the azomethine N-atoms and the thiolate S-atoms. By contrast, the crystal structure of $[Zn(isa\text{-}sme)_2]\cdot MeOH$ shows a four-coordinate distorted tetrahedral geometry. The two dithiocarbazate ligands are coordinated as *N*,*S* bidentate chelates with the amide O-atom not coordinated. The structure of the copper(II) complex $[Cu(isa\text{-}sme)_2]\cdot DMSO$ is complicated and comprises two different complexes in the asymmetric unit, one four- and the other five-coordinate. The four-coordinate copper(II) has a distorted (flattened) tetrahedral geometry as seen in the Zn(II) analogue whereas the five-coordinate copper(II) has a distorted square-pyramidal geometry with one ligand coordinated to the copper(II) ion as a tridentate (*N*, *S*, *O*) ligand and the other coordinated as a bidentate *N*, *S* chelate. EPR spectroscopy indicates that in solution only one form is present, that being a distorted tetrahedral complex.

Keywords: Isatin Schiff base of *S*-methyldithiocarbazate; Nickel(II), zinc(II), copper(II) and cadmium(II) complexes

1. Introduction

Metal complexes of thiosemicarbazones [1–5] and Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid [6–10] have been the subjects of considerable study. The presence of hard N- and soft S-donor atoms in the backbones of these ligands enable them to react readily with both transition and main group metal ions yielding stable metal complexes some of which have been shown to exhibit interesting physico-chemical properties [11] and significant biological activities [12]. Istain (2,3-dihydroindole-2,3-dione) and its derivatives have also been shown to exhibit a wide range of biological activities [13–17]. Since thiosemicarbazones derived from heterocyclic aldehydes and ketones and Schiff bases derived from *S*-alkyl/aryl esters of dithiocarbazic acid often act as versatile chelating agents and exhibit promising bioactivities [12], it is likely that isatin thiosemicarbazones and their metal complexes might also exhibit

doi:10.1016/j.poly.2007.08.022

useful biological activity. Consequently, in recent years, the coordination chemistry as well as biological potentials of some complexes of istain- and *N*-methyl isatin thiosemicarbazones have been studied [18–20]. However, so far there have been no reports on metal complexes of isatin Schiff bases of *S*-alkyl/aryl dithiocarbazates. As part of our general study of metal complexes of dithiocarbazic acid and its derivatives, we report here the preparation and characterization of metal complexes of the istain Schiff base of *S*-methyldithiocarbazate together with the X-ray crystal and molecular structures of the free ligand and its nickel(II), zinc(II) and copper(II) complexes.

A particularly novel feature of the coordination arises from the structural rigidity brought about by the fused heterocyclic ring system. Unlike other Schiff base derivatives of heterocyclic aldehydes or ketones, the ligand presented here are special in that the O=C–C=N chelating moiety is inflexible and the O–M–N coordinate bite angle cannot adapt to metal ions of different sizes in contrast to more flexible ligand systems. As we shall demonstrate, in some cases this prevents coordination by the O-donor to the metal yet this O-atom acts as a blocking group preventing coordination by other ligands in the site it has left vacant.

2. Experimental

2.1. Materials and instrumentation

Isatin was purchased from Aldrich Chemical Company. *S*-methyldithiocarbazate was prepared as described previously [21]. The electronic spectra were recorded with a Shimadzu UV-3100 spectrophotometer. The IR spectra were recorded as KBr discs with either a Perkin–Elmer 1600 FT IR or a Perkin–Elmer 2000 spectrometer. Conductance measurements were made by means of a CMD 400 conductivity meter. Magnetic susceptibilities were measured with a Sherwood Scientific magnetic susceptibility balance calibrated with $HgCo(NCS)_4$. Diamagnetic corrections were applied using Pascal's constants. NMR spectra were measured using Bruker AV300 (300 MHz), AV400 (400 MHz) and AV500 (500 MHz) instruments. Spectra were recorded in $CDCl_3$ or d^6-DMSO with chemical shifts reported in parts per million calibrated using the resonances for $CDCl_3$, ($\delta_H(CHCl_3) = 7.24$ ppm; $\delta_C(CDCl_3) = 77.0$ ppm) or d^6-DMSO ($\delta_H(DMSO) = 2.49$ ppm; $\delta_C(DMSO) = 39.5$ ppm). Abbreviations: s (singlet), d (doublet), t (triplet), and m (multiplet) are employed for reporting of spectral data. Where required water suppression sequences were applied. The electron paramagnetic resonance (EPR) spectrum was recorded at 77 K on a Bruker ER200D spectrometer at X-band frequency (9.307 GHz). The microwave power was 2 mW and the modulation amplitude was 10 G.

2.2. Preparation of the Schiff base

Isatin (1.50 g, 10 mmol) dissolved in boiling MeOH (100 cm^3) was mixed with a boiling solution of *S*-methyldithiocarbazate (1.22 g, 10 mmol) in the same solvent (50 cm^3). The resulting mixture was heated on a water bath for 10 min and then left to stand overnight. The yellow crystalline product which formed was separated by filtration, washed with MeOH and recrystallized from MeCN to obtain light yellow crystals (2.3 g; 88.0%); m.p. 228–230 °C. *Anal.* Calc. for $C_{10}H_9N_3OS_2$ requires: C, 47.79; H, 3.61; N, 16.72. Found: C, 47.69; H, 3.48; N, 16.51%. Selected IR data (KBr pellet, cm^{-1}): 3200 br (νNH); 1686 s (νCO); 1621 s (νCN); 1149 s (νN–N); 978m (νCSS). UV–Vis spectrum [λ_{max} DMF, nm, (ε, $mol^{-1}\,dm^3\,cm^{-1}$)]: 400 *sh*, 381(19100). ^{1}H NMR (d_6-DMSO): δ/ppm, 2.60 (s, 3H, SCH_3), 6.94 (d, 1H, Ph), 7.09 (t, 1H, Ph), 7.40(t, 1H, Ph), 7.53 (d, 1H, Ph); ^{13}C NMR (d_6-DMSO): δ/ppm 17.1 (S–CH_3); 111.4, 119.2, 121.1, 122.8, 132.4, 143.4 (isatin-Ph); 135.6 (C=N); 162.4 (C=O); 201.2 (C=S).

2.3. Preparation of complexes

2.3.1. General method of preparation of $[M(isasme_2)] \cdot xS$ (M=Ni^{2+},Cu^{2+}, Zn^{2+}, Cd^{2+}; S=CH_3CN, H_2O, CH_3OH; $(CH_3)_2SO$; x = 1, 1.5)

A solution of the appropriate hydrated metal nitrate salt (1.0 mmol) in hot MeOH (20 cm^3) was added to a boiling solution of the Schiff base (0.26 g; 0.002 mol) in MeCN (100 cm^3). The mixture was refluxed for 3–4 h and then left to stand overnight. The complexes that crystallized out of the reaction mixture were filtered off, washed with MeOH and dried over anhydrous silica gel in a desiccator (60–70%.). Crystals of $[Cu(isa\text{-}sme)_2] \cdot DMSO$ suitable for X-ray work were obtained by recrystallizing the copper complex from DMSO:MeOH (4:1).

2.3.2. $[Ni(isa\text{-}sme)_2] \cdot MeCN$ (**1**)

Anal. Calc. for $C_{22}H_{19}N_7NiO_2S_4$ requires: C, 44.01; H, 3.19; N, 16.33. Found: C, 43.65; H, 3.21; N, 16.15%. Selected IR data (KBr pellet, cm^{-1}): 3207 m (νNH); 1677 s (νCO); 1608 s (νCN); 1188 s (νN–N); 991 s, 1008 sh (νCSS). UV–Vis spectrum [λ_{max} (nm) DMF, (ε, mol^{-1} dm^3 cm^{-1})] 928 (1020), 484 (17989), 384 (25146). $\mu_B = 2.84$ B.M. Λ (DMF, $ohm^{-1}\,cm^2\,mol^{-1}$): 1.4.

2.3.3. $[Zn(isa\text{-}sme)_2] \cdot MeOH$ (**2**)

Anal. Calc. for $C_{21}H_{22}N_6O_5S_4Zn$ requires: C, 42.18, H, 3.37, N, 14.05. Found: C, 42.03; H, 3.66; N, 14.05%. ^{13}C NMR (d_6-DMSO): δ/ppm 16.1 (S–CH_3); 48.6 (CH_3 of MeOH); 111.9, 115.8, 123.4, 128.1, 134.3, 141.3, 144.3 (isatin-Ph); 166.1 (C=O); 198.0 (C=S). ^{1}H NMR (d_6-DMSO): δ/ppm 2.70 (s, 6H, SCH_3), 3.20 (s, CH_3 of MeOH); 7.04 (d, 2H, Ph), 7.20 (d, 2H), 7.48 (t, 2H, Ph), 8.09 (t, 2H, Ph). Selected IR data (KBr pellet, cm^{-1}): 3135 br, w (νNH); 1701 s (νCO); 1610 s (νCN); 1185 s (νN–N); 991 s, 1000 sh (νCSS). UV–Vis spectrum [λ_{max} DMF, nm, (ε, mol^{-1} $dm^3\,cm^{-1}$): 436 (28724), 381 (25224). Λ (DMF, $ohm^{-1}\,cm^2\,mol^{-1}$): 2.4.

2.3.4. [Cu(isa-sme)$_2$] · (CH$_3$)$_2$SO (3)

Anal. Calc. for $C_{22}H_{22}N_6O_5S_5Cu$ requires: C, 40.84; H, 3.55; N, 12.87. Found: C, 41.13; H, 3.45; N, 13.05%. Selected IR data (KBr pellet, cm^{-1}): 3423 br (νNH); 1717 s, 1676 s (νCO); 1615 s (νCN); 1189 s (νN–N); 996 s, 986 s (νCSS). UV–Vis spectrum [λ_{max} DMF, nm, (ε, mol^{-1} dm^3 cm^{-1})] 701 (356), 443 (19929), 364 (30055). $\mu_B = 2.10$. Λ (DMF, ohm^{-1} cm^2 mol^{-1}): 4.0.

2.3.5. [Cd(isa-sme)$_2$] · 1.5H$_2$O (4)

Anal. Calc. for $C_{20}H_{19}N_6O_{3.5}S_4Cd$ requires: C, 37.53; H, 2.99; N, 13.13. Found: C, 38.04; H, 3.40; N, 12.90%. ^{13}C NMR (d_6-DMSO): δ/ppm 15.9 (S–CH$_3$); 111.8, 116.1, 123.4, 127.7, 133.5, 140.6, 143.3 (isatin-Ph); 166.9 (C=O); 197.6 (C=S). ^{1}H NMR (d_6-DMSO): δ/ppm, 2.68 (s, 6H, SCH$_3$), 7.02 (d, 2H, Ph), 7.17 (t, 2H, Ph), 7.45 (t, 2H, Ph), 8.07 (d, 2H, Ph). Selected IR data (KBr pellet, cm^{-1}): 3205 m (νNH); 1705 s (νCO); 1610 s (νCN); 1185 s (νN–N); 987 s, 1007 w (νCSS). UV–Vis spectrum [λ_{max} DMF, nm, ε, mol^{-1} dm^3 cm^{-1}] 429 (33, 200), *ca.* 381 sh. Λ (DMF, ohm^{-1} cm^2 mol^{-1}): 19.3.

2.4. Crystallography

Cell constants were determined by a least-squares fit to the setting parameters of 25 independent reflections, measured on an Enraf-Nonius CAD 4 four-circle diffractometer using graphite monochromated Mo Kα radiation (0.71073 Å) and operating in the ω–2θ mode within the range $2 < 2\theta < 50°$. An empirical absorption correction (ψ scans) [22] and data reduction [23] were performed within the WINGX [24] suite of programs. The structures were solved by direct methods with SHELX86 [25] and refined by full-matrix least-squares analysis with SHELXL97 [26]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were included at estimated positions. Drawings of all molecules were produced with ORTEP3 [27]. A summary of the crystal data, structure solution and refinement parameters are given in Table 1. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. Syntheses

Isatin is a highly conjugated compound with an intense orange colour but its condensation with *S*-methyldithiocarbazate produces a light yellow crystalline Schiff base compound. Like most thiosemicarbazones and Schiff bases derived from dithiocarbazic acid, it can exhibit thione-thiol tautomerism [28] (Fig. 1) since it has a thioamide functional group –NH–C(=S)SR.

The solid state IR spectrum of Hisa-sme does not reveal any νSH band at *ca.* 2700 cm^{-1} indicating that, in the solid state, it remains as the thione form (1a). Its ^{1}H NMR spectrum in $CDCl_3$ also does not exhibit any signal attributable to the SH proton indicating that in solution, it also remains predominantly as the thione form. However, upon depro-

tonation, it is found in the thiolate form (1c) and is capable of coordination to divalent metal(II) ions to give compounds of the general formula, $[M(isa\text{-}sme)_2]\cdot n(solvate)$ ($M = Ni^{II}$, Cu^{II}, Zn^{II}, Cd^{II}; solvate = MeCN, DMSO, MeOH or H_2O; $n = 1, 1.5, 2.0$). Attempts to prepare mono-ligand complexes of the type $M(Hisa\text{-}sme)X_2$ or [M(isa-sme)X] ($M = Ni^{II}$, Zn^{II}, Cd^{II}; $X = Cl^-$, Br^-) were unsuccessful.

3.2. Crystallographic characterization

3.2.1. [Ni(isa-sme)$_2$] · MeCN (*1*)

The crystal structure of the nickel complex is shown in Fig. 2 and selected bond lengths and bond angles are given in Table 2. The structure reveals a six-coordinate nickel(II) ion in a distorted octahedral environment. An MeCN molecule (not shown here) is H-bonded to the amide N–H group of one ligand. The two isatin Schiff bases are coordinated to the nickel ion as uninegatively charged tridentate

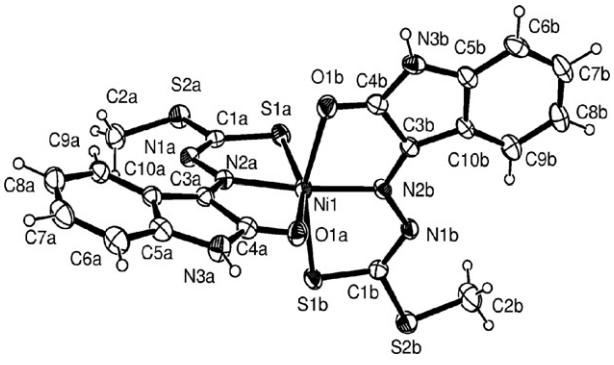

Fig. 2. The molecular structure of (**1**) Ni(isa-sme)$_2$ (30% probability ellipsoids). The MeCN molecule that co-crystallised is omitted for clarity.

chelating agents *via* the carbonyl oxygen atom, the azomethine nitrogen atom and the thiolate sulfur atom. Deprotonation of the ligand produces an iminothiolate ion with a

negative charge on the sulfur atom which is delocalized in the C–N–N–C chain of the dithiocarbazate moiety as indicated by the bond distances C(1A)–N(1A): 1.329(4) Å and C(1B)–N(1B): 1.315(4) Å; N(1A)–N(2A): 1.366(4) Å, N(1A)–N(2B): 1.372(4) Å; C(3A)–N(2A): 1.297(4) Å, C(3B)–N(2B): 1.288(4) Å which fall between the extrema anticipated for pure double or single bonds.

The Schiff bases are coordinated to the nickel(II) ion in meridional configurations with the azomethine N-atoms *trans* and the pairs of thiolate S- and carbonyl O-atoms *cis*. The angle between the two Ni···S···N···O planes defined by each ligand is 89°, i.e. the two ligands are essentially orthogonal. Similar meridional configurations have also been reported for related bis-ligand nickel(II) complexes of other *O*, *N*, *S* donor ligands [17,18,29]. The Ni–N bonds are the shortest and are similar to those of other six-coordinate high-spin nickel(II) complexes of related ligands [18–20]. The two Ni–S bond lengths are also similar to those of related bis-ligand nickel(II) complexes of isatin thiosemicarbazones [18–20]. The two Ni–O distances are different [2.228(3) Å, 2.294(3) Å] and also very long by comparison with the Ni–N distances. This is indicative of very weak coordination by these amide O-atoms. It is of note that similarly weak Ni–O coordinate bonds have been seen in an isatin-thiosemicarbazone complex $[Ni(isa\text{-}tsc)_2]\cdot EtOH$ [18]. This feature may be due to either an inherently poor nucleophilicity of the amide O-atom or it may be a consequence of rigidity in the chelate ring brought about by the bicyclic indole moiety which prevents any closer approach by the O-atom to the Ni ion. The C–S bond distances [1.715(4), 1.707(4) Å] in the complex are longer than that observed in related free Schiff base ligands derived from *S*-methyldithiocarbazate [28] confirming that the thiolate tautomer is present in the coordinated ligand (Fig. 1, structure 1c). For the purpose of comparison, Ni coordinate bond distances in closely related complexes are given in Table 3. The data indicate that bond distances in the most six-coordinate nickel(II) complexes of planar tridentate *O*, *N*, *S* ligands compare well, except that the Ni–S bond distances in the present nickel complex are longer than those in other such complexes, perhaps a reflection of the *mer* configuration and the resulting increased interaction between the sulfur donor atoms.

The stereochemistry of nickel(II) in the complex can be considered as a distorted octahedron. All coordinate angles within each five-membered chelate ring are around 80°, while the *trans* N(2B)–Ni(1)–N(2A) angle (172.6(1)) is somewhat distorted from linearity. A comparison of bond angles in the present nickel complex with those of related complexes of *O*, *N*, *S* chelates [18–20,28] indicates that none of the complexes of *O*, *N*, *S* donor ligands have regular octahedral geometries. The unequal field strengths provided by the three different donor atoms in this type of ligands are expected to cause substantial tetragonal distortion from octahedral symmetry which is what is actually observed in these complexes.

3.2.2. $[Zn(isa\text{-}sme)_2]\cdot MeOH$ (2)

The molecular structure of the zinc complex is shown in Fig. 3 and selected bond lengths and angles are included in Table 2. The structure shows that, in contrast with the bis-ligand nickel(II) complex which has a distorted octahedral

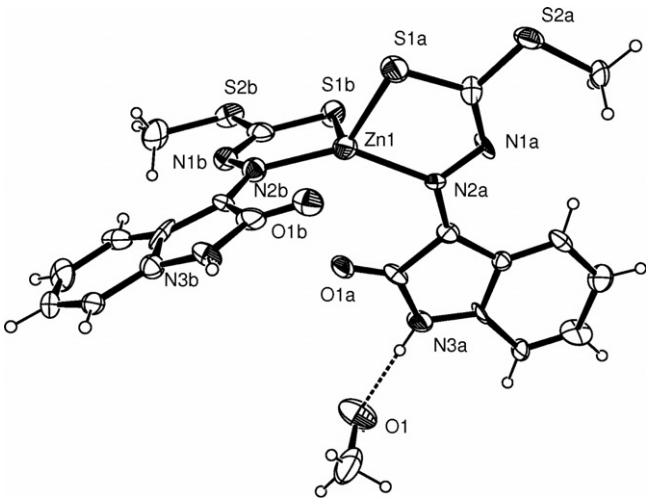

Fig. 3. View of (**2**) $[Zn(isa\text{-}sme)_2]\cdot MeOH$ structure (30% probability ellipsoids).

Table 3
Comparison of Ni-donor atom distances in bis-ligand six-coordinate nickel(II) complexes of ONS donor ligands

Compound[a]	Ni–S	Ni–$N_{azomethine}$	Ni–O	Ref.
$[Ni(isa\text{-}tsc)_2]\cdot C_2H_5OH$	2.368(2)	2.023(3)	2.226(3)	[17]
$[Ni(isa\text{-}tsc)_2]\cdot DMF$	2.378(3) 2.345(3)	2.027(6) 2.022(6)	2.177(5) 2.212(6)	[17]

$[Ni(isa\text{-}sme)_2]\cdot MeCN$	2.3847(11) 2.3818(11)	2.008(3) 1.995(3)	2.228(3) 2.294(3)	this work

[a] isa-tsc = monoanionic form of isatin thiosemicarbazone; misa-tsc = anionic form of 1-*N*-methyl isatin thiosemicarbazone; mpsme = anionic form of the methylpyruvate Schiff base of *S*-methyldithiocarbazate.

geometry, the zinc complex has a four-coordinate configuration in which the Schiff bases are coordinated to the zinc atom not as tridentate ONS ligands but as uninegatively charged NS bidentate chelating agents *via* the two azomethine nitrogen atoms and the two thiolate sulfur atoms. The methanol molecule is hydrogen bonded to the N3A atom of the isatin ring.

The angle between the two Zn···N···S planes is 80° thus the coordination geometry is best considered distorted tetrahedral. The coordinate angles are in the range 144.3(8)–81.3(7)°, the smallest being associated with the N2*n*-Zn–S1*n* chelate rings. The crystals for this structure determination were not of ideal quality and the precision is poorer than the other structures reported here. Nevertheless, the Zn–N [2.04(2) and 2.08(2) Å] and Zn–S [2.379(8) and 2.310(8) Å] bond distances are comparable with those of the analogous zinc(II) complex bis[*S*-methyl-b-*N*-(2-furylmethyl)methylenedithio-carbazato]zinc(II) of a bidentate *N*,*S* donor ligand, which also has a distorted tetrahedral geometry and the same ZnN_2S_2 coordination kernel [29]. As expected, the Zn–S and Zn–N bond lengths in the present zinc complex are shorter than similar bonds in octahedral zinc(II) complexes of tridentate *N*,*N*,*S* dithiocarbazate ligands [30]. The Zn···O distances are each in excess of 2.58 Å and thus are too long to be considered genuine coordinate bonds. Notwithstanding, it is very interesting that the amide O-atoms, due to their proximity to the Zn ion, effectively block coordination by any other monodentate ligands in these 'vacant' coordination sites.

3.2.3. [Cu(isa-sme)$_2$] · DMSO (3)

The crystal structure of the bis-ligand copper(II) complex is out of the ordinary in that it contains a four-coordinate copper(II) complex (Fig. 4a) and a five-coordinate copper(II) complex (Fig. 4b) within the asymmetric unit in addition to two DMSO molecules (one disordered). In the four-coordinate complex, the ligands are coordinated to the copper(II) ion *via* the thiolate S- and azomethine N-atoms. The Cu–S [2.215(3) and 2.242(2) Å] and Cu–N [2.037(4) and 1.998(4) Å] bond lengths are similar to those of the bis-chelated four coordinate copper(II) complex of related *p*-dimethylaminobenzaldehyde Schiff base of *S*-benzyldithiocarbazate [31]. The angle between the two Cu···N···S planes is 50° thus the CuN_2S_2 moiety is distorted to roughly half-way between a tetrahedral and a square planar geometry. The Cu···O distances are each in excess of 2.8 Å and are hence too remote to be included in the first coordination sphere.

In the five-coordinate copper(II) complex (Fig. 4b), one of the Schiff bases is coordinated to the copper(II) ion as a tridentate *O*,*N*,*S* chelate (as seen in the Ni(II) structure, Fig. 2) while the other ligand molecule is coordinated as a bidentate *N*,*S* chelate. The coordination geometry of the copper(II) ion in the five-coordinate unit can be considered as approximately square-pyramidal. The structural parameter τ is commonly used to describe 5-coordinate complexes distorted between an ideal square pyramid ($\tau = 0$) and a trigonal bipyramid ($\tau = 1$). The equation is $\tau = (\beta - \alpha)/60°$, with α and β being the two largest coordinate angles (160.4(1)° and 169.4(2)°, respectively in this case), to afford a value of 0.148 for this 5-coordinate complex.

The angle between the two Cu···N···S planes defined by the two coordinated ligands is 78° and clearly much closer to orthogonal than in the four-coordinate complex. The Cu–S bonds [2.455(2) and 2.379(8) Å] are very different and this disparity can be attributed to a Jahn–Teller distortion arising from the d^9 electronic configuration leading to elongation of the coordinate bonds along the Cu–S1A axis. This in part explains why O1A is not coordinated (CuÅ···O1A) > 2.62 Å as it lies along the same axis of elongation. The remaining equatorial coordinate bonds are shorter although once again an unusually elongated equatorial bond to the amide O-atom is seen (as with the Ni(II) analogue). The coordinate bonds compare well with other five-coordinate copper(II) complexes such as [Cu(NNS)(phen)]ClO_4 (where NNS = Schiff base formed from pyridine-2-*N*-oxide carbaldehyde Schiff base of

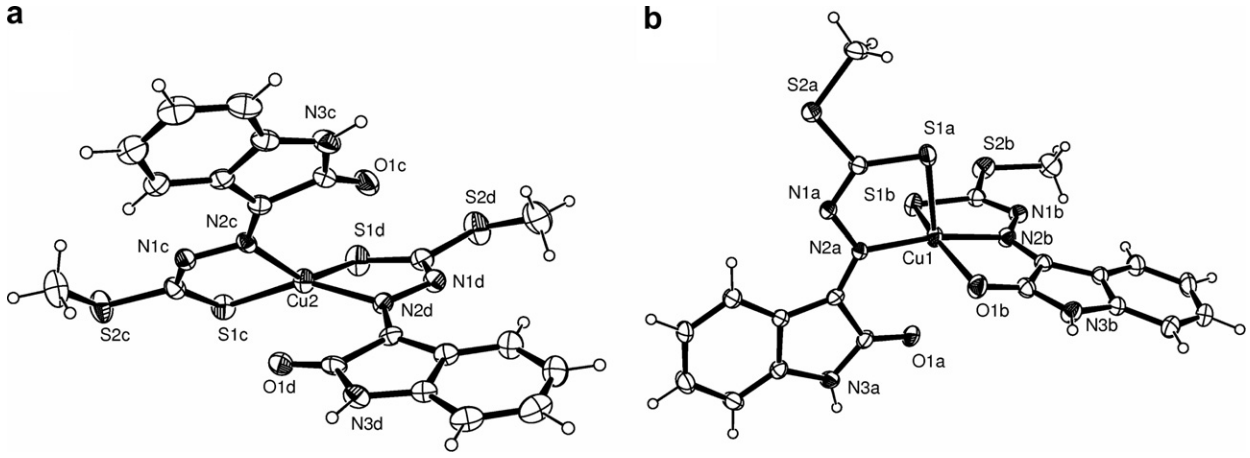

Fig. 4. The molecular structures of the complexes in (**3**): (a) four-coordinate Cu(isa-sme)$_2$ and (b) five-coordinate Cu(isa-sme)$_2$ found in the same asymmetric unit (30% probability ellipsoids). The DMSO molecules are omitted for clarity.

S-benzyldithiocarbazate) [32]. The bond distances in the dithiocarbazate chain are similar to those found in the nickel complex described above. In both copper(II) centres, the coordinate angles deviate significantly from the ideal values because of the restraint imposed by the five-membered chelate rings.

3.3. Physical and spectroscopic characterization of isa-sme complexes

The nickel(II), copper(II), zinc(II) and cadmium(II) complexes exhibit molar conductances of 1.4, 4.0, 2.4 and 19.3 $ohm^{-1}\,cm^2\,mol^{-1}$, respectively in DMF indicating that they behave essentially as non-electrolytes in this solvent. The non-electrolytic nature of the complexes also indicates that the ligands remain coordinated as monoanions in solution. The room-temperature magnetic moment of the nickel(II) complex (2.84 B.M.) indicates that it is high-spin and six-coordinate. The magnetic moment of the copper(II) complex (2.10 B.M.) is normal for a $3d^9$ metal ion in a magnetically dilute environment.

The IR spectrum of Hisa-sme exhibits a strong band at 1686 cm^{-1} assigned to the ν(C=O) of the carbonyl group. In the spectrum of the nickel(II) complex this band shifts to lower frequency in accordance with the observed coordination environment of the metal ion. The corresponding ν(C=O) band in the IR spectra of the zinc(II) and cadmium(II) complexes shifts to higher wave number suggesting that it is not coordinated. In contrast, for all three metal ions the IR spectrum exhibits a shift in the azomethine ν(C=N) band from the free ligand position (1621 cm^{-1}) to lower wave numbers indicates the involvement of this moiety in bonding in each case. The shift of the ν(N–N) band of the free ligand to higher wave numbers in the spectra of the complexes (from 1149 to *ca.*1185 cm^{-1}) supports the suggestion of the bonding of the azomethine nitrogen atom to the metal ions. The splitting of the νCSS band of the free ligand at 978 cm^{-1} in the spectra of the complexes is strong evidence that the ligand coordinates with the metal ions through one of the sulfur atoms [33].

The electronic spectrum of Ni(isa-sme)$_2$ (in DMF) displays bands at 928, 680 sh, 484 and 384 nm. Six-coordinate nickel(II) complexes are expected to exhibit three spin-allowed bands corresponding to the $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transitions. However, with sulfur-containing ligands the transition, $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ is invariably obscured by $S \rightarrow M$ charge transfer bands and consequently, only two bands are generally observed. The bands at 928 and 680 nm are thus assigned to the $^3A_{2g} \rightarrow {}^3T_{2g}$ and $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ transitions, respectively. For the six-coordinate nickel(II) complex of the methylpyruvate Schiff base of S-methyl dithiocarbazate, with the same $NiO_2N_2S_2$ chromophore, d–d bands at 915 and 550 nm were observed [28]. The intense band at 484 nm in the spectrum of [Ni(isa-sme)$_2$] is probably a combination of a d–d band corresponding to the transition $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ and the $S \rightarrow Ni^{II}$ charge-transfer band. The electronic spectrum of the [Cu(isa-sme)$_2$]·DMSO exhibits a broad d–d band at 771 nm and $S \rightarrow Cu^{II}$ C.T. band at 443 nm. The presence of a S–Cu^{II} C.T. band is typical of copper(II) complexes of dithiocarbazate ligands [34–37]. The electronic spectra of the d^{10} zinc(II) and cadmium(II) complexes are similar to those of the free ligand although bathochromic shifts of the bands seen in the free ligand are apparent.

The X-ray structural data shows that the ligand is bound to nickel(II) ion *via* the carbonyl oxygen atom, the azomethine nitrogen atom and the thiolate sulfur atom. However, the non-electrolyte character and the differences in the IR spectra between the nickel(II) and the zinc(II) and cadmium(II) complexes suggest that the latter are coordinated to the isa-sme ligand through the azomethine nitrogen and thiolate sulfur atoms. No crystals of the Cd complex suitable for X-ray work were obtained so its structure remains unknown. A tetrahedral geometry of the kind seen in the Zn analogue is consistent with the very similar IR results of the Cd and Zn complexes, but in the absence of a crystal structure this is only a speculative assignment.

The identification of two distinctly different Cu(II) complexes in the crystal structure of [Cu(isa-sme)$_2$]·DMSO poses the question of its structure in solution. In other words does it exist as a distorted tetrahedral CuN_2S_2 complex or a tetragonally elongated (4 + 1) square pyramidal CuN_2OS_2 or perhaps as an equilibrium mixture of the two? The electronic spectrum of the complex does not discriminate between these possibilities. EPR spectroscopy is very sensitive to angular distortions at the Cu(II) centre; particularly those involving a distortion from planar to tetrahedral geometry [38]. A Cu(II) complex with tetragonally elongated (axial) symmetry will yield an EPR spectrum with two sets of resonances parallel with and perpendicular to the axis of symmetry (designated ∥ and ⊥). Hyperfine coupling with the Cu nucleus (^{63,65}Cu $I = 3/2$) generates two sets of four lines centred at $g_\parallel$ and $g_\perp$; the splitting of each set of four lines being equal to the hyperfine coupling constants $A_\parallel$ and $A_\perp$, respectively. As a general rule, distortion from planar towards tetrahedral geometry results in a decrease in $A_\parallel$ and increase in $g_\parallel$ as shown in a number of synthetic and biological examples involving Cu(II) [39,40]. The experimental X-band EPR spectrum of [Cu(isa-sme)$_2$]·DMSO is shown in Fig. 5. The spin Hamiltonian parameters were obtained by spectral simulation [42] (also shown in Fig. 5). The most relevant (and accurately determined) parameters are $A_\parallel$ (105 G) and $g_\parallel$ (2.185) while the remaining parameters $A_\perp$ (∼45 G) and $g_\perp$ (∼2.06) are less certain as these transitions (in particular the hyperfine splittings) are not resolved due to the linewidths of the transitions. Nevertheless, the $A_\parallel$ value is very small and in line with that of a dominantly tetrahedral CuN_2S_2 complex [39–41].

For comparison, the EPR spectra of a series of CuN_2S_2 complexes of a tetradentate ligand were reported [39], where the tetrahedral twist angle was varied by structural

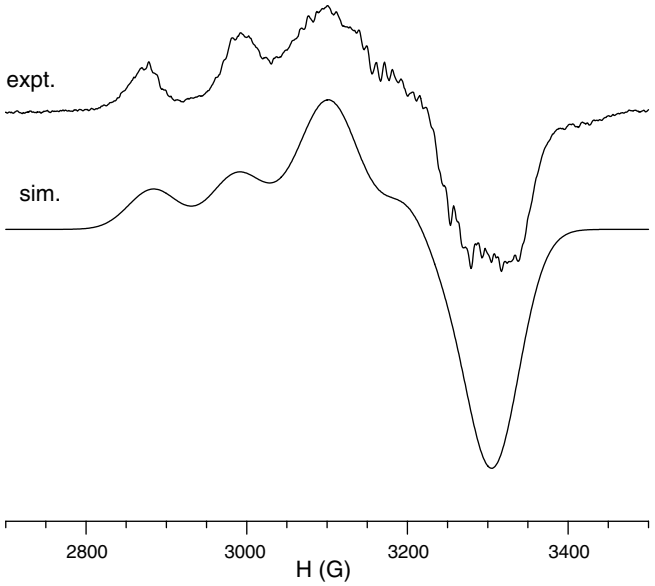

Fig. 5. Experimental and simulated X-band (9.307 GHz) EPR spectra of Cu(isa-sme)$_2$ in DMSO at 77 K (1 mM frozen solution). Simulation spin Hamiltonian parameters $g_{\|} = 2.185$, $A_{\|} = 105\ G$; $g_{\perp} = 2.06$ and $A_{\perp} = 45$ G. Linewidths 35 G, Lorentzian lineshapes.

changes to the chelate ring size. The Cu(II) complex exhibiting the greatest tetrahedral twist (57°) gave an EPR spectrum where $A_{\|}$ was 145 G, while a less twisted analogue (53°) gave an $A_{\|}$ value of 160 G. The even smaller $A_{\|}$ (105 G) seen in Cu(isa-sme)$_2$ is indicative of a tetrahedral twist angle greater that 57°. We contend that the solution structure of Cu(isa-sme)$_2$ approaches that of the Zn(II) analogue identified crystallographically where a twist angle of 80° was seen. Indeed this geometry can easily be derived from the 5-coordinate form of the complex seen in the crystal structure of [Cu(isa-sme)$_2$]·DMSO (twist angle 78°) by merely breaking the (already strained) Cu–O bond in the absence of any other conformational change. It is important to point out that the EPR spectrum of [Cu(isa-sme)$_2$]·DMSO is not consistent with a tetragonally elongated (4 + 1) Cu(II) complex (either square pyramidal or pseudo square planar) as both types of complexes invariably furnish EPR spectra where $A_{\|}$ is in the vicinity of 200 G [38–41]. In other words, we can conclude that the solid state structure of Cu(isa-sme)$_2$ is affected by packing forces and not representative of the structure of the complex in solution. The DMSO solvate molecules and the proximity of the 4- and 5-coordinate Cu(II) complexes in the structure results in distortions away from its ideal structure in solution.

4. Conclusions

The isatin Schiff base of *S*-methyldithiocarbazate behaves as a versatile chelating agent exhibiting variable denticity toward metal ions depending upon the requirements of the particular metal centre. Thus, it behaves as a uninegatively charged tridentate O,N,S chelate with nickel(II) forming a stable six-coordinate high-spin octahedral nickel(II) complex. However, with zinc(II) and cadmium(II) it behaves as an N,S bidentate chelating agent forming distorted tetrahedral complexes. With copper(II), in the solid state, it behaves both as a bidentate N,S ligand as well as a tridentate O,N,S donor chelate producing a novel structure comprising both 4- and 5-coordinate copper(II) complexes within the asymmetric unit. EPR spectroscopy of the Cu(II) complex reveals a homogeneous solution structure that is different to both of the crystallographically identified forms.

5. Supplementary material

CCDC 638441, 638442 and 638443 contain the supplementary crystallographic data for **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Abstract

Mononuclear complexes of cyclodiphosphazane with an uncoordinated phosphorus centre [$RuCl_2$(η^6-cymene){L-κP}] (**1a**) (L = *cis*-{(*o*-$MeOC_6H_4O$)P(μ-N^{t}Bu)}$_2$) and [$PdCl_2$(PEt_3){L-κP}] (**1b**) react with 1 equiv. of [AuCl(SMe_2)] to afford Ru^{II}/Au^{I} and Pd^{II}/Au^{I} heterodinuclear complexes [$RuCl_2$(η^6-cymene){μ-L-κP,κP}AuCl] (**2**) and [$PdCl_2$(PEt_3){μ-L-κP,κP}AuCl] (**3**), respectively. Heterotrinuclear complexes [$PdCl_2${μ-L-κP,κP}$_2$($AuCl)_2$] (**4**), [$PtCl_2${μ-L-κP,κP}$_2$($AuCl)_2$] (**5**) and [CuI{μ-L-κP,κP}$_2$($AuCl)_2$] (**6**) containing $Pd^{II}/2Au^{I}$, $Pt^{II}/2Au^{I}$ and $Cu^{I}/2Au^{I}$ metal centers have been synthesized from the reactions of *trans*-[$PdCl_2${L-κP}$_2$] (**1c**), *cis*-[$PtCl_2${L-κP}$_2$] (**1d**) and [CuI{{L-κP}$_2$] (**1f**) respectively, with 2 equiv. of [AuCl(SMe_2)]. Molecular structures of complexes **2**, **3** and **4** were established by single crystal X-ray diffraction studies.

Keywords: Cyclodiphosphazanes; Heterometallic complexes; Mono- and bidentate coordination; Crystal structures

1. Introduction

Over the past decade cyclodiphosphazanes have been extensively used for the syntheses of several phosphorus–nitrogen macrocycles and cages [1]. Stahl and Chivers utilized amide substituted cyclodiphosphazanes of the type *cis*-[(^{t}BuNH)P(E)(μ-N^{t}Bu)]$_2$ (E = lone pair, O, S, Se) to stabilize various main group and transition metals [2]. Earlier reports on the coordination chemistry of cyclodiphosphazanes were limited to group-6 and 10 metals [3]. Recently we investigated [4] the coordination behavior of the cyclodiphosphazane *cis*-[(*o*-$MeOC_6H_4O$)P(μ-N^{t}Bu)]$_2$ with various transition metal reagents and observed the *cis*-[(*o*-$MeOC_6H_4O$)P(μ-N^{t}Bu)]$_2$ ligand selectively forming mononuclear complexes with metal reagents such as [$RuCl_2$(η^6-cymene)]$_2$, [MCl(COD)]$_2$ (M = Rh, Ir), [$PdCl_2$-(PEt_3)]$_2$, [MCl_2(COD)] (M = Pd, Pt) and AgCN irrespective of the stoichiometry and the reaction conditions. In contrast, reactions with [$Rh(CO)_2Cl]_2$, [PdCl(η^3-C_3H_5)]$_2$, CuX (X = Cl, Br, I), AgOTf and AuCl(SMe_2) afforded complexes with ligand exhibiting both monodentate and bridged bidentate coordination modes. The bridging coordination mode of the cyclodiphosphazane leads to the formation of novel metallamacrocycles (Rh^{I}, Au^{I}) and one dimensional coordination polymers (Cu^{I} and Ag^{I}). The monodentate coordination of the cyclodiphosphazane leads to the complex having a free P^{III} site for further coordination. This interesting coordination behavior of *cis*-[(*o*-$MeOC_6H_4O$)P(μ-N^{t}Bu)]$_2$ can be utilized for the syntheses of numerous hetero-multinuclear complexes containing two or more different late transition metals. Heterometallic complexes containing two different early or late transition metals are difficult to synthesize due to the similar reactivity of late metals toward symmetrical ligands, whilst late-early heterometallic (LEHM) complexes can be conveniently prepared using amide or alkoxy functionalized phosphine ligands due to the preference of

doi:10.1016/j.poly.2007.08.024

early metals for hard centers and late metals for soft metal centers [5]. Heterometallic complexes containing platinum metals which are far apart with out metal–metal interactions can be utilized as one pot catalysts to promote more than one type of catalytic reaction [6]. In this context, we report the syntheses of Ru^{II}/Au^{I}, Pd^{II}/Au^{I}, $Pd^{II}/2Au^{I}$, $Pt^{II}/2Au^{I}$ and $Cu^{I}/2Au^{I}$ heterometallic complexes anchored by the cyclodiphosphazane, *cis*-[(*o*-$MeOC_6H_4O$)-P(μ-N^{t}Bu)]$_2$ and also the molecular structures of Ru^{II}/Au^{I}, Pd^{II}/Au^{I}, $Pd^{II}/2Au^{I}$ heterometallic derivatives.

2. Experimental

All experimental manipulations were carried out under an atmosphere of dry nitrogen using Schlenk techniques. Solvents were dried and distilled prior to use by conventional methods [7]. The compounds [$RuCl_2$-(η^6-cymene){μ-L-κP}] (**1a**), [$PdCl_2(PEt_3)${μ-L-κP}] (**1b**), *trans*-[$PdCl_2${μ-L-κP}$_2$] (**1c**), *cis*-[$PtCl_2${μ-L-κP}$_2$] (**1d**) [4b], [CuI{μ-L-κP}$_2$] (**1e**) [4c] (**L** = *cis*-{(*o*-$MeOC_6H_4O$)P-(μ-N^{t}Bu)}$_2$) and [$AuCl(SMe_2)$] [8] were prepared according to the published procedures.

The ^{1}H and ^{31}P{^{1}H} NMR spectra were recorded using Varian Mercury Plus spectrometer operating at the appropriate frequencies using TMS and 85% H_3PO_4 as internal and external references, respectively. Microanalyses were performed on a Carlo Erba Model 1112 elemental analyzer. Mass spectrometry experiments were carried out using Waters Q-Tof micro-YA-105. Melting points were recorded in capillary tubes and are uncorrected.

2.1. Synthesis of [$RuCl_2$(η^6-cymene){μ-L-κP,κP}AuCl] (2)

A dichloromethane (7 mL) solution of [$AuCl(SMe_2)$] (20.2 mg, 0.069 mmol) was added dropwise to [$RuCl_2$-(η^6-cymene){μ-L-κP}] (**1a**) (52.3 mg, 0.069 mmol) in CH_2Cl_2 (5 mL) at room temperature with stirring. Stirring was continued for 6 h with minimum light exposure. The reaction mixture was concentrated to 5 mL under reduced pressure and to this was added 3 mL of hexane. Storage at −30 °C for one day afforded the product as dark orange crystals (52.5 mg, 77%). M.p.: 170–172 °C (dec). *Anal*. Calc. for $C_{32}H_{46}N_2P_2O_4Cl_3RuAu$: C, 38.85; H, 4.68; N, 2.83. Found: C, 38.59; H, 4.71; N, 3.05%. ^{1}H NMR (400 MHz; $CDCl_3$, 25 °C): δ_H = 7.26–6.90 (m, 8H, Ph), 5.47 (d, J_{HH} = 6 Hz, 2H, *MeC$_6$H$_4$^{i}Pr-p*), 5.34 (d, 2H, *MeC$_6$H$_4$^{i}Pr-p*), 3.85 (s, 3H, OMe), 3.86 (s, 3H, OMe), 2.92 (sep, 1H, CH), 2.16 (s, 3H, Me), 1.54 (s, 18H, ^{t}Bu), 1.28 (d, J_{HH} = 6.8 Hz, 6H, CMe_2) ppm. ^{31}P{^{1}H} NMR (161.9 MHz, $CDCl_3$, 25 °C): δ_P = 129.3 (s, 1P, PRu), 105.3 (s, 1P, PAu) ppm.

2.2. Synthesis of [$PdCl_2(PEt_3)${μ-L-κP,κP}AuCl] (3)

[$AuCl(SMe_2)$] (19.2 mg, 0.065 mmol) dissolved in 5 mL of dichloromethane was added to [$PdCl_2(PEt_3)${μ-L-κP}] (**1b**) (48.7 mg, 0.065 mmol) also in dichloromethane at room temperature. The resulting reaction mixture was stirred for 4 h, concentrated to 5 mL and diluted with 5 mL CH_3CN. Slow evaporation of CH_2Cl_2 from this solution at room temperature yielded the product as yellow crystals (58.6 mg, 92%). M.p.: 218–220 °C (dec). *Anal*. Calc. for $C_{28}H_{47}N_2O_4P_3PdAuCl_3$: C, 34.37; H, 4.84; N, 2.86. Found: C, 34.56; H, 4.98; N, 2.79%. ^{1}H NMR (400 MHz; $CDCl_3$, 25 °C): δ_H = 7.05–6.84 (m, 8H, Ph), 3.87 (s, 3H, OMe), 3.79 (s, 3 H, OMe), 2.27 (m, 2H, CH_2), 1.55 (s, 18H, ^{t}Bu), 1.26 (m, 3H, CH_3) ppm. ^{31}P{^{1}H} NMR (161.9 MHz, $CDCl_3$, 25 °C): δ_P = 108.9 (d, $^2J_{PP}$ = 39 Hz, 1P, AuP), 83.8 (dd, 1P, PdP), 30.2 (d, $^2J_{PP}$ = 16 Hz, 1P, $PdPEt_3$) ppm. MS(EI, *m*/*z*): 942.76 (M–Cl).

2.3. Synthesis of [$PdCl_2${μ-L-κP,κP}$_2$($AuCl)_2$] (4)

A dichloromethane solution (7 mL) of [$AuCl(SMe_2)$] (48.1 mg, 0.164 mmol) was added dropwise to a well-stirred dichloromethane solution (10 mL) of *trans*-[$PdCl_2$-{μ-L-κP}$_2$] (**1c**) (88.3 mg, 0.082 mmol) at room temperature. The yellow reaction mixture was stirred at room temperature for 4 h, concentrated to 10 mL under reduced pressure and diluted with 5 mL of CH_3CN. Storage at room temperature for 3 days afforded the product as yellow crystals (110 mg, 87%). M.p.: 206–208 °C (dec). *Anal.* Calc. for $C_{44}H_{64}N_4P_4O_8PdAu_2Cl_4$: C, 34.24; H, 4.18; N, 3.63. Found: C, 34.48; H, 4.27; N, 3.44%. ^{1}H NMR (400 MHz; $CDCl_3$, 25 °C): δ_H = 8.04–6.83 (m, 16 H, Ph), 3.88 (s, 6H, OMe), 3.86 (s, 6H, OMe), 1.63 (s, 36H, ^{t}Bu) ppm. ^{31}P{^{1}H} NMR (161.9 MHz, $CDCl_3$, 25 °C): δ_P = 105.0 (d, $^2J_{PP}$ = 40 Hz, 1P, PAu), 70.5 (d, 1P, PPd) ppm.

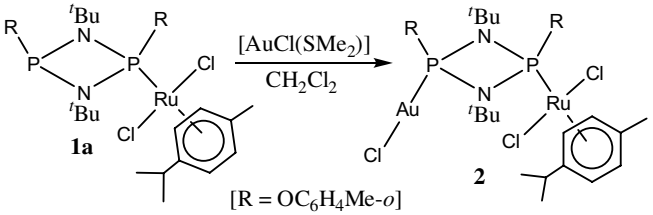
2.4. Synthesis of [$PtCl_2${μ-L-κP,κP}$_2$($AuCl)_2$] (5)

A dichloromethane solution (7 mL) of [$AuCl(SMe_2)$] (22.1 mg, 0.079 mmol) was added dropwise to a well-stirred dichloromethane solution (5 mL) of *cis*-[$PtCl_2${μ-L-κP}$_2$] (**1d**) (43.7 mg, 0.037 mmol) at room temperature. The reaction mixture was stirred for 4 h, concentrated to 5 mL and diluted with 3 mL of hexane. Storage at −30 °C for one day afforded a white crystalline product (41.1 mg, 68%). M.p.: 224–226 °C (dec). *Anal*. Calc. for $C_{44}H_{64}N_4O_8P_4Au_2PtCl_4$: C, 32.38; H, 3.95; N, 3.43. Found: C, 32.55; H, 4.12; N, 3.77%. ^{1}H NMR (400 MHz; $CDCl_3$, 25 °C): δ_H = 7.74–6.82 (m, 16 H, Ph), 3.87 (s, 6H, OMe), 3.83 (s, 6H, OMe), 1.45 (s, 36 H, ^{t}Bu) ppm. ^{31}P{^{1}H} NMR (161.9 MHz, $CDCl_3$, 25 °C): δ_P = 109.4 (d, $^3J_{PtP}$ = 81 Hz, 2P, AuP), 47.0 (d, $^1J_{PtP}$ = 5738 Hz, $^2J_{PP}$ = 36 Hz, 2P, PtP) ppm.

2.5. Synthesis of [CuI{μ-L-κP,κP}$_2$($AuCl)_2$] (6)

A solution of [$AuCl(SMe_2)$] (46.3 mg, 0.157 mmol) in 7 mL of CH_2Cl_2 was added dropwise to a well-stirred CH_2Cl_2 (5 mL) solution of [CuI{μ-L-κP}$_2$] (**1e**) (85.3 mg, 0.078 mmol) at room temperature. The colorless reaction

mixture was stirred for 4 h, concentrated to 5 mL under reduced pressure and diluted with 3 mL of hexane. Storage at −30 °C for one day afforded the product as a white crystalline solid (84.9 mg, 70%). M.p.: 194–196 °C (dec). *Anal.* Calc. for $C_{44}H_{64}N_4O_8P_4CuAu_2ICl_2$: C, 33.95; H, 4.14; N, 3.60. Found: C, 33.74; H, 4.06; N, 3.72%. ^{1}H NMR (400 MHz; $CDCl_3$, 25 °C): $\delta_H = 7.89–6.73$ (m, 16H, Ph), 3.85 (s, 6H, OMe), 3.77 (s, 6H, OMe), 1.52 (s, 36H, ^{t}Bu) ppm. $^{31}P\{^1H\}$ NMR (161.9 MHz, $CDCl_3$, 25 °C): $\delta_P = 120.9$ (br s, 2P, CuP), 105.9 (s, 2P, AuP) ppm.



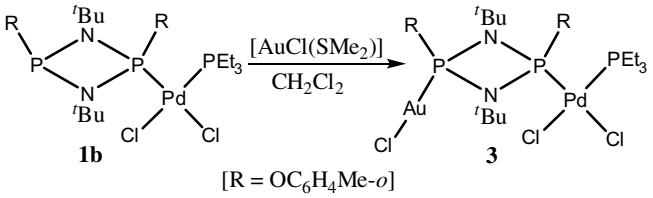
2.6. X-ray crystallography

Crystals of **2**, **3** and **4** were mounted in a CryoLoop with a drop of Paratone oil and placed in the cold nitrogen stream of the Kryoflex attachment of the Bruker APEX CCD diffractometer. Full spheres of intensity data were collected for each crystals as three sets of 400 scans in ω (0.5° per scan at $\phi = 0°$, 90° and 180°) and two sets of 800 scans in ϕ (0.45° per scan at $\omega = -30°$ and 210°). Intensity data were collected using the SMART software package [9] and these were reduced to F^2 values with the SAINT+ software [10] which also performed a global refinement of unit cell parameters using 9217 (for **2**), 9275 (for **3**) and 8300 (for **4**) reflections chosen from the full data set. Crystals of **2** and **3** proved to be twinned and the integration of the raw data was carried out with the two-component version of SAINT+ using the two-component orientation file prepared by CELL_NOW [11] and with the cell parameters of the second domain of the twin constrained to be identical to those of the first domain. Multiple measurements of equivalent reflections provided the basis for empirical absorption corrections as well as corrections for any crystal deterioration during the data collection (TWINABS [12] for **2** and **3** and SADABS [13] for **4**). The structures were solved by direct methods and refined by full-matrix least-squares procedures using the SHELXTL program package [14]. Hydrogen atoms were placed in calculated positions (C–H = 0.95 Å (aromatic rings) or 0.98 Å (methyl groups)) and included as riding contributions with isotropic displacement parameters 1.2 (aromatic rings) or 1.5 (methyl groups) times those of the attached non-hydrogen atoms.

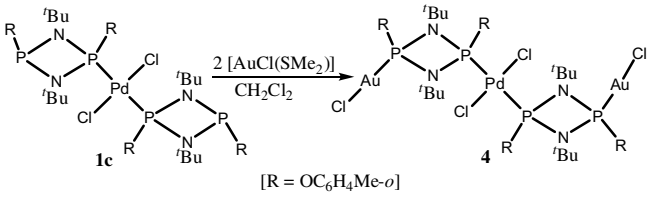
3. Results and discussion

3.1. Synthesis of heterometallic complexes

Mononuclear Ru^{II} and Pd^{II} complexes $[RuCl_2(\eta^6\text{-cymene})\{\mu\text{-L-}\kappa P\}]$ (**1a**) and $[PdCl_2(PEt_3)\{\mu\text{-L-}\kappa P\}]$ (**1b**) containing one uncoordinated P^{III} site were prepared from the reaction of *cis*-$\{(o\text{-MeOC}_6H_4O)P(\mu\text{-N}^t\text{Bu})\}_2$ (**L**) with $[RuCl_2(\eta^6\text{-cymene})]_2$ and $[PdCl_2(PEt_3)]$, respectively [4b]. Interestingly, the cyclodiphosphazane *cis*-$\{(o\text{-MeOC}_6H_4O)P(\mu\text{-N}^t\text{Bu})\}_2$ afforded exclusively the mononuclear derivatives **1a** and **1b**, irrespective of the reaction conditions and stoichiometry. The Ru^{II}/Au^I heterobimetallic

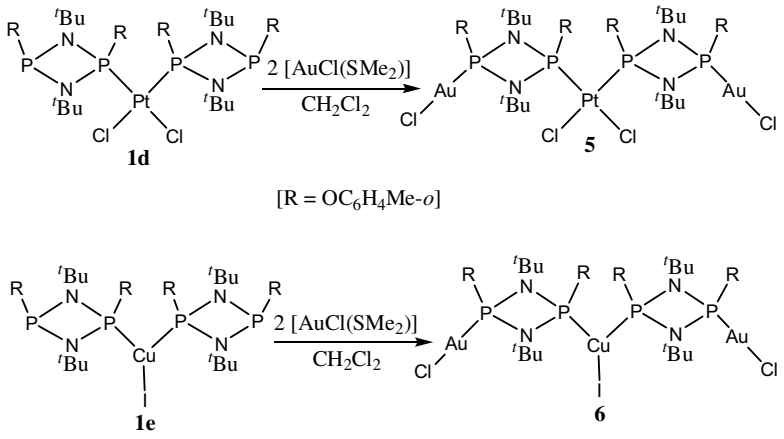


Scheme 1. Synthesis of Ru^{II}/Au^I complex.



complex $[RuCl_2(\eta^6\text{-cymene})\{\mu\text{-L-}\kappa P,P\}AuCl]$ (**2**) was synthesized by treating **1a** with 1 equiv. of $[AuCl(SMe_2)]$ in dichloromethane as shown in Scheme 1. The ^{31}P NMR spectrum of **2** exhibits two single resonances at 129.3 and 105.3 ppm, respectively, for ruthenium and gold coordinated phosphorus centers of the cyclodiphosphazane. Surprisingly, no $^2J_{PP}$ coupling was observed although complex **1a** shows a $^2J_{PP}$ coupling of 8.7 Hz.

Addition of 1 equiv. of $[AuCl(SMe_2)]$ to a dichloromethane solution of $[PdCl_2(PEt_3)\{\mu\text{-L-}\kappa P\}]$ (**1b**) results in the formation of a Pd^{II}/Au^I heterobimetallic complex $[PdCl_2(PEt_3)\{\mu\text{-L-}\kappa P,\kappa P\}AuCl]$ (**3**) in quantitative yield (Scheme 2). The ^{31}P NMR spectrum of **3** exhibits three signals due to the presence of three P-centers. The phosphorus-31 resonance corresponding to the Au-coordinated centre appears as a doublet at 108.9 ppm, with a $^2J_{PP}$ coupling of 39 Hz, whereas the Pd-bound phosphorus of the cyclodiphosphazane appears as a doublet of doublets centered at 83.8 ppm due to the coupling with two different neighboring phosphorus centers. The signal corresponding to PEt_3 appears as a doublet at 30.2 ppm with a $^2J_{pp}$ coupling of 16 Hz.



The reaction of 2 equiv. of *cis*-$\{(o\text{-MeOC}_6H_4O)P(\mu\text{-N}^t\text{Bu})\}_2$ with $[PdCl_2(NCPh)_2]$ or $[PdCl_2(SMe_2)_2]$ afforded *trans*-$[PdCl_2\{\mu\text{-L-}\kappa P\}_2]$ (**1c**) exclusively [4b]. The molecular structure of **1c** reveals the *trans* arrangement of two cyclodiphosphazanes with two uncoordinated P^{III} centers

Scheme 2. Synthesis of Pd^{II}/Au^I complex.

Scheme 3. Synthesis of $Pd^{II}/2Au^I$ complex.

Scheme 4. Synthesis of $Pt^{II}/2Au^{I}$ and $Cu^{I}/2Au^{I}$ complexes.

projecting in an anti-parallel manner so this compound can serve as an excellent metalloligand for designing hetero polynuclear complexes. The 1:2 reaction between *trans*-$[PdCl_2\{\mu\text{-L-}\kappa P\}_2]$ (**1c**) and $[AuCl(SMe_2)]$ in dichloromethane affords a $Pd^{II}/2Au^{I}$ hetero-trinuclear complex $[PdCl_2\{\mu\text{-L-}\kappa P,\kappa P\}_2(AuCl)_2]$ (**4**) as shown in Scheme 3. The ^{31}P NMR spectrum of **4** exhibits two doublets centered at 105 and 70.5 ppm, respectively, for Au and Pd coordinated centers with a $^{2}J_{PP}$ coupling of 40 Hz. Again, the $^{2}J_{PP}$ coupling is not observed in *trans*-$[PdCl_2\{\mu\text{-L-}\kappa P\}_2]$ (**1c**) which exhibited single resonances for coordinated and uncoordinated P-centers.

Heterotrinuclear complexes $[PtCl_2\{\mu\text{-L-}\kappa P,\kappa P\}_2(AuCl)_2]$ (**5**) and $[CuI\{\mu\text{-L-}\kappa P,\kappa P\}_2(AuCl)_2]$ (**6**) containing $Pt^{II}/2Au^{I}$ and $Cu^{I}/2Au^{I}$ metal centers were synthesized from

[b] $wR_2 = \{[\sum w(F_o^2 - F_c^2)/\sum w(F_o^2)^2]\}^{1/2}$; $w = 1/[\sigma^2(F_o^2) + (xP)^2]$ where $P = (F_o^2 + 2F_c^2)/3$.

the reaction of *cis*-[$PtCl_2$\{μ-L-κP\}$_2$] (**1d**) and [CuI\{μ-L-κP\}$_2$] (**1e**) with 2 equiv. of [$AuCl(SMe_2)$] in dichloromethane at room temperature (Scheme 4). The ^{31}P NMR spectrum of **5** exhibits a doublet centered at 109.4 ppm for the gold coordinated center with a $^2J_{PP}$ coupling of 36 Hz along with a $^3J_{PtP}$ coupling of 81 Hz. The platinum bound phosphorus center exhibits a doublet at 47.0 ppm along with very large $^1J_{PtP}$ coupling of 5738 Hz, which confirms the *cis* arrangement of the two cyclodiphosphazanes [15]. The ^{31}P NMR spectrum of complex **6** exhibits two singlets at 120.9 and 105.9 ppm, respectively, for copper and gold coordinated phosphorus centers of the cyclodiphosphazane.

3.2. Molecular structures of 2, 3 and 4

The molecular structure of complex **2** is shown in Fig. 1. Crystal data and details of the structure determination are presented in Table 1 while selected bond parameters are listed in Table 2. The X-ray quality crystals of **2** were obtained by slow diffusion of Et_2O into a dichloromethane solution of **2** at room temperature. In molecule **2**, the cyclodiphosphazane bridges {AuCl} and {$RuCl_2(\eta^6$-cymene)} fragments through P-coordination with the metals arranged in a *cis* orientation. The gold center is dicoordinated with a P2–Au–Cl3 angle of 176.51(2)°. The coordination geometry around the ruthenium center in **2** is the typical pseudo octahedral mode with a three-legged piano-stool arrangement commonly observed for half-sandwich phosphine complexes [16]. The Ru–P1 and Au–P2 bond distances are 2.348(1) and 2.205(1) Å, respectively, and agree well with reported values for similar complexes of the type [$Cp(PPh_3)$RuCl-{μ-$PPh_2(CH_2)_nPPh_2$}AuCl] [17].

Perspective views of the molecular structures of **3** and **4** are depicted in Figs. 2 and 3, respectively, with important bond parameters listed in Table 3. Single crystals of **3** and **4** suitable for X-ray diffraction studies were obtained by slow evaporation of dichloromethane from CH_3CN/CH_2Cl_2 solutions of the respective compounds at room temperature. In complexes **3** and **4** the cyclodiphosphazane ligand *cis*-{^{t}BuNP(OC_6H_4OMe-*o*)}$_2$ (L) bridges the gold and palladium centers to furnish Pd^{II}/Au^I, $Pd^{II}/2Au^I$ heterometallic complexes. The palladium atoms occupy the center of square planar ligand set with the corners occupied by two chlorides and two phosphorus atoms. As complex **4** has crystallographically-imposed centrosymmetry, the P1–Pd–P1^i and Cl1–Pd–Cl1^i bond angles in **4** are exactly linear and similar to the parent compound **1c** [4b]. The gold centers are linear in geometry with P–Au–Cl angles of 176.25(4)° and 179.27(3)°, respectively, for **3** and **4**. The Pd–P bond lengths in **3** and **4** are, respectively the same and slightly shorter than the corresponding bonds in the respective mononuclear complexes **1b** and **1c** [4b]. The exocyclic phenyl substituents on the phosphorus atoms are present in *exo,endo* orientations with respect to the planar P_2N_2 ring.

4. Conclusions

Variable coordination modes exhibited by the cyclodiphosphazane *cis*-{(*o*-MeOC$_6$H$_4$O)P(μ-N^{t}Bu)}$_2$ with different transition metal precursors offer straightforward synthetic routes to make a variety of heterometallic complexes in excellent yield. We are investigating the catalytic reactions of these heterometallic complexes for various organic transformations.

Abstract

The complexes [1-(9-anthracenylmethyl)-3-octylimy]$_2$Hg[HgCl$_4$] (**2a**) (imy = imidazol-2-ylidene) and [1-(9-anthracenylmethyl)-3-butylbimy]$_2$AgPF$_6$ (**2b**) (bimy = benzimidazol-2-ylidene) have been prepared and characterized. Crystal packing of complex **2a** revealed that 1D polymeric chains are formed by [1-(9-anthracenylmethyl)-3-octylimy]Hg and [HgCl$_4$]$^{2-}$ through weak Hg...Cl bonds. The packing diagram of **2b** showed that 1D supramolecular chains are formed by both benzimidazole ring head to tail π–π stacking interactions and anthracene ring face-to-face π–π stacking interactions.

Keywords: Carbene complex; Mercury; Silver; π–π stacking interactions

1. Introduction

Since the discovery of free *N*-heterocyclic carbene [1], metal carbene complexes based on imidazol-2-ylidene (imy) have received considerable attention, and a variety of related transition-metal complexes have been synthesized through deprotonation of *N*,*N*′-disubstituted imidazolium salts [2]. In the complexes some reports on the imidazol-2-ylidene complexes of Hg(II) and Ag(I) have appeared [3]. A new discovery shows that Ag(I)–carbene complexes can be used as effective antimicrobial agents [4], and they are also good carbene transfer agents for the synthesis of Ni, Pd, Pt, Cu, Au, Rh, Ir and Ru carbene complexes, such a route affording a convenient method for the preparation of these metal carbene complexes [5]. *N*-heterocyclic carbene complexes have also been shown to be remarkably stable towards heat, air and moisture [6]. Also many organic reactions using metal–NHC complexes as catalysts have been investigated, such as Heck, Suzuki and Kumada couplings, and olefin metathesis [7]. We are interested in *N*-heterocyclic carbene complexes exhibiting fluorescence [8] owing to their potential application as fluorescent switches. We report here the synthesis, structure and fluorescent emission spectra of two new complexes [1-(9-anthracenylmethyl)-3-octylimy]$_2$Hg[HgCl$_4$] (**2a**) (imy = imidazol-2-ylidene) and [1-(9-anthracenylmethyl)-3-butylbimy]$_2$AgPF$_6$ (**2b**) (bimy = benzimidazol-2-ylidene).

2. Experimental

2.1. General procedures

1-(9-Anthracenylmethyl)-3-octylimidazolium chloride (**1a**) was obtained according to a reported procedure [8a]. All manipulations were performed using Schlenk techniques, and solvents were purified by standard procedures. All the reagents for the syntheses and analyses were of analytical grade and were used without further purification. Melting points were determined with a Boetius Block apparatus. ^{1}H and ^{13}C{^{1}H} NMR spectra were recorded on a

Varian Mercury Vx 300 spectrometer at 300 MHz and 75 MHz, respectively. Chemical shifts, δ, are reported in ppm relative to the internal standard TMS for both ^1H and ^{13}C NMR. J values are given in Hz. Elemental analyses were measured using a Perkin–Elmer 2400C Elemental Analyzer. The luminescent spectra were conducted on a Cary Eclipse Fluorescence spectrophotometer.

2.2. 1-(9-Anthracenylmethyl)-3-butylbenzimidazolium hexafluorophosphate (*1c*)

A THF solution of benzimidazole (10.170 g, 86 mmol) was added to a suspension of oil-free sodium hydride (3.977 g, 95 mmol) in THF (100 mL) and stirred for 1 h at 60 °C. Then a THF (50 mL) solution of butyl iodide (16.634 g, 90 mmol) was added dropwise to the above solution. The mixture was continued to be stirred for 24 h at 60 °C, and a yellow solution was obtained. The solvent was removed with a rotary evaporator and H_2O (100 mL) was added to the residue. Then the solution was extracted with CH_2Cl_2 (3×50 mL), and the extracting solution was dried with anhydrous $MgSO_4$. After removing CH_2Cl_2, yellow liquid 1-butylbenzimidazole was obtained. Yield: 14.500 g (96.7%).

1-(9Anthracenylmethyl)-3-butylbenzimidazolium chloride (**1b**) was prepared by the reaction of 1-butylbenzimidazole with 9-chloromethylanthracene according to the literature procedures [8d]. M.p.: 239–241 °C. *Anal.* Calc. for $C_{26}H_{25}ClN_2$: C, 77.89; H, 6.29; N, 6.99. Found: C, 77.80; H, 6.33; N, 6.76%. ^1H NMR (300 MHz, $CDCl_3$): 1.02 (t, $J = 5.4$, 3H, CH_3), 1.41–1.49 (m, 2H, CH_2), 2.01–2.06 (m, 2H, CH_2), 4.57 (t, $J = 5.4$, 2H, CH_2), 6.92 (d, $J = 6.3$, 1H, PhH), 6.99 (s, 2H, CH_2An), 7.12 (t, $J = 6.3$, 1H, PhH), 7.38 (t, $J = 6.3$, 1H, PhH), 7.54 (d, $J = 6.3$, 1H, PhH), 7.68 (t, $J = 8.4$, 2H, AnH) (An: anthracene), 7.72 (t, $J = 8.4$, 2H, AnH), 8.10 (d, $J = 8.4$, 2H, AnH), 8.56 (d, $J = 8.4$, 2H, AnH), 8.59 (s, 1H, AnH), 12.17 (s, 1H, 2-benzimiH) (benzimi: benzimidazole).

1-(9-Anthracenylmethyl)-3-butylbenzimidazolium hexafluorophosphate (**1c**) was formed by an ion-exchange reaction of **1b** with NH_4PF_6 according to the literature methods [8d]. ^1H NMR (300 MHz, $CDCl_3$): δ 0.96 (t, $J = 5.4$, 3H, CH_3), 1.28–1.36 (m, 2H, CH_2), 1.86–1.91 (m, 2H, CH_2), 4.40 (t, $J = 5.4$, 2H, CH_2), 6.59 (s, 2H, CH_2An), 7.34–7.42 (m, 2H, PhH), 7.52–7.57 (m, 3H, AnH and PhH) (An: anthracene), 7.62–7.70 (m, 3H, AnH and PhH), 8.10 (d, $J = 8.4$, 2H, AnH), 8.27 (d, $J = 8.4$, 2H, AnH), 8.64 (s, 1H, AnH), 8.97 (s, 1H, 2-benzimiH) (benzimi: benzimidazole).

2.3. [1-(9-Anthracenylmethyl)-3-octylimy]$_2$ Hg[HgCl$_4$] (*2a*)

A suspension of $KOBu^t$ (0.090 g, 0.8 mmol), precursor **1a** (0.200 g, 0.5 mmol) and anhydrous mercury(II) chloride (0.136 g, 0.5 mmol) in THF (20 mL) and acetonitrile (20 mL) was refluxed for 24 h. A brown solution was formed and the solvent was removed with a rotary evaporator. Water (30 mL) was added to the residue and the solution was extracted with CH_2Cl_2 (3×20 mL). The extracting solution was dried with anhydrate $MgSO_4$, then the solution was concentrated to 10 mL and hexane (2 mL) was added, as a result, a pale yellow powder was obtained. Yield: 0.178 g (56.5%), M.p.: 248–250 °C. *Anal.* Calc. for $C_{52}H_{60}Cl_4Hg_2N_4$: C, 48.64; H, 4.71; N, 4.36. Found: C, 48.35; H, 4.27; N 4.18%. ^1H NMR (300 MHz, DMSO-d_6): δ 0.82 (t, $J = 6.0$, 3H, CH_3), 1.20–1.28 (m, 10H, CH_2), 1.73–1.78 (m, 2H, CH_2), 4.23 (t, $J = 6.0$, 2H, CH_2), 6.51 (s, 2H, CH_2An) (An: anthracene), 6.81 (s, 1H, 4 or 5-imiH) (imi: imidazole), 7.47 (s, 1H, 4 or 5-imiH), 7.57–7.63 (m, 4H, AnH), 8.20 (d, $J = 8.0$, 2H, AnH), 8.37 (d, $J = 8.0$, 2H, AnH), 8.80 (s, 1H, AnH). ^{13}C NMR (75 MHz, DMSO-d_6): δ 14.5 (CH_3), 22.7 (CH_2), 26.4 (CH_2), 26.8 (CH_2), 29.2 (CH_2), 31.2 (CH_2), 31.8 (CH_2), 46.9 (CCH_2N), 51.2 ($AnCH_2N$), 122.1, 123.9, 124.3 and 126.2 (AnC or 4, 5-imiC), 128.3, 130.0, 130.6, 131.5 and 131.7 (AnC), 176.8 ($C_{carbene}$).

2.4. [1-(9-Anthracenylmethyl)-3-butylbimy]$_2$ AgPF$_6$ (*2b*)

To a solution of **1c** (0.200 g, 0.4 mmol) in dichloromethane (30 mL) was added silver oxide (0.050 g, 0.2 mmol), and the suspension solution was refluxed under nitrogen for 24 h. The resulting solution was filtered and concentrated to 5 mL, and Et_2O (5 mL) was added to precipitate a pale yellow powder. Isolation by filtration yielded **2b**. Yield: 0.106 g (55%), M.p.: 272–274 °C. *Anal.* Calc. for $C_{52}H_{48}AgF_6N_4P$: C, 63.61; H, 4.93; N, 5.71. Found: C, 63.44; H, 4.63; N, 5.81%. ^1H NMR (300 MHz, DMSO-d_6): δ 0.30 (t, $J = 5.4$, 3H, CH_3), 0.57–0.62 (m, 2H, CH_2), 1.13–1.18 (m, 2H, CH_2), 3.33 (t, $J = 5.4$, 2H, CH_2), 6.18 (s, 2H, CH_2), 7.24 (t, $J = 6.3$, 1H, PhH), 7.43 (t, $J = 8.4$, 2H, AnH), 7.52–7.58 (m, 2H, AnH), 7.80 (d, $J = 6.3$, 1H, PhH), 7.92 (d, $J = 8.4$, 2H, AnH) (An: anthracene), 8.02 (d, $J = 8.4$, 2H, AnH), 8.08 (d, $J = 6.3$, 1H, PhH), 8.61 (s, 1H, AnH). ^{13}C NMR (75 MHz, DMSO-d_6): δ 13.5 (CH_3), 19.5 (CH_2), 31.9 (CH_2), 44.0 (CH_2), 49.6 (NCH_2An), 112.6, 124.1, 125.0, 125.8, 126.8, 127.5, 127.9, 128.5, 129.8, 130.2, 131.0 131.6, 132.9, 134.8 (AnC or PhC), 186.5 ($C_{carbene}$).

2.5. X-ray crystallography

For compounds **1a**, **2a** and **2b**, selected single crystals were mounted on a Bruker SMART 1000 CCD diffractometer operating at 50 kV and 20 mA using Mo Kα radiation (0.71073 Å). Data collection and reduction were performed using SMART and SAINT software [9] with frames of 0.6° oscillation in the θ range $1.8 < \theta < 25°$. An empirical absorption correction was applied using the SADABS program [10]. The structures were solved by direct methods and all non-hydrogen atoms were subjected to anisotropic refinement by full-matrix least squares on F^2 using the SHELXTL package [11]. All hydrogen atoms were generated

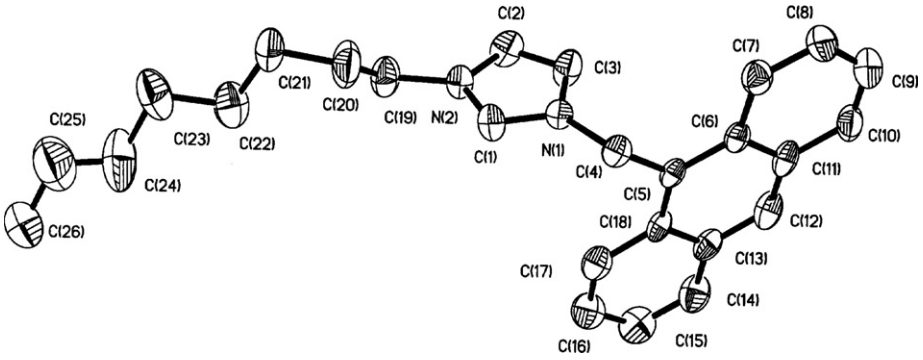
geometrically (C–H bond lengths fixed at 0.96 Å), assigned appropriated isotropic thermal parameters and included in structure factor calculations. Selected bond lengths (Å) and angles (°) and crystal data and structure refinement for **1a**, **2a** and **2b**, are presented in Tables 1 and 2.

3. Results and discussion

1-(9-Anthracenylmethyl)-3-butylbenzimidazolium chloride (**1b**) was prepared from benzimidazole by stepwise alkylation with butyl iodide followed by 9-chloromethylan-



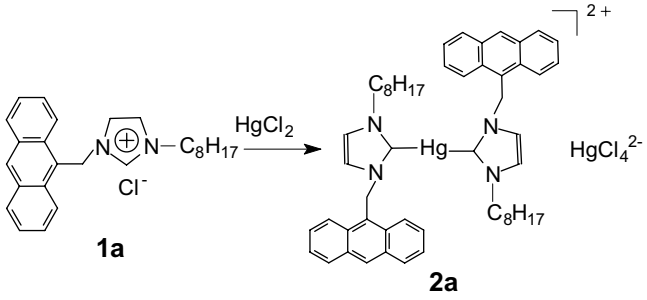


Fig. 1. Perspective view of **1a** and anisotropic displacement parameters depicting 30% probability. Hydrogen atoms have been omitted for clarity.

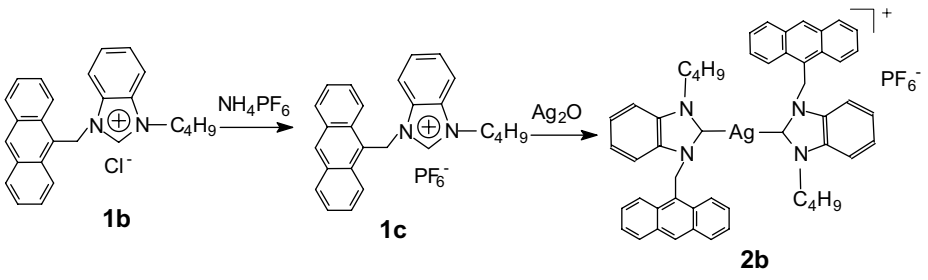
thracene in sequence. Compound **1b** was changed to 1-(9-anthracenylmethyl)-3-butylbenzimidazolium hexafluorophosphate (**1c**) by an anionic exchange reaction with NH_4PF_6. The compounds **1a** and **1c** are soluble in most polar organic solvents, such as CH_2Cl_2, CH_3OH and CH_3CN, and insoluble in diethyl ether and hydrocarbon solvents. In the ^1H NMR spectra of **1a** and **1c** the imidazolium proton signals (NCHN) appear at $\delta = 8.97$ and 11.45 ppm, which are consistent with the chemical shifts of known imidazolium salts [2]. Yellow crystals of **1a** were obtained by slowly evaporating its CH_2Cl_2 solution (Fig. 1). Although the poor quality of the crystal yielded a relatively high *R* value, nevertheless, the skeletal arrangement was correct. In the molecular structure of **1a** the dihedral angle between the imidazole ring and anthracene ring is 91.5°.

In CH_3CN and THF solution, compound**1a** was reacted with $HgCl_2$ in the presence of $KOBu^t$ to afford complex **2a** (Scheme 1). Complex **2a** is light-sensitive in solution, but



Scheme 1.

light-stable as a solid. In CH_2Cl_2 solution compound **1c** was reacted with Ag_2O to give complex **2b** (Scheme 2). Complexes **2a** and **2b** are soluble in DMSO, soluble partly in $CHCl_3$ and CH_3CN, and insoluble in diethyl ether and petroleum ether. Yellow crystals of **2a** and **2b** suitable for X-ray diffraction were obtained from slow diffusion of diethyl ether into their DMSO solutions, and they were characterized by elemental analysis and ^1H and ^{13}C NMR spectroscopy. In the ^1H NMR spectra of **2a** and **2b**, the disappearance of the resonances for the imidazolium (or benzimidazolium) protons (NCHN) shows the formation of the expected metal carbene complexes. In the ^{13}C NMR spectra the signals for the carbene carbon appears at 176.8 ppm for **2a** and 186.5 ppm for **2b**, which are characteristic for carbene metal complexes [3].

As depicted in Fig. 2a, the coordination geometry on the mercury atom in **2a** is essentially linear, with a C(1)–Hg(1A)–C(27) bond angle of 174.8(2)°. The C–Hg bond distance of 2.074(6) Å is slightly longer than those of known Hg–carbene complexes (2.02–2.06 Å) [3a,3b,3c,3d]. The internal ring angle (N–C–N) at the carbene center is 105.8(5)°, which is somewhat smaller than that of the precursor **1a** (109.2(8)°) but similar to those in some known mercury complexes. One of the imidazole rings forms dihedral angles of 14.6° and 86.4°, respectively, with another imidazole ring and adjacent anthracene ring. The dihedral angle between two anthracene rings is 14.7°. The two 9-anthracylmethyl groups and two octyl groups point to contrary directions due to steric demands.

A notable feature in the crystal packing of complex **2a** (Fig. 2b) is that one dimensional polymeric chains are formed by [1-(9-anthracenylmethyl)-3-octylimy]$_2$Hg and

Scheme 2.

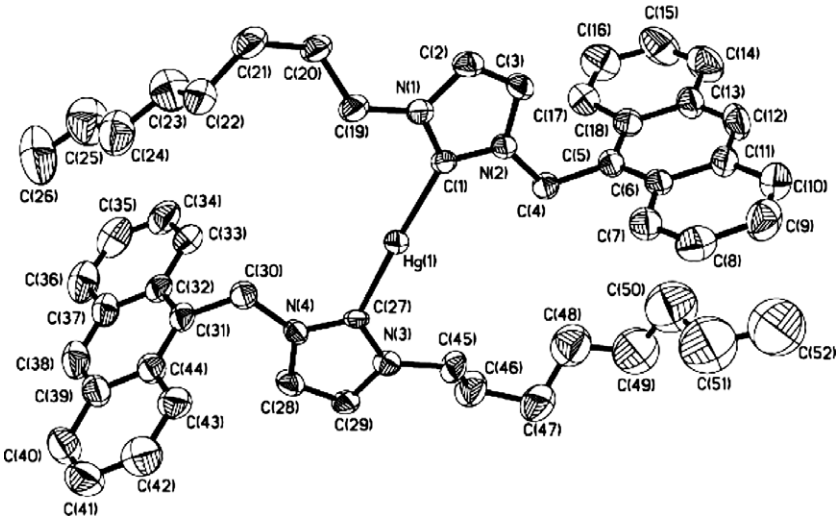


Fig. 2a. Perspective view of **2a** and anisotropic displacement parameters depicting 30% probability. Hydrogen atoms have been omitted for clarity.

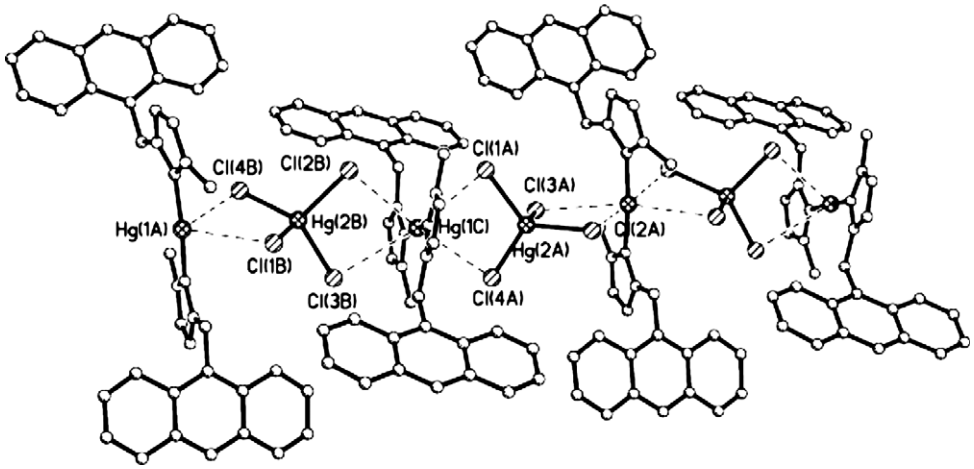

Fig. 2b. 1D polymeric chain by weak Hg...Cl bonds in **2a**. Seven carbon atoms of the octyl group have been omitted and only one carbon atom is reserved for clarity.

$[HgCl_4]^{2-}$ via weak Hg...Cl bonds (Hg...Cl bond separations being 3.1–3.4 Å, whereas regular Hg–Cl bond lengths are 2.4–2.5 Å). The Hg(1A)...Hg(2B) separation of 4.256 Å shows no metal–metal interactions. The atoms Hg(1A)...Cl(1B)–Hg(2B)–Cl(4B) (plane 1), Hg(2B)–Cl(2B)...Hg(1C)...Cl(3B) (plane 2) and Hg(1C)...Cl(1A)–Hg(2A)–Cl(4A) (plane 3) are coplanar. Plane 1 forms dihedral angles of 80.3° and 86.9° with the two adjacent imidazole rings. Plane 2 forms dihedral angles of 70.3° and 15.7°, respectively, with plane 1 and plane 3.

The X-ray structural analysis of **2b** shows that the central silver atom has a linear two-coordinate structure (Fig. 3a) with a C(1)–Ag(1)–C(27) bond angle of 177.2(2)°. The C–Ag bond distance of 2.077(6) Å is similar to those of some known NHC silver complexes [3e,3f,3g,3h,3i,3j,3k,3l]. In **2b** the two benzimidazole rings are almost perpendicular (the dihedral angle being 93.4°), and one of benzimidazole ring forms dihedral angles of 105.1° and 6°, respectively, with one anthracene rings

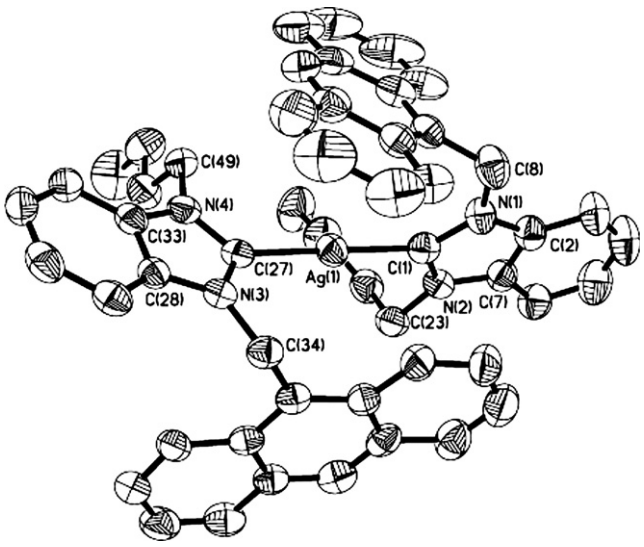

Fig. 3a. Perspective view of **2b** and anisotropic displacement parameters depicting 30% probability. Hydrogen atoms have been omitted for clarity.

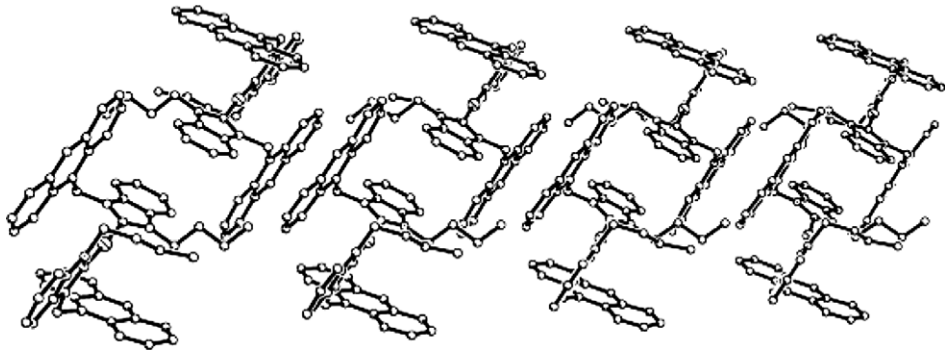

Fig. 3b. The 1D supramolecular chain by π–π stacking interactions from benzimidazole rings and anthracene rings in **2b**.

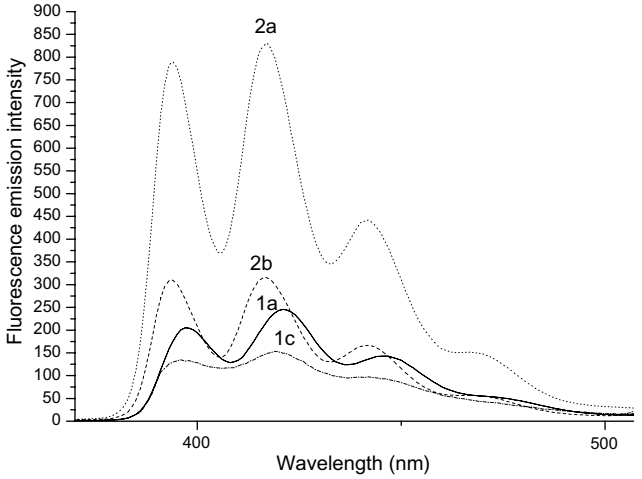

Fig. 4. Emission spectra of **1a** (—), **1c** (-·-·-), **2a** (· · ·) and **2b** (– – –) at 298 K upon excitation at 256 nm in CH_2Cl_2 (5.0×10^{-6} M).

from an identical ligand and another from a different ligand.

An interesting feature in the packing diagrams of **2b** is that both types of aromatic π–π stacking interactions are observed [12] (Fig. 3b). One type is the head to tail π–π stacking interactions from inter-molecular benzimidazole rings with an inter-planar separation of 3.541 Å (center-to-center separation: 3.890 Å), which form dimeric units. Another type is the face-to-face π–π interactions from inter-dimeric anthracene rings, which extends the dimeric units into 1D supramolecular chains. In the packing diagrams the distance of neighboring parallel anthracene rings is 3.261 Å, with a center-to-center separation of 4.960 Å. Thus aromatic π–π stacking interactions are mainly responsible for the formation of dimeric units and expanding the dimeric units to 1D supramolecular chains in **2b**.

The fluorescent emission spectra of **1a**, **1c**, **2a** and **2b** are shown in Fig. 4. In dichloromethane **2a** and **2b** showed an anthracene-type fluorescence emission in the region 370–510 nm, similar to but stronger than those of the corresponding precursors **1a** and **1c**. This can be attributed to the electron-withdrawing effect of mercury(II) or silver(I), which inhibits the photoinduced electron transfer (PET) process of the lone-pair electron of the nitrogen atom to the anthracene ring [13].

4. Conclusion

In summary, two new *N*-heterocyclic carbene Hg(II) and Ag(I) complexes have been synthesized and characterized. In complex **2a** 1D polymeric chains are formed by [1-(9-anthracenylmethyl)-3-octylimy]Hg and $[HgCl_4]^{2-}$ through weak Hg...Cl bonds. In complex **2b** 1D supramolecular chains are formed by both types of aromatic π–π stacking interactions. The fluorescent emission spectra of **2a** and **2b** are stronger than those of their corresponding precursors **1a** and **1c**. Further studies on new fluorescent organometallic compounds from precursor **1** and analogous ligands are underway.

Abstract

The syntheses and crystal structures of four new uranyl complexes with [*O*,*N*,*O*,*N*′]-type ligands are described. The reaction between uranyl nitrate hexahydrate and the phenolic ligand [(*N*,*N*-bis(2-hydroxy-3,5-dimethylbenzyl)-*N*′,*N*′-dimethylethylenediamine)], H_2L1 in a 1:2 molar ratio (M to L), yields a uranyl complex with the formula $[UO_2(HL1)(NO_3)] \cdot CH_3CN$ (**1**). In the presence of a base (triethylamine, one mole per ligand mole) with the same molar ratio, the uranyl complex $[UO_2(HL1)_2]$ (**2**) is formed. The reaction between uranyl nitrate hexahydrate and the ligand [(*N*,*N*-bis(2-hydroxy-3,5-di-*t*-butylbenzyl)-*N*′,*N*′-dimethylethylenediamine)], H_2L2, yields a uranyl complex with the formula $[UO_2(HL2)(NO_3)] \cdot 2CH_3CN$ (**3**) and the ligand [*N*-(2-pyridylmethyl)-*N*,*N*-bis(2-hydroxy-3,5-dimethylbenzyl)amine], H_2L3, in the presence of a base yields a uranyl complex with the formula $[UO_2(HL3)_2] \cdot 2CH_3CN$ (**4**). The molecular structures of **1**–**4** were verified by X-ray crystallography. The complexes **1**–**4** are zwitter ions with a neutral net charge. Compounds **1** and **3** are rare neutral mononuclear $[UO_2(HLn)(NO_3)]$ complexes with the nitrate bonded in η^2-fashion to the uranyl ion. Furthermore, the ability of the ligands H_2L1–H_2L4 to extract the uranyl ion from water to dichloromethane, and the selectivity of extraction with ligands H_2L1, H_3L5 (*N*,*N*-bis(2-hydroxy-3,5-dimethylbenzyl)-3-amino-1-propanol), $H_2L6 \cdot HCl$ (*N*,*N*-bis(2-hydroxy-5-*tert*-butyl-3-methylbenzyl)-1-aminobutane · HCl) and $H_3L7 \cdot HCl$ (*N*,*N*-bis(2-hydroxy-5-*tert*-butyl-3-methylbenzyl)-6-amino-1-hexanol · HCl) under varied chemical conditions were studied. As a result, the most efficient and selective ligand for uranyl ion extraction proved to be $H_3L7 \cdot HCl$.

1. Introduction

Ligands with a good selectivity towards particular metal ions in different chemical surroundings have found use in biological and environmental applications of coordination chemistry. For example, in a metal ion recognition ligand architecture is a key factor [1] which is clearly demonstrated, e.g. by Karmazin et al. [2]. Moreover, in industrially interesting applications of catalytically active coordination compounds, the three-dimensional geometry of the used complexes has a crucial role for the catalytic efficiency [3–5]. As an example, multidentate [*O*,*N*,*O*,*N*′]-type ligands and their metal complexes, among others, have been under intense research due to their versatility in chemistry. An indication of this is the number of crystal structure determinations of the complexes mentioned above [4,6–10] along with the number of reports presenting their use as catalysts in various chemical reactions [5,11–16]. Our group has earlier prepared uranyl complexes with [*O*,*N*,*O*,*O*′][17,18]- and [*O*,*N*,*O*][19]-type aminobis(phenolate) ligands in which the coordination of the aminobis(phenol) ligand to the UO_2^{2+} ion is associated with the protonation of the central nitrogen atom of the ligand backbone. This protonation evokes potentially tridentate, dianionic aminobis(phenol)s to react as bidentate, monoanionic ligands. To enlarge our studies concerning the chemistry of uranium(VI), we were interested in investigating the behavior of [*O*,*N*,*O*,*N*′]-type ligands with a UO_2^{2+}

ion. This ligand type has two possible sites (two nitrogen donors) to accommodate the proton freed in the complexation process, a feature which may significantly affect the coordination mode of the ligand and consequently the properties of the formed complex, e.g. in catalysis or in extraction processes. Furthermore, the new uranyl ion complexes are of interest since the linear uranyl cation is present in the majority of naturally occurring uranium minerals and in nuclear waste reprocessing systems [20] and there thus exists a need to selectively extract the uranyl ion from other chemical species.

In our earlier studies concerning the complexation of the uranyl ion with various aminoalcoholbis(phenol)s (H_3L) [17,18], two structurally different type of uranyl complexes were isolated. In general, complexes of the type $[UO_2(H_2L)_2] \cdot S$ (one H^+ ion at the nitrogen atom) with solvent molecules (S), like acetonitrile, crystallized from the solutions, but in one case when $H_3L = N,N$-bis(2-hydroxy-3,5-dimethylbenzyl)-2-aminoethanol, also a dinuclear complex $[(UO_2)_2(H_2L)_2(NO_3)_2]$ was formed. If the ligands are aminoalkylbis(phenol)s (H_2L), only complexes with the formula $[UO_2(HL)_2] \cdot S$ (H^+ ion at the nitrogen) crystallized from the solutions [19]. When the monomeric complexes of type $[UO_2(HL)_2]$ were dissolved in coordinating solvents, such as DMSO or pyridine, they dissociate to produce $[UO_2(HL)(solvent)_n]^+$ complexes, but in chloroform the $[UO_2(HL)_2]$ species dissolve in the molecular form.

In this paper we report the complexation and extraction studies of the uranyl ion with selected diaminobis(phenol)s. The ligand family used is presented in Fig. 1.

The ligands H_3L5 (N,N-bis(2-hydroxy-3,5-dimethylbenzyl)-3-amino-1-propanol), $H_2L6 \cdot HCl$ (N,N-bis(2-hydroxy-5-*tert*-butyl-3-methylbenzyl)-1-aminobutane $\cdot$ HCl) and $H_3L7 \cdot HCl$ (N,N-bis(2-hydroxy-5-*tert*-butyl-3-methylbenzyl)-6-amino-1-hexanol $\cdot$ HCl), prepared in our earlier studies [17–19] and used in the uranyl extraction experiments in this paper, are presented in Fig. 2.

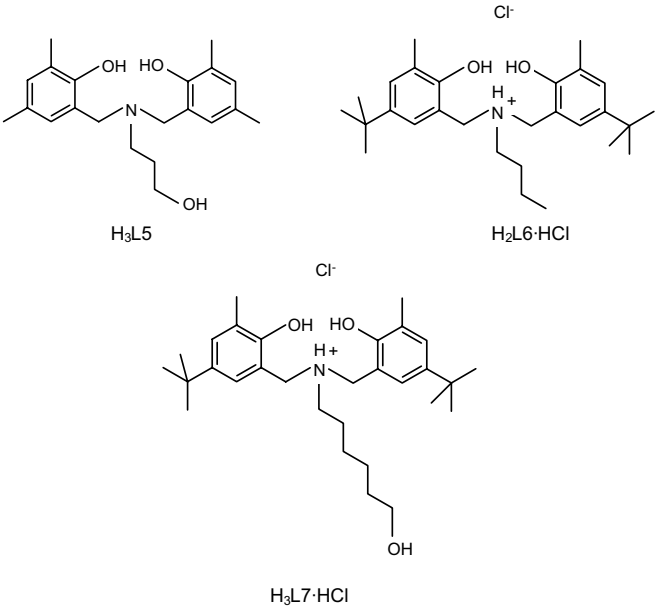

Fig. 2. Ligands H_3L5, $H_2L6 \cdot HCl$ and $H_3L7 \cdot HCl$ used in the uranyl extraction experiments.

2. Experimental

2.1. General information

The starting materials for all syntheses were purchased from Fluka, Merck or Riedel and were of reagent grade and used as received. Solvents were of HPLC grade and used as purchased. All syntheses and extraction experiments were performed under ambient laboratory atmosphere. The NMR spectra were recorded on a Bruker AVANCE DPX 250 FT-NMR spectrometer or Bruker AVANCE DRX 500 FT-NMR spectrometer. The ^1H and ^{13}C NMR spectra were recorded either in $CDCl_3$ or d_6-DMSO at 30 °C. The chemical shifts are reported in ppm and referenced internally using the residual protic solvent resonances relative to tetramethylsilane ($CDCl_3$ δ 7.26, ^1H NMR; δ 77.0, ^{13}C NMR; DMSO-d_6 δ 2.50, ^1H NMR; δ 39.50, ^{13}C NMR). IR spectra were recorded on a Perkin–Elmer System 2000 FT-IR spectrometer in KBr discs. Elemental analysis was performed using a VarioEl III elemental analyzer. Single crystal X-ray measurements were performed using an Enraf Nonius Kappa CCD area-detector diffractometer. The uranyl extraction samples were analyzed with inductively coupled plasma optical emission spectrometry (ICP-OES) at 385.958 nm using a Perkin–Elmer Optima 4300DV instrument. The pH values were measured with an ORION SA520 pH-meter.

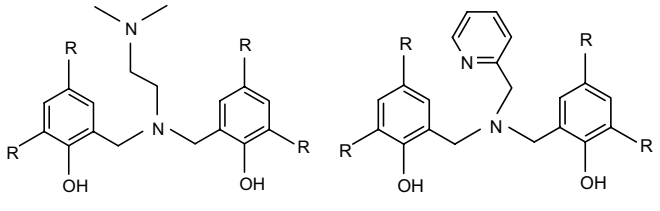

Fig. 1. Diaminobis(phenol) ligands used in this paper.

2.2. Ligand syntheses

The ligands H_2L3 and H_2L4 were prepared according to a known procedure [4]. H_2L1 and H_2L2 were prepared by a slightly modified method described below. The NMR spectra of the prepared ligands were in agreement with the literature [4,6,7,16].

2.2.1. H_2L1

To a solution of 2,4-dimethylphenol (3.00 g, 0.025 mol) in EtOH (15 ml) and water (3 ml), was added aqueous formaldehyde (37%, 3.26 g, 0.040 mol), N,N-dimethylethylenediamine (1.00 g, 0.011 mol) and triethylamine

($V = 0.500$ ml, 0.004 mol) for a catalyst. The resulting solution was kept in a water bath (50 °C) for 47 h. The colourless crystals formed were filtered, washed with cold MeOH (2×10 ml) and dried. Yield 3.41 g (87%). A single crystal X-ray analysis was done on one of these crystals and the results were in agreement with the literature [11,16].

2.2.2. H_2L2

Prepared as H_2L1, except the amount of water was 2 ml and that the time in the water bath (50 °C) was 140 h. Yield 3.22 g (56%) as colourless crystals.

2.3. $[UO_2(HL1)(NO_3)] \cdot CH_3CN$ (1)

Complex **1** was prepared by dissolving 0.053 g (0.15 mmol) of H_2L1 and 0.038 g (0.075 mmol) of $UO_2(NO_3)_2 \cdot 6H_2O$ in 10 ml of CH_3CN with 4 Å molecular sieves to remove water. The resulting red solution was kept in a freezer for three weeks leading to the formation of red crystals. After that the crystals were filtered off and dried. Yield 0.022 g (40%). The crystals are soluble in DMSO and acetone. ^{1}H NMR (DMSO-d_6, 250 MHz; Co for coordinated ligand and Un for uncoordinated ligand (20% of complex is dissociated, see NMR discussion)): 7.02, 6.99 (s, 4H, aryl, Co), 6.81, 6.74 (s, 1H, aryl, Un), 4.35 (m, 4H, N–CH_2-aryl, Co), 3.57 (s, 1H, N–CH_2-aryl, Un), 3.28 (m, 1H, N–CH_2CH_2–N, Un), 3.10, 2.87 (m, 4H, N–CH_2CH_2–N, Co), 2.59, 2.32 (s, 12H, aryl-CH_3, Co), 2.29, 2.14 (s, 3H, aryl-CH_3, Un), 2.14 (s, 6H, N–(CH_3)$_2$, Co) 2.08 (s, 1.5H, N–(CH_3)$_2$, Un), 2.07 (s, 4H, H_3CCN). ^{13}C NMR (DMSO-d_6, 63 MHz): 164.7–122.2 (aryl), 59.7 (N–CH_2–*C*(aryl)), 54.9, 51.5 (N–*C*H_2-aryl, N–(*C*H_2)$_2$–N), 46.1, 43.7 (N–(*C*H_3)$_2$), 19.9, 16.9, 16.0 (aryl-*C*H_3). IR (KBr, ν/cm^{-1}): 3428(m), 2913(m), 1610(w), 1472(s), 1382(s), 1263(s), 891(s), 858(m), 804(m), 790(m), 501(m). Elemental *Anal.* Calc. for $C_{24}H_{34}N_4O_7U$: C, 39.56; H, 4.70; N, 7.69. Found: C, 38.55; H, 4.30; N, 7.69%. Single crystal X-ray analysis was made for one of these crystals (Fig. 3).

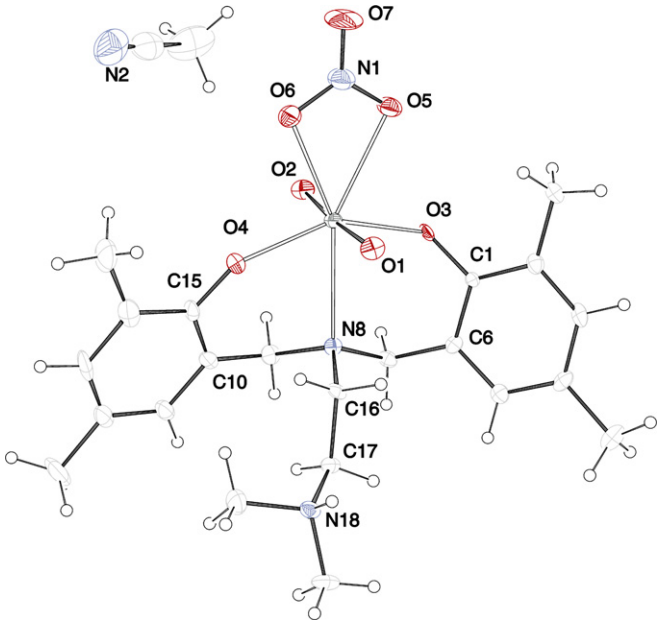

Fig. 3. Molecular structure of $[UO_2(HL1)(NO_3)] \cdot CH_3CN$ (**1**). Thermal ellipsoids have been drawn at the 30% probability level.

2.4. $[UO_2(HL1)_2]$ (2)

Complex **2** was prepared by dissolving 0.053 g (0.15 mmol) of H_2L1, 21.0 μl (0.15 mmol) of triethylamine and 0.038 g (0.075 mmol) of $UO_2(NO_3)_2 \cdot 6H_2O$ in 10 ml of CH_3CN. The resulting red solution was kept at room temperature for three days and in a freezer for one week, leading to the formation of orange crystals. The crystals were filtered off, washed twice with 10 ml of diethyl ether and dried. Yield 0.062 g (84%). The crystals are soluble in DMSO, $CHCl_3$ and slightly soluble in acetone. ^{1}H NMR (DMSO-d_6, 500 MHz; about 33% of complex is dissociated): 6.99, 6.94 (s, 4H, aryl, Co), 6.80, 6.72 (s, 2H, aryl, Un), 4.38 (m, 4H, N–CH_2-aryl, Co), 3.54 (s, 2H, N–CH_2-aryl, Un), 3.28 (m, 2H, N–CH_2CH_2–N, Un), 2.95, 2.48 (m, 4H, N–CH_2CH_2–N, Co), 2.60, 2.31 (s, 12H, aryl-CH_3, Co), 2.15, 2.14 (s, 6H, aryl-CH_3, Un), 2.07 (s, 3H, N–(CH_3)$_2$, Un), 1.81 (s, 6H, N–(CH_3)$_2$, Co). ^{13}C NMR (DMSO-d_6, 126 MHz): 164.7–122.2 (aryl), 59.7 (N–CH_2–*C*(aryl)), 55.3, 54.5, 50.8, 48.9, 47.0 (N–*C*H_2-aryl, N–(*C*H_2)$_2$–N), 45.4, 44.6 (N–(*C*H_3)$_2$), 20.0, 17.0, 16.0 (aryl-*C*H_3). IR (KBr, ν/cm^{-1}): 3435(w), 2906(m), 1610(w), 1472(s), 1310(m), 1270(s), 858(s), 811(s), 768(m), 497(m). Elemental *Anal.* Calc. for $C_{44}H_{62}N_4O_6U$: C, 53.87; H, 6.37; N, 5.71. Found: C, 54.05; H, 6.40; N, 5.91%. Single crystal X-ray analysis was made for one of these crystals (Fig. 4).

2.5. $[UO_2(HL2)(NO_3)] \cdot 2CH_3CN$ (3)

Complex **3** was prepared by dissolving 0.079 g (0.15 mmol) of H_2L2 and 0.038 g (0.075 mmol) of $UO_2(NO_3)_2 \cdot 6H_2O$ in 10 ml of CH_3CN which contained 4 Å molecular sieves to remove water. The resulting dark red solution was kept in a freezer for three weeks leading to the formation of red crystals. The crystals were filtered off and washed with 5 ml of cold diethylether. Yield 0.027 g (38%). The crystals are soluble in DMSO and acetone. ^{1}H NMR (DMSO-d_6, 500 MHz; about 33% of complex is dissociated): δ 7.35, 7.23 (d, 4H, aryl, Co), 7.10, 6.95 (d, 2H, aryl, Un), 4.92, 3.98 (m, 4H, N–CH_2-aryl, Co), 3.58 (s, 2H, N–CH_2-aryl, Un), 3.02, 2.76 (m, 4H, N–CH_2CH_2–N, Co), 2.62, 2.52 (m, 2H, N–CH_2CH_2–N, Un), 2.25 (s, 3H, N–(CH_3)$_2$, Un), 2.07 (s, H_3CCN), 1.92 (s, 6H, N–(CH_3)$_2$, Co), 1.67, 1.31 (s, 36H, aryl-*t*-butyl, Co), 1.33, 1.23 (s, 18H, aryl-*t*-butyl, Un). ^{13}C NMR (DMSO-d_6, 126 MHz): δ 165.4–122.2 (aryl), 61.3, 55.4, 54.6, 51.5, 48.4 (N–*C*H_2-aryl, N–(*C*H_2)$_2$–N), 44.1, 43.8 (N–(*C*H_3)$_2$), 34.7, 34.5, 33.7, 33.4 (aryl-*C*(CH$_3$)$_3$), 32.0, 31.4, 30.4, 29.4 (aryl-C(*C*H$_3$)$_3$)). IR (KBr, ν/cm^{-1}):

2.6. $[UO_2(HL3)_2] \cdot 2CH_3CN$ (*4*)

Complex **4** was prepared by dissolving 0.034 g (0.09 mmol) of H_2L3, 0.009 g (12.6 μl, 0.09 mmol) of triethylamine and 0.023 g (0.045 mmol) of $UO_2(NO_3)_2 \cdot 6H_2O$ in 10 ml of CH_3CN. The resulting red solution was kept in a freezer for three weeks leading to the formation of orange crystals. The crystals were filtered off and dried. Yield 0.023 g (46%). The crystals are soluble in DMSO, $CHCl_3$ and acetone. ^{1}H NMR (DMSO-d_6, 250 MHz; about 50% of complex is dissociated): 10.02 (s, 2H, aryl-O*H*, Un), 8.63 (m, 2H, pyridyl, Co (1H) and Un (1H)), 7.85 (m, 1H, pyridyl, Un), 7.56 (m, 1H, pyridyl, Co), 7.36 (m, 2H, pyridyl, Un), 7.26 (m, 1H, pyridyl, Co), 6.62 (m, 1H, pyridyl, Co), 6.95, 6.63 (s, 4H, aryl, Co), 6.80, 6.76 (s, 4H, aryl, Un), 4.52 (s, 4H, N–CH_2-aryl, Co), 4.33 (s, 2H, N–CH_2-pyridyl, Co), 3.80 (s, 2H, N–CH_2-pyridyl, Un), 3.66 (s, 4H, N–CH_2-aryl, Un), 2.62, 2.22 (s, 12H, aryl-CH_3, Co), 2.15, 2.08 (s, 12H, aryl-CH_3, Un), 2.07 (s, 6H, H_3CCN). ^{13}C NMR (DMSO-d_6, 63 MHz): δ 164.7– 121.5 (aryl, pyridyl), 59.3, 56.6, 55.3, 55.0 (N–*C*H_2-aryl, N–*C*H_2-pyridyl), 20.0, 17.1, 16.0 (aryl-*C*H_3). IR (KBr, ν/cm^{-1}): 3442(w), 2913(m), 1606(w), 1584(m), 1574(w), 1472(s), 1303(s), 1256(s), 862(s), 804(s), 743(m), 493(s). Elemental *Anal.* Calc. for $C_{52}H_{60}N_6O_6U$: C, 56.62; H, 5.48; N, 7.62. Found: C, 56.24; H, 5.21; N, 7.75%. Single crystal X-ray analysis was made for one of these crystals (Fig. 6).

2.7. X-ray crystallography

Crystals suitable for single crystal X-ray measurements were obtained directly from the reaction vessels. The crystal data for compounds **1**–**4** are summarized in Table 1 along with other experimental details. The crystallographic data were collected at 173 K on an Enraf Nonius Kappa CCD area-detector diffractometer using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Data collection was performed using φ and ω scans and the data were processed using DENZO-SMN v0.93.0 [21]. SADABS [22a] absorption correction was applied for compounds **1**–**3** and SHELXA [22b] absorption correction for compound **4**. The structures were solved by direct methods using the

SIR-97 program [23a] and full-matrix least-squares refinements on F^2 were performed using the SHELXL-97 program [23b]. Figures were drawn with ORTEP-3 for Windows [24]. For all compounds the heavy atoms were refined anisotropically. The CH hydrogen atoms were included at fixed distances using fixed displacement parameters from their host atoms while other H atoms were refined using fixed displacement parameters (1.2 times that of the host atom).

2.8. Uranyl extraction

Two-phase uranyl ion extraction studies from water to dichloromethane were performed at room temperature (21–22 °C) to determine the extraction ability of the ligands and the influence of several factors on the extraction process. The study consisted of three different tests:

1. The extraction ability for the uranyl ion of the ligands H_2L1–H_2L4 without stirring the extraction system (pH around 3).
2. The selectivity of the ligand toward several metal ions in an extraction process from water at pH 1.8 to dichloromethane. The ligands were H_2L1, H_3L5, $H_2L6 \cdot HCl$ and $H_3L7 \cdot HCl$ whereas the metal ions were $UO_2(aq)^{2+}$, $Fe(aq)^{3+}$, $Co(aq)^{2+}$, $Ni(aq)^{2+}$, $Cu(aq)^{2+}$ and $Zn(aq)^{2+}$.
3. This experiment was done as experiment 2, but now the metal ions were in an acetate buffer solution (225 mmol/L) at pH 4.2.

In the first experiment with the ligands H_2L1–H_2L4 the experimental setup was the following: into a test tube were placed 3 ml of CH_2Cl_2 with the ligand (0.210 mmol) and on top of this CH_2Cl_2 layer was placed 2 ml of a water solution of uranyl nitrate hexahydrate (0.0525 mmol) leading to a U:ligand ratio of 1:4. The samples for ICP ($V = 50$ μl, diluted to a 10 ml of H_2O) were taken from the water layer within a 120-h period of time. The samples were analyzed with ICP-OES at 385.958 nm using a Perkin–Elmer Optima 4300DV instrument in every experiment.

In the second experiment with the ligands H_2L1, H_3L5, $H_2L6 \cdot HCl$ and $H_3L7 \cdot HCl$ the experimental setup was as follows: into a test tube was placed 3 ml of CH_2Cl_2 with the ligand (0.320 mmol) and Et_3N (0.320 mmol, to neutralize HCl in $H_2L6 \cdot HCl$ and $H_3L7 \cdot HCl$) and on the top of this layer was placed 3 ml of water solution containing uranyl nitrate (0.078 mmol), iron(III) nitrate (0.078 mmol), copper(II) nitrate (0.078 mmol), nickel(II) nitrate (0.078 mmol), zinc(II) nitrate (0.078 mmol) and cobalt(II) nitrate (0.078 mmol) leading to a $UO_2(aq)^{2+}$:$Fe(aq)^{3+}$:$Co(aq)^{2+}$:$Ni(aq)^{2+}$:$Cu(aq)^{2+}$:$Zn(aq)^{2+}$:ligand ratio of 1:1:1:1:1:1:4 (the total ratio of the metal ions to the ligand being 6:4). One test tube containing no ligand and no base was also prepared. The solutions were stirred with a magnetic stirrer (900–1100 rpm) throughout the experiment. Before the samples were taken, the stirring was interrupted and the solutions were allowed to settle for 5 min. The samples for ICP (V = 50 μl, diluted to 10 ml) were taken from the water layer during a 44-h period of time.

The third experiment was done similarly to the second one with the exception that the pH of the water solution was adjusted to 4.2 with an acetate buffer.

3. Results and discussion

3.1. Complexation studies

In the reactions of the uranyl ion with the diaminobis(phenolato) ligands, two types of complexes are formed, i.e. $[UO_2(HLn)(NO_3)]$ ($n = 1, 2$) and $[UO_2(HLn)_2]$ ($n = 1,3$). For example, if the reaction between uranyl nitrate and H_2L1 is performed in a 1:2 metal to ligand ratio without any additional base and using acetonitrile as the solvent, a complex with the formula $[UO_2(HL1)(NO_3)]\cdot CH_3CN$ (**1**) can be isolated. When the reaction was carried out under similar conditions in the presence of a base (1:1 ratio of ligand to triethylamine), the reaction produced a complex with the formula $[UO_2(HL1)_2]$ (**2**). Apparently, in a higher stoichiometry, i.e. when the metal to ligand ratio in the reaction mixture is 1:2, one ligand molecule acts as a proton acceptor causing the formation of a 1:1 complex. The presence of an extra base (triethylamine) favours the formation of the 1:2 complexes. Both of the phenolic OH-groups are deprotonated during the complexation process, and principally either of the two nitrogen donors of the coordinated ligand could accept the proton to form a zwitter ion HLn^-. The site of the protonation defines the coordination mode of the ligand – the protonation of the bridging amino group makes the aminobis(phenol) coordinate as a bidentate $[O,O]$ donor, whereas the protonation of the side-arm nitrogen allows tridentate $[O,N,O]$ coordination. Certainly, in **1**, the proton is located on the side-arm amino group, whereas in **2** it is on the bridging nitrogen (see the structural part of the work). So, we can sum up that the ligand H_2L1 formed both 1:1 and 1:2 (metal–ligand ratio) complexes with the uranyl ion, while the ligand H_2L2 formed only a 1:1 complex (**3**) and the ligand H_2L3 formed solely a 1:2 complex (**4**) with the uranyl ion. The ligand H_2L2 did not form the 1:2 complex, apparently due to the steric reasons. Ligand H_2L4 formed a red solution with the uranyl ion, but no crystalline compound was formed under the applied conditions.

The slight discrepancy in the elemental analyses of compounds **1** and **3** originate from the fact that the crystals of **1** and **3** contain weakly bonded acetonitrile molecules, some of which are loosened during the sample preparation. On the other hand, if acetonitrile is removed in vacuum prior to analyses, the resulting solids can absorb atmospheric moisture. In both cases, the elemental analyses give slightly lower analytical results than the calculated ones.

3.2. NMR studies of the complexes in the solution

Complexes **1**–**4** were dissolved in deuterated DMSO and complex **2** also in deuterated chloroform and their behaviour in these solutions was studied by ^1H NMR. In DMSO the complexes **1**–**4** evoke two sets of peaks: one set for a coordinated ligand and the other set for an uncoordinated ligand. Dissociation of the uncoordinated ligand from the uranyl complex is possibly due to the protonation of the phenoxide moiety by possible proton sources, e.g. traces of water or the protonated side-arm aminogroup of the ligand. The degree of dissociation varies, e.g. for **2**, about 33% of the dissolved complex has been dissociated, whereas complex **4** seems to be predominantly in the dissociated form (the ratio of the coordinated ligand to the uncoordinated ligand being approximately 1:1).

The NMR for complex **2** in $CDCl_3$ revealed that compound **2** hydrolyses due to atmospheric moisture and traces of water in the solvent. This leads to the decomposition of the complex according to the following scheme (1–2):

$$[UO_2(HL1)_2](CDCl_3)_n + xH_2O \rightarrow [UO_2(HL1)(H_2O)_x]^+ + HL1^- + nCDCl_3 \quad (1)$$

$$[UO_2(HL1)(H_2O)_x]^+ + HL1^- \rightarrow [UO_2(HL1)(OH)(H_2O)_{x-1}] + H_2L1 \quad (2)$$

These reactions were followed with two different ^1H NMR samples: one sample was exposed to atmospheric moisture, while another sample was sealed under ambient conditions, so that the system contained only a small amount of water that was absorbed during the preparation of the sample. As a result, it was found that in the "open" tube the decomposition of the complex carried on until the experiment was interrupted after 216 h. In the sealed tube reaction the decomposition ended after about 72 h as all water molecules in the system were consumed in hydrolysis. After a follow-up of 144 h, the sealed sample tube was opened and exposed to air for 10 min. From the NMR spectra it could be clearly noticed that the solution immediately absorbed water from air and the complex decomposition started again, continuing until all the complex was decomposed. After 216 h the solution contained only the free ligand, whereas all the uranium was in the precipitate, which has the possible composition $[UO_2(HL1)(OH)(aq)]$. On the whole, the studied complexes seem to be remarkably less stable towards hydrolysis than their congeners without a basic side-arm donor.

3.3. Structural studies of the uranyl complexes

With the ligand H_2L1 used in the study, two types of complexes are formed, namely 1:1 complexes $[UO_2(HL1)(NO_3)]$ (Fig. 3) and 1:2 complexes $[UO_2(HL1)_2]$ (Fig. 4). Ligand H_2L2 formed only a $[UO_2(HL2)(NO_3)]$ complex (Fig. 5) and ligand H_2L3 formed a $[UO_2(HL3)_2]$ complex (Fig. 6) in the solid state. Crystals of the studied complexes were obtained from the reaction mixtures. Selected bond parameters for **1** and **3** are presented in Table 2 and for **2** and **4** in Table 3.

In complexes **1** and **3** the nitrate anion is coordinated in the bidentate mode and the ligand HL^- in a tridentate manner to the uranyl(VI) ion. This evokes a pentagonal bipyramidal geometry around the metal centre. These kinds of neutral mononitrate complexes of uranyl are very

rare. For example, $[UO_2(L)_x(NO_3)_2]$ complexes (L = neutral ligand with one to three donor atoms and x depending on the number of donor atoms in L) are quite common.[1] Only one example having the stoichiometry $[UO_2(L)(NO_3)]$ (L = monoanionic ligand) is reported [17], while four examples with a stoichiometry of $[UO_2(L)(L')(NO_3)]$ (L = a monoanionic ligand and L′ = a neutral ligand) are described [25]. However, all these five uranyl complexes are dinuclear ones, although one nitrate ion is coordinated to the uranyl ion in a η^2-fashion. The uranyl coordination in complexes **1** and **3** resembles that in the anionic uranyl complex with the bis[2-(2-hydroxyphenoxy)ethoxy]ethane dianion [26].

The ligand HL^- bonds to the uranyl ion in compounds **1** and **3** as a tridentate dianion via two phenoxo oxygens and the benzylic amine nitrogen, while the labile proton is located on the side-arm nitrogen N18. The η^2-coordinated nitrate oxygen atoms are at a distance of 2.518(4) and 2.551(5) Å from the U(VI) ion in **1** and at a distance of 2.526(6) and 2.546(5) Å in **3**. In the compound presented in Ref. [26] both η^2-coordinated nitrate oxygen atoms are at a distance of 2.521(7) Å from the uranyl ion. The U–N8 distances are also quite long, 2.662(5) Å for **1** and 2.614(7) Å for **3**. This causes the U–O(phenoxo) bonds in the $[UO_2(HLn)(NO_3)]$ complexes to be shorter than in the $[UO_2(HLn)_2]$ complexes. For example, the average of the alkoxo bonds in **1** and **3** is 2.205 Å and in **2** and **4** it is 2.262 Å. These bond distances are in agreement with the relevant bond lengths of the uranyl ion with alkoxide and phenoxide ligands [27].

The O=U=O groups are not exactly linear as the O=U=O angles are 174.8(2)° in **1** and 179.4(3)° in **3**. Non-linear O=U=O bonds are found generally in uranyl complexes with five non-symmetrically bonding equatorial ligands, two of them being nitrate oxygen atoms [17,25,26]. The presence of nitrate is not essential as the phenomenon is found in other uranyl complexes with oxygen donors [28]. The reason for the bending of the O=U=O bonds is presumably due to uneven π donation from the ligands to the UO_2^{2+} moiety, which results from the asymmetrical location of the donor atoms around the uranium caused by the pentacoordination [29].

It is interesting to note that the coordination sphere around the uranyl ion is less distorted in **3**, where the ligand has more bulky substituents than the ligand in **1**. In both structures, the packing of molecules is supported by intermolecular H-bonds (Table 4) and acetonitrile molecules, which fill the empty holes in both structures.

The $[UO_2(HLn)_2]$ type of complexes (**2** and **4**) show similar centrosymmetric structures as the earlier reported related complexes with aminoalcoholbis(phenolate) and aminoalkylbis(phenolate) ligands [17–19]. In the *xy*-plane (the linear O=U=O group is along the *z* axis) there are four phenoxo oxygens bonded to the uranyl ion. This results that the labile proton could be attached principally to two different nitrogen atoms (N8 and N18). In both ligands, the nitrogen N8 is protonated, which leads to the bidentate coordination mode of the ligand. The hydrogens at N8 form weak intramolecular H-bonds with O2 and O3 (Table 4).

[1] A search in the Cambridge Structure database (version 5.28, November 2006) gives about 120 entries with the $UO_2(NO_3)_2$ fragment.

[a] Atom generated by symmetry transformation: $-x+1/2$, $y-1/2$, $-z+3/2$.

In Table 5 selected torsion angles in the coordinated ligands are presented. Clearly compounds **1** and **3** have similar torsion angles as do compounds **2** and **4**. The largest difference between **1** and **2** is in the torsion angle C16–N8–C9–C10, which has the values 43.0(7)° and 85.0(3)° for **1** and **2**, respectively. The intramolecular O···O distances in the aminobis(phenolato) ligands of **1** and **2** are 3.3033(3) and 4.214(7) Å, respectively. These changes in the torsion angles and intramolecular distances in the ligands in different uranyl complexes indicate the flexibility of these bisphenolate ligands in the complexation processes.

3.4. Uranyl ion extraction studies

The results of uranyl ion extraction studies with ligands H_2L1–H_2L4 (experiment 1) at room temperature are shown in Fig. 7. The ratio of the ligand to the uranyl ion was 4:1. The extraction was done without stirring at the pH of the 0.026 M uranyl nitrate in unbuffered water solution (pH around 3). The extraction curves show that the extraction abilities of these ligands under the applied conditions were not very good. Only about 28% of the uranyl ions are transferred into the dichloromethane phase, whereas in our previous studies with long chain aminoalcohol ligands they transferred more than 90% of the uranyl ions into the dichloromethane phase under similar conditions [18]. There are two possible reasons for the low extraction ability of the H_2L1–H_2L4 ligands. First, the ligands H_2L1–H_2L4 have very good solubility in dichloromethane and low solubility in water, so the low concentration of the ligand in the water phase leads to the slow extraction rate. Second, the low stability of the neutral $[UO_2(HLn)_2]$ complexes in moist CH_2Cl_2, as shown by the ^1H NMR studies, causes a quick transfer of the uranyl ions back to the water phase. Also, the presence of several uranyl(VI) ion complexes with water and nitrate in the water phase can affect the complexation kinetics and thus the extraction speed of the uranyl ion, as shown by Bühl et al. [30]. A reason for the deviation in the extraction curve of H_2L2 is that this di-*tert*-butyl substituted ligand formed a jelly-like gel in the water phase at the beginning of the extractions process which hindered the sample taking, leading to dilute samples.

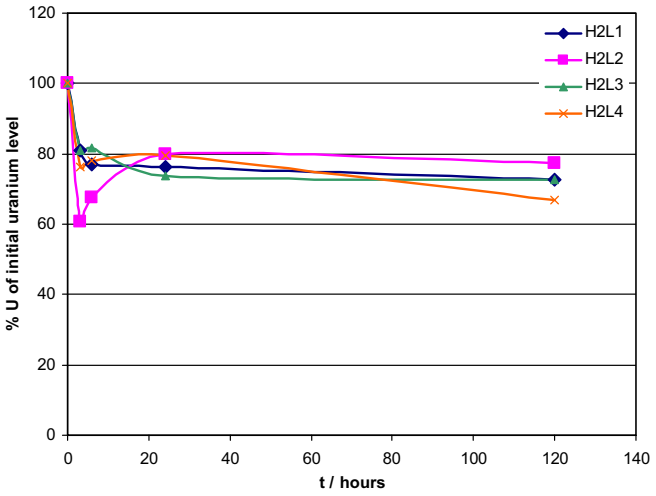

Fig. 7. Decrease of the uranyl ion concentration (%) in the water layer as a function of time during the extraction process with ligands H_2L1–H_2L4 (experiment 1).

In order to find out the selectivity of the several different aminobis(phenol) ligands, studied in this as well as in our earlier works, towards several metal ions, two tests were performed. The selectivity tests were performed with the metal ions in a water solution at two different pH values (1.8 and 4.2) using one ligand at a time as an extractor. During the extraction process the system was stirred in order to speed up the process. The first selectivity tests were done at pH 1.8, the value which was achieved after all the metal ions had been dissolved. The concentration of each metal ion ($UO_2(aq)^{2+}$, $Fe(aq)^{3+}$, $Co(aq)^{2+}$, $Ni(aq)^{2+}$, $Cu(aq)^{2+}$ and $Zn(aq)^{2+}$) in the water layer was 0.026 mol/l whereas the ligand concentration was 0.101 mol/l. Cations Co^{2+}, Ni^{2+} and Zn^{2+} were not extracted at all by any of the ligands H_2L1, H_3L5, $H_2L6 \cdot HCl$ and $H_3L7 \cdot HCl$ during the 44 h of extraction at pH 1.8.

Table 5
Selected torsion angles (°) for **1**–**4**

	1	**2**	**3**	**4**
C5–C6–C7–N8	111.1 (7)	127.7 (3)	120.6 (7)	135.2 (5)
C1–C6–C7–N8	−68.6 (8)	−57.4 (4)	−60.4 (9)	−48.6 (7)
N8–C9–C10–C11	−129.8 (7)	−119.3 (3)	−123.9 (8)	−117.6 (6)
N8–C9–C10–C15	53.0 (8)	62.7 (4)	59.3 (10)	67.7 (6)
C16–N8–C7–C6	−62.6 (7)	−61.0 (3)	−48.8 (8)	−60.4 (6)
C9–N8–C7–C6	173.5 (5)	171.6 (3)	−169.8 (6)	169.3 (4)
C16–N8–C9–C10	43.0 (7)	85.0 (3)	48.7 (8)	75.9 (6)
C7–N8–C9–C10	166.0 (5)	−149.4 (3)	169.8 (6)	−152.6 (5)

Ligands H_3L5 (extracted 38% of uranyl ions), $H_2L6 \cdot HCl$ (extracted 47% of uranyl ions) and $H_3L7 \cdot HCl$ (extracted 41% of uranyl ions) extracted quite selectively uranyl ions; only small amounts of iron(III) ions were also co-extracted and no copper(II) ions at all. Ligand H_2L1 instead preferred copper and iron over the uranyl ion. The concentrations of the metal salts in the control experiment were constant during the extraction follow-up.

In the third set of experiments, the extractions were done whilst stirring the solutions at pH 4.2 using an acetate buffer in a water phase. Again Co^{2+}, Ni^{2+} and Zn^{2+} ions were not extracted practically at all by any of the ligands H_2L1, H_3L5, $H_2L6 \cdot HCl$ and $H_3L7 \cdot HCl$ (only H_2L1 extracted 10% of Ni-ions). The uranyl ion was extracted quite well by ligands $H_2L6 \cdot HCl$ and $H_3L7 \cdot HCl$ (65%) with moderate amounts of Fe^{3+} ions (44% and 30%, respectively). H_2L1 extracted Fe^{3+} and Cu^{2+} ions practically quantitatively. H_3L5 extracted Fe^{3+} ions also quantitatively (97%) with 50% of uranyl ions. These results can be seen in Figs. 8–11. The concentrations of the metal ions in the water layer of the control sample were constant during the follow-up.

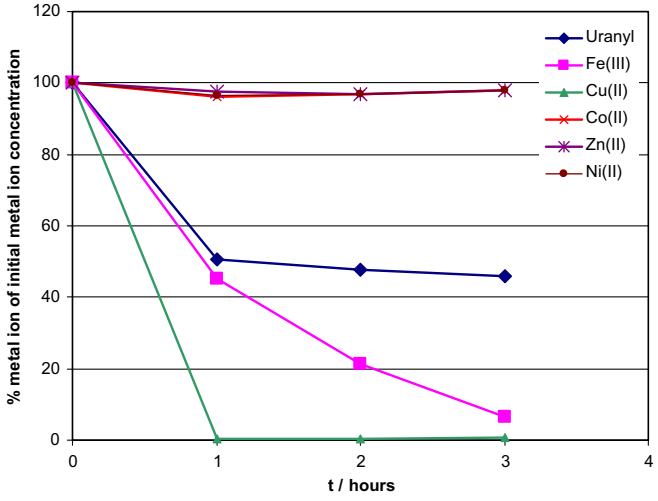

Fig. 8. Decrease of the metal ion concentrations (%) in the water layer as a function of time during the extraction process with H_2L1 at pH 4.2.

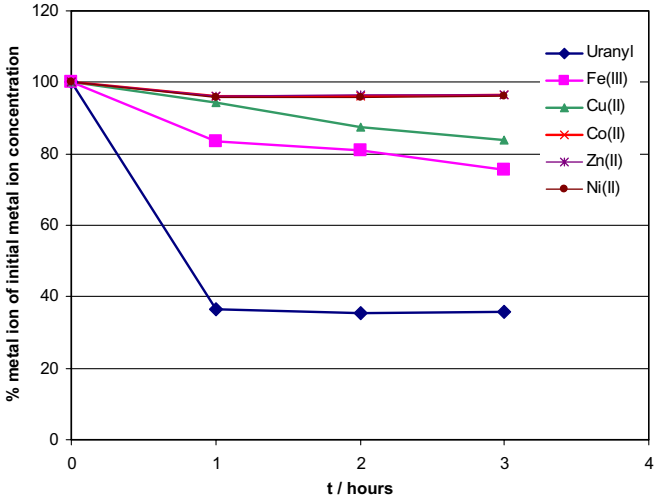

Fig. 10. Decrease of the metal ion concentrations (%) in the water layer as a function of time during the extraction process with $H_2L6 \cdot HCl$ at pH 4.2.

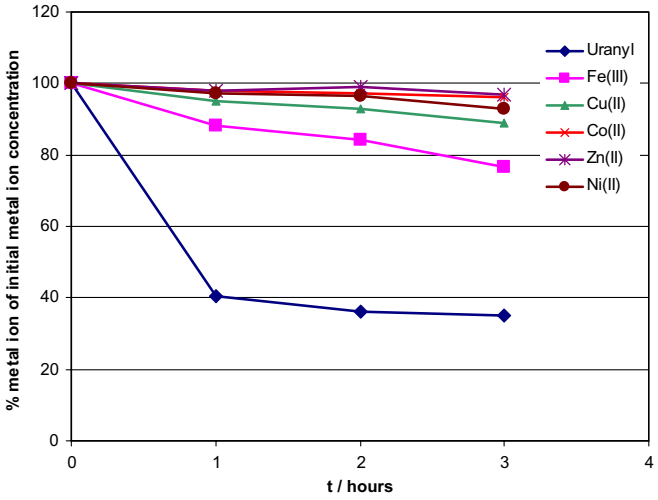

Fig. 11. Decrease of the metal ion concentrations (%) in the water layer as a function of time during the extraction process with $H_3L7 \cdot HCl$ at pH 4.2.

4. Conclusions

The diaminobisphenolates reported here can form two types of complexes with the uranyl ion: $[UO_2(HLn)(NO_3)] \cdot CH_3CN$ and $[UO_2(HLn)_2]$. Earlier studied amino-alcohol- and aminoalkylbis(phenolate)s are found to form only the latter type of complex. In these new $[UO_2(HLn)(NO_3)]$ complexes the organic ligand bonds tridentately and the nitrate ion bidentately to the uranyl ion. The possible reason for the formation of these new

uranyl complexes is the existence of two basic nitrogen atoms in the ligand, with which one can bond to the uranyl ion while the another acts as a proton acceptor.

The ^{1}H NMR studies show that the $[UO_2(HLn)_2]$ complexes reported are sensitive to water in organic solvents, as the complexes decompose slowly in chloroform. This can be one of the reasons why these diaminobis(phenol) ligands are weak uranyl ion extractors from water to dichloromethane, although the $[UO_2(HLn)_2]$ complexes are soluble in dichloromethane.

Even though the ligands H_2L1–H_2L4 did not show good uranyl ion extraction properties in the experiments made in this study, the ligand H_2L1 proved to be a good iron and copper extractor from water to dichloromethane. In the selectivity studies the ligands H_3L6 (*N*,*N*-bis(2-hydroxy-5-*tert*-butyl-3-methylbenzyl)-1-aminobutane · HCl) and H_3L7 · HCl (*N*,*N*-bis(2-hydroxy-5-*tert*-butyl-3-methylbenzyl)-6-amino-1-hexanol · HCl) showed good selectivity towards the uranyl ion in extraction experiments, thus possessing the potential ability to selectively extract uranyl under environmental and physiological conditions.

Abstract

The synthesis and structure of a pyrazole-based orthogonal ferromagnetically coupled tetracopper(II) 2 × 2 homoleptic grid complex $[Cu_4(PzOAPyz)_4(ClO_4)_2](ClO_4)_2 \cdot 6H_2O$ (**1**), formed by the reaction between the ditopic ligand PzOAPyz and $Cu(ClO_4)_2 \cdot 6H_2O$, are described. The ligand contains terminal pyrazole and pyrazine residues bound to a central flexible diazine subunit (N–N) as well as one potentially bridging alkoxo group. The two adjacent metal centers are linked by an alkoxo oxygen forming essentially a square $Cu_4(\mu\text{-}O_4)$ cluster. In the $Cu_4(\mu\text{-}O_4)$ core, out of the four copper centers, two copper centers are penta-coordinated and the remaining two are hexa-coordinated. In each case of hexa-coordination, the sixth position is occupied by one of the oxygen atoms of a coordinated perchlorate ion. Complex **1** has been characterized structurally and magnetically. Although the large Cu–O–Cu bridge angles (137–138°) and short Cu–Cu distances (3.964–3.970 Å) are suitable for the transmission of the expected antiferromagnetic coupling, the square-based $Cu_4(\mu\text{-}O_4)$ cluster exhibits an intramolecular ferromagnetic exchange ($J = 7.47\ cm^{-1}$) between the metal centers with an $S = 2$ magnetic ground state associated with the quasi orthogonal arrangement of the magnetic orbitals ($d_{x^2-y^2}$). The exchange pathway parameters have been evaluated from density functional calculations.

1. Introduction

Self-assembly processes involving carefully designed multidentate ligands and metal ions with appropriate stereoelectronic preferences can lead to the efficient and specific formation of aesthetically looking sophisticated polynuclear grids [1,2]. Although at the beginning, many of these structures arose accidentally, recently worldwide systematic attempts are in line to determine the relationship between the number, type and spatial disposition of the binding sites of the ligand for a proper metal ion. This newly found relationship allows a considerable degree of control over the nature of the structure [3]. A significant amount of control can be exerted over the formation of relatively low nuclearity molecular clusters ($<M_6$) by the use of poly-functional and polytopic ligands with well defined and appropriately positioned coordination pockets. Hence, with the proper choice of paramagnetic metal ions to form complexes with these ligands, magnetic coupling can be fine-tuned in order to achieve the result of desired and interesting supramolecular magnetic properties. The major interest so far in these types of grid complexes has emerged from their remarkable and fantastic structures. The specific self-assembly processes leading to these grid-like complexes find immense application in information

doi:10.1016/j.poly.2007.08.040

storage and processing technology [4–6]. However, there is also considerable scope for the study of magnetic interactions in these complexes where several metal ions are assembled in a well-defined spatial array linked by suitable bridging ligands to transmit the interaction. Physicochemical properties and magnetic exchange interactions have been extensively studied between the pairs of metal centers in tetranuclear complexes. Recently, the magnetic properties of high-nuclearity clusters have also created immense interest [2] for the development of new magnetic materials. Transition metal template cyclisations have successfully produced many tetranuclear Mn_4, Ni_4, Cu_4 and Zn_4 complexes, [7–13] in which the bridging arrays among the metal ions involve oxygen donor centers. Most of the so far reported alkoxo-bridged poly-nuclear grids [Mn(II), Co(II) and Ni(II)] show anti-ferromagnetic coupling [9–13], while a few Cu(II) grids [14–18] exhibit a ferromagnetic interaction. The origin of this ferromagnetic exchange emerges from the orthogonal orientation of the magnetic orbitals ($d_{x^2-y^2}$).

In continuation of our very recent report [15] of a square Cu_4-grid, in this paper we describe the syntheses, structural characterisation and magnetic properties of a tetranuclear copper(II) complex prepared from the simple multidentate chelating ligand PzOAPyz, containing pyrazine and pyrazole as heterocyclic rings. The assembly of this structure is driven by the stereoelectronic requirement of the copper(II) ion for an elongated tetragonal geometry. The resultant grid-like copper(II) complex contains arrays of four copper(II) ions linked by alkoxide bridges, which are known to be effective mediators of magnetic exchange interactions; accordingly, detailed magnetic susceptibility studies on this complex are described. A brief discussion of its DFT study has also been made.

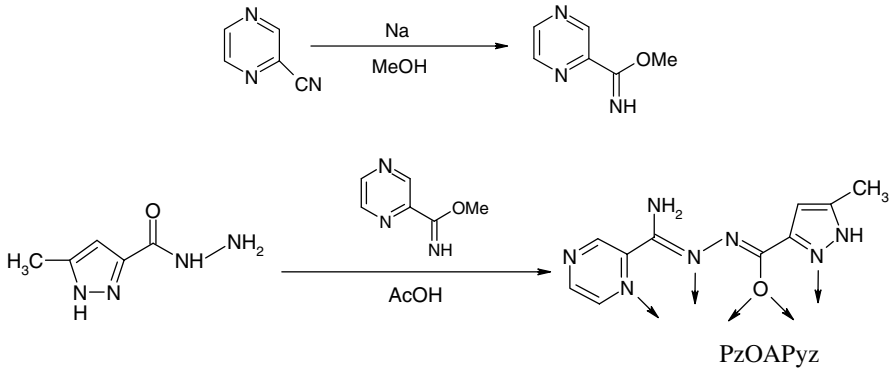
2. Experimental

2.1. Materials

2-Cyanopyrazine was purchased from Aldrich Chemical Company. Other commercially available chemicals and solvents were used and purified by standard procedures [19].

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) of the ligand PzOAPyz and the metal complex **1** were carried out with a Perkin-Elmer CHNS/O analyzer 2400 at the Indian Association for the Cultivation of Science, Kolkata. The electronic spectra of **1** in purified CH_3CN solution were recorded on a Hitachi model U-3501 spectrophotometer. IR spectra (KBr pellet, 4000–400 cm^{-1}) were recorded on a Perkin Elmer model 883 infrared spectrophotometer. The mass spectrum of the ligand was done at the Indian Institute for Chemical Biology, Kolkata with a JEOLJMS-AX 500 mass spectrometer. Room temperature magnetic susceptibility was measured with a PAR 155 vibrating sample magnetometer. Magnetic susceptibility measurements for the compound were carried out on polycrystalline samples at the Servei de Magnetoquímica of the Universitat de Barcelona, with a Quantum Design SQUID MPMS-XL susceptometer apparatus working in the range 2–300 K under magnetic field of approximately 500 G (2–30 K) and 1000 G (35–300 K). Diamagnetic corrections were estimated from Pascal Tables.



2.3. Synthesis and characterization of the ligand

2.3.1. Synthesis of 5-methylpyrazole-3-carbohydrazide

5-Methylpyrazole-3-carbohydrazide was prepared following an established method [20].

2.3.2. Synthesis of PzOAPyz

The methyl ester of iminopyrazine-2-carboxylic acid, isolated as a white precipitate, was prepared in situ (Scheme 1) by the direct reaction of 2-cyanopyrazine (1.75 g, 0.0166 mol) with sodium methoxide solution, preproduced by dissolving sodium metal (2.63 g, 0.114 mol) in dry methanol (10 mL) when required. 5-Methylpyrazole-3-carbohydrazide (3.5 g, 0.025 mol) in 15–20 mL dry methanol was added to the above precipitate with stirring. Within a few minutes, the white precipitate was found to be dissolved. The stirring was continued for an additional 1 h. Then the mixture was refluxed for 5 h and cooled to room temperature. Excess methanol was removed in a rotary

Scheme 1.

evaporator, leaving a red coloured oily sticky liquid. This was then mixed with water (30 mL) and neutralized with AcOH (pH ~5), which afforded a yellow shining powder. The solid was filtered off, washed thoroughly with methanol and dried in vacuo over fused $CaCl_2$. Yield (3.32 g, 60%). M.p. >250 °C. MS (*m*/*z*) 245 (M^+, 100%). IR/cm^{-1}: ν_{NH} 3350; $\nu_{CO/CN}$ 1659(s), 1548(s); $\nu_{N\text{-}Npz}$ 1065(s); ν_{py} 1020(s). *Anal.* Calc. for $C_{11}H_{12}N_6O$: C, 48.97; H, 4.49; N, 40.00. Found: C, 48.91; H, 4.51; N, 39.93%.

2.4. Preparation of the complex

2.4.1. $[Cu_4(PzOAPyz)_4(ClO_4)_2](ClO_4)_2 \cdot 6H_2O$ (1)

The ligand PzOAPyz (0.122 g, 0.5 mmol) was added to a hot solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.185 g, 0.5 mmol) in H_2O–CH_3OH (30 mL) (60:40 v/v). The resulting suspension was stirred at 60 °C until complete dissolution of the ligand occurred. The resulting deep green solution was filtered to remove any undissolved ligand and left at room temperature. Dark green crystals suitable for X-ray diffraction were isolated from the filtrate after standing for several days (yield 0.108 g, 40%). IR/cm^{-1}: ν_{NH/H_2O} 3371, 3458; $\nu_{CO/CN}$ 1669(s), 1536(s); $\nu_{N\text{-}Npz}$ 1084(s); ν_{py} 1032(s). UV–Vis (λ_{max}): 316(sh), 400(sh), 730(br) nm. μ_{RT} 3.42 B.M. *Anal.* Calc. for $[Cu_4(PzOAPyz)_4(ClO_4)_2](ClO_4)_2 \cdot 6H_2O$ (**1**): C, 27.63; H, 2.99; N, 22.56. Found: C, 27.49; H, 3.12; N, 22.51%.

2.5. Crystallographic data collection and refinement of the structure

Selected crystal data for **1** are given in Table 1. Data collections for **1** were made using a Bruker SMART CCD area detector diffractometer equipped with a Mo Kα radiation ($\lambda = 0.71073$ Å) source in the ϕ and ω scan modes at 100(2) K. Cell parameters were determined and refined using SMART software [21]. Data reductions were carried out using the SAINT program [22]. The structure was solved by conventional direct methods and refined by full-matrix least square methods using F^2 data. SHELXS-97 and SHELXL-97 programs [23] were used for structure solution and refinement, respectively. H-atoms bonded to water oxygens had their coordinates refined. Refinement of F^2 was done against all reflections. The weighted *R*-factor *wR* and goodness-of-fit *S* are based on F^2, conventional *R*-factors *R* are based on *F*, with *F* set to zero for negative F^2. The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating *R*-factors (gt), etc. and is not relevant to the choice of reflections for refinement. *R*-factors based on F^2 are statistically about twice as large as those based on *F*, and *R*-factors based on all data will be even larger.

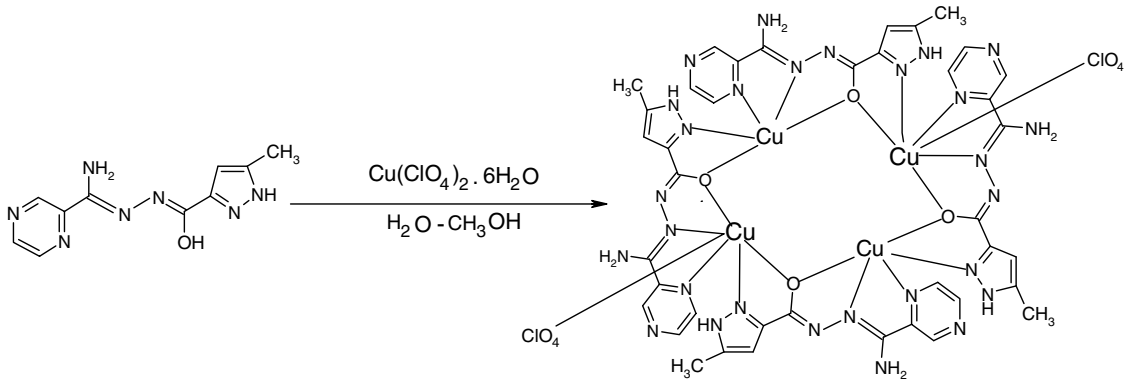
3. Result and discussion



3.1. Syntheses

The ditopic ligand PzOAPyz (Scheme 1) on treatment with a water–methanol solution (60:40 v/v) of copper perchlorate hexahydrate in a 1:1 ratio yielded an interesting orthogonal ferromagnetically coupled tetracopper(II) 2 × 2 homoleptic square grid complex. In methanol, the complex readily precipitated out from the metal–ligand reaction mixture, hence a water–methanol (60:40 v/v) mixed solvent system was chosen as the reaction medium to prevent the precipitation. The formation and stability of this self-assembled square tetrameric complex may be visualized in the following way (Scheme 2).

Each of the four chelating ditopic ligands in the tetrameric $Cu_4(\mu\text{-}O_4)$ core coordinates to any two neighbouring Cu(II) centers, occupying three and two coordination sites respectively, using the alkoxide fragment as a bridger. The repetition of this process leads to the formation of the self-assembled square $Cu_4(\mu\text{-}O_4)$ unit, where the successive four ligand molecules are orthogonal in orientation.

3.2. Description of the crystal structure $[Cu_4(PzOAPyz)_4(ClO_4)_2](ClO_4)_2 \cdot 6H_2O$ (1)

The structure of the tetranuclear cluster cation complex is illustrated in Fig. 1. An ORTEP view of the asymmetric unit is shown in Fig. 2. Selected crystal data for **1** are summarized in Table 1. Important bond distances and angles

Scheme 2.

located below the Cu_4 plane and other two bridging oxygen atoms (O1B) are located above the plane in boat-like conformation. The two five coordinated and two six coordinated copper(II) centers of the Cu_4 (μ-O_4) core are arranged in a slightly distorted square (displacement of metals from the Cu_4 least square plane; two Cu(1) +0.122 Å, two Cu(2) −0.122 Å) and are bridged by four alkoxide oxygens (two O1A and two O1B) from the four deprotonated ligands, arranged in pairs above and below the Cu_4 pseudo plane in a boat-like conformation. The O–Cu–O angles fall in the range 92–100° and the Cu–Cu separations are close to 4 Å (Cu1–Cu2 3.97 Å, Cu2–Cu1 3.96 Å). The ligands allow an orientational distinction among its four moieties and are arranged in two groups of parallel pairs, with each ligand in a roughly eclipsed arrangement compared with its partner. The total coordination sites requirement of the four metals (22 bonds) is completed by four ligands, which fill 20 coordination sites and two ClO_4^- ions, binding to each of the diagonally related Cu1 centers. The square pyramidal Cu2 centers

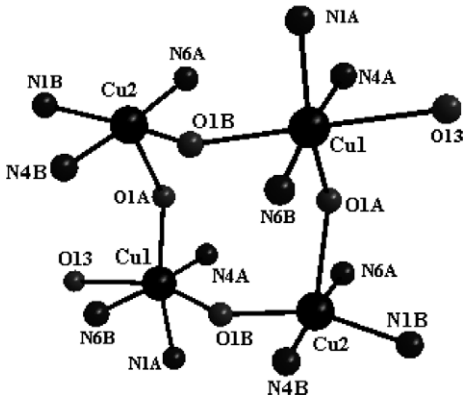

Fig. 3. Structural representation and atom numbering scheme of the tetranuclear core in **1**.

have a N_4O chromophore (all the donor centers are from ligand moieties), while the axially distorted octahedral Cu1 centers have a N_4O_2 chromophore (the additional sixth donor center is occupied by the perchlorate oxygen).

The copper–oxygen (alkoxide) bond distances are quite variable, but an interesting trend is observed based on the copper chromophore. The two Cu1 centres have long and short contacts to O1B and O1A, respectively (Cu1–O1B 2.285(2) Å, Cu1–O1A 1.965(2) Å). Similarly the other two Cu2 centres also have alternate long and short contacts to O1A and O1B respectively (Cu2–O1A 2.279(2) Å, Cu2–O1B 1.970(2) Å). This establishes an asymmetric, alternating long–short bridging arrangement within the Cu_4 square plane. The Cu–O–Cu angles fall in the range 137.69–138.10°. Both the separations and angle values are quite typical for these grid systems [14–16].

The most prominent feature of the structure involves the encapsulation of the two five-coordinate and two six-coordinate Cu(II) centers within the grid, an unusual feature in related non-homoleptic Cu_4 (2×2) square grid complexes [17,18]. Hexa-coordinated Cu(II) undergoes Jahn-Teller distortion and in this case each of two six-coordinate Cu(II) ions undergo a tetragonal elongation. The axis of elongation of the copper center includes two bridging oxygen connections (O1A and O1B), leading to a situation where the copper equatorial planes are tilted at 86.45° to the neighbouring penta-coordinated metal center. This orbital orthogonality situation leads to significant intramolecular ferromagnetic interaction. In the asymmetric unit, the two independent perchlorate groups are disordered, one about a twofold axis and the other about an inversion center. Systematic and regular solvent and perchlorate channels alternate in between the layer structures of the cluster molecules. This stabilizes the lattice structure through hydrogen bonding. In the tetrameric complex, there are also weak hydrogen bonds (Table 3) between H3AD and O3W and between H3W1 and O3W. This makes an infinite straight chain throughout the crystal.

The lattice structure involves a number of water molecules (here six) as is typical for grids in this class [14–18]. In this crystal structure, one of the water molecules (O1W) is present with unit-occupancy and there are also two half-occupancy water molecules (O2W, O3W) in the asymmetric unit.

4. Magnetic behaviour

The variable temperature magnetic susceptibility data for the compound were recorded between 300 and 2 K. Plot of $\chi_m T$ versus T in Fig. 4 shows a ferromagnetic behavior. The $\chi_m T$ value is 1.568 $cm^3\ mol^{-1}$ K at 300 K, being close to that expected for four uncoupled $S = 1/2$ spins (with $g = 2.00$). $\chi_m T$ increases slightly when temperature is lowered and reached a maximum value of 2.885 $cm^3\ mol^{-1}$ K at 3 K. This maximum is consistent with that expected for ferromagnetically coupled copper(II) ions.

The structure of **1** consists of copper ions linked by the ligand (PzOAPyz), giving a tetranuclear compound. Taking into account the compound topology (slight distortion from square array, see crystallographic data), three coupling parameters J_1, J_2 and J_3 can be considered to interpret the magnetic interactions in the complex, using the Hamiltonian:

$$H = -J_1(S_1 \cdot S_2 + S_3 \cdot S_4) - J_2(S_1 \cdot S_4 + S_2 \cdot S_3) - J_3(S_1 \cdot S_3 + S_2 \cdot S_4)$$

Based on the structural data of the $Cu_4(\mu\text{-}O_4)$ core, we have considered that $J_1 = J_2 = J$ and $J_3 = 0$ (no cross-coupling connection). For this square disposition, the E_n value can

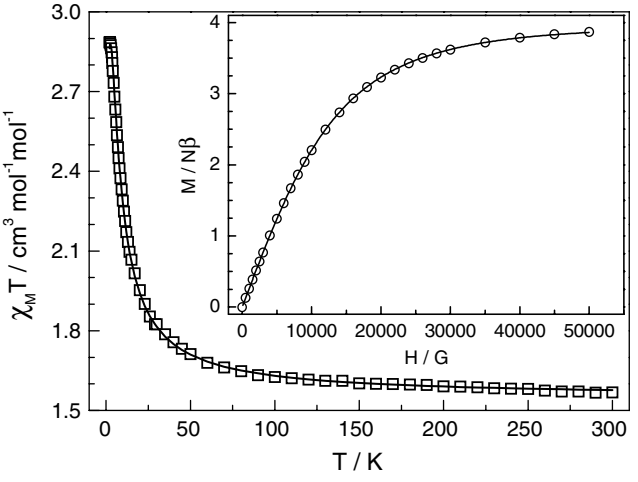

Fig. 4. Plots of $\chi_m T$ vs. T and M/Nβ vs. H at $T = 2$ K (inset) for **1**. Solid lines correspond to the best fit (see text).

be obtained by using the Kambe method [24] from the Hamiltonian:

$$H = -J_1(S_1 \cdot S_2 + S_2 \cdot S_3 + S_3 \cdot S_4 + S_1 \cdot S_4) \quad (1)$$

The analysis of the experimental susceptibility data have been performed by the use of the expression:

$$\chi_m T = Ng^2\beta^2 T(f(J,T)/3K) \quad (2)$$

Here

$$f(J,T) = \frac{6\exp(J/KT) + 12\exp(2J/KT) + 30\exp(3J/KT)}{1 + 3\exp(J/KT) + 7\exp(2J/KT) + 5\exp(3J/KT)} \quad (3)$$

The best fit parameters found are: $J = +7.47\ cm^{-1}$ and $g = 2.03$ with an error $R = 4.2 \times 10^{-5}$, where $R = \chi[(\chi_m T)_{obs} - (\chi_m T)_{calc}]^2/\chi(\chi_m T)_{obs}{}^2$. The field dependence of magnetization (0–5 T) measured at 2 K (Fig. 4, inset) suggests that the magnetization tends to 4.0 electrons, which is close to the expected value for the ferromagnetically coupled four Cu^{II} ions ($S = 1/2$ and $g = 2.03$).

4.1. Magneto-structural correlations

The value of the superexchange parameter $J = +7.47\ cm^{-1}$ for compound **1**, should be considered as normal, taking into account the structural and magnetic data reported in the literature [12,14,15,25]. In Table 4, we report significant structural data and the calculated J values for the published ferromagnetic [2 × 2] square Cu_4 complexes, along with those of complex **1**. These fit nicely into the list. It might be interesting to compare the ferromagnetic behavior of these complexes, which increases when the Cu–O distance decreases, as can be observed in Fig. 5. The variation observed can be rationalized-based on the Hay–Thibeault–Hoffmann model [26] where the global coupling constant is given by

$$J = 2K_{ab} - \frac{(\varepsilon_1 - \varepsilon_2)^2}{J_{aa} - J_{ab}} = J_F + J_{AF} \quad (4)$$

The poor overlap between the nearly orthogonal $d_{x^2-y^2}$ orbitals (Fig. 6) approaches to zero or reduces considerably the antiferromagnetic contributions (second term). In this situation, we would expect the first term, $2K_{ab}$, to dominate giving overall positive and large J values, which diminish with longer Cu–O distances as we can observe as a general trend (Fig. 5).

On the other hand, the DFT calculation carried out on the real structure of complex **1** confirms with accuracy the value of the magnetic interaction reported before, being $7.2\ cm^{-1}$. The computational methodology was reported recently in a similar case [15]. The analysis of the spin density distribution shows the predominance of a delocalization mechanism in the coordinated atoms to the copper ions (Fig. 6) [27]. The spin population on the copper atoms is around 0.63e−, and the missing spin density, relative to one unpaired electron, appears mainly to be delocalized over the bridging ligands (∼0.13e−). The topology of the SOMOs and the spin density map in this case indicates that adjacent copper(II) centres are quasi orthogonal, leading a ferromagnetic interaction.

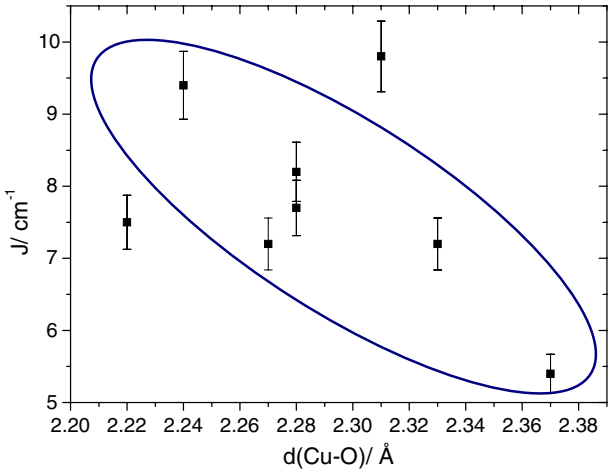

Fig. 5. Plot of the J values vs. longer d(Cu–O) distances (5% error bars were added) for the ferromagnetic [2 × 2] square Cu_4 complexes characterized to date (see Table 4).

5. Concluding remarks

The mixed pyrazole-pyrazine-based ditopic ligand PzOAPyz forms a homoleptic 2×2 square grid-complex in the presence of the Cu(II) ion, in which the pyrazole rings remain protonated. The structural backbone of the ligand contains two diazine nitrogens linking two peripheral heterocyclic rings. The ligand is made by tracing the same synthetic route as before [15] in which a hydrazide was reacted with a methyl imino ester. This leads to the desired ligand with a pyrazole and a pyrazine fragment at the two ends. The alkoxide fragment (–OH group) in the ligand PzOAPyz plays an important role towards the self-assembly process, forming a grid by bridging two adjacent copper centers simultaneously. The –OH group is deprotonated during the course of the reaction and serves as a ferromagnetic mediator between the two adjacent paramagnetic copper ions. The $–NH_2$ groups are not involved in the coordination. The ligand donor set combination provides a template for binding the two adjacent metals which leads to the formation of the cluster by a self-assembly process. The four metal centers in the tetrameric complex are arranged in a distorted square shape with two pairs of roughly parallel ligands. The self-assembly mechanism is difficult to predict but one could rationalize an initial step of coordination of the ligand at three sites, one pyrazole or pyrazine nitrogen, one diazine nitrogen and the adjacent deprotonated –OH, in a meridional fashion.

In the present grid complex, the two copper centers are square pyramidal and other two are axially distorted octahedral. In the $Cu_4(\mu\text{-}O_4)$ core, alternative short and long contacts lead to an unsymmetrical orientation from a perfect square grid arrangement. However, in the $Cu_4(\mu\text{-}O_4)$ unit, the main backbone of the complex arises through a self-assembly process. This is controlled by employing the sense that a predetermined structural arrangement is logically based on the strategic positions of the donor groups within the ligand moiety. Variable temperature magnetic susceptibility studies show that the square copper cluster exhibits an intramolecular ferromagnetic spin exchange, associated with the orthogonal alkoxide bridging arrangement and the close proximity of the copper centers. The origin of this ferromagnetic coupling lies in the approximately orthogonal orientation of the magnetic orbitals $d_{x^2-y^2}$.

Abstract

Two new mixed ligand complexes of copper(II) with acetylacetonate (acac), 2,2′-bipyridine (bpy) and 1,10-phenanthroline (phen) belonging to the class of cytotoxic and antineoplastic compounds known as CASIOPEINAS® were synthesized and structurally characterized. Crystals of both complexes $[Cu(acac)(bpy)(H_2O)]NO_3 \cdot H_2O$ (**1**), [Cu(acac)(phen)Br] (**2**) contain square pyramidal Cu(II) complex species. In frozen solution both compounds give well resolved EPR spectra with very similar parameters.

Keywords: Copper(II) complex; Mixed ligand chelate; EPR spectroscopy; UV–Vis spectroscopy; Casiopeinas®

1. Introduction

Mixed chelate complexes of Cu(II) having the general formulae $[Cu(NN)(OO)]^+$ and $[Cu(NN)(ON)]^+$ are reported to have potentially useful pharmacological properties [1–3]. In the above formulae, (NN) represents a diimine ligand, 2,2′-bipyridine (bpy) or 1,10-phenanthroline (phen) or their ring substituted derivatives, (OO) stands for acetyl acetonate and (ON) is an aminoacidate. The class of compounds [Cu(N–N)(O–O)]NO_3 has been registered under the trade name, CASIOPEINAS® [1,4]. As early as 1970, Fukuda and Sone reported the formation and absorption spectra of mixed ligand complexes of Cu(II) with acac and bpy/phen [5]. Subsequently, a number of mixed ligand complexes of copper (II) with acac and phen have been structurally characterized which include, $[Cu(acac)(phen)(OH_2)][hfac] \cdot H_2O$ (hfac = hexafluoroacetylacetonate) [6], [Cu(acac)(phen)NCS] [7], $[Cu(acac)(phen)H_2O]NO_3 \cdot 2H_2O$ [8], $[Cu(acac)(phen)NO_3] \cdot H_2O$ [9], $[Cu(acac)(2,9\text{-}Me_2phen)NO_3]$ [9], $[Cu(acac)(phen)ClO_4][Cu(acac)(phen)(CH_3CN)]ClO_4$ [10], $[Cu(acac)(phen)(H_2O)]ClO_4$ [11]. Azido bridged polynuclear complexes containing acac and phen/bpy have also been reported [12]. However, only the structure of one mononuclear mixed chelate of Cu(II) with bpy and acac, $[Cu(acac)(bpy)(H_2O)][Cu(acac)(bpy)N_3] \cdot 2ClO_4$ has been reported so far [13], although there were reports of $[Cu(acac)(4,4'\text{-}Me_2bpy)]^+$ [4,7]. Herein we report the synthesis, structure and spectral properties of $[Cu(acac)(bpy)(H_2O)]NO_3 \cdot H_2O$ (**1**), [Cu(acac)(phen)Br] (**2**).

2. Experimental

2.1. Materials and physical measurements

All the chemicals used were of the reagent grade and were used as received. IR spectra were recorded using KBr discs on a Jasco FT/IR 5300 spectrometer in the range 4000–400 cm^{-1}. Elemental analysis for C, H and N was performed on a Perkin–Elmer 240C elemental analyzer. Electronic spectral measurements were obtained using a Shimadzu UV-3101 PC spectrophotometer and the diffuse

reflectance spectra with an ISR-3100 integrating sphere attachment. The EPR spectra of the frozen solution at 130 K in ethanol were collected on a JEOL JES – FA 200 spectrometer operating at X-band frequency. Spectra were simulated using a previously described computer program [14]. Powder diffractograms were measured using PW3710 model Philips Analytical X-ray diffractometer.

2.2. Synthesis

2.2.1. [Cu(acac)(bpy)(H_2O)]$NO_3 \cdot H_2O$ (1)

To a 25 mL of ethanolic solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.242 g, 1.00 mmol), acetylacetone (0.103 mL, 0.99 mmol) was added and stirred. To the resulting green solution solid 2,2′-bipyridine (0.156 g, 0.99 mmol) was added followed 2 mL aqueous solution of KOCN (0.081 g, 0.99 mmol). The resulting mixture was stirred for 30 min and a light blue precipitate was filtered off (0.045 g) and dark blue filtrate kept for evaporation at RT. In one week, dark blue crystals of **1** suitable for X-ray determination were formed. Yield: 0.281 g (0.674 mmol, 67%). *Anal.* Calc. for $C_{15}H_{19}CuN_3O_7$ (MW 416.87): C, 43.22; H, 4.59; N, 10.08. Found: C, 43.17; H, 4.73; N, 10.19%. IR (KBr disk, cm^{-1}) 3516, 3420, 1575, 1521, 1383, 1018, 1275, 821, 731.

2.2.2. [Cu(acac)(phen)Br] (2)

To a 20 mL ethanolic solution of acetylacetone (0.103 mL, 0.99 mmol) and 1,10-phenanthroline monohydrate (0.198 g, 1 mmol), solid $CuBr_2$ (0.223 g, 1.00 mmol) was added and stirred. The pH of the resulting brown solution was adjusted to 6–7 by adding dilute sodium hydroxide and stirring. The color of the solution changed to green, with the formation of green precipitate of **2** which was filtered and dried. Yield: 0.250 g (0.591 mmol, 59%). The filtrate was kept for evaporation at RT to get dark green crystals suitable for X-ray crystallography. Powder diffractograms revealed that both the crystals and the microcrystalline precipitate are identical. *Anal.* Calc. for $C_{17}H_{15}BrCuN_2O_2$ (MW 422.76): C, 48.30; H, 3.58; N, 6.63. Found: C, 47.88; H, 3.33; N, 6.36%. IR (KBr disk, cm^{-1}) 3414, 1585, 1518, 1429, 1381, 1273, 1018, 925, 855, 766, 722, 646.

2.3. X-ray crystallography

X-ray data were collected on a Bruker SMART APEX CCD X-ray diffractometer, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 298 K. Data were reduced using SAINTPLUS [15] and a multi-scan absorption correction using SADABS [16] was performed. The structures were solved by direct method using SHELXS-97 and full-matrix least-square refinement was carried out using SHELXL-97 [17]. All ring hydrogen atoms were assigned on the basis of geometrical considerations and were allowed to ride upon the respective carbon atoms. Hydrogen atoms on the water molecules were located from the difference maps and geometrical constraints were applied. Drawings were made using ORTEP3 for windows [18] and Mercury [19].

3. Results and discussion

3.1. Synthesis

The adjustment of pH is essential for the formation of the mixed ligand complexes reported here. In the case of compound **1**, this was accomplished by the addition of KOCN while in the case of **2**, a dilute solution of NaOH could suffice. In the absence of KOCN, we could get only [Cu(bpy)(H_2O)$_3$(NO_3)]NO_3 [20]. The IR spectra of the initial precipitate formed as a minor product during the preparation shows peaks corresponding to NO_3^-, NCO^- and bpy ligands indicating a different compound than **1**. In fact, the role KOCN in the preparation of **1** was discovered while attempting to prepare a cyanate complex. It was found that compound **2** can be prepared also by the use of KOCN without adding any NaOH, but the yield of the product obtained was less and the side product formed was more. The side products are probably mixed ligand complexes containing coordinated cyanate, but they could not be obtained in a good crystalline form Table 1.

3.2. Structure of [Cu(acac)(bpy)(H_2O)]$NO_3 \cdot H_2O$ (1)

There are two molecules of [Cu(acac)(bpy)(H_2O)]-$NO_3 \cdot H_2O$ in the asymmetric unit, with slightly different geometric parameters (Fig. 1). The coordination around copper is distorted square pyramidal with acac and bpy

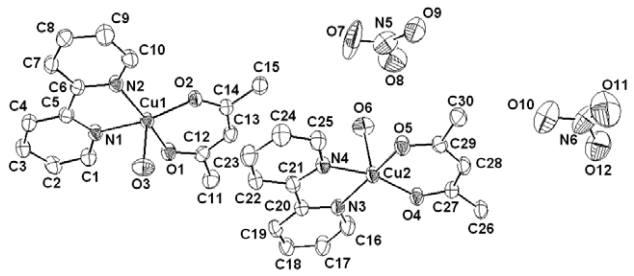

Fig. 1. ORTEP view of compound **1** showing atom labeling, thermal ellipsoids are drawn at the 50% probability ellipsoids and hydrogen atoms and solvent water molecules have been omitted for clarity.

in the equatorial plane and the water molecule at the axial position. The deviations (Å) of the Cu atoms from the mean equatorial coordination planes were 0.145(Cu1) and 0.182(Cu2). There exists in the lattice a 1-D H-bond network formed by the coordinated water molecule, solvent water molecules and the NO_3^- ion, with no H-bond contacts between these chains (Fig. 2). Selected bond lengths and angles are given in Table 2.

3.3. Structure of [Cu(acac)(phen)Br] (2)

The coordination around copper(II) is again a distorted square pyramidal with acac and phen in the equatorial plane and the Br^- ion coordinated at the axial position (Fig. 3). The mean plane deviation (Å) of the Cu from the equatorial plane was 0.282. Unlike in crystals of **1**, there is no H-bond network, as there are no solvent water molecules or anions in the lattice. The selected bond lengths and angles are given in Table 3.

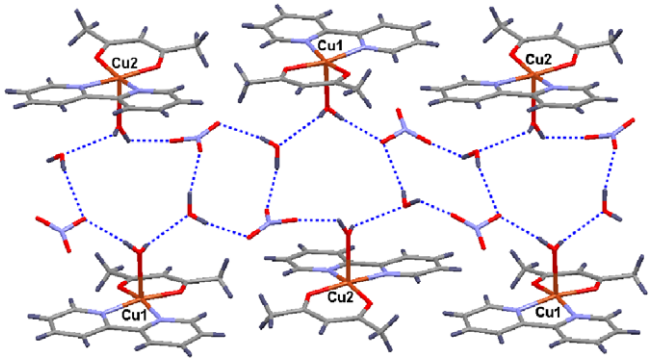

Fig. 2. 1D H-bonded network formed by the water molecules and nitrate ion existing in compound **1**.

3.4. Electronic and EPR spectra

Both solution (ethanol) and solid state (diffuse reflectance) spectra of compounds were measured. For compound **1** solid and solution spectra show similar trends with two broad peaks in the visible region at 11×10^3 cm^{-1}(sh) and 16.0×10^3 cm^{-1}. In square pyramidal Cu(II) complexes the plausible d-orbital energy level scheme (idealized symmetry group C_{4v}), is $d_{x^2-y^2} > d_{z^2} > d_{xy} > d_{xz}, d_{yz}$ so that the higher energy band can be assigned to $d_{xy} \rightarrow d_{x^2-y^2}$ and the lower energy band to $d_{z^2} \rightarrow d_{x^2-y^2}$. The other d–d bands are probably masked by intense $\pi \rightarrow \pi^*$ transitions with peaks at 32.0×10^3 cm^{-1} (shoulder), 33.5×10^3 cm^{-1}, and 40.8×10^3 cm^{-1} observed in both solution and solid. In the case of compound **2**, there were

significant differences between solution and solid-state band maxima. The two visible bands for the solid were observed at 9.9×10^3 cm^{-1}, 13.4×10^3 cm^{-1} and there were two broad UV bands at 28.5×10^3 cm^{-1} and 34.6×10^3 cm^{-1}. In solution the visible bands were greatly broadened and blue shifted to 10.4×10^3 cm^{-1} and 15.8×10^3 cm^{-1} while the UV bands remained narrow at 28.5×10^3 cm^{-1}, 33.8×10^3 cm^{-1} and 36.5×10^3 cm^{-1}. The low energy UV band which is most likely due to $Br^- \rightarrow Cu$ charge transfer has negligible intensity in solution. These observations lead to the following conclusion: in the case of compound **1**, the structure of the Cu(II) complex species is the same in both solid and solution while in the case of compound **2**, the bromide ligand is exchanged with the solvent or water present in the solvent.

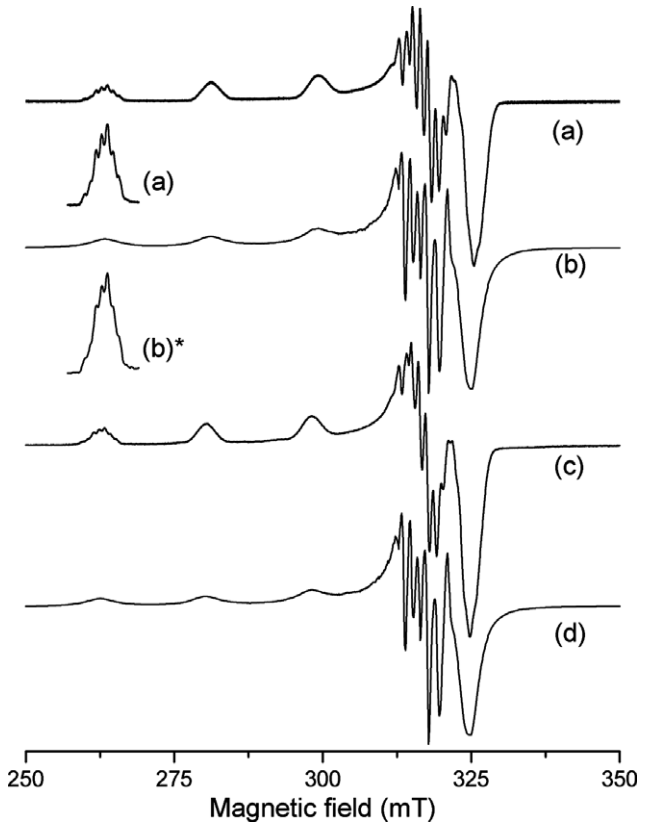

Fig. 4. Frozen solution EPR spectra, at X-band. Experimental: (a) compound **1**; (c) compound **2**. Simulated (with parameters given in the text): (b) compound **1**; (d) compound **2**. (b) * shows the simulated super-hyperfine splitting on the lowest field hyperfine component obtained as explained in the text.

The above conclusion is further supported by the observation of almost identical EPR spectra in frozen ethanol solutions for the two compounds (Fig. 4). The spectra correspond to an axial spin Hamiltonian with the following g and copper hyperfine coupling parameters (in units of 10^{-4} cm^{-1}) derived by computer simulation: $g_x = 2.048$, $g_y = 2.068$, $g_z = 2.250$ (compound **1**), 2.257 (compound **2**), $A_x = 20$, $A_y = 15$, $A_z = 187$. EPR spectra have been previously reported for some other members of the CASIOPEINAS® family [2] and the parameters are in agreement with a $d_{x^2-y^2}$ ground state and significant covalency. The most important feature, different from the previous reports, is the resolution of ^{14}N super-hyperfine (shf) splitting on the lowest field parallel component (Fig. 4). If the molecular structure found in the solid state is maintained in solution one should see a 5-line shf pattern corresponding to two equivalent N atoms in the equatorial plane. However the spectra clearly shows at least seven components on the lowest field parallel line. We considered three possible explanations. (i) Decomposition of the complex and formation of a species with three coordinated N atoms. This can be ruled out because it would have produced a mixture of different Cu(II) complex species and an overlapped EPR spectra. (ii) The shf pattern arises from unequal coupling to the two N atoms of the chelating ligand. The positions of the shf lines can be reproduced by assuming coupling constants of 8×10^{-4} cm^{-1} and 16×10^{-4} cm^{-1} for the two N atoms. This would mean that solvent perturbation and inherent plasticity of the Cu(II) coordination polyhedron leads to a distortion of the complex so as to make it an unsymmetrical chelate. However, this model fails to satisfactorily reproduce the intensity distribution within the multiplet. (iii) The additional lines arise from a resolution of ^{63}Cu/^{65}Cu hyperfine components on the lowest field line. In order to test this model we simulated the spectra for ^{65}Cu (using the hyperfine parameters give above) and ^{63}Cu with the coupling scaled down by a factor of 0.94 (the ratio of the nuclear g-factors) and added the two after weighting with the relative abundances (^{63}Cu:^{65}Cu = 0.69:0.31). This produces a satisfactory matching with the observed splittings (Fig. 4). ^{63,65}Cu resolution is often not seen in EPR from frozen solutions. In the present case, it results from narrow line widths combined with a high value for A_z.

4. Conclusions

Compound **1** is the simplest member of the CASIOPEINAS® family of compounds. Its synthesis in crystalline

form requires careful control of pH, this being accomplished in the present study by the use of potassium cyanate. Like other reported compounds in this series, both **1** and **2** contain five coordinate Cu(II) in distorted square pyramidal coordination in the solid state and presumably also in solution. Considering the electronic spectral data and the near identical EPR spectra of **1** and **2**, it would appear that in compound **2**, the coordinated bromide is displaced by the solvent, leading to similar structure for both compounds in solution.

Abstract

The complexation of Al(III) with D-gluconic acid was studied in solution by means of pH-potentiometry, ESI mass spectrometry and one- and two-dimensional NMR spectroscopy. Six complexes were found to form in solution from pH 2 to 10: $[AlL]^{2+}$, $[AlLH_{-1}]^{+}$, $[AlLH_{-2}]$, $[AlLH_{-3}]^{-}$, $[AlL_2H_{-1}]$ and $[AlL_2H_{-2}]^{-}$. NMR spectroscopy indicated very complicated chemical exchange processes between the free ligand and gluconic acid molecules bound in the metal complexes, with different coordination modes resulting in changes both of the chemical shift and of the line shape of the signals. A solid complex $[AlL_2H_{-1}] \cdot 2H_2O$ was isolated as a microcrystalline powder and characterized. The structures of the complexes are discussed on the basis of the spectroscopic results and MM force field calculations.

1. Introduction

Gluconic acid and its derivatives, especially sodium gluconate, have wide applications in food and pharmaceutical industry. This latter application is based on the outstanding properties of gluconic acid to chelate di- and trivalent metal ions. For example, calcium gluconate is used for treating calcium(II) deficiency, iron(III) gluconate is administered in iron therapy and zinc(II) gluconate is used as an ingredient for treating common cold and various diseases caused by zinc deficiency [1]. Due to its wide range of applications and good complexing ability, the study of metal gluconate complexes have received increasing attention in recent years [2–9] (see Scheme 1).

Al(III), as a typical hard metal ion, prefers coordination of oxygen donors, especially negatively charged ones, such as carboxylates, phosphates and alcoholates [10]. (Poly)hydroxy(poly)carboxylates including, citric acid [11], tartaric acid [12] and sugar carboxylates [2,13] are strong Al(III)-binders that are able to prevent hydrolysis of the metal ions under physiological conditions. Our previous study of C6 aldonic acids has revealed the versatile coordination possibilities of alcoholic OH/O^{-} groups which are in close proximity to negatively charged O-donors [13]. These sugar carboxylates act as polydentate ligands and form very stable complexes with Al(III). The solution state of Al(III)–gluconate was also studied in earlier works [14–16]. In these speciation studies only the occurrence of 1:1 complexes was considered. In recent investigations of the interactions between gluconate and trivalent metal ions (Fe(III) and lanthanides(III)) the

Scheme 1.

formation of 1:2 complexes were also found by potentiometry and some spectroscopic methods [5–7]. Similar speciation model could be in principle assumed also for the trivalent Al(III) which questions the correctness of the results published so far in the literature [14–16].

The aim of the present work was to clarify the solution speciation and structure of the complexes formed in the Al(III)–gluconic acid system through the use of pH-potentiometry, ESI-MS and NMR spectroscopy. The results of these investigations could provide a basis for a better understanding of the transport and toxicity of Al(III) as Al(III)–gluconate solutions are often employed in the experimental toxicology and provide much higher bioavailability of Al(III) than Al(III)–citrate or Al(III)–maltolate [17].

2. Experimental

2.1. Reagents

D-gluconic acid sodium salt of the highest analytical purity (Aldrich product) was used without further purification. Stock solution of the ligand had a slightly basic pH to avoid lactonization of the ligand [5] and was prepared freshly every day. The exact concentrations of the ligand solutions were determined by potentiometric titration, using the Gran method [18]. The Al(III) stock solution was prepared from recrystallized $AlCl_3 \cdot 6H_2O$, and its metal ion concentration was determined gravimetrically through its oxinate. The stock solution contained 0.1 M HCl to prevent hydrolysis of the metal ion.

2.2. Potentiometric measurements

The stability constants of the proton and Al(III) complexes of the ligand were determined by pH-potentiometric titrations of 50 mL samples. To avoid lactonization of gluconic acid the solutions were acidified just before the beginning of the titration, and the pH was never lower than 2. The ligand concentration was 0.004 M and 0.002 M and the metal ion to ligand ratio was varied between 1:1 and 1:10. The titrations were performed with 0.2 M carbonate-free KOH solution of known concentration under purified argon atmosphere. The ionic strength of all solutions was adjusted to 0.2 M KCl and the samples were thermostatted at 25.0 ± 0.1 °C. Duplicate titrations were performed. The reproducibility of the titrations was within 0.005 pH unit. Titration points obtained when 5 min was not enough to attain pH equilibrium were omitted from the evaluation. The pH was measured with a Radiometer PHM 84 instrument with a CMAWL Russel combined glass electrode, which was calibrated for hydrogen ion concentration according to Irving et al. [19]. The concentration stability constants $\beta_{pqr} = [M_pL_qH_r]/[M]^p[L]^q[H]^r$ were calculated with the aid of the computer program PSEQUAD [20]. The stability constants used for the hydroxo species of Al(III) were taken from Ref. [21] and corrected to $I = 0.2$ M using the Davies equation: -5.49 for $[AlH_{-1}]^{2+}$, -13.54 for $[Al_3H_{-4}]^{5+}$, -108.62 for $[Al_{13}H_{-32}]^{7+}$ and -23.40 for $[AlH_{-4}]^{-}$.

2.3. Preparation of the complex $[Al(C_6H_{10}O_7)(C_6H_9O_7)] \cdot 2H_2O$ (1)

A mixture of 0.242 g (1 mmol) $AlCl_3 \cdot 6H_2O$ and 0.438 g (2 mmol) D-gluconic acid sodium salt was dissolved in 10 mL distilled water. The pH of the solution was adjusted to ~4 with KOH. Addition of absolute ethanol (~70 mL) yielded a microcrystalline powder, which was isolated by filtration and dried at 40 °C under vacuum for 12 h. The yield was 0.16 g (55.17%). FTIR(KBr): ν_{COO}: 1646 cm^{-1}. Elemental *Anal.* Calc. for the microcrystalline powder: C, 31.86; H, 5.53. Found: C, 30.05; H, 5.22%. An explanation of the big discrepancy in the analytical results might be the uncertainty of the structural water content of the complex. We found this in other cases too, when we had *X*-ray evidences for some unstoichiometric amount of bound water in the intersticia of the crystal [13].

2.4. NMR spectroscopy

^1H, ^{13}C NMR and two-dimensional spectra were recorded at 25 °C at 400.13 and 100.61 MHz, respectively, on a Bruker Avance DRX-400 spectrometer equipped with a VSP-400 reverse detector broad-band probe and a Bruker VST-100 temperature controller. Chemical shifts were referenced to the signal of DSS as an internal standard. The samples were prepared in D_2O and the pH was adjusted with concentrated NaOD and DCl, using the relationship $pD = pH + 0.4$. The concentrations of the solutions were 0.01–0.1 M in Al(III) and the metal ion:ligand ratio was 1:1 or 1:2.

Presaturation of the H_2O signal was performed, when necessary. Suitable integral values for the proton spectra were obtained with a pre-scan delay of 10 s. The proton resonances were assigned by means of standard chemical shift correlations and COSY, TOCSY and NOESY experiments. The ^{13}C resonances were assigned through 2D-heterocorrelated COSY experiments (HMQC with the *bird* sequence [22] and quadrature along F1, achieved with the TPPI method [23] for the H-bonded carbon atoms, and HMBC [24] for the quaternary ones).

2.5. ESI-MS measurements

The mass-spectrometric measurements were recorded on a LCQ Deca (Finnigan PAF) mass spectrometer equipped with an electrospray ion source. MS and multiple mass-spectrometric (MS^n) experiments were performed both in positive and in negative ion mode by direct infusion of an aqueous solution of the analyte at a flow rate of 5 μL/min. The instrumental conditions were as follows: source potential 4 kV, capillary temperature 270 °C, sheath gas (N_2) flow rate 40 arbitrary units. Collisional experiments on preselected ion species were performed by application of a supplementary rf voltage in the range 0–5 V with helium as a target gas.

2.6. Energy calculations

Energy calculations were performed using the MM2 force field algorithm [25] included in the computer programme CS Chem 3D Ultra 6.0 (CambridgeSoft.Com, Cambridge, USA, 2000). Atom types and parameters available in the software were used for the calculations. Energies were calculated for structures described in the NMR results section.

3. Results and discussion

3.1. Potentiometric titrations

The protonation constant of the ligand was found to be 3.36. If the differences in the experimental conditions (the ionic strength and the type of electrolyte used) are taken into account, this value is in fairly good agreement with those reported in the literature: 3.44 at 25 °C and 0.1 M KNO_3 [14], 3.50 at 25 °C and 0.1 M $NaClO_4$ [3].

The formation constants of the Al(III) complexes are listed in Table 1, together with some derived data.

The Al(III)–gluconic acid titration data were evaluated on the basis of the literature results. As mentioned above early potentiometric measurements were fitted considering only mononuclear complexes: Motekaitis and Martell [14] proposed the formation of species $[AlL]^{2+}$, $[AlLH_{-1}]^{+}$ and $[AlLH_{-3}]^{-}$ whereas Escandar et al. [16] assumed an even simpler complexation model involving the species $[AlLH_{-1}]^{+}$ and $[AlLH_{-3}]^{-}$. When these simple models were assumed in our calculations, rather poor fits were obtained between the experimental and the calculated titration curves. The speciation models obtained recently for other trivalent metal ions interacting with gluconic acid reveal the formation of bis complexes, besides mononuclear 1:1 complexes [5–7]. Other metal ions such as Cu(II) [2] and VO(IV) [8] were also proved to form 1:2 complexes with D-gluconic acid. When the formation of bis complexes was considered in our calculations the fitting parameter improved considerably as compared with the model including only mono complexes. The best fit between the experimental and the calculated titration curves was obtained with the species and stability constants listed in Table 1. The distribution of the complexes formed in the Al(III)–D-gluconic acid system as a function of pH is depicted in Fig. 1a.

Complexation starts with the formation of the species $[AlL]^{2+}$ in the slightly acidic pH range. Stepwise deprotonations of this complex occur at higher pH with pK values of 3.87, 4.46 and 5.99 leading to the formation of species $[AlLH_{-1}]^{+}$, $[AlLH_{-2}]$ and $[AlLH_{-3}]^{-}$, respectively. The relatively low values of the first two constants (significantly lower than $pK_{Al(H_2O)_6} = 5.52$) suggest that the metal bound water molecules are not deprotonating. Thus, the species $[AlLH_{-1}]^{+}$ is most probably formed by the simultaneous coordination of the carboxylate group and the deprotonated alcoholic function in the α-position, and in the complex $[AlLH_{-2}]$ a (O^-, COO^-, O^-) tridentate coordination may be assumed. The species $[AlLH_{-3}]^{-}$ may be formed into two different ways: (i) by the deprotonation of another alcoholic group or (ii) by the deprotonation of one of the water molecules from the coordination sphere of the metal ion. The relatively high value of the deprotonation constant of $[AlLH_{-2}]$ indicates that process (ii) is more likely in this case. At ligand excess 1:2 species are also formed: $[AlL_2H_{-1}]$ and $[AlL_2H_{-2}]^{-}$. In these complexes again the parallel deprotonation and subsequent coordination of the alcoholic-OH functions or ionization of the Al(III) coordinated water molecules may be assumed in overlapping processes. Moreover, the ligand molecules can coordinate either in a bidentate or in a tridentate way involving one or two protonated OH groups of the polyalcoholic chain. Stability constant comparison with the formation constants of the corresponding Al(III) complexes of lactic acid [26,27] reveals that one of the ligand molecules coordinates in a tridentate way. Namely the basicity adjusted equilibrium constant $\log \beta_{AlL_2H_{-1}} - \log \beta_{HL}$ is 0.59 log unit higher for the Al(III)–gluconic acid complex than that for the corresponding Al(III)–lactic acid complex ($\log \beta_{AlL_2H_{-1}} - \log \beta_{HL} = 1.48–3.36 = -1.88$ for gluconic acid and −2.47 for lactic acid) suggesting the participation of an extra alcoholic-OH function in Al(III) binding in the

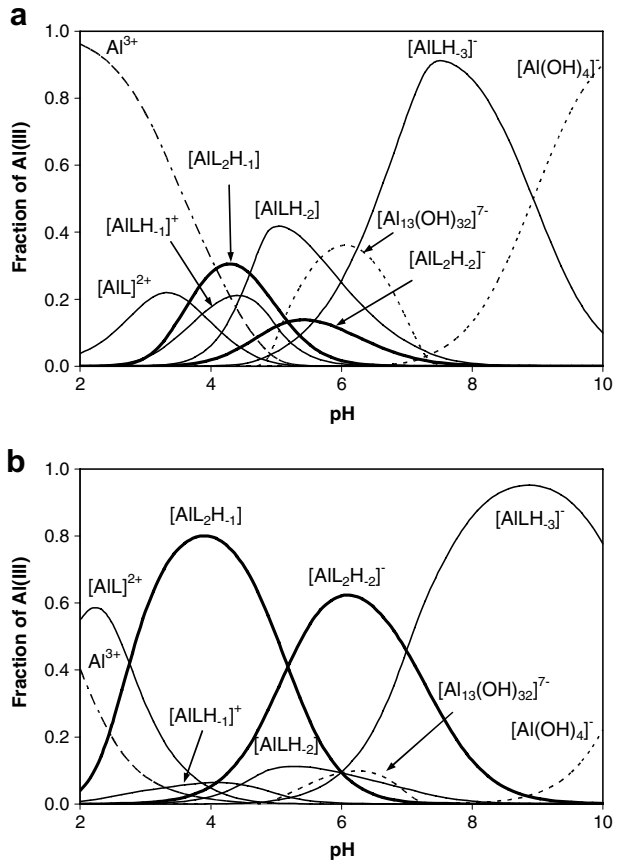

Fig. 1. Species distribution curves as a function of pH in the Al(III)–D-gluconic acid system at a metal ion to ligand ratio of 1:2 and at (a) $c_{Al(III)} = 0.002$ M; (b) $c_{Al(III)} = 0.1$ M. Solid lines indicate the 1:1, bold lines the 1:2 and dashed lines the binary hydroxo complexes.

case of the former ligand [26]. At pH 5 the complex $[AlL_2H_{-1}]$ starts to liberate a proton with a $pK = 5.18$. This, in accordance with other aliphatic hydroxycarboxylates [26,27] would rather be ascribed to the ionization of the water molecule in the coordination sphere of metal ion than to the deprotonation of a second alcoholic-OH group of the sugar carboxylate.

Further investigations were primarily focused on the characterizations of the bis complexes, since they are "new" species with respect to the literature data. Attempts have also been made to crystallize one of the two bis complexes which was partially successful as the neutral complex $[AlL_2H_{-1}]$ was obtained as a microcrystalline powder (**1**). Fig. 1b shows the species distribution calculated at concentrations used for preparation of the solid complex and used in the NMR spectroscopic measurements. In these conditions the bis complexes are the predominant species in the system in wide pH range (pH 3–7) except the acidic and the basic pH range.

3.2. ESI-MS measurements

ESI-MS measurements were carried out to prove the stoichiometry of the solid compound **1**. ESI-MS is often used to characterize metal–ligand complexes which seems to be not involved in solution equilibria. ESI-MS, however, is more and more widely used to study solutions at equilibrium (for example, to see the resulting species formed in solution upon dissolution of a solid complex) [28] and, despite of some limitations, it seems to be a suitable tool for the determination of the stoichiometry of species present in solution. The exact proton content of the complexes usually can not be determined by ESI-MS, because protonation reactions easily occur in the ESI chamber [28]. Our previous experiences show that in the case of Al(III)–ligand solution equilibria, ESI-MS gave a fairly good qualitative picture of the solution speciation as compared with the pH-potentiometric results [13,29,30].

ESI measurements were carried out both in positive and negative ion mode, in a solution containing 0.001 g of **1** dissolved in water/methanol 3:1 mixture. The spectra unambiguously proved the 1:2 metal to ligand stoichiometry in complex **1**. The main signals present in the spectra and their assignment are summarized in Table 2.

In negative ion mode two signals could be detected at m/z 195 and 415. The first peak is that of the free gluconic acid. The second is attributed to the complex ion $[AlL_2H_{-2}]^-$ originated from compound **1** ($[AlL_2H_{-1}]$), which loses a proton in the ESI source.

In positive ion mode the spectrum is richer in signals (Fig. 2) due to formation of Na^+ adducts. Adduct formation with alkali metal ions (especially sodium) in the ESI source is also a common feature of ESI-measurements. Thus **1** is detected as the protonated species $[AlL_2]^+$ (m/z 417) and two sodium adducts (m/z 439, 461). The latter signal is a result of the deprotonation of **1** and simultaneous addition of two sodium ions. The signal at m/z 221 corresponds to the mono complex $[AlLH_{-1}]^+$ which is a result of the partial dissociation of **1** upon dissolution. Mono complexes could not be detected in the negative ion mode. A reasonable explanation of this fact is that according to potentiometry at pH ~ 4.5 the two mono complexes are positively charged ($[AlLH_{-1}]^+$) and neutral ($[AlLH_{-2}]$). To be detectable in negative ion mode they should lose 2 and 1 protons, respectively. Their ion response factor is therefore smaller in negative ion mode than in positive.

Table 2
Main signals observed in the solution of the solid complex **1**

Detection mode	m/z	Relative abundance %	Stoichiometries
Negative ion	195	100	$[L]^-$
	415	55	$[AlL_2H_{-2}]^-$
Positive ion	219	14	$[LH \cdot Na]^+$
	221	20	$[AlLH_{-1}]^+$
	241	13	$[L \cdot 2Na]^+$
	417	30	$[AlL_2]^+$
	439	100	$[AlL_2H_{-1} \cdot Na]^+$
	459	32	$[2L \cdot 3Na]^+$
	461	60	$[AlL_2H_{-2} \cdot 2Na]^+$

[a]Expressed in the percentage of the intensity of the signal with maximum intensity (100%).

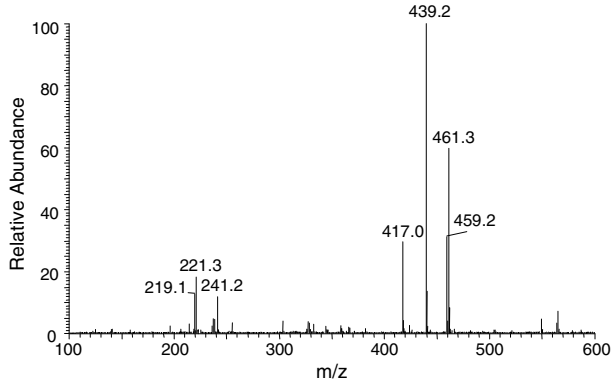

Fig. 2. ESI-MS spectrum of the solid compound **1** dissolved in water–methanol 3:1 mixture, recorded in positive ion mode.

Moreover, in-source deprotonation at acidic pH is less favoured than protonation. The free ligand is detected as sodium adducts at *m*/*z* 219, 241 and 459 corresponding to the species $[LH+Na]^+$, $[L+2Na]^+$ and $[2L+3Na]^+$ respectively. We should mention here, that gluconic acid has a high tendency to form adducts with Na^+: the ESI spectrum recorded in the solution containing only gluconic acid at pH ~ 4 shows the signals of a series of sodium adducts of the type $[nL+(n+1)Na]^+$, detected in the 100–2000 *m*/*z* range. MS^n experiments carried out on the ion at *m*/*z* 417 shows that the first two steps of fragmentation occur with the loss of two water molecules, whereas the third step is the simultaneous loss of two CO_2 molecules, most probably from the carboxylic group of the two ligands. This is another proof of the 1:2 metal–ligand stoichiometry of **1**.

4. NMR spectroscopy

The proton and carbon resonances of gluconic acid were assigned by two-dimensional H–H and C–H correlation measurements, and they are in agreement with the literature data. The chemical shift values of the ^1H and ^{13}C resonances obtained at p*D* 3.9 in a solution of 0.2 M gluconic acid are listed in Table 3.

The ^1H NMR spectrum recorded in the solution of **1** dissolved in D_2O (p*D* = 3.9) in a concentration of 0.1 M is depicted in Fig. 3b. A considerable downfield shift and selective broadening of the signals of H(2) and H(3) could be observed with respect to the free ligand (Fig. 3a). COSY and HMQC measurements show that also the peak corresponding to H(4) is shifted downfield; it appears under the signal of H(6a) at 3.816 ppm. The other resonances (those of H5, H(6a) and H(6b)) remain practically at the same positions as in the spectrum of gluconic acid alone. The ^{13}C spectrum recorded in the same sample presents a similar picture: the signals ascribed to C(1), C(2), C(3) and C(4) are shifted and broadened as compared with the signals of gluconic acid itself, whereas the signals corresponding to C(5) and C(6) are much less affected. This selective line broadening and chemical shift changes of some of the signals indicate that the affected protons and carbon atoms may be close to functional groups involved in the Al(III) coordination, namely the alcoholic/alcoholate groups of C2, C3 and C4 are assumed to participate in the metal chelation.

Table 3
Characteristic NMR parameters in D_2O at 25 °C for free gluconic acid and its complex $[AlL_2H_{-1}]$

	Chemical shifts in δ (ppm) at p*D* = 3.9					
	H2	H3	H4	H5	H6a	H6b

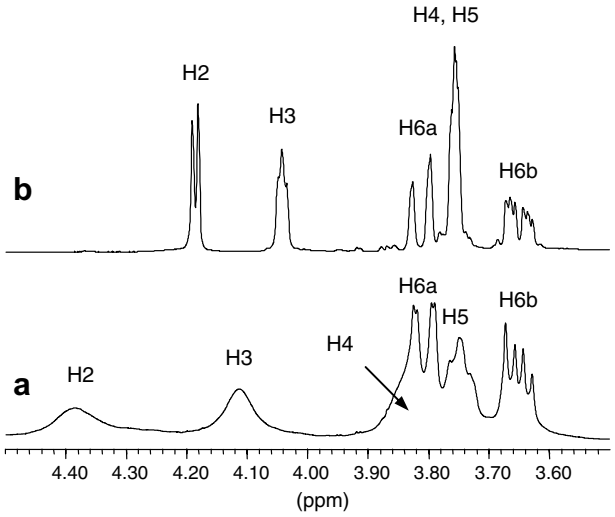

Fig. 3. ^1H NMR spectrum of (a) complex **1** dissolved in D_2O at autogenous p*D* = 4.2 and concentration of 0.1 M; (b) free gluconic acid at p*D* = 4.2.

Participation of the alcoholic-OH/alcoholate-O^- groups in the coordination is mostly determined by their steric arrangement within the molecule. MM force field calculations performed for AlL_2H_{-1} show that the more favoured structures are formed by the tridentate coordination of one ligand and a bidentate coordination of the other. The tridentate chelation of both ligands is less favoured, their steric energy level is about 20–30% higher and this increase is probably not counterbalanced by the bond energy of the additional Al-OH interaction. Among the species with tridentate-bidentate chelation, the (COO^-, C(2)–O^-, C(3)–OH) coordination of the tridentate ligand is the energetically less favoured structure. All the other possible binding namely e.g. (COO^-, C(2)–O^-, C(4)–OH) or (COO^-, C(3)–O^-, C(4)–OH) have fairly little energy differences and they can be considered equally probable. For the bidentate ligand, MM calculations can not distinguish among the three possible coordination modes, i.e. (COO^-, C(2)–

OH), (COO^-, C(3)–OH), (COO^-, C(4)–OH). Previous studies on Al(III)-(poly)hydroxycarboxylates show that the first is the main coordination mode in these systems [10,11,13]. Accordingly, we can assume that the tridentate (COO^-, C(2)–O^-, C(4)–OH) coordination of one of the ligand molecules and a bidentate (COO^-, C(2)–OH) coordination of the other one is the most favoured. This structure is depicted in Fig. 4 A similar structure, but with the tridentate (COO^-, C(2)–OH, C(4)–OH) coordination of the second ligand molecule was proposed for the ML_2H_{-1} complex of D-gluconic acid formed with praseodymium(III) ion [5].

The NMR spectra of complex **1** display one rather broad set of signals for the bound ligand (Fig. 3), but the phase sensitive NOESY spectrum indicates unambiguously the presence of exchange processes. These reactions may occur between the bis complex and the free gluconic acid molecules, (the presence of a small amount of the free ligand can be detected at this pH by pH-potentiometry, see Fig. 1b) and/or between the ligand molecules of the different coordination isomers of the bis complex. These processes are in the fast exchange regime on the NMR time-scale, and they explain the line broadening of the signals observed upon coordination of Al(III) to gluconic acid.

Fig. 5 depicts the pH dependence of the NMR signals at metal ion to ligand ratio of 1:2. In the more acidic pH range two sets of signals are detected in the ^{1}H NMR spectra. The assignment is straightforward if we compare the spectra recorded at 1:1 and 1:2 metal-to-ligand ratios at pD 2 (Fig. 5a and b) and take into account the pH-metric results. The signals, the intensities of which increase at 1:2 ratio, were ascribed to the bis complex $[AlL_2H_{-1}]$ and the other set of signals should belong to the mono complex $[AlL]^{2+}$. These two complexes are in slow ligand exchange between each other and in fast ligand exchange with the uncomplexed gluconic acid which has a significant concentration at pD 2. Thus, the observed chemical shifts of these two complexes are a weighted average of those corresponding to the complex and unbound ligand, and their position is dependent on the ratios between the complex and the free ligand. The upfield shift of these signals with increasing pH

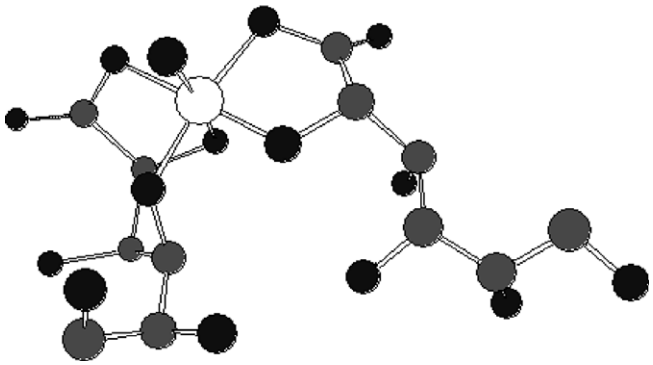

Fig. 4. Most probable structure of $[AlL_2H_{-1}]$.

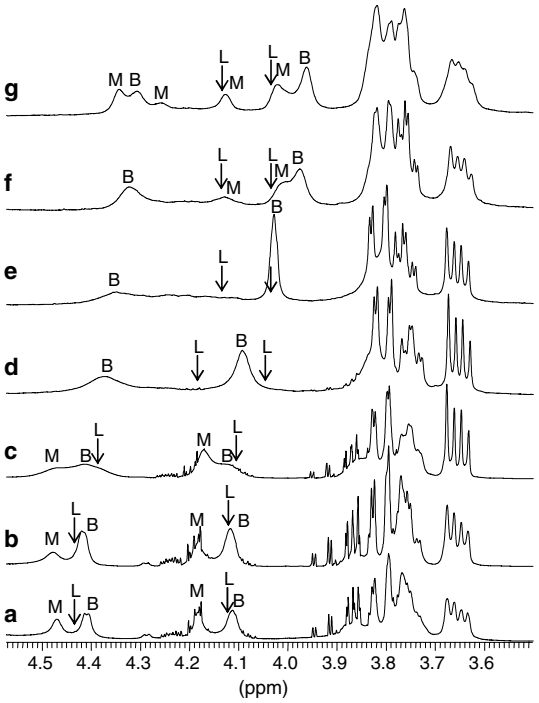

Fig. 5. ^{1}H NMR spectra obtained for the Al(III)–gluconic acid system at an Al(III) concentration of 0.1 M at ratios (a) 1:1 ratio, pD = 2.0; and 1:2 ratios at pD values of (b) pD =2.0, (c) pD = 2.6, (d) pD = 3.9, (e) pD = 5.4, (f) pD = 6.7, (g) pD = 7.6. The arrows indicates the chemical shifts of the H(2) and H(3) protons of gluconic acid taken from the spectra obtained in solution containing the ligand alone at the corresponding pD values. Notations: M = mononuclear complex, B = bis complex, L = free ligand.

is explained in one hand by the change in the complex/free ligand ratio, and in the other hand by the deprotonation of the complexes. The proton exchange reactions between the differently protonated complexes with the same metal to ligand ratios are fast in the NMR time-scale. Accordingly, until pH 4 $[AlL]^{2+}$ and $[AlL_2H_{-1}]^+$ are present in different ratios, whereas at pH > 4 the bis complex deprotonates to form $[AlL_2H_{-2}]^-$ and its signal shifts upfield.

Above pH 7 new signals (M) appear which could be ascribed to the complex $[AlLH_{-3}]^-$ found potentiometrically most probably present in the form of two coordination isomers, involving one or two deprotonated alcoholate functions in metal ion binding. MM calculations cannot distinguish between the two isomers, but in agreement with Escandar et al. [16] participation of two deprotonated alcoholate-O^- in Al(III) binding seems to be more probable.

5. Conclusions

The calculations from potentiometric experiments allowed us to conclude that besides the 1:1 species two bis complexes $[AlL_2H_{-1}]$ and $[AlL_2H_{-2}]^-$ are also formed in the Al(III)–gluconic acid system. These species have not been considered in earlier works. A basic question concerning the binding mode of the deprotonated mono and

bis complexes is whether the proton is liberated from a coordinated water molecule resulting in a mixed hydroxo species or from the ligand molecule through the formation of a gluconato complex with coordination of one or more alcoholate-O^- functions. The different methods: stability constant comparison, multinuclear NMR spectroscopy, ESI-MS and MM calculations provided enough information to suggest the most probable binding mode in these complexes. Accordingly, in the bis complexes a bidentate–tridentate coordination of the ligands is the most probable binding mode according to the MM calculations, the sixth position of Al(III) is occupied by a water molecule, which can deprotonate to form the mixed hydroxo species $[AlL_2H_{-2}]^-$. While, in the solid state this binding mode can be mostly assumed, in solution various binding isomers with the participation of alcoholic functions in C2, C3 and C4 carbon atoms may be formed, as indicated by NMR spectroscopy. Stability constant comparisons suggest that in the 1:1 complex the ligand also coordinates in a tridentate way, and depending on the stoichiometry of the species one or two alcoholic-OH groups are deprotonated due to a stepwise coordination to the metal ion. The ionization of one of the coordinated water molecules is an overlapping process, results finally in the formation of species $[AlLH_{-3}]^-$.

Acknowledgements

The authors thank to Nicola Bonato for his assistance in the experimental work. One of the authors (T.K.) is very thankful to Professors G. Bombi and B. Corain for the technical help and everyday useful discussions during his COST-PECO study in Padova. The work was mostly carried out in the frame of a bilateral collaboration agreement between the Academy Institutions of Italy and Hungary, CNR and HAS (Project Nos. 11/2004 and 11/2007). L.A. gratefully acknowledges financial support through the award of a János Bólyai research fellowship.

Abstract

A new cobalt Schiff-base complex, [Co(L)(OH)(H_2O)] (where L = [*N*,*N*′-bis(2-aminothiophenol)-1,4-bis(carboxylidene phenoxy)butane), was synthesized and its electrochemical and spectroelectochemical properties were investigated using cyclic voltammetry (CV), differential pulse voltammetry (DPV) and thin-layer spectro-electrochemistry in solutions of dimethyl sulfoxide (DMSO) and dichloromethane (CH_2Cl_2). The [Co(L)(OH)(H_2O)] complex displays two well-defined reversible reduction processes with the corresponding anodic waves. The half-wave potentials of the first and second reduction processes were displayed at $E_{1/2} = 0.08$ V and $E_{1/2} = -1.21$ V (scan rate: 0.100 Vs^{-1}) in DMSO, and $E_{1/2} = -0.124$ V and $E_{1/2} = -1.32$ V (scan rate: 0.100 Vs^{-1}) in CH_2Cl_2. The potentials of the reduction processes in DMSO are shifted toward negative potentials (0.220–0.112 V) compared to those in CH_2Cl_2. The electrochemical results are assigned to two one-electron reduction processes; $[Co(III)L] + {}^{-}e \rightarrow [Co(II)L]^{-}$ and $[Co(II)L]^{-} + {}^{-}e \rightarrow [Co(I)L]^{2-}$. The six-coordination of the complex remains unchanged during the reduction processes and the electron transfer processes were not followed by a chemical reaction upon scan reversal. It was also seen that [Co(L)(OH)(H_2O)] was reduced at a more positive potential than the corresponding salen analogs. The shift and reversibility are apparently related to the high degree of electron delocalization of the [Co(L)(OH)(H_2O)] complex, having a $N_2O_2S_2$ donor set and two additional benzene units. Additionally, *in situ* spectroelectrochemical measurements support Co(III)/Co(II) and Co(II)/Co(I) reversible reduction processes with the observation of the corresponding spectral changes with the applied potentials $E_{app} = -0.40$ and -1.60 V. Application of the spectroelectrochemical results allowed the determination of$E_{1/2}$ and n (the number of electrons) from the spectra of the fully oxidized and reduced species in one unified experiment as well. The results obtained by this method are in agreement with those by the CV and DPV methods.

1. Introduction

Transition metal Schiff-base complexes with tetradentate (N_2X_2) ligands (N is imine nitrogen; $X = O^{-}$ (salen), S^{-} (thiosalen), OR, SR, PR_2, etc.) have been extensively studied [1]. Some of these complexes have interesting applications, e.g., in catalytic oxidation reactions and electrochemical reduction processes [2], in metalloenzyme-mediated catalysis [3,1e] and asymmetric catalysis, as catalytically active materials to develop surface modified electrodes in many reactions [4], photochromism [5] and complexing towards certain toxic metals [6]. Among these metal complexes, cobalt Schiff-base complexes have especially attracted considerable interest due to their ability to bind reversibly O_2 and CO_2, their potential catalytic behavior for electrochemical reduction of organic halides, and their oxidative coupling catalytic reactions of phenols

and oxidation of olefins [1b,1c,3a,7]. Recently, the discovery that cobalt(III) Schiff-base complexes are potent antiviral agents prompted researchers to initiate an investigation of Co(III) interactions with proteins and nucleic acids [8]. Co(III) Schiff-base complexes with two amines in axial positions have been used as antimicrobial agents as well [9]. On the other hand, electro-generated cobalt(I) salen complexes were described for the catalytic reduction of halogenated organic species [10]. Thiosalen derivatives are Schiff-base ligands where the sulfur atoms are substituted with oxygen atoms in salen ligands. The replacement of two phenoxide oxygen atoms in salen by two thiolate sulfur atoms should, in principle, lead to changes in the redox properties of the corresponding complexes. Since sulfur is a medium-strength soft base, whereas oxygen is a strong hard base, it is often expected that coordination by sulfur will stabilize metals in low oxidation states, i.e., lead to a decrease in the potential of the complex based on the metal [11]. There have been numerous transition metal complexes containing salen and thiosalen, with two sulfur and two nitrogen donor atoms (N_2S_2 donor set), [11b,12] but only a few examples of complexes containing a NSO donor set have been reported in the literature [13]. Recently, some complexes of bis(alkylthio)salen were studied in view of them acting as templates for Diels–Alder reactions and their potential surfactant character, and they were anticipated to have a wide range of interesting stereochemical, redox and physical properties [12d,14]. The study of transition metal thiolates is frequently complicated by air sensitivity and a tendency to form polymetallic complexes with bridging μ-SR groups. The air sensitivity of transition metal thiolates typically results in degradation of the enzymatic and catalytic sites due to disulfide formation, expulsion of metal ion and metal oxide formation [15]. Fine tuning of the electronic structure by the introduction of electron donating and withdrawing substituents in the equatorial or axial position of ligand is known to enhance the reactivity of Schiff-base complexes in particular applications.

In the present paper, we report the synthesis and characterization of a new thio Schiff- base ligand L (L = [*N*,*N*′-bis(2-aminothiophenol)-1,4-bis(carboxylidene phenoxy)butane]), involving an $N_2O_2S_2$ donor set, and its cobalt(III) complex. It is known that a combination of electrochemical and spectroelectrochemical methods provides a powerful tool to reveal the complementary nature of the molecular structure and to supply a better understanding of the electrochemical behavior of the electro-generated species in bulk solution [16–21]. Little attention has been given to transition metal Schiff-base complexes based on thiosalen, as compared to salen analogs. Moreover, no *in situ* spectroelectrochemical study on thiosalen or thiolate derivatives has been reported in the literature. The aim of this study is to present for the first time detailed information on the electro-spectroelectrochemical behavior of a new cobalt(III) thio Schiff-base complex bearing the $N_2O_2S_2$ donor set and two additional aromatic groups.

2. Experimental

2.1. Physical measurements

Conductivities of 10^{-3} M solutions of the complex were measured in DMF at 25 °C using a Conductivity Hand-Held Meter LF 330. The IR spectra of the complex were recorded with a Midac 1700 instrument in KBr pellets. ^{1}H NMR spectra were recorded on a BRUKER DPX-400 High Performance Digital FT-NMR spectrometer in DMSO-d_6. LC/MS-API-ES mass spectra were recorded using an AGILENT model 1100 MSD mass spectrophotometer. Magnetic moments were determined on a Sherwood Scientific magnetic moment balance (Model No: MK1) at room temperature (23 °C) using $Hg[Co(SCN)_4]$ as a calibrant: diamagnetic corrections were calculated from Pascal's constants [22]. The elemental analyses were conducted on a Carlo Erba instrument. UV–Vis spectra were recorded on an Agillent Model 8453 diode array spectrophotometer. Cyclic voltammograms (CV) were carried out using CV measurements with a Princeton Applied Research Model 2263 potentiostat controlled by an external PC. A three electrode system (BAS model solid cell stand) was used for CV measurements in DMSO and consisted of a 2 mm sized platinum disc electrode as the working electrode, a platinum wire counter electrode and an Ag/AgCl reference electrode. The reference electrode was separated from the bulk solution by a fritted-glass bridge filled with the solvent/supporting electrolyte mixture. The ferrocene/ferrocenium couple (Fc/Fc^+) was used as an internal standard but all potentials in the paper are referenced to the Ag/AgCl reference electrode. Solutions containing the complex were deoxygenated by a stream of high purity nitrogen for at least 5 min before running the experiment. The solution was protected from air by a blanket of nitrogen during the experiment. Controlled potential electrolysis (CPE) was performed with a Princeton Applied Research Model 2263 potentiostat/Galvanostat. A BAS model electrolysis cell with a fritted glass to separate the cathodic and anodic portions of the cell was used for bulk electrolysis. The sample and solvent were placed into the electrolysis cell under nitrogen. UV–Vis spectroelectrochemical experiments were performed with a home-built thin-layer cell that utilized a light transparent platinum gauze working electrode [23]. Potentials were applied and monitored with a Princeton Applied Research Model 2263 potentiostat. Time- and potential-resolved UV–Vis spectra were recorded on an Agillent Model 8453 diode array spectrophotometer.

2.2. Materials

All the chemicals and solvents were purchased from Merck and Fluka Chemical Co. 1,4-Bis(2-carboxyaldehyde phenoxy)butane was prepared as in the literature

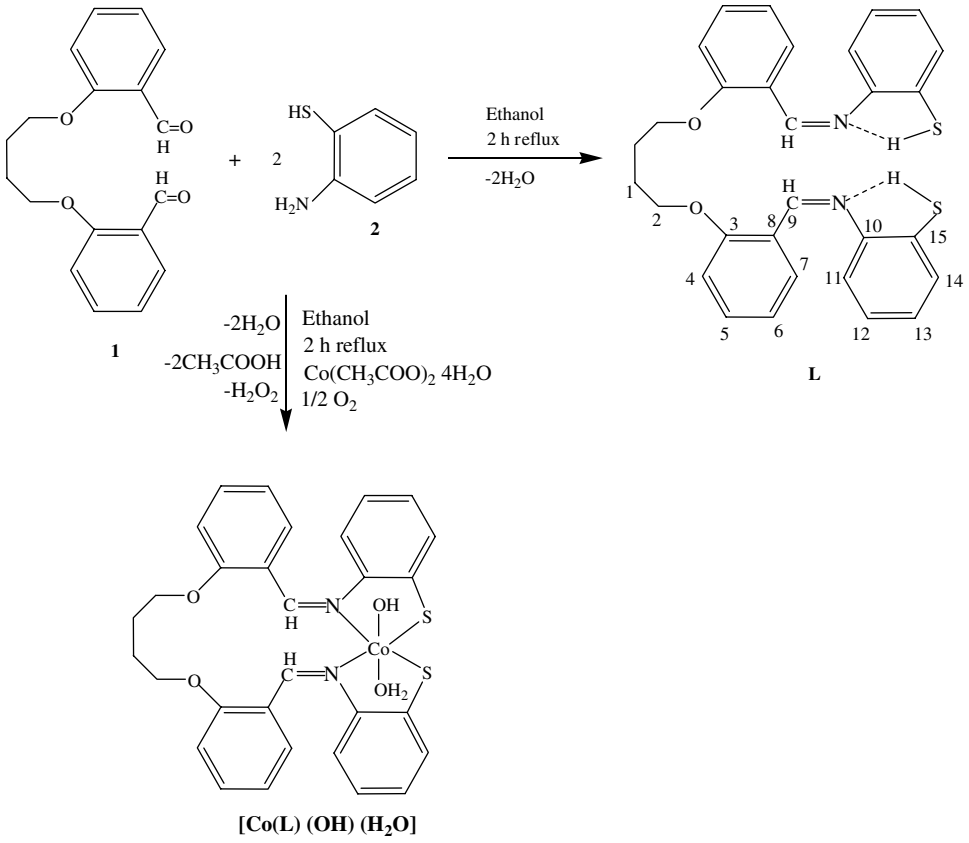
[24]. Dimethyl sulfoxide (DMSO) was dried over a molecular sieve of 4 Å. Dichloromethane (CH_2Cl_2) was three times treated with H_2SO_4 and distilled over P_2O_5 and CaH_2 prior to use. Electrochemical grade tetrabutylammonium perchlorate (TBAP, Fluka Chemical Co.) was recrystallized from ethyl alcohol and dried in a vacuum oven at 40 °C for at least 1 week prior to use.

2.3. Synthesis of the ligand [N,N′-bis(2-aminothiophenol)-1,4-bis(carboxylidene phenoxy)butane]

A solution of 1,4-bis(2-carboxyaldehyde phenoxy)butane (10.0 mmol, 2.98 g) in 50 ml absolute ethanol was added dropwise over 2 h to a stirred solution of 2-aminothiophenol (20.0 mmol, 2.50 g) dissolved in 50 ml hot absolute ethanol. A solid mass separated out on cooling, which was kept in a refrigerator for better crystallization. It was then filtered and recrystallized from a mixture of absolute ethanol–DMF, m.p. 140–142 °C; yield: 4.11 g (80%). *Anal.* Calc. C, 70.3; H, 5.46; N, 5.47; S, 12.5. Found: C, 70.4; H, 5.67; N, 5.65; S, 12.6%. IR (KBr cm^{-1}): 3316 $\nu(N^+H)$, 3066 ν(Ar–C–H), 2953, 2916, 2870 ν(Aliph-C–H), 1599 ν(C=N), 1486, 1469, 1452 ν(Ar–C=C), 1280, 1241 ν(Ar–O), 1157, 1112, 1051 ν(R–O), 749, 740 ν(C–S). ^{1}H NMR (DMSO-d_6, δ ppm): 2.30 (CH_2–CH_2–O) (s), 4.45 (CH_2–O) (s), 7.10–8.00 (Arom-H) (m, $J = 8$ Hz), 8.40 (CH=N) (s). ^{13}C NMR (DMSO-d_6, δ ppm): C1: 26.7, C2: 68.7, C9: 163, Arom. C's: 111, 121, 121, 122, 123, 125, 126, 130, 132, 136, 152. UV–Vis (λ_{max}): $\lambda_1 = 229$ ($\varepsilon = 49100\ M^{-1}\ cm^{-1}$), $\lambda_2 = 282$ ($\varepsilon = 5880\ M^{-1}\ cm^{-1}$), $\lambda_3 = 322$ ($\varepsilon = 7720\ M^{-1}\ cm^{-1}$) (in ethanol). $\lambda_1 = 283$ ($\varepsilon = 10620\ M^{-1}\ cm^{-1}$), $\lambda_2 = 325$ ($\varepsilon = 14740\ M^{-1}\ cm^{-1}$) (in DMF). Mass spectra: 511.2 $[L-H]^+$ (M_A: 512 g/mol).

2.4. Synthesis of the Co(III) complex [Co(L)(OH)(H2O)]

To a stirred solution of 1,4-bis(2-carboxyaldehyde phenoxy)butane (0.447 g, 1.50 mmol) and $Co(CH_3COO)_2 \cdot 4H_2O$ (0.374 g, 1.50 mmol) in methanol (60 ml) was added dropwise 2-aminothiophenol (0.375 g, 3.00 mmol) in methanol (40 mL). After the addition was completed, the stirring was continued for 2 h. A blue colored precipitation was filtered off and washed with acetic acid and diethyl ether, respectively. The product was purified from a mixture of absolute ethanol–acetone, then dried in air. Yield: 0.702 g (80%). m.p. 188–189 °C. *Anal.* Calc. C, 59.6; H, 4.80; N, 4.64; S, 10.6. Found: C, 59.5; H, 4.95; N, 4.82; S, 10.4%. $\Lambda = 8.70\ \Omega^{-1}\ mol^{-1}\ cm^2$. $\mu_{eff} = 3.96$ B.M. IR (KBr, ν cm^{-1}): 3400 $\nu(H_2O)$, 3022 ν(Ar–CH), 2923, 2856 ν(Aliph-CH), 1542 ν(C=N), 1470, 1458, ν(Ar–C=C), 1283, 1247 ν(Ar–O), 1159, 1108, 1050 ν(R–O), 752, 739 ν(C–S), 520 ν(Co–O) 458 ν(Co–N). UV–Vis (λmax, nm) (DMSO): $\lambda_1 = 330$, $\lambda_2 = 579$, $\lambda_3 = 664$, $\lambda_3 = 809$. Mass spectra: m/z: 571.6 $[Co(L)–(H_2O)–(OH)]^+$ (M_A: 604 g/mol).



3. Results and discussion

3.1. Synthesis

The new thio Schiff-base [*N*,*N*′-bis(2-aminothiophenol)-1,4-bis(carboxylidene phenoxy)butane] (**L**) was synthesized by the condensation of 1,4-bis(2-carboxyaldehyde phenoxy)butane and 2-aminothiophenol in absolute ethanol. The preparation of the ligand (**L**) and its cobalt complex [Co(L)(OH)(H_2O)] is illustrated in Scheme 1. The stoichiometries of the ligand and its complex were confirmed by their elemental analyses. The molar conductance measured in DMF of a 10^{-3} M solution of the complex gave a value of 8.70 $ohm^{-1}\ cm^2\ mol^{-1}$, which indicated its non-electrolytic behavior [25–27]. The metal/ligand mole ratio was found to be 1:1, in accord with the elemental analysis (Scheme 1). The observed magnetic moment of the Co(III) complex is 3.96 B.M. This value suggests an octahedral stereochemistry of the complex. The proposed structure is presented in Scheme 1. The complex was fine powder hence we could not manage to prepare single crystals for X-ray crystallography.

The IR spectrum of the thio Schiff-base ligand exhibited a strong sharp band at 3316 cm^{-1}. This band was assigned to the stretching frequency of the N^+H group, due to the presence of the intramolecular hydrogen bond (N···SH) in the molecule (Scheme 1). This band disappeared in the IR spectrum of the cobalt complex, as previously reported in the literature [28]. It was seen from the solid state IR spectra of the ligand and its Co(III) complex that the C=N band of the complex shifted to a lower value compared with that of the ligand [25–27,29–31]. Conclusive evidence of the bonding was also shown by the observation that new bands in the spectra of the metal complex appeared at 458 and 520 cm^{-1}, assigned to (Co–O) and (Co–N) stretching vibrations, that were not observed in the spectrum of the ligand [25–27,29–31]. A broad and weak band around 3400 cm^{-1} is attributed to the OH vibration of water molecules in the complex [26]. A ^{1}H NMR spectrum of the Co(III) complex could not be obtained because of its paramagnetic nature. The data of the ^{1}NMR and ^{13}C NMR spectra of the ligand are given in experimental section. The mass spectra of the ligand and its cobalt complex showed peaks attributable to the molecular ions, m/z: 511.2 $[L-H]^+$ and 571.6 $[Co(L)–(H_2O)–(OH)]^+$, respectively.

The electronic spectrum of the ligand (**L**) in ethanol shows absorption bands at 229 ($\varepsilon = 49100\ M^{-1}\ cm^{-1}$), 282 ($\varepsilon = 5880\ M^{-1}\ cm^{-1}$) and 322 nm ($\varepsilon = 7720\ M^{-1}\ cm^{-1}$). The bands appearing at the low energy side are attributable to $\pi \rightarrow \pi^*$ transitions associated with the azomethine chromophores. The bands at higher energy arise from $\pi \rightarrow \pi^*$ transitions within the phenyl rings. The absorption bands of the complex are shifted to longer wave numbers compared to those of the ligand [32]. A moderately intensive band observed in the range of 325–345 nm is attributable to the $n \rightarrow \pi^*$ transitions of the complex. The most prominent feature in the visible region of the

Scheme 1. Synthesis of the ligand (**L**) and the cobalt complex, [Co(L)(OH)(H_2O)].

spectrum of the complex in DMSO solution is two main bands observed at 664 and 809 nm, which are attributed to thio S(σ) → Co(III) (dπ) and thio S(π) → Co(III) (dπ) ligand to metal charge transfer transitions (LMCT). The intense blue color of the complex is probably due to these LMCT transitions and is not sensitive to different solvent systems, indicating the inertness of the axial ligands coordinated to the central metal ion. The blue-green color is a prominent feature for thiosalen complexes.

3.2. Electrochemistry

The cyclic voltammograms (CVs) of the complex [Co(L)(OH)(H_2O)] in the potential range 1.10–1.50 V (versus Ag/AgCl) and for scan rates of 0.025–0.50 Vs^{-1} in DMSO and CH_2Cl_2 solutions containing 0.1 M TBAP supporting electrolyte are shown in Fig. 1, where the inset figures represent differential pulse voltammograms (DPV) under the same experimental conditions. As can be seen from Fig. 1a and b, [Co(L)(OH)(H_2O)] displays two well-defined reversible reduction processes with the corresponding anodic waves. The half-wave potentials for the reversible Co(III)/Co(II) and Co(II)/Co(I) redox couples were calculated as the average of the cathodic and anodic peak potentials of the processes. The half-wave potentials of the first and second reduction processes are displayed at $E_{1/2} = 0.08$ V and $E_{1/2} = -1.21$ V (scan rate: 0.100 Vs^{-1}) in DMSO, and $E_{1/2} = -0.124$ V and $E_{1/2} = -1.32$ V (scan rate: 0.100 Vs^{-1}) in CH_2Cl_2. The potentials of the reduction processes in DMSO are shifted toward negative potentials (0.220–0.112 V) compared to those in CH_2Cl_2 because of the different donor number effect under the same experimental conditions. The first reduction process has about a unit ratio of anodic to cathodic peak currents (i_{pa}/i_{pc}). The ratio observed for the second reduction process deviates from unity due to the residual current at low potential. These results are assigned to a simple one-electron processes: $[Co(III)L] + {}^{-}e \rightarrow [Co(II)L]^{-}$ and $[Co(II)L]^{-} + {}^{-}e \rightarrow [Co(I)L]^{2-}$. The value of the anodic to cathodic peak separation of the Co(III)/Co(II) and Co(II)/Co(I) couples are 68–117 mV (scan rate: 0.025–0.50 Vs^{-1}) and 70–110 mV (scan rate 0.025–0.50 Vs^{-1}) in DMSO, respectively. These values are a little larger than expected theoretically for a reversible one-electron process [33]. However, under our experimental conditions, the peak separation of the ferrocene/ferrocenium couple was observed to be 70–100 mV (scan rate: 0.025–0.50 Vs^{-1}), which can be used as a criterion for electrochemical reversibility. The peak separation increased only slightly with increasing scan rate, and this case was true for the ferrocene/ferrocenium couple under our experimental conditions. These reduction processes were diffusion controlled with the anodic current function ($I_{pa}/v^{1/2}$) independent of the scan rate (v) over the scan range 0.0250–0.500 Vs^{-1} [33]. Very similar electrochemical behavior was observed in CH_2Cl_2 under the same experimental conditions. Controlled potential electrolysis

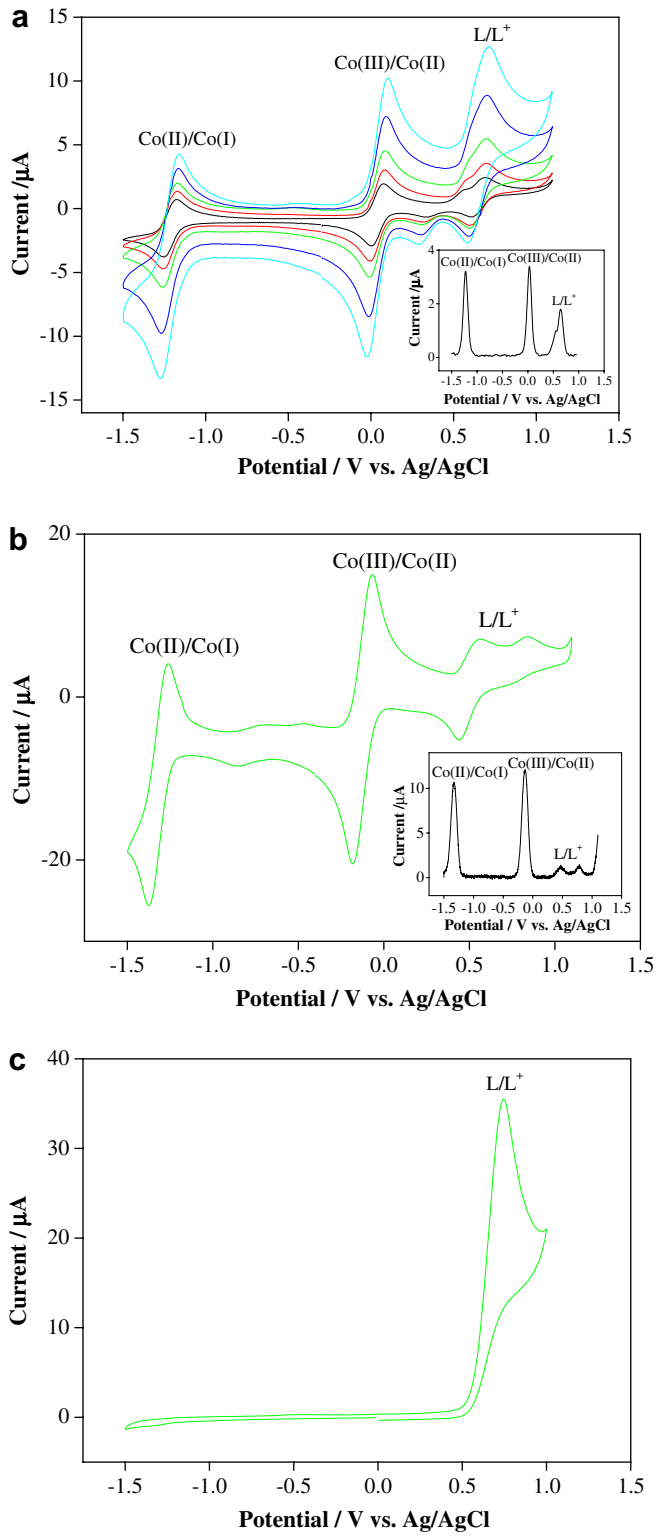


Fig. 1. Cyclic voltammograms (CV) of [Co(L)(OH)(H_2O)] in DMSO (a) and CH_2Cl_2 (b) solutions containing 0.1 M TBAP. Scan rates between 0.025 and 0.500 Vs^{-1} for (a) and 0.100 Vs^{-1} for (b) The inset figures in (a) and (b) represent differential pulse voltammograms (DPV). CV of ligand (**L**) in DMSO (scan rate 0.100 Vs^{-1}) (c).

revealed that a single electron was involved in each reduction step. The low peak separation observed for the Co(III)/Co(II) and Co(II)/Co(I) couples indicates that the six-coordination of the complex remains unchanged during the reduction processes and the electron transfer processes are not followed by a chemical reaction upon a reversal scan. On scanning through a second cycle, no change of the cathodic and anodic waves was observed for these electrode processes; the reductions occurred at the same potentials as observed in the first cycle. Multiple scans resulted in nearly superposable cyclic voltammograms, thereby showing the marked stability of the two reduction states of cobalt involved in the electrochemical study. It was reported in the literature that Co(III) salen complexes reduce to Co(II) species followed by a chemical reaction due to the loss of an axial ligand upon one electron being added to the d_{z^2} orbital. In this case, either the re-oxidation wave appeared at a higher potential or no corresponding anodic wave was observed upon reversal scan [34]. In our study, the reduction processes have reversible character, indicating that the axial ligands bound to the central atom are not released on the electrode surface in the timescale of the cyclic voltammetric measurement. It was also observed that [Co(L)(OH)(H_2O)] reduced at a more positive potential than the corresponding salen analogs. The shifts and reversibility are apparently related to the high degree of electron delocalization in the [Co(L)(OH)(H_2O)] complex, having a $N_2O_2S_2$ donor set and two additional benzene units. The high positive potential for the first reduction processes of some thiolate complexes was previously observed in the literature [12b]. The lower oxidation states, Co(I), are probably stabilized by the thio Schiff-base ligand system where the sulfur atom, having dπ orbitals, and imines groups (π^*) play an effective role with back donation [11]. It is known that increasing the number of aromatic rings or double bonds in the equatorial ligand facilitates reduction of Co(II) to Co(I) [11b]. The fact is clearly observed in our study. The electro-generated Co(I) species exhibiting reversible and stable character will likely facilitate a catalytic reduction of halogenated organic species as well as the Co(III)/Co(II) species [10]. The complex exhibited one oxidation wave at high scan rates (0.25–0.50 Vs^{-1}) and showed two peaks at low scan rates (0.25–0.50 Vs^{-1}). These two oxidation processes could be better differentiated by the CV (Fig. 1b) and DPV (Fig. 1b, the inset one) in CH_2Cl_2 solution. The ligand (**L**) exhibited one irreversible two electron-oxidation process without the corresponding cathodic wave (Fig. 1c). Its anodic peak potential (E_{pa}) was observed at 0.74 V. The anodic peak potentials of the complex appeared at almost same value in DMSO. So the oxidation processes of the complex are based on the ligand character. The splitting of the wave is probably due to the presence of two thiolate groups of the complex, oxidized at the different potentials.

3.3. UV–Vis spectra of the electro-oxidized and electro-reduced complexes

The spectroelectrochemical behavior of the [Co(L)-(OH)(H_2O)] complex was investigated using an *in situ*

spectroelectrochemical technique including chronoamperometry and UV–Vis spectroscopy in DMSO solution containing 0.2 M TBAP. The UV–Vis spectral changes for the reduced and oxidized species of the corresponding complex were obtained in a thin-layer cell the potentials were applied. The absorption spectra of the neutral complex and its electrochemically generated species are given in Fig. 2. The convenient applied potential values for the *in situ* spectroelectrochemical experiment were determined for each processes by taking CVs of the complexes in the thin-layer cell.

Fig. 2a shows the changes of the electronic spectrum of [Co(L)(OH)(H_2O)] during the first reduction process in the thin-layer cell. Well-defined isosbestic points were observed at 342, 442, 476 and 593 nm, confirming that the electrode reaction proceeded in a quantitative fashion and therefore with the absence of any coupled chemistry [16–21]. The main bands of the neutral complex observed at 664 and 809 nm can be attributed to the thio S(σ) → Co(III) (dπ) and thio S(π) → Co(III) (dπ) ligand to metal charge transfer transitions (LMCT). The intensity of these bands decreased and new bands formed at 571 and 389 nm, and a broad band at 315 nm in the timescale of the applied potential at $E_{app} = -0.4$ V (this process was completed within 300 s). A few new bands of low intensity were also observed between 300 and 600 nm. As a result of adding one electron to the Co(III) ion in the complex, one-electron reduction results in a Co(III) (d^6) → Co(II) (d^7) process, which makes the electron transition from the ligand to the metal harder. So the LMCT was observed at higher energy compared with that of the neutral complex, as expected. It is well known that spectroelectrochemistry provides the best knowledge on the redox process of complexes which is based on metal or ligand, reduction or oxidation [16–21]. The reduction process observed at the potential $E_{1/2} = 0.08$ V in DMSO and $E_{1/2} = -0.124$ V in CH_2Cl_2 was confirmed by this technique. As seen, the corresponding spectral changes were observed at low cathodic peak potential ($E_{app} = -0.4$ V) (Fig. 2a), but no spectral changes were observed with applied potentials at more positive values (E_{app}, 0.15–0.35 V) than the cathodic peak potential of the first reduction ($E_{pc} = 0.08$ V). It clearly indicates that this process is the first reduction of the complex based on the cobalt ion. The original spectrum of the complex was obtained upon re-oxidation during spectroelectrochemical measurement. It is concluded that the singly-reduced species remains stable and is not accompanied by a chemical reaction in the timescale of the spectroelectrochemical measurement. The fact that the axial ligand was not released from the metal during the first reduction process was verified by this way. The spectroelectrochemical results are also in agreement with the results of the cyclic voltammetric measurement. The controlled potential coulometric (CPC) study indicated that the number of electrons transferred for the forward and reverse electrochemical reaction of the complex was one for the reduction and re-oxidation processes based on the

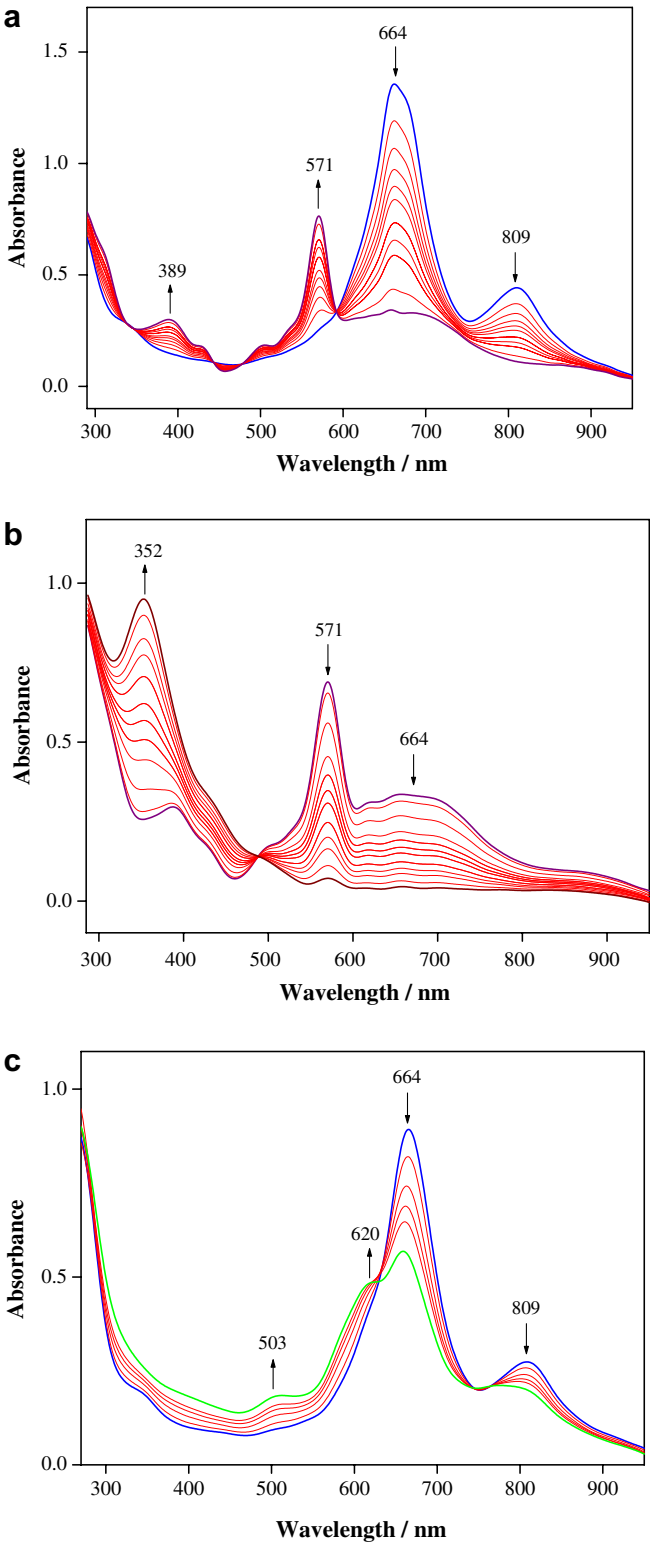

Fig. 2. Time-resolved UV–Vis spectral changes of [Co(L)(OH)(H_2O)] during the first reduction at $E_{app} = -0.4$ V (a), during the second reduction at $E_{app} = -1.60$ V (b), during the oxidation at $E_{app} = 1.0$ V (c), in DMSO solution containing 0.2 M TBAP.

Co(III)/Cu(II) couples. It was also seen by the *in situ* spectroelectrochemical measurement that the blue color of the complex changed to purple during the reduction process.

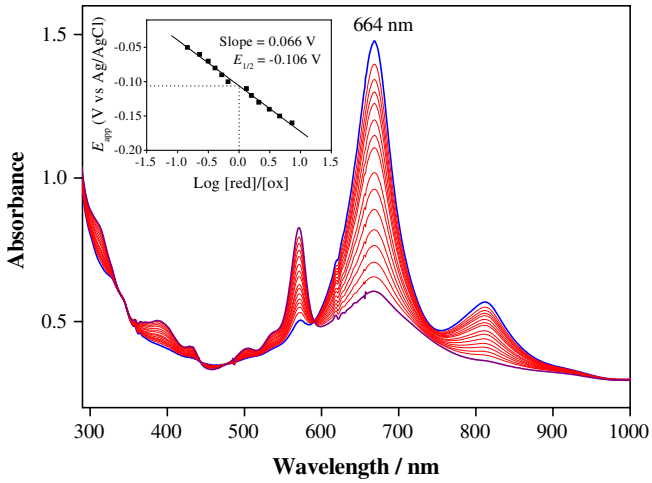

Fig. 3. Potential-resolved UV–Vis spectral changes of [Co(L)(OH)(H_2O)] during the first reduction (the potentials were applied in the range −0.05 to −0.20 V) in CH_2Cl_2 containing 0.2 M TBAP where the inset figure shows the plot of log([red]/[ox]) vs. applied potentials (E_{app}) for the Co(III)/Co(II) process.

It is known from the literature that some thiolate complexes with N_2S_2 or S_4 donor sets show absorptions in the visible region and have a blue-green color [12b,35].

The UV–Vis spectral changes upon the second reduction of [Co(L)(OH)(H_2O)] are shown in Fig. 2b. The isosbestic point is found at 487 nm, which clearly verifies the formation of the doubly-reduced species of the cobalt complex. As seen from Fig. 2b, the bands at 664 and 571 nm disappeared. Also, the band intensity corresponding to the 389 nm peak increases and its position shifts to lower energy (352 nm). This band is probably attributed to a metal to ligand charge transfer transition (MLCT) on the bases of the Co(II) (d^7) → Co(I) (d^8) process as a result of adding a second electron into the d orbital system. The original spectrum corresponding to the neutral complex was recovered upon re-reduction at the applied potential ($E_{app} = 0.25$ V).

The UV–Vis spectral changes upon oxidation of [Co(L)(OH)(H_2O)] are shown in Fig. 2c. The intensity of the main bands corresponding to the LMCT transition decrease and a shoulder develops at 620 nm. Isosbestic points are observed at 628 and 762 nm for the complex.

Application of the *in situ* spectroelectrochemical method allows determination of $E_{1/2}$, n (the number of electrons) with the spectra of fully oxidized and reduced species in one unified experiment. In this experiment, a series of potentials was applied to the optically transparent thin-layer cell in CH_2Cl_2, and individual spectra were measured after equilibrium was attained at each potential, as monitored by the current decay to a small, essentially zero value. Fig. 3 (potential-resolved spectra) shows such a result. The absorbance changes at a given wavelength (664 nm) can be related to the concentration ratio of the reduced to oxidized species by Eq. (1):

$$[R]/[O] = (A_2 - A_3)/(A_1 - A_2) \quad (1)$$

where A_2 is the absorbance of the mixture of oxidized and reduced forms, A_1 is the absorbance of the totally reduced form, and A_3 is the absorbance of the totally oxidized form. The Nernst Eq. (2)

$$E_{app} = E_{1/2} - (0.059)/n \log([R]/[O]) \quad (2)$$

indicates that a plot of E_{app} versus log[R]/[O] should be linear with a slope $59/n$ mV and an intercept of $E_{1/2}$, assuming Nernstian reversibility. For the $[Co(III)L] + {}^{-}e \rightarrow [Co(II)L]^{-}$ process, $E_{1/2} = -0.106$ V and $n = 0.90$ electron (slope = 66 mV, correlation coefficient = 0.997 for the plot) were found (Fig. 3, inset figure). These results are in agreement with those obtained from the cyclic voltammetric measurement and the bulk electrolysis.

4. Conclusion

A new cobalt Schiff-base complex, [Co(L)(OH)(H_2O)] (where L = [*N*,*N*′-bis(2-aminothiophenol)-1,4-bis(carboxylidene phenoxy)butane), was synthesized and its electrospectrochemical properties were investigated using CV, DPV and thin-layer spectroelectrochemical techniques in DMSO and CH_2Cl_2 solutions. This study presents for the first time detailed information on the electro-spectroelectrochemical behavior of the electro-generated species of a new thio Schiff-base cobalt (III) complex bearing the $N_2O_2S_2$ donor set and two additional aromatic groups. It is clear that this new blue cobalt(III) complex exhibits reversible and stable single- and double-reduced species in non-aqueous solution, based on the cobalt center, and has intense absorption bands in the visible region, and it will be a potential candidate molecule in electrocatalytic applications.

Abstract

The mononuclear complex of the second-generation quinolone antibacterial agent ciprofloxacin with UO_2^{2+} has been prepared and characterized with physicochemical and spectroscopic techniques. In this complex, ciprofloxacin acts as a bidentate deprotonated ligand bound to the metal through the pyridone oxygen and one carboxylate oxygen. The central U(VI) atom is six-coordinate and a slightly distorted octahedral geometry is proposed. The lowest energy model structure of the complex has been determined with molecular modelling calculations. The biological activity of the complex has been evaluated by examining its ability to bind to calf-thymus DNA.

Keywords: Ciprofloxacin; Quinolones; Uranyl(VI) complex; Molecular modelling; Interaction with calf-thymus DNA

1. Introduction

Ciprofloxacin, Hcf, (Fig. 1) is a typical second-generation quinolone (4-quinolone or quinolonecarboxylic acid) antibacterial agent used to treat diverse gram-negative infections [1]. Quinolones are a group of synthetic antibacterial agents [2], they can act as antibacterial drugs that effectively inhibit DNA replication and are commonly used as a treatment for many infections [3,4]. More specifically, ciprofloxacin can be used for the treatment of complicated and uncomplicated urinary tract infections and pyelonephritis, lower respiratory tract infections, skin and skin-structure infections, urethral and cervical gonococcal infections, bone and joint infections, infectious diarrhea, typhoid fever and acute sinusitis [1]. Because of its good penetration into bone, orally administered ciprofloxacin is a useful alternative to parenterally administered antibiotics for the treatment of osteomyelitis caused by susceptible organisms [5].

Ciprofloxacin can act as a bidentate ligand through the pyridone oxygen and one carboxylate oxygen. In the literature, the structures and the properties of diverse transition metal complexes of ciprofloxacin have been reported. More specifically, binary ciprofloxacin complexes with Cu(II) [2], $V(IV)O^{2+}$ [6], Cd(II), Co(II), Zn(II) [7,8], Mn(III) [8] and Mg(II) [9], as well as mixed-ligands ciprofloxacin complexes with Fe(III) [2], Cu(II) [10–12], Mn(II), Cd(II), Co(II), Zn(II), Ca(II), Ba(II), Sr(II) [8] and Ag(I) [13] have been structurally characterized.

The role of UO_2^{2+} as an element of biological interest is well known [14], while the biocoordination behavior of the uranyl cation is still relatively unexplored [15]. The uranyl(VI) ion has been used as a staining agent in electron microscopy [16], mainly due to its high affinity for the phosphates of the DNA backbone [17]. For UO_2^{2+}, three other quinolone complexes with pipemidato [18], *N*-propyl-norfloxacinato [19] and oxolinato ligands [20] have been studied.

We have initiated a study of the structure, spectroscopic and biological properties of diverse transition metal

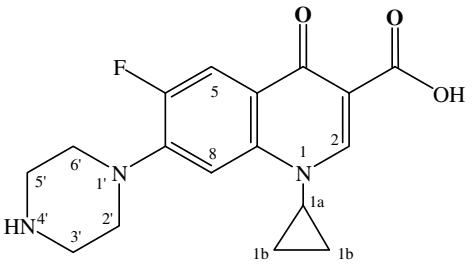

Fig. 1. Ciprofloxacin (Hcf = 1-cyclopropyl-6-fluoro-1,4-dihydro-4-oxo-7-(1-piperazinyl)-3-quinoline carboxylic acid) and H atom labelling.

complexes with various quinolone antibacterial drugs [18–27]. In this context, the interaction of UO_2^{2+} with deprotonated ciprofloxacin has been studied in an attempt to examine the mode of binding and possible synergetic effects. The resultant neutral mononuclear complex $UO_2(cf)_2$ has been characterized by elemental analysis and spectroscopic techniques. Molecular modelling techniques have been employed to assess the lowest energy model structure of the complex. The interaction of the complex with calf-thymus (CT) DNA has been studied with UV and circular dichroism (CD) spectroscopies.

2. Experimental

2.1. Materials

All the chemicals and solvents were reagent grade and were purchased from Aldrich Co., while ciprofloxacin was purchased from Sigma. Dimethylformamide (dmf) was distilled from calcium hydride (CaH_2) and CH_3OH from magnesium (Mg) and these solvents were stored over 3 Å molecular sieves. Diethyl ether and absolute ethanol were used without any further purification.

DNA stock solutions (5 mM) were prepared by dilution of CT-DNA with buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0), followed by exhaustive stirring at 4 °C for three days [28], and they were kept at 4 °C for no longer than a week. The nucleotide concentrations were determined by their absorption at 260 nm using $\varepsilon = 6600\ M^{-1}\ cm^{-1}$ (expressed as phosphate).

2.2. Synthesis of the complex $UO_2(cf)_2$ (1)

A methanolic solution (15 mL) of ciprofloxacin (0.4 mmol, 132 mg), deprotonated with KOH (0.4 mmol, 22 mg), was added to a methanolic solution (10 mL) of $UO_2(NO_3)_2 \cdot 6H_2O$ (0.2 mmol, 100 mg) and the reaction mixture was refluxed for 2 h. The solution was filtered and left for slow evaporation. After a few days a yellow-orange microcrystalline product was deposited, collected with filtration, washed with methanol and dried. Yield: 140 mg, 75 %. *Anal.* Calc. for $UO_2(cf)_2$ ($C_{34}H_{34}F_2N_6O_8U$) (MW = 930.71): C, 43.88; H, 3.68; N, 9.03. Found: C, 44.08; H, 3.80; N, 8.87%.

IR (KBr pellet, cm^{-1}): $\nu(C{=}O)_p$, 1635 (vs); $\nu(CO_2)_{asym}$, 1614 (vs); $\nu(CO_2)_{sym}$, 1385 (vs); $\nu(U{=}O)$, 935 (m). UV–Vis, λ (nm) (ε, $M^{-1}\ cm^{-1}$) as a nujol mull: 434 (sh), 347, 320, 294; in dmso: 433 (sh) (210), 370 (1350), 333 (1950), 292 (4700). ^1H NMR in dmso-d_6, δ (ppm): 1.20, (t, 4H, H1b); 1.45, (t, 1H, H1a); 3.40–3.55, (m, 4H, H2′ and H6′ or H3′ and H5′); 3.95, (m, 4H, H3′ and H5′ or H2′ and H6′); 7.45, (s, 1H, H8); 8.10, (s, 1H, H5); 8.85, (s, 1H, H2). The complex is soluble in dmso, dmf and partially soluble in water and is a non-electrolyte.

2.3. Instrumentation – physical measurements

Infrared (IR) spectra (400–4000 cm^{-1}) were recorded on a Nicolet Magna–IR 550 with samples prepared as KBr pellets. UV–Vis spectra (concentration range 2×10^{-5} – 10^{-3} M) were recorded on a Thermo Electron Corporation Helios α dual beam spectrophotometer. C, H and N elemental analysis was performed on a Perkin–Elmer 240B elemental analyzer. Electric conductance measurements were carried out with a WTW model LF 530 conductivity outfit and a type C cell, which had a cell constant of 0.996. NMR spectra were recorded with a Bruker Avance 500 MHz instrument and were processed by X-WIN NMR 2.6 (Bruker Analytik GmbH).

The interaction of complex **1** with CT DNA has been investigated with UV and CD spectroscopies. For the complex a DMSO stock solution (1 mM) was prepared, while for CT DNA the DNA aqueous stock solution, prepared as previously described, was used. In both techniques, the spectra of CT DNA in the presence of the complex have been recorded for a constant CT DNA concentration (3.125×10^{-4} M) in diverse complex:CT DNA mixing ratios (r) of the complex and CT DNA stock solutions. All the UV and CD spectra were recorded after incubation of the complex with CT DNA for 24 h at 37 °C.

The CD spectra were recorded on a Jasco J-700 spectropolarimeter using a 1.0 cm path quartz cell and the following acquisition parameters: $\lambda = 190$–400 nm, scan speed 50 nm min^{-1}, resolution step 0.2 nm, sensitivity 50 mdeg, response 1 s, bandwidth 1.0 nm, accumulations 10. In some cases, the spectra were averaged over an appropriate number of scans. The UV spectra were recorded in the region $\lambda = 200$–400 nm on a Thermo Electron Corporation Helios α dual beam spectrophotometer.

2.4. Molecular modelling

With the aim of presenting a molecular model for the complex that is unbiased by the starting structure, we have used Langevin dynamics with a simulated annealing protocol. Using this method, the mean total energy of an ensemble of structures guides the selection of the most favorable configuration for the complex. The starting structures were constructed using the program HyperChem and a MM+ force field that is based on Allinger's MM2 force field [29]. For the metal ion we have used a default parameter

set with $R^* = 2.20$ Å and $e^* = 0.02$ Kcal mol^{-1}, since the van der Waals interactions are not expected to play a major role in such bonded representations as in octahedral complexes. The metal–ligand bond lengths were corrected in the final model using harmonic restraints with equilibrium values that were extracted from crystallographic data of similar compounds [15,30,31] (Table S1). Non-bonded interactions were calculated in vacuo with no cutoff and the electrostatic energy term was treated using bond dipoles. Initial energy minimizations were carried out by a conjugate gradient method with rms gradient <0.01 as the convergence criterion.

Each model (Scheme S1) was subjected to 20 individual rounds of simulated annealing, setting different values to the seed for the assignment of the starting velocities. To integrate the Langevin equation [32] the step size was set to 1 fs and the collision frequency to 1 ps^{-1}. The annealing calculation comprised of three phases: (i) raising the temperature of the system from 10 to 1000 K over 2 ps, (ii) keeping the system at 1000 K for 3 ps and (iii) cooling the system down to 0 K over 15 ps. A tight coupling of the system with temperature (0.1 ps) was used for the heating and equilibration phases. During the cooling phase the bath relaxation time was gradually decreased from 5.0 ps (7000 steps), 2.0 ps (3000 steps), 1.0 ps (2000 steps), 0.5 ps (2000 steps) to 0.05 ps (1000 steps). At the final step all the structures had a rms gradient <0.01 and their total energy was recorded (Table S2). The model presented herein was selected from the lowest energy structures that were generated for each starting geometry. A final minimization of the energy was performed as above, but having applied the metal–ligand distance restraints.

3. Results and discussion

3.1. Spectroscopic study of the complex

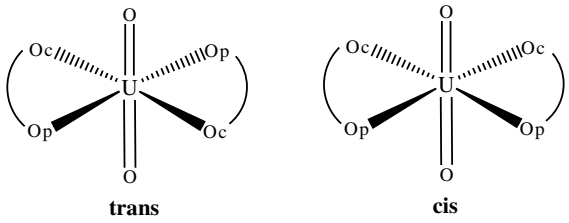
The complex has been prepared in high yield (75%) via the addition of a methanolic solution of deprotonated ciprofloxacin to a methanolic solution of the UO_2^{2+} ion at a 2:1 metal–ligand ratio. The resultant complex **1** is soluble in dmso and dmf, is partially soluble in water and is a non-electrolyte.

In the IR spectrum of complex **1** the absorption at 1707 cm^{-1}, observed in the spectrum of Hcf and attributed to ν(C=O)$_{carb}$, has been replaced by two very strong characteristic bands at 1614 and 1385 cm^{-1}, assigned as ν(O–C–O) asymmetric and symmetric stretching vibrations, respectively. The difference $\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$, a useful characteristic for determining the coordination mode of carboxylato ligands, is 229 cm^{-1}, indicating the monodentate coordination mode of the carboxylato group [33]. The vibration ν(C=O)$_p$ is shifted from 1623 cm^{-1} to 1635 cm^{-1} upon bonding. The overall changes in the IR spectrum suggest that the ciprofloxacinato ligand is coordinated to central U(VI) atom via the pyridone oxygen and one carboxylato oxygen [2].

The UV–Vis spectra of the complex have been recorded as nujol mulls and in dmso solution. Practically, the spectra in solution are identical with those in nujol, with the exception of a few nm shifts in some cases. The UV–Vis spectra of the complex are practically identical with that of the ligand ciprofloxacin but slightly shifted, indicative of coordination through the pyridone oxygen and one carboxylate oxygen. Additionally, an absorption band at 433 nm ($\varepsilon = 210$ M^{-1} cm^{-1}) is present in the spectrum of **1** and can be assigned to a ligand-to-metal charge transfer transition for the quinolone ligand [18–27].

^{1}H NMR spectra of Hcf and UO_2 (cf)$_2$ have been recorded in dmso-d_6. The assignment of every signal has been achieved by comparing the ^{1}H NMR spectrum of the complex to that of the ligand and the spectra of other quinolone–metal complexes reported in the literature [18–20,34]. The results are shown in Table 1.

Comparison of the ^{1}H NMR spectrum of UO_2 (cf)$_2$ with that of Hcf shows a significant perturbation of the chemical shift (up to 0.6 ppm) of the aromatic protons H2 and H5, indicating that H2 and H5 are close to the coordination site of the ligand. The signals for the aromatic proton H8, the aliphatic protons H1a and H1b and the piperazine protons are practically unchanged since they lie far from the binding site of the ligand. The overall changes of the NMR spectrum of the complex are indicative of coordination of the ciprofloxacinato ligand to the central U(VI) atom via the pyridone oxygen and one carboxylate oxygen [18–20,34].



3.2. Proposed structure of the complex with molecular modelling

The complex was collected as a microcrystalline product. Diverse crystallization techniques were employed but no crystals of the complex suitable for determination of the structure with X-ray crystallography were obtained. In order to present a model for the complex, only the enantiomers having the two uranyl oxygen atoms in *trans* positions were constructed as starting models of UO_2(cf)$_2$ (Scheme 1). This is in accordance with the structure of all the uranyl(VI) complexes reported in the literature [15,30,31].

After the Langevin dynamics simulated annealing calculations, we obtained the total energy results of 20 different

Table 1
Chemical shifts (in ppm) in the ^{1}H NMR spectra of Hcf and UO_2(cf)$_2$ in dmso-d_6

	Hcf	UO_2(cf)$_2$
H2	8.60 (1H)	8.85 (1H)
H5	7.50 (1H)	8.10 (1H)
H8	7.42 (1H)	7.45 (1H)
H1a	1.47 (1H)	1.45 (1H)
H1b	1.21 (4H)	1.20 (4H)
H2′, H6′ or H3′, H5′	3.56 (4H)	3.40–3.55 (4H)
H3′, H5′ or H2′, H6′	3.85 (4H)	3.90 (4H)

Scheme 1. The two diastereoisomers of $UO_2(cf)_2$ employed in the simulated annealing calculations. Oc and Op are the carboxylate and the pyridone oxygen atoms, respectively, of the ciprofloxacinato ligands.

conformations for each starting model (Table S2). The average energy of the isomers is almost equal, as expected [35], and, since the energy difference is very low ($\sim$0.22 Kcal mol^{-1}), it is difficult to distinguish between *trans* or *cis* isomers. Nevertheless, the *cis*-isomers exhibit the lowest average energy and the lowest energy model structure found for the *cis*-isomers is presented in Fig. 2.

3.3. Interaction with DNA

DNA can provide three distinctive binding sites for quinolone metal complexes; namely, groove binding, binding to the phosphate group and intercalation [36]. This behavior is of great importance with regard to the relevant biological role of quinolone antibiotics in the body [37].

3.3.1. UV spectroscopy

The absorption spectra of the interaction of complex **1** with CT DNA have been recorded for a constant CT DNA concentration (3.125×10^{-4} M) with different r values. The UV spectra of the complex with CT DNA derived for diverse complex:CT DNA mixing ratios are shown in Fig. 3. The changes observed in the absorption spectra of the complex after mixing with CT DNA (either the increase of the intensity at $\lambda_{max} = 258$ nm or the shift of λ_{max} up to 265 nm) indicate that the interaction of complex **1** with CT DNA takes place by the direct formation of a new complex with double-helical CT DNA [38].

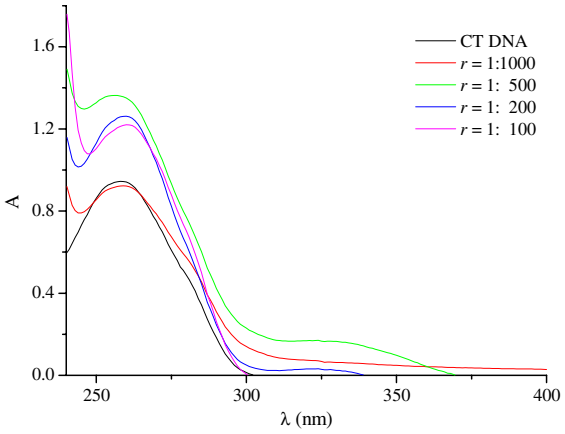


Fig. 3. Absorption spectra of complex **1** in the presence of CT DNA for diverse r values. The spectra were recorded at 25 °C after the complex had been incubated with CT DNA for 24 h at 37 °C.

3.3.2. CD spectroscopy

CD spectroscopy is useful in diagnosing changes in DNA morphology during drug–DNA interactions, as the positive band due to base stacking (273 nm) and the negative one due to right–handed helicity (246 nm) are quite sensitive to the mode of DNA interactions with small molecules [39,40]. The changes in the CD signals of DNA observed on interaction with drugs may often be assigned to the corresponding changes in the DNA structure [41]. Thus, simple groove binding and electrostatic interaction of small molecules show less or no perturbation on the base-stacking and helicity bands, while intercalation enhances the intensities of both the bands, stabilizing the right-handed B conformation of CT DNA, as observed for the classical intercalator methylene blue [42].

The CD spectra of the complex with double-stranded CT DNA for different r values can provide us with useful information concerning the complex–nucleotide interaction. The CD spectrum of free CT DNA is conservative and consists of a negative band at 246 nm and a positive one at 273 nm, characteristic of the B-form of DNA [43,44].

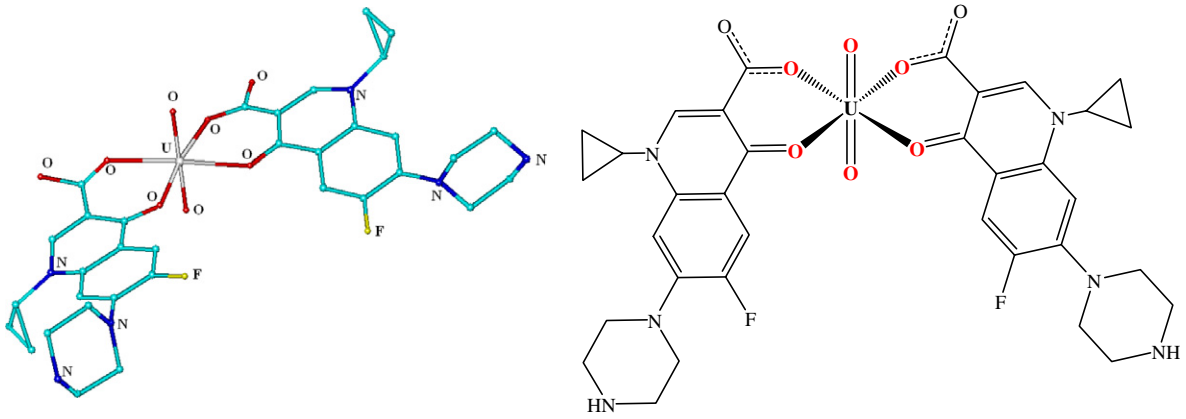

Fig. 2. Lowest energy model structure of $UO_2(cf)_2$.

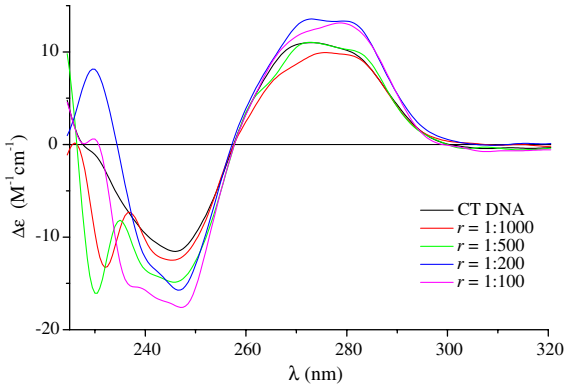

Fig. 4. CD spectra of CT DNA in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of complex **1** $UO_2(cf)_2$, with different *r* values. The spectra were recorded at 25 °C after the samples had been incubated with CT DNA for 24 h at 37 °C.

The CD spectra of CT DNA in the presence of complex **1** are shown in Fig. 4. For $r = 1{:}1000$, the spectrum consists of a strong negative band I at 245 nm and two discrete positive ones, band II at 273 nm and band III (observed as a shoulder) at 281 nm. When *r* increases up to 1:200, the position of the peaks remains unchanged, whilst a slight increase of both the intensities is observed. For a further increase of *r* (higher than 1:200), the two positive bands II and III cannot be distinguished, resulting in a unique broad band at $\lambda_{max} = 280$ nm and the intensity slightly increases. The λ_{max} value of 245 nm of the negative band I remains practically stable in all the spectra, while an increase of the intensity is observed with the increase of the *r* value.

The overall changes in the CD spectra indicate that the complex can be bound to CD DNA. The exact mode of binding cannot be safely concluded; nevertheless, the slight increase of the intensity of the negative band I and positive ones II–III shows that the intercalative mode between complex **1** and CT DNA is possible and it cannot be ruled out [36,38,45].

4. Conclusions

The synthesis and the characterization of a new ciprofloxacin mononuclear complex with UO_2^{2+} have been realized with physicochemical and spectroscopic methods. Ciprofloxacin is in the deprotonated mode and acts as a bidentate ligand bound to U(VI) through the pyridone oxygen and one carboxylate oxygen. The uranium(VI) atom is six-coordinate and the environment around it could be described as a distorted octahedron. With the use of molecular modelling, the lowest energy model structure of complex $UO_2(cf)_2$ has been determined, revealing the possible arrangement of the ligands around the metal. The study of the interaction of the complex with CT DNA has revealed that the complex can be bound to DNA, but the exact mode of binding cannot be safely concluded, although the intercalation is possible and cannot be ruled out.

Abstract

Reaction of five *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamides (H_2L-R, where H_2 denotes the two acidic protons and R (R = OCH_3, CH_3, H, Cl and NO_2) the *para* substituent in the aryl fragment) with [Ru(trpy)Cl_3](trpy = 2,2′,2″-terpyridine) in refluxing ethanol in the presence of a base (NEt_3) affords a group of complexes of the type [Ru^{II}(trpy)(L-R)], each of which contains an amide ligand coordinated to the metal center as a dianionic tridentate N,N,N-donor along with a terpyridine ligand. Structure of the [Ru^{II}-(trpy)(L-Cl)] complex has been determined by X-ray crystallography. All the Ru(II) complexes are diamagnetic, and show characteristic ^{1}H NMR signals and intense MLCT transitions in the visible region. Cyclic voltammetry on the [Ru^{II}(trpy)(L-R)] complexes shows a Ru(II)–Ru(III) oxidation within 0.16–0.33 V versus SCE. An oxidation of the coordinated amide ligand is also observed within 0.94–1.33 V versus SCE and a reduction of coordinated terpyridine ligand within −1.10 to −1.15 V versus SCE. Constant potential coulometric oxidation of the [Ru^{II}(trpy)(L-R)] complexes produces the corresponding [Ru^{III}(trpy)(L-R)]$^+$ complexes, which have been isolated as the perchlorate salts. Structure of the [Ru^{III}(trpy)(L-CH_3)]ClO_4 complex has been determined by X-ray crystallography. All the Ru(III) complexes are one-electron paramagnetic, and show anisotropic ESR spectra at 77 K and intense LMCT transitions in the visible region. A weak ligand-field band has also been shown by all the [Ru^{III}(trpy)(L-R)]ClO_4 complexes near 1600 nm.

1. Introduction

The chemistry of ruthenium has been receiving considerable attention [1], primarily because of the fascinating redox, photophysical and photochemical properties exhibited by complexes of this metal. As properties are dependent mostly on the coordination environment around the metal center, complexation of ruthenium by ligands of selected types is of significant importance, and the present work has originated from our continued interest in this area in general [2], and our recent findings on the chemistry of some ruthenium amide complexes in particular [2j]. It may be relevant to mention here that chemistry of the amide ligands is of particular interest with reference to their role in biological processes [3]. For example, the amide linkage plays a key role in the formation and maintenance of protein architectures, which are crucial for their performance in biological systems [4]. Apart from their relevance in biological phenomena, coordination chemistry of the amide ligands is also interesting with regard to their variable binding modes. The amides usually display two modes of binding to metal ions, through the nitrogen (amidate mode) via dissociation of the N–H proton and through the oxygen (amide mode). While binding in the amidate mode is known to stabilize metal ions in their high oxidation states, that in the amide mode is reported to favor relatively lower oxidation states of a metal [5]. Interconversion between the amide and amidate modes

of binding has been efficiently utilized to manipulate redox properties of the metal center [6]. In a recent study on a group of tris-complexes of *N*-(aryl)picolinamides (**1**) [2j], where the amides are bound to ruthenium through the pyridine-nitrogen (N^p) and the amide-nitrogen (N^a) (as in **2**) creating a $N^p_3N^a_3$ coordination sphere, the trivalent state of ruthenium has been found to be highly stable as reflected in the Ru(III)–Ru(II) reduction potential (−0.38 V versus SCE, for the R = H complex). From the magnitude of this reduction potential it became evident that the bivalent state of ruthenium cannot be stabilized in the same $N^p_3N^a_3$ environment. In order to have stable ruthenium(II) complexes of such amides, a logical approach seems to be to reduce the number of hard amide nitrogens and increase that of soft pyridine nitrogens in the coordination sphere. Thus we have planned to create a $N^p_4N^a_2$ coordination sphere around ruthenium, and with this simple strategy a group of *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamides (**3**), derived from 2,2′-dipicolinic acid and five different *para*-substituted anilines, have been selected as the ligands and [Ru(trpy)Cl_3](trpy = 2,2′,2″-terpyridine) as the ruthenium starting material. The selected amides (**3**) are known to bind to metal ions usually as dianaionic tridentate N^a,N^p, N^a-donors (**4**) via loss of the two amide protons [7]. However, there are few instances where they also bind to metal ions as monoanaionic N^a,N^p,O-donors as well as neutral O,N^p,O-donors [8]. It may be mentioned here that though chemistry of amide complexes of many transition metals has been extensively studied [9], that of ruthenium appears to have received much less attention [2j,o,7a,10]. As the source of ruthenium the [Ru(trpy)Cl_3] complex has been selected because of its demonstrated ability to accommodate tridentate ligands via displacement of three chlorides and thus providing three pyridine nitrogens in the coordination sphere [11]. Reaction of the selected amides (**3**) with [Ru(trpy)Cl_3] has indeed been found to afford a family of complexes having the targeted $N^p_4N^a_2$ coordination sphere around ruthenium. An account of the chemistry of all these complexes is presented in this report, with special reference to their formation, characterization and, spectral and electrochemical properties.

2. Experimental

2.1. Materials

Commercial ruthenium trichloride was purchased from Arora Matthey, Kolkata, India. The *para*-substituted anilines, 2,2′,2″-terpyridine and 2,6-dipicolinic acid were obtained from Aldrich, India. All other chemicals and solvents were reagent grade commercial materials and were used as received. [Ru(trpy)Cl_3] was synthesized by following a reported procedure [12]. The *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamides (**3**, H_2L-R) were prepared by condensing 2,6-dipicolinic acid with *para*-substituted anilines [10a]. Purification of dichloromethane and acetonitrile, and preparation of tetrabutylammonium perchlorate (TBAP) for electrochemical work were performed as reported in the literature [13].

2.2. Synthesis

2.2.1. [Ru^{II}(trpy)(L-R)]

The [Ru^{II}(trpy)(L-R)] complexes were obtained by following a general procedure. Specific details are given below for a particular complex.

2.2.1.1. [Ru^{II}(trpy)(L-H)]. To a solution of the H_2L-H ligand (70 mg, 0.22 mmol) in ethanol (40 mL) was added triethylamine (70 mg, 0.70 mmol) followed by [Ru(trpy)Cl_3] (100 mg, 0.22 mmol), and the mixture was then refluxed for 24 h to yield a brown solution. The solvent was evaporated and the brown residue, thus obtained, was subjected to purification by thin layer chromatography on a silica plate. With 1:1 acetonitrile–toluene as the eluant, a brown band separated, which was extracted with acetonitrile. Evaporation of this acetonitrile extract gave [Ru^{II}(trpy)(L-H)] as a brown crystalline solid. Yield: 103 mg (70%).

2.2.1.2. [Ru^{II}(trpy)(L-OCH_3)]. Anal. Calc. for $C_{36}H_{28}N_6O_4Ru$: C, 60.93; H, 3.94; N, 11.84. Found: C, 60.83; H, 3.72; N, 11.95%. ^{1}H NMR in $CDCl_3$, δ ppm[1]: 3.57 (s, 6H, OCH_3); 5.55 (d, 4H, $J = 6.2$); 6.57 (d, 4H, $J = 6.2$); 7.32 (t, 2H, $J = 7.8$); 7.49–7.61 (4H)*; 7.78 (d, 2H, $J = 7.7$); 7.81 (d, 2H, $J = 7.7$); 8.15 (t, 2H, $J = 7.4$)*; 8.31 (2H)*.

2.2.1.3. [Ru^{II}(trpy)(L-CH_3)]. Anal. Calc. for $C_{36}H_{28}N_6O_2Ru$: C, 63.81; H, 4.13; N, 12.40. Found: C, 63.77; H, 4.04; N, 12.48%. ^{1}H NMR in $CDCl_3$, δ ppm[1]: 2.10 (s, 6H, CH_3); 5.35 (d, 4H, $J = 6.1$); 6.37 (d, 4H, $J = 6.2$); 7.34 (t, 2H, $J = 7.8$); 7.51–7.66 (4H)*; 7.77 (d, 2H,

[1] Chemical shifts are given in ppm and multiplicity of the signals along with the associated coupling constants (*J* in Hz) are given in parentheses. Overlapping signals are marked with an asterisk.

2.2.2. [Ru^{III}(trpy)(L-R)]ClO$_4$

The [Ru^{III}(trpy)(L-R)]ClO$_4$ complexes were obtained by following a general procedure. Specific details are given below for a particular complex.

2.2.2.1. [Ru^{III}(trpy)(L-H)]ClO$_4$. A solution of [Ru^{II}(trpy)(L-H)] (22 mg, 0.03 mmol) in 50 mL of 1:9 dichloromethane–acetonitrile (0.1 M TBAP) was coulometrically oxidized at 0.4 V versus SCE. Color of the solution gradually changed from brown to green during the oxidation. After the electrolysis was complete ($Q_{observed} = 3.47$ C, $Q_{calculated} = 3.36$ C), the resulting acetonitrile solution was then layered over toluene. Green crystals of the [Ru^{III}(trpy)(L-H)]ClO$_4$ complex were obtained upon slow diffusion of toluene into the acetonitrile solution, which were collected manually. The yield was quantitative.

2.2.2.1.1. [Ru^{III}(trpy)(L-OCH$_3$)]ClO$_4$. Anal. Calc. for $C_{36}H_{28}N_6O_8ClRu$: C, 53.43; H, 3.46; N, 10.38. Found: C, 53.78; H, 3.34; N, 10.44%.

2.2.2.1.2. [Ru^{III}(trpy)(L-CH$_3$)]ClO$_4$. Anal. Calc. for $C_{36}H_{28}N_6O_6ClRu$: C, 55.63; H, 3.60; N, 10.81. Found: C, 55.92; H, 3.32; N, 10.94%.

2.2.2.1.3. [Ru^{III}(trpy)(L-H)]ClO$_4$. Anal. Calc. for $C_{34}H_{24}N_6O_6ClRu$: C, 54.50; H, 3.20; N, 11.22. Found: C, 54.62; H, 3.63; N, 11.10%.

2.2.2.1.4. [Ru^{III}(trpy)(L-Cl)]ClO$_4$. Anal. Calc. for $C_{34}H_{22}N_6O_6Cl_3Ru$: C, 49.90; H, 2.69; N, 10.27. Found: C, 49.75; H, 2.77; N, 10.45%.

2.2.2.1.5. [Ru^{III}(trpy)(L-NO$_2$)]ClO$_4$. Anal. Calc. for $C_{34}H_{22}N_8O_{10}ClRu$: C, 48.65; H, 2.62; N, 13.35. Found: C, 48.55; H, 2.80; N, 13.45%.

2.3. Physical measurements

Microanalyses (C, H, N) were performed using a Heraeus Carlo Erba 1108 elemental analyzer. IR spectra were obtained on a Perkin–Elmer 783 spectrometer with samples prepared as KBr pellets. Electronic spectra were recorded on a JASCO V-570 spectrophotometer. Magnetic susceptibilities were measured using a PAR 155 vibrating sample magnetometer fitted with a Walker Scientific L75FBAL magnet. NMR spectra were recorded in $CDCl_3$ solution with a Bruker AV 300 NMR spectrometer. ESR spectra were recorded with a JEOL JES-FA200 X-band spectrometer fitted with a quartz Dewar for measurements at 77 K (liquid dinitrogen). All ESR spectra were calibrated with an aid of DPPH ($g = 2.0037$). Electrochemical measurements were made using a CH Instruments model 600A electrochemical analyzer. A platinum disc working electrode, a platinum wire auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in the cyclic voltammetry experiments. A platinum-wire-gauge working electrode was used in the coulometric experiments. All electrochemical experiments were performed under a dinitrogen atmosphere. All electrochemical data were collected at 298 K and are uncorrected for junction potentials.

2.4. X-ray crystallography

Single crystals of [Ru^{II}(trpy)(L-Cl)] were obtained by slow evaporation of an acetonitrile solution of the complex. Single crystals of [Ru^{III}(trpy)(L-Me)]ClO$_4$ were obtained by slow diffusion of toluene into an acetonitrile solution of the complex. Data were collected on a Bruker SMART APEX CCD diffractometer using graphite monochromated and Mo Kα radiation ($\lambda = 0.71073$ Å). X-ray data reduction and, structure solution and refinement were done using SHELXS-97 and SHELXL-97 programs [14]. The structures were solved by the direct methods.

Crystal data for $C_{51}H_{33}N_9O_6Cl_3Ru_{1.5}$, $M = 1125.34$, $0.33 \times 0.34 \times 0.45$ mm^3, monoclinic, space group $C2/c$, $a = 32.244(7)$ Å, $b = 15.797(4)$ Å, $c = 19.331(4)$ Å, $\beta = 102.458(4)°$, $V = 9615(4)$ Å^3, $Z = 8$, $D_{calc} = 1.556$ Mg m^{-3}, $F(000) = 4536$, $\lambda = 0.71073$ Å, $T = 293$ K, $\mu = 0.702$ mm^{-1}, 49 734 reflections collected, 10 279 unique ($R_{int} = 0.036$). Final goodness-of-fit = 0.95, $R_1 = 0.0595$, $wR_2 = 0.2266$, R indices based on 8382 reflections with $I > 2\sigma(I)$ (refinement on F_2), 638 parameters.

Crystal data for $C_{36}H_{28}N_6O_6ClRu$, $M = 813.20$, $0.24 \times 0.28 \times 0.42$ mm^3, monoclinic, space group $P2_1/c$, $a = 14.0441(3)$ Å, $b = 21.9700(5)$ Å, $c = 12.5956(3)$ Å, $\beta = 115.2980(10)°$, $V = 3513.65(14)$ Å^3, $Z = 4$, $D_{calc} = 1.537$ mg m^{-3}, $F(000) = 1660$, $\lambda = 0.71073$ Å, $T = 273$ K, $\mu = 0.584$ mm^{-1}, 40 809 reflections collected, 8523 unique ($R_{int} = 0.032$). Final goodness-of-fit = 1.07, $R_1 = 0.0386$, $wR_2 = 0.1044$, R indices based on 8523 reflections with $I > 2\sigma(I)$ (refinement on F_2), 487 parameters.

3. Results and discussion

3.1. [Ru^{II}(trpy)(L-R)] complexes

3.1.1. Synthesis and crystal structure

As delineated in the introduction, the primary objective of the present study has been to synthesize a group of mixed-ligand complexes of ruthenium containing both 2,2′,2″-terpyridine and the *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamide (**3**). For this purpose five *N*,*N*′-bis(aryl)-pyridine-2,6-dicarboxamides with different substituents (R = OCH_3, CH_3, H, Cl and NO_2) at the *para* position of the two pendant phenyl rings have been used, in order to study their influence, if any, on the redox properties of the resulting ruthenium complexes. These amide ligands (**3**) are abbreviated in general as H_2L-R, where H_2 stands for the two dissociable protons and R for the substituents. Reactions of the selected amides (**3**) with [Ru(trpy)Cl_3] proceed smoothly in refluxing ethanol in the presence of triethylamine to afford the targeted mixed-ligand complexes of type [Ru^{II}(trpy)(L-R)] in decent yields. It may be noted here that during the synthetic reaction ruthenium has undergone a one-electron reduction, and triethylamine might have served as the reducing agent. Preliminary (microanalytical, spectroscopic, magnetic, etc.) characterizations on these complexes (vide infra) are found to be in well accordance with their compositions. In order to find out coordination mode of the *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamides in these complexes, structure of a representative member of this family, *viz*. [Ru^{II}(trpy)(L-Cl)], has been determined by X-ray crystallography. The structure is shown in Fig. 1 and selected bond parameters are listed in Table 1. The structure shows that the *N*,*N*′-bis(4′-chlorophenyl)pyridine-2,6-dicarboxamide is coordinated to ruthenium, via dissociation of two acidic protons, as a dianionic tridentate N,N,N-donor (**4**). A terpyridine is also coordinated to the metal center in the usual fashion. Ruthenium is therefore sitting in a N_6 coordination environment, which is distorted octahedral in nature, as reflected in all the bond parameters around ruthenium. The observed bond distances in the Ru(L-Cl) fragment are all quite normal [2j,n], and so are those in the Ru(trpy) fragment [11a]. In the crystal lattice of the [Ru^{II}(trpy)-(L-Cl)] complex, there are three molecules of water per two complex molecules. In order to find out the link between these water molecules and the complex molecule, packing pattern in the lattice has been scrutinized (Fig. 2), which shows that besides links with the water molecules, the complex molecules also have direct links between themselves. A closer inspection into the network reveals that three types of hydrogen-bonding interactions, *viz*. C–H–O, O–H–O, C–H–Cl and C–H–π, are active in the lattice. The amide oxygen is linked with one trpy C–H as well as O–H of water. A C–H fragment from the pyridine ring of the amide is hydrogen bonded to water molecule. The central C–H fragment from the pyridine ring of the amide is linked to the π-cloud over a terminal pyridine ring of trpy in a η^2-fashion. C–H fragments of the terpyridine and the pendent phenyl ring of the amide are found to be hydrogen bonded to the chlorine atom in the amide. One C–H fragment of the terpyridine is also hydrogen bonded to the π-cloud in the pendent phenyl ring of the amide. These hydrogen-bonding interactions appear to be responsible for holding the complex molecules together in the crystal lattice. It may be relevant to note here that such interactions are of significant importance in molecular recognition processes as well as in crystal engineering [15]. As all the [Ru^{II}(trpy)(L-R)] complexes have been synthesized similarly and they show similar properties (vide infra), the other four [Ru^{II}(trpy)(L-R)] (R ≠ Cl) complexes are assumed to have similar structure as the [Ru^{II}(trpy)-(L-Cl)] complex.

3.1.2. Spectral properties

^{1}H NMR spectra of these complexes show many signals, most of which are overlapping, and hence assignment of each signal to a specific proton has not been possible. However, two distinct doublets observed near 5.3 and 6.3 ppm in the complexes with R ≠ H, each integrating to four protons, are assignable to the hydrogens in the two pendent phenyl rings in the coordinated amide ligand. Signals for the methoxy and methyl groups in the [Ru^{II}(trpy)-(L-OCH_3)] and [Ru^{II}(trpy)(L-CH_3)] complexes are observed respectively at 3.57 and 2.10 ppm. The infrared and ^{1}H NMR spectral data of the [Ru^{II}(trpy)(L-R)] complexes are therefore consistent with their compositions.

Infrared spectra of each [Ru^{II}(trpy)(L-R)] complex shows many bands of different intensities in the 400–4000 cm^{-1} region. Assignment of each individual band to a specific vibration has not been attempted. However, comparison with spectrum of the respective uncoordinated ligand shows that the N–H stretch, observed near 3140 cm^{-1} in the uncoordinated ligands, is absent in the complexes. The amide C=O stretch, observed near 1680 cm^{-1} in the uncoordinated ligands, is also found to be shifted to around 1595 cm^{-1} in the complexes. Comparison with the spectrum of [Ru(trpy)Cl_3] shows the presence of some common bands (near 648, 670, 729, 781, 1240 and 1444 cm^{-1}) as well as some new bands (near 808, 1008, 1083, 1379 and 1595 cm^{-1}) in the spectra of the [Ru^{II}(trpy)-(L-R)] complexes indicating presence coordinated terpyridine and amide ligands [8a,2n,j]. The [Ru^{II}(trpy)-(L-R)] complexes are found to be diamagnetic, which is in accordance with the +2 oxidation state of ruthenium (low-spin d^6, $S = 0$) in these complexes.

The [Ru^{II}(trpy)(L-R)] complexes are soluble in acetone, acetonitrile, dichloromethane, chloroform, etc., producing deep brown solutions. Electronic spectra of the complexes have been recorded in dichloromethane solution. All the complexes show several intense absorptions in the visible and ultraviolet regions (Table 2). The absorptions in the ultraviolet region are attributable to transitions within the ligand orbitals and those in the visible region are probably due to charge-transfer transitions. To have a better

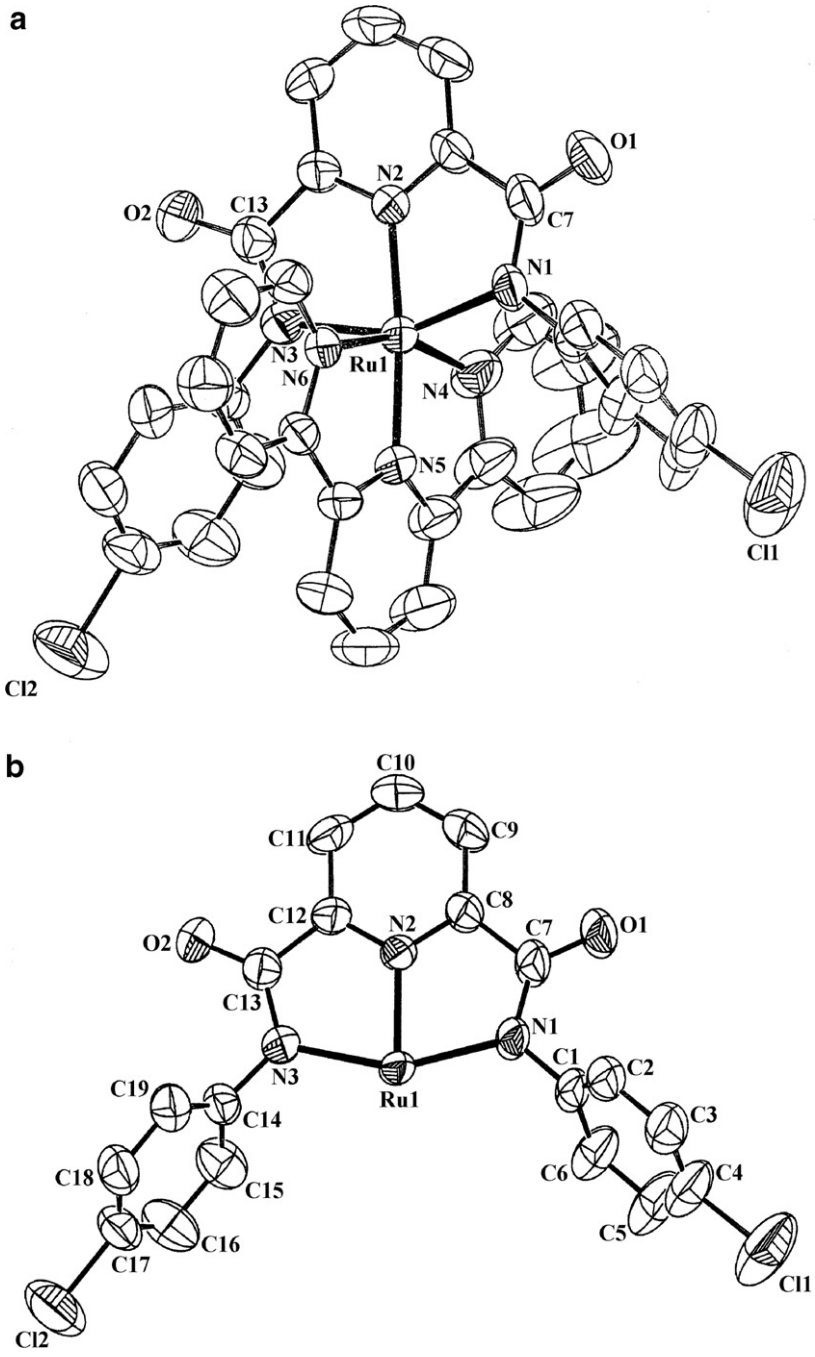

Fig. 1. (a) Structure of the [Ru^{II}(trpy)(L-Cl)] complex and (b) view of the Ru(L-Cl) fragment.

insight into the nature of the absorptions in the visible region, qualitative EHMO calculations have been performed [16] on the structurally characterized [Ru^{II}(trpy)-(L-Cl)] complex. Partial MO diagrams are shown in Fig. 3 and composition of selected molecular orbitals is presented in Table S1 (Supplementary material). The highest occupied molecular orbital (HOMO) and the next two filled orbitals (HOMO − 1 and HOMO − 2) have major (~60%) contribution from the ruthenium d_{xy}, d_{yz} and d_{zx} orbitals. These three occupied orbitals may therefore be regarded as the ruthenium t_2 orbitals. The lowest unoccupied molecular orbital (LUMO) has 70% contribution from the coordinated terpyridine and is dispersed over the entire ligand. Among the next few vacant orbitals (LUMO + 1, LUMO + 2, etc.), LUMO + 1 is primarily centered on the amide ligand and concentrated heavily on pyridine nitrogen, while LUMO + 2 is delocalized over both the amide ligand and terpyridine. The lowest energy absorption, displayed by the [Ru^{II}(trpy)(L-R)] complexes near 540 nm, may therefore be assigned to the charge-transfer transition taking place from the highest filled ruthenium t_2 orbital (HOMO) to the vacant orbital delocalized over the terpyridine (LUMO). The other intense absorptions in the visible region may be assigned to

3.1.3. Electrochemical properties

Electrochemical properties of the $[Ru^{II}(trpy)(L\text{-}R)]$ complexes have been studied by cyclic voltammetry in 1:9 dichloromethane–acetonitrile solution (0.1 M TBAP).[2] Each complex shows two oxidative responses at potentials positive of the SCE reference electrode and a reductive response at negative potentials (Table 2). A representative voltammogram is shown in Fig. 4. The first oxidation, observed within 0.16–0.33 V, is reversible in nature, characterized by a peak-to-peak separation (ΔE_p) of ~70 mV, which remains unchanged upon changing the scan rate, and the anodic peak-current (i_{pa}) is almost equal to the cathodic peak-current (i_{pc}) as expected for a reversible electron-transfer process. In view of composition of the HOMO, this oxidation is assigned to Ru(II)–Ru(III) oxidation. It is interesting to note here that in the tris-complexes of *N*-(aryl)picolinamides (**1**) [2j], where ruthenium was nested in a $N_3^pN_3^a$ coordination sphere, the Ru(III)–Ru(II) couple appeared on the negative side of SCE (*e.g.* −0.38 V, for the R = H complex), whereas in these $[Ru^{II}(trpy)(L\text{-}R)]$ complexes, in which the coordination environment around the metal center has changed to $N_4^pN_2^a$, the same couple appears on the positive side of SCE (*e.g.* 0.20 V, for the R = H complex). Hence replacement of an amide nitrogen by a pyridine nitrogen in the coordination sphere of ruthenium has truly stabilized the bivalent state of the metal to a significant extent, which has been manifested in the positive shift of the Ru(II)–Ru(III) potential by about 580 mV.

The second oxidation, observed within 0.94–1.33 V, is quasi-reversible in nature, and is tentatively assigned to Ru(III)–Ru(IV) oxidation. Based on composition of the LUMO, the irreversible reduction observed around −1.1 V is assigned to reduction of the coordinated terpyridine ligand. Potential of Ru(II)–Ru(III) oxidation has been observed to be sensitive to nature of the substituent R in the *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamide. The potential ($E_{1/2}$) increases with increasing electron-withdrawing character of the substituent R. The plot of $E_{1/2}$ versus 2σ [σ = Hammett constant of R [17]; $OCH_3 = -0.27$, $CH_3 = -0.17$, $H = 0.00$, $Cl = 0.23$, $NO_2 = 0.78$] is linear for these complexes (Fig. S1, Supplementary material) with a slope (ρ) of 0.08 (ρ = reaction constant of this oxidation [18]). This linear correlation of the Ru(II)–Ru(III) oxidation potentials with the electronic nature of the substituents having a reasonable slope clearly shows that the substituent on the phenyl ring of the amide, which is six bonds away from the metal center, can still influence the metal-centered redox potential in a predictable manner. Similarly potential ($E_{1/2}$) of the Ru(III)–Ru(IV) oxidation also shows linear correlation with the electron-withdrawing nature (2σ) of substituent R with a slope (ρ) of 0.18 V (Fig. S1, Supplementary materials). The higher slope of the second plot indicates that the second oxidation probably involves an orbital having significant amide character. Potentials of the irreversible reductive responses do not show any systematic variation with the nature of the substituent.

3.2. $[Ru^{III}(trpy)(L\text{-}R)]^+$ complexes

3.2.1. Synthesis and crystal structure

Reversibility of the Ru(II)–Ru(III) oxidation in the $[Ru^{II}(trpy)(L\text{-}R)]$ complexes indicates that the one-electron oxidized species, *viz.* $[Ru^{III}(trpy)(L\text{-}R)]^+$, might be stable on a time scale much longer than the cyclic voltammetric time scale. To investigate this, each $[Ru^{II}(trpy)(L\text{-}R)]$ complex has been coulometrically oxidized at an appropriate potential[3] in acetonitrile solution (0.1 M TBAP). The oxidation has been smooth and quantitative, associated with a color change from brown to green, and the oxidized product has been isolated as $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ in the solid state. Preliminary characterization data on these complexes are found to be consistent with their compositions. To examine the difference in structural features, if any, associated with one-electron oxidation of the metal center, structure of a selected member of this new family, *viz.* $[Ru^{III}(trpy)(L\text{-}CH_3)]ClO_4$, has also been determined by X-ray crystallography. The structure (Fig. 5) shows that apart from small differences in the Ru–N lengths (Table 1),

[2] A little dichloromethane was necessary to take the complex into solution. Addition of large excess of acetonitrile was necessary to record the redox responses in proper shape.

[3] Coulometric oxidation has been carried out at a potential 200 mV higher than the E_{pa}.

[f] E_{pc} value.

the other features are qualitatively very similar to those of the [Ru^{II}(trpy)(L-R)] complex. The Ru–N distances in the Ru(L-R) fragment are shorter in the Ru(III) complex, probably due to enhanced electrostatic attraction of the dianionic amide ligand with the trivalent metal. The Ru–N lengths in the Ru(trpy) fragment are, however, slightly longer in the Ru(III) complexes, which is attributable to the lack of back-donation from the oxidized metal center that probably wins over the electrostatic effect. The packing pattern in the lattice (Fig. 6) shows that

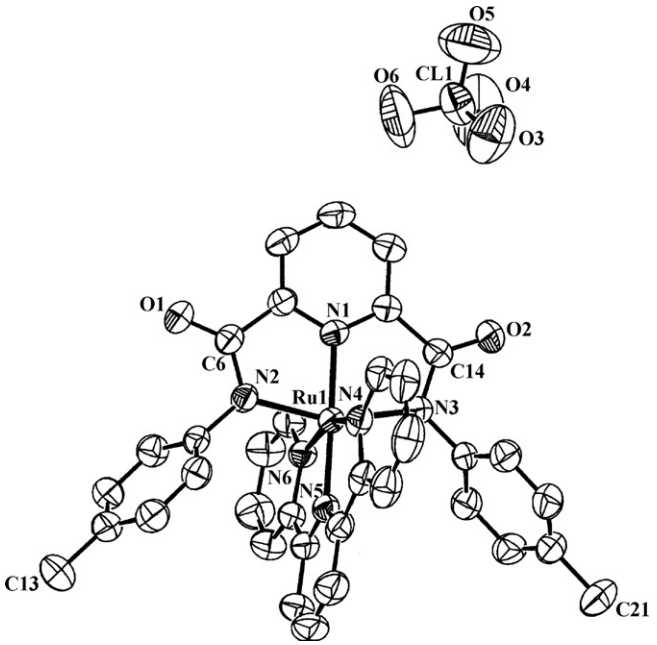

Fig. 5. Structure of the $[Ru^{III}(trpy)(L\text{-}CH_3)]ClO_4$ complex.

hydrogen-bonding interactions of three types, *viz.* C–H–O, O–H–O and C–H–π, are active. The perchlorate oxygens are hydrogen bonded to water and C–H fragment of the trpy ligand. The amide oxygen is also hydrogen bonded to water and C–H fragment of the trpy ligand. One C–H fragment of the trpy ligand is hydrogen bonded to the π-cloud over the tolyl ring of the amide ligand. Due to such hydrogen-bonded arrangements of the complex molecules, several nearly rectangular cavities have been created throughout the lattice. Based on the similarity in their syn-

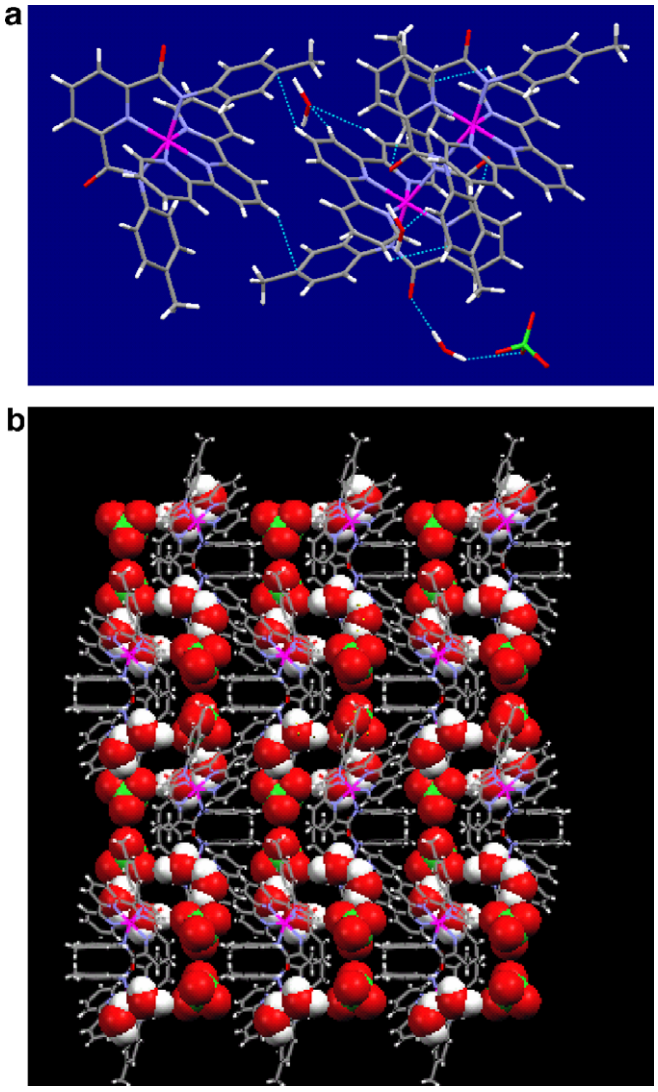

Fig. 6. Packing diagram of the $[Ru^{III}(trpy)(L\text{-}CH_3)]ClO_4$ crystal.

thesis and properties (*vide infra*), the other four $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ ($R \neq CH_3$) complexes are assumed to have similar structures as $[Ru^{III}(trpy)(L\text{-}CH_3)]ClO_4$.

3.2.2. Spectral properties

Apart from the appearance of two additional intense bands around 1100 and 620 cm^{-1} due to presence of the perchlorate anion and small shifts in the position of the other bands, infrared spectra of each $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ complex is qualitatively similar to that of the respective $[Ru^{II}(trpy)(L\text{-}R)]$ complex. Magnetic susceptibility measurements show that the $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ complexes are one-electron paramagnetic ($\mu_{eff} = 1.83$–$1.90\ \mu_B$), which corresponds to the +3 oxidation state of ruthenium (low-spin d^5, $S = 1/2$) in these complexes. ESR spectra of the $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ complexes have been recorded in 1:1 dichloromethane–toluene solution at 77 K. Each complex shows an axial ESR spectrum with two distinct signals ($g_\perp$ and $g_\parallel$; in the order of decreasing magnitude). A selected spectrum is shown in Fig. 7 and the spectral data for all complexes are given in Table 3. The anisotropy of the spectra reflects the asymmetry of the electronic environment around ruthenium in these $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ complexes. When an octahedral geometry suffers from an axial distortion (Δ), the t_2 level splits into a and e components (Fig. 7). Spin–orbit coupling causes minor additional changes in energy of all the three levels. Thus two closely spaced electronic transitions (transition energies ΔE_1 and ΔE_2; $\Delta E_1 < \Delta E_2$) are, in principle, probable within these three levels. All these energy parameters have been computed (Table 3) using the observed g values, the g-tensor theory of low-spin d^5 complexes [19], and a reported method [20]. The axial distortion is found to be around 6000 cm^{-1}.[4] The calculated values of ΔE_1 and ΔE_2 are also close to ~6000 cm^{-1} (~1670 nm), which indicate that two ligand-field transitions, which are close in energy, should take place in the near-infrared region, and indeed a broad band of weak intensity has been observed in the spectra of all the complexes near the predicted energy (*vide infra*). Closeness of the two expected transitions appears to have vitiated their resolution. The ESR spectral data thus show that these $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ complexes are significantly distorted from the ideal octahedral geometry, as was also indicated by the structure determination.

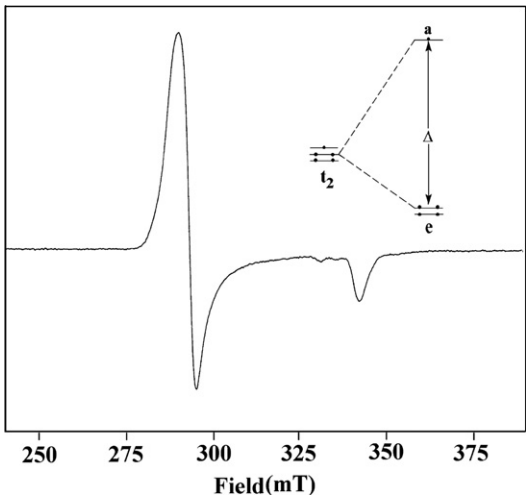

Fig. 7. ESR spectrum of the $[Ru^{III}(trpy)(L\text{-}Cl)]ClO_4$ complex in 1:1 dichloromethane–toluene solution at 77 K.

Electronic spectra of the green $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ complexes, recorded in acetonitrile solutions, show absorptions in the near-infrared, visible and ultraviolet regions (Table 4). The absorptions in the ultraviolet region are again believed to be due to transitions within the ligand orbitals. To understand the origin of the absorptions in the visible region, qualitative EHMO calculations have been performed on the structurally characterized $[Ru^{III}(trpy)(L\text{-}CH_3)]ClO_4$ complex. Composition of selected

[4] The spin–orbit coupling constant (λ) is taken to be 1000 cm^{-1} for complexed ruthenium(III) [20].

Table 3
ESR g-values[a] and derived parameters[b] of the $[Ru^{III}(trpy)(L\text{-}R)]ClO_4$ complexes

Compounds	$g_\perp$	$g_\parallel$	Δ, λ	ΔE_1, λ	ΔE_2, λ
$[Ru^{III}(trpy)(L\text{-}OCH_3)]ClO_4$	2.209	1.921	6.219	5.891	6.805
$[Ru^{III}(trpy)(L\text{-}CH_3)]ClO_4$	2.217	1.916	6.050	5.727	6.638
$[Ru^{III}(trpy)(L\text{-}H)]ClO_4$	2.222	1.914	5.988	5.667	6.577

[a] In dichloromethane.
[b] Shoulder.

molecular orbitals is given in Table S2 (Supplementary material) and partial MO diagram is shown in Fig. 8. In this complex, the HOMO (singly occupied), HOMO − 1 and HOMO − 2 are found to have large contributions (nearly 60%) from ruthenium d_{xy}, d_{yz} and d_{xz} orbitals, while the HOMO − 3 has predominant terpyridine character. The absorption near 650 nm may therefore be assigned to a ligand-to-metal charge-transfer transition from HOMO − 3 to HOMO (singly occupied). The weak absorption in the near-infrared region (near 1600 nm) has already been assigned to ligand-field transitions (*vide supra*).

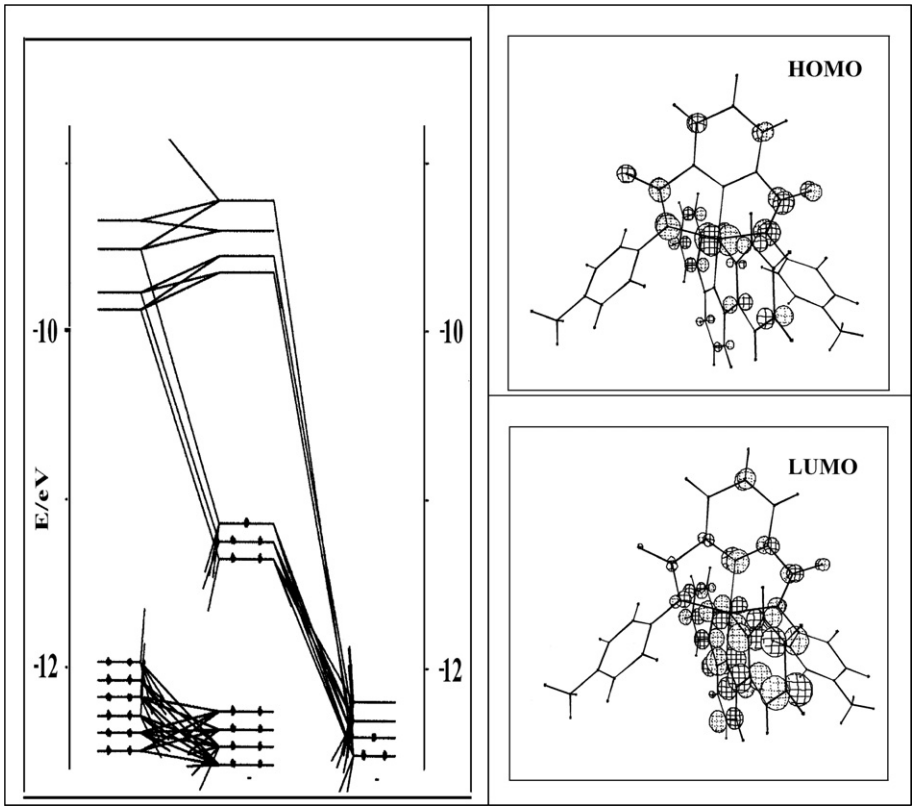

Fig. 8. Partial MO diagram of the $[Ru^{II}(trpy)(L\text{-}CH_3)]ClO_4$ complex.

3.2.3. Electrochemical properties

Cyclic voltammetric properties of the $[Ru^{III}(trpy)(L\text{-}R)]^{+}$ complexes are identical to those of their Ru(II) precursors, only the Ru(II)–Ru(III) couple appears as a reductive response. The green $[Ru^{III}(trpy)(L\text{-}R)]^{+}$ complexes could be quantitatively converted back, upon coulometric reduction at 0.0 V, to the respective brown $[Ru^{II}(trpy)(L\text{-}R)]$ complexes, identified by their characteristic electronic spectra. In terms of their Ru(II)–Ru(II) reduction potentials, these green $[Ru^{III}(trpy)(L\text{-}R)]^{+}$ complexes are very mild oxidants.

4. Conclusions

The present study shows that the *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamides (**3**) can efficiently bind to ruthenium(II) in the dianionic N,N,N-fashion (**4**) and in combination with 2,2′,2″-terpyridine can stabilize the metal in its +2 state. This study further demonstrates that binding by the amides (**3**) in the N,N,N-fashion (**4**) can also sufficiently stabilize the +3 oxidation state of ruthenium. The coordination environment provided by the *N*,*N*′-bis(aryl)pyridine-2,6-dicarboxamides and 2,2′,2″-terpyridine appears to be unique in supporting both the +2 and +3 states of ruthenium.

Abstract

Dibutylmagnesium (contaminated with $Al(n\text{-}Bu)_3$; n_{Mg}:n_{Al} ca. 1:0.2) was found to react with $MeOCH_2CH_2OH$ followed by the addition of PhSCH(Me)Ph in the presence of 0.2 equiv *n*-butyllithium yielding $[Mg_7(\mu_3\text{-}OCH_2CH_2OMe)_6(\mu\text{-}OCH_2CH_2OMe)_6][Al(n\text{-}Bu)_4]_2$ (**1**) as the principal product (yield 40–45% referred to $MeOCH_2CH_2OH$). The single-crystal X-ray diffraction analysis revealed that the centrosymmetric cationic heptamagnesium complex is built up from seven edge-shared MgO_6 octahedra. The $[Al(n\text{-}Bu)_4]^-$ anions adopt approximately a tetrahedral AlC_4 symmetry. ^1H, ^{13}C and ^{27}Al NMR spectroscopic measurements showed that in THF solution the structures both of the heptamagnesium complex and the tetrabutylaluminate anion are preserved and that there are no cation–anion interactions reducing the symmetry. The ^{27}Al resonance (151.6 ppm) was found to be very sharp ($w_{1/2} = 5$ Hz), the coupling constant $^1J(^{27}Al,^{13}C)$ amounts to 72.3 Hz.

Keywords: Magnesium complexes; Oligonuclear complexes; Alkyl aluminates; ^{27}Al NMR spectroscopy; Crystal structures

1. Introduction

Metal alkoxides – among them magnesium alkoxides – have drawn increasing attention not only in chemical vapour decomposition processes but also as catalyst components for olefin polymerization or metathesis processes [1–4]. In this context, crystalline oligonuclear complexes – both monometallic and mixed-metal complexes – may have serious advantages due to their definite stoichiometry and structures. In the case of magnesium, bidentate alkoxo ligands of the types $RO\overset{\frown}{\ }O^-$ (**I**; $\overset{\frown}{\ } = C_2$ spacer) have been successfully used to build up oligonulcear magnesium complexes. Examples are the tetranuclear complexes ($[Mg_4(OCHMeCH_2OMe)_8]$ [5], $[Mg_4(THFFO)_6Cl_2]$ [6], $[Mg_4(DDBFO)_8]$ [7], $[Mg_4(OMe)_2(DDBFO)_6(MeOH)_5]$ [7]), the heptanuclear complex $[Mg_7(DDBFO)_{12}][FeCl_4]$ [8] and bimetallic complexes of the type $[Mg_4(THFFO)_6X_2]$ having terminal Ti and Si containing ligands X, respectively [7,9]. In all these complexes the ligands **II**–**IV** are bound with different coordination modes to the magnesium centres acting as bridging (μ_3,μ), chelating and/or as terminal ligands.

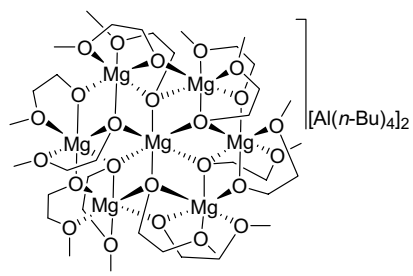
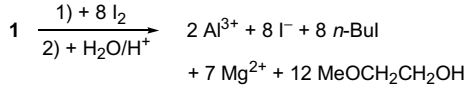
Here we report on a heptanuclear magnesium complex with the most simple bidentate alkoxo ligand of type **I**, namely with the 2-methoxyethoxo ligand ($MeOCH_2$-CH_2O^-). The complex $[Mg_7(OCH_2CH_2OMe)_{12}][Al(n\text{-}Bu)_4]_2$ (**1**) was obtained as the main product in a reaction that was directed to the metallation of a thioether using $MeOCH_2$-CH_2OMgBu/*n*-BuLi. As source of the aluminium a severe impurity of, likely, $Al(n\text{-}Bu)_3$, in the magnesiumdibutyl used has been identified.



2. Results and discussion

2.1. Synthesis



With the objective to metallate 1-(phenyl)ethyl phenyl sulfide (PhSCH(Me)Ph) with $MeOCH_2CH_2OMgBu$ yielding $MeOCH_2CH_2OMgC(Me)(Ph)SPh$, we let react in an one-pot reaction dibutylmagnesium with 2-methoxyethanol (1:1) followed by the addition of 1 equiv. PhSCH(Me)Ph and a substoichiometric amount (0.2 equiv.) of *n*-butyllithium. The synthesis resulted in the formation of a larger amount of well-shaped colourless crystals. Unexpectedly, single-crystal X-ray diffraction measurements revealed them to have the composition $[Mg_7(\mu_3\text{-}OCH_2CH_2OMe)_6(\mu\text{-}OCH_2CH_2OMe)_6][Al(n\text{-}Bu)_4]_2$ (**1**) consisting of a cationic heptamagnesium complex and tetra(*n*-butyl)aluminate anions (Scheme 1).

Analytical investigations of all starting materials made unambiguously clear that the source for the aluminium is the "dibutylmagnesium" solution in heptane that contained a considerable amount of aluminium (n_{Mg}:n_{Al} ca. 1:0.2) most likely as $Al(n\text{-}Bu)_3$. Although PhSCH(Me)Ph is not a constituent part of complex **1**, in the absence of the sulfide no formation of the complex was observed. All these findings prompted us to investigate the constitution of complex **1** carefully and independently from the X-ray crystallographic measurements.

Complex **1** is a colourless, air- and moisture-sensitive crystalline substance. It is the main product of the synthesis; the isolated yield of **1** is 40–45% referred to methoxyethanol. Furthermore, 40–45% and about 30% of the total amount of Al and Mg, respectively, were found in the complex **1**. In tetrahydrofuran complex **1** was found to react with iodine with cleavage of the Al–C bonds yielding AlI_3/I^- and butyliodide (Scheme 1). Iodometric titration (using an excess of I_2 and back titration of the surplus I_2 with $Na_2S_2O_3$) exhibited a very good agreement between the experimentally found consumption of I_2 (16.07 ± 0.36 mol I/mol **1**) and the calculated one (16.00 mol I/mol **1**). Furthermore, the constitution of complex **1** was unambiguously proven by the results of microanalysis as well as by ^1H, ^{13}C and ^{27}Al NMR investigations.

Scheme 1.

2.2. Structure

Crystals of compound **1** consist of tetra(*n*-butyl)aluminate anions and twofold-positively charged $[Mg_7(\mu_3\text{-}OCH_2CH_2OMe)_6(\mu\text{-}OCH_2CH_2OMe)_6]^{2+}$ cations that are shown in Fig. 1. Selected bond lengths and angles are given in Table 1. The filling of the unit cell in crystals of **1** is shown in Fig. 2. There are no specific cation–anion, cation–cation or anion–anion interactions; the shortest contacts between non-hydrogen atoms are 3.553(4) Å (C3···C19′), 3.851(4) Å (C2···C9′) and 3.962(5) Å (C30···C30′), respectively.

The $[Al(n\text{-}Bu)_4]^-$ anions adopt approximately a tetrahedral AlC_4 symmetry; all C–Al–C angles (108.9(1)–110.1(1)°) are very close to the tetrahedral one. The Al–C distances range from 2.006(3) to 2.024(3) Å (mean value: 2.014 Å). They are slightly longer than those in tetracoordinated organoaluminium compounds having the fragment "Al–R" (R = ethyl–butyl): median: 1.972 Å, lower/upper quartile: 1.955/1.991 Å, $n = 369$ (n – number of observations) [10].

The cation $[Mg_7(\mu_3\text{-}OCH_2CH_2OMe)_6(\mu\text{-}OCH_2CH_2OMe)_6]^{2+}$ exhibits crystallographically imposed inversion symmetry; overall, the symmetry is close to the point group S_6. The seven magnesium atoms build up a puckered hexagon with the magnesium atom Mg1 in the centre. Deviations of Mg2–Mg4 from the Mg_7 mean plane are between ±0.1586(8) and ±0.1595(7) Å. All Mg···Mg distances between neighboured magnesium atoms are between 3.1042(8) and 3.135(1) Å. Thus, the Mg···Mg separation is in a range that is expected for $[Mg^{II}O_6]$ coordination as found, for example, in the NaCl-type lattice of MgO (2.980 Å) [11]. Each three of the six Mg–μ_3-O bridging oxygen atoms lie above and below of the Mg_7 plane such that the central magnesium atom Mg1 adopts approximately an octahedral O_6 coordination (Mg1–O: 2.089(1)–2.099(2) Å; O–Mg1–O: 83.34(6)–96.66(6)°). Each of the six μ-O atoms bridges two peripheral magnesium atoms. Thus, each of them is coordinated by two μ-O and two μ_3-O bridging atoms as well as by two terminal ether oxygen atoms. Thus, all magnesium atoms are surrounded by six oxygen atoms and the Mg_7O_{24} unit is built up by seven MgO_6 octahedra linked by sharing edges (Fig. 1c). Comparison of the Mg–O bond lengths revealed the order Mg–μ-O (1.979(2)–2.019(2) Å) < Mg–μ_3-O (2.080(2)–2.122(2) Å) < $Mg\text{–}O_{terminal}$ (2.150(2)–2.205(2) Å).

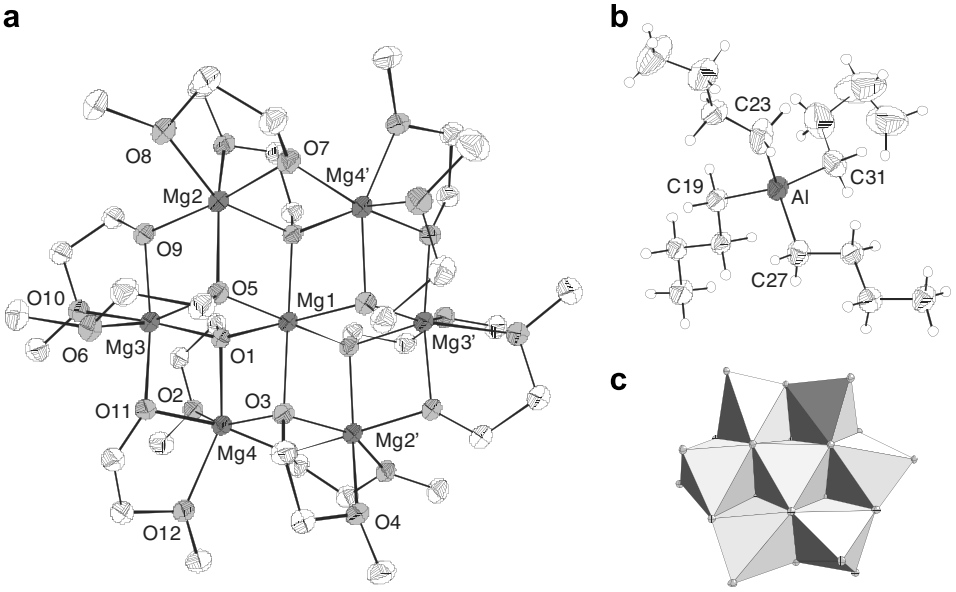

Fig. 1. Molecular structure of the cation (a) and anion (b) in crystals of $[Mg_7(\mu_3\text{-}OCH_2CH_2OMe)_6(\mu\text{-}OCH_2CH_2OMe)_6][Al(n\text{-}Bu)_4]_2$ (**1**) (displacement ellipsoids at 30 % probability; hydrogen atoms of the cation are omitted). (c) Structure of the Mg_7O_{24} unit in crystals of **1** shown as edge-shared MgO_6 octahedra.

An analogous heptamagnesium complex with the bidentate alkoxo ligand $THFFO^{\ominus}$ (THFFOH: 2-tetrahydrofurfuryl alcohol) has been found in $[Mg_7(\mu_3\text{-}THFFO)_6(\mu\text{-}THFFO)_6][FeCl_4]\cdot 3CH_2Cl_2$ (**2**) prepared by the reaction of $Mg(THFFO)_2$ with $FeCl_2\cdot 1.5THF$ [8]. The cation in **2** has crystallographically imposed C_3 symmetry. It is worth noting that a tetranuclear magnesium complex, $[Mg_4(\mu_3\text{-}OCHMeCH_2OMe)_2(\mu\text{-}OCHMeCH_2OMe)_2(OCHMeCH_2OMe)_2]$, has been obtained with the 2-methoxypropoxo ligand that is structurally closely analogous to the ligand in the heptanuclear complex **1** [5]. In lithium and sodium tetraalkylaluminate complexes ($M[AlR_4]$, M = Li, Na; R = Me, Et, *n*-Pr) cation–anion contacts were found through Al–C–M bridges and/or agostic α-C–H···M interactions [12–14] and, likely, also in tetramethylaluminates of K, Rb and Cs [15,16]. On the other hand, tetraalkylaluminates were found to crystallize in discrete ions with bulky counter cations such as $[K(pmdta)_2][AlMe_4]$ [17], $[CoMe_2(bpy)_2][AlEt_4]$ [18] and $[Yb(\eta^5\text{-fluorenyl})(THF)_4][AlMe_4]$ [19]. In complex **1**, the bulkiness of the heptamagnesium complex cation having coordinatively saturated magnesium centres seems to be decisive to prevent cation–anion interactions. Recently, the solid-state structure of a complex was reported in which interstitial $[Mg(n\text{-}Bu)_4]^{2-}$ dianions within a polycationic network were found [20].

2.3. Spectroscopic investigation

^1H, ^{13}C and ^{27}Al NMR investigations confirm the constitution of complex **1**. All spectra show the expected signals; ^1H NMR signals exhibited the correct intensities. The assignment of the signals of the tetrabutylaluminate anion has been established by H,H and H,C COSY experiments. The signal of the α-C atom of the butyl group is split into six lines of equal intensity as expected for coupling with one ^{27}Al nucleus ($I = 5/2$, nat. abundance:

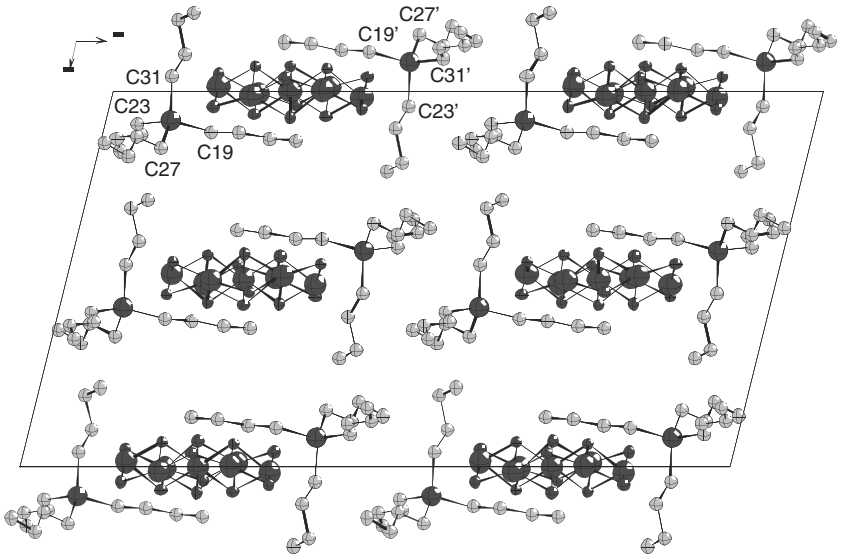

Fig. 2. View of the packing of cations (only the cluster core is shown) and anions in crystals of **1** along the monoclinic *b* axis.

100%), see Fig. 3. The coupling constant $^{1}J(^{27}Al,^{13}C)$ was found to be 72.3 Hz that is fully consistent with that in $[AlEt_4]^-$ (73.2 Hz) [21] and in $[AlMe_4]^-$ (71.2 Hz) [22]. Due to the very sharp resonance signals (see below), the Al–C coupling constant could also be obtained from the ^{13}C satellites in the ^{27}Al NMR spectrum.

The chemical shift (151.6 ppm) of the signal in the ^{27}Al NMR spectrum gives proof of tetracoordinated aluminium. Typical shift range of tetracoordinated aluminium is 125–180 ppm whereas in three- and fivecoordinated aluminium chemical shifts from 210 to 280 ppm and from 100 to 125 ppm, respectively, were found [23]. For quadrupole nuclei like ^{27}Al ($I = 5/2$) line broadening of NMR resonances is characteristic. Only in the case of highly symmetric ligand spheres, signals with normal line widths are observed [24]. Thus, the very sharp signal having a half line width of only 5 Hz indicates a much longer T_2 relaxation time. This suggests that the aluminium atom has local tetrahedral symmetry. The results of the NMR experiments show that in THF solution the structures both of the heptamagnesium complex and the tetrabutylaluminate anion are preserved and that there are no cation–anion interactions reducing the symmetry.

In conclusion, complex **1** is the first example of an oligonuclear main group metal complex with a tetraalkylaluminate counter anion that crystallizes in discrete ions and one of the few examples where the high symmetry of the tetraalkylaluminate anion is preserved even in THF solution exhibiting that the molecules exist, most likely, as solvent-separated ion pairs [25].

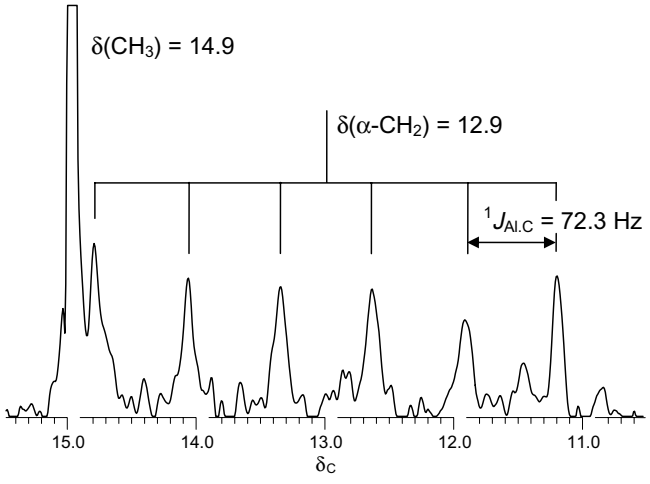

Fig. 3. 101 MHz ^{13}C NMR spectrum of **1** in THF-d_8 showing the resonance of the aluminium bound carbon atoms.

3. Experimental

3.1. General considerations

All reactions were performed under Ar atmospheres using standard Schlenk techniques. Toluene and THF were distilled from Na/benzophenone prior to use. Methoxyethanol was distilled under argon prior to use. NMR spectra were recorded on Varian VXR 400 and Unity 500 NMR spectrometers. Chemical shifts are relative to solvent signals (^1H, ^{13}C) as internal references and $Al(NO_3)_3$ (1 M in D_2O) as external reference (^{27}Al), respectively. PhSCH(Me)Ph was prepared according to [26] and *n*-BuLi (Aldrich) was used as supplied. $MgBu_2/Al(n\text{-}Bu)_3$ was purchased from Fluka (handled over Aldrich) supplied as dibutylmagnesium solution (1 M in heptane); the synthesis of **1** described below was reproducible with different bottles of the reagent. Hydrolysis of an aliquot followed by evaporation of all solvents in vacuo revealed a ratio of $n_{Mg}:n_{Al}$ ca. 1:0.2 (determined by X-ray fluorescence analysis using a RFA SRS 3000).

3.2. Synthesis of $[Mg_7(OCH_2CH_2OMe)_{12}][Al(n\text{-}Bu)_4]_2$ (1)

To $MgBu_2/Al(n\text{-}Bu)_3$ (8 mmol) in heptane/toluene (7/15 ml) methoxyethanol (8 mmol) was dropwise added. The reaction mixture was stirred for 20 min at room temperature. Then, PhSCH(Me)Ph (8 mmol) and after 10 min tetrahydrofuran (3 ml) were added by means of syringes. After about 1 h *n*-BuLi (1.6 mmol) in *n*-hexane (1 ml) was dropwise added with stirring. Standing (without stirring) for 12–24 h resulted in precipitation of well-shaped colourless crystals that were used for single-crystal X-ray diffraction measurements or were filtered off, washed with diethyl ether (5×2 ml) and dried in vacuo. Yield: 430–470 mg (40–45% referred to methoxyethanol).

$C_{68}H_{156}Al_2Mg_7O_{24}$ (1582.05) requires C 51.62; H 9.94. Found: C 51.01; H 9.82%. ^{1}H NMR (THF-d_8, 400 MHz): δ −0.43 (br, 2H, α-CH_2, butyl), 0.81 (t, 3H, CH_3, butyl), 1.20 ('tq', 2H, γ-CH_2, butyl), 1.35 (br, 2H, β-CH_2, butyl), 3.48 ('dd', 1H, CH_2), 3.54 ('dd', 1H, CH_2), 3.58 (s, 3H, OCH_3), 3.71 (s, 3H, OCH_3), 3.78 (m, 3H, CH_2), 3.88 ('dd', 1H, CH_2), 3.99 ('dt', 1H, CH_2), 4.19 ('dt', 1H, CH_2). H,H COSY spectrum revealed that signals at 3.48, 3.78 (1H), 3.88, 4.19 ppm and at 3.54, 3.78 (2H), 3.99 ppm belong to the same CH_2CH_2 moiety. ^{13}C NMR (THF-d_8, 101 MHz): δ 12.9 (sextet, $^1J(^{27}Al,^{13}C) = 72.3$ Hz, α-*C*H_2, butyl), 14.9 (s, *C*H_3, butyl), 31.0 (s (br), γ-*C*H_2, butyl), 32.5 (s, β-*C*H_2, butyl), 59.4/59.6 (s/s, $2 \times$ O*C*H_3), 61.9/62.8/75.5/76.6 (s/s/s/s, $4 \times$ *C*H_2). ^{27}Al NMR (THF-d_8, 130 MHz): δ 151.6 (s + d, $w_{1/2} = 5$ Hz, $^1J(^{27}Al,^{13}C) =$ 73 Hz). Two smaller signals (impurities) were found at 151.0 and 152.3 ppm.

3.3. Iodometric titration of 1

Under strictly anaerobic conditions, a Schlenk tube was filled with a standard solution of iodine in THF (25.0 ml; 0.025 M), additional THF (200–250 ml) and an ampoule containing 45–75 mg of **1**. Then, the ampoule was broken. After few minutes the Schlenk tube was opened, water (ca. 50 ml) was added and the excess of iodine was titrated with $Na_2S_2O_3$ (0.05 M) using starch as indicator.

3.4. X-ray crystal structure determination of 1

Intensity data of a suitable crystal ($0.54 \times 0.53 \times 0.31$ mm) were collected on a STOE IPDS2 diffractometer at 150(2) K with Mo–Kα radiation (0.71073 Å, graphite monochromator). A summary of the crystallographic data, the data collection parameters, and the refinement parameters is given in Table 2. Absorption correction was carried out numerically (T_{min}/T_{max} 0.90/0.95). The structure was solved by direct methods using SHELXS-97 and refined with full-matrix least-squares routines against F^2 using SHELXL-97 [27]. All non-H atoms were refined with anisotropic displacement parameters. The H atoms were added to the model in their calculated positions according to the riding model and refined isotropically.

Abstract

A series of conformationally rigid half-sandwich organoruthenium(II) complexes with the general formula [(η^6-*p*-cymene)RuCl(L)] (where L = mono anionic 2-(naphthylazo)phenolato ligands) have been synthesized from the reaction of [{(η^6-*p*-cymene)RuCl}$_2$-(μ-Cl)$_2$] with a set of 2-(naphthylazo)phenolato O,N-donor ligands. All the ruthenium complexes were fully characterized by FT-IR, ^{1}H NMR, and UV–Vis spectroscopy as well as elemental analysis. In dichloromethane solution all the metal complexes exhibits characteristic metal-to-ligand charge transfer bands (MLCT) and emission bands in the visible region. The molecular structure of one of the complexes [Ru(η^6-*p*-cymene)(Cl)(L2)] (**2**) was determined by X-ray crystallography. Electrochemical data of all the ruthenium complexes show a two metal centered voltammetric responses with respect to Ag/AgCl at scan rate 100 mV s^{-1}. Further, the complex (**2**) efficiently catalyzes the oxidation of a wide range of alcohols to their corresponding carbonyl compounds in the presence of *N*-methylmorpholine-*N*-oxide (NMO) up to 97%.

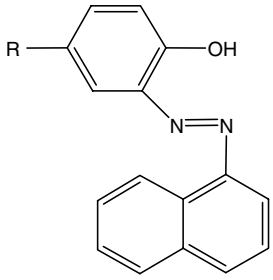
Keywords: (η^6-*p*-Cymene)-ruthenium(II) complexes; Spectra; Crystal structure; Redox property; Oxidation of alcohols



1. Introduction

For many decades arene ruthenium complexes are playing important role in organometallic chemistry [1]. There has been an increasing interest in the chemistry of half-sandwich organoruthenium(II) complexes due to numerous application in new catalytic systems for a variety of organic transformations [2,3]. Ruthenium(II)-arene complexes display a three-legged piano stool structure in which the metal center has a quasi-octahedral geometry were occupied by an arene ligands. This structural feature opens the possibility to introduce in the molecule two types of stereogenic centers: the metal and ligands. The O,N-donor type of ligands have been prepared to optimize the catalytic potential of their metal complexes [4]. It is well-known that the uses of nitrogen containing ligands lead to an increased catalytic activity [5]. Many methods for specific catalytic oxidation of various organic substrates such as alcohols, amines, amides and hydrocarbons have been studied extensively using low-valent metal complex catalysts [6,7]. It is to be noted that ruthenium compounds are intensively studied transition metal compounds and many methodologies have been developed with them [8–10]. Ru-based oxidation catalysis is a powerful and extremely versatile synthetic tool to afford selectively oxygenate products both in homogeneous and in heterogeneous conversions [11–14].

In early studies Oshima and co-workers reported that primary alcohols are selectively oxidized to aldehydes in the presence of secondary ones by using stoichiometric $Ru(PPh_3)_3Cl_2$ or a $Ru(PPh_3)_3Cl_2$ and TMSOOTMS system [15]. Ishii and co-workers successfully achieved aerobic

oxidation using $Ru(PPh_3)_3Cl_2$ as the catalyst in the presence of hydroquinone without diminishing chemoselectivity [16]. Though several ruthenium catalytic systems have been reported with a wide range of oxidants viz., *tert*-butyl hydroperoxide [17], chloramine-T [18], benzoquinone [19], hydrogen peroxide [20], molecular oxygen [21], iodosylbenzene [22] and $NaIO_4$ [23], *N*-methylmorpholine-*N*-oxide (NMO) as oxidant is less covered in the literature. To the best of our knowledge there are no reports available on catalytic oxidation of alcohols by (η^6-*p*-cyemene)ruthenium(II) 2-(naphthylazo)phenolato complexes incorporating N,O-donors in presence of NMO.

In this paper, we report the synthesis, characterization of (η^6-*p*-cyemene)Ru(II) complexes containing naphthylazophenolato ligands (Scheme 1). The molecular and electronic structure of the bivalent complexes are probed with the help of X-ray crystal structure in combination with spectral and emission studies. The redox properties of the complexes are monitored by cyclic voltammetry. Further, the catalytic activity of the (η^6-*p*-cyemene)Ru(II) complexes are investigated in the case of oxidation of primary and secondary alcohols in presence of NMO as oxidant.

2. Experimental

2.1. Materials and physical measurements

All the reagents used were chemically pure or analytical reagent grade. Solvents were purified and dried according to standard procedures. $RuCl_3 \cdot 3H_2O$ was purchased from Loba Chemie Pvt. Ltd., Bombay, India and was used without further purification. The alcohols and their corresponding ketones or aldehydes, which were used in the catalytic studies, were purchased from Merck and Aldrich. The analysis of carbon, hydrogen and nitrogen were performed in Carlo-Erba 1106-model 240 Perkin Elmer analyzer at Sophisticated Test and Instrumentation Centre (STIC), Cochin University, Kochi, India. FT-IR spectra were recorded in KBr Pellets with a JASCO 200 plus spectrophotometer. A CARY 300 Bio UV–Vis Varian spectrophotometer was used to record the electronic spectra. ^1H NMR spectra were recorded on a Bruker 400 MHz instrument using tetramethylsilane (TMS) as an internal reference. Emission intensity measurements were carried out by using a Jasco FP-6500 spectrofluorimeter with 5 nm exit slit. Electrochemical measurements were made using a Princeton EG and G-PARC model potentiostat using a glassy carbon working electrode, Pt wire as counter electrode and all the potentials were referenced to Ag/AgCl electrode. Melting points were recorded with a Boetius micro-heating table and are uncorrected. The catalytic yields were determined using HP 6890 series GC-FID with a DP-5 column of 30 m length, 0.32 mm diameter and 0.25 μm film thickness. The ruthenium(II) precursor complex $[\{(\eta^6\text{-}p\text{-cymene})RuCl\}_2(\mu\text{-}Cl)_2]$, was prepared according to literature method [24]. The 2-(naphthylazo)phenolate ligands were prepared by coupling diazotized α-naphthylamine with *p*-substituted phenols [25].

2.2. Synthesis of (η^6-*p*-cymene)Ru(II) 2-(naphthylazo)phenolate complexes

Synthesis of (η^6-*p*-cymene)Ru(II) 2-(naphthylazo)phenolate complexes were carried out under strictly anhydrous conditions. The (*p*-cymene)ruthenium(II)complex $[\{(\eta^6\text{-}p\text{-cymene})RuCl\}_2(\mu\text{-}Cl)_2]$ (0.163 mmol; 0.100 g) and 2-(naphthylazo)phenolate ligands (HL1-HL5) (0.163 mmol; 0.042-0.047 g) were taken in 1:1 molar ratio in methanol and kept stirring for 3 h. Then the solvent was removed through vaccum, the dark red mass was dissolved in chloroform (15 ml) and filtered through short path of silica gel column to remove insoluble materials. The red solution was then concentrated into 2 ml, addition of excess hexane dark-red product separated out, washed with diethylether and dried in vaccum (yield: 65–70%).

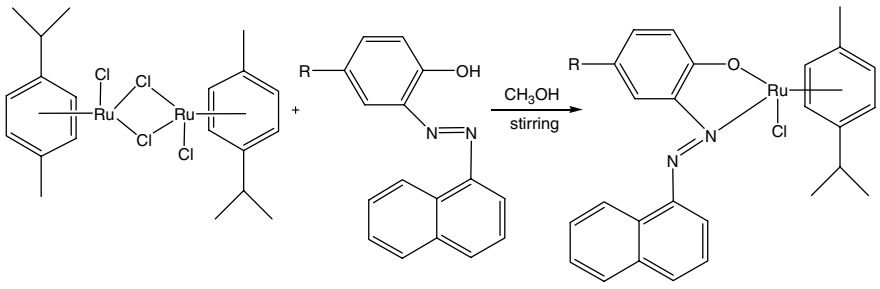
2.3. X-ray crystallography

Single crystals suitable for X-ray diffraction were grown from mixture of chloroform/acetonitrile solution at room temperature. The single crystals of suitable size was covered with Paratone oil, mounted on the top of a glass fiber, and transferred to a Stoe IPDS diffractometer using monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data were collected at 183 K. Corrections were made for Lorentz and polarization effects as well as for absorption (numerical). Structures were solved with direct method using SHELXS-97 or SIR-97 [26–28] and were refined by full-matrix least-squares method [29] on F^2 with SHELXL-97. Non-hydrogen atoms were refined with anisotropy thermal parameters. All hydrogen atoms were geometrically fixed and allowed to refine using a riding model.

2.4. Procedure for catalytic oxidation

Catalytic oxidation of primary alcohols to corresponding aldehydes and secondary alcohols to ketones by (η^6-*p*-cymene)Ru(II) 2-(naphthylazo)phenolate complex was studied in the presence of NMO. A typical reaction using the complex [(η^6-*p*-cymene)RuCl(L2)] (**2**) as a catalyst

and primary or secondary alcohol as substrates at 1:100 molar ratio is described as follows. A solution of ruthenium complex (**2**) (0.01 mmol) in 20 ml CH_2Cl_2 was added to the solution of substrate (1 mmol) and NMO (3 mmol). The solution mixture was refluxed for 3 h and the solvent was then evaporated from the mother liquor under reduced pressure. The reaction mixture containing the complex **2** and the oxidized product was then extracted with pet. ether (60–80 °C) (20 ml). The complex **2** was precipitated as solid mass on addition of pet. ether and was recovered quantitatively for next catalytic cycle. Further, the oxidized product was separated out along with pet. ether and was analyzed by GC.



3. Results and discussion

3.1. Synthesis and characterization

The reaction of 2-(naphthylazo)phenolate ligands with chloro-bridged (η^6-*p*-cymene) ruthenium complex [{(η^6-*p*-cymene)RuCl}$_2$(μ-Cl)$_2$] in methanol at room temperature in 1:1 molar ratio resulted in the formation of conformationally rigid new monomeric ruthenium(II) complexes (Scheme 2). The complexes were found to be air stable and are soluble in polar solvents such as dichloromethane and acetone, but insoluble in non-polar solvents such as pentane and hexane. The diamagnetic nature of all the complexes is consistent with the +2 oxidation state and low spin character of the metal ions in these complexes. Elemental analyses (C, H and N) were consistent with the composition proposed for all complexes (Table 1).

Infrared spectra of all the ligands displayed strong bands around 1425–1438 and 1275–1284 cm^{-1} corresponding to $\nu_{-N=N-}$ and phenolic ν_{C-O} stretching, respectively. After complexation $\nu_{-N=N-}$ appears at 1360–1390 cm^{-1} and the red shifting is corroborated with N(azo) coordination. The coordination through phenolic oxygen is confirmed by the increase of C–O at higher frequencies in the region 1290–1325 cm^{-1} in all the complexes (Table 2). This is further supported by the disappearance of ν_{OH} band in the range 3440–3457 cm^{-1} in all the complexes. Further, all the complexes show strong bands corresponding to ν_{M-N} and ν_{M-O} in the region 440–464 and 510–545 cm^{-1}, respectively. The ν_{M-Cl} stretching frequency has been observed for all the complexes in the region 320 cm^{-1} [30–32].

The ^{1}H NMR spectra of the complexes have been recorded in $CDCl_3$ solution to probe the solution structure (Table 3) and the representative spectrum is shown in Fig. 1. All the complexes show multiplets at δ 6.8–8.6 ppm for the presence of naphthylazo phenol ligands. The methyl protons appear as singlet and isopropyl protons appear as two doublets of the *p*-cymene ligand in the range of δ 2.1–2.2 ppm and δ 0.8–0.9 ppm, respectively. The isopropyl CH protons appear as a septet in the range of δ 2.4–2.5 ppm and the *p*-cymene ring protons are observed in the ranges of δ 3.6–5.7 ppm as either four doublets (4H) or two doublets (2H) and one singlet (2H). Additional methyl signals are observed as singlet for complex **2** at δ 2.1 and methoxy signals are observed as singlet for complex **3** at δ 4.0 ppm. A triplet observed for methyl protons for complex **4** at δ 1.45 ppm and OCH_2 protons

appeared as quartet in the region of 3.85 ppm. A sharp singlet appeared for OH protons of all the 2-(napthylazo) phenol ligands in the region δ 13.0 ppm was disappeared in all the complexes [33].

The electronic transition for all the complexes were recorded in dichloromethane solution and are listed in Table 2. All the (η^6-*p*-cymene) ruthenium(II) 2-(naphthylazo)phenolato complexes show three to four intense absorptions in the visible and ultraviolet region 613–252 nm. The intense absorption in the visible region at 613-592 nm and the absorption at 410–418 nm are probably due to metal-to-ligand charge transfer transitions. The charge transfer transitions taking place from the highest filled ruthenium t_2 orbital (highest occupied molecular orbital) to the vacant π^*(–N=N–) orbital of the 2-(naphthylazo)phenolato ligand (lowest unoccupied molecular orbital) or to the higher energy vacant orbitals of other fragment of ligands. It has been observed that many

charge-transfer transitions in such mixed-ligand complexes may result from the lower symmetry splitting of the metal level, the presence of different acceptor orbitals, and the mixing of singlet and triplet configurations in the excited state through spin–orbit coupling [34]. In addition, the other high intensity bands in the 330–252 nm regions were characterized by ligand-centered (LC) transitions taking place in the coordinated 2-(naphthylazo)phenolate ligands. The absorption in the ultraviolet region may be attributed to usual n–π^*, π–π^* transitions occurring within ligand orbitals. The pattern of the electronic spectra of all the complexes indicated the presence of an octahedral environment around ruthenium(II) ion, similar to that of other ruthenium(II) octahedral complexes [35].

The luminescent property of (η^6-*p*-cymene) ruthenium(II) complexes of ligand containing strong chromophoric groups often show in addition to intense MLCT transitions interesting luminescence properties [36,37], such properties have also been explored in the [(η^6-*p*-cymene)-RuCl(L)] complexes (Table 2). The luminescence studies were carried out in dichloromethane solution at ambient temperature (298 K). No emission was observed, when an excitation wavelength corresponding to the lowest energy absorption (~500 nm) was used. However, the excitation wavelength of ~400 nm was used, all the [(η^6-*p*-cymene)RuCl(L2)] complexes showed strong emission (Fig. 2) within 465–494 nm. This indicates that transition of a metal electron to metallated *p*-cymene ring (or) *p*-cresol ring leads to photochemical excited state, which is much more stable compared to excitation of metal electron to π^*(azo –N=N–) [38].

The structure of the compound (**2**) consist of neutral arene ring bonded to the ruthenium along with chloride and O,N-donors of 2-(napthylazo)phenolate ligands. The molecular structure of complex (**2**) with atom labeling scheme is shown in Fig. 3. The summary of single crystal X-ray structure refinement is shown in Table 4 and the selected bond parameters are presented in Table 5. The complexes crystallize in the *C*2/*c* space group. The *p*-cymene ligand is bonded to the ruthenium atom in η^6-fashion with ruthenium centroid of the ring being 1.710(4). The complexes adopt a typical three-legged piano stool conformation with N, O and Cl atoms as the legs. The 2-(naphthylazo)phenolate ligands bind the metal center at O and N forming the five membered chelate ring with bite angle 79.5(3) O(1)–Ru(1)–N(1) and bond lengths of Ru(1)–O(1) and Ru(1)–N(1) are 2.077(6) and 2.122(7), respectively. The Ru–Cl bond length is found to be 2.412(2). As all the complexes display similar spectral and electrochemical properties, the other four complexes are assumed to have similar structure to that of complex (**2**). The structural features correspond well with the reported Schiff base (*p*-cymene)ruthenium(II) complexes [39,40].

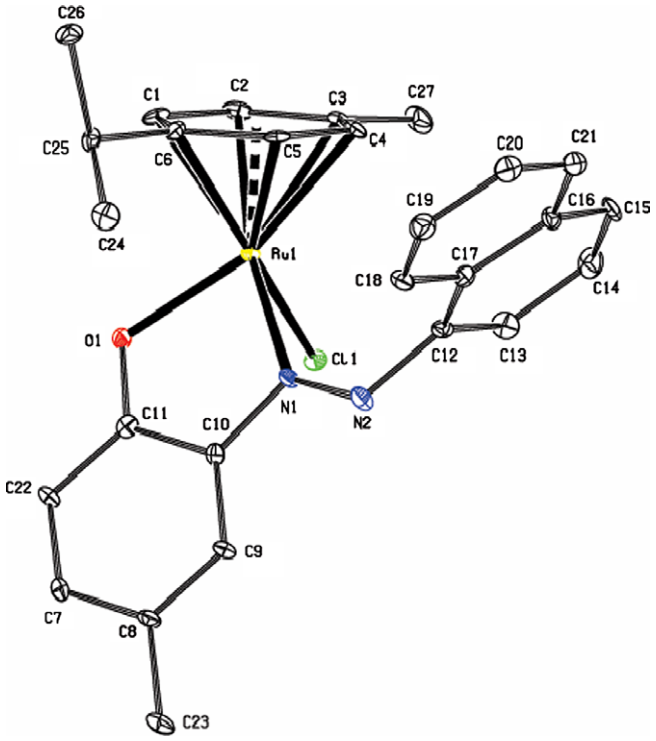

Fig. 3. Molecular structure of [Ru(η^6-*p*-cymene)(Cl)(L2)] (**2**), the hydrogen atoms were omitted for clarity.

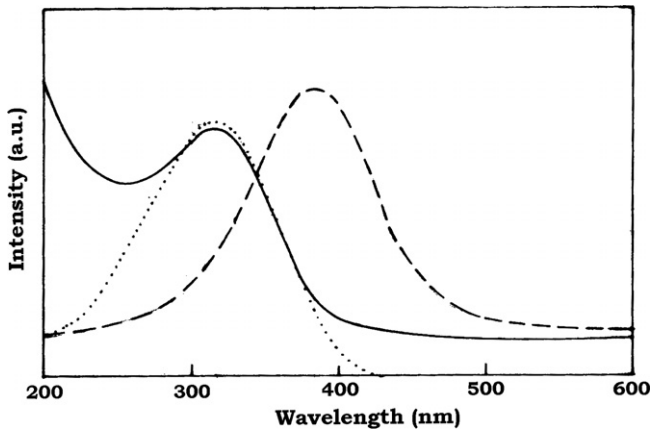

Fig. 2. Absroption (—), flurescence (- - -) and excitation (···) spectra of [Ru(η^6-*p*-cymene)(Cl)(L3)] (**3**).

The electrochemical property of all the complexes were studied by cyclic voltammetry. The electrochemical data are given in Table 6 and the representative voltammogram is shown in Fig. 4. Cyclic voltammogram of all the complexes were recorded in dichloromethane at glassy carbon working electrode and all the potentials are expressed with reference to Ag/AgCl. All the complexes (1×10^{-3}) show two metal centered voltammetric responses, a quasi-reversible oxidation (Ru^{III}/Ru^{II}) with $E_{1/2}$ values +0.89 to +1.07 V and an irreversible reduction with $E_{1/2}$ values −0.72 to −0.93 V with respect to the Ag/AgCl at scan rate 100 mV s^{-1}. The changes in oxidation and reduction potentials are probably due to the relative stabilization of the ruthenium(II) state over ruthenium(III) by a combination of σ and π effects exhibited by the ligand. The oxidation observed is quasi-reversible in nature, characterized by a

rather large peak-to-peak separation (ΔE_p) of 110–220 mV and cathodic peak current (i_{pc}) is less than the anodic peak current (i_{pa}). The one electron nature of this oxidation has been verified by comparing its current height (i_{pa}) with that of the standard ferrocene–ferrocenium couple under identical experimental conditions [41]. The oxidation at more positive and less negative are believed to be corresponding metal oxidation and metal reduction, respectively.

Table 6
Cyclic voltammetric data of (*p*-cymene)ruthenium(II) 2-(naphthylazo)-phenolate complexes

Complexes	Ru^{III}/Ru^{II}				Ru^{II}/Ru^{I}
	E_{pa} (V)	E_{pc} (V)	$E_{1/2}$ (V)	ΔE_p (mV)	E_{pc} (V)

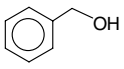
$$[(\eta^6\text{-}p\text{-cymene})Ru^{II}Cl(L)] \overset{\text{oxidation}}{\rightleftharpoons} [(\eta^6\text{-}p\text{-cymene})Ru^{III}Cl(L)] + e^-$$

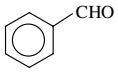
$$[(\eta^6\text{-}p\text{-cymene})Ru^{II}Cl(L)] + e^- \overset{\text{reduction}}{\rightleftharpoons} [(\eta^6\text{-}p\text{-cymene})Ru^{II}Cl(L)]^-$$

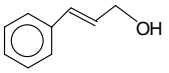
From the electrochemical data, it is inferred that the present ligand system is ideally suitable for stabilizing the higher oxidation state of ruthenium ion and the electron transfer reactions take place without gross changes in the stereochemistry of the complexes [42,43].

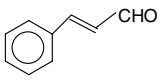
3.2. Catalytic oxidation

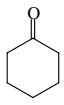
The catalytic performance of complex [(η^6-*p*-cymene)-RuCl(L2)] (**2**) has been evaluated in a classical oxidation system developed for the oxidation of primary and secondary alcohols in CH_2Cl_2 in the presence of NMO (Scheme 3). Complex (**2**) oxidizes primary alcohols to the corresponding aldehydes and secondary alcohols to ketones with high conversion and the results are listed in Table 7 (entries 1–15). The crude reaction mixture were quantitatively analyzed by gas chromatography with authentic samples after 3 and 8 h (entries 6 and 7) of reaction with complex (**2**). The catalytic activity of the complex was

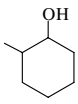


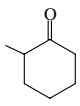


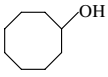


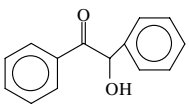


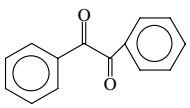








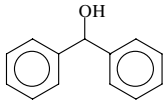


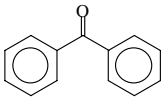


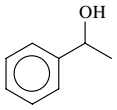
Scheme 3.

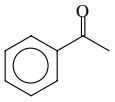
examined under a set of conditions (see Section 2 for reaction conditions) and a series of blank or control experiments suggest that none of ruthenium(II) 2-(naphthylazo)phenolate complexes and NMO alone causes these transformations under identical reaction conditions. This ascertained the necessity of ruthenium(II) complex to observe the ensuing catalytic organic transformations.

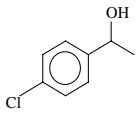
Results of the present investigation suggest that the complexes are able to react efficiently with NMO to yield high valent ruthenium-oxo species responsible for dehydrogenation of alcohols. This was further supported by spectral changes that occur by addition of NMO to a dichloromethane solution of the ruthenium(II) complexes. The appearance of peak at 390 nm is attributed to the formation of Ru^{IV}=O species, which is in conformity with other oxo ruthenium(II) complexes [44–46]. Further support in favor of the formation of such species was identified from the IR spectrum of the solid mass (obtained by evaporation of the resultant solution to dryness), which showed a band at 860 cm^{-1}, characteristic of Ru^{IV}=O species [45–47]. The *N*-methylmorpholine and water are the by products during the course of the reaction.

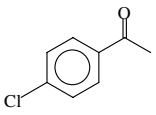


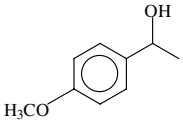


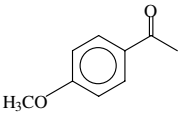


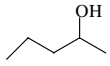


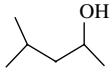












In the present study of oxidation, the catalytic oxidation of benzyl alcohol to benzaldehyde consequences 77%

conversion. An important characteristic of ruthenium NMO system results in the selective oxidation at alcoholic group of unsaturated cinnamyl alcohol to cinnamaldehyde yielded >94% to tolerating other functional groups (double bond). The complex effectively catalyze the oxidation of allylic and benzylic alcohols with maximum selectivity to aldehydes with, importantly, no further oxidation to the corresponding carboxylic acids. Unsaturated aliphatic alcohols such as butan-2-ol, methylpropyl carbinol and isobutyl methyl carbinol are converted to corresponding ketones with high conversion >94%. In case of saturated aromatic secondary alcohols such as 1-phenyl ethanol, 4-chloro-1-phenyl ethanol and 4-methoxy-1-phenyl ethanol to undergo significant oxidation to give their corresponding ketones with high selectivity with 88%, 96% and 92%, respectively. The higher conversion in case of 4-chloro-1-phenyl ethanol and 4-methoxy-1-phenyl ethanol when compared to the 1-phenyl ethanol is due to the presence of substituents in the *para* position, which increase the reactivity by destabilizing the ruthenium-oxo intermediate making it a more reactive oxidant [48].

Further, the complex effectively catalyzes benzhydrol and benzoin to corresponding ketones. Particularly, in the case of benzoin the oxidation product was isolated and characterized by melting point, IR and ^{1}H NMR. In view of comparison, oxidation of benzoin was carried out in presence of *t*-BuOOH and H_2O_2 in addition to NMO. It was found that

the conversions are poor (Table 7) when compared to ruthenium/NMO catalytic system. Moreover, the complex efficiently catalyze the five, six, substituted six membered, seven and eight membered cyclic alcohols into corresponding ketones with high conversion >83%. It has been observed that the complex **2** has better catalytic efficiency in the case of oxidation of primary and secondary alcohols when compared to similar ruthenium complexes as catalysts in the presence of NMO/*t*-BuOOH reported earlier [44–49].

4. Conclusions

In conclusion, we have synthesized and characterized five mononuclear half-sandwich organoruthenium(II) naphthylazophenolato complexes. Complex **2** was structurally characterized by X-ray crystallography, which witnessed a typical three-legged piano stool conformation with N, O and Cl atoms as the legs. All the complexes exhibit characteristic metal-to-ligand charge transfer (MLCT) absorption and emission bands in the visible region. Further, the complex **2** efficiently catalyze the oxidation of variety of primary and secondary alcohol to the corresponding oxidized products in the presence of NMO.

Abstract

Treatment of $[Co_2(CO)_6(\mu\text{-}\eta^2\text{-}HOCH_2C{\equiv}CCH_2OH)]$ (**1a**) with a catalytic quantity of $HBF_4 \cdot OEt_2$ affords $[\{Co_2(CO)_6\}_2\{cyclo\text{-}\mu\text{-}\eta^2\text{:}\mu\text{-}\eta^2\text{-}OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2\text{–}\}]$ (**2**) and $[\{Co_2(CO)_6\}_3\{cyclo\text{-}\mu\text{-}\eta^2\text{:}\mu\text{-}\eta^2\text{:}\mu\text{-}\eta^2\text{-}OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2\text{–}\}]$ (**3**), in which cyclodimerisation and cyclotrimerisation of **1a** has occurred, respectively. The molecular structures of **2** and **3** reveal non-bonding oxygen–oxygen separations within the macrocycles of 4.716 Å (**2**) and 3.968–5.045 Å (**3**). On the other hand, introduction of one equivalent of the cyclohexyl-substituted diyne-diol, (1-HO-*cyclo*-C_6H_{10})$C{\equiv}CC{\equiv}C$(1-HO-*cyclo*-C_6H_{10}), to the reaction furnishes the macrocyclic complexes $[\{Co_2(CO)_6\}_2\{cyclo\text{-}\mu\text{-}\eta^2\text{:}\mu\text{-}\eta^2\text{-}OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2O(cyclo\text{-}C_6H_{10})C_2C_2(cyclo\text{-}C_6H_{10})\text{–}\}]$ (**4**) and $[\{Co_2(CO)_6\}_3\{cyclo\text{-}\mu\text{-}\eta^2\text{:}\mu\text{-}\eta^2\text{:}\mu\text{-}\eta^2\text{-}OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2O(cyclo\text{-}1\text{-}C_6H_{10})C_2C_2(cyclo\text{-}1\text{-}C_6H_{10})\text{–}\}]$ (**5**), in which the chain ends of the rigid 1,3-diyne unit are linked by either di- or tri-merised derivatives of **1a**. Also isolated in the reaction is the open-chain species $[\{Co_2(CO)_6\}_2(\mu\text{-}\eta^2\text{:}\mu\text{-}\eta^2\text{-}HOCH_2C{\equiv}CCH_2O(cyclo\text{-}1\text{-}C_6H_{10})C_2C_2(cyclo\text{-}1\text{-}C_6H_{10})\text{-}OCH_2C{\equiv}CCH_2OH)]$ (**6**). Inspection of the molecular structure of **4** reveals a 17-membered ring with the non-bonding oxygen–oxygen separations ranging from 4.958 to 7.257 Å.

Keywords: Cobalt complexes; Alkyne; Self-cyclisation; 1,3-Diyne; Macrocycle; Nicholas reaction

1. Introduction

The amenability of the Nicholas reaction [1] to facilitate the assembly of cyclic structures has been the topic of a number of studies [2–4] in recent years due, in some measure, to the association the resulting materials have to natural products [2–4], molecular sensors [5] and nanoscience [6]. In particular, the acid-catalysed intermolecular reactions of butyne-1,4-diol-$Co_2(CO)_6$ (**1a**, Fig. 1) with suitable bifunctional nucleophiles [e.g., alkyldithiols, bis(mercaptoalkyl)sulfides/ethers] has allowed access to a diversity of unusual macrocycles containing a range of donor atoms [7,8]. As an extension to these studies our group [9] and others [4,10,11] have been attracted by the potential of the more extended bis(propargyl alcohol/ether)-$\{Co_2(CO)_6\}_2$ substrates (e.g., **1b**, Fig. 1) to act as building blocks for larger cyclic systems incorporating diyne units. During the course of our study we have found that self-cyclisation can be a competitive side reaction when **1b** is treated with a co-reactant that displays only modest nucleophilicity (e.g., alkyl diols) [9d]. Indeed, when **1b** is treated with catalytic quantities of acid alone, the cyclodimerised crown-type species 1,8-dioxacyclotetradeca-3,5,10,12-tetrayne-$\{Co_2(CO)_8\}_4$ (Fig. 1) can be isolated as the sole product [9d].

In this paper, we are concerned with examining whether **1a** has a similar propensity to undergo acid-catalysed self-cyclisation reactions. Martin et al. have disclosed the formation of 1,6-dioxa-cyclodeca-3,8-diyne-$Co_2(CO)_6$ from

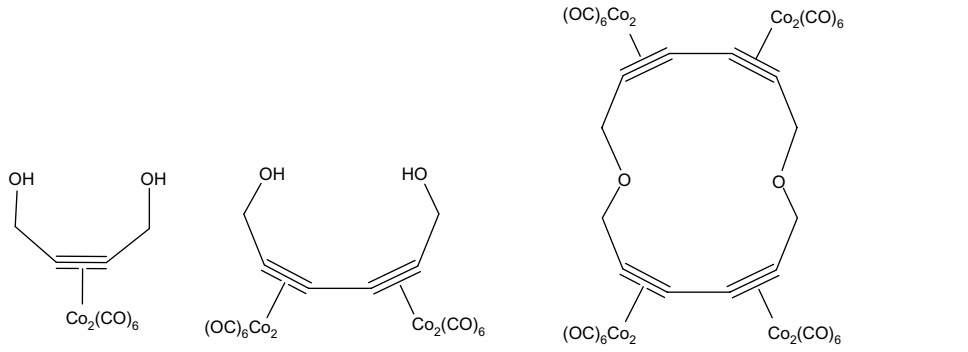

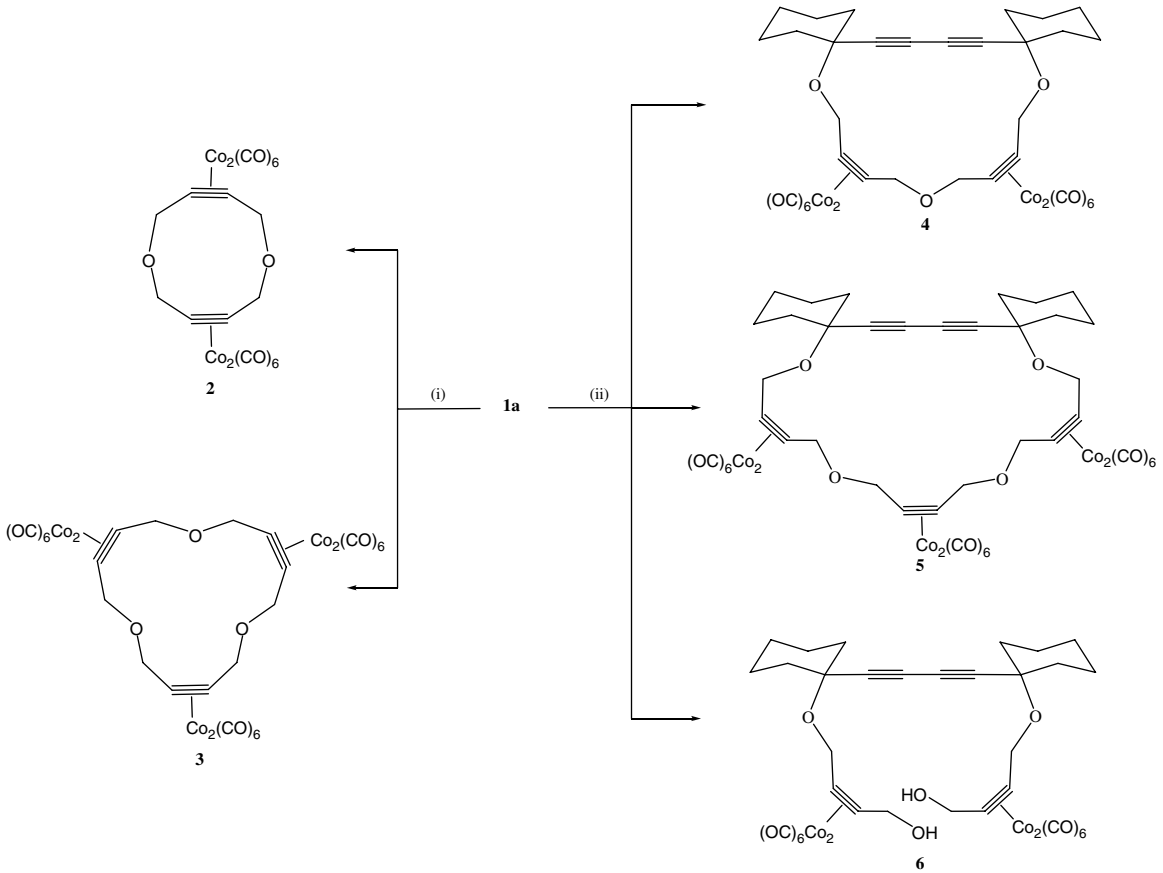

Fig. 1. Butyne-1,4-diol-$Co_2(CO)_6$ (**1a**), hexa-2,4-diyne-1,6-diol-$\{Co_2(CO)_6\}_2$ (**1b**) and 1,8-dioxacyclotetradeca-3,5,10,12-tetrayne-$\{Co_2(CO)_6\}_4$.

the reaction of **1a** with the non-coordinated butyne-1,4-diol [8] while, to the knowledge of the authors, no reports have appeared with regard to the reactivity of **1a** per se. In addition, we probe the potential of the free diyne diol (1-HO-*cyclo*-C_6H_{10})C≡CC≡C(1-HO-*cyclo*-C_6H_{10}) to undergo intermolecular cyclisation reactions with **1a** or its self-reacted derivatives [12]. This latter study is of added interest since alkyl-substituted 1,3-diyne diols of the type XC≡CC≡CX (X = C_5H_8OH [13], $C_6H_{10}OH$ [13], CMe_2OH [14]) when complexed with two $Co_2(CO)_6$ units have instead shown a preference to undergo dehydration reactions under Nicholas conditions.

2. Results and discussion

Treatment of [$Co_2(CO)_6$(μ-η^2-$HOCH_2$-C≡C-CH_2OH)] (**1a**) [15] in dichloromethane with a catalytic amount of $HBF_4 \cdot OEt_2$ at −78 °C afforded, following chromatographic work-up, the cyclic dimer [$\{Co_2(CO)_6\}_2$\{*cyclo*-μ-η^2:μ-η^2-OCH_2C≡CCH_2OCH_2C≡CCH_2–\}] (**2**) and the

Scheme 1. Reagents and conditions: (i) $HBF_4 \cdot OEt_2$ (catalyst), −78 °C, CH_2Cl_2; (ii) (1-HO-*cyclo*-C_6H_{10})CCCC(1-HO-*cyclo*-C_6H_{10}), $HBF_4 \cdot OEt_2$ (catalyst), −78 °C, CH_2Cl_2.

cyclic trimer [{$Co_2(CO)_6$}$_3${*cyclo*-μ-η^2:μ-η^2:μ-η^2-$OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2$–}] (**3**) in moderate yield (Scheme 1). Both complexes have been characterised by IR, ^{1}H and ^{13}C NMR spectroscopy, liquid secondary ion (LSI) mass spectrometry and gave satisfactory microanalyses (see Section 4). In addition, **2** and **3** have been the subject of single crystal X-ray diffraction studies.

The IR spectra of complexes **2** and **3** are characteristic of dicobalt hexacarbonyl-coordinated monoyne complexes [7,16], with three major CO stretching bands. The ^{1}H NMR spectra of **2** and **3** show singlet resonances for the propargyl CH_2 groups at ca. δ 4.90 consistent with symmetric structures which is further supported by the presence of only one type of alkynic carbon signal (at ca. δ 91.1) in their ^{13}C NMR spectra. The LSI mass spectra of both complexes show protonated molecular ion peaks (along with M^++Na peaks) corresponding to the proposed cyclic structures and also display fragmentation patterns that match with the loss of carbonyl groups from the molecular ions.

Crystals of **2** suitable for an X-ray diffraction study were grown from dichloromethane:hexane at 0 °C by slow vapour diffusion of additional hexane. The molecular structure of **2** is shown in Fig. 2; selected bond lengths and angles are collected in Table 1. The structure consists of a 10-membered 1,6-dioxa-cyclodeca-3,8-diyne ring in which each alkynic group is perpendicularly bound by dicobalt hexacarbonyl units. The Co_2C_2 cores adopt the expected tetrahedral arrangements with the Co–Co and C (alkyne)–C (alkyne) bond distances falling within the normal ranges [16,17]; the coordinated carbonyl ligands display the expected linear geometries. The C–C≡C *bend-back* angles [143.4(3)°, 143.9(3)°, 142.9(3)°, 143.2(3)°] are similar in magnitude and typical of those found in related macrocyclic complexes [7]. In comparison with the chair-like conformation found in the structure of the free 1,6-dioxa-cyclodeca-3,8-diyne ligand [18], **2** exhibits a more boat-like arrangement with the triple bonds no longer oriented in a parallel fashion and the oxygen–oxygen separation reduced [4.716 Å (**2**) versus 4.935 Å]. The separation between the complexed triple bonds in **2** is also slightly shorter than that found in its dithio analogue [{$Co_2(CO)_6$}$_2${*cyclo*-μ-η^2:μ-η^2-$SCH_2C{\equiv}CCH_2SCH_2C{\equiv}CCH_2$–}] [3.446 Å (**2**) versus 3.635 Å] [19]. An intermolecular interaction is apparent between a propargylic hydrogen atom in one molecule of **2** and an oxygen atom belonging to one of the bis-propargyl ether bridges in an adjacent molecule [H(20B)···O(14) 2.670 Å].

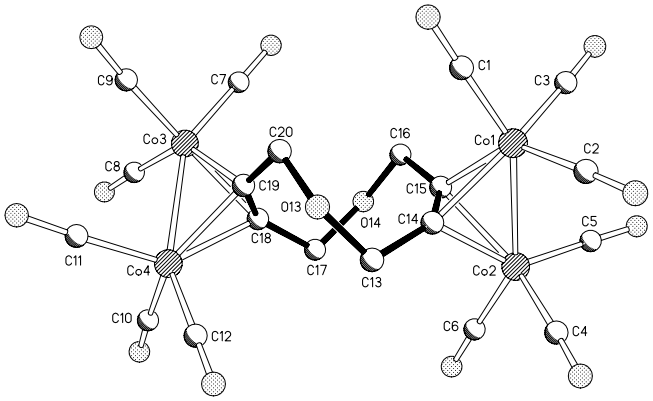

Fig. 2. Molecular structure of **2** with partial atom labeling scheme; all hydrogen atoms have been omitted for clarity.

Crystals of **3** suitable for an X-ray diffraction study were also grown from dichloromethane:hexane at 0 °C. The molecular structure of **3** is shown in Fig. 3; selected bond lengths and angles are listed in Table 2. The structure comprises a 15-membered 1,6,11-trioxa-cyclopentadeca-3,8,13-triyne ring in which each alkyne functionality is bound by a $Co_2(CO)_6$ unit. The expected tetrahedral arrangements are adopted by the Co_2C_2 cores and the Co–Co and C (alkyne)–C (alkyne) bond distances fall within the normal ranges [16,17]. The C–C≡C *bend-back* angles [141.8(2)°, 142.3(3)°, 142.4(3)°, 142.5(3)°, 147.7(3)°, 146.3(3)°] show some variation when compared with the values found in **2** indicating some uneven distribution of strain within the ring. The oxygen–oxygen separations within the macrocycle

also vary [O(19)···O(20) 5.045 Å, O(19)···O(21) 4.048 Å, O(20)···O(21) 3.968 Å] with the average value lower than that in **2**. Intermolecular short contacts are also a feature of the packing in **3** most noticeably between the oxygen atoms of the CO ligands in one molecule and the hydrogen atoms of the propargyl CH_2 groups in another [e.g., O(9)···H(19B) 2.540 Å, O(13)···H(27A) 2.696 Å, O(14)···H(23A) 2.837 Å, O(3)···H(26A) 2.794 Å].

The capacity of alkyl diols of the type HO-$(CH_2)_n$-OH ($n = 4$–6) to undergo ring closing reactions with the dppm-bridged derivative of **1a** has been previously been reported by Went et al. [7f]. We have been interested in exploring the use of less flexible alkyl diols (e.g., 1,3-diyne alkyl diols) in which ring closure of **1a** would be expected to proceed less efficiently. Thus, reaction of **1a** with the diynediol (1-HO-*cyclo*-C_6H_{10})C≡CC≡C(1-HO-*cyclo*-C_6H_{10}) in dichloromethane in the presence of a catalytic amount of $HBF_4 \cdot OEt_2$ gave, on work-up by TLC, [{$Co_2(CO)_6$}$_2${*cyclo*-μ-η^2:μ-η^2-$OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2O$(*cyclo*-$C_6H_{10}$)$C_2C_2$(*cyclo*-$C_6H_{10}$)–}] (**4**), [{$Co_2(CO)_6$}$_3$-{*cyclo*-μ-η^2:μ-η^2:μ-η^2-$OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2O$-$CH_2C{\equiv}CCH_2O$(*cyclo*-1-$C_6H_{10}$)$C_2C_2$(*cyclo*-1-$C_6H_{10}$)–}] (**5**) and [{$Co_2(CO)_6$}$_2$(μ-η^2:μ-η^2-$HOCH_2C{\equiv}CCH_2O$(*cyclo*-1-$C_6H_{10}$)$C_2C_2$(*cyclo*-1-$C_6H_{10}$)-$OCH_2C{\equiv}CCH_2OH$)] (**6**) (Scheme 1). Only low yields of **4**–**6** could be obtained which were further reduced by the need for repeated elution (with hexane) to allow satisfactory separation of the products. Nevertheless, the complexes have been characterised by a combination of IR, ^{1}H and ^{13}C NMR spectroscopy and LSI mass spectrometry (Table 1 and Section 4). In addition, **4** has been the subject of a single crystal X-ray diffraction study.

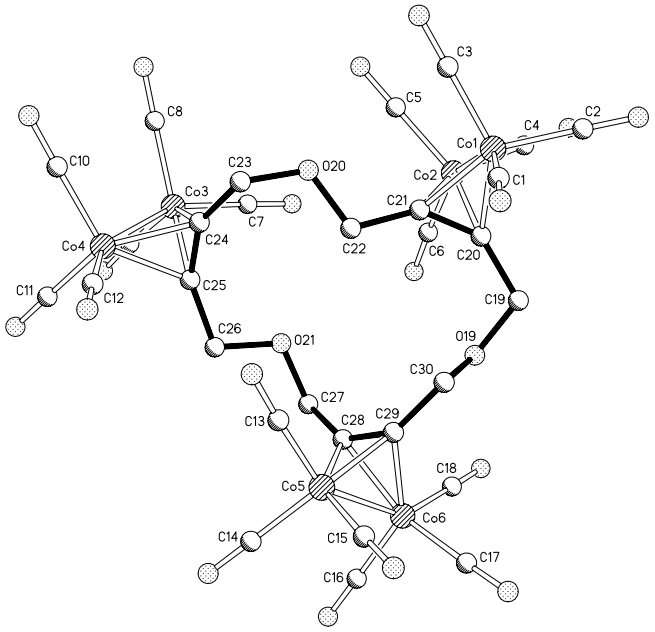

Fig. 3. Molecular structure of **3** with partial atom labeling scheme; all hydrogen atoms have been omitted for clarity.

Crystals of **4** were grown by prolonged standing at 0 °C of a hexane:dichloromethane solution containing the complex. The asymmetric unit of **4** contains two crystallographically independent molecules (A and B) differing in the orientations of the *cyclo*-hexyl groups with respect to the rigid diyne moiety. The molecular structure of one of the independent molecules of **4** is shown in Fig. 4a; selected bond lengths and angles are listed for both molecules in Table 3. The structure consists of a 17-membered 1,6,13-trioxa-cycloheptadeca-3,8,10,15-tetrayne ring in which two of the alkynic groups are η^2:η^2 bound by $Co_2(CO)_6$ units. Both cyclohexyl substituents adopt the "chair" conformation. As expected there is considerable variation in the magnitude of the C–C≡C *bend back* angles with those

for the bound alkynes [144.4(8)°, 140.2(8)°, 140.3(8)°, 143.7(7)°] being significantly less than for the unbound ones [173.7(8)°, 176.0(8)°]. Nevertheless, the divergence from linearity in the 1,3-diyne unit suggests some strain within this section of the macrocycle. The bond parameters within the Co_2C_2 cores are unexceptional. The oxygen–oxygen separations [O(13)···O(14) 4.956 Å, O(13)···O(15) 7.257 Å, O(14)···O(15) 4.950 Å] indicate the cavity size of the macrocycle is larger than in both **2** and **3**.

Within the unit cell the four molecules assemble in such a way that the pseudo-linear diyne moieties within each molecule of **4** are oriented approximately parallel (Fig. 4b). Along the b axis the $-C{\equiv}CCH_2OCH_2C{\equiv}C-\{Co_2(CO)_6\}_2$ sections of the macrocycle line up facing each other as do the less polar neighbouring diyne sections. There are a number of intermolecular short contacts between the oxygen atoms of the CO ligands and the hydrogen atoms of both the propargyl CH_2 groups (shortest contact: 2.633 Å) and the cyclohexyl groups (shortest contact: 2.670 Å) in neighbouring molecules. In addition, disordered solvent molecules fill the voids between molecules of **4**.

As with **2** and **3**, the IR spectra of complexes **4**–**6** display the typical pattern of ν(CO) bands for alkyne-bridged $Co_2(CO)_6$ units [16]. In the case of **4** and **6**, broad weak bands attributable to the free alkyne units are also visible at ca. 2253 cm^{-1} [20]. In their ^1H NMR spectra, in addition to poorly resolved signals due to the C_6H_{10} groups, signals due to the propargyl CH_2 protons are seen as two singlets (at δ 4.84 and 4.75) for **4**, three singlets (at δ 4.82, 4.75 and 4.64) for **5** and two singlets (at δ 4.90 and 4.64) for **6**; consistent with a plane of symmetry that bisects the 1,3-diyne moieties. This is further supported in the ^{13}C NMR spectra which display either two (**4**: δ 72.2, 63.6), three (**5**: δ 72.2, 71.4, 63.7) or two (**6**: δ 72.1, 63.6) propargylic carbon signals. In the LSI mass spectra of **4** and **5** peaks corresponding to the protonated molecular ion (and M^++Na peaks) are visible along with fragmentation peaks corresponding to the loss of carbonyl groups.

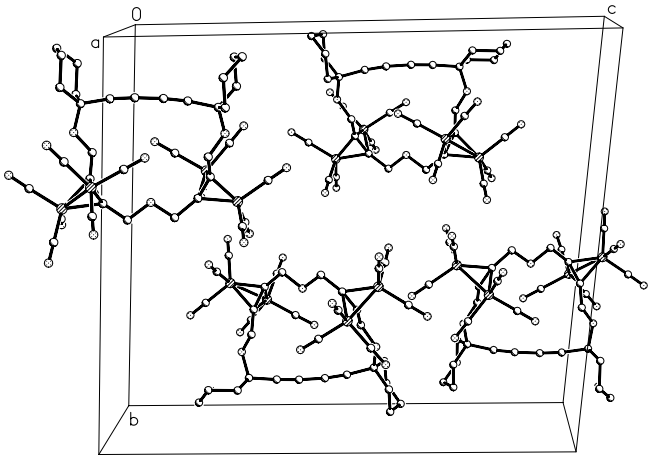

Fig. 4b. Packing in crystal of **4** with respect to the unit cell axis.

In our previous studies using the more extended **1b** as the substrate, we have shown that a 1,3-diyne-diol [viz. $HOR_2C{\equiv}CC{\equiv}CCR_2OH$ (R = H, Me)] can promote an acid-mediated intermolecular ring closure in **1b** leading to both monomeric and dimeric cyclic products [9d]. The reason for the absence of related oligomeric complexes during the reaction of **1a** with (1-HO-*cyclo*-C_6H_{10})$C{\equiv}CC{\equiv}$C(1-HO-*cyclo*-C_6H_{10}) is uncertain, but it would seem likely that the mis-match in size of **1a** with the diynediol employed prevents the facile formation of a monomeric cyclised product. To circumvent the latter pathway, it is possible that **1a** reacts with itself to form dimeric or trimeric cationic derivatives which are larger than the cation derived from **1a** itself and thus enable ring closure by the diynediol to take place (to give **4** or **5**). Alternatively, two molecules of **1a** react with both ends of the diynediol to give initially **6** (or its cationic derivative) which can then further react with itself to give **4** or with more **1a** to give **5**. Unfortunately, the limited quantities isolated of **6** have precluded a more thorough investigation.

3. Conclusions

The capacity of **1a** to undergo self-cyclisation reactions under acidic conditions to give crown-type macrocycles has been exploited with both dimeric (**2**) and trimeric species (**3**) being successfully isolated. In addition, the free cyclohexyl-substituted diyne-diol has been shown to undergo intermolecular cyclisation reactions, a reaction pathway not observed with the corresponding bis{$Co_2(CO)_6$}-coordinated derivative [13]. Furthermore, the products of the cyclisation (**5**, **6**) further illustrate the aptitude of **1a** to self-react in order to accommodate the rigid diyne unit into the macrocycle.

4. Experimental

4.1. General procedures and materials

Unless otherwise stated all experiments were carried out under an atmosphere of dry, oxygen-free argon, using standard Schlenk line techniques and solvents freshly distilled from appropriate drying agent [21]. NMR spectra were recorded in $CDCl_3$ using a Bruker DRX-500 or a AM-400 spectrometer with TMS as an external standard for ^1H and ^{13}C spectra. ^1H–^1H COSY and HMQC NMR experiments were employed to obtain ^1H–^1H and ^1H–^{13}C correlated spectra [22]. Infrared spectra were, unless otherwise stated, recorded in dichloromethane solution in 0.5 mm NaCl solution cells, using a Perkin–Elmer 1710 Fourier Transform Spectrometer. LSI (liquid secondary ion) mass spectra were recorded on a Micromass Autospec high resolution double focusing mass spectrometer at the EPSRC National Mass Spectrometry Service Centre at the University of Wales Swansea. Elemental analyses were performed at the Science Technical Support Unit, London Metropolitan University. Preparative TLC was carried out on 1 mm silica plates prepared at the University of Cambridge. All products are listed in order of decreasing R_f. Tetrafluoroboric acid (48 wt% in diethyl ether) was obtained from Aldrich Chemical Co. and 1,4-bis(1-hydroxycyclohexyl)-1,3-butadiyne from Alfa Aesar; both reagents were used without further purification. [$Co_2(CO)_6$(μ-η^2-$HOCH_2C{\equiv}CCH_2OH$)] (**1a**) was prepared by the literature method [15].

4.2. Reaction of *1a* in the presence of HBF_4

To a stirred solution of **1a** (0.372 g, 1.0 mmol) in dichloromethane (200 ml) at −78 °C was added three drops of 48% $HBF_4 \cdot OEt_2$ under a flow of argon. After stirring overnight at room temperature an excess of $NaHCO_3$ was added. Following filtration through a plug of $MgSO_4$, the solvent was removed on a rotary evaporator. The resulting residue was re-dissolved in the minimum amount of dichloromethane and applied to the base of preparative TLC plates. Repeated elution with hexane gave red-orange crystalline [{$Co_2(CO)_6$}$_3${*cyclo*-μ-η^2:μ-η^2:μ-η^2-$OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2$–}] (**3**) (0.032 g, 9%) and [{$Co_2(CO)_6$}$_2${*cyclo*-μ-η^2:μ-η^2-$OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2$–}] (**2**) (0.110 g, 30%). Spectroscopic and analytical data for **2**: *Anal*. Calc. $C_{20}H_8O_{14}Co_4$: C, 33.91; H, 1.13. Found: C, 34.01; H, 1.25%. Spectroscopic and analytical data for **3**: *Anal*. Calc. $C_{30}H_{12}O_{21}Co_6$: C, 33.91; H, 1.13. Found: C, 34.16; H, 1.27%. IR (*ν*(CO), cm^{-1}): 2093s, 2061vs, 2054sh, 2029vs; ^1H NMR ($CDCl_3$): *δ* 4.90 (s, 12H, CH_2); HMQC: *δ* 4.90 (72.0); $^{13}C\{^1H\}$ NMR: *δ* 199.2 (CO), 91.3 (C≡C), 72.0 (CH_2); LSI mass spectrum: (MW for $C_{30}H_{12}O_{21}Co_6$: 1062): MNa^+: 1086 (weak); MH^+: 1063 (weak); M^+-nCO (*n* = 2–5,7,10–13): 1006–923, 867, 783–699.

4.3. Reaction of *1a* with (1-HO-cyclo-C_6H_{10}-C≡C-)$_2$ in the presence of HBF_4

To a stirred suspension of (1-HO-*cyclo*-C_6H_{10})$C{\equiv}CC{\equiv}$C(1-HO-*cyclo*-C_6H_{10}) (0.246 g, 1.0 mmol) in dichloromethane (200 ml) was added **1a** (0.372 g, 1.0 mmol) in small portions under a flow of argon. Upon dissolution the mixture was cooled down to −78 °C and three drops of 48% $HBF_4 \cdot OEt_2$ introduced. The resulting deep red solution was allowed to warm to room temperature and stirred overnight. An excess of $NaHCO_3$ was added and the resulting mixture was filtered through a plug of $MgSO_4$. The solvent was removed on a rotary evaporator, the residue re-dissolved in the minimum amount of dichloromethane and applied to the base of preparative TLC plates. Repeated elution with hexane yielded red-orange crystalline [{$Co_2(CO)_6$}$_2${*cyclo*-μ-η^2:μ-η^2-$OCH_2C{\equiv}CCH_2OCH_2C{\equiv}CCH_2O$(*cyclo*-$C_6H_{10}$)$C_2C_2$(*cyclo*-$C_6H_{10}$)–}]

4.4. X-ray crystallography

Single crystal X-ray diffraction data for **2**, **3** and **4** were collected using a Nonius-Kappa CCD diffractometer, equipped with an Oxford Cryosystems cryostream and employing Mo Kα ($\lambda = 0.71073$ Å) irradiation from a sealed tube X-ray source. Cell refinement, data collection and data reduction were performed with the programs DENZO [23] and COLLECT [24] and multi-scan absorption corrections were applied to all intensity data with the program SORTAV [25]. All structures were solved and refined with the programs SHELXS-97 and SHELXL-97 [26], respectively. Hydrogen atoms were included in calculated positions (C–H = 0.96 Å) riding on the bonded atom with isotropic displacement parameters set to $1.5U_{eq}$(C) for methyl H atoms and $1.2U_{eq}$(C) for all other H atoms. Details of the data collection, refinement and crystal data are listed in Table 4.

Abstract

Reactions of copper(I) halides with 2-(diphenylphosphano)benzaldehyde (PCHO) in 1:2 molar ratio afforded mononuclear complexes of the type $[CuX(PCHO)_2]$, whereas treatment of these compounds with equimolar amounts of pyridine-2-thione or pyrimidine-2-thione gave rise to the formation of mixed-ligand dimers of the formula $[CuX(PCHO)(thione)]_2$. The molecular structures of $[CuCl(PCHO)_2]$, $[CuBr(PCHO)_2]$ and $[CuCl(PCHO)(pymtH)]_2$ have been established by single-crystal X-ray diffraction. The two homoleptic complexes feature a trigonal copper(I) centre with the phosphane acting as a monodentate ligand via the P atom. In the structure of the dimeric mixed-ligand complex each of the two metal centres exhibit a distorted tetrahedral environment with the thione-S atoms acting in a doubly bridging mode.

Keywords: Copper(I) halide complexes; 2-(Diphenylphosphano)benzaldehyde; Heterocyclic thiones; Structures

1. Introduction

There is much current interest in copper(I) coordination chemistry, mainly because of its participation in certain biochemical redox reactions [1]. Due to the favorable soft acid–soft base interaction, the chemistry of this closed-shell d^{10} metal ion is largely based upon coordination to ligands containing phosphorus and sulfur donor atoms. Thus, with tertiary phosphanes, copper(I) produces a vast number of complexes which feature an extraordinary stoichiometric and geometrical variety. Many of these complexes have been intensively employed in catalytic processes [2] and some of them were even found to exhibit antitumor activity [3]. As far as the sulfur containing ligands are concerned, heterocyclic thioamides represent a class of compounds that have attracted substantial interest over the last few decades, largely because of their relevance to biological systems [4,5].

Based on the rich chemistry so far found for each of the two aforementioned classes of ligands, we have been interested in examining univalent copper and silver mixed-ligand complexes bearing both neutral heterocyclic thiones and bulky triaryl phosphane ligands with respect to the factors that influence the structural characteristics of these compounds [6,7]. Since our findings showed the coordination number to be related to the steric requirements on the part of the phosphane ligand only [8], we recently focused on phosphanes that may introduce imposed steric effects around the metal centre. In the present work we report on the synthesis and characterization of some Cu^I complexes derived from 2-(diphenylphosphano)benzaldehyde (PCHO). Apart from its steric demands, the selection of PCHO as ligand is further based on its salient feature to bear, besides the "soft" phosphorus donor, a "hard" oxygen atom, thus being capable of behaving as a P,O-chelate [9].

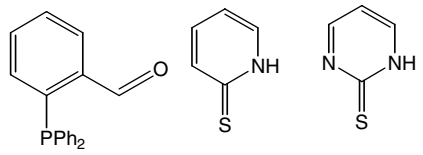
2. Experimental

2.1. Materials and instrumentation



Commercially available copper(I) halides and 2-(diphenylphosphano)benzaldehyde (Aldrich) were used as received while the thiones (Merck) were re-crystallized from hot ethanol prior to their use (Scheme 1). All the solvents were purified by respective suitable methods and allowed to stand over molecular sieves. Infra-red spectra in the region of 4000–250 cm^{-1} were obtained in KBr discs with Perkin–Elmer FT-IR Spectrum 1 spectrophotometer, while a Perkin–Elmer-Hitachi 200 spectrophotometer was used to obtain the electronic absorption spectra. ^1H NMR spectra were recorded on a Brucker AM 300 spectrometer at 298 K with positive chemical shifts given downfield from internal TMS. Melting points were measured in open tubes with a STUART scientific instrument and are uncorrected.

2.2. Crystal structure determination

Single crystals suitable for crystal structure analysis were obtained by slow evaporation of acetonitrile/methanol solutions of the complexes at room temperature. X-ray diffraction data were collected on an Enraf-Nonius Kappa CCD area-detector diffractometer. The programs DENZO [10] and COLLECT [11] were used in data collection and cell refinement. Details of crystal and structure refinement are shown in Table 1. The structures were solved using program SIR97 [12] and refined with program SHELX-97 [13]. Molecular plots were obtained with program ORTEP-3 [14].

2.3. Synthesis of complexes **1–3**

A suspension of 0.25 mmol of copper(I) halide (24.75 mg for CuCl, 35.85.7 mg for CuBr, 47.6 mg for CuI) in 30 cm^3 of dry acetonitrile was stirred at 50 °C until a clear yellow solution was formed. To this, a solution of 145 mg (0.5 mmol) of 2-(diphenylphosphano)benzaldehyde in 25 cm^3 of dry acetonitrile was added and the mixture was stirred for 2 h at 50 °C. The resulting bright yellow solution was filtered off and left to evaporate at ambient. The microcrystalline solid, which was deposited upon standing for several days, was filtered off and dried *in vacuo*.

2.4. Synthesis of complexes **4–6**

To a stirred solution of 0.25 mmol of copper(I) halide (24.75 mg for CuCl, 35.85.7 mg for CuBr) was suspended in 60 cm^3 of dry acetonitrile, solid 2-(diphenylphosphano)benzaldehyde (145 mg, 0.5 mmol) was suspended and the mixture was stirred for 2 h at 50 °C. The resulting clear solution was then treated with the appropriate thione (0.5 mmol) dissolved in a small amount (~20 cm^3) of methanol. The new reaction mixture was stirred for additional two hours at 50 °C and then was filtered off and left several days at ambient to provide a yellow microcrystalline product.

2.4.1. *[CuBr(PCHO)(py2SH)]$_2$ (**4**)*

Yellow crystals (32 mg, 23%), m.p. 179 °C; *Anal.* Calc. for $C_{48}H_{40}Br_2Cu_2N_2O_2P_2S_2$: C, 52.90; H, 3.70, N: 2.57. Found: C, 64.47; H, 4.81; N, 3.47%. 3. Results and discussion

3.1. Synthesis

Treatment of 2-(diphenylphosphano)benzaldehyde and CuX (X = Cl, Br, I) resulted in the formation of orange-yellow colored crystalline compounds formulated as $[CuX(PCHO)_2]$ (compounds **1**–**3**), regardless of the molar ratio (1:1 or 2:1) applied. Aiming to obtain phosphane/thione mixed-ligand complexes, we further treated the solutions of these precursors, skipping their isolation, with a methanolic solution of 1 equiv. of a heterocyclic thione. Stirring of such a mixture at 50 °C gradually caused slight

darkening of the solution, from which, on slow evaporation, microcrystalline or powdery solids were deposited. These proved, however, to correspond to the desired pure compounds only in a few cases, although the described one-top two-step synthetic procedure applied has already produced a number of such copper(I) halide derivatives, virtually for any thione and copper(I) halide applied. In particular, pyridine-2-thione (py2SH) and pyrimidine-2-thione (pymtH) yielded small amounts of well-formed bright orange crystals, which could be satisfactory defined as compounds **4**–**6**, but inseparable mixtures of two or more products resulted in all the other cases. All prepared compounds are air stable diamagnetic solids, moderately soluble in acetonitrile, chloroform and acetone. Their solutions in common organic solvents are non-conducting.

3.2. Spectroscopy

The room temperature ^{1}H NMR spectra of the complexes under investigation, recorded in deuterated chloroform, are dominated by the presence of two separated multiplets in the regions $\delta = 7.40$ and $\delta = 7.25$ ppm attributed to the resonances of the non-substituted phenyl rings of the PCHO ligand. With respect to the complex multiplet assigned to the PPh_2 resonances of the un-coordinated phosphane, this splitting indicates coordination to the metal through the P atom which causes a typical upfield shift of the *ortho*-positioned protons by ca. 0.20 ppm. The resonances attributed to the formylated phenyl ring appear as well separated signals assignable to the discrete aromatic protons only for the thione-free compounds **1**–**3**, whereas for compounds **4**–**6** the extent of overlapping makes assignments of the splitting pattern for the individual phosphane and thione resonances very difficult.

The infrared spectra of compounds **1**–**6**, recorded in the range 4000–250 cm^{-1} display strong vibrational phosphane bands, which remain practically unshifted upon coordination. In addition, the spectra of the mixed-ligand complexes **4**–**6** contain the expected characteristic ''thioamide bands'', with shifts due to coordination indicative of an exclusive S-coordination mode. As expected, upon coordination no significant shift is noticed for the ν(C=O) vibration of the PCHO ligand.

3.3. X-ray structural investigations

The X-ray crystal structures of $[CuCl(PCHO)_2]$ (**1**), $[CuBr(PCHO)_2]$ (**2**) and $[CuCl(PCHO)(pymtH)]_2$ (**5**) (details of crystal and structure refinement are shown in Table 1) corroborate the spectroscopic results discussed above. Tables 2 and 3 list selected distances and angles of these complexes.

Compounds **1** and **2** crystallize in the monoclinic space group $P2_1/n$ and $C2/c$ respectively, both with four discrete formula units in the unit cell. Likewise, compound **5** crystallizes in the monoclinic space group $P2_1/n$ with four discrete formula units in the unit cell. It should be mentioned that there is a small impurity in the structure of **5**, indicated by the presence of a formyl substituent attached to C(25), apparently due to a small amount of doubly formylated phosphane. Hence a population parameter of 0.13 corresponds to C(47), O(3) and H(47), whereas the population parameter of H(25) is 0.87 (see also Table 1).

By comparison to the vast number of known four-coordinate species, examples of three coordination among Cu^{I} complexes are far less common, mostly represented by cations of the type CuL_3^+. The more rarely reported neutral complexes of the formula CuL_2X are usually formed by bulky ligands such as triarylphosphanes or aromatic amines. A literature search of published data on Cu^{I} complexes of 2-(diphenylphosphano)benzaldehyde revealed that there were structures of six cationic species known [15,16], featuring tetrahedral or trigonal planar environment around Cu^{I}, thus the three structures presented here are the first examples of neutral Cu^{I} complexes bearing PCHO.

The crystal structures of compounds **1** and **2** (Figs. 1 and 2) are quite similar having in common trigonal coordination of the copper(I) centre. Nevertheless, considering the interligand bond angles involving the central metal atom in the two structures described here, there are some

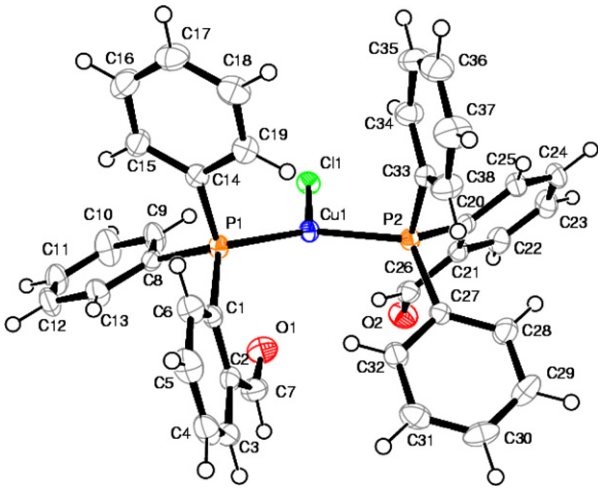

Fig. 1. A view of compound **1** with atom labels. Displacement ellipsoids are shown in the 50% probability level.

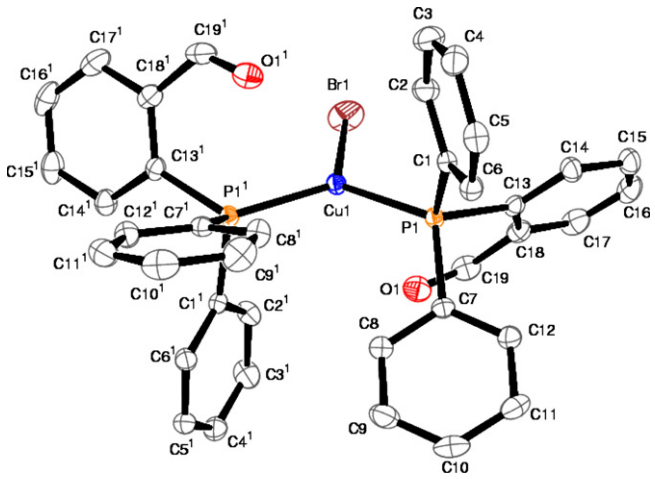

Fig. 2. A view of compound **2** with atom labels. Displacement ellipsoids are shown in the 50% probability level.

obvious differences. Thus, angular deviations from the ideal trigonal value in **1** are remarkable but not at all unexpected, at least regarding the appropriate opening up of the angle between the sterically demanding groups of the PHCO units. The sum of the three angles around Cu is 358.72°, and the Cu atom is displaced from the basal trigonal plane by 0.1465(3) Å. Another remarkable feature of **1** is the different orientation of the formyl groups of the two PCHO ligands, one of them having oriented its oxygen atom toward the copper atom to a distance of 2.804(2) Å, whereas the second one is twisted outwards. This short Cu(1)···O(1) contact is less than the sum of the van der Waal radii (1.40 (Cu) + 1.52 (O) = 2.92Å) and may be considered as a dipole–ion interaction [16,17]. The carbon–oxygen bond distance of the formyl group in the two individual PCHO units remains essential the same. Moreover, the formyl groups are both essentially coplanar with the C atoms of the attached phenyl rings.

Contrary to that, **2** exhibits a symmetric arrangement of the two PCHO units. Here the trigonal environment within

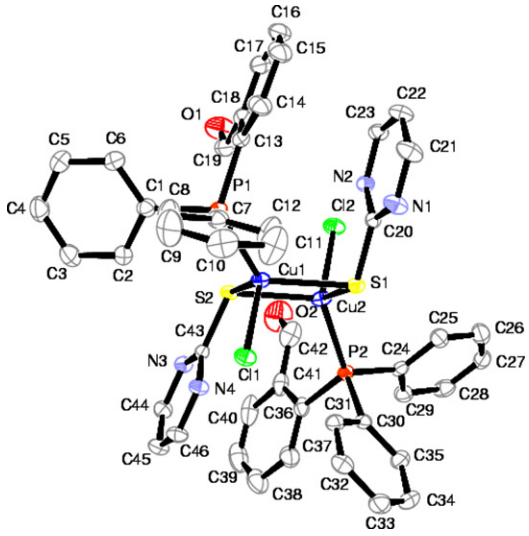

Fig. 3. A view of compound **5** with atom labels. Displacement ellipsoids are shown in the 50% probability level.

the exactly planar CuP_2Br core can be considered as essentially regular with the largest P–Cu–P angle deviating only by 3.5° from the ideal trigonal expectation of 120°. The Cu–P bond distances of 2.2266(5) and 2.2448(5) Å in **1** and 2.2366(4) Å in **2** are comparable to those found in PCHO ligated cationic Cu^{I} complexes such as $[Cu(PCHO)_2(CH_3CN)]BF_4$ or $[Cu(PCHO)_3]BF_4$ [15]. Moreover the PCHO units have both their formyl groups oriented toward the copper atom with a short Cu···O separation of 3.002(2) Å. As a further difference between the two structures, the co-planarity within the formyl groups and the C atoms of the attached phenyl rings in **2** is substantially distorted.

In the dimeric complex **5** each copper atom displays a distorted tetrahedral environment formed by one P atom from PCHO, one Br atom and two inequivalent bridging S atoms from the thione ligands. Within the essentially planar Cu_2S_2 central core respective bond lengths and angles around the two copper atoms differ slightly. This is in contrast to other related structures with simple monodentate arylphosphane ligands like triphenylphosphane or tri-tolylphosphanes, where doubly bridging S atoms were found to generate a Cu_2S_2 rhombus with the dimeric molecule generally having a crystallographic centre of symmetry. Nonetheless, this is another example of dicopper(I) halide complex comprising a neutral thione ligand coordinated in a μ_2-S bridging mode, which is in line with our assumption that primary control of the coordination behavior (terminal or bridging) of the thione and halide ligands can be achieved by the choice of the halide ligand, with the "soft" iodide being capable to serve as bridging ligand rather than the "hard" chloride which prefers, at least in the presence of a "soft" thione-S donor atom, the terminal coordination mode [18] (Fig. 3).

An interesting structural feature within molecule **5** is the almost parallel orientation of each of the six-membered pyrimidine rings relative to the formylated phenyl ring of the respective PCHO unit. The dihedral angle between the

C13–C18 and N1,N2,C20–C23 rings is 12.68(8)° and the dihedral angle between rings C36–C41 and N3,N4,C43–C46 is 16.12(5)°. The respective stacking distances between ring centroids are 3.743(1) and 3.728(1) Å, respectively, suggesting the presence of significant $\pi\cdots\pi$ interactions [19]. These may be considered to significantly contribute, together with the intramolecular hydrogen bonds (see Table 3), to the alignment of the molecule in the crystalline state.

4. Conclusion

The aim of this work was the study of the coordination capability of 2-(diphenylphosphano)benzaldehyde (PCHO) toward copper(I) halides. We have found that PCHO acts as a monodentate, coordinating to the metal exclusively via the "soft" phosphorus atom, whereas no bonding interaction could be proposed for the formyl group, despite the observed marked orientation of its oxygen atom towards the copper centre. Thus, the resulting complexes of composition $[CuX(PCHO)_2]$, are monomers with the copper atom in a fairly trigonal environment. These compounds prove to be good precursors for the preparation of other derivatives; in the course of the present study these are chosen for the synthesis of mixed-ligand dimeric complexes, which contain, besides the PCHO unit, a heterocyclic thioamide. The structure of the mixed-ligand complex presented here, comprising the neutral thione ligand coordinated in a μ_2-S bridging mode, confirms once more our assumption that primary control of the coordination behavior (terminal or bridging) of the thione and halide ligands in such dimers can be achieved by the choice of the halide.

Abstract

A novel Schiff-base, *N*,*N*′-di-(4′-pentyloxybenzoate)salicylidene-1,8-diamino-3,6-dioxaoctane (H_2L_4) with the mesogenic phase, *nematic droplets*, was prepared and its structure studied by elemental analyses and mass, NMR and IR spectra. The di-negative tetra-dentate bonding of the Schiff-base in the non-mesogenic complex, [ZnL_4], as implied on the basis of IR and NMR spectral data, was confirmed in the crystal structure of the monomeric tetrahedral Zn(II) complex. As per the crystal structure of the complex, the dinegative species of the ligand, L_4^{2-}, coordinates to the Zn(II) ion through two phenolate oxygens and two azomethine nitrogens, rendering the overall geometry around Zn(II) to distorted tetrahedron.

1. Introduction

Liquid crystals with transition metal core groups are increasingly a topic of investigation since metals can impart useful shapes and properties which are not easily produced in totally organic liquid crystals [1]. A major distinction between metallomesogens and most organic mesogens is the greater tendency in the former type to exhibit intermolecular dative coordination in the solid state [1]. However, it should be noted that rigid tetrahedral molecules usually seem to prevent mesophase formation [2]. As a part of our investigation on systematic structural and spectroscopic studies of 3d metal complexes of a series of mesogenic organic Schiff-bases, we report here, synthesis and spectroscopic studies on the mesogenic Schiff-base, *N*,*N*′-di-(4′-pentyloxybenzoate)salicylidene-1,8-diamino-3,6-dioxaoctane (H_2L_4) and crystal structure of the corresponding Zn(II) complex. We have observed that despite the mesogenic behaviour of the [CuL_4] (unpublished work), the zinc homologue, [ZnL_4], does not exhibit liquid crystalline properties presumably due to the tetrahedral coordination of the latter [2].

2. Experimental

2.1. Materials

All reagents were purchased from the following and used as received: 4-hydroxy benzoic acid, 1-bromopentane, 2,4-dihydroxy benzaldehyde, *N*,*N*′-dicyclohexylcarbodiimide (DCC), *N*,*N*-dimethylaminopyridine (DMAP) and 1,8-diamino-3,6-dioxaoctane from Sigma–Aldrich, USA, and $Zn(OAc)_2 \cdot 2H_2O$ and KOH from Merck. The solvents received from commercial sources were used as such without further purification and were dried using standard methods [3] when required.

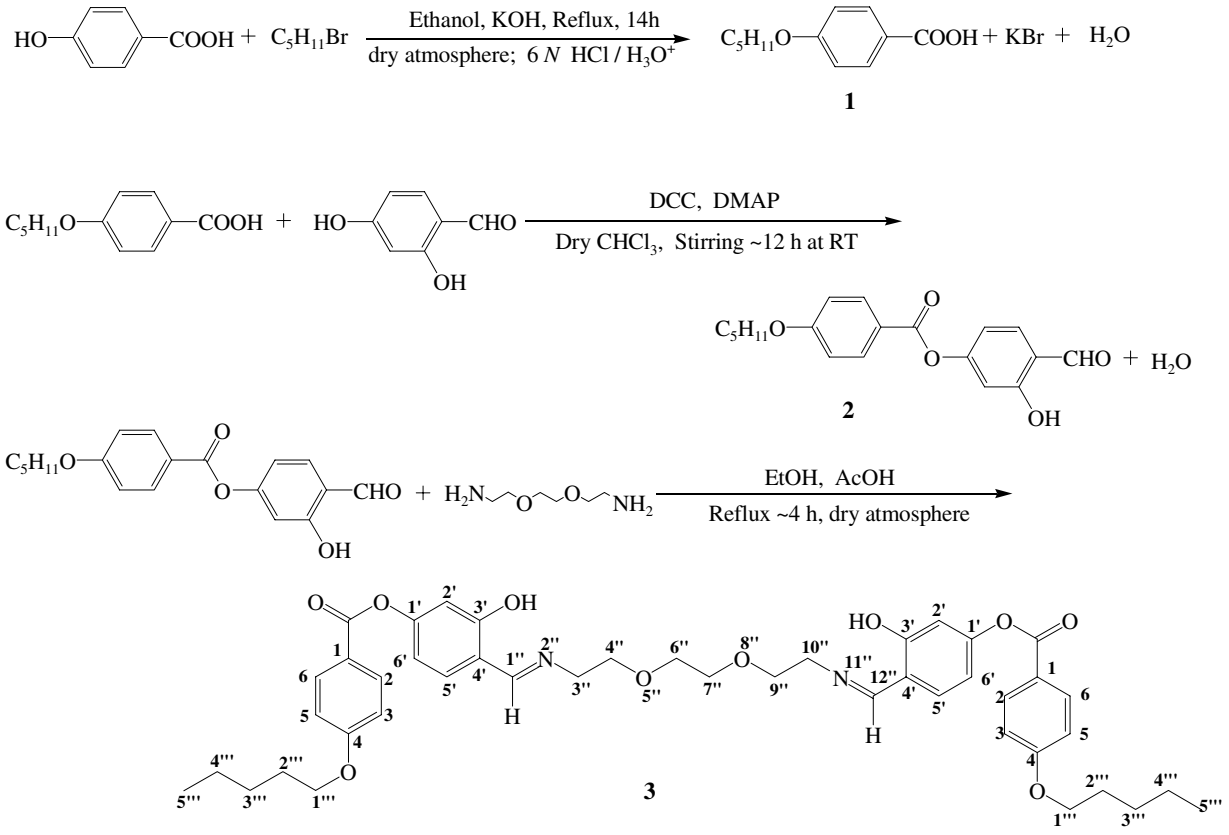
2.2. Synthesis

The synthesis of *N*,*N*′-di-(4′-pentyloxybenzoate)-salicylidene-1,8-diamino-3,6-dioxaoctane (H_2L_4) (**3**), was achieved by proceeding through three major steps, viz., alkylation of 4-hydroxy benzoic acid with *n*-pentyl bromide, followed by esterification and Schiff-base formation; all the experimental details are given in Scheme 1.

2.2.1. Preparation of 4-pentyloxybenzoic acid (*1*)



Solutions of 4-hydroxybenzoic acid (11.05 g, 80 mmol) in dry ethanol (150 mL) and of KOH (8.97 g, 160 mmol) in dry ethanol (50 mL) were magnetically stirred with simultaneous drop-wise addition of 1-bromopentane (10.00 mL, 80 mmol). The reaction mixture was refluxed for ~14 h under dry atmosphere and allowed to come to room temperature. The solid alkoxy potassium salt thus obtained was separated out by filtration under suction and treated with dilute HCl until the pH of the reaction mixture reached to ~2. The crude solid white product was filtered off, washed thoroughly with water and recrystallized successively from solutions of glacial acetic acid and toluene. Yield: 11.65 g (70%).

2.2.2. Preparation of 4-pentyloxy (4′-formyl-3′-hydroxy)-benzoate (*2*)

Solutions of 4-pentyloxy benzoic acid (10.40 g, 50 mmol in 50 mL), 2,4-dihydroxybenzaldehyde (6.90 g, 50 mmol in 50 mL), DCC (11.35 g, 55 mmol in 100 mL) in dry chloroform along with solid DMAP (0.3 g, 2.5 mmol as a catalyst) were magnetically stirred at room temperature for ~12 h. The byproduct (dicyclohexyl urea) was filtered off under suction and the solvent was removed on rotavapor. The crude product was recrystallized from hot solution of ethanol and purified by column chromatography over SiO_2 by eluting with a mixture of *n*-hexane and chloroform (v/v, 1:1); evaporation of this eluent yielded the ester, **2**, in the form of a white solid. Yield: 10.17 g (62%).

2.2.3. Synthesis of N,N′-di-(4′-pentyloxybenzoate)-salicylidene-1,8-diamino-3,6-dioxaoctane (*3*)

Absolute ethanolic solutions of 4-pentyloxy-(4′-formyl-3′-hydroxy)benzoate (6.56 g, 20 mmol, in 100 mL) and 1,8-diamino-3,6-dioxaoctane (1.50 mL, 10 mmol in 20 mL) were refluxed for ~4 h in presence of a few drops of acetic acid and the resultant solution was left over-night in the reaction flask at room temperature. The micro-crystalline yellow coloured product, **3**, was suction-filtered, thoroughly washed with ethanol, recrystallized from a solution of absolute ethanol/chloroform (v/v, 1/1) and dried at room temperature. Yield: 4.61 g (60%); m.p., 110 °C. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C, TMS): $\delta = 0.945$ (t, $^3J_{H-H} = 6.9$ Hz, 3H, CH_3), 1.847–1.390 (m, 6H, $H^{methylene}$), 3.614 (s, 2H, $H_{6''}$), 3.721 (s, 4H, $H^{3'',4''}$), 4.035 (t, $^3J_{H-H} = 6.6$ Hz, 2H, $H^{1'''}$), 6.720 (dd,

2.2.4. Synthesis of the zinc complex, [ZnL4]

Anhydrous solutions of *N*,*N*′-di-(4′-pentyloxybenzoate)salicylidene-1,8-diamino-3,6-dioxaoctane (**3**), (0.77 g, 1.0 mmol) in dichloromethane (30 mL) and of zinc acetate (0.22 g, 1.0 mmol) in ethanol (20 mL) were refluxed for ~6 h and the reaction mixture left over-night in the reaction flask after reducing the volume to ~10 mL. The crude solid complex, [ZnL_4], was filtered off under suction, washed repeatedly with cold ethanol, recrystallised from the solution of chloroform/ethanol and dried over fused $CaCl_2$ in a desiccator. Yield: 0.68 g (82%); m.p. 210 °C. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C, TMS): $\delta = 0.947$ (t, $^3J_{H-H} = 6.9$ Hz, 3H, CH_3), 1.850–1.392 (m, 6H, $H^{methylene}$), 4.040 (t, $^3J_{H-H} = 6.9$ Hz, 2H, $H^{1'''}$), 6.973 (d, $^3J_{H-H} = 8.1$ Hz, 1H, H^3), 7.185 (d, $^3J_{H-H} = 8.4$ Hz, 1H, $H^{5'}$), 8.133 (d, $^3J_{H-H} = 7.8$ Hz, 1H, H^2), 8.197 (s, 1H, N=CH) ppm. IR (KBr, cm^{-1}): ν(>C=O) 1730, ν(C=N) 1535, ν(C–O)$_{phenol}$ 1253, ν(C(O)O) 1151. *Anal.* Calc. for $C_{44}H_{50}N_2O_{10}Zn$ (832.23): C, 63.50; H, 6.06; N, 3.37; Zn, 7.86. Found: C, 63.27; H, 6.01; N, 3.22; Zn, 7.79%.

2.3. Physical measurements

Infrared spectra were recorded on a JASCO-5300 FT IR spectrophotometer and the ^{1}H and ^{13}C NMR spectra were recorded on a JEOL AL300 FT NMR spectrometer. Mass spectra were recorded on JEOL SX-102 (EI/CI/FAB) mass spectrometers. C, H, and N were micro-analyzed on Elementar Vario EL III Carlo Erba 1108 analyzer.

2.4. X-ray crystallographic data collection and refinement of the structure

X-ray data for the compound ZnL_4, [aq74m], was collected at room temperature using a Bruker Smart Apex CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) with ω-scan method. Preliminary lattice parameters and orientation matrices were obtained from four sets of frames. Unit cell dimensions were determined from the setting angles of 7224 reflections in the range of $2.31° < \theta < 24.66°$. Integration and scaling of intensity data was accomplished using SAINT program [4]. The structure was solved by direct methods using SHELXS97 [5] and refinement was carried out by full-matrix least-squares technique using SHELXL97 [5]. Anisotropic displacement parameters were included for all non-hydrogen atoms. All other hydrogen atoms were positioned geometrically and treated as riding atoms, with C–H distances in the range of 0.93–0.96 Å and with U_{iso}(H) values of $1.5U_{eq}$(C) for methyl hydrogens and $1.2U_{eq}$(C) for other hydrogen atoms. The geometries of the atoms C17, C18 and C19 were restrained, where distances C17–C18=C18–C19 were set to the target value, 1.55 Å.

3. Results and discussion

3.1. Spectral investigation

The Schiff-base ligand (H_2L_4), **3**, is yellow-coloured while the Zn(II) complex, [ZnL_4] is colourless. Both

the parent ligand and the metal complex are soluble in chloroform, dichloromethane, DMF and DMSO but are insoluble in water, methanol, ethanol, and acetonitrile. The structures and purities of the Schiff-base ligand, **3**, and of the metal complex, [ZnL_4], were confirmed by IR and ^1H NMR spectroscopy and elemental analyses. The structure of the ligand was further confirmed by FAB Mass spectrum. The mass spectral features of H_2L_4 were characterized by the base peak ($m/e = 191$ corresponding to the fragment, $C_5H_{11}OC_6H_4CO^+$), the molecular ion peak with ~75% intensity ($m/e = 769$) and the major fragment peaks ($m/e = 398$, 370, 340, 121) due to $C_5H_{11}OC_6H_4COOC_6H_3(OH)CH{=}N(CH_2)_2OCH_2CH_2^+$, $C_5H_{11}OC_6H_4COOC_6H_3(OH)CH{=}N(CH_2)_2O^+$, $C_5H_{11}OC_6H_4COOC_6H_3(OH)CH{=}NCH_2^+$ and $HOC_6H_4CO^+$. A comparison of the ^1H and $^{13}C\{^1H\}$ NMR spectral data of the ligand with those of the Zn(II) complex shows the absence of the phenolic–OH signal (13.813 ppm in H_2L_4) and a significant shift (8.324–8.197 ppm) in the peak position of the –N=C*H* in the spectrum of the metal complex, which implies bonding through the phenolate anion and the azomethine nitrogen atom [6] of the ligand to the metal ion. Similar shifts observed in the $^{13}C\{^1H\}$ NMR spectra were of considerable magnitude in the case of the carbon atoms directly attached to the bonding atoms (phenolate–O and azomethine–N) while those observed for the carbons close to the bonding atoms were of lesser magnitude. Thus, the NMR spectral data imply tetradentate bonding of H_2L through the two >C=N groups and two phenolate oxygen atoms. In the IR spectrum of H_2L_4 the broad absorption centered on 3439 and 3450 cm^{-1}, in the solid and solution states, respectively, may be assigned to the O–H stretching vibration of the phenolic group [7]. The strong intensity band occurring at 1633 cm^{-1} may be assigned [8] to ν(C=N) absorption of the azomethine moiety. The strong bands occurring at 1722 cm^{-1} and 1145 cm^{-1} in the solution state of the parent ligand may be assigned [7] to ν(>C=O) and ν(C–O) stretching modes of aromatic ester. The characteristic response of ether in the infrared is associated with the stretching vibration of the C–O–C system. The bands appearing at 1246 and 1064 cm^{-1} may be assigned [7] to ν_{as}(C–O–C) and ν_s(C–O–C) stretching of aryl alkyl ether. Bonding of the parent ligand with the metal ions through phenolate oxygen and azomethine nitrogen was inferred [8] on the basis of (i) disappearance of the ν(O–H) (phenolic) band, and (ii) bathochromic shifts observed in the *ν*(>C=N) frequencies in the spectra of the metal complexes.

3.2. Crystal structure and molecular association

The crystal data and structure refinement details for [ZnL_4], [aq74m], are given in Table 1. The molecular structure and atomic labeling scheme of the complex, [ZnL_4], is as shown in Fig. 1.

As per the crystal structure of the complex, the ligand, H_2L_4, coordinates to the Zn(II) ion through two phenolate oxygens (O(1), O(5)) and two azomethine nitrogens (N(1), N(2)), rendering the overall

geometry around Zn(II) to distorted tetrahedron where the bond lengths and the bond angles are as shown in Table 2. The hydrogen bond geometry is tabulated in Table 3. The crystal structure is stabilized by intermolecular C–H···O interactions which exist between the atom C(30) of the benzoate ring and the carbonyl oxygen atom O(3). Similarly, the aliphatic atom C(39) forms an intermolecular C–H···O interaction with the ethereal oxygen atom O(10), thereby forming an infinite glide-related chain running along crystallographic *c*-axis. The packing diagram is depicted in Fig. 2. Considerable torsion has been observed between benzoate ring and salicylaldimine ring on either side of the metal atom.

4. Conclusion

The Schiff-base, *N*,*N*′-di-(4′-pentyloxybenzoate)salicylidene-1,8-diamino-3,6-dioxaoctane (H_2L_4) with the mesogenic phase, nematic droplets, coordinates to Zn(II) as a di-negative tetra-dentate species, to yield the non-mesogenic tetrahedral complex, [ZnL_4]. As per the crystal structure of the complex, the dinegative species of the ligand, L_4^{2-}, coordinates to the Zn(II) ion through two phenolate oxygens and two azomethine nitrogens, rendering the overall geometry around Zn(II) to distorted tetrahedron.

Abstract

Novel [ReOX(quin-2-c)$_2$] complexes (X = Cl, Br; quin-2-c = quinoline-2-carboxylate ion) have been prepared by treatment of [ReOX$_3$(AsPh$_3$)$_2$] with an excess of quinoline-2-carboxylic acid in acetonitrile. The complexes were characterised structurally and spectroscopically. The electronic structure of [ReOBr(quin-2-c)$_2$] has been calculated with the density functional theory (DFT) method, and additional information about binding has been obtained by NBO analysis. The UV–Vis spectrum of [ReOBr(quin-2-c)$_2$] has been discussed on the basis of TD-DFT calculations.

1. Introduction

There is considerable interest in the chemistry of inorganic compounds containing an oxygen atom that is multiply bonding to a transition metal in a high oxidation state. These compounds can transfer an oxygen atom to reductants such as phosphines, sulfides and alkenes. For many years they have been in the center of interest to those scientists engaged in basic research and to those trying to employ these complexes in catalytic processes. Oxygen atom transfer chemistry has been implicated in various reactions of industrial and biological importance, including olefin epoxidation and catalysis by cytochrome P-450 [1–3].

The chemistry of oxo rhenium complexes arouses particular interest among these compounds. Methyltrioxorhenium and its derivatives are among the most versatile oxidation catalysts known to date [4]. The oxorhenium(V) chelates [ReOCl$_2$(O–N)(PPh$_3$)] with pyridinecarboxylate ligands exhibit remarkable catalytic activity for the conversion of ethane, under relatively mild conditions, to a mixture of propionic and acetic acids in a single-pot process, with various advantages over the industrial ones [5]. The [CH$_3$ReO(pic)$_2$] complex is an active precursor in olefin oxidation and forms epoxides in a two-phase H_2O_2–H_2O/CH_2Cl_2 system [6].

Furthermore, favourable nuclear properties of ^{186}Re and ^{188}Re nuclides make the compounds with these radioisotopes useful for applications in radioimmunotherapy [7,8].

In this context, the design, synthesis and reactivity of novel rhenium oxocomplexes has become the aim of several laboratories, including ours.

Previously, we investigated the reactivity of oxorhenium(V) species – [ReO(OEt)X$_2$(PPh$_3$)$_2$], [ReOX$_3$(PPh$_3$)$_2$] and [ReOX$_3$(AsPh$_3$)(OAsPh$_3$)] (X = Cl or Br) – towards

doi:10.1016/j.poly.2007.09.010

pyrazole, 3,5-dimethylopyrazole, benzotriazole and pyrazine [9]. In this report, we focus on the examinations of the reactions of $[ReOX_3(AsPh_3)_2]$ with quinoline-2-carboxylic acid. Quinoline-2-carboxylic acid is the biological compound involved in the metabolism of tryptophan. It is a strong chelator providing a donor set similar to that responsible for binding the metal ion in PQQ (pyrroloquinilnequinone) cofactor of the quinoprotein family [10].

Here we present the synthesis, spectroscopic data and X-ray structures of $[ReOBr(quin\text{-}2\text{-}c)_2]$ and $[ReOCl(quin\text{-}2\text{-}c)_2]$. In addition, this paper includes density functional theory (DFT) and time-dependent DFT (TD-DFT) calculations for the bromide complex. Recently, the electronic structures of nitrido, oxo, carbonyl, nitrosyl and nitrile rhenium complexes, as well as their spectroscopic properties, bonding and reactivity have been theoretically studied at the HF, MP2, EHT and DFT levels of theory using various basis sets [11–20]. Gancheff and co-workers [13] have performed extended tests of the ability of the B3LYP method in LANL2DZ basis set for rhenium compounds in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has been shown to be sufficient for geometry optimization and calculation of spectral properties. The correctness of the B3LYP method with the LANL2DZ basis set for rhenium complexes has been also proven in this paper. The experimental geometry of $[ReOBr(quin\text{-}2\text{-}c)_2]$ is well reproduced and the calculated electronic spectrum is in good accordance with the experimental one.

2. Experimental

2.1. General procedure

All the reagents used in the synthesis were commercially available and were used without further purification. The $[ReOX_3(AsPh_3)_2]$ (X = Cl, Br) complexes were prepared according to the literature methods [21].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in acetonitrile solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOBr(quin\text{-}2\text{-}c)_2]$

$[ReOBr_3(AsPh_3)_2]$ (0.5 g, 0.47 mmol) was added to quinoline-2-carboxylic acid (0.2 g, 1.15 mmol) in acetonitrile (50 ml) and the reaction mixture was refluxed for 6 h. The resulting solution was allowed to cool to room temperature and reduced in volume to ~10 ml. A brown crystalline precipitate of $[ReOBr(quin\text{-}2\text{-}c)_2]$ was filtered off and dried in the air. Yield: 85%. Single crystals of $[ReOBr(quin\text{-}2\text{-}c)_2]$ were obtained by recrystallization from acetonitrile.

Anal. Calc. for $C_{20}H_{12}BrN_2O_5Re$: C, 38.55; H, 1.90; N, 4.40. Found: C, 38.35; H, 1.93; N, 4.47%.

2.3. Preparation of $[ReOCl(quin\text{-}2\text{-}c)]$

A procedure similar to that for $[ReOBr(quin\text{-}2\text{-}c)_2]$ was used with $[ReOCl_3(AsPh_3)_2]$ (0.5 g, 0.54 mmol) and quinoline-2-carboxylic (0.2 g, 1.15 mmol). The crystalline precipitate of $[ReOCl(quin\text{-}2\text{-}c)_2]$ was collected in 90% yield.

Anal. Calc. for $C_{20}H_{12}ClN_2O_5Re$: C, 41.38; H, 2.11; N, 4.72. Found: C, 41.28; H, 2.08; N, 4.81%.

2.4. Crystal structure determination and refinement

The X-ray intensity data of $[ReOX(quin\text{-}2\text{-}c)_2]$ were collected on a KM-4-CCD automatic diffractometer equipped with a CCD detector and graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a temperature of 295(2) K. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption

corrections using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [22] were applied. The structures were solved by the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent atom. SHELXS-97 [23], SHELXL-97 [24] and SHELXTL [25] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Computational details

The GAUSSIAN-03 program [26] was used in the calculations. The geometry optimization of [ReOBr(quin-2-c)$_2$] in a singlet state was carried out with the DFT method with the use of the B3LYP functional [27,28]. The electronic spectrum of [ReOBr(quin-2-c)$_2$] was calculated with the TD-DFT method [29], and the solvent effect was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM). The calculations were performed by using the ECP basis set on the rhenium atom, the standard 6-31+G** basis for bromine, oxygen and nitrogen, 6-31G* for carbon and 6-31G for hydrogen atoms [30,31]. The Xe core electrons of Re were replaced by an effective core potential and a DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [32] was used for the valence electrons. An additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ on the rhenium atom were added [33].

Natural bond orbital (NBO) calculations were performed with the NBO code [34] included in GAUSSIAN-03.

4. Results and discussion

4.1. Preparation and infrared data

The [ReOX(quin-2-c)$_2$] complexes were prepared in good yields by ligand exchange reactions starting from [ReOX$_3$(AsPh$_3$)$_2$] complexes and quinoline-2-carboxylic acid in acetone:

$$[ReOX_3(AsPh_3)_2] + 2\text{quin-2-cH} \rightarrow [ReOX(\text{quin-2-c})_2] + 2HX + 2AsPh_3 \quad X = Cl, Br$$

They were isolated as brown microcrystalline solids, soluble in common organic solvents.

The selected frequencies observed in the IR spectra of the [ReOX(quin-2-c)$_2$] complexes are collected in Table 2. The IR spectra of the [ReOX(quin-2-c)$_2$] complexes show features comparable to those of mononuclear picolinato species [6]. In addition to strong bands assigned to $\nu_{sym}(CO_2)$ and $\nu_{as}(CO_2)$, there are sharp bands at $\approx$990 cm^{-1} assignable to the ν(Re=O) mode. The presence of the ν_s(Re=O) bands in the high end of the range observed for $\{ReO\}^{3+}$ core complexes suggests that the Re–carboxylate bond *trans* to the oxo ligand does not compete effectively for the d_{Re} orbitals, and the bond is relatively weak.

Table 2
Selected IR frequencies (cm^{-1}) of [ReOX(quin-2-c)$_2$] complexes

Complex	ν(Re=O)	ν_{as}(COO)	ν_s(COO)
[ReOBr(quin-2-c)$_2$]	987	1724, 1693	1317, 1304
[ReOCl(quin-2-c)$_2$]	988	1625, 1693	1318, 1305

4.2. Crystal structures

Both complexes are isostructural, they crystallise in the monoclinic space group $P2_1/n$ and their structures consist of discrete and well-separated monomers. Classical hydrogen bonds were not found in the [ReOX(quin-2-c)$_2$] structures, only some C—H···O weak inter- and intramolecular hydrogen bonds (Table 3) were detected [35,36].

The molecular structure of [ReOBr(quin-2-c)$_2$] is presented in Fig. 1, and the selected bond distances and angles of the [ReOX(quin-2-c)$_2$] complexes are collected in Tables 4 and 5, respectively.

The geometry of the [ReOX(quin-2-c)$_2$] compounds reveals typical features of quasi-octahedral oxorhenium(V) complexes with oxygenated bidentate ligands. For the complex [ReOBr(quin-2-c)$_2$], the rhenium atom is displaced 0.2852(18) Å from the equatorial plane formed by the two nitrogens, one oxygen and one bromide atom (plane A), and 0.0891(20) and 0.0192(17) Å from the axial planes formed, respectively, by the three oxygen and one nitrogen atom (plane B) and two oxygens, one bromide and one nitrogen atom (plane C). The least squares plane A is inclined at 89.14(9)° to plane B and 89.24(10)° to plane C. The planes B and C are inclined at 85.83(9)°. These values for the chloride analogue are, respectively, 0.2829(9), 0.0870(10) and 0.0137(8) Å, 89.38(5)°, 89.30(5)° and 85.25(5)°. Clear distortions of the pseudo-octahedral envi-

The Re–O_t bond lengths fall in the range 1.639–1.76 Å, which is typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicates the presence of a triple Re≡O bond [37]. The interatomic distance between the rhenium atom and the oxygen atom of quin-2-c in the *trans* position to the terminal oxo ion is somewhat longer than the corresponding Re–O bond in the equatorial plane. This structural *trans* influ-

ence is common in mononuclear six-coordinate oxo Re(V) complexes with a monoanionic oxygen *trans* to the oxo group [38].

Table 6
Atomic charges from the natural population analysis (NPA) for [ReOBr(quin-2-c)$_2$]

4.3. Geometry optimization, charge distribution, electronic structure and NBO analysis

The geometry of [ReOBr(quin-2-c)$_2$] was optimized in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters of [ReOBr-(quin-2-c)$_2$] are gathered in Table 4. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations. The calculated least squares plane A is inclined at 89.22° to plane B and 88.77° to plane C. The planes B and C are inclined at 83.94°.

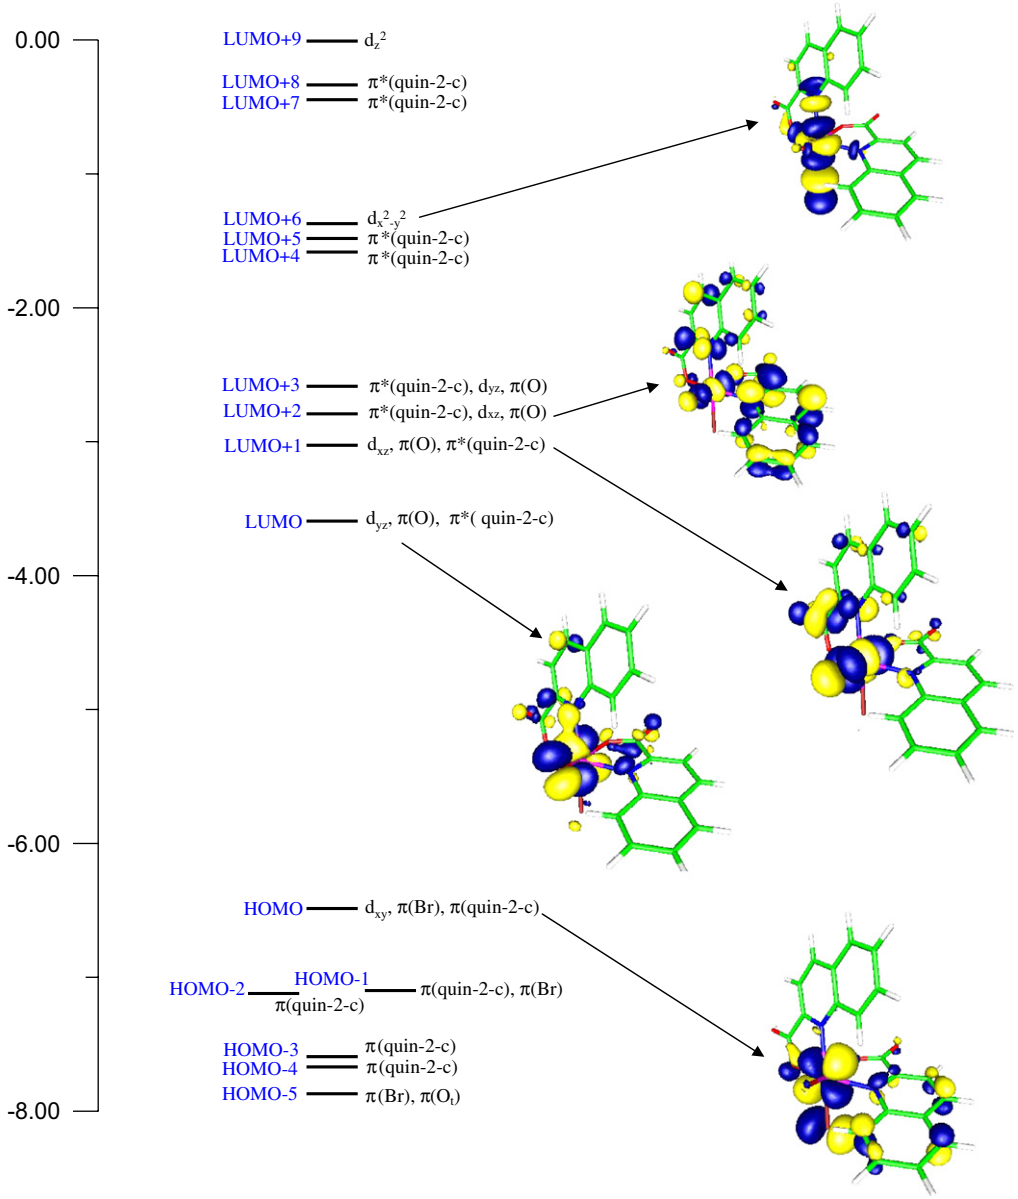

Fig. 2. The energy (eV), character and some contours of the occupied and unoccupied molecular orbitals of [ReOBr(quin-2-c)$_2$]. Positive values of the orbital contour are represented in blue (0.04 a.u.) and negative values in yellow (−0.04 a.u.). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Table 6 presents the atomic charges from the natural population analysis (NPA) for [ReOBr(quin-2-c)$_2$]. The calculated charge on the rhenium atom in [ReOBr(quin-2-c)$_2$] is considerable lower than the formal charge +5, corresponding to a d^2 configuration of the central ion. It results from significant charge donation from the ligands. The charges on the terminal oxo, bromide and oxygen atom of quin-2-c are significantly smaller than −2, −1 and −1, respectively. The terminal oxo ion is less negative in comparison with the oxygen atom of the quin-2-c ligand. It indicates higher electron density delocalization from the O_t ligand towards the central ion and corresponds to differences in the Re–$O_{carboxylate}$ and Re–$O_{terminal}$ bonds lengths.

The complex [ReOBr(quin-2-c)$_2$] has a closed-shell structure. Its molecular orbital diagram with several highest and lowest molecular orbital contours is presented in Fig. 2. The local symmetry of the rhenium center has been considered in the discussion: the *z*-axis goes along the O–Re–O linkage, and the *x*-axis through the N(2)–Re–O(2) bonds. The value of the energy separation between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) equals to 2.89 eV. This value is higher in comparison with the HOMO–LUMO gap (2.55 eV) calculated for the related [ReOBr(hqn)$_2$] complex (hqn = 8-hydroxyquinoline) [39]. The bigger absolute value of the gap energies means better stability of the title complex.

The highest occupied MO of [ReOBr(quin-2-c)$_2$] is of the d_{xy} type with some contributions from p_π bromide and quin-2-c orbitals. The remaining four d-type orbitals of rhenium are found among the unoccuppied MOs. It confirms the d^2 configuration of the rhenium atom. The LUMO and LUMO+1 can be ascribed as π-antibonding rhenium–oxygen molecular orbitals.

Table 7
The occupancy of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligand for [ReOBr(quin-2-c)$_2$]

BD	Occupancy	Composition of NBO	BD*	Occupancy
Re–O_t	1.994	$0.552(d)_{Re} + 0.834(p)_O$	$0.834(d)_{Re} - 0.552(p)_O$	0.265
Re–O_t	1.984	$0.567(d)_{Re} + 0.824(p)_O$	$0.824(d)_{Re} - 0.567(p)_O$	0.273

BD denotes 2-center bond, * denotes antibonding NBO.

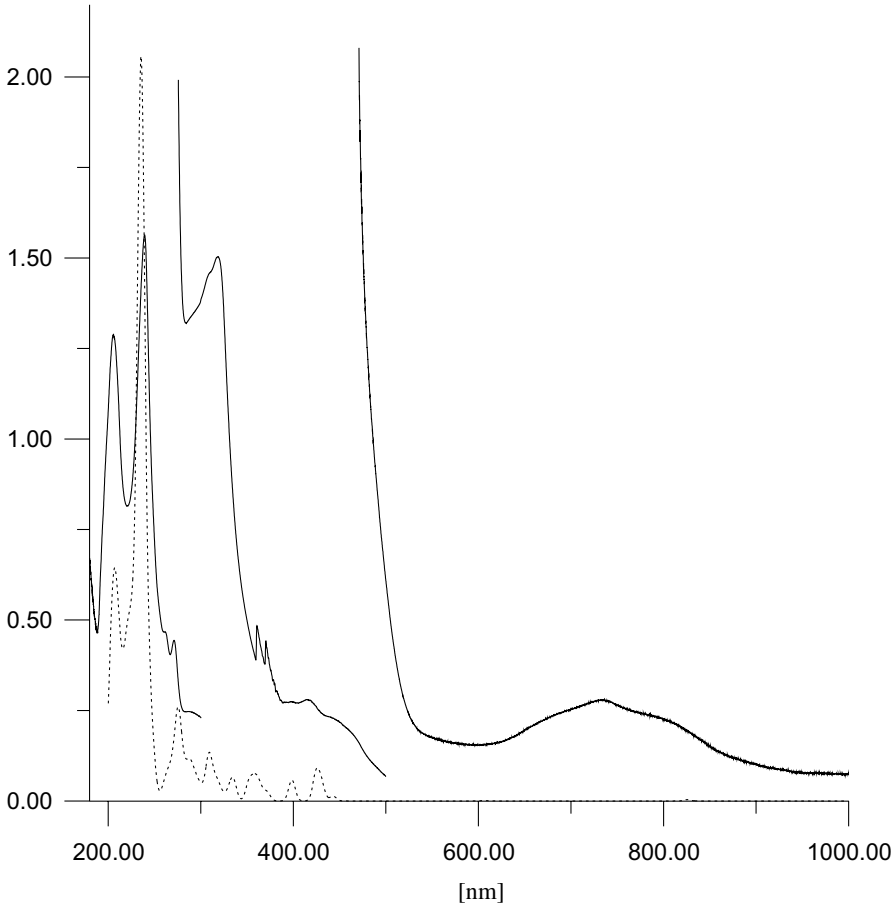

Fig. 3. The experimental (——) and calculated (------) electronic absorption spectra of [ReOBr(quin-2-c)$_2$].

Additional information about nature of the rhenium–terminal oxygen bonding has been obtained by NBO analysis. The occupancy and composition of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 7. Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in

ε, molar absorption coefficient (dm^3 mol^{-1} cm^{-1}); f, oscillator strength; H, highest occupied molecular orbital; L, lowest unoccupied molecular orbital.

an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [34].

The detected natural Re–O_t bond orbitals of [ReOBr(quin-2-c)$_2$] are π orbitals – the p_x and p_y oxygen orbitals and d_{xz} and d_{yz} rhenium orbitals are involved in their formation. Not detected, the $\sigma_{Re–Ot}$ bond has character of predominant Coulomb-type interactions between the central ion and ligands [40]. The terminal oxo ligand of [ReOBr(quin-2-c)$_2$] has two lone pair orbitals, and electron density from one of them is strongly delocalized into the non-Lewis rhenium orbital. Accordingly, NBO analysis confirms a triple bond between the rhenium and the terminal oxygen ligand.

4.4. Electronic spectra

The experimental and calculated electronic spectra of [ReOBr(quin-2-c)$_2$] are presented in Fig. 3. Each calculated transition is represented by a Gaussian function $y = c\,e^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. The shape of the UV–Vis spectrum of [ReOCl(quin-2-c)$_2$] is the same as for the bromo analogue; the absorption bands of the chloro complex were recorded at 842.1, 731.7, 432.6, 370.4, 360.7 269.5, 241.2 and 208.7 nm.

The spin-allowed singlet–singlet electronic transitions calculated with the TD-DFT method for [ReOBr(quin-2-c)$_2$] are gathered in Table 8. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.020 are listed in Table 8.

The TD-DFT/PCM calculations show that the two longest wavelength experimental bands of [ReOBr(quin-2-c)$_2$] at 815.0 and 743.7 nm originate in the HOMO → LUMO and HOMO → LUMO + 1 transitions, respectively. As d_{Re} orbitals take the main part in the HOMO, LUMO and LUMO + 1 orbitals, the HOMO → LUMO and HOMO → LUMO + 1 transitions may be attributed to transitions of d → d character. However, as it can be seen from Fig. 2, the HOMO, LUMO and LUMO + 1 orbitals are delocalized amongst the rhenium ion, bromide, oxo and quin-2-c ligands so a delocalized *MLLCT* (metal–ligand-to-ligand CT) description also can be used. In Table 8, the assignment of the calculated transitions to the experimental bands is based on consideration of main components of the molecular orbital.

The absorption bands with maxima at 435.4, 370.3 and 360.6 nm are assigned to the *Ligand–Metal Charge Transfer* transitions. The *Metal–Ligand Charge Transfer* transitions ($d \rightarrow \pi^*_{quin\text{-}2\text{-}c}$) make the largest contribution into the experimental band at 417.9 nm.

The experimental bands below 300 nm result mainly from *Ligand–Ligand Charge Transfer* and interligand (*IL*) transitions.

5. Supplementary material

CCDC 645437 and 645438 contain the supplementary crystallographic data for $C_{20}H_{12}BrN_2O_5Re$ and $C_{20}H_{12}ClN_2O_5Re$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Abstract

N,*N*-Bis(diphenylphosphino)ethylaniline compounds, $[Ph_2P]_2N\text{-}C_6H_4\text{-}C_2H_5$, with ethyl groups at the *ortho*- and *para*-positions have been synthesized. Oxidation of the aminophosphines with hydrogen peroxide, elemental sulfur and selenium gave the corresponding oxides, sulfides and selenides $[Ph_2P(E)]_2N\text{-}C_6H_4\text{-}C_2H_5$ (E = O, S, Se). Complexes $[MCl_2\{(Ph_2P)_2N\text{-}C_6H_4\text{-}(C_2H_5)\}]$ (M = Pd, Pt) and $[Cu\{(Ph_2P)_2N\text{-}C_6H_4\text{-}C_2H_5\}_2]PF_6$ were obtained by the reaction of *N*,*N*-bis(diphenylphosphino)ethylaniline with $[MCl_2(COD)]$ (M = Pd, Pt) and $[Cu(MeCN)_4]PF_6$. The new compounds were characterized by NMR, IR spectroscopy and microanalysis. In addition, representative solid-state structures of the palladium and platinum complexes were determined using single crystal X-ray diffraction analyses.

1. Introduction

The chemistry of aminophosphines containing direct P–N bonds is one of the most challenging areas in main group chemistry [1]. Among the numerous aminophosphines, bis(diphenylphosphino)alkylaniline derivatives are particularly interesting due to their relatively high stability and their ability to chelate transition metals such as palladium, platinum and copper [2,3]. Many aminophosphine ligands and their complexes have been investigated as co-catalysts in a number of catalytic processes [4,5]. Some aminophosphines and derivatives have also found application as anticancer drugs [6], herbicides and antimicrobial agents, as well as neuroactive agents [7,8]. The synthesis of bis(diphenylphosphino)alkylaniline is usually achieved in high yield via the aminolysis of aniline [9,10], which allows for the incorporation of additional functional groups such as O and N donors [11,12], or π-donors such as allyl groups [13]. The presence of the bulky groups attached to the phosphorus center renders the aminophosphine more stable against hydrolysis. The substituents at the aniline backbone can also play an important role in determining the outcome of the products [14]. In a recent study [15], we found that electron-donating groups often lead to the exclusive formation of aminophosphines [P(III)–N–P(III)], whereas electron-withdrawing groups, such as nitrile and trifluoromethyl at the *ortho*-position can lead to formation of iminobiphosphine [P(III)–P(V)=N] species.

Herein, we describe the synthesis of new *N*,*N*-bis(diphenylphosphino)ethylaniline with an ethyl group at the *ortho*- and *para*-positions. In order to study their reactivities, we prepared their corresponding complexes with selected transition metals (Cu, Pd, Pt), and also the aminophosphine oxides, sulfides and selenides. The compounds were fully characterized using multi-nuclear NMR spectroscopic methods and the solid-state structures of two of the products were established by single crystal X-ray diffraction analyses.

2. Experimental

All reactions were performed under argon unless otherwise stated. Ph_2PCl and the ethyl anilines were purchased from Fluka and used directly. The starting materials $[MCl_2(COD)]$ (M = Pd, Pt, COD = 1,5-cyclooctadiene) [16,17] and $[Cu(MeCN)_4]PF_6$ [18] were prepared according to the literature procedures. Solvents were dried using the appropriate reagents and distilled prior to use. Infrared spectra were recorded as KBr pellets in the range 4000–400 cm^{-1} on a Mattson 1000 ATI UNICAM FT-IR spectrometer. ^1H NMR (400.1 MHz) spectra were recorded on a Bruker AC 400 spectrometer, and $^{31}P-\{^1H\}$ NMR spectra at 162 MHz with δ referenced to external 85% H_3PO_4. Microanalysis was carried out on a Fisons EA 1108 CHNS-O instrument.

2.1. General procedure for the synthesis of *N,N-bis(diphenylphosphino)ethylanilines*

2.1.1. *[(Ph$_2$P)$_2$N-C$_6$H$_4$-C$_2$H$_5$] (**1**, **2**)*

N,*N*-Bis(diphenylphosphino)ethylanilines were prepared by the aminolysis reaction of $H_2N-C_6H_4-C_2H_5$ (**1**: 2-C_2H_5; **2**: 4-C_2H_5) with two equivalents of Ph_2PCl according to the procedure given in the literature [19].

2.2. General procedure for the synthesis of the chalcogenides

2.2.1. *N,N-Bis(diphenyloxophosphino)ethylanilines [(Ph$_2$P(O))$_2$N-C$_6$H$_4$-C$_2$H$_5$] (**1a**, **2a**)*

A THF solution (10 mL) of *N*,*N*-bis(diphenylphosphino)ethylaniline (0.20 g, 0.420 mmol) and aqueous H_2O_2 (30% w/w, 0.083 mL) was stirred for 2 h at room temperature. The solution was evaporated to dryness under reduced pressure and the white solids **1a** and **2a** were obtained.

*N,N-Bis(diphenyloxophosphino)-2-ethylaniline (**1a**)*: Yield: 0.065 g, 25%, mp 180–181 °C. ^1H NMR ($CDCl_3$) δ (ppm): 6.85–7.89 (m, 24H, Ar H), 2.72–2.78 (q, 2H, CH_2, $^3J_{HH} = 7.4$ Hz), 0.90–0.94 (t, 3H, CH_3, $^3J_{HH} = 7.3$ Hz). $^{31}P-\{^1H\}$ NMR ($CDCl_3$) δ (ppm): 23.6 (s). Selected IR, ν (cm^{-1}): 901 (P–N–P), 1219 (PO). *Anal*. Calc. for $C_{32}H_{29}NP_2O_2$: C, 73.70; H, 5.56; N, 2.68. Found: C, 73.56; H, 5.47; N, 2.46%.

*N,N-Bis(diphenyloxophosphino)-4-ethylaniline (**2a**)*: Yield: 0.18 g, 70%, mp 215–217 °C. ^1H NMR ($CDCl_3$) δ (ppm): 6.74–7.88 (m, 24H, Ar H), 2.32–2.38 (q, 2H, CH_2, $^3J_{HH} = 7.8$ Hz), 0.96–1.00 (t, 3H, CH_3, $^3J_{HH} = 7.6$ Hz). $^{31}P-\{^1H\}$ NMR ($CDCl_3$) δ (ppm): 24.3 (s). Selected IR, ν (cm^{-1}): 909 (P–N–P), 1213 (PO). *Anal*. Calc. for $C_{32}H_{29}NP_2O_2$: C, 73.70; H, 5.56; N, 2.68. Found: C, 73.84; H, 5.36; N, 2.59%.

2.2.2. *N,N-Bis(diphenylthiophosphino)ethylanilines [(Ph$_2$P(S))$_2$N-C$_6$H$_4$-C$_2$H$_5$] (**1b**, **2b**)*

To solid *N*,*N*-bis(diphenylphosphino)ethylaniline (0.20 g, 0.420 mmol) and S_8 (0.027 g, 0.840 mmol) was added THF (20 mL) and this was refluxed for 6 h. The volume was concentrated in vacuum to ca. 1–2 mL and addition of *n*-hexane (20 mL) gave **1b** and **2b** as white solids which were collected by suction filtration.

*N,N-Bis(diphenylthiophosphino)-2-ethylaniline (**1b**)*: Yield: 0.117 g, 52%, mp 172–174 °C. ^1H NMR ($CDCl_3$) δ (ppm): 6.85–8.13 (m, 24H, Ar H), 2.43–2.48 (q, 2H, CH_2, $^3J_{HH} = 7.4$ Hz), 0.85–0.89 (t, 3H, CH_3, $^3J_{HH} = 7.5$ Hz). $^{31}P-\{^1H\}$ NMR ($CDCl_3$) δ (ppm): 68.3 (s). Selected IR, ν (cm^{-1}): 862 (P–N–P), 650 (P–S). *Anal*. Calc. for $C_{32}H_{29}NP_2S_2$: C, 69.44; H, 5.24; N, 2.53; S, 11.57. Found: C, 69.63; H, 5.18; N, 2.73; S, 11.62%.

*N,N-Bis(diphenylthiophosphino)-4-ethylaniline (**2b**)*: Yield: 0.132 g, 58%, mp 196–197 °C. ^1H NMR ($CDCl_3$) δ (ppm): 6.68–8.09 (m, 24H, Ar H), 2.32–2.34 (q, 2H, CH_2, $^3J_{HH} = 7.8$ Hz), 0.97–1.00 (t, 3H, CH_3, $^3J_{HH} = 7.6$ Hz). $^{31}P-\{^1H\}$ NMR ($CDCl_3$) δ (ppm): 68.8 (s). Selected IR, ν (cm^{-1}): 882 (P–N–P), 658 (P–S). *Anal*. Calc. for $C_{32}H_{29}NP_2S_2$: C, 69.44; H, 5.24; N, 2.53; S, 11.57. Found: C, 69.31; H, 5.30; N, 2.24; S, 11.41%.

2.2.3. *N,N-Bis(diphenylselenophosphino)ethylanilines [(Ph$_2$P(Se))$_2$N-C$_6$H$_4$-C$_2$H$_5$] (**1c**, **2c**)*

To solid *N*,*N*-bis(diphenylphosphino)ethylaniline (0.20 g, 0.420 mmol) and grey Se (0.064 g, 0.840 mmol) was added THF (20 mL) and this was refluxed for 6 h. The volume was concentrated in vacuum to ca. 1–2 mL and addition of *n*-hexane (20 mL) gave **1c** and **2c** which were collected by suction filtration.

*N,N-Bis(diphenylselenophosphino)-2-ethylaniline (**1c**)*: Yield: 0.155 g, 59%, mp 174–175 °C. ^1H NMR ($CDCl_3$) δ (ppm): 6.87–8.15 (m, 24H, Ar H), 2.38–2.44 (q, 2H, CH_2, $^3J_{HH} = 7.4$ Hz), 0.88–0.91 (t, 3H, CH_3, $^3J_{HH} = 7.4$ Hz). $^{31}P-\{^1H\}$ NMR ($CDCl_3$) δ (ppm): 67.5, $J_{(PSe)}$: 788 Hz. Selected IR, ν (cm^{-1}): 855 (P–N–P), 579 (P–Se). *Anal*. Calc. for $C_{32}H_{29}NP_2Se_2$: C, 59.35; H, 4.48; N, 2.16. Found: C, 59.34; H, 4.22; N, 2.03%.

*N,N-Bis(diphenylselenophosphino)-4-ethylaniline (**2c**)*: Yield: 0.176 g, 67%, mp 182–184 °C. ^1H NMR ($CDCl_3$) δ (ppm): 6.68–8.19 (m, 24H, Ar H), 2.32–2.35 (q, 2H, CH_2, $^3J_{HH} = 7.5$ Hz), 0.96–1.00 (t, 3H, CH_3, $^3J_{HH} = 7.5$ Hz). $^{31}P-\{^1H\}$ NMR ($CDCl_3$) δ (ppm): 69.6, $J_{(PSe)}$: 782 Hz. Selected IR, ν (cm^{-1}): 876 (P–N–P), 565 (P–Se). *Anal*. Calc. for $C_{32}H_{29}NP_2Se_2$: C, 59.35; H, 4.48; N, 2.16. Found: C, 59.48; H, 4.53; N, 2.07%.

2.3. General procedure for the synthesis of the complexes

2.3.1. Dichloro{*N,N*-bis(diphenylphosphino)ethylaniline}-palladium (II) (**1d, 2d**)

A solution of [$PdCl_2$(COD)] (0.049 g, 0.172 mmol) and *N,N*-bis(diphenylphosphino) ethylaniline (0.086 g, 0.175 mmol) in CH_2Cl_2 (10 mL) was stirred for 1.5 h. The volume was concentrated in vacuum to ca. 1–2 mL and addition of diethyl ether (20 mL) gave **1d** and **2d** as yellow solids which were collected by suction filtration and dried in vacuum.

*Dichloro{N,N-bis(diphenylphosphino)-2-ethylaniline}-palladium (II) (**1d**)*: Yield: 0.094 g, 85%, mp >300 °C. ^{1}H NMR ($CDCl_3$) δ (ppm): 6.57–7.94 (m, 24H, Ar H), 1.38–1.41 (q, 2H, CH_2, $^3J_{HH} = 7.4$ Hz), 0.91–0.95 (t, 3H, CH_3, $^3J_{HH} = 7.5$ Hz). ^{31}P–{^{1}H} NMR ($CDCl_3$) δ (ppm): 37.2 (s). Selected IR, ν (cm^{-1}): 900 (P–N–P). *Anal.* Calc. for $C_{32}H_{29}NP_2PdCl_2$: C, 60.86; H, 4.59; N, 2.22. Found: C, 60.77; H, 4.39; N, 2.05%.

*Dichloro{N,N-bis(diphenylphosphino)-4-ethylaniline}-palladium (II) (**2d**)*: Yield: 0.10 g, 97%, mp >300 °C. ^{1}H NMR ($CDCl_3$) δ (ppm): 6.43–7.92 (m, 24H, Ar H); 2.52–2.54 (q, 2H, CH_2, $^3J_{HH} = 7.5$ Hz), 1.15–1.18 (t, 3H, CH_3, $^3J_{HH} = 7.5$ Hz). ^{31}P–{^{1}H} NMR ($CDCl_3$) δ (ppm): 34.8 (s). Selected IR, ν (cm^{-1}): 913 (P–N–P). *Anal.* Calc. for $C_{32}H_{29}NP_2PdCl_2$: C, 60.86; H, 4.59; N, 2.22. Found: C, 60.66; H, 4.38; N, 2.33%. Slow diffusion of diethyl ether into a CH_2Cl_2 solution of **2d** over 48 h gave crystals suitable for X-ray diffraction.

2.3.2. Dichloro{*N,N*-bis(diphenylphosphino)ethylaniline}-platinum (II) (**1e, 2e**)

A solution of [$PtCl_2$(COD)] (0.034 g, 0.0860 mmol) and *N,N*-bis(diphenylphosphino)ethylaniline (0.0427 g, 0.0875 mmol) in CH_2Cl_2 (10 mL) was stirred for 1.5 h. The volume was concentrated in vacuum to ca. 1–2 mL and addition of diethyl ether (20 mL) gave **1e** and **2e** as white solids which were collected by suction filtration and dried in vacuum.

*Dichloro{N,N-bis(diphenylphosphino)-2-ethylaniline}-platinum (II) (**1e**)*: Yield: 0.056 g, 86%, mp 339–341 °C. ^{1}H NMR ($CDCl_3$) δ (ppm): 6.48–7.93 (m, 24H, Ar H), 1.21–1.25 (q, 2H, CH_2, $^3J_{HH} = 7.1$ Hz), 0.23–0.27 (t, 3H, CH_3, $^3J_{HH} = 7.2$ Hz). ^{31}P–{^{1}H} NMR ($CDCl_3$) δ (ppm): 22.3, $J_{(PtP)}$: 3348.6 Hz. Selected IR, ν (cm^{-1}): 900 (P–N–P). *Anal.* Calc. for $C_{32}H_{29}NP_2PtCl_2$: C, 50.86; H, 3.84; N, 1.85. Found: C, 50.84; H, 3.63; N, 1.67%. Slow diffusion of diethyl ether into a $CHCl_3$ solution of **1e** over 48 h gave crystals suitable for X-ray crystallography.

*Dichloro{N,N-bis(diphenylphosphino)-4-ethylaniline}-platinum (II) (**2e**)*: Yield: 0.057 g, 88%, mp 339–340 °C. ^{1}H NMR ($CDCl_3$) δ (ppm): 6.36–7.90 (m, 24H, Ar H), 2.51–2.56 (q, 2H, CH_2, $^3J_{HH} = 7.5$ Hz), 1.14–1.17 (t, 3H, CH_3, $^3J_{HH} = 7.5$ Hz). ^{31}P–{^{1}H} NMR ($CDCl_3$) δ (ppm): 20.6, $J_{(PtP)}$: 3324 Hz. Selected IR, ν (cm^{-1}): 906 (P–N–P). *Anal.* Calc. for $C_{32}H_{29}NP_2PtCl_2$: C, 50.86; H, 3.84; N, 1.85. Found: C, 50.71; H, 3.78; N, 1.76%.

2.3.3. Bis[*N,N*-bis(diphenylphosphino)ethylaniline]copper (I) hexafluorophosphates (**1f, 2f**)

To a solution of [$Cu(MeCN)_4$]PF_6 (0.071 g, 0.191 mmol) in CH_2Cl_2 (20 mL) was added *N,N*-bis(diphenylphosphino)ethylaniline (0.185 g, 0.380 mmol) and the resulting solution was stirred for 2 h. The volume was concentrated in vacuum to ca. 1–2 mL and addition of diethyl ether (20 mL) gave **1f** and **2f** as white solids which were collected by suction filtration and dried in vacuum.

*Bis[N,N-bis(diphenylphosphino)-2-ethylaniline]copper (I) hexafluorophosphate (**1f**)*: Yield: 0.183 g, 83%, mp 204–205 °C. ^{1}H NMR ($CDCl_3$) δ (ppm): 6.87–8.15 (m, 24H, Ar H), 1.21–1.27 (q, 2H, CH_2, $^3J_{HH} = 7.6$ Hz), 0.02–0.05 (t, 3H, CH_3, $^3J_{HH} = 7.5$ Hz). ^{31}P–{^{1}H} NMR ($CDCl_3$) δ (ppm): 87.7 (s), $\delta_{(PF6)}$: −144.3(m); $J_{(PF6)}$: 1418 Hz. Selected IR, ν (cm^{-1}): 843 (P–N–P). *Anal.* Calc. for $C_{64}H_{58}N_2P_5F_6Cu$: C, 64.73; H, 4.89; N, 2.36. Found: C, 64.69; H, 5.02; N, 2.21%.

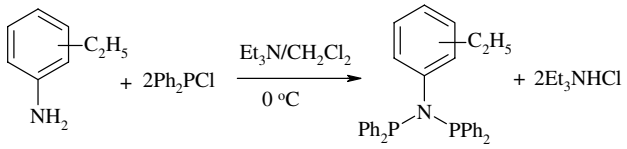
*Bis[N,N-bis(diphenylphosphino)-4-ethylaniline]copper (I) hexafluorophosphate (**2f**)*: Yield: 0.20 g, 91%, mp 339–340 °C. ^{1}H NMR ($CDCl_3$) δ (ppm): 6.68–8.19 (m, 24H, Ar H), 2.45–2.51 (q, 2H, CH_2, $^3J_{HH} = 7.6$ Hz), 1.08–1.12 (t, 3H, CH_3, $^3J_{HH} = 7.6$ Hz). ^{31}P–{^{1}H} NMR ($CDCl_3$) δ (ppm): 88.2 (s), $\delta_{(PF_6)}$: −144.3(m); $J_{(PF_6)}$: 1424 Hz. Selected IR, ν (cm^{-1}): 848 (P–N–P). *Anal.* Calc. for $C_{64}H_{58}N_2P_5F_6Cu$: C, 64.73; H, 4.89; N, 2.36. Found: C, 64.79; H, 4.95; N, 2.41%.

2.3.4. Structure determination in the solid state

Data collection for **1e** and **2d** was performed on an Oxford-Kuma Xcalibur diffractor with a Sapphire CCD area detector at 140(2) K and data reduction was performed using CrysAlis RED [20]. The structures were solved by direct methods using SIR-92 [21], and refined by full-matrix least-squares refinement (against F^2) using SHELXTL [22,23], with all non-hydrogen atoms refined anisotropically. The hydrogen atoms were placed in their geometrically generated positions and treated as riding on their parent atoms with $U_{iso}(H) = 1.2U_{eq}(C)$, except for the terminal H-atoms on C8 where $U_{iso}(H) = 1.5U_{eq}(C)$. Empirical absorption corrections were applied using DELABS [24]. Relevant crystallographic data are compiled in Table 1 and graphical representations of the structures were made with DIAMOND [25].

3. Results and discussion

N,N-Bis(diphenylphosphino)ethylanilines, $(Ph_2P)_2N$-C_6H_4-C_2H_5 (**1**: 2-C_2H_5; **2**: 4-C_2H_5) were prepared from H_2-N-C_6H_4-C_2H_5 and Ph_2PCl by aminolysis in CH_2Cl_2 in accordance with our previous reports [19] (Scheme 1).



The reaction was monitored by ^{31}P–{^{1}H} NMR spectroscopy. In contrast to reactions of diphenylphosphorus chloride (Ph_2PCl) with anilines bearing electron-withdrawing groups [15], the reaction mixture of Ph_2PCl with 2-ethylaniline or 4-ethylaniline gave a single resonance at δ(P) 61.6 ppm for **1** and 68.5 ppm for **2**, and no formation of

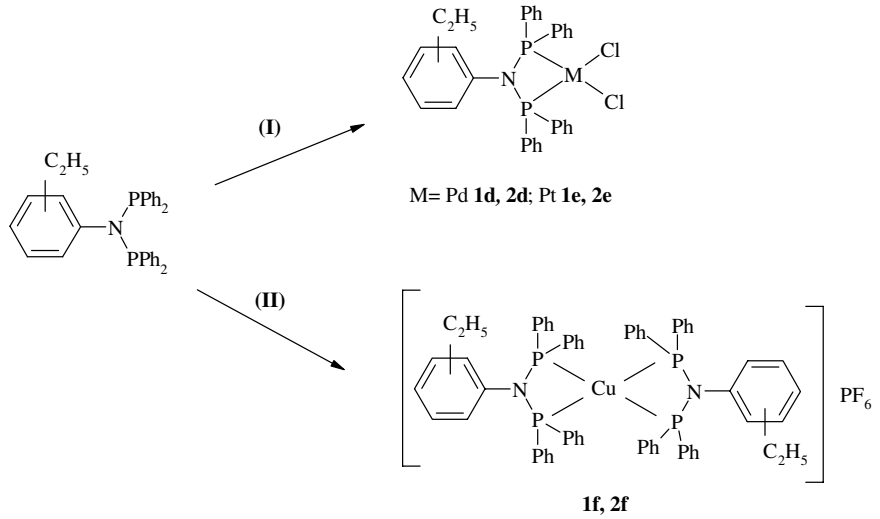
Scheme 1. Syntheses of *N*,*N*-bis(diphenylphosphino)ethylanilines by the aminolysis reaction of H_2N-C_6H_4-$C_2H_5$with Ph_2PCl (**1**: 2-C_2H_5; **2**: 4-C_2H_5).

iminobiphosphine species (Ph_2P–PPh_2=$NC_6H_4(C_2H_5)$) could be observed. The ^{31}P–{^1H} NMR signal of compound **1** is shifted upfield compared to that of **2**, although they both lie in the expected region of 60–70 ppm [26]. The compounds are air-stable solids but gradually undergo decomposition on exposure to moisture.

Oxidation of **1** and **2** with aqueous hydrogen peroxide, elemental sulfur and selenium gave the corresponding oxides **1a**, **2a**, sulfides **1b**, **2b** and selenides **1c**, **2c** (Scheme 2). The ^{31}P NMR spectrum of **1a** and **2a** displays one singlet at 23.6 ppm and 24.3 ppm, respectively, suggesting the two phosphorus atoms are chemically equivalent in both compounds. Similarly, singlet resonances were also found in the ^{31}P NMR spectra of **1b** and **2b** (68.3 ppm and

Scheme 2. Oxidation of $(Ph_2P)_2$N-C_6H_4-C_2H_5 with aqueous H_2O_2 (**1a**, **2a**), elemental sulfur (**1b**, **2b**) and powder selenium (**1c**, **2c**).

68.8 ppm) and **1c**, **2c** (67.5 ppm and 69.6 ppm). The composition of the oxidized derivatives **1a**, **2a**, **1b**, **2b**, **1c** and **2c** were further confirmed by using microanalysis and IR spectroscopy, and were found to be in good agreement with the theoretical values [12,13,15].



Reactions of compounds **1** and **2** with [M(COD)Cl_2] (M = Pd, Pt; COD = 1,5-cyclooctadiene) and [Cu(CH_3-$CN)_4$]PF_6 in CH_2C1_2 gave the corresponding complexes **1d**, **2d**, **1e**, **2e** [M{$(Ph_2P)_2$N-C_6H_4-C_2H_5}Cl_2] (M = Pd; Pt) and **1f**, **2f** [Cu{$(Ph_2P)_2$N-C_6H_4-C_2H_5}$_2$]PF_6 in good yields (Scheme 3).

The ^{31}P NMR chemical shifts of complexes **1d** and **2d** (37.2 ppm and 34.8 ppm) are within the range expected for structurally similar complexes where an electron-withdrawing group is attached to the aniline ring [27]. The chemical shifts of **1e**, **2e**, **1f** and **2f** in the ^{31}P NMR spectra are also within the expected range and they show minor solvent dependence [13]. In the ^1H NMR spectra, these complexes display overlapped multiplets in the region 6.70–8.10 ppm for the aromatic H-atoms, and a quartet at 2.50 ppm and a triplet at 1.15 ppm for the hydrogen atoms of the ethyl group.

Single crystals of **1e** and **2d** suitable for X-ray diffraction analyses were obtained by slow diffusion of diethyl ether into a solution of the complexes in chloroform and dichloromethane, respectively. They both crystallized as 1:1 solvent adducts and the crystallographic data of **1e** · $CHCl_3$ and **2d** · CH_2Cl_2 are listed in Table 1.

The molecular representation of complexes **1e** and **2d** are shown in Figs. 1 and 2, with key bond parameters given in the figure captions. In general, the key bond lengths and angles of complexes **1e** and **2d** in the solid state are very similar, with minimal structural differences due to the relocation of the ethyl groups. The P–N bond distances of 1.734(7) and 1.738(6) Å in complex **2d** are essentially the same, but they are longer than that of the platinum complex **1e** [1.715(4) and 1.719(4) Å], although they are within the expected value range on comparison to similar structures [27]. Both complexes form metallacycles, i.e. P–N–P–Pd and P–N–P–Pt, respectively, that are nearly planar with torsion angles P–N–P–Pd of 0.5(4)° in **2d** and P–N–P–Pt of 5.78(17)° in **1e**. Despite the difference of the two metal atoms, the P–Pd–P angle in **2d** [72.30(9)°] is not too different from that of the P–Pt–P angle in **1e** [72.80(4)°].

It is interesting to note that compounds **1e** and **2d** crystallised under similar conditions, both forming 1:1 adducts with solvent molecules, presumably driven by H-bonding interactions with the solvent molecules. In both instances,

Scheme 3. Reactions of aminophosphines **1** and **2** with $[M(COD)Cl_2]$ (M = Pd, Pt) and $[Cu(CH_3CN)_4]PF_6$ in CH_2C1_2.

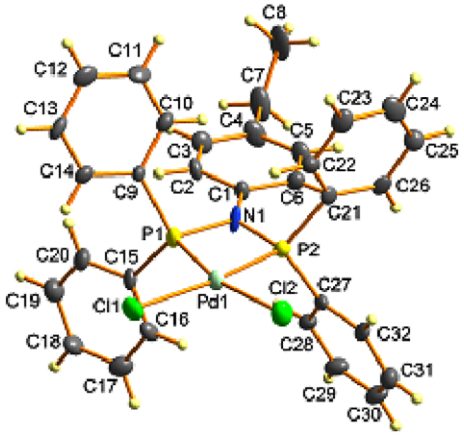


Fig. 1. Solid-state structure of compound **2d**; selected bond lengths (Å) and angles (°): Pd(1)–P(1), 2.212(3), Pd(1)–P(2), 2.215(3), Pd(1)–Cl(1), 2.373(2), Pd(1)–Cl(2), 2.379(3), N(1)–C(1), 1.419(11), N(1)–P(2), 1.734(7), N(1)–P(1), 1.738(6); P(1)–Pd(1)–P(2), 72.30(9), P(1)–Pd(1)–Cl(1), 95.18(9), P(2)–Pd(1)–Cl(1), 167.18(10), P(1)–Pd(1)–Cl(2), 165.81(9), P(2)–Pd(1)–Cl(2), 94.28(9), Cl(1)–Pd(1)–Cl(2), 98.41(9), C(1)–N(1)–P(2), 132.8(6), C(1)–N(1)–P(1), 129.5(6), P(2)–N(1)–P(1), 97.6(4).

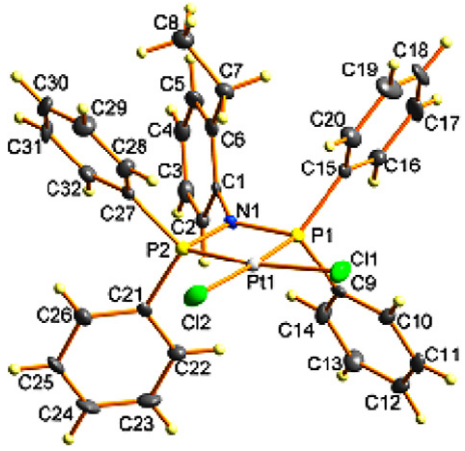

Fig. 2. Solid-state structure of compound **1e**; selected bond lengths (Å) and angles (°): Pt(1)–P(1), 2.2096(12), Pt(1)–P(2), 2.2151(12), Pt(1)–Cl(2), 2.3592(12), Pt(1)–Cl(1), 2.3633(12), N(1)–C(1), 1.449(5)N(1)–P(1), 1.715(4), N(1)–P(2), 1.719(4), P(1)–Pt(1)–P(2), 72.80(4), P(1)–Pt(1)–Cl(2), 171.69(5), P(2)–Pt(1)–Cl(2), 98.97(4), P(1)–Pt(1)–Cl(1), 97.54(5), P(2)–Pt(1)–P(1), 169.93(4), Cl(2)–Pt(1)–Cl(1), 90.74(4), C(1)–N(1)–P(1), 132.7(3), C(1)–N(1)–P(2), 126.9(3), P(1)–N(1)–P(2), 99.72(18).

the solvent molecule interacts via C–H bonds directly with the metal chloride bonds, the C–H···Cl(Pd) distance in **2d** and C–H···Cl(Pt) distance in **1e** being 2.589 and 2.471 Å, respectively. In addition, the chloride of the solvent molecules also interacts with the C–H bonds of the aromatic benzene ring, and the C–H···Cl values range from 2.80 to 2.90 Å (see Fig. 3).

4. Conclusion

In conclusion, we have prepared a series of aminophosphine compounds and their derivatives including oxides, sulfides, selenides, as well as transition-metal complexes containing Pd, Pt and Cu centers. Although the positions of the ethyl groups in the aniline substituent are different, they exhibit similar reactivities towards different oxidants due to the presence of the bulky diphenyl groups at the phosphorus atom. In addition, they also show similar coordination properties towards Pd, Pt and Cu. All these new compounds were characterized using NMR and IR spectroscopy, with two representative structures studied by single crystal X-ray diffraction analyses. Investigations of these compounds as potential catalysts are ongoing and will be reported separately.

5. Supplementary material

CCDC 643157 and 643158 contain the supplementary crystallographic data for this paper. These data can be

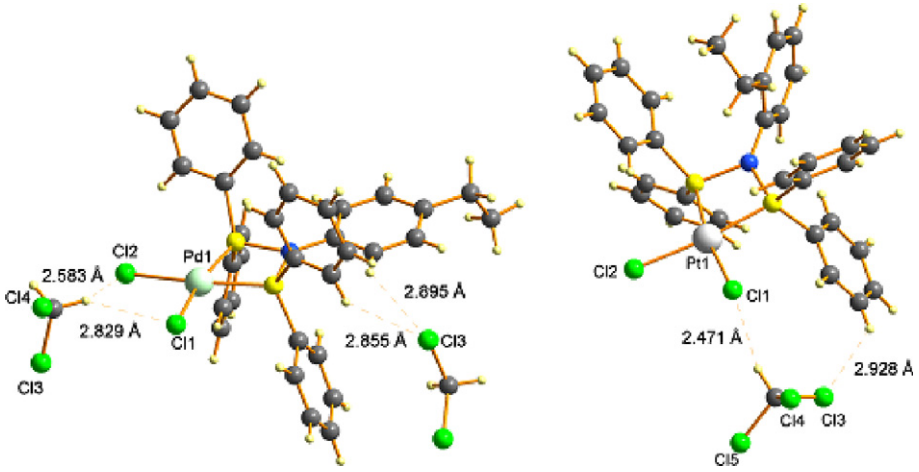

Fig. 3. Hydrogen bonding interactions in **2d** (left) and **1e** (right).

Abstract

Based on *N*,*N*′-bis(5-ethyl-1,3,4-thiadiazol-2-yl)-2,6-pyridinedicarboxamide (H_2**L**) and inorganic Zn^{II} and Cd^{II} salts, three polynuclear complexes $[Zn_6(\mu_4\text{-}O)_2(L)_4]$ (**1**), $[Zn_3(\mu_3\text{-}O)_2(L)_2(H_2L)]$ (**2**) and $[Cd_5(\mu_3\text{-}O)_2(L)_3(H_2L)(CH_3OH)(DMF)]$ (**3**) have been prepared and their crystal structures have been determined by single-crystal X-ray analysis. The thermal behaviors of these complexes in nitrogen and the thermal decomposition kinetics of complex **2** in the temperature range 350–540 °C have been studied, and kinetic parameters were also obtained. Kinetic results show that the decomposition of complex **2** is double-step reaction: a 1st-order reaction (F1) is followed by an *n*th-order reaction (Fn).

1. Introduction

Polynuclear complexes continue to attract a great deal of interest, not only because of their fascinating structural diversities, but also for their potential application in the fields of catalysis, functional materials and biological recognition [1], as models of active sites in metal enzymes [2–5], etc. So far, various preparation methods have been proposed to obtain such polynuclear complexes [6–9], of which, a successful strategy is to design a polytopic ligand for the coordination of metal centers [10–14]. Depending on these carefully designed ligands and the versatile coordination geometries of metal, a large number of polynuclear metal clusters with magnetic, optical or electronic properties have been synthesized. Diamides incorporating an –NH–CO–pyridine–CO–NH– core based on pyridine-2,6-dicarboxylic acid are versatile ligands and a number of novel architectures such as helicates, cages and metallamacrocycle have been prepared recently [15–20].

As part of our interest in preparing metalla-assemblies with ligands that contain 5-(ethyl-2-yl)-amide-1,3,4-thiadiazole, we have recently synthesized a new compound, *N*,*N*′-bis(5-ethyl-1,3,4-thiadiazol-2-yl)-2,6-pyridinedicarboxamide (H_2**L**). Obviously, this compound easily acts as a multidentate ligand to construct polynuclear complexes and its *pocket*-like nature can result in structurally complicated complexes. For example, it can take different bonding modes, such as **A**, **B** and **C** coordination fashions under different conditions (Fig. 1). In addition, the ligand still retains O and S donors for further hydrogen-bonding and/or metal–ligand interactions.

In this paper, we report the syntheses, structures and thermal behaviors of three polynuclear d^{10} metal complexes, namely, $[Zn_6(\mu\text{-}O)_2(L)_4]$ (**1**), $[Zn_3(\mu\text{-}O)_2(H_2L)(L)_2]$ (**2**) and

$[Cd_5(\mu_3\text{-}O)_2(H_2L)(L)_3(CH_3OH)\ (DMF)]$ (**3**). Based on the results of thermogravimetry (TG) analysis, the thermal decomposition mechanism of complex **2** in the temperature range 350–540 °C has been studied and kinetic parameters of the thermal decomposition reaction have been obtained by means of the non-linear regression method.

2. Experimental

The ligand precursor and metal salts were commercial samples and were used in the syntheses as received.

2.1. Ligand preparation (H_2**L**)

2,6-Pyridinedicarboxylic acid (1.67 g, 10 mmol) was dissolved in 10 ml of $SOCl_2$. The mixture was refluxed for 2 h until the white powder was dissolved completely. The residual $SOCl_2$ was then removed under reduced pressure. The resulting 2,6-pyridinedicarbonyl dichloride was dissolved and added dropwise to a 20 ml pyridine solution containing 5-ethyl-2-amino-1,3,4-thiadiazole (2.58 g, 20 mmol) whilst stirring. Two hours later, white precipitates were formed. The pure product was obtained by being filtered under reduced pressure, washed with water and recrystallized in absolute ethanol. Yields: 2.92 g (75%). M.P. 309–310 °C. *Anal*. Calc. for H_2**L** ($C_{15}H_{15}N_7O_2S_2$): C, 46.27; H, 3.86; N, 25.19. Found: C, 46.25; H, 3.79; N, 25.20%. ^{1}H NMR (DMSO): $\delta_H = 8.47$, 8.45 (m, 2H, CONH), 8.38-8.31(w, 3H, py), 3.09–3.05 (m, 4H, CH_2), 1.34 (s, 6H, CH_3) ppm. IR (KBr, cm^{-1}): 3295s, 3163s, 2937m, 1684s, 1534s, 1438m, 1298s, 1071m, 1001w, 888m, 704w, 650m.

2.2. Synthesis of $[Zn_6(\mu_4\text{-}O)_2(L)_4]$ (**1**)

An EtOH solution (10 ml) of $Zn(OAc)_2 \cdot 2H_2O$ (0.0587 g, 0.1 mmol) was added slowly to a DMF solution (10 ml) of H_2**L** (0.0389 g, 0.1 mmol) with continuous stirring. KSCN (0.0097 g, 0.1 mmol) in 10 ml of EtOH was then added to the above solution. The mixture was refluxed for 1 h and filtered. The filtrate was evaporated slowly at room temperature. After a week colorless crystals suitable for X-ray diffraction were obtained by being filtered, washed with cooled water and dried under vacuum. Yield: 36%. *Anal*. Calc. for **1** ($C_{60}H_{52}N_{28}O_{10}S_8Zn_6$): C, 36.51; H, 2.65; N, 19.87. Found: C, 36.54; H, 2.55; N, 19.88%. IR (KBr, cm^{-1}): 3448s, 3134s, 2975s, 2935w, 1660s, 1617s, 1593s, 1463s, 1442s, 1379s, 1308s, 1287m, 1073m, 956m, 845m, 696m.

2.3. Synthesis of $[Zn_3(\mu_3\text{-}O)_2(H_2L)(L)_2]$ (**2**)

$Zn(OAc)_2 \cdot 2H_2O$ (0.0587 g, 0.1 mmol) in 10 ml of methanol and KSCN (0.0097 g, 0.1 mmol) in 5 ml of water were added slowly to a 20 ml of ethanol solution containing H_2**L** (0.0389 g, 0.1 mmol) with continuous stirring for 1 h. The mixture was filtered and after a month light-yellow crystals were formed from the filtrate at room temperature. The crystals were collected, washed with water and dried under vacuum. Yield: 47%. *Anal*. Calc. for **2** $\cdot 4H_2O$ ($C_{45}H_{49}N_{21}O_{11}S_6Zn_3$): C, 37.36; H, 3.41; N, 20.31. Found: C, 73.31; H, 3.39; N, 20.24%. IR (KBr, cm^{-1}): 3422s, 3197s, 2971m, 1617m, 1593m, 1576s, 1456s, 1425s, 1387s, 1367s, 1306m, 1073w, 1045w, 963w, 903m, 762w, 675m.

2.4. Synthesis of $[Cd_5(\mu_3\text{-}O)_2(H_2L)(L)_3(CH_3OH)(DMF)]$ (**3**)

A solution of $Cd(NO_3)_2 \cdot 4H_2O$ (0.0308 g, 0.1 mmol) in EtOH (5 ml) and a solution of NaOOCH (0.007 g, 0.1 mmol) in EtOH (5 ml) were added to a solution of H_2**L** (0.0389 g, 0.1 mmol) in DMF (10 ml). The mixture was refluxed for 1 h and filtered. The filtrate was allowed to stand undisturbed at room temperature and colorless block crystals were obtained after six months. The crystals were washed with water and dried under vacuum. Yield: 20%. *Anal*. Calc. for **3** $\cdot H_2O$ ($C_{64}H_{67}N_{29}O_{13}S_6Cd_5$): C, 33.88; H, 2.98; N, 17.90%. Found: C, 33.82; H, 2.88, N, 17.85%. IR (KBr, cm^{-1}): 3411s, 2971m, 1660s, 1577s, 1490m, 1450s, 1420s, 1374s, 1354s, 1299w, 951m, 898m, 756m, 670m.

2.5. Physical measurements

Elemental analyses were performed on a Perkin–Elmer 240C analyzer and IR spectra were recorded on a Nicolet IR-470 spectrometer using KBr pellets in the range 4000–400 cm^{-1}. ^{1}H NMR spectra were obtained on a Bruke-DPX400 NMR spectrometer (300 MHz) at 25 °C in DMSO. The thermal decomposition experiments were carried out using a Netzsch TG 209 instrument under a nitrogen atmosphere. The heating rate for the thermal decomposition employed was 10 °C min^{-1}.

Data collection were made using graphite monochromated Mo Kα ($\lambda = 0.071073$ nm) radiation on a Rigaku Raxis-IV X-ray diffractometer at 291(2) K. The structures were solved by direct methods and refined on F^2 by

full-matrix least squares using SHELXTL [21]. Non-hydrogen atoms were located by direct phase determination and subjected to anisotropic refinement. All the hydrogen atoms were placed in calculated positions. Details of crystal structure determination of complexes **1**–**3** are listed in Table 1, and selected bond distances and angles are listed in Tables 2–4.

3. Results and discussion

3.1. Synthesis

The single crystals of **1** would not form unless in the presence of KSCN. Since KSCN did not participate in the formation of the structure of **1**, the role it played may be an improvement of the ionic strength (I) of the solution, which is the key factor in the self-assemble of the hexanuclear Zn complex. The same case appears in the process of the synthesis of complex **3**, but the strong electrolyte here is NaOOCH.

The synthetic method of crystal **2** is the same as that of crystal**1**, except the solvent. The different solvents result in the formation of hexanuclear and trinuclear Zn complexes, which indicate that the solvent used can affect the self-assembly process.

3.2. Crystal structure of $[Zn_6(\mu_4\text{-}O)_2(L)_4]$ (**1**)

Complex **1** crystallizes in the monoclinic space group $P2_{1/n}$. As shown in Fig. 2a, the complex motif contains a

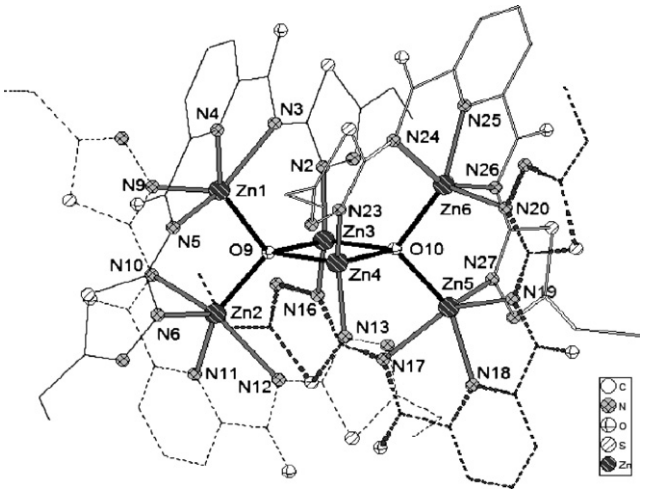

Fig. 2a. Molecular structure of complex **1**.

$[Zn_6(\mu_4\text{-}O)_2]$ core and can be considered as two tetrahedrons, in which μ_4-O (O9, O10) atoms occupy the centre of each tetrahedron (see Fig. 2b). The edge-shared (Zn3, Zn4) tetrahedrons constitute the core of complex **1**. On the other hand, the 6-atom Zn core can also be described as a contracted octahedron with Zn3 and Zn4 in the axial coordination sites of the minor axis. The Zn3···Zn4 distance of 2.711(19) Å indicates that there is a strong interaction between them. The outer coordination shell of the $[Zn_6(\mu_4\text{-}O)_2]$ core is occupied by four ligands.

Two types of Zn atoms can be distinguished (see Fig. 2a). In the first type (including Zn1, Zn2, Zn5 and Zn6), the distorted square pyramids of each Zn atom is completed by one μ_4-O, three nitrogen atoms of the –NH–CO–pyridine–CO–NH– core of one ligand and

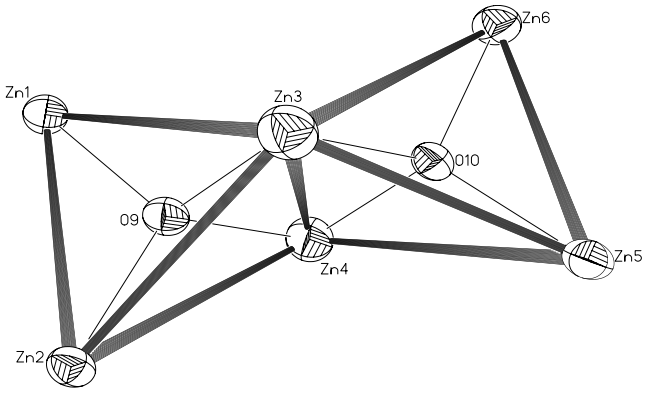

Fig. 2b. Edge-shared tetrahedron core of complex **1**.

another nitrogen atom from the thiadiazole of another ligand, forming a $ZnON_4$ coordination environment. The Zn–O bond lengths are almost the same (1.955(5)–1.968(5) Å), and the Zn–N bond distances fall in the range of 2.004(7)–2.275(8) Å. The large range of Zn–N bond distances suggests that these Zn–N bonds have different bond strength, and this may be caused by the difference in the steric hindrance of the rigid part (–NH–CO–pyridine–CO–NH–) of the ligand. A similar situation of M–N bonds can also be seen in those polynuclear complexes constructed from substituted pyridine ligands [15–17]. In the second type (Zn3 and Zn4), the tetrahedral sphere of each Zn is completed by two μ_4-O and two nitrogen atoms from the thiadiazole ring of two ligands, forming a ZnO_2N_2 coordination environment. The Zn–O bond distances (1.962(6)–1.968(5) Å) in this type are similar to the Zn–N bonds (1.939(8)–1.977(8) Å). In complex **1**, four $\mathbf{L}^{2-}$ chelate Zn atoms with the same coordination mode, namely the **A** type mode.

3.3. Crystal structure of $[Zn_3(\mu_3\text{-}O)_2(H_2L)(L)_2]$ (**2**)

Single-crystal structural analysis reveals that complex $\mathbf{2}\cdot 4H_2O$ crystallizes in the monoclinic space group $C2/c$ and in the structure there exists a twofold symmetric axis on which the Zn2, N11 and O4 atoms lie (Fig. 3). The lattice water molecules reside on three crystallographic sites with partial occupancies which are summed to "two". There are two crystallographically different Zn atoms in the structure. Each Zn atom has a distorted octahedral geometry with a μ_3-O atom and five nitrogen atoms. The Zn–O bond lengths in complex **2** are 1.865(7), 1.976(4) and 1.976(4) Å, and as is the case for complex **1**, a wide range for the Zn–N bond distances (2.043(8)–2.440(6) Å) are also caused by the steric hindrance of the ligand. Although the three ligands take the same coordination mode, **A** type, one of them is not deprotonated, as is deduced from charge balance and bond lengths. Thus, complex **2** has a cage-like structure with the conventional $[Zn_3(\mu_3\text{-}O)]$ core and two deprotonated $\mathbf{L}^{2-}$ ligands as well as one $H_2\mathbf{L}$.

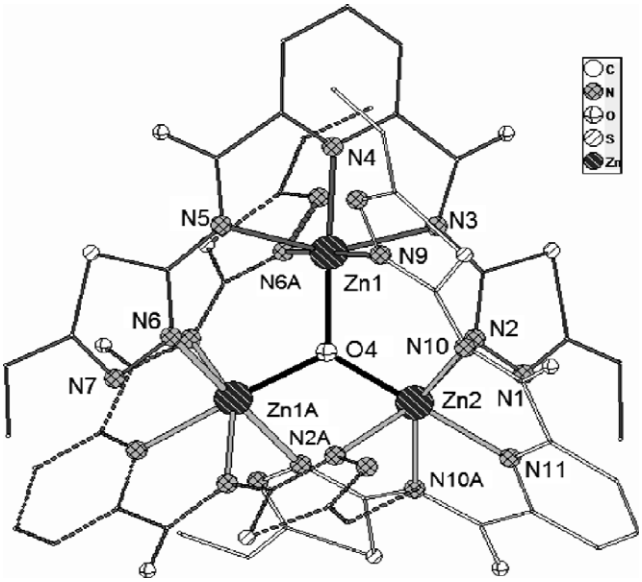

Fig. 3. Molecular structure of complex **2**.

A network of H-bonds is present in the structure. Six O atoms (O5A, O6A, O7A, O5B, O6B, O7B) of H_2O from two adjacent units connect each other to form a six-member ring through H-bonds, and O atoms in these rings further link all the neighboring acyl O atoms (O1, O2, O3) of the $[Zn_3(\mu_3\text{-}O)_2(H_2L)(L)_2]$ core to form a 3D structure.

3.4. Crystal structure of $[Cd_5(\mu_3\text{-}O)_2(H_2L)(L)_3(CH_3OH)(DMF)]$ (3)

Complex **3** · H_2O crystallizes in the triclinic space group $P\bar{1}$. The structure unit is shown in Fig. 4a. The core of **3** can be described as two trinuclear oxo-centered $[Cd_3(\mu_3\text{-}O)]$ units sharing one vertex (Cd2) through two ligands and two μ_3-oxygen atoms (Fig. 4b).

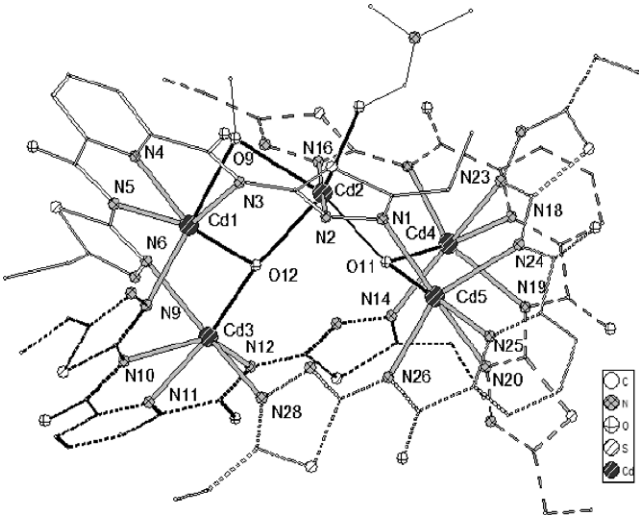

Fig. 4a. Molecular structure of complex **3**.

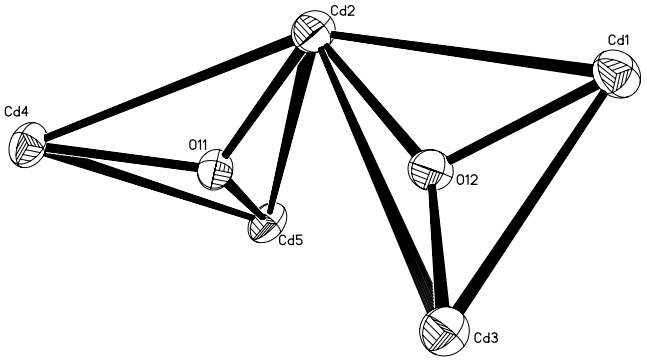

Fig. 4b. Vertex-shared core of complex **3**.

There are four different kinds of coordination modes for the Cd atoms. Cd1 is six-coordinated by three pyridinedicarboxamide nitrogen atoms (N3, N4, N5), one nitrogen atom of the 3-position of the thiadiazole ring (N9), one oxygen atom of methanol (O9) and a μ_3-O atom (O12). N3, N4, N5 and O12 constitute the equatorial plane, and N9 together with O9 occupy the axial positions. Cd2 also has an octahedral geometry but with a CdO_4N_2 coordinate environment, i.e. the two nitrogen atoms of the 3-position of the thiadiazole ring of two ligands (N2, N16) and four oxygen atoms, which come from solvent molecules (O9, O10) and μ_3-O (O11, O12). Cd3 has a CdN_5O coordination mode with one μ_3-O, three pyridinedicarboxamide nitrogen atoms and another two nitrogen atoms of the 3-position of the thiadiazole rings from different ligands. Cd4 and Cd5 have a similar coordination mode, except that one of the N atoms coordinating to Cd5 is a 4-position nitrogen of the thiadiazole ring. In complex **3**, the lengths of the Cd–N bonds are also in a wide range, 2.290(3)–2.573(6) Å, and are slightly longer than those of the Cd–O(μ_3-O) bonds (2.189(2)–2.292(2) Å) for the same reason mentioned above. Water molecules do not participate in hydrogen bonds and are only wrapped in the crystal.

The ligands in complex **3** have two distinguishable states, H_2**L** and deprotonated $\mathbf{L}^{2-}$. The H_2**L** ligand takes **B** type of coordination modes while the three deprotonated $\mathbf{L}^{2-}$ ligands employ **A**, **B** and **C** coordination fashions.

3.5. Thermal stabilities of the title complexes

Typical TG curves of the title complexes are shown in Fig. 5. The weight losses in the TG curves of complexes **2** and **3** appear at a temperature below 120 °C, and are related to the removal of lattice water in these crystals. Complexes **1** and **2** have the same decomposition temperature with onset at 411 °C, suggesting that they both have high thermal stabilities and may have similar decomposition pathways.

The mass losses that occurred in the temperature range 400–500 °C for complexes **1** and **2**, and 300–500 °C for complex **3** are mainly due to the breakage of coordinated bonds and the decomposition of the ligand, the values of which are 36%, 41% and 44% for complexes **1**, **2** and **3**,

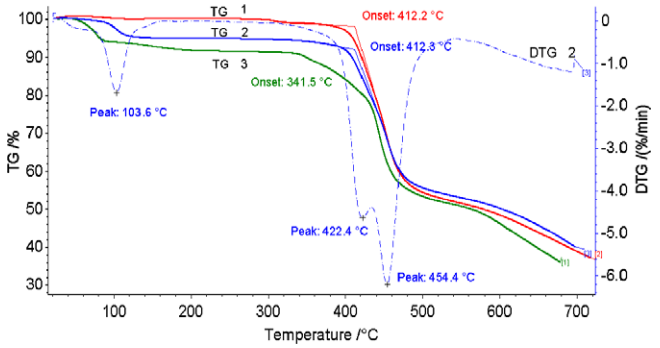

Fig. 5. TG–DTG curves of complexes **1**, **2** and **3**.

respectively. From Fig. 5 it can also be seen that the decomposition of complex **3** is different from that of complexes **1** and **2** because of the coordination of the solvent molecules in complex **3**.

The continuing weight losses in the TG curves of **1**, **2** and **3** above 540 °C are entirely caused by the gradual elimination of carbon deposition resulting from compound decomposition under the N_2 atmosphere [22].

In order to provide basic data for further investigation, kinetic studies of the thermal decomposition process of these complexes is needed, and we used complex **2** as an example to discuss the decomposition mode of the complexes within the temperature range 350–540 °C.

3.6. Non-isothermal kinetics of the complex $[Zn_3(\mu_3\text{-}O)(H_2L)(L)_2]$ (2)

A series of dynamic scans with different heating rates results in a set of data which exhibits the same degree of conversion (α) at different temperatures. TG curves of complex **2** in the temperature range 350–540 °C with heating rates of 5, 10, 20 and 30 °C min^{-1} were measured. The basic data (β, α, T) taken from the TG curves are used in the equations below:

Ozawa–Flynn–Wall equation [23],

$$\ln\beta = \ln\left(\frac{AE}{R}\right) - \ln g(\alpha) - 5.3305 - 1.052\cdot\frac{E}{RT} \quad (1)$$

where β is the heating rate, α degree of conversion, $g(\alpha)$ mechanism function, E activation energy, A pre-exponential factor and R gas constant.

From Eq. (1) it can be seen that the graphs $\ln\beta$ versus $1/T$ show straight lines with slopes $m = -1.052E/R$. The slopes of these straight lines are directly proportional to the reaction activation energy (E). The calculated results of the main decomposition process by using Eq. (1) are listed Table 5.

From Table 5 it can be seen that the activation energy is not a constant and two maximums appear at $\alpha = 0.5$ and 0.95 for the decomposition process, which indicates that the thermal decomposition of $[Zn_3(\mu_3\text{-}O)(H_2L)(L)_2]$ could be considered as a double-step reaction [24]. According to the OFW method, the activation energies and pre-exponential factors of thermal decomposition are approximately $E_1 = 416.9$ kJ mol^{-1}, $\lg(A_1/s^{-1}) = 28.09$ and $E_2 = 371.1$ kJ mol^{-1}, $\lg(A_2/s^{-1}) = 23.09$, respectively. These data would offer initial values for getting a reaction model by means of non-linear regression (NLR) and would be optimized finally.

Non-linear regression [25] allows a direct fit of the model to the experimental data without a transformation and there are no limitations with respect to the complexity of the model. For this reason, the NLR method can be employed for estimating the decomposition model of complex **2**. Selecting mechanism functions $f(\alpha)$ of different singular reaction types [26]; testing all double-step reaction types to which individual steps are linked for the first and second transition; Setting the initial values of the parameters of E and $\lg A$ according to the OFW method, calculated curves were obtained by means of NLR. During this procedure kinetic parameters of the initial values were optimized to get high fitting quality. Considering the fitting quality (characterized by the correlation coefficient and the relative precision), the mechanism of d:f, $A \overset{F_1}{\rightarrow} B \overset{F_n}{\rightarrow} C$, is the most suitable for the main decomposition of $[Zn_3(\mu_3\text{-}O)(H_2L)(L)_2]$. The calculated results are listed in Table 6 and the graphic presentation of the curve fitting is presented in Fig. 6, which shows that the non-linear regression curves fit the experimental data nicely.

Table 5
Parameters E (kJ mol^{-1}) and $\lg(A/s^{-1})$ for the main thermal decomposition of complex **2**

Partial mass loss (α)	E (kJ · mol^{-1})	$\lg(A/s^{-1})$
0.05	88.88 ± 4.87	7.06
0.10	141.47 ± 39.11	4.89
0.20	302.95 ± 77.44	20.29
0.30	307.75 ± 63.67	20.63
0.40	332.04 ± 53.31	22.16
0.50	416.89 ± 50.74	28.09
0.60	395.15 ± 26.26	26.34
0.70	360.75 ± 25.12	23.78
0.80	325.70 ± 27.32	21.09
0.90	326.39 ± 23.12	20.63
0.95	371.10 ± 48.05	23.09
0.98	353.57 ± 62.53	21.49

Table 6
Kinetic data and fitting quality on complex **2**

Corr. coeff.	Reg. par.	Step	Mode	E (kJ mol^{-1})	$\lg(A/s^{-1})$	Order
0.999456	0.00100	I	F_1	345.29049	24.22900	
		II	F_n	396.02971	26.69950	2.34924

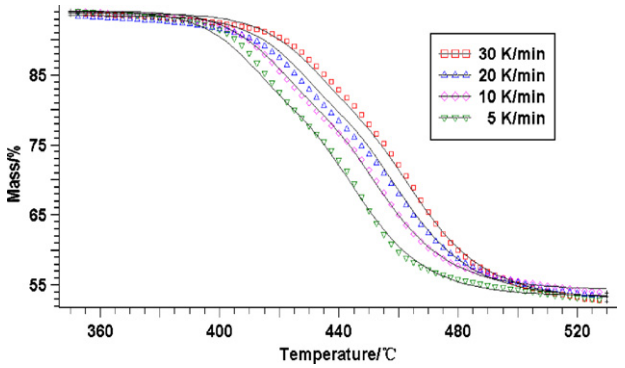

Fig. 6. Curve fitting of the second transition of **2**: ◇, △, ▽, □, experimental plots, — integral plots.

In short, the result of the kinetic analysis above shows the decomposition mode of the main process of $[Zn_3(\mu_3\text{-}O)(H_2L)(L)_2]$ is double-step, following the reaction, $A \xrightarrow{F_1} B \xrightarrow{F_n} C$, with $E_1 = 345.3$ kJ mol^{-1}, $\lg(A_1/s^{-1}) = 24.3$; $E_2 = 396.0$ kJ mol^{-1}, $\lg(A_2/s^{-1}) = 26.7$, $n = 2.35$.

4. Conclusion

Three polynuclear complexes have been prepared for the first time by using a new multidentate ligand, *N*,*N*′-bis-(5-ethyl-1,3,4-thiadiazol-2-yl)-2,6-pyridinedicarboxamide (H_2**L**). Structural studies reveal that μ-O plays an important role in the construction of all these complexes. The ligand in these complexes has two distinguishable states, H_2**L** and deprotonated $\mathbf{L}^{2-}$. Meanwhile, there are three coordination modes of the ligand shown as **A**, **B** and **C**, respectively, in these crystals.

Thermal analysis shows that complexes **1** and **2** possess high thermal stabilities and kinetics analysis of complex **2** shows that the mechanism of main decomposition process is a double-step reaction: a 1st-order reaction (F_1) with $E_1 = 345.3$ kJ mol^{-1} and $\lg(A_1/s^{-1}) = 24.23$ is followed by an *n*th-order reaction (F_n) with $E_2 = 396.0$ kJ mol^{-1}, $\lg(A_2/s^{-1}) = 26.7$ and $n = 2.35$.

Abstract

Three complexes of picolinamide (pyridine-2-carboxamide, pia) and metal thiocyanates, $M(SCN)_2$, (M = Zn, Cd, Hg), namely two polymorphs of bis(picolinamide-*N,O*)-bis-(thiocyanato-*N*)zinc(II) (**1a** and **1b**), *catena*-[bis(μ-thiocyanato-*S,N*)-picolinamide-*N,O*-cadmium(II)] (**2**) and bis[(μ_2-thiocyanato-*S*-thiocyanato-*S*-picolinamide-*N,O*)mercury(II)] (**3**) have been prepared and characterized by spectroscopic, thermal and X-ray crystallographic methods. The IR and thermal data correlate with the structures of the complexes in the solid state. The vibration bands of diagnostic value are compared to the values of the free ligands.

1. Introduction

The carboxamide group, [–C(O)NH–], ubiquitous throughout Nature in the primary structure of proteins, is an important ligand construction unit for coordination chemists. The behavior of pyridine carboxamides towards biologically relevant d-block metals has been widely investigated while much lesser attention had been paid toward exclusively toxic metals such as cadmium and mercury. In our recent research we examined the behavior of pyridinemono- and dicarboxylic acids and their derivatives and established that they act as efficient competitive ligands toward halides for coordination sites of these metal centres coexisting as anionic *N,O*-bidentate [1–4], *N,O,O*-tridentate [5], *O*-monodentate [3] and *O,O*-bidentate ligands [6], as well as neutral molecules [2]. Our interest is currently engaged with exploring not only the coordination abilities of picolinamide with thiocyanate complexes of group 12 metals but also in getting some information possibly useful in understanding the role of the thiocyanate ion in biologically important processes recently discovered [7,8]. Here we report the synthesis of thiocyanate complexes of group 12 metals with picolinamide, their structural characterization by spectroscopic and diffraction methods as well as their thermal stability using TGA/DTA methods. The crystal and molecular structures of the two polymorphs $[Zn(NCS)_2(pia)_2]$ (**1a** and **1b**), and $[Cd(SCN)_2(pia)]_n$ (**2**) and $[Hg(SCN)_2(pia)]_2$ (**3**) were determined by single crystal X-ray diffraction.

2. Experimental

2.1. Materials and physical measurements

All reagents were supplied by Aldrich Chemical Co. and were used as received without further purification. The

CHNS-microanalyses were performed by the Chemical Analytical Service of the Ruđer Bošković Institut, Zagreb.

Infrared spectra were obtained from KBr pellets within the range 4000–400 cm^{-1} with a Perkin–Elmer FTIR spectrometer 1600 Series.

The one-dimensional ^{1}H and ^{13}C NMR spectra were recorded with a Bruker AV 600 spectrometer, operating at 600.133 MHz and 150.971 MHz for the ^{1}H and ^{13}C nuclei, respectively. Samples were measured in DMSO-d_6 solution and chemical shifts (ppm) are referred to TMS.

The thermal measurements were performed using a simultaneous TGA–DTA analyzer (*TA Instruments*, SDT Model 2960). The TGA and DTA curves were obtained by placing samples of about 6 mg in mass, in small open platinum pans, with a heating rate of 10 °C/min and nitrogen (purity above 99.996%) pouring at a flow rate of 50 mL/min. All samples were heated from room temperature up to 700 °C. The SDT was calibrated with indium and silver.

2.2. Preparation of the complexes

2.2.1. Preparation of $[Zn(NCS)_2(pia)_2]$ (**1a** and **1b**)

A warm solution (50 mL) of picolinamide (0.24 g; 0.2 mmol) in water was slowly added to an aqueous solution (10 mL) of zinc nitrate hexahydrate (0.30 g; 0.1 mmol). Into the resulting solution was then added an aqueous solution (10 mL) of potassium thiocyanate (0.18 g; 0.2 mmol). After keeping the mother liquid for few days, white crystals suitable for further X-ray diffraction experiments were obtained. Total yield corresponds to 88% (0.37 g; 0.88 mmol) based on Zn. *Anal.* Calc. for $C_{14}H_{12}ZnN_6O_2S_2$ (**1**): C, 39.49; H, 2.84; N, 19.74; S, 15.06. Found: C, 39.61; H, 2.98; N, 19.95; S, 15.16%. Selected IR data (cm^{-1}, KBr pellets): 3330s, 3184s, 2096vs, 1688s, 1666vs, 1624m, 1612m, 1593s, 1585s, 1569s, 1423s, 1184w, 1160w, 1124w, 1109m-w, 1074w, 1056w, 1024m, 798w, 780w, 755m, 744m, 724m-w, 528w. From the reaction mixture, in which an excess of a picolinamide was present, **1a** together with a few crystals of another polymorph **1b** were obtained.

2.2.2. Preparation of $[Cd(SCN)_2(pia)]_n$ (**2**)

Compound **2** was prepared in an analogous way to **1**, only using cadmium nitrate tetrahydrate (0.31 g; 0.1 mmol) as the starting metal salt. Total yield corresponds to 77% (0.28 g; 0.77 mmol) based on Cd. *Anal.* Calc. for $C_8H_6CdN_4OS_2$ (**2**): C, 27.40; H, 1.72; N, 15.98; S, 18.29. Found: C, 27.48; H, 1.81; N, 16.03; S, 18.32%. Selected IR data (cm^{-1}, KBr pellets): 3408s, 3343m, 3284m, 3203s, 2119vs, 2094vs, 1669vs, 1610m-s, 1584s, 1571s, 1419s, 1181w, 1161w, 1117m, 1092w, 1054w, 1016s, 782w, 747s, 659s, 638m-w, 541m.

2.2.3. Preparation of $[Hg(SCN)_2(pia)]_2$ (**3**)

Into an aqueous solution (100 mL) of mercury(II) nitrate monohydrate (0.68 g; 2 mmol) with a few drops of diluted nitric acid (20% by weight), an aqueous solution (10 mL) of potassium thiocyanate (0.36 g; 4 mmol) was slowly added. After several hours colourless crystals of mercury(II) thiocyanate were obtained. The crystals were filtered off, washed with water and dried. Total yield 85% (0.54 g; 1.7 mmol). $Hg(SCN)_2$ was then dissolved in ethanol (0.32 g; 1 mmol in 100 mL) by gentle heating and the ethanol solution (30 mL) of picolinamide (0.24 g; 2 mmol) was added in it. The resulting mixture was refluxed for 1 h. The clear solution thus formed was allowed to stand for a few days to yield colourless crystals of compound **3** suitable for X-ray investigations. Total yield corresponds to 82% (0.36 g; 0.82 mmol) based on Hg. *Anal.* Calc. for $C_{16}H_{12}Hg_2N_8O_2S_4$ (**3**): C, 21.89; H, 1.38; N, 12.77; S, 14.61. Found: C, 21.95; H, 1.40; N, 12.82; S, 14.73%. Selected IR data (cm^{-1}, KBr pellets): 3409s, 3292s, 2130vs, 1691vs, 1616m-s, 1583s, 1568m, 1142w, 1095m, 1044w, 999m, 749s, 676m-w, 636m-w, 617m-s, 559m-s, 496m, 462m.

2.3. X-ray structural analysis

The general and crystal data, and summary of intensity data collection and structure refinement for compounds **1**–**3** are given in Table 1.

Data for structure **1a** were collected at 200 K on a Nonius KappaCCD diffractometer with a crystal-detector distance of 30 mm. The extraction and correction of the intensity data, absorption correction and the refinement of the unit cell parameters were performed with the program package DENZO-SMN [9].

Data for structures **1b**, **2** and **3** were collected at 293 K on an Oxford Diffraction Xcalibur four-circle kappa geometry single-crystal diffractometer with a Sapphire 3 CCD detector, by applying the CrysAlis software system [10]. The crystal-detector distance was 60 mm. Data reduction, including absorption correction, was done by the CrysAlis RED application of the CrysAlis software system [10].

The structures were solved by direct methods using the SHELXS97 program [11]. The coordinates and the anisotropic thermal parameters for all non-hydrogen atoms were refined by the least-squares methods based on F^2 using the SHELXL97 program [12]. The hydrogen atoms were generated geometrically using the riding model with the isotropic factor set at $1.2U_{eq}$ of the parent atom. Hydrogen atoms on the amide nitrogen atom, as well as on the oxygen atom of the H_2O molecule were located in the difference Fourier map at the final stage of the refinement and were refined freely. Graphical work has been performed by the program ORTEP-3 *for Windows* [13] and Mercury 1.4.1 [14]. The thermal ellipsoides are drawn at the 50% probability level.

3. Results and discussion

3.1. Preparation of the complexes

The zinc and cadmium thiocyanato complexes **1** (**1a** and **1b**) and **2** were prepared *in situ* from aqueous solutions. The mercury complex **3** could not be obtained in the same way due to very low solubility of mercuric thiocyanate in

water, while *in situ* reaction from an ethanol solution gave a mixture of products. Complex **3** was the only product from the reaction performed by refluxing the mixture of ethanolic solutions of mercuric thiocyanate and picolinamide. It was also established that in **1**–**3** the reaction products were not influenced by the molar ratio of the reactants (1:1 or 1:2 metal thiocyanate versus picolinamide). All complexes are soluble in solvents with pronounced coordination properties such as dimethyl sulfoxide (DMSO) and *N,N*-dimethyl formamide (DMF).

3.2. Structure descriptions

All crystals were grown by slow evaporation of the reaction mixture under ambient conditions in periods from two days to one week. Selected bond distances and bond angles relevant to the coordination of the central metal ions are given in Table 2, while the hydrogen bonds are presented in Table 1. The structures are shown in Figs. 1–4.

3.2.1. Crystal structure of $[Zn(NCS)_2(pia)_2]$ (**1a**) and (**1b**)

The compound **1** crystallizes in two polymorphic forms, **1a** and **1b**. The different packing in the unit cell is caused by the slight differences in their molecular structures.

The compound **1a** crystallizes in the space group $P2_1/c$. The crystal structure of bis(picolinamide-*N*,*O*)-bis(thiocyanato-*N*)zinc(II) consists of discrete octahedral complex molecules. An octahedral polyhedron is achieved through [4N + 2O] coordination of the zinc atom, where two nitrogen atoms originate from picolinamides and two from *cis*-positioned NCS-groups (Fig. 1a). The octahedron is almost regular with the two smallest angles being 75.06(5)° and 75.69(5)° for N3–Zn1–O1 and N5–Zn1–O2, respectively. All other angles around the zinc atom are in the range 87.44(5)–96.59(6)°, while all the opposite atoms in the coordination sphere form angles in the range 162.89(5)–171.51(5)°. The sums of four angles around the zinc atom closed by coordinating atoms lying in a plane are very close to 360° [359.06°, 359.44°, 361.35°], indicating the planarity of the planes containing the zinc(II) ion and thus also supporting the almost regular octahedral coordination of the central metal atom.

The Zn–N distances are in the range between 2.058(2) and 2.106(2) Å, with the Zn–NCS bonds [2.053(2) and 2.087(2) Å] being shorter than the Zn–N(pia) bonds [2.103(2) and 2.106(2) Å]. The Zn–O distances [2.258(1) Å and 2.218(1) Å] are somewhat longer than in other octahedral zinc complexes with picolinamide or its derivatives: 2.073(2) Å in $[Zn(picolinamide)_2(H_2O)_2I_2]$ [15] and

2.110(3) Å in [Zn(3-hydroxypicolinamide)$_2$(OH)$_2$] [16]. The set of bond lengths around zinc in **1a** indicates that the Zn–N bond involving the thiocyanate anion is stronger than that originating from picolinamide.

The NCS ligand, labelled as 1, (N(1)–C(1)–S(1)), shows a very small distortion from linearity (178.2(2)°), while the isothiocyanate ligand with a disordered sulfur atom deviates significantly [167.0(5)° and 172.0(4)°] and both NCS ligands bind to the metal in a non-linear mode with Zn–N–CS angles of 154.3(2)° and 147.9(2)°, which is generally usual for thiocyanates. The M–N–CS angle for zinc thiocyanate has been found to be in the range 132–180°, but is usually between 150° and 180° [17,18]. The pyridine rings are almost planar [torsion angles are 0.83(1)° and 1.27(1)°] while the chelate rings deviate from planarity [torsion angles 5.32(7)° and 8.36(7)°].

The crystal structure is predominantly determined by hydrogen bonding – there are N–H···O, N–H···S and

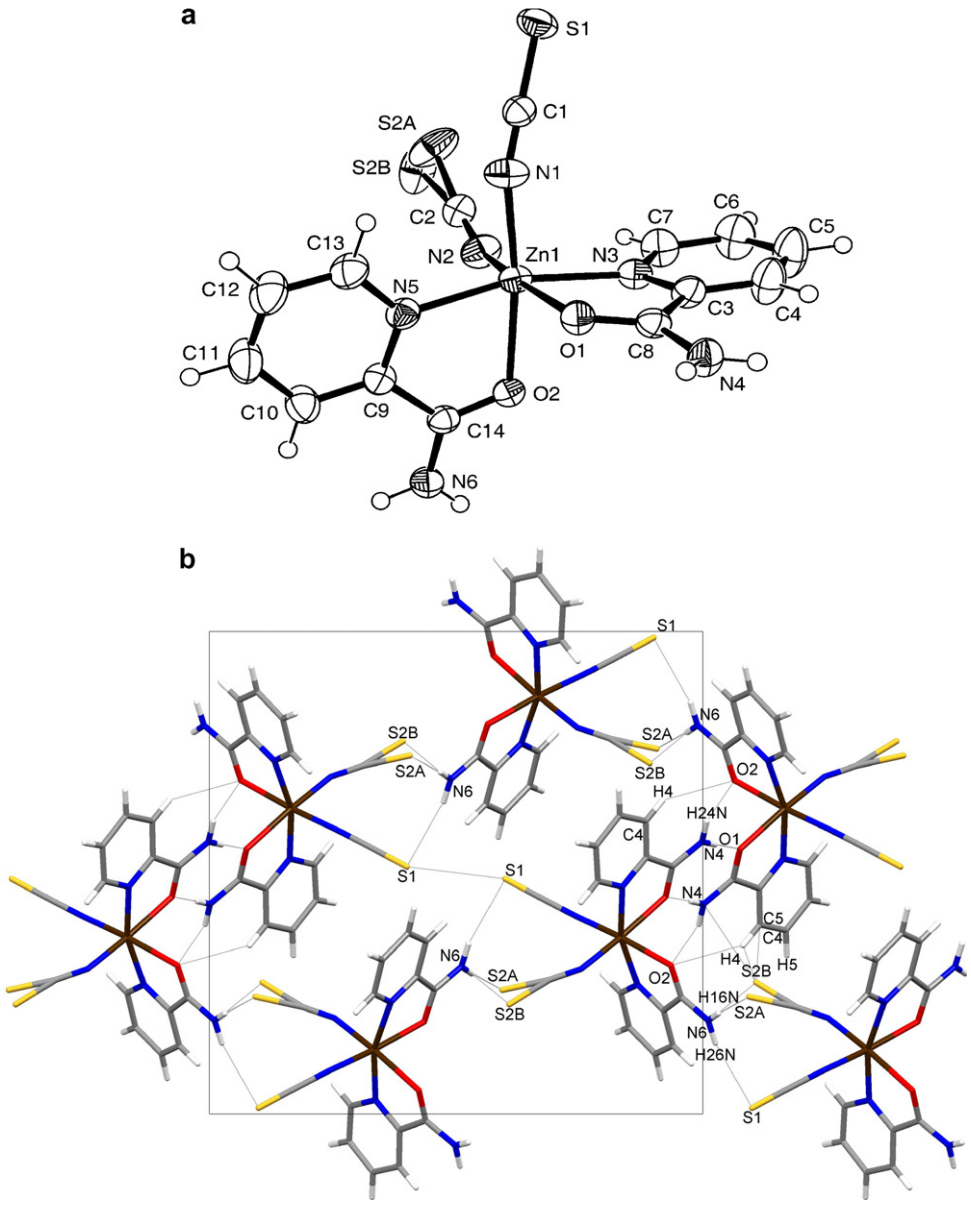

Fig. 1. (a) ORTEP3 drawing of the structural unit of complex **1a**; (b) perspective view along the *a*-axis; hydrogen bonds and contacts are drawn as dotted lines.

C–H···O types of hydrogen bonds. The geometric parameters of these bonds are given in Table 5. The amide nitrogen atoms from both picolinamide ligands, N(4) and N(6), are involved in two hydrogen bonds to two oxygen and two sulfur atoms, respectively (N(4)–H···O and N(6)–H···S). As a consequence of these two different hydrogen bondings the two carboxamide groups have different twist angles (13.0(1)° and 2.06(6)°). The amide nitrogen atom N(4) participates in a centrosymmetric head-to-head hydrogen bond of the R_2^2 (8) type with the amide oxygen atom O(1) from the neighbouring molecule (symmetry code: $-x$, $-y$, $1-z$). The same amide nitrogen atom N(4) also forms a hydrogen bond with the amide oxygen atom from the neighbouring molecule along the *a*-axis, O(2), which also acts as a bifurcated acceptor in the C(4)–H(4)···O(2) hydrogen bond. The amide nitrogen atom from the other picolinamide ligand, N(6), also participates in two hydrogen bonds, but of the N–H···S type. Thus each complex molecule bridges adjacent molecules forming chains along the *a*-axis. As shown in Fig. 1b, the molecules are further stabilized through short S···S contacts of the NCS ligands (3.392 Å).

The sulfur atom S(2), is found to be disordered. The same disorder is also observed in space groups of lower symmetries, $P2_1$ and *Pc*. It could, probably, be the consequence of the few short contacts resulting from the vicinity of neighbouring molecules: C(4)–H(4)···S(2b), C(4)···S(2b) and N(4)···S(2b), symmetry code: x, $1/2-y$, $-1/2+z$, and N(6)–H(16N)···S(2b), symmetry code: $1-x$, $1/2+y$, $1/2-z$, as designated in Fig. 1b.

In addition to hydrogen bonds there are also weak π···π interactions with a short distance between the centroids of

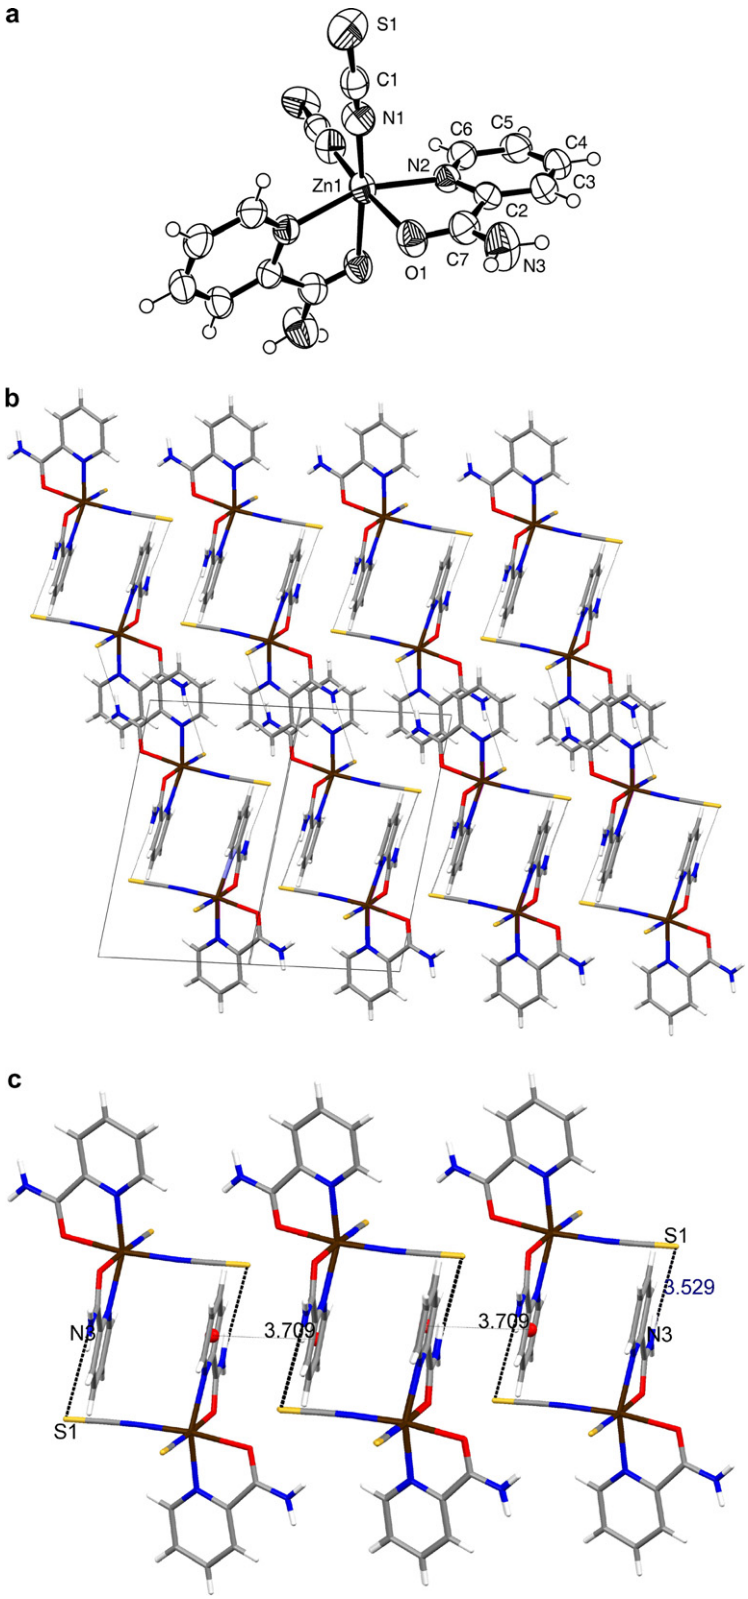

Fig. 2. (a) ORTEP3 drawing of the structural unit of complex **1b** with the atomic numbering scheme of asymmetric unit; (b) perspective view of the crystal packing of compound **1b** along the [101] direction; (c) π···π and N–H···S contacts are drawn as dotted lines.

the two aromatic rings N3,C3 → C7 and N5,C9 → C13, 4.434(2) Å (Table 5).

1b, the polymorph of **1a**, crystallizes in space group *C*2/*c* with a central metal ion in a special position. The octahedral coordination polyhedra of the zinc(II) ion was found in both polymorphs. Apart from deviations in the crystal packing of the two polymorphs, there are also some other discrepancies in the molecular geometry.

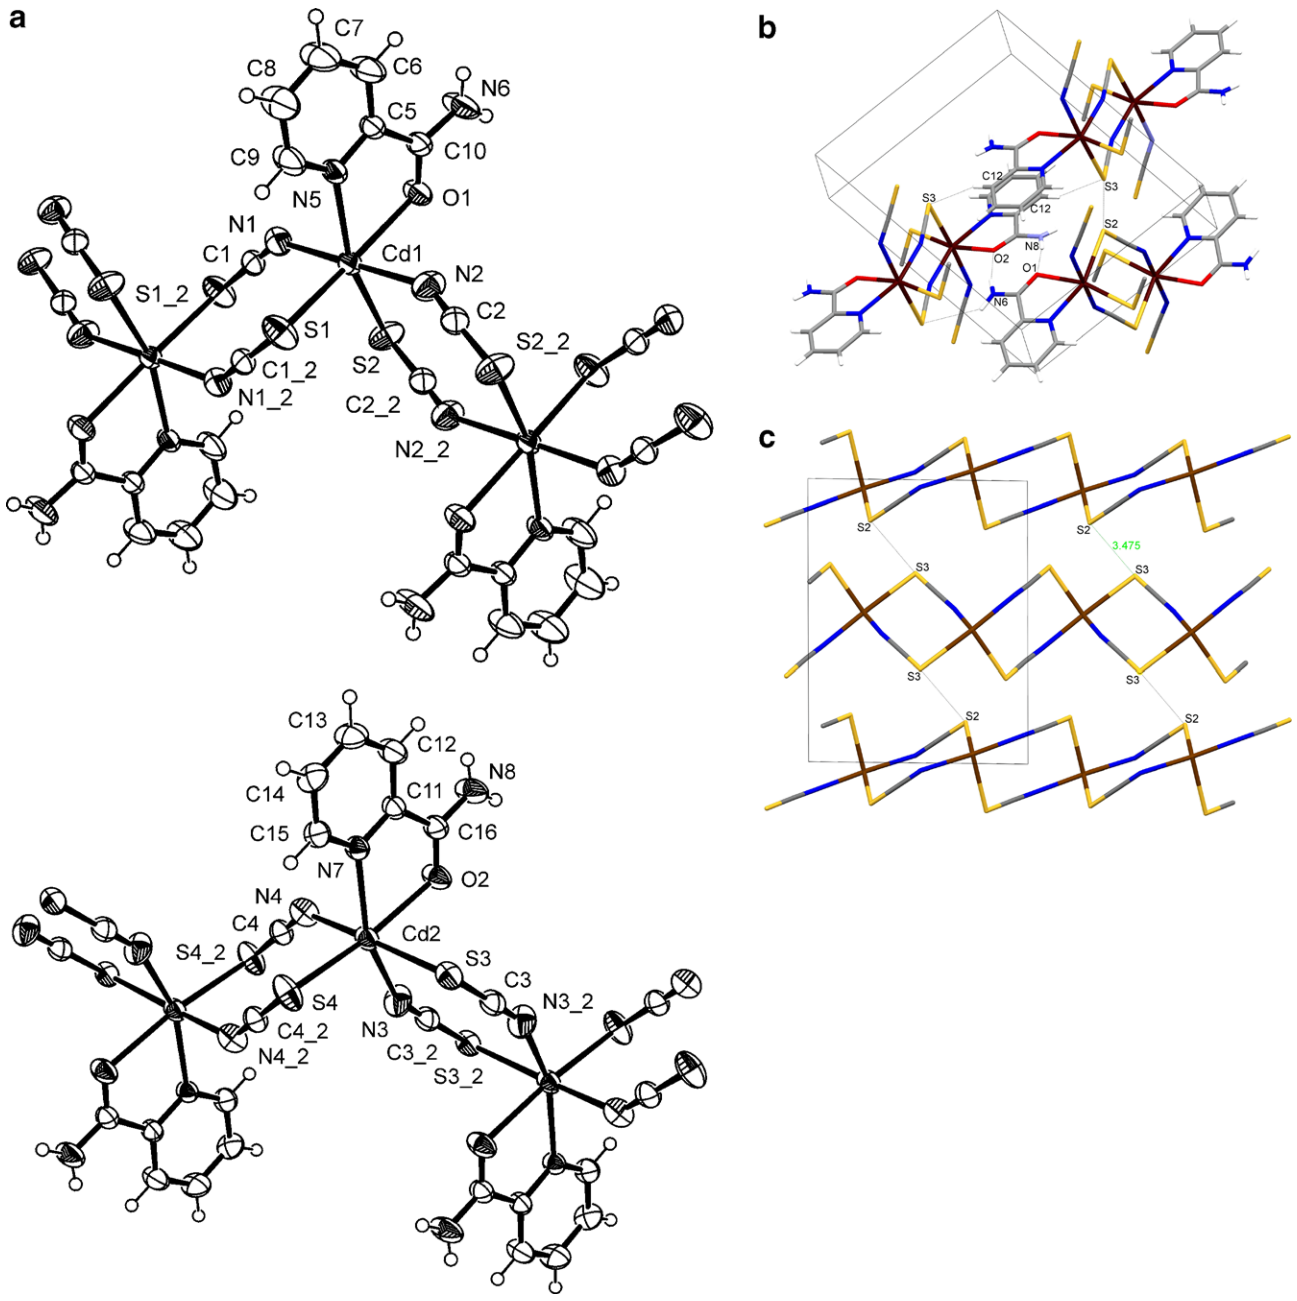

Fig. 3. (a) ORTEP3 drawing of the two crystallographically independent chains of complex **2** with the atomic numbering scheme of the asymmetric unit; (b) perspective view of intermolecular hydrogen bonds and S···S contacts between adjacent polymer chains; (c) a view of the $Cd(SCN)_2$ chains along the *b*-axis. The picolinamide ligands are omitted for clarity.

The bite angles of the chelate picolinamide ligands are retained in both polymorphs, while significant deviations in bond distances toward the zinc(II) ions are observed. The Zn–O(pia) bond length in polymorph **1b** is shorter than it is in polymorph **1a** [2.197(2) Å, **1b**; 2.258(1) Å and 2.218(1) Å, **1a**]. Further, the Zn–N(py) bond length is elongated to a somewhat smaller extend [2.117(2) Å, **1b**; 2.106(2) Å and 2.103(2) Å, **1a**]. But it is still the case, as in polymorph **1a**, that the thiocyanato ligand is bound to the central zinc(II) ion more tightly than the picolinamide ligand.

The isothiocyanato ligand is more tilted towards the carboxamide group in **1b** than in **1a**. Smaller N(NCS)–Zn–O [88.05(6)° **1a**; 89.44(6)° and 91.25(6)° **1b**] and larger N(NCS)–Zn–N(py) [97.89(6)° **1b**; 95.41(6)–96.59(6)° **1a**] angles in **1b** than in **1a** are established. The chelate ring also deviates more from planarity in polymorph **1b** than in **1a** (Table 3).

There are other differences in the crystal than in the molecular structures of both polymorphs. In crystal structure of **1b** hydrogen bonds are not pronounced. There is just one weak intermolecular interaction of the N–H···S

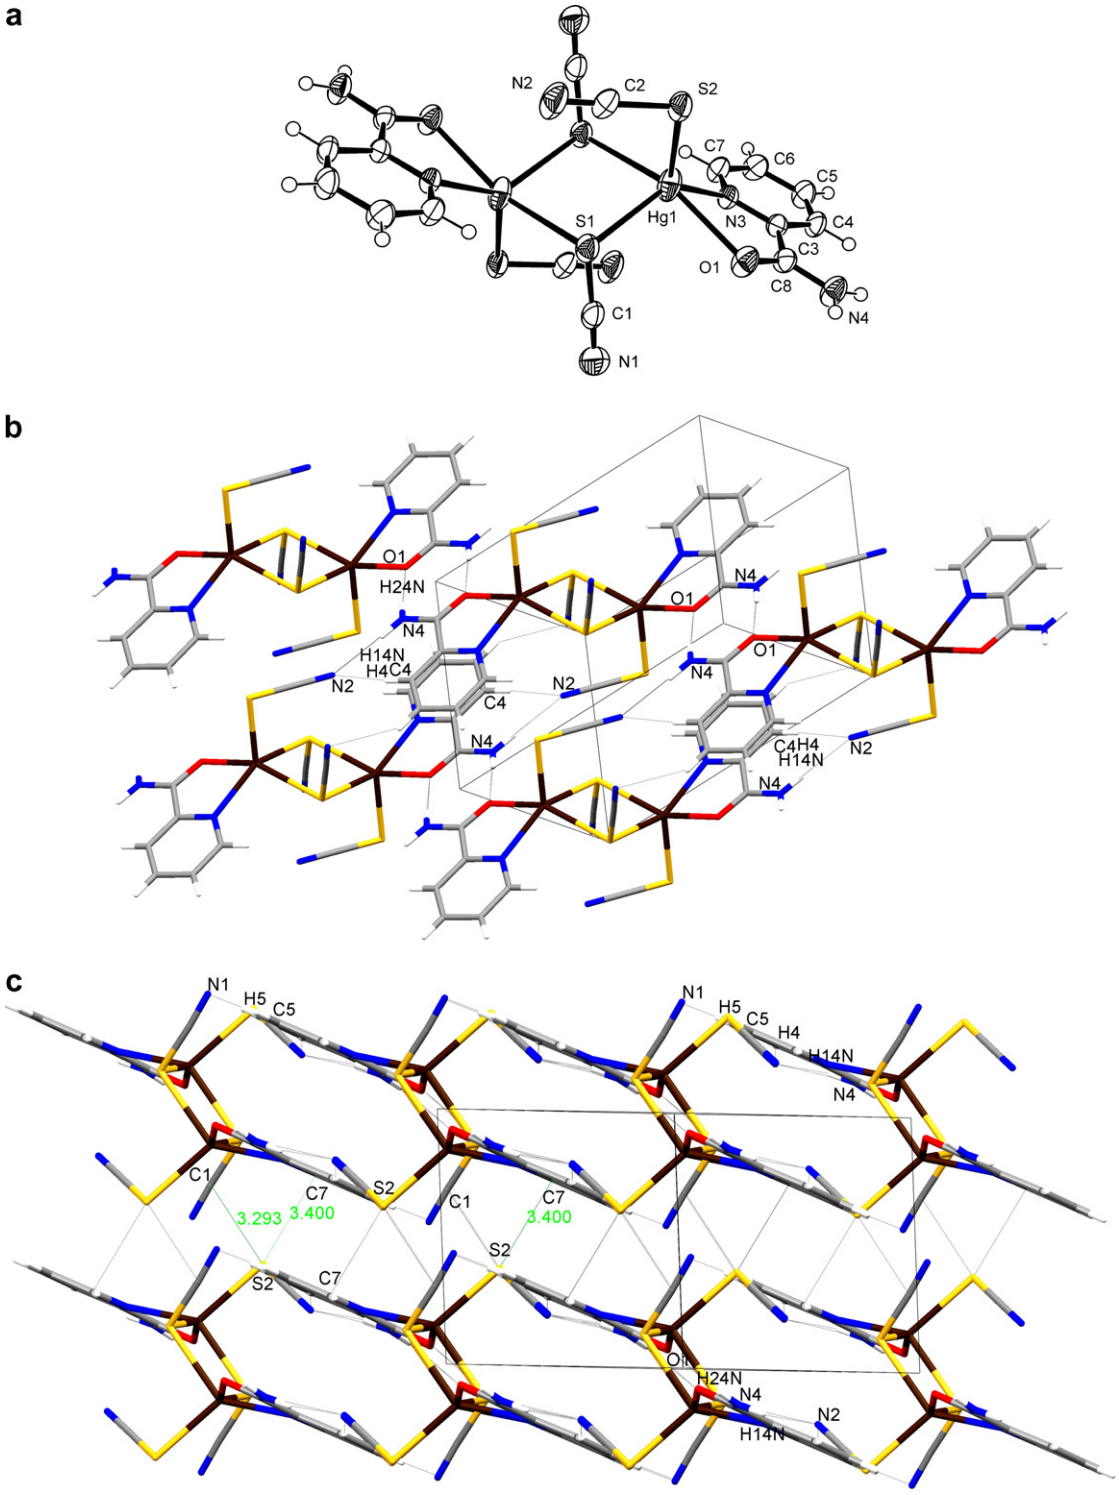

Fig. 4. (a) ORTEP3 drawing of the structural unit of complex **3**, [Hg $(SCN)_2$(pia)] with the atomic numbering scheme; (b) formation of the 2D architecture established by hydrogen bonds; the dotted lines represent hydrogen bonds; (c) the perspective view of the molecular packing of complex **3** showing the channels formed by the C···S interactions and hydrogen bonds.

type (3.529(2) Å) found between the nitrogen atom of the carboxamide group and the isothiocyanate sulfur atom. Two neighbouring molecules are held together by two interactions of this type forming stair like chains of complex molecules. Two adjacent molecules in this chains form 16-membered rings which leave the holes in crystal structure in the [1 0 1] direction. Two such formed neighbouring chains are held together by weak π–π interactions with *Cg*···*Cg* of distances 3.709(1) Å (Table 6). The differences in intermolecular interactions between these two poly-

morphs are also affirmed by different melting temperatures, 169.0(5) °C for **1a** and 167.1(5) °C for **1b**.

3.2.2. Crystal structure of $[Cd(SCN)_2(pia)]_n$ (**2**)

The molecular structure of *catena*-[bis(μ-thiocyanato-*S*,*N*)-picolinamide-*N*,*O*-cadmium(II)] comprises of two crystallographically independent chains along the *a*-axis (Fig. 3a). In both chains the cadmium atom shows a distorted octahedral environment with [3N + O + 2S] coordination. Two adjacent cadmium atoms are bridged by two inversely related μ-SCN^--*N,S* and the remaining coordination sites are occupied by the chelate picolinamide ligand, resulting in a structure comprising of eight-membered $(N–C–S–Cd)_2$ rings. These chains differ in the *cis*- and *trans*-orientation of the two bridging thiocyanato-*N* groups resulting in different chair conformations of the Cd–NCS skeleton, as illustrated in Fig. 3c. The intra-chain Cd···Cd distances from two crystallographically independent chains also differ: 5.743 Å and 5.847 Å for chains containing Cd(1) and Cd(2), respectively, the values are close to those already found for structures with two bridged thiocyanato ligands [19]. The Cd–N(NCS) (2.271(1)–2.346(2) Å) and Cd–S (2.6154(6)–2.7831(6) Å) distances are also very close to those ones reported for complexes containing eight-membered $[Cd_2(SCN)_2]$ rings [20,21]. The crystal structure is realized through various non-covalent interactions: (a) N–H···O (between two amido groups) head-to-head double hydrogen bonds of the $R_2^2(8)$ type (originated from the amide group of two picolinamide ligands coordinated on two symmetrically independent cadmium(II) atoms from adjacent chains, Cd(1) and Cd(2)), (b) N–H···S and (c) C–H···S interactions (Table 4), as well as (d) π–π stacking interactions (Table 6). The nitrogen atoms from each amide group are involved in N–H···O hydrogen bonds (N···O 2.948(3) Å and 2.983(3) Å) but the nitrogen atom from the amide group coordinated to Cd(1) also participates in a N–H···S interaction with a N···S distance of 3.456 Å, acting as a bifurcated donor. The weak intermolecular interaction C–H···S between two symmetrically related chains involves aromatic C(12)–H(12) and thiocyanate S(3) (Table 4). As shown in Fig. 3b, the layers are further packed into a three-dimensional framework also through weak S···S interactions of the NCS^- ligands (3.475(8) Å). The observed interaction is slightly shorter than in comparable cadmium complexes already reported [19]. In the present structure the pyridyl rings from each one-dimensional polymer chain π–π stack in an offset face to face arrangement with adjacent chains (3.817(1) Å) contributing to the stability of the crystal structure and resulting in the highest decomposition temperature of all three isolated complexes.

3.2.3. Crystal structure of $[Hg(SCN)_2(pia)]_2$ (**3**)

Bis[(μ$_2$-thiocyanato-*S*-thiocyanato-*S*-picolinamide-*N*,*O*)-mercury(II)] crystallizes in space group $P\bar{1}$ and the crystal lattice (molecular structure) consists of a neutral centrosymmetric dinuclear unit $[Hg_2(L)_2(SCN)_4]$, Fig. 4a. The coordination polyhedron around the mercury is best described as a distorted tetragonal pyramid. The metal ion is ligated by three sulfur atoms from thiocyanate, and an amide oxygen and an endocyclic nitrogen from the pic-

olinamide ligand. One thiocyanate ligand is terminal, while the other bridges two mercuric ions in an end-on fashion.

The distances in the thiocyanato ligands are 1.151(7) and 1.144(6) Å for N–C bonds, and 1.679(5) and 1.668(5) Å for C–S bonds, in the bridging and terminal ligand, respectively, as expected for *S*-coordination of thiocyanates [22]. The thiocyanates are coordinated in a linear fashion as can be seen from the N1–C1–S1 and N2–C2–S2 angles [176.7(4)° and 179.1(5)°], as evident, the bridging SCN-ligand deviates more from linearity than the terminal one.

The pyridyl and chelate rings deviate the most from planarity as compared with structures of **1** and **2** (Table 3) but the amide group, at the same time, closes the smallest torsion angle with the pyridyl ring.

Two dimers are connected together by a N–H···O hydrogen bond of the $R_2^2(8)$ type (Fig. 4b) forming infinite one-dimensional chains in the [101] direction (N(4)–H(24 N)···O(1), Table 4). The well known tendency of the mercury(II) ion towards soft basis, in this case the sulfur atom of the amibdentate thiocyanate ion, releases the thiocyanate nitrogen atom to participate in hydrogen bonding. So, both thiocyanate nitrogens, N(1) and N(2), from one chain of dimers participate in hydrogen bonds holding together two such adjacent chains. While N(1) participates in C–H···N bonding, N(2) acts as a bifurcated acceptor for C–H···N and N–H···N chelate hydrogen bonds. In such a way infinite two-dimensional sheets of channels, closed by two adjacent chains of dimers, are formed. These 2D sheets are probably held together by weak C···S contacts, C(1)···S(2) 3.293 Å and C(7)···S(2) 3.400 Å.

3.3. Spectroscopic properties

3.3.1. IR spectra

In general, C–N stretching frequencies, *ν*(CN), of thiocyanates are lower in *N*-bonded complexes (near or below 2050 cm^{-1}) than *S*-bonded complexes (near 2100 cm^{-1}). For bridging complexes (M–SCN–M) the CN stretching frequency is above 2100 cm^{-1} [23]. The stretching CN frequencies observed at 2096 cm^{-1} for **1a** and **1b**, at 2118 and 2094 cm^{-1} for **2** and at 2130 cm^{-1} for **3** clearly indicate a different coordination mode of the SCN-ligand. The thiocyanate is coordinated to zinc through the nitrogen atom, and to mercury through the sulfur atom, while cadmium is coordinated *via* both, *N*- and *S*- atoms. All above mentioned frequencies are significantly higher than the corresponding one found in the IR spectrum of KSCN (2048 cm^{-1} [24]). The SCN group is a good electron supplier and the electron transfer from SCN^- to Zn^{2+}, Cd^{2+} and Hg^{2+} ions cause the significant increase of the CN stretching frequency [25]. It is worth emphasising that in **1** the *ν*(CN) frequency is significantly higher (2096 cm^{-1}) than that in the reported zinc *N*-bonded thiocyanate complexes (2077 cm^{-1}, 2073 cm^{-1}) [26,27].

The position of the C–S stretching frequencies in the region 860–690 cm^{-1} is usually employed for differentiating *S*- from *N*-bonded terminal thiocyanates; *ν*(CS) bands that are observed in the range 860–780 cm^{-1} and 720–690 cm^{-1} indicate the *N*- and *S*-coordination mode of the SCN-ligand, respectively [28]. However, the *ν*(CS) modes in the IR spectra of compounds **1**–**3**, are overlapped by selected bands of the ligand in this region and make the assignment quite uncertain.

3.3.2. NMR spectra

The ^1H and ^{13}C NMR data of the parent picolinamide (pia) molecule together with the data of its zinc(II), cadmium(II) and mercury(II) thiocyanato complexes **1**, **2** and **3** are presented in Tables 6 and 7, respectively, while the Scheme 1 shows the labelling of the atoms. Complexation ^1H and ^{13}C NMR shifts are defined as the difference of proton and carbon shifts, respectively, in the complexes and the free ligand molecule. The ^1H NMR data of the free picolinamide in DMSO-d_6 are cited from the literature [29], and all other measurements are also performed in DMSO-d_6.

Table 6

[b] Complexation shift is defined as the ^{13}C chemical shift difference of corresponding nuclei in complex and free picolinamide molecule.
[c] Sign (+) denotes deshielding effect, while (−) denotes shielding effect.

Scheme 1.

In the ^{1}H NMR spectra of all three complexes shielding of all protons is established. The only one exception found is the proton of the amido group of the zinc complex, which is deshielded. It is probably caused by different H-bonding in the Zn complex than in the free ligand. The greatest complexation shifts ($\Delta\delta$) are observed for the H-6 and H-3 protons, which are three or four bonds remote from the metal centers.

In the ^{13}C NMR spectra of all the complexes, in general, the greatest changes upon complexation were observed for the chemical shifts in the zinc complex (**1**), and the smallest changes were for the mercury complex (**3**). In all three complexes carbon atom C-2 is found to be the most shielded (−1.42 to −2.36 ppm). The carboxamido carbon atom is also greatly influenced by coordination to the metal centers and is the only C atom for which the greatest complexation shift is found for mercury in comparison with the other complexes. The C-4 carbon atom, which is *para* to the pyridine nitrogen atom, is found to be deshielded in all complexes due to delocalisation of π-electrons through the pyridine ring.

The formation of thiocyanate and isothiocyanate complexes can be easily detected by the characteristic ^{13}C signal for –SCN and –NCS groups that are usually found at ~111 and ~145 ppm, respectively [30]. In the ^{13}C spectra of the investigated thiocyanato complexes there are signals at 135, 133 and 116 ppm in the zinc, cadmium and mercury complexes respectively, indicating coordination of the thiocyanato ligands to the metal centers through *N*- in the cases of Zn (**1**) and Cd (**2**) and through *S*- in the case of Hg (**3**).

3.4. Thermal analysis

Thermal decomposition of the complex **1** is shown in Fig. 5. At normal temperature and pressure the crystals possess good stability and do not show any hygroscopic effect. The analysis of the TGA and DTA curves shows that the thermal decomposition of **1** starts around 160 °C. The first step is the decomposition of **1** to $Zn(SCN)_2$, corresponding to the endothermic DTA peaks at 172.9 °C. In the temperature range 270–700 °C two endothermic peaks (a main large one at 273 °C, and a second small around 350 °C) were observed.

The TGA curve of **2** (Fig. 6) shows a large weight loss in the range 200–350 °C followed by an endothermic DTA peak with a minimum at 251.6 °C, and subsequently continues with a weight loss in range up to 350 °C without any peak in the DTA curve. The decomposition process suggests that the loss of picolinamide and thiocyanate groups occurs almost simultaneously. The final product after 700 °C should mainly be CdS.

The thermal analysis of **3** reveals that the thermal decomposition of the complex involves three processes, two endothermal and one exothermal process (Fig. 7). The first step is the decomposition of **3** to $Hg(SCN)_2$ (minimum at 145.9 °C), and the second one is the decomposition of $Hg(SCN)_2$ due to elimination of CS_2, $(CN)_2$ and N_2 gases (maximum at 200.8 °C) The last one is the sublimation of HgS, corresponding to the endothermic peak in the temperature range 350–450 °C.

4. Conclusion

Three new heteroleptic complexes of the group 12 metals with picolinamide and thiocyanate have been synthesized. The zinc and cadmium complex have been readily prepared by the *in situ* reaction from water solution, while the mercury complex has been prepared by prior isolation of mercury(II) thiocyante. The isolated title compounds were investigated by X-ray analysis, spectroscopic and thermal methods.

Having the amide group in a *para* position to the endocyclic nitrogen atom, picolinamide acts as a chelating *N,O*-ligand towards all three metals of group 12, leaving the amido *N*-atom for participation in hydrogen bonding and contacts. The thiocyanate ion acts as *N*- for the zinc complex **1**, *S*-/μ-*S*- for the mercury complex **3** and a μ-*N,S*-donor ligand for the cadmium thiocyanato complex **2**. Compound **1** is comprised of monomeric units and compound **3** dimeric units, while compound **2** is comprised of polymeric units. The thiocyanate shows a great variety of bonding modes with the group 12 metals, as a terminal as well as a bridging ligand. As a terminal ligand it is bound to metal ion from almost linear in **1b** [∠M–N–

C = 171.9(2)°] to almost perpendicular bonding mode in **3** [∠M–S–C = 96.5(2)°]. It is also noticed that there is elongation of the C–S bond lengths for the *S*-coordination in **3** in comparison to the *N*-coordination of the terminal thiocyanate ligand in **1**, while as a bridging μ-*N,S*-ligand in **2** the C–S bond length is somewhere in between the values for **1** and **3**. Although Zn and Cd have the same coordination number and Hg a smaller one, the bite angle in the case of Cd and Hg is the same, and in the case of Zn it is somewhat larger.

Abstract

Two novel one-dimensional polymeric cyano-bridged platinum(II) complexes of *N*-(2-hydroxyethyl)-ethylenediamine (*hydeten*), $[M^{II}(hydeten)Pt(CN)_2(\mu\text{-}CN)_2]_n$ ($M^{II} = Zn^{II}$ (**1**) and Cd^{II} (**2**)), were synthesized and characterized by physico-chemical methods (elemental analysis, IR spectroscopy and thermoanalytical measurements) and X-ray diffraction. Thermal behaviours of **1** and **2** were followed using TG and DTA (DSC) techniques. The 1D chain structures of **1** and **2** were verified by X-ray diffraction studies. According to the positions of the bridging cyano groups, in complex **1** the polymeric chains are built up via the 2,2-CT type, while in complex **2** the polymeric chains are built up via the 2,2-TT type.

1. Introduction

Cyano-bridged complexes, which have been of interest since the XVIIth century, have been shown to form polymeric structures by studies over the last few decades. These polymeric metal complexes are especially macromolecules formed by metal–metal or metal–ligand–metal bridge connections in one, two or three dimensions. These types of complexes have applications in the fields of chemistry, biology and material science and therefore they have been attracting increasing attention from scientists [1]. The applications are mainly focused on catalysts [2], non-linear optic, molecular magnets [3], molecular sieves and ion exchange materials [4].

Functional polymeric cyano complexes can be prepared with two or more dentate ligands. These types of materials are packed to form crystal structures due to bridging groups and intermolecular interactions. Cyano-bridged polymeric complexes structurally contain chains oriented in one dimension. These structures may be linear, zig-zag, stepwise, lateral and pipe shaped [5].

Cyano ligands are used to synthesize one, two- or three-dimensional structures in the branches of organometallic coordination and supramolecular structures because of their ability to behaving as σ-donors and π-acceptors at the same time, their negative charge and ambidentate character.

Hydeten (*N*-(2-hydroxyethyl)-ethylenediamine; alternatively named 2-(2-aminoethylamino)-ethanol {H_2NCH_2-$CH_2NHCH_2CH_2OH$}) is used in this study as a ligand which can coordinate to a metal ion through its three donor atoms. In our previous studies, we have observed two different coordination modes of the *hydeten* ligand. It

was determined in these studies that it was either coordinated as a bidentate ligand to metal ion through its two *N*,*N*′ donor sites [6] or as a tridentate ligand through its *N*,*N*′,O donor sites [7].

Cyanocomplexes, such as tetracyanopalladate [8], and especially tetracyanonickelate complexes [9], have been systematically studied to evaluate their structural properties, but tetracyanoplatinate complexes have rarely appeared in the literature [10]. Apart from that, the importance of the Pt(II)–*hydeten* complex as a potential agent for cancer therapy [11] led us to synthesize two new cyano-bridged Pt(II)–*hydeten* complexes (**1** and **2**). This study reports the synthesis, spectroscopic, thermal and structural characterization of these two novel compounds by IR, TG/DTA (DSC) and X-ray diffraction techniques.

2. Experimental details

2.1. Materials and instrumentation

Zinc(II) chloride ($ZnCl_2$), cadmium(II) sulfate 8/3 hydrate ($CdSO_4 \cdot 8/3H_2O$), [*N*-(2-hydroxyethyl)-ethylenediamine ($C_4H_{12}N_2O$)], platinum(II) chloride ($PtCl_2$), and potassium cyanide (KCN) were purchased from commercial sources and used without further purification.

Microanalytical (C, N, H) data were performed by standard methods (TÜBITAK Ankara Test and Analysis Laboratory, Turkey). The IR spectra were recorded on a Jasco 430 FTIR spectrophotometer using KBr pellets in the 4000–200 cm^{-1} range. The TG, DTG and DTA curves were obtained using a PYRIS Diamond TG/DTA (DSC) apparatus in a dynamic nitrogen atmosphere (heating rate: 10 °C/min., platinum crucibles, mass ~10 mg and temperature range 35–1300 °C).

2.2. Syntheses

2.2.1. *[Zn(hydeten)$_2$Pt(CN)$_4$] (1)*

A solution of $PtCl_2$ (0.077 g, 0.29 mmol) in 1:1 ethanol:water (20 mL) was dropped with stirring onto solid KCN (4 mmol, 0.075 g). Afterwards, $ZnCl_2$ (1 mmol, 0.039 g) in ethanol (10 mL) was added slowly to the solution, resulting in a cloudy cream mixture. This was dissolved by effusion slowly into the bulk containing *hydeten* (2 mmol, 0.061 g) in 10 mL ethanol. The resultant light-yellow solution was filtered and left to crystallize at room temperature. White crystals of **1** suitable for X-ray measurements were formed by slow evaporation after a week. The yield was 153 mg, 92.26%. *Anal.* Calc. C, 25.16; H, 4.22; N, 19.56. Found: C, 25.31; H, 3.94; N, 19.60%.

2.2.2. [Cd(hydeten)$_2$Pt(CN)$_4$] (2)

Solid KCN (4 mmol, 0.087 g) was added to 20 mL $PtCl_2$ (0.089 g, 0.33 mmol) solution in a 1:1 ethanol:water mixture. $CdSO_4 \cdot 8/3H_2O$ (1 mmol, 0.086 g) was then added slowly to the solution and a cloudy cream mixture appeared. Then, the suspension was added slowly to *hydeten* (2 mmol, 0.069 g) with stirring. The resultant yellowish solution was left to crystallize at room temperature, and white crystals of **2**, suitable for X-ray analysis, formed by slow evaporation after about a week. The yield was 154 mg, 74.25%. *Anal*. Calc. C, 23.25; H, 3.90; N, 18.08. Found: C, 23.39; H, 3.10; N, 18.10%.

2.3. Crystal structure analysis

Suitable single crystals were mounted on a glass fiber and data collections were performed on a STOE IPDS(II) image plate detector system using Mo Kα radiation ($\lambda = 0.71019$ Å) at 298 K. Details of the crystal structures of **1** and **2** are given in Table 1. Data collection: Stoe X-AREA [12]. Cell refinement: Stoe X-AREA [12]. Data reduction: Stoe X-RED [12]. The structure was solved by direct-methods using SHELXS-97 [13] and anisotropic displacement parameters were applied to non-hydrogen atoms in a full-matrix least-squares refinement based on F^2 using SHELXL-97 [13]. All carbon hydrogens were positioned geometrically and refined with a riding model with U_{iso} 1.2 times that of the attached atoms, and remaining hydrogen atoms were found by Fourier difference. Molecular drawings were obtained using ORTEP-III [14].

3. Results and discussion

3.1. FTIR spectra

The significant absorption bands of *hydeten*, $K_2[Pt(CN)_4]$, complex **1** and complex **2** are given in Table 2. It is observed that ν(O–H) of **2** shifts to higher wavenumbers than ν(O–H) of **1**, it was observed in the Zn^{II}/Cd^{II}–Pd^{II} complexes [15]. The difference between the OH stretching vibrations of the complexes may be explained by the variations of the surroundings of the crystals. The ν(N–H) band of **1** splits into three, and two of those are shoulder peaks, while ν(N–H) of **2** splits into four, consistent with the Zn^{II}/Cd^{II}–Pd^{II} complexes [15]. The splitting of the NH stretching vibrations is probably due to coordination of the Zn^{II} and Cd^{II} ions with nitrogen atoms of the *hydeten* ligand. In addition, the splitting of the ν(C–H) bands of complexes **1** and **2** might be attributed to changing the moiety of the CH_2 groups in the complexes.

The ν(C≡N) vibrations are the most important absorption bands for complexes **1** and **2** since the ν(C≡N) vibrational peaks in the IR spectra are used to reveal the bridging formation in the polymeric complexes. For

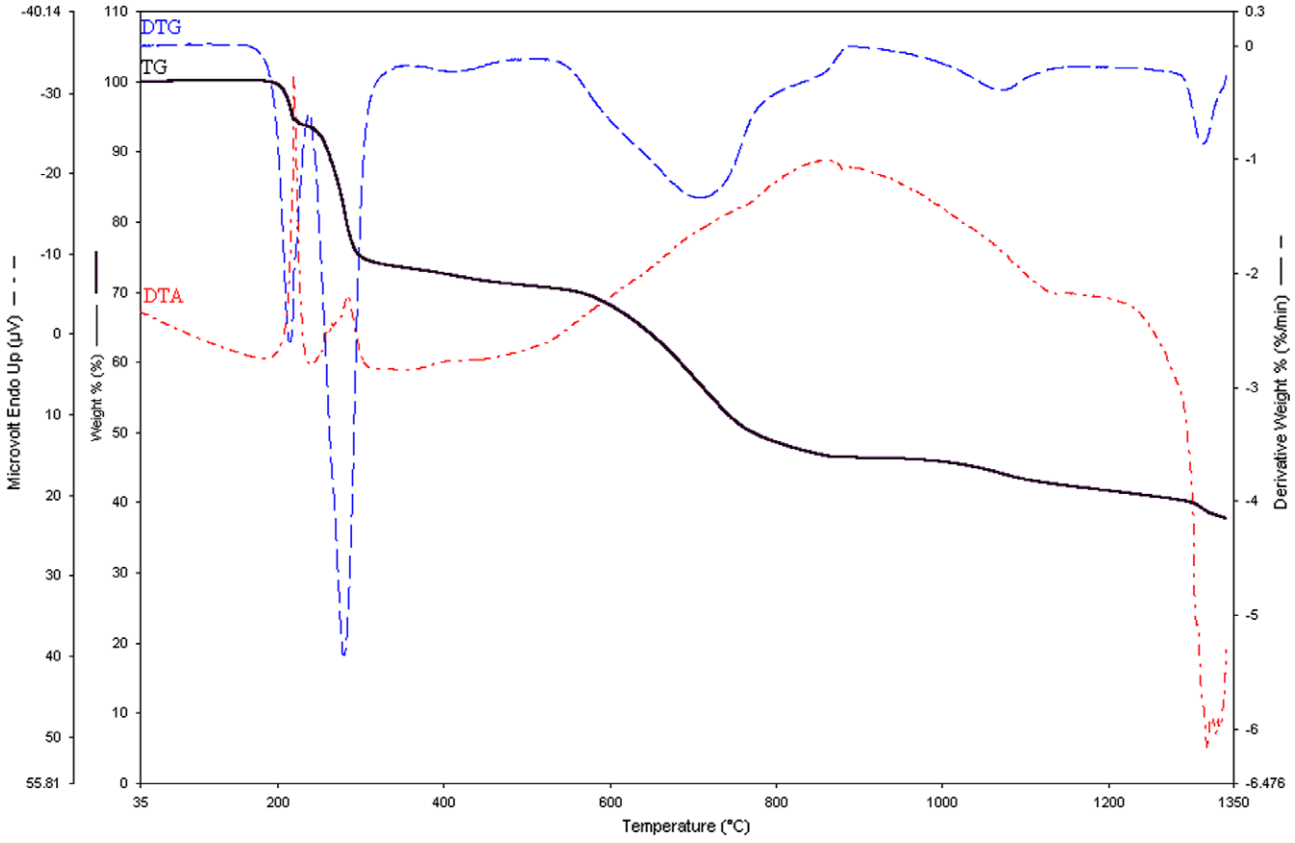

Fig. 1. Thermal curves of complex **1**.

complexes **1** and **2**, the $\nu(C{\equiv}N)$ vibrations are observed in the 2156–2138 cm^{-1} region. Taking into consideration the known structures of complexes **1** and **2**, the strong and sharp bands at 2142 and 2138 cm^{-1}, respectively, can be attributed to the stretching vibration of the terminal cyano groups, while those at 2156 and 2144 cm^{-1} arise from the bridging cyano groups. The bridging cyano frequencies in cyano-bridged complexes are generally observed at a higher frequency, due to the kinematic coupling which is a mechanical constraint upon the bridging-cyano confined to the second metal [16]. Besides, the N atoms at the *trans* position of the cyano groups of both **1** and **2** complexes are bonded to the second metal (Zn and Cd) to form a bridge, the D_{4h} local symmetry of the $[Pt(CN)_4]^{2-}$ ion changes slightly and reduces to D_{2h} symmetry.

In the low energy region of the spectra, Pt–C stretches and Pt–CN bending bands in the region 650–400 cm^{-1} were observed for complexes **1** and **2**. The bands observed at 501 and 432 cm^{-1} in the IR spectra of complex **1** might be attributed to the stretching vibrations of Pt–C and bending vibrations of Pt–CN, respectively. The same vibrational bands were observed at 499 and 411 cm^{-1} for complex **2**.

3.2. Thermal properties

The TG, DTG and DTA curves and data related to the thermal decomposition of complexes **1** and **2** are illustrated in Figs. 1, 2 and Table 3. The thermal decomposition of complex **1** follows a seven-step mechanism as seen in Fig. 1. The first four stages in the temperature range 185–648 °C correspond to the endothermic decomposition of the *hydeten* ligands (calc. 36.36%, found 35.93%). The decomposition of neutral *hydeten* ligands follows a multi-step process where the decomposition starts with the release of the CH_2CH_2OH groups of the *hydeten* ligands. Both weight losses and broadened DTG curve shows that the fourth and fifth decomposition steps are overlapped and on completion of *hydeten* decomposition (calc. 36.36%, found 35.93%), decomposition of the cyano groups starts at 650 °C. The decomposition of the anionic ligands are completed at the end of the fifth step, where $DTG_{max.}$ is 705 °C. Finally, there are Zn and Pt in the residual part (calc. 45.47%, found 46.11%). The boiling point of Zn is 907 °C and it is vaporized at the sixth and seventh steps of the decomposition mechanism. The vaporization of Zn is an exothermic process leaving only Pt in the medium above 1350 °C. Following scheme may be put forward for the thermal decomposition of complex **1**:

$$Zn(hydeten)_2Pt(CN)_4 \xrightarrow[2hydeten]{185\text{–}648\ ^\circ C} ZnPt(CN)_4 \xrightarrow[4CN]{648\text{–}954\ ^\circ C} Zn + Pt \xrightarrow[Zn]{954-(\cong 1350)^\circ C} Pt$$

The decomposition enthalpies (ΔH, J/g) of each stage were calculated by converting DTA signals to DSC data. The details are given in Table 3 which indicates that the

[a] The solid–solid transition temperature and transformation enthalpy.

enthalpies of the first five decomposition stages are endothermic while those of the last two stages are exothermic.

It is revealed from the DTA analysis that complex **2** shows an endothermic transition at around 182 °C which is assigned to a solid–solid transition since there is no melting observed at this temperature. The same behaviour was also observed for the $[Cu(hydeten)_2Pd(CN)_4]$ complex [17]. The thermal decomposition of complex **2** is more complicated than that of complex **1**, as nine distinguishable stages, corresponding to separate releases of *hydeten* molecules and cyano groups decomposing were observed during its decomposition. The TG curve for complex **2** indicates that it is stable up to 188 °C, at which point slow decomposition begins. In the temperature range 188–508 °C, there are six processes and the total weight loss by 33.21% corresponds to the release of two *hydeten* ligands (calc. 33.60%) by an endothermic process. The cyano groups are liberated in two separated steps (7th and 8th steps in the 508–725 °C range), both connected with endothermic process. The 8th step is overlapped by the 9th process in the 725–1093 °C range, with a weight loss of 18.02%, corresponding to the vaporization of cadmium (calc. 18.13%), the boiling point of which is 765 °C. The final thermal decomposition product is metallic Pt (calc. 31.48%, found 31.91%). The most probable thermal decomposition scheme for complex **2** is:

$$Cd(hydeten)_2Pt(CN)_4 \xrightarrow[2hydeten]{188\text{–}508\ ^\circ C} CdPt(CN)_4 \xrightarrow[4CN]{508\text{–}725\ ^\circ C} Cd + Pt \xrightarrow[Cd]{725\text{–}1093\ ^\circ C} Pt$$

The enthalpy of some of the decomposition stages were given in total due to the consecutive stages. Thus, the decomposition enthalpy values were found to be 1459.67 J/g for the first stage, 374.37 J/g for the second and third stages, 169.63, 1059.64, 95.03, 1290.52 (J/g) for the fourth, fifth, seventh and eighth stages, respectively and 8551.60 J/g for the final two stages.

3.3. Structure of complexes *1* and *2*

Single crystal X-ray diffraction analysis revealed that both complexes $[Zn(hydeten)_2Pt(CN)_4]$ (**1**), {*catena-poly*[μ-cyano- 1:2κ^{2}C:N-dicyano-1 κ^{2}C-*trans*-bis[*N*-(2-hydroxyethyl)ethane-1,2-diamine-2κ^2*N,N′*] zinc(II) platinum(II)]-μ-cyano-1:2′κ^2 C:N]}, and $[Cd(hydeten)_2Pt(CN)_4]$ (**2**), {*catena-poly*[μ-cyano-1:2κ^{2}C:N-dicyano-1 κ^{2}C-*trans*-bis[*N*-(2-hydroxyethyl)ethane-1,2-diamine-2κ^{2}N, N′]cadmium(II)platinum(II)]-μ-cyano-1:2′κ^2 C:N]}, have a cyanide-bridged polymeric chain structure where Pt^{II} is coordinated by four cyanide ligands, and Zn^{II} and Cd^{II} ions are coordinated by two *hydeten* and two bridging cyanide ligands, as shown in Figs. 3 and 4. Both

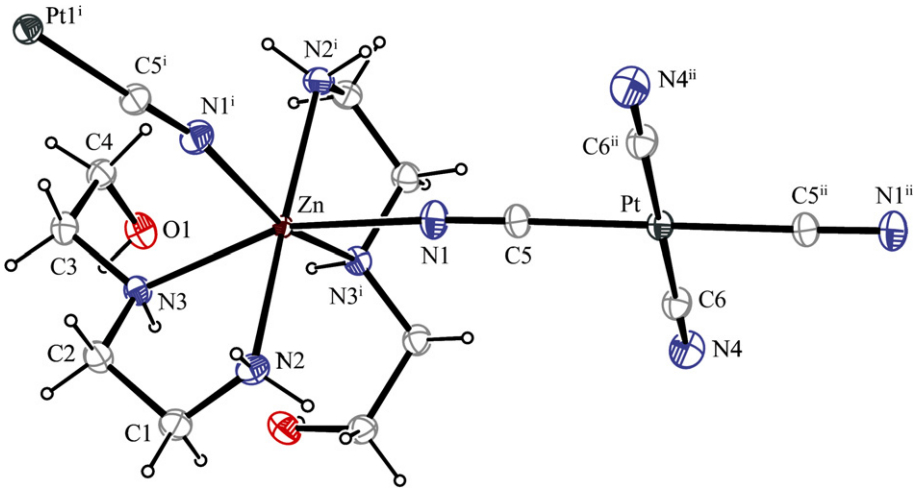

Fig. 3. An ORTEP plot of complex **1**.

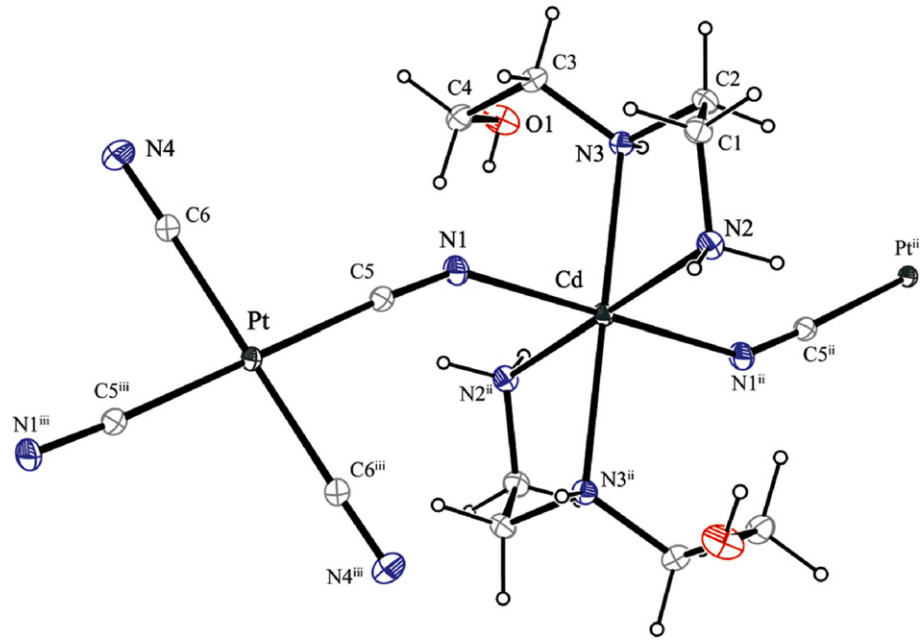

Fig. 4. An ORTEP plot of complex **2**.

complexes consist of a 1D polymeric chain –Zn(*hydeten*)$_2$–NC–Pt(CN)$_2$–CN–Zn(*hydeten*)$_2$ and –Cd(*hydeten*)$_2$–NC–Pt(CN)$_2$–CN–Cd(*hydeten*)$_2$ in which Zn^{II}–Pt^{II} and Cd^{II}–Pt^{II} atoms are linked by CN groups. The four cyanide-carbon coordinated Pt^{II} ion [two cyano groups are terminal in both complexes and the other two cyano groups (in the *cis* position for **1** and in the *trans* position for **2**) are bridged] has a square-planar geometry and the bond distances of Pt–C [1.963(13)–1.982(13) Å for **1** and 1.981(3)–1.987(3) Å for **2**] in the Pt(CN)$_4$ moiety are in accordance with the reported values for other tetracyanoplatinate complexes [18]. In complex **1**, the polymeric chains are built up via the 2,2-CT type in which one of the bridging cyano groups is in a *cis* position and the other cyano group is in a *trans* position, while in complex **2** the polymeric chains are built up via the 2,2-TT type in which both bridging cyano groups are in trans positions.

The coordination environment of the Zn^{II} and Cd^{II} ions can be described as distorted octahedral. In complex **1**, the basal plane is constructed by the coordination of three N atoms of the bidentate *hydeten* ligand and N1^{i} [symmetry code (i): $1 - x$, y, $0.5 - z$] atom of the cyanide group, whereas the N1 and N3 atoms occupy the axial positions. In complex **2**, four N atoms of two *hydeten* ligands form the basal plane, while the two cyanide N atoms are in the apical positions. The Zn–N and Cd–N distances reveal a small tetragonal distortion of the Zn–N4 and Cd–N4

planes, with the Zn–N and Cd–N bonds (Table 4) to the secondary amines [2.390(11) Å for **1** and 2.433(3) Å for **2**] being longer than the Zn–N and Cd–N bonds to the primary amines [2.359(13) Å for **1** and 2.284(3) Å for **2**]. This may be a consequence of the steric differences between the N atoms. These distances are found to be similar to those of our previously reported heteronuclear [Zn(*hydeten*)$_2$Pd(CN)$_4$], [Cd(*hydeten*)$_2$Pd(CN)$_4$] [15] and [Cd(*hydeten*)$_2$Ni(CN)$_4$] [6a] complexes.

All the N–Zn–N and N–Cd–N bond angles deviate significantly from the 90° and 180°, which is presumably the result of the steric constraints arising from the shape of the ligands. The angles subtended at the Zn(II) and Cd(II) atoms by the *hydeten* ligands are 73.8(4)° and 76.65(10)°, respectively, which are in agreement with previously reported values for other *hydeten* containing complexes [19,6b]. The C5≡N1–Zn and C5≡N1–Cd bond angles are 166.4(15)° and 147.1(3)°, respectively, which result in the formation of a one-dimensional zig-zag chain, while the Pt–C5≡N1 angle [178.7(15)° for **1** and 176.9(3)° for **2**] is essentially linear. The C5≡N1–Zn angle is comparable with that found in heteronuclear [Zn(*hydeten*)$_2$Pd(CN)$_4$], [Cd(*hydeten*)$_2$Pd(CN)$_4$] and [Cd(*hydeten*)$_2$Ni(CN)$_4$] complexes [C≡N–Zn: 168.70(2)° for [15], C≡N–Cd: 167.9(2)° for [15] and 167.3(1)° for [6a]. This deviation from linearity is greater than those observed in related structures [9c]. However, the C5≡N1–Cd angle is significantly smaller than the C5≡N1–Zn angle, indicating a degree of ionic character to the Cd–N bond. Similarly, in the [Cu(en)$_2$Pd(CN)$_4$] [8b] complex the C≡N–Cu angle [121.6(2)°; a bent bond value suggesting some degree of ionic character of the Cu–N bond] is found to be smaller than that of observed in the title compounds. The

N2–H2D···O1^{d}	0.90	2.21	3.01(4)	147
N2–H2C···N4^{e}	0.90	2.38	3.13(5)	141
O1–H1···N4^{f}	0.82	2.44	3.01(4)	127

Symmetry codes: (a) x, $-y+2$, $z-0.5$; (b) $-x+1.5$, $-y+1.5$; (c) $-z+1$, x, $-y+2$, $z-0.5$; (d) $-x+1$, $y-0.5$, $-z+1.5$; (e) $-x$, $y-0.5$, $-z+0.5$; (f) $-x+1$, $y+0.5$, $-z+1.5$.

Pt–C6≡N4 angles [177.4(17)° for **1** and 177.1(4)° for **2**] are found to be almost linear, as expected.

The crystal packing in both complexes shows interchain hydrogen bonding interactions between NH, NH_2 and OH groups. In both complexes, each polymeric chain is linked to a second chain via weak interchain N–H···N, N–H···O and O–H···N hydrogen bonding interactions (Figs. 5 and 6). These interactions are also effective in forming a layered structure, and the geometry of the interactions is illustrated in Table 5. The intramolecular $Zn\cdots Zn^{ii}$ and $Cd\cdots Cd^{iii}$ distances are 10.826(1) and 10.512(2) Å, respectively, whereas the shortest interchain $Zn\cdots Zn^{iv}$ and $Cd\cdots Cd^{v}$ distances are 7.559(1) and 7.708(1) Å, respectively [symmetry codes (ii) $1-x$, $1-y$, $1-z$, (iii) $-x$, $1-y$, $-z$, (iv) $x-0.5$, $y-0.5$, z, (v) $-x$, $1-y$, $1-z$].

4. Conclusion

Using $Zn(hydeten)_2^{2+}$ or $Cd(hydeten)_2^{2+}$ as bricks and the $[Pt(CN)_4]^{2-}$ anion as mortar, the novel binuclear one dimensional polymeric complexes **1** and **2** were prepared, and their structures were determined. The X-ray analysis revealed the formation of Zn^{II}–Pt^{II} and Cd^{II}–Pt^{II} polymers showing CT and TT chain structures, respectively. Also in our previous studies on Zn^{II}–Pd^{II} and Cd^{II}–Pd^{II} polymers the formation of TT and CT chains, respectively, was observed [15]. Pd^{II} and Pt^{II} polymers of Zn^{II} and Cd^{II} with the same ligand, *hydeten* resulted in a different orientation in the chain, which may be due to the difference in ionic diameters of Pd^{II} and Pt^{II}. The ionic diameter of Pt^{II} (94 pm) and Zn^{II} (88 pm) are similar and the Zn^{II}–Pt^{II} polymer forms a CT chain structure. A similarity is also observed in the ionic diameters of Pd^{II} (100 pm) and Cd^{II} (109 pm) which also formed a Cd^{II}–Pd^{II} polymer with *hydeten* with a CT chain structure. However, the differences between the ionic diameters of Cd^{II} and Pt^{II} and the ionic diameters of Zn^{II} and Pd^{II} are bigger than the differences between the ionic diameters of Zn^{II} and Pt^{II} and the ionic diameters of Cd^{II} and Pd^{II}, respectively. Probably for this reason, Cd^{II}–Pt^{II} and Zn^{II}–Pd^{II} polymers with *hydeten* formed a TT chain structure.

Abstract

Solvothermal reactions of H_2SSS (H_2SSS = 1,3,4-thiadiazole-2,5-dithiolate) with CuCN and $[WOS_3CuCN]^{2-}$ or $[W(Mo)S_4]^{2-}$ in organic solvents produced three novel 2D layered polymers, namely, $[Et_4N][WS_{3.5}O_{0.5}Cu_3(CN)_{0.5}(SSSH_{0.5})]$ (**1**), $[Et_4N][WS_4Cu_3(SSS)]$ (**2**) and $[Et_4N]_2[MoS_4Cu_4(CN)(SSSH_{0.5})_2]$ (**3**). X-ray diffraction analyses reveal that in **1** or **3**, the nest-shaped clusters $\{WS(O)S_3Cu_3\}$ or saddle-shaped clusters $\{MoS_4Cu_4\}$ are linked together by SSS ligands to form a double chain $[WS_{3.5}O_{0.5}Cu_3(SSSH_{0.5})]_n^{-1/2}$ or a zigzag chain $[MoS_4Cu_4(SSSH_{0.5})_2]_n^-$, respectively. The CN^- groups bridge the chains in **1** or **3** resulting in the formation of a 2D anionic network. Compound **2** is constructed from T-shaped $\{WS_4Cu_3\}$ subunits and SSS, also producing a 2D anionic sheet structure. The SSS ligand in **1** or **2** coordinates to five Cu atoms via its exocyclic sulfur and endocyclic nitrogen atoms in an unprecedented fashion, while in **3**, it acts as a rare tridentate ligand to connect three Cu atoms. Complexes **1**–**3** show optical transitions with band gaps ranging from 1.90 to 2.24 eV.

1. Introduction

N-heterocyclic thiones containing one or more thioamide groups are intriguing ligands in coordination chemistry since they can achieve versatile coordination modes by using exocyclic sulfur or endocyclic nitrogen atoms [1–11]. In the assembly reactions with metal ions, they usually show protoprotic tautomerism, acid–base equilibrium, and redox behavior based on a mercapto → disulfido conversion [2–8]. Among various N-heterocyclic thiones, 1,3,4-thiadiazole-2,5-dithiolate (H_2SSS, commonly known as "Bismuthiol I") is particularly interesting because its five available donor atoms in either protonated or deprotonated forms enable it to bind to one or more metal ions (Scheme 1) [5–9]. Compared to other N-heterocyclic thiones, only a few metal complexes containing SSS have been structurally determined due to the difficulties with insolubility and poor crystal habit [10d]. For example, several dinuclear transition metal (such as Au, Pt, etc.) complexes with SSS have been prepared and their structures, optical spectra and electrochemical properties have been studied [5–7]. A few main group metal thiol clusters with intriguing structures constructed from SSS, like the pentanuclear 35-membered tin macrocycle, have also been reported [7]. In addition, only two examples of coordination polymers constructed from SSS have been structurally characterized

Scheme 1. Three tautomeric forms of H_2SSS.

[8c,11]. One is an infinite 1D polymer whose basic repeating unit is $[(Me)_2Sn(SSS)]$ [8c]. The other is the helical chain polymers $[Et_4N]_2[W(Mo)S_4Cu_2(SSS)]$ (**4**) reported previously by us [11]. In compound **4**, the SSS linked two $\{W(Mo)S_4Cu_2\}$ subunits by its exocyclic sulfur atoms leaving the nitrogen atoms uncoordinated [11]. As far as we are aware, no higher dimensional (2D or 3D) coordination polymers and supramolecular complexes containing SSS have been reported so far.

Recently, the rational design and construction of supramolecular structures based on metal clusters has attracted considerable attention due to the formation of fascinating structures and applications as functional materials [12–15]. The use of metal clusters instead of single metal ions as structural and functional building blocks may offer the possibility of rational design and allow for better control over the structural and physical properties of these extended solids [14]. So far, the construction of cluster-containing supramolecular compounds has mostly focused on using metal–oxygen clusters as a building block [12,14,15], there have only been a few reports on the employment of metal–sulfur clusters [16–19]. Typical examples are the supramolecular compounds based on Mo(W)/Cu/S clusters with rigid or flexible multi-dentate linkers like 4,4′-bipy or bix [bix = 1,4-bis(imidazole-1-ylmethyl)benzene] [17,19a]. We have recently employed bidentate thiolato ligands to assemble Mo(W)/Cu/S cluster-based supramolecular architectures. For example, the reactions of $[MOS_3]^{2-}$ (M = Mo, W) or $[WS_4]^{2-}$ with $CuS_2P(OR)_2$ (R = Et, Me) gave rise to 2D layered polymers $[Et_4N][MOS_3Cu_3\{S_2P(OMe)_2\}_2]$ or 1D polymers $[Et_4N][\{MS_4Cu_4\}\{S_2P(OEt)_2\}_3]$ [19b,19c]. As an extension of these studies, we have investigated the self-assembly reactions of $[WOS_3CuCN]^{2-}$ or $[W(Mo)S_4]^{2-}$ with CuCN in the presence of H_2SSS at elevated temperature and successfully isolated three novel 2D coordination polymers $[Et_4N][WS_{3.5}O_{0.5}Cu_3(CN)_{0.5}(SSSH_{0.5})]$ (**1**), $[Et_4N][WS_4Cu_3(SSS)]$ (**2**) and $[Et_4N]_2[MoS_4Cu_4(CN)(SSSH_{0.5})_2]$ (**3**). In contrast to **4**, the nitrogen atoms in SSS ligands in **1**–**3** are also involved in the coordination and the SSS ligands adopt novel coordination modes to connect W(Mo)/Cu/S cluster subunits leading to 2D cluster arrays.

2. Experimental

2.1. General remarks

H_2SSS and CuCN (AR) were purchased from Acrōs Organics and used as received without further purification. Compounds $[Et_4N]_2[WOS_3CuCN]$ and $[Et_4N]_2[W(Mo)S_4]$ were prepared according to literature procedures [20]. CH_3CN and acetone were purified by the standard method before use. Infrared spectra were recorded on a Nicolet Magna 750 FT-IR spectrophotometer (KBr pellets). Elemental analyses were carried out using a Perkin–Elmer 2400 II elemental analyzer. The diffuse-reflectance spectrum has been measured on a Lambda 900 spectrophotometer using $BaSO_4$ powder as 100% reflectance reference at room temperature.

It should be cautioned that all the manipulations should be carried out in a well-ventilated fumehood due to the production of toxic gases (HCN and/or H_2S) in the preparation of the title compounds.

2.2. Preparation of $[Et_4N][WS_{3.5}O_{0.5}Cu_3(CN)_{0.5}(SSSH_{0.5})]$ (1)

H_2SSS (12 mg, 0.08 mmol), CuCN (11 mg, 0.125 mmol), $[Et_4N]_2[WOS_3CuCN]$ (54 mg, 0.08 mmol) and 3.0 mL of CH_3CN were placed in a $15.0 \times 0.8 \times 0.8$ cm^3 glass tube. The tube was evacuated and sealed before it was heated at 160 °C for 24 h. After cooling to room temperature over 48 h, red crystals suitable for X-ray single-crystal diffraction were formed. Yield, 10% (based on CuCN). *Anal.* Calc. for **1**: C, 16.03; H, 2.63; N, 6.23. Found: C, 15.99; H, 2.89; N, 6.13%. IR (KBr pellet, cm^{-1}): ν(C≡N): 2144 (m); ν(C=N): 1456 (m); ν(W–O_t): 920 (m); ν(W–S_t): 500 (m); ν(W–μ_3-S): 432 (s).

2.3. Preparation of $[Et_4N][WS_4Cu_3(SSS)]$ (2)

Compound **2** was synthesized by a similar procedure as **1** with the exception that the reactants were H_2SSS (19 mg, 0.125 mmol), CuCN (22.5 mg, 0.25 mmol) and $[Et_4N]_2[WS_4]$ (71.6 mg, 0.125 mmol). After cooling to room temperature over 48 h, red crystals suitable for X-ray single-crystal diffraction were obtained. Yield, 26% (based on CuCN). *Anal.* Calc. for **2**: C, 15.37; H, 2.58; N, 5.38. Found: C, 15.34; H, 2.69; N, 5.40%. IR (KBr pellet, cm^{-1}): ν(C=N): 1455 (m); ν(W–μ_2-S): 470 (s); ν(W–μ_3-S): 432 (m).

2.4. Preparation of $[Et_4N]_2[MoS_4Cu_4(CN)(SSSH_{0.5})_2]$ (3)

The synthesis procedure was similar to that of **2**. A mixture of H_2SSS (12 mg, 0.08 mmol), CuCN (22.5 mg, 0.25 mmol), $[Et_4N]_2[MoS_4]$ (40 mg, 0.08 mmol) and 3 mL of acetone was heated at 120 °C for 48 h. After cooling to room temperature over 36 h, dark red crystals suitable for X-ray single-crystal diffraction were formed. Yield, 31% (based on CuCN). *Anal.* Calc. for **3**: C, 23.74; H, 3.89; N, 9.23. Found: C, 23.60; H, 4.26; N, 8.95%. IR (KBr pellet, cm^{-1}): ν(C≡N): 2137 (m); ν(C=N): 1453 (m); ν(Mo–μ_3-S): 443 (m).

2.5. X-ray crystallographic study

Suitable single crystals of the compounds were carefully selected and glued to thin glass fibers with epoxy resin.

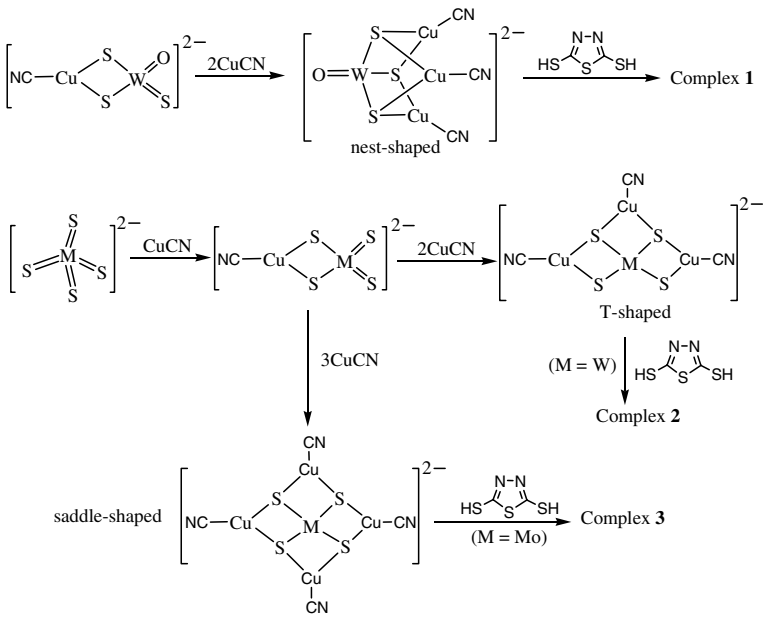
[a] $R_1 = \sum||F_o| - |F_c||/\sum|F_o|$.
[b] $wR_2 = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)]^{0.5}$.



Intensity data were collected at room temperature on a Rigaku Mercury CCD area-detector diffractometer with a graphite monochromator utilizing Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and refined on F^2 by full-matrix least-squares using the SHELXL-97 program package [21]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms in $[Et_4N]^+$ were treated as riding, with C–H 0.96 or 0.97 Å and U(H) values set as 1.2 or 1.5 times U_{eq}(C). In compounds **1** and **3**, the μ_2-bridging cyanides between two Cu atoms indicated disorder with respect to the C and N termini; this disorder was treated by adopting 50% C and N occupancies at those sites. In compound **1**, the unique C atom connected to N4 is disordered over two positions, and was refined as two atoms of 37% or 63% occupancy, viz. C3 and C31. The terminal O1 and S4 in compound **1** are disordered and was refined by adopting 50% O and S occupancies at the same site based on the best fit of the disorder. H2A in **1** and H2A, H4A in **3** were generated in calculated positions with half-occupancy for the balance of the charge and N–H distance being 0.86 Å. The crystallographic data for **1**–**3** are listed in Table 1.

3. Results and discussion

3.1. Synthetic considerations

As reported previously, the reactions of thiomolybdates or thiotungstates with CuCN in solution produced a number of heterometallic compounds with various structural types [20b,23]. The CN^- groups in these compounds can be partially or completely removed by other donor ligands, such as PhS^-, PPh_3 and bix to form either discrete complexes or polymeric compounds [19a,20b,24]. It was also observed that by acidifying a linear cluster anion $[NCCuS_2WS_2CuCN]^{2-}$ with acetic acid, some of the terminally bonded cyanides at Cu centers were easily removed resulting in the formation of a cyanide-bridged 2D layer framework [24d]. Since the H_2SSS ligand has five potential coordination sites, the replacement of CN^- groups at Cu atoms in W(Mo)/Cu/S clusters by SSS may lead to the assembly of new compounds with interesting structural motifs. In addition, the acidity of the H_2SSS ligand may facilitate this process. Thus, the reaction of CuCN, H_2SSS and $[Et_4N]_2[WOS_3CuCN]$ in CH_3CN at 160 °C for 24 h afforded red crystals of $[Et_4N][WS_{3.5}O_{0.5}Cu_3(CN)_{0.5}(SSSH_{0.5})]$ (**1**) in low yield. The formation of **1** may involve the addition of two CuCN moieties to the linear cluster $[Et_4N]_2[WOS_3CuCN]$ followed by the replacement of two cyanide groups by SSS ligands (Scheme 2). During the reaction a small amount of W=O groups were replaced by W=S, presumably due to the formation of H_2S gas under the solvothermal conditions and this has frequently been observed in the formation of other W(Mo)/Cu/S clusters [22].

Analogous reaction of CuCN with $[Et_4N]_2[WS_4]$ in the presence of H_2SSS produced $[Et_4N][WS_4Cu_3(SSS)]$ (**2**) as red crystals in moderate yield. As shown in Scheme 2, the initial step of the reaction may be the formation of a T-shaped cluster anion $[WS_4(CuCN)_3]^{2-}$, which by completely replacement of CN^- with SSS yields a 2D anionic layer of **2**. The composition of the anion seems to be independent upon the ratio of CuCN to $[Et_4N]_2[WS_4]$. Changing the ratio only decrease the yield of compound **2**. Similar procedures involving CuCN, H_2SSS and $[Et_4N]_2[MoS_4]$ failed to get any products. However, when the reaction

Scheme 2. The possible self-assembly pathways for the syntheses of **1**–**3**.

was carried out in acetone at 120 °C, dark-red crystals identified as $[Et_4N]_2[MoS_4Cu_4(CN)(SSSH_{0.5})_2]$ (**3**) were obtained. Apparently, the formation of **3** can be described as the displacement of three CN^- groups in the saddle-shaped cluster anion $[MoS_4(CuCN)_4]^{2-}$ with SSS leading to the formation of a 1D $[MoS_4Cu_4(SSSH_{0.5})_2]_n^-$ anionic chain. The remaining CN^- groups bridge these chain structures to generate a 2D layer.

3.2. Description of the crystal structure of $[Et_4N][WS_{3.5}O_{0.5}Cu_3(CN)_{0.5}(SSSH_{0.5})]$ 1

An X-ray crystal analysis reveals that the asymmetric unit of **1** contains a nest-shaped $\{WO(S)S_3Cu_3\}$ cluster anion, half of CN^- group, one SSS ligand and a $[Et_4N]^+$ cation. The selected bond lengths and angles for **1** are quoted in Table 2. The W atom lies in the center of the distorted tetrahedron $\{WO(S)S_3\}$, of which the terminal site is occupied by 1/2 S and 1/2 O with the length W–O(S) being 2.028(5) Å. All three copper centers in **1** adopt a distorted tetrahedral geometry but in different coordination environment: Cu1 coordinates to one nitrogen atom and one sulfur atom provided by SSS and two sulfur atoms from $\{WO(S)S_3\}$; Cu2 coordinates to two sulfur atoms from $\{WO(S)S_3\}$ and two sulfur atoms from different SSS; Cu3 coordinates to one C/N atom from CN^-, one S atom from SSS and two S atoms from $\{WO(S)S_3\}$. The interconnection of $\{WO(S)S_3Cu_3\}$ clusters by SSS linkers results in a double chain of $[WS_{3.5}O_{0.5}Cu_3(SSSH_{0.5})]_n^{-1/2}$ extended along the *a*-axis (Fig. 1a). Alternatively, the basic repeating unit of **1** can be described as a double incomplete cubane-like cluster where two incomplete cubane-like $\{WS_{3.5}O_{0.5}Cu_3(SSSH_{0.5})\}$ fragments are linked via a pair of SSS ligands in a fashion similar to those of $[Et_4N]_2[(OWS_3Cu_3)_2(\mu\text{-}SBu^t)_2]$ [25]. These double incomplete cubane-like clusters are connected via Cu1–S5 to form a unique chain. The adjacent double chains are further linked each other by bridging CN^- groups to form a 2D anionic layer that extends in the *ab*-plane (Fig. 1b). The $[Et_4N]^+$ cations are enchased between the adjacent layers.

In compound **1**, the SSS ligand acts as a k_5 (two-S/one-N) form to link five Cu atoms from three different $\{WO(S)S_3Cu_3\}$ subunits by S5, S7 and N3, of which S7 and N3 coordinate to two and one Cu atoms from the same $\{WO(S)S_3Cu_3\}$ subunit, respectively, while S5 connects two Cu atoms from two adjacent $\{WO(S)S_3Cu_3\}$ clusters (Fig. 1a). As can be seen from Scheme 3, which summarizes all the reported coordination modes of the SSS ligand, the SSS ligand in **1** presents an unprecedented coordination pattern (mode g). The bond lengths of Cu1–S5 and Cu2b–S5 [2.376(2) and 2.249(2) Å, respectively] are comparable to the Cu–S distances in the Cu(I) thiolates reported before [2c,2d,2e,2f,11]. The bond distances of Cu2a–S7 [2.617(3) Å] and Cu3a–S7 [2.589(3) Å] are slightly longer than the common Cu–S bond lengths, but are similar to those observed in the Cu(I) complexes containing N-heterocyclic thiones, such as 2.6572(13) Å in $[Cu(pymtH)I]_2$ (pymtH = pyrimidine-2-thione) and 2.5871(16) Å in $\{Cu_6I_6(2\text{-}SC_5H_4NH)_6\}_n \cdot 2n$MeCN [2c,2f]. The lengths of 1.724(8) and 1.710(8) Å for the S5–C1 and S7–C2 bonds, respectively, coincide with the fact that the SSS ligand in **1** is in the thiolate form rather than the thione form. The mean N=C distance in **1** (1.302(10)–1.304(10) Å) is only slightly longer than that of Au(I)–, Pt(II)– and Ru(II)–SSS complexes (1.292 Å) but close to that of Sn(II)–SSS complexes (1.305 Å). The lengthening of C=N may be due to the coordination of N to Cu atoms. The N2–N3 separation (1.391(9) Å) is normal and within the range for a

Symmetry transformations used to generate equivalent atoms: For **1**, a: $1-x, 1-y, 1-z$; b: $1+x, y, z$; For **2**, a: $x, 0.5-y, 0.5+z$; b: $x, 0.5-y, z-0.5$; c: $-x, y+0.5, 0.5-z$; For **3**, a: $1.5-x, 0.5+y, 0.5-z$; b: $1.5-x, y-0.5, 0.5-z$.

typical N–N single bond (1.40 Å) [26]. In SSS ligand, the uncoordinated azole-N atom is protonated, and the two adjacent SSS share one proton by forming a N2–H···N2 hydrogen bond (N–N distance is 2.59(1) Å).

3.3. Description of the crystal structure of $[Et_4N][WS_4Cu_3(SSS)]$ 2

As shown in Fig. 2a, the asymmetric anion of **2** contains one T-shaped cluster unit $\{WS_4Cu_3\}$ and one SSS ligand. The selected bond lengths and angles for **2** are listed in Table 2. The bond angles of Cu1–W1–Cu3, Cu1–W1–Cu2 and Cu2–W1–Cu3 are 169.15(2)°, 81.46(2)° and 87.81(2)°, respectively, indicating a slightly distorted T-shaped $\{WS_4Cu_3\}$ skeleton. The W–S and Cu–S separations are comparable to those in compound $[PPh_4][WS_4Cu_3(CN)_2]\cdot MeCN$ which also contains a T-shaped $\{WS_4Cu_3\}$ cluster core [23b]. There are two types of Cu atoms: (a) the tetrahedral Cu1 and Cu2 atoms coordinated to two S atoms of the $\{WS_4\}$ unit, one S atom from SSS and one N atom from another SSS and (b) the trigonal Cu3 atom coordinated to two S atoms of the $\{WS_4\}$ unit and one thio-S atom. The W···Cu3 [2.6465(7) Å] separation is slightly shorter than those of the other two [2.6972(7) and 2.6869(7) Å], suggesting that the interactions between the W and Cu are somewhat influenced by the coordination geometry of Cu [22]. As shown in Fig. 2b, the T-shaped cluster $\{WS_4Cu_3\}$ connects eight equivalent clusters through four SSS ligands to form a 2D anionic network that extends in the *bc*-plane. The $[Et_4N]^+$ cations are situated between the adjacent layers.

Similar to **1**, the SSS ligand in **2** also links five Cu atoms but in a slightly different way. The SSS ligand coordinates to Cu atoms from four different $\{WS_4Cu_3\}$ subunits through two nitrogen atoms and two sulfur atoms in an unprecedented k_5 (two-S/two-N) coordination mode (Scheme 3, mode h). Compared to **1**, where both the thio-S atoms function as μ_2-bridges, one of the thio-S atoms of SSS in **2** bridges two Cu atoms while the other coordinates to only one Cu atom. The other difference of the SSS coordination modes from **1** is that in **2**, both the azole-N atoms are bonded to Cu atoms. Although similar coordination mode of the SSS ligand has been proposed for the polymeric compound $[Au_2(SSS)_n]$, it has not been confirmed by X-ray crystallography [5c]. All the Cu–S bond lengths ranging from 2.185(1) to 2.478(1) Å are

(a) Part of the double chain linked by nest-shaped $WS(O)S_3Cu_3$ clusters and SSS in the anion of **1**, with partial atom numbering scheme (50% probability displacement ellipsoids, H atoms have been omitted for clarity). Symmetry transformations used to generate equivalent atoms – a: $1-x, 1-y, 1-z$; b: $1+x, y, z$. (b) Polyhedral and ball-stick view of part of the 2D anionic network within **1** ($WS(O)S_3$ as black and CuS_4 or $CuN(C)S_3$ as gray).

Scheme 3. The coordination modes of SSS.

normal compared to those for the Cu(I) thiolates reported [2c,2d,2e,2f,11]. Although both N-donors of the SSS unit are coordinated to Cu atoms, there is no significant length-

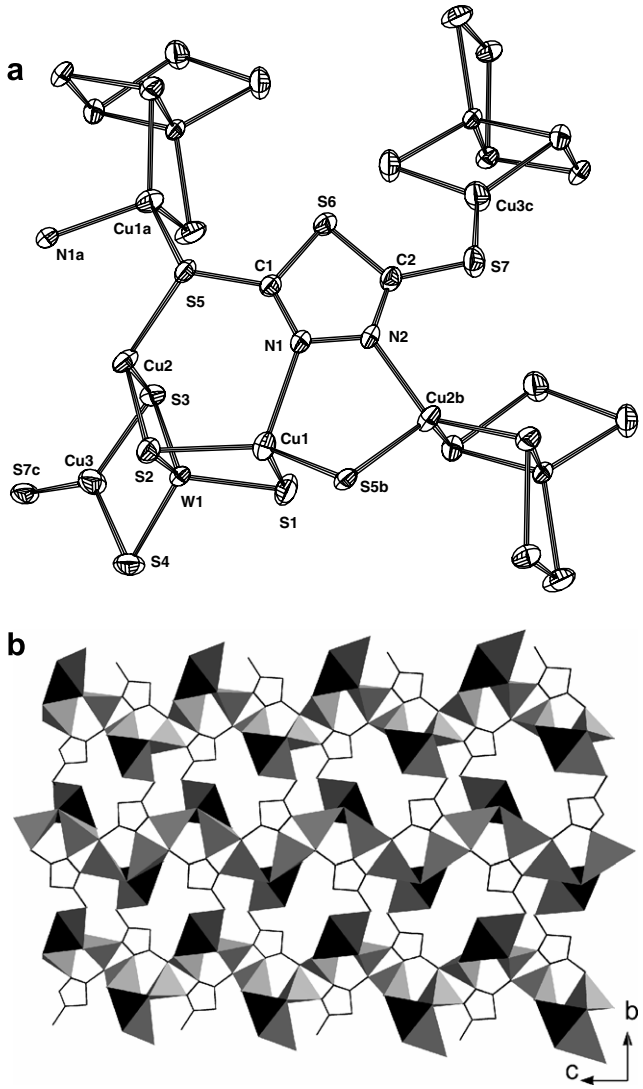

Fig. 2. (a) Fragment of the chain structure of $[WS_4Cu_3(C_2N_2S_3)]_n^{1-}$ anion in **2**, showing the coordination environment of the SSS ligand (50% probability displacement ellipsoids). Symmetry transformations used to generate equivalent atoms – a: $x, 0.5-y, 0.5+z$; b: $x, 0.5-y, z-0.5$; c: $-x, y+0.5, 0.5-z$; d: $-x, y-0.5, 0.5-z$. (b) Polyhedral and ball-stick view of part of the 2D anionic network within **2** (WS_4, black; $CuNS_3$/CuS_3, gray).

ening of the C=N distances (1.303(5) and 1.305(6) Å), as also observed in **1**. The N1–N2 distance (1.396(4) Å) is close to that of **1** and is considered to be a single bond.

3.4. Description of the crystal structure of $[Et_4N]_2[MoS_4Cu_4(CN)(SSSH_{0.5})_2]$ 3

Compound **3** crystallizes in the monoclinic space group $P2(1)/n$ and the asymmetric unit contains one saddle-shaped $\{MoS_4Cu_4\}$ core, one cyanide group, two SSS ligands and two $[Et_4N]^{2+}$ cations. The selected bond lengths and angles for **3** are given in Table 2. The anion $[MoS_4Cu_4(CN)(SSSH_{0.5})_2]^{2-}$ consists of a saddle-shaped $\{MoS_4Cu_4\}$ core, which closely resembles those in

$[MoS_4Cu_4L_4]^{2-}$ (L = Cl, CN, NCS, etc.) [16c,27]. The average Mo1–Cu, Mo1–μ_3-S, and Cu–μ_3-S bond lengths in the $\{MoS_4Cu_4\}$ core are similar to those in the related Mo/Cu/S clusters [27]. All four copper centers in **3** adopt a distorted tetrahedral coordination geometry. Cu1 or Cu2 coordinates to one C/N atom of the bridging cyanide, one thio-S atom and two S atoms provided by the $\{MoS_4\}$ moiety whereas Cu3 or Cu4 coordinates to one azole-N atom, one thio-S atom and two S atoms from the $\{MoS_4\}$ unit. Each $\{MoS_4Cu_4\}$ cluster is linked to two crystallographically equivalent clusters through four SSS ligands to form a zigzag chain of $[MoS_4Cu_4(SSSH_{0.5})_2]_n^-$ along the *b*-axis (Fig. 3a). The adjacent zigzag chains are further linked together by bridging CN^- groups to form a 2D anionic layer that extends in the *ab*-plane (Fig. 3b). The $[Et_4N]^+$ cations reside between two layers.

In compound **3**, the SSS moiety acts as a tridentate ligand in which two S atoms and one N atom links three Cu atoms of two $\{MoS_4Cu_4\}$ subunits (Scheme 3, mode i). This coordination mode is also rare for the SSS ligand and has been only reported most recently in a novel trinuclear Re(I) complex $[SSS(Re(CO)_5)_3](CF_3SO_3)$ [7]. The exocyclic S–C bond distances (range from 1.694(6) to 1.717(6) Å) are consistent with S–C single bonds as those observed in triphenyltin benzoxazole-2-thiolate (1.724 Å) [28]. The N1–N2 distance (1.381(6) Å) is slightly shorter than that of N3–N4 (1.393(7) Å), both of which are close to that of a single bond [26]. The C–N distances (range from 1.306(8) to 1.316(7) Å) are within the range of a C=N double bond and are comparable to those found in $[SSS(Re(CO)_5)_3](CF_3SO_3)$ (1.278(8)–1.317(8) Å) [7]. The bond parameters of the SSS ligand together with the IR spectral data further reveal that the coordinated SSS ligand in **3** takes thiolate form. The uncoordinated endocyclic nitrogen atom is protonated, and the adjacent two SSS ligands share one proton by a weak N–H···N hydrogen bond as observed in compound **1** (N–N distance is 2.62 Å).

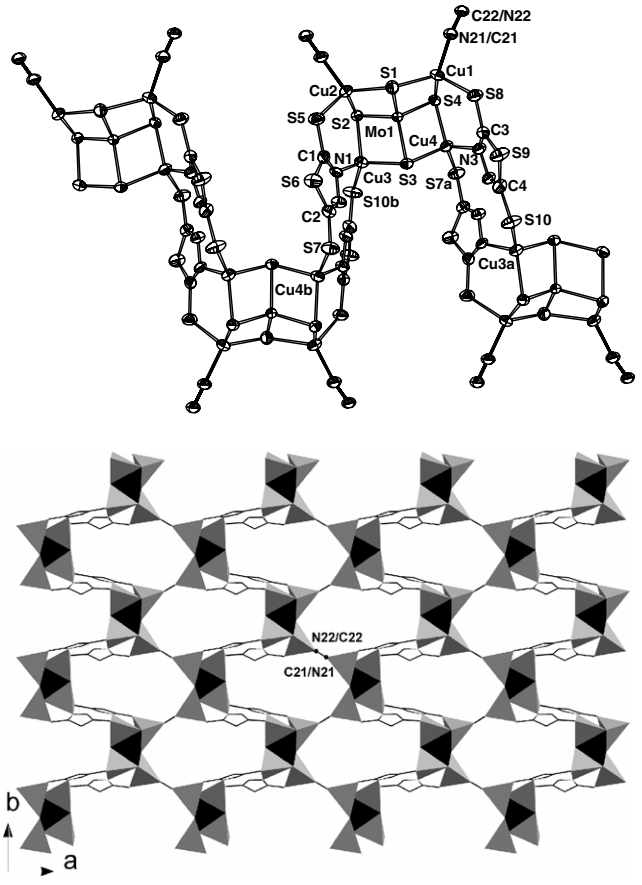

Fig. 3. (a) Part of the zigzig chain linked by saddle-shaped $\{MoS_4Cu_4\}$ clusters and SSS in the anion of **3**, with partial atom numbering scheme (50% probability displacement ellipsoids, H atoms have been omitted for clarity). Symmetry transformations used to generate equivalent atoms – a: $1.5 - x$, $0.5 + y$, $0.5 - z$; b: $1.5 - x$, $y - 0.5$, $0.5 - z$. (b) Polyhedral and ball-stick view of part of the 2D anionic network within **3** (MoS_4, black and $CuN(C)S_3$, gray).

3.5. IR and UV absorptional properties

In the infrared spectra of the title complexes, the bands ranging from 1453 to 1456 cm^{-1} are assigned to the C=N vibrations as those reported for complex Cu(SSSH) [6a]. The W(Mo)–S_t, W(Mo)–μ_2-S and W(Mo)–μ_3-S stretching vibrations are observed in the range of 520–400 cm^{-1}, which are comparable to those for the related W(Mo)/Cu/S complexes [11,19–25]. The observation of both ν(W–S_t) (500 cm^{-1}) and ν(W–O_t) (920 cm^{-1}) in compound **1** confirmed the partial replacement of W=O groups by W=S groups. The strong, sharp absorptions observed at 2144 and 2137 cm^{-1} in **1** and **3** are assigned to the vibrations of the bridging cyanides.

The optical absorption spectra of compounds **1**–**3** have been measured by diffuse-reflectance experiments. The UV–Vis absorption data were calculated from the reflectance data using the Kubelka–Munk function [29]: $\alpha/S = (1 - R)^2/2R$. Where R is the experimentally observed

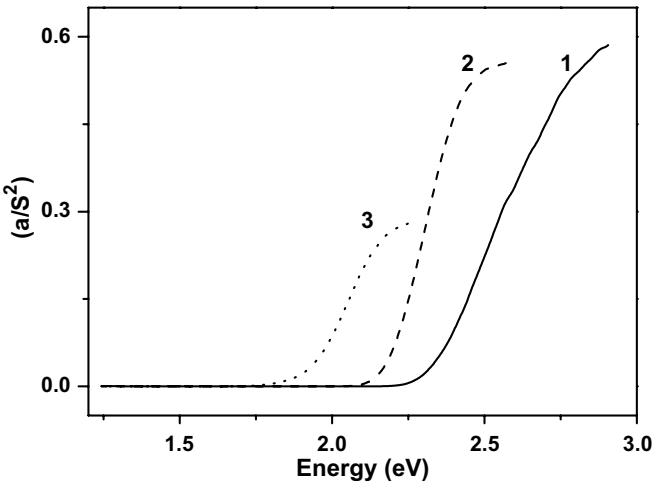

Fig. 4. Optical absorption spectra of compounds **1**–**3** at room temperature.

reflectance, α the coefficient and S the scattering coefficient. The spectra reveal the presence of the optical gaps, as shown in Fig. 4. The band gaps of **1**–**3** were assessed at ca. 2.24, 2.07 and 1.90 eV, respectively, determined as the intersection point by $(\alpha/S)^2 = 0$ in a $(\alpha/S)^2$ vs E plot [30]. These results show that compounds **1**–**3** may be classed as semiconductors.

4. Conclusion

In this paper, we demonstrated new approaches to the construction of three novel heterobimetallic complexes with layered structures. In these complexes, the nest-shaped $\{WS(O)S_3Cu_3\}$ core in **1**, the T-shaped $\{WS_4Cu_3\}$ core in **2** and the saddle-shaped $\{MoS_4Cu_4\}$ subunit in **3** serve as metal nodes whereas the SSS ligands function as multi-dentate linkers. The SSS ligand in **1** or **2** coordinates to five Cu atoms via its exocyclic sulfur and endocyclic nitrogen atoms in an unusual pattern, while in **3**, it acts as a rare tridentate ligand to connect three copper atoms. To the best of our knowledge, these complexes are the first examples of 2D metal-SSS coordination polymers determined by single crystal X-ray diffraction. The novel coordination fashions of SSS ligands observed in **1**–**3** imply that SSS is a very promising linker for the rational design and construction of cluster-based supramolecular compounds. In addition, the title complexes show optical transitions with band gaps varying from 1.90 to 2.24 eV, which indicates that they belong to semiconductors.

Abstract

Schiff base *N*,*N*′-bis(salicylidene)-*p*-phenylenediamine (LH_2) complexed with Pt(en)Cl_2 and Pd(en)Cl_2 provided [Pt(en)L]$_2 \cdot 4PF_6$ (**1**) and Pd(Salen) (**2**) (Salen = *N*,*N*′-bis(salicylidene)-ethylenediamine), respectively, which were characterized by their elemental analysis, spectroscopic data and X-ray data. A solid complex obtained by the reaction of hexafluorobenzene (hfb) with the representative complex **1** has been isolated and characterized as **3** (**1** · hfb) using UV–Vis, NMR (^1H, ^{13}C and ^{19}F) data. A solid complex of hfb with a reported Zn-cyclophane **4** has also been prepared and characterized **5** (**4** · hfb) for comparison with complex **3**. The association of hfb with **1** and **4** has also been monitored using UV–Vis and luminescence data.

1. Introduction

Supramolecular chemistry involving self assembly, inclusion phenomena, molecular recognition and non-covalent interactions are at the forefront of modern chemistry. These phenomena are commonly accessed by various macrocycles and related assemblies. Diverse macrocycles such as crown ethers, cyclophanes, cyclodextrins, calixarenes, cryptands, spherands, clathrates, cryptophanes and molecular clefts as receptors are well known. The majority of these macrocycles are reasonably flexible organic molecules that preferentially interact with cationic guests [1–10]. Conformationally, more rigid macrocycles incorporating metal centres have emerged as interesting members of supramolecular assemblies [11]. Molecules containing larger cavities bearing several functional groups open the possibility of the encapsulation of various guest molecules. However, among intermolecular interactions, those involving organic fluorine have also been a field of current interest [12]. Several reports in the literature subscribe to the conclusion that organic fluorine hardly accepts hydrogen bonds and does not contribute to crystal packing [13,14]. We, therefore, thought to interact some fluorine containing moieties, especially a strong electron acceptor molecule like hexafluorobenzene, with newly synthesized metallocyclophanes and to evaluate their association behaviour. In this context, the tetradentate Schiff base *N*,*N*′-bis(salicylidene)-*p*-phenylenediamine was chosen for its condensation with well protected Pd^{II} and Pt^{II} metal centres. The association of hfb with a representative complex of Pt^{II}-based cyclophane **1** has been monitored using spectroscopic techniques. Its association behaviour has also been compared with the earlier reported Zn^{II} cyclophane [15].

2. Experimental

2.1. Materials and methods

$PdCl_2$ and K_2PtCl_4 purchased from Sigma–Aldrich were converted into Pd(en)Cl_2 and Pt(en)Cl_2 using the reported

procedures [16,17]. Elemental analysis and mass measurements were carried on a Carbo-Erba elemental analyzer 1108 and a JEOL SX-102 mass spectrometer, respectively. IR spectra were recorded as KBr pellets on a JASCO FT-IR 5300 spectrometer and ^{1}H NMR spectra were recorded on a JEOL AL 300 MHZ spectrometer using $CDCl_3$ and DMSO-d_6 as solvents and TMS as an internal reference. ^{19}F NMR spectra are recorded on a JEOL AL 300 MHz spectrometer using DMSO-d_6 as the solvent and trifluoroacetic acid as an external reference at 282.5 MHz. UV–Vis and luminescence measurements were made in the range 200–700 nm on a Shimadzu UV-1601 spectrometer and Perkin–Elmer LS-45 Luminescence spectrometer, respectively, and TGA-DTA measurements have been performed on a Perkin–Elmer Pyris diamond TG-DTA instrument at a heating rate of 20 °C/min in the temperature range 50–400 °C.

2.2. Preparation of *N,N′-bis(salicylidene)-p-phenylenediamine (LH$_2$)*

N,N′-Bis(salicylidene)-*p*-phenylenediamine (LH_2) was prepared and characterized using a reported procedure [18].

2.3. Preparation of *Pt^{II} complex 1*

A solution of Pt(en)Cl_2 (0.672 g, 2.0 mmol) in DMF (10 ml) was added to a solution of LH_2 (0.630 g, 2.0 mmol) in DMF followed by the addition of Et_3N (~5.0 mmol) while stirring. The resulting mixture was stirred whilst heating on a water bath for 5 h. The solid product obtained after the addition of an aqueous solution of NH_4PF_6 was filtered, washed with distilled water and methanol followed by diethyl ether and recrystallised with a DMSO/MeOH mixture and finally dried in vacuo as $[Pt(en)LH_2]_2 \cdot 4PF_6$ (**1**). However, crystals suitable for single crystal X-ray crystallography could not be obtained. Yield: 35%. m.p.: >230 °C (dec). Elemental *Anal.* Calc. for $C_{44}H_{48}N_8O_4P_4F_{24}Pt_2$: C, 30.66; H, 2.78; N, 6.50. Found: C, 30.78; H, 3.14; N, 6.72%. IR (KBr pellet, cm^{-1}): 1633 ($\nu_{HC=N}$), 1264 ($\nu_{O-H\ phenolic}$), 2924 ($\nu_{C-H\ phenyl}$), 846 (ν_{PF6}). ^{1}H NMR (DMSO-d_6, 300 MHz, ppm): δ 13.1 (s, 4H, OH), 9.0 (s, 4H, HC=N), 7.5 (m, 20H, aromatic), 7.0 (m, 8H, NH_2), 6.5 (m, 4H, aromatic), 3.6 (s, 4H, N–CH_2), 3.5 (s, 4H, N–CH_2). FAB-MS: *m/z*: 1722 $[M]^+$, 1577 $[M-PF_6]$, 1142 $[M-4PF_6]$. UV–Vis (DMSO, 10^{-4} M): $\lambda_{max/(nm)}$ (ε_{max} 10^4 M^{-1} cm^{-1}) 339 (1.69), 354 (1.68), 439 (0.43); Emission excited at λ 340 nm (DMSO, 10^{-4} M): $\lambda_{max\,(nm)}$ (intensity in a.u.) 493 (459). Conductivity: Λ_m (DMSO, 10^{-4} M) 360 Ω^{-1} cm^2 mol^{-1}.

2.4. Preparation of *Pd^{II} complex 2*

Pd^{II} complex **2** has also been prepared using a method similar to that adopted for complex **1** by the addition of a solution of Pd(en)Cl_2 (0.472 g, 2.0 mmol) in DMF (10 ml) to a solution of LH_2 (0.630 g, 2.0 mmol) in DMF containing Et_3N (~5.0 mmol) while stirring. The product, after heating on a sand bath for 4 h with stirring, was isolated after the addition of H_2O to the reaction mixture. It was then filtered and washed with distilled water and methanol followed by diethyl ether. The product was then recrystallized in dichloromethane and characterized. Yield: 40%. m.p.: >230 °C. Elemental *Anal.* Calc. for $C_{16}H_{14}N_2O_2Pd$: C, 51.56; H, 3.60; N, 8.56. Found: C, 50.56; H, 3.62; N, 8.03%. IR (KBr pellet, cm^{-1}): 1622 ($\nu_{HC=N}$), 2934 ($\nu_{C-H\ phenyl}$). ^{1}H NMR (DMSO-d_6, 300 MHz, ppm): δ 8.5 (s, 2H, HC=N), 7.4 (m, 8H, aromatic), 6.5–6.8 (m, 8H, aromatic), 4.0 (s, 4H, N–CH_2). FAB-MS: *m/z*: 372 $[M]^+$. UV–Vis (DMSO, 10^{-4} M): $\lambda_{max/(nm)}$ (ε_{max} 10^4 M^{-1} cm^{-1}) 403 (1.94). Emission: non-emissive. Conductivity: Λ_m (DMSO, 10^{-4} M) 11.4 Ω^{-1} cm^2 mol^{-1}.

This indicates that the Pd^{II} compound did not follow the same reaction pattern as is followed by the Pt^{II} compound. Instead it turned out to be a neutral Pd^{II}(Salen) [Salen = *N,N′*-bis(salicylidene)-ethylenediamine] complex.

2.5. Preparation of complex *3 (1 · hfb)*

The adduct of complex **1** with hexafluorobenzene was prepared by the dropwise addition of a methanolic solution of hfb to the solution of complex **1** in minimum amount of DMSO. The resulting solution was stirred for 4 h and cooled in a refrigerator for 24 h. After the addition of an aqueous solution of NH_4PF_6, the solid thus obtained was filtered and washed with methanol followed by diethyl ether. It was further purified by dissolving it in a minimum amount of DMSO followed by the addition of excess methanol. Finally, the crystallized solid was dried in vacuo and characterized as $[Pt(en)LH_2]_2 \cdot$ hfb **3**. Yield 30%; m.p.: >230 °C. Elemental *Anal.* Calc. for $C_{50}H_{48}N_8O_4P_4F_{30}Pt_2$: C, 31.44; H, 2.51; N, 5.87. Found: C, 31.78; H, 2.55; N, 5.63%. IR (KBr pellet, cm^{-1}): 1622 ($\nu_{CH=N}$), 1254 (ν_{OH}), 844 (ν_{PF6}). ^{1}H NMR (DMSO-d_6, 300 MHz, ppm): δ 13.04 (s, OH), 9.02 (s, HC=N), 7.6–7.4 (m, aromatic), 6.9 (m, aromatic + NH_2), 6.61 (m, aromatic), 3.6 (s, N–CH_2), 3.5 (s, 4H, N–CH_2), ^{19}F NMR (DMSO-d_6, 282.5 MHz, ppm): δ −71 (s; PF_6), 162.35 (s; Ar–F). FAB-MS: *m/z*: 1908 $[M]^+$, 1722 $[M-hfb]^+$, 1619 $[M-2PF_6+1]^+$, 1142 $[M-hfb-4PF_6]^+$, 1022 $[M-hfb-4PF_6-2en]^+$. UV/Vis (DMSO, 10^{-4} M): $\lambda_{max/nm}$ (ε_{max} 10^4 M^{-1} cm^{-1}) 343 (1.41), 358 (1.49), 258 (4.27). Emission excited at λ 340 nm (DMSO, 10^{-4} M): $\lambda_{max\,(nm)}$ (intensity in a.u.) = 503.39 (362). Conductivity: Λ_m (DMSO 10^{-4} M) 370 Ω^{-1} cm^2 mol^{-1}.

2.6. Preparation of *Zn^{II} complex 4*

The metallocyclophane $[Zn(bpy)L]_2$ (bpy = 2,2′-bipyridine) **4** was prepared and characterized using the reported procedure [15].

2.7. Preparation of complex 5 (4 · hfb)

The adduct of complex **4** with hfb was also prepared using a similar method as followed for **3** by the addition of a methanolic solution of excess hfb to the solution of complex **4** in minimum amount of DMSO. The resulting solution was stirred for 4 h then cooled in a refrigerator for 24 h. The solid thus obtained was filtered and washed with methanol followed by diethyl ether. It was further purified by dissolving in a minimum amount of DMSO followed by the addition of excess methanol. Finally, the crystallized solid was dried in vacuo and characterized as [**4** · hfb]. Yield: 36%. m.p.: >230 °C. Elemental *Anal*. Calc. (%) for $C_{66}H_{44}N_8O_4Zn_2F_6$: C, 63.1; H, 3.5; N, 8.9. Found: C, 63.4; H, 3.4; N, 8.6%. IR (KBr pellet, cm^{-1}): 1601 ($\nu_{CH=N}$), 1531 (ν_{phenyl}), 1149 (ν_{hfb}). ^1H NMR (DMSO-d_6, 300 MHz, ppm): δ 8.9 (s, 4H, HC=N), 6.4–6.7 (m, 12H, bpy), 7.3–7.5 (m, 12H, phenyl), 6.9–7.1 (s, 4H, phenyl). ^{19}F NMR (DMSO d_6, 282.5 MHz, ppm): δ 162.47 (s, 6F, Ar–F). FAB-MS: *m/z*: 1256 $[M]^+$, 1071 $[M-hfb+1]^+$, 1036 $[M-hfb-2OH]^+$, 1018 $[M-hfb-3OH+1]^+$. UV/Vis (DMSO, 10^{-4} M): $\lambda_{max/nm}$ (ε_{max} 10^4 M^{-1} cm^{-1}) 396 (1.59), 379 (2.40), 328 (1.41). Emission excited at λ 396 nm (DMSO, 10^{-4} M): $\lambda_{max\,(nm)}$ (intensity in a.u.) 532 (150). Conductivity: Λ_m (DMSO, 10^{-4} M) 5 Ω^{-1} cm^2 mol^{-1}.

3. Results and discussion

The complexes are soluble in DMF and DMSO, complex **1** and its adduct **3** show electrolytic behaviour (1:4) in DMSO (10^{-3} M), whereas complexes **2**,**4** and **5** are found to be non-electrolytic in nature [19].

In the infrared spectra, the peak observed at 1610 cm^{-1} (free ligand), assigned to ν(CH=N), shifted to 1633 cm^{-1} (complex **1**). This indicates that the HC=N groups had coordinated during complex formation. The peak observed at 1282 cm^{-1}, assigned to νOH, (free ligand) [18] remains constant in the spectrum of its complex and shows the presence of free OH groups. This observation is further supported by its ^1H NMR spectrum, which shows a peak at δ 13.1 ppm assigned to OH protons. Additionally, in the IR spectrum of adduct **3**, peaks due to νHC=N are observed at 1622 cm^{-1} as compared to 1633 cm^{-1} in complex **1**, showing that the HC=N groups are involved in the association with hexafluorobenzene.

Additionally, the peaks of the phenyl ring protons in the ^1H NMR spectrum of adduct **3** are broadened as compared to the peaks in the spectrum of complex **1**, in which they are sharp (Fig. 1). The broadening of aromatic protons could occur due to its restricted rotation on the NMR time-scale upon the inclusion of hexafluorobenzene in the cavity of complex **1**. This behaviour is consistent with an earlier report [20] on the inclusion complexes.

The UV/Vis spectra recorded in DMSO solution (10^{-4} M) showed that the single peak observed at λ_{max} 261 nm in the spectrum of free hfb is enhanced to twice the intensity in the spectrum of its adduct **3** at λ_{max} 260 nm. Additional peaks observed at λ_{max} 340, 356 and 378 nm in the spectrum of complex **1** are assigned to intra-ligand transitions, whereas the peak at λ_{max} 439 nm arises from a MLCT transition. In the adduct of **1** with hfb, most of the peaks, including that of the MLCT transition, are blue shifted. This indicates that hfb is bound with complex **1** internally.

The composition of complex **2**, assigned as Pd(Salen) on the basis of its elemental analysis and mass measurements, is further substantiated by its ^1H NMR spectrum which shows the presence of N–CH_2–CH_2-N and HC=N protons at $\delta = 4.0$ (s, 4H) and 8.5 (s, 2H) ppm, respectively. However, the disappearance of the signal of the phenolic OH proton of the free ligand shows that the deprotonated OH groups had coordinated with the Pd^{II} ion. To get additional support for its structure, it has been characterized by single crystal X-ray crystallography.

Suitable X-ray quality crystals of complex **2** were grown from a DMSO/MeOH solvent mixture at room temperature, and X-ray crystallographic data are recorded by mounting a single-crystal of sample **2** (0.26 × 0.18 ×

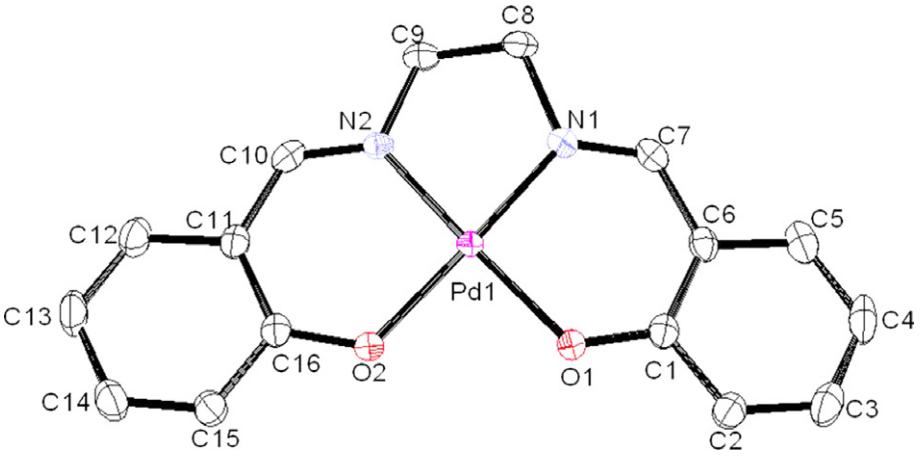
0.16) mm^3 on a glass fiber. An Oxford diffraction XCALIBUR-S CCD area detector diffractometer equipped with an LN-2 low-temperature attachment was used for the cell determination and intensity data collection. Appropriate empirical absorption corrections using the programs multi-scan were applied. Monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) was used for the measurements.

Important crystallographic data and the structure refinement details are listed in Table 1, selected bond lengths and bond angles are summarized in Table 2, and its ORTEP view is shown in Fig. 2. Crystallographic data shows that the Pd–N distance, observed to be about 1.95 Å, is shorter than the reported [20] value of 2.1 Å. The N–Pd–N bond angle of 84.2° is a bit smaller than that of a square (90°). Thus, the geometry around the Pd^{II} centre is a little deviated from the normal square planar. In other words, although, the molecule's shape is indeed that of a square, it is not planar. The deviation from planarity is about 3 Å. It is important to note that N1–C8–C9–N2 is largely deviated by 34.5°, which is quite logical as it contains a flexible alkyl chain. The deviation from planarity is also observed in the chelate ring but to a smaller extent (5 Å). It shows that this deviation is again caused by the flexible alkyl chain.

Thus, the formation of Pd(Salen) shows that upon the addition of Pd(en)Cl$_2$ to a solution of LH$_2$, the ligand rearranges itself into the formation of an imine linkage between ethylenediamine appended with Pd^{II} and salicylaldehyde (most likely formed due to hydrolysis of the imine groups followed by oxidation) as depicted in Scheme 1. The contribution of ethylenediamine in this type of condensation is further supported by the condensation of [Pd(bpy)Cl$_2$] with the Schiff base, which like the Pt^{II} complex, led to a (2 + 2) condensation instead of the formation of Pd(Salen).

As mentioned above, upon the complexation of Pt(en)Cl$_2$ with LH$_2$, a (2 + 2) condensation between the two components occurred and it resulted in the formation of a metallocyclophane, as reported earlier for the Zn(bpy) system [15].



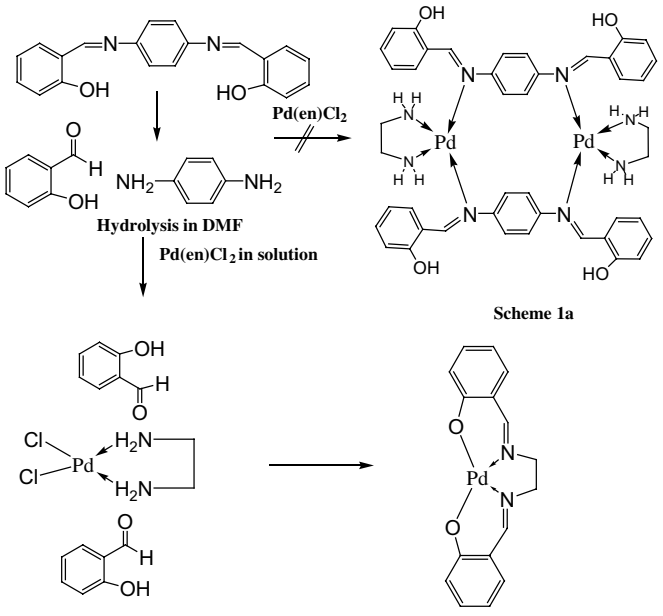


Fig. 2. ORTEP diagram of complex **2**. Thermal ellipsoids are at 50% probability.

Scheme 1.

Although the reason for this difference in reactivity of Pd^{II} and Pt^{II} with the Schiff base cannot be understood accurately, it may be considered in view of the stronger Pt–N=C bond as compared to the Pd–N=C bond [21]. Theoretical calculations also support that the relativistic bond stabilization is stronger for third-row transition metal complexes (Pt) than for second-row transition metal complexes (Pd) [22].

The crystal packing pattern of complex **2** in the solid state is shown in Fig. 4. The squares are stacked along the '*b*'-axis, resulting in long channel like cavities of ~25 Å diameter as shown by the centroid–centroid perpendicular distance ~3.3 Å and parallel distance of 8.2 Å. It is worth mentioning that π–π stacking between the phenyl rings produces a near contact between the two Pd centres, being separated by 3.206 Å, though the presence of a Pd–Pd bond between the metal centres has been ruled out in view of the literature report [23,24]. Furthermore, it is quite interesting to note that a cavity as desired from Scheme 1a could be looked upon from this stacking pattern. Thus, the stacking pattern of the complex as shown in Fig. 3 prompted us to make binding studies of phenol similar to that reported earlier with a Zn^{II} containing cyclophane. Since this structure is obtained by π–π stacking interactions, the association of phenol with this compound is considered to be weaker and in fact its binding constant [15] gave the value $K = 1.6 \times 10^4$, which is lower than that reported for the Zn^{II} analogue ($K = 7.5 \times 10^4$) [15].

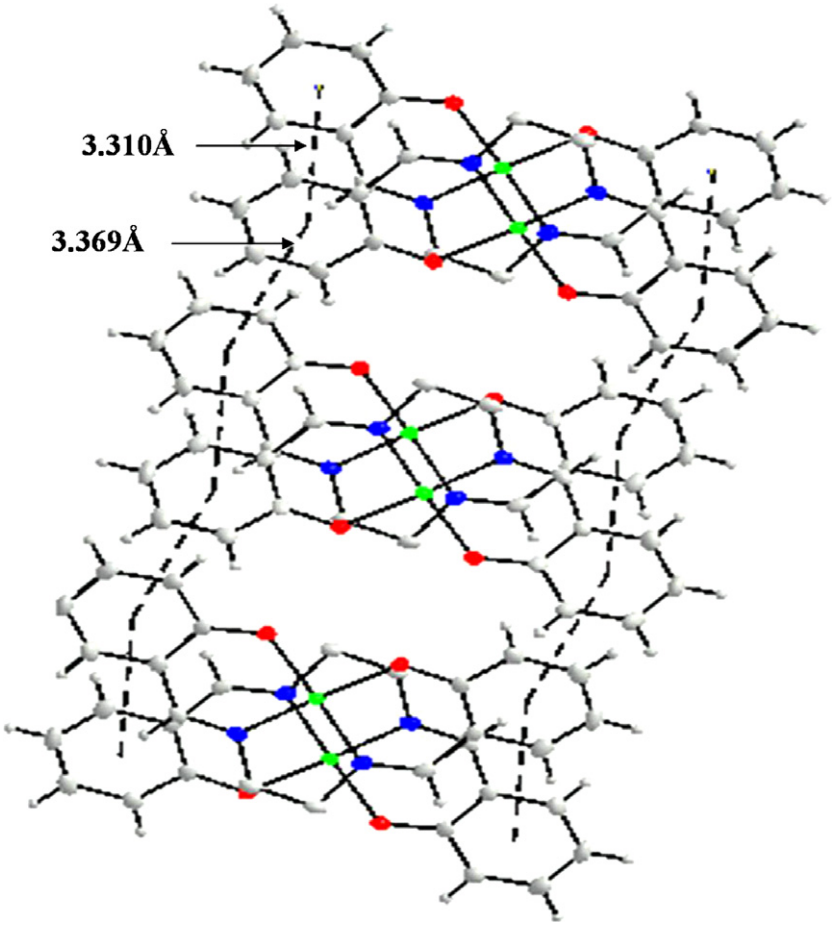

Fig. 3. Stacking pattern in complex **2**.

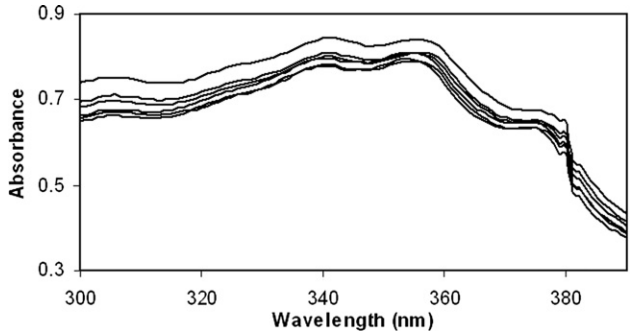

Fig. 4. UV/Vis absorption spectrum of **1** titrated against hexafluorobenzene.

Since the formation constant K_c is an important parameter that measures the extent of inclusion of a guest in a host complex, hexafluorobenzene being electron deficient in nature was considered as a novel guest. The selectivity of an electron acceptor molecule like hfb has been made in view of the possibility of the electron rich nature of the cavity of the macrocyclic frame due to the attachment of electron donor groups like 1,2-diaminoethanes to the metal centres as well as the presence of phenyl rings as electron sinks in the skeleton of the metallocyclophane. Thus, the binding of hexafluorobenzene with the representative complex **1** has been monitored by UV–Vis spectral data (Fig. 4). The variation of spectral pattern obtained by the addition of increasing concentrations of hexafluorobenzene (2×10^{-5}–1×10^{-4} M) to a fixed concentration of the complex (5×10^{-5} M) monitored at λ 340 nm is shown in Fig. 4. The formation constant as calculated using the Benesi-Hilde brand (BH) equation [15] is found to be 3.17×10^{4} M^{-1}.

To support the inclusion of hexafluorobenzene inside the cavity of the complex, the ^{19}F NMR spectrum of complex **3** was recorded. A ^{19}F signal observed at δ −162.35 ppm is found to be deshielded as compared to the signal observed at δ −161.54 for free hexafluorobenzene, as depicted in Fig. 5. It is worth mentioning that the observed difference in ^{19}F chemical shifts between the included hexafluorobenzene and the free hexafluorobenzene, being 0.8 ppm, is almost two orders higher than the digital resolution 0.01 ppm (acquisition time = 0.328 s). Thus, the observed difference in chemical shifts is definitely significant. It is further clear that upon heating, the ^{19}F signal shifts towards high field (tending towards the ^{19}F signal of free hfb). Additionally, upon heating, the number of ^{13}C peaks of the phenyl rings also get enhanced. This could happen only when hbf is included in the cavity since upon heating hfb would tend to come out of the cavity and get closer to the phenyl ring of ligand skeleton. A variable temperature ^{1}H NMR spectrum of adduct **3** was also recorded, and it shows extensive splitting of the phenyl protons in the temperature range 130–140 °C. For further support, ^{19}F VT NMR of adduct **3** was also recorded from room temperature 27.7 to 70 °C. The variable temperature ^{19}F NMR spectrum shows a substantial decrease in the change of chemical shift as compared to the position of the ^{19}F sig-

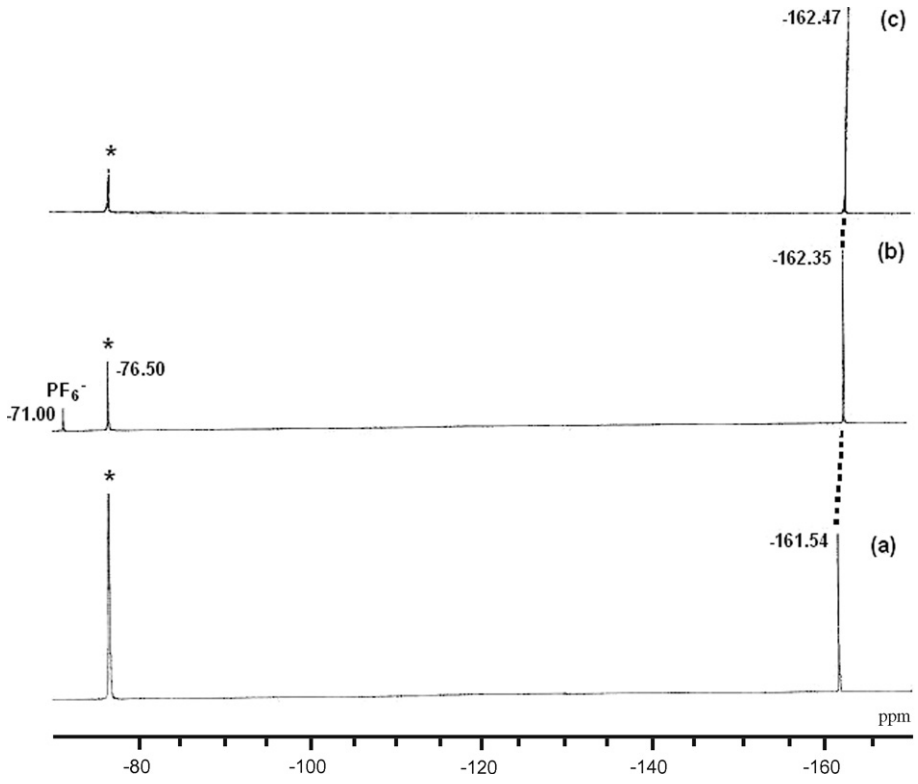

Fig. 5. Comparison of ^{19}F NMR spectra of free hexafluorobenzene (a); complex **3** (b) and complex **5** (c). The signal labelled with an asterisk represents trifluoroacetic acid (external reference).

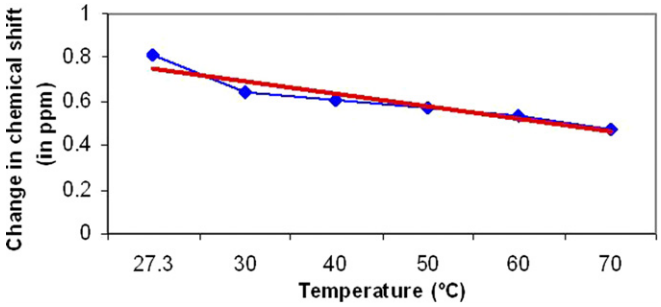

Fig. 6. Change in chemical shift in ^{19}F VT NMR spectra of complex **3** (blue), trendline (red). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

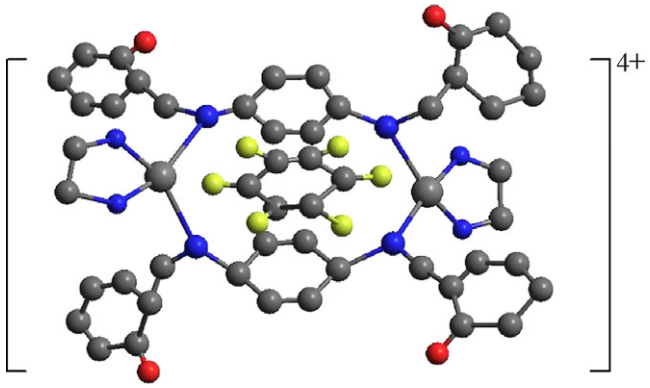

Fig. 7. Ball and stick model showing the fitting of one hfb molecule within the cavity of complex **1**. All H atoms have been omitted for clarity.

nal of free hfb with an increase in temperature, as depicted in Fig. 6.

Thus, the ^{1}H, ^{13}C and ^{19}F NMR spectral pattern of the adduct show that the guest is included in the cavity generated by the metallocyclophane **1**, consistent with the earlier report. Since suitable crystals could not be grown, a model of such host–guest binding was tried and is depicted in Fig. 7, which shows that hfb is accommodated by the cavity formed by metallocyclophane.

In order to compare the association of hfb with metallocyclophane **1**, hfb has also been allowed to interact with the earlier reported metallocyclophane **4** and the association constant thus evaluated was found to be 2.52×10^4 M^{-1}. An ^{19}F NMR spectrum of its adduct **5** along with the spectrum of free hfb is also shown in Fig. 5.

Thus, the results indicate that Pt^{II}–cyclophane derived from the Schiff base (LH_2) binds hexafluorobenzene more strongly compared to the earlier reported Zn^{II}–cyclophane.

To get evidence of guest mobility and framework stability, thermal gravimetric analysis of adduct **3** has been made and the corresponding thermogram is shown in Fig. 8. Crystalline sample **3** (2.128 mg) was heated at a constant rate of 20 °C min^{-1} in a N_2 atmosphere with 180 ml/min flow rate from 50 to 400 °C. Three weight-loss steps were observed: the first, corresponding to 9.39%, occurred between 50 and 130 °C, which could be attributed to the loss of the guest molecules (calculated 9.74%). This is further supported by its DTA thermogram which shows an endothermic peak for this temperature range, indicating that a phase transition occurs most likely due to the removal of hexafluorobenzene (guest) as reported for the metal organic frameworks [25]. The second weight loss of 30.39% between 200 and 240 °C is due to the removal of four counter PF_6^- anions (30.54%) in view of the decomposition temperature of complex **1**, i.e. >230 °C. The appearance of an exotherm at 230 °C in the DTA thermogram also strengthens this finding. The second weight loss in the TGA thermogram profile is followed by a third weight loss in the temperature range 250–400 °C. After 400 °C about 12% mass remains, which may be due to metal oxide.

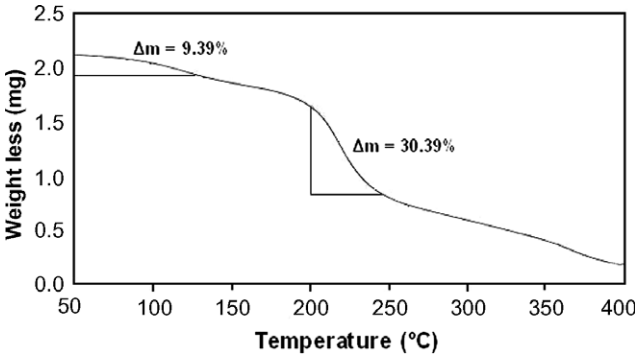

Fig. 8. TGA thermogram of complex **3**.

4. Conclusion

The present study shows the construction of a Pt^{II}-based metallocyclophane on the skeleton of a simple tetradentate Schiff base which provides an electron rich cavity. The space provided by the cavity is found to be suitable for comparatively stronger binding of an electron acceptor molecule like hexafluorobenzene. Additionally, the presently used Schiff base provides an alternate route to prepare the Pd(Salen) complex in the form of beautiful coloured crystals suitable for X-ray studies. This study also allows the difference in the reactivity of Pd^{II} and Pt^{II} complexes with a tetradentate Schiff base to be understood.

Abstract

The structure, spectroscopy and electrochemical properties of a novel dinuclear copper(II) complex, $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ where phen = 1,10-phenanthroline, is reported. The crystal structure contains two independent Cu(II) ions, with different geometry around each copper center, which are bridged by an acetate anion. The acetate-bridged ligand shows a *syn–anti* coordination mode with a trigonal bipyramidal geometry for the Cu(1) center and a distorted square-based pyramidal geometry for the Cu(2) center. The angular structural index parameter τ for Cu(1) and Cu(2) is 0.9 and 0.33, respectively. The copper(II) atoms display a different geometry with a N_4O chromophore group and with Cu–O distances of 1.993(5)–1.996(5) Å and Cu–N distances which vary from 1.980(5) to 2.161(6) Å. The intra Cu...Cu separation is 4.9904(5) Å. The effective magnetic moment (μ_{eff}) of the complex was measured by the Evans method. The cyclic voltammogram of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ shows two waves at positive potential which are assigned to the two Cu(II/I) reduction couples.

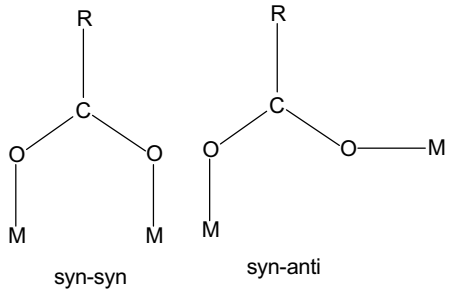
1. Introduction



In recent decades, metal-carboxylate chemistry has received a great deal of attention in different fields ranging from metallobiochemistry to catalysis and materials science [1]. The main interest in the chemistry of metal-carboxylates arises from: (i) the versatility of the coordination modes of the simple carboxylate anions which leads to fascinating molecular architectures; (ii) the key role of the carboxylate as a ligand in biological systems involving mono- or polymetallic active sites; and (iii) the property of the carboxylate bridge to exhibit an exchange path mediating the interaction among spins that are localized on paramagnetic centers [2–7]. Carboxylate ligands exhibit several coordination modes to metal centers leading to a variety of polynuclear complexes ranging from discrete entities to multi-dimensional systems. One-dimensional copper(II) compounds containing carboxylate bridges are especially important in the area of molecule based magnets [8,9] and high-temperature oxide-superconductors [10].

Bridged dinuclear copper(II) carboxylato compounds with bidentate chelating ligands and a five coordination of the Cu(II) ion show an extensive range of compounds with a distortion between regular trigonal bipyramidal and regular square-based pyramidal. This feature can be useful for understanding the relationships between structural features and the value of the intramolecular magnetic exchange interaction in the dinuclear units [11].

With acetate as a bridging ligand, several interesting structures with special magnetic properties have been

Scheme 1.

reported for a number of dinuclear Cu(II) compounds [12–16]. The acetate ligand can adopt two different bridging conformations; the *syn–syn* mode and the *syn–anti* mode (see Scheme 1). The *syn–anti* mode conformation is very rare and only a limited number of X-ray structures have been reported with this bridging mode [12,13,15,17–28].

In this investigation, we report the synthesis, crystal structure, spectroscopic characterization and magnetic and electrochemical behaviors of a novel copper(II) complex, $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$, having the acetate ligand in a *syn–anti* bridging mode.

2. Experimental

2.1. Materials and physical measurements

All chemicals and solvents were reagent grade, obtained from either Merck or Aldrich and used without further purification. Elemental analysis was performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (4000–400 cm^{-1}) were measured on a FT-IR JASCO 460 spectrophotometer with KBr pellets. UV–Vis spectroscopy was performed on a JASCO 7850 spectrophotometer. The effective magnetic moment (μ_{eff}) of the complex was measured by the Evans method on a ^1H NMR Bruker DRX-500 MHz, Avance spectrometer at ambient temperature. Cyclic voltammograms were recorded using a Metrohm 694 apparatus. Three electrodes were utilized in this system, a platinum disk working electrode (RDE), a platinum wire auxiliary electrode and a Ag/AgCl reference electrode. The platinum disk working electrode was manually cleaned with 1-μm diamond polish prior to each scan. The supporting electrolyte, tetrabutylammonium hexafluorophosphate (TBAH), was twice recrystallized from 1:1 ethanol/water and vacuum-dried at 110 °C. Acetonitrile was dried over P_2O_5 and vacuum distilled. The solutions were deoxygenated by bubbling with argon (Ar) for 15 min. Ferrocene ($E^\circ = 0.665$ V) was used as an internal reference.

2.2. Synthesis of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$

A mixture of $Cu(CH_3COO)_2 \cdot H_2O$ (0.4 g, 2 mmol) and 1,10-phenanthroline (0.7 g, 4 mmol) was placed in 80 mL of EtOH and the solution was stirred and kept at 40 °C for 12 h. To the reaction mixture was then added excess NH_4PF_6 (1.5 g). The green precipitate, $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$, which formed was collected by suction filtration, washed with ethanol and ether, and then air dried. The crude product was recrystallized by diffusion of diethyl ether into an acetonitrile solution of the complex. After 5 days, green crystals formed. Yield: 818 mg, 61%. *Anal*. Calc. for $C_{50}H_{35}Cu_2F_{18}N_8O_2P_3$: C, 44.75; H, 2.63; N, 8.35. Found: C, 45.11; H, 2.67; N, 8.46%.

2.3. X-ray crystallographic study of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$

A green single crystal of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ with dimensions $0.40 \times 0.20 \times 0.12$ mm was chosen for the X-ray diffraction study. Diffraction measurements were carried out on a STOE IPDS II two-circle diffractometer using graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation at 293(2) K. Unit cell parameters were determined by the least-squares procedures with the θ angle ranging from 1.67° to 26.86°. A numerical absorption correction was applied to the data with the help of the programs X-RED and X-SHAPE [29]. A total of 11 919 independent reflections were collected, giving 5752 observed reflections with $I > 2\sigma(I)$. The structure was solved by the direct method [30] and refined by full-matrix least-squares on F^2 using the X-STEP32 program package [31], giving a final $R_1 = 0.0878$, $wR_2 = 0.2224$ values. The R_1 value is slightly

high due to data collection at room temperature and is related to the high vibrational motion of the fluorine atoms of PF_6^- and also the carbon atoms in the Phen rings. These disorders are common especially with room temperature data collection when the structure contains PF_6^-, ClO_4^- and similar groups. We tried refining these atoms in two positions with reduced occupancy but while this model converged satisfactorily, there was no decrease in the *R* value and therefore we consider that our original refinement is the best that can be achieved and should be reported. The largest diffraction peak and hole on the final difference-Fourier map were 1.169 and -0.395 e Å^{-3}, respectively. The largest peak is not close to a heavy scatterer (the distance is more than 1 Å), so it is related to disordering of some atoms in the structure. Further details of the structural analyses are given in Table 1. Selected bond lengths and bond angles are listed in Table 2.

3. Results and discussion

The dinuclear Cu(II) complex was synthesized in good yield. $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ is air-stable and can be readily recrystallized. Elemental analysis of the complex was entirely consistent with its proposed stoichiometry. This complex was further characterized by IR, UV–Vis spectroscopies and cyclic voltammetry. Green crystals of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ were grown by ether diffusion into an acetonitrile solution of the complex.

An ORTEP plot of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ with the atomic labelling scheme is shown in Fig. 1, and selected bond lengths and bond angles are listed in Table 2. Both Cu(II) ions in the dinuclear unit are linked through a bridging acetate ligand with a *syn–anti* mode conformation. The molecular structures of five-coordinate copper(II) complexes show an extensive range from regular trigonal bipyramidal (RTBP) to regular square-based pyramidal (RSBP) [32,33]. The structure index parameter, $\tau = (\beta - \alpha/60)$, was evaluated by the two large angles ($\alpha < \beta$) in the five-coordinated geometry, where $\tau = 1.0$ for a RTBP geometry and $\tau = 0.0$ for a RSBP [34]. The coordination geometry of Cu(1) ($\tau = 0.9$) is best described as trigonal bipyramidal with the equatorial plane comprising of N(3), N(1), Cu(1) and O(1) (see Fig. 2). There is a small difference in the axial and equatorial Cu–N bond lengths. In the Cu(1) coordination site, the equatorial Cu–N bond lengths are considerably longer than the corresponding axial Cu–N bond lengths. The coordination geometry around Cu(2) is approximately square pyramidal with a N_4O donor set (see Fig. 2). This coordination geometry is slightly distorted from regular square-based pyramidal, as ascertained by the observed τ value of 0.33. One oxygen atom of the acetate bridge and three nitrogen atoms of the phen ligands constitute the basal plane of the square pyramid, and a nitrogen of phen occupies the apical position.

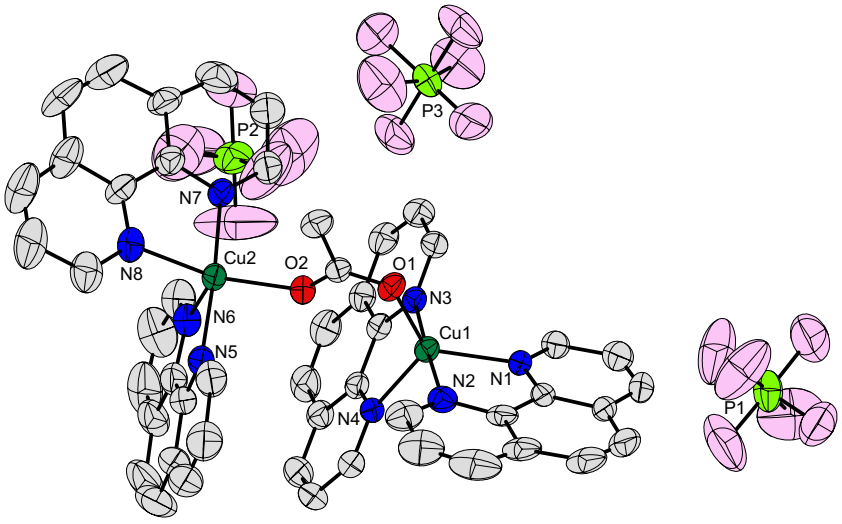

Fig. 1. ORTEP diagram of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ showing 30% probability ellipsoids. Hydrogen atoms and some atoms numbering are deleted for clarity.

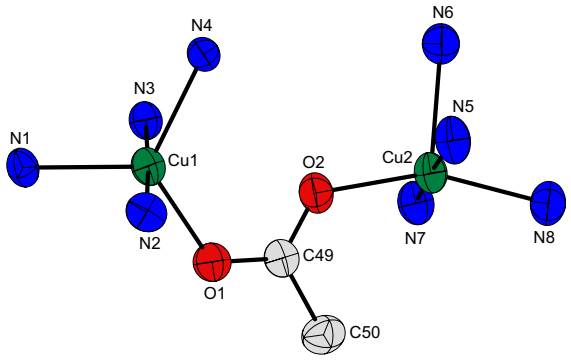

Fig. 2. The inner coordination sphere of the copper(II) ions bridged by acetate in $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$.

The Cu(2) atom lies 0.223(3) Å above the basal plane. The Cu(II) centers are connected through a single *syn–anti* acetate bridge with a Cu...Cu separation of 4.9904(5) Å. In the crystal of this dinuclear complex, the distances between the copper(II) ions and the fluorine of PF_6^- are too great to suggest coordination. The lattice structure is further stabilized by a network of hydrogen bonds between the H atoms of the phen ligands and the F atoms of the PF_6^- anions, with C–H...F distances of 2.371(0.035)–3.931(0.001) Å. As is shown in Fig. 3, there are some weak π–π aromatic interactions between two of the four phenanthroline ligands, N(3)–N(4) and N(5)–N(6), and the angles between the phenanthroline planes are about 18° in the lattice.

The infrared spectrum of the complex exhibits the bands expected for the organic ligands and counter ions. Particularly, the asymmetric stretching vibration of the acetate anion, $\nu_{asym}(COO)$, is observed at 1613 cm^{-1}, while the band at 1449 cm^{-1} is assigned to the symmetric stretching vibration of the acetate anion ($\nu_{sym}(COO)$). The difference between $\nu_{asym}(COO)$ and $\nu_{sym}(COO)$ of about 164 cm^{-1} agrees with the bridging coordination mode for the acetate anion [12,15,35]. The strong absorption band at 841 cm^{-1} is assigned to ν(P–F) and demonstrates the existence of PF_6^- as a counter ion [35].

The electronic spectrum of the complex was taken in acetonitrile. The spectrum shows two absorption bands in the UV region and two absorption bands in the visible region. The absorption bands centered at 234 nm ($\log\varepsilon = 4.53$) and 313 nm ($\log\varepsilon = 4.18$) are assigned to ligand-centered ($\pi \rightarrow \pi^*$) transitions. The intense absorption band centered at 412 nm ($\log\varepsilon = 3.25$) is assigned to a LMCT transition. Due to the different coordination geometries around the Cu(II) centers, the ligand field transitions (LFT) overlap with each other and appear as a broad band around 700 nm ($\log\varepsilon = 1.22$) [36].

The effective magnetic moment (μ_{eff}) of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ was measured to be 1.63 BM per Cu(II) ion by the Evans method [37]. The effective magnetic moment (μ_{eff}) is slightly below the theoretical value expected for a Cu(II) center with $S = 1/2$ and suggests antiferromagnetic exchange between the Cu(II) ions. As the Cu...Cu distance is fairly large (4.9904(5) Å), this antiferromagnetic interaction most likely occurs via the Cu–O–C–O–Cu pathway. This is consistent with a few other acetate-bridged complexes such as $\{[Cu(diethylenetriamine)(\mu\text{-}CH_3COO)]_n(ClO_4)_n\}$ and $\{[Cu\text{-}(dpa)(CH_3COO)](ClO_4)\cdot 0.5THF\}_n$, which also exhibit a weak antiferromagnetic interaction [38,39].

Cyclic voltammetry was performed on an acetonitrile solution of the complex with 0.1 M TBAH as a supporting electrolyte. The cyclic voltammograms of the

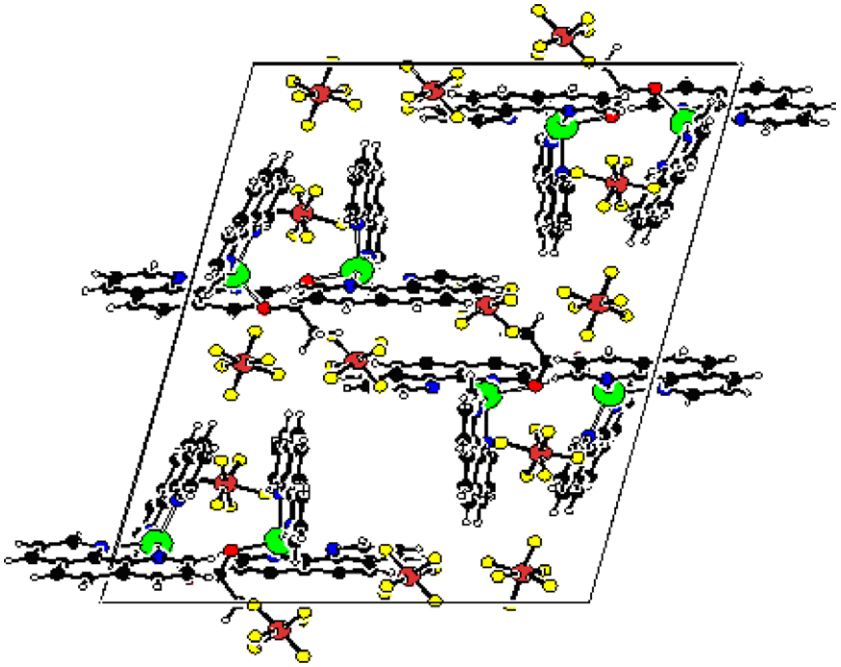

Fig. 3. Packing diagram of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ viewed in the b-direction.

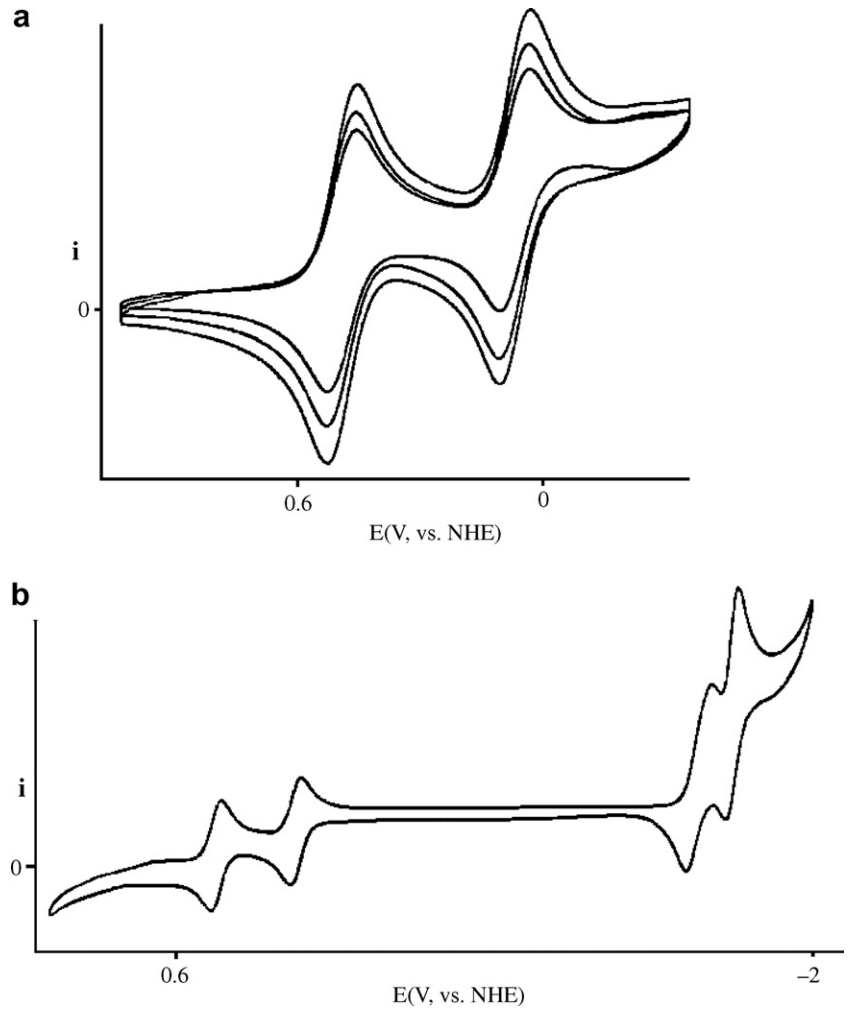

Fig. 4. Cyclic voltammograms of $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ in CH_3CN/0.1 M TBAH. (a) Scan rates of 100, 200 and 300 mV/s; (b) at a scan rate of 100 mV/s.

$[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$ complex are shown in Fig. 4. The copper redox couples in the dinuclear complex occur in approximately the same region as the Cu(II/I) of mononuclear Cu(II) complexes with phen ligands. However, these reduction couples are split into two one-electron waves at 0.544 and 0.135 V which correspond to Cu(II,II/II,I) and Cu(II,I/I,I), respectively, and is indicative of significant metal–metal coupling. These redox couples seem to be quasi-reversible with an average separation between the cathodic and anodic waves of 98 mV, which is independent of the scan rate between 100 and 400 mV/s.

The stability of a mixed-valance form can be quantified by the comproportionation equilibrium constant (K_c). The larger K_c is, the greater the electronic coupling. K_c is usually deduced from the difference in potential between metal center reduction couples, $\log K_c = 16.9(\Delta E)$. From the difference in Cu(II/I) couples of the dinuclear complexes (ΔE), the comproportionation constant (K_c) for the formation of the Cu(II/I) mixed-valence complex,

$$Cu(II) - Cu(II) + Cu(I) - Cu(I) \overset{K_c}{\rightleftharpoons} 2Cu(II) - Cu(I)$$

was determined to be 0.8×10^7. This value is on the borderline between Classes II and III behavior in the Robin and Day classification [40–45] and requires further study before an absolute assignment can be given. In particular, the difference in solid state coordination environments may significantly perturb the Cu(II/I) couples and hence make a contribution to the comproportionation equilibrium. Whether this difference exists in solution is at the present unknown. The two quasi-reversible reduction couples at negative potential are assigned to the sequential reductions of the phenanthroline ligands.

4. Conclusion

The combination of spectral, structural and electrochemical measurements we have described has illustrated the main features of the coordination, magnetic property and redox chemistry of a novel dinuclear Cu(II) complex, $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$. The coordination geometry around the Cu(II) centers is different. The acetate-bridged ligand between two Cu(II) centers shows

a*syn–anti* coordination mode with a trigonal bipyramidal geometry for the Cu(1) center and a distorted square-based pyramidal geometry for the Cu(2) center. The effective magnetic moment is slightly less than the theoretical value expected for one non-coupled Cu(II) center. The magnitude of μ_{eff} suggests a weak antiferromagnetic interaction between the two paramagnetic Cu(II) centers. The comproportionation constant of this complex suggests strong coupling between the copper(II) ions, however the difference in coordination environment may also make a significant contribution.

5. Supplementary material

CCDC 629592 contains the supplementary crystallographic data for $[\{Cu(phen)_2\}_2(\mu\text{-}CH_3COO)][PF_6]_3$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Synthesis, structure and metallation of spiro-$N_3P_3(O_2C_{12}H_8)(OC_5H_4N\text{-}2)_4$: A heptacoordinate Co(II) in the molecular structure of $N_3P_3(O_2C_{12}H_8)(OC_5H_4N\text{-}2)_4 \cdot Co(NO_3)_2$

Abstract

Spiro-$N_3P_3(O_2C_{12}H_8)(OC_5H_4N\text{-}2)_4$ (**L**) is an efficient multi-site coordination ligand which binds with transition metal ions to afford the mononuclear complexes $[LCu(NO_3)_2]$, $[LCo(NO_3)_2]$ and $[LZnCl_2]$. In $[LCu(NO_3)_2]$ the copper atom is six-coordinate with the cyclophosphazene ligand coordinating to the metal ion through one skeletal ring nitrogen atom and two nitrogen atoms of geminal pyridyloxy substituents in a η^3-*gem*-N_3 mode. The two nitrate ligands provide monodentate as well as chelating coordination. In $[LCo(NO_3)_2]$ the coordination geometry around Co(II) is pentagonal bipyramidal with a 3N, 4O coordination environment. The cyclophosphazene ligand binds to the metal ion in a η^3-*non-gem*-N_3 mode. The two nitrate ligands function as chelating ligands and complete the coordination around cobalt. The coordination response of **L** in the complex $[LZnCl_2]$ is also η^3-*non-gem*-N_3. Two chloride ligands complete the coordination environment around zinc.

1. Introduction

Cyclophosphazene-based ligand systems have been attracting a great deal of interest in recent times [1,2]. One of the important reasons for this is because it is possible to use the cyclophosphazene rings as supports for the design and assembly of a large variety of ligands each of which can provide unique steric and electronic environments for transition metal coordination. Such ligands possess multi-site coordination capabilities and are quite effective in binding transition and lanthanide metal ions [2–5]. Another reason of interest in the cyclophosphazene-based ligand systems is the close inter-relationship between cyclo- and polyphosphazenes which allows the cyclophosphazene chemistry to be readily translated to the polymeric analogues [1a]. Thus, we have recently shown the utility of pyrazolyl cyclophosphazenes and cyclophosphazene hydrazides in metallation reactions [6]. This chemistry could be readily adapted for the preparation of the corresponding polymers [7,8] some of which were used to generate recyclable polymeric catalysts for plasmid cleavage, phosphate ester hydrolysis as well as in the Heck reaction involving C–C bond formation [8]. In view of this success, we have been interested in extending this methodology to other types of ligands. Recently, we and others have shown that pyridyloxy cyclophosphazenes containing P–O bonds are quite effective in the preparation of mono-, di- and trinuclear metal complexes [9]. It is of interest to compare the coordination behavior of the hexakis(pyridyloxy)cyclophosphazenes with modified ligands where some sites on the cyclophosphazene are blocked by non-coordinating groups. Accordingly, herein we report the synthesis, structure and metallation studies of spiro-$N_3P_3(O_2C_{12}H_8)(OC_5H_4N\text{-}2)_4$ (**L**). The cobalt(II) complex formed from this ligand, $N_3P_3(O_2C_{12}H_8)(OC_5H_4N\text{-}2)_4 \cdot$

$Co(NO_3)_2$ shows a heptacoordinate Co(II) with a 3N, 4O coordination environment. This is the first example of stabilization of the rare hepta-coordination for Co(II) using cyclophosphazene ligands.

2. Experimental

2.1. Materials and instrumentation

Solvents and other general reagents used in this work were purified according to standard procedures. Hexachlorocyclotriphosphazene (Nippon Soda, Japan) was recrystallized from *n*-hexane before use. Anhydrous $ZnCl_2$ (Fluka, Switzerland), $Cu(NO_3)_2 \cdot 3H_2O$, $Co(NO_3)_2 \cdot 6H_2O$ (S.D. Fine Chemicals Mumbai, India) and 2-hydroxypyridine (Lancaster, UK) were used as obtained. Spiro-$N_3P_3(O_2C_{12}H_8)Cl_4$ (**1**) was prepared according to the procedure reported in the literature [10]. ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded on a JEOL spectrometer operating at 400.0 and 161.7 MHz, respectively. Chemical shifts are reported with respect to internal tetramethylsilane (^1H) and external 85% H_3PO_4 (^{31}P). Mass spectra were recorded on a JEOL SX 102/DA 6000 mass spectrometer using xenon (6 kV, 10 mA) as the FAB gas. IR spectra were recorded as KBr pellets on a Bruker Vector 22 FT IR spectrophotometer operating from 400 to 4000 cm^{-1}. Electronic spectra were recorded on a Perkin–Elmer-Lambda 20 UV–Vis spectrometer and on a Shimadzu UV-160 spectrometer using chloroform as the solvent. EPR spectra were recorded on a Bruker EMX 1444 X-band EPR spectrometer (fitted with a quartz Dewar for measurements up to 120 K). The EPR spectra were calibrated with diphenylpicrylhydrazyl, DPPH ($g = 2.0037$). Magnetic susceptibility measurements were carried out by SQUID (Superconducting Quantum Interference Device) using a Quantum Design Magnetic property measurement system XL (USA) at 300 K and the results were corrected for the magnetization of the sample holder and capsule and the diamagnetic contributions to the samples, which were estimated from Pascal's constants [11]. Elemental analyses of the compounds were obtained on a Thermoquest CE instruments CHNS-O, EA/110 model.

2.2. Preparation of spiro-$N_3P_3(O_2C_{12}H_8)(O\text{-}C_5H_4N\text{-}2)_4$ (**L**)

A mixture of spiro-$N_3P_3(O_2C_{12}H_8)Cl_4$(**1**) (2.300 g, 5.00 mmol), 2-hydroxypyridine (2.300 g, 24.000 mmol) and anhydrous potassium carbonate (10.000 g, 72.500 mmol) was heated under reflux in acetone (150 mL) for 2 days. The volatiles were evaporated in vacuo and the residue was extracted twice with dichloromethane (2 × 40 mL). Evaporation of the solvent in vacuo gave spectroscopically and analytically pure compound **L** as a white solid. Yield: 2.8 g (79%). M.p.: 209 °C. ^1H NMR ($CDCl_3$, ppm): 6.73 (m, 2H, aromatic), 6.98–7.17 (m, 12H, aromatic), 7.38 (m, 2H, aromatic), 7.57 (m, 4H, aromatic), 8.17 (m, 4H, aromatic). $^{31}P\{^1H\}$ NMR ($CDCl_3$, ppm) 26.7 (t, $P(OC_{12}H_8)$), 7.8 (d, $P(O\text{-}C_5H_4N\text{-}2)_2$, ^2J(P–N–P) = 93.8 Hz). FAB-MS: 696 $[L]^+$. IR (KBr, cm^{-1}) 3429 (b), 3061 (m), 1590 (s), 1468 (s), 1431 (s), 1223 (m), 1094 (sh), 1000 (sh), 933 (m), 785 (s), 621 (s), 532 (m). *Anal.* Calc. for $C_{32}H_{24}N_7O_6P_3$: C, 55.26; H, 3.48; N, 14.10. Found: C, 55.06; H, 3.35; N, 13.85%.

2.3. Synthesis of metal complexes **2**–**4**

2.3.1. Spiro-$N_3P_3(O_2C_{12}H_8)(O\text{-}C_5H_4N\text{-}2)_4 \cdot Cu(NO_3)_2$ (**2**)

Hydrated copper nitrate, $Cu(NO_3) \cdot 3H_2O$ (0.070 g, 0.288 mmol), was added to a solution of **L** (0.200 g, 0.288 mmol) in dichloromethane (50 mL). The reaction mixture was stirred for 12 h at room temperature. Filtration, followed by removal of the solvent from the filtrate, gave **2**. Yield: 0.200 g (78.8%). M.p.:187–189 °C, FAB-MS: 821 $[L \cdot CuNO_3]^+$, 759 $[L \cdot Cu]^+$, 696 $[L]^+$. EPR: $g_\parallel = 2.35$, $A_\parallel = 146$ G, $g_\perp = 2.07$. Room temperature magnetic moment (after applying diamagnetic corrections), $\mu_B = 1.65$ BM. UV–Vis ($CHCl_3$): λ_{max} (ε_{max}) 768 nm (73 $M^{-1}\,cm^{-1}$). IR (KBr, cm^{-1}) 3427 (b), 3080 (m), 1599 (s), 1471 (s), 1434 (s), 1384 (s), 1290 (s), 1225 (sh), 1181 (s), 1097 (sh), 1001 (sh), 953 (s), 832 (s), 785 (s), 618 (s), 534 (s). *Anal.* Calc. for $C_{32}H_{24}N_9O_{12}P_3Cu$: C, 43.53; H, 2.74; N, 14.29. Found: C, 43.54; H, 2.75; N, 14.14%.

2.3.2. Spiro-$N_3P_3(O_2C_{12}H_8)(O\text{-}C_5H_4N\text{-}2)_4 \cdot Co(NO_3)_2$ (**3**)

Hydrated cobalt nitrate, $Co(NO_3) \cdot 6H_2O$ (0.084 g, 0.288 mmol), was added to a solution of **L** (0.200 g, 0.288 mmol) in dichloromethane (50 mL). The reaction mixture was stirred for 12 h at room temperature. Filtration, followed by removal of the solvent from the filtrate afforded **3**. Yield: 0.19 g (75.2%). M.p.: 178–179 °C, FAB-MS: 817 $[LCo(NO_3)]^+$, 755 $[LCo]^+$, 696 $[L]^+$. Room temperature magnetic moment (after applying diamagnetic corrections), $\mu_B = 4.02$ BM. UV–Vis ($CHCl_3$): $\lambda_{max(\epsilon max)}$ 506 nm (33 $M^{-1}\,cm^{-1}$). IR (KBr, cm^{-1}) 3404 (b), 3066 (m), 1647 (s), 1472 (s), 1434 (s), 1384 (s), 1291 (s), 1228 (sh), 1182 (s), 1095 (sh), 1043 (sh), 950 (s), 893 (s), 785 (s), 617 (s), 532 (s). *Anal.* Calc. for $C_{32}H_{24}N_9O_{12}P_3Co$: C, 43.75; H, 2.75; N, 14.35. Found: C, 43.54; H, 2.91; N, 13.94%.

2.3.3. Spiro-$N_3P_3(O_2C_{12}H_8)(O\text{-}C_5H_4N\text{-}2)_4 \cdot ZnCl_2$ (**4**)

Anhydrous zinc chloride (0.040 g, 0.288 mmol) was added to a solution of **L** (0.200 g, 0.288 mmol) in dichloromethane (50 mL) solution. The reaction mixture was stirred for 12 h at room temperature. Filtration, followed by removal of the solvent from the filtrate, yielded metal complex **4**. Yield: 0.18 g (73.2%). M.p.: 205–206 °C, ^1H NMR ($CDCl_3$, ppm): 6.74 (m, 2H, aromatic), 6.93 (m, 4H, aromatic), 7.08–7.25 (m, 8H, aromatic), 7.45 (m, 2H aromatic), 7.67 (m, 4H, aromatic), 8.41 (m, 4H, aromatic). $^{31}P\{^1H\}$ NMR ($CDCl_3$, ppm) 23.9 (t, $P(OC_{12}H_8)$), 7.6

(d, P(O-C_5H_4N-2)$_2$), ^2J(P–N–P) = 98.6 Hz. FAB-MS: 795 $[LZnCl]^+$, 696 $[L]^+$. IR (KBr, cm^{-1}) 3428 (b), 3065 (m), 1599 (s), 1471 (s), 1435 (s), 1299 (s), 1221 (m), 1164 (s), 1055 (sh), 941 (s), 894 (s), 789 (s), 759 (sh), 622 (s), 529 (s). *Anal*. Calc. for $C_{32}H_{24}N_7O_6P_3ZnCl_2$: C, 46.32; H, 2.91; N, 11.82. Found: C, 46.10; H, 2.89; N, 11.52%.

2.4. X-ray crystallography

A suitable crystal for **L** was obtained by slow evaporation of its dichloromethane solution. Suitable crystals for **2–4** were obtained by slow diffusion of *n*-hexane into their dichloromethane solutions. The crystal data for compounds **L** and **2–4** were collected on a Bruker SMART APEX CCD diffractometer. The program SMART (version 6.45) was used for integration of the intensity of reflections and scaling. The program SADABS was used for absorption correction. The crystal structures were solved and refined by full-matrix least-squares methods against F^2 by using the program SHELXTL (version 6.14) [12]. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen positions were fixed at calculated positions and refined isotropically. Compounds **3** and **4** contained disordered solvent molecules that could not be modelled satisfactorily. These were removed by using the PLATON/SQUEEZE program [13]. The squeeze method found the electron count to be 169 and 21 e in a volume of 616.5 and 199.6 Å^3 in the solvent region in the unit cells of **3** and **4**, respectively. The calculated electron counts shows that 4 dichloromethane and 2 water molecules are present in the unit cells of **3** and **4**, respectively. The crystal data for **L** and **2–4** are given in Table 1.

3. Results and discussion

3.1. Synthetic and spectroscopic aspects

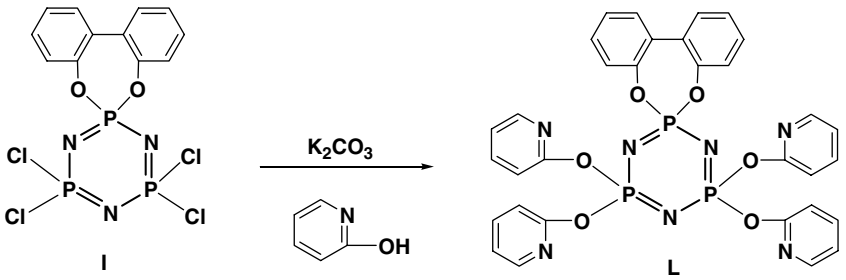
Spiro-$N_3P_3(O_2C_{12}H_8)Cl_4$ (**1**) has four reactive chlorine atoms which can be substituted quite readily. Utilizing this feature, we have synthesized spiro-$N_3P_3(O_2C_{12}H_8)$-(OC_5H_4N-2)$_4$ (**L**), by the reaction of **1** with 2-hydroxypyridine in the presence of anhydrous K_2CO_3 in refluxing acetone medium (Scheme 1). Ligand **L** showed a prominent parent ion peak at *m*/*e* 696 $[L]^+$ in its FAB-MS. $^{31}P\{^1H\}$ NMR of **L** is of the AB_2 type. A triplet centered at 26.7 ppm [*P*($OC_{12}H_8$)] and a doublet centered at 7.8 ppm [*P*(O-C_5H_4N-2)$_2$] were observed with a ^2J(P–N–P) value of 93.8 Hz. By comparison, in the parent tetrachloro derivative **1**, *P*($OC_{12}H_8$) resonates at 12.9 ppm while the signal for PCl_2 is seen at 24.8 ppm [^2J(P–N–P) = 71.2 Hz]. It is also of interest to note that the hexakis derivative, $N_3P_3(OC_5H_4N$-2)$_6$ shows a singlet in its $^{31}P\{^1H\}$ NMR spectrum at 6.4 ppm [14].

The reaction of **L** with hydrated copper and cobalt nitrates or anhydrous zinc chloride afforded 1:1 metal complexes (Scheme 2). The metal uptake does not increase upon varying the stoichiometry of the reactants. Further, in contrast to the hydrolytic sensitivity of other cyclophosphazene-based ligands, particularly pyrazolyl cyclophosphazenes, **L** is remarkably insensitive. It may also be noted that we have previously observed P–O bond scission in the reaction between N_3P_3(O-C_5H_4N-2)$_6$, $CuCl_2$ and $Co(NO_3)_2 \cdot 6H_2O$ [9d]. Such a P–O bond scission was also observed in the reaction of N_3P_3(O-C_5H_3-4-CH_3-N-2)$_6$ and $[Cu(MeCN)_4]PF_6$ [9c].

Metal complexes **2–4** were characterized by a variety of techniques. Although these complexes do not show the parent ion peaks in their FAB-MS, they do show prominent fragment ions: $[LCuNO_3]^+$, 821; $[LCu]^+$, *m*/*z* 759; $[LCo(NO_3)]^+$, *m*/*z* 817; $[LCo]^+$, *m*/*z* 755 and $[LZnCl]^+$, *m*/*z* 795.

Complexes **2** and **3** show a broad d–d band at 768 and 506 nm, respectively. The EPR spectrum of the copper complex **2** has been recorded in dichloromethane–toluene glass (120 K). It shows a resolved axial Cu(II) species with a four-line pattern in the parallel region ($g_\parallel = 2.35$; $A_\parallel = 146$ G; $g_\perp = 2.07$ for compound **2**). The *g* values obtained (greater than 2.0) as well as the observation that $g_\parallel > g_\perp$, indicates a $d_{x^2-y^2}$ ground state for the Cu(II) ion [15]. Room temperature magnetic studies of **2** and **3** support that the metal ions are in a divalent state. Thus, the room temperature magnetic moment value of complex **2** is 1.80 BM (*spin only* $\mu_B = 1.73$ BM) while the magnetic moment value of **3** is 4.02 BM (*spin only* $\mu_B = 3.87$ BM).

The $^{31}P\{^1H\}$ NMR spectra of complexes **2** and **3** were affected by the paramagnetic nature of the metal ions and were uninformative. The zinc complex **4**, on the other hand, shows a triplet at 23.9 ppm [which is slightly upfield shifted with respect to the free ligand (26.7 ppm)] and a doublet at 7.6 ppm (which is shifted by 0.2 ppm vis-a-vis the free ligand). The coupling constant ^2J(P–N–P) = 98.6 Hz in **4** is slightly higher than that observed in **L**. Infrared spectra of **2–4** reveal that ν(P=N) seen for the free ligand at 1223 cm^{-1} is altered upon complexation. New peaks at 1290 (s), 1225 (s) for **2**; 1291 (s), 1228 (s) for **3**; 1299 (s), 1221 (s) for **4** are seen, while the peak at 1223 $cm^{-1}$is split, indicating the involvement of the cyclophosphazene ring nitrogen atom in coordination to the metal ion. This feature is similar to that observed previously in the case of pyrazolyl cyclophosphazenes [6] as well as pyridyloxy cyclophosphazenes [9]. The involvement of the cyclophosphazene ring nitrogen coordination is confirmed by the X-ray crystal structure analysis of **2–4**.



3.2. X-ray crystal structures of L and 2–4

The ligand **L** crystallized in the monoclinic cell system (*C*2/*c*). The molecular structure of **L** is shown in Fig. 1. One face of the molecule is non-coordinating because of the spirocyclic ring formation. The other side of the cyclophosphazene ring contains four pyridyloxy substituents as potential coordination sites. The cyclophosphazene ring is nearly planar. The P–N bond distances in **L** do not show large variations (Table 2).

Scheme 1. Synthesis of ligand **L**.

Compound **2** crystallized in the monoclinic cell system ($P2_1/c$). The molecular structure of **2** is shown in Fig. 2. The metric parameters of **2** are summarized in Table 2. The molecular structure of **2** reveals that the copper atom in **2** has a coordination number of six (3N, 3O) and is present in a distorted octahedral geometry (Fig. 2) with a facial coordination mode. The nitrogen coordination environment around copper can be described as η^3-*gem*-N_3 with two of the three coordinating nitrogen atoms being derived from the geminally substituted pyridyloxy groups. The third donor nitrogen atom is from the cyclophosphazene ring nitrogen atom which is located adjacent to the phosphorus atom bearing the coordinating pyridyloxy arms. The remaining coordination environment around copper is satisfied by the two nitrate ligands. One of the nitrate ligands is chelating while the other acts in a unidentate mode. The bond distance Cu–O8 [2.5867(7) Å] is considerably longer than the remaining Cu–O distances [average

Scheme 2. Synthesis of complexes **2**–**4** from ligand **L**.

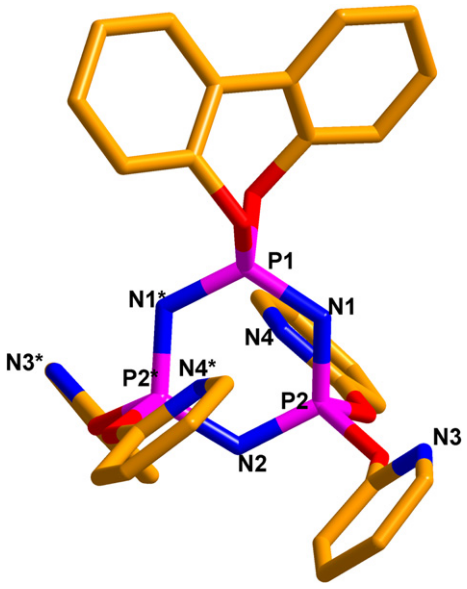

Fig. 1. Diamond view of **L**.

1.986(3) Å]. Among the Cu–N distances, while one, Cu–N6 [2.351(3) Å], is longer, the other two are slightly shorter [Cu–N7, 1.984(3) Å; Cu–N2, 2.057(3) Å]. It is interesting to compare the coordination behavior observed in the present instance with that seen in earlier instances involving $N_3P_3(O\text{-}C_5H_4N\text{-}2)_6$. In general, with the latter ligand coordination modes such as η^5-*gem*-N_5; η^3-*non-gem*-N_3 and η^2-*gem*-N_2 are seen. The η^3-*gem*-N_3 coordination mode observed in the present instance is quite rare. Previous examples of such coordination behavior are provided by the complexes $N_3P_3Ph_4(Me_2Pz)_2 \cdot M(CO)_3$ [M = Mo or W] [3b] and $[\{N_3P_3(MeNC_2H_4NMe)_2Pz_2\}Re(CO)_3]^+$ [5b].

Compound **3** crystallized in a monoclinic cell system (*C*2/*c* space group). The molecular structure of **3** is shown in Fig. 3a. It reveals that in **3** the cobalt atom has a coordination number of seven (3N, 4O) and is present in a pentagonal bipyramidal geometry (Fig. 3), with the two pyridyl groups axially disposed (N3 and N3*). The remaining ligands viz., two chelating nitrate anions and the linearly bound phosphazene nitrogen (N2, O4, O4*, O5 and O5*) occupy the equatorial positions. The nitrogen coordination environment around cobalt can be described as η^3-*non-gem*-N_3 with two of the three coordinating nitrogen atoms derived from the non-geminally substituted pyridyloxy groups; the third donor nitrogen atom is from the cyclophosphazene ring. Compound **3** represents the first example of the stabilization of a heptacoordinate Co(II) by any cyclophosphazene ligand. Among the Co–N distances, Co–N2 (involving the cyclophosphazene ring nitrogen atom) is shorter [2.053(3) Å] in comparison with the distances involving the pyridyloxy

nitrogen atoms [2.235(3) Å]. The nitrate ligand is bound in an anisobidentate mode as shown by the presence of two types of Co–O distances [Co–O5, 2.132(3) Å; Co–O4, 2.393(3) Å]. The metric parameters for this compound are given in Table 2.

Compound **4** crystallized in a triclinic cell system ($P\bar{1}$). The molecular structure of **4** is shown in Fig. 4. Zinc has

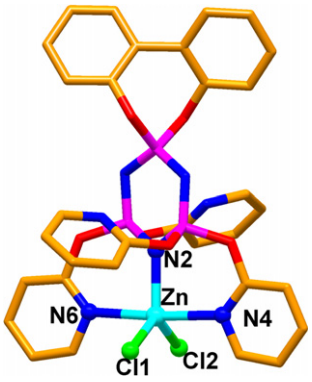

Fig. 4. Diamond picture of compound **4**. Hydrogen atoms have been omitted for clarity.

a coordination number of five (3N, 2Cl) and is present in a trigonal bipyramidal geometry (Fig. 4) with the two pyridyl groups being axially disposed (N4 and N6; N4–Zn2–N6: 175.95(6)°). Other ligands viz., the two chloride anions and the linearly bound phosphazene nitrogen atom are present in equatorial positions (N2, Cl1 and Cl2). The nitrogen coordination environment around zinc can be described as η^3-*non-gem*-N_3 with two of the three coordinating nitrogen atoms derived from the non-geminally substituted pyridyloxy groups; the third donor nitrogen atom is from the cyclophosphazene ring. This coordination mode leads to the generation of two six-membered rings (Zn-N6-C-O-P-N2 and Zn-N4-C-O-P-N2). The structural index τ which defines the extent of deviation from trigonal bipyramidal to square pyramidal geometry ($\tau = 1$ for a perfect trigonal bipyramidal; $\tau = 0$ for a perfect square based pyramid) [16] is 0.946 indicating only a small deviation from the regular trigonal bipyramidal geometry. The coordination response of **L** towards the zinc is similar to that found in dinuclear zinc complexes obtained from N_3P_3-(2-OC_5H_4N)$_6$ [9d] and N_3P_3(3,5-Me_2Pz)$_6$ [3d]. The Zn–N distances reveal that the distance involving the cyclophosphazene ring (Zn–N2; 2.0685(2) Å) is shorter than those involving the pyridyloxy nitrogen atoms (Zn–N4 2.303(3) Å and Zn–N6 2.2857(2) Å), consistent with the situation found in compounds **2** and **3** (Table 2).

3.3. Comparison of the structural features of the cyclophosphazene ring in *L* and *2–4*

The cyclophosphazene ring in ligand **L** is reasonably planar with two pairs of atoms (P2 and P2*) and (N1 and N1*) deviating slightly from the mean plane of the six-membered P_3N_3 ring. Interestingly, within each pair, the two atoms deviate from the mean plane in opposite directions (Table S1). The average P–N distance in **L** is 1.5816(11) Å. The average ring N–P–N angle is 118.57(8)° while the average P–N–P angle is slightly wider, 120.35(9)°. It must be mentioned here that in contrast to the situation found in metal complexes formed with pyrazolyl cyclophosphazenes, metallation does not cause any distortion in the cyclophosphazene ring skeleton in **2–4**. This feature is quite characteristic of pyridyloxy cyclophosphazenes and has been attributed to the flexibility of the coordinating pyridyloxy arms. It has been argued that the spacer oxygen atom acts as a hinge and provides rotational flexibility to the coordinating arm [9]. Because of this the ligand does not encounter any geometric constraint upon coordination to the metal ion. Whereas in **3** and **4** the metal is coplanar with the cyclophosphazene ring, in **2** the metal is deviated away by 0.19 Å. The P–N ring bond distances flanking the coordinating pyridyloxy arms are longer [average 1.614(3) Å for **2**, 1.601(2) Å for **3** and 1.608(2) Å for **4**], in comparison to the other P–N bond distances. This feature is similar to that observed in other cyclophosphazene metal complexes [9].

4. Conclusion

In conclusion, spiro-$N_3P_3(O_2C_{12}H_8)(OC_5H_4N\text{-}2)_4$ has been shown to be an efficient multi-site coordination ligand towards the transition metal ions Cu(II), Co(II) and Zn(II), affording mononuclear complexes [$LCu(NO_3)_2$], [$LCo(NO_3)_2$] and [$LZnCl_2$]. The η^3-*gem*-N_3 coordination mode in **2** is quite uncommon among pyridyloxy cylcophosphazenes, and in fact among other cyclophosphazene ligands also. In [$LCo(NO_3)_2$], Co(II) is heptacoordinate in a pentagonal bipyramidal geometry with a 3N, 4O coordination environment. This represents the first example where a heptacoordinate Co(II) is stabilized by a cyclophosphazene ligand. The coordination response of **L** in the complexes [$LCo(NO_3)_2$] and [$LZnCl_2$] is η^3-*non-gem*-N_3 and corresponds to a situation found with pyridyloxy cyclophosphazens [9], pyrazolyl cyclophosphazenes [2a,6a–c] as well as cyclophosphazene hydrazides [6d].

Hybrid inorganic–organic layered structures of $[AuCl_4]^-$ and protonated bipyridyl derivatives

Susan A. Bourne *, Lesego J. Moitsheki [1]

Department of Chemistry, University of Cape Town, Rondebosch 7701, South Africa

Received 13 August 2007; accepted 11 September 2007
Available online 22 October 2007

Abstract

Complexes of $[AuCl_4]^-$ with 4,4′-dipyridylethane, 4,4′-dipyridylethene and 4,4′-bipyridine-*N*,*N*′-dioxide have been prepared by a solvent layering method. All three complexes pack in distinct organic and inorganic layers: $[H_2\text{-dpa}][AuCl_4]Cl$ (**1**) and $[H_2\text{-dpe}][AuCl_4]Cl$ (**2**) are isostructural and consist of layers of $[AuCl_4]^-$ anions alternating with hydrogen-bonded dipyridyl···Cl···dipyridyl layers. In [H-bpdo][$AuCl_4$] (**3**), the organic layers consist instead of hydrogen-bonded bipyridyldioxide cations. This structure is the first report of a structure containing protonated 4,4′-bipyridine-1,1′-dioxide.

1. Introduction

Novel metal–organic compounds are of interest for their extensive structural diversity and potential functional properties [1–3]. A considerable amount of research has exploited bridging ligands such as 4,4′-bipyridine and its analogues, bound to different metals [4–8]. These complexes are usually held together by supramolecular interactions such as hydrogen bonding, van der Waals forces or π–π interactions, all of which play a role in the self-assembly process [9,10].

We have become interested in preparing self-assembled hybrid organic/inorganic materials as either coordination polymers or layered structures. In some cases the same components can be used to prepare metal–organic networks or inorganic–organic layered structures [11–13]. Among the latter, the hybrid perovskites [14] have attracted a great deal of interest because of their structural, magnetic, optical and electrical properties. These properties can be readily modified by replacement of the metal, halide or amine. The tendency of the hybrids to self-assemble from the solid or liquid phase arises from the range of interactions seen in these compounds, from van der Waals forces between organic components, hydrogen bonding within the organic layer or between organic and inorganic components to ionic and covalent bonds within the metal halide sheets [15,16]. This strategy has been extended to allow the preparation of a wide variety of ionic hydrogen-bonded materials, by combining perhalometallate anions with organic cations [17,18]. While [4,4′-H_2bipy] salts with MCl_4^{n-} are not uncommon, there are no reports of protonated dipyridylethane (4,4′-H_2dpa) or dipyridylethene (4,4′-H_2dpe) with $[MCl_4]^{n-}$ anions. Furthermore, a search of the CSD [19] showed that a protonated form of 4,4′-bipyridine-1,1′-dioxide $[H\text{-bpdo}]^+$ has never been reported in a crystal structure [20]. On the other hand, $[AuCl_4]^-$ has been found previously to be a poor acceptor of hydrogen bonds [21]. In this paper we report three structures of $[AuCl_4]^-$ with the protonated forms of 1,2-bis(4-pyridyl)ethane (H_2-dpa) (**1**), *trans*-1,2-bis(4-pyridyl)ethene (H_2-dpe) (**2**) and 4,4′-bipyridine-1,1′-dioxide (H-bpdo) (**3**).

2. Experimental

2.1. Materials and general methods

All the reagents for syntheses were commercially available and employed without further purification. Elemental analyses were performed on a Carlo Erba elemental analyzer Model 1106 and IR spectra on a Perkin–Elmer 983 IR spectrometer using KBr pellets.

2.2. Syntheses of complexes *1–3*

Single crystals of **1–3** suitable for X-ray analysis were obtained by the slow diffusion of layers containing 0.2 mmol of the respective dipyridyl compound (dissolved in 5 cm^3 methanol) and 3 cm^3 of $H[AuCl_4]$. Crystals suitable for X-ray diffraction were obtained after several weeks. Powder X-ray diffraction (Huber Guinier 670 Imaging Plate diffractometer with Cu Kα radiation, 1.542 Å) was used to confirm that the bulk sample crystallized matched that of the single crystal selected for structure elucidation in each case. Compounds **1–3** are thermally stable to temperatures above 200°C.

2.3. Crystal structure solution and refinement

Data for crystal and molecular structure determination were measured on a Nonius KappaCCD diffractometer using graphite-monochromated Mo Kα radiation (0.7107 Å) at 113 K. In each case, a series of frames were recorded with width ranging from 1° to 1.5° in ϕ or in ω (with $\kappa \neq 0$) to ensure completeness of the data collected to $\theta > 25°$. The unit cell was indexed from the first 20 frames and positional data were refined along with diffractometer constants to give the final cell parameters. Integration and scaling correction [22] resulted in unique data sets corrected for Lorentz-polarization effects and for the effects of crystal decay and absorption by a combination of averaging of equivalence reflections and an overall volume and scaling correction. The structures were solved using SHELXS-97 and refined using the full-matrix least-squares methods in SHELXL-97 [23] with the aid of the program XSEED [24].

[a] $R_1 = \sum(|F_o| - |F_c|)/|F_o|$.
[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]\}^{1/2}$.

Crystal structure refinement data are given in Table 1. Non-hydrogen atoms were modelled anisotropically. Hydrogen atoms attached to pyridyl nitrogens (**1** and **2**) or pyridyl oxygen (**3**) were located in the difference electron density maps and refined independently, while other hydrogen atoms were assigned an isotropic thermal parameter 1.2 times that of their parent atom and refined using a 'riding' model. Compounds **1** and **2** are isostructural; to render this easier to see the unit cell of **2** is reported in the alternative, non-reduced setting. Images of crystal and molecular structures were rendered using the program POV-Ray [25].

Perspective diagrams, showing thermal ellipsoids and atom labels are shown in Fig. 1.

3. Results and discussion

Compounds **1** and **2** are isostructural, while in **3** the unit cell is significantly longer in two dimensions. The asymmetric unit in **1** (and **2)** consists of half a gold atom (on a centre of inversion at the origin), two coordinated chlorine atoms, one chloride ion and half a dipyridyl molecule (with the central C7–C7′ bond on the centre of inversion at (1/2, 1/2, 1)). The asymmetric unit of **3** consists of two half $[AuCl_4]^-$ units (Au1 and its associated chlorines lie on the mirror plane at Wyckoff position *a*, while Au2 lies on the mirror with its chlorines perpendicular to the mirror plane) and a complete $[H\text{-bpdo}]^+$ cation. In all three structures the immediate environment of the gold atom is square planar with chlorine atoms at distances 2.280(2)–

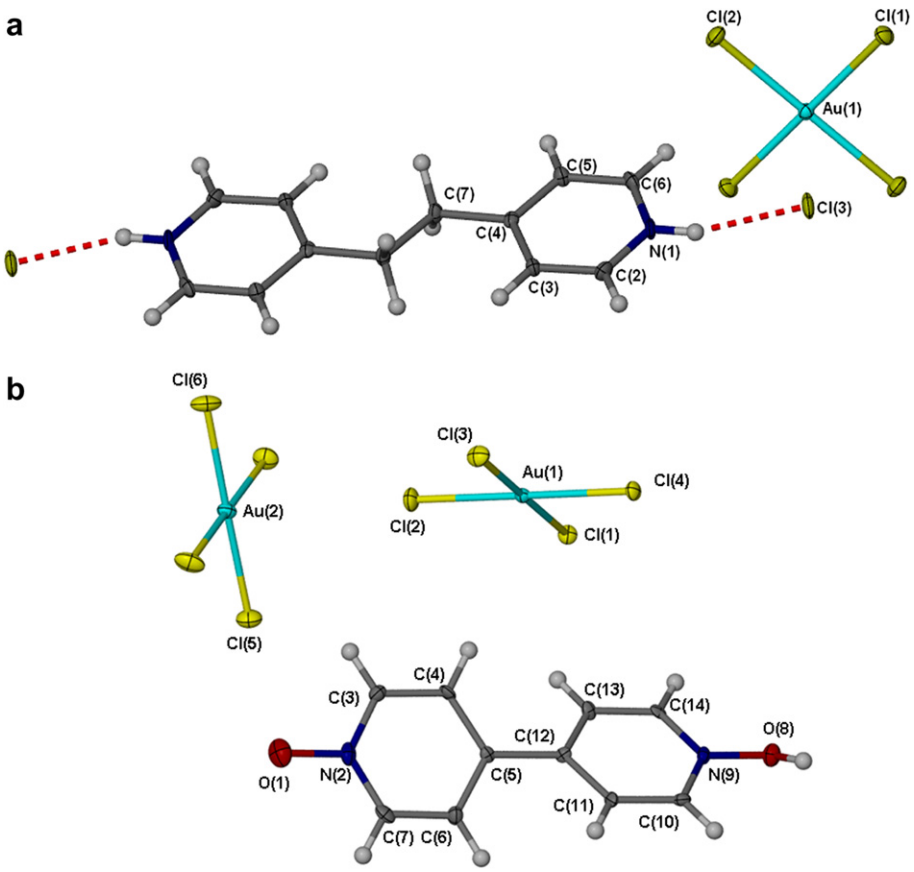

Fig. 1. Perspective diagrams of (a) **1** and (b) **3**, showing atomic displacement parameters (ellipsoids drawn at 50% probability) and atom labels.

2.291(2) Å and Cl–Au–Cl angles of 88.63(7)–90.90(6)°. In **1** and **2** there are also longer apical Au···Cl contacts with the chloride ion (3.670(1) Å in **1**; 3.640(1) Å in **2**), somewhat longer than the sum of van der Waals radii for Au and Cl (3.41 Å). This additional contact causes the Au^{III} centre to take on a distorted octahedral coordination environment and results in the formation of a polymeric $[AuCl_6]_n^{n-}$ anionic chain (Fig. 2). This is analogous to the polymeric chain formed in (*n*-butyl-3-methylimadazolium)$[AuCl_4]$ (Au···Cl 3.356 Å) and $[(H_7O_3)$(15-crown-5)$][AuCl_4]$[9] (Au···Cl 3.845 Å) [26]. Polymeric anionic chains with distorted square pyramidal gold ions and Au···Cl intermolecular interactions between 3.2 and 3.7 Å have also been reported [21,27]. There are no Au···Cl contacts in **3**, which lacks an uncoordinated chloride ion.

Fig. 2 also shows the N–H···Cl hydrogen bonds which link the $[H_2\text{-dpa}]^{2+}$ (**1**) or $[H_2\text{-dpe}]^{2+}$ (**2**) cations and the chloride ion. These are detailed in Table 2 and result in the formation of ribbons running along the crystallographic *b*-direction, with each layer of parallel $[AuCl_4]^-$ anions surrounded by ribbons of bipyridinium cations and Cl^- anions. All atoms in the pyridyl rings are within two standard deviations of the least-squares plane defined by the non-hydrogen atoms in the ring. The inversion symmetry forces coplanarity of the pyridyl rings in $[H_2\text{-dpa}]$ (**1**) and $[H_2\text{-dpe}]$ (**2**). Both $[H_2\text{-dpa}]$ and $[H_2\text{-dpe}]$ have been

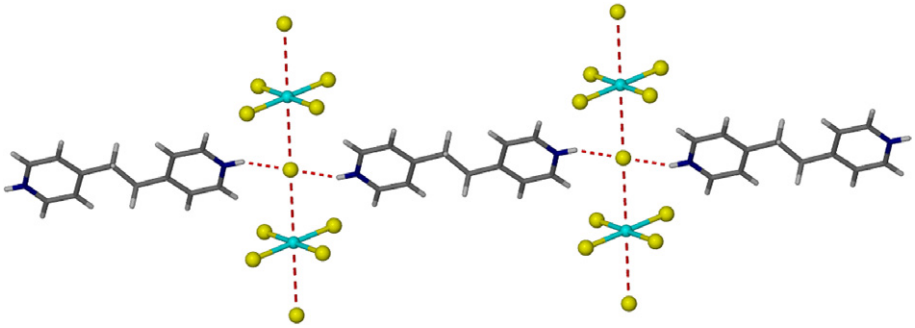

Fig. 2. Packing diagram of **1** showing the polymeric $AuCl_6$ chains and pyridinium–chloride hydrogen-bonded chains.

Table 2
Hydrogen bonds and intermolecular contacts

	D–H (Å)	D···A (Å)	D–H···A (°)	Symmetry operator
1				
N1–H1···Cl3	0.86(4)	3.022(3)	157(4)	x, y, z
2				
N1–H1···Cl3	0.91(5)	3.003(4)	165(4)	x, y, z
3				
O8–H8···O1	1.00(4)	2.433(5)	174(6)	$1/2 - x, y - 1/2, z$

crystallized with $[MnF_4(H_2O)_2]^{2-}$; the structures [28] (ERETEA and ERETIE) are isostructural and form extended hydrogen-bonded ribbons similar to those reported by Orpen *et al* for pyridyl cations with metal halides [29].

Fig. 3 shows layers of $[H\text{-bpdo}]^+$ cations surrounded by stacks of $[AuCl_4]^-$ anions which are arranged in an ···ABBA··· fashion (where A and B represent mutually perpendicular orientations). In **3**, the $[H\text{-bpdo}]^+$ cations are linked by short O–H···O hydrogen bonds (Table 2) into a chain running parallel to the crystallographic *b*-direction. The dihedral angle between least-squares planes through the linked pyridyl rings is 31.41°, a typical value for the bpdo molecule [20]. This twist between the rings causes a slight zigzag in the H-bonded chain (Fig. 3). The O···O distance in the [H-bpdo] diadduct is 2.433(5) Å, which is comparable to the 2.426(4) Å reported in the analogous 2,6-dimethylpyridine-*N*-oxide structure [30]. The oxygen atoms of the pyNO lie 2.974 Å from gold, completing a distorted octahedron around the gold atom, which is not the case in **3**. Nangia and co-workers recently studied short hydrogen bonds in pyrazine carboxylic acids by neutron diffraction [31]. Short O–H···O hydrogen bonds (O···O = 2.5–3.0 Å) are highly electrostatic in nature while very short hydrogen bonds (O···O = 2.2–2.5 Å) have an increasingly covalent character. Gilli and co-workers [32] report that very strong hydrogen bonds are of three main types: (i) negative charge-assisted H-bonds, O–H···O^-; (ii) positive charge-assisted H-bonds, O^+–H···O; (iii) resonance-assisted H-bonds, ···O=C–C=C–O–H··· **3** is of type (i), other examples of which include H-bonds between inorganic oxoacids and their conjugate bases and short, intramolecular H-bonds in dicarboxylic acids (O···O = 2.30–2.50 Å).

The CSD contains seven crystal structures of protonated pyridyl-*N*-oxide[2] but none containing protonated bpdo. A consideration of pK_a values may provide an explanation: the pK_a for pyridine-*N*-oxide (0.73 ± 0.15) is far lower than that of pyridine (5.23 ± 0.10). The pK_a for 4,4′-bipyridine is 3.27 ± 0.26, while that for 4,4′-bipyridine-1,1′-dioxide is not available in the literature. For comparison, pK_a values for 1,2-bis(4-pyridyl)ethane and *trans*-1,2-bis(4-pyridyl)ethene are 6.11 ± 0.20 and 5.50 ± 0.20. Compound **3** thus is the first report of a crystal structure containing $[H\text{-bpdo}]^+$. As expected, the N–O bonds are longer (1.348(5) and 1.351(5) Å) than the N–O bonds in free bpdo (1.301–1.343 Å, mean: 1.319(3) Å) and comparable to those in coordinated bpdo (1.291–1.365 Å, mean: 1.329(1) Å). The IR spectrum of **3** shows an intense and broad absorption within the 1600–400 cm^{-1} region, which appears instead of the usual OH stretching band in the

[2] CSD REFCODES: BALGUQ10, JIFREV, LOKFEW, LUPPUH, MIWYEW, PIKDES and QUSLUL.

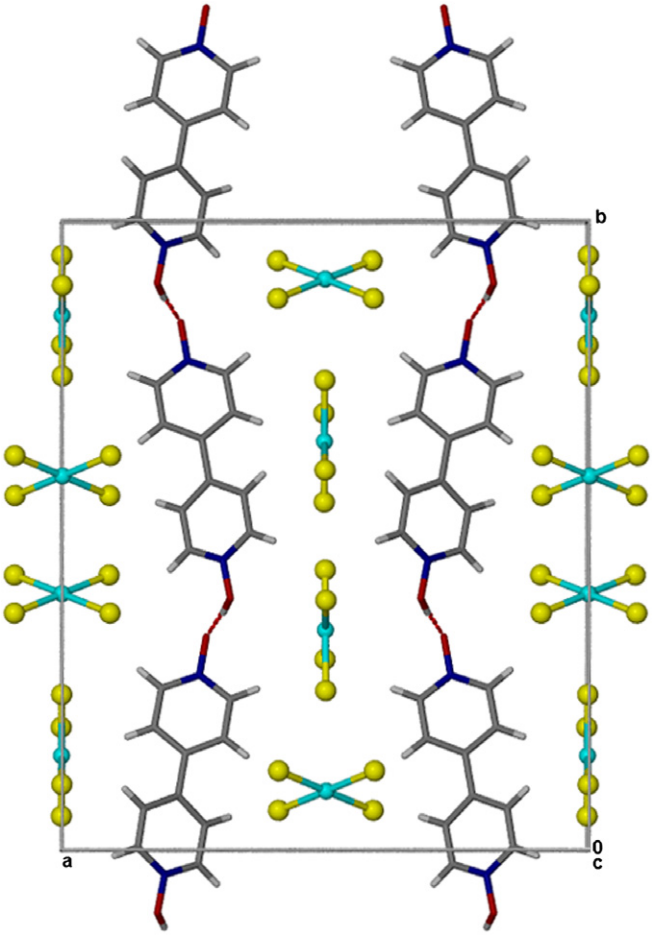

Fig. 3. Packing diagram of **3** showing the alternating stacks of $[AuCl_4]^-$ and $[H\text{-bpdo}]^+$ ions.

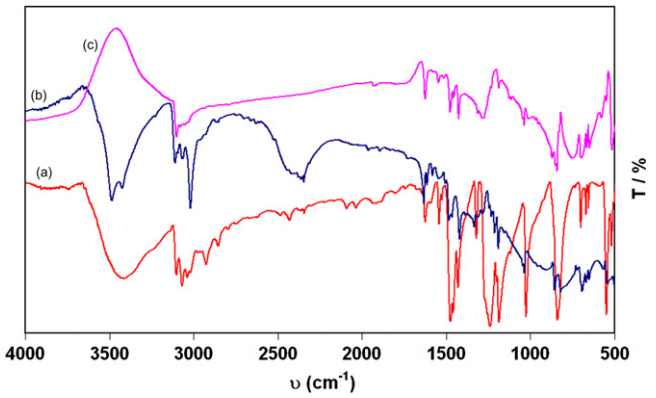

Fig. 4. Infrared spectrum of (a) bpdo, (b) bpdo protonated by addition of HCl, (c) compound **3**.

higher frequency region (Fig. 4). This absorption is characteristic of a short O–H···O bond [33] and was also observed for a protonated pyridine-*N*-oxide salt with sulfate [34].

4. Conclusion

The crystal structures of **1**–**3** contain distinct layers of $AuCl_4^-$ anions and protonated dipyridyl cations. The organic layers are stabilized by the formation of C–H···Cl (**1** and **2**) or O–H···O (**3**) hydrogen bonds. In **1** and **2**, Au···Cl contacts give rise to a polymeric $[AuCl_6]_n^{n-}$ anionic chain perpendicular to the hybrid layers. This paper is, to the best of our knowledge, the first report of a protonated bpdo structure, that of **3**.

Abstract

New chiral *N*,*N*-bidentate 2,2′-bis-(4-isopropyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-one) ligands have been prepared and characterised by their ^{1}H and ^{13}C NMR spectra and/or optical rotation. The ligands prepared were then tested for their ability to form complexes with copper(II) salts. It was found that the most stable complex is formed from the 2,2′-bis-(4-isopropyl-1,4-dimethyl-4,5-dihydro-1*H*-imidazol-5-one) ligand and copper(II) chloride. The structure of this complex was determined by means of quantum-chemical computations at the B3LYP or UB3LYP/6-31G(d,p) level. According to the computations, the geometry of the copper atom most resembles a tetrahedral arrangement, which was also confirmed by means of X-ray structural analysis. It was found that the structure of this copper(II) complex does not allow the copper atom to coordinate to additional ligands; therefore, it is catalytically inactive in the asymmetric *Henry* reaction.

Keywords: Nitrogen bidentate ligands; 4,5-Dihydro-1*H*-imidazol-5-ones; Copper(II) complexes; B3LYP/6-31G(d,p); Asymmetric catalysis

1. Introduction

The importance of syntheses and tests of the properties of new nitrogen-containing heterocyclic compounds and their complex compounds with metals lies in the fact that they may be suitable catalysts in many chemical processes. If, in addition to that, the complex is formed by a heterocyclic system that involves a stereogenic centre, then the substance can be applied as a homogeneous or heterogeneous catalyst in many asymmetric syntheses [1]. Among such chiral nitrogen ligands are the derivatives of 4,5-dihydro-1*H*-imidazol-5-ones [2]. In our previous papers we dealt with the syntheses and catalytic properties of iron(III) [3], rhodium(III) [4] and copper(II) [5] complexes prepared from substituted 2-(4-alkyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-on-2-yl)pyridines (Fig. 1A) [4] or 2,6-bis(4-alkyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-on-2-yl)pyridines [3,4] (Fig. 1B). These chiral substituted 2-(4-alkyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-on-2-yl)pyridines represented new types of *N*,*N*-bidentate and *N*,*N*-tridentate ligands, whose complexes were applied as enantioselective catalysts of the asymmetric *Henry* reaction [5] or as very effective catalysts of the deallylation reaction of substituted allyl malonates [4].

In the present paper we have dealt with the synthesis and characterisation of substituted 2,2′-bis-(4-isopropyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-ones) (Scheme 1). The structure of these newly prepared chiral ligands is very similar to the well-known *N*,*N*-bidentate derivatives of oxazolines (“Boxes”) [6]. However, in comparison with the previous *N*,*N*-bidentate 2-(4,5-dihydro-1*H*-imidazol-

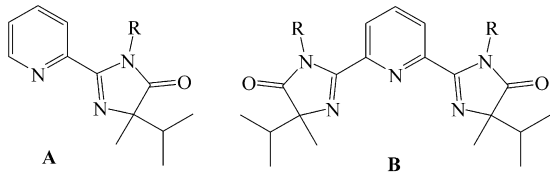

Fig. 1. Previous 4,5-dihydro-1 *H*-imidazol-5-one ligands.

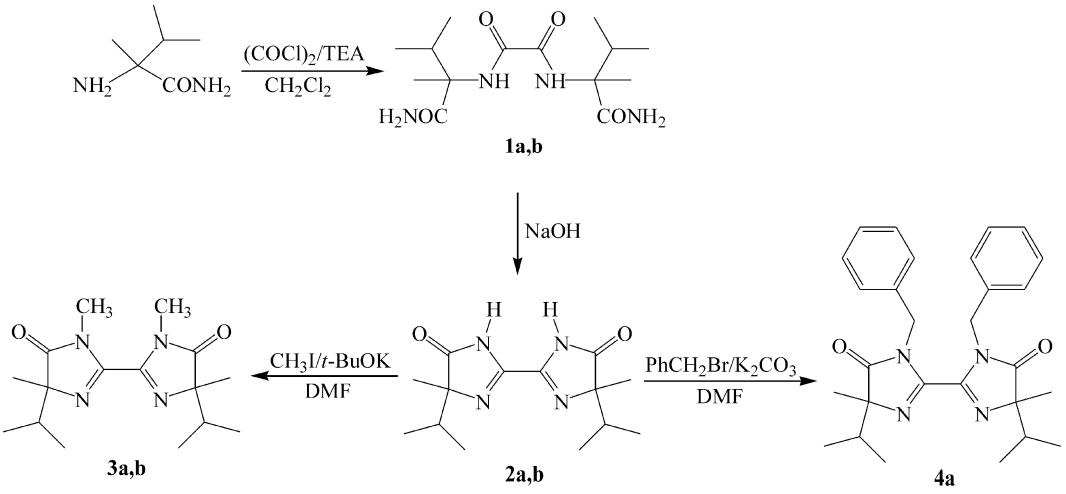
5-on-2-yl)pyridine ligands (Fig. 1A), the present compounds contain two chiral centres and their structure is characterised by C_2-symmetry. Generally, complexes of ligands having this type of symmetry are very suitable for use as enantioselective catalysts, because they form a highly ordered chiral activated complex with the reactants, which results in formation of products of high optical purity. Hence, we decided to prepare copper(II) complexes of these ligands and to study their structure by means of both experimental and theoretical methods. The selected complexes were tested for enantiocatalytic properties in the asymmetric *Henry* reaction.

2. Results and discussion



2.1. Syntheses and characterisation of the ligands and complexes

Substituted 2,2′-bis-(4-isopropyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-ones) (**3a**,**b**; **4a**) were prepared by the sequence of reactions given in Scheme 1. First, we acylated the racemic or optically pure 2-amino-2,3-dimethylbutanamide [7] with oxalyl chloride in the presence of triethylamine. Acylaminobutanamide **1a**,**b** was obtained in a good yield of almost 90%. Subsequent base-catalysed ring closure of compounds **1a**,**b** gave racemic **2a** (93%) and (*S*,*S*)-2,2′-bis-(4-isopropyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-one) (**2b**) (85%). The reaction time of the ring closure reaction was relatively long (2 days) to achieve the maximum conversion; however, it was not optimised, because the product formed is stable in basic medium. The alkylation of the nitrogen atom at the 1-position of the 1*H*-imidazol-5-one cycle in compound **2a**,**b** with methyl iodide or benzyl bromide in anhydrous dimethylformamide gave the final ligands **3**–**4** in the yields of 78–84%. 2,2′-Bis-(4-isopropyl-1,4-dimethyl-4,5-dihydro-1*H*-imidazol-5-one) (**3a**) was also prepared in the optically pure form of (*S*,*S*) **3b**. The base used in the alkylation with methyl iodide was *t*-BuOK, whilst in the reaction with benzyl bromide anhydrous K_2CO_3 was adopted [5]. The ligands synthesised were characterised by means of ^{1}H and ^{13}C NMR spectroscopy, elemental analysis, determination of melting point and their optical rotatory power.

Complexes **5a**,**b** were prepared by the reaction of copper(II) chloride dihydrate with the corresponding ligand in methanol in yields of 84% (**5a**) and 81% (**5b**). The complexes were characterised by elemental analyses, and the structure of complex (**5b**) was determined by X-ray structural analysis. Complexes **5a**,**b** were found to be readily soluble in organic solvents, particularly alcohols, chloroform and acetone; on the other hand, they are virtually insoluble in ether and alkanes. Isolation of the complex of 2,2′-bis-(1-benzyl-4-isopropyl-4-methyl-4,5-dihydro-1*H*-imidazol-5-one) (**4a**) with copper(II) chloride failed, probably due to its very low stability. The syntheses of the complexes of ligands **3a**, **3b** and **4** with copper(II) acetate failed too. Since ligand **4a** exhibits bad chelate-forming ability, i.e. it is not suitable for the study of enantiocatalytic activity, its optically pure form was not prepared.

2.2. Quantum-chemical computations of the structure and stability of the complexes

The complex-forming abilities of the ligands and the stabilities of the complexes were studied by means of quantum-chemical computations at the B3LYP or

Scheme 1. Synthesis of ligands (**3a**,**b** and **4a**).

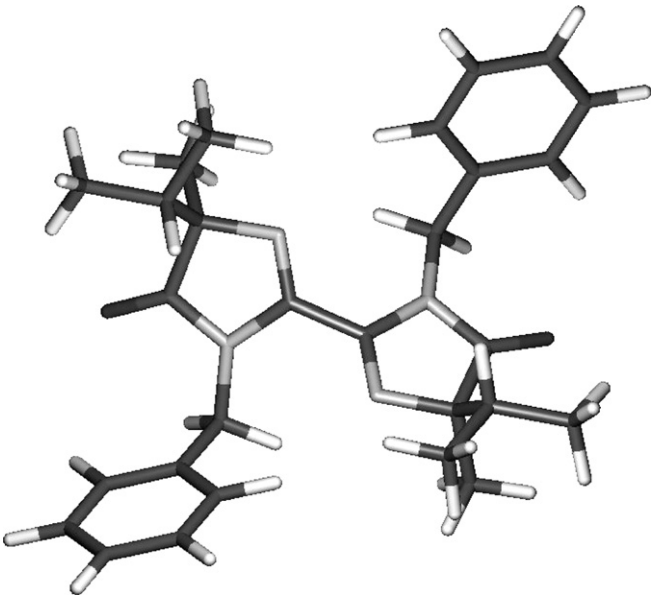


Fig. 2. Structure of ligand **4a** at the B3LYP/6-31G(d,p) level.

UB3LYP/6-31G(d,p) level; for details, see Section 4.5. It was found that compound **4a** assumes the most stable conformation, depicted in Fig. 2. Due to the presence of the bulky benzyl substituents, the 1*H*-imidazol-5-one cycles are deviated to such an extent that the molecule loses its property as an *N*,*N*-bidentate ligand. According to the potential energy surface (PES) scan there exists only one local minimum during rotation around the single bond connecting both cycles. Next there are four local energy minima during rotation of the benzyl or isopropyl groups, but none of these conformations are able to coordinate to a metal ion. The computation shows that the formation of a complex based on **4a** with $CuCl_2$ is energetically unfavourable by 21 kJ/mol. Such a complex should not be stable. This finding agrees with the experimental results.

Fig. 3 depicts the structure of the complex of ligand **3a** with $CuCl_2$. This representation shows that the substituents at the chiral centres disturb the usual planar geometry of the copper atom. The structure of this complex does not allow the copper atom to coordinate to a further two ligands. The absence of free coordination sites at the copper atom explains the lack of effectiveness of this complex in the enantioselective *Henry* reaction [5,9], because this reaction requires the presence of two free coordination sites at the transition metal atom [5]. These coordination properties of ligand **3a** also explain the lesser stability of the complex with $Cu(OAc)_2$. Stable complexes with acetates of transition metals are formed in those cases in which the anion of acetate behaves as an η^2-ligand [8]. In the complex of **3a** with $Cu(OAc)_2$ there are only two coordination sites per two acetate anions, hence the complex is less stable.

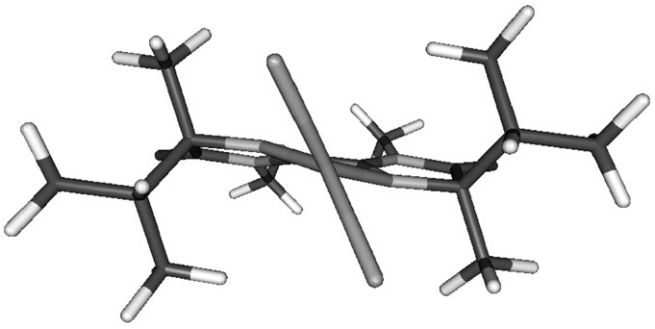

Fig. 3. Structure of complex **5a** at the UB3LYP/6-31G(d,p) level.

2.3. X-ray analysis of complex *5b*

The molecular structure of complex **5b** was determined by means of X-ray analysis (Fig. 4). The geometry of the copper atom most resembles a tetrahedral arrangement: Cl1–Cu1–Cl2 106.00(6)°, Cl1–Cu1–N1 103.69(13)°, Cl1–Cu1–N2 133.19(14)°, Cl2–Cu1–N1 131.79(14)°, Cl2–Cu1–N2 104.22(14)°, N1–Cu1–N2 80.78(18)°. However, the plane defined by atoms Cl1, Cl2 and Cu1 makes an angle of 65.2(4)° with the plane defined by atoms N1, N2 and Cu1. Hence, the chlorine atoms are considerably deviated from the ideal tetrahedral arrangement (90°). This deviation is probably caused by the large steric demands of the isopropyl groups of the ligand: there are van der Waals interactions between the hydrogen atoms of the carbons of the isopropyl group, C15 and C16, with chlorine atom Cl1 and/or an interaction among the hydrogen atoms at carbons C7 and C8 with the chlorine atom Cl2. The 1*H*-imidazol-5-one rings are not coplanar; their planes are mutually deviated by an angle of 12.11°. This anomaly probably follows from an interaction between the methyl groups at the 1-position of the 1*H*-imidazol-5-one ring (atoms C4 and C12). The experimental structure of complex **5b** agrees (Fig. 5) with the structure predicted by means of quantum-chemical methods. The two structures differ only in the position of the isopropyl group. The inter-atomic distances and bond angles in the 1*H*-imidazol-5-one rings are similar to those published earlier for the structures of copper(II) [5] and iron(III) [3] complexes of 1*H*-imidazol-5-one ligands.

2.4. Study of the enantioselectivity of ligand *3b*

The copper(II) complexes of ligand **3b** were studied as enantioselective catalysts of the asymmetric *Henry* reaction [5,9]. This choice of model reaction is rationalised by the fact that copper(II) complexes are amongst the most effective catalysts of the *Henry* reaction [9]. We found out that 5 mol% of ligand **3b** together with 5 mol% of copper(II) acetate catalyse the reaction of 4-nitrobenzaldehyde with nitromethane, the yield of the isolated 2-nitro-1-(4-nitrophenyl)ethanol being 75% after 22 days at room temperature, but the enantioselectivity was virtually zero ($\leqslant$3% ee). This result can be explained by the fact that the reaction is only catalysed by free copper(II) acetate, no

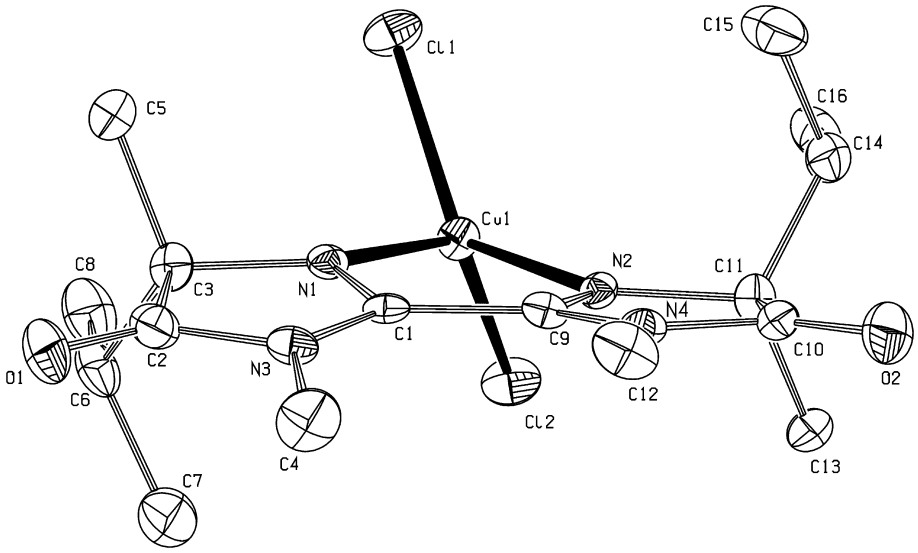

Fig. 4. Molecular structure of **5b**, ORTEP 40% probability level. Hydrogen atoms are omitted for clarity. Selected interatomic distances (Å) and angles (°): Cl1–Cu1 2.2153(14), Cl2–Cu1 2.2272(15), N1–Cu1 1.970(4), N2–Cu1 1.973(4), C1–N1 1.298(7), C9–N2 1.289(7), C1–C9 1.489(9), Cl1–N1 3.295(4), Cl1–N2 3.845(4), Cl2–N1 3.833(5), Cl2–N2 3.318(5), N1–N2 2.555(6), Cu1–C1 2.782(6), Cu1–C9 2.774(6); Cl1–Cu1–Cl2 106.00(6), Cl1–Cu1–N1 103.69(13), Cl1–Cu1–N2 133.19(14), Cl2–Cu1–N1 131.79(14), Cl2–Cu1–N2 104.22(14), N1–Cu1–N2 80.78(18), N1–C1–C9 113.4(5), N2–C9–C1 114.7(5), Cu1–N1–C1 115.2(4), Cu1–N2–C9 114.0(4), Cu1–N1–C3 135.1(4), Cu1–N2–C11 136.0(4).

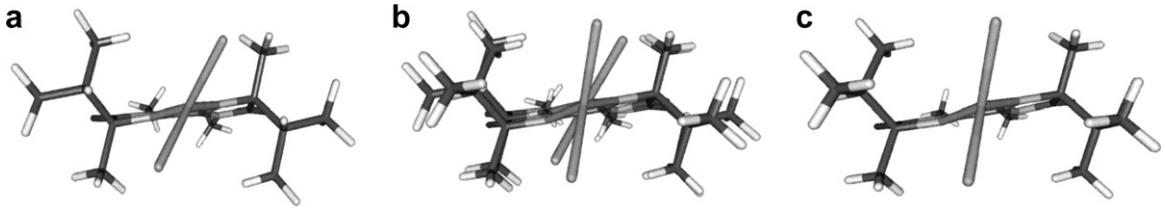

Fig. 5. (a) Structure of complex **5b** at the UB3LYP/6-31G(d,p) level, (b) overlay, and (c) X-ray analysis of complex **5b**.

complex being formed at all between copper(II) acetate and ligand **3b**. Although zero enantioselectivity was observed in both cases, it cannot be excluded that ligand **3b** may form catalytic systems with other metal ions, which may be effective in other asymmetric reactions.

3. Conclusion

While the *N*-methyl derivatives **3a** and **3b** form isolatable and air-stable complexes with copper(II) chloride, the *N*-benzyl derivative **4a** does not produce such complexes, since its structure lacks the properties of an *N*,*N*-bidentate ligand. Likewise, the isolation of complexes of ligands **3a** and **3b** with copper(II) acetate failed. These experimentally found complex-forming properties of the ligands were analysed by means of quantum-chemical methods. Using the B3LYP/6-31G(d,p) model we computed the structure of complex **5b**, in which the geometry of the copper atom most resembles a tetrahedral arrangement. Since the copper atom does not contain any further free coordination sites, it is not able to catalyse the *Henry* nitroaldol reaction. The structure of complex **5b** determined by the quantum-chemical computations was confirmed by X-ray structural analysis.

4. Experimental

4.1. NMR measurements

The ^{1}H and ^{13}C NMR spectra were recorded on a Bruker Avance spectrometer at 500.13 (^{1}H) and 125.76 MHz (^{13}C) in d_6-DMSO. The ^{1}H and ^{13}C chemical shifts were referenced to the central peaks of the solvent ($\delta = 2.55$ and 39.60, respectively).

4.2. Optical rotatory power determination

Optical rotation was measured on a Perkin–Elmer 341 Instrument, the concentration c is given in g/100 ml.

4.3. HPLC analyses

The optical purity of 2-nitro-1-(4-nitrophenyl)ethanol was determined by means of HPLC using a Chiralcel OD–

H column (85:15 hexane: propan-2-ol, 0.8 ml/min, 220 nm; (*R*)-isomer: $t_R = 21.0$ min, (*S*)-isomer: $t_R = 25.9$ min).

4.4. X-ray crystallography

The single crystals of **5b** were grown from ca. 10% methanol/ethyl acetate solution. The relevant crystallographic parameters and procedures are as follows: The data for a colourless crystal were collected at 150(1) K on a Nonius Kappa CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å), a graphite monochromator, the structure was solved by direct methods (SIR92 [10]). All reflections were used in the structure refinement based on F^2 by the full-matrix least-squares technique (SHELXL97 [11]). Hydrogen atoms were mostly localised on a difference Fourier map; however, to ensure uniformity of the treatment of all crystals, all hydrogen atoms were recalculated into idealised positions (riding model) and assigned temperature factors $H_{iso}(H) = 1.2\ U_{eq}$ (pivot atom) or 1.5 U_{eq} for a methyl moiety (C–H = 0.96 Å for CH_3 and 0.98 Å for CH group hydrogen atoms). Absorption corrections were carried out using Gaussian integration from crystal shape (Coppens [12]). Empirical formula $C_{16}H_{26}Cl_2Cu_1N_4O_2$; Formula weight 440.85; Crystal system Orthorhombic; Space group $P2_12_12_1$; Unit cell dimensions *a*, *b*, *c* (Å) 6.8720(7), 13.8020(19), 20.447(4); Volume (Å^3) 1939.3(5); *Z* 4; Density (Mg/m^3) (calc.) 1.510; Absorption coefficient (mm^{-1}) 1.419; *F*(000) 916; Crystal size (mm) $0.27 \times 0.20 \times 0.06$; Theta range for data collection 1.0–27.5; *h* range $-8 \rightarrow 8$; *k* $-16 \rightarrow 17$; *l* $-26 \rightarrow 26$; Reflections collected 17153; T_{min}, T_{max} 0.806, 0.937; Independent/Observed reflections ($I > 2\delta(I)$) 4351/3344; R_{int} ($R_{int} = \sum|F_o^2 - F_{o,mean}^2|/\sum F_o^2$) 0.079; Absorption correction multi-scans (SORTAV) No. of parameters 226; *S* all data ($S = [\sum(w(F_o^2 - F_c^2)^2)/(N_{diffrs} - N_{params})]^{1/2}$) 1.156; R_1, wR_2 [$I > 2\delta(I)$] ($R(F) = \sum||F_o| - |F_c||/\sum|F_o|$, $wR(F^2) = [\sum(w(F_o^2 - F_c^2)^2)/(\sum w(F_o^2)^2)]^{1/2}$) 0.0525, 0.1165; R_1, wR_2 (all data) 0.0872, 0.1330; Flack parameter 0.00(2); $\Delta\rho_{max}$, $\Delta\rho_{min}$ (e/Å^3) 0.860, −0.772.

4.5. Computational method

Quantum-chemical computations were carried out with the GAUSSIAN03 program [13] employing the hybrid density functional B3LYP [14]. Full geometry optimisations were performed by using the 6-31G(d,p) basis set [15]. The nature of the stationary points was verified by analytical computations of harmonic vibration frequencies. Solvation effects were included using the polarizable continuum model (PCM) [16], (solvent: methanol as in Section 4.6.8). The starting structure for optimisation was obtained after energy minimisation using the software Chem3D Ultra 10.0. Full conformational analysis was performed using the potential energy surface (PES) scan method which is directly implemented in the Gaussian software. Scans for each bond where the free rotation is possible were evaluated for 12 conformations differing in dihedral angle (30° step). The $CuCl_2$ structure with four solvent molecules was used together with the PCM model.

4.6. Synthesis of the ligands and the copper(II) complexes

4.6.1. Preparation of (±)-N,N′-bis[1-(carbamoyl)-1,2-dimethylpropyl]ethanediamide (*1a*)

A solution of (±)-2-amino-2,3-dimethylbutanamide (2,6 g; 20 mmol) and triethylamine (2.8 ml; 20 mmol) in 20 ml dry CH_2Cl_2 was stirred at room temperature and a solution of oxalyl chloride (1.27 g; 10 mmol) in 15 ml CH_2Cl_2 was added drop by drop. The suspension obtained was stirred at room temperature for another 10 h, whereupon the mixture was evaporated, and the dry evaporation residue was thoroughly washed with water. Yield 2.76 g (88%) white crystalline solid melting at 196–198 °C. ^{1}H NMR (d_6-DMSO, δ ppm): 0.84 (d, $^3J = 6.8$ Hz, 6H, $1 \times i\text{Pr}CH_3$), 0.85 (d, $^3J = 6.8$ Hz, 6H, $1 \times i\text{Pr}CH_3$), 1.52 (s, 6H, CH_3), 2.19 (sp, $^3J = 6.8$ Hz, 2H, *i*Pr*CH*), 7.28 (bs, 2H, $1 \times CONH_2$), 7.41 (bs, 2H, $1 \times CONH_2$), 8.41 (bs, 2H, *CONH*). ^{13}C NMR (d_6-DMSO, δ ppm): 17.6, 17.7, 17.9, 34.6, 62.7, 158.8, 174.2. *Anal.* Calc. for $C_{14}H_{26}N_4O_4$: C, 53.47; H, 8.34; N, 17.82. Found: C, 53.31; H, 8.39; N, 17.63%.

4.6.2. Preparation of (S,S)-N,N′-bis[1-(carbamoyl)-1,2-dimethylpropyl]ethanediamide (*1b*)

Compound **1b** was prepared in the same way as compound **1a** in a yield of 89% and with a melting point of 266–267 °C; $[\alpha]_D^{25} = +38.0°$ ($c = 0.25$, CH_3OH). ^{1}H NMR (d_6-DMSO, δ ppm): 0.84 (d, $^3J = 6.8$ Hz, 6H, *i*PrCH_3), 0.86 (d, $^3J = 6.8$ Hz, 6H, *i*PrCH_3), 1.53 (s, 6H, CH_3), 2.20 (sp, $^3J = 6.8$ Hz, 2H, *i*Pr*CH*), 7.32 (bs, 2H, $1 \times CONH_2$), 7.40 (bs, 2H, $1 \times CONH_2$), 8.44 (bs, 2H, *CONH*). ^{13}C NMR (d_6-DMSO, δ ppm): 17.4, 17.5, 17.9, 34.6, 62.7, 158.9, 174.2. *Anal.* Calc. for $C_{14}H_{26}N_4O_4$: C, 53.47; H, 8.34; N, 17.82. Found: C, 53.64; H, 8.41; N, 17.60%.

4.6.3. Preparation of (±)-2,2′-bis-(4-isopropyl-4-methyl-4,5-dihydro-1H-imidazol-5-one) (*2a*)

A mixture of substance **1a** (2.51 g, 8 mmol) and 40 ml 1 M NaOH (40 mmol) was stirred at room temperature. After 2 days, the mixture was neutralised with concentrated HCl to pH ~7 and extracted with 4×30 ml CH_2Cl_2. The combined extracts were evaporated until dry to give 2.07 g (93%) product melting at 227–230 °C. ^{1}H NMR (d_6-DMSO, δ ppm): 0.77 (d, $^3J = 7.0$ Hz, 6H, *i*PrCH_3), 0.94 (d, $^3J = 7.0$ Hz, 6H, *i*PrCH_3), 1.23 (s, 6H, CH_3), 1.91 (sp, $^3J = 7.0$ Hz, 2H, *i*Pr*CH*), 11.50 (s, 2H, *NH*). ^{13}C NMR (d_6-DMSO, δ ppm): 16.4, 16.5, 20.6, 34.1, 74.9, 152.4, 185.9. *Anal.* Calc. for $C_{14}H_{22}N_4O_2$: C, 60.41; H, 7.97; N, 20.13. Found: C, 60.21; H, 8.19; N, 19.95%.

4.6.4. Preparation of (S,S)-2,2′-bis-(4-isopropyl-4-methyl-4,5-dihydro-1H-imidazol-5-one) (*2b*)

Compound **2b** was prepared in the same way as compound **2a** in a yield of 85% and with a melting point of

219–221 °C; $[\alpha]_D^{25} = -47.4°$ ($c = 0.50$, CH_3OH). ^1H NMR (d_6-DMSO, δ ppm): 0.77 (d, $^3J = 7.0$ Hz, 6H, *i*PrCH_3), 0.93 (d, $^3J = 7.0$ Hz, 6H, *i*PrCH_3), 1.23 (s, 6H, CH_3), 1.92 (sp, $^3J = 7.0$ Hz, 2H, *i*Pr*CH*), 11.59 (s, 2H, *NH*). ^{13}C NMR (d_6-DMSO, δ ppm): 16.4, 16.4, 20.5, 34.0, 74.7, 152.4, 185.9. *Anal.* Calc. for $C_{14}H_{22}N_4O_2$: C, 60.41; H, 7.97; N, 20.13. Found: C, 60.23; H, 7.85; N, 19.98%.

4.6.5. Preparation of (±)-2,2′-bis-(4-isopropyl-1,4-dimethyl-4,5-dihydro-1H-imidazol-5-one) (**3a**)

Compound **2a** (1.39 g, 5 mmol), kept under argon atmosphere, was treated with a solution of potassium *t*-butyl alcoholate (20 mmol, 2 equiv.) in *t*-butyl alcohol. The mixture was stirred at room temperature for 1 h, whereupon *t*-butyl alcohol was distilled off under reduced pressure. The evaporation residue was dissolved in 10 ml dry DMF, the reaction mixture was cooled to 0 °C, and methyl iodide (1.25 ml, 20 mmol) was added under an argon atmosphere. The suspension formed was stirred at room temperature overnight. Then the solvent was evaporated under reduced pressure, and the evaporation residue was purified by chromatography (silica gel; ethyl acetate) to give 1.21 g (79%) product melting at 60–62 °C. ^1H NMR (d_6-DMSO, δ ppm): 0.80 (d, $^3J = 6.8$ Hz, 6H, *i*PrCH_3), 1.00 (d, $^3J = 6.8$ Hz, 6H, *i*PrCH_3), 1.31 (s, 6H, CH_3), 2.00 (sp, $^3J = 6.8$ Hz, 2H, *i*Pr*CH*), 3.24 (s, 6H, NCH_3). ^{13}C NMR (d_6-DMSO, δ ppm): 16.7, 17.0, 20.5, 28.3, 34.1, 73.8, 152.4, 184.6. *Anal.* Calc. for $C_{16}H_{26}N_4O_2$: C, 62.72; H, 8.55; N, 18.29. Found: C, 62.86; H, 8.39; N, 18.18%.

4.6.6. Preparation of (S,S)-2,2′-bis-(4-isopropyl-1,4-dimethyl-4,5-dihydro-1H-imidazol-5-one) (**3b**)

Compound **3b** was prepared in the same way as compound **3a** in a yield of 84% and with a melting point of 63–65 °C; $[\alpha]_D^{25} = -51.3°$ ($c = 0.74$, CH_3OH). ^1H NMR (d_6-DMSO, δ ppm): 0.80 (d, $^3J = 6.8$ Hz, 6H, *i*PrCH_3), 1.01 (d, $^3J = 6.8$ Hz, 6H, *i*PrCH_3), 1.30 (s, 6H, CH_3), 2.01 (sp, $^3J = 6.8$ Hz, 2H, *i*Pr*CH*), 3.25 (s, 6H, NCH_3). ^{13}C NMR (d_6-DMSO, δ ppm): 16.7, 17.1, 20.5, 28.3, 34.2, 73.8, 152.3, 184.6. *Anal.* Calc. for $C_{16}H_{26}N_4O_2$: C, 62.72; H, 8.55; N, 18.29. Found: C, 62.68; H, 8.35; N, 18.17%.

4.6.7. Preparation of (±)-2,2′-bis-(1-benzyl-4-isopropyl-4-methyl-4,5-dihydro-1H-imidazol-5-one) (**4a**)

A mixture of compound **2a** (1.11 g, 4 mmol), anhydrous K_2CO_3 (1.66 g; 12 mmol), KI (50 mg) and benzyl bromide (2.05 g, 12 mmol) in 10 ml dry DMF was heated under an inert atmosphere at a temperature of 150 °C for a period of 2 days. After cooling, the mixture was filtered and the solid on the filter was washed with 3 × 10 ml DMF. The combined filtrates were evaporated under reduced pressure until dry. The residue was recrystallised from methanol with charcoal to give 1.43 g (78%) product melting at 107–117 °C. ^1H NMR (d_6-DMSO, δ ppm): 0.65 (d, $^3J = 6.9$ Hz, 6H, *i*PrCH_3), 0.95 (d, $^3J = 6.9$ Hz, 6H, *i*PrCH_3), 1.27 (s, 6H, CH_3), 2.03 (sp, $^3J = 6.9$ Hz, 2H, *i*Pr*CH*), 5.09–5.22 (m, 4H, BzCH_2), 6.95 (m, 4H, PhH_o), 7.19 (m, 6H, PhH_m,H_p). ^{13}C NMR (d_6-DMSO, δ ppm): 16.7, 17.0, 21.1, 34.6, 44.5, 74.6, 126.8, 127.2, 128.5, 136.9, 151.3, 185.0. *Anal.* Calc. for $C_{28}H_{34}N_4O_2$: C, 73.33; H, 7.47; N, 12.22. Found: C, 73.24; H, 7.67; N, 12.09%.

4.6.8. Synthesis of copper(II) complex **5a**

A solution of ligand **3a** (61.3 mg; 0.2 mmol) in 10 ml dry methanol was mixed with $CuCl_2 \cdot 2H_2O$ (34.1 mg; 0.2 mmol). The mixture was refluxed with exclusion of air moisture for 1 h. After cooling, the solvent was removed at reduced pressure, and the residue was suspended in 10 ml dry ether. The solid was collected by suction and washed with 20 ml ether. Yield 74 mg (84%) orange product. *Anal.* Calc. for $C_{16}H_{26}Cl_2CuN_4O_2$: C, 43.59; H, 5.94; N, 12.71. Found: C, 43.85; H, 6.16; N, 12.68%.

4.6.9. Synthesis of copper(II) complex **5b**

Compound **5b** was prepared in the same way as compound **5a** in a yield of 81%; $[\alpha]_D^{25} = -35.9°$ ($c = 0.51$, CH_3OH). *Anal.* Calc. for $C_{16}H_{26}Cl_2CuN_4O_2$: C, 43.59; H, 5.94; N, 12.71. Found: C, 43.77; H, 6.12; N, 12.59%.

4.6.10. Nitroaldol (Henry) reaction of 4-nitrobenzaldehyde with nitromethane

A typical procedure of the nitroaldol (*Henry*) reaction of 4-nitrobenzaldehyde with nitromethane is described in Ref. [5] (Method C and Method D).

Available online 5 November 2007

Abstract

Nickel(II) complexes of quinoline-2-carbaldehyde *N*(4),*N*(4)-(butane-1,4-diyl) thiosemicarbazone (HL^1) and 2-benzoylpyridine *N*(4),*N*(4)-(butane-1,4-diyl) thiosemicarbazone (HL^2) have been synthesized and physico-chemically characterized by means of partial elemental analyses, molar conductance measurements, magnetic measurements, electronic and infrared spectral studies. Three complexes were given the formulae $[Ni(HL^1)_2]Cl_2$ (**1**), $[Ni(HL^2)L^2]ClO_4 \cdot 7H_2O$ (**2**) and $[NiL^2Cl] \cdot 0.5H_2O$ (**3**). The structure of compound **1** has been solved by single crystal X-ray crystallography and is found to be distorted octahedral. Compound **2**, when crystallized in DMSO solution, got deprotonated to form a new compound $[Ni(L^2)_2]$ (**2a**), with a distorted octahedral Ni(II) center. In compound **1**, HL^1 coordinates to the metal in the thione form, while in compounds **2a** and **3**, HL^2 coordinates in its deprotonated thiolate form.

Keywords: Thiosemicarbazone; Ni(II) complex; Quinoline-2-carbaldehyde; 2-Benzoylpyridine; Crystal structure

1. Introduction

Heterocyclic thiosemicarbazones have aroused considerable interest in chemistry due to their remarkable coordination properties and in biology owing to a wide spectrum of potential biological activities [1–4]. The formation of complexes with transition metal ions has been proposed as a step in the biological activity of thiosemicarbazones and is related to its chelating ability with transition metal ions, bonding through nitrogen, nitrogen and sulfur atoms [4] or oxygen, nitrogen and sulfur atoms [5–7]. The activity of thiosemicarbazones depends very much on the parent aldehyde or ketone [8,9] and is affected also by the presence of *N*(4) substitution [10,11]. The real impetus towards developing the coordination chemistry of thiosemicarbazones has been provided by remarkable biological activities observed for these compounds, which has since been shown to be related to their metal complexing ability. Previously we have reported the synthesis, spectral and X-ray crystal studies of 2-benzoylpyridine-*N*(4),*N*(4)-(butane-1,4-diyl) thiosemicarbazone and its iron(III) [12], Cu(II) [13] and Mn(II) complexes [14]. Here we report the structural characterizations of one new thiosemicarbazone viz. quinoline-2-carbaldehyde *N*(4),*N*(4)-(butane-1,4-diyl) thiosemicarbazone (HL^1) and its Ni(II) complex along with two Ni(II) complexes of 2-benzoylpyridine-*N*(4),*N*(4)-(butane-1,4-diyl) thiosemicarbazone (HL^2).

2. Experimental

Quinoline-2-carbaldehyde (Aldrich), 2-benzoylpyridine (Aldrich) were used as received. 4-Methyl-4-phenyl-3-thiosemicarbazide was prepared as reported previously [15]. Nickel(II) chloride hexahydrate and nickel(II) perchlorate hexahydrate (Merck) were used as supplied and solvents were purified by standard procedures before use. *Caution*! Perchlorate complexes of metals with organic ligands are potentially explosive and should be handled with care.

2.1. Synthesis of the ligands

The thiosemicarbazone ligands (Scheme 1) were synthesized by adapting a reported procedure of Scovill [15].

HL^1: A solution of 1.000 g (5.52 mmol) of 4-methyl-4-phenyl-3-thiosemicarbazide in 10 ml of acetonitrile was refluxed with 0.392 g (5.52 mmol) of pyrrolidine and 0.894 g (5.52 mmol) of quinoline 2-carbaldehyde for 1.5 h. The solution was chilled (overnight) and the crystals that separated were collected and washed well with acetonitrile. The compound was recrystallized from ethanol and dried *in vacuo* over P_4O_{10}. Yield 46%. Elemental *Anal.* Calc.: C, 63.35; H, 5.67; N, 19.70; S, 11.28. Found: C, 63.15; H, 5.99; N, 19.66; S, 11.26%.

HL^2: The same procedure was followed for HL^2 also, except with the use of 1.021 g (5.52 mmol) of 2-benzoylpyridine instead of quinoline 2-carbaldehyde.

2.2. Synthesis of the complexes

The complexes were synthesized by a general method. To a hot solution of the respective ligand (0.5 mmol) {HL^1 for **1**, HL^2 for **2** and **3**} in 10 ml chloroform was added an equimolar amount of the nickel salt {nickel(II) chloride hexahydrate (0.120 g) for **1** and **3**, nickel(II) perchlorate hexahydrate (0.183 g) for **2**} dissolved in 20 ml hot methanol. The mixture was refluxed for an hour and allowed to stand at room temperature. The reddish brown compound that precipitated was filtered, washed with methanol and ether and dried *in vacuo* over P_4O_{10}.

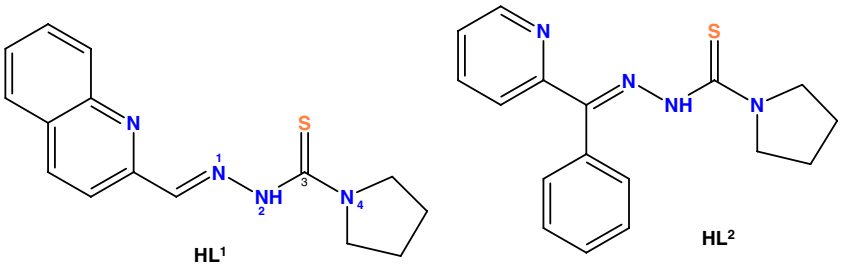
$[Ni(HL^1)_2]Cl_2$ (**1**): Yield 53%. XRD quality single crystals of **1** were obtained by the slow evaporation of its methanol solution in air. Elemental *Anal.* Calc.: C, 51.60; H, 4.62; N, 16.05; S, 9.18. Found: C, 51.46; H, 5.01; N, 16.17; S, 9.09%.

$[Ni(HL^2)L^2]ClO_4 \cdot 7H_2O$ (**2**): Yield 78%. Elemental *Anal.* Calc.: C, 45.17; H, 5.46; N, 12.39; S, 7.09. Found: C, 44.65; H, 5.32; N, 12.28; S, 6.83%.

$[Ni(L^2)_2]$ (**2a**): The complex $[Ni(HL^2)L^2]ClO_4 \cdot 7H_2O$ (**2**) on crystallization in DMSO solution by slow evaporation in air yielded **2a** with deprotonation of HL^2 from **2**.

$[NiL^2Cl] \cdot 0.5H_2O$ (**3**): Yield 56%. Elemental *Anal.* Calc.: C, 49.49; H, 4.40; N, 13.58; S, 7.77. Found: C, 49.94; H, 4.15; N, 13.75; S, 7.72%.

2.3. Physical measurements



Elemental analyses were carried out using an Elementar Vario EL III CHNS analyzer at SAIF, Kochi, India. Infrared spectra were recorded on a Thermo Nicolet, AVATAR 370 DTGS model FT-IR spectrophotometer with KBr pellets and the ATR technique at SAIF, Kochi, India. The far IR spectra were recorded using polyethylene pellets in the 500–100 cm^{-1} region on a Nicolet Magna 550 FTIR instrument at the Regional Sophisticated Instrumentation Facility, Indian Institute of Technology, Bombay, India. Electronic spectra were recorded on a Cary 5000 version 1.09 UV–vis spectrophotometer from solutions in DMF. The magnetic susceptibility measurements were carried out at the Indian Institute of Technology, Roorkee, India at room temperature in the polycrystalline state on a PAR model 155 Vibrating Sample Magnetometer at 5 kOe field strength. The molar conductances of the complexes in DMF solutions (10^{-3} M) at room temperature were measured using a direct reading conductivity meter.

2.4. X-ray crystallography

The crystallographic data and structure refinement parameters for the compounds are given in Table 1. The data of single crystals of suitable dimensions of **1** and **2a** were collected using a CRYSALIS CCD, Oxford Diffraction Ltd. with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation at a temperature of 150(2) K at the National Single Crystal X-ray Diffraction Facility, IIT, Bombay, India. Both crystals were found to be monoclinic. The trial structure was solved using SHELXS-97 [16] and refinement was carried out by full-matrix least squares on F^2 (SHELXL-97). One of the pyrrolidine groups is disordered over C(15) and C(16) in complex **2a**. All non-hydrogen atoms were refined anisotropically, while the hydrogen atoms were placed at calculated positions and allowed to ride on their parent atoms. The molecular graphics employed were ORTEP-III [17], PLATON [18] and MERCURY [19].

3. Results and discussion

Based on spectral and magnetic susceptibility studies, compounds **1** and **2** are found to be six coordinate around

the Ni(II) centers, while compound **3** is four coordinate around the Ni(II) center. The stoichiometries of the complexes are in agreement with the partial elemental analyses and spectral studies. Infrared spectral evidences support the presence of coordination through the thione form of HL^1 in compound **1**, through the thiolate form of HL^2 in **3** and through the thione and thiolate forms of HL^2 in **2**. Molar conductivity measurements in 10^{-3} M DMF solution show non-electrolytic nature (8 ohm^{-1} cm^2 mol^{-1}) for **3**, a 1:1 electrolyte for **2** (89 ohm^{-1} cm^2 mol^{-1}) and a 2:1 electrolyte for **1** (138 ohm^{-1} cm^2 mol^{-1}). Like compound **2**, copper and cobalt complexes with both neutral and deprotonated forms of a thiosemicarbazone ligand in the same complexes with a perchlorate ion have been reported [20]. The room temperature effective magnetic moments μ_{eff} of the three compounds **1**, **2** and **3** are found to be 2.80, 2.66 and 0.89 μ_B, respectively; consistent with the octahedral geometry for complexes **1** and **2**. The anomalous magnetic moment of 0.89 μ_B shown by **3** is attributed to a four coordinated Ni(II) center. For a perfect square planar complex of Ni(II), diamagnetism is expected. The low magnetic moment may be due to deviation from a perfect square planar geometry or the presence of impurities. The structure of **1** has been confirmed by a single crystal X-ray study and it is found that a distorted octahedral geometry around the Ni(II) center is formed by two neutral HL^1 ligands. However the single crystal X-ray study of **2a** shows that the Ni(II) center is coordinated by two monodeprotonated ligands of HL^2 to form a distorted octahedral geometry around the Ni(II) center. The relevant bond lengths and bond angles of $[Ni(HL^1)_2]Cl_2\cdot 2.5H_2O$ ($\mathbf{1}\cdot 2.5H_2O$) and $[Ni(L^2)_2]$ (**2a**) are listed in Tables 2 and 3.

3.1. Crystal structures of $[Ni(HL^1)_2]Cl_2 \cdot 2.5H_2O$ ($\mathbf{1} \cdot 2.5H_2O$) and $[Ni(L^2)_2]$ (**2a**)

The molecular structures of $\mathbf{1} \cdot 2.5H_2O$ and **2a**, along with the atom numbering schemes, are depicted in Figs. 1 and 2. In compound $\mathbf{1} \cdot 2.5H_2O$, two molecules of the neutral ligand HL^1 are coordinated in the *meridional* fashion [21] using pairs of *cis* quinolyl nitrogen, *trans* azomethine nitrogen and *cis* thione sulfur atoms, while in compound **2a**, the Ni(II) ion is coordinated in a *meridional* fashion using pairs of *cis* pyridyl nitrogen, *trans* azomethine nitrogen and *cis* thiolate sulfur atoms [22–24] of two monoanionic ligands, resulting in two bicyclic chelate systems. The thione coordination as found in $\mathbf{1} \cdot 2.5H_2O$ is rare for thiosemicarbazones. In $\mathbf{1} \cdot 2.5H_2O$, the bicyclic chelate systems Ni(1), S(1), C(11), N(3), N(2), C(10), C(9), N(1) and Ni(1), S(2), C(26), N(7), N(6), C(25), C(24), N(5) are slightly deviated from planarity, as evidenced by the maximum deviation of 0.183(6) Å for C(9) and −0.121(5) Å for N(7), respectively, from their respective mean planes. However in **2a**, the bicyclic chelate system Ni(1), S(1), C(13), N(3), N(2), C(6), C(5), N(1) and Ni(1), S(2), C(30), N(7), N(6), C(23), C(22), N(5) are approximately planar with a maximum mean plane deviation of 0.100(5) Å for N(1) and −0.070(6) Å for C(23), respectively. The dihedral angle formed by the mean planes of the bicyclic chelate systems of each of the ligands is 83.50(10)° in $\mathbf{1} \cdot 2.5H_2O$, and 86.98(11)° in $[Ni(L^2)_2]$. In compound $\mathbf{1} \cdot 2.5H_2O$ the trans angles N(1)–Ni(1)–S(1), N(5)–Ni(1)–S(2) and N(2)–Ni(1)–N(6) are 159.12(13)°, 159.64(14)° and 168.86(19)°, respectively, while in compound **2a**, the angles N(1)–Ni(1)–S(1), N(5)–Ni(1)–S(2) and N(2)–Ni(1)–N(6) are 158.54(14)°, 158.79(14)° and 165.8(2)°, respectively. These factors suggest considerable distortion from an octahedral geometry around the Ni(II) centers in both complexes.

The bond lengths Ni–$N_{azomethine}$, Ni–N_{py} and Ni–S in **2a** increase in that order, as in similar compounds [21–25]. A similar increase is seen in the quinoline substi-

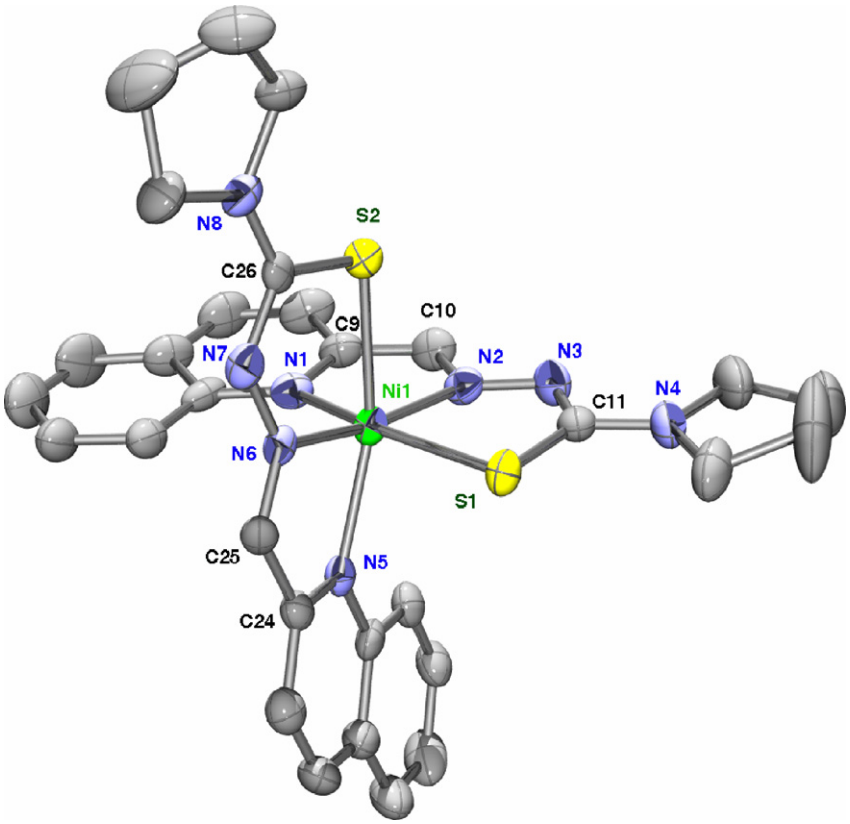

Fig. 1. ORTEP diagram of the cation of $[Ni(HL^1)_2]Cl_2 \cdot 2.5H_2O$ with 50% probability ellipsoids. Hydrogen atoms are omitted for clarity.

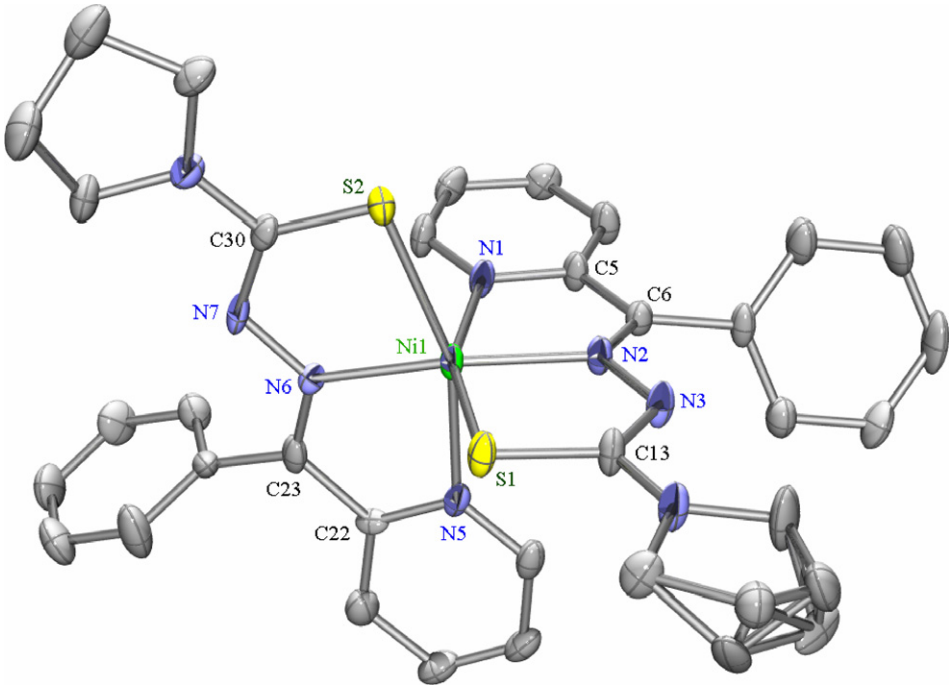

Fig. 2. ORTEP diagram for the compound $[Ni(L^2)_2]$ (**2a**) with 50% probability ellipsoids. Hydrogen atoms are omitted for clarity.

tuted compound $\mathbf{1}\cdot 2.5H_2O$. The Ni–N_{qu} bonds are of the same strength as both show lengths of 2.139(5) Å and are weaker compared to the Ni–N_{py} bonds in compound **2a**. The Ni–$N_{azomethine}$ bond lengths are less compared to Ni–$N_{py/qu}$ in complexes $\mathbf{1}\cdot 2.5H_2O$ and **2a**, indicating the higher strength of former bond than the latter. The Ni–S bond lengths in complex $\mathbf{1}\cdot 2.5H_2O$ are found to be less compared to that in **2a**, indicating stronger bonds in $\mathbf{1}\cdot 2.5H_2O$. However, the C–S bond lengths in compound **2a** are greater compared to the 1.681(3) Å seen in the free ligand HL^2 [12] and also compared to that in compound $\mathbf{1}\cdot 2.5H_2O$. Also the C–N bond lengths in **2a** {1.334(8) Å for N(3)–C(13) and 1.371(8) Å for C(30)–N(7)} are consistent with partial double bond character. These factors confirm the coordination through the thiolate form by deprotonation after enolization of the ligand HL^2 in compound **2a**. However in $\mathbf{1}\cdot 2.5H_2O$, the coordination occurs via the thione form of HL^1 as evidenced by the lesser C–S and greater C–$N_{azomethine}$ bond lengths. These bond lengths are comparable to that seen in thiosemicarbazones with delocalization of electron density [26].

In complex $\mathbf{1}\cdot 2.5H_2O$ the molecules are connected by various hydrogen bonding interactions including water molecules (Table 4) and are packed in the lattice (Fig. 3) in an ordered manner along the *c* axis by making use of C–H···π ring interactions. While in compound **2a**, the molecules are packed in the same manner along the *a* axis, as seen in Fig. 4, as a result of one intermolecular hydrogen bonding interaction and diverse C–H···π ring interactions (Table 5). However, no significant π···π interactions are found in the packing for both compounds.

3.2. IR and electronic spectral studies

The characteristic IR bands of the complexes differ from their free ligands HL^1 and HL^2, and provide significant indications regarding the coordination and bonding sites of the ligands. Relevant characteristic bands of all the compounds are listed in Table 6. The ligand HL^1 shows a broad peak at 3442 cm^{-1} which is attributed to a $\nu(^2N–H)$ vibration. In compound **1**, this peak is shifted slightly downwards but is indicative of the presence of $^2N–H$. However in compounds **2** and **3** due to the presence of lattice water broad bands are seen at frequencies 3415 and 3440 cm^{-1},

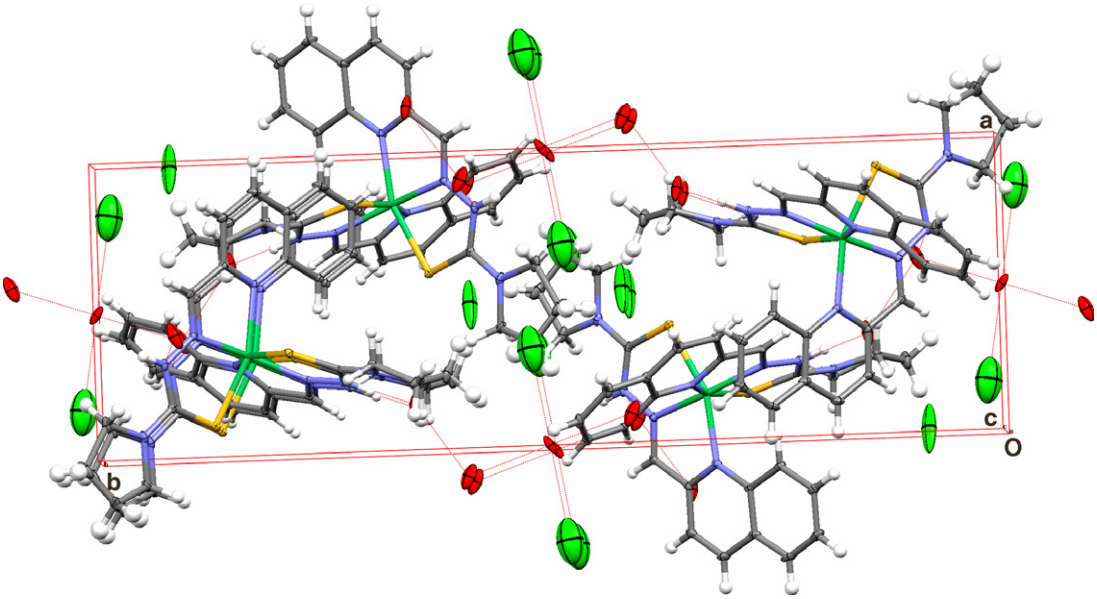

Fig. 3. A view of the unit cell of $[Ni(HL^1)_2]Cl_2 \cdot 2.5H_2O$ along the *c* axis showing the molecules packed along the *c* axis (left part) and connected through hydrogen bonding interactions involving chloride and water molecules.

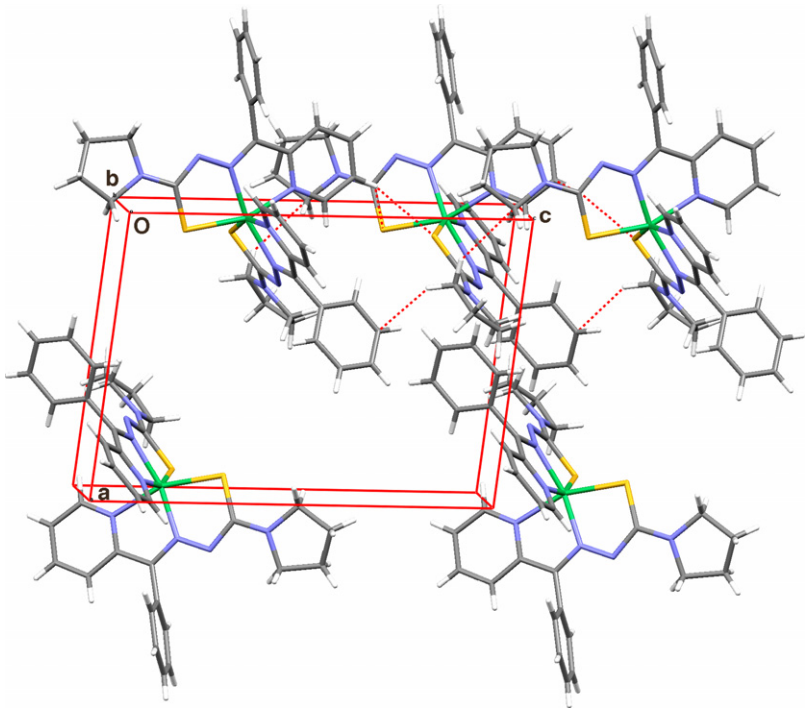

Fig. 4. Unit cell of the molecule $[Ni(L^2)_2]$ (**2a**) along the *b* axis showing molecules packed along the *c* axis (bottom part) and connected through intermolecular hydrogen bonding interactions with molecules of the nearby layer (top part).

respectively. No other bands in the nearby region may be due to the absence of N–H hydrogens. Also the strong peak at 1282, assigned as the ν(C=S) vibration for HL^1, shows only a marginal shift in compound **1**, supporting the coordination through the thione form. However for compound **2** two strong bands seen at 1337 and 1283 cm^{-1} are assigned to ν(C=S) and ν(C–S) frequencies, showing a shift from 1342 cm^{-1} assigned to the ν(C=S) band of HL^2 [12,13]. For compound **3** the strong band at 1296 cm^{-1} is assigned to a ν(C–S) band. Additionally, no band due to the SH group is observed between 2600 and 2500 cm^{-1} [27] in agreement with the deprotonated thiolate form of the ligand in these complexes. The bands seen at ~350 cm^{-1} for these complexes are assigned as νNi–S, which further supports their coordination. Bands ranging from 1600 to 1400 cm^{-1}, attributed to ν(C=C) and

Table 5

ν(C=N) vibration modes, in the spectra of the complexes suffer significant shifts and their mixing patterns are different from that in the spectra of the respective ligands. The azomethine ν(C=N) vibrations at 1580 and 1630 cm^{-1} in the free ligands HL^1 and HL^2, respectively, suffered negative shifts. These bands are seen at 1561 cm^{-1} in the spectrum of **1** and at 1553 and 1537 cm^{-1} in the spectra of compounds **2** and **3**, respectively. The new bands seen at frequencies 1590 and 1594 cm^{-1} for **2** and **3** are assigned to the newly formed $\nu(^2N{=}C)$ and this band is absent in the spectrum of **1**. The coordination through the azomethine nitrogen is further evidenced by the $\nu Ni–N_{azo}$ peaks ~440 cm^{-1} for these compounds. The shifts in the ν(N–N) frequencies also support coordination through the azomethine nitrogen in all the complexes. Coordination of the pyridine nitrogen atom is seen by the shifts in frequencies of the deformation mode bands that appear in the range 649–455 cm^{-1} in the spectrum of HL^2 [13]. This is further supported by $\nu Ni–N_{py/qu}$ bands seen at ~250 cm^{-1} for all these compounds.

The perchlorate complex **2** shows a broad band at 1090 cm^{-1} and strong band at 625 cm^{-1}, indicating the presence of ionic perchlorate [28]. The band at 1090 cm^{-1} is assignable to $\nu_3(ClO_4)$ and the unsplit band at 625 cm^{-1} assignable to $\nu_4(ClO_4)$. These indicate that the ClO_4 species is not coordinated (T_d symmetry). The other bands at 938 and 467 cm^{-1}, assignable to ν_1 and ν_2 vibrations of perchlorate, are very weak.

The electronic spectral data of the ligands and complexes in DMF solutions are summarized in Table 7. The intraligand electronic transitions of HL^1 suffered considerable shift on coordination, as evidenced by the absorptions obtained for **1**. The band with the highest molar absorptivity at 20750 cm^{-1} is assigned as a S→Ni LMCT transition. The ground state of Ni(II) in an octahedral coordination is $^3A_{2g}$ and expects three spin allowed transitions $^3T_{2g}(F) \leftarrow {}^3A_{2g}(F)(\nu_1)$, $^3T_{1g}(F) \leftarrow A_{2g}(F)(\nu_2)$ and $^3T_{1g}(P) \leftarrow {}^3A_{2g}(F)(\nu_3)$ in an increasing order of energy, with molar absorptivities generally below 20. However we could not locate any of these bands, probably due to masking by the high-intensity charge transfer bands. For compound **2** also the S→Ni charge transfer band at 22470 cm^{-1} masks the possible d–d bands in that region. For compound **3**, the CT band is obtained at 24150 cm^{-1}, assigned as an S→Ni LMCT. Another absorption obtained at 31250 cm^{-1} is assigned as an $n \rightarrow \pi^*$ transition. For a diamagnetic Ni(II) complex, as a consequence of eight electrons being paired in the four low-lying d orbitals with the upper orbital being $d_{x^2} - y^2$, the four lower orbitals are often so close in energy that individual transitions from them to the upper d level cannot be distinguished, resulting in a single absorption band. The shoulder band obtained at 19380 cm^{-1} (1870 $M^{-1}\,cm^{-1}$) for **3** may be attributed to a d–d band of this type. The d–d bands appearing as weak shoulders centered around the 20000 cm^{-1} region are typical of square planar monoligated Ni(II) complexes [29].

Abstract

Lanthanide nitrates and bis(diphenylphosphino)hexane dioxide ($dpphO_2$) formed under solvothermal conditions a series of coordination polymers $[Ln(dpphO_2)_2(NO_3)_2](NO_3)$ (Ln = Pr (**1**), Nd (**2**), Sm (**3**), Dy (**4**), Lu (**5**)), featuring two-dimensional network structure of the (4,4) topology. The compounds $[Ln(dpphO_2)_2Cl_2]Cl$ (Ln = Pr (**6**), Nd (**7**), Gd (**8**)) were obtained from corresponding chlorides. Coordination polymer **7** formed regular single crystals of the orthorhombic $Pna2_1$ space group. The nitrate complexes crystallized in the orthorhombic $Aea2$ space group, however, the crystals were pseudo-merohedral twins simulating a tetragonal diffraction pattern. Unlike our previously characterized neutral polymers with bis(diphenylphosphino)ethane dioxide, all present coordination networks are cationic, with anions located between or within the two-dimensional layers.

1. Introduction

A current revolutionary increase in the number of synthesized and structurally characterized metal-organic coordination frameworks reflects the demand for new materials with predesigned functionalities [1]. The structures of polymeric networks and their properties are largely determined by a suitable combination of elemental building blocks, *e.g.* metal containing nodes and polyfunctional organic linkers. Their considerate choice together with synthetic strategy employed lead to different types of branching, topologies, and dimensionality [2]. Lanthanides are often utilized as nodes because of their propensity to high coordination numbers and inherent luminescent properties, which are essential for the formation of unusual network topologies and luminescent materials, respectively [3].

Our current investigations are focused on the reactivity of bis(diphenylphosphino)alkane dioxides $Ph_2P(O)–(CH_2)_n–P(O)Ph_2$ with lanthanide salts. In two recent articles we presented polymeric coordination compounds of 1,2-bis(diphenylphosphino)ethane dioxide and binuclear complexes of 1,4-bis(diphenylphosphino)butane dioxide with lanthanides. We also discussed factors affecting the structure of the products, *i.e.* the lanthanide atom size, the choice of the salt anion, and the ligand length [4]. To extend our knowledge of how the length of the ligand chain is related to the structure of the resulting complexes, we have performed a series of reactions of lanthanide salts with 1,6-bis(diphenylphosphino)hexane dioxide ($dpphO_2$).

The reactivity of $dpphO_2$ with metal cations is rather unexplored. A series of reports on spectroscopic and magnetic properties of Fe(II)/Fe(III) chelates with $dpphO_2$ was published in the 1980's [5]. According to the CSD, there are no crystallographically characterized molecular or polymeric $dpphO_2$ complexes [6]. However, aliphatic chain

based ligands of similar length were already used in the construction of metal-organic frameworks; for example 1,8-octanedioic (suberic) acid which possesses the same hexamethylene chain between the two carboxyl groups [7]. Dicarboxylic acids are only partially comparable with diphosphine dioxides as their terminal groups often feature in deprotonated anionic forms unlike the $Ph_2P(O)$ moieties. We can therefore expect that in case of diphosphine dioxides the displacement of other ligands from the coordination sphere of lanthanides might be less common and the resulting architectures different.

2. Results and discussion

The reaction mixture of $dpphO_2$ and praseodymium nitrate in methanol was heated in an autoclave at 140 °C for 24 h. After cooling and opening the autoclave, the product was obtained in the form of plate-shaped crystals which were markedly diagonally segmented into four overlapping triangular regions. The X-ray diffraction data of the entire segmented crystal showed a tetragonal Laue symmetry and the attempts to solve the structure by both direct and heavy atom methods were fruitless. Therefore one of the larger plates was carefully treated to cut out the fraction from within the overlapping wedges. This fragment gave diffraction data which strongly violated tetragonal symmetry and suggested rather the orthorhombic one. Using the latter dataset, we could solve the structure of $\{[Pr(dpphO_2)_2(NO_3)_2]^+(NO_3)^-\}_n$ (**1**). More details on the solution and subsequent refinement are given in Section 5. The solvothermal reactions of $dpphO_2$ with other lanthanide nitrates afforded similarly twinned crystals of **4** (Dy) and **5** (Lu). Using the information obtained during the solution and refinement of the structure of **1**, we carried out the refinement of **4** with comparable results. The Lu compound gave very poor data which were not suitable for the refinement. Nevertheless, the lattice parameters of **5** correspond to the lattice parameters of **1** and **4**.[1] On the basis of the lattice parameters and microanalytical data, we can conclude that the complexes of $dpphO_2$ with lanthanide nitrates are isostructural. Only the structure of **1** is described below, the general features are applicable to the Dy analogue **4** and most probably to other nitrate compounds.

The reactions of $dpphO_2$ with $PrCl_3$, $NdCl_3$, and $GdCl_3$ were also carried out in an autoclave, however, clear solutions were obtained in the Teflon liner after the autoclave was opened. The crystallization occurred spontaneously after the solutions were transferred to glass flasks. Single crystals suitable for X-ray diffraction were only available for $[Nd(dpphO_2)_2Cl_2]Cl$ (**7**).

A common feature of the coordination polymers containing the four atoms shorter $dppeO_2$ ligand and the present $dpphO_2$ compounds is the two-dimensional structure. Unlike the former, the latter are based on the 1:2 instead of 2:3 metal-to-ligand stoichiometry. The lanthanide coordination polyhedra of both nitrate and chloride complexes result from the addition of four Ph_2PO oxygens and the simultaneous displacement of either one nitrate or one chloride ligand from the original coordination sphere. Both polymeric networks are therefore of the (4,4) type and might be considered as derivatives of square grid architectures. As pointed out by Paine et al. the displacement of anions from the metal inner coordination sphere is quite uncommon with neutral donor ligands [8a]. However, it was observed that the diphosphine dioxide ligands may displace the inner-sphere nitrate ions from lanthanides under certain conditions [4a,8].

We first describe the structural features of compound **7** derived from $NdCl_3$, because it was crystallographically the simple case. Here the Nd center is octahedrally coordinated by four O and two *trans*-positioned Cl. The Nd–O–P bonds are almost linear and perpendicular to the adjacent hexamethylene chains, so that the structural motif closely resembles four-connected swastikas (Fig. 1). The Cl atoms displaced from the Nd(III) salt are located approximately in the centers of tetragonal building blocks. The polymeric layers are perpendicular to the crystallographic *b*-axis and the average interlayer separation, measured as a distance between the planes through the Nd atoms, is 9.35 Å.

The coordination polyhedron in $[Pr(dpphO_2)_2(NO_3)_2](NO_3)$ (**1**) contains two chelating (η^2) nitrate ligands in the *trans* geometry (Fig. 2). Because of the greater steric demand of nitrate anions in comparison to chlorides, the N–Pr–N arrangement is markedly less linear than Cl–Nd–Cl in **7** (167.4° versus 177.4°). The planes through

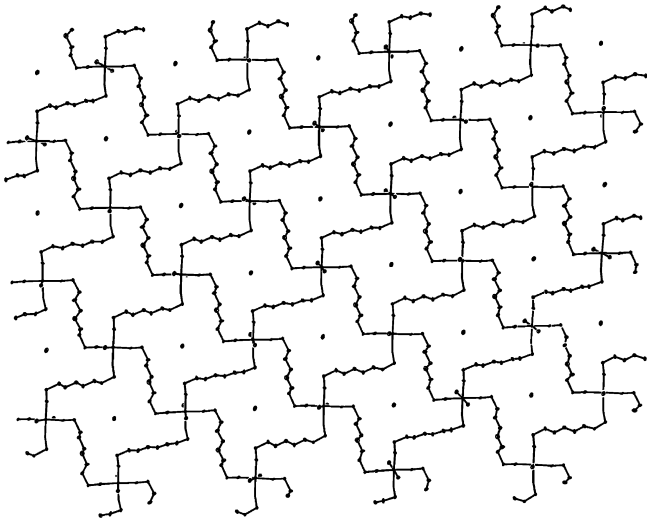

Fig. 1. Top view of 2D polymeric layer in $[Nd(dpphO_2)_2Cl_2]Cl$ (**7**). All hydrogen atoms and phenyl groups were omitted to emphasize the structural motif. Chloride anions are visible as isolated atoms throughout the network.

[1] Lattice parameters of **5**: $a = 25.855(2)$ Å, $b = 23.823(2)$ Å, $c = 23.744(2)$ Å, $V = 14625(2)$ Å^3.

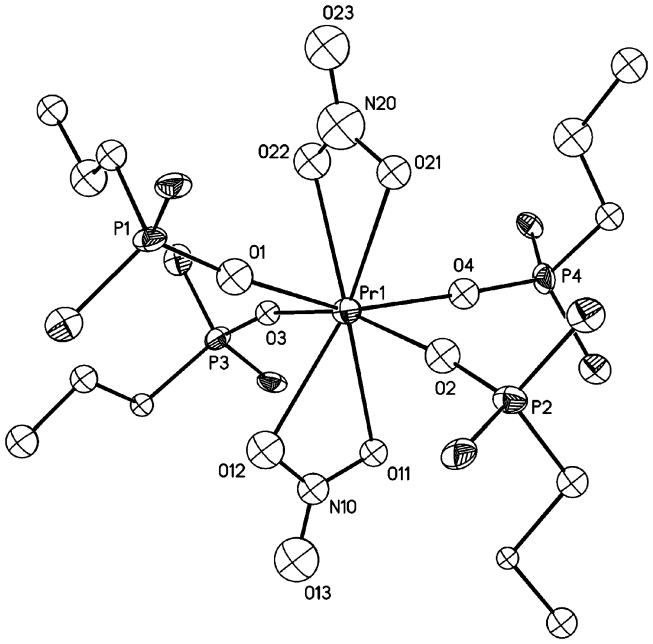

Fig. 2. Coordination polyhedron in $[Pr(dpphO_2)_2(NO_3)_2]NO_3$ (**1**). All hydrogen atoms were omitted and phenyl groups reduced to their *ipso* carbons for clarity. Thermal ellipsoids are drawn at the 50% probability level; the ellipsoids without octant shading represent atoms which were refined only isotropically.

the opposite nitrate ligands are almost perpendicular. Although we were not fully successful in definite positioning of the nitrate anions displaced from the $Ln(NO_3)_3$ centers to the second coordination sphere, we arrived at the general formula $[Ln(dpphO_2)_2(NO_3)_2](NO_3)$ for the nitrate compounds on the basis of electroneutrality, the presence of ionic nitrate bands in the IR spectra (below), and analogy with $[Nd(dpphO_2)_2Cl_2]Cl$ (**7**), in which the anion is also displaced from the coordination sphere. The layers are perpendicular to the crystallographic *a*-direction and the interlayer space is occupied by the nitrate anions and solvent molecules (methanol, water) (see Fig. 3). The distance between the 2D network layers, measured as a distance between the planes through the Pr atoms, is 12.85 Å.

The microanalytical results for C seemed to be systematically overestimated when compared to the calculated values whereas H analyses were lower for compounds **1** to **5**. This can be explained by the water of crystallization present in the crystals, which is visible as isolated maxima of varying density in residual Fourier maps. The experimental analytical values would require ca. 4–5 molecules of water per monomeric unit. The current model which includes two molecules of methanol and two and a half molecules of water per asymmetric part of the unit cell in **1** and **4** also fits the analyses quite well. Other data show that the crystalline products are chemically consistent (melting points on multiple randomly selected crystals, IR spectra). The IR spectra of all nitrate compounds show the presence of both chelating (1458–1506, 1300–1310, 1028–1029, and 817–818 cm^{-1}) and ionic nitrates (1384 cm^{-1}). Along with the chloride complexes, there are also very strong absorptions in the range of 1138–1150 cm^{-1} which is typical for the P=O stretch.

In spite of the 2D network structure of compounds **1**, **2**, **4**, and **5**, their solubility in water was sufficient to allow recording the ESI-MS spectra. All four compounds display the same kind of pattern with similar relative peak intensities. The parent peaks in all spectra belong to the binuclear $[Ln_2(dpphO_2)_2(NO_3)_5]^+$ fragments. The presence of two lanthanide atoms in these ions was clearly demonstrated by the correspondence of the measured and theoretical isotope patterns for the Nd complex **2**. The base peaks in the spectra are $[Ln(dpphO_2)_2(NO_3)_2]^+$ which are formed by the loss of a neutral $Ln(NO_3)_3$ moiety from the previous fragment as it was confirmed by the MS2 experiments. This sequence is completed by the expulsion of the $dpphO_2$ and the formation of $[Ln(dpphO_2)(NO_3)_2]^+$, the further fragmentation of which results in the HNO_2 loss. It is interesting to note that the polymeric $[Ln(dpphO_2)_2(NO_3)_2](NO_3)$ complexes with 1:2 metal-to-ligand stoichiometry provide the same fragmentation paths as the binuclear complexes $[Lu_2(dppeO_2)_3(NO_3)_6]$ [4a] and $[Ln_2(dppbO_2)_3(NO_3)_6]$ [4b] with 2:3 metal-to-ligand ratio.

3. Conclusion

We have described the structural determination of the coordination polymer from twinned crystals. From the chemical point of view, we have observed the formation of 2D cationic polymers by the interaction of the long-chain diphosphine dioxide ligand $dpphO_2$ with lanthanide cations (Pr, Nd, Sm, Gd, Dy, and Lu). Although the ligand possesses a rather flexible central part, the separation between the donor atoms is too large to allow the formation of chelates. Therefore, after obtaining the series of polymers with shorter ligands and molecular binuclear compounds with medium size ligands, we have prepared

the bis(diphenylphosphino)hexane dioxide complexes that again prefer the polymeric architecture. The present polymers do not afford porous structures, nevertheless, the preliminary experiments indicate promising luminescent properties.

4. Experimental

Commercially available 1,6-bis(diphenylphosphino)hexane was dissolved in tetrahydrofuran and oxidized by 30% aqueous solution of H_2O_2 to give $Ph_2P(O)$–$(CH_2)_6$–$P(O)Ph_2$ ($dpphO_2$). IR spectra (KBr pellets, 4000–400 cm^{-1}) were collected on an Equinox 55/S/NIR FTIR spectrometer. Microanalyses were performed using a Thermo Finnigan CHN Analyzer Flash EA 1112. Melting points were measured on a Boetius melting-point apparatus. The ion trap mass spectrometer Esquire 2000 (Bruker, Germany) with electrospray ionization was used for the ESI-MS analyses. Solid samples were dissolved in water and diluted in acetonitrile/water (1:1). The samples were injected directly into the electrospray ion source at a flow rate of 4 μl min^{-1}. The spectra were recorded both in positive and negative mode. The capillary voltage was 4500 V.

A mixture of $dpphO_2$ (250 mg, 0.514 mmol) and the hydrated lanthanide salt (0.257 mmol) in methanol (30 mL) was sealed in a 250-mL stainless-steel reactor Berghof HR-200 with a Teflon liner, heated for 24 h to 140 °C with a RHS-295 heater controlled by a BAR-945 unit, and then slowly cooled to room temperature. After additional 24 h the autoclave was opened. For nitrate complexes **1** to **5**, the crystals were already formed and could be collected. The chloride compounds yielded solutions which spontaneously crystallized after they were transferred to glass flasks (within 3 h). Alternatively, both nitrate and chloride compounds may be also prepared as powders by simple reactions of $dpphO_2$ with respective salts in methanol under laboratory conditions, as proven by consistent microanalytical data. However, these materials are amorphous to powder XRD and only the solvothermal reactions afforded the crystalline samples suitable for the X-ray diffraction.

5. Crystallography

Diffraction data were collected on a KUMA KM-4 κ-axis diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å) equipped with a CCD detector. The temperature during data collection was 120(2) K. The intensity data were corrected for Lorentz and polarization effects; absorption cor-

rection was applied for all data. The structure of **7** was solved by direct methods and refined by standard methods using the SHELXTL software package [9]. The details of the data collection and structure refinement are summarized in Table 1 and the important bond lengths and angles are listed in Table 2.

The crystals of **1** were pseudo-merohedral twins simulating a tetragonal diffraction pattern and the attempts to solve the structure using the "tetragonal" data set were unsuccessful. Therefore the crystals were fragmented and the diffraction data recorded on one of the fragments were taken as a starting point for further investigation. The analysis of extinctions showed two most probable space groups *Aea*2 and *Aeam* related by the inversion center. A more detailed study showed that some relatively weak reflections violating the extinction conditions are generated by the twinning operation. This effect was much weaker for the small crystal but clearly apparent. This indicated that even the cut crystal is composed of twin domains. In the non-centrosymmetric space group *Aea*2, the direct methods on this data set gave a model, which was refined to a reasonable minimum using conventional techniques. The group-subgroup relationship between the idealized lattice symmetry 4/mmm and the orthorhombic Laue group led to the equivalent twinning matrices from which the fourfold axis, directed in the standard orthorhombic setting along the *a* axis, has been chosen. Introducing the twinning operation improved the fit significantly and ended with relatively small but significant volume fraction ~16.2(2)% for the minor domain. Unfortunately the small crystal had much worse statistics than the original one. This was the reason why the final refinement was made against the data collected from the original large crystal. The volume fraction of the second domain for the large crystal was about 49% which is in full accordance with the preliminary observations on the crystal morphology. In the final stages, the fact that the space group is non-centrosymmetric was taken into account and the additional twin domains were used that were related by the inversion center to already existing ones. The final refined values of the volume fractions of the four twin components (generated by operations 1, 4, −1 and −4) were 0.248(12), 0.373(13), 0.273(13) and 0.106(12) for **1**, and 0.286(13), 0.401(13), 0.286(13) and 0.027(12) for **4**.

The refinement was performed using JANA2000 crystallographic computing system [10]. We introduced the phenyl rings as rigid bodies whose average shapes were appropriately translated and rotated to address a rather unclear electron density in the vicinity of phosphorus atoms. The positioning of the ionic nitrate anions was only partially successful. One of the N–O vectors was found to coincide with the twofold axis so that only a half of the nitrate anion contributes to the asymmetric part of the unit cell. The other half of the anion has not been clearly identified in the electron density maps. The residual maxima are located between the polymeric layers rather than in the vicinity of the heavy atoms. However, the attempts to address the residual electron density peaks using the molecules of solvent (water or methanol) included in the model have not lead to meaningful results. The refinement of **1** converged to $R = 0.0476$, $Rw = 0.0541$.

The pseudo-merohedral twinning present in the crystal can generally lead to splitting of related diffraction spots. Due to the fact that the condition $b \approx c$ was closely fulfilled, no obvious splitting was detected. Nevertheless, the

Abstract

Electronic structure calculation techniques (DFT) have been used to decipher the bonding of the trihalide ligands in a series of homo- and hetero-trihalide Cu(II) Schiff base complexes formulated as $[Cu(RdienR)(X)(XY_2)]$ (RdienR = Schiff base; R = furan, thiophene or pyrrol; X = Cl or Br; Y = Cl, Br or I). The association of the incoming Y_2 halogen molecule with one of the halide X ligands of the precursor $[Cu(RdienR)(X)_2]$ complexes alters their distorted trigonal bipyramidal stereochemistry which is transformed to a distorted square pyramidal geometry. The bonding mechanism between the halogen Y_2 molecule and the halide X ligand was thoroughly explored by means of various electronic parameters and charge decomposition analysis techniques. The bond dissociation energy of the Cu–XY_2 bond, $BDE_{Cu–XY_2}$, was estimated in the range of 61.9–68.4 kcal/mol, while the bond dissociation energy of the X–Y_2 bond, $BDE_{Cu–XY_2}$, was found in the range of 10.6–12.5 kcal/mol. It was found that the $X\cdots Y_2$ interactions correspond to weak hyperconjugative donor–acceptor interactions between a non-bonding n(X) molecular orbital (donor orbital) localized on the coordinated halide X ligand and an antibonding σ^*(Y–Y) molecular orbital (acceptor orbital) localized on the Y_2 halogen molecule. The n(X) $\rightarrow$ σ^*(Y–Y) donor–acceptor interactions are associated with a second-order perturbation stabilization energy, $\Delta E(2)$ of 34.5–52.5 kcal/mol. The loose association of the halogen molecules with the coordinated halide ligand renders the $[Cu(RdienR)(X)(XY_2)]$ complexes good halogen carrier molecules.

1. Introduction

The structural features, the nature of the bonding and the relative stability of the "free" polyhalide anions $[X_mY_nZ_l]^-$ (X, Y, Z = F, Cl, Br or I; *m*, *n*, *l* integer numbers with $m + n + l =$ odd) has long been a subject of research and investigation both experimentally and theoretically [1–14]. Extensive theoretical studies have been devoted [15,16] to obtaining a detailed description of the electronic structure of the aforementioned anionic counterions of simple or complex cations and numerous crystal structures have been reported in the literature as well. From all possible combinations of the $[X_mY_nZ_l]^-$ anionic species, the most interesting and extensively studied are the trihalide anions $[XYZ]^-$ (X, Y, Z = Cl, Br or I). These species either homo- or hetero-nuclear adopt a linear or almost linear conformation, while for the homo-trihalide $[X_3]^-$ anions both symmetrical and unsymmetrical structures have been identified, depending on the type of the individual cations.

A decade ago Hoffmann et al. [15] have reported the results of a systematic, unified theoretical analysis concerning the bonding in the trihalides $[X_3]^-$, mixed trihalides $[XY_2]^-$ and hydrogen bihalides $[HY_2]^-$, based upon qualitative molecular orbital theory and DFT computational techniques. The authors showed that the nature of the

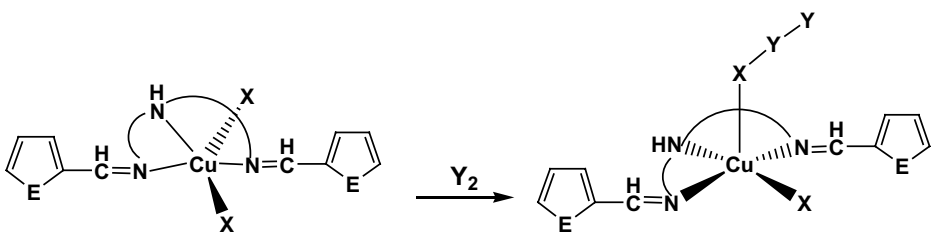
doi:10.1016/j.poly.2007.09.005

bonding in all these species may be viewed as either electron-rich three-centre or as donor–acceptor bonding. The electron-rich three-centre bonding scheme resembles the "classical" view of the bonding in hypervalent molecules put forth by Pimentel [17] and Rundle [18] which invokes delocalized three-center σ bonding involving one bonding, one non-bonding and one antibonding molecular orbital. The alternative donor–acceptor view of the bonding corresponds to the interaction between closed-shell fragments, where X^- is the donor of a pair of electrons (occupied p_σ-orbital) and the Y_2 fragment acts as acceptor through its σ^* MO (σ^* LUMO). On the other hand, Kikuchi et al. [16] have studied the structure and dissociation of the heteronuclear $[XY_2]^-$ anions both in the gas phase and in solution using ab initio computational methods. They concluded that the $[X–Y–X]^-$ and $[Y–Y–X]^-$ isomers are energetically favoured over the $[Y–X–X]^-$ and $[Y–X–Y]^-$ ones, when Y is heavier than X. It was also suggested that the structures of $[Y–X–X]^-$ and $[Y–Y–X]^-$ anions in solution are quite different from those in the gas phase, being like an ion–dipole complex in aqueous solution.

Despite the vast number of theoretical and experimental works concerning the "free" $[XY_2]^-$ anions, the investigation of the structure and bonding of the homo- and hetero-trihalide anions occupying a coordination site in the coordination sphere of transition metal complexes is scarce. Very recently, we reported on the synthesis, structure elucidation, bioactivity and DNA-cleavage capability of a new series of Cu(II) trihalide complexes of the general formula $[Cu(RdienR)(X)(XY_2)]$, (R = furan, thiophene or pyrrole and X, Y = Cl, Br or I) (Scheme 1) [19]. Moreover, the crystal structure of the $[Cu(dpta)(Br)(BrI_2)]$ complex has recently also been reported [20].

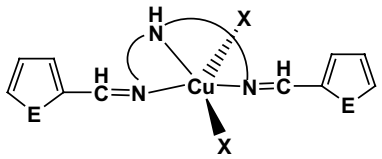
In this paper, we explore the molecular and electronic structure of the $[Cu(RdienR)(X)(XY_2)]$ complexes and their $[Cu(RdienR)(X)_2]$ precursors with the help of DFT methods pursuing a twofold objective: (i) the understanding of the nature of the bonding between the $[XY_2]^-$ ligands and the Cu(II) central metal ion, and (ii) the unveiling of the effect, if any, of coordination on the bonding mechanism in the coordinated $[XY_2]^-$ ligands in comparison to that of the "free" $[XY_2]^-$ anions, using a variety of theoretical analysis techniques, which include charge decomposition analysis (CDA), natural bond orbital (NBO) population analysis, and percentage compositions of molecular orbitals.



2. Computational details

The structural, electronic and energetic properties of all compounds under investigation were computed using the Becke's three parameter hybrid functional [21,22] combined with the Lee–Yang–Parr [23] correlation functional (B3LYP level of density functional theory) using an all-electron double-zeta (DZVP) basis set [24]. No constraints were imposed on the geometry. Full geometry optimization was performed for each structure using Schlegel's analytical gradient method [25], and the attainment of the energy minimum was verified by calculating the vibrational frequencies that result in an absence of imaginary eigenvalues. All the stationary points were identified for minima (number of imaginary frequencies NImag = 0). The computed electronic energy was corrected to constant pressure and 298 K, for zero point energy (ZPE) differences and for the contributions of the translational, rotational and vibrational partition functions. The natural bond orbital (NBO) population analysis was performed using Weinhold's methodology [26]. All calculations were performed using the GAUSSIAN 03 series of programs [27]. The charge decomposition analysis (CDA) and the extended charge decomposition analysis (ECDA) of Frenking and coworkers [28,29], were performed as implemented in the AOMIX program [30–32].

3. Results and discussion



3.1. Equilibrium structures and electronic properties of the precursor [Cu(RdienR)(X)$_2$] (RdienR = Schiff base; X = Cl or Br) complexes

The equilibrium structures of the precursor $[Cu(RdienR)(X)_2]$ complexes (Scheme 2) computed at the B3LYP/DZVP level of theory correspond to a distorted trigonal bipyramidal geometry (TBP). The equilibrium geometry of the representative complex **1p** along with the coordinated atom numbering scheme is depicted schematically in Fig. 1. Selected geometrical, energetic and electronic parameters of **1p**–**6p** precursors are collected in Table 1.

E = O, S, NH, **X** = Cl, Br and **Y** = Br, I

Scheme 1.

E	X	Complex
O	Cl	**1p**
O	Br	**2p**
S	Cl	**3p**
S	Br	**4p**
NH	Cl	**5p**
NH	Br	**6p**

Scheme 2.

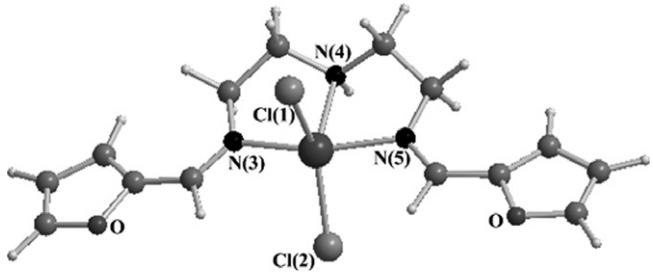


Fig. 1. The equilibrium structure of complex **1p** calculated at the B3LYP/DZVP level.

The two axial sites of the trigonal bipyramidal structure are occupied by the two N-donor atoms of the Schiff base ligand, while the equatorial sites are occupied by the third N-donor atom of the Schiff base and the two halide ligands. The X(1)–X(2)–N(4)–Cu dihedral angle is 180.0°. No significant structural differences are observed in the precursor Cu(II) complexes **1p**–**6p**. The only exception concerns the more acute ∠X(1)–Cu–X(2) bond angles in **5p** and **6p** complexes involving the pyrrole groups in the tridendate Schiff base ligand. It is interesting to be noticed that in all precursors the Cu–X(2) bond is slightly shorter than the Cu–X(1) bond. The different bond distances of the Cu–X(1) and Cu–X(2) bonds could be attributed to the participation of the X(2) halide ligand in hydrogen bond formation with the methylenic, CH_2, hydrogen atoms of the Schiff base ligand (the Cl(1)···H and Br(1)···H distances are found in the range of 2.822–2.906 and 3.052–3.205 Å, respectively) In general, the Cu–X bonds are predicted to be relatively strong with estimated bond dissociation energies, BDE_{Cu-X} in the range of 87.7–97.2 kcal/mol (Table 1).

Dissociation of the second halide X^- ligand from the cationic $[Cu(RdienR)(X)]^+$ species to yield the three-coordinated dicationic $[Cu(RdienR)]^{2+}$ species is much more difficult, the estimated bond dissociation energy was found in the range of 190–202 kcal/mol. This is due to the energy demand for the detachment of the negatively charged halide anion from the positively charged $[Cu(RdienR)(X)]^+$ species.

The calculated hardness, η, values given in Table 1 reflects the relative stability of the **1p**–**6p** precursors. The

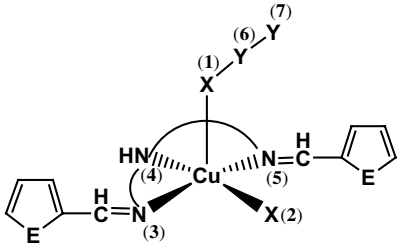
computed dipole moments, μ, are of the same magnitude for **1p**–**4p** complexes (6.8–6.3 D), but are much lower (4.2 and 3.9 D) for **5p** and **6p** precursors. According to the natural bond orbital (NBO) population analysis the copper(II) central metal atom acquires a positive natural atomic charge of 1.2–1.3 |e|, thus accepting electron density from the ligands to both its 3d and 4s AOs. Noteworthy the X(1) halide ligand acquires higher negative natural atomic charge than the X(2) one illustrating that X(1) is more nucleophilic than X(2), thereby it would be expected to be the halide ligand which would interact with the incoming halogen molecule to afford the anionic trihalide ligand.

The pictures of the frontier molecular orbitals (FMOs) of the representative precursor **1p** are depicted in Scheme 3. Analogous are the relevant MOs of the rest of the precursor complexes **2p**–**6p**.

The degenerate lowest unoccupied molecular orbital (LUMO) and LUMO+1 are primarily localized on the furan rings (π^*-type MOs), while the singly occupied MO (SOMO) and the HOMO-1,2,3,4,8 are mainly composed from halide non-bonding np AOs. The SOMO is constructed from the out-of-phase combination of the $3d_{z^2}$ AO of Cu(II) with the p_σ AOs of the halide ligands. The nature of the occupied MOs strongly suggest that the halide ligands are the nucleophilic centers (donors) of the precursor [Cu(RdienR)$(X)_2$] complexes, thus accounting for their capability to associate with the electrophilic halogen Y_2 molecules (acceptors) converting the halide X^- to trihalide $[XY_2]^-$ ligands. Finally, the spin density on the Cu(II) central metal atom amounted to 0.54 and 0.49 |e| for the dichloro, **1p**–**3p**, and dibromo, **4p**–**6p**, derivatives, respectively comes primarily from the difference in 3d orbital occupation and highly altered by spin polarization of the s and p orbitals localized on the five coordinated donor atoms constituting the coordination sphere. Noteworthy is the higher polarization of the spin density for the dibromo **4p**–**6p** derivatives.



Scheme 3.

3.2. Equilibrium structures, bonding mechanism and electronic properties of the trihalide [Cu(RdienR)(X)(XY$_2$)] (RdienR = Schiff base; X = Cl or Br, Y = Cl, Br or I) complexes

The equilibrium structures of the [Cu(RdienR)(X)(XY$_2$)] complexes **1**–**12** (Scheme 4) computed at the B3LYP/DZVP level correspond to a distorted square pyramidal (SP) stereochemistry similar to that of a representative complex **1** depicted schematically in Fig. 2.

It can be seen that the trihalide ligand occupies the axial position of the square pyramidal structure, while the tridentate Schiff base and the halide ligands occupy the four sites in the basal square plane. In all cases, the two heterocyclic rings of the Schiff base are approximately coplanar with respect to the basal plane of the square pyramid. Noteworthy is the TBP → SP stereochemical change introduced by the balkier XY$_2$ ligand probably as a result of steric interactions. Selected geometrical parameters of the [Cu(RdienR)(X)(XY$_2$)] complexes are given in Table 2.

The trihalide [XY$_2$]$^-$ ligand adopting an almost linear configuration (∠X(1)–Y(6)–Y(7) bond angle found in the range of 176.4–178.0°) is coordinated with the copper(II) central atom in a bent fashion (the ∠Cu–X(1)–Y(6) bond angles range from 105.2° up to 114.6°). The latter depends on both the nature of the halide ligand which upon association with the incoming halogen molecule affords the trihalide [XY$_2$]$^-$ ligand and the nature of the R moiety of the Schiff base ligand, following the trend: pyrrol > furan > thiophene.

Scheme 4.

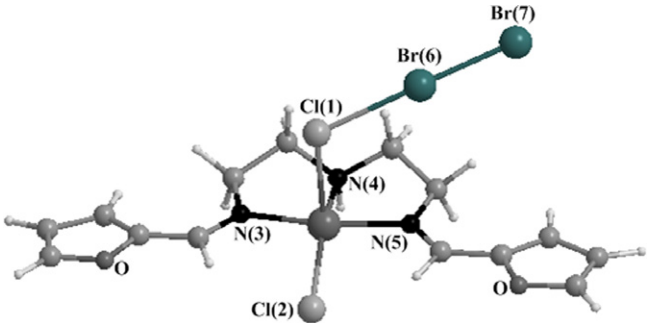

Fig. 2. The equilibrium structure of complex **1** calculated at the b3lyp/dgdzvp level along with the coordinated atom numbering scheme.

Selected energetic and electronic parameters of the [Cu(RdienR)(X)(XY$_2$)] complexes are compiled in Table 3.

Perusal of Table 3 reveals that the dissociation energy of the Cu–X(1) bond, BDE$_{Cu–X(1)}$ was predicted to be 61.9–68.4 kcal/mol. In contrast, the association of the Y$_2$ ligand with the halide ligand of the Cu(II) precursor complexes is characterized by weak interactions; the bond dissociation energy of the X(1)–Y(6) bond, BDE$_{X(1)–Y(6)}$ was predicted to be 10.6–12.5 kcal/mol at the B3LYP/DZVP level. The weak donor–acceptor interactions in the coordinated trihalide ligand is also reflected on the relatively long R$_{X(1)–Y(6)}$ bond distances (2.616–3.014 Å).

The X···Y interactions of the coordinated halide X$^-$ ligand with the halogen Y$_2$ molecules are much weaker than the X···Y interactions in the corresponding "free" [XY$_2$]$^-$ anionic species. Thus, the BDE$_{X–Y}$ values for the [Br$_3$]$^-$, [ClI$_2$]$^-$ and [BrI$_2$]$^-$ anions calculated by ADF methods [15] were 39.6, 37.0 and 36.6 kcal/mol, respectively. In the respective coordinated trihalide ligands the BDE$_{X–Y}$ values are 11.5, 10.9 and 10.8, respectively (Table 3). The stronger X···Y interactions in the "free" [XY$_2$]$^-$ anionic species is also reflected on the R$_{X–Y}$ and R$_{Y–Y}$ bond lengths, the former being shorter and the latter longer than the corresponding bond lengths in the coordinated [XY$_2$]$^-$ ligands (Table 2). It is interesting to be noticed that the Y–Y bond in the coordinated [XY$_2$]$^-$ ligands is elongated by 0.121–0.159 Å with respect to the Y–Y bond of the "free" halogen molecules.

According to the NBO analysis there is a charge transfer from the halide X(1) ligand to Y$_2$ molecule amounted to 0.17–0.26 |e|. The charge density is mainly transferred from the np AOs of the halide X(1) ligand to the np AOs of the terminal Y(7) halogen atom of the associated Y$_2$ molecule, which acquires a negative natural atomic charge of about −0.24 to −0.27 |e| (Table 3). In contrast, the natural atomic charge of the internal Y(6) halogen atom remains practically unaltered and was found to be close to zero. The stabilization energy $\Delta E(2)$ associated with the charge transfer (CT) interactions between the relevant donor–acceptor orbitals computed from the second-order perturbative estimates of the Fock matrix in the NBO analysis according to the equation:

$$\Delta E(2) = q_i F_{ij}^2/(\varepsilon_i - \varepsilon_j)$$

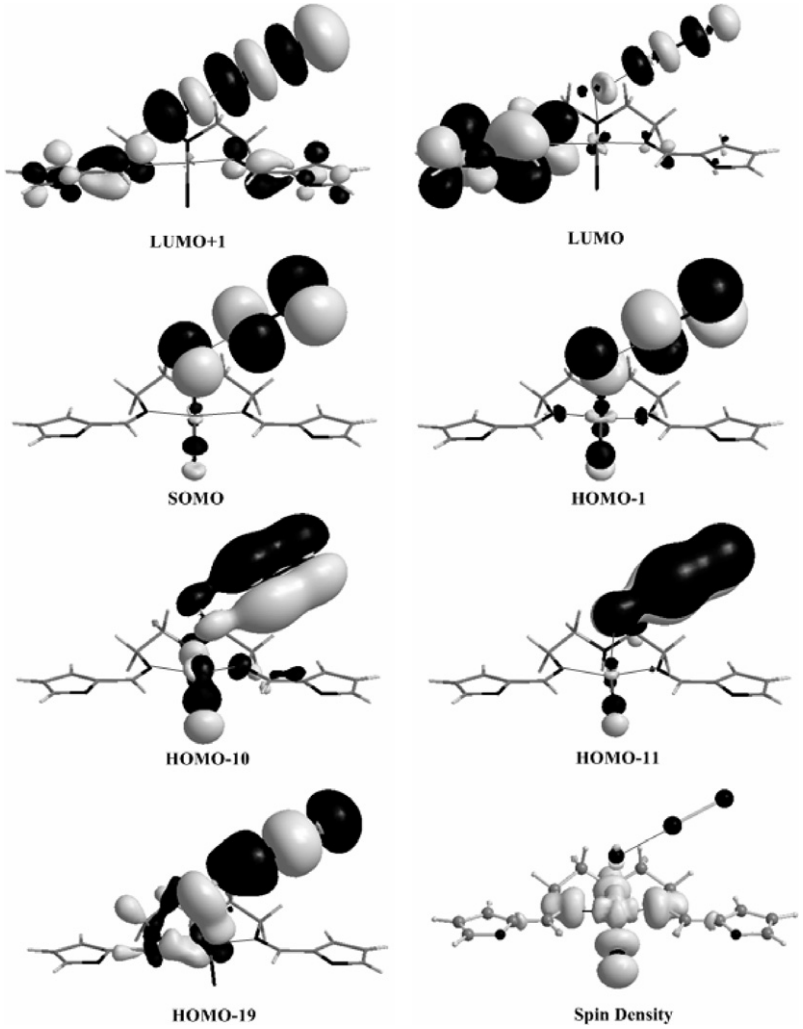
[a] Interaction energies (without BSSE corrections) between the respective fragments estimated by charge decomposition (CDA) analysis techniques.

accounts well for the elongation of the $R_{Y–Y}$ bond in the coordinated trihalide ligands. This equation evaluates the magnitude of the donor–acceptor interaction in terms of the spatial overlap of the NBO, using the off-diagonal Fock-matrix elements F_{ij} and the difference in energy between the NBOs, ε_i–ε_j, weighted by the occupancy of the donor NBO, q_i. The stabilization energies $\Delta E(2)$ introduced by the $n(X) \rightarrow \sigma^*(Y–Y)$ hyperconjugative (stereoelectronic) interactions in the [Cu(RdienR)(X)(XY_2)] complexes along with the occupation of the n(X) and σ^*(Y–Y) MOs are compiled in Table 4.



The most relevant MOs describing the Cl(1)···Br(6)–Br(7) interactions in **1** are depicted schematically in Scheme 5. Analogous are the pictures of the most relevant MOs of the rest complexes **2**–**12**.

The degenerate HOMO−10 and HOMO−11 are π-type MOs primarily localized on the incoming halogen molecules constructed from the np_π orbitals of the halogen

Table 4
Stabilization energies $\Delta E(2)$ (in kcal/mol) introduced by the n(X) → σ*(Y–Y) hyperconjugative interactions in the [Cu(RdienR)(X)(XY_2)] complexes along with the occupation of the n(X) ($P_{n(X)}$) and σ*(Y–Y) ($P_{\sigma^*(Y-Y)}$) MOs computed at the B3LYP/DZVP level

atoms, while the degenerate SOMO and HOMO−1 are their antibonding π* counterparts. The HOMO−19 is a bonding σ-type MO with respect to the Cl(1)···Br(6)–Br(7) interaction constructed from the in-phase interaction of the np_σ orbitals of the halogen atoms (in other words it is a three orbital in-phase interaction localized on the Cl(1)–Br(6)–Br(7) nuclear framework), while the LUMO+1 is its antibonding counterpart. The HOMO−19 corresponds to the perturbative donor–acceptor interactions involving the n(X) donor orbitals localized on the coordinated halide ligand with the antibonding σ*(Y–Y) acceptor orbital localized on the Y–Y moiety. A qualitative orbital interaction diagram of the perturbative donor–acceptor interactions along with the 3D isosurface plot of the n(X) → σ*(Y–Y) hyperconjugative interactions in the representative complex **1** are given in Fig. 3. Finally, the LUMO is mainly localized on the furan ring of the Schiff base ligand in **1**. The spin density on the Cu(II) central metal atom amounted to 0.494 and 0.529 |e| comes primarily from the difference in 3d orbital occupation

Scheme 5.

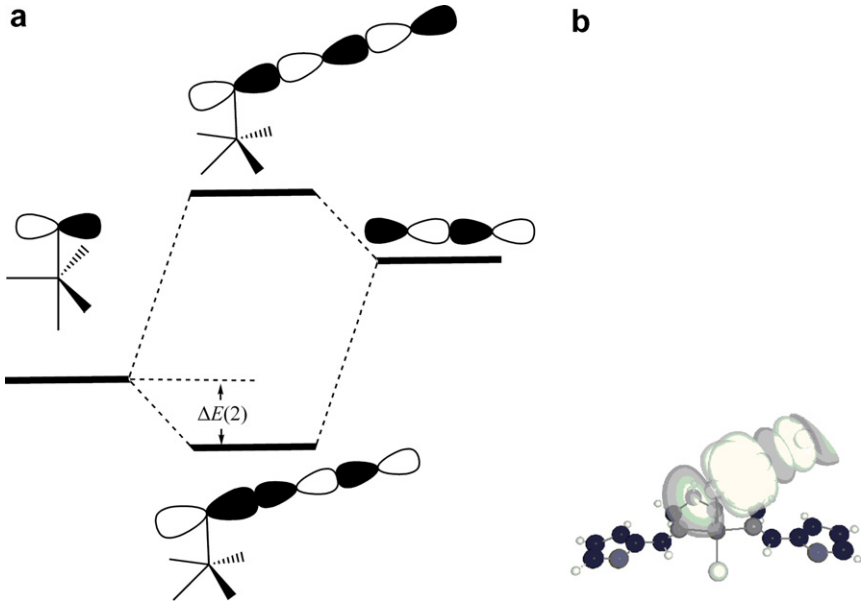

Fig. 3. (a) Perturbative donor–acceptor interactions involving a nonbonding n(X) donor orbital localized on the halide ligand with the antibonding σ*(Y–Y) acceptor orbital localized on the Y–Y moiety of the [Cu(RdienR)(X)(XY_2)] complexes (energy on an arbitrary scale). (b) 3D isosurface plot of the n(Cl) → σ*(Br–Br) hyperconjugative interactions in the representative complex **1**.

(0.522–0.556) and are highly altered by spin polarization of the s and p orbitals localized on the five coordination atoms constituting the coordination sphere.

The favourable n(X) → σ*(Y–Y) interactions primarily affect the $R_{Y–Y}$ bond length through electron delocalization. These hyperconjugative (stereoelectronic) interactions evolved in the course of the formation of the [Cu(RdienR)(X)(XY_2)] complexes upon reacting the precursor [Cu(RdienR)(X_2)] complexes with the Y_2 molecules lead to delocalization of negative charge due to the lone pair of electrons on the halide X^- ligand into the high-energy vacant antibonding σ*(Y–Y) orbital. This charge transfer is reflected on the occupation of the σ*(Y–Y) orbital, which amounts to 0.231–0.345 |e|. Therefore, the occupation of the n(X) orbital is lower than 2.000 (1.636–1.750 |e|). Noteworthy is the higher occupation of the σ*(Y–Y) orbital in the "free" $[XY_2]^-$ anions (0.406–0.518 |e|), while the occupation of the n(X) orbital is lower (1.463–1.568 |e|) than in the coordinated $[XY_2]^-$ ligand. Obviously, the lone pair (donor) → antibonding (acceptor) orbital interactions would have as a result the weakening of the Y–Y bond in the coordinated $[XY_2]^-$ ligand. It should be noticed that the occupation of the n(X) orbital follows the trend: n(Cl) → σ*(I–I) > n(Br) → σ*(I–I) > n(Cl) → σ*(Br–Br) > n(Br) → σ*(Br–Br). Noteworthy is the high contribution of the Y(6)–Y(7) fragment orbitals (FOs) to the bonding HOMO−10 and HOMO−11 and the antibonding SOMO that are involved in the X(1)···Y(6)–Y(7) interactions.

The results from CDA calculations on the complexes **1**–**12** are summarized in Table 5. In all cases the value of the rest term, Δ, in CDA is estimated to be essentially zero suggesting that compounds **1**–**12** could be considered as X(1) → Y(6)–Y(7) donor–acceptor complexes formed by donor–acceptor interactions between the X(1) halide ligand of the precursor complexes and the Y_2 molecule.

Table 5
Charge decomposition analysis of complexes **1**–**12** ($CT_{2→1}$ donation, $CT_{1→2}$ back-donation, $CT_{2→1} - CT_{1→2}$, net charge donation, and gross spin density on Cu, in |e|)[a]

[a] At the B3LYP/DZVP geometries.

Perusal of Table 5 shows that the X(1) → Y_2 donation is much larger than the X(1) ← Y_2 back-donation. As it is expected, the charge transferred from the halide ligand to the halogen molecule follows the trend: Cl → I_2 > Br → I_2 > Cl → Br_2 > Br → Br_2, in line with the trend followed by the occupation of the n(X) donor orbital of the complexes. The same holds true for the "free"

$[XY_2]^-$ anions (Table 5) where the charge transfer is much higher than in the corresponding coordinated anionic trihalide ligands. It is interesting to be noticed that the net charge donation between the fragments is not equal to the difference $CT_{2\rightarrow1} - CT_{1\rightarrow2}$, for the terms donation and back-donation in the CDA method do not include only charge transfer interactions but rather an overall reorganization of electronic density that includes both charge transfer between fragments and electronic polarization of fragments [30–32].

4. Conclusions

The equilibrium geometries and electronic properties of a series of [Cu(RdienR)(X)(XY_2)] (RdienR = Schiff base and X = Cl or Br, Y = Cl, Br or I) complexes and their precursors [Cu(RdienR)(X_2)] were calculated at the B3LYP/DZVP level. The [Cu(RdienR)(X)(XY_2)] complexes adopt a distorted square pyramidal geometry, while their precursors exhibit a trigonal bipyranidal stereochemistry.

According to the NBO population analysis, the association of the incoming halogen Y_2 molecule with a halide X(1) ligand of the precursor complexes correspond to donor–acceptor hyperconjugative interactions involving a nonbonding molecular orbital localized on the coordinated X(1) halide ligand, n(X), (donor orbital) and an antibonding molecular orbital localized on the Y_2 molecule, σ^*(Y–Y) (acceptor orbital). The n(X) $\rightarrow$ σ^*(Y–Y) donor–acceptor interactions are associated with a second-order perturbation stabilization energy, $\Delta E(2)$ of 34.5–52.5 kcal/mol. The n(X) $\rightarrow$ σ^*(Y–Y) interactions lead to delocalization of electron density from the n(X) to σ^*(Y–Y) orbitals resulting in the lowering of the occupation of the n(X) orbital (1.636–1.750 |e|) and the increase of the occupation of the σ^*(Y–Y) orbital (0.231–0.345 |e|). The occupation of the n(X) orbital follows the trend: n(Cl) $\rightarrow$ σ^*(I–I) > n(Br) $\rightarrow$ σ^*(I–I) > n(Cl) $\rightarrow$ σ^*(Br–Br) > n(Br) $\rightarrow$ σ^*(Br–Br). The dissociation energy of the Cu–X(1) bond, $BDE_{Cu-X(1)}$, was estimated in the range of 61.9–68.4 kcal/mol, while the bond dissociation energy of the X(1)–Y(6) bond, $BDE_{Cu-X(1)}$, was found in the range of 10.6–12.5 kcal/mol, thus reflecting the loose association of the Y_2 with the X(1) halide ligand. The loose association of the halogen molecules with the coordinated halide ligand renders the [Cu(RdienR)(X)(XY_2)] complexes good halogen carrier molecules.

The donor–acceptor n(X) $\rightarrow$ σ^*(Y–Y) bonding mechanism was also corroborated by CDA calculations. The estimated interaction energies between the precursor and the halogen molecules amounting −16.2 to −20.0 kcal/mol illustrate that these interactions are much weaker than the donor–acceptor interactions in the "free" $[XY_2]^-$ anions (the estimated interaction energies are found in the range of −44.9 to −49.2 kcal/mol). The charge transferred from the halide ligand to the halogen molecule in the [Cu(RdienR)(X)(XY_2)] complexes follows the trend: Cl $\rightarrow$ I_2 > Br $\rightarrow$ I_2 > Cl $\rightarrow$ Br_2 > Br $\rightarrow$ Br_2, in line with the trend followed by the occupation of the n(X) donor orbital of the complexes.

Abstract

A cyanide-bridged Ni_9Mo_6 cluster (**1**) capped with chelating bidentate ligands was prepared by self-assembling $[Mo(CN)_8]^{3-}$, Ni^{2+}, and bipyridine in a stoichiometric ratio. Compound **1** crystallized in the triclinic system with space group $P\bar{1}$ shows a body-centered Ni cube capped with six Mo entities. The non-covalent π–π stackings present in **1** lead to the extension of the molecule to a 2D sheet. Magnetic data exhibit that intracluster ferromagnetic interactions in **1** are operative through the CN linkage coupled with zero-field splitting of the cluster with an $S = 12$ ground state.

1. Introduction

The chemical design of unique anisotropic materials such as single-molecule magnets (SMMs) and single-chain magnets (SCMs) is dependent on essential ingredients: paramagnetic metal ions as spin carriers and organic spacers as magnetic exchange couplers. The metal ions should be magnetically anisotropic to meet the requirements for SMMs and SCMs. As a useful ligand, cyanide merits to be considered because of its structural and magnetic predictabilities [1].

To achieve such anisotropic systems, blocked molecular precursors, $[M(CN)_pL_q]^{n-}$ (M = anisotropic metal ion, Fe^{III}, Mo^{III}, Re^{II}; L = polydentate ligand) were rationally chosen because the synthons are able to be propagated toward one direction and construct low-dimensional structures [2]. Incorporation of the precursors into their proper counterparts $[ML'_xL''_y]^{m+}$ (M = paramagnetic metal ion, L′ = capping ligand, L″ = labile group) formed discrete bimetallic clusters and one-dimensional (1D) coordination polymers, displaying superparamagnetic properties with slow relaxation of magnetization [2,3].

Among cyanide-bridged systems, some of the octacyanometallate-based clusters showed higher ground-state spins. For instance, the total spin in the ground state of bimetallic assemblies $[Mn\{Mn(MeOH)_3\}_8\{M'(CN)_8\}_6]\cdot x MeOH \cdot y H_2O$ (M′ = W, Mo) has been finally identified as an $S = 39/2$ state resulting from intracluster antiferromagnetic couplings between nine Mn^{II} ($S_{Mn} = 5/2$) and six M'^{V} ($S_{M'} = 1/2$) [4–6]. Subsequently, a family of $M_9M'_6$ clusters (M = Co, Ni; M′ = Mo, W) were characterized with $S = 21/2$ for M = Co and $S = 12$ for M = Ni, respectively [7,8]. In particular, the $Co_9M'_6$ complexes act as SMMs owing to the involvement of single-ion anisotropy of Co(II) [7]. On the other hand, it should be mentioned that all the prepared $M_9M'_6$ analogues to date are however subject to decomposition in air because of facile loss of labile terminal alcohol ligands. It is thus desirable to improve their chemical stability for physical measurements and practical uses.

doi:10.1016/j.poly.2007.09.006

Recently, we demonstrated that the chemical modification of the Ni_9W_6 cluster led to the capped bimetallic molecule exhibiting SMM behavior [9]. To get more insights into structural and magnetic variations of related systems we attempted to examine a bimetallic Ni–Mo system in terms of structure and magnetism.

Herein we report the synthesis, structure, and magnetic properties of a new bimetallic cluster compound $[Ni\{Ni(bpy)(H_2O)\}_8\{Mo(CN)_8\}_6]\cdot 12H_2O$ (**1**) (bpy = 2,2′-bipyridine), which contains the chelating ligand bpy with aromatic pyridyl rings additionally capable of making intermolecular contacts. The ligand substitution on the periphery of the cluster, which gives rise to the symmetry lowering of the molecule and overall crystal system, makes the cluster stable when exposed to air. The intermolecular forces through the aromatic rings of the substituted ligands are established, which play a role in affecting the apparent magnetic nature.

2. Experimental

2.1. Materials

$(Bu_4N)_3[Mo(CN)_8]$ was prepared according to the literature procedure [10]. All the other chemicals and solvents in the synthesis were of reagent grade and used as received.

2.2. Preparation of $[Ni\{Ni(bpy)(H_2O)\}_8\{Mo(CN)_8\}_6]\cdot 12H_2O$ (1)

$(Bu_4N)_3[Mo(CN)_8]$ (0.10 mmol) in MeCN (8 mL) was slowly added on top of a mixed reaction solution of $Ni(ClO_4)_2\cdot 6H_2O$ (0.15 mmol) in H_2O (8 mL) and bpy (0.15 mmol) in MeCN (2 mL). In the dark, red crystals of $[Ni\{Ni(bpy)(H_2O)\}_8\{Mo(CN)_8\}_6]\cdot 38H_2O\cdot MeCN$ were formed after a few days, which are suitable for X-ray. The air-dried product $[Ni\{Ni(bpy)(H_2O)\}_8\{Mo(CN)_8\}_6]\cdot 12H_2O$ (**1**) was obtained in a yield of 8%. Elemental *Anal.* Calc. for $C_{128}H_{104}Mo_6N_{64}Ni_9O_{20}$ (**1**): C, 38.80; H, 2.65; N, 22.62. Found: C, 39.00; H, 2.35; N, 22.26%.

2.3. Physical measurements

Elemental analyses for C, H, and N were performed at the Elemental Analysis Service Center of Seoul Branch, Korea Basic Science Institute. Infrared spectra were obtained from KBr pellets with a Bomen MB-104 spectrometer. Magnetic susceptibilities for **1** were carried out using a Quantum Design MPMS-7 SQUID (dc) and PPMS (ac) susceptometers. Diamagnetic corrections of **1** were estimated from Pascal's tables.

2.4. X-ray structural analysis

X-ray data for **1** were collected on a Bruker SMART APEXII diffractometer equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Preliminary orientation matrix and cell parameters were determined from three sets of ω scans at different starting angles. Data frames were obtained at scan intervals of 0.5° with an exposure time of 10 s per frame. The reflection data were corrected for Lorentz and polarization factors. Absorption corrections were carried out using SADABS [11]. The structure was solved by direct method and refined by full-matrix least-squares analysis using anisotropic thermal parameters for non-hydrogen atoms with the SHELXTL program [12]. All hydrogen atoms except for hydrogens bound to water molecules were calculated at idealized positions and refined with the riding models. Crystallographic data and the details of data collection are listed in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

A reaction of $(Bu_4N)_3[Mo(CN)_8]$:$Ni(ClO_4)_2\cdot 6H_2O$:bpy in a ratio of 2:3:3 in MeCN/H_2O mixed solvent produced red crystals of $[Ni\{Ni(bpy)(H_2O)\}_8\{Mo(CN)_8\}_6]\cdot 12H_2O$ (**1**) in 8% yield. No Cl–O stretching vibrations in the IR spectrum suggest the completion of the reaction. The peculiar CN bands occur at 2179w and 2152w cm^{-1}. The observation of the peaks at higher frequencies, compared with the $[Mo(CN)_8]^{3-}$ molecule (2139w and 2123w cm^{-1}), is definitely associated with the presence of bridging CN groups [13]. The shift stems from both the kinematic coupling, which takes place when a second mass is linked to the cyanide unit, and the fact that the N lone pair on CN is antibonding with respect to the C≡N bond [14].

3.2. Description of the structure

Compound **1** crystallizes in the triclinic system with space group $P\bar{1}$ as analyzed by X-ray crystallography. As

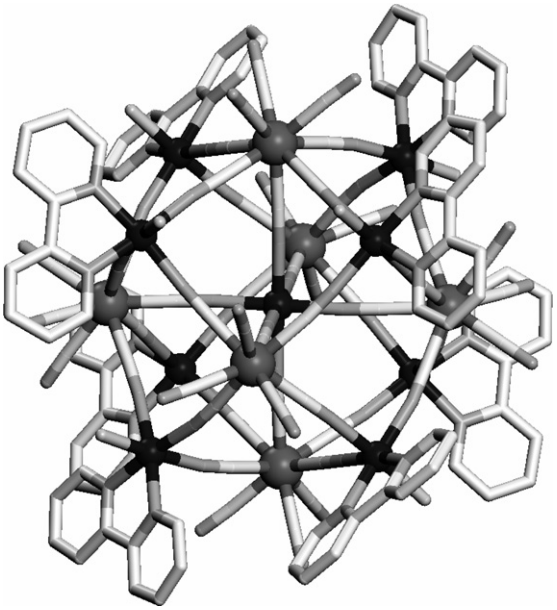

Fig. 1. Molecular view of **1**. Progressively darker shades of gray present C, O, N, Mo, and Ni, respectively.

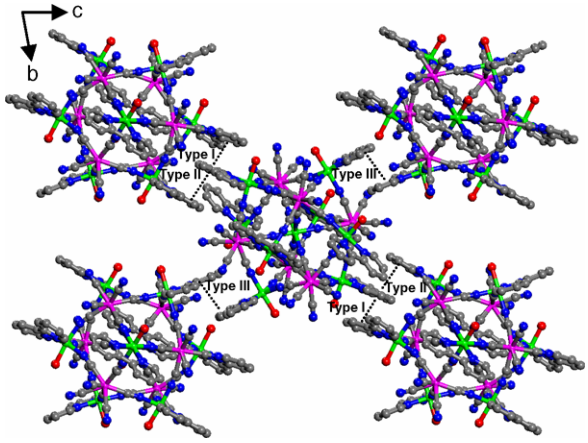

Fig. 2. Extended view of **1** showing three types of intermolecular π–π interactions, resulting in a 2D sheet structure.

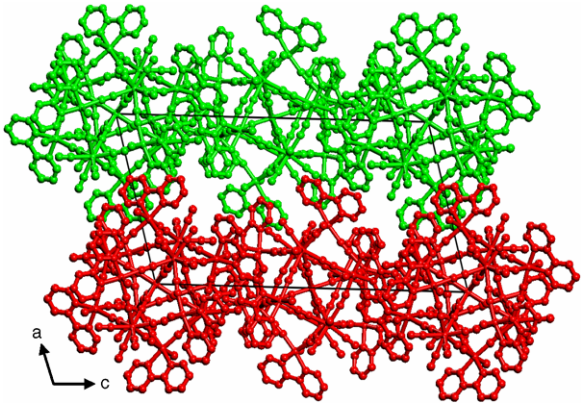

Fig. 3. Side view of **1** illustrating the extended layers.

shown in Fig. 1, the Mo center of $[Mo(CN)_8]^{3-}$ can be described as a distorted dodecahedron [5]. Five among the eight CN groups of octacyanomolybdate are subject to coordination to one central and four peripheral Ni atoms whereas the remaining ones are unbound. The intracluster distances between Ni and Mo atoms are in the range of 5.288–5.364 Å. The geometry of each terminal Ni atom is distorted octahedral, comprising three N atoms from bridging CN groups, two N atoms from bpy, and one O atom from a coordinated water molecule. The overall structure features a body-centered Ni cube capped with six Mo entities. It deserves to be noted that the cluster is air-stable, which is compared with other reported $M_9M'_6$ clusters that are readily decomposed upon exposure to air [4–8]. The stability of **1** evidently arises from the fact that the replacement of the alcohol molecules on the peripheral Ni atoms with the chelating bpy ligands and water molecules would prevent clusters from decomposing as a result of the loss of the labile solvent molecules.

The packing diagram of **1** (Fig. 2) depicts that each cluster has non-covalent π–π contacts where three types of π–π forces exist: the contact spacings are in the range of 3.366–3.774 Å for type I, 3.567–3.893 Å for type II, and 3.437–4.090 Å for type III. These non-covalent stackings generate an extended 2D sheet. In comparison, the bpy-capped Ni_9W_6 possesses only two types of π–π interactions (3.515–3.900 Å for type I and 3.398–3.907 Å for type II), constructing a 1D polymer [9]. Hence, clusters in **1** are more contacted than those in the Ni_9W_6 analogue. The shortest intermolecular metal–metal distance in **1** is 7.897 Å through the type I pathway, which is much longer by ~1 Å than the $M_9M'_6$ clusters [4–8]. Fig. 3 shows the side view of **1** in the ac plane, confirming the layered structure. Despite the longer intercluster distance, each cluster is not well isolated because of the pronounced intermolecular π–π stackings in **1** [15,16].

3.3. Magnetic properties

The cryomagnetic data were collected in the temperature range of 2–300 K (Fig. 4). The room-temperature $\chi_m T$ value is 15.49 cm^3 K mol^{-1}, which is somewhat larger than the spin-only case (11.25 cm^3 K mol^{-1}) expected for non-coupled nine Ni ($S_{Ni} = 1$) and six Mo ions ($S_{Mo} = 1/2$). Decreasing the temperature makes $\chi_m T$ increased to 117.24 cm^3 K mol^{-1}at 20 K and then abruptly reduced to 25.07 cm^3 K mol^{-1} at 2 K. The gradual rise in $\chi_m T$ on cooling indicates the operation of ferromagnetic interactions within the cluster and the drop at $T < 20$ K is relevant with the combined contributions from zero-field splitting, Zeeman effects under the applied field, and intercluster magnetic interactions. To roughly estimate the magnetic behavior among spin centers we fitted the high-temperature data ($T > 80$ K) with the Curie–Weiss equation, affording

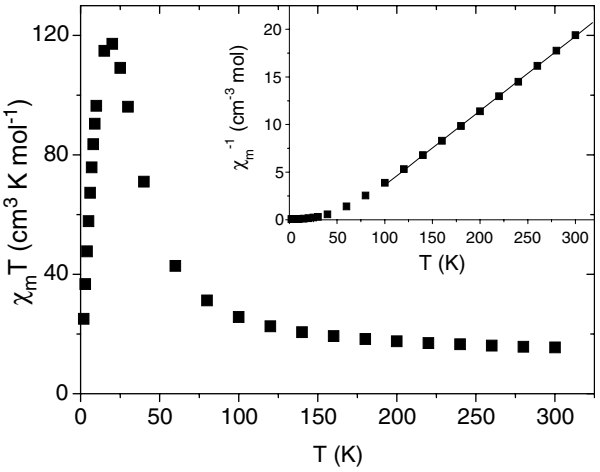

Fig. 4. Plot of $\chi_m T$ vs. T. The inset shows the inverse magnetic susceptibility data. The solid line denotes the result of the Curie–Weiss fit.

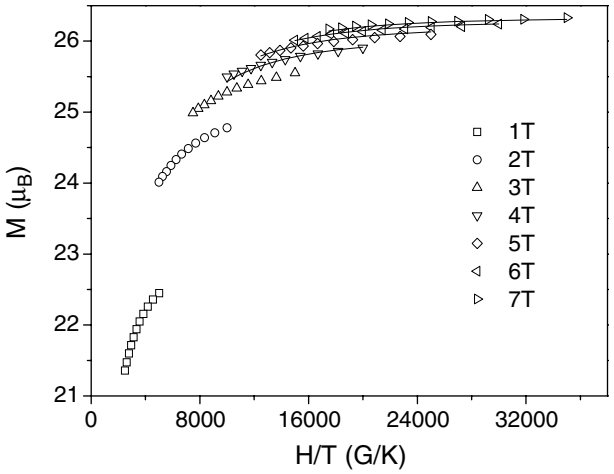

Fig. 6. Plot of reduced magnetization vs. H/T at several magnetic fields. The solid lines are fits to $S = 12$.

$\theta = 50.4$ K (inset of Fig. 4). The positive Weiss constant might indicate that ferromagnetic couplings are present between Ni(II) and Mo(V) spins through the CN bridges.

To inspect a ground state of the cluster the M(H) data were measured at 2 K (Fig. 5). The magnetization is rapidly saturated, reaching 26.27 μ_B at 7 T. The early saturation at low fields pertains to intracluster ferromagnetic interactions, which is affirmed by the theoretical curve (dotted line in Fig. 5) from the Brillouin function for magnetically isolated nine Ni(II) and six Mo(V) ions with $g = 2.2$. The ferromagnetic nature within the cluster can be interpreted on the basis of a simple orbital consideration. The magnetic 4d orbital of Mo matches in π-symmetry with the corresponding pπ orbital of C on the CN bridge whereas on the Ni side the e_g orbital is overlapped with the respective N pσ orbital on CN. As a consequence, the magnetic orbitals of the Mo and Ni centers are orthogonal to each other, eventually leading to the observed ferromagnetic behavior. The ground state of the cluster is confirmed to be an $S = 12$ as the experimental data are fairly reproduced by the Brillouin curve (solid line in Fig. 5) assuming $S = 12$.

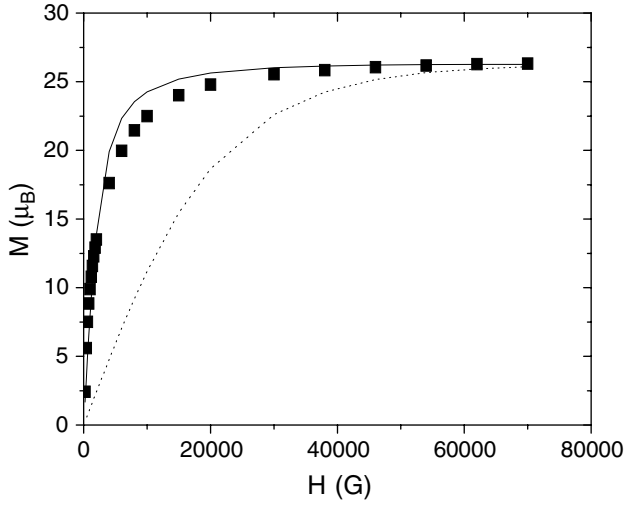

Fig. 5. Field dependence of the magnetization (M). The solid and dotted lines represent the theoretical curves calculated from the Brillouin function with $S = 12$ and non-interacting $9S_{Ni} + 6S_{Mo}$, respectively.

To examine the total spin ground state and the D parameter the reduced magnetization at low temperatures (2–4 K) and high magnetic fields (1–7 T) was investigated (Fig. 6). The isofield lines are not superimposable, clearly disclosing the onset of zero-field splitting. The fit of the data by using the ANISOFIT 2.0 program [17] is feasible only at $H = 4$–7 T, giving the values of $g = 2.2$, $D = -0.08$ cm^{-1}, and $E = 0.02$ cm^{-1}, where D and E denote the axial and rhombic zero-field splitting parameters, on the condition of an $S = 12$ and the absence of intermolecular magnetic interactions. This is because the low-field data are more significantly influenced by intercluster magnetic interactions and/or the population of low-lying excited states [18]. The surface modification of the solvated parent cluster by bpy causes the crystal system of **1** to change from monoclinic ($C2/c$) to triclinic ($P\bar{1}$), the lowest symmetry found in the $M_9M'_6$ family [4–8]. The lowering of the crystal symmetry may be associated with the observed magnetic anisotropy.

Fig. 7 illustrates out-of-phase ac susceptibility signals (χ''_m) at low temperatures and several oscillating frequencies. The observation of the frequency dependence supports that the magnetization is relaxed slowly, which is reminiscent of SMM properties. However, since no maxima in the $\chi''_m(T)$ plot are present, it is not possible to conclude the genuine magnetic nature and perform any quantitative analysis on spin dynamics. When compared with the bpy-capped Ni_9W_6 complex that exhibits peaks in $\chi''_m(T)$, the absence of the cusp temperatures in **1** probably concerns the weaker intracluster magnetic interactions and the more extended intermolecular contacts of **1**.

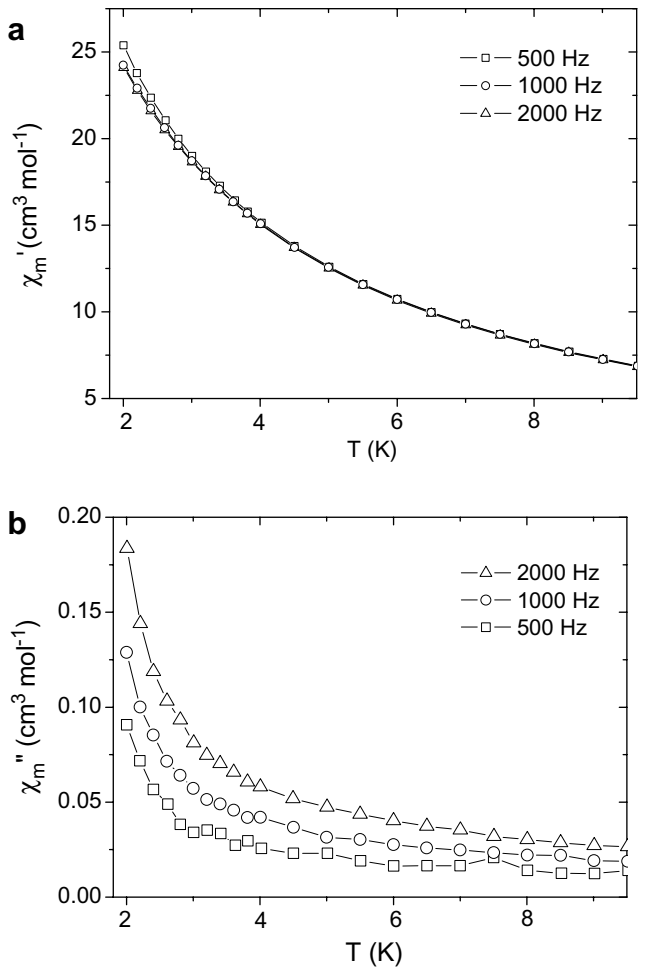

Fig. 7. Plots of (a) χ'_m and (b) χ''_m vs. T at an ac field of 5 G, zero dc field, and several frequencies.

4. Conclusion

In summary, we have prepared a cyanide-bridged Ni_9Mo_6 cluster (**1**) chelated with chelating bidentate ligands by self-assembling $[Mo(CN)_8]^{3-}$, Ni^{2+}, and bpy in a stoichiometric ratio. The 2D extended architecture is generated by the π–π interactions between pyridyl groups of bpy ligands. Magnetic data for **1** show that intracluster ferromagnetic interactions are mediated through the CN linkage and zero-field splitting of the cluster with an $S = 12$ ground state is present.

Abstract

The new triply-bridged dinuclear copper(II) complexes, $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)_2(dpyam)_2](ClO_4)\cdot H_2O$ (**1**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(dpyam)_2](S_2O_8)$ (**2**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(bpy)_2](NO_3)_2$ (**3**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](BF_4)_2\cdot 0.5H_2O$ (**4**), $[Cu_2(\mu\text{-}O_2CCH_2CH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](NO_3)_2$ (**5**) and $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}Cl)(bpy)_2]Cl\cdot 8.5H_2O$ (**6**) (dpyam = di-2-pyridylamine, bpy = 2,2′-bipyridine, phen = 1,10-phenanthroline), have been synthesized and characterized crystallographically and also their spectroscopic and magnetic properties have been studied. A structural classification of this type of dimers, based on the data obtained from X-ray diffraction analysis in the present work and those reported in the literature has been performed. In these complexes, the local geometry around the copper centre is generally a distorted square pyramid and distorted trigonal bipyramid with different degrees of distortion. The global geometry of the dinuclear complexes can be described in terms of the relative arrangement of the two five-coordinate environments, giving rise to different classes (A–F) of complexes. The most logical explanations have been provided for each class describing different magnetic interactions. Practically, there is a clear correlation between structural data and *J* values of the class B complexes. Extended Hückel calculations were performed for the present complexes **1**–**6**, as well as for some other class B complexes, showing the different molecular orbitals involved in their corresponding frontier orbitals, together with their energy. The results are found to be useful for the proper interpretation and correlation of the magnetic data and the dinuclear structure of the present complexes.

1. Introduction

Dinuclear copper(II) carboxylates with a pair of copper atoms held by carboxylato-O,O′ bridges are of interest toward understanding intramolecular magnetic exchange phenomena and for deriving magneto-structural correlations [1–12]. The magnetic interaction in the triply-bridged dinuclear copper(II) complexes can occur via bridging ligands in various pathways [2,7,13–15], which depends on the coordination geometry of copper(II) ion, the Cu···Cu separation, the bond angles at the bridging atoms, the dihedral angle between the planes containing the copper(II) ions and the copper-bridging ligand bond lengths. Structurally, the triply-bridged dinuclear copper(II) carboxylato compounds with didentate chelating ligands and a five coordination of the Cu(II) ion show an extensive

doi:10.1016/j.poly.2007.09.009

range of compounds with a distortion between regular trigonal bipyramidal and regular square-based pyramidal. This feature can be useful for understanding the relationships between structural features and the value of the intramolecular magnetic exchange interaction in the triply-bridged dinuclear unit.

Our previous reports [10–12] dealt with the distortion of the geometries ranging between regular trigonal bipyramidal and regular square-based pyramidal, and the structurally dependent magnetic properties displayed by the five-coordinate dinuclear copper(II) ions. The structures of complexes $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)(\mu\text{-}Cl)(dpyam)_2](PF_6)$, $[Cu_2(\mu\text{-}O_2CH)_2(\mu\text{-}OH)(dpyam)_2](PF_6)$, $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)(\mu\text{-}Cl)(dpyam)_2](ClO_4)\cdot 0.5H_2O$ [10,11] reveal a distorted trigonal bipyramidal stereochemistry, with a d_{z^2} ground state and thus the major lobe of the magnetic orbital will be axially directed towards a single bridging ligand: the hydroxido anion in these cases. This feature contributes to the observed ferromagnetic coupling between copper(II) magnetic centres. However, the structures of complexes $[Cu_2(\mu\text{-}O_2CCH_2CH_3)_2(\mu\text{-}OH)(dpyam)_2](ClO_4)$ [11], $[Cu_2(\mu\text{-}O_2CCH_2CH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(bpy)_2](ClO_4)_2$ [12] and $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](ClO_4)_2$ [12], reveal a square-pyramidal stereochemistry with a $d_{x^2-y^2}$ ground state and the ferromagnetic coupling is still observed between copper(II) magnetic centres. On the contrary, the complex $[Cu_2(\mu\text{-}O_2CCH_3)_2(\mu\text{-}OCOCH_3)(dpyam)_2](BF_4)$ [12], which has a square-pyramidal stereochemistry with a $d_{x^2-y^2}$ ground state, reveals an antiferromagnetic interaction between the Cu(II) ions. For a better understanding of the magneto-structural correlation of the triply-bridged dinuclear copper(II) carboxylato complexes with different copper(II) environment and bridging configuration now an additional six new triply-bridged dinuclear copper(II) compounds are reported with different degrees of distortion, i.e. $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)_2(dpyam)_2](ClO_4)\cdot H_2O$ (**1**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(dpyam)_2](S_2O_8)$ (**2**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(bpy)_2](NO_3)_2$ (**3**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](BF_4)_2\cdot 0.5H_2O$ (**4**), $[Cu_2(\mu\text{-}O_2CCH_2CH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](NO_3)_2$ (**5**) and $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}Cl)(bpy)_2]Cl\cdot 8.5H_2O$ (**6**). The compounds have been characterized by X-ray crystallography, IR, EPR and electronic spectra. The results of magnetic susceptibility measurements of compounds **1**–**6** from 5 to 250 K are investigated and discussed in relation with those of other relevant compounds. We have also undertaken a theoretical calculation using Extended Hückel methods on the different degree of structural distortion that influence their electronic and magnetic properties.

2. Experimental

2.1. Materials and measurements

1,10-Phenanthroline, 2,2′-bipyridyl and di-2-pyridylamine were purchased as commercial chemicals from Aldrich. All reagents are commercial grade materials and were used without further purification. Elemental analyses (C, H, N) were determined on a Perkin–Elmer PE 2400 CHNS/O Analyzer. IR spectra were recorded on Spectrum One FT-IR spectrophotometer as KBr disc in the 4000–450 cm^{-1} spectral range. Solid-state (diffuse reflectance) electronic spectra were measured as polycrystalline samples on a Perkin–Elmer Lambda2S spectrophotometer, over the range 8000–18 000 cm^{-1}. The X-band powder EPR spectra were recorded using a Bruker ESR-300 X-band instrument operating at room temperature with DPPH ($g = 2.0036$) as a reference. Magnetic susceptibility measurements (5–250 K) were carried out using a Quantum Design MPMS-5 5T SQUID magnetometer (measurements carried out at 0.1 T). Data were corrected for magnetisation of the sample holder and for diamagnetic contributions, which were estimated from the Pascal constants.

Molecular orbital calculations have been carried out with the CACAO (computer-aided composition of atomic orbitals) program [16], which is a program based on extended Hückel (EH) type of analysis, using the crystallographic coordinates. This approach was followed to obtain a better idea on how geometric distortion and the disposition of the magnetic orbitals of each Cu(II) ion influence their electronic and magnetic properties and to compare the magnitude of the ferromagnetic interaction of complexes within the same class. The present work has focused on class B complexes **2**–**6**, **8** and **9**, as well as class A complex **1**.

2.2. Synthesis

2.2.1. $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)_2(dpyam)_2](ClO_4)\cdot H_2O$ (**1**)

A hot methanol solution (10 ml) of dpyam (0.171 g, 1.0 mmol) was added to a hot aqueous solution (20 ml) of $Cu(O_2CH)_2$ (0.154 g, 1.0 mmol). Then solid HCOONa (0.204 g, 3.0 mmol) was added, followed by solid $NaClO_4$ (0.195 g, 1.0 mmol). A green powder immediately formed, after which the mixture was warmed with adding methanol (10 ml) and water (10 ml), yielding a clear green solution. On slow evaporation at room temperature for two weeks product **1** was isolated as blue rod-shape crystals. They were filtered off, washed with the mother liquid and air-dried. Yield: ca. 30%. *Anal.* Calc. for $C_{21}H_{23}ClCu_2N_6O_9$: C, 37.87; H, 3.48; N, 12.62. Found: C, 37.59; H, 3.33; N, 12.53%.

2.2.2. $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(dpyam)_2](S_2O_8)$ (**2**)

A hot methanol solution (10 ml) of dpyam (0.171 g, 1.0 mmol) was added to a hot methanol solution (20 ml) of $Cu(O_2CCH_3)_2\cdot H_2O$ (0.181 g, 1.0 mmol). Then a hot aqueous solution (10 ml) of $Na_2S_2O_8$ (0.119 g, 0.5 mmol) was added to the mixture, yielding a green solution. After two weeks, green-square crystals of compound **2** were obtained. The crystals were filtered off, washed with mother liquor and air-dried. Yield: ca. 60%. *Anal.* Calc.

for $C_{22}H_{24}Cu_2N_6O_{12}S_2$: C, 34.97; H, 3.20; N, 11.12. Found: C, 34.91; H, 3.09; N, 11.42%.

2.2.3. $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(bpy)_2](NO_3)_2$ (3)

The warm methanol solution (20 ml) of bpy (0.156 g, 1.0 mmol) was added to a warm aqueous solution (5 ml) of $Cu(O_2CCH_3)_2 \cdot H_2O$ (0.181 g, 1.0 mmol). Then solid $NaNO_3$ (0.043 g, 0.5 mmol) was added to the mixture, yielding a clear blue solution. After one week, blue needle-shaped crystals of compound **3** were obtained. The crystals were filtered off, washed with mother liquor and air-dried. *Anal.* Calc. for $C_{22}H_{22}Cu_2N_6O_{10}$: C, 40.18; H, 3.37; N, 12.78. Found: C, 40.10; H, 3.31; N, 12.97%.

2.2.4. $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](BF_4)_2 \cdot 0.5H_2O$ (4)

The warm methanol solution (20 ml) of phen (0.198 g, 1.0 mmol) was added to a warm aqueous solution (5 ml) of $Cu(O_2CCH_3)_2 \cdot H_2O$ (0.181 g, 1.0 mmol). Then solid $NaBF_4$ (0.055 g, 0.5 mmol) was added to the mixture, yielding a clear greenish-blue solution. After one week, violet-coloured crystals of compound **4** were obtained as needles. The crystals were filtered off, washed with mother liquor and air-dried. *Anal.* Calc. for $C_{26}H_{24}B_2Cu_2F_8N_4O_{4.5}$: C, 40.81; H, 3.16; N, 7.32. Found: C, 40.88; H, 2.91; N, 7.49%.

2.2.5. $[Cu_2(\mu\text{-}O_2CCH_2CH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](NO_3)_2$ (5)

The warm methanol solution (20 ml) of phen (0.198 g, 1.0 mmol) was added to a warm aqueous solution (5 ml) of $Cu(NO_3)_2 \cdot 3H_2O$ (0.241 g, 1.0 mmol). Then solid $NaO_2CCH_2CH_3$ (0.047 g, 0.5 mmol) was added to the mixture, yielding a blue solution. On slow evaporation, its color became greenish-blue. After one week, greenish-blue crystals of compound **5** were obtained. The crystals were filtered off, washed with mother liquor and air-dried. *Anal.* Calc. for $C_{27}H_{24}Cu_2N_6O_{10}$: C, 45.07; H, 3.36; N, 11.68. Found: C, 45.01; H, 3.25; N, 11.83%.

2.2.6. $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}Cl)(bpy)_2]Cl \cdot 8.5H_2O$ (6)

The warm methanol solution (20 ml) of bpy (0.156 g, 1.0 mmol) was added to a warm aqueous solution (5 ml) of $Cu(O_2CCH_3)_2 \cdot H_2O$ (0.181 g, 1.0 mmol). Then solid NaCl (0.029 g, 0.5 mmol) was added to the mixture, yielding a clear blue solution. After one week, greenish-blue crystals of compound **6** were obtained. The crystals were filtered off, washed with mother liquor and air-dried. *Anal.* Calc. for $C_{22}H_{37}Cl_2Cu_2N_4O_{11.5}$: C, 35.72; H, 5.05; N, 7.57. Found: C, 35.55; H, 5.24; N, 7.61%.

2.3. Crystallography

The X-ray single-crystal data for all compounds were collected at 298 K on a 1 K Bruker SMART CCD area-detector diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a detector distance of 4.5 cm and swing angle of −35°. A hemisphere of the reciprocal space was covered by combination of three sets of exposures; each set had a different ϕ angle (0, 88, 180°) and each exposure of 40 s covered 0.3° in ω. Data reduction and cell refinements were performed using the program SAINT [17] An empirical absorption correction by using the SADABS [18] program was applied, which resulted in transmission coefficients ranging from 0.683 to 1.000 for compound **1**, 0.862–1.000 for compound **2**, 0.679–1.000 for compound **3**, 0.744–1.000 for compound **4**, 0.764–1.000 for compound **5** and 0.581–1.000 for compound **6**.

The structures were solved by direct methods and refined by full-matrix least-squares method on $(F_{obs})^2$ with anisotropic thermal parameters for all non-hydrogen atoms using the SHELXTL-PC V 6.12 software package [19] All hydrogen atoms in **1, 2, 3** and **5** were located geometrically and refined isotropically while all hydrogen atoms in **4** and **6** were fixed and allowed to ride on attached atoms. A water molecule in **4** was located with an occupancy of 0.5. For the best results of the refinement of the structure of **6** the oxygen atoms of the overall 8.5 water molecules were refined without hydrogen atoms except a few of them. Two water molecules are disordered with site occupancy of 0.5 for both conformers and two water molecules are located with site occupancies 0.25. All non-H atoms in **6** were refined anisotropically except three oxygen atoms of water molecules. The ClO_4^- anion in **1**, $S_2O_8^{2-}$ in **2**, NO_3^- in **3** and **5**, and BF_4^- in **4** showed disorder; the occupancies of the disordered positions were initially refined and later fixed at 0.5. These disordered counterions have some unreasonable Cl/S/N···O distances with quite high U_{eq} values, which are usually found for the disordered groups. However, the average Cl/S/N···O distances are not significantly different from the normal ordered ones (ClO_4(**1**), 1.334–1.460 Å, $d_{av} = 1.408$ Å (1.414 Å); S_2O_8 (**2**), 1.344–1.671 Å, $d_{av} = 1.470$ Å (1.472 Å); NO_3 (**3**), 1.072–1.350 Å, $d_{av} = 1.222$ Å (1.239 Å); NO_3 (**5**), 1.069–1.350 Å, $d_{av} = 1.208$ Å (1.239 Å).

The molecular graphics were created by using the SHELXTL-PC [19] package. The crystal and refinement details for compounds **1**–**6** are listed in Table 1. Selected bond lengths and angles are given in Tables S4 and S5.

3. Results and discussion

3.1. Description of the crystal structures

3.1.1. Crystal structure of $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)_2(dpyam)_2](ClO_4) \cdot H_2O$ (1)

The structure of **1** consists of a symmetric dinuclear $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)_2(dpyam)_2]^+$ cation, with ClO_4^- counter anions. This unit is depicted in Fig. 1, together with the numbering scheme. Both copper(II) ions of the complex cation are linked through a double hydroxido

and a formato bridge, leading to a Cu–Cu distance of 2.902(1) Å. The coordination environment around each copper(II) ion can be best described as tetrahedrally distorted square pyramidal CuN_2O_2O' chromophore with a τ value of 0.27, the structure index is defined as $\tau = (\beta - \alpha)/60$, where β and α are the largest coordination angles, $\tau = 0$ for square pyramidal (SP) and $\tau = 1$ for trigonal bipyramidal (TBP) geometry) [20]. The four shorter bonds in the basal plane involve two nitrogen atoms of the dpyam ligand (Cu–N 2.005(3) and 2.030(3) Å), two oxygen atoms of bridging hydroxido ligands (Cu–O 1.952(3) and 1.955 Å). An oxygen atom of the triatomic bridging formato ligand completes the five-coordination at Cu(1) atom (Cu–O(3) 2.345(3) Å), consistent with the typical square-pyramidal geometry. The four basal atoms are not coplanar, showing a significant tetrahedral distortion with a dihedral angle of 23.8° formed between CuO_2 and CuN_2 planes and the copper atom is displaced by 0.189 Å from the basal plane toward the O(3) atom. The dinuclear unit is nearly planar and the dihedral angle between the basal N_2O_2 planes is 165.6°. The bridging angles in the equatorial positions, Cu(1)–O(1)–Cu(1A) and Cu(1)–O(2)–Cu(1A) are 95.8(1)° and 96.0(1)°, respectively. This structural feature is comparable to the planar dihydroxido-copper(II) complexes to which their structures and magnetic properties are well characterized

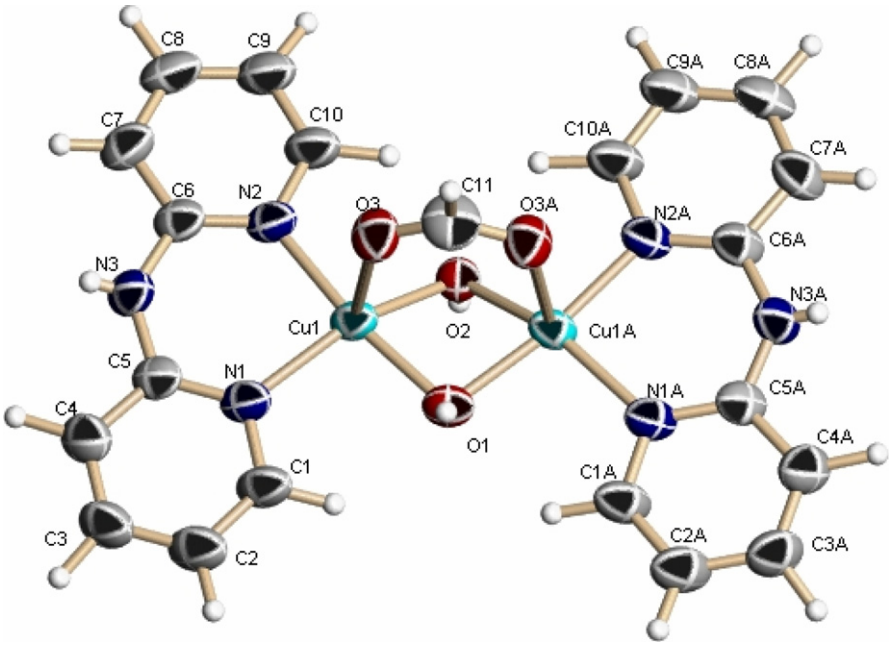

Fig. 1. ORTEP 50% probability plot of the cation in $[Cu_2(\mu\text{-}O_2CH)(\mu\text{-}OH)_2(dpyam)_2](ClO_4)\cdot H_2O$ (**1**), atoms with an "A" are generated by a mirror plane. The uncoordinating anion and water molecules are omitted for clarity.

experimentally and theoretically [21–28]. The dpyam ligands are essentially planar with small dihedral angles of 6.6° between the individual pyridine rings. The bite angles of the dpyam ligands (N–Cu–N, 91.9(1)°) are only slightly greater than 90°.

The lattice is further stabilized by a hydrogen bonding between the amine N and the oxygen atom of formato group with N···O contact of 2.796(1) Å; between the oxygen atom of bridging hydroxido group and the oxygen atom of lattice water molecules with O···O contacts of 2.865(1) Å; between the oxygen atom of bridging of both hydroxido groups O···O contacts of 2.855(1) Å along *a*- and *b*-axes, leading to a two dimensional supramolecular structure (see Fig. 2).

*3.1.2. Crystal structures of $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(dpyam)_2](S_2O_8)$ (**2**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(bpy)_2](NO_3)_2$ (**3**), $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](BF_4)_2\cdot H_2O$ (**4**), $[Cu_2(\mu\text{-}O_2CCH_2CH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(phen)_2](NO_3)_2$ (**5**)*

The structure of compounds **2**–**5** are made up of a dinuclear $[Cu_2(\mu\text{-}O_2CCH_3/O_2CCH_2CH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(dpyam/bpy\text{ or }phen)_2]^+$ cation, an uncoordinated $S_2O_8^{2-}$, NO_3^-, BF_4^- and NO_3^- anion, respectively. This unit is depicted in Fig. 3 for complex **2** and Figs. S1–S3 for complexes **3**–**5**, together with the numbering scheme, with selected distances and angles listed in Tables S4 and S5. In complexes **2**–**5**, both Cu(II) ions in the dinuclear unit are linked through a hydroxido, an aqua and a didentate

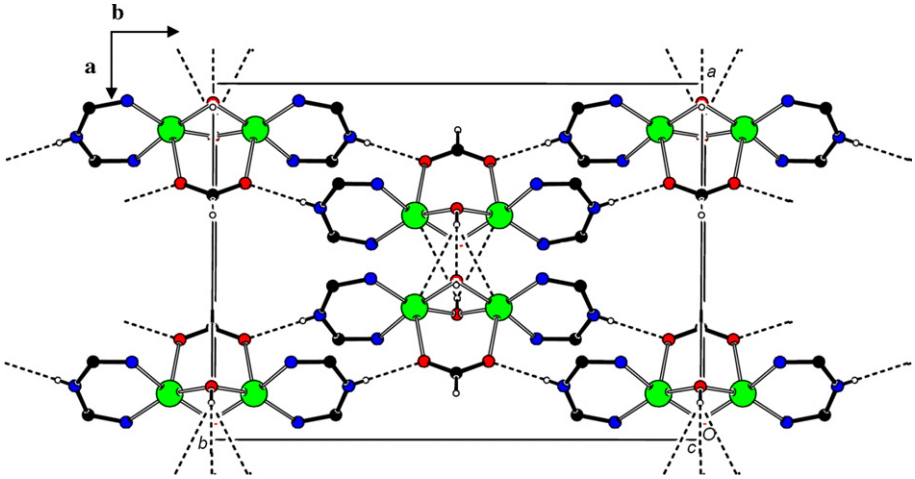

Fig. 2. H-bond system providing an two-dimensional array of complex **1**.

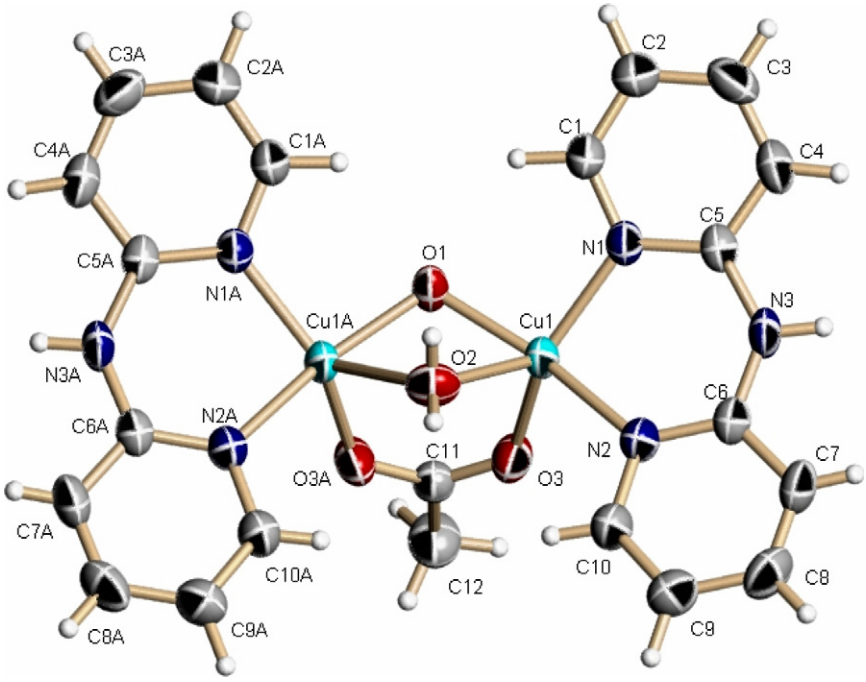

Fig. 3. ORTEP 50% probability plot of the cation in $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}OH_2)(dpyam)_2](S_2O_8)$ (**2**), atoms with an "A" are generated by a mirror plane. The uncoordinating anion is omitted for clarity.

κ-O^1,O^2 bridging carboxylate ligand resulting in a five-coordinate species at each copper atom. The coordination environment around each Cu(II) ion can be best described as distorted square pyramidal, with a CuN_2O_2O' chromophore (see Fig. 3 and Figs. S1–S3) and the τ values of 0.43 for **2**, 0.21 and 0.19 for **3**, 0.21 and 0.16 for **4** and 0.08 and 0.19 for **5**. The carboxylate groups are in the didentate η^1:η^1:μ-bridging mode, locating in the equatorial positions. The fifth axial position is occupied by a bridging water molecule at a longer distance of 2.414(2) Å for **2**, 2.347(1) and 2.460(2) Å for **3**, 2.374(3) and 2.390(3) Å for **4** and, 2.344(4) and 2.368(4) Å for **5**. The copper atoms are displaced from the basal plane towards the apical O atom of aqua by 0.225(4) Å for **2**, 0.152(2) and 0.115(1) Å for **3**, 0.124(1) and 0.090(1) Å for **4** and 0.147(1) and 0.148(1) Å for **5**. The CuN_2O_2 chromophores are non-planar with dihedral angles of 40.4(1)° for **2**, 14.5(1) and 11.6(1)° for **3**, 17.0(1)° and 8.6(1)° for **4** and 14.6(1)° and 12.2(1)° for **5**, between the CuN_2 and CuO_2 planes. The dihedral angle between the basal planes is 164.4(1)° for **2**, 120.5(1)° for **3**, 114.6(3)° for **4** and 122.3(2)° for **5**.

For compound **2**, the lattice is stabilized by a hydrogen bonding between the amine N and the oxygen atom of S_2O_8 with N···O distance of 2.799–2.919 Å and between the oxygen atom of bridging hydroxido/aqueous groups and the oxygen atoms of S_2O_8 with O···O contacts of 2.659–3.364 Å parallel to *a*- and *b*-axes, leading to a two-dimensional supramolecular structure (see Fig. 4).

For compounds **3** and **5**, the lattice is stabilized by a hydrogen bonding between the oxygen atom of bridging hydroxido/aqueous groups and the oxygen atoms of NO_3^- with O···O contacts of 2.712–3.020 Å for **3** and 2.785–3.168 Å for **5**. That of compound **4** is stabilized by a hydrogen bonding between the oxygen atom of bridging hydroxido/aqueous groups and fluoride atoms of BF_4^- with O···F contacts of 2.744–3.390 Å.

3.1.3. Crystal structure of $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}Cl)(bpy)_2]Cl \cdot 8.5H_2O$ (6)

The structure of compound **6** consists of a dinuclear $[Cu_2(\mu\text{-}OH)(\mu\text{-}O_2CCH_3)(\mu\text{-}Cl)(bpy)]^+$ cation, with Cl^- counter anions and 8.5 molecules of lattice water. This cation is depicted in Fig. 5, together with the numbering scheme, with selected distances and angles listed in Table S5. Each copper(II) ion has a distorted square pyramidal geometry of the CuN_2O_2Cl chromophore, with a τ value of 0.41 and 0.28 for Cu1 and Cu2, respectively. Two nitrogen atoms of the bpy ligand, two oxygen atoms of the bridging acetato and hydroxido ligands form the square bases. The axial site of each copper(II) atom is occupied by a chlorido ligand at distances of 2.632 and 2.657 Å. The *syn*,*syn*-coordinated acetato ligand bridges the two equatorial planes, giving a Cu–Cu distance of 3.040(1) Å. The CuN_2O_2 chromophore are non-planar with dihedral angles of 27.4(1)° and 18.9(1)° for **6**, between the CuN_2 and CuO_2 planes. The dihedral angle between the equatorial planes are 123.0(4)° for Cu1 and Cu2. The bridging angles (Cu(1)–O(1)–Cu(2) and Cu(1)–Cl(1)–Cu(2) are 103.3(1)° and 70.2(1)°, respectively.

The lattice is further stabilized by hydrogen bonding between the hydroxido O and the chloride anion with a short O···Cl contact of 2.910(1) Å.

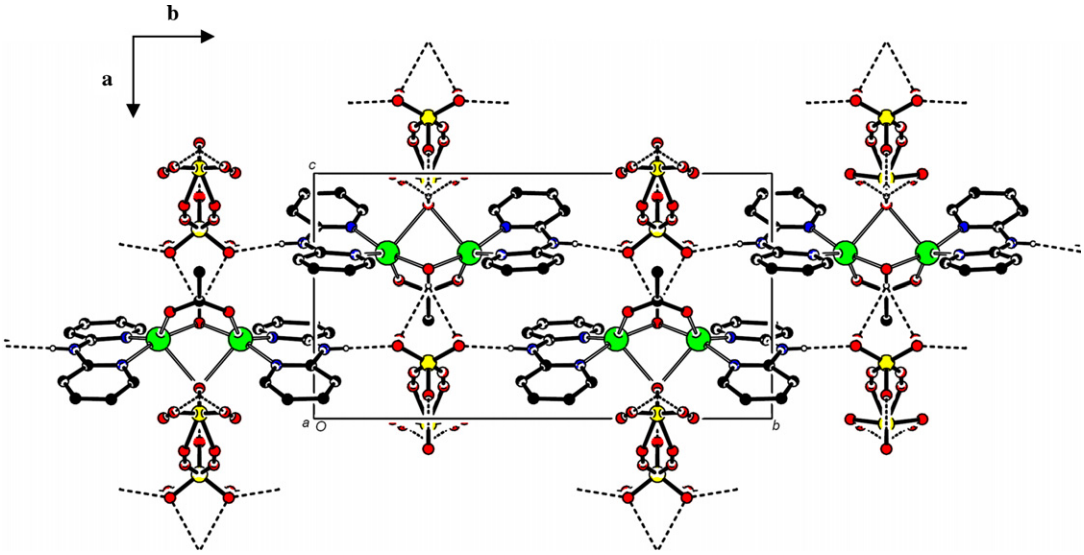

Fig. 4. H-bond system providing an two-dimensional array of complex **2**.

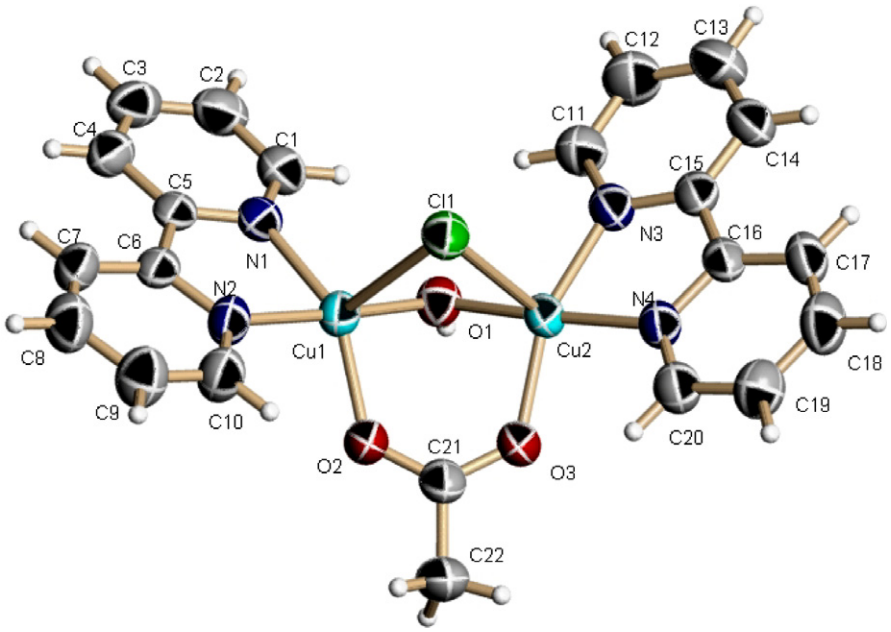

Fig. 5. ORTEP 50% probability plot of the cation in $[Cu_2(\mu\text{-}O_2CCH_3)(\mu\text{-}OH)(\mu\text{-}Cl)(bpy)_2]Cl \cdot 8.5H_2O$ (**6**). The uncoordinating anion and water molecules are omitted for clarity.

3.2. Structure comparison

The several structural and magnetic parameters of the compounds, together with those of a number of related dinuclear triply-bridged copper(II) compounds are listed in Table 2 and Fig. 6. The arrangement of the five-coordinate chromophores in the triply-bridged dinuclear copper(II) complexes containing a carboxylato bridge may be represented in six different classes (Scheme 1): (A) coplanar bases with a square pyramidal geometry for both Cu(II) environments and two dihydroxido bridges lying in the equatorial positions; (B) non-coplanar bases with a square pyramidal geometry for both Cu(II) ions, triatomic carboxylato and hydroxido bridges in the equatorial positions; (C) non-coplanar bases with a square pyramidal geometry for both Cu(II) ions and two triatomic carboxylato bridges lying in the equatorial positions; (D) non-coplanar bases with a square pyramidal geometry for both Cu(II) ions, one single-atom or triatomic bridge in an equatorial–equatorial configuration and two carboxylato (two triatomic or monoatomic/triatomic) bridges in an axial–equatorial configuration; (E) non-coplanar with a trigonal bipyramidal geometry for both Cu(II) ions and one hydroxido bridge in an axial–axial configuration; (F) non-coplanar bases with square pyramidal and trigonal bipyramidal geometries and two bridges, which occupy

the axial–equatorial positions, the other one is in an equatorial–equatorial configuration. An example of each class is presented in Fig. 6.

3.3. Spectral characterization

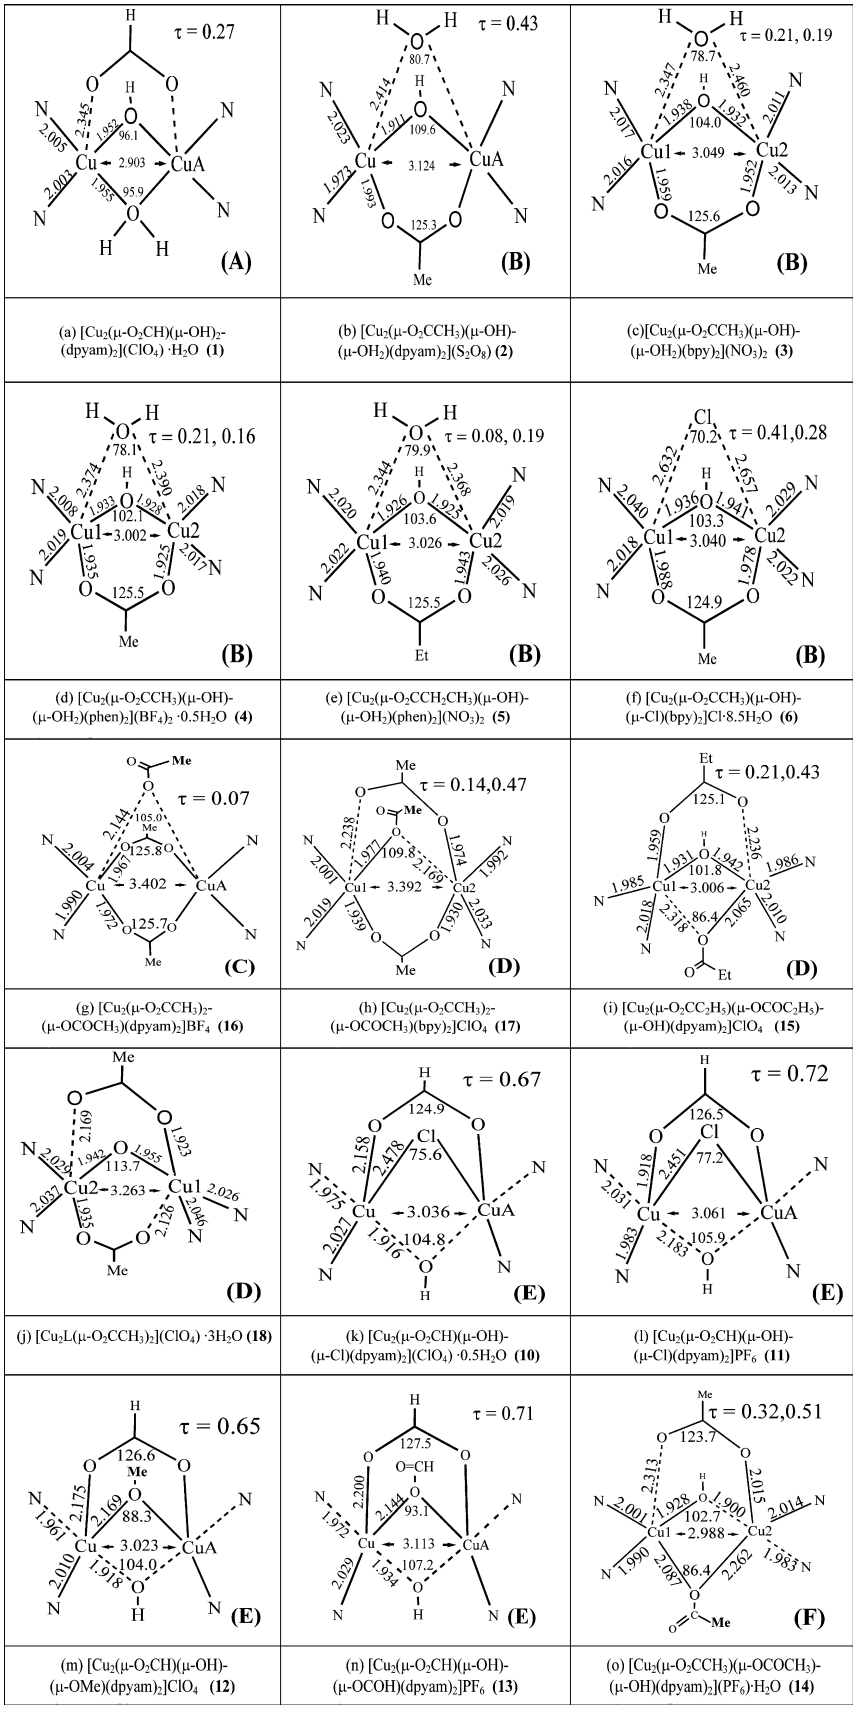
The infrared spectra display a broad band at ~3500 cm^{-1}, which can be assigned to the bridging OH vibration of the hydroxido ligands and/or lattice water. The spectrum in complex **1** also exhibits a broad and intense band at 1570 cm^{-1}, corresponding to the $\nu_{as}(COO^-)$ vibration and a medium broad band at 1350 cm^{-1}, corresponding to the $\nu_s(COO^-)$ vibration, the difference Δ [$\Delta = \nu_{as}(COO^-) - \nu_s(COO^-)$; 220 cm^{-1}] is close to that of NaO_2CH (201 cm^{-1}) as expected for the triatomic bridging coordination mode of the formate anion within a dinuclear species [1,21]. Owing to the presence of two different coordination modes of carboxylate bridges in **2**–**6**, $\nu_{as}(COO^-)$ and $\nu_s(COO^-)$ bands are observed in their IR spectra (1556 and 1385 cm^{-1} bands for **2**, 1558 and 1384 cm^{-1} bands for **3**, 1559 and 1396 cm^{-1} bands for **4**, 1553 and 1395 cm^{-1} bands for **5** and 1549 and 1384 cm^{-1} for **6**). The IR spectra of compounds **1**–**5** show broad and intense bands of the ionic ClO_4^- anion (1089–1100 cm^{-1} for **1**), ionic $S_2O_8^{2-}$ (1232–1280 cm^{-1} for **2**), ionic NO_3^- anion (1365–1386 cm^{-1} for **3** and 1362–1384 cm^{-1} for **5**) and ionic BF_4^- anion (1084–1100 cm^{-1} for **4**) [29].

The electronic diffuse reflectance spectra of **1** and **2** show a single broad band centered at 14000 and 13300 cm^{-1}. This observed single broad peak is consistent with the tetrahedrally-distorted square pyramidal stereochemistry and assigned to be the $d_{z^2}, d_{xy}, d_{xz}, d_{yz} \rightarrow d_{x^2-y^2}$ transition [30].

The diffuse reflectance spectra of **3**–**6** display a broad band (16500, 16200, 16100 and 15600 cm^{-1} for **3**, **4**, **5** and **6**, respectively) and a lower energy shoulder (14200, 14100, 13600 and 13200 cm^{-1} for **3**, **4**, **5** and **6**, respectively), the relatively higher energy of this triply-bridged dinuclear species is unusual for the square-pyramidal geometry. However, they are consistent with those observed for the related dpyam, bpy and phen complexes [10–12] and the $d_{xy}, d_{yz} \rightarrow d_{x^2-y^2}$ and $d_{xz}, d_{z^2} \rightarrow d_{x^2-y^2}$ transitions are assigned for a broad band and a lower energy shoulder, respectively.

3.4. EPR and magnetic properties

The X-band EPR was measured on polycrystalline samples at RT and 77 K for all six compounds. All compounds (except compound **2**) showed at RT and at 77 K broad bands at the high field and at the low field side both at RT and 77 K, typical for triplet $S = 1$ signal with a large zero-field splitting. The occurrence of other peaks at high field indicates that the axial zero-field splitting parameter D is larger than the EPR quantum (ca. 0.3 cm^{-1}). No attempts were undertaken to determine the value of the zero-field splitting. Compound **1** shows,



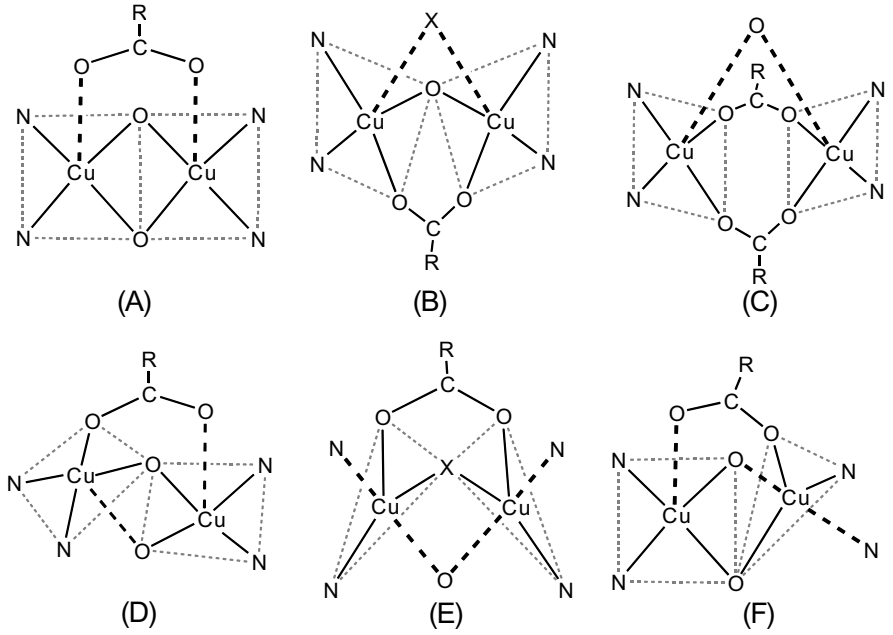


Fig. 6. Comparison of triply-bridged Cu(II) chromophores.

Scheme 1.

however, a somewhat more complicated $S = 1$ signal, which is stronger and more pronounced at 77 K (see Figs. S6 and S7), while compound **2** shows a peculiar, very broad signal at $g = 2.08$ and a small hump at $g = 24$ (see Fig. S8). All spectra also contain at around 320 mT a weak signal which arrises from a monomeric impurity, which is almost always present in dinuclear compounds. In compound **6** this signal is rather strong and sharp. Detailed analysis is not possible as the signals are too weak and too broad at 77 K, and as EPR at 4 K is not available. The same type of spectra was also observed for other triply-bridged compounds [10–12].

To investigate the magnetic behavior in more detail we undertook magnetic susceptibility measurements from 5 to 250 K for a selection of compounds, i.e. **1**, **4** and **6**. The susceptibility measurements from the other three compounds (**2**, **3** and **5**) did not give clear data, probably due to the fact that the structure gradually changes upon cooling and/or loosing solvent in the lattice. The magnetic properties are depicted in Figs. 7–9, for compounds **1**, **4** and **6**, respectively, in the form of μ_{eff} versus T plots for two Cu(II) ions. All three compounds show a similar behaviour. At 250 K the μ_{eff} is 2.75 μ_B per 2 Cu ions for compound **1** (2.64 μ_B, for **4** and 2.68 μ_B, for **4**) which agrees reasonable with the spin-only value calculated for two uncoupled spin $S = 1/2$ Cu(II) centres. Upon cooling μ_{eff} raises gradually to reach 2.87, 2.81 and 2.79 μ_B, at around 30 K, for compounds **1**, **4** and **6**, respectively. This behaviour is typical for a ferromagnetically coupled Cu(II) dinuclear compounds. Below that temperature, μ_{eff} then diminishes till a value around 2.47 μ_B for compound **1** (2.77 μ_B for **4** and 2.73 μ_B for **6**) at 5 K for the three compounds, which may originate from intermolecular antiferromagnetic interactions, and/or from zero-field splitting of the $S = 1$ state of the dinuclear species. The theoretical expression for the magnetic susceptibility for two interacting $S = 1/2$ centres, based on the general Hamiltonian [31] is: $H_{\text{ex}} = -JS_1S_2$, in which the exchange parameter J, is negative for antiferromagnetic and positive for ferromagnetic interaction. The magnetic data were fitted to the equation given in the literature for dinuclear copper compounds [31]: $\chi_m = (2Ng^2\beta^2)[kT - (2zJ'/(3 + \exp(-J/kT)))]^{-1}$ $[3 + \exp(-J/kT)]^{-1}(1 - p) + \chi_p p + \text{TIP}$, in which N, g, β, k and T have their usual meanings [31]. The parameter p denotes the fraction of paramagnetic impurity in the sample and zJ' the interaction between neighbouring dinuclear identities. A temperature independent paramagnetism (TIP) was also considered and fixed at 60×10^{-6} per copper ion. The fit was accomplished by minimisation of $R = \sum(\chi_m \cdot T_{\text{calc}} - \chi_m \cdot T_{\text{obs}})^2/(\chi_m \cdot T_{\text{obs}})^2$ by least-squares procedure.

The best fit was obtained for compound **1** with the following values: $J = 112.7\ \text{cm}^{-1}$, $g = 2.09$, $zJ' = -10.0\ \text{cm}^{-1}$, $p = 0.06$, with a final R of 2.0×10^{-3} (see solid line in Fig. 7). For compound **4** these values are $J = 120.8\ \text{cm}^{-1}$, $g = 1.98$, $zJ' = -0.21\ \text{cm}^{-1}$, $p = 0.0$, with a final R of $2.0 \cdot 10^{-3}$ (see solid line in Fig. 8). For compound **6** these values are $J = 145.3\ \text{cm}^{-1}$, $g = 1.98$, $zJ' = -0.8\ \text{cm}^{-1}$, $p = 0.06$, with a final R of 4.0×10^{-4} (see solid line in Fig. 9).

4. Magneto-structural correlation

For planar dihydroxido-bridged copper(II) dinuclear species, a linear correlation between the Cu–O–Cu bridging angle and the singlet–triplet energy gap (J) was first observed by Hodgson and co-workers [22,23]. An antiferromagnetic interaction is found when the Cu–O–Cu angle is larger than 97.5°, but when the Cu–O–Cu angle is smaller than 97.5°, a ferromagnetic interaction would be

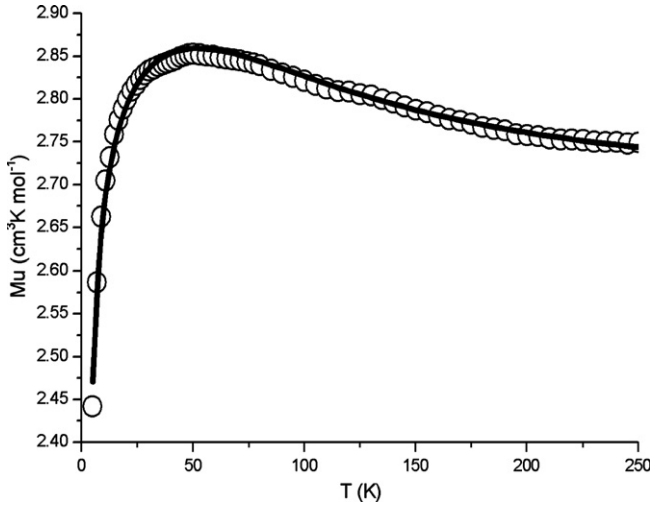

Fig. 7. A plot of the temperature dependence of μ_{eff} vs. T for compound **1**. The solid line represents the calculated curve (see text).

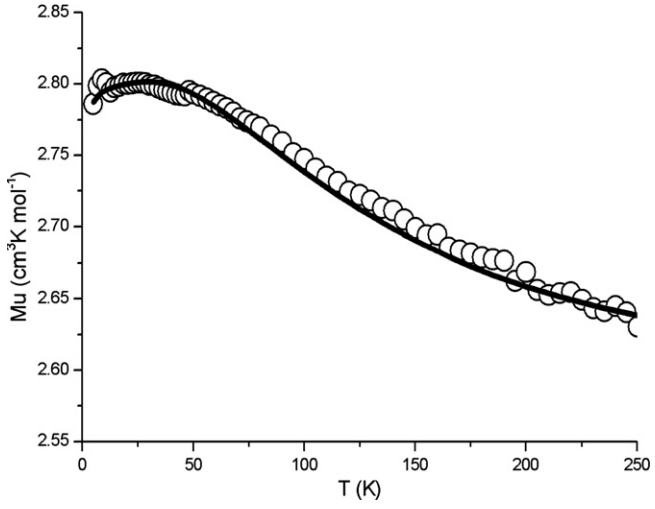

Fig. 8. A plot of the temperature dependence of μ_{eff} vs. T for compound **4**. The solid line represents the calculated curve (see text).

expected. Several theoretical approaches were applied to understand the behavior of the antiferromagnetic and ferromagnetic interaction of such dihydroxido-bridged copper(II) dinuclear species [22–27]. In this case, complex **1** can be analyzed using Hodgson and Hatfield's linear relationship to predict the magnetic properties in complex **1**.

Complex **1** exhibits a distorted square pyramidal geometry (class A), in which the unpaired electron is located in a $d_{x^2-y^2}$ type orbital. The $d_{x^2-y^2}$ magnetic orbital in **1** is directed toward the dihydroxido bridges, the Cu–O–Cu angles of 95.9° and 96.0°. For these bridging angles, a moderate ferromagnetic coupling ($J = 122.5\ cm^{-1}$) should be expected following Hodgson and Hatfield's linear relationship [22,23]. However, the tetrahedral distortion of the square bases may slightly reduce the magnitude of interaction. In fact, this feature can be predicted from the

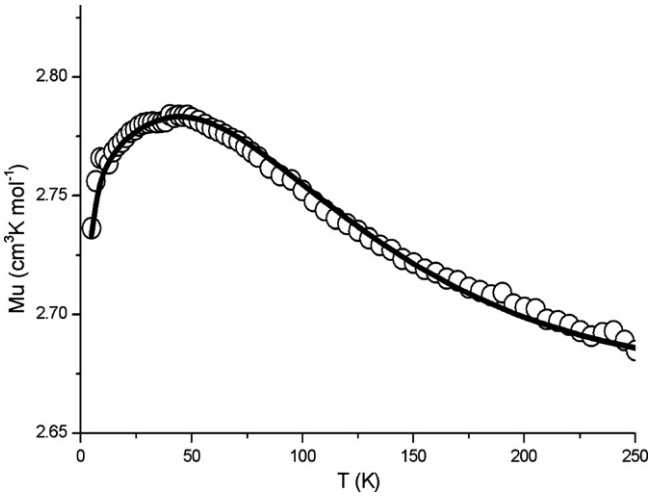

Fig. 9. A plot of the temperature dependence of μ_{eff} vs. T for compound **6**. The solid line represents the calculated curve (see text).

HOMO–LUMO energy gap using extended Hückel molecular orbital (EHMO) calculation (see Section 5).

Complexes **2**–**6** are classified in class B, Scheme 1 and Table 2, together with few relevant complexes with their previously reported J values, therefore the correlation between structure and magnetic exchange interaction can be performed for class B complexes with four data points (complexes **4**, **6**, **8**, **9**). These complexes offer the clear linear correlations in the plots of J versus Cu–OH–Cu (Fig. 10), J versus angle between basal planes (Fig. S9) and J versus Cu–Cu distance (Fig. S10). The J value increases upon increasing these structural parameters. Consequently, the J values of complexes **2**, **3** and **5** could be predicted to be 205.2, 146.1 and 142.0 cm^{-1}, respectively, following the J versus Cu–OH–Cu plot (see Fig. 10). However, a large number of the detailed structures and their magnetic properties are required for a clear correlation to be observed. An explanation for such a trend can be made in term of countercomplementary effect between the hydroxido bridge which generates ferromagnetic interaction due to the orbital orthogonality and one triatomic bridge in *syn–syn*. equatorial–equatorial configuration which usually contributes a weak antiferromagnetic interaction.

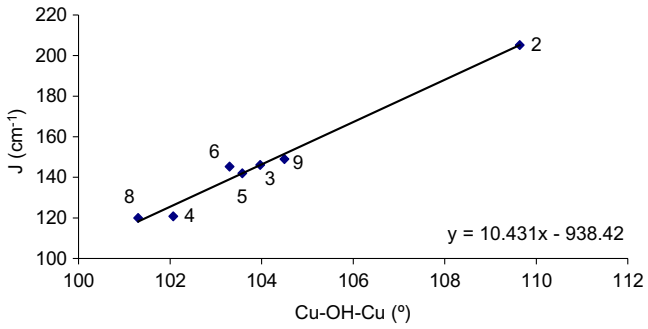

Fig. 10. Plot of J (cm^{-1}) vs. Cu–OH–Cu (°) for class B, the data points of complexes **2**, **3** and **5** are expected from this linear correlation.

Class C complex **16** (see Table 2) revealed a moderate antiferromagnetic interaction with a J value of $-55\ cm^{-1}$, a similar trend found for the classical dinuclear paddle-wheel copper(II) species with four bridges, but with a different number of carboxylate bridges in complex **16**, leading to a smaller J value compared to those of the dinuclear paddle-wheel copper(II) species ($J = -142$ to $-300\ cm^{-1}$).

A possible magnetic exchange pathway for class-D complexes (see Fig. 6 and Table 2) is a single Cu–OH–Cu (101.8°) unit for complex **15** and a triatomic carboxylato bridge for complex**17** which links Cu(II) centres in an equatorial–equatorial configuration. This structure can occur with less electron density due to the nearly intermediate geometry ($\tau = 0.43$ for **15** and 0.47 for **17**) of one Cu(II) centre. Consequently, another possible pathway with less electron density is the triatomic carboxyato bridge for **15** and the monoatomic carboxylato Cu–O–Cu unit (109.8°) for **17**. Hence, a small J value ($24.5\ cm^{-1}$ for **15** and $3.6\ cm^{-1}$ for **17**) observed for both complexes may result from a countercomplementary effect between the monoatomic bridge with a small bridging angle which usually contributes the ferromagnetic interaction due to the orthogonality between the copper magnetic orbitals and the oxygen p-orbital, and the triatomic carboxylato bridge which usually contributes to an antiferromagnetic interaction. Another unique orientation of three bridges in the class-D complex was found in $[Cu_2L(\mu\text{-}O_2CCH_3)_2](ClO_4)\cdot 3H_2O$ (**18**) where LH = 2,6-bis(*N*-methypiperazino)methyl-4-chlorophenol (see Fig. 6 and Table 2) in which a possible pathway occurs via the Cu–O–Cu unit with an equatorial–equatorial configuration and a large bridging angle of 113.7°, leading to a negative J value of $-72\ cm^{-1}$ [32]. It is quite clear that the antiferromagnetic contribution increases upon increasing this bridging angle, thus allowing electron delocalization along the Cu–O–Cu unit. The remaining two triatomic carboxylato bridges which link Cu(II) centres in an axial–equatorial configuration provide a minor influence on the magnetic exchange interaction of the compound.

Class E complexes have a moderate ferromagnetic interaction. The superexchange mechanism for these complexes may be described in term of orbital orthogonality between the copper magnetic orbitals and oxygen p-orbital via Cu–OH–Cu unit allowing two unpaired electrons spins paralleled. As a result, it seems to be reliable to mention that the dominant ferromagnetic interaction increases with increasing in bridging angle Cu···Cu distance (compounds **10**–**12**, Table 2) till a certain maximum value, then decreases (compounds **10**–**13**, Table 2). However, no clear correlation has been observed for class E complexes reported in the literature. Hence, more detailed structures and magnetic properties are required to study the magneto-structural correlation in class E complexes.

A class F complex revealed a weak ferromagnetic nature. The τ values of 0.32 and 0.51 of Cu centres indicate magnetic orbital mainly to be $d_{x^2-y^2}$ and intermediate between $d_{x^2-y^2}$ and d_{z^2}, respectively. This situation usually results in a weak ferromagnetic interaction. Additionally, the presence of the $\eta^1{:}\eta^1{:}\mu$-carboxylate with axial–equatorial configuration may lead to countercomplementary effect giving rise to a small J value, Table 2.

5. Theoretical calculations

Extended Hückel molecular orbital (EHMO) calculations have been carried out on complexes **1**–**6, 8** and **9** (see Table 2) with the CACAO program [16], keeping the overall molecular structure unchanged to establish the mechanism of magnetic superexchange interaction through the triple bridges. The singlet–triplet energy gap could decrease with decrease in antiferromagnetic interaction. As the results, the calculated HOMO–LUMO energy gap are 0.55, 0.005, 0.115, 0.147, 0.134, 0.133, 0.162 and 0.111 eV for **1**–**6**, **8** and **9**, respectively. The results imply that a small difference in energy gap has a large influence on the magnetic interactions, the overall ferromagnetic interaction increases with decrease in energy gap as show in Fig. S11. This plot can confirm the predicted J value for class B complexes. The HOMO and LUMO of class B complexes (**2**–**6**, **8** and **9**) are close in energy while the energy gap of **1** is significantly larger. The complexes **1**–**6** are clarified drawing the two corresponding molecular orbitals (Figs. S12–S17). In both MOs the magnetic orbitals are mainly centered in the $d_{x^2-y^2}$ copper orbitals, in agreement with the geometry of the metal ions. The HOMO of **1** is delocalized on the atomic orbitals of both hydroxido bridging ligands, no overlapping through both hydroxido bridges is observed for the LUMO. The important contribution of each Cu(II) ion of 15% is found in the HOMO and a few contribution (2%) of each Cu(II) ion is found in LUMO orbitals. A possible reason of the large

HOMO–LUMO energy gap is the determining factor for the antiferromagnetic contribution to J (singlet–triplet energy difference) of compound **1**. This is in agreement with the large singlet–triplet energy difference observed for planar hydroxido-bridged copper(II) complexes [33].

The HOMO and LUMO of **2** are slightly different in energy and the overlap through the OH and carboxylate bridges is small, resulting ferromagnetic interaction. In complex **2**, the important contribution of each copper(II) ion of 16% is found in HOMO orbital (see Table 3).

The HOMO and LUMO of **3**–**6** are delocalized on the atomic orbital of hydroxido and O of carboxylate bridging and absent in the OH_2 (complexes **3**–**5**) or Cl (complex **6**) bridging which are in the axial position for each complex (see Table 3). In complexes **3**–**6**, the important contribution in HOMO of one of the copper(II) ions (21%, 23%, 21%, 18% in **3**–**6**, respectively) and smaller contribution to the other one (14%, 11%, 16%, 7% in **3**–**6**, respectively) are found. The HOMO and LUMO are slightly different in energy and the overlap through the OH and carboxylate bridges is small. This feature should result in a ferromagnetic interaction that can occur through this bridging ligand, as there is the orthogonality between the copper molecular orbital and the oxygen orbital of the OH bridge. A summary of the results obtained from EH analysis performed for **1**–**6** is shown in Table 3. However, DFT calculations have generally superseded EHMO, but if the results are not significantly different then EHMO is sufficient and faster. The theoretical investigation of magnetic properties are well studied for the dihydroxido-bridged [28], paddle-wheel carboxylato-bridged [34] and azido-bridged [35] dinuclear copper(II) complexes while that for the triply-bridged dinuclear copper(II) complexes has not been reported so far.

6. Conclusions

As a summary, a family of dinuclear triply-bridged copper(II) complexes bearing carboxylato bridges has been classified in terms of their relative arrangements of both local copper(II) chromophores, geometries and carboxylate bridging modes into different classes (A–F) and the efforts have been made to develop the magneto-structural correlation. The most logical explanation for their different magnetic behaviors have been provided in order to gain better understanding in the influence of various types of structures on the sign and magnitude of magnetic exchange interaction in this family of complexes. The results obtained from the EH calculations have proven to be useful for the proper interpretation and correlation of the magnetic and structural data. Linear correlations have been found for class B complexes and revealed that small geometric deviations may produce large energy gaps and therefore significant differences in the magnitude of the magnetic exchange interaction. So, more compounds with a careful inspection of structural parameters combined with their magnetic properties are demanded for both experimental and theoretical analyses which may lead to a very good magneto-structural correlation and using also the more accurate DFT calculations. A better understanding of factors that favor ferromagnetism in this family of complexes is expected to be useful for the design of novel ferromagnetic materials.

Abstract

The reaction between $ZnCl_2$ and (*S*)-*N*-ethyl-*N*-phenyl-2-pyrrolidinemethanamine (***S*-EPP**) as a chiral ligand affords [$\mathbf{ZnCl_2}$(***S*-EPP**)], whose structure has been determined by X-ray crystallography. [$\mathbf{ZnEt_2}$(***S*-EPP**)] has demonstrated high activity toward the polymerization of *rac*-lactide with a maximum turnover frequency (TOF) of 121. Despite the intended stereocontrol by employing a chiral ligand, however, the observed heterotacticity was limited to under 0.6. The MWDs of the PLAs were found to be modulated by changing the solvent or controlling the concentration of the monomer in the solution. The glass transition temperature (T_g) was critically dependent on the MW within the narrow MWD regime, but the dependence became significantly shallow when the MWD was broadened.

1. Introduction

Environmental pollution by the disposal of non-degradable plastics has emerged as a major concern worldwide. Poly(lactic acid) or polylactide (PLA), first synthesized half a century ago [1,2] has attracted great interest in recent years as a new environmentally friendly plastic material, not only because it degrades several orders of magnitude faster than petroleum-based polymers and thus can be composted locally into soil amendments but also it requires 30–50% less fossil fuel during the production step [3]. Also importantly, PLA's raw material is from annually renewable resources such as corn and sugar beats while many other polymers' are from continuously depleting petroleum sources. Despite these green benefits, the primary application of this material still remains in the medicinal purpose where the benefits of performance and the economical cost intersect. While its applications continue to expand to commodity purposes that include film, fiber and non-woven materials, the replacement of petroleum-based polymers, especially PET and flexible PVC, by PLA is expected to be accelerated as demands for preserving the environment are increasing.

The synthetic protocol of this material is mostly by the ring-opening polymerization of lactides [4]. This approach has been clearly advantageous in terms of a higher polymerization rate, a higher molecular weight, and a better conversion. A number of different kinds of metals have been used towards this purpose that include not only the relatively non-hazardous lithium [5,6], magnesium and zinc [7–10], aluminum [7,11–16], and iron [17,18], but also the highly toxic tin [4,9,19–22], lead and bismuth [23], and lanthanides [24–29]. Although many commercial PLAs with high molecular weight are currently produced by toxic transition metal catalysts, it is highly desirable for these catalyst residues to be completely absent in the final

doi:10.1016/j.poly.2007.09.021

product for biomedical and food packaging applications. Since it is practically unviable to remove catalyst residues completely from the polymer, the use of environmentally friendly catalyst species must be a good approach.

The stereochemical control of PLA's microstructures has emerged as an important issue to establish the structure-property relationship of the PLA [3]. High P_r (the probability of a *R*,*R*-lactide unit to be enchained after a *S*,*S*-lactide unit or vice versa) values of over 0.90, for example, have been reported by Coates et al. [10] for the polymerization reaction of *meso*-lactide by employing the achiral catalyst [(BDI)Zn(O^{i}Pr)]$_2$ [(BDI) = 2-((2,6-dialkylphenyl)amido)-4-((2,6-diiso-propylphenyl)imino)-2-pentene]. However, only a limited body of work has been accumulated for the investigation of the microstructure related properties. More studies are thus necessary for a wider application of this material.

Within this view, we attempted to prepare PLA with a newly synthesized zinc catalyst containing (*S*)-*N*-ethyl-*N*-phenyl-2-pyrrolidinemethanamine (***S*-EPP**). The design motives of this catalyst species involve: (1) the use of non-toxic zinc as a central metal of the catalyst, (2) the incorporation of the chiral ***S*-EPP** ligand, which can be easily prepared from relatively inexpensive *L*-proline and possibly control the PLA's microstructure by stereospecific polymerization [30] (3) the easy synthesis of catalyst species by simple mixing of diethylzinc and the ***S*-EPP** ligand. Herein, we report the polymerization reaction of *rac*-lactide with the [**ZnEt$_2$**(***S*-EPP**)] complex. The X-ray crystal structure of the dichloro derivative of the catalyst species, [**ZnCl$_2$**(***S*-EPP**)], is also described.

2. Experimental

2.1. Materials

All manipulations were carried out under nitrogen prepurified by passage through an O_2 scrubbing tower (Schweizerhall R3-11 catalyst) and a drying tower (Linde 3Å molecular sieves) unless otherwise noted. Standard Schlenk techniques were employed to manipulate air sensitive materials. All solvents were purchased from Duksan Chemical Co. (reagent grade). Tetrahydrofuran (THF) and toluene were dried over Na/benzophenone ketyl, while CH_2Cl_2 was dried over CaH_2; these solvents were subsequently distilled from these reagents under nitrogen prior to use. The *rac*-Lactide was purchased from Aldrich and was sublimed prior to use. Zinc chloride and diethylzinc (1.1 M in toluene) were purchased from Aldrich. ***S*-EPP** was prepared as described in the literature [30].

2.2. Instrumentation

NMR spectra were recorded on a 400-MHz Bruker AD 400 FT NMR spectrometer. Chemical shifts for ^{1}H NMR spectra are relative to residual protons in the deuterated solvents ($CDCl_3$, $\delta = 7.24$). All coupling constants are reported in Hz. Gel permeation chromatography (GPC) analyses were carried out on a Waters Alliance GPCV2000, equipped with differential refractive index detectors. The GPC columns were eluted with tetrahydrofuran with a 1 ml/min rate at 25 °C and were calibrated with monodisperse polystyrene standards. Glass transition temperatures were measured on an Auto DSC 2910 system (TA instruments).

2.3. Synthesis of [*ZnCl$_2$*(***S*-EPP**)]

A 100 ml one-necked round-bottomed flask was charged with ***S*-EPP** (1.26 g, 6.19 mmol), $ZnCl_2$ (0.84 g, 6.16 mmol) and THF (20 ml). The mixture was stirred at room temperature for 3 days and then the solvent was removed under reduced pressure. The residual solids were dissolved in CH_2Cl_2 and filtered through a filter paper. The filtrate was evaporated in vacuo to afford white solids. Recrystallization of the crude product from the solvent pair of CH_2Cl_2/hexane gave white crystals (2.04 g, 97% yield). ^{1}H NMR (300 MHz, $CDCl_3$): δ 7.60 (d, 2H), 7.43 (t, 2H), 7.30 (t, 1H), 3.7–3.5 (m, 2H), 3.4–3.2(m, 3H), 2.06 (m, 1H), 1.83 (m, 1H), 1.59 (m, 1H), 0.97 (t, 3H).

2.4. Polymerization reaction with in situ generated [*ZnEt$_2$*(***S*-EPP**)]

To a 100 ml storage tube charged with $ZnEt_2$ (5.6 ml of 1.1 M solution in toluene, 6.2 mmol) and toluene (22 ml) was added ***S*-EPP** (1.26 g, 6.2 mmol in 5 ml toluene) at room temperature. After being stirred for 1 h, the resulting catalyst solution was used for the polymerization reaction. The general procedure for the polymerization reaction was as follows. A 100 ml Schlenk flask was charged with *rac*-Lactide (1.5 g, 10.4 mmol) and toluene (5 ml). The reaction was initiated by adding the catalyst solution (0.5 ml, 0.1 mmol) using a syringe. The reaction mixture was stirred at ambient temperature. This mixture was washed with water and all volatiles were removed under reduced pressure to obtain white crumbly solids (1.5 g, 99% based on *rac*-Lactide). ^{1}H NMR(400 MHz, $CDCl_3$): δ 5.19–5.04 (m, 1H), 1.52–1.47 (m, 3H).

2.5. X-ray crystallographic analysis

An X-ray quality single crystal of [**ZnCl$_2$**(***S*-EPP**)] was mounted in a thin-walled glass capillary on an Enraf-Noius CAD-4 diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). Unit cell parameters were determined by least-squares analysis of 25 reflections ($10° < \theta < 13°$). Intensity data were collected with the θ range 1.88–24.97° in the $\omega/2\theta$ scan mode. Three standard reflections were monitored every 1 h during data collection. The data were corrected for Lorentz-polarization effects and decay. Empirical absorption corrections with ψ-scans were applied to the data. The structure was solved by using the Patterson method and refined by full-matrix least-

squares techniques on F^2 using SHELXS-97 and SHELXL-97 program packages [31,32]. All hydrogen atoms were refined, positioned geometrically using the riding model with fixed isotropic thermal factors ($U = 0.08$ Å^2). The final cycle of the refinement converged with $R_1 = 0.034$ and $wR_2 = 0.067$. Crystal data, details of the data collection and refinement parameters are listed in Table 1.

3. Results and discussion

3.1. Synthesis and X-ray crystal structure of the [*ZnCl$_2$-(S-EPP)*] complex

[**ZnCl$_2$(*S*-EPP)**] was synthesized by a simple mixing of the ***S*-EPP** ligand and $ZnCl_2$ in THF solvent. The complexation reaction proceeded smoothly at room temperature and the product was easily purified by recrystallization. A single crystal suitable for X-ray crystallography was obtained by diffusional crystallization of [**ZnCl$_2$(*S*-EPP)**] in CH_2Cl_2 and hexane. The ORTEP drawing of the complex is shown in Fig. 1, with atomic labelling for non-hydrogen atoms. Selected bond distances and angles are listed in Table 2. The geometry of the complex is basically a tetrahedron comprising the zinc metal as a center linked with two N atoms of the ***S*-EPP** ligand in a bidentate coordination mode along with two chloro ligands. The Cl–Zn–Cl and N–Zn–N bond angles are 115.58(2)° and 86.66(7)°, respectively. These values are surprisingly similar with those found in dichloro(*N*,*N*,*N*′-trimethylethylenediamine)zinc(II) [33], which has a similar skeleton to [**ZnCl$_2$(*S*-EPP)**]. The average value of the N–Zn–N angle in TMEDA/zinc complexes (TMEDA = tetramethylethylenediamine) found in the Cambridge Structural Database (CSD) is 84.3 ± 2.7° [33]. The Zn–N bond distances are 2.036(2) Å for Zn–N(1) and 2.132(2) Å for Zn–N(2). The corresponding values for the dichloro(*N*,*N*,*N*′-trimethylethylenediamine)zinc(II) compound were 2.065(2) and 2.081(2) Å [33].

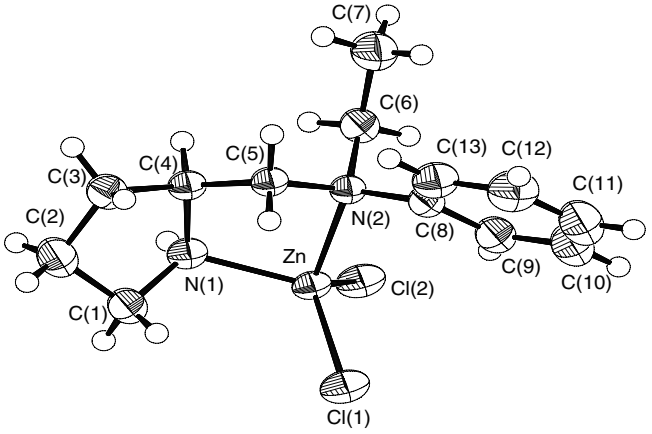

Fig. 1. An ORTEP drawing of [**ZnCl$_2$(*S*-EPP)**] with the numbering scheme.

Table 2
Selected bond lengths (Å) and angles (°) for [**ZnCl$_2$(*S*-EPP)**]

The synthesized [**ZnCl$_2$(*S*-EPP)**] has two stereogenic N atoms from the ligand (***S*-EPP**) possessing only one chiral center (Fig. 1). This is a diastereoselective reaction that gives rise to two chiral centers at the nitrogen atoms. Interestingly, the resolved structure was found to be enantiomerically pure, possessing two *S* configurations for both N(1) and N(2) atoms, respectively (*S*,*S*). The five-membered chelate ring made up of Zn–N(1)–C(4)–C(4)–N(2) atoms is thus in the λ-conformation. Being induced by the intrinsic chirality of the*S* configuration at the C(4) atom, the resulting *S* configuration at N(1) atom is not surprising. However, the *S* configuration at N(2) atom is not clear. Considering the

fact that this structural feature prevailed in the [(*S*)-2-(anilinomethyl)pyrrolidine-*N*,*N*′]chloro(η^6-*para*-cymene)ruthenium(II) chloride complex [34], one would expect that the *S* configuration at the N(2) atom might be thermodynamically favorable against the *R* configuration. Heat of formation data for two diastereomeric [**ZnCl$_2$**(***S*-EPP**)] complexes calculated by the PM3 method [35–37], however, were estimated to be −63.92 and −64.51 kcal/mol for the (*S*, *S*) and (*S*, *R*) configurations, respectively. The energy difference between these two enantiomers is only 0.59 kcal/mol, which is even smaller than the thermal energy at room temperature ($k_bT_{298} = 0.60$ kcal/mol). Since the difference in the entropic term for the two enantiomers is expected to be negligible, the observed crystal structure with only the (*S*, *S*) configuration is most likely due to packing effects.

3.2. Polymerization of rac-Lactide with in situ generated Zn catalyst

The polymerization reaction of *rac*-Lactide was carried out with in situ prepared Zn catalyst, [**ZnEt$_2$**(***S*-EPP**)]. The ***S*-EPP** ligand was mixed with diethylzinc in toluene at room temperature. Since an approximate pK_a value of pyrolidine is known to be ~44 in DMSO solvent [38], which is one of the highest among reported secondary amine compounds, and is expected to be further increased in a non-polar solvent, the chemical formula of the catalyst species is most likely [**ZnEt$_2$**(***S*-EPP**)]. This hypothesis can be supported by the work reported by Mimoun et al. in which two amine protons of (*S*,*S*)-*N*,*N*′-ethylenebis-(1-phenylethylamine) were not deprotonated after being reacted with dimethylzinc [39].

The polymerization reaction of *rac*-Lactide in three different solvents produced PLA in high conversion. The polymerization results are summarized in Table 3. In moderately polar CH_2Cl_2 and THF solvents, the polymerization reaction was completed within 1 h with a minimum 85% conversion. In non-polar toluene solvent, however, it took significantly more time to complete the reaction and the conversion varied from 43% to 99%. It should be noted that the relatively low conversions of entry 3 in THF and entries 7 and 8 in toluene (Table 3) were due to the unexpectedly early termination of the reaction by increased viscosity of the reaction mixture. Turnover frequency (TOF) calculated as moles of consumed lactide per moles of catalyst per hour ([Lactide]/[Cat]/h) was up to 121 (entry 2 in Table 3), indicating that the catalyst species is highly efficient for the formation of PLA.

Since it is commonly accepted that the polymerization reaction of lactide by an organometallic catalyst (or initiator) proceeds via a living polymerization mechanism [10,16], the number averaged molecular weight (M_n) of the polymer should be approximately $\sim C \times M \times R$, where *C* is the conversion, *M* is the molecular weight of the monomer, and *R* is the monomer/catalyst ratio. Observed M_n values of PLAs prepared in CH_2Cl_2 solvent were 13 700 and 26 000 for *R* values of 67 and 122, respectively. Although these values are a factor of ~1.5 larger than the theoretically calculated ones (8689 and 17 404) [10,16], it is important to note that both values are in good linear relationship. Slightly larger experimental M_n values relative to that of the theoretical counterparts are probably due to the reduction of the real catalyst amount by unexpected decomposition. Considering the fact that the conversion weighted theoretical M_n values are in good agreement with the experimental ones and the MWD of these polymers are near to 1, it is thus reasonable to affirm that the polymerization reactions of lactide by [**ZnEt$_2$**(***S*-EPP**)] in CH_2Cl_2 solvent are well controlled by a living polymerization mechanism.

The experimentally observed M_n values of PLAs are, however, not in a linear relationship with the theoretically calculated ones when the polymerization reaction was carried out in THF and toluene solvents. The ratio between experimentally observed M_n values and theoretically calculated ones varied 2.0–5.4 and 1.4–4.9 for the PLAs prepared in THF and toluene solvent, respectively. These large deviations even in the same solvent system cannot be merely explained by reduction of the catalyst amount

Table 3
Polymerization of *rac*-Lactide with in situ prepared [**ZnEt$_2$**(***S*-EPP**)]

Entry	Solvent	Concentration[a] (mM)	Time (h)	Conversion (%)	TOF	$M_n \times 10^3$	$M_w \times 10^3$	MWD	T_g (°C)

[a] Concentration of *rac*-Lactide.
[b] [Monomer]/[Cat] = 67.
[c] [Monomer]/[Cat] = 122.
[d] [Monomer]/[Cat] = 100.

due to the contamination. We thus emphasize that these results involve other factors as well. It should be noted that the MWDs of PLAs prepared in toluene were broader than those prepared in CH_2Cl_2 ($2.39 \leqslant MWD \leqslant 2.63$, entries 7–10 in Table 3). Even the MWD of PLA prepared from a high concentration solution of monomer in THF (6.94 mM) was exceptionally high (MWD = 4.41, entry 3 in Table 3). These results are most likely due to the fact that all the monomers were not in the solution phase, which causes inhomogeneity around the catalyst species during the polymerization process, and thus breaks the living polymerization condition.

The trend of the glass transition temperature (T_g) in relation to molecular weight and MWD deserve comments. In general, T_g of PLA is linearly dependent on the molecular weight until it reaches its maximum [18,40]. The T_g values of commercial PLA are in the range 55–70 °C for $100\,000 \leqslant M_w \leqslant 300\,000$. The tendency that T_g is dependent on molecular weight of PLA prevails in our results when the MWD is narrow (entries 1–6 in Table 3 except 3). However, to the PLAs synthesized in toluene solvent in which MWD is over 2 (entries 7–10 in Table 3), values of T_g were confined to within 52–55 °C over the $41\,200 \leqslant M_w \leqslant 112\,000$ range (Fig. 2). The relation between MWD and T_g has not been respected very much, probably due to the fact that most PLAs synthesized by the ring opening polymerization method in academic laboratories have MWD values near 1.0 [10,16]. Considering the effort devoted to lowering the T_g of PLA in order to reduce the brittleness of this polymer, the possibility to control T_g by a simple change of solvent and thus by modulating the MWD is worth further study.

Despite the intended stereocontrol of the PLA microstructure by employing a chiral catalyst, no pronouncing stereospecificity of PLA was observed. For instance, PLA

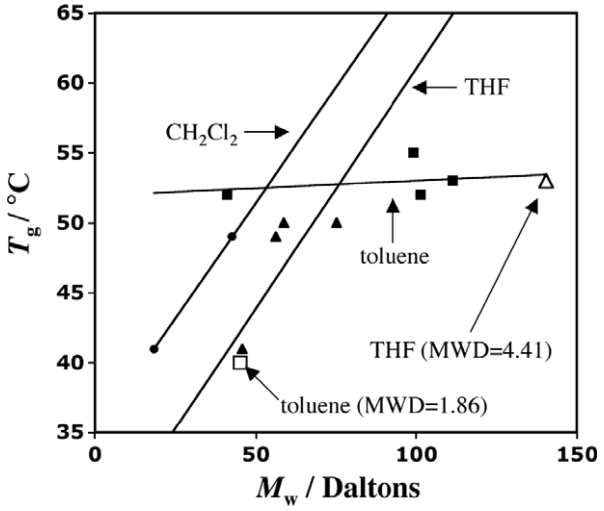

Fig. 2. The relation between T_g vs M_w of PLAs prepared in CH_2Cl_2 (circle), THF (triangle) and toluene (square) solvents. The open square and open triangle indicates entries 11 and 3 in Table 3, respectively.

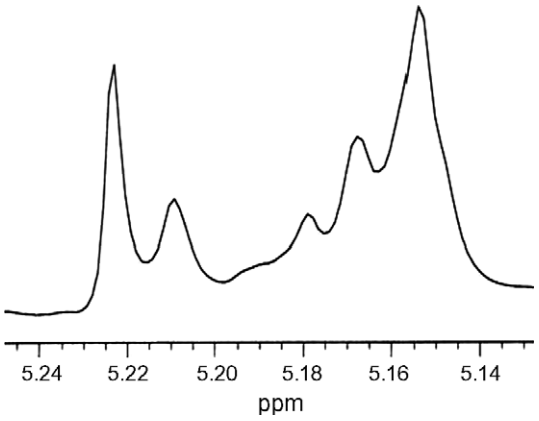

Fig. 3. Homonuclear decoupled ^1H NMR spectrum of PLA (for the preparation conditions, see entry 6 in Table 3).

synthesized in THF (entry 6 in Table 3) exhibit only 0.55 of heterotacticity (P_r), determined by homonuclear decoupled ^1H NMR spectra (Fig. 3) [41]. Given the very high heterotacticity ($P_r \geqslant 0.9$) of PLA polymerized with racemic [40] or achiral [10,42] catalysts, providing a chiral environment on the metal center by simply employing a chiral ligand might not be a clever approach for the stereochemical microstructure control of PLA.

4. Conclusion

The complex [**$ZnCl_2$(*S*-EPP)**] was synthesized for the first time and its structure was determined by X-ray crystallography. The diethyl derivative [**$ZnEt_2$(*S*-EPP)**], which is prepared in situ by the reaction of ***S*-EPP** ligand and $ZnEt_2$in toluene solvent, has demonstrated high activity on the polymerization of *rac*-Lactide, with a maximum TOF of 121. The polymerization reaction is controlled by the living polymerization mechanism due to the fact that the produced PLA has a narrow MWD near 1.0 and there is a linear dependence between the molecular weight and the catalyst/monomer ratio. However, the MWDs of PLAs were found to be modulated by changing the solvent or controlling the concentration of the monomer in the solution. T_g was critically dependent on the MW within the narrow MWD regime but the dependence became significantly shallow when the MWD was broadened. Despite the intended stereocontrol by employing a chiral ligand, the observed heterotacticity was limited to under 0.6.

Supplementary material

CCDC 654084 contain the supplementary crystallographic data for [**$ZnCl_2$(*S*-EPP)**]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Abstract

Direct template macrocyclization of the three dimethylglyoxime molecules on the iron(II) ion and the capping of nonmacrocyclic K_3CoDm_3 tris-dimethylglyoximate with triethylantimony(V) derivatives led to the formation of triethylantimony-capped iron(II) and cobalt(III) clathrochelates. The complexes obtained have been characterized using elemental analysis, MALDI-TOF mass, IR, UV–Vis, ^{57}Fe Mössbauer and ^{1}H and ^{13}C NMR spectroscopies, and X-ray crystallography. The influence of the nature of an encapsulated metal ion, the capping groups and the chelate fragments on a clathrochelate framework geometry is discussed. The cyclic voltammograms show oxidation and reduction waves assignable to $Fe^{2+/3+}$ and $Co^{2+/3+}$ couples of the encapsulated metal ion.

1. Introduction

Polytopic d-metals cage complexes with relatively spacially and electronically independent fragments that are linked by a system of σ- and π-bonds, have been proposed as promising entities for the design of molecular (photo)electronic devices and mechanical molecular machines [1,2].

The synthesis of such complexes by a direct template reaction is hindered or not possible in principle. The polytopic hybrid iron(II) α-oximehydrazonates and α-dioximates have been obtained by transmetallation reactions of the initially synthesized labile antimony-capped precursors [1–3] (Fig. 1). However, the presence of only one reactive macrobicyclic precursor of apically functionalized hybrid tris-dioximate clathrochelates, the triethylantimony-capped $FeNx_3(Sb(C_2H_5)_3)_2$ complex (where Nx^{2-} is cyclohexandione-1,2-dioxime (nioxime) dianion), limits the possibilities for obtaining such hybrid polytopic compounds. Moreover, the cobalt complexes of this type, which are most promising for the development of mentioned above devices and machines because of the formation of stable species with an encapsulated metal ion in different oxidation states (usually, the encapsulated cobalt(II) and cobalt(III) ions), have not been synthesized previously.

Therefore, we attempted to synthesize the di(triethylantimony)-capped iron(II) and cobalt(III) clathrochelates, which are derivatives of the available dimethylglyoxime, as potential precursors of polytopic iron(II) and cobalt(II,III) cage compounds. Using the X-ray crystallography data obtained, we also discuss the influence of the nature of an encapsulated metal ion, the capping groups and the chelate fragments on a clathrochelate framework geometry.

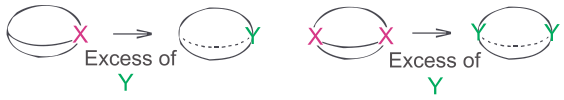

Fig. 1. Exchange of capping group(s) (transmetallation) reaction.

2. Experimental

2.1. General procedures

The reagents used, $FeCl_2 \cdot 4H_2O$, $CoCl_2 \cdot 6H_2O$, dimethylglyoxime (H_2Dm), sorbents, organic bases, and solvents were obtained commercially (Fluka). K_3CoDm_3 complex was prepared as described elsewhere [4]. The triethylantimony(V) dibromide was synthesized by known procedure [5]. The triethylantimony(V) carbonate was obtained from triethylantimony(V) dibromide with Na_2CO_3 in methanol.

The analytical, IR, UV–Vis, NMR, ^{57}Fe Mossbauer and electrochemicals data were obtained as described previously [2] (see Supplementary material for the experimental details, IR and NMR data).

2.2. Syntheses

2.2.1. $FeDm_3(Sb(C_2H_5)_3)_2$

$FeCl_2 \cdot 4H_2O$ (0.20 g, 1 mmol), dimethylglyoxime (0.38 g, 3.3 mmol) and $NaClO_4$ (1.5 g) were dissolved/suspended in methanol (15 ml) under argon. The reaction mixture was stirred at 50°C for 1.5 h and the solution of $(C_2H_5)_3SbCO_3$ (0.59 g, 2.2 mmol) in methanol (5 ml) was added. After stirring for 10 min, the reaction mixture was added dropwise to the stirring suspension of $CaCO_3$ (2 g) in 10% aqueous methanol (30 ml). The solution/suspension obtained was stirred for 30 min and then filtered. The precipitate was washed with methanol and dissolved in methylene dichloride. The methylene dichloride extract was filtered, evaporated to a small volume (~1.5 ml) and precipitated with hexane. The solid product was filtered, washed with hexane and dried *in vacuo*. Yield: 0.36 g (40%). *Anal.* Calc. for $C_{24}H_{48}N_6O_6FeSb_2$: C, 35.32; H, 5.94; N, 10.30; Fe, 6.84. Found: C, 35.20; H, 6.00; N, 10.31; Fe, 6.98%. MS (MALDI-TOF): *m/z* (*I*, %): 845(100) $[M + Et]^{+\cdot}$, 816(20) $[M]^{+\cdot}$, 729(70) $[M-3Et]^{+\cdot}$. UV–Vis (CH_2Cl_2): λ_{max}/nm ($\varepsilon \times 10^{-3}$, $mol^{-1}\,l\,cm^{-1}$) 270 (6.5), 300 (13), 330 (2.5), 355 (0.6), 389 (0.8), 424 (0.6), 450 (2.1), 476 (3.3), 536 (3.0).

2.2.2. $[CoDm_3(Sb(C_2H_5)_3)_2]Br$

Complex K_3CoDm_3 (1 g, 1.9 mmol) and $(C_2H_5)_3SbBr_2$ (1.55 g, 4.2 mmol) were dissolved in methanol (25 ml), the reaction mixture was stirred for 1 h and then rotary evaporated to dryness. The solid residue was washed with diethyl ether (20 ml) and filtered. The precipitate was washed with diethyl ether (30 ml, in 3 portions), and dissolved in methylene dichloride. The methylene dichloride solution was filtered and precipitated with hexane. The precipitate was washed with diethyl ether, reprecipitate from chloroform with hexane, washed with hexane and dried *in vacuo*. Yield: 0.90 g (50%). *Anal.* Calc. for $C_{24}H_{48}N_6O_6BrCoSb_2$: C, 32.06; H, 5.39; N, 9.35. Found: C, 32.22; H, 5.32; N, 9.41%. MS (MALDI-TOF): *m/z* 819 $[M-Br^-]^+$. UV–Vis (CH_2Cl_2): λ_{max}/nm ($\varepsilon \times 10^{-3}$, $mol^{-1}\,l\,cm^{-1}$) 256 (28), 278 (9.0), 299 (8.5), 337 (6.3), 382 (1.4), 408 (1.0).

2.3. X-ray crystallography

The details of crystal data collection and refinement parameters for $FeDm_3(Sb(C_2H_5)_3)_2$ and $[CoDm_3(Sb(C_2H_5)_3)_2]Br \cdot 2.5CHCl_3$ complexes are listed in Table 1. Single crystals of these complexes were grown from methylene dichloride – hexane and chloroform – heptane mixtures, respectively.

Data were collected with a Bruker SMART 1K CCD diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å, ω-scans with a 0.3° step in ω and 10 s per frame exposure, $2\theta < 60°$) at 295 K $\{FeDm_3(Sb(C_2H_5)_3)_2\}$ and 120 K $\{[CoDm_3(Sb(C_2H_5)_3)_2]Br \cdot 2.5CHCl_3\}$. Reflections intensities were integrated using SAINT software [6] and corrected for absorption by semi-empirical method using SADABS program [7].

Due to the proximity of all angles to 90° in the $FeDm_3(Sb(C_2H_5)_3)_2$ unit cell, the choice of crystal system was done on the base of the detail analysis of the R_{int} values and systematic absences for all possible variants. All attempts to describe the crystal as a twin (monoclinic which emulate orthorhombic) gave no any change in the convergence factors as well as the standard deviations and residual Fourier electron density synthesis.

The structures were solved by the direct method and refined by full-matrix least squares method against F^2 of all data using SHELXTL-97 [8]. Non-hydrogen atoms were refined in anisotropic approximation (except for methyl groups in the $FeDm_3(Sb(C_2H_5)_3)_2$ molecules). Positions of hydrogen atoms were calculated and included in refinement in isotropic approximation by the riding model with $U_{iso}(H) = U_{eq}(C)$, where $n = 1.5$ for methyl groups and 1.2 for the other groups.

The terminal methyl groups in $FeDm_3(Sb(C_2H_5)_3)_2$ molecule are disordered at two positions with occupation 3:2 (C14 and C14′ atoms), 4:1 (C16 and C16′ atoms, C22 and C22′ atoms), 1:1 (C18 and C18′, C20 and C20′, C24 and C24′ atoms), and were included in refinement in isotropic approximation with constrained C–C bond lengths (1.50 Å). One of the chlorine atoms of one of the solvate chloroform molecules is disordered at two positions (Cl9 and Cl9′) with occupation 7:3.

3. Results and discussion

3.1. Synthesis

The synthesis of the labile in transmetallation reactions antimony-capped clathrochelates is a key step in the prep-

aration of macrobicycle-based hybrid compounds. While inert boron-, tin-, and germanium-capped clathrochelates can be synthesized in many cases using different pathways in high yields, the antimony-capped complexes are formed and isolated in the specific conditions only because of their lability. Therefore, the evaluation of such conditions is an important synthetic challenge.

The clathrochelate $FeDm_3(Sb(C_2H_5)_3)_2$ precursor was obtained by direct template macrocyclization of three dimethylglyoximate fragments with two molecules of a triethylantimony(V)-containing cross-linking agent as a Lewis acid

Scheme 1.

(Scheme 1) on the iron(II) ion matrix, analogous to the system for obtaining of the clathrochelate $FeNx_3(Sb(C_2H_5)_3)_2$ nioximate [9].

Despite the "one-pot" template synthetic procedure for the antimony-capped iron(II) clathrochelate, we failed to succeed with the same pathway for the synthesis of analogous cobalt(III) complex. Our attempts to use the nonmacrocyclic $Co(HDm)_3$ tris-dimethylglyoximate, initially synthesized by a known procedure [10], as a precursor led to a mixture of products, which was contaminated by paramagnetic Co^{2+} impurities. Further cross-linking of this mixture with triethylantimony(V) dibromide both in water and in methanol–water 1:1 medium in the presence of acetate buffer afforded mainly products that were insoluble in either chloroform or methylene dichloride. These products presumably had a polymeric structure, formed *via* cross-linking with Co^{2+} ions. As a result, either the yield of the target $[CoDm_3(Sb(C_2H_5)_3)_2]Br$ clathrochelate was low or the complex we obtained was contaminated by paramagnetic impurities. We also failed to obtain the target clathrochelate in water–methanol medium when we used the nonmacrocyclic tris-dimethylglyoximate $CoDm_3^{3-}$ anion as a precursor without isolating this initial complex from

the reaction mixture, because the clathrochelate product we obtained was also contaminated by paramagnetic impurities.

The nonmacrocyclic K_3CoDm_3 complex was isolated in the solid state as described in [4], and its reaction with $(C_2H_5)_3SbBr_2$ in methanol–water 1:1 mixture led to a light brown reaction mixture, which was extracted with chloroform. Most of the target product was found in this chloroform extract (the total yield was approximately 44%). In the same time, the initial K_3CoDm_3 complex was not extracted with chloroform from its aqueous solution. The reaction of nonmacrocyclic K_3CoDm_3 tris-dimethylglyoximate with $(C_2H_5)_3SbBr_2$ in methanol (Scheme 2) gave the target $[CoDm_3(Sb(C_2H_5)_3)_2]Br$ clathrochelate in 50% yield.

3.2. Structure and spectra

The parameters of ^{57}Fe Mössbauer spectrum of the $FeDm_3(Sb(C_2H_5)_3)_2$ clathrochelate (isomeric shift [IS] is equal to 0.33 mm/s; quadrupole splitting [QS] absolute value is equal to 0.24 mm/s) characterize it as low-spin complex of Fe^{2+} ion in the high field of the clathrochelate ligand. Because QSs for all antimony-capped clathrochelates have a negative sign [1–3], we suggested that QS for the $FeDm_3(Sb(C_2H_5)_3)_2$ complex also has a negative sign.

The solution ^1H and $^{13}C\{^1H\}$ NMR spectra of the diamagnetic iron(II) and cobalt(III) complexes we obtained confirmed the composition and C_3-symmetry of their molecules (in particular, the ratio of line integral intensities of the ethyl substituents in the apical capping triethylantimony fragment) and the methyl substituents in the α-dioximate chelate cycles in the ^1H NMR spectra as well as the number of signals of the carbon atoms of the clathrochelate framework, apical and ribbed substituents in the $^{13}C\{^1H\}$ NMR spectra.

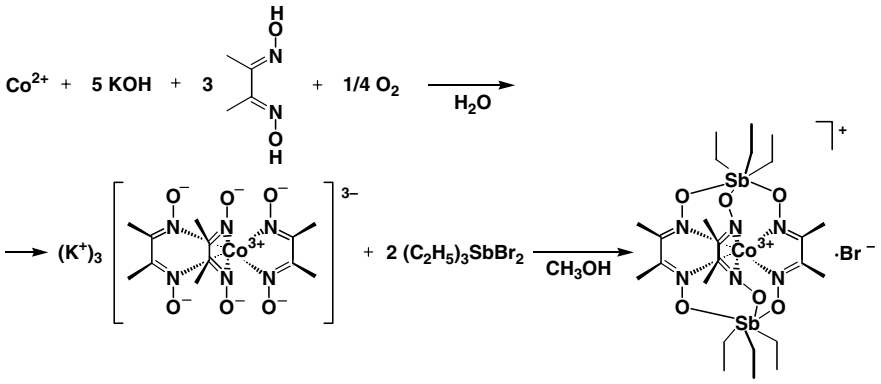
The UV–Vis spectrum of the methylene dichloride solution of the $FeDm_3(Sb(C_2H_5)_3)_2$ complex in the visible region contains three bands with the same intensities ($\varepsilon \sim 2\text{–}3 \cdot 10^3$ mol^{-1} l;cm^{-1}), assigned to the metal – to – clathrochelate ligand $Fed \rightarrow L\pi^*$ charge transfer bands (CTBs). Such high-intensity CTBs mask the low-intensity d–d transitions bands of low-spin Fe^{2+} ion [11]. The same UV–Vis spectra were observed earlier for TAP tin-, antimony- and germanium-capped iron(II) clathrochelates [3,9,12–16].

The deconvoluted UV–Vis spectrum of the clathrochelate synthesized with an encapsulated low-spin cobalt(III) ion, which is isoelectronic (d^6) to iron(II) ion, contains in the visible and near UV regions two bands of d–d transitions $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ (Table 4). This allows one use equations from [17] to calculate both the ligand field Dq and the Racah B parameters for TAP cobalt complexes:

$$\nu_1 = E(^1A_{1g} \rightarrow {}^1T_{1g}) = 10Dq - C$$

$$\nu_2 = E(^1A_{1g} \rightarrow {}^1T_{2g}) = 10Dq - C + 16B$$

We calculated the Dq and B values with the estimation of $C = 4B$ as follows:



$$Dq = (3\nu_1 + \nu_2)/40$$

$$B = (\nu_2 - \nu_1)/16$$

The calculated values as well as the analogous data for the boron- and tin-capped clathrochelate tris-dioximate ligands [12] are listed in Table 5. As seen, all clathrochelate ligands of this type possess the same high ligand field strength, which results in high stability of the low-spin d^6 electronic configuration.

The X-ray crystallography data for the antimony-capped iron(II) and cobalt(III) clathrochelates we synthesized allow one to discuss the changes in the molecular structure of the given metal ion complexes in a series of the clathrochelate ligands with different boron-, tin- and antimony-capping fragments as well as to compare the geometry of the isoelectronic low-spin iron(II) and cobalt(III) complexes with a given clathrochelate ligand.

The intramolecular $FeDm_3(Sb(C_2H_5)_3)_2$ complex (Fig. 2) and the clathrochelate $[CoDm_3(Sb(C_2H_5)_3)_2]^+$ cation (Fig. 3) possess a geometry intermediate between that of a trigonal prism (TP, the distortion angle $\varphi = 0°$) and a trigonal antiprism (TAP, $\varphi = 60°$), which is characteristic of the hexadentate macrobicyclic ligands [12].

Scheme 2.

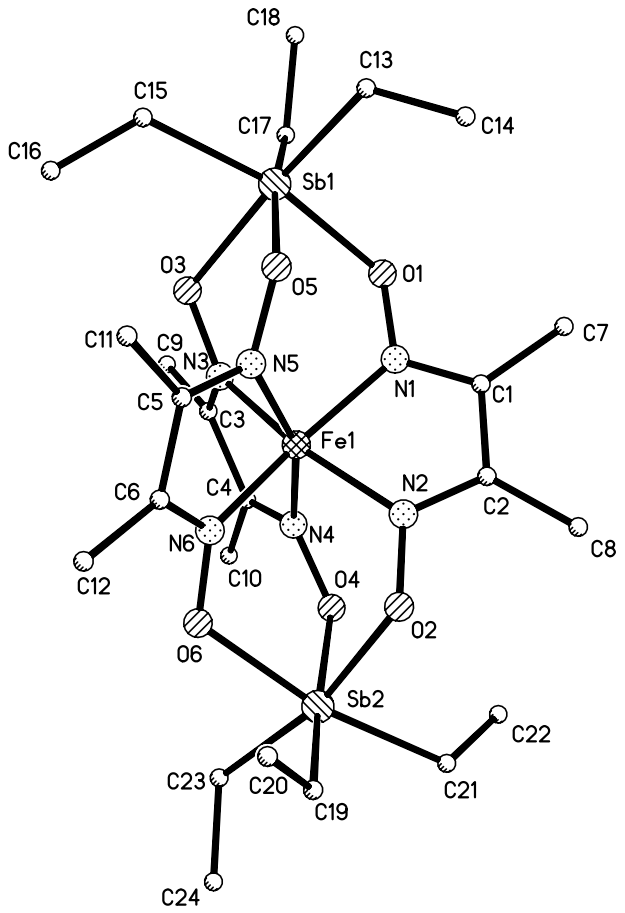


Fig. 2. Molecular structure of the $FeDm_3(Sb(C_2H_5)_3)_2$ clathrochelate (one of the two disordered methyl group is shown). Hydrogen atoms are omitted for clarity.

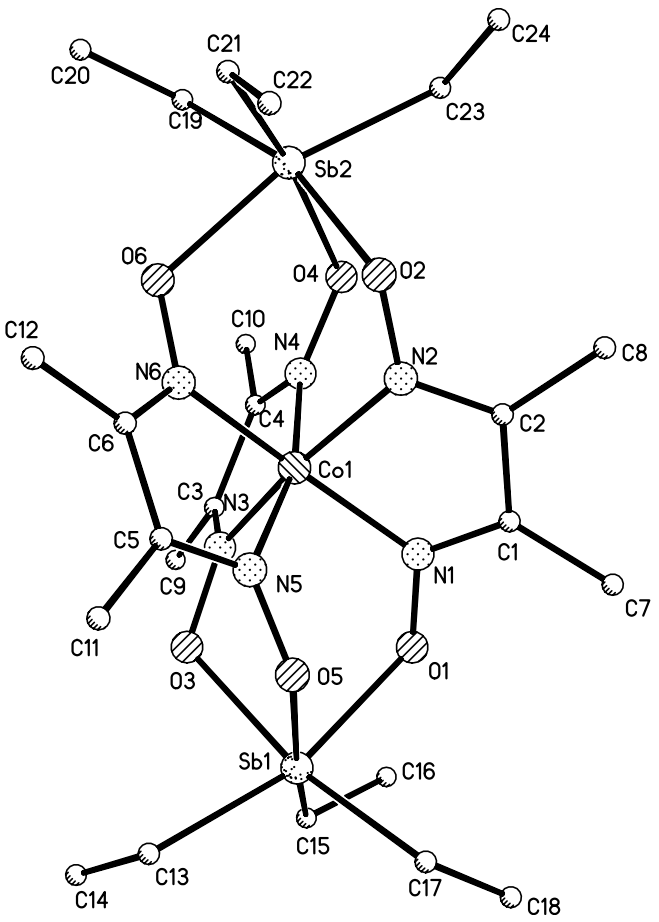

Fig. 3. Molecular structure of the clathrochelate $[CoDm_3(Sb(C_2H_5)_3)_2]^+$ cation. Hydrogen atoms are omitted for clarity.

A previously obtained [3] analogous nioximate $FeNx_3(Sb(C_2H_5)_3)_2$ clathrochelate has a similar molecular structure and geometric parameters close to those of the macrobicyclic framework (Table 2). The coordination N_6-polyhedra of the $FeDm_3(Sb(C_2H_5)_3)_2$ and $FeNx_3(Sb(C_2H_5)_3)_2$ complexes approach a TAP: their average distortion angles φ are close to 36°. The cyclic nature of the peripheral substituents in α-dioximate fragments of the $FeNx_3(Sb(C_2H_5)_3)_2$ molecule has a negligible effect on the orientation of these chelate rings to the symmetry C_3-pseudoaxis, which passes through the capping antimony atoms and the encapsulated iron(II) ion, but results in an increase in the height h of the coordination polyhedron from 2.24 Å for the $FeDm_3(Sb(C_2H_5)_3)_2$ molecule to 2.26 Å for the $FeNx_3(Sb(C_2H_5)_3)_2$ molecule.

The molecular structures of boron-capped iron(II) dimethylglyoximate $FeDm_3(BF)_2$ and nioximate $FeNx_3(Bn\text{-}C_4H_9)_2$ clathrochelates had previously been solved by X-ray crystallography [18]. Nevertheless, in the former clathrochelate molecule, the donor nitrogen atoms are disordered at various temperatures (298, 208 and 138 K), and this made it impossible to compare the data for this complex. The main geometric parameters for the $FeNx_3(Bn\text{-}C_4H_9)_2$ molecule are listed in Table 2, as well as the data for the fluoroboronic $FeBd_3(BF)_2$ [19,22] and $Fe(Cl_2Gm)_3(BF)_2$ [20] complexes with aromatic (phenyl) and halogenide (chloride) substituents, respectively, in the α-dioximate chelate fragments. For the former complex, the X-ray structures of two (chloroform and toluene) solvates have been described [19,22]. Because the molecular and crystal structure of the toluene solvate was solved with lower convergence factors [19], we discuss the X-ray data for this solvate.

We observe significant changes in the geometry of the clathrochelate framework as we move from the antimony-capped $FeDm_3(Sb(C_2H_5)_3)_2$ and $FeNx_3(Sb(C_2H_5)_3)_2$ complexes to their boron-containing $FeNx_3(Bn\text{-}C_4H_9)_2$, $FeBd_3(BF)_2$ and $Fe(Cl_2Gm)_3(BF)_2$ analogs. First, the distortion angle φ values for the encapsulated iron(II) ion coordination polyhedra decrease significantly (by 15–20°), whereas the Fe–N distances and bite angles α remain constant. As a result, the heights h increase by ~0.1 Å, the polyhedron geometry approaches that of a TP (average φ values are equal to 20°), and the deviation angles ω between the chelate rings and C_3-pseudoaxes decrease by approximately 10°. TAP distortion of the clathrochelate frameworks is determined by the nature of the apical capping atoms Q, rather than the alkyl, aryl, or halogenide

[a] Mean deviation of the coordinated nitrogen atoms from the C–Fe–C plane.
[b] Distortion angle.
[c] Bite angle (half the chelate angle).
[d] Distance between the coordination polyhedron bases (the height of the distorted TP).
[e] Deviation of the iron(II) ion from N_6-coordination polyhedron trigonal bases.
[f] Dihedral angle between the N_6-coordination polyhedron trigonal bases.
[g] The angles between the chelate N...N and capping Q...Q axes.
[h] Iron(II) ion is in special position.

substituents in the chelate α-dioximate ribbed fragments. It should be noted that the distortion angle φ values for dianionic tin-capped $[FeNx_3(SnCl_3)_2]^{2-}$ [21] and $[Fe(Cl_2Gm)_3(SnCl_3)_2]^{2-}$ clathrochelates [14] are slightly higher (average 38–40°) then those for antimony-capped $FeDm_3(Sb(C_2H_5)_3)_2$ and $FeNx_3(Sb(C_2H_5)_3)_2$ complexes. In an attempt to explain the influence of the nature of capping atoms on the macrobicyclic ligand geometry, we compared both the bond lengths and angles in the coordination polyhedra of the encapsulated iron(II) ions for the $FeDm_3(Sb(C_2H_5)_3)_2$, $FeNx_3(Bn\text{-}C_4H_9)_3$, $FeBd_3(BF)_2$, and $Fe(Cl_2Gm)_3(BF)_2$ molecules, because their X-ray data were collected at similar temperatures and with approximately equal convergence factors. The average Fe–N distances in these molecules are the same, the C–N and N–O bond lengths are also practically constant. More significant differences are observed in the values of Sb–O–N and B–O–N bond angles (*av.* 119 and 112°, respectively). The distances between the encapsulated iron(II) ion and the N1.N3.N5 and N2.N4.N6 bases of a TP–TAP coordination polyhedron in the $FeNx_3(Bn\text{-}C_4H_9)_2$, $FeBd_3(BF)_2$ and $Fe(Cl_2Gm)_3(BF)_2$ molecules are significantly greater than those of the $FeDm_3(Sb(C_2H_5)_3)_2$ clathrochelate. The elongation of the Q–O bonds is caused by the small Shannon radius of the capping boron atom compared with that of the apical antimony atom. This results in a decrease in the average values of both the bond Q–O angles and the deviation angles ω between the chelate fragments and the Q...Q axis of the clathrochelate framework. As a result, the height h of the coordination polyhedron in boron-capped molecules increases. In the $FeDm_3(Sb(C_2H_5)_3)_2$ molecule, the average deviation angle ω between the Q...Q axis and the N...N axes in chelate fragments is equal to 23.5°, whereas in the $FeNx_3(Bn\text{-}C_4H_9)_2$, $FeBd_3(BF)_2$ and $Fe(Cl_2Gm)_3(BF)_2$ molecules, these angles are appreciably smaller (*av.* 13°).

We attribute major discrepancies in the geometry of the clathrochelate framework in the $[FeNx_3(SnCl_3)_2]^{2-}$ dianion and the $FeNx_3(Sb(C_2H_5)_3)_2$ intracomplex to slight differences in the Fe–N bond lengths and the mutual orientation of chelate cycles. The average Fe–N distance in the $[FeNx_3(SnCl_3)_2]^{2-}$ dianion is somewhat longer (1.923 Å) than that in the $FeNx_3(Sb(C_2H_5)_3)_2$ molecule (1.914 Å). In the former case, the bond angles at the oxygen atoms are reduced (*av.* 114.9°), whereas in the latter case, they are close to 120°, but the Sb–O and Sn–O distances are the same. In the tin-capped clathrochelate $[Fe(Cl_2Gm)_3(SnCl_3)_2]^{2-}$ anion, the Fe–N, Sn–O, C=N, and chelate C–C bond lengths, as well as the average Sn–O–N, O–N–C, and N=C–C bond angles in the clathrochelate framework, remain practically unchanged from those in its nioximate analog. However, the N–O distances in the $[Fe(Cl_2Gm)_3(SnCl_3)_2]^{2-}$ dianion are markedly lower than those in the $[FeNx_3(SnCl_3)_2]^{2-}$ anion (*av.* 1.349 and 1.376 Å, respectively).

The main geometric parameters of the clathrochelate $[CoDm_3(Sb(C_2H_5)_3)_2]^+$ cation and its macrobicyclic analogs with an encapsulated cobalt(III) ion are listed in Table 3. The coordination polyhedra of antimony- and tin-capped cobalt(III) clathrochelates approach a TAP: the distortion angles φ are in the range 40.5–46.4° and they are essentially higher than those of the analogous iron(II) complexes and those of the boron-capped $[CoDm_3(BF)_2]^+$ cation ($\varphi = 31.3°$). The TAP distortion of the cobalt(III) coordination polyhedra causes an increase in the deviation angle ω value, but the flatness of the chelate fragments remaines unaffected (the changes in the N=C–C=N torsion angles are negligible). The contraction along the Q...Q axis, which results in a decrease in the h values for the clathrochelate $[CoDm_3(Sb(C_2H_5)_3)_2]^+$, $[CoDm_3(SnBr_3)_2]^-$, and $[CoDm_3(SnCl_3)_2]^-$ ions, is larger than that of the $[CoNx_3(SnCl_3)_2]^-$ anion. The C=N and N–O bond length remain practically constant (within the experimental errors), whereas the Q–O distances and Q–O–N bond angles are characteristic of the corresponding capping atoms. The average Co–N distances in the clathrochelate $[CoDm_3(Sb(C_2H_5)_3)_2]^+$, $[CoNx_3(SnCl_3)_2]^-$, $[CoDm_3(SnBr_3)_2]^-$, $[CoDm_3(SnCl_3)_2]^-$, and $[CoDm_3(BF)_2]^+$ ions are close to those typical for low-spin tris-α-dioximate cobalt(III) complexes (1.89 Å) [26].

Thus, as seen in Tables 2 and 3, the C=N, N–O, and chelate C–C bond lengths and the N=C–C=N torsion angles remain practically unchanged in the different types of clathrochelate molecules. The Q–O–N bond angles are more sensitive to the nature of the clathrochelate framework. However, these angles are governed by a capping atom Q and, like the Q–O distances, are constant in the tris-dioximate clathrochelates with the same apical capping atoms.

The distortion angle φ, bite angle α, and height h values are the main characteristics of a TP–TAP coordination polyhedron (Table 4). These polyhedra for boron-capped clathrochelate molecules are contracted in the direction of the C_3-pseudoaxis compared with those for their tin- and antimony-capped analogs. This contraction correlates with the Shannon ionic radius values for the corresponding capping atoms Q (B^{3+} (0.25 Å), Sn^{4+} (0.83 Å) and Sb^{5+} (0.74 Å)): the B–O bond lengths are essentially shorter than the Sn–O and Sb–O lengths (*av.* 1.49, 2.10 and 2.13 Å, respectively). Because the N–O, C=N and chelate C–C bond lengths are equal for all α-dioximate clathrochelate molecules an, increase in the Q–O distances causes a decrease in the Q–O–N angles (112°, 115° and 119° for the boron-, tin-, and antimony-capped compounds, respectively) and the contraction of the coordination polyhedron (the height h decreases). In the case of TAP tin- and antimony-capped molecules, the deviation angle ω values are essentially higher than those of their TP boron-capped analogs.

The contraction (expansion) of the coordination N_6-polyhedron is also determined by the Shannon ionic radius of an encapsulated metal ion (the Shannon radii are equal to 0.75 and 0.68 Å for low-spin hexacoordinate Fe^{2+} and Co^{3+} ions, respectively). The average Fe^{2+}–N (~1.91 Å) and Co^{3+}–N (~1.89 Å) distances differ only slightly, but

$[CoDm_3(SnCl_3)_2]^-$ [24]	1.902	2.177	42.8	40.2	27.6
$[CoDm_3(BF)_2]^+$ [25]	1.894	2.290	31.2	40.0	19.5

for the complexes with the same macrobicyclic ligand, the distortion angle φ value is significantly higher for the corresponding cobalt(III) clathrochelate than for its iron(II)-containing analog.

It should be noted that the height h is characteristic of a linear shift of the coordination polyhedron bases from each other, but does not indicate a change in the deviation angle ω. In contrast, the distortion angle φ is characteristic of the mutual angular distortion of these bases, but does not indicate a their linear shift. Both the height h and the distortion angle φ are independent parameters and change in the opposite directions, which allow one to describe the rotary-translational contraction (expansion) of the coordination polyhedron.

3.3. Electrochemistry

Electrochemical investigation of the new antimony-capped iron(II) and cobalt(III) clathrochelates was performed in two solvents with different polarity and donor numbers (methylene dichloride and acetonitrile). CVs obtained for both complexes are shown in Fig. 4. For the iron complex, the electrochemical response of the $Fe^{2+/3+}$ redox couple ($E_0 = 580$ mV) is diffusionally controlled (as follows from the linear relationship $I_p - \upsilon^{1/2}$, where υ is the scan rate) and quasi-reversible (the current ratio $I_c/I_a = 1$, and the peak separation ΔE_p is equal to 110 mV). Two additional peaks at 1460 and −2040 mV were assigned to the further oxidation and reduction of the clathrochelate framework followed by its destruction. The E_p values are listed in Table 6. The cobalt(III) clathrochelate differs from its iron(II)-containing analog by the presence of the outer-sphere Br^- counter-ion, which can be detected by two characteristic oxidation peaks at 1030 and 1280 mV (see Fig. 4) attributed to the consecutive oxidation of the Br^- and Br_3^- species [27].

Furthermore, the redox process assigned to the $Co^{3+/2+}$ redox couple ($E_0 = -810$ mV) is observed in the cathodic region of CV. As seen from the linear I_p–$\upsilon^{1/2}$ relationship, the reduction of the cobalt(III) clathrochelate is diffusionally controlled. The ratios of peak currents for direct (cathodic) and reverse (anodic) peaks I_a/I_c are equal to 1

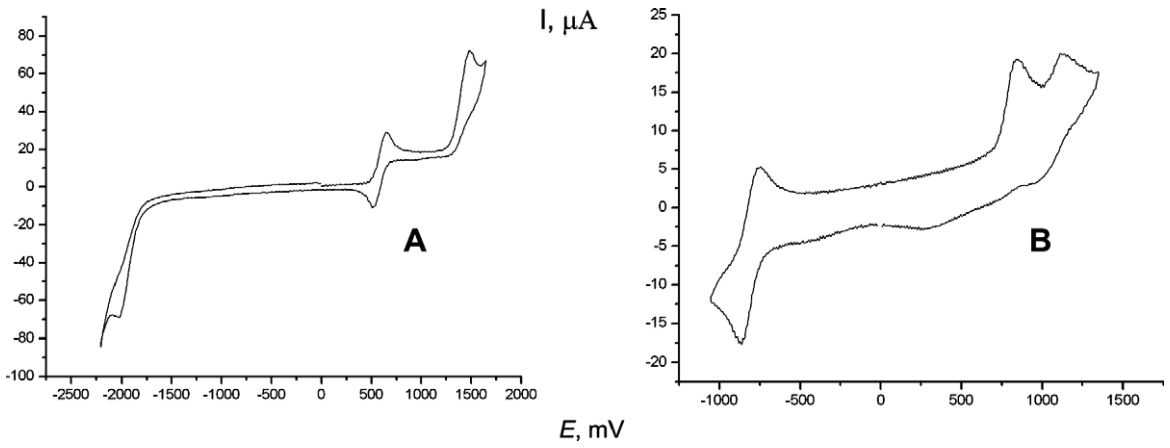

Fig. 4. Cyclic voltammograms for $FeDm_3(Sb(C_2H_5)_3)_2$ (A, in methylene dichloride) and $[CoDm_3(Sb(C_2H_5)_3)_2]Br$ (B, in acetonitrile) clathrochelates ($c = 0.7$ mM, Pt, 0.15 M $(Bu_4N)BF_4$, 100 mV/s, vs. Ag/AgCl/KCl).

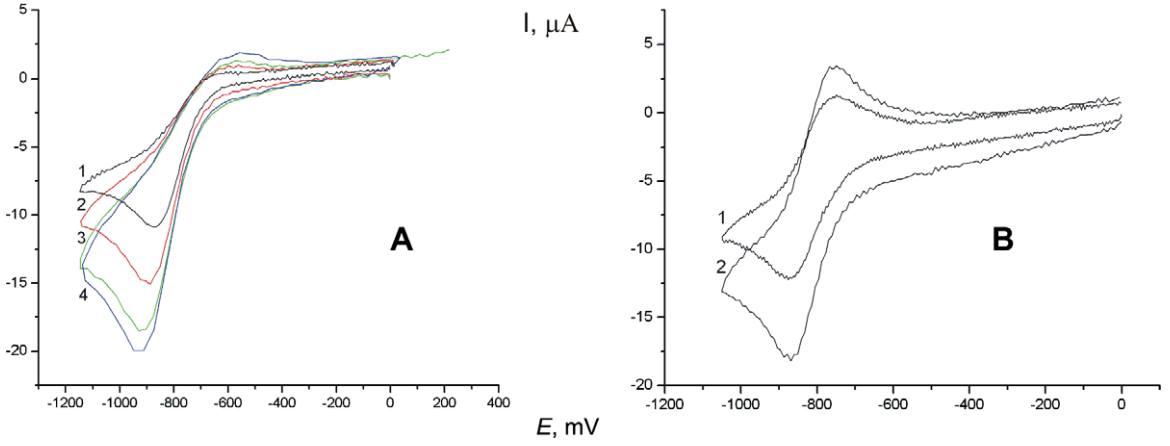

Fig. 5. Cyclic voltammograms for $[CoDm_3(Sb(C_2H_5)_3)_2]Br$ complex at the different potential scan rates in methylene dichloride (A, 100 (**1**), 200 (**2**), 300 (**3**) and 400 (**4**) mV/s) and in acetonitrile (B, 100 (**1**) and 200 (**2**) mV/s) solutions ($c = 0.7$ mM, Pt, 0.15 M $(Bu_4N)BF_4$, vs. Ag/AgCl/KCl).

at the potential scan rates of more than 50 mV/s (see Fig. 5). However, it should be noted that in acetonitrile solution the reduced cobalt(II) clathrochelate was more stable than this complex in methylene dichloride solution. The CVs of the $[CoDm_3(Sb(C_2H_5)_3)_2]Br$ clathrochelate, which were recorded in methylene dichloride at the scan rate lower than 200 mV/s, exhibited no reoxidation peaks. A small reoxidation peak appeared at the scan rate equal to 400 mV/s with $I_a/I_c = 0.45$. This allowed us to estimate the lifetime of the reduced $CoDm_3(Sb(C_2H_5)_3)_2$ macrobicycle in methylene dichloride solution in the time scale of the method. The $\tau_{1/2}$ value obtained falls within the interval

Table 6
Cyclic voltammetry data (mV, [a]) for iron(II) and cobalt(III) clathrochelates obtained

Complex	Solvent	Electrode material	Oxidation		Reduction	
			E_p^a	E_p	E_p	E_p^a
$FeDm_3$-$(Sb(C_2H_5)_3)_2$	CH_2Cl_2	Pt	640 1460	530	–2040	
		GC	640 1440	550	−2000	
$[CoDm_3(Sb$-$(C_2H_5)_3)_2]Br$	CH_2Cl_2	Pt	1030 1280		−910	−580
		GC	1050 1300		−880	−580
	CH_3CN	Pt	870 1150		−880	−730
		GC	910 1230		−870	−770

[a] 0.15 M $(Bu_4N)BF_4$, 200 mV/s, *vs.* Ag/AgCl/KCl.

of 2–3 s in methylene dichloride solution, whereas in acetonitrile solution the $\tau_{1/2}$ value is more than 5 s. However, the formal potential values for the Co^{3+}/Co^{2+} redox couple in methylene dichloride and acetonitrile are rather close ($E_0 = -750$ and -810 mV, respectively).

Changing of the working electrode material from platinum to glassy carbon did not influence the peak potential values observed for both complexes: as seen in Table 6, the potential values are almost identical.

Thus, the cyclic voltammetry data present information about the stability of the electrochemically generated forms of the cobalt clathrochelates in different solvents, and this allows one to choose the optimal preparative pathways and conditions for further synthesis and modifications of the polytopic cobalt(II) and cobalt(III) cage compounds.

Abstract

A set of four Cu(II) complexes, [Cu(cdnapen)], [Cu(cdnappd)], [Cu(cdMenappd)] and [Cu(cdMeMeOsalpd)], derived from Schiff base ligands with an asymmetric NN′OS coordination sphere have been synthesized. The molecular and the crystal structures have been determined by X-ray diffractometry. The structural results confirm that the complexes are tetra coordinated. The copper (II) ion coordinates to two nitrogen atoms from the imine moiety of the ligand, a sulfur atom from the methyl dithiocarboxylate moiety and a phenolic oxygen atom. The complexes show an unusual tetrahedral distortion to the square-planar geometry around the metal centre in spite of the pseudomacrocyclic skeleton of the ligand. The complexes were further characterized by cyclic voltammetry and electron paramagnetic resonance spectroscopy. The degree of tetrahedral distortion of the complexes appears to be dependent on the number of carbon atoms of the aliphatic bridge and the nature of the coordinating atoms.

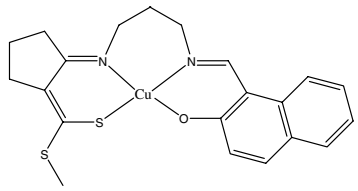
1. Introduction



Cu(II)/Cu(I) chemistry has received renewed attention since the characterization and the structural elucidation of blue copper proteins [1–4], e.g. hemocyanin, tyrosinase, cytochrome *c* oxidase and laccase. These proteins have been reported to play an important role in electron transfer during biochemical metabolism. The metal centre responsible for the electron transfer has been identified as containing the redox pair Cu(II)/Cu(I) with quite positive reduction potentials. This feature has been attributed to the unusual coordination geometry around the metal centre. Blue copper proteins have an active copper centre with a N_2S_2 or a N_2OS_2 coordination sphere. Several attempts of preparing lower molecular weight compounds for modelling the redox behaviour of this active centre have been made [5–11]. The copper (II) moiety in biological proteins is asymmetric and, for the tetracoordinated active centre, the geometry around the Cu(II) ion seems to have a significant tetrahedral distortion from square planar geometry. We have prepared a series of Cu(II) complexes with a pseudomacrocyclic Schiff base ligand with a N_2OS asymmetric coordination sphere, as depicted in Scheme 1. The complexes have a sulfur donor atom that can act as a π acceptor, an oxygen donor atom as a π donor and the coordination around the copper ion allows for π electronic

Scheme 1.

delocalization. These complexes were characterized in the solid state by X-ray diffractometry in order to elucidate their molecular and crystal structures and to evaluate their degree of tetrahedral distortion to the square planar geometry. Also they have been characterized by EPR spectroscopy in solution at 298 K and at 77 K. Further, their electrochemical behaviour was studied by cyclic voltammetry. The structural and the electrochemical results are compared with those obtained for the corresponding symmetric N_2O_2 and N_2S_2 Cu(II) complexes.

2. Experimental

2.1. Reagents and solvents

All solvents and reagents used in the synthesis and characterization were of reagent grade and were used as received. Solvents used in the electrochemical studies (Merk *pro analysis*) were dried by standard methods. Tetra(*n*-butyl)ammonium perchlorate, TBAP, was prepared following published procedures [12]. *CAUTION*: perchlorates may be hazardous and may explode.

2.2. Synthesis of the ligands

Methyl 2-{*N*-(2-aminoethane)}-amino-1-cyclopentenedithiocarboxylate (Hcden) and methyl 2-{*N*-(2-aminopropane)}-amino-1-cyclopentenedithiocarboxylate (Hcdpd) were prepared by published methods [13,14]. The other ligands were prepared following the general published procedure [15,16].

2.3. Synthesis of the Cu(II) complexes

2.3.1. General procedure

A solution of copper (II) acetate monohydrate (0.1 mmol in 10 cm^3 of methanol) was added to 0.1 mmol of the appropriate ligand in chloroform/methanol (2:1) v/v solution. The mixture was stirred for about 20 min and allowed to react at room temperature for about 24 h. The resulting green or brown powder was recrystallized from acetonitrile/methanol (1:1) v/v. Single crystals for X-ray diffraction were obtained by slow evaporation of the acetonitrile/methanol (1:1) v/v solution.

2.4. Instrumentation and electrochemical measurements

Elemental analysis (C, H and N) were performed at the Micro Analytical Laboratory, University of Manchester.

The electrochemical studies were performed with an EG&G PAR 362 instrument. Cyclic voltammetry was carried at room temperature under nitrogen atmosphere on a three-electrode system cell consisting of a microplatinum electrode, a platinum wire counter electrode and an Ag/AgCl (1 mol dm^{-3} NaCl) reference electrode. The cyclic voltammograms were recorded from $\sim 10^{-3}$ mol dm^{-3} solutions of the complexes in dmf, $(CH_3)SO$ and CH_3CN solutions. The potentials were corrected for the ferrocenium/ferrocene (Fc^+/Fc) couple. The potentials were scanned between 0.0 and −2.0 V at a scan rate of 50 mV s^{-1}. Vol-

tammograms were also obtained with scan rates from 20 to 500 mV s^{-1}, to check the reversibility of the redox process.

The EPR spectra were obtained with a Bruker ESP300E spectrometer (9 GHz) in a dual cavity, using diphenylpicrylhydrazyl ($g = 2.0037$) as an external standard; the magnetic field was calibrated with Mn^{2+} in MgO.

2.5. Structure determination

The data acquisition was made using a Stoe Stadi IV diffractometer for [Cu(cdnapen)] and [Cu(cdMeMeOsalpd)] and an image plate Stoe Ipds diffractometer for [Cu(cdnappd)] and [Cu(cdMenappd)], $\lambda = 0.71073$ nm. Intensities were corrected for Lorentz and polarization effects. Empirical absorption correction was performed for compounds [Cu(cdnapen)] and [Cu(cdMeMeOsalpd)] and numerical absorption correction was performed for [Cu(cdnappd)] and [Cu(cdMenappd)] using the package SADABS [17]. SHELX-97 [18] was used to make the structure solution and refinement. The structures were solved by direct methods and subsequent Fourier difference techniques. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares on F^2. Hydrogen atoms were treated as riding atoms with C–H(aromatic) 0.93 Å, C–H(CH_2) 0.97 Å, C–H(CH_3) 0.96 Å, and given an isotropic displacement parameter equal to 1.2 (CH, CH_2) and 1.5 (CH_3) times the equivalent isotropic displacement parameter of the atom to which it is attached. Details for crystallographic data and refinement of the four complexes are shown in Table 1. Molecular and packing diagrams were generated by ORTEP-32 [19] and PLATON [20].

3. Results and discussion

3.1. Structures of the complexes

The X-ray structure determinations confirmed that the complexes show the expected molecular structure. For compounds [Cu(cdnapen)], [Cu(cdnappd)] and [Cu(cdMenappd)], the metal is bonded to the two imine nitrogen atoms, to the sulfur atom from the methyl dithiocarboxylate residue and to the naphtholic oxygen atom of the ligand, assuming a *cis* configuration. For the complex [Cu(cdMeMeOsalpd)], the ligand is a Schiff base that is formed with a fragment derived from the 5-methoxyketophenone and another one derived from the 2-aminocyclopentenedithiocarboxylate methyl ester. Complex [Cu(cdnapen)] has an ethylenic diimine chain while the remaining complexes have a propylenic one.

The structures of complexes are depicted in Figs. 1–5. The main bond lengths for the compounds studied as well as for the homologous compounds with a symmetric coordination sphere, are shown in Table 2. The bond lengths are within the expected range for copper (II) complexes with

Schiff base ligands [21]. The analysis of the bond length within the metallocyclic part of the molecule is indicative of a strong delocalization of the π-electron density through the six member rings. For the cyclopentene fragment, the mean value for the S21–C221 bond length is 1.7150(7) Å, which is considerably lower than what is usually found for a single S–Csp^3 bond, 1.808(10) Å, and similar to the 1.712(17) Å attributed to the S–Csp^2 bond in thiophene, showing a high delocalization of the π-electron density in this part of the molecules [22]; in addition, the distances found between the C21/C41 and C22/C42 carbon atoms of the cyclopentene ring have a mean value within the range 1.439(5)–1.443(9) Å that is similar to the mean value for the Csp^2–Csp^2 bond in conjugated systems [22]. Finally, the similarity of the C21–N2 and C1–N1 bond length values is indicative that this fragment coordinates in a Schiff base mode. This electronic delocalization was reported for complexes containing this type of ligand with other metals [23,24] and for complexes of related ligands [25,26].

The cyclopropene ring defined by the atoms C*n*1–C*n*2–C*n*3–C*n*4–C*n*5 (where *n* is 2 or 4) is puckered in all cases except the compound [Cu(cdMenappd)]. This puckering can be quantified in terms of the pseudorotation parameters P and τ [27]. In all cases the reference bond is C*n*1–C*n*2. For [Cu(cdnapen)], the pucker values P and τ are $P = 296.8(19)°$, $\tau = 11.5(4)°$ corresponding to a twist on C24 and C25 for molecule **A**, and $P = 80.9(19)°$, $\tau = 10.4(4)°$ corresponding to an envelope on C44 for molecule **B**. For [Cu(cdnappd)] these values are $P = 98.6(12)°$, $\tau = 23.2(5)°$ corresponding to an envelope on C24 and for [Cu(cdMeMeOsalpd)] $P = 89.4(6)°$, $\tau = 29.8(3)°$ corresponding to an envelope on C24.

All the Cu(II) complexes show a square planar geometry but with different degrees of tetrahedral distortion. The degree of the distortion will be quantified by measuring the dihedral angle, θ, between planes formed by the N/Cu/O and N/Cu/S atoms of the two semi-coordination spheres.

3.1.1. [Cu(cdnapen)]

The ORTEP representation of the structure of this complex, including the atom numbering scheme is shown in Fig. 1. The crystal structure determination revealed the existence of two independent molecules in the asymmetric unit. These are assigned as molecule **A** (labelled as Cu1) and molecule **B** (labelled as Cu2). The two molecules have different tetrahedral distortions relative to the square-planar geometry. Molecule **A** presents a dihedral angle of 5.28(17)° and molecule **B** of 11.52(9)°. In both of them, the geometry around the coordination centre is more planar than that in the homologous N_2S_2 complex [Cu(cden)] that presents an dihedral angle of about 20° [21]. On the other hand, the analogous N_2O_2 [Cu(napen)] seems to be more planar with $\theta \approx 7°$ [28].

The minimum distance between the copper atoms is 3.879 Å which rules out the existence of an interaction between them. This observation contrasts with that described for the homologous symmetric N_2O_2 complex, [Cu(napen)], for which the crystallographic results pointed to the existence of an interaction between the copper ion (placed in an apical position) of the complex and the donor oxygen atom of the above one.

3.1.2. [Cu(cdnappd)]

The molecular diagram of this complex, together with the atom numbering scheme is depicted in Fig. 2. The molecular structure revealed that the geometry around the coordination centre is a square planar one with a tetrahedral distortion. The dihedral angle is 37.36(25)°, higher than that reported for [Cu(nappd)], 6.1° [30], the analogous symmetric N_2O_2 complex, but lower than that shown by the analogous N_2S_2 complex, [Cu(cdpd)], which has a value of ca. 50° [25]. The aliphatic chain is in the *twist* conformation.

In this compound C18 acts as a hydrogen bond donor to atom O12 in the molecule at $(x, 1.5 - y, 0.5 + z)$, so forming a C(6) chain [29] which runs parallel to the *c*-axis (Fig. 3). The C–H distance is 0.93 Å, the H···O distance is 2.48 Å and the C—O distance is 3.397(7) Å. The angle at H is 171°. The same O12 oxygen atom establishes a short contact with H1–C1 of the *c*-glide related complex, O12···H1–C1 (distance 2.64 Å).

3.1.3. [Cu(cdMenappd)]

The structure of [Cu(cdMenappd)] is depicted in Fig. 4. The propylenic aliphatic chain of the ligand assumes a

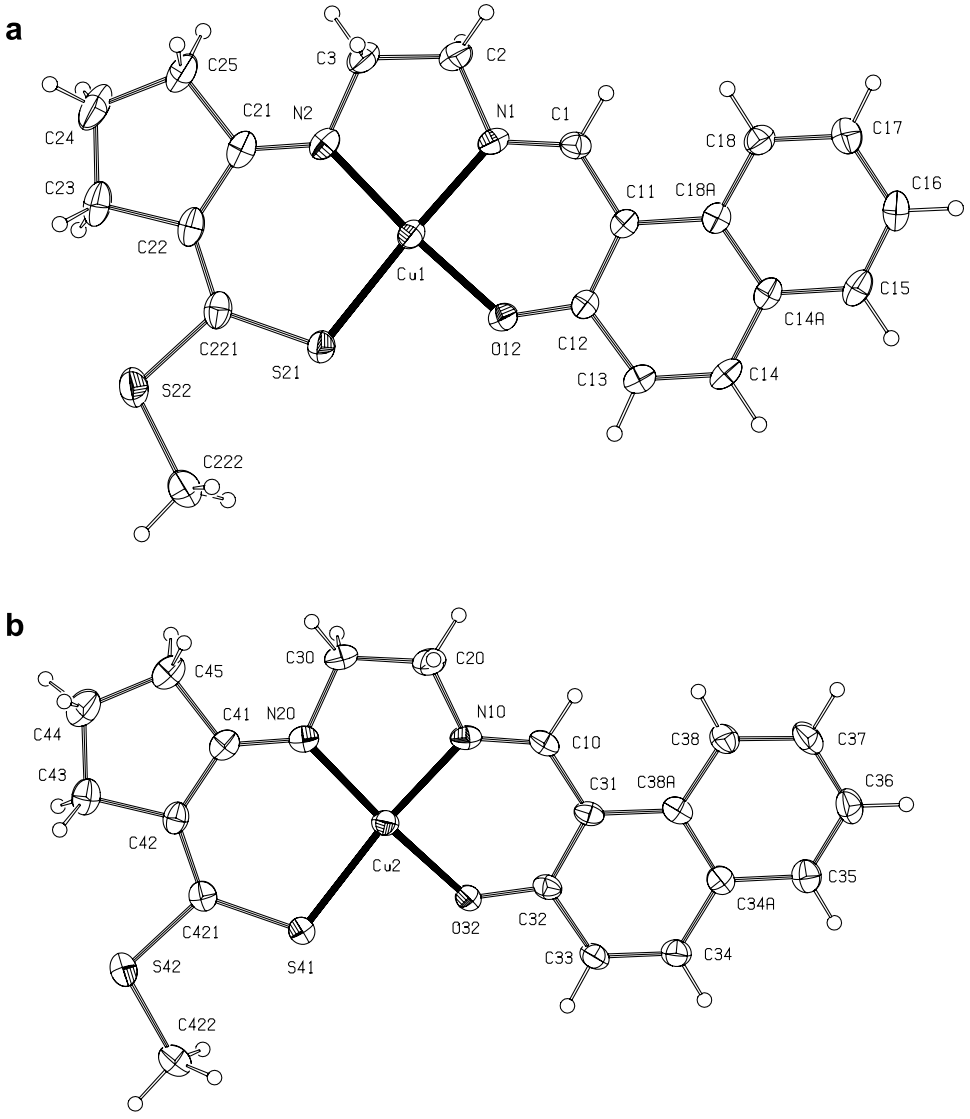

Fig. 1. A view of [Cu(cdnapen)] **A** (labelled with Cu1) and **B** (labelled with Cu2) with the adopted numbering scheme. Displacement ellipsoids are drawn at the 30% probability level.

"*boat*"-shape conformation in the complex. The coordination around the Cu(II) ion is square planar with a tetrahedral distortion. For this compound $\theta = 28.44(15)°$. This value is lower than that of 50° reported for [Cu(cdpd)] [25], and higher than the dihedral angle for the symmetric [Cu(nappd)], with a reported value of 6.1° [30].

3.1.4. [Cu(cdMeMeOsalpd)]

Fig. 5 shows the perspective view and the atomic numbering scheme for the [Cu(cdMeMeOsalpd)] complex. The trimethylenic chain of the ligand is *twisted* and the chelating rings assume an *umbrella* conformation relative to each other. The complex also presents some degree of tetrahedral distortion around the metal centre relative to the square-planar geometry. The dihedral angle between the N/Cu/S and N/Cu/O planes is 41.79(10)°. This complex is more tetrahedrally distorted than [Cu(salpd)] [31], for which the θ angle is ca. 21.0°, but the distortion value is similar to that for [Cu(Me_2salpd)], which is 43.8° [32]. Anyhow, the symmetric homologous N_2S_2 complex [Cu(cdpd)] [25] exhibits even higher distortion ($\theta = 50°$) showing that the presence of the sulfur atom also plays an important role in the geometrical distortion from the square planar shape in these complexes.

Our structural results point out some factors that can change the degree of tetrahedron distortion of these Cu(II) complexes, namely, (i) the number of ethylene groups in the ligand bridge and (ii) the type of donor atoms. Comparing the theta values for the [Cu(salen)]/[Cu(salpd)] (1.7° and 21°), [Cu(cden)]/[Cu(cdpd)] (20° and 50°) and [Cu(cdnapen)]/[Cu(cdnappd)] (5.5°/11.6° and 37.3°) set of pairs, it is clear that the three carbon atom chain induces a higher distortion than the two carbon atom chain. This has been reported for several other studies on Schiff base metal complexes that have even lower electronic preferences for square planar geometries.

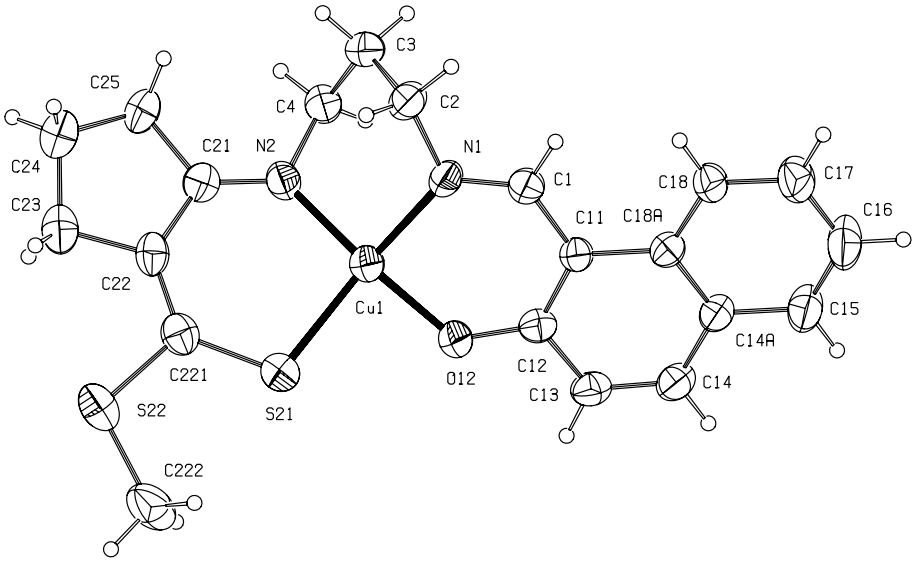

Fig. 2. A view of [Cu(cdnappd)] with the adopted numbering scheme. Displacement ellipsoids are drawn at the 30% probability level.

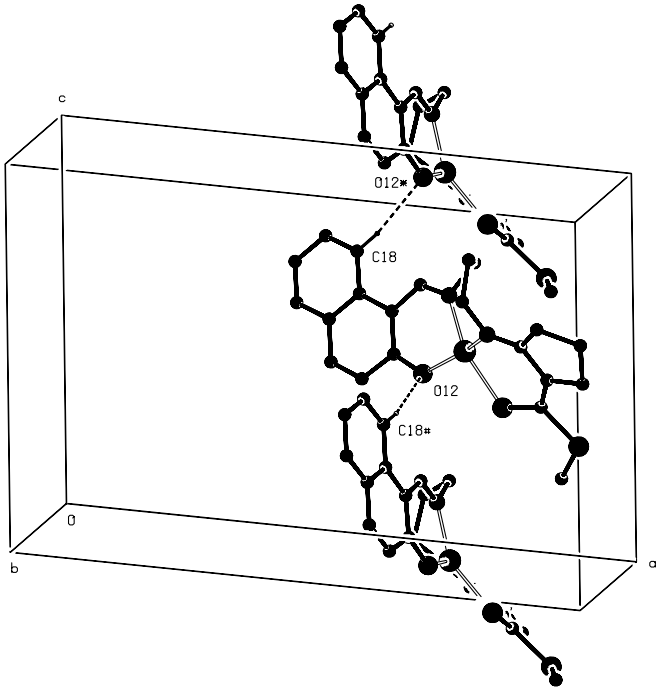

Fig. 3. Part of the structure of compound [Cu(cdnappd)] showing a C(6) chain running parallel to the *c*-axis. Hydrogen atoms not involved in the hydrogen bonding are omitted for clarity. The atom marked with an asterisk, (*), and hash, (#), are at symmetry positions (x, $1.5 - y$, $0.5 + z$) and (x, $1.5 - y$, $-0.5 + z$), respectively.

The complexes with an N_2O_2 coordination sphere are more planar than those with a N_2OS coordination sphere, that are, on the other hand, more planar than those with N_2S_2. A larger difference is observed for [Cu(nappd)]/[Cu(cdnappd)] and [Cu(cdpd)], which have 6.1°, 37° and 50° theta angles values, respectively. A sulfur donor, which gives a lower ligand field strength, shows a higher tendency than oxygen towards tetrahedral distortion.

3.2. Electron paramagnetic resonance spectroscopy

The EPR characterization of the complexes in dmf solution was made at room temperature and at 77 K. In Table 3, EPR parameters that were obtained after computational simulation of the experimental spectra are presented and in Fig. 6 a typical spectrum obtained for the complexes, together with the graphic computational simulation is shown.

The EPR parameters are in the range expected for tetra-coordinate copper (II) complexes with N_2S_2 and N_2O_2 coordination spheres and show the typical hyperfine splitting with the ^{63}Cu and ^{65}Cu nuclei. Super-hyperfine coupling with the two magnetically equivalent nitrogen nuclei (^{14}N, $I = 1$) is also observed either at room temperature or in frozen solution, in accordance with the similarity between the two nitrogen donor atoms revealed in the molecular structures of the complexes.

A comparison of the EPR parameters shows that the g and A values are very sensitive to the tetrahedral distortion of the complexes, as usually observed for tetra-coordinated copper (II), with a marked decrease of A values and an increase in g_1 with the tetrahedral distortion [33–36]. The dependence of the EPR parameters on the coordination sphere is not so important, and in fact the ERP parameters obtained for the N_2OS complexes are more similar to the N_2S_2 parent complexes than to the N_2O_2 copper (II) Schiff base complexes [37,38].

3.3. Electrochemistry

The results obtained in the electrochemical studies are summarized in Table 4. The symmetric N_2S_2 Cu(II) complexes were also studied under the same conditions for a direct comparison of the results. For all the complexes one anodic peak is observed in the potential range from

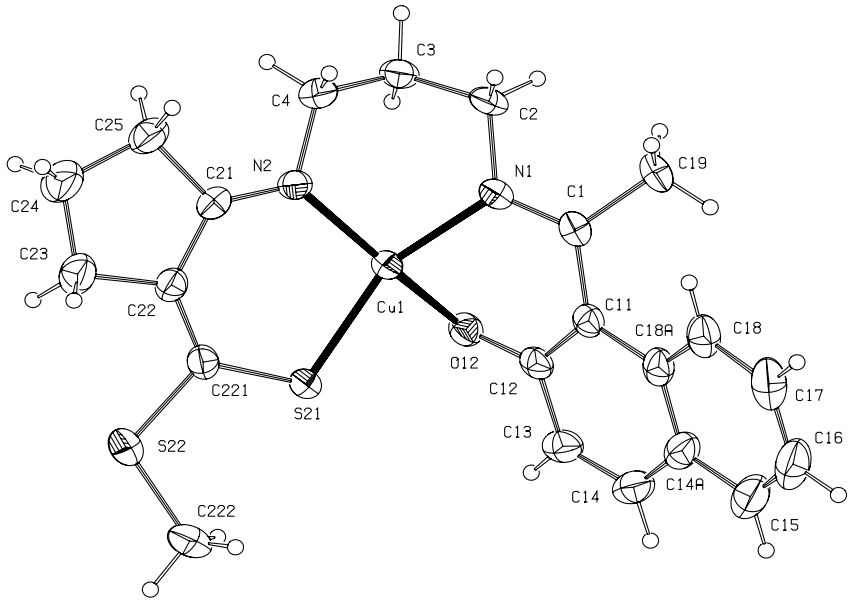

Fig. 4. A view of [Cu(cdMenappd)] with the adopted numbering scheme. Displacement ellipsoids are drawn at the 30% probability level.

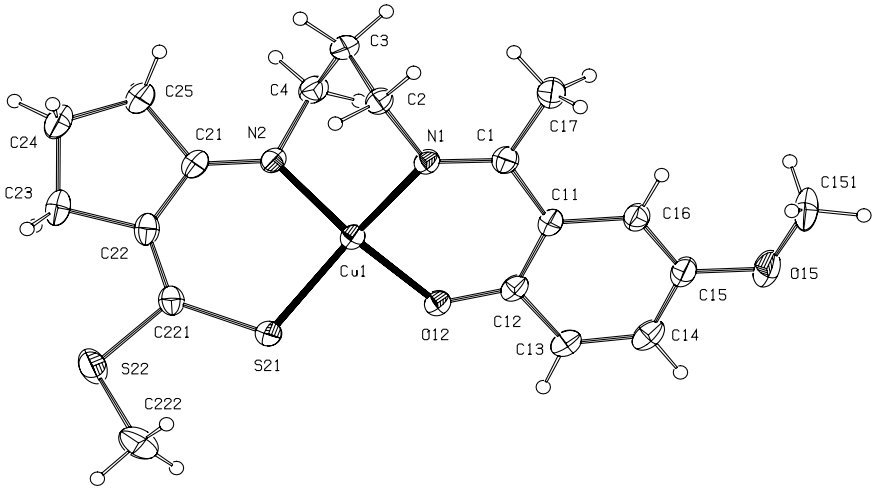

Fig. 5. A view of [Cu(cdMeMeOsalpd)] with the adopted numbering scheme. Displacement ellipsoids are drawn at the 30% probability level.

[b] The spectral resolution did not allow the determination of this value.

+0.7 V to +0.9 V, but no evidence for a corresponding cathodic peak is observed, except for the compound [Cu(cdnapen)]. The voltammograms are not repeatable, and a dark material precipitates at the electrode. For the compound [Cu(cdnapen)], the i_{pc}/i_{pa} ratio increases with the scan rate, showing that the irreversible voltammetric behaviour is due to a slow chemical reaction after electron-transfer. In addition, in the negative potential scan, a cathodic peak is detected for all the complexes in the potential range from −0.8 V to −1.1 V. In this case, the corresponding anodic peaks are observed in the range from −0.6 V to −1.0 V, except for the compound

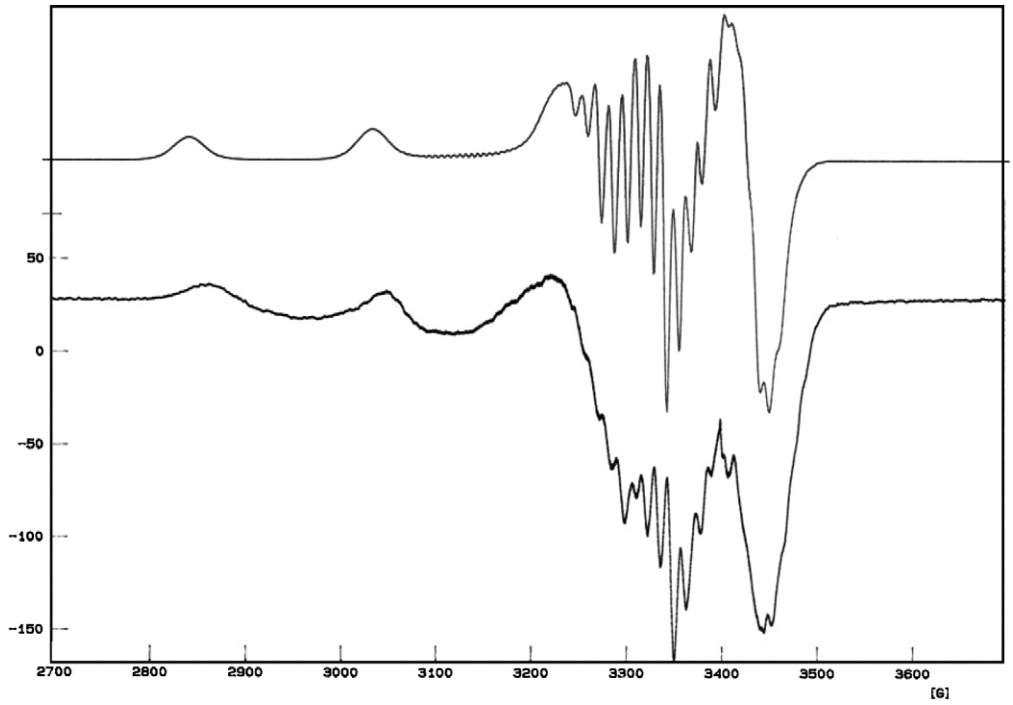

Fig. 6. EPR spectrum of [Cu(cdMenappd)] in DMF at 77 K (bottom) and simulation (top) using the software Symphonia WIN-EPR (Bruker).

Table 4
Voltammetric parameters obtained for the copper (II) complexes

Complex	E_{pa} (V)	E_{pc} (V)	ΔE (V)	i_{pa}/i_{pc}
[Cu(cdnapen)]	−0.978	−1.073	0.095	0.92[a]
[Cu(cdnappd)]	−0.780	−0.880	0.100	0.99[a]
[Cu(cdMenappd)]	−0.64	−0.80	0.16	[b]
[Cu(cdMeMeOsalpd)]	−0.770	−0.900	0.130	0.76[b]
[Cu(cden)]	−0.992	−1.070	0.078	0.93[a]
[Cu(cdpd)]	−0.80	−0.86	0.06	[b]

Potentials are reported in V relative to the Ag/AgCl (1 mol dm^{-3} NaCl) reference electrode and corrected for the Fc^+/Fc couple ($E_{1/2} = 0.485$ V). i_{pa} and i_{pc} values are base line corrected. Scan rate: 0.050 V s^{-1}.

[a] The i_{pa}/i_{pc} ratio decreases with the increase of scan rate.

[b] The i_{pa}/i_{pc} ratio increases with the increase in scan rate.

[Cu(cdMeMeOsalpd)], which shows totally irreversible behaviour. The variation of the CV parameters with scan rate shows that in all the other compounds the redox behaviour is not reversible. For compounds [Cu(cdnapen)], [Cu(cdnappd)] and [Cu(cden)], the i_{pc}/i_{pa} ratio decreases with the scan rate, typical of an irreversible electron transfer, whereas for compounds [Cu(cdMenappd)], [Cu(cdMeMeOsalpd)] and [Cu(cdpd)], the i_{pc}/i_{pa} ratio increases with the scan rate, showing that the reduced form undergoes a slow chemical reaction.

Due to the irreversible redox behaviour, it is not possible to correlate the redox potentials with the coordination spheres of the complexes, Nevertheless, the cathodic peak potential corresponding to the reduction of the copper (II) complexes seems to be lower for complexes with a dimethylene bridge than for those with propylene bridges. This trend is also observed for the reduction potentials for the Ni(II)/Ni(I) couple of the analogous Ni(II) complexes [15,16]. These observations have been attributed to the fact that the trimethylene bridge complexes are more tetrahedrally distorted and the distortion could favour the lower oxidation states for the metal complex. This is confirmed also for the compounds under study by the X-ray structural data. The reduction potentials obtained for the asymmetric complexes are similar to those obtained for homologous symmetric ones with the same number of ethylene residues in the bridge. This data is in agreement with the EPR results, and suggests that the change of a soft sulfur donor for a hardest oxygen donor does not significantly affect the properties of the complexes.

Abstract

A new category of dinucleating macrocyclic Schiff base ligands with ring sizes from 34- to 52-membered have been synthesised employing metal template procedures involving the reaction of *o*-phenylenediamine with a series of α,ω-bis(3′-hydroxy-4′-formylphenyloxy)alkanes in the presence of calcium(II), barium(II) or manganese(II). The latter cations act as 'transient' templates for formation of the corresponding metal-free Schiff base macrocyclic ligands, H_4L^n (where *n* signifies the number of carbons in each linking bis-alkoxy chain); the macrocycles corresponding to $n = 4$, 6 and 8 were isolated and characterised while, for $n = 1$, in which single methylene groups acts as the bridges between salicyl moieties, the cyclic product was used directly for preparation of its dinuclear complex, $[Zn_2L^1]$, without prior isolation. Evidence for the templating role of barium in the preparation of H_4L^6 and H_4L^8 was obtained by isolation of the corresponding species of type $H_4L^n{\cdot}2Ba(ClO_4)_2$ ($n = 6$ or 8) as 'intermediates' before generation of the respective metal-free macrocycles. Reaction of zinc(II) acetate with the free macrocycles in methanol yielded complexes of type $[Zn_2L^n]$ in all cases. A related non-cyclic ligand, H_2L^0 and its corresponding mononuclear complex, $[ZnL^0]{\cdot}H_2O$, were also synthesised and its spectral properties compared with those of the macrocyclic derivatives. The elemental analyses, ^1H NMR, IR, UV–Vis and MS spectra of the respective zinc complexes in each case were in accord with the formation of the expected 2:2 condensation product. The results of DFT calculations to probe aspects of the electronic and structural natures of both H_2L^1 and H_4L^4 are briefly presented.

Keywords: Zinc(II); Dinucleating macrocycles; Template synthesis; Schiff base

1. Introduction

Reflecting their usual relative ease of synthesis and excellent metal complexing properties, Schiff base complexes have been extensively investigated for more than a century and have been employed in areas that include analytical and bioinorganic chemistry, non-linear optics, fluorescence studies, catalysis and materials chemistry [1–12].

The metal coordination chemistry of dinucleating macrocyclic ligands remains an area of considerable research activity [13]. Apart from unusual properties (in particular, spectral, electrochemical and magnetic properties) [14,15] resulting from the proximity of the metal centres, there has long been an interest in such dinuclear species as model compounds for particular metallo-enzymes [16,17].

Beginning with the pioneering work of Robson [18], Schiff base linkages have been incorporated in many dinucleating macrocyclic derivatives [15,19] whose corresponding metal complexes exhibit a wide structure range. In many instances such complexes were prepared by metal template procedures and the ability of metal ions to promote the template synthesis of macrocyclic ligand species has been well documented for many years; in

doi:10.1016/j.poly.2007.09.012

particular, it is known to depend on a range of factors that relate to both the nature of the ligand precursors and the metal ion involved [20]. For example, metal ions with a 'symmetrical' electron shell such as Mn^{2+} (d^5), Zn^{2+} (d^{10}) or an alkaline earth cation have frequently been employed as templates. We now report the template synthesis of a series of new, potentially dinucleating macrocyclic Schiff base ligands of type H_4L^n ($n = 1$, 4, 6 and 8) along with the results of an investigation of their interaction with zinc(II). For comparison, the related open-chain complex of zinc(II) was also synthesised.

2. Experimental

2.1. General

Zinc acetate dihydrate, 1,4-dibromobutane, 1,6-dibromohexane, 1,8-dibromooctane, 4-hydroxy-salicylaldehyde were obtained commercially and 5,5′-methylene-bis-salicylaldehyde were synthesised using the reported procedure [21,22]. Solvents were purified according to literature methods [23]. The series of α,ω-bis(3′-hydroxy-4′-formylphenyloxy)alkanes (in which the alkyl bridge has four, six or eight carbons) were synthesised as reported elsewhere [24].

The ^{1}H NMR spectra were recorded on a JEOL ECX 500 MHz spectrometer. FT-IR spectra (KBr pellets) in the 400–4000 cm^{-1} range were recorded on a Bio-Rad FTIR spectrophotometer; selected assignments only are reported. Elemental analysis was performed on a Vario ELIII analyzer. ESI mass spectra were recorded on an Agilent 1100 Series ESI/MSD spectrometer. Density functional theory (DFT) calculations were carried out using GAUSSIAN03.

All new products were dried in a vacuum over silica gel.

2.2. Synthesis of $[ZnL^0]$ and H_2L^0

4-Dihydroxybenzaldehyde (1.106 g, 8.00 mmol) was added with stirring to *o*-phenylenediamine (0.432 g, 4.00 mmol) in methanol (25 mL) at room temperature. Zinc acetate dihydrate (0.698 g, 4.00 mmol) in methanol (20 mL) was added and the mixture was heated at reflux for 2 h. After allowing the solution to cool, the precipitate was collected by filtration, washed with water and dried; the yellow solid was crystallised from a THF/*n*-hexane mixture. Yield: 1.449 g (88%). MS (ESI) *m*/*z*: 412 (M^+). *Anal.* Calc. for $C_{20}H_{14}N_2O_4Zn$: C, 58.34; H, 3.43; N, 6.80. Found: C, 58.05; H, 3.38; N, 6.89%. NMR ^{1}H (DMSO-d_6) δ 9.79 (OH); 8.79 (s, CH=N); 6.03–6.04, 7.18–7.25, 7.75 (arom). FT-IR (KBr, cm^{-1}) 1612 ($\nu_{C=N}$); UV–Vis (DMSO, nm) λ_{max}: 258, 280, 315.

Repeat of the above synthesis in the absence of added zinc acetate, yielded a sample of metal-free H_2L^0. *Anal.* Calc. for $C_{20}H_{16}N_2O_4$: C, 68.96; H, 4.63; N, 8.04. Found: C, 68.56; H, 4.42; N, 6.91%. MS (ESI) *m*/*z*: 348 (M^+). NMR ^{1}H (DMSO-d_6) δ 13.41, 10.33 (OH); 8.73 (s, CH=N); 6.27–6.38, 7.29–7.43, 7.75 (arom). UV–Vis (DMSO, nm) λ_{max}: 265, 313, 390 and 425(sh).

2.3. Syntheses of the macrocyclic ligands and corresponding dinuclear zinc(II) complexes

2.3.1. Synthesis of $[Zn_2L^1]$ via H_4L^1

5,5′-Methylene-bis-salicylaldehyde (1.005 g, 4.00 mmol) in tetrahydrofuran (8 mL) was added slowly with stirring to *o*-phenylenediamine (0.425 g, 4.00 mmol) and $CaCl_2$ (0.45 g, 4.00 mmol) in methanol (25 mL) and the mixture was heated at reflux for 5 h. The solution was allowed to cool and the precipitate of H_4L^1 was collected by filtration and washed with methanol then water. Yield: 0.735 g (56%), m.p. 116–118 °C. MS (ESI) *m*/*z*: 656 (M^+). *Anal.* Calc. for $C_{42}H_{32}N_4O_4$: C, 76.81; H, 4.91; N, 8.43. Found: C, 77.02; H, 4.52; N, 8.52% FT-IR (KBr, cm^{-1}) 1618, 1610 ($\nu_{C=N}$). NMR ^{1}H (DMSO-d_6) δ 12.40 (OH); 8.79 (s, CH=N); 6.63–6.65, 7.10–7.52, 7.85 (arom); 3.75 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 262, 301, 414.

Zinc acetate dihydrate (0.349 g, 2.00 mmol) in methanol (15 mL) was added to a solution of the above product (1.316 g, 2.00 mmol) in methanol (25 mL) at room temperature and the reaction solution was heated at reflux for 2 h. The solution was allowed to cool and the precipitate of $[Zn_2L^1]$ was collected by filtration and washed with methanol. Yield: 0.886 g (61%), m.p. 118–120 °C. MS (ESI) *m*/*z*: 783 (M^+). *Anal.* Calc. for $C_{42}H_{28}N_4O_4Zn_2{\cdot}H_2O$: C, 62.94; H, 3.77; N, 6.99. Found: C, 63.04; H, 3.52; N, 7.02%. FT-IR (KBr, cm^{-1}) 1618 ($\nu_{C=N}$), 621(ν_{Zn-O}), 511(ν_{Zn-N}). NMR ^{1}H (DMSO-d_6) δ 8.94 (s, CH=N); 6.63–6.65, 7.10–7.51 (arom); 3.68 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 260, 274, 343.

2.3.2. Synthesis of H_4 L^n (where n = 4, 6 and 8)

2.3.2.1. H_4L^4. 1,4-Bis(3′-hydroxy-4′-formylphenyloxy)-butane (0.66 g, 2 mmol) in THF (8 mL) was added slowly, with stirring, to *o*-phenylenediamine (0.22 g, 2 mmol) and $MnCl_2{\cdot}4H_2O$ (0.396 g, 2 mmol) in methanol (25 mL). The mixture was heated at reflux for 5 h. After allowing the solution to cool, the yellow precipitate of H_4L^4 was collected by filtration and washed with hot methanol (3×5 mL). Yield: 0.322 g (40%), m.p. 145–147 °C. MS (ESI) *m*/*z*: 804 (M^+). *Anal.* Calc. for $C_{48}H_{44}N_4O_8$: C, 71.64; H, 5.47; N, 6.97. Found: C, 71.63; H, 5.51; N, 6.96%. FT-IR (KBr, cm^{-1}) 1640 ($\nu_{C=N}$). NMR ^{1}H (DMSO-d_6) δ 11.00 (OH); 9.99 (s, CH=N); 6.47–6.57, 7.59–7.62 (arom); 4.09 (OCH_2); 1.86 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 253, 282, 320.

2.3.2.2. H_4L^6 via $H_4L^6{\cdot}2Ba(ClO_4)_2$. 1,6-Bis(3′-hydroxy-4′-formylphenyloxy)hexane 0.776 g (2 mmol) in THF (8 mL) was added slowly, with stirring, to *o*-phenylenediamine (0.22 g, 2 mmol) and $Ba(ClO_4)_2{\cdot}4H_2O$ (0.781 g, 2 mmol) in methanol (25 mL). The mixture was heated at reflux for 5 h and then allowed to cool. The yellow solid of $H_4L^6{\cdot}2Ba(ClO_4)_2$ was collected by filtration and washed with hot

methanol (3 × 5 mL). Yield: 1.103 g (72%), m.p. >300 °C. MS (ESI) *m/z*: 860 ($M^+-2Ba(ClO_4)_2$), 1333 ($M^+-2ClO_4^-$). *Anal.* Calc. for $C_{52}H_{52}N_4O_8{\cdot}2Ba(ClO_4)_2$: C, 40.73; H, 3.41; N, 3.65. Found: C, 41.01; H, 3.39; N, 3.61%.

Caution! Perchlorate salts are potentially explosive and need to be handled in small quantities with appropriate care and safeguards.

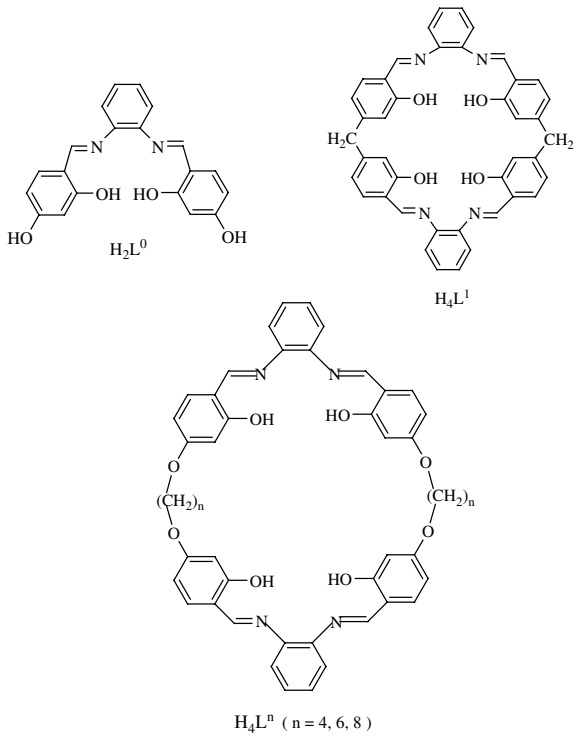
An aqueous solution of Na_2SO_4 (0.284 g, 2 mmol) was added slowly, with stirring, to a solution of $H_4L^6{\cdot}2Ba(ClO_4)_2$ (0.776 g, 2.00 mmol) in acetonitrile (50 mL). Stirring was continued for 1 h then the solution was filtered and the acetonitrile was removed under reduced pressure. The oily material that remained was extracted into $CHCl_3$ (3 × 10 mL) then the $CHCl_3$ was removed under reduced pressure to obtain H_4L^6 as an orange solid. Yield: 0.472 g (55%), m.p. 134–136 °C. MS (ESI) *m/z*: 860 (M^+). *Anal.* Calc. for $C_{52}H_{52}N_4O_8$: C, 72.56; H, 6.05; N, 6.51. Found: C, 72.54; H, 6.09; N, 6.68%. FT-IR (KBr, cm^{-1}) 1637, 1629 ($\nu_{C=N}$). NMR ^1H (DMSO-d_6) δ 11.00 (OH); 9.98 (s, CH=N); 6.43–6.53, 7.56–7.58 (arom); 4.00 (OCH_2); 1.70, 1.42 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 253, 282, 319.

2.3.2.3. H_4L^8 via $H_4L^8{\cdot}2Ba(ClO_4)_2$. The synthetic procedure was similar to that employed for $H_4L^6{\cdot}2Ba(ClO_4)_2$ and H_4L^6 and used Ba^{2+} as a template. $H_4L^8{\cdot}2Ba(ClO_4)_2$ is an orange solid. Yield: 0.472 g (72%), m.p. > 300 °C. MS (ESI) *m/z*: 915 [$M^+-2Ba(ClO_4)_2$], 1389 ($M^+-2ClO_4^-$). *Anal.* Calc. for $C_{56}H_{60}N_4O_8{\cdot}2Ba(ClO_4)_2$: C, 42.31; H, 3.80; N, 3.52. Found: C, 41.96; H, 3.65; N, 3.28%. Yield: 0.472 g (52%), m.p. 125–127 °C. MS (ESI) *m/z*: 916 (M^+). *Anal.* Calc. for $C_{56}H_{60}N_4O_8$: C, 73.34; H, 6.59; N, 6.11. Found: C, 73.23; H, 6.59; N, 6.26%. FT-IR (KBr, cm^{-1}) 1639, 1627 ($\nu_{C=N}$). NMR ^1H (DMSO-d_6) δ 11.02 (OH); 9.98 (s, CH=N); 6.45–6.55, 7.58–7.60 (arom); 4.00 (OCH_2); 1.68–1.72, 1.21–1.39 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 253, 282, 320.

2.3.3. Synthesis of $[Zn_2L^n]$ (n = 4, 6 and 8)

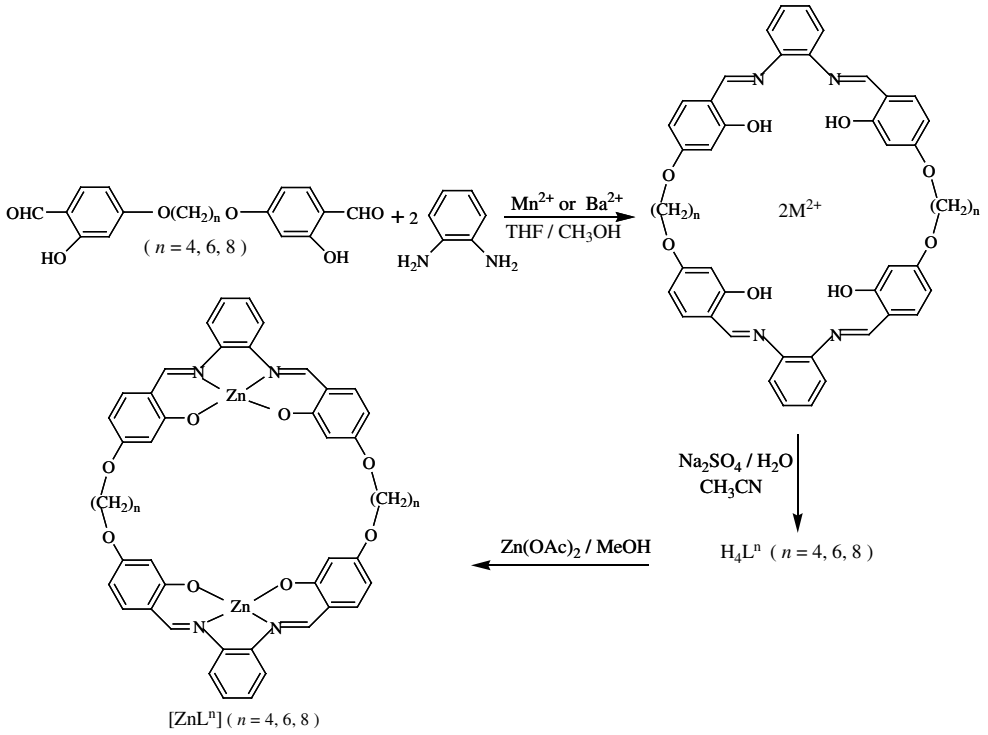
2.3.3.1. $[Zn_2L^4]2H_2O$. Zinc acetate dihydrate (0.111 g, 0.60 mmol) in methanol (10 mL) was added to H_4L^4 (0.201 g, 0.25 mmol) in methanol (20 mL). The solution was stirred for 5 h at room temperature and the precipitate of Zn_2L^4 that formed was filtered off and washed several times with methanol. Yield, 0.185 g (77%). MS (ESI) *m/z*: 931 (M^+). *Anal.* Calc. for $C_{48}H_{40}N_4O_8Zn_2{\cdot}2H_2O$: C, 59.81; H, 4.15; N, 5.82. Found: C, 59.58; H, 4.58; N, 5.79%. FT-IR (KBr, cm^{-1}) 1608 ($\nu_{C=N}$), 634 (ν_{Zn-O}), 420 (ν_{Zn-N}). NMR ^1H (DMSO-d_6) δ 9.97 (s, CH=N); 6.40–6.52, 7.24–7.42 (arom); 4.07 (OCH_2); 1.98, 1.55 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 241, 282, 292, 322, 336, 363.

2.3.3.2. $[Zn_2L^6]$ and $[Zn_2L^8]$. The synthesis of these complexes, starting from the appropriate dialdehyde, was similar to that described above for $[Zn_2L^4]$.



$[Zn_2L^6]$. Yield: 0.173 g (70%). MS (ESI) *m/z*: 987 (M^+). *Anal.* Calc. for $C_{52}H_{48}N_4O_8Zn_2$: C, 63.23; H, 4.90; N, 5.67. Found: C, 63.35; H, 4.88; N, 5.38%. FT-IR (KBr, cm^{-1}) 1608 ($\nu_{C=N}$), 655 (ν_{Zn-O}), 418 (ν_{Zn-N}). NMR ^1H (DMSO-d_6) δ 9.95 (s, CH=N); 6.40–6.52, 7.24–7.42 (arom); 4.03 (OCH_2); 1.45–1.73, 1.03–1.22 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 241, 282, 292, 322, 335, 364.

$[Zn_2L^8]{\cdot}4H_2O$. Yield: 0.207 g (75%). MS (ESI) *m/z*:1043 (M^+). *Anal.* Calc. for $C_{56}H_{56}N_4O_8Zn_2{\cdot}2CH_3OH$: C, 60.27; H, 5.78; N, 5.02. Found: C, 60.23; H; 5.49; N, 5.21%. FT-IR (KBr, cm^{-1}) 1608 ($\nu_{C=N}$), 655 (ν_{Zn-O}), 419 (ν_{Zn-N}). NMR ^1H (DMSO-d_6) δ 9.95 (s, CH=N); 6.42–6.52, 7.56–7.58 (arom); 3.98 (OCH_2); 1.66–1.68, 1.32–1.37 (CH_2). UV–Vis (DMSO, nm) λ_{max}: 241, 282, 292, 322, 335, 363.



3. Results and discussion

The preparation of the new macrocyclic Schiff base ligands, H_4L^n ($n = 1$, 4, 6 and 8), in each case involved reaction of the corresponding dialdehyde and *o*-phenylenediamine in a 1:1 ratio in methanol in the presence of Ca^{2+}, Ba^{2+} or Mn^{2+} as 'transient' templates (Scheme 1). Indirect evidence for a templating role for Ba^{2+} in the preparation of H_4L^6 and H_4L^8 was given by the isolation of species of type $H_4L^n{\cdot}2Ba(ClO_4)_2$ ($n = 6$ and 8) as 'intermediates' before generation of the corresponding metal-free macrocycle. In the absence of a templating metal, the above Schiff base condensations produced oily solids which were assumed to be polymeric in nature.

Zinc(II) complexes of type $[Zn_2L^n]$ incorporating ligands of type H_4L^n, where $n = 1$, 4, 6 or 8, have also been synthesised by reaction of zinc acetate with the respective ligands in a 2.4:1 ratio in methanol (see Scheme 2 for the

Scheme 1. The ligands.

Scheme 2. Metal template synthesis of $[ZnL^n]$ ($n = 4$, 6, 8).

cases where $n = 4$, 6 or 8). For comparison, the related open-chain complex, $[ZnL^0]$, was also prepared by means of an *in situ* condensation between the required aldehyde derivative and *o*-phenylenediamine in a 2:1 ratio in methanol in the presence of zinc(II) acetate (see Scheme 2).

The FT-IR spectra of the free ligands and their corresponding complexes were determined. The O–H stretching frequencies of ligands are evident in the 3300–3800 cm^{-1} region but absent in the spectra of the corresponding complexes, again in keeping with the loss of the four hydroxy protons of each macrocycle on metal binding. The C=N stretching frequencies of the uncomplexed ligands and their zinc complexes fall in the range 1608–1640 cm^{-1} as reported for similar ligands and their complexes [25].

The ^1H NMR data (see Section 2) for the free ligands and their zinc complexes are in all cases consistent with the assigned structures. The peaks for the 'salicyl' OH protons in the free Schiff base ligands are present near 11–12 ppm and, as expected, are absent in the spectra of the corresponding zinc complexes confirming that loss of these protons occurs on uptake of zinc. Peaks with chemical shifts near 8.8–8.9 ppm are present for the HC=N protons in both H_2L^0 and H_4L^1 as well as for the corresponding zinc complexes, while they occur near 9.9 ppm For H_4L^4, H_4L^6 and H_4L^8 and their corresponding zinc complexes. The occurrence of this resonance in each of the above species as a 'clean' singlet is in keeping with the presence of intact (non hydrolyzed) imine groups in each case.

Attempts to obtain suitable crystals for X-ray structure determinations of the new ligands (or indeed, their zinc complexes) were unsuccessful. However, geometry optimizations were carried out using density functional theory (DFT) at the B3LYP/6-31 G* level employing Gaussing03 to probe the gas phase structures of H_4L^1 and H_4L^4. The minimum energy structure found for H_4L^1 has a rhomboidal-shaped cavity with the two phenyl rings derived from *o*-phenylenediamine inclined on the same side of the cavity to give the molecule a 'butterfly' shape when viewed laterally with respect to the cavity. In contrast, for H_4L^4 the dihedral angle between the *o*-phenylenediamine phenyl rings was calculated to be 89°, giving rise to a somewhat twisted, less symmetrical cavity. Gaussian03 was also employed to calculate the charge distributions for atoms in the HC=N double bonds of H_4L^1 and H_4L^4; the values obtained for the imine hydrogens are, respectively, 0.14*e* for ligand H_4L^1 and 0.11*e* for H_4L^4. Although the situation is not necessarily straight forward, these values correlate with the amount of shielding for each proton type obtained from the corresponding ^1H NMR chemical shifts (see Section 2); that is, the spectra indicated that the HC=N protons in H_4L^1 are more shielded than occurs for these protons in H_4L^4.

The electronic spectra of the two ligands in DMSO were recorded over 200–700 nm. Intense absorption bands for these conjugated aromatic systems were present at 262, 301and 414 nm for H_4L^1 and 253, 282 and 320 nm for H_4L^4. The calculated E(HOMO) for $H_4L^1$is −0.204 a.u. and −0.183 a.u. for H_4L^4. The E(LUMO) are −0.065 a.u. for H_4L^1 and −0.036 a.u. for H_4L^4. The ΔE(LUMO–HOMO) is thus 0.139 a.u. for H_4L^1 and 0.147 a.u. for H_4L^4. In general terms these results are in keeping with the electronic transitions in H_4L^4 occurring

at higher energies than in H_4L^1 and hence correlate with the observed blue shifts of the absorptions for H_4L^4 relative to those of H_4L^1.

4. Conclusions

In this report we describe the facile synthesis and characterisation of a series of new macrocyclic Schiff base ligands of varying ring size via a 'transient' metal template procedure. The ability of these derivatives to act as dinucleating ligands towards zinc has been demonstrated. The new macrocyclic ligands are now available for further studies. These include investigating the coordination behaviour of a range of other metal ions, use in synthesising new dinuclear complexes as models for selected metallo-enzymes and, in the case of complexes incorporating coordinately unsaturated metal centres, use as a 'platform' for the construction of extended molecular systems by reaction with appropriate bridging ligands such as 4,4′-bipyridine (or other suitable difunctional derivatives). Studies of these types are planned for the future in our laboratories.

Abstract

The neutral mononuclear dioxomolybdenum(VI) complexes of the quinolone antibacterial agents enrofloxacin and sparfloxacin have been prepared and characterized with physicochemical and spectroscopic techniques. In these complexes, enrofloxacin and sparfloxacin act as bidentate deprotonated ligands bound to the metal through the pyridone oxygen and one carboxylate oxygen. The central molybdenum atoms are six-coordinate with slightly distorted octahedral geometry. The lowest energy model structure of each complex has been proposed with molecular modeling calculations. The antimicrobial activity of the complexes has been tested on three different microorganisms. The investigation of the interaction of the complexes with calf-thymus DNA has been performed with diverse spectroscopic techniques.

Keywords: Quinolones; Enrofloxacin; Sparfloxacin; Dioxomolybdenum(VI) complexes; Interaction with calf-thymus DNA; MIC

1. Introduction

Quinolones is a term commonly used for the quinolonecarboxylic acids or 4-quinolones, a group of synthetic antibacterial agents containing a 4-oxo-1,4-dihydroquinoline skeleton [1–3]. Quinolones are extremely useful for the treatment of diverse infections [4–6]. The activity of quinolones as antibacterial drugs is due to the effective inhibition of DNA replication. The proposed mechanism of the interaction between quinolone and metal cations was chelation between the metal and the 4-oxo and adjacent carboxyl groups [7].

Enrofloxacin, Herx (Fig. 1a), is a typical second-generation quinolone antimicrobial drug with a broad spectrum of activity against a wide range of Gram-negative and Gram-positive bacteria, including those resistant to β-lactam antibiotics and sulfonamides [8,9]. Enrofloxacin is the first fluoroquinolone developed for veterinary application and is potentially available for the treatment of some urinary tract, respiratory tract and skin infectious diseases in pets and livestock [10–13]. It is also used for the treatment of uncomplicated and complicated urinary tract infections, pyelonephritis, sexually transmitted diseases, prostatitis, skin and tissue infections, urethral and cervical gonococcal infections [14–16]. Sparfloxacin, Hsf (Fig. 1b), is a third-generation quinolone antimicrobial drug mainly used for the treatment of acute exacerbations of chronic bronchitis and community-acquired pneumonia [17].

The role of molybdenum as an element of biological interest is well known [18–21]. Molybdenum can be found

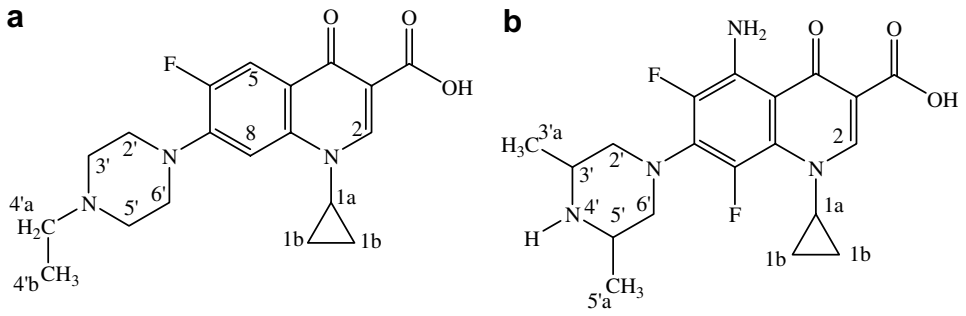

Fig. 1. (a) Enrofloxacin (Herx = 1-cyclopropyl-7-(4-ethyl-piperazin-1-yl)-6-fluoro-4-oxo-1,4-dihydro-quinoline-3-carboxylic acid) and (b) sparfloxacin (Hsf = 5-amino-1-cyclohexyl-7-(*cis*-3,5-dimethylpiperazino)-6,8-difluoro-1,4-dihydro-4-oxo-3-quinolinecarboxylic acid) and H atom labeling.

in the Mo nitrogenases [22] and in the molybdenum oxidases [23], enzymes that catalyze a number of biologically important oxotransfer reactions, such as the conversion of sulfite to sulfate, aldehyde to the corresponding carboxylic acid, or nitrate to nitrite [21]. For Mo, only two ciprofloxacin complexes as polyoxometalates have been characterized [24], while dioxomolybdenum(VI) binary complexes have been reported only with the first-generation quinolones pipemidic acid [25] and oxolinic acid [26] as well as with the second-generation quinolone *N*-propyl-norfloxacin [27].

We have initiated the study of the structure, spectroscopic and biological properties of diverse transition metal complexes with various quinolone antibacterial drugs [25–35]. Here, we present the interaction of MoO_2^{2+} with the second-generation quinolone enrofloxacin and third-generation quinolone sparfloxacin in an attempt to examine the mode of coordination and the biological properties of the resultant complexes. More specifically, the complexes have been synthesized and characterized with elemental analysis and diverse spectroscopic techniques (IR, UV–Vis and NMR spectroscopies). Molecular modeling techniques have been employed to assess the lowest energy model structure of the complexes. The biological activity of the complexes has been evaluated by determining the minimum inhibitory concentration (MIC) against three microorganisms. The interaction of the complexes with calf-thymus (CT) DNA has been investigated with UV and circular dichroism (CD) spectroscopy.

2. Experimental

2.1. Materials

Enrofloxacin, sparfloxacin and CT DNA were purchased from Sigma, NaCl was purchased from Merck, trisodium citrate was purchased from Riedel-de Haen, $MoO_2(acac)_2$, KOH and all the solvents were purchased from Aldrich Co. Agarose was purchased from BRL. Tryptone and yeast extract were purchased from Oxoid (Unipath, Hampshire, UK). All the chemicals for the synthesis of the compounds were reagent grade and were used as purchased.

DNA stock solutions (5 mM) were prepared by dilution of CT DNA to buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) followed by exhaustive stirring at 4 °C for three days [36], and kept at 4 °C for no longer than a week. The nucleotide concentrations were determined by their absorption at 260 nm using $\varepsilon = 6600\ M^{-1}\ cm^{-1}$.

2.2. Synthesis of the complexes

2.2.1. $MoO_2(erx)_2$ (**1**)

A methanolic solution (10 mL) of enrofloxacin (0.6 mmol, 216 mg), deprotonated with KOH (0.6 mmol, 34 mg), was added to a methanolic solution (10 mL) of $MoO_2(acac)_2$ (0.3 mmol, 100 mg) and the reaction mixture was refluxed for 2.5 h. The solution was filtered and left for slow evaporation. After a few days a light yellow microcrystalline product was deposited, collected with filtration, washed with methanol and dried. Yield: 190 mg, 75%. *Anal.* Calc. for $MoO_2(erx)_2$ ($C_{38}H_{42}F_2N_6O_8Mo$) (MW = 844.72): C, 54.03; H, 5.01; N, 9.95. Found: C, 53.71; H, 4.85; N, 10.21%. The complex is soluble in DMSO and DMF and is a non-electrolyte.

2.2.2. $MoO_2(sf)_2$ (**2**)

In a similar way, complex **2** was prepared with the use of sparfloxacin (0.4 mmol, 235 mg). A light yellow microcrystalline product was collected. Yield: 135 mg, 75%. *Anal.* Calc. for $MoO_2(sf)_2$ ($C_{38}H_{42}F_4N_8O_8Mo$) (MW = 910.74): C, 50.12; H, 4.65; N, 12.30. Found: C, 50.41; H, 4.75; N, 12.20%. The complex is soluble in DMSO and DMF and is a non-electrolyte.

2.3. Instrumentation

IR spectra (400–4000 cm^{-1}) were recorded on a Nicolet Magna-IR 550 with samples prepared as KBr pellets. UV–Vis spectra were recorded as nujol mulls and in solution at concentrations in the range 10^{-5}–10^{-3} M on a Thermo Electron Corporation Helios α dual beam spectrophotometer. C, H and N elemental analysis were performed on a Perkin–Elmer 240B elemental analyzer. Electric conductance measurements were carried out with

a WTW model LF 530 conductivity outfit and a type C cell, which had a cell constant of 0.996. NMR spectra were recorded with a Bruker Avance 500 MHz instrument and were processed by X-WIN NMR 2.6 (Bruker Analytik GmbH).

The interaction of the complexes with CT DNA has been investigated with UV and CD spectroscopies. In both techniques, the spectra of CT DNA in the presence of each complex have been recorded for a constant CT DNA concentration (3.125×10^{-4} M) in diverse complex/CT DNA mixing ratios (r). All the UV and CD spectra were recorded after incubation of each complex with CT DNA for 24 h at 37 °C.

The CD spectra were recorded on a Jasco J-700 spectropolarimeter using a 1.0 cm path quartz cell and the following acquisition parameters: $\lambda = 190$–400 nm, scan speed 50 nm min^{-1}, resolution step 0.2 nm, sensitivity 50 mdeg, response 1 s, bandwidth 1.0 nm, accumulations 10. In some cases, the spectra were averaged over an appropriate number of scans.

2.4. Molecular modeling

With the aim to present a molecular model for each new complex that is unbiased by the starting structure, we have used Langevin dynamics with a simulated annealing protocol. Using this method, the mean total energy of an ensemble of structures guides the selection of the most favorable configuration for each complex. Starting structures were constructed using the program HYPERCHEM and the MM+ force field that is based on the Allinger's MM2 force field [37]. For molybdenum, we used a default parameter set with $R^* = 2.20$ Å and $e^* = 0.02$ kcal mol^{-1}, since the van der Waals interactions are not expected to play a major role in such bonded representations as in octahedral complexes. Metal–ligand bond lengths were corrected in the final models using harmonic restraints with equilibrium values that were extracted from crystallographic data of similar compounds [38–41] (Table S1). Non-bonded interactions were calculated in vacuo with no cutoff and the electrostatic energy term was treated using bond dipoles. Initial energy minimizations were carried out by a conjugate gradient method with RMS gradient <0.01 as convergence criterion.

Each model (Scheme S1) was subjected to 20 individual rounds of simulated annealing setting different value to the seed for the assignment of the starting velocities. To integrate the Langevin equation [42] the step size was set to 1 fs and the collision frequency to 1 ps^{-1}. The annealing calculation comprised three phases: (i) raising the temperature of the system from 10 to 1000 K over 2 ps, (ii) keeping the system at 1000 K for 3 ps and (iii) cooling the system down to 0 K over 15 ps. A tight coupling of the system with temperature (0.1 ps) was used for the heating and equilibration phases. During the cooling phase the bath relaxation time was gradually decreased from 5.0 ps (7000 steps), 2.0 ps (3000 steps), 1.0 ps (2000 steps), 0.5 ps (2000 steps) to 0.05 ps (1000 steps). At the final step all the resultant structures had RMS gradient <0.01 and their total energy was recorded (Tables S2 and S3). The models presented herein were selected among the lowest energy structures generated for each starting geometry. A final minimization of the energy was performed as above, but having applied the metal–ligand distance restraints.

2.5. Antibacterial activity – minimum inhibitory concentration

The antibacterial activity of the compounds (ligands and complexes) was studied against *Staphylococcus aureus* (*S. aureus*), *Escherichia coli* (*E. coli*) and *Pseudomonas aeruginosa* (*P. aeruginosa*). The microorganisms were maintained in the laboratory of "Chemical Biology" of NCSR "Demokritos". Screening was performed by determining the MIC. Two different media [Luria broth medium (=LB, containing 1% w/v tryptone, 0.5% w/v NaCl and 0.5% w/v yeast extract) and minimal medium salts broth (=MMS, containing 1.5% w/v glucose, 0.5% w/v NH_4Cl, 0.5% w/v K_2HPO_4, 0.1% w/v NaCl, 0.01% w/v $MgSO_4 \cdot 7H_2O$ and 0.1% w/v yeast extract)] were used. The compounds were dissolved in distilled water with twofold serial dilutions from 8 to 0.125 μg mL^{-1}. All the cultures were incubated at 37 °C. Control tests with no active ingredients were also performed.

MIC was determined using twofold serial dilutions in liquid media containing 0.125–8 μg mL^{-1} of the compound being tested. A preculture of bacteria was grown in LB overnight at the optimal temperature of each species. Two milliliters of MMS were inoculated with 20 mL of this preculture. This culture was used as a control to examine if the growth of the bacteria tested is normal. In a similar second culture, 20 μL of the bacteria as well as the tested compound at the desired concentration were added. A third sample containing 2 mL MMS supplemented with the same compound concentration was used as a second control to check the effect of the compound on MMS. All samples were measured in duplicate. We monitored bacterial growth by measuring the turbidity of the culture after 12 and 24 h. If a certain concentration of a compound inhibited bacterial growth, half the concentration of the compound was tested. This procedure was carried on to a concentration where bacteria grow normally. The lowest concentration that inhibited bacterial growth was determined as the MIC value. All the equipment and culture media were sterile.

3. Results and discussion

3.1. Synthesis and spectroscopic study of the complexes

The complexes have been prepared in high yield (75%) via the addition of methanolic solutions of the deprotonated quinolone to MoO_2^{2+} at a 2/1 ratio. Both complexes are soluble in DMSO and DMF and are non-electrolytes.

Table 1
Characteristic absorptions (in cm^{-1}) of the IR spectra of the complexes

	$\nu(C{=}O)_p$[a]	$\nu(CO_2)_{asym}$[a]	$\nu(CO_2)_{sym}$[a]	Δ[b]	ν(Mo=O)
Herx	1622	1733[c]			
$MoO_2(erx)_2$	1628	1606	1388	218	932, 904
$Cu(erx)_2(H_2O)$ [28]	1630	1611	1381	230	
Hsf	1641	1716[c]			
$MoO_2(sf)_2$	1634	1601	1392	209	931, 907
$Cu(sf)_2$ [29]	1635	1605	1385	220	

[a] p, pyridone; asym, asymmetric; sym, symmetric.
[b] $\Delta = \nu(CO_2)_{asym} - \nu(CO_2)_{sym}$.
[c] As ν(COOH).

In Table 1, the characteristic absorptions of the IR spectra of complexes **1** and **2** are listed. In the IR spectra of complexes **1** and **2**, the absorptions at 1733 cm^{-1} in the spectrum of Herx and at 1716 cm^{-1} for Hsf, respectively, attributed to the absorption of the $\nu(C{=}O)_c$ (c = carboxylato) have disappeared. Two very strong characteristic bands are present in the range of 1601–1606 cm^{-1} and at ~1390 cm^{-1} that could be assigned as ν(O–C–O) asymmetric and symmetric stretching vibrations, respectively, whereas $\nu(C{=}O)_p$ (p = pyridone) is slightly shifted from 1622 to 1629 cm^{-1} for **1** and from 1641 to 1634 cm^{-1} for **2** upon bonding. The difference $\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$ is a useful characteristic for determining the coordination mode of the ligands. The Δ values are 218 cm^{-1} for **1** and 209 cm^{-1} for **2**, indicating a monodentate coordination mode of the carboxylato group [43,44] of the ligands. These changes in the IR spectra suggest that enrofloxacinato and sparfloxacinato ligands are coordinated to molybdenum via the pyridone (O_p) and one carboxylato (O_c) oxygen atoms [1,25–35].

The existence and the number of the ν(Mo=O) absorptions is a useful diagnostic tool of the characterization of the complex. The existence of two ν(Mo=O) absorptions at ~930 cm^{-1} and ~905 cm^{-1} for both the complexes are indicative of a *cis* arrangement of the two dioxomolybdenum oxygen atoms around Mo [25–27].

The UV–Vis spectra of the complexes have been recorded as nujol mulls and in DMSO solution. Practically, the spectra in DMSO solution and those in nujol are alike, although in some cases they differ for a few nanometers, indicating that both complexes **1** and **2** retain their structure in solution. The UV–Vis spectral data for the complexes in DMSO solution are given in Table 2.

Table 2
Characteristic bands [λ_{max} in nm (ε in $M^{-1}\,cm^{-1}$)] in the UV–Vis spectra of the complexes in DMSO solution

	IL[a] bands			CT band[b]
Herx	280 (11200)	310(sh)[c] (6100)	335 (2800)	
$MoO_2(erx)_2$	287 (8200)	315 (4950)	340 (2910)	430(sh) (200)
Hsf	285 (6200)	320 (4100)	365 (2100)	
$MoO_2(sf)_2$	289 (5800)	322 (3950)	360 (2150)	432(sh) (210)

[a] IL, intraligand.
[b] CT, charge transfer.
[c] sh, shoulder.

The UV spectra of the complexes are practically identical with that of the quinolone ligands but slightly shifted, indicative of coordination through the O_p and one O_c. The complexes also exhibit an absorption band at ~430 nm ($\varepsilon \sim 200$–$210\ M^{-1}\,cm^{-1}$) which can be assigned to the ligand-to-metal charge-transfer transition for the quinolone ligand, as observed in a series of other quinolones binary complexes [25–35].

^{1}H NMR spectra of the ligands and the complexes have been recorded in DMSO-d_6. The assignment of every signal has been achieved by comparing the ^{1}H NMR spectra of the complexes to those of the ligands and to spectra reported in the literature [25–27,45]. The results are shown in Table 3.

Comparison of the ^{1}H NMR spectrum of complex **1** with that of Herx shows a significant perturbation of the chemical shift (up to 0.4 ppm) of the aromatic protons H2 and H5 indicating that H2 and H5 are close to the coordination site of the ligand. The signals for H8, the aliphatic H1a and H1b and the piperazine protons are practically unchanged since they lie far from the binding site of the ligand.

Quite similar results are derived from the comparison of the ^{1}H NMR spectrum of complex **2** with that of Hsf where a perturbation of the chemical shift (0.3 ppm) of the aromatic proton H2 is observed indicating adjacency to the coordination site of the ligand, while the rest protons (the aliphatic H1a and H1b, the piperazine H2′, H3′, H5′ and H6′ as well as the methyl protons H3′a and H5′a) lie far from the binding site of the ligand and their signals remain practically unchanged.

The overall changes in the NMR spectra of the complexes are indicative of coordination of the enrofloxacinato and sparfloxacinato ligands to molybdenum via the pyridone and one carboxylate oxygen atoms [25–27,45].

Table 3
Chemical shifts (ppm) in ^{1}H NMR spectra of Herx, $MoO_2(erx)_2$, Hsf and $MoO_2(sf)_2$ in DMSO-d_6

Atom	Herx	$MoO_2(erx)_2$
H1a[a]	1.49 (1H)	1.47 (1H)
H1b and H4′b	1.20 (7H)	1.20 (7H)
H2	8.85 (1H)	9.10 (1H)
H5	7.80 (1H)	8.20 (1H)
H8	7.40 (1H)	7.50 (1H)
H2′, H6′ or H3′, H5′	3.20–3.30 (4H), 3.65–3.70 (4H)	3.15–3.25 (4H), 3.75 (4H)
H4′a	3.35 (2H)	3.35 (2H)
	Hsf	$MoO_2(sf)_2$
H1a	1.47 (1H)	1.45 (1H)
H1b, H3′a, H5′a	1.20 (10H)	1.20 (10H)

3.2. Molecular dynamics

Diverse crystallization techniques were employed in order to obtain a crystal suitable for the structure determination with X-ray crystallography. Nevertheless, the complexes were collected only as microcrystalline product. In order to present a model for each complex three pairs of enantiomers have been constructed as starting models for $MoO_2(erx)_2$ and $MoO_2(sf)_2$ (Scheme 1). After the Langevin dynamics simulated annealing calculations for each complex, we obtained the total energy results of 20 different conformations for each starting model, which guide us to select the lowest-energy isomers as the more favorable.

For $MoO_2(erx)_2$, the *transOc* isomers can be selected as the more favorable. Their average energy is almost equal, as expected [38], and is lower than the other four isomers by more than 3 kcal mol^{-1} (Table S2). We have applied a set of harmonic restraints at the metal–ligand bonds [39–41] during an additional minimization phase (Table S1). Based on these results, the lowest energy model structure of one *transOc*–$MoO_2(erx)_2$ enantiomer as the favorable configuration of the complex is illustrated in Fig. 2.

For $MoO_2(sf)_2$, the *transOc* isomers, with average energy lower than the other four isomers by more than 3 kcal mol^{-1} (Table S3), were also selected as the more favorable. The lowest energy model structure for $MoO_2(sf)_2$ has been found in the same way and is illustrated in Fig. S2. However, we can neither exclude the formation of any of the other isomers, nor unambiguously distinguish between the favorable enantiomers.

Scheme 1. The isomers of $MoO_2(erx)_2$ or $MoO_2(sf)_2$ that were employed in the simulated annealing calculations. O_c and O_p are the carboxylate and the pyridone oxygen atoms, respectively, of enrofloxacinato/sparfloxacinato ligands.

3.3. Antibacterial activity

The efficiencies of the ligands and the complexes have been tested against two Gram(−), *E. coli* and *P. aeruginosa*, and one Gram(+), *S. aureus*, microorganisms. The results are presented in Table 4.

It is evident (Table 4) that the ligands and the complexes have inhibitory action against all the microorganisms tested and the coordination of the quinolones enrofloxacin (MIC = 1–8 μg mL^{-1}) and sparfloxacin (MIC = 0.25–8 μg mL^{-1}) with MoO_2^{2+} results to a diverse biological activity (MIC for the complexes = 1–4 μg mL^{-1}). The antimicrobial activity of $MoO_2(acac)_2$ has also been investigated and it has been found that it does not exhibit antimicrobial activity, at the concentration range used to assay the activity of the complexes in this work. The MIC values found for the complexes are low and can be mainly attributed to the existence of the quinolone ligand in the molecule.

When the antimicrobial activity of metal complexes is investigated, the following principal factors [46–49] should be considered: (i) the chelate effect of the ligands; (ii) the nature of the N-donor ligands; (iii) the total charge of

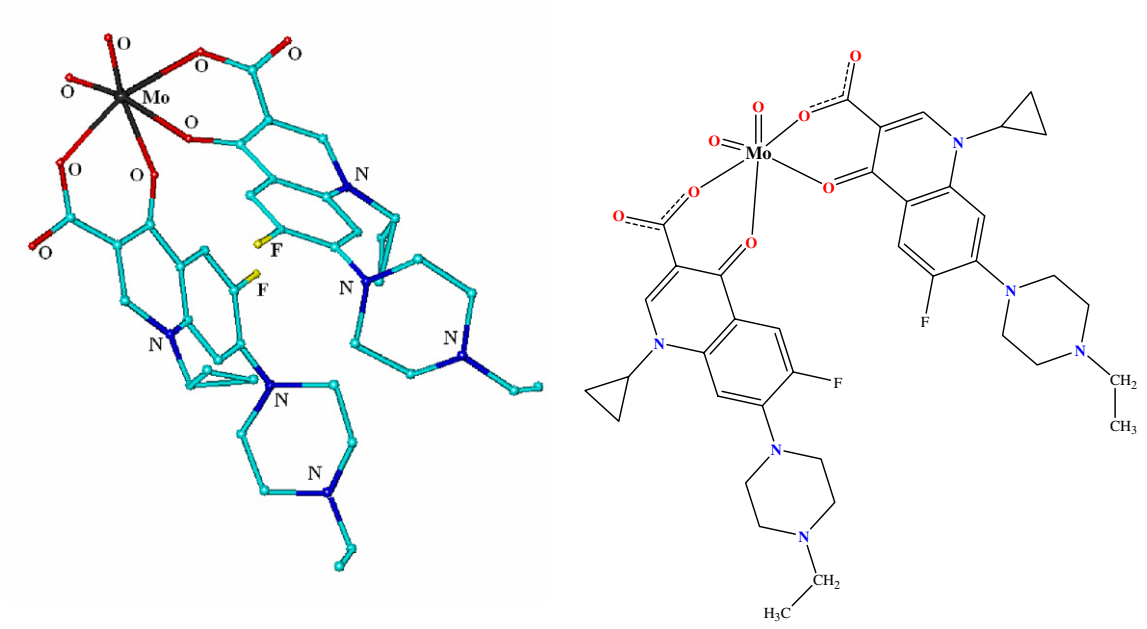

Fig. 2. Lowest energy model structure for $MoO_2(erx)_2$.

Table 4
MIC in μg mL^{-1}

	E. coli	*P. aeruginosa*	*S. aureus*
Herx	1 (2.78)[a]	1 (2.78)[a]	8 (22.22)[a]
$MoO_2(erx)_2$	1 (1.18)	1 (1.18)	4 (4.74)
$Cu(erx)_2(H_2O)$ [28]	0.125 (0.16)	0.125 (0.16)	4 (5.01)
$VO(erx)_2(H_2O)$ [32]	4 (4.99)	4 (4.99)	8 (9.98)
Hsf	8.0 (20.4)	0.25 (0.64)	0.5 (1.28)
$MoO_2(sf)_2$	4 (4.40)	1 (1.10)	2 (2.20)
$Cu(sf)_2$ [29]	2 (2.36)	0.25 (0.30)	1 (1.18)

[a] The values in parentheses represent the MIC in μM.

the complex; (iv) the existence and the nature of the ion neutralizing the ionic complex; and (v) the nuclearity of the metal center in the complex. For complexes **1** and **2**, only the first of these factors is present, i.e. the chelate effect of the ligand. This is probably one of the reasons for the diverse antibacterial activity shown by the complexes while the nature of the metal ion coordinated to the quinolone ligand may have a significant role to this diversity.

Complex **1** shows equal activity against the two Gram(−) microorganisms (MIC = 1 μg mL^{-1}) and is more active than Herx only against *S. aureus*. Comparing the activity of complex **1** to other enrofloxacinato complexes, $MoO_2(erx)_2$ is more active than $VO(erx)_2(H_2O)$ (MIC = 4–8 μg mL^{-1}) [32] against all the microorganisms tested and it is less active than $Cu(erx)_2(H_2O)$ against only the two Gram(−) microorganisms (MIC = 0.125 μg mL^{-1}) [28] while both complexes present equal inhibition (MIC = 4 μg mL^{-1}) against *S. aureus*.

On the other hand, complex **2** is more active than Hsf against *E. coli* (MIC = 4 μg mL^{-1}) and less active against *P. aeruginosa* (MIC = 1 μg mL^{-1}) and *S. aureus* (MIC = 2 μg mL^{-1}). Sparfloxacinato ligand shows a slightly better inhibition, against all the microorganisms tested, when it is coordinated to Cu(II) in $Cu(sf)_2$ (MIC = 0.25–2 μg mL^{-1}) [29].

3.4. Interaction of the complexes with DNA

DNA can provide three distinctive binding sites for quinolone metal complexes: namely, groove binding, binding to phosphate group and intercalation [50]. This behavior is of great importance with regard to the relevant biological role of quinolone antibiotics in the body [51].

3.4.1. UV spectroscopy

The absorption spectra of the interaction of complexes **1** and **2** with CT DNA have been recorded for a constant DNA concentration (3.125×10^{-4} M) in different complex: CT DNA mixing ratios (r) and are shown in Fig. 3. The changes observed (mainly the increase of the intensity at $\lambda_{max} = 258$ nm) in the UV spectra of the complexes after mixing with CT DNA indicate that complexes **1** and **2** can bind to CT DNA and the interaction of each complex, **1** and **2**, with CT DNA takes place by a direct formation of a new complex with double-helical CT DNA [52].

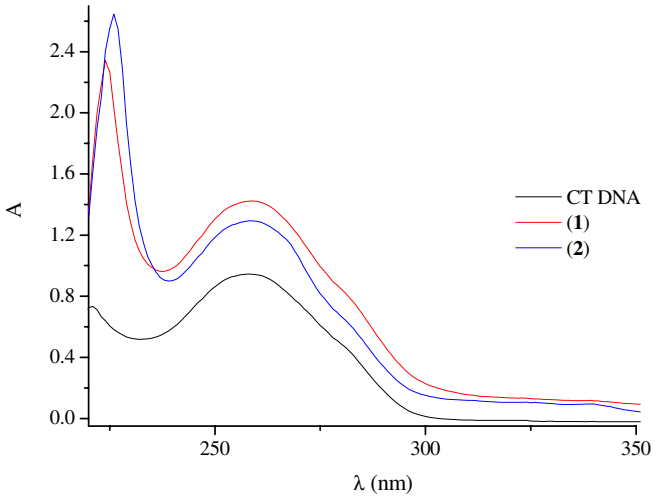

Fig. 3. UV spectra of CT DNA in the presence of complexes **1** and **2** for r = 1:200 (r = complex/CT DNA mixing ratio). The spectra were recorded at 25 °C after the complexes had been incubated with CT DNA for 24 h at 37 °C.

3.4.2. CD spectroscopy

CD spectroscopy is a useful tool to diagnose changes in DNA morphology during drug–DNA interactions, since the positive band due to base stacking (273 nm) and the negative one due to right-handed helicity (246 nm) are quite sensitive to the interaction mode of DNA with small molecules [53,54]. The changes in CD signals of DNA observed on interaction with drugs may often be assigned to the corresponding changes in DNA structure [55]. Thus, simple groove binding and electrostatic interaction of small molecules show less or no perturbation on the base-stacking and helicity bands, while intercalation enhances the intensities of both the bands stabilizing the right-handed B conformation of CT DNA as observed for the classical intercalator methylene blue [56].

The CD spectra of the complexes with double-stranded CT DNA for different r values can provide us with useful information concerning the complex–nucleotide interaction. The CD spectra of the interaction of the free ligands with CT DNA do not show any transitions because there is not any asymmetry or chirality in the molecules [25–35,52,57]. The CD spectrum of free CT DNA is conservative and consists of a negative band at 246 nm and a positive one at 273 nm, characteristic of the B-form of DNA [58].

The CD spectra of CT DNA in the presence of complex **1** are shown in Fig. 4. They consist of a strong negative band I at 246 nm and two discrete positive band II at 273 nm and band III (observed as a shoulder) at 280 nm. When complex **1** is incubated with CT DNA at diverse r values, the CD spectrum of CT DNA undergoes changes mainly in the positive bands showing that complex **1** is bound to CT DNA. For r values up to 1:400, each spectrum consists of one negative band I at 246 nm and two positive band II at 274 nm and band III at 280 nm. Upon increase of the r value, the λ_{max} of these three bands remain

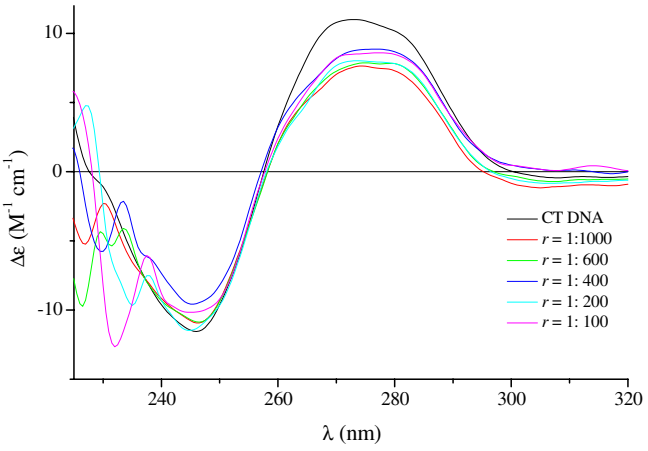

Fig. 4. CD spectra of CT DNA in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of complex $MoO_2(erx)_2$ (**1**) in different r values. The spectra were recorded at 25 °C after the samples had been incubated with CT DNA for 24 h at 37 °C.

practically unchanged and their intensities are marginally decreased. When r increases further (up to 1:100), the two positive bands II and III are consolidated and cannot be distinguished resulting to a unique broad band at $\lambda_{max} = 276$ nm while the intensity remains practically unchanged. On the other hand, the λ_{max} of the negative band I at 246 nm remains unchanged.

These changes indicate that **1** can be bound to CT DNA but we cannot safely suggest the exact mode of binding. Nevertheless, for high r values, the coexistence of bands II and III could be possibly concerned as a partial redshift of the CT DNA positive band (expected at 273 nm due to base stacking) to higher wavelengths being a hint for a probable B- to A-conformation DNA change due to $\pi \rightarrow \pi^*$ transitions [53,59], while for lower r values, where the dominating spectral feature is the lack of any perturbation on both bands I and II of CT DNA, the existence of simple groove binding or electrostatic interaction [56] could not be ruled out.

Quite similar behavior is observed in the CD spectra of CT DNA in the presence of complex **2**.

4. Conclusions

The synthesis and characterization of two neutral mononuclear MoO_2^{2+} complexes with the second and third-generation quinolone antibacterial drugs enrofloxacin and sparfloxacin, respectively, has been realized with physicochemical and spectroscopic methods. In both complexes, the quinolone ligands are bound to the metal via the pyridone and one carboxylate oxygen atoms. Each molybdenum(VI) atom is six-coordinate and the environment around could be described as distorted octahedron. With the use of molecular modeling calculations, we have proposed a low-energy model for the structures of both the complexes. The antimicrobial activity of the complexes has been tested on three different microorganisms. The complexes show a diverse biological activity in comparison to the free quinolone ligands and in some cases they provide better inhibition. The investigation of the interaction of the complexes with CT DNA has been performed with diverse spectroscopic techniques and has shown that the complexes can be bound to CT DNA.

Abstract

Trinuclear mixed oxidation state Co(III/II/III) complexes with a different coordination geometry at each cobalt center of a pyrazole derived Schiff base and mononuclear cobalt (III) complexes of another pyrazole containing Schiff base having N-donor atoms have been prepared and structurally characterized. Reaction of 5-methyl-3-formylpyrazole (MPA) and 1,3-diamino-2-propanol (DAP) with $CoX_2 \cdot 6H_2O$ (X = Cl, Br) in a 2:1:1 ratio produces unusual trinuclear mixed-valent complexes $[Co_3(L_1)_2Cl_4]$ (**1**) and $[Co_3(L_1)_2Br_4]$ (**2**) [where $H_2L_1 = 1$, 3-bis(5-methyl-3-formylpyrazolylmethinimino)propane-2-ol], and the same reaction when carried out with $CoX_2 \cdot 6H_2O$ ($X = CH_3COO^-, ClO_4^-$ NO_3^-, BF_4^-) produces mononuclear $[Co(L_1)(H_2O)_2]X \cdot H_2O$, of which only $[Co(L_1)(H_2O)_2]CH_3COO \cdot H_2O$ (**3**) was isolated. In contrast, the reaction of 5-methyl-3-formylpyrazole (MPA) and 1,3-diamino-2-propanol (DAP) with $CoX_2 \cdot 6H_2O$ (where $X = ClO_4^- NO_3^-$, BF_4^-) in a 1:1:1 ratio produces mononuclear Schiff base complexes $[Co(L)_2]$ ClO_4 (**4**), $[Co(L)_2]$ NO_3 (**5**) and $[Co(L)_2]$ BF_4 (**6**) [where HL = 1-(5-methyl-3-formylpyrazolylmethinimino)-3-aminopropane-2-ol], whereas when X = Cl and Br a hygroscopic intractable material was isolated. Among the above species, **1** and **4** have been crystallographically characterized. In **1**, three cobalt atoms are arranged in a linear fashion and are bridged through pyrazolate rings. The terminal diamagnetic low spin cobalt(III) ions with a N_4Cl_2 chromophore are in a distorted octahedral environment. These two outer cobalt(III) complexes individually act as bidentate chelating ligands and encapsulate the central cobalt(II) ion, which adopts a distorted flattened, tetrahedral geometry with a N_4 chromophore. The interatomic separations are 3.794 Å (Co1···Co2) and 3.791 Å (Co2···Co3). In **4**, the cobalt(III) atom is also in a distorted octahedral geometry with a N_6 chromophore. Variable temperature (300–2 K) magnetic susceptibility measurements have been carried out for **1** and **2**. Zero field splitting of the tetrahedral cobalt(II) ion has been noticed. The EPR spectrum of **1** and **2** at low temperature is associated with a Kramer doublet $\pm 1/2$ arising from the $S = 3/2$ ground state. Some of the complexes are further characterized by UV–Vis, IR and electrochemical studies. The IR spectrum of **3** shows the typical vibration of ionic acetate at 1577 cm^{-1} (ν_{asym}) and 1397 cm^{-1} (ν_{sym}).

1. Introduction

Multinuclear transition metal complexes have become a central theme of current research because of their potentially useful properties in the realm of relevant scientific and technological fields. They are involved in some notable catalytic processes [1]. Their important use for modelling the metal active sites of metalloproteins [2] and also their recent applications in the area of nanoscale materials [3] have drawn the focal point of attraction of modern chemists towards the synthesis and characterization of such metal complexes. Especially, there is currently a great deal of interest in the synthesis and characterization of polynuclear cobalt complexes due to their wide-ranging potential applications such as catalysts [4], electron transfer mediators in dye-sensitized solar cells [5], anti-viral agents [6] and molecular nano-magnets [7]. In particular, trinuclear cobalt complexes draw their speciality from their use as catalysts in epoxidation of olefins [8] and in the autoxidation of hydrocarbons [9]. One of the synthetic strategies to prepare polynuclear transition metal complexes is the use of simple metal ion complexes which have the appropriate functionality to act as ligands for another metal ion or ions. The speciality of these strategies is the use of a mononuclear transition metal complex as a bidentate chelate for a second metal ion. One attractive feature of this scheme is that the second metal ion will usually be in a different coordination pocket from the first one, potentially allowing the facile synthesis of homonuclear complexes in which the metals having different oxidation states are in different geometries.

Studies in metal ion mediated anion dependent formation of polynuclear Schiff base complexes has been one of the prime topics of our recent research [10]. In continuation of our earlier work, attempts have been made to prepare Co(II) complexes of the Schiff base ligand H_2L_1 [2:1 condensation product of MPA (5-methyl-3-formylpyrazole) and DAP (1,3-diamino-2-propanol)], employing the template methodology. Interestingly, when 2 equiv. of MPA and 1 equiv. of DAP are condensed in the presence of 1 equiv. of Co(II) chloride/bromide, the unusual mixed oxidation state pyrazolate bridged complexes $[Co_3(L_1)_2X_4]$, X = Cl, Br (**1** and **2**) are isolated. Under similar conditions $CoX_2 \cdot 6H_2O$ ($X = CH_3COO^-, ClO_4^-$, NO_3^-, BF_4^-) produces the mononuclear complexes $[Co(L_1)(H_2O)_2]X \cdot H_2O$, of which only the acetate complex (**3**) [$X = CH_3COO^-$] was isolated; the other products being intractable materials that could not be isolated. In contrast, the same reaction when carried out in MPA and DAP in a 2:2 equiv. ratio in the presence of 1 equiv. of $CoX_2 \cdot 6H_2O$ ($X = ClO_4^-$, NO_3^- and BF_4^-) ended in forming the desired mononuclear Schiff base complexes $[Co(L)_2]X$ ($X = ClO_4^-$, NO_3^- and BF_4^-) (**4**, **5** and **6**). An intractable green mass was obtained in the same reaction when Cl^-/Br^- were used as counterions. The structures of the ligands H_2L_1 and HL are given in Fig. 1.

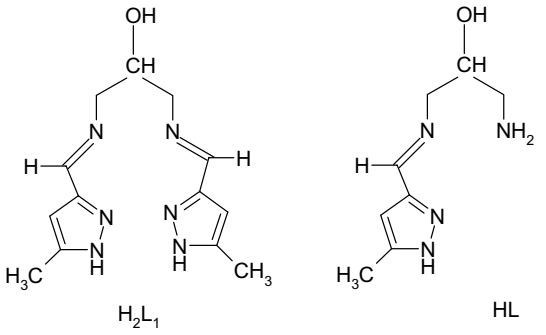

Fig. 1. Structure of the ligands.

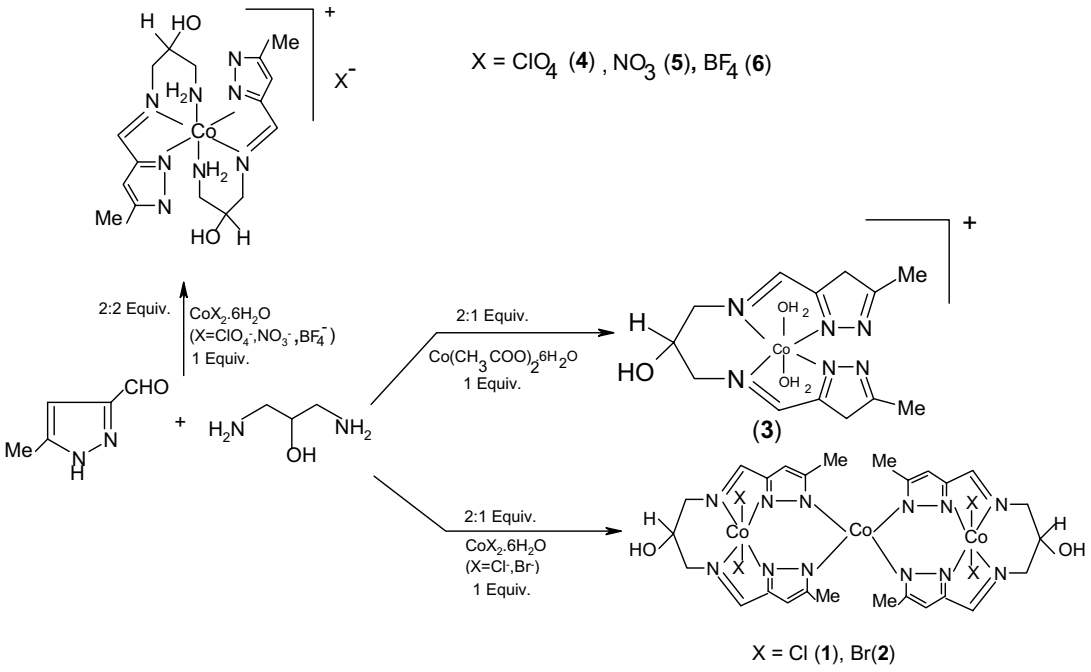
All the observations are depicted in Scheme 1 for clarity.

2. Experimental

2.1. Materials

1,3-Diamino-2-propanol (DAP) was purchased from Aldrich, USA. 5-Methyl-3-formylpyrazole (MPA) was synthesized as described earlier [11]. Spectrograde solvents were used for physical measurements. All the other reagents and solvents were purchased from commercial sources and purified by standard procedures [12].



Synthesis: Warning! Perchlorate salts are potentially explosive and were handled only in small quantities with care.

2.2. Preparation of the Co(III/II) complexes $[Co_3(L_1)_2X_4]$ [X = Cl^- (1), Br^- (2)]

A mixture of MPA (0.22 g, 2 mmol) and DAP (0.09 g, 1 mmol) was refluxed for 4 h in 50 ml dry ethanol. The light red solution was filtered off, cooled to room temperature and the corresponding Co(II) salt (1 mmol) was added. Immediately a green precipitate was separated. The mixture was stirred for 2 h and filtered. The precipitate was washed with ethanol and dried over fused $CaCl_2$ in a desiccator. Yield 58% (**1**), 53% (**2**). X-ray quality crystals of **1** were grown by slow diffusion of *n*-hexane into a dichloromethane–ethanol (1:1 V/V mixture) solution of the compound.

UV–Vis (DMF) (λ_{max}, nm) (ε, $1\,M^{-1}\,cm^{-1}$): 1060 (65), 648 (795), 625 (732), 595 (565). Molar conductivity (DMF solution): $\Lambda_M = 52\,\Omega^{-1}\,cm^2\,mol^{-1}$. Magnetism (solid state, room temperature): $\mu_{eff} = 4.2$ B.M.

2.3. Preparation of $[Co(L_1)(H_2O)_2]CH_3COO \cdot H_2O$ (3)

To a filtered solution of a mixture of MPA (0.22 g, 2 mmol) and DAP (0.09 g, 1 mmol) in 30 ml dry ethanol, prepared following the same procedure outlined above, the cobalt(II) salt $Co(II)X_2 \cdot xH_2O$ (1 mmol) was added ($X = ClO_4^-, BF_4^-, CH_3COO^-, NO_3^-$). The solution in each case was refluxed for 4 h to get a red solution. Only the complex with acetate as a counterion has been isolated, while in all other cases hygroscopic intractable materials were found. In spite of our several attempts, we were unsuccessful to isolate the X-ray quality crystals of **3**.

Anal. Calc. for $C_{15}H_{25}CoN_6O_6$ (**3**): C, 40.54; H, 5.68; N, 18.92%. Found: C, 40.51; H, 5.20; N, 18.45%. IR (KBr; cm^{-1}): 3600–2900 (v.b.) (ν_{OH}, ν_{H_2O}, ν_{NH}), 1610 ($\nu_{C=Niminyl}$), 1577 ($\nu_{C=NPz}$ and $\nu_{ionic\ acetate}$), 1397 ($\nu_{ionic\ acetate}$). Diffuse reflectance spectroscopy (DRS) (λ_{max}, nm): 462, 373. UV–Vis (MeOH) (λ_{max}, nm) (ε, $1\,M^{-1}\,cm^{-1}$): 505 (12). Molar conductivity (MeOH solution): $\Lambda_M = 82\,\Omega^{-1}\,cm^2\,mol^{-1}$. Magnetism (solid state, room temperature): $\mu_{eff} = 0$. TGA: Loss of lattice water (calc. 4.05%, found 4.12%) in the temperature range 75–85 °C and that of the coordinated water molecules (calc. 8.1%, found 7.98%) in the temperature range 170–195 °C.

2.4. Preparation of Co(III) complexes with HL: $[Co(L)_2]X$ [$X = ClO_4^-$ (4), NO_3^- (5), BF_4^- (6)]

A mixture of MPA (0.11 g, 1 mmol) and DAP (0.09 g, 1 mmol) was refluxed for 4–5 h in ethanol. To the light yellow filtrate, an ethanolic solution of the corresponding $CoX_2 \cdot 6H_2O$ ($X = ClO_4^-$, NO_3^-, BF_4^-) (1 mmol) was added and again refluxed for 4 h. The resulting deep red solution was left for slow evaporation at room temperature in a fused $CaCl_2$ desiccator. After 5 days red coloured crystalline compounds were isolated. Yield 60–65%. X-ray quality crystals of **4** were grown by the slow evaporation of a methanolic solution of the compound.

Anal. Calc. for $C_{16}H_{26}CoN_8ClO_6$ (**4**): C, 36.92; H, 5.03; N, 21.50. Found: C, 36.10; H, 4.98; N, 21.22%. Diffuse reflectance spectroscopy (DRS) (λ_{max}, nm): 368, 453. UV–Vis (DMF), λ_{max}, nm (ε, $1\,M^{-1}\,cm^{-1}$): 449 (35). Molar conductivity (DMF solution): $\Lambda_M = 80\,\Omega^{-1}\,cm^2\,mol^{-1}$.

Anal. Calc. for $C_{16}H_{26}CoN_9O_5$ (**5**): C, 39.75; H, 5.38; N, 26.08. Found: C, 40.01; H, 5.21; N, 26.03%. IR (KBr: cm^{-1}): 3322 (br) (ν_{OH}, ν_{NH}), 1609 ($\nu_{C=N(iminyl)}$), 1563 (s, $\nu_{C=NPz}$), 1010 (ν_{N-NPz}). Diffuse reflectance spectroscopy (DRS) (λ_{max}, nm): 370, 453. UV–Vis (DMF) (λ_{max}, nm) (ε, $1\,M^{-1}\,cm^{-1}$): 448 (35). Molar conductivity (DMF solution): $\Lambda_M = 76\,\Omega^{-1}\,cm^2\,mol^{-1}$.

Anal. Calc. for $C_{16}H_{26}CoN_8O_2BF_4$ (**6**): C, 37.79; H, 5.11; N, 22.04. Found: C, 37.12; H, 5.02; N, 21.15%. IR (KBr: cm^{-1}): 3322 (br) (ν_{OH}, ν_{NH}), 1609 ($\nu_{C=N(iminyl)}$),

1563 (s, $\nu_{C=NPz}$), 1011 (ν_{N-NPz}). Diffuse reflectance spectroscopy (DRS) (λ_{max}, nm): 370, 453. UV–Vis (DMF) (λ_{max}, nm) (ε, $1\,M^{-1}\,cm^{-1}$): 445 (35). Molar conductivity (DMF solution): $\Lambda_M = 82\,\Omega^{-1}\,cm^2\,mol^{-1}$.

2.5. Physical methods

Infrared spectra were recorded on KBr disks (4000–400 cm^{-1}) with a Perkin–Elmer FTIR spectrophotometer. UV–Vis spectra were measured on a Hitachi U-3501 spectrophotometer. Room temperature magnetic moments were measured with a vibrating sample magnetometer. Variable temperature susceptibility measurements for **1** and **2** were carried out on polycrystalline samples at the Servei de Magnetoquimica of the Universitat de Barcelona with a Quantum Design SQUID MPMS-XL susceptometer apparatus working in the range 2–300 K under a magnetic field of approximately 200 G (2–30 K) and 5000 G (35–300 K). Diamagnetic corrections were estimated from Pascal Tables. The EPR spectra have been recorded on an X-band Bruker spectrometer (ESR 300E) working with an Oxford helium liquid cryostat for variable temperature measurements. The diffuse reflectance spectra of the reported complexes were recorded on a Hitachi U-3501 spectrophotometer. Electrical conductivity measurements were carried out in methanol solution using a Systronics model 304 digital conductivity meter. Elemental analyses were carried out at IACS, Calcutta with a Perkin–Elmer model 2400 CHN analyzer. Cyclic voltammetry was carried out using Sycopel model AEW2 1820F/S instrument. The measurements were performed at 300 K in DMF solutions containing 0.2 M TEAP and 10^{-3}–10^{-4} M cobalt complex **1** deoxygenated by bubbling with nitrogen. The working, counter and reference electrodes used were a platinum wire, a platinum coil and an SCE.

2.6. X-ray crystal structure analysis

Selected crystal data for **1** and **4** are given in Table 1. Data collections were made using a Bruker SMART CCD area detector (for **1**) and a Bruker P4 diffractometer (for **4**) equipped with a graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) source in the ω scan mode at 295(2) and 293(2) K, respectively. Cell parameter refinement and data reduction for **1** were carried out using the Bruker SAINT program [13]. For **4**, cell parameters were refined by Bruker XSCANS and the corresponding data reduction were done by Bruker SHELXTL software [14]. The structures were solved by conventional direct methods and refined by full-matrix least square methods using F^2 data. SHELXS-97 and SHELXL-97 programs [15] were used for structure solution and refinement, respectively. Positions of H-atoms were treated as riding on their parent atoms. For **4**, this was a room temperature structure containing perchlorate. As is usual for this group, it was disordered. However, an added complication was that this group was also near a symmetry element. This made it much harder to idealize this group during the refinement process. Because of symmetry one O atom was in two positions. The best model was obtained by constraining the Cl–O distance and the O–O separation.

3. Results and discussion

The Schiff base ligand H_2L_1, acting as a binegative hexadentate ligand, forms linear trinuclear pyrazolate bridged mixed valent cobalt complexes $[Co_3(L_1)_2Cl_4]$ (**1**) and $[Co_3(L_1)_2Br_4]$ (**2**) in the presence of the Cl^- and Br^- anion, respectively. The same ligand forms mononuclear complexes $[Co(L_1)(H_2O)_2]X \cdot H_2O$ for other anions like CH_3COO^- (**3**), ClO_4^-, NO_3^- and BF_4^-, where it acts as a tetradentate binegative ligand. The other Schiff base HL, functioning as a uninegative tridentate ligand, forms mononuclear complexes $[Co(L)_2]ClO_4$ (**4**), $[Co(L)_2]NO_3$

(**5**) and $[Co(L)_2]BF_4$ (**6**). The crystal structures of **1** and **3** are depicted below.

3.1. Description of crystal structures

Fig. 2 shows a perspective view of compound **1** including the atom numbering scheme. The crystal data and selected bond lengths along with angles are presented in Tables 1 and 2, respectively. The crystal structure reveals the formation of a neutral, linear, trinuclear complex with mixed oxidation states of cobalt. The trinuclear cobalt complex locates at a general position in *C*2/*c*, there is no crystallographic symmetry in the complex. The hydroxyl group attached to C7 is disordered at the axial and equatorial positions with half occupancies. The other sites of the six-membered ring (Co3–N9–C19–C20–C21–N10) are seriously disordered on C20, C21 and O1 with half occupancies. Some restraints are applied in the refinement. The difference in bond lengths discriminate between the Co(II) and Co(III) ions. Each of the two terminal cobalt centers, Co1 and Co3, is clearly low spin octahedral cobalt(III) with short Co–N distances (av. 1.911 Å). Co1 has a six coordinate pseudo octahedral geometry in which N2, N3, N4 and N5 atoms of the deprotonated di-Schiff base $[L_1]^{2-}$ constitute the equatorial plane and two Cl [1 and 2] atoms define the axial directions of the *trans* isomer. The analysis of bond angle values Table 2 suggests a small deviation from the expected octahedral geometry. This is due to the restrictions imposed by the tetradentate ligand $[L_1]^{2-}$, the five- and six-membered chelate ring bite angles being 82° and 98°, respectively. The coordination environment around Co3 is very similar to that of Co1. Co3 is also in a pseudo octahedral environment in which the $[L_1]^{2-}$ ligand forms the equatorial plane [N(8), N(9), N(10), N(11)] and the two apical positions are occupied by two Cl-atoms [Cl3, Cl4]; here the five- and six-membered chelate ring bite angles are 82° and 97°, respectively.

Two of these mononuclear anionic $[trans\text{-}Co(L_1)Cl_2]^-$ complexes act as ligands to the central cobalt(II) center, [Co2] with the formation of four pyrazolate bridges. The metal ion sits in a slightly flattened tetrahedral geometry with an average Co2–N distance of 1.993 Å and an average chelate bite angle of 103°. The angle between the N1–Co2–N6 and N7–Co2–N12 chelate planes is 84°. This orthogonality in approach of the two ligands (obviously terminal octahedral complexes) is a consequence of the steric

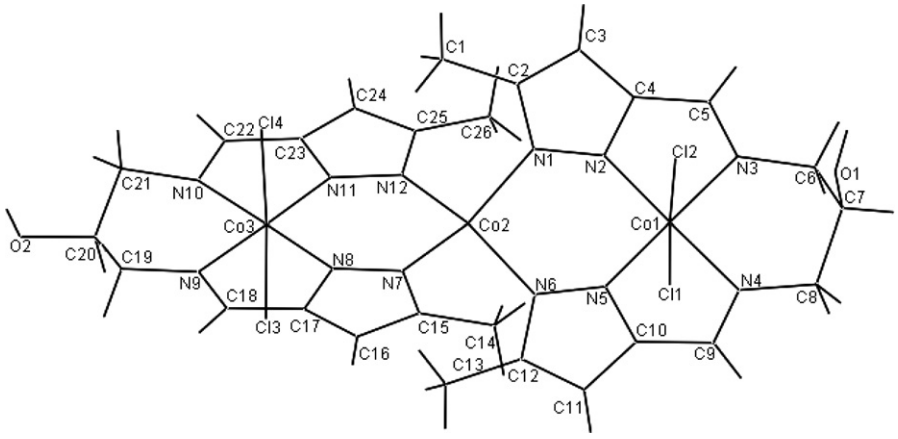

Fig. 2. Molecular structure of **1**.

hindrance of the interlacing methyl groups on the pyrazole rings. These methyl groups also effectively prevent the central Co(II) ion from adopting a higher coordination number.

The Co1···Co2 and Co2···Co3 interatomic distances are 3.794 Å and 3.791 Å, respectively. None of these distances is sufficiently short to imply any metal–metal bonding or allow intra-metal spin exchange through mutual interactions [16–18]. In the present complex, the Co(II)–N distances vary from 1.979(9) to 2.004(10) Å, and are typical for high spin Co(II)–N distances. The Co(III)–N distances are in the range 1.874(10)–1.963(11) Å, as expected for low spin Co(III) [16,19]. Thus the bond lengths about the terminal cobalt ions are significantly shorter than those about the central cobalt ion, indicating that the terminal ones are trivalent while the central one is divalent.

A perspective view of compound **4**, including the atom-numbering scheme, is shown in Fig. 3. The asymmetric unit consists of a $[Co(L)_2]^+$ cation and ClO_4^- anion. In the crystal structure the two potentially uninegative tridentate (NNN) donor ligand molecules form an octahedral geometry around the central cobalt atom. Each ligand molecule offers its respective deprotonated pyrazolyl nitrogen, azoimine nitrogen and terminal primary nitrogen atoms as the coordination sites, providing an N_6 chromophore. The equatorial plane of the octahedral geometry is defined by N1(deprotonated pyrazolide), N3(azoimine), N4(primary NH_2) and N3a(azoimine), and the two apical positions are coordinated by N1a (deprotonated pyrazolide) and N4a (primary NH_2). The coordination polyhedron of the said complex is best described as a distorted octahedron, which is reflected through the difference in N–Co–N bond angles. Quite obviously all the bond angles are deviated from the respective ideal bond angle values. The maximum deviation occurs for N1–Co–N3 [82.00(13)°], N3#1–Co–N3 [175.49(17)°], N3–Co–N4 [95.59(13)°]. The two Co–N pyrazolide bonds, being equal in length [1.902(3) Å], are still shorter than the two equal Co–N(azoimine) bonds [1.945(3) Å]. This difference in bond lengths is quite evident from the difference in the basic property between the deprotonated pyrazolide nitrogen (stronger base) and the neutral azoimine nitrogen (weaker base). The other two Co–N (terminal NH_2) bonds are also equal [1.972(3) Å] in themselves, but are longer than the other Co–N bonds. This is because of the difference in hybridization state (sp^2 for azoimine nitrogen and sp^3 for terminal NH_2). The two ligand molecules approach the central metal ion almost orthogonally, as suggested from the dihedral angle analysis (the dihedral angle being 88°). The ligands are coordinated to the central Co(III) ion in the meridional fashion (the pyrazolide and primary amine nitrogen atoms are cis to each other and the azoimine nitrogen atoms are *trans*). The origin of this meridional disposition arises from the maximum back bonding effect between the filled t_{2g} orbitals on the Co(III) ion and the vacant π^* M.O.s on the pyrazole ring. The perchlorate anion in this structure lies proximate to an inversion center. The crystal structure is stabilized through a network of both intramolecular and intermolecular H-bonding. The uncoordinated-OH of one ligand HL (in one asymmetric unit) forms a strong intermolecular H-bond with the pyrazolide N of another asymmetric unit [the O–N distance being 2.755(5) Å]. Likewise, the N4–O1 contact [3.011(5) Å] is also an indication of weak intramolecular H-bonding. The details of H-bond parameters are presented in Table 3. For clarity, the H-bonding interaction is shown in Fig. 4.

3.2. Diffuse reflectance and solution spectra

The spectral pattern in both DRS and in methanol solution of **1** (as a representative example) exhibits bands mainly characteristic of cobalt(II) in a tetrahedral geome-

Table 3

try. In the diffuse reflectance spectrum, in addition to the tetrahedral bands, (one spanning between 600–650 nm and the other between 1000–1100 nm) another spectral band is observed at *ca.* 400 nm, attributable to the low-spin octahedral Co(III) center. In solution, however, only Co(II) tetrahedral bands are obtained. Although three spin-allowed electronic transitions are expected to occur for tetrahedral Co(II), the visible spectrum is actually dominated by the highest energy transition, $^4A_2 \rightarrow {}^4T_1(P)$ with the $^4A_2 \rightarrow {}^4T_1(F)$ transition in the near IR region. The visible transition in tetrahedral complexes generally has complex envelopes because a number of transitions to doublet excited states occur in the same region, and these acquire some intensity by means of spin–orbit coupling. Thus from the above discussion it may be stated that, both in solid and in solution the weak absorption band at *ca.* 1065 nm and the strong one at *ca* 620 nm may be assigned as $^4A_2 \rightarrow {}^4T_1(F)$ (ν_2) and $^4A_2 \rightarrow {}^4T_1(P)$ (ν_3), respectively.

The diffuse reflectance spectrum of **3** exhibits two broad bands at 373 nm and 462 nm corresponding to two spin-allowed transitions ($^1A_{1g} \rightarrow {}^1T_{2g}$ and $^1A_{1g} \rightarrow {}^1T_{1g}$) for the low spin Co(III) octahedral species. The DMF solution of the complex does not display any band in the visible region. The d–d bands in the electronic spectrum of the present Co(III) complex is obscured by the intense CT bands [20].

The diffuse reflectance spectrum of **4** (as a representative example), exhibiting two bands at 368 nm ($^1A_{1g} \rightarrow {}^1T_{2g}$) and 453 nm ($^1A_{1g} \rightarrow {}^1T_{1g}$), indicates the low-spin octahedral geometry of the $[Co(L)_2]^+$ cation. The intense charge-transfer bands in the UV-region probably mask the other bands. The DMF solution of the complex displays a characteristic absorption in the UV–Vis region. The characteristic visible spectrum may be ascribed to transitions from $^1A_{1g}$ to $^1T_{1g}$ and $^1T_{2g}$ states, respectively. Here only one band at 449 nm ($^1A_{1g} \rightarrow {}^1T_{1g}$) is obtained. The second transition is obscured by either intense charge transfer bands or intraligand transitions [20].

3.3. Electrochemistry

The cyclic voltammetry experiment of **1** (Fig. 5) was performed in methanol solution within the potential range ±2 V versus Pt wire electrode at ambient temperature (300 K) using a three-electrode configuration. The complex exhibits no oxidation response. However, an irreversible reduction couple at −1.11 V is ascribed to a Co(III) → Co(II) reduction. The redox signal remains almost unaltered under different scan rates (0.02–1.0 vs^{-1}) in the temperature range 300–280 K.

3.4. Magnetic and EPR study of 1 and 2

The magnetic properties of compounds **1** and **2** are as expected, taking into account the linear trinuclear mixed valence cobalt(III/II/III) (Fig. 2) in which the surrounding Co(III) centres have an octahedral geometry with $S = 0$

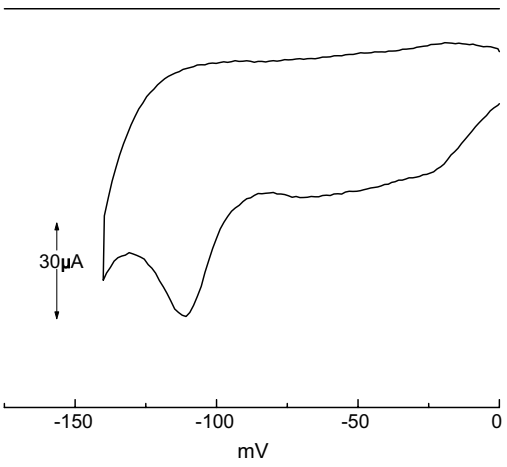

Fig. 5. Cyclic voltammogram of **1**.

and the central Co(II) centre has a distorted tetrahedral geometry possessing spin ($S = 3/2$) without spin–orbit splitting. Susceptibility measurements in the 300–2 K range shows a constant $\chi_M T$ value of 2.293 and 2.458 cm^3 K mol^{-1}, down to approximately 65 and 50 K, respectively, and below this temperature decrease to 1.373 and 1.476 cm^3 K mol^{-1} at 2 K for **1** and **2**, respectively (Fig. 6). Structural data of compound **1** indicate that it is a linear trinuclear cobalt complex with pyrazolate bridges and the main factor determining the decrease in the $\chi_M T$ value could be the Zero Field Splitting (ZFS) of the cobalt(II) ion in a distorted tetrahedral environment. To determine this parameter, we have fitted the experimental data to the following expression [21]:

$$\chi_M = \{[Ng^2\mu_\beta^2/KT][(1/4)(1 + 9e^{-2x})/(1 + e^{-2x})] + 2[1 + (3/4x)(1 - e^{-2x})/(1 + e^{-2x})]\}/3$$

where $x = D/KT$.

The best fit parameters obtained minimizing the function $R = (\sum \chi_M T_{calc} - \chi_M T_{obs})^2/(\sum \chi_M T_{obs})^2$ are $D = 16.1\ cm^{-1}$, $g = 2.21$ for **1** and $D = 12.3\ cm^{-1}$, $g = 2.28$ for

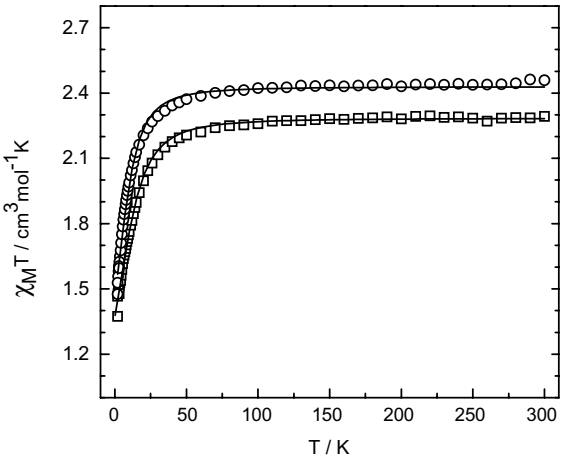

Fig. 6. Plot of $\chi_M T$ vs. T of a polycrystalline sample of **1** (□) and **2** (○). The solid line corresponds to the best fit.

2. In both cases the *R* factor value is found to be inferior to 10^{-5}. It should be pointed out that these D values seem to be too high because in the fits we do not take into account the intermolecular interactions (currently AF).

The field dependence of magnetization (0–5 T) measured at 2 K is shown in Fig. 7 in the form of M/Nβ per Co(III)–Co(II)–Co(III) unit versus H. The magnetization reaches a value of 1.91 and 2.25 electrons at 5 T for **1** and **2**, respectively. Comparison of the overall shape of the experimental plots with the Brillouin plot (solid plot) for one isolated ion with $S = 3/2$ system and $g = 2$ indicates slower magnetization, which is consistent with the presence of the ZFS effect.

The powder EPR spectra of **1** and **2** at 4 K are shown in Fig. 8. They exhibit a resonance with a maximum at approximately $g = 4.80$ and 5.13 and a broad band centred at $g = 2.16$ and 2.24 for **1** and **2**, respectively. No new transition is observed when the temperature is increased. These spectra are in good agreement with those expected for a $S_T = 3/2$ system: the spectrum at low temperature is associated with the Kramer doublet $\pm 1/2$ arising from the $S = 3/2$ ground state [22,23], which must present two signals approximately in the ratio $g_\perp = 2g_\parallel$.

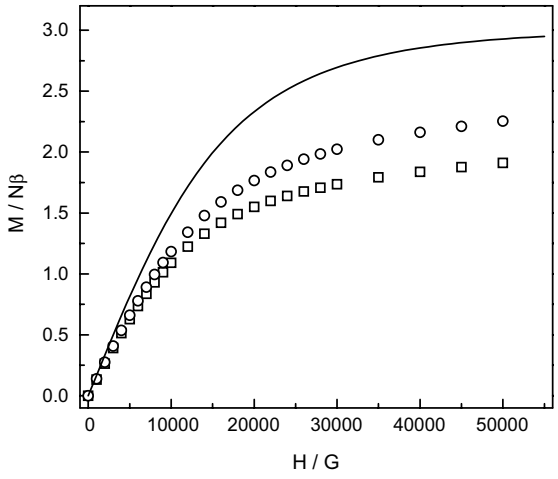

Fig. 7. Plot of reduced magnetization M/Nβ vs. applied field H at 2 K for **1** (□) and **2** (○). Solid line corresponds to the Brillouin function for an isolated $S = 3/2$ with $g = 2.0$.

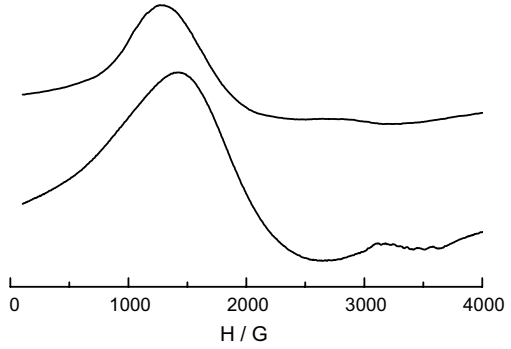

Fig. 8. Polycrystalline powder EPR spectra of **1** (bottom) and **2** (top) at 4 K.

4. Conclusion

The peculiarity of the coordinating behaviour of the same Schiff base (H_2L_1) towards Cu(II) and Ni(II) metal ions has already been reported in our earlier paper [10]. There we found that the composition of the metal complexes depends upon two factors – firstly the mole proportion of each of the aldehyde (MPA), the diamine (DAP) and the metal salt used and secondly the specification of the metal used. The compositions as well as internal cyclisation (in part) leading to the formation of a new ligand system are also related to the nature of the anion of the metal salt used [10]. This peculiarity was exclusively specific for the Cu(II) ion. Tracing the same synthetic route for the Co(II) ion, we find a different but unusual observation.

Using the aldehyde and amine (2:1 equiv.) and 1 equiv. of the Co(II) salts in the presence of Cl^- and Br^- ions, unusual linear trinuclear mixed valence Co(III/II/III) complexes of H_2L_1 are isolated, unlike the mononuclear Cu(II) complexes of H_2L_1 formed earlier in a similar reaction [10]. A mononuclear complex of Co(III) is formed when the CH_3COO^- salt is used. Whereas the mixed ligand system (HL_2 and partially cyclised HL_1), formed in situ by 1:1 condensation of MPA and DAP in the presence of Cu(II) nitrate, resulted in a tetra Cu(II) complex, and the same reaction when carried out with Ni(II) salts ClO_4^-, NO_3^-andBF_4^- formed intractable materials in our earlier work [10], whilst in the present study for Co(III) using the same counter ions the usual mononuclear bischelate complexes are isolated. When Cl^- and Br^- anions were used as counterions in this latest study, an intractable material was isolated.

Abstract

The reactions of $[ReOX_3(EPh_3)_2]$ with 8-hydroxyquinoline-2-carboxylic acid (Hhquin-2-COOH) have been examined and $[ReOX_2(hquin\text{-}2\text{-}COOH)(EPh_3)] \cdot MeCN$ (X = Cl, Br; E = As, P) complexes have been obtained. All the complexes were characterised by IR, UV–Vis spectroscopy and elemental analysis. The crystal and molecular structures have been determined for $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)] \cdot MeCN$ and $[ReOCl_2(hquin\text{-}2\text{-}COOH)(PPh_3)] \cdot MeCN$. The electronic structure of $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]$ has been calculated with the density functional theory (DFT) method, and TDDFT calculations have been employed to produce a hundred of singlet excited-states starting from the ground-state geometry optimized in the gas phase.

Keywords: Rhenium oxo complexes; 8-Hydroxyquinoline-2-carboxylic acid; X-ray and electronic structure; DFT calculations; NBO analysis

1. Introduction

For many years inorganic compounds containing an oxygen atom multiply bonding to a transition metal have been in the centre of interest to those scientists engaged in basic research and to those trying to employ these complexes in catalytic processes. Oxygen atom transfer chemistry has been implicated in various reactions of industrial and biological importance, including olefin epoxidation and catalysis by cytochrome P-450 [1–3].

The chemistry of oxo rhenium complexes arouses particular interest among these compounds. Methyltrioxorhenium and its derivatives are among the most versatile oxidation catalysts known to date [4]. The oxorhenium(V) chelates $[ReOCl_2(O\text{–}N)(PPh_3)]$ with pyridinecarboxylate ligands exhibit a remarkable catalytic activity for the conversion of ethane, under relatively mild conditions, to a mixture of propionic and acetic acids in a single-pot process with various advantages over the industrial ones [5].

Furthermore, the favourable nuclear properties of ^{186}Re and ^{188}Re nuclides make the compounds with these radioisotopes useful for applications in radioimmunotheraphy [6,7]. Consequently, the inorganic chemistry studies with the naturally occurring non-radioactive rhenium isotopes are very attractive in order to clearly establish the molecular structure of ^{99m}Tc- and $^{186/188}Re$-based radiopharmaceuticals.

In this context, the design, synthesis and reactivity of novel rhenium oxocomplexes has become the aim of several laboratories, including ours.

Previously, we investigated the reactivity of oxorhenium(V) species – $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)_2]$ (X = Cl or Br) – towards 8-hydroxyquinoline (Hhqn) and quinoline-2-carboxylic acid (quin-2-c) [8,9]. In this report we focus on the examinations of the reactions of $[ReOX_3(AsPh_3)_2]$ and $[ReOX_3(PPh_3)_2]$ with 8-hydroxyquinoline-2-carboxylic acid (hquin-2-COOH). This compound contains both hydroxy and carboxylate fragments, and can be considered as a bidentate or tridentate chelating agent. Similar to 8-hydroxyquinoline and quinoline-2-carboxylic acid, 8-hydroxyquinoline-2-carboxylic acid is a biological compound. It is one of the tryptophan metabolites formed through the kynurenine metabolic pathway [10].

Here we present synthesis and spectroscopic data for $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ (**1** · MeCN), $[ReOBr_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ (**2** · MeCN), $[ReOCl_2(hquin\text{-}2\text{-}COOH)(PPh_3)]\cdot MeCN$ (**3** · MeCN) and $[ReOBr_2(hquin\text{-}2\text{-}COOH)(PPh_3)]\cdot MeCN$ (**4** · MeCN) complexes. X-ray studies have been performed for **1** · MeCN and **3** · MeCN, and electronic structure of **1** has been calculated with the density functional theory (DFT). TDDFT calculations have been employed to produce a hundred of singlet excited-states starting from the ground-state geometry optimized in the gas phase, and the UV–Vis spectrum of the complex has been discussed on this basis.

Currently density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [11]. Recent calculations with TDDFT method for open- and closed-shell of 5d-metal complexes (including rhenium complexes) have also supported the TDDFT method to be applicable for such systems giving good assignment of experimental spectra [12,13].

Some theoretical investigations have been carried out on rhenium compounds. The electronic structures of nitrido, oxo, carbonyl, nitrosyl and nitrile rhenium complexes, as well as their spectroscopic properties, bonding and reactivity have been theoretically studied at the HF, MP2, EHT and DFT levels of theory using various basis sets [14–22]. Gancheff et al. [16] have performed extended tests of the ability of the B3LYP method in LANL2DZ basis set for rhenium compounds in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has shown to be sufficient for the geometry optimization and calculation of spectral properties. It gives good agreement with the experimental data and its use is justified in the case of large molecules.

2. Experimental

2.1. General procedure

The reagents used to the synthesis were commercially available and were used without further purification. The $[ReOX_3(AsPh_3)_2]$ and $[ReOX_3(PPh_3)_2]$ complexes were prepared according to the literature methods [23].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–180 nm in acetonitrile solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ (**1** · MeCN)

A mixture of $[ReOCl_3(AsPh_3)_2]$ (0.50 g, 0.54 mmol), 8-hydroxyquinoline-2-carboxylic acid (0.12 g, 0.63 mmol) and acetone (50 ml) was stirred at room temperature for 3 h. Half of the solvent was removed and diethyl ether (50 ml) was added to precipitate the product as a brown solid, which was filtered off and dried. Yield 80%. Crystals suitable for X-ray investigation were obtained by recrystallization from acetonitrile.

Anal. Calc. for $C_{30}H_{24}Cl_2N_2O_4AsRe$: C, 44.56; H, 2.99; N, 3.46. Found: C, 44.70; H, 3.06; N, 3.55%.

2.3. Preparation of $[ReOBr_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ (**2** · MeCN)

A procedure similar to that for $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ was used with $[ReOBr_3(AsPh_3)_2]$ (0.50 g, 0.47 mmol) and 8-hydroxyquinoline-2-carboxylic acid (0.11 g, 0.58 mmol). Crystalline precipitate of $[ReOBr_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ was collected in 85% yield.

Anal. Calc. for $C_{30}H_{24}Br_2N_2O_4AsRe$: C, 40.15; H, 2.70; N, 3.12. Found: C, 40.29; H, 2.72; N, 3.20%.

2.4. Preparation of $[ReOCl_2(hquin\text{-}2\text{-}COOH)(PPh_3)]\cdot MeCN$ (**3** · MeCN)

A procedure similar to that for $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ was used with $[ReOCl_3(PPh_3)_2]$ (0.50 g, 0.60 mmol) and 8-hydroxyquinoline-2-carboxylic acid (0.13 g, 0.69 mmol). Crystalline precipitate of $[ReOCl_2(hquin\text{-}2\text{-}COOH)(PPh_3)]\cdot MeCN$ was collected in 80% yield.

Anal. Calc. for $C_{30}H_{24}Cl_2N_2O_4PRe$: C, 47.13; H, 3.16; N, 3.66. Found: C, 47.35; H, 3.12; N, 3.78%.

2.5. Preparation of $[ReOBr_2(hquin\text{-}2\text{-}COOH)(PPh_3)]\cdot MeCN$ (**4** · MeCN)

A procedure similar to that for $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]\cdot MeCN$ was used with $[ReOBr_3(PPh_3)_2]$ (0.50 g, 0.52 mmol) and 8-hydroxyquinoline-2-carboxylic acid (0.12 g, 0.63 mmol). Crystalline precipitate of $[ReOBr_2(hquin\text{-}2\text{-}COOH)(PPh_3)]\cdot MeCN$ was collected in 85% yield.

Anal. Calc. for $C_{30}H_{24}Br_2N_2O_4PRe$: C, 42.22; H, 2.83; N, 3.28. Found: C, 42.37; H, 2.73; N, 3.35%.

2.6. Crystal structures determination and refinement

The X-ray intensity data of **1** · MeCN and **3** · MeCN were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and absorption correction [24] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as ''riding'' on their adjacent atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the aromatic parent atoms and equal 1.5 times the value of equivalent temperature factor of the methyl parent carbon atom and oxygen atom (OH). SHELXS97 [25], SHELXL97 [26] and SHELXTL [27] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Computational details

The gas phase geometry of **1** was optimized in the singlet ground-state with the DFT method using the hybrid B3LYP [28,29] functional of GAUSSIAN-03 [30]. The LANL2DZ with additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ basis set [31,32] was chosen for the rhenium atom and the standard 6-31G basis set for all the other atoms. For chloride, oxygen, phosphorous and nitrogen atoms, diffuse and polarization functions were added [33,34]. TDDFT calculations were employed to produce a hundred singlet excited-states starting from the ground-state geometry optimized in the gas phase. The solvent (acetonitrile) effect was simulated using the polarizable continuum model (PCM) [35].

Natural bond orbital (NBO) calculations were performed with the NBO code [36,37] included in GAUSSIAN03.

4. Results and discussion

4.1. Preparation and infrared data

The $[ReOX_2(hquin\text{-}2\text{-}COOH)(EPh_3)]$ (X = Cl, Br; E = As, P) complexes were prepared in good yields by ligand exchange reactions starting from $[ReOX_3(EPh_3)_2]$ complexes and 8-hydroxyquinoline-2-carboxylic acid in acetone:

$$ReOX_3(EPh_3)_2] + \text{hquin-2-COOH} \rightarrow [ReOX_2(\text{hquin-2-COOH})(EPh_3)] + HX + EPh_3,$$
$$X = Cl, Br;\ E = As, P$$

They were isolated as brown microcrystalline solids, soluble in common organic solvents.

The selected frequencies observed in the IR spectra of $[ReOX_2(hquin\text{-}2\text{-}COOH)(EPh_3)]$ complexes are collected in Table 2. The non-coordinated carboxylic acid group of the *hquin-2-COOH* ligand is characterized by the ν_{O-H} absorption situated in the range 3050–3060 cm^{-1} and $\nu_{C=O}$ absorption observed at ≈1720 cm^{-1} [38,39].

The strong ν(Re=O) stretching bands of $[ReOX_2(hquin\text{-}2\text{-}COOH)(EPh_3)]$ compounds are in the higher end of the

Table 2
Selected IR frequencies (cm^{-1}) values of $[ReOX_2(hquin\text{-}2\text{-}COOH)(EPh_3)]$ complexes

Complex	ν_{OH} (COOH)	$\nu_{C=O}$(COOH)	ν(Re=O)
1	3064	1719	972
2	3052	1715	971
3	3060	1719	972
4	3060	1720	972

range observed for $\{ReO\}^{3+}$ core complexes. Similar to the reported previously $[ReOX_2(hqn)(EPh_3)]$ and $[ReOX_2$-(quin-2-c)$(EPh_3)]$ complexes, the Re–hydroxy bond *trans* to the oxo ligand does not compete effectively for the d_{Re} orbitals. Moreover, the narrow range in which the ν(Re=O) bands appear is very similar to those observed for Re(V)-oxo complexes with 8-quinolinolato or quinoline-2-carboxylate ligands [8,9].

4.2. Crystal structures

Both complexes crystallise as acetonitrile solvates in the monoclinic space group $P2_1/c$. The hydroxyl oxygen O(4) atoms of **1** · MeCN and **3** · MeCN are involved in an intermolecular O(4)—H(4A)···O(3) $(1-x, 1-y, -z)$ hydrogen bond, resulting in formation of carboxylic dimer synthons (Fig. 3 and Table 3). The other intra- and intermolecular contacts presented in Table 3 can be considered as weak hydrogen bonds [40,41]. Table 4 presents short analysis of π···π stacking interactions detected between the rings of the *hquin-2-COOH* ligand and one of the triphenyl phosphine rings, and between the ring of the *hquin-2-COOH* ligand and a symmetry related partner $(1-x, -y, -z)$ [42].

Table 3

			Cl(2)–Re(1)–As(1)	171.51(2)	169.85

multiple bonding ligand in the coordination sphere and narrow bite angle of the chelating ligand. The high concentration of electronic density along the Re—O_t (O_t – terminal oxo ligand) axis strongly influences the positions of the adjacent halogen atoms, which are pushed away. In each complex, the rhenium atom is coordinated by a terminal oxygen atom, two halide ions in *cis* arrangement, the phosphorus or arsine atom from EPh_3 molecule, and the bidentate N,O donors of the *hquin-2-COOH* ligand. The oxygen atom of *hquin-2-COOH* ligand lies in *trans* position to the terminal oxo ion.

The Re–O_t bond lengths of [$ReOX_2$(hquin-2-COOH)-(EPh_3)] complexes fall in the range 1.639–1.76 Å, typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicate the presence of a triple bond Re≡O [43]. The interatomic distances between the rhenium atom and the oxygen atom of *hquin-2-COOH* ligand are somewhat shorter than an ideal single Re–O bond length (ca. 2.04 Å) [44], indicating small delocalization in the O(2)–Re(1)–O(1) moiety. The similar trend is observed for many Re(V)–oxo complexes with an monoanionic oxygen *trans* to the oxo group [45].

Table 6
The experimental bond lengths (Å) and angles (°) for **3**

Bond lengths	Experimental	Bond angles	Experimental
Re(1)–O(1)	1.6767(18)	O(1)–Re(1)–O(2)	161.32(9)
Re(1)–O(2)	1.9812(18)	O(1)–Re(1)–N(1)	89.19(9)

Re(1)–Cl(1)	2.3372(9)	O(1)–Re(1)–Cl(1)	104.59(7)
Re(1)–Cl(2)	2.3831(8)	O(2)–Re(1)–Cl(1)	90.96(7)
Re(1)–P(1)	2.4815(7)	N(1)–Re(1)–Cl(1)	166.16(6)
		O(1)–Re(1)–Cl(2)	101.69(7)
		O(2)–Re(1)–Cl(2)	88.77(6)
		N(1)–Re(1)–Cl(2)	87.30(6)
		Cl(1)–Re(1)–Cl(2)	88.63(3)
		O(1)–Re(1)–P(1)	87.15(7)
		O(2)–Re(1)–P(1)	82.60(6)
		N(1)–Re(1)–P(1)	92.47(6)
		Cl(1)–Re(1)–P(1)	89.54(3)
		Cl(2)–Re(1)–P(1)	171.15(3)

The Re1–X(2) distances *trans* to the phosphorus or arsine atom of EPh_3 molecule are slightly longer than the Re1–X(1) bonds *trans* to the nitrogen atom of the *hquin-2-COOH* ligand. It is a consequence of *structural trans* effect of the EPh_3 ligands.

Table 7
Atomic charges from the natural population analysis (NPA) for **1**

Atom	Charge

N(1)	−0.454
Cl(1)	−0.364
Cl(2)	−0.405
As(1)	1.396

4.3. Geometry optimisation, charge distribution, electronic structure and NBO analysis

The geometry of **1** was optimised in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters of **1** are gathered in Table 5. In general, the predicted bond lengths and angles are in

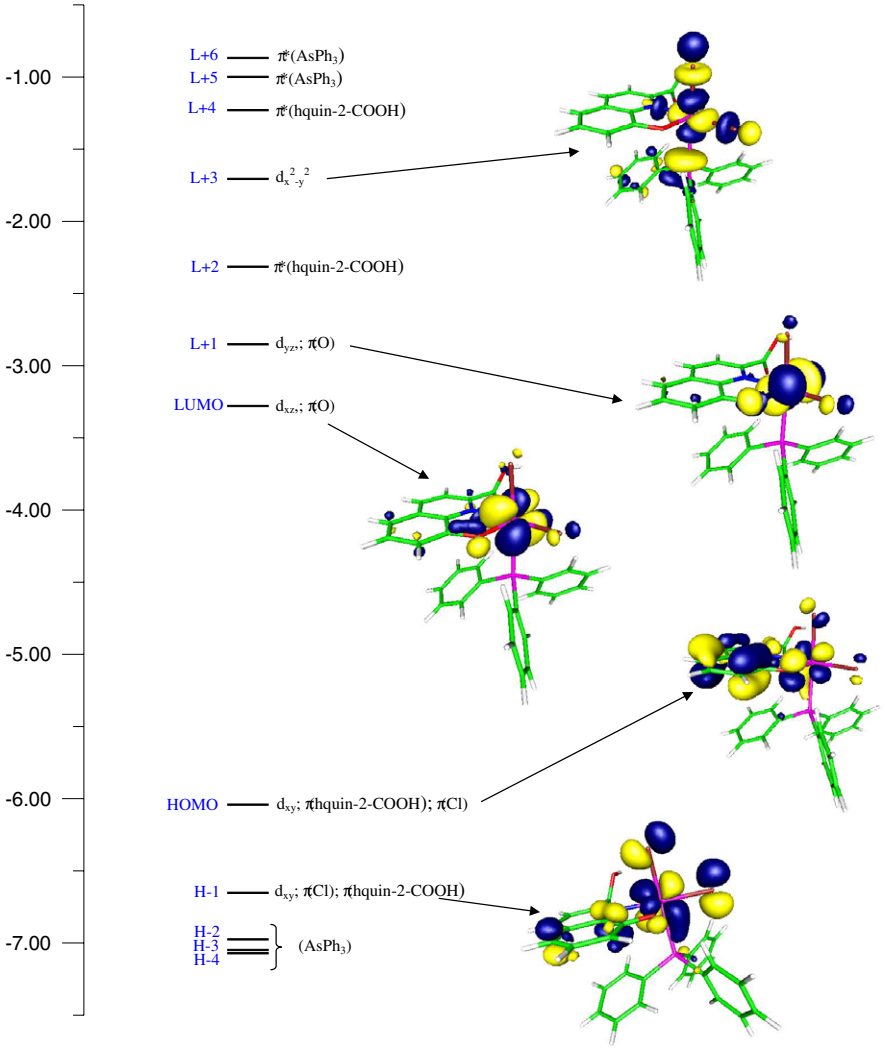

Fig. 4. The energy (eV), character and some contours of the unoccupied molecular orbitals of **1**. Positive values of the orbital contour are represented in blue (0.04 a.u.) and negative values – in yellow (−0.04 a.u.). (For interpretation of the references in colour in this figure legend, the reader is referred to the web version of this article.)

Table 8
The occupancy of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligand for **1**

BD	Occupancy	BD	BD*	Occupancy
Re–O_t	1.993	$0.570(d)_{Re} + 0.822(p)_O$	$0.822(d)_{Re} - 0.570(p)_O$	0.310
Re–O_t	1.984	$0.568(d)_{Re} + 0.823(p)_O$	$0.823(d)_{Re} - 0.568(p)_O$	0.256

BD denotes 2-center bond, * denotes antibond NBO.

agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data (discussed above) are well reproduced in the calculations.

Table 7 presents the atomic charges from the Natural Population Analysis (NPA) for **1**. The calculated charge on the rhenium atom in **1** is considerable lower than the formal charge +5, corresponding d^2 configuration of the central ion. It results from charge donation from the oxo ligands, halide ions and arsine molecule. ligands. The As atom is positively charged, and the charges on the terminal oxo, halide and oxygen atom of *hquin-2-COOH* are significantly smaller than −2, −1 and −1, respectively. The terminal oxo ions are less negative in comparison with the oxygen atoms of *hquin-2-COOH* ligand. It confirms the higher electron density delocalization from the terminal ligand towards the rhenium center and corresponds to differences in the Re–O(1) and Re–O(2) bond lengths.

The $[ReOX_2(hquin\text{-}2\text{-}COOH)(EPh_3)]$ complexes are closed-shell structures. The energies and characters of several highest occupied and lowest unoccupied molecular orbitals of **1** are presented in Fig. 4. The local symmetry of the rhenium center has been considered in the discussion: *z*-axis goes along the O–Re–O linkage, and *x*-axis – through the As–Re–Cl bonds. The HOMO–LUMO gap equals to 2.76 eV. Two highest occupied MOs are delocalized among d_{xy} rhenium orbital, chloride and *hquin-2-COOH* orbitals. The LUMO and LUMO + 1 are predominately localized on the rhenium atom (d_{xz} and d_{yz} orbitals) with some contribution of p_π oxygen orbitals. They can be ascribed as π-antibonding rhenium–oxygen molecular orbitals. The LUMO + 3 is of $d_{x^2-y^2}$ character, and d_{z^2} rhenium orbital contributes to the LUMO + 12.

Since the rhenium atom has d^2 electronic configuration, the empty $5d_{xz}$ and $5d_{yz}$ orbitals are available to overlap with $2p_x$ and $2p_y$ orbitals of the terminal oxygen to form an effective triple bond.

The nature of rhenium–terminal oxygen interaction in **1** has been studied by NBO analysis. Each natural bond orbital (NBO) σ_{AB} is written in terms of two directed valence hybrids (HHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [36,37].

The results of NBO analysis for complex **1** are shown in Table 8. Two detected natural Re–O_t bond orbitals are of π character – they arise from overlap of the two occupied oxygen p_π orbitals with the empty d_{xz} and d_{yz} metal orbitals. Not detected σ_{Re-Ot} bond has character of predominant Coulomb-type interactions between the central ion

Table 9

and terminal oxo ligand [46]. The O_t ligand has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital. Accordingly, the rhenium–oxygen interaction in the investigated complexes can be described as a triple bond.

4.4. Electronic spectra

The electronic spectra of $[ReOX_2$(hquin-2-COOH)-$(EPh_3)]$ complexes are very similar in terms of the position, intensity and shape of the bands in the whole region 1000–180 nm. The positions and molar absorption coefficients of electronic bands for $[ReOX_2$(hquin-2-COOH)$(EPh_3)]$ complexes are given in Table 9.

The experimental and calculated electronic spectra of **1** are presented in Fig. 5. Each calculated transition is represented by a gaussian function $y = ce^{-b(x-x_0)^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. Table 10 presents the calculated singlet–singlet electronic transitions of **1** and their assignments to the experimental bands. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.020 are listed in Table 10.

The assignment of the calculated transitions to the experimental bands is based on the criterion of the energy and oscillator strength of the calculated transitions. In the description of the electronic transitions the HOMO orbital is described as d_{Re} orbital, whereas the participation of d_{Re} in the H-1 orbital is omitted.

The longest wavelength experimental band at 693.4 nm is attributed to the transitions of d → d character. The broad and asymmetrical absorption band with maximum at 386.9 nm results mainly from *Ligand–Metal Charge Transfer* (π(Cl)/π(hquin-2-COOH) → d). However the contribution of the *Metal–Ligand Charge Transfer* excitations (d → π*(hquin-2-COOH)) into this band is also confirmed by the calculations. The *Ligand–Metal Charge Transfer* transitions occurring from the triphenylarsine orbitals to the *d* rhenium orbitals make the largest contribution into the experimental band at 254.1 nm. The absorption band at 208.1 nm is assigned to *Ligand–Ligand Charge Transfer* and interligand (IL) transitions.

Abstract

$[Cu(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$ (**2**) and $[Ag(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$ (**3**) complexes of a new flexible thioamide ligand; *N*,*N*′-ethane-1,2-bis(4-methoxyphenyl)carbothioamide H_2L (**1**) have been synthesized using PPh_3 as a coligand. The synthesized compounds have been characterized with the help of elemental analyses, IR, ^1H, ^{13}C and ^{31}P NMR spectroscopy. The ligand and its Cu(I) complex have been studied by single crystal X-ray crystallography. The ligand acts as a neutral S-donor and forms a nine-membered chelate ring in $[Cu(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$. The molecular packing is stabilized by an anionic cavity formed by intermolecular hydrogen bonding between the basal plane of the complex molecule and the nitrate ions. The square shaped columnar channel has dimensions of 5.489(25) [N(11)–H(11A)···O(13)···H(21A)N(21)] × 3.693(7) [N(11)–C(11)–C(21)–N(21)] Å.

Keywords: Thioamide ligand; β-Sheet hydrogen bonding; Cu(I) and Ag(I) complexes; Nine-membered chelate ring

1. Introduction

The role of copper(I) is evident in several biologically important reactions [1–3], such as a dioxygen carrier and models for several enzymes [4]. Following our interest in the coordination properties of ligands containing the –NH–C(=S)– group, and their potential biological activity, which is probably related to their chelating ability towards vital metal ions, we have recently reported copper(II) and manganese(III) complexes of *N*′-[(2-hydroxyphenyl)carbothioyl]pyridine-2-carbohydrazide: a novel therapeutic agent for cancer [5]. The use of such Cu(II) systems is bound to involve the reduction of Cu(II) to Cu(I) in the cell (especially in the presence of S), thus the stability of the Cu(I) species is crucial to biological activity. However, the low solubility of copper (I and II) complexes has restricted us studying the structures from single crystal X-ray crystallography. The presence of tertiary phosphines are known to play an important role in enhancing the solubility of Cu(I) compounds of heterocyclic thioamide ligands [6].

From the above viewpoints and with the aim of elucidating the coordination geometry of ligands containing the –NH–C(=S)– moiety, *N*,*N*′-ethane-1,2-bis(4-methoxyphenyl)carbothioamide and its Cu(I) and Ag(I) complexes with PPh_3 as a coligand, viz. $[Cu(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$ and $[Ag(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$, have been prepared and characterized. The ligand and the Cu(I) complex have been characterized by X-ray crystallography.

2. Experimental

2.1. Materials and methods

Commercial reagents were used without further purification and all experiments were carried out in the open atmosphere. 4-Methoxybenzaldehyde (Sigma Aldrich) and ethylenediamine (Loba Chemie) were used as such. All the solvents were purchased from Merck Chemicals, India and used after purification. Ammonium polysulfide [7] and the sodium salt of (4-methoxyphenyl)carbothioylthioacetic acid [8] were prepared by the reported methods. The orange yellow colored (4-methoxyphenyl)carbothioylthioacetic acid was recrystallized from MeOH in the presence of charcoal. M.p. 127 °C (lit. [8] 122–125 °C). [$M(PPh_3)_2NO_3$], [M = Cu(I) and Ag(I)] were prepared according to literature procedures [9].

2.2. Preparation of the ligand

N,*N*′-Ethane-1,2-bis(4-methoxyphenyl)carbothioamide-(H_2L) (**1**) was prepared by reacting an aqueous NaOH (1 N, 10 mL) solution of (4-methoxyphenyl)carbothioylthioacetic acid (10 mmol) with ethylenediamine (en) (6 mmol). The mixture was kept at room temperature for 2 h and then acidified with dilute AcOH (20% v/v), whereupon a white precipitate formed. It was suction filtered, washed with water, dried under reduced pressure and recrystallized from a MeOH–$CHCl_3$ mixture (50:50 v/v).

2.2.1. Compound (*1*)

White single crystals of (**1**) suitable for X-ray analyses were obtained by slow evaporation of its methanol–chloroform (50:50 v/v) solution over a period of 4 days. Yield 60%; m.p. 108 °C; *Anal.* Calc. for $C_{18}H_{20}N_2O_2S_2$ (360.48): C, 59.97; H, 5.59; N, 7.77; S, 17.79; Found: C, 59.97; H, 5.54; N, 7.78; S, 17.79%. IR (ν cm^{-1}, KBr): ν(NH) 3308 m, [β(NH) + ν(CN)] (thioamide I) 1417 s, [ν(NH)+β(CN)] (thioamide II) 1377 s, [ν(C–N) + ν(C–S)] (thioamide III) 1008 s, ν(C=S) (thioamide IV) 835 m. ^{1}H NMR (DMSO-d_6, δ ppm): 9.36 (m, 2H, –NH), 2.9 (m, 4H, –CH_2–), 3.58 (s, 6H, –OCH_3), 6.89,7.99 (multiplets, 8H, benzene ring). ^{13}C NMR (DMSO-d_6, δ ppm): 202.03 (>C=S), 49.02 (>CH_2), 56.85 (–OCH_3), 134.2 (C3A, C3B), 130.5 (C4A, C4B, C8A, C8B), 113.5 (C5A, C5B, C7A, C7B), 164.11 (C6A, C6B). The structure was further confirmed by XRD (Fig. 1).

2.3. Preparation of complexes (*2*) and (*3*)

An equimolar amount (1 mmol) of a methanolic solution of the metal precursor complexes [$Cu(PPh_3)_2NO_3$], (M = Cu(I) and Ag(I)) were refluxed with a $CHCl_3$solution of H_2L for 2 h. The soluble complexes were filtered off to remove any co-precipitated impurity. The pale yellow, air stable complexes [$M(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$ (M = Cu(I) and Ag(I)) were obtained by adding hexane to the solution. Pale yellow single crystals of (**2**) suitable for X-ray analyses, were obtained by slow evaporation of its methanol–chloroform (50:50 v/v) solution over a period of 10 days. Yield 53%; m.p. 185 °C; *Anal.* Calc. for $C_{54}H_{51}CuN_3O_{5.5}P_2S_2$ (1019.58): C, 63.61; H, 5.04; N, 4.12; S, 6.29. Found: C, 63.60; H, 5.04; N, 4.16; S, 6.32%. IR (ν cm^{-1}, KBr): ν(NH) 3209 m, [β(NH) + ν(CN)] (thioamide I) 1433 s, [ν(NH) + β(CN)] (thioamide II) 1385 s, ν(C–N) + ν(C–S) (thioamide III) 1028 s, ν(C=S) (thioamide IV) 742 m, ν(P–C_{ph}) 1093 s, (NO_3^-) 1307, 1091, 839. ^{1}H NMR (DMSO-d_6, δ ppm): 10.35 (m, 2H, –NH), 4.05 (m, 4H, –CH_2–), 3.81 (s, 6H, –OCH_3), 6.97, 7.81 (multiplets, 8H, benzene ring) 7.38, 7.78 (multiplets, 30H, phenyl ring). ^{13}C NMR (DMSO-d_6, δ ppm): 194.58 (>C=S), 43.54 (>CH_2), 55.50 (–OCH_3), 132.46 (C13, C23), 132.09 (C14, C18, C24, C28), 113.35 (C15, C17, C25, C27), 162.05 (C16, C26), 133.34 ($C1_{ph}$), 133.15 ($C2_{ph}$, $C6_{ph}$), 128.86 ($C3_{ph}$, $C5_{ph}$), 128.75 ($C4_{ph}$). ^{31}P NMR (DMSO-d_6, δ ppm): −1.63.

2.3.1. Compound (*3*)

Yield 74%; m.p. 147 °C; *Anal.* Calc. for $C_{54}H_{51}AgN_3O_{5.5}P_2S_2$ (1063.90): C, 60.99; H, 4.83; N, 3.95; S, 6.03; Found: C, 60.52; H, 4.80; N, 3.95; S, 6.07%. IR (ν cm^{-1}, KBr): ν(NH) 3302 m, [β(NH) + ν(CN)] (thioamide I) 1435 s, [ν(NH) + β(CN)] (thioamide II) 1383 s, ν(C–N) + ν(C–S) (thioamide III) 1026 s, ν(C=S) (thioamide IV) 744 m, ν (P–C_{ph}) 1072 s, (NO_3^-) 1305, 1091, 839. ^{1}H NMR (DMSO-d_6, δ ppm): 10.19 (m, 2H, –NH), 4.04 (m, 4H, –CH_2–), 3.80 (s, 6H, –OCH_3), 6.95, 7.83 (multiplets, 8H, benzene ring) 7.44, 7.82 (multiplets, 30H, phenyl ring). ^{13}C NMR (DMSO-d_6, δ ppm): 196.58 (>C=S), 44.34 (>CH_2), 55.44 (–OCH_3), 130.15 (C13, C23), 129.30 (C14,

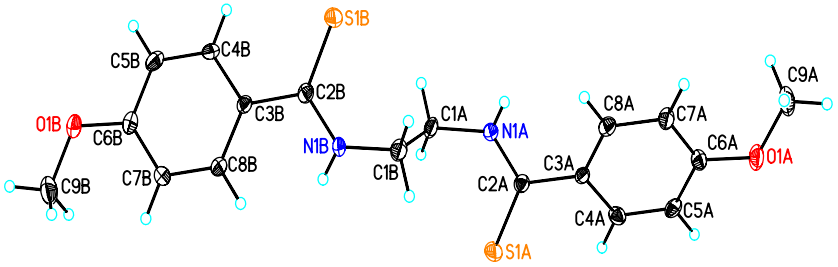

Fig. 1. ORTEP plot of H_2L showing atomic numbering scheme with ellipsoids of 30% probability.

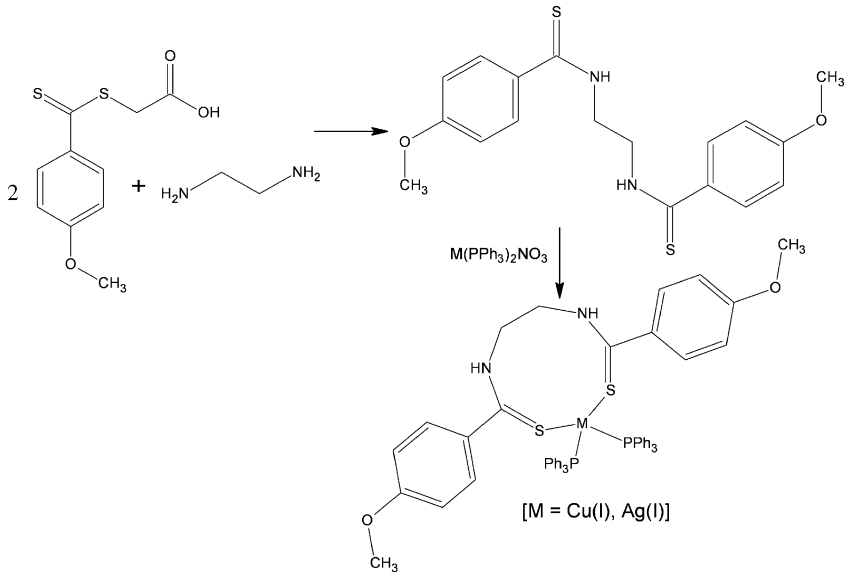
C18, C24, C28), 113.14, (C15, C17, C25, C27), 161.64 (C16, C26), 133.33 ($C1_{ph}$), 133.11 ($C2_{ph}$, $C6_{ph}$), 128.96 ($C3_{ph}$, $C5_{ph}$), 128.85 ($C6_{ph}$). ^{31}P NMR (DMSO-d_6, δ ppm): 6.23.

2.4. Physical measurements

Carbon, hydrogen, nitrogen and sulfur contents were estimated on a Carlo Erba 1108 model microanalyser. Electronic spectra of **1**, **2** and **3** were recorded on a CARY 100 Varian EL01055314 UV–Vis spectrophotometer in MeOH–$CHCl_3$ (50:50 v/v). IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a JASCO FT-IR-5300 spectrophotometer. ^1H and ^{13}C NMR spectra were recorded in DMSO-d_6 on a JEOL AL300 FT NMR spectrometer using TMS as an internal reference. ^{31}P NMR spectra were recorded in DMSO-d_6 using PCl_3 as an external reference.

3. Crystal structure determination



Data for the structure were obtained at 298 K(2) on a Bruker three-circle diffractometer equipped with a SMART 6000 CCD diffractometer using a graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation source. Intensity measurements were performed on a rapidly cooled crystal. The structure was solved by direct methods (SHELX-97) and refined against all data by full-matrix least-squares on F^2 using anisotropic displacement parameters for all non-hydrogen atoms. All hydrogen atoms were included in the refinement at geometrically ideal positions and refined with a riding model [10,11]. The MERCURY and DIAMOND package was used for molecular graphics [12,13]. Crystal structure diagrams were generated by use of the ORTEP-3 for Windows program [14].

4. Results and discussion

The ligand (4-methoxyphenyl-C(S)–NH–CH_2)$_2$ reacts with $[M(PPh_3)_2NO_3]$ in a MeOH–$CHCl_3$ mixture to give $[M(H_2L)(PPh_3)]NO_3 \cdot 0.5H_2O$, [M = Cu(I) and Ag(I)]. The complexes are stable towards air and moisture for several days. The soft Lewis bases H_2L (S-donor) and Ph_3P (P-donor) have stabilized the Cu(I) state, which is otherwise susceptible to oxidation by air. Scheme 1 shows the formation of Cu(I) and Ag(I) complexes with H_2L as a ligand and Ph_3P as a coligand. All the compounds are soluble in methanol–chloroform mixture and other polar solvents such as DMF and DMSO.

4.1. IR spectra

The ligand H_2L contains the –NH–C(=S)– group which may adopt either the thione –NH–C(=S)– or thiol –N=C(–SH)– form. However, the ligand adopts the thione form in the free state and in the complexes. This is evident by the absence of the ν(SH) band in the region ca. 2500 cm^{-1} and by the presence of ν(NH) at 3308 cm^{-1}. Since H_2L contains the thioamide group, –NH–C(=S)–, it gives rise to four characteristic bands, namely thioamide I, II, III and IV at 1417, 1377, 1008 and 835 cm^{-1} which have contributions from [β(NH) + ν(CN)], [β(CN) + ν(NH)], [ν(C–N) + ν(C–S)] and ν(C=S) modes of vibrations, respectively. The IR spectra of the complexes show the presence of the ν(N–H) band in the region 3200–3305 cm^{-1}, suggesting that H_2L is coordinated to M(I) in the neutral form. A negative shift in the ν(N–H) band is probably due to the hydrogen bonding in the complexes. The thioamide I and II bands shift slightly towards the higher frequency region, indicating the involvement of the C=S group in coordination. This is also supported

Scheme 1. Preparation of the ligand and the complexes.

by the negative shift of the ν(C=S) band. All these observations clearly indicate the involvement of the C=S group in coordination. Bonding through the sulfur atom is favored because copper(I), being a soft acid, should prefer to interact with a soft base such as sulfur. Further, the characteristic ν(P–C_{ph}) bands at 1050-1100 cm^{-1} show an increase in frequency and intensity, indicating P-metal coordination. The uncoordinated nature of the anion is inferred from its peaks in the region 1500–700 cm^{-1} where the characteristic absorption bands (1307, 1091 and 839) of the free nitrate ion appear [15].

4.2. Electronic spectra

The electronic spectrum of the complexes in a MeOH–$CHCl_3$ mixture exhibits two strong broad absorptions with maxima at 245 and 333 nm. Considering the fact that the spectrum of the free phosphine reveals a band at 245 nm, which usually remains unshifted upon coordination to Cu(I) [16], the rather strong first band corresponds to intraligand phosphine excitation. The second one can be considered as a thione originating intraligand band which exhibits a small red shift (11 nm) relative to that observed in the spectrum of the free ligand, and suggests that it contains some MLCT character.

4.3. ^1H and ^{13}C NMR spectra

The ^1H NMR spectrum of H_2L shows peaks due to –NH, –CH_2–, –OCH_3 and multiplets in the aromatic region. The ^{13}C NMR spectrum exhibits peaks due to C=S, >CH_2, –OCH_3 and benzene rings, as expected for the structure shown in Fig. 1.

The ^1H NMR spectra of the complexes in DMSO-d_6 reveal the presence of NH (thioamide) protons in the range of ca. 10.19–10.35 ppm which are downfield compared to the free ligand, indicating that the ligand coordinates to the metal ions as a neutral ligand, probably through the sulfur atoms only [17,18].

The ^{13}C NMR spectra of the complexes display signals associated with H_2L and PPh_3. The position and integrated intensities of various resonances supported well the presence of H_2L and the formulation of the complexes. The thione carbon in the complexes resonates in the range 194.58–196.58 ppm, which are upfield compared to the free ligand [19], suggesting involvement of the thione sulfur in bonding.

The ^{31}P NMR spectra of complexes (**2**) and (**3**) in DMSO-d_6 show a single resonance at $\delta_p = -1.63$ and 6.23 ppm, respectively, indicating that all the phosphorus atoms are chemically equivalent, which is also in accordance with the mononuclear nature of the complexes. As expected, only one sharp ^{31}P NMR signal for triphenylphospine is observed in the complexes with a downfield shift as compared to −4.50 ppm for free triphenylphosphine [20]. The downfield shift in the peak indicates coordination of PPh_3 with the metal ion.

4.4. Crystal structure of H_2L

The crystallographic data and structural refinement details are given in Table 1. The main bond distances and bond angles of the free ligand and the Cu(I) complex are given in Table 2. The relatively non-rigid functional group (*N*,*N* substituted-1,2-diaminoethane moiety) can attain a *cis* or *trans* configuration with two *p*-methoxyphenyl rings positioned on opposite sides. However, it has been observed that the HN–CH_2–CH_2–NH group acquires a staggered configuration (the torsion angle being −179.0(4)°), which is also energetically favored. This also favors the *anti* orientation of the symmetrical halves (if bisected along the C1A–C1B axes) of the molecule to minimize the steric hindrance by the bulkier groups placed on C(2). The structure is in turn stabilized by intermolecular

NH···SH-bonding, responsible for producing a β-sheet pattern [21]. The C–S bond distance of 1.666(5) Å in H_2L agrees well with that in related compounds, being intermediate between 1.82 for a C–S single bond and 1.56 Å for a C=S double bond [22]. The corresponding C(2A)–N(1A) and C(2B)–N(1B) bond distances [1.317(6) and 1.331(6) Å] are indicative of some double bond character. The methoxy groups are almost coplanar (torsion angle −11.0(7)° and −9.5(7)° with respect to A and B moieties, respectively) (Fig. 1), however the *p*-methoxyphenyl rings are observed to be twisted with a dihedral angle of 60.98° between the best defined planes of $(C(=S)NHCH_2)_2$ and $(CH_3O–C_6H_4)$.

The intermolecular N–H···S hydrogen bonds, involving the imino-N and thione-S atoms, form an infinite chain along the *b* axis [23,24] (as shown in Fig. 2). The two

N···S distances of 3.299(5) and 3.305(5) Å (Table 3) are close to the mean N···S distance reported for NH···S hydrogen bonds by Srinivasan and Chacko [25]. The sheet further grows in the *a* direction by O1A···H9BA–C9B hydrogen bonding.

4.5. Crystal structure of complex (*2*)

Fig. 3 shows a Mercury view of the Cu(I) complex with the atomic numbering scheme. Reaction of $[Cu(PPh_3)_2NO_3]$ with H_2L in boiling methanol–chloroform gave the complex $[Cu(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$ which consists of a mononuclear metal cation $[Cu(H_2L)(PPh_3)_2]^+$, (NO_3^-) anion and an isolated water between two molecules (Fig. 4). The metal centre is bonded to the ligand through the sulfur atom in an isobidentate fashion forming a nine-membered chelate ring. The geometry around the CuS_2P_2 core is approximately tetrahedral [26]. Geometrical distortion from ideal angles can be explained by the need to accommodate the bulky triphenylphosphine groups and the nine-membered chelate ring. The Cu–S bond lengths are 2.3910(11) and 2.4212(11) Å, consistent with values found for tetrahedrally coordinated Cu(I) with S-donor atoms [27]. The P–Cu–P angle [122.19(3)°] is in good agreement with the value reported for other bis(triphenylphosphine)copper(I) compounds, such as 125.0(2)° for $[Cu(PyZSH)(PPh_3)_2Br]$ [28], 121.71(3)° for $[Cu(PPh_3)_2(bzintH_2)Cl]$ [29] and 123.8(2)° for $[Cu(PPh_3)_2(C_2H_4N_2S_2)Br]$ [30]. The Cu–P bond distances 2.3216(10) and 2.3292(11) Å are slightly longer than the sum of the covalent radii (2.27 Å) and the values reported for other copper(I)–phos-

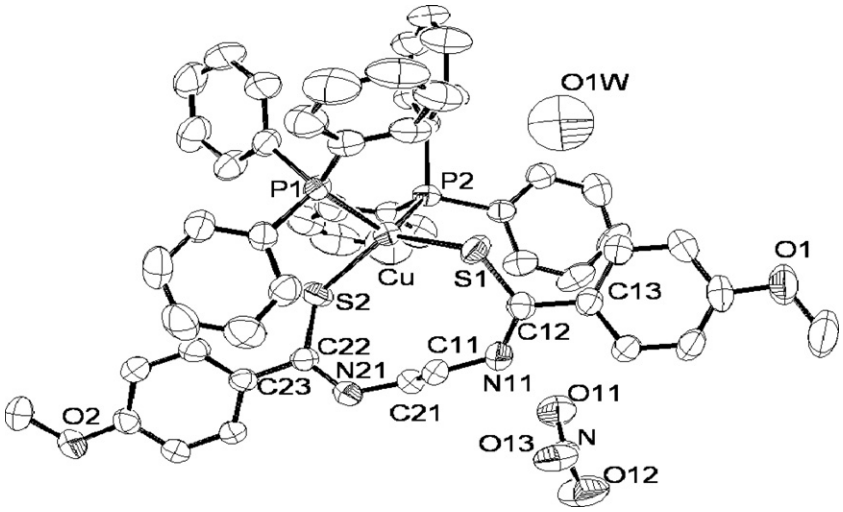

Fig. 3. ORTEP plot of $[Cu(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$ showing atomic numbering scheme with ellipsoids of 30% probability. Hydrogen atoms are omitted for clarity.

phine complexes, ranging between 2.15 and 2.30 Å [31]. On the other hand, the S(1)–Cu–S(2) angle [132.56(4)°] is larger than that observed in $[Cu(PPh_3)(quintH)]$ [32] [114.24(7)°], indicating repulsion between the thiones caused by their negative charges. The C–S bond distances, 1.697(3) and 1.700(3) Å, are closer than that observed (1.66–1.72 Å) for $[CuX(4\text{-}H_2tsc)Ph_3P]$ (X = Br, I) [27].

Nine-membered chelate rings are very rare mainly because of their destabilization caused by non-bonding interactions within the nine-membered rings due to unfavorable torsion angles imposed by the ring size. It has been observed that –NH–C(=S)– containing ligands prefer to bridge metals to give polynuclear products [33] rather than forming a mononuclear chelate with an 8–11 membered ring [34]. The flexibility within the $(–C(=S)–NH–CH_2–)_2$ backbone, the presence of suitably positioned sterically demanding substituents, and heteroatoms (–NH– or –S–) stabilize the large ring. Additionally, the presence of two *p*-methoxyphenyl rings on the backbone probably contributes to the stability of the nine-membered chelate ring.

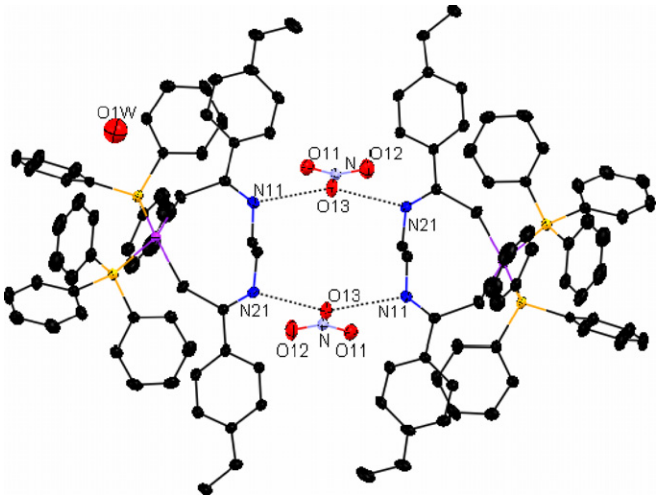

Fig. 4. Rectangular anionic column in the structure of $[Cu(H_2L)(PPh_3)]NO_3 \cdot 0.5H_2O$.

4.6. Molecular packing of the complex

The molecular packing is dominated by hydrogen bonding offered by the (NO_3^-) ion and the basal plane of the CuS_2 chelate ring. The anion, which exhibits no disorder even at room temperature, is held in the *x*,*y*,*z* plane by intermolecular hydrogen bonds (Table 4). Another symmetry related (NO_3^-) ion lies parallel but in an inverted manner along the *a* axis. The specific arrangement of two nitrate ions and two complex cations results in the formation of a rectangular shaped anionic channel (Fig. 4). The intermolecular N11–H11A···O13#1 hydrogen bond is one component of a bifurcated interaction based on O13(*x*,*y*,*z*); while the second one is O13···H21A–N21#2 of the symmetry related complex molecule (−*x*, 1 − *y*, 1 − *z*). The other amide hydrogen atom of H_2L#1 is involved in a similar N21–H21A···O13#2 (−*x*, 1 − *y*, 1 − *z*) interaction and O13#2 further with H11A–N11#2. Thus four intermolecular contacts effectively link two molecules of the complex into a 2-dimensional structure resulting in an unstrained chair-like close cavity. The rectangular shaped cavity has dimensions

Table 4
Hydrogen bonds for $[Cu(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$ (Å and °)

D–H···A	*d*(D–H)	*d*(H···A)	*d*(D···A)	∠(DHA)
O(1W)–H(1W2)···S(1)	1.07(14) 2.8(5)	3.6(4)	132(18)	
N(11)–H(11)···O(13)	0.93	2.49	3.2(6)	132
N(21)–H(21)···O(13)	0.93	2.03	2.9(6)	150

Symmetry transformations used to generate equivalent atoms.

of 5.489(25) [N11–H11A···O13···H21AN21] × 3.693(7) [N11–C11–C21–N21] Å, as shown in Fig. 4.

The water molecule in the complex forms intermolecular hydrogen bonding with the sulfur atom present in the CuS_2 chelate ring. The intermolecular H1W2···S2 hydrogen bond is 2.686 Å and H1W1···S1 is 2.797 Å, which interlink two complex molecules together and thus stabilize the whole structure. The edge-to-face C–H···π interaction formed between C5F···H4CA is found to be 2.895 Å, and this propagates the chain along the a axis. This tendency appears to have facilitated the position and orientation of the molecules, forming a cavity. The methoxy protons and oxygen of two different molecules are involved in forming intermolecular hydrogen bonding, with dimensions of 2.656[O2···H29A] × 1.984 [O2–C29] Å. The C–H···π interactions together with intermolecular hydrogen bonding [O2···H29A] leads to a supramolecular continuum (Fig. 5).

5. Conclusion

New mononuclear tetrahedral Cu(I) and Ag(I) complexes obtained from a flexible thioamide ligand contain a nine-membered chelate ring structure with the MS_2P_2 core. Complex **2** involves face to edge weak interactions in its molecular packing.

Antiferromagnetic spin-coupling between Mn^{II} and amminium radical cation ligands: Models for coordination polymer magnets

Richard J. Bushby *, Colin Kilner, Norman Taylor, Rhidian A. Williams

Abstract

One- and two-electron oxidation of the manganese(II) complex $[L_2Mn(hfac)_2]$ (L = 4″,4‴-di-*tert*-butyl-2′,2″,2‴trimethoxy-{4-(4′-diphenylaminophenyl)pyridine}) were studied by ultra violet/visible/near infra red spectroscopy, cyclic voltammetry and magnetometry. A one-electron oxidation converts the triarylamine ligand to its radical cation and gives a complex in which the antiferromagnetic coupling between the spin on the ligand and that on the metal J/k_b is −1.5 K. In a dilute frozen matrix and at low temperature this behaves as an $S = 2$ system. A two-electron oxidation gives $[L_2Mn(hfac)_2]^{2\bullet+}$ which at low enough temperatures behaves as an $S = 3/2$ system but the spin-coupling between the metal and the ligand is weaker ($J/k_b = -0.3$ K). The weakness of these spin-couplings mean that Mn^{II}/amminium radical cation complexes are not promising systems on which to base coordination polymer magnets. The equivalent copper(II) complex $[L_2Cu(hfac)_2]$ was also investigated but this decomposes when an attempt is made to oxidise the ligand to its amminium radical cation.

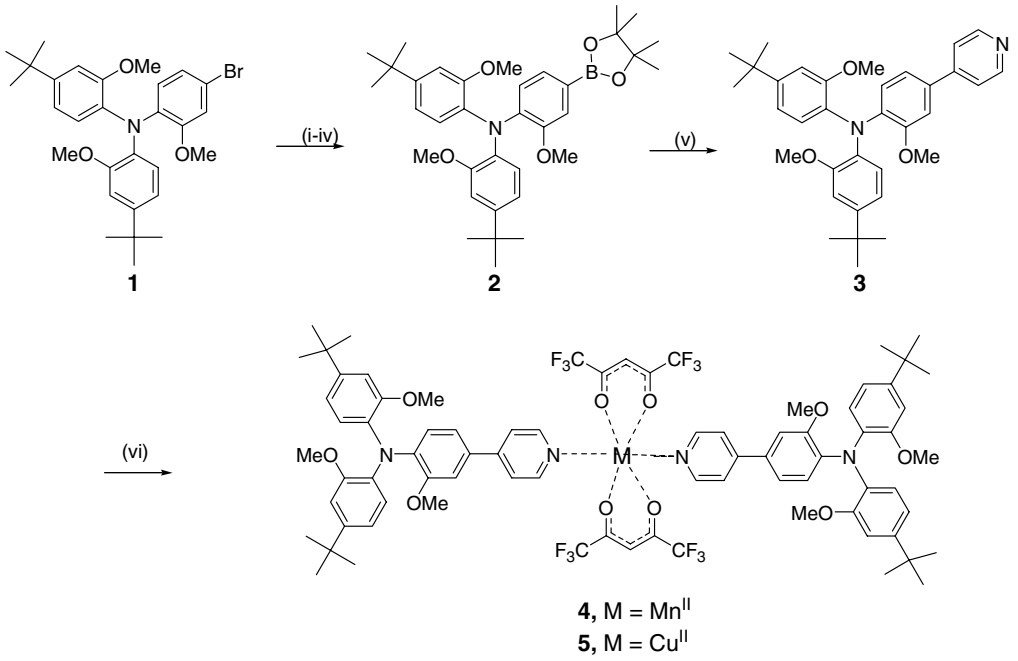
1. Introduction

One of the most successful strategies for producing molecular magnets is that originally pioneered by Gatteschi and co-workers [1,2] which relies on the creation of coordination polymers in which spin-bearing ligands and spin-bearing transition metal centres alternate with each other. At low enough temperatures, such systems can show bulk magnetic properties regardless of whether the coupling between metal and ligand is ferromagnetic or antiferromagnetic [2]. Systems of this type include a vanadium/TCNE complex which has a Curie temperature which is above room temperature but in most such systems there is weak or very weak spin-coupling between the ligand and the metal and, as a result, Curie temperatures are also low [3]. Most other examples exploit nitroxide [4] or nitronyl nitroxide [2,5] as the spin-bearing ligand although several others have been investigated [6,7]. This paper explores the possibility of using amminium radical cation ligands. We have used the monopyridyl functionalised triarylamine ligand **3** to make the model 'monomers' **4** and **5** (Scheme 1) and then tried to oxidise the ligands to the amminium radical cation level. The sign of the spin coupling between the ligand radical cation and the metal ion centre in the resulting $\mathbf{4}^{n\bullet+}$ and $\mathbf{5}^{n\bullet+}$ complexes is expected to depend on whether the spin orbitals overlap or are orthogonal [7]. In the Mn^{II} complexes, the non-zero overlap between spin orbitals should result in an antiferromagnetic interaction but, in the case of the copper complex the spin orbitals are orthogonal and the interaction should be ferromagnetic [8].



2. Results

2.1. Synthesis and X-ray crystal structures

As shown in Scheme 1, the ligand **3** was prepared by a Suzuki coupling reaction between the monoboronic acid

Scheme 1. Synthesis of the complexes: Reagents: (i) *n*-BuLi/THF/−78 °C; (ii) $B(O^iPr)_3$/THF/−78 °C; (iii) H^+/H_2O/−78 °C; (iv) pinacol/4 Å molecular sieve/Δ, 46% (overall); (v) 4-bromopyridine hydrochloride/$Pd(PPh_3)_4$/$Ba(OH)_2$/DME/Ar atmosphere/Δ; and (vi) $[Cu(hfac)_2]$ or $[Mn(hfac)_2]$/heptane/ether/DCM.

2 (from the bromocompound **1** [9]) and 4-bromopyridine. The required 2:1 complexes **4** and **5** were obtained by mixing solutions of the ligand with $[Mn(hfac)_2]$ or $[Cu(hfac)_2]$. Recrystalisation of the complexes **4** and **5** from THF/hexane gave orange and green crystals, respectively. Single crystal X-ray structures were obtained for all three compounds **3**–**5**, the derived molecular structures are shown in Fig. 1 and crystal structure refinement data are given in Section 4 and Table 1. As expected, ligand **3** shows a propeller-like twist of the aryl residues around an almost planar central nitrogen. Like other triarylamines, the dihedral angles range between 53° and 74°. The torsional angle between the pyridine and benzene rings of 36° is also similar to that in related compounds [10]. As expected, the geometry of the ligand is only slightly changed on forming the complexes **4** and **5** and complexation occurs through the pyridyl rather than arylamine nitrogen. The Mn complex **4** has dihedral angles between 56° and 68° with a torsional angle of 29° and in the Cu complex **5** the dihedral angles range between 56° and 69° with a torsional angle of 31°.

2.2. Cyclic voltammetry

A cyclic voltammogram for the ligand **3** is shown in Fig. 2 [11]. There is a clean one-electron redox process at 0.71 V (versus silver/silver chloride) with a width at half height of about 0.1 V. Both forward and reverse scans match in amplitude and there are no additional peaks of the type associated with benzidine formation, even after many cycles [10]. This indicates that a fast reversible electrochemical process is occurring and that the amminium radical cation $\mathbf{3}^{\bullet+}$ is chemically stable on the CV timescale. Both of the complexes **4** and **5** show oxidation potentials and peak widths that are essentially the same as those of the uncomplexed ligand **3**.[1] This is the first indication that oxidation is occurring at the ligand rather than at the metal centre: something that is confirmed by the spectroscopy and magnetometry studies described below. This is not surprising since oxidation of manganese(II) to manganese(III) in similar complexes is known to require much higher potentials [12]. If each of the ligands in turn is being oxidised to the radical cation level and the complex remains intact (for example, **4**, $[Ar_3NMn^{II}Ar_3N] \rightarrow \mathbf{4}^{\bullet+}$, $[Ar_3N^{\bullet+}\text{-}Mn^{II}Ar_3N] \rightarrow \mathbf{4}^{2,\bullet+}$, $[Ar_3N^{\bullet+}Mn^{II}Ar_3N^{\bullet+}]$) one could argue that there should be shifts in ligand oxidation potentials arising from coulombic repulsion between the charge on the ligand and that on the metal ion (as in $\mathbf{4}^{\bullet+}$) and between the charges on the two ligands (as in $\mathbf{4}^{2,\bullet+}$). However, the charged centres are well separated from each other and in dichloromethane these systems are strongly ion-paired so that the charge–charge repulsion is screened out by the counter-ion. Based on data reported by McGill and coworkers [13] for related ion-paired dication diradical species in dichloromethane and given the separation between the charged centres (which is known from crystal structure data) the shifts in the oxidation potentials due to such coulombic repulsions would be <25 mV. Such small differences would be difficult to observe and so the similarity of the CV data for complexed and uncomplexed ligands does not indicate whether or not the complexes remain intact.

[1] See supplementary material.

2.3. Ultra violet/visible/near infra red spectroscopic studies

These studies were carried out using thianthrenium tetrafluoroborate ($THBF_4$) as the oxidant [14]. This has the advantage of being dichloromethane soluble so that it can be used in a quantitative titration. The results of these titrations are shown in Fig. 3 and the numerical data are summarised in Section 4. The electronic absorption

spectrum (250–1250 nm) for the neutral amine **3** in dichloromethane shows one main absorption band at 354 nm. When it is oxidised with one molar equivalent of $THBF_4$ the spectrum is replaced by that of the radical cation $\mathbf{3}^{\bullet+}$ showing bands at 467, 620 and 920 nm. Because of the lowered symmetry the D_0–D_1 transition is split [10,15]. There are sharp isosbestic points at 297 and 377 nm, indicating a clean oxidation. Relative to the uncomplexed ligand $\mathbf{3}^{\bullet+}$, the spectrum of the complex $\mathbf{4}^{\bullet+}$ (Fig. 3, bottom) is slightly shifted with the main absorption band at 370 nm. On adding another equivalent of $THBF_4$, both of the ligands are oxidised to the radical cation level. The resulting diradical dication $\mathbf{4}^{2,+}$ shows three bands at 469, 619 and 925 nm. These changes parallel those for the uncomplexed ligand **3** but all of the bands are all slightly shifted. This confirms that the complex does not dissociate upon oxidation. There is a clean isosbestic point for the first one-electron oxidation step although this is less clear for the second (Fig. 3, insets). Whereas the results for the oxidation of the ligand **3** and of the manganese complex **4** are straightforward and easy to interpret the results obtained for the copper complex **5** are not. As expected the electronic absorption spectrum for the neutral complex **5** in dichloromethane shows one main absorption band at 369 nm but on oxidation, using either $THBF_4$ or $NOBF_4$ as the oxidant, a complex series of

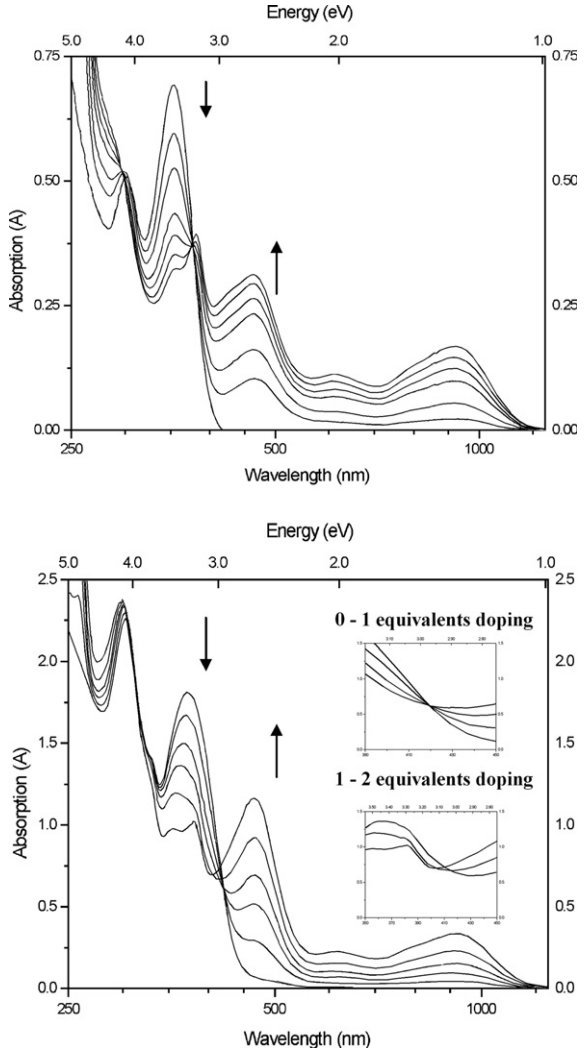

Fig. 3. (Top) Ultra violet/visible/near infra red spectra for the oxidation for monopyridyl ligand **3** to the radical cation species $\mathbf{3}^{+}$. changes occurs which is quite different to those normally associated with amminium radical cation formation. It appears that even though the amminium ion/copper complexes are stable on the short time-scale of the cyclic voltammetry experiments they are not stable on the longer time-scale of these spectroscopic studies.

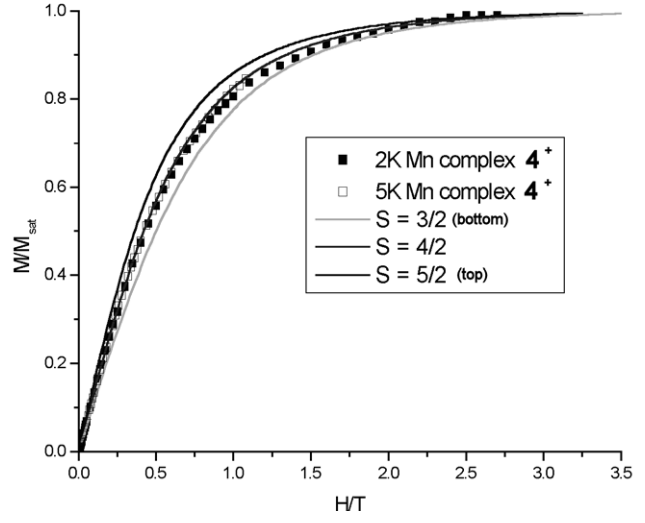
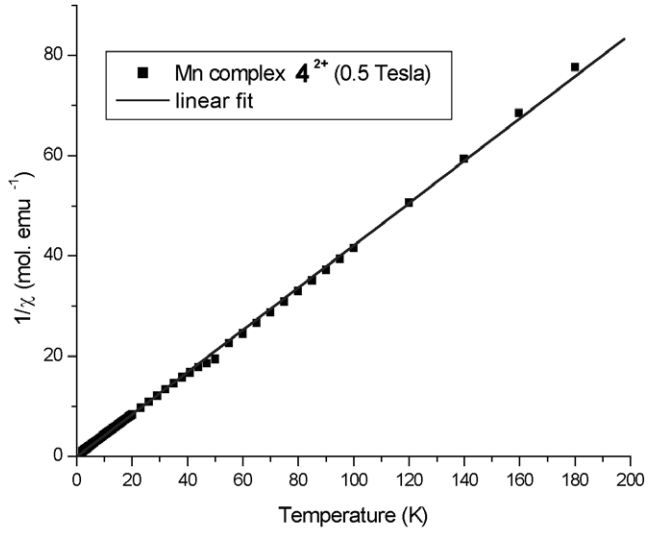
2.4. Magnetometry

Magnetometry studies were carried out using dilute frozen solutions which were prepared by the mixture of syringe and vacuum line techniques described previously [9]. This method minimises exposure to air during sample preparation and transfer, and requires less material than using dry powered samples. It also has the advantage that intermolecular spin interactions, which can complicate the interpretation of the data, can be ignored. The disadvantage is that, at higher temperatures, the signal becomes weak relative to the diamagnetic correction and the errors can be larger. Magnetic measurements were made on the neutral complex **4**, the monoradical monocation $\mathbf{4}^{\cdot+}$ and diradical dication complex $\mathbf{4}^{2,+}$. For the neutral Mn complex **4**, since we have a dilute frozen matrix, the individual manganese(II) $S = 5/2$ centres are expected to behave independently. It was found that the Curie law was obeyed and χT was 4.35 emu K mol^{-1} which is about the value expected for a dilute paramagnet of $S = 5/2$. This is confirmed by plots of the normalized magnetisation versus the ratio of magnetic field and temperature (M/M_{sat} versus H/T) which is consistent with a Brillouin function of $S = 5/2$ at both 2 and 5 K.[1] Magnetic data for the mono and diradical complexes were obtained by selectively oxidising the sample with one or two equivalents of $THBF_4$, respectively. For the monoradical monocation $\mathbf{4}^{\cdot+}$ the Curie law is obeyed. Hence, the plot ($1/\chi$ versus T) at low field (0.5 T) is linear as shown in Fig. 4 (top) and intercepts around 0 K. The product of susceptibility and temperature versus temperature (χT versus T) gradually increases from 2 K and flattens out around 50 K giving a high temperature χT value of 4.71 emu K mol^{-1} (Fig. 4, middle). This is close to the value expected for a system with isolated $S = 1/2$ and $S = 5/2$ spins. However, at low enough temperatures the spins are antiferromagnetically coupled and the system behaves as if comprised of isolated $S = (5/2 - 1/2) = 2$ spin centres. This is confirmed by plots of the normalized magnetisation versus the ratio of magnetic field and temperature (M/M_{sat} versus H/T) which fit reasonably closely to a Brillouin function of $S = 2$ (Fig. 4, bottom). The strength of the spin coupling (J_{ab}) was determined by fitting the χT versus T curve using the Bleaney–Bowers equation [16] for a system with an antiferromagnetic interaction between $S = 5/2$ and $S = 1/2$ spins [17].

$$\chi T = Ng^2\mu_B^2 T/k_B T \cdot [28 + 10\exp(-6J/k_B T)]/[7 + 5 \times \exp(-6J/K_B T)] + N_\alpha$$

The experimental data best fits a weak intramolecular antiferromagnetic coupling of $J/k_B = -1.5$ K. For the dication $\mathbf{4}^{2,+}$, the Curie law is obeyed, the plot ($1/\chi$ versus T) at low field (0.5 T) is linear as shown in Fig. 5 (top) and intercepts around 0 K. The product of susceptibility and temperature versus temperature (χT versus T) gradually increases from 2 K and flattens out around 30 K giving a high temperature χT value of 5.06 emu K mol^{-1} (Fig. 5, middle). This value is close to that expected for a system with isolated $S = 5/2$ and a pair of isolated $S = 1/2$ spins. If, at low enough temperatures the spins are antiferromagnetically coupled we should get magnetically isolated $S = (5/2 - 1/2 - 1/2) = 3/2$ spin centres. This is confirmed by plots of the normalized magnetisation versus the ratio of magnetic field and temperature (M/M_{sat} versus H/T) which fit reasonably closely to a Brillouin function of $S = 3/2$ at 2 and 5 K (Fig. 5, bottom). The strength of the intramolecular coupling (J_{ab}) was determined by fitting the χT versus T





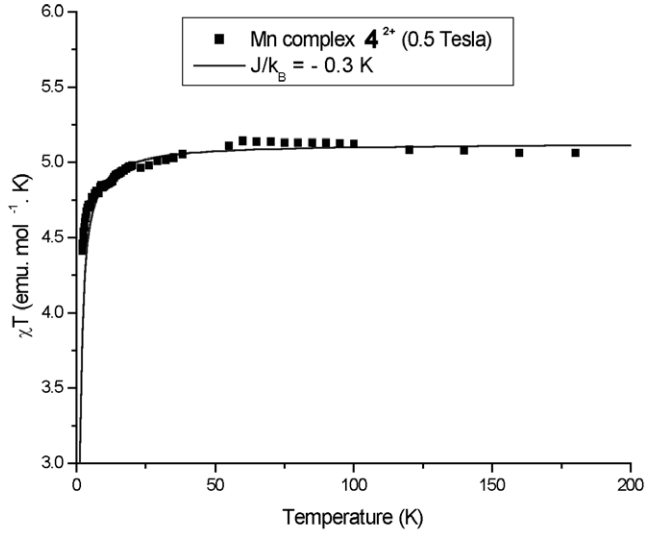


Fig. 4. (Top) 'Curie' law plot of the reciprocal of magnetic susceptibility (χ) vs. temperature for a frozen dilute solution of the radical cation $\mathbf{4}^{\bullet+}$. (Middle) Plot of product of susceptibility and temperature (χT vs. T) fitted to the Bleaney–Bowers equation. (Bottom) Plot of normalized magnetisation vs. ratio of field and temperature (Brillouin plot).

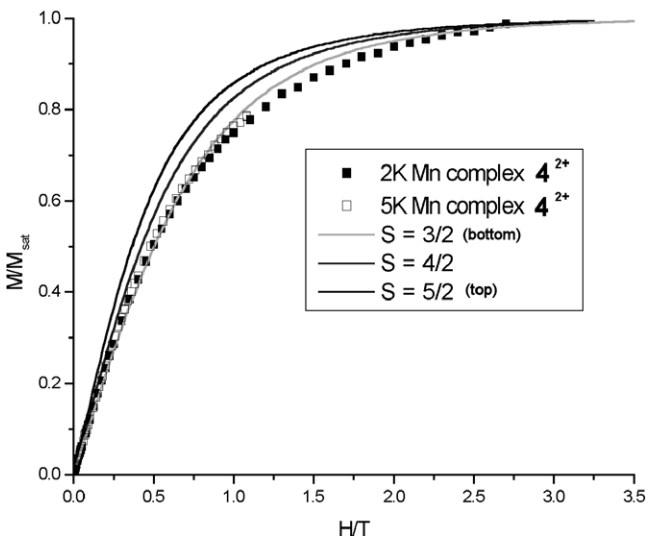

Fig. 5. (Top) 'Curie' law plot of the reciprocal of magnetic susceptibility (χ) vs. temperature for a frozen dilute solution of the diradical dication $\mathbf{4}^{2\bullet+}$. (Middle) Plot of product of susceptibility and temperature (χT vs. T) fitted to the Bleaney–Bowers equation. (Bottom) Plot of normalized magnetisation vs. ratio of field and temperature (Brillouin plot).

curve using the Bleaney–Bowers equation for a symmetrical ($S = 1/2$)–($S = 5/2$)–($S = 1/2$) system with antiferromagnetic coupling between the $S = 5/2$ and $S = 1/2$ centres and zero coupling between the two $S = 1/2$ centres [18].

$$\chi = \left\{Ng^2\mu_B^2 T/4k_B T\right\} \cdot \{[84\exp(5J/k_B T) + 35\exp(-2J/k_B T) + 10\exp(-7J/k_B T) + 35]/[4\exp(5J/k_B T) + 3\exp(-2J/k_B T) + 2\exp(-7J/k_B T) + 3]\} + N_\alpha$$

The experimental data best fits weak intramolecular antiferromagnetic coupling with a value of $J/k_B = -0.3$ K (Fig. 5, middle).

For a dilute frozen solution of the neutral Cu^{II} complex **5** the Curie law is obeyed and the plot intercepts around 0 K indicating that there is negligible intermolecular interactions. χT is 0.39 emu K mol^{-1}; a value which is consistent with $\chi T = 0.37$ emu K mol^{-1} calculated for a dilute paramagnet of $S = 1/2$, indicating that the unpaired d electron of copper(II) is magnetically isolated. Plots of the normalized magnetisation versus the ratio of magnetic field and temperature (M/M_{sat} versus H/T) which is consistent with a Brillouin function of $S = 1/2$ at 2 and 5 K.[1]

3. Discussion

It is very difficult to design a high-spin polymer that is purely organic [19,20] because both the range of ferromagnetic coupling units [21] and the number of stable free radicals is very limited. On the other hand, coordination polymers allow us to exploit the d orbitals of stable metal complexes and because we can use two metals with different moments or a metal and ligand with different moments it is not even necessary to engineer ferromagnetic coupling. This is a much easier strategy. One way to view the relationship between the purely organic high-spin polymers and the coordination polymers is illustrated in Fig. 6. As can be seen, in terms of the spin-coupling pathways, either a transition metal centre or an organic ferromagnetic coupling unit (metaphenylene, 3,4′-disubstituted biphenyl or 4,4″-disubstituted metaterphenyl, etc.) [21] can have the same function. It mediates an overall ferromagnetic coupling between radical, radical ion or carbene centres. Hence, the copper(I) in **6** [22] has the same function of feromagnetically coupling perchlorotrityl centres as the tertrachlorometaphenylene in **7** [24], the manganese(II) in **8** [25] has the same function of coupling carbene centres as the metaphenylene in **9** [23] and the manganese(II) in **10**[2] has the same function of coupling triarylamminium radical cation centres as the 4,4″-disubstituted metaterphenyl in **11** [9,13,26]. However, in all systems, whether purely organic or organometallic, the strength of the interaction is critical [9,10,20] Unfortunately, couplings are often weak and so low Curie temperatures result. In our work aimed at purely organic systems

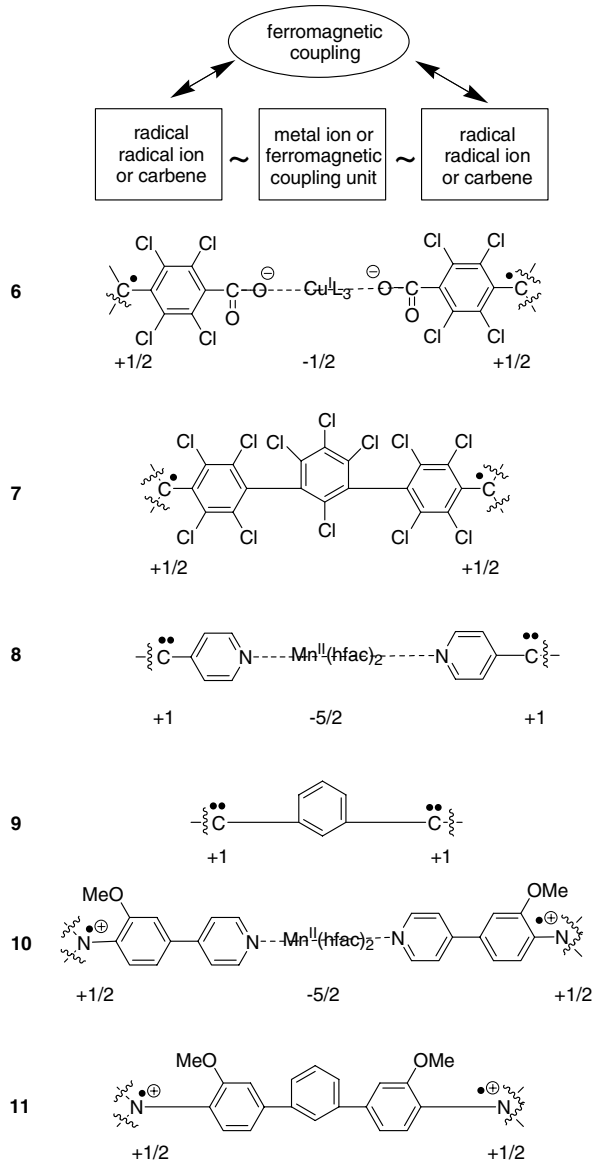

Fig. 6. Schematic of the parallels between spin-coupling pathways in high-spin organic polymers and those in coordination polymer magnets (see text).

we used amminium ion spin-bearing centres ferromagnetically coupled 1,3 through benzene, 3,4′-through biphenyl or (mostly) 4,4″-through metaterphenyl [9,10,13,26] In the present work, we have explored the coupling of similar amminium ion spin-bearing centres through Mn^{II}. These were generated by one- and two-electron oxidation of a neutral triarlyamine/Mn^{II} complex **4**. The complex remained stable when the ligands were oxidised to the amminium ion level but the antiferromagnetic spin-coupling between amminium ion and Mn^{II} centres proved to be weak in the monoradical monocation $\mathbf{4}^{\bullet+}$ and weaker still in the diradical dication $\mathbf{4}^{2,+}$. This seems to indicate a decrease in the overlap of the spin orbitals when the second electron is removed. A possible explanation is in terms of a space charge effect: that increased

[2] This work.

coulombic repulsion in the diradical dication leads to a small extension of the Mn–pyridyl bonds and a decrease in the d–π overlap. If space charge is indeed the cause it is clear that using radical ion spin-bearing centres is a less good strategy than using neutral radicals in designing coordination polymer magnets.

4. Experimental

4.1. General details

The general procedures adopted in the synthetic work were the same as those described in previous papers [9,10].

4.2. Synthesis

4.2.1. 4″,4‴-Ditertbutyl-2′,2″,2‴trimethoxy-{4-(4′-diphenylaminophenyl)pyridine} (3)

4-Bromopyridine hydrochloride (580 mg, 3.0 mmol) was added to a mixture of ethylene glycol 1,2-dimethyl ether (40 ml) and water (2 ml). Argon was bubbled through the mixture for 0.5 h. Tetrakis-triphenylphosphine palladium (0) (32 mg, 28 μmol) was added under a stream of argon. The boronic ester **2** (1.3 g, 2.5 mmol) [9] was dissolved in DME (10 ml) and degassed under a stream of argon for 0.5 h. The boronic ester solution was cannulated into the reaction vessel, barium hydroxide (1.54 g, 10 mmol) was finally added and the reaction mixture was refluxed for 48 h. The reaction was left to cool and the organic phase was extracted with dichloromethane (3 × 20 ml) washed with water (2 × 50 ml) and dried over anhydrous magnesium sulfate. Purification by flash chromatography gave *the amine* **3** as small light red crystals (1.1 g, 84%). *Anal.* Calc. for $C_{34}H_{40}N_2O_3$: C, 77.82; H, 7.68; N, 5.33. Found: C, 77.50; H, 7.90; N, 5.20%. MS (EI+) *m*/*z*: 524.1 (M^+, 100%).m.p. 167.3 °C. ^{1}H NMR (C_6D_6, 300 MHz) δ_H: 8.60 (2H, dd, *J* 7.2 and 1.55), 7.01 (2H, d, *J* 8.1), 7.0 (1H, m), 6.89 (2H, m), 6.86 (2H, d, *J* 2.14), 6.76 (2H, dd, *J* 8.2 and 2.2), 3.28 (12H, s, OMe), 3.17 (6H, s, OMe), 1.15 (36H, s, Bu). ^{13}C NMR (300 MHz, C_6D_6) δ_C: 154.2, 154.0, 153.8, 151.1, 147.9, 145.2, 140.5, 136.2, 126.1, 125.0, 121.3, 120.4, 118.6, 112.8, 111.8, 56.3, 56.2, 34.9, 32.0.

4.2.2. Manganese complex (4)

A solution of [Mn(hfac)$_2 \cdot 3H_2O$] (45 mg, 0.068 mmol) was prepared in *n*-heptane (15 ml) by the addition of the minimum amount of dry diethyl ether (ca. 1 ml). To this solution was added a solution of ligand **3** (100 mg, 0.190 mmol) in dichloromethane (5 ml) under nitrogen. The resulting solution was left under a flow of nitrogen for 12 h. The resulting orange precipitate was collected. The complex **4** was obtained as orange crystals (ca. 90 mg crude) and recrystalised from THF/hexane. *Anal.* Calc. for $C_{78}H_{82}N_4O_{10}F_{12}Mn$: C, 61.70; H, 5.44; N, 3.69. Found: C, 61.50; H, 5.35; N, 3.90%.

4.2.3. Copper complex (5)

In the same manner, the complex **5** was obtained as green crystals by recrystalisation from THF/hexane. *Anal.* Calc. for $C_{78}H_{82}N_4O_{10}F_{12}Cu$: C, 61.35; H, 5.41; N, 3.67. Found: C, 61.20; H, 5.55; N, 3.40%.

4.3. X-ray crystallography

Crystallographic data for **3**, **4** and **5** were collected at 150 K using a Nonius Kappa CCD diffractometer (with graphite-monochromated Mo Kα radiation; $\lambda = 0.71073$ Å) fitted with an Oxford Cryosystems nitrogen-cooled low-temperature device. Data processing for all structures was carried out using DENZO [27] while an absorption correction was applied using SORTAV [28]. The structures were all solved by direct methods and refined on F^2 using full-matrix least-squares methods with SHELXL-97 [29]. Hydrogen atoms were placed geometrically and treated with a riding model. Data are summarised in Table 1. In 4″,4‴-di-*tert*-butyl-2′,2″,2‴ trimethoxy-{4-(4′-diphenylaminophenyl)pyridine} (**3**), the *tert*-butyl group centred on C27 is disordered and was modelled over two positions with relative occupancies of 0.71:0.29. The Mn atom in the complex **4** lies on a centre of inversion and so the asymmetric unit contains half the complex molecule together with two disordered molecules of THF. Each THF molecule was modeled over two positions with relative occupancies of 0.73:0.27 in one case and 0.72:0.28 for the other. The Cu atom in the complex **5** lies on a centre of inversion and so the asymmetric unit contains half the complex molecule together with two molecules of THF, one of which is disordered. The disordered molecule was modeled over two positions with equal occupancies.

4.4. Cyclic voltammetry

These studies were carried out using a conventional three electrode system coupled to an EG&G Model 362 scanning potentiostat and the system was controlled by a PC unit running the 'Condecon 320' cyclic voltammetry software. The working electrode was a small platinum disc, ca. 2 mm diameter; the counter electrode was a platinum coiled wire and the reference electrode, a silver wire immersed in a saturated lithium chloride–dichloromethane mixture containing the supporting electrolyte tetrabutylammonium hexafluoroborate (0.1 M). Prior to use, solvents were thoroughly dried and degassed and the concentrations for the amines were approximately 1 mg cm^{-3}. The ferrocene/ferrocenium couple (fast electron transfer) was used as a standard and its oxidation potential was checked before and after each experiment for the solvent used. For the voltammograms shown in Fig. 2 the potential was swept in the anodic direction (upper trace) and the lower trace represents the reverse sweep in the cathodic direction.

4.5. Ultra violet/visible/near infra red spectroscopic studies

UV/Vis spectra in the range of 200–650 nm were recorded using a Perkin–Elmer Lambda 3000 UV/Vis/IR Spectrophotometer with a resolution of 0.1 nm in dichloromethane. Experiments were carried out using a pair of quartz cells with the corresponding solvent as reference. The path length of the cells was 10 mm. In a typical experiment, a dilute solution of the model diamine (1.6×10^{-5} mol l^{-1}) in dichloromethane was titrated against a known concentration of $THBF_4$ (1 mol l^{-1}), also in dichloromethane [14]. Ligand **3**, λ_{max} 354 nm, 3.50 eV ($\log_{10}\varepsilon$, 4.08); radical cation $\mathbf{3}^{\bullet+}$, λ_{max} 467 nm, 2.66 eV ($\log_{10}\varepsilon$, 4.01); 620, 2.02 (3.56); 920(s), 1.34 (3.75); isosbestic points $\mathbf{3}/\mathbf{3}^{\bullet+}$, 297 nm; 377. Complex **4**, λ_{max} 370 nm, 3.31 eV ($\log_{10}\varepsilon$, 4.78); diradical dication $\mathbf{4}^{\bullet+}$, λ_{max} 354 nm, 3.50 eV ($\log_{10}\varepsilon$, 4.46); 469, 2.66 (4.58); 619, 2.00 (3.87); 925, 1.34 (4.01); isosbestic point $\mathbf{4}/\mathbf{4}^{2,+}$, 419 nm. Complex **5**, λ_{max} 369 nm, 3.40 eV ($\log_{10}\varepsilon$, 4.56).

4.6. Magnetometry

Magnetic measurements were carried out using a SQUID magnetometer (MPMS, Quantum Design) at the University of Sheffield. Samples were prepared as a dilute frozen matrix using the same apparatus and combination of vacuum line and syringe techniques as previously described in detail in Ref. [9].

Acknowledgements

We thank EPSRC for funding this work and Dr. H. Blythe (Physics, University of Sheffield) for assistance with the SQUID magnetometry.

Appendix A. Supplementary material

CCDC 634674, 186580 and 636674 contain the supplementary crystallographic data for ligand **3**, Mn complex **4** and Cu complex **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2007.09.020.

Abstract

Crystal and molecular structure of the novel tetrakis hexafluoroacetyloacetonate neodymium(III) single crystal, $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ (*hfa* – hexafluoroacetylacetone), obtained by us, has been determined by X-ray diffractometry. The complex was characterized using IR spectroscopy and thermogravimetric analysis. An absorption spectrum of the single crystal was recorded and parameterized in terms of Judd–Ofelt intensity parameters Ω_λ. The experimental values of Ω_λ have been compared with those calculated based on the crystallographic data and taking into account the forced electric dipole and dynamic coupling mechanisms. Our study reveals a strong effect of hydrogen bonds, formed between the ligand's ketone oxygens and the water molecule from the neighboring complex anion, on the polarisation of the chemical environment of Nd^{3+} ions as well as a high value of Ω_2 intensity parameter. The molecular structure of the complex can be satisfactorily predicted by the SMLC/AM1 (sparkle model for the calculation of lanthanide complexes within Austin model 1) method.

Keywords: Neodymium tetrakis complex; β-Diketone; Crystal structure; Judd–Ofelt analysis; Infrared and UV–Vis spectra

1. Introduction

The lanthanides are known to form stable complexes with different groups of the organic ligands like calixarenes, ligands containing heterobiaryl groups or macrocyclic ligands [1]. Especially, worth attention are the lanthanide complexes with β-diketones [2], which in the last three decades have been intensively studied due to their potential applications in design of chelate lasers [3], efficient organic light emitting diodes (OLEDs) [4] and polymer light emitting diodes (PLEDs) [5], as NMR shift reagents [6], in analytical applications and as a modern antibody catalysts in biochemistry [7], to name just a few examples.

The most of hitherto studied rare-earth β-diketonate complexes belong to the group of tris complexes of the type M(β-diketone)$_3$L or M(β-diketone)$_3$L$_2$. Here, the two unoccupied coordination positions are usually filled up by additional neutral organic ligands L, which can serve as an antenna providing efficient pathway for excitation of lanthanide ion. Moreover, the L ligands prevent water or other solvent molecules, which possess a high energy vibrations and thus might quench efficiently the lanthanide complexes emission, from entering into the first coordination sphere. An alternative possibility is the complex of the type $(C^+)[ML_4^-]$, where all metal coordination positions are filled up by ligand donor atoms and the charge neutrality is provided by a C^+ counter cation, not coordinated to the lanthanide. An additional advantage of this type of complexes is that they exhibit usually a higher thermal stability compared to their tris-type counterparts. This property is of primary importance for applications as polymer light emitting diodes (PLEDs) and polymeric optical waveguides and amplifiers. Survey of the literature reveals, however, only a few reports on the lanthanide complexes of the general formula $(C^+)[Ln(\beta\text{-diketone})_4^-]$ [8–10]. Moreover, the search of the Cambridge Crystallographic Data Base results in only 20 crystal structures determined for

doi:10.1016/j.poly.2007.09.031

lanthanide tertakis complexes in general, and only one for neodymium tetrakis complex. Therefore, in view of potential applications of tetrakis(β-diketonates) type of complexes and scarcity of relevant data in the literature, studies of physico-chemical properties of these group of compounds are timely.

In this paper the synthesis of a new $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)](N(C_2H_5)_4)$ (*hfa* = hexafluoroacetyloacetone) compound, belonging to the tetrakis(β-diketonates) type of complexes, and its characterisation, are presented. The crystal structure at 100 K was determined by a single crystal X-ray measurements. The molecular structure of the complex was also calculated using the SMLC/AM1 (sparkle model for the calculation of lanthanide complexes within Austin model 1) method [11]. The thermal stability of the compound was studied using the TGA measurements. The detailed assignment of vibrational bands observed in the IR spectra was made, whereas the room and low-temperature absorption spectra of the single crystal were recorded to obtain the insight into the optical properties of the material. The observed transition intensities have been theoretically interpreted in terms of the Judd–Ofelt Ω_λ intensity parameters.

2. Experimental

2.1. Materials and sample preparation

The starting materials were $NdCl_3 \cdot 6H_2O$ (99.99%, Aldrich), 1,1,1,5,5,5-hexafluoro-2,4-pentanedione (*hfa*, hexafluoroacetylacetone) (99%, Aldrich) and $N(C_2H_5)_4Cl$ monohydrate (99.8%, Merck). The $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ was prepared by deprotonating 22 mmols of the hexafluoroacetylacetone ligand with NaOH in absolute ethanol, followed by addition of 10 mmoles of ethanolic solution of $N(C_2H_5)_4Cl$, and subsequent dropwise addition of 5 mmoles of the $NdCl_3 \cdot 6H_2O$ also dissolved in absolute ethanol. The sodium chloride, which precipitates immediately after the first drop of the counter ion is added to the solution, was filtered off. The obtained solution was concentrated by heating until the crystallization started. Afterwards, the small amount of absolute ethanol was added to dissolve the solid and the so obtained clear solution was then left at room temperature overnight. The formed light-violet single crystals of a good optical quality were separated by filtering and dried in air at room temperature. *Anal.* Calc. for $NdC_{28}H_{26}NO_9F_{24}$ (M_r = 1124.74): C, 30.08; N, 1.27; H, 2.37. Found: C, 30.0; N, 1.25; H, 2.3%.

2.2. Crystallography

A crystal suitable for X-ray analysis was cut from a larger one and mounted on a Kuma KM4 diffractometer with κ geometry and a graphite monochromator. The data were collected at 100 K and the unit cell parameters were refined from angular settings of 25 005 reflections with 2θ between 18° and 27°. The obtained data were corrected for Lorentz and polarisations factors as well as for extinction.

The position of the neodymium ion was found from the Patterson map; those of other atoms were found subsequently from the difference Fourier syntheses. The C-bonded hydrogen atoms were located from geometry, with the C–H distances constrained to 0.96 Å, and the position of the hydrogen atom in the water molecule was found from the difference Fourier syntheses. The structure was refined with a full-matrix least-squares method with all non-hydrogen atoms anisotropic and hydrogen atoms isotropic with common temperatures factors. Four (F(19), F(20), F(21) and F(24)) of the 24 F atoms reflect high anisotropic temperature factors, therefore in the crystal

structure refinement the disordered model was applied. Thus, in the refinement they were split over two sites with an assumed 50/50 occupancy.

The crystal structure calculations were performed with SHELXS-97 [12] and SHELXL-97 [13] programs. Other details of the data collection and the structure refinement are given in Table 1. Figs. 1–3 presenting the crystal structure of the title compound were drawn using with the DIAMOND 2.1d program [14].

2.3. Measurements

Electronic absorption spectra were recorded on a Cary 50 UV–Vis–NIR spectrophotometer in the 2500–28 000 cm^{-1} range. For the low temperature measurements the crystal was mounted in a helium Oxford Instruments optical cryostat and cooled to ~4.2 K. The FIR and IR spectra in the 60–600 cm^{-1} and 600–4000 cm^{-1} spectral range, respectively, were obtained in the room temperature with a BRUKER 113v FTIR spectrophotometer. The KBr disc and Nujol mull suspension techniques were applied. The DSC measurements were performed with a PERKIN–ELMER DSC-7 instrument equipped with a CCA-7 low-temperature accessory. The sample of the mass of ca. 18.2 mg was sealed in the aluminium pan. The measurements were carried out in the temperature range between 100 and 420 K.

3. Results and discussion

3.1. Crystal structure

The $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ crystallizes in the $P2_1/n$ space group of the monoclinic system. The determined parameters describing the geometry of the first coordination sphere of the Nd^{3+} ion are presented in Table 2.

The structure of the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ consists of the $[Nd(hfa)_4^-]$ complex anion and the $N(C_2H_5)_4^+$ cation, presented in Fig. 1, which arranged alternately are forming chains in the [0 1 0] direction. These chains, shown in Fig. 2, determine the molecular packing of the crystal. The packing diagram of the ions in the unit cell is presented in Fig. 3.

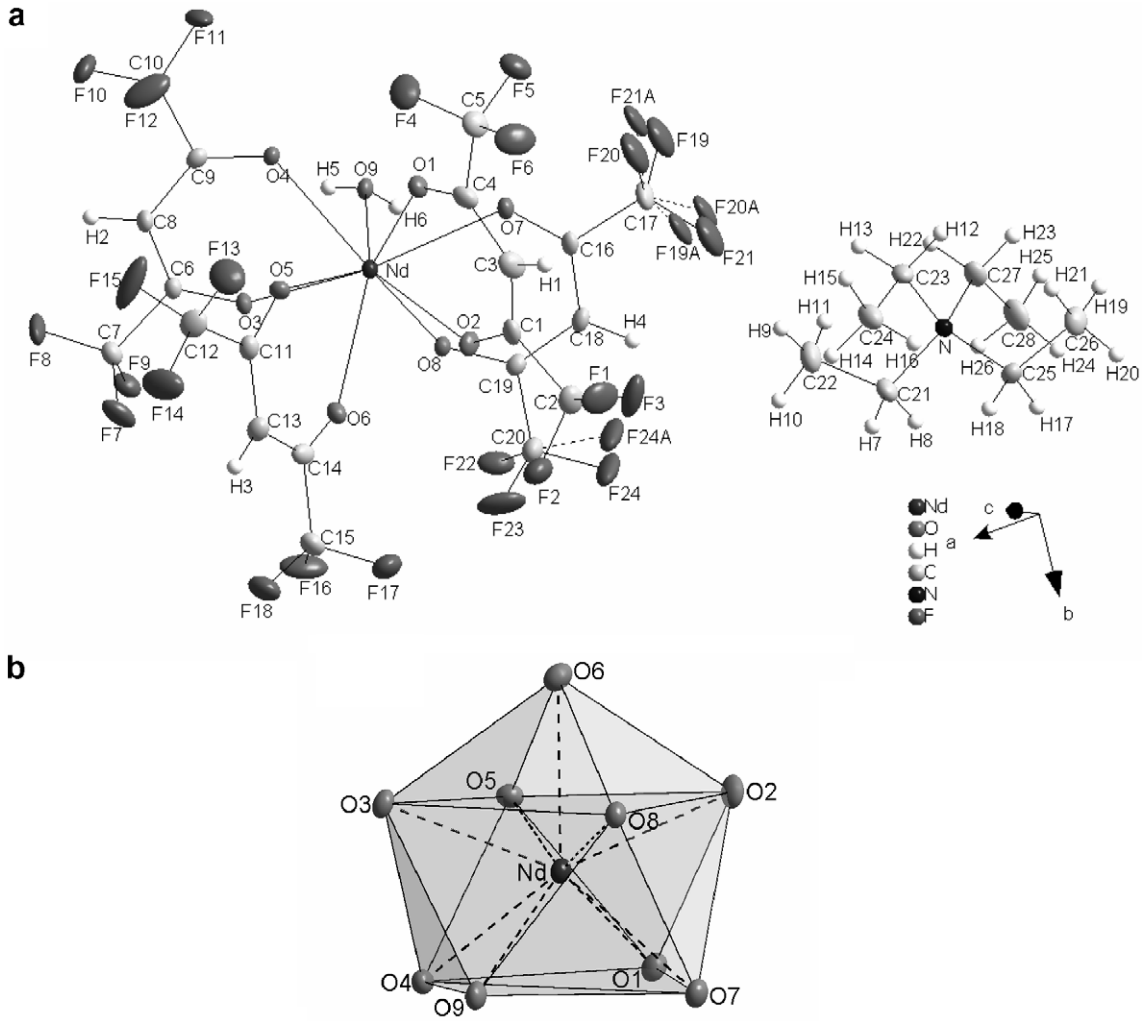

Fig. 1. (a) The molecular structure of the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$. Displacement ellipsoids are shown at 30% probability. The hydrogen atoms are shown as a small circle of arbitrary radii. (b) The coordination geometry of the Nd^{3+} ion in the distorted capped square antiprism.

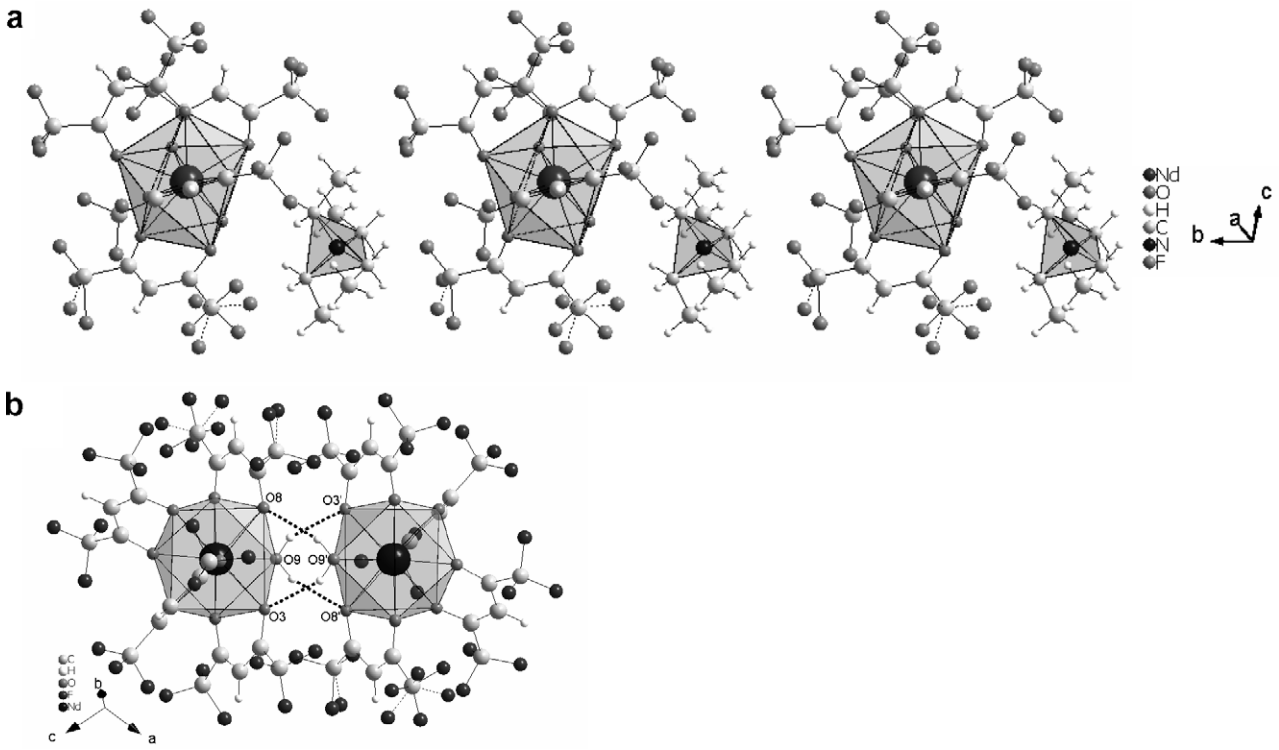

Fig. 2. (a) The fragment of the $(N(C_2H_5)_4)^+[Nd(hfa)_4(H_2O)]^-$ chain viewed along [1 0 1] direction. (b) The view of the pseudo-dimer with the dashed lines showing strong O–H···O hydrogen bonds; symmetry code is: (′) $-x+1, -y+1, -z$. All atoms are shown as a circle of arbitrary radii.

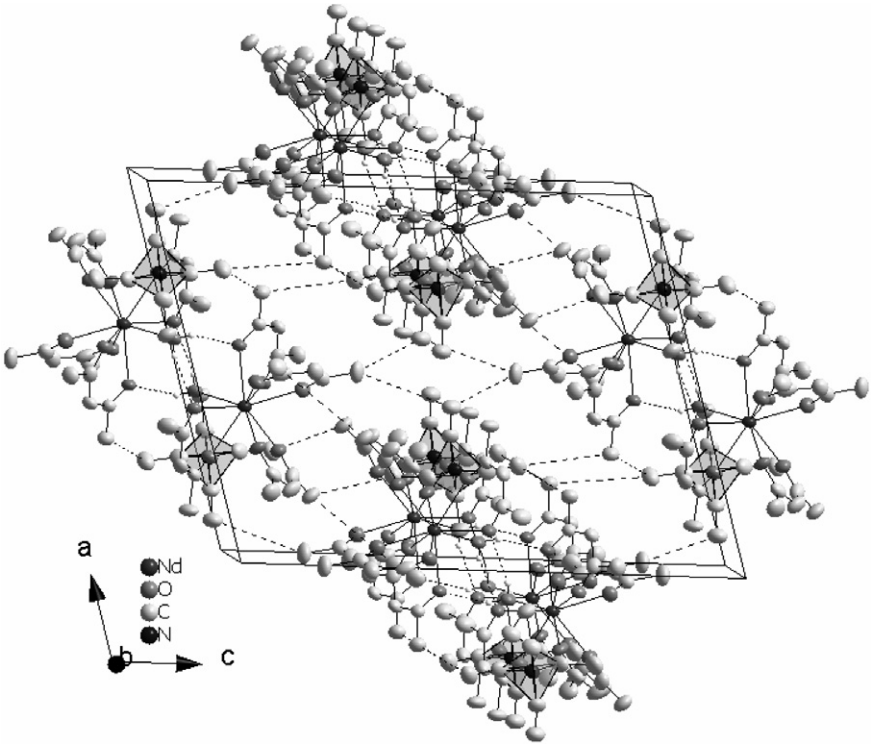

Fig. 3. The crystal packing diagram of the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$. The fluorine and hydrogen atoms are omitted for clarity. The hydrogen bonds are shown as the dashed lines (D···A).

The each neodymium ion is coordinated by nine oxygen atoms. Eight of them originate from the four hexafluoroacetyloacetonate chelating ligands and one from the water molecule. The Nd–O distances range from 2.437(3) to 2.572(4) Å (Table 2) and are shorter by ca. 0.05–0.15 Å then those reported for the neodymium eight-coordinated

$Nd(tta)_4Pyr$ (tta = thenoyltrifluoroacetylacetonate) β-diketone complex [15]. The O–Nd–O angles observed in the chelate ring range from 68.16° to 70.28° and are somewhat lower as compared to those found in the neodymium tris(β-diketonates) type of complexes [16]. The average length of the C–O bond equals to 1.262 Å and is much shorter then in other lanthanide tris [17,18] and neodymium tetrakis β-diketonates [19], which might reflect the lower π electron delocalization of the C=O double bond in the $(N(C_2H_5)_4)$-$Nd(hfa)_4(H_2O)]$ complex. Furthermore, the C1–C3 distances (1.382(7) Å) between two carbon atoms in the chelating ring are much shorter then the $C(1)–C(2)F_3$ distances (1.570(7) Å), which suggests the enhancement of the double character of the C=C bond inside the ring. In fact, the C1–C3 bond length is very close to the value of 1.34 Å expected for the C=C double bond [20]. This conclusion is further confirmed by results of the IR spectra analysis, presented in Section 3.2.

The Nd atoms are located at C_1 symmetry sites, which have an approximate 2-fold axis. The geometry around the Nd atom may be seen as a distorted capped square antiprism (CSA). A view of the coordination polyhedra is presented in Fig. 1b. The non-capped base is spanned by the O(1), O(4), O(7) and O(9) atoms, whereas the O(2), O(3), O(5) and O(8) atoms form the capped one, and the O(6) atom is the cap.

Unlike other Ln^{3+} (Ln = Sm–Yb) ions, which form anhydrous complexes of the $(N(C_2H_5)_4)[Ln(hfa)_4]$ type, the tetrakis complex of the Nd^{3+} ion with *hfa* ligand contains one-coordinated water molecule, and thus is not isostructural with its heavier lanthanide analogues [19]. The presence of the water molecule coordinated to the Nd^{3+} cation influences the conformations of the ligands chelate rings, and for those two that are the nearest neighbors of the water molecule, the deviation from the planarity with the mean value of 1.757(4) Å is observed.

The characteristic feature of the $(N(C_2H_5)_4)[Nd(hfa)_4]$ structure is the existence of strong hydrogen bonds between the O(3) and O(8) oxygen atoms, originating from the β-diketonate chelating ring, and the water molecule of the neighboring complex anion, with the lengths equal to 2.084(5) and 2.092(5) Å, respectively. They link the neodymium nine-coordinated polyhedra into pseudo-dimers, with the Nd–Nd distance equal to 6.694 Å. The weaker hydrogen bonds, with the lengths ranging from 2.470(6) to 2.570(6) Å, are observed between the fluorine atoms of the anion and the CH_3 group belonging to the $N(C_2H_5)_4^+$ counter cation. These bonds link the neighboring chains into a three dimensional network. The details of the proposed hydrogen-bond geometry are given in Table 3.

3.2. IR spectra

The IR absorption spectra of the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ measured in the 60–4000 cm^{-1} range are shown in Fig. 4. The proposed assignment of the observed fundamental bands is given in Table 4. Only one broad

band is observed at 3460 cm^{-1} in the spectral region between 1700 and 4000 cm^{-1}. It is associated with the O–H vibrations of the water molecule.

Although, in the 2000–4000 cm^{-1} spectral range both the asymmetric and symmetric CH_2 and CH_3 stretching modes are expected, we did not observe any bands, except for some very low intensity features. Similarly, all other bands ascribable to the vibrational modes of the tetraethylammonium molecule are very week, see e.g. σ(C–C–N) in Fig. 4a, and only a few among the numerous expected bands could have been localized in the spectrum. This unusual phenomenon is observed also for other $(N(C_2H_5)_4)[Ln(hfa)_4(H_2O)]$ type complexes and is related to the centrosymmetricity of the crystal [19].

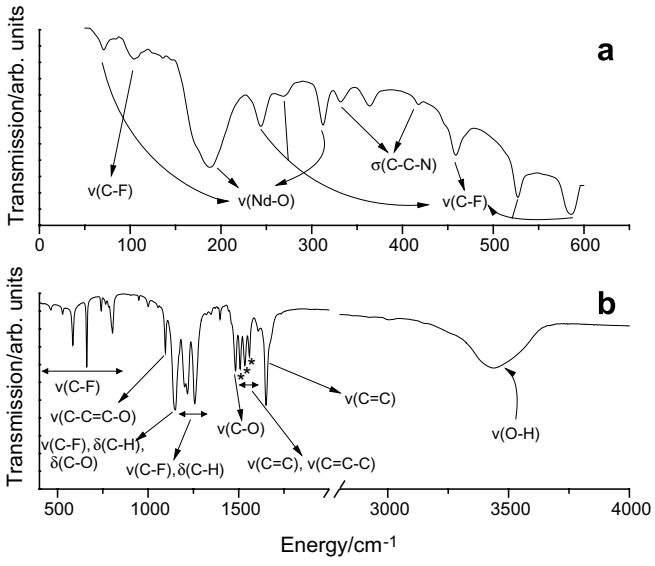

Fig. 4. (a) FIR and (b) NIR spectrum of the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ compound at room temperature.

The single band observed at 1650 cm^{-1}, that is within the region of C=O and C=C vibrations, should be assigned to the C=C stretching mode. Similarly, in the IR spectra of the $(N(C_2H_5)_4)[Ln(hfa)_4]$ [19] or $Cr(hfa)_3$ [21] complexes, unlike in the spectra of free hexafluoroacetylacetone or trifluoroacetylacetone ligands, only one single band has been observed at 1651 cm^{-1}. The absence of any feature attributable to the C=O stretching mode, otherwise observed as the intense band at about 1700 cm^{-1} and being characteristic for the keto form, confirms the coordination of both β-diketone's oxygen atoms to the Nd^{3+} ion [22].

In the 1470–1580 cm^{-1} region the group of relatively intense bands is observed. The band centered at 1482 cm^{-1} should be assigned to the C–O stretching vibration. However, over the years there has been extensive dispute in the literature [22] on the assignment of three remaining bands of this group, marked with asterisks in Fig. 4, usually observed in the IR spectra of metal ions β-diketonate complexes. These bands, which are not characteristic for the β-diketone itself, were proposed [21] to be due to delocalisation of the π-electron in the chelate ring forming in the complex. Our assignment of these bands, given in Table 4, is in agreement with that presented in Refs. [22,23]. Comparison of the IR spectra of metal complexes with different type of β-diketonates indicates that the intensity of these bands increases with increasing distance between ketonate oxygen atoms [24]. Since in the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ compound the O···O distance is rather

long (~2.82 Å), one observes in the IR spectrum three quite intense peaks at 1510 cm^{-1}, 1545 cm^{-1}, and 1570 cm^{-1}. This reveals the relatively high delocalisation of the π-electron and the enhancement of the double character of the C═C bond.

In the 400–1300 cm^{-1} spectral range the abundance of week bands, most of them corresponding to the C–F and C–N vibrations, is observed. The band at 1142 cm^{-1} is attributed to the CH in-plane bending mode, whereas the very strong band at 1187 cm^{-1} is assigned to the out-of-plane asymmetric CF_3 stretching mode. The strong band at 1099 cm^{-1} is due to the ν_s(C–C═C–O) coupled to the ν(C–F) mode.

Most of the bands at energy lower than 600 cm^{-1} can be assigned to the ν(C–F) as well as the δ(C–C–N) vibrations occurring within the counter ion. The expected intensive bands due to the metal–oxygen stretching modes are very weak in the recorded spectrum, which results from the presence of CF_3 groups. This phenomenon has been already reported by Nakamoto [24] and confirmed by Liang et al. [22] for lanthanide β-diketonates. It was ascribed to the strong positive inductive effect of the CF_3 groups strengthening the C═C bonds and weakening the metal–oxygen bonds.

3.3. Differential scanning calorimetry

In Fig. 5 two DSC curves measured for the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ are shown. They have been obtained when the sample was first heated to 460 K and then cooled to 170 K, under the same experimental conditions.

The DSC measurement does not reveal any low-temperature phase transition. However, two first-order phase transitions are found at above room temperature, as is indicated by the single peak at 297 K and the composed peak at ca. 405 K observed on DCS curve on heating.

The first up-temperature DSC scan, Fig. 5a, exhibits only one broad endothermic peak at approximately 361 K, corresponding to the loss of the water molecule. The down-temperature DSC curve (Fig. 5b) reveals the structural phase transition occurring at 297 K. This first-order type transition turns out to be characteristic for the anhydrous $(N(C_2H_5)_4)[Ln(hfa)_4]$ type compounds [19]. Hence, its occurrence implies that the anhydrous $(N(C_2H_5)_4)[Nd(hfa)_4]$ complex, which is formed after loosing of water molecule at 360 K, is isostructural with its lanthanide analogous. The compound melts at 408 K and just below this temperature another anomaly is observed on the

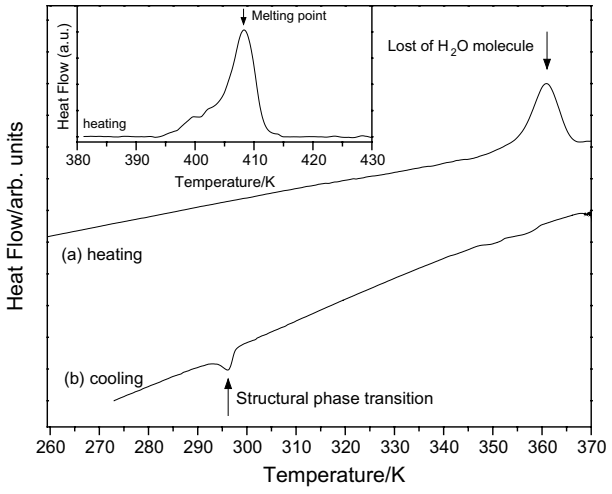

Fig. 5. Differential Scanning Calorimetry up-temperature (a) and down-temperature (b) curves recorded for $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ in the 170–420 K temperature range. The inset shows the anomalies observed on the heating curve at temperatures close to the melting point.

heating DSC curve (inset in Fig. 5). This feature may be also associated with the structural phase transition and it has been observed, similarly as that at 361 K, in all other hitherto studied anhydrous $(N(C_2H_5)_4)[Ln(hfa)_4]$ complexes [19]. The thermal data determined by the DSC measurements are summarised in Table 5.

3.4. Absorption spectra

In Fig. 6 the survey absorption spectrum recorded at 298 K in the 3500–30 000 cm^{-1} range, is shown. The observed lines result from the intraconfigurational $4f^3 \rightarrow 4f^3$ transitions from the Stark components of the ground $^4I_{9/2}$ multiplet to the crystal-field levels of the excited $^{2S+1}L_J$ multiplets of the Nd^{3+} ion. The SLJ labels of terminal levels are indicated in Fig. 6. The lines occurring in the 3800–4600 cm^{-1} spectral range may result from Nd^{3+} $^4I_{9/2} \rightarrow {}^4I_{13/2}$ transitions expected in this region, or may be due to overtones and combinations of vibrational bands.

In 4.2 K spectrum (inset (b) in Fig. 6) the $^4I_{9/2} \rightarrow {}^2P_{1/2}$ transition is observed as a single, sharp peak at 23312 cm^{-1}, with a FWHM of 6 cm^{-1}. This is indicative of a single site occupancy of Nd^{3+} ions, in accordance with the crystal structure data. Due to the low symmetry of the Nd^{3+} ion environment the absorption spectrum is dominated by electronic origins and vibronic lines are not observed.

Since, there is one water molecule in the first Nd^{3+} coordination sphere, the emission from the excited states is very efficiently quenched by the multiphonon relaxation process with participation of OH vibrations. Thus the five crystal-field components resulting from the splitting of the $^4I_{9/2}$ ground multiplet could not be experimentally determined from emission spectra. However, from analysis of the hot bands observed at 298 K in the region of the $^4I_{9/2} \rightarrow {}^4F_{3/2}$ and $^4I_{9/2} \rightarrow {}^2P_{1/2}$ absorption transitions, the three crystal-field components of the $^4I_{9/2}$ ground multiplet could be assigned at 204, 355 and 426 cm^{-1}.This relatively large splitting of the ground multiplet indicates rather strong CF effect in the studied compound.

The edge of broad and very intense bands, attributed to the ligand absorption transitions, is observed above 28 000 cm^{-1}. These bands totally obscure the f–f transitions occurring in this range of the spectrum.

Table 5
Thermal data (onset, peak temperature and energy) obtained by Differential Scanning Calorimetry for the $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$

Onset (K)	Peak from–to (K)	Energy (J g^{-1})
297	291–298	0.93
355	346–367	17.47
403	391–414	55.70

3.5. f–f transition intensities

The experimental intensities of the induced electric dipole transitions are analyzed in terms of the Judd–Ofelt theory [25,26], whereas the theoretical calculations of 4f–4f intensities are performed using the procedure proposed by de Sá et al. [27] The experimental dipole strengths of transitions from the ground $^4I_{9/2}$ multiplet to the excited states have been determined from the unpolarized room

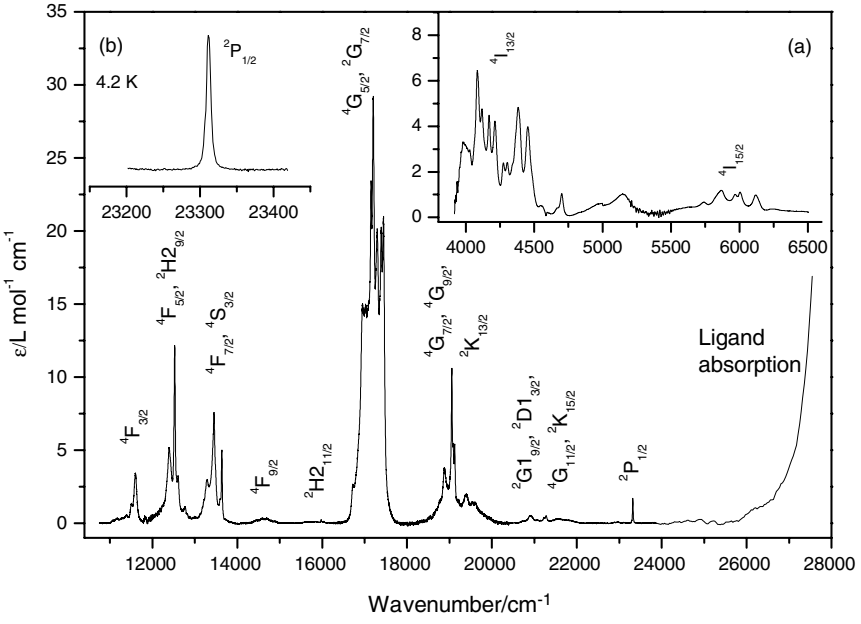

Fig. 6. UV–Vis electronic absorption spectrum recorded at 298 K for $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ monocrystal. The inset (a) shows the absorption transitions in the IR spectral region. All transitions start from the $^4I_{9/2}$ ground state of Nd^{3+} and the terminal multiplets are labeled in the figure. The inset (b) shows the $^4I_{9/2} \rightarrow {}^2P_{1/2}$ transition recorded at 4.2 K.

temperature absorption spectrum measured for the random orientation of the crystal. The observed absorption bands were integrated and the dipole strengths (D) expressed in the squared Debye units (D^2) ($D = 3.3356 \times 10^{-30}$ Cm) were determined from the equation

$$D = \frac{9.188 \cdot 10^{-3}}{C \cdot d} \int \frac{A(\bar{\nu})}{\bar{\nu}} d\bar{\nu}, \quad (1)$$

where C is the molar concentration (mol l^{-1}) of the neodymium ions in the crystal, d – the optical path length (cm), A – the absorbance ($A = -\log(I/I_0)$) and $\bar{\nu}$ – the wavenumber (cm^{-1}). All transitions observed in the analyzed region of the spectrum are the induced electric dipole transitions. The assignment of absorption transitions observed in 10 000–25 000 cm^{-1} region and their experimental dipole strengths are listed in Table 6.

According to the Judd–Ofelt theory, the intensity of the lines resulting from the electric dipole transitions, is described in terms of three phenomenological intensity parameters Ω_λ, which are related to D in Eq. (1) as

$$D = \frac{10^{36}}{2J+1} \chi_{ed} e^2 \sum_{\lambda=2,4,6} \Omega_\lambda |\langle \mathrm{SLJ}|U^{(\lambda)}|S'L'J'\rangle|^2 \quad (2)$$

where the correction factor for bulk refractivity χ_{ed} is defined as $\chi_{ed} = \frac{(n^2+2)^2}{9n}$ and, for the assumed value of an average index of refraction $n = 1.5$, typical for rare-earth β-diketonate complexes [27], $\chi_{ed} = 1.34$. The factor 10 [36] converts the esu cm units into squared Debye (D^2) units, e is the elementary charge (4.803×10^{-10} esu), $(2J+1 = 10)$ is the degeneracy of the ground state, and $|\langle \mathrm{SLJ}|U^{(\lambda)}\ |S'L'J'\rangle^2|$ are the squared reduced matrix elements. We have applied the reduced matrix elements calculated on the basis of free-ion parameters obtained from the crystal-field analysis of the investigated complex [28]. In the case of overlapping transitions, the sum of the appropriate reduced matrix elements of the component multiplets was taken as the reduced matrix element.

The Ω_λ parameters have been determined by a least-squares adjustment of $\sum_{i=1-n}(D_{\mathrm{exp}}(i) - D_{calc}(i))^2$, where $D_{\mathrm{exp}}(i)$ and $D_{\mathrm{calc}}(i)$ are the experimental and calculated dipole strengths of the ith transition. The fitting yields $\Omega_2 = (15.3 \pm 1.1) \times 10^{-20}$ cm^2, $\Omega_4 = (7.3 \pm 1.5) \times 10^{-20}$ cm^2 and $\Omega_4 = (3.9 \pm 1.3) \times 10^{-20}$ cm^2 with the r.m.s. deviation of 79×10^{-6} D^2. The calculated dipole strengths are given in Table 6.

Similarly as for tris β-diketonates complexes [27], the high value of Ω_2 parameter resulted from our calculations for $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$. The dominance of the Ω_2 intensity parameter may be related to the hypersensitive nature of the $^4I_{92} \rightarrow (^4G_{5/2} + {}^2G_{7/2})$ transition, suggesting also the important contribution of the dynamic coupling mechanism to the transition intensities [29,30].

To gain the deeper insight into the mechanism governing the f–f intensities, we have calculated the intensity parameters Ω_λ using the theoretical expression [27]

$$\Omega_\lambda = (2\lambda+1) \sum_{t,\mathrm{p}} \frac{|B_{\lambda \mathrm{tp}}|^2}{(2t+1)}, \quad (3)$$

where the $B_{\lambda \mathrm{tp}}$ intensity parameters are given by

$$B_{\lambda \mathrm{tp}} = \frac{2}{\Delta E} \langle r^{t+1} \rangle \theta(t,\lambda) \gamma_{\mathrm{p}}^t - \left[\frac{(\lambda+1)(2\lambda+3)}{(2\lambda+1)}\right]^{1/2} \times \langle r^\lambda \rangle (1-\sigma_\lambda) \langle f \| C^{(\lambda)} \| f \rangle \Gamma_{\mathrm{p}}^t \delta_{\mathrm{t},\lambda+1}. \quad (4)$$

In Eq. (4) ΔE is the energy difference between the barycenters of the excited $4f^{N-1}$ 5d and ground $4f^N$ configuration, $\theta(t,\lambda)$ – a numerical factor, σ_λ is a screening factor, $C^{(\lambda)}$ – a Racah tensor operator of rank λ and $\delta_{\mathrm{t},\lambda+1}$ – the Kronecker delta function [27]. The quantities γ_{p}^t and Γ_{p}^t account for the dependence of transition intensities on geometry and chemical environment of the lanthanide ion; Γ_{p}^t is given by

$$\Gamma_{\mathrm{p}}^t = \left(\frac{4\pi}{2t+1}\right)^{1/2} \sum_j \frac{\alpha_j}{R_j^{t+1}} Y_{\mathrm{p}}^{t^*}(\theta_j, \varphi_j), \quad (5)$$

where α_j is the isotropic polarizability of the jth ligand atom at distance R_j and Y_{p}^t are the spherical harmonics of rank t [27]. According to the simple overlap model (SOM) [31] the parameters γ_{p}^t can be expressed as

$$\gamma_{\mathrm{p}}^t = \left(\frac{4\pi}{2t+1}\right)^{1/2} e^2 \sum_j \rho_j (2\beta_j)^{t+1} \frac{g_j}{R_j^{t+1}} Y_{\mathrm{p}}^{t^*}(\theta_j, \varphi_j), \quad (6)$$

where ρ_j is the magnitude of the total overlap between the 4f wave functions and the ligand ones, $\beta_j = 1/(1 \pm \rho_j)$ and

Table 6

$^2P_{1/2}$	23 320	31	93	−62	0.33

[a] Judd–Ofelt parameters used for obtaining of D_{calc} values are: $\Omega_2 = (15.3 \pm 1.1) \times 10^{-20}$ cm^2, $\Omega_4 = (7.3 \pm 1.5) \times 10^{-20}$ cm^2 and $\Omega_4 = (3.9 \pm 1.3) \times 10^{-20}$ cm^2. The r.m.s. value is 79×10^{-6} D^2.

g_j are the charge factors. It may be assumed that overlap ρ_j vary with the distance as $\rho_j = 0.05(R_0/R_j)^{3.5}$, where R_0 is the smallest among the R_j's. Further details pertinent to this model may be found in Ref. [27] and references cited therein.

For the Eu^{3+} ion the values of the screening factors in Eq. (4) were assumed as $\sigma_2 = 0.6$, $\sigma_4 = 0.139$, and $\sigma_6 = 0.1$ [30]. A somewhat larger value of σ_2 is expected for Nd^{3+}. The σ_2 screening factors computed by the Sternheimer method equal to 0.686 and 0.714 for Eu^{3+} and Nd^{3+}, respectively [32]. Thus, in our calculations we use $\sigma_2 = 0.62$ for Nd^{3+} ion. The numerical values of $\langle r^k \rangle$ radial integrals were taken from Ref. [33] and for ΔE we assumed the value of 55 000 cm^{-1} [34].

The charge factors g_j for coordination compounds usually differ significantly from the nominal valence of the ligating atoms. As is discussed in Ref. [36], g_j should be rather interpreted as a measure of the "capacity" of an atomic species to donate charge to the formation of a bond in a molecule and may be identified with an ionic specific valence (ISV). Therefore, in our calculations the g_j were treated as adjustable parameters to be optimized until the best agreement between the calculated and experimental Ω_λ intensity parameters is obtained. The polarizabilities α_j, which depend not only on the type of atoms, but also on the chemical group in which it is present, as well as on its geometry and the next nearest neighbors, were also treated as variable parameters in fitting the experimental Ω_λ intensity parameters. Each Ω_λ depends, however, on both g_j and α_j. Note that the even rank crystal-field parameters of the SOM model, which describe the Stark splitting of the SLJ manifolds, are given by $B^k_q = \langle r^k \rangle \gamma^k_q$ (where γ^k_q are defined by Eq. (6)) and thus depend parametrically on g_j only, assuming that the relation $\rho_j = 0.05(R_0/R_j)^{3.5}$ holds for the overlap [27].

The CF parameters B^k_q can be related to quadratic rotational invariants $s_k{}^2$ (Ref. [35]):

$$s_k^2 = (1/(2k+1)) \sum_{q=-k}^{q=k} |B_q^k|^2 \tag{7}$$

and thus, in turn, to the quadratic moments of the multiplets, $(\sigma_2(\mathrm{SLJ}))^2$,

$$(\sigma_2(\mathrm{LSJ}))^2 = (1/(2J+1) \sum_{k=2,4,6} s_k^2 \langle \mathrm{LSJ} \| C^{(k)} \| \mathrm{LSJ} \rangle^2, \tag{8}$$

where $\langle \mathrm{SLJ} \| C^{(k)} \| \mathrm{SLJ} \rangle$ is a reduced matrix element. Finally, the quadratic moment, $(\sigma_2(\mathrm{SLJ}))^2$, is defined as [35]

$$(\sigma_2(\mathrm{SLJ}))^2 = (1/(2J+1) \sum_i [E_i(\mathrm{SLJ}) - E^0(\mathrm{SLJ})]^2 \tag{9}$$

where E^0 is the mean energy of the SLJ multiplet.

The splitting of the $^4F_{3/2}$ multiplet is usually easily available experimentally In the case of Nd^{3+} ion. For the studied compound the two Stark components of $^4F_{3/2}$ are observed at 11 500 and 11 597 cm^{-1}. From these, the $(\sigma_2(\mathrm{SLJ}))^2$ moment is obtained as 1176 cm^{-1}. For the $^4F_{3/2}$ multiplet only the $\langle {}^4F_{3/2} \| C^{(2)} \| {}^4F_{3/2} \rangle$ matrix element has non-zero value (0.1144 – calculated for the free-ion parameters resulted from CF analysis [28]. Substituting of $(\sigma_2(\mathrm{SLJ}))^2$ and the matrix element value into Eq. (8) yields $s_2 = 202.8$ cm^{-1}. Hence, the charge factors g_i can be optimized by minimizing the difference between thus determined experimental s_2 value and those calculated from Eqs. (7) and (6).

In our calculations for $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ we use the axis system centered at Nd^{3+} ions with the z-axis along the Nd–O(9) direction (O(9) is the water molecule oxygen) and the y-axis coinciding with the Nd–O(1) bond. The spherical coordinates of ligating atoms forming the first coordination sphere in this axis system are listed in Table 7.

The charge factors g_j and polarizabilities α_j were optimized by least-square fittings of the calculated and experimental Ω_λ intensity parameters as well as the Stark splittings of the $^4F_{3/2}$ multiplet. Initially, we assume g_1 (α_1) for each β-diketonate oxygen and g_2 (α_2) for water molecule oxygen. However, this assumption yields reasonable agreement for Ω_6 and $^4F_{3/2}$ splitting only, whereas Ω_2/Ω_4 ratio was significantly lower than the experimental ratio. To obtain a good agreement with the experiment for all Ω_λ parameters and the $^4F_{3/2}$ splitting, and particularly to reproduce the high value of Ω_2, it was necessary to distinguish the two oxygen atoms, O(3) and O(8). Thus we allow the polarizablilities for these atoms to take on values different from those for remaining β-diketonate's oxygens. To avoid, however, the pitfall of overparameterisation (the number of parameters exceeding the number of observables), we arbitrary fix the polarizability of water molecule oxygen at the value of 4.0, typical for Eu^{3+} tris complexes [36]. Thus, in the final procedure a total of four parameters were varied and determined simultaneously. The results are listed in Table 8. In Table 9 the experimental and calculated Ω_λ intensity parameters as well as the s_2 rotational invariants are listed.

The agreement between calculated and experimental Ω_λ and s_2 parameters so excellent, should not be overvalued, since four adjustable parameters were fitted to four experimental quantities. More meaningful is to comment shortly on the g_j and α_1 values. The g_j determine almost exclusively

Table 7
Spherical coordinates of the bonding β-diketone's oxygens (O1–08) and water molecule oxygen (O9) in coordination system centered at Nd^{3+} ion, with z and y axis coincide with Nd–O(9) and Nd–O(1) bonds, respectively

Ligand	R (Å)	θ (°)	φ (°)
O1	2.453	111.32	90.00
O2	2.437	137.52	173.67
O3	2.469	72.01	−48.02
O4	2.501	68.68	26.40
O5	2.438	135.64	3.99
O6	2.479	125.73	−92.42
O8	2.471	72.40	−141.77
O9	2.570	0.00	0.00

Table 8
Optimized values of charge factors (g) and polarizabilities (α) obtained for $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$

Ligand	G	α (Å^3)
O1, O2, O4 − O7	0.78	4.25
O3, O8	0.78	2.32
O9	0.52	4.0

The O1–O8 oxygen atoms are from β-diketone's ligands, whereas the O9 atom is from the coordinated water molecule.

Table 9
Experimental and theoretical Ω_λ ($\times 10^{-20}$ cm^2) and s_2 (in cm^{-1})

	Experimental	Theoretical
Ω_2	15.3	15.4
Ω_4	7.3	7.3
Ω_6	3.9	3.8
s_2	202.8	201.7

the values of Ω_6 and s_2. The obtained charge factors of 0.78 for β-diketonate oxygen atoms are very close to values of 0.88 and 0.87 determined for $Eu(tta)_3 \cdot 2H_2O$ and $Eu(btfa)_3 \cdot 2H_2O$ [36]. The charge factor of 0.52 for oxygen from the water molecule is lower as compared to 1.48 and 1.24 determined experimentally [36], but not far from the values of 0.61 and 0.71 calculated theoretically, for the europium tris complexes [36]. Thus the charge factors g_1 and g_2 seems to be determined reliably.

Also the resulting values of polarizabilities fall in the physically acceptable range and do not deviate from those reported earlier for europium tris β-diketonate complexes [36]. An intriguing question is, however, the reason for the lower values obtained for the polarizabilities for O(3) and O(8) atoms, as compared to the remaining β-diketonate's oxygens. We are aware that the absolute values of polarizabilities may be not well determined, since they strongly depends also, e.g. on σ_λ screening factors, however, even in a such case, the trend emerging from calculations is unambiguous and in spite of many efforts we have not been able to obtain satisfactory results, without allowing the lower α_j values for those two atoms. The answer to this question may result from inspection of the molecular structure of the complex described in previous sections. Both the O(3) and O(8) atoms participate in formation of the H–O–H···O–Nd hydrogen bonds with water molecule coordinated to the adjacent Nd atom. This interaction may change the electron density on O(3) and O(8) atoms and, thus also their polarizabilities. Thus the β-diketonate's oxygens not bounded by hydrogen bonds have softer character as compared to O(3) and O(8). Probably, also the charge factors for those two oxygen atoms may be lower as well, however, the attempt to include this effect would lead to the number of adjustable parameters larger than that of the experimental quantities.

In Eq. (4) the first term corresponds to the forced electric dipole mechanism and the second one to the dynamic coupling mechanism. Comparison of intensity parameters $B_{\lambda tp}$ calculated for both mechanisms separately indicates, that contribution from the latter strongly dominates. Moreover, if one assumes the same polarizabilities for all β-diketonate's oxygens the contribution from the dynamic coupling mechanism decreases and the calculated Ω_2 value would be significantly lower as compared to the experimental one. It seems therefore, that the formation of hydrogen bonds is a factor responsible for the polarisation of chemical environment of Nd^{3+} ions, thus increasing the contribution from the dynamic coupling mechanism and leading to the high value of Ω_2 intensity parameter.

3.6. Structure optimization

The knowledge of the ground state geometry of the complex is required for theoretical predictions, e.g. of its electronic spectrum. For some complexes the experimental structural data are not available, for instance due to the difficulties in obtaining of X-ray quality crystals. Then the molecular structure may be predicted using theoretical methods. Moreover, it has been shown [37] than even if experimental structure is known, the use of calculated molecular structure instead of experimental one as the input geometry for the spectral calculation results in a better agreement between calculated and measured spectrum. The ground state geometry of the large lanthanide complexes can be successfully optimized using a SMLC/AM1 model (sparkle model for the calculation of lanthanide complexes within Austin model 1) [27]. However, most of the existing calculations have been performed for europium complexes. The $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$ complex seems to be an interesting subject for such modelling. Since the X-ray structure of this compound is available, it is possible to compare the calculated results with the experimental ones. Moreover, the presence of the coordinated water molecule affects the molecular structure of the complex. Particularly, the hydrogen bonds link two adjacent complex anions into pseudo-dimers (Fig. 2b) with a relatively short Nd–Nd distances of 5.913 Å. Thus, it is interesting to examine to what extent the molecular structure of the complex is correctly reflected by model calculations.

In the present work we use SMLC/AM1 for Nd(III) implemented within the MOPAC 6.00 program [11]. The geometry of the complex determined by X-ray diffraction was used as the input data in our calculations performed for the single $[Nd(hfa)_4(H_2O)]^-$ complex anion as well as for the $[Nd_2(hfa)_8(H_2O)_2]^{2-}$ pseudo-dimer. The results indicate that inclusion or omission of the counter ion has no noticeable influence on the geometry of the anion and in both cases the Nd–O distances are predicted with similar accuracy. However, in the calculations for the single $[Nd(hfa)_4(H_2O)]^-$ anion the bending of the chelate rings is not accurately reproduced. The obtained torsion angle between O8–Nd–O7–C16 atoms of about −15° is significantly lower than that determined by the X-ray diffraction

(−38.4°). Even worse correspondence is observed for the second ring, which was calculated to be almost flat, with the torsion angle between O3–Nd–O4–C9 atoms of about 5°, whereas the experimental value is 33.7°. Thus, though some steric effect of the water molecule is observed, our modelling suggests that this effect is not the most important one. Far better correspondence between calculated and experimental geometry is found in the calculations carried out for the pseudo-dimer. Some of the calculated Nd–O distances as well as angles and torsion angles between atoms are included in Table 2 (values in brackets). However, whereas in the real structure the both anions forming the pseudo-dimer are symmetrically equivalent, in the calculations slightly different surroundings are obtained for two Nd atoms, which therefore are denoted in Table 2 as Nd(1) and Nd(2). The Nd–O distances are predicted with a good accuracy, with an average deviation of 18 calculated values from experimental ones of 0.056 Å, and the largest difference between calculated and experimental distance equal to 0.107 Å. The agreement between the bond angles is not so good, although still acceptable. The calculated O3–Nd–O4–C9 and O8–Nd–O7–C16 torsion angles are somewhat lower compared to those determined experimentally. This probably results from the larger Nd–Nd distance (6.694 Å) resulted from calculations as compared to that of 5.913 Å found from X-ray determined structure, which decreases the steric effect. Nevertheless, the model calculations prove unambiguously that the steric hindrance between the two anions forming the pseudo-dimer, linked by hydrogen bonds, is responsible for the bending of chelate rings of the water adjoining ligands.

4. Summary

In this paper, the synthesis of a novel $(N(C_2H_5)_4)$-$[Nd(hfa)_4(H_2O)]$ (hfa = hexafluoroacetylacetonate) compound, belonging to the tetrakis (β-diketonates) type of complexes is presented. This complex crystallizes in the $P2_1/n$ space group of the monoclinic system. The neodymium ion is coordinated by nine oxygen atoms forming a distorted capped square antiprism. It is worth to notice that, to the best of our knowledge, this is only the second crystal structure reported hitherto for a tetrakis β-diketonate complex containing neodymium ions.

In contrast to other Ln^{3+}(Ln = Sm–Yb) ions, which form tetrakis(hexafluoroacetylacetone) anhydrous complexes of the $(N(C_2H_5)_4)[Ln(hfa)_4]$ type, the complex of Nd^{3+} with hfa contains one-coordinated water molecule and hence is not isostructural with its heavier lanthanide analogues. Further studies aimed at verification whether this feature is typical for all light lanthanides are currently under progress. The DSC analysis shows the loss of the water molecule at 361 K. After that the compound exhibits the first-order phase transitions at 297 K and ~403 K, typical for anhydrous $(N(C_2H_5)_4)[Ln(hfa)_4]$ type compounds.

Unexpectedly, the usually intense bands corresponding to the vibrational modes of the tetraethylammonium molecule, are very week or unobserved in the IR spectrum of the studied complex, which can be ascribed to the centrosymmetricity of the crystal. Moreover, the analysis of the IR spectra proves the coordination of both β-diketones oxygen atoms to the Nd^{3+} ion and indicates the relatively high delocalisation of the π-electron in the chelate ring forming in the metal–β-diketonate complex.

Analysis of the experimental absorption spectrum enables determination of the Ω_λ intensity parameters as: $\Omega_2 = (15.3 \pm 1.1) \times 10^{-20}$ cm^2, $\Omega_4 = (7.3 \pm 1.5) \times 10^{-20}$ cm^2 and $\Omega_6 = (3.9 \pm 1.3) \times 10^{-20}$ cm^2. The theoretical calculations indicate, that the important factor responsible for the high value of the Ω_2 parameter is formation of the hydrogen bonds by two of β-diketonate's oxygens, which leads to the polarisation of the chemical environment of Nd^{3+} ion and increases the contribution from the dynamic coupling mechanism to the $B_{\lambda tp}$ intensity parameters. The ground state geometry of the studied complex can be reasonably well predicted by means of the SMLC/AM1 method. The calculations reveal, that the bending of the chelate rings of two ligands adjoining the water molecule is caused by the steric effect arising in the pseudo-dimer, formed by two complex anions linked by the hydrogen bonds. This also leads to the shortening of the Nd–Nd distance to 5.913 Å, as compared to about 9.2–9.9 Å observed for analogous anhydrous tetrakis complexes [19].

Supplementary material

CCDC 631505 contains the supplementary crystallographic data for $(N(C_2H_5)_4)[Nd(hfa)_4(H_2O)]$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk.

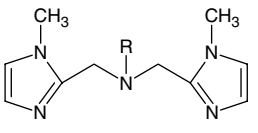
Abstract



Three monocationic rhenium(I) complexes of the type $[Re(CO)_3(L)]Br$, containing the bis-imidazole tridentate ligands bis-(2-(1-methylimidazolyl)methyl)amine (L^1), bis-(2-(1-methylimidazolyl)methyl)aminoethanol (L^2) and bis-(2-(benzimidazolyl)ethyl)sulfide (L^3), were prepared and characterized by ^1H NMR and IR spectroscopy. The complex salt $[Re(CO)_3(L^2)]Br$ (**2**) was also characterized by X-ray crystallography. The structure consists of discrete monocationic monomers with a *fac*-$[Re(CO)_3]^+$ coordination unit, and the remaining three sites are occupied by one amine and two imidazolyl nitrogen donor atoms.

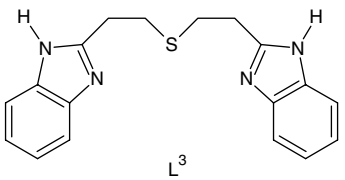
Keywords: *fac*-$[Re(CO)_3]^+$; Tridentate; Imidazole; Crystal structure



1. Introduction

The widespread interest in the development of rhenium radiopharmaceuticals is a direct result of the ideal nuclear properties of the $^{186/188}Re$ isotopes (strong β-emission energies of 1070 keV and 2120 keV, and long half-lives of 90 h and 17 h, respectively) which are suitable for targeted radiotherapy of cancers [1–3]. Recently, the interest in the chemistry of the *fac*-$[M(CO)_3]^+$ (M = Tc and Re) complexes has accelerated research in this field due to the easy availability of the $[M(OH_2)_3(CO)_3]^+$ precursor, which can be obtained directly from MO_4^- in aqueous solution [4,5]. Its convenient synthesis and quantitative preparation is in line with the principles of radiopharmaceutical synthesis, which are based on "instant kit" formulation and clean radio-labelling procedures from accessible radioisotopes of these metals [6,7]. The substitutional lability of the coordinated water molecules allows for the preparation of a range of *fac*-$[Re(CO)_3]^+$ complexes which are both thermodynamically and kinetically stable. However, this robust core only possesses three coordination sites to exploit with functional groups, and most work has been done with tridentate ligands to further enhance the kinetic inertness of the low-spin d^6 system [8,9]. The real challenge still rests in the adaptation of biomolecules to act as carrier groups in order to achieve the cellular specificity and localization of the complexes *in vivo*.

We have synthesized the tridentate imidazole-containing ligands bis-(2-(1-methylimidazolyl)methyl)amine (L^1), bis-(2-(1-methylimidazolyl)methyl)aminoethanol (L^2) and bis-(2-(benzimidazolyl)ethyl)sulfide (L^3) to study their coordination behaviour with rhenium(I), by using $[Re(OH_2)_3(CO)_3]Br$ or $(NEt_4)_2[ReBr_3(CO)_3]$ as precursor compounds. The two imidazole rings can be viewed as primitive models for multi-histidine coordination in biological systems [10].

$R^1 = H$ (L^1); $R^2 = CH_2CH_2OH$ (L^2)

2. Experimental

2.1. Reagents and instrumentation

$Re(CO)_5Br$, 1-methylimidazole, *o*-phenylenediamine, 3,3′-thiodipropionic acid, 2-aminoethanol, deuterated chloroform, and deuterated dimethylsulfoxide were purchased from Sigma–Aldrich and used as received. The reagents 1-methyl-2-aminomethylimidazole dihydrochloride [11], 1-methyl-2-imidazolecarboxaldehyde [11], 2-chloromethyl-1-methylimidazole hydrochloride [12], $[Re(OH_2)_3(CO)_3]Br$ [13] and $(NEt_4)_2[ReBr_3(CO)_3]$[14] were synthesized using published procedures. The ligands L^1, L^2 and L^3 were prepared from methods in the literature [11,15,16]. Solvents were purified and dried before use.

IR spectra were recorded in KBr pellets on a Perkin–Elmer spectrum 200 FTIR spectrophotometer. ^1H HMR spectra were recorded by using either a Bruker EMX-400 MHz or a Bruker AMX-300MHz NMR spectrometer. All chemical shifts are relative to TMS. Reversed phase HPLC separations were performed at a flow rate of 1 ml/min on a Phenomenex Luna 10m C18 column, gradient on an Agilent HP1100 LC-MSD (consisting of a quaternary pump, a degasser, a DAD detector, an 1100 MSD and a ChemStation for data acquisition and processing). Conductivity measurements (in units $cm^2\,\Omega^{-1}\,mol^{-1}$) were carried out with 10^{-3} M solutions in DMF at 293 K on a Phillips PW9509 digital conductometer. Elemental analyses were carried out by the Department of Chemistry at the University of Cape Town.

2.2. Synthesis

2.2.1. $[Re(CO)_3(L^1)]Br$ (1)

Under a nitrogen blanket, a mixture of $(NEt_4)_2[ReBr_3(CO)_3]$ (100 mg, 171 μmol) and L^1 (56 mg, 179 μmol) was dissolved in 10 ml of methanol. The solution was heated to reflux for an hour, and then 2 ml of water was added. The solution was allowed to cool to room temperature, and was left to stand for 3 days, after which a white precipitate was collected. It was washed with cold methanol and dried in an oven at 50 °C. Yield = 88%. *Anal.* Calc. for **1**: C, 28.11; H, 2.72; N, 12.61. Found: C, 28.23; H, 2.77; N, 12.55%. ^1H NMR (300 MHz): 3.61 (6H, s, $2\times CH_3$); 4.48 (4H, s, $2\times CH_2$); 7.06 and 7.23 (4H, 2xd, Ar-*H*) ppm. IR (cm^{-1}): *ν*(N–H) 2965; *ν*(C≡O) 1885, 2005, 2024; *ν*(C=N) 1621; *ν*(C=N–C=C) 1458. Conductivity (10^{-3} M) = 75.6.

2.2.2. $[Re(CO)_3(L^2)]Br$ (2)

The synthetic procedure was similar to that for **1** above, except that 1 ml of water was added, and the solution was allowed to stand at 5 °C to deposit crystals that were suitable for X-ray analysis. Yield = 92%. *Anal.* Calc. for **2**: C, 30.05; H, 3.19; N, 11.69. Found: C, 29.98; H, 3.21; N, 11.75%. ^1H NMR (D_2O, 300 MHz): 3.47 (6H, s, H(12), H(15)); 3.82 (2H, t, H(13)); 3.98 (2H, t, H(14)); 4.52 (4H, s, H(7), H(8)); 6.86 (2H, d, Ar–H(5), H10); 7.00 (2H, d, H(4), H(11)) (see Fig. 3 for labelling). IR (cm^{-1}): *ν*(C≡O) 1895, 1930, 2025; *ν*(C=N) 1624; *ν*(CH_2–O) 1263. Conductivity (10^{-3} M) = 79.2.

2.2.3. $[Re(CO)_3(L^3)]Br$ (3)

This procedure was the same as for **1**, except that the product crystallised out at room temperature in methanol, without addition of water. Yield = 78%. Anal. Calc. for **3**: C, 37.50; H, 2.70; N, 8.33; S, 4.77. Found: C, 37.44; H, 2.76; N, 8.49; S, 4.83%. ^1H NMR (400 MHz): 3.21 (4H, t, H(6)); 3.41 (4H, t, H(5)); 7.23 (2H, t, H(2)); 7.29 (2H, d, H(1)); 7.37 (2H, t, H(3)); 7.64 (2H, d, H(4)); 13.64 (2H, s, NH) ppm (see Fig. 2 for labelling). IR (cm^{-1}): *ν*(N–H) 3385; *ν*(C=N) 1618, *ν*(C≡O) 1909, 2004, 2027; *ν*(C=N–C=C) 1460. Conductivity (10^{-3} M) = 69.7.

2.3. X-ray crystallography

A single crystal of $[Re(CO)_3(L^2)]Br$ (**2**) was used for data collection on a Nonius Kappa CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Details of the crystal data and refinement are given in Table 1, with selected bond lengths and angles in Table 2. Unit cell and space group determinations were carried out in the usual manner [17]. The structure was solved by direct methods and refined by full-matrix least-squares procedures using SHELXL-97 [18]. Non-hydrogen atoms were refined anisotropically, and the hydrogen atoms were

geometrically constrained. An ORTEP view of **2** along with the atom numbering scheme is given in Fig. 3.

3. Results and discussion

3.1. Synthesis

Complexes **1**–**3** were prepared from methanolic solutions of $(NEt_4)_2[ReBr_3(CO)_3]$ and the ligands L^{1-3} in slight excess to obtain white solids as products in good yields. Small amounts of water were added for **1** and **2** to prevent the co-precipitation of NEt_4Br with the complexes. $(NEt_4)_2[ReBr_3(CO)_3]$ was rather used as starting material instead of the ideal and accessible $[Re(OH_2)_3(CO)_3]Br$, mainly to isolate and characterize the complexes at a macroscopic level. Attempts to isolate pure crystalline solids using $[Re(OH_2)_3(CO)_3]Br$ proved difficult due to the oily nature of the products that resulted under the same experimental conditions employed as above (reflux in methanol, followed by slow evaporation or cold crystallization).

However, the interaction of $[Re(OH_2)_3(CO)_3]Br$ and L^2 was studied in solution state by HPLC analyses with methanol as the mobile phase, but the chromatographic conditions were not optimised and the results are semi-quantitative. The formation of the complex (monitored using a UV detector at 254 nm) was verified by co-injection of the complex isolated at a microscopic level (RT = 2.6 min) with the reaction products. The starting materials, $[Re(OH_2)_3(CO)_3]Br$ and L^2 both showed the same retention time of 2.8 min. Interestingly, on mixing equimolar (4 μmol) amounts of these materials together in methanol in a vial and incubating at 50 °C for 15 min resulted in the formation of more than 60% of the desired complex (Fig. 1a). An almost quantitative formation was obtained on incubating the mixture at 60 °C for 1 h (Fig. 1b). This is an indication of the ease of substitution of the labile water molecules and the relevance of this ligand moiety of L^2 for coordination to $[M(OH_2)_3(CO)_3]Br$ ($M = {}^{99m}Tc$, ^{186}Re and ^{188}Re) in radiopharmaceutical preparations.

The conductivity measurements of **1**–**3** in DMF suggest 1:1 electrolytes. Conductivity readings between 65 and 90 $\Omega^{-1}\,mol^{-1}\,cm^2$ are consistent with 1:1 electrolytes in DMF [19]. Complexes **1** and **2** show a greater solubility in water than **3**, and all three complexes are soluble in polar organic solvents such as methanol, DMF, and DMSO.

3.2. Spectral characterization

In the infrared spectra of **1**–**3** three strong ν(CO) stretching bands appear in the region of 1880–2030 cm^{-1}, indicating the presence of the *fac*-$[Re(CO)_3]^+$ core [20]. Coordination of the imidazolyl nitrogens is indicated by the shifts of ν(C=N) from 1645 cm^{-1} in the free ligand (L^1) to 1620 cm^{-1} in **1**, and from 1655 to 1624 cm^{-1}, and from 1621 to 1618 cm^{-1} in **2** and **3**, respectively. This coordination-induced frequency change is typical for ring systems of this type [21,22].

In the ^1H NMR spectra of **1** and **2** the imidazole ring protons appear as two doublets, and are shifted markedly downfield relative to the free ligands (from 6.78 and 6.89 ppm to 7.06 and 7.23 ppm, respectively in **1**; and 6.76 and 6.91 ppm to 6.86 and 7.00 ppm in **2**). These signals also signify the symmetrical coordination of the imidazolyl groups to the *fac*-$[Re(CO)_3]^+$ core. The NH proton signal was absent in the spectrum of **1**, however, the coordination of the aliphatic amine nitrogen in **2** was confirmed by the significant shifts in H(13) and H(14) signals which appear as triplets at 2.89 and 3.68 ppm in the free ligand, and at 3.82 and 3.98 ppm in the complex. The signals of the methylene protons (H(7) and H(8) for **2**, see Fig. 3 for labelling) confirm the coordination of the amine nitrogen in both **1** and **2**, and appear as singlets at 3.82 and 3.81 ppm in the free ligands and at 4.48 and 4.52 ppm, respectively, in **1** and **2**. The ^1H NMR spectrum of **3** also confirms the tridentate coordination of L^3. The triplet signals of the methylene protons (H(6), see Fig. 2 for labelling) show a downfield shift from 3.04 ppm in the free ligand to 3.21 ppm, indicating the coordination of the sulfur atom; and the shift of the NH signal from 12.31 ppm in L^3 to 13.64 ppm in **3** is indicative of the coordination of the benzimidazole groups. The H(2) and H(3) proton signals appear as clearly resolved triplets at 7.23 and 7.37 ppm in the complex, but appeared as a multiplet in the free ligand (see Fig. 2); and this is also indicative of the coordination of the benzimidazolyl group.

3.3. Crystal structure

The crystallization of **2** in methanol/water gave crystals that were suitable for X-ray crystallography. The rhenium(I) ion lies in a distorted octahedral environment, with the amine and two imidazolyl nitrogen donors of L^2 in a facial arrangement, imposed by the *fac*-$[Re(CO)_3]^+$ core (Fig. 3). Ligand L^2 therefore acts as a neutral tridentate

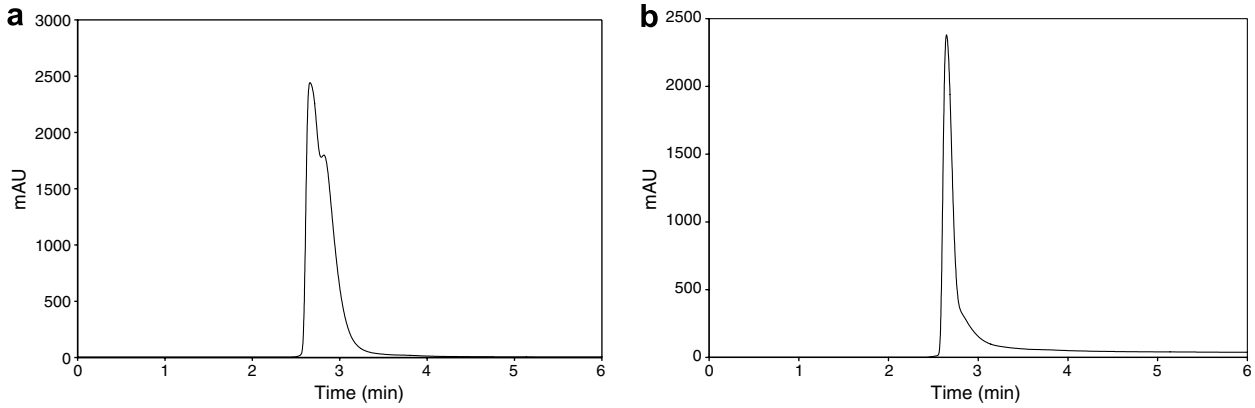

Fig. 1. The HPLC chromatograms of $[Re(OH_2)_3(CO)_3]Br + L^2$ after (a) 15 min at 50 °C (RT = 2.6 min for **2** and 2.8 for the unreacted $[Re(OH_2)_3(CO)_3]Br$ and L^2), and (b) after 1 h at 60 °C (RT = 2.6 min).

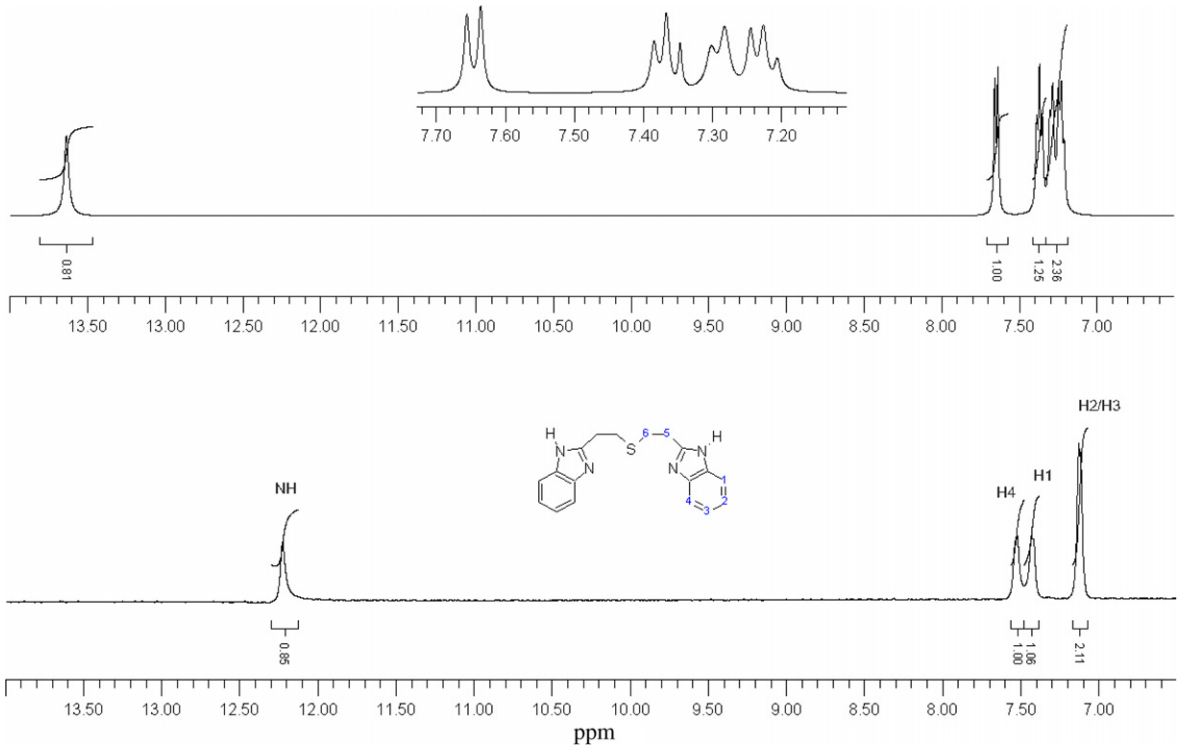

Fig. 2. The ^1H NMR overlay spectra of L^3 (bottom) and $[Re(CO)_3(L^3)]Br$ (**3**) (top).

chelate, with the alcohol pendant arm not interacting with the metal center. This terminal alcohol group presents possibilities to derivatize the ligand with, for example, carbohydrates, which have been shown to be selective in targeting tumour cells [23]. The closest contact of the discrete bromide counterion is with a hydrogen atom on C(7) (2.728 Å), and it is also involved in weak hydrogen-bonds with O(4)H, C(7)H and C(12)H.

The Re–C(carbonyl) bond distances (1.909–1.922(3) Å) are similar to those in related complexes [24–26]. The Re–N(3) distance of 2.302(3)Å is significantly longer than that of Re–N(1) and Re–N(4) (both at 2.154(3) Å), signifying the π-acidity of the imidazolyl ring systems compared to the σ basicity of the sp^3 hybridized amine nitrogen N(3). The two bite angles of the ligand L^2, N(1)–Re–N(3) (77.07(9)°) and N(3)–Re–N(4) (76.8(1)°), contribute significantly to the distortions in the molecule, resulting in the non-linear *trans* angles N(1)–Re–C(1) (174.8(1)°), N(3)–Re–C(2) (174.3(1)°) and N(4)–Re–C(3) (169.4(1)°). The bond angles around N(3) result in an approximately tetrahedral environment, with all the angles close to 109°.

The imidazole rings remain planar, as can be expected from an aromatic system, with torsion angles C(6)–N(1)–C(4)–C(5) = −0.6(4)° and C(9)–N(5)–C(10)–C(11) = 0.1(4)°, for example. The C(4)–C(5) and C(10)–C(11) bonds are double at 1.351(4) Å and 1.350(5) Å, respec-

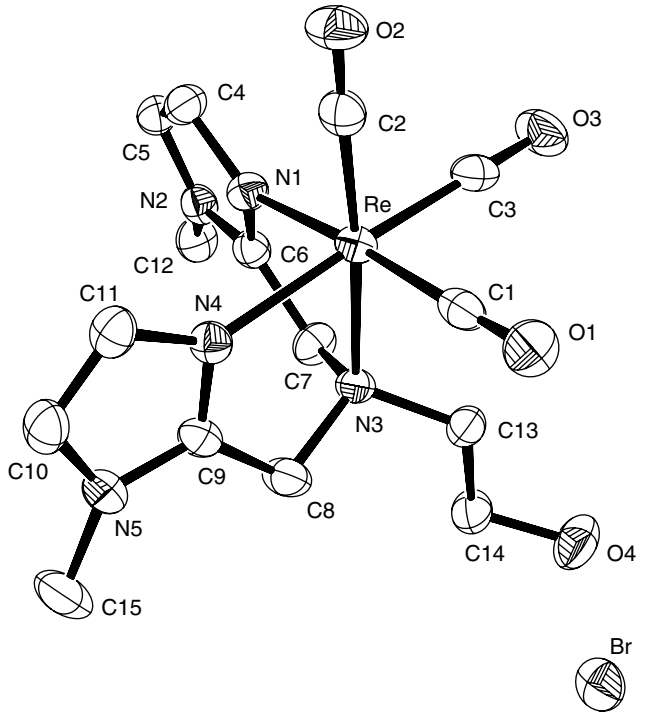

Fig. 3. An ORTEP view of $[Re(CO)_3(L^2)]Br$ (**2**), showing the atom labelling scheme and 50% probability ellipsoids.

tively, with the N(1)–C(4), N(2)–C(5), N(4)–C(11) and N(5)–C(10) all single bonds at an average of 1.380(5) Å. There are delocalized double bonds over the N(1)–C(6)–N(2) and N(4)–C(9)–N(5) parts of the imidazole rings, with the bonds N(1)–C(6) = 1.312(4), N(2)–C(6) = 1.346(4), N(4)–C(9) = 1.319(4) and N(5)–C(9) = 1.337(4) Å. The bond angles N(1)–C(6)–C(7) (123.8(3)°) and N(4)–C(9)–C(8) (121.9(3)°) illustrate the sp^2 hybridization of the imidazole carbon atoms C(6) and C(9).

There is nothing unusual about the backbone of the L^2 chelate. However, the angle N(3)–C(13)–C(14) = 115.4(2)° is bigger than expected for a sp^3 hybridized carbon. Significantly, the torsion angle N(3)–C(13)–C(14)–O(4) equals −175.6(3)°, with a strong hydrogen-bond (2.36(6) Å) between O(4)H and the bromide counterion.

In a previous study $(Et_4N)[Re(CO)_3Br_3]$ was reacted with tridentate N,N,N,-donor derivatives of benzimidazole, quinoline and tryptophan (N_3) to also give complex salts of the type *fac*-$[Re(CO)_3(N_3)]Br$ [27].

4. Supplementary material

CCDC 658077 contains the supplementary crystallographic data for **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK, fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

Available online 5 November 2007

Abstract

A series of novel octahedral nickel(II) dithiocarbamate complexes involving bidentate nitrogen-donor ligands (phen = 1,10-phenanthroline, bpy = 2,2′-bipyridine) or a tetradentate ligand (cyclam = 1,4,8,11-tetraazacycloteradecane) of the composition $[Ni(BzMetdtc)(phen)_2]ClO_4$ (**1**), $[Ni(Pe_2dtc)(phen)_2]ClO_4$ (**2**), $[Ni(Bzppzdtc)(phen)_2]ClO_4 \cdot CHCl_3$ (**3**), $[Ni(Bzppzdtc)(phen)_2](SCN)$ (**4**), $[Ni(BzMetdtc)(bpy)_2]ClO_4 \cdot 2H_2O$ (**5**), $[Ni(Pe_2dtc)(cyclam)]ClO_4$ (**6**), $[Ni(BzMetdtc)_2(cyclam)]$ (**7**), $[Ni(Bz_2dtc)_2(cyclam)]$ (**8**) and $[Ni(Bz_2dtc)_2(phen)]$ (**9**) (BzMetdtc = *N*,*N*-benzyl-methyldithiocarbamate(1-) anion, Pe_2dtc = *N*,*N*-dipentyldithiocarbamate(1-) anion, Bz_2dtc = *N*,*N*-dibenzyldithiocarbamate(1-) anion, Bzppzdtc = 4-benzylpiperazinedithiocarbamate(1-) anion), have been synthesized. Spectroscopic (electronic and infrared), magnetic moment and molar conductivity data, and thermal behaviour of the complexes are discussed. Single crystal X-ray analysis of **3** and **8** confirmed a distorted octahedral arrangement in the vicinity of the nickel atom with a N_4S_2 donor set. They represent the first X-ray structures of such type complexes. The catalytic influence of complexes **2**, **3**, **6**, and **7** on graphite oxidation was studied and discussed.

1. Introduction

Generally, it is well known that square-planar dithiocarbamates (dtc) of nickel(II) of the type $[Ni(dtc)_2]$ react very unreadily with nitrogen-donor ligands. To date, only a few data regarding this topic have been found in the literature. For instance, Coucouvanis and Fackler [1] studied reactions of the mentioned Ni(II)-dithiocarbamates with monodentate N-donor ligands and synthesized paramagnetic octahedral complexes $[Ni(H_2dtc)_2(\gamma\text{-pic})_2]$, $[Ni(H_2dtc)_2(py)_2]$ and $[Ni(HRdtc)_2(\gamma\text{-pic})_2]$ (R = chlorophenyl; γ-pic = γ-picoline, py = pyridine). Moreover, the authors also found that $[Ni(Et_2dtc)_2]$ (Et = ethyl) forms adducts with pyridine and γ-picoline at liquid nitrogen temperature. The same conclusion was also confirmed by Dingle [2]. On the contrary, Ramalingam and co-workers [3] were unsuccessful in the preparation of pyridine and ethylenediamine (en) adducts of $[Ni(Et_2dtc)_2]$, $[Ni(HEadtc)_2]$ and $[Ni(Ea_2dtc)_2]$ (H_2Eadtc = ethanoldithiocarbamic acid). They had only found that in the case of attempts to prepare the discussed adducts with ethylenediamine, the reactions led to the formation of $[Ni(en)_3]^{2+}[(dtc)_2]^{2-}$ and/or $[Ni(en)_3]S_2O_3$, respectively.

Formerly, as a continuation in our systematic study of dithiocarbamate transition metal complexes, especially of nickel, we have prepared and characterized a binuclear complex $\{[Ni(Ea_2dtc)_2]_2(\mu\text{-en})\}$ in which two nickel(II) ions

doi:10.1016/j.poly.2007.09.024

are connected via an ethylenediamine bridge [4]. We have also synthesized octahedral [Ni(Bz^{i}Prdtc)$_2$(cyclam)] and [Ni(Bz^{i}Prdtc)(cyclam)]X complexes, where cyclam = 1,4,8,11-tetraazacyclodecane, Bz^{i}Prdtc = *N*,*N*-benzylisopropyldithiocarbamate, (X = ClO_4, BPh_4) [5]. Moreover, the [Ni(Bz^{i}Prdtc)(cyclam)]$BPh_4 \cdot CHCl_3$ complex has been structurally characterized by single crystal X-ray analysis. In search for X-ray structures deposited within the Cambridge Structural Database [6] involving any transition metal in combination with a dithiocarbamate moiety and any N-donor ligand, and bearing a N_4S_2 donor set, ten molecular structures complying with the above-mentioned requirement have been found, i.e. four mononuclear Ru(II) complexes [7–9], three dinuclear Mo(V) complexes [10–12], two mononuclear Co(III) [13,14] complexes, and one mononuclear Ni(II) complex [15].

In this paper, we report the synthesis and characterization of novel octahedral Ni(II)-dithiocarbamate complexes **1**–**9** along with the single crystal X-ray structures of **3** and **8**. Moreover, the methods of thermal analysis have been used for the study of influence of selected complexes on graphite oxidation. This possible practical utilization of Ni(II)-dithiocarbamates have been also described and discussed recently in case of similar complexes [16,17].

2. Experimental

2.1. Materials

Dipentylamine (97%), 1-benzylpiperazine (98%), 1,4,8,11-tetraazacyclodecane (cyclam), nitromethane and K[PF_6] were supplied by FLUKA Co. 1,10-Phenanthroline (phen), 2,2′-bipyridine (bpy), $LiClO_4 \cdot 3H_2O$ and dibenzylamine (97%) were acquired from SIGMA ALDRICH Co. and *N*-benzylamine (97%) from LANCASTER Co. The remaining reagents were obtained from LACHEMA Co., all of p.a. purity.

2.2. Syntheses

2.2.1. [Ni(BzMetdtc)$_2$]

The complex was prepared by a slightly modified procedure described previously [18]. *N*-Benzylmethylamine (64 mL, 50 mmol) was added drop-wise into a solution of CS_2 (3 mL, 50 mmol) in ethanol (96%, 25 mL) with stirring. The reaction mixture was left to stand at room temperature for a short time period. Then, a warm solution of $NiCl_2 \cdot 6H_2O$ (5.9 g, 25 mmol) in distilled water (50 mL) was added. After the solution addition, the light green precipitate of [Ni(BzMetdtc)$_2$] appeared. It was filtered off, washed with warm water (until negative reaction on Cl^- ions) and dried at 40 °C under an infrared lamp. Yield: 72%. *Anal.* Calc. for $C_{18}H_{20}N_2NiS_4$: C, 47.9; H, 4.5; N, 6.2; Ni, 13.0; S, 28.4. Found: C, 48.0; H, 4.4; N, 5.9; Ni, 12.8; S, 28.7%.

2.2.2. [Ni(BzMetdtc)(phen)$_2$]ClO_4 (**1**) and [Ni(BzMetdtc)(bpy)$_2$]$ClO_4 \cdot 2H_2O$ (**5**)

To a suspension of finely powdered [Ni(BzMetdtc)$_2$] (0.23 g, 0.5 mmol) in an ethanol/chloroform mixture (30/30 mL), $NiCl_2 \cdot 6H_2O$ (0.11 g, 0.5 mmol), $LiClO_4 \cdot 3H_2O$ (0.16 g, 1 mmol) and bpy (0.31 g, 2 mmol) or phen (0.39 g, 2 mmol) were added in this sequence. The reaction mixture was stirred under reflux for 20 h and then filtered. The solid formed after 5 days. It was filtered off, washed with ethanol and diethyl ether, and recrystallized from a chloroform solution with activated carbon. The substance which formed, was filtered off, washed with diethyl ether and dried under an infrared lamp at 40 °C. Yields: 56% (**1**) and 73% (**5**). *Anal.* Calc. for $C_{33}H_{26}N_5NiS_2ClO_4$ (**1**): C, 55.4; H, 3.7; N, 9.8; Ni, 8.2; S, 9.0; Cl, 5.0. Found: C, 54.9; H, 3.4; N, 9.5; Ni, 8.3; S, 8.8; Cl, 4.8%. *Anal.* Calc. for $C_{29}H_{30}N_5NiS_2ClO_6$ (**5**): C, 49.6; H, 4.3; N, 10.0; Ni, 8.3; S, 9.1; Cl, 5.0. Found: C, 49.8; H, 4.2; N, 10.2; Ni, 8.2; S, 8.9; Cl, 4.7%.

2.2.3. [Ni(Pe$_2$dtc)(phen)$_2$]ClO_4 (**2**)

Phen (0.40 g, 2 mmol) and $LiClO_4 \cdot 3H_2O$ (0.16 g, 1 mmol) were added in this sequence to a suspension of finely powdered [Ni(Pe$_2$dtc)$_2$] [8] (0.52 g, 1 mmol) in methanol (15 mL). The reaction mixture was stirred under reflux until the colour of the solution turned to red (2 h). Then, the solution was filtered with activated carbon and the filtrate was left to stand at room temperature. After several hours, crystals formed in the mother liquor from which single crystals suitable for X-ray analysis were selected. The remaining portion of the crystalline product was filtered off, washed with methanol and diethyl ether and dried under an infrared lamp at 40 °C. Yield: 81%. *Anal.* Calc. for $C_{35}H_{38}N_5NiS_2ClO_4$ (**2**): C, 56.0; H, 5.1; N, 9.3; Ni, 7.8; S, 8.5; Cl, 4.7. Found: C, 56.1; H, 5.0; N, 9.3; Ni, 8.0; S, 8.3; Cl, 4.8%.

2.2.4. [Ni(Bzppzdtc)$_2$]

The complex was prepared by a slightly modified procedure described previously [18]. 1-Benzylpiperazine (8.7 mL, 50 mmol) was added drop-wise to a solution of CS_2 (3 mL, 50 mmol) in ethanol (96%, 25 mL) with stirring. A white precipitate, which formed during the above reaction, was dissolved by adding a solution of NaOH (1.9 g, 50 mmol) in water (10 mL). The resulting solution was filtered and a warm solution of $NiCl_2 \cdot 6H_2O$ (5.9 g, 25 mmol) in water (50 mL) was added with stirring to the filtrate. Subsequent steps are identical to those described for the preparation of [Ni(BzMetdtc)$_2$] (see Section 2.2.1). Yield: 81%. *Anal.* Calc. for $C_{24}H_{30}N_4NiS_4$: C, 51.3; H, 5.4; N, 10.0; Ni, 10.5; S, 22.8. Found: C, 51.0; H, 5.1; N, 9.8; Ni, 10.6; S, 22.5%.

2.2.5. [Ni(Bzppzdtc)(phen)$_2$]$ClO_4 \cdot CHCl_3$ (**3**)

A mixture of finely powdered [Ni(Bzppzdtc)$_2$] (0.39 g, 2 mmol), phen (0.39 g, 2 mmol), $NiCl_2 \cdot 6H_2O$ (0.11 g, 0.5 mmol) and $LiClO_4 \cdot 3H_2O$ (0.16 g, 1 mmol) were suspended in an ethanol/chloroform mixture (15/15 mL).

The reaction mixture was stirred under reflux until all components dissolved and the colour of the solution turned to dark red (*ca.* 4 h). Then, the solution was filtered with activated carbon and the filtrate was left to stand at room temperature for 7 days. During this period, a green substance appeared and it was separated by filtration and discarded. Subsequently, brown crystals suitable for X-ray analysis formed in the mother liquor after several days. They were filtered off, washed with hexane and dried under an infrared lamp at 40 °C. Yield: 56%. *Anal.* Calc. for $C_{37}H_{32}N_6NiS_2Cl_4O_4$ (**3**): C, 50.0; H, 3.6; N, 9.4; Ni, 6.6; S, 7.2; Cl, 15.9. Found: C, 50.4; H, 3.3; N, 9.5; Ni, 6.3; S, 7.0; Cl, 15.6%.

2.2.6. *[Ni(Bzppzdtc)(phen)$_2$](SCN) (**4**)*

Finely powdered [Ni(Bzppzdtc)$_2$] (0.28 g, 0.5 mmol) together with phen (0.39 g, 2 mmol) and $Ni(SCN)_2 \cdot 2H_2O$ (0.11 g, 0.5 mmol) were suspended in an ethanol/chloroform mixture (15/15 mL) and stirred under reflux for 4 h. After filtration of the reaction mixture with activated carbon, a light brown precipitate formed in the mother liquor in the course of a few days. The product was filtered off, washed with hexane and dried under an infrared lamp at 40 °C. Yield: 57%. *Anal.* Calc. for $C_{37}H_{31}N_7NiS_3$ (**4**): C, 61.0; H, 4.3; N, 13.5; Ni, 8.1; S, 13.2. Found: C, 60.4; H, 4.2; N, 13.2; Ni, 7.9; S, 13.5%.

2.2.7. *[Ni(Pe$_2$dtc)(cyclam)]ClO$_4$ (**6**)*

A suspension of finely powdered [Ni(Pe$_2$dtc)$_2$] (0.52 g, 1 mmol) in chloroform (5 mL) was mixed while stirring with 1,4,8,11-tetraazacyclodecane (0.2 g, 1 mmol) in 96% ethanol (5 mL) and $LiClO_4 \cdot 3H_2O$ (0.16 g, 1 mmol) in 96% ethanol (3 mL). The reaction mixture was stirred under reflux for 10 h. The resulting violet solution was filtered with activated carbon and left to stand at room temperature. After one week, a viscous product was obtained which was extracted with diethyl ether. After three days, the viscous product was formed again from which a powdered substance was isolated by means of diethyl ether. It was filtered off and dried under an infrared lamp at 40 °C. Yield: 46%. *Anal.* Calc. for $C_{21}H_{46}N_5NiS_2ClO_4$ (**6**): C, 42.7; H, 7.8; N, 11.8; Ni, 9.9; S, 10.8; Cl, 6.0. Found: C, 42.5; H, 7.5; N, 11.6; Ni, 9.8; S, 10.5; Cl, 5.5%.

2.2.8. *[Ni(BzMetdtc)$_2$(cyclam)] (**7**) and [Ni(Bz$_2$dtc)$_2$(cyclam)] (**8**)*

These compounds were obtained by the reaction of finely powdered [Ni(Bz$_2$dtc)$_2$] (0.6 g, 1 mmol) or [Ni(BzMetdtc)$_2$] (0.45 g, 1 mmol) in chloroform (5 mL) with 1,4,8,11-tetraazacyclodecane (cyclam) (0.2 g, 1 mmol) in 96% ethanol (10 mL). The mixture was stirred under reflux for 10 h and the resulting violet solution was filtered. During a few days, violet crystals, or a violet powder substance appeared. The product was recrystallized from chloroform by addition of methanol or hexane. The violet powder substance and violet crystals were isolated in the case of (**7**), and (**8**), respectively, which were washed with methanol or hexane and dried under an infrared lamp at 40 °C. Yields: 62% (**7**) and 58% (**8**). *Anal.* Calc. for $C_{28}H_{44}N_4NiS_4$ (**7**): C, 51.6; H, 6.8; N, 12.9; Ni, 9.0; S, 19.7. Found: C, 51.1; H, 7.2; N, 12.8; Ni, 8.9; S, 19.5%. *Anal.* Calc. for $C_{40}H_{52}N_6NiS_4$ (**8**): C, 59.8; H, 6.5; N, 10.4; Ni, 7.3; S, 16.0. Found: C, 59.3; H, 6.9; N, 10.5; Ni, 7.8; S, 15.7%.

2.2.9. *[Ni(Bz$_2$dtc)$_2$(phen)] (**9**)*

Phen (0.20 g, 1 mmol) and $LiClO_4 \cdot 3H_2O$ (0.16 g, 1 mmol) were added to a suspension of finely powdered [Ni(Bz$_2$dtc)$_2$] (0.60 g, 1 mmol) in methanol (15 mL) with stirring and the mixture was refluxed for 30 min. Then, a yellow substance formed. It was filtered off, washed with methanol, and dried under an infrared lamp at 40 °C. Yield: 85%. *Anal.* Calc. for $C_{42}H_{36}N_4NiS_4$ (**9**): C, 64.4; H, 4.6; N, 7.1; Ni, 7.5; S, 16.4. Found: C, 64.1; H, 4.2; N, 7.4; Ni, 7.3; S, 16.1%.

2.3. Physical measurements

The nickel content was determined by chelatometric titration using murexide as an indicator [19]. Chlorine content was determined by the Schöniger method [20]. CHNS analyses were performed on an EA 1108 analyzer (Fisons Instruments) instrument with satisfactory results for all the prepared complexes. Room temperature magnetic susceptibilities were measured by Faraday method on a laboratory designed instrument equipped with a Sartorius 4434 MP-8 microbalance, using Co[Hg(NCS)$_4$] as a calibrant. The correction for diamagnetism was performed using Pascal constants. Conductivities were measured with an LF 330/SET conductivity meter (WTW GmbH) at 25 °C. Diffuse-reflectance (45 000–9090 cm^{-1}) and DMFA solution (30 000–9090 cm^{-1}) electronic spectra were carried out on a Perkin–Elmer Lambda35 UV/Vis spectrometer. Nujol technique. IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer Spectrum One FT-IR spectrometer using the KBr technique. TG/DTA analyses were performed on an Exstar TG/DTA 6200 (Seiko Instruments, Inc.) with the heating rate of 2.5 °C min^{-1}, sample weight of 7–11 mg, and temperature range of 20–1050 °C.

The study the catalytic influence of the complexes **2**, **3**, **6**, and **7** on graphite was performed on a Netzsch STA 449C device with an α-Al_2O_3 crucible without a standard, heating rate of 10 °C min^{-1}, a sample weight of 4.4–5.1 mg, and in a dynamic atmosphere (air, 100 cm^3 min^{-1}). Samples for the study were prepared by the mixing of graphite (0.6 g, diameter of particles less than 0.1 mm, ash residue max. 0.2%, mass drying loss max. 0.2%) with an acetone solution (2 mL) of the appropriate complex (**2**, **3**, **6** and **7**; [Ni] = 2.5 mM). All samples were homogenized by means of stirring and drying at room temperature for 24 h. Each experimental result is represented as an arithmetic mean of three independent experiments. The kinetic parameters were calculated by a direct non-linear regression method [21].

2.4. X-ray structures

X-ray data collections for **3** and **8** were performed on an Oxford Diffraction Xcalibur™2 equipped with a Sapphire2 CCD detector using Mo Kα radiation at 105 K. The CRYSALIS program package (version 1.171.32.5, Oxford Diffraction) was used for data collection and reduction. The molecular structure of **3** was solved by direct methods [SHELXS-97] [22] and all non-hydrogen atoms were refined anisotropically on F^2 using full-matrix least-squares procedure [SHELXL-97] [23] with weight: $w = 1/[\sigma^2(F_o)^2 + (0.08P)^2 + 5.00P]$, where $P = ({F_o}^2 + 2{F_c}^2)/3$. All H-atoms of **3** were found in differential maps of electron density and their parameters were refined using the riding model with the C–H distance of 0.95, 0.99, and 1.00 Å, respectively, and with $U_{iso}(H) = 1.2U_{eq}(C)$. Additional calculations were performed using the DIAMOND program [24]. The molecular structure of **8** was solved by direct methods [SHELXS-97] and all non-hydrogen atoms were refined anisotropically on F^2 using full-matrix least-squares procedure [SHELXL-97] with weight: $w = 1/[\sigma^2(F_o)^2 + (0.03P)^2 + 5.00P]$. The structure of **8** consists of a centrosymmetric $Ni_{1/2}(Bz_2dtc)(cyclam)_{1/2}$ moiety which is connected with its second part by means of an inversion centre [symmetry code: [a] $-x, -y+1, -z+1$] lying in the middle of Ni1···Ni1a distance. The separation of Ni1···Ni1a is 2.3962(16) Å. The N2–N4 and C20 atoms of the moiety belonging to cyclam are disordered over two positions with the occupancy of 36% (for N2 and N4), 64% (for N3), 32% (for C20) and 33% (for C20b), and 14% (for N2a and N4a), 36% (for N3a), 15% (for C20a) and 20% (for C20c). Owing to the high degree of disorder, a relatively high number of restrains (≈91) have been applied during the structural refinement of **8**, and moreover, a few H-atoms were not included into the refinement. H-atoms were positioned theoretically and refined using the riding model with the C–H distances of 0.95 and 0.99 Å, and N–H distance of 0.93 Å. Crystal data and structure refinements for both the structures are given in Table 1.

3. Results and discussion

3.1. General characterization

Colours, magnetic moment, molar conductivity and spectral data of all the prepared complexes **1**–**9** are summarized in Table 2. All complexes are paramagnetic with values of effective magnetic moments ranging from 3.02 to 3.41 μ_{eff}/μ_B. These values indicate the presence of two unpaired electrons and show on octahedral geometry in the vicinity of the nickel atom [25]. The octahedral geometry can also be supported by the d–d transition bands revealed both in electronic diffuse-reflectance and DMFA solution spectra at 10280–11720, 16180–19960 and 21929–26230 cm^{-1} (see Table 3). They may be assigned to the $^3A_{2g} \rightarrow {}^3T_{2g}$ (ν_1), $^3A_{2g} \rightarrow {}^3T_{1g}$ (F) (ν_2), and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ (ν_3) transitions, respectively [26]. The maxima above 30000 cm^{-1} are probably caused by charge-transfer transitions. An ionic nature of complexes **1**–**6** may be supported by their molar conductivity data. It has been found that the complexes behave as 1:1 electrolytes in acetone or DMFA solution [27]. Their molar conductivity values are

in the interval of 111.1–148.6 S cm^2 mol^{-1}. On the other hand, the values obtained for complexes **7**–**9** clearly show on the fact that they are non-electrolytes (see Table 2). Characteristic IR bands and their assignment are given in Table 2.

3.2. IR spectral studies

For all complexes **1**–**9**, the bands belonging to ν(C···S) and ν(C···N) vibrations were observed at 983–999 cm^{-1}, and 1493–1542 cm^{-1}, respectively [28,29]. These values clearly characterize the dithiocarbamate moiety. Owing to the fact that intensive bands pertaining to ν(C···S) are not splitted into two components, we can conclude that dithiocarbamate anion is coordinated to nickel in a bidentate fashion. The presence of ClO_4^- in complexes **1**–**3**, **5** and **6**, as well as its ionic nature, can be supported by bands at 1084–1096 cm^{-1} (ν_3) and 622–626 cm^{-1}(ν_4) [30]. The peak recorded at 2083 cm^{-1} in the spectrum of **4** may be assigned to an asymmetric stretching vibration of an ionic bonded NCS^- anion [31]. The conclusions following from the interpretation of IR spectral data of [Ni(BzMetdtc)$_2$(cyclam)] (**7**) and [Ni(Bz$_2$dtc)$_2$(cyclam)] (**8**) are not unambiguous and at this point, and unfortunately, we cannot make decision if the bidentate manner of coordination of dithiocarbamate would be possible in the case of the discussed complexes. Generally, we may assume the tetradentate coordination of cyclam and the bidentate coordination of each of two dithiocarbamate ligands, and thus, to accept the non-ionic nature of the complexes as determined by conductivity measurements. It would point out that the coordination number for nickel would be eight, and evidently, this is not possible in the case of the ligand's combination used. However, the manner of ligand coordinations in **7** and **8** has been resolved by means of single crystal X-ray analysis and will be explained and discussed in greater details in the Section 3.3.

3.3. X-ray structures of $[Ni(Bzppzdtc)(phen)_2]ClO_4 \cdot CHCl_3$ (3) and $[Ni(Bz_2dtc)_2(cyclam)]$ (8)

The molecular structure of complex **3** and **8** is depicted in Figs. 1 and 2, respectively. Selected bond lengths and angles are given in Table 4. The molecular structure of $[Ni(Bzppzdtc)(phen)_2]ClO_4 \cdot CHCl_3$ (**3**) consists of the $[Ni(Bzppzdtc)(phen)_2]^+$ cation, perchlorate anion, and $CHCl_3$ as a solvent molecule. The nickel(II) ion is six-coordinated by four nitrogen atoms from two phen ligands and two sulphur atoms from 4-benzylpiperazinedithiocarbamate anion in a distorted octahedral geometry. The $[Ni(Bzppzdtc)(phen)_2]^+$ cation contains three different rings, i.e. the phen ligand containing N1 and N2 atoms (ring 1), phen ligand containing N3 and N4 atoms (ring 2) and a part of dithiocarbamate moiety together with the nickel atom involving a NiS_2C moiety (ring 3). All three rings are nearly planar with maximal deviation being 0.099(5) Å for C(8), 0.054(4) Å for C(20) and 0.074(4) Å for C(25) in rings 1–3, respectively [24]. The dihedral angle between rings 1 and 2, 1 and 3, and 2 and 3 are equal to 81.88(4)°, 88.65(4)°, and 86.02(4)°, respectively. The delocalization of π-electron density over the S_2CN moiety, as typical for a bidentate coordination of any dithiocarbamate anion to a transition metal, may be evident from the C–N and C–S bond length values (see Table 4). For comparison, mean values for C–N, C=S and C–S bonds, as found in Cambridge Structural Database (CSD Version 5.28), are 1.331 Å (valid for S_2CNR_2 moiety), 1.661 Å (valid for S_2CNR_2 moiety), and 1.753 Å (valid for R–S–R), respectively [6]. On the other hand, the C–S bond lengths in **3** and **8** are comparable to those as determined for bidentate coordinated dithiocarbamate moieties in case of Ni-complexes (the mean value in delocalized C–S bonds is 1.713 Å) [6]. The ionic nature of ClO_4^- in **3** can be seen from the Ni···Cl separation which is 6.5912(13) Å.

The structure of **8** consists of a centrosymmetric $Ni_{1/2}(Bz_2dtc)(cyclam)_{1/2}$ moiety which is connected with its second part by means of inversion centre [symmetry code: [a] $-x, -y+1, -z+1$]. Thus, the Ni1 atom and some atoms of cyclam adopt non-unit occupancy factors. The crystallographically independent part of the complex molecule is connected with its second centrosymmetric part through partially disordered cyclam ligand. The separation of Ni1···Ni1a is 2.3962(16) Å. The presence of the above-mentioned symmetry operation together with the disorder causes that each of the two parts of the nickel atom is six coordinated by four N atoms from cyclam and two S atoms from a bidentate coordinated dithiocarbamate ligand. Moreover, it also explains why may be coordinated the dithiocarbamate ligand to nickel via two S atoms. It also clearly supports conclusions following from IR data. Similarly as in **3**, a significant delocalization of π-electron density over the S_2CN moiety in **8**, as typical for a bidentate coordination of any dithiocarbamate anion to a transition metal, may be evident from the C–N and C–S bond length values (see Table 4).

In conclusion of this section, it is necessary to emphasize that the discussed structures represent the first examples of structurally characterized octahedral Ni-dithiocarbamate complexes bearing a combination of the ligands used.

3.4. TG and DTA studies

Thermal stability studies were performed for complexes **4**, **7**, **8** and **9**. The remaining compounds, i.e. those containing perchlorate anions, were not studied for safety reasons.

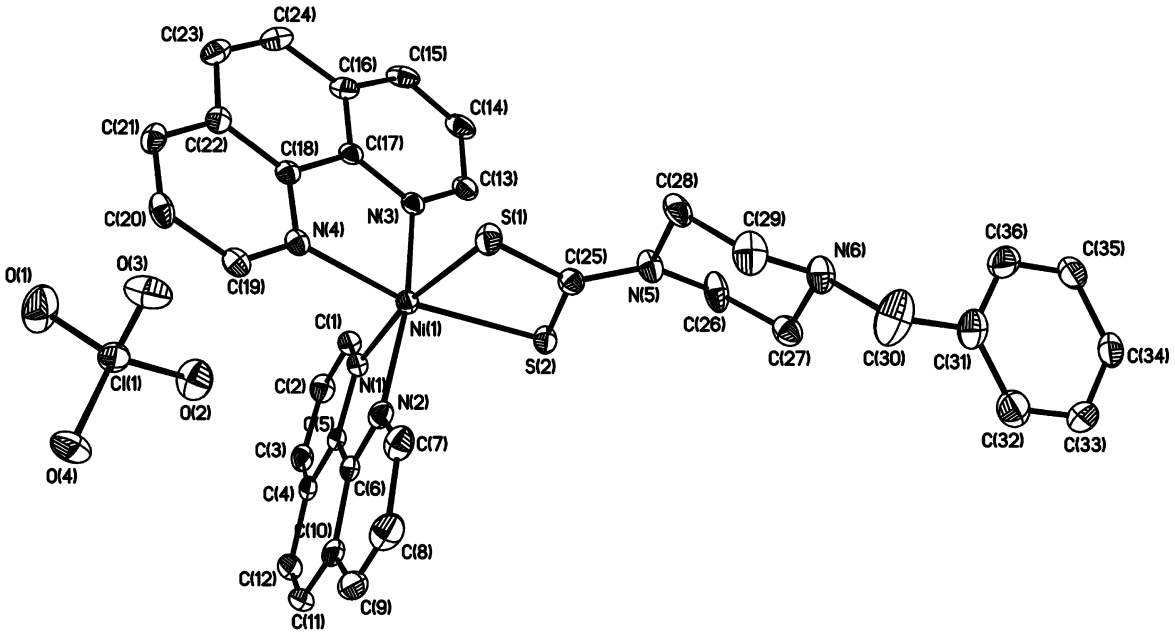

Fig. 1. The molecular structure of $[Ni(Bzppzdtc)(phen)_2]ClO_4 \cdot CHCl_3$ (**3**) with the atom labelling scheme. Thermal ellipsoids are drawn at the 40% probability level. H-atoms and $CHCl_3$ molecule have been omitted for clarity.

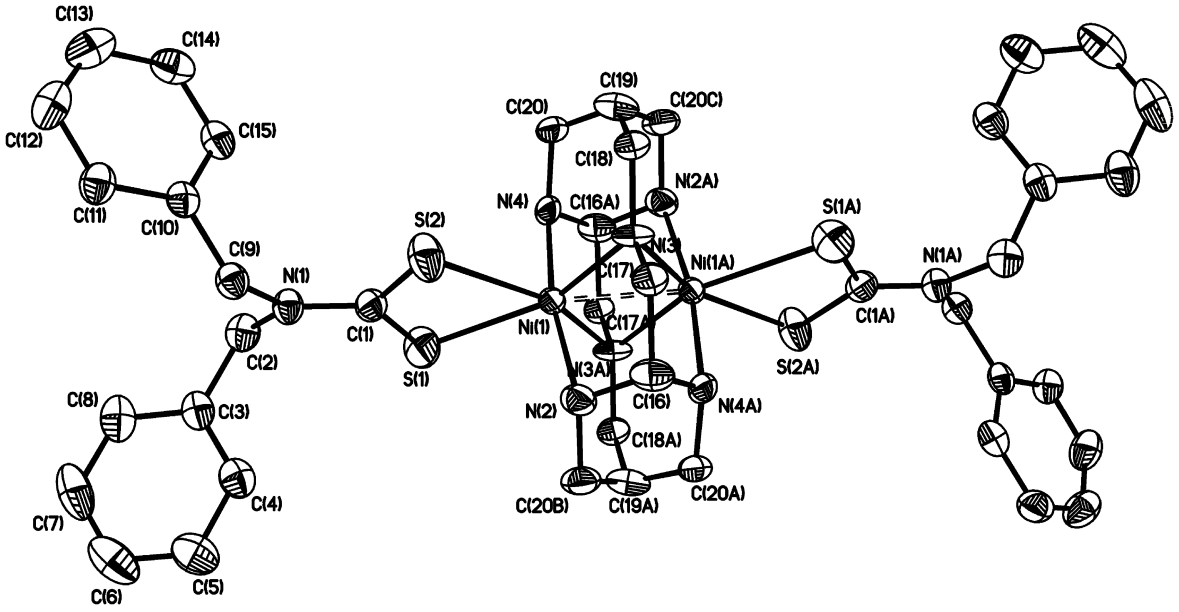

Fig. 2. The molecular structure of $[Ni(Bz_2dtc)_2(cyclam)]$ (**8**) with the atom labelling scheme, showing partially disordered cyclam ligand. Thermal ellipsoids are drawn at the 40% probability level. H-atoms and some of disordered cyclam atoms have been omitted for clarity.

Generally, we can note that the studied complexes are not comparatively thermally stable. They start to decompose within a relatively broad temperature interval of 134–193 °C. In the case of complexes **4**, **7** and **8**, the decays proceed without formation of thermally stable intermediates in several steps and are not finished even at 1050 °C. The decompositions are accompanied by several *exo*-effects on DTA curves in the case of the discussed complexes. The dominant *exo*-effects were observed at *ca.* 480 °C and it may be probably connected with the decomposition of the organic part of the complex. As for the thermal decay of **9**, the situation is a little bit different. That is why we will discuss it in greater detail. The complex **9** starts to decompose at 190 °C and the beginning of the decay is accompanied by significant decrease in the sample weight (*ca.* 56%). At the first stage of the decomposition, three small *endo*-effects can be seen on the DTA curve with the minimum at 236, 267, and 350 °C, respectively (see Fig. 3). The *endo*-effect with the maximum at 236 °C may be related to melting of the sample which was determined using melting point apparatus to be 234 °C. Next thermal decay proceeds in two waves and is finished at 705 °C. A sharp *exo*-effect with the maximum at 476 °C is clearly seen on the DTA curve, and is probably connected with the burning of the organic part of the molecule. Then, a plateau exists on the TG curve between 706 and 1050 °C. It has been found that the end-product of the thermal degradation is NiO (Δm found/calcd., 89.2/91.7%). The product was identified using the Bede ZDS program package [32] and PDF-2 database [33] as NiO (PDF-2 card number: 47–1049).

3.5. The catalytic study

For representative complexes **2**, **3**, **6** and **7**, their influence on graphite oxidation was studied. In quest to evaluate obtained results objectively, we also measured the oxidation of pure graphite (gr) and considered an impact of pure acetone (sample 0), as a solvent used for the preparation of the

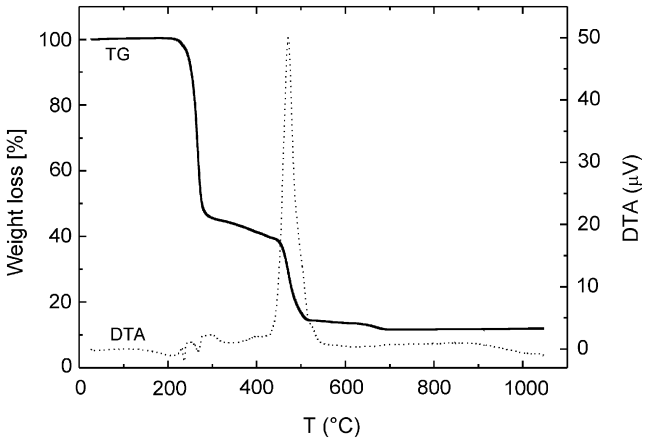

Fig. 3. TG and DTA curves for [Ni(Bz_2dtc)$_2$(phen)] (**9**).

samples containing the complexes, on the course of the oxidation. A comparison of the oxidation courses of the abovementioned samples is depicted in the form of their DTG curves in Fig. 4. Characteristic temperatures and kinetic parameters obtained from TG curves are summarized in Tables 5 and 6, respectively. It has been found that acetone application has no significant impact on the graphite oxidation. However, its presence causes only small decrease in temperature of the oxidation (*ca.* 10 °C) together with the decreasing of the activation energy of the process. The presence of the complexes even in applied trace amount (Ni content is about 100 mol ppm) has significant impact on the course of the graphite oxidation, however, this effect is practically independent on the quality of the admixture used, i.e. on the complexes themselves. In the presence of the complexes, the oxidation of graphite starts about 60 °C lower as compared to the sample containing graphite and acetone but the temperature relating to the termination of graphite oxidation is not influenced much. It follows that the width of the temperature interval in which the graphite oxidation with the samples proceeds is about 50 °C greater as compared to pure graphite. It can be seen from shapes of DTG curves that the presence of complexes causes bifurcating of the formerly simple DTG peak, thus graphite enriched by the complexes is oxidized in two steps in comparison of pure graphite.

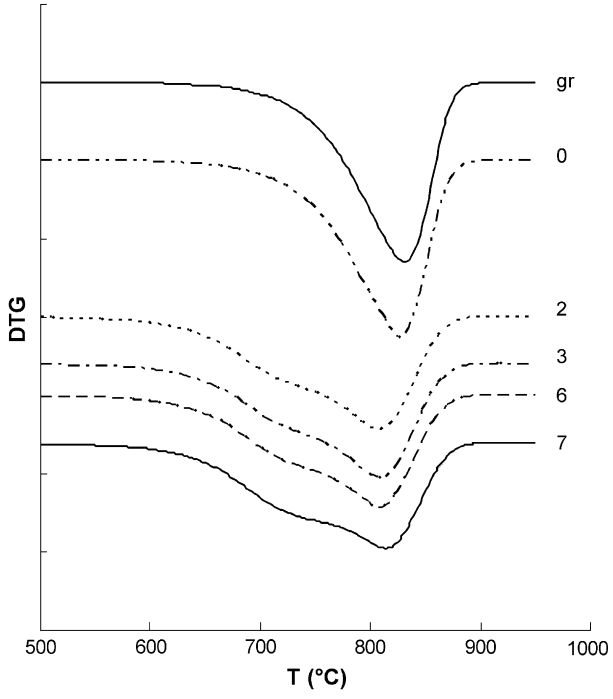

Fig. 4. DTG curves of graphite samples containing complexes **2**, **3**, **6** and, their comparison with DTG curves for pure graphite (gr) and pure acetone (0).

Table 5
Characteristic temperatures (°C) of graphite, acetone and their mixtures with complexes

Sample	T_p	T_m	T_k	$T_k - T_p$
Pure graphite (gr)	775	834	862	87
Pure acetone (0)	763	822	854	91
2	704	806	848	144
3	706	804	846	140
6	705	807	848	143
7	702	807	849	147

T_p – the beginning of oxidation; T_m – oxidation rate maximum; T_k – the end of oxidation.

Table 6
Kinetic parameters of oxidation of graphite, acetone and their mixtures with complexes

Sample	Step	n	A (s^{-1})	E (kJ mol^{-1})	w (%)
Pure graphite (gr)		0.7	9.50×10^8	241	
Pure acetone (0)		0.7	1.47×10^8	222	
2	I	1.0	5.36×10^5	160	53.66
	II	1.3	1.17×10^{17}	400	46.34
3	I	0.9	1.24×10^5	150	58.30
	II	1.1	1.35×10^{14}	341	41.70
6	I	1.0	6.00×10^5	162	60.91
	II	1.4	3.92×10^{20}	474	39.09
7	I	1.0	2.43×10^5	155	63.13
	II	1.2	3.23×10^{17}	412	36.87

n – reaction order; A – frequency factor, E – activation energy, w – mass of sample oxidized.

The calculated values of activation energies (E) and frequency factors (A) show that two observed oxidative steps of the enriched graphite differ significantly. A bigger portion of graphite is oxidized in the first step with activation energy values of 150–160 kJ mol^{-1} and frequency factors in the order of 10^5–10^6 s^{-1}. Significantly higher values of both parameters were determined for the second step. The reaction order was determined to be slightly higher for both steps ($n = 1.0$–1.4; see Table 6) as compared to free graphite ($n = 0.7$). It shows the fact that the kinetics of pure graphite is determined by its contracting volume ($n = 2/3$ corresponds to phase boundary controlled reaction, i.e. mechanism R3), however, the kinetics of oxidation of

graphite enriched by the complexes can be described better by the model of the first-order reaction.

Abstract

Six organotin compounds with 4,4′-thiodibenzenethiol (LH_2) of the type $R_nSnL_{4-n}SnR_n$ ($n = 3$: R = Me **1**, Ph **2**, $PhCH_2$ **3**, $n = 2$: R = Me **4**, Ph **5**, $PhCH_2$ **6**) have been synthesized. All compounds were characterized by elemental analysis, IR and NMR (^1H, ^{13}C, and ^{119}Sn) spectra. The structures of compounds **1**, **2**, **4**, **5** and **6** were also determined by X-ray diffraction analysis, which revealed that compounds **1** and **2** were monomeric structures, compounds **4**, **5** and **6** were centrosymmetric dinuclear macrocyclic structures, and all the tin(IV) atoms are four-coordinated. Furthermore, supramolecular structures were also found in compounds **1**, **2**, **4**, **5** and **6**, which exhibit one-dimensional chains, two-dimensional networks or three-dimensional structures through intermolecular C–H···S weak hydrogen bonds (WHBs), non-bonded Sn···S interactions or C–H···π interactions.

1. Introduction

Recently, developments in coordination chemistry have produced numerous macrocyclic compounds through the appropriate coordination geometry of organometallic compounds and certain organic ligands [1]. Furthermore, noncovalent weak molecular forces (such as hydrogen bonds, van der Waals forces, non-bonded contacts and C–H···π interactions), capable of connecting these metallic subunits into looser and more intriguing supramolecular infrastructures, have been widely investigated in structural biology, structural chemistry and the pharmaceutical sciences [2]. Among them organotin compounds are attracting more and more attention mainly due to their intriguing, and often complicated, architectures and topologies [3], and also for their potential industrial applications and biological activities [4]. More recently, flexible multidentate ligands have been employed in order to gain access to topologies not available from logical combinations of rigid building blocks. de Sousa, for example, has reported a series of diorganotin compounds based on the flexible 2,6-diacetylpyridine ligand [5], Silva et al. have reported some five- and six-membered chelate organotin mercaptide compounds [6], and in particular Baul and co-workers have reported a cyclic dinuclear organotin compound [7]. In our previous work, we have reported several novel organotin mercaptide compounds which were obtained from flexible multidentate ligands, such as pentacoordinated compounds with 2,5-dithiobiurea [8], tetranuclear or dinuclear monomers or three-dimensional polymers with *meso*-2,3-dimercaptosuccinic acid [9]. To continue our research on organotin(IV) complexes in this field, we choose another interesting ligand: 4,4′-thiodibenzenethiol.

doi:10.1016/j.poly.2007.09.033

This ligand was chosen for the following reasons: first, it has two thiol groups so it should form strong covalent bonds with an organotin moiety; second, the conformational flexibility of this ligand will allow for the formation of various and interesting molecular and supramolecular structures; third, 4,4′-thiodibenzenethiol can bond to more than one organotin moiety in one discrete molecule, which will increase the opportunities for supramolecular assembly from these compounds through intermolecular weak interactions. Here, we report the syntheses and characterizations of six organotin compounds constructed from 4,4′-thiodibenzenethiol (LH_2). With a 1:2:2 molar ratio of LH_2:R_3SnCl:EtONa three dinuclear monomeric compounds (**1**–**3**) of the type $R_3SnLSnR_3$ [R = Me **1**, Ph **2**, $PhCH_2$ **3**] were obtained, and with a 1:1:2 molar ratio of LH_2:R_2SnCl_2:EtONa three dinuclear macrocyclic compounds (**4**–**6**) of the type $(R_2SnL)_2$ [R = Me **4**, Ph **5**, $PhCH_2$ **6**] were obtained.

2. Experimental

2.1. Materials and measurements

Trimethyltin chloride, triphenyltin chloride, dimethyltin dichloride, diphenyltin dichloride and 4,4′-thiodibenzenethiol are commercially available, and they were used without further purification. Dibenzyltin dichloride and tribenzyltin chloride were prepared by a standard method reported in the literature [10]. The melting points were obtained with a Kofler micro-melting point apparatus and were uncorrected. Infrared-spectra were recorded on a Nicolet-6700 spectrophotometer using KBr discs and sodium chloride optics. ^1H, ^{13}C and ^{119}Sn NMR spectra were recorded on a Varian Mercury Plus 400 spectrometer operating at 400, 100.6 and 149.2 MHz, respectively. The spectra were acquired at 298 K; ^{13}C spectra are broadband proton decoupled. The chemical shifts are reported in ppm with respect to the references and are stated relative to external tetramethylsilane (TMS) for ^1H and ^{13}C NMR, and neat tetramethyltin for ^{119}Sn NMR. Elemental analyses were performed with a PE-2400II apparatus.

2.2. X-ray crystallography

Crystals were mounted in Lindemann capillaries under nitrogen. All X-ray crystallographic data were collected on a Bruker SMART CCD 1000 diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 298(2) K. A semi-empirical absorption correction was applied to the data. The structures were solved by direct methods using SHELXS-97 and refined against F^2 by full-matrix least squares using SHELXL-97. Hydrogen atoms were placed in calculated positions. Crystal data and experimental details of the structure determinations are listed in Table 1.

2.3. Syntheses of the complexes *1*–*6*

2.3.1. *$[(CH_3)_3SnSC_6H_4]_2S$ (1)*

The reaction was carried out under a nitrogen atmosphere. 4,4′-Thiodibenzenethiol (0.250 g, 1 mmol) and sodium ethoxide (0.136 g, 2 mmol) were added to benzene (20 ml) in a Schlenk flask and stirred for 5 min. Trimethyltin chloride (0.399 g, 2 mmol) was added to the reaction mixture, which was then stirred for 12 h at 40 °C. After filtration the solvent was gradually removed by evaporation under vacuum until a solid product was obtained. The solid was recrystallized from ether-petroleum and colorless crystals were formed. Yield: 86%. M.p. 97–99 °C. *Anal.* Calc.

2.3.3. $[(PhCH_2)_3\ SnSC_6H_4]_2S$ (3)

Compound **3** was prepared in the same way as that for compound **1**. Yield: 80%. M.p. 100–102 °C. *Anal.* Calc. for $[(PhCH_2)_3SnSC_6H_4]_2S$: C, 62.81; H, 4.88. Found: C, 62.96; H, 4.74%. IR (KBr, cm^{-1}): ν(Sn–C), 551; ν(Sn–S), 322. ^1H NMR ($CDCl_3$, ppm): δ 2.4 (s, 6H), 6.7–7.4 (m, 19H). ^{13}C NMR ($CDCl_3$, ppm): δ 22.7 ($^1J(^{119}Sn–^{13}C) = 440.3$ Hz), 124.7, 124.8, 127.9–128.1, 128.7–129.1, 130.9–131.5, 132.4, 134, 135.8–135.9, 139.4. ^{119}Sn NMR ($CDCl_3$, ppm): 37.7.

2.3.4. $[(CH_3)_2Sn(SC_6H_4)_2S]_2$ (4)

The reaction was carried out under a nitrogen atmosphere. 4,4′-Thiodibenzenethiol (0.250 g, 1 mmol) and sodium ethoxide (0.136 g, 2 mmol) were added to benzene (20 ml) in a Schlenk flask and stirred for 5 min. Dimethyltin dichloride (0.219 g, 1 mmol) was added to the reaction mixture, which was then stirred for 12 h at 40 °C. After filtration, the solvent was gradually removed by evaporation under vacuum until a solid product was obtained. The solid was recrystallized from ether–petroleum and colorless crystals were formed. Yield: 89%. M.p. 199–201 °C. *Anal.* Calc. for $[(CH_3)_2Sn(SC_6H_4)_2S]_2$: C, 42.34; H, 3.55. Found: C, 42.10; H, 3.32%. 2.3.5. $[(Ph)_2Sn(SC_6H_4)_2S]_2$ (5)

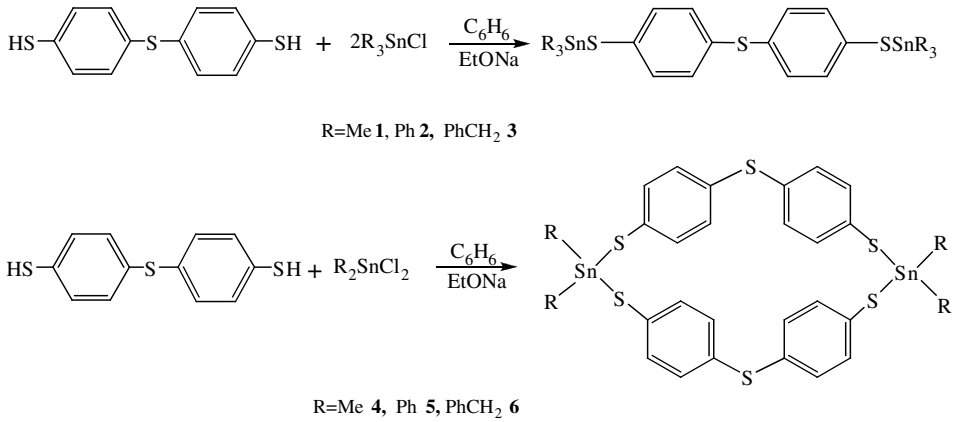
Compound **5** was prepared in the same way as that for compound **4**. Yield: 81%. M.p. 160–162 °C. *Anal.* Calc. for $[(Ph)_2Sn(SC_6H_4)_2S]_2$: C, 55.30; H, 3.48. Found: C, 55.05; H, 3.20%. IR (KBr, cm^{-1}): ν(Sn–C), 558; ν(Sn–S), 305. ^1H NMR ($CDCl_3$, ppm): δ 6.8–7.5 (m, 18H). ^{13}C NMR ($CDCl_3$, ppm): δ 128.8 ($^1J(^{119}Sn–^{13}C) = 503.3$ Hz), 129.1, 129.4, 130.2, 131.1, 131.8, 133.8, 135.8, 136.0, 136.7, 136.9, 137.5. ^{119}Sn NMR ($CDCl_3$, ppm): −61.2.



2.3.6. $[(PhCH_2)_2Sn(SC_6H_4)_2S]_2$ (6)

Compound **6** was prepared in the same way as that for compound **4**. Yield: 79%. M.p. 143–145 °C. *Anal.* Calc. for $[(PhCH_2)_2Sn(SC_6H_4)_2S]_2$: C, 56.84; H, 4.04. Found: C, 56.62; H, 3.81%. IR (KBr, cm^{-1}): ν(Sn–C), 530; ν(Sn–S), 320. ^1H NMR ($CDCl_3$, ppm): δ 2.5 (s, 4H), 6.7–7.4 (m, 18H). ^{13}C NMR ($CDCl_3$, ppm): δ 26.0 ($^1J(^{119}Sn–^{13}C) = 443.8$ Hz), 27.9, 125.4, 128.0–128.4, 128.8–128.9, 130.7–131.4, 134.9, 135.8, 136.4, 136.5, 137.2. ^{119}Sn NMR ($CDCl_3$, ppm): 23.0.

3. Results and discussion

3.1. Syntheses

The reactions of triorganotin(IV) chloride with 4,4′-thiodibenzenethiol in a 2:1 stoichiometry and diorganotin(IV) dichloride with 4,4′-thiodibenzenethiol in a 1:1 stoichiometry, depending on the nature of the starting acceptor and reaction conditions, afforded air-stable compounds. The syntheses procedures are shown in Scheme 1.

Scheme 1.

3.2. IR spectra

The IR spectra show that the strong absorption at 2560 cm^{-1} in the free ligand due to the –SH group is absent in the spectra of all the compounds **1–6**, and at the same time a new absorption appears in the region 305–322 cm^{-1}. All these values are located within the range for Sn–S vibrations observed in common organotin thiolate derivatives (300–400 cm^{-1}) [11], consequently, they can be assigned to ν(Sn–S).

3.3. NMR spectra

The ^{1}H NMR data show that the signal of the –SH proton in the spectrum of the ligand is absent in all of the compounds, indicating the removal of the –SH proton and the formation of Sn–S bonds. The $^{2}J_{SnH}$ values of compounds **1** and **4** are 27.2 Hz and 83.2 Hz, which are similar to those previously reported for four-coordinated tetrahedral tin(IV) adducts [12]. The ^{13}C NMR spectra of all the compounds show a significant downfield shift of all carbon resonances, compared with the free ligand.

The ^{119}Sn NMR data show that compounds **1–6** have only one signal (100.4, −60.5, 37.7, 86.4, −61.2 and 23 ppm, respectively), they are all well in accordance with values that have been reported in the literature which lie in the range from +200 to −60 ppm [13].

3.4. X-ray crystallographic studies

3.4.1. Crystal structures of *1* and *2*

The molecular structures of compounds **1** and **2** are illustrated in Figs. 1 and 3, respectively. Selected bond lengths (Å) and angles (°) are listed in Table 2.

X-ray crystal structure analysis reveals that compounds **1** and **2** are monomeric with one ligand bonding to two tin atoms through Sn–S bonds. Each of the tin atoms is four-coordinated. Distortion from strict tetrahedral coordination is partly because of the bonding variance. The four primary bonds to Sn are three methyl groups and one sulfur atom for **1** and three phenyl groups and one sulfur atom for **2**. The Sn–C bond lengths are consistent with those reported in other triorganotin derivatives [14]. The

Sn–S bonds lengths [the Sn–S bond lengths are between 2.43(6) and 2.44(4) Å] are slightly less than the sum of the covalent radii of Sn and S (2.44 Å) [15].

Compounds **1** and **2** exhibit interesting intermolecular interactions as shown in Figs. 2, 4 and 5: the molecules of **1** are connected through C(15)–H(15)···S(2) (C···S, 3.85 Å; H···S, 2.94 Å; C–H···S, 158.5°) and C(3)–H(3)···S(1) WHBs (C···S, 3.91 Å; H···S, 2.99 Å; C–H···S, 175.9°) into a two-dimensional network in the *bc* plane. In compound **2**, there are two loose two-dimensional networks through different WHBs in different directions: one that consists of discrete molecules connected through C(24)–H(24)···S(3) (C···S, 3.70 Å; H···S, 2.98 Å; C–H···S, 135.1°) and C(28)–H(28)···S(2) (C···S, 3.80 Å; H···S, 2.99Å; C–H···S, 146.3°) WHBs (Fig. 4) in the *bc* plane, and another that is connected through C(30)–H(30)···π (37–42) [H···π (centroid), 3.51 Å; C–H···π (centroid), 122.0°] and C(46)–H(46)···π (37–42) [H···π (centroid), 3.38 Å; C–H···π (centroid), 138.1°] interactions (Fig. 5) along the [1 1 $\bar{1}$] and [$\bar{1}$ 1 0] directions.

The values for the C–H···S WHB are longer than an intramolecular C–H···S WHB in (r-2, c-4)-3-benzyl-2,4,5,5-tetraphenyl-1,3-thiazolidine (C···S, 3.04 Å; H···S, 2.55 Å and C–H···S, 110°) [16], but they are closely in agreement with values that have been reported in the literature [15,17], whilst the parameters for the C–H···π interactions in the compound are in agreement with those that have been reported in the literature [17,18].

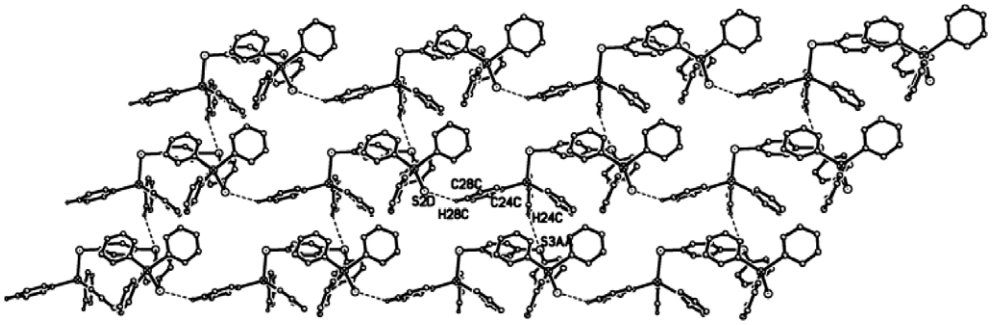

Fig. 4. Two-dimensional network of compound **2** by C–H···S WHBs along the *bc* plane, unattached hydrogen atoms have been removed for clarity.

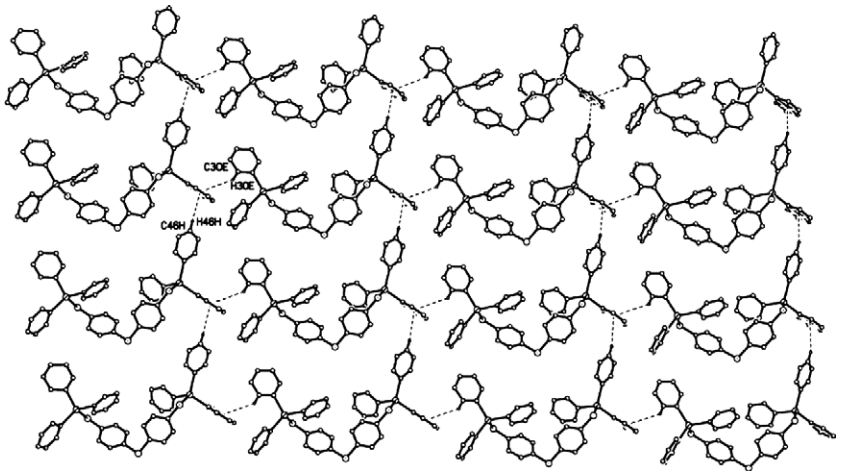

Fig. 5. Two-dimensional network of compound **2** connected through C–H···π interactions along the [1 1 $\bar{1}$] and [$\bar{1}$ 1 0] directions, unattached hydrogen atoms have been removed for clarity.

*3.4.2. Crystal structure of **4**, **5** and **6***

Perspective view of the molecular structures of compounds **4**, **5** and **6** are illustrated in Figs. 6, 8 and 10, respectively. Selected bond lengths (Å) and angles (°) are listed in Table 3.

Compounds **4**, **5** and **6** all proved to be centrosymmetric dinuclear macrocyclic compounds with 4,4′-thiodibenzenethiol bridging the adjacent tin atoms with a twenty-four member $Sn_2S_6C_{16}$ ring, and the ring can be valued by the transcyclic distances (Sn(1)–Sn(1)# = 12.51 Å and C(2)–

*[(Ph)$_2$Sn(SC$_6$H$_4$)$_2$S]$_2$ (**5**)*			
Sn(1)–C(13)	2.12(6)	Sn(1)–S(3)	2.42(19)
Sn(1)–C(19)	2.13(5)	Sn(1)–S(2)	2.42(18)
C(13)–Sn(1)–C(19)	120.9(2)	C(13)–Sn(1)–S(2)	107.8 (15)
C(13)–Sn(1)–S(3)	112.2(17)	C(19)–Sn(1)–S(2)	101.1(16)
C(19)–Sn(1)–S(3)	107.5(19)	S(3)–Sn(1)–S(2)	105.7(7)
*[(PhCH$_2$)$_2$Sn(SC$_6$H$_4$)$_2$S]$_2$ (**6**)*			
Sn(1)–C(20)	2.15(6)	Sn(1)–S(2)	2.41(18)
Sn(1)–C(13)	2.15(6)	Sn(1)–S(3)	2.43(19)
C(20)–Sn(1)–C(13)	115.7(2)	C(20)–Sn(1)–S(3)	114.4(16)
C(20)–Sn(1)–S(2)	108.0(17)	C(13)–Sn(1)–S(3)	106.7(19)
C(13)–Sn(1)–S(2)	111.5(19)	S(2)–Sn(1)–S(3)	99.4(7)

C(2)# = 3.89 Å for **4**; Sn(1)–Sn(1)# = 10.42 Å and C(8)–C(8)# = 6.75 Å for **5**; Sn(1)–Sn(1)# = 11.42 Å and C(2)–C(2)# = 4.44 Å for **6**). The units are [(CH$_3$)$_2$SnL], [(Ph)$_2$SnL] and [(PhCH$_2$)$_2$SnL], respectively, in which the primary bonds of the ligand to tin occur through the two sulfur atoms. To the best of our knowledge, dinuclear macrocyclic compounds in common organotin derivatives of thionate have so far only rarely been reported [19].

Each of the tin atoms in compounds **4**, **5** and **6** has a distorted tetrahedral coordination. The four primary bonds to Sn are two Sn–C and two Sn–S bonds. The Sn–C bond lengths are consistent with those found in compounds **1** and **2**. The Sn–S bond lengths are 2.42(17) Å [Sn(1)–S(2)], 2.45(2) Å [Sn(1)–S(3)#1] (#1 = $-x+2, -y+1, -z+1$) for **4**; 2.42(19) Å [Sn(1)–S(3)], 2.42(18) Å [Sn(1)–S(2)] for **5** and 2.41(18) Å [Sn(1)–S(2)], 2.43(19) Å [Sn(1)–S(3)] for **6**, similar to those found in compounds **1** and **2**. Distortion from a strict tetrahedral coordination is partly because of the bonding variance. The deviation from an ideal tetrahedron is manifested by the bond angles (see Table 3), all of which deviate from the idea value of 109.5°.

Analyses of the supramolecular infrastructure of the compounds **4**, **5** and **6** reveal that weak intermolecular non-bonded Sn···S contacts, C–H...S and C–H···π WHBs play important roles in the supramolecular arrangements. The C–H···π interactions can also be viewed as an edge-to face π–π interaction [18d].

The supramolecular structure of compound **4** is a two-dimensional network in the *bc* plane, as shown in Fig. 7, in which the discrete molecules are connected through intermolecular C–H···S (C···S, 3.62–3.75 Å; H···S, 2.87–2.96 Å; C–H···S, 135.0–140.6°) WHBs. This loose structure is further stabilized by non-bonded Sn(1)···S(3) interactions. The Sn(1)···S(3) distance (3.700 Å) is shorter than that in compounds (PhCH$_2$)$_2$Sn(SC$_5$H$_5$N$_2$)$_2$ and (PhCH$_2$)$_2$SnCl(SC$_5$H$_5$N$_2$) [20], and also shorter than the sum of the Van der waals radii of Sn and S (4.0 Å) [21].

In compound **5**, an intermolecular C(5)–H(5)···S(3) (C···S, 3.65Å; H···S, 2.97 Å; C–H···S, 130.3°) WHB connects the discrete molecules into a linear chain, as shown in Fig. 9.

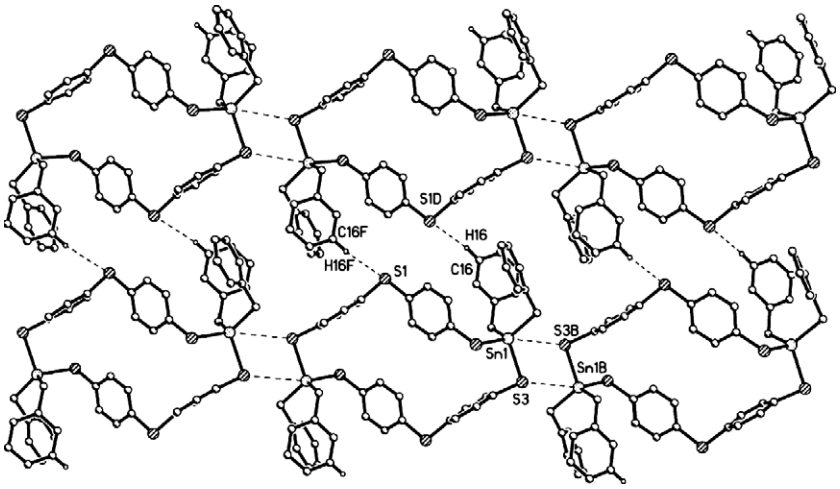

Fig. 11. Two-dimensional network of compound **6** connected through C–H···S WHBs and non-bonded Sn···S contacts, unattached hydrogen atoms have been removed for clarity.

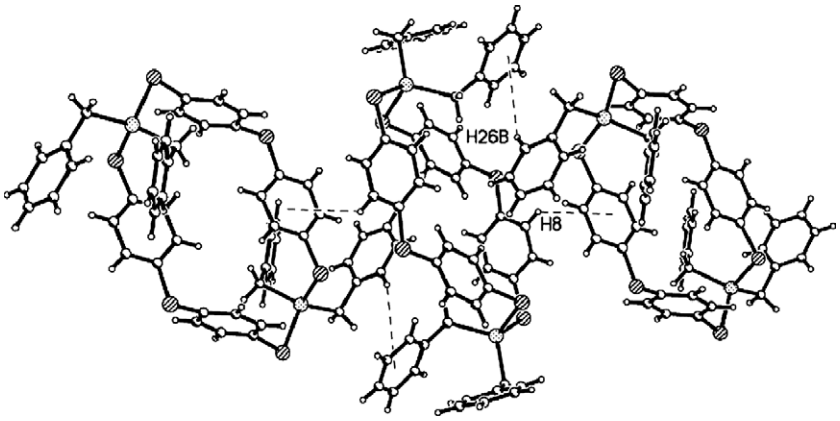

Fig. 12. One dimensional chain of compound **6** connected through C–H···π interactions along the [1 1 1] direction.

In compound **6**, the two-dimensional network in the *ac* plane (as shown in Fig. 11) is connected by C–H···S WHBs (C···S, 3.81Å; H···S, 2.95 Å; C–H···S, 153.6°) and non-bonded Sn···S interactions, and the linear chain along the [1 1 1] direction is connected by C–H···π [H···π (centroid), 3.36–3.51 Å; C–H···π (centroid), 131.5–136.3°] interactions at the same time (as shown in Fig. 12), forming a three-dimensional structure.

4. Conclusion

4,4′-Thiobisbenzenethiol has been shown to be able to form monomeric compounds with triorganotin moieties, and also to form dinuclear macrocyclic compounds with diorganotin moieties due to the flexibility of the ligand and the nature of the starting acceptor. The supramolecular structures described in this paper demonstrate that weak intermolecular interactions have enormous potential for assembling discrete molecular systems into one-dimensional chains, two-dimensional networks or three-dimensional structures, in which the subunits are organometallic compounds.

The current study also provides aids in the fundamental understanding of molecular recognition, and insight into the interpretation of supramolecular aggregation in crystal engineering.

5. Supplementary material

CCDC 636269, 636268, 636266, 636267, 636265 contains the supplementary crystallographic data for **1**, **2**, **4**, **5** and **6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Abstract

The synthesis of a new series of impregnated metal oxides with different Fe/Si ratios (0.5, 1 and 2) was obtained by the direct precipitation method. Physico-chemical properties and molecular formula of the obtained products were identified with different analytical techniques, such as chemical stability, XRD, IR, elemental and thermal analyses. Thermal kinetic parameters, such as order (n) and activation energy (E_a), of the solid-state phase transformations of the first dehydration process have been studied for the obtained materials from DTA thermograms. The ion exchange applications and the sorption properties of the materials with some radioactive nuclides have been studied, depending on the Fe/Si molar ratios. These investigations indicated that the ion exchange capacities as well as the selectivities of different materials towards the studied nuclides show the order $Co^{2+} > Cs^{+} > Na^{+}$ at a certain pH.

1. Introduction

Ion exchange technologies are widely used for water and waste treatment, in hydrometallurgy, biochemistry, medicine, environmental protection, etc. Among various components, oxides and hydrous oxides (including oxyhydroxides and hydroxides) of Fe, Al and Si are important sorbents because of their abundance in the natural geologic environment and their high sorption capacity [1–3]. The sorption characteristics of the materials, however, are not easy to describe unambiguously, because they are controlled by a number of complicated physical and chemical interfacial properties. Tochiyama et al. reported [4] that amorphous-$Fe_2O_3 \cdot 3.5H_2O$ was obtained when NH_4OH was used as a precipitating agent while α-$FeOOH \cdot 0.6H_2O$ was obtained when NaOH was used for precipitation. Also, the same authors studied the sorption of Np(V) on various iron oxides and hydrous iron oxides [5]. Qualitative evidence for the chemical interaction of silicic acid with iron(III) in dilute aqueous solution has been reported earlier [6], but neither information regarding the nature of the interaction nor that of the chemical species formed is available. In 1965 Weber and Stumm [7] reported UV absorption data used to study the equilibrium relationships for complex formation between Fe(III) (in dilute acidic aqueous solutions of $HClO_4$) and orthosilicic acid. The data indicated that Fe^{3+} forms relatively stable $FeSiO(OH)_2^{2+}$ complexes with $Si(OH)_4$ according to the equation:

$$Fe^{3+} + Si(OH)_4 === FeSiO(OH)_2^{2+} + H^{+} \quad (1)$$

Recently, a method for preparing iron(III)-based binary oxide adsorbents in a granulated form for arsenic removal was studied [8]. The addition of silica enhanced the granulated adsorbent strength but reduced the arsenic adsorption capacity. Several iron(III) oxides, such as amorphous hydrous ferric oxide (FeOOH), poorly crystalline hydrous ferric oxide (ferrihydrite) and goethite (α-FeOOH), are

doi:10.1016/j.poly.2007.09.034

promising adsorptive materials for removing both As(V) and As(III) from aqueous solutions [9–13]. However, most iron(III) oxides are available only as fine powders or are generated in situ as gels or suspensions in aqueous solution. These forms of iron(III) oxides retain their strong affinities for As(V) and As(III), but are limited to reactor configurations incorporating large sedimentation and filtration units, which cause difficulty in solid/liquid separation [14]. Thus, they are not suitable for column adsorption in water and waste water treatment. Furthermore, iron(III) oxide alone is not suitable as a filter medium due to its low hydraulic conductivity [15].

In principle, silica sol can be produced by reacting a sodium silicate solution with hydrochloric acid. Initially, silica acid ($Si(OH)_4$) is released,

$$Na_2SiO_3 + H_2O + 2HCl ==== = (Si(OH)_4) + 2NaCl \quad (2)$$

Also, amorphous-FeOOH can be prepared by mixing iron(III) salt and caustic solution in terms of the following reaction:

$$Fe^{3+} + 3OH^- ======= Fe_2O_3 + H_2O \quad (3)$$

Condensing free silicic acid with the elimination of water then forms polymeric silicic acid and further leads to gelling, i.e. formation of hydro gel [16]. When $Si(OH)_4$ contacts with FeOOH, polymerization of silicic acid on FeOOH likely occurs to form silicato-iron(III) surface complexes between Si and Fe [17–19], possibly by the following scheme.

Fe-O-Si(OH)$_3$ Fe-O(OH)$_2$-Si(OH)$_3$ (OH)Si-Fe-(OH)O-O-O(OH)-Fe-Si(OH)

(a) (b) (c)

Schematic bonding between $Si(OH)_4$ and FeOOH (a) bonding with $Si(OH)_4$ monomer, (b) polymerization, and (c) siloxane linkage between $Si(OH)_4$ monomers [17].

It is known that iron(III) salt solution is strongly acidic. If iron(III) salt solution, for example, $FeCl_3$, is mixed with a mixture of Na_2SiO_3 and NaOH, the above reactions (2) and (3) should occur simultaneously. This means that FeOOH and $Si(OH)_4$ form instantly in situ. Under such circumstance, FeOOH sol and SiO_2 sol are believed to have a better contact and Fe–Si complexes are most likely to form. The complexation between Fe and Si likely enhances the binding of FeOOH microns and hence increases the physical strength of the adsorbents produced. Since the crystallization of iron oxides, for instance the transformation of ferrihydrite to goethite, is strongly retarded by the presence of silicate species [20–23], the FeOOH formed through co-precipitation with silicate should be in an amorphous (or poorly crystalline) form. However, the quantity of the silica sol to be added in the adsorbent should be determined as the balance of two factors: strength of the adsorbent (resistance to disintegration) and adsorption capacity for any designated species.

Based on the above data, the aim of this study was directed to synthesize a new extensive series of impregnated metal oxides with Fe/Si ratios equal to 0.5, 1 and 2 by using ammonium hydroxide as a precipitating agent, so that a direct comparison of the structure, solid-state dehydration and ion exchange properties between the different metal oxides could be done. A correlation between the metal ratios, the water contents and the structures and/or the ion exchange properties towards some radionuclides was investigated.

2. Experimental

2.1. Reagents and analytical procedures

All reagents were of analytical grade (Aldrich, Merk) and were used without further purification. The radioactive ^{22}Na, ^{134}Cs, ^{60}Co and ^{144}Ce tracers for the ion exchange studies were obtained from Amersham International.

2.2. Synthesis

An extensive series of iron(III) silicates were synthesized by dropwise addition of equimolar solutions (0.5 M) of iron trichloride and sodium silicate. Different volumes of Fe/Si ratios equal to 1.0, 0.5 and 2.0 were used to obtain the FeSi-I, FeSi-II and FeSi-III series, respectively, as given in Table 1. In the formation reactions, 1 M of ammonia solution was added to the reaction mixtures until the pH of the supernatant solutions was about 5. After overnight standing, the resultant mixtures of each reaction containing the precipitate was divided into two equal portions; one of the portions was filtered directly and the other portion was treated with 0.1 M HNO_3 for 24 h to produce the H^+-form of the iron silicate products. The precipitates were washed several times with bidistilled water, filtered by using a centrifuge (about 10^4 rpm), and dried at 50 °C. The glassy brown solid products were cracked with bidistilled water in order to remove fine adherent particles, then redried at 50 °C. The products were ground, sieved and finally air dried at room temperature and stored in a dark bottle. Details of the precipitations are summarized in Table 1.

2.3. Characterization of iron(III) silicates

The physico-chemical properties of the prepared silicates (FeSi-I, FeSi-II and FeSi-III) were identified with different analytical techniques, such as XRD, FTIR, Thermal analysis (DTA/TG), elemental analysis and chemical stability.

Powder X-ray diffraction patterns were carried out using Shimadzu X-ray diffractometer, Model XD 490 Shimadzu, Kyoto (Japan) with a nickel filter and Cu Kα radiation tube.

FTIR spectra were measured with BOMEM FTIR spectrometer, model MB 147 (Canada) using the KBr disc technique in the range 400–4000 cm^{-1}.

Table 1
Details of precipitation, chemical formula and some physical properties of the obtained iron silicates

Exchanger	Reactant molar ratios Fe:Si	Fe/Si ratio	Chemical formula	M.Wt.	XRD	Color
FeSi-I	1:1	1.0	$(Fe_2O_3)_{1.14}.SiO_2 \cdot 3.8H_2O$	264.45	amorphous	D.B*
FeSi-II	1:2	0.5	$(Fe_2O_3)_{0.55}.SiO_2 \cdot 1.3H_2O$	172.22	amorphous	D.B*
FeSi-III	2:1	2.0	$(Fe_2O_3)_{1.83}.SiO_2 \cdot 6.0H_2O$	460.90	amorphous	D.B*

D.B* = dark brown.

Thermal stability, water content and solid-state dehydration changes of the obtained products were carried out using a Shimadzu DT-60H thermal analyzer, Shimadzu, Kyoto, Japan by heating the samples up to 1000 °C.

The chemical composition of the iron silicates was obtained by X-ray fluorescence (XRF) of solid samples with a Philips XRF detector, Holland. Iron(III) oxide (Aldrich) and silica (Merk) were thoroughly ground together to obtain solid reference samples for calibration. The error in the Fe:Si calibration curve was ±0.1. The chemical data of the products and some physical properties are given in Table 1.

The number of water molecules (n) per mole of the material can be calculated from the Alberti equation [24]:

$$18n = x(M + 18n)/100$$

where x is the percent of water content and $M + 18n$ is the molecular weight of the materials.

The chemical stability of the iron silicates was determined in water, nitric and hydrochloric acids by mixing of 0.05 g of the exchanger with 10 ml of 0.1–3 M acid. The mixtures were equilibrated in a thermostated shaker water bath for one week at room temperature. The slurry was filtered of and the solid was determined gravimetrically while the Si and iron in the filtrate were detected by using an ICP Shemadzu Model 1200 product, from Shemadzu-Kyoto (Japan).

2.4. Ion exchange study

2.4.1. Capacity measurements

The capacities of the iron(III) silicate samples for Na^+, Cs^+ and Co^{2+} ions were determined by batch experiment techniques. 0.05 g of the solid materials were equilibrated with 2.5 ml (V/m ratio 50 $cm^3\ g^{-1}$) of the nitrate solutions of sodium, cesium and cobalt ions. Equilibration was done in a thermostated shaker water bath at 25 ± 1 °C until equilibrium was attained. The procedures were repeated until no further adsorption of cations occurred. The capacity (meq/g) was calculated from the formula:

$$\text{Capacity} = C_0 \times Z \times \frac{\%\ \text{uptake}}{100} \times \frac{V}{m} \times (\text{meq/g}) \qquad (4)$$

where C_0 is the initial concentration of solution (g/l), V is the solution volume (ml), M is the weight of the exchanger (g) and Z is the charge of the metal ion adsorbed.

2.4.2. Distribution coefficient (k_d) measurements

The affinity of the product materials for the ions of interest was expressed in terms of distribution coefficient (K_d, ml/g) values. A batch technique was followed to determine the distribution coefficient values of iron(III) silicates as a function of pH. The pH values of the solutions were adjusted using nitric acid solutions, where 0.05 g of the exchanger was added to 2.5 ml of 10^{-3} M of the metal nitrate solutions (Na^+, Cs^+, Co^{2+} and Ce^{3+}) labelled with ^{22}Na, ^{134}Cs, ^{60}Co and ^{144}Ce, respectively. The batch equilibrations were settled overnight (sufficient to attain equilibrium) at a V/m ratio of 50 cm^3/g in a thermostated shaker waterbath. The mixtures were centrifuged and the pH of the solution after equilibration was determined. The values of distribution coefficient (k_d) were calculated using the relation:

$$K_d = \frac{A_0 - A_f}{A_f} \times \frac{V}{m}\,\text{ml/g} \qquad (5)$$

where A_0 is the initial counting rate of the considered element in solution, A_f is the final counting rate of the considered element in solution at equilibrium, V is the volume of the solution (ml) and m is the mass of the exchanger (g).

All the experiments were conducted in triplicate and average values were used in the data analysis, and the results agreed to ±3%.

3. Results and discussion

3.1. Preparation and characterization of iron(III) silicates

Initial forms of iron(III) silicates as cation exchange materials were prepared by adding equimolar solutions of iron trichloride and sodium silicate of different volumes to obtain different Fe/Si molar ratios of 1.0, 0.5 and 2.0 of FeSi-I, FeSi-II and FeSi-III, respectively, as given in Table 1. All the samples of the iron silicates were hard granules in nature and suitable to use in a packed column. All of the three products of iron silicates still exhibit their original brown color after rough washing with distilled water and drying at 50 °C. Gradual changes in color from brown to reddish brown then dark brown were observed when the prepared materials were heated from 50 to 400 °C and finally up to 850 °C. Physico-chemical properties of these silicate samples were identified by using different techniques as given in Table 1.

3.1.1. Chemical stability

Chemical stability (solubility) of synthetic inorganic ion exchangers plays an important role in their analytical applications. Exchangers which have a high solubility in water as well as in acid media may not be useful for separation investigations. It is therefore advisable to have a guide of the solubility of an ion exchanger. In this concern, the chemical stability of the prepared iron silicate samples was investigated in water, nitric and hydrochloric acids at different concentrations (0.1–3.0 M). The results of the chemical stability of the prepared materials (FeSi-I, FeSi-II and FeSi-III) under different conditions are presented in Table 2. From the data in Table 2, it was found that all the prepared materials are stable in water and in the acids up to 1 M, while they partially dissolved in the 2–3 M range of acid concentrations. As far as the chemical stability of the prepared samples with respect to the composition of the materials is concerned (Table 2). Unexpected results of chemical stability of the iron silicates were obtained at higher acid concentrations (>1 M), where the samples are partially dissolved with the formation of two phases. The first is a white residual phase obtained at the bottom of the glass tube, while the filtrate phase is a brownish color solution that can be precipitated with alkali, forming dark brown hydrous iron(III) oxide. The white precipitate represents the silica content of the materials.

Furthermore, the chemical stability experiments indicated that the iron silicate samples follow the stability order:

$$\text{FeSi-II}(\text{Si/Fe} = 2.0) > \text{FeSi-I}(\text{Si/Fe} = 1) > \text{FeSi-III}(\text{Si/Fe} = 0.5)$$

Similar behaviors have been observed and reported [17–22]. From the analysis of the chemical stability measurement results, it can be concluded that the materials behave as mixed oxides of Fe_2O_3 and SiO_2 and the solubility of Fe_2O_3 is the fact which determines the stability of the mixed products. In another way, the results confirm that the obtained silicato-iron(III) is not one phase but a homogenous mixture with a better contact of Fe(III) and silica, and Fe–Si complexes are most likely to form. Also, the presence of Si indicates that the stabilization of the materials is probably related to its incorporation into the structure of the hydrous iron oxide as previously suggested [25]. Thus, the results of chemical stability measurements as well as the elemental analysis of the obtained silicates confirmed the chemical formula given in Table 1.

3.1.2. IR spectra

The IR spectra of the iron silicates preheated at different temperatures (50, 200, 400, 600 and 850 °C) were studied (Fig. 1 shows the IR spectra of FeSi-II as an example). The spectral analysis of different samples are nearly the same, just with slightly differences in details, and this may be due to the difference in the preparation conditions (Fe/Si ratios) and/or surface structural differences among the Fe–Si oxides. In all the spectra, three main absorption bands at ~3400, ~1600 and ~600 cm^{-1} were detected. The first band at ~3400 cm^{-1} is due to strong inter- and intra-molecular stretching vibrations of hydrogen bonds [26]. The second observed band at ~1600 cm^{-1} is related to the water in the crystal lattice of the iron silicate samples. Finally, the smallest third band, which is observed at ~600 cm^{-1}, may be ascribed to the metal oxygen bond [26]. In addition, semi-quantitative IR spectra of all the materials reveal that the characteristic bands of vibrational water (~3400 and ~1600 cm^{-1}) are still present up to 600 °C, while these bands suffer from a slight decrease in intensity on increasing the heating temperatures. This decrease may be assigned to molecular water dehydration on increasing the drying temperature [27]. In contrast, the peaks at 600 cm^{-1} become more intense on increasing the drying temperatures up to 850 °C, which supports the relative dehydration of mixed hydrous oxides of Fe–Si to the more stable oxide forms.

3.1.3. X-ray diffraction patterns

The powder X-ray diffraction patterns of the prepared materials preheated at 50, 200, 400, 600 and 850 °C indicated that all the samples (FeSi-I, FeSi-II and FeSi-III) are mostly amorphous materials under all the conditions studied, and there is no change in the structures on increasing the drying temperature up to 850 °C. From the aforementioned data, we can suggest that the basic structures of the prepared materials remain unchanged even on changing the metal ratios or even by heating these materials up to 850 °C. According to the literature [4], heat treatment of the laboratory prepared hydrous iron oxides revealed that the hydrous oxides retained their original amorphous structures below 200 °C and gradually changed

Table 2
Chemical stability of the different iron(III) silicates (g/l) at 25 ± 1 °C

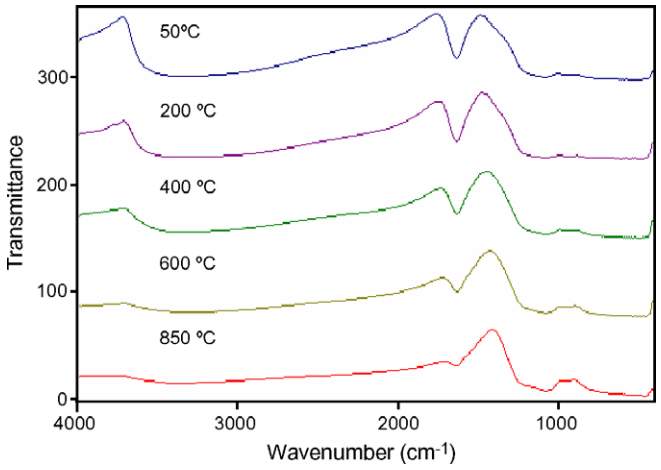

Fig. 1. Infrared spectra of FeSi-II at different drying temperatures.

into the α-Fe_2O_3 structure above 300 °C [4]. In this work, all the obtained materials retained their original amorphous structures after heating up to 850 °C. This unexpected result may be because either the hydrous oxides suffer from reversible phase transformation phenomena or the transformation of amorphous-Fe_2O_3 to metastable α-Fe_2O_3 is strongly retarded by the presence of silicate species. These probabilities can be confirmed by different tools of analyses, such as IR spectra and DTA/TG, as will be discussed later.

3.1.4. Thermal analysis

Fig. 2a–c shows the DTA/TGA of the different synthesized iron silicates, FeSi-I, FeSi-II and FeSi-III, respectively. Fig. 2a shows two endothermic peaks with maxima at $T_{m1} \approx 86$ °C resulting from a 12% mass loss and at $T_{m2} \approx 178$ °C resulting from an 8% mass loss from FeSi-I. The first peak is possibly assigned to dehydration of free absorbed water and the second one is possibly due to the loss of coordinated water molecules. The mass loss is continuous up to 500 °C, indicating a total loss of ≈22%, equivalent to 3.8 mol of water (Table 3).

Fig. 2b represents the DTA/TG thermogram of (FeSi-II) which indicates that there is only one endothermic peak at $T_{max} = 86.5$ °C, resulting from an 11.36% mass loss. This mass loss may be assigned to dehydration of surface absorbed water. The mass loss is continuous up to ~500 °C, giving a total mass loss of ≈14.75%, equivalent to 1.34 mol of water (Table 3). Finally, Fig. 2c shows the DTA/TG thermogram of FeSi-III which displays an endothermic peak at $T_{max} = 95$ °C, resulting from a 23.3% mass loss, equivalent to 6.0 mol of water. It is worth noting that, as shown in Tables 1 and 3, the water content of different silicate samples increased on increasing the iron species, in the order:

$$\text{FeSi-II}(\text{Fe/Si} = 0.5, \text{H}_2\text{O} = 14.7\%) > \text{FeSi-I}(\text{Fe/Si} = 1.0, \text{H}_2\text{O} = 22\%) > \text{FeSi-III}(\text{Fe/Si} = 2.0, \text{H}_2\text{O} = 23.3\%)$$

On the other hand, another alternative measurement of the DTA/TG of the iron silicate samples preheated at ≈150 °C then equilibrated with moist air were made and the results are shown in Fig. 3a–c. Fig. 3a of FeSi-I preheated at 150 °C also reveals two endothermic peaks, but they are shifted to higher temperatures (being at 93 and 215 °C, respectively) with a total mass loss of ≈15%. This result may confirm that the amorphous iron oxide changes to a new temporarily high thermally stable phase (α-Fe_2O_3 of lower water content instead of amorphous-Fe_2O_3) in parallel with restoring its water content to be nearly equal that of the original FeSi-I (22%). At the same time, Fig. 3a supports the IR spectra of the heated sample (Fig. 1), where the bands corresponding to water molecules are still present.

Based on the literature data [28,29], the structural water molecules may play an important rule as exchange sites. Also, from the view point of separation chemistry, especially in the field of fission products and removal of hazards elements, the last results of high chemical and thermal stability caused by increasing the silica content (besides the moisture reversibility nature) may reinforce our efforts on studying the application of impregnated Fe–Si oxides in new forms as promising exchange materials.

3.1.4.1. Kinetic studies of silicato-iron solid-state transformations processes. As indicated, the XRD patterns of heated Fe-silicates still show completely clear amorphous nature at higher temperatures (850 °C) in a parallel with their water restoring properties. This may be proven by the reversible endothermic peaks (DTA peaks) of the phase transformation processes of these materials, as observed from their DTA thermograms (Figs. 3a–c). The kinetics of the solid-state transformation processes of FeSi-I, FeSi-II and FeSi-III samples can be calculated from DTA thermograms by the T_{max} peak of the dehydration processes. Thus, the order of reactions (n) of the first dehydration processes of compounds FeSi-I, FeSi-II and FeSi-III, corresponding to T_{max} values of 89, 86.5 and 95.4 °C, respectively (Figs. 2a–c), may be calculated using the Kissingar empirical relation [30,31]:

$$n = 1.26S^{1/2} \quad \text{and} \quad S = a/b \tag{6}$$

where n is the reaction order, S is the peak shape factor and a and b are the length in cm on the base line of the dehydration peak (Fig. 2b). Additionally, it can be considered that the dehydration transformation process is one of the solid-state reactions, namely the solid-state reaction of a single reactant, according to the equation:

$$A_{(s)} \rightarrow \overline{A}_{(s)} + \text{H}_2\text{O}_{(g)} \tag{7}$$

Thus, for the materials studied, the FeSi-I dehydration can be represented by the equation:

$$(\text{Fe}_2\text{O}_3)_{1.14} \cdot \text{SiO}_2 \cdot 3.8\text{H}_2\text{O}_{(s)} \overset{89\ ^\circ\text{C}}{\rightarrow} (\text{Fe}_2\text{O}_3)_{1.14} \cdot \text{SiO}_2 \cdot 2.6\text{H}_2\text{O}_{(s)} + 1.2\text{H}_2\text{O}_{(g)} \tag{8}$$

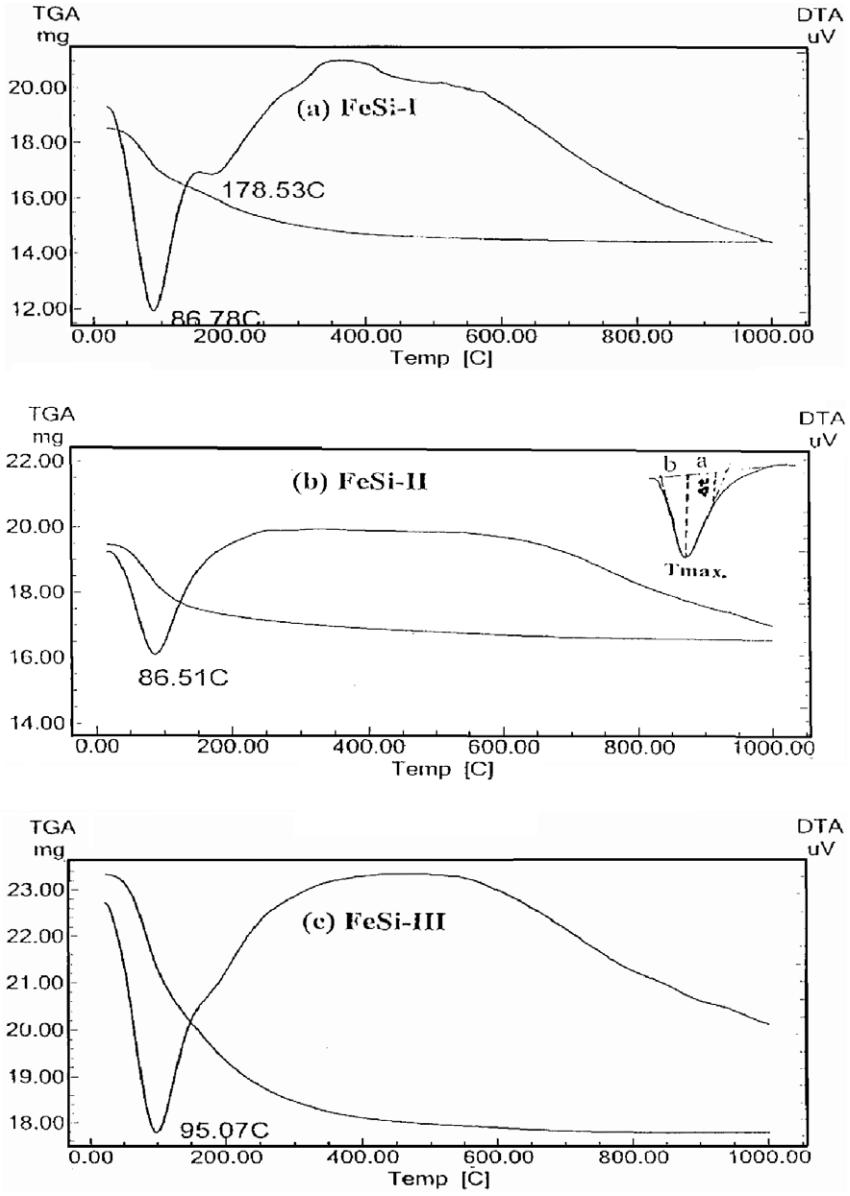

Fig. 2. DTA–TG thermograms of iron silicate with different Fe/Si ratios (a) 1, (b) 0.5 and (b) 2.

Table 3
Water contents of iron silicates in their initial forms and their different loaded forms

Exchanger	% water content		
	FeSi-I	FeSi-II	FeSi-III
Initial form	21.95	14.75	23.40
Cs^{+}-loaded	21.47	21.09	25.35
Na^{+}-loaded	17.96	17.93	23.20
Co^{2+}-loaded	22.40	22.03	24.865
Ce^{3+}-loaded	21.30	22.38	24.579

This type of reaction is assumed to be controlled by nucleation, diffusion and phase boundary advancement or by partial liquefaction, depending on the values of n. So, the order of the dehydration processes are calculated by employing the above equation and, given in Table 4, the values are found to be close to unity. From these results we can conclude that the dehydration processes of the different silicate samples are solid-state reactions that follow first order kinetics and the rate-determining step is the nucleation process [32,33]. Also, the activation energy (E_a) of the transformation dehydration process of all the prepared samples (FeSi-I, FeSi-II and FeSi-III) to form the semi-anhydrous products can be calculated using the Piloyan et al. equation [33]:

$$\ln \Delta t = C - \frac{E_a}{RT} \tag{9}$$

where Δt is the deviation from the base line (its value being taken directly from the DTA curve in length units of cm or mm, as shown in Fig. 2b), C is a constant, E_a is the energy of activation, R is the universal gas constant and T is the

FeSi-II	1.37 1st	1.58	86.5	11.36
FeSi-III	1.47 1st	1.88	95.1	19.20

absolute temperature. The plot of $\ln\Delta t$ versus $1000/T$ gave a straight line, represented in Fig. 4 for all compounds, with a slope of $-E_a/R$. From these lines, the calculated values of E_a were found and these are given in Table 4. Table 4 shows low values of E_a for all the dehydration processes indicating the ease of water evaporation in the dehydration reactions. Also, the E_a values of the different silicates decrease in the order:

FeSi-I(2.23) > FeSi-III(1.88) > FeSi-II(1.58)

This indicates that FeSi-II has the lowest energy consumption for removal of water molecules.

3.2. Ion exchange and distribution studies

The potential use of the prepared iron silicates in removal and separation of some radioactive nuclides, including cesium, sodium, cobalt and cerium ions, were studied in order to assess and evaluate the prepared materials for the application as adsorbents.

Initially, the ion exchange capacity (IEC) of Na^+, Cs^+ and Co^{2+} ions on various iron silicates (FeSi-I, FeSi-II and FeSi-III) in both initial (treated with water), protonated (pretreated with 0.1 M HNO_3) forms and those dried at different temperatures (50, 200, 400 and 850 °C) are given in Table 5. The data in Table 5 shows clearly that all the iron silicates in the H^+-form (acidic form) have extremely low ion affinity compared to their initial forms.

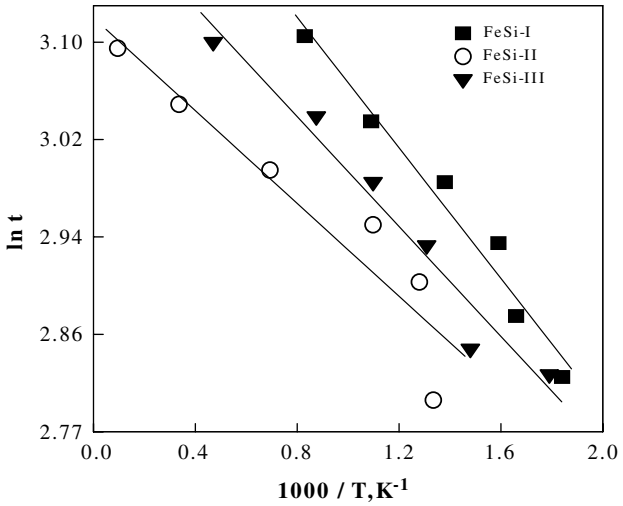

Fig. 4. Plot of $\ln \Delta t$ vs. $1000/T$ (K^{-1}) for iron silicates of different Fe/Si molar ratios.

The low sorption affinity of the H^+-forms of the different prepared iron silicates is expected, as many studies have reported the same behavior [34]. We can say that the lower values of the IEC of acid pretreated iron silicates may indicate a disturbance in the elemental structure (Fe/Si ratios). This disturbance may be due to either the dissolving of iron oxide [5] or the high affinity of the solid towards H^+ compared to the Na^+ ions (Na^+ ions are initially present in the silicate matrix by in situ precipitation from sodium silicate). These positive results of sorption experiments direct our attention towards the initial forms of the obtained silicates. This is very important from an economic point of view.

Generally, it is found that: (i) The ion exchange capacity of the prepared materials towards the studied cations (Na^+, Cs^+ and Co^{2+} ions) increases in the order:

FeSi-II > FeSi-I > FeSi-III

This trend may be due to the increase of acidities of materials on increasing the silicon content (high electronegativity) which may lead to an increase of electrostatic interaction of the counter ions with the exchange sites [35]. (ii) The ion exchange capacities of all the studied cations are slightly decreased by increasing the drying temperatures from 50 to 200 °C, this is then followed by a fast decrease with continuous heating up to 850 °C. *Firstly*, the slightly decrease in the ion exchange capacity for samples heated up to 200 °C, which is not accompanied by crystalline changes, may be discussed from the view point of DTA/TG and IR analyses for samples preheated at 200 °C. The IR peaks at 3400 and 1600 cm^{-1} of OH^- groups are still present after drying up to 200 °C, as shown in Fig. 1.

Table 5
Ion exchange capacities (meq/g) and percentage water content of the iron silicates at different drying temperatures

Exchanger	Drying temperature	% Water content	Ion exchange capacity (meq/g)		
			Na^+	Cs^+	Co^{2+}
FeSi-I	50	22.0	0.42 (0.04)[a]	0.45 (0.06)[a]	0.62 (0.06)[a]

	200	5.9	0.14 (0.02)[a]	0.19 (0.02)[a]	0.24 (0.03)[a]
	400	0.7	0.04 (0.02)[a]	0.50 (0.03)[a]	0.10 (0.04)[a]
	850	0.3	0.02	0.03	0.02

[a] For samples pretreated with 0.1 M HNO_3.

Furthermore, the reversibility of the first endothermic peaks of the DTA/TG for all the silicate samples (Figs. 2 and 3) shows that the iron silicate samples still reveal a high percentage water content. This result can be considered as being based on a reversible phase transformation nature of the iron silicates. Hence, silicate samples heated at 200 °C retain their original structures, where water molecules are restored to near equality of the original forms. The results support the idea of construction of new active sites by pre-heated iron silicates when equilibrated with moist air. A similar trend was observed in the case of goethite (α-FeO-OH) [5]. *Secondly*, the fast decrease of the ion exchange capacity of the iron silicates at higher temperatures (400 to 850 °C) may be related to the condensation of the surface OH^- groups which may act as the sites of exchange [36,37]. This result is also noticed from the IR spectra (Fig. 1) where the peaks due to water molecules become low in intensity on increasing the drying temperatures, which may suggest a decrease of active sites. (iii) The ion exchange capacity of the prepared iron silicates (FeSi-I, FeSi-II and FeSi-III) for the studied cations takes the order,

$$Co^{2+} > Cs^{+} > Na^{+}.$$

This order of ion exchange capacity (Table 5) agrees with the fundamental theory of hydrous ionic radii of these cations [38]. It must be notice that although the water molecules play an important role as exchange sites in the obtained materials, the sorption affinity trend of the iron silicates does not depend on the percentage of water molecules only. Other factors may have an affect, such as channel loading, diffusion of ions, pH, pore size, porosity, surface area and ordinal structuring of these materials.

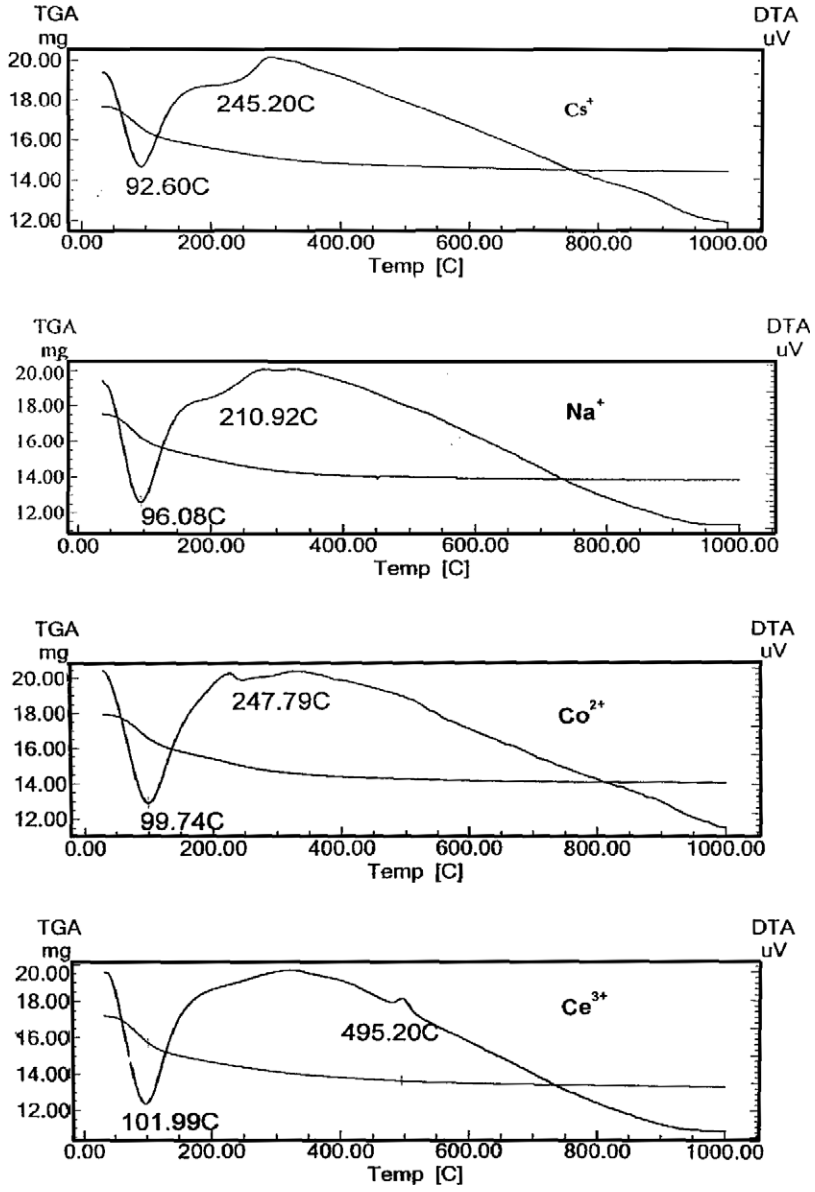

Fig. 5. DTA–TG thermograms of FeSi-II loaded with Cs^+, Na^+, Co^{2+} and Ce^{3+} ions.

Additional studies on the thermal behavior of iron silicates in different cation forms (-Na^+, -Cs^+, -Co^{2+} and -Ce^{3+}) have been carried out. Based on a comparison of the percentage water content for all the iron silicate samples (initial and their perspective cationic form) obtained from TG analysis and given in Table 3, it is clear that each of the Na^+, Cs^+, Co^{2+} and Ce^{3+} ions were adsorbed in their coordinated form in the case of FeSi-II, while this behavior is in contrast to that which occurs for FeSi-I and FeSi-III samples. The same result was confirmed from the DTA thermograms of Na–FeSi-II, Cs–FeSi-II, Co–FeSi-II and Ce–FeSi-II, as shown in Fig. 5. Fig. 5 indicates that a new second endothermic peak at ≈211, 245, 248 and 495 °C for Na–FeSi-II, Cs–FeSi-II, Co–FeSi-II and Ce–FeSi-II, respectively, was obtained. This peak may correspond to the dehydration of coordination water of different adsorbed cations. Thus the different FeSi-II cation forms can be arranged in the following order, according to the percentage water content:

$$\text{FeSi-II}(14.75\%) < \text{Na–FeSi-II}(17.93\%) < \text{Cs–FeSi-II}(21.1\%) < \text{Co–FeSi-II}(22.03\%) < \text{Ce–FeSi-II}(22.3\%)$$

On the other hand, the preliminary investigation indicates that the time for equilibration for the exchange of Cs^+, Na^+, Co^{2+} and Ce^{3+} ions with the initial form of the iron silicates were within 24 h (sufficient to attain the equilibrium). In this concern, to investigate the selectivity of the prepared materials for the studied metal ions, distribution coefficients (K_d) were determined in different pH values using different concentrations of HNO_3 of each of Cs^+, Na^+, Co^{2+} and Ce^{3+} labelled with ^{134}Cs, ^{22}Na, ^{60}Co and ^{142}Ce, respectively. Fig. 6a–c shows the results of variations of $\log K_d$ versus pH of solutions for the studied cations and it can be found that the distribution coefficients for all the metal ions increased on increasing the pH of

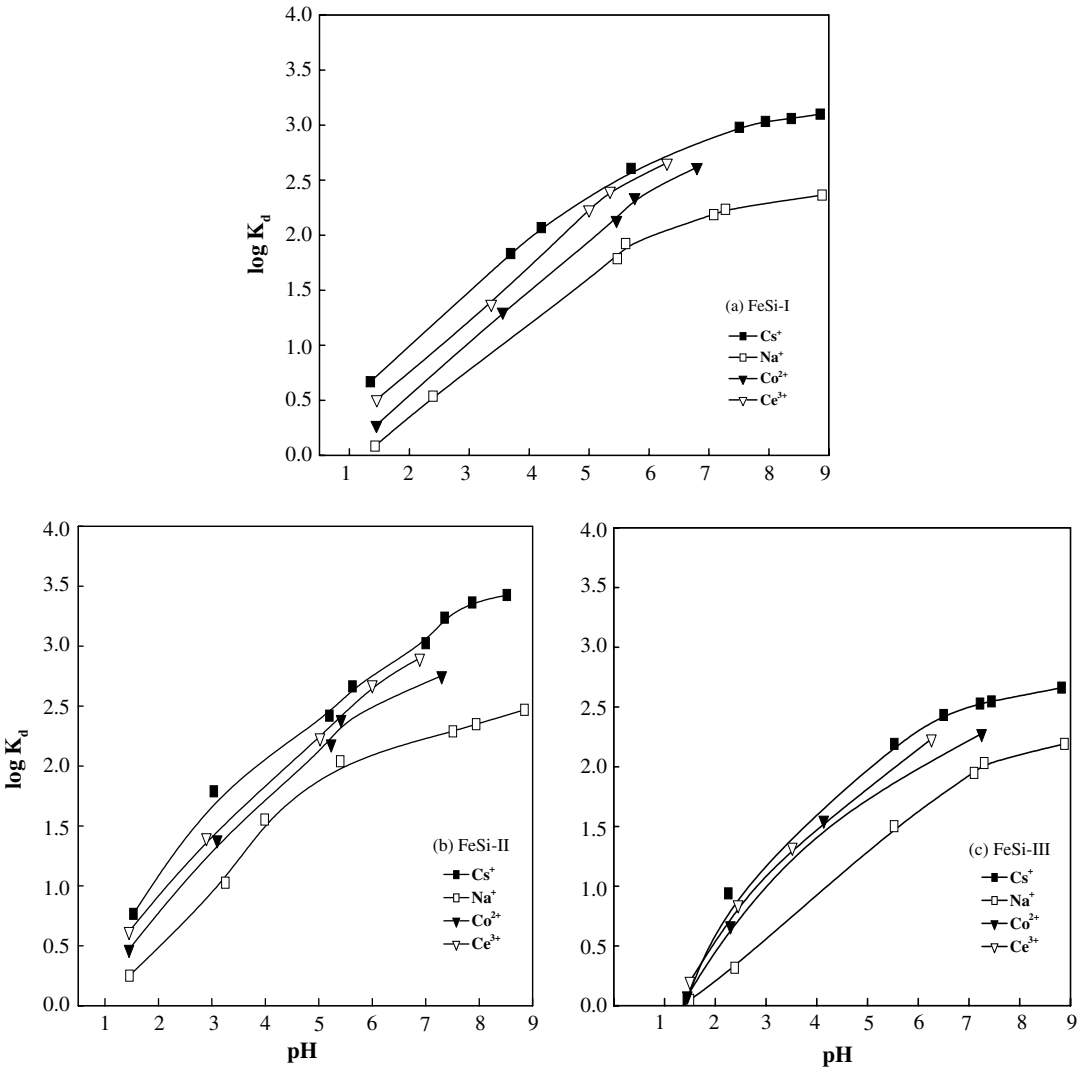

Fig. 6. Distribution coefficients of Cs^+, Na^+, Co^{2+} and Ce^{3+} ions as a function of pH on FeSi-I, FeSi-II and FeSi-III (dried at 50 °C) at 25 ± 1 °C.

the solutions. This trend is an obvious phenomenon and was observed by others [28,37–40]. Also, from the plots of $\log K_d$ at infinitesimal exchange versus pH of solutions of different cations (Fig. 6a–c) of the prepared materials (FeSi-I, FeSi-II and FeSi-III), a linear relationship with a slope smaller than the valences of the studied cations were obtained, indicating that the ion exchange reaction deviated from the ideal process. The non-ideality may due to a different mechanism such as physical adsorption, chemical reaction or other effects, that takes place besides the ion exchange process.

4. Conclusions

Composites of Fe–Si oxides were obtained from iron oxide impregnation with silica in different Fe/Si molar ratios. A chemical stability investigation indicated that the silicato-iron products were mixed oxides and the iron oxide is partially soluble in high acidic media, while the solubility decreased with increasing silica content. Kinetics of dehydration transformation indicated a 1st order process for different silicate ratios. Application of the materials as ion exchangers showed a high affinity for ions of different charges on increasing the solution pH as well as with the silica content increasing.

I dedicate this paper to B. Ulkuseven, *the mentor of my research career*, on the occasion of his 50th birthday.

Abstract

Mixed-ligand zinc complexes with *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (*tmen*) and R-salicylaldehyde N(4)-allyl thiosemicarbazones (R: 3-OCH_3 (L_1), 5-Br(L_2)), [$ZnL_{1,2}$(*tmen*)], were synthesized and the complexes were characterized by elemental analysis, atomic absorption spectrometer, magnetic susceptibility, molar conductivity, electrospray ionization (ESI) and atmospheric pressure chemical ionization (APCI) mass spectra and IR, UV–Vis, ^{1}H NMR and ^{15}N spectroscopies. Crystal of [ZnL_2(*tmen*)] have a slightly distorted square pyramid involving O, N, S atoms of thiosemicarbazone and one N atom of *tmen* in basal plane and the other N atom of *tmen* in apex of the pyramid. The non-coordinated allyl group is disordered.

1. Introduction

Thiosemicarbazones and their transition metal complexes are of considerable interest because of biological activities as antiviral [1,2], antifungal [3], antibacterial [4,5], antitumor [6,7], anticancerogenic [8–10] and insulin mimetic properties [11]. The thiosemicarbazones have also been used for analysis of metal as analytical reagent [12–14], for device applications relative to telecommunications, optical storage and optical information processing [15,16]. Biological activities of the metal complexes of thiosemicarbazones have been found in some instances to have enhanced depending on metal ion [17] and the parent aldehyde or ketone [5]. There are reports that the presence of alkyl groups at the terminal N(4) position can considerably increase their activity [18]. Moreover, most transition metal complexes of thiosemicarbazones have more activities than free ligands as regards biological activities [19,20].

In recent years a considerable amount of work has been done in the biological activities and synthesis of zinc(II) with thiosemicarbazone [21–27]. Perez et al. found that cytotoxic activity of zinc and cadmium complexes of *p*-isopropylbenzaldehyde thiosemicarbazone are resemble antitumor drug cisplatin, even they are much more active than cisplatin in cells resistant to cisplatin [28,29]. Zinc is an essential constituent of the enzymes catalysing hydrolyses and complexes of zinc(II) are catalysts for the cleavage of RNA target [30–34]. Thiosemicarbazones are effective inhibitors of ribonucleotide reductase (RR), and of key regulatory enzymes as well [35,36]. It had been reported that zinc complexes of thiosemicarbazones are antioxidant [37] and have an effect in vitro on cell proliferation and differentiation [38–40]. Therefore, the aim of this

doi:10.1016/j.poly.2007.10.001

work was to synthesis mixed-ligand Zn(II) complexes with N(4)-allyl thiosemicarbazone and *N,N,N′,N′*-tetramethylethylenediamine (*tmen*) and to define the X-ray structure of the complex.

No reaction of *tmen* with thiosemicarbazone in the presence metal ion, so far as I know, gave mixed-ligand complex because dimeric complex was obtained [41,42]. In the present paper, I report the synthesis, spectroscopic data and crystal structure of Zinc(II) complex of [Zn(tsc)(*tmen*)]. The compound is the first mixed-ligand complex of zinc(II)–thiosemicarbazone with a *tmen* ligand.

2. Experimental

2.1. General procedures

All chemicals were of reagent grade and used as commercially purchased without further purification. The elemental analyses were determined on a Thermo Finnigan Flash EA 1112 Series Elemantar Analyser and Varian Spectra-220/FS Atomic Absorption spectrometer. I.r. spectra of the compounds were recorded on KBr pellets with a Mattson 1000 FT-infrared spectrometer. UV/Vis Spectra were obtained from ATI-Unicam UV/Visible Spectrometer UV2 Series. The ^{1}H, and ^{15}N Nuclear Magnetic Resonance spectra were recorded on Bruker AVANCE- 500 model spectrometer. Magnetic measurements were carried out at room temperature by the Gouy technique with an MK I model device obtained from Sherwood Scientific. The molar conductivities of the compounds were measured in 10^{-3} M DMSO solution at 25 ± 1 °C using a digital WPA CMD 750 conductivity meter. The ESI-MS and APCI-MS analyses were carried out in positive ion modes using a Thermo Finnigan LCQ Advantage MAX LC/MS/MS. Hypersil Betabasic-8 (5 μm, 100 mm × 4.6 mm) column was used at a flowrate of 0.3 ml/min at 25 °C. The mobile phase consisted of MeOH. ESI-MS/APCI-MS inlet conditions in the positive ion mode: heated capillary temp., 200/200 °C; sheath gas flow rate, 70/70 U; capillary voltage, 32/46 V and tube lens offset, 30/55 V.

2.2. Synthesis of ligands and complexes

2.2.1. Ligands

The 5-bromo- and 3-methoxysalicylaldehyde N(4)-allyl thiosemicarbazone were prepared according to the literature [10]. The colours, m.p., yields, Rf (CH_2Cl_2), Elemental Analysis, I.r., UV–Vis and ^{1}H NMR data of $\mathbf{L}_{1-2}$ were given as follows:

$\mathbf{L}_1$: cream; 229–230 °C; %94; 0.2065; *Anal*. Calc. for $C_{12}H_{15}N_3O_2S$ (265 g): C, 54.34; H, 5.66; N,15.85; S, 12.07. Found: C, 54.32; H, 5.61; N, 15.91; S, 11.96%. FT-IR (KBr, cm^{-1}): *ν*(NH) 3451, 3307, *ν*(OH) 3550–3250, *δ*(NH) 1646, 1615, *ν*(C=N) 1584, *ν*(C=CH_2) 3092, 3007, *ν*(–OCH_3) 2846, *ν*(–CS–NH) 1538, *ν*(–C=S) 1215. UV–Vis spectrum in $CHCl_3$ [λ_{max} (nm), *ε* ($dm^3\,cm^{-1}\,mol^{-1}$)]: 217 (7340), 240 (5890), 320 (11 600), 346 (shoulder). ^{1}H NMR (DMSO-d_6, 25 °C, ppm): 11.19 (s, 1H, OH), 9.13 (s, 1H, NH), 8.34 (t, 1H, N*H*-allyl), 8.16 (s, 1H, CH=N), 7.27 (d, *J*: 7.91, 1H, *d*), 6.74 (d, *J*: 7.82, 1H, *b*), 6.57 (t, *J*: 7.97, 1H, *c*), 5.65 (m, 1H, –CH=), 4.89 (m, 2H, =CH_2), 3.96 (d, *J*: 5.12, 2H, N–CH_2–), 3.56 (s, 1H, –OCH_3).

$\mathbf{L}_2$: light yellow; 179–180 °C; %69; 0.1848; *Anal*. Calc. for $C_{11}H_{12}N_3OSBr$ (314 g): C, 42.04; H, 3.82; N, 13.37; S, 10.19. Found: C, 42.09; H, 3.79; N, 13.46; S, 10.25%. FT-IR (KBr, cm^{-1}): *ν*(NH) 3407, 3153, *ν*(OH) 3600–3300, *δ*(NH) 1646, 1623, *ν*(C=N) 1607, *ν*(C=CH_2) 3092, 3000, *ν*(–CS–NH) 1538, *ν*(–C=S) 1230. UV–Vis spectrum in $CHCl_3$ [λ_{max} (nm), *ε* ($dm^3\,cm^{-1}\,mol^{-1}$)]: 218 (8450), 248 (10 450), 315 (14 040), 346 (15 000). ^{1}H NMR (DMSO-d_6, 25 °C, ppm): 11.21 (s, 1H, OH), 10.30 (s, 1H, NH), 8.51 (t, 1H, N*H*-allyl), 8.07 (s, 1H, CH=N), 7.89 (d, *J*: 2.24, 1H, *d*), 7.11 (dd, *J*: 2.49, *J*: 8.71, 1H, *b*), 6.60 (d, *J*: 8.72, 1H, *a*), 5.65 (m, 1H, –CH=), 4.89 (d, *J*: 1.52, *J*: 17.88, 1H, =CH_{2a}), 4.86 (dd, *J*: 1.28, *J*: 10.69, 1H, =CH_{2b}), 3.96 (d, *J*: 5.03, 2H, N–CH_2–).

2.2.2. Complexes

[**ZnL**$_1$(***tmen***)]: 3-Methoxysalicylaldehyde *N*(4)-allyl thiosemicarbazone (0.5 g, 1 mmol) in 20 ml EtOH was added to the solution of *N,N,N′,N′*-tetramethylethylenediamine (0.219 g, 0.28 ml, 1 mmol) in 20 ml of dry EtOH at 20 °C. The reaction mixture was poured with continuous stirring to 20 ml of an ethanol solution containing of $Zn(CH_3COO)_2 \cdot 2H_2O$ (0.41, 1 mmol). The resulting solution was stirred for 5 h at room temperature in nitrogen atmosphere. The solvent was removed on a rotary evaporator under reduced pressure. The residue was dissolved in ethanol (10 ml) and mixed with ether (10 ml). The mixture was kept for 48 h at 0 °C. The yellow coloured crystals were separated, filtered and dried in vacuo.

[ZnL_2(*tmen*)] complex was obtained by using 5-bromosalicylaldehyde *N*(4)-allyl thiosemicarbazone as to above procedure. The colours, m.p., yields, Rf (CH_2Cl_2), elemental analysis, molar conductivity, I.r., UV–Vis, ^{1}H NMR, ^{15}N NMR and mass (ESI, APCI) spectra, data of [ZnL_1(*tmen*)] and [ZnL_2(*tmen*)] were given as follows:

[ZnL$_1$(***tmen***)]: yellow; 192–193 °C; %62; 0.2212; *Anal*. Calc. for $C_{18}H_{29}N_5O_2SZn$ (444,37 g): C, 48.61; H, 6.53; N,15.75; S, 7.20; Zn, 14.71. Found: C, 48.57; H, 6.38; N, 15.69; S, 7.80; Zn, 14.66%; *Λ* (in 10^{-3} M DMSO, $\omega^{-1}\,cm^2\,mol^{-1}$): 9.2. 3. Results and discussion

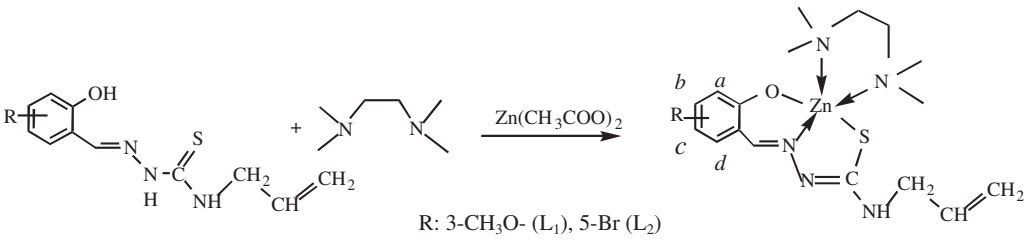
3-Methoxy/5-bromosalicylaldehyde N(4)-allyl thiosemicarbazidato *N*,*N*,*N*′,*N*′-tetramethylethylenediamine zinc(II) complexes, [ZnL$_1$(*tmen*)] and [ZnL$_2$(*tmen*)], were obtained from reaction of *N*,*N*,*N*′,*N*′-tetramethylethylenediamine and thiosemicarbazone ligands in presence of $Zn(CH_3COO)_2\cdot 2H_2O$ in 1:1:1 molar in nitrogen atmosphere. The tridentate thiosemicarbazone ligands (L$_1$, L$_2$) coordinate to zinc(II) atom through the phenolic oxygen, imine nitrogen and thiolato sulphur atom, bidentate *tmen* ligand coordinates to zinc(II) atom through nitrogen atoms. The elemental analyses of complexes suggest the general formula as [ZnL$_1$(*tmen*)] and [ZnL$_2$(*tmen*)] according to Scheme 1.

Ligands melt at 229–230 °C (L$_1$) and 179–180 °C (L$_2$). [ZnL$_1$(*tmen*)] and [ZnL$_2$(*tmen*)] have melting points at 192–193 °C and 175–176 °C, respectively. The complexes compounds insoluble in H_2O, but soluble in alcohol, halocarbone solvents and polar organic solvents such as DMSO and MeCN. The μ_{eff} values of zinc chelates showed that they are diamagnetic. The molar conductance values are in the range 9.2–8.4 $\Omega^{-1}\,cm^2\,mol^{-1}$, indicating non-electrolytic behavior.



3.1. Structural characterization

3.1.1. X-ray structural determination of [ZnL$_2$(tmen)] structure

Suitable single crystal of complex [ZnL$_2$(*tmen*)] was obtained by crystallization from ethanol by ether diffusion. A yellow block crystal of $C_{17}H_{26}N_5OBrZnS$ having approximate dimensions of $0.40\times0.30\times0.20$ mm was mounted on a glass fiber. All measurements were made on a Rigaku RAXIS RAPID imaging plate area detector with graphite monochromated Mo Kα radiation. The structure was solved by direct methods (SHELXS-97) [43]. The non-hydrogen atoms were refined anisotropically. Unique F^2 data (3693) were used in the final cycle of the full-matrix least-squares refinement of 254 variables. Additional information to the structure determinations are given in Table 1. Selected bond distances, angles and torsion angles are listed in Table 2.

H atoms were positioned geometrically and treated using a riding model, fixing the bond lengths. In the molecule, (C10–C11) group shows positional disorder and the refined site-occupancy factors of the disordered parts, *viz*. C10A–C11A and C10B–C11B, are 64(1)% and 36(1)%, respectively. The disordered atoms were refined using the following restraints of SHELXL97: SIMU, DELU and SADI [44].

Compound [ZnL$_2$(*tmen*)] crystallizes in the triclinic space group, *P*21/*n*.The complex is described as a square pyramid with a phenolic oxygen atom [Zn(1)–O(1): 1.949(3) Å], an imin nitrogen atom [Zn(1)–N(1): 2.138(4) Å], a thiolato sulphur atom [Zn(1)–S(1): 2.3467(14) Å] and an nitrogen atom of *tmen* ligand [Zn(1)–N(4): 2.235(4) Å] at the corners of pyramidal base and the other nitrogen atom of *tmen* ligand [Zn(1)–N(5): 2.144(4) Å] at the top of pyramid (Fig. 1). The

angle [N(4)$_{tmen}$–Zn(1)–N(5)$_{tmen}$] between the apical and basal nitrogen atoms of the pyramid is 83.91°. The Zn–N(4)$_{tmen}$ and Zn–N(5)$_{tmen}$ distances are somewhat longer than those of other zinc(II) complexes containing *tmen*; [Zn–N(1)$_{tmen}$: 2.132(1) Å, Zn–N(2)$_{tmen}$: 2.079(1) Å] [45], [Zn–N(1)$_{tmen}$: 2.192(1) Å, Zn–N(2)$_{tmen}$: 2.150(1) Å] [46].

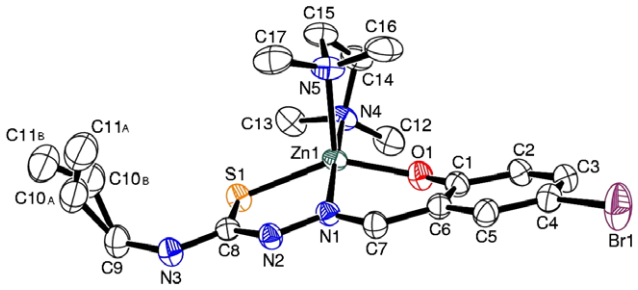

Fig. 1. A view of [ZnL$_2$(*tmen*)], showing 30% probability displacement ellipsoids and the atom-numbering scheme. The H atoms have been omitted for clarity.

Terdentate thiosemicarbazone ligand shows a Z configuration about N(2)–C(8) [torsion angle N(1)–N(2)–C(8)–N(3)] and N(1)–C(7) [torsion angle N(2)–N(1)–C(7)–C(6)] bonds, whereas an E configuration about N(2)–C(8) [torsion angle N(1)–N(2)–C(8)–S(1)] and Zn(1)–N(4) [torsion angle S(1)–Zn(1)–N(4)–C(13)] bonds is shown.

There is intermolecular hydrogen bonding in [**ZnL**$_2$-(***tmen***)]. C(9)–H(9B) interacts with a non-bonding pair of electrons on a coordinated thiolato sulphur Table 3. Configuration at the stereogenic centers, C(9) and C(10) of allyl moiety showed static disorder due to large thermal vibrations. Torsion angle N(3)–C(9)–C(10A)–C(11A) is 21.7(18) in conformation A, while torsion angle N(3)–C(9)–C(10B)–C(11B) is −105(2) in conformation B. The bond lengths and angles for allyl moiety in both conformations A and B are listed in Table 2.

In the molecular structure of [**ZnL**$_2$(***tmen***)], two intramolecular interactions are observed. One of these is between

Table 2

[a] Symmetry code: $-x+1, -y+2, -z$.

the methyl H atom belonging to the *tmen* and the O atom. The second is between the methylene H atom belonging to the allyl group and the S atom. Each of these interactions leads to the formation of five-membered ring with graph-set descriptor *S*(5) [47]. Examination of the structure with *PLATON* [48] reveals that the molecules of compound [ZnL$_2$(tmen)] are linked into centrosymmetric R_2^2 (8) – dimers (Fig. 2) by paired N–H···N hydrogen bonds [49–51]. Thioamide nitrogen atom N(3) in the molecule at (x, y, z) acts as hydrogen-bond donor to imin N(2) atom in the molecule at ($1-x$, $2-y$, $-z$), so forming a centrosymmetric R_2^2 (8) ring centred at (1/2, 1, 0). The detailed geometry of the intra- and intermolecular interactions is given in Table 3.

3.1.2. IR spectroscopy

IR spectral data of the thiosemicarbazone ligands show *v*(–NH–) stretchings of –NH–C(S)–NH– moiety at 3451 (L_1), 3407 (L_2) and at 3307 (L_1), 3153 (L_2). The absence of any band *v*(–SH–) in the 2700–2500 cm^{-1} region of the IR spectrum of ligands signify thione tautomer of free ligand in the solid state. The broad stretching band *v*(–OH–) in the range 3600–3250 cm^{-1} and the band at 3307 cm^{-1} (L_1) or 3153 cm^{-1} (L_2) corresponding to *v*(–N^{2}H–) disappear in the spectra of the complexes due to the deprotonation in the presence of Zn(II) and *tmen* ligand, and coordinates to zinc(II) ion via thiolate sulphur atom and phenolic oxygen. The *v*(–N^{4}H–) band and *v*(C=N) band of thiosemicarbazone ligands shift to lower wave numbers in the spectra of complexes. The bands assigned to *v*(CH$_3$–N), *v*(C–N–C), *v*(–CH$_2$–) and *v*(–CH$_3$) of *tmen* ligand are shown in the 1331–1306 cm^{-1}, 1175–1173 cm^{-1}, 2998–2860 cm^{-1} region, respectively.

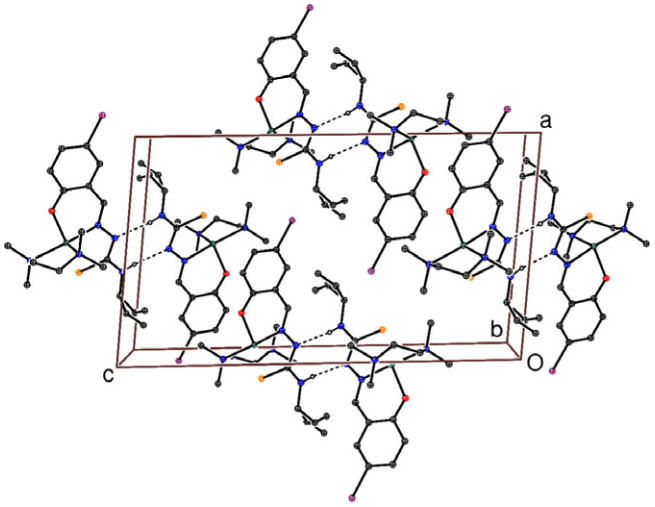

Fig. 2. Part of the crystal structure of [ZnL$_2$(*tmen*)], showing the formation of centrosymmetric R_2^2 (8) dimers. Hydrogen bonds are shown as dashed lines. For the sake of clarity, H atoms not involved in the motif shown have been omitted.

3.1.3. UV–Vis spectra

The UV–Vis spectra of the ligands in chloroform show four bands at *ca.* 217 nm which corresponds to $\pi \rightarrow \pi^*$ transition of phenol, at *ca.* 245 nm which corresponds to $\pi \rightarrow \pi^*$ transition of aromatic ring and at *ca.* 317 nm which corresponds to $n \rightarrow \pi^*$ transition of azomethine group and at *ca.* 346 nm with a shoulder which corresponds to $\pi \rightarrow \pi^*$ transition of thioamide. In the spectra of the complexes, the band of *tmen* ligand overlaps with the intense phenyl at *ca.* 245 nm. The band of at *ca.* 370 nm is attributable to the thioamide $n \rightarrow \pi^*$ transition on the complexation of the thiolato sulphur due to tautomer form.The higher energy bands can be assigned to d–d transitions at *ca.* 584 and 656 nm.

3.1.4. NMR spectra

^{1}H NMR spectra of the thiosemicarbazone ligands show a sharp singlet at 11.19 ppm (L_1) and 11.21 ppm (L_2) due to the OH group. These bands are not found in the spectra of the complexes, which is consistent with deprotonation of these ligands upon metal complexation. Moreover, in the ^{1}H NMR spectrum of the complexes, the absence of signals assigned N^{2}H of the free ligands at 9.13 ppm (L_1) and 10.30 ppm (L_2) confirms that N^2 deprotonates and thiosemicarbazon coordinate to zinc atom via thiolate sulphur atom. The complexation by azomethine nitrogen affects the chemical shift of the C=N protons about 0.2 ppm. The signals of *tmen* as a second ligand are observed in the range 3.87–2.53 ppm.

^{15}N NMR spectra of the complexes show five signal at *app.* 317 ppm, 201 ppm, 199 ppm, 198 ppm.

3.1.5. Mass spectra

Molecular ions are present at *m*/*z* 493 (100% relative abundance) in the both spectra of [ZnL$_2$(*tmen*)]. The peaks at *m*/*z* 495, 494, 492 and 491 correspond to (MH_2^+), (MH^+), (M^+-H), (M^+-2H), respectively. In the APCI-MS spectrum of [ZnL$_2$(*tmen*)], low mass ions below *m*/*z* 493 are present at 377 and 281, respectively, corresponding to *tmen* ligand molecule and Br–C$_6$H$_3$–(O)–CH=N–N– fragment. The spectrum shows seven prominent ions at *m*/*z* 756, 872, 986, 1247, 1366, 1626, 1743, respectively, corresponding to {2[ZnL$_2$(*tmen*)] + 2H$^+$ − 2*tmen*}, {2[ZnL$_2$(*tmen*)] + 2H$^+$ − 1*tmen*}, {2[ZnL$_2$(*tmen*)]}, {3[ZnL$_2$-(*tmen*)] − 2*tmen*}, {3[ZnL$_2$(*tmen*)] + 3H$^+$ − 1*tmen*}, {4[ZnL$_2$-(*tmen*)] + 2H$^+$ − 3*tmen*}, {4[ZnL$_2$(*tmen*)] + 3H$^+$ − 2*tmen*}. In the ESI-MS spectrum of [ZnL$_2$(*tmen*)], low mass ions below *m*/*z* 493 are present at 377 and 196, respectively, *tmen* ligand molecule and Br–C$_6$H$_3$–(O)–CH=N–N–CS–NH–C$_2$H$_2$– fragment. The spectrum shows seven prominent ions

at m/z 674, 872, 988, 1247, 1363, 1626, 1742, respectively, corresponding to {[ZnL_2 (*tmen*)] + Zn(*tmen*)}, {2[ZnL_2-(*tmen*)] + $2H^+$ − 1*tmen*}, {2[ZnL_2(*tmen*)] + $2H^+$}, {3[ZnL_2-(*tmen*)] − 2*tmen*}, {3[ZnL_2(*tmen*)] − 1*tmen*}, {4[ZnL_2(*tmen*)] + $2H^+$ − 3*tmen*}, {4[ZnL_2(*tmen*)] + $2H^+$ − 2*tmen*}. In comparison with the ESI-MS, APCI-MS shows a similar pattern of peaks above molecular ion peak, m/z 493. The higher mass ions are condensation products of lower mass ions. The polymer peaks in the spectrum must be formed by the association of the initially formed molecular ion with the neutral *tmen* molecule.

Molecular ions are present at m/z 444 (100% relative abundance) in the both spectra of [ZnL_1(*tmen*)]. In the APCI-MS spectrum of [ZnL_1(*tmen*)], the peaks at m/z 328, 443, 444, 445, 774, 890, 1218, 1332, 1431, 1546, 1662 corresponds to (M^+−*tmen*), (M^+−H), (M^+), (MH^+), {2[ZnL_1 (*tmen*)] + $2H^+$ − 1*tmen*}, {2[ZnL_1 (*tmen*)] + $2H^+$}, {3[ZnL_1(*tmen*)] + $2H^+$ − 1*tmen*}, {3[ZnL_1(*tmen*)]}, {4[ZnL_1(*tmen*)] + + $3H^+$ − 3*tmen*}, {4[ZnL_1(*tmen*)] + $2H^+$ − 2*tmen*}, {4[ZnL_1(*tmen*)] + $2H^+$ − 1*tmen*}, respectively. In the ESI-MS spectrum of [ZnL_1(*tmen*)], the peaks at m/z 328, 443, 444, 445, 773, 890, 1218, 1332, 1430, 1546, 1662 corresponds to (M^+ -*tmen*), (M^+−H), (M^+), (MH^+), {2[ZnL_1(*tmen*)] + $1H^+$ − 1*tmen*}, {2[ZnL_2(*tmen*)] + $2H^+$}, {3[ZnL_2(*tmen*)] + $2H^+$ − 1*tmen*}, {3[ZnL_2(*tmen*)]}, {4[ZnL_2-(*tmen*)] + $2H^+$ − 3*tmen*}, {4[ZnL_2(*tmen*)] + $2H^+$ − 2*tmen*}, {4[ZnL_2(*tmen*)] + $2H^+$ − 1*tmen*}, respectively.

4. Conclusion

I have presented the synthesis and characterisation of two novel zinc complexes containing chelating ligands. The mixed ligand complexes of type [ZnL(*tmen*)] are obtained with bidendate chelating *tmen* and dianionic thiosemicarbazone ligands. Up to this study, I know that the reaction of *tmen* with thiosemicarbazone in the presence metal ion gave dimeric complex containing no *tmen* molecule [18,19]. In this study, the presence of coordinated *tmen* molecule was confirmed by X-ray structure analysis, elemental analysis, atomic absorption spectrometer, magnetic susceptibility, molar conductivity, electrospray ionization (ESI) and atmospheric pressure chemical ionization (APCI) mass spectra and IR, UV–Vis, ^{1}H NMR and ^{15}N spectroscopies.

Abstract

The dinuclear Mn(II) complex, $[Mn_2(Hbida)_2(H_2O)_2]$, was prepared using a tetradentate tripodal ligand, *N*-(benzimidazol-2-ylmethyl)iminodiacetic acid (H_3bida) which has two carboxylate and one benzimidazole groups. The manganese ions are doubly bridged using μ,η^1-bridging monodentate carboxylate oxygen atoms. The Mn–Mn bond distance of 3.446 Å in the complex is comparable to that observed in the active site of the native *manganese arginase* enzyme (3.30 Å). The geometry of the complex with four carboxylates in two different types of binding modes, non-bridging monodentate and μ,η^1-type bridging monodentate, mimics the active site structure of *manganese arginase*. The magnetic properties of the complex show a coupling constant of $J = -0.471(1)$ cm^{-1}, which is consistent with weakly coupled antiferromagnetic Mn^{II} ($S = 5/2$) centers. The cyclic voltammograms of the Mn(II) complex in DMF show irreversible oxidation occurring around 570 mV (versus Ag/AgCl).

Keywords: Dinuclear manganese complex; Carboxylate bridge; Tetradentate tripodal ligand; Arginase

1. Introduction

Many of the studies on the synthesis and characterization of multinuclear manganese complexes have been directed towards the development of synthetic models [1–3] for diverse manganese enzymes, such as manganese arginase [4], manganese catalase [5] and the oxygen-evolving complex (OEC) of photosystem II [6]. These synthetic complexes have been prepared using multidentate ligands having various donor groups, among which a carboxylate donor group is important because of its role in forming the active site of metalloenzymes [7]. Various binding modes of carboxylates have been observed at the active sites of manganese metalloenzymes [4–7b,7d] (Scheme 1). The active site of manganese arginase that catalyzes the hydrolysis of L-arginine to L-ornithine and urea contains a dinuclear manganese center associated with four carboxylate groups, with all of which are in different binding modes [4f]. The manganese(II) ions in the arginase are bridged by a *syn–syn*-μ-carboxylate group, a μ,η^1-carboxylate group, and a water molecule, which leads to a Mn–Mn bond distance of 3.3 Å [4f]. Each manganese coordination sphere is completed by a histidine and either a monodentate carboxylate or a chelating bidentate carboxylate group, giving either a penta-coordinate square pyramidal or a hexa-coordinate distorted octahedral manganese center, respectively. The bridging water molecule is involved in a hydrogen bond interaction with the monodentate carboxylate oxygen atom and is supposed to participate in the hydrolysis of L-arginine through a metal-activated hydroxide mechanism [4d]. Even though numerous model complexes for either the manganese catalase [2] or the OEC [3] have been proposed and characterized,

Scheme 1. The carboxylate binding modes observed in various manganese metalloproteins.

only a few manganese model complexes for the arginase have been reported so far [1].

Here we report on the preparation and characterization of a dinuclear manganese(II) complex, which has two important structural features of the active site of the manganese arginase: the bridging μ,η^1-carboxylate group and intramolecular hydrogen bonding between the ligated water molecule and a non-bridging monodentate carboxylate. The complex was prepared using a manganese(II) acetate tetrahydrate and a tripodal tetradentate ligand, *N*-(benzimidazol-2-ylmethyl)iminodiacetic acid (H_3bida) that contains two carboxylate and one benzimidazole groups.

2. Experimental

2.1. Materials

The following commercially available chemicals were purchased and used without further purification: Mn(II) acetate tetrahydrate from Yakuri; methanol from Junsei; and pyridine from Aldrich Chemicals. *N*-(benzimidazol-2-ylmethyl)iminodiacetic acid (H_3bida) was prepared according to a literature procedure [8].

2.2. Physical measurements

Elemental analysis was performed at the Organic Chemistry Research Center in Sogang University (Korea) using a TE Flash EA 1112 series elemental analyzer. Infrared spectra were recorded using KBr pellets in the range 4000–400 cm^{-1} employing a Varian FTS 1000 FT-IR spectrometer.

2.3. Synthesis

$[Mn_2(Hbida)_2(H_2O)_2]$ (**1**) 0.132 g (0.502 mmol) of H_3bida was dissolved in 10 mL of methanol and 10 mL of pyridine. Then 0.123 g (0.502 mmol) of Mn(II) acetate tetrahydrate was added to the solution. The solution was stirred until the solution became clear, and then it was allowed to stand for a period of 7 days. Pale yellow crystals were separated from the solution, washed with methanol and water, and vacuum dried. (0.088 g, 53% yield). *Anal.* Calc. for $[Mn_2(Hbida)_2(H_2O)_2]$ ($Mn_2C_{24}H_{26}N_6O_{10}$) ($fw = 668.38$): C, 43.13; H, 3.92; N, 12.57. Found: C, 43.10; H, 3.99; N, 12.61%. IR (cm^{-1}): 3391.7(br), 3208.4(br), 3115.6(w), 3063.3(w), 2922.2(w), 1638.5(w), 1626.3(m), 1612.2(s), 1592.0(m), 1490.4(m), 1467.2(w), 1453.7(s), 1435.8(w), 1402.7(s), 1367.0(s), 1328.4(s), 1316.4(w), 1277.2(s), 1264.1(m), 1129.4(s), 1116.7(m), 1039.3(s), 1003.6(s), 977.0(s), 932.5(s), 911.0(m), 899.1(s), 844.7(w), 768.8(m), 754.1(s), 622.1(m), 428.9(m).

2.4. Electrochemistry

Electrochemical measurements were performed using a BAS CV-50W under an argon atmosphere in a conventional three-electrode cell consisting of an Ag/AgCl (3 M KCl) reference electrode, Pt wire counter electrode, and a glassy carbon working electrode. The glassy carbon electrode was freshly polished using alumina before each scan. The cyclic voltammogram of complex **1** was recorded using a DMF solution of the complex ($\sim$1 mmol/dm^3) with 0.1 mol/dm^3 of tetrabutylammonium tetrafluoroborate ($[CH_3(CH_2)_3]_4NBF_4$) as the supporting electrolyte.

2.5. Magnetic measurements

Magnetization measurements were carried out on powdered sample using a SQUID magnetometer (Quantum Design MPMS-7XL). Field-cooled magnetization data were collected in an applied magnetic field of $H = 500$ Oe in the temperature range $2\ K < T < 300\ K$. All the data shown were corrected for the diamagnetic background.

2.6. X-ray crystallography

A crystal was coated with paratone oil to prevent loss of crystallinity on exposure to air. The data collection was performed at -100 °C using Mo Kα radiation ($\lambda = 0.71073$ Å) employing a Bruker SMART CCD equipped with a graphite crystal, incident-beam monochromator. The SMART and SAINT software packages [9] were used for data collection and integration, respectively. The collected data were corrected for absorbance using SADABS [10] based upon Laue symmetry using equivalent reflections. Structures were solved by direct methods, and refined using full-matrix least-squares calculations employing the SHELXTL-PLUS software package [11]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms, except those attached to the lattice solvents, were found by difference Fourier peaks, and refined isotropically. Two pyridine sites were found as lattice solvents: one was located at a general position and the other was on a crys-

tallographic inversion center. The position of the largest electron density in the pyridine site of the general position was assigned as pyridyl nitrogen because there were no other indications, such as the involvement of a hydrogen bonding interaction, for any atoms around the site. All the atoms of the other pyridine site with the inversion symmetry were treated using the PART instruction to refine each position as 5/6 carbon and 1/6 nitrogen atom site, because the pyridyl nitrogen had to be disordered and it was not possible to distinguish it from other carbon atoms. Hydrogen atoms of the pyridine molecule on the inversion center were not included in the final least-squares refinement. Crystal and intensity data are given in Table 1.

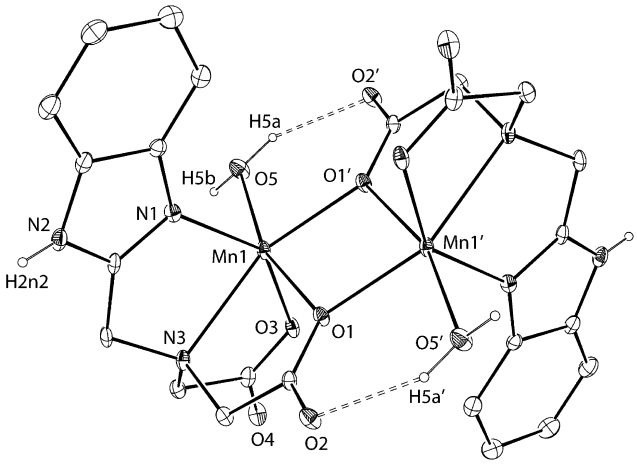
3. Results and discussion

3.1. Preparation and characterization

$[Mn_2(Hbida)_2(H_2O)_2]$ (**1**) was prepared using manganese(II) acetate tetrahydrate as a metal source and $Hbida^{2-}$ as a dianionic tripodal tetradentate ligand in the presence of pyridine as base (Scheme 2). Two different sets of carboxylate peaks in the IR spectrum of complex **1** suggest the presence of two different binding modes of the carboxylate groups. The bands occurring at 1612 cm^{-1} and 1403 cm^{-1} were assigned to an asymmetric and symmetric stretching vibrational mode of the bridging monodentate carboxylate group, respectively, and the bands occurring at 1592 cm^{-1} and 1454 cm^{-1} were assigned to an asymmetric and symmetric stretching vibrational mode of the non-bridging monodentate carboxylate group [12]. The $\Delta(\mu_{as} - \mu_s)$ splittings of 209 and 138 cm^{-1} for the carboxylate groups are similar to those of manganese complexes that have both a bridging monodentate carboxylate group and a non-bridging monodentate carboxylate group [13a,13c,14]. The two different carboxylate binding modes in complex **1** were identified from the single crystal structural analysis of the compound.

3.2. Molecular structure

An ORTEP drawing [15] of $[Mn_2(Hbida)_2(H_2O)_2]\cdot 3py$ (**1**) is shown in Fig. 1. Each hexa-coordinate manganese(II) center in the dinuclear complex with an inversion symmetry has an N_2O_4 donor environment, where the nitrogen (N1) atom is from the benzimidazolyl group and the other nitrogen (N3) atom is from the tertiary amine nitrogen of the ligand, one oxygen (O5) atom is from a water molecule,



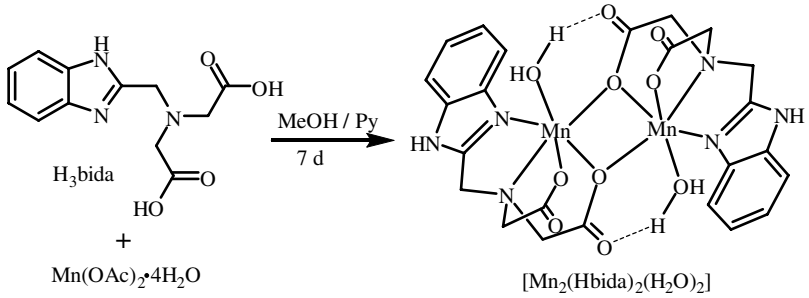


Fig. 1. An ORTEP drawing of $[Mn_2(Hbida)_2(H_2O)_2]\cdot 3py$ (**1**) at 30% probability thermal ellipsoids. Only the hydrogen atoms involved hydrogen bonding are shown, and the lattice solvent molecules have been omitted for clarity.

Scheme 2. Reaction scheme for $[Mn_2(Hbida)_2(H_2O)_2]$ (**1**).

and the remaining three oxygen atoms (O1, O1′, and O3) are from the carboxylate groups. The distorted octahedral coordination geometry of the manganese center is not unusual for a high-spin six-coordinate Mn(II) ion [16] (Table 2). The Mn–O bond distances (2.140(4)–2.184(3) Å) are in the range of the usual Mn^{II}–O bond distances. The distance between the manganese and the nitrogen atoms of the tertiary amine, 2.399(4) Å, is long for a Mn^{II}–N bond distance. This type of weak coordination has also been reported in the other Mn^{II} complexes having similar tertiary nitrogen atoms [13,17]. The two carboxylate groups in $Hbida^{2-}$ are in different binding modes: one in the non-bridging monodentate binding mode and the other in the bridging monodentate, μ,η^1-binding mode. This bridging mode leads to a dinuclear metal complex with a bis-μ,η^1-bridging Mn_2O_2 core. The Mn–Mn distance in this dinuclear complex (3.446(8) Å) is shorter than that of any known bis-μ,η^1-bridging dinuclear manganese model complex (3.489–4.091 Å range) [13,17,18], and nearly equal to that of the manganese arginase core (3.3 Å) [4f]. The sixth coordination site of the manganese(II) center is occupied by a water molecule, which is involved in intramolecular hydrogen bonding as the water molecule in the active site of the arginase. While the water molecule in the active site of the arginase enzyme bridges the two manganese(II) ions and participates in intramolecular hydrogen bonding with a non-coordinating oxygen atom of a monodentate terminal carboxylate, in complex **1**, the non-bridging terminal water molecule participates in intramolecular hydrogen bonding with a non-coordinating oxygen atom of a μ,η^1-bridging monodentate carboxylate. In addition to this intramolecular hydrogen bonding, the coordinate water molecule simultaneously participates in intermolecular hydrogen bonding with the carboxylate oxygen atom of the neighboring dinuclear complex (Table 3). A similar simultaneous intra- and intermolecular hydrogen bonding pattern has already been reported in a hepta-coordinated bis-μ,η^1-bridging dinuclear manganese complex prepared using a tripodal tetradentate ligand with two imidazole and one carboxylate groups [17a]. It is reported that the reaction of H_3bida with other transition metal ions such as V(IV), Ni(II), Co(II), and Zn(II) ions has led to only mononuclear six-coordinate complexes, where none of the carboxylates of the ligand are involved in any bridging modes [19]. While the reaction with Cu(II) ion in the presence of an additional chelating bidentate ligand has also led to a mononuclear complex [19b], but in the absence of the additional chelating bidentate ligand one-dimension coordination polymer has been obtained, where one carboxylate group is involved in a *syn–anti*-type bridging mode [19c]. Even though numerous carboxylate-bridged manganese complexes have been reported, most of these are of the *syn-syn*-type carboxylate-bridged complexes [20], and only a few μ,η^1-bridged manganese complexes have been reported in the literature [13,17]. All known μ,η^1-bridged manganese complexes have only one type of carboxylate group [13b,17]. μ,η^1-Bridged manganese complexes with more than one type of carboxylate group are: $[Mn^{II}_2(2,6\text{-dimethoxybenzoate})_4(Me_2Phen)_2(H_2O)_2]\cdot 2EtOH$ [13a] and $Mn^{II}_2(2,6\text{-dimethoxybenzoate})_4(bpy)_2(H_2O)_2$ [13c]. These complexes contain four carboxylate groups of two different types, where one is a non-bridging monodentate carboxylate group and the other is a μ,η^1-bridging monodentate group. Complex **1** is another example of a bis-μ,η^1-bridging dinuclear manganese complex with two different types of carboxylate groups prepared using a tripodal tetradentate ligand with two carboxylates and an benzimidazole group that provides a N_2O_2 coordination environment.

3.3. Magnetic properties

The magnetic susceptibility of complex **1** was measured in the temperature range 2–300 K. The effective magnetic moment (μ_{eff}) decreases slightly with decreasing temperature from 8.16 μ_B at 300 K to 7.88 μ_B at 30 K. Below 30 K, μ_{eff} decreases rapidly, and reaches a value of 4.57 μ_B at 2 K (Fig. 2). This behavior is typical of a weakly coupled antiferromagnetic system. We analyzed the χ_{mol} data by fitting it to the Eq. (1) derived from the isotopic Heisenberg exchange Hamiltonian $H = -2JS_1 \cdot S_2$ (where $S_1 = S_2 = 5/2$ for Mn^{II} high-spin d^5 ion systems) [21]. N is the Avogadro's number, μ_B is Bohr magneton, g is the Landé g-value, J is the exchange integral, and k is the Boltzmann's constant. A good fit curve was obtained for $J = -0.471(1)\ cm^{-1}$ and $g = 1.940$. This weakly antiferromagnetically coupled value of J for complex **1** is similar

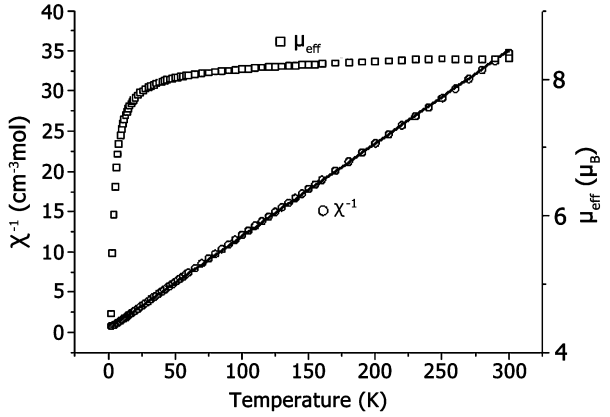

Fig. 2. The effective magnetic moment, μ_{eff}, of **1** and the Curie–Weiss plot ($1/\chi_{mol}$ vs. T).

to that of the other bis-μ,η^1-carboxylate bridged manganese complexes [13b,14a,17]

$$\chi_{mol} = \frac{2Ng^2\mu_B^2}{kT} \times \left[\frac{e^{J/kT} + 5e^{3J/kT} + 14e^{6J/kT} + 30e^{10J/kT} + 55e^{15J/kT}}{1 + 3e^{J/kT} + 5e^{3J/kT} + 7e^{6J/kT} + 9e^{10J/kT} + 11e^{15J/kT}}\right] \quad (1)$$

3.4. Electrochemical properties

The cyclic voltammogram of complex **1** in a DMF solution showed an irreversible oxidation wave around 570 mV (versus Ag/AgCl) as shown in Fig. 3. This irreversible redox feature of complex **1** is also similar to those in the other manganese(II) complexes with bis-μ,η^1-bridged carboxylate groups [13b,17b].

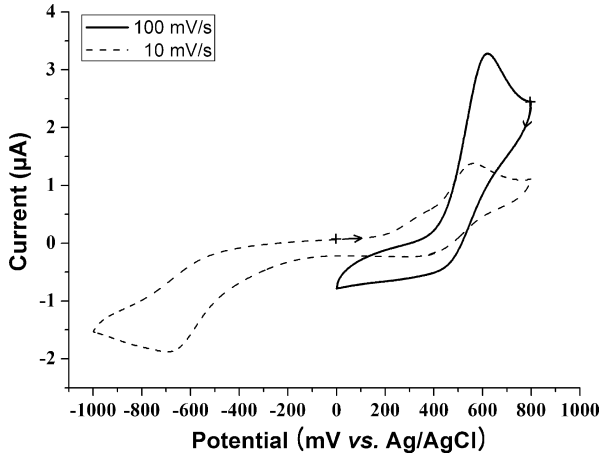

Fig. 3. Cyclovoltammogram of $[Mn_2(Hbida)_2(H_2O)_2]$ (**1**) in DMF with 0.1 mol/dm^3 of $[CH_3(CH_2)_3]_4NBF_4$ as supporting electrolyte. The scan presented with dashed lines was performed from 0 mV with initial anodic sweep at 10 mV/s scan rate, followed by cathodic sweep till −1000 mV, and then reversed back to 0 mV. The scan presented with solid line was performed from 800 mV with initial cathodic sweep at 100 mV/s scan rate, and then reversed at 0 mV.

4. Conclusions

We have characterized a hexa-coordinate dinuclear manganese(II) complex prepared using a tripodal tetradentate ligand, *N*-(benzimidazol-2-ylmethyl)iminodiacetic acid, having one benzimidazole and two carboxylate podal units. The coordination environment of complex **1** resembles that of the first coordination sphere of the native manganese *arginase*. Complex **1** mimics important structural features of the *manganese arginase* active site, such as the Mn–Mn distance, the hydrogen bonding pattern, the presence of four carboxylate groups with the same μ,η^1-bridging monodentate and non-bridging monodentate carboxylate groups. The Mn–Mn distance of 3.446 Å in complex **1** is closer to the value observed in the native *manganese arginase* core (Mn–Mn distance, 3.3 Å) than in any other dinuclear manganese complexes with the same μ,η^1-bridging monodentate carboxylate group. A similar intramolecular hydrogen bonding structure was also observed between the coordinated water molecule and the oxygen atom of the carboxylate group that is not involved in the coordination, as in the active site of the arginase. The magnetic properties and the redox behavior of complex **1** are similar to those reported in other bis-μ,η^1-bridging manganese(II) complexes [13,17].

In vitro and *in vivo* studies of *N*,*N*′-bis[2(2-pyridyl)-methyl]pyridine-2,6-dicarboxamide–copper(II) and rheumatoid arthritis

Sebusi Odisitse, Graham E. Jackson *

Department of Chemistry, University of Cape Town, Private Bag Rondebosch, 7701 Cape Town, South Africa

Abstract

The thermodynamic equilibria of copper(II), zinc(II) and calcium(II) with *N*,*N*′-bis[2(2-pyridyl)-methyl]pyridine-2,6-dicarboxamide (L1) have been studied at 25 °C and an ionic strength of 0.15 mol dm^{-3}. Spectroscopic studies suggest metal ion complexation promotes deprotonation and coordination of the amide nitrogens resulting in overall tetragonal coordination of Cu^{2+}. Blood–plasma modelling predicts that Cu(II) competes effectively against Zn(II) and Ca(II) for L1 *in vivo*. Octanol–water partition coefficient studies show that Cu(II)–L1 complexes are reasonably lipophilic. However, the $CuL1H_{-2}$ species which predominates at the physiological pH of 7.4 has poor superoxide dismutase activity. Bio-distribution experiments showed activity accumulation and retention in the body of about 50% of the injected dose for the [^{64}Cu]Cu(II)–L1 complex after 24 h.

1. Introduction

Rheumatoid arthritis (RA) is a chronic, debilitating disease for which there is no cure [1,2]. It is characterized by joint pain and swelling, joint destruction and pannus formation [2,3]. RA remains a medical challenge because it affects about 1% of the general population [4] and so far the exact cause of the disease is still unknown. However, the symptoms and progression of the disease can be treated using immunosuppressive and anti-inflammatory drugs [3,5]. Cu^{2+} has been observed to be effective in the treatment of RA [6]. Elevation of low molecular mass (lmm) Cu(II) complex species concentration in the plasma and synovial fluids of RA patients is well documented [6–8]. This suggests that Cu^{2+} may be a natural defence against inflammation and so an increase in lmm copper from either endogenous or exogenous sources may be beneficial.

With this hypothesis in mind, we have embarked on a programme of ligand design [9–11] with the aim of increasing lmm copper concentration *in vivo*. Recently, we have shown that 3,5-diaminodiamido-4-oxahexacyclododecane (cageL) (Fig. 1), forms stable, lipophilic, Cu(II) complexes capable of surviving *in vivo* as demonstrated by speciation calculations using a blood–plasma model and animal bio-distribution experiments [12]. In order to further improve the lipophilicity, the *N*,*N*′-bis[2(2-pyridyl)-methyl]pyridine-2,6-dicarboxamide (L1) shown in Fig. 1 was synthesised. This ligand has pyridyl groups which are found in most of the non-steroidal anti-inflammatory drugs (NSAIDs) and Cu(II)–NSAIDs complexes are reported to be more effective than their parent compounds [13]. The aromatic ring would also be able to increase the rigidity to the ligand system due to the aromatic ring system. Pre-organisation of the ligand structure for coordination as

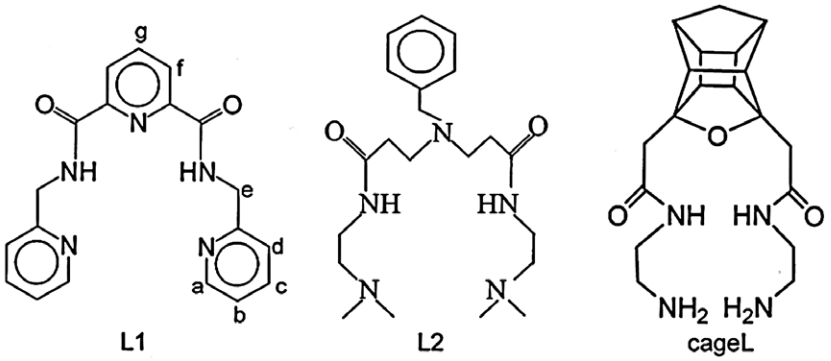

Fig. 1. Schematic structures of ligands discussed.

well as the aromatic groups on the ligand should increase both complex stability and lipophilicity.

The coordination chemistry of L1 with Cu^{2+} was explored by potentiometry, molecular mechanics (MM) calculation and, nuclear magnetic resonance (NMR), infrared (IR) and UV–Vis spectroscopy. Bio-modelling experiments include blood–plasma model simulations, octanol–water partition coefficients and superoxide dismutase (SOD) mimetic activity studies of the copper complexes. The *in vivo* verification of the modelling results was carried out by performing bio-distribution and dermal absorption studies on mice using radioactive ^{64}Cu(II) as a tracer. As Zn^{2+} and Ca^{2+} are potential *in vivo* competitors of Cu(II), their speciation with L1 has also been measured.

2. Experimental

2.1. Synthesis of N,N′-bis[2(2-pyridyl)-methyl]pyridine-2,6-dicarboxamide (L1)

N,*N*′-bis[2(2-pyridyl)-methyl]pyridine-2,6-dicarboxamide was synthesised following the method of Marlin et al. [14] and Hirao et al. [15]. Under nitrogen atmosphere 2,6-pyridinedicarbonyl dichloride (5 g, 0.0245 mol) in 100 cm^3 chloroform was added dropwise to a stirred solution of 2(2-aminomethyl)-pyridine (7.95 g, 0.0735 mol) in 150 cm^3 chloroform at 0 °C. The mixture was stirred for 1 h and then heated to reflux at 60 °C for 2 h. The solvent and excess 2(2-aminomethyl)-pyridine were removed under reduced pressure using a rotary evaporator. Recrystallisation from acetone gave a white solid that was dried under vacuum. The structure of the compound was confirmed by NMR spectroscopy, melting point and elemental micro analysis (CHN).

Yield: 5.1 g (60%), m.p. 150–154 °C (lit. 151–153 °C) [14] ^1H NMR(400 MHz) δ_H ($CDCl_3$) 4.81 (d, 4H, NCH_2), 7.23 (m, 2H, Py–H), 7.39 (m, 2H, Py–H), 7.68 (m, 2H, Py–H), 8.01 (t, 1H, Py–H), 8.34 (d, 2H, Py–H), 8.47 (dd, 2H, Py–H), 9.18 (t, 2H, C(O)NH), ^{13}C NMR(100.6 MHz) δ_C ($CDCl_3$) 44.43 ($NHCH_2$), 122.49, 122.66, 124.78, 137.27, 138.73, 148.75 (Py–C), 148.71, 157.08 (Py–C_{tert}), 163.74 (C(O)NH). Elemental *Anal*. Calc. for $C_{19}H_{17}N_5O_2$) C, 64.00; H, 4.90; N, 19.70. Found: C, 63.30; H, 4.89; N, 19.26%.

2.2. Potentiometric measurements

All solutions for potentiometry were prepared in glass distilled water which had been boiled to remove dissolved carbon dioxide. Recrystallized NaCl was used as background electrolyte at an ionic strength of 0.15 mol dm^{-3} (Cl^-). Other reagents, copper(II) chloride dihydrate, zinc(II) chloride, calcium chloride dihydrate, HCl, NaOH and EDTA (Merck) were commercially available and of analytical grade. These were used without purification. The 0.1 mol dm^{-3} solutions of NaOH and HCl were prepared from Merck Titrisol ampoules and standardized by titrating with potassium hydrogen phthalate (KHP) and sodium tetra borate decahydrate (Borax), respectively. The NaOH solutions were further standardized against the standard HCl solution. Acid–base titration was also used to check carbonate contamination of the sodium hydroxide titrant solution using the Gran method [16]. Otherwise these standardised solutions were used within a short period of time after preparation and were discarded whenever there were signs of carbonate contamination.

The potentiometric titrations were performed under an inert atmosphere of purified nitrogen, at 25 °C, using Radiometer PHM 84 research pH meter and Metrohm Dosimat 665 piston burette, which were linked and controlled by a computer. The pH meter was equipped with a Metrohm 6.0222.100 glass electrode, its slope determined from a buffer line and the response intercept, E^0, determined *in situ*. Titrations were performed in the pH range 2–11 in the concentration range 3×10^{-4}–1×10^{-3} mol dm^{-3} at metal ion to ligand ratios ranging from 1: 1 to 1: 3. Precipitation was observed in the titrations at metal to ligand ratio 1: 1 and at a pH > 8. The data were analysed using the ESTA suite of computer programs [17] which gave only models given in Table 1 for Cu(II), Zn(II) and Ca(II) systems. Various speciation models were tried based on the experimental Z_M-bar and Q_M-bar curves. The water ionization constant was determined to be 13.73 log units. The protonation constants of the ligand and the overall formation

σ_{pqr} denotes standard deviation in log β_{pqr}, R^H and R^H_{lim} are the Hamiltonian R-factor and its limit. The general formula of a complex is $M_pL_qH_r$.

constants of the Cu(II), Zn(II) and Ca(II) systems were computed using general expressions given as

$$pM + qL + rH \rightleftharpoons M_pL_qH_r \quad (1)$$

$$\beta_{pqr} = [M_pL_qH_r]/[M]^p[L]^q[H]^r \quad (2)$$

where p, q and r are stoichiometric coefficients of the components in the complex.

2.3. Spectroscopic and molecular mechanics measurements

UV–Vis spectra were recorded at 25 °C on a Cary 100 Conc spectrophotometer. Aqueous solutions containing 1:2 ratio of Cu(II):L1 were investigated in the pH range 2–11 and wavelength region 340–800 nm. Small amounts of 0.1 mol dm^{-3} NaOH or HCl were used to adjust the pH during the titration. NMR samples were prepared in D_2O at ligand concentration of 0.015 mol dm^{-3} and a Cu(II) concentration of 0.007 mol dm^{-3}. ^{1}H NMR spectra were recorded on a Varian Unity Plus 400 MHz instrument. The pH values were corrected for the deuterium isotope effect using Eq. (3) [18].

$$pH = 0.929pH^* + 0.41 \quad (3)$$

where pH* is a direct reading in D_2O solution of the H_2O-calibrated pH meter.

IR spectra were recorded at 25 °C on a Perkin Elmer Spectra One FT-IR spectrometer (Overhead–ATR ZnSe top plate). Solutions of ligand concentration of 0.1 mol dm^{-3} and a Cu(II) concentration of 0.09 mol dm^{-3} were prepared in D_2O and scanned in the pH range 1–12 and wavenumber region 1400–1700 cm^{-1}. The pH of the solutions was adjusted using NaOD or DCl for both NMR and IR studies.

Molecular mechanics calculations were performed using the Discover 3 module of the Accelrys life sciences molecular modelling software, InsightII [19]. For the free ligand, the cvff force field was used while for the metal complex the esff force field was used.

2.4. Bio-modelling measurements

Blood–plasma modelling was performed using a blood–plasma equilibrium database consisting of 10 metal ions and more than 5000 ligands [20]. To this database, the protonation and Cu(II), Zn(II) and Ca(II) formation constants determined in this study were added. The database was used together with typical constituent concentrations of blood–plasma [20] to calculate the speciation of the system and the plasma mobilizing index (pmi) of the ligand. This was achieved using the evaluation of constituent concentration in large equilibrium systems (ECCLES) program [21]. Pmi is a measure of the ability of a ligand to move metal ion from a protein bound form to a low molecular weight form. It is defined by:

$$\text{pmi} = \frac{(\text{total concentration of low-molecular-weight metal complex species in the presence of drug})}{(\text{total concentration of low-molecular-weight metal complex species in normal plasma})}$$

The superoxide dismutase (SOD) mimetic activity of the Cu(II)–L1 system was measured using the nitro blue tetrazolium (NBT) assay at a physiological pH of 7.4 [22–24]. Standard solutions of (i) 0.0004 M xanthine, (ii) 0.0001 M EDTA, (iii) 0.0001 g/cm^3 of catalase, (iv) 0.018 U/cm^3 xanthine oxidase and (v) 0.001 mol dm^{-3} solutions of Cu(II)–L1 complex in 0.05 M phosphate buffer were prepared. In a 4 cm^3 cuvette, 0.6 cm^3 xanthine, 0.2 cm^3 EDTA, 0.2 cm^3 NBT, 0.1 cm^3 catalase and 2.9 cm^3 of phosphate buffer were added and this constituted a blank solution. In a control experiment, in addition to these compounds, 0.4 cm^3 xanthine oxidase and 2.5 cm^3 instead of 2.9 cm^3 phosphate buffer solution were added while in the test solutions, varying volumes of the Cu(II)–L1 complex solutions were added prior to the addition of xanthine oxidase. The concentrations of Cu(II)–L1 SOD mimics ranged from 2.5×10^{-6} mol dm^{-3} to 4.5×10^{-4} mol dm^{-3}. The absorbance readings at 560 nm were obtained at 30 s intervals for a total period of 10 min for the control and experimental SOD solutions. For each set of readings corresponding to a control and a particular concentration of the complex, the absorbance was plotted against time and the slopes of the resulting plots were computed. The %inhibition of the reduction of NBT to formazan was calculated and IC_{50}

values similarly determined from plots of %inhibition versus concentration of the Cu(II)–L1 complex.

Partition coefficients were measured at 25 °C and an ionic strength of 0.15 mol dm^{-3} (Cl^-) using ^{64}Cu and the shake flask method [10,25]. Briefly, into 15 20 cm^3 glass vials, 5 cm^3 portions of Cu(II) (0.001 mol dm^{-3})–L1 (0.002 mol dm^{-3}) solutions were pipetted. The first vial was left at pH 3.0 while the rest of the vials were adjusted in 0.5 pH increments apart using 0.1 mol dm^{-3} of NaOH. These solutions were then spiked with $^{64}CuCl_2$ solution of activity 5 mCi. To each vial containing the spiked metal–ligand solution, 5 cm^3 portions of water saturated 1-octanol were added. These were then stoppered and shaken for 10 min, swirled to collect droplets from the sides of the vials and set aside to allow the two phases to separate at a constant temperature of 25 °C. 1 cm^3 of each phase was pipetted into radioactive counting vials using a microlitre pipette and activity of each phase counted for 5 min in a Minaxi Auto gamma counter (5000 Series-Packard) using a window set at 340–540 eV.

2.5. Bio-distribution and dermal absorption studies

^{64}Cu was prepared by neutron irradiation of 1.7–2.5 mg copper(II) oxide (99.9999%, Aldrich Chem. Co., WI, USA) for 24 h at a thermal neutron flux of 1.0×10^{14} neutrons cm^{-2} s^{-1} in a Safari-1 Research Reactor. The targets were dissolved in 1.0 ml, 1.0 M HCl and diluted to 3.0 ml with 1.0 M HCl. Typical specific activities of 98% radioactively pure ^{64}Cu of ~600 MBq mg^{-1} target material were obtained.

^{64}Cu-labelled Cu(II)–L1 complexes were prepared by spiking 20 cm^3 of Cu^{2+} (0.001 mol dm^{-3})–L (0.003 mol dm^{-3}) solutions with 10–14 mCi $^{64}CuCl_2$(aq). Bio-distribution studies were carried out by injecting 6–8 weeks old Balb/c mice with 0.2 cm^3 of 5 μCi [^{64}Cu]Cu(II)–L1 solutions or $^{64}CuCl_2$(aq) as a control. The mice were kept individually in polycarbonate cages and allowed water and food *ad libitum*. At 6 and 24 h post-injection time points, groups of mice (three at a time) were anaesthetized by carbon dioxide inhalation and aliquots of blood taken from the heart. Various samples were removed, rinsed with NaCl (0.9%), dried and then weighed. The radioactivity in these samples as well as the collected urine were counted using a Minaxi Auto-gamma 5000 Series counter with the window set at 340–540 keV. Dermal absorption experiments were performed by applying 0.2 cm^3 of 5 μCi solutions to an enclosed portion of skin on the anterior dorsal side of the test animals. The application site was prepared 15 h prior to dosing by clipping an area of approximately 2×2 cm on the dorsal side of the test animals. The animals were anaesthetized with a saline solution of ketamine/xylazine following clipping and a small tubing ring (1.2 cm diameter and 0.5 cm height) was fixed to their backs using cyanoacrylate adhesive. At 24 h post-dosing, groups of mice (four at a time) were anaesthetized by carbon dioxide inhalation and the same procedure followed as above. The percentages of radio-activity dose per organ and/or per gram (g) tissue were computed from the mean organ weights after correction for radio-activity decay.

The bio-distribution and dermal absorption studies on mice were approved by the Research Animals Ethics Committee of the University of Cape Town (permission number 005/039). The authority to possess and use radioactive nuclide ^{64}Cu was granted by the university's radiation protection and health safety committee in conjunction with Department of Health (authority number 33/01/0327).

Caution: ^{64}Cu decays by positrons emissions, which annihilate to produce tissue penetrating high energy γ-radiation. Therefore, it is advisable to use low activity of ^{64}Cu and perform all experiments behind lead bricks inside a fume cupboard.

3. Results and discussion

3.1. Potentiometry

The three measurable acid dissociation (protonation) constants corresponding to the pyridyl nitrogens of L1 are given in Table 1. Deprotonation of the amide nitrogens was not observed because they are too basic ($pK_a \geqslant 15$) [11,26,27] for the measurable pH range 2–11 of our glass electrode system. The $pK_{a1} = 1.98$ is assigned to the protonation of the central pyridyl nitrogen whereas $pK_{a2} = 3.51$ and $pK_{a3} = 4.62$ are for the protonation of the terminal pyridyl nitrogens. The low value of the first protonation constant (pK_{a1}) is due to the electronic repulsion effect and the base weakening effect of the adjacent amide groups [28]. The pK_a values of pyridine and 2-methylpyridine are reported as 5.34 and 6.14, respectively [29], whereas the introduction of a carbonyl group in 2-methylpyridine resulted in a pK_a value of 2.66 [30]. Therefore, it would be expected that the protonation constant corresponding to the central pyridyl nitrogen in L1 should decrease further when two amide groups are present. The difference of 1.11 log units between pK_{a2} and pK_{a3} indicates electronic repulsion on addition of a proton to a charged species or rather to an already doubly protonated molecule. On statistical grounds a difference of only 0.6 is expected for equivalent protonation sites.

The complex formation (Z_M-bar) and the deprotonation (Q_M-bar) functions [10,25] derived from the experimental data have been used to visualize the experimental data and to decide on the speciation model. The Z_M-bar function measures the number of ligands bound per metal ion while Q_M-bar indicates the number of protons released upon metal ion complexation. The two functions are derived from the free and total concentrations of the participating components as well as the measured protonation constants. The classical complex formation function should level at a Z_M-bar value of 1 for mononuclear ML species formation. This was not observed to be the case for the Cu^{2+}, Zn^{2+} and Ca^{2+}-L1 systems. Fig. 2a shows the

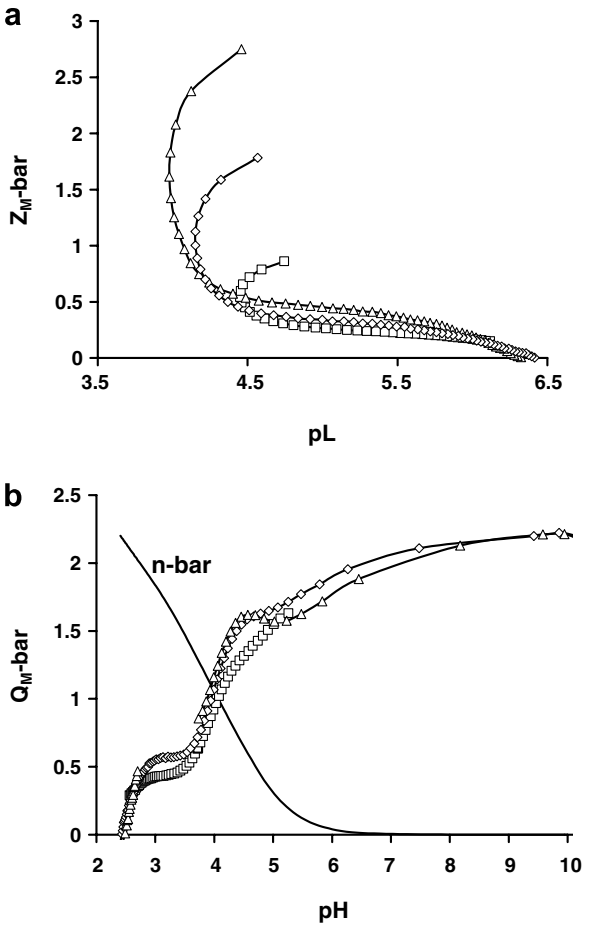

Fig. 2. Experimental and theoretical (solid line) (a) formation function and (b) deprotonation function curves for Cu(II)–L1 system at 25 °C and an ionic strength 0.15 M (Cl^{-1}). M:L ratios 1:1 (□), 1:2 (◇) and 1:3 (Δ) are displayed. The theoretical line was calculated using the model given in Table 1.

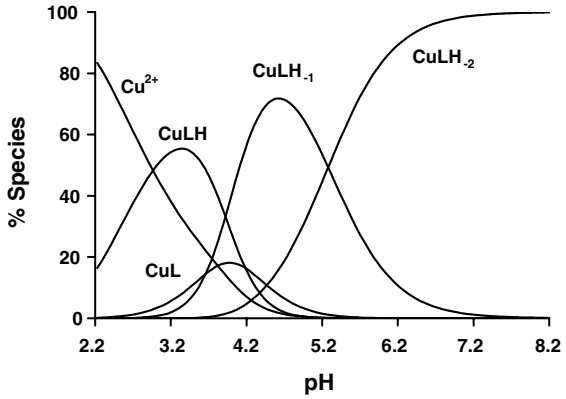

Fig. 3. Calculated speciation distribution graphs for a Cu(II)–L1 solution ([M] = 0.00051 mol dm^{-3}, [L] = 0.00101 mol dm^{-3}) as a function of pH.

Z_M-bar function plotted against pL (−log[L]). The Z_M-bars level off at 0.5 indicating that ML is not the predominant species in solution. The splitting of the curves for different metal to ligand ratios is due to the presence of polynuclear or protonated species. In fact the protonated CuLH is a majority species in solution as shown by the speciation graphs in Fig. 3. The fanning back of the curves is indicative of hydroxo and/or mixed hydroxo species formation.

The Q_M-bar function (Fig. 2b) rises vertically at pH 2.5 indicating that complexation occurs at the beginning of the titrations. In fact the speciation graphs in Fig. 3 show that CuLH is already formed (18% formation) at the start of the titration. The Q_M-bar curves rise from 0 to a maximum value of about 2.3 (n-bar > 2) indicating that approximately three protons have been released as a result of complexation. The n-bar function measures the average number of protons that would be bound to the ligand in the absence of the metal ion. Since a complete deprotonation (n-bar = 0) of L1 occurs at pH 6.2, the metal assisted deprotonation of the amide is likely to occur at an early stage thus forming $CuLH_{-1}$ and/or $CuLH_{-2}$. The analysis of these curves using the ESTA suite of programs [17,31], yielded the results given in Table 1. Despite the split of the curves at different metal to ligand ratios, the reproducibility of repeat titrations, low standard deviations and the Hamilton R-factors as well as an excellent agreement between the theoretical and experimental complex formation and deprotonation functions lend confidence to the results. The Zn(II) system showed similar complexation behaviour while for the Ca(II) system, no amide deprotonation was detected.

The formation constants (log β'_{pqr}s) for the MLH, ML, MLH_{-1} and MLH_{-2} complexes of the Cu(II)–L1 are given in Table 1. These values are lower than the corresponding values for the Cu(II)–cageL and Cu(II)–L2 systems [12,32]. The decrease in stability is due to the incorporation of the less basic or rather acidic pyridyl groups in L1. Zn(II) and Ca(II) were also found to form reasonably stable complexes with L1 but their stability is much lower than that of Cu(II). The order of stability Cu(II) > Zn(II) > Ca(II) is as expected [33]. Although Ca(II) and Zn(II) are weaker chelators than Cu(II), the *in vivo* concentration of these two essential metal ions is far higher than that of Cu(II) and so they could potentially compete for the ligand. The speciation distribution curves given in Fig. 3 show that $CuLH_{-2}$ is the predominant species at a physiological pH of 7.4.

From potentiometric data alone it is not possible to deduce the structure of the different complexes formed in solution. Therefore, spectroscopic measurements and molecular mechanics (MM) calculations were carried out in order to support or verify the potentiometric results.

3.2. Nuclear magnetic resonance studies

Nuclear magnetic resonance has been used to determine the sequence of protonation of L1 and also to gain some insights into the sites of metal coordination. Fig. 4 shows plots of chemical shifts as a function of pH where (a), (b), (c), (d), (e), (f) and (g) refer to the chemical shifts of the protons attached to carbons labelled (a)–(f) in Fig. 1. The

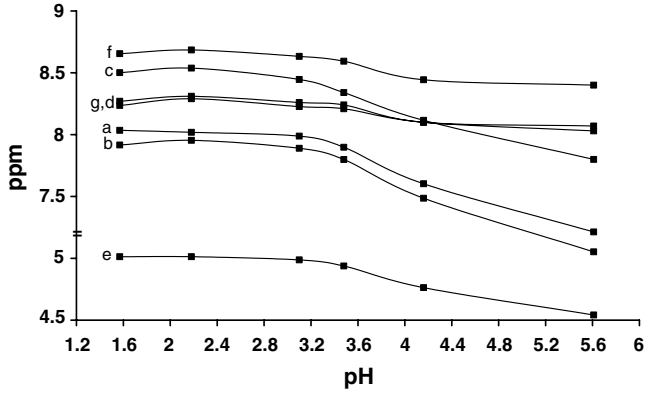

Fig. 4. Change in proton chemical shift (ppm) as a function of pH for L1 system. The protons are labelled according to Fig. 1.

assignment of these resonances is based on their chemical shifts and coupling patterns. Since the molecule is symmetrical and the protons undergo rapid chemical exchange, only a single set of resonances is seen for each species. A single inflection is seen in Fig. 4 with protons (a), (b) and (c) being most affected. These protons must be closest to the protonation site and hence confirm that it is the terminal pyridines that are being protonated. The inflection point in the chemical shift curves can be used to estimate a single pK_a value of 4.3 for these two protonation sites. This value is in good agreement with the potentiometric results. The chemical shift changes in the pH range 1.2–3.0 are too small to reliably estimate the pK_a of the central pyridine.

Fig. 5 shows the effect of Cu(II) on the spectrum of L1. Cu(II) is paramagnetic which can affect both the chemical

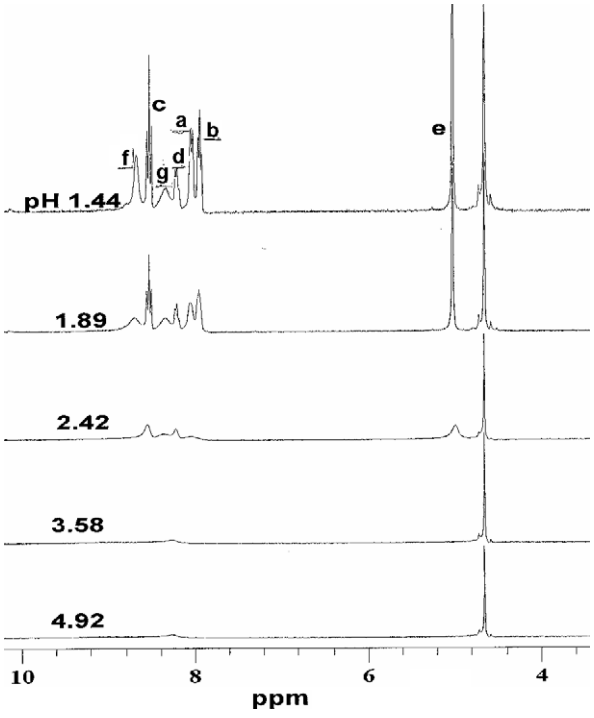

Fig. 5. Proton NMR spectra for the complexation of Cu(II) with L1 ([M] = 0.0075 mol dm^{-3}, [L] = 0.015 mol dm^{-3}) as a function of pH. The protons are labelled according to Fig. 1.

shift and relaxation time of the protons [34]. This manifests in a broadening and shifting of the NMR signals. Unless there is pseudo-contact shift, the broadening effect is usually more apparent. This is attenuated by $1/r^6$, where r is the internuclear distance between the Cu(II) and the observed proton. Cu(II) exchange for non-macrocyclic ligands is normally very rapid and so only average spectra will be seen. The spectrum shows that there is complexation at pH 1.44, with the (f) and (g) protons being preferentially broadened suggesting that the central pyridine is coordinated to the Cu(II). The fact that the other protons are not substantially broadened indicates that the terminal pyridines are not coordinated at this low pH. Between pH 1.89 and 2.44, the protons of the terminal pyridines and the methylene protons also broaden, indicating coordination of the terminal pyridine/s to the Cu(II). At this pH, the MLH species predominates (Fig. 3). These results support the structure postulated for MLH in Fig. 7. Further, the NMR results suggest that another species, presumably MLH_2 is formed at low pH. This species would not have been detected in our potentiometric study whose lower limit was pH 2.0.

3.3. Infrared studies

We have used infrared spectroscopy to establish the involvement of the amide oxygen or nitrogen in the course of the complexation process [19,35]. The infrared spectral data of the asymmetric amide carbonyl stretching vibration for L1 system are given in Table 2. Protonated L1 has an amide carbonyl band frequency of 1656 cm^{-1} and this band shifts slightly to lower frequency at higher pH. At pH 3.0, upon complexation by Cu(II), besides the 1656 cm^{-1} band, two new absorption bands at 1568 and 1591 cm^{-1} appear. The 1656 cm^{-1} band indicates that there is uncoordinated carbonyl amide present in the complex. Steenland et al. have assigned the 1591 cm^{-1} band to a carbonyl group with strong coordination through the oxygen. The 1568 cm^{-1} band was assigned to an amide carbonyl with coordination through the amide nitrogen. At pH 3.0, the MLH species predominates and the observed IR bands accord with the structure proposed in Fig. 7. Above pH 3 the ML and MLH_{-1} species begin to appear and a new band at 1578 cm^{-1} appears. This band can be assigned to a second amide nitrogen coordination [35]. At pH 5.4 no MLH is present and the 1656 cm^{-1} band disap-

Table 2
Infrared spectral data of the asymmetric amide carbonyl stretching vibration in the Cu(II) complexes of L1 in D_2O solution at 25 °C as a function of pH

Metal–ligand	pH	Wave number (cm^{-1})			
H–L1	1.21	1656			
Cu(II)–L1	2.58	1656	1591	1568	
	2.97	1656	1591	1565	
	3.34	1656	1594	1578	1565
	5.40		1594	1578	1565

pears. In Fig. 7, two possible structures are proposed for the MLH_{-1} species. The IR data support structure 7a because both amide are coordinated. The results would also suggest that for the ML species, the second amide carbonyl is also coordinated.

3.4. UV–Vis spectrophotometry

Distinct changes were observed in the colour of a solution of Cu(II) and L1 as the pH of the solution was increased. This was a result of the changing speciation of the solution, different species with different absorption spectra predominating at different pH values. Fig. 6 shows the absorption spectra for the Cu(II)–L1 system as a function of pH. At pH 2.39, an absorption maximum of 660 nm is seen indicating that there is already complexation at the start of titration. This was also observed in the potentiometric (Fig. 3) and NMR (Fig. 5) studies. As the pH increases, the band increases in intensity and shifts to shorter wavelength. Above pH 5.81 a slight red shift is observed. The spectra were deconvoluted using the UV-SPEC program [36] to yield spectra for the individual species. This deconvolution was based on the metal ion speciation calculated from the potentiometric model given in Table 1 and incorporated into an expanded Beer–Lambert Law which was then solved for the molar absorptivity of the different species at each wavelength. The smoothness of these spectra lends confidence to the potentiometric model. A single broad absorption band was obtained which envelopes the expected three spin allowed $^2A_{1g} \leftarrow {}^2B_{1g}$, $^2B_{2g} \leftarrow {}^2B_{1g}$ and $^2E_g \leftarrow {}^2B_{1g}$ transitions of a tetragonally distorted Cu(II) complex [37,38].

Analysis of the data yielded wavelength absorption maxima (λ_{max}) and molar extinction coefficients (ε) listed in Table 3 for the MLH, ML, MLH_{-1} and MLH_{-2} complexes. The electronic spectra are useful because the coordination sphere of the metal ion influences the energy of the transition. Therefore, λ_{max} affords a measure of the solution structure of the complex. Billo [39] and subsequently Sigel and Martin [40] have proposed a simple empirical method for estimating the electronic energy of a proposed configuration. In addition to contributions by donors

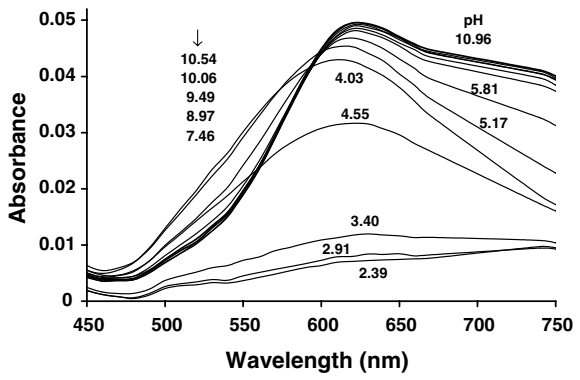

Fig. 6. Electronic absorption spectra of Cu(II)–L1 solution as a function of pH ([M] = 0.00051 mol dm^{-3}, [L] = 0.00101 mol dm^{-3}) at 25 °C.

Table 3
Wavelength absorption maxima (λ_{max}) corresponding to molar extinction coefficients (ε) of the various Cu(II)–L1, Cu(II)-L2 and Cu(II)-cageL complex species in solution

Ligand	λ_{max} (nm) ε (mol^{-1} dm^{-3} cm^{-1})			MLH_{-1}	MLH_{-2}
	Cu^{2+}	MLH	ML		
L1	760(22)	660(24)	610(15)	600(92)	620(95)
L2	780(20)	600(40)	580(115)	580(120)	540(110)
CageL	790(20)	720(40)	660(115)	590(120)	

reported by these authors, we deduced contribution due to the pyridine nitrogen ($\nu_{py-N} = 4.22 \times 10^3$ cm^{-1}) from the study by Osz et al. [41]. The MLH species has a $\lambda_{max}(\varepsilon)$ of 660 nm (24 mol^{-1} dm^{-3} cm^{-1}) which is close to a calculated λ_{max} of 668 nm, calculated for when the metal ion is coordinated to oxygen and two pyridine nitrogens. The blue shift in λ_{max} in forming MLH from hydrated Cu(II) reflects the increased ligand field splitting of L1 as opposed to H_2O. Similarly, the λ_{max} (ε) value, 610 nm (15 mol^{-1} dm^{-3} cm^{-1}) for the ML species is close to the 613 nm, calculated for the structure proposed in Fig. 7. However, the λ_{max} of 600 nm (92 mol^{-1} dm^{-3} cm^{-1}) observed for the MLH_{-1} species is significantly different from the values calculated for the structures MLH_{-1} (a) (551 nm) and MLH_{-1} (b) (571 nm) in Fig. 7. Notwithstanding this, we believe that the MLH_{-1} (a) structure in Fig. 7 is the correct structure and the red shift in the spectrum is due to the considerable distortion of the metal coordination sphere. This distortion is supported by the extinction coefficient of the complex. Marlin et al. obtained a band with λ_{max} at 613 nm ($\varepsilon = 220$ mol^{-1} dm^{-3} cm^{-1}) for this system in methanol [42].

The MLH_{-2} species shows a red shift of 20 nm which suggests axial coordination of a fifth nitrogen donor as in the structure Fig. 7 MLH_{-2} (b). A red shift of 50 nm was also observed for the formation of $[Cu(NH_3)_5(H_2O)]^{2+}$ complex from $[Cu(NH_3)_4(H_2O)_2]^{2+}$ [37]. The absorption maxima for the Cu(II)–L1 system is somewhat red shifted as compared to those of Cu(II)–cageL and Cu(II)–L2 given in Table 3 [12,32]. The coordination geometry of the MLH_{-2} species in this system is likely to be overall tetragonal with only weak axial coordination of the fifth nitrogen. A strong axial interaction by nitrogen donor in MLH_{-2} would certainly shift its d–d absorption band to lower wave numbers relative to MLH_{-1} resulting from weakening of the in-plane ligand field by a synergic effect [26,38].

The structures proposed for the MLH_{-2} complex from potentiometric, NMR, IR and UV–Vis studies are supported by crystal structures of L1 and related ligands with Cu(II), Ni(II) and Zn(II) [42,43]. Using a tridentate ligand *N*,*N*′-dimethylpyridine-2,6-dicarboxamide, Marlin et al. [44] found that Cu(II) promoted deprotonation of the amide nitrogens. Using L1, it was found that again coordination was through the central pyridine, the two deprotonated amide nitrogens and one of the terminal pyridines [42,43].

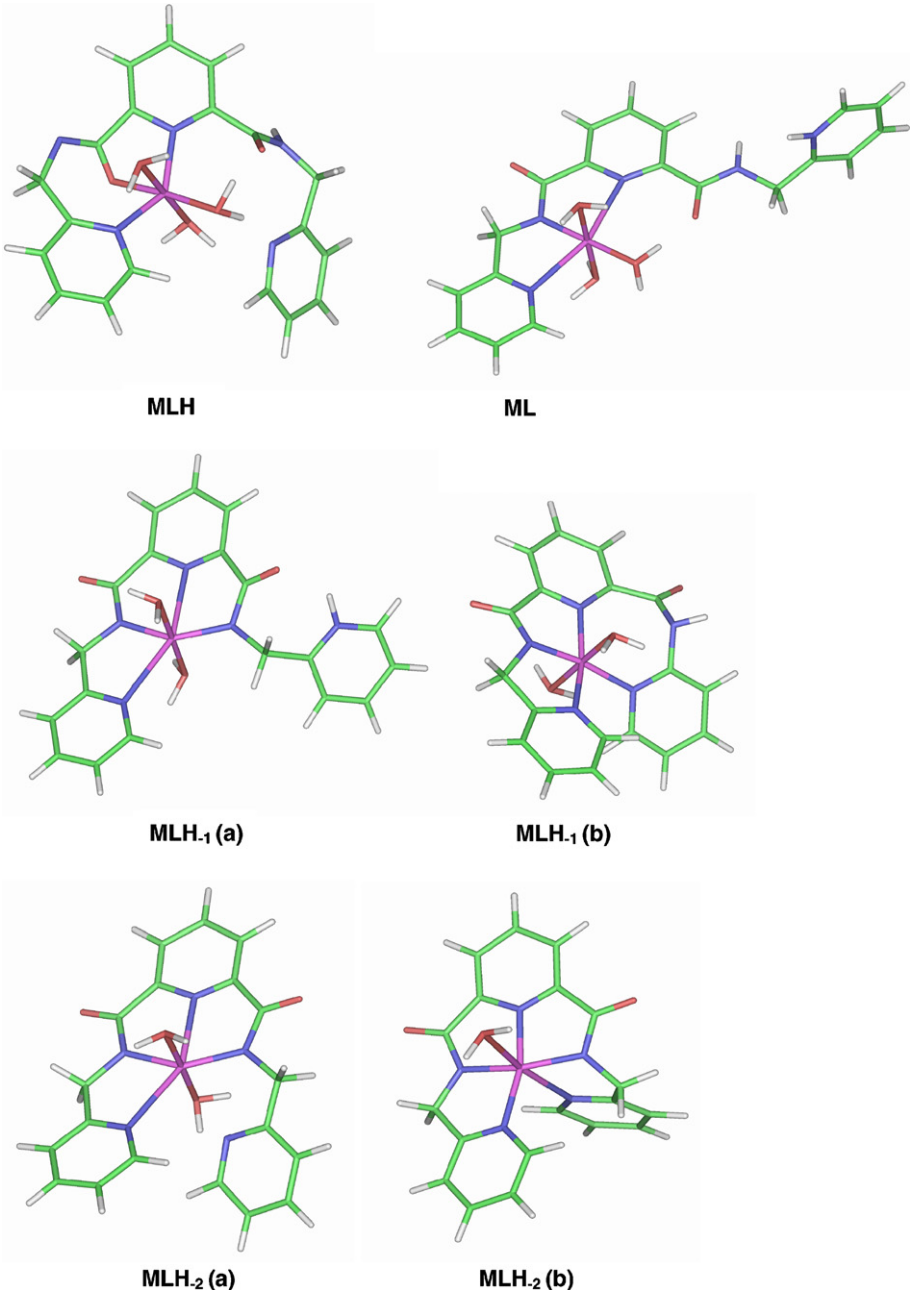

Fig. 7. Energy minimised structures for the Cu(II)–L1 species.

3.5. Molecular mechanics calculations

Molecular mechanics (MM) is a very popular tool for describing the structures and relative energies of many classes of molecules [45,46]. Its wide use is primarily due to its computational simplicity and efficiency whereas quantum mechanical modelling is far more computationally intensive and until recently, has been used only rarely for metal complexes. In this study, we have used MM to calculate the internal energy (strain energy) of different possible ligand conformations found in the different metal complexes. This strain energy would be one of the energy contributions to the overall stability of the complex. The chelate effect, as an entropic contribution, and the ligand field stabilisation energy of the metal ion, are two other important energy contributions, but are not taken into account in these calculations.

Fig. 7 shows the energy minimised structures for the different, mostly likely, formed isomers of Cu(II)–L1. In the structure proposed for MLH (Fig. 7), the central nitrogen, one terminal pyridyl group, and a carbonyl oxygen are coordinated to the metal ion whereas in ML, an amide nitrogen donor atom is coordinated instead of the carbonyl oxygen. The MLH species has a larger strain energy than ML. This may be due to the rigidity of the pyridine moiety that contributes more to the strain energy when the car-

bonyl oxygen donor atom is coordinated to the metal ion. Two different coordination modes are presented for the MLH_{-1} and MLH_{-2} species. For the MLH_{-1} species, the isomer MLH_{-1}(a), has a larger strain energy than MLH_{-1}(b) whereas MLH_{-2}(b) is more strained than MLH_{-2}(a). The strain energy corresponding to chelate ring formation is in the order $5,5,5,5 > 5,5,5 > 5,5 > 5,8,5 > 5,5,8$, where the numbers refer to the size of the chelate rings.

It is worth noting that molecular mechanics has been used as a simple computational tool for providing more evidence in support of the potentiometric and spectroscopic studies. In all calculations, no account was taken of electronic contribution, Jahn-Teller distorsion of Cu(II), entropy or solvent effects.

3.6. Blood–plasma simulation

In the design of copper based anti-inflammatory agents, blood–plasma modelling has been used to estimate the ability of L1 to mobilize Cu(II) *in vivo* [21]. This was done by calculating the plasma mobilizing index (pmi) of the ligand using a thermodynamic model of blood–plasma. The pmi of a ligand for a metal ion is defined as the percentage increase in the total concentration of low molecular mass (lmm) complexes of the metal ion caused by the ligand. This takes into account competition between the ligand and all the endogenous metal ions and l.m.m ligands present in blood–plasma. In calculating the pmi curves use has been made of the ECCLES model [47,48] of blood–plasma to which constants determined in this study have been added.

Fig. 8a gives the pmi curves for L1 and related ligands. In comparison, L1 is three to four orders of magnitude better at mobilizing Cu(II) *in vivo* than cageL. The improved mobilizing ability of L1 compared to cageL is related to the stable complexes it forms with Cu(II). However, it is poorer than 3,6,9,12-tetra-azatetradecanedioic acid (TTDA) [47] by about six orders of magnitude. Inspection of Fig. 8b shows that L1 is selective to Cu(II) *in vivo* relative to Zn(II) and Ca(II). In fact, the remarkably high mobilizing ability of this ligand is related to this selectivity. At a total ligand concentration of 3.1×10^{-3} mol dm^{-3} for L1, the pmi's for Zn(II) and Ca(II) pmi's are very low (<0.01). In addition, the predominant copper complex present at physiological pH is the neutral $CuLH_{-2}$ species.

3.7. Superoxide dismutase activity studies

Along with hydrogen peroxide and the hydroxyl radical, superoxide has been implicated in oxidative damage phenomena related to aging, inflammation and post-ischemic injury via reperfusion [49,50]. The beneficial role of copper in minimizing inflammation has been attributed to its redox activity, particularly that of copper in such enzymes as superoxide dismutase (SOD) [22,50]. The important requirements for SOD-like activity are a medium donor

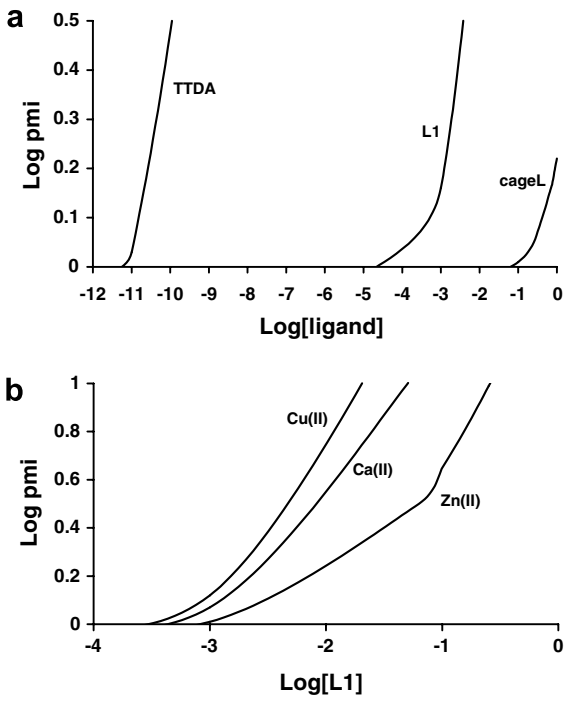

Fig. 8. Plasma mobilizing index for (a) Cu(II) with L1, cageL and TTDA, and (b) L1 with Cu(II), Zn(II) and Ca(II).

power and flexibility of the ligand, in order to facilitate the reduction and the accommodation of Cu(I), which is known to prefer tetrahedral or linear environments [51]. Of importance in this study is copper–zinc SOD which provides a cellular defence against the oxidative stress by catalyzing superoxide dispropotionation into less toxic dioxygen and hydrogen peroxide. The coordination geometry of the native SOD enzyme is distorted square-pyramidal for the Cu(II) and distorted tetrahedral for Zn(II).

Copper(II) complexes, including those of low molecular mass ligands and polypeptides, have been reported to exhibit SOD-mimic activity and thus are viewed as alternative human therapeutics to remove pro-inflammatory superoxide anion radical *in vivo* [22,52,53]. Although this is not an essential feature of or ligand design, we investigated the SOD activity of the [Cu(II)–$L1H_{-2}$] complex using the NBT assay [22–24]. EDTA was added to mimic the coordinating environment found *in vivo* because the Cu(II)EDTA complex has no SOD activity. An IC_{50} value of 275 μmol dm^{-3} for the [Cu(II)–$L1H_{-2}$] species was determined. This value is far higher than that of native CuZn-SOD (0.011 μmol dm^{-3}) [54]. The low activity of [Cu(II)–$L1H_{-2}$], relative to the native enzyme, may be due to the lack of suitable binding sites for the superoxide anion radical to coordinate to the metal ion.

3.8. Octan-1-ol–water partition coefficient studies

When administered orally and intravenously, copper(II) complexes do increase available copper. However, it is difficult to move this coordinated metal ion through a series

of body compartments without protein binding [21]. Transport across the skin and bio-membranes in general, is a process of limited diffusion governed by the drug's chemical and physical properties such as lipophilicity and protein binding [55,56]. We have determined the octanol–water partition coefficients of our copper complexes in order to ascertain if they can be applied as topical agents in the alleviation of the inflammatory process in RA.

Fig. 9 shows the partition coefficients ($\log P_{oct/aq}$) as a function of pH for the CuII)–L1 system. From this, it is possible to estimate the $\log P_{oct/aq}$'s of the individual species. The MLH species that is formed at the start of the titration (pH 2.2) has a $\log P_{oct/aq}$ value of −2.21. The low $\log P_{oct/aq}$ value is a result of high concentration of hydrated Cu(II) complex. The ML species coexists with MLH and MLH_{-1} and so it is difficult to measure its partition coefficient. However, the MLH_{-1} species predominates at pH 4.8 which corresponds to a $\log P_{oct/aq}$ value of −0.98. At a physiological pH of 7.4, MLH_{-2} is the predominant species and has a $\log P_{oct/aq}$ value of −0.58. Although these complexes are relatively hydrophilic, they are more lipophilic than previously studied copper complexes [12,32]. Pehourcq et al. [25] have reported positive $\log P_{oct/aq}$ values in the range 0.618–4.128 of some anti-inflammatory drugs. However, several workers have reported negative values in the range −1.60 to −3.02 for ^{64}Cu-labeled complexes [57–59].

For percutaneous absorption the drug should not be too lipophilic or it will be trapped in the epidermis. With our system, 19% of the Cu(II)–L1 complex was extracted into the organic phase of the octanol–water mixture at pH 7. We ascribe this to the presence of the bulky aromatic groups which suggests the importance of such groups in percutaneous drug administration.

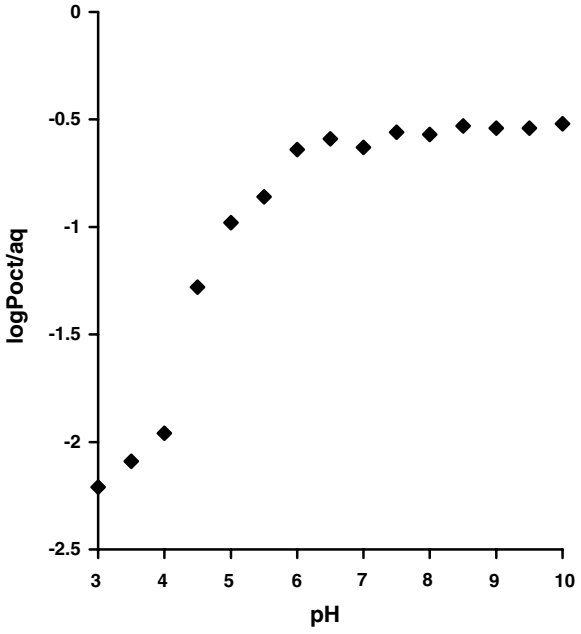

Fig. 9. Octanol–water partition coefficients of Cu(II)–L1 as a function of pH.

3.9. Bio-distribution and dermal absorption studies

Since the *in vitro* and bio-modelling showed encouraging results, we performed *in vivo* bio-distribution experiments. The bio-distribution was measured as a function of time in mice using ^{64}Cu(II) as a tracer or radiolabel. Table 4 shows the bio-distribution of ^{64}Cu(II) labelled Cu(II)–L1 and $CuCl_2$ at 6 and 24 h post-injection. The results show an initial rapid clearance from blood circulation and rapid uptake by the liver for both systems. The observed uptake of more than 60% of the administered dose by the liver is expected because copper storage and metabolism occur in this organ.

[^{64}Cu(II)]$CuCl_2$ used as a control, was rapidly excreted *via* hepatobiliary and renal routes. The Cu(II)–L1 complex has a much longer biological half-life than the copper complexes recently studied by Jackson et al. [9,32]. The activity retention over 24 h in the body of >50% dose for the [^{64}Cu]Cu(II)–L1 system is more or less the same as that of [^{64}Cu]Cu(II)-cageL [12]. This compares with only 20% of the [^{64}Cu]$CuCl_2$ control. Of interest is the fact that the carcass activity is higher after 24 h than 6 h. This is because after the rapid clearance from the blood by the liver, it is slowly released and redistributed into other tissues. For the control, most of the copper is excreted in the urine while for L1, there is a substantial amount in the intestines and retained in the liver.

Since the preferred route of administration is as a cream via the skin, bio-distribution studies were also performed using dermal absorption. The results in Table 5 show that a significant amount of activity is absorbed within 24 h.

Table 4
% Dose per organ and per gram tissue (in brackets) for bio-distribution in Bulb/c mice of [^{64}Cu]Cu(II)–L1 complexes following intravenous injection via the tail vein (mean ± std.dev., $n = 3$) after 6 and 24 h post-injection

Spleen	0.03 ± 0.01	0.3 ± 0.1	0.19 ± 0.02	2.1 ± 0.4
Urine	53 ± 12		38 ± 13	

Of note in these results is that the same bio-distribution as intravenous injection is not obtained. This is because of the different route of administration. Less activity is excreted in the urine and more activity is retained in the body. For the control, substantial hepatobiliary and urinary excretion is seen. This is the normal route of excretion of Cu(II). It was observed that up to 37% of the dose applied to the enclosed skin was absorbed over a period of 24 h. The activity accumulation and retention over 24 h in the body is encouraging and merits evaluation of this copper chelating agent for possible use in chemotherapy.

No attempt was made to isolate the excreted copper so it is not possible to say whether the complex remained intact or not. However, because different bio-distribution results were obtained for $CuCl_2$ and Cu(II)–L1 we conclude that the speciation of the metal ion is different in the two systems *in vivo*.

4. Conclusion

The ligand L1 is quite selective towards Cu(II) over Zn(II) and Ca(II) due to the ease with which Cu(II) deprotonates the amide nitrogen groups. The rigidity of the pyridyl moiety and pyridyl nitrogen that acts as an anchor enhanced the ionization of the amide protons in the presence of the metal ion. The geometries of the different species in solution were successfully determined by potentiometric, NMR, IR, UV–Vis and MM calculation studies. The $CuL1H_{-2}$ species predominates at the physiological pH of 7.4 and is reasonably lipophilic according to octanol–water partition coefficient measurements. However, the complex has limited SOD activity. Animal studies showed that L1 changed the bio-distribution of the copper upon both intravenous and dermal absorption.

Previous studies have shown that simple copper salts have anti-inflammatory activity, although the mechanism is unknown. The purpose of this study, then, was to design ligands that would increase the level of endogenous copper through dermal absorption and retention of copper in the body. This would increase the amount of bio-available copper. This objective has been achieved and the results warrant the testing of this system in animal models of arthritis. The lack of SOD activity is not important as simple copper salts do not have SOD activity either.

Abstract

Zinc(II) and mercury(II) thiocyanate complexes with nicotinamide, bis(nicotinamide-*N*)-bis(thiocyanato-*N*)zinc(II) (**1**) and *catena*-[nicotinamide-*N*-(μ-thiocyanato-*S*,*N*)(thiocyanato-*S*)mercury(II)] (**2**), have been prepared and characterized by spectroscopic, thermal and X-ray crystallographic methods. The vibrational bands of diagnostic value are compared to the values of the free ligand and the data are in good correlation with the X-ray results. Centrosymmetrical hydrogen bonded dimers are found, $R_2^2(10)$ in **1** and $R_2^2(8)$ in **2**.

Keywords: Zinc and mercury(II) thiocyanate complexes; Nicotinamide; X-ray crystal structure; IR, NMR spectra; TGA/DTA analysis

1. Introduction

Nicotinamide (pyridine-3-carboxamide, niacinamide, commonly known as vitamin B_3) shows important biological activity *e.g.* in the form of a coenzyme called NAD, nicotinamide adenine dinucleotide, it participates in many amino acid and carbohydrate metabolic reactions; it is also a vital compound in the drug industry. Metal complexes of biologically important ligands are sometimes more effective than the free ligand. Due to the relatively high abundance of zinc in living organisms and its participation in a large number of enzymatic reactions, the zinc complexes of nicotinamide are of great interest – especially those of the heteroleptic type [1]. In this context, we have chosen a thiocyanate ion, a well known ambidentate ligand, which is able to form different molecular architectures through its versatile ligation modes [2]. Beside this, it is interesting that thiocyanates have been found in human biofluids, saliva and cerebrospinal fluid, and recently it was established that psychological stress induces them in oral cavities [3–5]. In addition, the nicotinamide molecule can form a variety of molecular associations via hydrogen bonding, and the present work stems from our interest in finding out the predominant factors to form complexes with desired structural properties so as to create functional ones [6]. In this paper we report the preparation, IR and NMR characterization and structure analysis of $Zn(NCS)_2(nicotinamide)_2$ and $[Hg(SCN)_2(nicotinamide)]_n$. The thermal behaviour of the complexes has also been investigated by TG and DTA techniques. The structural features are compared with a congeneric cadmium(II) nicotinamide complex as well as with analogous zinc complexes, $ZnX_2(nicotinamide)_2$ (X = Cl, Br, I).

2. Experimental

2.1. Materials and physical measurements

All reagents were supplied by Aldrich Chemical Co. and were used as received without further purification. The CHNS microanalyses were measured by the Chemical Analytical Service of the Ruđer Bošković Institute, Zagreb.

Infrared spectra were obtained from KBr pellets within the range 4000–400 cm^{-1} with a Perkin–Elmer FTIR spectrometer 1600 Series.

The one-dimensional ^1H and ^{13}C NMR spectra were recorded with a Bruker AV 600 spectrometer, operating at 600.133 MHz and 150.971 MHz for the ^1H and ^{13}C nuclei, respectively. Samples were measured in DMSO-d_6 solution and chemical shifts (ppm) are referred to TMS.

The thermal measurements were performed using a simultaneous TGA–DTA analyser (*TA Instruments*, SDT Model 2960). The TGA and DTA curves were obtained by placing the samples of about 6 mg in mass in small open platinum pans, with a heating rate of 10 °C/min and a nitrogen (purity above 99.996%) flow rate of 50 mL/min. All samples were heated from room temperature up to 700 °C. The SDT was calibrated with indium and silver.

2.2. Preparation of the complexes

2.2.1. Preparation of *[Zn(NCS)$_2$(nia)$_2$]* (**1**)

A warm aqueous solution of nicotinamide (nia) (0.24 g, 0.2 mmol in 50 mL of H_2O) was added to an aqueous solution of zinc nitrate hexahydrate (0.30 g, 0.1 mmol in 10 mL of H_2O). Into the resulting solution was then added an aqueous solution of potassium thiocyanate (0.18 g, 0.2 mmol in 10 mL of H_2O). After keeping the mother liquid for few days, white crystals suitable for X-ray diffraction study were obtained. Total yield corresponds to 85% (0.36 g, 0.87 mmol) based on Zn. *Anal.* Calc. for $C_{14}H_{12}ZnN_6O_2S_2$ (**1**): C, 39.49; H, 2.84; N, 19.74; S, 15.06. Found: C, 39.64; H, 2.94; N, 20.03; S, 15.26%. IR data (cm^{-1}, KBr pellets): 3340s, 3283m-s, 3176m, 3053w, 2358vw, 2343vw, 2094vs, 2044m, 1665vs, 1608s, 1593m, 1482w, 1445w, 1428m-s, 1399m-s, 1338w-m, 1239w, 1202m, 1151w, 1129w, 1113w, 1060m, 1032vw, 961vw, 944w, 855w, 832w-m, 796w, 763w, 704m, 668w-m, 657m, 638m, 589m, 540m.

2.2.2. Preparation of *[Hg(SCN)$_2$(nia)]$_2$* (**2**)

In an aqueous solution of mercury(II) nitrate monohydrate (0.68 g, 0.2 mmol in 100 mL of H_2O) containing a few drops of nitric acid (20% by weight), an aqueous solution of potassium thiocyanate (0.36 g, 4 mmol in 10 mL of H_2O) was added. In a few hours a white crystalline product of mercury(II) thiocyanate was obtained. The crystals were filtered off, washed with water and dried. Total yield of 85% (0.54 g, 1.7 mmol).

Afterwards $Hg(SCN)_2$ was dissolved in ethanol (0.32 g, 1 mmol in 100 mL) by gentle heating and into this still warm solution an ethanol solution of nicotinamide (2 mmol in 30 mL) was added. The mixture was refluxed for 1 h. The clear solution was kept for a few days until white crystals of **2** suitable for X-ray diffraction study were obtained. Total yield corresponds to 77% (0.34 g, 0.77 mmol) based on Hg. *Anal.* Calc. for $C_8H_6HgN_4OS_2$ (**2**): C, 21.89; H, 1.38; N, 12.77; S, 14.61. Found: C, 22.03; H, 1.52; N, 12.89; S, 14.83%. IR data (cm^{-1}, KBr pellets): 3852w, 3452s, 3356s, 2112vs, 1671vs, 1601s, 1572m, 1476w, 1422m, 1394m-s, 1200w-m, 1135w, 1045w, 1028w-m, 829w, 785w, 747w-m, 704m, 641m, 513m.

2.3. X-ray structural analysis

The general and crystal data, and summary of intensity data collection and structure refinement for compounds **1** and **2** are given in Table 1.

Data for structure **1** were collected at 200 K on a Nonius KappaCCD diffractometer with a crystal-detector distance of 30 mm. The extraction and correction of the intensity data, absorption correction and the refinement of the unit cell parameters were performed with the program package DENZO-SMN [7].

Data for structure **2** were collected 293 K on an Oxford Diffraction Xcalibur four-circle kappa geometry single-crystal diffractometer with a Sapphire 3 CCD detector, by applying the CRYSALIS software system [8]. The crystal-detector distance was 60 mm. Data reduction, including absorption correction, was done by the CRYSALIS RED application of the CRYSALIS software system [8].

The structures were solved by direct methods implemented in the SHELXS-97 program [9]. The coordinates and the anisotropic thermal parameters for all non-

hydrogen atoms were refined by the least-squares method based on F^2 using the SHELXL-97 program [10]. The hydrogen atoms were generated geometrically using the riding model with the isotropic factor set at 1.2 U_{eq} of the parent atom. Hydrogen atoms on carboxamide nitrogen atoms were located in the difference Fourier map at the final stage of the refinement and were refined freely. Graphical work has been performed by the program ORTEP-3 *for Windows* [11] and Mercury 1.4.1 [12]. Thermal ellipsoids are drawn at the 50% probability level.

3. Results and discussion

3.1. Preparation of the complexes

The zinc thiocyanato complex was prepared *in situ* from aqueous solutions by reacting of all the components at room temperature. The mercury complex could not be obtained in the analogous way due to the very low solubility of mercuric thiocyanate in water. By addition of an ethanol solution under *in situ* conditions a mixture of products was obtained instead. But by refluxing the mixture of ethanol solutions of mercuric thiocyanate and nicotinamide, one can prepare the pure titled mercury compound.

3.2. Structure descriptions

All crystals were grown by slow evaporation of the reaction mixture under ambient conditions in a period of two days to one week. Selected bond distances, bond angles and hydrogen bonds are presented in Table 2. The structures are shown in Figs. 1 and 2.

3.2.1. Crystal structure of $Zn(NCS)_2(nia)_2$ (1)

In the molecular structure of bis(nicotinamide-*N*)-bis(thiocyanato-*N*)zinc(II), the zinc atom is located on a center of symmetry and is four coordinated by *N*-atoms from two nicotinamide and two isothiocyanate ligands, as shown in Fig. 1a. The coordination sphere around the central ion is distorted tetrahedral. The angles that deviate the most from regularity are N2–Zn1–N2[1] and N1–Zn1–N1[1] (symmetry code: (1) $-x$, y, $-z+3/2$), closed by two nia and two NCS^- ligands, 112.42(6)° and 123.82(8)°, respectively. Comparing the aforementioned angles in the title compound with the corresponding ones in the analogous tetrahedral zinc(II) halide complex [$ZnX_2(nia)_2$, X = Cl, Br, I] [13–15], compound **1** shows the greatest deviation from an ideal tetrahedral geometry (see Table 3). The largest deviation from ideal tetrahedral angles in all three reported structures occurs for the angles between the same ligands, ∠(X–Zn–X) and ∠(N–Zn–N)py, and this deviation is inversely proportional to the size of the coordinating atom; a small digression in the structure of the bromine complex was observed, Table 3. The Zn–N1/N1[1] (symmetry code: (1) $-x$, y, $-z+3/2$) bond distance (1.928(1) Å) is in the range for reported Zn–N(NCS) bonds in tetrahedral zinc(II) thiocyanate complexes with *m*-substituted pyridine ligands [16–18]. All other bond lengths and angles follow the usual values [19]. The NCS^- groups are almost linear with a N–C–S angle of 177.9(1)° and are coordinated to the zinc ion in a linear fashion with a Zn–N–C angle of 178.8(1)°. The pyridine rings are essentially planar (with a maximum deviation from the mean plane of 0.020(1)Å for the N atom) and the carboxamide group has a dihedral angle of 39.37(7)° with the pyridine plane, Table 4.

Fig. 2b shows the crystal packing of **1**, viewed down the *b* axis. In the crystal structure three types of hydrogen bonds, N–H···O, N–H···S and C–H···O, are established. The geometrical parameters are given in Table 5. The centrosymmetric head-to-head hydrogen bond of $R_2^2(8)$ type, usually found in amide structures, is not established in the crystal structure of complex **1**. The carboxamide oxygen atom O(1) participates in a centrosymmetric hydrogen bond of the $R_2^2(10)$ type [20], Scheme 1, with the C4 atom from a pyridine ring of the adjacent molecule [C–H···O, 3.397(2) Å; symmetry code: $1-x$, $2-y$, $-z$]. The oxygen atom is a bifurcated acceptor and it simultaneously accepts an amide hydrogen atom of the neighbouring molecule down the *b* axis [N–H···O, 2.895(2) Å; symmetry code: x, $-1+y$, z] thus forming C(4) hydrogen bond chains in the [0 1 0] direction. The short S···S contacts, very often present in thiocyanate structures [21,22], were not found in the crystal structure of **1**. The sulfur atom from the thiocyanate ligand participates in a N–H···S hydrogen bond with the amide nitrogen [N–H···S, 3.526(2) Å; symmetry code: $1/2-x$, $1/2-y$, $-z$]. Very short Zn···Cg contacts (3.886 Å) between the zinc atom and the pyridine ring of a neighbouring complex molecule located in the direction of the *b* axis are found. Similar short contacts between the metal ion and the aromatic ring have been observed in the crystal structures of aromatic amino acids complexes [23].

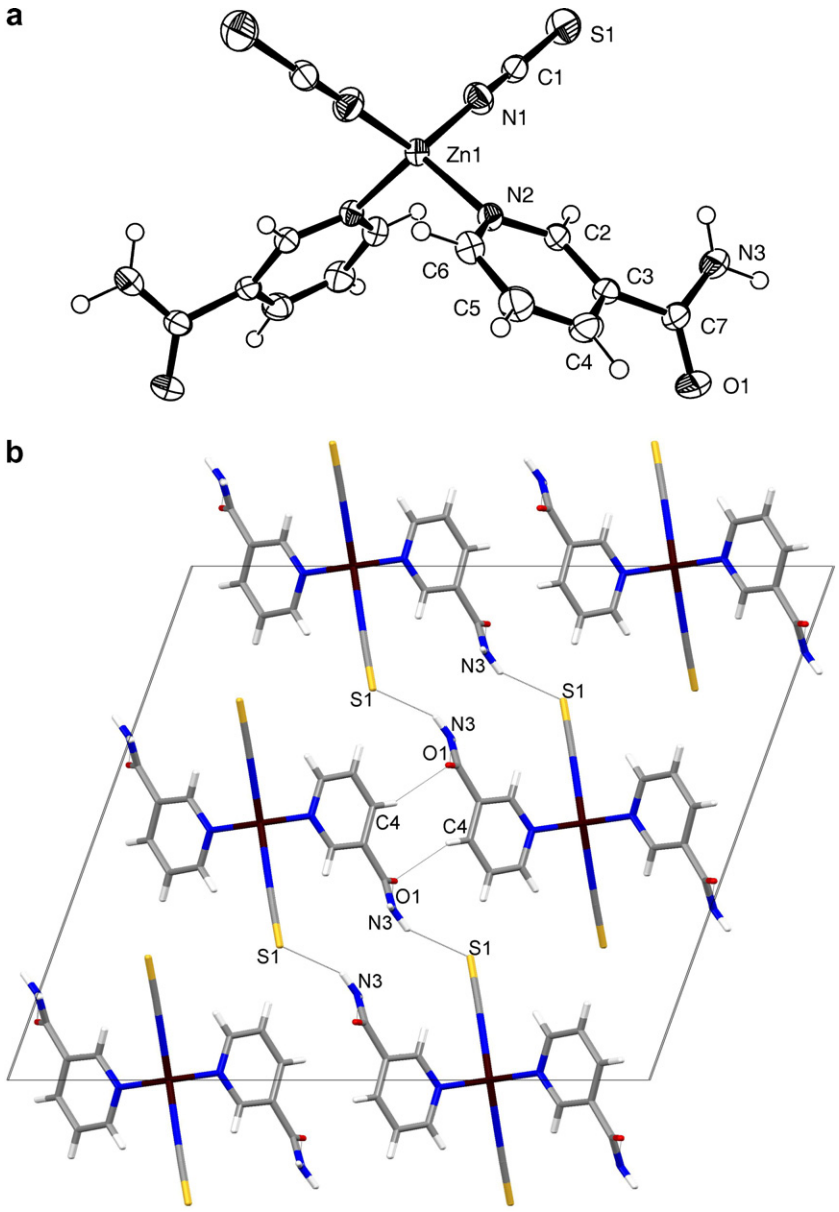

Fig. 1. (a) The ORTEP-3 drawing of the structural unit of complex **1** with the atomic numbering scheme; (b) crystal packing of complex **1** viewed down the *b* axis; hydrogen bonds are represented by dotted lines.

3.2.2. Crystal structure of $[Hg(SCN)_2(nia)]_n$ (**2**)

The X-ray structure analysis of **2** revealed the formation of a single-stranded chain structure, as is displayed in Fig. 2a. Each mercury(II) atom is four coordinated by two bridging μ-SCN-*S*,*N*, one terminal thiocyanate and one nicotinamide ligand in a quite distorted tetrahedral S_2N_2 geometry (the bond angles around the mercury atom are in the range 91.0(2)° to 128.74(4)°, Table 2). The Hg–N as well as the Hg–S bond distances are in the range of those distances found in other Hg^{II} thiocyanate complexes of substituted pyridine-*N* ligands [24–28]. As is expected, both bridging bond distances of coordinated thiocyanate ligands, Hg–N1 [2.387(4) Å] and Hg–S1 [2.459(1) Å] are somewhat longer than those ones of terminal ligands [Hg–N3 2.333(3) Å and Hg–S2 2.419(1) Å]. In **2**, the pyridine ring is less deformed in comparison with **1**, Table 4, and the dihedral angle closed by the pyridine ring and the carboxamide group is also much smaller in **2** than in **1**. Both thiocyanate ligands, bridging and terminal, are coordinated to mercury in a non-linear fashion [∠Hg1–S1–C1 94.3(2)°; ∠Hg1–S2–C2 98.2(2)°], especially the terminal one; its coordination geometry is probably caused by formation of hydrogen bonds. The terminal thiocyanate nitrogen atom is a very common H-bond acceptor and usually participates in more than one hydrogen bonding interaction [22]. In **2** it is a trifurcated acceptor. It participates in two *intra*molecular N–H···N and C–H···N hydrogen bonds of S(10) and S(7) type, respectively, and one *inter*molecular C–H···N hydrogen bond, forming C(7) chains.

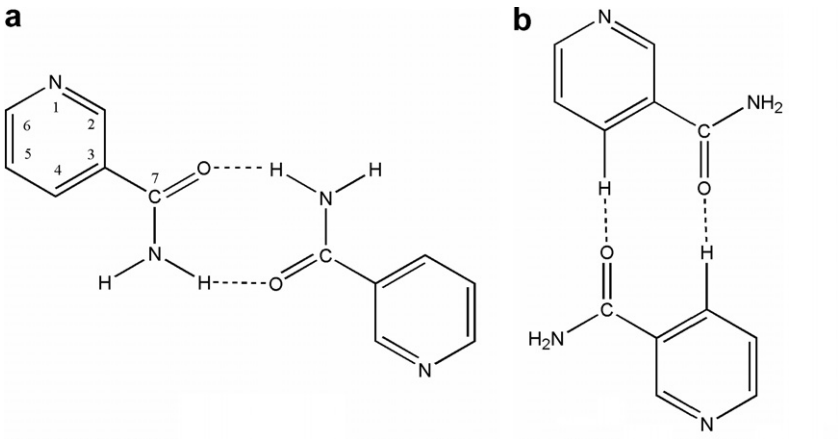
	(**1**)	(**2**)
Py ring (I)	2.16(8)	0.5(3)
Py ring (I) – amido group (I)	39.37(7)	3.0(3)

The details of the hydrogen bonding geometry of **2** are shown in Fig. 2b and geometric parameters are included in Table 4. As shown in Fig. 2b, the polymeric chains are further linked through centrosymmetrical amide–amide hydrogen bonds of the $R_2^2(8)$ type [N···O 2.922(6) Å; symmetry code: $1-x, -y, 1-z$] and in such a way double-chains are formed. These double-chains are packed into a 3D network by the above mentioned C–H···N H–bond in the *c* axis direction. Short C···S contacts [C···S 3.455 Å] are also observed in the structure of **2** between two parallel thiocyanate chains. *Intra* chain pyridine rings, although coplanar, are apart from each other, and no π–π stacking interactions are found.

3.3. Spectroscopic properties



3.3.1. IR spectra

There are two possibilities for nicotinamide to coordinate to a central metal atom, either through the endocyclic nitrogen or the carboxamide oxygen atom. In its Zn and Hg complexes it usually behaves as a monodentate ligand through the pyridine ring nitrogen atom. The coordination mode of the nia ligand could easily be deduced from IR spectra by comparing the IR spectra of the free ligand and the complex molecule. The absorption bands of the carbonyl group (1697, 1679 cm^{-1}) are shifted to lower values if the amide oxygen atom is involved in coordination. In the case of coordination through the pyridine ring nitrogen atom, a significant negative shift of the carbonyl absorption bands takes place [15].

The IR bands of complexes **1** and **2** were assigned by comparing with the free ligand data. In both complexes a shift to lower wavenumbers of *ν*(CO) is observed (1665 cm^{-1} in **1**; 1671 cm^{-1} in **2**). It could be concluded that nia-*O* coordination occurred. Concerning the facts (a) that the CO stretching of picolinamide (pia) in

Table 5

C(3)–H(3)···N(2)	0.93	2.44	3.317(8)	135	$x, 5/2-y, -1/2-z$
C(7)–H(7)···N(2)	0.93	2.59	3.370(7)	176	$-1/2+x, 1/2-y, z$

Scheme 1. The bridging modes of nicotinamide established in complexes (a) **1** and (b) **2** with the labelling mode used in the discussion of the NMR data.

acetonitrile solution occurs at 1690 cm^{-1} while it is observed at around 1660 cm^{-1} in solid pia and its complexes [15] where such a negative shift is attributed to hydrogen bonding in the solids, and (b) that halide Zn complexes with nia, as well as Hg complexes with py ligands, are *N*-coordinated, it can be concluded that it could also be the case here, which is confirmed by the X-ray results. Moreover, a greater shift to lower frequencies observed in **1** compared to **2** could be explained by the fact that the carbonyl oxygen atom in **1** participates in two H-bonds as a bifurcated acceptor and significant elongation of C=O bond occurs in comparison to **2** where the carboxamide *O*-atom participates in one H-bond [C–O: 1.232(2) Å in **1**, 1.223(5) Å in **2**].

The *ν*(NH) absorption bands of the amide group in nia appear at 3368 and 3161 cm^{-1}. In both complexes some positive shifts of NH bands occur, and in **1** they are split, while in **2** they are broadened. These shifts to higher frequencies are obviously the consequence of hydrogen bonding in the crystalline state of the complexes. The broadening in **2** could be attributed to three hydrogen bonds in which the amide N-atom is involved as a trifurcated acceptor.

Concerning the C–N stretching frequencies of thiocyanates in general, *ν*(CN) are lower in *N*-bonded complexes (near or below 2050 cm^{-1}) than *S*-bonded complexes (near 2100 cm^{-1}). For bridging complexes (M–SCN–M) the CN stretching frequency is above 2100 cm^{-1} [29]. The stretching CN frequencies of compounds **1** and **2** were observed at 2094 and 2112 cm^{-1}, from which it could be clearly seen that the thiocyanate is coordinated to zinc through the nitrogen atom and to mercury through the sulfur atom. No separate bands were observed for bridging and terminal thiocyanate groups in the mercury complex **2**.

The position of the C–S stretching frequencies in the region 860–690 cm^{-1} is usually employed for differentiating *S*- from *N*-bonded terminal thiocyanates; *ν*(CS) in the range 860–780 cm^{-1} and 720–690 cm^{-1} for *N*- and *S*-coordinated, respectively [30]. However, the *ν*(CS) modes are, for both compounds **1** and **2**, overlapped by pyridine ligand stretching and deformation bands, making the assignment of the C–S stretches quite uncertain.

3.3.2. NMR spectra

The ^{1}H and ^{13}C data for **1** and **2**, together with the literature values of the parent nicotinamide molecule, are presented in Tables 6 and 7, respectively. Scheme 1 shows the labelling of the atoms. The ^{1}H and ^{13}C NMR data of free nia are cited from the literature [31], while the other measurements are performed in DMSO-d_6 solutions. The complexation ^{1}H and ^{13}C NMR shifts are defined as the difference of the proton and carbon shifts, respectively, in the complexes and the free ligand molecule.

Table 6
^{1}H NMR chemical shifts (δ ppm^{-1})[a], complexation shifts ($\Delta\delta$ ppm^{-1})[b,d] and H–H coupling constants (J_{HH}/Hz)[e] in the ligand molecule, nicotinamide, and their complexes with zinc(II) and mercury(II) thiocyanate, **1** and **2**

[a] Referred to TMS in DMSO solutions.
[b] Complexation shift is defined as the difference of carbon chemical shifts in the complex and the parent molecule.
[c] Taken from Ref. [31].
[d] Sign (+) denotes deshielding effect, while (−) denotes shielding effect.

The ^{1}H spectra of both complexes display six signals, four belonging to aromatic protons and two to carboxamide ones. The signals of the amido group protons as well as the aromatic H–2 proton are found to be shielded in both complexes **1** and **2**.

In the ^{13}C spectra of both complexes **1** and **2**, all the aromatic carbon atoms are shifted 0.06–0.84 ppm downfield relatively to the corresponding ones in the parent ligand molecule. On the basis of the ^{13}C spectra it could be concluded that the aromaticity of the pyridine ring is preserved upon complexation, which can be supported by the short ring C–C distances obtained from the X-ray analysis. The greatest change of ^{13}C chemical shift upon complexation was found at C-4 which is *para* to the nitrogen and *ortho* to the amide group. The complexation shifts of the aromatic carbon atoms are found to be more pronounced by on average 2–3 times more in the mercury complex **2** than in the zinc complex **1**, except for carbon C-2 where the differences in complexation shift are negligible. The carboxamide carbons in **1** and **2** are found to be shielded and the shielding is more pronounced in **2**. In the crystal structure of **1**, the carboxamide oxygen atom participates in two H-bonds as a bifurcated acceptor. This elongates the carbonyl bond and withdraws electron density towards the O-atom more than just one hydrogen bond in which the carboxamide oxygen atom of **2** participates, so the shielding complexation effect is smaller in **1** than in **2**. The hydrogen bonds of the carboxamide groups found in the crystal structure probably also exist in solution.

The formation of thiocyanate and isothiocyanate complexes can be easily detected by the characteristic ^{13}C signal for the -SCN and -NCS groups that are usually found at ~111 and ~145 ppm, respectively [32]. In the ^{13}C spectra of the investigated thiocyanate complexes there are signals at 135 and 116 in the zinc and mercury complex, respectively, indicating the coordination of the thiocyanate ligands to the metal centers through (SCN)-*N* in **1** and through the (SCN)-*S* atom in **2**.

3.4. Thermal analysis

The analysis of the TGA and DTA curves showed that the thermal decomposition of **1** consists of three steps. The first one is the decomposition of **1** to $Zn(SCN)_2$, which corresponds to an endothermic DTA peak at 232.5(5) °C. In the temperature range 250–400 °C two endothermic peaks (a main large one at 283.6(5) °C and a second small one at 351.7(5) °C) were observed. This can be attributed to the thermal decomposition of $Zn(SCN)_2$, and the final residue is ZnS (about 23%).

The thermal analysis of **2** reveals that the thermal decomposition of the investigated complex involves three major processes; two endothermal and an exothermal one. The first endothermal peak corresponds to the melting process of **2** (minimum at 127.8(5) °C). The second one (exothermal at 218.8(5) °C) is followed and overlapped by a small endothermal peak, presenting degradation of the ligands. The incurred $Hg(SCN)_2$ continues the decomposition followed

by sublimation of HgS, corresponding to the endothermic peak with a maximum at 431.2(5) °C.

4. Conclusion

Zinc(II) and mercury(II) thiocyanato complexes with nicotinamide have been synthesized, the zinc complex by the *in situ* reaction in aqueous solution, while the mercury complex by using the previously isolated mercury(II) thiocyanate complex as the mercury starting reagent. The isolated complexes were investigated by X-ray structural analysis, spectroscopic and thermal methods.

The nicotinamide, with the carboxamide group in the *m*-position to the pyridine nitrogen atom acts as a monodentate-*N* ligand for the zinc(II) and mercury(II) ions, coordinating to the metal ions through the pyridine nitrogen atom and leaving both carboxamide moieties available for participation in hydrogen bond formation. The centrosymmetrical amide–amide hydrogen bonds of the $R_2^2(8)$ type, usually found in the structures of amides, are also established in the mercury(II) complex **2**, but in the zinc(II) complex **1**, the presence of a centrosymmetrical head-to-head hydrogen bond of the $R_2^2(10)$ type was found, comprising the aromatic carbon and carboxamide nitrogen atom, Scheme 1. The thiocyanate ion acts as a *N*-donor ligand for zinc, **1**, and a *S*-/μ-*S*,*N*-donor ligand for the mercury complex, **2**. In the thiocyanate complexes of the group 12 metals, the thiocyanate ligand shows its versatile coordination modes, from almost linear in **1** to almost perpendicular in **2**, and with the M-(SCN) angle intermediate in its congeneric cadmium complex [21]. Moreover, in **1** monomeric zinc–thiocyanate units are formed, in **2** there are one-dimensional mercury–thiocyanate chains, while in the cadmium complexes [21] two-dimensional cadmium–thiocyanate sheets are found.

Abstract

Charge transfer reactions of piperidine with *p*-chloranil (CHL) and 7,7′,8,8′-tetracyanoquinodimethane (TCNQ) in chloroform have produced stable complexes with the general formula [$(Pip)_2$(acceptor)] with a 1:2 acceptor:donor molar ratio. Elemental analysis (CHN), electronic spectra, photometric titration, mid infrared spectra, ^{1}H NMR spectra and thermogravimetric analysis (TGA/DTG) were used to predict the position of the charge transfer interaction between the donating and accepting sites. The crystal structure of the Pip/TCNQ system was determined by single crystal X-ray diffraction.

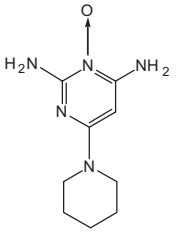
1. Introduction

Piperidine (Formula I) is an organic compound with the molecular formula $C_5H_{11}N$. It is a cyclic amine with a six-member ring. The piperidine skeleton is present in numerous natural alkaloids such as piperine, the main active chemical agent in black pepper and relatives, pharmaceutical drugs such as raloxifene (Formula II) and minoxidil (Formula III).



The major industrial application of piperidine is for the production of dipiperidinyl dithium tetrasulfide, which is used as a rubber vulcanization accelerator.

Its charge transfer (CT) interaction has been widely reported recently. Charge transfer complexes are known to take part in many chemical reactions like addition, substitution and condensation [1,2]. These complexes have had great attention for non-linear optical materials and electrical conductivity [3–6]. The electron donor–acceptor (EDA) interaction is also important in the field of drug-receptor binding mechanisms [7], in solar energy storage [8] and in surface chemistry [9] as well as in many biological fields [10]. On the other hand, the EDA reactions of certain π-acceptors have successfully utilized in pharmaceutical analysis [11]. For these wide applications extensive studies on CT complexes of π-acceptors have been performed [12].

A literature survey [13–16] reveals that little attention has been paid to thermodynamic and electronic spectral characteristics, and it does not contain any information on the structural behavior of the CT interactions of this compound (Pip) with σ- and π-acceptors.

Charge transfer complexes of organic species are intensively studied because of their special type of interaction, which is accompanied by the transfer of an electron from the donor to the acceptor [17,18]. Also, protonation of the donor by acidic acceptors is generally the route for the formation of ion pair adducts [19–21].

Charge transfer (CT) complexes formed between piperidine (Pip) as the donor with *p*-chloranil (CHL) and 7,7′,8,8′-tetracyanoquinodi methane (TCNQ) as π-acceptors have been studied spectrophotometrically. The synthesis and characterization of piperidine CT complexes of *p*-chloranil, [(Pip)$_2$(CHL)] (**1**) and 7,7′,8,8′-tetracyanoquinodimethane, [(Pip)$_2$(TCNQ)] (**2**) are described. These complexes are readily prepared from the reaction of Pip with CHL and TCNQ using $CHCl_3$ as the solvent. IR,^{1}H NMR, mass spectra, UV–Vis techniques and elemental analyses (CHN), characterize the two piperidine charge-transfer complexes. Benesi-Hildebrand and its modification methods were applied for the determination of the association constant (K) and molar extinction coefficient (ε).

2. Experimental

Pure piperidine, *p*-chloranil (CHL) and 7,7,8,8-tetracyanoquinodimethane (TCNQ) were obtained from (Merck) and were used without further purification.

2.1. Materials and measurements

The electronic absorption spectra were recorded in the region 800–200 nm using a UV–Vis spectrophotometer, model Jenway 6405, with a quartz cell of 1.0 cm path length. The mid infrared spectra of the reactants and the resulted CT-complexes were measured from KBr discs using a Gensis II FT IR spectrophotometer. ^{1}H NMR spectra were obtained on a Varian spectrophotometer Gemini 200 MHz using TMS as an internal reference and d_6-DMSO as the solvent.

Thermogravimetric (TG) and differential (DTG) analyses were carried out in the temperature range 25–600 °C in nitrogen atmosphere using a Shimadzu TGA 50 H thermal analyzer. The experimental conditions were: aluminium crucible with a definite mg of sample, nitrogen atmosphere (nitrogen flow 30 ml/min) and heating rate of 15 °C/min. The elemental analyses were performed by the microanalysis unit at Cairo University, Egypt using a Perkin Elmer CHN 2400. The data of the elemental analyses (CHN) of the reaction products, the CT-complexes, were matched with the molar ratio results from the photometric titrations.

The two solid CT-complexes formed in the reaction of Pip with CHL and TCNQ were isolated by the addition of 1.0 mmol of Pip (10 ml) to a 1.0 mmol solution of CHL and TCNQ (20 ml) in chloroform followed by stirring for about 30 min. Dark brown and yellow precipitates were formed in the case of Pip/CHL and Pip/TCNQ, respectively, and these were filtered off, washed several times with $CHCl_3$ and dried in vacuo. The products were identified as: [(Pip)$_2$(CHL)] (**1**) ($C_{16}H_{22}N_2O_2Cl_4$; $M_w = 416$, m.p. 155 °C). *Anal.* Calc.: C, 46.20; H, 5.29; N, 6.73. Found: C, 46.12; H, 4.85; N, 6.69%; and 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct (**2**) ($C_{20}H_{24}N_4$; $M_w = 320$, m.p. 187 °C). *Anal.* Calc.: C, 75.00; H, 7.50; N, 17.50. Found: C, 74.78; H, 7.46; N, 17.29%.

2.2. Crystallographic analysis

Data collection was performed on a Bruker SMART CCDC area detector diffractometer using Mo Kα radiation (α = 0.71073 Å). The structure was solved by direct-methods using SIR97 [22] and anisotropic displacement parameters were applied to non-hydrogen atoms in a full-matrix least-squares refinement based on F^2 using SHELXL-97 [23]. Molecular drawings were obtained using ORTEP-III [24].

Crystallographic data for [(Pip)$_2$(TCNQ)]: crystal dimensions $0.38 \times 0.29 \times 0.23$ mm; $F_w = 320.43$ g mol^{-1}, triclinic, space group $P\bar{1}$, $a = 8.7775(6)$, $b = 13.5503(9)$, $c = 16.2521(11)$ Å, $\alpha = 95.596(1)°$, $\beta = 101.804(1)°$, $\gamma = 104.797(1)°$; $V = 1806.3(2)$ Å^3, $Z = 4$, $D_c = 1.178$ Mg m^{-3}, $R_{int} = 0.050$ and $wR = 0.224$ for 7765 independent reflections; $S = 1.265$.

3. Results and discussion

3.1. Electronic absorption spectra of the Pip/CHL and Pip/TCNQ systems

In the case of the Pip/CHL system, once beginning the addition of CHL to a solution of Pip in chloroform, the color of the solution changes in four steps until it is constant: light blue → yellow → gray → olive green. On the other hand, in the case of the Pip/TCNQ system, upon addition of TCNQ to the donor (Pip) dissolved in chloroform, a dark green precipitate was formed immediately. The electronic absorption spectra of the reaction mixtures

containing CHL and TCNQ with piperidine as donor in $CHCl_3$ were recorded. Fig. 1A and B shows the spectra in the 800–200 nm region of the reactants piperidine (Pip), *p*-chloranil (CHL) and 7,7′,8,8′-tetracyanoquinodimethane (TCNQ) and the final products, with a concentration of each in the order of 1.0×10^{-4} M in $CHCl_3$. The electronic absorption spectra of the resultant Pip charge transfer complexes, shown in Fig. 1A and B, revealed new strong absorption bands assigned to the CT interaction. These bands are not present in the spectra of the free reactants (Pip, CHL and TCNQ) and were at 248, 330, 449 and 575 nm for Pip/CHL and at 324 nm for Pip/TCNQ. In the photometric titration measurements [25], the concentration of CHL and TCNQ was kept fixed at 1.00×10^{-4} M, while the concentration of Pip was varied over the range 0.25×10^{-4}–4.00×10^{-4} M. Furthermore, photometric titrations measurements between (Pip) and the defined acceptors CHL and TCNQ in $CHCl_3$ based on the characteristic absorption bands which refer to the CT complexes, Fig. 2A and B, proved that the molar ratio of the resultant complexes is 2:1 Pip:acceptor. A comparison of the absorption spectra of the free piperidine donor and the π-acceptor reveals that the two new CT complexes synthesized were characterized by definite maximum absorption bands at the wavelengths 330 and 575 nm, and 324 nm for the Pip/CHL and Pip/TCNQ systems, respectively. The formation of 1:2 complexes was supported by both elemental analysis and thermal measurements.

It was necessary to calculate the values of the equilibrium constant, the extinction coefficient, ε, and the oscillator strength, *f*, of the Pip complexes, $[(Pip)_2(CHL)]$ and $[(Pip)_2(TCNQ)]$ in chloroform solvent. The known equation for 1:2 complexes [26] was used in the calculations

$$\frac{C_A^{0^2} C_D^0}{A} = \frac{1}{K\varepsilon} + \frac{1}{\varepsilon} \cdot C_A^0 (4C_D^0 + C_A^0) \quad (1)$$

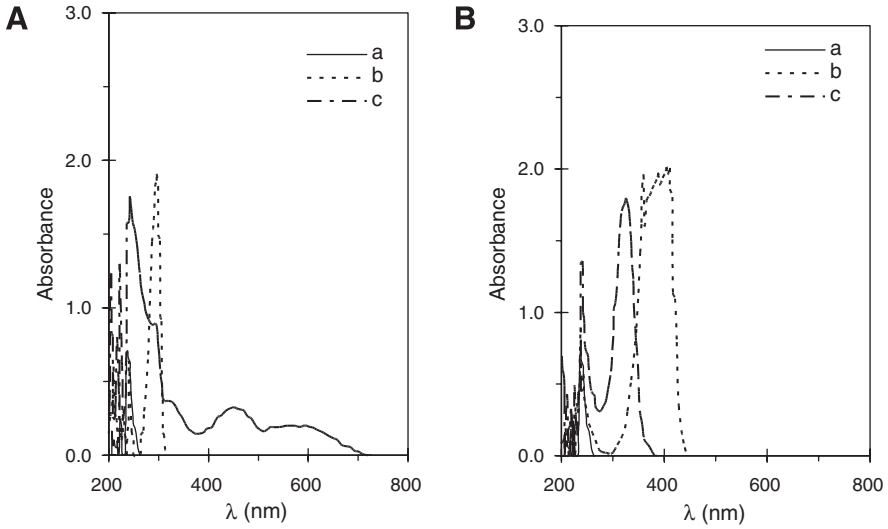

Fig. 1. Electronic absorption spectra of (A) Pip–CHL and (B) Pip–TCNQ reactions in $CHCl_3$. (a) Donor (1.0×10^{-4} M), (b) acceptor (1.0×10^{-4} M) and (c) CT-complex.

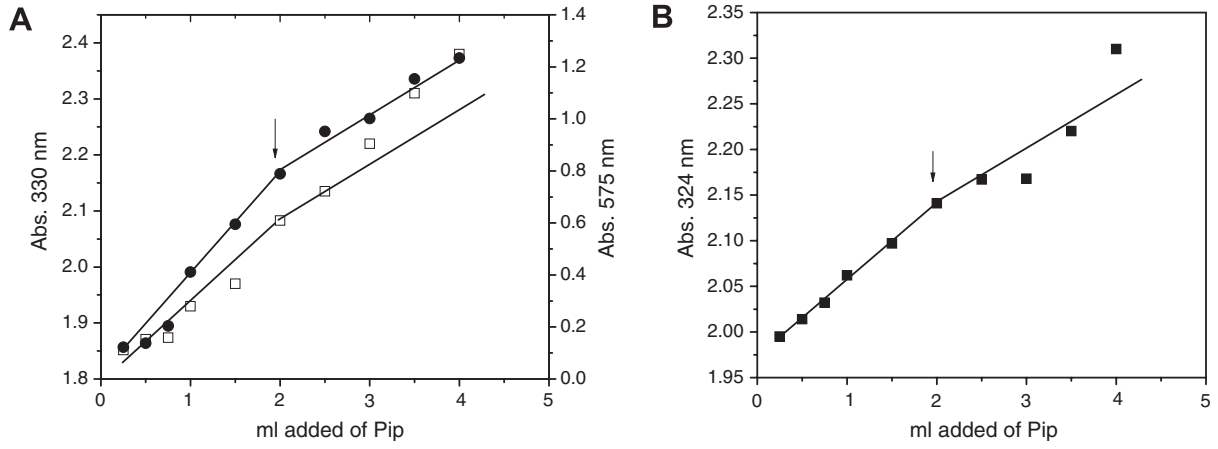

Fig. 2. Photometric titration curves for (A) the Pip–CHL system in $CHCl_3$ at 330 and 575 nm, and (B) the Pip–TCNQ system in $CHCl_3$ at 324 nm.

where C_A^{02} and are the initial concentration of the π-acceptor and donor (Pip), respectively, and A is the absorbance of the detected CT-band. By plotting $(C_A^{02} \cdot C_D^0)/A$ values versus $C_A^0(4C_D^0 + C_A^0)$, straight lines were obtained with a slope of $1/\varepsilon$ and an intercept of $1/K\varepsilon$, as shown in Fig. 3A and B for the reaction mixtures in $CHCl_3$. The values of both K and ε associated with these complexes, [(Pip)$_2$(CHL)] and [(Pip)$_2$(TCNQ)], are given in Table 1. The oscillator strength (f), which is a dimensionless quantity used to express the transition probability of the CT band [27], and the transition dipole moment (μ) of the CT-complexes [28], Table 1, have been calculated from Eqs. (2) and (3), respectively [29]. The high values of both the formation constant (K) and extinction coefficient (ε) of the resultant CT complexes caused high stabilities of the formed CT complexes to be expected as a result of the expected high donation of the Pip nucleus.

The dissociation energy (W) of the Pip/CHL CT-complex system can be calculated by applying Eq. (4), and this value is 4.13 eV. The ionization potential (I_p) of the free donor of the highest filled molecular orbital on the donor was determined from the CT energies of the CT band of its complexes with CHL and TCNQ using Eqs. (5)–(7) [30–32]:

$$f = (4.319 \times 10^{-9})\,\varepsilon_{max} \cdot \nu_{1/2} \quad (2)$$

$$\mu = 0.0958[\varepsilon_{max}\nu_{1/2}/\nu_{max}]1/2 \quad (3)$$

$$E_{CT} = I_p - E_A - W \quad (4)$$

$$I_p\ (\text{eV}) = 5.00 + 1.53 \times 10^{-4}\nu\text{CHL}\ (\text{cm}^{-1}) \quad (5)$$

$$I_p\ (\text{eV}) = a + b(h\nu_{max}) \quad (6)$$

where $h\nu_{max}$ is the lowest n–π^* transition energy in electron volts; a and b are 5.11 and 0.701 [32], respectively.

$$E_{CT} = 1243.667/\lambda_{CT}\ (\text{nm}) \quad (7)$$

where λ_{CT} is the wavelength of the complexation band.

3.2. Infrared spectra of the [(Pip)$_2$(CHL)] and [(Pip)$_2$(TCNQ)] solid complexes

The band assignments of the infrared spectra of the reactants CHL, TCNQ and the reaction products [(Pip)$_2$(CHL)] and [(Pip)$_2$(TCNQ)] are presented in Table 2.

The resultant charge transfer complexes produced from the interaction of Pip with CHL and TCNQ contain the characteristic bands of the Pip donor and acceptors (CHL and TCNQ) with an observed shift in the frequencies (Table 2), as well as some change in the band intensities. This could be assigned to the expected symmetry and electronic structure changes upon the formation of the CT-complexes. The infrared interpretation for the CT-complexes was dealt with as follows;

(i) In the case of the [(Pip)$_2$(CHL)] CT-complex: the vibration frequency of the ν(N–H) group for Pip, observed at 3393 cm^{-1}, is shifted to 3424 cm^{-1} in the IR spectrum of the Pip/CHL complex; this new band has a strong broad intensity for the (2Pip–H_2CHL) charge transfer complex. The assignment of this band is, interestingly, due to the ν(O–H) stretching vibration of the hydrogen of donor against the oxygen of the two carbonyl groups of the acceptor. The group of bands at 2948, 2840, 2808 and 2737 cm^{-1}

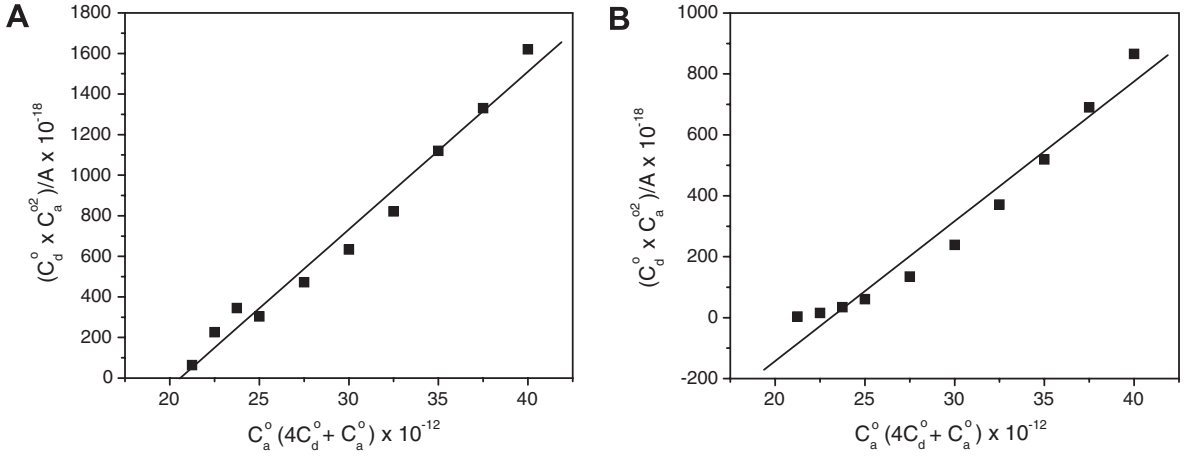

Fig. 3. The plot of $C_A^0(4C_D^0 + C_A^0)$ against $C_D^0 \cdot C_A^{02}/A$, for the (A) [(Pip)$_2$(CHL)] and (B) [(Pip)$_2$(TCNQ)] CT-complexes at 575 and 324 nm, respectively.

Table 1

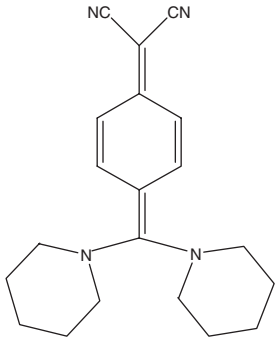
in this complex were assigned to ν_s(C–H) + ν_{as}(C–H) vibrations, with the same positional wavenumbers as compared with free Pip. The spectrum of the [$(Pip)_2$(CHL)] CT-complex includes a few medium strong absorption bands located at 2629, 2519 and 2421 cm^{-1}, which could be assigned to hydrogen bonding [33]. The stretching vibration of the ν(C=O) absorption band in the case of free CHL appears at 1685 cm^{-1}, but under complexation this band was shifted to a lower value (1648 cm^{-1}). Doubtless, the IR spectra strongly supported that the CT-interaction in the case of the Pip/CHL complex take place through a n–π^* transition (Scheme 1). Evidently, in the spectrum of the [$(Pip)_2$(CHL)] complex, the vibrations group of δ(N–H), ν(C–N) and CNC deformation clearly show changes compared with those of free Pip, Table 2. The bands associated with the ν(C–Cl) vibration that appeared at 903, 750 and 709 cm^{-1} in free CHL were shifted to lower wavenumbers, with decreasing intensities of the characteristic peaks. This result is due to the increase in electron density around the CHL moiety, and therefore the charge transfer interaction and deprotonation of the donor upon complexation. This observation proves that the complexation of (Pip) with CHL takes place via the –NH group, with the formation of hydrogen bonding as shown in Scheme 1.



Scheme 1. The structure of the [$(Pip)_2$(CHL)] CT-complex.

(ii) In the case of the [$(Pip)_2$(TCNQ)] CT-complex: the IR spectrum of the solid reaction product 7,7-dicyano-8,8-di-piperidinoquinodimethane contains characteristic bands for both Pip (donor) and TCNQ (acceptor). The CN stretching of TCNQ show a drastic shift to a lower wavenumber. The distinguish stretching vibration, ν(C≡N), of free TCNQ is observed at 2220 cm^{-1} as single peak, but in the case of the Pip/TCNQ complex, after complexation two peaks at 2120 and 2132 cm^{-1} values were

detected, having very strong band intensities. This shift is indicative of higher charge density on the cyano groups of the TCNQ charge transfer complex. On the other hand, the –NH stretching bands of Pip were shifted to higher frequencies in the spectrum of the Pip/TCNQ complex. This is reasonably based on the increasing polarity of the NH band during complexation. The interaction of TCNQ and piperidine causes the formation of a stable adduct which is assigned the structure 7,7-dicyano-8,8-di-piperidinoquinodimethane (Scheme 2) on the basis of spectroscopic investigation and elemental analysis.

3.3. ^1H NMR spectrum of 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct

The ^1H NMR spectrum of the 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct in d_6-DMSO displayed distinct signals with the appropriate multiplets, Fig. 4. The singlet accounting for six protons centered at δ 1.673 ppm (6H; $3 \times CH_2$) is assigned to the protons of three methyl groups of piperidine, and the other singlet peak at δ 2.523 ppm should be due to the hydrogen protons of the two methyl groups attached with the nitrogen atom of the Pip donor (4H; $N(CH_2)_2$). The strong singlet peak at δ 3.365 ppm was ^1H (HDO), which is seen in protic solvents due to exchange with the solvent deuteriums. The aromatic region corresponds to four protons in the TCNQ ring (4H; aromatic TCNQ ring) – doublets centered at δ 6.863, 6.906, 7.294 and 7.336 ppm for the TCNQ ring. Comparison between the free reactants and the new stable adduct reveals that the signal of –NH (2.24 ppm) of the free donor disappeared, this indicates that two of the CN groups of TCNQ participate with two hydrogen atoms of two Pip donors (elimination reaction, −2HCN), Scheme 2.

Scheme 2. The structure of the 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct.

3.4. Crystal structure of the 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct

The asymmetric unit of the 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct is composed of two crystallographic independent $[(pip)_2TCNQ]_2$ units, as shown in Fig. 5. The piperidine rings of each of the two independent molecules exhibit a chair conformation, while the TCNQ fragment is nearly planar (Fig. 5), with deviations from the mean planes of 0.025 Å for the CN groups (molecule A), and 0.0015 Å for the CN groups (molecule B). The dihedral angles between the mean planes of the piperidine rings is 75.8(3)° in molecule A and 76.4(3)° in molecule B and between the piperidine and TCNQ fragments 45.4(2)° and 48.4(2)° in molecule A and 43.4(2)° and 53.0(2)° in molecule B (see Fig. 6).

3.5. Thermal investigations of the $[(Pip)_2(TCNQ)]$ and 7,7-dicyano-8,8-di-piperidinoquinodimethane adducts

Thermal analysis (TGA and DTG) play an important role to study the physicochemical behaviors and the stability of the CT complexes. Thermal data of the complexes are given in Table 3.

The thermal analysis curve of the Pip/CHL CT complex, of the general formula $[(Pip)_2(CHL)]$, is shown in Fig. 7. It gives a pattern of four maximum stages of decomposition supported by DTG data (Table 3). The first step in the decomposition is from 25 to 175 °C, with a maximum peak at (158 °C) and corresponds to the decomposition of one HCl molecule from a CHL molecule, with an estimated mass loss of 8.35% (calc. mass loss 8.77%), while the subsequent second step is from 175 °C to 242 °C at $DTG_{max} = 214$ °C and is accompanied by the loss of

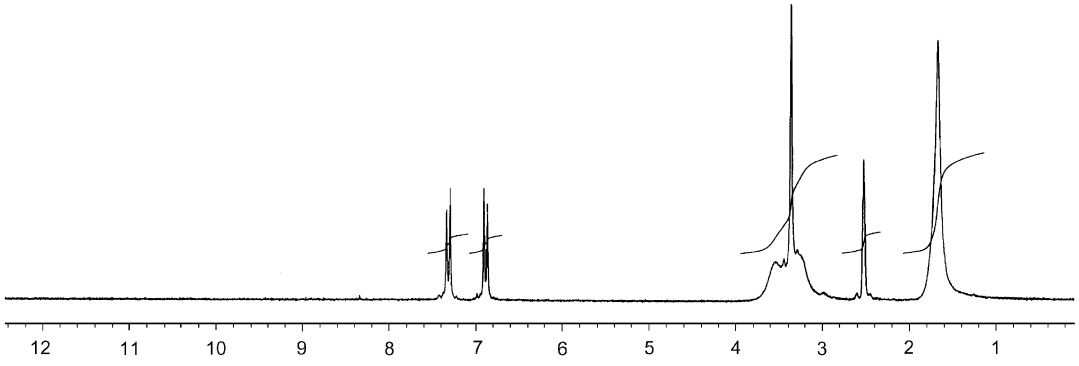


Fig. 4. ^1H NMR spectra of the 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct.

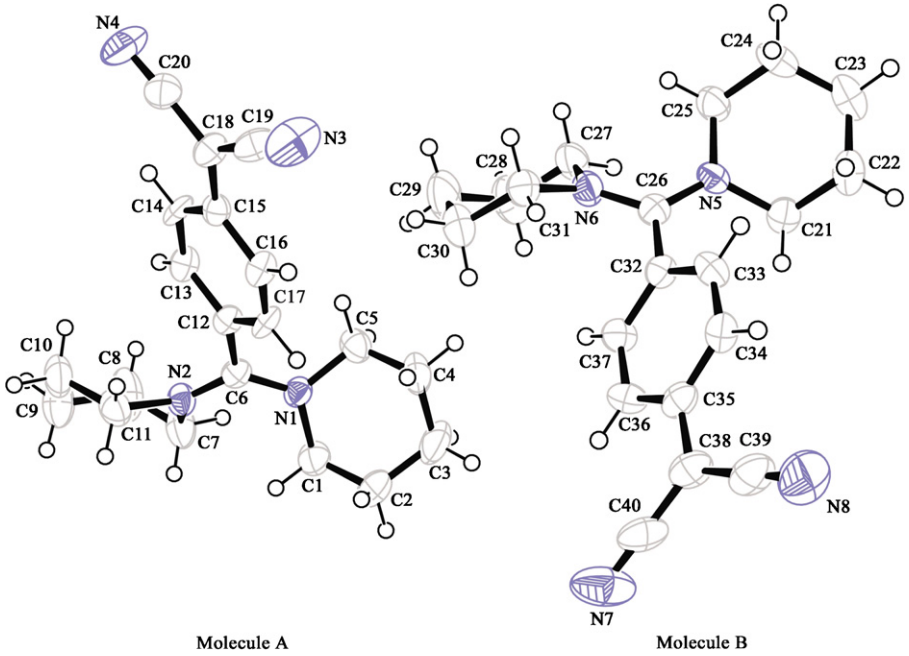

Fig. 5. ORTEP III view of the 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct with the atom numbering scheme (50% probability ellipsoids).

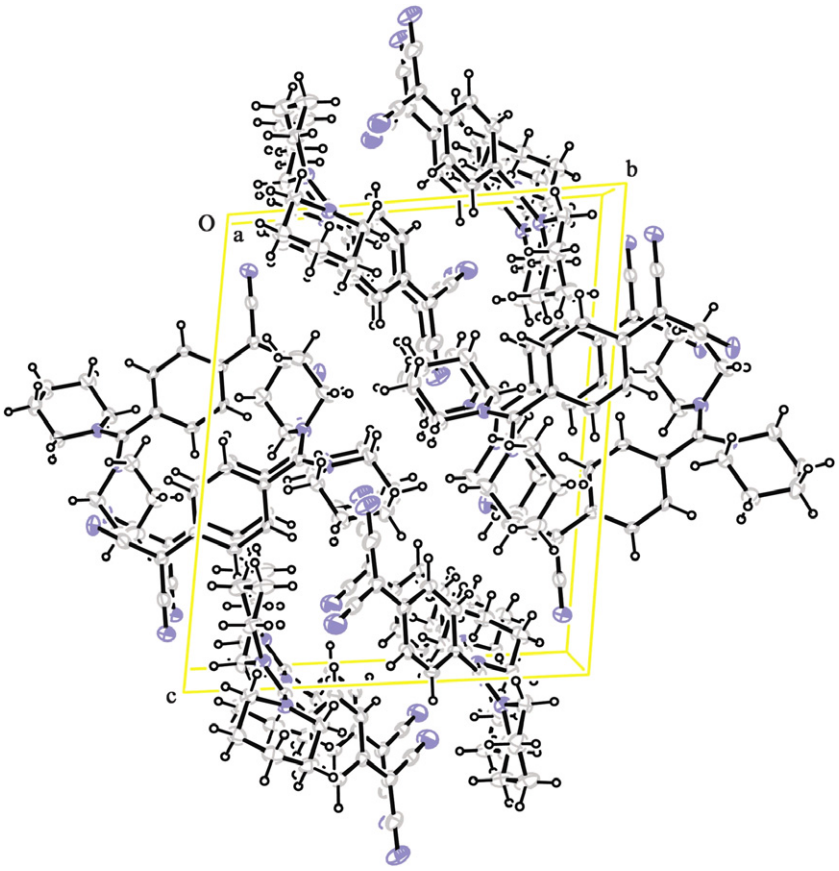

Fig. 6. Crystal packing of the 7,7-dicyano-8,8-di-piperidinoquinodimethane adduct.

2HCl molecules with a weight loss 16.70% (calc. 17.50%). The third and fourth stages are in the range 242–600 °C, with maximum peaks at 283 and 581 °C, respectively, and involve the loss of $HCl + C_6H_{18}N_2O_2$, leaving ten carbon atoms as a residue resulting from the process of decomposition under nitrogen. The remains of 10 carbon atoms

Table 3
Thermo analytical results for the (A) $[(Pip)_2(CHL)]$ and (B) 7,7-dicyano-8,8-di-piperidinoquinodimethane compounds

Samples	Stage	TGA range (°C)	DTG_{max} (°C)	Weight loss (%)		Evolved moiety
				Found	Calc.	
A	I	25–175	158	8.35	8.77	HCl
	175–242	214	16.70	17.50	2HCl	
	242–600	283, 581	46.70	44.90	$HCl + C_6H_{18}N_2O_2$	
	residue					10C
B	I	30–600	376	58.10	58.80	$C_9H_{24}N_4$
	residue					11C

confirm that the interaction between donor:acceptor occurs in a 2:1 molar ratio, in agreement with that obtained from the elemental analysis, this fact proves that the Pip/CHL complex contain two piperidine moieties. The overall weight loss amounts to 71.76% (calc. 71.20%).

Interestingly, Fig. 8, the thermogravimetric curve (TGA) of the new adduct, 7,7-dicyano-8,8-di-piperidinoquinodimethane, formed from the elimination reaction between two molecules of Pip and the powerful acceptor TCNQ has only one maximum peak at 376 °C, this result proves that the formed compound is a new organic compound that has only one sharp melting point. The thermograms of the Pip/TCNQ adduct shows one decomposition step within the temperature range 30–600 °C which corresponds to the loss of the $C_9H_{24}N_4$ organic moiety with a mass loss of 58.10% (calc. 58.80%).

3.6. Kinetic studies of the $[(Pip)_2(TCNQ)]$ and 7,7-dicyano-8,8-di-piperidinoquinodimethane adducts

In recent years there has been increasing interest in determining the rate dependent parameters of solid-state non-isothermal decomposition reactions by analysis of TG curves. Several equations [34–41] have been proposed as a means of analyzing a TG curve and obtaining values for kinetic parameters. Many authors [34–38] have discussed the advantages of this method over the conventional isothermal method. The rate of a decomposition process can be described as the product of two separate functions of temperature and conversion [35], using

$$d\alpha/dt = k(T)f(\alpha) \tag{8}$$

where α is the fraction decomposed at time t, $k(T)$ is the temperature dependent function and $f(\alpha)$ is the conversion function dependent on the mechanism of decomposition. It has been established that the temperature dependent function $k(T)$ is of the Arrhenius type and can be considered as the rate constant k.

$$k = Ae^{-E*/RT} \tag{9}$$

where, R is the gas constant in (J mol^{-1} K^{-1}). Substituting Eq. (9) into Eq. (8), we get,

$$d\alpha/dT = (A/\phi e^{-E*/RT})f(\alpha) \tag{10}$$

where ϕ is the linear heating rate dT/dt. On integration and approximation, this equation can be obtained in the following form

$$\ln g(\alpha) = -E^*/RT + \ln[AR/\phi E^*] \tag{11}$$

where $g(\alpha)$ is a function of α, dependent on the mechanism of the reaction. The integral on the right-hand side is known as the temperature integral and has no closed solution. So, several techniques have been used for the evaluation of the temperature integral. Most commonly used methods for this purpose are the differential method of

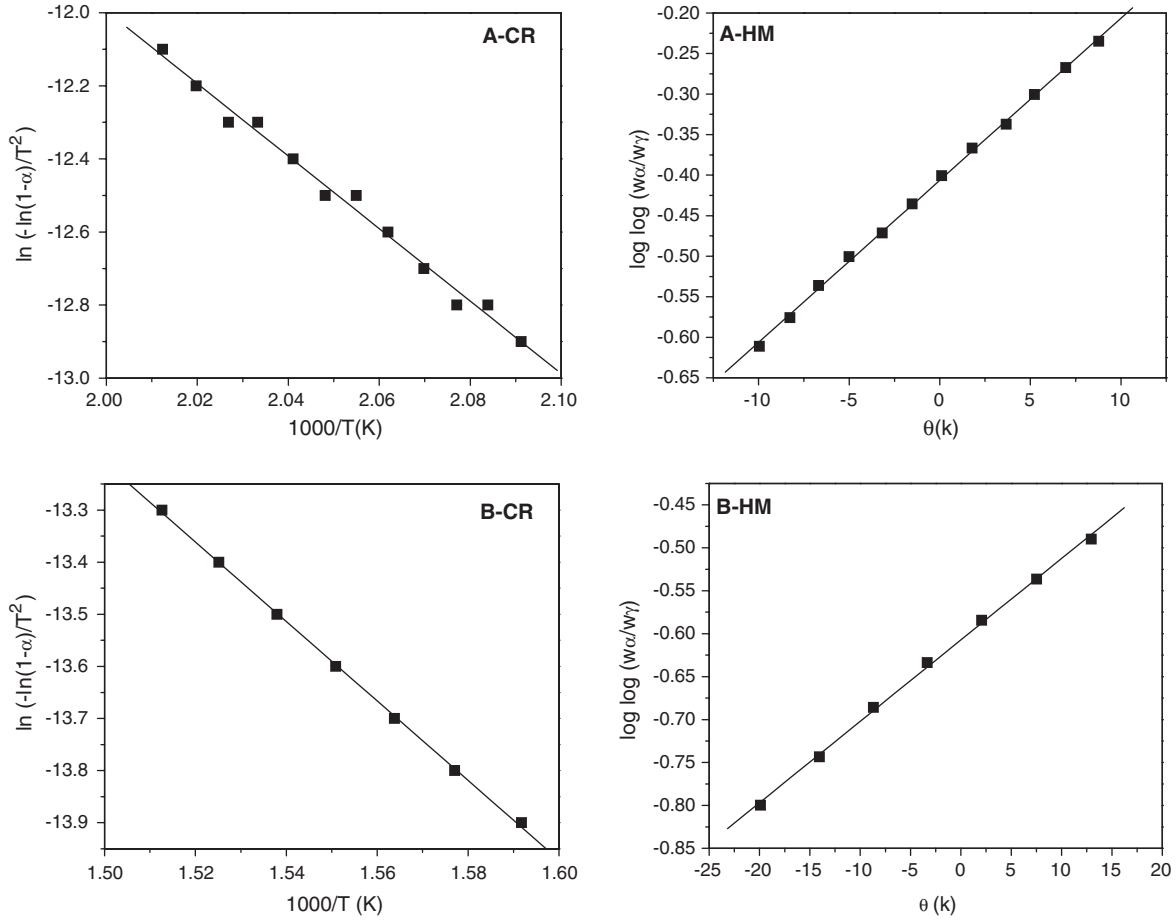

Fig. 9. Kinetic diagrams of the Coats–Redfern (CR) and Horowitz–Metzger (HM) equations for (a) the [(Pip)$_2$(CHL)] and (b) the 7,7-dicyano-8,8-dipiperidinoquinodimethane compounds.

Freeman and Carroll [34], the integral method of Coat and Redfern [36] and the approximation method of Horowitz and Metzger [39].

In the present investigation the general thermal behaviors of the two Pip CT complexes in terms of stability ranges, peak temperatures and values of kinetic parameters, are shown in Fig. 9 and Table 4. The kinetic parameters have been evaluated using the following methods and the results obtained by these methods are compared with one another. The following two methods are discussed briefly.

3.6.1. Coats–Redfern equation

The Coats–Redfern Eq. (12), which is a typical integral method, can be represented as

$$\int_0^{\alpha}\frac{d\alpha}{(1-\alpha)^n}=\frac{A}{\varphi}\int_{T_1}^{T_2}\exp\left(\frac{-E^*}{RT}\right)dt \tag{12}$$

For convenience of integration, the lower limit T_1 is usually taken as zero. This equation on integration gives

$$\ln[-\ln(1-\alpha)/T^2]=-E^*/RT+\ln[AR/\varphi E^*] \tag{13}$$

A plot of the left-hand side (LHS) against $1/T$ was drawn. E^* is the energy of activation in kJ mol^{-1} and is calculated from the slope, and A in (s^{-1}) is obtained from the intercept value. The entropy of activation ΔS^* in (J K^{-1} mol^{-1}) was calculated using

$$\Delta S^*=R\ln(Ah/k_BT_s) \tag{14}$$

where k_B is the Boltzmann constant, h is Plank's constant and T_s is the DTG peak temperature [42].

3.6.2. Horowitz–Metzger equation

The Horowitz–Metzger equation is illustrative of the approximation methods. These authors derived the relation:

$$\log[\{1-(1-\alpha)^{1-n}\}/(1-n)] = E^*\theta/2.303RT_s^2 \quad \text{for} \quad n \neq 1 \tag{15}$$

when $n = 1$, the LHS of Eq. (14) would be $\log[-\log(1-\alpha)]$. For a first-order kinetic process the Horowitz–Metzger Eq. (16) may be written in the form:

$$\log[\log(w_\alpha/w_\gamma)] = E^*\theta/2.303RT_s^2 - \log 2.303 \tag{16}$$

where $\theta = T - T_s$, $w_\gamma = w_\alpha - w$, $w_\alpha =$ mass loss at completion of the reaction; $w =$ mass loss up to time t. A plot of $\log[\log(w_\alpha/w_\gamma)]$ versus θ was drawn and found to be linear from the slope, from which E^* was calculated. The pre-exponential factor, A, was calculated from:

$$E^*/RT_s^2 = A/[\varphi \exp(-E^*/RT_s)] \tag{17}$$

The enthalpy activation, ΔH^*, and Gibbs free energy, ΔG^*, were calculated from:

$$\Delta H^* = E^* - RT \tag{18}$$

$$\text{and}\Delta G^* = \Delta H^* - T\Delta S^* \tag{19}$$

The kinetic parameters E^*, ΔH^*, ΔS^* and ΔG^* calculated with the Coats–Redfern and Horowitz–Metzger equations are tabulated in Table 4. Taking the main decomposition steps as a criterion, the values of the activation entropies, $-\Delta S^*$ in these two compounds indicate that the activated complexes have a more ordered structure than the reactants, this deduced the formation of the Pip CT complexes.

4. Supplementary material

CCDC 648793 contains the supplementary crystallographic data for [$(Pip)_2$(TCNQ)]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail:deposit@ccdc.cam.ac.uk.

Selenated Schiff bases of 2-hydroxyacetophenone and their palladium(II) and platinum(II) complexes: Syntheses, crystal structures and applications in the Heck reaction

Arun Kumar, Monika Agarwal, Ajai K. Singh *

Department of Chemistry, Indian Institute of Technology, New Delhi 110 016, India

Received 20 August 2007; accepted 13 September 2007
Available online 14 November 2007

Abstract

Selenated Schiff bases 2-HO-$C_6H_4C(CH_3)$=$N(CH_2)_n$SePh ($n = 2$, $\mathbf{L}^1$; $n = 3$, $\mathbf{L}^2$) and their complexes with Pd(II) and Pt(II), viz [Pd($\mathbf{L}^1$–H)Cl] (**1**), [Pt($\mathbf{L}^1$–H)Cl] (**2**), [Pd($\mathbf{L}^2$–H)Cl] (**3**) and [Pt$\mathbf{L}^2Cl_2$] (**4**), have been synthesized and characterized with proton, carbon-13 and ^{77}Se{^{1}H} NMR spectra. In the ^{77}Se{^{1}H} NMR spectrum of **2** the signal at δ 387.4 ppm appears as a triplet due to $^1J(^{195}Pt–Se)$ coupling (2043 Hz). The single-crystal structures of $\mathbf{L}^1$, $\mathbf{L}^2$, **1** and **2** were solved. The C–Se–C bond angles in $\mathbf{L}^1$ and $\mathbf{L}^2$ have been found to be around 99°. The geometry around Pd and Pt is square planar. The Pd–Se and Pt–Se bond distances are 2.3669(11) and 2.3543(16) Å, respectively. Complexes **1** and **2** are the first examples of crystal structures of Pd and Pt complexes of a (Se, N, O^-) ligand. Complex **1** has been explored as a homogeneous catalyst for a Heck type C–C coupling reaction between methyl acrylate and *p*-iodonitrobenzene (yield ~80%; reaction time 14 h).

1. Introduction

Schiff bases constitute an important class of ligands, which have very rich and extensive chemistry, reviewed recently by Vigato and Tamburini [1]. Metal complexes of Schiff bases have found diverse applications in addition to interesting structural chemistry. Ruthenium complexes containing bidentate Schiff bases have been used [2] in catalyzing Kharasch addition, enol-ester synthesis, alkyne dimerization, olefin metathesis and atom transfer radical polymerization. Metal complexes of chiral binaphthyl Schiff bases have been used for stereoselective organic transformations [3]. Oxovanadium(III–V) complexes of tetradentate Schiff bases have the potential for multi-electron redox catalysis [4]. Metal complexes containing Schiff-base ligands have also been found to show mesomorphic behaviour [5]. Among Schiff bases, 'Salen' and related derivatives have been found to be very interesting. Their complexes with transition metals are suitable catalysts for epoxidation reactions [6–10] and a variety of other reactions like dehydrogenation plus intramolecular Diels-Alder cycloaddition [11], enantioselective conjugate addition [12] and ring opening polymerization [13]. However, selenated Schiff bases of mono ketones or aldehydes have not been studied in detail so far and recently we have reported such tellurated derivatives [14,15]. The presence of Se as a donor site in Schiff bases may modify significantly their known catalytic roles. Therefore, such systems are worth exploring. A wide range of selenated Schiff-base ligands may be designed by the reaction of a selenated amine with different aldehydes or ketones. To use this strategy we have made

doi:10.1016/j.poly.2007.09.027

$NH_2CH_2CH_2SePh$ and $NH_2CH_2CH_2CH_2SePh$ [3], which have been used for designing selenated Schiff bases. Thus $\mathbf{L}^1$ and $\mathbf{L}^2$ and their complexes with Pd(II) and Pd(II), in which a metal–selenium bond is formed, have been synthesized. Selenium being a very "soft" donor in nature does not coordinate with 3-d transition metal ions in their common oxidation states. The ligands $\mathbf{L}^1$ and $\mathbf{L}^2$ and their complexes were characterized by NMR spectroscopy (including $^{77}Se\{^1H\}$) and X-ray diffraction studies, when single crystals were obtained. The results of these investigations are reported in this paper. The catalytic activity of the selenide–Pd(II) complexes not only rivals but may outperform that of the corresponding phosphorus and sulfur analogues [16,17]. Practical advantages of the selenium-based catalysts for the Heck reaction have been reported as their straightforward synthesis and high activity in the absence of any additives as well as the enhanced stability of the selenide ligands toward air oxidation [17]. Therefore, **1** was thought to be a good candidate for exploring for the Heck reaction. Preliminary results of these explorations are also reported in this paper.

2. Experimental

The C and H analyses were carried out with a Perkin–Elmer 2400 Series II C, H, N analyzer. The ^1H, $^{13}C\{^1H\}$ and $^{77}Se\{^1H\}$ NMR spectra were recorded on a Bruker Spectrospin DPX-300 NMR spectrometer at 300.13, 75.47 and 57.24 MHz, respectively. IR spectra in the range 4000–250 cm^{-1} were recorded on a Nicolet Protége 460 FT-IR spectrometer as KBr pellets. The melting points determined in open capillary are reported as such. The conductivity measurements were carried out in CH_3CN (concentration ca 1 mM) using an ORION conductivity meter model 162.

Single-crystal diffraction studies were carried out with a Bruker AXS SMART Apex CCD diffractometer using Mo Kα (0.71073 Å) radiation at 298(2) K. The software SADABS was used for absorption correction (if needed) and SHELXTL for space group, structure determination and refinements [18a,18b]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they are attached. The least-squares refinement cycles on F^2 were performed until the model converged.

2-(Phenylseleno)ethylamine [19] and 3-(phenylseleno)-propylamine [19] were prepared by the reported methods [$^{77}Se\{^1H\}$ NMR (vs Me_2Se, 25 °C) δ, ppm: 256.6 and 257.5, respectively].

2.1. Synthesis of L^1

2-(Phenylseleno)ethylamine (1.00 g, 5.0 mmol) was stirred in dry ethanol (20 mL) at room temperature for 0.5 h. *o*-Hydroxyacetophenone (0.68 g, 5.0 mmol), dissolved in dry ethanol (20 mL), was mixed dropwise with stirring. The mixture was stirred further at room temperature for 2 h. The solvent was evaporated on a rotary evaporator which resulted in a yellow precipitate. The precipitate on recrystallization from chloroform–hexane (1:1) gave yellow coloured single-crystals of $\mathbf{L}^1$. Yield 1.43 g (~90%); m.p. 84–85 °C. $\Lambda_M = 0.88\ cm^2\ mol^{-1}\ \Omega^{-1}$. *Anal.* Calc. for $C_{16}H_{17}NOSe$: C, 60.33; H, 5.34; N, 4.39. Found: C, 60.46; H, 5.28; N, 4.46%. NMR (^1H, $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 2.25 (s, 3H, CH_3), 3.22 (t, $J = 6.9$ Hz, 2H, $SeCH_2$), 3.81 (t, $J = 6.9$ Hz, 2H, H_6), 6.78 (t, $J = 7.2$ Hz, 1H, H_{12}), 6.94 (d, $J = 8.4$ Hz, 1H, H_{13}), 7.25–7.30, (m, 4H, H_2, H_1 and H_{11}), 7.49 (d, $J = 8.4$ Hz, 1H, H_{10}), 7.52–7.55 (m, 2H, H_3), 15.93 (bs, 1H, OH) ($^{13}C\{^1H\}$, $CDCl_3$, 25 °C vs $SiMe_4$) δ, ppm: 14.6 (CH_3), 27.8 ($SeCH_2$), 49.4 (C_6), 117.2 (C_{10}), 118.5 (C_{12}), 119.3 (C_8), 127.2 (C_1), 128.0 (C_{13}), 129.1 (C_2), 129.2 (C_4), 132.4 (C_{11}), 133.0 (C_3), 163.2 (C_9), 171.8 (C_7) ($^{77}Se\{^1H\}$, $CDCl_3$, 25 °C vs Me_2Se) δ, ppm: 282.3. IR (KBr, cm^{-1}): 3484, 1607, 470, 734.

2.2. Synthesis of L^2

3-(Phenylseleno)propylamine (1.07 g, 5.0 mmol) was stirred in dry ethanol (20 mL) at room temperature for 0.5 h. *o*-Hydroxyacetophenone (0.68 g, 5.0 mmol), also dissolved in dry ethanol (20 mL), was added to it dropwise with stirring. The mixture was stirred further at room temperature for 2 h. On evaporating the solvent on a rotary evaporator a yellow precipitate of $\mathbf{L}^2$ was obtained, which on recrystallization from a chloroform–hexane mixture (1:1) afforded yellow single-crystals of $\mathbf{L}^2$. Yield 1.49 g (~90%); m.p. 82–83 °C. *Anal.* Calc. for $C_{17}H_{19}NOSe$: C, 61.40; H, 5.71; N, 4.21. Found: C, 61.45; H, 5.73; N, 4.28%. NMR (^1H $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 2.15 (quintet, $J = 6.6$ Hz, 2H, H_6), 2.29 (s, 3H, CH_3), 3.06 (t, $J = 6.9$ Hz, 2H, $SeCH_2$), 3.66 (t, $J = 6.6$ Hz, 2H, H_7), 6.77 (t, $J = 7.5$ Hz, 1H, H_{13}), 6.92 (d, $J = 8.1$ Hz, 1H, H_{14}), 7.23–7.31 (m, 4H, H_2, H_1 and H_{12}), 7.48–7.50 (m, 2H, H_{11} and H_3), 16.40 (bs, 1H, OH) ($^{13}C\{^1H\}$ $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 14.3 (CH_3), 25.2 ($SeCH_2$), 30.46 (C6), 48.4 (C_7), 116.9 (C_{11}), 118.7 (C_{13}), 119.1 (C_9), 126.8 (C_1), 127.9 (C_{14}), 129.0 (C_2), 129.7 (C_4), 132.4 (C_{12}), 132.5 (C_3), 164.0 (C_{10}), 172.0 (C_8) (^{77}Se $\{^1H\}$, $CDCl_3$, 25 °C, vs Me_2Se) δ, ppm: 286.6. IR (KBr, cm^{-1}): 1612, 461, 734.

2.3. Synthesis of [PdCl(L^1–H)] (1)

An aqueous solution (5 mL) of $Na_2[PdCl_4]$ (0.294 g, 1 mmol) was mixed with a solution of $\mathbf{L}^1$ (0.3182 g,

1 mmol) prepared in acetone (10 mL) with vigorous stirring. An orange precipitate of **1**, obtained instantaneously, was filtered and dried. It was recrystallized from chloroform–hexane (2:1) mixture. Single-crystals of **1** were obtained from the same solvent system (a few drops of MeOH were added additionally). Yield ca. 0.3626 g (~79%); m.p. 159 °C. $\Lambda_M = 7.0\ cm^2\ mol^{-1}\ \Omega^{-1}$. *Anal.* Calc. for $C_{16}H_{16}ClNOPdSe$ (powder form): C, 41.83; H, 3.49; N, 3.05. Found: C, 41.68; H, 3.41; N, 3.10%. NMR (^1H, $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 2.22 (s, 3H, CH_3), 2.69–2.72 (m, 1H, H_5), 3.56–3.71 (m, 2H, $H_5 + H_6$), 4.48–4.53 (m, 1H, H_6), 6.62 (t, $J = 7.8$ Hz, 1H, H_{12}), 7.12 (d, $J = 8.7$ Hz, 1H, H_{13}), 7.23–7.38 (m, 2H, H_{11} and H_{10}), 7.41–7.43 (m, 3H, H_2 and H_1), 8.16–8.19 (m, 2H, H_3) ($^{13}C\{^1H\}$, $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 19.7 (CH_3), 32.4 ($SeCH_2$), 60.7 (=NCH_2), 115.4 (C_{10}), 121.6 (C_{12}), 123.4 (C_4), 125.7 (C_8), 129.9 (C_2), 130.1 (C_{11}), 131.1 (C_1), 133.4 (C_{13}), 133.6 (C_3), 164.2 (C_9), 168.1 (C_7). ($^{77}Se\{^1H\}$ $CDCl_3$, 25 °C vs Me_2Se) δ, ppm: 440.4. IR (KBr, cm^{-1}): 1572, 463, 747.

2.4. Synthesis [PtCl(**L**^{1}–H)] (**2**)

$K_2[PtCl_4]$ (0.415 g, 1 mmol) was dissolved in water (5 mL). A solution of $\mathbf{L}^1$ (0.3182 g, 1 mmol) prepared in acetone (10 mL) was added to it with vigorous stirring. An orange precipitate of **2** was obtained, which was filtered and dried. The orange solid was recrystallized from chloroform–hexane (2:1). Single-crystals of **2** were obtained from the same solvent system. Yield ca. 0.3626 g (~79%); m.p. 162 °C $\Lambda_M = 5.0\ cm^2\ mol^{-1}\ \Omega^{-1}$. *Anal.* Calc. for $C_{16}H_{16}ClNOPtSe$: C, 35.10; H, 2.92; N 2.56. Found: C, 35.50; H, 2.96; N, 2.51%. NMR (^1H, $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 2.14 (s, 3H, CH_3), 2.55 (t of d, $J = 2.7$ Hz, $J = 12.3$ Hz, 1H, H_5), 3.38 (d of t, $J = 4.2$ Hz, $J = 12$ Hz, 1H, H_5), 3.56 (d of t, $J = 3.9$ Hz, 12.3 Hz, 1H, H_6) 4.37 (t of d, $J = 2.4$ Hz, $J = 13.5$ Hz, 1H, H_6), 6.66 (t, $J = 7.2$ Hz, 1H, H_{12}), 7.20 (d, $J = 8.4$ Hz, 1H, H_{13}), 7.34 (t, $J = 8.4$ Hz, 1H, H_{11}), 7.39–7.42 (m, 3H, H_2, H_1), 7.47 (d, $J = 8.4$ Hz, H_{10}), 8.10–8.13 (m, 2H, H_3) ($^{13}C\{^1H\}$, $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 20.6 (CH_3), 34.2 ($SeCH_2$), 61.9 (=NCH_2), 116.4 (C_{10}), 122.0 (C_{12}), 123.1 (C_4), 124.7 (C_8), 129.5 (C_2), 130.2 (C_{11}), 130.5 (C_1), 132.9 (C_{13}), 133.1 (C_3), 162.5 (C_9), 163.7 (C_7) ($^{77}Se\{^1H\}$, 25 °C, vs Me_2Se) δ, ppm: 387.36. IR (KBr, cm^{-1}): 1572, 465, 747.

2.5. Synthesis of [PdCl(**L**^{2}–H)] (**3**)

$Na_2[PdCl_4]$ (0.294 g, 1 mmol) dissolved in water (5 mL) and a solution of $\mathbf{L}^2$ (0.332 g, 1 mmol) prepared in acetone (10 mL) were stirred together vigorously. An orange precipitate of **3** was immediately obtained, which was filtered and dried. It was recrystallized from a chloroform–hexane (60:40) mixture. Yield ~0.42 g (~90%); m.p. 170 °C. $\Lambda_M = 6.0\ cm^2\ mol^{-1}\ \Omega^{-1}$ *Anal.* Calc. for $C_{17}H_{18}NOSePdCl$: C, 43.12; H, 3.80; N, 2.95. Found: C, 42.82; H, 3.99; N, 3.15%. NMR (^1H, $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 2.02–2.07 (m, 2H, H_6), 2.34 (s, 3H, CH_3), 2.88 (d of t, $J = 4.2$ Hz, 1H, H_5), 3.10 (d of t, $J = 4.2$ Hz, $J = 11.1$ Hz, 1H, H_5), 3.65–3.69 (m, 2H, H_7), 6.65 (t, $J = 7.8$ Hz, 1H, H_{13}), 7.10 (d, $J = 8.7$ Hz, 1H, H_{14}), 7.22 (t, $J = 7.5$ Hz, 1H, H_{12}), 7.33–7.44 (m, 4H, H_{11}, H_2, H_1), 8.05–8.07 (m, 2H, H_3) ($^{13}C\{^1H\}$ $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 19.6 (CH_3), 26.3 ($SeCH_2$), 29.7 (C6), 53.4 (NCH_2), 116.0 (C_{11}), 121.8 (C_{13}), 126.6 (C_9), 129.7 (C_4), 129.8 (C_2), 129.8 (C_{12}), 130.3 (C_1), 133.3 (C_3), 134.1 (C_{14}), 164.6 (C_{10}), 169.1 (C_8) ($^{77}Se\{^1H\}$, 25 °C, vs Me_2Se) δ, ppm: 293.6. IR (KBr, cm^{-1}): 1592, 468, 748.

2.6. Synthesis [PtCl(**L**^{2})] (**4**)

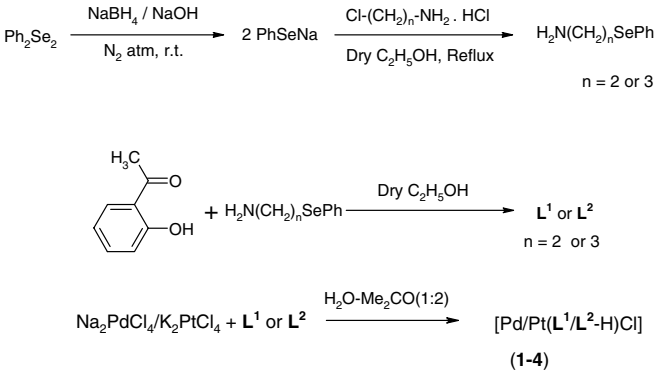
$K_2[PtCl_4]$ (0.415 g, 1 mmol) was dissolved in water (5 mL). A solution of $\mathbf{L}^2$ (0.332 g, 1 mmol) in acetone (10 mL) was added with vigorous stirring. An orange coloured precipitate of **4** was immediately obtained, which was filtered and dried. It was recrystallized from a chloroform–hexane (60:40) mixture. Yield ~0.415 g (~50%); m.p. 147 °C. $\Lambda_M = 6.8\ cm^2\ mol^{-1}\ \Omega^{-1}$. *Anal.* Calc. for $C_{17}H_{19}NOSePtCl_2$: C, 34.11; H, 3.18; N, 2.34. Found: C, 33.67; H, 3.58; N, 2.43%. NMR (^1H, CDCl3, 25 °C, vs $SiMe_4$) δ, ppm: 2.21–2.41 (m, 5H, $H_6 + CH_3$), 3.10 (t of d, $J = 3.6$ Hz, $J = 8.1$ Hz, 1H, H_5), 3.54–3.58(m, 1H, H_5), 3.65–3.66 (m, 2H, NCH_2), 6.78 (t, $J = 7.2$ Hz, 1H, H_{13}), 6.91 (d, $J = 8.4$ Hz, 1H, H_{14}), 7.28 (t, $J = 8.1$ Hz, 1H, H_{12}), 7.34–7.42 (m, 3H, H_2, H_1), 7.49 (d, $J = 7.8$ Hz, H_{11}), 7.86–7.89 (m, 2H, H_3), 16.28 (bs, 1H, OH); ($^{13}C\{^1H\}$ $CDCl_3$, 25 °C, vs $SiMe_4$) δ, ppm: 14.6 (CH_3), 28.2 ($SeCH_2$), 31.6 (C_6) 48.7 (NCH_2), 117.3 (C_{11}), 118.5 (C_{13}), 119.3 (C_9), 128.1 (C_{14}), 129.6 (C_2), 130.2 (C_1), 132.5 (C_{12}), 132.9 (C_4), 133.0 (C_3), 163.4 (C_{10}), 172.5 (C_8); ($^{77}Se\{^1H\}$, 25 °C, vs Me_2Se) δ, ppm: 337.4, 338.5. IR (KBr, cm^{-1}): 3395, 1582, 465, 739, 685.

2.7. Procedure for the homogeneous catalytic Heck reaction with **1**

A mixture of methyl acrylate (0.172 g, 2 mmol), *p*-iodonitrobenzene (0.62 g, 2.5 mmol), Et_3N (0.54 g, 3.0 mmol), *p*-xylene (2.0 mL) and **1** (22.95 mg) was stirred for 14 h at 140 °C and cooled thereafter to room temperature. It was treated with chloroform (40 mL) and filtered. The filtrate was evaporated on a rotary-evaporator to obtain the product.

It was purified through a silica gel column using hexane:ethylacetate mixture (9:1); yield 0. 33 g (~80%); NMR (^1H, $CDCl_3$, 25 °C, vs TMS) δ, ppm: 3.84 (s, 3H, OCH_3), 6.58 (d, $J = 15.9$ Hz, 1H, =CH–COOMe), 7.69 (d, 2H, $J = 9$ Hz, ArH, *o* to NO_2), 7.74 (d, $J = 15.9$ Hz, 1H, =CH–Ar), 8.27 (d, 2H, $J = 9$ Hz, Ar H, *m* to NO_2).

3. Results and discussion



The ligands $\mathbf{L}^1$ and $\mathbf{L}^2$ and their complexes have been synthesized by the reactions given in Scheme 1. The ligands are stable and can be stored under ambient conditions up to 6 months. They have good solubility in $CHCl_3$, CH_2Cl_2, CH_3CN, MeOH, EtOH and acetone. In hexane both ligands are sparingly soluble. Both ligands are non-electrolytes. Complexes **1**–**4** are stable under ambient conditions and are soluble in $CHCl_3$, CH_2Cl_2, CH_3CN, EtOH, MeOH and acetone, but insoluble in hexane. All of them are non-ionic in nature. In the IR spectra of complexes **1**–**4** the $\rangle C{=}N-$ stretching frequency has been observed to be red shifted by 20–35 cm^{-1} with respect to those of $\mathbf{L}^1$ and $\mathbf{L}^2$, indicating the involvement of its nitrogen in coordination. Elemental analyses of **1** and **2** were carried out using their non-crystalline samples.

3.1. NMR spectra
