Fig. 10. View of the two-dimensional polymeric nature of **12**, showing the bridging nitrates and the π–π stacking between the aromatic ligands.

the molecule is twisted in this way, and formation of complexes from this non-planar ligand could allow interesting structures to form.

The coordination chemistry of **2** was investigated by the formation of complexes with $AgNO_3$, $PdCl_2$ and $CuCl_2$. Reaction with silver nitrate produced a complex **9** that analysed with an intriguing 2:3 ligand–metal stoichiometry. Such a ligand–metal ratio was observed in three silver complexes of 2,2′-dimethyl-4,4′-bipyrimidine, a molecule similar to **2** [23]. These complexes were polymeric, with the ligands being tetradentate with both the chelating and bridging sites occupied. Unfortunately, no crystals of **9** were obtained from attempted recrystallisations. Reaction with Li_2PdCl_4 produced a 1:1 complex **10** that was highly insoluble and not further investigated. Reaction with copper(II) chloride produced a crystalline 1:1 complex **11** but, alas, the crystals were too small for X-ray structure determination. Thus, in the absence of crystallographic evidence we are unable to confirm the structure of any complex of **2**.

2,2′-Biquinoxaline (**3**) is also an ambivergent ligand. The free ligand itself exists in a *transoid* conformation [12] in which case it would be expected to act as a divergent, "stepped-linear" bridging ligand, with coordination by the less hindered nitrogens [24], as shown in Fig. 8a. Unlike **1** and **2**, in order to chelate to a metal it must use the more hindered nitrogens and convert to the *cisoid* conformation (Fig. 8b). Finally, it could use all four available nitrogens and act in an ambivergent manner (Fig. 8c).

The coordination chemistry of **3** was investigated *via* the synthesis of complexes using $AgNO_3$, $CuCl_2$, CuI, $Cd(NO_3)_2$ and $Cu(PPh_3)_2NO_3$. The silver nitrate complex **12** was isolated as orange crystals in good yield. It has a two-dimensional polymeric structure, and crystallises in the monoclinic space group $P2_1/n$. The asymmetric unit contains two independent half molecules of ligand **3** and one silver nitrate unit (Fig. 9). The organic ligands both lie with centres of inversion at the midpoint of the interring bond and are consequently planar and in *transoid* conformations. The coordination mode is that shown in Fig. 8a, wherein the organic ligand acts as a "stepped-linear" bridge between two silver atoms separated by 10.088(1) Å.

The geometry of the silver atom can best be described as distorted tetrahedral, with the largest deviation from ideal geometry being an angle of 140.85(8)° subtended by the two coordinated nitrogens. The silver atoms are also bridged by nitrate anions, which separate them by a distance of 5.204(2) Å. This results in a two-dimensional network (Fig. 10), within which the coplanar rings of both the

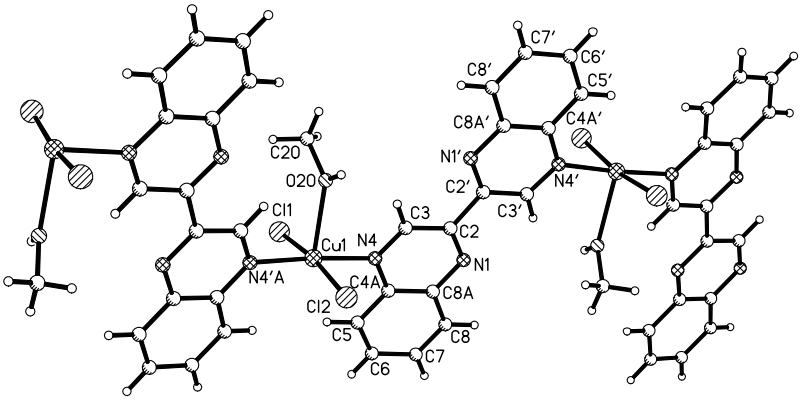

Fig. 11. Perspective view of **13**, with the atomic labelling shown. Selected bond lengths (Å) and bond angles (°): Cu1–N4 2.030(3), Cu1–N4′A 2.038(3), Cu1–Cl2 2.259(1), Cu1–Cl1 2.276(1), Cu1–O20 2.390(3), N4–Cu1–N4′A 176.1(1), N4–Cu1–Cl2 89.1(1), N4′A–Cu1–Cl2 88.12(9), N4–Cu1–Cl1 91.02(9), N4′A–Cu1–Cl1 91.26(9), Cl2–Cu1–Cl1 170.96(4), N4–Cu1–O20 91.5(1), N4′A–Cu1–O20 91.6(1), Cl2–Cu1–O20 97.92(8), Cl1–Cu1–O20 91.11(8).

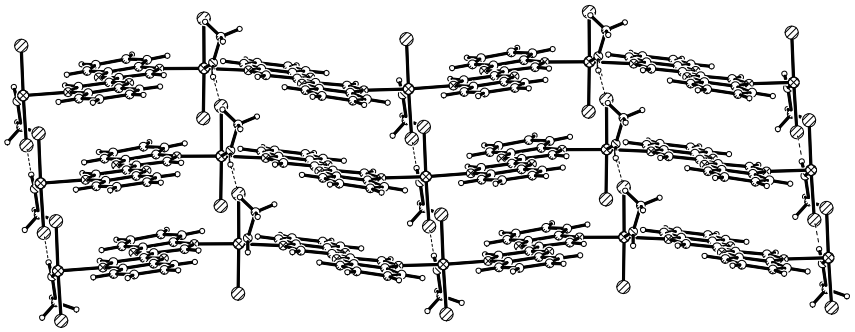

Fig. 12. Perspective view of the polymeric chains of **13**, showing the hydrogen bonds.

independent ligands stack in different directions, with the rings lying 3.585(4) and 3.462(4) Å apart, indicating weak π–π stacking interactions.

Reaction of **3** with copper(II) chloride produced a crystalline complex **13** which was suitable for X-ray crystallography. It is a one-dimensional coordination polymer that crystallises in the monoclinic space group $P2_1/c$, with one molecule of **3**, one copper(II) chloride and one coordinated methanol in the asymmetric unit (Fig. 11). The ligand **3** has a planar *transoid* conformation (mean deviation from plane: 0.026(5) Å) and bridges two copper atoms using the least hindered nitrogens, with a Cu···Cu separation of 9.549(1) Å. The geometry around the copper atom is slightly distorted square pyramidal, with *trans*-chlorine atoms and *trans*-nitrogens of **3** in the basal plane and the copper atom positioned 0.391(3) Å above the basal plane.

The polymer propagates along the *b*-axis of the unit cell in an undulating fashion with adjacent polymer chains arranged with the molecules of **3** π–π stacked and coplanar, the edge of each quinoxaline ring lying above another at a distance of 3.281(5) Å. There is also a hydrogen bond between the hydroxyl hydrogen of the methanol and a chlorine atom of an adjacent chain, as shown in Fig. 12, with a O–Cl distance of 3.091(3) Å and an O–H···Cl angle of 161(4)°. Thus, in both **12** and **13** the ligand acts in a divergent mode (Fig. 8a).

A copper(I) iodide complex with an intriguing 5:2 metal:ligand ratio was obtained as a black precipitate from reaction of CuI with **3**. However, recrystallisation of this from DMSO furnished red plates of a complex **14** with a 1:1 ratio. This crystallises in the triclinic space group $P\bar{1}$, with one molecule of **3** and one copper(I) iodide in the asymmetric unit (Fig. 13). The complex is binuclear, with two copper atoms bridged by iodine atoms, giving a Cu···Cu separation of 2.712(1) Å, about a crystallographic centre of inversion. The ligand **3** chelates the copper using the most hindered nitrogen atoms (mode (b) of Fig. 8), and this restricts **3** to planarity, with a mean deviation of

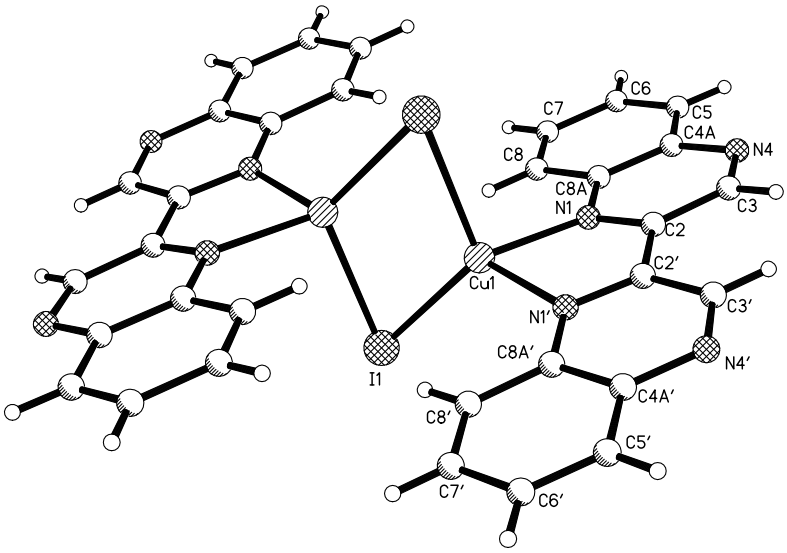

Fig. 13. Perspective view of **14**, with the asymmetric unit labelled. Selected bond lengths (Å) and bond angles (°): Cu1–N1 2.099(2), Cu1–N1′ 2.114(2), Cu1–I1 2.5742(9), Cu1–I1′ 2.6815(9), N1–Cu1–N1′ 78.66(9), N1–Cu1–I1 125.95(7), N1′–Cu1–I1 120.66(6), N1–Cu1–I1′ 99.66(6), N1′–Cu1–I1′ 106.43(6), I1–Cu1–I1′ 117.90(2).

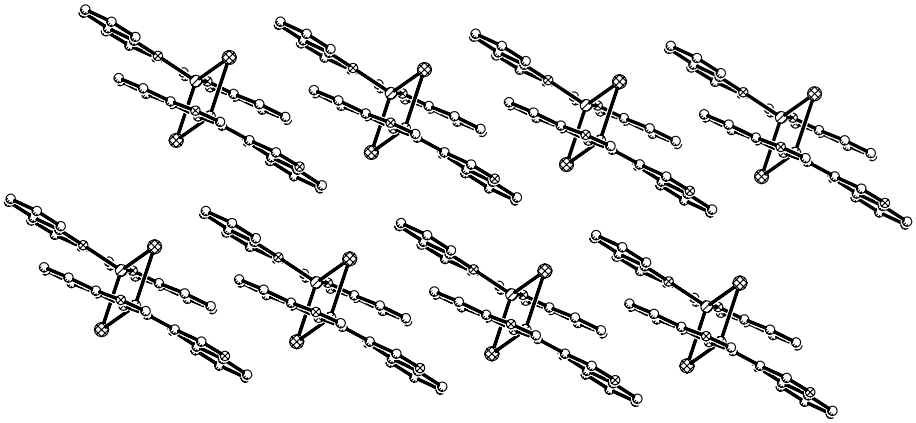

Fig. 14. View of the packing of **14**, with hydrogen atoms removed for clarity.

0.062(5) Å from the plane. The copper has a distorted tetrahedral geometry. The two molecules of **3** are coplanar, but are stepped with respect to one another, there being a distance of 2.338(5) Å between the planes. This stepping pulls the copper out of the coordination plane of **3** by 0.497(5) Å.

In the crystal packing the binuclear units stack with the C4A–C8A ring of one molecule coplanar and 3.389(5) Å above the C4A′–C8A′ ring of an adjacent ligand, and vice versa (Fig. 14). The rings of adjacent stacks also lie coplanar, with C6 of one ligand lying 3.275(5) Å above the centroid of the C4A–C8A ring of another. The structure of **14** is similar to the copper(I) iodide complex of 2,9-dimethyl-1,10-phenanthralene, which has similar bond lengths and geometry, although the Cu···Cu distance of 3.024(2) Å is slightly longer [25].

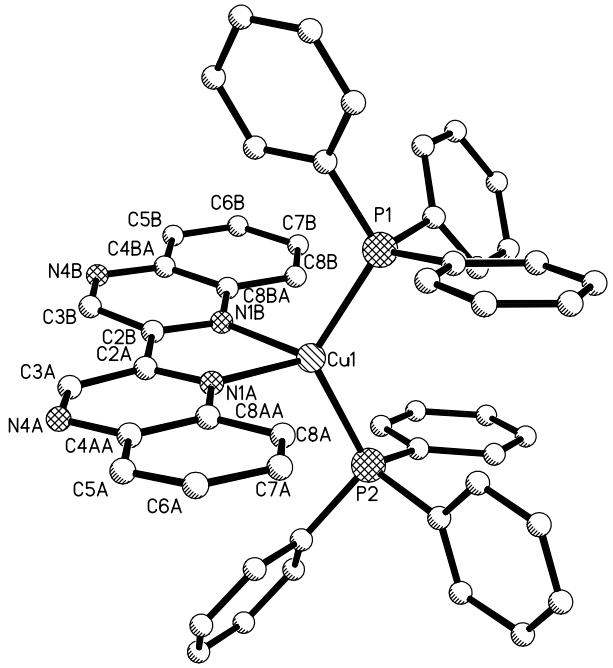

Fig. 15. Perspective view of **15**, with the labelling of **3** shown. Disordered nitrate, solvate molecules and hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and bond angles (°): Cu1–N1A 2.101(6), Cu1–N1B 2.109(4), Cu1–P1 2.283(2), Cu1–P2 2.293(2), N1A–Cu1–N1B 78.6(2), N1A–Cu1–P1 114.6(2), N1B–Cu1–P1 107.8(2), N1A–Cu1–P2 112.3(2), P1–Cu1–P2 122.23(7).

Finally, a second copper(I) complex **15** was prepared by reaction of **3** with bis(triphenylphosphine)copper(I) nitrate. It crystallises in $P\bar{1}$ with the bis(triphenylphosphine)copper chelated to **3** and a highly disordered nitrate counterion, as well as methanol and water solvate molecules in the asymmetric unit (Fig. 15). The ligand **3** is coordinated to the copper atom through the most hindered nitrogens, and is in a planar *cisoid* conformation (mean deviation from planarity 0.16(1) Å). One of the phenyl groups of a triphenylphosphine points towards the plane of **3**, with the closest approach made by C6, 3.270(8) Å above the ring.

One of the triphenylphosphine groups of **15** is involved in a 'hexa-aryl embrace' type interaction [26], as shown in Fig. 16. The PPh_3 groups, related by a centre of symmetry, are close, with a P···P distance of 6.422(6) Å, and are approximately colinear [170.4(2)°]. The closest interactions of the 'hexa-aryl embrace' occur between H6 of the aryl groups of the triphenylphosphine and the C1–C6 bond, with distances within the range 2.708(8)–2.791(8) Å. The second PPh_3 group of **15**, while not involved in a 'hexa-aryl embrace', is interacting with another PPh_3 group via an edge-to-face interaction. The closest approach involves H5F which lies 2.64(1) Å away from the centre of the C5H–C6H bond. The bulky triphenylphosphine groups of **15** preclude the face-to-face stacking of the heterocyclic ligand molecules that were seen in the previous compounds. The molecules pack into columns along the *c*-axis of the unit cell, leaving large voids that are occupied by disordered solvent molecules and nitrate counterions.

A 1:1 complex **16** of **3** with cadmium(II) nitrate was also prepared but proved to be curiously insoluble in all common solvents and was not investigated further.

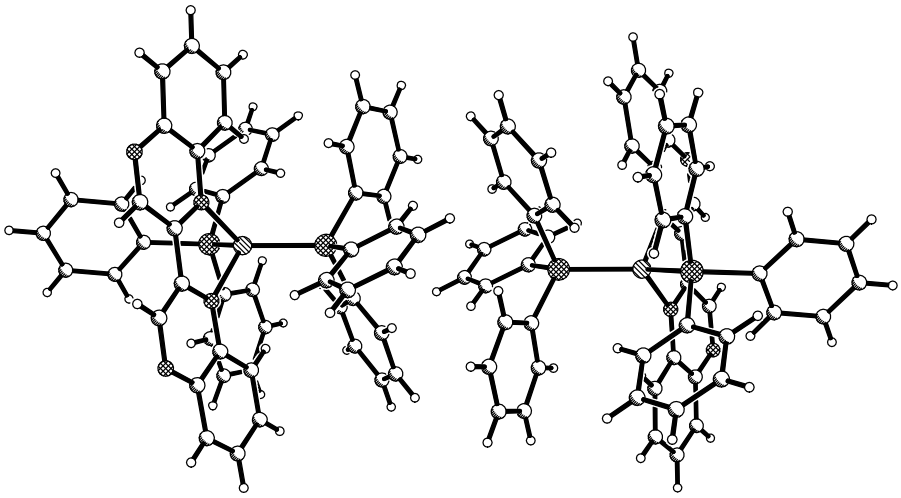

Fig. 16. Perspective view of the 'hexa-phenyl embrace' between the PPh_3 groups in the structure of **15**.

4. Conclusion

It has been shown that 2,2′-biquinazoline (**1**) prefers to form mononuclear complexes with chelation by the less hindered nitrogen donors. Complexes of 4,4′-biquinazoline (**2**) failed to provide suitable crystals for X-ray structure determination. 2,2′-Biquinoxaline (**3**) has been shown to offer two modes of coordination; in the first it acts as a "stepped-linear" bridging ligand using the two less hindered nitrogens. In the second mode it chelates to copper(I) centres using its more hindered nitrogens. Compared to the related ligands 2,2′-bipyrimidine and 2,2′-bipyrazine, the presence of the fused benzo rings leads to a higher propensity for π–π stacking of the heterocyclic ligands within the complexes, a phenomenon we have recently identified in other systems [24,27].

Peptides possess many unusual features to be specific ligands for a variety of metal ions. They contain a lot of potential donor atoms like amino and amide nitrogens and oxygens from carboxyl or carbonyl groups. The side chains of some amino acids have very efficient donor atoms, i.e. the imidazole moiety in the histidine residue. The cooperativity of all three donor groups of the histidine residue in the metal binding properties is made by the formation of two fused chelate rings. First is a five-membered $\{NH_2, COO^-\}$ amino acid-like ring, and the second one a six-membered $\{NH_2, N_{im}\}$ histamine-like ring [4].

The metal ion coordination to the histidine residue generally takes place via the N(1) or N(3) atoms of the imidazole, as is found in copper, zinc and iron proteins including myoglobin and other heme proteins, carbonic anhydrase and blue copper proteins [5].

The multi-histidine sequence is characteristic for Cu^{2+} binding motifs in proteins like prions [2], amyloid precursor protein (APP) [6–8] or secreted protein acidic and rich in cysteine (SPARC) [9] and also some groups of enzymes, i.e. copper containing oxidases (-His-His-Gly-His-) in the catecholase catalytic centre [10].

A number of in vivo studies have shown that metal ions such as copper, iron and zinc can cause oxidative damage to neuronal cells [11–13]. These observations are significant due to the fact that, for example, the plaques in Alzheimer disease contain elevated concentration of copper, zinc and iron. Surprisingly, although Cu^{2+}-amyloid β is more toxic to cultured neurons than amyloid β alone, these complexes are less toxic than copper alone. It is suggested that the complex with the three histidines of amyloid β peptide control the redox activity of the copper and iron [14].

Thus, peptides containing histidine residues are *per se* interesting for studies of Cu^{2+} complexation. The presence of a multi-histidine sequence in the peptide determines the high structural variety in the complex formation with Cu^{2+} in addition to the general coordination modes of peptides in formation of macrochelates or bent structures. Although the macrochelation by the histidine residues is crucial in acidic pH, especially for N-terminally protected peptides, it cannot protect against the deprotonation of the amide nitrogen and its coordination to the metal ion in the physiological pH range.

Very efficient coordination abilities of histidine residues towards transition metal ions and the stabilizing role in the complex formation reactions caused that previous studies were focused on oligopeptides having potentially favorable Cu^{2+} ions binding features. In the previous papers, the role of one histidine residue in a specific position in the peptide sequence was investigated [15]. Furthermore, cyclic peptides with two histidine residues were analyzed with basic and acidic side-chains added to the sequence [16,17]. Surprisingly, for the cyclic peptides the 3N coordination mode with two amide nitrogens and imidazole was determined, while for linear N,C-terminally protected peptides the 4N binding mode with three amide nitrogens and imidazole was found.

The effect of further increasing of the number of histidine residues in the peptide sequence has been studied below. It has induced us to perform a detailed analysis of a group of linear hexapeptides with three histidine residues located in different positions in the peptide sequence. The studies were focused on the influence of the histidine residue position on the binding possibilities towards Cu^{2+} ions.

The investigated group consist four N-protected peptides Ac-His-Arg-His-Gly-His-Gly, Ac-His-Gly-His-Arg-His-Gly, Ac-Gly-His-His-Arg-His-Gly and Ac-His-His-Gly-His-Arg-Gly, and four analogs with an unprotected amino group His-Arg-His-Gly-His-Gly, His-Gly-His-Arg-His-Gly, Gly-His-His-Arg-His-Gly and His-His-Gly-His-Arg-Gly. Spectroscopic and potentiometric methods were used to analyze the species formed. Binding properties and the coordination modes in the formed Cu^{2+}-peptide complexes have been proposed. For each system only the mononuclear species have been found, as was described by Kállay et al. for similar systems [18].

2. Experimental

2.1. Synthesis and purification of the peptides

All peptides were synthesized by a manual solid phase peptide synthesis method. Syntheses were performed in 5 ml disposable reaction columns (Intavis) starting from Fmoc-Gly-Wang resin (0.86 mmol/g from Iris or 1 mmol/g from Novabiochem). Fmoc-Gly-OH, Fmoc-His(Trt)-OH and Fmoc-Arg(Pbf)-OH were used as amino acid derivatives. Deprotection of the Fmoc groups was performed with 25% piperidine in DMF. The coupling reactions were performed by using an excess of the amino acids, HOBt and HBTU (3 eq.) and of DIEA (6 eq.) in DMF, under mixing for 2 h. Coupling reactions were controlled by the Kaiser test and repeated if the test was positive. The final acetylation of the hexapeptides was performed directly on the solid phase by adding a solution of 50% acetic anhydride in 0.4 M *N*-ethylmorpholine in DMF, with mixing for 1 h. The resin was then washed with DMF, DCM and methanol, and dried under vacuum.

Crude peptides were cleaved from the resin, simultaneously with the removal of the side-chain protecting groups, by treatment with the Reagent K (trifluoroacetic acid/water/phenol/tioanisole/triisopropylsilane, 82.5/5/5/5/2.5 v/v/m/v/v) for 3 h. The TFA solutions were filtered into cold *t*-butylmethyl ether, precipitated, filtered, washed few times with ether, dissolved in water and lyophilized.

Peptides were purified by semi-preparative HPLC using a Varian ProStar HPLC apparatus equipped with a TOSOH Bioscience C18 column (300 × 21.5 mm, 10 μm beads) and 220 nm UV/Vis detector. Water–acetonitrile gradients containing 0.1% TFA at a flow rate of 7 ml/min. were used for the purifications. The final purity of

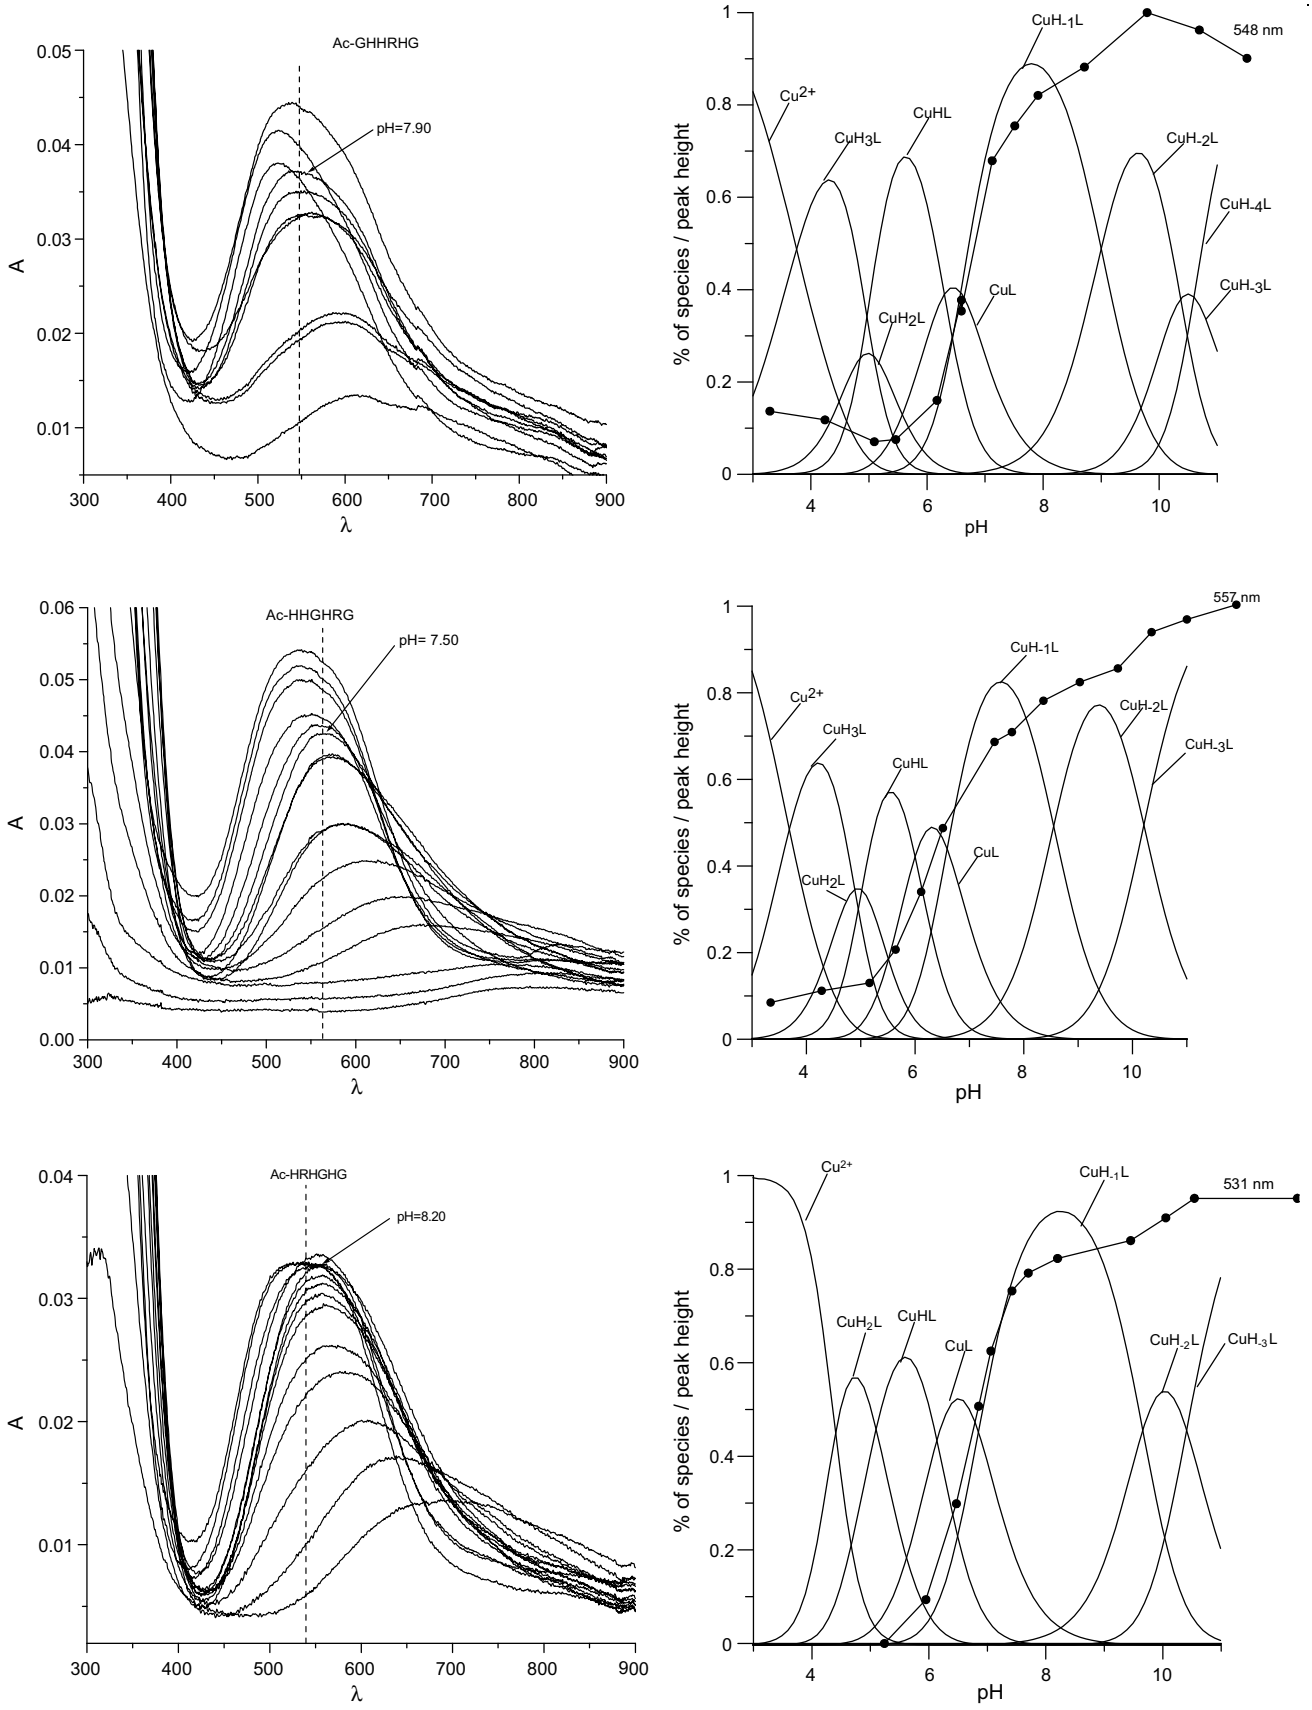

Fig. 1. Contribution of each distributed species to the UV/Vis spectra and corresponding peak heights in a single spectrum decomposed in the SPECPEAK program.

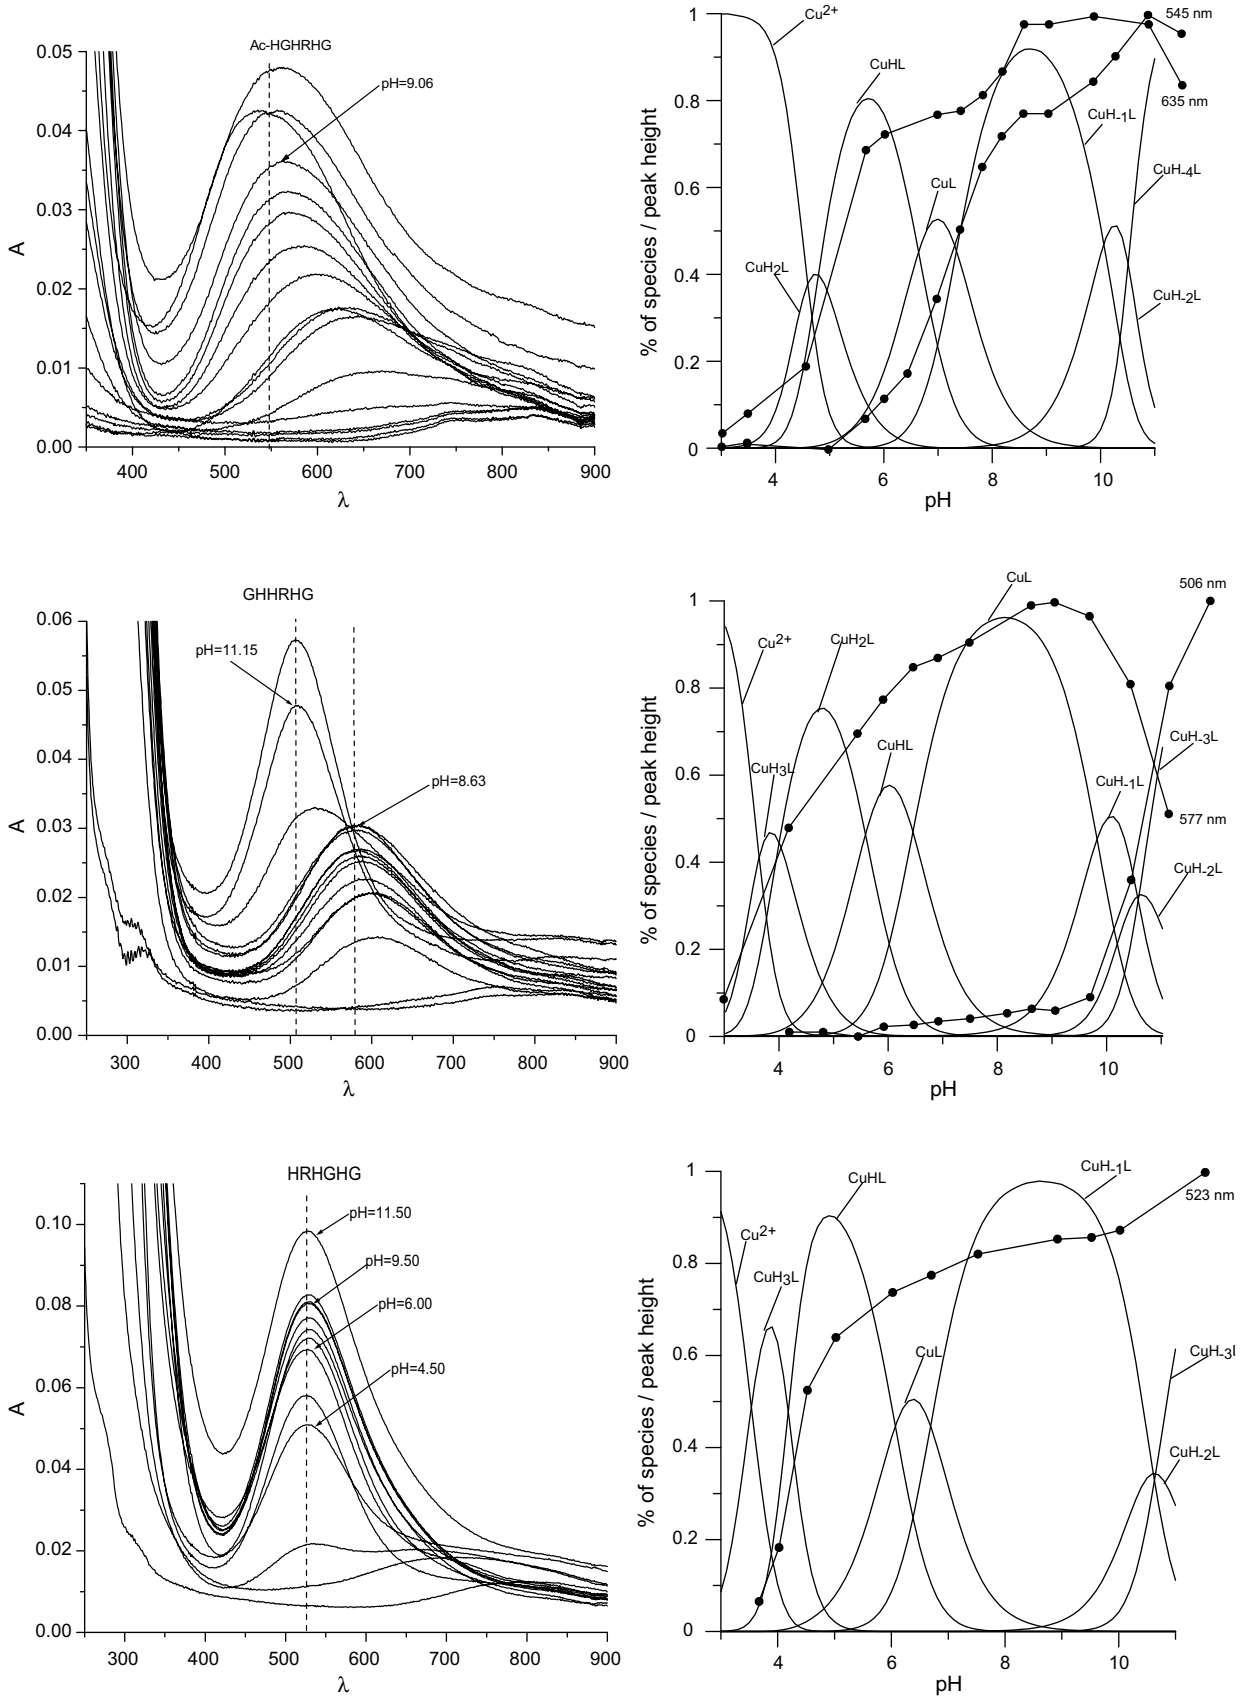

Fig. 1 (*continued*)

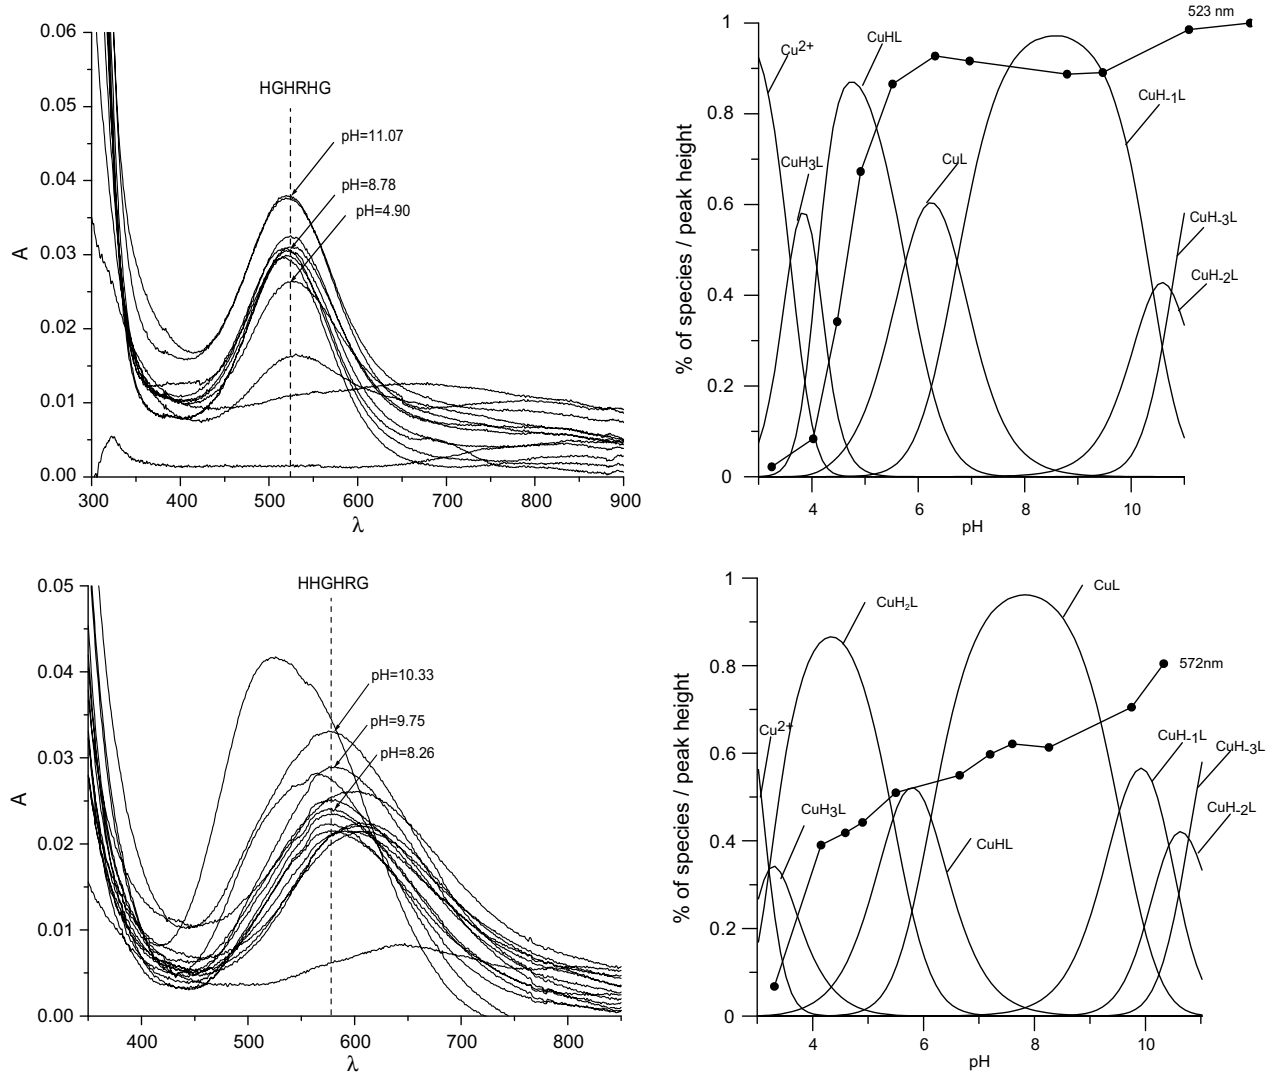

Fig. 1 (*continued*)

the lyophilized peptides was better than 98% by analytical HPLC. The chemical identity of the ligands was confirmed by ESI-MS on a Finnigan MAT TQS 700. Ms measurements were also made on a micrOTOF-Q Bruker Daltonics in the Laboratory of Spectrometry in the Faculty of Chemistry, University of Wroclaw.

2.2. Potentiometric measurements

Stability constants were calculated from the potentiometric titrations, carried out at 25 °C, using sample volumes of 1.5 ml. The ligand concentration was 1×10^{-3} M, and the metal-to-ligand ratio was 1:2 apart from the ligand Ac-His-His-Gly-His-Arg-Gly, where the metal-to-ligand ratio was 1:3. The pH-metric titrations were performed in 0.1 M KNO_3 on a MOLSPIN pH-meter system using a Mettler Toledo InLab 422 semi-micro combined electrode calibrated in hydrogen ion concentration using HNO_3. Stability constants $\beta_{pqr} = [M_pH_qL_r]/[M]^p[H]^q[L]^r$ and the stoichiometry of complexes were calculated with the SUPERQUAD [19] program. The standard deviations quoted were also computed by SUPERQUAD and referred to random errors only. The range of pH for each titration for the free ligand and metal–ligand system was 3–11. In the manuscript the charge for each forming species is omitted.

2.3. Spectroscopic measurements

Absorption spectra were recorded on a Perkin–Elmer Lambda Bio 20 spectrophotometer, circular dichroism (CD) spectra on a JASCO J 715 spectropolarimeter in the 850–200 nm range and electron paramagnetic resonance (EPR) spectra on a Bruker ESP 300E spectrometer at the X-band frequency (9.4 GHz) at 120 K. The ligand concentration was 1×10^{-3} M and the metal-to-ligand ratio was 1:2. For the ligand Ac-His-His-Gly-His-Arg-Gly the metal-to-ligand ratio was 1:3.

Table 1

$\log K_{CuHL} - \log K_{HL}$	8.20	8.00	8.14	8.02

2.4. Deconvolution of the spectra into the constituent Gaussian peaks

The obtained UV/Vis spectra were deconvoluted into their constituent Gaussian peaks by the SPECPEAK computer program according to the procedure which has been described elsewhere [20,21]. It allows for optimisation of the wavelengths of the maxima and the half-band-widths of all the spectra while the heights of each peak are optimized in each single spectrum [21]. It makes it possible to evaluate the spectroscopic parameters for each separate species and to follow a trend for the concentration of each single absorbing component as a function of the reagent concentrations [22]. The results are shown in Fig. 1.

The overlay of the trend of the height for the principal deconvoluted band and a specific form of complex, obtained from potentiometric calculations, determines the convergence of the corresponding spectroscopic parameters to a detailed forming species (i.e. for the Ac-GHHRHG–Cu^{2+} system the band at 548 nm, which was calculated from SPECPEAK program, corresponds to the formation of the $CuH_{-1}L$ species with the maximum of the form at pH 7.90, Fig. 1; the error of the calculated and experimentally obtained wavelength is 5 nm and can be neglected).

3. Results

3.1. Protonation constants of the free ligands

The acid-base properties of the metal-free peptides were investigated by potentiometric titrations. For each ligand at least five titrations were done to determine the pK values.

All the peptides with a protected N-terminal amino group are characterized by five protonation constants which could be assigned to the same set of functions (Table 1). The highest pK value corresponds to the arginine side chain, the following three lower pKs could be attributed to the imidazole histidine residues and the lowest pK value to the carboxyl group of the C-terminal amino acid.

The unprotected peptides are characterized by six protonation constants (Table 2). The additional sixth pK value, ranged from 7.29 to 7.95, can be assigned to the N-terminal amino group.

3.2. Coordination abilities of the N-protected peptides towards Cu^{2+} ions

According to the calculations based on potentiometric titrations, the investigated peptides form a different number of mononuclear complexes.

Ac-GHHRHG with Cu^{2+} ions forms eight distinct species: CuH_3L, CuH_2L, CuHL, CuL, $CuH_{-1}L$, $CuH_{-2}L$, $CuH_{-3}L$ and $CuH_{-4}L$ (Table 1). The coordination begins around pH 3 with the loss of two protons from the ligand molecule and the formation of CuH_3L. At pH 4 the maximum of this species is observed (Fig. 1). The absorption spectra with a d–d band at 740 nm may suggest the coordination of one nitrogen donor (Table 3). It is supposed that one imidazole from the histidine residue is involved in the Cu^{2+} binding centre. CuH_2L, present around pH 5, is a minor species and its spectroscopic data are not available. Nevertheless, $\log K = \log K_{CuH_2L} - \log K_{H_2L} = 5.75$ suggests the involvement of two imidazole rings in the complex formation as was proposed in previous papers [23–25]. As the pH increases, the CuHL species is formed, which is a dominant form in the pH range 5–6.5. The d–d transitions at 688 nm in the UV/Vis spectrum and the EPR parameters ($A_{II} = 196$ and $g_{II} = 2.24$) suggest the involvement of the third nitrogen donor. The $\log K = \log K_{CuHL} - \log K_{HL} = 8.2$ value can be assigned to the species involving three imidazoles in the metal ion binding [23]. The successive species dominating in the pH range 7–9 is $CuH_{-1}L$, with the d–d transitions at 562 nm and the EPR parameters $A_{II} = 203$ and $g_{II} = 2.20$, is most likely the 4N complex. The CD spectra with d–d bands at 553 and 476 nm suggest involvement of at least two amide donors. It involves two or three imidazole nitrogens, as was proved in the case of a similar three-His ligand using NMR studies [7]. The coordination is suggested to occur via His^3 and His^5 imidazole nitrogens and the amide nitrogens of Arg and His^5 in the plane, while His^2 is thought to be bound in the apical position. Above pH 9.5 the dominant species is $CuH_{-2}L$. The shift of the band by 14 nm may suggest the involvement of a third amide nitrogen in the coordination sphere. The presence of a new band in the CD spectrum at 633 nm supports this assumption. The coordination could involve the $\{N^-, N^-, N^-, N_{im}, N_{im}\}$ donor system [7]. Above pH 10.5, where $CuH_{-3}L$ is formed, there is another shift of the d–d transition energy to 523 nm, suggesting the increase of electron density around the metal ion derived from the proton dissociation from the metal bound imidazole [26]. The final proton dissociation ($CuH_{-4}L$), with $pK = 10.40$, occurs most probably on the arginine residue ($pK = 10.42$ of the free ligand).

For Ac-HHGHRG-Cu^{2+} seven distinct species are formed according to the potentiometric data calculations: CuH_3L, CuH_2L, CuHL, CuL, $CuH_{-1}L$, $CuH_{-2}L$ and $CuH_{-3}L$ (Table 1 and Fig. 1). The CuH_3L, CuH_2L and CuHL complexes involve one, two and three imidazole nitrogens respectively, similar to the Ac-GHHRHG-

Cu^{2+} system. Both the spectroscopic parameters and pK values of the single deprotonation steps are similar to each other (Tables 1 and 3). As the pH increases, the CuL species is formed (Fig. 1). The significant shift of the absorption band by 65 nm indicates binding of the consecutive nitrogen donor atom. The $CuH_{-1}L$ and $CuH_{-2}L$ species exhibit a similar coordination pattern as that found for the Ac-GHHRHG-Cu^{2+} system (Table 3). The last complex, $CuH_{-3}L$, is formed as a result of proton dissociation from the arginine side chain. Lack of any distinct changes in the spectroscopic parameters and the pK value of 10.21 confirm the above assumptions.

Ac-HRHGHG with Cu^{2+} ions forms six distinct species in the pH range 3–11: CuH_2L, CuHL, CuL, $CuH_{-1}L$, $CuH_{-2}L$ and $CuH_{-3}L$ (Table 1). The coordination begins near pH 4, when the CuH_2L species is formed (Fig. 1). The d–d transitions at 687 nm in the absorption spectra indicate the 2N binding mode (Table 3). The $\log K = \log K_{CuH_2L} - \log K_{H_2L} = 6.16$ value (Table 1) suggests coordination of two imidazole nitrogens [23]. Further deprotonation and formation of CuHL, CuL and $CuH_{-1}L$ can be assigned to the coordination modes determined for the previous peptide-Cu^{2+} systems. The reaction $[CuH_{-1}L] \leftrightarrow [CuH_{-2}L]+H^+$ at p$K = 9.67$ and a minor modification seen in CD and UV/Vis spectra suggests that the deprotonation occurs at the arginine residue side chain (p$K = 10.28$ in the free ligand). Further deprotonation and formation of $CuH_{-3}L$ at p$K = 10.42$ derives from the binding of the third amide nitrogen. This is strongly supported by the d–d band shift from 557 to 525 nm and the distinct changes in the CD spectra at the CT range (at 322 nm) and formation of the bands at 595 and 476 nm (Table 3).

Ac-HGHRHG with Cu^{2+} forms six distinct species in the pH range 3-11: CuH_2L, CuHL, CuL, $CuH_{-1}L$, $CuH_{-2}L$ and $CuH_{-4}L$ (Table 1 and Fig. 1). The only differences in the coordination modes between Ac-HRHGHG and Ac-HGHRHG are seen where the $CuH_{-4}L$ species is formed (Fig. 1) The latter species results most likely from proton dissociation from the metal bound imidazole [26].

3.3. Coordination abilities of the group of unprotected peptides towards Cu^{2+} ions

According to the results which have been obtained from potentiometric and spectroscopic measurements, each ligand–Cu^{2+} system forms mononuclear complexes in the pH range 3–11. The coordination mode is dependent on the position of the histidine residue in the peptide sequence.

GHHRHG is representative of a peptide with histidine residues at the second and third positions in the peptide chain with an unprotected N-terminal amino group. Seven distinct species have been found in the Cu^{2+}-GHHRHG system (Fig. 1 and Table 2). The first complex, CuH_3L, is the result of dissociation of three protons from the ligand molecule. The band at 259 nm in the CD spectrum suggests involvement of the amino nitrogen in the coordination binding centre. The EPR parameters ($A_{II} = 185$, $g_{II} = 2.23$) clearly indicate a 2N complex (Table 4). Moreover, $\log K = \log K_{CuH_3L} - \log K_{H_3L} = 7.62$ suggests that the amino and imidazole nitrogen donors are bound to the metal ion centre [4,5]. The third proton dissociation could be assigned to a carboxyl group from the C-terminal amino acid.

The pK value of 3.98 for the reaction $[CuH_3L] \leftrightarrow [CuH_2L]+H^+$ may suggest the deprotonation of the amide nitrogen and formation of the $\{NH_2, N^-, N_{im}\}$ donor set, characteristic for peptides with Xaa-His units, where the first amide deprotonation occurs near pH 4 [4,5]. This binding mode is confirmed by the spectroscopic data (Table 4). Further deprotonations to CuHL and CuL species occurring below pH 10 do not affect distinctly the spectroscopic parameters, suggesting that both proton releases are from non-coordinating imidazole moieties (Fig. 1). Above pH 10 the $CuH_{-1}L$ complex is formed. The presence of a new band at 500 nm in the CD spectra may suggest the involvement of an additional nitrogen donor atom in the metal ion coordination sphere. It is derived from the second amide nitrogen binding and the albumin-like coordination mode formation (Table 4) [4,5]. Further deprotonations, resulting in $CuH_{-2}L$ and $CuH_{-3}L$ formation, have no impact on the metal ion coordination mode. It is suggested that it derives most likely from the arginine side chain. The second deprotonation can be assigned to the metal bound imidazole [26].

HRHGHG and HGHRHG form six distinct species: CuH_3L, CuHL, CuL, $CuH_{-1}L$, $CuH_{-2}L$ and $CuH_{-3}L$ (Table 3 and Fig. 1). The presence of the histidine residue in the N-terminal position implies differences in the binding ability and coordination mode when compared to the protected ligands discussed above [4,5]. The CuH_3L species is formed by coordination of the imidazole and amino nitrogen, resulting in a 2N complex with a histamine-like $\{NH_2, N_{im}\}$ binding mode, specific for His^1 peptides [19]. UV/Vis spectroscopy and EPR parameters confirm the 2N coordination mode (Table 4). The CuHL species, which is a dominant form in the pH range 4–6, results from two consecutive deprotonations. The large shift in the absorption spectrum from 662 to 526 nm (in the case of the HRHGHG-Cu^{2+} system) and the presence of the distinct bands in the CD spectrum (562, 487, 311 and 272 nm) strongly suggest coordination of the amidic donors to the metal ion and formation of the albumin-like 4N complex, typical for His^3 motif peptides [26] (Fig. 1 and Table 4). The $\{NH_2, 2N^-, N_{im}\}$ binding mode seems to be the final mode of coordination to the Cu^{2+} ions. Further deprotonations to CuL and $CuH_{-1}L$ are concerned with the loss of protons from the imidazole moieties, without taking part in a binding process. The last forming species, $CuH_{-2}L$ and $CuH_{-3}L$, are the

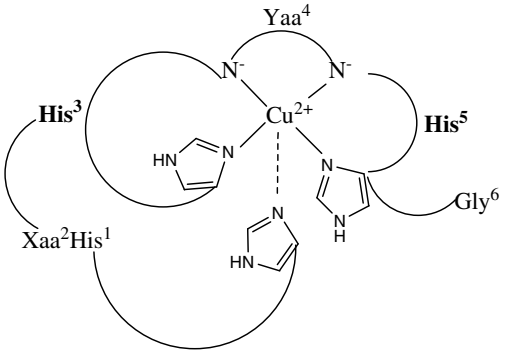
result of the loss of a proton from the arginine side chain and metal bound imidazole [21].



According to the potentiometric data, HHGHRG forms seven distinct species: CuH_3L, CuH_2L, CuHL, CuL, $CuH_{-1}L$, $CuH_{-2}L$ and $CuH_{-3}L$ (Fig. 1 and Table 2). The CuH_3L species is formed with the 2N coordination mode. $\log K = \log K_{CuH_3L} - \log K_{H_3L} = 7.35$ suggests an amino and an imidazole nitrogen involved in the binding of Cu^{2+}, as was suggested for the ligands discussed above. CuH_2L, with the d–d band at 605 nm and $A_{II} = 193$, is the 3N complex with the $\{NH_2, N^-, N_{im}\}$ binding pattern (Table 4). The proton dissociation $[CuH_2L] \leftrightarrow [CuHL] + H^+$ with $pK = 5.43$ could be assigned to the imidazole moiety as well as the further deprotonation with $pK = 6.11$, resulting in the formation of CuL, dominating in the pH range 6–9.5 (Fig. 1). Any relevant spectroscopic changes suggest the same coordination mode $\{NH_2, N^-, N_{im}\}$, only the deprotonations of imidazole moieties take place without taking part in metal ion coordination [26]. The $CuH_{-1}L$ species is characterized by the same spectroscopic parameters as CuL, indicating proton loss from the arginine side chain ($pK = 9.51$) (Table 4). The formation of $CuH_{-3}L$ corresponds to distinct changes in the d–d transitions, shifting from 578 to 526 nm (628 to 493 nm in the CD spectrum). This strongly suggests that $CuH_{-3}L$ is the 4N complex with a $\{NH_2, 3N^-\}$ binding mode (Table 4 and Fig. 1).

4. Discussion

The histidine residue is well known for its critical impact on complex stability and its structure [2,4–7]. According to data obtained for N-terminally protected peptides, the impact of histidine residues in the multi-histidine peptides on the binding mode is critical and it has a crucial contribution to the Cu^{2+} binding affinity of protein fragments [2,6–9].

A comparison of binding abilities of N-terminally protected peptides towards Cu^{2+} ions determine some differences. For peptides with the His-His motif (Ac-GHHRHG and Ac-HHGHRG) the coordination begins with 1N species involving the imidazole nitrogen, while for ligands with His-Xaa-His (Ac-HRHGHG, Ac-HGHRHG), the first species formed is the 2N complex (Fig. 2).

However, a peptide with the His-Xaa-His motif in the presence of the copper ion undergoes two strongly overlap-

ping amide deprotonations ($\Delta pK = pK_{CuH_{-1}L} - pK_{CuL} = 0.19$ for Ac-HLHWH-NH_2 [27]) due to the favored formation of the $\{N_{im}, N^-, N^-, N_{im}, N_{im}\}$ binding mode (Scheme 1). According to the investigated N-terminally protected systems, strongly cooperative amide deprotonations are observed for each system, but for Ac-GHHRHG (Scheme 2) the value of $\Delta pK = 0.28$ is much lower than for the other systems ($\Delta pK_{Ac\text{-}HHGHRG} = 0.59$, $\Delta pK_{Ac\text{-}HGHRHG} = 0.70$, $\Delta pK_{Ac\text{-}HRHGHG} = 0.71$). Moreover, the final mode of binding with three amide nitrogens occurs for each N-terminally protected ligand–Cu^{2+} systems, but deprotonation of the third amide nitrogen seems to be easier for His-His peptides; the pK of reaction is 9.00, around 1.5 units lower than that for His-Xaa-His peptides.

Comparison of Ac-HHGHRG with Ac-HHGH-NH_2 [10] may suggest some involvement the in coordination mode of the arginine residue or C-terminal carboxyl group, which may contribute to the stabilization of the forming species. Although the binding modes are the same for both systems, the stability constants of the forming species are about 10 units higher for Ac-HHGHRG-Cu^{2+} (Fig. 3).

Despite the fact that $pK_{Ac\text{-}HHGHRG}$ of the second imidazole nitrogen coordination to the metal ion binding centre is about 0.5 units higher, the deprotonation of consecutive donors has occurred with lower pK values. The binding of the amidic donors begins at pH 5 with strong perturbations seen in the CD spectra, while for Ac-HHGH-NH_2 the coordination of the amide nitrogen occurs in distinctly more basic pH. In the physiological pH range, the second amide coordination is observed for Ac-HHGHRG

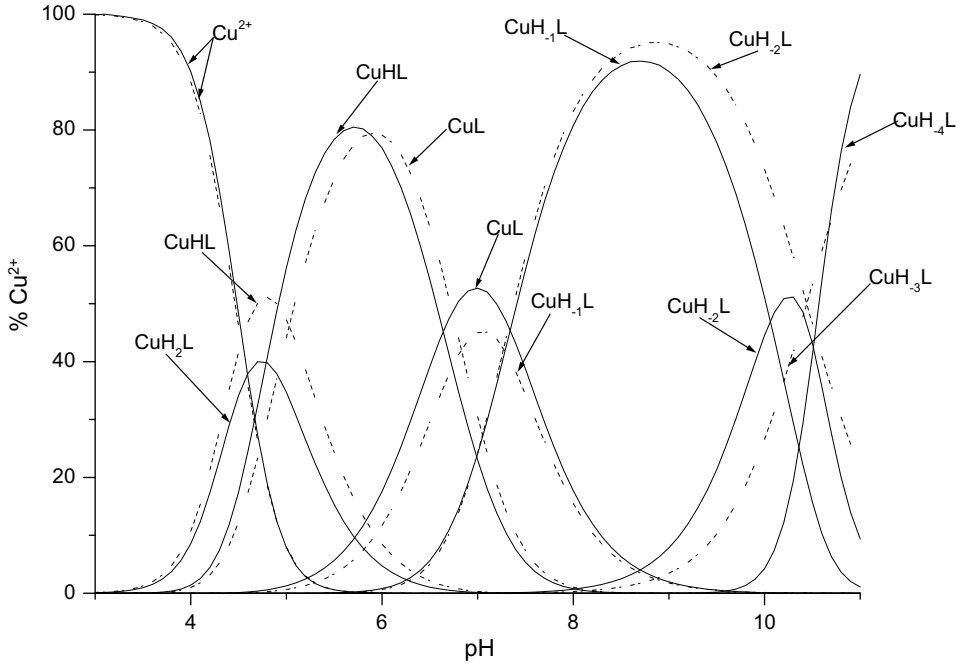

Fig. 4. Distribution diagram of complexed species formed as a function of pH in the Ac-His-Gly-His-Arg-His-Gly-Cu^{2+} (solid line) and Ac-His-Gly-His-Val-His-NH_2-Cu^{2+} [18] (dashed line) systems.

(Scheme 3), while for Ac-HHGH-NH_2 the imidazole macrochelate ring dominates [10].

According to the peptides with the His-Xaa-His motif in the sequence, the coordination modes which have been obtained for the investigated peptide-Cu^{2+} systems (Ac-HGHRHG, Ac-HRHGHG) are similar to that seen in the fragment (145–155) of the amyloid precursor protein [7] and Ac-HGHVH-NH_2 [18] with metal to ligand ratios of 1:1 and 1:2, respectively.

At acidic pH, the macrochelates including imidazole donors are present, while in physiological pH second amide coordination to the metal ion binding centre occurs. The p*K* values of donor deprotonations and distribution profiles are strictly similar with Ac-HGHVH-NH_2, which can suggest that in the ion case of Ac-HGHRHG and Ac-HRHGHG the involvement of arginine or carboxyl residues do not occur as was supposed in the Ac-HHGHRG-Cu^{2+} system (Fig. 4).

According to the study on the unprotected peptides, the increase of the thermodynamic stability of the complex species is caused by the presence of both anchoring sites: the terminal amino group and the histidine residue [4,5]. The position of the histidine residues within the peptide sequence strongly influences the binding properties in the unprotected ligands (see Fig. 5).

Peptides which contain His at the first position in the peptide sequence have specific coordination towards metal ions unlike ordinary peptides. The first major species involves a histamine-like donor set $\{NH_2, N_{im}\}$ [4]. Thus, for HRHGHG, HGHRHG and HHGHRG the first defined species is a histamine-like 2N chelate $\{NH_2, N_{im}\}$ ring [4]. Deprotonation and coordination of amide nitrogens takes place above pH 5, as it is found for oligoglicynes [28,29].

Nevertheless, the presence of multi-histidine sequences (His-Xaa-His) implies a crucial difference in the complex formation. As far as the histamine-like donor set was determined for peptides with the His^1 motif, a second characteristic albumin-like binding mode for His^3 is also observed [4,5,26]. It occurs not only for HRHGHG and HGHRHG peptides (Scheme 4), but also for GHHRHG. Moreover, the $\{NH_2, N^-, N^-, N_{im}\}$ binding mode takes place much easier for HRHGHG and HGHRHG than for GHHRHG, because of the fact that for peptides with a histidine residue in the second position in the peptide chain the most stable form is the 3N species with very high thermodynamic stability. It is caused by the simultaneous participation of $\{NH_2, N_{im}$ and $N^-\}$ donor atoms and formation of two fused chelate rings: five membered $\{NH_2, N^-\}$ and six-membered $\{N^-, N_{im}\}^-$. For ligands with His^2 the 3N complex with the $\{NH_2, N^-, N_{im}\}$ binding mode is the dominant species in the physiological pH range (Scheme 5).

For ligands with the His-His motif the final $\{N_{im}, 3N^-\}$ coordination mode occurs, e.g. for HHGHRG-Cu^{2+}. The formation of this binding mode is rather unusual for GHHRHG-Cu^{2+}, where albumin-like binding is more stable.

A comparison of the species distribution curves for unprotected ligands with the His-Xaa-His and His-His motif clearly shows that at low pH the coordination process is more effective for HHGHRG (Fig. 6) than for HGHRHG. At pH 3 around 50% of the Cu^{2+} ions are bound with HHGHRG, while only 10% of the Cu^{2+} ions are coordinated by HGHRHG. The formation of $\{NH_2,$

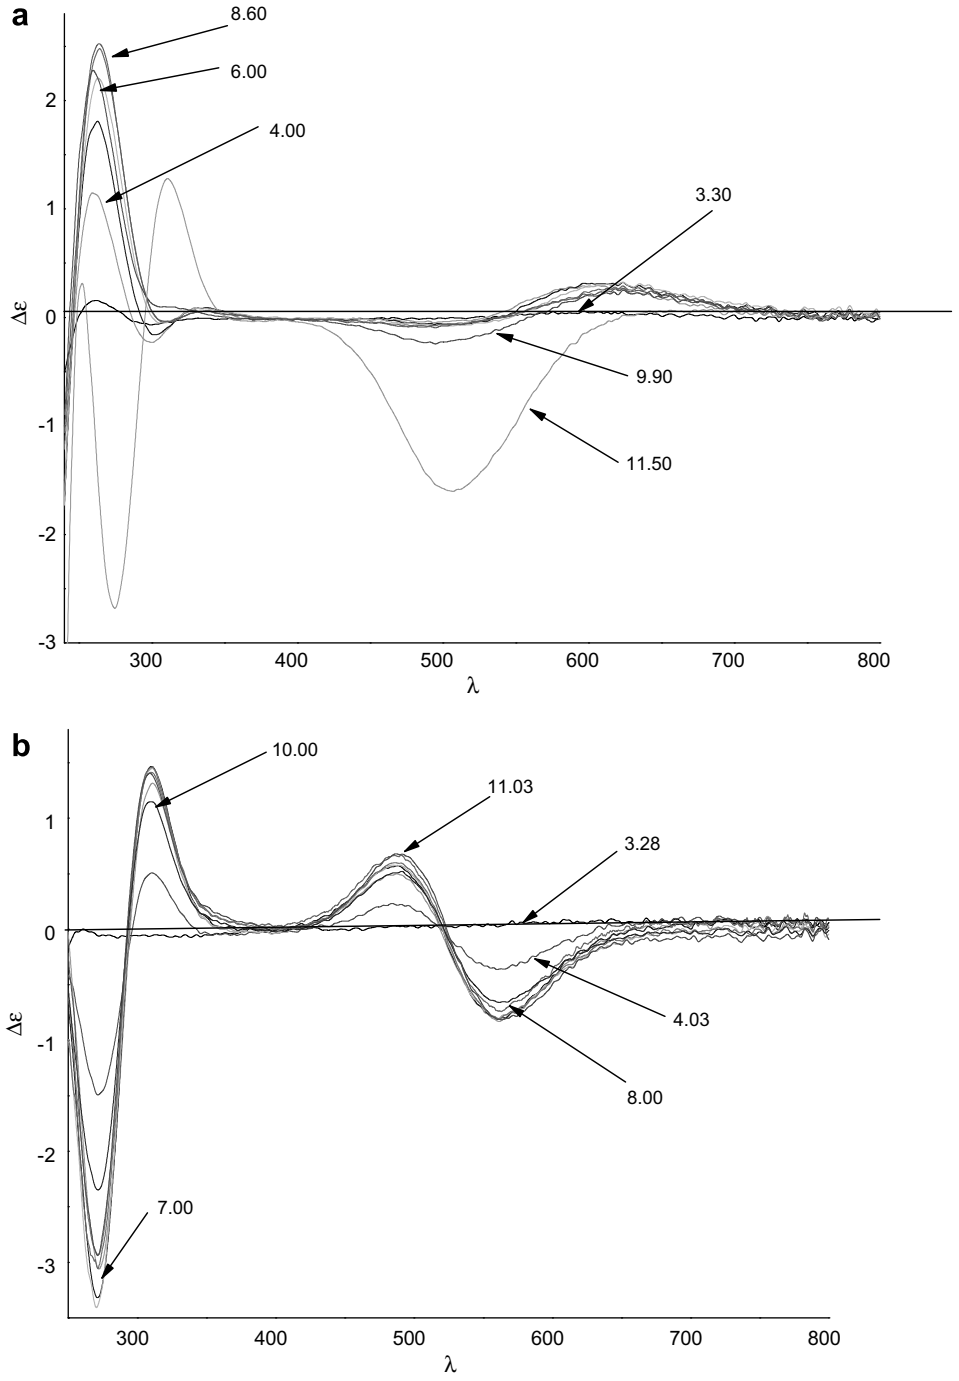

Fig. 5. CD spectra for (A) Gly-His-His-Arg-His-Gly-Cu^{2+}, (B) His-Arg-His-Gly-His-Gly-Cu^{2+}, (C) His-Gly-His-Arg-His-Gly-Cu^{2+} and (D) His-His-Gly-His-Arg-Gly-Cu^{2+}.

N^-, N_{im}} in the case of HHGHRG determines the dominance of this ligand at acidic pH. Above pH 5.5 the albumin-like coordination possible in the latter peptide causes HGHRHG to become a more effective ligand for Cu^{2+} ions (Fig. 7).

The obtained results have shown clear trends in the formation of complexes of Cu^{2+} ions with N-protected peptides. Metal ion coordination begins at the imidazole nitrogens which act as the anchoring groups [30,31]. The formation of CuL species involves the amide nitrogen. At physiological pH the dominant species is $CuH_{-1}L$ with the {$3N_{im}$, $2N^-$} binding mode. At high pH three amide nitrogens could be involved in Cu^{2+} ion binding [24].

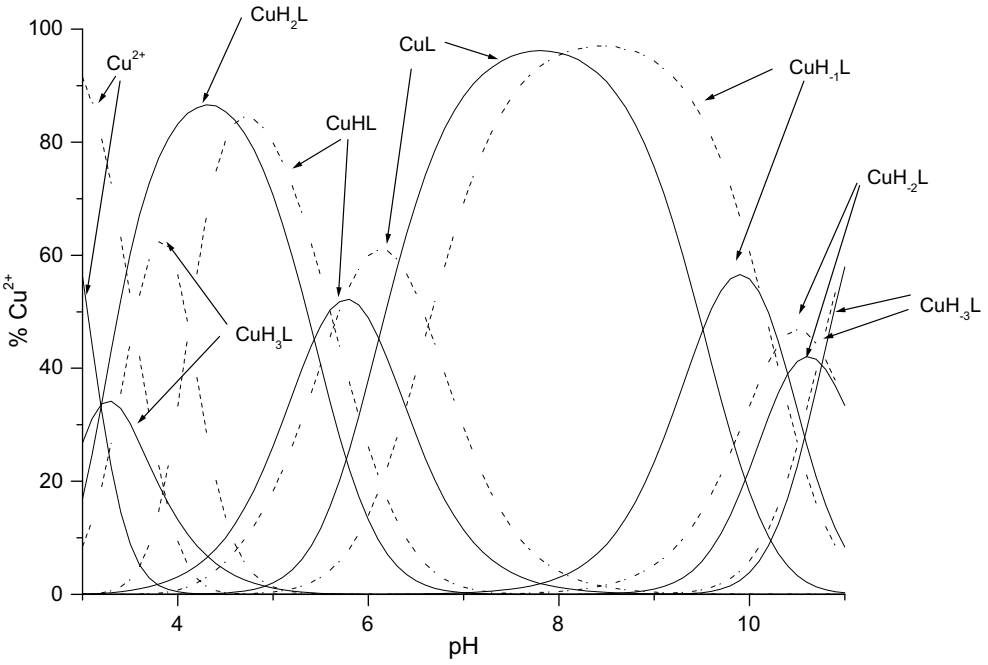

Fig. 6. Distribution diagram of complexed species formed as a function of pH in the His-His-Gly-His-Arg-Gly-Cu^{2+} (solid line) and His-Gly-His-Arg-His-Gly-Cu^{2+} (dashed line) systems.

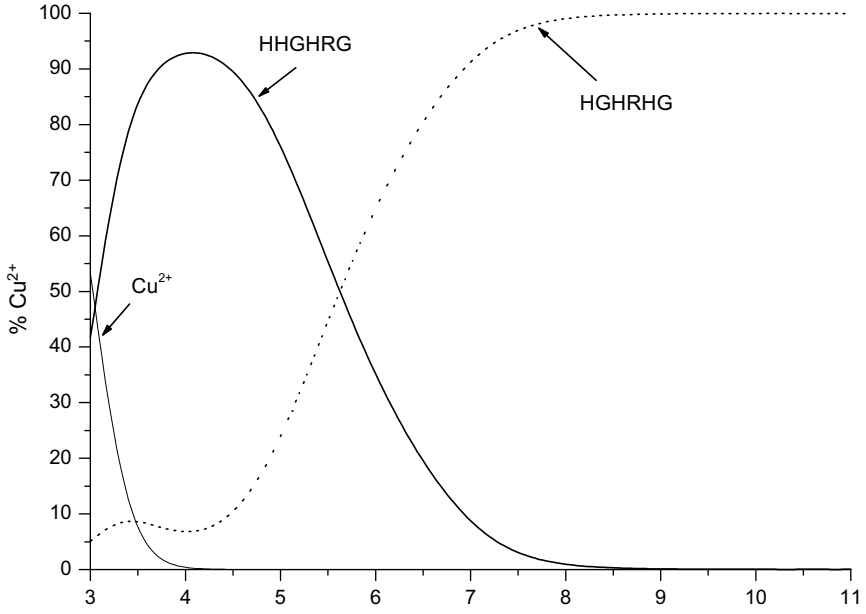

Fig. 7. Distribution profiles of free and complexed fractions of Cu^{2+} ions in the presence of both His-His-Gly-Arg-His-Gly (solid line) and His-Gly-His-Arg-His-Gly (dashed line).

The protection of the N-terminal amino group has a great impact on the binding affinity of the peptide. As seen in Fig. 8, a competition diagram obtained for Ac-HRHGHG and HRHGHG clearly shows that around pH 4 almost 100% of the Cu^{2+} ions are bound by an unprotected ligand, while the protected analog coordinates less than 5% of Cu^{2+}. The main reason derives from the involvement of the amino group in the coordination of Cu^{2+}.

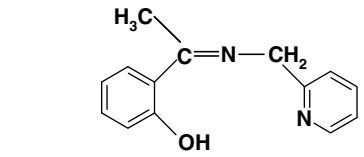
heterogeneous catalysts. Studies on oxidation reactions catalyzed by such hybrid materials have received intense attention in the last few decades [18–21]. Copper(II) Schiff-base complexes, upon immobilization into microporous or mesoporous aluminosilicates, are capable of catalyzing olefin epoxidations and/or oxidations [20,21]. However, the activity of Schiff-base copper(II) complexes towards catalytic oxidation in a homogeneous medium is not well documented in the literature. So far only a few copper(II) Schiff-base complexes are reported to be catalytically active towards olefin oxidation [22].

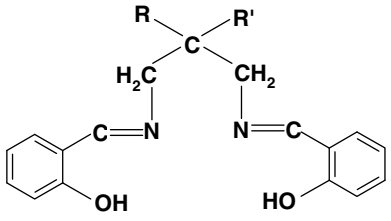
There are some reports of molecular oxygen catalyzed oxidation, and 30% hydrogen peroxide is usually considered an environmental friendly oxidant, nevertheless, due to the explosive nature of hydrogen peroxide, industrial processes still mainly rely on *tert*-butyl-hydroperoxide (*tert*-BuOOH) [23]. Alkyl-hydroperoxides are used on a large scale in industrial epoxidation, for example in the Halcon-Arco and Sumitomo processes [24,25]. The recycling of the end-product of the oxidant, *viz.* *tert*-BuOH, has been realized in the Sumitomo process. Notably, *tert*-BuOOH has seldom been used as an oxidant in the investigations of the catalytic efficiency of copper(II) complexes towards epoxidation/oxidation reactions in a homogeneous medium.

We report here the synthesis, characterization and catalytic efficacy of three copper(II) Schiff-base complexes towards olefin oxidation of a variety of alkenes in different solvent media using *tert*-butyl-hydroperoxide as an oxidant. The molecular structure of complex **1** is determined by single crystal X-ray analysis.



2. Experimental

2.1. General



All solvents used were of AR grade and were distilled and dried before use. Salicyaldehyde, *ortho*-hydroxyacetophenone, copper(II) nitrate trihydrate and copper(II) perchlorate hexahydrate were purchased from Merck (India) and were used as received. Styrene, norbornene, cyclooctene, cyclohexene, *tert*-BuOOH (70% aq.), 2,2-dimethyl-1,3-diamino-propane, 1,3-diamino-2-propanol and 2-aminomethyl-pyridine were purchased form Aldrich and were used as received. Elemental analyses (CHN) were performed using a Perkin–Elmer 240 elemental analyzer. IR spectra were recorded on a Nicolate Magna IR 750 Series II FT-IR spectrometer and UV/Vis spectra were recorded on a Perkin–Elmer LAMBDA EZ-301 spectrophotometer. The ligands HL^1, H_2L^2 and H_2L^3 (Scheme 1) were synthesized following the reported procedures [26].

2.1.1. Synthesis of the complexes $[Cu(L^1)(H_2O)](ClO_4)$ (1), $[Cu(L^2)]$ (2) and $[Cu(L^3)]$ (3)

To prepare complex **1**, a methanolic solution of HL^1 (1 mmol, 0.226 g) was added to a methanolic solution of copper (II) perchlorate hexahydrate (1 mmol, 0.371 g)

2.2. X-ray crystallography

2.2.1. Crystal data for complex 1

$C_{14}H_{15}ClCuN_2O_6$, $M = 406.27$, monoclinic, space group $P2_1/c$, $a = 15.148(3)$, $b = 14.491(3)$, $c = 15.364(3)$ Å, $\gamma = 112.02(2)°$, $V = 3126.5(11)$ Å^3, $Z = 8$, $R_{int} = 0.0711$, $D_{calc} = 1.726$ g cm^{-3}, $F_{000} = 1656$, $\mu = 1.602$ mm^{-1}, dimensions = 0.05 × 0.07 × 0.09 mm, $T = 293$ K.

2.2.2. X-ray single crystal structure determination of 1

Cell dimensions and intensity data for complex **1** were measured at 293 K with graphite-monochromated Mo Kα radiation, on a Bruker AXS Smart single crystal diffractometer with a CCD area detector. The data were corrected for Lorentz, polarisation and absorption effects. The structure was solved by direct methods using SHELXS [28] and refined by the full-matrix least-squares method based on $|F_{obs}|^2$ using SHELXL [28]. The non-hydrogen atoms were refined anisotropically, while the hydrogen atoms, generated using idealized geometry, were made to 'ride' on their parent atoms and used in the structure factor calculations. Neutral atom scattering factors were taken from Cromer

and Weber [29a] and anomalous dispersion effects were included in F_{calc} [29b].

2.3. Catalytic reactions

The catalytic reactions were carried out in a glass batch reactor according to the following procedure. The olefin (9–12 mmol) and catalyst (0.005 mmol) were added to 8 ml of acetonitrile in a round-bottom flask. The mixture was then equilibrated to 70 °C in an oil bath. After addition of *tert*-BuOOH (20 mmol) the mixture was stirred continuously. The products of the catalytic reactions were collected at different time intervals and were identified and quantified with a VARIAN CP-3800 gas chromatograph equipped with an FID detector. A CP-Sil 8 CB capillary column was used for analysis of the products.

3. Results and discussion

3.1. Description of the structure of complex *1*

Fig. 1 shows the ORTEP diagram of complex **1** with thermal ellipsoids drawn at 50% probability. Selected bond distances and angles of complex **1** are collated in Table 1. The crystal structure of complex **1** consists of two independent molecules, labelled A and B, in the crystallographic asymmetric unit. In both the molecules, the copper(II) ion assumes a distorted square planar geometry. The coordination plane is composed of NNO donor atoms (nitrogen atoms of the azomethine and pyridine ring and the phenoxo oxygen atom, respectively) of the tridentate Schiff-base ligand and an oxygen atom of the water molecule. The deviation of the four basal donor atoms, O(1A), O(2A), N(2A) and N(1A), in molecule A from the least-squares plane through them were −0.134(3), 0.210(3), −0.206(3) and 0.170(3) Å, respectively. Similarly the deviation of the four basal donor atoms, O(1B), O(2B), N(2B) and N(1B), in molecule B from the least-squares mean plane through them were 0.107(3), −0.157(3), 0.194(3) and −0.176(3) Å, respectively. In both the molecules, the perchlorate ions are coordinated to the copper center distally via oxygen atoms [O(3C) and O(3D) for molecule A and molecule B, respectively]. In this complex, the coordinated water molecules, the phenoxo oxygen atoms and the perchlorate oxygen atoms are involved in the formation of multiple bifurcated and trifurcated hydrogen bonds.

3.2. Catalytic activities

Aromatic and aliphatic alkenes react with *tert*-BuOOH to produce the corresponding oxides and/or epoxides in good yield, with moderate selectivity, in acetonitrile when catalyzed by the Cu Schiff-base complexes (Fig. 2). The results of the catalytic oxidation of different substrates are given in Table 2. The oxidation of styrene with *tert*-BuOOH gives styrene epoxide in 54–39% yield (selectivity 72–39%) (Table 2) under the homogeneous conditions, and along with this a moderate amount (60–21%) of benzaldehyde is also detected. A turnover frequency of 79–60 has been attained in the styrene oxidation reaction. While complex **3** shows the lowest selectivity in the production of styrene epoxide, complex **2** shows the highest selectivity. Consequently the benzaldehyde production was highest in the case of complex **3** whereas it was lowest in the case of complex **2**. Even though copper(II) Schiff-base complexes have been well known for some time, they have scarcely been used as homogeneous catalysts in olefin oxidation reactions. Epoxidation of styrene with different oxidizing agents over copper(II) Schiff-base catalysts under homogeneous conditions have been studied in the recent past [22]. Das et al. have obtained a moderate yield of olefin epoxide using a copper(II) Schiff-base complex as a catalyst in the presence of 2-methylpropanal and molecular oxygen under homogeneous conditions [22a], while a maximum yield of ca. 15% of styrene epoxide has been achieved with iodosylbenzene using Schiff-base copper complexes [22c]. It is noteworthy that complex **2** has been studied as a possible galactose oxidase model in an earlier study and showed remarkable catalytic activity in the oxidation of *n*-propanol or hydroxyacetone in the presence of KOH under O_2 [27c].

Table 2

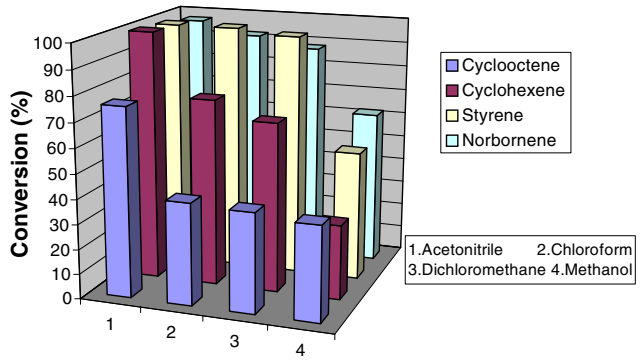

Fig. 4. Effect of solvent on the conversion in olefin oxidation reactions catalyzed by complex $[Cu(L^3)]$ (**3**).

preferentially the C–H bond over the C=C bond. Moreover the presence of 1-(*tert*-butylperoxy)-2-cyclohexene among the products indicates the possibility of the occurrence of a radical mechanism in the allylic C–H oxidation in this case. Salavati-Niasari et al. have proposed that alumina supported transition metal catalysts with *tert*-BuOOH as an oxidant promotes the allylic oxidation pathway while epoxidation attains the least preference due to the highly acidic properties of the alumina support [21h]. In contrast, epoxidation of cyclohexene with *tert*-BuOOH catalyzed by complexes **1**–**3** afforded a considerable

amount of cyclohexene-oxide while CH_3CN was found to be the preferred solvent for this reaction in our study (Table 3).

Among the bulkier cycloalkenes, such as norbornene and cyclooctene, norbornene has been effectively converted selectively to *exo*-epoxynorbornane (conversion 98–97%, selectivity 100%). On the other hand in the case of cyclooctene, its epoxide was not the sole product, along with the desired epoxide, cyclooctane-1,2-diol (19–13%) was also generated (Table 2).

The effect of various reaction media on the oxidation of cyclohexene catalyzed by complexes **1**–**3** has been studied. The results of this study have been collated in Table 3. The variation of catalytic efficacies of complexes **1**–**3** in different solvents has been compared with the other similar kinds of catalytic systems reported earlier [21g,21h]. A graphical representation of the relative efficacies of the catalysts in different solvents has been given in Figs. 3 and 4 for complexes **1** and **3**, respectively. Even from a cursory look at Table 3 it is apparent that the efficiency of the catalysts [Cu(salpnMe_2)]–Al_2O_3 and [Cu(Me_2salpnMe_2)]–Al_2O_3 for the oxidation of cyclohexene in different solvents decreases in the order: dichloromethane > chloroform > methanol > acetonitrile [21g,21h]. However, our results showed a completely different trend. The efficiency of the catalysts, in general, followed the order: acetonitrile > chloroform > dichloromethane > methanol.

4. Conclusions

In summary, we have synthesized and characterized three Schiff-base copper(II) complexes, and have used them as catalysts in olefin oxidation. All of them are found to be catalytically active in industrially important epoxidation reactions in different solvent media under homogeneous conditions. At a variance with the earlier reports, complexes **1**–**3** have shown the highest catalytic efficacy in CH_3CN. *tert*-BuOOH was used as the oxidant in these reactions. It is known that copper(II) can bind the peroxo-group on treatment with peroxides [30] and the precatalyst species containing L_xCu–OOR (where L = ligand) type moieties seem to be capable of transferring the oxo functionality to the organic substrates to give the corresponding oxidized products [31]. We speculate that, in our case, a similar kind of mechanism is operative. X-ray crystal structure analysis of complexes **1**–**3** shows that the coordination environment around the copper(II) ion in these complexes is easily accessible for an external ligand, as a result alkyl-hydroperoxide gets enough space to bind copper in the intermediate stages of the catalytic cycle.

in aqueous solution [15,20]. The aromatic nitrogen of L-histidine significantly enhances the stability of the metal complexes. For histidine complexes, in the oxo-dimer each V(III) center is coordinated tridentately (N_{im}, N_{am}, O) with one imidazole ring of histidine and bidentately (N_{im}, N_{am}) with another one [17–19]. Such a complex predominantly exists in aqueous solution in the pH 6–8.5 range [20].

In the present work we have investigated the interaction of vanadium(III) with L-histidine derivatives: urocanic acid (UA), imidazole carboxylic acid (Im(COOH)) and imidazole-4,5-dicarboxylic acid ($Im(COOH)_2$).

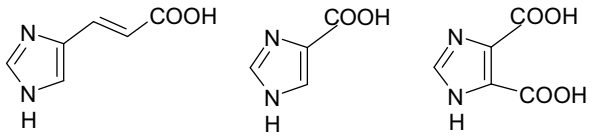
Urocanic acid (2-propenoic acid, 3-[1H-imidazol-4(5)-yl]) is a metabolic product of histidine. It is present (in quite high concentration) in the skin epidermis as a *trans* isomer. Absorption of UV radiation is responsible for the conversion of *trans* urocanic acid to its *cis* form [21,22].

Detailed studies of the electronic structure, absorption and emission spectra and possible mechanisms of photoisomerization of urocanic acid are the subject of numerous papers in the last decade [22–27]. It has been proposed that the *cis* isomer is immunosuppressive and is also connected to skin cancer [28,29]. Both UA and DNA are present in the skin of animals most exposed to sunlight, so it is very important to recognize all environmental factors which allow penetration of more sun UVB radiation to living organisms and create damage in nucleic acids [30,31].

The interaction of such an interesting molecule with different metals ions is almost unknown. We have only found the X-ray structure and catalytic activity of the manganese complex $[Mn(E\text{-}UA)_2(H_2O)_4]$, isolated from aqueous solutions [32].

Imidazole-4-carboxylic acid is one of the natural oxidation products of urocanic acid [33]. This compound is present also in UV-B-exposed human stratum corneum and may play some role in UV-B-induced immunosuppression [33]. To the best of our knowledge, complexes of imidazole-4-carboxylic acid with metal ions are almost unknown. In the solid phase only the complex $[^{99}Tc(OH)_2(imc)(CO)_3]$ has been isolated and coordination of the metal ion by the oxygen atom of the carboxylic group and one nitrogen atom of the imidazole ring was proved by X-ray data. This complex has importance in a clinical application [34].

Complex compounds of another derivative of urocanic acid – imidazole-4-acetic acid with different metal ions [Ni^{2+}, Cu^{2+}, Cd^{2+}, Zn^{2+}, Co^{2+}, Mn^{2+}, and VO^{2+}] were, on the other hand, extensively investigated [35–39]. The chelating character of imidazole-4-acetic acid has been demonstrated in the solid phase [35] and in aqueous solution [36–39]. As was studied by Sanna and coworkers [39], the oxovanadium(IV) ion forms monomeric and/or mixed hydroxo-bridged dimeric species in which both the oxygen of the carboxylate group and the nitrogen of the imidazole ring atoms are coordinated to metal ions.



Some results of the coordination properties of imidazole-4,5-dicarboxylic acid are also available in the literature. Solid state complexes were isolated with Rh and Ir [40,41], where this ligand acts as a dinucleating ligand. For VO^{2+}, the formation of dimeric and cyclic tetrameric species is strongly favored in aqueous solution [39].

The aim of the present study is to determine the complex equilibria of the V^{3+} ion with urocanic acid (UA), imidazole-4-carboxylic acid (ImCOOH) and imidazole-4,5-dicarboxylic acid ($Im(COOH)_2$). Potentiometry was used to determine the stoichiometries and stability constants of the complexes formed in aqueous solution. Spectroscopic methods have been used to confirm of these models of complexation and to understand the structures of the species formed in aqueous solution. We also have isolated a complex of vanadium(III) with urocanic acid in the solid phase.

2. Experimental

2.1. Reagents

VCl_3 p.a (Riedel-de-Ha,n), $VCl_3(THF)_3$ (Sigma–Aldrich), tetrahydrofuran (Sigma–Aldrich), NaOH (Merck), $NaClO_4$ (Merck), the *trans* isomer of urocanic acid (Sigma–Aldrich), imidazole-4-carboxylic acid (Sigma–Aldrich), imidazole-4,5-dicarboxylic acid (Sigma–Aldrich).

The bottle of VCl_3 was kept in a nitrogen filled box.

2.2. Preparation of solutions

All manipulations were performed in a nitrogen filled box. The vanadium(III) solutions were prepared just before each measurement by direct dissolution of accurately weighed amounts of VCl_3 salt (in deoxygenated water or $HClO_4$ solution). The molar percentage of VO^{2+} in each investigated solution did not exceed 1% (the concentration of VO^{2+} was determined potentiometrically by titration with an oxygen free $KMnO_4$ standard solution and spectrophotometrically). We checked the total vanadium concentration by the ICP method. Hydrogen ion concentrations in VCl_3 solutions were determined by the

Gran method according to the procedure described by Pajdowski and Krzewska [42]. The titration of V(III) solution was carried with an acid solution ($HClO_4$) of relatively high concentration in order to minimize the hydrolysis of the vanadium(III) ion.

The ligands solutions were prepared just before each measurement and their purity and concentrations were checked by NaOH potentiometric titrations (by the Gran method) [43]. The NaOH solution was standardized against potassium hydrogen phthalate.

All solutions were prepared in an inert atmosphere and using doubly distilled water.

The total metal concentrations varied from 0.1 to 10 mM. The ligand to metal ratios varied from L/M = 1–10.

2.3. Measurements

Both potentiometric and spectroscopic measurements were performed at 25 °C at constant ionic strength (0.5 M $NaClO_4$). An EMU/0 (electrochemical universal meter) produced by the Technical University of Wrocław was applied to the potentiometric measurements. This instrument was combined with an automatic burette and an appropriate computer set. The pH measurements were also taken with a precise digital pH-meter PHM-84 "Radiometer".

The potentiometric measurements were taken by means of the cell SCE‖S|GE, where SCE = $Hg|Hg_2Cl_2|$ saturated NaCl solution; S-equilibrium solution and GE the glass electrode ("pHG 211-8 Radiometer"). The calibration procedure was described in Ref. [9]. Anaerobic conditions were maintained both in the titration vessel and in the titrant solutions by circulating argon.

Protonation constants of the ligands and concentration stability constants of the vanadium(III) complexes, $\beta_{pqr} = [M_p\ L_q H_r]/[M]^p[L]^q\ [H]^r$, were calculated by the HYPERQUAD program [44]. Formation constants of V(III)-hydroxo complexes were taken into account in these calculations. The applied constants were recalculated to the ionic strength 0.5 M $NaClO_4$, from Pajdowski data [45]. The following set of hydrolytic species were assumed: $[V(OH)]^{2+}$, $\log\beta_{1-1} = -3.1$; $[V_2O]^{4+}$ $\log\beta_{2-2} = -4.28$; and $[V(OH)_2]^{+}$, $\log\beta_{1-2} = -7.24$.

Cary 50 and Cary 5 – Varian spectrophotometers were used to perform the measurements of UV–VIS absorption spectra. IR spectra were measured in KBr pellets with a Bruker IFS 113 v IR spectrophotometer in the 4000–200 cm^{-1} range. For measurements of fluorescence spectra a SLM Aminco APF-500 spectrophotometer was applied, using a Xenon arc lamp as the excitation source with 7.5 and 2.5 mm excitation and emission slits.

All operations were performed in a nitrogen filled box. The cuvettes used for absorption and fluorescence measurements were closed in these conditions.

The magnetic moment was measured at room temperature with a Bruker BM-4 system.

2.4. Syntheses of the solid compound of vanadium(III) with urocanic acid

0.327 g $VCl_3(THF)_3$ (1 mmol) was dissolved in 20 cm^3 hot tetrahydrofuran (THF) (under a stream of N_2). 0.2428 g (2 mmol) of urocanic acid was added to this solution. The mixture was kept at 60 °C for 0.5 h and stirred. After some time, dark green microcrystals precipitated. This product was filtered off, washed with dry diethylether and dried in a dessicator (yield: 49.5%) in N_2 atmosphere.

The solid compound was characterized by thermogravimetric, elemental and IR analysis. The vanadium concentration was determined by the ICP method. Chloride ions were determined potentiometrically using an ion-selective electrode.

Anal. Calc.: V, 11.0; N, 12.1; C, 41.4; Cl, 7.7.

Found: V, 10.8; N, 12.2; C, 40.8, Cl: 8.1%.

The results of the thermogravimetric analysis indicate that in this compound vanadium is coordinated to the urocanic ligand, a chloride ion and tetrahydrofuran molecules. It is consistent with the elemental formula: $V^{III}(THF)(UA)_2Cl$.

3. Results and discussion

3.1. Solid compound: $V^{III}(THF)(UA)_2Cl$

IR spectra confirmed the coordination of urocanic ligand molecules by the V(III) ion (Table 1).

A significant shift of OCO and NH stretching frequencies of the imidazole ring suggests that the ligand molecule coordinates by the carboxylic group and the nitrogen atom of the imidazole ring. On the other hand, the difference $[\nu(COO^-)_{as} - \nu(COO^-)_{sym}] = 171.9\ cm^{-1}$ can indicate bridging character of a carboxylic group [46]. The complex of vanadium(III) with urocanic acid is probably dimeric or a polymeric compound bridging through COO^- groups.

The magnetic moment of the complex is 2.72 B.M. at room temperature, confirming the +3 state of vanadium (d^2 electronic structure). The diffuse reflectance spectrum (Fig. 1a, curve 1) and the absorption spectrum of this compound dissolved in water (Fig. 1a, curve 2) unequivocally proved that both in the solid phase and in aqueous solution the V^{3+} ion was the coordination center. The wide unstructured band with a maximum about 600 nm can be identified as d–d transitions of the V^{3+} ion, which corresponds to splitting in the low symmetry ligand field states.

It should be pointed out that in the solid phase the complex $V^{III}(THF)(UA)_2Cl$ exhibits quite intense luminescence even at 25 °C. The emission spectrum of the complex

Table 1
IR spectral characteristics for the vanadium(III)–urocanic acid complex

Compound	ν (NH)	ν (NH) + ν (CH)	ν_{as} (OCO)	ν_{sym} (OCO)
Urocanic acid	2590	3162.2, 3087.48	1664.6, 1589	1343, 1470
V(III)–UA	2614.98	3123.47	1580.9	1409

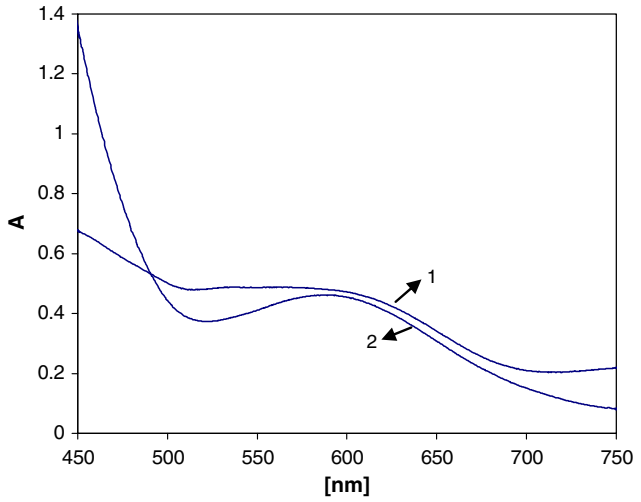


Fig. 1a. Diffuse reflectance spectrum of the solid complex $V^{III}(THF)(UA)_2Cl$ (curve 1) and absorption spectrum of this compound diluted in water (curve 2, pH 5).

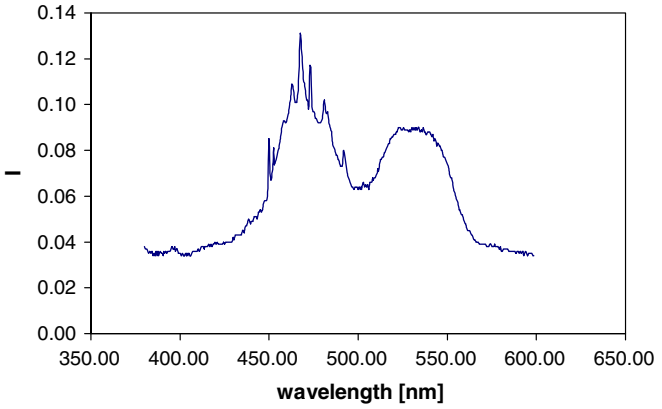

Fig. 1b. The emission spectrum of $V^{III}(THF)(UA)_2Cl$ in the solid state. $\lambda_{exc} = 330$ nm.

$V^{III}(THF)(UA)_2Cl$ is presented in Fig. 1b. It means that quite an effective conversion processes from the excited ligand state (presumably $^1\pi^* \rightarrow {}^1\pi$) through a lower lying triplet state of the ligand occurs to the split d–d states of V^{3+}. All these results well confirm the mode of the urocanate ligand coordination to V(III).

3.2. Complexation studies in aqueous solution

3.2.1. Protonation constants

Protonation constants of the ligands were calculated from titrations curves of the H^+-ligand systems in the pH range 1.8–12. In the case of imidazole-4,5-dicarboxylic acid, back titrations ($HClO_4$ as the titrant) were also performed because of the low solubility of the neutral ligand form. The values of the evaluated protonation constants are presented in Table 2, together with the vanadium(III) complex formation constants. All the ligands exhibit two protonation processes in the measurable pH region. The proton related to the N pyrrole site does not dissociate in this pH range. The protonation constant of the imidazole site is equal to $\log K_1 = 5.78$ for urocanic acid, 6.28 for imidazole-4-carboxylic acid and 7.84 for imidazole-4,5-dicarboxylic acid. The protonation constant of the carboxylic group is $\log K_2 = 3.48$ for UA, 2.3 for ImCOOH and 3.17 for $Im(COOH)_2$. Because a strong internal hydrogen bond exists between the carboxylic groups in $Im(COOH)_2$, the second proton of the carboxylic group of the ligand dissociates in a more acidic pH range ($\log K_3$ is about 1.5).

The log K values for urocanic acid and imidazole-4,5-dicarboxylic acid are in good agreement with earlier published data [21,39], considering the differences in ionic strength and ionic medium.

3.2.2. Vanadium(III) complexes

3.2.2.1. Vanadium(III)–urocanic acid system.

3.2.2.1.1. Potentiometric results. Only a weak interaction between the metal ions and the ligand in aqueous solution was stated, considering the potentiometric titration data. Hydrolysis of vanadium(III) competes with the complexation processes. This is a reason that in aqueous solutions only 1:1 species are formed. The competition between ML and MLH complex species with hydrolysis products is observed in the pH 2.5–4.5 range for the considered metal ion and ligand concentrations (Fig. 2). The slightly

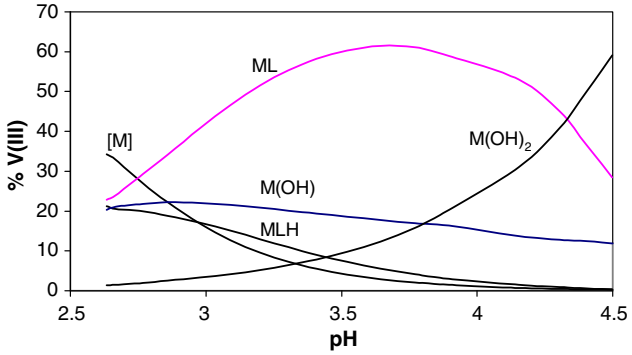

Fig. 2. Concentration distribution of the complexes formed in the V(III)–urocanic acid system in aqueous solution in the pH range 2.5–4.5 using β_{pqr} of the equilibrium model of Table 2 ($C_V = 3.75$ mM, $C_{UA} = 9.89$ mM).

soluble vanadium(III) mixed hydroxo urocanate species are probably formed above pH 4.5.

3.2.2.1.2. Spectroscopic results. Urocanic acid exhibits fluorescence even in aqueous solutions. Absorption and fluorescence spectra of urocanic acid in aqueous solutions at different pH values are presented in Figs. 3a and 3b respectively.

The absorption spectra of urocanic acid in aqueous solutions exhibit a distinct difference between the protonated and unprotonated form of this ligand (Fig. 3a). For the more stable *trans* isomer of this compound two electronic transitions $^1\pi \rightarrow {}^1\pi^*$ and $n \rightarrow \pi^*$ should be observed in this spectral range, however this last one is significantly less intense.

The most efficient excitation of fluorescence was found in the range 300-350 nm [22]. In agreement with recent studies [27] this excitation occurs via the n state which is hidden in the tail of the absorption resulting from the $^1\pi \rightarrow {}^1\pi^*$ transition. It should be pointed out that such an excitation result is wave dependent fluorescence which is very characteristic for the emission spectra of urocanic acid [23–27].

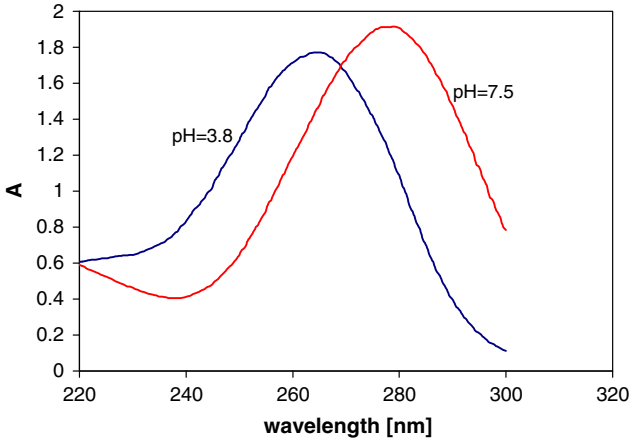

Fig. 3a. Absorption spectra of urocanic acid in aqueous solution. [UA] = 0.1 mM.

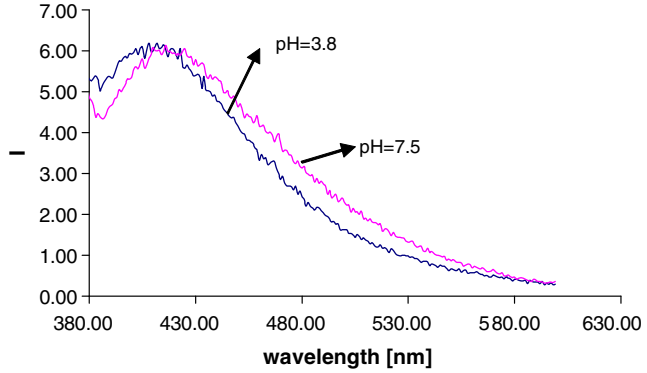

Fig. 3b. Fluorescence spectra of urocanic acid at different pH values. [UA] = 2 mM. $\lambda_{exc} = 330$ nm.

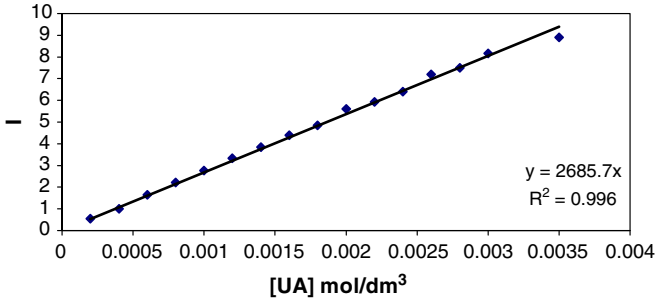

Fig. 4. Concentration dependence of the fluorescence intensity of urocanic acid at 410 nm. $\lambda_{exc} = 330$ nm, pH 3.

We have measured fluorescence of this ligand excited in such a spectral region in which the quantum efficiency of emission was the highest. The fluorescence spectra of urocanic acid in aqueous solutions of its protonated and deprotonated forms are presented in Fig. 3b. Fig. 4 presents the relationship between fluorescence intensity and concentration of urocanic acid at a constant pH value. The relationship is linear in the concentration range 0.2-3 mM UA.

We have also measured the influence of vanadium(III) concentration on the emission intensity of the $^1\pi \leftarrow {}^1\pi^*$ transition of urocanic acid. For the solutions with constant pH value and constant ligand concentration, distinct fluorescence quenching of urocanate by the vanadium(III) ion was observed (Fig. 5). These results enabled us to determine the stability constant of the V(III)–urocanate complex. The fluorescence titration technique was used to determine 1:1 conditional stability constants of fluorescing ligands with metal ions by several authors [47,48]. The results of the potentiometric measurements (Table 2 and Fig. 2) show that urocanic acid forms only 1:1 species with vanadium(III). As can be seen in Fig. 2, the complex ML is the prevailing form existing in aqueous solution. We decided to use the fluorescence quenching method for determination of stability constant of the ML species. The formation of the protonated species MHL was neglected because its concentration in the pH range 3–4

Where K_{ML} is the conditional stability constant at a constant pH value.
β_{ML} is the stability constant of the ML complex.
$\log \beta_{ML} = \log K_{ML} + \log \alpha_{L(H)} + \log \alpha_{M(H)}$.
Where $\alpha_{L(H)} = 1 + [H^+]\,K_1 + [H^+]^2\,K_1\,K_2$.
K_1, K_2 is the protonation constants of urocanic acid.
$\alpha_{M(H)} = 1 + K_{1h}/[H]^+ + K_{2h}/[H+]^2$.
Where K_{1h}, K_{2h} is the hydrolysis constants of vanadium(III).

is low (see Fig. 2). The experimental fluorescence data for the titrations of urocanic acid with V^{3+} at constant pH value have been fit to the non-linear fluorescence data treatment model of Ryan and Weber [47]. This method is based on the relationship linking fluorescence quenching of a ligand L by complexation with the metal ion M.

$$[ML]/C_L = (I_0 - I)/(I_0 - I_{RES})$$

where [ML] is the concentration of the metal–ligand complex, C_L is the concentration of the ligand, I_0 is the initial intensity value (before any metal ions have been added to the sample of the ligand), and I_{RES} is the residual intensity, when all the ligand is bound to the complex.

The simple 1:1 equilibrium between a metal ion and ligand can be written as follows:

$$K = [ML]/[M][L]$$

where K is a conditional stability constant at a given pH value.

Ryan and Weber [47] derived a final non-linear expression:

$$I = [(I_{RES} - I_0)/2KC_L]\{[KC_L + KC_M + 1] - [(KC_L + KC_M + 1)^2 - 4KC_LC_M]^{0.5}\} + I_0$$

In this equation K, C_L and I_{RES} are parameters to be fit by the program NLREG [49].

The results of fluorescence quenching are presented in Fig. 5 and the values K, C_L and I_{RES} as well as the correlation coefficients are presented in Table 3.

When conditional stability constants were recalculated, taking into account the protonation constants of urocanic acid and the hydrolysis constant of vanadium(III) ions (for a comparison with potentiometric results), quite a good agreement between both sets of values was found (Table 3).

The weak interaction between the vanadium(III) ion and the ligand in the aqueous solution can be confirmed by the measurements of absorption spectra. These spectra in the pH range 1–4 are presented in Fig. 6.

The spectra of the metal ion in aqueous solution ($I = 0.5$ M $NaClO_4$) are also included for comparison, in the same figure (curves 1 and 7). At low pH values, the

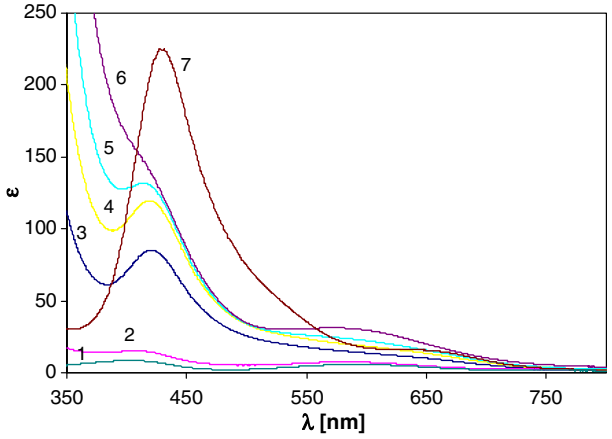

Fig. 6. Absorption spectra of VCl_3 aqueous solutions (curves 1 and 7) and absorption spectra of the vanadium(III)–urocanic acid system (curves 2–6) at different pH values ([V] = [UA] = 10 mM) (1) VCl_3 pH 0.864, (2) V(III) + UA pH 1.53, (3) V(III) + UA pH 2.36, (4) V(III) + UA pH 2.62, (5) V(III) + UA pH 2.88, (6) V(III) + UA pH 3.34, (7) VCl_3 pH 2.45.

spectra of vanadium(III) and vanadium(III) with ligand added do not differ significantly between each other (curves 1 and 2). These spectra are typical for vanadium(III) where two weak bands corresponding to the d–d transitions of the d^2 configuration of vanadium(III) are observed. This spectral picture distinctly changes for solutions with higher pH values (curves 3–7, Fig. 6). For the spectrum of an aqueous solution of V(III) alone at pH 2.45, a distinct intensity increase and a small red-shift of the band at 400–450 nm is observed (curve 7). As it was proved earlier [45,50], a small amount of hydrolytic vanadium(III) μ-oxo dinuclear species ($[V–O–V]^{4+}$) exists under such conditions and the CT band origin from the bridge bounded oxygen to vanadium(III) of this species overlaps with the weak d–d transition. Curves 3–6 (Fig. 6) present the spectra of vanadium(III) solutions with urocanic acid at different pH values. A distinct intensity increase of the 400–450 nm band is observed, however, in all the measured solutions their intensity is lower than in the spectrum of V(III) alone at pH 2.45 (curve 7). It means that urocanic acid reverses, to some degree, the hydrolysis process of

the vanadium(III) ion. This process obviously lowers the concentration of hydrolytic dimeric vanadium(III) μ-oxo species in the presence of the ligand. Such behaviors of absorption spectra were observed earlier for different V(III) complexes with amino acids as well [9,20,51].

3.2.2.2. Vanadium(III) complexes with imidazole-4-carboxylic and imidazole-4,5-dicarboxylic acids. Imidazole-4-carboxylic acid and imidazole-4,5-dicarboxylic acid are more efficient ligands than urocanic acid. Both ligands can form stable [N,O] chelates with V(III) and suppress the hydrolysis process. For the vanadium(III)–imidazole-4,5-dicarboxylic acid system, however, a precipitate was observed above pH 5.

The results of potentiometric titration prove that both ligands form mono and dinuclear species with vanadium(III). The average ligand number depends both on the total concentration of the metal ion and on the concentration of the free ligand (see Figs. 1 and 2 in the Supplementary Material). The stability constants of the complexes formed are presented in Table 2.

Comparison of the stability constants for the complexes of vanadium(III) with these ligands to the stability constants of complexes of VO^{2+} with imidazole-4,5-dicarboxylic acid and imidazole-4-acetic acid [39] indicates higher thermodynamic stability of the vanadium(III) complexes.

A relatively simple model of the complexation was observed in the vanadium(III)–imidazole-4,5-dicarboxylic acid system (Fig. 7).

As is shown in Fig. 7, in the prevailing pH range, the complex $M_2L_2H_{-2}$ exists in solution. This complex formation was also monitored by UV–Vis spectroscopy. The absorption spectra in this system (Fig. 8) are dominated by the strong CT band in the range 400–550 nm.

The presence of this intense absorption CT band in the visible region (400–550 nm) indicates that the complex $M_2L_2H_{-2}$ contains a μ-oxo $[V–O–V]^{4+}$ core [10,11,16–20]. As can be seen in Fig. 8 and Tables 1 and 2 in the Supplementary Material, both the energy and intensity of this band strongly depend on the pH value, the ligand concentration and the metal concentration. High average molar absorbance coefficients indicate that in this case dinuclear μ-oxo species are formed (see Tables 1 and 2 in the Supplementary Material). Such a spectral feature becomes clear when we assume a composed nature of this band. The $[V–O–V]^{4+}$ unit in the hydrolytic vanadium complex has an intense charge-transfer band at 428 nm (Fig. 6, curve 7). Significant changes of both energy and intensity of this band with changing pH and L/M ratios (Tables 1 and 2 in the Supplementary Material) clearly indicate that in the V(III)–imidazole-4,5-dicarboxylic acid system in aqueous solution at pH > 2, coordination of this dimeric species with the ligand occurs. Above pH 3.5 the energy of this CT band does not change (Fig. 8, Table 2 in the Supplementary Material) and its intensity increase depends on the vanadium(III) concentration. These results are in good agreement with recent data for μ-oxo-bridged species of vanadium(III) for which a chelate bond with a N aromatic atom exists (e.g. 2,2′bipyridine, 1,10-phenanthroline, L-histidine) [52,53,16–20]. The second absorption band at $\lambda_{max} = 650$ nm ($\varepsilon \sim 300\ M^{-1}\ cm^{-1}$ in Fig. 8) corresponds probably to a V^{3+} d–d transition, which is presumably intensified by the neighboring strong CT band, by a splitting of the d^2 states in a low symmetry field (by the coordination of the N-heterocyclic atom). This coordination is confirmed as well by the shift of this band towards lower energies in comparison with the aqua ion ($\lambda_{max} = 590$ nm for the aqua ion and $\lambda_{max} = 650$ nm for the complexes with imidazole-4,5-dicarboxylate). At a pH above 4.3, the intensity of the two transitions decreases (Fig. 8). It is in good agreement with the potentiometric data (Fig. 7). Above pH 5 in the solution of vanadium(III) with imidazole-4,5-dicarboxylic acid, a precipitate was observed even for low concentrations of the metal ion and ligand. The V_2OL_2 species formed in aqueous solution has a neutral charge. The $[V–O–V]^{4+}$ core in this species is complexed with two bidentate ligands (five-membered chelate rings are formed by the N_{im}, COO^- donor set). The remaining carboxylic groups may form hydrogen bonds with water molecules or bind to the next vanadium ions forming insoluble polymeric complexes.

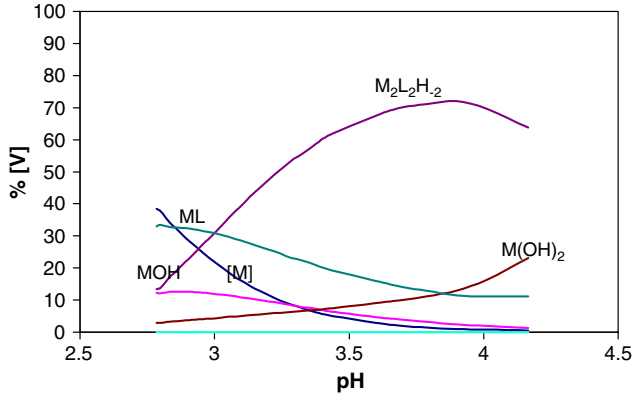

Fig. 7. Species distribution diagram as a function of pH for the V(III)–imidazole-4,5-dicarboxylic acid system. [V] = 2.7 mM, [Im(COOH)$_2$] = 5.8 mM.

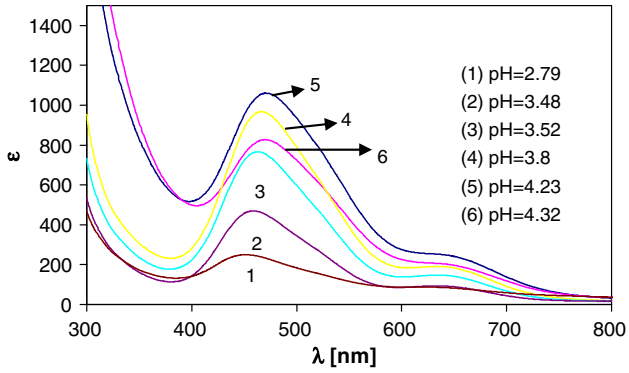

Fig. 8. Absorption spectra in the V(III)–Im(COOH)$_2$ system [V] = 2 mM, [Im(COOH)$_2$] = 10 mM.

In the V(III)–imidazole-4-carboxylic acid system we obtained clear solutions in the pH range of about 2–9 with L/M > 5. The rather limited ligand excess needed for complete metal complex formation prove the chelate nature of the species formed by imidazole-4-carboxylic acid. A typical species distribution diagram is presented in Fig. 9.

Complex formation starts with ML species at pH < 2. The "basicity adjusted" stability constant for the reaction: $V^{3+} + HL = VL + H^{+}$ is 0.67, which is greater by about two orders of magnitude than V(III)-complexes of simple amino acids (−1.41 for alanine [51]) and is comparable with V(III) – picolinic and 6-methylpicolinic acid ($\log K = 1.12$ and 0.12, respectively [5]). This is a further proof for the chelating nature of the species formed by imidazole-4-carboxylic acid. As can be seen in Fig. 9, in the pH range ~2–4, two main species, ML_2 and $M_2L_2H_{-2}$, are present in the equilibrium. In the pH range 4–7, new species, ML_2H_{-1} and $M_2L_4H_{-2}$ exist in solution. Above pH 7, ML_2H_{-2} starts to appear.

In Figs. 10a and 10b the spectra of the V(III)–imidazole-4-carboxylic acid system are presented in the pH range 1.52–8.89.

In the absorption spectra of all the solutions investigated two bands in the visible region were observed. In acidic solutions (Fig. 10a) the weak band at about 600 nm obviously corresponds to the V^{3+} ion d–d transitions ($^3T_{2g}(F) \leftarrow {}^3T_{1g}(F)$ in O_h symmetry). This band is very wide, because lower than O_h symmetry of both species ML and ML_2 exist in solution. The absorption spectra at higher pH values for this system are very similar to those obtained in the V(III)–$Im(COOH)_2$ system. As can be seen in Fig. 10b, a strong absorption band, CT in origin, appears in the range 400–550 nm. This is in good agreement with the potentiometric data (Fig. 9) which indicate that the formation of the $M_2L_2H_{-2}$ species begins at pH > 2. When the formation of this complex starts, the solution turns a red–brown color, typical for μ-oxo V(III)-complexes. $M_2L_2H_{-2}$ (V_2OL_2) has a CT band at $\lambda = 450$ nm (average ε ~200 $M^{-1}\,cm^{-1}$). In the pH range ~4–8 two main species, ML_2H_{-1} and $M_2L_4H_{-2}$ (V_2OL_4), exist in solution. As can be seen in Fig. 9, the amount of

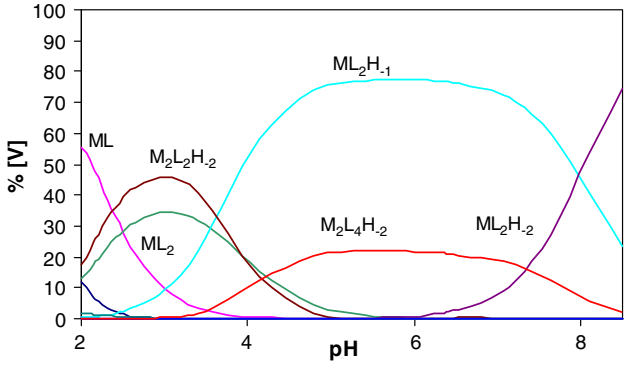

Fig. 9. Species distribution diagram as a function of pH for the V(III)–imidazole-carboxylic acid system. [V] = 4.71 mM, [L] = 25.88.

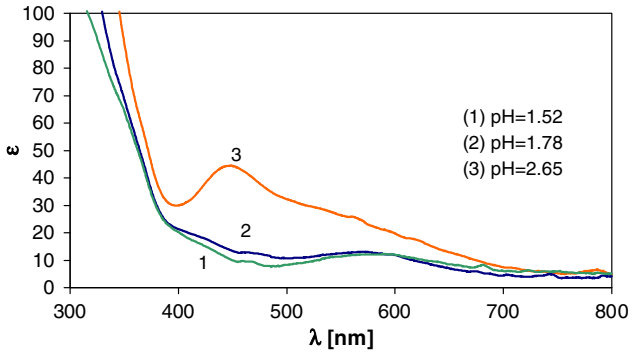

Fig. 10a. Absorption spectra for the V(III)–ImCOOH system in the pH range 1.52–2.65.

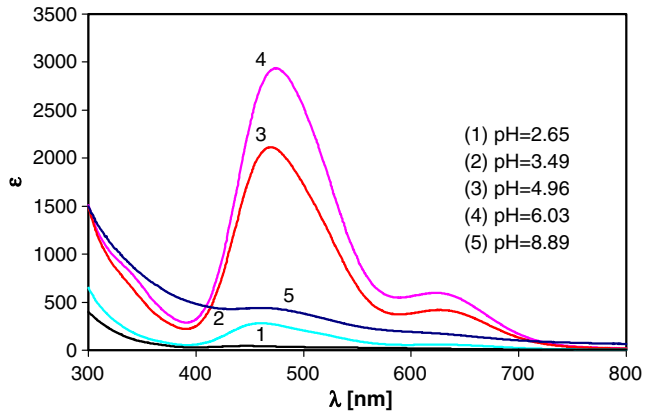

Fig. 10b. Absorption spectra for the V(III)–ImCOOH system in the pH range 2.65–8.89 [V] = 4.71 mM, [Im(COOH)] = 26.1 mM.

$[V_2OL_4]$ species is relatively small, but its presence determines the character of the spectral picture. The $[V_2OL_4]$ complex shows a CT band at $\lambda_{max} = 480$ nm (average ε ~3000 $M^{-1}\,cm^{-1}$) and a d–d transition at $\lambda_{max} = 630$ nm (average ε~800 $M^{-1}\,cm^{-1}$1), which is presumably intensified by the neighboring strong CT band. At the highest pH values, the intensity of these transitions decreases (Fig. 10b – spectrum at pH 8.89). This is related to the progress of hydrolysis. As can be seen in Fig. 9 at pH > 8, the $ML_2(OH)_2$ complex exists in solution.

4. Conclusions

The presented results clearly indicate that urocanic acid is a weak V(III) binder. Imidazole mono and di-carboxylate are relatively stronger ligands and are able to prevent the hydrolysis processes to some degree. Similarly, as for other ligands in quite a large pH range of investigated systems, the existence of several di-nuclear complex species with a $[V–O–V]^{4+}$core has been stated [11,14–20,52,53].

Imidazole-4-carboxylic and imidazole-4,5-dicarboxylic complexes of vanadium(III) in solution, however, have behaved differently. The main complex species in the V(III)–imidazole-4,5-dicarboxylic acid system that exists in the 3–4.5 pH range is $M_2L_2H_{-2}$ (V_2OL_2) (Fig. 7). In

the absorption spectra of the investigated solutions in this pH range the spectrum of this species is dominant (Fig. 8).

These results are in good agreement with the coordination mode of the V^{3+} ion [11,14–20,52,53]. Each V^{3+}ion is coordinated by the oxygen of one carboxylate group and the imidazole nitrogen atom. The coordination sphere of vanadium(III) is fulfilled by the bridge-oxygen and water molecule. However, the V_2OL_2 species can very easy form oligomers by polymerization through the carboxylic bridges. Such oligomers have low solubility, so it is difficult to keep them in solutions at higher pH values. The formation of cyclic oligomeric species has been observed in aqueous solutions of vanadium(IV) and imidazole-4,5-dicarboxylic acid at pH > 4, however, they are more soluble in this case [39].

For the vanadium(III) complexation with the imidazole-4-carboxylate ligand, formation of several mononuclear and dinuclear complex species in equilibrium is very characteristic. It is worth noticing that no such equilibrium has been observed in the solution of V(III) and imidazole-4,5-dicarboxylic acid so far. This can be explained by the differences in the coordination mode between both ligands. In imidazole monocarboxylate complex species both donor groups of the ligand (O, N_{im}) are involved in the complexation process. On the other hand in imidazole-4,5-dicarboxylate complex species a free carboxylic group, which is not involved in the complexation process, can form relatively strong hydrogen bonds with water molecules. This tendency is limited in solutions at higher pH values, in which there are significantly more negatively charged OH^- groups. It also confirms the formation of low soluble oligomers by the imidazole-4,5-dicarboxylate ligand.

As one can expect, the weakest ligand among those investigated is the urocanate ligand. With the vanadium(III) ion only two mononuclear complex species (MLH, ML) exist in aqueous solution. The steric hindrance is responsible for such behavior. Nevertheless, we should assume that whereas in MLH species vanadium(III) is bound with the ligand through an oxygen of carboxylate group, in the ML species presumably a weak chelate ring through the O and imidazole N atoms can be also expected. We cannot exclude also some equilibrium with the mixed hydroxo M(HL)(OH) species. Unfortunately potentiometric and spectroscopic results cannot explain this question unequivocally. The ''basicity adjusted'' stability constants ($\log K$) for the ML complexes are: 0.14 for V(III)–UA species, 0.67 for V(III)–ImCOOH species and 0.71 for V(III)–$Im(COOH)_2$ species. These values indicate that urocanic acid is the weakest ligand, however a weak chelation bond is possible. The chelating bond in the V(III)–UA species is too weak to prevent the hydrolysis. So far, in this system we have not observed either formation of ML_2 species or dinuclear complexes.

In contrast to the unsuccessful efforts of the syntheses of a vanadium(III) complex with the urocanate ligand in aqueous solutions, we have been able to get a solid compound in the microcrystalline form from a non-aqueous solvent (tetrahydrofuran). This compound, contrary to the species in aqueous solution, consists of two ligand molecules in the first coordination sphere of the vanadium(III) ion. The elemental formula is $[V^{III}(THF)(UA)_2Cl]$. We assume that the formation of oligomers through the carboxylic group is possible in the solid phase. This compound has very interesting luminescent properties, which result in an effective energy transfer from the ligand molecule to the d electronic vanadium(III) states. The unusual photophysical properties of the urocanate ligand [21–31] (among others the *trans–cis* isomerization) are presumably responsible for this phenomenon. It seems that further investigation of such phenomena may be quite interesting – both for the better knowledge of the energy transfer mechanism and for possible applications.

We have applied the photophysical properties of this ligand to the determination of the conditional stability constant of the V(III) complex species in aqueous solution by the fluorescence quenching method. It should be noted that other analytical applications of this system to quantitative determination of urocanic acid is possible.

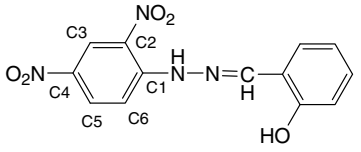
with both electron rich and electron poor metals [20–22]. The mode of bonding depends on the nature of the ligand, the metal ion and the solvent used [23,24]. As the substituents present in the hydrazone strongly influence the reactivity of proximal C–H bonds, a CNO mode of bonding of aryl hydrazones may be expected, provided suitable substituents are located on the aryl ring. With this background, the present work was carried out to study the role of nitro groups towards metal assisted C–H activation of 2,4-dinitrophenyl hydrazone derivatives [25] (Chart 1) using $[RuHCl(CO)(PPh_3)_3]$ [26] and $[RuHCl(CO)(AsPh_3)_3]$ [27] as the metal complex precursors.

2. Experimental

2.1. Materials and methods



All chemicals were of reagent grade and were used without further purification. Solvents were purified and dried according to standard procedures [25]. Commercially available TBAP (tetra butyl ammonium phosphate) was properly dried and used as a supporting electrolyte for recording cyclic voltammograms of the complexes. FT-IR spectra (4000–400 cm^{-1}) of the complexes and the free ligand were recorded from KBr pellets with a Nicolet Avatar Model FT-IR spectrophotometer. UV–Vis spectra (800–250 nm) of the complexes were obtained on a Systronics 119 UV–Vis spectrophotometer. ^1H NMR spectra of the complexes were recorded using a Varian-Australia AMX-400 spectrometer. Micro analyses (C, H and N) were performed on a Vario EL III Elementary analyzer. Cyclic voltammograms were recorded on a CHI 1120A electrochemical analyzer with a three electrode compartment consisting of a platinum disc working electrode, platinum wire counter electrode and Ag/Ag^+ reference electrode.

2.2. X-ray crystallography

Crystal parameters and details of the collection and refinement are given in Table 1. X-ray diffraction measurements for **1** and **2** were performed on a Bruker AXS SMART APEX CCD diffractometer with graphite mono-

chromatized Mo Kα radiation. The unit cells were determined using SMART [28] and SAINT+ [29], and the data were corrected for absorption using SADABS [30]. The structures were solved by direct methods and refinements were carried out by full-matrix least-square techniques. The hydrogen atoms were treated by a mixture of independent and constrained refinement. The computer program SHELXTL 6.14 [31] was used for structure solution, refinement and molecular graphics.

The structure of **2** is heavily disordered with both the solvate DMF molecule as well as the complex molecule disordered as a whole. Only the central Ru atom and the phosphine P atom show no disorder. The DMF solvate molecule is disordered around the twofold axis. The two methyl nitrogen distances within the DMF molecule were restrained to be identical within a standard deviation of 0.02 Å, and all DMF atoms were restrained to be isotropic within a standard deviation of 0.1 Å^2. The different types of disorder within the complex molecule are all related to each other. They are caused by the molecule being located on a crystallographic twofold axis (perpendicular to the Ru–P axis) that is not resembled by the symmetry of the complex molecule. Attempts to solve the structure in the space group Pn (without the twofold axis) resulted in less satisfactory results. The disorder consists in detail of the following. The azo-ligand, which has no twofold symmetry, is rotated by the twofold axis through the Ru atom, resulting in two alternative positions for the ligand with a 1:1 occupancy ratio. The two positions are taking up nearly the same space around the Ru atom. The slight differences for the two orientations are causing disorder for the phenyl rings of the triphenylphosphine ligand, and for the carbon monoxide ligand, which thus also show a 1:1 disorder. For the refinement the following restraints were applied to the complex molecule. All anisotropic displacement parameters of the azo ligand were restraint to have the same U_{ij} components (within a standard deviation of 0.04 for *s* and 0.08 for *st*) using a SIMU command in SHELXTL [31]. The carbonyl carbon atoms C51 and C43 and nitrogen atoms N3 and N7 (which are all nearly superimposed with symmetry generated counterparts) were restrained to be isotropic within standard deviations of 0.01 (C51, C43, N7) or 0.001 Å^2 (N3). All the aromatic rings of the azo ligand and the triphenylphosphine were restrained to be ideal six membered rings (AFIX 66 command) with C–C distances of 1.39 Å. No further positional restraints were applied. All hydrogen atoms were placed in calculated positions and were isotropically refined with a displacement parameter of 1.5 (methyl) or 1.2 times (all others) that of the adjacent carbon atom. With the beta angle in the structure of **2** being very close to 90°, we tested for the possibility of pseudo-merohedral twinning. Refinement using the usual twinning laws (twin instructions 1000 −1000 −1 and 1000 −10001) however, did not result in a significant improvement of the structure quality, and the BASF values refined to values less than one percent. It was thus assumed that the structure was not twinned and the twin instruction was omitted from the refinement instructions.

2.3. Synthesis

2.3.1. Synthesis of [Ru(CO)(PPh$_3$)$_2$(php)] (1)

[RuHCl(CO)(PPh$_3$)$_3$] (0.1 g, 0.105 mmol) and the ligand H$_2$php (0.0317 g) were mixed and heated to reflux in dry ethanol (30 mL) for 9 h. The resulting brown crystalline product was collected and washed with cold ethanol and diethyl ether. Subsequent recrystallization by slow diffusion of $CHCl_3$ vapour into a concentrated DMF solution of the complex yielded brown crystals. Yield: 71 mg (71%). *Anal.* Calc. for $C_{50}H_{38}N_4O_6P_2Ru$: C, 62.99; H, 4.01; N, 5.87. Found: C, 62.96; H, 4.04; N, 5.84%. IR (KBr) ν/cm^{-1}: 1595 (νC=N)imine, 1264 (νC–O). UV/Vis ($CHCl_3$) λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}): 264 (11 870), 336 (3400), 454 (3820), 504 (3300). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm: 6.60 (1H, s, CH), 6.90 (1H, s, CH) 7.18–7.85 (multiplet, aromatic protons), 8.4 (1H, s, –CH=N), 11.0 (1H, s, NH).

2.3.2. Synthesis of [Ru(CO)(PPh$_3$)$_2$(phm)] (2)

This was prepared by the same procedure as **1** with [RuHCl(CO)(PPh$_3$)$_3$] (0.1 g, 0.105 mmol) and H$_2$phm (0.0349 g). Yield: 89 mg (86%). *Anal.* Calc. for $C_{51}H_{40}N_4O_7P_2Ru$: C, 62.35; H, 4.10; N, 5.70. Found: C, 62.36; H, 4.08; N, 5.74%. IR (KBr) ν/cm^{-1}: 1600 (νC=N)imine, 1264 (νC–O). UV/Vis ($CHCl_3$) λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}): 263 (21 580), 313 (7550), 384 (1710), 515 (345). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm: 3.90 (3H, s, –OCH$_3$), 6.47 (1H, s, CH), 6.67 (1H, s, CH) 7.14–7.82 (multiplet, aromatic protons), 8.4 (1H, s, –CH=N), 11.01 (1H, s, NH).

2.3.3. Synthesis of [Ru(CO)(PPh$_3$)$_2$(phn)] (3)

This was prepared by the same procedure as **1** with [RuHCl(CO)(PPh$_3$)$_3$] (0.1 g, 0.105 mmol) and H$_2$phn (0.0369 g). Yield: 61 mg (58%). *Anal.* Calc. for $C_{54}H_{42}N_4O_6P_2Ru$: C, 64.50; H, 4.21; N, 5.57. Found: C, 64.56; H, 4.20; N, 5.51%. IR (KBr) ν/cm^{-1}: 1610 (νC=N)imine, 1254 (νC–O). UV/Vis ($CHCl_3$) λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}): 272 (12 650), 359 (5800), 431 (2260). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm: 6.52 (1H, s, CH), 6.85 (1H, s, CH) 7.12–7.90 (multiplet, aromatic protons), 8.35 (1H, s, –CH=N), 11.0 (1H, s, NH).

2.3.4. Synthesis of [Ru(CO)(AsPh$_3$)$_2$(php)] (4)

This was prepared by the same procedure as **1** with [RuHCl(CO)(AsPh$_3$)$_3$] (0.1 g, 0.107 mmol) and H$_2$php (0.0323 g). Yield: 77 mg (69%). *Anal.* Calc. for $C_{50}H_{38}N_4O_6As_2Ru$: C, 57.67; H, 3.67; N, 5.38. Found: C, 57.61; H, 3.68; N, 5.35%. IR (KBr) ν/cm^{-1}: 1607 (νC=N)imine, 1268 (νC–O). UV/Vis ($CHCl_3$) λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}): 266 (13 820), 340 (4450). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm: 6.58 (1H, s, CH), 6.90 (1H, s, CH) 7.20–7.88 (multiplet, aromatic protons), 8.4 (1H, s, –CH=N), 11.0 (1H, s, NH).

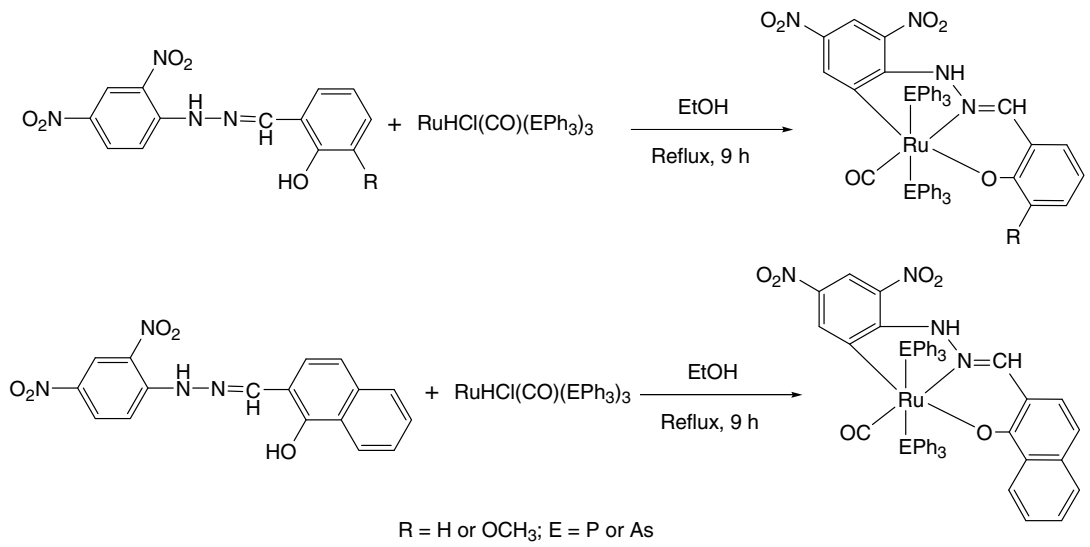
*2.3.5. Synthesis of [Ru(CO)(AsPh$_3$)$_2$(phm)] (**5**)*

This was prepared by the same procedure as **1** with [RuHCl(CO)(AsPh$_3$)$_3$] (0.1 g, 0.107 mmol) and H$_2$phm (0.0356 g). Yield: 87 mg (76%). *Anal.* Calc. for $C_{51}H_{40}N_4O_7As_2Ru$: C, 57.23; H, 3.76; N, 5.23. Found: C, 57.26; H, 3.78; N, 5.27%. IR (KBr) ν/cm^{-1}: 1602 (νC=N)imine, 1472, 1263 (νC–O). UV/Vis ($CHCl_3$) λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}): 268 (3720), 360 (4230). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm: 3.90 (3H, s, –OCH$_3$), 6.58 (1H, s, CH), 6.78 (1H, s, CH) 7.0-7.82 (multiplet, aromatic protons), 8.3 (1H, s, –CH=N), 11.01 (1H, s, NH).

*2.3.6. Synthesis of [Ru(CO)(AsPh$_3$)$_2$(phn)] (**6**)*

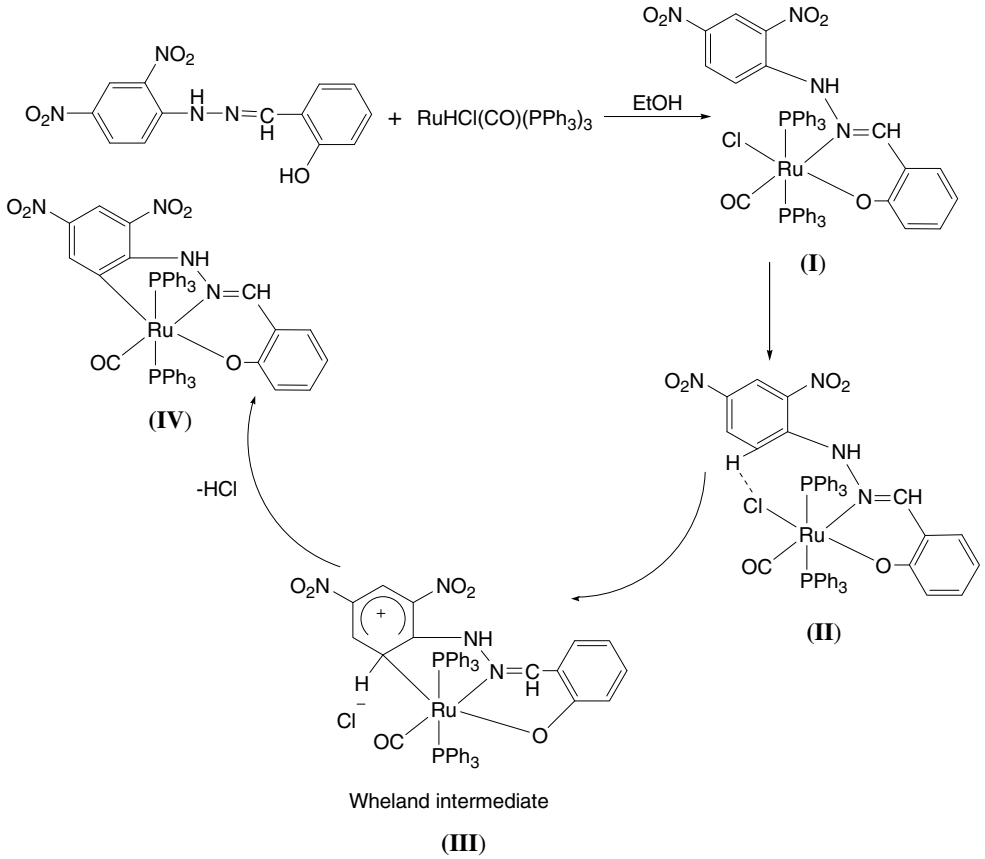
This was prepared by the same procedure as **1** with [RuHCl(CO)(AsPh$_3$)$_3$] (0.1 g, 0.107 mmol) and H$_2$phn (0.0376 g). Yield: 76 mg (65%). *Anal.* Calc. for $C_{54}H_{42}N_4O_6As_2Ru$: C, 59.32; H, 3.87; N, 5.12. Found: C, 59.36; H, 3.88; N, 5.16%. IR (KBr) ν/cm^{-1}: 1610 (νC=N)imine, 1258 (νC–O). UV/Vis ($CHCl_3$) λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}): 268 (24 550), 340 (5930), 444 (2560). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm: 6.48 (1H, s, CH), 6.75 (1H, s, CH) 7.10–7.86 (multiplet, aromatic protons), 8.38 (1H, s, –CH=N), 11.0 (1H, s, NH).

3. Results and discussion



The reaction of 2,4-dinitrophenyl hydrazone ligands with [RuHCl(CO)(EPh$_3$)$_3$] (E = P or As) in a 1:1 molar ratio proceeds smoothly in refluxing ethanol, yielding the cycloruthenated complexes through the carbon atom, which is *meta* to both the NO$_2$ groups, the azomethine nitrogen atom and the phenolate oxygen atom by substitution of one chloride, one of the triphenylphosphines or arsines and one hydride from the Ru(II) precursor. All the complexes are non-hygroscopic, brown in color and found to be air stable at room temperature. Most of the cyclometallation reactions carried out earlier were thought to be favored when the reaction medium contained added bases [32–34] (like NaOH, NaOAc, N(Et)$_3$, etc.), and the presence of electron releasing substituents such as CH$_3$, OCH$_3$ and NH$_2$ in the aryl ring that is to be cyclometallated seemed to be essential [35,36]. The presence of electron withdrawing substituents such as a NO$_2$ group on the aryl ring was regarded to inhibit cyclometallation by rendering the aryl ring as an electrophile, which in turn would have made it unavailable for the attack of an electron deficient metal center [37]. In contrast to these two criteria, cyclometallation has been achieved in the present case without any added base in the reaction medium and with the presence of two electron withdrawing NO$_2$ groups in the hydrazine moiety. A possible explanation could be given the nature of the metal center and that of the electron withdrawing group. The two most likely mechanisms proposed for metal complex promoted C-H activation reactions are oxidative addition and electrophilic substitution. These two alternatives have different requirements for electron density at the metal center. The metal center may behave as an electrophile or as a nucleophile in its attack on the aromatic ring. In general, electrophilic attack is favored by electron poor metal centers whilst oxidative addition is favored by electron rich metal centers. There are many instances of cyclometallation where the oxidative addition and electrophilic mechanism cannot be easily distinguished [38,39]. In the present case the C–H activation seems to proceed via an eletrophilic attack of the electron deficient metal center on the C–H bond present in the aryl ring which is *meta* to both the nitro substituents. The primary ligands (CO and PPh$_3$/AsPh$_3$) present in the precursor complexes are π-acidic in nature and are capable of acquiring electron density from the metal through back bonding, thereby making the metal center electron deficient (an electrophile). At the same time, the *meta*-directing NO$_2$ groups, which are *meta* to each other, withdraw electron density only from the C3 (*ortho* to both NO$_2$ groups) and C5 (*ortho* to the 4-NO$_2$ group and *para* to the 2-NO$_2$ group) atoms and makes the C6 atom (*meta* to both NO$_2$ groups) relatively electron rich (a nucleophile). These two key steps, i.e. the formation of an electrophile and a nucleophile initiate cyclometallation, which is propagated through a series of steps as detailed below Scheme 1.

3.1. Mechanism for C–H activation



On the basis of the above points, the mechanism of the C–H activation has been deduced and depicted in Scheme 2. In the first step, the weakly coordinated hydrido ligand and a neutrally coordinated PPh$_3$/AsPh$_3$ are substituted by the phenolate oxygen and azomethine nitrogen of the hydrazone ligand. In the second step, the metal center is located in close proximity to the C6 atom of the aryl ring to be cyclometallated, which has become a nucleophile due to the meta-directing effect of the NO$_2$ groups. Then, the C6–H bond is considerably weakened by the interaction of the proton with the metal bound chloride and may be envisaged as an activated bond. In the next step, the electrophilicity of the ruthenium center is further increased due to the reduced σ-donation of the chloride to the metal center. The electrophilic attack at the C6–H bond is instigated by **II** affording the Wheland intermediate **III** and deprotonation occurs subsequently to expel HCl. The proposed electrophilic substitution is supported by the elimination of HCl during the cyclometallation, which is a unique feature of the electrophilic pathway [5,40,41].

3.2. IR spectra

The important IR frequencies of the complexes are given in the experimental section. The band due to NH stretching in the free ligands occurs in the 3400–3290 cm^{-1} region and remains unaffected after complexation. This precludes the possibility of coordination through the hydrazinic nitrogen atom. In the IR spectra of the complexes a considerable negative shift in ν(C=N) is observed, indicating coordina-

Scheme 1. Synthesis of complexes **1**–**6**.

Scheme 2. Proposed mechanism for C–H activation.

tion through the azomethine nitrogen atom. The hypsochromic shift of the N–N vibration also supports the above coordination. A peak at around 3100 cm^{-1} due to ν(O–H) stretching is absent in the spectra of the complexes, suggesting the deprotonation of the –OH group of the ligands prior to coordination to the metal. The ν(C–O) phenolic modes of the ligands appearing in the region 1218–1222 cm^{-1} are shifted to 1254–1268 cm^{-1} in the complexes, indicating complex formation via deprotonation of the phenolic OH. The presence of the nitro group in the complexes are characterized by the two bands observed at around 1518–1534 cm^{-1} and 1322–1340 cm^{-1} which arise due to symmetric and asymmetric stretching modes of NO_2.

3.3. Electronic spectra

The UV–Vis spectral bands of all the complexes were measured in dichloromethane. All the complexes exhibited two to four bands in the region 264–504 nm. The two absorption bands appearing in the range 264–272 nm and 336–360 nm may be assigned to a $\pi \rightarrow \pi^*$ transition of the aromatic ring and a $n \rightarrow \pi^*$ transition of the –C=N group, respectively. In addition, the low energy absorption peaks in the wavelength range 431–504 nm are associated with a charge transfer transition. The spectra of the complexes do not show any d–d transitions [42,43].

3.4. ^1H NMR spectra

^{1}H NMR spectra of the complexes show all the expected signals. In all the spectra, a singlet corresponding to a single proton is observed in the range δ 8.0–8.4 ppm, which is attributed to the azomethine proton (–HC=N). The singlet due to the NH proton appears at δ 11.0 ppm. Two singlets observed around δ 6.40–6.60 and 6.70–6.90 ppm are due to the protons of the metallated ring. The triphenylphosphine/triphenylarsine and other ring protons are observed as overlapping signals around δ 7.1–7.9 ppm. A sharp singlet at δ 3.9 ppm is assigned to the methoxy protons of complexes **2** and **5**.

3.5. X-ray crystallography

The molecular structures of complexes **1** and **2** have been determined by single crystal X-ray diffraction. The molecular structures of **1** and **2** are shown in Figs. 1 and 2. Selected bond distances and bond angles are given in Table 2. The $RuNOC_2P_2$ coordination sphere is distorted octahedral, as can be seen from the angles subtended at the ruthenium center. The basal plane is made up from C, N and O atoms of the dibasic tridentate hydrazone ligand and one carbonyl carbon, while the two PPh_3 groups occupy the apical positions. The structure shows that the hydrazone ligand is coordinated to Ru through the imine

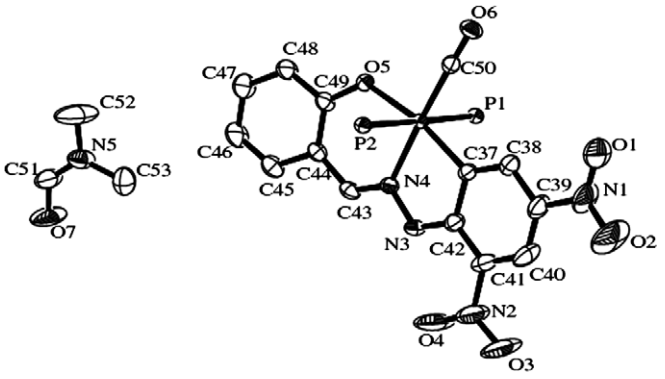


Fig. 1. Labelled ORTEP diagram of **1** with the thermal ellipsoids at 50% probability. Hydrogen atoms and phenyl rings of PPh_3 are omitted for clarity.

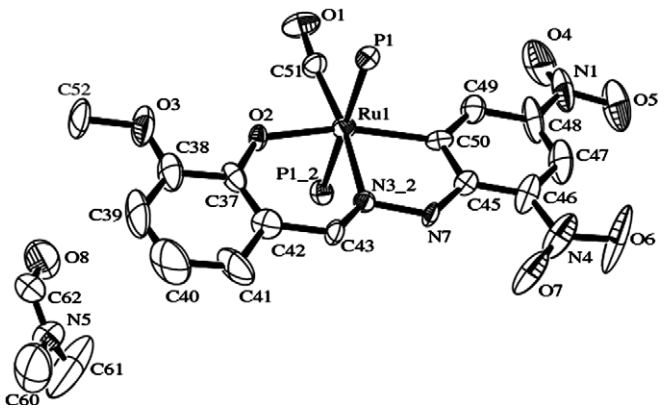

Fig. 2. Labelled ORTEP diagram of **2** with the thermal ellipsoids at 50% probability. Hydrogen atoms and phenyl rings of PPh_3 are omitted for clarity.

nitrogen, phenolic oxygen and aryl carbon, forming a six membered ring by O, N chelation and a five member ring by C, N chelation with bite angles O5–Ru1–N4 (87.75°) and N4–Ru1–C37 (80.15°). From the covalent radii values, the Ru(II)–C(sp^2) length is estimated to be 2.06 Å [44] and the observed values span the range 1.96–2.16 Å [45]. In our complex the Ru1–C37 distance is 2.040 Å, which is identical to that of the other structurally characterized cyclometallated Ru(II) complexes [46,33]. The Ru1–C50 bond distance (1.860 Å) is in accordance with those found in another Ru(II) complex [47]. The Ru–C37(sp^2) bond is 0.18 Å longer than the Ru1–C50(sp) distance, due to Ru–CO back bonding. The two Ru–P bond lengths are similar and are comparable to those reported for other PPh_3 coordinated Ru(II) complexes [48,49]. The Ru1–O5(phenolato) distance of 2.139 Å is slightly longer than those reported previously for similar Ru(II) complexes [50–53]. This lengthening of the Ru–O bond distance can be explained by the trans influence of the soft aryl carbon atom which is present trans to the phenolic oxygen. The trans weakening effect of CO is evident in the Ru1–N4 bond distance (2.065 Å), which is significantly longer than those that found for $[Ru(pabh)_2]$ [54] (pabh = *N*-(aryl)-*N*′-(picolinylidene)hydrazine) (1.960(3) and 1.958(3) Å), *trans*-$[Ru(pamh)(PPh_3)_2Cl]$ [55] (pamh = *N*-(aryl)-*N*′-(picolinylidene)hydrazine) (1.933(3) Å), $[Ru(HL)(PPh_3)Cl]Cl$ (1.984(5) Å) and $[Ru(HL)(PPh_3)(mpi)]Cl_2$ (1.991(5) Å) (HL = methyl 2-pyridylketone 4-(4-tolyl)thiosemicarbazones), (mpi = methyl (2-pyridylmethyleneimine)) [56].

3.6. Electrochemistry

Dichloromethane solutions of the complexes have been used to study the electrochemical properties, with the help of cyclic voltammetry. The potential data are listed in Table 3 and a representative voltammogram of **2** is illustrated in Fig. 3. The potentials of both the metal centered oxidation and reduction reflect the influence of the electronic nature of the substitutions present in the ligands.

6	0.83[c]	−0.48(680)	−1.34

[a] Oxidation couple.
[b] Reduction couple.
[c] Irreversible, Ep_a value.
[d] Irreversible, Ep_c value.

Each complex displays a reductive response on the negative side and an oxidative response on the positive side of the Ag/AgCl electrode. The oxidation couple observed for complex **2** is assigned to the Ru(III)–Ru(II) oxidation. In all the other complexes, the Ru(III)–Ru(II) oxidation process takes place irreversibly in the range 0.82–0.84 V. Thus, as the σ-bonding ability of the O-atom of the deprotonated phenol functionality decreases with the increasing electron withdrawing ability of the substituents, the Ru(III)–Ru(II) oxidation becomes more difficult. The reductive response, observed in the range −0.40 to −0.60 V is quasireversible with a peak-to-peak separation (ΔEp) of 210–680 mV, and it is attributed to the Ru(II)–Ru(I) couple. The electron withdrawing substituents on the ligands have a significant effect on the observed reduction peak potentials. Electron withdrawing groups lower the electron density on the metal center even further and lead to less negative

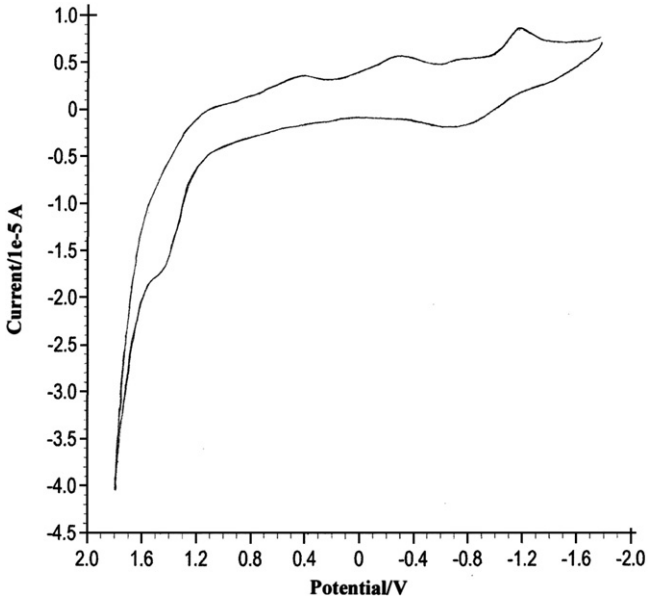

Fig. 3. Cyclic voltammogram of complex **2**.

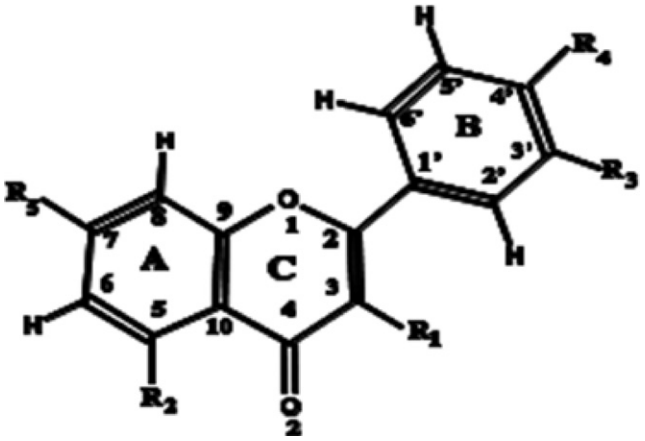
potentials than for complexes with electro releasing groups. In addition, the M–C bond largely lowers the redox potentials of Ru(II) complexes [3]. Generally, the presence of an electron withdrawing group stabilizes the lower oxidation state and an electron donating group favors the higher oxidation state of the metal. The cyclic voltammograms of all the complexes were unfailing with one irreversible ligand based reduction due to the reduction of the HC=N group. These reduction peaks were shifted to more negative potentials with respect to the free ligands, which was consistent with the complex formation. It is interesting to note that a substituent which is somewhat away from the electroactive metal center can influence the metal centered redox potentials in a predictable manner.

4. Conclusion

A new family of cyclometallated Ru(II) complexes has been prepared and characterized. This C–H activation process is believed to proceed via an electrophilic substitution mechanism. What is more interesting is that the cyclometallation reaction presented here takes place under neutral conditions and without auxiliaries. Voltammetric results obtained in this study showed that the hydrazone ligands stabilize a lower oxidation state of the metal complexes. The substituents on the hydrazone ligands were found to have a significant effect on the redox potential. All the new complexes seem of interest for general synthetic and theoretical chemical research and may have some potential for catalytic applications.



Appendix A. Supplementary data

CCDC 663252 and 613459 contain the supplementary crystallographic data for **1** and **2**. These data can be

obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.01.032.

second step, the quercetin ligand was studied under the same conditions with the same methodology. Quercetin (Q) is a flavonol that is ubiquitous in edible plant material, and has been the subject of detailed examination for its antioxidant, complexing and other biological properties [22–26]. This ligand simultaneously presents within its structure the three potential sites previously studied. The goal of this second part is to determine which of these sites presents the greatest affinity for Al(III) and to check if the classification obtained by means of the study of the mono-site compounds is preserved for this multi-site ligand. Density functional theory (DFT) and time-dependent density functional theory (TD-DFT) were used to calculate the theoretical electronic spectra of quercetin complexes, the results of which were compared with the experimental spectrum to identify the preferential chelating site of Al(III).

2. Experimental and theoretical methods

2.1. Reagents and chemicals

The hydroxyflavones were obtained from Extrasynthèse (France). Aluminium chloride and spectroscopic grade methanol were used without purification. Water was delivered by a Milli-Q-water purification system. The stoichiometries of the complexes were determined by the molar ratio method from the UV–Vis data set. For this method, solutions containing a constant concentration (4×10^{-5} M) of hydroxyflavone in methanol/water and variable concentrations of $AlCl_3$ (from 4×10^{-7} to 1×10^{-4} M) were used. A broad range of metal-to-ligand molar ratios was used in the equilibrium studies. The stoichiometries of the complexes were also verified by the method of continuous variation (Job's method). The ionic strength was fixed to 0.1 M with NaCl.

2.2. Instrumentation

The UV–Vis spectra were recorded on a Cary-l (Varian) spectrophotometer with cells of 1 cm path length, at 25 °C. A flow cell was used to allow successive additions of small amounts of aluminium chloride directly to the flavonoid solution.

2.3. Chemometric methods

The absorption spectra collected during the course of the metal-binding experiment were analyzed with the fitting program SPECFIT (version 3.0) [27]. This software allows the determination of the number of species that contribute to the absorption spectra using a factor analysis procedure (EFA) [28–30], and the electronic spectrum of each pure complex. The SPECFIT software has also been used to estimate the apparent stability constants (β) of the different complexed forms. In order to obtain the best fit between the complexation model and the experimental data, several models of complexes have been envisaged for the refinement of the stability constants. The stability constant:

$$\beta = \frac{[Al_aF_b]}{[Al]^a \cdot [F]^b}$$

results from the equilibrium between the flavonoid F and the complex Al_aF_b (without taking into account the protonation state of the ligand):

$$aAl(III) + bF \leftrightarrow Al_aF_b$$

2.4. Quantum chemical calculations

All calculations were performed at the density functional level of theory with the B3LYP hybrid functional

[31,32], using the GAUSSIAN (G03) program package [33]. Geometry optimizations were carried out, without any symmetry constraints, using the 6-31+G(d,p) basis set [34], including polarization functions to correctly take into account intramolecular H-bonding in the ligand. Vibrational frequency calculations have been performed to ensure that all the optimized structures of the free and complexed quercetin correspond to energy minima. The low-lying excited states were treated within the adiabatic approximation of time-dependent density functional theory (DFT-RPA) [35] with the B3LYP hybrid functional. Vertical excitation energies were computed for the first 60 singlet excited states, in order to reproduce the UV–Vis spectra of the free and complexed ligands. As it is well known that UV–Vis absorption spectra are very sensitive to solvent effects, these were introduced by the SCRF method, via the polarized continuum model (IEF-PCM) [36,37] implemented in the GAUSSIAN program, with the default parameters. In the results, only transitions presenting high oscillator strengths (>0.05) have been considered.

3. Results

3.1. 3-Hydroxyflavone

The absorption spectrum of 3HF in a methanol/water 1:1 mixture is characterized by a double band at 343 and 308 nm (band I) and another one at 241 nm (band II). By successive additions of Al(III) to the solution, the intensity of band I of free 3HF decreases gradually, being stabilized

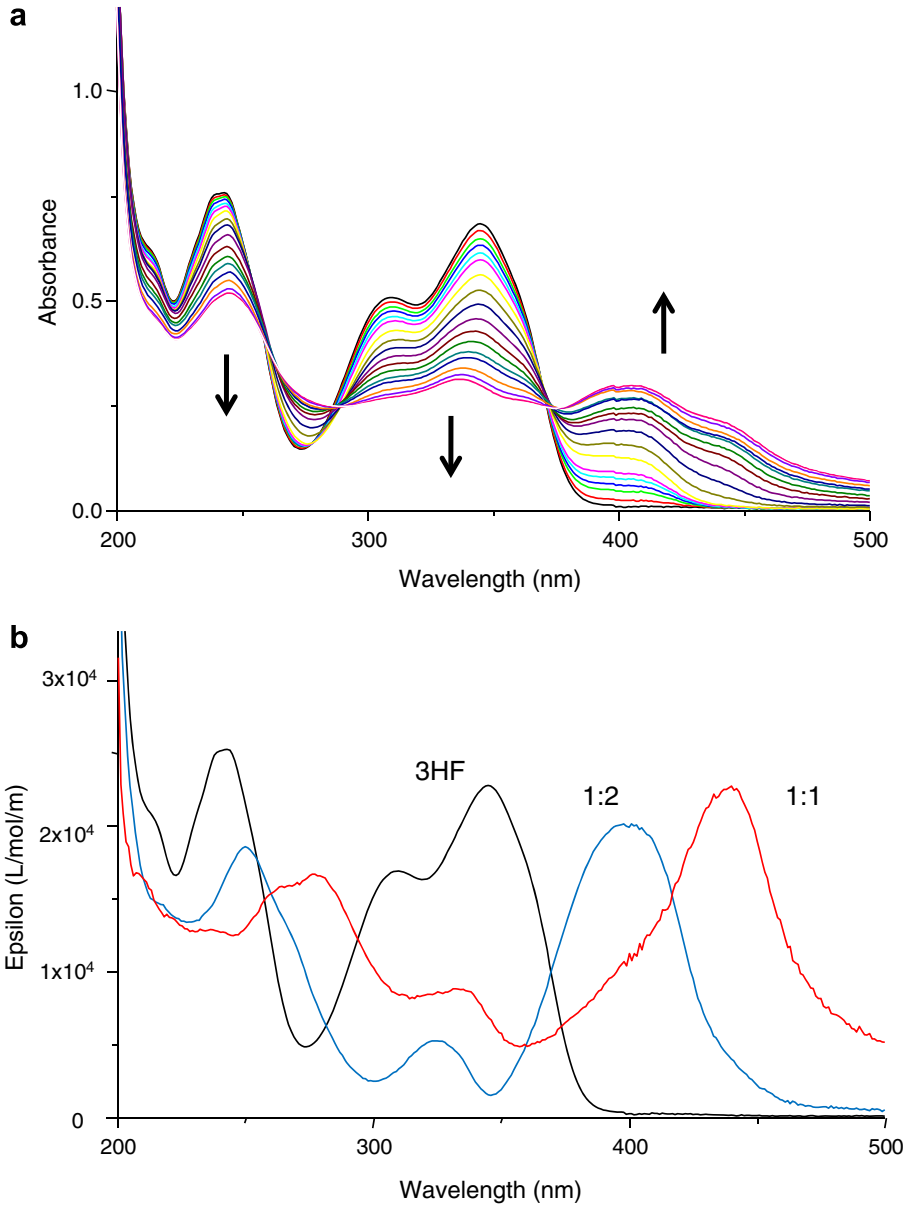

Fig. 2. UV–Vis spectra of 3HF in the absence and in the presence of Al(III). [Al(III)]/[3HF] molar ratios vary from 0 to 2.5 (a) and pure absorption spectra of 3HF, 1:2 and 1:1 complexes in methanol/water mixture (b).

towards a molar ratio of 1.5. At the same time, two new bands appear with wavelengths ranging between 400 and 470 nm (404 and 440 nm), reflecting the formation of at least two complexes (Fig. 2a).

For a relatively significant amount of Al(III) added, the appearance of a continuous background is observed for wavelengths higher than 450 nm, which is due to a scattering phenomenon caused by the beginning of precipitation. The presence of an aluminium hydroxide precipitate can be excluded because the concentrations of Al(III) used in the dosage are too low, but, due to the presence of water, it can be assumed that the solubility of the complexed forms in methanol/water mixture is lower than that of the free ligand, and the precipitation of the second complex is possible when it reaches significant concentrations. Only the spectra that did not present a background were taken into account in the numerical treatment.

The molar ratio method applied to the spectra set shows the formation of three complexes of stoichiometry (metal:-ligand) 1:3, 1:2 and 1:1. The analysis by numerical treatment of the spectra set allows the extraction of only three spectra, corresponding to majority pure species (the free and two complexed forms). The model which allows the best fit with the experimental data shows the predominant presence of the complexes 1:2 and 1:1. The spectra of these species are presented in Fig. 2b. The 1:2 complex spectrum is very similar to that obtained in neat methanol ($\lambda_{max} = 402$ nm), apart from the solvent effects [38], whereas the 1:1 complex spectrum has never been reported in the literature. The values of the formation constants are $\log\beta_{1:2} = 9.91 \pm 0.15$ and $\log\beta_{1:1} = 5.17 \pm 0.12$ for the $[Al(3HF)_2]^+$ and $[Al(3HF)]^{2+}$ complexes, respectively. The complex $[Al(3HF)_3]^0$ must be a minority species, present at a very weak concentration at the beginning of the dosage and it is not highlighted by the numerical treatment.

Fig. 3 presents the variation of the concentrations of the various species during the dosage. For small added quantities of Al(III) ($R < 0.4$) the 1:2 complex is in the majority. From a molar ratio of 0.5, the concentration of the 1:2 complex decreases in favour of 1:1 complex formation. For a molar ratio of 2.5, only 7% of the free ligand remains in solution.

In pure methanol, 3HF also forms a complex of 1:2 stoichiometry on the addition of Al(III), and the 1:3 complex was not detected in this medium [38]. A comparison of the chelating power of 3HF in the two different media shows that Al(III) is more easily complexed in neat methanol than in the presence of water at pH 6. Indeed, for a molar ratio of 1:1, the complexation reaction is complete and less than 10% of free ligand remains in the methanol

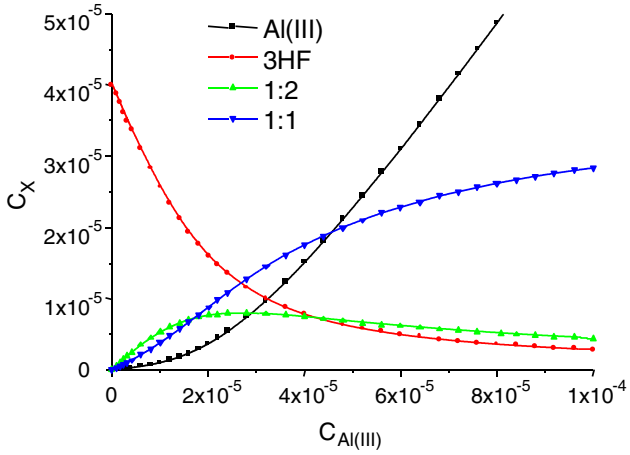

Fig. 3. Distribution curves of the concentration of the aluminium complexes of 3HF as a function of Al(III) concentration.

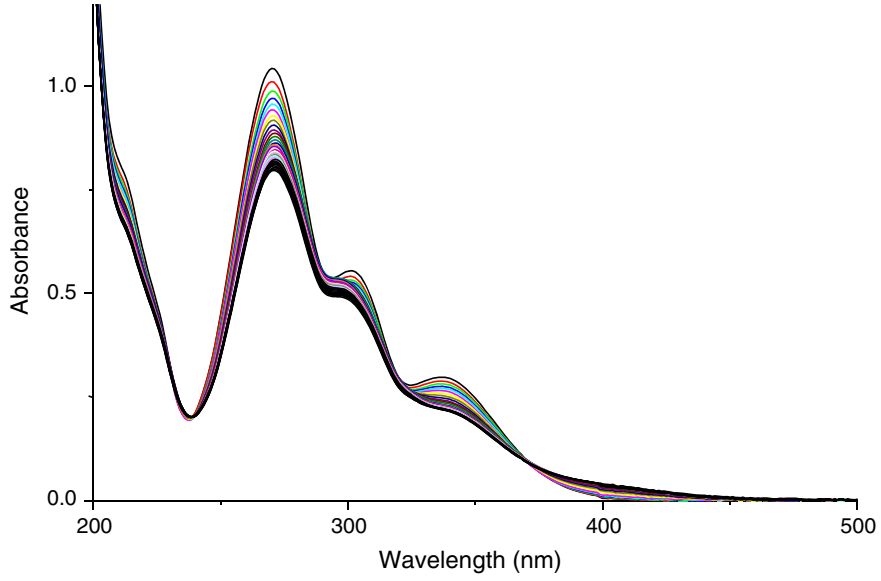

Fig. 4. UV–Vis spectra of 5HF in the absence and in the presence of Al(III). [Al(III)]/[5HF] molar ratios vary from 0 to 2.5.

solution, whereas 20% of free 3HF is still present in the mixed medium at pH 6 for this same ratio.

3.2. 5-Hydroxyflavone

Free 5HF presents an intramolecular hydrogen bond stronger than 3HF, and consequently the complexing power of 5HF is generally weaker than that of 3HF [39].

The spectra set resulting from the complexation of Al(III) by 5HF shows weak variations of the intensity of bands I (339 nm) and II (270 nm) of the free ligand (Fig. 4). A new band of low intensity appears towards 400 nm with the addition of Al(III) and a light hypsochromic effect (4 nm) is observed on the band of 5HF at 300 nm. The presence of an isosbestic point at 370 nm indicates the presence of an equilibrium between the free ligand and one complexed species.

The molar ratio method clearly shows the formation of a species with a 1:2 stoichiometry. The hydroxyl group of the ligand is deprotonated and the formula of the complex is $[Al(5HF)_2]^+$. The computed value of the formation constant of the complex is $\log \beta_{1:2} = 8.37 \pm 0.03$.

In neat methanol, 5HF forms a 1:1 complex with Al(III), with a red shift of 61 and 23 nm for bands I and II, respectively [40]. In $50\%_{aq}$ MeOH, the complex stoichiometry is different, and consequently the absorption spectrum of the 1:2 complex formed in methanol/water differs from the spectrum of the 1:1 complex in pure methanol (a shift of 65 nm of band I and only a few nanometers for band II).

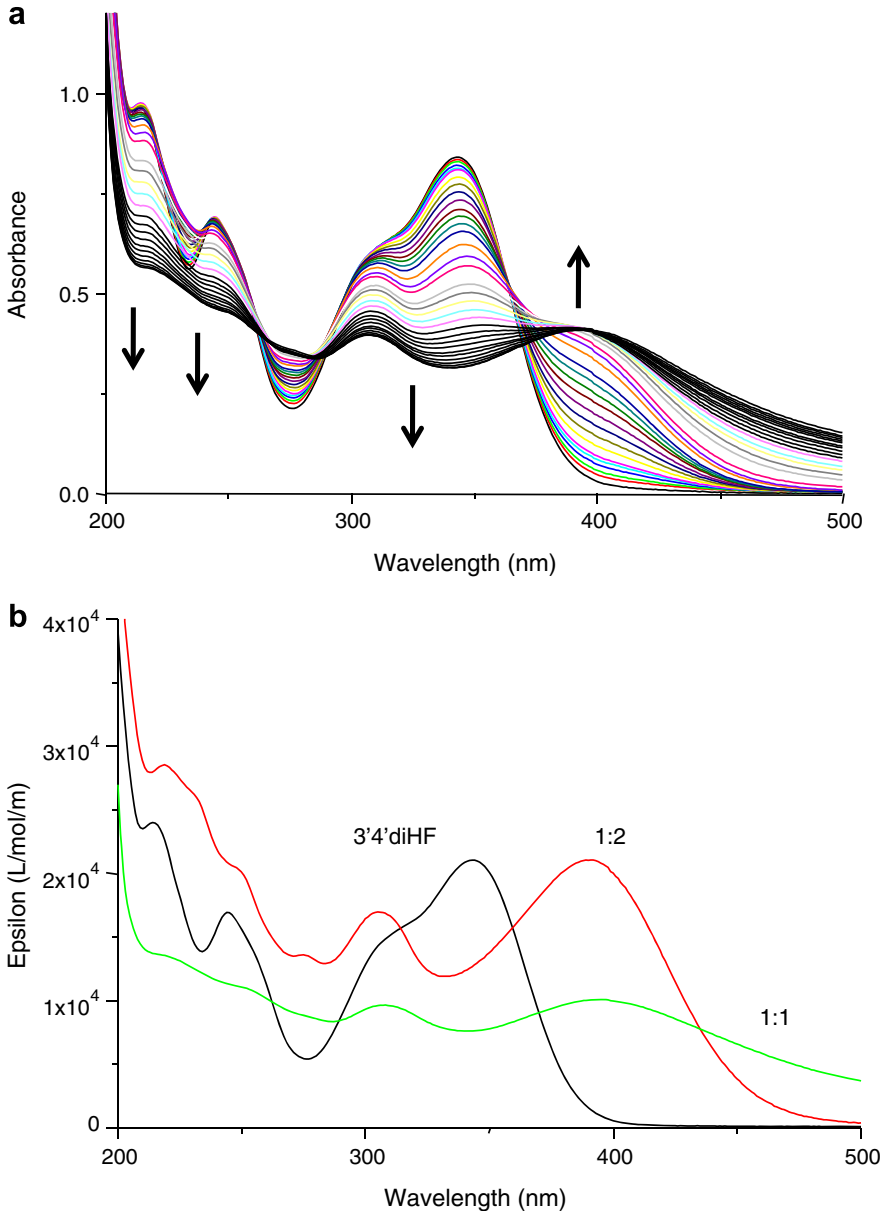

Fig. 5. UV–Vis spectra of 3′4′diHF in the absence and in the presence of Al(III). [Al(III)]/[3′4′diHF] molar ratios vary from 0 to 2.5 (a) and pure absorption spectra of 3′4′diHF, 1:2 and 1:1 complexes in methanol/water mixture (b).

Even if the complex stoichiometry obtained in mixed solvent is higher than that observed in neat methanol, complexation in this last medium is favoured. For instance, for a molar ratio of 2.5, all the ligand is implicated in the formation of the complex in methanol whereas 44% of the free ligand remains in solution in the mixed medium. Al(III) is less complexed by 5HF than by 3HF in the methanol/water mixture, since the quantity of complex measured at the end of the dosage is much smaller. It should be noted that no background appeared on the 5HF data set, which can be explained by the weakest concentration of complex, confirming the assumption of a lower solubility of the complex than that of the ligand in the presence of water.

3.3. 3′,4′-Dihydroxyflavone

The spectrum of 3′4′diHF in methanol/water solution at pH 6 presents a double absorption band at 341–308 nm (band I), a band centred at 243 nm (band II) and a shoulder at 212 nm. The increasing addition of Al(III) metal ions causes the appearance of new bands (Fig. 5a). No isosbestic point is observed throughout the dosage, which indicates the simultaneous formation of several complexes. However, it is difficult to distinguish, in the spectra obtained, the maxima corresponding to distinct complexes. The molar ratio method applied to the experimental data highlights two complexes of stoichiometry 1:2 and 1:1. Numerical analyses made it possible to extract the spectra of the two pure complexes and to obtain the formation constants of $[Al(3'4'diHF)_2]^-$ and $[Al(3'4'diHF)]^+$: $\log\beta_{1:2} = 9.24 \pm 0.07$ and $\log\beta_{1:1} = 4.85 \pm 0.04$.

The spectra of the $[Al(3'4'diHF)_2]^-$ and $[Al(3'4'diHF)]^+$ complexes are very similar, only a slight shift of 4 nm between the absorption band located at high wavelengths for $[Al(3'4'diHF)_2]^-$ (387 nm) and $[Al(3'4'diHF)]^+$ (391 nm) is observed (Fig. 5b). The curves of Fig. 6 illustrate the evolution of the concentration of the different species in solution. Until a molar ratio of 0.3, the $[Al(3'4'diHF)_2]^-$ and $[Al(3'4'diHF)]^+$ complexes are formed simultaneously in the same proportions, for a ratio higher than 0.3 the 1:1 complex becomes predominant. For a molar ratio of 1, 25% of the free ligand remains in the mixed solution. It should be noted that a background towards high wavelengths is observed in the spectra when significant concentrations of Al(III) are added. Once more, this is in agreement with the formation of a complex to a considerable extent, and consequently the beginning of precipitation.

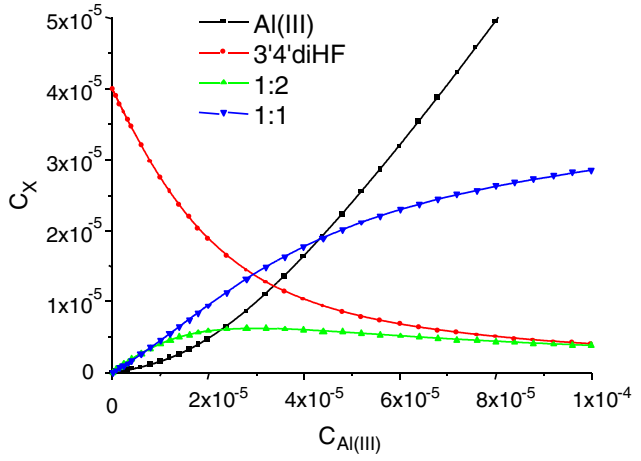

Fig. 6. Distribution curves of the concentration of the aluminium complexes of 3′4′diHF as a function of Al(III) concentration.

In pure MeOH, the formation of a 1:1 complex has been reported [40], and it has been shown that a twofold excess of Al(III) was necessary to obtain a full complexation of 3′4′diHF. Porter and Markham [41] reported the formation of a 1:2 and 1:3 complex in methanol in the presence of potassium acetate and sodium methoxide, respectively. This result shows that an increase in pH, facilitating the deprotonation of the catechol function leads to complexes of a high stoichiometry.

3.4. Comparison of the hydroxyflavones complexation

The principal results obtained previously for the complexation of aluminium(III) by flavonoids in methanol [39], like those obtained at pH 6 in a methanol/water mixed solvent, are joined together in Table 1.

Whatever the ligand, the stoichiometry of the complex formed in pure methanol is lower than that obtained in the methanol/water mixture at pH 6. The complexation of Al(III) is accompanied by the deprotonation of the hydroxyl functions of the ligand, and consequently an increase of pH facilitates this deprotonation and leads to the formation of complexes of higher stoichiometry. This observation was reported on several occasions for similar ligands, which present, in particular, a catechol group [42–44]. In our case, the apparent pH of the pure methanol solution must be lower than 6, and the pure methanol solution must be more "acidic" than the mixed solution of pH 6, which explains the difference in the stoichiometry of the complexes formed in these two media.

Whatever the ligand, for a given quantity of Al(III) added, the percentage of free ligand in the mixed solvent

Table 1
Comparison of the Al(III) complexation by hydroxyflavones in methanol and methanol/water medium

	Methanol			Methanol/water pH 6		
	Al:L	$\Delta\lambda$ (nm)	Logβ	Al:L	$\Delta\lambda$ (nm)	Logβ
3HF				1:3		
	1:2	58	12.3	1:2	61	9.91
				1:1	97	5.17
5HF				1:2	65	8.37
	1:1	61	6.5			
3′4′diHF				1:2	46	9.24
	1:1	43	6.7	1:1	50	4.85

$\Delta\lambda$ is the shift of band I upon complexation.

is always higher than in pure methanol. The complexation of Al(III) is thus more important in neat methanol than in the mixed solvent at pH 6. That has been checked for complexes having identical stoichiometries in the two media, the formation constant of the complex in pure methanol is always higher than that calculated in the mixed solvent. The presence of water inhibits partially the metal cation complexation. The hydration of the cation and/or the free ligand decreases the chelating capacity of the studied functions. Moreover complementary experiments, with constant pH and constant molar ratio, showed that an increase in the percentage of water (from 0% to 50%) in the solution decreased in a significant way the quantity of the formed complexes.

In a given medium, the complexation capacity of the studied chelating sites with respect to the Al(III) ion can be compared. The greater the stoichiometry of the obtained complexes, the more the function is chelating. If two hydroxyflavone complexes have the same stoichiometry, the complex which has the highest formation constant presents the chelating site having the greatest affinity towards the metal cation. Thus for Al(III), one can classify the sites according to their capacity of complexation in the following way:

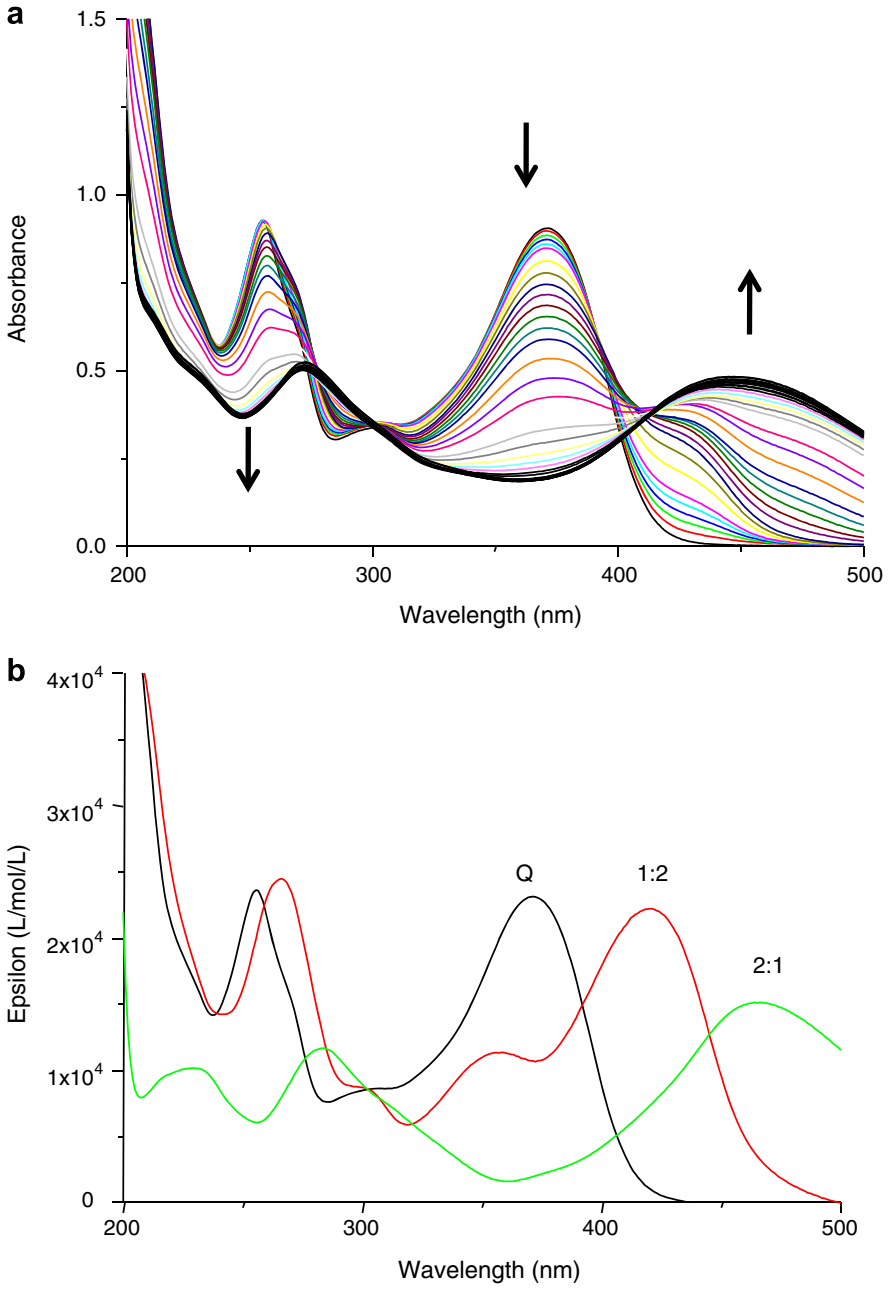

Fig. 7. UV–Vis spectra of Q in the absence and in the presence of Al(III). [Al(III)]/[Q] molar ratios vary from 0 to 2.5 (a) and pure absorption spectra of Q, 1:2 and 2:1 complexes in methanol/water mixture (b).

α-hydroxy − carbonyl > catechol > β-hydroxy − carbonyl

This order is the same in a mixed solvent as in neat methanol. Thus, if the presence of water decreases the chelating power of the hydroxyflavone site, it does not modify the order of the studied functions in their complexing capacity towards Al(III).

3.5. Complexation of Al(III) by a multi-binding site flavonoid

Q presents the three complexing sites (α-hydroxy-carbonyl, β-hydroxy-carbonyl and catechol) in competition towards the Al(III) fixation.

The electronic spectrum of free quercetin in methanol/water solution exhibits two major absorption bands: the band I lies at 370 nm and the second one is located at 253 nm (band II) with a shoulder at 265 nm (Fig. 7a). Upon addition of Al(III) to the quercetin solution, significant changes are observed in the electronic spectra. The intensity of band I decreases and a new band appears around 420 nm. From a molar ration higher than 0.3, the maximum of this band shifts towards longer wavelengths and a broad absorption band is observed around 450 nm. The set of obtained spectra does not clearly show an isosbestic point, which would mean that several complexes are simultaneously formed. The molar ratio method was used to determine the stoichiometry of the different complexed forms of quercetin with Al(III). The molar ratio plots at different wavelengths clearly indicate the formation of complexes of stoichiometry 1:3, 1:2 and 2:1.

From the UV–Vis absorption spectra, a finer determination of the number of different absorbing species was estimated by evolving factor analysis. Only three distinct components were found, corresponding to free quercetin and two complexes with 1:2 and 2:1 stoichiometries, and temporarily noted AlQ_2 and Al_2Q, respectively. To estimate the stability constants, a numerical treatment of the electronic spectra has been carried out with a model implicating the two complexes. The best fitting model to the experimental data gives the following stability constants: $\log\beta_{1:2} = 9.55 \pm 0.11$, and $\log\beta_{2:1} = 10.22 \pm 0.16$ for the AlQ_2 and Al_2Q complexes, respectively. Once more, the numerical analysis could not highlight the presence of the 1:3 complex. This complex must exist in a very weak concentration at the beginning of the dosage.

The pure electronic spectra of AlQ_2 and Al_2Q (Fig. 7b) present an absorption maximum at 420 and 464 nm, respectively. The 1:2 complex, where only one preferential site is implied, is formed in a great quantity at the beginning of the dosage, and its concentration reaches a maximum for a molar ratio of 0.5 (Fig. 8). Even if the 2:1 complex appears relatively rapidly in solution on metal cation addition (for a molar ratio of ~0.1), this one is formed in a lesser proportion. The fact that the second complexation site is involved also quickly shows that

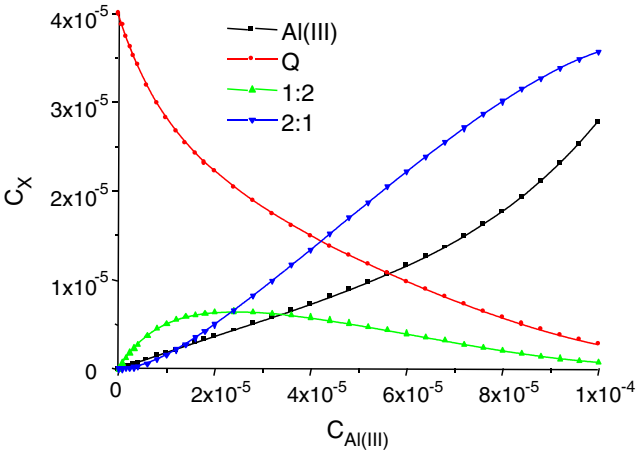

Fig. 8. Distribution curves of the concentration of the aluminium complexes of Q as a function of Al(III) concentration.

the two chelating functions, in competition within Q, have relatively close capacities of Al(III) fixing. However, for weak metal concentrations, compared to the number of potential complexation sites within the ligand, only one site is implied in AlQ_2 and one can reasonably think, on the basis of the results obtained previously with the mono-site flavonoids, that only the catechol and 3-hydroxy-carbonyl functions are in competition in the complex formation.

To determine which of these sites is involved in Al(III) fixation, the theoretical absorption spectra of the various possible complexed forms have been calculated. Firstly, the structures of $[Al(H_2O)(OH)Q_2]^0_\alpha$ and $[Al(H_2O)(OH)Q_2]^{2-}_{cat}$, corresponding, respectively, to complexation with the α-hydroxy-carbonyl and catechol function, were optimized at the B3LYP/6-31+G(d,p)/IEF-PCM level of theory. A water molecule and a hydroxyl ion have been added to the Al atom to complete its valence. The presence of the hydroxyl ion makes it possible to take into account the pH of the medium, since under the experimental conditions the $[Al(H_2O)_5(OH)]^{2+}$ species is predominant in aqueous solution. It should be noted that the two complexes do not have the same charge insofar as the number of deprotonations occurring with Al(III) chelation is different according to the site. Then, from these optimized structures, the electronic transitions were calculated by TD-DFT. For each complex, several stable conformers exist, their structures depending on the respective orientation of the ligands. These conformers present very similar theoretical electronic spectra, and this makes it impossible to differentiate them. In Fig. 9, the calculated absorption spectra of $[Al(H_2O)(OH)Q_2]^0_\alpha$ and $[Al(H_2O)(OH)Q_2]^{2-}_{cat}$, represented in the form of a vertical line corresponding to the absorption wavelength, can be compared with the spectrum of AlQ_2, obtained by fitting the experimental data. The theoretical spectra of $[Al(H_2O)(OH)Q_2]^0_\alpha$ and $[Al(H_2O)(OH)Q_2]^{2-}_{cat}$ present a very great number of calculated transitions, and both are likely to reproduce the absorption bands observed in the

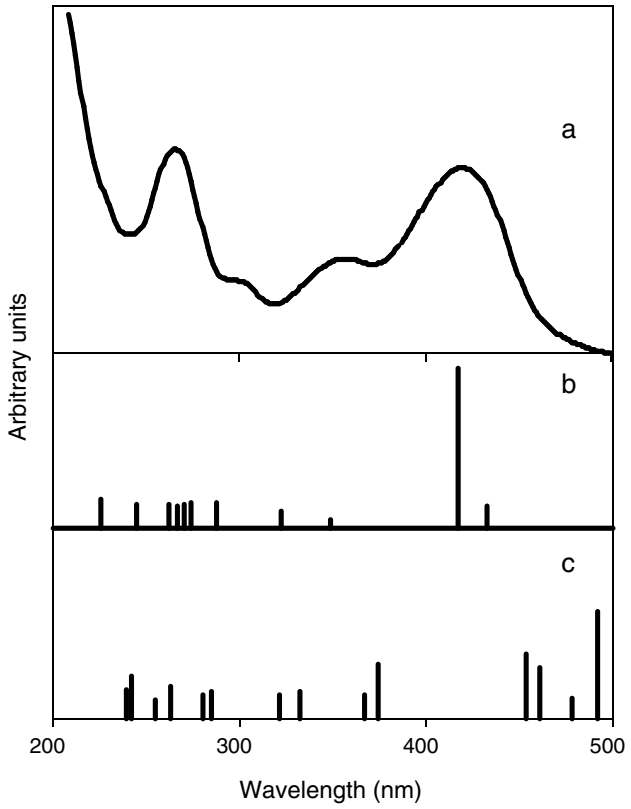

Fig. 9. Experimental spectrum of the 1:2 complex of Q (obtained by the EFA method) (a) and theoretical spectra of $[Al(H_2O)(OH)Q_2]^0_\alpha$ (b) and $[Al(H_2O)(OH)Q_2]^{2-}_{cat}$ (c).

UV range. The band observed at 420 nm in the experimental spectrum is reproduced perfectly in the theoretical spectrum of $[Al(H_2O)(OH)Q_2]^0_\alpha$ (417 nm), while no transition calculated for the complex $[Al(H_2O)(OH)Q_2]^{2-}_{cat}$ makes it possible to explain this absorption. The good agreement between the experimental features and theoretical spectrum of $[Al(H_2O)(OH)Q_2]^0_\alpha$ ensures that the fixing of Al(III) with Q is done via the α-hydroxy-carbonyl function. This function was that which presented the most important complexing capacity with respect to Al(III) in the study of the mono-site flavonoids. This result obtained with Q shows that the classification obtained for the mono-site ligands is preserved when these different sites are in competition within the same structure.

For reasons of steric hindrance, after the first site involving the carbonyl function in the formation of the AlQ_2 complex, it could be envisaged that the catechol group is the second fixing site in Al_2Q, whose formula would be $[Al_2(H_2O)_6(OH)_2Q]^+$. A comparison of these results with those obtained for the system Al(III)–quercetin in neat methanol shows that the same mechanism is observed whatever the solvent [12,14,45]. But once more, the presence of water in solution reduces the quantity of the formed complexes. The α-hydroxy-carbonyl group of Q also presents the highest affinity for the Zn(II) cation in the hydro-organic solvent [46].

4. Conclusion

This study made it possible to establish a classification of three chelating sites of flavonoid compounds towards Al(III) in a methanol/water medium, at pH 6. This classification is the same as that obtained in pure methanol, namely the α-hydroxy-carbonyl group presents the greatest affinity with respect to Al(III). Nevertheless the presence of water in the medium decreases the chelating power of all the studied sites. Combined spectroscopic and theoretical approaches have been used to determine the preferential complexing site of quercetin that presents the three investigated sites in competition. The results show that the α-hydroxy-carbonyl site remains the most powerful for Al(III) fixation.

If it is not possible to obtain structural information on the studied system using electronic absorption spectroscopy alone, the last part of this paper shows that when it is associated to the techniques of quantum chemistry, it is possible to elucidate a complexation mechanism.

scales, respectively, may be observed [4–11]. In addition, ^{113}Cd and ^{199}Hg NMR have been used as metallobioprobes for characterization of a variety of metal-substituted proteins [12–16].

Previously, we have reported solid- and solution-state characterization of group 12 metal ion bis-tridentate chelate complexes with symmetric pyridine-containing ligands bis(2-methylpyridyl)amine ($\mathbf{L}^1$) [8,9], bis(2-methylpyridyl)sulfide ($\mathbf{L}^2$) [5] and 2,6-bis(methylthiomethyl)pyridine ($\mathbf{L}^3$) [4]. Conditions for slow intermolecular change were found for dilute solutions of these complexes in acetonitrile-d_3. In this paper, the synthesis and characterization of $M(ClO_4)_2$ (M = Zn(II), Cd(II), Hg(II)) complexes of the non-C_2 symmetric ligand *N*-(2-pyridylmethyl)-*N*-(2-(methylthio)ethyl)amine (**L**) are reported. X-ray crystallography revealed homologous *trans* facial octahedral $[M(\mathbf{L})_2](ClO_4)_2$ complex structures. In dilute acetonitrile-d_3 solutions, each complex was in slow intermolecular exchange even at elevated temperatures. Furthermore, $[M(\mathbf{L})_2]^{2+}$ are the first group 12 bis-tridentate chelates for which conditions favoring slow intramolecular isomerization have been accessible in acetonitrile-d_3. These results are discussed in the context of the nine regular polyhedral forms of bis-tridentate chelate complexes.

2. Experimental

2.1. Methods and materials

Solvents and reagents were of commercial grade and used as received unless otherwise stated. Elemental analyses were carried out by Atlantic Microlab Inc., Norcross, Georgia. *J* values are given in Hz. *Caution!* All the perchlorate salts of metal complexes included in this work were stable for routine synthesis and purification procedures. However, organic perchlorates are potentially explosive and should be handled with care [17].

2.2. Solution-state NMR spectroscopy

Proton NMR spectra were collected in 5 mm o.d. NMR tubes on a Varian Mercury 400VX NMR spectrometer operating in the pulse Fourier transform mode. Calibrated autopipets were used to prepare nominally 2 mM solutions for variable temperature NMR measurements by dissolution of elementally analyzed complexes. The sample temperature was maintained by blowing chilled nitrogen over the NMR tube in the probe. Proton chemical shifts were measured relative to internal solvent but are reported relative to tetramethylsilane (TMS).

2.3. X-ray crystallography

Selected crystallographic data are given in Tables 1 and 2. Data were collected on a Siemens P4 four-circle diffractometer using a graphite-monochromated Mo Kα X-radia-

tion ($\lambda = 0.71073$ Å). During data collection three standard reflections were measured after every 97 reflections. The structures were solved by direct methods and refined on F^2 by full-matrix least squares using the SHELXTL 97 program package [18,19]. All non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were refined as riding atoms with relative displacement parameters.

2.4. Synthesis of N-(2-pyridylmethyl)-N-(2-(methylthio)ethyl)-amine (*L*)

The ligand was prepared by adaptation of procedures for related ligands [20]. A solution of 2-chloroethyl methyl sulfide (2.4 mL, 24 mmol) in 20 mL deionized water was cooled to 0 °C in an ice bath. To this solution was added slowly with stirring a solution of 2-(aminomethyl)pyridine (2.1 mL, 20 mmol) in 35 mL methylene chloride. The mixture was then allowed to warm to room temperature. Over a 48 h period, 12 mL of 2 M NaOH was added by syringe pump. The crude mixture was washed with 40 mL of 4 M NaOH. The organic phase was dried with sodium sulfate and filtered. Removal of methylene chloride yielded a brown liquid. Fractional vacuum distillation yielded **L** as a colorless oil (94 °C/0.05 mmHg, 1.8 g, 49%). (*Anal.* Calc. for $C_9H_{14}N_2S$ requires: C, 59.3; H, 7.7; N, 15.4. Found: C, 58.0; H, 7.8; N, 15.0%) ^{1}H NMR (CD_3CN, −40 °C): δ 2.02 (3H, s, H_i), 2.62 (2H, t, J_{HH} 7, H_h), 2.73 (2H, t,J_{HH} 7, H_g), 3.83 (2H, s, H_f), 7.23 (1H, dd, J_{HH} 5,7, H_b), 7.37 (1H, d, J_{HH} 8, H_d), 7.72 (1H, dt, J_{HH} 2,8, H_c), 8.51 (1H, d, J_{HH} 5, H_a).

2.5. Preparation of $Zn(L)_2(ClO_4)_2 \cdot H_2O$ (*1a*)

A solution of $Zn(ClO_4)_2 \cdot 6\,H_2O$ (190 mg, 0.50 mmol) in 3 mL acetonitrile was added to a solution of **L** (190 mg, 1.0 mmol) in 3 mL methanol with stirring. Pale pink crystals of **1a** (105 mg, 32.5%) suitable for X-ray crystallography were obtained in 5 mm glass tubes after a week by slow diffusion of the mixture into benzene. M.p.: 188–189 °C. (*Anal.* Calc. for $C_{18}H_{30}Cl_2N_4O_9S_2Zn$ requires: C, 33.4; H, 4.7; N, 8.7. Found: C, 33.4; H, 4.7; N, 8.8%) ^{1}H NMR (2 mM, CD_3CN, 60 °C): δ 1.92 (3H, s, H_i), 2.74 (2H, bs, H_h), 2.96 (2H, bs, H_g), 4.05 (1H, bs, H_f), 4.22 (2H, bs, H_e), 7.60 (1H, dd, J_{HH} 5, 8, H_b), 7.65 (1H, d, J_{HH} 8 Hz, H_d), 8.14 (1H, dt, J_{HH} 1, 8, H_c), 8.21 (1H, bs, H_a).

2.6. Preparation of $Cd(L)_2(ClO_4)_2 \cdot H_2O$ (*1b*)

A solution of $Cd(ClO_4)_2 \cdot 6H_2O$ (210 mg, 0.50 mmol) in 3 mL acetonitrile was added to a solution of **L** (190 mg, 1.0 mmol) in 3 mL methanol with stirring. Small, colorless crystals of **1b** (70 mg, 20 %) suitable for X-ray crystallography were obtained in 5 mm glass tubes after a week of slow diffusion into toluene. M.p.: 163–165 °C. (*Anal.* Calc. for $C_{18}H_{30}CdCl_2N_4O_9S_2$ requires: C, 31.15; H, 4.4; N, 8.1%. Found: C, 31.3; H, 4.3; N, 8.1.) ^{1}H NMR (2 mM, CD_3CN, 20 °C): δ 1.98 (3H, s, H_i), 2.55 (1H, bs, H_g), 2.79 (2H, bs, H_h), 3.26 (1H, bs, $H_{g'}$), 3.66 (1H, bs, H_f), 4.06 (1H, bs, H_e), 4.27 (1H, bs, $H_{e'}$), 7.54 (1H, dd, J_{HH} 5,8, H_b), 7.60 (1H, d, J_{HH} 8, H_d), 8.08 (1H, dt, J_{HH} 1, 8, H_c), 8.15 (1H, bs, H_a).

2.7. Preparation of the complex $Hg(L)_2(ClO_4)_2$ (*1c*)

A solution of $Hg(ClO_4)_2 \cdot 3H_2O$ (230 mg, 0.50 mmol) in 3 mL acetonitrile was added to a solution of **L** (190 mg, 1.0 mmol) in 3 mL methanol with stirring. Colorless small crystals of **1** (48 mg, 13%) suitable for X-ray crystallography were obtained in 5 mm glass tubes after 6 days of slow diffusion into benzene. M.p.: 101–102 °C. (*Anal.* Calc. for $C_{18}H_{28}Cl_2HgN_4O_8S_2$ requires C, 28.3; H, 3.7; N, 7.3. Found: C, 28.2; H, 3.6; N, 7.3%.) ^{1}H NMR (2 mM, CD_3CN, 60 °C): δ 2.10 (3H, s, H_i), 2.92 (2H, bt, H_h), 3.07 (2H, bs, H_g), 4.03 (1H, bs, H_f), 4.26 (2 H, s, J_{HgH} 70, H_e), 7.53 (1H, dd, J_{HH} 4, 8, H_b), 7.56 (1H, d, J_{HH} 8, H_d), 8.04 (1H, dt, J_{HH} 2,7, H_c), 8.27 (1H, d, $J = 4$, H_a).

3. Results

3.1. Crystal structures of $M(L)_2(ClO_4)_2$ complexes

Complexes $[Zn(\mathbf{L})_2](ClO_4)_2 \cdot H_2O$ (**1a**), $[Cd(\mathbf{L})_2](ClO_4)_2 \cdot H_2O$ (**1b**) and $[Hg(\mathbf{L})_2](ClO_4)_2$ (**1c**) contain $[M(\mathbf{L})_2]^{2+}$ dications (Figs. 2–4) and well-separated perchlorate anions. These are the first structurally characterized complexes of divalent zinc triad metal ions with an $N_4(SR)_2$ coordination sphere involving a non-C_2 symmetric ligand. Selected crystallographic data for complexes **1a**–**1c** are given in Table 2. All three $[M(\mathbf{L})_2]^{2+}$ cations have *trans* facial octahedral geometry with the metal ion as an inversion center within a rectangular basal plane formed by the four nitrogen donor groups. Each pair of ligand nitrogens forms a pseudo-envelope chelate ring with the alkyl amino nitrogen on the flap (Fig. 1a). Complexes **1a** and **1b** are isostructural and isomorphous, containing twisted conformation *N*,*S* chelate rings with the ethylene carbons out of the plane formed by the other atoms (Fig. 1b). In contrast, these chelate rings have a pseudo-envelope conformation in **1c** with the ethylene carbons closest to S on the flaps (Fig. 1c).

3.2. Crystal structure of $Zn(L)_2(ClO_4)_2H_2O$ (**1a**)

Seven structurally characterized complexes of Zn(II) with a $N_4(SR)_2$ coordination sphere have been reported [5,21–25]. Complex **1a** contains a $[Zn(\mathbf{L})_2]^{2+}$ cation (Fig. 2), two perchlorate anions and a non-coordinated water molecule. The ligands have $N_{pyridyl}$–N_{alkyl}–S angles of 66.4°. The planes formed by the coordinating atoms from each of the individual ligand are 2.88 Å apart. The methyl groups are oriented toward the opposing ligand in the crystal structure.

The intraligand S–M–N_{alkyl} and N_{alkyl}–M–$N_{pyridyl}$ bond angles of 84.15(5)° and 79.80(5)° are closer to 90° than those observed for **1b** and **1c** in which the metal ions are larger. Shorter M–N and M–S distances are observed in complex **1a** than **1b** and **1c** as expected for the smaller zinc ion. The Zn–$N_{pyridyl}$ distance of 2.1059(19) Å is normal for six coordinate Zn(II) complexes [5,26–29]. The Zn–N_{alkyl} distance of 2.1773(17) Å is within the range (2.07–2.229 Å) reported for $N_4(SR)_2$ Zn(II) complexes. The Zn–S bond distance of 2.5978(13) Å is in the known range for six-coordinate thioether-containing complexes of Zn(II) [5,23,25,30].

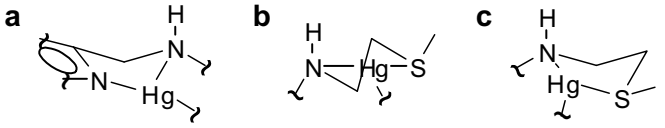

Fig. 1. Schematic diagrams of chelate ring conformations in complexes **1a**–**c**. (a) Psuedo-envelope *N*,*N* chelate ring in all three complexes with N_{alkyl} out of plane formed by other atoms. (b) Twisted *N*,*S* chelate ring in **1a** and **1b**. (c) Psuedo-envelope *N*,*S* chelate ring in **1c** with C8 out of plane formed by other atoms.

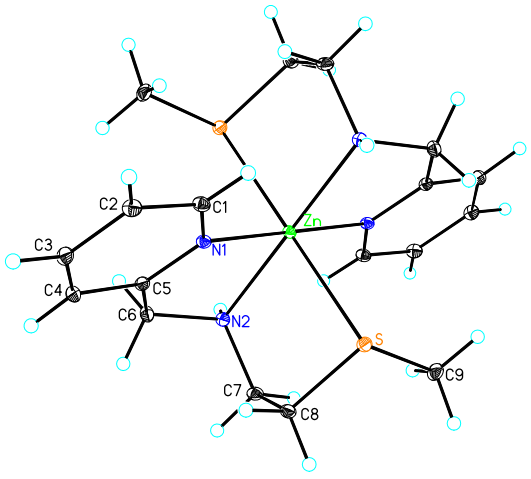

Fig. 2. Structure of $Zn(\mathbf{L})_2^{2+}$ in **1a**. Thermal ellipsoids shown at 50% level.

3.3. Crystal structure of $Cd(L)_2(ClO_4)_2 \cdot H_2O$ (**1b**)

Similar to complex **1a**, complex **1b** consists of a $[Cd(\mathbf{L})_2]^{2+}$ cation (Fig. 3), two perchlorate anions and a non-coordinated water molecule. Distorted octahedral $[Cd(\mathbf{L}^3)_2](ClO_4)_2$ is the only other structurally characterized Cd(II) complex with a $N_4(SR)_2$ coordination sphere [4]. The ligands in **1b** have $N_{pyridyl}$–N_{alkyl}–S angles of 69.1° forming coordinating atom planes that are 3.25 Å apart. The methyl groups are oriented toward the opposing ligand in the crystal structure as observed in **1a**.

The intraligand S–M–N_{alkyl} and N_{alkyl}–M–$N_{pyridyl}$ bond angles of 80.24(4)° and 74.38(5)° are somewhat smaller in complex **1b** than in complex **1a**. The Cd–$N_{pyridyl}$ distance of 2.3132(17) Å is comparable to those (2.266–2.442 Å) found in pyridine-containing six-coordinate Cd(II) complexes [5]. The Cd–N_{alkyl} distance of 2.3826(17) Å resembles those found in the six coordinate complex $[Cd(TAT)](ClO_4) \cdot 0.5H_2O$ (TAT = 1,4,7-tris(*o*-aminobenzyl)-1,4,7-triazacyclononane) [31]. The Cd–S distance of 2.7115(7) Å is similar to other six coordinate thioether Cd(II) complexes [5,30,32].

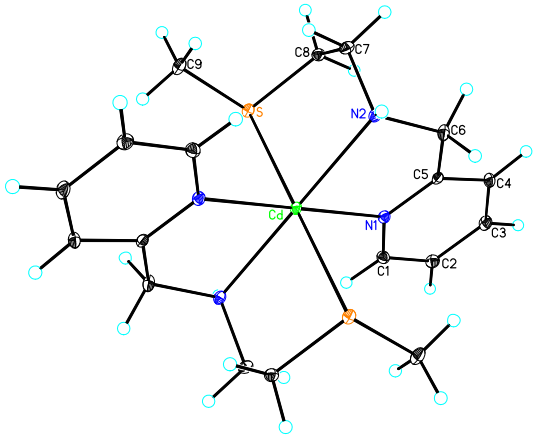

Fig. 3. Structure of $Cd(\mathbf{L})_2^{2+}$ in **1b**. Thermal ellipsoids shown at 50% level.

3.4. Crystal structure of $Hg(L)_2(ClO_4)_2$ (1c)

Complex **1c** (Fig. 4) is the third structurally characterized complex of Hg(II) with a $N_4(SR)_2$ coordination sphere [4,33]. The other two complexes have significantly more trigonal prismatic coordination geometry, however in solution bis-tridentate chelates of divalent zinc triad metal ions typically exhibit exchange between as many as nine geometric isomers [9]. The ligands have $N_{pyridyl}$–N_{alkyl}–S angles of 77.8°, significantly larger than both **1a** and **1b**. The coordinated ligand atoms form planes that are 3.19 Å apart, further apart than **1a** but closer than **1b**. Unlike the complexes of the smaller metal ions, the methyl groups are oriented away from the opposing ligand in the crystal structure of **1c**.

Complex **1c** has intraligand S–Hg–N_{alkyl} and N_{alkyl}–Hg–$N_{pyridyl}$ bond angles of 80.41(7)° and 73.26(8)°, respectively, which are very close to the bond angles observed for **1b**. The 2.424(2) Å Hg–$N_{pyridyl}$ distance is comparable to those observed in other six coordinate Hg(II) complexes including $[Hg(\mathbf{L}^1)_2](ClO_4)_2$, [9] $[Hg(\mathbf{L}^3)_2](ClO_4)_2$ [4] and $[Hg(pyridine)_6](CF_3SO_3)_2$ [34]. The 2.305(2) Å Hg–N_{alkyl} distance is slightly shorter than the range of 2.37(2)–2.473(11) Å observed in the six coordinate complexes $[Hg(TAT)](ClO_4)_2 \cdot 0.5H_2O$ [31] $[Hg(TDO)](PF_6)_2$ (TDO = 1,4,10, 13-tetrathia-7,16-diazacyclooctadecane) [35] and $[Hg([9]aneN_2S)_2](HgBr_4)$ ([9]aneN$_2$S = 1-thia-4,7-diazacyclononane) [33]. In contrast, the Hg–S bond distance of 2.7989(13) Å is slightly longer than the previously reported range of 2.458–2.751 Å for six coordinate Hg(II) complexes involving thioether donors [5,33].

3.5. Solution state investigation of L coordination to divalent zinc triad metal ions

The solution state coordination chemistry of bis-tridentate chelates of **L** with divalent zinc triad perchlorates was studied in acetonitrile-d_3 using variable temperature ^{1}H NMR spectroscopy. The NMR samples were prepared from elementally analyzed, X-ray quality crystalline materials, creating samples with well defined metal-to-ligand mole ratios. The labeling scheme for the protons of **L** is provided in the introduction.

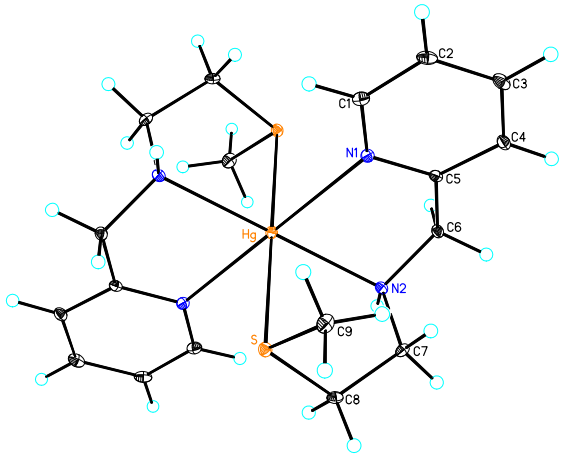

Fig. 4. Structure of $Hg(\mathbf{L})_2^{2+}$ in **1c**. Thermal ellipsoids shown at 50% level.

The proton NMR spectra of **1a**–**c** were qualitatively similar with severely broadened resonances for H_a, H_e, H_g and H_h at 20 °C (Fig. 5). Cooling to −40 °C had previously generated slow intermolecular exchange conditions on the J_{HH}, J_{CdH} and J_{HgH} time scales for related complexes [4,5,8,9]. Although the proton NMR spectra of **1a**–**c** lacked evidence for J_{CdH} or J_{HgH} interactions at −40 °C, they were surprisingly complex. Resonances for H_b, H_c and H_d changed little upon cooling. In contrast, extensive geminal coupling of the methylene and ethylene protons appeared for all three complexes indicating the ligands remained tridentate on the J_{HH} time scale [8,9]. Furthermore, major and minor environments were evident for some ligand protons. For example, the doublet with J_{HH} 5 Hz for H_a appeared at approximately 8.4 and 8.0 ppm in the minor and major environments, respectively, placing an upper limit of approximately 15 ms on their rate of exchange. Neither H_a environment grew in relative intensity following addition of excess ligand or metal salt to the samples (data not shown). As will be elaborated in the discussion, the simplest explanation for these observations is slow intramolecular exchange between isomeric bis-tridentate chelate forms.

Further proton spectra for these samples were collected at 20 °C intervals up to 80 °C (Fig. 5). Resonances were generally observed to broaden and coalesce as the temperature was raised until there were only nine ligand proton resonances. The coalescence temperature for the various peaks increased in the order Zn(II) > Cd(II) > Hg(II). Interestingly, the major H_a resonance for **1a** originally got sharper as the temperature was raised. To determine whether additional exchange processes could be frozen out at lower temperature, a 2 mM solution of **1a** in acetone-d_6 was prepared. The proton NMR of **1a** was qualitatively similar at −40 °C in the two solvents (data not shown). Unfortunately, further cooling of the acetone-d_6 solution to −90 °C resulted in broadening to extinction, foiling efforts to better characterize the species contributing to the major environment (data not shown). Further analysis of the H_a chemical shifts of $[M(\mathbf{L})_2]^{2+}$ as a function of temperature indicated near temperature independence for the minor resonance observed at low temperature, as expected for a single species. In contrast, the major resonance shifted significantly with temperature, consistent with an exchange equilibrium occurring on a submillisecond time scale. As a result, detailed quantitative analysis of the spectra for calculation of activation energies or accurate exchange rates is precluded.

Significantly, J_{HgH} 70 Hz involving H_e was observed for dilute solutions of **1c**, but only at elevated temperatures between 40 and 80 °C. Comparable magnitude coupling interactions between H_g and ^{199}Hg were also evident but

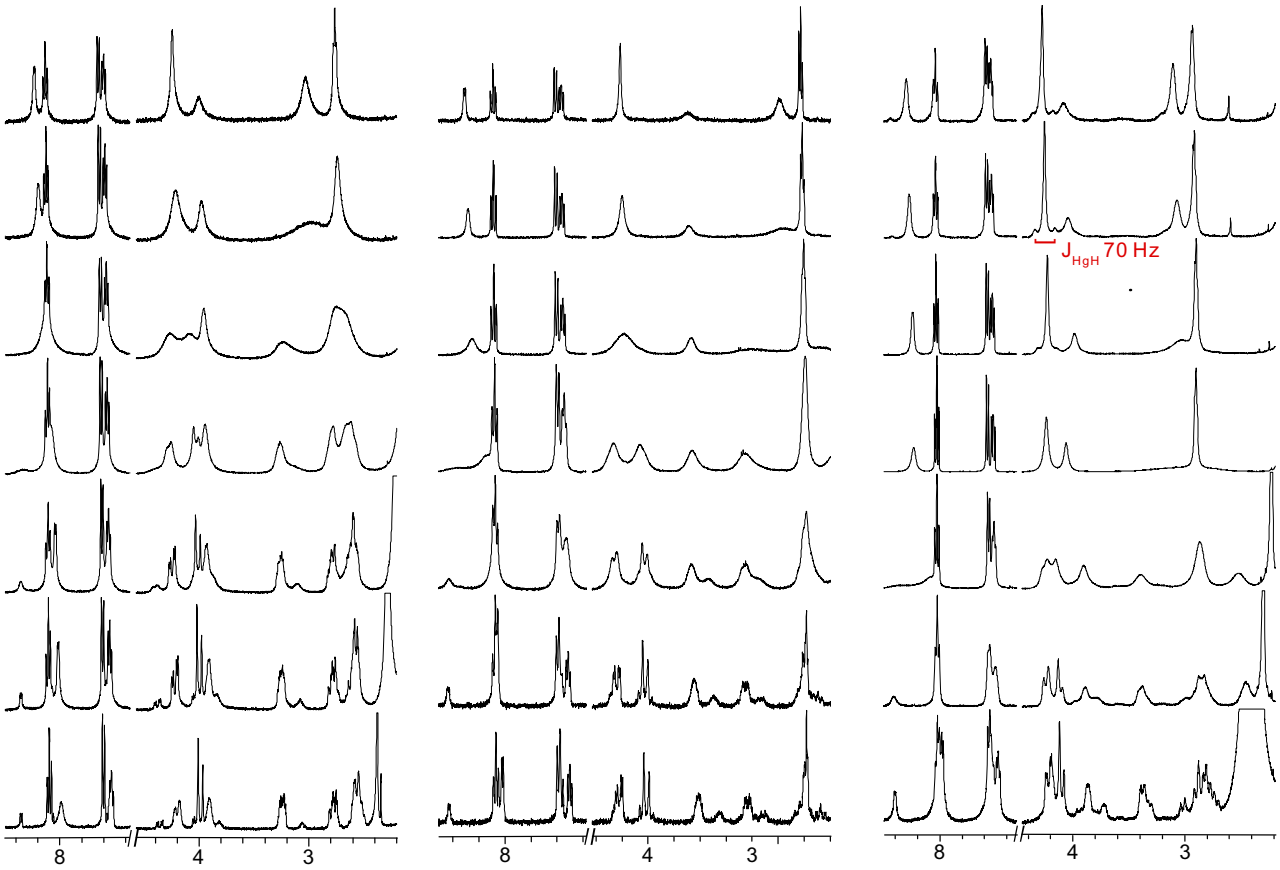

Fig. 5. Variable temperature proton NMR spectra highlights: nominally 2 mM CD_3CN solutions of **1a** (left), **1b** (center) and **1c** (right) at (from top) 80, 60, 40, 20, 0, −20 and −40 °C.

poorly resolved. Notoriously rapid intermolecular exchange processes are commonly associated with coordination complexes of Hg(II). Heteronuclear coupling between ^{199}Hg and ligand protons provides definitive evidence for slow intermolecular exchange. These coupling interactions indirectly suggest the ligands remain tridentate on the coupling constant time scale, since J_{HgH} have not been reported between ^{199}Hg and bidentate nitrogen or N,S donor ligands. Furthermore, this interaction was not observed in a more concentrated solution of **1c** (data not shown), likely because intermolecular exchange processes became more rapid. Significant broadening of resonances was observed for **1c** in dilute solution at 80 °C, suggesting intermolecular exchange at an appreciable rate. In contrast, resonances for **1a** and **1b** were still getting progressively sharper as the upper temperature limit for studies in acetonitrile-d_3 was approached.

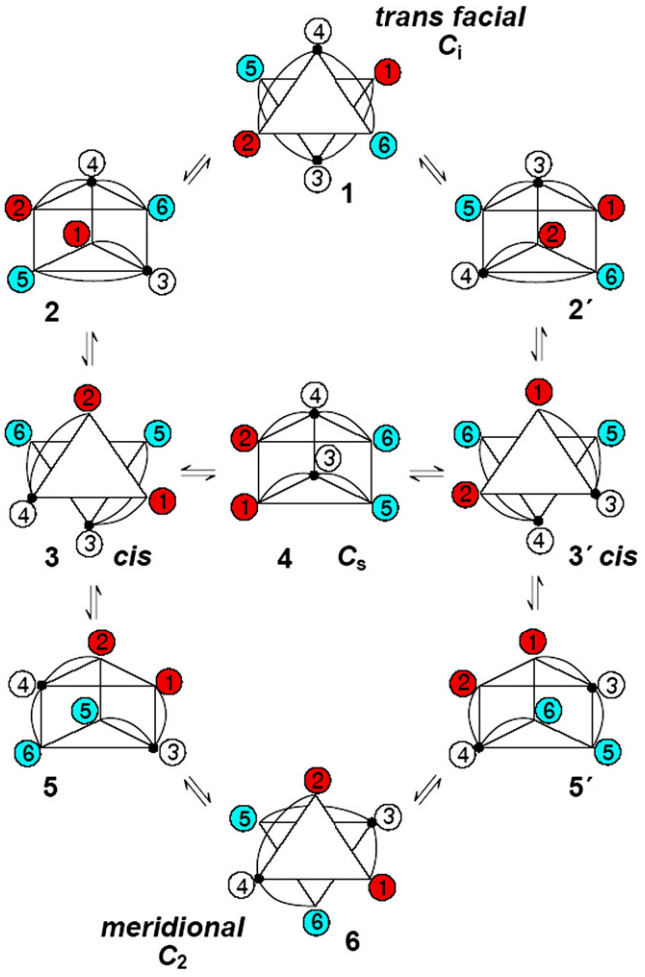
4. Discussion

Detailed investigation of the coordination chemistry of divalent zinc triad metal ions is generally hampered by plasticity in coordination number and geometry, which leads to rapid intramolecular isomerization and intermolecular exchange rates. A variety of multidentate ligands have been used to create complexes with slow intermolecular exchange behavior on the NMR chemical shift and coupling constant time scales. Multidentate ligands have also provided group 12 coordination complexes in which different types of intramolecular exchange behavior was amenable to detailed characterization. Published studies have documented ligand-centered isomerization processes with no metal coordination changes [36] and slow intramolecular isomerization involving either changes in coordination number or identity of ligating atoms [10,37–39]. In addition, exclusion of specific geometric isomers from solution equilibria has been observed [8,9]. However, to the best of our knowledge only the novel $N_4(SR_2)_2$ coordination sphere divalent zinc triad metal ion complexes investigated here have enabled any characterization of individual geometric isomerization processes without cleavage of metal–ligand bonds.

Bis-tridentate chelates have nine regular polyhedral isomeric forms [9]. A mechanism for concerted isomer interconversion without bond cleavage is depicted in Fig. 6, patterned after the mechanism for racemization of tris-bidentate complexes described by Rodger and Johnson [40]. In this model, the terminal ligating atoms form 60° or 90° angles, respectively, around the central ligating atom in **1**–**4** and **5**–**6**. Polyhedra **1**–**4** can be interconverted, ostensibly without ligand reorganization, by rotation about a single pseudo-C_3 axis perpendicular to the planes formed

by the ligating atoms of the individual ligands. Polyhedra **3**–**6** can be interconverted by rotation about an orthogonal pseudo-C_3, but both ligand reorganization and changes in the relative orientation of the ligating atom planes occur. Repulsion-energy calculations have predicted octahedral isomers **1**, **3**, and **6** to be associated with potential energy minima [41]. Calculations with updated methodologies have not been identified.

Another hurdle to detailed characterization of the coordination chemistry of divalent zinc triad metal ions is the limited number of applicable instrumental methods. X-ray crystallography provides detailed bond lengths and bond angles, but these solid state measurements cannot be assumed to provide a complete description of solution species. Both kinetic and thermodynamic factors determine what crystallizes and crystallizes first from a mixture in solution and can favor isolation of minor solution species. All three divalent zinc triad metal ion complexes of type $M(\mathbf{L})_2(ClO_4)_2$ were isolated in bis-tridentate chelate form **1**. In contrast, bis-tridentate chelates of other pyridyl ligands have crystallized in different forms, and not necessarily the same form for all three metals (Table 3).



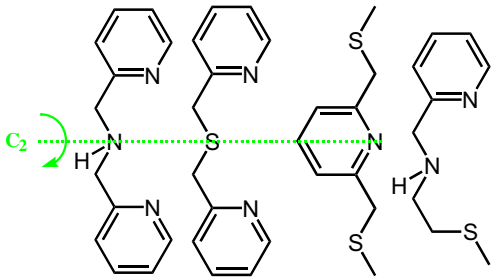


Fig. 6. Model of concerted isomerization for asymmetric bis-tridentate chelates involving regular polyhedral forms.

Crystallization documents the presence of a complex with a particular structure in solution, but not its relative abundance. Furthermore, correlations between crystallographic and solution state methods have to be made especially carefully with divalent zinc triad metal ions in the context of the facility with which they normally undergo intramolecular isomerization and intermolecular exchange.

NMR is one of the most valuable solution methods for characterization of divalent zinc triad metal ion complexes of organic ligands because chemical shift, coupling constant and exchange time information can be collected simultaneously for selected nuclei. Furthermore, both cadmium and mercury have high natural abundance spin $I = 1/2$ isotopes. In the absence of coincidental chemical shifts and exchange processes faster than the chemical shift time scale in solution, the symmetry of complexes of form **1** and **4** would lead to a singlet methyl proton resonance and one discrete resonance for every other ligand proton. Similarly, asymmetric complexes of form **2**, **3** and **5** would have two singlet methyl proton resonances and discrete resonances for every other proton of both ligands. In contrast, complex **6** is a higher symmetry form with four pyridyl proton resonances, three methylene proton resonances and one methyl resonance expected. Either coincident chemical

[c] Major and minor resonances were resolved for H_a only.
[d] More than three major and three minor methylene proton resonances were observed.

shifts or exchange rates faster than the chemical shift time scale can reduce the number of discrete proton resonances observed.

The proton NMR spectra of **1a**–**c** were strongly temperature dependent. At low temperature, extensive geminal coupling of methylene proton resonances provided definitive evidence for slow intermolecular exchange and preservation of all metal-ligand bonds. Even more significant were protons giving rise to two resonances in slow exchange on the chemical shift time scale of inequivalent intensity for all three metals. Detection of independent sets of ligand resonances for $[M(\mathbf{L})_2]^{2+}$ supports slow intramolecular geometric isomerization between bis-tridentate chelate forms on the NMR chemical shift time scale.

Structural and chemical shift considerations can be used to generate initial form assignments for the major and minor ligand environments observed in low temperature NMR experiments. Interligand steric interactions are anticipated to be greater in trigonal prismatic forms **2**, **4** and **5** than the octahedral complexes. However, in previous studies of bis-tridentate chelates the differences were not great enough to observe slow exchange between individual octahedral and trigonal prismatic forms [4,5,8,9]. Strong geminal coupling of the methylene protons of $\mathbf{L}^1$ provided evidence that form **6** was excluded from the solution equilibria between all or most of the other $[M(\mathbf{L}^1)_2]^{2+}$ forms at low temperature [8,9]. Similarly, geminal coupling is evident for both minor and major $[M(\mathbf{L})_2]^{2+}$ ligand environments observed at low temperature, leaving forms **1** and **3** as their most likely assignments.

Although some ligand protons only had one well-resolved resonance at −40 °C, for H_a there were two resonances with an approximate 0.4 ppm chemical shift differences. A difference of this magnitude is often induced by interactions with the ring current of opposing ligands in bis-chelates [8,9,11,42]. Significantly, the enantiomeric **3** and **3′** forms have the pyridyl rings in close proximity where interactions could occur between them while form **1** does not. Based on this analysis, the minor low temperature species with H_a resonance only slightly upfield of free ligand at ~8.4 ppm is assigned to form **1**, which has C_i symmetry and one environment for each proton type. Assignment of the major ligand environment at ~8.0 ppm to chiral enantiomeric forms **3** and **3′** then follows, but requires either widespread unresolved chemical shift differences or a rapid exchange process on the chemical shift time scale for the two ligands.

Significantly, for $Zn(\mathbf{L})_2^{2+}$ the fairly sharp major ~8.0 ppm H_a resonance observed below 0 °C began to broaden as the temperature approached −40 °C, suggesting an exchange process was approaching the slow exchange limit. Unfortunately, while the proton spectra of $[Zn(\mathbf{L})_2]^{2+}$ were qualitatively similar in acetone-d_6 and CD_3CN solutions at −40 °C, further cooling of the acetone-d_6 sample resulted in broadening to extinction (data not shown). A suitable NMR solvent with lower freezing point could not be found. Since the slow exchange limit could not be reached for these H_a environments, neither the number of exchanged average species nor their NMR parameters could be readily determined experimentally. Given evidence for an exchange process, interconversion of complexes with forms **3** and **3′** through form **4** becomes an attractive hypothesis. Significantly, the interconversion of **3** and **3′** became rapid on the chemical shift time scale at a higher temperature for $Zn(\mathbf{L})_2^{2+}$ than for the complexes involving larger metal ions and larger interligand separations.

Proposing involvement of a complex with trigonal pyramidal form **4** in low temperature equilibria, but not complexes with forms **2**, **2′**, **5** and **5′**, requires further comment. Examination of space filling crystal structure diagrams for **1a**–**1c** suggested that the *trans* facial orientation permitted the smallest interligand separation (Figs. S1–3). In structures **1a** and **1b**, for example, the thioether methyls extended more than halfway across the space between the donor atom planes associated with the two ligands. The opposing ligand had H_b of the pyridyl rings in distant opposition with the thioether methyl and aliphatic amine hydrogen blocking rotation in either direction. As a result, rotating through trigonal planar forms **2** and **2′** would require energetically demanding lengthening of many metal–ligand bonds. In contrast, form **4** has equivalent donor groups eclipsed and therefore has the potential to alter the angle between the planes formed by the donor atom. The energetic cost of lengthening a pair of M–L bonds can then be offset by shortening another pair without ligand reorganization. This model can also explain why the exchange rate between forms **3** and **3′** approaches the chemical shift time scale for Zn(II) but not its larger congeners. The distance separating the parallel donor atom planes of the two ligands is smaller for Zn(II) and interligand steric constraints would become significant with lesser deviations from parallel. As mentioned earlier, forms **5** and **5′** formally require increasing the N(1)–N(2)–S angle from 60° to 90°. The necessary ligand reorganization and requisite M–L bond stretches likely create an energy barrier that cannot be overcome on the chemical shift time scale at low temperature.

Thus, the simplest explanation for the low temperature proton NMR spectra of **1a**–**1c** is slow exchange on the chemical shift time scale between a complex of form **1** and an equilibrated form involving **3**, **3′** and **4** (or a variant with non-parallel donor atom planes). Assuming the concentration of the form most resembling **4** is modest compared to octahedral forms **3** and **3′**, the relative size of the two H_a peaks in the low temperature spectra suggests the stabilities of the three octahedral forms are comparable but form **1** is slightly less thermodynamically stable with all three metal ions. This is consistent with the conclusions of repulsion-energy calculations for bis-tridentate chelates of asymmetric ligands [41]. As the temperature is increased, exchange with the other complexes becomes possible,

particularly **6**, which allows exchange of methylene protons and collapses geminal coupling.

This model is fully consistent with the observed zinc triad metal ion coordination behavior of symmetric tridentate ligands $\mathbf{L}^1$, $\mathbf{L}^2$ and $\mathbf{L}^3$ (Table 3). Differences in the nature of the central donor atom of these ligands typically impact speciation equilibria at temperatures approaching −40 °C. Slow inversion at the secondary aliphatic amine excludes form **6** from low temperature equilibria for $M(\mathbf{L}^1)_2^{2+}$[8,9]. In contrast, thioethers have a much lower barrier to inversion and $M(\mathbf{L}^3)_2^{2+}$ had no detectable geometric preferences [5]. For $M(\mathbf{L}^3)_2^{2+}$, ligand geometry suggests form **6** is preferred, although rapid exchange between multiple forms including form **6** could not be distinguished [4].

Interestingly, the bis-tridentate chelates of symmetric ligands had readily detected J_{HgH} and smaller J_{CdH} at low temperature for pyridyl and methylene protons (Table 3). These complexes were either in rapid intramolecular exchange on the chemical shift time scale or non-exchanging. Rapid intramolecular isomerization with preservation of bonding interactions leads to exchange averaged coupling constants. On the other hand, slow exchange on the chemical shift time scale for major and minor forms of $M(\mathbf{L})_2^{2+}$ led to chemical shift differences of 0.4 ppm for H_a. Isomer interconversion at a rate which is slow relative to the chemical shift time scale but intermediate on the J_{MH} time scale for $Hg(\mathbf{L})_2^{2+}$ and $Cd(\mathbf{L})_2^{2+}$ would explain the absence of metal coupling satellites in low temperature proton NMR spectra.

In this study, samples that had exchange broadened NMR spectra at room temperature were also examined at higher temperature, resulting in coalescence and significant sharpening of some resonances. For $Hg(\mathbf{L})_2^{2+}$, J_{HgH} 70 Hz with H_e was measurable at 40 °C and notably broadened at 80 °C. In addition, less distinct J_{HgH} with H_g was evident between 60 and 80 °C. At these temperatures, the intramolecular isomerization between bis-tridentate forms **1**–**6** has become rapid enough for exchange averaged chemical shifts and coupling constants to be observed. Increasing the sample concentration increased the rate of intermolecular exchange and obscured the J_{HgH} interactions. Although comparable J_{CdH} interactions were not observed for $Cd(\mathbf{L})_2^{2+}$, their typically smaller magnitude and the comparable chemical shift behavior for all three zinc triad bis-tridentate chelates suggests that intermolecular exchange was slow even at elevated temperatures. Interestingly, exchange broadening of resonances has been observed for other bis-tridentate chelates at ambient temperature [9]. Spectra were never taken at higher temperature to possibly distinguish between intramolecular and intermolecular exchange processes as the source of broadening.

5. Conclusions

An asymmetric tridentate ligand permitted more detailed comparisons of the coordination chemistry of divalent group 12 metal ions to be made than related symmetric ligands. Fortuitous crystallization of isostructural bis-tridentate zinc triad complexes allowed for detailed structural comparisons. Unfortunately, the properties of the crystallized complexes were incompatible with assignment to the predominant solution species at −40 °C and prospects for crystallizing additional species associated with the complex solution equilibria are limited.

These studies suggest the resilience of high coordination number divalent zinc triad metal ion complexes to intermolecular exchange may be obscured by intramolecular exchange processes. These findings need to be thoughtfully considered when designing experiments to probe the bioactivity differences of Zn(II), Cd(II) and Hg(II).

Fig. 1. Structural formulae of dioxovanadium(V) complexes with deprotonated 1:1 condensation products of (*S*,*S*)-(−)-1,2-diphenyl-1,2-diaminoethane and of (*R*,*R*)-(+)-1,2-diphenyl-1,2-diaminoethane with salicylaldehyde and its derivatives. The numbers without the alphabetical symbol denote complexes with ligands derived from (*S*,*S*)-(−) configurated diamine, but those which are "r" signed denote complexes with ligands derived from (*R*,*R*)-(+) configurated diamine.

between chiral β-aminoalcohols and salicylaldehydes [10], hydroxybinaphtylcarbaldehydes [11] and hydroxybiphenylcarbaldehydes [12]. Vanadium complexes bearing tridentate Schiff base ligands derived from amino acid and amino acid esters [13] and the reported by us very recently dioxovanadium(V) complexes with the monobasic tridentate Schiff base ligands that were synthesized by 1:1 condensation of chiral 1,2-diaminocyclohexane with aromatic *o*-hydroxycarbonyl compounds [14] are catalysts in mediated oxidation of prochiral sulfides to enantiometrically enriched sulfoxides. To our best knowledge, the vanadium complexes with 1:1 condensation products between hydroxycarbonyl compounds and chiral diamines that possess primary amino groups bound to asymmetric carbon atoms were reported to date only in one paper [14]. To continue exploring structural and electronic effects of chiral dioxovanadium(V) complexes applied in asymmetric catalysis we report here the synthesis, spectroscopic characterization, efficiency in mediated asymmetric sulfide oxidation of a series of dioxovanadium(V) complexes comprising coordinated single condensation products of (*S*,*S*)-(−)-1,2-diphenyl-1,2-diaminoethane and (*R*,*R*)-(+)-1,2-diphenyl-1,2-diaminoethane with aromatic *o*-hydroxyaldehydes along with the X-ray structure analysis carried out on one representative complex. Structural formulae of the synthesized compounds with omitted solvated water molecules are displayed in Fig. 1.

2. Experimental

2.1. Abbreviations

To avoid in the discussion part lengthy systematic names of ligands, the abbreviation HpnSal was used for the referred single condensation product of salicylaldehyde with 1,2-diaminopropane [15] and HMepnSalXY, HchxnSalXY for single condensation products of the XY-substituted salicylaldehydes with 1,2-diamino-2-methylpropane [16] and 1,2-diaminocyclohexane [14], respectively. HchxnNaph denotes the single condensation product of 1-hydroxy-2-acetonaphthone.

2.2. Measurements

Carbon, hydrogen and nitrogen contents were determined on a Carlo Erba MOD 1106 elemental analyzer. FTIR spectra of solid samples (KBr pellets) were run on a Brucker IFS 66, and electronic spectra on the Perkin–Elmer LAMBDA 18 spectrophotometer. ^1H and ^{51}V NMR spectra were obtained in DMSO-d_6 solutions with a Varian Mercury-400BB (400 MHz) spectrometer using TMS (^1H) and $VOCl_3$ (^{51}V) as reference compounds. Chro-

matography was carried out with a Hewlett–Packard 1050 chromatograph.

2.3. X-ray investigations

Diffraction measurements were made on an Xcalibur PX kappa-geometry diffractometer with CCD Onyx camera (graphite monochromatized Cu Kα radiation $\lambda = 1.5418$ Å) and determination of unit cell parameters was performed according to established procedures. Intensities were recorded at 120(2) K. Data collection and processing parameters are summarized in Table 1. The structure of $(\mathbf{4} \cdot H_2O)_2$ was solved by direct methods using SHELXS-97 [17]. All non-hydrogen atoms in the molecule were subjected to anisotropic refinement [18]. The hydrogen atoms of Schiff base ligand were generated geometrically (C_{ar}–H, C_{en}–H and N–H fixed at 0.95, 1.00 and 0.92 Å, respectively) and were allowed to ride on their parent atoms. They were included along with hydrogen atoms of water molecules in structure factor calculations with assigned isotropic thermal parameters. Analysis utilizes the 2003 version of the program PLATON [19].

2.4. Catalytic oxidation of sulfides

A DMSO solution containing a dioxovanadium(V) Schiff base complex (4×10^{-5} mol) and cumene hydroperoxide (4×10^{-3} mol) was stirred for 5 h at 20 °C. To the resulting yellow solution thermostated to 20 °C methyl phenyl sulfide (4×10^{-4} mol) was added. The kinetics of the oxidation reaction was investigated by high performance chromatography. Samples of the reaction mixture were withdrawn at intervals and then analyzed with a Hewlett–Packard 1050 chromatograph equipped with a Shimadzu C-R4A Chromatopack area peak calculator and with a Kromasil-100 C-8 column (Knauer GmBH, Germany) using acetonitrile–water (4:6 v/v) as eluent. Chromatography was carried out with a flow rate of 1 ml min^{-1} and the components were detected with a UV Detector ($\lambda = 254$ nm). The enantiomeric excesses (ee) were determined either from the specific rotation at 589 nm of the sulfoxide isolated by chromatographic elution or by measurement of intensities of ^{1}H NMR signals of sulfoxide in the presence of chiral shift reagent Eu(hfc)$_3$. In order to perform the latter procedure the sample (10 ml) withdrawn from of the reaction mixture was poured in the 40% aqueous solution (30 ml) of sodium bisulfite and the resulting suspension was extracted several times with methylene chloride. The collected extracts were dried over sodium sulfate, filtered and evaporated to dryness under diminished pressure. The solid product dissolved in $CDCl_3$ was analyzed by ^{1}H NMR in the presence of chiral shift reagent.

2.5. Complexes

Ten dioxovanadium(V) complexes incorporating 1:1 condensation products of chiral 1,2-diphenyl-1,2-diaminoethane and aromatic *o*-hydroxyaldehydes were prepared according to the following synthetic procedure. A solution of 10 mmol of (*S*,*S*)-(−)-1,2-diphenyl-1,2-diaminoethane or (*R*,*R*)-(+)-1,2-diphenyl-1,2-diaminoethane in absolute ethanol was added under stirring to a freshly filtered solution of triethyl vanadate (10 mmol) in 250 ml of absolute EtOH [15] producing a dark suspension of the intermediate. An aromatic *o*-hydroxyaldehyde (salicylaldehyde, 3-methoxysalicylaldehyde, 5-methoxysalicylaldehyde, 4,6-dimethoxysalicylaldehyde, 5-methylsalicylaldehyde, 5-bromosalicylaldehyde, 5-nitrosalicylaldehyde, 2-hydroxy-1-naphthaldehyde) dissolved in absolute EtOH was added to the aforementioned suspension. After refluxing of the resulting mixture for 2 h and its cooling to room temperature the separated solids were filtered off, washed several times with EtOH, recrystallized from DMSO–EtOH mixtures and dried over molecular sieves.

3. Results and discussion

A series of dioxovanadium(V) complexes with singly condensed chiral 1,2-diphenyl-1,2-diaminoethane and aromatic *o*-hydroxycarbonyl compounds were prepared by the same procedure that was used to prepare V(V) complexes with other singly condensed diamines following the strategy of Root et al. [15]. The complexes were obtained in high yields. Their analytical data summarized in Section 2 are consistent with their Fig. 1 formulation. Complex **4** crystallizes from ethanol after one month at room temperature yielding crystals of $(\mathbf{4} \cdot H_2O)_2$ suitable for X-ray diffraction studies.

3.1. Crystal and molecular structure of $(\mathbf{4} \cdot H_2O)_2$

An ORTEP diagram of **4** is shown in Fig. 2 and important bond lengths and angles are collected in Table 2. The structure indicates that each vanadium atom is six-coordinated, while both V29–O31A and V29–O31 distances of 2.370(2) Å and 2.415(2) Å, respectively, are considered as V–O bond lengths like the 2.427 Å V–O distance in $[VO_2(pnSal)]_2$ [15]. It may be noted that the PLATON program [19] does not handle the longest V–O approach (2.415 Å) as a coordination since it describes V29A as five-coordinate. The vanadium atoms V29 and V29A are joined together through two oxygen bridges, O31 and O31A being the bridging atoms coordinated to vanadium atoms at short and long distances [V29–O31 = 1.675(2) Å; V29A–O31 = 2.413(3) Å; V29–O31A = 2.370 (2) Å; V29A–O31A = 1.678(2) Å]. The coordination sphere around each vanadium atom is composed of phenolate oxygen atoms (O7 or O7A) and of primary amine nitrogen atom (N16 or N16A) occupying axial positions and of imine nitrogen atom (N13 or N13A), two strongly coordinated terminal oxo (O30, O31 or O30A, O31A) and one weakly associated oxo group (O31A or O31) derived from the neighbouring VO_2 unit defining the equatorial plane; symbols in parentheses written before the conjuction "or" refer to the coordination sphere of V29, those behind it to that around V29A. The polyhedron that describes the quadrilateral core consisting of the non-centrosymmetric V_2O_2 unit and the spatial arrangement of remaining coordinated atoms resembles two edge shared octahedrons that are significantly distorted. The V29═O30 and V29A═O30A bond lengths of 1.622(2) and 1.619(3) Å, respectively, compare well with the distances between vanadium and the doubly bonded oxygen atoms, which do not participate in bridging, reported for $[VO_2(pnSal)]_2$ [15] and VO_2(MepnSalXY) (X = 4-OMe, Y = 6-OMe) [16] complexes. The V29–O31 and V29A–O31A bonds (average 1.677 Å) are longer than V29–O30 and V29A–O30A bonds (average 1.621 Å) by 0.056(4) Å due to involvement of O31 and O31A atoms in V29–V29A bridging and hydrogen

bonding interactions with water molecules (*vide infra*). The V29–V29A distance of 3.204(2) Å is somewhat shorter than the V(V)–V(V) distance of 3.222 Å found in $[VO_2(pnSal)]_2$ [15]. The O30–V29–O31 and O30A–V29A–O31A angles of 106.85(12)° and 107.37(12)°, respectively, indicate significant double bond character of these bonds [20] and are close to other *cis*-VO_2 units [21]. Both six-membered chelate rings assume a non-typical conformation since two atoms of each ring (vanadium and imine nitrogen) are out the plane defined by remaining four non-hydrogen atoms, their displacements in Å from the respective C_3O planes being: 0.791(7) for V29; 0.196(7) for N13; −0.967(6) for V29A and −0.283(6) for N13A. The two five-membered chelate rings adopt envelope conformations which are differently puckered. The ring defined by V29, N13, C14, C15, N16 chooses an envelope conformation on C15, the asymmetric carbon atom attached to the amino nitrogen while the other, formed by V29A, N13A, C14A, C15A, N16A takes the envelope conformation on C14A, the asymmetric carbon atom linked to the imine nitrogen. Fig. 3 shows that the crystal structure of $(\mathbf{4}\cdot H_2O)_2$ is stabilized by intermolecular hydrogen bonds linking dimeric molecules both directly by N–H···O interactions and indirectly through water molecules giving rise to O···H–O–H···O chain formation. The remaining hydrogen atoms of NH_2 groups are involved in intramolecular interactions linking the N16 atom to the phenolate oxygen O7A and the N16A atom to both O7 and O31 forming a tricenter hydrogen bond. In addition, there are relatively close intramolecular contacts between O10, O10A, the oxygen atoms of the 6-OMe phenyl ring substituents, and the methine hydrogens bonded to C12 and C12A, respectively. These distances are collected in Table 2. In contrast to $(\mathbf{4}\cdot H_2O)_2$ the solid VO_2(MepnSalXY) (X = 4-OMe, Y = 6-OMe) [16] and VO_2(chxnNaph) [14], which bear similar ligands and contain mononuclear species, have no hydrogen bonds linking the NH_2 nitrogen of one species with the phenolate oxygen of the other species. This may imply that hydrogen bonds stabilize the dimeric species in solid $(\mathbf{4}\cdot H_2O)_2$ essentially.

3.2. Spectroscopic properties of complexes

The electronic, circular dichroism, NMR spectral data and selected solid-state infrared spectral data are listed in Section 2. Strong C=N stretch (around 1630 cm^{-1}) indicates the C=N group of the coordinated Schiff base ligands [22,23]. The *cis*-dioxo nature of **1**–**6**, **8** complexes is evidenced by two V=O stretching vibrations one in the 924–935 cm^{-1} and the other in the 855–865 cm^{-1}

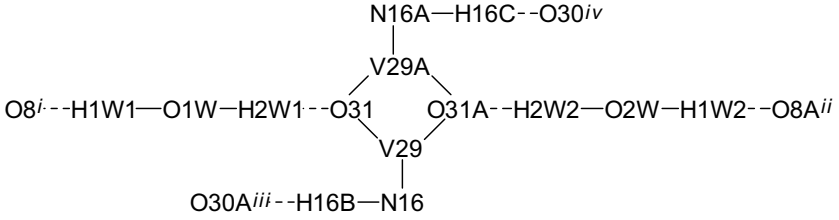

Fig. 3. Schematic representation of intermolecular hydrogen bonds in $(\mathbf{4}\cdot H_2O)_2$.

ranges which are close to V=O vibrations reported for related VO_2–Schiff base complexes [24]. Infrared spectrum of anhydrous **7** reveals two V=O stretching bands above 900 cm^{-1} (at 904 and 917 cm^{-1}) as the reported spectra of VO_2(bispyridineimine ligand) complexes (at 926 and 949 cm^{-1} and also at 918 and 953 cm^{-1}), which in the solid state do not show intermolecular interaction *via* O-bridges [25]. Since the variation of V=O stretching frequencies indicates differing strengths and/or different lengths of V=O bonds [24] its value of 13 cm^{-1} (917–904 cm^{-1}) for **7** compared with 74.5 cm^{-1} (928.3–853.8 cm^{-1}) for **4** suggests for the former compound a considerably smaller difference between V=O bond lengths within the VO_2 unit than that of 0.053(4) Å known from X-ray diffraction studies of $(\mathbf{4}\cdot H_2O)_2$. Moreover, the IR spectrum of **7** reveals two sharp bands at 3307.6 and 3254.8 cm^{-1} arising from the ν_{as} and ν_sN–H modes of the NH_2 group, respectively, and a very strong absorption band at 1318.8 cm^{-1}, corresponding to the presence of the nitro group. The stretching vibrations of OH groups in **1**–**6**, **8** complexes giving rise to medium bands in the range 3417–3108 cm^{-1} are in agreement with the microanalysis data as they support the presence of water molecules in composition of complexes. The appearance of weak/medium band near 2830 cm^{-1} separate from other C–H stretching vibrations in **2**, **2r**, **3**, **3r**, **4** complexes indicates the presence of the methoxy substituents [26].

The electronic absorption spectra recorded for **1**–**3**, **5**, **6**, **8** complexes dissolved in DMSO exhibit two absorption bands one in the 260–281 nm range ($\log\varepsilon_{max} = 4.4 - 4.3$) assigned to π–π* transition of an aromatic ring and the other in the 379–413 nm range ($\log\varepsilon_{max} = 3.6$) attributed to ligand-to-metal charge transfer band overlapped by π–π* transition encompassing the azomethine chromophore. The spectra of **4**, **7**, **8** complexes examined in the same spectral region display single bands in the 320–354 nm region ($\log\varepsilon = 4.4 - 4.3$) having in the case of **8** and **4** shoulders at around 310 nm ($\log\varepsilon_{max} = 4.0$) and at 370 nm ($\log\varepsilon_{max} = 3.7$), respectively. Circular dichroism spectra of **2**, **2r** and **4** complexes revealed an additional band at 280–300 nm which was not resolved in ordinary absorption spectrum. In contrast to the CD spectra of **1**, **3**–**8** the CD spectra of **2** and **2r** complexes reveal small bisignated couplets centered at about 330 nm (Fig. 4), arising probably due to weak exciton coupling between chromophores undergoing electronic transition near 330 nm. Bosnich [27] assigned the positive-negative couplet at 28 700 cm^{-1} (348 nm) in the CD spectrum of *N*,*N*′-bis(salicylidene)-(−)-propylenediaminozinc(II) to π–π* transitions encompassing the two azomethine chromophores. An evidence of a similar couplet in the same spectral region was given for oxovanadium(IV) complexes with tetradentate Schiff bases derived from (*S*)-(+)-propane-1,2-diamine and (*S*,*S*)-(+)-cyclohexane-1,2-diamine [28]. Positions of couplets in the CD spectra of **2** and **2r** near the wavelength value reported for π–π* transitions assigned to azomethine

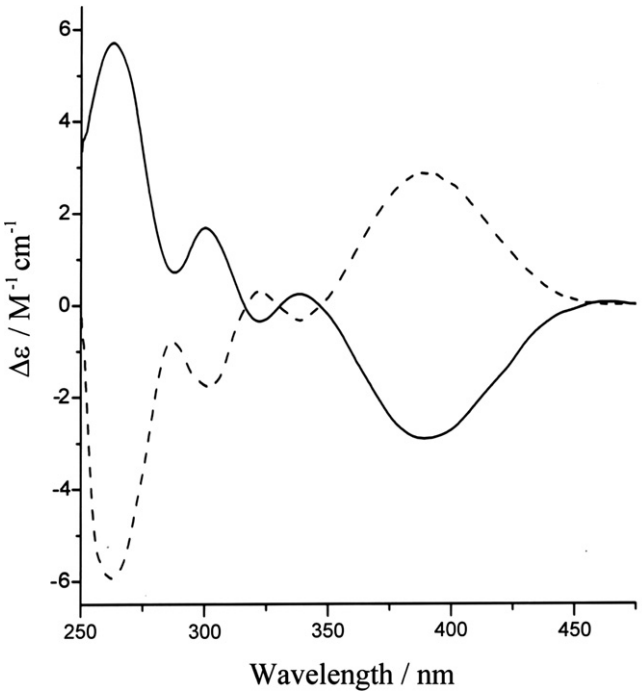

Fig. 4. CD spectra of **2** and **2r** complexes containing singly condensed (*S*,*S*)-(−)-1,2-diphenyl-1,2-diaminoethane and singly condensed (*R*,*R*)-(+)-1,2-diphenyl-1,2-diaminoethane with 3-methoxysalicylaldehyde (*o*-vanillin), respectively, in DMSO solution.

chromophore suggest that the single azomethine group in monomeric forms of **2** and **2r** complexes may interact with the other chromophores positioned in their close proximity to produce an exciton splitting. The sign of the low energy component of the couplet in the spectrum of **2** and the sign of the Cotton effect of transitions around 330 nm in other complexes derived from diamine of *S*,*S* configuration are positive, in contrast to the negative sign of **2r** couplet and of the Cotton effect for the corresponding transition in **3r** compound, derived from diamine of *R*,*R* configuration.

The ^1H and ^{51}V NMR spectral data were recorded in DMSO-d_6. Signals are assigned on the basis of intensity, spin–spin coupling pattern, chemical shift and deuteration experiment. Since the ^1H NMR spectra derived from (*R*,*R*)-(+) and (*S*,*S*)-(−)-1,2-diphenyl-1,2-diaminoethane are superimposable, Section 2 lists NMR data only for the latter complexes. Single condensation of the 1,2-diphenyl-1,2-diaminoethane is confirmed by the presence of amine and azomethine proton signals in the spectra of all complexes. The two NH_2 protons are magnetically inequivalent and produce a doublet in the 5.94–6.25 ppm range and a triplet in the 5.72–5.99 ppm range the multiciplity of the latter is due to geminal and vicinal coupling with the proton attached to the nearest asymmetric carbon atom. Signals originating from the methine protons attached to asymmetric carbon atoms are by *ca.* 1.5 ppm downfield with respect to those, which have been found in the spectra of the VO_2(chxnSalXY) complexes [14], due to their increased deshielding, as a result of the mag-

netic anisotropy (ring current effect) of phenyl substituents. The aromatic protons of the salicylidene moiety, which in the **2**, **2r**, **3**, **4**, **6** and **7** complexes are not overlapped by signals of the phenyl substituents and the signals of all complexes, which originate from the methine protons, show first order splitting pattern and could be assigned straightforward. Protons of phenyl substituents in **2**, **2r**, **3**, **4**, **6** and **7** complexes give rise to two separate 5-H multiplets one in 7.27–7.34 ppm and the other one in 7.16–7.24 ppm ranges.

All the complexes exhibit single ^{51}V resonances in the narrower range −547.8 to −551.3 ppm than that of −547.8 to −556 ppm found for dimeric $[VO_2(pnSal)]_2$, monomeric VO_2(MepnSalXY) and VO_2(chxnSalXY) complexes. Single ^{51}V resonances indicate that the complexes occur in single (presumably monomeric) form in DMSO solution, since the weakly associated $(\mathbf{4}\cdot H_2O)_2$ dimer as well as the remaining (**1**–**3**, **5**–**8**) compounds, supposed to be also weakly associated in the solid state can be considered as dissociated into monomers in this solvent by analogy to $[VO_2(pnSal)]_2$.

3.3. Catalytic oxidation of methyl phenyl sulfide (thioanisole)

Yields and enantiomeric excesses in oxidation catalysis of methyl phenyl sulfide at 20 °C and the configurations of the formed sulfoxide are given in Table 3. It is evident that **2**, **2r**, **3** and **3r** complexes attained in high yields and in higher enantiomeric excesses (34–39%) than the reported earlier VO_2(chxnSalXY) complexes with ligands bearing X = 3-OMe and X = 5-OMe phenyl ring substituents (19–23%) [14].

4. Supplementary data

CCDC 669707 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

(diphenylphoshino) ethyl amine ($\mathbf{L}^4$) and *N*-(1′-methyl)-1′-(2-hydroxyphenyl)-2-(diphenylphosphino) ethyl amine ($\mathbf{L}^5$) are potentially of the (N,O,S) or (N,O,P) type (Fig. 1) and their complexation reactions have not been investigated so far. It was therefore was thought worthwhile to investigate them. Additionally, the catalytic activity of metal complexes [22–29] of 'Salen' type of ligands is a motivating factor for exploring $\mathbf{L}^1$–$\mathbf{L}^5$, as the introduction of one soft donor site in a framework of a tridentate ligand may tune the activity towards a new direction. In this paper their syntheses and complexation with Pd(II) and Ni(II) are described. Single crystal structures of $\mathbf{L}^1$, $\mathbf{L}^2$, [PdCl ($\mathbf{L}^1$–H)] (**1**), [PdCl($\mathbf{L}^3$–H)] (**3**) and [NiCl($\mathbf{L}^4$–H)] (**6**) have been reported. The Pd(II) complex of $\mathbf{L}^2$ was immobilized on silica gel via a $-CH_2CH_2CH_2Si$ linker and the resulting matrix was found suitable for the Suzuki–Miyaura reaction. These results are also part of the present paper.

2. Experimental

The C and H analyses were carried out with a Perkin–Elmer elemental analyzer 240 C. The ^1H, $^{13}C\{^1H\}$ and $^{31}P\{^1H\}$ NMR spectra were recorded on a Bruker Spectrospin DPX-300 NMR spectrometer at 300.13, 75.47 and 121.49 MHz, respectively.

The ^{13}C CPMAS NMR spectrum was recorded on a Bruker FT-NMR Spectrometer (DSX 300) at 75.46 MHz. IR spectra in the range 4000–250 cm^{-1} were recorded on a Nicolet Protége 460 FT-IR spectrometer as KBr pellets. The melting points were determined in open capillary, and are reported as such. The conductivity measurements were carried out in CH_3CN (concentration ca. 1 mM) using an ORION conductivity meter model 162.

$PhSCH_2CH_2NH_2$ was synthesized by the literature method [30,31]. To prepare $Ph_2PCH_2CH_2NH_2$ the literature method [30,31] was modified as detailed below. 2-Chloroethylamine hydrochloride (0.58 g, 5 mmol) dissolved in 20 ml of freshly distilled THF was taken in a Schlenk flask and stirred for 10 min under nitrogen atmosphere at −78 °C. A freshly prepared solution of $LiPPh_2$ (5 mmol) in THF (50 ml) was added to it dropwise with stirring. After complete addition, the temperature of the flask was slowly increased to room temperature and then its contents were refluxed for 10 h under nitrogen atmosphere. During this period the deep red solution became colourless. The reaction mixture was cooled to room temperature and the solvent was removed on a rotary evaporator. The resulting semi-solid was treated with 10% HCl solution and the solution was washed with benzene (3 × 15 ml) and made alkaline with 10% NaOH solution. The phosphinated amine from this solution was extracted into benzene, washed with brine (2 × 25 ml) and dried with anhydrous Na_2SO_4. After evaporation of the solvent on a rotary evaporator, a colourless highly viscous liquid was obtained. It was further purified by dissolving in 20 ml of benzene and washing with brine (20 ml). The benzene layer was dried with Na_2SO_4 and filtered through celite before evaporating off the solvent again on a rotary evaporator to get the viscous liquid. Yield: 60%; ^1H NMR: 2.23–2.28 (t, 2H, CH_2N), 2.82–2.89 (m, 2H, CH_2P), 7.32–7.46 (m, 10H, ArH).

2.1. Synthesis of $\mathbf{L}^1$

o-Hydroxyacetophenone (0.71 g, 5.26 mmol) dissolved in 20 ml of dry methanol was stirred for 30 min and mixed with a solution of $PhSCH_2CH_2NH_2$ (0.81 g, 5.26 mmol) made in 10 ml of dry methanol, which was added dropwise with stirring. The mixture, which became yellow instantaneously, was stirred further for ~5–6 h at room tempera-

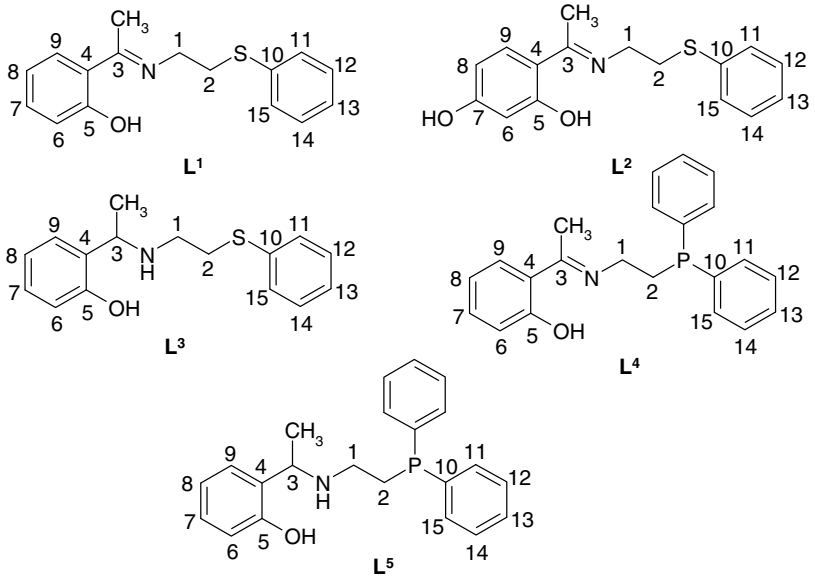

Fig. 1. Structures of $\mathbf{L}^1$ to $\mathbf{L}^5$.

ture. The solvent was evaporated off on a rotary evaporator to yield a yellow solid. The single crystals of $\mathbf{L}^1$ were grown from its solution in a chloroform–hexane (1:2) mixture at low temperature (0–5 °C). Yield: 1.36 g; 95% m.p. 55 °C. *Anal.* Calc. for $C_{16}H_{17}NOS$: C, 70.82; H, 6.31; N, 5.16. Found C, 70.52; H, 6.26; N, 5.31%. NMR: (^{1}H, 25 °C, $CDCl_3$) δ: 2.27 (s, 3H, CH_3), 3.29 (t, $J = 7.0$ Hz, 2H, H_2), 3.76 (t, $J = 6.9$ Hz, 2H, H_1), 6.79 (t, $J = 7.3$ Hz, 2H, H_{13}), 6.92–6.95 (d, d, $J = 8.3$ Hz, 1H, H_6), 7.17–7.41, (m, 6H, H_{11} to H_{15} and H_7), 7.48–7.51 (d, $J = 8.0$ Hz, 1H, H_9), 15.82 (bs, 1H, OH); (^{13}C{^{1}H}, 25 °C, $CDCl_3$) δ: 14.3 (CH_3), 34.1 (C_2), 48.3 (C_1), 117.0 (C_6), 118.2 (C_8), 121.7 (C_4), 126.1 (C_{13}), 127.9 ($C_{12,14}$), 129.4 ($C_{11,15}$), 129.9 (C_9), 132.1 (C_7), 135.2 (C_{10}), 163.0 (C_5), 172.1 (C_3).

2.2. Synthesis of $\mathbf{L}^2$

2,4-Dihydroxyacetophenone (0.61 g, 4.0 mmol) was dissolved in 20 ml of dry methanol and stirred for 30 min. $PhSCH_2CH_2NH_2$ (0.81 g, 5.26 mmol) dissolved in 10 ml of methanol was added and the mixture was heated over a water bath at 50 °C for 3 h. The solvent was evaporated off on a rotary evaporator to give a light yellow solid $\mathbf{L}^2$. Yellow single crystals of $\mathbf{L}^2$ were obtained by slow evaporation of its solution made in a chloroform–hexane (2:1) mixture. Yield: 1.04 g; 90%; m.p. 113 °C. *Anal.* Calc. for $C_{16}H_{17}NO_2S$: C, 66.87; H, 5.96; N, 4.87. Found: C, 66.52; H, 6.12; N, 4.71%. NMR: (^{1}H, 25 °C, DMSO-d_6) δ: 2.23 (s, 3H, CH_3), 3.31 (t, $J = 6.2$ Hz, 2H, H_2), 3.71 (t, $J = 6.2$ Hz, 2H, H_1), 6.11 (s, 1H, H_6), 6.17–6.19 (d, $J = 10.5$ Hz, 1H, H_8), 7.20–7.30 (d, $J = 9.0$ Hz, 1H, H_9), 7.36–7.48 (m, 5H, H_{11-15}), 9.82 (bs, 1H, OH *p* to C=N), 16.43 (s, 1H, OH *o* to C=N); (^{13}C{^{1}H}, 25 °C, DMSO-d_6) δ: 14.3 (CH_3), 33.1 (C_2), 46.5 (C_1), 103.5 (C_6), 105.7 (C_8), 111.5 (C_4), 125.9 (C_{13}), 128.4 ($C_{12,14}$), 129.1 ($C_{11,15}$), 129.1 (C_9), 135.6 (C_{10}), 161.7 (C_5), 167.4 (C_7), 172.1 (C_3).

2.3. Synthesis of $\mathbf{L}^3$

$\mathbf{L}^1$ (0.2714 g, 1 mmol) and $NaBH_4$ (0.2 g, 5 mmol) were taken in 50 ml of dry ethanol and refluxed for 24 h. The reaction mixture was cooled and its solvent evaporated off on a rotary evaporator to result in a semi-solid product. $\mathbf{L}^3$ was leached out from this product with dry dichloromethane (5×25 ml). The combined dichloromethane extract was filtered through celite, washed with distilled water (4×25 ml) and dried with anhydrous sodium sulfate. The solvent from the extract was removed on a rotary evaporator and $\mathbf{L}^3$ was obtained as a highly viscous colorless oil. Yield: 0.23 g; 85%. NMR: (^{1}H, 25 °C, $CDCl_3$) δ: 1.37–1.40 (d, $J = 6.7$ Hz, 3H, CH_3), 2.75–2.45 (m, 2H, H_2), 2.92–3.00 (m, 1H, H_1), 3.06–3.15 (m, 1H, H_1), 3.80–3.87 (q, $J = 6.5$ Hz, 1H, CH), 6.71–6.90 (m, 3H, H_6, H_7, H_8), 7.01–7.27 (m, 5H, H_{11} to H_{15}), 7.23–7.32 (d, $J = 6.3$ Hz, 1H, H_9); (^{13}C{^{1}H}, 25 °C, $CDCl_3$) δ: 22.12 (CH_3), 33.41 (C_2), 45.22 (C_1), 58.31 (C_3), 116.6 (C_6), 119.0 (C_8), 126.4 (C_{13}), 127.9 (C_7), 127.3 (C_4), 128.3 (C_9), 128.9 ($C_{12,14}$), 129.7 ($C_{11,15}$), 135.0 (C_{10}), 157.0 (C_5).

2.4. Synthesis of $\mathbf{L}^4$

(2-Aminoethyl)diphenylphosphine (1.2 g, 5.0 mmol) was stirred for 0.5 h in 5 ml dry ethanol at room temperature. *o*-Hydroxyacetophenone (0.13 g, 1.0 mmol) dissolved in 5 ml of dry ethanol was added to the above solution dropwise with stirring under a N_2 atmosphere. The mixture was stirred further for 6 h at room temperature. Its solvent was evaporated off on a rotary evaporator resulting in $\mathbf{L}^4$ as a viscous yellow liquid, which on recrystallization from a chloroform–hexane mixture (1:10) gave $\mathbf{L}^4$ as a yellow solid. Single crystals of $\mathbf{L}^4$ were grown by slow evaporation of its solution made in a mixture of chloroform and hexane (1:10). Yield 1.36 g; 78%; m.p. 82-83 °C *Anal.* Calc. for $C_{22}H_{22}NOP$: C, 76.06; H, 6.38; N, 4.03. Found: C, 75.20; H, 6.52; N, 4.25%. NMR: (^{1}H, 25 °C, $CDCl_3$) δ: 2.21 (s, 3H, CH_3), 2.51 (t, $J = 8.0$ Hz, 2H, H_2), 3.59–3.67 (q, $J = 7.7$ Hz, 2H, H_1), 6.75 (t, $J = 7.4$ Hz, 2H, $H_{13,19}$), 6.90–6.93 (d, $J = 8.2$ Hz, 1H, H_6), 7.24–7.46, (m, 11H, ArH), 16.27 (bs, 1H, OH); (^{13}C{^{1}H}, 25 °C, $CDCl_3$) δ: 14.3 (CH_3), 29.4–29.6 (d, $J_{P-C} = 12$ Hz, C_2), 46.0–46.3 (d, $J_{P-C} = 22.5$ Hz, C_1), 116.9 (C_6), 118.7 (C_8), 119.2 (C_4), 127.9 (C_{13}), 128.5–128.8 ($C_{12,14}$), 132.4–132.5 (d, $C_{11,15}$), 132.8 (C_7), 137.8 (C_{10}), 163.8 (C_5), 171.4 (C_3); (^{31}P{1H}, 25 °C, $CDCl_3$): δ −20.4.

2.5. Synthesis of $\mathbf{L}^5$

$\mathbf{L}^4$ (0.3474, 1 mmol) and $NaBH_4$ (0.2 g, 5 mmol) were refluxed together in 50 ml dry ethanol under a N_2 atmosphere for 12 h. The mixture was cooled and the solvent was evaporated off on a rotary evaporator. $\mathbf{L}^5$ was extracted from the residue into dry dichloromethane (4×20 ml) and the extract was filtered through celite. The filtrate was washed with distilled water (4×25 ml) and dried with anhydrous sodium sulfate. $\mathbf{L}^5$ was obtained from the dried extract as a viscous colourless oil by evaporation of the solvent on a rotary evaporator. Yield 0.26 g; 75%. NMR: (^{1}H, 25 °C, $CDCl_3$) δ: 1.34–1.37 (d, $J = 11.63$ Hz, 3H, CH_3), 2.16–2.35 (m, 2H, H_1), 2.69–2.77 (m, 2H, H_2), 3.80–3.86 (q, $J = 7.4$ Hz, 1H, H_3), 6.86–6.88 (d, $J = 6.00$ Hz, 2H, $H_{11,15}$), 6.78–6.80 (d, $J = 6.00$ Hz, 1H, H_6), 7.09 (t, $J = 7.7$ Hz, 1H, H_7), 7.28–7.69 (m, 10H, ArH); (^{13}C{^{1}H}, 25 °C, $CDCl_3$) δ: 22.0 (CH_3), 28.2–28.3 (d, $J_{P-C} = 12$ Hz, C_2), 46.0–46.3 (d, $J_{P-C} = 21.9$ Hz, C_1), 61.4 (C_3), 116.9 (C_6), 118.7 (C_8), 126.3 (C_4), 127.8 (C_7), 128.0 (C_9), 128.3 ($C_{12,14}$), 132.4 (C_{13}), 137.4–137.6 ($C_{11,15}$), 138.8 (C_{10}), 157.0 (C_5); (^{31}P{^{1}H}, 25 °C, $CDCl_3$): δ −21.4.

2.6. Synthesis of [PdCl($\mathbf{L}^1$–H)] (1)

To a stirred solution of $Na_2[PdCl_4]$ (0.294 g, 1 mmol) made in 5 ml of distilled water was added a solution of

$\mathbf{L}^1$ (0.2714 g, 1 mmol) made in 10 ml of acetone. The mixture was stirred for 30 min and thereafter it was poured into 50 ml of distilled water. The complex was extracted with 100 ml of chloroform. The chloroform extract was washed with distilled water (3×20 ml) and dried with anhydrous sodium sulfate. The solvent was evaporated off on a rotary evaporator and the residue was dried under vacuum to obtain an orange powder of **1**. On recrystallization of the powder from a mixture (1:1) of chloroform and hexane, single crystals of **1** were obtained. Yield: 0.32 g; 78%; m.p. 140 °C. *Anal.* Calc. for $C_{16}H_{16}NOSPdCl$: C, 46.62; H, 3.91; N, 3.40. Found: C, 46.71; H, 3.92; N, 3.61%. NMR: (^1H, 25 °C, $CDCl_3$) δ: 2.47 (s, 3H, CH_3), 2.75–2.81 (td, $J = 13.5$ Hz, 1H, H_1), 3.32–3.42 (dt, $J = 4.5$ Hz, $J = 13.4$ Hz, 1H, H_2), 3.72–3.82 (dt, $J = 3.5$ Hz, $J = 14.0$ Hz, 1H, H_2), 4.03–4.11 (td, $J = 13.4$ Hz, 1H, H_1), 6.64 (t, $J = 7.7$ Hz, 1H, H_6), 7.14–7.24 (m, 3H, $H_{8,12-14}$), 7.29–7.33 (m, $H_{11,15,7}$), 8.17–8.21 (m, 1H, H_9); ($^{13}C\{^1H\}$, 25 °C, $CDCl_3$) δ: 18.6 (CH_3), 39.7 (C_2), 58.3 (C_1), 114.7 (C_6), 120.3 (C_8), 121.7 (C_4), 127.5 (C_{10}), 128.8 ($C_{12,14}$), 129.6 (C_{13}), 129.9 (C_9), 131.8 ($C_{11,15}$), 132.5 (C_7), 163.0 (C_5), 167.2 (C_3).

2.7. Synthesis of [PdCl($\mathbf{L}^2$–H)] (2)

$Na_2[PdCl_4]$ (0.294 g, 1 mmol) dissolved in 5 ml of water was treated with $\mathbf{L}^2$ (0.2874 g, 1 mmol) dissolved in 10 ml of acetone as described above for **1**, except that the complex was extracted into 50 ml of chloroform. The extract was dried with anhydrous sodium sulfate. Its solvent was evaporated off on a rotary evaporator resulting in an orange coloured powder of **2**. The orange coloured crystals of **2** were grown by slow evaporation of its solution made in a mixture of chloroform and methanol (10:1). Yield: 0.30 g; 70%; m.p. 170–172 °C. *Anal.* Calc. for $C_{16}H_{16}NO_2SPdCl$: C, 44.88; H, 3.77; N, 3.27. Found: C, 44.75; H, 3.76; N, 3.27%. NMR: (^1H, 25 °C, DMSO-d_6) δ: 2.23 (s, 3H, CH_3), 2.70–2.74 (td, $J = 13.3$ Hz, 1H, H_1), 3.30–3.46 (dt, $J = 4.4$ Hz, $J = 13.2$ Hz, 1H, H_2), 3.55–3.62 (dt, $J = 11.0$ Hz, 1H, H_2), 3.87–3.92 (td, $J = 12.9$ Hz, 1H, H_1), 7.15–7.19 (d, $J = 9.2$ Hz, 1H, H_8), 7.4–7.44 (m, 4H, $H_{11,12,14,15}$), 6.13–6.17 (m, 1H, H_{13}), 6.44–6.45 (d, $J = 3.0$ Hz, 1H, H_6), 8.08–8.11 (m, 1H, H_9), 9.32 (bs, 1H, OH); ($^{13}C\{^1H\}$, 25 °C, DMSO-d_6) δ: 17.6 (CH_3), 39.3 (C_2), 57.5 (C_1), 103.0 (C_6), 105.9 (C_8), 114.5 (C_4), 127.4 (C_{10}), 129.1 ($C_{9,13}$), 128.4 ($C_{12,14}$), 131.3 ($C_{11,15}$), 161.3 (C_5), 164.1 (C_7), 165.4 (C_3).

2.8. Synthesis of [PdCl($\mathbf{L}^3$–H)] (3)

A solution of $Na_2[PdCl_4]$ (0.294 g, 1 mmol) made in 5 ml of water was added to a solution of $\mathbf{L}^3$ (0.2734 g, 1 mmol) prepared in 10 ml of acetone with vigorous stirring. The mixture was stirred further for 2 h. It was then poured into 50 ml of distilled water. Complex **3** was extracted into 100 ml of chloroform. The chloroform extract was washed with distilled water (2×25 ml) and dried with anhydrous sodium sulfate. Slow evaporation of solvent from the dried extract at room temperature gave orange-red single crystals of **3**. Yield 0.32 g; 78%; m.p. 185 °C. *Anal.* Calc. for $C_{16}H_{18}NOSPdCl$: C, 46.39; H, 4.38; N, 3.38. Found: C, 46.52; H, 4.26; N, 3.43%. NMR: (^1H, 25 °C, $CDCl_3$) δ: 1.60 (bs, 3H, CH_3), 2.86 (bs, 1H, NH), 3.14–3.26 (two bs, 2H, H_2), 3.63 (bs, 2H, H_1), 6.95 (bs, 2H, $H_{12,14}$), 7.58 (bs, $H_{11,13,15}$), 8.00 (bs, 1H, H_7), 8.30 (bs, 1H, H_9); ($^{13}C\{^1H\}$, 25 °C, $CDCl_3$) δ: 18.7 (CH_3), 41.6 (C_2), 51.8 (C_1), 57.4 (C_3), 114.2 (C_6), 118.6 (C_8), 127.3 (C_4), 128.7 (C_{13}), 129.4 (C_7), 130.5 (C_9), 129.9 ($C_{12,14}$), 132.4 ($C_{11,15}$), 135.0 (C_{10}), 162.2 (C_5).

2.9. Synthesis of [PdCl($\mathbf{L}^4$–H)] (4)

$Na_2[PdCl_4]$ (0.294 g, 1 mmol) was dissolved in 5 ml of water. A solution of $\mathbf{L}^4$ (0.3474 g, 1 mmol) made in 10 ml of acetone was added to it with stirring. The mixture was stirred for a further 30 min which resulted in a yellow coloured solution. The complex was extracted into 50 ml of chloroform. The chloroform layer was washed with 20 ml of distilled water, dried with anhydrous sodium sulfate and reduced in volume to 10 ml by evaporating off the solvent on a rotary evaporator. The resulting precipitate was filtered, washed with hexane and dried under vacuum to give **4** as a yellow solid. Yield: 0.39 g; 80%; m.p. 158 °C. *Anal.* Calc. for $C_{22}H_{21}NOPPdCl$: C, 54.12; H, 4.34; N, 2.87. Found: C, 54.01; H, 4.32; N, 2.81%. NMR: (^1H, 25 °C, $CDCl_3$) δ: 2.17 (s, 3H, CH_3), 2.38–2.45 (two t, $J = 6.5$ Hz, 2H, H_2), 3.81 (t, $J = 6.2$ Hz, 2H, H_1), 3.92 (t, $J = 6.2$ Hz, 1H, H_1), 6.57 (t, $J = 7.9$ Hz, 1H, H_{13}), 7.14–7.17 (d, $J = 8.5$ Hz, 1H, H_6), 7.26 (t, merged with $CHCl_3$ signal, 2H, H_8), 7.44–7.53 (m, 8H, ArH *o* and *m* to P), 7.91–7.97 (m, 2H, $H_{7,9}$); ($^{13}C\{^1H\}$, 25 °C, $CDCl_3$) δ: 21.2 (CH_3), 30.1–30.5 (d, $J_{P-C} = 12$ Hz C_2), 56.6 (C_1), 114.8 (C_6), 119.2 (C_4), 123.3 (C_8), 128.0 (C_9), 129.0–129.1 ($C_{12,14}$), 130.4 (C_{13}), 133.3–133.5 ($C_{11,15}$), 132.4 (C_7), 144.6 (C_{10}), 158.0 (C_5), 170.7 (C_3); ($^{31}P\{^1H\}$, 25 °C, $CDCl_3$): δ 35.1.

2.10. Synthesis of [PdCl($\mathbf{L}^5$–H)] (5)

$Na_2[PdCl_4]$ (0.294 g, 1 mmol) dissolved in 5 ml of water and a solution of $\mathbf{L}^5$ (0.35 g, 1 mmol) made in 10 ml of acetone were mixed with vigorous stirring. The stirring was continued further for 1 h. The complex was extracted into 40 ml of chloroform. The organic layer was washed with distilled water (2×20 ml), dried with anhydrous sodium sulfate and evaporated on a rotary evaporator. The resulting residue was recrystallized with a chloroform–hexane mixture (1:10) to obtain **5** as a yellow solid, which was separated and dried under vacuo. Yield: 0.32 g; 65%; m.p. 169 °C. *Anal.* Calc. for $C_{22}H_{23}NO$ PPdCl: C, 53.79; H, 4.92; N, 2.85. Found: C, 53.81; H, 4.86; N, 2.94%.

2.11. Synthesis of [NiCl($\mathbf{L}^4$–H)] (6)

$NiCl_2 \cdot 6H_2O$ (0.284 g, 1 mmol) was dissolved in 2 ml of dry methanol. A solution of $\mathbf{L}^4$ (0.3474 g, 1 mmol) made in

10 ml of chloroform was added to it with vigorous stirring. The mixture was stirred for a further 0.5 h. The resulting red coloured solution was poured into 50 ml of distilled water. The complex was extracted into 50 ml of chloroform. The chloroform layer was washed with 25 ml of distilled water and dried with anhydrous sodium sulfate. The solvent of the extract was evaporated off on a rotary evaporator to get **6** as a red solid. Its single crystals were grown in a chloroform and hexane mixture (2:1). Yield: 0.39 g; 88%; m.p. 140 °C. *Anal.* Calc. for $C_{22}H_{21}NO$ PNiCl: C, 59.98; H, 4.80; N, 3.18. Found: C, 60.01; H, 4.92; N, 3.21%. NMR: (^{1}H, 25 °C, $CDCl_3$) δ: 2.48 (s, 3H, CH_3), 2.02–2.10 (two t, $J = 6.78$ Hz, 2H, H_2), 3.50 (t, $J = 6.53$ Hz, 1H, H_1), 3.59 (t, $J = 6.5$ Hz, 1H, H_1), 6.56, (t, $J = 7.3$ Hz, 1H, H_{13}), 7.08–7.11 (d, $J = 8.4$ Hz, 1H, H_6), 7.21 (t, $J = 7.5$ Hz, 1H, H_8), 7.41–7.57 (m, 8H, ArH *o* and *m* to P), 8.04–8.10 (m, 2H, $H_{7,9}$); (^{13}C{^{1}H}, 25 °C, $CDCl_3$) δ: 20.4 (CH_3), 28.9–29.3 (d, $J_{P-C} =$ Hz C_2), 55.0 (C_1), 114.8 (C_6), 121.7 (C_8), 127.4 (C_4), 128.9–129.2 ($C_{12,14}$), 130.4 (C_{13}), 131.5 (C_9), 133.0 (C_7), 133.1–133.4 (d, $C_{11,15}$), 144.6 (C_{10}), 158.0 (C_5), 170.7 (C_3); (^{31}P{^{1}H}, 25 °C, $CDCl_3$): δ 37.0.

2.12. Synthesis of [NiCl(L^5–H)] (7)

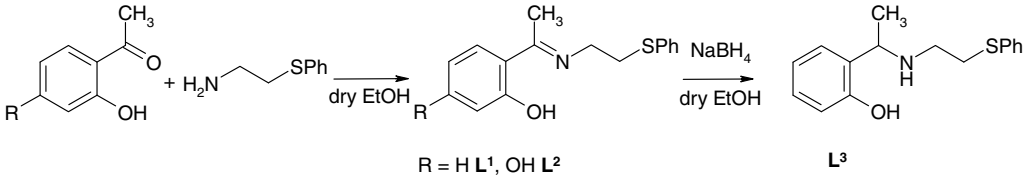
$NiCl_2 \cdot 6H_2O$ (0.284 g, 1 mmol) was dissolved in 5 ml of dry methanol. A solution of L^5 (0.35 g, 1 mmol) made in 10 ml of methanol was added to it with vigorous stirring. The mixture was stirred for a further 0.5 h. Complex **7** was extracted and treated further as given above in Section 2.11, to get it as a red solid. Yield: 0.35 g; 80%; m.p. 140 °C. *Anal.* Calc. for $C_{22}H_{23}NO$ PNiCl: C, 59.57; H, 5.45; N, 3.16. Found: C, 59.54; H, 5.42; N, 3.25%. NMR: (^{1}H, 25 °C, $CDCl_3$) δ: 1.58–1.60 (d, $J = 5.13$ Hz, 3H, CH_3), 2.50 (bs, 1H, NH), 2.90 (bs, 2H, H_2), 3.13 (bs, 2H, H_1), 4.46 (q, 1H, CH), 6.76 (t, $J = 7.2$ Hz, 2H, H_{13}), 7.03 (d, 1H, H_6), 7.12 (t, $J = 6.91$ Hz, 1H, H_8), 7.60–7.90 (bs, 1H, $H_{7,9}$), 7.24–7.48 (m, 8H, ArH *o* and *m* to P).

2.13. [PdCl(L^2–H)] (2) anchored silica gel (Catalyst 1)

Activated silica gel [32] (30 g), suspended in 100 ml solution of (3-chloropropyl)triethoxysilane in dry xylene (15% v/v), was refluxed with stirring for 72 h under a nitrogen atmosphere. The solid 3-chloropropyl silica gel (CPSG), separated by filtration, was washed (4 × 25 ml) successively with xylene, ethanol and diethylether. It was dried and degassed at 373 K under vacuum for 6 h, under anhydrous conditions. The CPSG (1 g) was added to a mixture made by stirring for about 15 min, 1 mmol (0.024 g) of sodium hydride (60% in mineral oil), 10 ml of a DMF–THF mixture (1:1) and an orange-red solution of complex **2** (1 mmol, 0.429 g) made in 2 ml of DMF (the solution of **2** was added dropwise with stirring with a magnetic bead at room temperature to the other contents taken in a 100 ml round bottom flask). The mixture was stirred further for 12 h. The silica gel became orange in colour. It was filtered, washed with DMF (3 × 5 ml) and THF (3 × 5 ml), dried in vacuo, to give a slippery orange-yellow solid (**Catalyst 1**). The palladium content was found to be 0.08 mmol/g in **Catalyst 1** by flame AAS after decomposing 0.1 g of it with 20 ml of concentrated $HNO_3 + HCl$ (1:3) and 70% $HClO_4$ (5 ml).

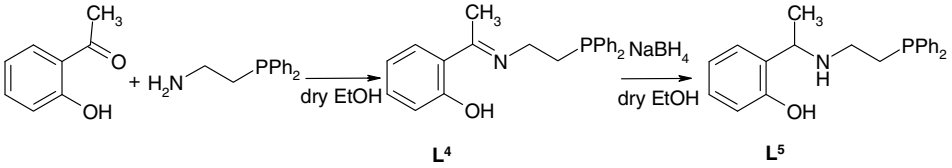
2.14. Coupling of aryl bromides with benzeneboronic acid

A mixture of bromobenzene or its derivative (1 mmol), benzeneboronic acid (0.183 g, 1.5 mmol), Na_2CO_3 (0.212 g, 2 mmol), distilled water (0.5 ml), isopropanol (10 ml) and **Catalyst 1** (0.1 g, ~0.008 mmol of Pd) was stirred under reflux over an oil bath for 8–10 h under ambient conditions. The reaction mixture was cooled to room temperature. The solid was filtered off and the filtrate was extracted with hexane/diethyl ether (25–50 ml). The solvent from the extract was evaporated off to give a white crystalline solid product, which was authenticated by NMR. Further details and results are given in Table 8.



2.15. X-ray diffraction analysis

Single crystal X-ray diffraction studies of L^1, L^2, **3** and **6** were carried out with a Bruker SMART CCD diffractometer (at IIT Delhi) using Mo Kα ($\lambda = 0.71073$ Å) radiation at 298(2) °C. The software SADABS was used for absorption corrections and SHELXTL for space group, structure determination and refinements [33]. All non-hydrogen atoms were located from a difference Fourier map using geometrical constraints and were refined anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. The least-squares refinement cycles on F^2 were performed until the model converged. Data for **1** was collected (at the Instituto de Quimica, UNAM, Mexico) on a Bruker Smart APEX CCD diffractometer, using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 293(2) K. An analytical face indexed absorption correction was applied. The structure was solved by direct methods. Refinement was carried out by full-matrix least-squares analysis with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were placed into calculated positions and refined using a riding model with fixed isotropic thermal parameters. Calculations were carried out with SMART software for data collection and reduction, and SHELXTL for solution and refinement [34].



3. Results and discussion

The ligands L^1 to L^5 were synthesized by the reactions given in Eqs. (1) and (2). They are soluble in common organic solvents, except L^2 which is sparingly soluble in chloroform, dichloromethane and methanol and insoluble in hexane and diethyl ether. L^4 and L^5 are highly viscous oily liquids and consequently could not be subjected to

elemental analyses. The Pd(II) and Ni(II) complexes (**1**–**7**) of $\mathbf{L}^1$–$\mathbf{L}^5$ were synthesized according to Eqs. (3) and (4).

(1)

(2)

$$\mathbf{L^1}\text{ to }\mathbf{L^5} \quad + \quad Na_2PdCl_4 \xrightarrow[H_2O]{\text{Acetone}} [PdCl(\mathbf{L}\text{-H})]\ (\mathbf{1\text{-}5}) \quad + 2\,NaCl + HCl \tag{3}$$

$$\mathbf{L^4}\text{ to }\mathbf{L^5} \quad + \quad NiCl_2{\cdot}6\,H_2O \xrightarrow{\text{Methanol}} [NiCl(\mathbf{L}\text{-H})]\ (\mathbf{6\text{-}7}) \quad + HCl \tag{4}$$

All the complexes were soluble in common organic solvents such as chloroform, dichloromethane, acetonitrile, methanol, ethanol, DMF and DMSO, except **5**. In hexane and diethyl ether all the complexes were sparingly soluble. However, the solubility of **7** in common organic solvents was to be found relatively low. The molar conductance (Λ_M) of the ligands and the complexes was measured in acetonitrile at a concentration of about 1 mM at room temperature. The values of 0.5–10 Omega^{-1} cm^2 mol^{-1} suggest that they are non-electrolytic in nature.

In the IR spectra of $\mathbf{L}^1$, $\mathbf{L}^2$ and $\mathbf{L}^4$ the >C=N stretching vibration appears at 1612, 1618 and 1605 cm^{-1} respectively, while the C–S stretching band in the case of $\mathbf{L}^1$ to $\mathbf{L}^3$ appears between 782 and 797 cm^{-1}. The N–H bending absorption appears at 1595 cm^{-1} in the IR spectrum of $\mathbf{L}^3$. In the IR spectra of **1**, **2** and **6**, the >C=N stretching band shows a red shift with respect to those of the corresponding free ligands by ~15 cm^{-1}. In the IR spectra of the complexes of $\mathbf{L}^1$–$\mathbf{L}^3$, the C–S stretching bands appear at around 745 cm^{-1} (red shifted in comparison to those of the corresponding free ligands). In the IR spectra of **3**, **5** and **7** the N–H stretching and bending absorptions also show a red shift of the order of 10–15 cm^{-1} with respect to those of the corresponding ligands.

3.1. NMR spectra

The ^{1}H NMR spectra of the ligands $\mathbf{L}^1$ to $\mathbf{L}^5$ were found to be characteristic. The OH (*ortho* to azomethine) proton appears as a singlet at 15.82 ppm in the spectrum of $\mathbf{L}^1$ and at 16.43 ppm in that of $\mathbf{L}^2$. They are highly deshielded due to OH···N intra-molecular hydrogen bonding (supported by their single crystal structures). In the ^{1}H NMR spectrum of $\mathbf{L}^2$, the OH (*para* to azomethine) proton appears as a broad singlet at 9.82 ppm. The OH proton appears as a singlet at 16.27 ppm in the spectrum of $\mathbf{L}^4$, which is also highly deshielded due to OH···N intra-molecular hydrogen bonding. The OH signal could not be observed in the spectra of $\mathbf{L}^3$ and $\mathbf{L}^5$, which have reduced >C–NH rather than >C=N groups. Most probably the OH proton is not stabilized by intra-molecular hydrogen bonding in $\mathbf{L}^3$ and $\mathbf{L}^5$ and consequently intermolecular exchange between the phenolic protons broadens the OH signal so that it is not identifiable. In the ^{1}H NMR spectra of **1** and **2** the CH_3 protons were deshielded by ~0.2 ppm relative to those of the corresponding free ligand protons. The two protons of each CH_2 in the S–CH_2–CH_2–N system i.e. H_2 and H_1

are diastereotopic and magnetically non-equivalent, thus producing a group of four signals, each one corresponding to a single proton. The H_2 protons give two doublets of a triplet in which one signal is deshielded by 0.2–0.3 ppm and the other one by 0.3–0.4 ppm with respect to those of the free ligand. The H_1 protons give two triplets of a doublet in which one signal is deshielded by ~0.3–0.4 ppm and the other is shielded by ~1 ppm (relative to those of free $\mathbf{L}^1/\mathbf{L}^2$). The signals of the H_6 proton appear shielded (~0.3 ppm) compared to those of free ligands. In the ^1H NMR spectrum of **3** the signals were somewhat broad. The CH_3 protons were deshielded (~0.3 ppm) with respect to the corresponding protons of $\mathbf{L}^3$. The H_2 and H_1 protons also appear deshielded (~0.2 and 0.5 ppm, respectively) relative to the corresponding protons of the ligand $\mathbf{L}^3$. Additionally, the NH proton signal has been observed at 2.86 ppm. The signal of the H_6 proton was shielded (~0.3 ppm) whereas the signals of the other aromatic protons were deshielded (0.2–1.0 ppm) in comparison to the corresponding protons of $\mathbf{L}^3$. In the proton NMR spectrum of **4** the H_2 protons were shielded (~0.1 ppm). The H_1 protons give two characteristic triplets which were deshielded by ~0.4 and 0.5 ppm compared to the corresponding $\mathbf{L}^4$ protons. The OH signal present in the spectra of ligands $\mathbf{L}^1$, $\mathbf{L}^2$ and $\mathbf{L}^4$ was found to be absent in the spectra of complexes **1**, **2**, **4** and **6**. In the ^1H NMR spectra of **6** and **7**, the CH_3 protons were deshielded by ~0.3 ppm compared to those of the ligands. The H_2 protons in the spectrum of **6** give two triplets (due to P–H coupling) merged with each other, but these signals are shielded by 0.5 ppm with respect to the signals of the corresponding ligand protons. The H_1 protons also gave characteristic triplets (due to coupling with P) at 3.50 and 3.59 ppm. The signals of the H_2 and H_1 protons were also deshielded by ~0.7 ppm in the spectrum of **7** with respect to the signals of the corresponding ligand protons. The solubility of **5** was inadequate even for proton NMR.

The carbon-13 NMR spectra of $\mathbf{L}^1$–$\mathbf{L}^5$ and their metal complexes are characteristic. In the spectrum of $\mathbf{L}^3$, the signal of the C_3 carbon atom appears shielded by about 113.8 ppm relative to that of $\mathbf{L}^1$. The methyl carbon peak was also deshielded by 7.8 ppm with respect to that of $\mathbf{L}^1$. In the carbon-13 NMR spectrum of $\mathbf{L}^4$, the signals of the C_2 and C_1 carbon atoms appear as doublets at 29.4–29.6 and 46.0–46.3 ppm, respectively. The splitting of these peaks into doublets is due to coupling with phosphorous. The signal of the azomethine carbon atom has been observed at 171.4 ppm. On reduction of $\mathbf{L}^4$ to $\mathbf{L}^5$ the signal of the azomethine carbon was replaced with a signal of a CH carbon atom, shielded by 110 ppm with respect to the signal of the corresponding carbon of $\mathbf{L}^4$. In the $^{13}C\{^1H\}$ NMR spectra of **1** and **2** the signals of C_1 and C_2 carbon atoms were deshielded by ~10 and 5–6 ppm, respectively, relative to the signals of the corresponding carbon atoms of the ligands. The signals of the CH_3 carbon atoms were also deshielded by ~4 ppm on complexation, with respect to those of $\mathbf{L}^1$ and $\mathbf{L}^2$. The signal of the azomethine carbon atom was shielded by ~5 and 7 ppm, respectively, (relative to the ligands) in the spectra of **1** and **2**. The signals of C_{10} show a deshielding of ~7–8 ppm in comparison to those of the ligands. In the carbon-13 spectrum of **3** the signals of the C_1 and C_2 carbon atoms were deshielded by ~5 and 7 ppm respectively. The $^{13}C\{^1H\}$ NMR spectra of **4** and **6** exhibit signals for C_1, C_2 and CH_3 which are deshielded by ~6–7 ppm with respect to those of the ligands. Thus the above mentioned deshielding of the signals in the $^{13}C\{^1H\}$ and ^1H NMR spectra suggests that ligands $\mathbf{L}^1$ to $\mathbf{L}^5$ behave as $(N, O^-, S/P)$ donors in all the complexes. This is corroborated by the single crystal structures of **1**, **3** and **6**, indicating similarity in the solid state and solution structures. The $^{13}C\{^1H\}$ NMR spectrum of **7** could not be recorded due to its inadequate solubility.

In the $^{31}P\{^1H\}$ NMR spectra of $\mathbf{L}^4$ and $\mathbf{L}^5$ a sharp singlet was observed at −20.2 and −21.4 ppm, respectively, indicating the presence of only one type of phosphorus

containing species. In the $^{31}P\{^{1}H\}$ NMR spectra of complexes **4** and **6** sharp signals at 35 and 37 ppm were observed, deshielded by ~55–57 ppm in comparison to those of the corresponding ligands. This supports the ligation of L^4 and L^5 through phosphorus in solution as well.

3.2. Single crystal structures

The crystal structures of L^1, L^2, **1**, **3** and **6** have been determined by X-ray diffraction on their single crystals. The twinning in crystals of **2** restricted us from solving its structure. The crystal data and structure refinement details

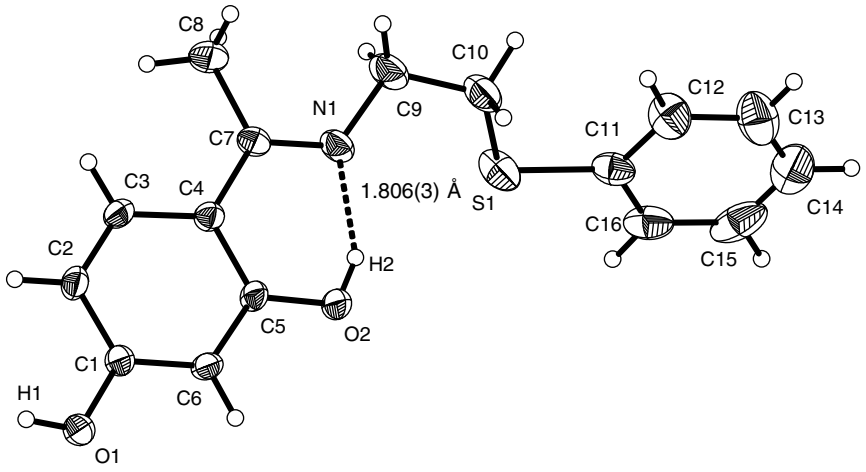

Fig. 3. ORTEP diagram of $\mathbf{L}^2$ (thermal ellipsoids are drawn with 30% probability).

are given in Tables 1 and 2. The molecular structures of $\mathbf{L}^1$ and $\mathbf{L}^2$ are shown in Figs. 2 and 3. Selected bond lengths and bond angles are given in Tables 3 and 4. The S–C (alkyl) bond length is longer than the S–C (aryl) bond, as expected. The geometry around the sulfur is V-shaped. The C–S–C bond angle is almost normal. The bond lengths and angles in the benzene ring and alkyl chain were also found to be normal. There exists a strong O–H···N intramolecular H-bond in $\mathbf{L}^1$ and $\mathbf{L}^2$.

The molecular structure of **1** is shown in Fig. 4. Selected bond lengths and bond angles are given in Table 5. The Pd centre has a square planar geometry in **1**. The ligand is coordinated with Pd in a monoanionic tridentate (O, N, S) mode, forming a six membered chelate ring with O^- and N (azomethine) and a five membered ring with S and N (azomethine). The Pd–N, Pd–O, Pd–S and Pd–Cl bond lengths 2.005(3), 1.971(2), 2.2644(11) and 2.3091(11) Å are in agreement with the reported values [35] for [PdCl{EtNHC(=S)NH–N=CH–C_6H_4-2-O^-}] [Pd–N = 1.965(2) Å, Pd–O = 2.019(2) Å, Pd–S = 2.2456 (9) Å and Pd–Cl = 2.3078(8) Å]. The Pd–S and Pd–Cl bond length of **1** are

consistent with the values (2.268(4) and 2.316(4) Å) reported for [$PdCl_2${4-$MeOC_6H_4TeCH_2CH_2SEt$}] [36]. Surprisingly, the Pd–S bond distance in *cis*-Pd(SNNMe$_2$-S)($AsPh_3$)Cl_2 (2.249(1) Å) is some what shorter [37] than that of **1**. In *trans*-[Pd(SCN)$_2$[P(OPh)$_3$]$_2$] the Pd–S bond length is 2.352 Å [38], longer than that of **1**, probably due to the *trans* influence of S. The four bond lengths of **1** involving Pd are also consistent with the sum of the covalent radii for Pd–Cl, Pd–N, Pd–O and Pd–S (2.27, 1.98, 2.01 and 2.32 Å respectively).

The molecular structure of **3** is shown in the Fig. 5. Selected bond lengths and bond angles are given in Table 6. The crystal of **3** contains two types of molecules, consequently there are two types of N–H···Cl intermolecular hydrogen bonds (2.407(3) and 2.502(5) Å) (Fig. 5a and 5b). The Pd–N, Pd–O, Pd–S and Pd–Cl bond lengths 2.042(7)/2.035(7), 1.996(6), 2.257(2)/2.263(2) and 2.321(2)/2.329(2) Å are in agreement with the reported values [35] for [PdCl{EtNHC(=S)NH–N=CH–C_6H_4-2-O^-}] mentioned above as well as with those of **1**. The Pd–S and Pd–Cl bond lengths of **3** are also consistent with those of [$PdCl_2${4-$MeOC_6H_4TeCH_2CH_2SEt$}] [36], mentioned above. They are also consistent with the sum of covalent radii mentioned above. The Pd in **3** also has a square planar geometry. Generally the Pd–N bond distance [39–42] is close to 2.0 Å, however the values 1.857(4) [43] and 2.461(3) Å [44] have also been reported. Thus the Pd–N bond distance values in the present complexes **1** and **3** (2.005(3)–2.042(7) Å) fall in the common range. Pd–S bond lengths are commonly between 2.25 and 2.30 Å [45–47]. Our values (2.257(2)–2.2644(11) Å) are closer to the lower end as the uninegative ligands coordinate with Pd strongly due to the formation of two chelate rings. Pd–O bond distances are generally observed between 2.0 and 2.1 Å [48–50]. These distances in the case of the present complexes

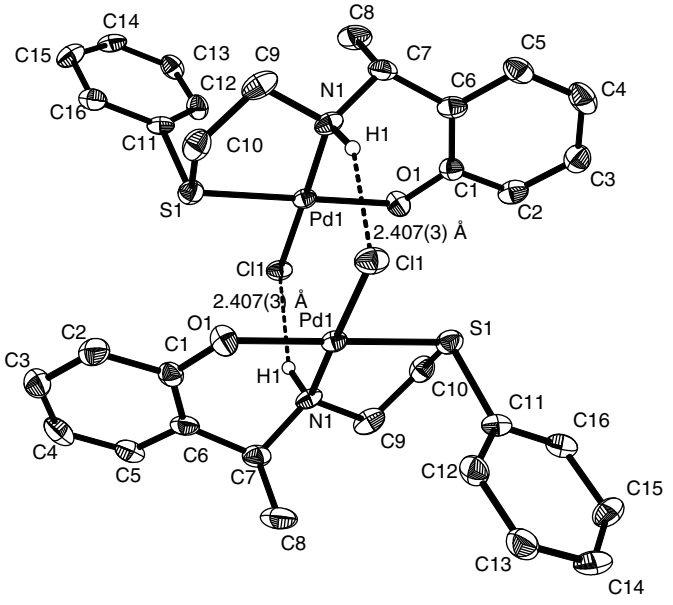

Fig. 5a. NH···Cl weak interactions in **3** (H atoms have been omitted for clarity).

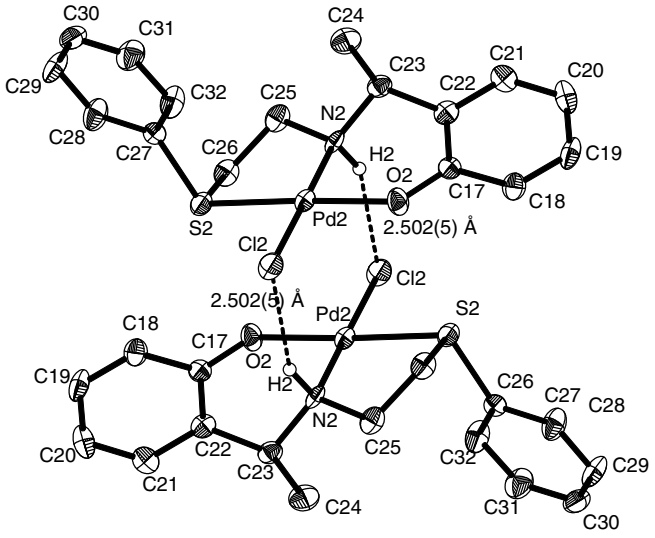
1 and **3** (1.971(2)–1.999(6) Å) are somewhat on the lower side, suggesting strong chelation by the uninegative tridentate ligand.

The molecular structure of **6** is shown in Fig. 6. Selected bond lengths and bond angles are given in Table 7. The geometry around Ni is square planar. The ligand is coordinated with Ni in a monoanionic tridentate mode, forming a six membered chelate ring with O^- and N (azomethine) and a five membered ring with P and N (azomethine). The Ni–P, Ni–N, Ni–O and Ni–Cl bond lengths 2.1324(8), 1.896(2) 1.8428(19) and 2.1940(7) Å are consistent with the earlier reported values, Ni–P = 2.142(2) Å, Ni–N = 1.900(7) Å, Ni–O = 1.875(5) Å and Ni–Cl =



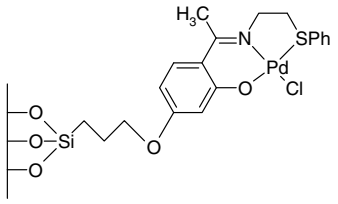


Fig. 5b. NH···Cl weak interactions in **3** (H atoms have been omitted for clarity).

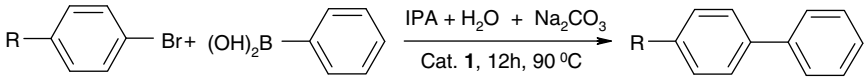
2.148(3) Å for [NiCl(2-$PPh_2C_6H_4$–CH=N–C_6H_4-2-O^-)] [19]. The Ni–P bond distance of **6** is shorter than that of bis[1,2-bis(diphenylphosphino)ethene]nickel(II) diperchlorate (2.2374(7) Å) [51] but longer than that of tetrakis-(2-thienyldifluorophosphine)nickel (2.092(3) Å) [52]. The sum of the covalent radii for Ni–P, Ni–O, Ni–N and Ni–Cl are 2.21, 1.88, 1.90 and 2.14 Å, respectively. The values of the bond lengths of **6** are consistent with the sum of the radii, except Ni–P which is somewhat shorter. Generally the Ni–O bond distance is around 2.0 or 2.1 Å [53–55]. Values around 1.82 Å have also been reported for this bond length [56,57]. The Ni–O distance in **6** (1.8428(19) Å) is closer to the later value, which is interesting and indicates strong chelation of Ni by the (P, N, O^-) ligand. The Ni–N bond length of **6** (1.896(2) Å) is also shorter than the commonly observed value of around 2.05/2.10 Å [58,59], indicating its strong nature. On the contrary the commonly found value of around 2.15 Å for the Ni–P bond [60,61] is similar to that of **6** (2.1324(8) Å).



3.3. Catalytic coupling reaction

'**Catalyst 1**' is stable under ambient conditions. Its IR spectrum has bands at 2943 (ν_{C-H}), 1600 (b, $\nu_{C=N}$), 1219 (ν_{C-O}) and 799 (ν_{C-S}) cm^{-1}. There are similarities between the ^{13}C CPMAS NMR spectrum of '**Catalyst 1**′ and the solution $^{13}C\{^1H\}$ NMR spectrum of **2**. Additional signals for the propyl group (-Si-$CH_2CH_2CH_2$–O–) have been observed in the case of the ^{13}C CPMAS NMR spectrum. The $SiCH_2$, middle CH_2 and OCH_2 carbon atom signals appear at 10.5, 26.4 and 47.0 ppm respectively. The methyl carbon signal appears at 18.6 ppm. The signals for the C_2 and C_1 atoms appear at 38.8 and 60.5 ppm, respectively. The signals of C_{10}, C_9, C_{13}, C_{12} and C_{14} merge and appear as a broad peak at 130.5 ppm. The signals for C_{11} and C_{15} appear at 132.0 ppm, for C_3 and C_7 at 164.1 ppm and for C_5, C_6/C_8 and C_4 at 158.8, 106.6 and 119.8 ppm, respectively (see Fig. 1 for the numbering of the carbon atoms).

Catalyst 1.

'**Catalyst 1**' was used in the Suzuki–Miyaura C–C coupling reactions of benzeneboronic acid with bromobenzene and substituted bromobenzenes (Eq. (5)) in an isopropanol and water mixture using Na_2CO_3 as a base at 90 °C.

where R = CH_3O, CH_3, H, NO_2, CO_2H
IPA = isopropanol

(5)

The yields were maximal when 0.001 mol% of catalyst (Pd) was taken. The catalytic activity was dependent on

the nature of the halide. The presence of electron withdrawing groups on the aryl ring increased the yield of the product biphenyl. The results are given in Table 8. The turnover number was between 75 000 and 90 000.

4. Conclusion

New (N, O, S) and (N, O, P) types of ligands $\mathbf{L}^1$ to $\mathbf{L}^5$ have been synthesized and explored for ligation with Pd(II) and Ni(II). They all behave as uni-negative tridenate donor ligands as evidenced in the case of [PdCl($\mathbf{L}^1$–H)] (**1**), [PdCl($\mathbf{L}^3$–H)] (**3**) and [NiCl($\mathbf{L}^4$–H)] (**6**) by their single crystal structures. The palladium complex of $\mathbf{L}^2$ has been grafted on silica gel to prepare '**Catalyst 1**', which was used for Suzuki–Miyaura C–C coupling reactions with good yields.

Acknowledgements

A.K.S. is grateful to Professor John E. Drake, University of Windsor, Canada for his valuable help in solving the single crystal structures of the compounds synthesized in the research group of AKS at IIT Delhi, for more than one and a half decades. To acknowledge it further, this paper is dedicated to John. He thanks Department of Science and Technology (India) for research project SR/S1/IC-23/06. The authors also thank the Department of Science and Technology (India) for partial financial assistance given to establish the single crystal X-ray diffraction facility under its FIST program at IIT Delhi. R.K.P. thanks the University Grants Commission (India) for a Senior Research Fellowship.

Appendix A. Supplementary data

CCDC numbers 639950, 639951, 639952, 639953 and 639954 contain the supplementary crystallographic data for $\mathbf{L}^1$, $\mathbf{L}^2$, **1**, **3** and **6**, respectively. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk]. interactions of some copper(II) salts with 2-pmpe and 2-qmpe ligands lead to the formation of several copper-picolinate or quinaldinate species [10,11] in an oxidative P-dealcylation/dephosphorylation reaction. These products are interesting from a structural and magnetic point of view. The studies of these reactions clearly demonstrate that copper(II) ions promote/enhance the decomposition of $R–CH_2P(O)(OEt)_2$ *N*-heterocyclic ligands (R = pyridine or quinoline) and catalyze the oxidation process by atmospheric oxygen.

It is worth mentioning that the continuing interest in metal-assisted transformations of organic functionalities is primary due to the quest for convenient synthetic methods and region- and stereoselective processes [12–17].

In this paper, we present the synthetic studies, spectral and magnetic properties, and the X-ray single-crystal analysis of a cobalt(II) compound of the formula $[Co(2\text{-qca})_2(EtOH)_2]$. This compound was formed in an interesting reaction in which diethyl(quinolin-2-ylmethyl) phosphonate (2-qmpe) was transformed to the quinoline-2-carboxylate (2-qca) ligand.

2. Experimental

2.1. Reagents and physical measurements

The starting materials and solvents for the synthesis were obtained commercially and were used as received. The metal content was determined using a Carl–Zeiss–Jena atomic absorption spectrophotometer. Elemental analyses were carried out using a Perkin–Elmer elemental analyzer 2400CHN.

Infrared spectra (100–4000 cm^{-1}) were recorded on a Bruker IFS 113v spectrophotometer using KBr pellets, and solid-state electronic spectra (28 000–4000 cm^{-1}) were recorded on a Cary 500 spectrophotometer.

The EPR spectra of a powder sample were recorded (at 295 and 77 K) on a Bruker ESP 300E spectrometer operating at the X-band frequency and equipped with a Bruker NMR. The spectrum at 4.5 K was measured with an X-band radiopan SE/X 2543 spectrometer.

Magnetic measurements of a polycrystalline sample were carried out with a Quantum Design SQUID magnetometer (MPMSXL-5 type). The measurements were recorded at a magnetic field of 0.5 T over the temperature range 1.8–300 K. The correction for diamagnetism of the experimental susceptibility was based on subtracting the sample-holder signal and estimating the contribution χ_D from Pascal constants [18]. The effective magnetic moments were calculated from $\mu_{eff} = 2.83(\chi_M T)^{1/2}$, using a temperature-independent paramagnetism of 150×10^{-6} cm^3 mol^{-1} for Co(II) [18,19].

2.2. Crystal structure determination of $[Co(2\text{-qca})_2(EtOH)_2]$

The X-ray data were collected at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. Data were corrected for Lorentz polarization effects and a correction absorption was also applied. The crystal structure was solved by direct methods (program SHELXS97 [20]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL97 [21] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from the geometry of the molecules and $\Delta\rho$ maps, and were refined isotropically. Crystal data are given in Table 1, together with refinement details.

2.3. Synthesis of the ligand (2-qmpe) and the $[Co(2\text{-qca})_2(EtOH)_2]$ compound

The diethyl(quinolin-2-ylmethyl)phosphonate (2-qmpe) ligand was prepared according to the procedure described in detail elsewhere [7].

The coordination compound was prepared by dissolving $CoCl_2 \cdot 2H_2O$ (1 mmol) in ethanol (10 cm^3) and dropwise adding this to a stirred solution of the ligand (2 mmol) in ethanol (15 cm^3), according to the procedure described earlier [9]. The dark green product of $[Co(2\text{-qmpe})_2Cl_2]$ slowly precipitated from the dark green reaction mixture after evaporation of the solvent [9]. This compound was then dissolved in ethanol. The yellow single crystals of $[Co(2\text{-qca})_2(EtOH)_2]$, suitable for X-ray analysis, were slowly grown after evaporation of the solvent. The yellow product was filtered off and washed carefully with ethanol and ether.

3. Results and discussion

A compound of the formula $[Co(2\text{-qmpe})_2Cl_2]$ is formed in the reaction of $CoCl_2 \cdot 2H_2O$ with the diethyl(quinolin-2-ylmethyl)phosphonate ligand, (2-qmpe). The physicochemical properties of this compound were presented earlier [9]. In solution this compound undergoes a slowly transformation to $[Co(2\text{-qca})_2(EtOH)_2]$. Thus, an oxidative decomposition process of the starting 2-qmpe ligand through the cleavage of the C–P bond occurs, according to the scheme presented in Fig. 1.

Aspects of this reaction are presented in Section 3.4.

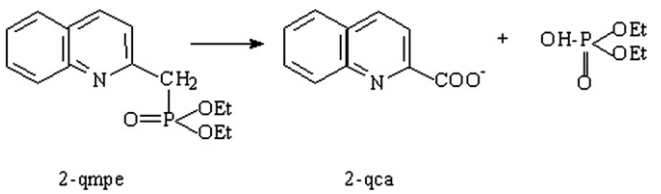

Fig. 1. A schematic drawing showing the transformation of the starting 2-qmpe ligand to 2-qca.

3.1. Description of the structure of $[Co(2\text{-qca})_2(EtOH)_2]$

The crystallographic parameters are summarized in Table 1. The most important bond lengths and angles are listed in Table 2.

Table 2
Selected bond lengths (Å) and angles (°) for $[Co(2\text{-qca})_2(EtOH)_2]$

Co(1)–O(2)	2.0179(17)	O(2)–Co(1)–N(1)	79.04(6)

$O(2)$–Co(1)–$O(3)^i$	91.67(7)		

Symmetry transformations used to generate equivalent atoms: (i) $1-x+1$, $-y$, $-z$.

Fig. 2 shows the structure and labelling scheme of the Co(II) complex. Its crystal structure consists of mononuclear units in which the cobalt atom lies at the centre of symmetry. The quinoline-2-carboxylate (2-qic) anion acts as a chelating ligand coordinating through a quinoline nitrogen and carboxylate oxygen, forming a five-membered ring. The other remaining carboxylate oxygen atoms are not involved in coordination to the metal ion. Two strongly N,O-bonded picolinate ligands lie on the equatorial plane. In other words, the monomeric unit $Co(2\text{-qca})_2$, treated as a whole molecule, is planar. The cobalt atom is octahedrally surrounded by two quinoline nitrogens at a distance of 2.203(15) Å and two oxygen atoms of the carboxylate groups from two 2-qca ligands at a distance of 2.0179(17) Å. Two ethanol molecules occupy the fifth and the sixth coordination sites, with Co–O bond distances of

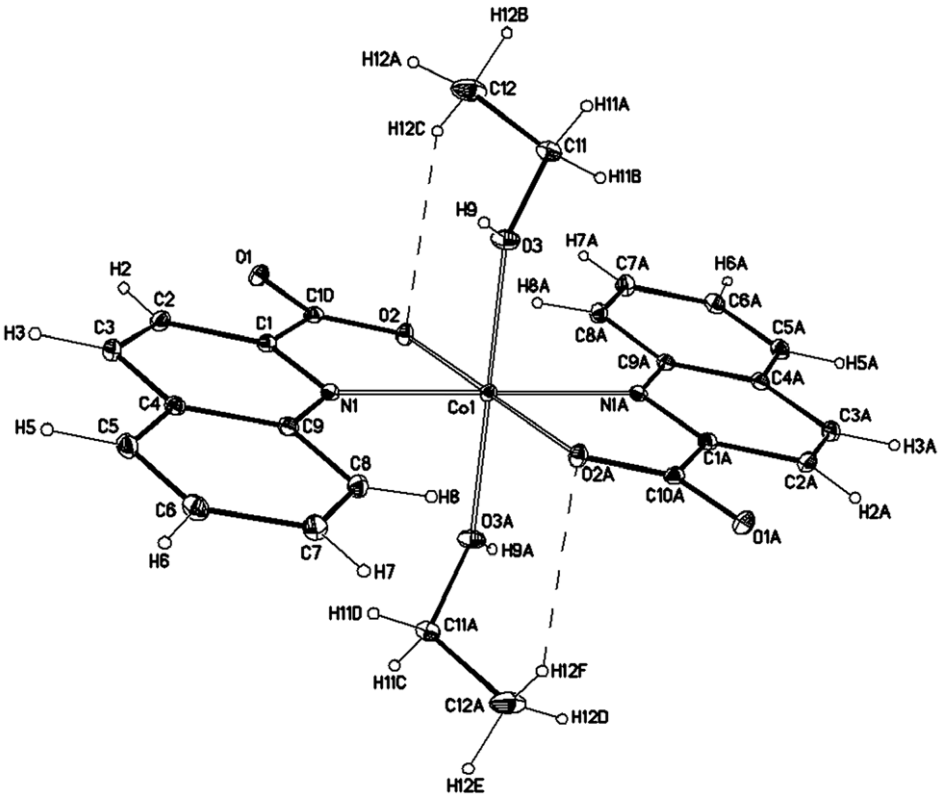

Fig. 2. Molecular structure of $[Co(2\text{-qca})_2(EtOH)_2]$ showing the atomic numbering. Intramolecular hydrogen bonds are indicated by a dotted line.

2.0998(16) Å. As shown in Table 2, the Co–N bonds are significantly longer compared to the Co–O bonds, causing a distortion of the coordination polyhedron around the metal ion. In fact, the polyhedron can be described as an elongated octahedron, elongated symmetrically along the Co–N direction.

The values observed for the Co–N and Co–O distances are characteristic of high-spin cobalt(II) [6,7,22]. The average C–C and C–N lengths in the quinoline ring of 1.398 and 1.353 Å, respectively, are typical [23]. The crystal packing is depicted in Fig. 3. There are three types of intermolecular hydrogen bonds linking the molecules in different directions.

In the first of these interactions, weak C–H···O contacts are formed between aromatic C–H groups of the quinoline rings and the coordinated [C(8)–H(8)···O(2)^{i}] and uncoordinated carboxylic oxygens [C(3)–H(3)···O(1)^{i} and C(5)–H(5)···O(1)^{iii}] (symmetry codes are given in Table 3) with the values of the hydrogen donor···acceptor distance, D···A bond distance and D–H···A angle suggested for C–H···O hydrogen bonds [24]. Another, the strong O–H···O type of interactions, are formed between the O–H group of the ethanol molecule and the coordinated and uncoordinated carboxylic oxygens of an adjacent molecule [O(3)–H(9)···O(1)^{ii} and O(3)–H(9)···O(2)^{ii}]. The shortest O···O length for the O–H···O bond systems is found between the ethanol O(3) atom and the coordinated carboxylate oxygen O(1)^{ii}. This bond O(3)–H(9)···O(1)^{ii} is short, $d_{D-A} = 2.664(2)$ Å, and approaches linearity, with an angle of 174(3)°. The last type of intermolecular contacts in this structure is a weak C–H···π interaction formed between the C(12)–H(12B) group of an ethanol molecule and the quinoline ring from the neighboring molecule [H···centroid 2.88 Å, C(12)···centroid 3.659(4) Å, C–H···centroid angle 134(2)°].

Additionally, the crystal packing is due to π–π stacking interactions involving quinoline rings of adjacent molecules. This stacking results in a Co···Co distance of 4.156 Å. The corresponding plane distances are 3.392 and 3.444 Å, with offsets of 0.874 and 0.844 Å, respectively, and these are slightly longer than those for typical aromatic–aromatic π-stacking interactions [25]. These H-bonds and π–π interactions result in the formation of a three-dimensional (3D) network (Fig. 3). The shortest metal–metal separation (Co···Co^{i}, i = $x + 1$, y, z and $x - 1$, y, z) is 5.839 Å. Further examination of the structure reveals weak intramolecular hydrogen bond contacts (Table 3).

3.2. Spectroscopic properties

The title compound shows in the IR spectrum strong carboxylate stretching frequencies ν_{as}(COO) and ν_{s}(COO) at 1626 and 1397 cm^{-1}, respectively, in the range character-

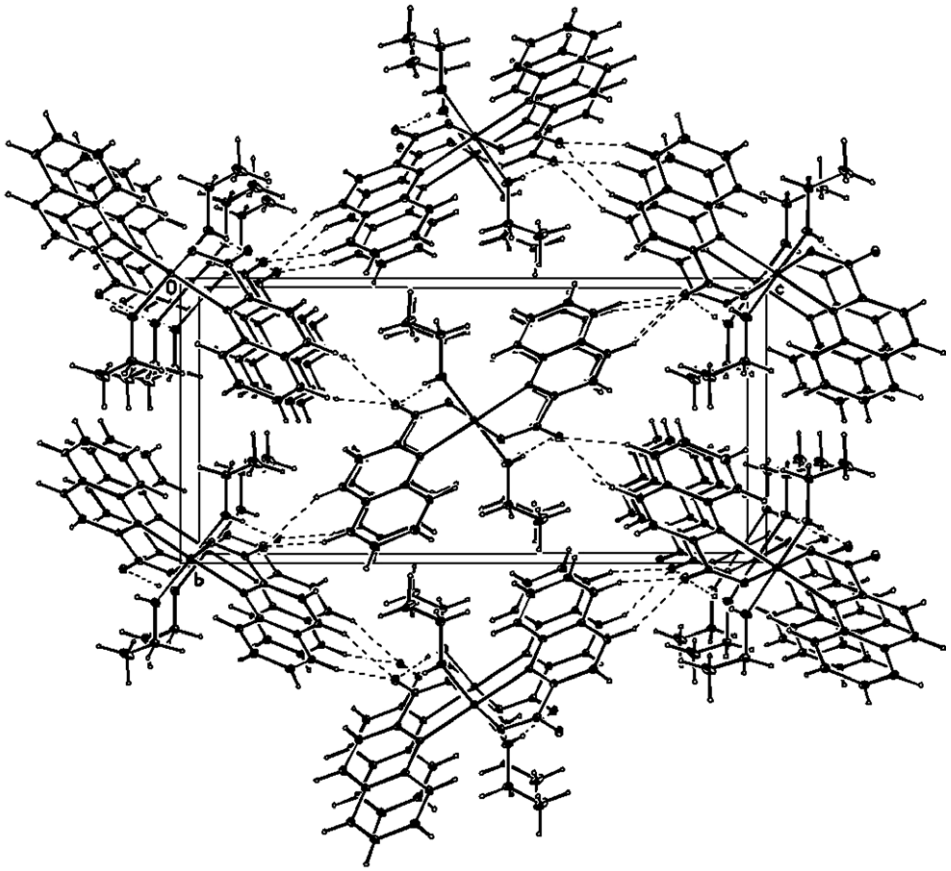

Fig. 3. Crystal packing of [Co(2-qic)$_2$(EtOH)$_2$] showing the 3D intermolecular H-bonding.

Table 3
Hydrogen-bonds and contacts for $[Co(2\text{-qca})_2(EtOH)_2]$ (Å, °)

istic of the carboxylate compounds. The observed $\Delta\nu$ separation value of 229 cm^{-1} is in the range expected for a monodentate carboxylate group [26,27].

The d–d spectrum shows bands (21 620, 18 700 and 8730 cm^{-1}) typical for an octahedral environment of a high-spin cobalt(II) ion, corresponding to the $^4T_{1g}(F) \rightarrow {}^4T_{2g}(F)$, $^4T_{1g}(F) \rightarrow {}^4A_{2g}$ and $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transitions [28,29]. Asymmetric bands in the near-IR region show that the Co(II) ion is in an octahedral tetragonally distorted N_2O_4 environment. The calculated spectrochemical parameters D_q and B (940 and 950 cm^{-1}, respectively) were calculated by a well-known method [29]. The relatively high value of the ligand-field Racah parameter B might reflect the deviation from an octahedral geometry [28,29].

The EPR spectrum of a polycrystalline powder of the studied complex shows no lines at room temperature but does display a broad isotropic signal with $g = 4.08$ at 77 K, as expected for a high-spin Co(II) complex for which the electron spin-lattice relaxation time is very fast.

3.3. Magnetic properties

The magnetic behavior of the complex is depicted in Fig. 4 in the form $\chi_M T$ versus T (χ_M is the molar magnetic susceptibility of the cobalt(II) ion). The value of $\chi_M T$ at room temperature is 2.90 $cm^3\,mol^{-1}\,K$ ($\mu_{eff} = 4.82\ \mu_B$), which is larger than that calculated for a spin quartet ($\chi_M T = 1.87\ cm^3\,mol^{-1}\,K$, 3.87 μ_B, for $S = 3/2$ with $g = 2.0$), but it agrees with the values observed for octahedral cobalt(II) complexes with a significant first-order orbital contribution to the magnetic moment [30,31], typical of the $^4T_{1g}$ ground state.

The $\chi_M T$ plot (Fig. 4) gradually decreases with temperature and reaches a minimum value of 1.78 $cm^3\,K\,mol^{-1}$ ($\mu_{eff} = 3.77\ \mu_B$) at 1.8 K; therefore cobalt(II) remains totally in the high-spin state down to 1.8 K. The $\chi_M T$ values follow the Curie–Weiss law $\chi_M(T) = C/(T-\theta)$ from room temperature to 130 K with $C = 3.04\ cm^3\,K/mol$ and $\theta = -15.13$ K, where C and θ are the Curie and Weiss constants, respectively. The calculated [32] effective magnetic moment μ_{eff} per cobalt is 4.91 μ_B. This is close to the experimental value and to the values of 4.7 and 5.1 μ_B calculated for the medium and weak octahedral crystal fields, respectively [33].

The decrease of the $\chi_M T$ value is mainly due to zero-field splitting [34,35], but a steeper decreases is observed at lower temperatures. This is probably due to weak antiferromagnetic intermolecular interactions between the Co(II) ions.

With the assumption that the non-axial zero-field parameter E is negligible, the magnetic data for $[Co(2\text{-qic})_2(EtOH)_2]$ could be fitted very well to the appropriate axial spin Hamiltonian, where $S = 3/2$ [34,35]: $\widehat{H} = g\beta H \cdot S + D[S_z^2 - 1/3S(S+1)]$, and D is the axial ZFS parameter and g is a factor for the 3/2 quartet. The fitting results provide a typical parameter set of $|D| = 65.1\ cm^{-1}$, $g_{\parallel} = 2.14$ and $g_{\perp} = 2.58$ [36,37]. The plot of the best fit is shown in Fig. 4 as a solid line. The good fit ($R = 2.52 \times 10^{-4}$) does not reflect the need to include a rhombic (E) zero-field splitting term in the Hamiltonian.

The molar magnetization M of a powder sample of the studied complex was measured as a function of the applied magnetic field H at 2 K (Fig. 5). No differences were

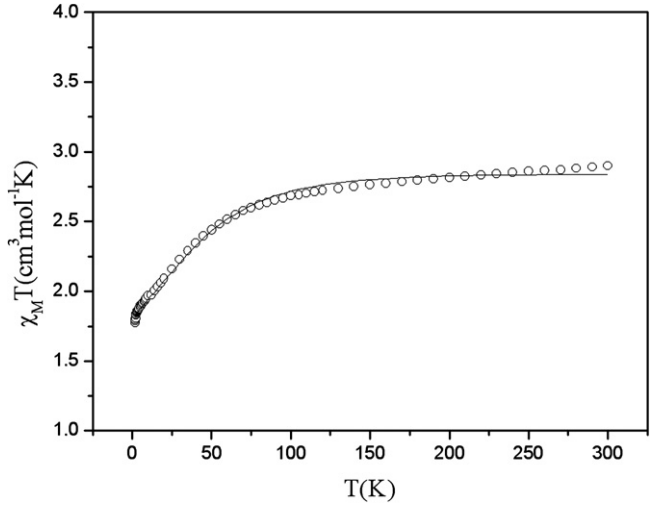

Fig. 4. Plot of $\chi_M T$ (○) vs. temperature for $[Co(2\text{-qic})_2(EtOH)_2]$. The solid line is calculated with the use of the spin Hamiltonian analysis described in the text.

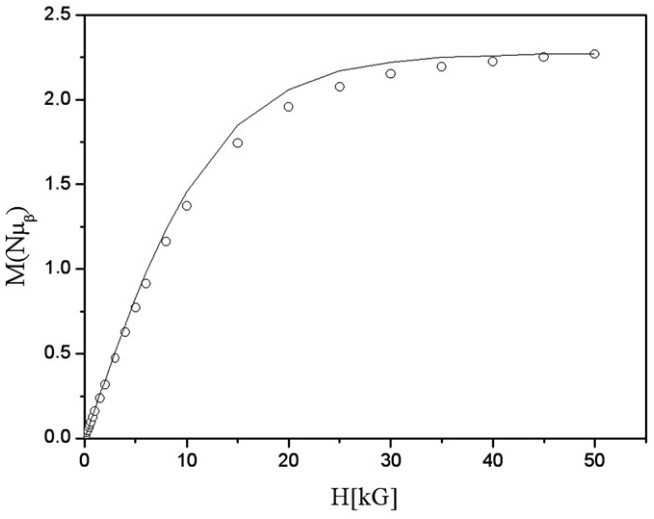

Fig. 5. Molar magnetization in $N\mu_\beta$ units of $[Co(2\text{-qic})_2(EtOH)_2]$ measured in 2 K as a function of magnetic field.

observed between the $M(H)$ curves measured with increasing or decreasing magnetic field strength.

Upon applying a magnetic field, the magnetization increases gradually. The value of $M_{sat} = 2.27\ N\mu_B$ was reached at 50 kG. The solid line (Fig. 5) represent the theoretical magnetization curves for a system in a ground state with an effective spin $S' = 1/2$ and effective g value equal to 4.58. The shape of the experimental points do not exactly follow the Brillouin formula for isolated Co(II) ions. At intermediate fields the experimental points are below the theoretical curve, indicating a weak antiferromagnetic interaction.

The intermolecular exchange does not affect the magnetic moment in the Curie–Weiss region, but it influences the very low-temperature magnetic behavior. Parameters C of 1.95 cm^3 K/mol and θ of −0.17 K were obtained from a fit to the Curie–Weiss law in the 1.8–7 K temperature region (Fig. 6) where $1/\chi_M = f(T)$ is linear (inset of Fig. 6). At low temperatures this small negative value of θ may suggest the existence of a very weak intermolecular antiferromagnetic exchange between the cobalt ions (within the crystal lattice) via the hydrogen bond system and stacking interactions in the crystal lattice.

In general, the effect of weak spin interactions on the magnetic susceptibility may be treated by the molecular field approximation. Therefore, in order to evaluate the interaction of the magnetic center of the three-dimensional network of the $[Co(2\text{-qca})_2(EtOH)_2]$ compound, a molecular exchange field model was used, Eqs. (1) and (2) [38]:

$$\chi_M = \frac{N\beta^2 g^2}{3kT} S(S+1) \tag{1}$$

$$\chi_M^{corr} = \frac{\chi_M}{1 - \frac{2zJ'}{N\beta^2 g^2}\chi_M} \tag{2}$$

where χ_M is the molar susceptibility of a paramagnetic center, χ_M^{corr} is the measured experimental susceptibility,

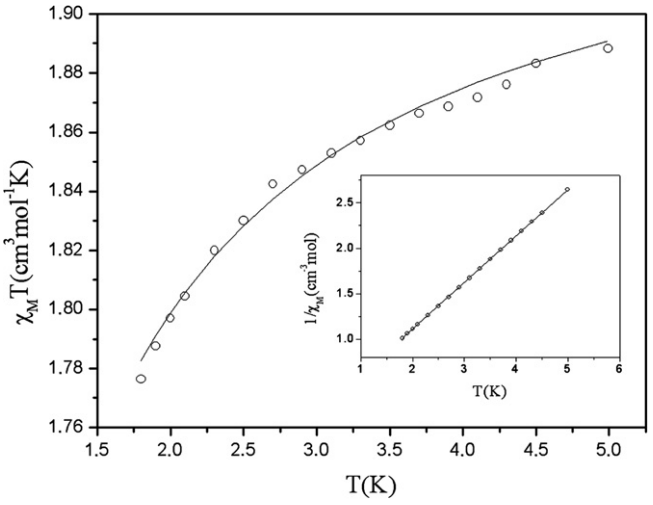

Fig. 6. Plot of $\chi_M T$ (o) vs. temperature in the $T < 5$ K. temperature region for $[Co(2\text{-qic})_2(EtOH)_2]$. The solid line is calculated with the use of the model described in the text using an effective spin $S' = 1/2$. The inset shows the fit to the Curie–Weiss law.

zJ' is the exchange between magnetic ions belonging to different molecules, z is the number of nearest neighbors and the other symbols have their usual meanings. Since the EPR transition occurs only within the ground Kramers doublet, the cobalt(II) system may be characterized by an effective spin of 1/2. Therefore, an attempt to describe the intermolecular exchange has been made in Eq. (2), using the effective $S' = 1/2$. The fitting procedure provides the following parameters: $zJ' = -0.25\ cm^{-1}$, $g = 4.57$ and $R = 1.33 \times 10^{-4}$. R is the agreement factor defined as $R = \sum_{i=1}^{n}(\chi_i^{exp} - \chi_i^{calc})^2/(\chi_i^{exp})^2$. The result is shown in Fig. 6. The effective g value is consistent with the value of 4.58 obtained with the theoretical magnetization. The small value of zJ obtained in the above approximations is compatible with the expected limit $|J| < 0.5\ cm^{-1}$ for an exchange interaction between the cobalt(II) ions with a Co···Co distance of 5.84 Å, transmitted through weak intermolecular non-covalent interactions [39].

3.4. Aspects of the synthesis

As mentioned earlier, the reaction of the (quinolin-2-ylmethyl)phosphonate ligand (2-qmpe) with $CoCl_2 \cdot 2H_2O$ performed in air in ethanol solution primarily leads to the formation of the green compound of the formula $[Co(2\text{-qmpe})_2Cl_2]$, containing the O-bonded 2-qmpe ligand as previously observed [9]. This compound is unstable in solution and slowly undergoes decomposition to a compound of the formula $[Co(2\text{-qca})_2(EtOH)_2]$, (2-qca = quinoline-2-carboxylate). The starting compound is stable in solution under an inert atmosphere (N_2). In a recent paper [10] we demonstrated that copper(II) ions promote and catalyze oxidative decomposition of the phosphonate ligands 2-pmpe and 2-qmpe according to the scheme:

$$R\text{–}CH_2\text{–}P(O)(OEt)_2 \rightarrow R\text{–}COOH + OH\text{–}P(OEt)_2.$$

Additionally, we showed that the other divalent transition metal ions do not exhibit this activity under comparable experimental conditions. The process of decomposition of the primary formed compounds of Cu(II) strongly depends on the bonding properties of the ligands. The copper(II) coordination compounds with monodentate coordinating phosphonate ligands undergo decomposition. However, with the N,O-bonded ligands 2-pmpe and 4-pmpe, chelating and bridging, respectively, these compounds are stable in solution in air. These complexes are probably stabilized by the didentate coordination of the ligands to the copper(II) ion.

The present results also indicate that the Co(II) ion, with participation of dioxygen, promotes conversion of the 2-qmpe ligand into quinoline-2-carboxylate (2-qca) according to the scheme presented in Fig. 1. All the remaining phosphonate Co(II) complexes studied by us so far [6–9], in which the ligands are N,O-bonded to the Co(II) ion, are stable in solution in air, supporting our earlier suppositions for Cu(II) compounds. Namely, the didentate coordination of the phosphonate ligands to Co(II) ions stabilized

these complexes, preventing oxidative cleavage of the starting organophosphonate ligands and the formation of the carboxylate ligands.

Our experiments do not provide us with clear information of the mechanism of these reactions with the participation of the Cu(II) and Co(II) ions. Oxidation reactions that involve copper-ion promoted activation of dioxygen are well known and have numerous catalytic and synthetic applications [40–43], although the mechanism is still poorly understood. The Co(II) complexes are also known as being active toward O_2 [44–46]. However, to the best of our knowledge, there is no example of a reaction between O_2 and cobalt(II) complexes in which ligand degradation occurs.

Within any mechanistic implication we suggest that the formation of the carboxylate compounds under strictly aerobic conditions involves cobalt ion promoted activation of dioxygen.

4. Conclusions

We have synthesized and characterized the Co(II) complex with quinoline-2-carboxylate (2-qca), which has been obtained in the decomposition reaction of the Co(II) compound with diethyl(quinolin-2-ylmethyl)phosphonate (2-qmpe). In this reaction oxidative cleavage of the starting ligand occurs. The final product of this process was the Co(II) compound with 2-qca. Detailed characterization of $[Co(2\text{-qca})_2(EtOH)_2]$ includes structural, spectroscopic and magnetic studies.

In our recent paper [10] we have reported on an oxidative reaction with the aid of the copper(II) ion in which oxidative cleavage of the C–P bond occurs. In this paper we have presented this reaction with the participation of the cobalt(II) ion. This reaction is an important issue in contemporary research of the interaction of molecular oxygen with copper(II) and cobalt(II) species and will be the subject of further studies.

Finally, it is worth highlighting that the chemical degradation of organic phosphonates is of fundamental importance. This is due to their role played in the environment as pesticides, herbicides and other products of economic activity, which are an ecological problem. The importance of the chemistry exploited during the chemical degradation is difficult to understate given its direct relevance to detoxification of herbicides, pesticides, insecticides and other agents containing the organophosphonate moiety.

Scheme 1.

2-[2-(2-formylphenoxy)ethoxy]benzaldehyde in the presence of Mn(II) and/or Cd(II) ions.

2. Experimental

2.1. Starting materials

All solvents were of reagent grade quality and were purchased commercially. *N*1-(2-Nitrobenzyl)-*N*1-(2-aminoethyl)-ethane-1,2-diaminetrishydrochloride (I), *N*1-(2-nitrobenzyl)-*N*1-(2-aminoethyl)propane-1,3-diaminetrishydrochloride (II) and 2-[2-(2-formylphenoxy)ethoxy]benzaldehyde were synthesized according to the literature method [14,15].

2.2. Instrumentation

NMR spectra were obtained using a Bruker A V 300 MHz spectrometer. Infrared spectra were recorded in KBr pellets using a BIO-RAD FTS-40A spectrophotometer (4000–400 cm^{-1}).

2.3. X-ray crystal structure determination

Vapor diffusion of diethyl ether into a solution of $[MnL^4(CH_3OH)](ClO_4)_2$ and $[CdL^5(H_2O)](NO_3)_2$ in MeOH afforded pale yellow crystalline needles. X-ray data for $[MnL^4(CH_3OH)](ClO_4)_2$ were measured on a STOE IPDS-II two circle diffractometer at 293 °C, using graphite monochromated Mo Kα X-ray radiation ($\lambda = 0.7107$ nm) for $[MnL^4(CH_3OH)](ClO_4)_2$. X-ray data for $[CdL^5(H_2O)](NO_3)_2$ were also measured on a Bruker SMART-1000 diffractometer. Other crystallographic data are summarized in Table 1.

A full minimization of the structure for each macrocyclic complex was performed at the ab initio HF level of theory using gradient techniques with the GAUSSIAN-98 set of programs [16], on a Pentium-PC computer with a 3000 MHz processor. The effective core potential (ECP) standard basis set LanL2DZ [17] was utilized for the cadmium and manganese metal ions. The full-electron standard basis set 3-21G* or 6-31G* [18] were used for all other atoms. A starting semi-empirical structure for the ab initio 3-21G* calculations was obtained using the HYPERCHEM 5.02 program [19]. The resulting structures of the 3-21G* calculations were then used for the 6-31G* basis set.

2.4. Synthesis

2.4.1. Ligand synthesis

2.4.1.1. 2-((Bis(2-aminoethyl)amino)methyl)benzenamine (L^2). A mixture of *N*1-(2-nitrobenzyl)-*N*1-(2-aminoethyl)ethane-1,2-diaminetrishydrochloride (I) (3.47 g, 10 mmol), ammonium chloride (4 g) and water (2 ml) in 100 ml of ethanol was heated to boiling and 3 g of zinc dust was added. When the solution was pale green it was filtered. The volume was then reduced to 20 ml by rotary evaporation. Excess water was added to the mixture and the pH was adjusted to 12 with potassium hydroxide. The solution was extracted with chloroform (×3). The chloroform extracts were combined and dried over anhydrous sodium sulfate. The dried extracts were then reduced to a small volume on a rotary evaporator. The product was obtained as an oil. Yield (1.3 g, 62%). *Anal.* Calc. for ($C_{11}H_{20}N_4 + 1/10CHCl_3$): C, 60.53; H, 9.20; N, 25.44. Found: C, 60.61; H, 9.23; N, 25.31%. IR (Nujol, cm^{-1}) 3360, 3380 $\nu(NH_2)$, 3082 $\nu(CH)$; ^1H NMR δ_H ($CDCl_3$, ppm) 2.59 (t, 4H), 2.75 (t, 4H), 3.08 (NH_2, 6H, b), 3.56 (s, 2H), 6.62 (m, Ph, 2H), 6.91 (m, Ph, 2H); ^{13}C NMR δ_C ($CDCl_3$, ppm) 39.95, 58.81, 59.87,115.11, 116.30, 123.41, 129.90, 131.27, 147.47.

2.4.1.2. 2-(((2-Aminoethyl)(3-aminopropyl)amino)methyl) benzenamine (L^3). The ligand (L^3) can be readily prepared by the above procedure except using *N*1-(2-nitrobenzyl)-*N*1-(2-aminoethyl)propane-1,3-diaminetrishydrochloride (II) (3.61 g, 10 mmol) instead of (I). Yield (1.4 g, 63%) *Anal.* Calc. for ($C_{12}H_{22}N_4 + 1/11CHCl_3$): C, 62.28; H, 9.55; N, 24.03. Found: C, 62.22; H, 9.39; N, 24.13%. IR (KBr, cm^{-1}) 3361 and 3385 (NH_2), 3070 (CH); ^1H NMR δ_H ($CDCl_3$, ppm) 1.52 (m, 2H), 2.19, 2.40, 2.60 (m, 14H), 3.79 (s, 2H), 7.25–7.88 (b, 4H); ^{13}C NMR δ_C ($CDCl_3$, ppm) 29.49, 38.97, 39.52, 51.10, 56.22, 58.16, 114.84, 116.82, 122.35, 127.78, 130.04, 146.32.

2.5. Preparation of the complexes

2.5.1. General procedure

All the complexes were readily prepared by template condensation. The required amine (0.5 mmol) in methanol (10 ml) was added dropwise to a mixture of the appropriate manganese (II) or cadmium (II) salts (0.5 mmol) in methanol

3. Results and discussion

3.1. Synthesis and characterization

Template condensation of 2-[2-(2-formylphenoxy)ethoxy]benzaldehyde with (L^2) and (L^3) in the presence of a Mn(II) or Cd(II) template in refluxing methanol cleanly yields the target macrocyclic Schiff base complexes

Scheme 2.

$[MnL^4(CH_3OH)](ClO_4)_2$, $[MnL^5(CH_3OH)](ClO_4)_2$, $[CdL^4(H_2O)](NO_3)_2$ and $[CdL^5(H_2O)](NO_3)_2$ (Scheme 1). All the complexes are air-stable solids, moderately soluble in CH_3CN and DMSO and have similar IR spectra, and the data are consistent with the presence of imine bonds. Each complex exhibits the (C=N) mode at *ca.* 1642–1644 cm^{-1} and the (NH_2) mode at *ca.* 3228–3317 cm^{-1}, while no bands attributable to C=O are detected. All the manganese complexes exhibit a broad medium-intensity band at 3428–3445 cm^{-1} assigned to the (OH) group of MeOH, a very strong band at ≈1100 cm^{-1} and a medium band at ≈625 cm^{-1} due to the uncoordinated perchlorate ion.

The cadmium complexes exhibit a broad medium-intensity doublet band at ≈3422 and 3577 cm^{-1} assigned to the H_2O group. The NMR studies of the Cd(II) complexes also provide strong evidence for the formation of the macrocyclic complexes.

3.2. X-ray crystal structures

The molecular structures of $[MnL^4(CH_3OH)](ClO_4)_2$ and $[CdL^5(H_2O)](NO_3)_2$ are shown in Fig. 1, together with the atomic numbering scheme. Selected bond lengths and angles are given in Table 2. The ligands are 17-membered and 18-membered [1+1] Schiff base macrocycles with a 2-aminobenzyl pendant-arm. The coordination sphere around the Mn(II) and Cd(II) ions can be described as slightly distorted pentagonal bipyramidal with the metal ion, three nitrogen and two oxygen atoms lying in an approximately pentagonal plane and a 2-aminobenzyl nitrogen atom situated in the axial position. The coordinated solvent oxygen atom is situated in the axial position in both $[MnL^4(CH_3OH)](ClO_4)_2$ and $[CdL^5(H_2O)](NO_3)_2$, with the *trans* angles O(3)–Mn(1)–N(1) [172.08(19)°] and O(3)–Cd(1)–N(4) [168.3(2)°] close to linearity. The X-ray crystal structure of **1** shows that the macrocyclic ring is not strictly planar and the Mn–N(3) and Mn–O(2) bond lengths are significantly longer than their related Mn–N(4) and Mn–O(1) bond lengths. This suggests that the binding cavity presented by the 17-membered macrocycle, L^4, is slightly larger than the optimum amount for Mn(II).

The sum of the angles subtended by the donor atoms at Mn is 364.89°, the plane containing N(3), N(2), N(4), O(2) and O(1) has a r.m.s. value of 0.2839 Å and the metal atom

is close to co-planarity, being only 0.034 Å out of this plane. The r.m.s. value of the plane of the aromatic carbon ring of the pendant arm is 0.0162 Å and among them the C_1 carbon atom has the maximum displacement. The angle between the plane containing the aromatic ring of the pendant arm and that of the macrocyclic ring containing N(3), N(2), N(4), O(2) and O(1) is 143.92°. The r.m.s. values of the aromatic rings within the macrocyclic framework are 0.0145 and 0.0067 Å and the angle between these rings is 137.58°.

The structure **4** also shows that the macrocyclic ring is not strictly planar and the Cd–N(1) and Cd–O(1) bond lengths are significantly longer than the Cd–N(2) and Cd–O(2) bond lengths, respectively. This suggests that

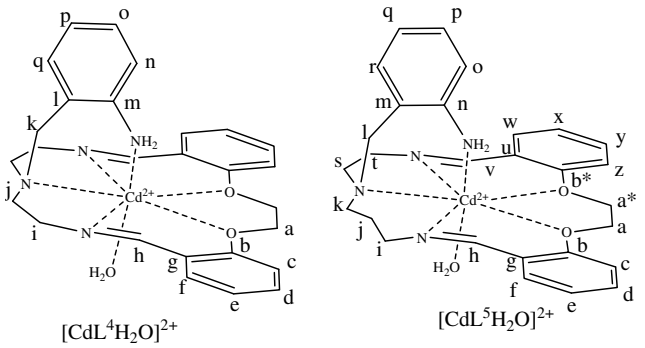
the binding cavity presented by the 18-membered macrcocyle, L^5, is slightly larger than the optimum amount for Cd(II).

The sum of the angles subtended by the donor atoms at Cd is 364.24° and the plane containing N(2), N(3), N(1), O(1) and O(2) atoms has a r.m.s. value of 0.2761 Å. The 2-aminobenzyl pendant arm in both complexes is orientated on the same side of the macrocyclic plane so that steric hindrance is small. While the L^4 and L^5 macrocycles in the Mn(II) and Cd(II) complexes are 17- and 18-membered

rings, respectively, their r.m.s. values are almost the same due to the larger size of Cd(II).

3.3. Ab initio modelling studies



We assumed that the same mode of [1+1] cyclization as found for $[CdL^5(H_2O)]^{2+}$ had occurred with other cadmium complexes, due to the similarity of their IR, NMR spectra and microanalyses, and so undertook a full geometry optimization at the HF/3-21G* and HF/6-31G* levels of theory, using the LanL2DZ basis set for cadmium. We applied such an assumption for the manganese complexes. The resulting structural diagrams are shown in Fig. 2 and corresponding selected calculated bond distances and angles are shown in Table 2 along with the corresponding values obtained for $[CdL^5(H_2O)]^{2+}$ and $[MnL^4(CH_3OH)]^{2+}$. As can be seen, the results of the 3-21G* calculations for both the $[CdL^5(H_2O)]^{2+}$ and $[MnL^4(CH_3OH)]^{2+}$ complexes are slightly closer to the experimental data than those of the 6-31G* calculations. There are good agreements between the calculated and observed distances. It is thus the results of these calculations that are considered further.

The 3-21G* calculated r.m.s. values of the planes containing N(3), N(2), N(4), O(2) and O(1) in complexes **1** and **2** are 0.2616 and 0.3149 Å, respectively. The similar r.m.s. values of the planes containing N(1), N(2), N(3), O(1) and O(2) in complexes **4** and **5** are 0.2670 and 0.3273 Å, respectively. The sum of the bond lengths subtended by the donor atoms at Mn in **1** and **2** are 16.268 and 16.59 Å, respectively, and those at Cd in **3** and **4** are 16.609 and 16.953, respectively, and these show that the L^4 macrocycle has a suitable cavity in comparison with the other macrocycle, and on the other hand the cadmium ion is more appropriate than the manganese ion for the L^4 macrocycle.

3.4. NMR studies

The ^1H as well as $^{13}C\{1H\}$ NMR data for $[CdL^n]^{2+}$ ($n = 4$ and 5) dissolved in DMSO-d_6 are shown in Table 3, which uses the lettering scheme shown in Scheme 3. The ^1H and ^{13}C signals were assigned using one- and two-dimensional ^1H–^1H COSY, ^1H–^{13}C HMQC and DEPT spectra. The ^{13}C NMR spectrum of $[CdL^4]^{2+}$ shows seventeen carbons as expected. The $[CdL^5]^{2+}$ complex, in the region corresponding to the signals of aliphatic carbons (28.21–67.55 ppm) shows eight peaks, indicating all aliphatic methylene carbons are inequivalent. In the region corresponding to the signals of the aromatic ring carbons (113.90–1147.97 ppm) fourteen peaks instead of eighteen expected peaks are observed, due to the high similarity of the head unit and low resolution of the instrument.

In each complex, two signals corresponding to the methylene protons of 2-aminobenzyl are observed and these show that the protons are inequivalent, due to the bend orientation of the 2-aminobenzyl group in the complexes. The ^1H NMR spectra of the complexes show a signal at *ca.* 5.02 ppm, corresponding to coordinated H_2O. Unfortunately, since the protons do not show scalar-coupling, we were not able to assign explicitly the coupling constants.

Scheme 3.

4. Conclusions

Cd(II) and Mn(II) ions are effective as templates for the Schiff base condensation of 2-[2-(2-formylphenoxy)ethoxy]benzaldehyde and two tetraamine tripodal ligands (L^2 and L^3), resulting in the formation of macrocyclic complexes having a pendant arm (2-aminobenzyl) based on the X-membered N_3O_2 rings (X = 17 and 18).

Scheme 1. Chemical structures of the synthesized compounds.

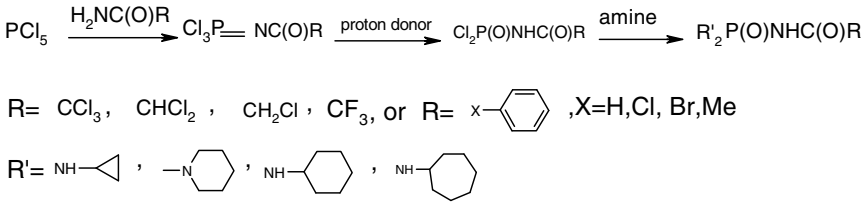
characterization and crystal structure study of $CCl_3C(O)NHP(O)[N(C_5H_{10})]_2$ (**1d**), $CHCl_2C(O)NHP(O)[N(C_5H_{10})]_2$ (**2d**), $Cl–C_6H_4C(O)NHP(O)[NH(C_5H_9)]_2$ (**5b**) and $Cl–C_6H_4C(O)NHP(O)[N(C_4H_8)O]_2$ (**5e**), we also recorded their mass spectra together with 29 of our previously synthesized compounds [15–18]. Also, the observed fragmentation behaviors are compared with those reported in the literature [7].

2. Experimental

2.1. Materials

2,2,2-Trichloroacetamide, 2,2-dichloroacetamide, 2-chloroacetamide, 2,2,2-trifluoroacetamide, phosphorus pentachloride (⩾98%), formic acid (⩾98%), cyclohexylamine (⩾98%), cyclopropylamine (⩾98%) (Merck) and cycloheptylamine (⩾98%), 4-bromobenzamide (⩾98%), 4-methylbenzamide (⩾98%) (Fluka) were used as supplied. In all reactions low temperatures were used.

2.2. Spectroscopic measurements



All reactions were performed under an argon atmosphere and in dry solvents. ^1H, ^{13}C and ^{31}P NMR spectra were recorded on a Bruker Avance DRS 500 spectrometer. ^1H and ^{13}C chemical shifts were determined relative to internal TMS and ^{31}P chemical shifts relative to 85% H_3PO_4 as an external standard. Infrared (IR) spectra were recorded on a Shimadzu model IR-60 spectrometer. Elemental analysis was performed using a Heraeus CHN-O-RAPID apparatus. Mass spectra were obtained with a Finnigan-mat gaschromatograph/mass spectrometer (Bremen, Germany), magnetic sector, high resolution, double focusing, model 8430. It was operated in the 70 ev positive ionization mode. Instrument calibration was performed

routinely using the calibration compound, perfluorokerosene (PFK) through the reference inlet system. All samples were introduced to the ion source through the introduction solid probe system. The scanning rate of the mass spectrometer was set as 1 s/decade at a mass range of 33–600 a.m.u. All mass spectra were taken by the manufacturer's software SS300.

3. Results and discussion

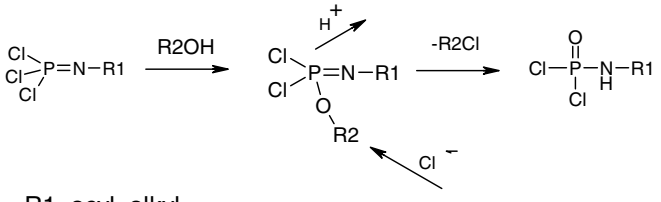
3.1. Synthesis procedure

A series of new carbacylamidophosphates with various substituents based on phosphorus pentachloride as a starting material, shown in the scheme below, were synthesized

2.3. X-ray measurements

X-ray data of compounds **1d**, **2d**, **5b** and **5e** were collected on a Bruker SMART 1000CCD [19] with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by the direct method using the SHELX-97 program package [20]. The non-hydrogen atoms were refined anisotropically and all located from subsequent difference Fourier maps and refer to final *R* values of 0.0471, 0.0322, 0.0518 and 0.0412 for **1d**, **2d**, **5b** and **5e**, respectively.

2.4. Synthesis



2.4.1. General procedure for the synthesis of compounds as starting materials

2,2,2-Trichloroacetyl phosphoramidic dichloride, 2,2-dichloroacetyl phosphoramidic dichloride, 2-chloroacetyl phosphoramidic dichloride, 2,2,2-trifluroacetyl phosphoramidic dichloride, benzoyl phosphoramidic dichloride, 4-chlorobenzoyl phosphoramidic dichloride, 4-bromobenzoyl phosphoramidic dichloride and 4-methylbenzoyl phosphoramidic dichloride were prepared according to the literature methods [21,22].

2.4.2. General procedure for the synthesis of compounds *(1–7)a, (1–3)d, (1–3)d, (1–3)c and (1–7)f*

The above mentioned compounds were prepared by the reaction of 15 mmol of the phosphoric dichloride derivatives (described in Section 2.4.1) with 60 mmol of the corresponding amines in dry chloroform or acetonitrile. The amines were added dropwise to a solution with stirring. The temperature was controlled in range −5 to −8 °C. After stirring for 6–8 h, the products were filtered off and then washed with H_2O. The compounds were recrystallized from chloroform and *n*-heptane. Colorless crystals of compounds **1d**, **2d**, **5b** and **5e** were obtained by slow evaporation of *n*-heptane–chloroform (1:5) as rod shaped crystals which were air stable. The crystallographic data for these compounds are listed in Table 3.

The method for the preparation of compounds with a –C(O)NHP(O)- core unit was presented first by Kirsanov and coworkers [22]. The protonation of trichlorophosphazene, formed from the reaction of PCl_5 with a proper amide, has been strictly followed when the proton donor is a weak acid like a carboxylic acid. Considering the much reduced basicity of the N atom in trichlorophosphazene, the acidolysis with weak proton donors, especially formic acid, starts with the initially nucleophilic P atom, and this is followed by protonation on the N atom:

Irrespective of the protic agent used, no changes are observed in the structure of the protonated product.

3.1.1. Spectral study

As shown in Table 1, the C=O vibrational frequencies of compounds **1a**, **2a**, **3a**, **1c**, **2c**, **3c**, **1d**, **2d**, **3d**, **1f**, **2f** and **3f** with the $CH_xCl_yC(O)NH$– moiety (haloacetamide derivatives) appear in the range 1637–1714 cm^{-1} and those of compounds **4a**, **5a**, **6a**, **7a**, **4f**, **5f** and **6f** containing the $XC_6H_4C(O)NH$– moiety (halo and alkyl benzoyl amide derivatives) are at 1627–1654 cm^{-1}, due to greater electronegativity of the halo-acetamide than the halo or methyl-benzoyl amide groups. These results are confirmed by crystallographic data by comparing the C=O bond lengths, which will be discussed in the X-ray structural investigation (Section 3.1.3). In all the synthesized compounds, the $P–N_{amine}$ stretching vibrations (1015–1161 cm^{-1}) appear at higher frequencies than the $P–N_{amide}$

Table 1
IR vibration frequencies (cm^{-1}) in the synthesized compounds

vibrational bands (834–948 cm^{-1}). The NMR data, summarized in Table 2, show that in compounds **1c**, **2c** and **3c**, with cyclohexylamine substituents, the ^{31}P chemical shifts (5.1–4.2 ppm) appear more upfield relative to the other synthesized molecules. Also, the ^{31}P chemical shifts in structurally similar compounds are very close to each other. ^{13}C NMR spectral studies show that $^2J_{(P,Caliphatic)}$ is only observed in **1d**, **2d** and **3d**, and this coupling is absent in the other synthesized compounds (Table 2). Also, in these compounds (**1d**, **2d** and **3d**) with a tertiary amine, $^3J_{(P,Calphatic)} > {}^2J_{(P,Caliphatic)}$ is in agreement with our previous studies [23,24]. It is observed from Table 2 that the carbons with two bond distances from the N atom in **1d**, **2d** and **3d** are equivalent and $^3J_{(P,Caliphatic)}$ values are between 4.5 and 4.8 Hz, but in compounds **1a**–**7a**, **1c**–**3c** and **1f**–**7f** non-equivalent β-carbon atoms are indicated. However, two different $^3J_{(P,Caliphatic)}$ values are observed which are between 3.8–5.5 Hz and 4.1–6.98 Hz. As shown in Table 2, on increasing the ring size of the amine groups, the $^3J_{(P,Caliphatic)}$ value becomes smaller and the results are similar to our previous work [12]. The $^2J_{(P,C(O))}$ couplings are only observed in **3a**, **3c**, **3d** and **3f**, with the CF_3 amide derivatives. The ^{13}C NMR spectra of those compounds show quartets for CF_3 and C(O) carbon atoms which are due to the three fluorine atoms with coupling constants ranging from 290.3–304.2 Hz for $^1J_{CF}$ and 38.5–45.7 Hz for $^2J_{CF}$, respectively. The quartets are further split into doublets, arising from coupling to the phosphorus atom with coupling constants in the range 10.9–12.1 Hz ($^3J_{PC}$) for CF_3 and 2.6–3.8 Hz ($^2J_{PC}$) for C(O) carbon atoms. Since the former involves three bonds and the later only two, it must be concluded that through space coupling is significant in those four molecules. Furthermore, three bond distance coupling between the phosphorous atom and haloalkyl carbon atom in **1a**, **1c**, **1d** and **1f** are observed and vary between 5.1 and 13.7 Hz. No coupling between the phosphorous atom and the hydrogen atom of the NH amide group in the ^1H NMR spectral data for all the synthesized compounds could be observed.

3.1.2. X-ray structural investigation

The results of the single crystal X-ray structure analysis for compounds **1d**, **2d**, **5b** and **5e** are shown in Figs. 1, 3, 5 and 7, respectively, along with their numbering schemes. Crystallographic data are summarized in Table 3 and selected bond lengths and bond angles are given in Tables 4 and 5. Details of the hydrogen bonding interactions for all four structures are summarized in Table 6. Unit cell packing diagrams for compounds **1d**, **2d**, **5b** and **5e** are shown in Figs. 2, 4, 6 and 8. The four reported crystals contain one amidic hydrogen atom and form dimers via intermolecular –P=O...H–N– hydrogen bonds, that in **1d** is a dimeric aggregate (Fig. 2). Similarly, the intermolecular hydrogen bonds formed via the haloalkyl hydrogen atom and the phosphoryl oxygen, in addition to the amidic hydrogen, lead to the formation of dimeric aggregates in the unit cell of **2d** (Fig. 4). As shown in Fig. 6, the carbonyl oxygen atom, O(1), makes an intermolecular hydrogen

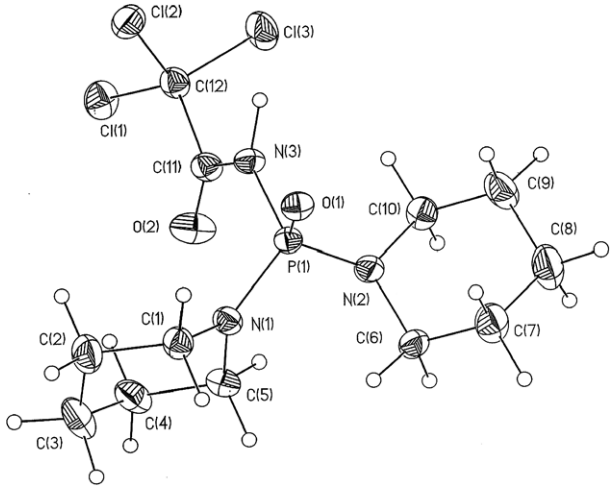

Fig. 1. Molecular structure for **1d** with the atomic numbering (50% probability ellipsoids).

bond with the proton which is connected to N(2) (aminic hydrogen) and the other aminic hydrogen, bonded to N(1) makes a hydrogen bond with the terminal chlorine atom of the benzoyl amide derivative. Also, the formation of hydrogen bonds between the amidic hydrogen and the phosphoryl oxygen in **5b** leads to a centrosymmetric dimer, similar to the dimer in the unit cell of **5e** (Fig. 8). In all four crystal structures, the phosphoryl and the carbonyl groups are in anti positions to each other, which is in accordance with other carbacylamidophosphates with a –C(O)NHP(O)– core unit [23–25]. As shown in Table 7, the P=O bond lengths in molecules **1d**, **2d**, **5b** and **5e** are longer than the normal P=O bond length (1.45 Å) [26] and they in accord with another similar compounds previously synthesized (listed in Table 7). Also, the C=O bond length is the longest (1.23(3) Å) in **5b** relative to the other reported structures in Table 7. Structural studies of those crystals show that the P–N_{amine} bond lengths are shorter than the P–N_{amide} bond lengths. It is electrostatic

interactions in the –C(O)–NH–P(O)–N– moiety that cause shortening of the C–N_{amide} bond lengths and the longer C–N_{amine} bond lengths [27]. A comparison to the P–N bond lengths in the literature [27] shows that the P–N_{amine} bond lengths are shorter than typical P–N single bonds (1.77 Å) and longer than P=N double bond lengths (1.57 Å). The coordination environment around the phosphorus atoms of these compounds is approximately tetrahedral, since the average of the six angles involving P atoms for **1d**, **2d**, **5b** and **5e** are 108.49°, 109.45°, 109.45° and 109.46°, respectively. The configurations around the phosphorus atoms, due to their substituents, are slightly disordered tetrahedral and the distortion is much greater in **1d** relative to the other compounds. It is of interest to note that the low values of some OPN angles in the –C(O)NHP(O)– moieties can be explained by the influence of hydrogen bonds formed in the unit cell packing of the compounds. The environments of the nitrogen atoms are nearly planar. The average of the angles around the amine nitrogens in the four crystal structures are 118.58 and 119.07° for **1d**, 118.01 and 119.45° for **2d**, 117.5 and 119.05° for **5b**, 119.98 and 119.59° for **5e**. Also, the sums of the surrounding angles for each aminic nitrogen atom are 355.76 and

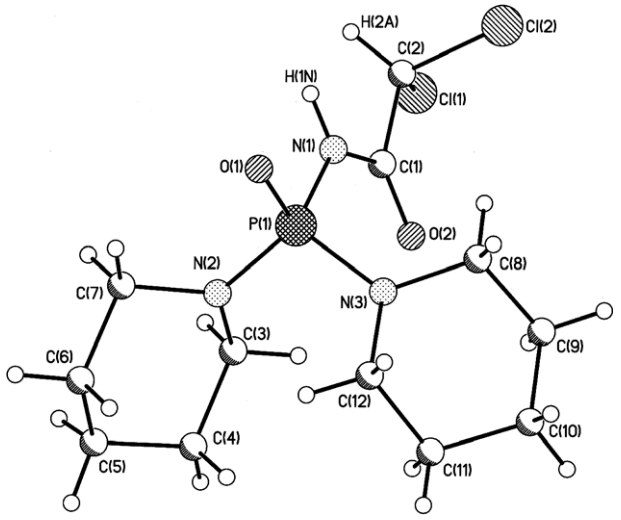

Fig. 3. Molecular structure for **2d** with the atomic numbering (50% probability ellipsoids).

359.63° (**1d**), 354.03 and 358.35° (**2d**), 352.5 and 357.05° (**5b**) and 359.95 and 358.77° (**5e**). The trigonal–planar bond

angles observed in these compounds suggested that π delocalization exist in the O–P–N_{amine} moiety, leading to a change in the nitrogen amines hybridization from sp^3 to sp^2. Furthermore, the repulsion and steric hindrances in

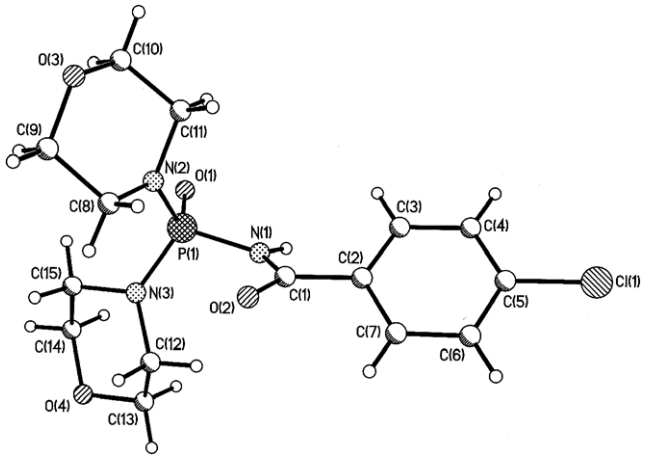

Fig. 7. Molecular structure for **5e** with the atomic numbering (50% probability ellipsoids).

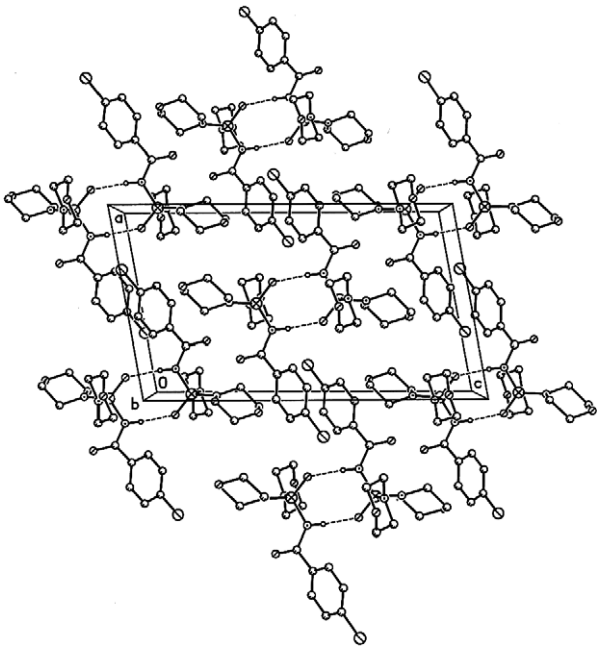
the above mentioned compounds cause some deviation from planarity in the angles around the aminic nitrogen atoms.

3.1.3. Mass spectral study

The mass spectra of the 20 newly synthesized carbacylamidophosphates and the 29 compounds which were synthesized in our previous works were recorded. Fragmentation data are listed in Tables S1 and S2. Molecular ions derived from all the substrates are relatively stable since they were observed for all compounds except for **5f** and **6c**, and varied in intensity from 2% to 42%. As the carbacylamidophosphates with the general formula $R'_2P(O)NHC(O)R$ are derived from both carboxylic and phosphoric amides, the interpretation of their mass spectra



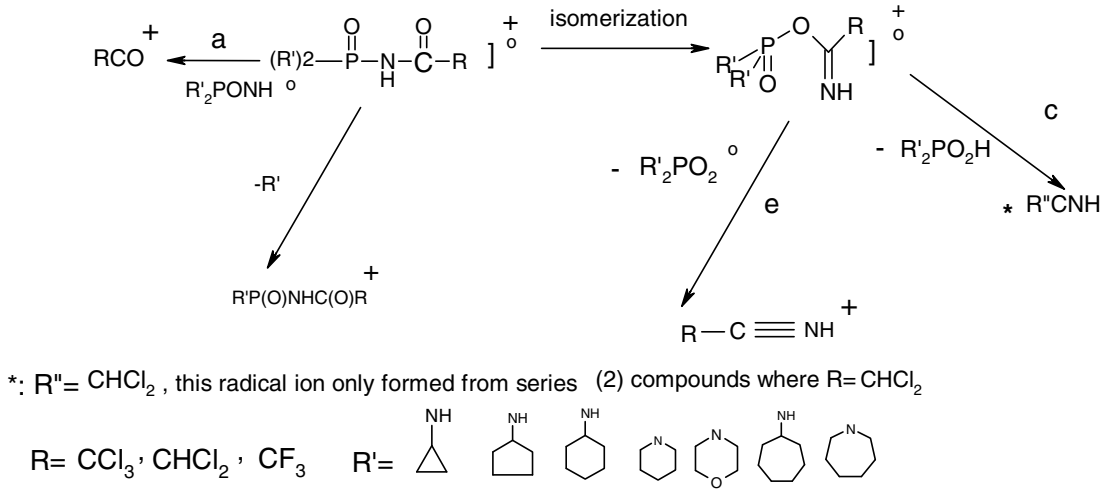


Fig. 8. Unit cell for **5e**, showing the hydrogen bonds.

is related to the behavior of the parent system. Also, the detailed electron distribution in these compounds should of course modify the ionization potential of the oxygen and nitrogen atoms of the (O)PNC(O) linkage and thus determine the predominant structures of the radical ions derived from the above mentioned structures upon electron impact [7]. Besides the structural studies, the fragmentation pattern under the conditions of electron impact seems to be a useful probe for investigation of the bonding characteristics of these phosphoramidic derivatives. Mass spectral studies of carbacylamidophosphates are scarce in the literature and only the fragmentation pattern for some secondary (R = H) and tertiary (R = alkyl) derivatives of phosphoric amides, $X_2P(O)NRC(O)R'$, have been recorded by Modro and coworkers [7] where X = MeO, EtO, Et, R′= Me, Ph and R = H, Me. Since we are interested in determining the degree of the fragmentation pattern characteristics of carbacylamidophosphates with many kinds of cyclic amines connected to a P(O) group, as well as finding new pathways, the mass spectra of those types of phosphoric amides were recorded and the available information derived from the spectra. In this respect, we considered two categories of carbacylamidophosphate, groups, ones with acetamide derivatives and the others with benzamide derivatives. As was studied before, the characteristic features of the mass spectra of aromatic amides are the presence of an M-1 peak (loss of H° from the aromatic ring) and a benzoylium ion peak, resulting from acyl-nitrogen bond cleavage [28]. The typical mass spectral behavior of acetamides, most relevant to our discussion, is the loss of ketene from the parent ion [29]. However, the fragmentation behaviors of the mixed phosphoric carboxylic amides are derived with respect to the behavior of the two phosphoryl and carbonyl groups, but at the same time some new features are also observed. Lapidot and Samuel reported on the pyrolysis of *N*-benzoyl phosphoramidates during a mass spectral process that led to the formation of PhCN+ and the related amidophosphoric acids [30]. In our previous work, during the study of the mass spectra of some new phosphoramidate derivatives [31], we considered the formation of PhCN+ and related amidophosphoric acid derivatives. It was assumed that the fragmentation pathway contains P–N cleavage and P–O formation and then the rearranged molecule is cleaved in a pseudo MacLafferty mechanism to PhCN+ and the related amidophosphoric acid cations [31]. Later, Modro and coworkers [7] suggested new fragmentation pathways for benzoyl and acetyl amide derivatives of some *N*-acyl phosphoramidates. According to those pathways, we studied the fragmentation of our synthesized products, resulting in two different patterns which are presented in Schemes 2 and 3. Also, the most important fragmentation products and their intensities observed for *N*-acetyl and *N*-benzoyl derivatives of 49 synthesized com-

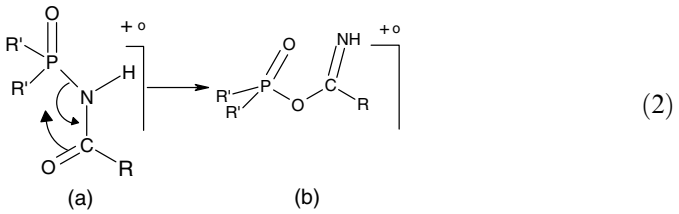
Scheme 2. Fragmentation pathway for the synthesized *N*-acetyl phosphoramidate derivatives in the mass spectra.



Scheme 3. Fragmentation pathway for the synthesized *N*-benzoyl phosphoramidate derivatives in the mass spectra.

pounds are listed in Tables S1 and S2. For the *N*-benzoyl derivatives, only **6b** and **6g** show the loss of H° from the parent ion (pathway g, Scheme 3) but all 28 compounds undergo carbonyl–nitrogen bond cleavage producing the benzoylium derivative ions (pathway a, Scheme 3). Similar carboxylic–nitrogen fission yielding acetylium derivative ions are found for all 21 *N*-acetyl derivative compounds (pathway a, Scheme 2). The analogous cleavage of the P-N bond in the parent ion should produce the corresponding phosphorylium ion and the carboxylic amide radical (Eq. (1)):

$$R'_2P(O)NHC(O)R]^{+\cdot} \rightarrow R'_2PO^+ + R - C(O)NH^{\cdot} \qquad (1)$$

Although we observed the formation of R'_2PO^+ in the mass spectra of some of our synthesized compounds, we did not report those ion formations due to lesser relative intensities in comparison with $RC(O)^+$ or $X\text{-}C_6H_4C(O)^+$ ions. Such a difference in the N–P(O) versus N–C(O) bond cleavage can be produced by two different reasons. Firstly, the acylium ions $RC(O)^+$ or $X\text{-}C_6H_4C(O)^+$ are much more stable species than the phosphorylium ions R'_2PO^+ [7]. Acylium ions can easily be generated in solution from a variety of precursors [32], whereas there is no evidence for the participation of phosphorylium ions in the reactions of phosphoryl compounds [33]. Secondly, the observed fragmentation preference can indicate that in the parent ions derived from the parent compounds the radical ion character is localized at the N–C(O) function rather than at the N–P(O) function [7]. In all of the 28 benzoyl derivatives, the benzoylium derivative ions have large intensities and in some of them they can be observed as the base peak (Table S2), which is indicative of the high stability of the ions. Loss of ketene which was reported by Modro and coworkers [7] to give radical ions such as $[(R')_2P(O)NH_2]^{+\cdot}$

in *N*-acetyl amide derivatives was not observed. Another feature of the mass spectra of carbacylamidophosphates with *N*-benzoyl derivatives is the loss of C(O), which can be observed in Scheme 3 (pathway c). The *m/e* and intensities of the driven radical ions with the formula $[(R')_2P(O)NH(C_6H_4\text{-}X)]^{+\cdot}$ are reported in Table S2. The common property of all the *N*-benzoyl and *N*-acetyl phosphoramidates (a) is that they rearrange to the corresponding *O*-phosphorylated benz- or acetamides (b) (Eq. (2)):

(2)

The rearranged products (b) give rise to new fragmentation patterns, also included in Scheme 2 and scheme IV (pathway e). The compounds (b) readily lose the $(R')_2PO_2^{\cdot}$ radical and yield the N-protonated nitrilium ions R–C≡NH^+ and X-C_6H_4–C≡NH^+. As shown in Tables S1and S2, the X-C_6H_4–C≡NH^+ ions have much greater intensity relative to R–C≡NH^+ which indicates higher stability of the X-C_6H_4–C≡NH^+ ions relative to the R–C≡NH^+ ions. The crystal structures of some of synthesized compounds in our previous works and the four new synthesized compounds **1d**, **2d**, **5b** and **5e** are summarized in Table 7. Comparing the P–N_{amide}, C–N_{amide}, P=O and C=O bond lengths for the *N*-benzoyl and *N*-acetyl phosphoramidate derivatives shows that the C=O bond lengths are shorter in the *N*-acetyl derivatives, which may be due to the greater electrostatic interactions between the oxygen lone pair of the C=O bond with the σ^* orbital of the C–N_{amide} bond and the lone pair of the amidic nitrogen atom with the π^* orbital of the C=O double bond [34]. It can be suggested that halogen atoms (chlorine and fluorine) may increase these electrostatic interactions. Also, as shown in Table 7, the C–N_{amide} bond lengths in the *N*-acetyl derivatives are shorter than the C–N_{amide} bond lengths in the*N*-benzoyl derivatives. This can be emphasise our above mentioned suggestion. On the other hand, comparing the P=O and P–N_{amide} bond lengths in the *N*-acetyl and *N*-benzoyl derivatives (Table 7) shows that these bonds are longer in *N*-acetyl than *N*-benzoyl derivatives (in accordance with $\nu_{P=O}$ and $\nu_{C=O}$). In spite of the fact that the P–N_{amide} and P=O bond lengths are longer in the *N*-acetyl derivatives, it can be considered that the low intensities for R–C≡NH^+ relative to X-C_6H_4–C≡NH^+ (Tables S1 and S2) may be due to length shortening in the C–N_{amide} and C=O bonds in *N*-acetyl rather than *N*-benzoyl derivatives, which hardens the rearrangement according to Eq. (2). Furthermore, as indicated in Scheme 3, the rearranged products (b) via pathway f can produce $(R')_2PO_2H^{+\cdot}$ radical ions. Hydrogen transfer to the phosphoryl group accompanied by C–O bond fission takes place and the above mentioned radical ions are formed. Although the formation of these radical ions has been mentioned in the literature [7], we did not observe them in the *N*-acetyl derivatives of our synthesized carbacylamidophosphates (Table S1).

4. Conclusion

This investigation establishes that carbacylamidophosphates with a –P(O)C(O)NH– core with different amide structures have different NMR splitting patterns. Their X-ray structural studies show that the *N*-acetyl derivatives have shorter C=O and C–N_{amide} bond lengths relative to the *N*-benzoyl derivatives. This may be due to greater electrostatic interactions between the lone pairs of the oxygen atom in the C=O bond and the amidic nitrogen atom with σ^* and π^* orbitals of C–N_{amide} and C=O bonds, respectively. These different interactions in the *N*-acetyl and *N*-benzoyl derivatives cause different pathways in the mass spectral studies and it can affect the intensities of R–C≡NH^+ relative to X-C_6H_4–C≡NH^+, which are the most important ions in the phosphoramidates fragmentation.

Appendix A. Supplementary data

CCDC 240148, 286222, 601418 and 292753 contain the supplementary crystallographic data for **1d**, **2d**, **5b** and **5e**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.01.023.

prepared according to the literature. All reagents and solvents were of reagent grade quality and were obtained from commercial suppliers. All solvents were dried and purified as described by Perrin and Armarego [25]. The IR spectra were recorded on a Perkin–Elmer 1600 FT-IR spectrophotometer, using KBr pellets or NaCl discs. ^{1}H and ^{13}C NMR spectra were recorded on a Varian Mercury 200 MHz spectrometer in $CDCl_3$, and chemical shifts were reported (δ) relative to Me_4Si as an internal standard. Mass spectra were measured on a Micromass Quatro LC/ULTIMA LC–MS/MS spectrometer. The elemental analyses were performed on a Costech ECS 4010 instrument. Melting points were measured on an electrothermal apparatus and are uncorrected. Optical spectra in the UV–Vis region were recorded with a Unicam UV2-100 spectrophotometer, using 1 cm pathlength cuvettes at room temperature. Domestic ovens were used in all syntheses of the phthalocyanines.

2.2. Synthesis

2.2.1. *N,N*-Bis{2-[2-(3,4-dicyanophenoxy)ethoxy]ethyl}-4-methylbenzenesulfonamide (**3**)

N,N-Bis[2-(2-hydroxyethoxy)ethyl]-4-methylbenzenesulfonamide (**1**) (2.5 g, 7.20 mmol) was dissolved in dry DMF (25 ml) under N_2 atmosphere and 4-nitrophthalonitrile (**2**) (2.49 g, 14.40 mmol) was added to the solution. After stirring for 10 min, finely ground anhydrous K_2CO_3 (2.98 g, 21.60 mmol) was added portion-wise over 2 h, with efficient stirring. The reaction mixture was stirred under N_2 at 50 °C for 4 days. Then the solution was poured into ice-water (100 ml) and the aqueous phase was extracted with chloroform (3 × 60 ml). The combined extracts were dried over anhydrous sodium sulfate. Purification of the product was accomplished by column chromatography with silica gel (chloroform). Yield: 2.67 g (62%), *Anal.* Calc. for $C_{31}H_{29}N_5O_6S$: C, 62.09; H, 4.87; N, 11.68; S, 5.35. Found: C, 62.19; H, 4.97; N, 11.60; S, 5.46%. IR (KBr tablet) ν_{max}/cm^{-1}: 3076 (Ar-H), 2924–28,681 (Aliph. C–H), 2230 (C≡N), 1598, 1562, 1492, 1453, 1322–1158 (SO_2), 1255, 1126, 1089, 965, 816, 653 (C–S). ^{1}H NMR ($CDCl_3$) (δ: ppm): 7.71 (d, 2H, Ar-H), 7.66 (d, 2H, Ar-H), 7.30 (s, 2H, Ar-H), 7.25 (d, 2H, Ar-H), 7.20 (d, 2H, Ar-H), 4.18 (t, 4H, CH_2–O), 3.82 (t, 4H, CH_2–O), 3.65 (m, 4H, CH_2–O), 3.36 (t, 4H, CH_2–N), 2.41 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$) (δ: ppm): 162.13, 143.85, 136.37, 135.52, 129.99, 127.38, 120.08, 119.78, 117.50, 115.92, 115.55, 107.82, 72.58, 68.68, 61.82, 49.42, 21.76. MS (EI) (*m*/*z*): 617 $[M+H_2O]^+$.

2.2.2. Metal-free polymeric phthalocyanine (**4**)

A mixture of *N,N*-bis{2-[2-(3,4-dicyanophenoxy)ethoxy]ethyl}-4-methylbenzenesul-fonamide (**3**) (0.4 g, 0.66 mmol) and 2-(dimethylamino)ethanol (DMAE) (3 ml) was irradiated in a microwave oven at 175 °C, 350 W for 10 min. After cooling to room temperature the reaction mixture refluxed with ethanol to precipitate the product, which was filtered off. The green solid product was washed with hot ethanol and diethyl ether. The product was purified by preparative thin layer chromatography (TLC) using a $CHCl_3$ solvent system. Yield: 158 mg (20%), m.p. > 300 °C. Elemental *Anal.* (for CN end groups) Calc. $(C_{124}H_{118}N_{20}O_{24}S_4)_n$ $(2400.64)_n$: C, 62.04; H, 4.95; N, 11.67; S, 5.34. Found: C, 62.40; H, 5.13; N, 11.30; S, 5.42%. 3307 (imide N–H), 3054 (Ar-H), 2924–2873 (Aliph. C–H), 1711 (C=O), 1599, 1487, 1448, 1334–1124 (SO_2), 1286 (Ar-O–C), 1089, 952, 746, 549. UV–Vis (chloroform): λ_{max}/nm (10^{-5} ε dm^3 mol^{-1} cm^{-1}): 295 (5.13), 345 (5.09), 629 (4.57), 689 (5.22).

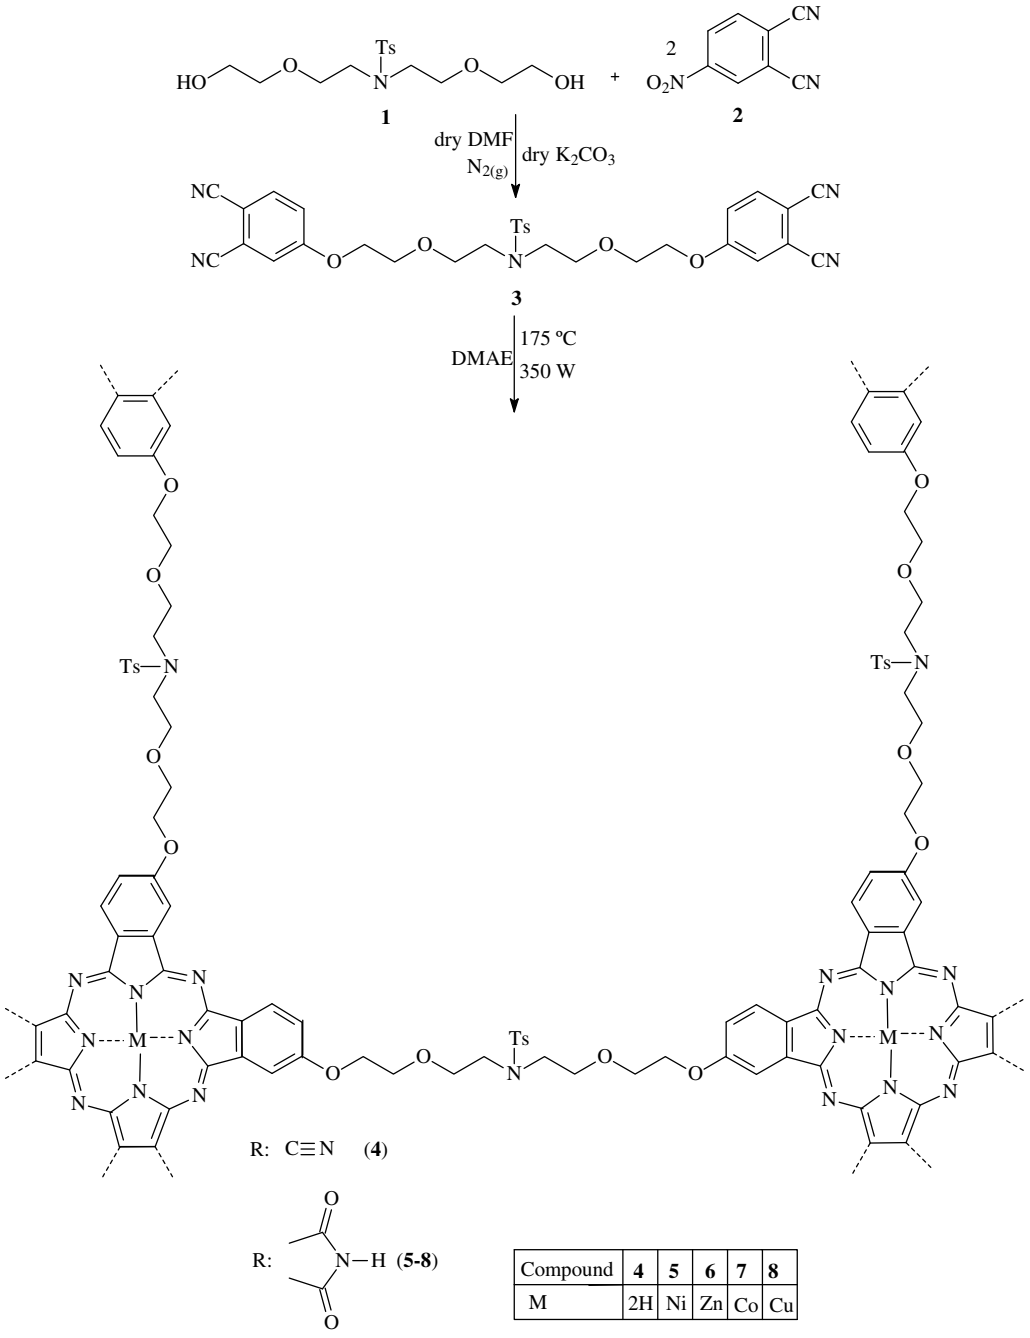
2.2.5. Co(II)-containing polymer (7)

A mixture of *N*,*N*-bis{2-[2-(3,4-dicyanophenoxy)ethoxy]ethyl}-4-methylbenzenesul-fonamide (**3**) (0.4 g, 0.66 mmol), anhydrous $CoCl_2$ (42.8 mg, 0.33 mmol) and 2-(dimethylamino)ethanol (DMAE) (3 ml) was irradiated in a microwave oven at 175 °C, 350 W for 10 min. After cooling to room temperature the reaction mixture refluxed with ethanol to precipitate the product, which was filtered off. The green solid product was washed with hot ethanol and diethyl ether. The product was purified by preparative thin layer chromatography (TLC) using a $CHCl_3$ solvent system. Yield: 250 mg (30%), m.p. > 300 °C. Elemental *Anal*. (for imide end groups) Calc. $(C_{124}H_{120}N_{16}O_{32}S_4Co)_n$ $(2533.58)_n$: C, 58.78; H, 4.77; N, 8.85; S, 5.06; Co, 2.33. Found: C, 58.96; H, 4.80; N, 8.80; S, 5.01; Co, 2.42%. IR (KBr tablet) ν_{max}/cm^{-1}: 3296 (imide N–H), 3054 (Ar-H), 2923–2865 (Aliph. C–H), 1708 (C=O), 1607, 1481, 1451, 1404, 1332–1121 (SO_2), 1238 (Ar-O–C), 1090, 815, 732, 652, 548. UV–Vis (chloroform): λ_{max}/nm (10^{-5} ε dm^3 mol^{-1} cm^{-1}): 280 (5.08), 341 (5.06), 623 (4.49), 680 (5.16).

2.2.6. Cu(II)-containing polymer (8)

A mixture of *N*,*N*-bis{2-[2-(3,4-dicyanophenoxy) ethoxy]ethyl}-4-methylbenzenesul-fonamide (**3**) (0.4 g, 0.66 mmol), anhydrous $CuCl_2$ (44.3 mg, 0.33 mmol) and 2-(dimethylamino)ethanol (DMAE) (3 ml) was irradiated in a microwave oven at 175 °C, 350 W for 10 min. After cooling to room temperature the reaction mixture refluxed with ethanol to precipitate the product, which was filtered off. The green solid product was washed with hot ethanol and diethyl ether. The product was purified by preparative thin layer chromatography (TLC) using a $CHCl_3$ solvent system. Yield: 326 mg (39%), m.p. > 300 °C. Elemental *Anal*. (for imide end groups) Calc. $(C_{124}H_{120}N_{16}O_{32}S_4Cu)_n$ $(2538.19)_n$: C, 58.68; H, 4.77; N, 8.83; S, 5.05; Cu, 2.50. Found: C, 58.60; H, 4.90; N, 8.72; S, 5.16; Cu, 2.62%. IR (KBr tablet) ν_{max}/cm^{-1}: 3253 (imide N–H), 3060 (Ar-H), 2917–2869 (Aliph. C–H), 1703 (C=O), 1595, 1486, 1454, 1331–1150 (SO_2), 1287 (Ar-O–C), 1088, 956, 815, 734, 652, 549. UV–Vis (chloroform): λ_{max}/nm (10^{-5} ε dm^3 mol^{-1} cm^{-1}): 275 (5.07), 377 (5.08), 635 (4.54), 692 (5.20). MS (FAB) (*m*/*z*): 2555 $[M+H_2O-H]^+$.



3. Results and discussion

Metal-free **4** and metallophthalocyanine polymers **5**–**8** were synthesized by a polymeric tetramerization reaction of bisphthalonitrile monomer with the appropriate materials (Scheme 1). At the beginning, the base-catalyzed nucleophilic aromatic nitro displacement [26,27] of 4-nitrophthalonitrile (**2**) with **1** afforded the bisphthalonitrile monomer **2**. After that, metal-free and metallophthalocyanine polymers were synthesized. The yields of all the synthesized polymers were between 20% and 39% conversion. The metal-free phthalocyanine (**4**) was synthesized by microwave irridation of the corresponding dicyano compound **3** in 2-(dimethylamino)ethanol for 8 min. The metallophthalocyanines **5**–**8** were obtained from the tetracyano derivative **3** and the corresponding anhydrous metal salt, $NiCl_2$, $Zn(CH_3COO)_2$, $CoCl_2$ and CuCl, respectively, by microwave irradiation [15–19] in 2-(dimethylamino)ethanol for 8 min.

In the IR spectra, the formation of compound **3** was clearly confirmed by the disappearance of the OH and NO_2 bands at 3400 and 1538–1355 cm^{-1} and the appearance of the C≡N band at 2230 cm^{-1}. In the ^{1}H NMR spectrum of **3**, the OH group of compound **1** disappeared, as expected. The ^{1}H NMR spectrum of **3** showed new signals at $\delta = 7.71$ (d, 2H, Ar-H), 7.66 (d, 2H, Ar-H), 7.30 (s, 2H, Ar-H) and 4.18 (t, 4H, CH_2–O). The ^{13}C NMR spectrum of **3** indicated the presence of nitrile carbon atoms at $\delta = 115.92$ and 115.55 ppm. Elemental analysis and EI mass spectral data were satisfactory: 617 $[M+H_2O]^+$.

In the IR spectrum of **4** characteristic peaks for the metal-free phthalocyanine were observed. The peak at 3285 cm^{-1} is the characteristic metal-free phthalocyanine N–H stretching band. The end groups of the metal-free phthalocyanine polymer were cyano groups, with a peak at 2230 cm^{-1}. In the ^{1}H NMR spectrum of **4**, the typical shielding of the inner core protons could not be observed due to the probable strong aggregation of the molecules [28]. The signals related to aromatic protons 7.66–7.64 (d, 8H, Ar-H), 7.62 (s, 8H, Ar-H) and 7.48 (m, 8H, Ar-H) and aliphatic protons in compound **3** and the phthalocyanine skeleton gave significant absorbances characteristic of the proposed structure. The MS mass spectrum of compound **4** displayed the $[M]^+$ parent ion peak at $m/z = 2400$, which confirms the same structure. The results of the elemental analysis confirmed the proposed structure of compound **4**.

The IR spectra of the metallophthalocyanine polymers **5**–**8** are very similar, and they differ from the metal-free phthalocyanine polymer (**4**) which showed an N–H stretching band at 3281 cm^{-1}. This band disappears in the spectra of the metallophthalocyanine polymers. The end groups of the metallophthalocyanine polymers are imido groups (~1703–1714 cm^{-1}) [20–22]. ^{1}H NMR measurements of the cobalt and copper metallophthalocyanine polymers were precluded due to their paramagnetic nature. Also, the ^{1}H NMR spectra of the soluble part of the nickel and zinc metallophthalocyanine polymers in $CDCl_3$ displayed broad signals, and the protons of the phthalocyanine core were invisible. This effect was attributed to strong aggregation of the molecules [21]. In the mass spectra of the Ni and Cu polymers, the presence of molecular ion peaks at $m/z = 2532$ $[M-H]^+$ and 2555 $[M+H_2O-H]^+$, respectively, confirmed the proposed structures. Elemental analysis data were satisfactory.

Compound	4	5	6	7	8
M	2H	Ni	Zn	Co	Cu

Scheme 1. Synthesis of the polymeric metal-free phthalocyanine and metallophthalocyanines (Ts = *p*-toluenesulphonyl).

The end groups of the metal-free phthalocyanine polymer were cyano groups while the end groups of the metallophthalocyanine polymers were imido groups [20–22]. The existence of imido groups in the case of the metallophthalocyanine polymers was attributed to the presence of moisture during work-up [29,30]. Because the phthalocyanines were polymeric, one monomer molecule was calculated to determine the molecular mass of the phthalocyanines. On the other hand, according to the FAB mass spectra analysis of **4**, **5** and **8**, we can say they are monomer molecules [21].

The UV–Vis absorption spectra of these polymers exhibit Q and B bands, which are the characteristic bands for phthalocyanine polymers. The experimental UV–Vis bands of the phthalocyanine polymers were slightly different from the theoretical values [31]. The metal-free phthalocyanine polymer (**4**) showed a typical electronic spectrum with two absorption regions, one of them in the UV region at 285 and 326 nm (B band) and the other in the visible region at 644, 674 and 704 nm (Q band) in chloroform (Fig. 1).

The UV–Vis absorption spectra of metallophthalocyanine polymers **5**–**8** in chloroform show an intense Q absorption at $\lambda_{max} = 680$, 689, 680 and 692 nm, with a weaker absorption at 629, 629, 623 and 635 nm, respectively

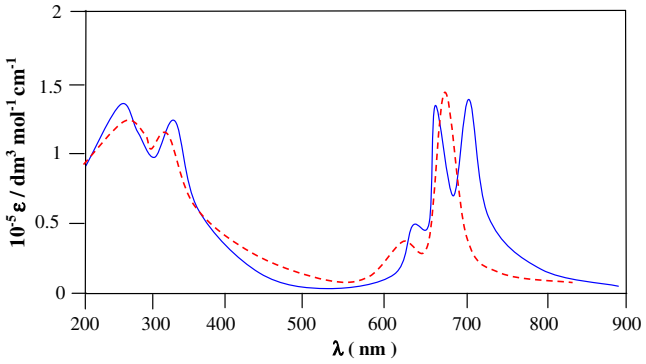


Fig. 1. UV–Vis spectra of compounds **4** (—) and **5** (---) in chloroform.

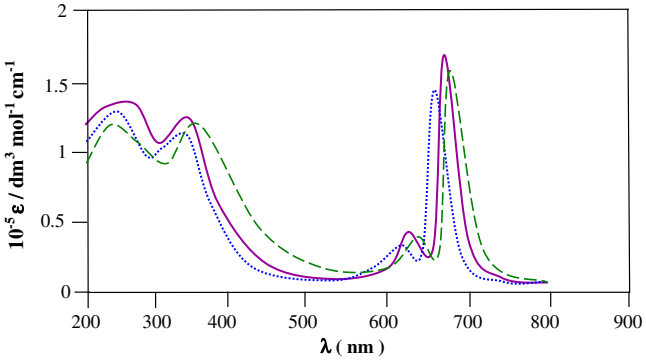

Fig. 2. UV–Vis spectra of compounds **6** (—), **7** (···) and 8 (---) in chloroform.

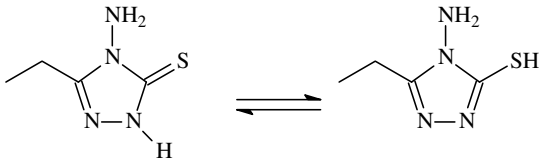

(Figs. 1 and 2). The single Q bands in the metallo derivatives **5**–**8** are characteristic. This result is typical of metal complexes of substituted and unsubstituted metallophthalocyanines with D_{4h} symmetry [32]. B band absorptions of compound **5**–**8** were observed at $\lambda_{max} =$ (292, 317), (295, 345), (280, 341) and (275, 377) nm as expected, respectively.

I II

Scheme 1. Tautomeric forms in AETT.

of this compound with silver(I), copper(I), palladium(II) and platinum(II) ions, including their molecular structures [6b,6c]. According to the molecular structures, ATT acts in presence of sodium acetate as a ionic bidentate ligand with palladium(II) and platinum(II) ions to give the dimeric tetranuclear Pd(II) complex $[\{(L_4Pd_2)NaCl\}_2]\cdot 8MeOH$ and the air-stable dinuclear Pt(III) complex $[L_4Pt_2Cl_2]\cdot 6MeOH\cdot H_2O$ [6c]. Similar complexes could be obtained by the reaction of several Schiff-bases based on 1,2,4-triazines and 1,2,4-trizoles with silver(I) and copper(I) ions [6b,7].

In this communication, we wish to report on the synthesis and characterization of a new Ag(I) complex of AETT with an interesting "mosaic" pattern, and furthermore on a Schiff-base based on AETT and its mixed-ligand Ag(I) and Pd(II) complexes.

2. Experimental

2.1. Materials

AETT (**L1**) was prepared according to the literature procedures [8]. All chemicals were purchased from Merck and Fluka and were used without further purification.

2.2. Physical measurements

IR spectra were recorded on a Shimadzu spectrometer 470 (KBr pellets 4000–400 cm^{-1}). ^1H NMR and ^{31}P NMR spectra were recorded on a Bruker-AQS advance 300 MHz and a Bruker AVANCE 400 MHz using TMS ($\delta = 0.0$ ppm) as an internal standard and 85% aqueous H_3PO_4 as an external standard. Mass spectra were recorded on a Fisons Instruments Trio 1000 spectrometer. Elemental analyses were performed by the following methods: C, H, N analyses; combustion method; sulfur analyses: combustion and titration with $Ba(ClO_4)_2$.

2.3. Synthesis

2.3.1. Synthesis of *HL1a*

A solution of AETT (0.14 g, 1 mmol) in methanol (40 mL) was treated with thiophene-2-carboxaldehyde (0.16 g, 1.5 mmol) and was refluxed for 6 hrs. The progress of the reaction was monitored by TLC using ethyl acetate:petroleum ether (1:2) as the eluent. After completion of the reaction, the solvent was evaporated to 20 mL, the solid crude was filtered and washed with cold methanol (2×5 mL). The clear filtrate was kept at 4 °C to give colorless single crystals of the corresponding Schiff base **LH1a**. Yield: 0.19 g, 80%, m.p.: 185 °C, *Anal.* Calc. for $C_9H_{10}N_4S_2$ (238.03): C, 45.36; H, 4.23; N, 23.51; S, 26.91. Found: C, 45.30; H, 4.25; N, 23.49; S, 26.88%. IR (KBr) [ν/cm^{-1}] 3043w, 2872s, 1583vs, 1500s, 1427s, 1280s, 714s. 2.3.2. Synthesis of complex *1*

To a solution of **L1** (0.14 g, 1 mmol) in methanol (20 mL) was added silver nitrate (0.17 g, 1 mmol) and the reaction mixture was stirred for 5 h at room temperature. After completion of the reaction, which was monitored by TLC using ethyl acetate/petroleum ether (1/2), a white precipitate was filtered off and washed with cold methanol (5 mL). The filtrate was stored at room temperature for 1 week to yield colorless crystals suitable for X-ray diffraction measurements. Yield: 0.26 g, 84%. *Anal.* Calc. for $C_4H_8AgN_5O_3S$ (314.07): C, 15.30; H, 2.57; N, 22.30; S, 10.21. Found: C, 15.29; H, 2.40; N, 21.90; S, 10.03%. 2.3.3. Synthesis of complex *2*

A solution of **HL1a** (0.48 g, 2 mmol) in methanol/acetonitrile (1/1, 30 mL) was treated with silver nitrate (0.17 g, 1 mmol) and stirred for 3 h, then a solution of triphenylphosphine (0.52 g, 2 mmol) in the same solvent (15 mL) was added. The reaction mixture was stirred for a further 3 h and the completion of the reaction was monitored by TLC using ethyl acetate/petroleum ether (1/2 v/v) as the eluent. After completion, the reaction mixture was filtered off and washed with cold methanol. The filtrate was kept at 4 °C to give colorless single crystals after a few weeks. Yield: 0.93 g, 80%. *Anal.* Calc. for $C_{54}H_{50}AgN_9O_3P_2S_4$ (1171.11): C, 55.38; H, 4.30; N, 10.76; S, 10.95. Found: C, 55.02; H, 4.18; N, 10.68; S, 10.80%. IR (KBr) [ν/cm^{-1}]: 3048m, 2925–2840w, br, 2910s, 1718s, 1606s, 1543s, 1460s, 1429s, 1379s, 1287m, 1245w, 1094s, 1014s, 966s, 937m, 856m, 821m, 745s, 694s, 540s, 530s, 501s, 430m. EI-MS (70 eV): m/z (%) 238 (100) $(\mathbf{HL1a})^+$, 145 (5), 146 (4), 129 (29), 128 (42), 113 (40), 111 (14), 98 (25), 96 (13), 71 (18), 69 (38), 60 (70), 56 (65), 54 (35), 45 (10), 43 (25), 41 (31), 29 (17), 28 (69); ^1H NMR δ ($CDCl_3$) 1.25 (t, 3H, Me), 2.74 (q, 2H, CH_2), 7.00–7.80 (m, 4H, thiophene), 10.01 (s, 1H N=C**H**), 12.71 (s, 1H, imine NH); ^{31}P NMR δ ($CDCl_3$) 29.39s.

*2.3.4. Synthesis of complex **3***

A solution of **HL1a** (0.48 g, 2 mmol) in methanol/acetonitrile (1/1, 30 mL) was treated with sodium acetate (0.16 g, 2 mmol) and stirred for 3 h. To this solution was added $[(PPh_3)_2PdCl_2]$ (0.70 g, 1 mmol) in methanol (15 mL) (prepared *in situ* from palladium chloride (0.18 g, 1 mmol) and triphenylphosphine (0.52 g, 2 mmol)) under stirring. After 3 h and the completion of the reaction, which was monitored by TLC using ethyl acetate/petroleum ether (1/2 v/v) as eluent, the reaction mixture was filtered off, washed with water (5 mL) and cold methanol (2 × 5 mL). The filtrate was kept at 4 °C to give yellow single crystals after a few days. Yield: 0.91 g, 83%. *Anal.* Calc. for $C_{54}H_{48}N_8P_2PdS_4$ (1105.65): C, 58.66; H, 4.38; N, 10.13; S, 11.60. Found: C, 58.59; H, 4.32; N, 10.21; S, 11.71%. IR (KBr) [ν/cm^{-1}]: 3398s, 3285m, 2974m, 2931m, 2875w, 2359w, 2332w, 1591m, 1531m, 1477w, 1433s, 1375m, 1265s, 1178m, 1091m, 1035w, 945w, 744s, 698s, 514s, 460w. EI-MS (70 eV): *m/z* (%) 262 (32) PPh_3, 237 (5) $(\mathbf{L1a})^+$, 183 (85), 152 (25), 139 (14), 129 (18), 128 (20), 127 (32), 115 (8), 110 (25), 108 (35), 107 (49), 97 (60), 95 (100), 77 (60), 51 (49); ^{1}H NMR δ ($CDCl_3$) 1.20 (t, 3H, Me), 2.70 (q, 2H, CH_2), 6.95–7.75 (m, 4H, thiophene), 9.97 (s, 1H N=C**H**); ^{31}P NMR δ ($CDCl_3$) 29.76 (s).

*2.4. Crystal structure analyses of HL1a, **1**, **2** and **3***

Table 1 shows the crystallographic data of **HL1a**, **1**, **2** and **3**. The crystals of **HL1a**, **1**, **2** and **3** were covered with perfluorinated oil and mounted on the top of a glass capillary under a flow of cold gaseous nitrogen. The orientation matrix and unit cell dimensions were determined from *ca.* 3000 (**HL1a**; Stoe IPDS II), *ca.* 4500 (**1**, Stoe IPDS I), *ca.* 8000 (**2**; Stoe IPDS I) and *ca.* 8000 (**3**; Stoe IPDS I) reflections (graphite-monochromated Mo Kα radiation, $\lambda = 71.073$ pm). The intensities were corrected for Lorentz and polarization effects. In addition, absorption corrections were applied for **1**, **2** and **3** (numerical). The structures were solved by the direct methods for **HL1a** (SHELXS-97) and **3** (SIR-92) and by the Patterson method for **1** and **2** (SHELXTL-PLUS) and refined against F^2 by full-matrix least-squares using the program SHELXL-97 (see Section 5). The positions of the carbon bonded hydrogen atoms (except H1 for **HL1a** and **3**) in all the compounds

were calculated for ideal positions and refined with a common displacement parameter. H1 atoms in **HL1a** and **3** were included with a free refinement. The programs used were SHELXS-97 [9], SIR-92 [10], SHELXL-97 [11], SHELXTL-Plus [12] and PLATON [13].

3. Results and discussion

3.1. Syntheses and characterization of *HL1a, 1, 2 and 3*

Treatment of **L1** with 2-thiophene carbaldehyde in methanol under reflux conditions led to the corresponding imine compound **HL1a** in high yield

L1 **HL1a** (1)

Compound **1** can be obtained by the reaction of **L1** with $AgNO_3$ in methanol according to the following equation:

$$2\mathbf{L1} + 2AgNO_3 \xrightarrow{MeOH} \underset{\mathbf{1}}{[\{(\mathbf{L1})_2Ag_2\}NO_3]_n} \quad (2)$$

Compound **2** can be prepared by the reaction of **HL1a**, $AgNO_3$ and PPh_3 in a 2:1:2 molar ratio in ethanol and acetonitrile, and compound **3** can be obtained by the treatment of the same ligand with $PdCl_2$ and PPh_3 in methanol in the presence of sodium acetate in a 2:1:2:2 molar ratio, according to the following equations:

$$2\mathbf{HL1a} + AgNO_3 + 2PPh_3 \xrightarrow{EtOH/CH_3CN} \underset{\mathbf{2}}{[(PPh_3)_2Ag(\mathbf{HL1a})_2]NO_3 \cdot CH_3CN} \quad (3)$$

$$2\mathbf{HL1a} + PdCl_2 + 2PPh_3 \xrightarrow[-2NaCl;\ -2\ AcOH]{2NaOAc;\ MeOH} \underset{\mathbf{3}}{[(PPh_3)_2Pd(\mathbf{L1a})_2] \cdot 4MeOH} \quad (4)$$

The synthesized compounds **HL1a** and both silver complexes are colorless, while **3** is a yellow solid material and all of them are air-stable. The absorptions at about 3043 cm^{-1} **HL1a**, 3124 cm^{-1} **1** and 3048 cm^{-1} **2** can be assigned to N–H stretching vibrations, which disappeared in the IR spectrum of **3**. The $C{=}N_{ring}$ causes vibrations at 1583 cm^{-1} in the free ligand, and these vibrations were observed at 1527 cm^{-1} in **1**, 1543 cm^{-1} in **2** and 1591 cm^{-1} in **3**. Broad weak absorptions due to O–H stretching vibrations could be found at 3398 cm^{-1} for **3**. Strong absorptions at about 2910–2935 cm^{-1} are ascribed to the vibrations of the $–CH_2$-groups in the free ligand and the complexes. The P–C vibrations of the PPh_3 moiety are found in the range 744–691 cm^{-1} for both complexes **2** and **3** [14]. The NO_3^- anion in **1** presents its N–O asymmetric stretching mode at 1373 cm^{-1}, and at 1379 cm^{-1} for **2**.

The mass spectra of the complexes show only the main peak of the corresponding ligand [$m/z = 144$ (**1**), $m/z = 238$ (**2**) and $m/z = 237$ (**3**)].

Consistent with the structures of **2** and **3**, the solution ^{31}P NMR in $CDCl_3$ of **2** and **3** showed only one ^{31}P resonance at δ 29.39 ppm and 29.76 ppm, respectively. On the other hand, the ^1H NMR assignments for complex **2** were similar to those for the ligand, while in the ^1H NMR spectrum of **3** no NH signal was observed, in accordance with the deprotonated ligand in the complex.

3.2. Crystal structure of *HL1a, 1, 2 and 3*

3.2.1. Compound *HL1a*

Selected bond distances and angles of all the synthesized compounds are given in Table 2. Compound **HL1a** crystallizes in the triclinic space group $P\bar{1}$. The basic five-membered ring skeleton in this compound is planar and the dihedral angle between the best planes through the triazole ring and the aldehyde fragment is 12° (Fig. 1). The bond distances in the triazole five-membered heterocycles are in good agreement with those observed in iminic derivatives of 1,2,4-triazole, such as 4-(4-methoxybenzylidene-amino)-5-methyl-2H-1,2,4-triazole-3(4H)-thione and 4-(3-methoxybenzylideneamino)-5-methyl-2H-1,2,4-triazole-3(4H)-thione [7b].

In **HL1a**, the S1–C1 mean bond length of 168.5(2) pm shows significantly high double bond character, such as observed in AMTT [15]. The iminic C–N mean bond distance of 127.2(3) pm lies in the range observed in similar compounds, such as 2-acetylthiophene thiosemicarbazone (129.2(3) pm) and 2-acetyl thiophene 4-phenyl thiosemicarbazone (128.2(3) pm) [16].

In **LH1a**, intermolecular weak hydrogen bonding links the thiocarbonyl sulfur atom of one molecule to the NH-group of the adjacent one (N4–H1···S1a: 330.5(3) pm) and is responsible for the centrosymmetric geometry of the compound.

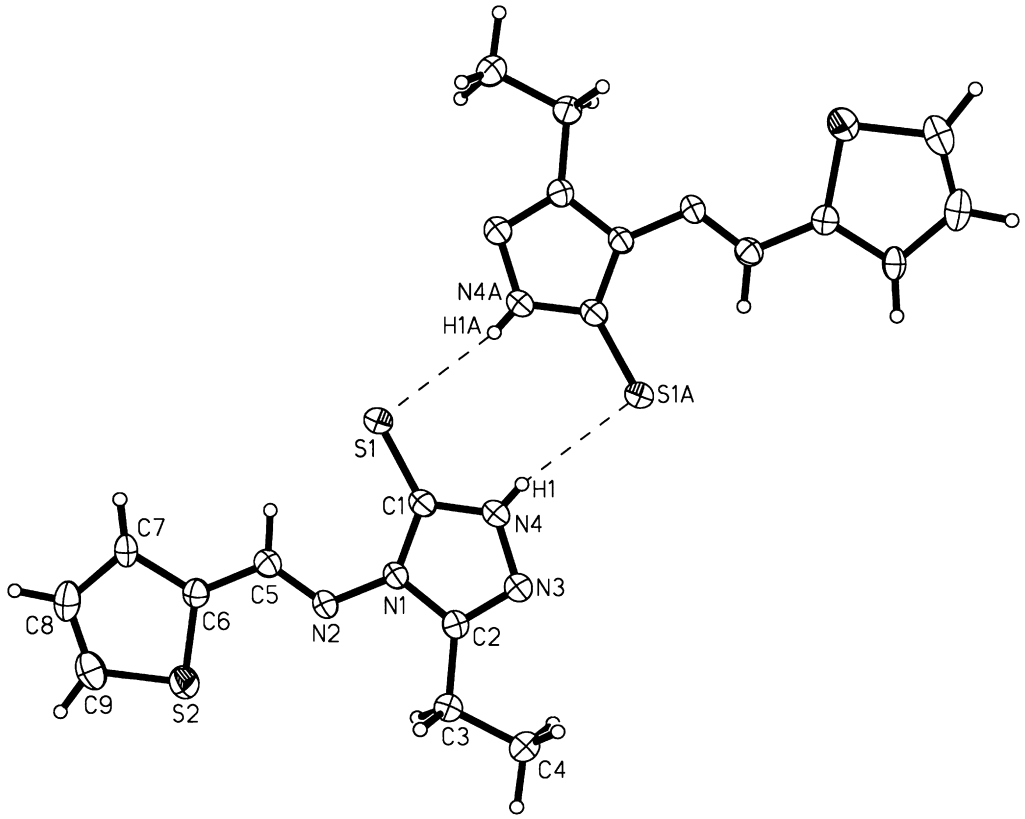
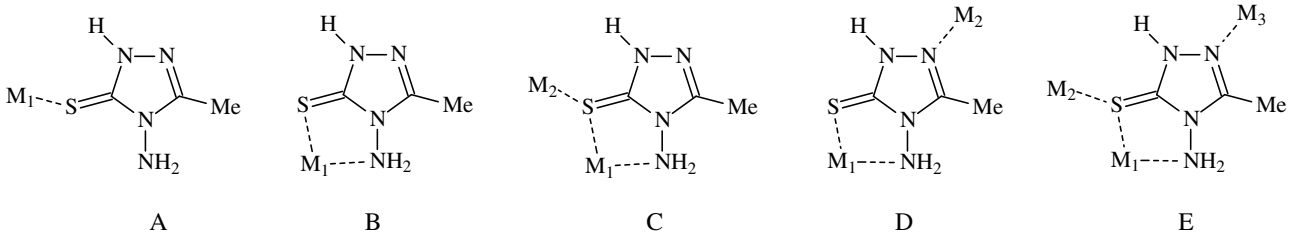
3.2.2. Complex *1*

As mentioned above, 4-amino-5-ethyl-2H-1,2,4-triazole-3(4H)-thione (AETT, **L1**) shows thione-thiol tautomerism (Scheme 1). It is also reported that such ligands can act as a neutral thione (**I**), a bidentate chelating one through the sulfur and the amine nitrogen atoms, as a deprotonated thiol (**II**) ligand or as a tridentate chelating *N*,*S* agent with an additional bridge through the endocyclic nitrogen atom with the metal atoms as shown in Scheme 2 [17].





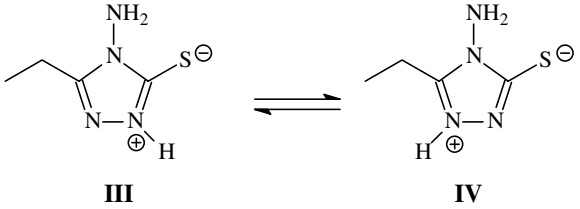


Fig. 1. Molecular structure of **HL1a** dimerized by H bridges (thermal ellipsoids are at the 40% probability level).

Scheme 2.

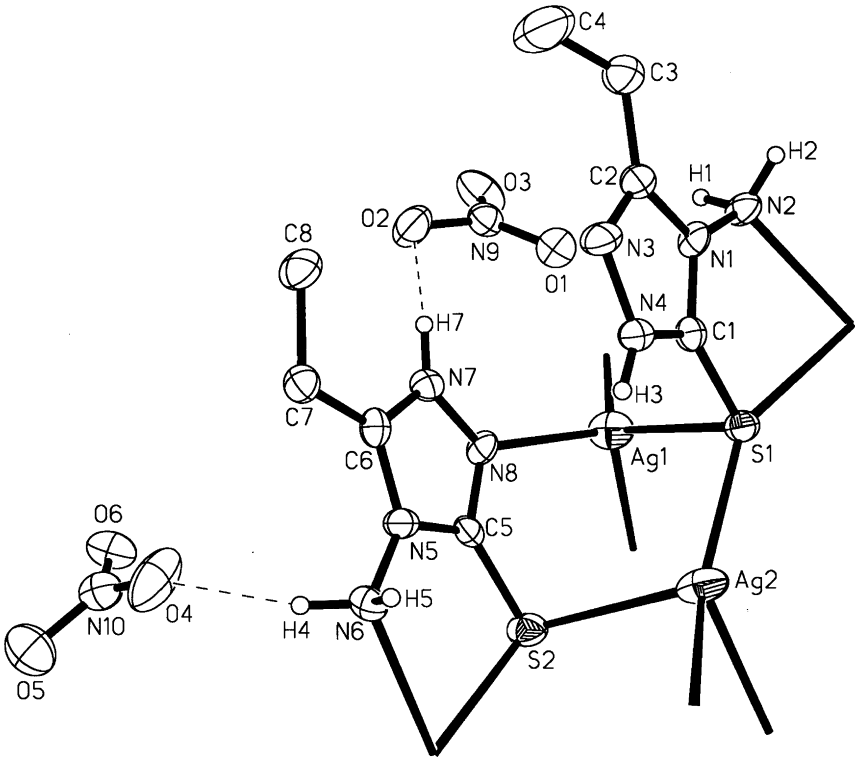
Scheme 3.

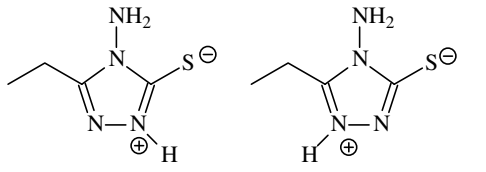
They can also act as ionic ligands in the form of **III** or **IV**, which have a *Hückel* aromaticity, with the metal atoms (Scheme 3).

Complex **1** consists of two dimensional polymers of $\{(\mathbf{L1})_2Ag_2\}^{2+}$ cations and NO_3^- anions (Fig. 2). In the cation of **1**, both ligands exist in two tautomeric forms **III** and **IV**, as shown in Scheme 4.

The coordination mode of the ligands to the metal centers can be described as a combination of form E and the modified form of C (with an additional coordination of a sulfur atom to a third metal center, form F) as shown in Scheme 5.

The Ag1 atom links the sulfur atom of one ligand to the endocyclic nitrogen atom of another one and the completion of the distorted tetrahedral geometry around Ag1 occurs by the coordination of the sulfur atom and the NH_2-group of the adjacent ligand. The Ag2 atom acts also as a bridging agent and links the sulfur atoms of two ligands of different layers. The linear geometry around Ag2 is also distorted by the coordination of the sulfur atom and one hydrazine nitrogen atom of two adjacent ligands. So, in the cation of **1**, each metal atom is coordinated to three different adjacent triazole ligands. This coordination mode of silver atoms and sulfur atoms lead to the forma-





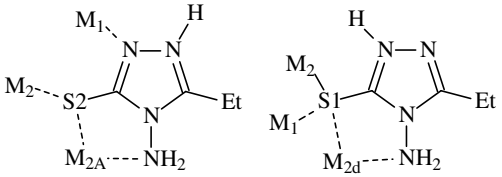


Fig. 2. Graphical representation of a part of the coordination polymer **1** (thermal ellipsoids at the 30% probability level).

Ring around S1 Ring around S2

Scheme 4.

E F

Scheme 5.

tion of a 10-membered Ag–S "mosaic" pattern as shown in Fig. 3. This coordination mode caused a two dimensional endless framework and is responsible for the formation of layers parallel to (0 0 1).

The C–N bond distances in the triazole ligands, C1–N1: 133(1) pm, C2–N3: 129(1) pm, C5–N8: 131(1) pm and C6–N7: 132(1) pm, show that both ligands exist in forms **III** and **IV** and show *Hückel* aromaticity.

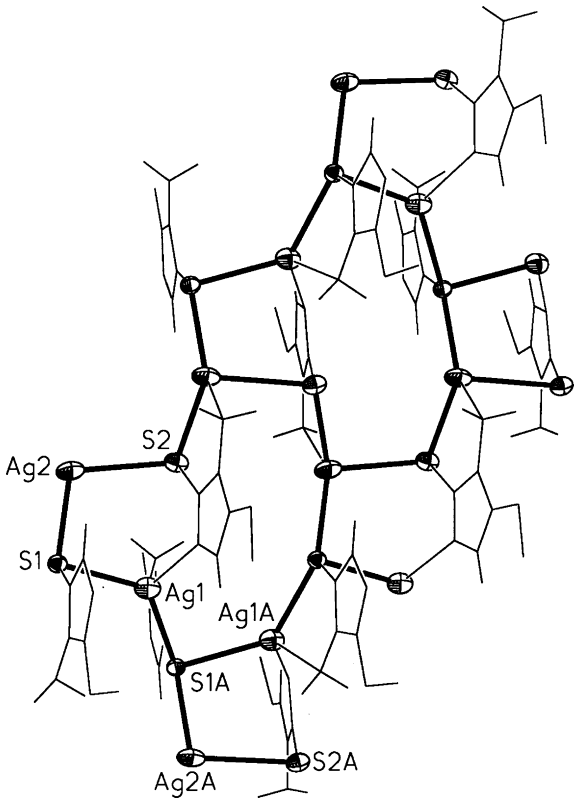

Fig. 3. Graphical representation of the Ag–S "mosaic" pattern in **1**. Only the cations are shown.

The Ag1–S1 and Ag1–S1a bond distances in **1** of 264.7(3) and 258.7(3) pm lie within the ranges observed

for silver complexes containing a sulfur atom with a coordination number (c.n.) of four (256.8–272.1 pm) [18]. While the Ag1–N8 bond length of 231.8(8) pm is near in the generally accepted Ag–N distance of 234 pm [19], the Ag1–N2a bond length of 241.7(8) pm is clearly longer than 234 pm but is significantly shorter than the 250.4(3) pm observed in $[(AMTTO)_2Ag]NO_3$ [4]. It is also shorter than the sum of the van der Waals radii of silver and nitrogen (155 + 170 = 325 pm) [20]. In addition, the AgS2 axis in **1** with a S1–Ag–S1a angle of 131.0(1)° is clearly smaller than the observed angle in $[(AMTTO)_2Ag]NO_3$ (S–Ag–S: 160.77(3)° [4]) caused by stronger Ag–N bonds. Therefore, the coordination sphere around Ag1 can be described as distorted tetrahedral or as a 3+1 coordination.

The Ag2–S1 and Ag2–S2d bond distances in **1** of 245.1(3) and 247.4(3) pm lie within the range observed for silver complexes containing a sulfur atom with a c.n. of two (236.2–241.8 pm) [18,21] and c.n. of three (246.4–253.7 pm) [22], while the Ag2–S2 bond length of 289.9(4) pm is clearly longer than the distances observed for silver complexes containing sulfur atom with a c.n. of four (256.8–272.1 pm) [18]. The Ag2–N6d bond distance in **1** of 244.1(8) pm is longer than the Ag–N distance of 234 pm [19] but it is clearly shorter than the sum of the van der Waals radii of silver and nitrogen [20]. In addition, the S1–Ag2–S2d angle of 147.3(1)° is somewhat smaller than the observed angle in $[(AMTTO)_2Ag]NO_3$ [4], caused by stronger Ag–N bonds. They are characteristic for a distorted linear coordination sphere, caused by additional Ag–S and Ag–N contacts. The coordination sphere around the Ag2-center can be described as 2+2.

Table 3
Hydrogen bonding distances (pm) in **1**

	X···Y
N2–H1···O1	283(1)
N2–H1···O5a	326(1)
N2–H2···O3b	289(1)
N4–H3···O6b	266(1)
N6–H4···O4	293(1)
N6–H5···O5b	302(1)
N6–H6···O6b	300(1)
N7–H7···O1	311(1)
N7–H7···O2	263(1)

The two nitrate anions are linked to cations *via* hydrogen bonding, using their oxygen atoms, and link the NH_2 and NH groups in the same cations. The hydrogen bonds observed in this molecule are listed in Table 3. These hydrogen bridges cause slightly different N–O bond lengths and O–N–O bond angles within the standard deviations of nitrate ions (Table 3).

The dihedral angles formed by the "best" planes through the five-membered triazole heterocycles (A: N1 N3 N4 C1 C2 and B: N5 N7 N8 C5 C6) is 4°.

3.2.3. Complex 2

The ionic complex **2** crystallizes in the monoclinic space group $C2/c$. In the cation of **2**, $[(PPh_3)_2Ag(\mathbf{HL1a})_2]^+$, the silver atom displays a distorted tetrahedral environment (Fig. 4). The coordination spheres around the metal centre are occupied with two P atoms of the phosphane molecules

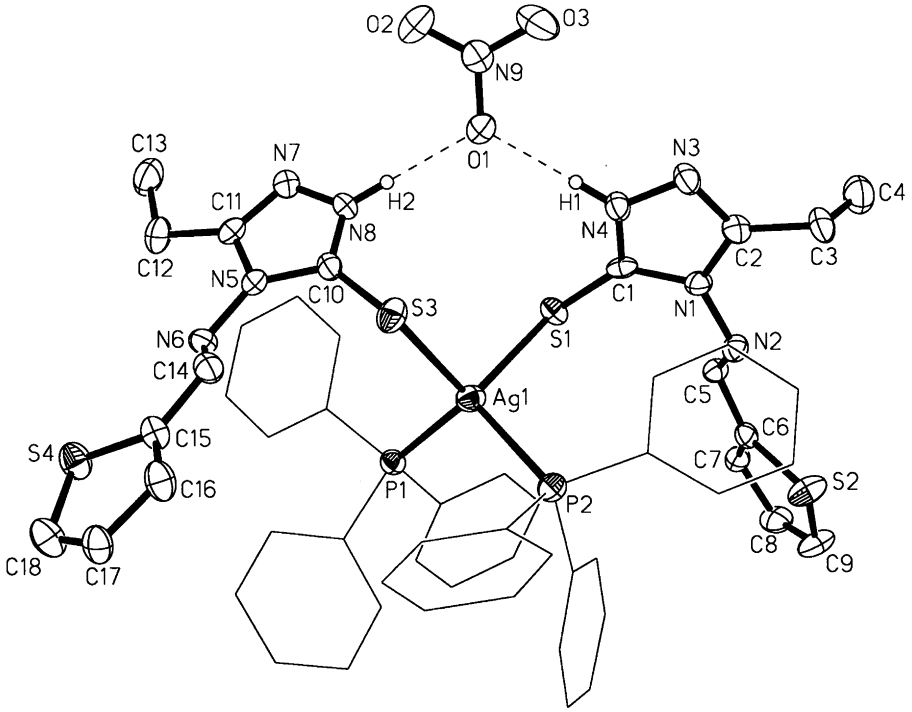

Fig. 4. Molecular structure of **2** (thermal ellipsoids at the 40% probability level).

and two thione S atoms of two **LH1a** Schiff-bases. This arrangement is slightly distorted since, except the S angle at the metal site of 109.18(5)° (S1–Ag1–S3), the other three selected angles in the AgP_2S_2 group, P1–Ag1–P2, S1–Ag1–P2 and S3–Ag1–P1 with 114.20(5)°, 111.46(5)° and 113.72(5)°, are greater than those of a regular tetrahedron. The tetrahedral distortion is due to steric hindrance of the bulky phosphane ligands and was observed in a series of analogous complexes [23]. The Ag–P bond distances, mean 248.3(1) pm, are within the range of the corresponding distances reported for other silver(I) complexes (227.7–230.7 pm) [7a,18b]. The Ag1–S1 and Ag1–S3 bond distances of 260.6(1) pm and 259.0(1) pm lie in the range observed for complexes with tetrahedral Ag(I) centers [24]. The nitrate ion acts as a bridging agent between two NH groups of the Schiff-bases of the cation through one of its oxygen atoms *via* hydrogen bonds (N4–H1···O1: 274.3(5) pm and N8–H2···O1: 275.6(6) pm). This coordination mode causes a slightly lengthening of the N9–O1 bond distance (125.9(5) pm) compared to the other N–O distances in the nitrate ion (N9–O2: 122.1(5) and N9–O3: 123.8(5) pm).

3.2.4. Complex *3*

The Pd atom in **3** has the usual ideal square planar coordination arrangement with P–Pd–P and S–Pd–S axes of 180° (Fig. 5). The metal atom is located on the point of intersection of the mirror plane (center) and sits on the twofold axis. Each ligand in **3** is singly deprotonated, and therefore can be assigned as a compound with *Hückel* aromaticity. They occupy the positions *trans* to each other and

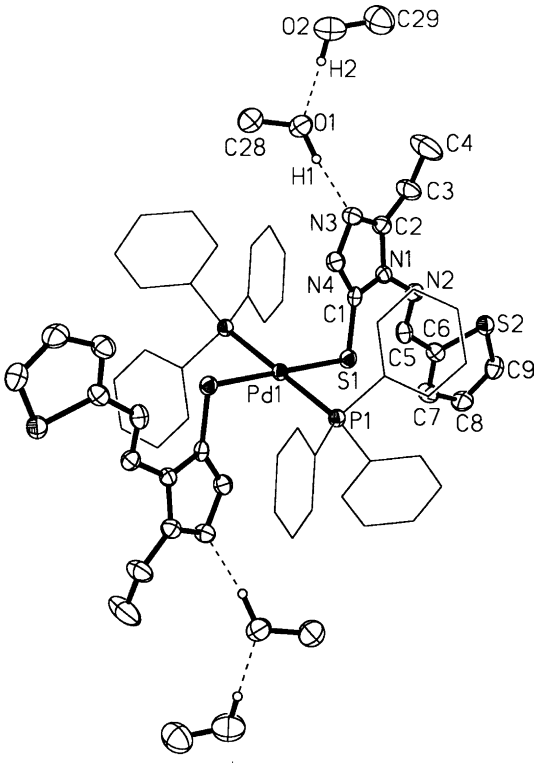

Fig. 5. Molecular structure of **3** (thermal ellipsoids at the 40% probability level).

are coordinated to the metal center as monodentate ligands using their thione sulfur atoms.

The Pd–P bond length of 232.4(1) pm is shorter than the sum of the single bond radii for palladium and phosphorus, i.e. 241 pm [25], is slightly longer than the Pd^{II}–PPh_3 bond reference value (320.2 pm) encountered in 248 entries [26], and falls in the middle of the wide range of values (221–246 pm).

The Pd–S bond distance of 232.7(1) pm is in the range observed in the complexes $[(HL)_4Pd]Cl_2 \cdot 8MeOH$ (mean Pd–S: 231.97 pm) [6c], $[(HL)_2PdI_2] \cdot 2MeOH$ (Pd–S: 232.1(1) pm) [6c] and $[\{(L_4Pd_2)NaCl\}_2] \cdot 8MeOH$ (mean Pd–S: 231.95 pm) [6c]. In **3**, one methanol molecule acts as a bridging agent using its oxygen atom between each heterocycle and another solvate molecule, and links the endocyclic nitrogen atom of the heterocycle to the oxygen atom of the solvate molecule *via* medium to strong hydrogen bonds (N3···O1–H1: 286.2(5) pm, O2–H2···O1: 273.3(6) pm). The dihedral angle between the "best" planes of the complex (A: Pd1 S1 S1a P1 P1a, B: N1 N2 N3 N4 C1 C2, C: S2 C5 C6 C7 C8 C9) are 116° (A, B), 93° (A, C) and 29° (B, C).

4. Conclusion

Two new complexes containing silver(I) atoms and a new complex with a palladium(II) core have been synthesized and characterized. All the complexes contain 1,2,4-triazoles derivatives as ligands. The molecular structure of complex **1** shows a new coordination mode between the metal atom and the sulfur atoms of the triazole moieties, which has not been observed previously to the best of our knowledge. This coordination mode leads to the formation of a 10-membered Ag–S "mosaic" pattern, causing a two dimensional endless framework and is responsible for the formation of layers parallel to (0 0 1). The two other complexes, **2** and **3**, can be assigned as the first examples with the coordination of two Schiff-bases based on 1,2,4-triazole to metal-bis(triphenylphosphine) moieties. The silver(I) complex (**2**) is an ionic one, while the palladium complex contains two singly deprotonated Schiff-bases and is therefore a neutral complex.

5. Supplementary data

CCDC 661633, 661634, 661635, 661636 contain the supplementary crystallographic data for **HL1a**, **1**, **2**, **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

the heterometal alkoxide clusters of lanthanide and sodium $[Ln_2Na_8(OCH_2CH_2NMe_2)_{12}(OH)_2]$ (Ln = Nd, Pr, Sm, Y, Ho) are very active single-component catalysts for the polymerization of ε-CL and TMC. The reactivity is as high as 1.03×10^5 kg/mol h for the polymerization of ε-CL and 4.61×10^4 kg/mol h for TMC at room temperature [12]. These results promote us to further understanding the relationship between the structures and reactivity of heterometal alkoxides clusters and their cooperative bimetallic mechanism in the polymerization of cyclic esters.

With this goal in mind we have synthesized and structurally characterized the new heterometal alkoxide clusters of lanthanide and sodium $Ln_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (Ln = Sm **1**, Y **2**, Yb **3**), and further tested their catalytic activities for the ring-opening polymerization of ε-CL as well as TMC. It was found that these clusters can initiate the polymerizations of both monomers in high activity as single-component initiators, and the activities are much higher than those found for the related monometallic lanthanide alkoxides complexes reported, such as $Ln(OAr)_3$, $Ln_5O(O^iPr)_{13}$ and LLn(OR) (L = bridged biphenolate, OR = OMe, O^{i}Pr and OCH_2Ph) [2–5] as well as anionic phenoxide complex $[Ln(OAr)_4][Na(DME)_3]$ [11]. Here we would like to report these results.

2. Experimental

2.1. Materials

All the manipulations are conducted under pure Ar atmosphere with rigorous exclusion of air and moisture using Schlenk tube and vacuum-line technique. ε-CL was purchased from Acros, dried over CaH_2 and distilled at reduced pressure. TMC was prepared by the reaction of 1,3-propandeidol with diethyl carbonate according to published method [13], and further dried over CaH_2 and purified by recrystallization before use. Anhydrous lanthanides $LnCl_3$ were prepared according to the literature [14]. Toluene, dimethoxy-ethane (DME) and tetrahydrofuran (THF) were distilled from sodium/benzophenone ketyl.

2.2. Synthesis of the clusters

2.2.1. $Sm_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (*1*)

To a suspension of $SmCl_3$ (0.51 g, 2.0 mmol) in 40 ml THF was slowly added a solution of $NaOCH_2CF_3$ (11.2 ml, 14.0 mmol) in THF at r.t. The solution changed gradually from light gray to pale yellow. The resulting solution was stirred for another 24 h, and then evaporated to dry *via* vacuum. The residue was extracted with toluene and NaCl was removed by centrifugation. After the solution was concentrated, the product was obtained as colorless powder. Yield: 1.57 g (68%). Crystallization from THF–toluene gave colorless crystals at r.t.. Decomposition point: 162–164 °C. *Anal.* Calc. for $C_{52}H_{76}F_{42}Na_8O_{20}Sm_2$ (2303.75): C, 27.10; H, 3.33; Sm, 13.05. Found: C, 27.09; H, 3.29; Sm, 13.02%. IR (KBr pellets cm^{-1}): 3442 (s), 2863 (m), 1643 (w), 1443 (s), 1273 (m), 1158 (s), 957 (w), 880 (m), 826 (w), 671 (m), 556 (w), 509 (w).

2.2.2. $Y_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (*2*)

By the same procedure as that for **1**, **2** was prepared from the reaction of YCl_3 (0.39 g, 2.0 mmol) with $NaOCH_2CF_3$ (11.2 ml, 14.0 mmol) in THF as colorless powder. Yield: 1.64 g (75%). Crystallization from THF–toluene gave colorless crystals at r.t.. Decomposition point: 149–151 °C. *Anal.* Calc. for $C_{52}H_{76}F_{42}Na_8O_{20}Y_2$ (2180.87): C, 28.64; H, 3.51; Y, 8.15. Found: C, 28.56; H, 3.44; Y, 8.14%. ^{1}H NMR (400 MHz, THF-d_8 25 °C): $\delta = 4.15$ (s, 28H, OCH_2CF_3), 3.60 (m, 24H, THF), 1.76 (m, 24H, THF) ppm. ^{13}C NMR (400 MHz, THF-d_8 25 °C): $\delta = 65.44$ (s, OCH_2CF_3), 130.16 (m, OCH_2CF_3), 67.40 (m, THF), 25.30 (m, THF) ppm. IR (KBr pellets cm^{-1}): 3454 (s), 2988 (w), 2860 (m), 1686 (m), 1455 (w), 1267 (s), 1158 (s), 894 (w), 820 (m), 672 (m), 552 (w), 477 (m).

2.2.3. $Yb_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (*3*)

By the same procedure as that for **1**, **3** was prepared from the reaction of $YbCl_3$ (0.56 g, 2.0 mmol) with $NaOCH_2CF_3$ (11.2 ml, 14.0 mmol) as colorless powder. Yield: 1.69 g (72%). Crystallization from THF–toluene gave colorless crystals at r.t.. Decomposition point: 171–174 °C. *Anal.* Calc. for $C_{52}H_{76}F_{42}Na_8O_{20}Yb_2$ (2349.13): C, 26.59; H, 3.26; Yb, 14.73. Found: C, 26.57; H, 3.24; Yb, 14.70%. IR (KBr pellets cm^{-1}): 3419 (s), 2862 (m), 1528 (m), 1389 (m), 1219 (s), 1158 (s), 864 (w), 632 (m), 556 (w), 509 (s).

2.3. Polymerization

2.3.1. General procedure

To a stirred solution of TMC or ε-CL in toluene, a toluene solution of initiator was added with a syringe. The polymerization mixture was stirred for a definite time at the desired temperature and then quenched with an ethanol solution containing a small amount of hydrochloric acid. The polymer was precipitated from ethanol and washed with ethanol three times and dried under vacuum.

2.3.2. Oligomer for end group analysis

The oligomerization of ε-CL was carried out with **1** in toluene at 25 °C under the condition of [ε-CL]/[**1**](mole ratio) of 30. The reaction was terminated by adding 1 ml of 5% HCl/^{i}PrOH after 30 min. The oligomer was precipitated from ethanol. The product was dissolved in THF, followed by precipitation in ethanol. The procedure was repeated two times. The white product was dried in vacuum.

2.4. Analysis and characterization

Metal analyses were carried out by complexometric titration. Carbon, hydrogen, and nitrogen analyses were

performed by direct combustion on a Carlo-Erba EA = 1110 instrument. Melting points were determined on a Yanaco MP-500 melting point apparatus and were uncorrected. The IR spectra were recorded on a Nicolet Magna-IR 550 spectrometer. The ^{1}H NMR spectrums were recorded on a Unity Inova-400 spectrometer. The number-average (M_n) and weight-average (M_w) molecular weights and molecular weight distributions (M_w/M_n) were determined by gel permeation chromatography (GPC) with THF as an eluent and polystyrene as a standard on a Waters 1515 apparatus equipped with three HR columns (HR-1, HR-2, and HR-4) and an ultraviolet visible detector.

The suitable single crystals of clusters **1**–**3** were sealed in thin-walled glass capillaries for single-crystal structure determination. Intensity data were collected at a low temperature on a Rigaku Mercury CCD. The crystal structure was solved by a direct method and expanded by Fourier techniques. Atomic coordinates and thermal parameters were refined anisotropically.

3. Results and discussion

3.1. Synthesis of 1–3

As reported in our previous work, the metathesis reaction of anhydrous $LnCl_3$ with 3 equiv. of $NaOCH_2CF_3$ in THF gave the cluster $[Y_6(\mu_6\text{-}O)(OCH_2CF_3)_{18}][Na(THF)_3]_2 \cdot PhMe$ in low yield [15]. In our effort to prepare heterometal alkoxide clusters of lanthanide and sodium, a new cluster $Sm_2Na_8(OCH_2CF_3)_{14}(THF)_6$ **1** was synthesized by treatment of anhydrous $SmCl_3$ with a large excess of $NaOCH_2CF_3$ (7 equiv.) in 68% yield (yield based on samarium) (Eq. (1)). The synthesis can be reproduced.

$$2LnCl_3 + 14NaOCH_2CF_3 \xrightarrow{THF} Ln_2Na_8(OCH_2CF_3)_{14}(THF)_6 + 6NaCl \quad (Ln = Sm\ \mathbf{1}, Y\ \mathbf{2}, Yb\ \mathbf{3}) \quad (1)$$

The outcome of the metathesis reaction of $LnCl_3$ with alkali metal alkoxide was reported to depend on the metals used. For example, the reaction of YCl_3 with $NaOCMe_3$ in the molar ratio of 1:3 afforded the complex $Y_3(OCMe_3)_8Cl(THF)_2$, while the same reaction with $LaCl_3$ produced the complex $La_3(OCMe_3)_9(THF)_2$ [16]. Therefore, the syntheses of clusters of Y and Yb were also tried to evaluate the validity of this approach. The same reaction with YCl_3 and $YbCl_3$, respectively, went smoothly and gave the corresponding clusters $Y_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (**2**) and $Yb_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (**3**) in 75% and 72% yields, respectively. Clusters **1**–**3** are all soluble in THF and toluene but not in hexane. The results of elemental analysis for **1**–**3** were all identical to the formula; and indicated the molar ratio of Ln and Na to be 1:4. The ^{1}H NMR spectra for paramagnetic clusters **1** and **3** showed a very broad shift range, while the ^{1}H NMR spectrum of **2** in THF-d_8 showed the chemical shifts of CH_2CF_3 at 4.15 ppm. To understand the structure of cluster in THF solution the ^{1}H NMR spectrum of $NaOCH_2CF_3$ in THF-d_8 was measured and the chemical shift of CH_2CF_3 was appeared at 4.11 ppm. The result demonstrates that a dynamic of ligand going on and off might be existed.

Clusters **1**–**3** were further characterized by X-ray crystallography. The determination of crystal structures revealed **1**–**3** have the same solid-state structure. The molecular structures diagram with all the CH_2CF_3 groups omitted for clarity are shown in Fig. 1. The details of the crystallographic data are listed in Table 1, and the selected bond lengths and bond angles are provided in Tables 2 and 3, respectively.

The clusters are centrosymmetric and the overall structure in each case is composed of two cubanes and a double open cubane, with one face of an $Ln_1Na_2O_4$ open cubane cluster capped by an additional Ln_1O_2 layer. The double open cubane locates as a core capped by two cubanes in opposite side via two lanthanide atoms. The synthesis of such an extended series of structurally identical heterometal alkoxide clusters indicated that the structure framework here is particularly stable.

Each lanthanide atom is coordinated by four triple-bridged oxygen atoms [O(2), O(4), O(5), O(6)] and two double-bridged oxygen atoms [O(3), O(1)] from OCH_2CF_3 groups. The coordination geometry around the lanthanide atom can be best described as a distorted octahedron geometry, in which O(1), O(3), O(4) and O(6) can be considered to occupy equatorial positions with the angles sum about the lanthanide center of $\sum$O–Ln–O = 360.3° for **1**; 360.2° for **2**, and 360.2° for **3**; O(2) and O(5) occupy axial positions with the O(2)–Ln–O(5) angle of 167.7° for **1**, 171.7° for **2** and 171.8° for **3**, which is slightly distorted away from the idealized value of 180°. Each Na atoms coordinated to four oxygen atoms forming a distorted tetrahedral geometry. There is different coordinated environment around Na atoms between the Na atoms [Na(1), Na(1A)] in a double open cubane and the Na atoms [Na(2), Na(2A); Na(3), Na(3A); Na(4), Na(4A)] in cubane; in the former the four oxygen atoms all come from OCH_2CF_3 groups in two μ_2-O and two μ_3-O fashion, respectively, in the later case three μ_3-O from OCH_2CF_3 groups and one terminal-O from THF molecule.

The Ln–O(OCH_2CF_3) bond are of two types: Ln-μ_2-O and Ln-μ_3-O. The average bond length of Ln–O(μ_2-OCH_2CF_3) is 2.266(4), 2.213(3) and 2.187(4) Å for **1**, **2** and **3**, respectively, and the average bond length of Ln–O(μ_3-OCH_2CF_3) is 2.333(3), 2.260(3) and 2.234(3) Å for **1**, **2** and **3**, respectively. The 0.06 Å larger for Ln–O(μ_3-OCH_2CF_3) in comparison with Ln–O(μ_2-OCH_2CF_3) is reasonable, and it is also observed in other alkoxides complexes [7,16,17]. These bond parameters are comparable with each other when the difference in the ionic radii among Sm, Y and Yb is considered. Therefore, the comparison of the data for **2** with those found in other yttrium clusters is made as an example. The range of Y–O(μ_3-OCH_2CF_3) bond distances from 2.232(3) to 2.278(3) Å

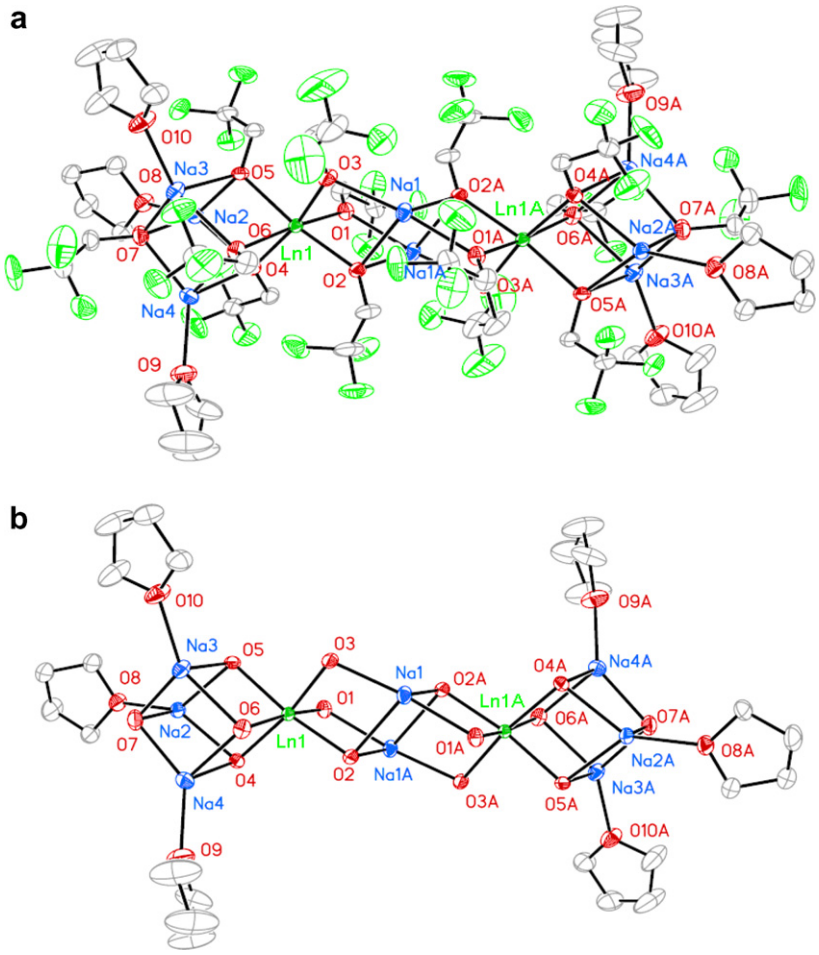

Fig. 1. (a) Molecular structures of **1**–**3**; (b) ORTEP diagram of **1**–**3** all the CH_2CF_3 groups deleted for clarity (atomic displacement parameters set at the 30% level).

are consistent with the values of Y–O(μ_3-OR) previously observed: 2.275(6)–2.287(6) Å for $YNa_8(OCMe_3)_{10}Cl$ and 2.263(13)–2.291(14) Å for $YNa_8(OCMe_3)_{10}(OH)$ [8b]. The range of 2.209(3)–2.217(3) Å for Y–O(μ_2-OCH_2CF_3) distances lie in the low end of the range of analogous distances for clusters in which only yttrium atoms are contained in the bonding: 2.25(2)–2.32(2) Å for $Y_7Cl_5(OCMe_3)_{14}$-$(THF)_2O$; 2.241(10)–2.358(10) Å for $Y_3Cl(OCMe_3)_8$-$(THF)_2$ and 2.26(2)–2.34(2) Å for $Y_4Cl_2(OCMe_3)_{10}O$ [17].

The Na–O bonds are of three types. The average bond length of the terminate Na–O(THF) for **1**, **2** and **3** is 2.306(5), 2.312(4) and 2.312(5) Å, respectively, which are almost equal. The average bond lengths of Na–O(μ_2-OCH_2CF_3) and Na–O(μ_3-OCH_2CF_3) for **1**, **2** and **3** are also normal, and comparable each other.

3.2. Polymerization of ε-CL and TMC with clusters *1*–*3*

Clusters **1**–**3** were found to be able to initiate the ring-opening polymerization of ε-CL in toluene at room temperature with high activity. In contrast, no polymer was obtained under the same reaction conditions when $Na(OCH_2CF_3)$ was used as initiator (Table 4, entry 13). The dependence of activity on lanthanide metals was observed. For example, when the mole ratio of [M]/[I] was 4000 at 25 °C within 30 min, the conversion was as high as 96% for **1**, while only trace for **2** and 12% for **3** (Table 4, entries 3, 9 and 12). The active sequence of Yb ≈ Y < Sm observed here is almost consistent with the increase in ionic radius (Yb < Y < Sm), which is similar to those found in the polymerization systems based lanthanide complexes [3a,18]. The conversion can still reach to 81% even the mole ratio of [M]/[I] as high as 7000 for the system with cluster **1** (Table 4, entry 4). Such high reactivity has not been found for the systems with monometallic lanthanide alkoxides (phenoxides) complexes published previously (Table 4, entries 15–19), indicating that the extremely high reactivity shown by **1**–**3** may result from the activation of monomer via coordination to both lanthanide metal and alkali metal and the rapid ligand exchange existed in solution. It was noticed that the reactivity of **1**–**3** is lower than that of the heterobimetallic alkoxide clusters $[Ln_2Na_8(OCH_2CH_2NMe_2)_{12}(OH)_2]$ (Table 4, entry 14) published recently [12]. The lower reactivity of **1**–**3** in comparison with clusters $[Ln_2Na_8(OCH_2CH_2NMe_2)_{12}(OH)_2]$ demonstrates that the reactivity of heterometal alkoxides

clusters depends profoundly on the alkoxide groups and/or on the skeleton of clusters.

The polymers resulted by **1**–**3** show a unimodal molecular weight distribution with moderate polydispersities ($M_w/M_n < 1.70$), indicating **1**–**3** are really used as single-component catalysts in the ring-opening polymerization of ε-CL. However, the molecular weights of the resulting polymers are always lower than those expected from the monomer-to-initiator ratio. This may be caused from the multi-active species existed in cluster, which come from the distinct

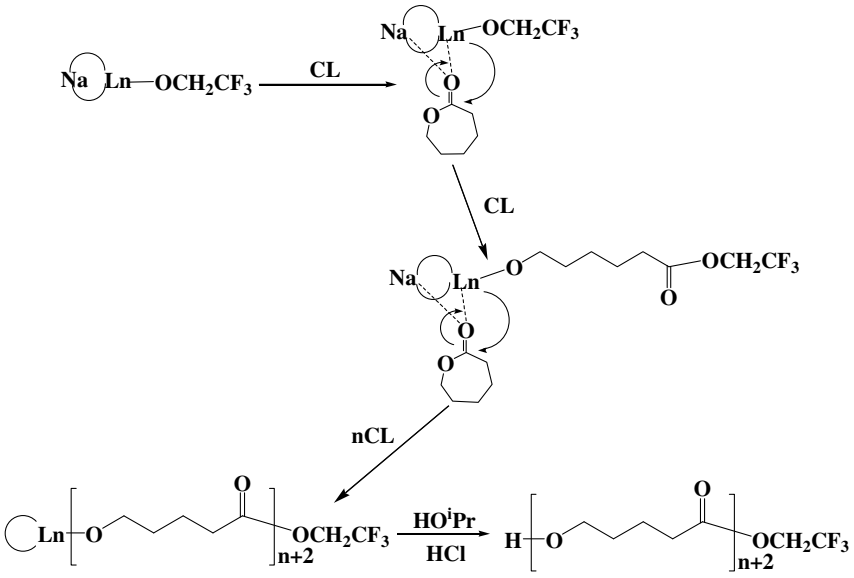
[a] Conditions: [cat] = 0.01 mol/L, toluene as solvent, $V_{sol.}/V_{mon.}$ = 5:1.
[b] Conv. %: weight of polymer obtained/weight of monomer used.
[c] Measured by GPC calibrated with standard polystyrene samples.
[d] THF as solvent.
[e] OAr′ = 2,6-*tert*-butyl-phenoxo.
[f] OAr = 2,6-*tert*-butyl-4-methylphenoxo.
[g] mbmp = 2,2′-methylenebis(6-*tert*-butyl-4-methylphenoxo).



types of Ln–O bond, both in terms of connectivity count and length, or from the possible transesterification. Moreover, the polymerization in toluene yielded much higher conversion and the polymers with higher molecular weight than that in THF (Table 4, entries 3 and 6). The result indicates the present polymerization may belong to a coordinate/insertion mechanism. That is way the polymerization in protic solvent gives the worse result.

In order to understand the catalytic behavior of clusters **1**–**3** further, the ring-opening polymerizations of TMC catalyzed by them were tested. The representative results are listed in Table 5. Clusters **1**–**3** are all very active catalysts for the ring-opening polymerizations of TMC at 25 °C in toluene while the complex $Na(OCH_2CF_3)$ shows no activity under the same conditions (Table 5, entry 14). The catalytic behavior of clusters **1**–**3** for TMC is similar to that for ε-CL. For example, The activities of clusters **1**–**3** are much higher than those of the related lanthanide complexes published [19], the similar dependence of reactivity on lanthanide metals, Yb < Y < Sm, and the same solvent dependence of the polymerization (the polymerization in toluene yields higher conversion and the polymers with higher molecular weight than that in THF) were observed (Table 5, entries 2, 8–13). All the resulting polymers show unimodal molecular weight distributions with moderate polydispersities (M_w/M_n around 1.50), although the molecular weights of the resulting polymers are lower than those expected from the monomer-to-cluster ratio. It is unexpected that the difference in polymerization rate between the two polymerizations was observed. Polymerization of TMC is much faster than that of the ε-CL. For example, complete conversion of TMC into PTMC is achieved within 1 min for monomer to initiator ratios of up to 4000 with cluster **1** as initiator (Table 5, entry 2), while only 72% conversion is obtained within 15 min for the polymerization of ε-CL under the same conditions (Table 4, entry 2).

Scheme 1. Postulated cooperation mechanism for the ring-opening polymerization of ε-CL.

3.3. Polymerization mechanism

The dependence of activity on lanthanide metals for polymerization of both monomers demonstrates the active species here is the intermediate containing Ln–O bond. Much better results obtained in toluene than in THF indicates the present polymerization system may be conducted by the coordination–insertion mechanism.

In addition, the ring-opening polymerization of cyclolactones is known to conduct by either acyl–oxygen bond cleavage or alkyl–oxygen bond cleavage depending on the initiator used. To understand further the polymerization mechanism, the end-group of the oligomer was analyzed by ^{1}H NMR and ^{9}F NMR. An oligomer of ε-CL was produced from the oligomerization of ε-CL with a [ε-CL]/[**1**] of 30 and terminated by isopropyl alcohol. The ^{1}H NMR spectroscopy showed the signal at 4.48 ppm assigned to OCH_2CF_3 group and the ^{9}F NMR spectroscopy indicated the existence of an OCH_2CF_3 end group. These results obviously demonstrate the polymerization conducted by an acyl–oxygen bond cleavage. To explain the very high reactivity shown by clusters **1**–**3**, a cooperation mechanism of bimetals is supposed as shown in Scheme 1. First, ε-CL could coordinate to both Ln and Na metals concomitantly and then activated ε-CL inserts into one of Ln–OCH_2CF_3 bonds. The process repeats to yield the polymer.

4. Conclusion

New heterometal alkoxide clusters of lanthanide and sodium **1**–**3** were synthesized by the reaction of anhydrous $LnCl_3$ with $NaOCH_2CF_3$ at the mole ratio of 1:7 and structurally characterized. The clusters are found to be the highly active single-component initiators for the ring-opening polymerization of ε-CL and TMC. The activities are much higher than related monometallic alkoxides lanthanide complexes published previously. The polymerization reactions yield the polymers with moderate molecular weight distributions ranging from 1.4 to 1.7 for both PCL and PTMC. The cooperation of Ln and Na metals and the coordination–insertion mechanism were supposed. The further study on the catalytic behavior of the heterometal clusters of lanthanide and alkali with diverse alkoxide groups and structural motifies in polymerization reactions of polar monomers are preceeding in our laboratory.

Co(III), Ni(II), Cu(II), Zn(II), Zr(IV), Pd(II), Ag(I), Cd(II), Hg(II), Sn(II), Sn(IV), Pb(II), P(III), As(III), Sb(III), Bi(III), Se(II), Te(II), Th(IV) and U(VI). Other studies include the synthesis of a few series of compounds of the type, $M[O(S)P(OR)_2]_3$ (M = As, Sb and Bi) [12], $R_2As[O(S)P(OR)_2]$ [13] and mixed ligand complexes of arsenic(III), $[OCMe_2CH_2CHMeOAsO(S)P(OR)_2]$ [14], $R_2Sb[O(S)P(OR)_2]$ [15] and $[Sb(S_2CNR_2)_2\{O(S)P(OR)_2\}]$ [12]. Limited information about a cobalt(II) diisopropyl monothiophosphate complex has been presented in the literature [11,16].

Variation in the mode of coordination to the central atom and in the core geometry is common; the central Sn_2O_2 core in $[(Me_2Sn\{O(S)P(OEt)_2\})_2O]_2$ [9], connected via an oxygen atom of the thiophosphate ligand, is coordinated through oxygen to give a distorted trigonal bipyramid arrangement around tin; $[Ph_2Sn(\mu\text{-}OH)\{O(S)P(OPh)_2\}]_2$ [10] has a similar structure except that the tin atoms are connected by hydroxo bridges; $[Zn_4\{O(S)P(OPh)_2\}_6O]$ [17] and $[Zn_4\{O(S)P(OMe)_2\}_6O]$ [17] possess a central tetrahedral Zn_4O core and the monothiophosphates ligands bridge the three basal zinc atoms through sulfur and oxygen atoms (bridging chelation); and $[Cd_2\{O(S)P(OPr^i)_2\}_3]$ [16] comprises pairs of tetrahedral coordinated cadmium atoms linked via three monothiophosphates ligands to give Cd_2L_3 units. The ligands bridge through sulfur and oxygen atoms to two cadmium atoms, giving rise to a polymeric chain.

This background led us to work on the synthesis and characterization of a series of bis(*O*,*O*-dialkylmonothiophosphato)cobalt(II) complexes and to determine the variations in the electronic environment, bonding modes and geometrical configuration. Nitrogen base donors such as pyridine or 2,2-bipyridyl were added to the tetrahedral cobalt(II) complexes to yield adducts of the type $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$, $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$ and $[Co\{O(S)P(OBu^n)_2\}_2(C_{10}H_8N_2)_2]$. Single crystal X-ray studies of $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$ and $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$ are the first examples of structurally characterized nitrogen base adducts of monothiophosphate complexes of cobalt(II).

2. Results and discussion

The reactions of cobalt(II) chloride hexahydrate with sodium salts of *O*,*O*-dialkylmonothiophosphoric acids in a 1:2 molar ratio in benzene yield bis(*O*,*O*-dialkylmonothiophosphato)cobalt(II) complexes of the type $[Co\{O(S)P(OR)_2\}_2]$.

$$CoCl_2\cdot 6H_2O + 2NaO(S)P(OR)_2 \xrightarrow{3\text{ h, stirring}} [Co\{O(S)P(OR)_2\}_2] + 2NaCl \quad (R = Pr^n, Pr^i, Bu^n)$$

Further reaction of these cobalt(II) complexes with neutral nitrogen donor bases such as pyridine and 2,2-bipyridyl results in the formation of adducts of the type, $[Co\{O(S)P(OR)_2\}_2L_n]$.

$$[Co\{O(S)P(OR)_2\}_2] + nL \xrightarrow{C_6H_6} [Co\{O(S)P(OR)_2\}_2L_n] \quad (R = Pr^i, n = 4, L = \text{pyridine}; R = Pr^n, Bu^n, n = 2, L = 2,2'\text{-bipyridyl})$$

These reactions are quite facile, but to ensure completion the reaction solutions were stirred for 3 h. All of the bis(*O*,*O*-dialkylmonothiophosphato)cobalt(II) complexes are blue solids and their adducts are pink or orange solids. The cobalt(II) complexes as well as their adducts are soluble in common organic solvents such as benzene, chloroform and dichloromethane. The products were characterized by elemental analysis, IR and UV–Vis spectroscopy and magnetic susceptibility measurements.

Despite extensive efforts at crystallization by various methods, it was not possible to obtain single crystals of good enough quality to obtain a crystal structure for complexes **1**–**3**. It has been claimed that the structure of these complexes is polymeric with cobalt having tetrahedral coordination and they are isostructural to $[Cd_2\{O(S)P(OPr^i)_2\}_3]$ [16]. X-ray quality crystals of adducts **4** and **5** were obtained, however, on re-crystallization from benzene: hexane (1:1 ratio).

2.1. IR spectra

The IR spectra of the bis(*O*,*O*-dialkylmonothiophosphato)cobalt(II) complexes and their adducts are summarized in Table 1. The effect of coordination is most evident in the shifts of the peaks attributable to the P–S and P–O stretching vibrations. In the cobalt(II) complexes **1**–**3**, a single broad strong band or two close bands are seen in the region 613–629 cm^{-1} that are shifted to higher frequencies by ca. 20–30 cm^{-1} compared to their corresponding sodium salts, suggesting that the P–S bond is involved in the coordination sphere of these tetrahedral complexes, as was proposed for $[Co\{O(S)P(OPr^i)_2\}_2]$ [16]. By contrast, in adducts **4**–**6**, two close bands are seen at almost the same frequencies as in the sodium salts, suggesting that cobalt is not coordinated through the P=S bond in these adducts. The medium to very strong intensity bands observed in the regions 1140–1149 and 1091–1110 cm^{-1} are assigned to the P–O stretching vibrations in complexes **1**–**6**, consistent with coordination of the oxygen atom to the metal centre. The vibrations for (P)–O–C and P–O–(C) bonds are observed in the region 958–994 and 753–764 cm^{-1}, respectively. In complexes **1**–**3**, new bands of medium to weak intensity in the region 341–358 cm^{-1} can be assigned to the Co–S stretching vibration, resulting from coordination of the metal to the ligand. In adducts **4**–**6**, strong bands due to the C–N bond are seen in the region 1570–1602 cm^{-1} which are shifted to higher frequency in comparison to free pyridine (1580, 1600 cm^{-1}) and bipyridyl (1579, 1595 cm^{-1}).

Table 1
IR spectral data (cm^{-1}) for the bis(*O*,*O*′-dialkylmonothiophosphato)cobalt(II) complexes and their nitrogen base adducts[a]

No.	Compound	*ν*(C–N)	*ν*(P–O)	*ν*[(P)–O–C]	*ν*[P–O–(C)]	*ν*(P–S)	*ν*(Co–S)
1	$[Co\{O(S)P(OPr^n)_2\}_2]$		1174m, 1149s	990s	757s	613s	341w
2	$[Co\{O(S)P(OPr^i)_2\}_2]$		1173m, 1144s	988s	760s	616s	358w

[a] Key: s = strong, m = medium, w = weak.

2.2. Magnetic measurements

The magnetic susceptibilities of these paramagnetic compounds were determined using the Evans NMR method [18]. The values are in the range 4.5–5.3 and 5.0–5.3 BM and are in the range expected for the tetrahedral (**1**–**3**) and the octahedral (**4**–**6**) cobalt(II) complexes [19], respectively.

2.3. Crystal structures of $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$ and $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$

$[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$, **4** and $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$, **5**, crystallize as triclinic in the space group $P\bar{1}$ and monoclinic in the space group $C2/c$, respectively. In both **4** and **5** the geometry around cobalt(II) is distorted octahedral with the CoO_2N_4 chromophore arising because the unidentate monothiophosphate ligands are linked through oxygen, as is evident from the molecular structures shown in Figs. 1 and 2. Bond distances and bond angles for **4** and **5** are given in Tables 3 and 4, respectively. The outstanding difference between the two structures is that in **4** the two monothiophosphate ligands are *trans* with a O–Co–O bond angle of 180°, as required by symmetry. By contrast, in **5** these ligands are *cis* with a O–Co–O bond angle of 97.19(7)°. In general, the distortion, not surprisingly, is more obvious in **5** with the constraints on the bidentate nitrogen base resulting in N–Co–N bite angles of 76.05(6)° compared with the N–Co–N bite angles in **4** of 87.67(3)°. The remaining *cis* angles in **4** are all close to 90°, ranging from 88.34(3)° to 92.33(3)°, whereas those in **5** range from 76.05(6)° to 97.29(6)°. Also, whereas all of the *trans* angles in **4** are 180.00 those in **5** range from 164.95(5)° to 171.04(8)°.

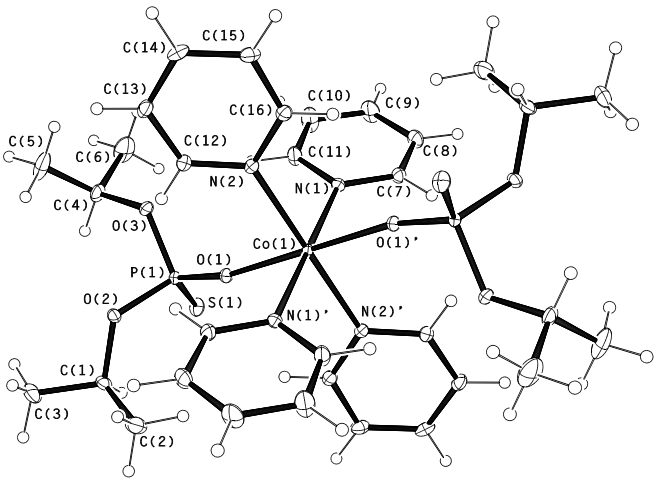

Fig. 1. ORTEP plot of the molecule $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$. The non-hydrogen atoms are drawn with 50% probability ellipsoids.

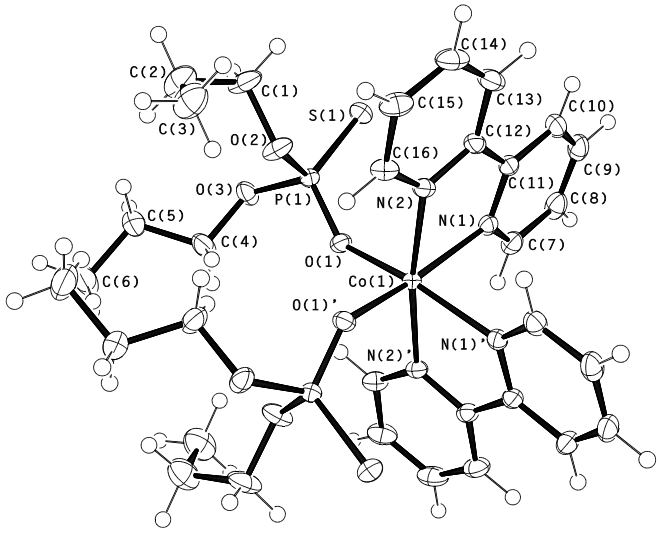

Fig. 2. ORTEP plot of the molecule $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$. The non-hydrogen atoms are drawn with 50% probability ellipsoids.

The Co–O bond distance (2.0757(8) Å) is slightly longer in **4** than in **5** (2.045(1) Å), as might be expected from the *trans* influence of O relative to N. The values are close to that obtained for $Co_5(OH_2)_4(HPO_4)_2(PO_4)_2$ (~2.05 Å) [20]. The average Co–N bond distances (2.1800(9) Å in **4**) and (2.146(2) Å in **5**) are comparable to those obtained for $[Co\{S_2P(OC_6H_5Me\text{-}p)_2\}_2(C_5H_5N)_2]$ [21] (2.162(2) Å) and $[Co\{S_2P(OEt)_2\}_2(C_5H_5N)_2]$ (2.164(3) Å) [22]. The cobalt to sulfur distances of 4.740(1) and 4.397(1) Å in **4** and **5**, respectively, emphasize that there is no Co–S intramolecular interaction in these adducts. A similar coordination pattern is seen in $Me_2Sn\{O(S)PPh_2\}_2$ [23] where the ligand is attached through oxygen and no appreciable Sn–S interaction is observed, with Sn–S distances of 3.901(3) and 3.530(4) Å. The average P–S bond length is 1.9565(4) Å in **4** and 1.9568(7) Å in **5**. A slightly shorter P–S bond (1.944(1) Å) was found in $[HOPh_2SnO(S)P(OPh)_2]_2$ [10], where the monothiophosphate ligand is

monodentate, and a longer P–S bonds were found in $[Cd_2\{O(S)P(OPr^i)_2\}_3]$ (ave. 1.971(9) Å) and $[Zn_4O\{O(S)P(OPh)_2\}_6]$ (ave. 1.980(3) Å), where the ligand is bridging bidentate. The closest Co–S intermolecular distances are 8.786(1) in **4** and 7.742(1) Å in **5**. The S–P–O bond angles are 117.94(7)° and 119.58(6)° in **4** and **5**, respectively; slightly higher than reported for $Me_2Sn\{S(O)PPh_2\}_2$ [23] (113.7(3)° and 115.0(3)°).

3. Experimental

Solvents (benzene, dichloromethane, *n*-hexane and diethyl ether) were dried by standard methods before use. All reactions were carried out in pre-dried glassware under anhydrous conditions. Sodium salts of *O*,*O*-dialkylmonothiophosphoric acids were prepared according to the literature procedure [24]. Sulfur was estimated gravimetrically as barium sulfate (Messengers Method) and cobalt by the pyridine method [25]. IR spectra were recorded on a Perkin–Elmer PE 983G spectrophotometer as Nujol mulls in the range 4000–200 cm^{-1}.

3.1. Preparations

3.1.1. $[Co\{O(S)P(OPr^n)_2\}_2]$ (**1**)

Typically, $CoCl_2 \cdot 6H_2O$ (0.078 g, 0.328 mmol) was added to a solution of $NaO(S)P(OPr^n)_2$ (0.145 g, 0.658 mmol) in benzene (10 mL) with constant stirring. The solution turned blue, was filtered and concentrated in vacuo before hexane (10 mL) was added to precipitate the blue solid. This was then filtered, washed with *n*-hexane and dried in vacuo. Yield: 0.216 g (72.3%). *Anal.* Calc. for $C_{12}H_{28}S_2P_2O_6Co$ (453.36): Co, 13.00; S, 14.15. Found: Co, 12.67; S, 13.84%. μ_{eff} 4.5 BM.

3.1.2. $[Co\{O(S)P(OPr^i)_2\}_2]$ (**2**)

Same as for $[Co\{O(S)P(OPr^n)_2\}_2]$. Yield: 0.179 g (68%). *Anal.* Cacl. for $C_{12}H_{28}S_2P_2O_6Co$ (453.36): Co, 13.01; S, 14.13. Found: Co, 13.17; S, 14.29%. μ_{eff} 4.7 BM.

3.1.3. $[Co\{O(S)P(OBu^n)_2\}_2]$ (**3**)

Same as for $[Co\{O(S)P(OPr^n)_2\}_2]$. Yield: 0.241 g (63%). *Anal.* Cacl. for $C_{16}H_{36}S_2P_2O_6Co$ (504.47): Co, 11.57; S, 12.59. Found: Co, 11.38; S, 12.25%. μ_{eff} 4.6 BM.

3.1.4. $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$ (**4**)

Typically, pyridine (0.134 g, 1.696 mmol) in benzene (5 mL) was added dropwise, with constant stirring, to a solution of $[Co\{O(S)P(OPr^i)_2\}_2]$ (0.192 g, 0.423 mmol) in benzene (10 mL). The colour of solution turned from blue to pink. The solution was concentrated in vacuo before hexane (10 mL) was added to precipitate a pink solid, which was then filtered, washed with hexane and dried in vacuo. Yield: 0.293 g (89.9%). *Anal.* Calc. for $C_{32}H_{48}S_2P_2O_6N_4Co$ (769.76): Co, 7.66; S, 8.33. Found: Co, 6.95; S, 8.46%. μ_{eff} 5.0 BM.

3.1.5. $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$ (**5**)

Same as $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$. Yield: 0.252 g (88%). *Anal.* Calc. for $C_{32}H_{44}S_2P_2O_6N_4Co$ (765.73): Co, 7.70; S, 8.38. Found: Co, 7.88; S, 8.51%. μ_{eff} 5.3 BM.

3.1.6. $[Co\{O(S)P(OBu^n)_2\}_2(C_{10}H_8N_2)_2]$ (**6**)

Same as $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$. Yield: 0.176 g (89%). *Anal.* Cacl. for $C_{36}H_{52}S_2P_2O_6N_4Co$ (821.83): Co, 7.17; S, 7.80. Found: Co, 6.79; S, 7.56%. μ_{eff} 5.2 BM.

3.2. Crystallography

A pink block crystal of $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$, **4**, and an orange block crystal of $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$, **5**, were mounted on glass fibres. Data were collected on a Bruker-Nonius Kappa CCD area detector diffractometer, with ϕ and ω scans chosen to give a complete asymmetric unit. Cell refinement [26] gave cell constants corresponding to triclinic and monoclinic cells for **4** and **5**, respectively, whose dimensions are given in

Table 2
Crystal data and structure refinements for $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$ and $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$

Table 2, along with other experimental parameters. An absorption correction was applied [27]. The structures were solved by the direct method [28] and were refined using the WINGX version [29] of SHELX-97 [30]. All of the non-hydrogen atoms were treated anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. The final cycle of full-matrix least-squares refinement was based on 4417 observed reflections (4121 for $F^2 > 4\sigma(F^2)$) for **4** and 4107 observed reflections (3629 for $F^2 > 4\sigma(F^2)$) for **5**, and 219 variable parameters for **4** and 216 variable parameters for **5**, and converged (the largest parameter shift was 0.001 times its esd). Selected distances and bond angles are given in Tables 3 and 4 and the molecules are displayed as ORTEP diagrams in Figs. 1 and 2.

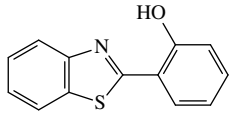
4. Concluding comments

We have successfully prepared and characterized the following complexes: $[Co\{O(S)P(OPr^n)_2\}_2]$, $[Co\{O(S)P(OPr^i)_2\}_2]$, $[Co\{O(S)P(OBu^n)_2\}_2]$, $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$, $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$ and $[Co\{O(S)P(OBu^n)_2\}_2(C_{10}H_8N_2)_2]$. The IR spectra and magnetic measurements of all of these cobalt complexes are consistent with the proposed structures. The molecular structures of $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$ and $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$ were determined to have distorted octahedral environments around cobalt with *trans* and *cis* arrangements of the monothiophosphate ligands, respectively.

Acknowledgements

One of us (M.N.) is grateful to CSIR, New Delhi for financial support. M.E.L. thanks the UK Engineering and Physical Sciences Council for support of the X-ray facilities and IR and magnetic measurement facilities at the Department of Chemistry, University of Southampton. J.E.D. wishes to thank the University of Windsor for financial support.



Appendix A. Supplementary data

CCDC 660401 and 660402 contain the supplementary crystallographic data for $[Co\{O(S)P(OPr^i)_2\}_2(C_5H_5N)_4]$ and $[Co\{O(S)P(OPr^n)_2\}_2(C_{10}H_8N_2)_2]$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.01.037.

Scheme 1. Structure of hbtH ligand.

Continuing our researchers we focus on the synthesis and characterization of oxorhenium(V) chelates $[ReOX_2(O–N)(PPh_3)]$ and $[ReOX_2(O–N)(AsPh_3)]$ with 2-(2′-hydroxyphenyl)-2-benzothiazolinato ligand (hbtH, Scheme 1). Some other mono- and bis(2-(2′-hydroxyphenyl)-2-benzothiazolinato) complexes of Re(V) have been reported previously [9,10].

The $[ReOX_2(hbt)(EPh_3)]$ (X = Cl, Br; E = As, P) chelates have been prepared in the reactions of $[ReOX_3(EPh_3)_2]$ complexes (X = Cl, Br; E = P, As) with 2-(2′-hydroxyphenyl)-2-benzothiazole in acetone. From the reactions of $[ReOX_3(PPh_3)_2]$ with 2-(2′-hydroxyphenyl)-2-benzothiazole (hbtH) two kind of crystals $[ReOX_2(hbt)(PPh_3)] \cdot MeCN$ and $[ReOX_2(hbt)(PPh_3)]$ with different arrangement of halide ions (*cis* and *trans*, respectively) were isolated, whereas the $[ReOX_3(AsPh_3)_2]$ oxocompounds react with hbtH to give only *cis*-halide isomers $[ReOX_2(hbt)(AsPh_3)] \cdot MeCN$. The *cis* and *trans* geometry of the halide ligands in the oxorhenium complexes of the $[ReOX_2(O–N)(PPh_3)]$ and $[ReOX_2(O–P)(py)]$ type has been confirmed previously [11,12]. The number of the structurally characterized $[ReOX_2(O–N)(AsPh_3)]$ complexes is relatively small and all they are *cis* stereoisomers [13–15].

Here, we presents results of our studies on the structural and spectral properties of $[ReOX_2(hbt)(EPh_3)] \cdot MeCN$ (**1a**, **2a**, **3** and **4**) and $[ReOX_2(hbt)(EPh_3)]$ (**1b** and **2b**).

The electronic structures of **1a** and **1b** have been calculated with the density functional theory (DFT), and TDDFT/PCM calculations have been employed to produce a hundred of singlet excited-states starting from the ground-state geometries optimized in the gas phase.

Currently, density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes, including rhenium compounds [16,17].

2. Experimental

2.1. General procedure

All the reagents used to the synthesis were commercially available and were used without further purification. The $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)_2]$ complexes were prepared according to the literature methods [18].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 1100–180 nm in acetonitrile solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOBr_2(hbt)(PPh_3)] \cdot MeCN$ and $[ReOBr_2(hbt)(PPh_3)]$ (*1a* and *1b*)

A mixture of $[ReOBr_3(PPh_3)_2]$ (0.50 g, 0.52 mmol), hbtH (0.125 g, 0.55 mmol) and acetone (70 ml) was stirred for 3 h. 50 ml of acetone was distilled off and 100 ml of diethyl ether was added. $[ReOBr_2(hbt)(PPh_3)]$ was filtered off, washed with ethanol, diethyl ether, dried and recrystallized from acetonitrile. Green crystals of $[ReOBr_2(hbt)(PPh_3)] \cdot MeCN$ (**1a**) and red crystals of $[ReOBr_2(hbt)(PPh_3)]$ (**1b**) were collected in 70% and 10% yield, respectively. Crystals of **1a** and **1b** were separated using microscope.

IR of **1a** (KBr; ν/cm^{-1}): 1596 (m) and 1561 (m) ν_{CN} and $\nu_{C=C}$; 961 (s) $\nu_{Re=O}$.

IR of **1b** (KBr; ν/cm^{-1}): 1595 (m) and 1561(m) ν_{CN} and $\nu_{C=C}$; 960 (s) $\nu_{Re=O}$.

Anal. Calc. for $C_{33}H_{26}Br_2N_2O_2PSRe$: C, 44.45; H, 2.94; N, 3.14. Found: C, 44.80; H, 3.05; N, 3.35%.

2.3. Preparation of $[ReOCl_2(hbt)(PPh_3)] \cdot MeCN$ and $[ReOCl_2(hbt)(PPh_3)]$ (*2a* and *2b*)

A procedure similar to that for **1a** and **1b** was used with $[ReOCl_3(PPh_3)_2]$ (0.50 g, 0.60 mmol) and hbtH (0.145 g, 0.64 mmol). Green crystals of $[ReOBr_2(hbt)(PPh_3)] \cdot MeCN$ (**2a**) and red crystals of $[ReOBr_2(hbt)(PPh_3)]$ (**2b**) were collected in 68% and 8% yield, respectively. Crystals of **2a** and **2b** were separated using microscope.

IR of **2a** (KBr; ν/cm^{-1}): 1597 (m) and 1566 (m) ν_{CN} and $\nu_{C=C}$; 965 (s) $\nu_{Re=O}$.

IR of **2b** (KBr; ν/cm^{-1}): 1597 (m) and 1567 (m) ν_{CN} and $\nu_{C=C}$; 966 (s) $\nu_{Re=O}$.

UV–Vis of **2a** (CH_3CN; λ_{max} [nm] (ε; [$dm^3\ mol^{-1}\ cm^{-1}$])): 647.0 (50), 454.0 (400), 370.0 (2500), 323.0 (4680), 256.0 (6740) and 207.5 (25 900).

UV–Vis of **2b** (CH_3CN; λ_{max} [nm] (ε; [$dm^3\ mol^{-1}\ cm^{-1}$])): 638.5 (60), 453.0 (560), 365.5 (3100), 318.0 (4450), 259.0 (9960) and 207.5 (28 950).

Anal. Calc. for $C_{31}H_{23}Cl_2NO_2PSRe$: C, 48.88; H, 3.04; N, 1.84. Found: C, 48.15; H, 2.87; N, 1.92%.

2.4. $[ReOCl_2(hbt)(AsPh_3)] \cdot MeCN$ (*3*)

A procedure similar to that for phosphine analogues was used with $[ReOCl_3(AsPh_3)_2]$ (0.50 g, 0.54 mmol) and hbtH (0.13 g, 0.57 mmol). Crystalline green precipitate of $[ReOCl_2(hbt)(AsPh_3)] \cdot MeCN$ was collected in 85% yield.

IR (KBr; ν/cm^{-1}): 1598 (m) and 1566 (m) ν_{CN} and $\nu_{C=C}$; 965 (s) $\nu_{Re=O}$.

Anal. Calc. for $C_{33}H_{26}Cl_2N_2O_2AsSRe$: C, 46.81; H, 3.10; N, 3.31. Found: C, 46.52; H, 3.16; N, 3.42%.

2.5. Preparation of $[ReOBr_2(hbt)(AsPh_3)] \cdot MeCN$ (4)

A procedure similar to that for phosphine analogues was used with $[ReOBr_3(AsPh_3)_2]$ (0.50 g, 0.47 mmol) and hbtH (0.115 g, 0.50 mmol). Crystalline green precipitate of $[ReOBr_2(hbt)(AsPh_3)] \cdot MeCN$ was collected in 80% yield.

IR (KBr; ν/cm^{-1}): 1597 (m) and 1566 (m) ν_{CN} and $\nu_{C=C}$; 966 (s) $\nu_{Re=O}$.

UV–Vis (CH_3CN; λ_{max} [nm] (ε; [$dm^3\,mol^{-1}\,cm^{-1}$])): 672.0 (70), 439.5 (900), 358.5 (6700), 315.0 (12 400), 245,5 (18 100) and 210.5 (52 500).

Anal. Calc. for $C_{33}H_{26}Br_2N_2O_2AsSRe$: C, 42.37; H, 2.80; N, 2.99. Found: C, 42.92; H, 3.13; N, 3.22%.

2.6. Crystal structures determination and refinement

The X-ray intensity data of **1a**, **1b**, **2a**, **2b**, **3** and **4** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and absorption correction [19] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 (non-methyl) and 1.5 (methyl) times the value of equivalent temperature factor of the parent atom. The methyl groups were allowed to rotate about their local threefold axis. In containing solvent compounds the MeCN molecules show symptoms of disorder, what exhibits in relatively large displacement parameters and residual density

around acetonitrile atoms. This is probably caused by absence of strong intermolecular interactions, which could stabilise the solvent in the crystal net. SHELXS97 [20], SHELXL97 [21] and SHELXTL [22] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Computational details

The gas phase geometries of **1a** and **1b** were optimized without any symmetry restrictions in the singlet ground-state with the DFT method using the hybrid B3LYP functional of GAUSSIAN-03 [23–25]. The calculations were performed by using ECP basis set on the rhenium atom,

the standard 6-31+G** basis for bromine, phosphorous, oxygen and nitrogen, 6-31G* for carbon and 6-31G for hydrogen atoms [26,27]. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [28] was used for the valence electrons. Additional d function with exponent $\alpha = 0.3811$ and f function with exponent $\alpha = 2.033$ on the rhenium atom were added [29]. All vibrations in the calculated vibrational spectrum of **1a** and **1b** were real thus the both geometries correspond to true energy minimum.

The electronic spectrum of **1a** and **1b** were calculated with the TDDFT method, and the solvent effect was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM) [30].

Natural bond orbital (NBO) calculations were performed with the NBO code [31] included in GAUSSIAN03.

4. Results and discussion

4.1. Preparation and infrared data

The $[ReOX_2(hbt)(EPh_3)]$ (X = Cl, Br; E = As, P) complexes were prepared in good yield by ligand exchange reactions starting from $[ReOX_3(EPh_3)_2]$ complexes and 2-(2′-hydroxyphenyl)-2-benzothiazole (hbtH) in acetone:

$$[ReOX_3(EPh_3)_2] + hbtH \rightarrow [ReOX_2(hbt)(EPh_3)] + HX + EPh_3 \quad X = Cl, Br;\ E = As, P$$

From the reactions of $[ReOX_3(PPh_3)_2]$ with 2-(2′-hydroxyphenyl)-2-benzothiazole two kind of crystals $[ReOX_2(hbt)(PPh_3)] \cdot MeCN$ and $[ReOX_2(hbt)(PPh_3)]$ with different arrangement of halide ions (*cis* and *trans*, respectively) were isolated, whereas the arsine starting oxocompounds react with hbtH to give only $[ReOX_2(hbt)(AsPh_3)] \cdot MeCN$ with halide ligands in *cis* arrangement. The examined previously reactions of $[ReOX_3(EPh_3)_2]$ (E = P, As) with 2-(2′-hydroxyphenyl)-2-benzoxazole, 8-hydroxyquinoline and quinoline-2-carboxylic acid resulted in the isolation only $[ReOX_2(N–O)(EPh_3)]$ with *cis* halide arrangement [13–15].

All the isolated complexes are air stable and slightly soluble in acetonitrile, dichloromethane, chloroform, sparingly soluble in benzene and toluene. The solubility of the *trans* stereoisomers are somewhat better than the *cis* ones. All the crystals suitable for X-ray investigation were obtained by recrystallization from acetonitrile.

The IR spectroscopic measurements outlined in the Section 2 are not distinctive for molecular structure determination. The IR spectra of the *cis* and *trans* stereoisomers are very similar in terms of the position, intensity and shape of the bands in the whole region 4000–400 cm^{-1}. The strong ν(Re=O) stretching bands of both *cis* and *trans* stereoisomers of $[ReOX_2(hbt)(EPh_3)]$ are found in the narrow range 960–966 cm^{-1}, similar to those observed for the other $[ReOX_2(O–N)(PPh_3)]$ chelates [13–15]. Relatively high wavenumbers of the ν(Re=O) absorption bands suggest that the Re–hydroxy bond *trans* to the oxo ligand does not compete effectively for the Re_d orbitals and indicate the presence of very stable {O≡Re–O} structural moiety in the examined structures.

The calculated (non-scaled) vibrational spectra of the *cis* and *trans* stereoisomers are in a reasonable agreement with the experimental data. Similar to the experimental, the calculated IR spectra of both isomers are very similar in terms of the position, intensity and shape of the bands. The calculated ν(Re=O) values (1019 cm^{-1} for of **1a** and 1024 cm^{-1} for **1b**) are higher than the experimental ones by ~7%, what is usual for this approach.

[a] Denotes antibond NBO.

4.2. Crystal structures

The crystallographic data of $[ReOX_2(hbt)(EPh_3)]\cdot MeCN$ and $[ReOX_2(O–N)(PPh_3)]$ (X = Cl, Br; E = P, As) complexes are summarized in Table 1. The *cis*-halide complexes are isostructural and crystallise as acetonitrile solvates in the triclinic $P\bar{1}$ space group. The *trans* stereoisomers are also isostructural but consist of discrete and well-separated $[ReOX_2(O–N)(PPh_3)]$ monomers and crystallise in the monoclinic $P2_1/n$ space group.

The perspective drawing of $[ReOBr_2(hbt)(PPh_3)]\cdot MeCN$ (**1a**) is presented in Fig. 1, and the selected bond distances and angles of **1a** are collected in Table 2. Fig. 2 presents the molecular structure of $[ReOBr_2(hbt)(PPh_3)]$ (**1b**), and its selected bond distances and angles are gathered in Table 3.

All the complexes show octahedral geometry about the central rhenium atom defined by the terminal oxo-group, two halide ions, the phosphorus or arsine atom of EPh_3 molecule, and the bidentate *N*,*O* donors of the hbt ligand. The halide ions of $[ReOX_2(hbt)(PPh_3)]\cdot MeCN$ (**1a**, **2a**, **3** and **4**) are arranged in *cis* geometry, whereas the halide ligands of $[ReOX_2(hbt)(PPh_3)]$ occupy *trans* positions to each other. In all the complexes triphenylphosphine or triphenylarsine molecule with their π-acidity adopts *cis* position with respect to the linear O≡Re–O unit. Consequently, the O≡Re–O core with multiply bonded oxo ligand is stabilized to some extent due to accessible π-donation from rhenium to phosphine or arsine molecule. The multiple bonding ligand (terminal oxo) and narrow bite angle of the chelating ligand contribute to clear distortions of the pseudooctahedral environment of Re center in both *cis*- and *trans*-halide complexes.

In complexes **1a**, **2a**, **3** and **4** the rhenium atom is displaced, respectively, 0.121(3), 0.128(3), 0.1289(10), 0.133(2) Å from the plane formed by the two halogen, one nitrogen and one phosphorous (or arsine) atoms (plane A), 0.043(3), 0.033(4), 0.0396(10), 0.037(2) Å from the plane formed by the two oxygen, one halogen and one phosphorous (or arsine) atoms (plane B) and 0.029(4), 0.049(8), 0.0667(14), 0.061(3) Å from the plane formed by two oxygen, one halogen and one nitrogen atoms (plane C). Least squares plane A is inclined at 89.78(23)°, 89.3(2)°, 89.75(7)°, 89.77(18)° to plane B and at 87.38(24)°, 86.5(3)°, 87.38(8)°, 87.15(18)° to plane C; planes B and C are inclined at 89.53(13)°, 89.08(14)°, 89.42(4)°, 89.92(9)°, respectively as above.

In complexes **1b** and **2b** the rhenium atom is displaced, respectively, 0.1834(10), 0.1855(7) Å from the plane formed by the two halogen, one nitrogen and one phosphorous atoms (plane A), 0.0636(11), 0.0480(7) Å from the plane formed by the two oxygen and two halogen ions (plane B) and 0.0379(14), 0.0380(9) Å from the plane formed by two oxygen, one nitrogen and one phosphorous atoms (plane C). Least squares plane A is inclined at 87.33(7)°, 87.21(4)° to plane B and at 89.07(6)°, 89.39(4)° to plane C; planes B and C are inclined at 87.66(7)°, 87.90(4)°, respectively as above.

The 2-hydroxyphenyl moiety is inclined to the benzothiazolie moiety at 11.2(9)°, 10.3(9)°, 11.0(3)°, 12.9(6)°, 12.2(3)°, 12.62(15)°, respectively, for compound **1a**, **2a**, **3**, **4**, **1b**, **2b**.

No extraordinary features in terms of bond lengths and angles can be noticed between *cis*- and *trans*-halide $[ReOX_2(hbt)(PPh_3)]$ complexes. The Re–O_t (O_t = terminal

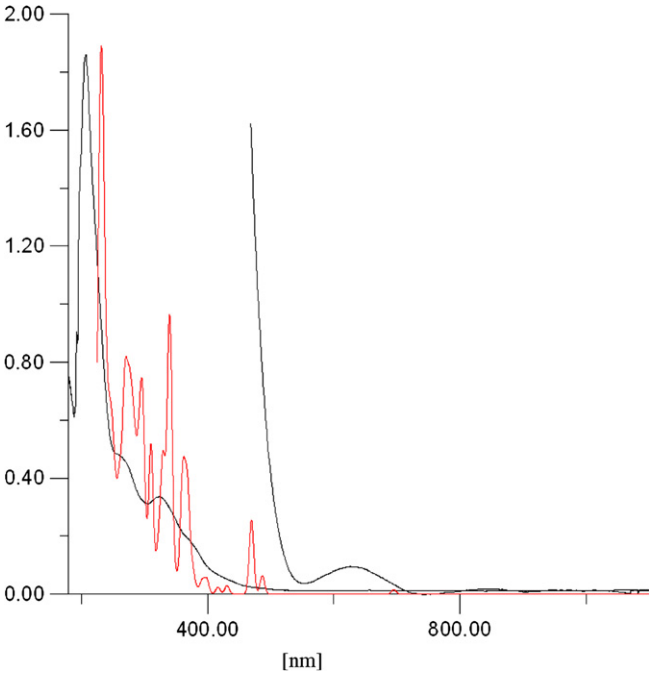

Fig. 3. The experimental (black) and calculated (red) electronic absorption spectra of **1a**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

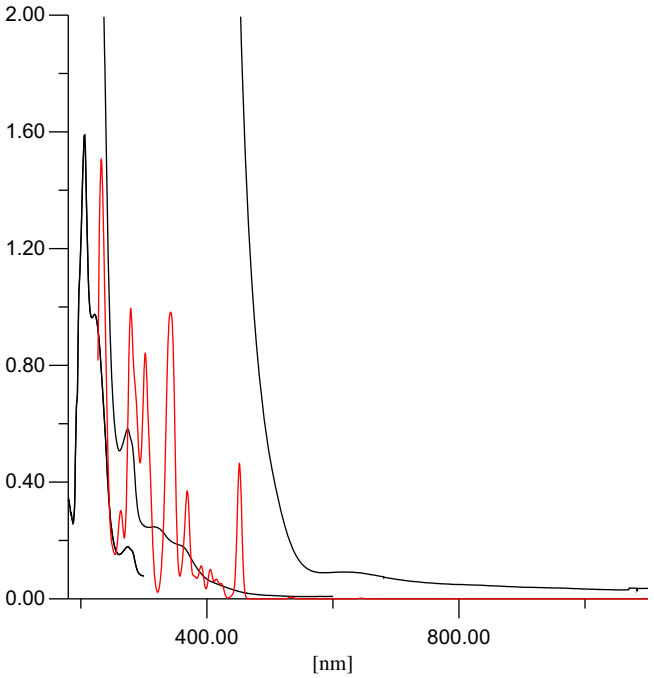

Fig. 4. The experimental (black) and calculated (red) electronic absorption spectra of **1b**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

oxygen) bond lengths fall in the range 1.639–1.76 Å, typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicate the presence of a triple bond Re≡O [32].

The interatomic distances between the rhenium atom and the oxygen atom of 2-(2′-hydroxyphenyl)-2-benzothiazolinato ligand are somewhat shorter than an ideal single Re–O bond length (*ca.* 2.04 Å) [33], indicating only small delocalization in the O(2)–Re(1)–O(1) moiety.

For *cis*-halide $[ReOX_2(hbt)(PPh_3)]$ complexes clear difference between Re(1)–X(1) and Re(1)–X(2) bond lengths can be noticed. The Re(1)–X(1) distances *trans* to the phosphorus or arsine atom of EPh_3 molecule are slightly longer than the Re(1)–X(2) bonds *trans* to the nitrogen atom of the hbt^- ligand. It indicates *structural trans* effect of the EPh_3 ligands. A similar trend was observed in the other $[ReOCl_2(O–N)(PPh_3)]$ chelates [13–15].

4.3. Geometry optimisation, charge distribution, electronic structure and NBO analysis

The geometries of **1a** and **1b** were optimized in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters of **1a** and **1b** are gathered in Tables 2 and 3, respectively. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

Table 4 presents electron population of the valence core of metal and donor atoms for **1a** and **1b**. The population at Re center and oxygen O(1) and O(2) atoms of both isomers remains almost constant. The calculated charges on the rhenium atoms in **1a** and **1b** are considerably lower than the formal charge +5, which results from significant charge donation from the oxygen atoms, bromine ions and triphenylphosphine molecule. The considerable differences in values of charges are observed for the terminal oxo ligand and the oxygen atom of hbt ligand – less negative are the terminal oxo ligands, which indicate the higher electron density delocalization from the terminal ligands towards the rhenium centers and correspond to differences in the Re–O_t and Re–O_{hbt} bonds lengths. The higher charge donation from the bromide ions can be noticed for the *cis*-halide $[ReOBr_2(hbt)(PPh_3)]$ complex, whereas the population at

ε – molar absorption coefficient [$dm^3\ mol^{-1}\ cm^{-1}$]; f – oscillator strength; H – highest occupied molecular orbital; L – lowest unoccupied molecular orbital.

the p-orbitals of the phosphorous atom of *trans*-halide is smaller.

The nature of rhenium–terminal oxygen (O_t) interaction in **1a** and **1b** has been studied by NBO analysis. The occupancy and composition of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 5. The Re–O_{hbt} bond orbital were not detected indicating a conceivable predominant Coulomb-type Re–ligand interaction in both isomers.

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [31].

Similar to the previous described [$ReOX_2$(O–N)(PPh_3)] chelates [13–15], two strongly polarized to the oxygen atom natural Re–O_t bond orbitals were detected for **1a** and **1b**, whereas the NBO analysis of [$ReOX_3$(N–N)] oxocompounds [34,35] confirms three natural bond orbitals between metal and oxygen. As the results for the last ones are very clear (one σ-bond and two π bonds), the interpretation of NBO analysis for **1a** and **1b** is not straightforward. The both detected natural Re–O_t bond orbitals of **1a** and **1b** are similar in energy and they are composed of the p oxygen and d rhenium orbitals. The terminal oxo ligand of **1a** and **1b** has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital. It can be assumed that the detected natural Re–O_t bond orbitals are of π character and not detected σ_{Re-Ot} bond has ionic character, similar as Re–N bond orbital in [$ReCl_4(MeCN)_2$] [17]. However, another interpretation may be also concluded from the NBO analysis for the examined isomers. Instead of the mentioned triple bond, the double Re–O_t bond with relevant negative hyperconjugation may be proposed for **1a** and **1b**.

4.4. Electronic spectra

The experimental electronic spectra of **1a** and **1b** are presented in Figs. 3 and 4, respectively. The positions of absorption bands for the other [$ReOX_2$(hbo)(EPh_3)] complexes are given in the experimental part. As can be seen from Figs. 3 and 4 the UV–Vis spectra of the *cis* and *trans* stereoisomers are very similar in terms of the position, intensity and shape of the bands in the whole region 1100–180 nm. Similar to the IR measurements they are

indistinctive for molecular structure determination. In order to discussion this observation in more detail, the time-dependent density functional calculations (TDDFT) were employed to produce a hundred of singlet excited-states starting from the ground-state geometries of **1a** and **1b** optimized in the gas phase. The calculated electronic spectra of **1a** and **1b** are presented in Figs. 3 and 4, respectively. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

Tables 6 and 7 present the most important electronic transitions calculated with the TDDFT method assigned to the observed absorption bands of **1a** and **1b**. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy to the orbitals HOMO and LUMO involved in the electronic transitions. The simplified molecular orbital diagrams of **1a** and **1b** with several contours of occupied and unoccupied MOs (active in the electronic transitions) are presented in Figs. 5 and 6, respectively.

The TDDFT/PCM calculations show that the longest wavelength experimental bands of **1a** and **1b** (at 649.5 for *cis* and 638.5 nm for *trans*) originate in the HOMO → LUMO and HOMO → LUMO + 1 transitions. The HOMO, LUMO and LUMO + 1 orbitals are delocalized among rhenium ion, bromide, oxo and hbt ligands, so a delocalized *MLLCT* (metal-ligand-to-ligand CT) description also can be used. However, considering that these molecular orbitals comprise mainly rhenium 5d atomic orbitals (Figs. 5 and 6), the HOMO → LUMO and

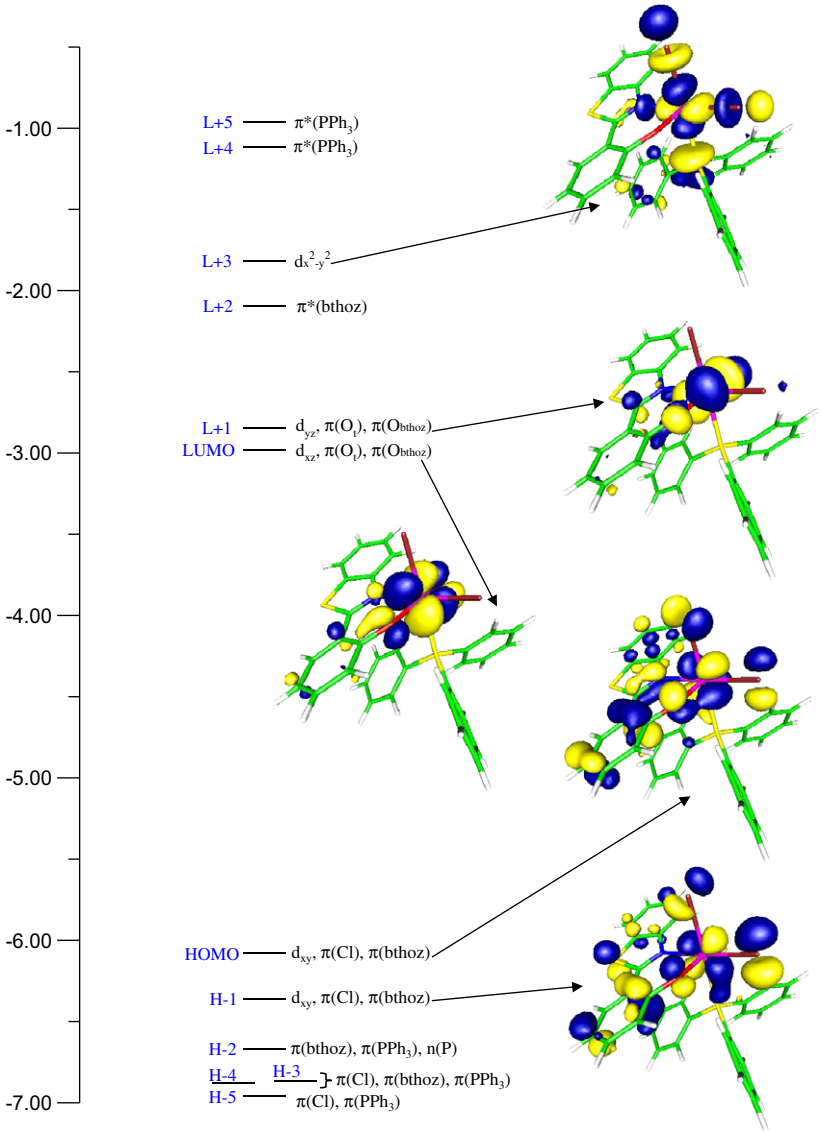

Fig. 5. The energy (eV), character and some contours of the unoccupied molecular orbitals of **1a**. Positive values of the orbital contour are represented in blue (0.04 a.u.) and negative values – in yellow (−0.04 a.u.). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

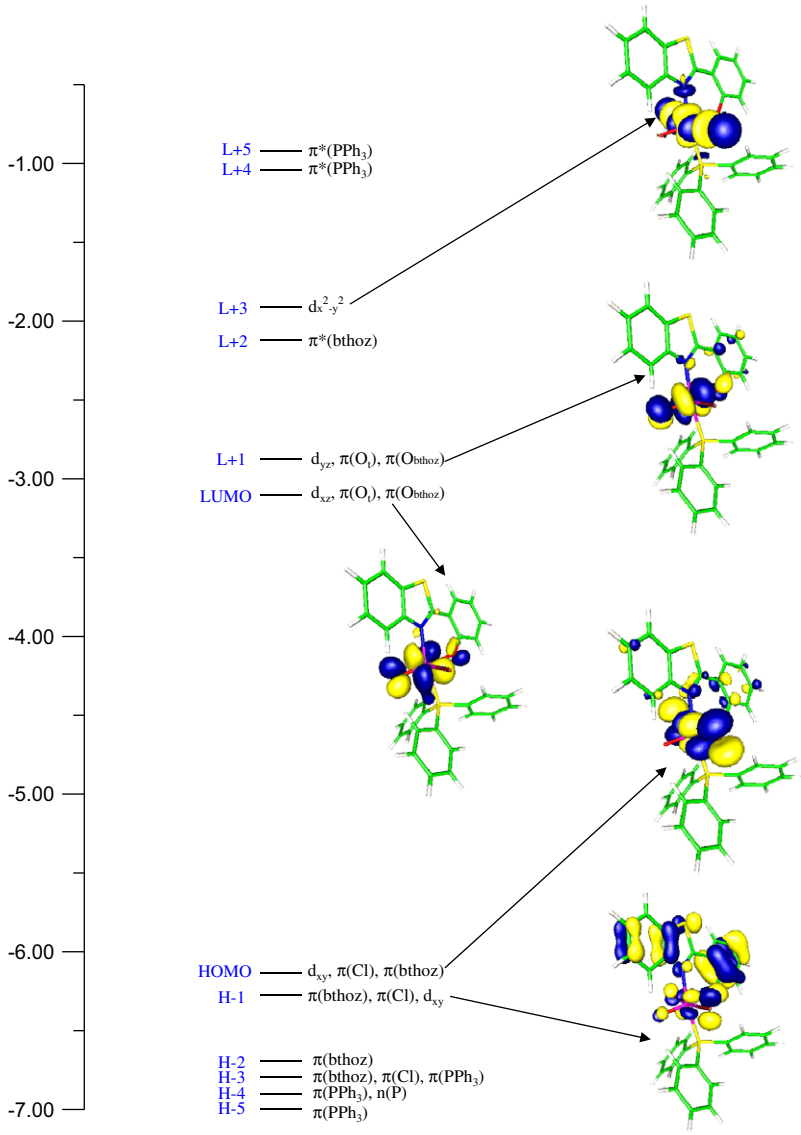

Fig. 6. The energy (eV), character and some contours of the unoccupied molecular orbitals of **1b**. Positive values of the orbital contour are represented in blue (0.04 a.u.) and negative values – in yellow (−0.04 a.u.). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

HOMO → LUMO+1 transitions may be ascribed as transitions of d → d character.

The observed absorptions at 446.0 nm (*cis*-Br) and 445.0 nm (*trans*-Br) can be assigned to *Ligand-Metal Charge Transfer* transitions occurring from the bromide and hbt^- ligand for *cis* and bromide, hbt^- and phosphine ligand for *trans* halide complex.

The absorption band at 361.2 nm (*cis*-Br) and 359.0 nm (*trans*-Br) can be related to HOMO → LUMO + 2 excitation of d/π(Br)/π(bthoz) → π*(bthoz) character with a certain contribution of *Ligand-Metal Charge Transfer* transitions.

For both stereoisomers the experimental bands below 300 nm result mainly from *Ligand–Ligand Charge Transfer* and interligand (IL) transitions.

Acknowledgement

The Gaussian03 calculations were carried out in the Wrocł aw Centre for Networking and Supercomputing, WCSS, Wrocław, Poland.

occurring. For example, CD can coordinate a number of metals in alkaline media. On deprotonation, the anionic hydroxyls on the CD primary face become effective ligands [5]. If these metals have appropriate redox properties, they may participate in photoinduced redox reactions, with appended luminophores and provide a means of interrogating the ability of the CD to support electron transfer through the CD framework as opposed to through inclusion.

Our group reported previously on the synthesis and characterization of a novel donor–acceptor complex comprised of an OH bridged manganese(III) dimer covalently linked to a ruthenium polypyridyl sensitizer via a β-cyclodextrin moiety [6]. We observed photoinduced intramolecular transfer in this species, the k_{et} was modest, estimated to be $2 \times 10^6\ s^{-1}$, but suggested that the CD framework can support electron transfer.

In addition to manganese(III), copper(II) can coordinate effectively to CD. Cyclodextrin is known to bind copper(II) under neutral and particularly under alkaline conditions [7–11]. It has been demonstrated to form a hydroxyo-bridged dimer, this copper dimer is considerably more stable than the analogous manganese system, and is also expected, on the basis of thermodynamic arguments to quench the excited state of a pendant ruthenium polypyridyl complex. Copper is of particular interest because it is both an essential trace element whereby it acts as a cofactor for a number of metalloenzymes, and it is an important environmental pollutant.

We report here on a donor–acceptor system incorporating a ruthenium polypyridyl functionalized β-cyclodextrin moiety with an hydroxo bridged Cu(II) dimer and provide evidence for photoinduced electron transfer between the copper centre and the ruthenium. We illustrate the effects of solution phase binding of Cu^{2+} and Zn^{2+} ions to the ruthenium modified CD on the photophysics of the ruthenium luminophore. This work demonstrates that ruthenium polypyridyl functionalized β-cyclodextrin moiety binds copper(II) with concomitant transduction of this binding through modulation of luminescence intensity and lifetime. Such materials may have potential in analytical applications for metal ion sensing. Ultimately, because of the synthetic versatility of the metal luminophore, selectivity in sensing applications may be exerted by modifying the ligands in this complex, thereby altering the redox chemistry and thermodynamics of a given excited-state reaction.

2. Experimental

2.1. Chemicals and materials

β-Cyclodextrin, 5-nitro-1,10-phenanthroline, 2,2′-bipyridine, $RuCl_3 \cdot 3H_2O$, Cu(II)acetate monohydrate, zinc acetate dihydrate, DMF and NMP were all obtained from Sigma Aldrich and used as received.

6^A-Deoxy-6^A-*p*-toluenesulphonyl-β-cyclodextrin, *cis*-$Ru(bpy)_2Cl_2$, 6^A-(5-amino-1,10-phenanthroline)-6^A-deoxy-β-cycoldextrin, and Cu_2CD were synthesized and purified according to published procedures [8,12,6,13].

Ruthenium(II)(bisbipyridine)(6^A-(5-amino-1,10-phenanthroline)-6^A-deoxy-β-cyclodextrin: CDRu was synthesized as described previously,[6] and purified using size-exclusion chromatography on Sephadex G-75, with water as eluent. {$m/z = 878.8$, $[M-2PF6]^{+2}$, 1637, $[M-PF6]^{+1}$, structure was confirmed from 2D ^1H NMR which conformed with previously reported values [6].

Synthesis of dicopper-dihydroxo-ruthenium (II)(bisbipyridine) (6^A-deoxy-5-amino-1,10-phenanthroline)-6^A-deoxy-β-cyclodextrin: Cu_2CDRu: (0.10 g, 0.05 mmol) CDRu was dissolved in 0.5 M NaOH, (0.03 g, 0.1 mmol) $Cu(CH_3CHOO)_2$ (cupric acetate) was added, the mixture was stirred for 2 h under N_2. Ethanol was added to precipitate the product. The dark red product was recrystallized from 0.2 M NaOH [14]. ($m/z = 2022$, $[Cu_2CDRu][PF_6]$).

2.2. Physical measurements

Electronic absorption spectroscopy was conducted on a Shimadzu 3500 UV–Vis/NIR spectrophotometer.

Cyclic voltammetry was carried out using a CH instrument Model 660 electrochemical work station. A conventional three-electrode cell arrangement was used. This comprised a platinum microelectrode (50 μm ϕ) polished and electrochemically cleaned as described previously, an Ag/AgCl reference electrode and platinum wire counter electrode [15]. The complexes were dissolved in DMF with 0.1 M tetrabutylammonium hexaflourophosphate as supporting electrolyte. The working electrode was polished using 0.05 mm alumina. The solution was degassed for 30 minutes with N_2 and a gas blanket was maintained over the solution surface during all experiments. The solution was sonicated between each experiment.

Fourier transform Infrared experiments (FT-IR) were recorded in a KBr Discs using a Perkin Elmer FT-IR spectrometer.

Magnetic moments were determined via the Evans method on a Sherwood Scientific, magnetic susceptibility balance, spin only values were calculated according to $\mu_{Cu} = 2[S_{Cu}(S_{Cu}+1)]^{1/2}$ [16].

^1H NMR spectra were recorded on a Bruker Avance series 400 MHz NMR spectrometer; chemical shifts are reported relative to the solvent reference [D_6] DMSO 2.49 ppm.

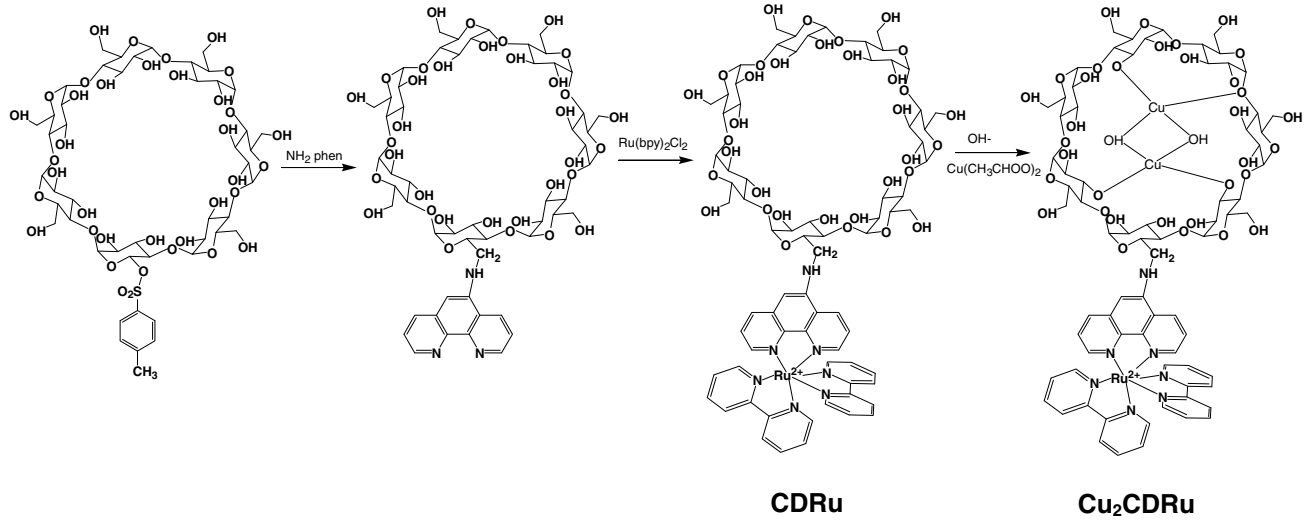
Mass spectra were obtained by Electrospray Ionization in positive ion mode using a Bruker LC/MS Esquire series. Steady-state emission spectra were recorded on a Varian Cary Eclipse luminescence spectrophotometer. Luminescence lifetimes were measured using the third harmonic (355 nm, 30 mJ/pulse) of a continuum surelite Q-switched ND:YAG laser for excitation, emission was detected in a right-angled configuration to the laser using Andor Model M20 gated intensified CCD coupled to an Oriel Model MS125 spectrograph. This configuration allows a complete emission spectrum (spectral width 250 nm) to be obtained

within times as short as 10 ns. The gate width, i.e. the exposure time of the CCD was never more than 5% of the excited-state lifetime. The step size, i.e., the time between the acquisition of discrete spectra was typically 5% of the excited half-life. Time-resolved absorption spectra were collected using the instrumentation in absorption mode with an Applied Photophysics 300 W pulsed Xe arc lamp as a monitoring source. In this instance, spectra were typically recorded using the average of 25 laser shots. The gate width was never more than 10% of the excited-state lifetime.

Luminescence titration of CDRu with $M(CH_3COO)_2 \cdot H_2O$ ($M = Cu^{2+}$, Zn^{2+}) was conducted using stock solutions of 2.7×10^{-4} M CDRu and 0.01 M $M(CH_3COO)_2 \cdot H_2O$ in aqueous solution at pH 12. Eighteen solutions were prepared by combining 40 μL of CDRu solution with increasing aliquots of $M(CH_3COO)_2 \cdot H_2O$ titrant up to 2 mM. The final volume was made up in order that CDRu concentration remains constant in all experiments at 2.1×10^{-6} M.

Raman spectroscopy was conducted on a Dilor.Jobinyvon.Spex HR Labram. The exciting Argon ion laser, Coherant Innova 300c (514.5, 488, 457.9 nm) was focused on the sample using a 10× objective lens. Focusing was confirmed by using an imaging video camera. A spectral resolution of 0.5 cm^{-1} per pixel was achieved using an 1800 lines mm^{-1} grating and the *x*-axis was calibrated against the phonon mode of silicon and the Rayleigh line.

Quantum yields were measured using the comparative method of Williams et al. [17].



3. Results and discussion

3.1. Synthesis

The synthetic steps leading to production of Cu_2CDRu are shown in Scheme 1. The synthesis of the phenanthroline substituted β-CD and ruthenium polypyridyl complex, CDRu, were reported previously and the mass spectral, NMR and elemental analysis conformed to those reported [6,18]. The ability of β-CD to coordinate Cu(II) is well established. Under alkaline conditions a combination of cupric acetate and β-CD yields a 2:1 hydroxy-bridged Cu(II) dimer coordinated to the deprotonated hydroxyls on the secondary face of β-CD [19,7–9]. This complex is quite stable in alkaline solution [20,10,21]. An analogous procedure to that reported for β-CD was followed here, except that CDRu complex was employed instead of β-CD, this was treated with cupric acetate in 0.5 M NaOH. The resulting paramagnetic complex was studied using mass spectrometry, magnetochemistry, vibrational spectroscopy and elemental analysis which all confirmed that the Cu had coordinated in 2:1 ratio. The coordination mode to the CD is expected to be the same as that described for free β-CD and this is consistent with our vibrational spectral and magnetic results. The complex was stable in the solid state, in the absence of air for months and in aqueous alkaline media for at least a week. It was stable for several hours in DMF, however, the copper centre was very labile in neutral aqueous media.

3.2. Magnetic susceptibility studies

The effective magnetic moment for Cu_2CDRu was found to be $1.075\mu_B$ per Cu at 294 K which is lower than the anticipated value of $1.79\mu_B$ for the spin only value of the d^9 electronic configuration of Cu(II), calculated on the basis that no magnetic interactions are occurring between the metal ions. These values are in good agreement with those reported for the parent unfunctionalised Cu_2(II,II)-CD complex [21,22]. Detailed temperature dependent magnetic studies for this analogous complex indicated a weak antiferromagnetic exchange between the two high spin Cu(II) metal ions acting through the hydroxyl bridged system [19].

Scheme 1. Schematic showing the synthetic route to Cu_2CDRu.

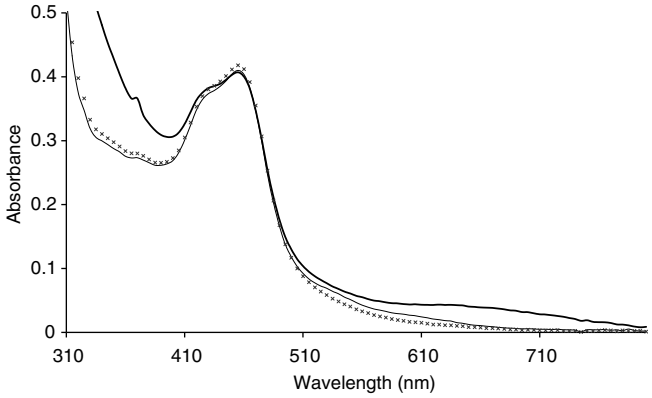


Fig. 1. Electronic absorption spectroscopy of Cu_2CDRu (heavy line), CDRu at pH 7 (dotted line), and CDRu at pH 12 (light line) in DMF.

3.3. FTIR spectroscopy

The FTIR spectra of the CDRu complexes before and after coordination to Cu were compared.[1] The region between 1200 and 1000 cm^{-1} are dominated by exocyclic OH modes, which are shifted to higher frequency on coordination of the Cu site. These changes conformed to those reported previously for Cu_2CD and are attributed to perturbations of CH_2 and OH bending modes induced by coordination of metal to the secondary side of CD [21]. There is also significant broadening to the OH stretch band with the appearance of a shoulder at approximately 3250 cm^{-1} not apparent in CDRu. This is attributed to the copper bridged OH stretching mode [24,21].

3.4. Electronic spectroscopy

Fig. 1 shows the UV–vis spectra of CDRu under neutral aqueous conditions and pH 12 respectively. In the latter case this corresponds to the pH at which the copper is coordinated. The spectra exhibit maxima around 455 nm attributed to Ru (dπ) to L (π*) MLCT transitions and ligand centred (LC) features below 300 nm. The spectra are essentially identical, indicating any new transitions on coordination of the copper do not arise from deprotonation of the CD. The absorbance spectrum of Cu_2CDRu is also shown in Fig. 1. Coordination of the dinuclear copper centre to the CDRu complex results in a slight red shift of the MLCT and the appearance of a feature centred around 620 nm, this feature is weak and very broad extending to approximately 700 nm. It is attributed to the Cu(II) d–d transition from comparison with the Cu_2CD complex [8,10]. In addition, there are changes in the UV spectral region, a new feature appears (from spectral fitting) centred around 320 nm, a similar feature appears in the spectrum of the Cu_2CD complex and is also associated with the copper coordination, possibly attributed to a Cu → OH charge transfer transition [21,25]. There is no evidence for any new optical transitions arising from interaction between the Ru and Cu centres in the trinuclear complex, as the electronic spectrum of Cu_2CDRu appears to be largely a composite of the two separate complexes.

To gain insight into the origin of the optical transitions resonance Raman spectroscopy was conducted for both CDRu and Cu_2CDRu, Fig. 2. In resonance Raman spectroscopy, the exciting laser line is resonant with an optical transition and this yields enhancements in vibrational modes associated with the chromophores of up to 7 orders of magnitude. This provides a relatively unambiguous means of characterizing optical transitions. The results are shown in Fig. 3, for optical excitation at 488, and 514.5 nm. The Raman spectra exciting at 514 nm are similar for Cu_2CDRu and CDRu. The spectra contain signature bipyridyl modes and an Ru–N stretch vibration (~372 cm^{-1}) typical of resonance with a Ru (dπ) to bpy (π*) MLCT transition. Exciting at 488 nm, however there are significant differences between the complexes in which the copper is present and absent. Both Cu_2CDRu and CDRu share common features attributed to bpy or phen and Ru-modes, but in addition, the Cu_2CDRu complex contains additional modes, most notably an intense feature at 565 cm^{-1} and a second feature at 635 cm^{-1}. The identity

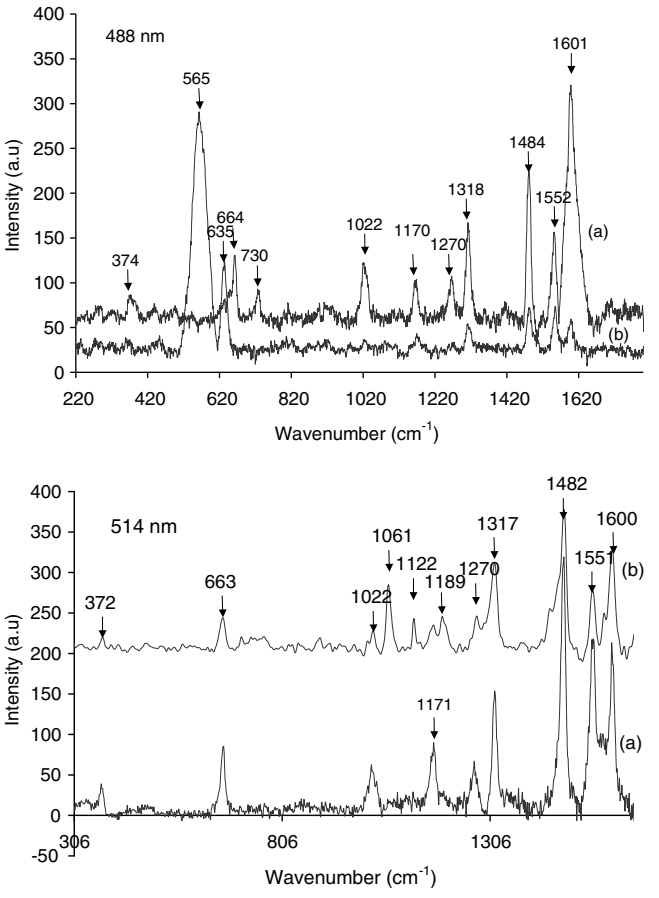

Fig. 2. Resonance Raman spectroscopy of (a) CDRu and (b) Cu_2CDRu excited at 488 nm (top) and (a) CDRu and (b) Cu_2CDRu 514.5 nm (bottom).

[1] See Supplementary material.

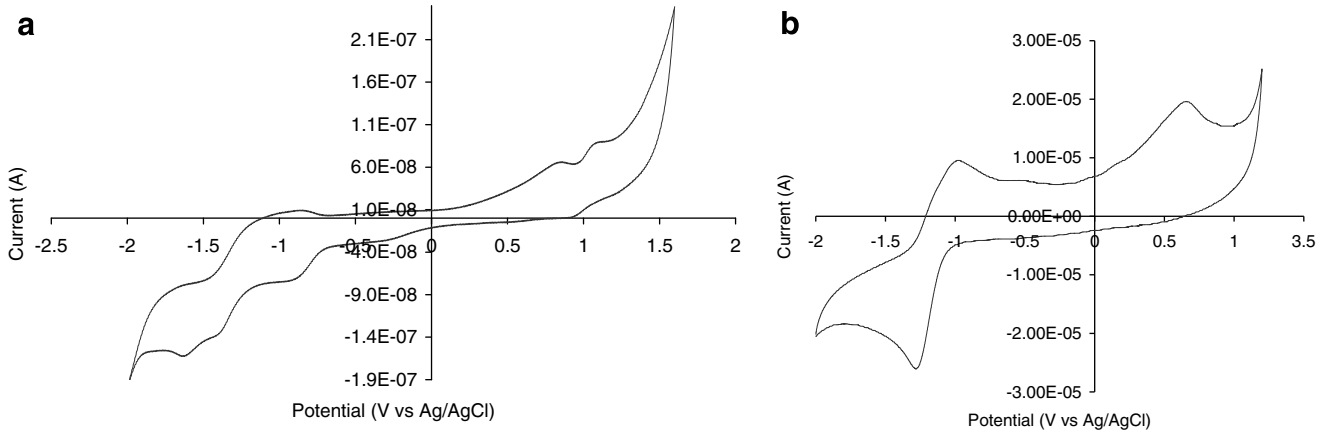

Fig. 3. Cyclic voltammetry of (a) Cu_2CDRu, on a platinum microelectrode (∅ 50 μm) working electrode, at $v = 500$ mV/s (b) Cu_2CD at (∅ 3 mm) diameter glassy carbon working electrode at $v = 100$ mV/s, potentials quoted vs. Ag/AgCl reference electrode, solvent was dry DMF with tetrabutylammoniumperclorate as a supporting electrolyte.

Table 1
Spectroscopic and photophysical data of CDRu, Cu_2CDRu and $[Ru(bpy)_3]^{+2}$ as a reference in spectroscopic grade DMF

Complex	Absolute λ_{max} (nm)	E_m λ_{max} (nm)	$\tau_{deaerated}$ (ns)	$\tau_{aerated}$ (ns)	$\Phi_{aerated}$	ε (M^{-1} cm^{-1})
CDRu	450	618	900	249	0.013	7500
Cu_2CDRu	455	618	336	159	0.006	6750
$[Ru(bpy)_3]^{+2}$	450	605	935	247	0.028	12500

of the latter is not clear, but may be associated with the CD, the former feature is attributed to a Cu–O stretch mode, which is enhanced from resonance with the underlying copper based electronic transition [24]. This provides useful evidence for the presence of the copper dimer. Similarly this mode is present when exciting at 458 nm in addition to a new feature at 1095 cm^{-1}, which is likely to originate from the CD backbone. The dominance of these new features at 488 and 458 nm excitation is likely to arise from post-resonance with the new feature at 320 nm, which, as described, may arise from a Cu(II) ← O^- ligand to metal charge transfer (LMCT) transition, possibly associated with deprotonated hydroxyl on cyclodextrin [26,21,27]. Resonance Raman spectroscopy of the low energy d–d optical transition at 620 nm was probed with 633 excitation, unfortunately luminescence interference from the ruthenium centre at this wavelength prevented the collection of meaningful Raman data.

3.5. Electrochemistry

Voltammetric data for CDRu, Cu_2CD and Cu_2CDRu in dry DMF is provided in Table 2. The electrochemistry of CDRu was reported previously, a reversible ruthenium based oxidation is observed at 0.95 V which conforms well to this reported value [6]. In the cathodic region, three irreversible one electron reductions are observed corresponding to reduction of the bpy and phen moieties.

The cyclic voltammetry for Cu_2CDRu in dry DMF using a carbon macroelectrode is shown in Fig. 3. Cu_2CDRu voltammetry displays a reversible oxidative process at 0.97 V versus Ag/AgCl, attributed to the $Ru^{(II/III)}$ couple and ligand-based reductions at −1.53 V and −1.71 V versus Ag/AgCl. In addition, new irreversible waves at 0.703 V and −0.96 V versus Ag/AgCl, appear which are not observed in the parent complex, CDRu appear.[2]

Table 2
Electrochemical data for Cu_2CD, Cu_2CDRu and CDRu in dry DMF $E_{1/2}$ values determined by cyclic voltammetry and differential pulse voltammetry

Complex	Ru(II)/Ru(III)	(bpy/bpy^{-1})	M(II)/M(III)	M(II)/M(I)
CDRu[a]	0.95	−1.21, −1.40	–	–
Cu_2CDRu	0.97	−1.53, −1.71	0.703 irr.	−0.96
Cu_2CD	–	–	0.592 irr.	−1.229

Potentials (V) vs. Ag/AgCl. The processes are reversible except when indicated (irr).
[a] From Ref. [6].

For comparison, Fig. 3b shows the CV for Cu_2CD in dry DMF, which exhibits an irreversible anodic wave at 0.59 V versus Ag/AgCl and a cathodic, quasi-reversible wave at $E_{1/2} = -1.23$ V ($\Delta E_p = 0.23$ V). The electrochemistry of this species has not, to our knowledge been reported previously. The latter process is assigned to the Cu(II)/Cu(I) redox couple and the former to the Cu(III)/Cu(II) couple. These data are consistent with reported values for other hydroxy-bridged Cu(II) dimers and are similar to those obtained for Cu(II,II) complexes with ligands other

[2] These potentials were also confirmed from differential pulse voltammetry.

than cyclodextrin [29–33]. The irreversibility of the oxidation response probably indicates that the oxidized copper undergoes bond cleavage within the timescale of the electrochemical experiment.

The changes to the electrochemistry of the copper centres on coordination to CDRu by comparison with Cu_2CD were surprisingly large. The ruthenium oxidation shifts anodically by approximately 20 mV on coordination of the copper centers, which small enough to originate from the influence of electrostatics. However, the new oxidation process for Cu_2CDRu at 0.703 V attributed to Cu(III)/Cu(II) is shifted by 111 mV by comparison with Cu_2CD. The identity of the new reduction process in Cu_2CDRu is not entirely clear, but if attributed to the copper centre, it has shifted by 270 mV. Overall, this suggests that derivatisation of the CD with the ruthenium centre exerts a surprisingly significant influence over the copper centre. The ligand-based reductions are also cathodically shifted and become irreversible in the copper complex, the reason for this is unclear but may arise from adsorption at the electrode.

3.6. Photophysical properties

As reported previously, CDRu exhibits an intense luminescence attributed to the ^{3}MLCT state with λ_{max} of 618 nm, Fig. 4, a quantum yield of 0.013 and a lifetime of 900 ns [6]. The luminescence lifetimes and emission quantum yields values are significantly reduced upon coordination of copper to the secondary rim of CDRu in both aerated and deaerated media, Table 1.

The quantum yield is reduced by over 50% compared with the free CDRu in DMF and the lifetime is reduced from 900 ns to 336 ns in deaerated DMF.

The association of copper with the CD was investigated using steady state and time resolved luminescence, whereby increasing aliquots of Cu(II) acetate were combined with aqueous solution of CDRu (2×10^{-6} M) at pH 12. Fig. 5a and b shows a comparison of the effects of addition of Cu(II) and Zn(II) on a solution of CDRu at high pH. Zn^{2+} is expected to bind to the CD centre in an analogous way to Cu, however, with its d^{10} electronic configuration it is unlikely to be involved in either energy or electron transfer with the ruthenium centre [34,34]. As anticipated, on the basis of the isolated Cu_2CDRu complex, binding of Cu to CD results in a decrease to the luminescence intensity by up to approximately 50%, whereas Zn^{2+} had negligible impact on luminescence intensity. Correspondingly, for Zn^{2+}, within experimental error, no change to the luminescent lifetime of CDRu was observed, whereas for Cu^{2+}, the luminescence quenching was confirmed to be static. Addition of this metal ion to a solution of CDRu caused a biexponential luminescent decay, whose components matched the lifetime of CDRu and Cu_2CDRu. Increasing concentrations of copper did not change the lifetimes, but merely changed the ratio of the short and long components in the luminescent decay.

3.7. Nature of the excited state process

The reduction in lifetime and luminescent quantum yield in the CDRu observed on coordination of the copper dimer suggests that a photoinduced process is occurring in Cu_2CDRu. Introduction of new non-radiative pathways as a consequence of structural changes on formation of the metallocyclodextrin can be excluded on the basis that no photophysical changes were observed on binding of Zn^{2+}. In a related study Balzani et al. [35] reported on a Cu(I)–catenate moiety covalently linked to $[Ru(tpy)_2]^{2+}$. The oxidation potential of Ru(III)/(II) occurred at +1.2 V and that of Cu II/I at +0.58 V versus SCE at a Pt working electrode. They observed quenching of ruthenium based emission at 77 K and 298 K. They suggested energy transfer from $Ru(II)^*$ to Cu(I) at 77 K with a rate constant of $3 \times 10^8\ s^{-1}$ and a thermodynamically allowed photoinduced electron transfer from Cu(I) to Ru(II) at 298 K with a rate constant of $1 \times 10^{10}\ s^{-1}$. Energy transfer is a possibility in

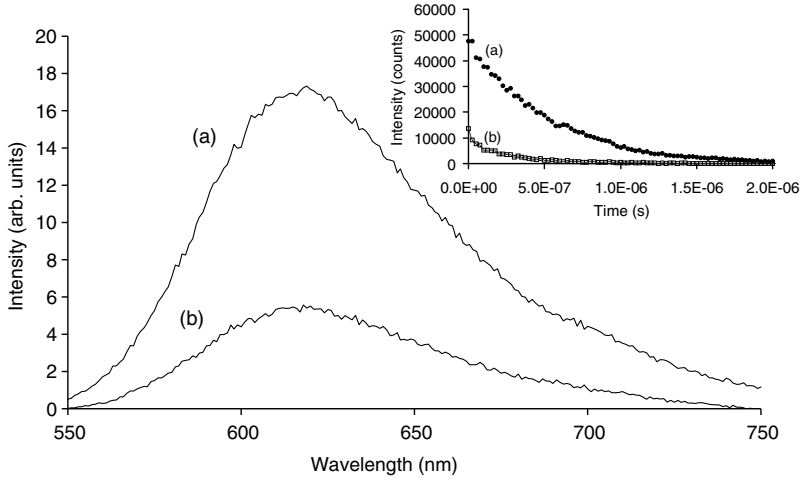

Fig. 4. Luminescence spectroscopy excited at 450 nm and emission decays, excited at 355 nm (inset) of (a) CDRu and (b) Cu_2CDRu in DMF, emission decays were monitored at 618 nm.

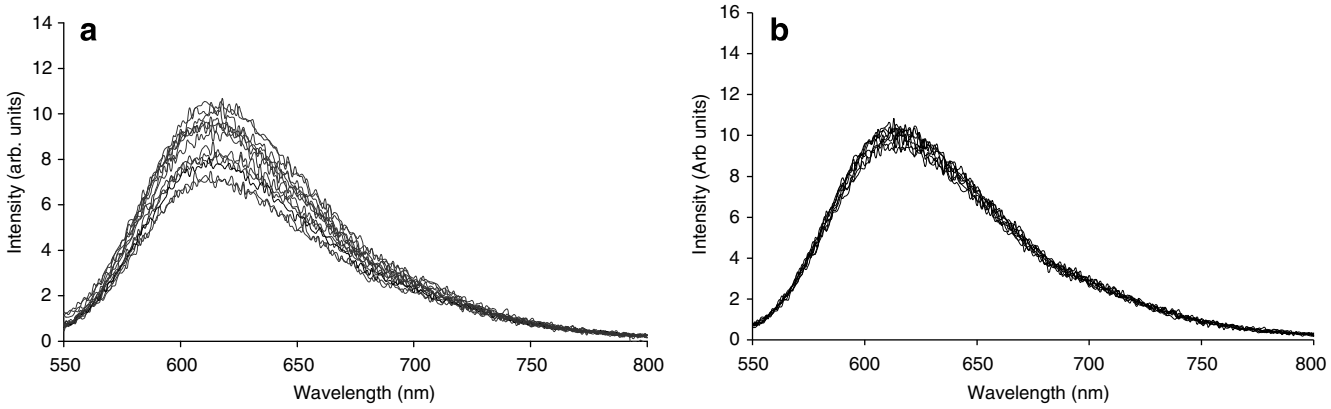

Fig. 5. Emission spectra of CDRu, 2.1×10^{-6} mol dm^{-3}, at pH 12 on addition of increasing aliquots (up to 1000 μl) of aqueous (a) 0.01 M $[Cu(CH_3COO)_2] \cdot 2H_2O$ and (b) 0.01 M $[Zn(CH_3COO)_2] \cdot 2H_2O$.

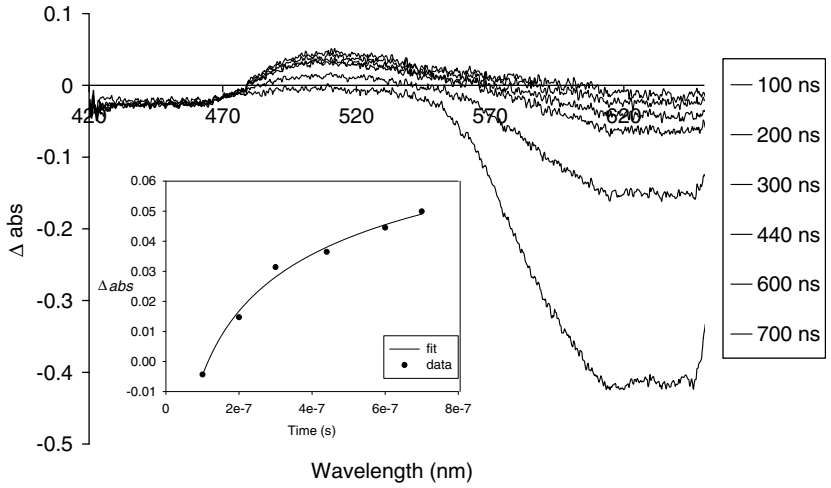

Fig. 6. Transient absorption of Cu_2CDRu (b) in spectroscopic grade DMF, 100, 200, 300, 440, 600, and 700 ns after the excitation at 355 nm. Inset, shows grow in of the absorbance at 510 nm.

the present case as the d–d transition at 620 nm for Cu_2CDRu overlaps effectively with the ruthenium emission. However, as the 620 nm absorbance is forbidden, it is very weak, ($\varepsilon = 33$ M cm^{-1}) and unlikely, on the basis of Laporte and spin selection rules to facilitate efficient energy transfer. On the other hand, photoinduced electron transfer is thermodynamically feasible. ΔG for a process in which the copper centre is reduced by excited-state ruthenium, calculated from electrochemical and photophysical data is estimated to be exoergonic at −0.16 eV. Reduction of the copper by photoexcited ruthenium is anticipated to be very modestly exoergonic at approximately −0.05 eV. [3]

To confirm that electron transfer is the origin of the luminescence quenching in Cu_2CDRu transient absorption studies were conducted on this complex and on CDRu for comparison. Firstly, following 355 nm excitation of a deoxygenated aqueous alkaline solution of CDRu, the depletion of the MLCT band is observed at 450 nm and negative amplitude signal ($-\Delta A$) in the region 600–700 nm arises from stimulated emission from the triplet MLCT state [37]. Unsurprisingly, the kinetics for both grow in of the depletion and emission are the same and match the luminescent lifetime.

Fig. 6 shows the transient absorption spectra of Cu_2CDRu in aqueous alkaline media. On excitation at 355 nm depletion of the MLCT occurs around 450 nm, however, in addition, a new absorption feature around 510 nm grows in. The luminescence, seen as a depletion centered around 610 nm is lost at a rate that matches the luminescence decay rate of Cu_2CDRu. However, the MLCT depletion remains relatively unchanged during the decay of the luminescence, while the 510 feature grows in. Over the time

[3] The driving force for an excited-state electron transfer can be evaluated from the approximation : $\Delta G^\circ \cong [E(B/B^+) - E(A/A^-)] - \Delta E^{\circ\circ}$, where $E(B/B^+)$, $E(A/A^-)$ are the energies (eV) of one-electron reduction processes and $E^{\circ\circ}$ is the spectroscopic energy, taken as the energy of the maximum of the emission spectrum at 77 K. $\Delta E^{\circ\circ}_{CDRu} = 2.069$ eV, $\Delta E^{\circ\circ}_{Cu2CDRu} = 2.085$ eV.

scale of the experiment, the MLCT is not recovered and the 510 feature remains. Absence of recovery of the MLCT confirms that the ruthenium is photooxidised and is consistent with the process predicted on thermodynamic grounds [38]. The identity of the 510 nm absorbance is unclear but may be due to Cu(I). The kinetics for grow in of this band are complex and appear be second order, inset, however as described below, the primary electron transfer process is intramolecular. The complex kinetics of the 510 nm grow in may be due to chemical reaction following reduction of the copper centre. The details of this mechanism and studies of the charge separated state are currently under more detailed study.

The rate constant for the photoinduced electron transfer was calculated according to Eq. (1).

$$k_{et} = 1/\tau_{complex} - 1/\tau_{model} \quad (1)$$

where $\tau_{complex}$ represents the luminescent lifetime of Cu_2CDRu, and τ_{model} represents lifetime of the model complex, CDRu in absence of any photoinduced process.

For Cu_2CDRu k_{et} was found to be $1.86 \times 10^6\ s^{-1}$ which is similar to the rate measure for electron transfer from an Mn(III) centre, the driving force for this process is also similar [39]. Importantly, in both cases, the photoinduced electron transfer rate is modest, while this is not surprising, given the likely poor conductivity of the CD bridge. It suggests that for such cyclodextrin complexes to be useful in sensing applications the luminophore must be relatively long lived to facilitate the electron transfer process.

Finally, the rate of electron transfer was measured over range of concentrations of Cu_2CDRu and laser powers (supplementary material), since a bimolecular reaction would be expected to be dependent on both these factors. However k_{et} was found, within experimental error, to be independent of these parameters confirming that the electron transfer is an intramolecular process.

Currently, detailed mechanistic studies on charge separation in this and analogous complexes with different metals is underway.

4. Conclusions

A new supramolecular donor–acceptor complex comprised of a ruthenium polypyridyl unit covalently linked to the secondary face of β-cyclodextrin which has a hydroxo bridged dinuclear copper(II) moiety at its primary face was synthesized. IR and magnetochemistry confirm that the structure of hydroxo bridged Cu(II) dimer is conserved from the parent Cu_2CD complex. Efficient photoinduced electron transfer from the copper centre to the pendant ruthenium polypyridyl centre is evident, with a rate constant of $1.86 \times 10^6\ s^{-1}$. The electron transfer process from transient absorption spectroscopy is attributed to a photooxidation of the excited ruthenium center by the copper dimer and this mechanism is consistent with thermodynamic predictions. The luminescence intensity of the ruthenium appended CD is correspondingly statically quenched on exposure to aqueous $Cu(CH_3COOH)_2$. This works suggests that luminescently labeled CDs may have value in metal sensing provided the luminophore is sufficiently long lived. The synthetic versatility of the ruthenium polypyridyl unit may mean that in the future the redox properties of this centre can be modified to tune selectivity for different metal ion.

–NCO– bridging ligands and their use as precursors of mononuclear N-bonded imidate derivatives [15,16]. Those dinuclear and mononuclear derivatives, containing an azobenzene, 2-phenylpyridine or benzoquinoline backbone, have shown to be active catalysts/precatalysts for the Suzuki–Miyaura cross-coupling reactions of aryl bromides with aryl boronic acids, and the Sonogashira reactions of aryl halides (in the presence and absence of Cu(I) salts) [17]. The conversions are dependent, to some extent, on the cyclometallated backbone and the imidate ligand, suggesting a role for these pseudohalides in the catalytic cycle in both cross-coupling processes and encouraging us to expand the range of systems under study.

On the other hand, the synthetic value of palladium(II) and platinum(II) di-μ-hydroxo-complexes is a subject of continuous study [18–22]. During the last few years we have also been developing the usefulness of binuclear hydroxo complexes of palladium, some of them with a cyclometallated backbone [23], in the preparation of an extensive selection of new compounds, by means of a simple acid–base reaction [24].

We report here the use of the hydroxo-complex [{Pd(μ-OH)(Phox)}$_2$] (Phox = 2-(2-oxazolinyl)phenyl) in the preparation of new dinuclear palladium(II) derivatives of simple and sterically not hindered 2-phenyl-2-oxazoline with bridging succinimide, phtalimide, maleimide, 2,3-dibromomaleimide and glutarimide ligands acting in the coordination mode mentioned above. We also describe the synthesis of mononuclear N-bonded imidate derivatives, by the reaction of the corresponding dinuclear precursor with neutral phosphine ligands. X-ray diffraction analyses of both mononuclear (**4a**, **5a**) and binuclear (**4**) derivatives are also given. To date, just three complexes containing an orthopalladated 2-phenyl-2-oxazoline ligand have been crystallographically characterised (searched at the Cambridge Structural Database (CSD) v. 5.28 updated till August 2007) [23a,25].

2. Experimental

2.1. Materials and methods

C, H, and N analyses were carried out with a Carlo Erba instrument. IR spectra were recorded on a Perkin–Elmer spectrophotometer 16F PC FT-IR, using Nujol mulls between polyethylene sheets. NMR data (^{1}H, ^{31}P) were recorded on Bruker Avance 300 spectrometer. Conductance measurements were performed with a Crison 525 conductimeter (in acetone, 5×10^{-4} M). Mass spectrometric analyses were performed on a Fisons VG Autospec double-focusing spectrometer, operated in the negative mode. Ions were produced by fast atom bombardment (FAB) with a beam of 25-keV Cs atoms. The mass spectrometer was operated with an accelerating voltage of 8 kV and a resolution of at least 1000.

The cyclometallated precursors [{Pd(μ-OOCMe)(Phox)}$_2$] [25] and [{Pd(μ-OH)(Phox)}$_2$] [23a] were prepared as described in the literature. The commercially available chemicals were purchased from Aldrich Chemical Co. and were used without further purification, and all the solvents were dried by standard methods before use.

2.2. Synthesis

2.2.1. Preparation of complexes [{Pd(μ-NCO)(Phox)}$_2$] (–NCO– = suc (**1**); R = phtal (**2**); R = mal (**3**); R = 2,3-diBrmal (**4**); R = glut (**5**))

The new complexes were obtained by treating [{Pd(μ-OH)(Phox)}$_2$] with the corresponding imidate ligand in molar ratio 1:2, using $(CH_3)_2CO$ as the solvent and according to the following general method. To an acetone suspension (20 mL) of the precursor (250 mg; 0.464 mmol) was added the stoichiometric amount of the corresponding imidate ligand. The resulting suspension was stirred for 60 min at reflux temperature and then concentrated to a quarter of volume under reduced pressure. Addition of $(CH_3CH_2)_2O$ caused precipitation of the new complexes, which were filtered off, air dried and recrystallised from CH_2Cl_2/C_6H_{14}.

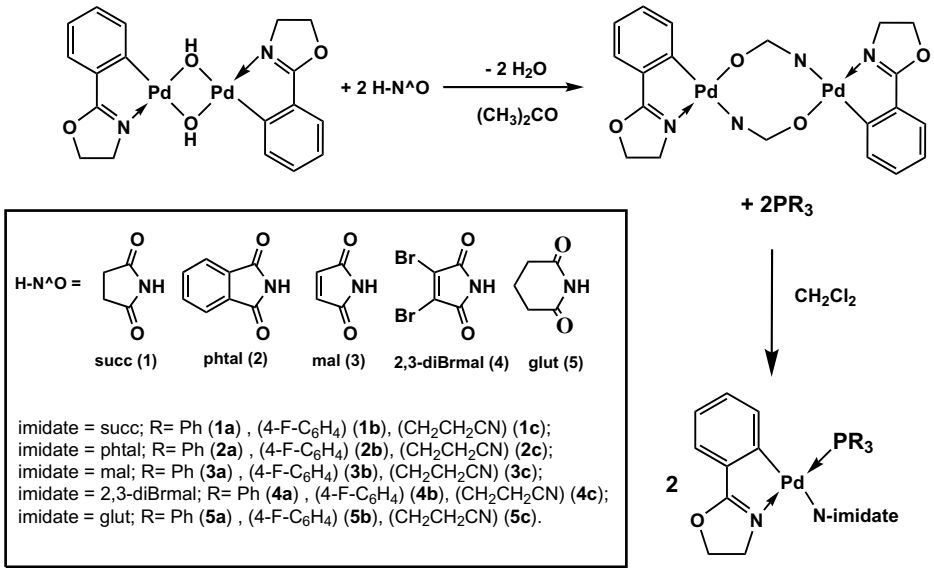
2.3. Crystal structure determination of [{Pd(μ-2,3-diBrmal)(Phox)}$_2$] (4), [Pd(2,3-diBrmal)(Phox)(PPh$_3$)] (4a) and [Pd(glut)(Phox)(PPh$_3$)] (5a)

Crystals suitable for a diffraction study were prepared by a slow diffusion of hexane into their CH_2Cl_2 solutions. Crystallographic data are summarized in Table 1. Data collection for **4** and **4a** was performed at −173 °C on a Bruker Smart CCD diffractometer with a nominal crystal to detector distance of 4.5 cm. Diffraction data were collected based on a ω scan run. A total of 2524 frames were collected at 0.3° intervals and 10 s per frame. The diffraction frames were integrated using the SAINT package [26] and corrected for absorption with SADABS [27]. For **5a** data collection was performed at 293 K on a Nonius Kappa-CCD single crystal diffractometer. Crystal-detector distance was fixed at 35 mm, and a total of 122 images were collected using the oscillation method, with scan angle per frame, 2° oscillation and 20 s exposure time per image. Data collection strategy was calculated with the program COLLECT [28]. Data reduction and cell refinement were performed with the programs HKL DENZO and SCALEPACK [29].

The structures were solved by direct methods [30] and refined by full-matrix least-squares techniques using anisotropic thermal parameters for non-H atoms [30] (Table 1). Hydrogen atoms were introduced in the calculated positions and refined during the last stages of the refinement.

3. Results and discussion



Under the conditions described in Section 2, [{Pd(μ-OH)(Phox)}$_2$] reacts with several imidate-type ligands to give dinuclear complexes **1**–**5** in which the imidate ligands replace the bridging hydroxo group as presented in Scheme 1.

Both the precursor and the new complexes are quite insoluble in the reaction media, so that just a change in the suspension colour is observed. The new 2-(2-oxazolinyl)phenyl) derivatives are air-stable yellow solids and their infrared spectra show only one absorption around 730 cm^{-1}, as expected for the region of out-of-plane C–H bending in disubstituted arenes. Also the characteristic

Scheme 1.

C=N absorption of the cyclometallated ligand around 1630 cm^{-1} is observed, shifted to lower frequencies compared to the free ligand (1649 cm^{-1}) and partially overlapped with those two strong bands attributed to imidato-carbonyl stretching in the range 1738–1720 and 1598–1562 cm^{-1}, respectively. According to the previously reported data [10] the appearance of two bands in this region suggests the coordination of one carbonyl group

to the metal as a part of an –NCO– bridging unit. Support for the proposed dinuclearity of complexes **1**–**5** comes from the FAB mass spectrometry, as can be implied by the *m*/*z* values for the observed fragments. Spectra of the new bridged compounds show a similar fragmentation pattern which includes the peaks corresponding to $[M]^+$, $[M^+$-imidate$]^+$ and $[Pd(Phox)]^+$. The abundances of the signals around the pattern ion are consistent with the natural isotopic ones.

Despite the low solubility in common solvents of some of the new derivatives, further evidence of the proposed coordination comes from the ^{1}H NMR spectroscopy. It has been reported for the related complex $[\{Pd(\mu\text{-OOCMe})(Phox)\}_2]$ that, as a consequence of its open-book structure, each of the two methylene protons of the oxazoline ring is non-equivalent, displaying a set of three unresolved multiplets (ratio 1:2:1) [25]. In $CDCl_3$ the new binuclear complexes showed this behaviour for the oxazoline protons, which appeared in the spectra together with the expected resonances of the imidate ligands (see Section 2). The preparation of single crystals of complex **4** suitable for X-ray diffraction was also possible and unambiguously confirmed the molecular structure. This is presented in Fig. 1 together with selected bond distances and angles.

The unit cell of complex **4** contains two molecules. In accordance with the geometries displayed by the previously

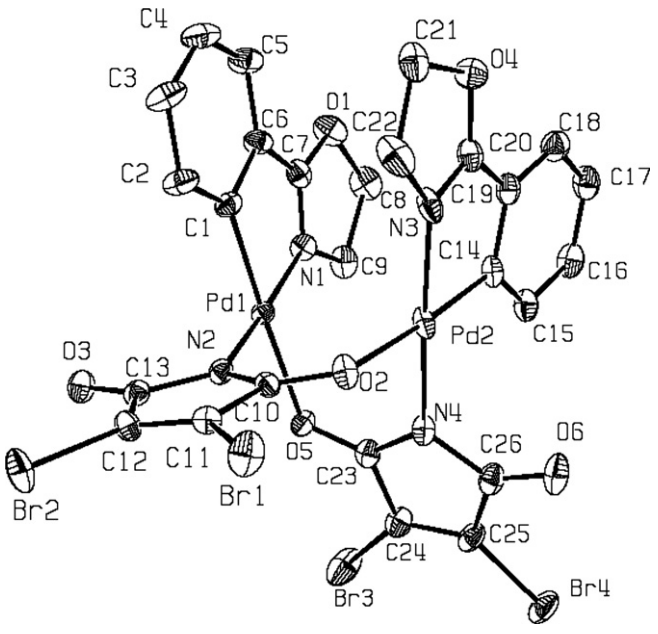

Fig. 1. ORTEP diagram of complex **4** with the atom numbering scheme; thermal ellipsoids are drawn at the 50% propability level. Hydrogen atoms are omitted for clarity. Selected distances (Å): Pd(1)–C(1) 1.976(4); Pd(1)–N(1) 2.017(3); Pd(1)–N(2) 2.024(3); Pd(1)–O(5) 2.175(3); Pd(1)–Pd(2) 2.9279(4); Pd(2)–C(14) 1.980(4); Pd(2)–N(3) 2.024(4); Pd(2)–N(4) 2.030(4); Pd(2)–O(2) 2.189(3). reported oxazoline-derived μ-chloro [31] and μ-acetate dimers [32], an *anti*-arrangement of identical donor atoms is found, supporting the pseudohalide character of imidate ligands. Also in common with the mentioned compounds and our previously described structure $[\{Pd(\mu\text{-suc})(Phpy)\}_2]$ [15] is the so-called open-book geometry accompanied by a rather short Pd(1)–Pd(2) distance of 2.9279(4) Å, within the generally accepted value for a Pd–Pd intramolecular interaction (<3.00 Å). An interesting structural aspect is that two hydrogens bonded to C22 ad C8, respectively, point towards the centre of the phenyl rings: distance H22B-centroid (C1–C6) = 3.106 Å; distance H8A-centroid (C14–C19) = 3.199 Å, suggesting an interaction between the rings of the two cyclometallated ligands. We have recently developed methods for the conformational classification of eight-membered rings [33]. From this perspective the Pd1–N2–C10–O2–Pd2–N4–C23–O5 ring displays a chair-chair conformation (CC = 0.9985; TCC = 0.0015 for $\sigma = 10$). Using the same Classification method, the five-membered palladacycles Pd1–C1–C6–C7–N1 and Pd2–C14–C19–C20–N3 exhibit almost planar conformations for $\sigma = 10$ (HC = 0.5095; E = 0.4905 and HC = 0.5138; E = 0.4862, respectively).

The structure around the two palladium atoms may be described as nearly planar, and their deviation from the planar coordination has been quantified by measures of improper torsion angles: 2.38° and −0.00° for Pd1 (square pyramidal); −0.96° and −1.01° for Pd2 (tetrahedral) [16]. In the 2,3-dibromomaleimide ligand the C=O distance, 1.228(5) and 1.232(5) Å, is elongated in the bridged group with respect to the non-coordinated C=O, 1.208(5) Å, in both Pd atoms.

As expected, the reactions of the imidate-bridged compounds against tertiary phosphines take place *via* bridge-splitting to yield the mononuclear N-bonded imidate derivatives $[Pd(imidate)(Phox)(PR_3)]$ presented in Scheme 1.

The yellow to orange air-stable solids display negligible molar conductivity values, and their IR spectra show the expected bands for the 2-(2-oxazolinyl)phenyl backbone, together with those attributed to the incoming phosphine ligand and just one strong carbonyl band around 1630 cm^{-1}, typical of N-bonded imidate ligands. The characterisation in solid state was completed with the FAB mass spectrometry, that shows fragments at $[M^+$-imidate] in all cases, being also possible to detect $[M^+]$ and $[Pd(Phox)]^+$ for several compounds. The ^{1}H and ^{31}P NMR data of the mononuclear complexes are collected in Section 2, the latter consisting of singlets with chemical shifts in the usual range of Pd(II) complexes. With regard to the ^{1}H NMR spectra, they show the expected resonances of the cyclometallated 2-phenyl-2-oxazoline, now with just two triplets for the NCH_2 and OCH_2 protons in the 3.70–4.80 ppm region, together with those signals attributed to the corresponding imidate ligand and coordinated phosphine.

The structures of $[Pd(2,3\text{-diBrmal})(Phox)(PPh_3)]$ (**4a**) and $[Pd(glut)(Phox)(PPh_3)]$ (**5a**) have been confirmed by X-ray diffraction study and are presented together with

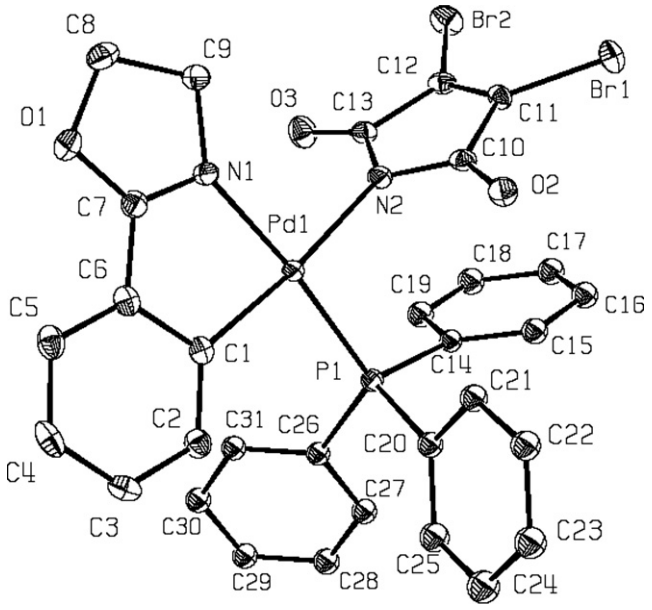

Fig. 2. ORTEP diagram of complex **4a**. Thermal ellipsoids are drawn at the 50% probability level. Hydrogen atoms are omitted for clarity. Selected distances (Å): Pd(1)–C(1) 2.027(3); Pd(1)–N(1) 2.068(3); Pd(1)–N(2) 2.113(3); Pd(1)–P(1) 2.2438(9). Selected angles (°): C(1)–Pd(1)–N(1) 81.04(12); C(1)–Pd(1)–N(2) 171.23(12); N(1)–Pd(1)–N(2) 91.43(11); C(1)–Pd(1)–P(1) 94.19(10); N(1)–Pd(1)–P(1) 174.12(8); N(2)–Pd(1)–P(1) 93.58(8).

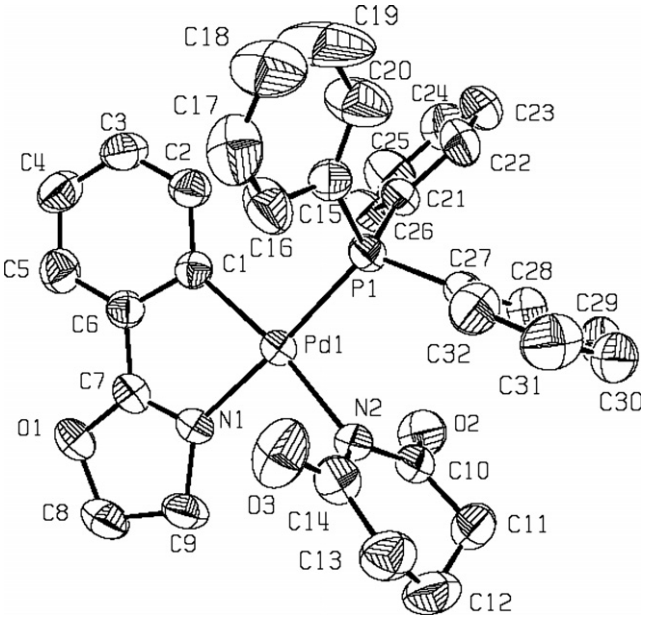

Fig. 3. ORTEP diagram of complex **5a**. Thermal ellipsoids are drawn at 50% probability. Hydrogen atoms are omitted for clarity. Selected distances (Å): Pd(1)–C(1) 2.046(12); Pd(1)–N(1) 2.062(10); Pd(1)–N(2) 2.091(10); Pd(1)–P(1) 2.246(3). Selected angles (°): C(1)–Pd(1)–N(1) 81.0(4); C(1)–Pd(1)–N(2) 171.4(4); N(1)–Pd(1)–N(2) 91.4(4); C(1)–Pd(1)–P(1) 94.8(4); N(1)–Pd(1)–P(1) 175.5(3); N(2)–Pd(1)–P(1) 92.9(3).

the selected bond distances and angles in Figs. 2 and 3, respectively. The coordination around the Pd atoms based on measures of torsion angles is approximately planar with slight tetrahedral distortion [16] (N1–C1–P1–Pd1 is 2.67° and −1.14°; N2–P1–C1–Pd1 2.72° and −2.42°, respectively). The displacement of the Pd atom from the mean coordination plane is 0.0524(57) and 0.1586(92) Å (rms = 0.0139 and 0.0017, respectively).

The N–Pd–C angle in the orthometallated moiety, around 81.0° in the three complexes, is similar to that found in complexes containing the same ligand [25,31,32]. The structural analysis of complexes **4a** and **5a** confirms the relative *cis*-position of the phosphine ligand and the metallated carbon atom suggested by the NMR data. This is the typical arrangement of the phosphine group in cyclopalladated complexes of the type [Pd(C^N)(phosphine)(X)] (X = anionic monodentate ligand) due to the so-called *transphobia* effect [34,35]. Following the classification of Dance and Scudder [36] for PPh_3 based on measures of torsion angles M–P–C_{ipso}–C, the conformation of Pd–PPh_3 groups is described as *no rotor* for the new complexes, presenting values $T_3 - T_2 = 38.55°$; $T_2 - T_1 = 31.28°$ for **4a** and $T_3 - T_2 = 22.17°$; $T_2 - T_1 = 88.30°$ for **5a**, that differ to those which would have the ideal *rotor* ($T_1 = T_2 = T_3 = 44°$).

As found for complexes **4**, **4a** and **5a** also display almost planar conformations in the five-membered palladacycles Pd1–C1–C6–C7–N1 (HC = 0.5138; E = 0.4862 and HC = 0.5114; E = 0.4886).

In complex **4a**, the C10–O2 and C13–O3 distances of 2,3-dibromomaleimide ligand are 1.204(4) and 1.209(4) Å, very close to the non-coordinated C=O distances in dinuclear complex **4** (1.208(5) Å). In complex **5a** those distances are slightly higher: 1.216(16) and 1.227(16) Å.

4. Conclusions

Twenty new imidate-palladium(II) complexes with 2-phenyl-2-oxazoline acting as cyclometallated backbone have been prepared and characterized by spectroscopic techniques and single crystal X-ray diffraction analysis. Imidate ligands exhibit two different coordination modes: –NCO– bridging two Pd atoms or N-bonded. We enlarge in this paper the range of imidate and phosphine systems under study in comparison with our previous results, and we present the first X-ray crystal structures of complexes containing 2,3 dibromomaleimide (bonded as –NCO– bridging group (**4**) and as N-bonded (**4a**)), as searched at the Cambridge Structural Database (CSD) v. 5.28 updated till August 2007. Preliminary results show that the new complexes are active catalysts/precatalysts in Suzuki–Miyaura cross-coupling reactions of aryl bromides with aryl boronic acids. A comprehensive study will be reported in due course.

5. Supplementary data

CCDC 671662, 671663 and 671664 contain the supplementary crystallographic data for **4**, **4a** and **5a**. These data

can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

We have previously synthesized phthalocyanines containing tetraaza [18], dithiadiaza [19] macrocyclic moieties, pyridyl groups [20] and polymeric [21,22]. In this paper, we describe the synthesis and characterization of metal-free **4** and metallophthalocyanine **5**–**8**. Cyclic voltammetry of these compounds is also presented.

2. Experimental

2-(Phenylthio)ethanol **1** [23] and 4-nitrophthalonitrile [24]**2** was prepared according to the literature. All reagents and solvents were of reagent grade quality and were obtained from commercial suppliers. All solvents were dried and purified as described by Perrin and Armarego [25]. The IR spectra were recorded on a Perkin Elmer 1600 FT-IR Spectrophotometer, using KBr pellets or NaCl disc. ^{1}H and ^{13}C NMR spectra were recorded on a Varian Mercury 200 MHz spectrometer in $CDCl_3$, and chemical shifts were reported (δ) relative to Me_4Si as internal standard. Mass spectra were measured on a Micromass Quatro LC/ULTIMA LC–MS/MS spectrometer. The elemental analyses were performed on a Costech ECS 4010 instrument. Melting points were measured on an electrothermal apparatus and are uncorrected. Optical spectra in the UV–Vis region were recorded with a Unicam UV2-100 spectrophotometer, using 1 cm pathlength cuvettes at room temperature.

The cyclic voltammetry (CV), differential pulse voltammetry (DPV) measurements were carried out with a Princeton Applied Research Model 2273 potentiostat/Galvanostat controlled by an external PC at 25 °C. A three electrode system was used: a platinum wire counter electrode, an Ag/AgCl reference electrode and a 2 mm sized glassy carbon disc electrode as working electrode. The surface of the working electrode was polished with a H_2O suspension of Al_2O_3 before each run. High purity N_2 was used for deoxygenating the solution for at least 15 min prior to each run and maintain a nitrogen blanked during the measurements.

2.1. 4-[2-(Phenylthio)ethoxy]phthalonitrile (3)

2-(Phenylthio)ethanol **1** (2 g, 12.96 mmol, 1.76 ml) was dissolved in dry DMF (20 ml) under N_2 atmosphere and 4-nitrophthalonitrile **2** (2.24 g, 12.96 mmol) was added to the solution. After stirring 10 min, finely ground anhydrous K_2CO_3 (5.36 g, 38.88 mmol) was added portionwise within 2 h with efficient stirring. The reaction mixture was stirred under N_2 at 50 °C for 3 days. Then the solution was poured into ice-water (200 ml). The precipitate formed was filtered off, washed first with water until the filtrate was neutral and then diethyl ether and dried in vacuo over P_2O_5. The crude product was crystallized from ethanol. Yield: 1.88 g (52%), mp: 78–80 °C. *Anal.* Calc. for $C_{16}H_{12}N_2SO$: C, 68.57; H, 4.28; N, 10.0; S, 11.43. Found: C, 68.77; H, 4.43; N, 10.22; S, 11.56%. IR (KBr tablet) ν_{max}/cm^{-1}: 3077 (Ar-H), 2933, 2851 (Aliph. C–H), 2229 (C≡N), 1598, 1562, 1489, 1319, 1253, 1090, 1012, 741, 691. ^{1}H NMR. ($CDCl_3$), (δ: ppm): 161.39, 135.20, 134.37, 130.38, 129.22, 127.13, 119.53, 119.29, 117.31, 115.61, 115.15, 115.42, 67.67, 32.63. MS (EI), (*m*/*z*): 319 $[M+K]^+$.

2.2. Metal-free phthalocyanine (4)

A mixture of 4-[2-(phenylthio)ethoxy]phthalonitrile **3** (250 mg, 0.89 mmol) and 2-(dimethylamino)ethanol (DMAE) (3 ml) was placed in Schlenk tube at 130 °C for 24 h. After cooling to room temperature the reaction mixture refluxed with ethanol (45 ml) to precipitate the product which was filtered off. The green solid product was washed with hot ethanol, diethyl ether and dried in vacuo. This product is soluble in $CHCl_3$, CH_2Cl_2, THF, DMF, DMSO. After that the green solid product is purified from the column in which is placed silicagel using only chloroform as solvent system. At the end of this purification step, the suitable fractions are put together and solvent of these is evaporated under low pressure until the dryness. Yield: 103 mg (41%), mp 145–147 °C. Elemental *Anal.* Calc. for $C_{64}H_{50}N_8O_4S_4$: C, 68.36; H, 4.45; N, 9.96; S, 11.39. Found: C, 67.90; H, 4.60; N, 9.60; S, 12.02%. UV–Vis (chloroform): λ_{max}/nm: [(10^{-5} ε dm^3 mol^{-1} cm^{-1})]: 287 (5.21), 335 (5.20), 392 (4.82), 644 (4.93), 671 (5.10), 707 (5.11). MS (FAB), (*m*/*z*): 1122 $[M-H]^+$.

2.3. Ni(II)-containing phthalocyanine (5)

A mixture of 4-[2-(phenylthio)ethoxy]phthalonitrile **3** (220 mg, 0.78 mmol), anhydrous $NiCl_2$ (25.34 mg, 0.196 mmol) and 2-(dimethylamino)ethanol (DMAE) (2 ml) placed in Schlenk tube at 130 °C for 24 h. After cooling to room temperature the reaction mixture refluxed with ethanol (40 ml) to precipitate the product which was filtered off. The green solid product was washed with hot ethanol, diethyl ether and dried in vacuo. This product is soluble in $CHCl_3$, CH_2Cl_2, THF, DMF, DMSO. After that the green solid product is purified from the column in which is placed silicagel using chloroform:methanol (9.9:0.1) as solvent system. At the end of this purification step, the suitable fractions are put together and solvent

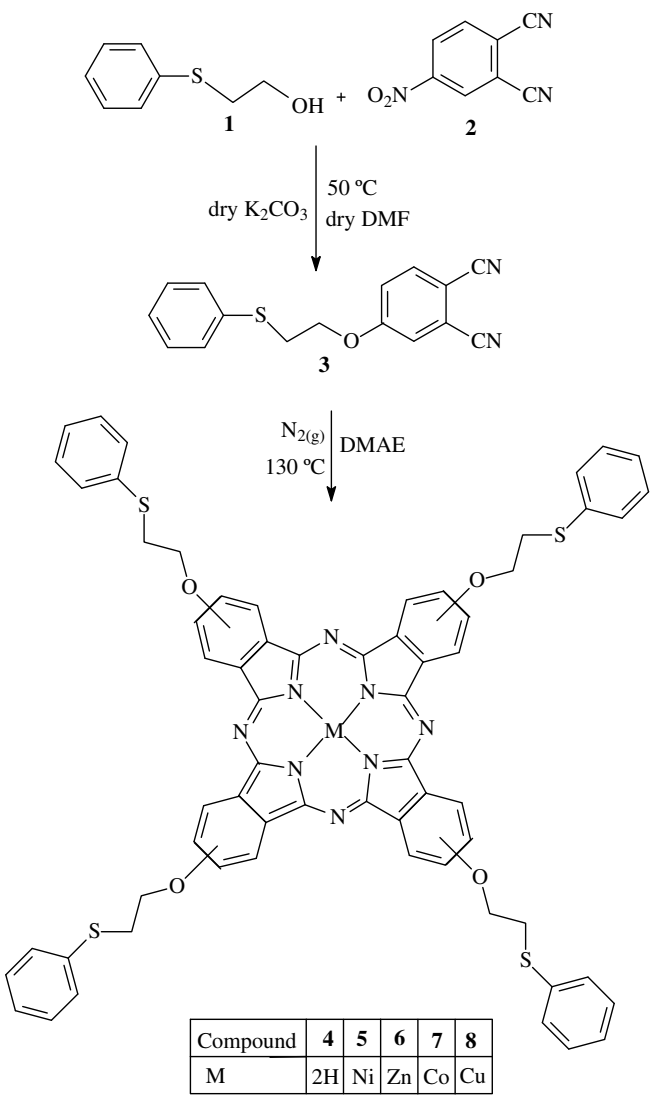
of these is evaporated under low pressure until the dryness. Yield: 37 mg (37%), mp > 300 °C. Elemental *Anal*. Calc. for $C_{64}H_{48}N_8O_4S_4Ni$: C, 65.08; H, 4.06; N, 9.49; S, 10.84. Found: C, 65.10; H, 4.40; N, 9.90; S, 10.90%. IR (KBr tablet) ν_{max}/cm^{-1}: 3043 (Ar-H), 2923, 2862 (Aliph. C–H), 1606 (C=N), 1529, 1479, 1415, 1329 1271, 1230 (Ar-O–C), 1120, 1090, 1012, 820, 737, 689. ^1H NMR ($CDCl_3$), (δ: ppm) 7.64 (d, 4H, ArH), 7.47 (d, 4H, ArH), 7.45 (s, 4H, ArH), 7.43 (d, 8H, ArH), 7.28 (t, 4H, ArH), 7.18 (d, 8H, ArH), 4.21 (t, 8H, CH_2–O), 3.53 (t, 8H, CH_2–S). ^{13}C NMR ($CDCl_3$), (δ: ppm) 167.74, 142.45, 132.52, 130.90, 129.23, 128.84, 125.88, 124.53, 123.68, 119.12, 102.24, 68.21, 38.80. UV–Vis (pyridine): λ_{max}/nm: [(10^{-5} ε dm^3 mol^{-1} cm^{-1})]: 295 (5.17), 329 (5.18), 389 (4.83), 620 (4.60), 677 (5.17). MS (FAB), (*m*/*z*): 1182 $[M+2H]^+$.

2.4. Zn(II)-containing phthalocyanine (6)

A mixture of 4-[2-(phenylthio)ethoxy]phthalonitrile **3** (230 mg, 0.82 mmol), anhydrous $Zn(CH_3COO)_2$ (44.97 mg, 0.205 mmol) and 2-(dimethylamino)ethanol (DMAE) (2 ml) was placed in Schlenk tube at 130 °C for 24 h. After cooling to room temperature the reaction mixture refluxed with ethanol (40 ml) to precipitate the product which was filtered off. The green solid product was washed with hot ethanol, diethyl ether and dried in vacuo. This product is soluble in $CHCl_3$, CH_2Cl_2, THF, DMF, DMSO. After that the green solid product is purified from the column in which is placed silicagel using only chloroform as solvent system. At the end of this purification step, the suitable fractions are put together and solvent of these is evaporated under low pressure until the dryness. Yield: 121 mg (%50), mp > 300 °C. Elemental *Anal*. Calc. for $C_{64}H_{48}N_8O_4S_4Zn$: C, 67.71; H, 4.04; N, 9.44; S, 10.79. Found: C, 66.60; H, 4.20; N, 10.0; S, 11.0%. IR (KBr tablet) ν_{max}/cm^{-1}: 3049 (Ar-H), 2924, 2857 (Aliph. C–H), 1606 (C=N), 1481, 1379, 1337, 1230 (Ar-O–C), 1092, 1045, 946, 823, 743, 690. ^1H NMR ($CDCl_3$), (δ: ppm) 7.69 (d, 4H, ArH), 7.55 (d, 4H, ArH), 7.53 (s, 4H, ArH), 7.50 (d, 8H, ArH), 7.26 (t, 4H, ArH), 7.16 (d, 8H, ArH), 4.28 (m, 8H, CH_2–O), 4.21 (m, 8H, CH_2–S). UV–Vis (chloroform): λ_{max}/nm: [(10^{-5} ε dm^3 mol^{-1} cm^{-1})]: 270 (5.22), 353 (5.19), 617 (4.64), 686 (5.23). MS (FAB), (*m*/*z*): 1186 $[M]^+$.

2.5. Co(II)-containing phthalocyanine (7)

A mixture of 4-[2-(phenylthio)ethoxy]phthalonitrile **3** (220 mg, 0.78 mmol), anhydrous $CoCl_2$ (25.53 mg, 0.196 mmol) and 2-(dimethylamino)ethanol (DMAE) (2 ml) was placed in Schlenk tube at 130 °C for 24 h. After cooling to room temperature the reaction mixture refluxed with ethanol (45 ml) to precipitate the product which was filtered off. The green solid product was washed with hot ethanol, diethyl ether and dried in vacuo. This product is soluble in $CHCl_3$, CH_2Cl_2, THF, DMF, DMSO. After that the green solid product is purified from the column in which is placed silicagel using chloroform:methanol (9.5:0.5) as solvent system. At the end of this purification step, the suitable fractions are put together and solvent of these is evaporated under low pressure until the dryness. Yield: 92 mg (40%), mp 171–173 °C. Elemental *Anal*. Calc. for $C_{64}H_{48}N_8O_4S_4Co$: C, 65.07; H, 4.07; N, 9.49; S, 10. Found: C, 65.10; H, 4.40; N, 9.90; S, 10.80%. IR (KBr tablet) ν_{max}/cm^{-1}: 3056 (Ar-H), 2926, 2868 (Aliph. C–H), 1603, 1481, 1382, 1279, 1228 (Ar-O–C), 1072, 1014, 829, 739, 690. ^1H NMR ($CDCl_3$), (δ: ppm) 7.71 (d, 4H, ArH), 7.69 (d, 4H, ArH), 7.54 (s, 4H, ArH), 7.50 (d, 8H, ArH), 7.27 (t, 4H, ArH), 7.23 (d, 8H, ArH), 4.29 (m, 8H, CH_2–O), 4.20 (m, 8H, CH_2–S). UV–Vis (pyridine): λ_{max}/nm: [(10^{-5} ε dm^3 mol^{-1} cm^{-1})]: 275 (5.14), 345 (5.16), 611 (4.59), 677 (5.18). MS (FAB), (*m*/*z*): 1181 $[M]^+$.



2.6. Cu(I)-containing phthalocyanine (8)

A mixture of 4-[2-(phenylthio)ethoxy]phthalonitrile **3** (240 mg, 0.857 mmol), anhydrous CuCl (21.21 mg, 0.214 mmol) and 2-(dimethylamino)ethanol (DMAE) (2 ml) was placed in Schlenk tube at 130 °C for 24 h. After cooling to room temperature the reaction mixture refluxed with ethanol (45 ml) to precipitate the product which was filtered off. The green solid product was washed with hot ethanol, diethyl ether and dried in vacuo. This product is soluble in $CHCl_3$, CH_2Cl_2, THF, DMF, DMSO. After that the green solid product is purified from the column in which is placed silicagel using only chloroform as solvent system. At the end of this purification step, the suitable fractions are put together and solvent of these is evaporated under low pressure until the dryness. Yield: 109 mg (43%), mp > 300 °C. Elemental *Anal*. Calc. for $C_{64}H_{48}N_8O_4S_4Cu$: C, 64.81; H, 4.05; N, 9.45; S, 10.80. Found: C, 64.90; H, 4.30; N, 9.90; S, 10%. IR (KBr tablet) ν_{max}/cm^{-1}: 3049 (Ar-H), 2923, 2851 (Aliph. C–H), 1592, 1484, 1382, 1327, 1224 (Ar-O–C), 1188, 1147, 1076, 1014, 897, 787, 737, 690. UV–Vis (pyridine): λ_{max}/nm: [(10^{-5} ε dm^3 mol^{-1} cm^{-1})]: 265 (5.15), 334 (5.17), 617 (4.52), 686 (5.20). MS (FAB), (*m*/*z*): 1184 $[M]^+$.

3. Results and discussion

3.1. Synthesis and characterization

Metal-free **4** and metallophthalocyanines **5**, **6**, **7** and **8** were synthesized in two steps (Scheme 1). In the first step, the base-catalyzed nucleophilic aromatic nitro displacement of 4-nitrophthalonitrile **2** with 2-(phenylthio)ethanol **1** afforded the dinitrile monomer **3**. In the second step, metal-free and metallophthalocyanine molecules were synthesized. The metal-free phthalocyanine **4** was synthesized with adding 2-(dimethylamino)ethanol in Schlenk tube at 130 °C for 24 h. The metallophthalocyanines **5**, **6**, **7** and **8** were obtained from tetracyano derivative **3** and corresponding anhydrous metal salts $NiCl_2$, $Zn(CH_3COO)_2$, $CoCl_2$ and CuCl, respectively, with adding 2-(dimethylamino)ethanol in Schlenk tube for at reflux temperature.

Compound	4	5	6	7	8
M	2H	Ni	Zn	Co	Cu

Scheme 1. The synthesis of the metal-free phthalocyanine and metallophthalocyanines.

In the IR spectrum of **3** the disappearance of NO_2 and OH groups stretching vibrations belong to compounds **1**, **2**, along with the appearance of new bands at 2229 and 1253 cm^{-1} arising from C≡N and Ar-O–C groups, respectively, are in agreement with the proposed structure. In the ^1H NMR spectrum of **3**, OH group of compound **1** disappeared as expected. ^1H NMR spectrum of **3** showed new signals at $\delta = 7.64$ (d, 1H, ArH), 7.39 (d, 1H, ArH), 7.38 (s, 1H, ArH), 7.32 (d, 2H, ArH), 7.28 (t, 1H, ArH), 7.15 (d, 2H, ArH), 4.20 (t, 2H, CH_2–O), 3.31 (t, 2H, CH_2–S). In the ^{13}C NMR spectrum of **3** indicated the presence of nitrile carbon atoms in **3** at $\delta = 115.61$ and 115.15 ppm. Elemental analysis and EI mass spectral data were satisfactory: 319 $[M+K]^+$.

In the IR spectrum of **4** characteristic peaks for phthalocyanines were observed. The peak at 3296 cm^{-1} is the characteristic metal-free phthalocyanine N–H stretching bands. Also, 3060 (Ar-H), 2926-2857 (Aliph. C–H), 1602 (N–H bending) bands were present in the spectrum. The disappearance of the C≡N stretching vibration on the IR spectra of **3** suggested the formation of compound **4**. In the ^1H NMR spectrum of **4**, the typical shielding of inner core protons could not be observed due to the probable strong aggregation of the molecules [26]. The MS mass spectrum of compound **4** displayed the $[M-2H]^+$ parent ion peak at $m/z = 1122$ which confirms the same structure. The results of the elemental analysis confirmed the proposed structure of compound **4**.

The IR spectra of metallophthalocyanines **5**, **6**, **7** and **8** the disappearance of strong C≡N stretching vibration of **3** is an evidence for the formation of metallophthalocyanines **5**, **6**, **7** and **8**. The rest of the IR spectra of metallophthalocyanines are very similar to those of the metal-free phthalocyanine **4**. In the ^1H NMR spectra of these compounds are almost identical to those of metal-free phthalocyanine **4**. In the mass spectrum of compounds **5**, **6**, **7** and **8**, the presence of molecular ion peaks at $m/z = 1182$ $[M+2H]^+$, 1186 $[M]^+$, 1181 $[M]^+$ and 1184 $[M]^+$, respectively, confirmed the proposed structures.

The electronic spectra of phthalocyanines **4**, **5**, **6**, **7** and **8** show the typical B and Q bands of symmetrical Pc. The energy level location corresponding to those bands is illustrated in Figs. 1 and 2. There are the split Q-band as expected and there are two strong bands in the visible

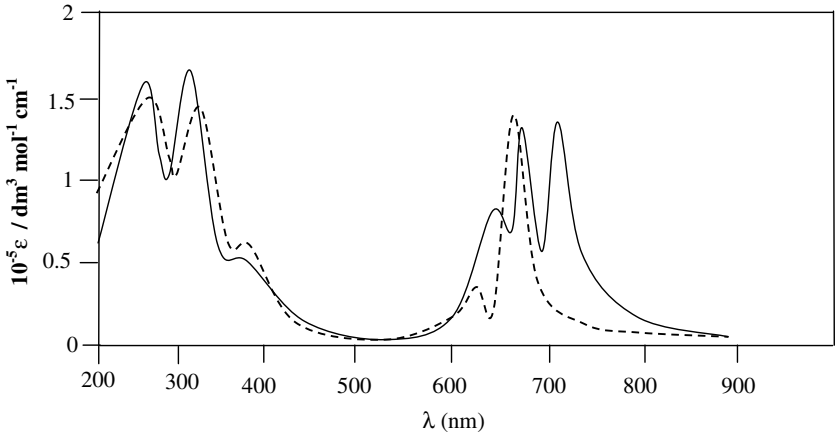


Fig. 1. UV–Vis spectra of compounds **4** (—) and **5** (---) and in chloroform.

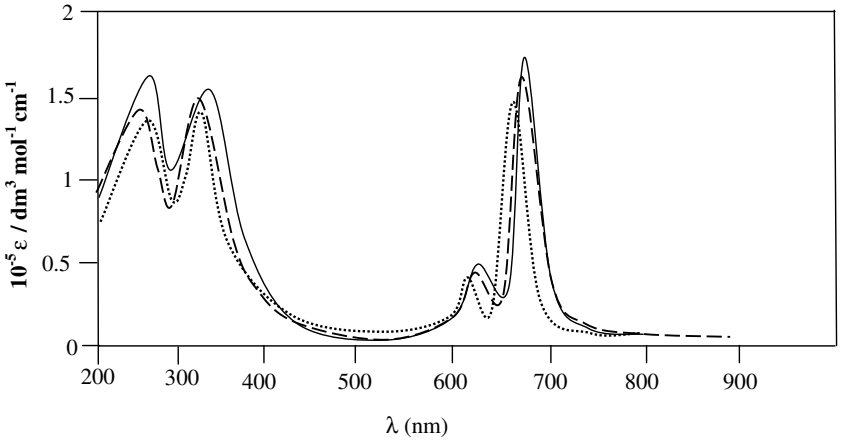

Fig. 2. UV–Vis spectra of compounds **6** (—), **7** (···) and **8** (---) in chloroform.

region [27]. The split Q-band which is characteristic for metal-free phthalocyanines **4** observed at $\lambda_{max} = 707$ and 671 nm with a shoulder at 644 nm, indicating the monomeric species with D_{2h} symmetry shows two intense absorptions at around 700 nm [28,29]. On the other hand, such split Q-band absorptions in chloroform are due to π–π* transition of this fully conjugated 18π electron systems [30].

The UV–Vis absorption spectra of metallophthalocyanines **5**, **6**, **7** and **8** in chloroform show intense Q absorption at $\lambda_{max} = 677$, 686, 677 and 686 nm, with a weaker absorptions at 620, 617, 611 and 617 nm, respectively. The single Q bands in metallo derivatives **5**, **6**, **7** and **8** are characteristic. This result is typical of metal complexes of substituted and unsubstituted metallophthalocyanines with D_{4h} symmetry [31]. B band absorptions of compound **5**, **6**, **7** and **8** were observed at $\lambda_{max} = (295, 329, 389)$, (270, 353), (275, 345), (265, 334) nm as expected.

3.2. Electrochemical measurements

Redox properties of the free base phthalocyanine (H_2Pc) and ZnPc, CoPc complexes were studied using cyclic voltammetry and differential pulse voltammetry in dichloromethane (DCM) containing 0.1 M tetra(*n*-butyl)ammonium tetrafluoroborate (TBATFB). Voltammetric data and the assignment of the redox couples recorded for the ligand and its complexes are listed in Table 1. The potentials are given versus Ag/AgCl reference electrode.

Fig. 3 shows the CV and DPV of the metal-free phthalocyanine. It gives three one-electron reduction processes labelled as R_1 at −0.820 V, R_2 at −1.058 V and R_3 −1.408 V and ill defined two oxidation processes labelled O_1 and O_2 at 0.1 V s^{-1} scan rate. The peak currents increased linearly with the square root of the scan rate at a range of 10–500 mV s^{-1} indicating the purely diffusion-controlled behaviours of the reduction couples. The values of $I_{p,a}/I_{p,c}$ for reduction couples of (H_2Pc) are close to unity, suggesting reversible redox processes. The anodic to cathodic peak separation (ΔE_p) changed from 58 to

Table 1
The electrochemical data of phthalocyanines

Compound	Redox process	E_p (V)	ΔE_p (mV)	$I_{p,a}/I_{p,c}$	$\Delta E^{1/2}$ (V)
FPc	R_1	−0.820 (−0.750)	70	0.70	1.530
	R_2	−1.058 (−1.010)	48	1.15	
	R_3	−1.408 (−1.284)	124	0.40	
	O_1	0.710[a]			
	O_2	0.850[a]			
CoPc	R_1	−0.406 (–)	70	–	1.228
	R_2	−1.204 (–)			
	R_3	−1.528 (−1.428)	100		
	O_1	0.822 (0.704)	118	0.96	
ZnPc	R_1	−1.072 (−1.004)	68	0.70	1.570
	R_2	−1.288 (−1.180)	108	1.12	
	O_1	0.498 (0.440)	58	0.75

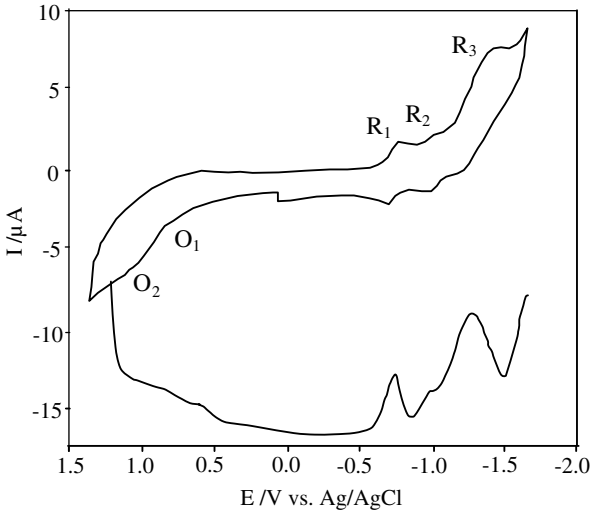

Fig. 3. Cyclic and differential pulse voltammograms of H_2Pc at 0.100 V s^{-1} scan rate on GCE in DCM/TBATFB. Inset: DPV of H_2Pc (1.10^{-3} mol dm^{-3}). Pulse width = 50 ms, pulse height = 100 mV, step height = 5 mV, step time = 100 mS.

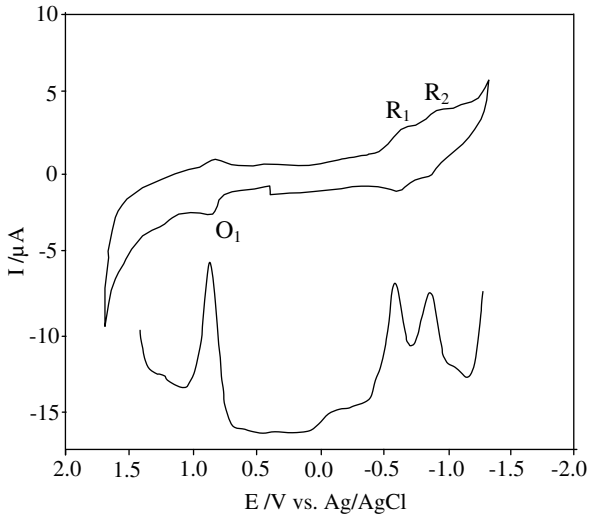

Fig. 4. Cyclic and differential pulse voltammograms of ZnPc at 0.100 V s^{-1} scan rate on GCE in DCM/TBATFB. Inset: DPV of ZnPc (1.10^{-3} mol dm^{-3}). Pulse width = 50 ms, pulse height = 100 mV, step height = 5 mV, step time = 100 mS.

124 mV with scan rate suggesting the reversible or a quasi-reversible electron transfer.

The ZnPc complex exhibited three redox couples in the +1.50 to −1.80 V range. Scanning the potential to positive side, a reversible oxidation process of the complex at +0.498 V was seen, and upon scanning cathodically, two reduction peaks with the corresponding anodic waves on the reverse step were recorded at −1.044 V and −1.380 V (Fig. 4). Fig. 5. shows the CV and DPV of the cobalt complex gives three reduction and two oxidation couples.

The reduction and oxidation behaviour of metallophthalocyanine derivatives is due to the interaction between the phthalocyanine ring and the central metal. The redox

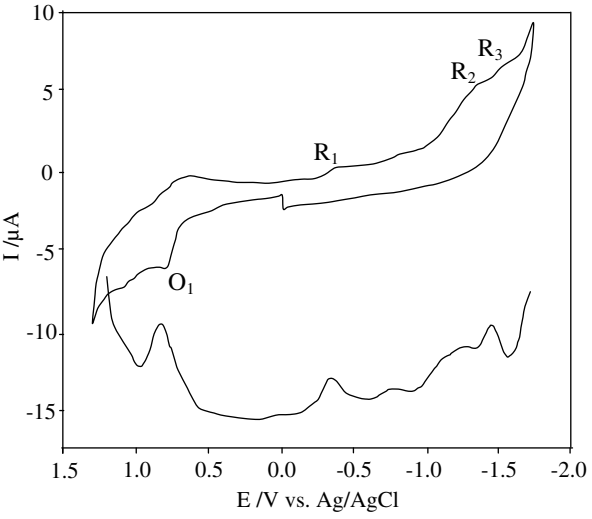

Fig. 5. Cyclic and differential pulse voltammograms of CoPc at 0.100 V s^{-1} scan rate on GCE in DCM/TBATFB. Inset: DPV of CoPc (1.10^{-3} mol dm^{-3}). Pulse width = 50 ms, pulse height = 100 mV, step height = 5 mV, step time = 100 mS.

properties of the of metallophthalocyanines have been studied by many authors [32–34]. According to these studies for the CoPc complexes, the first oxidation and first reduction processes occurs on the metal centre in polar solvent such as DMF and DMSO, however, the first oxidation processes occur on the Pc ring in apolar solvent such as DCM and THF. This study indicates that the first reduction at −0.406 V could be assigned easily to the [Co(II)Pc(-2)]/[Co(I)Pc(-2)]$^{-}$ redox couple and the remaining processes to the phthalocyanine ring. Since the difference between the first oxidation and reduction potentials ($\Delta E_{1/2}$) reflects the HOMO–LUMO gap in related molecule the $\Delta E_{1/2}$ value of CoPc are comparable to those given in corresponding papers and smaller than the (H_2Pc) [35]. In contrast to CoPc all redox processes of the ZnPc complex take place on the phthalocyanine ring system.

2. Experimental

2.1. Instrumentation and materials

A Perkin–Elmer Spectrum One spectrometer was used for recording FT–IR spectrum in the range 4000–250 cm^{-1} and Cary Eclipse EL05033882 for fluorescence. UV–Vis spectra were recorded in a Perkin–Elmer Lambda 25 spectrometer. The EPR spectra were recorded on a JEOL JES FA-200 X-band EPR spectrometer. The epr spectra were simulated using EPR-NMR programme package (version 6.08) developed by professor John Weil's group [8] and it was kindly supplied by Dr. P. Sambasiva Rao, Pondicherry University. The spin Hamiltonian parameters were determined by trial and error method and the exact diagonalization of the spin Hamiltonian was used in this programme. Isotropic *g*-values, *D* and *E* parameters were used as inputs in the simulation programme. The room temperature VSM data were recorded on a Lakshore VSM Setup.

X-ray crystallographic data were collected using Bruker SMART APEX-CCD diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). The intensity data were corrected for Lorentz and polarization effects and empirical absorption corrections was applied using SAINT programme [9,10]. All the structures were solved by direct methods using SHELXS-97 [11]. Non-hydrogen atoms located from the difference Fourier maps were refined anisotropically by full-matrix least-squares on F^2, using SHELXL-97 [11]. The hydrogen atoms were included in the calculated positions and refined isotropically using a riding model.

2-Acetylpyridine, 2-picolylamine (Aldrich, USA), $CrCl_3 \cdot 6H_2O$ (Fluka, USA), Zn powder, Na_2EDTA, KSCN, NaN_3 (Merck India Ltd.), and other reagent grade chemicals were used as received without further purification. 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine, **L**, was prepared using the procedure reported by us [7].

2.2. Synthesis of the complexes

2.2.1. $[Cr\mathbf{L}Cl_3] \cdot DMF$ (**1**)

To a hot ethanolic solution (20 mL) containing $CrCl_3 \cdot 6H_2O$ (65 mg, 0.24 mmol) and **L** (76 mg, 0.24 mmol), was added zinc powder (2 mg) and heated at reflux for 1 h. The green solid which precipitated was filtered, washed successively with water and ethanol. The solid was dissolved in minimum amount of DMF and kept undisturbed for about a week. The crystals deposited were collected and used for further characterizations. Yield: 36 mg, 31%. *Anal.* Calc. for $[Cr\mathbf{L}Cl_3] \cdot DMF = C_{23}H_{21}N_5OCl_3Cr$: C, 50.94; H, 3.87; N, 12.92. Found: C, 50.79; H, 3.91; N, 12.83%.

2.2.2. $[Cr\mathbf{L}(N_3)_3] \cdot CH_3CN$ (**2**)

To a hot methanolic solution (20 ml) containing $CrCl_3 \cdot 6H_2O$ (32 mg, 0.12 mmol), **L** (37 mg, 0.12 mmol) and NaN_3 (24 mg 0.38 mmol), zinc powder (1 mg) was added and heated at reflux for 0.5 h. The resulting greenish brown solution was filtered and left undisturbed. The brown crystals deposited after a week were separated and washed with ice-cold methanol. Yield: 15 mg (26%). Crystals suitable for X-ray crystallography were obtained by slow evaporation of acetonitrile solution of **2**. *Anal.* Calc. for $[Cr\mathbf{L}(N_3)_3] \cdot CH_3CN = C_{22}H_{17}N_{14}Cr$: C, 49.90; H, 3.21; N, 37.05. Found: C, 49.75; H, 3.14; N, 36.91%.

2.2.3. $Cr\mathbf{L}(NCS)_3] \cdot DMF$ (**3**)

An ethanolic solution (30 ml) containing $CrCl_3 \cdot 6H_2O$ (60 mg, 0.22 mmol) zinc powder (2 mg) and KSCN (67 mg, 0.68 mmol) were heated at reflux for few minutes. Then solid **L** (68 mg, 0.22 mmol) was added and refluxed for 0.5 h. The precipitated brown crystalline solid was filtered and washed with ethanol. Yield: 90 mg (74%). Crystals suitable for X-ray crystallography were obtained by slow evaporation of DMF solution of **3**. *Anal.* Calc. for $[Cr\mathbf{L}(NCS)_3] \cdot DMF = C_{26}H_{21}N_8OS_3Cr$: C, 51.17; H, 3.44; N, 18.37. Found: C, 51.29; H, 3.48; N, 18.26%.

3. Results and discussion

3.1. Syntheses

The common coordination number for chromium(III) is six and has a $t_{2g}^3e_g^0$ electronic configuration in an octahedral ligand field. Therefore, Cr^{3+} is a substitutionally inert metal ion. However, in the presence of trace quantities of reducing agent, catalytic amounts of Cr^{2+} are generated. Since Cr^{2+} in a weak field environment has $t_{2g}^3e_g^1$ electronic configuration, is substitutionally labile and readily undergo substitution reactions [12]. Using this principle, we could synthesize $[Cr\mathbf{L}(N_3)_3] \cdot DMF$ by heating equimolar quantities of $CrCl_3 \cdot 6H_2O$ and **L** in ethanol in the presence of catalytic amount of zinc powder. Similarly, in the presence of N_3^- and NCS^- ions, $[Cr\mathbf{L}(N_3)_3] \cdot CH_3CN$ and $[Cr\mathbf{L}(NCS)_3] \cdot DMF$ were obtained, respectively.

3.2. Optical spectra

The presence of **L** in **1**, **2**, and **3** can be inferred from the presence of ν(C=N) at 1605 cm^{-1}. In **1**, ν(Cr–Cl) at 400 cm^{-1} can be assigned to the equatorial bond and the IR active asymmetric ν(Cr–Cl) for the axial bonds occur at 350 cm^{-1}. In case of **2**, the bands at 2072 and 2036 cm^{-1} are due to ν(azide, axial) and ν(azide, equatorial), respectively. The ν(N≡C) occurs at 2074 and 2054 cm^{-1} in **3** [13]. The trends, ν(Cr–Cl, equatorial) > ν(Cr–Cl, axial) and $\nu(N_3$, axial) > $\nu(N_3$, equatorial) are in agreement with the bond distances determined through X-ray crystallography. Complexes **1** and **3** show characteristic amide band for DMF, the solvent of crystallization, at 1650 cm^{-1}.

All the three complexes **1**, **2**, and **3** have distorted octahedral geometry (*vide infra*) having one meridionally coordinating tridentate **L** and three anions. In DMF solution,

they exhibit some of d–d transitions in the visible region and intra-ligand transitions in the UV region. The λ_{max} and their molar extinction coefficient values are listed in Table 1. Chromium(III) is a d^3 ion in a perfect octahedral geometry has $^4A_{2g}$ as its electronic ground state along with the $^4T_{2g}$, $^4T_{1g}(F)$, and $^4T_{1g}(P)$ excited states. Usually, the d–d bands originating from $^4A_{2g} \rightarrow {}^4T_{2g}$, $^4A_{2g} \rightarrow {}^4T_{1g}(F)$ fall in the visible region and $^4A_2 \rightarrow {}^4T_1(P)$ in the UV region [14]. Since these complexes has a pseudo octahedral geometry and hence lower symmetry, the splitting of the orbitally degenerate terms should be possible. Observation of three bands in the visible region is reasonable with the lower symmetry. The lowest energy band is originating from the $^4A_{2g} \rightarrow {}^4T_{2g}$ (from O_h symmetry) transition, which directly corresponds to 10Dq, follow the trend $[CrLCl_3] < [CrL(N_3)_3] < [CrL(NCS)_3]$ consistent with the spectrochemical series, $Cl^- < N_3^- < NCS^-$. The energy trends of the other transitions also follow the same order, but with a small difference.

The emission spectra of **1**, **2**, and **3** were recorded in DMF and exhibit $\pi \rightarrow \pi^*$ character; which indicates an emission from the significant intra-ligand $\pi \rightarrow \pi^*$ state at higher energy [15]. In case of **1** an excitation band with vibronic components 504 and 517 nm observed for $\lambda_{ex} =$ 450 nm. For **2**, an excitation consists of a structured band with vibronic components 350 and 360 nm observed for $\lambda_{ex} = 285$ nm. But in case of **3** there is a single emission peak at 375 nm for $\lambda_{ex} = 290$ nm.

3.3. EPR and magnetism

The EPR spectra (9.49 GHz) of **1**, **2**, and **3**, recorded at 77 K in DMF, indicate deviation from the cubic symmetry along with the zero-field splitting. The Cr^{3+}, a d^3 ion ($S = 3/2$) with a $^4A_2$ ground state, in an octahedral field has an orbitally non-degenerate ground state. The spin–orbit coupling or a low symmetry ligand field may mix the ground state with the excited states, thus giving rise to zero-field splitting. Compounds **1** and **3** appear to have larger zero-field splitting compared to **2** [16].

The spectra were investigated in terms of the conventional spin Hamiltonian operator,

$$\mathscr{H} = g|\beta|S_z B_o + D[S_z^2 - (1/3)S(S+1)] + E(S_x^2 - S_y^2)$$

where β is the Bohr magneton, B_o is the static external magnetic field, D is the axial zero-field splitting parameter, and E is the rhombic component. Fig. 1 displays the computer simulated as well as experimental EPR spectra for complexes **1**–**3**. The spin Hamiltonian parameters were determined by trial and error method and isotropic g-values were used in the simulation. Exact diagonalization of the spin Hamiltonian was used for the computer-simulation of the spectrum, from which the following parameters were extracted: for **1**: $g = 1.990$; $D = 0.034\ cm^{-1}$; $E/D = 0.30$, **2**: $g = 1.983$; $D = 0.017\ cm^{-1}$; $E/D = 0.31$, **3**: $g = 2.010$; $D = 0.031\ cm^{-1}$; $E/D = 0.23$. From these parameters it is evident that **1** and **3** have greater distortions from cubic nature as compared **2**, which is more cubic. Overall, the deviation from cubic symmetry is only marginal since $D \ll hv$, where hv is the microwave energy and these results are consistent with their molecular structures (*vide infra*). A list of zero-field splitting parameters for Cr(III) complexes based primarily on pyridine ligand are provided in Supporting information Table S1.

Table 1
UV–Vis data

Complex	λ_{max}, nm (ε, $M^{-1}\ cm^{-1}$)	
	d–d transition	ILCT
1	600(120), 450(145)[a], 425(180)[a]	340(9160), 330(9615)[a], 290(20775)
2	560(235), 445(290)[a], 420(770)[a]	350(5380)[a], 330(6570)[a], 290(17010)
3	525(155), 443(310)[a], 417(1235)[a]	350(17475), 340(18310), 290(23830)

[a] Shoulder.

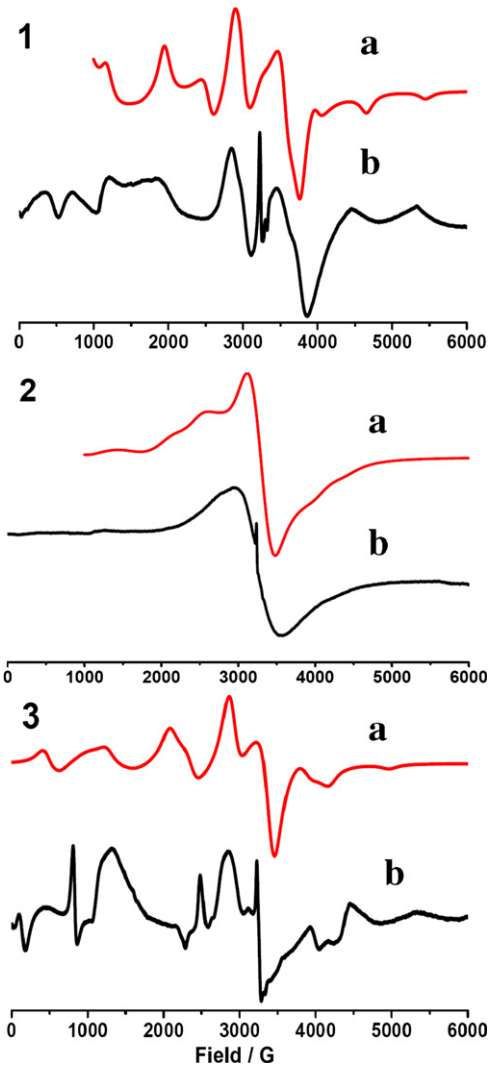

Fig. 1. EPR spectrum of **1**–**3** in DMF solution at 77 K (**a** is simulated and **b** is experimental).

The μ_{eff} values of **1**, **2**, and **3** are, respectively, 3.90, 3.72, and 3.73 B.M. and these values were calculated from the least square fitting of the initial magnetization curve ($\chi = M/H$). Only in case of **1** μ_{eff} is nearly closer to $\mu_{s.o.}$ value, where as in **2** and **3**, μ_{eff}, is slightly less than $\mu_{s.o.}$ value. In all the cases there is an increase in magnetic moment with respect to the applied magnetic field, which is a general behavior of paramagnetic substances. Only the complex **3** exhibits a distinct hysteresis loop and the coercivity loss is 570 G (Fig. 2) and the hysteresis exhibited by mononuclear complexes are reported [16e,16f].

3.4. Molecular structures

The molecular structures of $[CrLCl_3]\cdot DMF$ (**1**), $[CrL(N_3)_3]\cdot CH_3CN$ (**2**), and $[CrL(NCS)_3]\cdot DMF$ (**3**) were determined by X-ray crystallography. The crystallographic data and refinement parameters are summarized in Table 2 and selected bond parameters are listed in Tables 3 and 4. In all the three cases, Cr(III) is coordinated by three N atoms of **L** in a meridional fashion. The anions occupy the other three coordination sites completing the *mer*-N_3Cl_3 (in **1**) and *mer*-N_3N_3 (in **2** and **3**), distorted octahedral geometry.

A perspective view of **1** along with the packing diagram viewing down the a^*-axis, is shown in Fig. 3. The Cr1–N2 distance is shorter than that of Cr1–N1 and Cr1–N3 distances. This distortion, observed in 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine complexes of first-row transition metals is attributed to a more efficient overlap of metal t_{2g} orbitals with the π^* orbitals of the central pyridyl group compared to the other two pyridyl rings. The apical Cr–Cl distances are on average, 0.035(1) Å longer than the equatorial Cr1–Cl1 contact. This is due to stronger π back-bonding of **L** in the equatorial N_3Cl plane, which reduces the repulsive interaction between the lone-pair of electrons on the chlorine atom (Cl1) and the metal t_{2g} electrons. The basal plane containing N1, N2, N3, and Cl1 atoms is nearly planar as inferred from the following torsional angles

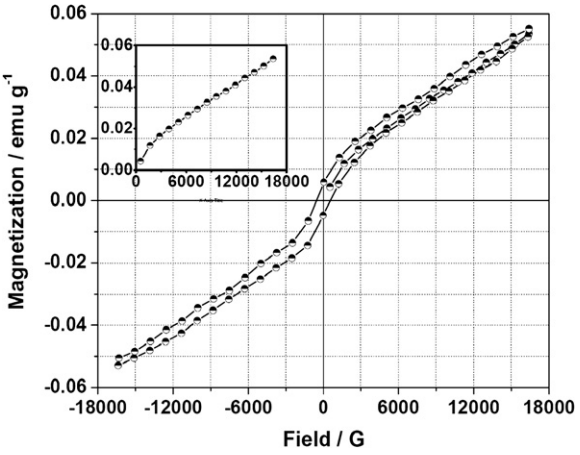

Fig. 2. Hysteresis loop and initial magnetization (inset) plot for **3**.

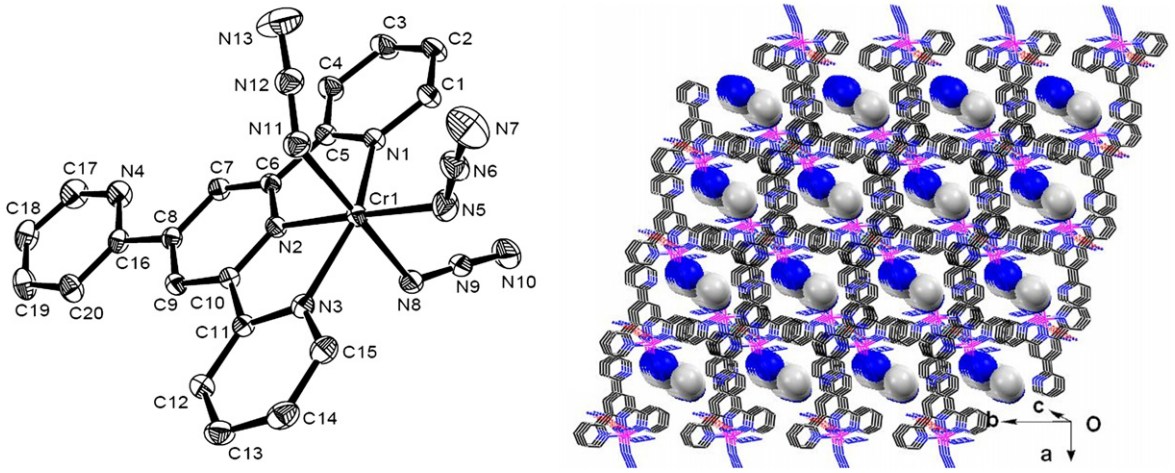

Fig. 4. ORTEP (30% probability) and packing diagram of **2**.

positions are occupied by N8 and N11. The trans-spanning Cr1–N1 and Cr1–N3 distances are longer by an average distance of 0.0755(5) Å as compared to Cr1–N2. The Cr–N(azido) apical distances are about 0.0215(5) Å longer than the equatorial one. In the crystal lattice, the molecule exists as a dimer (Fig. 5) with a non-bonded Cr···Cr distance of 6.974(1) Å. This dimeric form is generated as a result of an intermolecular interaction between the coordinated azide ligand having the non-bonded contact N8···N9 (3.086(1) Å). The molecular packing also shows the presence of π–π interaction of shortest C2···C13 contact of 3.372(1) Å along x, $+y+1$, $+z$. A channel of approximate dimension 7.818 × 8.632 Å is present along the c-axis and is occupied by the acetonitrile molecules and the equatorially coordinated azide groups. Within the azide moiety, N–N(terminal) bond is shorter by 0.048(1) Å than N–N(coordinated) and deviate from the linearity by an average of 3.29(8)°.

A perspective view of **3** along with the packing diagram viewing down the b-axis is shown in Fig. 6. The NCS^- anions bind in a monodentate end-on linear fashion. Cr^{3+} is a hard acid and NCS^- is an ambidentate base having hard-N and soft-S donor atoms. Coordination of NCS^- through N-atom is as per the HSAB principle. The basal plane is generated by N1, N2, N3, N5 and deviation from planarity is as shown by the torsional angles N2–Cr1–N1–C5, 0.40(5)°; N2–Cr1–N3–C11, 1.56(5)°; C1–N1–Cr1–N5, −8.35(7)°; C15–N3–Cr1–N5, 7.14(6)°. Cr1–N2 has a shorter distance than the trans-occupying Cr1–N1 and Cr1–N3 by an average of 0.09(3) Å. The molecular packing shows the presence of: (a) π–π interaction having shortest contact of N4···C15 of 3.247(1) Å along $-x$, $-y$, $-z$. (b) intermolecular hydrogen bonding between S3···O1 of 3.301(2) Å (c) D–H···A interaction C26–H26C···O1, 2.751(1) Å. These interactions create a channel of approximate rectangular cavity 7.913 × 20.269 Å, within which the DMF molecules are present. The central angle at NCS moiety deviates from linearity by about 3.96(4)°. The C–N(amide) length of DMF in **3** is shorter by 0.020(6) Å when compared to that in **1**. The O–C–N–C torsional angle is −0.35(10)° and 2.75(11)°, respectively, in **3** and **1**.

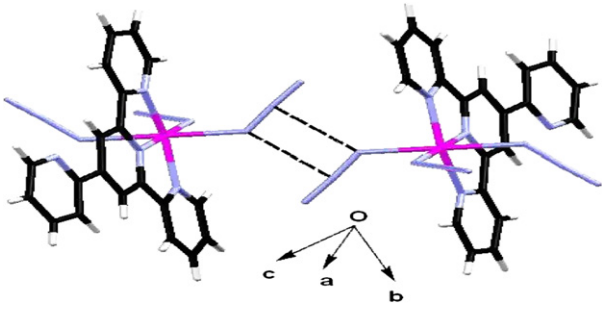

Fig. 5. Intermolecular interaction between the coordinated azide ligand in **2**.

4. Conclusion

Three complexes viz., $[CrLCl_3]\cdot DMF$ (**1**), $[CrL(N_3)_3]\cdot CH_3CN$ (**2**) and $[CrL(NCS)_3]\cdot DMF$ (**3**) were synthesized. Structural studies reveal that the Cr(III) ion is coordinated by three N atoms of **L** in a meridional fashion. The three anions occupy the other three coordination sites completing the *mer*-N_3Cl_3 (**1**) and *mer*-N_3N_3 (**2** and **3**), distorted octahedral geometry. Cr–N2 has a shorter length than the Cr–N1 and Cr–N3 distances and the order $Cr–N(NCS^-) < Cr–N(N_3^-) < Cr–Cl$ is observed. These complexes crystallize as solvate DMF (**1**, **3**) and CH_3CN (**2**) and the solvent molecules are present in the channel created by weak intermolecular forces. The complexes exhibit some of the d–d transitions in the visible and intra-ligand transitions in the UV regions. The lowest energy d–d transition follows the trend $[CrLCl_3] < [CrL(N_3)_3] < [CrL(NCS)_3]$ consistent with the spectrochemical series, $Cl^- < N_3^- < NCS^-$. In DMF, they exhibit fluorescence having $\pi \rightarrow \pi^*$ character. All the complexes show deviation from cubic symmetry as well as zero-field splitting (zfs) in X-band EPR spectra at 77 K.

complexes containing multidentate bridging ligand (e.g. COO, XCN, X = O, S, Se), the copper(II) compounds with OPO bridge for which also the magnetic interactions are reported are still rare [18–24].

It is worth emphasized that the structural and magnetic studies of binuclear and polynuclear complexes containing multidentate bridging ligands, in which such metal–metal interactions as magnetic coupling, energy or electron transfer, and intervalence transfer [25–27] may occur, are of considerable interest from the standpoint of inorganic and bio-inorganic chemistry [28–30]. Among these complexes the copper(II) compounds are of particular interest from a theoretical point of view, since they provide examples of the simplest case of magnetic interaction involving only two unpaired electrons [31–33].

In this work, we present a synthesis, the spectral and magnetic properties, and the X-ray crystal analysis of copper(II) compound with 2-mpmpe ligand of the formula $Cu_2(2\text{-mpmpe})_2(H_2O)_2(NO_3)_2$. The object of our particular interest was investigation of magnetic properties of this compound and estimation of the magnitude of the exchange interactions between copper(II) ions. It is, to the best of our knowledge, the first example structurally and magnetically characterized dinuclear copper(II) compound of phosphonate monoester bearing a heterocyclic nitrogen with phosphonate bridge. A detailed structural description as well as the magnetic behavior of the compound is presented.

2. Experimental

2.1. Reagents and physical measurements

Starting materials and solvents for the synthesis were obtained commercially and used as received. Metal content was determined using a Carl-Zeiss-Jena atomic absorption spectrophotometer. Elemental analyses were carried out using a Perkin–Elmer elemental analyzer 2400CHN.

Infrared spectra (100–4000 cm^{-1}) were recorded on a Bruker IFS 113v spectrophotometer using KBr pellets, and solid-state electronic spectra (28 000–4000 cm^{-1}) were performed on a Cary 500 spectrophotometer. Solid-state EPR spectra were recorded at room temperature and at 77 K on a Bruker ESP 300E spectrometer operating at X-band, equipped with a Bruker NMR gaussmeter ER 0.35 M and a Hewlett Packard microwave frequency counter HP 5350B. Magnetic measurements of a polycrystalline sample were carried out with a Quantum Design SQUID magnetometer (MPMSXL-5 type). The measurements were recorded at magnetic field of 0.5 T over the temperature range 1.8–300 K. The correction for diamagnetism of the experimental susceptibility was based on subtracting the sample-holder signal and estimating the contribution χ_D from Pascal constants [34]. The effective magnetic moments were calculated from $\mu_{eff} = 2.83(\chi_M T)^{1/2}$, using temperature-independent paramagnetism of 60×10^{-6} cm^3 mol^{-1} for Cu(II).

2.2. Crystal structure determination of $Cu_2(2\text{-mpmpe})_2(H_2O)_2(NO_3)_2$

X-ray data were collected at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The crystal was positioned at 65 mm from the CCD camera. Frames (612) were measured at 0.75° intervals with a counting time of 33 s. Accurate cell parameters were determined and refined by least-squares fit of 6000 the strongest reflections. Data were corrected for Lorentz and polarization effects. Analytical absorption correction was also applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) programs. The structure was solved by direct methods (program SHELXS 97 [35]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL 97 [36] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry of molecules and $\Delta\rho$ maps and were refined isotropically. Crystal data are given in Table 1, together with refinement details.

2.3. Synthesis of the ligand (2-pmpe) and $Cu_2(2\text{-mpmpe})_2(H_2O)_2(NO_3)_2$ compound

The diethyl (pyridyn-2-ylmethyl)phosphonate (2-pmpe) ligand was prepared according to the procedure described in detail elsewhere [14]. The copper compound with monoethyl (pyridyn-2-ylmethyl)phosphonate of formula $Cu_2(2\text{-mpmpe})_2(H_2O)_2(NO_3)_2$ was prepared by dissolving $Cu(NO_3)_2 \cdot 6H_2O$ (1 mmol) in warm ethanol (10 cm^3) and adding to a solution of the 2-pmpe ligand (2 mmol) in

3. Results and discussion

The title compound of formula Cu_2(2-mpmpe)$_2(H_2O)_2(NO_3)_2$ was obtained by a solvothermal reaction between $Cu(NO_3)_2 \cdot 6H_2O$ and diethyl (pyridyn-2-ylmethyl)phosphonate ligand (2-pmpe) at 80 °C. Thus, the process of a partial solvothermal hydrolysis of starting 2-pmpe ligand occurs according to the scheme (Fig. 1).

3.1. Description of the structure of Cu_2(2-mpmpe)$_2(H_2O)_2(NO_3)_2$

Crystallographic parameters of title compound are summarized in Table 1. Selected bond distances and angles are listed in Table 2.

Fig. 2 shows the structure and the labeling scheme of Cu(II) compound. As it can be seen from Fig. 2, the two Cu(II) ions, Cu(1) and Cu(1A) are connected by two OPO bridge groups creating a centrosymmetric dinuclear structure. Monoethyl (pyridyn-2-ylmethyl)phosphonate (2-mpmpe) acts as multidentate bonded ligand, chelates to the Cu(1) atom through its pyridyl nitrogen N(1), and

Symmetry transformations used to generate equivalent atoms: (i) $-x$, $-y$, $-z+1$.

phosphoryl oxygen O(1) from the P=O group, forming six-membered ring. The terminal oxygen atom O(3) from the phosphonate group bridges to Cu(1A) atom. The coordination about the copper atoms is five-coordinate. The equatorial plane is composed of the N(1), O(1) from 2-mpmpe ligand and bridging O(3A) from 2-mpmpe ligand, and O(5) from a coordinating nitrate anion with distance to Cu(1): 2.018(2), 1.9665(18), 1.9560(18), and 1.9979(18) Å, respectively, while the O(4) atom from water molecule occupy apical position with significantly longer Cu(1)–O(4) distance of 2.184(2) Å. The O(1)–Cu(1)–O(5) and O(3A)–Cu(1)–N(1) angles of the basal plane are 178.50(7)° and 161.80(8)°, respectively resulting in a τ value of 0.28 (parameter describing the degree of trigonal distortion τ is defined as $(\beta - \alpha)/60$, where β and α are the largest coordination angles). A regular trigonal-bipyramid (TBP) and square-based pyramid (SP) have τ values of 1 and 0, respectively [37]. Therefore, the geometry around Cu atoms can be better described as quite distorted square-pyramidal ($CuNO_4$ chromophore). The copper(II) centres are slightly deviated (0.154 Å) from the least-squares plane toward the axially coordinated water molecule. The least-squares planes corresponding to two nearest neighbours copper centers are parallel (dihedral angle of 0°). The nitrate anion has its expected planar trigonal geometry.

As previously noted, the two OPO phosphonate groups bridge two copper(II) ions through the O(1) and O(3) and O(1A) and O(3A) oxygen atoms of the pseudo-equatorial position on the copper(II) coordination polyhedron. The distortion of the coordination polyhedron gives rise to the formation of a chair-like eight-membered ring Cu(1)–O(1)–P(1)–O(3)–Cu(1A)–O(1A)–P(1A)–O(3A)–Cu(1) with the Cu(1)···Cu(1A) distance of 4.69 Å. This distance is near the range of reported values of ca. 5 Å observed for polyatomic bridges [38] and, hence, interesting magnetic exchange properties are anticipated (vide infra).

The most important features of the structure result from the fact that the copper(II) ions are a doubly bridged by OPO groups in μ_2-fashion to form a dinuclear structure. The O(1)–P(1)–O(3) angle is 117.60(10)° near value of 118.8(1)° observed in monoethyl (pyridyn-2-ylmethyl)phosphonate [39]. It is interesting that the bridging pathway Cu–O–P–O–Cu is asymmetric in its conformation with respect to the Cu–O–P angle and Cu–O bond length. The Cu(1)–O(1)–P(1) and Cu(1A)–O(3)–P(1) angles are 121.10(10)° and 125.41(10)°, respectively, and bond length Cu(1)–O(1) and Cu(1A)–O(3) bonds are 1.9665(18) and 1.9560(18) Å, respectively. The average C–C and C–N lengths in the pyridine ring of 1.380 Å and 1.345 Å, respectively, are typical. The lattice structure is stabilized by a complicated hydrogen-bonding 3D network (Table 3). The crystal packing is depicted in Fig. 3.

As mentioned above, two oxygen atoms of the phosphonate group are involved in the bridging as shown in Fig. 2 forming $Cu_2(–OPO–)_2$ dimeric unit. These units are further connected by two groups of H-bond: O(4) oxygen atom of the coordinated water molecule and phosphoryl oxygen

Symmetry transformations used to generate equivalent atoms:
(ii) $-x+1/2, y+1/2, -z+1/2$; (iii) $x+1, y, z$; (iv) $x-1, y, z$; (v) $x-1/2, -y+1/2, z-1/2$.

atom O(2)^{iii} of ester group OC_2H_5 and oxygens O(7)^{ii}, O(6)^{ii}, and N(2)^{ii} nitrogen atoms of nitrate group. These hydrogen bonds and additional hydrogen bonding between the aromatic C–H group of the pyridine ring and nitrate oxygen, C(2)–H(2)···O(5)^{iv}, form 2D layer network along *a* axis. The interlayer H-bond between C(6) atom of aliphatic CH_2 group and O(5)^{iv} atom of the nitrate group leads to 3D polymeric arrangement (symmetry codes are given in Table 3).

Additionally, interesting feature of the crystal structure results from the fact that the four dinuclear $Cu_2(\mu_2\text{-O})_2$ moiety are interconnected by hydrogen bonds between the aromatic C–H groups of the pyridine rings and phosphoryl oxygen of the P=O groups from adjacent dimeric unit results in the formation of $[Cu_2(\mu_2\text{-O})]_4$ hydrogen bonded ring. The regarding to observed weak C–H···O hydrogen bonds, the D···A bond distances and D–H···A angles are well within the range suggested for similar C–H···O hydrogen bonds [40]. Further examination of the structure reveals intramolecular hydrogen bonds and contacts. Details of the hydrogen bond network are given in Table 3. The shortest interdinuclear Cu···Cu separations are: Cu(1)···Cu(1)^{vi} 6.34 Å, vi $= -x+1, -y, -z+1$; Cu(1)···Cu(1)^{vii} 7.23 Å, vii $= -x+1/2, y-1/2, -z+1/2$; Cu(1)···Cu(1)^{ii} 7.52 Å, ii $= -x+1/2, y+1/2, -z+1/2$.

3.2. Spectroscopic properties

The very strong band at about 1250 cm^{-1}, which corresponds to the P=O stretching frequencies of the free ligand, in the spectrum of a studied compound is shifted by ca. 70 cm^{-1} towards lower frequency, suggesting the coordination of the phosphoryl oxygen to the metal ion. The infrared spectrum shows a very strong bands at 1314 and 1451 cm^{-1} typical for monodentate coordination of the nitrate ion ($\Delta\nu = 137\ cm^{-1}$), which is confirmed by the structure determination [41–43]. The δ(HOH) bending vibration and the O–H stretching band of coordinated water are observed at 1636 cm^{-1} and 3409 and 3539 cm^{-1}, respectively [42]. A split observed in the stretching O–H region is probably caused of the water molecule included in the strong hydrogen bond.

Ligand field spectrum shows a very broad absorption band in the visible region with two maxima centered at 14 100 and 11 100 cm^{-1}, corresponding to the d(xy), d(yz), d(zx) → d(x^2-y^2) and the d(z^2) → d(x^2-y^2) transitions, suggesting distorted square-pyramidal geometry for the copper ion [44,45], which is confirmed by the structure determination.

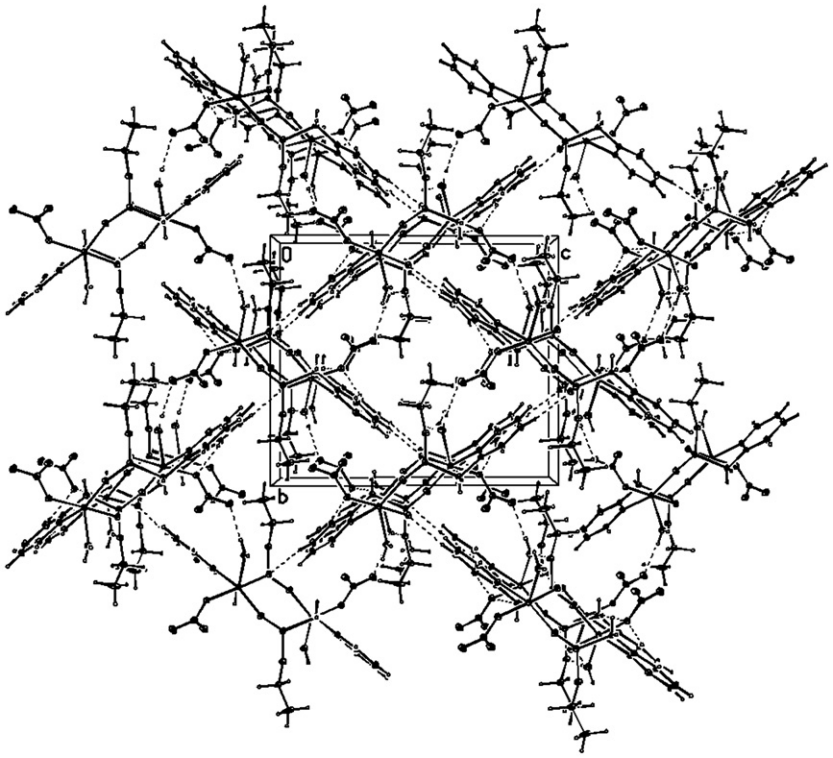

Fig. 3. Crystal packing of $Cu_2(2\text{-mpmpe})_2(H_2O)_2(NO_3)_2$ showing the 3D interdinuclear H-bonding.

The EPR X-band powder spectrum of the copper compound is of the rhombic type with g values of $g_1 = 2.27_2$, $g_2 = 2.18_8$, and $g_3 = 2.05_4$ at room temperature. The spectrum is independent of temperature.

3.3. Magnetic properties

The magnetic properties of the compound in the form of $\chi_{Cu}T$ versus temperature plots in the 1.8–300 K temperature range is shown in Fig. 4 (χ_{Cu} is the magnetic susceptibility per Cu(II) ions).

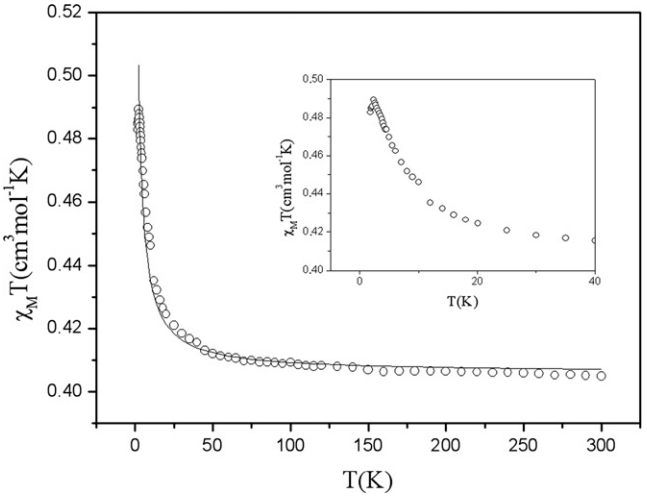

Fig. 4. Plot of $\chi_{Cu}T$ vs. temperature for $Cu_2(2\text{-mpmpe})_2(H_2O)_2(NO_3)_2$. Solid lines correspond to the best theoretical fit (see text).

The values of $\chi_{Cu}T$ at room temperature (0.405 cm^3 mol^{-1} K, $\mu_{eff} = 1.80\ \mu_B$) corresponds to one isolated copper(II) ion. However, upon cooling down, the $\chi_{Cu}T$ value increases, reaches a maximum at 2.3 K (0.489 cm^3 mol^{-1} K) and then decreases to a value of 0.483 cm^3 mol^{-1} K at 1.8 K (inset Fig. 4).

The shape of the curve is typical of intramolecular ferromagnetic coupling with the presence of intermolecular a weak antiferromagnetic interaction (J') and/or zero field splitting (D parameter) [46].

On the basis of the structural data, the magnetic experimental data were fitted using the Bleaney–Bowers equation (1) [47] to account for the ferromagnetic interaction within a dinuclear unit. The weaker interdimer antiferromagnetic exchange was introduced using the molecular field approximation (2) [48,49]:

$$\chi_{Cu} = \frac{Ng^2\beta^2}{3kT}[1 + 1/3\exp(-2J/kT)]^{-1} \quad (1)$$

$$\chi^{exp} = \frac{\chi_{Cu}}{1 - (2zJ'/Ng^2\mu_B^2)\chi_{Cu}} \quad (2)$$

where χ^{exp} is the measured magnetic susceptibility, zJ' is the interdimer exchange parameter, and z is the number of nearest neighbours. Within the frame of this approximation, with the interaction Hamiltonian $H = -J\hat{S}_1 \cdot \hat{S}_2$, the best-fit parameters obtained by least-squares fit through Eq. (2) are as follows: $J = 1.86\ cm^{-1}$, $zJ' = -0.17\ cm^{-1}$, $g = 2.075$ with R value of 6.70×10^{-6}, where R is the agreement factor defined as

$$R = \sqrt{\sum \frac{1}{(\chi_i^{exp})^2}(\chi_i^{exp} - \chi_i^{calc})^2 \Big/ \sum \frac{1}{(\chi_i^{exp})^2}}$$

The shape of the magnetization curve at 2 K does not exactly follow the Brillouin function (Fig. 5). At intermediate fields, the experimental points are above the theoretical curve, indicating weak ferromagnetic coupling. At 5 T the $M/N\beta$ value tends to 2.0, which corresponds to an $S = 1$ ground state (close saturation) [50].

3.4. Magneto-structural correlations

Inspection of the structure shows that the two exchange pathways are possible: one through Cu(1)–N(1)–C(1)–C(6)–P(1)–O(3)–Cu(1A) and the other through Cu(1)–O(1)–P(1)–O(3)–Cu(1A) phosphonate bridges with the Cu···Cu distance of 4.69 Å (path length 10.14 Å and 6.93 Å, respectively). The observed Cu···Cu distance suggests that both pathways may be operative but in former, only weak antiferromagnetic interaction is possible due to extended five-atom bridge (path length 10.14 Å). On the other hand, the O–P–O bridge is known to be efficient in transmitting weak to moderately strong antiferromagnetic and ferromagnetic exchange interaction [18–24] between two copper(II) ions. It is worth to mention here that these compounds presented in Refs. [18–24] are interesting structurally and magnetically organic–inorganic hybrid materials including inorganic phosphate, hydrogenophosphate, and pyrophosphate as bridging ligands in which magnetic interactions occur through the Cu–O–P–O–Cu pathway [18–24]. For the phosphate group (μ-OPO_3) coordination through a single oxygen atom (Cu–O–Cu) has been also obtained [18].

Among above complexes some magneto-structural correlations have been presented [18–24]. However, there is no obvious relationship between the structural parameter of the OPO bridge and the observed magnitude of the magnetic coupling exchange, often due to the complicated structures of these compounds and observed different conformation modes and structural parameters of the O–P–O triatomic bridge. It is worth to note, that within these compounds, the phosphate with the O–P–O bridge in *syn–syn* conformation has been obtained [18]. In the compound presented here, the O–P–O bridge is in *syn–anti* conformation, has not been described in literature. Because the exact bridging mode, the structural parameters of the bridge, and orbitals involved, all are responsible for the strength of magnetic exchange coupling in three atomic bridges (i.e. OCO carboxylate bridge) [50], magneto-structural correlations for phosphate bridging complexes [18–24] including of the title compound are not possible.

The influence of stereochemical and electronic features of the phosphonate bridge on the magnetic properties in our compounds is discussed below.

The OPO bridge in our compound indicates certain structural similarity to a *syn–anti* carboxylate group OCO, substituting the carbon atom from the carboxylate by phosphorous atom, because both indicate delocalized character (Fig. 6). Examination of the magneto-structural data of well-characterized copper(II) complexes in which the carboxylate adopts the *syn–anti* conformation [51,52] indicates that weak ferromagnetic or antiferromagnetic coupling depends on the structural features of the Cu–O–C–O–Cu bridge, the coordination geometry of the exchange-coupled copper ions, and the relative position of the carboxylate bridge with respect to the copper(II) ions: equatorial–equatorial (weak antiferromagnetic interaction), equatorial–apical (weak ferromagnetic interaction) and apical–apical (negligible interaction). These features decide of overlap of magnetic orbitals, thus of sign and magnitude of exchange interactions according to the concept of the overlap of magnetic orbitals developed by Kahn [53] and Alvarez [54]. On the other hand, some structural features of the bridging network would reduce the antiferromagnetic contribution according to Khan's model in which the exchange coupling constant J, is sum of both ferromagnetic (J_F) and antiferromagnetic (J_{AF}) contributions $J = J_F + J_{AF}$ and J_{AF} is sensitive on structural features of the bridging network.

As recently indicated [51,52], ferromagnetic coupling in the *syn–anti* carboxylato-bridged copper(II) compounds has been observed in the light of the following electronic and structural features: conformation of the carboxylate group, asymmetry with respect to the Cu–O bond, non-pla-

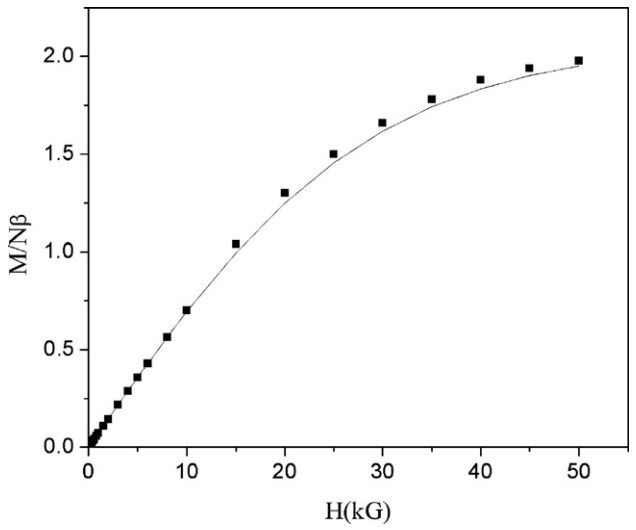

Fig. 5. Molar magnetization in $N\mu_\beta$ units of Cu_2(2-mpmpe)$_2$(-$H_2O)_2(NO_3)_2$ measured at 2 K as a function of magnetic field. The solid line represents the Brillouin function assuming $g = 2.075$ (the value of the fit).

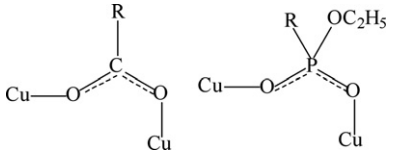

Fig. 6. Scheme of the carboxylate (OCO) and the phosphonate (OPO) bridges.

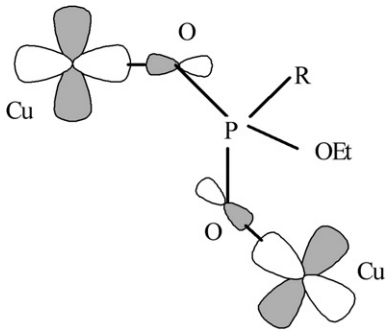

Fig. 7. Relative orientation of the copper(II) magnetic orbitals and their interaction through the phosphonate bridge with *syn–anti* conformation.

narity of the Cu–O–C–O–Cu bridging network and low symmetry of the chromophore.

As it was mentioned previously, the geometry around Cu atom in the studied compound is a distorted square-pyramidal ($\tau = 0.28$). The magnetic orbital on each copper atom is predominantly of the $d(x^2 - y^2)$ with some admixture of dz^2. Thus, both magnetic orbitals on Cu(1) and Cu(1A) are delocalized toward the 2p oxygen orbitals of the OPO bridge (Fig. 7) and, then, the exchange coupling through the phosphonate groups might be operative suggests the weak antiferromagnetic exchange coupling in contrary to the observed ferromagnetic interaction.

However, the overlap between the two non-coplanar copper centered magnetic orbital through the pseudo-equatorial O(1)–P(1)–O(3) and O(1A)–P(1A)–O(3A) bridging network cause that the exchange coupling through the phosphonate group to be less operative in comparison with the square-planar geometry, with the phosphonate group bridging two strictly equatorial positions at copper ions. In this case, the conformation is not planar reducing the antiferromagnetic coupling.

In the light of the above consideration, we can expect a weak ferromagnetic coupling through the O–P–O bridge in our compound, similar to that created by the *syn–anti* carboxylate bridge in the light of the following electronic and structural features: (i) conformation of the phosphonate group; (ii) non-planarity of the Cu–O–P–O–Cu bridging network (out-of-phase exchange pathway), thus reducing the antiferromagnetic contribution (iii) asymmetry with respect to the Cu–O bond (see Section 3.1). Additionally, the higher electronegativity of the phosphorous atom in comparison to the carbon atom and presence of the oxygen atom of OEt group could reduce of the antiferromagnetic contribution to such extent that the ferromagnetic one would become predominant as it is observed in our compound.

4. Conclusions

In this paper, we have discussed the synthesis, crystal structure, and magnetic behavior of the Cu(II) compound with monoethyl (pyridyn-2-ylmethyl)phosphonate ligand of the formula $Cu_2(2\text{-mpmpe})_2(H_2O)_2(NO_3)_2$. This complex is the first example of ferromagnetically coupled dinuclear copper(II) organophosphonate compound in which copper ions are double bridged by the OPO from phosphonate groups. To the best of our knowledge, the OPO bridging group in *syn–anti* conformation, has not reported in literature yet. The structure is extended to supramolecular 3D network. Interesting feature of the crystal structure results from the fact that the four dinuclear $Cu_2(\mu_2\text{-O})_2$ moiety are interconnected by hydrogen bonds between the aromatic C–H groups of the pyridine rings and phosphoryl oxygen of the P=O groups from adjacent dimeric unit results in the formation of $[Cu_2(\mu_2\text{-O})]_4$ hydrogen bonded ring. This cyclic motif is novel in supramolecular chemistry.

Variable temperature magnetic study shows the existence of dominant ferromagnetic interaction in the compound. The magnetic data were fitted using both intradinuclear and interdinuclear ($J = 1.86\ cm^{-1}$, $zJ' = -0.17\ cm^{-1}$) interactions. Another possible very weak antiferromagnetic contribution to J (pathway Cu–N–C–C–P–O–Cu) has been negligible due to the lack of a model including this interaction.

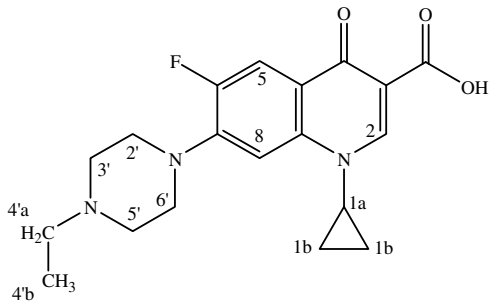

Fig. 1. Enrofloxacin (Herx = 1-cyclopropyl-7-(4-ethyl-piperazin-1-yl)-6-fluoro-4-oxo-1,4-dihydro-quinoline-3-carboxylic acid) and H atom labeling.

ation quinolone enrofloxacin in order to study the mode of coordination and the biological properties of the resultant complexes. More specifically, the binary complexes of enrofloxacin with Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Zn^{2+}, Cd^{2+} and UO_2^{2+} have been synthesized and characterized with elemental analysis and infrared (IR), UV–Visible (UV–Vis) and nuclear magnetic resonance (NMR) spectroscopies. Molecular modeling techniques have been employed to assess the lowest energy model structure of the Mn^{2+}, Fe^{3+} and UO_2^{2+} complexes. The interaction of the complexes with calf-thymus (CT) DNA has been investigated with UV and circular dichroism (CD) spectroscopy. The biological activity of the complexes has been evaluated by determining the minimum inhibitory concentration (MIC) against three microorganisms.

2. Experimental

2.1. Materials

Enrofloxacin and CT DNA were purchased from Sigma, NaCl was purchased from Merck, trisodium citrate was purchased from Riedel-de Haen, $MnCl_2 \cdot 4H_2O$, $FeCl_3 \cdot 3H_2O$, $CoCl_2 \cdot 6H_2O$, $NiCl_2 \cdot 6H_2O$, $ZnCl_2$, $CdCl_2 \cdot 2.5H_2O$, $UO_2(NO_3)_2 \cdot 6H_2O$, KOH and all the solvents were purchased from Aldrich Co. Tryptone and yeast extract were purchased from Oxoid (Unipath, Hampshire, UK). All the chemicals and solvents were reagent grade and were used as purchased.

DNA stock solutions (5 mM) were prepared by dilution of CT DNA to buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) followed by exhaustive stirring at 4 °C for three days [29], and kept at 4 °C for no longer than a week. The nucleotide concentrations were determined by their absorption at 260 nm using $\varepsilon = 6600$ $M^{-1}\,cm^{-1}$ (expressed as phosphate) [30].

2.2. Synthesis of the complexes

2.2.1. $Mn(erx)_2(H_2O)_2$ (**1**)

A methanolic solution (10 mL) of enrofloxacin (0.6 mmol, 216 mg), deprotonated with KOH (0.6 mmol, 34 mg), was added to a methanolic solution (10 mL) of $MnCl_2 \cdot 4H_2O$ (0.3 mmol, 60 mg) and the reaction mixture was refluxed for 2 h. The solution was filtered and left for slow evaporation. After a few days a light yellow microcrystalline product was deposited, collected with filtration, washed with methanol and dried. Yield: 180 mg, 75%. *Anal.* Calc. for $Mn(erx)_2(H_2O)_2$ ($C_{38}H_{46}N_6O_8F_2Mn$) ($M_W = 807.75$): C, 56.51; H, 5.74; N, 10.40. Found: C, 56.19; H, 5.57; N, 10.47%. The complex is soluble in dmso, dmf and H_2O and is non-electrolyte.

In a similar way, complexes **2**–**7** were prepared with the use of the corresponding metal salt. All the resultant complexes are non-electrolytes.

2.2.2. $Fe(erx)_3$ (**2**)

$FeCl_3 \cdot 3H_2O$ (0.2 mmol, 44 mg) was used. A yellow microcrystalline product was collected. Yield: 147 mg, 65%. *Anal.* Calc. for $Fe(erx)_3$ ($C_{57}H_{63}N_9O_9F_3Fe$) ($M_W = 1131.01$): C, 60.53; H, 5.61; N, 11.15. Found: C, 60.41; H, 5.78; N, 11.29%. The complex is soluble in dmso, dmf and H_2O.

2.2.3. $Co(erx)_2(H_2O)_2$ (**3**)

$CoCl_2 \cdot 6H_2O$ (0.3 mmol, 72 mg) was used. A yellow microcrystalline product was collected. Yield: 170 mg, 70%. *Anal.* Calc. for $Co(erx)_2(H_2O)_2$ ($C_{38}H_{46}N_6O_8F_2Co$) ($M_W = 811.75$): C, 56.23; H, 5.71; N, 10.35. Found: C, 56.05; H, 5.61; N, 10.32%. The complex is soluble in dmso, dmf and H_2O.

2.2.4. $Ni(erx)_2(H_2O)_2$ (**4**)

$NiCl_2 \cdot 6H_2O$ (0.3 mmol, 72 mg) was used. A pale green microcrystalline product was collected. Yield: 145 mg, 60%. *Anal.* Calc. for $Ni(erx)_2(H_2O)_2$ ($C_{38}H_{46}N_6O_8F_2Ni$) ($M_W = 811.53$): C, 56.24; H, 5.71; N, 10.35. Found: C, 55.89; H, 5.52; N, 10.17%. The complex is soluble in dmso, dmf and H_2O.

2.2.5. $Zn(erx)_2(H_2O)_2$ (**5**)

$ZnCl_2$ (0.3 mmol, 42 mg) was used. A pale yellow microcrystalline product was collected. Yield: 160 mg, 65%. *Anal.* Calc. for $Zn(erx)_2(H_2O)_2$ ($C_{38}H_{46}N_6O_8F_2Zn$) ($M_W = 818.20$): C, 55.78; H, 5.67; N, 10.27. Found: C, 55.92; H, 5.47; N, 10.08%. The complex is soluble in dmso and dmf.

2.2.6. $Cd(erx)_2(H_2O)_2$ (**6**)

$CdCl_2 \cdot 2.5H_2O$ (0.3 mmol, 69 mg) was used. A white microcrystalline product was collected. Yield: 155 mg, 60%. *Anal.* Calc. for $Cd(erx)_2(H_2O)_2$ ($C_{38}H_{46}N_6O_8F_2Cd$) ($M_W = 865.23$): C, 52.75; H, 5.36; N, 9.71. Found: C, 52.39; H, 5.27; N, 9.45%. The complex is soluble in dmso and dmf.

2.2.7. $UO_2(erx)_2$ (**7**)

$UO_2(NO_3)_2 \cdot 6H_2O$ (0.3 mmol, 150 mg) was used. A yellow microcrystalline product was collected. Yield: 180 mg, 60%. *Anal.* Calc. for $UO_2(erx)_2$ ($C_{38}H_{42}N_6O_8F_2U$)

($M_W = 986.80$): C, 46.25; H, 4.29; N, 8.52. Found: C, 45.87; H, 4.10; N, 8.37%. The complex is soluble in dmso and dmf.

2.3. Instrumentation

IR spectra (400–4000 cm^{-1}) were recorded on a Nicolet Magna-IR 550 with samples prepared as KBr pellets. UV–Vis spectra were recorded as nujol mulls and in solution at concentrations in the range 10^{-5}–2×10^{-3} M on a Thermo Electron Corporation Helios α dual beam spectrophotometer. C, H and N elemental analysis were performed on a Perkin–Elmer 240B elemental analyzer. Electric conductance measurements were carried out with a WTW model LF 530 conductivity outfit and a type C cell, which had a cell constant of 0.996. NMR spectra were recorded with a Bruker Avance 500 MHz instrument and were processed by X-WIN NMR 2.6 (Bruker Analytik GmbH).

The interaction of the complexes with CT DNA has been investigated with UV and CD spectroscopies. In both techniques, the spectra of CT DNA in the presence of each complex have been recorded for a constant CT DNA concentration (3.125×10^{-4} M) in diverse [complex]/[CT DNA] mixing ratios (r). All the UV and CD spectra were recorded after incubation of the sample with CT DNA for 24 h at 37 °C.

The CD spectra were recorded on a Jasco J-700 spectropolarimeter using a 1.0 cm path quartz cell and the following acquisition parameters: $\lambda = 190$–400 nm, scan speed 50 nm min^{-1}, resolution step 0.2 nm, sensitivity 50 mdeg, response 1 s, bandwidth 1.0 nm, accumulations 10. In some cases, the spectra were averaged over an appropriate number of scans.

2.4. Molecular modeling

Although diverse crystallization techniques were employed, we did not manage to obtain a crystal suitable for the structure determination with X-ray crystallography.

With the aim to present a molecular model for each new complex that is unbiased by the starting structure, we have used Langevin dynamics with a simulated annealing protocol. Using this method, the mean total energy of an ensemble of structures guides the selection of the most favorable configuration for each complex. Starting structures were constructed using the program HYPERCHEM and the MM+ force field that is based on the Allinger's MM2 force field [31]. For all the metal ions, we used a default parameter set with $R^* = 2.20$ Å and $e^* = 0.02$ kcal mol^{-1}, since the van der Waals interactions are not expected to play a major role in such bonded representations as in octahedral complexes. Metal–ligand bond lengths were corrected in the final models using harmonic restraints with equilibrium values that were extracted from crystallographic data of similar compounds [32–45] (Tables S1, S3 and S5). Non-bonded interactions were calculated in vacuo with no cutoff and the electrostatic energy term was treated using bond dipoles. Initial energy minimizations were carried out by a conjugate gradient method with rms gradient <0.01 as convergence criterion.

Each model (Schemes S1–S3) was subjected to 20 individual rounds of simulated annealing setting different value to the seed for the assignment of the starting velocities. To integrate the Langevin equation [46] the step size was set to 1 fs and the collision frequency to 1 ps^{-1}. The annealing calculation comprised three phases: (i) raising the temperature of the system from 10 to 1000 K over 2 ps, (ii) keeping the system at 1000 K for 3 ps and (iii) cooling the system down to 0 K over 15 ps. A tight coupling of the system with temperature (0.1 ps) was used for the heating and equilibration phases. During the cooling phase the bath relaxation time was gradually decreased from 5.0 ps (7000 steps), 2.0 ps (3000 steps), 1.0 ps (2000 steps), 0.5 ps (2000 steps) to 0.05 ps (1000 steps). At the final step all structures had rms gradient <0.01 and their total energy was recorded (Tables S2, S4 and S6). The models presented herein were selected among the lowest energy structures generated for each starting geometry. A final minimization of their energy was performed as above after applying the metal–ligand distance restraints.

2.5. Antibacterial activity – minimum inhibitory concentration

The antibacterial activity of the compounds (ligand and complexes) was studied against *Staphylococcus aureus* (*S. aureus*), *Escherichia coli* (*E. coli*) and *Pseudomonas aeruginosa* (*P. aeruginosa*). The microorganisms were generously supplied from the laboratory of Dr. I. Eskioglou, Department of Medical Laboratories, Technological and Educational Institution of Larissa, Greece and were maintained in the laboratory of "Chemical Biology" of NCSR "Demokritos". Screening was performed by determining the MIC. Two different media [Luria broth medium (=LB, containing 1% w/v tryptone, 0.5% w/v NaCl and 0.5% w/v yeast extract) and minimal medium salts broth (=MMS, containing 1.5% w/v glucose, 0.5% w/v NH_4Cl, 0.5% w/v K_2HPO_4, 0.1% w/v NaCl, 0.01% w/v $MgSO_4 \cdot 7H_2O$ and 0.1% w/v yeast extract)] were used. The compounds were dissolved in distilled water with twofold serial dilutions from 8 to 0.125 μg mL^{-1}. All cultures were incubated at 37 °C. Control tests with no active ingredients were also performed.

MIC was determined using twofold serial dilutions in liquid media containing 0.125–8 μg mL^{-1} of the compound being tested. A preculture of bacteria was grown in LB overnight at the optimal temperature of each species. Two mL of MMS were inoculated with 20 mL of this preculture. This culture was used as a control to examine if the growth of the bacteria tested is normal. In a similar second culture, 20 μL of the bacteria as well as the tested compound at the desired concentration were added. A third sample containing 2 mL MMS supplemented with the same compound concentration was used as a second control to

check the effect of the compound on MMS. All samples were measured in duplicate. We monitored bacterial growth by measuring the turbidity of the culture after 12 and 24 h. If a certain concentration of a compound inhibited bacterial growth, half the concentration of the compound was tested. This procedure was carried on to a concentration where bacteria grow normally. The lowest concentration that inhibited bacterial growth was determined as the MIC value. All the equipment and culture media were sterile.

3. Results and discussion

3.1. Synthesis and spectroscopic study of the complexes

All the complexes have been prepared in high yield (60–75%) via the addition of methanolic solution of deprotonated enrofloxacin to a methanolic solution of the metal ion at a 3:1 ratio for Fe^{3+} and 2:1 for the divalent metal ions.

In Table 1, the characteristic absorptions of the IR spectra of the complexes are listed. In the IR spectra of complexes **1**–**7**, the absorption at 1733 cm^{-1} in the spectrum of Herx attributed to the absorption of the $\nu(C{=}O)_{carb}$ has disappeared. Two very strong characteristic bands are present in the range 1595–1605 cm^{-1} and 1380–1395 cm^{-1} that could be assigned as ν(O–C–O) asymmetric and symmetric stretching vibrations, respectively, whereas $\nu(C{=}O)_p$ is shifted from 1622 cm^{-1} up to 1633 cm^{-1} upon bonding. The Δ values ($\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$, a useful characteristic for determining the coordination mode of the ligands) fall in the range 208–224 cm^{-1} indicating a monodentate coordination mode of the carboxylato group [47] of the enrofloxacinato ligands. These changes in the IR spectra suggest that enrofloxacin is coordinated to the metal via the pyridone (O_p) and one carboxylate (O_c) oxygen atoms [1,15].

Additionally, the band in the range 3405–3420 cm^{-1} in the IR spectra of complexes **1** and **3**–**6** can be attributed to ν(O–H) vibration of the coordinated water molecules [20,47].

The UV–Vis spectra of the complexes have been recorded as nujol mulls and in dmso solution. Practically, the spectra in dmso solution are identical with those in nujol, with the exception of a few nm shifts in some cases, suggesting that the complexes retain their structure in solution. The UV–Vis spectral data for the complexes in dmso solution are given in Table 2.

The UV spectra of the complexes are practically identical with those of enrofloxacin but slightly shifted, indicative of coordination through the O_p and one O_c atoms.

In the visible spectra, characteristic bands attributed to d–d transitions are observed only for the Fe^{3+}, Co^{2+} and Ni^{2+} complexes.

The spectrum of $Fe(erx)_3$ exhibits two bands that can be attributed to d–d transitions: one weak band (as a shoulder) at 610 nm ($\varepsilon = 40\ M^{-1}\ cm^{-1}$) which can be assigned as a $^6A_{1g} \rightarrow {}^5T_{1g}$ transition and an intense one at $\lambda = 505$ nm ($\varepsilon = 75\ M^{-1}\ cm^{-1}$) assigned as a $^6A_{1g} \rightarrow T_{2g}$ (G) transition. These bands are typical for distorted octahedral Fe^{3+} [39–42] complexes.

In the spectra of $Co(erx)_2(H_2O)_2$ and $Ni(erx)_2(H_2O)_2$ one band at 555 nm ($\varepsilon = 35\ M^{-1}\ cm^{-1}$) for **3** and 640 nm ($\varepsilon = 45\ M^{-1}\ cm^{-1}$) for **4** attributed to d–d transition has been observed, as it is expected for octahedral high-spin Co^{2+} [48,49] and Ni^{2+} [50,51] complexes. Similar behavior

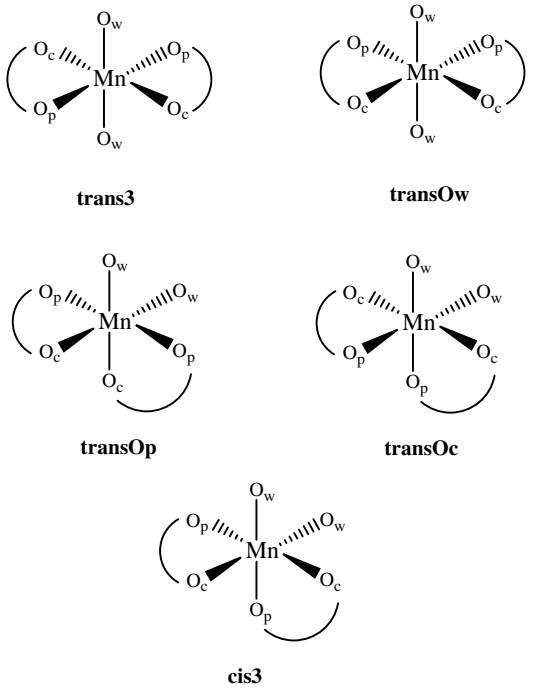
[a] Numbering of protons according to Fig. 1.

has been also observed for the octahedral high-spin Co^{2+} [52] and Ni^{2+} [53] cinoxacin complexes.

Additionally, all complexes also exhibit an absorption band (as a shoulder) at 430–435 nm ($\varepsilon = 155$–$190\ M^{-1}\ cm^{-1}$) which can be assigned to the ligand-to-metal charge-transfer transition for the quinolone ligand, as observed in a series of quinolone binary complexes [15–28].

^{1}H NMR spectra of Herx, $Zn(erx)_2(H_2O)_2$, $Cd(erx)_2(H_2O)_2$ and $UO_2(erx)_2$ were recorded in d_6-dmso. Full assignment of every signal in the ^{1}H NMR spectrum of complexes **5**–**7** was achieved by comparing the spectrum of each complex with the spectrum of the ligand and the spectra reported in the literature [20–23,26]. The results are shown in Table 3.

Comparison of the ^{1}H NMR spectra of $Zn(erx)_2(H_2O)_2$, $Cd(erx)_2(H_2O)_2$ and $UO_2(erx)_2$ with that of Herx shows a significant perturbation of the chemical shifts of the aromatic protons H2 (up to 0.3 ppm) and H5 (up to 0.4 ppm) indicating that H2 and H5 are adjacent to the coordination sites of the ligand. The signals for the aliphatic protons H1a and H1b as well as those of H8 and the piperazine ring protons (perturbations of the chemical shifts up to 0.1 ppm) are practically unchanged since they lie further than H2 and H5 from the binding site. The overall changes of the NMR spectra of the complexes are indicative of coordination of the enrofloxacinato ligands to the metal via the pyridone oxygen and one carboxylate oxygen [20–23,26].



3.2. Molecular dynamics

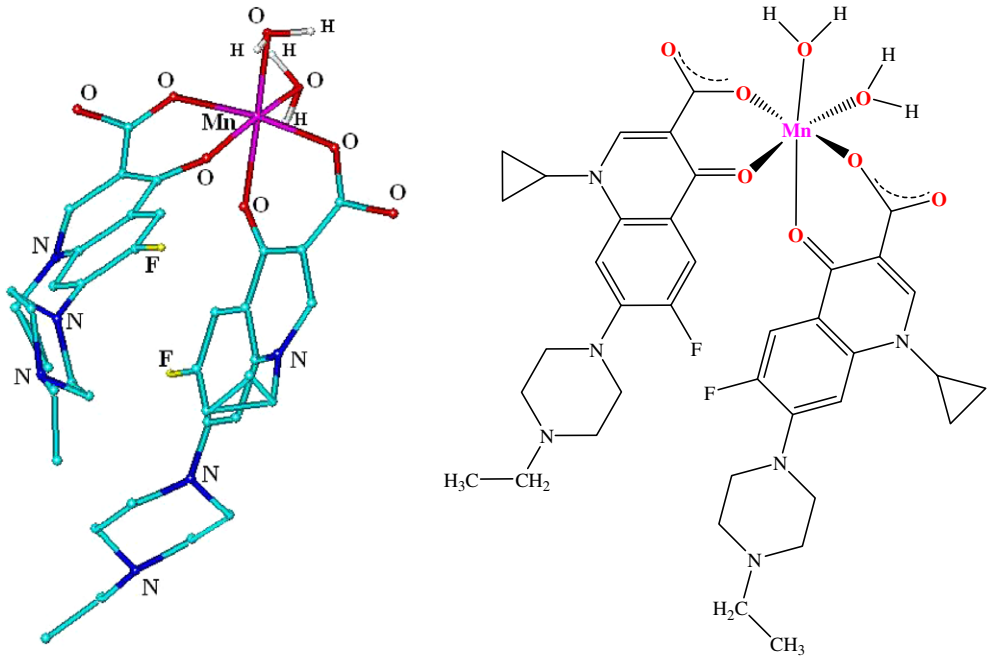
Diverse crystallization techniques were employed in order to obtain a crystal suitable for the structure determination with X-ray crystallography. Nevertheless, all the complexes were collected as microcrystalline products. In order to propose a possible structure for the complexes, the lowest energy model structures of $Mn(erx)_2(H_2O)_2$, $Fe(erx)_3$ and $UO_2(erx)_2$ have been determined with molecular modeling calculations.

3.2.1. $Mn(erx)_2(H_2O)_2$

We have constructed 10 diastereoisomers as starting models of $Mn(erx)_2(H_2O)_2$ (Scheme S1). The total number of all the possible diastereoisomers could not be limited since, according to similar Mn(II) complexes reported in the literature, the two Ow atoms can lie either at *trans* [33–35] or at *cis* [36–38] positions. After the Langevin dynamics simulated annealing calculations, we obtained the total energy results of 20 different conformations for each starting model (Table S2). The average energy of each set of enantiomers is almost equal, as it is expected from such molecular mechanics calculations [54]. However, the final structures of the *transOc* isomers (Scheme1) exhibit lower average energies by more than 1.0 kcal mol^{-1} than the other four isomers (*cis3*, *trans3*, *transOp* and *transOw*).

Applying the distance restraints (Table S1) to M–L bonds [32–38] for the *transOc* model with the lowest energy and making corrections of the geometry by minimizing the energy of the complex once again, the structure of the predicted most stable isomer (a *transOc* isomer) has been obtained (Fig. 2). However, we cannot exclude the formation of any of the other isomers.

Scheme 1. The isomers of $Mn(erx)_2(H_2O)_2$ employed in the simulated annealing calculations. Oc and Op are the carboxylate and the pyridone oxygen atoms, respectively, of enrofloxacin.



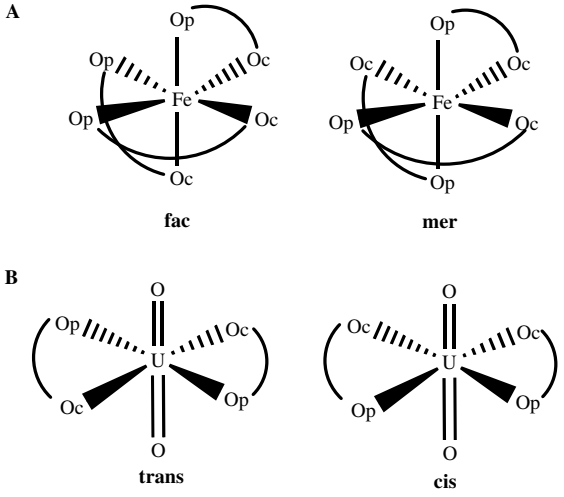


Fig. 2. Lowest model structure for $Mn(erx)_2(H_2O)_2$.

Scheme 2. The isomers of (A) $Fe(erx)_3$ and (B) $UO_2(erx)_2$ employed in the simulated annealing calculations. Oc and Op are the carboxylate and the pyridone oxygen atoms, respectively, of enrofloxacin.

3.2.2. $Fe(erx)_3$

In order to present a model for the complex, we have constructed the two *fac*- and the two *mer*-$Fe(erx)_3$ enantiomers (Scheme S2). The average energy of each set of enantiomers is almost equal (Table S4), as it is expected from such molecular mechanics calculations [54]. However, the final structures of *mer*-$Fe(erx)_3$ (Scheme2A) exhibit lower energies by more than 1 kcal mol^{-1} in comparison to the energies of the *fac* isomers.

For the *mer* models we have applied a set of harmonic restraints at the metal–ligand bonds [39–42] during an additional minimization phase (Table S3). Based on these results, we present the lowest energy model of one *mer*-$Fe(erx)_3$ enantiomer as the favorable configuration of the complex (Fig. 3). However, we can neither exclude the formation of any of the other isomers, nor unambiguously distinguish between the favorable enantiomers.

3.2.3. $UO_2(erx)_2$

Using the same approach as above, only the enantiomers having the two uranyl oxygen atoms at *trans* position were constructed as starting models of $UO_2(erx)_2$ (Scheme S3). This is in accordance with the structure of all the uranyl(VI) complexes reported in the literature [43–45]. After the Langevin dynamics simulated annealing calculations, we obtained the total energy results of 20 different conformations for each starting model (Table S6). The average energy of the isomers is almost equal, as expected [54]. Nevertheless, the *trans* isomers exhibit lower energy than the *cis* ones by more than 0.5 kcal mol^{-1}, which guide us to select the *trans* isomers (Scheme2B) as the most favorable.

Applying the distance restraints (Table S5) to M–L bonds [43–45] for the *trans* model with the lowest energy and making corrections of the geometry by minimizing the energy of the complex once again, the structure of the predicted most stable isomer (a *trans* isomer) has been obtained (Fig. 4). However, we cannot exclude the formation of the *cis* isomers, or distinguish unambiguously between the favorable enantiomers.

3.3. Antibacterial activity

The efficiencies of the ligand and the complexes have been tested against two Gram(−), *E. coli* and *P. aeruginosa*,

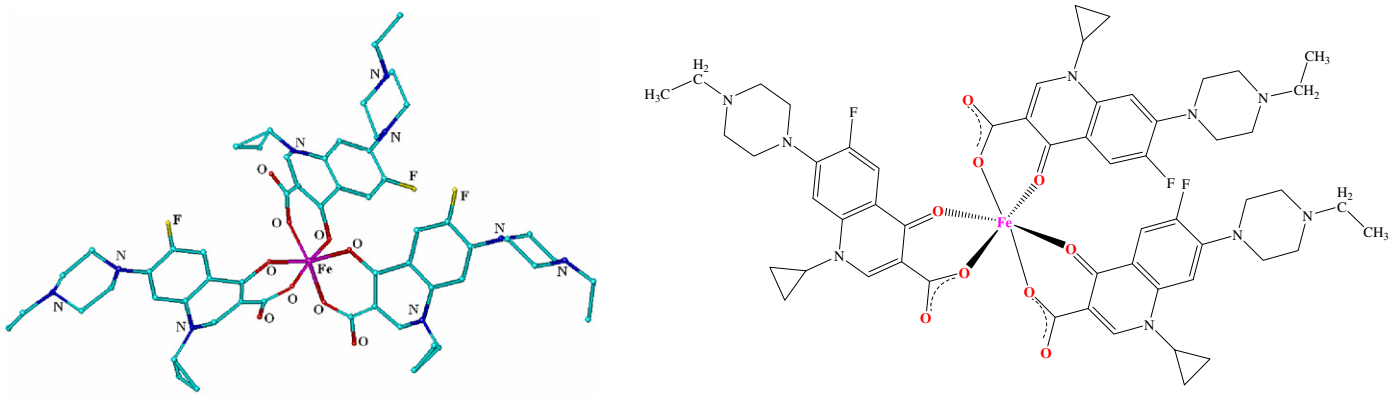

Fig. 3. Lowest model structure for $Fe(erx)_3$.

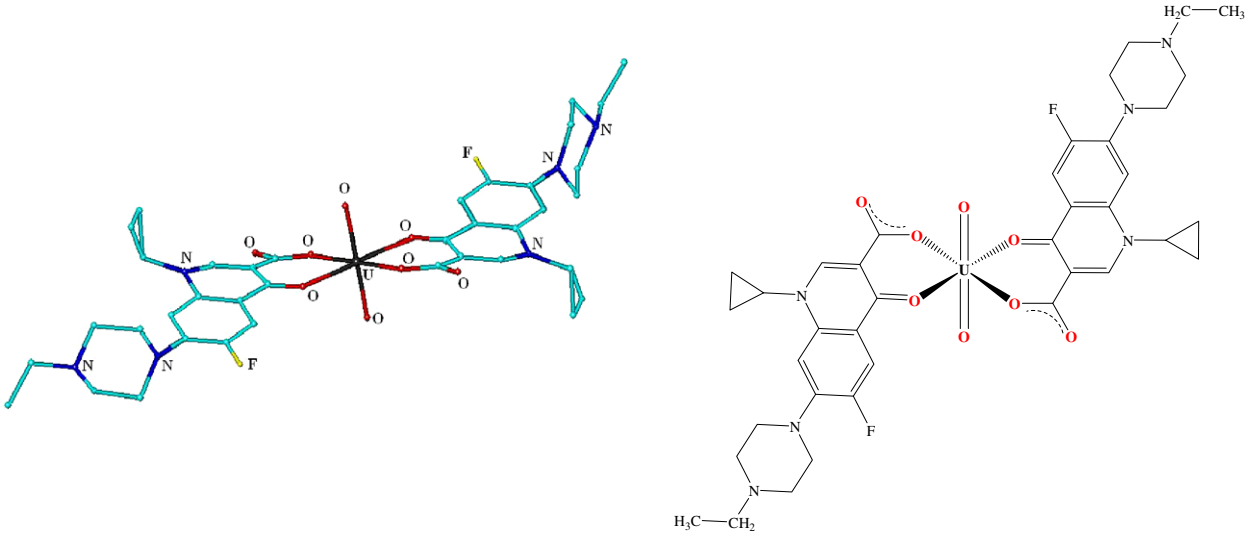

Fig. 4. Lowest model structure for $UO_2(erx)_2$.

and one Gram(+), *S. aureus*, microorganisms. The results are presented in Table 4.

The ligand and the complexes present inhibitory action against all the microorganisms tested (Table 4) and the coordination of enrofloxacin (MIC = 1–8 μg mL^{-1}) with transition metal ions results to an enhanced biological activity (MIC for the complexes = 0.25–4 μg mL^{-1}). The antimicrobial activity of the metal salts has also been investigated. It has been found that the metal salts do not exhibit antimicrobial activity, at the concentration range used to assay the activity of the complexes in this work. The MIC values found for the complexes are low and can be mainly attributed to the existence of the enrofloxacinato ligands in the molecule.

When the antimicrobial activity of metal complexes is investigated, the following principal factors [55–58] should be considered: (i) the chelate effect of the ligands; (ii) the nature of the N-donor ligands; (iii) the total charge of the complex; (iv) the existence and the nature of the ion neutralizing the ionic complex and (v) the nuclearity of the metal center in the complex. For complexes **1**–**7**, only the first factor is present, i.e. the chelate effect of the ligand. This is probably one of the reasons for the diverse antibacterial activity shown by the complexes while the nature of the metal ion coordinated to enrofloxacinato ligand may have a significant role to this diversity.

In general, all the complexes exhibit better inhibition than free enrofloxacin against *S. aureus* and equal or better

Table 4
MIC in μg mL^{-1}

	E. coli	*P. aeruginosa*	*S. aureus*
Herx	1.0	1.0	8.0
$Mn(erx)_2(H_2O)_2$	1.0	1.0	8.0
$Fe(erx)_3$	0.25	0.25	2.0
$Co(erx)_2(H_2O)_2$	1.0	1.0	2.0
$Ni(erx)_2(H_2O)_2$	1.0	1.0	8.0
$Zn(erx)_2(H_2O)_2$	1.0	1.0	2.0
$Cd(erx)_2(H_2O)_2$	1.0	1.0	8.0
$UO_2(erx)_2$	1.0	1.0	8.0
$VO(erx)_2(H_2O)$ [21]	4.0	4.0	8.0
$Cu(erx)_2(H_2O)$ [15]	0.125	0.125	4.0
$MoO_2(erx)_2$ [26]	1.0	1.0	4.0

inhibition against *E. coli* and *P. aeruginosa* (Table 4). More specifically, $Fe(erx)_3$ shows the best inhibition among all the complexes in this study and it is four times more active than enrofloxacin against all the microorganisms used, indicating that the coordination of the enrofloxacinato ligand to Fe^{3+} has enhanced its antimicrobial activity. On the other hand, the rest complexes present equal antimicrobial activity to enrofloxacin against the two Gram(−) microorganisms while they are two to four times more active than enrofloxacin against *S. aureus*. Nevertheless, the best inhibition among all the enrofloxacinato complexes reported has been provided by $Cu(erx)_2(H_2O)$ ($MIC = 0.125\ \mu g\ mL^{-1}$) [15,28] against the two Gram(−) microorganisms (Table 4).

3.4. Interaction of the complexes with DNA

DNA can provide three distinctive binding sites for quinolone metal complexes; namely, groove binding, binding to phosphate group and intercalation [59,60]. This behavior is of great importance with regard to the relevant biological role of quinolone antibiotics in the body [61,62].

3.4.1. UV spectroscopy

The absorption spectra of the interaction of complexes **1**–**7** with CT DNA have been recorded for a constant CT DNA concentration (3.125×10^{-4} M) in different [complex]/[CT DNA] mixing ratios (r). Representative spectra are shown in Fig. 5. The changes observed (either the increase of the intensity at $\lambda_{max} = 258$ nm or the shift of the λ_{max} up to 265 nm) in the UV spectra of the complexes after mixing with CT DNA indicate that complexes **1**–**7** can bind to CT DNA [63,64] and the interaction of each complex with CT DNA takes place by a direct formation of a new complex with double-helical CT DNA [62].

3.4.2. CD spectroscopy

CD spectroscopy is a useful tool to diagnose changes in DNA morphology during drug–DNA interactions, since the positive band due to base stacking (273 nm) and the negative one due to right-handed helicity (246 nm) are quite sensitive to the interaction mode of DNA with small molecules [65]. The changes in CD signals of DNA observed on interaction with drugs may often be assigned to the corresponding changes in DNA structure [66]. Thus, simple groove binding and electrostatic interaction of small molecules show less or no perturbation on the base stacking and helicity bands, while intercalation enhances the intensities of both the bands stabilizing the right-handed B conformation of CT DNA, as observed for the classical intercalator methylene blue [67].

The CD spectra of the complexes with double-stranded CT DNA for different r values can provide us with useful information concerning the complex-nucleotide interaction. The CD spectrum of free CT DNA is conservative and consists of a negative band at 246 nm and a positive one at 273 nm, characteristic of the B-form of DNA [68].

The CD spectra of CT DNA in the presence of complex $Mn(erx)_2(H_2O)_2$ (**1**) are shown in Fig. 6. They consist of a strong negative band I at 246 nm and two discrete positive bands II at 273 nm and III at 282 nm. More specifically, for r values up to 1:300, each CD spectrum consists of one negative band I at 246 nm and two positive bands II at 273 nm and III at 282 nm. Upon increase of the r value, the λ_{max} of these three bands remain, in general, unchanged while the intensity of helicity band I is increased and the intensity of bands II and III is decreased. Nevertheless, the exact mode of binding cannot be safely concluded. When r increases further (up to 1:50), the two positive bands II and III cannot be distinguished resulting to a unique broad band at $\lambda_{max} = 275$ nm while the intensity increases marginally. On the other hand, the negative band I at $\lambda_{max} = 246$ nm remains unchanged in all the spectra,

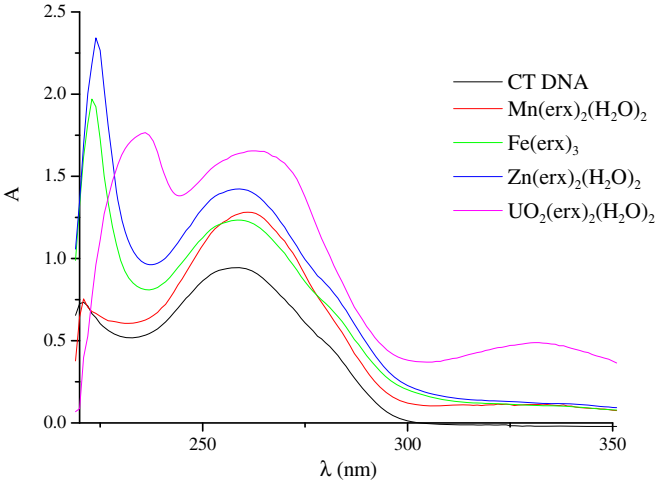

Fig. 5. Absorption spectra of complexes **1**, **2**, **5** and **7** in the presence of CT DNA ($[CT\ DNA] = 3.125 \times 10^{-4}$ M). The r value is 1:200 (r = [complex]/[CT DNA] mixing ratio). The spectra were recorded at 25 °C after incubation of the complexes with CT DNA for 24 h at 37 °C.

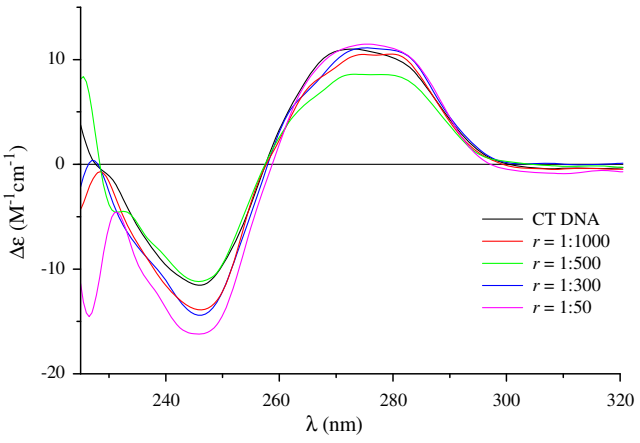

Fig. 6. CD spectra of CT DNA ($[CT\ DNA] = 3.125 \times 10^{-4}$ M) in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of complex **1** $Mn(erx)_2(H_2O)$ in different r values (r = [complex]/[CT DNA] mixing ratio). The spectra were recorded at 25 °C after incubation of the complex with CT DNA for 24 h at 37 °C.

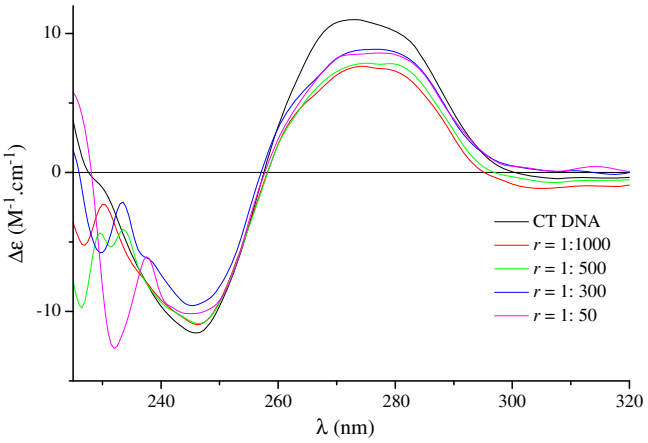

Fig. 7. CD spectra of CT DNA ([CT DNA] = 3.125×10^{-4} M) in 5 mM buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of complex **5** $Zn(erx)_2(H_2O)_2$ in different r values (r = [complex]/[CT DNA] mixing ratio). The spectra were recorded at 25 °C after incubation of the complex with CT DNA for 24 h at 37 °C.

although a slight increase of the intensity is observed. The dominating spectral feature for this series of spectra is the slight increase of the intensities of both the bands of CT DNA. Taking into account all the changes observed, the exact mode of binding of **1** to CT DNA cannot be safely concluded [67]. Similar behavior is observed in the CD spectra of CT DNA in the presence of complexes **2**–**4**.

The CD spectra of CT DNA in the presence of complex $Zn(erx)_2(H_2O)_2$ (**5**) are shown in Fig. 7. They consist of a strong negative band I at 246 nm and two discrete positive bands II at 273 nm and III at 281 nm. More specifically, for r values up to 1:300, each spectrum consists of one negative band I at 246 nm and two positive bands II at 273 nm and III at 281 nm. Upon increase of the r value, the λ_{max} of these three bands remain practically unchanged while the intensities of all the bands are marginally decreased. In these spectra, the exact mode of binding cannot be safely concluded. For further increase of r (up to 1:50), the two positive bands II and III are consolidated and cannot be distinguished resulting to a unique broad band at $\lambda_{max} = 276$ nm while the intensity remains practically unchanged. On the other hand, the λ_{max} of the negative band I at 246 nm remains unchanged in all the spectra. The dominating spectral feature for this series of spectra is the lack of any perturbation on both bands of CT DNA and shows the possible existence of simple groove binding or electrostatic interaction [67]. Quite similar behavior is observed in the CD spectra of CT DNA in the presence of complexes $Cd(erx)_2(H_2O)_2$ and $UO_2(erx)_2$.

In conclusion, the behavior of CT DNA in the presence of complexes **1**–**7** is interesting. All the complexes can bind to CT DNA and, at low r values, the exact mode of binding cannot be safely concluded. At high r values, the dominating spectral feature in the spectra of complexes **1**–**4** is the slight increase of the intensities of both the bands of CT DNA, while for complexes **5**–**7** the dominating spectral feature is the lack of any perturbation showing the possibility of simple groove binding or electrostatic interactions.

4. Conclusions

The synthesis and characterization of seven novel mononuclear complexes of the second-generation quinolone antibacterial drug enrofloxacin with the ions Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Zn^{2+}, Cd^{2+} and UO_2^{2+} has been realized with physicochemical and spectroscopic methods. In the complexes, enrofloxacin is bound to the metal via the pyridone and one carboxylate oxygen atoms. Each metal is six-coordinate and the environment around could be described as a distorted octahedron. With the use of molecular modeling calculations, we have proposed a low energy model for the structures of $Mn(erx)_2(H_2O)_2$, $Fe(erx)_3$ and $UO_2(erx)_2$. The antimicrobial activity of the complexes has been tested on three different microorganisms. In general, the complexes present equal or better inhibition than the free enrofloxacin against the three microorganisms tested. The best inhibition among the complexes studied is provided by $Fe(erx)_3$ (MIC = 0.25 μg mL^{-1}) against *E. coli* and *P. aeruginosa*. The interaction of complexes **1**–**7** with CT DNA has been investigated with UV and CD spectroscopies and has shown that the complexes can bind to CT DNA, but the exact binding mode cannot be safely concluded. Nevertheless, at high r values, the simple groove binding or electrostatic interactions for complexes **5**–**7** cannot be ruled out.

central ion occurs through the N–O chelating site. This coordination produces a five-membered ring containing an unsaturated α-iminoketo function which can act as a π acceptor towards a bound π electron-rich metal center such as rhenium(III). The α-iminoketo chelation plays an important role in the biosynthesis of the pterins, lumazines, flavins coenzymes [9,10]. Accordingly, complex **1** may be viewed as a simple model for such metalloenzymes. Furthermore, to our knowledge, *fac*-[$ReCl_3$(N–O)(PPh_3)] is the first structurally characterised complex with 1-isoquinolinyl phenyl ketone.

The electronic structure of **1** has been determined with the density functional theory (DFT) method, and time-dependent DFT (TD-DFT) calculations have been employed in order to discussion of its spectroscopic properties in more detail. Currently, density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [11]. Recent studies have also supported the TD-DFT method to be applicable for open- and closed-shell of 5d-metal complexes giving good assignment of experimental spectra [12,13].

2. Experimental

2.1. General procedure

All the reagents used to the syntheses were commercially available and were used without further purification. The [$ReCl_3$(MeCN)(PPh_3)$_2$] complex was prepared according to the literature method [7].

IR spectrum was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectrum was measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 1000–200 nm in acetonitrile solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of [$ReCl_3$(N–O)(PPh_3)] (1)

[Re(MeCN)Cl_3(PPh_3)$_2$] (0.5 g, 0.58 mmol) and 1-isoquinolinyl phenyl ketone (0.15 g, 0.64 mmol) in dichloromethane (40 cm^3) were refluxed for 4 h. The starting material gradually dissolved and the colour of the reaction solution became brown. The volume was condensed to 10 cm^3, diethyl ether (50 cm^3) was added and brown microcrystalline solid was filtered. The product was washed with EtOH and cold ether, and dried *in vacuo* (Yield 80%). The crystals suitable for X-ray investigation were obtained by recrystallization from a mixture dichloromethane/methanol.

IR (KBr; ν/cm^{-1}): ν_{CO} = 1677 cm^{-1}; ν_{CN} and $\nu_{C=C}$ = 1586(m), 1572(w) and 1539(m) ν_{CN} and $\nu_{C=C}$. *Anal*. Calc. for $C_{34}H_{26}Cl_3NOPRe$: C, 51.82; H, 3.33; N, 1.78. Found: C, 52.15; H, 3.24; N, 1.63%.

2.3. X-ray diffraction studies

A dark red crystal of **1** was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 295(1) K. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption correction using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [14] were applied. The structure was solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent atom. SHELXS97 [15], SHELXL97 [16] and SHELXTL [17] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.4. Magnetic measurement

Magnetization measurements of polycrystalline samples were carried out with a Quantum Design SQUID

Table 1
Crystal data and structure refinement for **1**

Empirical formula	$C_{34}H_{26}Cl_3NOPRe$
Formula weight	788.08
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system	orthorhombic
Space group	$P2_12_12_1$
Unit cell dimensions	
	a (Å) = 13.706(3)
	b (Å) = 14.172(3)
	c Å = 15.150(3)

F(000)	1544
Crystal size (mm)	0.12 × 0.10 × 0.07
θ Range for data collection (°)	2.87–25.04
Index ranges	$-14 \leqslant h \leqslant 16$
	$-16 \leqslant k \leqslant 16$
	$-18 \leqslant l \leqslant 16$
Reflections collected	18 558
Independent reflections (R_{int})	5206 (0.0448)
Completeness to 2θ	99.8%
Maximum and minimum transmission	0.586 and 0.260
Data/restraints/parameters	5206/0/370
Goodness-of-fit on F^2	0.988
Final R indices [$I > 2\sigma(I)$]	R_1 = 0.0269
	wR_2 = 0.0438
R indices (all data)	R_1 = 0.0395
	wR_2 = 0.0451
Absolute structure parameter	−0.004(6)
Largest difference in peak and hole (e Å^{-3})	0.641 and −0.684

magnetometer (MPMSXL-5-type) at a magnetic field of 0.5 T over the temperature range 1.8–300 K. Magnetization measurements versus magnetic field (0–5 T) were made at 2 K.

Corrections are based on subtracting the sample–holder signal and contribution χ_D estimated from the Pascal constants [18] and equal -411×10^{-6} for complex Re(III). The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83\chi_M^{corr} \times T^{1/2}$ B.M.

2.5. Computational details

GAUSSIAN03 program [19] was used in the calculations. The geometry optimizations of **1** in triplet and singlet states were carried out with the DFT method with the use of B3LYP functional [20,21]. The energy of the singlet state is of 12.8 kcal higher. All vibrations in the calculated vibrational spectrum of triplet state were real thus the geometry corresponds to true energy minimum.

The electronic spectrum of **1** was calculated with the TDDFT method [22]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31 + g** basis for chlorine, phosphorus, and nitrogen, 6-31g* basis for carbon and 6-31G basis for hydrogen atoms. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [23] was used for the valence electrons. Additional *d* function with exponent $\alpha = 0.3811$ and *f* function with exponent $\alpha = 2.033$ on the rhenium atom were added.

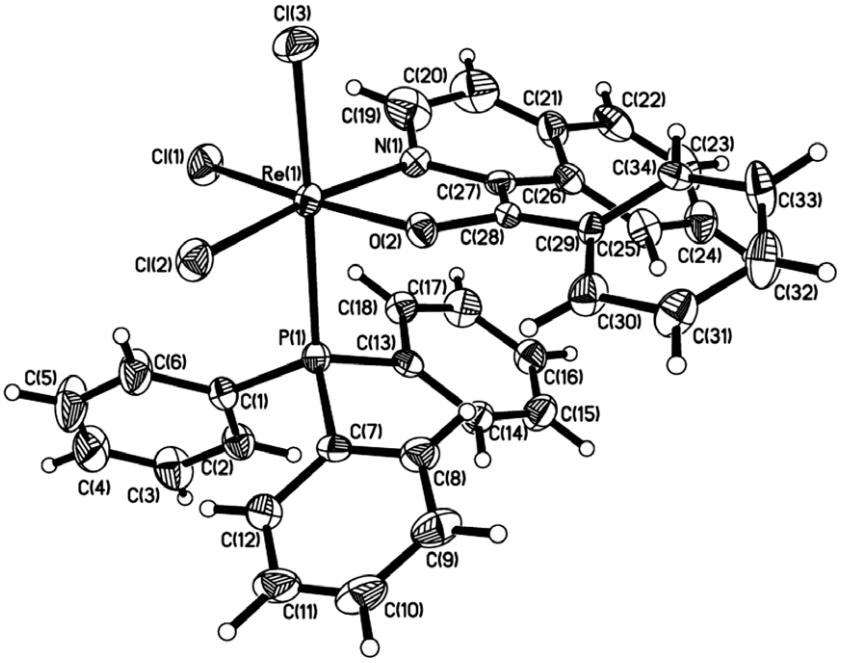

Fig. 1. The molecular structure of **1**. Displacement ellipsoids are drawn at 30% probability.

Table 2
The experimental and optimized bond lengths (Å) and angles (°) for **1**

Bond lengths	Experimental	Optimized	Bond angles	Experimental	Optimized

			Cl(1)–Re(1)–Cl(2)	95.44(5)	97.53
			Cl(1)–Re(1)–Cl(3)	90.72(6)	90.61
			Cl(2)–Re(1)–Cl(3)	91.12(7)	92.27

3. Results and discussion

The $[ReCl_3(N–O)(PPh_3)]$ (**1**) complex was prepared in good yield by ligand exchange reaction starting from $[ReCl_3(MeCN)(PPh_3)]$ and 1-isoquinolinyl phenyl ketone (N–O):

$$[ReCl_3(MeCN)(PPh_3)] + \text{1-isoquinolinyl phenyl ketone} \rightarrow [ReCl_3(N–O)(PPh_3)] + PPh_3$$

It was isolated as brown microcrystalline solid, soluble in common organic solvents. The elemental analysis of the complex is in good agreement with its formulation. A band due to the ν(C=O) vibration of 1-isoquinolinyl phenyl ketone appears at 1677 cm^{-1}, and characteristic bands of the C=C and C=N stretching modes are observed in the range 1600–1500 cm^{-1} [24].

3.1. Crystal structure

The molecular structure of **1** is given in Fig. 1, and the selected bond distances and angles are collected in Table 2.

The overall structure of **1** can be considered as a distorted octahedral with the largest deviations from the expected 90° bond angles coming from the bite angle of 1-isoquinolinyl phenyl ketone. It equals to 74.75(15)°, and it is similar to that reported for the related $[Re(CO)_3(6\text{-ATML})Cl] \cdot 3C_6H_6$ (6-ATML = 6-acetyl-1,3,7-trimethyllumazine) [75.2(1)°] [10]. The bite angles O–M–N in the structures with α-iminoketo chelate ligands bounded to transition metals depend mainly on the size of the metal center, the smallest values (down to 67°) were found for Ag^I complexes and the largest angles (up to 85°) were observed for compounds with Cu^{II} [9].

The central ion of **1** shows slightly larger affinity towards the less basic but strongly π accepting carbonyl oxo atom, and the Re–O(1) is shorter than the Re–N(1) bond (Table 2). The value $\Delta = d(M–N) - d(M–O)$, which reflects the symmetry of the chelate arrangement in such structures, is equal to 0.036 Å for **1**, indicating that the Re center is situated symmetrically between N(1) and O(1) donor atoms.

The chloride ions of **1** are arranged in a *facial* fashion, and the phosphorous atom of the phosphine ligand occupies the *trans* position to the Cl(3) ion. Geometrical preferences of the $ReCl_3$ unit in the $[ReCl_3(L–L)(PPh_3)]$ complexes can be rationalized in terms of the electronic nature of the L–L ligand. Triphenylphosphine is a π-accepting ligand, and trivalent rhenium is prone to

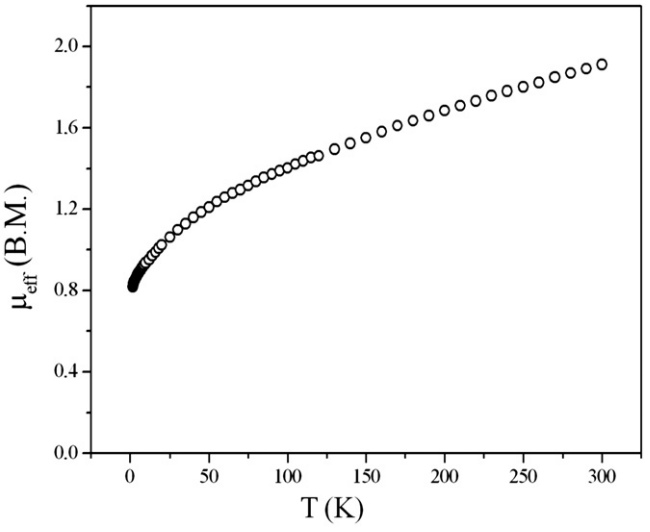

Fig. 2. The effective magnetic moment (μ_{eff}) vs temperature for complex **1**.

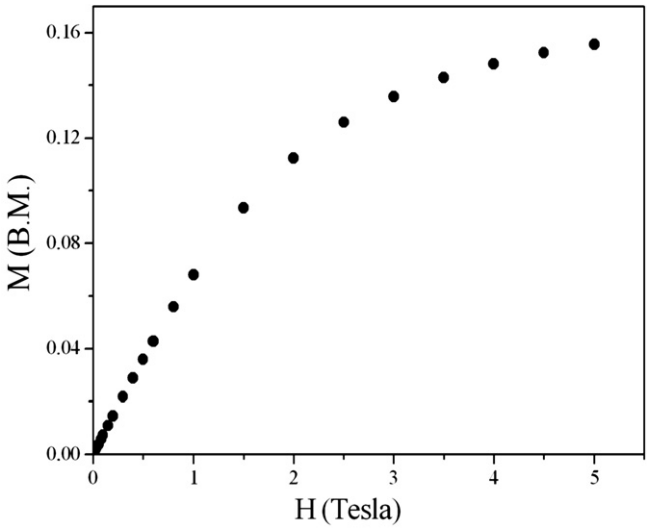

Fig. 3. The variation of the magnetization (M) vs the magnetic field (H) at 2 K for complex **1**.

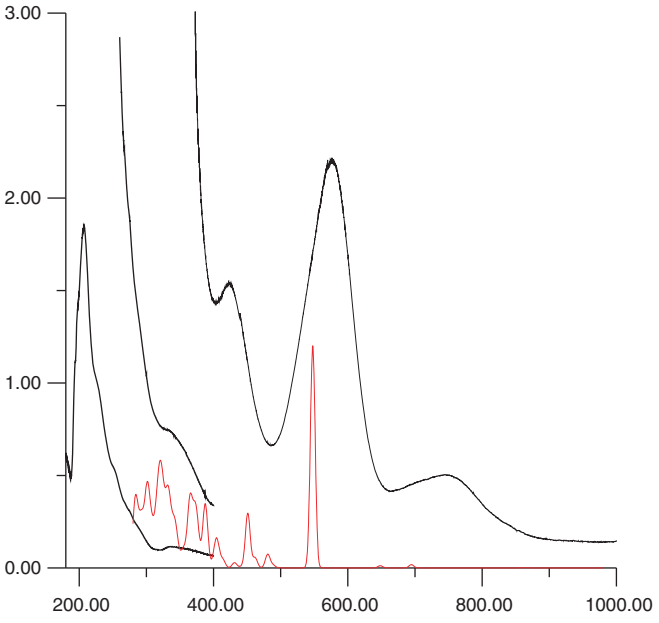

Fig. 4. The experimental (black) and calculated (red) electronic absorption spectrum of **1**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

back-bonding. When the L–L ligand is a strong π-acid, the *facial* geometry is preferred as it maximizes the back-bonding effect. Assuming idealized octahedral geometry the back-bonding has $t_{2g}(Re) \rightarrow \sigma^*(P–C)$ and $t_{2g}(Re) \rightarrow \pi^*(L–L)$ components. This bonding is maximized when the competition between ligands for identical metal orbitals is minimal – what requires facially disposed π acceptor ligands [25–31].

It is significant that the Re–N distance in **1** (2.026(3) Å) is shorter than comparable distances for saturated amine complexes, where metal-to-ligand π-back-bonding is not possible [32]. Similarly, the interatomic distance between the rhenium atom and the oxygen atom of 1-isoquinolinyl phenyl ketone is shorter than an ideal single Re–O bond length (*ca.* 2.04 Å) [33].

The Re–X(3) bond length is longer in comparison with the corresponding Re–X(1) and Re–X(2) distances. Furthermore, the Re–X(2) bond lengths in *trans* position to the N atom of the bidentate ligand are longer in comparison with the Re–Cl(1) bonds opposite the O atom of the 1-isoquinolinyl phenyl ketone. This is consistent with the presence of $t_{2g}(Re) \rightarrow \sigma^*(P–C)$ and $t_{2g}(Re) \rightarrow \pi^*(N–O)$ back-bonding discussed above.

3.2. Magnetic properties

The magnetic properties of complex under the form μ_{eff} versus temperature (μ_{eff} – the effective magnetic moment) is shown in Fig. 2.

The complex of rhenium(III) shows room temperature magnetic moment 1.91 B.M. (0.456 cm^3 mol^{-1} K). In the whole temperature range lowering magnetic moment is observed from 1.91 B.M. at 300 K up to 0.82 B.M. at 1.8 K.

					208.0 (5.96) 79100

This behavior is characteristic of mononuclear Re(III)complexes ($^3T_{1g}$ ground state) with d^4 low-spin octahedral [34–42] and arises from the large spin–orbit coupling ($\zeta = 2500\ cm^{-1}$ [43]), which gives diamagnetic ground state. It seems that in room temperature, in accordance Boltzmann's distribution, it is populated higher magnetic state, which is depopulated with temperature lowering and decreasing of the magnetic moment is observed.

The variation of the magnetization M versus the magnetic field H for complex at 2 K is shown in Fig. 3.

The magnetization versus magnetic field curve for complex very slowly increases and indicates value of the magnetization near zero (0.16 B.M) at 5 T. Magnetization of the sample confirms that the ground state is diamagnetic.

3.3. Geometry optimization

The optimized geometric parameters of the triplet state are gathered in Table 2. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data. However, some differences may be noticed between the experimental and optimized structures. The experimental Re(1)–Cl(2) is longer than the Re(1)–Cl(1), whereas the other relation is observed for the optimized structure. It may come from the basis sets which are approximated to a certain extent or may indicate the influence of the crystal packing on the values of the experimental bond lengths. The theoretical calculations do not consider the effects of chemical environment.

3.4. Electronic spectrum

The experimental and calculated electronic spectra of **1** are presented in Fig. 4. Each calculated transition is represented by a gaussian function $y = c\,e^{-bx2}$ with the height (c) equal to the oscillator strength and b equal to $0.04\ nm^{-2}$. The electronic absorption spectrum of **1** is similar to those

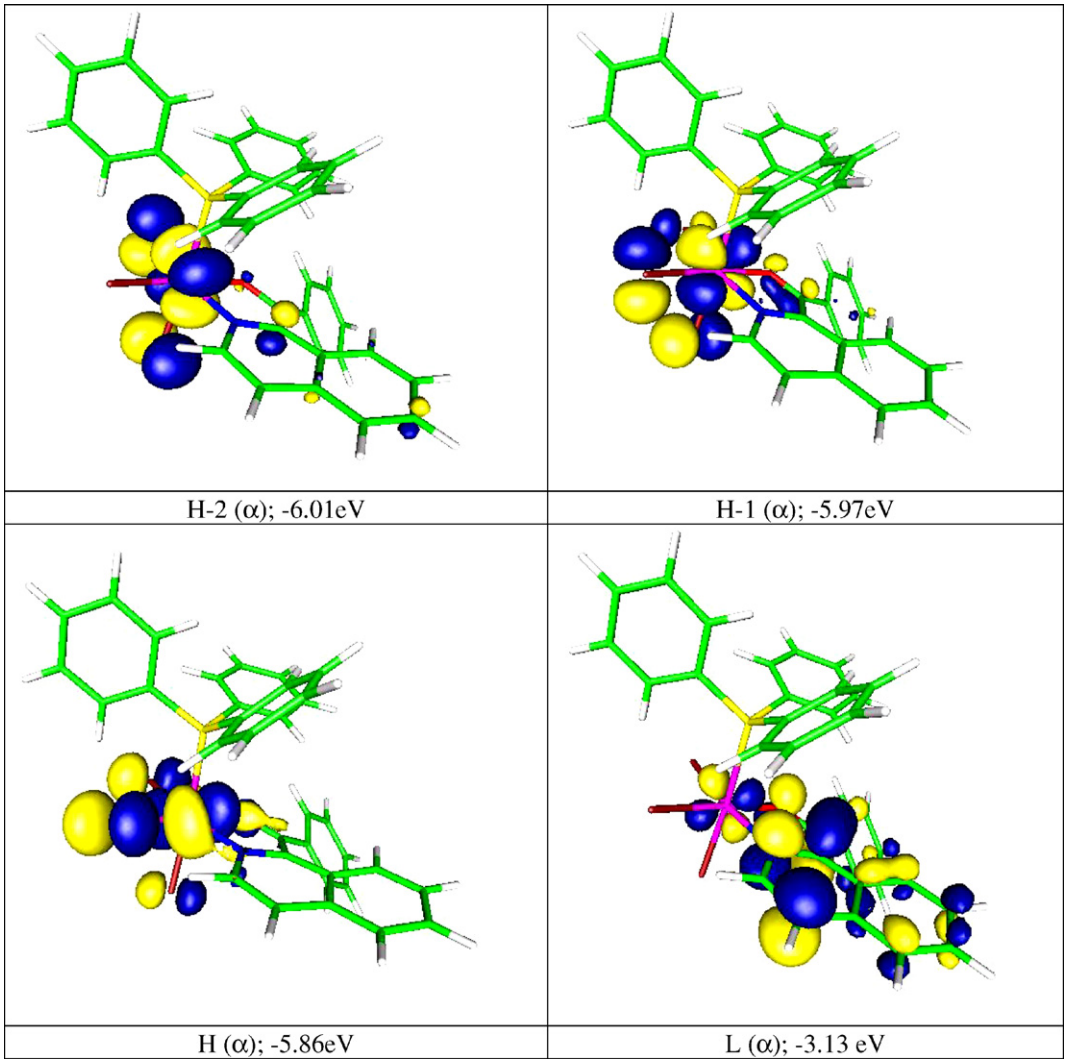

Fig. 5. Energy and contour plots of the selected occupied and unoccupied molecular orbitals with α spin active in the electronic transitions for complex **1**. Positive values of the orbital contour are represented in blue (0.04 au) and negative values – in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

observed for *fac*-[$ReCl_3$(L–L)(PPh_3)] with bipy-like ligands. It displays transitions of moderate intensity in the form of peaks and shoulders in the visible region (400–1000 nm).

Table 3 presents the most important spin-allowed triplet–triplet electronic transitions calculated with the TDDFT method assigned to the observed absorption bands of **1**. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy to the orbitals HOMO and LUMO involved in the electronic transitions. The selected HOMO and LUMO orbitals of **1** with α and β spins active in the electronic transitions are presented in Figs. 5 and 6.

The investigated complex is of large size, the number of basis functions is equal 686. A hundred electron transitions calculated by the TDDFT method do not comprise all the experimental absorption bands. The UV–Vis spectrum of **1** was calculated only to 280 nm, so the shortest wavelength experimental bands can not be assigned to the calculated transitions. Some additional intraligand and interligand transitions are expected to be found at higher energies in the calculation for **1**.

The TDDFT calculations show that two longest wavelength experimental bands of **1** at 777.1 and 570.0 nm originate in the HOMO−2(α) → LUMO(α), HUMO−1(α) → LUMO(α) and HOMO(α) → LUMO(α) transitions. The HOMO−2, HOMO−1 and HOMO orbitals with α-spin can be considered as π_{Re-Cl} orbitals – in all these MOs the rhenium d_{xz}, d_{yz} and d_{xy} orbitals bear antibonding character towards the p_π orbitals of the chloride ligands. The lowest unoccupied molecular orbital with α-spin is centered on the π-antibonding orbitals of the N–O ligand. Consequently, the HOMO−2(α) → LUMO(α), HUMO−1(α) → LUMO(α) and HOMO(α) → LUMO(α) excitations can be seen as mixed Re → N–O (MLCT) and Cl → N–O (LLCT) or a delocalized MLLCT (metal–ligand-to-ligand CT) description can be used.

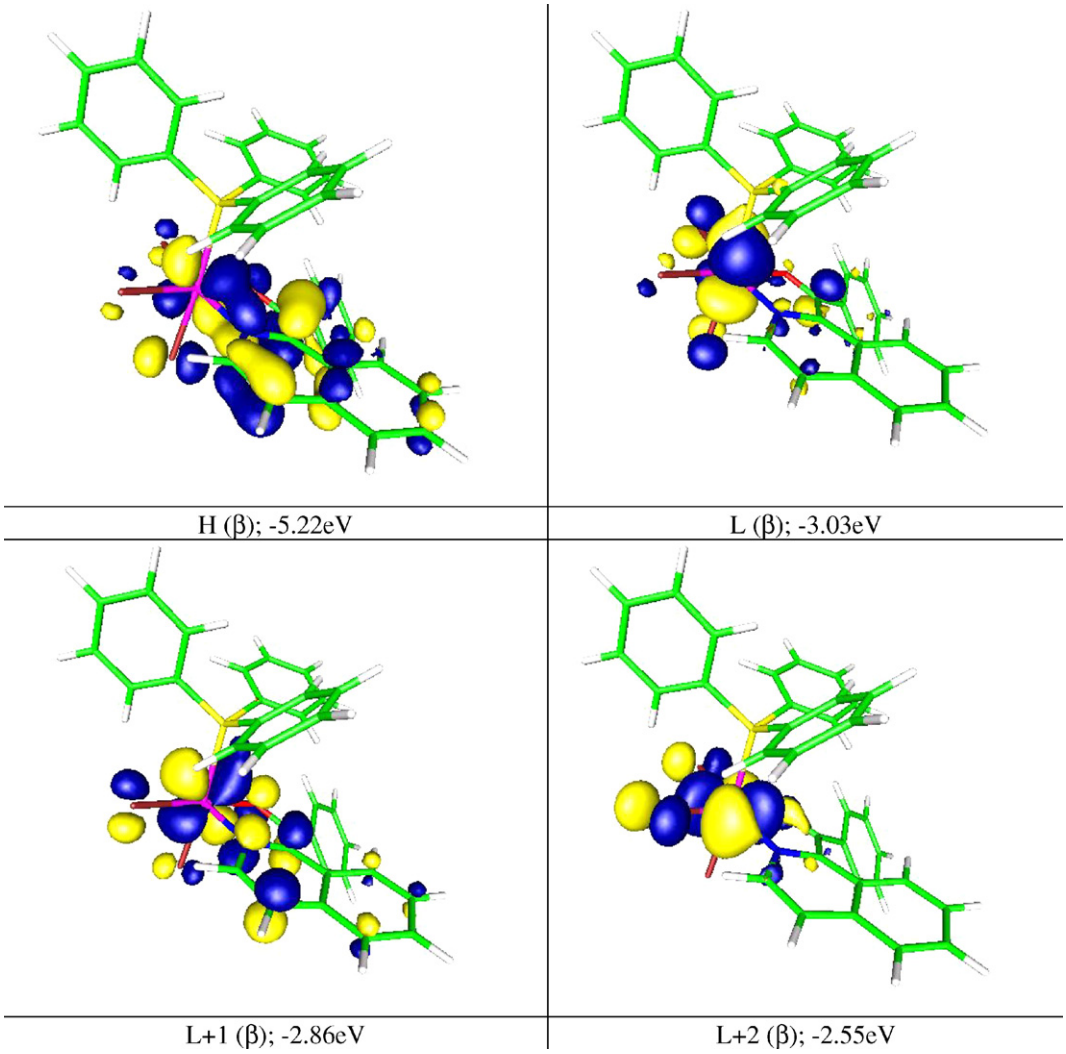

Fig. 6. Energy and contour plots of the selected occupied and unoccupied molecular orbitals with β spin active in the electronic transitions for complex **1**. Positive values of the orbital contour are represented in blue (0.04 au) and negative values – in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The absorption band at 432.4 nm originates mainly from the HOMO(β) → LUMO+3(β) transition of d/π (N–O)/π(Cl) → π*(N–O) character. The highest occupied molecular orbital with β-spin is delocalized among rhenium ion, chloride and N–O ligand, and the LUMO-3 orbital with β-spin is centered on the 1-isoquinolinyl phenyl ketone. To the absorption band at 432.4 nm have been also assigned *Ligand–Metal Charge Transfer* excitations calculated in 460–400 nm region.

Similarly, the absorption at 347.0 nm is attributed to *Ligand–Metal Charge Transfer* and *Ligand–Ligand Charge Transfer* excitations.

4. Supplementary data

CCDC 674873 contains the supplementary crystallographic data for $C_{26}H_{25}Cl_5N_4PRe$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgement

The GAUSSIAN03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland, under calculational Grant No. 51/96.

monoclinic system (space group $P2_1/m$) [8]. The phase transition between the hexagonal system and monoclinic system occurs through shifts of O(3) atom position in the crystal structure of mimetite [9,10]. The study of lead calcium arsenate apatites from Franklin, New Jersey and Langban, Sweden infers additional studies are necessary. In this study, hedyphane was redefined as $Ca_2Pb_3(AsO_4)_3Cl$. The space group is $P6_3/m$ with $a = 1.0140$ nm and $c = 0.7185$ nm and cation ordering in hedyphane is attributed to a preference by atoms with sterically active electron lone pairs, example, Pb(II), for the asymmetrically coordinated 6h site. The silent features drawn from tabulation of chemical composition indicate both the ions of phosphate and arsenate are involved [11]. Ca-bearing phosphatian mimetite (honey yellow colour) is composed of Pb (major), in addition, Ca, Cd, Mn, Sb, Fe, As and P in minor amounts. The unit cell parameters are $a = 1.0087$ nm and $c = 0.7335$ nm (space group, $P6_3/m$). X-ray and IR data have shown that it represents a transitional phase in the ternary system mimetite–pyromorphite–turneaureite [12]. Phosphohedyphane, $Ca_2Pb_3(PO_4)_3Cl$, the phosphate analog of hedyphane has been described recently shows the mineral has hexagonal structure (space group, $P6_3/m$, $a = 0.9857$ nm and $c = 0.7130$ nm) and chemical variability [13].

Minerals containing phosphate, arsenate and vanadinate anions have the general formulae $A_m[XO_4]_pZ_{q\cdot x}H_2O$ and $A_mB_m[XO_4]_pZ_{q\cdot x}H_2O$ where $[XO_4]$ is $[PO_4]$, $[AsO_4]$ and $[VO_4]$; Z is OH, F, Cl, O; A and B-metals. Mineral species are formed by the interaction of cations with phosphate, arsenate and vanadinate. Indeed minerals may contain mixed anionic species. Also many of these minerals may contain mixed cationic species. Many of these minerals contain Fe and also other metals like Ca, Al, Mn, Cu, etc. [14]. Farmer reported infrared bands for pyromorphite at 1030 and 970 cm^{-1} assigned to phosphate mode, ν_3, antisymmetric stretching vibrations and at 572 and 542 cm^{-1} for ν_4, bending modes [15]. The infrared spectrum of mimetite is different form pyromorphite, displacing bands at 815, 803 and 783 cm^{-1} attributed to arsenate ν_3, antisymmetric stretching vibrations and at 415 and 383 cm^{-1} assigned to arsenate ν_4 bending modes [15]. The free ion, AsO_4^{3-} has four vibrational modes and are observed by IR and Raman at 810 cm^{-1} (ν_1); ν_2 at 342 cm^{-1}; ν_3 at 810 cm^{-1} and ν_4 at 398 cm^{-1}[16]. For vanadinites, Ross reported ν_3-bands at 800 and 736 cm^{-1}, and the ν_4 modes at 419, 380 and 322 cm^{-1} [16]. Gadsen also investigated the infrared spectrum of the mimetite [17]. The ν_3 mode is reported to occur in the range, 700–900 cm^{-1} and the ν_4 mode between 300 and 410 cm^{-1}. Griffith reported the Raman spectrum of mimetite [18]. Levitt and Condrate reported the infrared and Raman spectra of lead apatite powdered minerals [6].

Earlier papers were limited to the mid-infrared absorption data on apatite, pyromorphite, mimetite and vanadinite [19,20]. Some other studies of Raman and IR spectra of calcium and lead apatites including mimetite show no detailed analysis [6,21,22]. The Raman and IR spectra of single crystals of pyromorphite, vanadinite, and mimetite were recorded and focused mainly on coordinate analysis and force constants of the three minerals that include the assignments of the vibrational frequencies [23]. For mimetite, this paper shows the ν_1 mode observed at 816 cm^{-1}, the ν_3 vibrations at 809 and 787 cm^{-1}, the ν_2 at 414, 390 and 335 cm^{-1} and ν_4 at 424, 373 and 314 cm^{-1}. None of these reports include NIR spectroscopy. There has been almost no research carried out on NIR spectroscopy of the mimetite and pyromorphite series.

In the present work, we analysed spectroscopically selected mimetite minerals, arsenian pyromorphite and hedyphane minerals and the spectra are related to the structure of the minerals.

2. Experimental

2.1. Minerals

The minerals used in this work, their formula and origin are listed in Table 1. The phase purity of the minerals was checked by X-ray diffraction and the chemical composition by EDX measurements.

2.2. Near-infrared (NIR) spectroscopy

NIR spectra were collected on a Nicolet Nexus FT-IR spectrometer with a Nicolet Near-IR Fibreport accessory (Madison, WI). A white light source was used, with a quartz beam splitter and TEC NIR InGaAs detector. Spectra were obtained from 13 000 to 4000 cm^{-1} (0.77–2.50 μm) by the co-addition of 64 scans at a spectral resolution of 8 cm^{-1}. A mirror velocity of 1.266 m s^{-1} was used. The spectra were transformed using the Kubelka-Munk algorithm to provide spectra for comparison with published absorption spectra. Spectral manipulations, such as baseline correction, smoothing and normalisation, were performed using the software package GRAMS (Galactic Industries Corporation, NH, USA).

2.3. Mid-IR spectroscopy

Infrared spectra were obtained using a Nicolet Nexus 870 FTIR spectrometer with a smart endurance single bounce diamond ATR cell. Spectra over the 4000–525 cm^{-1} range were obtained by the co-addition of 64 scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectra were co-added to improve the signal to noise ratio.

Band component analysis was undertaken using the Jandel 'Peakfit' (Erkrath, Germany) software package which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done using a Lorentz–Gauss cross-product function with the minimum number of component

Table 1
Table of the minerals, their origin and formula

Code	Mineral	Colour	Formula	Origin
Mime-1	mimetite	yellow	$Pb_5(AsO_4)_3Cl$	Tsumeb, Namibia, South Africa
Mime-2	mimetite	orange	$Pb_5(AsO_4)_3Cl$	Geronimo Mine, Yuma Co., AZ, USA
Mime-3	mimetite	black	$Pb_5(AsO_4)_3Cl$	Mount Bonnie Mine, Northern Territory, Australia
Pyro-8	arsenian pyromorphite	light brown	$Pb_5(PO_4,AsO_4)_3Cl$	Bunker Hill Mine, Kellogg, ID, USA
Hedy-1	hedyphane	grey white	$Pb_3Ca_2(AsO_4)_3Cl$	Puttapa Mine, Beltana, South Australia

bands used for the fitting process. The Lorentz–Gauss ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations (r^2) greater than 0.995. Band fitting of the spectra is quite reliable providing there is some band separation or changes in the spectral profile.

3. Results and discussion

3.1. Near-infrared (NIR) spectroscopy

Spectral studies have not been made to examine the effect of cation substitution and its symmetry in any of these minerals. The most common electronic process in minerals results from transition metals and iron is usually suspected in minerals either as a major or minor impurity. The electronic spectra of complex ferrous silicates have been interpreted by crystal field theory and attributed peaks in the 11 000–9000 cm^{-1} (0.91–1.11 μm) region to Fe^{2+} ion [24]. Results are given from electronic and vibrational spectra and are explained in terms of the structure of cations and anions in the minerals of mimetite, arsenian pyromorphite and hedyphane.

The spectra of the samples are presented in three parts: The spectra of electronic part in the high wavenumber region, 12 000–8000 cm^{-1} (0.83–1.25 μm) are depicted in Fig. 1. A unique spectral feature with variable band position and intensity observed at ~10 000 cm^{-1} (1.00 μm) (Fig. 1) results from the Fe^{2+} ion. This band is a common feature in all the spectra. This broad feature is resolved into two less intense bands in mimetite-1 and mimetite-2 and an additional intense band on high energy side at ~11 145 cm^{-1} (0.90 μm). Vibrational spectra in the wavenumber region from 8000 to 6500 cm^{-1} (1.25–1.54 μm) are shown in Fig. 2. A broad band observed in the region, 7500–7000 cm^{-1} (1.33–1.43 μm) is due to overtones of the first fundamental hydroxyl stretching modes observed in the mid-infrared spectra around 3600 cm^{-1} (2.78 μm). The spectra in the low wavenumber region, 6500–4000 cm^{-1} (1.54–2.50 μm) are shown in Fig. 3. The strong feature centred at ~5000 cm^{-1} (2.00 μm) is the result of overtones of OH-stretching bands observed in the lower range of IR spectrum at 3400 cm^{-1} (2.94 μm) The vibrational spectra, in the lower wavenumber region, a complex profile contains a series of multiple sharp bands at wavenumbers <4600 cm^{-1} (2.17 μm). These sharp series of bands are produced by the combination of vibrational modes of phosphate and or arsenate ions.

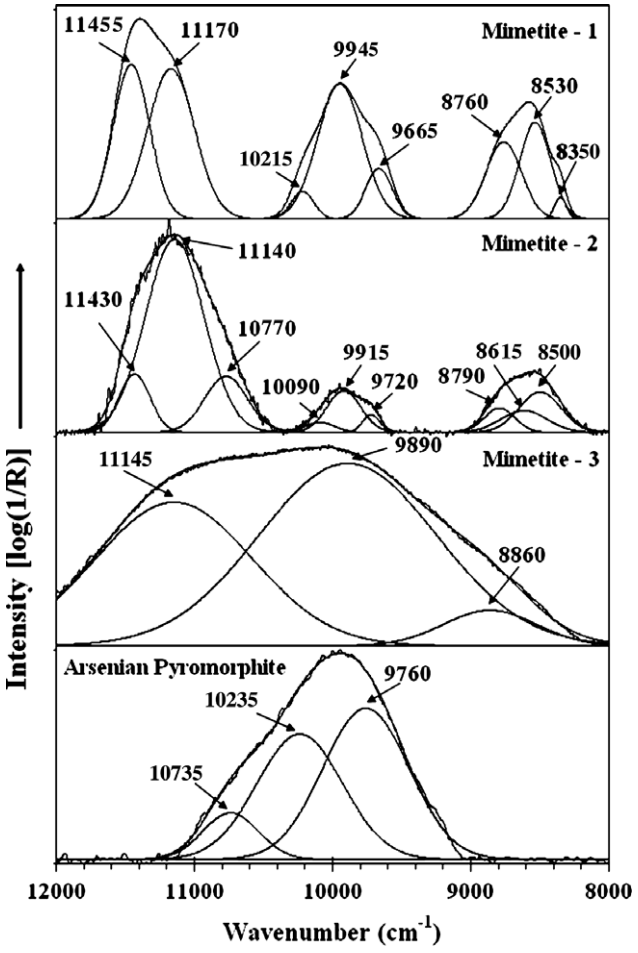

Fig. 1. Near-IR spectra of mimetite (samples 1–3) and arsenian pyromorphite in the 8000–12 000 cm^{-1} region.

3.1.1. Electronic spectra: 12 000–8000 cm^{-1} (0.83–1.25 μm) region

Divalent cations like Ca^{2+}, Cd^{2+}, Mn^{2+}, Fe^{2+} and Cu^{2+} in a complex influence the band positions in the electronic spectrum. The cations also cause shifts for the OH-stretching units, carbonate and arsenate bands both in the near-infrared and IR spectra of the minerals. Spectral properties are related to the structure of minerals. Distinctive band positions are shown in the spectra as depicted in Fig. 1. Mimetite (yellow-orange) and pyromorphite (brown) minerals are differentiated from their electronic spectral features. A vertical line may be drawn across the central portion of the spectral pattern to see an unique spectral feature with variable band position and intensity at

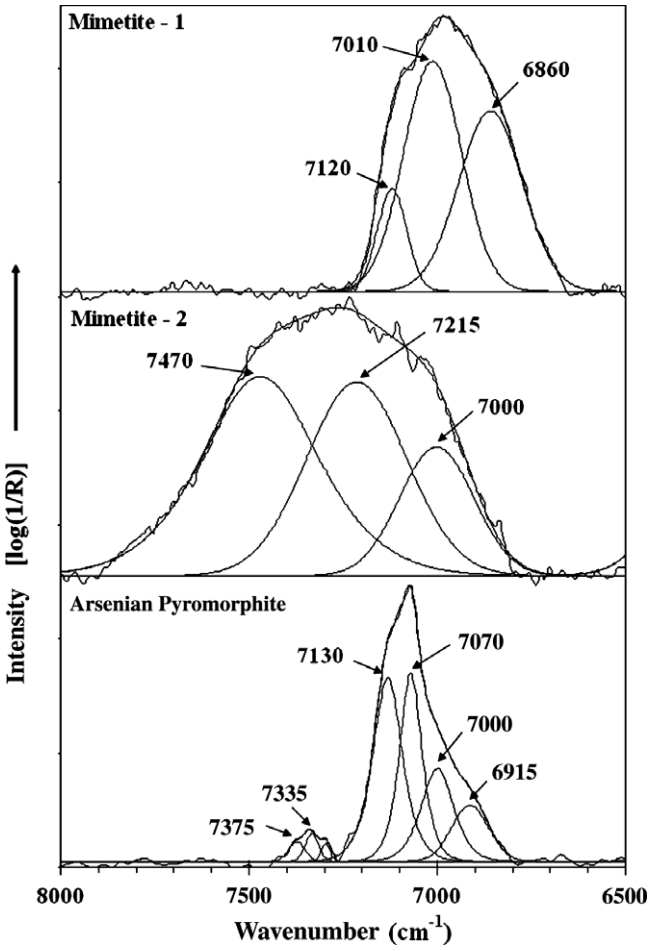

Fig. 2. Near-IR spectra of mimetite (samples 1 and 2) and arsenian pyromorphite in the 6500–8000 cm^{-1} region.

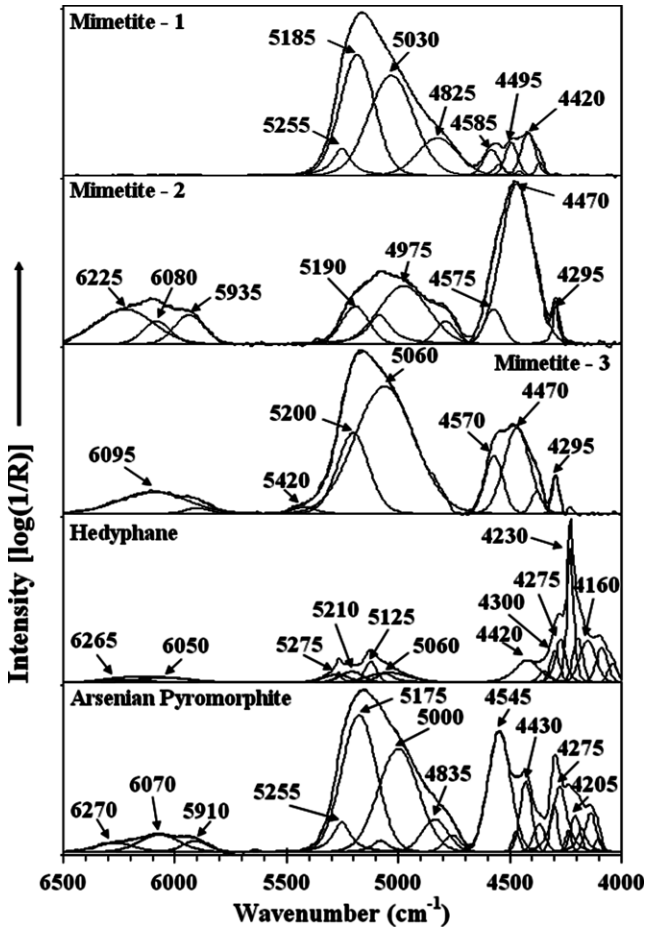

Fig. 3. Near-IR spectra of mimetite (samples 1–3), hedyphane and arsenian pyromorphite in the 4000–6500 cm^{-1} region.

~10000 cm^{-1} (1.00 μm) (Fig. 1) resulting from Fe^{2+} ion substitution. This band is a common feature in all the spectra. Burns [24] attributed peaks in cummintonite–grunerites and actinolite in the 11000–9000 cm^{-1} (0.91–1.11 μm) region to Fe^{2+}, while Goldman and Rossman [25] interpreted many of the amphibole spectra claiming that only iron in the M4 site causes the band at 10000 cm^{-1} (1.00 μm). Later it was confirmed the Fe^{2+} band at 10000 cm^{-1} (1.00 μm) for M4 site for the calcic amphibole [26]. The dependence of Fe(II) band with pressure shifts in ferromagnesian olivine has also been analysed [27]. A prominent feature reported for an iron-rich humite is a complex band system in the NIR and is assigned to dd-transitions of Fe^{2+} bands at 10800 and 7600 cm^{-1} (0.93 and1.32 μm) [28].

A broad profile shown (Fig. 1) by mimetite-3 is characterised by a single band at 9890 cm^{-1} (1.01 μm) attributable to Fe(II) ion. This band appears at ~10000 cm^{-1} (1.00 μm) in arsenian pyromorphite splits into two components and are displaced to 10235 and 9760 cm^{-1} (0.98 and 1.02 μm). For mimetite-1 and mimetite-2 samples, the Fe(II) band split into two with a separation of 1415 cm^{-1}. The two bands in mimetite-1 are shown at 9945 and 8530 cm^{-1} (1.00 and 1.17 μm) while they are weak in mimetite-2 at 9915 and 8615 cm^{-1} (1.01 and 1.16 μm). A similar situation was observed from the study of electronic absorption spectra of the orthorhombic olivine-type phosphate minerals of the triphylite–lithiophilite series. All triphylite–lithiophilite spectra showed an intense band system in the NIR around 9400–9100 cm^{-1} (1.06–1.10 μm) is a typical of spin allowed dd-transition in octahedral Fe(II) [29]. Electronic spectrum of Chevreul's salt $[Cu_2^{I}(SO_3)_2(SO_3)_2]^{6-}$ consists of two ligand field transitions for Cu(II) at 785 and 1000 nm (12740 and 10000 cm^{-1}) and the isomorphic species present distinct colours. The intense red colour of the Chevreul's salt changes to yellowish-brown, after the substitution of Cu(II) by Fe(II) and the observation of band at 865 nm (11560 cm^{-1}) supports the Fe(II) derivative [30]. Mimetite and pyromorphite minerals are distinguished by means of electronic spectra. An additional weak band in arsenian pyromorphite at 10735 cm^{-1} (0.93 μm) may be assigned to Cu(II) dd-transition. The intensity of this band is enhanced at the cost of Fe(II) in mimetite-1 and mimetite-2 and appeared at ~11140 cm^{-1} (0.90 μm). There is an exception in mimetite-3 in which more iron impurity

causes a complex broad band profile. The change of brown colour to orange-yellow relates to the amount of Cu and or Fe impurities in the mimetite minerals. Colour of the minerals may be related to the compositional variations in the minerals.

3.1.2. Vibrational spectra: 8000–6500 cm^{-1} (1.25–1.54 μm) region

The vibrational absorption characteristics of mimetite and arsenian pyromorphite minerals are shown in Fig. 2. Spectral variations support mineralogical variations especially in composition. Selected absorption bands were studied at high resolution. The minerals show fine structure particularly in the OH-stretching overtone region near 7000 cm^{-1} (1.43 μm) region [31]. The multi-component bands derived for each profile in spectra enhance the ability to discriminate between the minerals. Arsenian pyromorphite, $Pb_5(PO_4,AsO_4)_3Cl$ exhibits a sharp band at 7070 cm^{-1} (1.41 μm) with four components due to OH-stretching overtones. The observation of OH-stretching overtones implies substitution for Cl by OH. Mimetite samples show variable band positions with more intensity at 7010 and 7215 cm^{-1} (1.43–1.39 μm). The cause for the shifts of bands may be attributed to the presence of Fe and Cu in mimetites and Ca(II) perhaps substitution by Fe(II) and or Cu(II). Vibrational bands for several minerals like turquoise, rosasite, smithsonite, rhodochrosite, alunite, rectorite and jarosite reported in 7200–7000 region (1.39–1.43 μm) [31–34].

3.1.3. Near-IR spectra: 6500–4000 cm^{-1} (1.54–2.5 μm) region

The overtones of water are observed in the spectra of H_2O-bearing minerals near 5200 cm^{-1} (1.92 μm) [35,36]. Vibrational spectra of the minerals shown in Fig. 3 contain many significant absorption features. A strong feature at ~5000 cm^{-1} (2.00 μm) accompanied by a weak feature at 6100 cm^{-1} (1.64 μm) suggests incorporation of H_2O into the mineral structure. Arsenian pyromorphite band is strong at 5175 cm^{-1} (1.93 μm). For mimetites this band is almost equally strong but displaced differently at 5185, 5190 and 5200 cm^{-1} (1.93, 193 and 1.92 μm) respectively, because, the functional ions and cations are compositionally variant in the isomorphic series. The liquid water band was observed in sedimentary rocks at 1.90 μm (5260 cm^{-1}) [37]. A series of sharp bands are observed in the spectra of the lower wavenumbers. Despite the complexity of the overlapping bands a sequence of bands in each of the spectra can be observed. The sequence for mimetites is observed at ~4500, 4400 and 4300 cm^{-1} (2.22, 2.27 and 2.33 μm) in which a single anion (AsO_4) is involved. The sequence of bands in arsenian phosphate and hedyphane becomes much more complicated. The modified features result from the substitution of Pb(II) by Ca(II) and $(AsO_4)^{3-}$ by $(PO_4)^{3-}$ are reflected by the number of overlapping bands which are shifted to lower wavenumbers.

3.2. Mid-IR spectroscopy

In the mid-IR spectral region bands attributable to phosphate and arsenate anions can be observed. These features in the vibrational stretching region of 1300–500 cm^{-1} is shown in Fig. 4. The spectra of the minerals are complex with the spectral profile in the 900–500 cm^{-1} region. For three mineral samples mimetite-3, arsenian pyromorphite and hedyphane additional bands produced by the phosphate anion are included in the 900–1100 cm^{-1} region. Infrared spectra were poorly defined in the 3600–1500 cm^{-1} region and they are not included here. Bands are strong in Raman for mimetites and pyromorphites in high wavenumber region, 4000–3000 cm^{-1} as reported by Frost et al. [38,39] and the assignments of these bands are correlated with NIR data in the present work.

The observation of isomorphic substitution for $(PO_4)^{3-}$ by $(AsO_4)^{3-}$ in mimetites could easily be distinguished on the basis of their spectral properties from the mixed spectra of phosphate and arsenate ions in arsenian pyromorphite. As shown in Fig. 4, the spectrum of mimetite-3 is a simple system where arsenate bands are moderately resolved at 887 and 788 cm^{-1} and are identified as ν_1 and ν_3 modes of $(AsO_4)^{3-}$ ion. On either side of this low intensity profiles

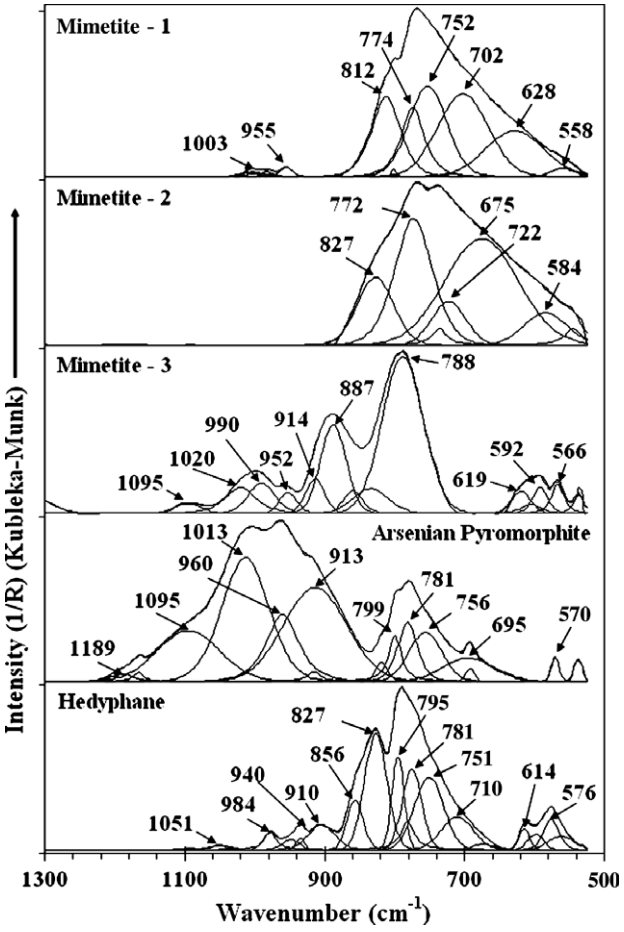

Fig. 4. Mid-IR spectra of mimetite (samples 1–3), hedyphane and arsenian pyromorphite in the 500–1300 cm^{-1} region.

that contain multiple bands are the cause of partial substitution for $(PO_4)^{3-}$. A series of bands observed on high wavenumbers side of the spectrum at 1095, 1020, 990 and 914 cm^{-1}. The first three bands are assigned to ν_3, antisymmetric mode, and last one at 914 cm^{-1} is attributed to ν_1, the symmetric mode of phosphate ion. Farmer reported infrared bands for pyromorphite at 1030 and 970 cm^{-1} assigned to phosphate mode, ν_3, and antisymmetric stretching vibrations [15]. The range of bands observed for phosphate in other samples are not found in mimetite-1 and mimetite-2 spectra but appeared with single broad profile having four component bands near 800 cm^{-1}. In this case $(PO_4)^{3-}$ is almost completely substituted by $(AsO_4)^{3-}$. Mimetite-1 bands are located at 812, 774, 752 and 702 cm^{-1}. Band at 812 cm^{-1} is attributed to ν_1 mode and the last three bands are due to ν_3 mode of AsO_4^{3-} ion. In mimetite-2, these bands are shifted to lower wavenumbers. A similar set of bands with variable band positions and intensity are seen in arsenian pyromorphite and hedyphane. The spectrum of hedyphane is significant with arsenate bands at 900–700 cm^{-1} and weak bands appear on either side of this due to the phosphate ion. Arsenian pyromorphite spectrum is also a mixed profile dominated by PO stretching vibrations at 1100–900 cm^{-1}. The effect of anion substitution is noticed in the spectra of mimetites and hedyphane. The substitution of $(PO_4)^{3-}$ for $(AsO_4)^{3-}$ characteristically decreases the vibrational frequencies of ν_3 and ν_1 modes of the $(PO_4)^{3-}$ slightly to lower wavenumbers with respect to arsenian pyromorphite. Investigations of anion substitutions in lead apatites reveal the effect of substitution of Ca^{2+} by Pb^{2+} and $(PO_4)^{3-}$ by $(AsO_4)^{3-}$ and $(VO_4)^{3-}$ in apatites cause a shift of the ν_3 (1082 cm^{-1}) and ν_1 (980 cm^{-1}) [40]. Raman studies show a complexity of band systems for phosphate and arsenate ions in mimetites, pyromorphite and hedyphane in three ranges at ~500–400 cm^{-1}, 400–300 cm^{-1} and 200–100 cm^{-1} assigned to $(PO_4)^{3-}$ and/or $(AsO_4)^3$ bending modes [38,39]. The low wavenumber region of the mid-IR spectrum (Fig. 4) are very weak from 650 to 500 cm^{-1} may be attributed to ν_4 bending modes of $(PO_4)^{3-}$. In the spectra in Fig. 4, the spectra for mimetites 1 and 2 are due to the $(AsO_4)^{3-}$ ion only. Whereas in Fig. 4, the spectra of the other three samples show bands attributable to both $(PO_4)^{3-}$ and $(AsO_4)^{3-}$ anions. Thus the fundamental bands of $(PO_4)^{3-}$ and $(AsO_4)^{3-}$ can be interpreted to identify the minerals. The spectra for mimetites 1 and 2 can be considered as standard. Mimetite 3 is strictly a phosphated mimetite.

4. Conclusions

The minerals of mimetite, arsenian pyromorphite and hedyphane have been analysed using NIR spectroscopy and the spectra related to the mineral structure.

(1) The minerals of mimetite and pyromorphite can be distinguished by means of the electronic spectra.
(2 In NIR spectra of the mimetite minerals, a prominent spectral feature observed for ferrous ion is a complex band system at ~10 000 cm^{-1} (1.00 μm).
(3) For arsenian pyromorphite, an additional feature observed at 10 735 cm^{-1} (0.93 μm) is assigned to the Cu(II) dd-transition. The intensity of this band is enhanced at the expense of Fe(II) in mimetite-1 and mimetite-2 and appeared at higher wavenumbers at ~11 140 cm^{-1} (0.90 μm).
(4) The cause of colour in mimetites (brown through to orange to yellow) depends on the impurities of Fe and/or Cu.
(5) The variation of spectral properties is related to the compositional variation of the minerals.
(6) The minerals show fine structure particularly in OH-stretching fundamental overtone region and the PO_4/AsO_4 stretching region. The multi-component bands derived for each profile in vibrational spectra enhance the ability to discriminate between the minerals. The presence of OH-stretching overtones at 7000 cm^{-1} (1.43 μm) is the effect of Cl substitution by OH.
(7) The observation of isomorphic substitution of $(AsO_4)^{3-}$ by $(PO_4)^{3-}$ in mimetites could easily be distinguished on the basis of their spectral properties from the mixed spectra of phosphate and arsenate ions in arsenian pyromorphite.
(8) The range of bands observed for phosphate in other samples are not observed in the spectra of mimetite-1 and mimetite-2 but appeared with a single broad profile having four component bands near 800 cm^{-1} attributed to the presence of the arsenate ion.
(9) The observation of single profile in the mid-IR with four component bands due to $(AsO_4)^{3-}$ ion near 800 cm^{-1} in mimetite-1 and mimetite-2 is evidence for isomorphic substitution of $(PO_4)^{3-}$ by $(AsO_4)^{3-}$.
(10) The substitution of $(PO_4)^{3-}$ for $(AsO_4)^{3-}$ characteristically decreases the vibrational wavenumbers of ν_3 and ν_1 modes of the $(PO_4)^{3-}$ slightly to lower wavenumbers when compared with the spectra of arsenian pyromorphite.

exclusively the cis complex [15,16]. The pronounced dependence of stereochemistry of the complex formed on the nature of the substituents on the phosphorus atom of the ligand prompted us to investigate the structure of tin complexes with other type of phosphoryl ligands.

In the present paper, we extend our studies to the complexation of the two fluoroalkyl phosphoramidates $(R_2N)_2P(O)OCH_2CF_3$ (R = Me and Et) with $SnCl_4$. The results are compared with those of related HMPA and $(Me_2N)_2P(O)F$ complexes [12,16].

2. Experimental

2.1. General experimental procedures

All preparations were carried out under a nitrogen atmosphere in solvents dried by standard techniques [17] and stored over molecular sieves. NMR spectra were recorded on a Bruker AC-300 spectrometer in CD_2Cl_2 solutions; ^{31}P at 121 MHz (85% H_3PO_4) and ^{119}Sn at 111.8 MHz ($SnCl_4$). ^{119}Sn NMR spectra were recorded in 10 mm NMR tubes containing 15–20% deuterated solvent. IR spectra: Perkin–Elmer Paragon 1000 PC.

Tin tetrachloride was distilled under vacuum before use. The ligands, 2,2,2-trifluoroethyl N,N,N′,N′-tetraalkylphosphorodiamidates $(R_2N)_2P(O)OCH_2CF_3$, were prepared as previously described in the literature [18].

2.2. Preparation of complexes

In a typical reaction $(R_2N)_2P(O)OCH_2CF_3$ (8 mmol) in dry $CHCl_3$ (10 cm^3) was slowly added to $SnCl_4$ (1.04 g, 4 mmol) in $CHCl_3$ (20 cm^3) and the mixture stirred at room temperature for 2 h. The complex $SnCl_4 \cdot 2(O)P(NR_2)_2OCH_2CF_3$ precipitated as a white powder which was filtered off, recrystallised from hot CH_2Cl_2 and dried in vacuo. Yields R = Me (**1**): 2.42 g, 83 % R = Et (**2**): 2.62 g, 78%. *Anal.* Calc. for $C_{12}H_{28}Cl_4F_6N_4O_4P_2Sn$ (**1**): C, 19.78; H, 3.87; N, 7.69. Found: C, 20.06; H, 3.95; N, 7.52%. *Anal.* Calc. for $C_{20}H_{44}Cl_4F_6N_4O_4P_2Sn$ (**2**): C, 28.56; H, 5.27; N, 6.66. Found: C, 28.22; H, 5.40; N, 6.70%. IR (KBr): $\nu_{P=O}$ (1150–1170 cm^{-1}); ν_{Sn-O} (470–480 cm^{-1}).

2.3. X-ray experimental

Details of the crystallographic data collection and refinement parameters are presented in Table 1. Crystals of **1** were obtained from a CH_2Cl_2 solution layered with hexane. Single crystal X-ray collection used an Enraf-Nonius CAD-4 automatic four-circle diffractometer operating at 298 K, using graphite-monochromated Mo Kα X-radiation ($\lambda = 0.71069$ Å). Structure solution and refinement were carried out using SHELX-97 computer programs [19,20] included in the WINGX software package [21]. Several attempts were made to grow good quality crystals of **2**, but these were unsuccessful.

R indices (all data)	$R = 0.036$, $wR = 0.089$

2.4. Computational details

Density functional theory (DFT) calculations were carried out on the cis and trans isomers of complex **1** and its ligand using the GAUSSIAN 98 suite of programs [22], with the hybrid functional B3LYP [23]. Basis sets used were LanL2DZ [24] for Sn and 6-31G* [25] for the other atoms. The geometries of both the cis and trans isomers of complex **1** and its ligand were optimised using analytical gradient. The harmonic vibrational frequencies of the different stationary points of the potential energy surfaces (PES) have been calculated at the same level of theory in order to identify the local minima as well as to estimate the corresponding zero-point vibrational energy (ZPE).

3. Results and discussion

3.1. Synthesis

The reaction of $SnCl_4$ with $(R_2N)_2P(O)OCH_2CF_3$ (R = Me or Et) in anhydrous chloroform resulted in the formation of white solids with the composition $SnCl_4 \cdot 2L$ ($L = (R_2N)_2P(O)OCH_2CF_3$). The solids are partially soluble in dichloromethane and chloroform, with **2** being more soluble. The complexes could be recrystallised from a large volume of anhydrous dichloromethane. They were characterised by elemental analysis and particularly by their NMR data and comparison with the corresponding data for the free ligands (see Table 2).

3.2. Spectroscopic studies

The infrared spectra show strong bands within the range 1150–1170 cm^{-1} attributed to $\nu_{P=O}$. The P=O stretching vibration is shifted towards lower wave numbers on coordination to the tin atom compared with its value for the free ligands. The coordination shift is about 130 cm^{-1} and is consistent with phosphoryl coordination to the tin atom. This shift is 128 cm^{-1} for $(Me_2N)_2P(O)OCH_2CF_3$ against 138 and 30 cm^{-1} for HMPA and $(Me_2N)_2P(O)F$, respectively [8,15] reflecting the relative similarity in the basicity strength with HMPA and the striking difference from $(Me_2N)_2P(O)F$. This is most probably due to the nature of the substituents on the phosphorus atom in these ligands (i.e. due to difference in the electronegativities of nitrogen, oxygen and fluorine atoms linked directly to the phosphorus atom of the ligand). The absorption band at 470–480 cm^{-1} corresponds to a stretching vibration of the Sn–O group.

The NMR spectra of the two complexes prepared are quite similar and the data obtained from these spectra are summarised in Table 2.

The ^{31}P NMR spectra of each of the complexes prepared showed at room temperature one signal flanked with Sn satellites. This signal is shifted to lower frequency compared with that of the free ligand. Such a behaviour is interpreted in terms of inductive effects resulting from a decrease in the electron density at phosphorus owing to the coordination of the phosphoryl oxygen of the ligand.

At low temperature (228 K), while the ^{31}P NMR spectrum of complex **2** remained practically unchanged, two signals displaying Sn satellites were observed in the spectrum of **1** (Fig. 1).

The corresponding ^{119}Sn NMR spectra of each complex displayed at room temperature a minor broad signal and a major lower frequency triplet in the region of hexacoordinated species [26]. The minor broad signal was converted at low temperature into the expected triplet. At 208 K, the spectrum showed therefore two triplet signals due to ^{119}Sn–^{31}P coupling (ratio of signals = ~1/1.3 for **1** and ~1/5 for **2**) (Fig. 2). Clearly, two species (isomers) with different proportions were present at this temperature and in each species the tin atom is coupled to two phosphorus

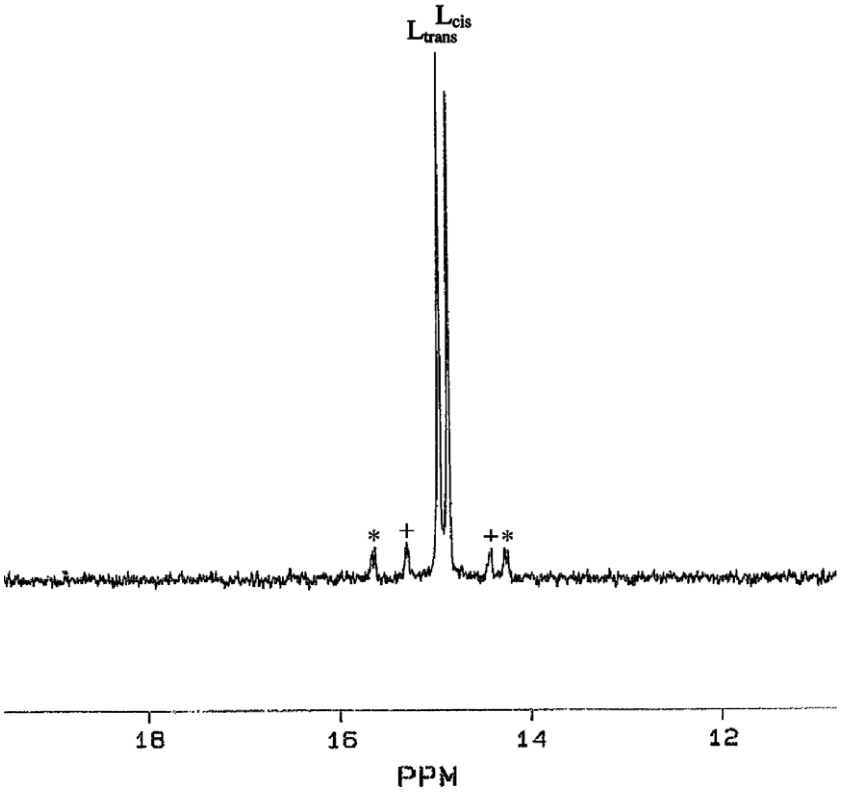

Fig. 1. ^{31}P–{^1H} NMR spectrum of complex **1** in CD_2Cl_2 at 228 K (* and + are Sn satellites of the ligand signal in trans (L_{trans}) and cis (L_{cis}) forms, respectively).

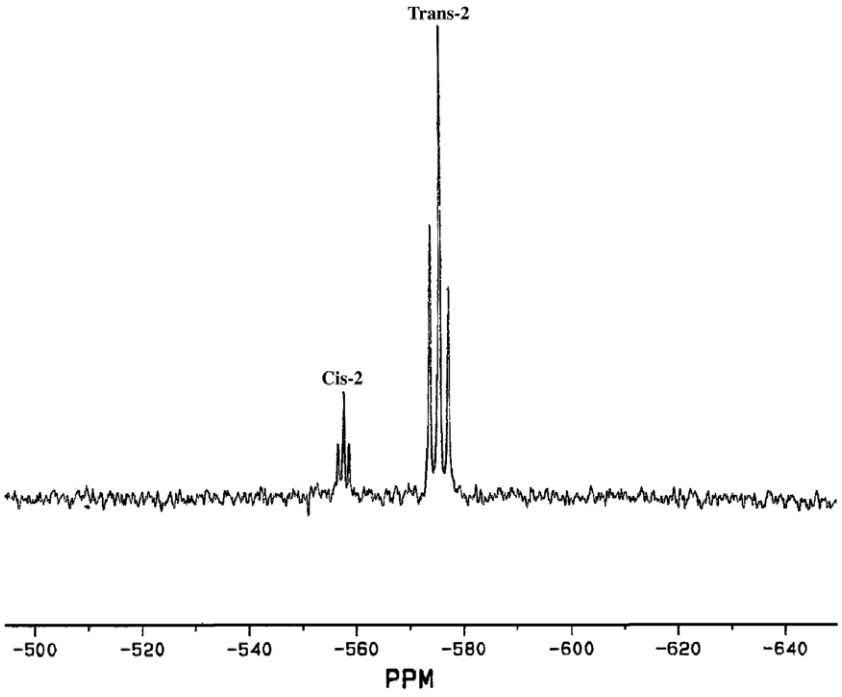

Fig. 2. ^{119}Sn NMR spectrum of complex **2** in CD_2Cl_2/CH_2Cl_2 at 208 K.

atoms, showing a stoichiometry of $SnCl_4 \cdot 2L$. This is in agreement with the ^{31}P NMR spectra where signals displaying Sn satellites with the corresponding coupling constants were observed.

It has been previously shown that the formation of hexacoordinate, 2:1, cis or trans-complexes of phosphoryl ligands with $SnCl_4$ is supported in solution by the appearance of a triplet pattern in the ^{119}Sn NMR spectrum [3,12]. In addition, the chemical shift and coupling constant of the ^{119}Sn signal provided valuable information on the geometry of the two phosphoramides in the hexacoordinate tin complex [11,12]. The trans hexacoordinate complexes have generally higher coupling constants than the corresponding cis complexes. For example, in the ^{119}Sn spectrum of $SnCl_4 \cdot 2$(HMPA), the trans complex has a $^2J(^{31}P–^{119}Sn)$ of 167 Hz at −727 ppm, whereas the cis-complex shows a $^2J(^{31}P–^{119}Sn)$ of 102 Hz at −719 ppm [12]. With this information, the isomers of the complexes in Table 2 could be assigned by analogy, i.e., all of the complexes which have higher $^2J(^{31}P–^{119}Sn)$ coupling constants could be assigned to the trans isomers and those with smaller $^2J(^{31}P–^{119}Sn)$ could be assigned to the cis ones.

It is therefore possible to assign the major species observed in the ^{31}P and ^{119}Sn NMR spectra of $SnCl_4 \cdot 2(O)P(NR_2)_2OCH_2CF_3$ (see Table 2) as the trans isomers. This is in contrast with the complex of $(Me_2N)_2P(O)F$ which forms predominantly the cis isomer, but in fair agreement with the HMPA complex that we have re-examined in the same conditions (see Table 3).

The ^{119}Sn NMR spectra also showed that the percentage of the trans isomer is, as expected, more important in **2** than in **1**. This difference between the methyl (**1**) and the ethyl (**2**) derivatives could be interpreted as due to steric effects, consistent with the ^{31}P NMR spectrum of **2** which showed only one signal (the trans isomer) even at low temperature.

Table 3
^{119}Sn NMR data[a] of the complexes $SnCl_4 \cdot 2L$ in dichloromethane

Ligand (L)	$\delta_{^{119}Sn}$		$^2J_{P–Sn}$		% trans[e]
	cis	trans	cis	trans	
$(Me_2N)_3P(O)$[b]	−569	−580	120	191	50
$(Me_2N)_2P(O)F$[c]	−548	−567	126	192	20
$(Me_2N)_2P(O)OCH_2CF_3$[d]	−555	−574	115	172	60

[a] Measured at slow exchange where both triplets are observed.
[b] 25 °C.
[c] −5 °C.
[d] −65 °C and e is the approximate percentage of the trans isomer measured from ^{119}Sn NMR signals.

3.3. X-ray crystallography

To elucidate the constitution of the complexes formed, as well as to provide a clear understanding of the effect of ligand structure on the stereochemistry of these complexes, we examined the solid state structure of complex **1**.

From a CH_2Cl_2 solution containing complex **1**, single crystals suitable for X-ray analysis were obtained through slow diffusion of hexane and found to contain 1:2 complex of the stoichiometry $SnCl_4 \cdot 2(O)P(NMe_2)_2OCH_2CF_3$. Selected bond lengths and angles are given in Table 4. The tin atom adopts an octahedral geometry with the two phosphoramide ligands trans to each other (Fig. 3) in agreement with $SnCl_4 \cdot 2$HMPA [10]. The molecule is

O1–Sn–O3	180.000(1)	O2–C5–C6	106.8(3)

[a] See Fig. 3 for labeling of the atoms, the tin atom is on a centre of symmetry.

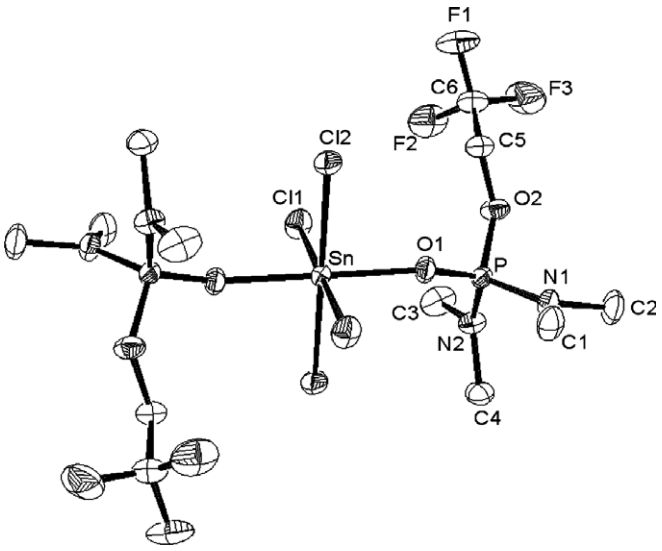

Fig. 3. ORTEP view of the crystal structure of complex **1** showing the atom numbering scheme. Atomic displacement ellipsoids are drawn at the 30% probability level and H atoms omitted for clarity. There is a centre of symmetry at the Sn atom.

centrosymmetric with Sn–Cl = 2.395(9), 2.400(10) Å. The Sn–O bond (2.094(2) Å) is slightly shorter than that in $SnCl_4 \cdot 2HMPA$ (2.130 Å) while the P=O bond is longer (1.507(2) versus 1.49 Å in $SnCl_4 \cdot 2HMPA$). These bond length changes presumably reflect the effect of the substitution of one dimethylamino group in HMPA by a fluoroalkoxy group. As a consequence, the P–N bonds in complex **1** are shorter (1.621(3) versus ~166 Å in $SnCl_4 \cdot 2HMPA$) due to increased hyperconjugation of the nitrogen lone pairs to the phosphorus atom [27]. This is also consistent with the sharper Sn–O–P bond angle (151° versus 165° in the HMPA complex) observed in **1** as compared to the HMPA complex.

3.4. Theoretical calculations

To shed more insight into the structures of the two complexes prepared, the geometries of the cis and trans isomers of **1** were optimised by means of the DFT/B3LYP method. The fully optimised structure of the trans isomer shown in Fig. 4 is very similar to the X-ray structure. The cis and trans isomers of complex **1** and its ligand have been identified as local minima on the singlet potential energy surfaces (PES). Optimised values of selected geometrical parameters are listed in Table 5. The potential energy difference between the two isomers of **1** was 4.2 kcal/mol, indicating the stability of the trans over the cis isomer (see Fig. 4). This difference is in good agreement with both the experimental NMR and X-ray data. For comparison purposes, we have also carried out DFT/B3LYP calculations at the same level of theory on the complex $SnCl_4 \cdot 2(O)PF(NMe_2)_2$ and found that, in contrast to complex **1**, the trans isomer was 2.1 kcal/mol less stable than the cis form which further confirms the interpretation of our NMR data.

The value of the Sn–O distance, 2.094 Å, as well as the other bond distances and angles are in good agreement with the values obtained in the crystal structure. Interestingly, complex **1** shows a lengthening of the Sn–O bond and a shortening of the Sn–Cl bond on going from the trans to the cis isomer (see Table 5), consistent with X-ray analysis reported for similar molecules [10,12,28].

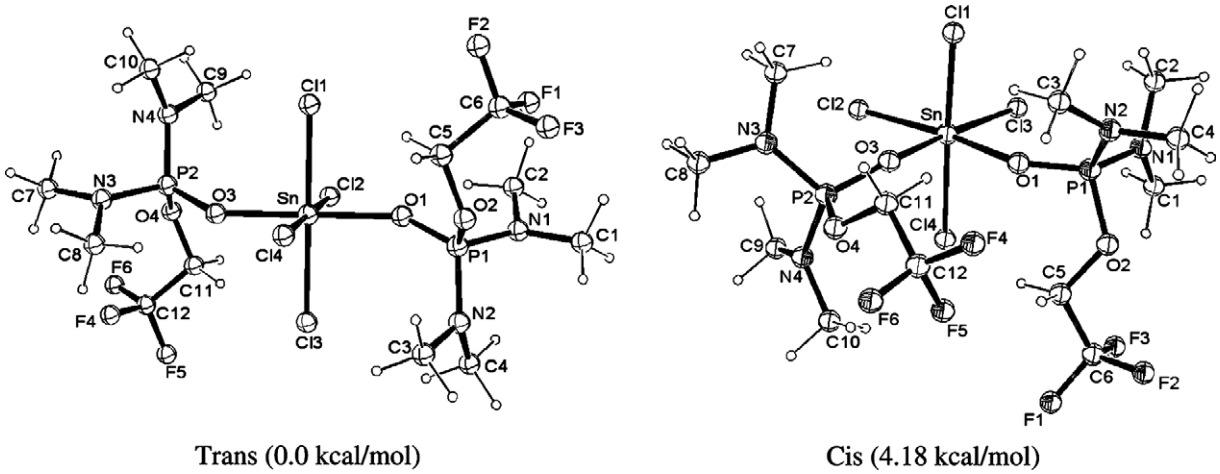

Fig. 4. ORTEP view of the DFT/B3LYP optimised structures and relative energies of cis and trans isomers of complex **1**.

Table 5
Selected DFT/B3LYP optimised geometrical parameters[a] for complex **1** and its ligand

Parameter	Ligand	cis	trans
Sn–Cl1		2.426	2.438
Sn–Cl2		2.408	2.429
Sn–Cl3		2.404	2.438
Sn–Cl4		2.443	2.429
Sn–O1		2.130	2.085

O2–C5–C6	108.9	106.8	109.3

[a] See Fig. 4 for labeling of the atoms. Distances are in Å and angles in °.

In complex **1**, the coordination mode is confirmed by a lengthening of the P═O bond compared to that of the free ligand (1.490 Å) calculated at the same level of theory. This lengthening is consistent with the low stretching frequency observed in the IR spectra and may also explain the differences observed in the ^{31}P NMR chemical shifts between the free and bound ligands in solution. On forming complex **1**, the ligand also shows a shortening of both the P–O and P–N bond distances by about 0.03 Å. This is accompanied by an increase in the bond angles at the phosphorus atom, i.e., the O–P–N and N–P–N angles are increased by ~2° and 3°, respectively, compared to those of the free ligand (see Table 5). Comparable changes in geometry, i.e., shortened bonds and increased angles at the phosphorus atom have been observed in related complexes [29,30].

It is worthnoting that, as shown in Tables 4 and 5, the overall agreement between theoretical and experimental X-ray structures leads further support to the structural characterisation discussed above. Differences in the details may be due in part to crystal packing influences. For example, in *trans*-**1**, the P–O–Sn angle is predicted to be more acute (see Table 5) than actually observed. Similarly, the predicted structure of *trans*-**1** is much more symmetrical than observed in the crystal (see Fig. 4).

4. Conclusion

New complexes of phosphoramidates with $SnCl_4$ have been synthesised and studied by a combination of NMR spectroscopy, X-ray analysis and DFT/B3LYP calculations. It was shown that, unlike the analogous $(R_2N)_2$-P(O)F, the phosphoramidates examined prefer to form a trans complex with $SnCl_4$. This preferential complexation is likely due to steric hindrance from the fluoroalkoxy group on the phosphorus atom of the phosphoramidate ligand. We have also shown that the insights provided by combining experimental and theoretical studies can offer new concepts for a better understanding of the stereochemistry of such complexes.

polymers of sac with mercury(II) [20], lead(II) [21–23], silver(I) [24–29] and copper(II) [30]. In the present study, we utilized the sac ligand together with piperazine (ppz) and *N*,*N*′-bis(2-hydroxyethyl)piperazine (bheppz). In this paper, we report synthesis and single-crystal structures of two new coordination polymers, $[Ag(\mu\text{-sac})(\mu\text{-ppz})]_n$, **1** and $[Ag(\mu\text{-sac})(\mu\text{-bheppz})]_n$, **2**, constructed from assembly of silver(I) with the corresponding ligands. Both complexes consist of single linear chains, and hydrogen bonding and π–π stacking interactions between these chains led to the generation of two-dimensional networks.

2. Experimental

2.1. Materials and measurements

All reagents were purchased from commercial sources and used without further purification. The elemental analyses (C, H and N) were performed on a Vario EL Elemental Analyser. IR spectra were recorded on a MATTSON 1000 FT/IR spectrophotometer as KBr pellets in the frequency range 4000–400 cm^{-1}. Thermal analysis curves (TG and DTA) were obtained from a Rigaku TG8110 thermal analyzer in a static air atmosphere using a sample size of 5–10 mg with a heating rate of 10 °C min^{-1}.

2.2. Synthesis of the silver(I) complexes

Complex **1** was prepared by the following method: $Na(sac) \cdot 2H_2O$ (1 mmol, 0.24 g) was added to the solution (20 ml) of $AgNO_3$ (1 mmol, 0.17 g) dissolved in the mixture of water and isopropanol (1:3, v:v) with stirring. Then, a suspension with a white precipitate formed and the drop-wise addition of the aqueous solution (10 ml) of ppz (1 mmol, 0.09 g) to the suspension resulted in a clear solution, which was kept in darkness at room temperature and pale yellow prisms were obtained after two months. $[Ag(\mu\text{-sac})(\mu\text{-ppz})]_n$ (**1**): Yield 83%. *Anal.* Calc. for $C_{11}H_{14}N_3O_3SAg$: C, 35.12; H, 3.75; N, 11.17. Found: C, 35.35; H, 3.84; N, 11.42%. IR data (KBr): *v* (cm^{-1}) 3538–3268 sb, 3062 w, 2937 vw, 2864 vw, 1651 vs, 1584 s, 1450 m, 1327 m, 1265 vs, 1141 vs, 966 s, 874 m, 750 m, 688 w, 616 m, 544 m.

Complex **2** was prepared using the same method as for **1**. The initial ligand was *N*,*N*′-bis(2-hydroxyethyl)piperazine (bheppz). Colorless prism-shaped crystals of **2** were obtained at room temperature after four days. $[Ag(\mu\text{-sac})(\mu\text{-bheppz})]_n$ (**2**): Yield 86%. *Anal.* Calc. for $C_{15}H_{22}N_3O_5SAg$: C, 35.03; H, 3.47; N, 7.43. Found: C, 35.25; H, 3.65; N, 7.66%. IR data (KBr): *v* (cm^{-1}) 3400–3147 sb, 3062 vw, 2981 vw, 1651 vs, 1630 vs, 1585 s, 1456 m, 1331 m, 1284 vs, 1250 vs, 1153 vs, 968 s, 928 s, 772 s, 705 m, 675 vs, 636 m, 609 s, 543 s, 509 m.

2.3. X-ray crystallography

Intensity data for the title complexes were collected using a Stoe-IPDS-2 diffractometer equipped with a graphite monochromated (Mo Kα radiation, $\lambda = 0.71073$ Å) at 100 K. The structure was solved by direct methods using SHELXS-97 [31] and refined by a full-matrix least-squares procedure using the program SHELXL-97 [31]. All non-hydrogen atoms were easily found from the difference Fourier map and refined anisotropically. All hydrogen atoms were included using a riding model. Details of crystal data, data collection, structure solution and refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis and FT-IR characterization

Complexes **1** and **2** were readily prepared by the direct reaction of $AgNO_3$ and $Na(sac) \cdot 2H_2O$ in the presence of corresponding co-ligands ppz and bheppz in dark at room temperature and obtained in high yields of over 80%. The analytical data (C, H, and N) and X-ray crystal structure analysis confirmed the chemical formulation of these complexes. The title complexes are non-hygroscopic and stable in air at ambient temperatures, but somewhat light sensitive after a long exposure to light. Complex **1** is insoluble in water and common organic solvents, but complex **2** shows moderate solubility in the mixtures of isopropanol and water.

The FT-IR spectra of both complexes exhibit the characteristic bands of the sac and secondary ligands. The strong and broad absorption bands occurred above 3150 cm^{-1} are assigned to the ν(OH) or ν(NH) vibrations of co-ligands involved in hydrogen bonding, while the relatively weak bands in the frequency range 2900–31 000 cm^{-1} are due to the absorption of the CH groups. The ν(C=O) vibrations of sac in the title complexes are observed as a very sharp band centered at *ca.* 1650 cm^{-1}. In complex **2**, the carbonyl O atom of the sac ligand does not participate in metal bonding and appears as two sharp bands at 1651 and 1630 cm^{-1}. However, complex **1** contains bridging sac ligands *via* the carbonyl O atom, and in this case, a significant shift to lower frequencies should be occurred due to a weakening of the carbon–oxygen bond. The spectral analysis shows that the band of the carbonyl group in **1** appears at 1651 cm^{-1} and no significant shift in the carbonyl band of **1** is observed compared to that of complex **2**. It is an unexpected observation and similar findings in the carbonyl band of sac were also observed in the IR spectra of $[Ag(sac)(nia)]_n$ [29]. It may be concluded that in the presence of intra- and intermolecular interactions such as hydrogen bonds, the ν(C=O) frequency does often not correlate to the coordination mode of the sac ligand. The asymmetric and symmetric stretchings of the SO_2 group in the spectra of **1** and **2** are observed as two strong IR bands at *ca.* 1260 and 1150 cm^{-1}, respectively. Among these complexes, the coordination of the sulfonyl group occurs only in **2**, but no significant changes were observed in the frequency of this group compared to those found in the spectra of **1**. In conclusion, the sulfonyl stretching modes in metal complexes are not easily assigned as that of the carbonyl stretching.

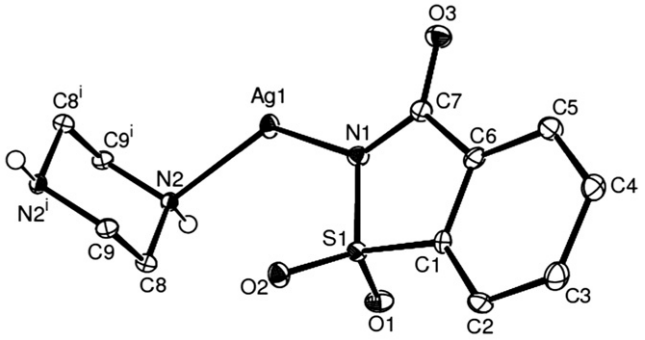

Fig. 1. The building-block unit of **1** with the atom labeling scheme. CH hydrogen atoms are omitted for clarity. Symmetry code (i) $-x, -y, 1-z$.

3.2. Description of crystal structures

The structure of the building-block unit of **1** is shown in Fig. 1, together with the atom labeling scheme. The selected bond lengths and angles are given in Table 2. Each sac anion adopts a μ_2-bridging mode to connect with two silver ions through the imino N and carbonyl O atoms, forming binuclear $[Ag_2(sac)_2]$ units. Thus, a planar eight-membered bimetallic ring is formed by two silver(I) ions linked by two N–C–O bridges. These dimeric units are further bridged by neutral ppz ligands, leading to an infinite linear chain propagating along *c* (Fig. 2). The Ag–Ag separation within the metallocycle is 3.673 Å, and slightly larger than the upper limit value of 3.30 Å for an Ag···Ag contact in coordination compounds [32]. The Ag–Ag distance separated by the ppz ligands is 6.063 Å. In the crystal structure of **1**, the silver(I) ions are coordinated by one nitrogen atom from ppz, one N atom from sac and one O atom from another sac. The coordination geometry is considered T-shaped rather than trigonal, because of the significant deviation from the ideal trigonal geometry (120°), N1–Ag1–N2 127.47(9)°, N1–Ag1–O3^{i} 143.95(9)°, N1–Ag1–O3^{i} 88.20(9)°.

Ag1–N2	2.2884(15)	N2–Ag1–O2^{ii}	88.08(5)
Ag1–O2^{ii}	2.5787(13)	N1–Ag1–O6	127.91(4)
Ag1–O6	2.4590(13)	N2–Ag1–O6	73.77(4)
N1–Ag1–N2	151.91(5)	O2^{ii}–Ag1–O6	86.43(3)

Symmetry operations: (i) $-x, -y, 2-z$ and (ii) $1-x, 1-y, 1-z$.

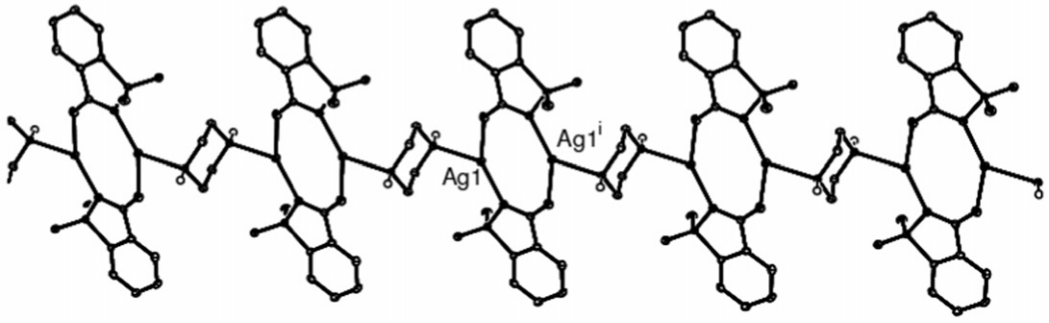

Fig. 2. A fragment of a one-dimensional chain in **1**. Symmetry code (i) $-x, -y, 2-z$.

Three coordination polymers, $[Ag_2(\mu\text{-sac})_2(\mu\text{-hep})_2]_n$ [25], $[Ag_2(sac)_2(en)(H_2O)]_n$ [27] and $[Ag(sac)(nia)]_n$ [29], containing N, $O_{carbonyl}$ bridging sac ligands have been reported so far. The Ag–N_{sac} bond distance of 2.172(3) Å in **1** is similar to those found in the reported complexes, while the Ag–$O_{carbonyl}$ bond distance of 2.297(2) Å is considerably shorter than that of $[Ag_2(\mu\text{-sac})_2(\mu\text{-hep})_2]_n$ [25].

The sac ligand is essentially planar and the puckering parameters of the ppz ring system in **1** are $q = 0.605(2)$ Å and $\theta = 0°$, suggesting that the ppz ring exhibits an essentially "undistorted" (cyclohexane like) chair conformation. The individual chains interact with each other *via* N–H···O hydrogen bonds (see Table 3), leading to a two-dimensional layer parallel to the *bc*-crystallographic plane as shown in Fig. 3a. The nearest Ag–Ag separation between the polymeric chains is 7.037 Å. These hydrogen bonded layers stack by way of face to face aromatic π(sac)···π(sac) interactions [$C_g \cdots C_g^i$ 3.605(2) Å; C_g = centroid of atoms C1–C6; (i): $1-x$, $1-y$, $2-z$], resulting in the formation of extended three-dimensional supramolecular network (Fig. 3).

The fundamental building unit of the crystal structure of **2** is shown in Fig. 4, together the atom labeling scheme. The selected bond lengths and angles are listed in Table 2. Each silver(I) ion in the building block of **2** is doubly bridged by two sac ligands forming non-planar eight-membered metallo-chelate rings as shown in Fig. 5. These dimeric units are further bridged by bheppz ligands leading to a one-dimensional polymeric chain running along the crystallographic axis *a* (Fig. 5). The coordination geometry around the silver(I) ions is a highly distorted tetrahedron with an AgN_2O_2 chromophore with two N, O bonds from sac, and two N, O bonds from bheppz. The large distortion in the coordination geometry is evident from the angles around the silver(I) ion (see Table 2). The Ag–Ag distances separated by bridging sac and bhep ligands are 4.462 Å and 5.935 Å, respectively, indicating that there is no metallophilic interaction between the two adjacent Ag atoms.

The bhep ligand has four donor sites and each end having a N atom and a O atom behaves as a bidentate donor, forming a five-membered chelate ring around silver(I). In contrast to $[Ag_2(sac)_2(heppz)]_n$ [30], containing a similar ligand with the same moiety of bheppz, all the silver atoms are equivalent in **2**. The most interesting aspect of complex **2** is the coordination of the sulfonyl O atom of the sac ligand, since the sulfonyl group is less basic and only occasionally involves in coordination and the only known examples are [Ag(sac)] [33], Na[$Ag(sac)_2$] [24] and $[Ag(sac)(dmpy)]_n$ [26], where dmpy is 2,6-pyridinedimethanol. The Ag–$O_{sulfonyl}$ bond distance of 2.5787(13) Å is similar to those of [Ag(sac)] [2.45 Å] [33] and Na[$Ag(sac)_2$] [2.6390(10) Å] [24], but much shorter than those found in $[Ag(sac)(dmpy)]_n$ [2.8218(13) and 2.9379(14) Å] [26]. A tetranuclear silver(I)-sac complex, $[Ag_4(sac)_4(pypr)_2]$, is an

Table 3
Hydrogen bond data for complexes **1** and **2**

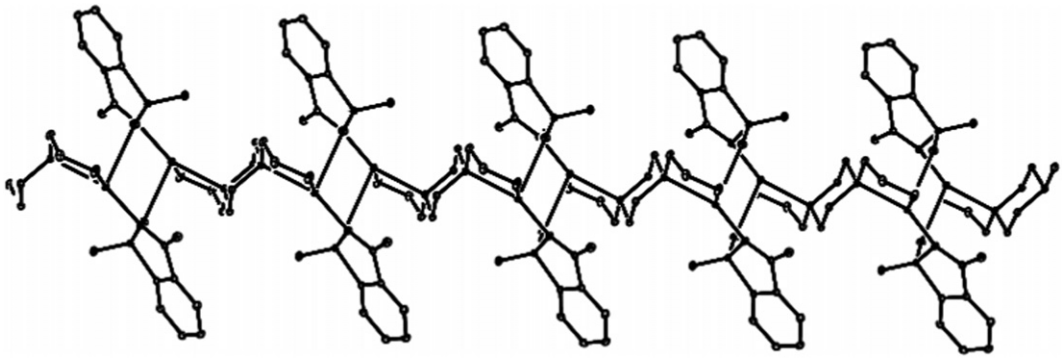

Fig. 5. View of one-dimensional chain of **2**.

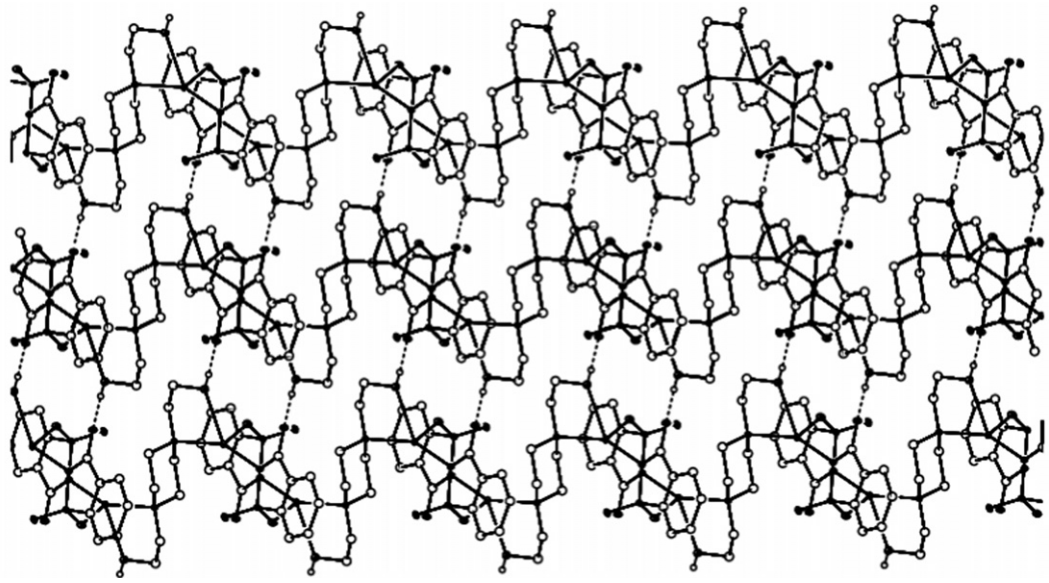

Fig. 6. Perspective view of the two-dimensional framework of **2** along *b* formed by O–H···O hydrogen bonds.

interesting example, exhibiting both N, $O_{carbonyl}$ and N, $O_{sulfonyl}$ bridges of sac [34].

The sac ligand in **2** is essentially planar, whereas the puckering parameters of the piperazine ring system of bheppz are $q = 0.600(2)$ Å and $\theta = 179.55°$, suggesting that the piperazine ring exhibits a typical chair conformation as in ppz in **1**. As shown in Fig. 6, individual polymeric chains are cross linked by the strong O–H···O and weak C–H···O intermolecular hydrogen bonds, leading to a hydrogen bonded two-dimensional layer parallel to the *ac* plane.

3.3. Thermal analysis

The thermal behaviors of complexes **1** and **2** were examined by DTA and TGA under the atmosphere of air. The DTA and TGA curves in Fig. 7a show that **1** does not decompose up to 215 °C. The total weight loss of 48.87% between 215 and 300 °C is consistent with the mass loss of one mole of ppz and 0.5 moles of sac ligands. The removal of ppz is indicated by an endothermic peak at 252 °C. The decomposition of the rest of sac is observed as a highly endothermic peak at 461 °C and completed at 498 °C. The remaining mass of 28.58% is metallic silver that is in agreement with the calculated value of 28.68%.

Thermal curves of **2** are illustrated in Fig. 7b. The DTA and TGA results indicate that the thermal stability of complex **2** is somewhat lower than that of complex **1**, and it begins to decompose at 188 °C displaying two stages of mass loss (Fig. 3b). The first mass loss of 37.02% from 188 to 331 °C is due to the loss of the bheppz ligand (calculated value 37.54%). An endothermic at 225 °C and an exothermic peak 273 °C are mainly attributed to the decomposition of the bhep ligand. Upon increasing temperature, the degradation of the sac anion occurs in the second step in the temperature range 332–619 °C with a violently exothermic reaction which is characteristic for the decomposition of the sac moiety in metal sac complexes [35]. The remaining mass of 22.90% is presumably metallic

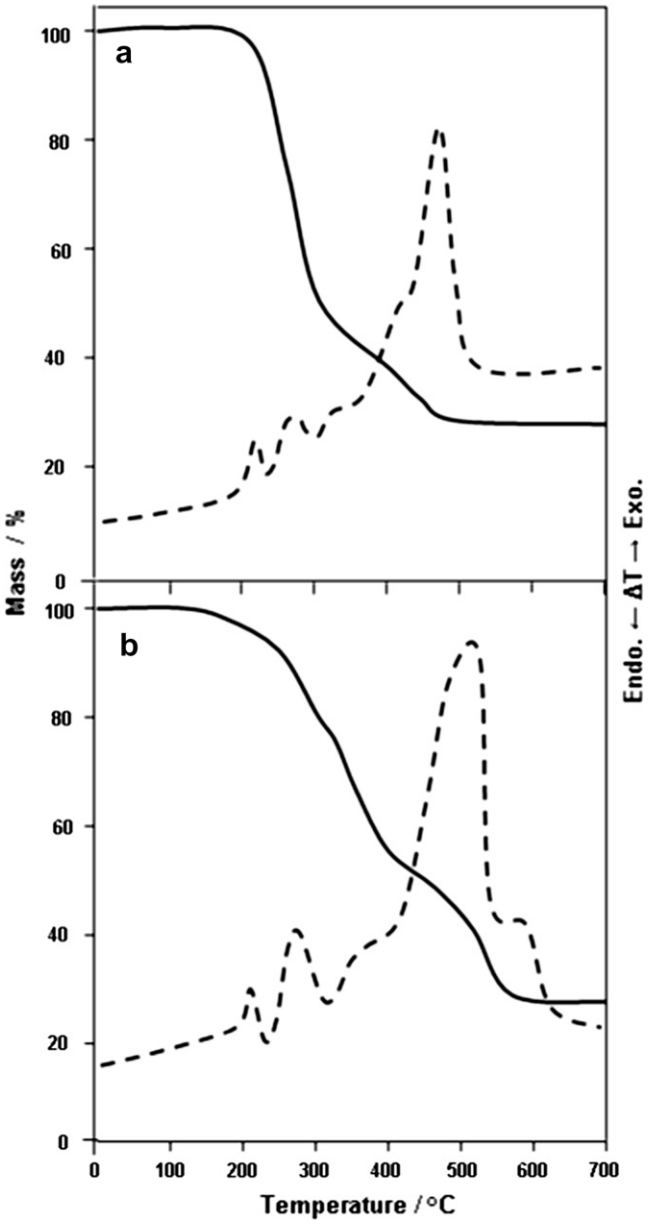

Fig. 7. Thermal analysis (TG and DTA) curves of **1** (a) and **2** (b).

silver that is in agreement with the calculated value of 23.25%.

Appendix A. Supplementary data

CCDC 281719 and 658776 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

The spectroscopic and redox behaviour of the Re(I) complexes are ligand dependent and can be tuned by varying the identity of their chelate ligands, so there is a clear need to synthesize and investigate novel species of this type.

Bis(pyrazol-1-yl)alkanes constitute a family of stable and flexible bidentate ligands, isoelectronic and isosteric with the well-known bis(pyrazolyl)borates. The coordination properties of bis(pyrazol-1-yl)alkanes may be varied in a rather wide range by introducing substituents into the pyrazole rings. Hence, the donor ability of the ligands is determined by the presence of electron-withdrawing or electron-donating functional groups, and steric factors are altered by the introduction of bulky alkyl groups into the rings and the alkane bridge between them [13].

These molecules form a variety of coordination compounds with main group and transition metals [14–19], but rhenium complexes with bis(pyrazol-1-yl)alkane ligands have been studied relatively little [20,21].

Here, we present the synthesis, spectroscopic characterization, crystal and molecular structures of two novel rhenium tricarbonyl complexes $[Re(CO)_3(bdmpzm)Cl]$ (**1**) and $[Re(CO)_3(bpzm)Cl]$ (**2**), where bdmpzm stands for bis(3,5-dimethylpyrazol-1-yl)methane and bpzm is bis(pyrazol-1-yl)methane.

The geometry of **1** has been optimized with density functional theory (DFT) calculations. Currently, the DFT method is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [22,23]. The spin-allowed singlet–singlet electronic transitions of **1** have been calculated with the time-dependent DFT method (TDDFT method), and a good assignment with the experimental spectrum has been observed. The lowest excited singlet and triplet sates were optimized for complex **1** and its photophysics was investigated.

2. Experimental

2.1. General procedure

The reactions were performed under an argon atmosphere. The solvents were dried before use, using the appropriate drying reagents. $Re(CO)_5Cl$ was purchased from Aldrich and used as received. The bis(3,5-dimethylpyrazol-1-yl)methane and bis(pyrazol-1-yl)methane were synthesized according to the literature methods [24].

The IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. The electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in chloroform solution. The ^1H NMR spectrum was recorded with a Bruker AM 400 spectrometer at room temperature using $CDCl_3$ as a solvent. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[Re(CO)_3(bdmpzm)Cl]$ (**1**)

$Re(CO)_5Cl$ (0.2 g, 0.55 mmol) and bdmpzm (0.13 g, 0.64 mmol) in toluene (80 cm^3) were refluxed for 6 h. The resulting reaction mixture was allowed to cool to room temperature and reduced in volume to ~10 ml. A white solid was filtered off, washed with hexane, then diethyl ether, and dried; yield 85%. Single crystals of complex **1**were grown by the slow diffusion of diethyl ether into a solution of the complex dissolved in dichloromethane.

IR (KBr, cm^{-1}): $\nu_{CO} = 2025$, 1923 and 1868; ν_{CN} and $\nu_{C=C} = 1574$ and 1560.

Anal. Calc. for $C_{14}H_{16}N_4O_3ClRe$: C, 31.97; H, 3.07; N, 10.65. Found: C, 31.76; H, 3.20; N, 10.76%.

^1H NMR (400 MHz, $CDCl_3$): $\delta = 2.40$ (s, 6H, $-CH_3$), 2.60 (s, 6H, $-CH_3$), 6.04 (s, 2H, $-CH_2-$), 7.56 (s, 2H, HC).

2.3. Preparation of $[Re(CO)_3(bpzm)Cl]$ (2)

A procedure similar to that for **1** was used with $Re(CO)_5Cl$ (0.2 g, 0.55 mmol) and bpzm (0.1 g, 0.67 mmol). A white precipitate of **2** was collected in 90% yield. Single crystals of complex **2** were grown by slow diffusion of diethyl ether into a solution of the complex dissolved in dichloromethane.

IR (KBr, cm^{-1}): $\nu_{CO} = 2028$, 1920 and 1895; ν_{CN} and $\nu_{C=C} = 1520$ and 1510.

Anal. Calc. for $C_{10}H_8N_4O_3ClRe$: C, 26.46; H, 1.78; N, 12.34. Found: C, 26.56; H, 1.70; N, 12.49%.

2.4. Crystal structure determination and refinement

The X-ray intensity data of **1** and **2** were collected on a KM-4-CCD automatic diffractometer equipped with a CCD detector and graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and absorption corrections [25] were applied. The structures were solved by the Patterson method and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent carbon atom with an individual isotropic temperature factor equal to 1.2 times the value of the equivalent temperature factor of the aromatic parent atom and equal to 1.5 times the value of the equivalent temperature factor of the methyl parent carbon atom. During refinement the methyl groups were allowed to rotate about their local threefold axis. SHELXS97 [26], SHELXL97 [27] and SHELXTL [28] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs. In compound **1**,

Re(1)–Cl(1)	2.5183(14)	C(1)–Re(1)–N(1)	93.72(13)
Re(1)–N(1)	2.185(3)	C(2)–Re(1)–N(1)	92.94(14)
Re(1)–N(3)	2.213(3)	C(3)–Re(1)–N(1)	176.07(12)
C(1)–O(1)	1.158(5)	C(1)–Re(1)–N(3)	95.67(14)
C(2)–O(2)	1.161(5)	C(2)–Re(1)–N(3)	172.09(13)
C(3)–O(3)	1.159(5)	C(3)–Re(1)–N(3)	96.33(14)
		C(1)–Re(1)–Cl(1)	178.76(11)
		C(2)–Re(1)–Cl(1)	89.78(13)
		C(3)–Re(1)–Cl(1)	89.90(12)
		N(1)–Re(1)–Cl(1)	87.28(8)
		N(3)–Re(1)–Cl(1)	85.22(8)
		N(1)–Re(1)–N(3)	80.72(10)
		O(1)–C(1)–Re(1)	177.6(3)
		O(2)–C(2)–Re(1)	177.6(4)
		O(3)–C(3)–Re(1)	179.2(4)

along the Re(1)–C(1)–O(1) bonds some peaks and holes are found on difference Fourier synthesis and the largest U values of the C(1) and O(1) atoms displacement parameters are directed along the bonds, so libration analysis was performed and corrected values of the lengthened Re(1)–C(1) bond and shortened C(1)–O(1) bond are given in Table 1.

3. Computational details

The gas phase geometry of the neutral complex **1** was optimized without any symmetry restrictions in the singlet ground-state using the hybrid B3LYP [29,30] and pure BP86 [31] functionals of GAUSSIAN-03 [32]. LANL2DZ with an additional *d* function with the exponent $\alpha = 0.3811$ and *f* function with the exponent $\alpha = 2.033$ or MWB60 with an additional *f* function with the exponent $\alpha = 0.48989$ basis sets were [33–35] chosen for the rhenium atom and the standard 6-31G basis set was used for all other atoms. For chloride, oxygen, carbon and nitrogen atoms, diffuse and polarization functions were added [36,37]. The optimized ground-state geometry of **1** was verified by performing a frequency calculation. All vibrations were real, thus the optimized geometry corresponds to a true energy minimum.

TDDFT and TDDFT/PCM [38] calculations were employed to produce a number (90) of singlet excited-states starting from the ground-state geometry optimized in the gas phase. The ground-state gas phase structure of **1** was not re-optimized in solvent using the PCM calculation.

The geometry of the singlet excited states was optimized in the gas phase with the use of the TURBOMOLE [39,40] program. The photophysical property calculations were performed with the use of the B3LYP functional and MBW60 basis set for the rhenium atom.

4. Results and discussion

4.1. Preparation and infrared data

The title complexes were prepared by refluxing $[Re(CO)_5Cl]$ with a small excess of the appropriate N–N ligand (bdmpzm or bpzm) in toluene. They were isolated as air-stable, microcrystalline solids, soluble in common organic solvents. The infrared spectra of **1** and **2** display three bands in the carbonyl stretching region: a sharp intense band at ~2025 cm^{-1} and two lower-energy bands. This pattern corresponds to three CO units in a *fac* isomer arrangement [41].

4.2. Crystal structures

The crystallographic data for the title complexes are given in Table 1, and the molecular structures of **1** and **2** are shown in Figs. 1 and 2. The two crystal structures belong to the centrosymmetric $P\bar{1}$ triclinic space group and the ligand arrangement around the rhenium atom is the same for both structures.

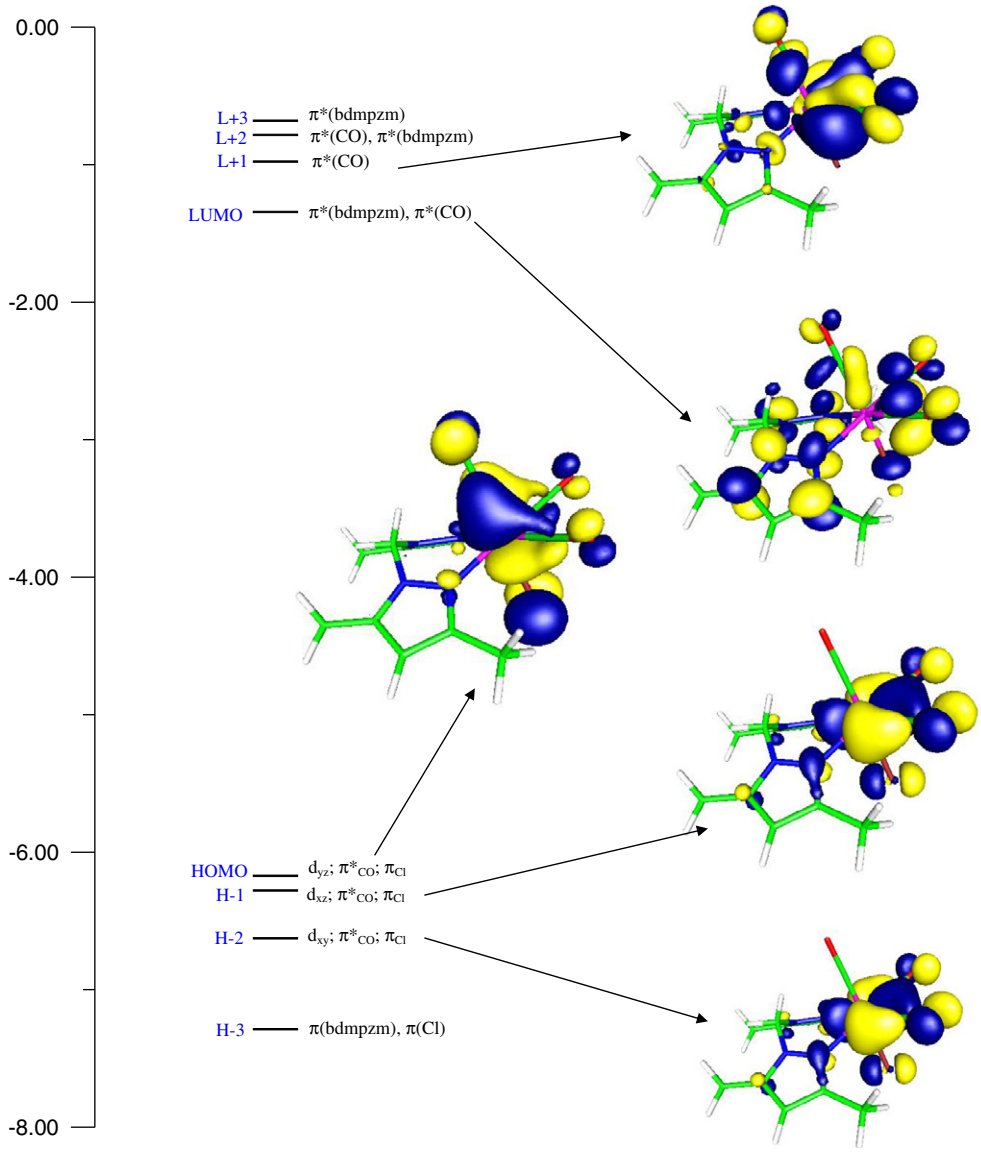

Fig. 3. The energy (eV), character and some contours of the occupied and unoccupied molecular orbitals of **1**.

Upon coordination of bis(3,5-dimethylpyrazol-1-yl)methane and bis(pyrazol-1-yl)methane to rhenium, a six-membered cycle (made by the four nitrogen atoms, the rhenium atom and the carbon atom) is formed, and the formed ring shows a *boat* conformation with the rhenium and the carbon atoms off the plane defined by the four nitrogen atoms (the deviations from the least-squares plane are equal to 0.728(11) and 0.660(11) Å for **1** and 0.772(5) and 0.627(5) Å for **2**). The planar pyrazole rings, in the range of experimental error, are inclined at 54.90(35)° and 60.81(13)°, respectively, for **1** and **2**. The major difference between **1** and **2** is caused by the presence of the additional methyl groups, which leads to overcrowding in the equatorial plane and interactions between the chloride and methyl groups in **1** (C(8)–H(8C)···Cl(1) with a D···A distance of 3.611(12) Å and a D–H···A angle of 141.5°) [42,43]. This manifests itself in bond length extensions and bond angle changes to overcome overcrowding. Thus, the Re–N distances in **1** are longer than the Re–N distances in **2** (Tables 2 and 3). Concomitant with the Re–N bond length extension, on going from **1** to **2**, there is a 3.18° increase in the N–Re–N angle.

4.3. Optimized geometry

The gas phase geometry of **1** was optimized in a singlet state by the DFT method with the hybrid B3LYP and pure BP86 functionals using two different basis sets (see Section 3). Selected calculated bond lengths and valence angles of **1** are gathered in Table 2.

For both functionals the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in

the calculations. The Re–Cl bond length is considerably better reproduced by the pure BP86 functional. In the case of the calculations with the hybrid functional, the Re–Cl bond is overestimated. However, the choice of the basis set has only a small effect on the geometric parameters of the optimized molecule.

4.4. Electronic structure

The simplified molecular orbital diagram of **1** with several contours of occupied and unoccupied MOs is presented in Fig. 3. The energy and compositions of the molecular orbitals were calculated by the DFT method with the hybrid B3LYP functional and MBW60 basis set for the rhenium atom, including a solvent effect. The HOMO–LUMO gap equals 4.83 eV. The low-lying virtual orbitals correspond mainly to π^*_{bdmpzm} and π^*_{CO}. The higher virtual orbitals are delocalized amongst the Re and carbonyls.

The three highest occupied molecular orbitals are predominately localized on the rhenium atom, corresponding to a $(5d_{xy})^2(5d_{xz})^2(5d_{yz})^2$ occupation of the central ion. However, ligand contributions are also important. All these orbitals have a considerable CO and Cl character.

4.5. Electronic spectra

The electronic absorption spectra of the prepared complexes were measured at room temperature in chloroform solution. The experimental and calculated electronic spectra of **1** are compared in Figs. 3a–3c. Each calculated transition is represented by the gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. The shape of the UV–Vis spectrum of **2** is the same as for **1**; the absorption bands of complex **2** were recorded at 289.0 ($\varepsilon = 8460\ dm^3\ mol^{-1}\ cm^{-1}$) and 227.2 nm ($\varepsilon = 22{,}320\ dm^3\ mol^{-1}\ cm^{-1}$).

Figs. 3a–3c present the effect of the functional, basis set and solvent on the TD-DFT simulation of the UV–Vis spectrum of **1**. As seen in Figs. 3a–3c, the use of the pure functional BP86 and neglecting the solvent strongly underestimate the energies of the low-lying electronic transitions. Changing the functional from BP86 to B3LYP shifts the

π,π* – Denote orbitals of the bdmpzm ligand.

low-lying CT transitions to higher energies. Including the solvent in the calculations has a similar effect – low-lying CT transitions are shifted to higher energies. The choice of the basis set has only a small effect on the transition energies. Thus, a very good agreement with the experimental spectrum is obtained when the hybrid B3LYP functional is used together with the PCM model for $CHCl_3$ solvent.

Table 4 shows the spin-allowed singlet–singlet electronic transitions of **1** calculated with the TDDFT method using the hybrid B3LYP functional and MBW60 basis set for the rhenium atom. The assignments of the transition states are based on the major contributing excitation. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.02 are listed in Table 4.

The TDDFT/PCM calculations show that the low-energy absorption band of **1** originates predominately in the transitions between the HOMO/HOMO−1 and LUMO/LUMO+1 orbitals. As can be seen from Fig. 3, the HOMO−1 and HOMO are delocalized on the whole $Re(CO)_3Cl$ unit, and the LUMO and LUMO+1 are centered on the bdmpzm and CO ligands. Accordingly, these transitions can be seen as mixed Re → bdmpzm/CO (*MLCT*) and Cl → bdmpzm/CO (*LLCT*), or a delocalized *MLLCT* (metal–ligand-to-ligand CT) description can be used.

The experimental absorption band at 239.5 nm is attributed to metal-to-ligand charge transfer (occurring from the rhenium ion to the π-antibonding orbitals of the bdmpzm ligand or π-antibonding orbitals of the carbonyl group), ligand–ligand charge transfer and intraligand (IL) transitions (Table 4).

Complex **1** does not exhibit any luminescence properties. To explain this fact we optimized the first excited singlet and triplet states of **1**. The triplet state was optimized by independent DFT calculations. In Table 5 the geometry parameters of the optimized lowest triplet (T_1) and singlet (S_1) states are gathered. It can be seen from Table 5 that the Re–Cl bond is shortened and Re–CO(1) is elongated in S_1, on comparison to the geometry of the ground state. The Re–CO(1) bond is even more elongated in the T_1 state. In T_1 the Re–C(1)–O(1) angle of the axial carbonyl is equal to 131°, which significantly differs from the almost linear arrangement in S_0 and S_1. The triplet state geometry of the Re–CO(1) fragment and the small energy difference between this state and the ground state (that is the first triplet state excitation energy, which is 1.01 eV, see Table 7) is an indication that a facile detachment of a carbonyl from this state could occur under the influence of light. One may expect that in coordinating solvents $[Re(CO)_3(bdmpzm)Cl]$ will undergo a photochemical axial carbonyl exchange reaction.

In Table 5 the energies of the S_1 and T_1 excited states, relative to the ground state (S_0) minimum, are given. The T_1 state has significantly lower energy than S_1 and, as stated above, there are considerable differences in the geometric parameters. We again performed an optimization of the singlet state geometry starting from T_1 geometry. We obtained another singlet state, denoted S_2. The relative energy and geometry of this state are also given in Table 5. It can be seen from Table 5 that the geometry of S_2 is very similar to that of T_1, with an even somewhat longer

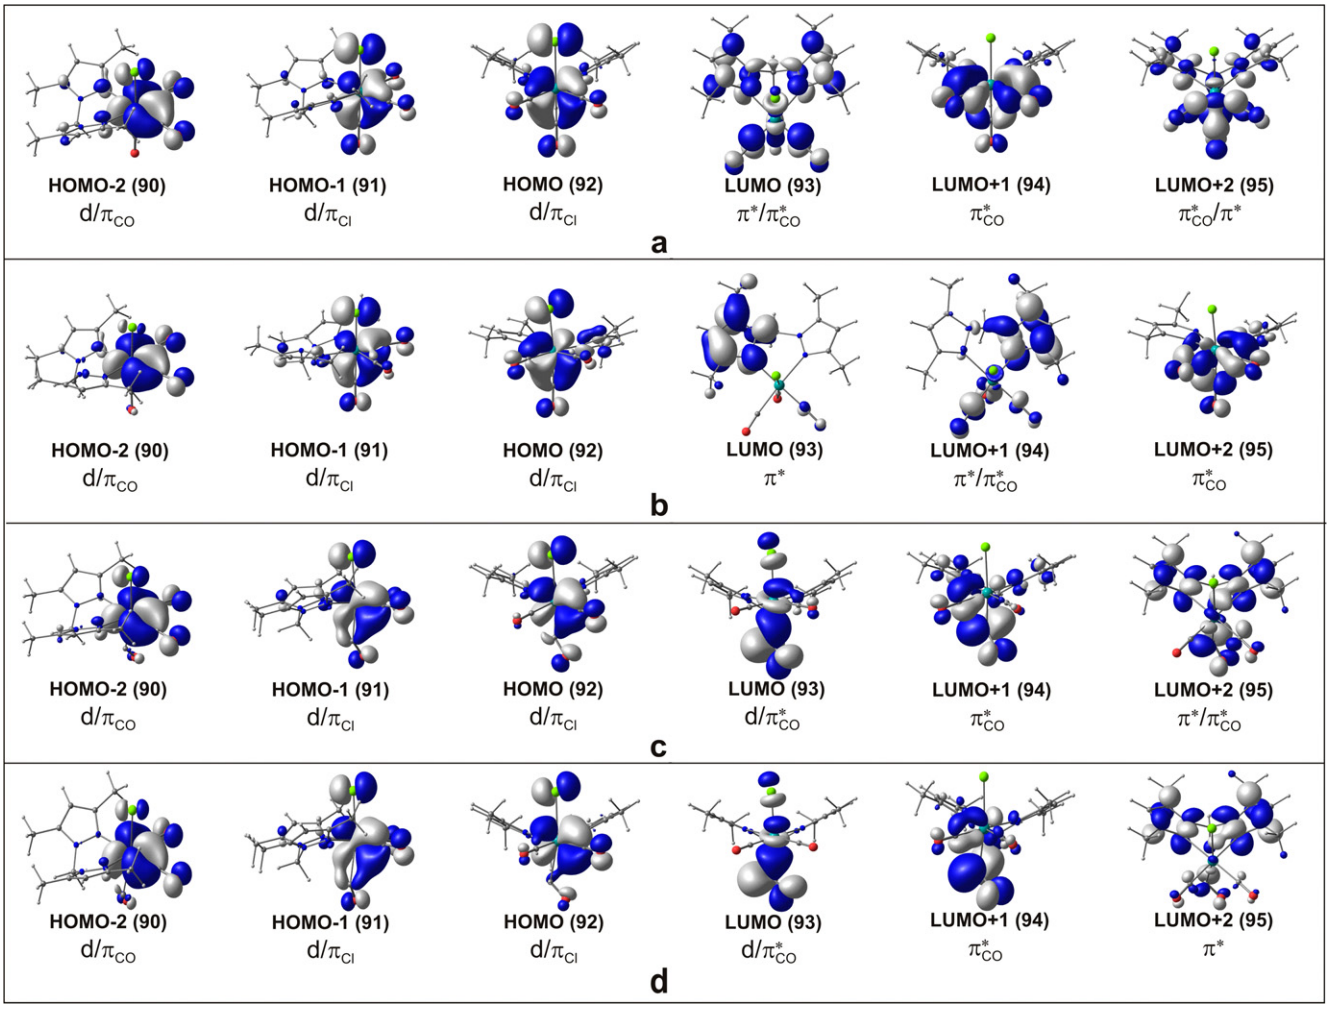

Fig. 4. Molecular orbitals in the ground state (a), S_1 state (b), T_1 state (c) and S_2 state (d) geometry of **1**.

Re-CO(1) bond and a more bent Re–C(1)–O(1) angle. The energy of S_2 is lower than that of S_1.

To characterize the photophysics of **1**, we calculated several singlet and triplet states in the geometries of the S_1, T_1 and S_2 excited states. Four calculated singlet excited states for each geometry are given in Table 6 (with the respective excited states in the ground state geometry for comparison). The relevant triplet states are given in Table 7. In Fig. 4 three HOMO and three LUMO orbitals of [Re(CO)$_3$(bdmpzm)Cl] are given for these geometries. In all cases the HOMO orbitals are rhenium d orbitals with an admixture of carbonyl and chlorine orbitals. The LUMO orbitals in the ground state and S_1 state geometries are bdmpzm ligand and carbonyl π orbitals. In the T_1 and S_2 state geometries, however, the LUMO orbital is basically the d_{z2} orbital of rhenium mixed with a π orbital of the axial carbonyl group. This is reflected in the electronic transitions character in these four geometries. The lowest singlet transitions at the ground state and S_1 state geometries are of the MLCT, $d \rightarrow \pi^*_{bdmpzm}$ type, while in the T_1 and S_2 geometries the lowest transitions are of $d \rightarrow d/\pi^*_{CO}$ character. The large participation of the d_{z2} orbital in the LUMO orbital makes this transition of partly LF type. The different character of the LUMO orbitals in T_1 and S_2 compared to the S_0 and S_1 states, and resulting from it the differences in the lowest excited states character, explain why S_2, although lower in energy than S_1, was not found in the optimization starting from the ground state geometry. The relevant state of $d \rightarrow d/\pi^*_{CO}$ is of very high energy in this geometry and is not accessible in the determination of the character of the excited state wave function.

In Fig. 5 a schematic depiction of the electronic excited states of the [Re(CO)$_3$(bdmpzm)Cl] complex is presented, which is based on the calculations described above. After the absorption at 307 nm (calculated at 319 nm) to the $d \rightarrow \pi^*_{bdmpzm}$ (^{1}MLCT, S_1) state (or absorption to a higher energy state and then internal conversion to S_1) a prompt intersystem crossing to the T_1 state can occur followed by radiationless conversion from T_1 to the ground state. The minimum of the T_1 state is only 1.01 eV higher than the ground state (Table 7), implying an even smaller energy barrier for the $T_1 \rightarrow S_0$ intersystem crossing which should make this process very fast.

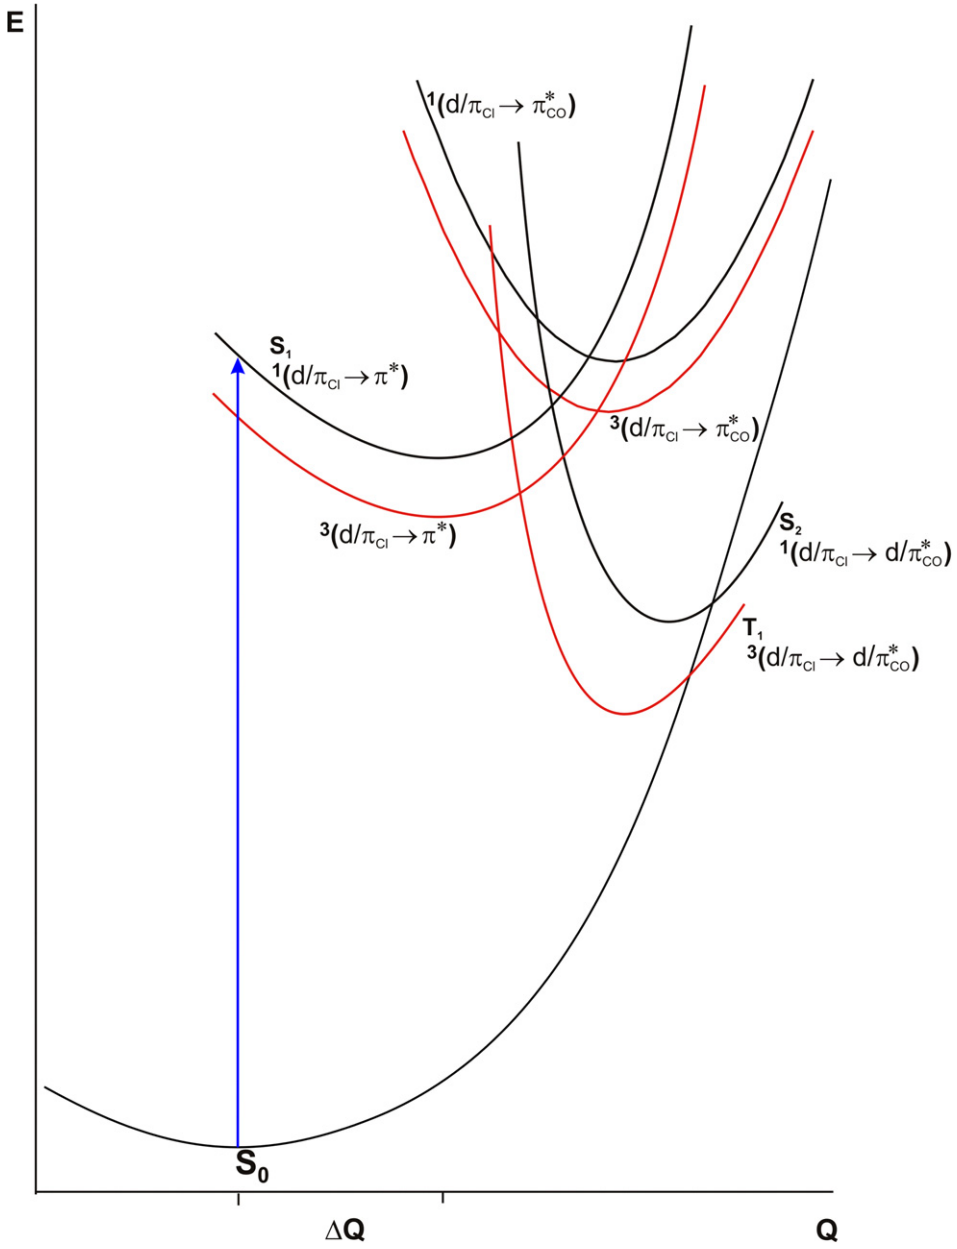

Fig. 5. Schematic representation of the ground and excited states of **1**.

5. Supplementary data

CCDC 674970 and 674971 contain the supplementary crystallographic data for $C_{14}H_{16}N_4O_3ClRe$ and $C_{10}H_8N_4O_3ClRe$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

cussed by Maeda et al. [8] and Seymour [9] – the process in which macromolecules accumulate within tumour tissue due to poor lymphatic clearance, *inter alia*. Zeevaart et al. [10] took this into consideration and proposed a novel water-soluble phosphonate polymer: *N*,*N*′,*N*′-trimethylenephosphonate-polyethyleneimine (PEI-MP) to be combined with a radioactive tin isotope. The radionuclide of interest was ^{117m}Sn, which reduces the risk of radiotoxicity to the marrow due to its favourable radiation characteristics: ^{117m}Sn has a half-life of 13.6 days and emits electrons with energies of 126–158 keV, and a range of 0.2–0.3 mm in bone tissue [13]. It also emits a photon (~160 keV, 88.5%) enabling visualisation of radio-treatment localization. In addition to these favourable radiation characteristics, tin-ions exhibit an inherent affinity for bone as observed in biodistribution experiments with rats [11] and adsorption studies of hydroxyapatite [12].

A fundamental aspect of the biological activity of the tin-based radiopharmaceutical could be the oxidation state of tin. The results may vary with different ligands. As Srivastava [13] found, the *in vivo* bone uptake of $[Sn(II)–HEDP]^0$ in rodents exceeded that of the Sn^{4+} analogue, whereas for methylenediphosphonate (MDP or medronate) and diethylenetriaminepentaacetate (DTPA) the inverse was observed. Notwithstanding the stability of tin-based radiopharmaceuticals [10], the fate of the drug-complex may also depend on the valence stability of the metal-ion *in vivo*. Oxidation of the Sn^{2+} *in vivo* could influence the biodistribution of the complex due to its overall charge. In a study towards determining the possible toxicological effects of tin in rats – in the exclusive divalent and tetravalent forms [11], Hiles reports that no interconversion of the oxidation states occurred. However, this was not based on any physicochemical measurement, but rationalized in terms of the relative biodistributions of the respective Sn-salts. Furthermore, Hiles highlighted the dependence of the biological fate of tin – in the respective oxidation state – on the "anion complement", i.e. counter ion or ligand. In an attempt to elucidate Sn^{2+} complexation by HEDP, combining ^{31}P NMR and ^{119}Sn NMR with ^{119m}Sn Mossbauer spectroscopy, Alberola [14] found that the $[Sn(II)–HEDP]^0$ indeed undergoes oxidation within 3 h of preparation. Whether this is complete, is unclear. Furthermore, with the exception of the free-ligand signal, the only visible ^{31}P peaks were those of $[Sn(IV)–HEDP]^{2+}$. The $[Sn(II)–HEDP]^0$ signal was not observed. The ^{119}Sn NMR spectrum (quintuplet, $J \sim 30$ Hz) revealed the possible existence of a symmetrical spiro-structure, with stoichiometry $[Sn(IV)–(HEDP)_2]^0$.

In the study presented here, we have addressed the question of the valence stability of prospective Sn-based radiopharmaceuticals with HEDP and PEI-MP as ligands (Fig. 1). The objective was to establish the extent of oxidation of Sn^{2+}, if any, in solution; with the intention of evaluating the complexes for eventual application *in vivo*.

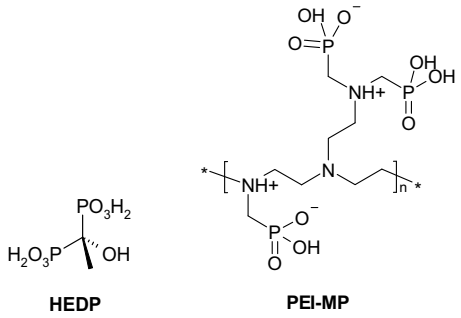

Fig. 1. Molecular structures of 1-hydroxyethylene-diphosphonate (HEDP), and *N*,*N*′,*N*′-trimethylenephosphonate-polyethyleneimine (PEI-MP). Both ligands are represented in arbitrary protonation states.

2. Experimental

2.1. Reagents

Analytical grade HEDP, $SnCl_2 \cdot 2H_2O$ and $SnCl_4 \cdot 5H_2O$ were obtained from Merck. PEI-MP was synthesized according to the method outlined by Jarvis et al. [15], with the final product – in form of the sodium salt – obtained as various size-fractions after ultra-filtration. Using appropriate membrane filters, the polymer was fractionated according to the following molecular sizes. The fraction of 10–30 kDa was used in the NMR study. All other reagents used were of analytical grade.

2.2. Preparation of the NMR samples

The NMR samples of the metal complexes were prepared by mixing appropriate amounts of a deuterated (D_2O) stock solution containing about 1 mol dm^{-3} of the metal chloride ($SnCl_2$, acidified $SnCl_4$, $CaCl_2$, or $CdCl_2$) and a stock solution of HEDP (1 mol dm^{-3}) or PEI-MP (0.0592 mol dm^{-3}, based on monomeric units). The tin–PEI-MP samples were prepared by firstly adjusting the stock solution of PEI-MP to pH 12 prior to the addition of the respective tin solutions. All solutions were allowed to equilibrate overnight at room temperature before measurements.

2.3. Solutions for oxidation and reduction experiments: hydrogen-peroxide and glutathione, respectively

Glutathione (GSH) was dissolved in 0.5 ml water to produce a 1.191 mol dm^{-3} solution. Three dilutions of hydrogen-peroxide were prepared from 30% H_2O_2: 0.500 mol dm^{-3}; 0.050 mol dm^{-3} and 0.010 mol dm^{-3}.

The H_2O_2 and GSH solutions were added directly to the NMR tubes for the respective studies, in increments of 30 μl – unless otherwise specified.

2.4. NMR spectroscopy

All NMR measurements were performed on Varian Unity Inova-300 spectrometer, in 5 mm tubes, operating

at 25 °C. Chemical shifts (δ) are reported in ppm. The proton-decoupled ^{31}P NMR spectra of these solutions were measured operating at 121.504 MHz. The acquisitions were performed using a relatively long delay (10 s) and short pulse (30°). Furthermore, gated-decoupling was applied to avoid nuclear Overhauser effect. In so doing it was possible to compare the intensities of signals that may have had different relaxation times. Changes in the chemical shifts of the phosphorous signals of the free and complexed ligand were observed by performing pH-titrations, within the NMR tubes, over the range pH 0–10. The pH was manipulated with a freshly prepared NaOH solution. An inner-tube with 30% H_3PO_4 was used for referencing the ^{31}P chemical shifts. All ^{13}C (proton-decoupled) measurements were referenced with an internal standard of tertiary-butanol with the methyl resonance calibrated at 31.2 ppm. ^{113}Cd spectra were obtained at a frequency of 66.557 MHz, using $CdCl_2$ (1 mol dm^{-3}) in D_2O as external reference.

3. Results and discussion

Extreme line broadening due to exchange between Sn-nuclei in various species made it difficult to obtain reasonable and reproducible ^{119}Sn NMR spectra, therefore ^{31}P NMR was applied to study the complexation phenomena.

3.1. Sn^{4+}–HEDP system

Upon addition of a small amount of Sn^{4+} to a sample with HEDP at pH 9, a new very complex cluster of resonances at about 17.16 ppm showed up next to the resonance for free HEDP at 19.52 ppm in the ^{31}P NMR spectrum, which may be attributed to Sn(IV)–HEDP complexes formed (Figs. 2 and 3). Upon increase of the molar ratio $[Sn^{4+}]_{tot}/[HEDP]_{tot}$, the intensity of the resonances at 17.16 ppm increased at the expense of those for the free ligand. Therefore, it can be concluded that the exchange between free and Sn^{4+} bound HEDP is slow on the NMR time scale.

From the integrals of the resonances at 17.16 ppm and 19.52 ppm, the mol% bound HEDP was calculated. The latter is displayed versus the molar ratio $[Sn^{4+}]_{tot}/[HEDP]_{tot}$ in Fig. 4.

The flattening of the curve in Fig. 4 at $[Sn^{4+}]_{tot}/[HEDP]_{tot} \approx 0.33$ suggests that the major species has 1:3 metal:ligand stoichiometry, although it cannot be excluded on the basis of the ^{31}P NMR spectra that dinuclear complexes play a role as well. Most likely the HEDP ligands in the major complex are bound to Sn^{4+} in a bidentate fashion through an oxygen atom of each of the phosphonate moieties. Such structures have a chiral Sn(IV) atom (Δ and Λ isomers). Furthermore, the C-atoms of the HEDP ligand become chiral upon binding to the Sn^{4+} ion and, consequently a large number of diastereomers are possible for this complex. Since the phosphorus nuclei in the bound ligand are chemically inequivalent, a large number of ^{31}P resonances may be observed for these complexes, which is in agreement with the observed spectrum. The situation becomes even more complex as result of couplings among the various P-nuclei in the complexes.

An NMR chemical shift pH titration with a sample with $[Sn^{4+}]_{tot}/[HEDP]_{tot} = 1/3$ shows inflections at about pH 2 and 6 for both the free ligand and the Sn(IV)-complexes (Fig. 7). Most likely, these inflections may be attributed to the pK_{a1} and pK_{a2} of the bisphosphonate functional groups, which means that these groups are deprotonated at physiological pH. This is in agreement with the generally observed trends in pK_as of bisphosphonates [20]. In the pH range 0–10, the ligand remained fully complexed. Similar experiments at higher $[Sn^{4+}]_{tot}/[HEDP]_{tot}$ ratios gave rise to precipitation at pH values higher than 3, which may be ascribed to hydrolysis of the Sn^{4+} present.

Sn(IV)–HEDP complexes are present as a cocktail of a variety of species, from the spiro-type structures as suggested by Alberola [14] to the multinuclear structures found by potentiometric data [16]. ^{13}C and ^{1}H spectra reveal a change in chemical shift of new resonances for the C-PO_3H_2 and CH_3 groups, respectively, as observed by the appearance of additional triplets at 51.40 ppm and 51.68 ppm ($^2J_{CP} = 133.94$ Hz and $^3J_{HP} = 14.34$ Hz, respectively) – other than that of the free ligand at 52.47 ppm – upon coordination of HEDP with tin. The appearance of additional peaks is consistent with the ^{31}P spectra. ^{119}Sn NMR spectrum by Alberola [14] reveals a quintuplet ($J \sim 30.00$ Hz), confirming the existence of a symmetrical spiro-structure.

3.2. Sn^{2+}–HEDP system

^{31}P NMR samples of Sn^{2+} and HEDP in molar ratios 1:1 to 1:3 species showed a major resonance in the same region as that of the uncomplexed ligand, 19.24 ppm, regardless of pH-conditions (see Fig. 2). The free ligand was therefore indistinguishable from the [Sn(II)–HEDP]^0 complex(es). In the absence of organic ligands, Sn(II) precipitates under the conditions applied, which suggests that a substantial part of the Sn(II) is coordinated to HEDP. At molar ratios of Sn^{2+} and HEDP higher than 1, precipitation of oxides occurs. Therefore most likely the stoichiometry of the dominant species at lower molar ratios has a Sn(II):ligand ratio of 1:1.

In this respect Sn^{2+} appears to behave much like other familiar divalent metal-ions such as Ca^{2+} and Cd^{2+}, which with the possibility a single symmetrical species predominating, results also in a ^{31}P NMR spectrum with a singlet in the same region as the free HEDP. For Cd^{2+} the binding by HEDP is demonstrated by ^{113}Cd NMR spectra, which display a single peak at approximately 34.00 ppm up-field from the reference $CdCl_2$. No free metal was observed, which indicates that all Cd-ions were successfully complexed. However, contrary to Sn^{2+} the Cd^{2+} complexation is rather complex, and produces ^{31}P NMR spectra that appear to be a result of many overlapping signals.

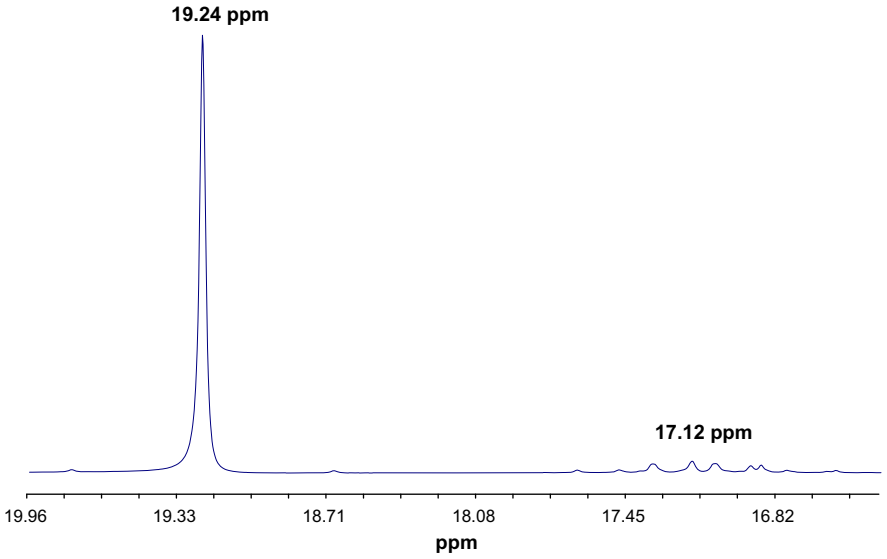

Fig. 2. ^{31}P NMR spectrum of Sn(II)–HEDP solution (M:L = 1:3) at pH 7.4; showing the free ligand and [Sn(II)–HEDP]^{0} complex(es) as a singlet at 19.24 ppm ($I = 87\%$) and the [Sn(IV)–HEDP]$^{2+}$ complex(es) as a multiplet centred at 17.12 ppm ($I = 13\%$).

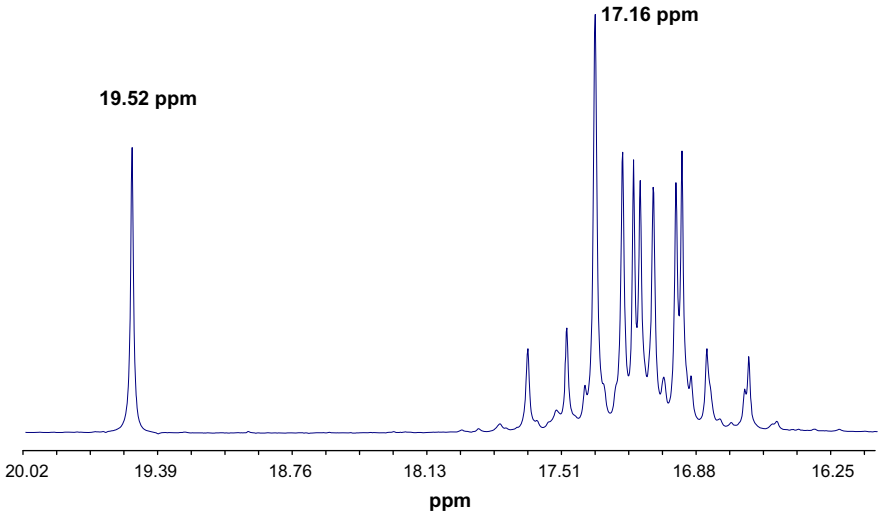

Fig. 3. ^{31}P NMR spectrum of Sn(IV)–HEDP solution (M:L = 1:3) at pH 7.4; showing the free ligand as a singlet at 19.52 ppm ($I = 9$) and the complex(es) [Sn(IV)–HEDP]$^{2+}$ as a multiplet centred at 17.16 ppm ($I = 91$).

This difference in complexation between Sn^{2+} and Sn^{4+} can be attributed to the charge, i.e. the greater the charge, the greater the affinity per ligand and hence more possibility for coordination.

It should be noted that in all ^{31}P NMR spectra of samples with Sn^{2+} and HEDP, an additional characteristic set of signals occurred in the 17.00 ppm region throughout the pH range studied (pH 0–10), which is evident to the presence of Sn^{4+} (Figs. 2 and 3). The intensity of these signals was about 15% of that of the resonance at about 19.00 ppm. The presence of resonances for Sn(IV) complexes is not surprising, since no special care was taken to eliminate/prevent its occurrence. However, the presence of Sn^{4+} did prove useful for the evaluation of the extent of oxidation of Sn^{2+} under normal working conditions. The same phenomenon was observed for [Cd(II)–HEDP]^{0} and [Ca(II)–HEDP]^{0}, with no other ^{31}P signals.

Probably due to rapid exchange within the Sn^{2+}-complex we do not see the ^{31}P signal due Sn^{2+} complexation, which is consistent with findings by Alberola [14]. The same was found to be true for [Ca(II)–HEDP]^{0} and [Cd(II)–HEDP]^{0}. Although unusual, the complex formation might occur within the same chemical shift region as the free ligand (19.71 ppm), therefore it is practically impossible to distinguish between [Sn(II)–HEDP]^{0} complexes and free ligand by merely considering the chemical shift. This is supported by potentiometric data of divalent metal-ions when complexed to HEDP [16], in which binuclear (M_2L) species occurred (Fig. 5). From the thermody-

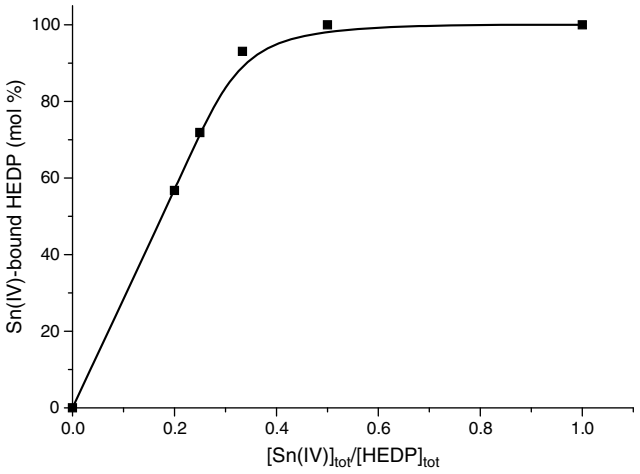

Fig. 4. Graph showing the change in the mole percentage of HEDP bound by Sn^{4+} vs. the molar ratio $[Sn^{4+}]_{tot}/[HEDP]_{tot}$.

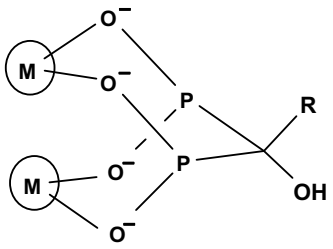

Fig. 5. Proposed binuclear diphosphonate complex according to potentiometric data.

namic data species such as ML and M_2L or M_2LH_{-2} could account for this phenomenon. For example, Ca^{2+}: $\log\beta_{110} = 5.34$ and $\log\beta_{210} = 9.53$, Cd^{2+}: $\log\beta_{110} = 7.26$ and $\log\beta_{210} = 12.67$ [16], and Sn^{2+}: $\log\beta_{21-2} = 11.85$ [10]. We would therefore expect a singlet since all phosphorous nuclei are equivalent. Furthermore, according to extensive crystallographic research of diphosphonates by Matczak-Jon et al. [17,18] and Zapf et al. [19], certain bridged-binuclear diphosphonate complexes were reported, particularly with Zn^{2+} and Mg^{2+}. Although unsymmetrical, the complexes yielded representative ^{31}P spectra.

The important information obtained from the ^{31}P spectra of HEDP when complexed with Sn^{2+} and Sn^{4+}, is the relative extent of complexation of the Sn^{4+} in each.

3.3. Sn(II)–Sn(IV)–PEI-MP system

The complexes of Sn^{2+} and Sn^{4+} with PEI-MP are also distinguishable by their ^{31}P chemical shifts, and especially when present in the same solution (Fig. 6). The Sn^{4+}–PEI-MP complexes appeared as a broad peak at about 16.63 ppm whilst the Sn^{2+}–PEI-MP species occurred at slightly lower chemical shift (16.26 ppm), with the free ligand at 15.68 ppm.

3.4. Elucidating the possible oxidation of Sn^{2+} within Sn–HEDP and Sn–PEI-MP complexes

There were no changes in the ^{31}P NMR spectra of samples of Sn(II) with HEDP or PEI-MP overnight, hence we can assume that no oxidation of Sn^{2+} occurred. Should this have been the case we would expect an increase in the ratio of intensities of the corresponding peaks, which would eventually approach the spectrum of the concerning Sn(IV)-complex at the respective pH.

In a study to understand the conditions needed for the oxidation of Sn^{2+} in the presence of HEDP, the complex was titrated with hydrogen-peroxide (30% H_2O_2). The metal to ligand ratio of 1:3 (pH 7.3) was chosen so as to limit any free/uncomplexed tin which would hydrolyze and precipitate out during the titrations. Throughout the investigation no precipitation was observed within the 1:3 mixtures, even over prolonged periods, which indicates that all tin was successfully complexed in solution and

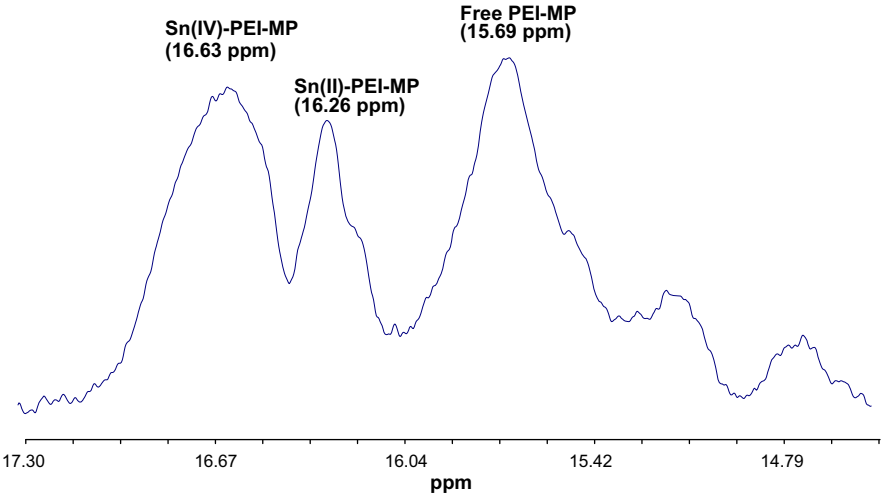

Fig. 6. ^{31}P spectrum of tin(II)–tin(IV)–PEI-MP system (1:1:8) at pH 12; where 15.69 ppm is free ligand, 16.26 ppm is the Sn^{2+}-complex(es) and 16.63 ppm represents the Sn^{4+}-complex(es).

variations in the pH did not influence the Sn-ions directly – the [Sn–HEDP] complexes are stable enough to withstand fluctuations in pH. Mixtures in which the metal-ion concentration was in excess, i.e. M:L > 1:1, exhibited immediate precipitation upon addition of NaOH. Precipitation eventually occurred in these solutions, even without any pH manipulation after a few hours – for both Sn^{2+} and Sn^{4+}.

Oxidation of the tin in the $[Sn(II)–HEDP]^0$ and the $[Sn(II)–Sn(IV)–PEI\text{-}MP]^{4+}$ systems was induced by the addition of 30 μl of H_2O_2, 0.05 mol dm^{-3} (Fig. 9) and 0.010 mol dm^{-3} (Fig. 8) respectively. As expected, an increase in intensity of the resonances of the Sn(IV) complexes was observed in the case of HEDP, with a steady decrease in the intensity of the resonance at about 19 ppm, and for PEI-MP we observed the disappearance of the signal for the Sn(II) chelate, although only realizing some increase (~35–45%) in intensity of the resonances for the Sn^{4+} complex. There is a increase in the free-ligand concentration (~40–~55%), which could be due to the liberation of ligand that had been previously bound to Sn^{2+}. The simultaneous increase in both amounts of [Sn(IV)–

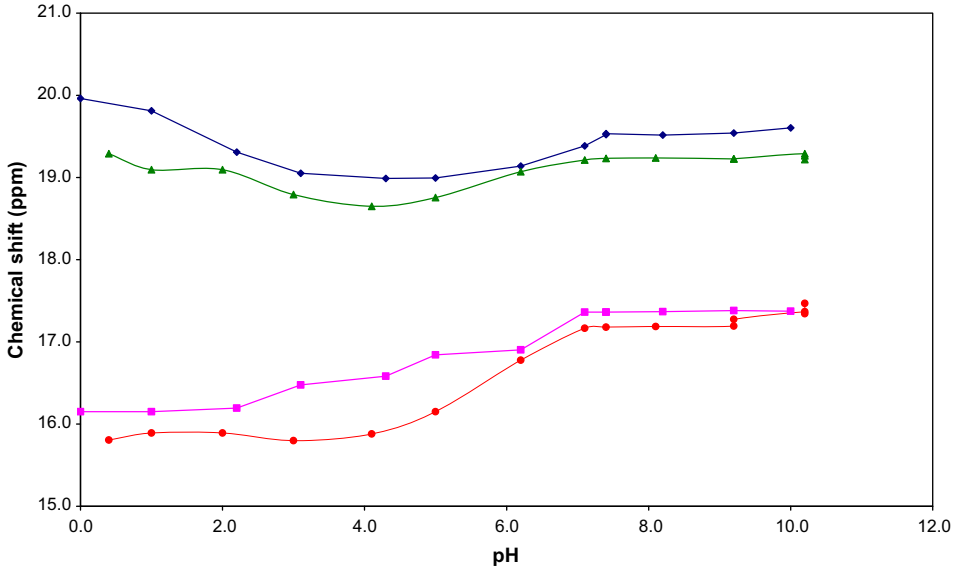

Fig. 7. Changes in the chemical shift of the ^{31}P signal for the free and complexed HEDP for the respective systems: Sn^{2+} and Sn^{4+}, at varying pH. (i) Sn^{4+} system: (■) complexed $[Sn(IV)–HEDP]^{2+}$; (◇) free HEDP; (ii) Sn^{2+} system; (●) complexed $[Sn(IV)–HEDP]^{2+}$; (▲) free HEDP + $[Sn(II)–HEDP]^0$.

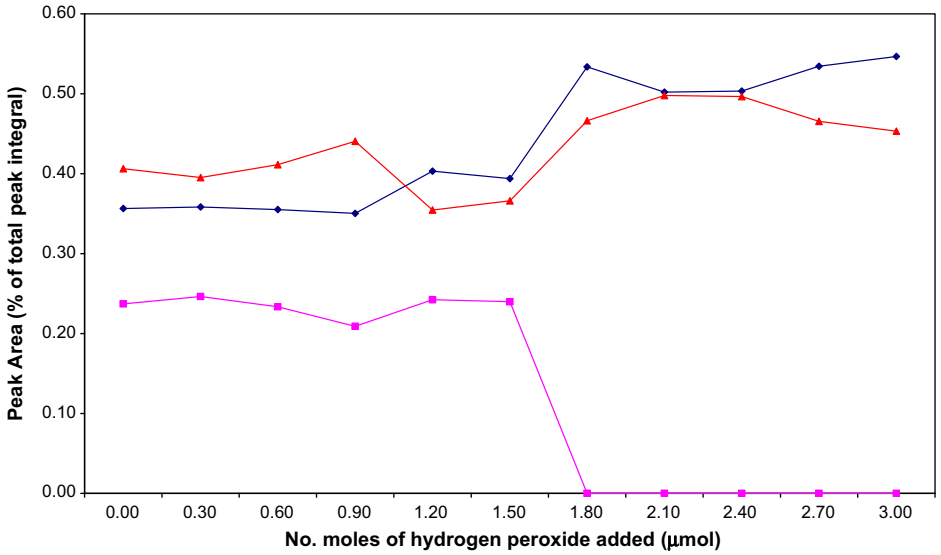

Fig. 8. Determination of the amount of hydrogen-peroxide needed to completely oxidize the Sn^{2+} in the PEI-MP complex in a sample containing Sn^{2+}:Sn^{4+}:ligand = 1:1:8 at pH 12. H_2O_2 concentration = 0.010 mol dm^{-3}, and ^{31}P spectra were recorded 30 min after each addition (i.e. total acquisition time = 30 min). (◇) Free PEI-MP, (■) $[Sn(II)–PEI\text{-}MP]^0$, and (▲) $[Sn(IV)–PEI\text{-}MP]^{2+}$.

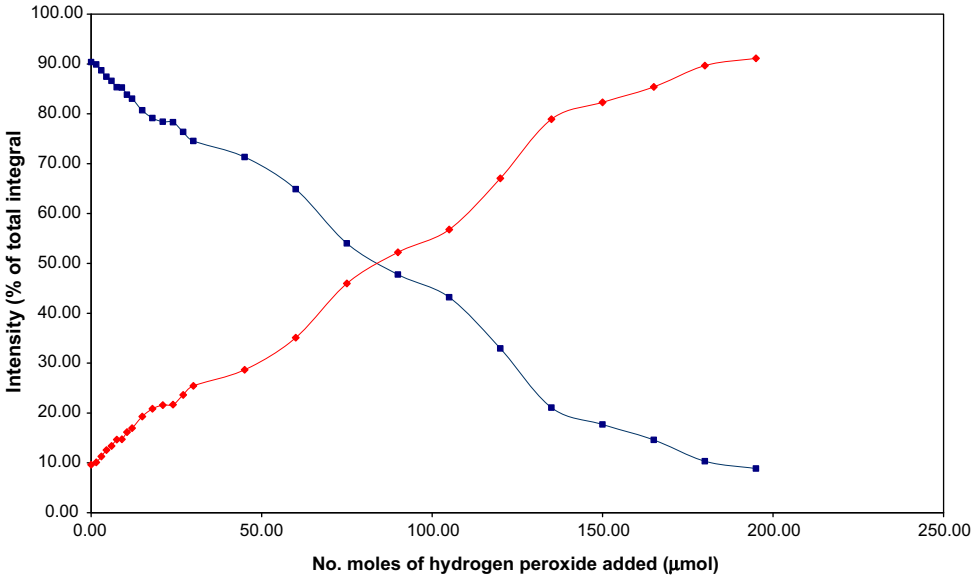

Fig. 9. Determination of the amount of hydrogen-peroxide needed to oxidize the Sn^{2+} in the HEDP complex in a sample containing metal-to-ligand = 1:3 at pH 7.3. H_2O_2 concentration = 0.050 mol dm^{-3}, and ^{31}P spectra were recorded 30 min after each addition (i.e. total acquisition time = 30 min). (■) Free + $[Sn(II)–HEDP]^0$ and (◇) $[Sn(IV)–HEDP]^{2+}$.

$PEI-MP]^{2+}$ and free ligand after oxidation implies that the PEI-MP that had formerly been bound to Sn^{2+} is evenly distributed between Sn^{4+}-bound and free ligand in solution. Furthermore, this would mean an increase in the free metal-ion concentration (i.e. at least half the tin-ions being released as reflected by the increase in free-ligand concentration). This is confirmed by the occurrence of slight precipitation upon completion of the oxidation driven by the reaction of $Sn(IV) + 4OH^- \leftrightharpoons Sn(OH)_{4(s)}$. Approximately 1.6 μmol of H_2O_2 per μmol of Sn^{2+} within the HEDP system, was needed to oxidize it in order to reach the equivalent complexation of Sn^{4+} at the same pH (Fig. 9). For the $[Sn(II)–PEI-MP]^0$ system 1.4 μmol H_2O_2 per μmol Sn(II)–PEI-MP is needed.

The rate at which the oxidation (induced) occurs was tested on a sample of 125 μmol $[Sn(II)–HEDP]^0$ (M:L = 1:3), by adding 30 μl of 0.5 mol dm^{-3} H_2O_2 and monitoring the change over the required period of time to reach saturation. The oxidation reaches a maximum at about 28% conversion within 40 min.

The oxidation was reversible to a certain extent. A sample containing $[Sn(II)–HEDP]^0$ that had previously been completely oxidized using ca. 70 μl of H_2O_2 (30%), and exhibiting 92% complexation due to Sn^{4+}, was treated with ca. 300 μl of 1 mol dm^{-3} glutathione (GSH). This resulted in decrease of the intensity of the Sn(IV) complexes with 50% and a corresponding increase of the resonance for free and complexed Sn(II). The results were reproduced with a fresh sample prepared exclusively with Sn^{4+}, using the same specifications as the previous. This experiment could not be performed with PEI-MP as it appeared that the glutathione possibly reduced the ligand, and as a result no meaningful ^{31}P spectra were obtainable – this was confirmed with a sample comprising of only free ligand.

4. Conclusion

We found that Sn^{2+} and Sn^{4+} diphosphonate complexes can co-exist in solution without any interconversion over prolonged periods. This serves to confirm a study conducted by Hiles [11] who found this to be true for the respective ions when introduced into the blood stream (in rats). However, upon complexation with bisphosphonates, immediate oxidation of Sn^{2+} did occur (to a limited extent and not continuing with time) with Sn(II)–HEDP. This could also have been attributed to the likelihood that the Sn(II) salt contained some Sn(IV). This can be regarded as acceptable since the experiments were conducted without extensive measures to avoid this (such as inert atmosphere or de-aerated solutions). In practice this can be avoided in preparing the complexes (and eventual radiopharmaceuticals) with de-aerated solutions under Ar. Oxidation was induced by addition of H_2O_2, in which a slight excess of the molar amount of Sn^{2+} was required to achieve equivalent Sn^{4+} complexation. This reaction reaches completion after about 40 min. The oxidation is reversible, by addition of reducing agent, such as glutathione (GSH). Although this was proven to a limited extent for HEDP, it does not hold true for PEI-MP – which itself appears to be reduced in the presence of excess GSH, given that $SnCl_2$ too is a reducing agent.

Considering the findings by Hiles [11], and the extreme oxidizing conditions employed in our experiments, the likelihood of oxidation of the Sn^{2+}-complex is minimal under mild physiological conditions. Should the complex dissociate *in vivo*, the Sn^{2+}-ion should still survive, and possibly be complexed by other blood plasma ligands, if not hydrolysed. This brings to question the stability of the Sn^{2+}-based radiopharmaceutical within blood plasma, where it would

be susceptible to dissociation due to competition by physiological ligands and metal-ions. This has been already been addressed by Zeevaart et al. [10] with the aid of a computational blood plasma model of Sn^{2+}. This model predicts whether the complex is strong enough to prevent dissociation and formation of $Sn(OH)_2$. Only ligands that pass this evaluation should be considered for bone-seeking radiopharmaceuticals.

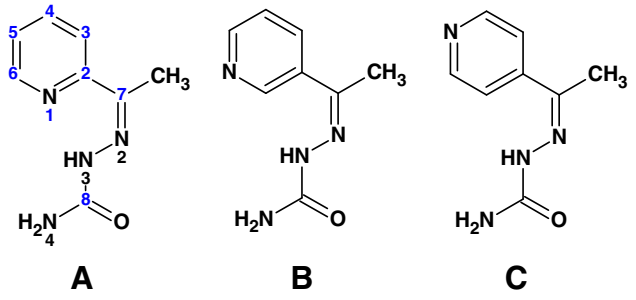

Fig. 1. Structural representation of 2-acetylpyridine semicarbazone (H2APS = A), 3-acetylpiridine semicarbazone (H3APS = B), and 4-acetylpyridine semicarbazone (H4APS = C).

2. Experimental

2.1. Materials and measurements

All common chemicals were purchased from Aldrich and used without further purification. The semicarbazones were prepared according to standard procedures [6].

Partial elemental analyses were performed on a Perkin–Elmer CHN 2400 analyzer. An YSI model 31 conductivity bridge was employed for molar conductivity measurements. Thermogravimetric curves were obtained with a Mettler TA-4000 equipment. Magnetic susceptibility measurements were carried out on a Johnson Matthey MSB/AUTO balance. UV spectra in solid-state were obtained with an UV-2401PC – (P/N 206-82201) – Shimadzu equipment using $BaSO_4$ as support; infrared spectra were recorded on a Perkin–Elmer FT-IR Spectrum GX spectrometer using nujol mulls between CsI plates; NMR spectra were obtained with a Bruker DRX-400 Avance (400 MHz) spectrometer using d_6-DMSO as the solvent and TMS as internal reference.

2.2. Preparation of [VO(H2APS)(acac)$_2$] (1), [VO(H3APS)(acac)$_2$] (2), [VO(4APS)(acac)(H$_2$O)] · 1/2H$_2$O (3) and [VO$_2$(2APS)] (4)

Complexes **1**–**3** were obtained by reacting the desired ligand with [VO(acac)$_2$] (acac = acetylacetonate), in 1:1 ligand-to-metal molar ratio (0.005 mol), in methanol under reflux and nitrogen atmosphere for 4 h. The solids were washed with ethanol followed by diethylether and then dried *in vacuo*. Upon reaction of [VO(acac)$_2$] with H2APS in acetonitrile in 1:1 ligand-to-metal molar ratio (0.005 mol) for 72 hours [VO$_2$(2APS)] (**4**) precipitates. Similar procedure using H3APS and H4APS did not lead to oxidation but gave the same oxovanadium(IV) complexes which had been obtained before in methanol.

2.3. Oxovanadium(IV) complex of 2-acetylpyridine semicarbazone [VO(H2APS)(acac)$_2$] (1)

Light green solid. *Anal.* Calc. for $VC_{18}H_{24}N_4O_6$: C, 48.8; H, 5.5; N, 12.6. Found: C, 48.6; H, 5.4; N, 12.5%. FW: 443.35 g mol^{-1}. UV$_{solid}$: λ_{max} (cm^{-1}): 37 453, 30 580, 23 640, 17 544, 13 227. IR (CsI/nujol, cm^{-1}): ν(C=N) 1584, ν(C=O) 1699, ν(V=O) 969, ρ(py) 624. $\Lambda_M = 2.92\ \Omega^{-1}\ cm^2\ mol^{-1}$ in DMF. Magnetic moment = 1.87 BM. Yield 74%.

2.4. Oxovanadium(IV) complex of 3-acetylpyridine semicarbazone [VO(H3APS)(acac)$_2$] (2)

Light green solid. *Anal.* Calc. for $VC_{18}H_{24}N_4O_6$: C, 48.8; H, 5.5; N, 12.6. Found: C, 48.6; H, 5.5; N, 12.6%. FW: 443.35 g mol^{-1}. UV$_{solid}$: λ_{max} (cm^{-1}): 34 247, 30 581, 24 450, 17 544, 12 903. IR (CsI/nujol, cm^{-1}): ν(C=N) 1579, ν(C=O) 1687, ν(V=O) 965, ρ(py) 631. $\Lambda_M = 8.69\ \Omega^{-1}\ cm^2\ mol^{-1}$ in DMF. Magnetic moment = 2.13 BM. Yield 72%.

2.5. Oxovanadium(IV) complex of 4-acetylpyridine semicarbazone [VO(4APS)(acac)(H$_2$O)] · 1/2H$_2$O (3)

Light green solid. *Anal.* Calc. for $VC_{13}H_{19}N_4O_{5.5}$: C, 42.2; H, 5.2; N, 15.1. Found: C, 42.3; H, 5.2; N, 15.0%. FW: 370.26 g mol^{-1}. UV$_{solid}$: λ_{max} (cm^{-1}): 36 364, 28 011, 23 838, 17 746, 12 903. IR (CsI/nujol, cm^{-1}): δ (H$_2$O) 1638, ν(C=N) 1603, ν(C=O) 1687, ν(V=O) 959, ρ(py) 591, ν(V–N) 504, ν(V–O) 416. $\Lambda_M = 18.88\ \Omega^{-1}\ cm^2\ mol^{-1}$ in DMF. Magnetic moment = 1.89 BM. Yield 81%.

2.6. Oxovanadium(V) complex of 2-acetylpyridine semicarbazone [VO$_2$(2APS)] (4)

Yellow solid. *Anal.* Calc. $VC_8H_9N_4O_3$: C, 36.9; H, 3.5; N, 21.5. Found: C, 36.8; H, 3.5; N, 21.4%. FW: 260.13 g mol^{-1}. UV$_{solid}$: λ_{max} (cm^{-1}): 34 014, 27 310, 22 321. IR (CsI/nujol, cm^{-1}): ν(C=N) 1562, ν(C=O) 1656, ν(V=O) 959, 941, ρ(py) 609, ν(V–N) 495, ν(V–O) 426. $\Lambda_M = 2.47\ \Omega^{-1}\ cm^2\ mol^{-1}$ in DMF. ^{1}H NMR (400 MHz, d_6-DMSO, 25 °C): δ (ppm) = 8.64 (d, 1H, H(6)), 8.27 (td, 1H, H(4)), 7.91 (d, 1H, H(3)), 7.65 (t, 1H, H(2)), 7.18 (s, 2H, N(4)H), 2.46 (s, 3H, CH_3). ^{13}C NMR (400 MHz, d_6-DMSO, 25 °C): δ (ppm) = 172.52 (1C, C(8)=O), 155.53 (1C, C(2)), 152.46 (1C, C(7)=N), 142.82 (1C, C(4)), 124.30 (1C, C(5)), 122.87 (1C, C(3)), 12.33 (1C, CH_3). ^{51}V NMR (400 MHz, d_6-DMSO, 25 °C): δ (ppm) = −528.44. Yield 77%.

2.7. Crystal structure determination

Single crystals of [VO(H2APS)(acac)$_2$] (**1**) and [VO$_2$(2APS)] (**4**) suitable for X-ray diffraction were obtained from CH_3CN solutions. Data collection were performed with Cu Kα radiation (λ = 154.184 pm) on an Enraf-Nonius CAD-4 diffractometer applying standard procedures.

The structures were solved by direct methods with SIR-92 [7] and refined with SHELXL-97 [8]. The hydrogen atoms of the methyl groups in **1** were fixed at idealized positions with

2.8. In vitro insulin-mimetic studies

2.8.1. Adipocyte isolation

Adipocytes were isolated from epididymal fat pads of Wistar male rats, by the method of Rodbell [9]. Digestion was carried out at 37 °C with constant shaking for 45 min. Cells were filtered through nylon mesh and washed three times with buffer containing (mM): 137 NaCl, 5 KCl, 4.2 $NaHCO_3$, 1.3 $CaCl_2$, 0.5 $MgCl_2$, 0.5 $MgSO_4$, 0.5 KH_2PO_4, 20 HEPES (pH 7.4), plus 1% BSA.

2.8.2. Glucose transport assay

After isolation, adipocytes were incubated for 45 min and 2-deoxy-[^{3}H]glucose uptake was used as an assay to determine the effect of the compounds (10^{-3} M) or insulin (50 ng/mL) on the rate of glucose transport, as previously described [10]. Glucose uptake was initiated by the addition of 2-deoxy-[^{3}H]glucose (0.2 μCi/tube) for 3 min. Thereafter, cells were separated by centrifugation through silicone oil and the cell associated radioactivity determined by scintillation counting. Nonspecific association of 2-deoxy-[^{3}H]glucose was determined by performing parallel incubations in the presence of phloretin (15 mM), and this value was subtracted from glucose transport activity at each condition.

2.8.3. Lipolysis assay

Lipolysis was measured by following the rate of glycerol release, as previously described [11]. After washing, adipocytes were preincubated at 37 °C in a water bath for 30 min, in basal conditions or in the presence of the vanadium compounds (10^{-3} M) [12] dissolved in DMSO (20% v/v). Then, isoproterenol (0.1 μM) was added in the tubes containing the compounds, and the cells were incubated for additional 30 min. At the end of the incubation period, an aliquot of the infranatant was removed for enzymatic determination of glycerol released into the incubation medium.

2.9. Statistical analysis

All experiments were performed in at least three replicates per compound and the results shown are the average of at least four independent experiments. Data, represented as the means ± SEM, were analyzed by one-way analysis of variance (ANOVA) followed by Newman–Keuls post hoc test to establish differences between the groups. A $P < 0.05$ was considered significant. All data and statistical analyses were performed using GraphPad Prism version 4.0 for Windows, GraphPad Software, San Diego, CA, USA.

3. Results and discussion

Microanalyses suggest the formation of [VO(H2APS)(acac)$_2$] (**1**), [VO(H3APS)(acac)$_2$] (**2**) and of [VO(4APS)(acac)(H_2O)] · 1/2H_2O (**3**). In complexes **1** and **2** the semicarbazone acts as a neutral ligand while in **3** the semicarbazone is attached to the metal centre in the anionic (4APS) form. A second product was isolated in the reaction with H2APS, [VO$_2$(2APS)] (**4**), containing vanadium(V) and an anionic semicarbazone. Complex **4** was also obtained by reacting [VO(acac)$_2$] with H2APS in acetonitrile during 72 h. The TG curve of [VO(4APS)(acac)(H_2O)] · 1/2H_2O (**3**) shows a weight loss of 2.7% (Calc. 2.4%) in the 33–70 °C range corresponding to the release of 1/2H_2O, followed by a second weight loss of 33.3% (Calc. 31.6%), corresponding to the release of the acac ligand along with the coordination water. Interestingly, the TG curves of **1**, **2** and **4** do not show weight losses attributable to the release of water molecules.

3.1. Spectroscopic characterization

Absorptions at 1550–1500 cm^{-1}, characteristic of coordinated acac [13] were observed in the infrared spectra of

complexes **1**–**3** but were not observed in the spectrum of **4**. In the spectra of H2APS and H3APS a broad absorption at 1700 and 1683 cm^{-1}, respectively, was attributed to ν(C=O) [6]. This absorption is observed as a narrow band at 1699 and 1687 cm^{-1} in the spectra of complexes **1** and **2**, respectively, suggesting coordination through the carbonyl oxygen. The absorptions assigned to ν(C=N) at 1583 and 1582 cm^{-1} and those at 626 and 627 cm^{-1} assigned to the in-plane deformation mode of pyridine in the spectra of H2APS and H3APS, respectively [6] do not change in the spectra of **1** and **2**, indicating that the semicarbazones are attached to the metal as monodentate ligands, as confirmed by the crystal structure determination of complex **1** (see Section 3.2).

The absorptions attributed to ν(C=O) at 1684 and 1700 cm^{-1} in the spectra of H4APS and H2APS [6], respectively, shift to 1687 and 1656 cm^{-1} in the spectra of complexes **3** and **4** respectively, indicating coordination through the oxygen. The bands associated to ν(C=N) at 1594 and 1583 cm^{-1} in the spectra of H4APS and H2APS, respectively, shift to 1603 and 1562 cm^{-1} in the spectra of **3** and **4**, respectively, suggesting coordination through the azomethine nitrogen [6,14]. The absorptions assigned to the in-plane deformation mode of pyridine observed at 629 and 626 cm^{-1} in the spectra of H4APS and H2APS, respectively, shift to 591 and 609 cm^{-1} in the spectra of **3** and **4**, respectively. However, since in H4APS the semicarbazone chain is located in γ-position in relation to the heteroaromatic nitrogen, coordination through the imine nitrogen and the oxygen is suggested for complex **3**. Hence the large shift of the pyridine deformation mode upon coordination is probably due to extensive conjugation involving the semicarbazone skeleton and the heteroaromatic ring. In complex **4** coordination through the N_{py}–N–O chelating system occurs, as confirmed by crystal structure determination (Section 3.2).

The ν(V=O) vibration of [VO(acac)$_2$] is found at ca. 999 cm^{-1} [13]. This absorption is shifted to 941–969 cm^{-1} in the spectra of complexes **1**–**4**, in accordance with the presence of a ligand in *trans* position to the V=O bond. For complex **4** the presence of two absorptions attributed to $\nu_{sym.}$ (O=V=O) and $\nu_{asym.}$ (O=V=O) at 959 and 941 cm^{-1} corroborates the formation of [VO_2(2APS)] [15].

The electronic spectrum of [VO(acac)$_2$] shows absorptions at 30 530–36 900 cm^{-1} associated to acac and at 25 000 cm^{-1} assigned to a ligand-to-metal charge transfer transition. Bands at 14 430 and 17 000 cm^{-1} were attributed to ligand field transitions. In the electronic spectra (solid) of the free semicarbazones the $\pi \rightarrow \pi^*$ transitions of the pyridine ring were found at 45 660–47 160 cm^{-1}. The $n \rightarrow \pi^*$ transitions of the carbonyl and the azomethine functions were observed at 34 250–39 680 cm^{-1} and 26 810–30 960 cm^{-1}, respectively [6,14].

In the spectra of complexes **1**–**3** absorptions at 26 800–36 760 cm^{-1} were assigned to the $n \rightarrow \pi^*$ transitions of the semicarbazones and to transitions of acac overlapped under the same envelope. Bands in the 23 810–26 320 cm^{-1} range were attributed to ligand-to-metal charge transfer transitions of the complexes and of acac $\rightarrow$ VO^{2+}. Ligand field transitions of **1**–**3** were observed at 13 120–17 760 cm^{-1}.

In the spectrum of **4** a large absorption at 25 500–39 000 cm^{-1} was assigned to the $n \rightarrow \pi^*$ transitions of the semicarbazone along with a ligand-to-metal charge transfer transition. In this case no absorptions attributable to ligand field transitions were observed, according to the presence of V(V).

The NMR spectra of H2APS and complex **4** were recorded in d_6-DMSO because this is the only solvent which dissolves both compounds. The ^{1}H resonances were assigned on the basis of chemical shifts, multiplicities and coupling constants. The carbon type (C, CH) was determined by using DEPT135 experiments. The assignments of the protonated carbons were made by 2D heteronuclear-correlated experiments (HMQC) using delay values which correspond to ^1J(C, H).

In the ^{1}H NMR spectrum of H2APS the signal of N(3)–H appears at 9.45 δ. This signal is not observed in the spectrum of complex **4**, indicating deprotonation upon coordination to the metal centre. On coordination the signals of the pyridine hydrogens as well as the signal of N(4)–H_2 undergo significant shifts, suggesting coordination through the heteroaromatic nitrogen and through the oxygen. In the ^{13}C NMR spectrum large shifts occur for C=O, C=N and the pyridine carbons, in accordance with coordination of the semicarbazone through the N_{py}–N–O tridentate chelating system. One signal was observed at −528.44 δ in the ^{51}V NMR spectrum, consistent with the presence of vanadium(V) [16].

3.2. X-ray crystallography

Crystal data and refinement results for [VO(H2APS)(acac)$_2$] (**1**) and [VO_2(2APS)] (**4**) are shown in Table 1. Selected intra-molecular bond distances and angles around the metal are given in Table 2. Figs. 2 and 3 show ellipsoid representations of **1** and **4**.

Complex **1** shows a quite distorted octahedral coordination sphere, with the semicarbazone attached to the vanadium centre as a neutral ligand, through the carbonyl oxygen atom O(1), which occupies the axial *trans* position to the oxo ligand O(2). The four acetylacetone oxygens O(3), O(4), O(5) and O(6) show a mean deviation of 1.37 pm from planarity. The vanadium center is displaced by 31.5(2) pm from the equatorial base toward the apical oxo ligand O(2). The rather long V–O(1) bond distance, 233.3(3) pm, is caused by the strong *trans* influence of the oxo ligand, with V–O(2) distance = 159.4(3) pm, which corresponds to a double bond. The interatomic distances within the [VO(acac)$_2$] entity of **1** are comparable with the values found in [VO(acac)$_2$] itself [18]. Furthermore, the average value of 99.4° observed for the O_{oxo}–V–O_{acac} angles in **1** is 6.6° smaller than the corresponding value for [VO(acac)$_2$] (106.2°) [18], due to coordination of the

oxygen from the semicarbazone in *trans* position to the oxo ligand.

The coordination sphere of the dioxocomplex **4** adopts a relatively distorted square pyramidal geometry, with the parameter $\tau = 0.23$ (for an ideal square pyramid $\tau = 0$ while for an ideal trigonal bipyramid $\tau = 1$) [19]. The oxo atom O(3) is considered to be in the apical position, with the basal positions being occupied by the remaining oxo atom O(2) and the N(1), N(2) and O(1) donor atoms from 2APS, which coordinates through the N–N–O-tridentate system. The vanadium centre is placed 54.1(1) pm above the basal atoms, which show a mean deviation from planarity of 19.58 pm.

The atoms of the semicarbazone remain almost planar in **1** and **4**, presenting mean deviations from planarity of 6.50 pm and 9.78 pm, respectively. The N(3)–C(8) bond distance is 1.8 pm shorter in **4** due to deprotonation at N(3) and formation of a predominantly double N–C bond. In addition, the C(8)–O(1) bond is 5.1 pm larger in **4** compared to **1** due to the formation of a predominantly single C–O bond upon deprotonation at N(3).

Supramolecular assemblies in the crystal structures of **1** and **4** are built up by diverse intermolecular hydrogen bonds, shown in Figs. 4 and 5, whose distances and angles are given in Table 3. In **1** the molecules of the complex are interconnected forming layers perpendicular to the [0 0 1] direction. In **4** the molecules linked in a zigzag outline form chains parallel to the [0 1 0] direction. In **4** N–H···N and N–H···O hydrogen bonds were observed. Besides these types of bonding, the structure of **1** also shows C–H···N, and C–H···O interactions (see Fig. 4).

*3.3. Insulin-mimic activity: effect of complexes **1–4** on glucose uptake and glycerol release from isolated adipocytes*

The insulin-mimetic activity was evaluated by means of *in vitro* measurements of the glucose transport in adipocytes incubated in the presence of insulin (50 ng/mL) as positive control, or in the presence of the vanadium complexes (10^{-3} M). As shown in Fig. 6, the presence of the complexes in the incubation medium stimulated glucose uptake, except for complex **4**, that did not have any influence on glucose transport. The results demonstrate that

[VO(acac)$_2$] is more effective than all its derivatives in enhancing glucose uptake by adipocytes (Fig. 6).

The effect of the vanadium complexes on lipolysis in adipocytes is illustrated in Fig. 7. As can be seen, all complexes inhibited glycerol release by adipocytes in a similar way to that observed with insulin.

Although several vanadium complexes have shown significant biological potential, new complexes are presently under investigation in an attempt to reduce the dose and increase safety and efficacy. Our experimental findings have shown that the studied vanadyl complexes alone enhance glucose uptake and inhibit glycerol release from adipocytes. The ability of these compounds to stimulate glucose uptake as well as to inhibit lipolysis in fat cells indicates potential mechanisms of their anti-diabetic insulin-like effects.

At the cellular level, it was demonstrated that vanadium activates several key elements of the insulin signal transduction pathway, such as the tyrosine phosphorylation of insulin receptor substrate 1, and extracellular signal-regulated kinase 1 and 2, phosphatidylinositol 3-kinase B activation [20]. These pathways are believed to mediate the metabolic actions of insulin, e.g. GLUT4 translocation [21], glucose uptake in muscle [12] and in adipocytes [22]. Because protein tyrosine phosphatases (PTPases) are considered to be negative regulators of the insulin-signaling pathway, it is suggested that the studied compounds could enhance insulin signaling and act by virtue of their capacity to inhibit protein tyrosine phosphatase activity and to increase phosphorylation of substrate proteins [23].

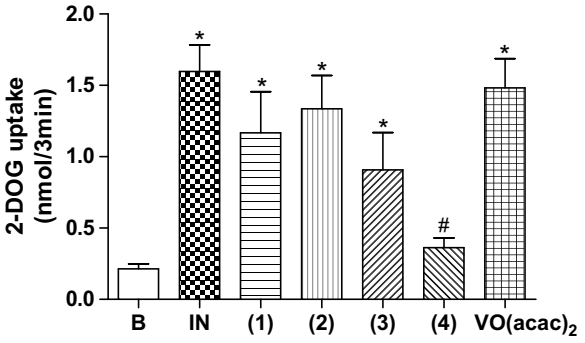

Fig. 6. Stimulation of glucose transport by the vanadium complexes in adipocytes. Freshly prepared rat adipocytes were preincubated with vanadyl complexes (10^{-3} M) or insulin (50 ng/mL) for 45 min. The cells were then supplemented with 2-deoxy-[^{3}H]glucose (0,2 μCi/tube) and after 3 min, deoxy-glucose uptake was evaluated. Cell associated radioactivity was determined by scintillation counting. Data are means ± SE. $^{*}P < 0.05$ vs Basal (B); $^{\#}P < 0.05$ vs insulin (In).

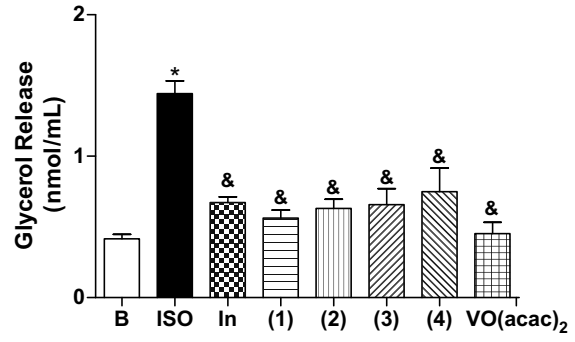

Fig. 7. Antilipolytic effects of the vanadium complexes (10^{-3} M) and insulin (50 ng/mL) on isoproterenol-stimulated lipolysis. Adipocytes were incubated for 30 min with the complexes, then 0,1 μM isoproterenol was added to incubation medium and lipolysis was measured by following the rate of glycerol release. Data are means ± SE. $^{*}P < 0.05$ vs Basal (B); $^{\&}P < 0.05$ vs isoproterenol (ISO).

For vanadyl complexes it has been suggested that *in situ* formation of peroxovanadates leads to inhibition of PTPases, as shown in the case of vanadium(IV) oxo bis(maltolato) (BMOV) [24]. Complexes **1**–**3** exhibited insulin mimic effect by enhancing glucose uptake, while complex **4** did not show such behavior. In the cases of complexes **1** and **2** the APS ligands coordinate as monodentate species, being probably easily released from the metal centre in biological media, with formation of [VO(acac)$_2$]. In the case of **3** the semicarbazone acts as a bidentate ligand, probably being equally well removed from the metal coordination sphere. Therefore in the cases of **1**–**3** uncomplexed vanadium is probably the species which undergoes oxidation after the release of all ligands. By contrast in **4**, the APS ligand is attached to the metal as a tridentate species, which possibly makes the metal centre less available for interaction in biological media.

In addition to their action on glucose metabolism, vanadium compounds can modulate lipolytic rates in adipose tissue, as shown in the present paper. An alternative hypothesis to account for the insulin-like actions of vanadium involves attenuation of signaling by 3′,5′-cyclic adenosine monophosphate (cAMP) through activation of cyclic nucleotide phosphodiesterase isoforms [25]. In other studies, however, the antilipolytic effects of vanadium were shown to be independent of phosphatidylinositol 3-kinase B and phosphodiesterase [26], or involve inhibition cAMP-dependent protein kinase [25]. Therefore, although insulin itself does enhance cAMP degradation, it is not clear if the antilipolytic effect of the vanadium complexes depends entirely on this mechanism.

4. Conclusions

The oxovanadium(IV) complexes with 2-, 3- and 4-acetylpyridine semicarbazones were able to enhance glucose uptake and inhibit glycerol release from adipocytes. In complex **4** the ability to promote glucose uptake was lost. Although the vanadyl complexes showed insulin-mimic properties, this effect is not better than that of the starting salt. Further investigation is underway with vanadium complexes of a variety of semicarbazones.

Scheme 1. TCEP mediated reduction of disulfide to thiol.

reported [8] and all crystal structures published to date describe only a metal–metal bridging mode for the TCEP ligand. Surprisingly, no reports of TCEP binding in a chelating, non-metal–metal bridging mode to a single ion have been described. An additional interest in hard–soft donor ligands such as TCEP is their ability to stabilize both high and low oxidation states in mixed-valence metal coordination complexes. One of us has recently described the synthesis and catalytic properties of a mixed-valence Co(I)(II) complex stabilized with the phosphine–phosphonic acid, triphenylphosphine triphosphonic acid (TPPTP) [9]. Finally, polydentate ligands are of interest as potential sequestering agents for radioactive heavy metals. Herein, we describe the reaction of TCEP with cobalt(II) chloride in aqueous solution to give a trimetallic mixed-valence Co(II)/Co(III) complex in which the ligand displays a previously unseen coordination mode involving non-metal–metal bonding of the TCEP ligand in a tridentate chelating fashion to Co(III). The spectral properties of this new complex are also described.

2. Experimental

2.1. General data

All reactions and manipulations were conducted in air. IR spectra were recorded on a Bruker Tensor 27 FT-IR spectrometer in the range of 4000–400 cm^{-1}. UV–Vis absorption spectra in aqueous solutions were recorded on a Hewlett–Packard 8453 diode array spectrometer at 23 °C over the spectral range 200–800 nm, in 1 cm quartz cuvettes. Measurements were made using the concentration range 6.470×10^{-5}–8.360×10^{-5} mol dm^{-3}. ESI-MS were recorded in methanol on an MDS Sciex API QStar Pulsar Quadrupole-TOF hybrid. Microanalyses were performed by Atlantic Microlab. Reagents and solvents were obtained as follows: cobalt chloride hexahydrate, sodium hydroxide, 95% ethanol (Sigma–Aldrich), and tris(2-carboxyethyl)phosphine hydrochloride (Pierce) used as received.

2.2. Synthesis of $[Co\{P(CH_2CH_2COO)_2(CH_2CH_2COOH)\}_2]_2[Co(H_2O)_4][Na_2(H_2O)_4]Cl_2 \cdot 6H_2O$ (1)

A round-bottomed flask was charged with $CoCl_2 \cdot 6H_2O$ (1.26 g, 5.30 mmol), tris(2-carboxyethyl)phosphine hydrochloride (1.72 g, 6.00 mmol), DI water (5 mL), and a stir bar. Then, 2 mL of 4 M NaOH was added drop-wise to the flask with stirring. The resulting deep-red solution was heated at 50 °C for 12 h. The solution was allowed to cool to room temperature, ethanol was added and the resulting solution cooled to 4 °C. After 4 days, the resulting purple crystals were collected by filtration and dried in air to give **1** (0.506 g, 22%). *Anal.* Calc. for $C_{36}H_{80}Cl_2Co_3Na_2O_{38}P_4$: C, 28.10; H, 5.24. Found: C, 28.18; H, 5.23%. IR (KBr pellet, cm^{-1}): ν(OH) 3383 (s, br), ν(C=O) 1721 (s), ν(C–O) 1602 (s, sh) 1564 (s). Electronic absorption spectra, λ_{max}, nm (ε, $dm^3\ mol^{-1}\ cm^{-1}$): H_2O, 208 (5.128×10^4), 276 (4.215×10^4), 446 (938), 578 (1022).

2.3. X-ray analysis

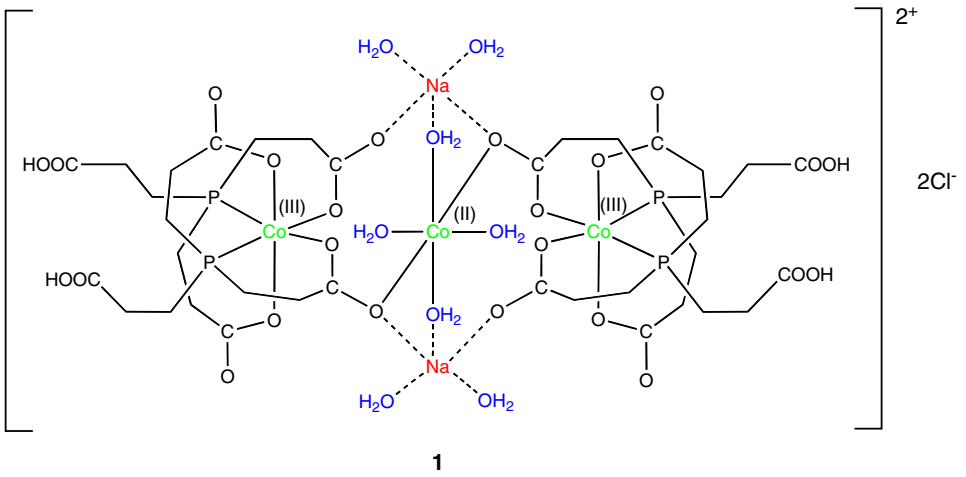
Single-crystal X-ray diffraction data on compound **1** were collected at 103 K using Mo Kα radiation and a Bruker APEX 2 CCD area detector. A $0.46 \times 0.16 \times 0.02$ mm^3 purple blade was prepared for data collection coating with high viscosity microscope oil (Paratone-N, Hampton Research). The oil-coated crystal was mounted on a glass rod and transferred immediately to the cold stream (−170 °C) on the diffractometer. The crystal was triclinic in space group $P\bar{1}$ with unit cell dimensions $a = 8.1927(12)$ Å, $b = 10.4031(15)$ Å, $c = 18.875(3)$ Å, $\alpha = 104.418(2)°$, $\beta = 93.904(2)°$, and $\gamma = 97.089(2)°$. Corrections were applied for Lorentz, polarization, and absorption effects. Data were 96.5% complete to 25.00° θ (approximately 0.72 Å) with an average redundancy of 1.9. The structure was solved by direct methods and refined by full-matrix least squares on F^2 values using the programs found in the SHELXTL suite [10]. Parameters refined included atomic coordinates and anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms on carbons were included using a riding model (coordinate shifts of C applied to H atoms) with C–H distance set at 0.96 Å.

3. Results and discussion

3.1. Synthesis

The synthesis of complex **1** was carried out by reaction of a slight molar excess of tris(2-carboxyethyl)phosphine hydrochloride (TCEP) with aqueous cobalt chloride in air as shown in Scheme 2.

The pH of the resulting solution was slowly adjusted to 4.0 using 4 M sodium hydroxide solution and a deep-red



$$CoCl_2{\cdot}6H_2O + P(CH_2CH_2CH_2COOH)_3 \xrightarrow[H_2O,\ 50\ ^\circ]{NaOH,\ pH\ 4.0} \mathbf{1}$$

Scheme 2. Synthesis of TCEP cobalt complex **1**.

solution resulted from which **1** was isolated as purple crystals after cooling the reaction mixture to 4 °C for 4 days. The molecular structure of **1** is shown in Fig. 1. No other discreet cobalt containing complexes could be isolated from the filtrate. Compound **1** is air stable as a solid for at least 6 months and is stable and very soluble in water giving dark green solutions. It is insoluble in most common organic solvents such as ether, acetone and dichloromethane.

3.2. Structure

Crystals of **1** obtained directly from the reaction described above were of sufficient quality to be used directly for X-ray crystal structure analysis. The ORTEP representation of **1** is shown in Fig. 2 and crystal structure data and refinement details are given in Table 1. Compound **1** crystallized in the space group $P\bar{1}$ with the unit cell containing one molecule. The unit cell contains three cobalt ions, one unique Co(II) ion and two identical Co(III) ions each with a distorted octahedral geometry. Presumably, partial oxidation of the aqua Co(II) ion takes place in the presence of air [11] and interestingly the phosphine does not reduce Co(III) to Co(II) in spite of being an excellent reducing agent. A symmetry plane passes through the central Co(II) ion and one sodium ion and two-coordinated TCEP ligands lie on each side of the symmetry plane. Co1 lies in a general position and Co2 lies on a crystallographic symmetric center. The complex is trinuclear with repeating units lying along the *c* axis. Six non-coordinated water molecules are also present along with two chloride anions which are located between the carboxy groups, again one on either side of the symmetry plane. The Co(III) ions are each coordinated to

two TCEP ligands in a tridentate chelating mode with two arms of the ligands binding through deprotonated carboxy groups, with the third arm containing an uncoordinated carboxylic acid moiety. All previous metal complexes of TCEP contain the ligand in the trianionic form, however the dianionic form is found in complex **1**. The Co(II) ion Co2 is coordinated by the carboxylate group from two different TCEP ligands. The carboxylate oxygen atoms are *trans* to each other around Co2 and the remaining axial and equatorial sites are occupied by coordinated water molecules. The phosphorus donor atoms have the *cis*-orientation and the P–Co–O bite angles for TCEP to Co1 fall in the range 87.22(6)–94.99(7)°, similar to those found in other cobalt(III) complexes containing P–O chelates [12]. The P–Co bond lengths 2.1735(8) and 2.1803(9) are shorter than those found in the complexes *cis*-$[Co(acac)_2(PMe_3)_2]PF_6$ and $[Co(acac)_2(dmpf)]B(C_6H_5)_4$ (bmpf = 1,1′bis(dimethylphosphino)ferrocene), Co–P = 2.226(2)–2.257(2) [13] but are similar to that found in the chelating ligand complex $[Co(acac)_2(edmp)]ClO_4$ (edmp = (2-aminoethyl)(dimethylphosphine)), Co–P = 2.192(2) [14,15]. Both TCEP and edmp are both less sterically demanding than either PMe_3 or bmpf resulting in shorter Co–P bond lengths than complexes with bulkier ligands.

A comparison of the Co–O(carboxylate) bond lengths of **1** with other cobalt(II) and cobalt(III) carboxylate complexes indicates that all Co–O bonds are within the normal range for this type of coordination [8,16–18]. The geometry

of the six-coordinate Na ion in **1** is distorted octahedral with coordination by four water oxygen and two carboxylate oxygen atoms. A list of bond lengths and angles for **1** is given in Table 2.

3.3. Spectroscopy

The UV–Vis spectrum of **1** recorded in H_2O at neutral pH contains two high energy bands at 208 nm ($5.128 \times$

10^4 dm^3 mol^{-1} cm^{-1}) and 276 nm (4.215×10^4 dm^3 mol^{-1} cm^{-1}). These absorptions can be assigned to charge transfer bands of bound TCEP and are consistent with those reported for other metal complexes in which the ligand is present in the deprotonated form [10]. Two lower intensity visible absorptions at 446 and 578 nm have been assigned to $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ transitions for a diamagnetic ground state Co^{3+} ion [11] although a weak absorption at 578 nm could correspond to a transition for octahedral Co^{2+} ion [19]. The UV–Vis spectrum of **1** is shown in Fig. 3. Precipitation of metal hydroxide precluded the spectrophotometric analysis of **1** at higher pH values.

The FT-IR spectrum of **1** recorded as a KBr disc, shows the presence of both free COOH and bound carboxylate functionalities. An intense broad absorption at 3383 cm^{-1} is typical of a carboxylic acid–OH stretching frequency and/or the presence of cobalt bound water and waters of crystallization. No –OH absorptions were seen at lower wave-numbers which would be attributed to strongly hydrogen bonded O–H groups. The intense carbonyl C=O stretching frequency of the free COOH is located at 1721 cm^{-1} and the asymmetric stretching vibrations of coordinated COO^- appear at 1602 and 1554 cm^{-1}.

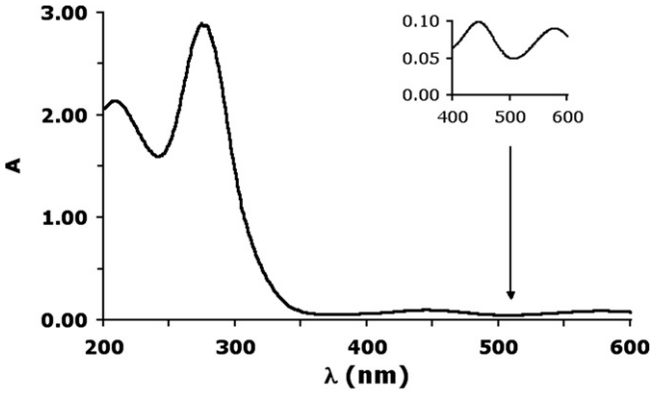

Fig. 3. UV–Vis spectrum of **1**.

3.4. Electrospray mass spectrometry

The ESI-MS spectrum of **1** was recorded in positive ion mode in methanol and shows a dominant doubly charged ion (100%) at 614 a.m.u. and has been tentatively assigned to species **2** in which the trimetalllic cobalt core found in **1** remains intact and two Na^+ ions and five water molecules have been lost giving rise to a seven-coordinate Co^{2+} ion (Fig. 4) [20]. A smaller doubly charged ion peak (20%) at 607 a.m.u. has been assigned to structure **3** (formed via loss of two Na^+ ions and six water molecules). Singly charged ions at 646 (15%) and 601 (23%) a.m.u. presumably arise from dissociation of the trimetallic cobalt core (see Supplementary Material).

4. Conclusions

The water-soluble phosphine ligand TCEP reacted with Co(II) in aqueous solution to give an unusual trimetallic mixed-valence Co(III)/Co(II)/Co(III) complex [21]. Single-crystal X-ray analysis reveals that the ligand is bound in a tridentate mode to Co(III) and additionally bridges a Co(II) and Na ion. Compound **1** represents the first mixed-valence complex of the ligand TCEP.

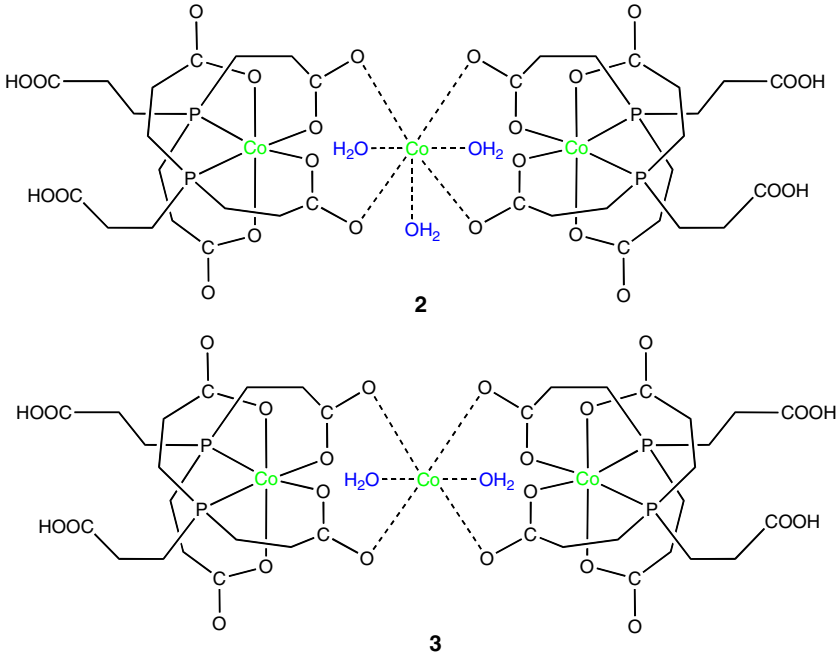

Fig. 4. Trimetallic species identified in ESI-MS analysis of **1**.

Scheme 1. Ligand H_3acshz (a), H_3acbshz (b) and the basic bonding sites of them in the compounds.

complex, $[Ni_3(H_2O)_2(DMA)_2(acshz)_2]\cdot 2DMF$ (**1**); use H_3acbshz and trivalent iron ion to form a new iron(III) 18-metallacrown-6 compound, $[Fe_6(acbshz)_6(DMF)(H_2O)_5]\cdot 5DMF$ (**2**). Minimum inhibitory concentrations (MIC) against four different bacteria species of the two compounds were also measured.

2. Experiment

2.1. General

All reagents for the syntheses were obtained commercially with analytical grade and were used without further purification. ^1H and ^{13}C NMR spectra were recorded on a Varian Inova 600 MHz NMR spectrometer at 25 °C. Chemical shifts were referenced to the residual solvent peak. IR spectra were recorded on AVATAR 360 FT-IR spectrophotometer in the range 4000–400 cm^{-1} (KBr pellets). Element analyses were performed on a Perkin–Elmer 2400 CHN elemental analytical instrument. TG analysis was performed on a Pekin–Elmer DF40 instrument in flowing N_2 with a heating rate of 10 °C min^{-1}. UV–Vis spectra were recorded on a Shimadzu-UV-2501 spectrophotometer. Positive and negative electrospray ionization mass spectra (ESI-MS) were performed on API-2000 LC/MS/MS system for the metallacrown dissolved in DMF.

2.2. Synthesis of the ligands and metal complexes

2.2.1. N-Acryloyl-5-bromosalicylhydrazide (H_3acbshz)

Acryloyl chloride (1.6 ml, 19.7 mmol) was added to a solution of chloroform (100 ml) containing water (0.36 ml, 20.0 mmol) and triethylamine (5.7 ml, 40.0 mmol) at 0 °C. The reaction mixture was slowly warmed to ambient temperature. Then a further amount of acryloyl chloride (1.6 ml, 19.7 mmol) was added to the mixture and stirred for a further 1 h. After the completion of the above reaction, 5-bromosalicylhydrazide (3.7 g, 16.4 mmol) was added to the reaction mixture. The resulting reaction mixture was stirred at ambient temperature for 1 day. The solution was diluted with hexane (90 ml), kept under refrigeration overnight, filtered, and washed with ether, and rinsed with water (30 ml × 3) followed by ether. It was then dried in vacuo over P_2O_5. Yield: 3.85 g, 82.5%. *Anal.* Calc. for $C_{10}H_9N_2O_3Br$: C, 42.10; H, 3.15; N, 9.82. Found: C, 42.04; H, 3.25; N, 9.92%. IR (KBr pellet, cm^{-1}): 3310 (s), 3190 (s, broad), 2900 (s, broad), 2690 (m), 2620 (m), 1640 (s), 1600 (s), 1480 (s), 1400 (m), 1290 (s). ^1H NMR (DMSO-d_6), δ ppm: 12.01 (s, 1H, Ar-OH); 10.83 (s, 1H, Ar-CO–NH–); 10.78 (s, 1H, C_2H_3–CO–NH–); 8.04 (dd, 1H, *o*-ArH); 7.60 (m, 1H, *p*-ArH); 7.11 (m, 1H, *m*-ArH); 7.02 (dd, 1H, *m*-ArH); 6.41 (dd, 1H, –CO–CH=); 6.24 (dd, 1H, –CO–C=CH–); 5.77 (dd, 1H, –CO–C=CH–). ^{13}C NMR (DMSO-d_6), δ ppm: 169.10; 167.96; 162.63; 141.80; 137.35; 136.70; 134.31; 124.95; 115.76.

2.2.2. N-Acryloyl-salicylhydrazide (H_3acshz)

The ligand *N*-acryloyl-salicylhydrazide (H_3acshz) was prepared in an analogous manner to that used for *N*-acryloyl-5-bromosalicylhydrazide (H_3acbshz). Salicylhydrazide (2.5 g, 16.4 mmol) was used. 85% yield. *Anal.* Calc. for $C_{10}H_{10}N_2O_3$: C, 58.25; H, 4.85; N, 13.59. Found: C, 58.19; H, 4.92; N, 13.65%. IR (KBr pellet, cm^{-1}): 3440 (vs, broad), 3150 (vs, broad), 2780 (m), 2680 (m), 2490 (m), 1720 (m), 1630 (s), 1400 (s). ^1H NMR (DMSO-d_6), δ ppm: 11.91 (s, 1H, Ar-OH); 10.75 (s, 1H, Ar-CO–NH–); 10.25 (b, 1H, C_2H_3–CO–NH–); 7.93 (d, 1H, *m*-ArH); 7.44 (t, 1H, *m*-ArH); 7.03 (d, 1H, *o*-ArH); 6.95 (t, 1H, *p*-ArH); 6.42 (q, 1H, –CO–CH=); 6.22 (d, 1H, –CO–C=CH–); 5.75 (d, 1H, –CO–C=CH–). ^{13}C NMR (DMSO-d_6), δ ppm: 166.40; 163.52; 159.19; 134.66; 129.67; 127.79; 119.84; 117.92; 115.65.

2.2.3. $[Ni_3(H_2O)_2(DMA)_2(acshz)_2]\cdot 2DMF$ (**1**)

H_3acshz (20.6 mg, 0.1 mmol) was dissolved in 30 ml of 2:1 methanol + DMF with sodium hydroxide (12 mg, 0.3 mmol), then nickel chloride hexahydrate (23.7 mg, 0.1 mmol) was added. The mixture was stirred for 1 h, the resulting solution was filtered. After standing for several days, red block crystals were obtained from the filtrate. *Anal.* Calc. for $[Ni_3(H_2O)_2(DMA)_2(acshz)_2]\cdot 2DMF$: C, 42.11; H, 5.38; N, 13.10. Found: C, 42.16; H, 5.30, N, 13.17. IR (KBr pellet, cm^{-1}): 1720 (m), 1630 (m), 1520 (m), 1400 (s), 753 (m), 558 (m).

2.2.4. $[Fe_6(acbshz)_6(DMF)(H_2O)_5]\cdot 5DMF$ (**2**)

H_3acbshz (28.5 mg, 0.1 mmol) was dissolved in 30 ml of 2:1 methanol + DMF, and iron(III) nitrate nonahydrate

(40.4 mg, 0.1 mmol) was added to it, stirred for 2 h with the color of the solution changing to dark brown, then the mixture was filtered. After slow evaporation of the mother liquor over several weeks, dark brown block crystals suitable for X-ray diffraction were obtained. Yield: 75.4%. IR (KBr pellet, cm^{-1}): 1650 (s), 1590 (s), 1480 (s), 1410 (s), 632 (m), 534 (m).

2.3. Crystallographic data collection and refinement of the structures

X-ray single-crystal diffraction data for compounds **1** and **2** were collected on a Bruker Smart APEX diffractometer at 292(2) K with Mo Kα radiation ($\lambda = 0.71073$ Å). There was no evidence of crystal decay during data collection of compound **1**. In the data collection of compound **2**, suitable crystal was mounted in glass capillaries with the mother liquor to prevent the loss of the structural solvent molecules. In the compound **2**, the crystals diffracted poorly, with a relatively low percentage of observed intensities above the threshold of $2\sigma(I)$ within the 0.94–26.00° θ range. The non-coordinated solvent molecules are severely disordered which could not be modeled by discrete atoms in the compound. Correspondingly, the contribution of the solvent to the diffraction pattern was subtracted using SQUEEZE procedure of the PLATON. These voids consist of about 24.4% of the crystal volume (1533.7 Å per unit cell). Conventional least-squares refinement of the same solvent-exclude structural model against the original data set converged only at $R_1 = 0.15$. Refinement calculations with the modified data converged at $R_1 = 0.0893$ for 5471 reflections with intensities above the threshold of $2\sigma(I)$. In both compounds, the structures were solved by direct methods and all non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were located in calculated positions and/or in the positions from difference Fourier map. The positions and anisotropy from difference of non-hydrogen atoms were refined on F^2 by full-matrix least-squares techniques with the SHELXTL program package [21,22]. Crystallographic data are summarized in Table 1. Selected bond lengths and angles for complex **1** are listed in Table 2.

2.4. Antimicrobial activities of the complexes

The antimicrobial activity of the complexes were assessed by their ability to inhibit the growth of *Staphylococcus aureus*, *Escherichia coli*, *Bacillus subtilis* and *Proteus vulgaris* in Mueller–Hinton broth medium. The minimum inhibitory concentration in μg/ml against the four bacteria species was measured. The bacteria concentration was $5 \times (10^5$–$10^6)$ cfu/ml and concentrations of 1600, 800, 400, 200, 100, 50 and 25 μg/ml of the complexes in DMF were tested. The solvent showed no antimicrobial action.

3. Results and discussion

3.1. Spectral characterization

In the IR spectra, the ligands H_3acbshz and H_3acshz show stretching bands attributed to C=O, PhO–H (phenolic, including intramolecular and intermolecular hydrogen bond) and N–H at 1600, 1640, 2620–3190, 3310 cm^{-1} and 1720, 1630, 2490–3150, 3440 cm^{-1}, respectively [23]. The infrared stretching bands for compounds **1** and **2** are quite similar. The absence of the N–H band and the weakness of the C=O stretching bands are consistent with the deprotonation of the CONH groups and coordination to the Fe(III) and Ni(II) ions, which indicate the same chelating modes of the ligands to metal ions. The deprotonation and coordination are also confirmed by the bands at 632 and 753 cm^{-1}, attributed to M–O linkages, and the bands

at 534 and 558 cm^{-1} assigned to M–N linkage [24]. The C=N–C=N framework bands are found at 1480 and 1400 cm^{-1}, respectively [25].

3.2. Integrity and stability of metallacrown

Solution stability of the metallacrowns is a fundamental property for the proposed applications of metallacrowns [26]. Electrospray ionization (ESI) mass spectroscopy, a soft ionization technique, has been proved useful in providing solution molecular weights of formally neutral metallacrown salt complexes [27]. The DMF solution of the compound **2** gave some peaks at *m/z* 1905.4 and 1018.1 in ESI(+)-MS, corresponding to the hexanuclear cluster ion, $[Fe_6(acbshz)_6(DMF)(H_2O)_5+2H]^{2+}$ and $[Fe_6(acbshz)_6+2H]^{2+}$, respectively. To explore the solution stability of the metallacrown in DMF solution, the concentration-dependent absorbance was measures at 319 nm for compound **2**. The concentration variation result to a linear change in absorbance across the range of 3.1 and 100 μM of concentrations (Fig. 1). No change was observed for the absorption of the solution after 2 weeks. The result indicates that the compound **2** retains the integrity of the ring and is stable at least in these concentration ranges in DMF.

UV–Vis titrations were undertaken both to determine the extent of solution integrity and gain insight into the formation of the compound **2**. Titration of the DMF solution of H_3acbshz with $Fe(NO_3)_3$ in steps of 0.1 equiv. causes obvious increase in the intensity of the broader at 319 nm, and also slight increase of d–d transition band at 470 nm. The plot of the ratio of concentrations of $Fe(NO_3)_3$ to H_3acbshz versus the molar absorptivity at 319 nm is shown in Fig. 2. We can see that an increase in the absorbance at 319 nm was observed with a metal ligand endpoint ratio of 1:1, which is consistent with the formation of the compound **2** in DMF solution. Addition of excess metal does not alter the field band. These observations are consistent with the stability of the compound **2** in DMF solution even in the presence of excess metal.

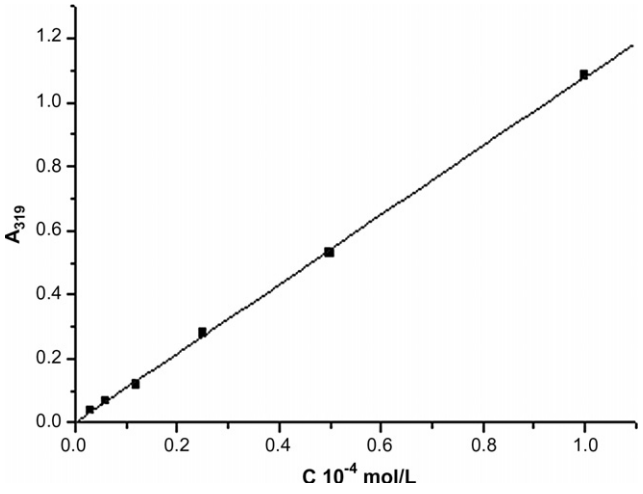

Fig. 1. The concentration-dependent absorbance of compound **2** in DMF was measured at 319 nm.

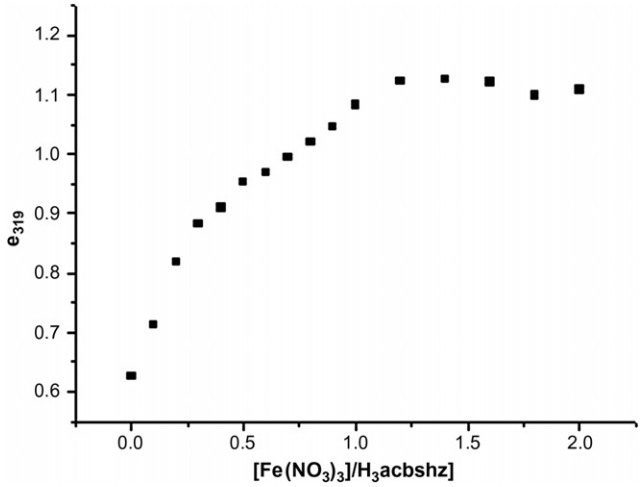

Fig. 2. UV–Vis titration curve of the addition of 0.0–2.0 equiv. of $Fe(NO_3)_3$ into 1 mM H_3acbshz in DMF.

3.3. Description of the structures of *1* and *2*

The structure of the linear trinuclear nickel compound **1** is provided in Fig. 3. The deprotonated ligand $acshz^{3-}$ acts as a trianionic pentadentate ligand, one phenolate oxygen, one carbonyl oxygen and one hydrazide nitrogen in one ligand are bound to the terminal nickel ions and the other carbonyl oxygen plus the other hydrazide nitrogen in the two ligands are chelated to the central nickel ion. Central nickel ion (Ni1) is octahedral while the other two terminal nickel ions are square-planar. They are connected by two bridging deprotonated $acshz^{3-}$ ligands, forming a linear trinuclear nickel structure unit with a Ni–N–N–Ni–N–N–Ni core with the neighboring Ni···Ni distance is 4.615 Å. The trinuclear nickel complex molecule is strictly linear by symmetry, because of that central nickel atom (Ni1) is on a crystallographic symmetry center. The equatorial plane of the octahedron is perfectly planar and the nickel ion (Ni1) lies in this plane. The axial coordination sites are occupied by two water molecules. The terminal nickel ions have a perfect square-planar surrounding with the rest site coordinated by dimethylamine molecules (DMA), which are believed to be the result of the decomposition of the DMF solvent under basic conditions. This phenomenon has been commonly observed in the literature [28,29]. The terminal Ni–O and Ni–N bond lengths for Ni–O(phenolate), Ni–O(carbonyl), Ni–N(diazine) and Ni–N(DMA) are 1.823, 1.850, 1.823 and 1.942 Å, respectively. They are slight shorter than the central Ni–O and Ni–N bond lengths for Ni–O(carbonyl), Ni–O(H_2O), Ni–N(diazine) which are 2.021, 2.097 and 2.076 Å, respectively. Adjacent molecules are linked by intermolecular H bonds to form a 2D infinite wave-like structure (Fig. 4).

A perspective view of the complete Fe_6 cluster molecule of $[Fe_6(acbshz)_6(DMF)(H_2O)_5]\cdot 5DMF$ is provided in

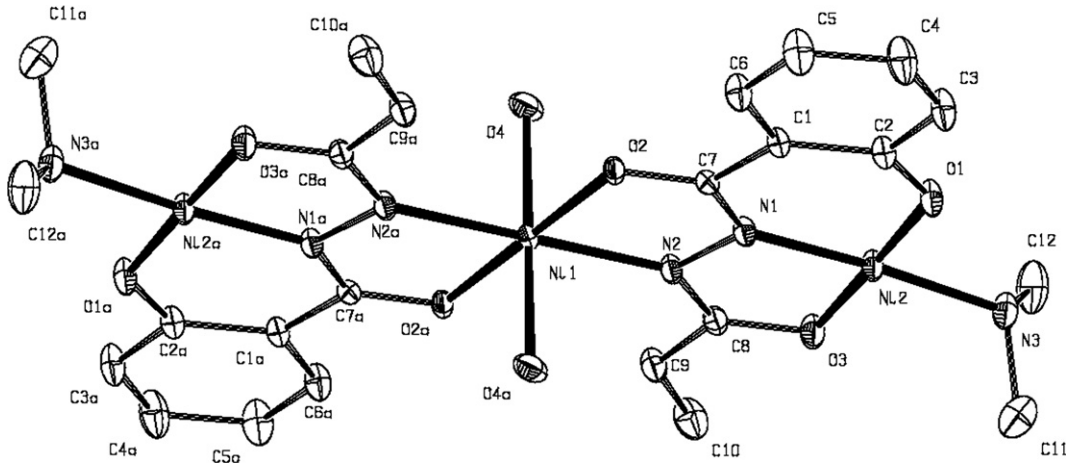

Fig. 3. Perspective view of compound **1**, solvent molecules and all hydrogen atoms have been omitted for clarity.

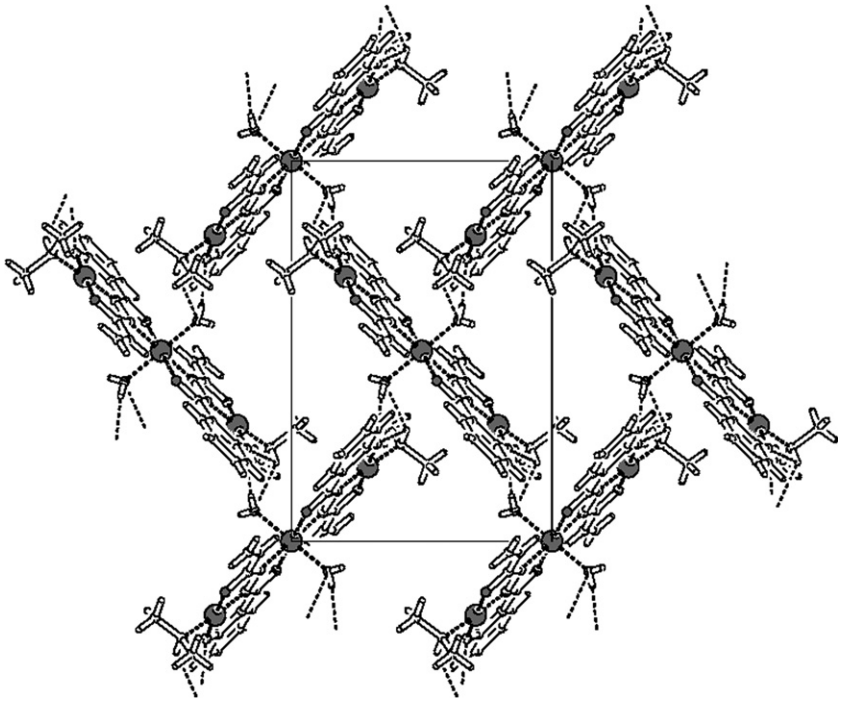

Fig. 4. The 2D structure formed by intermolecular H bond with the use of the trinuclear complex as a building block.

Fig. 5. The chelating modes of the ligands H_3acbshz and H_3acshz to metal ions are the same, the whole atoms in the ligand are almost in co-plane. All iron ions are in an octahedral FeN_2O_4 environment with one phenolate oxygen, one carbonyl oxygen and one hydrazine nitrogen in one ligand, one carbonyl oxygen and one hydrazine nitrogen in the other ligand. The rest site of five iron ions was occupied by oxygen atom from H_2O molecules while it was fitted by oxygen atom from DMF molecules in the other iron ion (Fe4). It is the first metallacrown that the coordination environments of metal ions in the cycle ring are different. The Jahn–Teller distortion is not observed because of the high-spin d^5 iron(III) ion configuration compared with some Mn(III) ion metallacrown compounds [10,14,30]. Meanwhile, the ligand forces all iron(III) cations into a propeller configuration with alternating Λ/Δ stereochemistry as ΛΔΛ forms. The specific connectivity of the atoms forming the ring is Fe1–N4–N3–Fe2–N5–N6–Fe3–N8–N7–Fe4–N10–N9–Fe5–N12–N11–Fe6–N2–N1–. This organization leads to the 18-numbered hexanuclear core ring system with [Fe–N–N] repeated unit. Three water groups coordinated at the metal centers with Λ configuration are found on one face of the metallacrown, and two water and one DMF groups coordinated to the other metal centers with Δ configuration are found on the other face of the metallacrown. Due to the difference coordination environments of the central metal ions, the two faces of the disc-shaped hexanuclear ring do not have opposite chiralities. But to our knowledge, the opposite chiratilies can be found in the all existent metallacrowns. The average

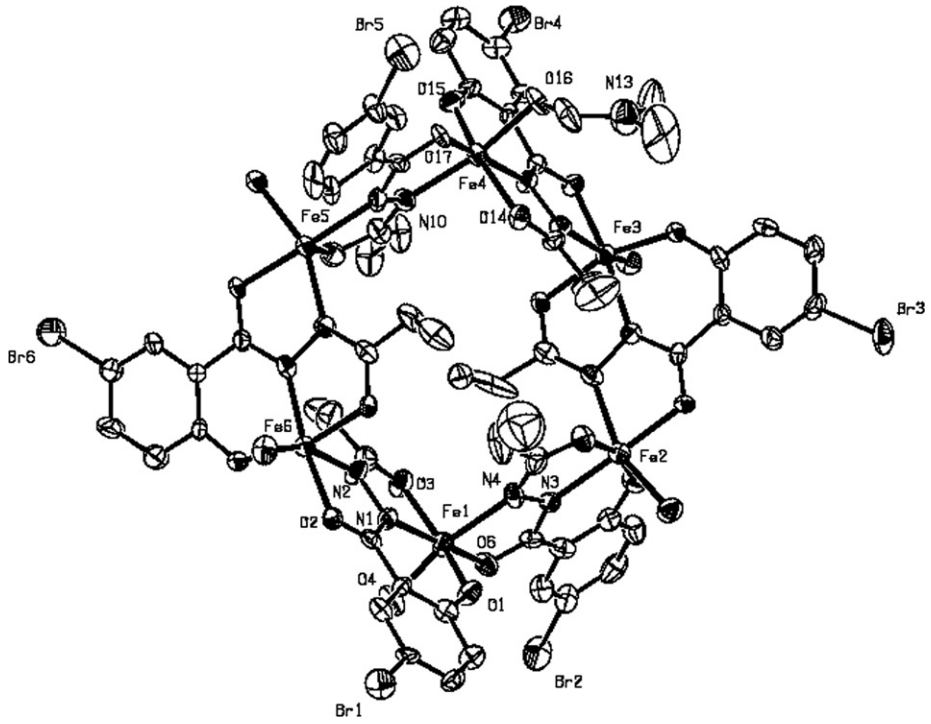

Fig. 5. Perspective view of compound **2**, solvent molecules and all hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): Fe(1)–O(1) 1.923(7), Fe(1)–O(6) 1.985 (7), Fe(1)–O(4) 2.042(7), Fe(1)–O(3) 2.048(8), Fe(1)–N(1) 2.077(9), Fe(1)–N(4) 2.113(9); O(1)–Fe(1)–O(6) 104.3(3), O(1)–Fe(1)–O(4) 93.5(3), O(4)–Fe(1)–O(3) 89.0(3), O(1)–Fe(1)–N(1) 84.9(3), O(6)–Fe(1)–N(1) 170.0(3), O(4)–Fe(1)–N(1) 95.6(3), O(3)–Fe(1)–N(1) 77.5(3), O(1)–Fe(1)–N(4) 91.5(3), O(6)–Fe(1)–N(4) 75.8(4), O(4)–Fe(1)–N(4) 155.6(4), O(3)–Fe(1)–N(3) 91.9(3), N(1)–Fe(1)–N(4) 108.4(4).

neighboring Fe···Fe separation is 4.924 Å. There are no solvent molecules in the 'host' cavity of the metallacrown.

3.4. TG analysis of compound *1*

The TG curve of compound **1** exhibits three steps of weight losses. The first weight loss is about 21.5% (Calc. value 21.3%) in the range of 30–170 °C, corresponds to the loss of two DMF molecules and two coordinated water molecules. The second weight loss is about 10.1% (Calc. value 10.3%) in the range of 170–272 °C, corresponds to the loss of two coordinated DMA molecules. The third weight loss is about 73.1% (Calc. value 73.6%), which can be attributed to the complete decomposition of the complex to form NiO as a final product.

3.5. Antimicrobial activities

Minimum inhibitory concentration of two ligands and compounds **1** and **2** against *S. aureus*, *E. coli*, *B. subtilis* and *P. vulgaris* are listed in Table 3. As can be clearly seen from the table, none of the ligands show strong antimicrobial activity against the tested microorganism while the compounds **1** and **2** all have strong antimicrobial activities. Moreover, in this study, the result do not indicate specificity against Gram-positive or Gram-negative bacterial in spite of it is generally expected that a much greater number would be active against Gram-positive than Gram-negative bacteria [31]. Antibacterial screening data indicated that the metallacrown **2** is more active than the trinuclear compound **1**.

Table 3
Minimum inhibitory concentration (MIC) of ligands (*N*-acryloyl-salicylhydrazide and *N*-acryloyl-5-bromosalicylhydrazide) and compounds (**1** and **2**) in μg/ml

Microorganisms	Ligands		Compounds	
	H_3acshz	H_3acbshz	**1**	**2**
Staphylococcus aureus (Gram$^+$)	800	800	200	50
Escherichia coli (Gram$^-$)	800	800	100	50
Bacillus subtilis (Gram$^+$)	800	400	100	25
P. vulgaris (Gram$^-$)	400	400	200	25

MIC showed that among all the compounds tested, metallacrowns are more active than the simple metal complexes. For the same type of salicylhydrazide derivatives, the best inhibition is given by $[Fe_6(acshz)_6(CH_3OH)_6]\cdot 6CH_3OH\cdot 6H_2O$ (MIC = 25–200 μg/ml against all microorganisms) [13]. But in this study, the compound **2** are more active than $[Fe_6(acshz)_6(CH_3OH)_6]\cdot 6CH_3OH\cdot 6H_2O$. Although it is risky to correlate the bioactivity of these compounds to the structural features, we can stress that the different bonding modes of iron(III) ions in compound **2** and $[Fe_6(acshz)_6(CH_3OH)_6]\cdot 6CH_3OH\cdot 6H_2O$ are important. Compared to the tetranuclear nickel(II) complex ($[12\text{-}MC_{Ni(II)N(Hshi)2(pko)2}\text{-}4](NNN)_2(DMF)(CH_3OH)$) with the low MIC value (12–25 μg/ml) [32], the MIC value in this trinuclear nickel(II) compound **1** is much

higher, but it is risky to correlate the nuclearity and antibacterial activity just based on these limited present complexes. The work to prepare more polynuclear nickel compounds and correlate the relationship between the nuclearity and antibacterial activity is in progress in our laboratory.

4. Conclusion

In this paper, we synthesize two trianionic pentadentate *N*-acylsalicylhydrazide ligands, *N*-acryloyl-salicylhydrazide (H_3acshz) and *N*-acryloyl-5-bromosalicylhydrazide (H_3acbshz), and use different metal ions with these ligands to form a new Fe(III) 18-metallacrown-6 and a new linear trinuclear Ni(II) complexes. The chelating modes of the two ligands to metal ions are the same. The three nickel ions in compound **1** arrange in a strictly linear structure, exhibit alternating square-planar and octahedral coordination environments. The six iron(III) ions in compound **2** are connected through hydrazide N–N groups to form a 18-membered ring. The ligand enforces the stereochemistry of the Fe^{3+} ions as a propeller configuration with alternating Λ/Δ forms. The coordination environments of iron ions in the cycle ring are different, and these differences make the two faces of the disc-shaped hexanuclear ring do not have opposite chiralities, which is different from all the existent metallacrowns. Antibacterial screening data showed that the metallacrown **2** has stronger antimicrobial activity than the trinuclear compound **1** against all tested microorganisms.

Scheme 1.

rich metal center. Previous studies in binuclear transition metal complexes were shown that, the bridging ligand can behave as an innocent or not during the superexchange process [26–33]. In the dicyanamidobenzene-bridge diruthenium complex, the dicyd bridging ligand was shown a non-innocent behavior [19].

Work on dinuclear and polynuclear systems derived from cyanamide or dicyanamide anions acting as bridging ligands is a fast-growing research field due to the large variety of topologies, dimensionalities, and magnetic properties that can be obtained [34].

We now report the preparation, crystal structure, spectroscopic characterization and electrochemical behavior of $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$, $[\{Cu(phen)_2\}_2(\mu\text{-Me}_2\text{dicyd})](PF_6)_2$, $[\{Cu(phen)_2\}_2(\mu\text{-Cl}_2\text{dicyd})](PF_6)_2$ (Scheme 1), and $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3$.

2. Experimental

2.1. Materials and measurements

All chemicals and solvents were reagent grade, obtained from either Merck or Aldrich and used without further purification. 1,4-dicyanamidobenzene, 1,4-dicyanamido-2,5-dimethylbenzene, 1,4-dicyanamido-2,5-dichlorobenzene, and 4-azo(phenylcyanamido)benzene were synthesized according to published procedures [23,35]. $[Cu(phen)_2Cl]PF_6$ was prepared according to the literature [36]. Elemental analyses were performed on a Perkin–Elmer 2400 CHNS/O elemental analyzer. IR spectra (4000–400 cm^{-1}) were measured on a FT-IR JASCO 460 spectrophotometer with KBr pellets and electronic spectra on a JASCO 7850 spectrophotometer. Cyclic voltammograms were recorded by using a Metrohm 694 apparatus. Three electrodes were utilized in this system, a platinum disk working electrode (RDE), a platinum wire auxiliary electrode and Ag/AgCl reference electrode. The platinum disk working electrode was manually cleaned with 1-μm diamond polish prior to each scan. The supporting electrolyte, tetrabutylammonium hexafluorophosphate (TBAH), was twice recrystallized from 1:1 ethanol/water and vacuum-dried at 110 °C. Acetonitrile was dried over P_2O_5 and vacuum distilled. The solutions were deoxygenated by bubbling with argon (Ar) for 15 min. Ferrocene ($E^\circ = 0.665$ V) was used as an internal reference [37].

2.2. Synthesis of $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$

A mixture of 1,10-phenanthroline (0.793 g, 4 mmol) and $Cu(NO_3)_2 \cdot 6H_2O$ (0.483 g, 2 mmol) was placed in 50 mL of water/ethanol (1:1 v/v) and stirred at room temperature for 24 h. To the reaction mixture was then added excess NH_4PF_6 (0.82 g, 5 mmol). The resulting light blue-green precipitate, $[Cu(phen)_2(H_2O)](PF_6)_2$, was collected by filtration, washed with cold water and diethyl ether, and then air dried. A solution of $[Cu(phen)_2(H_2O)](PF_6)_2$ (0.551 g, 1 mmol) in 100 mL acetone was degassed and under argon atmosphere, the neutral $dicydH_2$ (0.282 g, 0.5 mmol) was added. The solution was then stirred with slight heating (30°C) under Ar overnight. To this was added triethylamine (1.5 mL, 0.5 mmol), and the solution was stirred for 1 h. The dark brown precipitate, $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$, was collected by suction filtration, washed with diethyl ether, and then air dried. For further purification, the complex was recrystallized by diffusing diethyl ether into a saturated solution of the complex in DMF. After 3 days, green ultrafine crystals of the dinuclear complex, $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$, were collected and washed with diethyl ether and vacuum dried. Yield: 0.29 g (45%). *Anal.* Calc. for $Cu_2C_{56}H_{36}N_{12}P_2F_{12}$: C, 51.97; H, 2.80; N, 12.99. Found: C, 51.83; H, 2.75; N, 12.87%.

2.3. Synthesis of $[\{Cu(phen)_2\}_2(\mu\text{-Me}_2\text{dicyd})](PF_6)_2$

This complex was prepared by the same procedure, except that $dicydH_2$ was replaced by $Me_2dicydH_2$. Yield was 0.22 g (33%). *Anal.* Calc. for $Cu_2C_{58}H_{40}N_{12}P_2F_{12}$: C, 52.68; H, 3.05; N, 12.72. Found: C, 52.46; H, 2.99; N, 12.91%.

2.4. Synthesis of $[\{Cu(phen)_2\}_2(\mu\text{-Cl}_2\text{dicyd})](PF_6)_2$

Due to the poor solubility of $Cl_2dicydH_2$ in common organic solvents, the tetraphenylarsonium salt of Cl_2dicyd^{2-}, $[AsPh_4]_2[Cl_2dicyd]$ was used. $[AsPh_4]_2[Cl_2dicyd]$ was synthesized according to published procedure [23]. A solution of $[Cu(phen)_2(H_2O)](PF_6)_2$(0.551 g, 1 mmol) in 100 mL acetone was degassed and under argon atmosphere, $[AsPh_4]_2[Cl_2dicyd]$ (0.475 g, 0.5 mmol) was added. The solution was then stirred with slight heating (30 °C) under Ar overnight. The precipitated $[AsPh_4][PF_6]$ was then filtered off and the filtrate was evaporated to dryness by rotary evaporator. For further purification, the dark green precipitate, $[\{Cu(phen)_2\}_2(\mu\text{-Cl}_2\text{dicyd})](PF_6)_2$, was recrystallized by diffusing diethyl ether into a saturated solution of the complex in DMF. After 2 days, dark green ultrafine crystals of the dinuclear complex, $[\{Cu(phen)_2\}_2(\mu\text{-Cl}_2\text{dicyd})](PF_6)_2$, were collected, washed with diethyl ether and vacuum dried.

Yield: 0.28 g (41%). *Anal.* Calc. for $Cu_2C_{56}H_{34}N_{12}Cl_2P_2F_{12}$: C, 49.35; H, 2.51; N, 12.34. Found: C, 49.59; H, 2.48; N, 12.40%.

2.5. Synthesis of $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3 \cdot 2CH_3COCH_3$

$[Cu(phen)_2Cl]PF_6$ (1.212 g, 2 mmol) was dissolved in 150 mL of acetonitrile in a 250 mL round-bottom flask. To this was added thallium salt of 4-azo(phenylcyanamido)benzene (Tlapc) (0.426 g, 1 mmol). The reaction mixture was stirred at room temperature for 24 h. The reaction mixture was then chilled to −10 °C and filtrate to remove a fine white TlCl precipitate. The filtrate was then evaporated to dryness and the brown product was recrystallized by the diffusion of diethyl ether into an acetone solution of the complex. After 6 days, dark green crystals of $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3 \cdot 2CH_3COCH_3$ formed. Yield: 0.62 g (38%). *Anal.* Calc. for $Cu_2C_{67}H_{53}N_{12}O_2F_{18}P_3$: C, 49.67; H, 3.29; N, 10.37. Found: C, 49.93; H, 3.31; N, 10.44%.

2.6. X-ray crystallographic study of $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3 \cdot 2CH_3COCH_3$

Dark green crystals of $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3 \cdot 2CH_3COCH_3$ were grown by ether diffusion into an acetone solution of the complex. Single-crystal X-ray diffraction measurements were carried out on a Bruker Apex II, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å, $2\theta < 56°$) at 100(2) K. Unit cell parameters were determined by the least-squares calculation with θ angle ranging from 1.62° to 28.00°. Intensities of 38 055 reflections were measured using Bruker Apex II CCD Area detector giving 16 038 unique reflections. The structures were solved by direct method and refined by the full-matrix least-squares against F^2 in anisotropic (for non-hydrogen atoms) approximation. All hydrogen atoms were located from the difference Fourier syntheses and placed in geometrically calculated positions. All hydrogen atom positions were refined in isotropic approximation in riding model with the U_{iso}(H) parameters equal to $1.5U_{eq}$(Ci) for methyl groups and $1.2U_{eq}$(Ci) for other carbon atoms, where U(Ci) are the equivalent thermal parameters of the atoms to which corresponding H atoms are bonded. All calculations were performed on an IBM PC/AT using the SHELXTL version 5.1 software [38] giving a final $R_1 = 0.0541$, $wR_2 = 0.0833$ (for 9656 reflections with $I > 2\sigma(I)$). The largest diffraction peak and hole on the final difference-Fourier map were 0.633 and −0.551 e A^{-3}.

Further details of the structural analyses are given in Table 1. Selected bond lengths and bond angles are listed in Table 2.

3. Results and discussion

The dinuclear complexes, $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$ and $[\{Cu(phen)_2\}_2(\mu\text{-Me}_2\text{dicyd})](PF_6)_2$ were synthesized by the reaction of $[Cu(phen)_2(H_2O)](PF_6)_2$ with the neutral dicydH_2 or Me_2dicyd in the presence of triethylamine. As is shown in Scheme 2, the amine protons of neutral dicyanamidobenzene ligands are acidic, the anion is resonance stabilized and this increases the amine proton acidity [22,39]. The poor solubility of Cl_2dicydH_2 in acetone required $[AsPh_4]_2[Cl_2dicyd]$ to be used instead [40]. $[\{Cu(phen)_2\}_2(\mu\text{-}Cl_2dicyd)](PF_6)_2$ was synthesized by the reaction of $[Cu(phen)_2(H_2O)](PF_6)_2$ with the tetraphenylarsonium salt of Cl_2dicyd^{2-} in acetone. $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3$ was prepared by the metathesis reaction of $[Cu(phen)_2Cl]PF_6$ with the thallium salts of apc^- in acetonitrile. Elemental analysis of the complexes was entirely consistent with their formulation. The complexes were further characterized by IR and UV–Vis spectroscopies and cyclic voltammetry.

Dark green crystals of the dinuclear Cu(II) complex, $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3 \cdot 2CH_3COCH_3$, that were suitable for crystallography were grown by diffusion of diethyl ether into a solution of the complex in acetone. An ORTEP drawing of the complex cation with the atomic labeling scheme is shown in Fig. 1, and selected bond lengths and bond angles are listed in Table 2. Anionic phenylcyanamides (Ph–NCN) have three non-bonding pairs of electrons that can be involved in coordination chemistry. There are many crystal structures of monodentate phenylcyanamide ligands showing coordination through the cyano-nitrogen but there are no examples of amido-nitrogen coordination [22,41–45]. The neutral or anionic phenylcyanamides can function as bridging ligands although this has only been observed for the anionic cyanamide [22,34,46]. As is shown in Fig. 1, both five-coordinate Cu(II) ions in the dinuclear unit are linked through a bridging 4-azo(phenylcyanamido)benzene (apc) ligand. The cyanamide group (N=C=N) of the bridging ligand is coordinated to Cu(II) ions through the cyano-N(5) and amido-N(6) nitrogen atoms. The bond length between Cu(1) and cyano-N(5) nitrogen (Cu(1)–N(5) = 2.025(3) Å) is slightly larger than that formed by Cu(2) and amido-N(6) nitrogen (Cu(2)–N(6) = 2.016(3) Å). The Cu(1)–cyanamide bond angle (Cu(1)–NCN) is approximately linear, having an angle of 163.1(3)°. In Ni(II), Pd(II), Co(III) and Rh(III) complexes, the metal–cyanamide bond is bent [22,41,42]. The Cu–N(phen) bond distances are consistent with values in previously reported structures [47–52]. The copper–cyanamide distances, Cu(1)–N(5) and Cu(2)–N(6) [2.025(3) and 2.016(3) Å, respectively], have no significant difference with the Cu–N(phen) distances (mean 2.04 Å). The molecular structures of five-coordinate copper(II) complexes show an extensive range from a regular trigonal bipyramidal (RTBP) to regular square-based pyramidal (RSBP) [53–57]. The structure index parameter, $\tau = (\beta - \alpha/60)$, was evaluated by the two large angles ($\alpha < \beta$) in the five-coordinated geometry indicative of $\tau = 1.0$ for a RTBP geometry and $\tau = 0.0$ for a RSBP [55]. The coordination geometry of the Cu(1) ($\tau = 0.9$) is best described as a trigonal bipyramidal with the equatorial

plane comprised of N(1), N(3), Cu(1) and N(5) (see Fig. 1). There is a small difference in axial and equatorial Cu–N bond lengths. The coordination geometry around the Cu(2) is approximately trigonal bipyramidal with a N_5 donor set (see Fig. 1). This coordination geometry is distorted from regular trigonal bipyramidal, as ascertained by the observed τ value of 0.5. Two nitrogen atoms of the phen ligands are in the axial positions and amido-N(6) nitrogen of cyanamide group and two nitrogens of phen ligands constitute the basal plane of the TBP. In the crystal of this dinuclear complex (Fig. 2), the distances between copper(II) ions and the fluorine of PF_6^- are too great to suggest coordination. The Cu(1)···Cu(2) distance is fairly large (5.156(1) Å). There is no strong hydrogen bond in the crystal of the complex. The counter ions (PF_6^- anions) are not close enough to interact with hydrogens of phen or apc ligands. As is shown in Fig. 2, there are some very weak π–π aromatic interactions between phenanthroline rings (including N(1), N(2), N(9), and N(10) atoms) and the angle between rings is 15.1°. The shortest distance between carbon atoms of two phen ligands (C(55)–C(4)) is 3.525 Å. The shortest distance between C(54) and plane of neighboring phen ligand is 3.202 Å.

The IR spectra of the neutral ligands ($dicydH_2$ and $Me_2dicydH_2$) show a strong band around 2250 cm^{-1} that is assigned to ν(C≡N) of the cyanamide groups. The IR spectrum of the tetraphenylarsonium salt of the anion ligand, $[AsPh_4]_2[Cl_2dicyd]$, shows a very strong band at 2050 cm^{-1} that is assigned to ν(N=C=N). The strong band at 2059 cm^{-1} in IR spectrum of Tlapc is assigned to ν(N=C=N).

Coordination of neutral and anionic dicyanamidobenzene ligands to metal cations can occur via amine or nitrile nitrogens and there are examples in the literature of both types of coordination [22]. Transition metal complexes appear to prefer coordination to the nitrile nitrogen. This may be due to the π-back-bonding and donor properties of the nitrile groups and the steric hindrance that would be experienced upon coordination to the amine of N-alkyl- or N-phenyl-substituted cyanamides. The neutral cyanamide ligands have π-donor properties that are due to the delocalization of the amine electron lone pair into a nitrile π-bond of the correct symmetry [22,58,59]. The anionic cyanamide ligand is expected to be a strong π-donor ligand because two lone pairs can delocalize into the nitrile π system. It is suggested that the resonance structure Ia (Scheme 2) will dominate when the anion ligand is coordinated to Cu (II) or Cu(I).

Scheme 2.

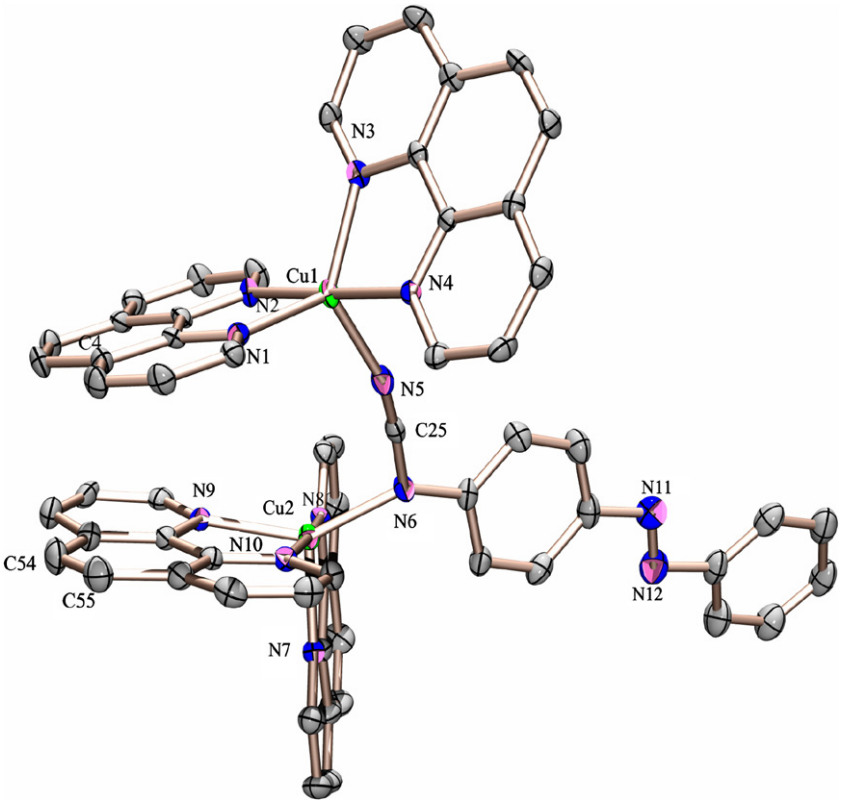

Fig. 1. ORTEP drawing of the $[\{Cu(phen)_2\}_2(\mu\text{-apc})]^{3+}$. The counterions, hydrogen atoms, and solvents of crystallization (two acetone) have been omitted for clarity.

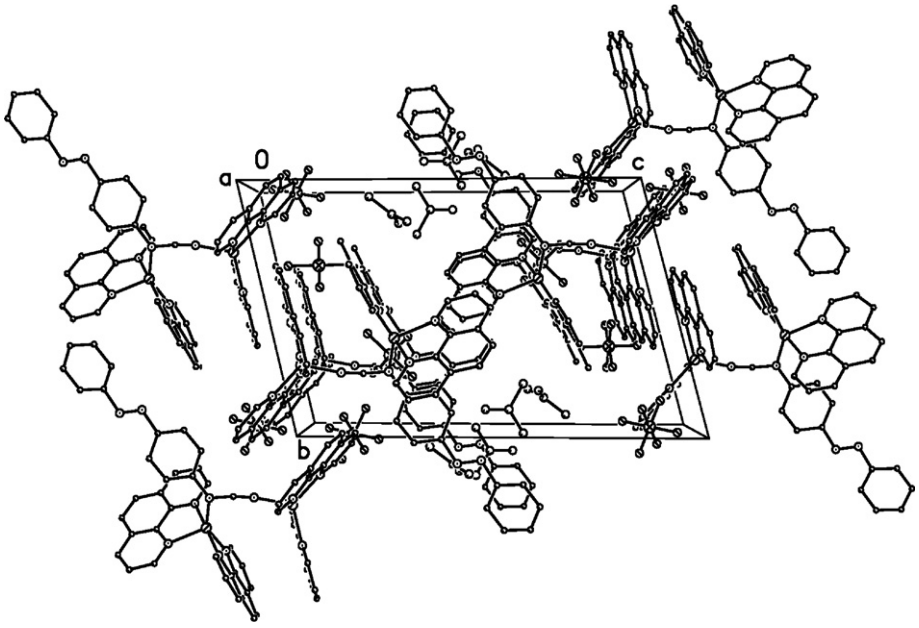

Fig. 2. Packing diagram of $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3 \cdot 2CH_3COCH_3$.

The IR spectra of the complexes exhibit a strong absorption band around 2100 cm^{-1} which can assigned to the ν(N=C=N) band. In these complexes, the ν(N=C=N) was shifted 100–150 cm^{-1} to the lower wave number in contrast of the neutral ligand. The presence of only one sharp and intense absorption band for the cyanamide stretching frequency in the dinuclear complexes, $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$, $[\{Cu(phen)_2\}_2(\mu\text{-Me}_2\text{dicyd})](PF_6)_2$ and $[\{Cu(phen)_2\}_2(\mu\text{-Cl}_2\text{dicyd})](PF_6)_2$ provides evidence that both cyanamide moieties on the phenyl ring of

the bridging ligands, dicyd, Me_2dicyd and Cl_2dicyd are equivalent in the solid state [22,35,60]. When the cyanamide moieties are inequivalent, multiple ν(N=C=N) bands are observed [61]. The presence of a strong absorption band at 840 cm^{-1} in the complexes, which is assigned to ν(P–F), demonstrates the existence of PF_6^- as a counter ion [62]. The IR spectral data of the complexes are given in Table 3.

Electronic spectral data for the dinuclear complexes in DMF are given in Table 4, and the representative spectrum of $[\{Cu(phen)_2\}_2(\mu\text{-}Me_2dicyd)](PF_6)_2$ is shown in Fig. 3. The absorption band seen in the UV region ($\lambda < 352$ nm) is assigned to ligand-centered transition ($\pi \rightarrow \pi^*$) [63]. Spectroelectrochemical study of the free $dicyd^{-2}$ ligand was shown the radical anion absorption spectrum. Solutions of 1,4-dicyanamidobenzene dianion and its substituted derivatives are very air sensitive and upon oxidation to the radical anion give blue solutions which show a characteristic three-band pattern in the visible region [64]. In the visible region for $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$, $[\{Cu(phen)_2\}_2(\mu\text{-}Me_2dicyd)](PF_6)_2$ and $[\{Cu(phen)_2\}_2(\mu\text{-}Cl_2dicyd)](PF_6)_2$ complexes, the three bands at $\lambda > 550$ nm are suggested to originate from radical anion absorption. Spectroscopic analyses of Cu(II)–NCN chromophore have shown one ligand-to-metal charge transfer (LMCT) transition [61,65]. In these complexes, the band at $\lambda < 400$ nm shifts to higher energy as the numbers of electron-withdrawing substituents increase on the phenyl ring or as the donor number of the solvent is increased [66]. This behavior is consistent with a LMCT transition, which can be assigned to cyanamide anion to Cu(II) [61,65]. In $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3$, the band at 712 nm is assigned to d-d transition. Two ligand field transitions for five-coordinated Cu(II) with distorted trigonal-bipyramidal geometry ($d_{xz} \approx d_{yz} \rightarrow d_{z^2}$ and $d_{x^2-y^2}$) are expected [36,56]. This complex showed only one broad transition at 712 nm. The transition with the higher wavelength ($\lambda > 900$ nm) cannot be detected by ordinary UV–Vis spectrophotometer.

Cyclic voltammetry data for the complexes in acetonitrile solution have been placed in Table 5, and a representative cyclic voltammogram of $[\{Cu(phen)_2\}_2(\mu\text{-}Me_2dicyd)](PF_6)_2$ complex is shown in Fig. 4. In these dinuclear complexes, the two quasi-reversible reduction couples at negative potential are assigned to the sequential reductions of phenanthroline ligands. Anionic phenylcyanamides do not have well-behaved cyclic voltammetry and generally give an irreversible oxidation wave [22,45]. However, 1,4-dicyanamidobenzene dianion ligands do give reversible oxidation waves with electrochemistry analogous to that of the quinone/hydroquinone system [67]. Cyclic voltammetry of the free $dicyd^{2-}$ and its derivatives (Cl_2dicyd^{2-} and Me_2dicyd^{2-}) in acetonitrile showed two redox couples corresponding to L(1−/2−) and L(0/1−), for example: $dicyd^{-/2-} = -0.200$ and $dicyd^{0/-} = 0.475$ V versus NHE [22,23]. These couples shift anodically when coordinated to Cu(II) (see Table 5). The L(1−/2−) and L(0/1−) couples also shift to more positive potentials as the electron-withdrawing ability of the substituents on the phenyl ring increase from CH_3 to Cl. This is consistent with the expected decrease in the basicity of 1,4-dicyanamidobenzene ligands [22,68]. Cyclic voltammetry of the thallium salt of apc^- in DMF showed one redox couple corresponding to apc(0/1−) = 0.86 V versus NHE [35]. For the complex $[\{Cu(phen)_2\}_2(\mu\text{-apc})]^{3+}$, the apc(0/1−) couple shifts to more positive potential (see Table 5). No reduction couple observed for the azo group (–N=N–) of the apc^- ligand.

According to the electronic spectral data for $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$, $[\{Cu(phen)_2\}_2(\mu\text{-}Me_2dicyd)](PF_6)_2$ and $[\{Cu(phen)_2\}_2(\mu\text{-}Cl_2dicyd)](PF_6)_2$, all of these complexes show radical anion absorption and to be consistent with the elemental analyses requires that a radical anion ($dicyd^{\cdot-}$) bridges Cu(I) and Cu(II). Therefore, the two couples seen between 0 and 0.5 V versus NHE (Fig. 4) are likely Cu(II/I) and dicyd(0/1−) and so their difference is not representative of the comproportionation constant (K_c). It is important to note that the dicyd-bridge dicopper complex is not really a mixed-valance system in the classical sense. The most positive couple in Fig. 4 is probably Cu(III/II).

The dinuclear copper(II) complex, $[\{Cu(phen)_2\}_2(\mu\text{-apc})](PF_6)_3$, can not show a radical anion absorption because the apc bridging ligand has one cyanamide group. The copper redox couples in this dinuclear complex occur in approximately the same region as the Cu(II/I) of mononuclear Cu(II) complexes with phen ligands. However, these reduction couples are split into two one-electron waves at 0.787 and 0.341 V which correspond to Cu(II,II/II,I) and Cu(II,I/I,I), respectively, and is indicative of significant metal–metal coupling. These redox couples seem to be quasi-reversible with an average separation between the cathodic and anodic waves of 100 mV, which is independent of the scan rate between 100–600 mV/s. The stability of a mixed-valance form can be quantified by the comproportionation equilibrium constant (K_c). The larger K_c is, the greater the electronic coupling. K_c is usually deduced from the difference in potential between metal center reduction couples, $\log K_c = 16.9(\Delta E)$. From the difference in Cu(II/I) couples of the dinuclear complexes (ΔE), the comproportionation constant (K_c) for the formation of the Cu(II/I) mixed-valence complex,

$$\text{Cu(II)–Cu(II)} + \text{Cu(I)–Cu(I)} \overset{K_c}{\rightleftharpoons} 2\text{Cu(II)–Cu(I)}$$

was determined to be 3.45×10^7. This value is on the borderline between Classes II and III behavior in the Robin and Day classification [22,35,40,57,69–72] and requires further study before an absolute assignment can be given. In particular, the difference in solid state coordination environments may significantly perturb the Cu(II/I) couples and hence make a contribution to the comproportionation equilibrium. Whether this difference exists in solution is at the present unknown.

4. Conclusion

Several dinuclear copper complexes with cyanamide ligands have been synthesized and characterized. The dicyd-bridge dicopper complexes, $[\{Cu(phen)_2\}_2(\mu\text{-dicyd})](PF_6)_2$, $[\{Cu(phen)_2\}_2(\mu\text{-Me}_2\text{dicyd})](PF_6)_2$ and

[{Cu(phen)$_2$}$_2$(μ-Cl$_2$dicyd)](PF$_6$)$_2$, show radical anion absorption. [{Cu(phen)$_2$}$_2$(μ-apc)](PF$_6$)$_3$. 2CH$_3$COCH$_3$ has been characterized by X-ray crystallography. The phenycyanamides are ambidentate ligands whether neutral or in anionic form and so the possibility of linkage isomerism must be recognized. In this complex, the cyanamide group (NCN) of the bridging ligand is coordinated to Cu(II) ions through the nitrile and the amine nitrogen atoms. In contrast, a crystal structure of the complex [Cu(bpy)(2,3-Cl$_2$pcyd)$_2$], where bpy = 2,2′-bipyridine, showed only monodentate phenylcyanamide ligand coordinated through the cyano-nitrogen and Cu(II) in a distorted square plane of nitrogen donor atoms [22,61]. It was suggested that the reason dimerization does not occur for this complex, may be the greater steric crowding of the Cl atoms and/or the inductive effect of chlorine which makes the cyanamide group less basic and therefore a poorer bridging ligand.

It is interesting to speculate about the magnitude of comproportionation constant that would be consist with full delocalization and class III properties. The Creutz-Taube ion, [{(NH$_3$)$_5$Ru}$_2$(μ-pyrazine)]$^{5+}$, has been studied extensively, with the majority of evidence supporting a class III assignment for this ion. Its comproportionation constant has been found to be 1.9×10^7 in acetonitrile [69]. This value is close to K_c for complex [{Cu(phen)$_2$}$_2$-(μ-apc)](PF$_6$)$_3$ and suggests a considerable degree of delocalization in this complex.

The coordination chemistry of phenylcyanamide ligands still requires much effort to complete. The ability of the dicyd^{2-} bridging ligands to mediate metal–metal coupling suggests that phenylcyanamide derivatives may find their way into molecular materials possessing useful electronic and/or magnetic properties.

surprisingly the corresponding selenium analogues, namely, diselenophosph(in)ato metal compounds are only observed for Ni(II) [7]. The reaction of Pd(II) and Pt(II) salts with diselenophosphonates $[(RO)RPSe_2]^-$ was proved unsuccessful by Woolins and co-workers [8] due to the immediate precipitation of black amorphous solids. Thus, this report provides not only non-covalent Se···Se secondary interactions revealed in adjacent, square-planar $M[Se_2P(OR)_2]_2$ units but also a valuable addition to the coordination chemistry of group 10 metals, incorporating a PSe_2 motif.

2. Experimental

2.1. General procedures and instrumentation

Commercial CH_2Cl_2 and alcohol were distilled from P_4O_{10} and Mg, respectively. Hexane was distilled from Na/K. All chemicals were purchased from commercial sources, and used as received. All reactions were performed in oven-dried Schlenk glassware by using standard inert-atmosphere techniques. $Pt(CH_3CH_2CN)_2Cl_2$ [9] and $NH_4[Se_2P(OR)_2]$ (R = Et, ^{n}Pr, ^{i}Pr) [10] were prepared according to the literature methods. $Pd(CH_3CN)_2Cl_2$ was obtained from Aldrich. The elemental analyses were done using a Perkin–Elmer 2400 CHN analyzer. ^{1}H, ^{31}P and ^{77}Se NMR spectra were recorded on an Advance-300 Fourier transform spectrometer. The $^{31}P\{^1H\}$ and $^{77}Se\{^1H\}$ are referenced externally against 85% H_3PO_4 ($\delta = 0$ ppm) and PhSeSePh ($\delta = 463$ ppm), respectively. Melting points were measured by using a Fargo melting point apparatus, MP-2D.

2.2. Preparation of $Pd[Se_2P(OR)_2]_2$ (R = Et, **1a**; ^{i}Pr, **1b**; ^{n}Pr, **1c**)

$Pd(CH_3CN)_2Cl_2$ (0.10 g, 0.38 mmol) and the diselenophosphate ligands $NH_4[Se_2P(OR)_2]$ (R = Et, 0.23 g; ^{i}Pr, 0.25 g; ^{n}Pr, 0.25 g, 0.77 mmol) were dissolved in 30 mL of dichloromethane in a 100 mL Schlenk flask. The solution was stirred for 12 h at room temperature under a nitrogen atmosphere. After filtration, the filtrate was evaporated under vacuum, re-dissolved in dichloromethane and layered with hexane which afforded the red brown crystalline material of $Pd[Se_2P(OR)_2]_2$.

Compound **1a**: Yield, 62% (0.20 g). Elemental *Anal.* Calc. for $PdSe_4P_2O_4C_8H_{20}$: C, 14.46; H, 3.03. Found: C, 14.50; H, 2.98%. ^{1}H NMR ($CDCl_3$): δ 1.37 (t, $^3J_{HH} = 7.2$ Hz, 12H, OCH_2CH_3), 4.17 (dq, $^3J_{PH} = 2.5$ Hz, $^3J_{HH} = 7.2$ Hz, 8H, OCH_2CH_3); m.p., 167 °C.

Compound **1b**: Yield, 82% (0.30 g). Elemental *Anal.* Calc. for $PdSe_4P_2O_4C_{12}H_{28}$: C, 20.00; H, 3.92. Found: C, 20.15; H, 4.03%. ^{1}H NMR ($CDCl_3$): δ 1.37 (d, $^3J_{HH} = 6.2$ Hz, 24H, $OCH(CH_3)_2$), 4.80 (m, 4H, $OCH(CH_3)_2$); m.p., 171 °C.

Compound **1c**: Yield, 65% (0.24 g). Elemental *Anal.* Calc. for $PdSe_4P_2O_4C_{12}H_{28}$: C, 20.00; H, 3.92. Found: C, 20.05; H, 4.06%. ^{1}H NMR ($CDCl_3$): δ 0.96 (t, $^3J_{HH} = 7.2$ Hz, 12H, $OCH_2CH_2CH_3$), 1.77 (sextet, $^3J_{HH} = 7.2$ Hz, 8H, $OCH_2CH_2CH_3$), 4.08 (td, $^3J_{PH} = 2.9$ Hz, $^3J_{HH} = 7.0$ Hz, 8H, $OCH_2CH_2CH_3$); m.p., 172 °C.

2.3. Preparation of $Pt[Se_2P(OR)_2]_2$ (R = Et, **2a**; ^{i}Pr, **2b**; ^{n}Pr, **2c**)

$Pt(CH_3CH_2CN)_2Cl_2$ (0.10 g, 0.26 mmol) and $NH_4[Se_2P(OR)_2]$ (R = Et, 0.16 g; ^{i}Pr, 0.17 g; ^{n}Pr, 0.17 g, 0.53 mmol) were dissolved in 30 mL of dichloromethane in a 100 mL Schlenk flask. The solution was stirred for 12 h at room temperature under a nitrogen atmosphere. After filtration, the filtrate was evaporated under vacuum, then re-dissolved in dichloromethane and layered with hexane, which afforded the red brown crystalline material of $Pt[Se_2P(OR)_2]_2$.

Compound **2a**: Yield, 62% (0.12 g). Elemental *Anal.* Calc. for $PtSe_4P_2O_4C_8H_{20}$: C, 12.76; H, 2.68. Found: C, 12.68; H, 2.59%. ^{1}H NMR ($CDCl_3$): δ 1.38 (t, $^3J_{HH} = 7.0$ Hz, 12H, OCH_2CH_3), 4.24 (dq, $^3J_{PH} = 3.0$ Hz, $^3J_{HH} = 7.0$ Hz, 8H, OCH_2CH_3); m.p., 165 °C.

Compound **2b**: Yield, 71% (0.14 g). Elemental *Anal.* Calc. for $PtSe_4P_2O_4C_{12}H_{28}$: C, 17.81; H, 3.49. Found: C, 17.95; H, 3.62%. ^{1}H NMR ($CDCl_3$): δ 1.40 (d, $^3J_{HH} = 6.2$ Hz, 24H, $OCH(CH_3)_2$), 4.96 (m, 4H, $OCH(CH_3)_2$); m.p., 168 °C.

Compound **2c**: Yield, 64% (0.13 g). Elemental *Anal.* Calc. for $PtSe_4P_2O_4C_{12}H_{28}$: C, 17.81; H, 3.49. Found: C, 17.75; H, 3.46%. ^{1}H NMR ($CDCl_3$): δ 0.96 (bs, 12H, $OCH_2CH_2CH_3$), 1.63 (m, 8H, $OCH_2CH_2CH_3$), 4.13 (m, 8H, $OCH_2CH_2CH_3$); m.p., 169 °C.

2.4. Crystallography

The structures of **1b** and **2b** were obtained by single crystal X-ray diffraction. Crystals were grown from CH_2Cl_2 layered with hexane and were mounted on the tips of glass fibers with epoxy resin. For compound **1b**, data were collected at 293 K on a Siemens P4, and were corrected for Lorentzian, polarization and ψ-scan absorption effects. Data were collected on a Siemens SMART CCD diffractometer for compound **2b**. Cell parameters were retrieved with SMART software [11] and refined with SAINT software [12] on all observed reflections ($I > 10\sigma(I)$). Data reduction was performed with SAINT, which corrects for Lorentzian, polarization and ψ-scan absorption effects. The structures of **1b** and **2b** were solved by the use of direct methods, and refinement was performed by the least-squares method on F^2 with the SHELXL-97 package [13], incorporated in SHELXTL/PC V5.10 [14]. Hydrogen atoms were added. Selected crystal data for compounds **1b** and **2b** are summarized in Table 1 and selected bond distances and angles are given in Table 2.

3. Results and discussion

3.1. Synthesis and multinuclear NMR spectroscopy

The reactions of dsep with $Pd(CH_3CN)_2Cl_2$ or $Pt(C_2H_5CN)_2Cl_2$ afford complexes which can be formulated as $M[Se_2P(OR)_2]_2$ (M = Pd, Pt). Two representative molecular structures, determined by single-crystal X-ray analysis, contain metal ions in a square-planar environment (vide infra). These complexes can be dissolved in any organic solvent but are insoluble in water. A summary of the $^{31}P\{^1H\}$ and $^{77}Se\{^1H\}$ NMR data for all of the compounds is shown in Table 3.

Table 3
^{31}P and ^{77}Se NMR data for compounds **1** and **2**

Complex	^{31}P δ (ppm) $J_{(P-Se)}$ or $^2J_{(P-Pt)}$ (Hz)	^{77}Se δ (ppm) $J_{(Se-P)}$ or $J_{(Se-Pt)}$ (Hz)
1a	65.3 $^1J_{(P-Se)} = 594.5, 618.0$ $^3J_{(P-Se)} = 22.4$	−12.0 (Se_A–P); −12.0 (Se_B–P) $J_{(SeA-P)} = 617.3$; $J_{(SeB-P)} = 595.6$
1b	60.2 $^1J_{(P-Se)} = 586.7, 610.9$ $^3J_{(P-Se)} = 22.4$	16.877 (Se_A–P); 16.875 (Se_B–P) $J_{(SeA-P)} = 609.4$; $J_{(SeB-P)} = 588.2$
1c	66.5 $^1J_{(P-Se)} = 594.4, 617.7$ $^3J_{(P-Se)} = 22.4$	−13.0 (Se_A–P); −13.0(Se_B–P) $J_{(SeA-P)} = 616.9$; $J_{(SeB-P)} = 595.2$
2a	56.2 $^1J_{(P-Se)} = 547, 576$ $^3J_{(P-Se)} = 15$ $^2J_{(P-Pt)} = 505$	80.1 $J_{(Se-Pt)} = 87$ $J_{(Se-P)} = 561$
2b	50.1 $^1J_{(P-Se)} = 540, 571$ $^3J_{(P-Se)} = 15$ $^2J_{(P-Pt)} = 498$	104.8 $J_{(Se-Pt)} = 85$ $J_{(Se-P)} = 556$
2c	57.5 $^1J_{(P-Se)} = 548, 577$ $^3J_{(P-Se)} = 14$ $^2J_{(P-Pt)} = 506$	75.0 $J_{(Se-Pt)} = 88$ $J_{(Se-P)} = 563$

Both ^{31}P and ^{77}Se NMR spectra display interesting structural characteristics. Three sets of selenium satellite peaks are identified in compounds **1** in the ^{31}P NMR spectra (Fig. 1). Two sets of satellite peaks are due to the one-bond coupling ($^1J_{P-Se} = 586$–618 Hz) between the phosphorus and selenium nuclei, a reflection of unequal Pd–Se bond lengths (vide infra). The third pair originates from the three-bond coupling ($^3J_{P-Se} = 22.4$ Hz) to the selenium nuclei on the opposite side. The $^{77}Se\{^1H\}$ NMR spectrum of **1b** (the inset of Fig. 1) displays two doublets with $^1J_{Se-P}$ values of 588 and 618 Hz, apparently arising from the phosphorus nuclei coupled to two different selenium nuclei (Se_A and Se_B), and these values are in good agreement with those obtained from the ^{31}P NMR spectrum. Presumably the Se_A and Se_B nuclei in **1b** have almost identical chemical shifts.

Thus, both chemically and magnetically inequivalent selenium nuclei within the PSe_2 moiety were identified in the square-planar palladium(II) complexes of **1**. Although a diselenoimidodiphosphinato compound of palladium, $Pd[(SePPh_2)_2N]_2$ [15], has been characterized, its ^{31}P NMR spectrum, which exhibited a singlet with selenium satellites ($^1J_{Se-P} = 543$ Hz), apparently did not display a coupling pattern as complicated as those in compounds **1a**–**1c**.

The ^{31}P NMR spectrum of compound **2b** (Fig. 2) exhibited a single resonance at 50.1 ppm (56.2 and 57.5 ppm for **2a** and **2c**). This peak was further flanked by four sets of satellites: one due to phosphorus–platinum coupling ($^2J_{P-Pt} = 505$ Hz), the other three attributable to phosphorus–selenium coupling ($^1J_{P-Se} = 571$, 540 Hz, and $^3J_{P-Se} =$ 15 Hz). Therefore, two non-equivalent selenium nuclei

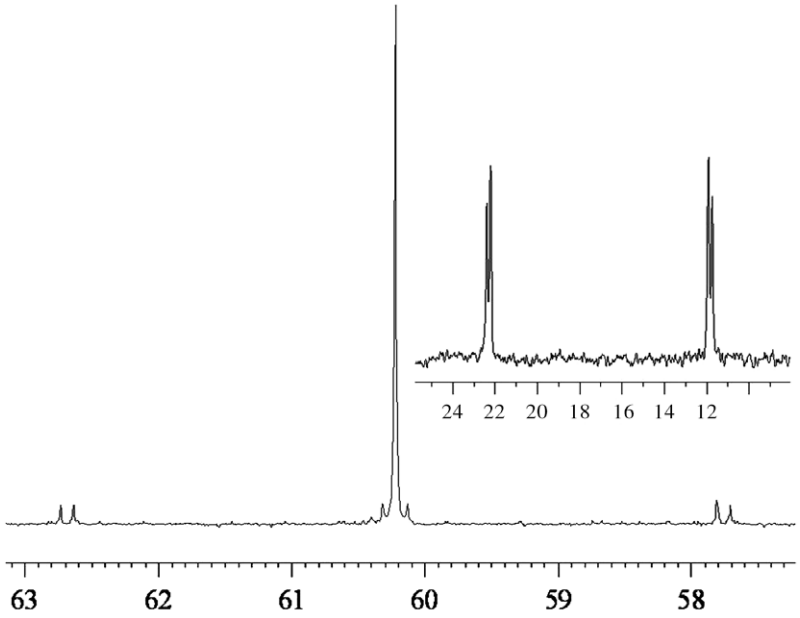

Fig. 1. The $^{31}P\{^{1}H\}$ and $^{77}Se\{^{1}H\}$ (inset) NMR spectra of $Pd[Se_2P(O^iPr)_2]_2$ (**1b**) in $CDCl_3$ solution.

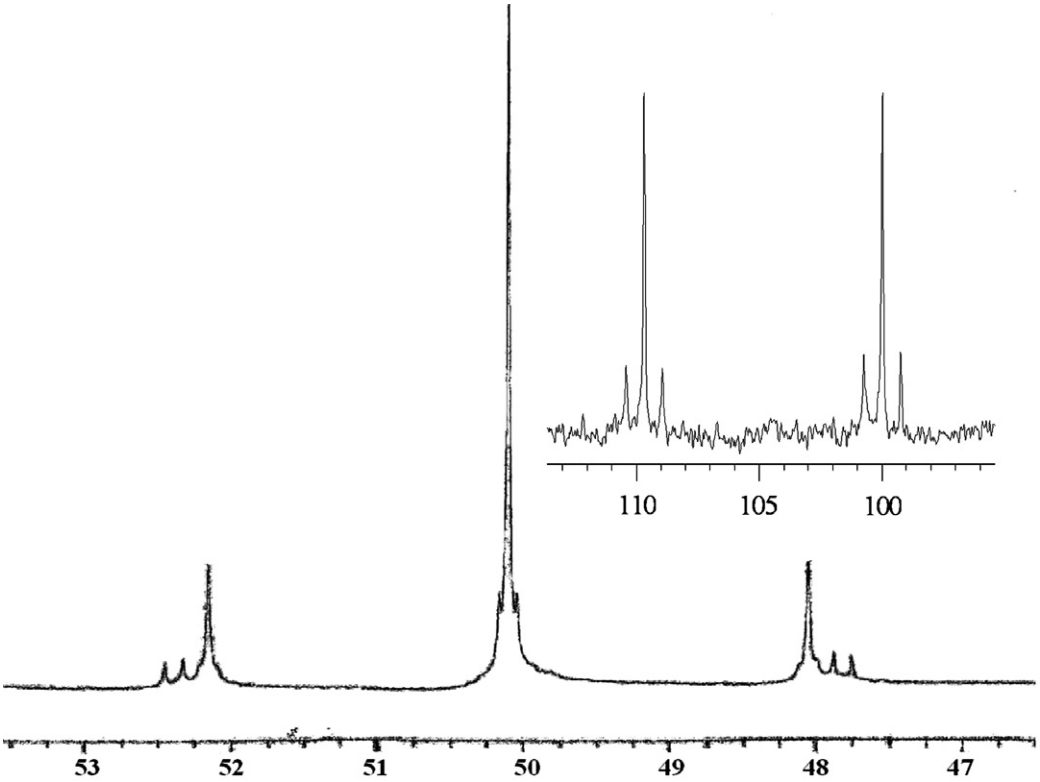

Fig. 2. The $^{31}P\{^{1}H\}$ and $^{77}Se\{^{1}H\}$ (inset) NMR spectra of $Pt[Se_2P(O^iPr)_2]_2$ (**2b**) in $CDCl_3$ solution.

within the PSe_2 moiety of the platinum complex were resolved, which was reminiscent of unequal Pt–Se bond distances (vide infra). Although the phosphorus–selenium coupling constant (539 Hz) in $Pt[(SePPh_2)_2N]_2$ [15] was similar to those in **2**; surprisingly the phosphorus–platinum coupling constant (105 Hz) was much smaller than those in **2**.

The $^{77}Se\{^{1}H\}$ NMR spectrum of **2** displayed a central doublet arising from selenium–phosphorous coupling ($^{1}J_{Se-P} = 561$, 556, 563 Hz, **2a**–**2c**) and two smaller doublets flanking the central doublet arising from selenium coupled to ^{195}Pt ($I = 1/2$, natural abundance 33.6%). The separation of these two doublets was $^{1}J_{Se-Pt} = 87$ Hz (85 and 88 Hz for **2b** and **2c**, respectively) and this is similar

to the reported values for $Pt(Se_2CNEt_2)PR_3Cl$ [16] and $Pt(dppe)(SePh)_2$ [17]. Presently, it is not known exactly why only one doublet due to coupling to the phosphorus nuclei is observed in the ^{77}Se NMR spectrum. Additionally, the $^1J_{Se-P}$ value revealed in the ^{77}Se NMR spectrum is approximately the average value of those from the ^{31}P NMR measurements (Table 3).

The ethyl and propyl derivatives of both compounds **1** and **2** always display a chemical shift in close proximity in both the ^{31}P and ^{77}Se NMR spectra, while the isopropyl derivatives are much further off. This is not unusual since a similar trend appears to be general to copper(I) and silver(I) cluster compounds incorporating diselenophosphate ligands [4]. Presumably, the chemical shift difference is due to the different steric effect of the isopropyl group.

3.2. Structure of $Pd[Se_2P(O^iPr)_2]_2$ (**1b**)

Compound **1b** crystallizes in the triclinic space group $P\bar{1}$ with a molecule per unit cell. A perspective view of complex **1** is shown in Fig. 3a. The Pd(II) ion is located on a center of symmetry and is linked by four selenium atoms of two dsep ligands in a square-planar arrangement. The Se–Pd bond distances are unequal, 2.440(1) and 2.456(1) Å, which are comparable to those observed in $Pd[(SePPh_2)_2N]_2$ (2.4368(6) and 2.4594(6) Å) [15]. The Se–Pd–Se angle within the chelated ring is 86.23(3)°. The average torsion angle of Se–P–Se–Pd is 4.32(6)°. A similar structural motif was revealed in $Pd[Se_2CN^iBu_2]_2$ [18] and $Pd[Se_2CC(CN)_2]_2^{2-}$ [19]. The average P–Se bond length, 2.154(2) Å, is intermediate between those expected for P–Se single (2.26 Å) and double (2.09 Å) bonds. Weak intermolecular interactions exist between the Se atoms of adjacent molecules, which lead to the formation of a polymeric chain in the solid state. A packing diagram along the *a* axis showing the Se···Se interactions is displayed in Fig. 3b. The Se···Se distances, depicted by broken lines, are 3.545 and 3.303 Å, which is much shorter than the sum of the van der Waals radii of selenium, 4.0 Å, and can be considered as weak secondary interactions.

3.3. Structure of $Pt[Se_2P(O^iPr)_2]_2$ (**2b**)

Compound **2b** crystallizes in the triclinic space group $P\bar{1}$ with one molecule per unit cell. The crystal structure of compound **2b** is shown in Fig. 4a. The Pt atom lies on a crystallographic inversion center and is tetragonally coordinated by four Se atoms from two dsep ligands. Thus, a four-membered chelate ring is formed. The average torsion

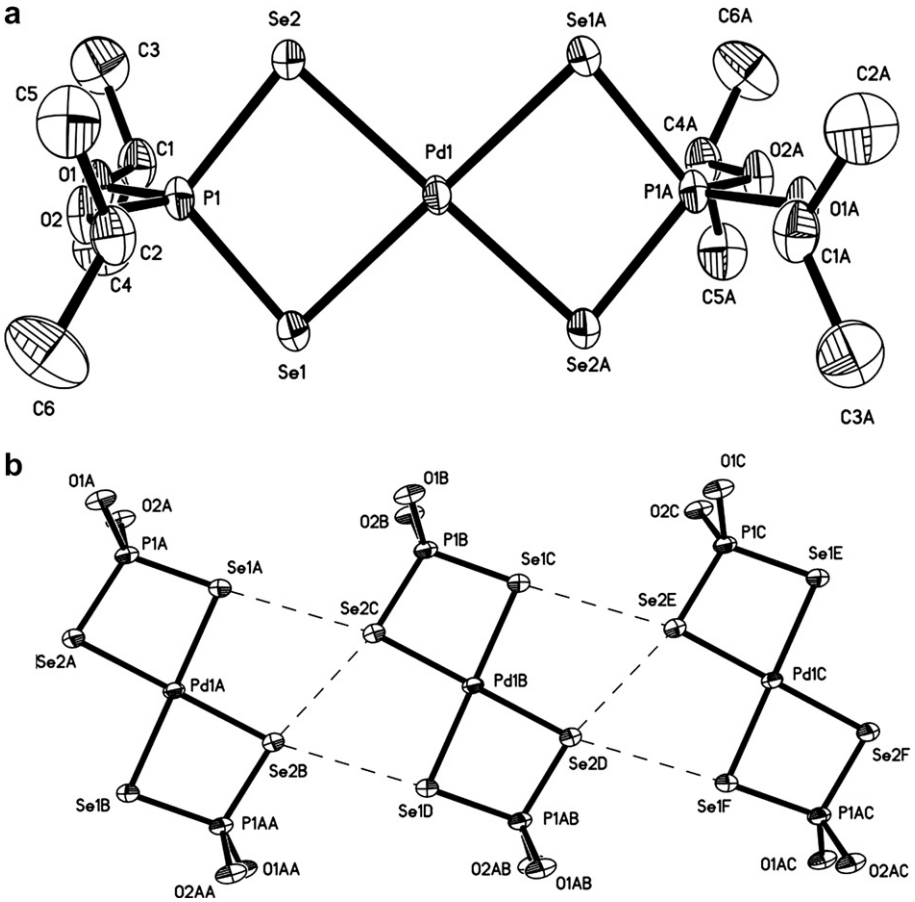

Fig. 3. (a) The structure of $[Pd\{Se_2P(O^iPr)_2\}_2]$ (**1b**) (thermal ellipsoids at the 30% probability level). (b) The packing diagram of $[Pd\{Se_2P(O^iPr)_2\}_2]$ (**1b**) along the *a* axis.

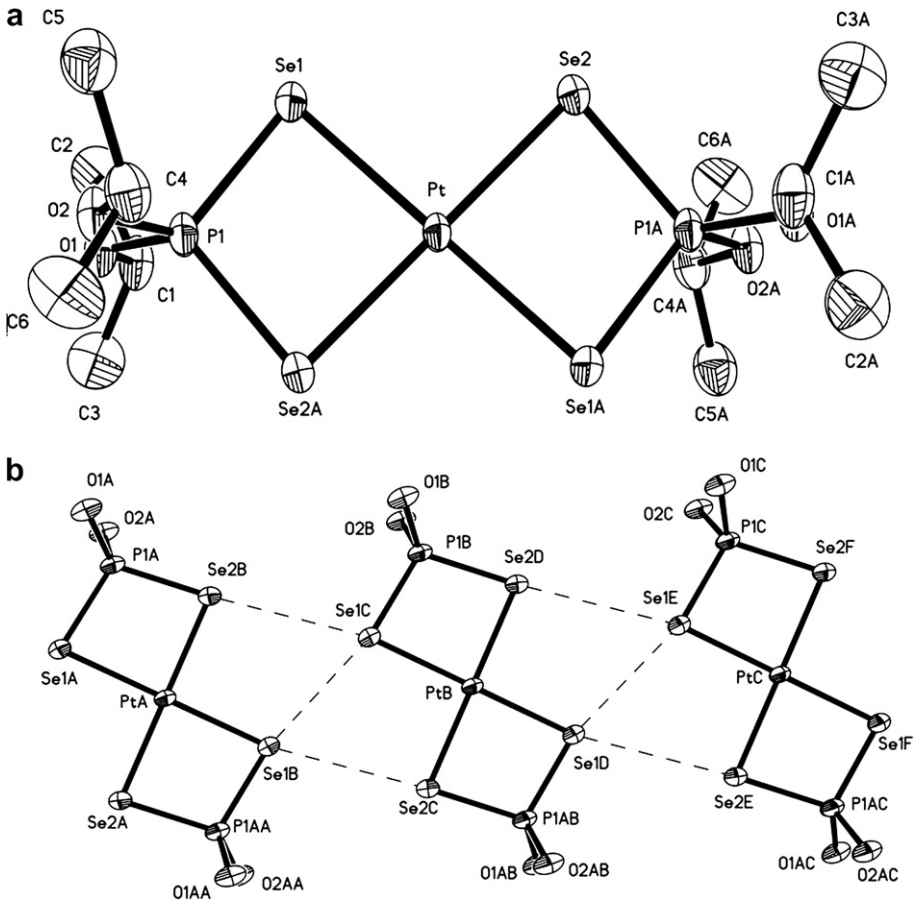

Fig. 4. (a) The structure of $[Pt\{Se_2P(O^iPr)_2\}_2]$ (**2b**) (thermal ellipsoids at the 30% probability level). (b) The packing diagram viewed down the *a* axis of $[Pt\{Se_2P(O^iPr)_2\}_2]$ (**2b**).

angle of Se–P–Se–Pt is 5.83(5)°. The geometry at the platinum center is square-planar as a consequence of the restricted bite, 100.55(7)°, of the chelating dsep ligand and the Se–Pt–Se bond angles are in the range 85.85(2)–94.15(2)°. Unequal Pt–Se bond distances, 2.439(1) and 2.451(1) Å, are also observed. These distances are comparable with those in $Pt[Se_2CC(CN)_2]_2^{2-}$, $Pt[(SePPh_2)_2N]_2$ and $Pt[(SeP^iPr_2)_2N]_2$ [20]. The P–Se bond distances, 2.165(2) Å, are almost identical and are indicative of delocalization of the negative charge across the PSe_2 unit. The packing diagram (Fig. 4b) displays a polymeric chain which is formed via Se···Se interactions with distances of 3.698 and 3.386 Å.

It is of interest to know that the observed M–Se bond distances for platinum(II) are almost identical to those for palladium(II). This is significant since the non-polar covalent radius of Pt (1.30 Å) is longer than that of Pd (1.28 Å) [21].

4. Conclusions

Square-planar complexes of palladium(II) and platinum(II) incorporating dialkyl diselenophsphato ligands have been successfully prepared. Weak intermolecular Se···Se interactions from adjacent dsep ligands yield a one-dimensional chain structure. Solution ^{31}P NMR studies reveal that the two selenium atoms within the four-membered chelate rings are both chemically and magnetically inequivalent. This observation is largely due to the existence of unequal M–Se bond lengths.

Keto (A) Enol (B)

Scheme 1.

structural reports on cadmium(II) complexes of a semicarbazone according to the best of our knowledge [5].

2. Experimental

2.1. Materials

Di-2-pyridyl ketone (Aldrich) was used as received. $CdBr_2 \cdot 4H_2O$, $(CH_3COO)_2Cd \cdot 2H_2O$ and NaN_3 were commercial products of higher grade (Aldrich) and solvents were purified according to standard procedures. Elemental analyses were carried out using a vario EL III CHNS analyzer at SAIF, Kochi, India. Infrared spectra were recorded on a JASCO FT-IR-5300 spectrometer in the range 4000–400 cm^{-1} using KBr pellets. Electronic spectra were recorded on a Cary 5000 version 1.09 UV–Vis–NIR spectrophotometer using solutions in DMF. The ^1H and ^{13}C NMR spectra were recorded using Bruker DRX 500, with $CDCl_3$ as solvent and TMS as standard at the Sophisticated Instruments Facility, Indian Institute of Science, Bangalore, India.

2.2. Synthesis of di-2-pyridyl ketone-N^4-phenyl semicarbazone (HL)

The semicarbazone was synthesized by the following method. A methanolic solution of di-2-pyridyl ketone (0.184 g, 1 mmol) was mixed with N^4-phenylsemicarbazide (0.151 g, 1 mmol) in methanol and three drops of glacial acetic acid. The reaction mixture was refluxed for 2 h. On slow evaporation, colorless crystalline compound formed was filtered, washed with ether and recrystallized from ethanol and dried over P_4O_{10} *in vacuo*. Melting point = 160 °C. ^1H NMR ($CDCl_3$, 400 MHz, δ from TMS): 13.37 (s, N^4H, 1H), 8.78 (d, C^1H, 1H, $J = 6.4$ Hz), 8.66 (d, $C^{11}H$, 1H, $J = 7.2$ Hz), 8.37 (s, N^5H, 1H), 7.87 (t, C^3H, 1H, $J = 7$), 7.79 (t, C^9H, 1H, $J = 6$), 7.56 (d, C^4H, 1H, J = 8), 7.51 (d, C^8H, 1H, $J = 8$), 7.34 (m, $C^{2,10,14,15,17,18}$, 6H), 7.07 (t, $C^{16}H$, 1H, $J = 7$). ^{13}C NMR ($CDCl_3$, δ from TMS): C(1), 148.68, C(2), 123.87, C(3), 136.81, C(4), 126.24, C(5), 151.96, C(6), 152.95, C(7), 148.0; C(8), 128.89, C(9), 137.98, C(10), 123.87, C(11), 140.28, C(12), 156.20, C(13), 137.98, C(14), 123.75, C(15), 123.38, C(16), 119.60, C(17), 123.38, C(18), 123.75 (see Fig. 1).

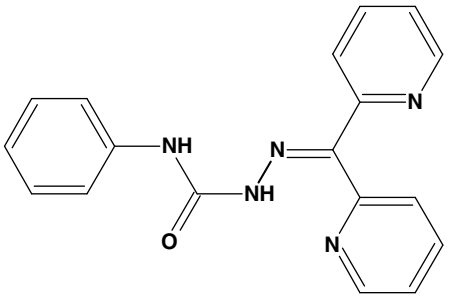

Fig. 1. Molecular structure of HL.

2.3. Synthesis of $[CdL(CH_3COO)]_2 \cdot 2CH_3OH$ (**1**)

A methanolic solution of HL (0.317 g, 1 mmol) and $Cd(CH_3COO)_2 \cdot 2H_2O$ (0.266 g, 1 mmol) were mixed and heated under reflux for 5 h. On slow evaporation, yellow crystals were obtained, which were separated, washed with ether and dried over P_4O_{10} *in vacuo.*

2.4. Synthesis of $Cd(HL)Br_2$ (**2**)

A methanolic solution of HL (0.317 g, 1 mmol) and $CdBr_2 \cdot 4H_2O$ (0.344 g, 1 mmol) were mixed and heated under reflux for 5 h. On slow evaporation, yellow coloured solid was resulted which were separated, washed with ether and dried over P_4O_{10} *in vacuo*.

2.5. Synthesis of $Cd_2L_2(N_3)_2 \cdot H_2O$ (**3**)

A methanolic solution of HL (0.317 g, 1 mmol) and $Cd(CH_3COO)_2 \cdot 2H_2O$ (0.266 g, 1 mmol) were mixed and heated under reflux for 2 h and then added methanolic solution of NaN_3 (0.065 g, 1 mmol). The resulting mixture was refluxed for 4 h. On slow evaporation yellow colored solid formed was separated, washed with ether and dried over P_4O_{10} *in vacuo*.

2.6. X-ray crystallography

Single crystals of compound **1** suitable for X-ray analysis were obtained from its methanolic solution and were found to be orthorhombic with a space group '*pbca*'. X-ray diffraction measurements were carried out on CrysAlis CCD diffractometer with graphite-monochromated

Mo Kα ($\lambda = 0.71073$ Å) radiation. The program CRYSALIS RED was used for data reduction and cell refinement [8]. The structure was solved by direct methods using SHELXS [9] and refined by full-matrix least-squares refinement on F^2 using SHELXL [10]. The N–H hydrogen atoms were located from difference Fourier maps and refined isotropically. The remainder of the H-atoms were included in calculated positions and refined as riding atoms using default SHELXL parameters. The structure of the compound **1** was plotted using the program DIAMOND Version 3.1d [11] and PLATON [12]. The final refinement cycle was based on all 3610 independent reflections and 290 variables with $R_1 = 0.0301$, $wR_2 = 0.0665$. The crystallographic data along with the structural refinements are given in Table 1.

Table 1
Crystal data and structure refinement parameters for $[CdL(CH_3COO)]_2 \cdot 2CH_3OH$

Empirical formula	$C_{42}H_{42}Cd_2N_{10}O_8$
Formula weight	1039.68

Wavelength (Å)	0.71073
Crystal system	orthorhombic
Space group	'*pbca*'
Unit cell dimensions	
a (Å)	13.8648(3)
b (Å)	15.3588(5)
c (Å)	19.2468(4)
α (°)	90
β (°)	90
γ (°)	90
Volume (Å^3)	4098.54(18)
Z	4
D_{calc} (g/cm^3)	1.685
Absorption coefficient	1.105 mm^{-1}
F(000)	2096
Crystal size (mm)	0.23 × 0.18 × 0.13
θ Range for data collection (°)	2.86–25
Index ranges	$-13 \leqslant h \leqslant 16$, $-18 \leqslant k \leqslant 15$, $-22 \leqslant l \leqslant 22$
Reflections collected	3610
Independent reflections [*R*(int)]	290 [0.0361]
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	5041/0/313
Goodness-of-fit on F^2	1.065
Final *R* indices [$I > 2\sigma(I)$]	$R_1 = 0.0301$, $wR_2 = 0.0665$
R indices (all data)	$R_1 = 0.0440$, $wR_2 = 0.0725$

3. Results and discussion

3.1. Synthesis of complexes

Compounds **1** and **2** were prepared by direct reaction between the ligand and the corresponding salts, while compound **3** was prepared by the replacement of the acetate in $Cd(CH_3COO)_2 \cdot 2H_2O$ by the azide ion. Elemental analyses data (Table 2) of complexes **1** and **3** reveal that metal–ligand are in the ratio 1:1 and in complex **2**, di-2-pyridyl ketone-N^4-phenyl semicarbazone (HL) interacts with Cd(II) ions in the presence of anion Br^- in the ratio 1:1.

3.2. Crystal structure of $[CdL(CH_3COO)]_2 \cdot 2CH_3OH$

Fig. 2 shows the molecular structure of the binuclear centrosymmetric Cd(II) complex with the atom numbering scheme. Both Cd centers being hexacoordinated and the coordination around the Cd(II) ion can be best described as a distorted octahedron with a CdO_3N_3 chromophore. Each Cd atom is coordinated by azomethine nitrogen, oxygen atom from the principal ligand, two pyridyl nitrogens and two oxygen atoms from the acetate group. The acetate groups serve as bidentate ligands and the semicarbazones as tetradentate ligands. The two pyridyl nitrogens from the principal ligand are coordinated to two different Cd centers forming a cyclic type architecture (Fig. 3). The coordination of oxygen from the semicarbazone ligand occurs through deprotonation after enolization, confirmed by the partial single and double bond nature of C7–O1 [1.350(4)] Å and N3–C7 [1.368(4) Å] bond lengths [13,14]. The C6–N2 and N2–N3 bond distances are 1.257(4) Å and 1.338(3) Å respectively, which reveal extensive delocalization over the entire binuclear coordination framework. Table 3 shows the selected bond lengths and bond angles of compound **1**.

In the case of this Cd-semicarbazone complex, Cd–O bond distances are Cd1–O1, 2.249(2) Å; Cd1–O2, 2.7666 Å; Cd1–O3, 2.434(2) Å and Cd–N bond distances are Cd1–N1, 2.168(3) Å; Cd1–N2, 2.515(3) Å and Cd1–N5, 2.155(3) Å respectively. The Cd1–O1 bond distance is slightly less than the other Cd–O bond distances reported for other octahedral Cd(II) complexes [15,16]. The Cd1–O2 and Cd1–O3 bond distances lie within the range of $Cd–O_{carboxylate}$ bond distances [2.209(2)–2.879(2) Å]

Table 2
Elemental analyses and color of Cd(II) complexes

N(4)–H(4N) 0.85(3)	O(1)–C(7)–N(3) 130.7(3)

reported for Cd(II)–$O_{carboxylate}$ coordination polymers [17]. The Cd1–N2 bond distance is slightly larger than the other Cd–N bond distances, which supports the lack of significant out-of-plane π-bonding. The trans angle, O2–Cd1–N2 is 155.84(8)° indicating that the compound **1** has large distortion from octahedral geometry [18]. Other indication of distorted octahedral geometry is the bond angle of O1–Cd1–O3, 85.51(8)°.

The unit cell packing diagram of the complex viewed along the *b* axis is given in Fig. 4. It can be observed that the molecules are packed in a zig-zag manner. The molecules in the unit cell are connected through intermolecular hydrogen bonding interactions involving the oxygen atom of the methanol molecule [O(4)–H(104)–O(3); O(4)–H(104), 0.81(4) Å; O(4)···O(3), 2.726(4) Å; H(104)···O(3), 1.92(4) Å; O(4)–H(104)···O3, 174(3)° and N4–H4N···$O4^{i}$ [i = $-x$, $-1/2 + y$, $3/2 - z$]; N4–H4N, 0.85(3) Å; N4···O4, 3.132(4) Å; H4N···O4, 2.30(3) Å; N4–H4N···O4, 166(3)°] (Fig. 5).

Ring puckering analysis show that the ring Cg(3) consisting of atoms Cd1–N1–C5–C6–N2 adopts an envelope on Cd1 [$Q_T = 0.1086$ (22) Å] [19]. The diverse π–π stacking and C–H–π interactions give rise to polymeric chains in the unit cell. The shortest π–π interactions are perceived at 3.1992 Å for Cg(2)–$Cg(3)^{ii}$ [Cg(2) = Cd1–O1–C7–N3–N2; ii = $-x$, $-y$, $2 - z$]. Two C–H–π interactions are present in the unit cell. They are C(11)–H(11)–$Cg(2)^{iii}$ [d_{H-Cg} = 2.94 Å; iii = $-1/2 + x$, y, $3/2 - z$] and C(21)–H(21)–$Cg(5)^{iii}$ [$d_{H-Cg} = 2.93$ Å; iii = x, $1/2 - y$, $-1/2 + z$]. The π–π, C–H–π and hydrogen bonding interactions contribute stability to the unit cell packing.

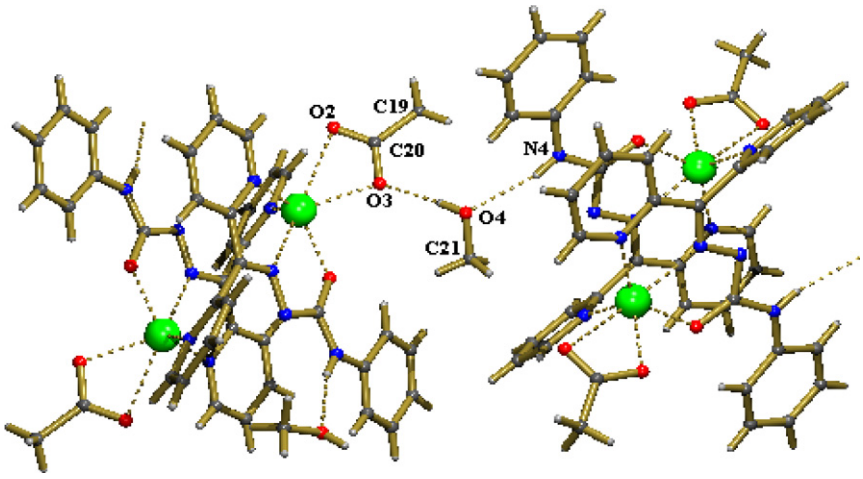

Fig. 5. Intermolecular hydrogen bonding interactions through methanol molecule.

3.3. Spectroscopic studies

The tentative assignments of the selected IR bands are listed in the Table 4. The spectrum of the ligand exhibits a medium band at 3369 cm^{-1} which is assigned to ν(NH) vibration. The absence of ν(NH) in the spectra of complexes **1** and **3** suggests that the ligand loses this proton on complexation, thus acting as uninegative ligand [20]. In complex **2**, the presence of a band at 3251 cm^{-1} corresponding to ν(NH) vibration indicates that the semicarbazone is coordinated in the neutral form. A band at 1718 cm^{-1} in the ligand has significant contribution from C=O stretching vibration and absence of such band in complexes **1** and **3** confirming the coordination through enolate oxygen. The presence of a band at 1656 cm^{-1} for complex **2** supports the keto form of the ligand in this complex.

On coordination of the azomethine nitrogen, the IR stretching frequency ν(C=N) at 1591 cm^{-1} shifts to 1605, 1597 and 1596 cm^{-1} for complexes **1**, **2** and **3**, respectively [21–23]. The spectra of the complexes exhibit a systematic shift in the position of ν(N–N) bands in the region 1148–1141 cm^{-1} and confirms the coordination of the azomethine nitrogen. The bands appearing at 457, 451 and 463 cm^{-1} which correspond to ν(Cd–N) for complexes **1**–**3** again confirm the coordination of the azomethine nitrogen [24]. Coordination of pyridyl nitrogen causes the out-of-plane bending vibrational band to shift from 601 cm^{-1} to higher frequencies 622, 621 and 627 cm^{-1} for complexes **1**–**3** [25]. Presence of a band at 1515 and 1521 cm^{-1} for complexes **1** and **3** are assigned to the newly formed ν(N=C) after enolization [26]. The asymmetric and symmetric stretching vibrations of the acetate group appear at 1568 and 1437 cm^{-1}, respectively, for complex **1** having the separation value $\Delta\nu = 131$ cm^{-1} suggests the presence of chelating acetate group linked with the metal center for the complex [27,28]. The azido complex **3** exhibits a strong band at 2052 cm^{-1} corresponding to ν_a(NNN) stretching vibration of the coordinating azido group.

Electronic spectrum of the ligand shows an absorption maximum at 40000 cm^{-1} attributed to intra-ligand $\pi \rightarrow \pi^*$ transitions of the pyridyl ring and imine function of the semicarbazone moiety. The peak at 30770 cm^{-1} indicate $n \rightarrow \pi^*$ transition of the amide function, which is shifted to higher energy values upon complexation [23] (Table 5).

The ^{1}H NMR spectrum of the compound HL along with the assignments is given in Fig. 6. A sharp singlet, which integrate as one hydrogen at $\delta = 13.37$ ppm is assigned to the proton attached to the nitrogen atom N(4). The downfield shift of this proton is assigned to its

Compound	ν(NH)	ν(C=N)	ν(CO)	ν(N=C)	ν(N–N)
HL	3369	1591	1718		1129
$[CdL(CH_3COO)]_2 \cdot 2CH_3OH$ (**1**)		1605		1515	1148
$[Cd(HL)Br_2]$ (**2**)	3257	1597	1656		1147
$[CdLN_3]_2$ (**3**)		1596		1521	1141

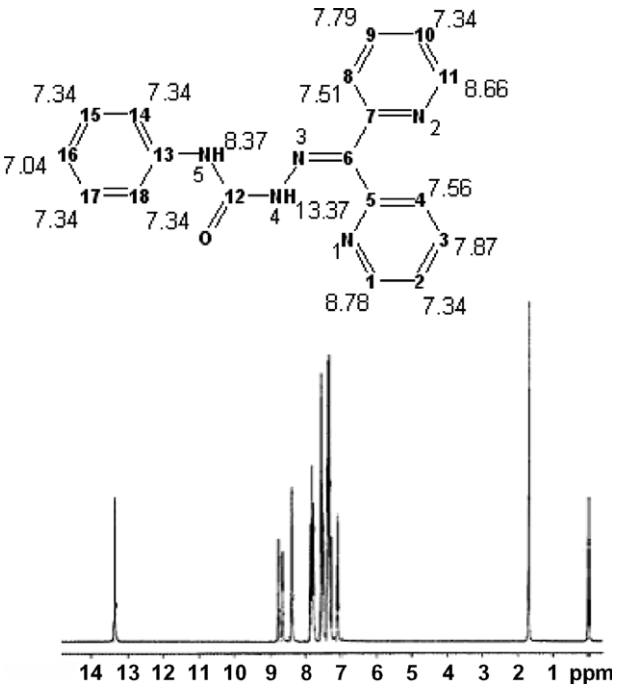

Fig. 6. ^{1}H NMR spectrum of HL.

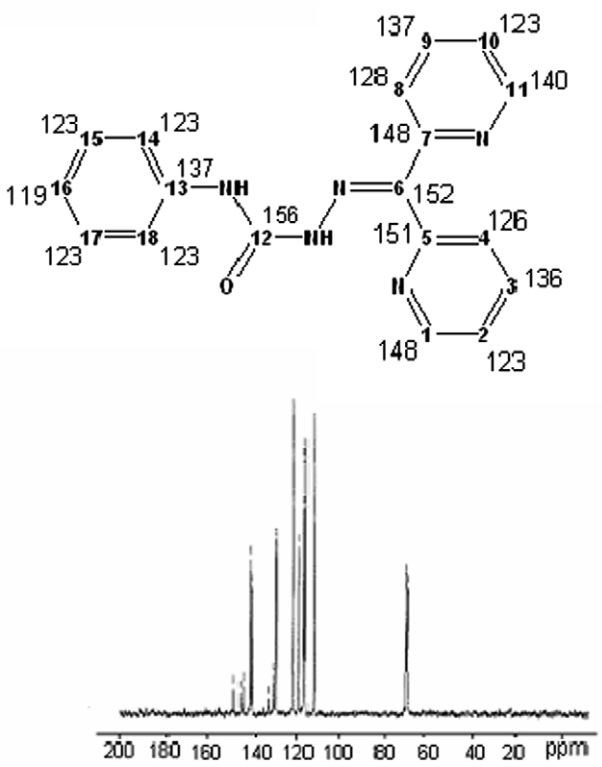

Fig. 7. ^{13}C NMR spectrum of HL.

hydrogen bonding interaction with adjacent nitrogen atom N(1). Another singlet at $\delta = 8.37$ ppm is assigned to the N(5) proton. This downfield also explained with the hydrogen bonding interaction with nitrogen atom N(3). Hydrogen bonding decreases the electron density around the proton and thus moves the proton absorption to a lower field. Absence of any coupling interactions by N(4) H and N(5) H protons due to the lack of availability of protons on neighboring atoms render singlet peaks for the imine protons.

Two doublets at $\delta = 8.78$ and 8.66 ppm are assigned to the C(1)H and C(11)H protons respectively. These signals are shifted to lower field due to electronic effect of the adjacent electronegative pyridyl nitrogens and the more downfield shift of C(1)H can be attributed to the increased charge density on N(1) resulted by its hydrogen bonding to N(4)H. The proton resonance of the two pyridyl rings also appear separately in the NMR spectrum, due to the intramolecular hydrogen bonding. There are two triplets at $\delta = 7.87$ and 7.79 ppm corresponding to similar protons on C(3) and C(9) of the two pyridyl rings, while the C(2) and C(10) protons resonances appear overlapped in the multiplet 7.345 ppm. Another two doublets at $\delta = 7.56$ and 7.51 ppm are assigned to C(4) and C(8) protons. The resonances for the C_6H_5-group appear as triplet at 7.04 ppm for para proton and as multiplets at 7.34 ppm for *ortho* and *meta* phenyl protons [29].

The ^{13}C NMR spectrum provides direct information about the carbon skeleton of the compound HL. Assignment of different resonant peaks to respective carbon atoms is presented in Fig. 7. Considering the two pyridyl rings non-equivalent, resulting from the hydrogen-bonding interaction, there are 15 unique carbon atoms in the molecule, which give a total of 15 different peaks in the ^{13}C NMR spectrum. In both the pyridyl rings, the C(1) and C(11) carbon atoms adjacent to the more electronegative nitrogen atoms N(1) and N(2) are shifted farther downfield when compared to the neighboring carbon atoms. Also the carbon atoms at para position to the hetero atoms viz. C(3) and C(9) resonate at lower field values when compared to the *meta* positioned carbons C(2), C(4), C(8) and C(10). The ^{13}C peaks are assigned as follows: C(1), 148.68 ppm; C(2), 123.87 ppm; C(3), 136.81 ppm; C(4), 126.24 ppm; C(5), 151.96; C(6), 152.95 ppm; C(7), 148.0 ppm C(8), 128.89 ppm; C(9), 137.01 ppm; C(10), 123.87 ppm; C(11), 140.28 ppm; C(12), 156.20 ppm; C(13), 137.98 ppm; C(14), 123.75 ppm; C(15), 123.38 ppm; C(16), 119.60 ppm; C(17), 123.38 ppm; C(18), 123,75 ppm. The non-protonated carbon atom at C(6) is found downfield in the spectrum ($\delta = 152.95$ ppm), effected by the magnetic interaction of two bulky pyridyl rings and π electron delocalization on the C(6)=N(3) bond. Similarly, the C(12) carbon atom resonance is also observed farthest downfield of 156.20 ppm resultant of the conjugative effect of the –N(3)–N(4)–C(O)–N(5)– semicarbazone skeleton. The NMR data for the complexes are not available because of poor solubility.

Scheme 1. Carbodimide insertion and deinsertion.

In this article, we report on the results of the thermolysis experiments with the aluminum guanidinate compound $[Me_2NC(N^iPr_2)]Al(NMe_2)_2$ (**1**) (Scheme 1), as well as the carbodiimide $[(CH_3)_2CHN{=}C{=}NCH(CH_3)_2]$ (**2**) and aluminum amide $[Al(NMe_2)_3]_2$ (**3d**). The results of MI FTIR spectroscopy and TOF MS will be discussed.

2. Experimental

2.1. General remarks

Complex **1** [3] and **3d** [8] were synthesized via known procedures and purified by sublimation prior to use (**1**: 50–55 °C, 10^{-2}–10^{-3} mbar; **3d**: 55–60 °C, 10^{-2}–10^{-3} mbar). Compound **2** was purchased from Aldrich Chemical Co. and purified via flask-to-flask condensation at ambient temperatures (approx. 10^{-2}–10^{-3} mbar).

The matrix-isolation and the time-of-flight MS apparatus were separate instruments. Each instrument was equipped with its own thermolysis oven, both identical in construction. Both instruments were in close proximity, so that the heatable container, loaded with the compound of interest, could be detached from one instrument and attached to the other instrument without exposing the sample to air. In addition to the sample container, both instruments used the same carrier gas supply and the same thermolysis oven temperature controller. The facility was constructed in this way so that a series of experiments with one sample batch could be performed using one method, e.g. MI FTIR spectroscopy, followed by a series of experiments using the other method, e.g. TOF MS, and still being able to keep the experimental conditions similar in both consecutive series of experiments.

A thermolysis oven was equipped with an Al_2O_3 tube (OD = 4 mm) with two parallel, inner canals (ID = 1 mm). The overall length of the tube was 35 mm with the last 10 mm heated with a tungsten wire, coiled around the outside and coated with ZrO_2 cement. One of the inner canals was equipped with a thermocouple (Thermocoax: NiCrSi/NiSi), while the second canal was used to let a carrier gas/sample mixture pass trough. With this set-up, reliable thermolysis temperatures at the inside of the thermolysis tube could be measured without exposing the thermocouple to the gaseous sample. A schematic drawing of the thermolysis oven can be found in Ref. [9].

Thermolysis series with compounds **1** and **3d**, respectively, were done in the temperature range between 300 and 600 °C (MI FTIR: 50 °C increments; TOF MS: 25 °C increments). The thermolysis of compound **2** was investigated exclusively at the temperatures 300, 500 and 700 °C for both MI FTIR and TOF MS. As compound **2** was thermally stable in this temperature range, a more detailed series of thermolysis experiments was not necessary.

2.2. Matrix-isolation FTIR spectroscopy

The matrix apparatus consisted of a vacuum line (Varian TV 551 Navigator; Varian DS 402) and a Sumitomo CSW-71 cryogenic closed cycle system (Sumitomo Heavy Industries, Ltd.) including a Sumitomo RDK-415D 4 K cold head fitted with CsI windows (vacuum shroud design and fabrication by Janis Research Company, Inc.). The sample was loaded into a heatable container connected to the thermolysis oven [9]. In a typical experiment, the evacuated container, loaded with the compound of interest, was kept at constant temperature (**1**: 45–50 °C; **2**: −20 °C; **3d**: 55–60 °C) while a flow of argon (1.250 sccm; Praxair 6.0) was conducted over the sample (mass flow controller: MKS Type 1179A). The resulting gaseous mixture was passed through a thermolysis oven for 30–90 min and deposited onto a CsI window cooled to 20 K. The distance between the end of the heated oven tube to the CsI window was 54 mm. The so-prepared matrices were cooled to 4 K for FTIR measurements (Bruker Tensor 27 FTIR; 200–5000 cm^{-1}; resolution of 1 cm^{-1}).

Compound **4** ($H_2C{=}NMe$) have been identified by its typical IR bands at 2953.7, 2900.9, 2854.8, 2849.4, 1658.6, 1469.7, 1440.3, 1221.0, 1026.5 and 949.5 cm^{-1}.

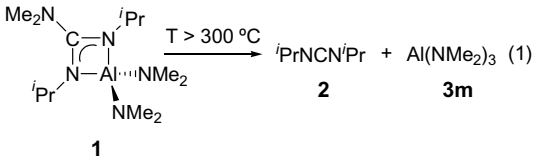
2.3. Time-of-flight mass spectrometry

The apparatus consisted of a custom designed vacuum chamber (designed by Stefan Kaesdorf, Geräte für Forschung und Industrie; built by Johnsen Ultravac Inc.), equipped with one roughing vacuum pump (Varian DS 602) and three turbo vacuum pumps, and a reflectron time-of-flight spectrometer with electron impact ionization (Stefan Kaesdorf, Geräte für Forschung und Industrie; time resolution under favorable conditions $T/\Delta T = 10\,000$). The apparatus was composed of three connected vacuum chambers, with the third chamber being the TOF MS itself (Figs. S1 and S2, Supplementary data). A fraction of the gaseous molecules that enter chamber 1 (Varian TV 1001 Navigator) through the thermolysis oven is sampled by a skimmer (model 2 from Beam Dynamics, Inc.; orifice 1.5 mm) so that a molecular beam enters chamber 2 (Varian TV 551 Navigator) where the electron impact ionization takes place. Produced ions are accelerated perpendicular to the molecular beam into the TOF MS (chamber 3; Varian TV 551 Navigator). The distance between the end of the heated oven tube to the orifice of the skimmer was 12 mm. During thermolysis experiments (argon flow of 1.250 sscm) the pressures in chambers 1, 2 and 3 were measured to be around 5.0×10^{-4}, 3.0×10^{-8}, 5.0×10^{-9} mbar, respectively. As described before,

in a typical experiment, the sample container was kept at constant temperature (**1**: 50–55 °C; **2**: 0 °C; **3d**: 60–65 °C) while a flow of argon was conducted over the sample. To get acceptable signal to noise ratios, the temperatures needed for the TOF MS measurements were slightly higher than those for MI FTIR spectroscopy (see above). For all measurements electron impact of 70 eV and 10 million sweeps per oven temperature were applied. The signal of the carrier gas argon at 40 u was reduced in intensity by using a mass filter at 4.35 kV (delay: 3.1000 μs; duration: 0.9000 μs). This prevented the MCP detector from exceeding its detection limit. Calibration of the flight time was done within every new series of measurements using Xe 132 (131.90415 u), Xe 129 (128.90478 u), Ar 40 (39.96230 u) and H_2O (18.01050 u) as internal standards.

Calculated masses of selected fragments (u): $\mathbf{1}^+$: 285.25; $\mathbf{2}^+$: 126.12; $\mathbf{2}^+$–$NCH(CH_3)_2$: 69.06; $\mathbf{3d}^+$: 318.26; $\mathbf{3m}^+$: 159.13; $\mathbf{3m}^+$–$N(CH_3)_2$: 115.08; $AlNH(CH_3)_2^+$: 72.04; $AlN(CH_3)_2^+$: 71.03; $AlNHCH_3^+$: 57.02, $HN(CH_3)_2^+$: 45.06; $N(CH_3)_2^+$: 44.05; $\mathbf{4}^+$: 43.04; $NC_2H_4^+$: 42.03.

2.4. DFT Calculations



All *ab initio* calculations were carried out using the GAUSSIAN 03 suite [10]. Geometry optimization and calculations of harmonic frequencies were done on the B3LYP/6-31G(d) level of theory using the Western Canada Research Grid (WESTGRID). First, compound **3m** was optimized in *z*-matrix coordinates to enforce a D_3 point group symmetry ($E_h = -646.226377$ hartree). Secondly, all symmetry constrains were removed and a full optimization followed by a frequency calculation have shown that the D_3 symmetrical species indeed refers to a local minimum at the potential energy surface ($E_h = -646.226397$ hartree; zero-point vibrational energy = 653.2 kJ/mol).

3. Results and discussion

In order to illuminate the fragmentation of the aluminum guanidinate precursor **1**, its gas-phase thermolysis in the range of 300–600 °C has been investigated with MI FTIR spectroscopy and TOF MS. We designed a facility that combines both methods. A series of experiments can be performed initially using one method, which can then be followed by a similar series of experiments, with the same precursor sample and carrier gas supply, using the second method (see Section 2). Even though MI FTIR and TOF MS data are collected consecutively and not simultaneously, conditions in both series of experiments can be kept similar that both methods independently illuminate the same chemical events, hence, providing data that complement one another.

3.1. MI FTIR spectroscopy

Between oven temperatures of 25 and 300 °C the matrix IR spectra did not change and indicated that precursor **1** is thermally stable in this range. At 350 °C a weak IR band with a maximum at 2118.8 cm^{-1} appeared, signaling the start of thermolysis of **1**. While the intensity of the band at 2118.8 cm^{-1} kept growing with increasing temperature, the typical IR bands of **1** could no longer be detected at oven temperatures above 450 °C. The IR band at 2118.8 cm^{-1}, which is in a typical area of asymmetric NCN stretching modes of carbodiimides, prompted us to propose that precursor **1** fragments according to Eq. (1), which is the reverse reaction of its preparative synthesis shown in Scheme 1.

However, for both the carbodiimide **2** and the aluminum amide **3m**, complete sets of matrix IR data were not available in the literature. In the context of studying astrophysical chemistry, compound **2** together with nitriles and isonitriles had been investigated in solid argon matrices, but only the IR range of 2050–2320 cm^{-1} was reported [11]. According to this paper, compound **2** showed a broad, structured IR band with a maximum at 2123.7 cm^{-1} (complete set: 2144.3, 2137.5, 2128.5, 2123.7, 2118.6 and 2112.7 cm^{-1}). In thermolysis experiments of precursor **1**, the IR band with the maximum at 2118.8 cm^{-1} also showed a structure with a second maximum at 2123.1 cm^{-1} and a shoulder at 2128.2 cm^{-1}. We measured compound **2**, matrix-isolated in argon, and based on these data an unequivocal identification of **2** as a thermolysis product was achieved (Fig. S3, Supplementary data). Fig. 1 illustrates the results with an IR spectrum obtained from a thermolysis at 450 °C. Under these conditions, small amounts of precursor **1** could still be trapped in solid argon.

As one can see from Fig. 1, the aluminum amide **3m** was also identified as a thermolysis product (indicated with ∅). Compound **3m** is unstable at ambient temperature, but can be synthesized as a dimer $[Al(NMe_2)_3]_2$ (**3d**) under ambient conditions, exhibiting the expected diborane(6) structure [8,12]. A series of experiments with **3d** as a precursor with oven temperatures of up to 600 °C was carried out. Between ambient temperatures and 300 °C the matrix IR spectra did not change, indicating that they were caused by matrix-isolated **3d**. At oven temperatures of 350 °C, new IR bands appeared while the intensity of precursor **3d** decreased. Fig. 2 shows a typical spectrum of matrix-isolated **3d** and spectra obtained from a thermolysis of **3d** at 450 °C.

Under these conditions a mixture of **3d** and **3m** was obtained in matrices. We could not find thermolysis conditions to trap the monomer **3m** without the starting dimer

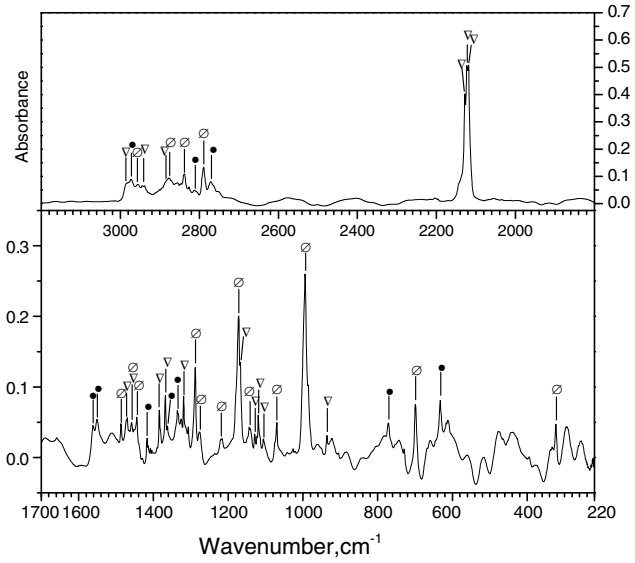


Fig. 1. IR spectrum of matrix-isolated products from a thermolysis at 400 °C of **1** (*x* axis, 1800–3200 cm^{-1} (top), 220–1700 cm^{-1} (bottom); *y* axis, absorbance). Compound **1**: ● (2969.7, 2944.4, 2870.4, 2863.8, 2825.8, 2812.5, 2769.9, 2753.9, 1561.6, 1551.1, 1496.2, 1486.2, 1470.8, 1465.2, 1445.3, 1429.9, 1417.1, 1412.2, 1408.5, 1380.9, 1362.8, 1335.0, 1325.9, 1294.9, 1279.0, 1216.7, 1179.9, 1173.6, 1148.3, 1128.2, 1075.4, 996.8, 991.5, 950.6, 845.5, 771.6, 753.6, 742.6, 668.5, 632.7, 464.3, 445.3 and 326.0 cm^{-1}); compound **2**: ∇ (2984.7, 2938.9, 2883.1, 2128.2, 2123.1, 2118.8, 1470.6, 1457.8, 1384.4, 1368.7, 1335.9, 1319.4, 1307.0, 1168.8, 1129.4, 1123.1, 1119.6, 1105.7, 936.4, 633.2 617.6, 609.6 and 425.5 cm^{-1}); compound **3m**: ∅ (see Table 2).

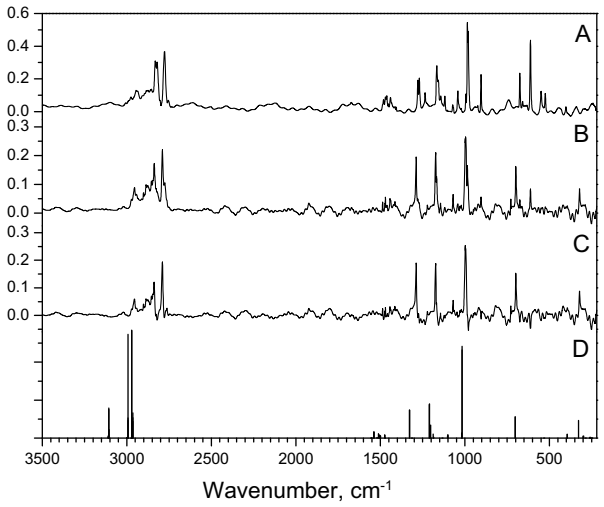

Fig. 2. Measured and calculated IR spectra of aluminum amides **3d** and **3m** (*x* axis, 220–3500 cm^{-1}; *y* axis, absorbance). Spectrum A: **3d** in solid argon (oven at ambient temperature). Spectrum B: results of a thermolysis of complex **3d** at 450 °C. Spectrum C: spectrum B from which the absorptions from **3d** (spectrum A) have been electronically eliminated. Spectrum D: calculated IR spectrum of **3m** (B3LYP/6-31G(d); see Tables 1 and 2).

3d. Fig. 2C shows a thermolysis IR spectrum from which the spectrum of the dimer **3d** has been electronically eliminated. The excellent match of spectrum C with the calculated spectrum of **3m** (B3LYP/6-31G(d) level) proves that

[a] Intensities of the E modes are the sum of the two degenerated vibrations.
[b] ip and oop: symmetrical equivalent atoms of within one NMe_2 moiety move in phase and out of phase, respectively.
[c] Wagging and rocking modes of the CH_3 groups are very similar: wagging modes are approximately in the molecular planes, whereas rocking modes are approximately perpendicular to the molecular plane.
[d] Appears like a motion of a trampoline: involves pyramidalizations at Al and N.

indeed **3d** monomerises to **3m**. Table 1 compiles the calculated harmonic vibrational modes and Table 2 shows the measured IR frequencies and their assignments. The D_3 symmetrical alane **3m** (Fig. 3) is expected to show 78 normal modes that transform to the irreducible representations A_1 (13), A_2 (13) and E (26). If one takes into account that A_1 symmetrical modes are IR inactive, the A_2 and E modes could result in 39 IR bands. Typically, a molecule of this size shows many CH stretching modes in a narrow range, and, as expected, an assignment of measured to calculated frequencies of CH stretching modes for **3m** was impossible. If one subtracts the CH stretches (3 A1 and 6 E modes) from the expected 39 IR bands, the modes below the detection limit of 200 cm^{-1} (ν_{25}, ν_{26}, ν_{50}, ν_{51}, ν_{52}), and all modes with calculated intensities below 10 km/mol (ν_{19}, ν_{22}, ν_{24}, ν_{33}, ν_{35}, ν_{41}, ν_{42}, ν_{47}, ν_{48}, ν_{49}), 15 IR bands remain to be expected in the range of 1500–200 cm^{-1}. All expected IR bands were found in these experiments; Table 2 illustrates the assignment and the match between experiment and theory by observed-to-calculated frequency ratios that vary between 0.95910 and 1.001. These are typical ratios for the B3LYP/6-31G(d) level and show the expected trend: the lower the frequency is the better the fit [13,14]. However, the assignment of IR bands in the range of 1400–1500 cm^{-1} is not straightforward. According to the calculation, 6 modes are expected with low intensities (11.8–31.5 km/mol) and 6 IR bands were detected. We assigned the IR bands to calculated modes taking the calculated frequencies and intensities into account. However, this resulted in an assignment of one IR band at 1487.0 to two calculated modes (ν_{17} at 1538.9 and ν_{34} at 1538.1), leaving the IR band at 1473.8 cm^{-1} unassigned. Even though the calculated frequencies for ν_{17} and ν_{34} are nearly identical, it is feasible that both modes do not result in overlapping IR bands in the experiment and one of the two modes causes the measured IR band at 1473.8 cm^{-1}. Without matrix-isolation experiments with isotopomers of **3m**, an assignment in this IR range will remain tentative. However, the remaining IR bands are spread over a larger IR range and most of them show high intensities and thus could be assigned with certainty (see Table 2 for details). Based on these data, the monomer **3m** could be identified as a thermolysis product of precursor **1** (Fig. 1). Furthermore, and very importantly, the formation of the dimer **3d** as a product of the fragmentation of **1** could be excluded.

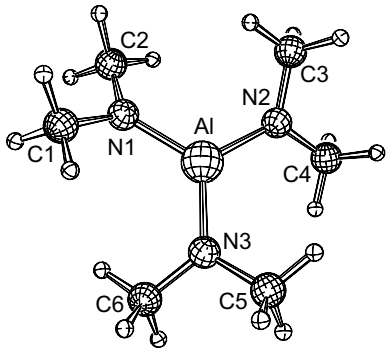

Fig. 3. D_3 symmetrical geometry of $Al(NMe_2)_3$ (**3m**) (B3LYP/6-31G(d) level). Selected bond lengths (Å), angles and torsion angles (°): Al–N = 1.7958, N–C = 1.4536, Al–N–C = 123.96, C–N–C = 112.08 and C1–N1–Al–N2 = −150.72.

While the intensities of the IR bands of the carbodiimide **2** were unaffected at higher thermolysis temperatures

[a] Most intense IR bands at 2955.3, 2837.6 and 2789.7 cm^{-1}.
[b] Could not be assigned; see text for discussion.
[c] Shoulder at 998.1 cm^{-1}.
[d] Less intense IR band at 986.0 cm^{-1} presumably caused by matrix effects.

(450–600 °C), those of the monomer **3m** were strongly temperature dependent. As the thermolysis temperature for precursor **1** was increased from 400 to 600 °C, the amount of the monomer **3m** decreased and it could no longer be detected at thermolysis temperatures above 500 °C. While the intensities of the IR bands of **3m** decreased, a new set of IR frequencies grew in, which were clearly identified as being due to methyl(methylene)amine, $H_2C{=}NCH_3$ (**4**). This product was previously identified by matrix-isolation thermolysis experiments with other dimethylamino-containing precursors [6]. Under our thermolysis conditions the first IR bands of **4** were detected at oven temperatures of 500 °C (see Section 2). Similar to the thermolysis of compound **1**, the thermolysis of the aluminum amide **3d** also gave product **4** at higher oven temperatures, with the IR bands of **4** being detectable starting at 450 °C. In addition to the IR bands of **4**, a very weak band at 729.0 cm^{-1} was detected in the temperature range between 400 and 600 °C. This IR band could be caused by small amounts of Me_2NH, which shows its most intense IR absorption at this frequency [15]. In the thermolysis series with precursor **1**, a weak IR band at 729.0 cm^{-1} was also detected. However, the identification of Me_2NH by only one frequency can only be tentative.

3.2. TOF mass spectrometry

As mentioned above, a series of thermolyses of compounds **1**, **2** and **3d** with similar conditions as for the MI FTIR spectroscopy have been performed using a TOF MS apparatus. The main disadvantage of MS with respect to MI FTIR spectroscopy stems from the fact that a detection of a species requires modification of the species: it needs to be ionized. We used electron impact ionization, and 70 eV were applied in order to have an optimum ion yield. However, through this method a species is provided with an excess of energy that leads to further fragmentation. Depending on the case, instead of the molecular ion M^+ of the species of interest, which results in the most informative signal, only signals of molecular fragments can be detected.

The TOF MS measurements of **1**, **2** and **3d** supported and complemented the conclusions drawn from the MI FTIR experiments. Fig. 4 compares mass-spectra of precursor **1** obtained at oven temperatures of 25 and 425 °C. The signals indicative of the precursor **1** were not detected at 425 °C. Instead, two ions at 126.14 and 69.07 u dominated the spectrum. Both masses belong to the carbodiimide **2**; the higher mass due to $\mathbf{2}^+$ and the more intense peak at 69.06 u due to a loss of $NCH(CH_3)_2$ from $\mathbf{2}^+$. Independent measurements of **2** alone supported this interpretation (Fig. S4, Supplementary data).

Fig. 5 shows a plot of intensities of selected ions with respect to oven temperatures. Above 225 °C the amount of precursor **1** (285.30 u) started to decrease while the amount of the carbodiimide **2** (126.14 and 69.06 u) increased. The most intense signals for **2** have been measured at 400 °C, above which their intensities decreased again.

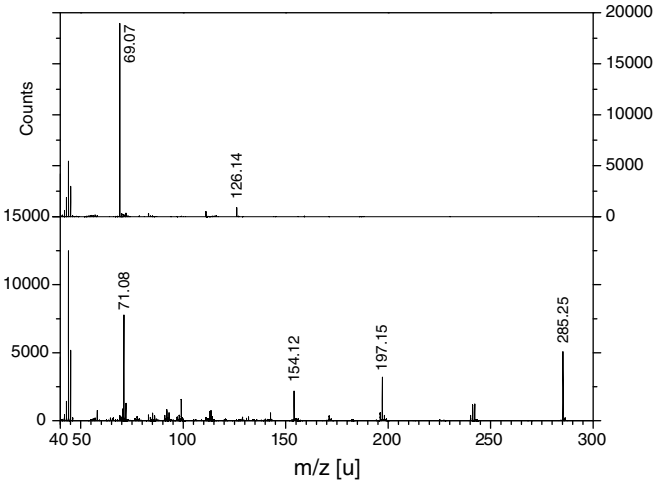

Fig. 4. Mass-spectra of complex **1** measured at oven temperatures of 25 °C (bottom) and 425 °C (top).

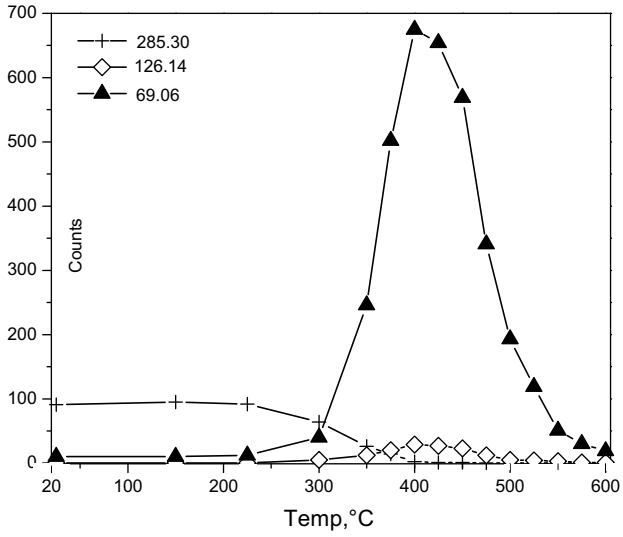

Fig. 5. Temperature dependence of selected ions of the thermolysis of **1** [m/z = 285.30 ($\mathbf{1}^+$), 126.14 ($\mathbf{2}^+$) and 69.06 ($\mathbf{2}^+$–NC_3H_7)].

For the same series of thermolysis experiments, Fig. 6 shows a similar plot as that of Fig. 5, with a focus on fragments that could be interpreted as being due to the formation of the aluminum amide **3m**. The signal at 159.14 u clearly indicates the presence of $\mathbf{3m}^+$, whereas the mass at 115.10 u can be interpreted as $Al[N(CH_3)_2]_2^+$ resulting from $\mathbf{3m}^+$ losing a $N(CH_3)_2$ group. In addition, the ion of mass 43.06 u indicates the presence of $H_2C{=}NCH_3$ (**4**). Fig. 6 shows that the presence of the monomeric aluminum amide **3m** (159.14 and 115.10 u) is restricted to the narrow temperature range of approximately 350–450 °C, whereas the signal for compound **4** (43.06 u) persisted over a broader temperature range. The fact that the signal of **4** at 43.06 u and the signals indicative of **3m** follow a different temperature profile indicates that **4** cannot result from the

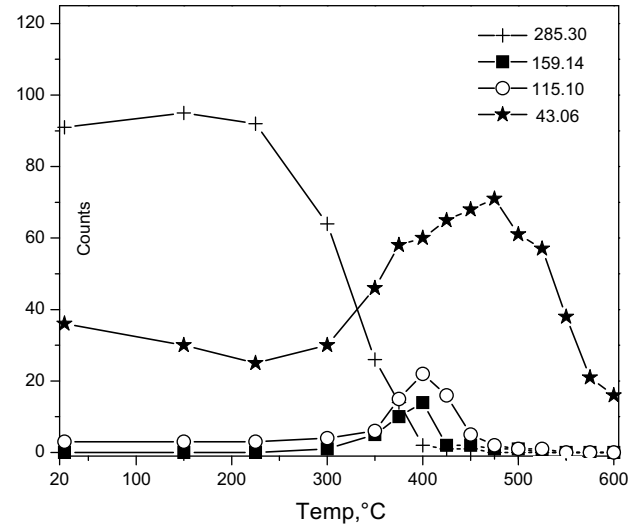

Fig. 6. Temperature dependence of selected ions of the thermolysis of **1** [m/z = 285.30 (**1**$^+$), 159.14 (**3m**$^+$), 115.10 (**3m**$^+$–N(CH$_3$)$_2$) and 43.06 (**4**$^+$)].

fragmentation of **3m**$^+$ in the MS. Combined with the fact that product **4** could be trapped in matrices in thermolysis experiments of precursor **1**, it seems likely to interpret the signal at 43.06 u as the molecular ion of the thermolysis product **4**. It is worth noting that the peaks caused by **3m** are very weak in intensity (Fig. 6); with a maximum count of 22 for 115.10 u at 400 °C, these signals are just above the threshold of being detectable with our set-up.

Similar to the matrix-isolation investigation, the thermolysis of the dimer **3d** has been investigated. Fig. 7 shows a comparison between the mass-spectrum of compound **3d** at room temperature and that at 450 °C. All signals corresponding to **3d** were no longer present at 450 °C, revealing a completed thermolysis of **3d** under these conditions. The most intense peaks at 450 °C were found at 45.06, 44.05, 43.04 and 42.03 u indicating the presence of HN(CH$_3$)$_2$$^+$, N(CH$_3$)$_2$$^+$, H$_2$C=NCH$_3$$^+$ (**4**$^+$), and N(CH$_2$)$_2$$^+$, respectively. The signals at 72.04 and 57.03 u can be interpreted as being caused by AlNH(CH$_3$)$_2$$^+$ and AlNH(CH$_3$)$^+$, respectively.

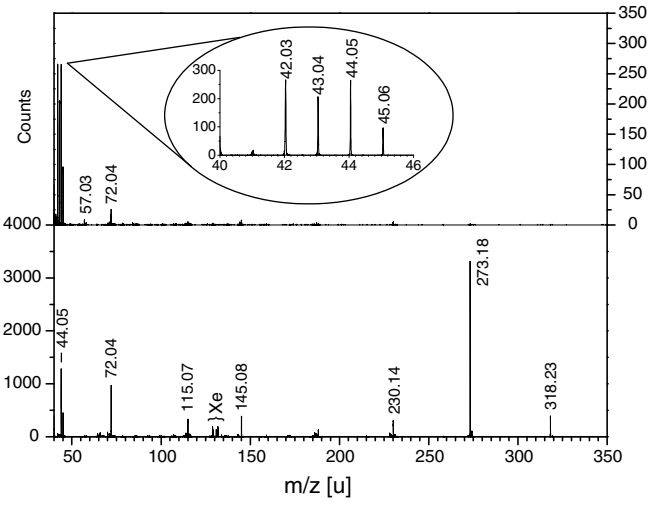

Fig. 7. Mass-spectra of complex **3d** measured at 25 °C (bottom) and 450 °C (top). Mass region 40–46 u expanded (top) for clarity.

Figs. 8 and 9 show temperature dependences of selected ions. The ions at 318.23, 159.12. 115.07, 72.04, 45.06 and 44.05 u show a decrease of intensity with increasing thermolysis temperature (Fig. 8), whereas those at 71.04 and 57.03 u (Fig. 8) and those at 43.04 and 42.03 u (Fig. 9) show an increase of intensity at elevated temperatures. In the case of the thermolysis of precursor **1**, the two peaks at 159.12 and 115.07 u were weak in intensity but indicative

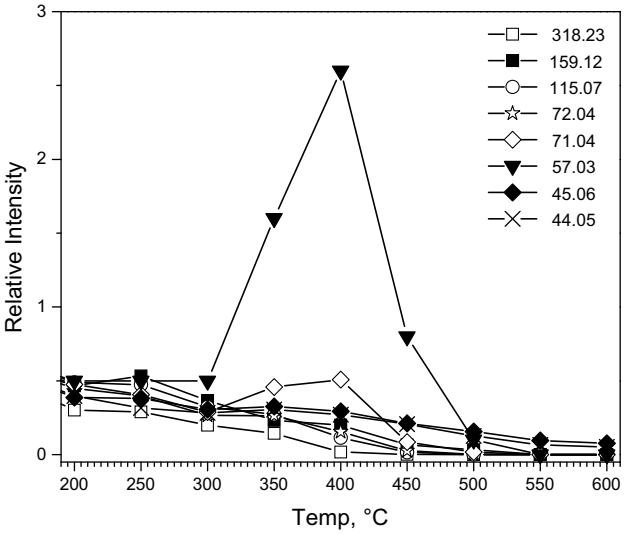

Fig. 8. Temperature dependence of selected ions of the thermolysis of **3d** [m/z = 318.23 (**3d**$^+$), 159.12 (**3m**$^+$), 115.07 (**3m**$^+$–N(CH$_3$)$_2$), 72.04 (AlNH(CH$_3$)$_2$$^+$), 71.04 (AlN(CH$_3$)$_2$$^+$), 57.03 (AlNHCH$_3$$^+$), 45.06 (HN(CH$_3$)$_2$$^+$) and 44.05 (N(CH$_3$)$_2$$^+$)]. Relative intensity normalized to data points at ambient temperature.

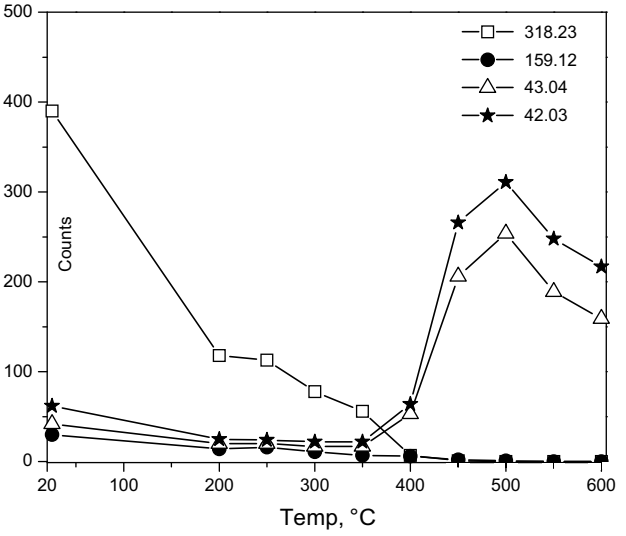

Fig. 9. Temperature dependence of selected mass fragments showing the formation of thermolysis product **4** [m/z = 318.23 (**3d**$^+$), 159.12 (**3m**$^+$), 43.04 (**4**$^+$) and 42.03 (N(CH$_2$)$_2$$^+$)].

of the production of monomer **3m** (Fig. 6). However, in the case of the thermolysis of **3d**, both signals at 159.12 and 115.07 u did not gain in intensities (Fig. 8), and, consequently, could not prove that **3d** monomerises to **3m** upon heating. Both signals are already present in the room temperature spectrum of **3d** and their intensities decrease with increasing thermolysis temperature. It seems that this decrease overcompensates the small increase in intensity caused by the formation of **3m**. However, from the matrix-isolation experiments discussed above, there is no doubt that **3m** is formed from **3d**. As it can be seen in Fig. 8, only the two masses at 71.04 and 57.03 u increase significantly in the thermolysis range of approx. 300–450 °C. The mass at 71.04 u can be interpreted as being caused by $AlN(CH_3)_2^+$, whereas that at 57.03 u fits to $AlNHCH_3^+$ and it is feasible that both ions stem from $\mathbf{3m}^+$. Fig. 9 clearly indicates that the two signals at 43.04 and 42.03 u start to increase in intensity above 350 °C and their temperature profiles are very similar. The peak at 43.04 u is caused by thermolysis product **4** that losses a H atom in the mass spectrometer to also cause the peak at 42.03 u [$N(CH_2)_2^+$].

4. Conclusion

With series of thermolysis experiments of aluminum guanidinate precursor **1** using matrix-isolation FTIR spectroscopy and time-of-flight mass spectrometry we demonstrated that **1** fragments above 300 °C to form the diisopropylcarbodimide **2** and monomeric tris(dimethylamino)alane **3m** (Eq. (1)). Independent thermolysis series with **2** and the aluminum amide dimer **3d** were conducted and had been used to interpret the results of the fragmentation of precursor **1**. Under our experimental conditions, monomer **3m** was present in the thermolysis range of 350–450 °C. Already at 500 °C signals indicative for methyl(methylene)amine (**4**) were found, showing that **3m** fragments further at higher temperature. The thermolysis product **2** (*i*PrCNC*i*Pr) withstands the higher thermolysis temperatures. With respect to material deposition processes we could show that precursor **1** cleanly delivers the monomeric aluminum alane **3m**, which then acts as the reactive material forming species.

Within this study, the monomeric aluminum amide **3m** has been characterized for the first time. Based on DFT calculations, all expected IR bands were found experimentally and could be assigned to normal modes. Species **3m** is one of the very few monomeric aminoalanes that could be characterized to date. The sterically crowded aminoalane $Al[N(SiMe_3)_2]_3$ was the first aminoalanes shown to be monomeric in the crystalline state [16]. The first sterically crowded monomeric aminoalane equipped with only one amino group had been described by Power et al. [17]. The first non-crowded monomeric aminoalane $Me_2Al{=}NH_2$ had been formed photolytically from $Me_3Al{-}NH_3$ in argon matrices and characterized by FTIR spectroscopy [18]. The parent compound H_2AlNH_2 was obtained from co-depositions of Al atoms with ammonia in argon matrices and was characterized by matrix-isolation FTIR spectroscopy [19].

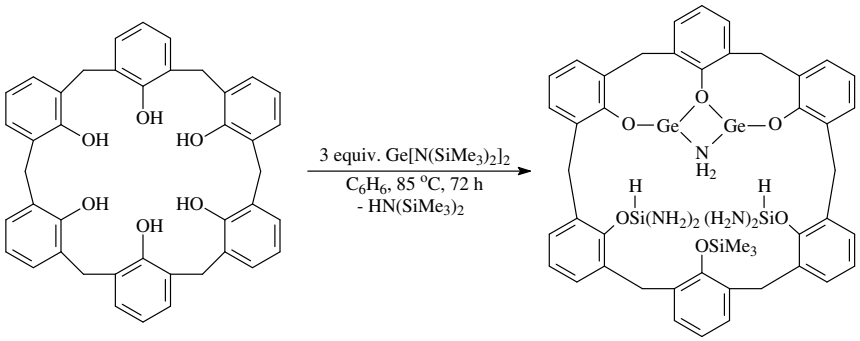
2. Results and discussion



2.1. Synthesis and structure of compound 1

Treatment of calix[6]arene with three equivalents of Ge[N(SiMe$_3$)$_2$]$_2$ yielded complex **1** in 41% yield as shown in Eq. (1). The identity of **1** was ascertained by obtaining its X-ray crystal structure, and an ORTEP diagram of **1** is shown in Fig. 1 while selected bond distances and angles are collected in Table 1. Of the six phenolic oxygen atoms present in **1**, three are bound to the two Ge atoms in either a terminal or bridging fashion while the remaining three oxygen atoms have been incorporated into to either –OSiMe$_3$ or –OSi(H)(NH$_2$)$_2$ groups. We have previously observed the transformation of hydroxyl groups to trimethylsiloxy groups in the reactions of 3,3′-disubstituted binaphthols with metal(II) amides M[N(SiMe$_3$)$_2$]$_2$ (M = Be, Zn, Ge, Sn) [48]; however, the conversion of –OH groups to silylamides has not been previously described.

Table 1
Selected bond distances (Å) and angles (°) for compound **1** · 0.5 (C_6H_6)

Ge(1)–O(1)	1.860(3)	O(1)–Ge(1)–O(3)	91.4(1)
Ge(1)–O(3)	1.992(3)	O(1)–Ge(1)–N(5)	89.7(1)
Ge(1)–N(5)	2.011(4)	O(2)–Ge(2)–O(3)	91.6(1)
Ge(2)–O(2)	1.835(3)	O(2)–Ge(2)–N(5)	91.4(1)
Ge(2)–O(3)	1.993(3)	O(3)–Ge(1)–N(5)	77.1(1)
Ge(2)–N(5)	1.995(4)	O(3)–Ge(2)–N(5)	77.4(1)
Si(1)–O(6)	1.664(3)	Ge(1)–O(3)–Ge(2)	103.0(1)
Si(2)–O(5)[a]	1.696(5)	Ge(1)–N(5)–Ge(2)	102.3(2)

Si(3)–O(4)[a]	1.712(4)	N(3)–Si(2)–N(4)[a]	122.8(5)
Si(3)–N(1)[a]	1.700(8)	O(4)–Si(3)–N(1)[a]	112.4(4)
Si(3)–N(2)[a]	1.806(9)	O(4)–Si(3)–N(2)[a]	108.8(4)
		N(1)–Si(3)–N(2)[a]	119.6(4)

[a] The atoms Si(2) and Si(3) are disordered over two positions. The tabulated values are for the average of the two positions.

(1)

Compound **1** contains an unusual bridging –NH$_2$– group between the two germanium centers, and the structure of **1** can be compared to the two related calixarene complexes {calix[4]}Ge$_2$ (**2**) and {calix[8]}Ge$_4$ (**3**) [47] as well as the dimeric species [(C$_6$H$_3${C$_6$H$_3$Pr$^i_2$-2,6}$_2$-2,6)GeNH$_2$]$_2$ (**4**) which also contains bridging –NH$_2$– moieties [49]. Similar to the Ge$_2$O$_2$ rhombus in compound **2** the Ge$_2$NO rhombus adopts a planar geometry. The Ge(1)–O(3)–Ge(2) angle of 103.0(1)° is significantly more acute than the Ge–O$_{br}$–Ge angles in **2** and **3** which range from 106.1(1) to 107.89(6)° [47]. Furthermore, the Ge(1)–N(5)–Ge(2) angle measures 102.3(2)° which is more obtuse than the average Ge–N$_{br}$–Ge angles in **4** (100.0(1)°) [49]. The O(3)–Ge(1)–N(5) and O(3)–Ge(2)–N(5) angles average 77.3(1)° which are wider than the O$_{br}$–Ge–O$_{br}$ angles in **2** and **3** but more acute than the N$_{br}$–Ge–N$_{br}$ ligands angles in **4**. These structural differences can be attributed to the presence of two different types of bridging atoms in **1** and the internal angles in the Ge$_2$NO rhombus can be regarded as being intermediate between the Ge$_2$O$_2$ rhombi of **2** and **3** and the Ge$_2$N$_2$ rhombus of **4**.

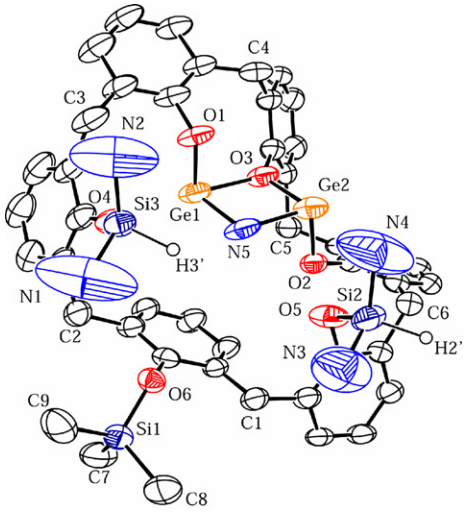

Fig. 1. ORTEP diagram of compound **1**. Thermal ellipsoids are drawn at 50% probability.

The terminal Ge(1)–O(1) and Ge(2)–O(2) bond lengths in **1** are typical for germanium(II)–oxygen distances and are comparable to those in compounds **2** and **3** [47] as well as in other Ge(II) aryloxides [50–54]. The bridging Ge(1)–O(3) and Ge(2)–O(3) bond lengths in **1** are 1.992(3) and 1.993(3) Å (respectively) which fall between the average Ge–O$_{br}$ bond distances in **2** (1.988 Å) and **3** (2.000 Å) [47]. The bridging N atom is not symmetrically disposed between the two germanium atoms in **1** as indicated by the two Ge–N bond lengths measuring 2.011(4) and 1.995(4) Å. These distances are shorter than those found in the structure of **4** which has an average Ge–N distance of 2.013(3) Å [49]. The Ge–N distances in **1** are longer than those in germanium(II) compounds bearing ligands with terminal Ge–N bonds, including the well-known bulky bisamide Ge[N(SiMe$_3$)$_2$]$_2$ which has Ge–N bond lengths of 1.873(5) and 1.878(5) Å [55] and the bis(piperidinato) complex Ge[NC$_5$H$_6$Me$_4$-2,2,6,6]$_2$ which has distances of 1.87(1) and 1.90(1) Å [56]. However, the Ge–N distances in **1** are considerably shorter than those in divalent germanium compounds having dative N → Ge bonds including those in [Ge(2-{(Me$_3$Si)$_2$C}-C$_5$H$_4$N)R] which measure 2.082(4) or 2.089(7) Å (R = Cl or CH(PPh$_2$)$_2$, respectively) [57]. These distances are also shorter than those in the divalent binhapthoxide complex

(*R*)-[Ge{$O_2C_{20}H_{10}(SiMe_2Ph)_2$-3, 3′}{$NH_3$}] (*d* Ge–N = 2.093(4) Å) which contains a coordinated NH_3 molecule [51] and also in [Ge{$OCH(CF_3)_2$}$_2${NH_2Ph}] (*d* Ge–N = 2.092(3) Å) which contains a coordinated aniline molecule [58].

The three remaining oxygen atoms in **1** are each attached to a silicon atom. One of these is incorporated into a –$OSiMe_3$ silyl ether group which arises from the transfer of the –$SiMe_3$ moiety from a –$N(SiMe_3)_2$ ligand in $Ge[N(SiMe_3)_2]_2$ to the phenolic oxygen atom [48]. The geometry of the silyl ether moiety is normal with an approximate tetrahedral environment at silicon and a typical Si–O bond distance of 1.664(3) Å. The Si–O–C_{ipso} angle is 123.7(2)° and the –$SiMe_3$ group is directed outward from the central cavity of the molecule. The other two oxygen atoms have been incorporated into unusual –$OSi(H)(NH_2)_2$ groups. The silicon atoms in both groups are disordered over two positions (50% occupancy) which also results in each of the nitrogen atoms of the four attached –NH_2 groups also being disordered over two positions. The four nitrogen atoms were also disordered with very small positional differences over the two individual positions, and these were refined with a broad thermal parameter which resulted in the large ellipsoids present in the ORTEP plot of **1** (Fig. 1).

The Si–N bond distances (when taking into consideration the distortion of the silicon atoms) are 1.816(8), 1.715(8), 1.700(8), and 1.806(9) Å while, the N–Si–N angles are 122.8(5) and 119.6(4)° at Si(2) and Si(3), respectively. Diaminosilyl ether groups similar to those attached to O(4) and O(5) in **1** have not been described previously and thus a direct comparison to other structurally characterized species is not possible. However, a few small molecules containing –NH_2 groups bound to silicon and having –NH_2 and –OH groups attached to the same silicon atom have been reported [59,60]. The structure of $Mes_2Si(NH_2)_2$ has Si–N distances of 1.713(2) and 1.717(2) Å and a N–Si–N angle of 106.89(5)° [59] while that of $Bu^t_2Si(OH)NH_2$ exhibits a Si–N distance of 1.746(4) Å [60].

The average of the four Si–N distances is 1.759(8) Å in **1** which is longer than the corresponding bond distance in $Bu^t_2Si(OH)NH_2$ [60] and can be attributed to the attachment of the –$Si(H)(NH_2)_2$ moieties in **1** to a phenolic oxygen atom. The two N–Si–N angles in **1** average 121.2(5)° which is significantly more obtuse than the N–Si–N angle in $Mes_2Si(NH_2)_2$ [59]. This structural difference is expected since the latter compound contains two sterically encumbering mesityl groups, while compound **1** instead has a proton and an oxygen atom bound to silicon.

2.2. NMR spectra of compound *1*

Spectroscopic (^{1}H, ^{13}C and ^{29}Si NMR) data in benzene-d_6 are consistent with the solid-state structure of **1**. Similar to compounds **2** and **3**, the conformational flexibility of **1** is restricted versus the calix[6]arene starting material due to the presence of the Ge_2NO rhombus and the relatively large –$OSiMe_3$ and –$OSi(H)(NH_2)_2$ groups. This renders the individual protons of the six methylene units in **1** magnetically non-equivalent, resulting in twelve distinct doublets in the ^{1}H NMR spectrum in the chemical shift range δ 3.1–4.8 ppm which are divided into two sets of six features. The downfield grouping of resonances correspond to the methylene protons directed inward toward the Ge_2NO rhombus while the upfield features are attributed to those directed away.

In the downfield grouping of resonances, the doublet at δ 4.74 (J = 13.2 Hz) ppm is assigned to the proton attached to C(5) which has two close contacts with O(2) and O(3) measuring 2.498 and 2.549 Å (respectively). The two sets of closely grouped doublets at δ 4.66 (J = 14.7 Hz) and 4.64 (J = 12.6 Hz) ppm correspond to the protons bound to C(4) and C(3) (respectively) due to their relative proximity to O(3) and O(1), and the features at δ 4.53 (J = 16.2 Hz) and 4.51 (J = 11.7 Hz) ppm are assigned to the protons attached to C(6) and C(2) (respectively) due to their proximity to the silylated oxygen atoms O(4) and O(5). The remaining doublet at δ 4.34 (J = 13.5 Hz) ppm arises from the proton attached to C(1) which only has long (>2.6 Å) contacts with the neighboring oxygen atoms.

Assignments for the upfield group of six resonances are based on a COSY NMR experiment. The doublet at δ 3.53 (J = 16.2 Hz) ppm corresponds to the second proton bound to C(6), while the four closely spaced features at δ 3.32 (J = 13.2 Hz), 3.30 (J = 14.7 Hz), 3.24 (J = 13.5 Hz), 3.23 (J = 12.6 Hz) ppm arise from the remaining protons attached to C(5), C(4), C(1) and C(3) (respectively). The resonance at δ 3.19 (J = 11.7 Hz) ppm results from the second proton bound to C(2). Due to the rigidity in the Ge_2NO rhombus, the protons in the bridging –NH_2 group also are magnetically non-equivalent, appearing as two broad but clearly resolved doublets at δ 1.66 (J = 9.6 Hz) and 1.04 (J = 9.6 Hz) ppm. The two Si–*H* protons are also non-equivalent and appear as two singlets in the ^{1}H NMR spectrum at δ 6.34 and 6.32 ppm. The –$Si(NH_2)_2$ protons appear as two upfield singlets at δ 0.27 and 0.24 ppm while the protons of the –$OSiMe_3$ moiety appear as a singlet at δ 0.42 ppm. The ^{13}C NMR spectrum of **1** also is consistent with its solid-state structure and exhibits six distinct lines for the each of non-equivalent *ipso*- and *para*-carbon atoms as well as twelve lines for both the *ortho*- and *meta*-carbons. The six methylene groups result in six features between δ 31–35 ppm and there is only one resonance in the –SiR_3 region of the spectrum at δ 1.6 ppm corresponding to the carbon atoms of the –$OSi(CH_3)_3$ group.

The ^{29}Si{^{1}H} NMR spectrum of **1** contains three singlets at δ 21.63, 21.17, and 21.07 ppm, where the downfield resonance arises from the silicon atom in the –$OSiMe_3$ group and the two upfield resonances correspond to the silicon atoms in the two –$Si(H)(NH_2)_2$ groups. The chemical shift for the silyl ether feature is similar to that of $C_6H_5OSiMe_3$ which appears at δ 19.43 ppm [61]. The proton-coupled ^{29}Si NMR spectrum of **1** was also recorded, and the singlet at δ 21.63 in the ^{1}H-decoupled spectrum splits into a multiplet with eight of the ten expected lines being clearly discernable. This arises from the two-bond coupling between the silicon atom and the protons of the methyl groups, with a coupling constant of 6.43 Hz. The two features for the –$Si(H)(NH_2)_2$ groups are more complex due to the presence of both one-bond Si–*H* and three bond Si–NH_2 coupling. Each of these features are expected to appear as a doublet of quintets but their proximity resulted in overlap with one another such that the expected one-bond Si–H coupling could not be clearly observed.

2.3. Analysis of compound *1* using mass spectrometry

The mass spectrum of compound **1** acquired using electrospray mass spectrometry (positive ion mode) exhibited a clear fragmentation pattern having nine well-defined peaks which are listed in Table 2. The proposed fragmentation pattern is illustrated in

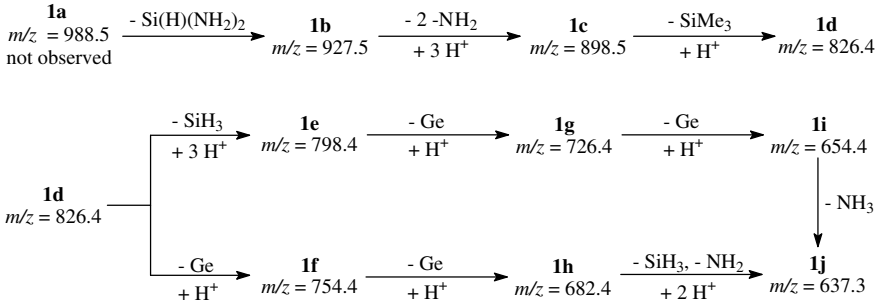
Table 2
Electrospray mass spectrometry data for compound **1**

Ion	*m*/*z*	Formula	Relative intensity (%)
1a	988.5	$[(C_6H_3)_6(CH_2)_6O_3Ge_2(NH_2)\{OSi(H)(NH_2)_2\}_2OSiMe_3]H^+$	n/a
1b	927.5	$[(C_6H_3)_6(CH_2)_6O_3Ge_2(NH_2)OSi(H)(NH_2)_2OSiMe_3O]H^+$	2
1c	898.5	$[(C_6H_3)_6(CH_2)_6O_3Ge_2(NH_2)OSiH_3OSiMe_3OH]H^+$	29
1d	826.4	$[(C_6H_3)_6(CH_2)_6O_3Ge_2(NH_2)OSiH_3(OH)_2]H^+$	72
1e	798.4	$[(C_6H_3)_6(CH_2)_6O_2Ge_2(NH_3)(OH)_4]H^+$	100
1f	754.4	$[(C_6H_3)_6(CH_2)_6O_2Ge(NH_2)OSiH_3(OH)_3]H^+$	8
1g	726.4	$[(C_6H_3)_6(CH_2)_6OGe(NH_3)(OH)_5]H^+$	12
1h	682.4	$[(C_6H_3)_6(CH_2)_6O(NH_2)OSiH_3(OH)_4]H^+$	16
1i	654.4	$[(C_6H_3)_6(CH_2)_6(NH_3)(OH)_6]H^+$	28
1j	637.3	$[(C_6H_3)_6(CH_2)_6(OH)_6]H^+$	4

Scheme 1. Although the parent molecular ion at m/z = 988.5 was not observed a feature at m/z = 927.5 corresponding to the loss of one –SiH$(NH_2)_2$ fragment and monoprotonation of the remaining molecule was present in the spectrum. Subsequent fragmentations involve the loss of the –$SiMe_3$ group, the two germanium atoms, the oxygen atoms, and the bridging –NH_2– group. The –O and –NH_2 groups to which these fragments were bound appear to be protonated during the course of this process to yield –OH or NH_3 groups (respectively). Ultimately, all of the substituents in compound **1** undergo fragmentation to produce the parent calix[6]arene in protonated form.

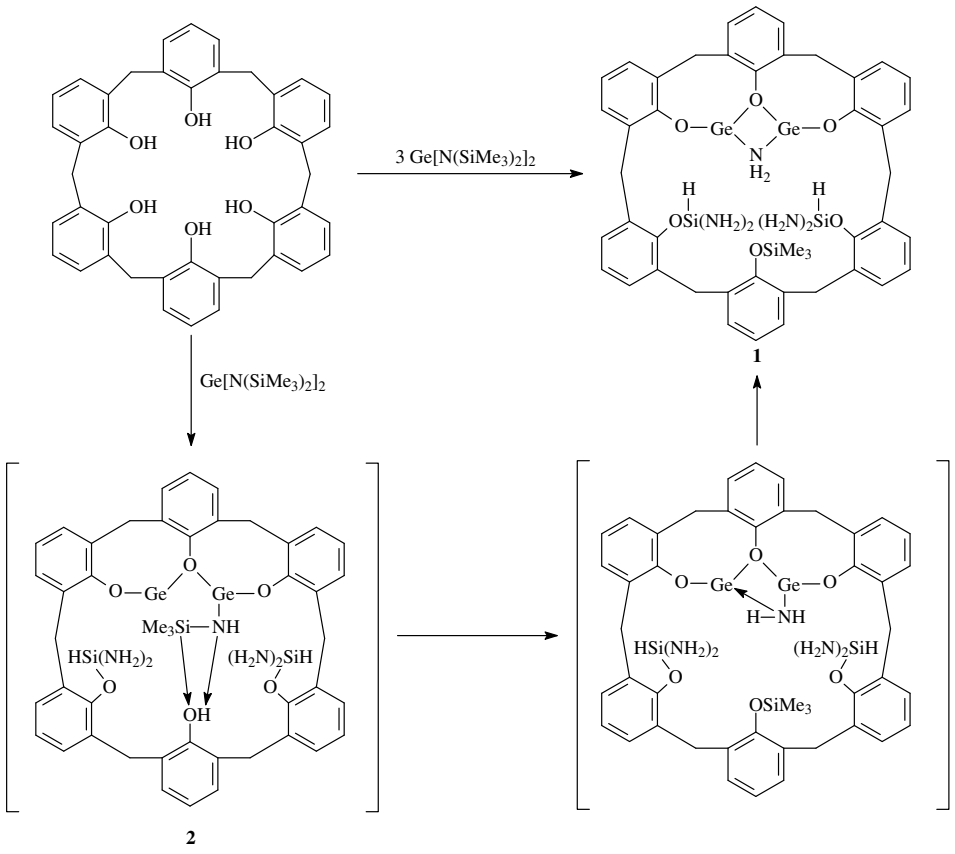
2.4. Pathway for the formation of compound *1*

The pathway for the formation of **1** is likely complex, but two key aspects for the generation of this species are evident. First, compound **1** contains twelve protons distributed among the single bridging –NH_2– and the two –Si(H)$(NH_2)_2$ groups. Since calix[6]arene is the only proton source present in the reaction, all of these must originate from this starting material. Furthermore, 2 equiv. of calix[6]arene must be consumed for every one equiv. of **1** generated in the reaction since calix[6]arene contains only six phenolic protons. This dictates a maximum theoretical yield of 50% for **1** with the concomitant formation of one or more other products, and this postulate is further supported by the complete consumption of calix[6]arene in the reaction. Compound **1** has been isolated in a maximum of 41% during the course of these studies.



Second, the –N$(SiMe_3)_2$ ligands of Ge[N$(SiMe_3)_2]_2$ are the source of both the bridging –NH_2– group and the –Si(H)$(NH_2)_2$ groups in **1**. We have recently demonstrated that Ge[N$(SiMe_3)_2]_2$ reacts with binaphthols via formation of an intermediate bearing a –OGe[N$(SiMe_3)_2$] moiety which subsequently transfers a –$SiMe_3$ fragment to the oxygen atom of one –OH substituent of the binaphthol [48]. This results in generation of a –OGe[NH$(SiMe_3)$] group and this process can occur a second time to yield a –OGe[NH_2] moiety which could then serve as the source of the bridging amide in **1**. The –Si(H)$(NH_2)_2$ groups, however, must ultimately result from the demethylation of a –$SiMe_3$ group during the course of the reaction. The transfer of a methyl group to gallium in the reaction of $GaCl_3$ with Li[N$(SiMe_3)_2$] has been reported [62], and similar methyl group migrations have been found upon treatment of $GaCl_3$ with N$(SiMe_3)_3$ [63] or $SiMe_4$ [64]. The germanium atoms present in **1** clearly are not methylated, but the generation of Me_4Ge or CH_4 might be expected to occur during the course of this reaction.

In order to probe the pathway for the formation of **1**, the progress of the reaction of one, two and three equivalents of Ge[N$(SiMe_3)_2]_2$ with calix[6]arene was monitored over time using ^{1}H NMR spectroscopy in benzene-d_6 in three separate experiments. The methylene (δ 5.2–3.0 ppm) and alkylsilyl (δ 0.4–0.0 ppm) regions of these spectra contained diagnostic features which were compared over a reaction period of 120 h in each case. Upon treatment of calix[6]arene with 3 equiv. of Ge[N$(SiMe_3)_2]_2$, a resonance for the formation of free HN$(SiMe_3)_2$ at δ 0.09 ppm was observed after 10 min at room temperature and Ge[N$(SiMe_3)_2]_2$ and a trace amount of calix[6]arene were still present in solution. After heating the sample at 85 °C for 1 h, the aromatic and methylene regions of the spectrum were complex but the appearance of peaks at δ 0.42, 0.29 and 0.25 ppm indicated that compound **1** was already present in solution. The absence of a resonance at δ 10.50 ppm attributable to the six phenolic protons also indicated all of the calix[6]arene had been consumed at this time.



After heating the sample at 85 °C for a total of 6 h, the overall appearance of the spectrum had simplified and suggested that compound **1** was present in solution along with a second intermediate species. The methylene region of the spectrum contained 24 doublets divided into an upfield and downfield grouping of 12 features. Some overlap of these resonances was observed but four distinct peaks at δ 5.08 (J = 15.0 Hz), 4.43 (J = 13.5 Hz), 3.15 (J = 12.3 Hz), and 3.13 (J = 12.9 Hz) ppm were visible, which clearly are not attributable to **1** but arise from a second compound present in solution. Similarly, two additional peaks at δ 0.36 and 0.30 ppm in the alkylsilyl region were observed at this time as were two additional downfield singlets at δ 6.32 and 6.30 ppm arising from Si–*H* protons.

The presence of the four features at δ 6.32, 6.30, 0.36 and 0.30 ppm along with the structural rigidity apparent in the intermediate species suggest that all or part of the Ge_2NO rhombus and the two –Si(H)$(NH_2)_2$ groups are generated prior to silylation of the remaining hydroxyl group to generate the silyl ether moiety. Further evidence for this results from the presence of a broad singlet at δ 5.92 ppm which suggests the presence of a single hydroxyl group in the intermediate species. Similar ^{1}H NMR –OH features were observed for the main group calixarenes {(OH)(calix[4]arene)P} (δ 5.4 ppm) [20], {(OH)(*p*-*tert*-butylcalix[4]arene)Si} (δ 4.59 ppm) [21], {(OH)(calix[4]arene)As} (δ 4.90 ppm) [19], and {(OH)(*p*-*tert*-butylcalix[4]arene)As} (δ 4.74 ppm) [19], all of which have a single unbound –OH group and three oxygen atoms bound to the main group element. The resonance at δ 5.92 ppm had significantly reduced in intensity after heating the sample for a total of 48 h, as had the two features at δ 6.32 and 6.30 ppm and the upfield peaks at δ 0.36 and 0.30 ppm. We therefore postulate that the structure of the intermediate detected by ^{1}H NMR spectroscopy is that of **2** illustrated in Scheme 2, which undergoes an exchange of the –$SiMe_3$ group attached to the nitrogen with the remaining hydroxyl proton followed by closure of the Ge_2NO rhombus.

After heating the sample for an additional 12 h resonances corresponding only to **1**, free HN$(SiMe_3)_2$, and unreacted Ge[N$(SiMe_3)_2]_2$ remained. The appearance of the spectrum remained unchanged with up to 120 h of heating at 85 °C. Nearly identical results were obtained when calix[6]arene was treated with 2 equiv. of Ge[N$(SiMe_3)_2]_2$ under the same reaction conditions except that Ge[N$(SiMe_3)_2]_2$ was absent after the reaction had gone

Scheme 1.

Scheme 2.

to completion. The outcome of this process is consistent with the overall reaction stoichiometry since two germanium atoms are present in the framework of **1**. The ^{1}H NMR spectra of the reaction of calix[6]arene with 1 equiv. of Ge[N(SiMe$_3$)$_2$]$_2$ in benzene-d_6 indicated the formation of a complex mixture of species which included **1** and the intermediate **2** which remained present in solution even after heating the reaction mixture for 120 h.

In the course of these studies, no conclusive evidence for the formation of Me_4Ge or CH_4 was found which exhibit similar ^{1}H NMR resonances at δ 0.14 and 0.15 ppm in benzene-d_6. However, identification of calix[6]arene as the source of all of the protons in the two –Si(H)(NH$_2$)$_2$ groups and in the bridging –NH$_2$– group was confirmed by the reaction of three equiv. of Ge[N(SiMe$_3$)$_2$]$_2$ with calix[6]arene-d_6 which contained six deuterated hydroxyl groups. The ^{1}H NMR spectrum of the resulting product contained only a single line at δ 0.42 ppm arising from the –OSiMe$_3$ moiety as well as a feature corresponding to unreacted germanium amide.

3. Conclusions

In conclusion, the reactivity of calix[6]arene with Ge[N(SiMe$_3$)$_2$]$_2$ differs considerably from that found in reactions involving calix[4]arene and calix[8]arene. Instead of forming complexes containing Ge_2O_2 rhombi, the germanium calix[6]arene complex **1** contains a central Ge_2NO rhombus incorporating three of the six oxygen atoms of the macrocycle. The remaining three oxygen atoms have been converted to two –OSi(H)(NH$_2$)$_2$ moieties and one –OSiMe$_3$ group. The pathway for the formation of **1** is likely complex, but involves the consumption of two equivalents of calix[6]arene for each equivalent of **1** produced in the reaction.

4. Experimental

All manipulations were carried out using standard Schlenk, syringe, and glovebox techniques [65]. Calix[6]arene was purchased from Alfa Aesar and Ge[N(SiMe$_3$)$_2$]$_2$ was synthesized according to the published procedure [66–68]. Solvents were dried using a Glass Contour Solvent Purification System. One and two-dimensional ^{1}H NMR spectra were recorded at 400 MHz on a Varian Unity INOVA 400 spectrometer and referenced to residual protio solvent. For the ^{1}H NMR assignments in **1**, the numbering scheme of the carbon atoms corresponds to the crystal structure of **1**, *i.e.* –C(5)H_2– refers to a proton bound to C(5). ^{13}C NMR spectra were recorded at a frequency of 100.6 MHz on a Varian Unity INOVA 400 and referenced to the solvent while ^{29}Si NMR were acquired using a Varian Unity INOVA 600 operating at 119.2 MHz and were referenced to external $SiMe_4$. Mass spectra were acquired using a Bruker Agilent 1100 LC/MSD System in acetonitrile solvent. Elemental analysis was performed by Midwest Microlab, LLC (Indianapolis, IN).

4.1. Synthesis of compound *1*

To a solution of calix[6]arene (0.458 g, 0.719 mmol) in benzene (10 mL) was added a solution of Ge[N(SiMe$_3$)$_2$]$_2$ (0.852 g, 2.17 mmol) in benzene (4 mL). The mixture was sealed in a Schlenk tube and heated at 85 °C for 72 h. The solvent was removed *in vacuo* to yield a white solid which was recrystallized from hot benzene (5 mL) to yield **1** as colorless crystals which were washed with hexane (3 × 5 mL) and dried *in vacuo*. Yield: 0.292 g (41%). ^{1}H NMR (C_6D_6, 25 °C): δ 7.29–6.75 (m, 18H, aromatics), 6.34 (s, 1H, –Si(*H*)(NH$_2$)$_2$), 6.32 (s, 1H, –Si(*H*)(NH$_2$)$_2$), 4.74 (d, J = 13.2 Hz, 1H –C(5)H_2–), 4.66 (d, J = 14.7 Hz, 1H, –C(4)H_2–), 4.64 (d, J = 12.6 Hz, 1H, –C(3)H_2-), 4.53 (d, J = 16.2 Hz, 1H, –C(6)H_2–), 4.51

(d, J = 11.7 Hz, 1H, –C(2)H_2–), 4.34 (d, J = 13.5 Hz, 1H, –C(1)H_2–), 3.53 (d, J = 16.2 Hz, 1H, –C(6)H_2-), 3.32 (d, J = 13.2 Hz, 1H, –C(5)H_2–), 3.30 (d, J = 14.7 Hz, 1H, –C(4)H_2–), 3.24 (d, J = 13.5 Hz, 1H, –C(1)H_2-), 3.23 (d, J = 12.6 Hz, 1H, –C(3)H_2–), 3.19 (d, J = 11.7 Hz, 1H, -C(2)H_2–), 1.66 (br d, J = 9.6 Hz, 1H, –NH_2–), 1.04 (br d, J = 9.6 Hz, 1H, –NH_2–), 0.42 (s, 9H, –OSi(CH_3)$_3$), 0.27 (s, 4H, –Si(H)(NH_2)$_2$), 0.24 (s, 4H, –Si(H)(NH_2)$_2$) ppm. ^{13}C NMR (C_6D_6, 25 °C) δ 156.1, 154.4, 152.0, 151.6, 151.1, 150.8 (*ipso*-C), 136.8, 136.6, 136.4, 136.1, 135.9, 135.2, 134.5, 133.3, 132.8, 132.6, 132.1, 132.0 (*meta*-C), 131.0, 130.8, 130.7, 130.5, 130.4, 130.3, 129.8, 129.7, 129.4, 129.3, 129.1, 128.8 (*ortho*-C), 123.6, 122.7, 122.3, 122.2, 120.9, 120.8 (*para*-C), 34.2, 34.0, 33.9, 33.4, 33.1, 31.1 (–CH_2–), 1.6 (-OSi(CH_3)$_3$) ppm. ^{29}Si{^{1}H} NMR (C_6D_6, 25 °C): δ 21.63, 21.17, and 21.07 ppm. IR (Nujol): 3348, 3266, 3255, 2720, 2664, 2288, 1916, 1859, 1807, 1713, 1661, 1589 cm^{-1}. *Anal.* Calc. for $C_{45}H_{51}Ge_2N_5O_6Si_3$: C, 54.74; H, 5.21. Found: 54.15; H, 5.41%.

4.2. NMR scale reaction of calix[6]arene with 3 equiv. Ge[N(SiMe$_3$)$_2$]$_2$

A solution of calix[6]arene (0.050 g, 0.078 mmol) in benzene-d_6 (0.25 mL) was treated with a solution of Ge[N(SiMe$_3$)$_2$]$_2$ (0.093 g, 0.24 mmol) in benzene-d_6 (0.25 mL) in a screw-cap NMR tube.

4.3. NMR scale reaction of calix[6]arene with 2 equiv. Ge[N(SiMe$_3$)$_2$]$_2$

A solution of calix[6]arene (0.050 g, 0.078 mmol) in benzene-d_6 (0.25 mL) was treated with a solution of Ge[N(SiMe$_3$)$_2$]$_2$ (0.062 g, 0.16 mmol) in benzene-d_6 (0.25 mL) in a screw-cap NMR tube.

4.4. NMR scale reaction of calix[6]arene with 1 equiv. Ge[N(SiMe$_3$)$_2$]$_2$

A solution of calix[6]arene (0.050 g, 0.078 mmol) in benzene-d_6 (0.25 mL) was treated with a solution of Ge[N(SiMe$_3$)$_2$]$_2$ (0.031 g, 0.079 mmol) in benzene-d_6 (0.25 mL) in a screw-cap NMR tube.

4.5. Synthesis of calix[6]arene-d_6

To a solution of calix[6]arene (0.300 g, 0.471 mmol) in diethyl ether (30 mL) was added a solution of 2.5 M Bu^{n}Li in hexanes (1.51 mL, 3.78 mmol) at −78 °C. The reaction mixture was allowed to come to room temperature and was stirred for 4 h. The reaction mixture was quenched with D_2O (5 mL) at −78 °C via cannula from a sure-seal bottle. The organic layer was separated and dried over anhydrous $MgSO_4$ and the solvent was removed *in vacuo* to yield calix[6]arene-d_6 (0.221 g, 72%). The ^{1}H NMR spectrum of the product recorded in benzene-d_6 did not exhibit an –OH resonance.

4.6. NMR scale reaction of calix[6]arene-d_6 with 3 equiv. Ge[N(SiMe$_3$)$_2$]$_2$

To a solution of calix[6]arene-d_6 (0.057 g, 0.088 mmol) in benzene-d_6 (0.35 mL) was added a solution of Ge[N(SiMe$_3$)$_2$]$_2$ (0.107 g, 0.272 mmol) in benzene-d_6 (0.30 mL). The reaction mixture was heated in an oil bath for 48 h and the ^{1}H NMR spectrum was recorded.

4.7. X-ray crystal structure of 1 · 0.5(C_6H_6)

Diffraction intensity data were collected with a Siemens P4/CCD diffractometer. Absorption corrections were applied for all data by SADABS. The structures were solved using direct methods, completed by Fourier syntheses, and refined by full-matrix least squares procedures on F^2. All non-hydrogen atoms were refined with anisotropic displacement coefficients, and hydrogen atoms were treated as idealized contributions. Contributions from the benzene solvent molecule were removed using SQUEEZE. All software and sources of scattering factors are contained in the SHEXTL (5.10) program package (G. Sheldrick, Bruker XRD, Madison, WI). ORTEP diagrams were drawn using the ORTEP3 program (L.J. Farrugia, Glasgow).

Crystallographic data for **1 · 0.5(C_6H_6)**: Crystal size: 0 × 0.22 × 0.17 mm. Crystal color and habit: colorless block. Empirical formula: $C_{48}H_{54}Ge_2N_5O_6Si_3$. Formula weight: 1026.42. Wavlength: 0.71073 Å. Temperature: 100(2) K. Crystal system: triclinic. Space group: $P\bar{1}$. Unit cell dimensions: a = 13.199(2) Å, b = 14.774(2) Å; c = 16.569(4) Å; α = 105.373(4)°; β = 102.641(4)°; γ = 115.225(3)°. Volume = 2606.5(9) Å^3. Z = 2. D_{calc} = 1.309 g/cm^3. Absorption coefficient = 1.274 mm^{-1}. F(000) = 1064. θ-Range for data collection = 1.67–25.00°. Index ranges: $-14 \leqslant h \leqslant -15$; $-15 \leqslant k \leqslant 17$; $-19 \leqslant l \leqslant 19$. Reflections collected = 15 228. Independent reflections = 9124 (R_{int} = 0.0295). Completeness to θ = 99.2% (θ = 25.00°). Absorption correction = multi-scan. Refinement method = full-matrix least-squares on F^2. Data/restraints/parameters = 9124/0/584. Goodness-of-fit on F^2 = 1.014. Final R indices [$I > 2\sigma(I)$]: R_1 = 0.0581; wR_2 = 0.1414. R indices (all data): R_1 = 0.0884; wR_2 = 0.1580. Largest difference in peak and hole = 0.512 and −0.547 e Å^{-3}.

Scheme 1. The synthetic route and numbering scheme of 2,2′-dimethyl 4,4′-bithiazole (dm4bt) (**1**).

($CDCl_3$): 7.61 (s, 2H, Ar) and 2.78 (s, 6H, CH_3). ^{13}C NMR δ_C ($CDCl_3$): 166.46, 150.08, 114.52 (Ar) and 19.45(CH_3). IR (KBr, cm^{-1}): 879 (νS–C), 1184 (νC–N), 1419 (νC–C), 1496 (νC=N), 1558 (νC=C), 3103 (νC–H, Me) and 3434 (νC–H, cycle). UV–Vis (CH_3OH): λ_{max}: 3.76×10^4 cm^{-1}. *Anal.* Calc. for **1**: C, 48.90; H, 4.07; N, 14.26. Found: C, 48.71; H, 3.96; N, 14.12%.

2.3. Synthesis of [Zn(dm4bt)Cl_2] (**2**)

$ZnCl_2$ (0.040 g, 0.285 mmol) was dissolved in water (10 ml), mixed with methanol (50 ml) and reacted with 2,2′-dimethyl-4,4′-bithiazole (0.056 g, 0.285 mmol) dissolved in 10 ml of methanol. The mixture was stirred at 40 °C for 2 h, then the resulting solution was filtered and left at room temperature. After a week, it began to produce colorless crystals of **2** (yield 0.073 g, 76%). ^1H NMR δ_H (DMSO): 7.74 (s, 2H, Ar) and 2.70 (s, 6H, CH_3). IR (KBr, cm^{-1}): 600, 856, 981 (νnew), 884 (νS–C), 1219 (νC–N), 1442 (νC–C), 1532 (νC=N), 1563 (νC=C), 3097 (νC–H, Me), 3429 (νC–H, cycle). UV–Vis (DMSO): λ_{max}: 3.21×10^4 cm^{-1}. *Anal.* Calc. for **2**: C, 28.86; H, 2.40; N, 8.42. Found: C, 28.71; H, 2.34; N, 8.26%.

2.4. Synthesis of [Hg(dm4bt)Cl_2] (**3**)

$HgCl_2$ (0.070 g, 0.255 mmol) and 2,2′-dimethyl-4,4′-bithiazole (0.050 g, 0.255 mmol) were separately dissolved in methanol (10 ml) and added together slowly (without stirring). The mixture was filtered and the solution was left at room temperature. After a week, complex **3** was obtained as colorless crystals (yield 0.10 g, 84%). ^1H NMR δ_H (DMSO): 7.86 (s, 2H, Ar) and 2.73 (s, 6H, CH_3). IR (KBr, cm^{-1}): 635, 863, 967 (νnew), 883 (νS–C), 1207 (νC–N), 1426 (νC–C), 1514 (νC=N), 1634 (νC=C), 3074 (νC–H, Me), 3440 (νC–H, cycle). UV–Vis (DMSO): λ_{max}: 3.62×10^4 cm^{-1}.*Anal.* Calc. for **3**: C, 20.52; H, 1.71; N, 5.98. Found: C, 20.41; H, 1.62; N, 5.83%.

2.5. Computational details

All calculations have been carried out by using GAUSSIAN-03 software [19]. In order to obtain local minima geometries in the ground states, two different ab initio methods, HF and B3LYP [20–22] have been employed with the 6-31G* set [23]. Atom hybridisation was obtained and partitioned using the natural bond orbital (NBO) method incorporated in GAUSSIAN-03 [19]. Also this method gives aromatic interaction energies both by deletion of the off-diagonal Fock matrix elements between the interacting orbitals and from the second-order perturbation approach.

2.6. Crystal structure determination and refinement

The X-ray diffraction measurements were made on a STOE IPDS-II diffractometer with graphite monochromated Mo Kα radiation. For 2,2′-dimethyl-4,4′-bithiazole (dm4bt) (**1**), [Zn(dm4bt)Cl_2] (**2**) and [Hg(dm4bt)Cl_2] (**3**), colorless prismatic crystals with dimensions of $0.50 \times 0.20 \times 0.15$ mm, $0.40 \times 0.35 \times 0.30$ mm and $0.40 \times 0.20 \times 0.17$ mm, were, respectively, chosen and mounted on a glass fiber and used for data collection. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of diffraction data from 1060 unique reflections for **1**, 2866 for **2** and 2908 for **3**. Data were collected at a temperature of 293(2) K to a maximum 2θ value of 56.00° for **1** and 55.88° for **3** and at a temperature of 120(2) K to a maximum 2θ value of 55.86° for **2**, in a series of ω scans in 1° oscillations, and integrated using the Stoe X-AREA [24] software package. The numerical absorption coefficient, μ, for Mo Kα radiation is 0.528 mm^{-1} for **1**, 2.685 mm^{-1} for **2** and 13.220 mm^{-1} for **3**. A numerical absorption correction was applied using X-RED [25] and X-SHAPE [26] software. The data were corrected for Lorentz and Polarizing effects. The structures were solved by direct methods [27] and subsequent difference Fourier maps and then refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [28]. All of the hydrogen atoms were located in a difference Fourier map and then refined isotropically. Subsequent refinement then converged with R factors and parameters errors significantly better than for all attempts to model the solvent disorder. Atomic factors are from the International Tables for X-ray Crystallography [29]. All refinements were performed using the X-STEP32 crystallographic software package [30]. A summary of the crystal data, experimental details and refinement results is given in Table 1.

3. Results and discussion

3.1. Synthesis of compounds 1–3

2,2′-Dimethyl-4,4′-bithiazole (**1**) was synthesized according to the reported procedure [18]. Suitable crystals of **1** for X-ray diffraction study were grown by slow evaporation of a 2:1 ratio of methanol:water solution at ambient temperature over 4 weeks.

To obtain details of the electronic nature of the ligand and coordinative ability of it relative to other bithiazole and bipyridine derivatives, a DFT calculation was performed on them by using HF and B3LYP with the 6-31G* basis set. The optimized geometry and thermal ellipsoid plot of **1**, with the atomic numbering, are shown in Fig. 1. As can be seen from this figure, the considered conformation of the ligand is anti. The calculated bond distances and angels are in good agreement with the experimental values. Calculated and experimental structural parameters (distances and angles) were compared and mean differences between the experimental and calculated data obtained by the SPSS program are about 0.007 Å for bond distances and about 0.15° for bond angles, confirming the fairness of the minimal consumed time and acceptable error. An electrostatic potential calculation was performed by the HF/6-31G* method/basis set on the optimized structure obtained at the B3LYP/6-31G* method/basis set to calculate the Mulliken and ESP filling charge for 4,4′-bithiazole (4bt), 2,2′-dimethyl-4,4′-bithiazole (dm4bt) and for their bipyridine analogues, 2,2′-bipyridine (bipy) and 6,6′-dimethyl-2,2′-bipyridine (dm2bipy). Table 2 summarizes the charges of the nitrogen and sulfur atoms in bithiazole and similar compounds. As can be seen from this table, the sulfur atoms in the bithiazole ligands have a positive or very slightly negative charge and cannot act as a donor atom in coordination to metals. Nevertheless the nitrogens have a considerable negative charge and play the role of coordination as expected.

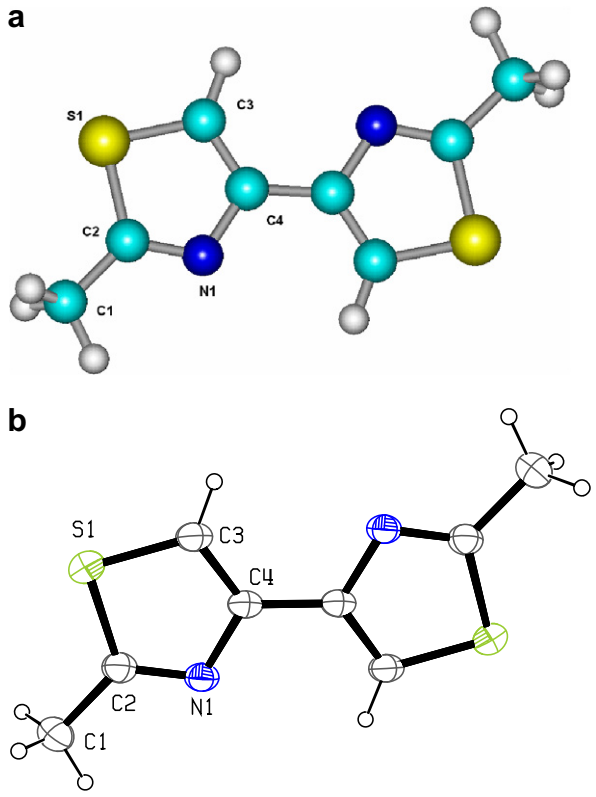

Fig. 1. (a) Optimized geometry and (b) thermal ellipsoid plot of 2,2′-dimethyl-4,4′-bithiazole (**1**) (30% probability level) showing the numbering scheme.

Table 2
Charge of nitrogen and sulfur atoms in bithiazole and similar compounds at B3LYP/6-31G*//HF/6-31G*

Compound	Nitrogen		Sulfur	
	MUL.	ESP	MUL.	ESP
dm4bt (**1**)	−0.491	−0.502	0.272	−0.081
4bt[a]	−0.441	−0.492	0.285	0.051
dm2bip[b]	−0.576	−0.695		
bipy[c]	−0.531	−0.661		

[a] 4bt is bithiazole.
[b] dm2bip is 6,6′-dimethyl-2,2′-bipyridine.
[c] bipy is 2,2′-bipyridine.

According to these calculations, the coordination ability of 4,4′-bithiazole is less than that of bipyridine, since the charge on the nitrogen is less. However, the negative charge on the nitrogens of dm4bt is a little larger than that of 4bt and is less than the charge for bipy, so we expect that dm4bt has a coordination ability close to that of bipy.

The addition of **1** in an equimolar ratio to a methanolic solution of $ZnCl_2$ after a few days, accompanied with slow evaporation of the solvent at room temperature, results in colorless crystals of **2**, Eq. (1). When $HgCl_2$ was used instead of $ZnCl_2$, the same reaction gives **3**. All efforts to prepare a 2:1 ratio of the ligand to the metals were not successful.

$$MCl_2 + \text{dm4bt} \rightarrow [M(\text{dm4bt})Cl_2] \quad \begin{matrix} M = Zn, \text{ compound } \mathbf{2} \\ M = Hg, \text{ compound } \mathbf{3} \end{matrix} \qquad (1)$$

3.2. Spectroscopic characterization

The infrared spectra for compounds **1**–**3** are presented in Table 3. They contain several bands in the region 800–3400 cm^{-1}, which are related to the hetero aromatic ring modes related to C–H, C=C, C=N, C–C, C–N and S-C [31,32]. For instance, bands observed at 1496, 1419, 1184 and 879 cm^{-1} for the free ligand are shifted to higher frequencies upon coordination and are observed at 1532, 1442, 1219 and 884 cm^{-1} in **2**. This shift to higher frequencies upon coordination to metal has been observed for bipyridine and other ligands coordinated to metals as well [33–37], and can be explained by changing the geometry of the free ligand from a syn to anti orientation in the coordinated case. The same trend was observed for compound **3**, Table 3. The IR spectra of **2** and **3** are distinguished from that of **1** mainly by the metal to ligand bands. Strong peaks at 266 and 240 cm^{-1} were assigned to the M–Cl frequencies for **2** and **3**, respectively [38,39]. The bands at 589 and 578 cm^{-1}, which are absent in **1**, can be assigned to the M–N frequencies, consistent with the other reported frequencies for similar compounds [40].

When a NBO calculation was performed on the non-coordinated dm4bt ligand, a bond order of 2 was only found for the C3–C4 and N–C2 bonds (Scheme 1). Furthermore, the C2 and C3 hybridization toward S is near to sp^3, showing a single C–S bond, Table 4.

The UV–Vis spectra of the colorless compounds lack any d–d transitions in the visible region, as expected, but a signal around 3.7×10^4 cm^{-1} is assigned to the π–π^* transition in the aromatic ligand. Furthermore, compounds **1**–**3** show the same ^1H NMR spectra, consisting of a singlet in the aromatic C–H region, around 7.7 ppm and another singlet at 2.7 ppm for the methyls groups. The similarity of the NMR pattern in **2** and **3** confirms the similarity of their structures in solution.

3.3. Description of the molecular structures

Compounds **1**, **2** and **3** crystallize in the space groups $P2_1/a$, $P2_1/n$ and $P2_1/c$, respectively, which belong to the monoclinic system.

Table 3
Selected IR frequencies of compounds **1**–**3** (cm^{-1})

Compound	ν(C–H) cycle	ν(C–H) Me	ν(c=c)	ν(C2=N)	ν(C4–C5)	ν(C4–N)	ν(S–C)	ν(M–N)	ν(M–Cl)

ORTEP diagrams of the ligand, zinc and mercury complexes with the atom numbering scheme are presented in Figs. 1–3, respectively. Table 5 summarizes the selected structural parameters for compounds **1**–**3**.

3.3.1. Structure of 2,2′-dimethyl-4,4′-bithiazole (dm4bt) (*1*)

The asymmetric unit of **1** contains one-half of a bithiazole molecule. As it is clear from Fig. 1, the ligand, **1** has an anti configuration, while its orientation has changed to the syn configuration to chelate to the metal centers in **2** and **3**. The DFT calculation shows there is about a 32.01 kJ/mol barrier energy for the syn to anti rotation, as is shown in the diagram of energy versus the torsion angle for (dm4bt), Fig. 4. The conversion of the anti orientation to the syn orientation is endothermic (22.83 kJ/mol), and this is compensated by the M–N bond formation in the complexes.

In compound **1**, the thiazole rings (N1/S1/C2–C4) are, of course, planar and according to the inversion point between C4 and C4′ for production of the molecule from the asymmetric unit, that it is a half of the molecule, the dihedral angle between them is 0°. The bond lengths and angles are within the normal ranges. As it is shown in Fig. 5, in compound **1** the bithiazole rings form π bonding stacks in which each thiazole ring of bithiazole lies between two thiazole rings of an adjacent molecule. The close contact distance between adjacent aromatic rings is 3.63(3) Å and it seems that this π–π stacking is effective in the packing formation.

3.3.2. Structure of [Zn(dm4bt)Cl_2] (*2*)

The Zn environment in complex **2** consists of two chloride ions and a bithiazole ligand which is coordinated to the Zn in a bidentate fashion via the nitrogen atoms. The geometry around the Zn atom is distorted tetrahedral. The different bond distances of Zn–N and Zn–Cl, accompanied with the small bite angle of 4,4′-dimethyl-2,2′-bithiazole (80.8° for N1–Zn–N2) and the compensated large angles of N1–Zn–Cl2 and N2–Zn–Cl2, which are 119.5° and 115.7° respectively, are the main factors accounting for this distortion. Most of the bithiazole derivative complexes with Zn found in the literature have six coordinate octahedral environments [41–43], although some tetrahedral complexes were found [32,44]. The Zn–N and Zn–Cl average bond distances are 2.07 and 2.20 Å. These bond distances are 0.5–1 Å smaller than the distances found in the analogous six-coordinated complexes, and are in the range of [Zn(bipy)Cl_2] bond distances [45]. This observation confirms that the donor ability of the 2,2′-dimethyl-4,4′-bithiazole ligand

[a] Structural amount for optimized dm4bt (**1**) at the B3LYP/6–31G* method/basis set.

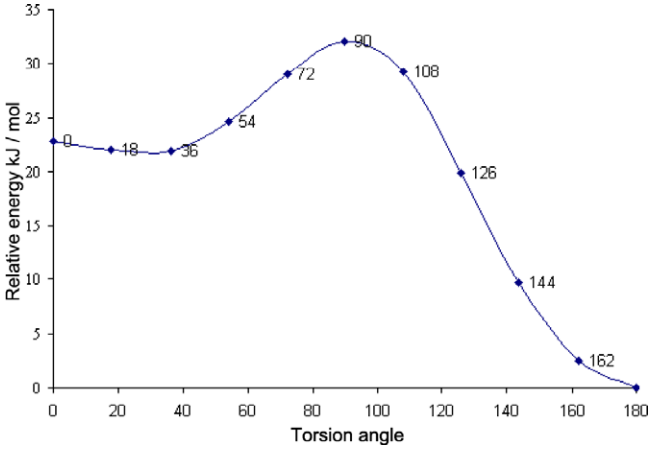

Fig. 4. Comparison of the relative torsion energies for dm4bt (**1**) at the B3LYP/6-31G* level.

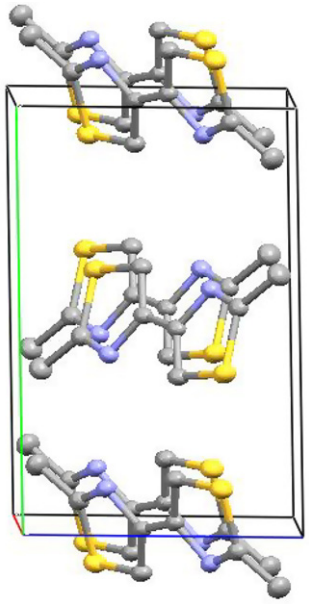

Fig. 5. Crystal packing diagram for compound **1**. Hydrogen atoms are omitted for clarity.

is the same as bipyridine, as is obvious from the charge calculation by the DFT method, Table 2.

No considerable change was observed in the ligand bond distances before and after coordination to the metal in **2**. The two thiazole rings are in the same plane in **1** with a dihedral angle of 0°, and this changes to 1.87° in the Zn complex. The dihedral angles vary from 2° to 14° in the literature for other reported Zn bithiazole derivatives. This small dihedral angle of 1.87° in **2** is in accord with the angle found in the six-coordinated 2,2′-diamine-4,4′-bithiazole complexes of Zn [41–43].

As can be seen from the packing diagram of complex **2**, Fig. 6, the closest distance between two adjacent bithiazole ring planes is 3.60(4) Å, which shows π–π stacking. There are also some C–H···Cl [H3···Cl1^{i} = 2.841(1), C3···Cl^{i} = 3.360(4) Å and C3–H3···Cl1^{i} = 115.9(2)°; H6···Cl2^{ii} = 2.919(1), C6···Cl2^{ii} = 3.663(3) Å and C6–H6···Cl2^{ii} = 137.9(2)°] short contacts [symmetry codes: (i) $x-1/2$, $-y+1/2+1$, $+z+1/2$ and (ii) $x-1$,$+y$,$+z$]. These π–π stacking and short contacts seem to be effective factors in the stabilization of the crystal structure.

3.3.3. Structure of [Hg(dm4bt)Cl$_2$] (**3**)

Fig. 3 illustrates the crystal structure of compound **3**. This compound has a highly distorted tetrahedral structure with four different bond distances and bond angles. The variations in bond angles are significant, from 71° to 133°, as is evident from Table 5. The bite angle for N1–Hg–N2 is 70.8(2)° and it is 10° smaller than the bite angle in the Zn complex **2**, 80.8(1)°. The smaller bite angle is dictated by the larger metal to ligand bond distances with Hg relative to Zn (2.40 Å relative to 2.06 Å).

The Hg–N and Hg–Cl distances are in the range 2.374(4)–2.457(2) Å, with almost the same range for Hg–N as Hg–Cl. This is in contrast to the Zn complex in which Zn–Cl is around 0.23 Å larger than Zn–N. However, the bond distances observed are in the ranges reported for analogous structures [31,45–47]. Many structures of four coordinated Hg have been found in which chloride acts as a bridging ligand [46–49]. In these structures the terminal Hg–Cl bond distances are in the range 2.29 (in $HgCl_2$) to

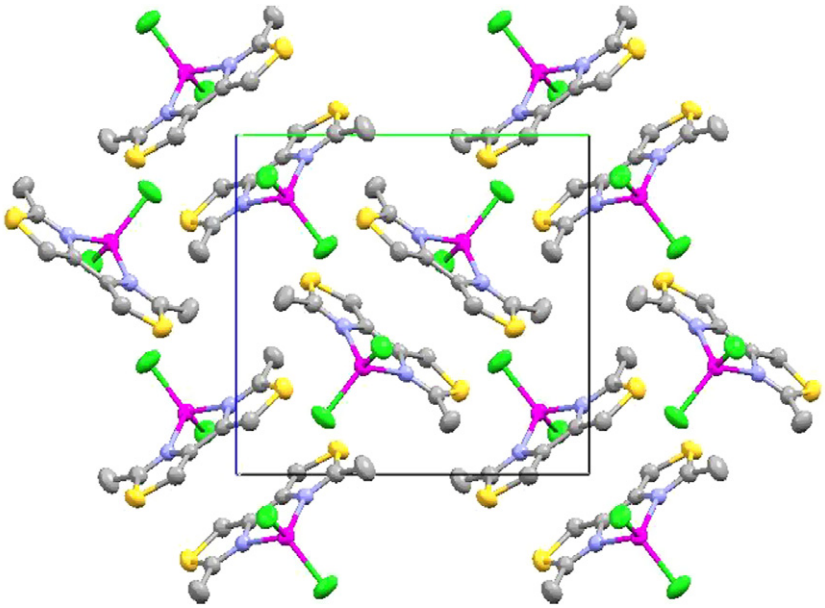

Fig. 6. Crystal packing diagram for complex **2** in the *a*-direction. Hydrogen atoms are omitted for clarity.

2.43 Å and bridge chloride ligands are in the range 2.42–2.96 Å. The bond distances of 2.394(2) and 2.457(2) Å in **3** are in accord with terminal bond coordination. A crystal packing diagram image for compound **3** is presented in Fig. 7. It is evident from this packing diagram that one of the chloride ligands is positioned towards the Hg from another neighboring molecule, and the distance of Hg–Cl'_1 is 3.098(6) Å. This distance is a little larger than the bond distance observed for bridging Hg···Cl–Hg. Therefore, we conclude that there is a semi-bridging interaction between this chloride and the neighboring Hg atom. This kind of interaction has shown itself in the difference of the Hg–Cl bond lengths which are 2.394(2) and 2.457(2) Å. The chloride which is towards Hg has a longer bond distance due to transfer of electron density to Hg. So there is a tendency to form a five coordinated structure, as shown in Fig. 4a. Other scientists observed the same interaction between Hg and chloride and they interpreted it as bridged five coordinated Hg complexes, although there is a significant difference between the two bridge bonds (around 0.65 Å) and one of the bridge bonds has a bond distance that is closer to terminal. So we believe that a better explanation is to look at this bond as a semi-bridging bond instead of as a bridging one. However, the Hg–Cl bond of the length 3.42 Å was reported as a bridging one [50] despite this length being longer than the sum of the Hg and Cl atomic distances, and a semi-bridging expression may be more suitable.

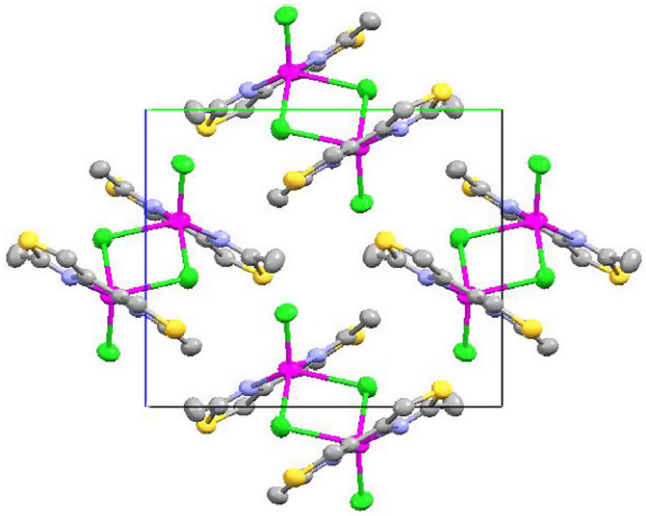

Fig. 7. Crystal packing diagram for complex **3** in the *a*-direction. Hydrogen atoms are omitted for clarity.

The spectroscopic data obtained for the Zn and Hg complexes **2** and **3** are very similar and show that in solution both complexes are monomers.

In complex **3** there are no π–π aromatic interactions between the thiazole rings, Fig. 7, but there are many kinds of C–H···N [H1b···N2 = 2.953(4), C1···N2 = 3.811(10) Å and C1–H1b···N2 = 149.5(5)°, symmetry code: $x,-y+1/2,+z+1/2$], C–H···Cl [H1a···$Cl2^{i}$ = 2.952(2), C1···$Cl2^{i}$ = 3.852(8) Å and C1–H1a···$Cl2^{i}$ = 156.7(5)°, H1b···$Cl2^{ii}$ = 2.991(2), C1···$Cl2^{ii}$ = 3.589(9) Å and C1–H1b···$Cl2^{ii}$ = 121.6(5)°, H3···$Cl1^{iii}$ = 2.839(2), C3···$Cl1^{iii}$ = 3.754(5) Å and C3–H3···$Cl1^{iii}$ = 168.2(3)° and H8b···$Cl1^{iv}$ = 2.748(2), C8···$Cl1^{iv}$ = 3.612(7) Å and C8–H8b···$Cl1^{iv}$ = 150.0(4)°, symmetry codes: (i) $-x+1,+y+1/2,-z+1/2$, (ii) $x,-y+1/2,+z+1/2$, (iii) $x+1,+y,+z$ and (iv) $-x+1,-y,-z+1$] and C–H···S [H8c···S2 = 2.790(2), C8···S2 = 2.819(6) Å and C8–H8c···S2 = 81.9(4)°, symmetry code: x,y,z] short contacts that are effective in stabilizing the lattice.

sodium silicate solution ($d = 1.35$) instead of Na_2SiO_3. Infrared spectra were recorded in KBr plates on a Thermo Nicolet FT-IR model Nexus-670 and NMR spectra were recorded on a BRX-500 AVANCE spectrometer. The resonance frequency is 125.75 and 99.36 MHz for ^{13}C and ^{29}Si, respectively. The chemical shifts are given with respect to chloroform for ^{13}C NMR spectra and TMS for ^{29}Si NMR spectra as an external standard.

Thermogravimetric Analysis (TGA) and Differential Scanning Calorimetric were carried out using a PL-1500 TGA and NETZSCH DSC 200 F3 apparatus, respectively. The electronic spectra were recorded on a Varian, CARY 1E UV–Vis spectrophotometer. ICP was used for the elemental analysis of yttrium, ytterbium, tungsten and silicon, whereas flame photometry was used for the elemental analysis of sodium and potassium. TGA was used for the analysis of carbon.

Strongly acidic (Dowex HCR-W2 H^+ form) and basic (Amberjet 4200 Cl^- form) resins packed into a column (20 cm length; 1 cm diameter) were used for ion exchange chromatography studies. For acidification, solutions of the complexes were eluted through the acidic form of the cationic resin column. For cation exchange, first 1 M NaOH or KOH was eluted through the acidic form of the cationic resin followed by distilled water and then the solutions of the complexes were eluted through it. For anion exchange, solutions of the complexes were eluted through the anion exchange resin column. The eluants were collected and studied by IR spectroscopy after solvent evaporation.

2.2. Preparation of complexes

2.2.1. $Na_{13}[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YOH_2)_3CO_3] \cdot 27H_2O$ (**1**)

A 0.45 g (1.5 mmol) sample of $YCl_3 \cdot 6H_2O$ was dissolved in 20 mL of twice distilled water, and 2 mL of 1 M Na_2CO_3 was slowly added to the solution with stirring. Solid $Na_9H[A\text{-}\beta\text{-}SiW_9O_{34}] \cdot xH_2O$ (3.00 g, 1.0 mmol) was quickly added with vigorous stirring. The solution was maintained at room temperature (30 °C) for 60 min and then centrifuged for the removal of insoluble material. Solid NaCl (1.5 g) was added and the solution was cooled in an ice water bath and then filtered off. The crude product was recrystallized at least twice in hot water. Colorless crystals were obtained by slow evaporation. Yield: 1.5 g, (51%). *Anal.* Calc. for $Na_{13}[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YOH_2)_3CO_3] \cdot 27H_2O$ (**1**): C, 0.21; Na, 5.32; Si, 1.00; W, 58.89; Y, 4.75; H_2O, 9.60. Found: C, 0.19; Na, 5.28; Si, 0.95; W, 58.00; Y, 4.84; H_2O, 9.66%.

2.2.2. $K_{11}Na_2[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YOH_2)_3CO_3] \cdot 18H_2O$ (**2**)

The procedure for **1** was repeated, but using KCl (0.57 g) instead of NaCl. Yield: 2.0 g (66.6%). Single crystals suitable for X-ray crystallography were obtained from the second recrystallization at 5 °C by slow evaporation.

Anal. Calc. for $K_{11}Na_2[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YOH_2)_3CO_3] \cdot 18H_2O$ (**2**): C, 0.21; K, 7.56; Na, 0.81; Si, 0.98; W, 58.18; Y, 4.69; H_2O, 6.64. Found: C, 0.19; K, 6.64; Na, 0.75; Si, 0.95; W, 57.51; Y, 4.70; H_2O, 6.46%.

2.2.3. $Na_{13}[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YbOH_2)_3CO_3] \cdot 32H_2O$ (**3**)

The procedure for **1** was repeated, but using $YbCl_3 \cdot 6H_2O$ (0.57 g) instead of $YCl_3 \cdot 6H_2O$. Yield: 1.5 g (48%). *Anal.* Calc. for $Na_{13}[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YbOH_2)_3CO_3] \cdot 32H_2O$: C, 0.20; Na, 5.02; Si, 0.94; W, 55.51; Yb, 8.71; H_2O, 10.50. Found: C, 0.17; Na, 4.85; Si, 0.95; W, 55.10; Yb, 8.85; H_2O, 10.6%.

2.2.4. $K_{11}Na_2[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YbOH_2)_3CO_3] \cdot 20H_2O$ (**4**)

The procedure for **3** was repeated, but using KCl (0.57 g) instead of NaCl. Yield: 1.9 g (59%). *Anal.* Calc. for $K_{11}Na_2[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YbOH_2)_3CO_3] \cdot 20H_2O$: C, 0.20; K, 7.26; Na, 0.78; Si, 0.95; W, 55.88; Yb, 8.77; H_2O, 7.00. Found: C, 0.17; K, 7.04; Na, 0.70; Si, 0.90; W, 55.91; Yb, 8.97; H_2O, 6.94%.

Single crystals suitable for X-ray crystallography were obtained from the second recrystallization at 5 °C by slow evaporation.

2.3. X-ray crystallographic structure determination

Crystal data collection and refinement parameters for **4** are given in Table 1. The data were collected at 100 K on a Bruker APEX 1000 CCD area detector single crystal diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data collection, indexing and initial cell refinements were all handled using APEX2 software [19]. The final cell parameters were determined from least-squares refinement on 7336 reflections. The multi-scan method was used to carry out absorption corrections. The structure was solved using direct methods and difference maps techniques (SHELXTL, V5.1) [20]. All metal atoms were refined anisotropically. Scattering factors and anomalous dispersion corrections were taken from the International Tables for X-ray Crystallography [21]. Structure solution, refinement and generation of publication materials were performed by using SHELXTL, V5.1 software. Selected bond lengths and bonds angles of **4** are given in Table 2.

3. Result and discussion

3.1. Syntheses and stabilities

A-β-$SiW_9O_{34}^{10-}$ at room temperature reacts with MCl_3 (M = Y^{3+} and Yb^{3+}) in aqueous Na_2CO_3 solution (~0.1 M) to form **1** and **3** in medium yields, respectively. Monitoring of the reaction progress by the pH of the solution shows a decrease with addition of MCl_3 (5.5) and increase with addition of A-β-$SiW_9O_{34}^{10-}$ (8.9). The trivalent metals react with the carbonate ion to form the corresponding insoluble metal carbonate (the solution become turbid) and then A-β-$SiW_9O_{34}^{10-}$ reacts with the metal carbonate (the solution become clearer). The syntheses of the complexes require the presence of CO_3^{2-}. In order to establish the compositions of the complexes in solution, turbidity variations of the solution as a function of addition of A-β-$SiW_9O_{34}^{10-}$ were recorded. The titration

Symmetry transformations used to generate equivalent atoms: A: $-x+2, y, -z+3/2$.

results show a breakpoint at a 2:3 L:M^{3+} (L = A-β-$SiW_9O_{34}^{10-}$) ratio (see the Electronic Supplementary material). Unlike MCl_3 salt solution behavior, when solutions of the complexes are eluted through the cation exchange resin column (K^+ or Na^+ form) no retention of the complexes is observed. The IR spectrum of each individual eluant is the same as that of the eluted parent complex. On the other hand, when solutions of the complexes are loaded onto an anion-exchange column (Cl^- form) the anionic complexes are retained on the column [22]. These observations provide good evidence for inner-sphere bonding of the M^{3+} cations to A-β-$SiW_9O_{34}^{10-}$. When the complex solutions are eluted through the strongly acidic ion exchange the product is the Keggin anion, β-$SiW_{12}O_{40}^{4-}$, which is isolated as β-$H_4SiW_{12}O_{40}$ and confirmed with its IR spectrum and cyclic voltamogram (CV). This observation confirms retention of the isomeric form of lacunary A-β-$SiW_9O_{34}^{10-}$ upon complexation with these M^{3+} ions. In a second series of experiments, we repeated the above synthetic procedure with A-α-$SiW_9O_{34}^{10-}$ [17,18] instead of A-β-$SiW_9O_{34}^{10-}$. The results show that the sandwich type complexes $[(A\text{-}\alpha\text{-}SiW_9O_{34})_2(MOH_2)_3CO_3]^{13-}$ are formed. IR spectra of the isolated complexes are almost the same as those of the A-β-$SiW_9O_{34}^{10-}$ complexes. However, the α-$H_4SiW_{12}O_{40}$ is a product of strongly acidic ion exchange treatment, which suggests that the $SiW_9O_{34}^{10-}$ units in these later complexes are α-isomers. The complexes are stable under reflux in unbuffered water for a long time. Decomposition of the complexes takes place by dissolving them in 10^{-2} M HCl and NaOH. Experimental results show that the complexes are stable from pH 3 (10^{-3} M HCl) to pH 11 (10^{-3} M NaOH). These observations are unlike the A-type sandwiches based on divalent d-block metals [8–10]. Preliminary studies suggest that the divalent first-row transition-metal and early-group lanthanide, such as La^{3+}, Ce^{3+} and Pr^{3+}, A-type sandwiches do not complex carbonate. However, A-β-$SiW_9O_{34}^{10-}$ and some of the lanthanides, such as Sm^{3+}, Gd^{3+} and Eu^{3+}, do appear to form carbonate encapsulated complexes. We repeated the above synthetic procedures with NO_3^- instead of CO_3^{2-} but we could not isolation any product containing the nitrate anion. It seems that products isostructural with the carbonate containing complexes are not formed.

3.2. Structures

Single crystal analysis was carried out on **4**, which is isostructural with **2**. The complex crystallizes in the monoclinic space group *C*2/*c*, with a total number of 51 atoms in the anionic part containing 9W (W1–W9), 1Si (Si1), 2Yb (Yb1–Yb2), 36O (O1–O36), 1C (C1) and $2H_2O$ (O1W–O2W) atoms in the asymmetric unit. The structure of **4** consists of two lacunary $SiW_9O_{34}^{10-}$ Keggin moieties which are linked by an equatorial $(H_2OYbO)_3C$ belt (Fig. 1). The W–Ob–W angle and W···W separation in the W–Ob–W linkage between the rotated group (the W_3O_{13} cap) and the rest of the anion are 143.20° and 3.63 Å, respectively, which are comparable with those of the A-β-$[SiW_{12}O_{40}]^{4-}$ Keggin anion, 145° and 3.65 Å, respectively. The corresponding data for α-$[SiW_{12}O_{40}]^{4-}$ are 155° and 3.72 Å, respectively. These results show that the $SiW_9O_{34}^{10-}$ units have the same A-β structure as the precursor trilacunary anion. Two A-β-$SiW_9O_{34}^{10-}$ units in the complex are slightly distorted toward Yb1 (Si1–C1–Si1A 177.8°). As a result of this distortion: (a) the symmetry of the anion is reduced from D_{3h} [12] to a virtual C_2 symmetry, (b) the average Yb1–O bond length is slightly shorter then that of Yb2–O, while Yb2–O(1W) is somewhat shorter than Yb1–O(2W) (Table 2). The C_2 axis of the anion passes through the Yb1 atom and between the Yb2 and Yb2A atoms. The metal ions form an isosceles triangle and are fixed together by oxygen atoms of a carbonate anion lying in the center and being coplanar to the metal ions. The oxygen atoms of the carbonate anion lie on the midpoint of the side of the isosceles triangle (Fig. 2). On the basis of valance bond sum (VBS) calculations, derived by Brown and Altermatt [22,23], the oxygen atoms of the belt act as an oxide (VBS = 2.11). This is opposite to the isostructural complex $[(A\text{-}\beta\text{-}SiW_9O_{34})_2(HOZr)_3]^{11-}$ in which the Zr^{4+} ions are linked by hydroxide groups [12]. The overall coordination geometry of the Yb atoms is close to mono capped trigonal prismatic, the local 3-fold axis of the YbO_7 group lying in the equatorial plane. The trigonal prismatic geometry is achieved by the two terminal oxygens of an edge shared pair of WO_6 octahedra to each A-β-$SiW_9O_{34}^{10-}$ moiety and two oxygens from the belt. Coordination of the A-β-$[SiW_9O_{34}]^{10-}$ moiety to the Yb atom has reduced the average O···O distance between the O atoms, now bridged by a Yb atom, to 3.125 Å compared with 3.38 Å for the same unshared atoms in the free ligand. This change results largely from the bond angle change [12]. The cap is achieved by one external water ligand (OnW). The Yb–O bond lengths in the YbO_6 group and Yb–O(nW) are in the range 2.198(14)–2.436(12) Å, average 2.273(9) Å, and 2.333(13)–2.443(19) Å, average 2.370(6) Å, respectively (Table 2). The VBS values for the ytterbium, tungsten, silicon and carbon atoms are 3.02(6), 6.18(5), 3.95 and 4.40, respectively.

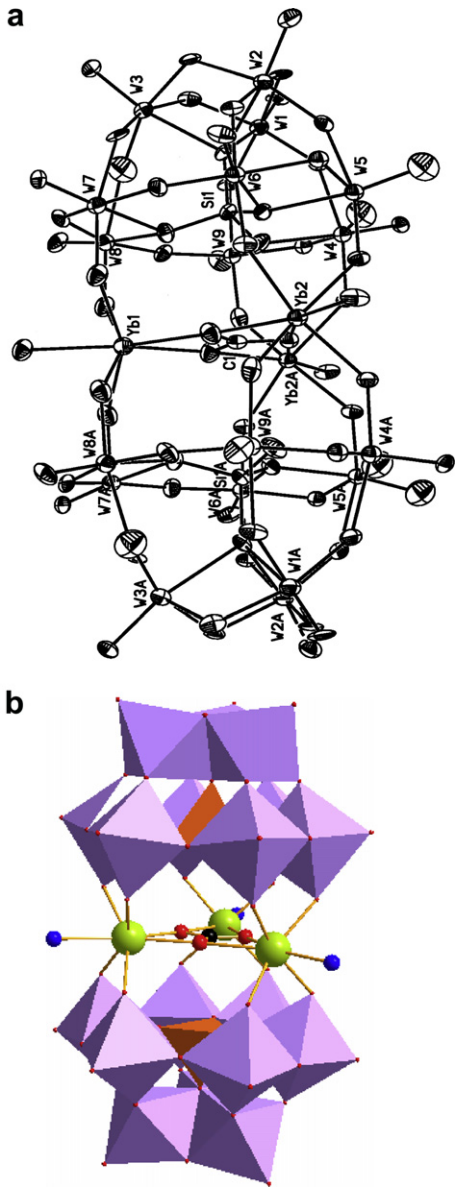

Fig. 1. (a) Structure of $[(A\text{-}\beta\text{-}SiW_9O_{34})_2(YbOH_2)_3CO_3]^{13-}$ (**4**) showing 50% probability thermal ellipsoids (b) Combination ball-and-stick/polyhedral representation of **4**. The W, Si, Yb, C, O atoms and water molecule are shown in lavender, orange, lime, black, red and blue, respectively. (For interpretation of the references in colour in this figure legend, the reader is referred to the web version of this article.)

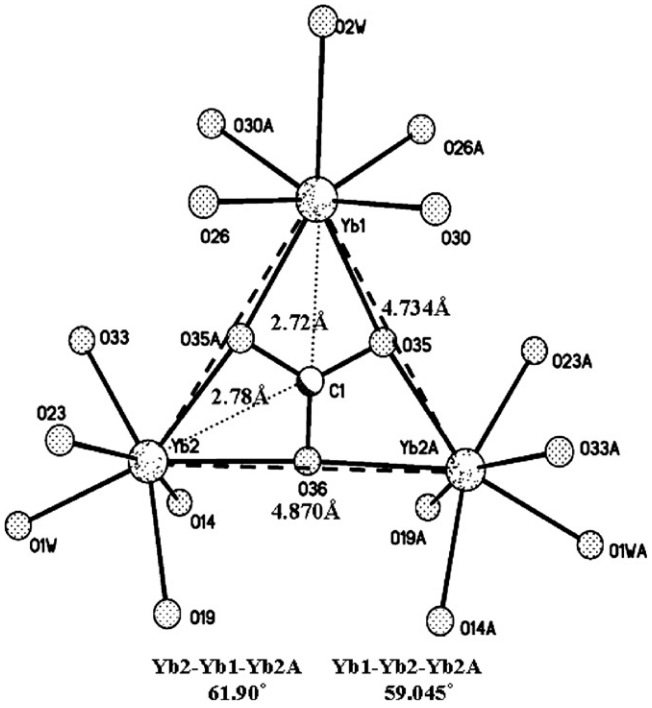

Fig. 2. SHELXP representation of the coordination spheres of the Yb atoms in **4**.

3.3. IR and NMR spectroscopy

IR spectra of **1** and **3** are similar to **2** and **4**, respectively. When comparing the IR spectra of the complexes with that of the trivacant lacunary $A\text{-}\beta\text{-}SiW_9O_{34}{}^{10}$, a shift of the stretching vibrations appearing in the 1200–700 cm^{-1} range towards higher frequencies is observed (Fig. 3). This is consistent with a decrease of the negative charge per $A\text{-}\beta\text{-}SiW_9O_{34}{}^{10-}$ moiety in the complexes. In the range 1000–700 cm^{-1}, characteristic bands were assigned to the asymmetric stretching vibrations of the bridges W–Oc–W (715–785 cm^{-1}), W–Ob–W (823 cm^{-1} and Si–Oa (885 cm^{-1}), and of the terminal bonds W–Od (950–1000 cm^{-1}) [24,25]. The IR spectra of the complexes show bands in the region 1492–1482 cm^{-1}, which were assigned to the doubly degenerate v_3 vibrational mode of $CO_3{}^{2-}$ with a small splitting of 10 cm^{-1}. This splitting is attributed to distortion of the $CO_3{}^{2-}$ group. This splitting is commonly observed in carbonate complexes [26]. The other two infrared active modes, v_2 and v_4, overlap with the W–O stretching bands.

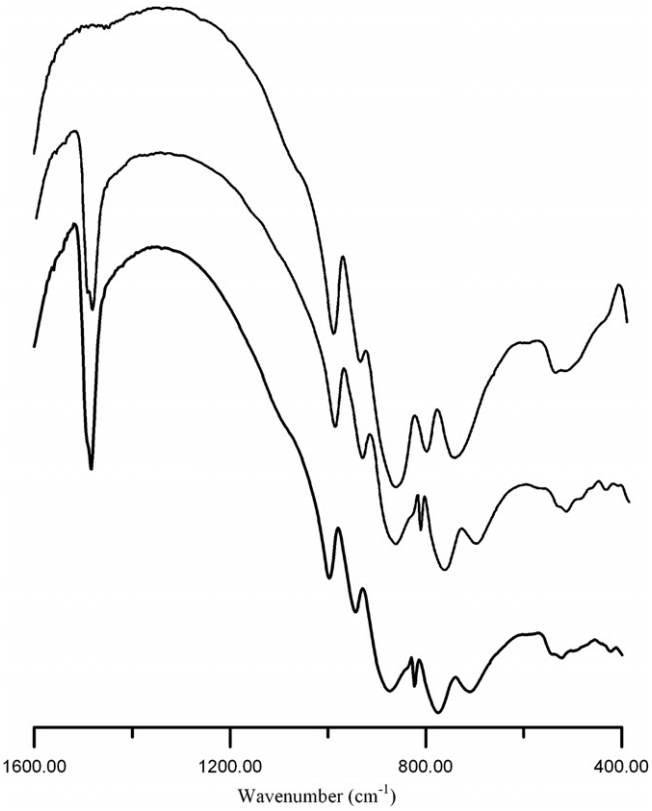

Fig. 3. IR spectra of **2** (inner), **4** (lower) and $Na_{10}[A\text{-}\beta\text{-}SiW_9O_{34}] \cdot xH_2O$ (upper) in KBr plates.

The ^{29}Si NMR spectrum of **2** shows one peak at −84.895 ppm corresponding to the two symmetry-equivalent Si atoms in each

A-β-$SiW_9O_{34}^{10-}$ unit and it is consistent with the solid-state C_2 structure. The values for the chemical shifts are similar to the values observed for other 3:2 sandwich complexes of $SiW_9O_{34}^{10-}$, $[(A\text{-}\alpha\text{-}SiW_9O_{34})_2Sn_3]^{14-}$, −85.2 ppm; $[(A\text{-}\beta\text{-}SiW_9O_{34})_2Sn_3]^{14-}$, −85.0 ppm [27] and $[(A\text{-}\beta\text{-}SiW_9O_{34})_2(HOZr)_3]^{11-}$, −84.2 ppm [12]. The ^{13}C NMR spectrum of **2** (0.1 mM) shows one peak at 170.297 ppm which is attributed to the encapsulated CO_3^{2-} anion In order to obtain a solution of **2** that was concentrated enough for ^{13}C NMR spectroscopy it was necessary to convert the potassium salt to the lithium salt by addition of $LiCLO_4$. The lithium salt of **2** is stable for several months and its solution is stable for at least the duration of the NMR scanning (see NMR spectra in the Electronic Supplementary material).

3.4. Thermal properties TGA and DSC

Thermogravimetric analysis (TGA) curves of **1**, **2**, **3** and **4** show two mass loss regions below 500 °C. First, 30–300 °C with 9.66%, 6.46%, 10.60% and 6.94% weight loss, which are assigned to lattice and coordinated (bond to Yb or Y atoms) water loss equal to 30, 21, 35 and 23 molecules for **1**, **2**, **3** and **4**, respectively. Second, 430–500 °C with approximately 0.68%, 0.68%, 0.63% and 0.63% weight loss for **1**, **2**, **3** and **4**, respectively, which are assigned to loss of one CO_2 molecule from the decomposition of CO_3^{2-} (Fig. 6). Differential Scanning Calorimetry (DSC) curves of **4** show two endothermal and some exothermal processes. The endothermal processes at 80–120 °C and 491 °C are attributed to exit of lattice and coordinated water and CO_2, respectively, and the exothermal process at 510 °C to decomposition of the structure. Another exothermal process possibility is attributed to SiO_2 formation. On the basis of the TGA and DSC studies it can be thus concluded that the complexes are thermally stable up to 430 °C (see TGA and DSC plots in the Electronic Supplementary material).

3.5. Electronic spectroscopy

The UV-electronic spectra of **2** and **4** exhibit two characteristic bands at ∼200 and ∼250 nm ($\varepsilon = 67\,500\ cm^{-1}\ M^{-1}$), assigned to W–Od and W–Ob–W transitions, respectively (Od is a terminal oxygen and Ob is a bridging oxygen) [1]. These bands are shifted to lower frequencies on comparison with the A-β-$SiW_9O_{34}^{10-}$ ligand, due to the coordination of the Y^{3+} and Yb^{3+} cations (see UV spectra in the Electronic Supplementary material).

4. Conclusion

Two (four salts) new sandwich-type polyoxometallate complexes $[(A\text{-}\beta\text{-}SiW_9O_{34})_2(MOH_2)_3CO_3]^{13-}$ (M = Y^{3+} and Yb^{3+}) were synthesized by the reaction of M^{3+} ions with A-β-$SiW_9O_{34}^{10}$ in carbonate solution. The experimental data show that the synthesis of the complexes requires the presence of the carbonate anion. The crystal structure of the complexes consist of two lacunary A-β-$SiW_9O_{34}^{10-}$ Keggin moieties which are linked by a $(H_2OMO)_3C$ belt into an assembly of virtual C_2 symmetry. The results prove the retention of the isomeric form of the starting lacunary anion A-β-$SiW_9O_{34}^{10-}$ upon the preparation of the complexes. The results suggest that the complexes are stable over a large range of pH, 3–11, and up to ∼430 °C, and decomposition of the complexes is followed by loss of the carbonate anion. Other tools such as IR, ^{13}C NMR, ^{29}Si NMR, UV spectroscopy, TGA and DSC confirm the structures.

Appendix A. Supplementary data

Crystallographic data (CIF file) for the structural analysis have been deposited with the Fachinformationszentium Karlsruhe (FIZ), CSD-number 418797. These data can be obtained free of charge via E-mail: crysdata@FIZ-Karsruhe.de. Tel.: +49 7247 808 310; fax: +49 7247 808 136. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.02.035.

$[Fe(C_{42}H_{32}N_8)](PF_6)$ (M chelate) = 993.8 g mol^{-1}. Calc. C, 50.72; H, 3.24; N, 11.26. Found: C, 50.55; H, 3.24; N, 11.26%. Tetraethylammonium perchlorate, TEAP (Fluka), was dried in an oven at 60 °C prior to use. All other reagents and solvents were of the highest purity grade available from Merck, Mallinckrodt and Sigma Chemical Co. Ltd., and were used as received.

2.2. Characterization

The elemental analysis was performed on a Carlo Erba Elemental Analyzer model EA1110. ^{1}H NMR spectra were obtained in CD_3CN and $CDCl_3$ solutions in a Bruker 300 MHz spectrometer model DPX 300. Electrochemical experiments were conducted using a PAR model 273 Potentiostat/Galvanostat. Cyclic voltammetric and chronoamperometric experiments were carried out in conventional three-compartment glass cells under argon atmosphere using a glassy-carbon disc working electrode (0.08 cm^2 area), a platinum wire auxiliary electrode and a Ag/AgCl reference electrode. The glassy-carbon electrode was polished to a mirror finish with different grades of alumina as low as 0.05 μm and ultrasonically cleaned before the experiments. Cyclic voltammetric, chronoamperometric and spectroelectrochemical experiments were performed in acetonitrile/TEAP solutions. UV–Vis spectra were obtained in quartz cells by using an 8452A Hewlett–Packard spectrophotometer. Polymer film electropolymerized on ITO was kept in a quartz cell equipped with a counter and reference electrode, and the electronic spectra were measured under controlled potential using a BAS CV27 Potentiostat. The spectra were recorded with an interval of 1 s during a potential sweep of 50 mV s^{-1}.

Apparent surface coverages (Γ_{app}, mol cm^{-2}) were calculated using the equation $\Gamma_{app} = Q/nFA$, where n is the number of transferred electrons, F is the Faraday's constant, A is the electrode area in cm^2, and Q is the charge (area) under the cyclic voltammetric oxidation $Fe^{III/II}$ wave at 50 mV s^{-1}.

3. Results and discussion

The ^{1}H NMR spectrum of a CD_3CN solution of $[Fe(tpy\text{-}NH_2)_2](PF_6)_2$ is shown in Fig. 1. The spectrum is relatively sharp and well resolved, and illustrates the high symmetry of the iron(II) complex in the ^{1}H NMR time-scale. The spectrum can be unambiguously assigned by comparison with the spectrum of $[Fe(tpy)_2](PF_6)_2$ [9]. The ^{1}H NMR spectra of the complex $[Fe(tpy\text{-}NH_2)_2](PF_6)_2$ exhibit characteristic coordination shifts $\Delta\delta$ ($\Delta\delta = \delta$ (complex, CD_3CN – δ (ligand, $CDCl_3$)), indicative of the conformational changes from a transoid arrangement about the interannular C–C bonds in the free ligand to a cisoid arrangement in the complex [10]. The use of coordination shifts is more reliable than the direct comparison of chemical shift in comparisons of this type of complex.

^{1}H NMR data are presented in Table 1. The protons of the amino groups in the complex can be observed as a broad singlet at $\delta = 4.58$. The remarkably constant coordination shifts observed for the iron complex of tpy[1] and terpy-NH_2 confirm that the structures of these complexes are similar. The consistency in the $\Delta\delta$ values for $H^{3'}$ suggests that the interplanar angles between the aryl substituent and the central pyridine ring are also similar in the tpy and tpy-NH_2 complex.

The cyclic voltammogram between 0 and +1.6 V (versus Ag/AgCl) in an acetonitrile solution containing 1.0 mM of the iron complex and 0.1 M of TEAP displays two overlapped waves with peak potential values of 0.88 and 1.12 V, which can be ascribed to irreversible aniline oxidation and reversible Fe(III)/Fe(II) oxidation/reduction, respectively. Repeatedly scanning the potential of a glassy-carbon electrode over the range 0–1.6 V versus Ag/AgCl results in a continuous increase in the size of the cyclic voltammetric wave for the $Fe^{III/II}$couple, as shown in Fig. 2. If after a scanning period the electrode is transferred (with thoroughly rinsing in acetonitrile) to a fresh electrolyte (containing no monomeric complex), the observed $Fe^{III/II}$ couple persists. The cyclic voltammogram response is quickly dominated by the polymer. Visual inspection of the electrode also gives evidence of deposition of a purple film.

The behavior shown in Fig. 2 suggests that an electroactive and presumably polymeric film of the complex is formed on the electrode as a consequence of oxidation. The current observed in Fig. 2 for the $Fe^{III/II}$ wave arises from the $Fe^{III/II}$ couple within the growing film and from the mediated oxidation of the monomeric complex in the external solution, part of which becomes incorporated into the film as it grows. The same results can also be obtained with Pt or highly doped SnO_2 electrodes. This modified electrode is also stable under repeated scanning (for at least 30 cycles) in the potential range 0 and 1.6 V in a clean electrolyte solution. In contrast, we should note that these films are unstable toward cycling through the potential where ligand reductions occur (0 and −1.8 V range). Scanning over this region destroys the electroactive behavior of the film.

The modified electrode obtained by electropolymerization exhibits reversible electrochromism, changing from purple to pale yellow due to Fe(II) to Fe(III) oxidation.

By scanning the potential from 0 to 1.6 V, a single reversible peak can be observed at 1.12 V, which leads to the complete decay

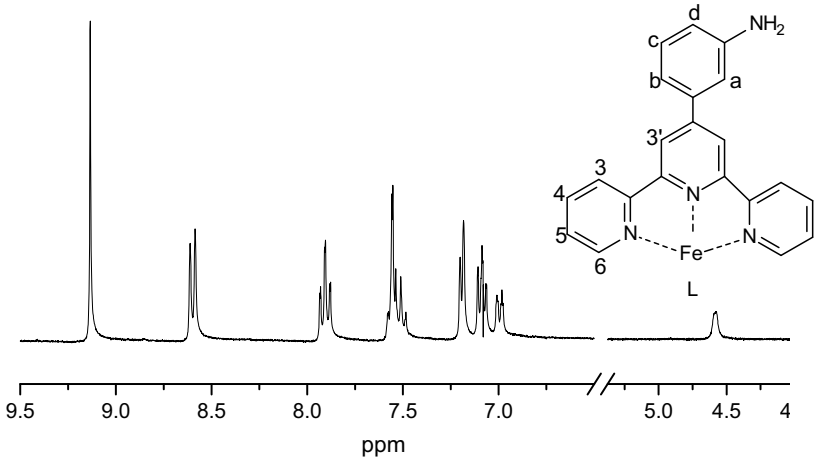

Fig. 1. 300 MHz ^{1}H NMR spectrum of a $[Fe(tpy\text{-}NH_2)_2]^{2+}$ CD_3CN solution.

Table 1
^{1}H NMR data and coordination shifts of the ligands tpy and terpy-NH_2 and its iron complexes

Ligand or complex	Proton chemical shift ($\Delta\delta^e$)

[g] CD_3CN solution.

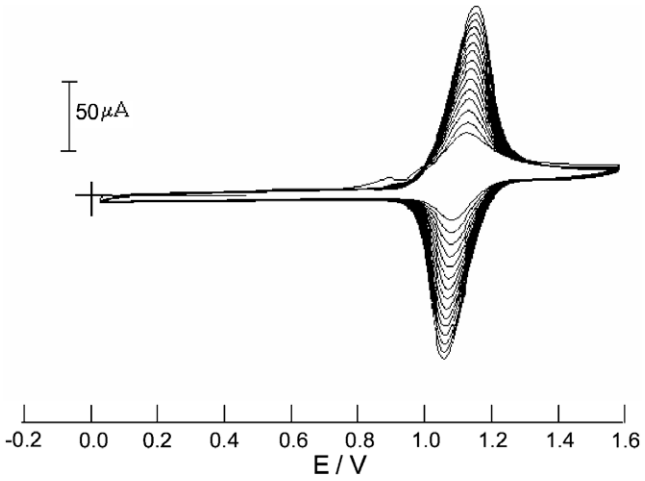

Fig. 2. Cyclic voltammogram showing deposition of poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ onto a glassy-carbon electrode by repeated potential scans between 0 and +1.6 V vs Ag/AgCl in acetonitrile 0.1 M in TEAP, scan rate = 100 mV s^{-1}.

of the characteristic MLCT bands in the visible region, as shown in the spectroelectrochemical results in Fig. 3. This electrochemical peak can be ascribed to the oxidation of Fe(II), by analogy with related iron–terpyridine complexes from the literature [11]. In the reverse sweep, the spectrum changed rapidly, to recover the original absorbance.

Polymeric films of different thicknesses were prepared by controlling the time of electropolymerization in a 1.0 mM $[Fe(tpy\text{-}NH_2)_2]^{2+}$ solution. The polymer coverage can be readily and reproducibly adjusted by varying the number of cyclic potential scans and sweep rate. Essentially identical plots of coverage versus number of scans were obtained in a series of experiments using several electrodes sequentially electropolymerized in the same monomer solution.

Fig. 4 shows how the charge under the $Fe^{III/II}$ surface wave increases with an increasing number of electropolymerizing potential scans for $[Fe(tpy\text{-}NH_2)_2]^{2+}$. The apparent surface coverage by the film increases linearly over the first three potential scans, and less rapidly thereafter. The extent of surface coverage is dependent on the scan rate, showing that the origin of the nonlinearity in Fig. 4 is due to the onset of charge transport limitations in the thickening film, where not all the $Fe^{III/II}$ sites are oxidized during an oxidative potential scan.

Two different types of behavior are observed for peak potential and peak current as a function of the scan rate. For the thin film (i.e. $\Gamma_{app} < 6 \times 10^{-9}$ mol cm^{-2}), the waves are symmetrically shaped irrespective of υ, and a linear dependence of the anodic peak current is observed. Thin layer/surface-type behavior is thus exhibited by thinner films. Such behavior is expected for a surface-immobilized electroactive film sufficiently thin for all of the redox sites within the film to undergo oxidation and reduction during one potential cycle [12].

For slow scan rates the thicker films display voltammetric waves with characteristics similar to those described for the thin film. With increasing υ, the voltammograms start to qualitatively resemble those of solution reactants diffusing to the electrode (current–potential responses show tailing), for which semi-infinitive diffusion predicts a linear relationship between i_p and $\upsilon^{1/2}$ (Fig. 5). This transition between the two regimes, due to the onset

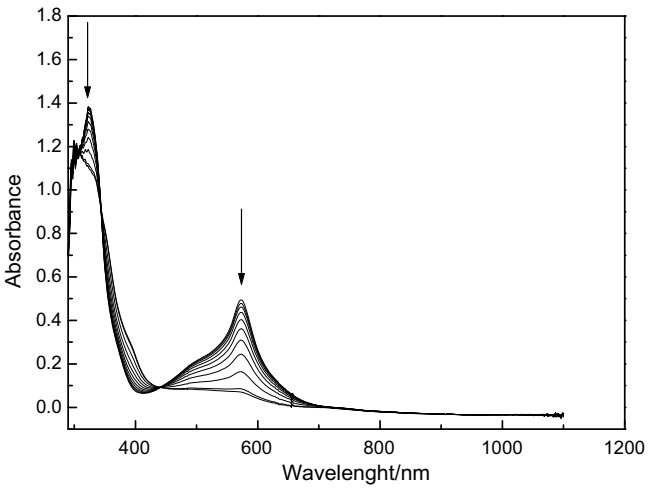

Fig. 3. Visible absorption spectra for ITO modified electrode during the potential sweep from 0 to 1.6 V at 50 mV interval.

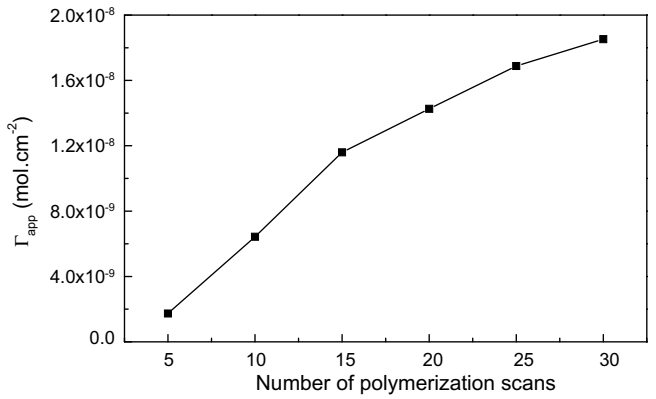

Fig. 4. Plot of the apparent surface coverage, Γ_{app}, with the number of scans employed in the polymerization. The modified electrodes were prepared as in Fig. 2. Note that the apparent surface coverages were determined after each scan in a fresh electrolyte solution.

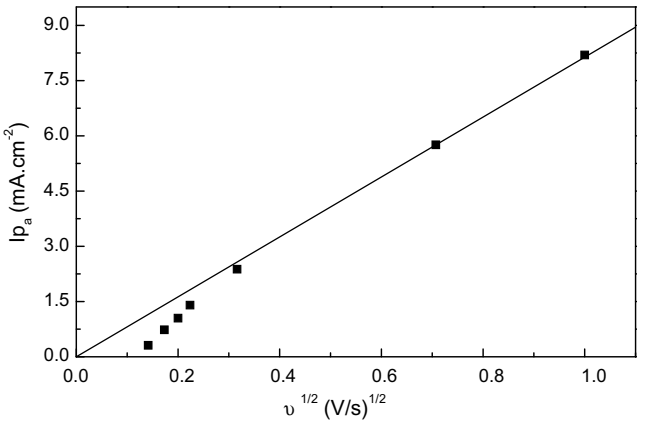

Fig. 5. Anodic peak current (Ip_a) vs $\upsilon^{1/2}$ (υ = scan rate) for a thick film, (i.e. $\Gamma_{app} = 1.8 \times 10^{-8}$ mol cm^{-2}) of poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ in a fresh electrolyte solution, acetonitrile 0.1 M in TEAP.

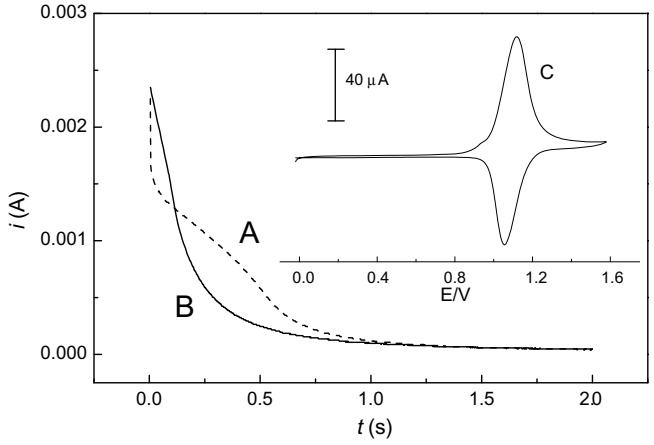

Fig. 6. (A, B) Potential step chronoamperometry of $\Gamma_{app} = 7.3 \times 10^{-8}$ mol cm^{-2} film of poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ in a fresh electrolyte solution, acetonitrile 0.1 M in TEAP; (A) 0–1.35 V potential step; (B) 0–1.6 V vs Ag/AgCl; (C) cyclic voltammetry of the same electrode at 20 mV s^{-1}.

of rate-limiting charge transport through film as thickness film increases, has been observed for other polymer-modified electrodes [11,13]. The peak splitting and the anodic peak FWHM (full width at half-maximum) increase with the sweep rate and the film thickness.

Potential-step chronoamperometry was employed in the study of the charge transport process close to the electrode surface.

The current response of redox polymer films depends upon the relative sizes of the diffusion layer δ (the layer adjacent to the electrode surface where the concentrations differ from those in the bulk polymer), the film thickness d, the diffusion coefficient (D_{ct}), and the experimental time-scale (t_e). In redox polymer films, D_{ct} is related to charge transfer through the polymer. There are two limiting cases to consider – semi-infinitive diffusion and thin layer behavior, finite diffusion. Many redox polymers exhibit behavior that is intermediate between these two limiting cases [14].

When the film thickness is much larger than the diffusion layer ($d \gg \delta$), the system will exhibit semi-infinite behavior. When the film thickness is the same as that of the diffusion layer ($d \approx \delta$), then thin layer behavior will be observed, where the electroactive material immobilized on the electrode surface is electrolyzed very rapidly when the applied potential is changed.

Potential step chronoamperometric experiments with films of several thicknesses were performed to assess the charge diffusion behavior of these polymers. In these experiments, a large-amplitude potential step was used to avoid any complication from ohmic resistance of the polymer film. Murray and Daum [15] showed that if the polymer film exhibits an ohmic resistance to charge flow, this can cause loss of potential control in the electrochemical experiment.

The consequence of an oxidative potential step from 0 to 1.35 V, insufficiently positive to overcome the film resistance, is shown in Fig. 6A. The slow potential scan cyclic voltammetry of Fig. 6C would suggest that 1.35 V is thermodynamically sufficient for rapid film oxidation. Yet the current–time curve exhibiting an abnormal maximum is seen. On the other hand, if the potential step is repeated on the same electrode, but now from 0 to 1.6 V versus Ag/AgCl a smoothly decaying current–time curve is seen (Fig. 6B). The current maximum for the 1.35 V step is recognized as an artefact resulting from the film's ohmic resistance. However, interpretation of the results in figure requires consideration of the film's ohmic resistance only and no association of ion migration rates in the film with the overall charge transport kinetics need or should be made from such data.

Kaufman et al. [16] proposed a charge transport model through polymer films where charge propagation takes place via electron-self-exchange reaction between oxidized and reduced neighbors within the film. Since the electron transport accomplishes an overall oxidation state change during the film's electrochemical reaction, charge neutrality within the polymer film requires uptake of counterions into the polymer matrix, or expulsion of co-ions initially in the film as an ion-pair, to coincide with charge propagation. Moreover, segmental motion of the polymer chain, and motion of the solvent, may also be important in dictating the overall charge transport rate. Murray refers to the overall process as charge transport [14]. This process is mathematically equivalent to diffusion of such localized states (whether electron hopping, or an associated event such as charge compensating counterion hopping, or polymer lattice motion governing either process, is the rate-determining step). If charge transport follows Fick's law, the potential step current–time response will be described by the Cottrell equation (1) [17]:

$$i = nFAD_{ct}^{1/2}C/\pi^{1/2}t^{1/2} \quad (1)$$

The current transient shown in Fig. 6B is plotted in this form in Fig. 7. It can clearly be seen that the experimental data do not yield a linear i versus $t^{-1/2}$ plot. Deviation from the predicted straight line, based on the Cottrell equation for a semi-infinitive diffusion system, is observed.

Two factors are responsible for this curvature. At short times, the current intensity is significantly smaller than the one expected

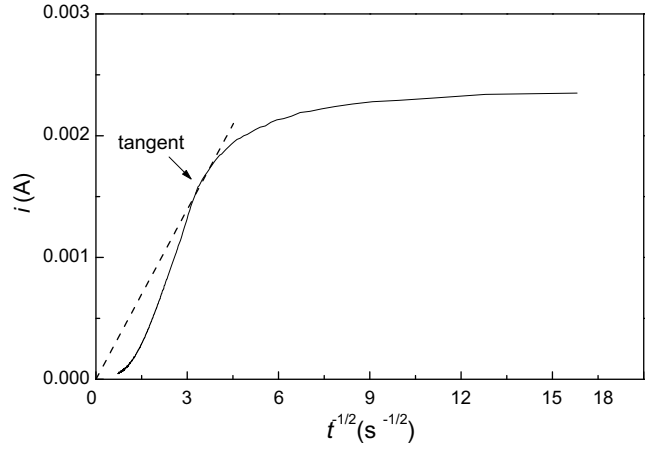

Fig. 7. i vs $t^{-1/2}$ plot for a 0–1.6 V potential step, $\Gamma_{app} = 7.3 \times 10^{-8}$ mol cm^{-2} film of poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ in a fresh electrolyte solution, acetonitrile 0.1 M in TEAP.

theoretically; this has been attributed to uncompensated solution resistance effects [13]. At long times, the fall-off of the current indicates that the volume of the polymer cannot be taken as infinite and a finite diffusion boundary condition must be invoked. Pause and Pickup [18] assume that the Cottrell equation (semi-infinitive diffusion system) pertains to the central portion of the i versus $t^{-1/2}$ plot, and the most reasonable slope to adopt for data analysis is the tangent to the curve from the origin. In this way, we can extract values for $D_{ct}{}^{1/2}C$, where D_{ct} is the diffusion coefficient and C is the concentration of the electroactive species.

At longer times, where the semi-infinitive boundary condition of Eq. 1 becomes violated, we were also interested to confirm the idea that deviations from the predicted values for semi-infinite Cottrell behavior were due to the finite boundary condition. For a potential step experiment with a reactant solution of thickness d, the finite diffusion current–time dependence is described by the following equation [14,15]:

$$i = \frac{nFAD^{1/2}C}{\pi^{1/2}t^{1/2}}\left[\sum_{K=0}^{\infty}(-1)^K\left\{\exp\left(\frac{-K^2d^2}{Dt}\right) - \exp\left(\frac{-(K+1)^2d^2}{Dt}\right)\right\}\right] \quad (2)$$

where A is the area of the electrode, D is taken to be D_{ct} (charge transport diffusion coefficient determined by chronoamperometry), C is the concentration of the redox species, d is the thickness of the film, and n, F, and t have their usual meanings. For a comparison of Eq. 2 with the experiment, D and d are required, or more precisely, the ratio d^2/D is needed. From $C = (\Gamma/d)$ it follows that $d^2/D = (\Gamma/D^{1/2}C)^2$, and using for $D^{1/2}C$ the $D_{ct}{}^{1/2}C$ values obtained from the slope of the tangent to the i versus $t^{-1/2}$ curve from the origin, and the apparent surface coverage, $\Gamma_{app} = Q/nFA$, it is possible to estimate d^2/D. Experimental i versus $t^{-1/2}$ curves and chronoamperometric current–time responses predicted by the Cottrell equation and by Eq. 2, for $\Gamma_{app} = 7.3 \times 10^{-8}$ mol cm^{-2}, are shown in Fig. 8.

The theoretical prediction (open cycles) reasonably agrees with the experimental points, except for very short times, where the current intensity is controlled by the solution resistance. This agreement clearly indicates that in these experiments a changeover occurs, from a semi-infinite diffusion condition described by the Cottrell equation to a finite diffusion regime, with time following the potential step. In the context of the above discussion, it is predicted that the changeover between the two regimes occurs at different times for polymers of different thickness. At longer times, the diffusion layer approaches the film thickness and a transition to thin layer behavior occurs: for thicker films, the transition between "diffusional" behavior to "monolayer" behavior will be observed at longer times. This means that as film thickness increases, the larger is its diffusional character behavior; the current response is that for a species in solution.

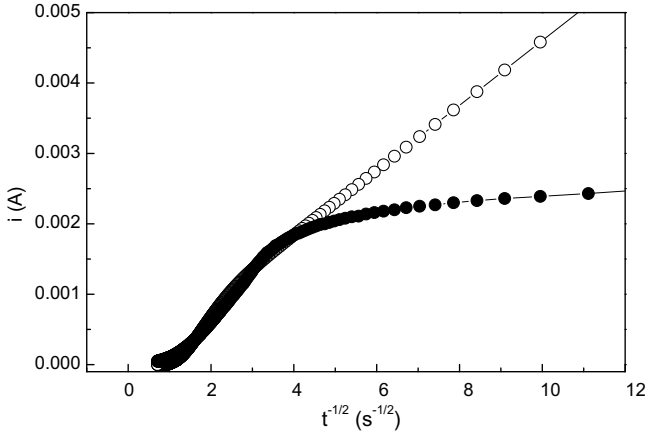

Fig. 8. i vs $t^{-1/2}$ plot for a 0–1.6 V potential step, $\Gamma_{app} = 7.3 \times 10^{-8}$ mol cm^{-2} film of poly-[[Fe(tpy-NH$_2$)$_2$]$^{2+}$]$_n$. Solid cycles, experimental data; open cycles are values calculated from finite-diffusion theory, $D_{ct}{}^{1/2}C = 1.0 \times 10^{-7}$ A s$^{-1/2}$, $A = 0.082$ cm^2.

Table 2 shows the $D_{ct}{}^{1/2}C$ values for poly-[[Fe(tpy-NH$_2$)$_2$]$^{2+}$]$_n$ with different thicknesses.

When the electron-exchange mechanism of Kaufman and Engler [16] is followed, electrons are removed from sites that are far from the electrode by successive electron transfers between neighboring sites in the film. The rate at which these electron transfers occur and the rate at which counterions enter the film for charge compensation influences D_{ct}. However, similar diffusion coefficients were observed when the film thickness was varied. A diffusion coefficient that is insensitive to the film thickness suggests that movement of charge compensating counterions through the polymeric matrix is relatively facile and does not limit the overall charge transport rate [19].

Studies where the electrolyte concentration was varied, using electrodes with the same film thickness, demonstrated that the cell resistance of the coated electrode is dominated by the solution resistance rather than the film resistance. At high electrolyte concentration, the solution resistance is reduced, as expected. This fact is evidenced by large increase in the current intensity in short times in the case of chronoamperometric experiments. The reverse occurs when we keep the electrolyte concentration constant and alter the film thickness; however, the chronoamperometric experiments give evidence of a smooth decrease in the current intensity.

With regard to the electrolyte concentration, other effects must be considered. In the chronoamperometric experiments, the changeover between the two regimes (from a semi-infinite diffusion condition to a finite diffusion regime) occurs at different times for polymers of the same thickness as a function of the TEAP concentration. The transition to a finite diffusion regime takes place in shorter times as the electrolyte concentration is changed from 0.05 to 0.5 M (Fig. 9). The cyclic voltammogram shows that there is a decrease in the peak currents as the electrolyte concentration is increased. Obviously, a good deal of electroactive Fe^{II} sites are not oxidized as the salt concentration is increased. This decrease in the maximum peak currents likely reflects swelling of the layer at higher electrolyte concentrations, which is related to changes in polymer structure, leading to increased redox site separation. In this way, the electron hopping of the redox sites within the polymeric matrix requires cooperative motion of the polymer backbone to which they are attached. Furthermore, transport of the companion counterion (and solvent) requires expansion of the polymer lattice, reducing the mobility of polymer segments. These facts suggest that polymer chain motion is the rate-limiting step in the case of poly-[[Fe(tpy-NH$_2$)$_2$]$^{2+}$]$_n$ films.

The ability of the polymer film to act as a mediator between the electrode and the external solution was evaluated. Electrodes coated with [[Fe(tpy-NH$_2$)$_2$]$^{2+}$]$_n$ film were examined by cyclic voltammetry in the presence of ferrocene, which undergoes one-electron oxidation at less positive potentials than the Fe(III)/Fe(II) couple inside the film ($E_{sol} = 0.40$ V and $E_{pol} = 1.12$ V, respectively). These experiments were carried out with an electrode covered with increasingly thicker films of [[Fe(tpy-NH$_2$)$_2$]$^{2+}$]$_n$, prepared by cycling the potential (0–1.6 V, 50 mV s^{-1}) in a 10^{-3} M solution of

Table 2
$D_{ct}{}^{1/2}C$ values obtained from chronoamperometry using Cottrell equation, for polymers with different thickness

Γ_{app} (mol cm^{-2})	$D_{ct}{}^{1/2}C$ (A s$^{-1/2}$)
1.4×10^{-8}	0.6×10^{-7}
7.3×10^{-8}	1.0×10^{-7}
1.2×10^{-7}	1.0×10^{-7}
1.6×10^{-7}	1.1×10^{-7}

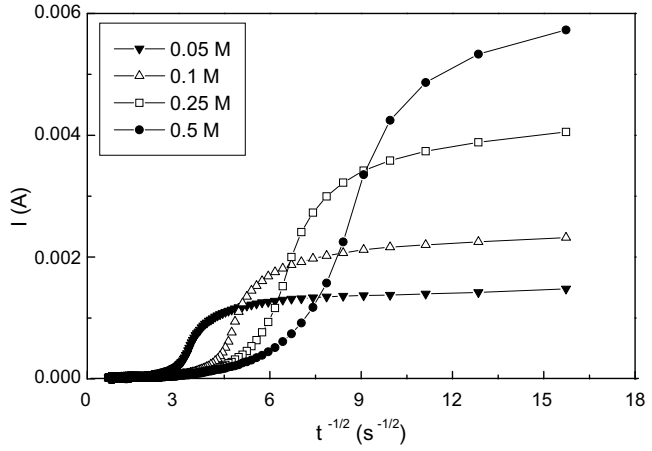

Fig. 9. Effect of electrolyte concentration (TEAP) on i vs $t^{-1/2}$ plot for poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ films of the same thickness. The potential was stepped from 0 to 1.6 V.

$[Fe(tpy\text{-}NH_2)_2]^{+2}$ in CH_3CN/0.1 M TEAP. They were washed with acetonitrile and transferred to a of ferrocene 4×10^{-3} M solution in clean supporting electrolyte. It is known that ferrocene may be oxidized at the electrode/polymer interface after diffusion through a continuous polymer film. Alternatively, it may be oxidized at a polymer film/solution interface, a process that requires either redox conduction through the film or an electronically conducting film. In the case of redox-conductivity-mediated electron transfer, irreversible oxidation of the solution species will occur at or near E_{pol}. For electron transfer mediated by an electronically conducting film, reversible oxidation will occur at or near E_{sol}. Electron transfer involving solution species at a redox-polymer-coated electrode at both E_{pol} and E_{sol} have been reported previously [20,21].

A cyclic voltammogram for a of 4×10^{-3} M ferrocene solution at an electrode freshly coated with 2.1×10^{-8} mol cm^{-2} $[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ is shown in Fig. 10. Almost all of the ferrocene oxidation occurs at E_{sol}, although some oxidation also occurs at E_{pol},. However, as the surface coverage is increased, the peak currents for the solution species decrease (E_{sol}) and may be interpreted as the onset of membrane-controlled diffusion [22], since the solution species must diffuse through hole channels in the film to get to the electrode. At thick films, oxidation of the external couple occurs by charge transfer through the films rather than mass transfer (diffusion).

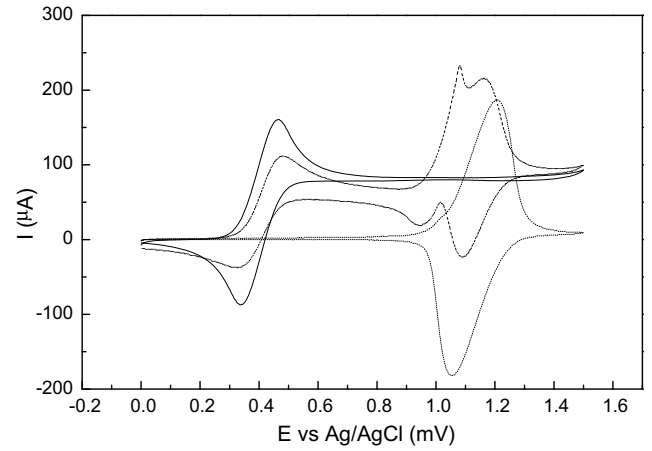

Fig. 10. Cyclic voltammogram of 4×10^{-3} ferrocene in acetonitrile 0.1 M TEAP (scan rate = 100 mVs^{-1}); (—) bare glassy-carbon electrode; (...) glassy-carbon coated with 2.1×10^{-8} mol cm^{-2} $[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$; (- - -) glassy-carbon/poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ without ferrocene.

Table 3
Roughness and thickness of poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ films as a function of deposition time

	20 cycles	50 cycles
Thickness (nm)	106	380
Roughness (nm)	9	19

The experiments demonstrate the existence of two discrete pathways for net charge transfer – a diffusional or mass-transfer pathway, which is a slow process at thick films (at least on the time-scale of cyclic voltammetry), and a charge-transfer pathway, which is dictated by the redox properties of the film.

Atomic force microscopy was used to obtain information concerning polymer morphology. Roughness and film thickness values are listed in Table 3. The table shows the thickness and roughness increase with the increasing number of electropolymerizing potential scans for poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$. The AFM image of a poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ film deposited onto an ITO electrode shows that the polymer looks compact and displays continuous morphology over the entire film. The image reveals that the polymer completely covers the electrode surface without pore or channel defects, indicating that there is a 2-D layer-by-layer growth mechanism, where the nuclei grow more quickly in the parallel direction than in the perpendicular direction until they meet and overlap. Conducting polymers deposited layer-by-layer via the lateral growth of 2-D nuclei may be expected to have a more uniform and compact arrangement [23] of polymer chains.

4. Conclusion

The characterization of the complex $[Fe(tpy\text{-}NH_2)_2](PF_6)_2$ by elemental analysis, and ^{1}H NMR spectra confirmed the composition of the monomer. By using the monomer, it was possible to electrogenerate polymer films having high conductivity, stability, permeability, and uniform and controllable thickness by oxidative polymerisation. Electrochemical measurements were reproducible over the potential range 0–1.6 V. The film completely loses its electroactivity when the potential is scanned from 0 to −1.6 V. We determined charge transport parameters as a function of time-scale and thickness of the modified electrode. The results showed that poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ can be made to exhibit the three regimes of charge transport behavior by manipulation of the film thickness and the experimental time-scale. Morphological characterization of the film was provided by atomic force microscopy. The polymer looks compact and displays continuous morphology over the entire film. The image reveals that the polymer completely covers the electrode surface without pore or channel defects. The results indicate that this system may be adequate for electrocatalytic purposes or application in electrochromic display devices.

Note: The table of the variation of peak splitting and anodic FWHM with sweep rate and film thickness, and an AFM image of the complex deposited onto an ITO electrode are available on request.

binuclear metalloproteins [14], their interesting catalytic properties [15] and their ability to stabilize unusual oxidation states and mixed-valance compounds. In particular, phenol based macrocyclic binucleating ligands containing two different compartments have particularly received great attention due to their capability to bind two metal centers in close proximity [16–21]. The influence of the donor atoms and their relative position, the number and size of the chelate ring formed, shape of the coordination moiety play important role in the biological and catalytic activity of the complexes formed [22–29]. Hence, synthesis of model compounds that mimic the physical and chemical properties of the active sites present in metalloenzymes is very essential and the studies on such compounds is becoming increasingly important in understanding biological functions of the bimetallic cores [30]. Various types of compartmental ligands and their complexes have been prepared, and their structures and reactivities were investigated by Bosnich [31–33] and Busch [34]. Such ligands contain two compartments: one includes six coordination atoms (N_4O_2) and the other with tetradentate N_2O_2 donor set.

Our research focuses on the synthesis of cyclam based dissimilar dicompartmental binuclear nickel(II) complexes containing hexa (amine compartment) and tetra (imine compartment) coordination sites. The amine compartment consists of two secondary nitrogens, two tertiary nitrogens and two phenolic oxygens (N_4O_2), whilst the imine compartment comprises of two imine nitrogens and two phenolic oxygens (N_2O_2). In these systems, one metal is in six-coordinate site and the other is in four-coordinate site, if a ligand like ClO_4^- is coordinated, this site can be made five-coordinate [34]. Spectral, electrochemical, catalytic and hydrolysis of 4-nitrophenyl phosphate of the complexes were discussed. Antifungal and antibacterial activities of the complexes were also discussed.

2. Experimental

2.1. Analytical and physical measurements

Elemental analysis of the complexes was obtained using Haereus CHN rapid analyzer. ^{1}H NMR spectra were recorded using JEOL GSX 400 MHz NMR spectrometer. Electronic spectral studies were carried out on a Hitachi 320 spectrophotometer in the range 200–1100 nm. IR spectra were recorded on a Shimadzu FTIR 8300 series spectrophotometer on KBr disks in the range 4000–400 cm^{-1}. Molar conductivity was measured by using an Elico digital conductivity bridge model CM-88 using freshly prepared solution of the complex in dimethylformamide. The atomic absorption spectral data were recorded using Varian spectra AA-200 model atomic absorption spectrophotometer. Mass spectra were obtained on a JEOL SX-102 (FAB) mass spectrometer. Cyclic voltammograms were obtained on CHI-600A electrochemical analyzer. The measurements were carried out under oxygen free condition using a three-electrode cell in which a glassy carbon electrode was the working electrode, a saturated Ag/AgCl electrode was the reference electrode and platinum wire was used as the auxiliary electrode. A ferrocene/ferrocenium (1+) couple was used as an internal standard and $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^+) couple under the experimental condition is 470 mV. Tetra(*n*-butyl)ammonium perchlorate (TBAP) was used as the supporting electrolyte. Room temperature magnetic moment was measured on a PAR vibrating sample magnetometer Model-155. The hydrolysis of 4-nitrophenylphosphate by the nickel(II) complexes were studied in a 10^{-3} M dimethylformamide solution. The reaction was followed spectrophotometrically and the hydrolysis of *p*-nitrophenylphosphate was monitored by following the UV absorbance change at 420 nm (assigned to the 4-nitrophenolate anion) as a function of time. A plot of $\log(A\alpha/A\alpha - A_t)$ versus time was made for each complex and the rate constant for the hydrolysis of 4-nitrophenylphosphate was calculated.

2.1.1. Chemicals and reagents

5-Methyl salicylaldehyde [35], 3-chloromethyl-5-methyl salicylaldehyde [36], 1,4,8,11-tetraazatricyclo[9.3.1.1[4,8]]-hexadecane [37] and 1,8-[bis(3-formyl-2-hydroxy-5-methyl)-benzyl]-4,11-diazaniatricyclo[9.3.1.1[4,8]]hexadecane dichloride [38] were prepared by following the literature methods. Analytical grade methanol, acetonitrile and dimethylformamide were purchased from Qualigens and used as such. TBAP used as supporting electrolyte in electrochemical measurement was purchased from Fluka and recrystallised from hot methanol. (*Caution!* TBAP is potentially explosive; hence care should be taken in handling the compound). All other chemicals and solvents were of analytical grade and were used as received without any further purification.

2.2. Synthesis of ligand (L)

2.2.1. Synthesis of 1,8-[bis(3-formyl-2-hydroxy-5-methyl)-benzyl]-l,4,8,11-tetraazacyclotetradecane (L)

The compound 1,8-[bis(3-formyl-2-hydroxy-5-methyl)-benzyl]-4,11-diazaniatricyclo[9.3.1.1[4,8]]hexadecane dichloride (1 g, 0.0017 mol) was dissolved in 200 ml of an aqueous NaOH solution (0.3 M) with stirring. After stirring for 4 h, the solution was extracted with $CHCl_3$ (5 × 30 ml). The combined $CHCl_3$ extracts were dried with anhydrous $MgSO_4$, and concentrated under vacuum to give the expected compound 1,8-[bis(3-formyl-2-hydroxy-5-methyl)benzyl]-l,4,8,-11-tetraazacyclotetradecane. Yield: 72%. m.p.: 282 °C (dec). *Anal.* Calc. for $C_{28}H_{40}N_4O_4$: C, 67.72; H, 8.12; N, 11.28. Found: C, 67.64; H, 8.02; N, 11.17%. IR data (KBr disc): 3389 cm^{-1}, 3285 cm^{-1}, 1680 cm^{-1}; ^{1}H NMR: δ (ppm in $CDCl_3$), 1.5 (q, 4H, β-CH_2), 2.32 (t, 16H, α-CH_2), 4.1 (s, 4H, N–CH_2–Ar), 7.26 (d, 4H, Ar–H), 9.92 (s, 2H, Ar–CHO), 12.5 4 (br, s, Ar–OH). ^{13}C NMR: δ (ppm in $CDCl_3$), 28.3, 49.4, 54.8, 55.2, 55.7, 60.5, 122.4, 126.2, 126.8, 131.0, 136.8, 157.6, 196.0.

2.3. Synthesis of the macrobicyclic binuclear nickel(II) complexes

2.3.1. $[Ni_2L[1a](ClO_4)](ClO_4)$

A methanolic solution of nickel(II) perchlorate hexahydrate (0.74 g, 0.002 mol) was added to a hot solution of ligand L (1.00 g, 0.002 mol) in methanol, followed by the addition of 1,2-diaminoethane (0.12 g, 0.002 mol) and triethylamine (0.41 g, 0.004 mol) in methanol. After an hour, another 1 equiv. of nickel(II) perchlorate (0.74 g, 0.002 mol) was added and the solution was refluxed in a water bath for 24 h. The resulting solution was filtered whilst hot and allowed to stand at room temperature. After slow evaporation of the solvent at 25 °C, dark green compound was collected by filtration, which was recrystallised in acetonitrile, and dried in vacuum.

Yield: 0.96 g (58%). *Anal*. Calc. for $C_{30}H_{42}N_6O_{10}Cl_2Ni_2$: C, 43.15; H, 5.07; N, 10.07; Ni, 14.06. Found: C, 43.09; H, 4.97; N, 10.01; Ni, 14.00%. 3. Results and discussion

A series of macrobicyclic binuclear nickel(II) complexes were synthesized by Schiff's base condensation of the precursor compounds with diamines in presence of metal ion. The synthetic pathway of binuclear complexes is shown in Scheme 1. In all the prepared nickel(II) complexes, one of the nickel(II) ion in the amine compartment is six coordinated, and the other in the imine compartment is five coordinated. Conductivity measurements of (Λ_m, 73–97 S cm^2 mol^{-1}) all the complexes show that they are 1:1 conductors in DMF solution [39]. The effective magnetic moments per mole of nickel for the nickel(II) complexes fall in the range of 2.94–3.05 μ_B at room temperature. This may be caused by a strong nickel–nickel interaction. The magnetic moment value for the nickel(II) complex fall in the range usually observed for octahedral nickel(II) complexes. All attempts to grow single crystals of the complexes (e.g. by the diffusion of diethyl ether vapor into DMF solutions or recrystallization of the complexes from acetonitrile) have failed and only green powder or micro crystals were obtained. Spectral, electrochemical, catalytic and antimicrobial studies of the complexes were carried out.

3.1. Spectral studies

The IR spectra of all the binuclear nickel(II) complexes show bands in the region 3245–3320 cm^{-1}, indicating the presence of NH groups in the complexes. The IR spectra of ligand L shows a band at 1680 cm^{-1} due to the presence of C=O (–CHO) group. All the complexes show a sharp band in the region of 1630–1650 cm^{-1} due to the presence of C=N in the complexes. This shows that the aldehyde groups had been completely converted into imine groups, by the disappearance of the aldehyde C=O stretching band at around 1680 cm^{-1} and the appearance of a strong band at around 1630–1650 cm^{-1} assigned to C=N stretching vibration mode (Schiff base condensation) [40,41,33]. All the binuclear nickel(II) complexes showed two sharp peaks at near 1100 cm^{-1} and 620 cm^{-1}, which are assigned to perchlorate ions [42]. The peak around 1100 cm^{-1} is split, which clearly explains the presence of a coordinated perchlorate ion [43], while the other peak does not show any splitting, indicating the presence of an uncoordinated perchlorate ion. The IR spectral data of the complexes, clearly shows that the presence of two different types of perchlorate ions. Further, the appearance of new bands in the 1530–1560 cm^{-1} region in all the complexes suggests phenoxide bridging with the metal ions [44].

Electronic spectra of all the complexes were obtained in DMF medium. The electronic spectra of all the complexes

Scheme 1.

exhibit three main features. One or two peaks in the range of 250–300 nm is assigned to the intra ligand charge transfer transition (π–π^*). An intense peak in the range of 380–420 nm is due to ligand-to-metal charge transfer transition, and the d–d transition for the nickel(II) complexes show three main bands in the range of 550–1040 nm, which is characteristic of Ni^{2+} in the 5/6 coordination environment [45]. Although the appearance of the spectra bear similarities with those for octahedrally coordinated Ni(II) ions, the assignment of the three most intense bands to the spin allowed transitions from the $^3A_{2g}$ ground state of an octahedrally coordinated d^8 ion to the next higher excited triplet states ($^3T_{1g}(P)$, $^3T_{1g}(F)$ and $^3T_{2g}(F)$) would be a misinterpretation. Furthermore, the molar extinction coefficients of the absorption band maxima of are unusually high. The spectra in fact indicate a square pyramidal or trigonal bipyramidal coordination environment of at least one of the Nickel(II) ions [45]. The electronic spectral studies inferred that an increase in λ_{max} (red shift) of the d–d transition of nickel(II) ion in the ligand L[1a] to L[1c] and L[1d] to L[1e]. This is due to the flexibility of the macrocyclic ring that is imparted by the distortion of the geometry of the complexes due to the increase in macrocyclic ring size, which causes more distortion of the geometry [46,47]. The electronic spectral data of the binuclear nickel(II) complexes are given in Table 1.

3.2. Electrochemical properties of the complexes

The electrochemical properties of all the binuclear nickel(II) complexes were studied by Cyclic voltammetry in dimethylformamide containing 10^{-1} M tetra(*n*-butyl)-ammonium perchlorate. The electrochemical data are summarized in Table 2. Cyclic voltammograms for the nickel(II) complexes are shown in Fig. 1.

Table 1
Electronic spectral data of binuclear nickel(II) complexes

No.	Complexes	λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$)	
		d–d	Charge transfer
1	$[Ni_2L[1a](ClO_4)](ClO_4)$	987 (48), 705 (85), 552 (367)	357 (10800), 269 (14400)
2	$[Ni_2L[1b](ClO_4)](ClO_4)$	997 (78), 717 (96), 564 (347)	363 (11400), 271 (14840)
3	$[Ni_2L[1c](ClO_4)](ClO_4)$	1017 (53), 723 (94), 581 (318)	370 (12100), 273 (15000)
4	$[Ni_2L[1d](ClO_4)](ClO_4)$	1030 (67), 742 (98), 605 (180)	375 (12800), 277 (17000)
5	$[Ni_2L[1e](ClO_4)](ClO_4)$	1037 (43), 754 (69), 613 (247)	383 (13600), 277 (17800)

Table 2
Electrochemical[a] and hydrolysis of 4-nitrophenylphosphate[b] data for the complexes

No.	Complexes	Reduction (at cathodic)		Oxidation (at anodic)		Rate constant (k) ($\times 10^{-3}$) min^{-1}
		E^1_{pc} (V)	E^2_{pc} (V)	E^1_{pc} (V)	E^1_{pc} (V)	
1	$[Ni_2L[1a](ClO_4)](ClO_4)$	−1.00	−1.43	0.72	1.23	10.36
2	$[Ni_2L[1b](ClO_4)](ClO_4)$	−0.91	−1.31	0.80	1.32	13.13
3	$[Ni_2L[1c](ClO_4)](ClO_4)$	−0.79	−1.28	0.98	1.39	16.81
4	$[Ni_2L[1d](ClO_4)](ClO_4)$	−1.27	−1.37	1.10	1.43	9.20
5	$[Ni_2L[1e](ClO_4)](ClO_4)$	−1.21	−1.31	1.18	1.52	9.87

Concentration of the complexes: 1×10^{-3} M. Concentration of 4-nitrophenylphosphate: 1×10^{-1} M. The rate constant values the are average of three experiments.

[a] Measured by CV at 50 mV/s. E vs. Ag/AgCl conditions: GC working and Ag/AgCl reference electrodes; supporting electrolyte TBAP; concentration of complex 1×10^{-3} M, concentration of TBAP 1×10^{-1} M.

[b] Measured spectrophotometrically in DMF. Concentration of the complexes: 1×10^{-3} M. Concentration of 4-nitrophenylphosphate: 1×10^{-1} M. The rate constant values are average of three experiments.

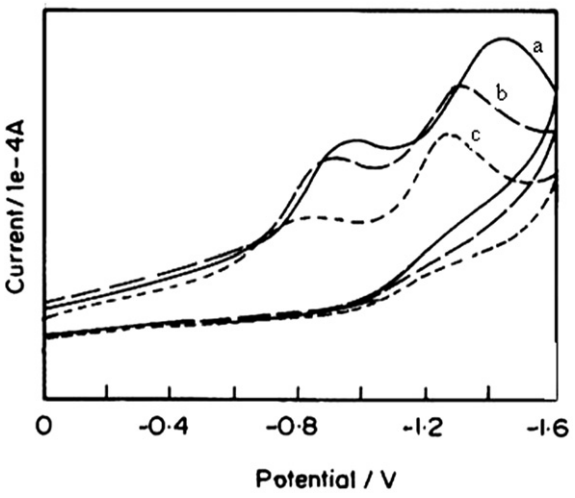

Fig. 1. Cyclic voltammogram of the binuclear nickel(II) complexes: (a) $[Ni_2L[1a](ClO_4)](ClO_4)$, (b) $[Ni_2L[1b](ClO_4)](ClO_4)$ and (c) $[Ni_2L[1c]-(ClO_4)](ClO_4)$ (reduction process).

3.3. Reduction process at negative potential

The cyclic voltammograms of the nickel(II) complexes were recorded in the potential range 0 to −1.6 V in DMF. Cyclic voltammogram for nickel(II) complexes are shown in Fig. 1. The electrochemical data are summarized in Table 2. The macrocyclic doubly phenoxo-bridged dinickel complexes typically undergo two well-separated one electron reductions [48,49a]. It is observed that all the binuclear complexes show two irreversible reduction waves in the cathodic potential region. The first reduction potential ranges from −0.79 to −1.27 V and the second reduction potential lies in the range of −1.19 to −1.43 V. Controlled potential electrolysis was also carried out and the experiment reports that each couple corresponds to one-electron transfer process. The two reduction processes are assigned as follows:

$$Ni^{II}Ni^{II} \rightarrow Ni^{II}Ni^{I} \rightarrow Ni^{I}Ni^{I}$$

The first reduction potential of the Ni^{2+}/Ni^{+} couple of $[NiL[1a–c](ClO_4)]ClO_4$ complexes in the range of −0.79 to −1.27 (Table 2) is similar to that observed for $[Ni(salen)]^{2+}$ complexes, and may suggest that the reduction wave observed for these bimetallic complexes refer to reduction of the nickel(II) in the four-coordinate site. Similarly, the second reduction wave observed for $[NiL[1a–c](ClO_4)]ClO_4$ in the range −1.28 to −1.43 V, is attributed reduction of nickel(II) ion in the amine compartment (N_4O_2). Hence the second reduction potential suggests that the reduction wave observed for these bimetallic complexes refers to the reduction of the nickel(II) in the six-coordinate site [49b,49c].

It seems, interesting to compare the reduction potential of the nickel(II) complexes. It is apparent to say that in the binuclear nickel(II) complexes, both first and second reduction potentials shift towards anodically, from −0.79 to −1.27 V and from −1.28 to −1.43 V, respectively, as the number of methylene groups is increased [50–53]. For example, the complex $[Ni_2L[1c](ClO_4)](ClO_4)$ (E^1_{pc} −0.79 V and E^2_{pc} −1.28 V), which are less negative in comparison to those of the complex $[Ni_2L[1b](ClO_4)]-(ClO_4)$ (E^1_{pc} −0.91 V and E^2_{pc} −1.31 V), which, in turn, are less negative in comparison to those of the complex $[Ni_2L[1a](ClO_4)](ClO_4)$ has the values of (E^1_{pc} −1.00 V and E^2_{pc} −1.43 V). This shows that as the number of methylene groups between the imine nitrogen (chain length) increases, the entire macrocyclic ring becomes more flexible, which causes easy reduction. Thus, the large size of the cavity easily holds the reduced cation and stabilizes the formation of Ni(I) in both compartments. The observed reduction potential for $[Ni_2L[1d](ClO_4)](ClO_4)$ (E^1_{pc} −1.06 V and E^2_{pc} −1.28 V) and $[Ni_2L[1e](ClO_4)](ClO_4)$ (E^1_{pc} −1.31 V and E^2_{pc} −1.47 V), shows that the reduction of complexes of the ligands L[1d] and L[1e] is rather difficult when compared to the reduction of the complexes of the ligands L[1a–1c] due to the planarity induced by the aromatic ring, which makes the system more rigid.

3.4. Oxidation process at anodic potential

All the nickel complexes show two oxidation processes in the range 0.72–1.52 V. The cyclic voltammogram of the complexes is shown in Fig. 2 and the data are

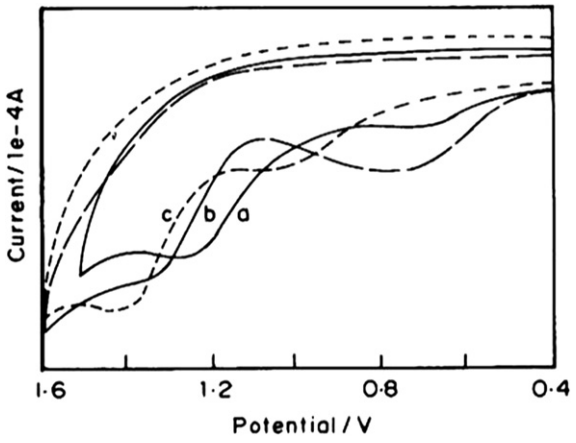

Fig. 2. Cyclic voltammogram of the binuclear nickel(II) complexes: (a) $[Ni_2L[1a](ClO_4)](ClO_4)$, (b) $[Ni_2L[1b](ClO_4)](ClO_4)$ and (c) $[Ni_2L[1c](ClO_4)](ClO_4)$ (oxidation process).

summarized in Table 2. The oxidation process is irreversible in nature. Controlled potential electrolysis experiment indicates that the two oxidation peaks are associated with stepwise oxidation process at nickel(II) center

$$Ni^{II}Ni^{II} \rightarrow Ni^{II}Ni^{III} \rightarrow Ni^{III}Ni^{III}$$

The first and second oxidation potential of the complexes $[Ni_2L[1a–c](ClO_4)](ClO_4)]$ shifts towards more positive value [53] (from E^1_{pc} 0.72 to 0.98 V and E^2_{pc} 1.23 to 1.39 V) as the number of methylene groups (chain length) increases in the imine compartment. This is because as the ring size increases due to flexibility, the planarity of the complex decreases and the electrochemical oxidation process occurs with difficult. For example the first oxidation potential of the complex $[NiL[1c](ClO_4)]ClO_4$ is 0.91 V (E^1_{pc}) and the second oxidation potential is 1.39 V (E^2_{pc}) which are more positive when compared $[NiL[1b](ClO_4)]ClO_4$ (E^1_{pc} 0.80 V and E^2_{pc} 1.32 V) which is more positive than $[NiL[1a](ClO_4)]ClO_4$ (E^1_{pc} 0.72 V and E^2_{pc} 1.23 V). Similar trend has been observed for complexes $[NiL[1d–e](ClO_4)]ClO_4$. This is because for complexes with aromatic diimines, an increase in unsaturation will decrease the electron on the metal through delocalization, on to the ligand and this increases the difficulty to oxidize the metal ion.

3.5. Kinetic studies of hydrolysis of 4-nitrophenylphosphate

The catalytic activity of the nickel(II) complexes on the hydrolysis of 4-nitrophenylphosphate was determined spectrophotometrically by monitoring the increase in the characteristic absorbance of the 4-nitrophenolate anion at 420 nm over the time in dimethylformamide at 25 °C. For this purpose, 10^{-3} mol dm^{-3} solutions of complexes in dimethylformamide were treated with 100 equivalents of 4-nitrophenyl phosphate in the presence of air.

The course of the reaction was followed at 420 nm for nearly 45 min at regular time intervals. The slope was determined by the method of initial rates by monitoring the growth of the 420 nm band of the product 4-nitrophenolate anion. A linear relationship for all the complexes shows a first-order dependence on the complex concentration for the systems. Plots of $\log(A_\infty/A_\alpha - A_t)$ versus time for hydrolysis of 4-nitrophenylphosphate activity of the complexes are obtained and shown in Fig. 2. The inset in Fig. 3 shows the time dependent growth of *p*-nitrophenolate chromophore in the presence of $[Ni_2L[1a](ClO_4)](ClO_4)$. The observed initial rate constant values for all the nickel(II) complexes are given in Table 2.

The catalytic activities of the binuclear complexes are found to increase as the macrocyclic ring size increases due to the intrinsic flexibility, i.e. increase in the chelate ring size enhances the rate constant of hydrolysis fairly well by producing distortion in the geometry around the metal ion that enhances the accessibility of the metal ion for the bonding of phosphate and OH groups. The catalytic activity of the complexes containing aromatic diimines $[Ni_2L[1d](ClO_4)](ClO_4)$ and $[Ni_2L[1e](ClO_4)](ClO_4)$ is found to be less than that of the complexes containing aliphatic diimines. This may be due to the planarity, which is associated with aromatic ring, imparts less catalytic efficiency due to the rigidity of the systems as observed in the case of previous literature reports [54–56].

3.6. Antifungal and antimicrobial activities

Antifungal and antimicrobial activities of the complexes were tested by the cup plate method using nutrient agar. The radial growth of the colony was recorded on completion of the incubation and the mean diameter for each complex at a concentration of 100 μg/ml was recorded. The average percentage inhibition of the bactericidal growth medium was compared using the Vincent (Vincent, 1947) equation: $I = 100(C - T)/C$, where I = percentage inhibition, T = average diameter of the bacterial growth on the tested plates and C = average diameter of the growth on the control plates.

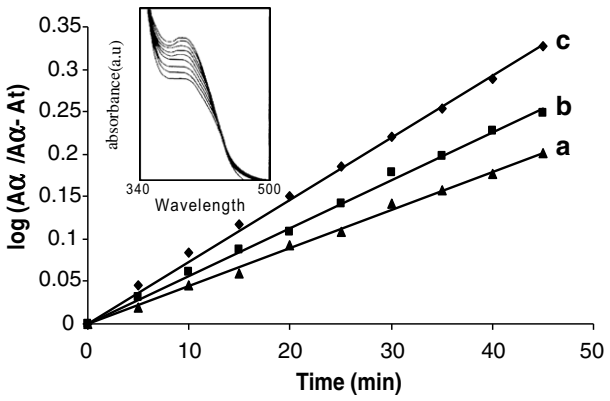

Fig. 3. Hydrolysis of 4-nitrophenylphosphate by binuclear nickel(II) complexes: (a) $[Ni_2L[1a](ClO_4)](ClO_4)$, (b) $[Ni_2L[1b](ClO_4)](ClO_4)$ and (c) $[Ni_2L[1c](ClO_4)](ClO_4)$ The inset is the time dependent growth of *p*-nitrophenolate chromophore in the presence of $[Ni_2L[1a](ClO_4)](ClO_4)$.

Table 3
Antibacterial and antifungal screening data of complexes

No.	Complexes	Representation zone of inhibition (100 μg/ml)					
		Antibacterial					Antifungal
		Staphylococcus aureus	*Bacillus cearus*	*Klebsiella pneumonia*	*pseudomonas aureginosa*	*Escherichia coli*	*Candida albicans*
1	$[Ni_2L[1a](ClO_4)](ClO_4)$	16	15	14	15		14
2	$[Ni_2L[1b](ClO_4)](ClO_4)$	14	14	15	14		14
3	$[Ni_2L[1c](ClO_4)](ClO_4)$	16	20	15	16		16
4	$[Ni_2L[1d](ClO_4)](ClO_4)$	18	24	25	20		18
5	$[Ni_2L[1e](ClO_4)](ClO_4)$	19	26	25	19		21

3.6.1. Antifungal activity

Studies on the antifungal activity of tetraazamacrocyclic ligands and their complexes are limited in the literature [57–60]. We have evaluated the antifungal activity of all the nickel(II) complexes against the phytopathogenic fungus *Candida albicans*. The screening data were reported in Table 3. It is observed from the results that all tested complexes show some antifungal activity. The activity reported by the present complexes was comparable with the *N*-substituted tetraazamacrocycles [58,61]. Generally nickel(II) complexes of *N*-substituted tetraazamacrocycles shows higher activity than their corresponding cobalt(III) complexes [62]. Another interesting result observed here is that the complexes of L[1d] and L[1e] shows higher activity than the complexes of the ligand L[1a] to L[1c], which contain aliphatic diimines. It seems from the results that the nature of the ligand and the coordinated metal ion plays a significant role in the inhibition activity.

3.6.2. Antibacterial activity

All the prepared binuclear nickel(II) complexes have been subjected to antibacterial activity against selected five bacteria's such as *Pseudomonas aeroginosa* (ATCC 2036), *Staphylococcus aureus* (ATCC 2079), *Escherichia coli* (ATCC 2567), *Bacillus cereus* (ATCC 11778), and *Klebsiella pneumonia* (ATCC 29665), respectively. The screening results are shown in Table 3. From the results it is observed that all the complexes shows higher activities against *S. aureus*, *P. aeroginosa*, *K. pneumonia* and *B. cearus*, but all the complexes were in-active against *E. coli*. The higher activity of the complexes may be ascribed to Tweedy's theory, according to which chelation reduces the polarity of the central metal atom because of partial sharing of its positive charge with the ligand, which favors the permeation of the complexes through the lipid layer of the membrane [63]. However, further more studies are needed to understand the functions, which are responsible for antifungal and antibacterial activities of the tested complexes.

4. Conclusion

In conclusion, it has been observed that the small variation in the chain length of the imine compartment, (i) cause red shift in the electronic spectra. (ii) Shift the reduction potential anodically on increasing chain length. (iii) Shift the oxidation potential to more positive potential as the chain length increases. (iv) Shows higher catalytic activity on increasing chain length. All these studies of the complexes which agree well with the established trend.

Scheme 1.

magnetic exchange interaction which occurs between two Cu(II) ions of a paddle-wheel moiety [10–29].

In the present paper, we report the synthesis, crystal structure, spectroscopic and magnetic properties of three copper(II) compounds, i.e. a polynuclear $\{[Cu_4(phen)_2(\mu\text{-}O_2CC_2H_5)_8]\cdot(H_2O)\}_n$ (**1**) and two dinuclear compounds, $[Cu_2(\mu\text{-}O_2CC_6H_4OH)_4(C_7H_7NO)_2]\cdot 6H_2O$ (**2**) and $[Cu_2(\mu\text{-}O_2CCH_3)_4(C_7H_7NO)_2]$ (**3**). The magnetism of the polynuclear compound can be understood on the basis of two species, *i.e.* 50% paddle-wheel (strongly coupled) and 50% dinuclear-propionato bridged (weakly coupled).

2. Experimental

2.1. Materials and measurements

The ligands 1,10-phenanthroline, propionic acid, 3-hydroxybenzoic acid and 4-acetylpyridine were purchased as commercial chemicals from Aldrich. All other reagents are commercial grade materials and were used without further purification. Elemental analyses (C, H, N) were determined on a Perkin–Elmer PE 2400 CHNS/O Analyzer.

IR spectra were recorded on a Perkin–Elmer Spectrum One FT-IR spectrophotometer as KBr disc in the 4000–450 cm^{-1} spectral range. Solid-state (diffuse reflectance) electronic spectra were measured as polycrystalline samples on a Perkin–Elmer Lambda2S spectrophotometer. X-band powder EPR spectra were obtained on a Bruker-EMX*plus* electron spin resonance spectrometer (Field calibrated with DPPH ($g = 2.0036$)). Magnetic susceptibility measurements (2–320 K for **1** and 5–350 K for **2** and **3**) were carried out using a Quantum design MPMS-5 S SQUID magnetometer (measurements carried out at 0.1 mT). Data were corrected for magnetization of the sample holder and for diamagnetic contributions, which were estimated from the Pascal constants.

2.2. Syntheses

2.2.1. $\{[Cu_4(phen)_2(\mu\text{-}O_2CC_2H_5)_8]\cdot(H_2O)\}_n$ (*1*)

A hot aqueous solution (10 ml) of $Cu(CO_3)\cdot Cu(OH)_2$ (0.22 g, 1.0 mmol) was stirred and a blue precipitate formed within a few minutes. The resulting suspension became clear and light blue in color by slow addition of the concentrate propionic acid (2 ml) and stirred for 1 h. A solution of phen (0.20 g, 1.0 mmol) in acetonitrile: ethanol (20:10 ml) was added to the mixture, followed by addition of an aqueous solution of $NaO_2CCH_2CH_3$ (0.10 g, 1.0 mmol) with continuous stirring. After a month, blue polygon-shaped crystals of compound **1** were obtained which were filtered off, washed with the mother liquid and air-dried. Yield, ca. 70%. IR (KBr, cm^{-1}) ν: 3435 s, 1632 s, 1588 s, 1567 s,1465 m, 1426 s, 1372 m, 1301 m, 1262 m, 1078 m, 848 m, 811 w, 723 m. The electronic diffuse reflectance spectrum of **1** exhibits a broad band centered at 13 510 cm^{-1}. These features are consistent with the square-pyramidal based geometry and all d_{xy}, d_{yz}, d_{xz}, $d_{z^2} \rightarrow d_{x^2-y^2}$ transitions are assigned to this broad band. *Anal.* Calc. for $C_{48}H_{56}Cu_4N_4O_{17}$: C, 47.4; H, 4.7; N, 4.6. Found: C, 47.3; H, 4.7; N, 4.6%.

2.2.2. $[Cu_2(\mu\text{-}O_2CC_6H_4OH)_4(C_7H_7NO)_2]\cdot 6H_2O$ (*2*)

A warm solution of 3-hydroxybenzoic acid (0.14 g, 1.0 mmol) in methanol (20 ml) was added to a hot aqueous solution (10 ml) of $Cu(BF_4)_2$ (0.24 g, 1.0 mmol). An aqueous solution (10 ml) of 4-Acetylpyridine (0.12 g, 1.0 mmol) was then added. The light blue solution was slowly evaporated at room temperature. After several days, green rod crystals of **2** were formed. The crystals were filtered off, washed with mother liquid and air-dried. Yield, ca. 80%. IR (KBr, cm^{-1}) ν: 3292 s, 1698 m, 1578 s, 1451 m, 1400 s, 1360 m, 1258 m, 1215 w, 1051 w, 938 w, 822 w, 802 m, 767 m. The electronic diffuse reflectance spectrum of **2** exhibits a broad band centered at 13 460 cm^{-1}. These features are consistent with the square-pyramidal based geometry and all d_{xy}, d_{yz}, d_{xz}, $d_{z^2} \rightarrow d_{x^2-y^2}$ transitions are assigned to this broad band. *Anal.* Calc. for $C_{42}H_{46}Cu_2N_2O_{20}$: C, 49.2; H, 4.5; N, 2.7. Found: C, 51.0; H, 4.2; N, 2.8%.

2.2.3. $[Cu_2(\mu\text{-}O_2CCH_3)_4(C_7H_7NO)_2]$ (*3*)

The ligand 4-acetylpyridine (0.12 g, 1.0 mmol), dissolved in acetonitrile (10 ml) and a warm solution of $Cu(CH_3COO)_2$ (0.18 g, 1.0 mmol) were mixed together. The blue solution was slowly evaporated at room temperature until dark blue crystals of **3** separated. Yield ca. 70%. IR (KBr, cm^{-1}) ν: 1697 s, 1625 s, 1433 s, 1366 m, 1261 s, 1060 w, 834 w, 684 w. The electronic diffuse reflectance spectrum of **3** exhibits a broad band centered at 14 470 cm^{-1}. These features are consistent with the square-pyramidal based geometry and all d_{xy}, d_{yz}, d_{xz}, $d_{z^2} \rightarrow d_{x^2-y^2}$ transitions are assigned to this broad band. *Anal.* Calc. for $C_{22}H_{26}Cu_2N_2O_{10}$: C, 43.6; H, 4.3; N, 4.6. Found: C, 43.4; H, 4.1; N, 4.6%.

2.3. Crystallography

The X-ray single-crystal data for the three compounds were collected at 273 K for compounds **1** and at 293 K for **2**, **3**, respectively, on a 1 K Bruker SMART CCD area-detector diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a detector distance of 4.5 cm and swing angle of −30°. A hemisphere of the reciprocal space was covered by combination of three sets of exposures; each set had a different ϕ angle (0°, 88°, 180°) and each exposure of 40 s covered 0.3° in ω. Data reduction and cell refinements were performed using the program SAINT [30]. An empirical absorption correction by using the SADABS [31] program was applied, which resulted in transmission coefficients ranging from 0.624 to 1.000 for compound **1**, 0.845 to 1.000 for compound **2** and 0.695 to 1.000 for compound **3**. The structures were solved by direct methods and refined by full matrix least-squares method on $(F_{obs})^2$ with anisotropic thermal parameters for all non-hydrogen atoms using the SHELXTL-PC V 6.12 software package [32]. All hydrogen atoms were located in a difference Fourier map and refined isotropically, except the H atoms of the propionate groups in **1**, which were fixed geometrically with the HFIX utility and the hydrogen atoms of one water molecule in **1** and four water molecules in **2**, which we were unable to locate and also could not be located at fixed positions. The terminal C atom in three propionate groups of **1** showed disorder; the occupancies of the

disordered positions were initially refined and later fixed at 0.5. The molecular graphics were created by using SHELXTL-PC [32] package. The crystal and refinement details for the three compounds are listed in Table 1.

3. Results and discussion

3.1. Crystal structure of $\{[Cu_4(phen)_2(\mu\text{-}O_2CC_2H_5)_8]\cdot(H_2O)\}_n$ (**1**)

The structure of compound **1** involves a one-dimensional overall structure constructed from tetranuclear units and consists of chains of dinuclear $Cu_2(\mu\text{-}OCOC_2H_5)_2(\mu\text{-}O_2CC_2H_5)_2(phen)_2$ repeating units which are connected to each other along the unit cell diagonal by $Cu_2(\mu\text{-}O_2CC_2H_5)_4$ paddle-wheel dinuclear units. This structure is depicted in Fig. 1 together with the numbering scheme. Selected distances and angles are listed in Table 2. The two dinuclear units are linked by the *syn,anti*-triatomic propionato bridge in an axial-equatorial configuration. The polynuclear copper(II) carboxylates are known to exhibit three classes of local paddle-wheel structure. Compound **1** has a structure derived from *class B*, with a dinuclear molecule bridging two dinuclear units [9].

The paddle-wheel dinuclear $Cu_2(\mu\text{-}O_2CC_2H_5)_4$ unit in the chain contains four bridging propionates in the *syn,syn*-$\eta^1:\eta^1:\mu$ coordination mode, as known for the compound $[Cu_2(\mu\text{-}O_2CC_2H_5)_4(H_2O)_2]$ [33]. The geometry around the Cu(2) and Cu(2)A atoms can be considered as square-pyramidal with a τ value of 0.005 (in which the structural parameter τ describes the relative amount of trigonality; $\tau = 0$ for square pyramid and $\tau = 1$ for trigonal bipyramidal [34]) arising from five oxygen atoms of five different propionate groups. The corresponding Cu–O distances in the basal plane are in the range 1.952(3)–1.962(3)(2) Å. An O atom of a bridging propionate molecule occupies the axial position at a distance of 2.120(2) Å.

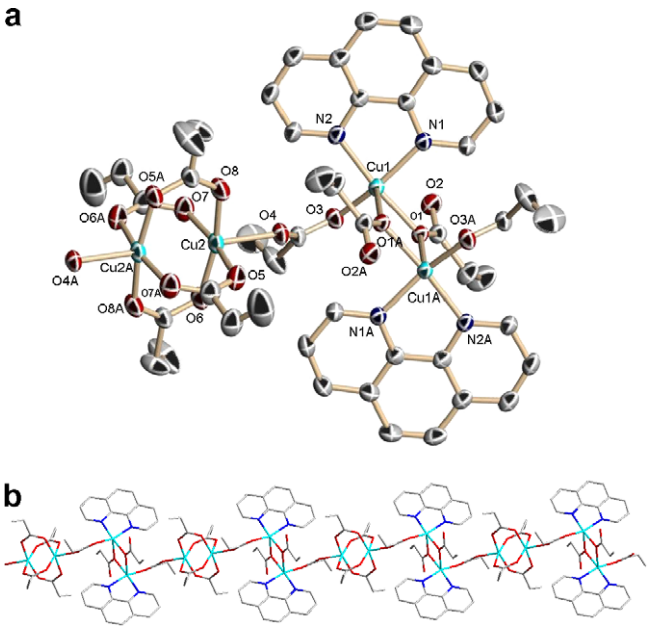

Fig. 1. (a) Thermal ellipsoid (30% probability) plot of $\{[Cu_4(phen)_2(\mu\text{-}O_2CC_2H_5)_8]\cdot(H_2O)\}_n$ (**1**). Hydrogen atoms and water molecules are omitted for clarity. (b) View of the 1-D polymeric chain.

Table 2
Selected bond lengths (Å) and angles (°) of $\{[Cu_4(phen)_2(\mu\text{-}O_2CC_2H_5)_8]\cdot(H_2O)\}_n$ (**1**)

Cu(1)–N(1)	2.031(3)	Cu(2)–O(4)	2.120(2)
Cu(1)–N(2)	2.044(3)	Cu(2)–O(5)	1.952(3)

O(3)–Cu(1)–N(2)	96.5(1)	O(7)–Cu(2)–O(8)	88.9(1)
O(3)–Cu(1)–O(1)A	109.5(1)	O(8)–Cu(2)–O(6)	167.9(1)
Cu(1)–O(1)–Cu(1)A	103.9(1)		

The basal planes have a slight tetrahedral twist of 16.72(1)°. The Cu atoms are displaced from the basal planes at distances of 0.003 Å. The Cu(2)–Cu(2)A distance is 2.623(1) Å and is slightly longer than the Cu···Cu distance in $[Cu_2(\mu\text{-}O_2CC_2H_5)_4(H_2O)_2]$ (2.611(2) Å) [33].

The dinuclear $[Cu_2(\mu\text{-}OCOC_2H_5)_2(\mu\text{-}O_2CC_2H_5)_2(phen)_2]$ unit has a CuN_2O_2O' chromophore and the geometry around the Cu(II) ions (Cu(1) and Cu(1)A) is distorted square pyramidal with a τ value of 0.290. The basal plane of CuN_2O_2O' chromophore consists of two N atoms from the phen ligand and two O atoms from two different propionato bridging molecules and is non-planar with a slight tetrahedral twist of 24.05(1)°. An O atom of a propionato bridging ligand occupies the axial position with a distance of 2.354(2) Å. The Cu atom is situated above the basal planes, 0.215 Å toward the axial sites. Both Cu(1) and Cu(1)A are linked by doubly bridged monoatomic propionato molecules in an axial-equatorial configuration with a Cu···Cu distance of 3.408(1) Å. The structural parameters of compound **1** are compared with some related compounds in Table 5.

The interplanar distances between the phen rings of two adjacent chains are 3.488–3.494 Å, indicating suggests π-stacking interactions. The π–π interaction between parallel phen rings of different chains are shown in Fig. 2. The 2D layer resulting form stacks in the crystal is presented in Fig. 2.

3.2. Crystal structure of $[Cu_2(\mu\text{-}O_2CC_6H_4OH)_4(C_7H_7NO)_2] \cdot 6H_2O$ (**2**)

The structure of compound **2** consists of centrosymmetric dinuclear paddle-wheel unit. The structure is depicted in Fig. 3 together with the numbering scheme. Selected distances and angles are listed in Table 3. Both Cu(II) ions are linked by four carboxylato groups of the 3-hydroxybenzoate ligand in a *syn,syn*-$\eta^1:\eta^1:\mu$ disposition. The pyridyl nitrogen atom of 4-acetylpyridine is axially coordinated, completing the square-pyramidal coordination geometry with a τ value of 0.002. The Cu–O distances are ranging from 1.958 to 1.970 Å and the Cu–N distance is 2.181(2) Å. The Cu···Cu distance is 2.654(1) Å. The basal plane is non-planar with a slight tetrahedral twist of 17.2(1)° and the Cu atoms lie 0.001 Å above the basal plane toward the axial sites. The structural parameters of compound **2** are in the normal range found for other paddle-wheel copper(II) dinuclear units [35], as shown in Table 5.

The crystal lattice is stabilized by hydrogen bonding between the O atom of uncoordinated water and an O atom of neighbouring carboxylato group; between the O atom of uncoordinated water and O atom of neighbouring hydroxy group of 3-hydroxybenzoate ligand (O···O distances vary from 2.591(1) to 3.257(1) Å) leading to the formation of a one-dimensional chain in the lattice. Details of the hydrogen bonding are listed in Table 3.

3.3. Crystal structure of $[Cu_2(\mu\text{-}O_2CCH_3)_4(C_7H_7NO)_2]$ (**3**)

Compound **3** consists of centrosymmetric dinuclear units, similar to other copper acetate derivates, in which four acetate groups are bridging two Cu atoms and 4-acetylpyridine as a ligand occupies the axial position, giving a CuO_4N chromophore. This structure is depicted in Fig. 4 together with the numbering scheme. Selected distances and angles are listed in Table 4. Each copper atom has a square-pyramidal geometry, with four oxygen atoms in a basal plane (Cu–O distances vary from 1.965(1) to 1.972(1) Å); the fifth coordination position is occupied by the nitrogen of a 4-acetylpyridine ligand with a distance of 2.198(1) Å. The CuO_4N chromophore

is non-planar with tetrahedral twist of 18.15(1)°. The copper atoms are displaced by 0.001 Å from the basal planes toward the apical positions. The value of τ is 0.002, corresponds to a square-pyramidal coordination [34]. Four acetate anions bridge two copper ions in a *syn*,*syn*-η^1:η^1:μ showing a paddle-wheel unit with a Cu···Cu distance of 2.631(4) Å. The structural parameters of compound **3** compare well with some related compounds, as shown in Table 5.

3.4. EPR and magnetic properties

The EPR spectra of the compounds were recorded as a polycrystalline powder at RT and at 70 K (compound **2** also 120 K) from 0 to 800 mT at X-band frequency ($h\nu$ = 0.325 cm^{-1}). The EPR spectrum of compound **1** is rather complicated and consists at RT of a very broad and strong signal centered around 290 mT and a shoulder at 249 mT (see Fig. 5A). Furthermore weak signals are observed at about 15, 369, 469 and 532 mT, which can be assigned to S = 1 triplet signals [36,37]. The signal at 159 mT can be assigned to the forbidden half-field signal (ΔM_s = ±2). At 70 K the signal decreases in intensity (see Fig. 5B), due to the depopulation of the triplet state and in this case at 325 mT the S = 1/2 resonance from a mononuclear impurity, which usually is present in dinuclear Cu(II) compounds, becomes visible. At RT this band is hidden under the strong resonance at 290 mT. The g values calculated from the EPR spectrum (considering the fact that the lines are broad and not resolved) is estimated as g_{xy} = 2.06 and g_z = 2.25, values considered normal for a Cu(II) signal.

As compounds **2** and **3** are almost isostructural, also the EPR spectra of both compounds are very similar as expected. The EPR spectrum of compound **2** is shown in Fig. 6 at RT, 120 and 70 K (the EPR spectrum of compound **3** is given as Supplementary material). The spectrum at RT (Fig. 6A) shows three bands at 23, 470 and 600 mT (that last band is only partly visible due to the limitations of the EPR magnetic field). These bands are typical for a triplet state of a copper(II) acetate hydrate type [11,24–27,36–39] with three resonance lines (H_{z1}, $H_{\perp}$, H_{z2}). At 120 K (Fig. 6B) the H_{z1} signal splits, due to hyperfine interaction of the unpaired electron within the dinuclear unit (A = 6.2 mT). The small feature at around 320 mT is from a monomeric impurity, which is in most cases always present in dinuclear bulk material. At 70 K the triplet signal becomes very weak (Fig. 6C), and therefore the monomeric impurity at 320 mT appears as relatively very strong. This behaviour is consistent with the magnetic susceptibility of these compounds (see magnetism below). The same type of signals was observed for compound **3** (see Supplementary material). Similar spectra with the same type of bands are observed for the compounds [Cu_2(OOC-C_5H_{11})$_4$(urea)$_2$] [11] and {[Cu_2(β-alanine)$_4$(H_2O)$_2$](NO_3)$_4$(H_2O)$_4$} [26]. For these compounds the zero-field splitting parameter D was calculated as being 0.34 cm^{-1}, so we can estimate that the value of D is also around 0.34 cm^{-1} for compound **2** and **3**.

The magnetic susceptibility of a powdered sample of compound **1** was measured from 2 to 320 K under a constant magnetic field of 0.1 T. The magnetic properties are depicted in Fig. 7 in the form of $\chi_M T$ *versus* T for four Cu(II) ions. At 320 K the $\chi_M T$ product has a value of 1.60 cm^3 · K · mol^{-1}, which is just a little higher than the value expected for four uncorrelated Cu(II) ions (1.40 cm^3 · K · mol^{-1} for g = 2) showing at best a very weak interaction between the metallic centers at 320 K. Upon cooling the $\chi_M T$ product gradually decreased as the temperature was lowered and reached a value of 1.05 cm^3 mol^{-1} K at 75 K, stays constant till about 20 K, where it decreases till it reached a value of 0.98 cm^3 mol^{-1} K at 2 K. This magnetic behaviour agrees with a overall strong antiferromagnetic interaction, at least for part of the Cu(II) ions.

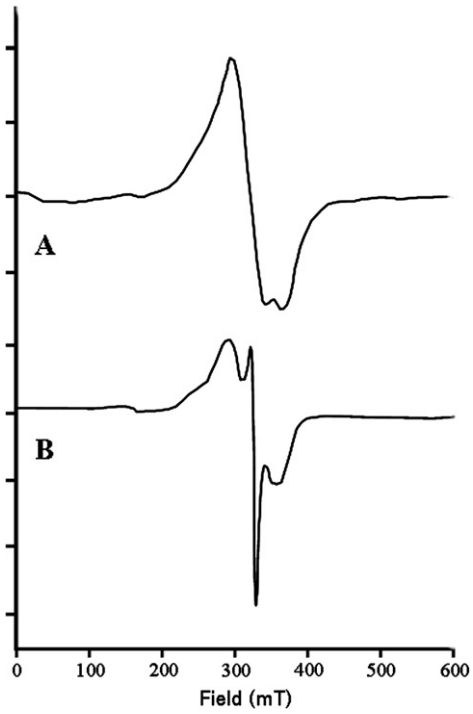

Fig. 5. X-band powder EPR spectrum of compound **1** at RT (A) and at 70 K (B).

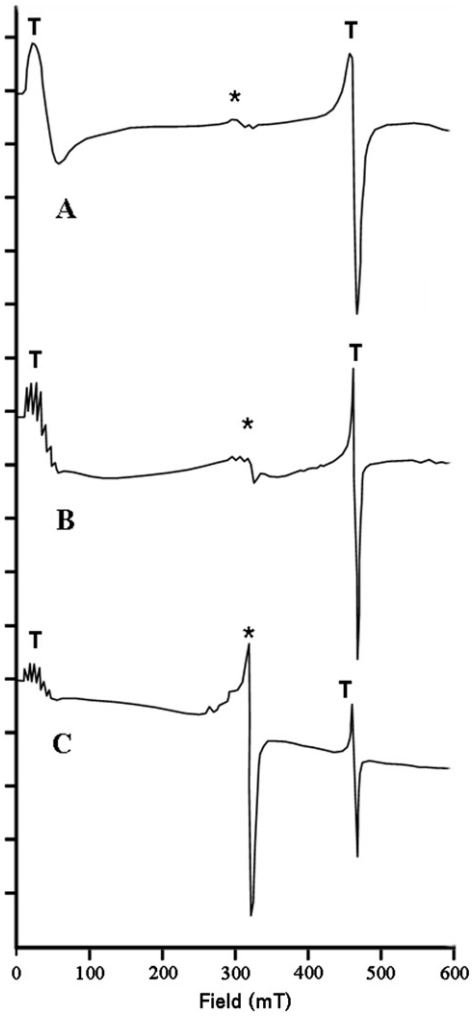

Fig. 6. X-band powder EPR spectrum of compound **2** at RT (A), at 120 K (B) and at 70 K (C). (* = signal of the mononuclear signal; T = triplet signal).

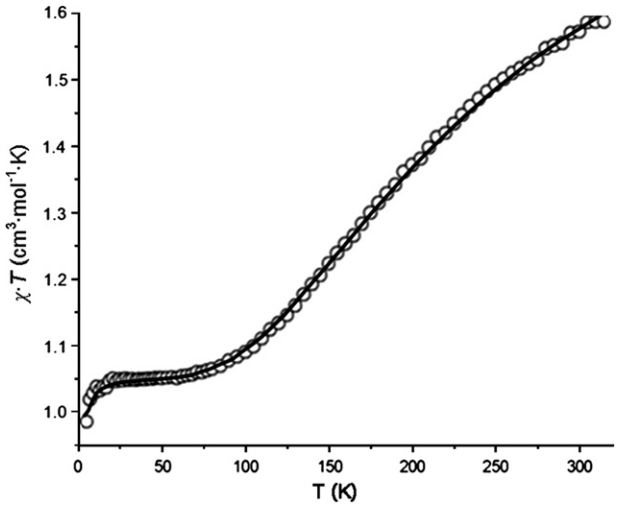

Fig. 7. A plot of the temperature dependence of $\chi_M T$ *vs. T* for compound **1** in the range 2–320 K.

To explain the magnetic interaction of compound **1** the general Heisenberg Hamiltonian [40] $H_{ex} = -JS_1S_2$, in which the exchange parameter J, is negative for antiferromagnetic and positive for ferromagnetic interaction.

To simplify the expression for the susceptibility it was decided to use a combination of a two term contribution, i.e. $\chi = \chi Cu(1) + \chi Cu(2)$, in which

$$\chi Cu(1) = 2Ng_1^2\beta^2[kT(3 + \exp(-J_1/kT))]^{-1} \quad \text{and}$$
$$\chi Cu(2) = 2Ng_2^2\beta^2[kT(3 + \exp(-J_2/kT))]^{-1}$$

In these expressions J_1 and J_2 corresponds to the singlet–triplet energy gap for the two dinuclear sub-units in compound **1** (J_1 for the Cu(1)–Cu(1)A unit; J_2 for the Cu(2)–Cu(2)A unit), and N, g, β, k and T have their usual meanings [40]. The best-fit parameters, depicted in Fig. 7 as a solid line, were: $g_1 = 2.35$, $g_2 = 2.22$, $J_1 = -0.75$ cm^{-1}, $J_2 = -299.5$ cm^{-1}, with $R = 5 \times 10^{-5}$, the agreement factor defined as $\sum_i(\chi_{calcd} - \chi_{obs})^2/\sum_i(\chi_{obs})^2$. In a first approximation the g values obtained by EPR have been used to properly fit the magnetic behavior, however, a poor result was achieved likely due to the fact that the formula of the magnetic susceptibility is of course based on a number of approximations.

The magnetic susceptibility of powdered samples of compounds **2** and **3** were measured from 5 to 350 K. As the two compounds are structural similar, also the magnetic properties are similar. The magnetic properties of the compounds are depicted in Fig. 8 for compound **2** and in Fig. S3 for compound **3** in the form of $\chi_M T$ *versus* T for two Cu(II) ions. At 350 K the $\chi_M T$ product of **2** has a value of 0.575 cm^3 mol^{-1} K (0.554 cm^3 mol^{-1} K for **3**), which is below the spin-only value for two non-interacting Cu(II) ions (0.75 cm^3 mol^{-1}K at RT). From 350 K the $\chi_M T$ product decreases gradually to a value of 0.014 cm^3 mol^{-1} K for compound **2** at 50 K (0.006 cm^3 mol^{-1} K for **3**) and stays constant till 5 K. This magnetic behaviour agrees with a strong antiferromagnetic interaction.

The theoretical expression for the magnetic susceptibility for two interacting $S = 1/2$ centres, which is based on the general Hamiltonian [40] is: $H_{ex} = -JS_1S_2$, in which the exchange parameter J, is negative for antiferromagnetic and positive for ferromagnetic interaction. The magnetic data were fitted to the equation given in the literature [40] for dinuclear copper compounds:

$$\chi_M = (2Ng^2\beta^2)[kT - (2zJ'/(3 + \exp(-J/kT)))]^{-1} \times [3 + \exp(-J/kT)]^{-1}(1 - p) + \chi_p p,$$

in which N, g, β, k and T have their usual meanings [40]. The parameter p denotes the fraction of paramagnetic impurity in the sample and zJ' the interaction between neighbouring dinuclear identities. The fit was accomplished by minimisation of $R = (\chi_M T_{calc} - \chi_M$-

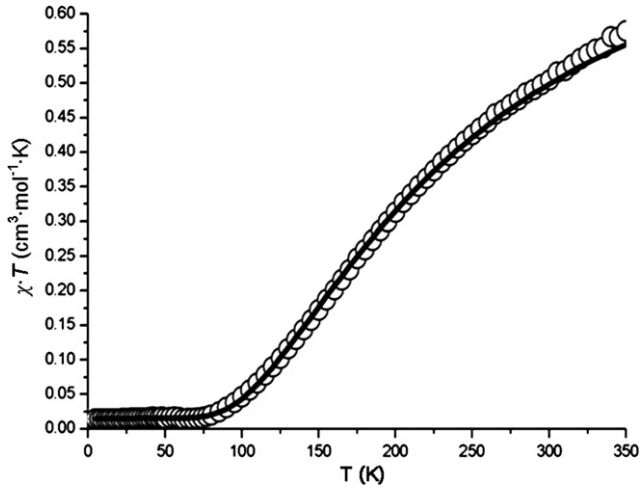

Fig. 8. A plot of the temperature dependence of $\chi_M T$ *vs. T* for compound **2**.

$T_{obs})^2/(\chi_M T_{obs})^2$ by a least-squares procedure. The best fit for compound **2**, depicted in Fig. 8 as a solid line, was obtained for $J = -278.5\ cm^{-1}$, $g = 2.15$, $zJ' = -26.3\ cm^{-1}$, $p = 0.02$, with a final R of 1.5×10^{-2}. The best fit for compound **3**, depicted in Fig. S3 as a solid line, was obtained for $J = -287.0\ cm^{-1}$, $g = 2.15$, $zJ' = -24.7\ cm^{-1}$, $p = 0.01$, with a final R of 1.5×10^{-2}. The R values appear a bit high, but can be ascribed to the fact that susceptibility measurements above 300 K are less accurate due to a reduced accuracy in temperature, in fact when only the temperature range of 5–280 K is considered the R-value is much better, *i.e.* 3×10^{-3}.

Recently, Rodr˘guez-Fortea et al.[24] have reported a density functional study of the exchange coupling in carboxylato-bridged dinuclear copper(II) compounds. They compared the J values for several substituents in $[Cu_2(\mu\text{-}RCOO)_4L_2]$ and concluded that the electron-withdrawing groups reduce the strength of the exchange coupling. Another factor is the Cu–O bridging bond in copper(II) carboxylate dinuclear units, which is considered to be quite important in the super-exchange mechanism; it is the basis for the super-exchange pathway of the Cu–O–C(R)–O–Cu fragments. When R is strongly σ-bonded to the carboxylato carbon, the strong coordination of the Cu–O bonds in the CuO_4 basal plane will become stronger, in order to maintain the electron neutrality over the whole molecule. Thus, the J value increases when the Cu–O bond length decreases. In addition the coupling constant is weakly dependent on the Cu···Cu distance. If the Cu···Cu distance increases, the overlap of the δ-bonding between the two Cu atoms decreases and the J value would be slightly lower.

The structure of compound **1** is compared with the most related carboxylato-bridged compound $[Cu_2(\mu\text{-}O_2CC_2H_5)_4(H_2O)_2]$ **10** ($J = -311\ cm^{-1}$) in Table 5. When water molecules in axial positions of compound **10** are replaced by propionate bridges (compound **1**), the average Cu–O distance is 1.959 Å and the Cu···Cu distance is 2.623 Å, which both are longer than those of the corresponding compound **10** (1.948 and 2.575 Å, respectively). Thus, the strong Cu–O bonds in the CuO_4 basal plane of **1** will become weaker than those of compound **10**; this may result in a decreased $-J$ value. In addition, a longer Cu···Cu distance would lead to a smaller $-J$ value (in this case $-299\ cm^{-1}$). Nevertheless, it should be mentioned that the approximation used to obtain the Hamiltonian to calculate the J value is somewhat simplified, which can explain that the g values are somewhat higher then expected for Cu(1) and Cu(2). Indeed, it was observed that below 50 K the magnetism of compound **1** can be depicted as a unidimensional assembly of antiferromagnetically coupled $S = 1/2$ spins. Confirmation of this magnetic chain behaviour is seen from the linear $\ln \chi_M T$ *versus* T^{-1} curve in this temperature range (Fig. S4) [41]. In addition, the value of the dinuclear coupling via Cu(1)···Cu(1)A for compound **1** is expected to be small, as predicted by the theoretical calculation. The Cu(1)–O(1)–Cu(1)A pathway involve the d_{z^2} and $d_{x^2-y^2}$ orbital for Cu(1) and for Cu(1)A, therefore and because of the copper symmetry, the unpaired electron around copper(II) are described mainly by a magnetic orbital built from the $d_{x^2-y^2}$, confirming the theoretical result.

Complexes with the $Cu_2(\mu\text{-}O_2CCH_3)_4$ basic unit all have relatively high negative magnetic exchange coupling constants. For $[Cu_2(\mu\text{-}O_2CCH_3)_4(H_2O)_2]$ **5** with a coupling constant J of $-299\ cm^{-1}$, water molecules in axial positions are replaced by NH_3 for compound **6** [24], or MeNHpy for compound **7** [37] the coupling constant is slightly less negative of −284 and −285 cm^{-1}, respectively. It is indicating that the change of the axial ligand induces smaller variations in the coupling constant. Consequently, compound **3** with the axial 4-acetylpyridine ligands, the slightly decreased $-J$ value is expected. When the acetate groups in compound **3** are replaced by 3-hydroxybenzoate groups (compound **2**), which is a stronger electron-donating group, the increased $-J$ value is expected. According to that, it is reasonable to imply that the 3-hydroxybenzoate bridge in **2** should provide a somewhat larger exchange coupling than the acetato bridge in compound **3**. However, the experimental results are almost the same ($J = -278.5$ and $-287.0\ cm^{-1}$ for complexes **2** and **3**, respectively) and lie almost in the experimental deviation for such large values.

4. Conclusion

We have presented the synthesis and magnetic study of three new polynuclear tetracarboxylato-bridged copper(II) complexes. Four carboxylate ligands bridge two copper ions in a *syn*,*syn*-η^1:η^1:μ showing the paddle-wheel unit. Compound **1** exhibits an one-dimensional chain structure build from two different dinuclear units. The adjacent chains are connected to form a 2D structure through the π–π interaction. Both compounds **2** and **3** are dinuclear with a paddle-wheel structure with 4-acetylpyridine at the apical position. The coordination geometry around each copper(II) ion is (distorted) square-pyramidal for all three compounds. All compounds show a strong antiferromagnetic interaction between the Cu(II) magnetic centres of the dinuclear units, with different magnitude of J values mainly depending on substituents of the carboxylate groups. The observed J values correspond nicely with values found in the literature for other carboxylato-bridged dinuclear units (see Table 5).

novel 4,4′-isopropylidendioxydiphenyl bridged bis-metallophthalocyanines Zn(II) and Co(II) (Scheme 1).

2. Experimental

2.1. Synthesis and characterization

The starting materials **2** and **4** were synthesized by the methods described previously in the literature [21]. Compound **1** was used as supplied commercially. IR Spectra were recorded on a Mattson 1000 FTIR spectrophotometer using KBr pellets. Electronic spectra were recorded on a Unicam UV/Vis spectrophotometer and elemental analyses were performed by the Instrumental Analysis Laboratory of Chemistry Department, Yildiz Technical University. ^{1}H NMR spectra were recorded in *d*-chloroform with an instrument Mercury-Vx 500 MHz. Mass spectra were acquired in linear and reflectron modes with average of 50 and 100 shots on a Voyager-DE™ PRO MALDI-TOF mass spectrometer (Applied Biosystems, USA) equipped with a nitrogen UV-Laser operating at 337 nm.

Dithranol (1,8-dihydroxy-10H-anthracene-9-one) (20 mg/mL in tetrahydrofuran) matrix for **5**, **6**, **8** and α-cyano-4-hydroxycinnamic acid (ACCA) (15 mg/mL 1:1 water–acetonitrile) MALDI matrix for **7** were prepared. MALDI samples were prepared by mixing complex (2 mg/mL in chloroform) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® micro tube. Finally 1 μL of this mixture was deposited on the sample plate, dried at room temperature and then analyzed.

*2.1.1. 4,4′-Isopropyliden-bis-dioxydiphthalonitrile (**3**)*

Compound **1** (1.979 g, 8.67 mmol) and compound **2** (3 g, 17.34 mmol) were dissolved in dry DMF under argon. After stirring for 15 min, finely ground anhydrous K_2CO_3 (2.39 g, 0.017 mmol) was added portion wise in 15 min with efficient stirring. The reaction mixture was heated and stirred at 90 °C for 24 h under argon. After cooling to room temperature it was treated with water and the product filtered off and washed with water and ethanol. The product was purified on a silica gel column with chloroform as a eluent. Yield: 2.5 g, (60.08%). This compound is soluble in $CHCl_3$, DCM, and MeOH. Mp: 160 °C. *Anal.* Calc. for $C_{31}H_{20}N_4O_2$: C, 77.45; H, 4.58; N, 11.66. Found: C, 77.52; H, 4.68; N, 11.46%. IR (KBr pellet) ν, cm^{-1}: 3074 (Ar–H), 2231 (C≡N), 1566–1587 (C=C), 1245–1282 (Ar–O–Ar); ^1H NMR ($CDCl_3$) δ 8.32 (d, J = 8.19 Hz, 2H), 7.92 (d, J = 8.58 Hz, 2H), 7.82 (d, J = 2.34 Hz, 2H), 7.70 (d, J = 8.58 Hz, 2H), 7.56 (m, 4H), 7.10 (brs, 2H), 6.92 (d, J = 2.34 Hz, 2H), 6.86 (dd, J = 8.78 Hz, J = 2.34 Hz, 2H), 4.95 (s, 2H) ppm.

*2.1.2. 14′[4,4′-Isopropylidendiphenoxy]bis- 3′,4′,7′,8′,11′, 12′(hexahexylthiophthalocyaninato) dizinc(II)(**5**)*

A mixture of compound **3** (0.449 g, 1.248 mmol), compound **4** (0,100 g, 0.208 mmol), and $Zn(OAc)_2 \cdot 2H_2O$ (0.035 g, 0.212 mmol) in 5 mL of DMF was refluxed in a sealed tube under Ar for 24 h. After cooling to room temperature the reaction mixture was treated with water to precipitate the product and then filtered. The crude product was washed with common organic solvents. The product was separated by column chromatography on silica gel with chloroform and a gradient of chloroform–MeOH up to 100% MeOH as eluent. Yield: 0.053 g (9.18%). This compound was soluble in $CHCl_3$, DCM and THF. Mp: > 300 °C. *Anal.* Calc. for $C_{151}H_{188}N_{16}O_2S_{12}Zn_2$: C, 65.42; H, 6.71; N, 8.09; S, 13.86. Found: C, 66.01; H, 6.86; N, 7.89; S, 13.76%. MS (MALDI-TOF): m/z 2772 $[M+H]^+$, IR (KBr pellet) ν, cm^{-1}: 3060 (arom. –CH), 2953–2853 (aliph. $-CH_2$), 1592 (C=C), 1229 (Ar–O–Ar); UV–Vis ($CHCl_3$) λ, nm ($\log\varepsilon$): 701 (4.88), 630 (4.34), 361 (4.88); ^1H NMR ($CDCl_3$): δ, ppm 7.51–6.97 (m, 30H, arom.), 1.62 (m, 6H, $-CH_3$), 1.33–1.19 (m, 120H, aliph. $-CH_2$), 0.95–0.93 (m, 36H, $-CH_3$).

*2.1.3. 14′[4,4′-Isopropylidendiphenoxy]bis- 3′,4′,7′,8′,11′,12′(hexahexylthiophthalocyaninato) dicobalt(II) (**6**)*

A mixture of compound **3** (0.449 g, 1.248 mmol), compound **4** (0,100 g, 0.208 mmol), and $Co(OAc)_2 \cdot 4H_2O$ (0.053 g, 0.212 mmol) in 5 mL of DMF was refluxed in a sealed tube under Ar for 24 h. After cooling to room temperature, the blue-green reaction product was obtained, isolated and purified with using the same procedure explained above for **5**. Yield: 0.078 g (13.56%). This compound was soluble in $CHCl_3$, THF, DMF. Mp: >300 °C. *Anal.* Calc. for $C_{151}H_{188}N_{16}O_2S_{12}Co_2$: C, 65.69; H, 6.74; N, 8.12; S, 13.92. Found: C, 64.88; H, 6.64; N, 7.88; S, 13.76%. MS (MALDI-TOF): m/z 2759 $[M+H]^+$, IR (KBr pellet) ν, cm^{-1}: 3060 (arom. –CH), 2953–2853 (aliph. $-CH_2$), 1592 (C=C), 1229 (Ar–O–Ar); UV–Vis ($CHCl_3$), λ, nm ($\log\varepsilon$): 682 (4.95), 624 (4.64), 325 (5.02).

*2.1.4. 2′,10′,16′,24′-[Tetrakis(4,4′-isopropylidenedioxydiphenyl)]bis-phthalocyaninatodizinc(II) (**7**)*

The mixture of compound **3** (0.100 g, 0.208 mmol) and $Zn(OAc)_2 \cdot 2H_2O$ (0.052 g, 0.312 mmol) was powdered in quartz crucible and heated in a sealed glass tube for 10 min under dry N_2 atmosphere at 250 °C. After cooling to room temperature, 5 mL of DMF was added to the residue to solve the product. The reaction mixture was precipitated by adding water. The precipitate was filtered, at first several times washed with hot water and then with hot ethanol in order to eliminate the unreacted starting materials and dried *in vacuo*. Then, the crude product was washed with methanol, ethanol, acetonitrile and acetone for 36 h, respectively in the Soxhlet apparatus. The product was separated by column chromatography on silica gel with chloroform as eluent. Yield: 0.040 g (9.39%). This compound is soluble in $CHCl_3$ and DCM. Mp >350 °C. *Anal.* Calc. for $C_{124}H_{72}N_{16}O_8Zn_2$: C, 72.84; H, 3.55; N, 10.96. Found: C, 72.94; H, 3.64; N, 10.77%. MS (MALDI-TOF): m/z 2044 $[M+H]^+$, IR (KBr pellet) ν, cm^{-1}: 3060 (arom. –CH), 1591 (C=C), 1231 (Ar–O–Ar); UV–Vis ($CHCl_3$), λ, nm ($\log\varepsilon$): 682 (4.56), 613 (3.88), 337 (4.33), 307 (4.49); ^1H NMR ($CDCl_3$): δ, ppm 7.75–6.92 (m, 72H, arom.), 1.68 (m, 24H, $-CH_3$).

*2.1.5. 2′,10′,16′,24′-[Tetrakis(4,4′-isopropylidenedioxydiphenyl)]bis-phthalocyaninatodicobalt(II) (**8**)*

The mixture of compound **3** (0.100 g, 0.208 mmol) and $Co(OAc)_2 \cdot 4H_2O$ (0.078 g, 0.313 mmol) was powdered in quartz crucible and heated in a sealed glass tube for 10 min under dry N_2 atmosphere at 250 °C. After cooling to room temperature, the blue-green reaction product was obtained, isolated and purified with using the same procedure explained above for **7**. Yield: 0.035 g (8.27%). This compound is soluble in $CHCl_3$, DCM and THF. Mp >350 °C. *Anal.* Calc. for $C_{124}H_{72}N_{16}O_8Co_2$: C, 73.30; H, 3.57; N, 11.03. Found: C, 73.45; H, 4.01; N, 11.12%. MS (MALDI-TOF): m/z 2031 $[M+H]^+$, IR (KBr pellet) ν, cm^{-1}: 3063 (arom. –CH), 1591 (C=C), 1231 (Ar–O–Ar); UV–Vis ($CHCl_3$), λ, nm ($\log\varepsilon$): 675 (4.70), 613 (4.32), 330 (4.67).

2.2. Electrochemical measurements

Electrochemical measurements were carried out with a PAR Model VersoStat II potentiostat/galvanostat controlled by an external PC, and utilizing a three electrode configuration at 25 °C. Tetrabutylammonium perchlorate (TBAP) (Electrochemical grade, Fluka Chemical Co.) was used as the supporting electrolyte in extra pure DCM. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a fritted glass bridge filled with the solvent/supporting electrolyte mixture. The ferrocene/ferrocenium couple (Fc/Fc^+) was used as an internal standard, but potentials were reported with respect to SCE. The working electrode was platinum in the measurements. The surface of the platinum working electrode was polished with a H_2O suspension of Al_2O_3 before each run. The last polishing was done with a particle size of 50 nm. A platinum spiral wire was used as the auxillary electrode. Solutions containing the complexes were deoxygenated by a stream of high-purity nitrogen for at least 20 min prior to running the experiment, and the solution was protected from air by a blanket of nitrogen during the experiment. For the controlled-potential coulometry (CPC) studies, a platinum gauze working electrode, a platinum wire counter electrode separated with a bridge and a SCE as reference electrode were used.

2.3. Electrical measurements

The measurement electrodes used in the dc and ac conductivity measurements consist of an interdigital array of metal electrodes photolitographically patterned on pre-cleaned glass substrate. Glass substrates were throughly cleaned by ultrasonically and then coated with 100 Å of chromium followed by 1200 Å of gold in a Leybold Univex 450 coater system. The film patterned photolitographically and etched to provide 10 fingers pairs of electrodes

having a width of 100 μm, spaced 100 μm from the adjacent electrodes. Gold was selected as the electrode material, since it is well-known that it forms ohmic contact to the phthalocyanine. Thin film of compounds was prepared by spin coating method on ohmic gold interdigital electrodes (IDT). For the spin coating, coating solutions were prepared by dissolving of the Pcs in extra pure grade chloroform at concentrations of 6.4×10^{-3} M for all compounds. Twenty micro liters of such solutions were added with a glass pipette onto the IDT structure held onto spinner (Speciality Coatings Systems Inc., Model P6700 Series). The substrate spun at 2000 rpm for 15 s and the solvent had evaporated during this period, producing a homogeneous film of phthalocyanine derivatives. The substrate temperature was kept constant at 300 K during deposition of the materials over the electrodes. Dc conductivity measurements were performed between 300 K and 470 K by using a Keithley 617 electrometer. Impedance spectroscopy and ac conductivity measurements were carried out with a Keithley 3330 LCZ meter in the frequency range, 40–10^5 Hz, and in the temperature range from 300 K to 470 K. All the measurements were performed under 10^{-3} mbar in the dark. Both dc and ac conductivity data were recorded using an IEEE 488 data acquisition system incorporated to a personnel computer.

3. Results and discussion

3.1. Synthesis and characterization

The synthesis of bisphthalodinitriles is based on the reaction of diols with excess of compound **2** (DMF or DMSO in the presence of K_2CO_3 as a base, at 20°C, for 60–96 h) [22,23]. Our key starting material is compound **3** which can be obtained via a reaction of compound **1** and **2**, in dry DMF in the presence of K_2CO_3 in a yield 60.08%. Bis-Pcs **5** and **6** were also obtained by the reaction of compound **3** with **4** using statistically mixed condensation method in dry DMF and in the presence of Zn(II)acetate and Co(II)acetate, respectively (Scheme 1).

In this work, for the synthesis of the new cofacial bis-Pcs, we have developed a solid phase method in the absence of catalysts. The preparation of phthalocyanine derivatives **7** and **8** were achieved by heating the homogenized mixture of **3** with Zn(II)acetate and Co(II)acetate in the ratio 1:1.5 through the cyclotetramerization reaction in a sealed tube at 250 °C in 10 min, respectively (Scheme 1).

Elemental analysis, IR, ^{1}H NMR, MASS and UV/Vis spectra confirmed the proposed structures of the compounds. A diagnostic feature of Pc formation from compound **3** was the disappearance of the sharp intense CN vibration band 2231 cm^{-1} in IR spectrum. The spectra of compounds **5**–**8** showed Ar–O–Ar peaks at 1246–1288 cm^{-1}, C=C (in phenyl) peaks at 1560–1689 cm^{-1}, aromatic CH peaks at 3060–3070 cm^{-1} and aliphatic CH_2 and CH_3 peaks at 2860–2945 cm^{-1}.

The UV–Vis spectra of **5**–**8** in $CHCl_3$ showed characteristic absorptions between 613 and 701 nm in the Q-band region (Table 1). The Q-band observed for the compounds was attributed to the $\pi \rightarrow \pi^*$ transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the Pc ring. The other bands (B) in the UV region at 307–361 nm were observed due to the transitions from the deeper π levels to LUMO. When aggregation occurs, a band ca. 630 nm arises in the electronic spectrum as a result of the intramolecular interactions between the Pc units [28,35]. Thus, the band at around 620 nm can be attributed to intramolecular interactions, although the Q-band is not split.

^{1}H NMR spectra were also in good correlation with the structure of the synthesized compounds. In the ^{1}H NMR spectrum of compound **3** which was taken in *d*-chloroform, phenyl protons appeared at 7.73 ppm(d), 7.34 ppm (dd), 7.28 ppm (dd), and 7.01 ppm (dd), and C–CH_3 protons at 1.75 ppm (s). In the ^{1}H NMR spectra of **5** and **7** which were taken in *d*-chloroform, the aromatic protons appeared at 7.75–6.92 ppm (m) and C–CH_3 peaks at 1.62 and 1.68 ppm (m). In addition, in the ^{1}H NMR spectrum of **5**, the –CH_3 protons at the end of the chain appeared at 0.95–0.87 ppm and aliphatic –CH_2– protons at 1.33–1.26 ppm.

Table 1
UV–Vis data in $CHCl_3$ for phthalocyanine complexes, **5**–**8**

Compound	λ/nm ($\log \varepsilon$/dm^3 mol^{-1} cm^{-1})
5	701 (4.88), 630 (4.34), 361 (4.88)
6	682 (4.95), 624 (4.64), 325 (5.02)
7	682 (4.56), 613 (3.88), 337 (4.33), 307 (4.49)
8	675 (4.70), 613 (4.32), 330 (4.67)

3.2. Electrochemistry

The voltammetric measurements were carried out on platinum in DCM for **5**–**8**. The relevant data are given in Table 2. Compound **5** displayed two reductions at $E_{1/2} = -0.78$ V and $E_{1/2} = -1.14$ V versus SCE, and a single oxidation at $E_{1/2} = 0.71$ V versus SCE. The electrochemical data for **6** is shown in Table 2. The CPC studies showed that each redox process of **5** and **6** involves the transfer of two electrons. Typical steady state cyclic voltammograms (CV) recorded after several scans for these complexes at 0.100 V s^{-1} are shown in Figs. 1 and 2. The redox behaviours of **5** and **6** are similar to mononuclear phthalocyanines, in terms of the half-wave potentials, suggesting that there is not any considerable interaction between two Pc rings and/or two metal centers in these complexes, and that two rings and/or two metal centers react electrochemically at the same potentials. The overall splitting of the molecular orbitals with a high degree on going from the monomeric to dimeric, trimeric or oligomeric Pcs depending on the intermolecular interactions between the rings are expected to occur only in the case that the rings are positioned in face to face orientation as in the sandwich-type Pcs. Thus, it can be concluded that two Pc rings in **5** and **6** are approximately planar in nature. The half-peak potential difference between the first oxidation and the first reduction, $\Delta E_{1/2}$, for **5** and **6** also provides an additional support for the absence of or very weak interactions between two Pc rings and/or two metal centers. $\Delta E_{1/2}$ values ranging from 1.36 to 1.70 V and 0.97 to 1.10 V have been reported for mononuclear and polynuclear no interacting Pc compounds involving redox inactive metal center such as Cu(II), Ni(II) and Zn(II), and involving redox active Co(II) center, respectively [36–40]. The separation between the first oxidation and the first reduction for **5** and **6** was found to be 1.49 and 1.23 V, respectively. In the case that there is strong interaction between two Pcs in a dimer, this separation is expected to decrease as a result of the splitting of molecular orbitals [8,41].

The voltammetric behaviour of cofacial bis-Pcs, **7** and **8**, are considerably different from those of **5** and **6**. These compounds show one-electron redox processes. Typical voltammograms for these compounds are presented in Figs. 3 and 4. The transfer of one electron in each step indicates that the splitting of the molecular orbitals occurs as a result of the strong interaction between the two Pc rings and/or two metal centers in each cofacial bis-Pcs, **7** and **8**, and thus the redox process of each Pc ring and/or metal center in coafacial complexes occurs at different potentials. The strong interaction between the molecular orbitals of two Pcs and/or two metal centers, in a dimer cause remarkable changes in redox potentials, compared with corresponding mono Pcs and non-interacting planar dimers. Generally, the oxidation potentials shift to less positive potentials while the reduction

[a] Potentials are reported with respect to the SCE. Half-wave potentials in DCM vs. Fc/Fc^+ couple correspond approximately with the above **5**–**8** data minus 0.45 V. $E_{1/2}$ values were measured by cyclic voltammetry [$E_{1/2} = (E_{pa} + E_{pc})/2$] and/or differential pulse voltammetry. The peak separation values ($\Delta E_p = E_{pa} - E_{pc}$) are reported at 0.100 V s^{-1}. $\Delta E_{1/2}$ is the potential difference between the first oxidation and first reduction potentials. It represents the HOMO–LUMO gap for **5** and **7**, but the charge transfer transition for **6** and **8** involving redox-active metal centers. ΔE_s indicates mixed-valence splitting energy for the relevant split redox couple.

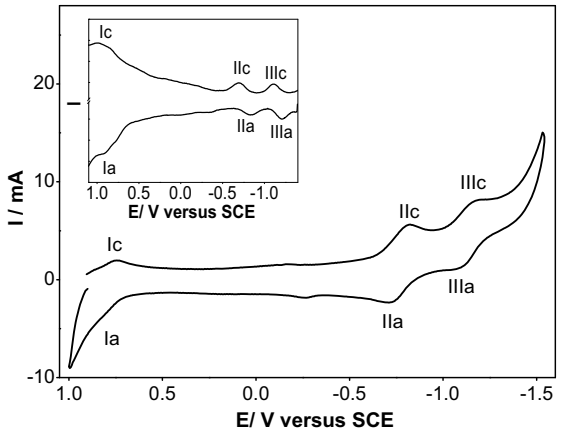

Fig. 1. Cyclic and differential pulse (inner) voltammograms of **5** at 0.100 V s^{-1} on Pt in DCM/TBAP.

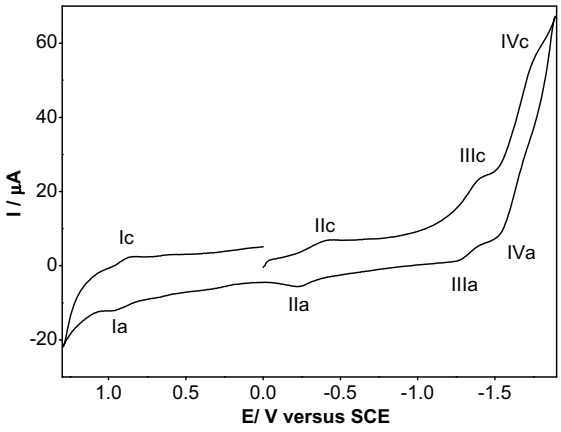

Fig. 2. Cyclic voltammograms of **6** at 0.100 V s^{-1} on Pt in DCM/TBAP.

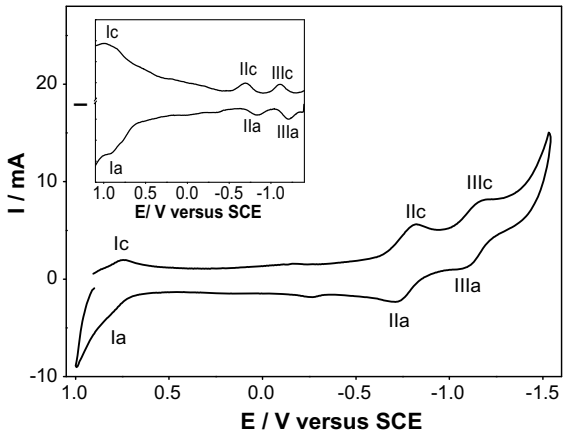

Fig. 3. Cyclic voltammograms of **7** at 0.100 V s^{-1} on Pt in DCM/TBAP.

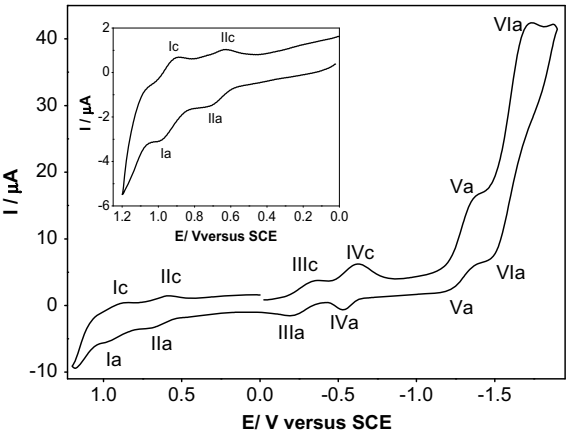

Fig. 4. Cyclic voltammograms of **8** at 0.100 V s^{-1} on Pt in DCM/TBAP.

potentials shift to less negative potentials, the shift in oxidation potentials being more remarkable. Taking this observed behaviour into consideration, it can be concluded from the comparison of voltammetric behaviour of **7** and **8** with the behaviour of **5** and **6** that the high splitting of the redox processes, i.e., mixed-valence behaviour is observed, and thus each redox process of **7** and **8**

occurs at remarkably different potentials as a result of the expected strong interactions between the cofacial Pc rings and/or metal centers. The electrode reactions are schematically illustrated in Chart 1 for **7** and in Chart 2 for **8**.

The mixed-valence splitting, ΔE_s, values in V for the redox processes of **7** and **8** are presented in Table 2. These values give evidence of the delocalization of charge among the cofacial Pc rings and/or metal centers in each cofacial bis-Psc, **7** and **8**, and thus the formation of electrochemically stable oxidized and reduced mixed-valence species.

Some binuclear and tetranuclear Pcs [14,17,35,42–44] showed metal-centered type or ring-centered type mixed-valence behaviour, but some of them did not. The difference was attributed mainly to the presence or absence of axial ligands, respectively inhibiting or facilitating the close approach of the rings, and to the other steric factors. The least strongly coupled systems include some zinc complexes of binuclear Pcs with flexible bridging links [14,17,35]. Moreover, mixed-valence ring reduction, Pc (-2) · Pc (-3), was observed previously only in strongly coupled silicon species [44], but was not unequivocally observed with the other bridged binuclear species. The presence of an extra π-electron repels the π-electron density in the other ring and therefore inhibits formation of these species unless they are constrained to lie close together. The large splitting values for the silicon species was attributed to the shorter Pc ·· Pc contacts than in the bridged systems. The splitting of the redox processes of the Pc ring for **7** and Pc ring and/or metal center for **8** are consistent with those observed previously in literature for a series of mixed-valence Pc complexes [14,17,35,42–44] and with the rigid structure of these cofacial complexes.

3.3. Electrical measurements

Dc electrical properties of thin film of compounds were investigated by means of current–voltage (*I–V*), measurements. The measurements were carried out at different temperatures between 300 K and 470 K. It was observed that the *I–V* curves are straight lines without hysteresis effect for the temperature below 380 K. This indicates that the material has an ohmic resistance, which can be calculated from the slope of the *I–V* curve at each temperature. Above this temperature, the measured *I–V* characteristics show considerable hysteresis between increasing and decreasing voltage sweeps. Fig. 5 shows the dependence of *I–V* characteristics on sweep direction at 300 K and 470 K for compound **5**. In this measurements the voltage has been incremented in steps of 50 mV from −1 to 1 V and back again. It can be seen from Fig. 5 that during the negative to positive voltage sweep, the magnitude of the current at zero applied voltage was higher than positive to negative sweep. It is also observed that the area within the loop increased with an increase in temperature. This effect is likely due to the presence of deep traps, which require a large time constant for charging and discharging in response to a change of the external voltage. Same type of hysteresis behaviour was observed in many other phthalocyanines [45,46]. The interpretation of appearance of the hysteresis effect at high temperature requires to take into account many elementary physical processes such as, density of mobile ions or deep trap level, delay time between two successive measurements separated by a potential step, bulk conductivity of the materials and temperature. High temperature hysteresis behavior suggests that this is due to the formation of space charge polarization in the phthalocyanine thin film. Hysteresis effect was observed for other compounds. The temperature at which the hysteresis effect observed is nearly the same for all compounds. The dc conductivity values of the films were calculated from the slope of the measured *I–V* characteristics by using,

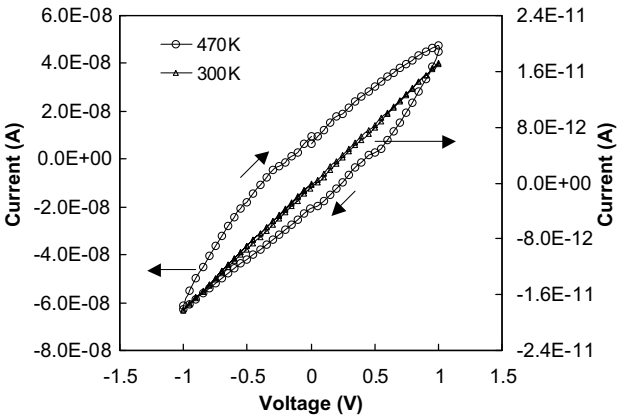

Fig. 5. *I–V* characteristics of the compound **5** at two different temperatures.

$$\sigma_{dc} = \frac{I}{V}\frac{d}{(2n-1)l \cdot h} \quad (1)$$

where I is the measured current, V is the applied voltage, d is the distance between the finger pair, n is the number of the finger pair, l is the overlap length and h is the thickness of the electrode. It was observed that the measured conductivity for the film of compound depend exponentially on temperature such that the conductivity exhibits a variation of the form,

$$\sigma_{dc} = \sigma_0 \exp(-E_A/kT) \quad (2)$$

where E_A is the activation energy, T is the temperature, k is the Boltzmann's constant and σ_0 is the constant of proportionality. The relationship between the conductivity and temperature which

Chart 2. Electrode reactions for **8**. M: Co.

is given by Eq. (2) shows that the materials behave as an intrinsic semiconductor in the measured temperature range (300–470 K).

The activation energies for the samples were evaluated from the slopes of the $\ln\sigma_{dc}$ versus $1/T$ graphs. The obtained conductivity values for two different temperature (300 K and 470 K), and the calculated activation energies are given in Table 3.

The ac electrical conductivity, σ_{ac}, as a function of temperature has also been investigated for all film of compounds at several frequencies. Fig. 6 shows semi logarithmic plot of ac conductivity versus reciprocal temperature at indicated frequencies for compound **5**. At least two temperature ranges, $300 < T < \sim 400$ K and $410 < T < 470$ K can be identified from Fig. 6 for the film of **5**. The same type temperature dependence with different temperature range was observed for other films. This indicates that the temperature dependence of the ac conductivity is not uniform process and results in activation energies corresponding to the different temperature range. The values of ac activation energies associated with this two temperatures region were calculated from the slope of $\log\sigma_{ac}$–$1/T$ graph for different frequencies and collected in Table 4.

Ac conductivity measurements as function of frequency on the film of compounds were also investigated at different temperatures. It was observed that ac conductivity follows power law as

$$\sigma_{ac} = A\omega^n \quad (3)$$

where ω is the angular frequency, A is the material dependent constant, and the frequency exponent n which normally takes the value of less than unity. The value of exponent n and its behavior with temperature determines the dominant conduction mechanism in phthalocyanine film.

In the models which are used to investigate the power law of ac conductivity, the frequency exponent n is found to have two different trends with temperature and frequency [47]. The value of frequency exponent is obtained from the measured conductivity data. It was observed that n strongly temperature dependent and decreases with increasing temperature for all films. This dependence of n on temperature is in agreement with the prediction of the correlated barrier-hoping model. The same type of temperature dependence for n were observed in our earlier report in different phthalocyanine films [48,49].

The effect of temperature on the capacitance of the films are investigated in the frequency range of 40–10^5 Hz. Variations of capacitance of the film of **5** with frequency for different temperatures is shown in Fig. 7. From Fig. 7, it becomes clear that there is a monotonic decrease in the capacitance for the film of **5** at low frequencies. At higher frequency the value of capacitance merges irrespective of temperature. It can also be seen from Fig. 7 that the effect of temperature on capacitance is more significant at lower frequencies. The increase in capacitance with increasing temperature can be explained in terms of ionization of acceptors, which causes an increase in carrier concentrations and hence an increase in the capacitance. The frequency dependence of the capacitance can qualitatively be explained employing equivalent circuit model developed by Goswami and Goswami [50]. Equivalent circuit model assumes that the measured capacitance C depends on a frequency a resistive element representing the resistance of the film. The value of resistive element decreases with

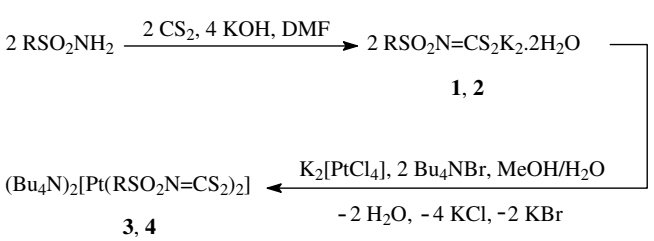
2. Experimental

2.1. Materials and methods

Solvents (dichloromethane, dimethylformamide, ethanol and methanol) were purchased from Merck and were used as supplied. 4-Fluorobenzenesulfonamide, 4-iodobenzenesulfonyl chloride, potassium tetrachloroplatinate(II) and tetrabutylammonium bromide were purchased from Aldrich. KOH and CS_2 were purchased from Vetec. The 4-iodobenzenesulfonamide was prepared from 4-iodobenzenesulfonyl chloride in reaction with concentrated ammonia solution, according to the methodology applied for the syntheses of similar compounds [13] and potassium *N*-4-iodophenylsulfonyldithiocarbimate was prepared from the parent sulfonamide as described in the literature [12]. This salt, which is soluble in H_2O and insoluble in most organic solvents, was recrystallized from a hot mixture of ethanol and water. IR spectra were recorded with a Perkin–Elmer 1000 FT-IR spectrophotometer using CsI pellets. The NMR spectra were recorded with a Bruker DPX-200-AVANCE or a VARIAN-300 spectrophotometers in D_2O (**1**, **2**), DMSO-D_6 (**3**) and $CDCl_3$ (**4**) with TMS as internal standard. Microanalyses for C, H and N were obtained from a Perkin–Elmer 2400 CHN elemental analyzer. Platinum was analyzed by atomic absorption on a Hitachi Z-8200 atomic absorption spectrophotometer. Uncorrected melting points were measured with a Mettler FP5 melting point apparatus. The molar conductances (Λ_M) were measured in acetonitrile solutions at 25 °C with a Conductivity Meter Jenway 4010.



2.2. Syntheses of the dithiocarbimate potassium salts

Compound **1** was prepared as described in the literature [12]. Compound **2** was prepared as described, see Scheme 1.

Carbon disulfide (0.02 mol) and potassium hydroxide (0.01 mol) were added to a solution of 4-fluorobenzenesulfonamide (0.02 mol) in DMF (20 mL). The mixture was stirred at room temperature for 2 h previous to the addition of a second portion of potassium hydroxide (0.01 mol). After stirring for further 1 h, the yellow solid formed was filtered, washed with DMF, ethanol and ethyl acetate and dried under reduced pressure yielding the potassium *N*-4-fluorophenylsulfonyldithiocarbimate (80% based on the sulfonamide). Suitable crystals for X-ray structure analysis were obtained after recrystallization in ethanol:water 1:1 mixture.

2.2.1. Potassium N-4-fluorophenylsulfonyldithiocarbimate dihydrate (**2**)

Elemental *Anal.* Calc. for $C_7H_8FNO_4S_3K_2$: C, 23.13; H, 2.22; N, 3.85. Found: C, 23.10; H, 2.02; N, 3.85%. IR (most important bands) (cm^{-1}): 3340 (water), 1259 (νCN) + (νSO_{2asym}), 1135 (νSO_{2sym}), 977 (νCS_{2asym}). ^{1}H NMR (300 MHz, D_2O), (δ): 7.72–7.65 (m, 4H, H2 and H6), 7.15–7.07 (m, 4H, H3 and H5). ^{13}C NMR (δ), *J* (Hz): 225.29 (N=CS_2), 164.35 (d, $^1J_{C,F}$ = 248.4, C4), 137.96 (C1), 129,31 (d, $^3J_{C,F}$ = 9.8, C2 and C6), 115.90 (d, $^2J_{C,F}$ = 22.9, C3 and C5).

1, 3 (R = 4-IC_6H_4) **2, 4** (R = 4-FC_6H_4)

Scheme 1. Syntheses of **1**–**4**.

2.3. Syntheses of the platinum complexes

The syntheses of the platinum complexes were performed according to Scheme 1. Potassium tetrachloroplatinate(II) (0.001 mol) and tetrabutylammonium bromide (0.002 mol) were added to a solution of potassium *N*-R-sulfonyldithiocarbimate dihydrate (**1** or **2**, 0.002 mol) in methanol/water 1:1 (10 mL). The reaction mixture was stirred for 3 h at room temperature. The yellow solid obtained was filtered, washed with distilled water and dried under reduced pressure for one day, yielding $(Bu_4N)_2$[Pt(*N*-$RSO_2N{=}CS_2)_2$] (*ca.* 70% based on the $K_2[PtCl_2]$). Suitable crystals for X-ray structure analyses were obtained after slow evaporation of the solutions of compounds **3** and **4** (R = 4-IC_6H_4 and 4-FC_6H_4, respectively) in methanol/water 4:1.

2.3.1. Tetrabutylammonium bis(N-4-iodophenylsulfonyldithiocarbimato)platinate(II) (**3**)

Elemental *Anal.* Calc. for $(C_{16}H_{36}N)_2C_{14}H_8I_2N_2O_4S_6Pt$: C, 39.62; H, 5.78; N, 4.02; Pt, 13.99. Found: C, 39.68; H, 5.63; N, 3.96; Pt, 13.72%. M.p. (°C): 168.3–169.7. Molar conductance [Λ_M (Ω^{-1} cm^2 mol^{-1})]: 220. 2.3.2. Tetrabutylammonium bis(N-4-fluorophenylsulfonyldithiocarbimato)platinate(II) (**4**)

Elemental *Anal.* Calc. for $(C_{16}H_{36}N)_2C_{14}H_8I_2N_2O_4S_6Pt$: C, 46.88; H, 6.84; N, 4.75; Pt, 16.55%. Found: C, 46.93; H, 6.79; N, 4.75; Pt, 16.52%. M.p. (°C): 163.8–165.0. Molar conductances [Λ_M (Ω^{-1} cm^2 mol^{-1})]: 249. IR (most important bands) (cm^{-1}): 1376 (νCN), 1283 (νSO_{2asym}), 1145 (νSO_{2sym}), 934 (νCS_{2asym}), 330 (νPtS). ^{1}H NMR (200 MHz, $CDCl_3$, complex anion signals) (δ), *J* (Hz): 8.05–7.95 (m, 4H, H2 and H6), 7.04 (br, t, 4H, $J \approx 8$, H3 and H5). ^{13}C NMR (50 MHz, $CDCl_3$, complex anion signals) (δ), *J* (Hz): 212.96 (N=CS_2), 164.27 (d, $^1J_{C,F}$ = 249.7, C4), 139.79 (C1), 130.32 (d, $^3J_{C,F}$ = 8.9, C2 and C6), 114.77 (d, $^2J_{C,F}$ = 22.0, C3 and C5).

2.4. X-ray diffraction experiments

X-ray intensity data for single crystals were collected using graphite monochromatic Mo Kα radiation on a four-circle κ-geometry KUMA KM-4 diffractometer with a two-dimensional area CCD detector. The ω-scan technique with $\Delta\omega = 0.80°$ for each image was used for data collection. The 880 images for six different runs covered about 98% of the Ewald sphere were collected using the CRYSALIS CCD program [14]. The lattice parameters were refined by least-squares methods based on all the reflections with $I > 2\sigma(F^2)$. One image was used as a standard for monitoring of the stability of the crystals as well as for monitoring the data collection after every 50 images, and no correction on the relative intensity variation was necessary. Integration of the intensities, correction for Lorenz and polarization effects and the numerical absorption correction were performed using a CRYSALIS RED program [14]. The structures were solved by direct methods using SHELXS97 [15]. The calculated E map revealed the metals, S, O, N and most of the C atoms. The remaining C atoms were located from the difference Fourier synthesis. The structures were refined with the anisotropic thermal parameters for all non-hydrogen atoms using SHELXL97 [15]. Difference Fourier maps gave electron density concentrations

approximately located for all hydrogen atoms positions; these positions were idealised (HFIX 43 for all H atoms of the phenyl rings with isotropic thermal parameters of 1.2 U_{eq} of the carbon atoms joined directly to the hydrogen atoms, and HFIX 137 for the CH_3 and HFIX 23 for the CH_{2l} with isotropic thermal parameters of 1.5 U_{eq} of the carbon atom). Final difference Fourier maps showed no peaks of chemical significance. Details of the data collection parameters and final agreement factors are collected in Table 1. Selected bond lengths and angles and torsion angles are listed in Table 2.

2.5. Theoretical calculations

Ab initio molecular orbital calculations full geometry optimizations were performed with the GAUSSIAN98 program package [16]. The calculations were performed for the isolated 4-fluorophenylsulfonyldithiocarbimate(2-) ligand by the density functional three-parameters hybrid (B3LYP) methods [17,18] with the 6-31+G(d) basis set starting from the X-ray geometry. As convergence criterion the threshold limits of 0.00025 and 0.0012 a.u. were applied for the maximum force and the displacement, respectively.

3. Results and discussion

Compounds **1** and **2** are yellow solids. They are insoluble in organic solvents and soluble in water. They are not very stable and a white solid is obtained from their aqueous solutions after some days at room temperature. At ambient temperature, the yellow solids are also converted into white solids after several months. Both, **3** and **4**, are yellow crystalline solids insoluble in water and very stable at room temperature. Compound **4** is soluble in polar organic solvents such as DMF, DMSO, ethanol, methanol, dichloromethane and chloroform. Compound **3** is soluble in DMF, DMSO, and differently from compound **4** and the analogues with R = C_6H_5 and 4-BrC_6H_4 [10], only slightly soluble in the other organic solvents mentioned above. The molar conductances of **3** and **4** at 10^{-3} mol L^{-1} in acetonitrile are in the range of 220–300 Ω^{-1} cm^2 mol^{-1}, commonly attributed to 1:2 electrolytes [19].

The spectroscopic properties of compounds **3** and **4** are similar to those presented by other platinum(II) complexes of dithiocarbimate from sulfonamides described in the literature [10] (Tables 3 and 4). In the IR spectra of the potassium dithiocarbimates **1** and **2**, there are no strong bands in the 1450–1550 cm^{-1} spectral region, the νCN band being observed at 1280 and 1259 cm^{-1}, respectively. A strong band observed at 1384 cm^{-1} in the spectrum of compound **3** and at 1376 cm^{-1} in the spectrum of compound **4** was assigned to the νCN. The CN bond is formally a double bond. However, because of the SO_2 neighbour group, the canonical forms (a) and (b) (Scheme 2) contribute appreciably to the resonance hybrid. This fact explains the low values observed for the νCN band wavenumbers. The νCS_{2asym} were observed at higher wavenumbers in the spectra of the potassium salts of dithiocarbimates (971 and 977 cm^{-1} for **1** and **2**, respectively) than in the spectra of compounds **3** and **4** (936 and 934 cm^{-1}, respectively). The shifts observed in the νCS_{2asym} and νCN bands in the vibrational spectra of the complexes when compared to the spectra of the free ligands, are consistent with the increased importance of the canonical form (c) after complexation (Scheme 2). The spectra of compounds **3** and **4** also show the expected medium/strong band in the 300–400 cm^{-1} range assigned to the νPtS.

The NMR spectra were typical for diamagnetic species and were consistent with the proposed structures. The integration curves on the ^{1}H NMR spectra of **3** and **4** were consistent with a 2:1 proportion between the tetrabutylammonium cation and the Pt-bis(dithiocarbimato) complex anion. In the ^{13}C NMR spectra of compounds **3** and **4** the signal of the quaternary carbon of the dithiocarbimate

Scheme 2. Three canonical forms for *N*-R-sulfonyldithiocarbimate anion.

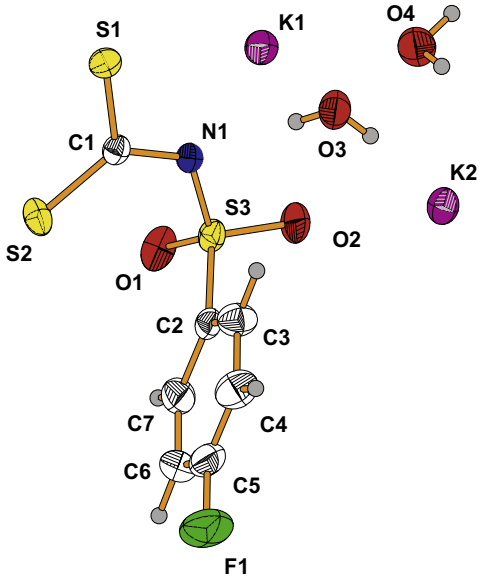

Fig. 1. The atomic numbering scheme of $K_2(4\text{-}FC_6H_4SO_2N{=}CS_2)\cdot 2(H_2O)$. Displacement ellipsoids are drawn at the 50% probability level.

moiety is shifted upfield when compared to the corresponding signal in the potassium dithiocarbimates spectra. This fact is also consistent with the increase in the contribution of canonical form (c) after the complexation (Scheme 2). The coupling constants between the fluorine and the carbon atoms in the spectra of compounds **2** and **4** were observed in the normal range for other fluorinated aromatic compounds ($^1J_{C4,F} \approx 249$ Hz and $^2J_{C3,F} \approx 22.5$ Hz), and it was also possible to observe the coupling with C-2 ($^3J_{C2,F} \approx 9$ Hz).

The asymmetric unit of compound **2** is illustrated in Fig. 1. The dithiocarbimate(2-) group together with the sulfur atom of sulfonyl group of the 4-fluorophenyl-sulfonyldithiocarbimate(2-) anion (the S1S2C1N1S3 fragment) is planar and almost perpendicular to the phenyl ring. The dihedral angle between the planes defined by the S1S2C1N1S3 atoms and by the C atoms of the phenyl ring is equal to 98.9(1)°. The potassium cations, K1 and K2, have different coordination envinronments. The K1 cation is surrounded by two 4-fluorophenylsulfonyldithiocarbimate(2-) anions and three water molecules (Fig. 2a). One of the 4-fluorophenylsulfonyldithiocarbimate(2-) ligands is joined to K1 by the S1 atom of dithiocarbimate group, while the other ligand by O2 of sulfonyl group and by the N1 atom. The K2 cation interacts with four neighbouring 4-fluorophenylsulfonyldithiocarbimate(2-) ligands and with two water molecules (Fig. 2b). Each of these 4-fluorophenylsulfonyldithiocarbimate(2-) ligands interacts differently with the K2 cation. One of them inteacts by both S atoms of CS_2 group, the other by the O atom of sulfonyl group and by one S atom of CS_2 group. The third 4-fluorophenylsulfonyldithiocarbimate(2-) ligand is directed towards the K2 cation by the F atom (K2–F1, 2.785(2) Å), and the fourth ligand is oriented to the K2 cation by the O atom of sulfonyl group (K2–O2, 2.725(2) Å). Thus the potassium cations, K1 and K2, have not only different environments, but also different coordination numbers. Ab initio molecular orbital calculations performed for an isolated 4-fluorophenylsulfonyldithiocarbimate(2-) ligand have shown a quite similar conformation of the anion as found in the crystal of the potassium salt (Table 5). Thus the interaction between the potassium cations and the 4-fluorophenylsulfonyldithiocarbimate(2-) anions is mainly ionic which does not disturb significantly the geometric conformation of the ligand. The bond lengths and angles, as well as the orientation of the almost planar dithiocarbimate group (CS_2), together with the sulfur atom of the sulfonyl group (S1S2C1N1S3 fragment) in relation to the phenyl ring in the potassium salt preserve almost the same values as in the gas-phase which describes the most stable conformation of the ligand. The arrangement of the molecules in the crystal **2** (Fig. 2c) is mainly determined by the ionic interaction of the oppositely charged moieties, i.e. the 4-fluorophenylsulfonyldithiocarbimate(2-) ligand and the potassium cations surrounded by the water molecules. The water molecules interact with the potassium cations forming infinite 2D-layers parallel to the (001) plane at $z = 0$ and $z = 1/2$, while the 4-fluorophenylsulfonyldithiocarbimate(2-) ligands are alternatively oriented and located almost per-

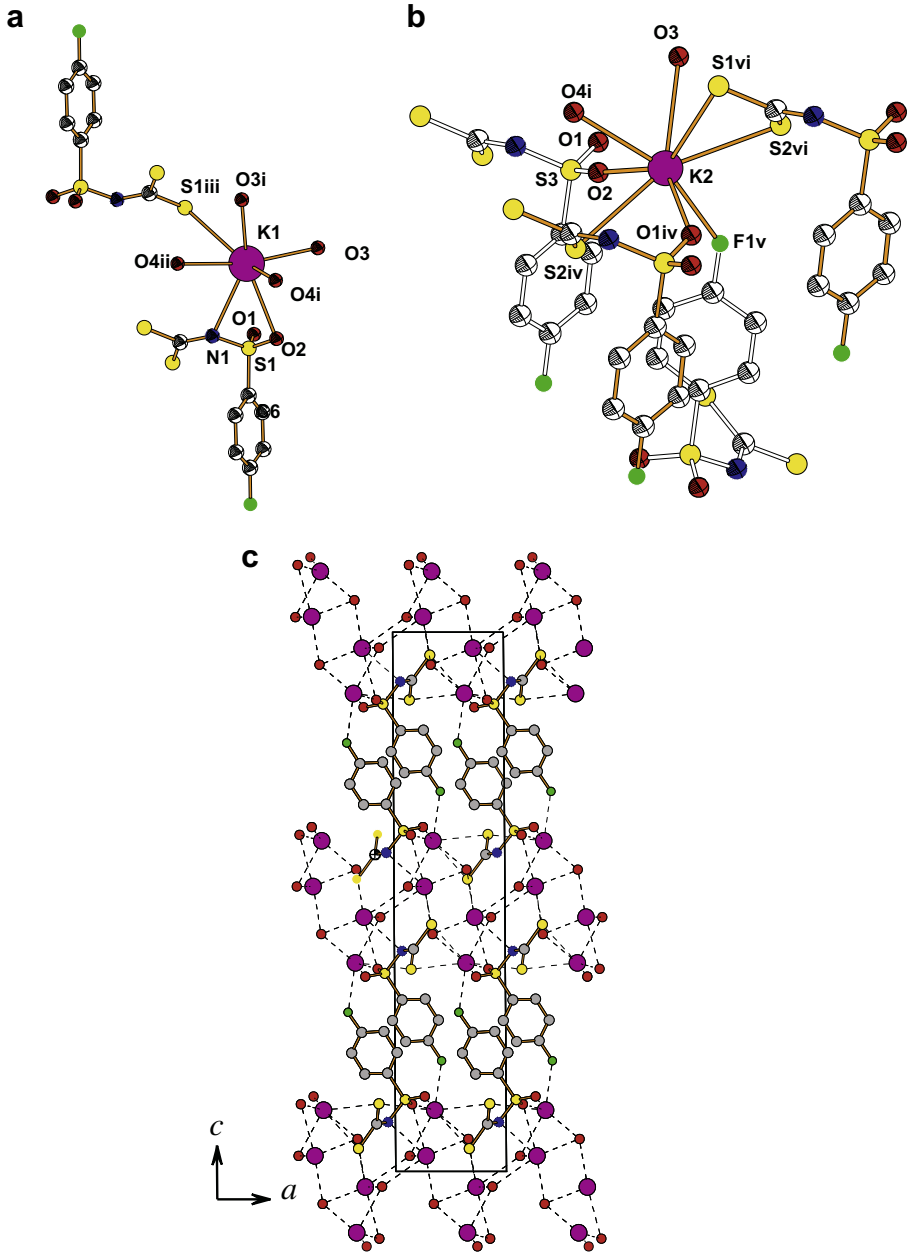

Fig. 2. Coordination environment of K1 (a) and K2 (b) and the molecular arrangement of compound **2** in the unit cell showing the 2D-layers of K1 and K2 surrounded by water at $z = 0$ and 1/2 and the layers of 4-fluorophenylsulfonyldithiocarbimate(2-) anions at $z = 1/4$ and 3/4 (c). H atoms are omitted for clarity. Symmetry code: (i) $-x + 1, -y + 1, -z$; (ii) $x - 1, y, z$; (iii) $-x, -y, -z$; (iv) $x, y + 1, z$; (v) $-x, y + 0.5, -z + 0.5$; (vi) $x + 1, y + 1, z$.

pendicularly to the (0 0 1) plane by their phenyl ring, and also form layers parallel to the (0 0 1) plane at $z = 1/4$ and $z = 3/4$. Besides, due to the ionic attraction between the oppositely charged layers, the hydrogen bond between the water molecule (O3) as a donor and the nitrogen atom (N1) as an acceptor is formed (O3–H31 ⋯ N1, the distance between donor and acceptor and the D–H⋯A angle are 2.970(3) Å, and 171.5°). This hydrogen bond slightly diminishes the steric effect of the lone pair of electrons at the N atom and leads to a decreased C1–N1–S3 angle by about 3° compared to the gas-phase structure.

The molecular structures of compounds **3** and **4** are shown in Fig. 3a and b, respectively. The crystals are built up from the $[Pt(R\text{-}SO_2N{=}CS_2)_2]^{2-}$ anions (R = 4-IC_6H_4 (**3**) and 4-FC_6H_4 (**4**)) and two univalent Bu_4N^+ cations related by the inversion centre at the Pt atom. In both complexes the Pt cation is coordinated by two symmetrically equivalent dithiocarbimate(2-) ligands into a distorted square-planar configuration. However, in compound **3**, due to mutual orientation of the $[Pt(4\text{-}IC_6H_4SO_2N{=}CS_2)_2]^{2-}$ anions, the iodine atoms of two neighbouring complex anions interact with the central Pt cation forming chains along the *b*-axis (Fig. 4a) with the elongated square bipyramid around the Pt cations (average Pt–S distance is 2.319(3) Å, Pt–I, 4.253(1) Å). For a comparison the axial Pt⋯Br distance in the isostructural 4-BrC_6H_4-derivative with a value of 4.249(3) Å [10] indicates significantly weaker interaction between the neighbouring complex anions than in the 4-IC_6H_5-derivative due to their ionic radii ($r_I = 2.20$ Å and $r_{Br} = 1.81$ Å) [20]. The bidentate chelation by two sulfur atoms of the dithiocarbimate(2-) ligands to Pt in both complexes makes the S1–C1–S2 angle significantly smaller (∼108°) than those found in the parent dipotassium salt (119.5(1)°) in

Dihedral angle between the S3N1=C1S1S2	98.9(1)	103.2(2)	98.3

which the interaction between the K^+ cations and the dithiocarbimate(2-) ligands is mainly ionic (Table 5). The arrangement of the molecules in the crystal of compound **4** is shown in Fig. 4b, as a packing diagram of the unit cell on the *bc* plane. The square plane of the Pt coordination in the $[Pt(4\text{-}FC_6H_4SO_2N{=}CS_2)_2]^{2-}$ entities is perpendicular to the (1 0 0) plane and the Bu_4N^+ cations are located on both sides of the anions.

In compounds **3** and **4**, the CS bond lengths are nearly equal and are slightly shorter than typical C–S single bond lengths (*ca.* 1.815 Å) but longer than typical C=S double bonds (*ca.* 1.671 Å) [21] due to the partial π-delocalization in the S–C–S group (Scheme 2). Quite similar behaviour is observed in the square-planar palladium(II) and nickel(II) complexes of dithiocarbimates [10,12,22,23]. However, in compound **2** they are slightly different [C1–S1 is 1.731(2) Å and C1–S2 is 1.706(2) Å] (Table 3). This difference can be explained by a balance between the repulsive interactions of the lone-pair of electrons on the nitrogen atom and the S2, as well as between the S1 and the RSO_2 group. When the complexation occurs two factors must be considered. First, the S1–C1–S2 angle decreases, weakening the interactions mentioned above, and diminishing the difference between the C1–S1 and the C1–S2 bond lengths. Another factor is the increasing importance of the canonical form (c) upon complexation, explaining not only a shorter CN bond length in **3** and **4** than in **2**, but also the lower wavenumbers for the νCS_2 in the spectra of the complexes when compared with the spectra of the ligands, the higher wavenumbers for the νCN in the spectra of the complexes, and the variation on the chemical shift of the dithiocarbimate group carbon atom signal in the ^{13}C NMR spectra after the complexation (Tables 3 and 4).

The bond lengths and angles of the tetrabuthylamonium cations are in agreement with the expected values (Table 2). However, the torsion angle C41–C42–C43–C44 in the compound **4** is deviated significantly from 180° due to repulsive interaction between the hydrogen atoms of the symmetrically equivalent Bu_4N^+ cations, which are oriented by the terminal methyl group of C44 atom, as well as due to attractive interaction of the H atom of the methyl group with the phenyl ring (C44–H44A···π(phenyl ring) ~3.2). The conformation of the tetrabuthylamonium cation is different from that found in the isostructural Pt-phenyl-derivative dithiocarbimate complex [10] in which all torsion angles of the carbonic chains of the tetrabuthylamonium cation are only slightly distorted from the expected value of 180° (Table 2).

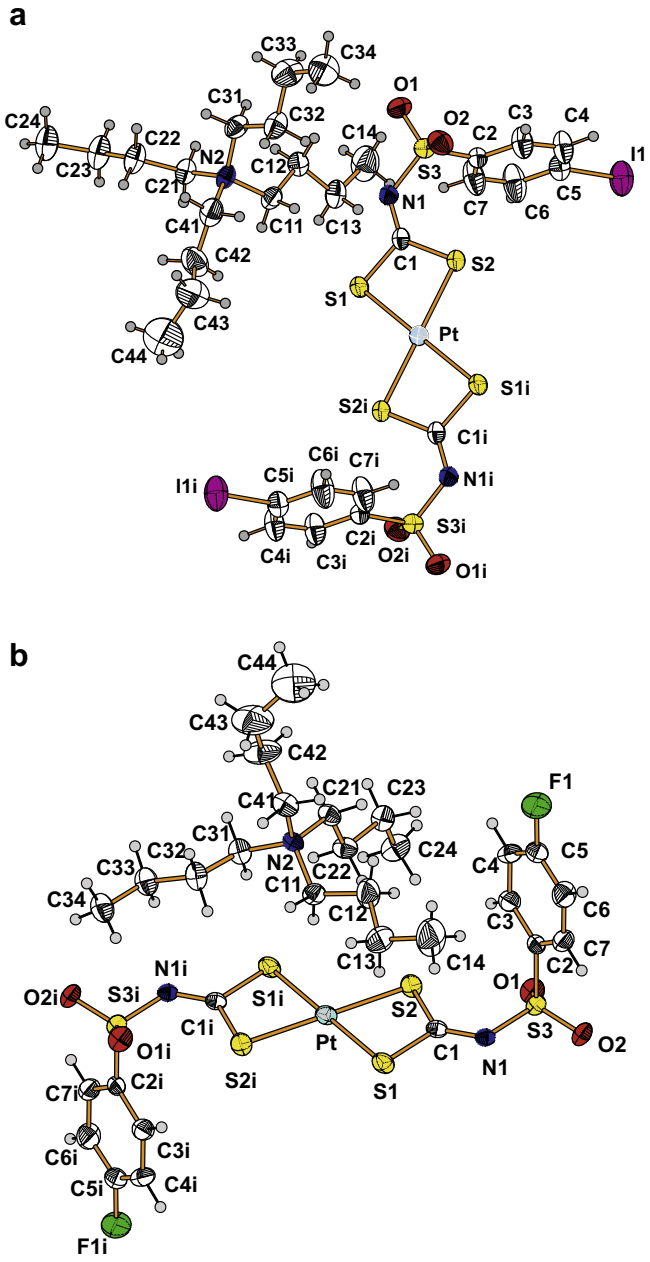

Fig. 3. View of the molecular structure of compounds **3** (a) and **4** (b) with the labelling scheme. Displacement ellipsoids are drawn at the 50% probability level.

4. Conclusion

A new dithiocarbimate anion (4-fluorophenylsulfonyldithiocarbimate) was obtained and its potassium salt was characterized by X-ray diffraction techniques. Besides, two new platinum(II)-bis(dithiocarbimato) complexes were obtained as tetrabutylammonium salts in the crystalline form and their structures were characterized by single crystal X-ray diffraction. The Pt^{2+} in both complexes is located at the inversion centre and the PtS_4 moiety has a square-planar configuration. Spectroscopic data are consistent with the X-ray experimental results and point to an increase of the contribution of the canonical form (c) to the resonance hybrid upon complexation with a consequent increase of the CN double bond character. Thus, in the IR spectra the wavenumbers of the νCN are smaller for the ligands than for the complexes, and the ^{13}C NMR spectra show that the carbon atom of the dithiocarbimate

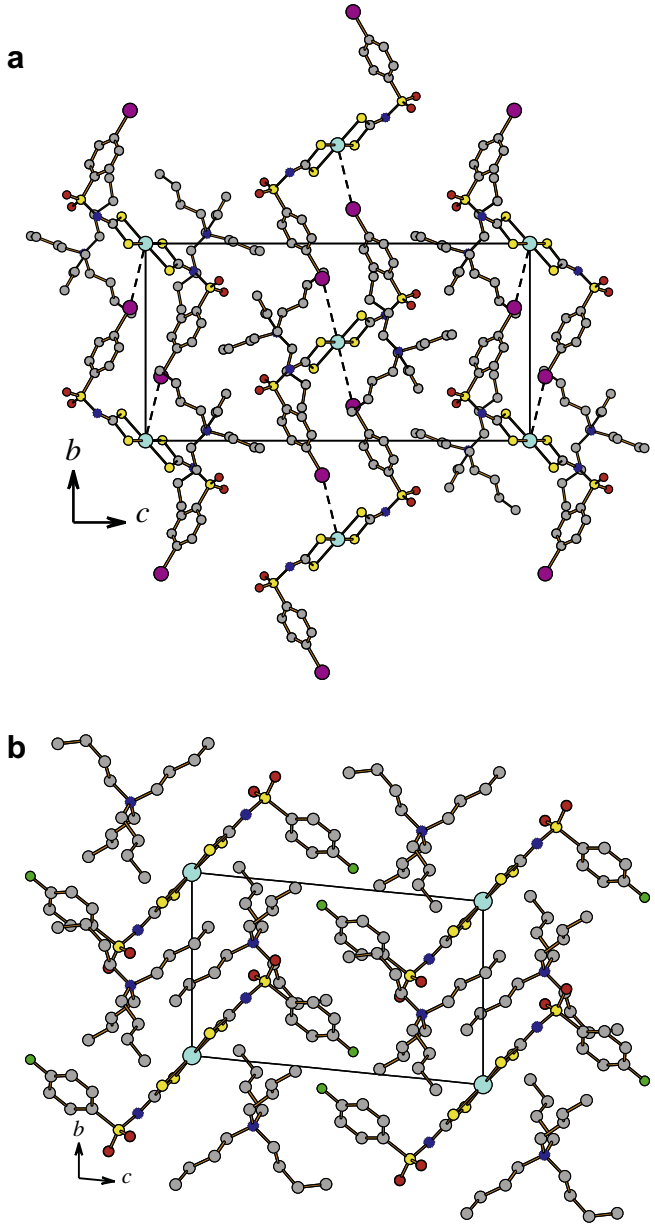

Fig. 4. Molecular arrangement of the complexes **3** (a) and **4** (b) in the unit cell. H atoms are omitted for clarity.

moiety is more shielded in the complexes than in free ligands. The ionic interaction between the potassium cations and the 4-fluorophenylsulfonyldithiocarbimate dianions does not disturb significantly the conformation of the anionic ligand, while the bidentate chelation by two S atoms of dithiocarbimate group to Pt cation is more covalent and leads to a decrease on the S1–C1–S2 angle in the ligand.

Scheme 1. Schematic illustration for all Cu(II) complexes (cation moiety).

2. Experimental

2.1. Materials and general information

5,5′-Dimethyl-2,2′-bipyridine was purchased from Sigma–Aldrich Chemical Co., 4,4′-dimethyl-2,2′-bipyridine was purchased from Alfa Aesar Co. Ltd. pBR322 DNA was purchased from MBI, catalase and Tris were purchased from BBI, CT-DNA and ethidium bromide were purchased from Sino-American Biotechnology. Other reagents of analytical grades were obtained from domestic chemical corporations and used without further purification. Milli-Q water was used in all physical measurement experiments.

Microanalyses (C, H and N) were carried out on an Elementar Vario EL elemental analyzer. ESI-Mass spectra were recorded using a LCMS-2010A Liquid Chromatograph Mass Spectrometer. ^{1}H NMR spectra were collected on a Varian Mercury-plus 300 NMR spectrometer.

2.2. Synthesis

2.2.1. 4,4′-Dibromomethyl-2,2′-bipyridine

To a stirred mixture of 4,4′-dihydroxymethyl-2,2′-bipyridine [56–59] (1.797 g, 8.310 mmol), 40% hydrobromic acid (50 mL) and sodium bromide (16.800 g, 0.163 mol), 16.8 mL concentrated sulfuric acid was added dropwise. The mixture was then refluxed for 24 h, followed by being cooled to 0 °C in ice-water bath and addition of 100 mL ice water. The pH was adjusted to 8–9 with saturated aqueous solution of sodium hydroxide. The produced precipitate was filtered, washed with cold water and dried to offer 2.026 g grey powder (71.3%).

All the ligands were prepared similarly, and the preparation of L^1Br_2 was presented as general procedure.

2.2.2. 5,5′-Bis(dimethylaminomethyl)-2,2′-bipyridine dihydrobromide (L^1Br_2)

5,5′-Dibromomethyl-2,2′-bipyridine [47] (0.300 g, 0.877 mmol) was suspended in 10 mL ethanol and stirred at room temperature, to which 33% aqueous dimethylamine (1.0 mL, 6.6 mmol) was added dropwise and the reaction mixture was stirred at room temperature until the reaction mixture became clear (about 30 min). The solvent was evaporated, then the solid was washed with 5 mL ethanol for three times and dried *in vacuum* to give white powder (0.312 g, 81.3%). *Anal.* Calc. for $C_{16}H_{22}N_4 \cdot 2HBr \cdot 0.3\,H_2O$ (437.61): C, 43.92; H, 5.67; N, 12.80. Found: C, 43.93; H, 5.56; N, 12.73%. ESI-MS, *m*/*z* (%): 136.25 (100), $[L^1]^{2+}$; 271.65 (43), $[L^1-H]^+$. ^{1}H NMR (D_2O, 300 MHz): δ 8.576 (d, J = 2.1 Hz, 2H, bpy-H); 8.051 (d, J = 8.1 Hz, 2H, bpy-H); 7.970 (dd, J_1 = 8.1 Hz, J_2 = 2.1 Hz, 2H, bpy-H); 4.303 (s, 4H, CH_2); 2.746 (s, 12H, CH_3).

2.2.3. 5,5′-Bis(trimethylaminomethyl)-2,2′-bipyridine dibromide (L^2Br_2)

Addition of 1.0 mL (5.0 mmol) trimethylamine to the solution of 5,5′-dibromomethyl-2,2′-bipyridine (0.200 g, 0.585 mmol) in ethanol gave 0.252 g L^2Br_2 as white powder (86.8%). *Anal.* Calc. for $C_{18}H_{28}N_4Br_2 \cdot 2H_2O$ (496.29): C, 43.56; H, 6.50; N, 11.29. Found: C, 43.91; H, 6.29; N, 11.28%. ESI-MS, *m*/*z* (%): 150.25 (100), $[L^2]^{2+}$. ^{1}H NMR (D_2O, 300 MHz): δ 8.729 (d, 2H, J = 2.1 Hz, bpy-H); 8.204 (d, 2H, J = 8.1 Hz, bpy-H); 8.130 (dd, 2H, J_1 = 8.1, J_2 = 2.1, bpy-H); 4.584 (s, 4H, CH_2); 3.094 (s, 18H, CH_3).

2.2.4. 4,4′-Bis(dimethylaminomethyl)-2,2′-bipyridine dihydrobromide (L^3Br_2)

The reaction of 1.0 mL dimethylamine and 0.310 g (0.906 mmol) 4,4′-dibromomethyl-2,2′-bipyridine produced 0.305 g L^3Br_2 as pale pink powder (77.9%). *Anal.* Calc. for $C_{16}H_{22}N_4 \cdot 2HBr$ (432.20): C, 44.46; H, 5.60; N, 12.96. Found: C, 44.33; H, 5.55; N, 12.78%. ESI-MS, *m*/*z* (%): 271.40 (100), $[L^3-H]^+$. ^{1}H NMR (D_2O, 300 MHz): δ: 8.526 (s, 2H, bpy-H); 7.930 (s, 2H, bpy-H); 7.406 (s, 2H, bpy-H); 3.950 (s, 4H, CH_2); 2.493 (s, 12H, CH_3).

2.2.5. 4,4′-Bis(trimethylaminomethyl)-2,2′-bipyridine dibromide (L^4Br_2)

0.200 g (0.585 mmol) 4,4′-dibromomethyl-2,2′-bipyridine and 1.0 mL trimethylamine offered 0.235 g L^4Br_2 as pale pink powder (87.2%). *Anal.* Calc. for $C_{18}H_{28}N_4Br_2$ (460.26): C, 46.97; H, 6.13; N, 12.17. Found: C, 46.88; H, 6.25; N, 12.18%. ESI-MS, *m*/*z* (%): 150.30 (100), $[L^4]^{2+}$. ^{1}H NMR (D_2O, 300 MHz): δ 8.723 (d, 2H, J = 5.1 Hz, bpy-H); 8.218 (s, 2H, bpy-H); 7.621 (dd, 2H, J_1 = 5.1, J_2 = 1.5, bpy-H); 4.572 (s, 4H, CH_2); 3.110 (s, 18H, CH_3).

All the Cu(II) complexes were prepared in a similar way, the preparation of **1** was described here as general procedure.

2.2.6. $[Cu(L^1)_2Br](ClO_4)_2Br_3 \cdot 3H_2O$ (**1**)

0.150 g $L^1Br_2 \cdot 0.3H2O$ (0.343 mmol) was suspended in 10 mL ethanol, followed by addition of 3 mL ethanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.300 g, 0.810 mmol). Brown precipitate appeared immediately, which was filtrated and washed with ethanol for several times. The precipitate was recrystallized from 1:4 H_2O–MeOH (~1 mL) at 4 °C overnight, then was filtrated and dried, 0.143 g green powder was obtained (70.6%). Elemental *Anal.* (EA) Calc. for $[Cu(C_{16}H_{24}N_4)_2Br](ClO_4)_2Br_3 \cdot 3H_2O$ (1180.90): C, 32.55; H, 4.61; N, 9.49. Found: C, 32.60; H, 4.38; N, 9.40%.

Green single crystals suitable for X-ray analysis were prepared by slow diffusion of methanol into aqueous solution of **1**.

2.2.7. $[Cu(L^2)_2Br](ClO_4)_5 \cdot 4H_2O$ (**2**)

0.200 g (0.402 mmol) L^2Br_2 gave 0.171 g **2** as green powder (64.7%). *Anal.* Calc. for $[Cu(C_{18}H_{28}N_4)_2Br](ClO_4)_5 \cdot 4H_2O$ (1313.66): C, 32.92; H, 4.91; N, 8.53. Found: C, 32.83; H, 4.49; N, 8.45%.

2.2.8. $[Cu(L^3)_2Br](ClO_4)_5 \cdot 2H_2O$ (**3**)

0.150 g (0.347 mmol) L^3Br_2 offered 0.135 g of **3** as green powder (63.9%). *Anal.* Calc. for $[Cu(C_{16}H_{24}N_4)_2Br](ClO_4)_5 \cdot 2H_2O$ (1217.01): C, 31.55; H, 4.31; N, 9.20. Found: C, 31.48; H, 4.48; N, 9.14%.

2.2.9. $[Cu(L^4)_2Br](ClO_4)_{4.5}(OH)_{0.5} \cdot 6H_2O$ (**4**)

0.195 g (0.424 mmol) L^4Br_2 produced 0.167 g **4** as green powder (60.2%). *Anal.* Calc. for $[Cu(C_{18}H_{28}N_4)_2Br](ClO_4)_{4.5}(OH)_{0.5} \cdot 6H_2O$ (1308.47): C, 33.05; H, 5.28; N, 8.56. Found: C, 33.55; H, 5.67; N, 8.09%.

Green single crystals suitable for X-ray analysis were prepared by slow evaporation of solution of **4** in 3:1 EtOH–H_2O solution.

2.3. X-ray crystallography

Single crystals sized 0.20 × 0.08 × 0.08 mm and 0.48 × 0.35 × 0.31 mm for **1** and **4**, respectively, were used for X-ray diffraction analyses. Data collections of **1** and **4** were performed with Cu Kα

(λ = 1.54178 Å) and Mo Kα (λ = 0.71073 Å) radiation, respectively, on an Oxford Germini S Ultra CCDC diffractometer at 293(2) K. An absorption correction by multi-scan was applied to the intensity data. The structure was solved by direct method and the heavy atoms were located from E-map. The remaining non-hydrogen atoms were determined from the successive difference Fourier syntheses. The non-hydrogen atoms were refined anisotropically, whereas the hydrogen atoms were generated geometrically with isotropic thermal parameters. The structure was refined on F^2 by full-matrix least-squares methods using the SHELXTL-97 program package [60].

2.4. Thermal-denaturation experiments

Thermal-denaturation experiments were carried out on a Varian Cary 300 UV/Vis spectrophotometer. UV absorbance of CT-DNA was recorded in 5 mM Tris–50 mM NaCl buffer solution (pH 7.5). The concentration of DNA was determined according to the literatures [28,61], and 100 μM DNA was used. The melting curves were recorded at different concentration ratio of complexes to DNA (r = 0, 0.1 and 0.2, r = [complex]/[DNA]) by plotting the absorption at 260 nm as function of temperature in the range of 55–95 °C. The melting temperature (T_m) was determined from the maximum of the first derivative or tangentially from the graph at midpoint of the transition curves. ΔT_m was defined as the difference between the T_m of free DNA and the T_m of DNA in the presence of complexes.

2.5. CD spectroscopy

CD spectra of CT-DNA were recorded on a Jasco J-810 spectropolarimeter at room temperature in the absence or presence of 45 μM complex. The concentration of DNA was 150 μM and the buffer solution was the same as thermal-denaturation experiments. Each test solution was scanned at a speed of 50 nm min^{-1} for five repetitions, and the average spectra were used. The buffer background was subtracted automatically.

2.6. DNA cleavage

The cleavage of plasmid DNA (pBR322, 38 μM bp) was performed in 20 mM Tris buffer (pH 7.5) by treating DNA with a certain concentration of complex. The total volume of 10 μL sample solution was incubated in a sealed plastic vessel and the cleavage was carried out at 37 °C for a defined time, then 4 μL loading buffer (bromophenol blue, 50% glycerol and 2 mM EDTA) was added. The sample was stored at −20 °C for preservation, then was loaded onto a 0.9% agarose gel and electrophoresed at a constant voltage of 120 V for 100 min in TBE buffer (100 mM Tris–2 mM EDTA–HBO_3, pH 8.3). DNA bands were visualized in an electrophoresis documentation and analysis system 120. Densitometeric calculations were made using analysis method in Image Tools 3.00. A correction factor of 1.47 was used for supercoiled DNA taking into account its weaker staining capacity by ethidium bromide compared to nicked and linear DNA. The apparent rate constant (k_{obs}) at a certain complex concentration, k_{cat} and K_M values were calculated according to the literature [23].

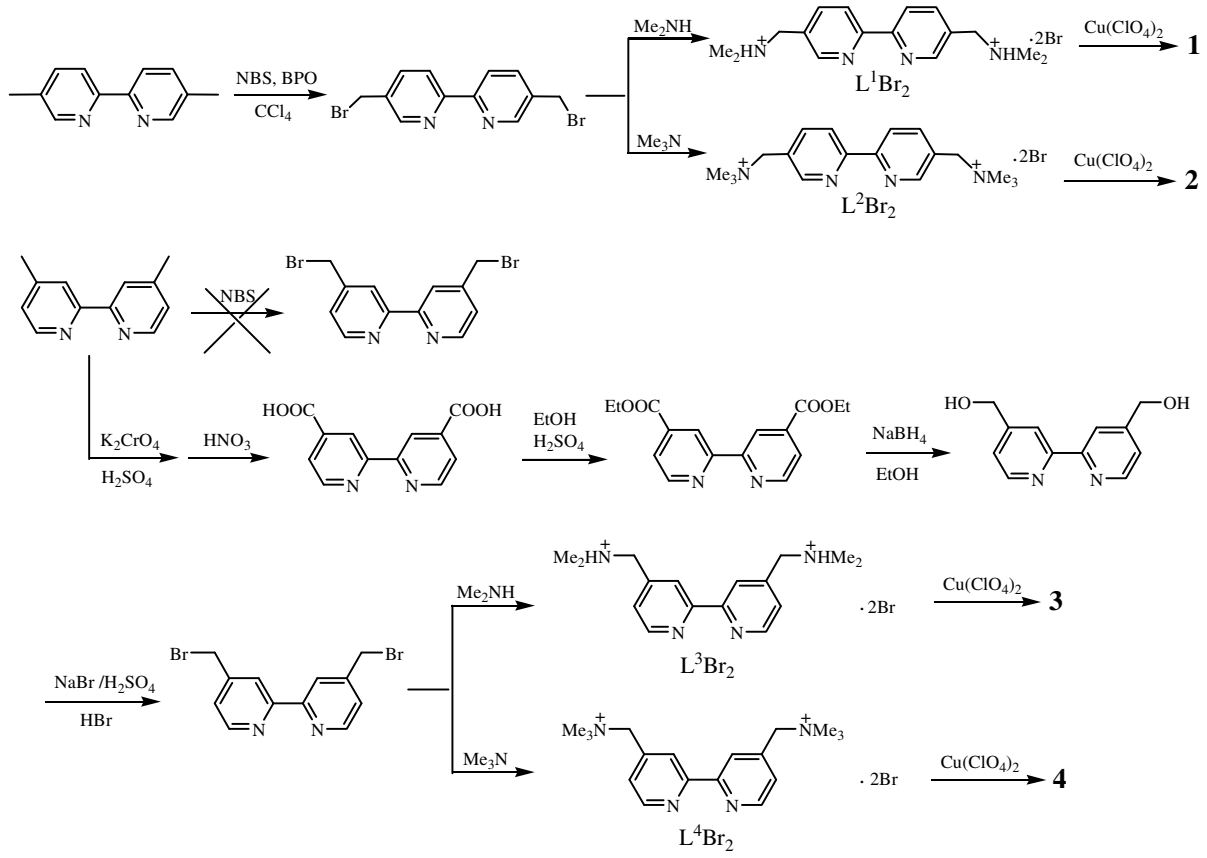
3. Results and discussion

3.1. Preparation of Cu(II) complexes

The synthesis route for these Cu(II) complexes is shown in Scheme 2. 5,5′-Dibromomethyl-2,2′-bipyridine was prepared according to the literature [55], it was allowed to react with dimethylamine or trimethylamine to give 5,5′-bis(dimethylaminomethyl)-2,2′-bipyridine dihydro-bromide (L^1Br_2) and 5,5′-bis(trimethylaminomethyl)-2,2′-bipyridine dibromide (L^2Br_2), respectively. The reaction of L^1Br_2 or L^2Br_2 with $Cu(ClO_4)_2$ gave complexes **1** and **2**, respectively.

4,4′-Dibromomethyl-2,2′-bipyridine cannot be successfully prepared by the direct bromization of 4,4′-dimethyl-2,2′-bipyridine using *N*-bromosuccinimide, and a four-step synthesis route was adopted. Firstly, 4,4′-dicarboxyl-2,2′-bipyridine was prepared according to the literature [56]. The following esterification similar to the literature procedure offered 4,4′-diethoxyacyl-2,2′-bipyridine [57]. The reduction of this diester using sodium borohydride in ethanol yielded 4,4′-dihydroxymethyl-2,2′-bipyridine [57,58]. 4,4′-Dibromomethyl-2,2′-bipyridine can be prepared according to the general bromization procedure for alkyl alcohols [58,59], and a modified method is described in experimental section. Then the dibromide was allowed to react with dimethylamine or trimethylamine to offer 4,4-bis(dimethylaminomethyl)-2,2′-bipyridine dihydrobromide (L^3Br_2) and 4,4′-bis(trimethylaminomethyl)-2,2′-bipyridine dibromide (L^4Br_2), respectively. The reaction of L^3Br_2 or L^4Br_2 with $Cu(ClO_4)_2$ gave Cu(II) complexes **3** and **4**, respectively.

The MS and ^1H NMR spectra of all ligands are presented in supplementary material (Figures S1 and S2, respectively). However the ESI-MS spectra of all Cu(II) complexes were not included since only m/z peaks of the ligands are found due to these Cu(II) complexes are degraded into ligands under strong electric field conditions of MS.



3.2. Crystal structure of complex *1* and *4*

A summary of the crystallographic data is given in Table 1. The molecular structure of **1** is very similar to those reported Cu(II) complexes of 2,2′-bipyridine or its derivatives [55,62]. It consists of a $[Cu(L^1)_2(Br)]^{5+}$ cation, two ClO_4^-, three Br^- anions and three water molecules. Each structural motif contains two independent symmetric molecules (A and B), and the other halve of the complex was generated by the twofold diad present in the space group $P2/c$. Both molecules display very similar coordination geometries. Selected bond lengths and angels for the coordination of Cu(II) are shown in Table 2, and the ORTEP drawing of the cationic moiety in molecule A is shown in Fig. 1 as an example. The coordination configuration of the divalent Cu(1) can be described as a distorted trigonal bipyramid, in which atoms N(1), N(1A) and Br(1) define the equatorial plane and atoms N(3) and N(3A) occupy the apical sites. The degree of trigonality (τ) of this molecule is calculated as 0.79 according to the literature [63]. The distances between the N atoms in ammonium groups and the Br^- anion defined by N(4)···Br(1) or N(4A)···Br(1) is 6.201 Å.

As shown in Fig. 2, the molecular structure of complex **4** is quite similar to that of **1**, and the configuration of five-coordinated Cu(1) ion can also be described as a distorted trigonal bipyramidal. Atoms N(2), N(5) and Br(1) define the equatorial plane while N(1) and N(6) occupy vertical sites. The calculated τ value is 0.53. The distances between tetraalkylammonium groups and Br^- anion defined by N(3)···Br(1) and N(8)···Br(1) are 7.835(1) Å and 8.117(1) Å, respectively (Table 3).

3.3. Interaction with CT-DNA

T_m of CT-DNA was measured in the presence of different molar ratio of complexes to DNA. ΔT_m values are listed in Table 4, and thermal melting curves are presented in the supporting information (Fig. S3). The result shows that with the addition of complexes to DNA, the melting temperature decreases slightly in each case, indicating the slight destabilization of the DNA duplex induced by all the complexes. Although ΔT_m values are quite low, they follows the order of **1** > **2** > **3** > **4**, which basically display the binding abilities of these complexes towards CT-DNA.

Scheme 2. Synthesis route for Cu(II) complexes.

The interaction between these complexes and CT-DNA was further investigated by CD spectroscopy (Fig. 3). The CD spectra consist of a positive band at 275 nm due to base stacking and a negative band at 245 nm due to the right-handed helicity. Both bands are quite sensitive to the intercalation mode with small molecules [64]. Addition of each complex into CT-DNA induced slight decrease in ellipticity of both positive and negative bands. The calculated percent of decrease in ellipticity are 13.4%, 9.4%, 3.1%, 2.4% at 275 nm and 15.0%, 9.5%, 4.1%, 3.4% at 245 nm for **1**, **2**, **3**, **4**, respectively, from which it can be concluded that the interaction of all complexes towards CT-DNA follows the same order as the thermal melting curves experiment. No evident red shift or blue shift was observed, indicating all complexes induced only slight loss of characteristic B-type DNA conformation, however did not resulted in the formation of other types of DNA.

Table 4
Thermal melting temperature of CT-DNA[a]

r[b]	$-\Delta T_m$ (°C)[c]			
	1	**2**	**3**	**4**
0.1	1.92	0.84	0.51	0.43
0.2	3.09	2.36	1.79	1.12

[a] Experimental conditions: 5 mM Tris–50 mM NaCl buffer, pH 7.5, [DNA] = 100 μM.
[b] r = [complex]/[DNA].
[c] ΔT_m (°C) = the melting temperature of DNA in the presence of complex – the melting temperature of free DNA. Errors of T_m = ±0.1 °C.

It has been widely accepted that there are three non-covalent interaction modes between metal complexes and DNA: outside binding, groove binding and intercalation binding. In general, intercalation binding causes evident increase (5–8 °C) in T_m of DNA [65] and obvious decrease in both positive and negative bands

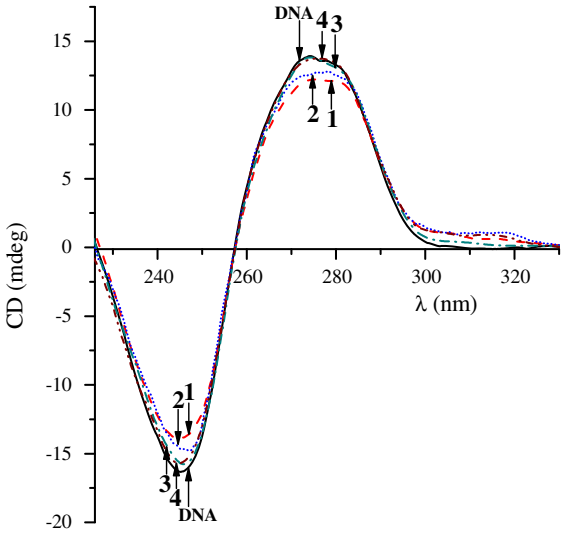

Fig. 3. CD spectra of 150 μM CT-DNA in the absence and presence of 45 μM complexes **1**–**4**: DNA (——), **1** (– – –), **2** (· · ·), 3 (–·–·–), 4 (–··–··). Experimental conditions: 5 mM Tris–50 mM NaCl buffer, pH 7.5, room temperature.

of CD spectra of DNA [66]. The quite low and negative ΔT_m values indicate that the interaction mode between these complexes and CT-DNA does not belong to intercalation. It also can be easily concluded from the structures of these complexes. In each complex, there are four ammonium groups in the side chains. According to Lewis theory, these positively-charged N atoms of ammonium groups belong to hard acid, and they are mostly bound to negatively-charged phosphate groups rather than bases pairs of DNA [67]. Therefore, outside electrostatic interaction is the most possible binding mode between theses complexes and CT-DNA.

3.4. Mechanism of DNA cleavage

The cleavage of supercoiled double-strand DNA by these complexes was studied in the absence of any reducing agents. In order to investigate the possible cleavage mechanism, DNA cleavage by complex **2** was examined as an example in the presence of hydroxyl radical scavengers (DMSO and *t*-BuOH) [68], peroxide scavenger (catalase), superoxide scavenger (SOD) [69] and chelating agent (EDTA). As shown in Fig. 4, all the scavengers threw little effect on DNA cleavage. This result basically rules out the possibility of DNA cleavage by hydroxyl radicals, superoxide anion and peroxide. EDTA can efficiently inhibit DNA cleavage, indicating Cu(II) complexes play the key role in the cleavage. Therefore, in the absence of any reducing agents, DNA cleavage by these Cu(II) complexes preferably undergoes a hydrolytic degradation pathway.

3.5. The identification of the hydrolytically active species

Bipyridine and its derivatives may form 1:1 or 1:2 copper complexes (CuL or CuL_2). The identification of the hydrolytically active species was investigated by the cleavage of DNA in the presence of ligands alone, the mixture of ligands and free copper with different molar ratio. Ligands L^1 and L^4 were chosen as examples to illustrate this question, and the results are shown in Fig. 5. For both ligands, with the increase of molar ratio (r = [L]/[Cu(II)]), the percent of nicked DNA (form II) increased and arrived at the maximum when r = 2, then stay on the maximum around. As the case stands, the brown CuL species has been prepared in dry organic solvent by us. It's extremely readily to become green CuL_2 in aqueous solution. The results indicate

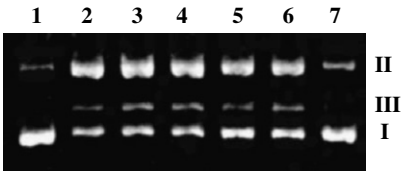

Fig. 4. The cleavage of pBR322 DNA after incubated with **2** (150 μM) for 0.5 h in the absence and presence of radical scavengers. Reaction conditions: [DNA] = 38 μM bp, 20 mM Tris–0.1 M $NaClO_4$ buffer, pH 7.5, 37 °C. Lane 1: DNA control; lane 2: DNA + 2; lanes 3–6: DNA + 2 + 1 M DMSO, 1 M *t*-BuOH, 1000 U/mL catalase, 1000 U/mL SOD, 0.1 M EDTA, respectively.

that CuL_2 species rather than CuL species are the hydrolytically active species in the cleavage of DNA.

3.6. Pseudo-Michaelis–Menten kinetics of DNA cleavage

Under hydrolytic conditions, DNA can be cleaved from supercoiled (form I) into nicked (form II) or linear form (form III) by each complex of varied concentrations. A series of DNA cleavage experiments have been performed, and time-dependent and concentration-dependent cleavages were observed. The time-dependent decrease of form I and increase of form II follow *pseudo*-first-order kinetic profiles and fit in well with single exponential function (supporting information, Fig. S4). A typical agarose gel electrophoresis pattern and the corresponding time course plot for DNA cleavage by **2** (120 μM) are shown in Fig. 6. The hydrolysis kinetics of DNA cleavage was studied with increased concentration of each complex (60–300 μM). The plots of k_{obs} values versus concentrations of all complexes are shown in Fig. S5. The *pseudo*-Michaelis–Menten kinetic parameter k_{cat}, affinity constant (K_M) and specificity constant k_{cat}/K_M are listed in Table 5. As is well known, the first-order hydrolysis rate constant for a phosphodiester bond of double-stranded DNA is estimated to be 3.6×10^{-8} h^{-1} [70]. Rate enhancements of reported Cu(II) complexes are in the range

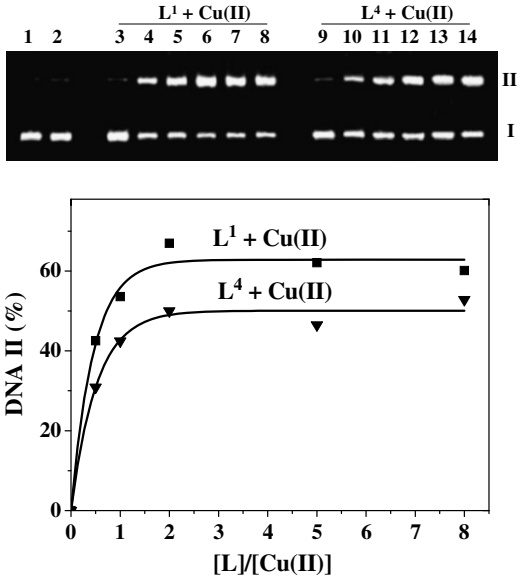

Fig. 5. The cleavage of pBR322 DNA in the presence of ligands alone and the mixture of ligands and $Cu(ClO_4)_2$ with different molar ratio. Reaction conditions: [DNA] = 38 μM bp, 20 mM Tris–0.1 M $NaClO_4$ buffer, pH 7.5, 37 °C. Lane 1: DNA control, 2 h; lane 2: DNA + 300 μM $Cu(ClO_4)_2$, 2 h; lane 3: DNA + 300 μM L^1, 0.5 h; lanes 4–8: DNA + 150 μ M $Cu(ClO_4)_2$ + L^1 (r = 0.5, 1, 2, 5 and 8, respectively, r = [L]/[Cu]), 0.5 h; lane 9: DNA + 600 μM L^4, 2 h; lanes 10–14: DNA + 300 μM $Cu(ClO_4)_2$ + L^4 (r = 0.5, 1, 2, 5 and 8, respectively), 2 h.

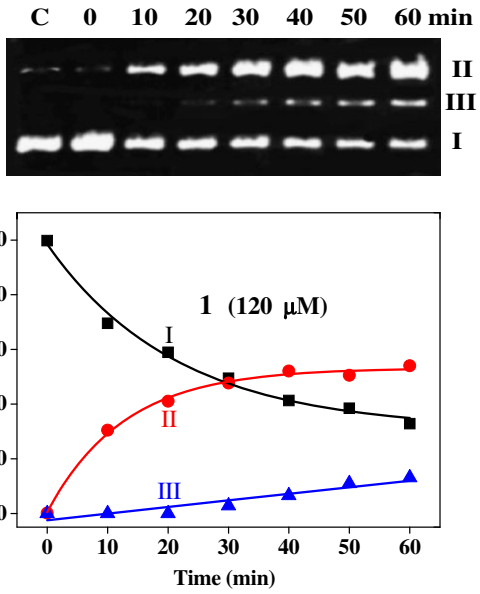

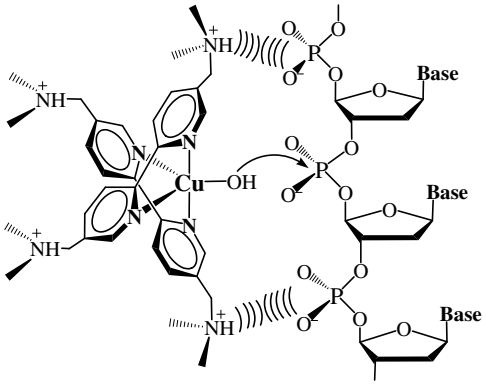

Fig. 6. Electrophoresis pattern and time course plot for the cleavage of pBR322 DNA by **2** (120 μM).

of 1.1×10^6–2.3×10^8 fold [27]. As shown in Table 5, the obtained k_{cat} values of 15.0, 13.7, 2.0 and 1.7 h^{-1} for **1**, **2**, **3** and **4**, respectively (37 °C, pH 7.5), indicate that these Cu(II) complexes exhibit very high hydrolytic cleavage reactivity, giving 4.7×10^7–4.2×10^8 fold rate enhancement.

Interestingly, the cleavage reactivity of **1** and **2** with 5,5′-ammonium groups is much higher than that of **3** and **4** with 4,4′-ammonium groups. The high cleavage reactivity may be attributed to the cooperativity between ammonium groups and the active Cu(II) center when these complexes are bound to DNA *via* electrostatic interactions (for all complexes) and hydrogen bonding (for **1** and **3**) (Scheme 3). Crystal data of **1** show that each distance between positively-charged N atoms in ammonium groups and the coordinated Br is 6.201 Å, which is in the range of the distance between the two adjacent phosphate groups in B-DNA (6–7 Å) [55,71]. However, distances between positively-charged N atoms and the coordinated Br atom in **4** are in the range of 7.835–8.117 Å (Table 3), which deviates from 6 to 7 Å. Although the crystal structures of **2** and **3** have not been obtained, one can conclude that their structures should be similar to **1** and **4** respectively. As a result, complexes **1** and **2** can more effectively match the phosphate groups of nucleic acid at space intervals than **3** and **4** do. The conclusion has also been supported by DNA binding experiments. The different position of the functional groups in **1**, **2** and **3**, **4**, results in the evident difference on their cleavage reactivity. On the other hand, the cleavage reactivity of **1** and **2** with 5,5′-dimethylamino/trimethylamino groups is also much higher than that of reported complex analogues with 5,5′-triethylamino/tributylamino groups [55]. It indicates that the steric hindrance of organic functional groups in mimics is also a significant factor to DNA cleavage activity of metal moiety in mimics.

Table 5
The kinetic parameters for hydrolytic cleavage of DNA by all complexes

Parameters	1	2	3	4
k_{cat} (h^{-1})	15.0 ± 0.4	13.7 ± 0.3	2.1 ± 0.2	1.7 ± 0.2
K_M (10^{-4} M)	4.5 ± 0.2	4.7 ± 0.3	2.8 ± 0.2	2.3 ± 0.1
k_{cat}/K_M (10^4 h^{-1} M^{-1})	3.37	2.94	0.75	0.75

Scheme 3. Proposed cooperativity between ammonium groups and cooper-coordinated hydroxyl in **1** when interact with DNA.

4. Conclusion

A series of Cu(II) complexes of disubstituted 2,2′-bipyridine bearing dimethylamino and trimethylamino groups at 5,5′- and 4,4′-positions were synthesized. The Cu(II) complexes with ammonium groups at 5,5′-positions exhibit very high DNA cleavage reactivity under hydrolytic conditions. The positively-charged functional groups of these complexes facilitate their binding to DNA and accelerate the cleavage of DNA especially when they match phosphodiester groups of nucleic acid better at space intervals.

prepared every day and standardized against standard potassium dichromate solution iodometrically [21]. The ammonium salt of Mn^{IV} complex, $(NH_4)_6[Mn^{IV}Mo_9O_{32}]$ was prepared by reported method [32] as follows: 50 g of ammonium molybdate was dissolved in 200 ml of water and excess of hydrogen peroxide as oxidant was added to it and the resultant solution was heated to 95 °C. To this hot solution, 5 g of $MnSO_4 \cdot H_2O$ in 50 ml of water was added slowly with constant stirring. The resultant orange-red colored solution was boiled for 10 min and quickly filtered and cooled. The orange-red colored crystals were recrystallized thrice from hot (70 °C) water. The solution of $(NH_4)_6[Mn^{IV}Mo_9O_{32}]$ was standardised by treating known amount of complex solution with excess of As^{III}, and back titrating As^{III}. The oxidation state of hetero-atom was also confirmed to be four, by iodometric method.

2.2. Kinetic study

The reaction between $[Mn^{IV}Mo_9O_{32}]^{6-}$ and P^I was carried out under pseudo-first-order conditions at a constant temperature of 27.0 ± 0.1 °C. The reaction was initiated by mixing the previously thermostated solutions of P^I and $[Mn^{IV}Mo_9O_{32}]^{6-}$, which also contained the required amount of perchloric acid, and doubly distilled water. The reaction was followed by determining the concentration of remaining $[Mn^{IV}Mo_9O_{32}]^{6-}$ iodometrically. The rate constants were determined from the linear pseudo-first-order plots of $\log[Mn^{IV}Mo_9O_{32}]^{6-}$ against time and the rate constants were reproducible within ±6%.

2.3. Stoichiometry and product analysis

The stoichiometry was studied by keeping concentration of $[Mn^{IV}Mo_9O_{32}]^{6-}$ constant at 8×10^{-3} mol dm^{-3} and varying concentration of P^I from 0.5×10^{-3} to 6.0×10^{-3} mol dm^{-3}. Different reaction mixtures containing varying concentration of P^I were prepared, which also contained required amount of perchloric acid. The concentration of unreacted $[Mn^{IV}Mo_9O_{32}]^{6-}$ was determined after 24 h iodometrically. The stoichiometry was found to be one mole of $[Mn^{IV}Mo_9O_{32}]^{6-}$ per mole of P^I. When the reaction mixture containing excess of hypophosphite was kept undisturbed up to 48 h a blue color was developed. The blue product was isolated from the reaction mixture by crystallization and recrystallized form alcohol. The UV–Vis spectra of the resulting blue product was recorded, which shows a peak at 840 nm corresponding to the molybdenum blue [20]. Further, when a strong reductant like ascorbic acid or hydrazine sulfate was added to the reaction mixture containing excess of hypophosphite there was rapid formation of molybdenum blue just after 24 h.

2.4. Atomic absorption analysis

The complex $(NH_4)_6[Mn^{IV}Mo_9O_{32}] \cdot 3H_2O$ was analyzed by AAS. The solution for AAS analysis was prepared by dissolving 100 mg of recrystallized sample in double distilled water and 5 ml of this stock solution was diluted to 100 ml. The diluted solution was used for AAS analysis of Mn and Mo using Perkin–Elmer AAnalyst-300 instrument. The complex $(NH_4)_6[Mn^{IV}Mo_9O_{32}] \cdot 3H_2O$ shows (theoretical): Mn – 3.501% (3.4493%) and Mo – 54.217% (54.2125%). The results of the AAS analysis of the blue products are Mn – 0%, Mo – 26.7% and P – 1.5%.

2.5. Spectrophotometric measurements

The visible spectra of $(NH_4)_6[Mn^{IV}Mo_9O_{32}]$ complex, the blue product and the reaction mixture were recorded by using Elico SL-177 spectrophotometer between the wavelength region 400 and 900 nm. The spectra of the $(NH_4)_6[Mn^{IV}Mo_9O_{32}]$ complex in water, in presence of 0.1 mol dm^{-3} perchloric acid and the reaction mixture soon after the mixing of reactants is given in Fig. 1. The spectrum of the blue product obtained is shown in Fig. 2.

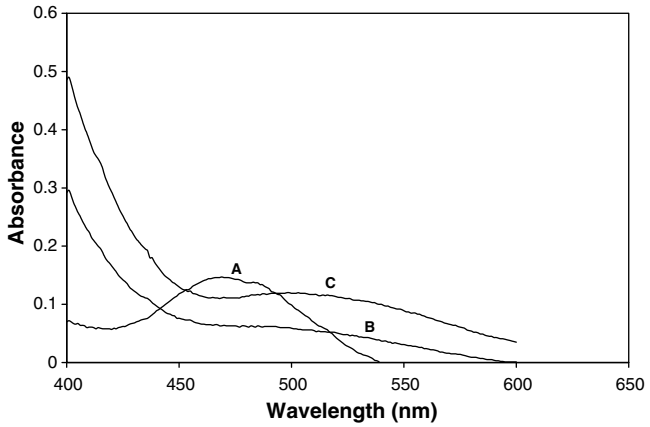

Fig. 1. UV–Vis spectra of $[Mn^{IV}Mo_9O_{32}]^{6-}$: (A) in water, (B) in 0.1 mol dm^{-3} $HClO_4$ and (C) reaction mixture. $10^3[Mn^{IV}Mo_9O_{32}]^{6-}$ = 1.0 mol dm^{-3}, 10^2[Hypophosphite] = 6.0 mol dm^{-3}.

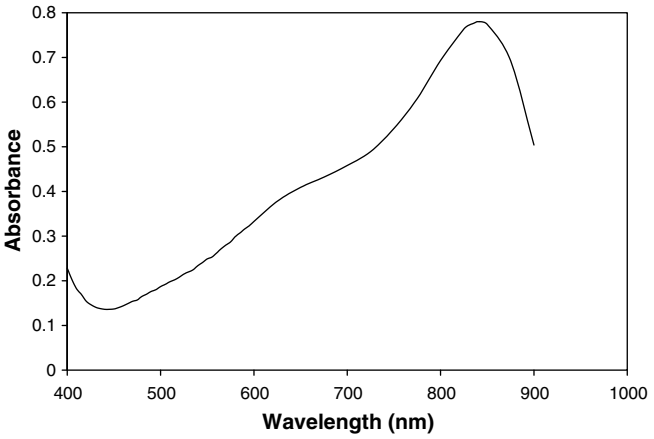

Fig. 2. UV–Vis spectrum of the blue product. $10^3[H_{10}(HP)Mo_6O_{26}]^{2-}$ = 1.4 mol dm^{-3}.

2.6. FTIR-spectral study

The FTIR-Spectra of $(NH_4)_6[Mn^{IV}Mo_9O_{32}]$ complex and the blue product were taken in KBr by using Perkin–Elmer Spectrumone spectrophotometer. The complex $(NH_4)_6[Mn^{IV}Mo_9O_{32}]$ contains Mn^{IV} as a hetero-atom surrounded by octahedral groups of MoO_6^{2-}. In the IR-spectrum of Mn^{IV} complex, the peaks obtained at 3521 cm^{-1}, 933 cm^{-1}, 918 cm^{-1} and 900 cm^{-1} corresponds to lattice water molecules [33], Mo–O stretching [34], Mn^{IV}–O stretching and tetrahedral MoO_4^{2-} groups [33], respectively. The FTIR spectra of the blue product shows the peaks at 3400, 2405, 1120, 1043, 941, 905, 804 and 626 cm^{-1} corresponding to lattice water [33], PH stretching [35], PO_3 groups [35], PH deformation, Mo–O stretching, MoO_4^{2-} groups, MoO_4^{3-} groups and Mo–O–P [34] stretching, respectively.

2.7. Test for free radicals

The reaction was also studied in presence of added acrylonitrile to understand the intervention of free radicals [36,37] in the reaction. There was no effect of added acrylonitrile on the reaction and

also no precipitate due to the polymerization of the added acrylonitrile was observed thus confirming the absence of any free radical formation in the reaction.

3. Results and discussion

3.1. Reaction order

The reaction was carried out under pseudo-first-order conditions, keeping the concentration of perchloric acid constant at 0.5 mol dm^{-3} and varying either [P^{I}] from 2.5×10^{-2} to 2.5×10^{-1} mol dm^{-3} at constant $[Mn^{IV}Mo_9O_{32}]^{6-}$ (2.0×10^{-3} mol dm^{-3}) or $[Mn^{IV}Mo_9O_{32}]^{6-}$ from 0.4×10^{-3} to 4.0×10^{-3} mol dm^{-3} at constant [P^{I}] (1.0×10^{-1} mol dm^{-3}). The pseudo-first-order rate constants were found to be increased with increase in the concentration of the reductant (Table 1) and the order was found to be fractional as determined by $\log(k_{obs})$ against log[P^{I}] plot. The Michaelis–Menten plot of $1/k_{obs}$ against 1/[Hypophosphite] was also found to be linear with an intercept (Fig. 3) indicating the formation of a complex between the two reactants. Therefore, the effect of hypophosphite was studied at four different temperatures and from the slope and intercept of Fig. 3, the formation constants of the complex and rate constants for its decomposition were determined at all the temperatures studied (Table 2). The pseudo-first-order plots were found to be linear and the pseudo-first-order rate constants were fairly constant as the concentration of oxidant is varied (Table 3), indicating the order in oxidant to be unity. There was no effect of added product, P^{III} whereas the added molybdate ion over the concentration range of 0.1×10^{-2} to 1.0×10^{-2} mol dm^{-3} decreases the values of k_{obs} considerably (Table 3). Free radical intervention during the reaction was tested by studying the reaction in presence of added acrylonitrile, a free radical scavenger. There was no precipitation due to polymerization of added acrylonitrile and the rate also remains unaffected which indicates no formation of free radicals in the reaction.

3.2. Effect of hydrogen ion concentration

The effect of hydrogen ion concentration on the reaction was studied in order to understand the nature of reactant species present in the solution. The concentration of H^+ ion was varied from 0.1 to 1.0 mol dm^{-3} keeping all other concentrations constant. It was found that the reaction rate increases with the concentration of H^+ ions (Table 3) and the graph of k_{obs} against $[H^+]$ was found to be linear without intercept. The order in hydrogen ion concentration was found to be 0.87 as found from $\log k_{obs}$ against $\log[H^+]$ plot.

3.3. Effect of solvent polarity, ionic strength and temperature

The effects of ionic strength, solvent polarity and temperature were studied keeping concentration of $[Mn^{IV}Mo_9O_{32}]^{6-}$, P^{I} and perchloric acid constant at 2.0×10^{-3} mol dm^{-3}, 0.1 mol dm^{-3} and 0.5 mol dm^{-3}, respectively, at 27 °C. Sodium perchlorate and acetonitrile were used to vary the ionic strength and solvent polarity, respectively. The rate of the reaction was unaffected by increase in ionic strength from 0.5 to 1.0 mol dm^{-3} and as the percentage of acetonitrile increases from 0% to 40% v/v. The effect of temperature was studied at 15, 20, 27 and 35 °C and the activation parameters were determined with respect to the slow step of the reaction are given in Table 2.

Enneamolybdomanganate(IV) is one of the stable heteropolymolybdate containing Mn^{IV} as a hetero atom and is noncentrosymmetric. It also shows a characteristic charge transfer band at 468 nm which has been assigned to $^4A_{2g} \rightarrow {}^4T_{2g}$ transition of Mn^{IV}. This band is sensitive [38] to the changes in the electronic state of the Mn^{IV} ion and any perturbations due to interaction of MnO_6 groups with neighboring ions will result in the shift of band. The arrangements of oxygen atoms [38] around $[MnMo_9O_{32}]^{6-}$ are of two different types A and B as shown in Fig. 4. From the spectrophotometric investigation on interaction [38] of various cations with the anion, it was concluded that metal cations will bind to site A due to their larger negative charge in comparison with that of site B. Such type of cation interaction at site A perturbs the electronic state of the central hetero atom, manganese, resulting in change of absorption spectra of the anion. In aqueous solution the UV–Vis spectrum of the anion, $[MnMo_9O_{32}]^{6-}$, shows a peak at 468 nm and in presence of acid two isosbestic points are obtained at 435 and 520 nm due to its protonation (Fig. 1A and B, respectively). At high metal ion concentrations the peak at 468 nm is reappeared [38] as a result of metal ion substitution on the anion at oxygen atoms of A type. In order to understand the interaction between the hypophosphite and $[MnMo_9O_{32}]^{6-}$ UV–Vis spectra of the reaction mixture was examined. The anion shows a characteristic peak at 468 nm in aqueous solution as in Fig. 1A and addition of 0.1 mol dm^{-3} perchloric acid the spectrum of protonated anion is obtained (Fig. 1B) with two isosbestic points are obtained at 435 and 520 nm due to its protonation. To an acidic solution of the anion when hypophosphite is added the reappearance of peak at 468 nm was not observed instead there was considerable increase in the intensity of absorption about 504 nm (Fig. 1C). The reappearance of peak at 468 nm in presence of hypophosphite is expected if the interaction of added hypophosphite would have been through oxygen atoms of site A. Therefore, the hypophosphite is interacting with the anion, $[MnMo_9O_{32}]^{6-}$, through the oxygen atoms of site B without perturbing the electronic state of MnO_6 octahedra. An increase in the intensity of peak at 504 nm in presence of hypophosphite is also an indication of formation of complex between the two. Such complex formation was also supported kinetically from the fractional order in [Hypophosphite] and Michaelis–Menten plot of $1/k_{obs}$ against 1/[Hypophosphite] as shown in Fig. 3.

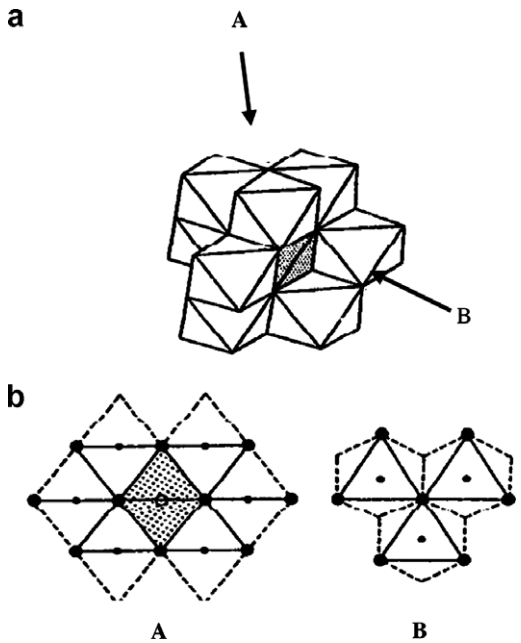

Fig. 4. Arrangements of oxygen atoms in $[MnMo_9O_{32}]^{6-}$ (from Ref. [36]): (a) structure of the $[MnMo_9O_{32}]^{6-}$ anion (shaded octahedron in (a) is MnO_6 and (b) two arrays of oxygen atoms as the potential metal binding sites. (large solid circles in (b) are oxygen atoms, small solid circles are Mo atoms and an open circle is a Mn atom.)

In aqueous solution hypophosphorous acid acts as a monobasic acid [19] and its dissociation constant is 5.9×10^{-2} mol dm^{-3} and in acidic solutions it exists in the undissociated form. The pK_a of hexaprotonated anion, $[MnMo_9O_{32}]^{6-}$, is reported [38] to be around 3.0 and at pH 2 approximately 90% of the anion is totally protonated and it is completely deprotonated at pH 4. Therefore, at a pH bellow 2 the protonation equilibria of the anion, $[MnMo_9O_{32}]^{6-}$, can be represented by Eq. (1). The dependence of rate of the reaction on hydrogen ion concentration is shown in Table 3 and the order in its concentration was found to be 0.87(R^2 = 0.996) as found from

$$[H_6Mn^{IV}Mo_9O_{32}] \overset{K_1}{\rightleftharpoons} [H_5Mn^{IV}Mo_9O_{32}] + H^+ \quad (1)$$

the plot of $\log k_{obs}$ against $\log[H^+]$ plot. The plot of k_{obs} against $[H^+]$ was also found to be linear (R^2 = 0.997) without any intercept indicating that only protonated form of the oxidant is the active species. Therefore, under the reaction conditions employed in the present study the hexaprotonated anion, $[MnMo_9O_{32}]^{6-}$, and the undissociated hypophosporous acid are the reactive species.

The rate of oxidation of phosphite ion under the experimental conditions was also examined in order to know its simultaneous oxidation by the oxidant, $[MnMo_9O_{32}]^{6-}$. The rate constant for the phosphite ion oxidation was found to be 1.2×10^{-4} s^{-1} which is approximately six times slower than that for the hypophosphite. Since the reaction was carried out under pseudo-first-order conditions keeping large excess of hypophosphite it was assumed that the contribution of the phosphite oxidation to the total rate constant is negligible. The color of the reaction mixture after 24 h during stoichiometric studies was light yellow and a blue color appears after 48 h. This appearance of blue color is due to the further reaction of the yellow product obtained after 24 h with excess reductant, hypophosphite. The blue color was not obtained when the reaction was carried out under second-order conditions which indicates that the excess hypophosphite during first-order conditions acts as a reductant. If another strong reductant like ascorbic acid or hydrazine sulfate was added to the light yellow reaction mixture the blue color appears immediately. This confirms that the light yellow product obtained undergo slow reduction with excess of hypophosphite or rapid reduction in presence of strong reductants. Spectrophotometric determination of phosphorous content is generally carried out by molybdenum blue method [21–23]. The basis for the analysis of phosphorous by this method involves initial formation of a yellow complex, phosphomolybdic acid, between phosphate and molybdate ions which then will be reduced by various reductants. This polyoxometalate is capable of undergoing reversible multivalent reduction forming reduced mixed-valence (Mo^V–Mo^{VI}) heteropolyblues. In the present investigation there was appearance of blue color in the reaction mixture containing excess of hypophosphite after 48 h. But, the stoichiometry of the reaction was found to be 1:1 in presence of excess of enneamolybdomanganate (IV) when analyzed after 24 h. Therefore, the hypophosphite ion is oxidized to phosphite ion with formation of a yellow phosphitomolybdate ion which then undergoes redox reaction with the available reductant to generate molybdenum blue. The mechanism up to the formation of yellow reaction product with the observed stoichiometry 1:1 can be represented as in Scheme 1 in terms of the active species of the reactants. The corresponding rate law according to Scheme 1 also considering protonation equilibria 1 of the oxidant is given by Eq. (6).

$$[H_6Mn^{IV}Mo_9O_{32}] + H_3PO_2 \overset{K_2}{\rightleftharpoons} \text{Complex} \quad (2)$$

$$\text{Complex} + 5H_2O \xrightarrow{k_1} [Mn^{II}Mo_6O_{24}]^{10-} + 3HMoO_4^- + H_3PO_3 + 13H^+ \quad (3)$$

$$[Mn^{II}Mo_6O_{24}]^{10-} \xrightarrow{\text{fast}} Mn^{2+} + 6MoO_4^{2-} \quad (4)$$

$$H_3PO_3 + 6MoO_4^{2-} + 10H^+ \xrightarrow{\text{fast}} [H_{10}(HP)Mo_6O_{26}]^{2-} + H_2O \quad (5)$$

Scheme 1.

The corresponding expression for observed pseudo-first-order rate constant can be represented by Eq. (7). According to Eq. (7) the plot of $1/k_{obs}$ against

$$\text{Rate} = \frac{k_1K_2[H_+][\ H_3PO_2][H_6Mn^{IV}Mo_9O_{32}]}{([H^+]+K_1)(1+K_2[H_3PO_2])} \quad (6)$$

$$k_{obs} = \frac{k_1K_2[H^+][\ H_3PO_2]}{([H^+]+K_1)(1+K_2[H_3PO_2])} \quad (7)$$

$1/[H_3PO_2]$ at four different temperatures were found to be linear with intercept (Fig. 3) and the formation constants of the complex as well as rate constant for its decomposition were calculated form such plots (Table 2). The plot of $1/k_{obs}$ against $1/[H^+]$ was also found to be linear with intercept (Fig. 5) and from the slope and intercept the dissociation constant of equilibria 1 was calculated as 1.71 mol dm^{-3}. Linearity of both Figs. 3 and 5 verify the rate law derived. The activation parameters for the slow step of the reaction were also determined and are given in Table 2. The inhibiting effect of added molybdate ion is due to the formation of a molybdate complex of hypophosphite thus decreasing the free hypophosphite ion concentration in the solution. The involvement of molybdate ion in reversible equilibria of the mechanism was ruled out as the pseudo-first-order plots were linear up to 80% of the reaction without any deviation.

The mechanism according to Scheme 1 proceeds with the formation of a complex between the hypophosphite and $[H_6Mn^{IV}Mo_9O_{32}]$ in a prior equilibria which then decomposes to give phosphite and $[Mn^{II}Mo_6O_{24}]^{10-}$ in a rate determining step. The interaction between hypophosphite and $[H_6MnMo_9O_{32}]$ during complex formation occurs through the oxygen atoms of the site B as evidenced by the increase in the absorbance of the peak at 504 nm (Fig. 1). The reduced polyoxometalate, $[Mn^{II}Mo_6O_{24}]^{10-}$, undergo fast decomposition to generate aqueous Mn^{2+} ion and molybdate ions. In an earlier ESR study the interaction between aqueous Mn^{2+} and molybdate ions was examined and the alteration of linewidth of the Mn^{2+} signal in presence of molybdate [39] was found to be comparable with that in presence of acetate ions. From this result it has been concluded that the interaction between molybdate ions and Mn^{2+} ions in aqueous solutions is weak one. Therefore, the dissociation of the $[Mn^{II}Mo_6O_{24}]^{10-}$ under the present reaction conditions is considered to be fast. In the next step the molybdate ions combine with phosphite ion to form a phosphitomolybdate ion again in a fast step. An equilibrium analysis of phosphite and molybdate ions in acidic solutions by potentiometry and ^{31}PNMR studies has been recently reported [40]. According to the study between pH 1 and 2 formation of $[H_{10}(HP)Mo_6O_{26}]^{2-}$ is most probable with a high formation constant ($\log\beta = 68.99$) therefore, in the present study Eq. (5) of Scheme 1 is also considered as a fast step. The blue product of the reaction after 48 h was also analysed by AAS and the molar ratio of P:Mo was found to be 1:6 without any Mn^{2+} further confirming the $[H_{10}(HP)Mo_6O_{26}]^{2-}$ ion formation under the reaction conditions. The FTIR spectra of the $(NH_4)_6[MnMo_9O_{32}]$, phosphite ion and the blue product were also examined to know the structure of the product formed and the assignment of various vibrational frequencies are given Table 4. The data of Table 4 for $(NH_4)_6[MnMo_9O_{32}]$ shows characteristic peaks for the lattice water, NH_3 groups and corresponding peaks due to Mo–O stretching, Mn^{IV}–O stretching and MoO_4^{2-} groups, respectively. The peak due to Mn^{IV}–O stretching is absent in the blue product obtained where as the peaks corresponding to Mo–O stretching and MoO_4^{2-} groups have been shifted slightly due to the change in their electronic environment. A new peak at 804 cm^{-1} in the blue product might be ascribed to $Mo^VO_4^{3-}$ groups generated due to the reduction of the yellow product after long standing. The reported frequencies [35] of aqueous phosphite ion

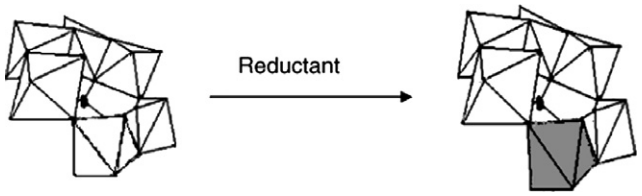

Fig. 6. Conversion of yellow product (from Ref. [39]) into blue product. (The shaded part in the figure represents the reduced Mo^{V}.)

due to PH stretching, PO_3 degenerate deformation and PH deformation are shifted in the blue product considerably as a result of its interaction with the molybdate ion to form phosphitomolybdate. The AAS analysis of the blue product also did not show the presence of Mn^{2+} and the molar ratio of P:Mo was found to be 1:6. On the basis of the FTIR and AAS results obtained the structure of the yellow product can be as that proposed earlier [40] which in presence of a reducing agent will be converted in to the blue product. The conversion of yellow product into the blue product can be shown as in Fig. 6. Acrylonitrile, free radical scavenger, did not affect the reaction rate indicate direct two-electron transfer from P^{I} to $[Mn^{IV}Mo_9O_{32}]^{6-}$. The effect of ionic strength and the solvent polarity on the rate qualitatively explains the reaction involves an uncharged species, as shown in Eq. (2) of Scheme 1. The moderate values of $\Delta H^{\#}$ and $\Delta S^{\#}$ were both favourable [41] for electron transfer processes. The negative value of $\Delta S^{\#}$, can be ascribed to the nature of electron pairing and unpairing processes and to the loss of degrees of freedom formerly available to the reactants upon the formation of transition state.

4. Conclusions

The reaction between hypophosphite and enneamolybdomanganate (IV) in perchloric acid was carried out under pseudo-first-order conditions keeping large excess of hypophosphite. The hexaprotonated oxidant and undissociated hypophosphite were found to be reactive species under the reaction conditions. The reaction proceeds with formation of complex between the active forms of the reactants supported by both kinetically and spectrophotometrically. The enneamolybdomanganate (IV) ion dissociates completely after its reduction to $[Mn^{II}Mo_6O_{24}]^{10-}$ in presence of phosphite ions forming $[H_{10}(HP)Mo_6O_{26}]^{2-}$. Comparatively higher stability of $[H_{10}(HP)Mo_6O_{26}]^{2-}$ than that of $[Mn^{II}Mo_6O_{24}]^{10-}$ ion under the reaction conditions makes the product formation feasible. The free radical intervention was not detected in the reaction as the added acrylonitrile did not affect the rate of the reaction. A mechanism involving complex formation and its decomposition in a rate determining two-electron transfer step is proposed. The effect of ionic strength, solvent polarity and the activation parameters were in support of the mechanism proposed.

2.4. GC–MS analysis

GC analyses were carried out using a Varian 3900 gas chromatograph equipped with an FID and a 30 m × 0.32 mm CP-Wax 52 CB column (0.25 μm film thickness). The carrier gas was helium at 5.0 psi. The oven was programmed to hold at 32 °C for 4 min and then to ramp to 200 °C at 10°/min and hold 5 min. GC–MS analyses for peak identification were performed using an Agilent 5973 gas chromatograph equipped with MSD and a 60 m × 0.25 mm Rtx-1 column (0.5 μm film thickness). The carrier gas was helium at 0.9 ml/min. The oven was programmed to hold at 50 °C for 2 min and then ramp to 250 °C at 10°/min and hold for 8 min.

2.5. Infrared spectroscopy

Infrared spectra were recorded on a Perkin–Elmer Spectrum One FT-IR spectrometer.

2.6. Materials

$Ru_3(CO)_{12}$ (**1**), $Os_3(CO)_{12}$, $Re_2(CO)_{10}$, $Co_2(CO)_8$, $Mo(CO)_6$, and $W(CO)_6$ were purchased from Aldrich and used without further purification. $PPh_2CH_2CH_2CH_2CH{=}CH_2$ [17] was prepared as previously described. The solvents were commercially available and distilled from dark purple solutions of sodium/benzophenone ketyl. ^1H and ^{31}P NMR spectra were recorded on a Bruker DMX-400 spectrometer and all ^1H chemical shifts are reported relative to the residual proton resonance in the deuterated solvents. The compounds **3**–**6** were prepared by the reported literature procedures [18,19].

2.6.1. $Ru_3(CO)_{11}[PPh_2(CH_2CH_2CH{=}CHCH_3)]$ (**2**)

In a Schlenk flask, $PPh_2CH_2CH_2CH_2CH{=}CH_2$ (248 mg, 0.975 mmol) was added to $Ru_3(CO)_{12}$ (750 mg, 1.173 mmol) in 50 ml acetonitrile. Slowly, the colour of the solution changed to intense red. The solution was heated 80 °C for 72 h under constant stirring to yield **2** as a product and the reaction was monitored by ^{31}P NMR. The product was isolated by using preparative TLC using dichloromethane as eluent. The major red band was extracted using dichloromethane. After removing the solvent, the product was dried under high vacuum for 6 h to give red crystals of **2**; m.p. 156–158 °C (with decomposition); yield 47%; ^1H NMR δ 7.28–7.46 (m, 10H, Ph); 5.34–5.39 (m, 2H, =CH); 2.41–2.54 (m, 2H, P–CH_2); 1.81–1.99 (m, 2H, CH_2); 2.17 (s, 3H, CH_3); $^{31}P\{^1H\}$ 26.70 (s) and 27.36 (s); *Anal.* Calc. for $C_{28}H_{19}O_{11}PRu_3$: C, 38.85; H, 2.21. Found: C, 38.69; H, 2.32%. IR data in CH_2Cl_2: ν (cm^{-1}) 2060 (s), 2045 (s), 2028 (broad), 2012 (broad), 1966 (broad). $Ru_3(CO)_9[PPh_2CH_2\text{-}CH_2CH{=}CHCH_3]_3$ was also isolated as a secondary product (12%) from the orange yellow band on preparative TLC. *Anal.* Calc. for $C_{60}H_{57}O_9P_3Ru_3$: C, 54.67; H, 4.36. Found: C, 55.04; H, 4.21%.

Table 1
Various substrates tested for the isomerization with $Ru_3(CO)_{12}$

Substrate	Experimental conditions	Product	% Conversion (a mixture of *cis* and *trans* isomers)[a]
1-Pentene	3 h, 80 °C	2-pentene	100
1-Hexene	3 h, 80 °C	2-hexene	100
1-Heptene	3 h, 80 °C	2-heptene	100
1-Octene	3 h, 80 °C	2-octene	100
1-Decene	3 h, 80 °C	2-decene	100
5-Bromo-1-pentene	10 d, 80 °C	5-bromo-2-pentene	84

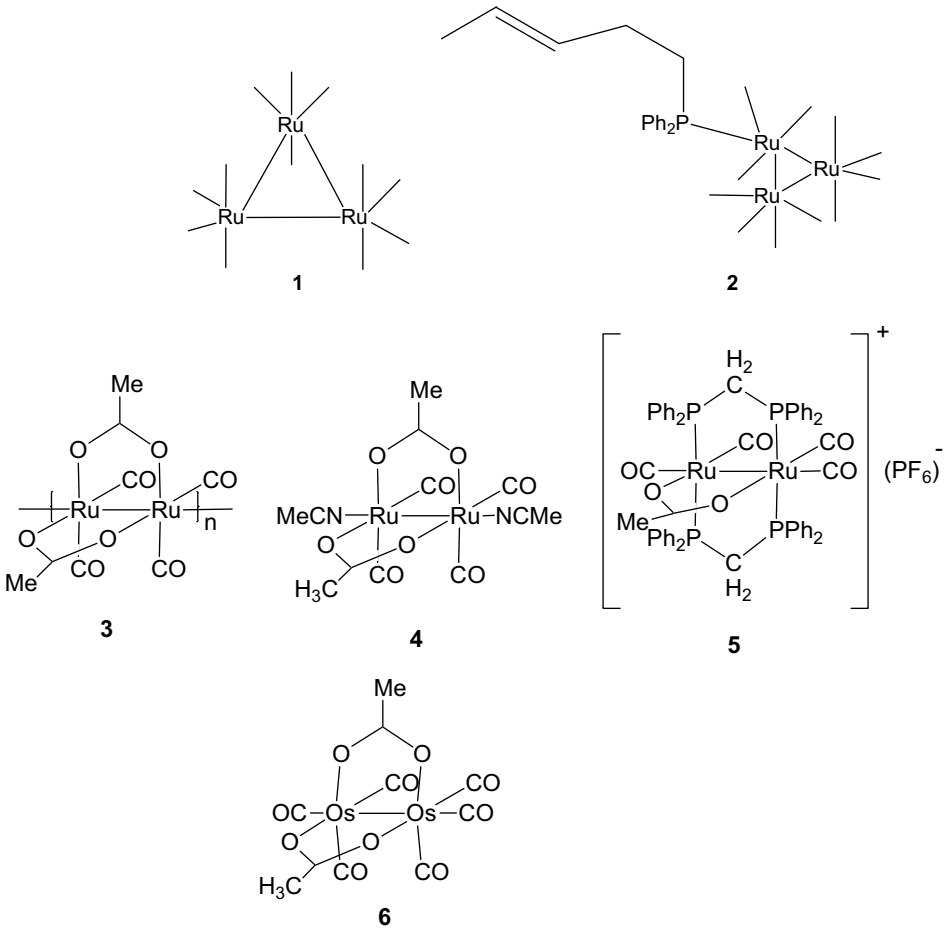
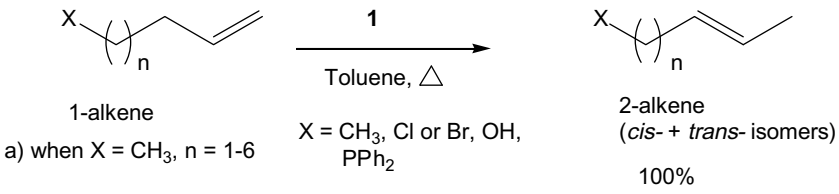
2.6.2. General procedure for 1-alkene isomerization reactions

All the isomerization reactions were carried out in sealed John-Young NMR tubes (Aldrich). The reaction mixture containing solvent, catalyst and olefin was cooled, evacuated and heated in an oil bath thermostated at the prescribed temperature (±1 °C). The reaction progress was monitored by ^1H NMR and then the products analyzed by GC and GC–MS to identify and quantify the final organic products. The results of these catalytic experiments are reported in Tables 1 and 2.

3. Results and discussion

$Ru_3(CO)_{12}$ (**1**), $Ru_3(CO)_{11}L$ [L = (2-pentenyl)diphenylphosphine] (**2**), $[Ru(CO)_2(MeCO_2)_2]_n$ (**3**), $[Ru_2(CO)_4(\mu\text{-}MeCO_2)_2(CH_3CN)_2]$ (**4**), $[Ru_2(CO)_4(\mu\text{-}MeCO_2)(\mu\text{-dppm})_2][PF_6]$ (**5**) [where dppm = bis(diphenylphosphino)methane], $[Os_2(CO)_6(\mu\text{-}MeCO_2)_2]$ (**6**), $Os_3(CO)_{12}$, $Re_2(CO)_{10}$, $Co_2(CO)_8$, $Mo(CO)_6$, and $W(CO)_6$ were all tested as homogeneous catalysts for the 1-alkene isomerization reactions (see Tables 1 and 2). Complexes **1** and **2** are catalytically active for olefin isomerization in a broad range of solvents (see below) and at temperatures above 60 °C. Our attempts to carry out the isomerization reaction of (1-pentenyl)diphenylphosphine with **1** on heating in order to examine the effect of the bulky phosphine group on the alkenyl chain, yielded **2** ($Ru_3(CO)_{11}L$) (Chart 1). Compound **2** was obtained as an intense red solid in good yield after the reaction of $Ru_3(CO)_{12}$with (1-pentenyl)diphenylphosphine [17] [L] as ligand in a molar ratio of 1:1. It was recrystallized from CH_2Cl_2/diethylether and was characterized spectroscopically and analytically. The studies with the phosphine derivative $Ru_3(CO)_{11}L$ (**2**) were carried out in order to explore the influence of this functionalized phosphine ligand on the catalytic activity in the isomerization reactions. The other compounds (**3**–**5**) were synthesized from $Ru_3(CO)_{12}$ (**1**) using literature procedures [19] to explore the catalytic activity towards 1-alkene isomerization reactions. In a similar way, compound **6** was obtained from the reaction of acetic acid with $Os_3(CO)_{12}$ [20]. Various 1-alkenes were tested for the isomerization reactions to give their corresponding 2-alkenes as shown in Eq. (1). In a similar way, the isomerization of 1,5-hexadiene yielded 2,4-hexadiene quantitatively (Eq. (2)).





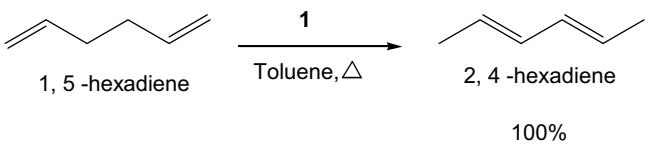


Chart 1. Catalysts used in olefin isomerization reactions.

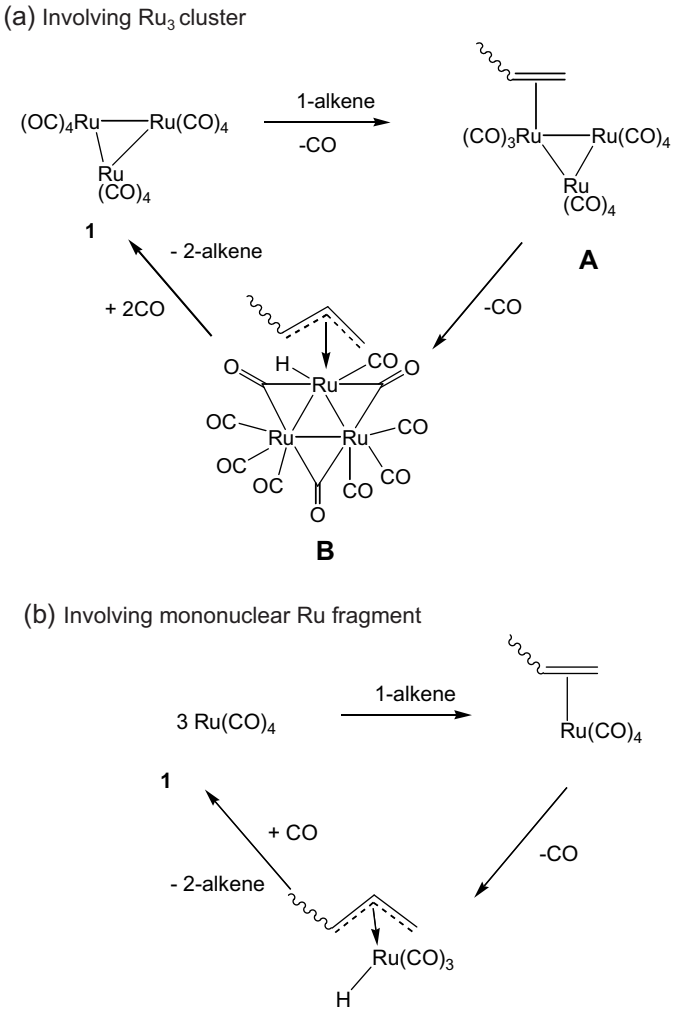
polymeric compound **3** is decreased considerably relative to **4**, which might be due to the insoluble nature of the compound in

(1)

(2)

Although we find that many mononuclear, binuclear and trinuclear metal carbonyl compounds can, in fact, isomerize olefins, significant differences in the activity of the various complexes are formed (see Table 2): $W(CO)_6$ and **6** are mainly inactive in isomerization reactions of aliphatic alkenes and dienes. In case of $Re_2(CO)_{10}$, the catalytic activity was extremely low. The activity of **5** was decreased relative to **4** due to the steric as well as chelating nature of diphosphine ligands. The catalytic activity of the aromatic solvents. In contrast, the compound **4**, which was derived from **3** by reaction with acetonitrile, catalyzes the isomerization of 1-pentene to 2-pentene quantitatively. The other metal carbonyl compounds such as $Os_3(CO)_{12}$, $Mo(CO)_6$ and $Co_2(CO)_8$ showed significant activity under similar experimental conditions. $Ru_3(CO)_{12}$ however showed the best results (the turnover number for $Ru_3(CO)_{12}$ was found to be 10000 h^{-1}) among the other catalysts, while the activity is quite dependent on the nature of the metal at 80 °C. The rate of the isomerization reaction decreases along the series: $Ru_3(CO)_{12} > Os_3(CO)_{12} > Mo(CO)_6 > Re_2(CO)_{10} > W(CO)_6$ (see Table 2). It was also found that the di-ruthenium compounds $L_2PtRu_2(CO)_8$ [20] and $[Cp^*Ru(CO)_2]_2$ were inactive towards the olefin isomerization reactions, which could be due to the steric, and electronic properties of these compounds. At high temperatures, the isomerization of 1-alkenes to their internal alkenes is



feasible with the other metal carbonyl compounds but the catalyst recovery is difficult. In all of these isomerizations of 1-olefins, the *trans*-2-olefin is the major product. Tables 1 and 2 summarize the results of the isomerization of aliphatic olefins. We find that the order of activity of the various catalysts we tested is as follows: $Ru_3(CO)_{12} > Ru_3(CO)_{11}L > Co_2(CO)_8 > Os_3(CO)_{12} > Mo(CO)_6 \gg Re_2(CO)_{10} \gg W(CO)_6$.

3.1. Mechanistic pathways

We have carried out a number of experiments to try and shed light on the mechanism of these isomerization reactions. Thus, we have carried out IR and NMR spectral studies of the reaction of $Ru_3(CO)_{12}$ with 1-octene in $CDCl_3$. We have made attempts using ^1H NMR to observe an η^3-allyl ruthenium hydride intermediate **B** in Scheme 1a, which is an established mechanism for other metal complexes [10,16]. However, these attempts were unsuccessful. We also used IR to obtain new information thus after heating the reaction mixture for 20 min at 80 °C, the reaction mixture was cooled and the IR spectrum was recorded [bands were now seen at 2100 (vw), 2061 (vs), 2028 (vs), 1985 (vw), 1825 (m), 1795 (m), 1652 (vs) cm^{-1}] (Fig. 1). Thus, new bands are seen which are not present in $Ru_3(CO)_{12}$ [the bands of $Ru_3(CO)_{12}$ are: ν(CO) 2061 (vs), 2028 (vs) and 1985 (vw) cm^{-1}]. Most striking bands are at 1825 (m) and 1795 (m) which could be due to bridging carbonyls of a ruthenium intermediate such as **B** in Scheme 1a.

A key step in the alkene isomerization reaction could be the dissociation of a CO ligand and olefin coordination to give the intermediate species **A**. That CO dissociation occurs during the isomerization reaction was supported by the observation that 1-alkene isomerization is inhibited when the reaction was carried out under a CO atmosphere. The oxidative addition of a C–H bond to the metal centre could lead to the formation of η^3-allyl metal hydride complex **B** which then decomposes to give the 2-alkene product and **1** as shown in Scheme 1. An alternative mechanism could involve mononuclear ruthenium species as shown in Scheme 1b. Both the mechanisms could be expected to be inhibited by CO, as is found.

We could not detect any ruthenium hydride species in the ^1H NMR spectra of the reaction mixtures even at temperatures up to 90 °C in $CD_3C_6D_5$. After heating at 80 °C for 3 h, the reaction was complete as the IR showed the disappearance of the new bands of the intermediate and indicated that the trinuclear ruthenium catalyst is restored (see Fig. 1). The GC analyses of the solution at the end of reaction showed mainly, the presence of *cis*-oct-2-ene (14%) and *trans*-oct-2-ene (86%). As the isomerization activity is high at high temperatures (>120 °C), there is a significant increase in the formation of oct-3-ene (>5%). The reactions of olefins in the presence of other catalysts showed similar trends in the isomerization reactions and analogous behaviour was noticed with **2**, which could go via a similar mechanism. These suggestions are also in agreement with previous studies reported where $Fe_3(CO)_{12}$ was used as catalyst [12].

Scheme 1. Two possible reaction mechanisms for the catalytic 1-alkene isomerization. (a) Involving Ru_3 cluster. (b) Involving mononuclear Ru fragment.

4. Factors affecting the isomerization reaction

4.1. Solvent effects

The factors influencing the rate of the alkene isomerization reactions are the solvent system, temperature, remote substituent on the alkene, and nature of catalyst used. The polarity of the solvent using either methanol or hexane did not affect the isomerization reaction. However, catalyst recovery was not possible when halogenated solvents were used as these solvents make the catalyst inactive. In the other solvent systems, the catalyst recovery was more than 60% in case of $Ru_3(CO)_{12}$. The absence of solvent increased the rate of reaction significantly, for example the isomerization of 1-octene to 2-octene occurred quantitatively within 60 s at 80 °C, in the presence of $Ru_3(CO)_{12}$. It was also found that these reactions do not involve heterogeneous catalysts as the dilute solutions (where catalytic amount of catalysts used) also perform the isomerization reaction in a similar way to concentrated solutions.

4.2. Effect of temperature

A series of experiments on the alkene isomerization reactions, using $Ru_3(CO)_{12}$, as a function of temperature were carried out. The ideal temperature range was found to be 80–100 °C. When the temperature was >120 °C, the catalyst recovery was not possible even though the rate of reaction was increased dramatically. With compound **2**, the recovery of the catalyst was not successful. It was observed however that this monosubstituted phosphine derivative at high temperatures was converted to the stable tris(phosphine) derivative, i.e. $Ru_3(CO)_9(PPh_2R)_3$. Also at high temperatures (>150 °C), the formation of traces of 3-alkenes is observed with the longer alkenyl chain, i.e. $\geqslant C_7$.

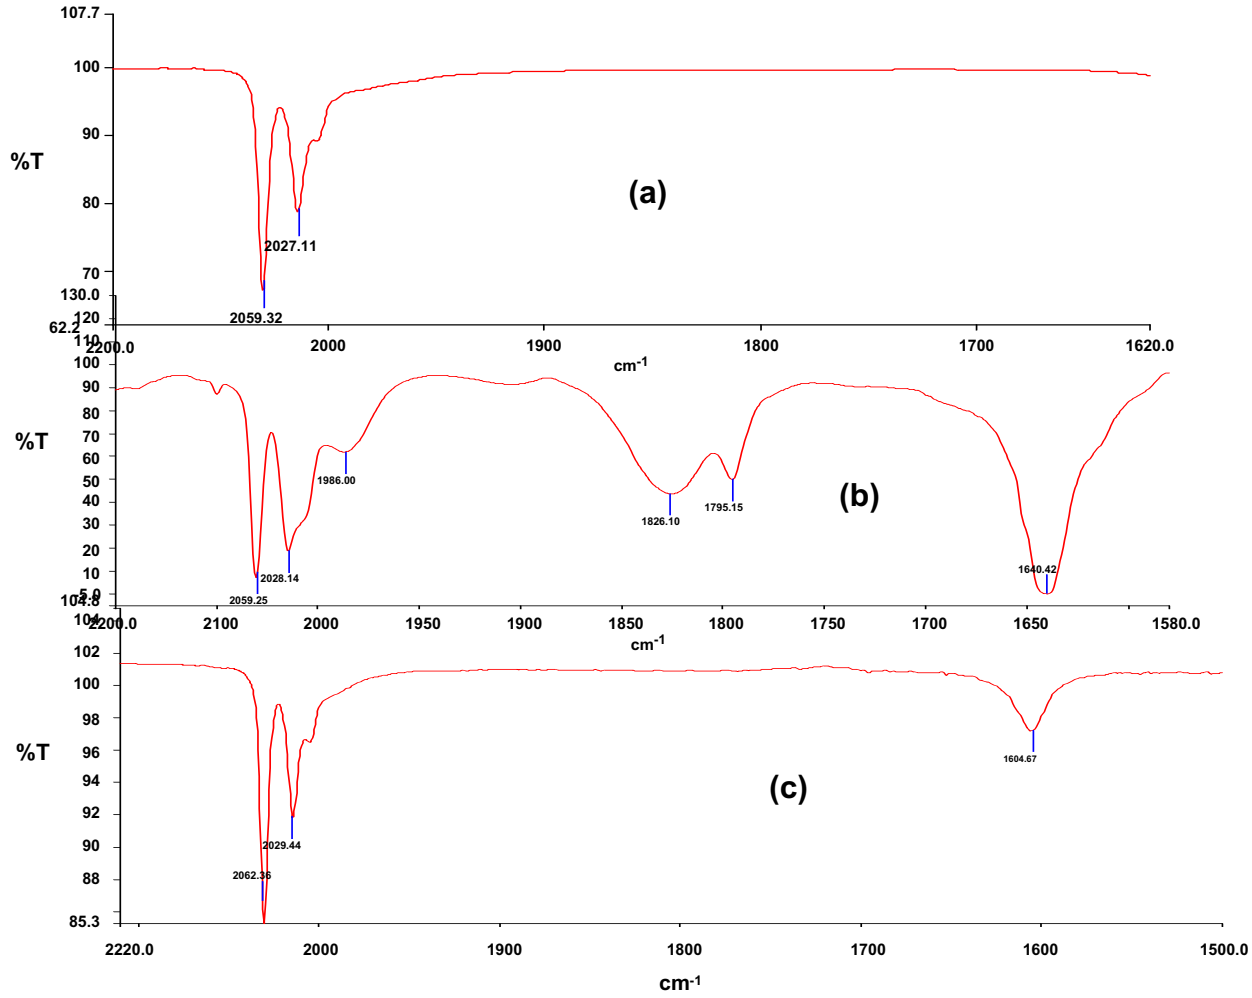


Fig. 1. IR spectra showing the intermediate formed during the olefin isomerization (spectra recorded in $CHCl_3$). (a) $Ru_3(CO)_{12}$. (b) The reaction mixture; after heating with 1-pentene for 20 min at 80 °C. (c) After the complete isomerization reaction after 3 h at 80 °C.

4.3. Substituent effect

Substituents on the alkenyl chains show a significant effect on the isomerization reaction (see Table 1). When X = Cl, Br, the rate of reaction decreases drastically and the formation of different isomeric species was also observed. This could be due to the electron withdrawing effect of the halogens in the alkenyl chain and competing reactions of catalysts with the haloalkenes. Mass spectral studies of the reaction of **1** with 6-chloro-1-hexene indicated the formation of $[Ru(CO)_3Cl]_2$ as one of the products. The presence of hydroxyl groups (X = OH or $(OH)_2$) did not have any significant effect on the isomerization (Eq. (1)). When X = PPh_2, the rate of reaction decreased sharply, which may be due to the steric bulk of the phosphine as well as the phosphine coordinating to the metal and positioning the alkenyl chain away from the cluster. However, on long heating at 80 °C, in acetonitrile for 72 h the corresponding complex **2** was formed. The ^{31}P NMR spectrum showed two singlets close together at δ 26.70 and 27.36 for this compound which could be due to the presence of possible alkene isomers of the compound.

4.4. Effect of catalyst

While $Ru_3(CO)_{12}$ was found to be the most active catalyst (see Table 2), some mononuclear carbonyls, notably $Mo(CO)_6$, were also found to be active. This may suggest that the first step in the mechanistic pathway can be CO loss (as for $Mo(CO)_6$ or $Ru_3(CO)_{12}$). It is also possible that both pathways involving either CO loss or metal–metal bond cleavage could operate for the cluster compounds (see Scheme 1a and b).

4.5. Addition of excess ligands

As expected, the addition of excess ligands such as (diphenylphosphino)methane (dppm) or acetonitrile to the reaction mixture ($Ru_3(CO)_{12}$ and 1-pentene in toulene) resulted in a dramatic decrease in isomerization activity. There was no isomerization observed in the presence of excess of dppm ligand even after the long heating at 80 °C. This is probably due to the phosphine ligand blocking the coordinating sites at ruthenium. Similarly, the isomerization was also retarded when the experiment was carried out under an atmosphere of CO. This suggests that the dissociation of CO from the metal carbonyls is a key step in these catalytic reactions.

5. Conclusions

Some ruthenium carbonyl cluster complexes are efficient and selective catalysts for the isomerization of 1-alkenes to their corresponding 2-alkenes under the mild conditions. The turnover number for the $Ru_3(CO)_{12}$ was found to be 10000 h^{-1} and possible mechanistic pathways for these isomerization reactions are discussed. Other metal carbonyl compounds also show some activity for this reaction.

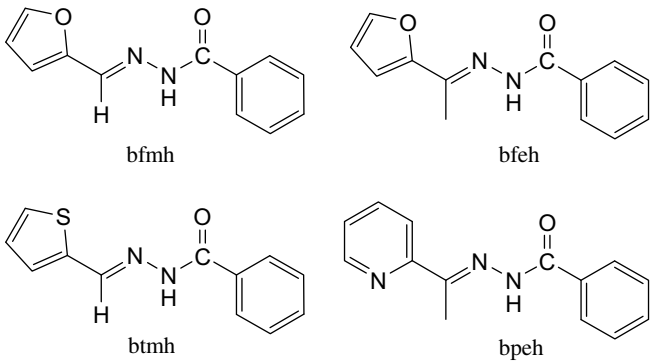

Chart 1. Structure of the hydrazone ligands.

double-distilled water and its pH was adjusted to 7.1 using 0.1 M NaOH solution. DNA stock solutions were freshly prepared before use with this buffer solution. Ethanol was purified following standard procedures for the preparation of the ligands and complexes. Distilled dmso was used for the preparation of the starting complex and for the preparation of solutions of complexes for DNA-binding studies. Purified dry methanol was used to record the electronic spectra of the complexes. Commercially available TBAP was properly dried and used as a supporting electrolyte for recording cyclic voltammograms of the complexes (except for DNA-binding studies). The starting complexes [9], *cis*-[$RuCl_2(dmso)_4$] (**Ru1**), *trans*(Cl)–[$RuCl_2(dmso)_2(bpy)$] (**Ru2**) and the ligands [10] were prepared according to the literature procedures.

2.2. Physical measurements

FT-IR spectra (4000–400 cm^{-1}) of the complexes and the free ligands were recorded as KBr pellets with a Nicolet Avatar Model FT-IR spectrophotometer. Electronic spectra (800–250 nm) of the complexes were obtained on a Systronics 119 UV–Vis spectrophotometer. ^1H NMR spectra were recorded on a Varian-Australia AMX-400. The absorption titrations were carried out with a JASCO spectrophotometer. Micro analyses (C, H, N and S) were performed on a Vario EL III Elementar analyzer. Cyclic voltammograms were recorded on a CHI 1120A electrochemical analyzer with a three electrode compartment consisting of a platinum disc working electrode, a platinum wire counter electrode and an Ag/Ag^+ reference electrode.

2.3. Synthesis

2.3.1. [$RuCl_2(dmso)_2(bfmh)$] (**1**)

Cis-[$RuCl_2(dmso)_4$] (0.21 mmol) and the ligand bfmh (0.21 mmol) were heated under reflux in ethanol for 6–8 h. Slow evaporation of the solvent after reduction to 50% gave crystals suitable for single crystal XRD studies. Yield, 70 mg, 61%. Elemental *Anal.* Calc. for $C_{16}H_{22}N_2S_2O_4Cl_2Ru$ (542.464): C, 35.42; H, 4.08; N, 5.16; S, 11.82. Found: C, 35.26; H, 4.12; N, 5.24; S, 11.37%. IR (KBr, cm^{-1}): ν(NH), 3112(w); ν(C=O), 1639(s); (νC=N), 1598(m) (s, strong; m, medium; w, weak). UV–Vis (dmso) λ, nm (ε, $mol^{-1}\,cm^{-1}\,L$): 308 (14900), 359 (3950). ^1H NMR (dmso-d_6, δ ppm): 3.2–3.5 (group of peaks, dmso protons, 12H), 8.1 (s, H–C=N, 1H), 7.5–8.1 (multiplet, aromatic protons, 8H), 9.2 (s, –NH, 1H).

2.3.2. [$RuCl_2(dmso)_2(bfmh)] \cdot 0.5C_2H_5OH$ (**1a**)

trans(Cl)–[$RuCl_2(dmso)_2(bpy)$] (0.21 mmol) and the ligand bfmh (0.21 mmol) were heated under reflux in ethanol for 6–8 h. Slow evaporation of the solvent after reduction to 50% gave crystals suitable for single crystal XRD studies. Yield, 69 mg, 58%. Elemental *Anal.* Calc. for $C_{17}H_{25}N_2S_2O_{4.5}Cl_2Ru$ (565.494): C, 36.10; H, 4.45; N, 4.95; S, 11.34. Found: C, 35.92; H, 4.33; N, 4.71; S, 11.27%. IR (KBr, cm^{-1}): ν(NH), 3110(w); ν(C=O), 1639(s); (νC=N), 1598(m).

2.3.3. [$RuCl_2(dmso)_2(btmh)$] (**2**)

Cis-[$RuCl_2(dmso)_4$] (0.21 mmol) and the ligand btmh (0.21 mmol) were heated under reflux in ethanol for 6–8 h. Slow evaporation of the solvent after reduction to 50% gave orange crystals suitable for single crystal XRD studies. Yield, 75 mg, 64%. Elemental *Anal.* Calc. for $C_{16}H_{22}N_2S_3O_3Cl_2Ru$ (558.531): C, 34.40; H, 3.97; N, 5.01; S, 17.22. Found: C, 34.28; H, 3.87; N, 5.32; S, 17.37%. IR (KBr, cm^{-1}): ν(NH), 3080(w); ν(C=O), 1620(s); ν(C=N), 1592(m). UV–Vis (dmso) λ, nm (ε, $mol^{-1}\,cm^{-1}\,L$): 254 (25320), 313 (19320), 392 (5480). ^1H NMR (dmso-d_6, δ ppm): 3.2–3.5 (group of peaks, dmso, 12H), 7.9 (s, H–C=N, 1H), 7.4–8.5 (multiplet, aromatic protons, 8H), 9.4 (s, –NH, 1H). The same reaction when carried out with *trans*(Cl)–[$RuCl_2(dmso)_2(bpy)$] yielded a crystalline product (**2a**) which conformed to the analytical and IR data of **2** but was not structurally characterized.

2.3.4. [$RuCl_2(dmso)_2(bfeh)$] (**3**)

Cis-[$RuCl_2(dmso)_4$] (0.21 mmol) and the ligand bfeh (0.21 mmol) were heated under reflux in ethanol for 6–8 h. Slow evaporation of the solvent gave only an amorphous powder which was recrystallised from hot dmso. Yield, 69 mg, 59%. Elemental *Anal.* Calc. for $C_{17}H_{24}N_2S_2O_4Cl_2Ru$ (556.491): C, 36.69; H, 4.34; N, 5.03; S, 11.52. Found: C, 36.28; H, 4.02; N, 5.39; S, 11.11%. IR (KBr, cm^{-1}): ν(NH), 3073(w); ν(C=O), 1650(s); ν(C=N), 1593(m). UV–Vis (dmso) λ, nm (ε, $mol^{-1}\,cm^{-1}\,L$): 288 (9780), 354 (2620). ^1H NMR (dmso-d_6, δ ppm): 3.1–3.4 (group of peaks, dmso, 12H), 2.2 (s, $-CH_3$, 3H), 7.2–8.2 (multiplet, aromatic protons, 8H), 9.4 (s, –NH, 1H). The same reaction when carried out with *trans*(Cl)–[$RuCl_2(dmso)_2(bpy)$] yielded an amorphous product (**3a**) which conformed to the analytical and IR data of **3**.

2.3.5. [$RuCl_2(dmso)_2(bpeh)$] (**4**)

Cis-[$RuCl_2(dmso)_4$] (0.21 mmol) and the ligand bpeh (0.21 mmol) were heated under reflux in ethanol for 6–8 h. Slow evaporation of the solvent gave only an amorphous powder which was recrystallised from hot dmso. Yield, 82 mg, 69%. Elemental *Anal.* Calc. for $C_{18}H_{25}N_3S_2O_3Cl_2Ru$ (567.518): C, 38.09; H, 4.40; N, 7.40; S, 11.30. Found: C, 38.44; H, 4.32; N, 7.12; S, 11.47%. IR (KBr, cm^{-1}): ν(NH), 3056(w); ν(C=O), 1689(s); ν(C=N), 1598(m). UV–Vis (dmso) λ, nm (ε, $mol^{-1}\,cm^{-1}\,L$): 275 (7540), 304 (5700). ^1H NMR (dmso-d_6, δ ppm): 3.1–3.4 (group of peaks, dmso, 12H), 2.2 (s, $-CH_3$, 3H), 7.3–8.3 (multiplet, aromatic protons, 9H), 9.4 (s, –NH, 1H). The same reaction when carried out with *trans*(Cl)–[$RuCl_2(dmso)_2(bpy)$] yielded an amorphous product (**4a**) which conformed to the analytical and IR data of **4**.

2.4. Crystallographic structure determination

Single crystal X-ray diffraction measurements were performed on a Nonius Kappa CCD (with Oxford Cryostream) diffractometer with graphite monochromatized Mo Kα radiation. The structures of **1** and **2** were solved by direct methods and refinements were carried out by full-matrix least-square techniques. The hydrogen atoms were treated by a mixture of independent and constrained refinement. The following computer programs were used: structure solution SIR-97 [11], refinement SHELXL-97 [12], molecular diagrams ORTEP-3 [13] for windows.

2.5. Anti-microbial screening

The bacterial strains, *Escherichia coli* NCIM 2831, *Staphylococcus aureus* NCIM 2492, *Staphylococcus epidermidis* NCIM 2493,

Klebsiella pneumoniae NCIM 5082 and *Shigella sonnei* MTCC 2957 were used in the study. The agar-well diffusion method [14] was employed for the determination of anti-microbial activities. MICs (minimum inhibitory concentration) of the compounds against test organisms were determined by the broth micro dilution method. All the tests were performed in duplicate and repeated twice. Modal values were selected.

2.5.1. Agar-well diffusion method

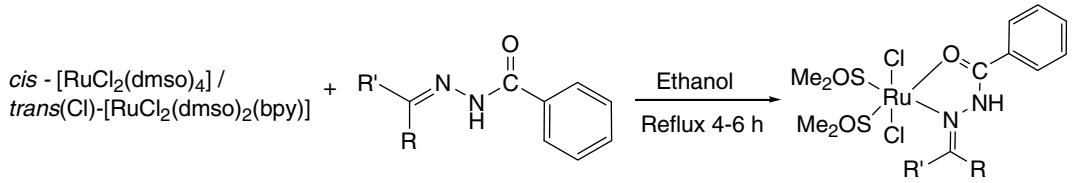
The compounds were weighed and dissolved in dimethyl sulfoxide (dmso), then the solutions were filter sterilized using a 0.45 μm membrane filter. Each microorganism was suspended in sterile saline and diluted at *ca.* 106 colony forming units (cfu/ml). They were flood inoculated onto the surface of Mueller–Hinton Agar (MHA). The wells (8 mm in diameter) were cut from the agar and 0.1 mL of solution was delivered into them. After incubation for 24 h at 37 °C, all the plates were examined for any zones of growth inhibition, and the diameter of these zones were measured in millimeters.

2.5.2. Determination of minimum inhibitory concentration (MIC)

A broth microdilution susceptibility assay was used as recommended [15] by NCCLS for determination of the MIC. All the tests were performed in Mueller–Hinton Broth (MHB) supplemented with Tween 80 detergent (final concentration 0.5% (v/v)). Bacterial strains were cultured overnight at 37 °C in MHA. Test strains were suspended in MHB to give a final density of 5×105 cfu/ml and these were confirmed by viable counts. Geometric dilutions of the compounds were prepared in a 96-well microtiter plate, including one growth control (MHB + Tween 80) and one sterility control (MHB + Tween 80 + compound). The plates were incubated under normal atmospheric conditions at 37 °C for 24 h. The MIC of kanamycin and oxytetracycline were individually determined in parallel experiments in order to control the sensitivity of the test organisms. The bacterial growth was indicated by the presence of a white "pellet" on the well bottom.

3. Results and discussion

The reactions of either **Ru1** or **Ru2** with the hydrazone ligands in a 1:1 mol ratio in ethanol has yielded complexes of the type $[RuCl_2(dmso)_2(L)]$ (L = hydrazone ligand), as illustrated in Scheme 1. All the complexes are stable to air and light, and are soluble in organic solvents such as dmso, dmf and dichloromethane. The hydrazone ligands act as neutral bidentate donors replacing two dmso ligands from **Ru1**. In the precursor **Ru2**, there is a bipyridine chelate and two S-bonded dmso ligands in the equatorial plane. Although the chelate effect should hinder the replacement of the bpy ligand from **Ru2**, the two mutually *cis* S-bonded dmso ligands that are capable of accepting π-back donated electrons from the metal, along with the larger trans influence, weakens the metal-N bonds, facilitating the replacement of the chelate [16].



3.1. IR and electronic spectra

The IR spectra of the free ligands and the new Ru(II) complexes were compared in order to ascertain the probable mode of coordination of the ligands. Vibration bands of primary importance of the free ligands were observed around 3250, 1650, 1600–1620 and 1080 cm^{-1} for ν(NH), ν(CO), ν(CN) and ν(NN) respectively. The presence of the ν(NH) band confirms that the free ligands are in the keto form. The IR spectra of the complex pairs **1** and **1a**, **2** and **2a**, **3** and **3a**, and **4** and **4a** were identical, suggesting the formation of the same complexes when the ligands are treated with either **Ru1** or **Ru2**. None of the complexes obtained from **Ru2** displayed a pyridine ring breathing band around 995 cm^{-1}, which implies the replacement of bpy from **Ru2** by the ligands. This directed us to formulate the complexes in general as $[RuCl_2(dmso)_2(L)]$(L = bfmh, bfeh, btmh or bpeh). In all of the complexes, the observed significant decrement of ν(CO) and ν(CN) does evidence the neutral bidentate nature of the ligands. Being so, the ligands have two possibilities for chelation with the metal, either replacing two S-bonded dmso ligands or one S-bonded and one O-bonded dmso ligand when treated with **Ru1**. Scrutinizing the IR spectra of the precursor *cis*-$[RuCl_2(dmso)_4]$ and that of the new complexes was useful in determining the elimination of one of the above possibilities. In the IR spectrum of *cis*-$[RuCl_2(dmso)_4]$, the S=O stretch of the S-bonded dmso appears at a higher frequency (1090 cm^{-1}) in comparison with that of the O-bonded dmso (915 cm^{-1}) due to the increase in the S=O bond order in the former case. The desertion and retention of the bands at 915 cm^{-1} and around 1090 cm^{-1} respectively in the new complexes indicate the replacement of one O-bonded and one S-bonded dmso ligand from the precursor by the Schiff base chelate. This is consistent with the previous observation that chelating ligands will replace first the weakly held O-bonded dmso and then the S-bonded dmso *cis* to it [9].

The absorption spectra of the diamagnetic Ru(II) complexes were recorded as 10^{-4} M dmso solutions in the range 800–250 nm using a quartz cuvette of 1 cm path length. All the new ruthenium(II) complexes, except **4**, exhibit bands in both UV and visible regions. Based on the position and nature of the peaks, all the bands are assigned to either $n \rightarrow \pi^*$ or $\pi \rightarrow \pi^*$ intraligand transitions (data given in experimental section).

3.2. X-ray crystallography

Though slow evaporation of the respective reaction mixtures yielded X-ray quality single crystals of **1**, **1a**, **2** and **2a**, only structures of the first three complexes were solved. Structure determination of **1** and **1a** showed that the two compounds are one and the same, as the unit cell parameters of the two complexes were very close and other structural features and geometric parameters were similar. The crystal data and data collection procedure are supplied in Table 1. Selected geometrical parameters are listed in Table 2. Figs. 1 and 2 show the ORTEP diagrams of **1** and **2** respectively. In both of the complexes, there are two independent

complexes (**A** and **B**) in the asymmetric units and a disordered solvent molecule. Refinement of the disordered regions of both **1** and **2** has been carried out, but the fit to the data did not really improved in either case, nor were there any significant changes in the interesting parts of the structure.

In complex **1**, the ruthenium(II) ion is in a distorted octahedral environment equatorially coordinated by an ON chelate of the hydrazone ligand and two sulfur atoms of the dmso ligands at *cis* positions. A pair of chlorine atoms at the axial positions completes the octahedral coordination. The Ru–N (Ru1a–N1a = 2.107(2) and Ru1b–N1b = 2.098(3) Å) and Ru–O (Ru1a–O1a = 2.123(2) and Ru1b–O1b = 2.101(2) Å) bond lengths observed in the two independent complexes are comparable to literature values [17–23]. The two Ru–S bond lengths observed in the independent complexes **A** and **B** are comparable with that of similar Ru(II) complexes [17] and with that of the precursor, *cis*-[$RuCl_2(dmso)_4$] [24]. As expected and previously observed [24,25] there is a change in the S–O bond length of dmso after coordination in comparison with the free ligand.

The substitution of one O-bonded dmso and one S-bonded dmso in the precursor *cis*-[$RuCl_2(dmso)_4$] by the ON chelating ligand has yielded **1** in which the two chloro ligands take mutual *trans* positions, which is in accordance with a previous study [17]. The two Cl ligands in the axial positions are faintly bent to-

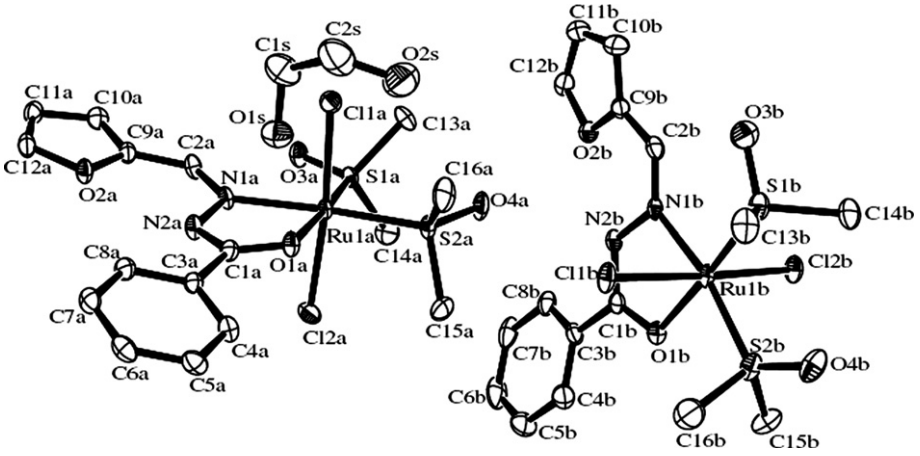

Fig. 1. Asymmetric unit of **1** with anisotropic displacement ellipsoids at 50% probability. Hydrogen atoms are omitted for clarity.

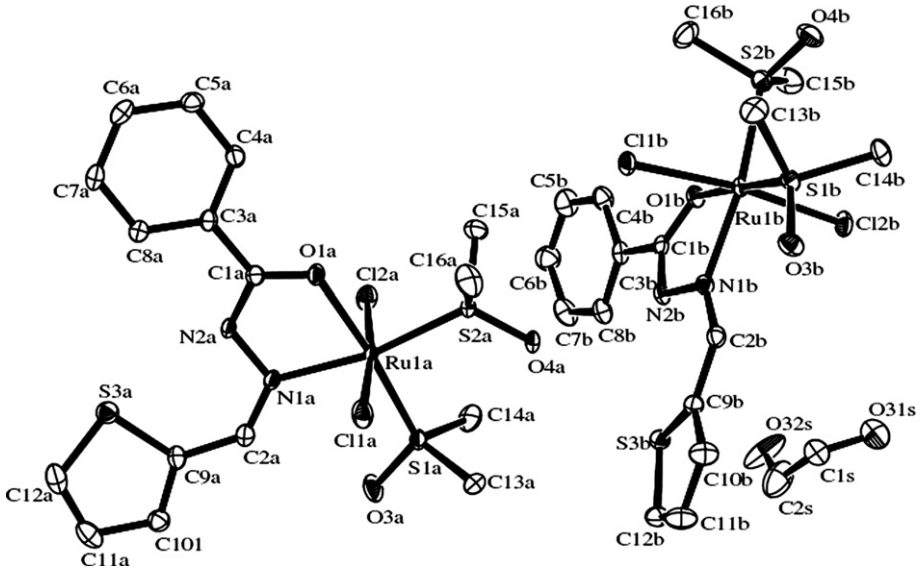

Fig. 2. Asymmetric unit of **2** with anisotropic displacement ellipsoids at 50% probability. Hydrogen atoms and disorder in thiophene ring are omitted for clarity.

wards the chelate (the angle Cl2a–Ru1a–Cl1a is 174.30(3)° and Cl2b–Ru1b–Cl1b is 172.28(3)°) due to the pushing by the somewhat bulky *cis* dmso ligands. The Ru–Cl distances in **1** (Ru1a–Cl1a = 2.4174(8), Ru1a–Cl2a = 2.3959(8) Å; Ru1b–Cl1b = 2.3934(8), Ru1b–Cl2b = 2.4091(8) Å) are shorter than that of **Ru1** (mean Ru–Cl distance of the different forms is 2.425 Å) and fairly comparable with that of **Ru2** (2.402 Å). This is in agreement with the greater trans influence of dmso [24].

The angles O–S–C and C–S–C in **A** and **B** of **1** are comparable with that of the S-bonded dmso ligands in *cis*- and *trans*-$[RuCl_2(dmso)_4]$. But these angles of O-bonded dmso in one of the precursors, **Ru1**, is relatively narrow when compared with that of S-bonded dmso ligands. This is due to the different electronic situation of the two types of sulfur atom and can be attributed to the compression effect of the bulkier lone pair of the pyramidal sulfur atoms on the bonding pairs [25]. The bite angles of the ON chelate in **A** and **B** are 77.31(9) and 77.86(9)° respectively, and these are comparable with that of a similar chelate [17].

The structure of **2** shares similar properties and the same discussion goes well with that for **1** except in a few aspects. The heterocyclic ring in **1** is furan whereas in **2** it is thiophene and there is a slight distortion in the thiophene moiety in one of the two independent complexes. Further refinement, using a number of restraints, of the disordered thiophene led to a slight improvement, most notably in the reduction of residual electron densities. However, full anisotropic refinement did not lead to realistic displacement parameters. The independent complexes in the asymmetric units of **1** are stabilized by intramolecular N(amide)–H···O(furan) bonds and intermolecular N(amide)–H···O(dmso) bonds in addition to bifurcated weak interactions, O(disordered ethanol)–H···Cl and O(disordered ethanol)–H···O(furan). In contrast to **1**, intermolecular hydrogen-bonding, N(amide)–H···O(dmso) appears to be predominant in complex **2**. The geometric parameters pertaining to hydrogen-bonding are provided in Table 3.

With the single crystal X-ray structures of **1** and **1a**, it is clear that the chelating ligands replace the coordinated ligands that are *trans* to the two S-bonded dmso from either of the precursors **Ru1** and **Ru2**. This is due to the strong *trans* influence of the S-bonded dmso ligands. Also, in **Ru2**, the chelating bpy ligands are replaced by the ON hydrazone chelate relatively easily compared to the two S-bonded dmso ligands because of the strong π-acceptor character of the two sulfur atoms. Hence, the complex pairs **2** and **2a**, **3** and **3a**, and **4** and **4a** will be mentioned henceforth as **2**, **3** and **4** respectively assuming that they have same chemical composition (based on the microanalyses) although no structural evidence is currently available for the other complexes.

Table 3

3.3. ^1H NMR spectra

The ^1H NMR spectra of the complexes recorded in dmso showed narrow signals typical for diamagnetic Ru(II) complexes. A comparison of the ^1H NMR data [9] of the precursor *cis*-$[RuCl_2(dmso)_4]$ with that of the new complexes seems indispensable in order to ascertain the bonding mode of the two dmso ligands, as evidenced by the single crystal X-ray diffraction studies (for **1** and **2**), and to predict the same in **3** and **4**. The resonance for methyl protons of free dmso is ~δ 2.5 ppm. The complex *cis*-$[RuCl_2(dmso)_4]$ (contains three S-bonded dmso and one O-bonded dmso) displayed six singlets at δ 3.50, 3.48, 3.43, 3.32, 2.72 and 2.66 ppm due to six sets of chemically different protons. The peak at δ 2.66 ppm has been assigned to free dmso which resulted from the 10% dissociation of O-bonded dmso. Similarly the peak at δ 2.72 ppm has been attributed to the O-bonded dmso since the methyl resonance is close to that of free dmso. The other peaks appearing in a group have been assigned to S-bonded dmso but the integration of these peaks had not been possible owing to their proximity and their sharing of the same broad base line. The three S-bonded dmso ligands in the complex are *trans* to either O-bonded dmso, S-bonded dmso or Cl ligands. This, along with some degree of methyl inequivalency, has been thought of as responsible for the complexity of the spectra. Keeping all these in mind, the group of peaks appearing in the new complexes around ~δ 3.2–3.4 ppm is attributed to S-bonded dmso resonances. Here no resonance was observed at δ

2.7 ppm for any of the complexes, suggesting that there is no O-bonded dmso in the complexes which is consistent with the single crystal X-ray diffraction results obtained for **1** and **2**, and predicts the same for **3** and **4**. Thus the inequivalency in the methyl groups is due to the chelating ligand. The resonance around δ 2.5 ppm in all the complexes is due to the solvent. The azomethine proton in **1** and **2** appears as a singlet at δ 8.1 and 7.9 ppm respectively. The protons of the methyl group in **3** and **4** gave a resonance at δ 2.2 ppm. The multiplet around δ 7.2–8.5 ppm is due to aromatic and heterocyclic ring protons. The appearance of a singlet in all the complexes around δ 9.2–9.4 ppm is due to the NH proton and this suggests that the chelating ligand coordinates in its keto form to the metal and supports a neutral bidentate coordination of the hydrazone ligands.

3.4. Cyclic voltammetric studies

The electrochemical behavior of the complexes was studied with the help of cyclic voltammetry using dmso solutions of the complexes and TBAP as a supporting electrolyte. All the potentials were referenced to the Ag/AgCl electrode and scanned at a rate of 0.1 V/s. The complexes show different redox behavior in the chosen potential window. Complexes **1** and **4** show only a Ru^{III}/Ru^{II} oxidation couple with the formal potentials 0.63 and 0.50 V respectively. Complex **2** shows only an irreversible oxidation wave with E_{pa} = 0.49 V. This irreversibility may be anticipated due to the transient lifetime of the reduced state. The peak-to-peak separation value ΔE_p for **1** and **4** is 240 and 80 mV suggesting a quasireversible and reversible one electron transfer process respectively. A reversible reduction (Ru^{II}/Ru^{I}) is observed for **3** with a formal potential of −0.39 V (ΔE_p = 80 mV). These different conducts of the complexes can be accredited to the different electronic nature of the substituents present in the hydrazone ligands. When the E_f values for the oxidation couple for **1** and **4** are compared, a negative shift in the potential is observed. This shift is due to the presence of an electron releasing CH_3 group and pyridine moiety in **4** which favor easier oxidation of the central metal ion. The more electron withdrawing furan ring of **3** renders the molecule prone to reduction of the ruthenium centre [26]. In summary it can be drawn that electron releasing substituents stabilize the +3 oxidation state whereas electron withdrawing substituents stabilize the +2 oxidation state of ruthenium.

3.5. DNA-binding studies

Most ruthenium complexes bind to DNA by non-covalent interactions such as electrostatic binding, groove binding, intercalative binding and partial intercalative binding [27]. A quantitative understanding of the factors that determine the recognition of DNA sites would be valuable in the rational drug design of new DNA targeted molecules for application in chemotherapy. The binding of the new ruthenium complexes to the Herring sperm ds DNA has been monitored through absorption titration and cyclic voltammetry.

3.5.1. Absorption titration

The experiments were carried out in Tris–HCl buffer (50 mM,pH 7.2) using a solution of Herring sperm DNA which gave a ratio of UV absorbance at 260 and 280 nm in the ratio 1.8:1, indicating that the DNA is sufficiently free from protein. So no further effort was made to purify the commercially obtained DNA. The concentration of DNA was determined by absorption spectroscopy using the ε value of 6600 M^{-1} cm^{-1} at 260 nm. Absorption titrations were performed using a fixed ruthenium concentration to which increments of the DNA stock solutions were added in different ratios ranging from 0 to 3 [DNA]/[Ru]. Complex–DNA solutions were allowed to stand for 5 min before recording their absorption. The titration process was repeated until no further change was observed in the spectra.

The binding of the ruthenium complexes to the DNA helix was characterized by following the changes in the absorbance and shift in wavelength upon each addition of DNA solution to the complex. Representative absorption spectra are given in Figs. 3 and 4. The ruthenium(II) complexes in dmso-buffer mixture exhibit an intense intraligand transition in the region around 315–330 nm. On the titration of Herring sperm DNA with the complexes, a considerable increase or decrease in the absorption along with a small red or blue shift was observed. The initial increase in absorption for complexes **2** and **3** is due to the electrostatic interaction of DNA and the complexes [28]. In complexes **2** and **4** remarkable hypochromicity is noted after the ratio [DNA]:[Ru] becomes 1. In complex **1** the absorption decreases and increases at random with a small red shift (2–4 nm) on titration with the DNA solution. These trends show that the complexes bind to the DNA double-helix in different modes to different extents [29]. As can be perceived from Figs. 3 and 4, the shift in absorption and λ_{max} are random and this tendency frustrated the calculation of intrinsic binding constants of the complexes using the equation valid for perfect intercalators.

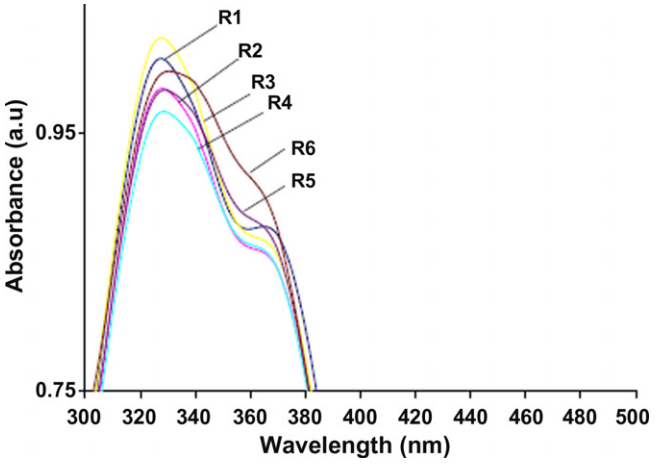

Fig. 3. Absorption bands of **1** on titration with DNA at different [DNA]/[Ru] ratios (*R*). *R*1 = 0, *R*2 = 0.25, *R*3 = 0.50, *R*4 = 0.75, *R*5 = 1 and *R*6 = 1.5.

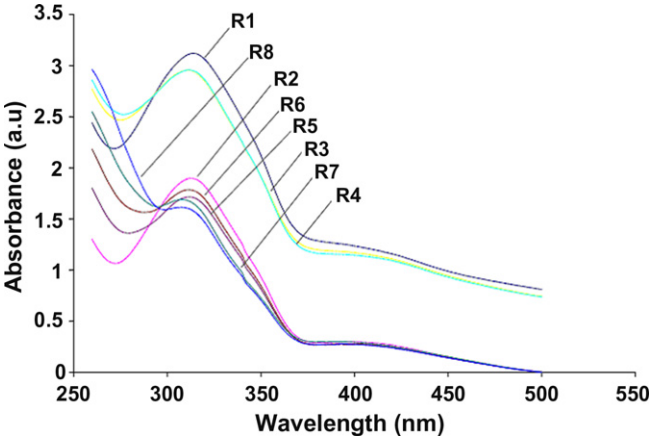

Fig. 4. Absorption bands of **4** on titration with DNA at different [DNA]/[Ru] ratios (*R*). *R*1 = 0, *R*2 = 0.25, *R*3 = 0.50, *R*4 = 0.75, *R*5 = 1, *R*6 = 1.5, *R*7 = 2 and *R*8 = 3.

[b] MIC, minimum inhibitory concentration.Values given as μg/ml for both compounds and antibiotics.

3.5.2. Cyclic voltammetry

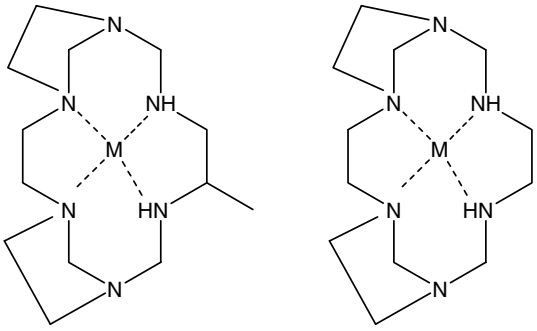
Since all the new complexes are electroactive, electrochemical methods such as cyclic voltammetry can be used effectively to monitor their binding to DNA as a complement to the absorption spectral technique. In a typical cyclic voltammetric titration, a fixed concentration of the complex was taken and DNA solution in buffer was added in different ratios as done in the absorption titration, and the voltammetric response was recorded. As observed in the UV experiments, an increase or decrease of the peak current was observed for all the complexes. The peak current increased initially and then decreased. The initial increase in the peak current is due to the absorption of the DNA bound complex onto the electrode surface [30]. The decrease in peak current on the addition of DNA to the complex is suggestive of an interaction between the complex and DNA [31]. Except for complex **1**, a decrease in the peak-to-peak separation was observed, which is consistent with non-coordinating intercalative binding of the complexes through the planar aromatic rings between the DNA base pairs [32]. The formal potential E_f shifts slightly towards the positive side and is attributed to characteristic behavior of intercalation of the complexes into the DNA double-helix [33], and suggests that Ru(II) and Ru(I) forms bind to DNA at different rates [34,35].

3.6. Antibacterial activity

All the ligands and their ruthenium complexes were screened *in vitro* for their growth inhibitory activity against the pathogenic bacteria *E. coli*, *S. aureus*, *S. epidermidis*, *K. pneumoniae* and *S. sonnei*. The inhibition zone (in mm) and MIC of the ligands and their ruthenium complexes are given in Table 4. From the figures it is perceived that the ligands bfmh and btmh inhibit the growth of all the test organisms to a moderately comparable extent to that of standard antibiotics and they can be said to be resistive to the organisms. The ligand btmh is resistive only to *S. sonnei* and *S. epidermidis* since no inhibition zone is found for the other organisms. Except for *S. aureus*, the ligand bpeh is resistive to all other pathogenic bacteria. All the complexes except **3** are resistive to at least one of the organisms under study. Complex **2** shows considerable resistivity to *S. aureus*, *S. epidermidis* and *S. sonnei*. Similarly **4** is active against *S. aureus* and *S. epidermidis* and **1** is active against only *S. sonnei*. None of the complexes are active against the other two organisms. Thus all the ligands and complexes **2** and **4** alone have been studied further to evaluate the MIC because only these two complexes demonstrate activity against at least two of the five organisms. A low value of MIC implies high resistivity against the particular organism. No serious attempts were made to correlate the activity to the structures of the compounds since too many chemical and biochemical factors are responsible for the process of inhibition of the growth of the bacteria.

4. Conclusions

The present study demonstrates a simplistic synthesis of a family of new Cl–dmso–Ru(II) complexes. The greater *trans* influence of mutually *cis* S-bonded dmso ligands in comparison to the bipyridine ligand has been proved by the observed replacement of bipyridine from **Ru2** by the hydrazone ligands, with crystallographic evidence. The electrochemical properties of the complexes are very sensitive to the electronic nature of the substituents present in the hydrazone ligands. The new complexes have been shown to possess DNA-binding abilities. The *in vitro* antineoplastic activity of the complexes against human breast cancer cell lines is under investigation and the results will be published shortly.



Appendix A. Supplementary data

CCDC 613460 and 632085 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.02.036.

2. Experimental

2.1. Materials

The reagents and solvents were purified and dried according to the standard literature methods [20]. The distilled water was further purified by passing through a purification train (MILLI-Q), Millipore water was used for the preparation of solutions.

Caution: Although no problems were encountered during this work with perchlorate salt, it should be regarded as potentially explosive.

2.2. Physical measurements

Electronic spectra were recorded on a HITACHI 320 UV–Vis double beam spectrophotometer. Infrared spectra were recorded on a Perkin–Elmer infrared spectrophotometer using KBr disks. Conductance measurements were performed on a ELICO CMI85 conductivity bridge and a DEEP VISION conductivity cell. ^{1}H and ^{13}C NMR spectra were recorded on a JEOL GSX 400 MHz NMR spectrometer. EPR measurement of copper complex was made using E-112 VARIAN EPR spectrometer. Mass spectra of both the complexes were recorded on a JEOL SX 102/DA-600 Mass spectrometer.

Equilibrium constants were calculated from UV–Vis spectra. For variable temperature measurements, the temperature variation was controlled with in ±0.2 °C using a thermostated cell holder, connected to a ULTRA CRYOSTAT, supplied by Inlab Equipments Pvt. Ltd. The concentration of the complex was maintained at 1×10^{-3} M in 0.1 M $NaClO_4$ aqueous solution and each spectrum has taken at 5 min interval with in a temperature range of 283–313 K. Cyclic voltammetry was performed using a CHI600A electrochemical analyzer. The measurements were conducted under oxygen free conditions, using a three-electrode cell in which a glassy carbon electrode was the working electrode, a saturated calomel electrode was the reference electrode, and platinum wire was used as the auxiliary electrode. The electrochemical data were obtained in aqueous medium containing 0.1 M $NaClO_4$ as a supporting electrolyte.

2.3. X-ray crystallography

A crystal of size $0.27 \times 0.48 \times 0.53$ mm was used for intensity data collection on a Bruker SMART APEX CCD area-detector diffractometer with Mo Kα radiation ($\lambda = 0.7107$ Å) at 100 K. Empirical absorption correction was applied by using the SADABS program. The structure was solved by direct methods and refined by full-matrix least-square technique on F^2 by using SHELXTL with 4932 reflections ($2.14° \leqslant \theta \leqslant 33.25°$) and 308 parameters. All non-hydrogen atoms were refined anisotropically, and C and N-bound hydrogen atoms were positioned geometrically and refined using a riding model. The final cycle of the refinement converged with $R = 0.061$. The crystal and refinement data are listed in Table 1.

2.4. Synthesis of the complexes

2.4.1. [Ni(PCHA)](ClO$_4$)$_2$(PCHA = $C_{13}H_{28}N_6$)

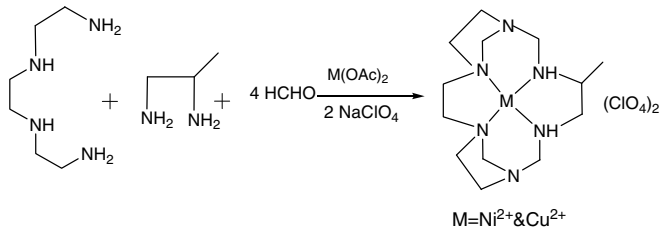
To a stirred methanolic solution (70 mL) of $Ni(OAc)_2 \cdot 4H_2O$ (0.95 g, 3.8 mmol) were added triethylenetetraamine (0.56 mL, 4.1 mmol), 36% formaldehyde (1.2 mL, 15.2 mmol) and 1,2-diaminopropane (0.33 mL, 3.8 mmol). The mixture was heated at reflux for 24 h. The solution was filtered to remove insoluble material. A saturated solution of excess $NaClO_4$ was added to the filtrate and the solution was allowed to stand at room temperature until orange crystals formed. The crystals were filtered out, washed with methanol, diethyl ether and recrystallized from hot water yield ~60%, (1.20 g).

2.4.2. [Cu(PCHA)](ClO$_4$)$_2$

The red crystals of $[Cu(PCHA)](ClO_4)_2$ was synthesized by a procedure similar to that of $[Ni(PCHA)]^{2+}$ using $Cu(OAc)_2 \cdot H_2O$ in place of $Ni(OAc)_2$. Yield ~80% (1.60 g).

3. Results and discussion

3.1. Synthesis of macrocyclic complexes



The hexaaza macrocyclic complexes $[M(PCHA)](ClO_4)_2$ ($M = Ni^{2+}$ and Cu^{2+}) have been synthesized in high yield (60–80%) by the simple template condensation of triethylenetetramine, 1,2-propanediamine and formaldehyde in the presence of divalent metal ion. Both Ni(II) and Cu(II) complexes are soluble in water, acetone, MeCN and Me_2SO but insoluble in alcohol. All efforts to obtain the free ligand from the complexes by treating the complexes with excess NaCN or strong acid were unsuccessful. Free ligand must be unstable because they contain methylene diamine moiety with secondary nitrogens. A possible route for the formation of hexaaza macrotricyclic complexes $[Ni(PCHA)](ClO_4)_2$ and $[Cu(PCHA)](ClO_4)_2$ is presented in Scheme 1.

3.2. Spectral studies

The spectral and conductance data of the complexes are summarized in Table 2. The molar conductance of the complexes mea-

Spectral and conductance data for hexaazamacrocylic nickel(II) and copper(II) complexes

Complex	Electronic spectral data[a], λ_{max} (ε, $M^{-1}\,cm^{-1}$)	IR frequency, ν_{NH} (cm^{-1})	Conductance[a] Λ_M ($\Omega^{-1}\,cm^{-2}\,M^{-1}$)
$[Ni(PCHA)](ClO_4)_2$	452(102) 226(20336)	3143	239
$[Cu(PCHA)](ClO_4)_2$	507(143) 268(5877)	3237	220

[a] Measured in water.

sured in aqueous solutions was 239 and 220 $\Omega^{-1}\,cm^{-2}\,M^{-1}$ for $[M(PCHA)]^{2+}$ corresponding to a 2:1 electrolyte [21]. The electronic spectrum of the aqueous solution of $[Ni(PCHA)]^{2+}$ complex exhibits a strong intense peak at 452 nm which may correspond to $^1A_{2g} \leftarrow {}^1A_{1g}$ transition in a d^8 system of D_{4h} symmetry. The copper complex shows a single peak at 507 nm, which may assigned to the $^2B_{1g} \leftarrow {}^2E_g$ which is also consistent with a square-planar geometry [22].

The charge transfer bands of Ni(II) and Cu(II) complexes appear at 226 and 268 nm, respectively (Table 2). The infrared spectra (Table 2) of the complexes show ν(NH) bands for the secondary amines of the ligands in the region 3143–3237 cm^{-1} and $\nu(ClO_4)$ 1045–1091 and 620–629 cm^{-1} [23]. The mass spectra of both nickel(II) and copper(II) complexes show (M–ClO_4) and (M–2ClO_4) peaks with m/e values 426, 326 and 431, 330, respectively.

The ^{1}H NMR spectrum of Ni(II) complex shows a doublet at 0.94 ppm which is attributed to methyl group present in the macrocycle. The N–CH_2–N signals appear as singlet at 4.56, 4.64 and 4.67 ppm. The N–CH– and N–CH_2–CH_2–N signals have been observed in the region 2.37–3.3 ppm, which is consistent with the ligand structure. The –NH protons are not observed in the spectrum owing to exchange with D_2O. Due to the introduction of methyl group in the macrocyle, the symmetry of the molecule is such that the ^{13}C NMR spectrum of the complex shows 13 signals (12.72, 47.9, 48.1, 53.9, 54.9, 55.1, 55.6, 58.0, 63.0, 68.5, 70.0, 74.4 and 75.0 ppm) which confirms the presence of 13 different types of aliphatic carbons in the complex. But in the case of unmethylated complex $[Ni(CHA)]^{2+}$, only six signals (47.8, 48.8, 55.8, 55.9, 70.7 and 76.1) are observed due to the symmetric nature of the molecule [19].

The ESR spectra of $[Cu(PCHA)]^{2+}$ and the corresponding unsubstituted complex $[Cu(CHA)]^{2+}$ were recorded as polycrystalline sample and in CH_3CN solution at liquid nitrogen temperature. The polycrystalline sample at LNT shows one intense absorption band in the high field region, which is isotropic due to the tumbling motion of the molecule. However in the CH_3CN solution at LNT both the complexes show hyperfine splitting, which indicates that there is an interaction with four nitrogen nuclei adjacent to the copper ions. The spectrum of $[Cu(PCHA)]^{2+}$ is similar to that of $[Cu(CHA)]^{2+}$ and so too are their electronic spectra, indicating that the geometries of the two chromophore in solution are essentially the same. The g tensor values of the Cu^{2+} complexes can be used to derive the ground state. In tetragonal and square-planar geometry the unpaired electron lies in the $d_{x^2-y^2}$ orbital with $^2B_{1g}$ as the ground state and also $g_\parallel > g_\perp$ [24]. The observed g values are summarized in Table 3.

According to Hathaway [25] $G = (g_\parallel - 2)/(g_\perp - 2)$ and if $G > 4$, the exchange interaction is negligible, whereas when $G < 4$, a considerable interaction is indicated in the solid complex. The calculated G values are less than four, suggesting that there is exchange interaction between adjacent copper centers. The spectral parameters indicate approximately square-planar co-ordination around the copper(II) ion [26]. The ESR parameters of the $[Cu(PCHA)]^{2+}$ in CH_3CN solution (LNT) are: $g_\parallel = 2.09$, $g_\perp = 1.93$ and $A_\parallel = 236 \times 10^{-4}\,cm^{-1}$ (Table 3) and the spectral trace is reproduced in Fig. 1.

3.3. The crystal structure of $[Ni(PCHA)](ClO_4)_2$

The ORTEP view of the complex with the atomic numbering scheme is presented in Fig. 2. The bond lengths and bond angles are listed in Table 4. A stereoscopic crystal packing diagram is shown in Fig. 3. There are two coordinated tertiary nitrogens N4 and N5, two coordinated secondary nitrogens N1 and N2 and two uncoordinated tertiary nitrogens N3 and N6 present in the ligand.

The structure of the complex consists of discrete mononuclear $[Ni(PCHA)]^{2+}$ cation and two perchlorate anions. The cation possess one methyl group in the five-membered chelate ring and two 1,3-diaza cyclopentane subunits in the six-membered chelate rings. The Ni–N bond distances range from 1.908(4) to 1.931(5) Å and the average of the four distances is 1.922 Å. The values are comparable to those of the square-planar nickel(II) complexes of various other related polyaza macrocycles [27,28] The N–Ni–N angles (93.8(2)° and 93.0(2)°) of six-membered chelate rings are larger than those of five-membered chelate rings. Interestingly, among the two five-membered chelate rings, the bond angle of

one which contains the methyl group (N1–Ni–N2) is small compared to the other ring (N4–Ni–N5). The N4–C5–C6–N5 torsion angle in the ethylene moiety is 49.8(9)°. The tetra co-ordination of nickel(II) ions cause the four macrocyclic donor atoms to lie in one plane. The axial sites on nickel are not sterically protected and are accessible to additional ligands so that planar ⇌ octahedral equilibrium is observed. The perchlorate ions form hydrogen bond with the secondary amine of the macrocycle (Fig. 3).

3.4. Electrochemical studies

The nickel(II) and copper(II) complexes exhibit an one electron irreversible oxidation and reduction process in aqueous medium. Both nickel(II) and copper(II) complexes show a chemically irreversible oxidation process ($Ni^{2+} \rightarrow Ni^{3+}$) with a peak potential of +1.20 and +1.13 V, respectively, at a scan rate of 100 mV s^{-1}. The irreversible reduction process ($Ni^{2+} \rightarrow Ni^{+}$) occurs at −1.22 V for nickel and −1.03 V for copper complex. The increase in scan rate shows a small change in the reduction peak position towards more negative potential (Fig. 4).

It has been reported [29] that *N*-alkylation of tetraaza macrocyclic ligands exhibits an anodic shift for both oxidation and reduction of the Ni(II) complexes. The average change in $E_{1/2}$ for the oxidation and reduction process due to the introduction of a methyl group is ∼0.14 and 0.1 V, respectively, for the $[Ni(cyclam)]^{2+}$ complexes. The cyclic voltammetric data (Table 5) show that the potentials for the *C*-alkylated hexaaza macrotricyclic complexes $[M(PCHA)]^{2+}$ (M = Ni, Cu) are more cathodic than the corresponding unsubstituted complexes with the difference in oxidation potential of 0.1 and 0.22 V, respectively, for nickel(II) and copper(II) complexes. The complexes $[M(PCHA)]^{2+}$ and $[M(CHA)]^{2+}$ exhibit an anodic shift for both oxidation and reduction potentials when compared to that of macromonocyclic complex [18] $[NiMe_2[14]aneN_6](ClO_4)_2$. This behaviour is attributed to the presence of tertiary amine donors present in the former ligands. The absence of reversible $M^{II} \rightarrow M^{I}$ reduction suggests [30] that the ligand assembly is not sufficiently flexible to support the increase in ionic radius. The more negative value observed in the case of the reduc-

tion process indicates the stability of the metal complexes in the divalent oxidation state.

3.5. Equilibrium between square-planar and octahedral species of $[Ni(PCHA)]^{2+}$

Ni(II) complexes exist in aqueous solution as an equilibrium mixture of a blue, octahedral, high-spin species and a yellow, planar, low-spin species [31–33] as described by the following equation:

$$[Ni(L)(H_2O)_2]^{2+} \rightleftharpoons [Ni(L)]^{2+} + 2(H_2O)$$

The equilibrium has been reported [34] to be dependant on temperature, ionic strength, and the nature of the added electrolyte. The electronic spectrum of $[Ni(PCHA)]^{2+}$ shows λ_{max} at 459 nm (ε = 107 M^{-1} cm^{-1}) in CH_3NO_2 medium at room temperature. The molar extinction coefficient measured in water is smaller (102 M^{-1} cm^{-1}) than that of in CH_3NO_2, indicating that some of the square-planar species are converted into octahedral species in water. Similar behaviour is observed in unmethylated complex $[Ni(CHA)]^{2+}$ in which the ε value is 89 and 84 M^{-1} cm^{-1}, respectively, in CH_3NO_2 and aqueous medium. The electronic spectrum of $[Ni(PCHA)]^{2+}$ which has λ_{max} at 454 nm (ε = 102 M^{-1} cm^{-1}) in aqueous solution is temperature dependant. The intensity of the band increases with increase in temperature, and it restores to the original value while reversing the temperature, which is a characteristic behaviour observed in many hexaaza Ni(II) macrocycles [18,19,35]. In CH_3NO_2 medium the complex is expected to be 100% planar and the equilibrium constant is obtained from the ratio $K=(\varepsilon_{lim} - \varepsilon)/\varepsilon$ where ε_{lim} and ε represent limiting values of molar extinction coefficient for the square-planar and the apparent molar extinction coefficient in 0.1 M $NaClO_4$, respectively. The ΔH° and ΔS° values were calculated as described in the literature [36]. A plot of $\ln K$ versus $1/T$ is linear, and the ΔH° and ΔS° values were found to be -10.83 ± 0.03 kJ mol^{-1} and $\Delta S = -46.59 \pm 0.04$ J K^{-1} mol^{-1}, respectively. In aqueous solution at 30 °C, 79.1% of the complex is planar and 20.9% is octahedral, and the equilibrium constant (K) value is 0.26 ± 0.05. Thermodynamic data for the equilibrium process are listed in Table 6. The values obtained for $[Ni(PCHA)]^{2+}$ is comparable to those previously obtained for the unmethylated hexaazamacrocylic complexes [18,19,35]. The formation constant of octahedral species viz. $[Ni(PCHA)]^{2+}$, $[Ni(CHA)]^{2+}$ and $[Ni(THA)]^{2+}$ are very small when compared to those of $[Ni(cyclam)]^{2+}$ and $[Ni(isocyclam)]^{2+}$ (Table 6). The Ni–N bond distances in octahedral species are longer than those in square-planar species (~1.9 Å for square-planar and ~2.1 Å for octahedral). The ligands cyclam and isocyclam have larger macrocyclic hole and are capable of accommodating the larger Ni(II) ion while the ligands PCHA, CHA and THA have rigid hole size and hardly accept it.

Noticeably both the ΔH° and ΔS° values in the case of C°-alkyl substituted macrocyles are smaller than those for the unsubstituted ligands (CHA and THA). It has been reported [37] that positive values of ΔS°, observed for the blue to yellow conversion of nickel complexes of cyclam and isocyclam are due to the increase in translational entropy. The presence of methyl group on the macrocyclic backbone may exert a steric repulsion and, hence the equilibrium constant for $[Ni(PCHA)]^{2+}$ is smaller when compared to those of $[Ni(CHA)]^{2+}$ and $[Ni(THA)]^{2+}$.

Table 6
Thermodynamic data for the equilibrium $[Ni(L)(H_2O)_2]^{2+} [Ni(L)]^{2+} + 2(H_2O)$

L	K_{25} (°C)	ΔH° (kJ mol^{-1})	ΔS° (J K^{-1} mol^{-1})	Ref.
PCHA	0.26 ± 0.05[a]	−10.83 ± 0.03	−46.59 ± 0.04	This work
CHA	0.07	−12.9	−65.4	[19]
THA	0.05	−21.4	−96.2	[19]
Cyclam	2.5	5.4	16.3	[36]
Isocylam	1.6	5.3	16.9	[36]

[a] Measured at 30 °C.

The negative ΔH° value for $[Ni(PCHA)]^{2+}$ indicates the endothermic effect resulting from the formation of the two axial Ni–OH_2 bonds. The Ni—N bond distances in octahedral species are longer than those in square-planar species. The high-spin to low-spin conversion of Ni(II) complexes can occur either by the release of apical water molecules or through elongation of the axial Ni–OH_2 bonds. However, the present results indicate that the value of ΔS° nearly corresponds to those expected for the loss of two water molecules in the octahedral species.

and deoxygenated by standard methods [13]. $ReOCl_3(OPPh_3)(SMe_2)$ was prepared according to the literature procedure [3]. IR and FIR measurements were performed in KBr pellets, either with a Nicolet FTIR Impact 400 instrument or in Nujol with a Brucker IFS 113V instrument. ^1H, $^{31}P\{^1H\}$ NMR spectra were obtained on a Bruker AMX and Avance III (300 MHz for ^1H NMR) device at room temperature. The chemical shifts δ, are given in ppm relative to TMS (^1H) and H_3PO_4 (^{31}P) using deuterated solvents as lock and reference (^1H), respectively. UV–Vis spectra in CH_2Cl_2 solution were obtained on a Carry 500 spectrophotometer. Elemental analyses were performed on a Vario EL III apparatus.

2.2. Synthesis of the complexes

2.2.1. *mer*-$ReOCl_3(OPPh_3)(pym)$ (**1** · CH_3CN)

Pyrimidine (0.02 cm^3, 0.25 mmol) was added to a stirred suspension of the complex $ReOCl_3(OPPh_3)(SMe_2)$ (0.15 g, 0.23 mmol) in acetonitrile (25 cm^3). The mixture was heated to reflux within 3 h generating a green solution. Upon slow cooling to room temperature, green crystals suitable for X-ray analysis were afforded. The product was filtered, washed with diethyl ether and dried in vacuo (0.1 g, 66%). (*Anal.* Calc. for $C_{22}H_{19}Cl_3N_2O_2PRe \cdot C_2H_3N$: C, 40.71; H, 3.13; N, 5.94; Cl, 15.02. Found: C, 40.69; H, 3.10; N, 5.77; Cl, 15.05%); ν_{max}(KBr)/cm^{-1} 540s, 1123vs (P═O), 990vs (Re═O), 1557w, 1592w (C═N); ν_{max}(nujol)/cm^{-1} 256m, 317vs, 332s, 341s (Re–N), (Re–Cl); $\lambda_{max}(CH_2Cl_2)$/nm 355 (ε/dm^3 mol^{-1} cm^{-1} 1520), 380 (1499), 745 (115).

2.2.2. *mer*-$ReOCl_3(OPPh_3)(pyz)$ (**2**)

Pyrazine (0.054 g, 0.675 mmol) was added to a stirred suspension of the complex $ReOCl_3(OPPh_3)(SMe_2)$ (0.27 g, 0.42 mmol) in acetonitrile (30 cm^3). The mixture was heated to reflux within 2 h, generating greenish-brown solution. The solution was concentrated to ~7 cm^3 and stored in a refrigerator. Green crystals of **2** suitable for X-ray analysis were formed overnight.[1] The product was filtered, washed with diethyl ether and dried in vacuo (0.18 g, 65%). (*Anal.* Calc for $C_{22}H_{19}Cl_3N_2O_2PRe$: C, 39.62; H, 2.87; N, 4.20; Cl, 15.95. Found: C, 39.61; H, 2.77; N, 4.21; Cl, 15.70%.); ν_{max}(KBr)/cm^{-1} 540s, 1122vs (P═O), 990vs (Re═O), 1557w, 1592w (C═N); ν_{max}(nujol)/cm^{-1} 253m, 317vs, 336s, 339vs (Re–N), (Re–Cl).

2.2.3. $[ReOCl_3(OPPh_3)]_2(\mu$-pym) (**3**)

Pyrimidine (0.015 cm^3, 0.19 mmol) was added to a stirred suspension of the complex $ReOCl_3(OPPh_3)(SMe_2)$ (0.24 g, 0.38 mmol) in acetonitrile (25 cm^3). The mixture was heated to reflux for 8 h, generating a yellow greenish solution. Upon slow cooling, a greenish crystalline precipitate was afforded. The product was filtered, washed with absolute ethanol, diethyl ether and dried in vacuo (0.14 g, 60%). The monomeric complex *mer*-$ReOCl_3(OPPh_3)$-(pym)**1** · CH_3CN was obtained from the mother liquor as a by-product. Single crystals suitable for X-ray analysis were obtained by re-crystallization from acetonitrile solution as yellow-green compound. (*Anal.* Calc for $C_{40}H_{34}O_4Cl_6N_2P_2Re_2$: C, 38.32; H, 2.73; N, 2.23; Cl, 16.97. Found: C, 38.62; H, 2.68; N, 2.65; Cl, 17.01%.) ν_{max}(KBr)/cm^{-1} 540s, 1123vs (P═O), 989vs (Re═O), 1603w C═N; ν_{max}(nujol)/cm^{-1} 259m, 306s, 329vs, 346vs (Re–N), (Re-Cl); $\lambda_{max}(CH_2Cl_2)$/nm 393 (ε/dm^3 mol^{-1} cm^{-1} 120) 450 (132), 752 (16).

2.2.4. $[ReOCl_3(OPPh_3)]_2(\mu$-pyz) (**4**)

A suspension of the light-green complex $ReOCl_3(OPPh_3)(SMe_2)$ (0.3 g, 0.46 mmol) and pyrazine (0.018 g, 0.22 mmol) in acetonitrile (10 cm^3) was stirred and boiled for 2 h until the starting rhenium compound reacted and a red-brown crystalline solid was afforded. The product was filtered, washed with absolute ethanol, diethyl ether and dried in vacuo (0.25 g, 86%). If the mother liquor was allowed to cool to room temperature, single crystals of a red-brown compound suitable for X-ray analysis were obtained. (*Anal.* Calc for $C_{40}H_{34}O_4Cl_6N_2P_2Re_2$: C, 38.32; H, 2.73; N, 2.23; Cl, 16.97. Found: C, 38.22; H, 2.66; N, 2.26; Cl, 16.74%.) ν_{max}(KBr)/cm^{-1} 538s, 1122vs (P═O), 990vs (Re═O), 1591w C═N; ν_{max}(nujol)/cm^{-1} 260s, 324s, 334s, 343vs, (Re–N), (Re–Cl); $\lambda_{max}(CH_2Cl_2)$/nm 485sh (ε/dm^3 mol^{-1} cm^{-1} 4727) 520 (8000), 780 (1160).

2.3. Crystal structure determination

The data collected on KM4CCD diffractometer were corrected for Lorentz and polarization effects. Data reduction were carried out using the Oxford Diffraction (Poland) programs. The structure was solved by Patterson method using SHELXS-97 and refined by the full-matrix least-squares method on F^2 using SHELXL-97 software [14]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were set in calculated positions and refined using the riding model with a common fixed isotropically thermal parameter.

3. Results and discussion

3.1. Synthesis of the complexes

Starting with $ReOCl_3(OPPh_3)(SMe_2)$, the reactions at a 1:1 metal-to-diaza ligand ratio gave the mononuclear oxo-rhenium(V) complexes $ReOCl_3(OPPh_3)$(pym) (**1**), and $ReOCl_3(OPPh_3)$(pyz) (**2**), whereas those performed at 2:1 ratio yielded dinuclear compounds $[ReOCl_3(OPPh_3)]_2(\mu$-pym) (**3**), and $[ReOCl_3(OPPh_3)]_2(\mu$-pyz) (**4**) (see Chart 1). All one-pot reactions were performed in boiling acetonitrile, whereas the analogous monosubstituted complexes $ReOCl_3(OPPh_3)$(py) or $ReOCl_3(OPPh_3)(Me_3Bzm)$ obtained by Marzilli et al. [15] had been obtained under mild reaction condition, at ambient temperature over several hours in the presence of a stoichiometric amount of the aza ligand. Similar gentle reaction conditions were used for the synthesis of even the disubstituted pyridine complex $ReOCl_3(py)_2$ obtained by Choi and Muetterties [16]. Apart from the sluggish synthesis of **3** which took 8 h, the preparation of **1**, **2**, and **4** was completed in 2–3 h.

Compounds **1** and **2** were achieved in ligand substitution reaction of the N ~ N heterocycle for the most labile dimethyl sulphide. Replacement of the second labile triphenylphosphine oxide ligand was not observed. Complexes **1** and **2** containing one bridging

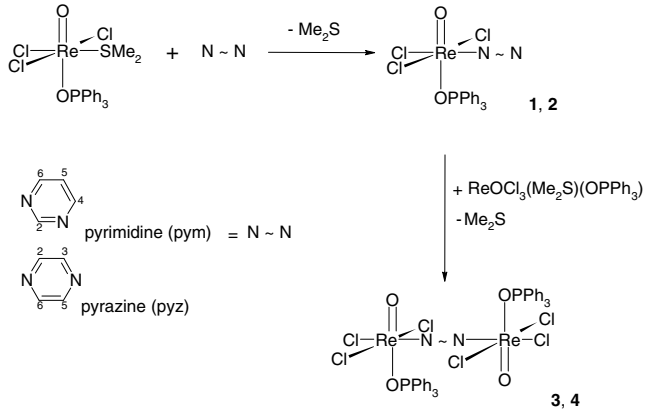

Chart 1.

[1] *mer*-$ReOCl_3(OPPh_3)$(pyz) 2 was characterized by X-ray crystallography, but the X-ray diffraction data were not of sufficient quality to publish because of additional high peaks on Fourier map. The preliminary results allowed us to estimate rugged geometry of the complex.

Table 1

[a] Signals overlapped with the resonances due to the phenyl groups of corresponding dimer **4**.

diaza ligand were still able to react further yielding the dimers **3** and **4**.

In contrast to **1**, complex **2** is unstable: when dissolved in acetonitrile it immediately reacts further, yielding a thermodynamically more stable product, dimer **4**. On this account, no UV–Vis spectrum was recorded for **2**, and NMR spectra consist of additional, partially overlapped signals attributed to phenyl protons belonging to **4**. The high yield and short reaction time of **4** also corroborate the lability of **2**. The lower stability of **2** in contrast to **1** can be cautiously explained as a less steric effect of pyrazine compared with pyrimidine as well as the effect of the increase in pyrazine basicity on complexation already announced in the literature for pentaaminaruthenium(II) complexes $(NH_3)_5Ru^{II}L^{2+}$ (where L = pyz or pym) [17].

Unlike the monomers **1** and **2**, the dimers **3** and **4** are slightly soluble in dichloromethane and poorly soluble in chloroform. They are stable on air both in solid state and in solution. Both compounds are inert to substitution reaction. Even prolonged heating with an excess of pyrazine or pyrimidine as a ligands in acetonitrile does not substitute triphenylphoshine oxide under applied reaction conditions. However, traces of water in the system generate a stable $Re_2O_3Cl_4(N\sim N)_4$, already known from the literature [8,18], which contains the (O═Re–O–Re═O) arrangement, due to hydrolysis.

3.2. Spectroscopic characterization

For all the complexes, monomeric as well as dimeric, strong IR band at around 990 cm^{-1} is relevant. The invariable position of the band corresponds to the stretching vibration ν(Re═O) and exists in the upper range observed for the *trans*-arrangement of the oxygen donors O═Re–O– [19]. The stretching vibrations of triphenylphosphine oxide ν(P═O) at 1193 cm^{-1} are shifted at ca. 70 cm^{-1} to a lower frequency when it coordinates to rhenium.

Based on our previous work on experimental and theoretical FIR spectra of oxo-rhenium(V) complexes [20], we identified the position of the stretching vibrations ν(Re–N) of medium and strong intensity at 250–260 cm^{-1}. FIR spectra permitted us to elucidate the geometry of the chloride ligands. Three ν(Re–Cl) absorptions occur in the 300–350 cm^{-1}. These data lead to a local C_{2v} symmetry and a meridional arrangement of halogen ligands around the metal.

The NMR spectra of all the compounds show sharp peaks in the 7–11 ppm range (summarized in Table 1, signals due to CH_3CN solvate were not presented). ^{1}H NMR spectroscopic studies revealed two sets of signals relevant to triphenylphosphine oxide and N-heterocycle. Moreover, they make it possible to distinguish between monomers or dimers. It is noteworthy that all the complexes at room temperature exhibit C_s symmetry around the metal centre. The spectra for **1**, **2** are simple: two multiplets at 7.46 and 7.63 ppm indicate phenyl protons of phosphine oxide (in a case of **2**, partly overlapped with the multiplets attributed to dimer **4**). Four signals relevant to H2, H4, H5 and H6 for **1** and two multiplets H2,6 and H3,5, for **2** correspond to one mono-coordinated pyrimidine and pyrazine molecule, respectively. For the mononuclear complexes **1** and **2**, coordination of diaza congeners to the $ReOCl_3(OPPh_3)$ unit lowers the symmetry of the ligand and shifts resonances slightly downfield ($\Delta\delta$ value) compared with the *trans*-$ReOCl_2(OEt)(N\sim N)_2$ complexes (ESI Table S1). The symmetry of the heterocycles in the dinuclear compounds **3** and **4** corresponds to the unsubstituted complexes and the resonances are moved slightly downfield for **3** ($\Delta\delta$ = 0.03–0.27). The highest downfield shift [(1.02) for H2, dimer **3**)] is exhibited by the H2 protons most sensitive to metallation. Thus, the spectrum of

N(*) corresponds to N(3) for $[ReOCl_3(OPPh_3)]_2$(μ-pym) (**3** · CH_3CN) or N(4) for $[ReOCl_3(OPPh_3)]_2$(μ-pyz) (**4** · CH_3CN).

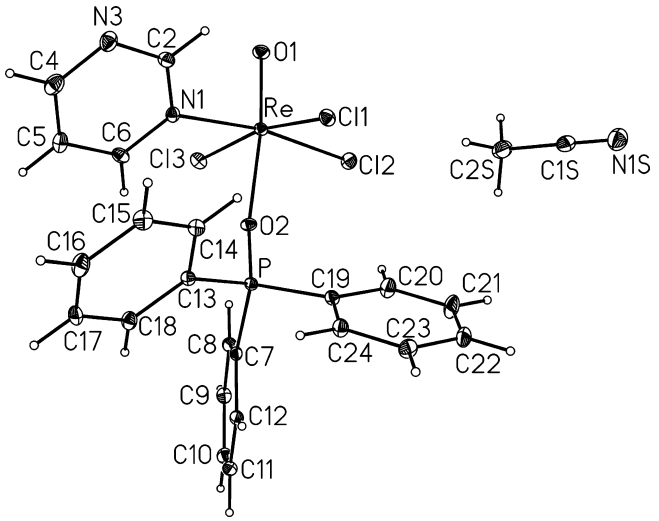

Fig. 1. Molecular structure of $ReOCl_3(OPPh_3)$(pym) (**1** · CH_3CN), the thermal displacement ellipsoids are drawn with 30% probability level.

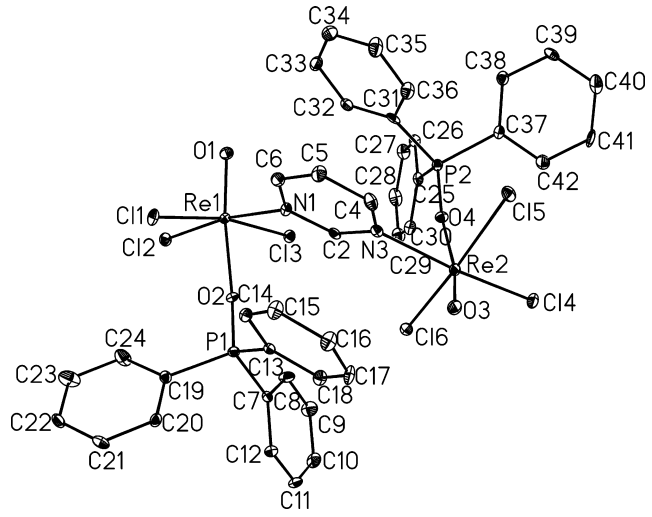

Fig. 2. Molecular structure of $[ReOCl_3(OPPh_3)]_2$(μ–pym) (**3**), the thermal displacement ellipsoids are drawn with 30% probability level. The hydrogen atoms have been omitted for clarity.

$[ReOCl_3(OPPh_3)]_2$(μ-pym) (**3**) consists of five group of signals. Two of them are characteristic for triphenylphosphine oxide, three others for bridging pyrimidine. Protons H4 and H6 are magnetically equivalent, in contrast to H2 and H5. Based on signals integration, two molecules of phosphine oxide and one molecule of the N-heterocyclic ligand form a dimeric molecule. Yet, the ^1H NMR spectrum of $[ReOCl_3(OPPh_3)]_2$(μ-pyz) (**4**) besides the resonances assigned to coordinated phosphine oxide contains a singlet, which is attributed to the equivalent protons of bridging pyrazine. The electrophilic nature of rhenium(V) shifts the proton signal of coordinated pyrazine, δ = 8.42 ppm, towards the high field region (free pyrazine δ 8.61 ppm).

$^{31}P\{^1H\}$ NMR spectra show singlets at δ 49 ppm or 50 ppm due to coordinated triphenylphosphine oxide for monomers and dimers, respectively.

The electronic absorption bands for **1**, **3** and **4** are given in Section 2. The differences for both dinuclear complexes are striking. Although **1** and **3** exhibit in solution a yellow green colour, complex **4** is dark pink. The visible spectrum of **4** consists of two bands at 780 nm and 520 nm with large absorption coefficient, ($1160\ M^{-1}\ cm^{-1}$) and ($8000\ M^{-1}\ cm^{-1}$) respectively, probably caused by a significant contribution of CT transitions. In contrast, **3** is characterized by a very weak absorption band at 752 (16) and 450 (132). High values of absorption coefficients are not unusual and have also been reported in the literature for other oxorhenium(V) complexes with N-heterocyclic ligands [8,21]. The lower energy bands observed in the spectra of $5d^2$ rhenium complexes are usually described as nd–σ^*d and nd–π^*d transitions [1]. Bands with large extinction exhibit CT character. The d–d transitions are forbidden, so they overlap with neighbouring transitions lowering these bands.

Unfortunately, we observed that neither of the complexes **3** and **4** is luminescent in aprotic solvent.[2]

4. X-ray structure analysis of complexes 1, 3 and 4

The crystal and molecular structure of complexes **1**, **3** and **4** determined by X-ray diffractometry confirms that the stereochem-

[2] Attempted measurement of the high-resolution luminescence excitation spectra was performed at 293, 77 K in dichloromethane, using a Spectra Pro 0.75-m monochromator equipped with Hamamatsu R928 photomultiplier tube as a detector.

istry of the molecules is the same in solution and in the solid state. The crystallographic data for **1** · CH_3CN, **3** · CH_3CN and **4** · CH_3CN, selected bond lengths and bond angles and the molecular structures with atomic labelling schemes, are shown in Tables 2, 3 and Figs. 1–3, respectively. The rugged geometries of the distorted octahedral $ReOCl_3NO$ coordination spheres are very similar for all complexes. The coordination geometry about rhenium is established by tree chlorides and one nitrogen atom in equatorial plane.

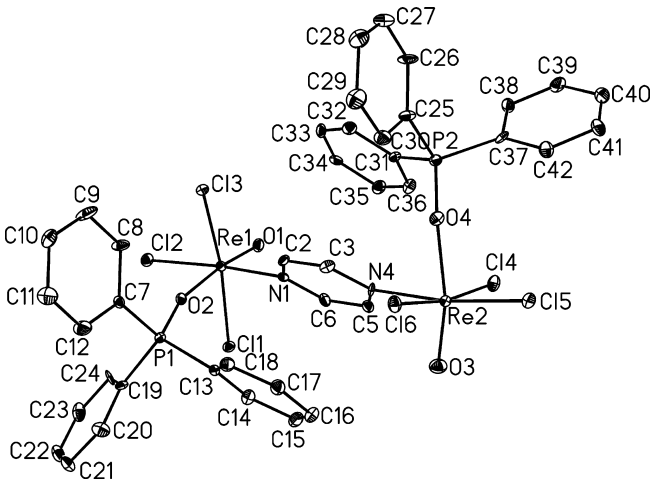

Fig. 3. Molecular structure of $[ReOCl_3(OPPh_3)]_2(\mu\text{-pyz})$ (**4**), the thermal displacement ellipsoids are drawn with 30% probability level. The hydrogen atoms have been omitted for clarity.

Two apical positions are occupied by two donor atoms: terminal oxygen and oxygen of triphenylphosphine oxide. The molecules of **3** and **4** consist of two units connected *via* pyrimidine or pyrazine rings which effect coordination of two metal centres at 120° and 180°, respectively. In all the complexes, the rhenium atoms deviate from the equatorial planes (Cl–Cl–Cl–N) towards the oxo atoms by 0.179–0.228 Å. The short Re(1)–O(1) and Re(2)–O(3) bonds lengths, 1.660–1.670 Å found for **1**, **3** and **4** are typical for rhenium (V) monooxo complexes and indicate formally triple bonds (Re≡O) [1,22]. The Re–$OPPh_3$ distances also lie within the usual range [15,23]. The other coordination bonds and distances fit well with the values found in the literature [24,25]. It is interesting to note that in complex **1** and **2**,[1] the pyrimidine or pyrazine ring is involved in stacking interaction with one phenyl ring belonging to phosphine oxide (3.87(2) Å centroid to centroid, c_t–c_t for **1**, ~3.6 Å for **2**). The same structural features are found for compounds **3** and **4**. The rhenium units are twisted almost perpendicular with respect diaza ligand, the pseudo torsion angles O(1)Re(1)···Re(2)O(3) being 125.6(1)° (**3**) and 105.2(3)° (**4**), respectively. Thus, one phenyl ring of each triphenylphosphine oxide is stacked with bridging diaza ring forming a π–π interactions (3.64(3) Å and 3.78(3) Å c_t–c_t (**3**)) and (3.62(2) and 3.62(2) Å c_t–c_t (**4**)). For all of the complexes **1**, **3** and **4**, the rings are displayed parallel and the angles formed by the ring normal and the vector between the diaza and phenyl ring centroid are approximately 20°. Hence, according to Janiak [26], such a parallel-displaced structures exhibit not only π–π interaction but also contribution from π–σ attraction. It is thought that π–π interactions may play a crucial role in the assembly process of complexes. In contrast to intermolecular π–π interaction, intramolecular ones are rare within ligands coordinated to transition metals [27–29]. Noncovalent

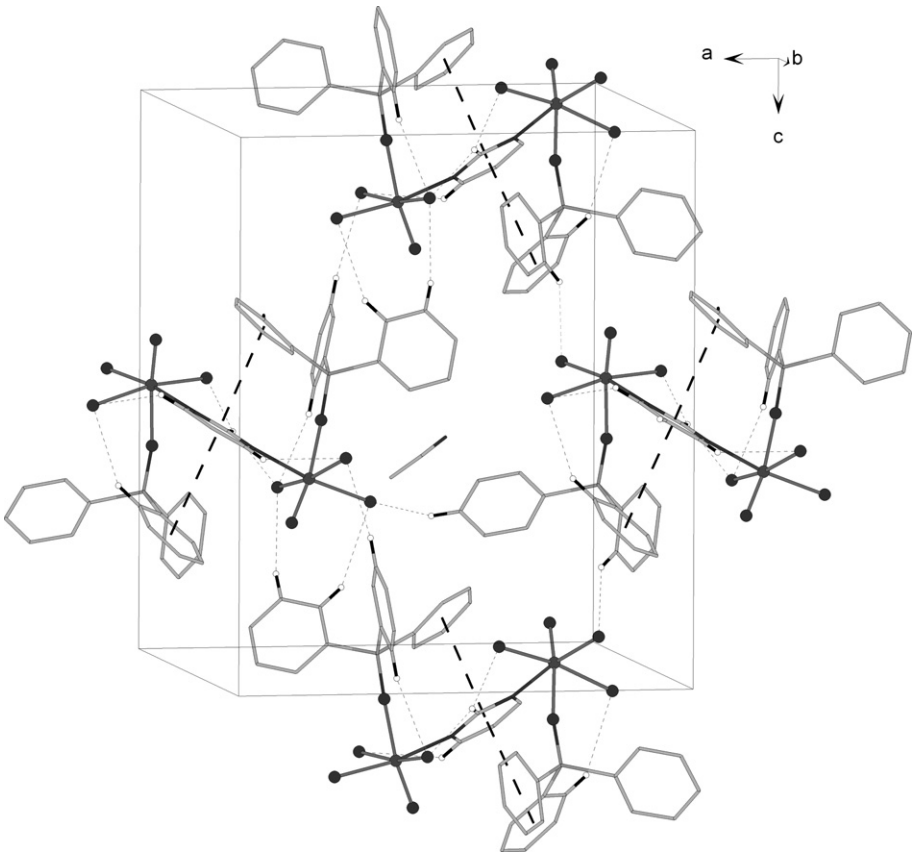

Fig. 4. Packing diagram for **3** showing intramolecular π–π stacking interactions (dashed line) and hydrogen bonding interactions (dotted line), hydrogens not involved in any interaction have been omitted for clarity.

π–π interactions between phenyl ring and the aza ligand are exhibited by the rhenium complex *fac*-$(CO)_3$(dmbpy)Re(I)Ph_3Sn(I) [30] (dmbpy = 4,4′-dimethyl-2,2′-bipyridine). Along with intermolecular ones, unusual intramolecular forces stabilise the coordination geometry of such organometallic complex. The stacking intramolecular interactions reported for complex $ReOCl_3(OPPh_3)(Me_3Bzm)$ [15] (3.58(2) Å c_t–c_t) between the imidazole ring of Me_3Bzm and the aromatic ring of $OPPh_3$ appeared to be responsible for the stability of the complex, too.

The extensive intramolecular π–π interactions observed for all complexes **1**–**4** may contribute to the lack of triphenylphosphine oxide substitution reaction. Another feature of interest is that beside π–π stacking, intra- and intermolecular hydrogen bonding (Figs. 4 and 5) could be responsible for the poor solubility of dimers **3** and **4** as well (see supporting materials).

5. Conclusions

Our endeavours to obtain mononuclear oxo-rhenium(V) complexes with diaza congeners resulted in the mono substituted $ReOCl_3(OPPh_3)$(pym) (**1**) and $ReOCl_3(OPPh_3)$(pyz) (**2**) complexes. Attempts to incorporate a second equivalent of the diaza ligand did not lead to any observable changes, although the pyridine analogue $ReOCl_3(OPPh_3)$(py) reacted further, generating $ReOCl_3(py)_2$. The higher basicity of pyridine compared with pyrimidine or pyrazine (pK_a values of 5.23 for py, 1.30 pym, 0.6 pyz [17]) makes it more favourable to obtain mono or disubstituted complexes as well. The coordination abilities of the monomers **1** and **2** were examined, as a result of which dinuclear complexes $[ReOCl_3(OPPh_3)]_2$(μ-pym) (**3**) and $[ReOCl_3(OPPh_3)]_2$(μ-pym) (**4**) with the diaza linkers were obtained. These are the first oxo-rhenium(V)

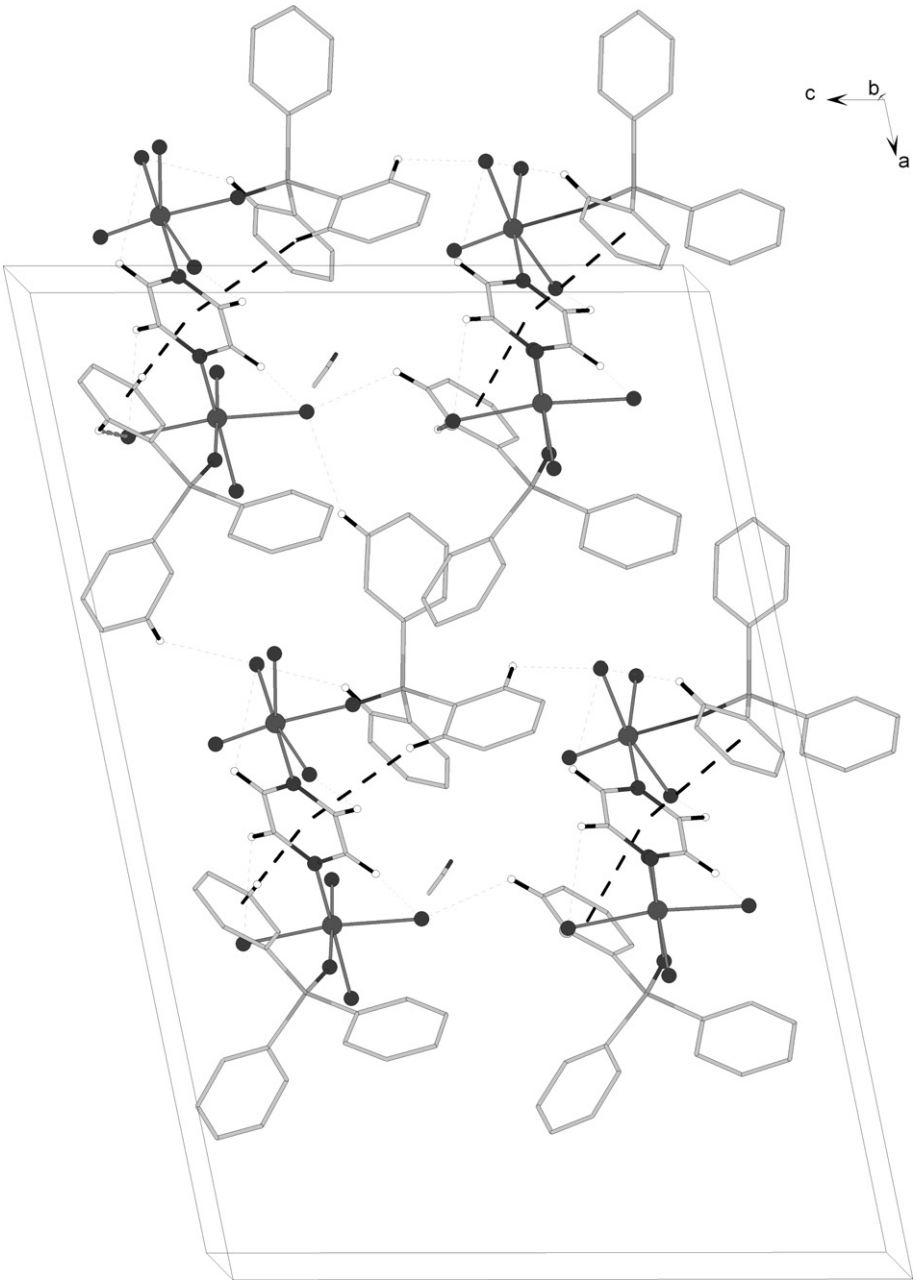

Fig. 5. Packing diagram for **4** showing intramolecular π–π stacking interactions (dashed line) and hydrogen bonding interactions (dotted line), hydrogens not involved in any interaction have been omitted for clarity.

complexes with bridging diaza ligands. All complexes were characterized in solution, three of them **1**, **3** and **4** in a solid state as well. The crystallographic analysis of mono **1** and dinuclear complexes **3**, **4** reveal uncommon examples of one or two intramolecular π–π interactions. The π–π stacking forces impose the geometric constrains on the two rhenium units in **3** and **4** as well. Furthermore, X-ray diffraction studies on **3** and **4** showed that the two units are twisted about Re–(N ∼ N)–Re linkage. The nitrogen ligands are stacked with two phenyl rings corresponding to two molecules of triphenylphospine oxide. ^{1}H NMR studies reveal that $ReOCl_3(OPPh_3)$ moiety induces insignificant coordination shifts in the hydrogens of the diaza ring. The resonances attributed to heterocycle ligands experience either slightly downfield or even upfield ($\Delta\delta = -0.19$ for **4**) chemical shifts. The NMR behaviour of the diaza rings manifests unique π–π stacking interactions that are considered to enhance stability of the structure and contribute significantly to inertness to further substitution reaction.

Acknowledgement

We would like to thank Dr Jerzy Sokolnicki from our Department for attempts to record luminescence excitation spectra.

Appendix A. Supplementary data

CCDC 657244, 657245 and 657246 contains the supplementary crystallographic data for **1**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.02.033.

2.2.2. Synthesis of [Ni(HL)$_2$]

The micro-crystalline product was recrystallized from a solution of absolute ethanol/chloroform (v/v, 1/1) and dried at room temperature; yield: 0.67 g (68%) as an orange coloured solid; m.p. 310 °C (decompose). ^{1}H NMR (300 MHz; $CDCl_3$; J(Hz), Me_4Si) δ = 0.922 (t, $^3J_{H-H}$ = 6.0, 3H, –CH_3), 1.255–1.852 (m, 8H, –CH_2), 4.053 (t, $^3J_{H-H}$ = 6.6, 2H, –OCH_2), 6.787 (d, $^3J_{H-H}$ = 6.9, 1H, –C_5H), 6.850 (s, 1H, –C_3H), 6.972 (d, $^3J_{H-H}$ = 8.4, 2H, —$C_{3'}$H), 7.129 (d, $^3J_{H-H}$ = 8.5, 1H, –C_6H), 8.103 (d, $^3J_{H-H}$ = 7.8, 2H, —$C_{3''}$H), 8.164 (d, $^3J_{H-H}$ = 8.0, 2H, —$C_{2'}$H), 8.770 (s, 1H, –NCH), 8.805 (d, $^3J_{H-H}$ = 7.9, 2H, —$C_{2''}$H), 11.399 (br s, 1H, –NH), and (Ph–OH) absent; ^{13}C{^{1}H} NMR (75.45 MHz; $CDCl_3$; Me_4Si at 25 °C, ppm) δ = 163.933 (–COO), 163.504 (py-CO), 164.132 (–NCH), 150.713 (–C_4), 132.433 (–C_6), 132.054 (—$C_{2'}$), 120.936 (—$C_{1'}$), 114.549 (—$C_{3'}$) and 110.791 (–C_3). m/z (FAB): 121 (py-CONH$^+$, 100), IR (KBr)/cm^{-1}: 3280br ν_s(N–H)$_{amide}$, 1722vs ν(>C=O), 1612w ν(C=N), 1255s ν_{as}(C–O)$_{esteric}$, 1150s ν(C–O)$_{phenol,}$ 485s ν(Ni–N), 450s ν(Ni–O). *Anal.* Calc. for $C_{52}H_{52}N_6O_{10}Ni$ (979.70): C, 63.75; N, 8.58; N_2H_4, 6.53; Ni, 5.99. Found: C, 63.72; N 8.51; N_2H_4, 6.50; Ni, 5.96%.

2.2.3. Synthesis of [Zn(HL)$_2$]

Yield: 0.71 g (72%) as a yellow solid; m.p. 230 °C (decompose); ^{1}H NMR (300 MHz; C_5D_5N; J (Hz), Me_4Si) δ = 0.847 (t, $^3J_{H-H}$ = 6.2, 3H, –CH_3), 1.235–1.718 (m, 8H, –CH_2), 3.981 (t, $^3J_{H-H}$ = 6.5, 2H, –OCH_2), 6.774 (d, $^3J_{H-H}$ = 6.0, 1H, –C_5H), 6.850 (s, 1H, –C_3H), 7.196 (d, $^3J_{H-H}$ = 8.0, 2H, —$C_{3'}$H), 7.438 (d, $^3J_{H-H}$ = 8.1, 1H, –C_6H), 7.387 (d, $^3J_{H-H}$ = 8.0, 2H, —$C_{3''}$H), 7.583 (d, ^3J_H–H = 8.0, 2H, —$C_{2'}$H), 8.750 (s, 1H, –NCH), 8.791 (d, $^3J_{H-H}$ = 7.9, 2H, —$C_{2''}$H), 11.394 (br s, 1H, –NH), and (Ph–OH) absent; ^{13}C{^{1}H} NMR (75.45 MHz; C_5D_5N; Me_4Si at 25 °C, ppm) δ = 163.930 (–COO), 172.415 (py-CO), 168.517 (–NCH), 150.369 (–C_4), 132.624 (–C_6), 114.979 (—$C_{3'}$) and 108.213 (–C_3). m/z (FAB): 121 (py-CONH$^+$, 100), IR (KBr)/cm^{-1}: 3280 ν_s(N–H)$_{amide}$, 1724vs ν(>C=O), 1608w ν(C=N), 1253s ν_{as}(C–O)$_{esteric}$, 1148s ν(C–O)$_{phenol,}$ 482s ν(Zn–N), 448s ν(Zn–O); the IR data for [M(HL)$_2$] (M = Mn, Co and Cu) are similar. *Anal.* Calc. for $C_{52}H_{52}N_6O_{10}Zn$(984.30): C, 63.32; N, 8.52; N_2H_4, 6.50; Zn, 6.63. Found: C, 63.29; N 8.50; N_2H_4, 6.47; Zn, 6.60%.

2.2.4. Synthesis of [ZnL · 2py]

Light-yellow coloured crystalline solid; ^{1}H NMR (300 MHz; C_5D_5N; J (Hz), Me_4Si) δ = 0.845 (t, $^3J_{H-H}$ = 6.1, 3H, –CH_3), 1.230–1.711 (m, 8H, –CH_2), 3.979 (t, $^3J_{H-H}$ = 6.3, 2H, –OCH_2), 6.769 (d, $^3J_{H-H}$ = 6.1, 1H, –C_5H), 6.852 (s, 1H, –C_3H), 7.211 (d, $^3J_{H-H}$ = 8.3, 2H, —$C_{3'}$H), 7.430 (d, $^3J_{H-H}$ = 8.0, 1H, –C_6H), 7.390 (d, $^3J_{H-H}$ = 8.3, 2H, —$C_{3''}$H), 7.580 (d, $^3J_{H-H}$ = 7.9, 2H, —$C_{2'}$H), 8.755 (s, 1H, –NCH), 8.788 (d, $^3J_{H-H}$ = 8.2, 2H, —$C_{2''}$H); ^{13}C{^{1}H} NMR (75.45 MHz; C_5D_5N; Me_4Si at 25 °C, ppm) δ = 164.330 (–COO), 170.517 (–NCH), 151.468 (–C_4), 131.689 (–C_6), 114.980 (—$C_{3'}$) and 108.218 (–C_3), IR (KBr)/cm^{-1}: 1725vs ν(>C=O), 1605s ν(C=N), 1256s ν_{as}(C–O)$_{esteric}$, 1140s ν(C–O)$_{phenol}$, 478s ν(Zn–N), 455s ν(Zn–O). *Anal.* Calc. for $C_{36}H_{35}N_5O_5Zn$ (683.08): C, 63.30; N, 10.25; N_2H_4, 4.68; Zn, 9.57. Found: C, 63.29; N 10.21; N_2H_4, 4.65; Zn, 9.55%.

2.3. Physical measurements

The ^{1}H and ^{13}C NMR spectra were recorded on a JEOL AL-300 MHz FTNMR multinuclear spectrometer; C, H, and N contents were micro analyzed on Elemental Vario EL III Carlo Erba 1108 analyzer. Infrared spectra were recorded on JASCO FT/IR (model-5300) spectrophotometer in the 4000–400 cm^{-1} region. The mass spectra were recorded on JEOL SX-102 (EI/FAB) mass spectrometers. The UV–Vis spectra were recorded on Shimadzu spectrophotometer, model, Pharmaspec, UV 1700. Magnetic susceptibility measurements were made at room temperature on a Cahn-Faraday balance.

2.4. X-ray crystallographic data collection and refinement of the structure

X-ray data for compounds **H_2L** [***ab83m***] and [**ZnL** · 2**py**] [***ab64m***] were collected at room temperature using a Bruker Smart Apex CCD diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) with ω-scan method. Preliminary lattice parameters and orientation matrices were obtained from four sets of frames. Unit cell dimensions were determined from the setting angles of 9745/8981 reflections in the range of 2.69° < θ < 27.85°/ 2.25° < θ < 27.37°. Integration and scaling of intensity data was accomplished using SAINT program [8]. The structure was solved by direct methods using SHELXS97 [9] and refinement was carried out by full-matrix least-squares technique using SHELXL97 [9]. Anisotropic displacement parameters were included for all non-hydrogen atoms. In [ZnL · 2py], the atoms C22, C23 and C24 are disordered over two positions and their site-occupation factors were refined to 0.737(6) and 0.263(6). The distance of the disordered side chain atoms were restraint with DFIX command. In H_2L, all N-bound H atoms, O-bound H atoms and H atoms of the water molecules were located in a difference Fourier map and their positions and isotropic parameters were refined. All other hydrogen atoms were positioned geometrically and treated as riding atoms, with C–H distances in the range of 0.93–0.97 Å and with U_{iso}(H) values of 1.5U_{eq}(C) for methyl hydrogen and 1.2U_{eq}(C) for other hydrogen atoms.

Table 1

3. Results and discussion

3.1. Physical properties and spectral investigation

The white-coloured Schiff-base ligand (H_2L) is soluble in hot chloroform, DMSO, DMF and pyridine but insoluble in water, methanol, ethanol, and acetonitrile; the orange-coloured Ni(II) complex, $[Ni(HL)_2]$, is soluble in chloroform, and hot DMSO and DMF; $[Zn(HL)_2]$/[ZnL · 2py] is only soluble in hot/cold pyridine; all other complexes are soluble in DMSO, DMF and pyridine. The Schiff-base showed a nematic meso-phase at 168 °C under a polarizing microscope while none of the corresponding metal complexes were found to show any mesogenic behaviour. The structures and purity of the parent ligand and of the complexes were checked and confirmed by elemental analyses and IR, ^{1}H NMR and EI/FAB mass spectra.

The room temperature magnetic moments and electronic spectral data of the present complexes are included in Table 1. The overall geometry around the metal ion has been assigned (Table 1) not only on the basis of μ_{eff} values and the nature of the electronic spectra, but also on the basis of denticity of the ligand (vide IR and NMR) and the number of the ligands coordinated to the metal ion (vide elemental analyses). The μ_{eff} values imply anti-ferromagnetic/ferromagnetic type interactions in the Mn(II) and Cu(II) complexes respectively. The Mn^{II} complex provides with extremely weak bands in the electronic spectrum in an octahedral environment of the metal ion [10]. The diamagnetic reddish brown complex, $[Co(HL)_2]$, may be understood to have a low-spin square-pyramidal geometry with M–M bonding [11]. The yellow-coloured complex, $[Ni(HL)_2]$, implies square-planar [12] type geometry; it is fairly common practice to assign the first band to the $^1A_{2g} \leftarrow {}^1A_{1g}$ transition and the second major band to the $^1B_{1g} \leftarrow {}^1A_{1g}$ transition assuming a square-planar geometry [13].

In the IR spectrum of H_2L the broad absorptions centered at 3435 and 3279 cm^{-1} may be assigned to the $\nu(O–H)_{phenol}$ and $\nu_s(N–H)_{amide}$ vibration [14]; further, the strong bands occurring at 1726 and 1253 cm^{-1} may be assigned [14] to $\nu(>C=O)$ and $\nu(C–O)$ modes of aromatic ester; the band occurring at 1626 cm^{-1} may be assigned to $\nu(C=N)$ absorption of the azomethine moiety; these bands are shifted to lower frequencies in the complexes, indicating that the nitrogen atom of the azomethine group is coordinated to the metal ion [15]. Coordination through a nitrogen atom of the ligand is also implied by the appearance of a new band in the complexes in the region, 468–485 cm^{-1}, assignable to $\nu(M–N)$ [16,17]. Coordination through phenolate oxygen to the metal ion is implied by the shifts of the $\nu(C–O)$ band in the complexes [18] and by the appearance of new bands, assignable to $\nu(M–O)$, in the 443–455 cm^{-1} region in the spectra of the complexes.

A comparison of the ^{1}H and $^{13}C\{^1H\}$ NMR spectral data of the ligand with those of the Ni(II) and Zn(II) complexes shows the absence of the phenolic-OH signal (12.311 ppm) and a significant shift in the peak position of the –N=CH signal [from 8.704 ppm of the ligand to 8.770, 8.750, and 8.755 ppm in $[Ni(HL)_2]$, $[Zn(HL)_2]$ and [ZnL · 2py], respectively] and the absence of the –N–H signal at 11.400 ppm exclusively in [ZnL · 2py], a complex of the di-deprotonated ligand, imply bonding through the phenolate oxygen and azomethine nitrogen atoms. Similar shifts observed in the $^{13}C\{^1H\}$ NMR spectra were of considerable magnitude in the case of the carbon atoms directly attached to the bonding atoms and

amidic carbon. Thus, the NMR spectral data imply bi-dentate bonding (>C=N, and phenolate oxygen) of HL^- in [$Ni(HL)_2$] and tri-dentate bonding (>C=N, phenolate oxygen and amidic oxygen) of HL^- and L^{2-}, respectively in [Zn(HL)2] and [ZnL · 2py].

3.2. Crystal structure and molecular association

Both ligands [H_2L] [***ab83m***] and [ZnL · 2py] [***ab64m***] are crystallized in triclinic space group, *viz.*, $P\bar{1}$ with $Z = 4$ and $Z = 2$,respectively. The crystal data and structure refinement details for [H_2L] [***ab83m***] and [ZnL · 2py] [***ab64m***] are given in Table 2. The asymmetric unit of H_2L contains two crystallographically independent molecules and two water molecules, while [ZnL · 2py] comprises one ligand molecule and two pyridine solvent molecules in the asymmetric unit. The molecular structure and atomic labeling scheme of the ligand and the Zn(II) complex are as shown in Figs. 1 and 3 and the packing diagrams of the ligand and the complex are as shown in Figs. 2 and 4.

The bond distances and angles for the [ZnL · 2py] complex are shown in Table 3. As per the crystal structure of the complex, the ligand coordinates to the Zn(II) ion through phenolate oxygen (O(2)), amidic oxygen (O(1))and azomethine nitrogens (N(1)); further, two pyridine molecules act as solvent molecules, thus, rendering the overall geometry around Zn(II) to distorted square pyramid. The details of the hydrogen-bonded geometry of H_2L are tabulated in Table 4. The crystal structure of H_2L is stabilized by both intra- and intermolecular N–H...O, O–H...N and O–H...O hydrogen bond interactions. The two water molecules bridge

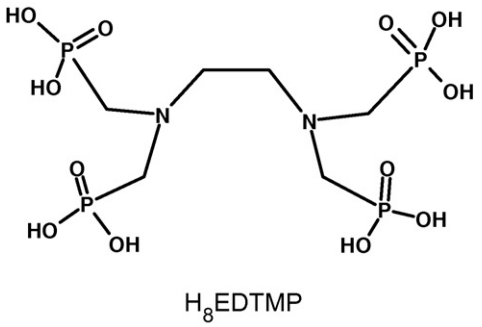
the two ligand molecules through O–H...N and O–H...O hydrogen bonds, thereby forming an infinite hydrogen bonded network chain along the crystallographic *a* axes. Only the non-conventional interactions, *viz*., C–H...O and C–H...N, are observed in the crystal structure of the [ZnL · 2py] complex.

4. Conclusion

The mesogenic (nematic) Schiff-base, *N*-(4″-pyridylcarboxamido)-4-(4′-hexyloxy-benzoato)salicylaldimine (H_2L) coordinates to M(II) (M = Mn, Co, Ni, Cu, Zn) as a uninegative tri-dentate species to yield non-mesogenic complexes of the type, $[M(HL)_2]$, which are believed to involve M–M bonding. The complex $[Zn(HL)_2]$ gives rise, from a solution of pyridine, to single crystals of the non-mesogenic square-pyramidal complex, [ZnL · 2py]; as per the crystal structure, the complex involves di-negative tridentate species of the ligand, L^{2-}, which coordinates to the metal ion through phenolate oxygen, amidic oxygen and azomethine nitrogen atoms.

5. Supplementary data



CCDC 672486 and 672487 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

absorption, the last being calculated from the crystal habit captured from photoscans. The positions of Eu atoms were found from Patterson maps, the rest of the non-H atoms were found from difference Fourier maps. The positions of the C-bonded hydrogen atoms were calculated geometrically. The refinement was full-matrix with all ordered non-H atoms being anisotropic. All computations were performed using SHELXS 97 and SHELXL 97 programs [7]. The molecular graphics was prepared with DIAMOND.[1] The crystal data and structure refinement for **I** are as follows: empirical formula $C_{24}H_{146}Eu_4K_{12}N_8O_{93}P_{16}$, $M = 3608.04$, $T = 100$ K, λ/Å = 0.71073, tetragonal $I\bar{4}c2$, $Z = 8$, $a = 27.43(2)$ Å, $c = 33.17(3)$ Å, $V = 24960(30)$ Å^3, $\mu = 2.702$ mm^{-1}, $\rho_{calc} = 1.920$ g cm^{-3}, $F(000) = 14640$, crystal size = 0.4 × 0.3 × 0.2 mm, $\theta = 3$–28.5°, index ranges = $-36 \leqslant h \leqslant 28$, $-36 \leqslant k \leqslant 35$, $-43 \leqslant l \leqslant 43$, reflections collected/unique = 85266/14973 ($R_{int} = 0.0943$). Final R indices [$I > 2\sigma(I)$] $R(F) = 0.0562$, $R_w(F^2) = 0.1264$ and $R(F) = 0.0793$, $R_w(F^2) = 0.1341$ (all data). Data completeness to $2\theta = 28.6°$, 95.6%. Largest difference in peak and hole 1.024 and −0.819 e Å^{-3}.

2.3. Spectroscopy

The luminescence spectra ($\lambda_{exc} = 394$ nm), corrected for the lamp characteristics, were measured on a SLM Aminco 500 spectrofluorometer at 298 and 77 K. The luminescence decay curves were detected on a device equipped with a Hamamatsu photomultiplier and a Tektronix TDS-3052 digital oscilloscope. The sample was excited with a N_2-pumped dye laser with the monitored emission at 612 nm.

The IR spectra of the complexes in KBr pellets and nujol suspensions were recorded in the range 50–4000 cm^{-1} with a Bruker IF S66 spectrometer.

Electronic absorption spectra were recorded on a Cary 500 UV–Vis–NIR spectrophotometer at 298 K. The oscillator strengths (P) were determined using the equation:

$$P = 4.32 \times 10^{-9}(cd)^{-1} \int A(\sigma)\mathrm{d}\sigma \qquad (1)$$

where c is the concentration of the Eu^{3+} ion in M, d is the length of the optical way in cm and $A(\sigma)$ is the absorbance as the function of the wavenumber in cm^{-1}.

3. Results and discussion

3.1. Structure

Compound **I** crystallizes in the tetragonal system in the $I\bar{4}c2$ space group. There are two symmetry independent Eu^{3+} cations,

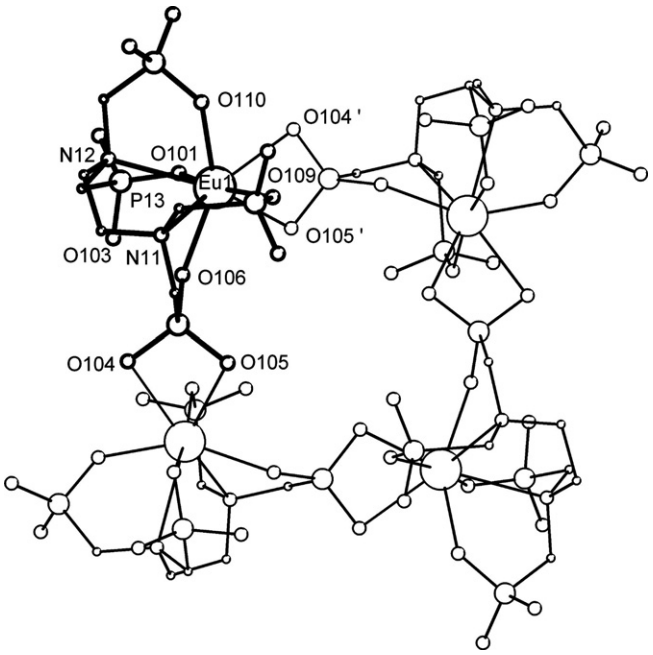

Fig. 1. A view of the tetrameric complex anions in **I**.

Table 1
Selected bond lengths (Å) for **I**

Eu(1)–EDTMP		Eu(2)–EDTMP	
Eu1–O110	2.349(6)	Eu2–O201	2.345(6)

Eu1–N11	2.640(7)	Eu2–N22	2.681(8)
Eu1–N12	2.683(8)	Eu2–N21	2.654(7)
Eu–N_{av}	2.66(3)	Eu–N_{av}	2.67(2)
Eu–Eu	6.301(8)	Eu–Eu	6.327(8)

both are octacoordinate and have an identical composition of the first coordination spheres. Each Eu^{3+} ion is surrounded by two nitrogen atoms and six oxygen atoms from phosphonic groups. The coordination sphere of the Eu^{3+} ions may be described as a distorted square antiprism. The EDTMP anion is involved in bonds with two neighbouring Eu^{3+} cations. Three of the ligand phosphonic groups are monodendate, whereas the fourth one is three-coordinate, *i.e.* one oxygen atom coordinates to Eu1 and the two others (hereinafter called 'bridging') coordinate to a Eu cation generated by symmetry from Eu1. In this way four Eu(EDTMP) entities are bonded together to create a cyclic tetramer with S_4 symmetry (Fig. 1). In a similar fashion, Eu2 generates another tetramer with the same symmetry. The conformations of the tetramers are very similar, the difference being only minute variations of bond lengths and angles. Inside each tetramer a hole is formed and its diameter is 5.2 Å in both cases. The cavities host in part potassium cations and water molecules. The whole structure is held together by a network of complicated hydrogen bonds and electrostatic interactions.

Selected bond lengths are presented in Table 1. In the present structure the average Eu–O bond length equals 2.35(4) Å (where the O atoms belong to the EDTMP molecule wrapped around the respective Eu cation) which is shorter than the average length of

[1] DIAMOND – Visual Crystal Structure Information System, CRYSTAL IMPACT, Postfach 1251, D-53002 Bonn, Germany.

the Eu–O bonds, 2.47(9) Å, formed by the bridging O atoms belonging to the neighbouring EDTMP anions. All Eu–O distances involving non-bridging O atoms are similar to those observed in **II** [6]. The average distance of the remaining four bridging Eu–O bonds is 0.03 Å longer as compared to the Eu–O (bidentate carbonate anion) observed in **II**, probably due to the greater bulkiness of the tetrahedral phosphonate group in comparison with a planar carbonate anion. In **I** the Eu–N average distance is 0.05 Å shorter than that in **II**. The shortest Eu–Eu distances are 6.301(8) Å for Eu(1) and 6.327(8) Å for Eu(2), and are smaller than that in **II** (9.998(3) Å). On average two of the phosphonic groups *per* EDTMP molecule are protonated. The longest P13–O103 distance, 1.582(7) Å, may indicate that the O103 oxygen atom is protonated. The three other protons seem to be disordered. Some of the potassium ions and water molecules are disordered too.

3.2. Spectroscopic results

The low symmetry of the Eu^{3+} ion surroundings has been reflected by the luminescence and absorption spectra of the crystal. The corrected luminescence spectra of **I**, presented in Fig. 2, were measured at 298 and 77 K. The large half-width (23 cm^{-1} at 77 K) of the symmetrical, unsplit $^5D_0 \rightarrow {}^7F_0$ band confirms the results obtained from the X-ray analysis, namely the Eu^{3+} ions are located in very similar coordination environments of a low symmetry.

It is worth stressing that in the present crystal, luminescence from the $^5D_1$ state could also be recorded. This emission, which is not common in Eu^{3+} compounds with organic ligands (it has been observed for example in Eu^{3+} chelates with β-diketones [8–10] and in 1:3 Eu^{3+}:oxydiacetate single crystals of D_3 symmetry at low temperatures [11] as well as in a macrocyclic carboxylate complex incorporated into sol–gel glass [12]), is probably brought about by the saturation of the europium coordination sphere with the phosphonate groups.

Although the $^5D_1$ emission for this compound is significantly less intense than the emission from the $^5D_0$ state, it is observed both at 77 K and at room temperature. The emission intensities of the $^5D_{0,1} \rightarrow {}^7F_J$ transitions determined from the spectra recorded under the same measurement conditions (excitation and emission slits, intensity of the light beam) as well as the ratios of intensities of the $^5D_1 \rightarrow {}^7F_J$ transitions relative to the $^5D_0 \rightarrow {}^7F_J$ ones are presented in Table 2. Since the distances between the $^5D_1$ and $^5D_0$ levels are comparable for both Eu^{3+}–EDTMP compounds and amount to 1744 and 1747 cm^{-1} for **I** and **II**, respectively, one may assume that the luminescence quenching from the $^5D_1$ state in the latter crystal is brought about by one or two high energy phonons which do not occur in **I**. Therefore, comparison between the IR spectra and the $^7F_0 \rightarrow {}^5D_2$ excitation spectra recorded at 77 K (the electron–phonon coupling is the strongest for the hypersensitive transition) of both compounds may be helpful in adjudicating which of the phonons is responsible for the luminescence quenching (Fig. 3). The intense bands observed in the IR spectrum of **I** at 1057 and 1653 cm^{-1} may be attributed to the ν_{P-O} vibration and an overtone or combination bands of the ν_{C-PO_3H} vibrations [13,14], whereas the bands at 1036, 1369 and 1663 cm^{-1} in the spectrum of **II** correspond to ν_{P-O}, ν_{C-O} and δ_{NH_2} vibrations.

As it may be seen in Fig. 3, the vibronics originating from the ν_{P-O} oscillations are observed in the excitation spectra of both compounds. Apart from that, in the spectrum of **II** the ν_{C-O} vibronic component at 22813 cm^{-1} (1369 cm^{-1} off the zero-phonon line) is also detected. Thus, the ν_{C-O} oscillation (with the C–O oscillators

located nearest to the Eu^{3+} cation) fits well in the $^5D_1$–$^5D_0$ gap and is probably responsible for the radiationless decay path of the $^5D_1$ state in the latter compound. Absence of this phonon in **I** may be one of the reasons of a longer luminescence lifetime in this compound than in **II**. The decay lifetimes with estimated error of measurements ±10%, obtained by fitting the curves to a single exponential function, were found as 1340 μs for the present crystal and 1036 μs for the previously studied one [6].

The absorption spectra of **I**, at different orientations of the crystal with respect to the incident light beam, were also measured at room temperature (Fig. 4). The crystal is anisotropic; the intensities of the bands, especially those of the hypersensitive $^7F_0 \rightarrow {}^5D_2$ transition, depend on the orientation of the crystal, whereas the energies of all the crystal field components do not change. The orientation averaged oscillator strength values of the f–f transitions of the complex are given in Table 3. One may notice that the average oscillator strength value of the $^7F_0 \rightarrow {}^5D_2$ transition for **I** is similar to that observed in **II**, which may result from the analogous arrangement of the first coordination sphere of the Eu^{3+} ion. The splitting of the f–f levels is also similar, although the $^7F_0 \rightarrow {}^5D_{0,1,2}$ bands in the present complex are slightly (a few cm^{-1}) red-shifted in comparison to those observed in **II** (Fig. 4). The high value of the oscillator strength of the $^7F_0 \rightarrow {}^5D_0$ transition as well as the large half-width of this band at 298 K (15 cm^{-1}) may be connected to the low symmetry of the surroundings of the Eu^{3+} ions.

Table 3
Oscillator strength values (P) of **I** determined at different orientations of the crystal (I–III)

Transitions	I, $P \times 10^8$	II, $P \times 10^8$	III, $P \times 10^8$	$P_{av} \times 10^8$
$^7F_0 \rightarrow {}^5D_0$	0.44	0.69	0.63	0.59
$^7F_0 \rightarrow {}^5D_1$	1.55	1.72	1.63	1.63
$^7F_0 \rightarrow {}^5D_2$	14.23	21.62	24.70	20.18
$^7F_0 \rightarrow {}^5L_6$	132.25	144.62	157.42	144.76

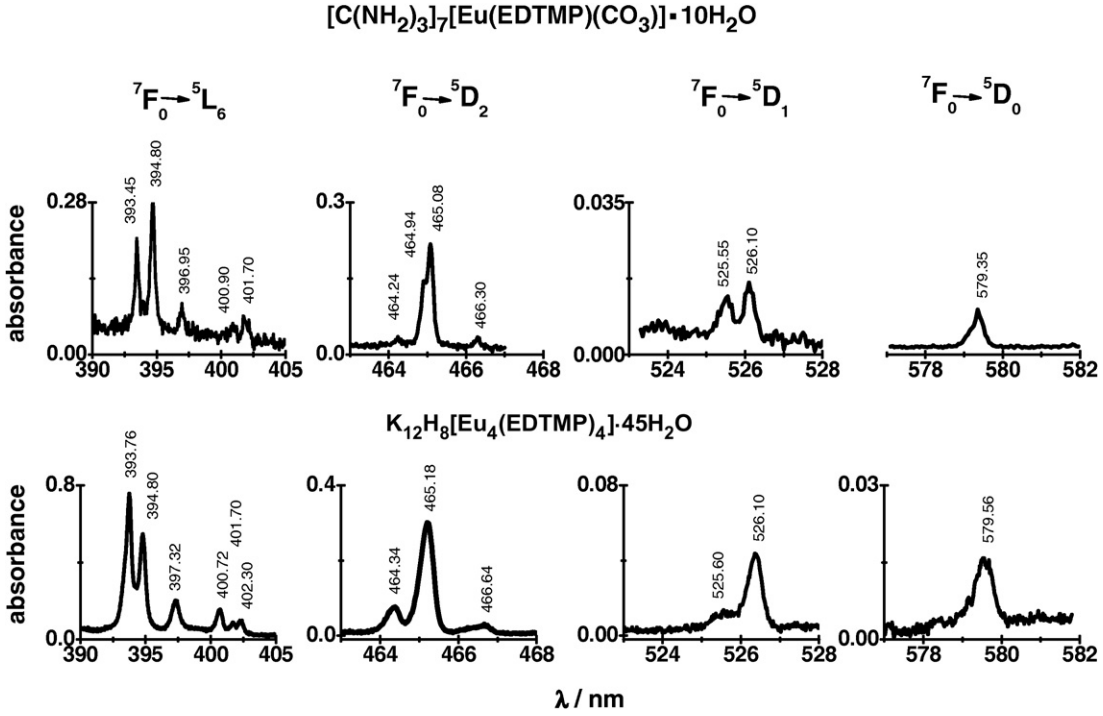

Fig. 4. Absorption spectra of the f–f transitions of **I** and **II** [6] at 298 K. For **II** instead of the the $^7F_0 \rightarrow {}^5D_0$ absorption spectrum, which could not be recorded due its low intensity, the luminescence excitation spectrum of this transition is displayed.

4. Conclusions

The coordination sphere of the Eu^{3+} ion in the studied crystal consists of the same donor atoms (six oxygen atoms, two nitrogen atoms) as in the previously reported structure of **II** [6]. However, it should be noted that two of the coordinated oxygen atoms are of different origin for the two crystals. In the present crystal they belong to a tridentate phosphonate group, giving thus rise to formation of cyclic tetrameric complex anions, whereas in the former monomeric complex anion they come from the bidentate carbonate anion.

Although such differences of the Eu^{3+}–EDTMP complex structure do not influence the oscillator strengths of the f–f transitions significantly, they affect the luminescence lifetimes of the excited states of the Eu^{3+} ion. The more rigid structure of **I** is a reason for a longer (approximately 300 μs) europium $^5D_0$ level lifetime, as compared to that found for **II**. The present crystal, contrary to the former one, also displays luminescence from both $^5D_0$ and $^5D_1$ states.

The structural and spectroscopic results presented here, show that the acyclic polyaminopolyphosphonate ligands, upon interacting with Ln^{3+} cations, may form non-trivial complexes with interesting properties.

Scheme 1. Versatility of the pincer framework.

and requires a series of steps to introduce different groups or donors. Moreover, complexes bearing asymmetric pincer ligands have shown enhanced and in many cases markedly different reactivities, such as hemilability [11].

From the above discussion, it clearly results that the design of ligands is one of the most important aspects in the chemistry of this kind of compounds, this being specially important in homogeneous catalysis. The ability to simply and independently vary the steric and electronic properties of a given ligand may provide a wealth of opportunities to influence reactivity, stability, catalysis and other important properties at the metal center. Hence, following our continuous interest in the development on pincer chemistry [12], herein we would like to report a simple protocol for the high yield synthesis of the asymmetric ligand [C_6H_4-1-(CH_2PPh_2)-3-($CH(CH_3)PPh_2$)] (**4**) and its Pd(II) derivative [PdCl{C_6H_3-2-(CH_2PPh_2)-6-($CH(CH_3)PPh_2$)}] (**5**).

2. Experimental

2.1. Materials and methods

Unless otherwise stated, all reactions were carried out under an atmosphere of purified argon using conventional Schlenk glassware and glovebox techniques; solvents were dried using the established procedures and distilled under dinitrogen and freeze–pump–thaw degassed immediately prior to use. The ^1H, $^{13}C\{1H\}$, $^{31}P\{^1H\}$ NMR spectra were recorded at 300, 75.4 and 121.4 MHz, respectively at 295 K, using a Bruker Avance DRX 300 MHz NMR spectrometer. ^1H NMR and $^{13}C\{^1H\}$ NMR chemical shifts are reported in ppm downfield from TMS. ^1H NMR chemical shifts are referenced to the residual hydrogen signal of the deuterated solvents and in $^{13}C\{^1H\}$ NMR the ^{13}C signal of the deuterated solvents was used as a reference. $^{31}P\{^1H\}$ NMR chemical shifts are reported in ppm downfield from H_3PO_4 and referenced to high frequency of 85% H_3PO_4. Elemental analyses were determined on a Heraeus CHN-O-RAPID elemental analyzer. The starting materials α,α′-dibromo-*m*-xylene, chlorodiphenylphosphine, $PdCl_2$, $CDCl_3$ were purchased from Aldrich Chemical Co. and used without further purification. The complex [$PdCl_2$-(COD)] was synthesized according to the published procedure [13].

2.2. Synthesis of {C_6H_4-1-(CH_2Br)-3-(CH_2PPh_3Br)} (**1**)

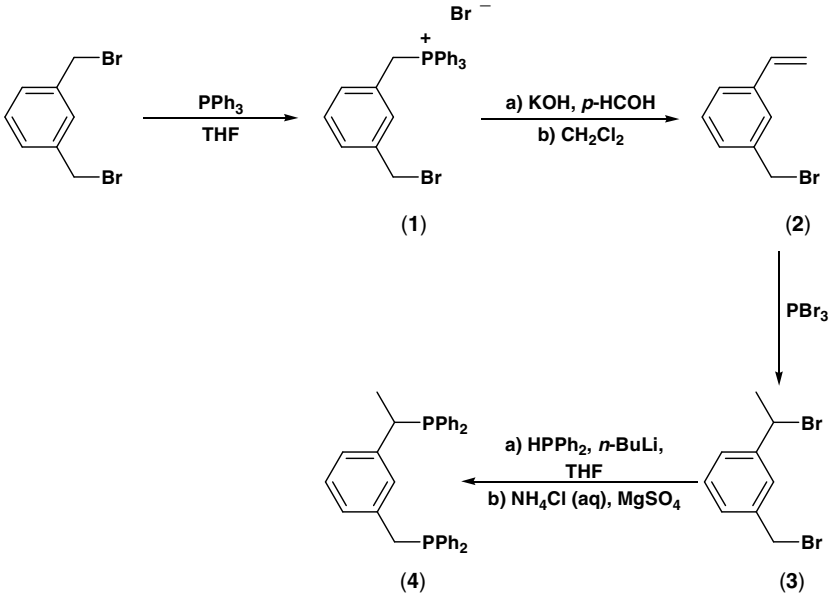
To a stirred solution of α,α′-dibromo-*m*-xylene (3.70 g, 14 mmol) in THF (100 ml) was added a solution of triphenylphosphine (4.3 g, 16 mmol) in THF (20 ml) at room temperature and the solution allowed to reach 60 °C slowly. The resulting white suspension was stirred overnight. The reaction mixture was allowed to reach room temperature, the mixture was filtered off and the remaining solid was washed with THF (3 × 10 ml) and dried under vacuum to give a pure white powder of **1** (6.3 g, 12 mmol, 85%). ^1H NMR (300 MHz, $CDCl_3$): δ 4.17 (s, 2H, CH_2Br); 5.32 (d, $J = 14.39$ Hz, CH_2P); 6.97–7.27 (m, 4H, Ph); 7.53–7.73 (m, 15H, PPh_3). $^{13}C\{^1H\}$ NMR (75.40 MHz, $CDCl_3$): δ 30.37 (d, $J_{CP} = 47.66$ Hz, CH_2P); 32.64 (CH_2Br); 116.62, 117.76, 127.64, 128.83, 129.09, 130.01 (d, $J = 12.1$ Hz), 131.29, 131.90, 134.09 (d, $J = 9.80$ Hz) 134.84, 138.08. $^{31}P\{^1H\}$ NMR (121 MHz, $CDCl_3$): δ 24.22. *Anal.* Calc. for $C_{26}H_{23}Br_2P$ ($M_r = 526.24$): C, 59.34; H, 4.41. Found: C, 59.38; H, 4.45%.

2.3. Synthesis of {C_6H_4-1-(CH_2Br)-3-($CH{=}CH_2$)} (**2**)

To a stirred solution of **1** (2.63 g, 5 mmol) in dichloromethane (40 ml) was added *para*-formaldehyde (0.27 g, 9 mmol) and KOH solution (6 ml, 50%) at room temperature, respectively and stirred for 1 h. The organic layer was separated and the aqueous layer extracted with ether. The combined organic extracts were washed and dried over $MgSO_4$. After filtration, the solution was passed through a short plug of celite and the solvent evaporated under vacuum to afford a white solid. The remaining solid was extracted with *n*-hexane and then the solvent evaporated under vacuum to afford **2** as a pure colorless oil (0.79 g, 4 mmol, 80%). ^1H NMR (300 MHz, $CDCl_3$): δ 4.37 (s, 2H, CH_2Br), 5.18 (d, $J_{HH} = 11.1$ Hz, 1H, CH_2), 5.67 (d, $J_{HH} = 17.4$ Hz, 1H, $CH{=}CH_2$), 6.60 (dd, $J_{HH} = 17.70$ HZ, $J_{HH} = 10.8$ Hz, $CH{=}CH_2$), 7.15–7.314 (m, 4H, Ar). $^{13}C\{^1H\}$ NMR (75.40 MHz, $CDCl_3$): δ 33.39 (CH_2Br), 114.54 ($CH{=}CH_2$), 126.17, 126.78, 128.32, 128.93, 136.13

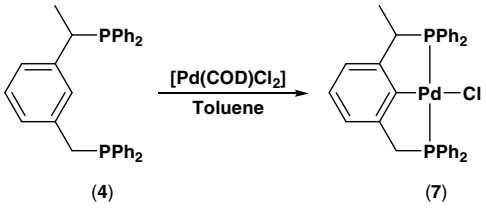
(CH=CH_2), 137.93, 138.02. *Anal.* Calc. for C_9H_9Br ($M_r = 197.07$): C, 54.85; H, 4.60. Found: C, 54.90; H, 4.57%.

2.4. Synthesis of {C_6H_4-1-(CH_2Br)-3-($CH(CH_3)Br$)} (3)



To a stirred solution of **2** (0.62 g, 3.1 mmol) in dichloromethane (15 ml), PBr_3 (0.123 ml, 1.3 mmol) was added at room temperature and stirred for 3 h. After this time, the solution is then washed with aqueous $NaHCO_3$ and then with water, the organic phase is separated and the aqueous layer extracted twice with CH_2Cl_2 (2 × 10 ml). The organic phase is dried over $MgSO_4$ and the solvent removed by rotary evaporation to afford **3** as a colorless oil (0.86 g, 3.1 mmol, 98%). ^{1}H NMR (300 MHz, $CDCl_3$): δ 1.95 (d, $J = 6.90$ Hz, 3H, CH_3); 4.39 (s, 2H, CH_2Br); 5.10 (q, $J = 6.90$ Hz, 1H, CH), 7.15–7.36 (m, 4h, Ar). $^{13}C\{^1H\}$ NMR (75.40 MHz, $CDCl_3$): δ 26.65 (CH_3), 33.01 (CH_2Br), 48.76 (CHBr), 126.83, 127.35, 128.94, 129.13, 138.13, 143.74. *Anal.* Calc. for $C_9H_{10}Br_2$ ($M_r = 277.98$): C, 38.89; H, 3.63. Found: C, 38.85; H, 3.65%.

2.5. Synthesis of {C_6H_4-1-(CH_2PPh_2)-3-($CH(CH_3)PPh_2$)} (4)



To a solution of Ph_2PH (1.17 g, 6 mmol) in THF (35 ml) was added dropwise a solution of *n*-BuLi in hexane (3.75 ml of 1.6 M/l hexane solution, 6 mmol) at −78 °C, over a period of 30 min with stirring. After this time, the reaction mixture was allowed to reach room temperature. The resulting orange suspension was cooled to −78 °C and a THF solution (20 ml) of **3** (0.834 g, 3 mmol) was added dropwise with a syringe over 30 min. The resulting mixture is allowed to reach room temperature and the stirring continued for an additional 1 h to give a clear mixture. After this time, the resulting reaction mixture is placed into a salt-ice bath (0 °C) and a solution of NH_4Cl in water (10 wt%, 45 ml) is carefully added to afford a colorless mixture. The THF layer was separated and the aqueous layer extracted twice with ether (2 × 15 ml). The combined extracts were dried over $MgSO_4$ and passed through a short column of alumina. Finally, the solvent was removed under vacuum to afford **4** as a colorless oil (1.39 g, 2.85 mmol, 95%). ^{1}H NMR (300 MHZ, $CDCl_3$): δ 1.02 (dd, $^3J_{HP} = 14.7$ Hz, $^3J_{HH} = 7.35$ Hz, 3H, CH_3), 2.94 (d, $^2J_{HP} = 18$ Hz, 2H, CH_2P), 3.10 (m, 1H, CHP), 6.52–6.91 (m, 20H, PPh_2), 7.04–7.30 (m, 4H, Ar). $^{13}C\{^1H\}$ NMR (75.40 MHz, $CDCl_3$): δ 20.17 (d, $J_{CP} = 21.2$ Hz, $CHPPh_2$), 36.26 (d, $J_{CP} = 16.1$ Hz, CH_2PPh_2); 39.47 (d, $J_{CP} = 13.2$ Hz, CH_3), 126.60 (d, $J = 5.3$ Hz), 127.67, 128.00, 128.15, 128.33, 128.52, 128..60, 128.69, 129.23, 129.90, 130.76, 131.34, 133.08, 133.28, 133.33, 133.39, 133.53, 133.62, 134.36, 134.64, 137.80, 137.91, 138.02, 138.49, 139.12 (d, $J = 4.8$ Hz), 143.96 (d, $J = 8.60$ Hz), Ar. $^{31}P\{^1H\}$ NMR (121 MHz, $CDCl_3$): δ −9.157 (CH_2PPh_2), 2.69 ($CHPPh_2$). *Anal.* Calc. for $C_{33}H_{30}P_2$ ($M_r = 488.54$): C, 81.13; H, 6.19. Found: C, 81.20; H, 6.25% (see Scheme 2).

2.6. Synthesis of [PdCl{C_6H_3-2-(CH_2PPh_2)-6-($CH(CH_3)PPh_2$)}] (7)

To a stirred suspension of [Pd(COD)Cl_2] (0.777 g, 2.72 mmol) in toluene (25 ml), a solution of ligand **4** (1.329 g, 2.72 mmol) in toluene (20 ml) was slowly added. The resulting solution was set to reflux for 5 h. After this time, the solution was filtered over cotton pad and pumped

Scheme 2. Synthesis of the asymmetric PCP pincer ligand (**4**).

Scheme 3. Synthesis of the asymmetric Pd(II)-PCP pincer complex (**7**).

off under vacuum to dryness. The crude solid was purified by recrystallization from $CHCl_3$/MeOH to afford complex **7** as a white microcrystalline powder (1.46 g, 2.31 mmol, 85%): ^{1}H NMR (300 MHZ, $CDCl_3$): δ 1.02 (dd, $^3J_{HP} = 16.04$ Hz, $^3J_{HH} = 7.1$ Hz, 3H, CH_3), 3.82 (d, $J = 6$ Hz, 2H, CH_2PPh_2), 4.00 (m, 1H, $CHPPh_2$), 6.95–7.04 (m, 3H, Ar), 7.26–7.82 (m, 20H, Ar). $^{13}C\{^1H\}$ NMR (75.40 MHz, $CDCl_3$): δ 21.46 (s, CH_3), 49.37 (d, $J =$ 31.0 Hz, CH_2PPh_2), 46.31 (d, $J = 30.4$ Hz, $CH(CH_3)PPh_2$), 122.56 (d, $J = 20.7$ Hz), 123.54 (d, $J = 22.4$ Hz), 126.21, 128.52 (d, $J = 24.1$ Hz), 128.55, 129.98, 130.42, 130.86, 132.13 (d, $J = 9.7$ Hz), 132.97 (d, $J = 17.3$ Hz), 132.99, 134.92 (d, $J = 10.86$ Hz), 147.67 (d, $J = 21.2$ Hz), 153.87(d, $J = 22.3$ Hz). $^{31}P\{^1H\}$ NMR (121 MHz, $CDCl_3$): δ 34.32 (d, $J_{PP} = 418$ Hz, CH_2PPh_2), 48.57 (d, $J_{PP} =$ 418 Hz, $CH(CH_3)PPh_2$). *Anal.* Calc. for $C_{33}H_{29}ClP_2Pd$ ($M_r = 629.40$): C, 62.97; H, 4.64. Found: C, 63.00; H, 4.60% (see Scheme 3).

3. Results and discussion

The initial step for the formation of PCP pincer ligand (**4**) very much resembles the initial step employed by Shaw on his seminal report in the 1970s [14]. Thus, α,α′-dibromo-*m*-xylene was treated with one equivalent of triphenylphosphine in THF to afford the single substituted triphenyphosphonium salt {C_6H_4-1-(CH_2Br)-3-(CH_2PPh_3Br)} (**1**). Analysis of the solid product (**1**) by ^{1}H reveals that the α,α′-dibromo-*m*-xylene has been substituted in only one arm. Thus, signals corresponding to two different CH_2 groups in the molecule can be observed, a singlet corresponding to the CH_2Br located at δ 4.17 ppm and a doublet due to the presence of the CH_2PPh_3Br found at δ 5.32 ppm. Similar assignation can be done from the results obtained from the analysis of the same sample by $^{13}C\{^1H\}$ NMR, where besides the signals observed for the aromatic carbons in the usual region (δ 116–138 ppm) signals corresponding to the two different CH_2 can be observed at δ 32.64 and δ 30.37 ppm for the CH_2Br and CH_2PPh_3Br moieties, respectively. Furthermore, the presence of the phosphonium group was detected by $^{31}P\{^1H\}$ NMR, this analysis showing a single signal at δ 22.24 ppm due to the PPh_3Br group. Elemental analysis is also consistent with the proposed formulation.

In contrast to the procedure employed by Shaw [14], where the phosphonium salt was treated with a mild base to afford the corresponding phosphine, compound (**1**) was treated with a strong base (KOH) in the presence of an excess of *para*-formaldehyde to afford the Witting [15] product {C_6H_4-1-(CH_2Br)-3-($CH{=}CH_2$)} (**2**). Analysis of this compound by ^{1}H NMR shows a typical pattern for a single substituted ethylene type olefin, exhibiting two sets of doublets for the terminal protons of the alkene at δ 5.18 and δ 5.67 ppm and a doublet of doublets for the methyne group at δ 6.60 ppm. A further singlet at δ 4.37 ppm and signals due to the aromatic protons between δ 7.15 and 7.31 ppm are also observed in the spectrum.

Bromination of the olefin compound (**2**) with PBr_3 gives place to the formation of the asymmetric dibromo starting material {C_6H_4-1-(CH_2Br)-3-($CH(CH_3)Br$)} (**3**). This compound afforded a ^{1}H NMR spectrum where the most notorious signal is a doublet located at δ 1.95 ppm corresponding to the newly formed CH_3 group in one of the arms. Complementary to this signal is a quartet at δ 5.10 ppm due to the methyne group of the same arm. While the signal corresponding to the un-substituted arm and those due to the aromatic protons can be observed at δ 4.39 and 7.15–7.36 ppm, respectively. Signals concurrent with the previous analysis can be observed at δ 26.65, 33.01 and 48.76 ppm in the $^{13}C\{^1H\}$ NMR spectrum, these signals being assigned to the methyl, methylene and methyne groups in (**3**), respectively. Results obtained from elemental analysis are also in agreement with the proposed formulation.

The final step leading to the synthesis of the PCP pincer ligand involved the reaction of the lithium salt of the diphenylphosphine with the dibromo compound (**3**), at a low temperature to afford compound {C_6H_4-1-(CH_2PPh_2)-3-($CH(CH_3)PPh_2$)} (**4**) as an air sensitive colorless oil in excellent yield (95%). Once again signals corresponding to the CH_3, CH_2 and CH groups can be observed in the corresponding ^{1}H NMR spectrum at δ 1.02 (dd), 2.94 (d) and 3.10 (m) ppm, respectively. The substitution of the bromides for the phosphine groups can be inferred for the multiplicity observed in these signals due to the coupling with the *P* nuclei and for the shift of these signals to higher field due to the inductive effect of the phosphine moieties. As is the case for the previous intermediates, a similar behavior is observed in the $^{13}C\{^1H\}$ NMR. More illustrative are the results of the analysis by $^{31}P\{^1H\}$ NMR, where two different signals, due to two inequivalent phosphorus nuclei are observed; one due to the substituted arm at a lower field (δ 2.69 ppm) and the other centered at δ −9.16 ppm. It is very interesting to note that these chemical shifts agree well when compared to the bis-disubstituted ligand {C_6H_4-1,3-($CH(CH_3)PPh_2$)} (**5**) reported by Venanzi [16] and Zhang [17] and the simple PCP pincer ligand {C_6H_4-1,3-(CH_2PPh_2)} (**6**) reported earlier by Venanzi [18] with only very slight variations (Fig. 1).

As for most of the cases, metallation of ligand (**4**) proceeds in a very facile manner via the C–H activation of the aromatic ring by $[Pd(COD)Cl_2]$ under reflux using toluene as solvent. The white product of [PdCl{C_6H_3-2-(CH_2PPh_2)-6-($CH(CH_3)PPh_2$)}] (**7**) thus obtained was

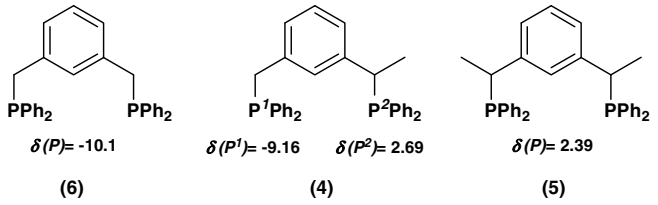


Fig. 1. Chemical shift (δ) Comparison between symmetric PCP pincer ligands and compound (**4**).

analyzed by ^{1}H NMR, showing signals similar to those of the free ligand but slightly shifted to lower field, a fact that agrees well with the metal being coordinated to the ligand. This argument is also supported for the more notorious shift to the lower field of the signals in the $^{31}P\{^{1}H\}$ NMR spectra, passing from δ −9.16 and δ 2.69 ppm in the free ligand (**4**) to δ 34.32 and δ 48.57 ppm in the metallated complex (**7**) for the CH_2PPh_2 and $CH(CH_3)PPh_2$, respectively. Moreover, the signals of the phosphorus nuclei of compound (**7**) are shown as doublets, which also accounts for the ligand to be coordinated to the metal in a κ^2-P,P form. Besides the J^2_{pp} value of 418 Hz, it is consistent with a *trans* arrangement of the two phosphorus nuclei. Once again, the chemical shifts observed for (**7**) agree well when compared to their symmetric analogous [PdCl{C_6H_3-2,6-($CH(CH_3)PPh_2$)$_2$}] (**8**) [16,17b] and [PdCl{C_6H_3-2,6-(CH_2PPh_2)$_2$}] (**9**) [18] (Fig. 2).

Results obtained from elemental analysis are also in agreement with the proposed formulation. Unfortunately, multiple attempts to obtain suitable crystals of complex (**7**) for their analysis by single crystals X-ray diffraction techniques afforded in amorphous powder or very low quality crystals all cases.

In summary, the present method represents an attractive and easy to perform methodology for the synthesis of asymmetric PCP pincer ligands and their palladium derivatives. It is important to note that the method may not be limited to the synthesis of ligand (**4**) but by careful selection of the aldehyde and reaction conditions, the methyl group in the substituted arm can be changed for various other substituents or even lead to the elongation of the arm thus affording another group of potentially interesting PCP pincer ligands having 5 and 6 membered rings. Moreover, exploitation of the different reactivities of the two different arms in compound (**3**) may offer the opportunity to attain PCP pincer ligands with different donor groups, since it is expected that the more substituted arm would react slowly when compared to the un-substituted arm. Experiments aimed to confirm these theories and the synthesis of other group 10 transition metal derivatives of ligand (**4**) and the study of the potential activity of complex (**7**) are currently underway in our laboratories.

Fig. 1. Molecular Structures of (a) zinc tetrasulfo phthalocyanine (ZnTSPc), (b) zinc tetracarboxy phthalocyanine (ZnTCPc) and (c) zinc octacarboxyphthalocyanine (ZnOCPc).

monohydrate, sodium borohydride, ammonium chloride, ammonium molybdate, urea, sodium hydroxide, and sulphuric acid were obtained from Saarchem. 1,8-Diazabicyclo[5,4,0]undec-7-ene (DBU) was obtained from Fluka. Ultra pure water was obtained from a Milli-Q Water System (Millipore Corp., Bedford, MA, USA). Solvent mixture: (1:1, 0.1 M NaOH, ethanol) was employed.

2.2. Synthesis of ZnPc derivatives and quantum dots

Zinc tetracarboxy (ZnTCPc), octacarboxy (ZnOCPc) and tetrasulphonated (ZnTSPc) phthalocyanines were synthesized and characterized according to reported methods [27–30]. CdTe quantum dots were synthesized using wet chemical routes with thioglycolic acid and 2-mercaptoethanol cappings, using reported methods [4]. Briefly, $CdCl_2$ 0.22 g (1.18 mmol) was dissolved in 65 mL of deionized water and 0.26 g (2.86 mmol) TGA or 2-ME was added to the $CdCl_2$ solution. The pH of this precursor solution was adjusted to 11.5 with 1 M NaOH and left under a flow of nitrogen gas for half an hour. The solution of NaHTe was prepared by modified literature method [4] as follows: 0.05 M NaOH was reacted with H_2Te gas (the latter generated by reaction of $NaBH_4$ with Te powder in the presence of 0.5 M H_2SO_4 under a flow of nitrogen gas). Then the freshly prepared NaHTe 0.18 g (1.2 mmol) was added to the precursor solution. The solution was then refluxed under air at 100 °C for different times to control the size of the CdTe QDs. Precipitation of the QDs from the aqueous colloidal solution was achieved by using propan-2-ol yielding a yellow–green and orange–maroon colour of CdTe quantum dots powder for 2-ME and TGA cappings, respectively.

The quantum dots sizes were estimated using a polynomial fitting function (Eq. (1)) derived in the literature [36]

$$D = (9.8127 \times 10 - 7)\lambda^3 - (1.7147 \times 10 - 3)\lambda^2 + (1.0064)\lambda - (194.84) \quad (1)$$

where λ is the absorption maxima of the QDs. The fitting function is not valid for sizes of quantum dots outside the size range of 1–9 nm [36]. It is valid in this work since as reported before [32] the quantum dots sizes are within this range.

2.3. Photophysical studies

Fluorescence quantum yields (Φ_F) were determined by comparative method [37] using the following equation:

$$\Phi_F = \Phi_{F(Std)} \frac{F \cdot A_{Std} \cdot n^2}{F_{Std} \cdot A \cdot n_{Std}^2} \quad (2)$$

where F and F_{Std} are the areas under the fluorescence curves of the MPc derivatives and the reference, respectively. A and A_{Std} are the absorbances of the sample and reference at the excitation wavelength, and n and n_{Std} are the refractive indices of solvents used for the sample and standard, respectively. ZnPc in DMSO was used as a standard, $\Phi_F = 0.20$ [38] for the determination of fluorescence quantum yields of the ZnPc derivatives in the 0.1 M NaOH:ethanol solvent mixture. Rhodamine 6G in ethanol with $\Phi_F = 0.94$ was employed as the standard for the quantum dots [39,40]. Both the sample and the standard were excited at the same relevant wavelength. The fluorescence quantum yields of the QDs are represented as $\Phi_{F(QD)}$, where QD represents either 2-ME or TGA capped QDs. And for ZnPc complexes the Φ_F are represented as $\Phi_{F(ZnPc)}$ (where ZnPc represents ZnTSPc, ZnOCPc, ZnTCPc). The determined fluorescence quantum yield values of the QDs were employed in determining their fluorescence quantum yields in the mixture with ZnPc derivatives ($\Phi_{F(QD)}^{Mix}$) using a modified form of Eq. (2) as shown by

$$\Phi_{F(QD)}^{Mix} = \Phi_{F(QD)} \frac{F_{QD}^{Mix}}{F_{QD}} \quad (3)$$

where $\Phi_{F(QD)}$ is the fluorescence quantum yield of the QDs alone, and was used as standard, $F_{QD}{}^{Mix}$ is the fluorescence intensity of QDs in the mixture (with ZnPc derivatives) when excited at the excitation wavelength of the QDs (500 nm) and F_{QD} is the fluorescence intensity of the QD alone at the same excitation wavelength.

Triplet quantum yields were determined using a comparative method based on triplet decay, using the following equation:

$$\Phi_T^{Sample} = \Phi_T^{Std} \frac{\Delta A_T^{Sample} \cdot \varepsilon_T^{Std}}{\Delta A_T^{Std} \cdot \varepsilon_T^{Sample}} \quad (4)$$

where ΔA_T^{Sample} and ΔA_T^{Std} are the changes in the triplet state absorbance of the MPc derivatives and the standard, respectively. ε_T^{Sample} and ε_T^{Std} are the triplet state extinction coefficients for the ZnPc derivative and standard, respectively, and were determined as previously reported [41]. Φ_T^{Std} is the triplet state quantum yield for the standard, ZnTSPc in aqueous solution, $\Phi_T^{Std} = 0.56$ [42]. Φ_T was also determined for the mixture of QDs and ZnPc derivatives and is represented as $\Phi_{T(ZnPc)}^{Mix}$ and the corresponding triplet lifetime as $\tau_{T(ZnPc)}^{Mix}$. The error in the determination of triplet yield was ±10%.

2.4. Determination of FRET parameters

Fluorescence resonance energy transfer (FRET) involves energy transfer from a photoexcited donor fluorophore to an acceptor fluorophore of a different species which is in close proximity. FRET is dependent on the center-to-center separation distance between

donor and acceptor (r), the degree of spectral overlap of the donor's fluorescence emission spectrum and the acceptor's absorption spectrum [33,40]. There is a decrease of the donor photoemission and an increase in the acceptor's fluorescence when FRET has occurred. FRET efficiency (Eff) is determined experimentally from the fluorescence quantum yields of the donor in the absence ($\Phi_{F(QD)}$) and presence ($\Phi^{Mix}_{F(QD)}$) of the acceptor using Eq. (5) [33,40]

$$\text{Eff} = 1 - \frac{\Phi^{Mix}_{F(QD)}}{\Phi_{F(QD)}} \quad (5)$$

FRET efficiency (Eff) is related to r (Å) by Eq. (6) [40]

$$\text{Eff} = \frac{R_0^6}{R_0^6 + r^6} \quad (6)$$

where R_0 (The Förster distance, Å) is the critical distance between the donor and the acceptor molecules for which efficiency of energy transfer is 50% and depends on the quantum yield of the donor, Eq. (7) [40]

$$R_0^6 = 8.8 \times 10^{23} \kappa^2 n^{-4} \Phi_{F(QD)} J \quad (7)$$

where κ^2 is the dipole orientation factor; n, the refractive index of the medium; Φ_F, the fluorescence quantum yield of the donor in the absence of the acceptor; and J (cm^6) is the Förster overlap integral, defined by

$$J = \int f_{QD}(\lambda)\varepsilon_{ZnPc}(\lambda)\lambda^4 d\lambda \quad (8)$$

where f_{QD} is the normalized QD emission spectrum and ε_{ZnPc}, is the molar extinction coefficient of ZnPc derivatives. In this case, it is assumed that κ^2 is 2/3; such assumption is often made for donor–acceptor pairs in a liquid medium, which are considered to be isotropically oriented during their fluorescence lifetimes. λ is the wavelength of the acceptor, the Q band. FRET parameters were computed using the programme PhotochemCAD [43]. The overlap integral (J) has been defined in several ways with different units [40]. The program PhotochemCAD gives the units as cm^6 using ε in $M^{-1}\,cm^{-1}$ and the wavelength in nm.

2.5. Equipment

Fluorescence excitation and emission spectra were recorded on a Varian Eclipse spectrofluoremeter. UV–Vis spectra were recorded on a Varian 500 UV–Vis/NIR spectrophotometer.

Laser flash photolysis experiments were performed with light pulses produced by a Quanta-Ray Nd: YAG laser providing 400 mJ, 90 ns pulses of laser light at 10 Hz, pumping a Lambda-Physik FL3002 dye (Pyridin 1 dye in methanol). Single pulse energy ranged from 2 to 7 mJ. The analyzing beam source was from a Thermo Oriel xenon arc lamp, and a photomultiplier tube was used as a detector. Signals were recorded with a digital real-time oscilloscope (Tektronix TDS 360). The triplet life times were determined by exponential fitting of the kinetic curves using the program Origin Pro 7.5.

3. Results and discussion

3.1. Absorption and emission spectra

The synthesis of the ZnPc complexes (ZnTCPc, ZnOCPc and ZnTSPc) is well established, and in this work literature methods of synthesis and characterization were employed and gave expected results [27–30]. The quantum dots (QDs) were also synthesized using literature methods [4]. QDs are characterized by their absorption and photoluminescence spectra which are also related to their size. The CdTe QDs synthesized in this work according to literature methods, gave characteristic spectral behavior [4]. As heating is prolonged during the formation of QDs, both the absorption and the emission spectra continue to get red shifted as the quantum dots grow [44]. The 2-ME capped CdTe QDs had their first emission peak at 524 nm after 15 min of heating under reflux, and their growth ceased when they reached 555 nm (Fig. 2a) after heating for 64 h. The first emission peak was observed around 525 nm after 15 min of heating for TGA capped CdTe quantum dots and the peak shifted to 645 nm (Fig. 2b) after 56 h of reflux, at which time they stopped growing. It was observed that the 2-ME capped CdTe nanoparticles grow at a much slower rate than those that were capped with TGA as was mentioned in literature [44]. The estimated full width at half maximum (FWHM) was 60 nm for the 2-ME capped CdTe nanoparticles (at 555 nm) and 83 nm for the TGA capped counterparts (at 645 nm). The sizes (diameter) of QDs were used for this study are 3.3 and 4.2 nm for 2-ME and TGA capped QDs, respectively.

Absorbance and fluorescence emission spectra of the MPc complexes are shown in Fig. 3 (for ZnTSPc and ZnOCPc) in a mixture of 0.1 M NaOH and ethanol (50:50). In this solvent mixture, the ZnPc derivatives are monomeric. Aggregation in MPc complexes is due to a coplanar association of rings, resulting in splitting and broadening of spectra, with a blue shifted peak at ~630 nm being due to the aggregate. Addition of organic solvents normally breaks the aggregates, resulting in monomeric species, hence the NaOH:ethanol solvent mixture was employed in this work. The ZnPc derivatives obeyed Beer's law for concentrations less than 1×10^{-5} mol dm^{-3} in this solvent mixture. For all the ZnPc complexes (Fig. 3), the fluorescence emission spectra were mirror images of the absorption spectra which in turn were similar to excitation spectra. At the high pH employed for the synthesis of the QDs and also used for the photophysical studies, the 2-ME and TGA capping will be ionized. It is known that the thiol moiety donates electrons to the surface of QDs, hence reducing the so called "blinking" [26]. The MPcs were not chemically linked to the ligands on the QDs surface, and thus the MPcs are most likely to adsorb onto the surface of the QDs.

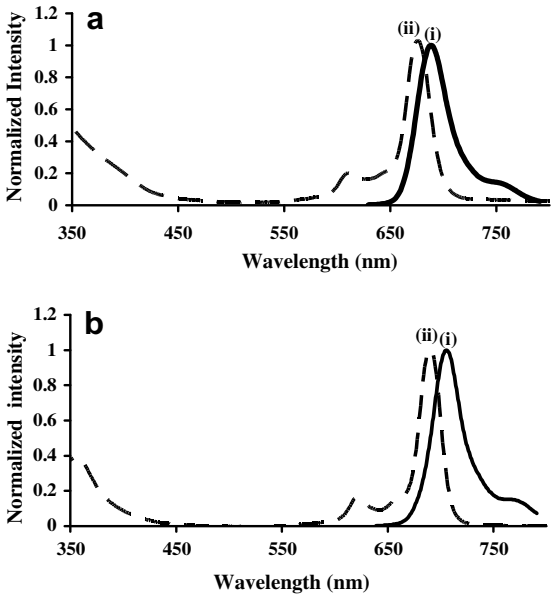

Fig. 3. Fluorescence (i) and absorbance (ii) spectra of (a) ZnTSPc (excitation = 610 nm) and (b) ZnOCPc (excitation = 620 nm) in 50:50, NaOH:EtOH solution.

3.2. Fluorescence quantum yields and energy transfer studies

Fluorescence quantum yield (Φ_F) values of the ZnPc derivatives (in the absence of QDs) are shown in Table 1 for excitation at 630 nm. ZnTSPc and ZnOCPc gave Φ_F values of 0.21 and a very low value for ZnTCPc (Φ_F values <0.01) was obtained. The Φ_F values for the CdTe QDs were calculated in 0.1 M NaOH:ethanol solvent mixture using Eq. (2) and are listed in Table 1. The fluorescence quantum yields (Φ_F) of the QDs were observed to be fairly low (0.037 for 2-ME capped and 0.11 for TGA capped) and they decreased further in the presence of Pc's. The lower fluorescence quantum yields of QDs was expected because as the QD (donor) particles fluoresce there is a transfer of energy to the MPc molecules (acceptor) and this reduces the fluorescence intensity of the QDs in the QD–MPc mixture through FRET (discussed below), hence the reduced quantum yields of the QDs in the QD–MPc mixture.

As stated above the efficiency of energy transfer depends upon the amount of spectral overlap between the emission spectrum of the donor and the absorption spectrum of the acceptor. A poor overlap was obtained for 2-ME capped QDs (Fig. 4). CdTe-TGA QDs had a good overlap with all the MPcs (Fig. 5), hence FRET parameters were calculated only for the mixture of CdTe-TGA capped QDs and ZnPc derivatives.

Excitation of the QDs at 500 nm in the presence of ZnPc derivatives, where Pcs do not absorb, resulted in significant fluorescence of the ZnPc derivatives as observed in Fig. 6. The 2-ME-QDs have been left out from Fig. 6 due to weak overlap between the emission spectra of 2-ME-QDs and absorption spectra of ZnPc derivatives. There was clear transfer of energy (FRET) from the TGA QDs to ZnPc derivatives (for ZnTSPc and ZnOCPc), Fig. 6a and b. This is judged by the increase in the emission spectra of ZnPc derivatives in the presence of QDs. There was insignificant emission by these two complexes (in the absence of QDs) on excitation at 500 nm, Fig. 6a–c (curves ii). For ZnTCPc there was no increase in the emission spectra of ZnTCPc probably due to a small fraction of fluorescing molecules of the Pc (Fig. 6c). This complex has a very low Φ_F (<0.01, Table 1), hence no fluorescence peak is observed, but there was a decrease in the fluorescence intensity of the QDs.

The overlap integral (J) values were computed using PhotochemCAD [43]. The J values are usually of the order 10^{-14} cm^6 for porphyrin based molecules and the values obtained in this work were of the order 10^{-13} cm^6 for the overlap between the ZnPc derivatives and CdTe QDs, Table 2. The overlap integral was largest for ZnTSPc in the presence of CdTe-TGA QDs and decreasing as follows: ZnTSPc > ZnOCPc > ZnTCPc. It would be reasonable to assume that the QD–Pc mixture having the highest J value would also have the highest efficiency of energy transfer (Eff, calculated using Eq. (5)) from the QD to the Pc, and this was observed in Table 2 for ZnTSPc.

The values of the Förster distance, R_0 (Å) which is the critical distance between the donor and the acceptor molecules for which efficiency of energy transfer is 50% [43,44], were computed with PhotochemCAD and the values are shown in Table 2. The center-to-center separation distance (r, Å) between donor and acceptor chromophores, were calculated using Eq. (6) and the values are shown in Table 2, ZnOCPc–CdTe-TGA QDs mixture showed the lowest value of r compared to the others. This indicates that the ZnOCPc is in close proximity to the donor (QDs) and thus there should be an ease of energy transfer (Eff) between the excited TGA capped QDs and the ZnOCPc. The center to center distance (r) increased with MPc in the order ZnTSPc > ZnTCPc > ZnOCPc for TGA capped QDs–MPc mixture. However it is ZnTSPc with the largest r (Å) and J (cm^6), which had the largest FRET efficiency and not ZnOCPc.

3.2.1. Triplet quantum yields (Φ_T) and lifetime (τ_T) studies

The transient absorption spectra were recorded in argon degassed solutions by exciting the ZnPc photosensitizer (in NaOH:EtOH mixture) in the Q band region and recording the transient absorption spectra point by point from 400 to 820 nm (Fig. 7), showing a triplet absorption near 530 nm. A representative decay profile is shown in Fig. 8. The triplet decay curves for ZnPc derivatives alone and in the presence of QDs were similar. The triplet

work were in this range hence triplet–triplet recombination is expected. Fig. 7 shows that the Q band is split upon laser excitation, thus suggesting change in symmetry.

Φ_T values provide a measure of the fraction of absorbing molecules that undergo intersystem crossing (ISC) to the triplet state (Φ_T). The variation of Φ_T values of ZnPc derivatives in 0.1 M NaOH:ethanol and in the presence of the QDs are shown in Table 1. The Φ_T of the ZnOCPc complex both in the presence and the absence of QDs was much larger than those of the ZnTSPc and ZnTCPc derivatives. This indicates that a greater portion of the ZnOCPc molecules undergoes ISC. Although it could be expected that the Φ_T would increase in the presence of the quantum dots because they contain Cd and Te atoms which are heavy and thus would encourage ISC, it was observed that the Φ_T of the MPcs decreased (except for ZnTCPc–CdTe-TGA and ZnOCPc–CdTe-2-ME which remained unchanged considering the experimental error) in the presence of the QDs. A slight increase in the Φ_T values was reported by us [32] for AlTSPc in the presence of CdTe QDs capped with thioglycolic acid or 3-mercaptopropionic acid and for cysteine capped QDs. Thus the QDs do not seem to induce an increase in Φ_T values as expected on the basis of the heavy atom effect.

The triplet lifetimes (τ_T) of the ZnPc derivatives were higher in the presence of QDs (except for ZnOCPc in the presence of 2-ME capped QDs, where τ_T values were slightly lower in the presence of QDs). The higher τ_T values of the MPc derivatives in the presence of QDs, corresponds well with the lowering of the Φ_T values of the ZnPc derivatives in the presence of QDs. The higher τ_T values in the presence of QDs then shows that the MPc molecules will spend more time in the triplet state thereby allowing for increased photosensitizing abilities.

4. Conclusions

The interaction of CdTe quantum dots with ZnPc derivatives shows that a strong overlap occurs between the emission of the TGA capped QDs and the absorption spectra of the ZnPc derivatives (ZnTSPc, ZnOCPc, and ZnTCPc). The largest fluorescence energy transfer (FRET) was observed for ZnTSPc followed by ZnOCPc and then ZnTCPc. The triplet quantum yields of the ZnPc derivatives decreased in the presence of QDs but the lifetimes increased, hence making the combination of ZnPc derivatives and QDs potential candidates for applications as photosensitisers in PDT.

for X-ray diffraction were grown by evaporation of a chloroform solution.

2.3. Preparation of $[Ir(SC_6F_5)(H)(SiPh_3)(XNC)_3](C_6H_6)$ (**2**)

A stirred mixture of $[Ir_2(\mu\text{-}SC_6F_5)_2(cod)_2]$ (0.015 g, 0.030 mmol) and Ph_3SiH (0.009 g, 0.035 mmol) in benzene (~1 ml) was treated with xylyl isocyanide (0.012 g, 0.091 mmol) to give (within seconds) a pale yellow solution. The solution was concentrated and hexane was added. After 3 days at −20 °C colourless crystals were obtained which were washed with hexane. Yield: 0.018 g (53%). ^{1}H NMR (C_6D_6, 300 K) δ 7.90–6.57 (mults, aromatic H), 2.13 (S, 6H, CH_3), 2.10 (S, 12H, CH_3), −8.55 (S, 1H, IrH). Elemental analysis showed the percentage of carbon to be lower than that calculated for **2**, possibly as a result of loss of co-crystallised benzene.

2.4. Preparation of $[Ir_3(\mu\text{-}SC_6F_5)_2(SC_6F_5)(\mu,\mu'\text{-}XNC)(XNC)_4(cod)]$ (**3**)

A mixture of **1** (0.085 g, 0.017 mmol) and xylyl isocyanide (0.0025 g, 0.019 mmol) was dissolved in CH_2Cl_2 (~1 ml) to give a dark red solution. The solution was treated with hexane, concentrated and allowed to stand at −20 °C for 6 days to give an orange powder (2.3 mg) and a few small orange crystals/crystalline lumps. Yield of crystalline material ~0.5 mg (~4% based on Ir). ^{1}H NMR of the powder indicated a mixture of products. Attempts to repeat the result failed to yield crystals.

2.5. NMR spectroscopy

^{1}H spectra were recorded on a Bruker DRX 400 spectrometer and referenced to TMS (internal standard).

2.6. X-ray structure determination

Intensity data were collected on a Bruker APEX II CCD area detector diffractometer with graphite monochromated Mo Kα radiation (50 kV, 30 mA) using the APEX2 [17] data collection software. The collection method involved ω-scans of width 0.5° and 512 × 512 bit data frames. Data reduction was carried out using the program SAINT+ [18]. Face indexed absorption corrections were carried out for **1** and **2** using XPREP [18] while multiscan absorption corrections were carried out for **3** using SADABS. The crystal structures were solved by direct methods using SHELXTL [19]. Non-hydrogen atoms were first refined isotropically followed by anisotropic refinement by full matrix least-squares calculations based on F^2 using SHELXTL. With the exception of the hydride (structure **2**) all hydrogen atoms were first located in the difference map, then positioned geometrically and allowed to ride on their respective parent atoms. The hydride of **2** was placed geometrically, equidistant from the adjacent C, S and Si atoms and 1.60 Å from the iridium atom.

The structure of **2** contains disorder. One of the phenyl groups of the triphenylsilane was found to be disordered and was refined with isotropic atoms over three positions using rigid body restraints. Final occupancies were 0.36(1), 0.30(1) and 0.34(1) for the three respective positions. One of the neighbouring isocyanide ligands was also found to be disordered and was refined over two positions using rigid body, SIMU, SADI and FLAT restraints with the final occupancies being 0.48(1) and 0.52(1), respectively. The structure also contains a benzene solvent molecule which was found to be disordered over a centre of inversion. This was refined isotropically as a rigid body with a site occupancy of 0.5. Crystal and refinement data are given in Table 1.

3. Results and discussion

The complex $[Ir_2(\mu\text{-}SC_6F_5)_2(cod)_2]$ (**1**) was reported a number of years ago by Terreros and co-workers [8] who prepared it from $[Ir_2(\mu\text{-}Cl)_2(cod)_2]$ using a mixture of C_6F_5SH and NEt_3. Our method, starting from $[Ir_2(\mu\text{-}OMe)_2(cod)_2]$, offers a slightly improved yield (75%). The structure of **1** (Fig. 1) has a geometry at Ir that can be described as square planar distorted towards square pyramidal, with the alkene groups each occupying a single coordination site. Selected bond lengths and angles are given in Table 2. The sharply angled Ir–S–Ir bonds cause the molecule to adopt a pyramidal structure with the dienes and C_6F_5 groups forming the base and the two sulphurs a truncated apex. Although the two iridiums bear identical substituents and bridging groups which closely approach a symmetrical arrangement, they are not related by any crystallographic symmetry element.

In dichloromethane at room temperature **1** is unreactive towards triphenylsilane, but upon addition of xylyl isocyanide (XNC) a product $[Ir(SC_6F_5)(H)(SiPh_3)(XNC)_3]$ (**2**) is rapidly formed regardless of whether one or three equivalents of XNC is used (Scheme 1). The geometry of **2** (Fig. 2) is distorted octahedral, with ligands showing displacement towards the hydride. The hydride (the presence of which was confirmed by a ^1H NMR signal at δ −8.55 ppm) was not located in the electron density map but instead geometrically inserted. One of the phenyl groups of the silane is disordered and was refined over three positions.

When complex **1** in dichloromethane is treated with one equivalent of XNC an immediate colour change from red to orange is observed. Attempts to isolate a product yielded small quantities of **3** (Scheme 1 and Fig. 3), a trinuclear complex containing two bridging thiolates and a triply bridging isocyanide. Complex **3** exists in two mirror image forms related, in the unit cell, by an inversion centre. Selected bond lengths and angles are given in Table 2. The N(60)–C(61) distance of 1.28 Å indicates a double bond consis-

Scheme 1.

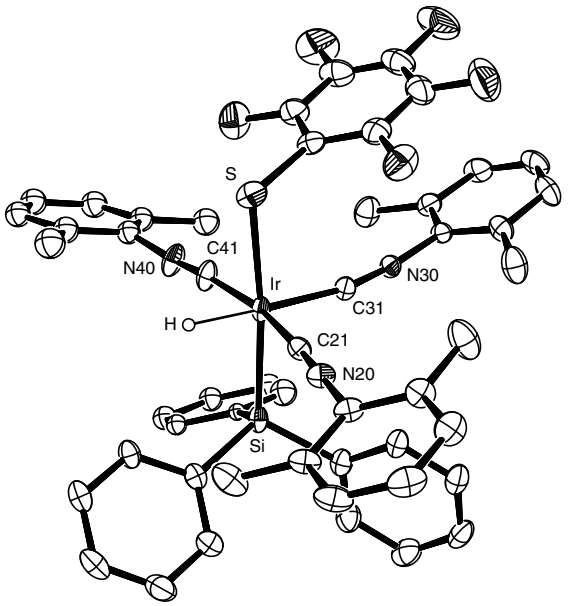

Fig. 2. Thermal ellipsoid plot of $[Ir(SC_6F_5)(H)(SiPh_3)(XNC)_3]$ (**2**) with ellipsoids drawn at the 30% probability level. A co-crystallised benzene is omitted. Hydride inserted geometrically.

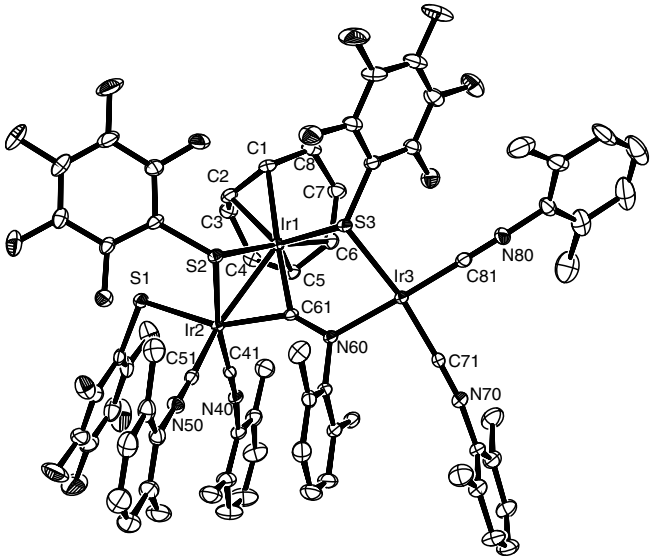

Fig. 3. Thermal ellipsoid plot of $[Ir_3(\mu\text{-}SC_6F_5)_2(SC_6F_5)(\mu\mu'\text{-}XNC)(XNC)_4(cod)]$ (**3**) with ellipsoids drawn at the 30% probability level. A co-crystallised *n*-hexane is omitted.

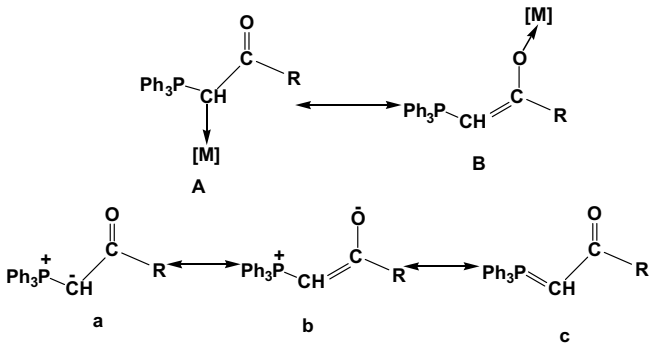
tent with an imino group, i.e. the bridging isocyanide might more accurately be regarded as an iminocarbene. In this formulation a lone pair of electrons becomes available on the nitrogen to partake in further bonding to give a triply bridged structure in which all three iridiums are nominally in the +1 oxidation state. Dinuclear iridium complexes having bridging (via carbon) isocyanides are known [20,21] as are trinuclear rhodium [22] and osmium [23–27] complexes having triply bridging isocyanides, bonded in the manner of complex **3**. To our knowledge **3** is the first example of an iridium complex exhibiting such bonding. Whilst it is possible to speculate that the initial stages of formation of **3** might involve nucleophilic attack of an electron-rich derivative of **1**, possibly $[Ir(SC_6F_5)(XNC)(cod)]$, on the α carbon of a coordinated isocyanide, further work is required to establish the identity of this reactive intermediate.

4. Supplementary data



CCDC 668581, 668582 and 668583 contain the supplementary crystallographic data for **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

series analyzer. Fourier transform IR spectra were recorded on a Shimadzu 435-U-04 spectrophotometer and samples were prepared as KBr pellets. ^{1}H, ^{13}C and ^{31}P spectra were recorded on a 90 MHz Jeol spectrometer. X-ray analysis was performed on a STOE IPDS-II diffractometer.

2.3. Synthesis of the ligand and the metal complexes

2.3.1. Synthesis of BAPPY

A solution of triphenylphosphine (0.52 g, 2 mmol) and bromobenzylacetate (0.42 g, 2 mmol) in dry chloroform (15 mL) was stirred at room temperature for 10 h. The resulting white precipitate was filtered off, washed with diethyl ether and dried. Further treatment with an aqueous solution of NaOH (0.5 M, 50 mL) led to elimination of HBr, giving the free ligand. Yield: 0.66 g (89.3%), m.p. 118–120 °C. *Anal.* Calc. for for $C_{27}H_{20}O_2P$: C, 79.00; H, 5.64. Found: C, 78.44; H, 5.43%.

2.3.2. Synthesis of $[(BAPPY)\cdot HgCl_2]_2$ (**1**)

General procedure: To a magnetically stirred solution of $HgCl_2$ (0.135 g, 0.5 mmol) in methanol (10 mL), was added a methanolic solution (5 mL) of the ylide BAPPY (0.205 g 0.5 mmol). After 8 h the solvent was removed under reduced pressure to 3 mL. After addition of diethyl ether (30 mL) a white solid product was separated by filtration. Yield: 0.28 g (82.7%), m.p. 173–176 °C. *Anal.* Calc. for $C_{54}H_{40}Cl_4Hg_2O_4P_2$: C, 47.55; H, 3.39. Found: C, 46.26; H, 3.17%.

2.3.3. Synthesis of $[(BAPPY)\cdot HgBr_2]_2$ (**2**)

Yield: 0.35 g (85.2%), m.p. 177–179 °C. *Anal.* Calc. for $C_{54}H_{40}Br_4Hg_2O_4P_2$: C, 42.07; H, 3.00. C, 41.18; H, 2.83%.

2.3.4. Synthesis of $[(BAPPY)\cdot HgI_2]_2$ (**3**)

Yield: 0.36 g (81.8%), m.p. 167–170 °C. *Anal.* Calc. for $C_{54}H_{40}I_4Hg_2O_4P_2$: C, 37.49; H, 2.67. C, 37.10; H, 2.55%.

2.4. X-ray crystallography

Crystals were obtained from a dichloromethane/diethyl ether solution by solvent diffusion. A block colorless crystal of **3** having approximate dimensions of 0.25 × 0.15 × 0.12 mm was mounted on a glass fiber. All measurements were made on a STOE IPDS-II diffractometer with graphite monochoromated Mo Kα radiation (λ = 0.7107 nm).

The data were collected at 298 K to a maximum θ value of 26.78 ° and in a series of ω scans in 1 ° oscillations with 60 s exposures. Of the 33 902 reflections that were collected, 11 871 were unique (R_{int} = 0.0442), equivalent reflections were merged. Data were collected and integrated using the STOE X-AREA software package [8]. The refinement was performed using the X-STEP32 crystallographic software package [9]. The numerical absorption coefficient, μ, for Mo Kα radiation is 7.748 mm^{-1}. A numerical absorption correction was applied using X-RED [10] and X-SHAPE [11] software packages which resulted in transmission factors ranging from 0.212 and 0.083. The data were corrected for Lorentz and polarizing effects. The structure was solved by direct methods [12]. All of the non-hydrogen atoms were refined anisotropically. All of the hydrogen atoms were located in ideal positions. Anomalous dispersion effects were included in F_{calc} [13], the values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley [14]. The values for the mass attenuation coefficient are those of Creagh and Hubbell [15].

2.5. Computational methods

The quantum chemical calculations were performed with GAUSSIAN03 [16]. The geometries were fully optimized using DFT at the B3LYP/LanL2MB level of theory [17]. This basis set includes effective core potentials (ECP) for both the mercury and phosphorus as well as halide (Cl, Br, and I) ions. The stability energy values for the complex and the energies of the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) of complex were calculated. Moreover, the HOMO–LUMO (H–L) energy gap, partial charges calculated from NBO analysis (natural bond orbital), structural parameters (such as bond lengths, bond angles), dipole and quadrupole moment were evaluated by DFT calculations. Atomic coordinates for the DFT calculations were obtained from the data of the X-ray crystal structure analyses for **3**.

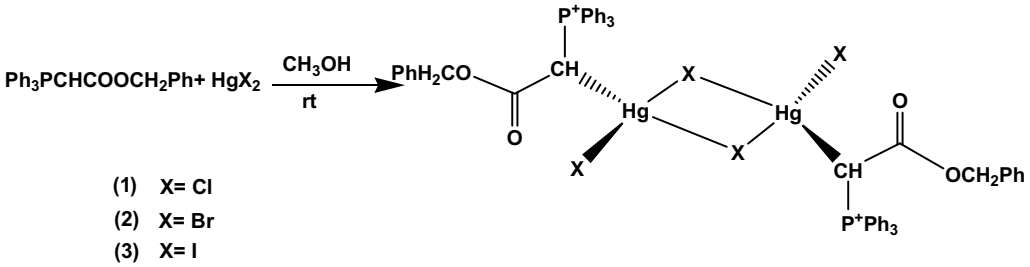
3. Results and discussion

3.1. Synthesis

Reactions of HgX_2 (X = Cl, Br and I) with ylides in a 1:1 stoichiometry afforded halide-bridged dimeric structures **1–3** (Scheme 2) containing C-coordinated ylide ligands.

3.2. Infra-red spectra

The ν(CO) band, which is sensitive to complexation, occurs at 1610 cm^{-1} for the parent ylide, as in the case of other resonance stabilized ylides [18]. Coordination of the ylide through carbon causes an increase in ν(CO), while for O-coordination a lowering of ν(CO) is expected (Table 1).



The infrared absorption bands observed for the three complexes at 1707, 1702 and 1688 cm^{-1} indicate coordination of the ylide through carbon. The $\nu(P^+–C^-)$ value, which is also diagnostic for the coordination, occurs at 958 cm^{-1} in $Ph_3P^+–^-CH_2$ and at 887 cm^{-1} in BAPPY. In the present study, the ν $(P^+–C^-)$ values for all three complexes were shifted to lower frequencies and were observed at 839, 831 and 827 cm^{-1} for **1**, **2** and **3**, respectively, suggesting some removal of electron density from the P–C bond [19].

3.3. NMR spectral data

The ^{1}H NMR data for the mercury(II) complexes, along with those of the parent ylide, are listed in Table 2.

The signals due to the methine protons, when recorded in $CDCl_3$, were either broad or unobserved, probably due to the very low solubility of all the complexes in $CDCl_3$. Similar behavior was observed earlier in the case of ylide complexes of mercury(II) halides [20,21].

The expected downfield shifts of ^{31}P and ^{1}H signals for the PCH group upon complexation were observed in their corresponding

spectra. The appearance of single signals for the PCH group in both the ^{31}P and ^{1}H NMR spectra at ambient temperature indicates the presence of only one molecule for all the three complexes, as expected for C-coordination. It must be noted that O-coordination of the ylide leads to the formation of *cis* and *trans* isomers which would give rise to two different signals in the ^{31}P and ^{1}H NMR spectra [6b]. The resonances in the ^{31}P NMR spectra of complexes **1**, **2** and **3** were observed to occur at a lower field with respect to the free ylide (Table 2). A comparison of the ^{31}P chemical shift of the three complexes at ambient temperature indicates a decrease in the order **1** > **2** > **3**. The ^{13}C NMR data of the complexes and the title ylide, along with possible assignments, are listed in Table 3.

The ^{13}C shifts of the CO group in the complexes are around 168 ppm, which is higher field than the 170 ppm noted for the same carbon in the parent ylide, indicating much higher shielding of the carbon atom of the CO group in the complexes [21]. No coupling to Hg was observed at room temperature in the ^{1}H, ^{13}C and ^{31}P NMR spectra. Failure to observe satellites in the above spectra was previously noted in the ylide complexes of Hg(II) [22] and Ag(I) [23], which had been explained by fast exchange of the ylide with the metal.

3.4. Crystal structures analysis

Table 4 provides the crystallographic results and refinement information for complex **3**. The molecular structure of **3** is shown in Fig. 1. Fractional atomic coordinates and equivalent isotropic displacement coefficients (U_{eq}) for the non-hydrogen atoms of complex **3** and a view of the crystal packing are shown in Fig. S1. Table 5 lists key bond lengths and angles for complex **3**.

The dimeric structure adopted by complexes **1**, **2** and **3** is in contrast to the O-coordinated trinuclear mercury(II) complex of the phosphorus ylide $Ph_3PCHCOPh$ [24], but is similar to the structure of the C-coordinated dinuclear mercury(II) halide complexes of $Ph_3PCHCOOEt$ (EPPY) [25a] and $Ph_3PCHCOPh$ (BPPY) [25b]. The C-coordination of BAPPY is in stark contrast to the O-coordination of the phosphorus ylide $Ph_3PC(COCH_3)(COC_6H_5)$ (ABPPY) to the Hg(II) center [26]. The difference in coordination mode between ABPPY and BAPPY to Hg(II) can be rationalized in terms of the electronic properties and steric requirements of the ylides. The nucleophilicity of the carbanion in ABPPY is less than for BAPPY; this is due to the additional delocalization of the ylide electron density in ABPPY which is facilitated by the second carbonyl group. This will reduce the ability of ABPPY to bind via the ylidic carbon. Belluco et al. have studied steric influences on the coordination modes of ylide molecules to Pt(II) systems [27]. These authors concluded that the preferred coordination mode is via the ylidic carbon, but that steric hindrance around the metal center or the ylidic carbon will necessitate O-coordination. Indeed, this trend is reflected here, both BPPY and BAPPY are slightly less sterically demanding than

ABPPY and are both C-coordinated to Hg(II). The Hg(II) in **3** is sp^3 hybridized and has a tetrahedral coordination environment with one short Hg–I bond, one Hg–C bond and two asymmetric bridging Hg–I bonds at distances of 2.841(9) and 3.129(8) Å. The significance of the Hg–C bond of length, 2.263(6) Å, compared to analogous distances in $[BPPY \cdot HgI_2]_2$ [25] and $[(C_6H_5)_3PC_5H_4 \cdot HgI_2]_2$ [22] (2.312(13) and 2.292(8) Å, respectively) must be attributed to the use of Hg(II) orbitals with high s character for bonding to the ylidic carbon. The use of non-equivalent hybrid orbitals with high s character to bond to low electronegative atoms was proposed by Bent in the concept of isovalent hybridization to account for the variation in bond lengths and bond angles around a central

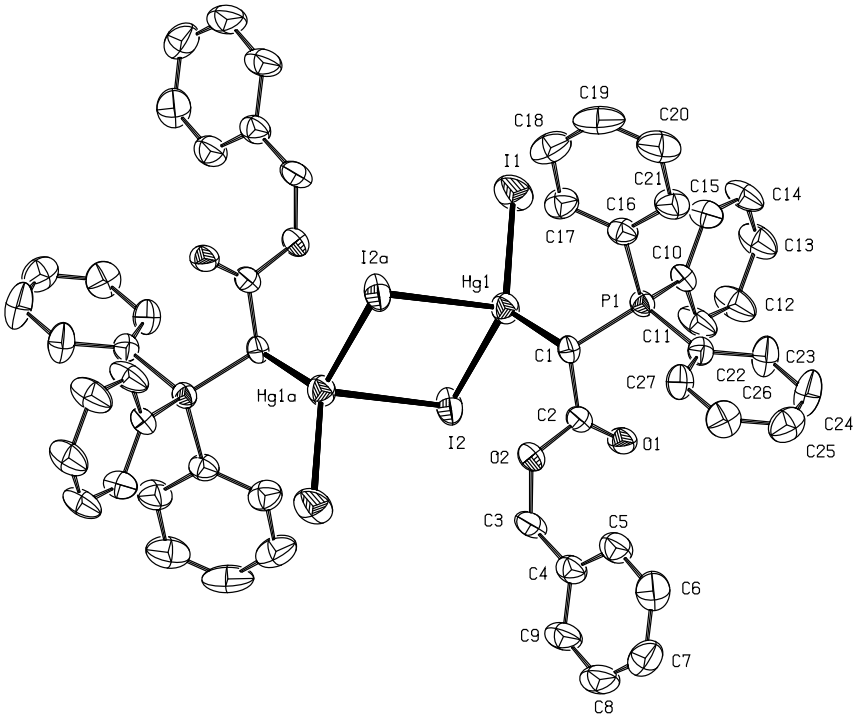

Fig. 1. Molecular structure of the complex $[(BAPPY) \cdot HgI_2]_2$. H atoms are omitted for clarity.

atom. The internuclear distances between mercury atoms were found to be 4.090(5), 4.014(1) and 3.810(2) Å in the structures **3**, $[BPPY \cdot HgI_2]_2$ and $[BPPY \cdot HgCl_2]_2$, respectively. These distances are much longer than the sum of the Van der Waals radii (1.5 Å) of the two mercury atoms [28] indicating the absence of significant bonding interactions between the mercury atoms in the molecular structures. The adaptation of dimeric structures in the Hg(II) ylide complexes may be explained by both the preference of Hg(II) for four coordination and the stability of the 18 electron configuration around Hg(II).

3.5. Theoretical studies

The optimized structure of this compound is shown in Fig. 2 and selected bond lengths and bond angles are given in Table 5.

As can be seen, the calculated bond lengths are slightly longer than the measured bond lengths but the similarity of calculated and measured bond angles reflects the similar geometrical structures for this compound in both the solid state and gas-phase. It is clear that the dimeric structure with the general formula $[BAPPY \cdot HgX_2]_2$ can be considered as both the observed *trans*-like or possible *cis*-like isomers. Table 5 shows the complete data collections for the X-ray results and theoretical calculation. In the *trans*-like structure of the compound, the internuclear distances between the mercury atoms were calculated to be 4.514 Å, indicating the absence of significant bonding interactions between the mercury atoms in the molecular structure. The Hg–C bond length in the trans structure is calculated to be 2.341 Å. A comparison of the bond lengths and bond angles from both methods (X-ray crystallography and quantum calculation) shows that the results of the calculation are the same as the X-ray crystallography results. For example the distances: P(1)–C(1), P(1)–C(10), P(1)–C(16), P(1)–C(22) have approximately equal values. These data show that the phenyl rings attached to phosphorus have little effect on the bond lengths between the phosphorus and carbon atoms. The stability energy values for this complex are reported in Table 6.

Furthermore, the energies of the HOMO and LUMO for the complex are summarized in Table 6. In this case, partial charge transfer will occur by a contribution from the mixing of the filled orbital of one component molecule with the vacant orbital of another. The most important terms in this kind of interaction are contributed from the partial charge transfer between the HOMO of one component and the LUMO of another. The HOMO–LUMO (H–L) energy gap is large in magnitude for this complex and corresponds to 4.161 eV. As listed in Table 6, the dipole moment of the trans complex in the *x*, *y* and *z* planes was only 0.0 De. This result shows that the complex has no polarity in the three planes. The structure of the HOMO and LUMO are shown in Figs. 3a and 3b.

4. Conclusions

The present study describes the synthesis and characterization of a new ylide (BAPPY) and its mercury(II) complexes of the general formula $[BAPPY.HgX_2]_2$ (X = Cl, Br, I). On the basis of the physicochemical and spectroscopic data we propose that BAPPY herein exhibits monodentate C-coordination to the metal center. In addition theoretical studies on the gas phase structure of **3** confirms the *trans*-like dimeric structure for this compound, as obtained by X-ray crystal structure analyses.

Acknowledgement

We are highly grateful to the University of Bu-AliSina for a Grant and Mr. Zebarjadian for recording the NMR spectra.

Appendix A. Supplementary data

CCDC 648218 contains the supplementary crystallographic data for **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.03.010.

The products, **2a**–**c**, have been purified by crystallization, and have been fully characterized by means of IR and NMR spectroscopies, and elemental analysis. Moreover, the molecular structure of **2b** has been ascertained by X-ray diffraction (Fig. 1 and Table 1).

The molecular structure of **2b** resembles those previously reported for $Ta_2Cl_8[\mu\text{-}OOC(p\text{-}ClC_6H_4)]_2$ and $Nb_2Cl_8(\mu\text{-}OOCC_6F_5)_2$ [4]. Compound **2b** possesses C_i symmetry and only half of the molecule is present in the asymmetric unit. The distorted octahedrally coordinated Ta(V) centres display a *cis* arrangement of the ligands and the Ta–Cl bond distances [range 2.2857(11)–2.3393(11) Å; average 2.303(2) Å] are comparable to those present in the dinuclear $Ta_2Cl_8[\mu\text{-}OOC(p\text{-}ClC_6H_4)]_2$ [range 2.282(4)–2.308(4) Å; average 2.296(10) Å] [4] and the tetranuclear $Ta_4Cl_8(\mu\text{-}O)_4[\mu\text{-}OOC(p\text{-}MeC_6H_4)]_4$ [range 2.263(7)–2.322(4) Å; average 2.292(8) Å] [6]. Conversely, the Ta–O interactions [2.104(3) and 2.008(3) Å] display some asymmetry, whereas they are almost identical in $Ta_2Cl_8[\mu\text{-}OOC(p\text{-}ClC_6H_4)]_2$ [2.001(8) and 2.006(9) Å]. The C(1)–O(1) [1.260(5) Å] and C(1)–O(2)#1 [1.282(5) Å] distances are in agreement with a delocalised π-interaction and C(1) displays an almost perfect sp^2 hybridisation [sum angles 360.0(7)°]. The tantalum–tantalum distance (4.913(8) Å) indicates that no direct interaction between the two metal atoms occurs.

The spectroscopic data collected for **2a**–**c** are coherent with the X-ray features of **2b**. The ^{1}H NMR spectra (in CD_2Cl_2 solutions) exhibit one singlet due to the methyl groups, occurring at *ca.* 2.7 ppm. The ^{13}C NMR resonances are seen at *ca.* 185 (*C*OO) and 24 (*C*H$_3$) ppm. Furthermore, the IR spectra (recorded in the solid state) display the absorptions typical of bridging carboxylate moieties [8], *e.g.* for **2a** at 1545 [ν_{as}(COO)] and 1489 [ν_s(COO)] cm^{-1}.

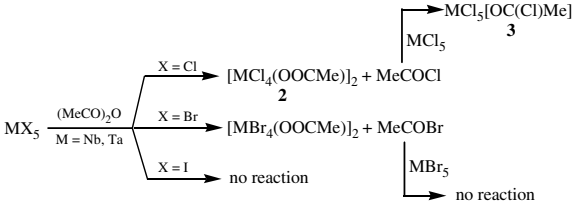
Symmetry transformations used to generate equivalent atoms: #1 $-x$, $-y+1$, $-z+1$.

Since the chemistry of **1** with carboxylic anhydrides has been explored in less detail than that with the corresponding acids, we decided to study the reactions of MX_5 with the stoichiometric amount of acetic anhydride. Particular care was taken in order to have an anhydrous reaction system, so to eliminate the presence of adventitious water and/or of acetic acid. The complete absence of acetic acid was verified before each reaction by ^{1}H NMR spectroscopy.

Thus, the reactions of **1** (M = Nb, X = Cl, M = Ta, X = Cl, Br) with a slight excess of $(MeCO)_2O$ resulted in the formation of the dimeric species **2a**–**c**, Eq. (2). Coherently to what reported above, when compound TaI_5, in $CDCl_3$, was mixed with one equivalent of $(MeCO)_2O$, the ^{1}H NMR spectrum of the solution exhibited the resonances due to the free anhydride only.

$$2MX_5 + 2(\mathrm{Me\ CO})_2O \rightarrow \underset{\mathbf{2a-c}}{[MX_4(\mu - OOCMe)]_2} + 2\mathrm{MeCOX} \qquad (2)$$

When the reaction of MX_5 with a slight excess of acetic anhydride was performed in a NMR tube, the ^{1}H NMR spectrum of the solution showed resonances due to **2**, MeCOX (X = Cl, Br) and to an additional compound characterized by a single resonance at *ca.* 2.8 ppm ($CDCl_3$, X = Cl). Although μ-oxo derivatives of niobium(V) and tantalum(V) have been obtained by reacting MCl_5 with acetic anhydride [3a,3c], our present result suggests that a different compound is formed in our system.



As a matter of fact, according to Eq. (2), see also [3c], the anhydride C–O bond activation produces MeCOX, a potentially good ligand for a strong Lewis acid such as MX_5 [7a,7c]. In order to investigate the hypothesis that the compounds formed in admixture with **2** are adducts of acetyl chloride, MeCOCl was added in 1:1 ratio to dichloromethane suspension of MCl_5: the soluble adducts $MCl_5[OC(Cl)Me]$ [M = Nb, **3a**; M = Ta, **3b**] formed rapidly, Eq. (3). It has to be noticed that $TaBr_5$ resulted unreactive towards MeCOBr.

$$MCl_5 + \mathrm{Me\ COCl} \rightarrow \underset{\mathbf{3a,b}}{MCl_5[OC(Cl)Me]} \qquad (3)$$

The complexes **3a**–**b** have been isolated as microcrystalline solids upon removal of the volatile materials, and characterized by means of IR and NMR spectroscopies, and elemental analysis. The infrared carbonyl stretching vibration has been found at 1560 cm^{-1}, *i.e.* at significantly lower frequencies with respect to the uncoordinated acetyl chloride (1806 cm^{-1} [9]). The ^{1}H and ^{13}C NMR resonances appear downfield shifted (2.81 ppm in **3a**) with respect to uncoordinated MeCOCl (2.66 ppm [10]).

At variance to what observed in the reactions of **1** with other C=O containing species [7a], the addition of a fivefold excess of acetyl chloride to $NbCl_5$ did not result in the formation of by-products. This evidence strongly suggests that only compounds **3** can result from combination of MCl_5 with *in situ* generated MeCOCl.

On the basis of these results, it has to be concluded that the reactivity of MX_5 with acetic anhydride depends on the nature of X, and it can be summarized as in Scheme 1. Indeed, when $NbCl_5$

Scheme 1. The reactivity of MX_5 with acetic anhydride.

was treated with $(MeCO)_2O$ in CD_2Cl_2 inside a NMR tube, some solid formed and the ^1H NMR spectrum of the solution revealed the presence of **2a**, MeCOCl and **3a** in 1:3:7 molar ratio, which changed to 1:2:3 on increasing the $(MeCO)_2O/NbCl_5$ molar ratio from 1 to 2. The formation of **3a** was almost suppressed by using a $(MeCO)_2O/NbCl_5$ molar ratio of 5. These evidences point out that acetyl chloride, formed as result of the anhydride fragmentation, competes with the uncoordinated anhydride in the coordination to the unreacted inorganic substrate to give **3a**, thus decreasing the yield of **2a**. The usage of an excess of anhydride limits the formation of **3a**. Under these conditions, we did not collect any evidence for the occurrence of *O*-abstraction reactions which appear instead to be the main process when the system is heated [3a].

Considerations similar to what reported above are valid for the reaction of $TaCl_5$ with MeCOCl (see Section 4). Furthermore, the reaction of $TaBr_5$ with acetic anhydride, followed by ^1H NMR spectroscopy, resulted in formation of **2c** and MeCOBr in 1:3 ratio: no traces of coordination adducts of MeCOBr with $TaBr_5$ were recognized, in accordance with the reactivity of MX_5 with acetyl halides discussed above.

2.2. Reactivity of MCl_5 (M = Nb, Ta) with halo-substituted acetic acids and acetic anhydrides

The results presented in the previous section have pointed out that **1** (M = Nb, Ta, X = Cl, Br) exhibit analogous reactivity towards acetic acid or acetic anhydride. Nevertheless, the dinuclear acetato complexes are obtained in high yields by using acetic acid as reactant, the use of the anhydride leading to lower yields.

In order to see if this chemistry could be extended to other acids/anhydrides, we studied the reactions of MCl_5 (M = Nb, Ta) with halo-substituted acetic acids and with the corresponding anhydrides. The reactions with halo acetic acids led to the isolation and identification of the complexes $[MCl_4(\mu\text{-}OOCR)]_2$ [M = Nb, R = CH_2Cl, **4a**; M = Ta, R = CH_2Cl, **4b**; M = Nb, R = $CHCl_2$, **4c**; M = Ta, R = $CHCl_2$, **4d**; M = Nb, R = CCl_3, **4e**; M = Ta, R = CCl_3, **4f**; M = Nb, R = CF_3, **4g**; M = Ta, R = CF_3, **4h**; M = Nb, R = $CHBr_2$, **4i**; M = Nb, R = CH_2I, **4j**] in good yields. In agreement with what reported in Section 1, most of compounds **4** could be prepared alternatively by reacting **1** with the appropriate anhydride (Scheme 2). These latter reactions are accompanied by production of RCOCl, which has been detected by ^1H NMR in the reaction medium in the majority of the cases (see Section 4). The ^1H NMR spectra of the mixtures suggest that $CH_2ClCOCl$ and $CHCl_2COCl$ give coordination adducts with unreacted **1** as discussed above about the reaction of MeCOCl and MCl_5.

Compounds **4** have been characterized by IR and NMR spectroscopies, and elemental analyses. Moreover, the X-ray molecular structure of **4e** has been determined (Fig. 2 and Table 2).

The molecular structure of **4e** is closely related to the one of **2b**, being the replacement of Ta(V) with Nb(V) and $-CH_3$ with $-CCl_3$ the major differences. Also in this case, each metal centre is coordinated to four chloride ligands and two bridging carboxylates with a relative *cis* geometry of the ligands and a distorted octahedral coordination. Despite the fact that the two halves of **4e** are crystallographically independent, their bonding parameters are almost identical (see Table 2) and comparable to the ones reported for the analogous Nb(V) dinuclear derivative $Nb_2Cl_8(\mu\text{-}OOCC_6F_5)_2$ [4]. Finally, it is noteworthy that the dimeric nature of both **2b** and **4e** originates an octa-membered ring, which is puckered in **2b** [mean deviation from the Ta(1)O(2)C(1)#1 O(1)#1 Ta(1)#1 O(2)#1 O(1) least squares plane 0.1882 Å] but almost planar in **4e** [mean deviation from the Nb(1)O(1)C(1)O(2)Nb(2)O(3)C(3)O(4) least squares plane 0.0850 Å].

Scheme 2. Preparation of halo-acetato derivatives of Nb(V) and Ta(V).

The IR spectra display the symmetric and asymmetric vibrations of the [COO] group in the ranges 1386–1515 cm^{-1} and 1522–1635 cm^{-1}, respectively. In particular, the values available for **4g** are coherent with those reported for bridging trifluoroacetato complexes [11]. More in general, the fact that the difference $\nu_{as} - \nu_s$ results always smaller than 200 cm^{-1} indicates that the carboxylato units behave as bidentate ligands, rather than monodentate [8].

Major ^{13}C NMR feature is given by the resonance due to the carboxylic carbon, which falls in the range 166.2 (**4h**) –182.7 (**4j**) ppm. The ^{13}C signal related to the [CF_3] unit, in **4g–h**, appears as a quartet due to coupling with three adjacent fluorines (J = 286 Hz).

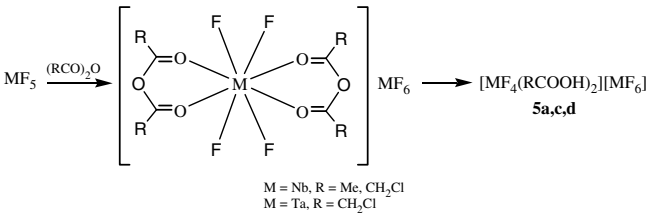
In addition, the ^{19}F NMR spectra (CD_2Cl_2 solutions) carried out on **4g–h** exhibit the singlet attributed to six equivalent fluorines, at *ca.* −74 ppm.

2.3. Reactivity of MF_5 (M = Nb, Ta) with haloacetic acids and haloacetic anhydrides

The pentafluorides MF_5 (M = Nb, Ta) react with RCOOH (R = Me, CH_2Cl), in 1:1 molar ratio, to give the ionic compounds $[MF_4(RCOOH)_2][MF_6]$ [M = Nb, R = Me, **5a**; M = Ta, R = Me, **5b**; M = Nb, R = CH_2Cl, **5c**; M = Ta, R = CH_2Cl, **5d**]:

$$2MF_5 + 2RCOOH \rightarrow \underset{\mathbf{5a-d}}{[MF_4(RCOOH)_2][MF_6]} \quad (4)$$

The products **5a–d** have been characterized by IR, ^1H, ^{13}C and ^{19}F NMR spectroscopies, and elemental analyses. The ^1H NMR spectra exhibit the resonance accounting for the R unit and a down-field resonance (11.61 ppm for **5c**) accounting for one oxygen-bound proton deshielded with respect to the uncoordinated acid [10]. In the ^{13}C NMR spectra, the carboxylic carbon is observed in the range 176.1(**5d**)–183.9(**5a**) ppm.[2] The ^{19}F NMR spectra are particularly diagnostic in determining the structure of compounds **5**, since they display a resonance occurring at typical negative δ values (*e.g.* −132.2 ppm for **5c**), accounting for the $[MF_6]^-$ anion, together with the broad resonance characteristic of the $[MF_4]$ moiety [7c,12].



The IR spectra (solid state) are characterized by a strong absorption in the range 1616–1661 cm^{-1}, ascribable to the carboxylic C=O bond of the RCOOH ligands, rather than to carboxylato units. For instance, the C–O stretching vibration is observed at 1635 cm^{-1} in the IR spectrum of **5b**: this value is significantly closer to 1714 cm^{-1} (uncoordinated MeCOOH [9]), rather than to the wavenumbers (1545–1558 cm^{-1}) found for the bidentate carboxylato moiety within **2a–c**. These data are in agreement with those observed in other metal complexes containing carboxylic acids as ligands, such as $Ru_2(OOCPh)_6(PhCOOH)_2$ [13], $[TiCl_2(OOCR)(RCOOH)]_2O$, R = Et [14], Bu^t [15]. Unfortunately, due to the fact that we were not able to grow crystals suitable for X-ray investigation, we cannot describe in more detail the structural features of the cation of **5**.

The reaction of NbF_5 with $(MeCO)_2O$, in 1:1 molar ratio, resulted in the clean formation of complex **5a**. On the other hand, TaF_5 gave a complicated and not well reproducible mixture of products on reaction with $(MeCO)_2O$, thus this was not investigated further. As far as chloroacetic anhydride is concerned, compounds **5c–d**, in admixture with minor by-products, could be isolated from the reactions with MF_5:

$$MF_5 \xrightarrow[\substack{M=Nb,R=Me,CH_2Cl\\M=Ta,R=CH_2Cl}]{(RCO)_2O} \underset{\mathbf{5a,c,d}}{[MF_4(RCOOH)_2][MF_6]} \quad (5)$$

The chemistry of MF_5 with anhydrides deserves some further comments, because a C–O bond activation and a protonation of an oxygen atom should occur in order to obtain the products of reaction (5). Three hypothesis may be formulated regarding the origin of the proton: it could descend (i) from the anhydride itself, (ii) from the solvent (CH_2Cl_2), or (iii) from adventitious water.

In order to investigate the point, and paying particular attention to maintain strictly anhydrous conditions with anhydrides free from acid residues, we checked the reactions of NbF_5 with $(RCO)_2O$ (R = CH_3, CH_2Cl, one equivalent), in CD_2Cl_2, by NMR spectroscopy (see Section 4). The ^1H NMR spectra, taken 30 min after the mixing of the reactants, indicated clearly the formation of compounds **5a**, **c**. More specifically, the spectra exhibited the resonance of the O–*H* proton, which integrated for the correct ratio with respect to the resonance of the protons on the α-carbon atom, suggesting that the anhydride itself is the source of the proton.

Scheme 3. Mechanism proposed for the reactions of MF_5 with carboxylic anhydrides.

The reaction of NbF_5 with $(CH_2ClCO)_2O$, being well slower than that with acetic anhydride, allowed an intermediate product to be detected and characterized. As a matter of fact, 5 min after the mixing of the reactants, the ^1H NMR spectrum indicated the complete disappearance of the free anhydride, and displayed only one resonance at 4.54 ppm. A quick ^{13}C NMR acquisition allowed to identify two peaks, at δ 167.4 (*C*O) and 48.7 (*C*H_2) ppm, respectively. Contextually, the ^{19}F NMR spectrum revealed the presence of the $[NbF_6]^-$ anion (δ = 133.0 ppm [12]). Twenty minutes later, the resonances attributed to **5c** clearly came out, together with signals ascribable to minor products. These results point to the conclusion that the reactions of MF_5 (M = Nb, Ta) with anhydrides $(RCO)_2O$ (R = CH_3, CH_2Cl) probably proceed *via* the formation of ionic intermediate species such as that reported in Scheme 3, in which two anhydrides coordinate the metal centre in a symmetric fashion [3b]: C–H and C–O bonds activation, and hydrogen migration to the oxygen atom, give the final, stable, products **5**. Unfortunately, neither NMR nor GC–MS investigations allowed the characterization of the organic material derived from the fragmentation of the anhydride. It has to be remarked that activation of C–H or C–O bonds occurs in the reactions of Group 5 metal halides with excess ketones (*e.g.* acetone and acetophenone) [7a], or ethers (the C–O bond activation represents a key step in the polymerization of tetrahydrofuran initiated by **1**) [7b,7d].

In view of the fact that the reaction of MF_5 with carboxylic anhydrides without hydrogen atoms on the α-carbon atom may potentially lead to the isolation of the intermediate represented in Scheme 3, NbF_5 was treated with anhydrous $(CF_3CO)_2O$. Unfortunately, the reaction gave a mixture of inseparable and unidentifiable products. Notwithstanding, when the reaction was performed in a NMR tube (see Section 4), the ^{19}F NMR spectrum of the solution exhibited a peak awarded to the $[NbF_6]^-$ anion. Moreover, the ^1H NMR spectrum did not show any resonance, especially in the O–*H* region. Even though insufficient to establish the nature of the product, these observations are coherent with the structure placed into square brackets in Scheme 3.

3. Conclusions

In this paper, we have presented the results concerning our research on the chemistry of niobium(V) and tantalum(V) pentahalides, MX_5, with haloacetic acids and haloacetic anhydrides.

According to our previous findings, the outcomes of the reactions do not generally depend on the metal but are strongly influenced by the nature of the halide: MCl_5 and MBr_5 show a similar behaviour in the reactions with acetic acids or anhydrides, whereas

[2] The ^{13}C NMR spectrum of **5b** could not be recorded for the low solubility of this complex.

MF_5 show a fully different reactivity. To complete the picture, TaI_5 is inert towards both CH_3COOH and $(CH_3CO)_2O$.

The high stability of the $[MF_6]^-$ anion may be considered as the driving force of the reactions involving MF_5. As a consequence of such stability, HF is not released in the course of the reactions with acids, by contrast with what observed in the reactions of MX_5 (X = Cl, Br) with RCOOH. More in detail, the reactions of MX_5 (X = Cl, Br) with haloacetic acids, which resemble those reported previously regarding the reactivity of $NbCl_5$ with aryl-carboxylic acids, proceed with releasing of HX and afford neutral dimeric complexes containing bridging coordinated acetates. On the other hand, MF_5 react with haloacetic acids with coordination of two intact acid molecules to the metal centre and contextual fluoride migration to give the $[MF_6]^-$ anion.

The reactions of MX_5 with anhydrides result in anhydride fragmentation and afford the same inorganic products obtained by the reactions with the corresponding acids, although in minor yields. With MX_5 (X = Cl, Br), anhydride C–O bond activation occurs, and the reactions proceed with releasing of acetyl halides, being the Lewis acid–base adducts of these latter with MX_5 the prevalent by-products. Beside, when MF_5 are involved, activation of both C–O and C–H bonds takes place within the anhydride, and proton migration afford final stable ionic species. These latter reactions can be accompanied by formation of complicated mixtures of minor products, which have not been identified.

All these investigations were conducted at room temperature, at which no evidences for the formation of *O*-abstraction products were found.

4. Experimental

4.1. General procedures

All manipulations of air and/or moisture sensitive compounds were performed under an atmosphere of pre-purified argon using standard Schlenk techniques. The reaction vessels were oven dried at 150 °C prior to use, evacuated (10^{-2} mm Hg) and then filled with argon. All the reagents, including MX_5 (M = Nb, Ta, X = Cl; M = Nb, Ta, X = F), were commercial products (Aldrich) of the highest purity available. $TaBr_5$ and TaI_5 [16] were prepared according to published procedures. Solid anhydrides and solid $CH_2ClCOOH$ were dried over P_4O_{10} and stored under argon atmosphere as received. Liquid acids and liquid anhydrides were distilled before use under argon atmosphere from P_4O_{10}. MeCOCl and MeCOBr were distilled before use under argon atmosphere discarding a large fraction of liquid before the collection of the distillate. Liquid anhydrides were filtered through a short column of alumina immediately before use and their purity was verified by ^1H NMR. Solvents were distilled before use under argon atmosphere from appropriate drying agents: CH_2Cl_2, CD_2Cl_2, $CDCl_3$ from P_4O_{10}, pentane from $LiAlH_4$.

Infrared spectra were recorded at 298 K on a FT-IR Perkin–Elmer Spectrometer equipped with a UATR sampling accessory (solid samples). NMR measurements were performed at 298 K on Varian Gemini 200BB spectrometer. The chemical shifts for ^1H, ^{13}C, and ^{19}F NMR spectra were referenced to TMS and to $CFCl_3$, respectively.

Carbon and hydrogen analyses were performed at the Dipartimento di Chimica Farmaceutica of the University of Pisa on a Carlo Erba mod. 1106 instrument, paying particular attention to the more sensitive compounds which were weighed and directly introduced into the analyzer. The halide content was determined by the Volhardt method [17] after exhaustive hydrolysis of the sample. The chlorocarboxylic acids did not give a precipitate of AgCl upon treatment with $AgNO_3$ under the conditions used for the hydrolysis of the sample. Metals were analyzed as M_2O_5 obtained by hydrolysis of the sample followed by calcination in a platinum crucible. The halide and the metal analyses were repeated twice in order to get reproducible results.

4.2. Preparation of $[MX_4(\mu\text{-}OOCMe)]_2$ [M = Nb, X = Cl, **2a**; M = Ta, X = Cl, **2b**; X = Br, **2c**]

4.2.1. General procedure

Acetic acid (0.031 mL, 0.54 mmol) was added to a suspension of MX_5 (0.500 mmol) in CH_2Cl_2 (25 mL), in a Schlenk tube. The mixture was stirred for 1 h, and the final solution was layered with pentane (2 × 10 mL). A microcrystalline solid was formed after 24 h at room temperature. In the same conditions, no reaction between TaI_5 and MeCOOH was observed. Crystals suitable for X-ray analysis were collected from a solution of **2b** layered with pentane, at −20 °C.

Found: C, 4.5; H, 0.6; Ta, 31.6; Br, 56.1%. ^1H NMR (CD_2Cl_2) δ = 2.67 (s, 6H, Me) ppm. ^{13}C NMR (CD_2Cl_2) δ = 186.3 (*CO*); 24.3 (Me) ppm. IR (solid state): ν = 2927w, 1545m, sh [ν_{as}(COO)], 1489s [ν_s(COO)], 1444vs, 1387vs, 1348m, 1262m, 1078w, 1029m, 939m, 804s, 680vs cm^{-1}.

4.3. Reactions of MX_5, **1** (M = Nb, X = Cl; M = Ta, X = Cl, Br, I), with $(MeCO)_2O$

4.3.1. General procedure

Acetic anhydride (0.031 mL, 0.33 mmol) was added to a suspension of MX_5 (0.300 mmol) in CD_2Cl_2 (0.8 mL), inside a NMR tube, and the mixture was stirred for 30 minutes. Hence, a precipitate was present, and the ^1H NMR spectrum of the overlying solution appeared as follows: (a) $NbCl_5$: **2a**, CH_3COCl and **3a** (vide infra) were detected in 1:3:7 ratios. (b) $TaCl_5$: **2b**, CH_3COCl and **3b** in 1:3:3 ratios. (c) $TaBr_5$: **2c** and CH_3COBr in 1:3 ratio. (d) TaI_5: only resonances due to free anhydride were seen.

The reaction of acetic anhydride (0.50 mmol) with $NbCl_5$ (0.250 mmol), in CD_2Cl_2 (0.8 mL), gave a mixture consisting of **2a**, CH_3COCl and **3a** in 1:2:3 ratios.

4.4. Preparation of $MCl_5[OC(Cl)Me]$ [M = Nb, **3a**; M = Ta, **3b**]

4.4.1. General procedure

A suspension of MCl_5 (0.500 mmol) in CH_2Cl_2 (10 mL), in a Schlenk tube, was treated with MeCOCl (0.043 mL, 0.60 mmol). The mixture was stirred for 30 min, during which progressive dissolution of the solid occurred. The final solution was dried in vacuo, and the resulting residue was washed with pentane (2 × 10 mL), affording microcrystalline **3**. The addition of a fivefold excess of MeCOCl to $NbCl_5$ (0.300 mmol), in $CDCl_3$ suspension, did result in the prevalent formation of **3a**, according to ^1H NMR spectroscopy. The addition of MeCOBr (0.035 ml, 0.47 mmol) to $TaBr_5$ (0.180 g, 0.310 mmol) in $CDCl_3$ (0.8 mL), inside a NMR tube, resulted in partial dissolution of the solid, but only uncoordinated MeCOBr was detected in solution by ^1H NMR.

3a: orange, 85% yield. *Anal.* Calc. for $C_2H_3Cl_6NbO$: C, 6.9; H, 0.9; Nb, 26.6; Cl, 61.0. Found: C, 6.6; H, 0.9; Nb, 26.3; Cl, 61.2%. Yield: 0.148 g, 85%. ^{1}H NMR ($CDCl_3$) δ = 2.81 (s, 3H, Me) ppm. ^{13}C NMR ($CDCl_3$) δ = 177.5 (CO); 34.2 (Me) ppm. IR (solid state): ν = 2957w, 2922w, 1560m (CO), 1479m, 1446s, 1393s, 1345ms, 1266m, 1154m, 1095m, 1028m, 880ms, 804vs, 778vs cm^{-1}.

3b: yellow, 82% yield. *Anal.* Calc. for $C_2H_3Cl_6TaO$: C, 5.5; H, 0.7; Ta, 41.4; Cl, 48.7. 4.5. Preparation of $[MCl_4(\mu\text{-}OOCCH_2Cl)]_2$ [M = Nb, **4a**; M = Ta, **4b**]

4.5.1. General procedure

Chloroacetic acid (47 mg, 0.50 mmol) was added to MCl_5 (0.450 mmol), in CH_2Cl_2 (15 mL) suspension. The mixture was stirred for 1 h and the final solution was layered with pentane (20 mL): precipitation of microcrystalline **4a**–**b** occurred after 12 h at room temperature. Alternatively, the reactions of MCl_5 (0.20 mmol) with a slight excess of $(CH_2ClCO)_2O$, in CD_2Cl_2 (0.8 mL) inside NMR tubes, afforded solutions containing $CH_2ClCOCl$ and **4a**–**b** in *ca.* 3:1 ratio.

4a: yellow, 70% yield. *Anal.* Calc. for $C_4H_4Cl_{10}Nb_2O_4$: C, 7.3; H, 0.6; Nb, 28.3; Cl, 43.2. Found: C, 7.1; H, 0.7; Nb, 27.9; Cl, 42.9%.[3] ^{1}H NMR (CD_2Cl_2) δ = 4.43 (s, 4H, CH_2) ppm. ^{13}C NMR (CD_2Cl_2) δ = 179.2 (CO); 45.9 (CH_2) ppm. IR (solid state): ν = 2932w, 2886w, 1558m, 1522s [ν_{as}(COO)], 1386vs [ν_s(COO)], 1257s, 1152ms, 965m, 808m, s cm^{-1}.

4b: light yellow, 71% yield. *Anal.* Calc. for $C_4H_4Cl_{10}O_4Ta_2$: C, 5.8; H, 0.5; Ta, 43.5; Cl, 34.1. Found: C, 5.6; H, 0.5; Ta, 43.1; Cl, 34.0%[3]. ^{1}H NMR (CD_2Cl_2) δ = 4.45 (s, 4H, CH_2) ppm. ^{13}C NMR (CD_2Cl_2) δ = 180.4 (CO); 45.8 (CH_2) ppm. IR (solid state): ν = 2999w, 2958w, 1558s, 1532vs [ν_{as}(COO)], 1386vs [ν_s(COO)], 1259s, 1174m, 970wm, 920m, 811m, s, 656m cm^{-1}.

4.6. Preparation of $[MCl_4(\mu\text{-}OOCCHCl_2)]_2$ [M = Nb, **4c**; M = Ta, **4d**]

4.6.1. General procedure

These compounds were prepared by a procedure analogous to that described for **4a**–**b**, by reacting MCl_5 (0.400 mmol) with $CHCl_2COOH$ (0.036 mL, 0.44 mmol), for 2 h. The reactions of MCl_5 (0.20 mmol) with a slight excess of $(CHCl_2CO)_2O$, in CD_2Cl_2 (0.8 mL) inside NMR tubes, afforded solutions containing $CHCl_2COCl$ and **4c**–**d**, in *ca.* 2:1 ratio.

4c: light brown, 75% yield. *Anal.* Calc. for $C_4H_2Cl_{12}Nb_2O_4$: C, 6.6; H, 0.3; Nb, 25.6; Cl, 39.1. Found: C, 6.4; H, 0.3; Nb, 25.1; Cl, 38.6%.[3] ^{1}H NMR (CD_2Cl_2) δ = 6.30 (s, 2H, CH) ppm. ^{13}C NMR (CD_2Cl_2) δ = 173.4 (CO); 63.9 (CH) ppm. IR (solid state): ν = 3003w, 2957w, 2924w, 1601vs [ν_{as}(COO)], 1408s [ν_s(COO)], 1266w, 1231vs, 1095m, 973w, 816vs, 783vs, 709vs cm^{-1}.

4d: light yellow, 71% yield. *Anal.* Calc. for $C_4H_2Cl_{12}O_4Ta_2$: C, 5.3; H, 0.2; Ta, 40.2; Cl, 31.5. IR (solid state): ν = 3006w, 2981w, 2969w, 1609vs [ν_{as}(COO)], 1450m, s [ν_s(COO)], 1422vs, 1264wm, 1236s, 1095w, 978w, 943w, 818s, 786m, 713s, 659ms cm^{-1}.

[3] Due to the fact that the carbon-bonded chloride does not precipitate with silver nitrate under conditions used for the analysis, the chloride content refers to the metal-bonded chloride ion.

4.7. Preparation of $[MCl_4(\mu\text{-}OOCCCl_3)]_2$ [M = Nb, **4e**; M = Ta, **4f**]

4.7.1. General procedure

These compounds were prepared by a procedure analogous to that described for **4a**–**b**, by reacting MCl_5 (0.420 mmol) with CCl_3COOH (0.048 mL, 0.48 mmol), for 3 h. Crystals suitable for X-ray analysis were collected by a CH_2Cl_2 solution of **4e**, layered with pentane, at −20 °C.

4e: yellow, 68% yield. *Anal.* Calc. for $C_4Cl_{14}Nb_2O_4$: C, 6.0; Nb, 23.4; Cl, 35.7. Found: C, 6.3; Nb, 23.2; Cl, 35.9%.[3] ^{13}C NMR (CD_2Cl_2) δ = 170.5 (CO); 90.0 (CCl_3) ppm. IR (solid state): ν = 1621vs [ν_{as}(COO)], 1505 m [ν_s(COO)], 1393s, 1362ms, 1262w, 978m, 855vs, 823vs, 726vs, 682vs cm^{-1}.

4.8. Preparation of $[MCl_4(\mu\text{-}OOCCF_3)]_2$ [M = Nb, **4g**; M = Ta, **4h**]

4.8.1. General procedure

These compounds were prepared by a procedure analogous to that described for **4a**–**b**, by reacting MCl_5 (0.500 mmol) with CF_3COOH (0.045 mL, 0.61 mmol). Alternatively, compounds **4g**–**h** were obtained in comparable yields by reacting MCl_5 (0.25 mmol) with one equivalent of $(CF_3CO)_2O$.

4g: yellow, 75% yield. *Anal.* Calc. for $C_4Cl_8F_6Nb_2O_4$: C, 6.9; Nb, 26.7; Cl, 40.8. IR (solid state): ν = 2978m, 2932w, 1760m, 1635m, s [ν_{as}(COO)], 1464m [ν_s(COO)], 1383s, 1259w, m, 1208m, 1163m, s, 1099vs, 1011s, 918m, 832vs, 804vs cm^{-1}.

4h: colourless, 67% yield. *Anal.* Calc. for $C_4Cl_8F_6O_4Ta_2$: C, 5.5; Ta, 41.5; Cl, 32.5. Found: C, 5.2; Ta, 41.1; Cl, 32.0%. ^{13}C NMR (CD_2Cl_2) δ = 166.2 (m, CO); 114.9 (q, $^1J_{CF}$ = 286 Hz, CF_3) ppm. ^{19}F NMR (CD_2Cl_2) δ = −73.9 (s, 6F, CF_3) ppm.

4.9. Preparation of $[NbCl_4(\mu\text{-}OOCCHBr_2)]_2$, **4i**, and of $[NbCl_4(OOCCH_2I)]_2$, **4j**

4.9.1. General procedure

These compounds were prepared by a procedure analogous to that described for **4a**–**b**, by reacting $NbCl_5$ (0.600 mmol) with a slight excess of $CHBr_2COOH$ or CH_2ICOOH, respectively.

4i: yellow, 77%. *Anal.* Calc. for $C_4H_2Br_4Cl_8Nb_2O_4$: C, 5.3; H, 0.2; Nb, 20.6. Found: C, 5.1; H, 0.2; Nb, 19.8%. ^{1}H NMR (CD_2Cl_2) δ = 6.19 (s, 2H, CH) ppm. ^{13}C NMR (CD_2Cl_2) δ = 175.5 (CO); 34.7 (CH) ppm.

4j: yellow, 70% yield. *Anal.* Calc. for $C_4H_4I_2Cl_8Nb_2O_4$: C, 5.7; H, 0.5; Nb, 22.1. Found: C, 5.6; H, 0.6; Nb, 20.9%. ^{1}H NMR (CD_2Cl_2) δ = 4.19 (s, 4H, CH_2) ppm. ^{13}C NMR (CD_2Cl_2) δ = 182.7 (CO); −3.9 (CH_2) ppm.

4.10. Preparation of $[MF_4(RCOOH)_2][MF_6]$ [M = Nb, R = Me, **5a**; M = Ta, R = Me, **5b**; M = Nb, R = CH_2Cl, **5c**; M = Ta, R = CH_2Cl, **5d**]

4.10.1. General procedure

A suspension of MF_5 (0.400 mmol) in CH_2Cl_2 (15 mL) was treated with RCOOH (0.42 mmol; R = Me, CH_2Cl). The mixture was stirred for 30 min and the resulting solution was layered with pentane (20 mL). Compounds **5a**–**d** were obtained as microcrystalline solids after 12 h.

5a: orange, 85% yield. *Anal.* Calc. for $C_4H_8F_{10}Nb_2O_4$: C, 9.7; H, 1.6; Nb, 37.5. Found: C, 9.9; H, 1.5; Nb, 37.0%. ^{1}H NMR (CD_2Cl_2)

δ = 12.28 (s, 2H, O*H*), 2.35 (s, 6H, Me) ppm. ^{13}C NMR (CD_2Cl_2) δ = 183.9 (*C*O), 22.2 (Me) ppm. ^{19}F NMR (CD_2Cl_2) δ = 151.2 (Nb*F*$_4$), −132.3 (Nb*F*$_6$) ppm. IR (solid state): ν = 3228w, br (O–H), 2956w, 1661vs (C=O), 1551m, 1432m, 1395ms, 1275m, 1203br, m, 906vs, 797vs cm^{-1}.

5d: pale yellow, 81% yield. *Anal.* Calc. for $C_4H_6Cl_2F_{10}O_4Ta_2$: C, 6.5; H, 0.8, Ta, 48.8. Found: C, 6.4; H, 1.0; Ta, 48.6%. ^{1}H NMR (CD_2Cl_2) δ = 11.59 (s, 2H, O*H*); 4.34 (s, 4H, C*H*$_2$) ppm. ^{13}C NMR (CD_2Cl_2) δ = 176.1 (*C*O); 40.9 (*C*H$_2$) ppm. ^{19}F NMR (CD_2Cl_2) δ = 83.3 (Ta*F*$_4$); −132.4 (Ta*F*$_6$) ppm. IR (solid state): ν = 3225m, br (O–H), 3013w, 2958w, 1630vs (C=O), 1555m, 1450m, 1390m, s, 1270m, 1170m, 923s, 903s, 850m, s, 804s, 712m, s cm^{-1}.

4.11. Reactions of MF_5 (M = Nb, Ta) with $(MeCO)_2O$ and $(CH_2ClCO)_2O$

Compound NbF_5 (0.350 mmol), in CH_2Cl_2 suspension (15 mL), was treated with $(MeCO)_2O$ (0.036 mL, 0.38 mmol). The mixture was stirred for 1 h, then the solvent was removed under vacuum. Hence, the resulting residue was washed with pentane (2 × 10 mL), giving a dark yellow solid. An aliquot of this solid was analyzed by ^{1}H NMR spectroscopy (CD_2Cl_2 solution), which revealed the presence of a mixture of products, being **5a** the prevalent one. The reaction of TaF_5 with $(MeCO)_2O$, which was carried out three times in conditions analogous to that described for NbF_5, afforded complicated mixtures of products and did not appear reproducible.

The reactions of MF_5 (0.400 mmol; M = Nb, Ta) with $(CH_2ClCO)_2O$ (72 mg, 0.42 mmol) in CH_2Cl_2, yielded yellow solids upon removal of the solvent under vacuo. These solids were dissolved in CD_2Cl_2 and analyzed by ^{1}H NMR spectroscopy. The resonances related to **5c–d** were found, together with minor signals due to unidentified by-products. The formation of **5c–d** was confirmed by IR spectroscopy.

4.12. Reaction of NbF_5 with $(CH_2ClCO)_2O$ followed by NMR

Compound NbF_5 (120 mg, 0.639 mmol), CD_2Cl_2 (0.8 mL) and $(CH_2ClCO)_2O$ were introduced into a NMR tube in the order given, and the mixture was shaken for ca. one minute. ^{1}H, ^{13}C and ^{19}F NMR spectra were recorded after 5 min: ^{1}H NMR δ = 4.54 (s, C*H*$_2$) ppm; ^{13}C NMR δ = 167.4 (*C*O); 48.7 (*C*H$_2$) ppm; ^{19}F NMR δ = −133.0 (Nb*F*$_6$) ppm. After 30 min, the ^{1}H NMR spectrum of the mixture indicated complete disappearance of the resonance at 4.54 ppm and the formation of **5c** together with some by-products.

4.13. Reaction of NbF_5 with $(CF_3CO)_2O$

Complex NbF_5 (180 mg, 0.958 mmol), in suspension of CH_2Cl_2 (15 mL), was treated with $(CF_3CO)_2$ (0.12 mL, 0.90 mmol). The mixture was stirred for 2 h, then the solvent was removed in vacuo. The resulting residue was washed with pentane (2 × 15 mL), thus a pale yellow solid was obtained. ^{19}F NMR (CD_2Cl_2) δ = −133.1 (Nb*F*$_6$) ppm. ^{1}H NMR (CD_2Cl_2): no resonances in the O–*H* region.

4.14. X-ray crystallographic study

Crystal data and collection details for $[TaCl_4(\mu\text{-}OOCMe)]_2$, **2b**, and $[NbCl_4(\mu\text{-}OOCCCl_3)]_2$, **4e**, are reported in Table 3. The diffraction experiments were carried out on a Bruker APEX II diffractometer equipped with a CCD detector using Mo Kα radiation. Data were corrected for Lorentz polarization and absorption effects (empirical absorption correction SADABS) [18]. Structures were solved by direct methods and refined by full-matrix least-squares based on all data using F^2 [19]. Hydrogen atoms bonded to C-atoms were fixed at calculated positions and refined by a riding model. All non-hydrogen atoms were refined with anisotropic displacement parameters. In the crystal structure of **2b**, the asymmetric unit contains only half of the molecule. The crystal of **4e** is racemically twinned with a refined Flack parameter of 0.23(3) [20], and it was, therefore, refined using the TWIN refinement routine of SHELXTL.

ketyl before use. ε-CL was purchased from Acros, dried by stirring with CaH_2 for 48 h, and then distilled under reduced pressure. The complexes $Li_2L(THF)_{0.5}$ [3], LYbCl(THF)$_2$ (**1**) [4a] and anhydrous $LnCl_3$ [6] were prepared according to the literature procedures. All other reagents were purchased from Acros and used as received without further purification. IR spectra were recorded on a Magna-IR 550 spectrometer. ^{1}H NMR spectra were measured on a Unity Inova-400 spectrometer. Melting points were determined in sealed capillary tube, and uncorrected. Lanthanide analyses were carried out by complexometric titration. Carbon, hydrogen and nitrogen analyses were preformed by direct combustion with a Carlo-Erba EA 1110 instrument. Molecular weight and molecular weight distributions were determined against polystyrene standard by gel permeation chromatography (GPC) on a Waters 1515 apparatus with three HR columns (HR-1, HR-2 and HR-4), THF was used as an eluent at 30 °C.

2.2. Synthesis of metal complexes

2.2.1. LYCl(DME) (*2*)

Method A. A solution of $LLi_2(THF)_{0.5}$ (0.99 g, 2.1 mmol) in THF (15 mL) was added to a stirring suspension of YCl_3 (0.41 g, 2.1 mmol) in THF (30 mL). After stirring at r.t. for 48 h the solvent was removed in vacuo. The residue was extracted with toluene (30 mL) and the volume of the extract was reduced to 10 mL followed by addition of DME (1 mL). Cooling to 0 °C afforded **2** as colorless crystals. Yield: 0.80 g (60%), melt point: 120–123 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ 7.78–6.95 (m, 10H, Ph), 3.79 (m, 4H, OCH_2CH_2O), 3.34 (m, 6H, OCH_3), 3.12 (m, 4H, CH_2N), 1.23 (m, 2H, C*H*H), 1.01 (m, 2H, CH*H*), 0.31 (s, 18H, $SiMe_3$) ppm. IR (KBr pellet, cm^{-1}): 2956 (m), 1635 (s), 1568 (m), 1446 (m), 1383 (m), 1251 (w), 1206 (w), 1062 (w), 892 (w), 841 (w), 781 (w), 700 (m). *Anal.* Calc. for $C_{27}H_{44}Cl_1N_4O_2Si_2Y$ (M_W: 637.20): C, 50.89; H, 6.97; N, 8.79; Y, 13.95. Found: C, 51.05; H, 6.84; N, 8.96; Y, 13.78%.

Method B. A clear solution of **6** (1.21 g, 1 mmol) in THF (25 mL) was added to a stirring solution of YCl_3 (0.47 g, 1 mmol) in THF (20 ml). Complex **2** was isolated as colorless crystals by the same procedure as outlined for method A. Yield: 0.48 g (75%).

2.2.2. $Yb_2(\mu_2\text{-}L)_3 \cdot DME$ (*3*)

Method A. A solution of $LLi_2(THF)_{0.5}$ (0.47 g, 1 mmol) in THF (15 mL) was added to a stirring solution of **1** (1.55 g, 2 mmol) in THF (20 ml). The reaction mixture was stirred for 48 h at r.t. to become a clear solution. The volatiles were removed under reduced pressure and the residue was extracted with toluene (40 mL) and evaporated to dry. The solid was dissolved in DME (10 mL) and filtered. Cooling the solution to 0 °C afforded **3** as colorless crystals. Yield: 1.28 g (75%), melt point: 284–287 °C. IR (KBr pellet, cm^{-1}): 2959 (m), 1628 (m), 1570 (m), 1543 (m), 1385 (m), 1253 (w), 1060 (w), 891 (w), 844 (w), 783 (w), 756 (w), 702 (m). *Anal.* Calc. for $C_{73}H_{112}N_{12}O_2Si_6Yb_2$ (M_W: 1704.37): C, 51.44; H, 6.64; N, 9.86; Yb, 20.31. Found: C, 51.64; H, 6.21; N, 9.97; Yb, 20.03%.

Method B. A solution of $LLi_2(THF)_{0.5}$ (1.41 g, 3 mmol) in THF (30 mL) was added to a stirring suspension of $YbCl_3$ (0.56 g, 2 mmol) in THF (25 mL). Complex **3** was obtained as colorless crystals by the same procedure as outlined for method A. Yield: 1.02 g (60%).

Method C. A clear solution of **5** (2.59 g, 2 mmol) in THF (25 mL) was added to a stirring solution of **1** (2 mmol) in THF (20 ml). Complex **3** was isolated as colorless crystals by the same procedure as outlined for method A. Yield: 2.08 g (61%).

2.2.3. $Y_2(\mu_2\text{-}L)_3 \cdot DME$ (*4*)

Method A. A solution of $LLi_2(THF)_{0.5}$ (0.24 g, 0.5 mmol) in THF (20 mL) was added to a stirring solution of **2** (0.64 g, 1 mmol) in THF (20 ml). The reaction mixture was stirred for 48 h at r.t. to become a clear solution. The volatiles were removed under reduced pressure and the residue was extracted with toluene (40 mL) and evaporated to dry. The solid was dissolved in DME (5 mL) and filtered. Cooling the solution to 0 °C afforded **4** as colorless crystals. Yield: 0.42 g (55%), melt point: 170–173 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ 7.44–7.07 (m, 30H, Ph), 3.64 (m, 4H, OCH_2CH_2O), 3.44 (m, 6H, OCH_3), 3.23 (m, 12H, CH_2N), 1.64 (m, 3H, C*H*H), 1.45 (m, 3H, CH*H*), 0.26 (s, 54H, $SiMe_3$) ppm. IR (KBr pellet, cm^{-1}): 2955 (m), 1643 (m), 1605 (s), 1559 (s), 1381 (w), 1250 (w), 903 (w), 833 (w), 779 (w), 702 (m). *Anal.* Calc. for $C_{73}H_{112}N_{12}O_2Si_6Y_2$ (M_W: 1536.11): C, 57.07; H, 7.36; N, 10.94; Y, 11.58. Found: C, 56.93; H, 7.05; N, 11.21; Y, 11.24%.

Method B. A THF (40 mL) solution of $LLi_2(THF)_{0.5}$ (1.41 g, 3 mmol) was added to a stirring suspension of YCl_3 (1.41 g, 3 mmol) in THF (30 mL). Cooling to 0 °C afforded Complex **4** was isolated as colorless crystals by the same procedure as outlined for method A. Yield: 1.06 g (69%).

Method C. A clear solution of **6** (1.21 g, 1 mmol) in THF (25 mL) was added to a stirring solution of **2** (0.64 g, 1 mmol) in THF (20 ml). Complex **4** was isolated as colorless crystals by the same procedure as outlined for method A. Yield: 0.95 g (62%).

2.2.4. [Li(DME)$_3$][L$_2$Yb] (*5*)

Method A. A stirred suspension of $YbCl_3$ (0.42 g, 1.5 mmol) in THF (20 mL) was treated with $LLi_2(THF)_{0.5}$ (1.41 g, 3 mmol) in THF (15 mL). After the reaction mixture was stirred at r.t. for 48 h, the solvent was removed in vacuo. The residue was extracted with toluene (40 mL) and the volume of the extract was reduced to 10 mL followed by addition of DME (1 mL). Cooling to 0 °C afforded **5** as colorless crystals. Yield: 1.46 g (75%), melt point: 116–118 °C. IR (KBr pellet, cm^{-1}): 2963 (m), 1628 (m), 1543 (m), 1443 (m), 1381 (m), 1258 (w), 1204 (w), 1095 (w), 1026 (w), 895 (w), 841 (w), 787 (w), 702 (m). *Anal.* Calc. for $C_{58}H_{98}LiN_8O_6Si_4Yb$ (M_W: 1295.78): C, 53.76; H, 7.64; N, 8.65; Yb, 13.35. Found: C, 53.91; H, 7.35; N, 8.86; Yb, 13.54%.

Method B. A stirring solution of LYbCl(THF)$_2$ (0.78 g, 1 mmol) in THF (20 ml) was treated with $LLi_2(THF)_{0.5}$ (0.47 g, 1 mmol) in THF. Complex **5** was isolated as colorless crystals by the same procedure as outlined for method A (0.91 g, 70%).

2.2.5. [Li(DME)$_3$][L$_2$Y] (*6*)

Method A. A stirred suspension of YCl_3 (0.20 g, 1 mmol) in THF (20 mL) was treated with $LLi_2(THF)_{0.5}$ (0.94 g 2 mmol) in THF (20 mL). The reaction mixture was stirred at r.t. for 48 h, the solvent was removed in vacuo. The residue was extracted with toluene (50 mL) and the volume of the extract was reduced to 5 mL followed by addition of DME (1 mL). Cooling to 0 °C afforded **6** as colorless crystals. Yield: 0.91 g (75%), melt point: 109–112 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ 7.85–6.97 (m, 20H, Ph), 3.87 (m, 12H, OCH_2CH_2O), 3.58 (m, 18H, OCH_3), 3.20 (m, 8H, CH_2N), 1.46 (m, 2H, C*H*H), 1.12 (m, 2H, CH*H*), 0.31 (m, 36H, $SiMe_3$) ppm. IR (KBr pellet, cm^{-1}): 2948 (m), 1643 (m), 1605 (s) 1559 (m), 1489 (m), 1443 (m), 1373 (m), 1250 (w), 1196 (w), 980 (w), 903 (w), 833 (w), 779 (w), 702 (m). *Anal.* Calc. for $C_{58}H_{98}LiN_8O_6Si_4Y$ (M_W: 1211.65): C, 57.49; H, 8.17; N, 9.25; Y, 7.34. Found: C, 57.74; H, 8.05; N, 9.51; Y, 7.62%.

Method B. A stirring solution of **2** (0.64 g, 1 mmol) in THF (20 ml) was treated with $LLi_2(THF)_{0.5}$ (0.47 g, 1 mmol) in THF. Complex **6** was isolated as colorless crystals by the same procedure as outlined for method A (Yield: 0.95 g (78%)).

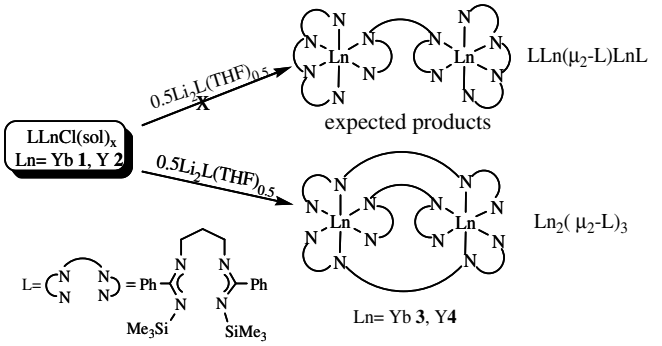
2.3. X-ray crystallographic study

Suitable crystals of complexes **2**–**6** for X-ray diffraction were sealed in a thin-walled glass capillary filled under argon for structural analysis. Diffraction data were collected on a Rigaku Mercury

CCD area detector. The structures were solved by direct methods and refined by full-matrix least-squares procedures based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement coefficients [7]. Hydrogen atoms were treated as idealized contributions. Crystal and refinement data are listed in Table 1.

2.4. Polymerization of ε-CL

To a stirred solution of ε-CL in toluene, a toluene solution of initiator was added with a syringe. The polymerization mixture was stirred for a definite time at the desired temperature and then quenched with an ethanol solution containing a small amount of hydrochloric acid. Polymer was precipitated from ethanol and washed with ethanol three times and dried under vacuum.



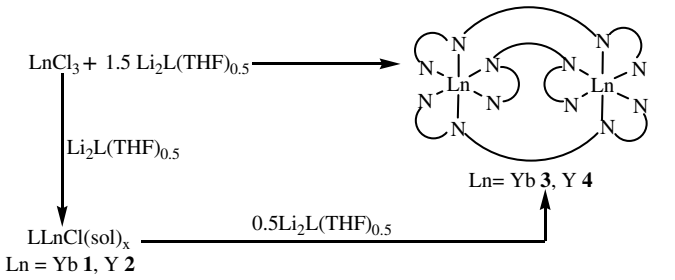
3. Results and discussion

3.1. Synthesis and molecular structure of LYClDME (2) and $Ln_2(\mu_2$-L)$_3 \cdot$ DME (Ln = Yb 3; Y 4)

Complex **1** [4a] was synthesized by the literature procedure as shown in Eq. (1). Treatment of **1** with 0.5 equiv. of $LLi_2(THF)_{0.5}$, followed by extraction with toluene, afforded colorless crystals upon crystallization from toluene. The full characterization by elemental analysis and X-ray crystal structural determination indicated that the product was the bimetallic complex $Yb_2(\mu_2\text{-L})_3 \cdot$ DME (**3**), not the expected complex LYb(μ_2-L)YbL as shown in Scheme 1

$$LnCl_3 + Li_2L(THF)_{0.5} \rightarrow LLnCL(sol)_xLn = Yb, sol = THF, x = 2, \mathbf{1}; Ln = Y, sol = DME, x = 1, \mathbf{2} \quad (1)$$

The isolation of **3**, instead of the complex LYb(μ_2-L)YbL, is somewhat surprised to us because the coordination mode of the L in **3** is quite different from that in LYb(μ_2-L)YbL. In **3** each of the three L acts as a bidented bridging ligand to link the two metals together, while each of the two L works as a chelating ligand and the third L as a bridging ligand to link the two YbL parts together in LYb(μ_2-L)YbL. Obviously, the formation of **3** should be included the change of coordination mode of L from a chelating fashion to a bridging one, i.e. the cleavage of two chelating Yb–amidinate bonds and then ligand redistribution during the reaction. In order to see whether this is the special case for Yb metal, the same reaction with Y was conducted. Complex **2** was then synthesized according to the procedure reported previously [4a] (Eq. (1)). The molecular structure of **2** was further determined by X-ray diffraction to be a monomeric structure with L as a chelating ligand (see the later part of this paragraph). Reaction of **2** with 0.5 equiv. of the dilithium salt went smoothly. After workup, colorless crystals were isolated in good yield. The crystals were fully characterized including elemental analysis, ^{1}H NMR and X-ray technique to be the analogous bimetallic complex $Y_2(\mu_2\text{-L})_3 \cdot$ DME (**4**) (Scheme 1). The results indicated that the occurrence of the ligand redistribution during the metathesis reaction here is independent on the metal used.



Scheme 1.

The pathway for the formations of **3** and **4** was proposed to be the same way that supposed for the preparation of the bimetallic lanthanocene hydride published [8]. The attack of lithium amidinate results in the cleavage of one of chelated Ln–bis(amidinate) bonds, followed by redistribution to another Ln metal. The same ligand redistribution, derived from the reaction of **1** with $NaN(TMS)_2$ was also described [4b]. These results indicate that the ligand redistribution of a linked bis(amidinate) ligand with a flexible bridge could be taken place under certain conditions and could become a strategy to various structure motifs by choice of right reagents and ligands.

Further study found that **3** and **4** can also be prepared directly by reaction of $LnCl_3$ with the dilithium salt in molar ratio of 1:1.5 (Scheme 2) in high yield. Its worth notice that **3**(**4**) was never isolated from the metathesis reaction of $LnCl_3$ with dilithium salt in 1:1 molar ratio, by prolonging reaction time and raising reaction

Scheme 2.

temperature. Therefore, the formation of **3**(**4**) in this procedure may supposed through two steps: the metathesis reaction affords **1**(**2**) first and then **1**(**2**) reacts further with the dilithium salt to form **3**(**4**) via ligand redistribution reaction as shown in Scheme 2.

Complexes **2**, **3** and **4**, have been characterized by IR, single-crystal X-ray diffraction and also ^{1}H NMR spectroscopy for **2** and **4**. No ^{1}H NMR data were obtained for **3**, due to the paramagnetism of the ytterbium. In their IR spectra a strong absorption of C=N stretch at approximate 1640 cm^{-1} for both complexes was observed indicating the delocalized double bond of the N–C–N linkage [9].

The molecular structure of **2** is shown in Fig. 1. Selected bond distances and angles are listed in Table 2. Complex **2** has a monomeric structure, in which the yttrium atom is ligated by two linked bidentate amidinate moieties through nitrogen atoms, one chlorine atom, and two oxygen atoms of a coordinated DME molecule. The coordination geometry about the yttrium atom can be best described as a distorted trigonal bipyramid with each chelating bidentate amidinate ligand to occupy one coordination vertex, which is similar to that of **1** reported previously. The bond lengths of all Y–N are around 2.370(3) Å, which is comparable to that found in **1** if the deviation in ion radium between Y and Yb was considered.

The crystal structures of **3** and **4** are shown in Fig. 2. Selected bond distances and angles are listed in Table 3. Complexes **3** and **4** are isostructure having a free DME molecule in the unit cell. In the two complexes the central metals are connected together by three bridged bis(amidinate)s and each central metal coordinates to three amidinates in dihapto fashion through the nitrogen atoms with the Ln–N–C–N units only deviating slight from planarity (the largest one is 0.0003 Å from the plane Y1–N5–C24–N6). The whole molecule has a cage-like structure with the two planes formed by

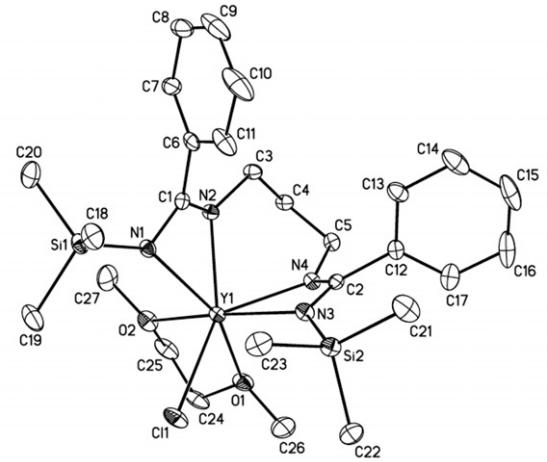

Fig. 1. Molecular structure of the complex **2**. Thermal ellipsoids are drawn at the 20% level. Hydrogen atoms are omitted for clarity.

LnCCC occupying on top (Ln1–C1–C24–C47) and bottom plane (Ln2–C2–C25–C48). The coordinated geometries about each metal can be best described as a distorted octahedron in which four nitrogen atoms can be considered to occupy equatorial positions (N1, N2, N5 and N10; N3, N4, N7 and N12) with the angles sum about the lanthanide center of ΣN–Ln–N = 363.4° for Yb1 and 363.8° for Y1; 365.8° for Yb2 and 366.3° for Y2, while another two nitrogen atoms occupy axial positions and the N–Ln–N angle is distorted away from the idealized 180° (N6–Yb1–N9, 158.7° and N8–Yb2–N11, 159.2°; N6–Y1–N9, 157.6° and N8–Y2–N11, 158.6°). The angles of N–Ln–N in the Ln–N–C–N units are almost equal for the two complexes and the average value is 58.3° for **3** and 57.5° for **4**, which are comparable to the values found in homoleptic lanthanide tri(amidinates) [1a]. The bond lengths of Ln–N range from 2.352(2) to 2.392(2) Å for **3**, and 2.307(2) to 2.354(2) Å for **4**. The average Ln–N bond length of **3**, 2.361(2) Å, is comparable to 2.325(2) Å found in **4**, if the difference in ionic radii between the two metals is considered. The values are also comparable with 2.342(8) Å for $[CyNC(Me)Cy]_3Yb$ [1a] and 2.326(5) Å for $[CyNC(Ph)Cy]_3Yb$ [1a]. The bond lengths of Ln–C on N–C–N are around 2.765(3) Å for **3**, and 2.731(3) Å for **4** which are comparable to the values for lanthanide amidinate complexes published [1a]. All C–N bond distances within the chelating NCN units are nearly equal with the average value 1.332(4) Å for both complexes, which reflects the delocalization of the π bond in the N–C–N unit.

*3.2. Synthesis, molecular structure and reactivity of anionic complexes $[Li(DME)_3][L_2Ln]$ (Ln = Yb **5**;Y **6**)*

Treatment of $YbCl_3$ with $Li_2L(THF)_{0.5}$ in a molar ratio of 1:2, after workup afforded colorless crystals in good yield. The crystals were full characterized including X-ray analysis to be the target product $[Li(DME)_3][L_2Yb]$ (**5**) (Scheme 3). The same reaction with YCl_3 gave

Scheme 3.

the analogous complex $[Li(DME)_3][L_2Y]$ (**6**) as colorless crystals in good yield (Scheme 3). ^1H NMR spectrum of **6** shows the signals of bis(amidinate) ligands [3], but no ^1H NMR data were obtained for**5** due to the paramagnetism of the ytterbium. In their IR spectra a strong absorption of C=N stretch at approximate 1640 cm^{-1} for both complexes was observed indicating the delocalized double bond of the N–C–N linkage [9].

Complexes **5** and **6** can also be prepared by reaction of **1** and **2**, respectively, with 1 equiv. of $Li_2L(THF)_{0.5}$ (Scheme 3).

The molecule structures of complexes **5** and **6** are shown in Fig. 3. Selected bond distances and angles are listed in Table 4. Complexes **5** and **6** have the same structure composed of a pairs of discrete cation and anion. The Ln atom in anion coordinates to two bis(amidinate)s to form a distorted tetrahedron, if each chelating amidinate ligand is considered to occupy a single coordination site. All four-membered rings Ln–N–C–N are essentially planar. The average bond angle of the N–Ln–N in the Ln–N–C–N unit, 54.8(2)°, for **5** is comparable to 54.4(1)° in **6**, but smaller than the corresponding values found in complexes **3** and **4**. The average bond length of the Ln–N (2.444(7) Å for **5** and 2.475(4) Å for **6)** and the bond lengths of the Ln– C on the N–C–N (around 2.869(7) Å for **5** and 2.890(5) Å for **6**) are longer than the corresponding values found in **1** and **2**. All these bond parameters reflect that four of amidinate groups make the coordinate sphere around the central metal more crowded. The coordinate geometry of the cation is normal.

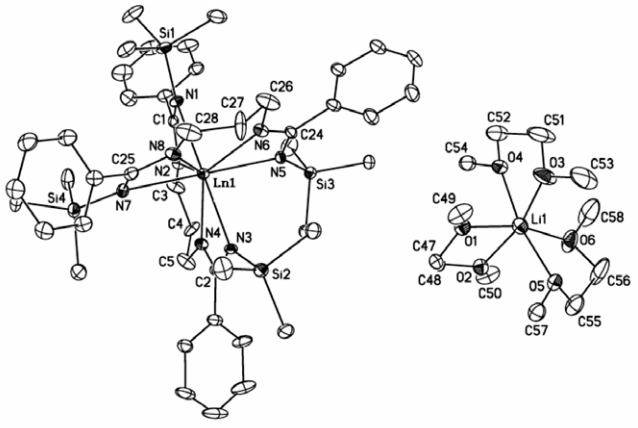

Fig. 3. Molecular structure of the complexes **5** (Ln = Yb) and **6** (Ln = Y). Thermal ellipsoids are drawn at the 30% level. Hydrogen atoms are omitted for clarity.

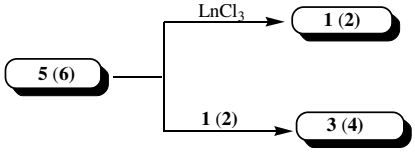
To see whether the complex LLn(μ_2-L)LnL (Ln = Yb, Y) could be prepared by the reaction of **5** and **6** with **1** and **2** respectively, the two reactions at room temperature were tried, respectively. Complexes **5** and **6** do react with **1** and **2** smoothly in THF, after workup, to afford colorless crystals in good yield for both metals, which were fully characterized to be complexes **3** and **4**, respectively, not the complexes LLn(μ_2-L)LnL as shown in Scheme 4. The results indicate again that complexes **3** and **4** are really much more stable than LLn(μ_2-L)LnL, which leads to the ligand redistribution reaction occurred easily during the present metathesis reaction.



Complexes **5** and **6** can react with $LnCl_3$ to afford complexes **1** and **2**, respectively (Scheme 4).

3.3. Catalytic activity for ring-opening polymerization of ε-CL

The catalytic activity of **3**, **4**, **5** and **6** for ring-opening polymerization of ε-CL was examined under variety of conditions. The preliminary results are listed in Table 5. In comparison the reactivity of Li_2L was also tested, and no reactivity was found under the same conditions (Table 5, entry 8). It can be seen that all complexes are active initiators under mild conditions. All systems yield the polymers with a unimodal molecular weight distribution, indicating they function as single component catalysts. The anionic complexes of **5** and **6** are less active related to **3** and **4**. This may be contributed to the crowded coordination environment around the lanthanide metal by two bridged bis(amidinate) ligands. The center metal has profoundly effect on the activity and the active sequence of Yb < Y was observed for both the anionic complexes (**5** and **6)** and the bimetallic complexes (**3** and **4)**. This may result from the more crowded coordination environment around the smaller Yb metal than Y metal, which leads to the coordination of monomer to metal and then insertion of activated monomer more difficulty. Among the four complexes **4** is the most efficient catalyst. For example, quantitative yield was obtained within 30 min at room temperature with **4** at the molar ratio of monomer to catalyst of 2500:1, while the yields were only 87% and 57% for **3** and **6**, even the molar ratio of monomer to catalyst decreased to 2000:1 (Table 5, entries 1, 3 and 7). The polymerization system with **4** could still give 55% yield within 30 min, when the molar ratio of monomer to initiator increased to 4000:1 (Table 5, entry 2). All polymerization systems gave the polymers with rather broad molecular weight distributions. The polydispersity index M_w/M_n

ranged from 1.87 to 2.80. The values are comparable to those found for the systems with homoleptic lanthanide triamidinate complex as initiator [1a,1b,1c]. The reason for broad molecular weight distribution might be attributed to multi-active Ln–amidinate bonds existed in these catalysts [1a,1b,1c]. However, the activity of **4** is lower than that of the related complex with unbridged amidinate ligands [1a]. The reason for it may be attributed to the bimetallic structure skeleton of **4** which may not favor the coordination and insertion of monomer to active species.

4. Conclusion

In conclusion, four novel lanthanide complexes bearing bridged bis(amidinate) ligand L ($Me_3SiNC(Ph)N(CH_2)_3NC(Ph)NSiMe_3$) in different coordination modes were synthesized in high yields including $Ln_2(\mu_2\text{-}L)_3 \cdot DME$ and $Li(DME)_3LnL_2$ (Ln = Yb, Y). The change of the coordination mode of L from a chelating fashion to a bridging one was occurred during the metathesis reaction of $LLnCl(sol)_x$ with 0.5 equiv. of Li_2L. The results presented here demonstrated that the different coordination mode of L, which leads to the different structure motif, can be realized under different conditions. The further work on designing definite catalysts with the bridged bis(amidinate) ligands are currently proceeding in our laboratory.

LH_2 (*Diprotonated*) LH^- (*Mono-protonated*) L^{2-} (*Fully deprotonated*)

Scheme 1.

calomel reference electrode (SCE) were used in a three electrode configuration. The supporting electrolyte was $[NEt_4]ClO_4$ and the solute concentration was $\sim 10^{-3}$ M. The half-wave potential E^0_{298} was set equal to $0.5(E_{pa} + E_{pc})$, where E_{pa} and E_{pc} are anodic and cathodic cyclic voltammetric peak potentials, respectively. All experiments were carried out under a dinitrogen atmosphere and were uncorrected for junction potentials. The elemental analyses were carried out with Perkin–Elmer elemental analyser.

2.3. Crystallography

Single crystals were grown by slow diffusion followed by slow evaporation technique. The intensity data were collected using a Bruker SMART APEX-II CCD diffractometer, equipped with a fine focus 1.75 kW sealed tube Mo Kα radiation ($\lambda = 0.71073$ Å) at 273(3) K, with increasing ω (width of 0.3° per frame) at a scan speed of 3 s/frame. The SMART software was used for data acquisition. Data integration and reduction were undertaken with SAINT and XPREP [16] software. Multi-scan empirical absorption corrections were applied to the data using the program SADABS [17]. Structures were solved by direct methods using SHELXS-97 and refined with full-matrix least squares on F^2 using SHELXL-97 [18]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located from the difference Fourier maps and refined. Structural illustrations have been drawn with ORTEP-3 for Windows [19].

2.4. Synthesis of the ligand, LH_2

The tridentate ligand, LH_2 has been synthesized in a modified reported route [20]. A mixture pyridine 2,6-dicarboxylic acid (835 mg, 5 mmol) and ortho-phyenlenediamine (1080 mg, 10 mmol) in 10 ml orthophosphoric acid was refluxed for 8 h. Then cool down to room temperature and poured into 200 ml pre-cooled water with constant stirring which gives a light blue precipitate. On washing with 200 ml with 20% sodium carbonate solution, pinkish precipitate of the ligand LH_2 was obtained. It was then recrystallized from hot methanolic solution (Yield = 40%). *Anal.* Calc.: C, 73.30; H, 4.21; N, 22.49. Found: C, 73.21; H, 4.23; N, 22.51%.

2.5. Synthesis of the complexes [**1**] $(ClO_4)_2$ and **2**

$Ru^{III}(trpy)Cl_3$ (200 mg; 0.44 mmol) and ligand (142 mg; 0.46 mmol) was dissolved in 20 ml ethanol and NEt_3 (0.7 mmol) was added dropwise in the mixture. It was then heated to reflux with constant stirring for 4 h. Then the volume of mixture was reduced to 5 ml under reduced pressure and a precooled saturated aqueous $NaClO_4$ solution was added. The mixture was kept in refrigerator for overnight. The dark precipitate was then filtered off and washed with ice cold distilled water. The product was dried in vacuo over P_4O_{10}. It was then passed through the silica column with CH_2Cl_2/CH_3CN. The reddish brown color complex, [**1**]$(ClO_4)_2$ was separated first with 4:1 CH_2Cl_2:CH_3CN followed by complex **2**. Yield: complex [**1**]$(ClO_4)_2$, 30% and **2**, 40%. *Anal.* Calc. for [**1**]$(ClO_4)_2 \cdot 2H_2O$: C, 46.05; H, 3.84; N, 12.64. Found: C, 46.11; H, 3.86; N, 12.61%. *Anal.* Calc. for **2** $\cdot$ $2H_2O$: C, 59.38; H, 4.98; N, 16.29. Found: C, 59.35; H, 4.96; N, 16.25%.

2.6. Crystal data

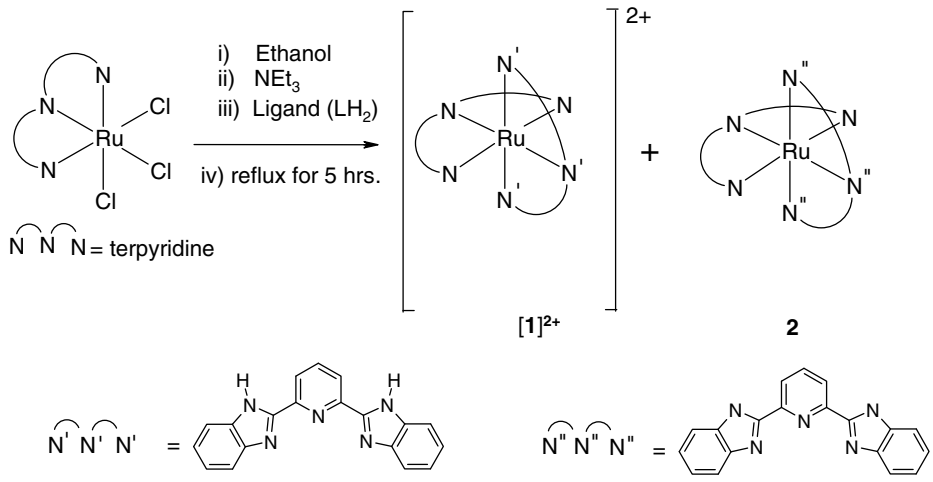
2.6.1. Complex [**1**]$(ClO_4)_2 \cdot CH_3OH$

CCDC No. 658689, $C_{35}H_{28}Cl_2N_8O_9Ru$, $M = 876.62$, triclinic, $a = 8.9369(5)$, $b = 12.9441(6)$, $c = 16.6331(8)$ Å, $\alpha = 79.843(3)$, $\beta = 76.981(2)$, $\gamma = 81.413(3)$, $V = 1833.20(16)$ Å^3, space group $P\bar{1}$, $Z = 2$, $T = 298(2)$ K, μ (Mo Kα) = 0.637 mm^{-1}, $F(000) = 805$, GOF = 1.051; final R indices: $R_1 = 0.0495$ [$I > 2\sigma(I)$], $wR_2 = 0.2087$; R indices (all data): $R_1 = 0.0713$, $wR_2 = 0.02325$.

2.6.2. Complex **2** $\cdot$ $2H_2O$

CCDC No. 658688, $C_{34}H_{26}N_8O_2Ru$, $M = 679.67$, monoclinic, $a = 14.8580(4)$, $b = 13.2833(3)$, $c = 18.4269(5)$ Å, $\beta = 106.779(2)$, $V = 3481.96(15)$ Å^3, space group $P_2(1)/n$, $Z = 4$, $T = 298(2)$ K, μ (Mo Kα) = 0.493 mm^{-1}, $F(000) = 1500$, GOF = 1.009; final R indices: $R_1 = 0.0757$ [$I > 2\sigma(I)$], $wR_2 = 0.2084$; R indices (all data): $R_1 = 0.0931$, $wR_2 = 0.2274$.

3. Results and discussion



The ligand has been synthesized following a reported procedure [20]. The reaction of LH_2 with the ruthenium precursor complex $Ru(trpy)Cl_3$, in ethanol afforded a dark solution, from which a dark colored solid mass has been isolated on addition of excess saturated aqueous $NaClO_4$ solution (Scheme 2). Chromatographic purification of the crude product on a silica gel column using CH_2Cl_2:CH_3CN mixture (4:1) as eluent results in initially the reddish complex [**1**]$(ClO_4)_2$ (112 mg, yield, 30%) (this complex has been synthesized by other group in a different process [21]) followed by the pink colored neutral complex **2** (114 mg, yield, 40%).

The complexes exhibit satisfactory elemental analyses {see experimental section} and [**1**]$(ClO_4)_2$ shows 1:2 conductivity [$\Lambda_M(\Omega^{-1}\,cm^2\,mol^{-1})$, 248] in acetonitrile solution whereas **2** is neutral. The formulation of the complexes has been further supported by the FT-IR and ^1H NMR spectral features (see later). $[\mathbf{1}]^{2+}$, in presence of one equivalent of base affords $[\mathbf{1a}]^+$ which on successive addition of another equivalent of base gives **2**. The formations of [**1**]$(ClO_4)_2$ and **2** have been authenticated by their single crystal X-ray structures.

3.1. X-ray crystallographic studies

Single crystals of [**1**]$(ClO_4)_2$ were grown by slow diffusion of an acetonitrile solution of it in benzene followed by slow evaporation and for **2**, a dichloromethane solution of it was allowed to diffuse slowly in hexane followed by slow evaporation. The crystal structures of [**1**]$(ClO_4)_2$ and **2** are shown in Fig. 1.

The single crystal of [**1**]$(ClO_4)_2$ contains one methanol and **2** contains water as solvent of crystallization in the ratio of **2**: H_2O = 1:2. The RuN_6 chromophores in [**1**]$(ClO_4)_2$ and **2** are in distorted octahedral arrangement as can be seen from the angles subtended at the metal ions in Table 1. It is found that the ligands LH_2

N6–Ru1–N3 90.6(3)	N3–Ru1–N4 92.5(3)
N1–Ru1–N3 158.6(3)	N6–Ru1–N4 156.8(3)

and L^{2-} in [**1**]$^{2+}$ and **2** are coordinated in the usual meridional fashion and terpyridine and LH_2 or L^{2-} in [**1**]$^{2+}$ or **2**, respectively, are in planes perpendicular to each other. The pyridine nitrogen of LH_2 or L^{2-} in [**1**]$^{2+}$ or **2** is in *trans* orientation with respect to the central pyridine nitrogen of terpyridine. Bond distances and angles associated with [**1**]$^{2+}$ and **2** match well with the reported analogous ruthenium-terpy [22–26] complexes. The geometrical constrains imposed on the meridional configurations of terpyridine and LH_2 in [**1**]$^{2+}$ and terpyridine and L^{2-} in **2** are reflected in the respective *trans* angles: N(1)–Ru(1)–N(3), 158.6(3)°/N(4)–Ru(1)–N(6), 156.0(3)° and N(1)–Ru(1)–N(3), 159.5(3)°/N(4)–Ru(1)–N(6), 156.8(3)°. Consequently, Ru(1)–N(2) (central pyridine nitrogen of terpyridine) distances in [**1**]$^{2+}$ and **2**, 1.964(7) and 1.951(7) Å, respectively, and the distance between ruthenium center and the central pyridine nitrogen (N_p) of the ancillary ligand (LH_2 and L^{2-}) in [**1**]$^{2+}$ and **2** are 2.017(7) and 2.029(8) Å, respectively, which are approximately 0.05 Å shorter than the corresponding terminal Ru–N bonds (Table 1). The average bite angles involving terpyridine/LH_2 in [**1**]$^{2+}$ and terpyridine/L^{2-} in **2** are 79.30°/78.00° and 79.75°/78.40°, respectively. It might be expected that an anionic ligand would be a better donor compared to the neutral and hence that will lead to shorter bonds. For complex [**1**](**ClO**$_4$)$_2$, the crystal

quality was not very good. We have tried several times to grow crystals from different solvent systems and at different conditions (e.g. at room temperature, at low temperature, etc.), also. However, we got the same results. The insignificant difference in the Ru–N bond distances in the two complexes might be because of this.

A poorly refined single crystal structure of complex $[\mathbf{1}](\mathbf{ClO_4})_2$ has been published previously along with spectroscopic and electrochemical measurements by Chattopadhyay et al. [21].

In the solid-state there is no π-stacking interactions due to the orthogonal orientation of the ligands in both the complexes. However, in complex $[\mathbf{1}](\mathbf{ClO_4})_2$, imidazole nitrogens are hydrogen bonded with perchlorate and methanol oxygen atoms. In addition to that they forms several weak C–HO and C–Hπ type hydrogen bond interactions. It is interesting to note that in solid-state it forms alternate hydrophobic and hydrophilic layers in the *bc* plane (Fig. 2a). On the other hand, complex **2** forms square boxes along *ab* plane in the solid-state with average dimension of the boxes is ~6 Å (Fig. 2b). Each box is filled with four water molecules of crystallization (Fig. 3).

One water molecule (O1) is double hydrogen bond donor while other one (O2) is as double hydrogen bond donor and single hydrogen bond acceptor. They form cyclic tetrameric water cluster with alternate arrangement of two symmetrically independent water molecules. This water cluster is highly stabilized by strong hydrogen bond between ligands.

3.2. UV–Vis spectroscopy

Complex $[\mathbf{1}]^{2+}$ exhibits metal-to-ligand charge transfer (MLCT) transition at 475 nm and intra-ligand $\pi \rightarrow \pi^*$ transitions appear at 347 and 314 nm at pH ~5 in acetonitrile/water (1:4 v/v) mixture. The MLCT band position is observed to change with the solution pH. It appears at 475 nm at a pH ⩽ 5; with increasing pH, 5–7, it is red shifted to 498 nm and finally, above pH 7, the band shifts further to 509 nm (Fig. 4). It is believed that in the acidic pH range of ⩽5, the di-protonated form of LH_2 exists in $[\mathbf{1}]^{2+}$ in solution, which with increasing pH gets transformed to $[\mathbf{1a}]^{+}$ containing the mono-protonated form of LH^- and the doubly-deprotonated form L^{2-} stabilizes in **2** in the alkaline pH range of 7–13 (Scheme 3, Fig. 4). The two pK_a values, 5.75 and 7.70 are determined from the spectral changes with the pH of the solution (Supporting Information). The similar spectral changes were reported for $[Ru(dtbimpy)(bimpyH_2)]^{2+}$ and $[Ru(dmbimpy)(bimpyH_2)]^{2+}$ in acetonitrile/buffer (1:1 v/v) with the pK_a values of 5.70, 7.33 and 6.35, 7.87, respectively [27]. Bond and Haga have reported similar pK_a values for $[Os(bpy)_2(BiBzImH_2)]^{2+}$ and $[Ru(bpy)_2(BiBzImH_2)]^{2+}$. The p$K_a$ values are also comparable to those of $[Ru(L18)(bimpyH_2)]^{2+}$ (L18 = 2,6-bis(1-octadecylbenzimidazol-2-yl)pyridine) in a micelle solution (10 mM Triton/0.1 M Na_2SO_4) (pK_a = 5.35 and 6.94) [28].

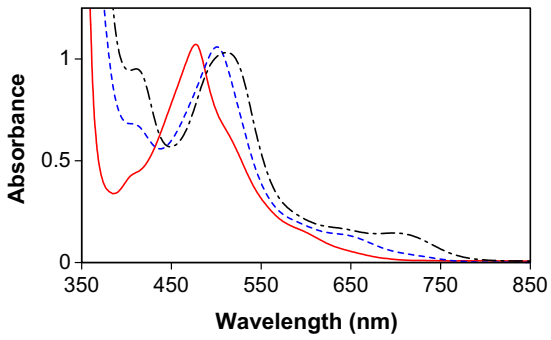

Fig. 4. UV–Vis spectra of $[\mathbf{1}]^{2+}$ (—), $[\mathbf{1a}]^{+}$ (- - -) and **2** (-·-·-) in acetonitrile:water (1:4 v/v) at pH: 1.25, 6.50 and 12, respectively.

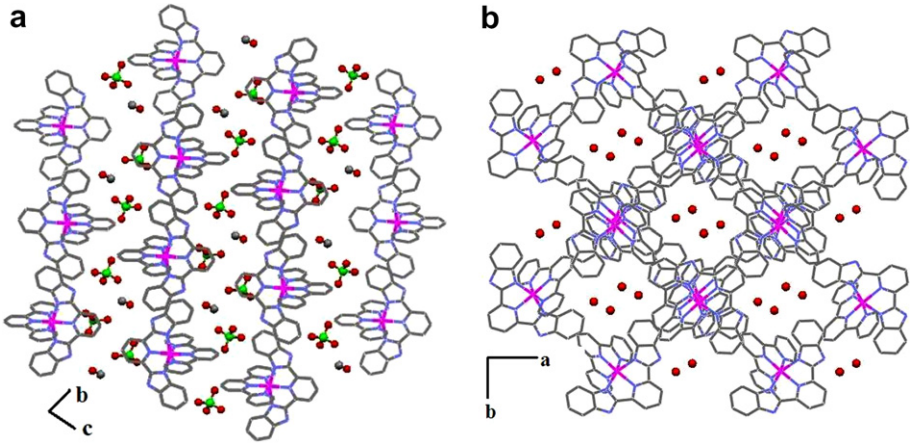
3.3. IR spectroscopy

The FT-IR spectra of the complexes were recorded in KBr pellets (Figs. S1 and S2; Supporting Information). The strong, sharp per-



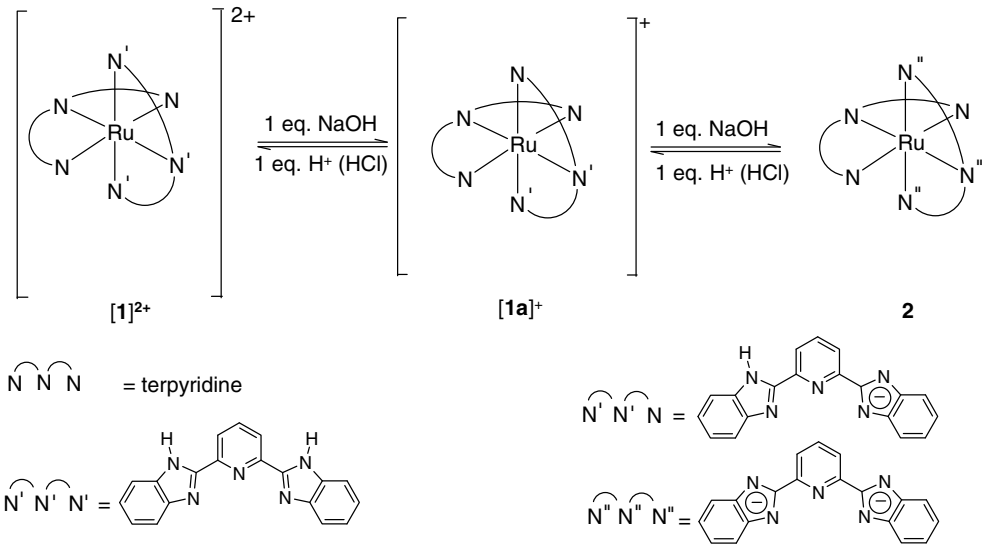


Fig. 2. Packing diagram of complexes (a) $[\mathbf{1}](\mathbf{ClO_4})_2$ viewed along *a*-axis and (b) **2** viewed along *c*-axis.

Scheme 3.

chlorate vibrations at ~1100 and ~625 cm^{-1} of complex $[\mathbf{1}]^{2+}$ were found to be absent in **2**; indicating the dianionic nature of the ligand LH_2 in complex **2**.

3.4. ^1H NMR spectroscopy

The ^1H NMR spectra of complexes $[\mathbf{1}]^{2+}$ and **2** in $(CD_3)_2SO$ (Supporting Information, Fig. S3) show the calculated number of 24 and 22 aromatic protons, respectively (overlapping between 5.5–9.2 ppm); eleven from the terpyridine group in each case; thirteen from the ancillary ligand LH_2 in case of complex $[\mathbf{1}]^{2+}$ and eleven from L^{2-} in **2**. The NH protons of LH_2 in $[\mathbf{1}]^{2+}$ are observed at 8.8 ppm, which have, as expected, disappeared on D_2O exchange [29]. The observed signals have been assigned to individual aromatic hydrogens (Supporting Information) with the aid of ^1H NMR correlation spectroscopic (COSY) experiments.

3.5. Electrochemical studies

Electrochemical studies have been performed in 1:4 acetonitrile–water solvent mixture since the complexes are not fully soluble in water. The Ru^{II}/Ru^{III} couple for **2** with fully deprotonated L^{2-} has been observed at 0.45 V versus SCE (I in Fig. 5) whereas the same for $[\mathbf{1}]^{2+}$ with doubly-protonated LH_2 appears at 0.99 V (II in Fig. 5). It is interesting to note that Ru^{II}/Ru^{III} couple for $[Ru(trpy)_2]^{2+}$ was reported to appear at 1.30 V [30]. Thus a decrease in potential of 0.30 V in case of $[\mathbf{1}]^{2+}$ and 0.85 V in case of **2** has been observed depending on the protonated (LH_2) or deprotonated (L^{2-}) form of the ancillary ligand. This can be attributed by the better σ-donor characteristic of the benzimidazol as compared to pyridine groups in trpy [31,32]. With the decrease in pH the redox wave (I in Fig. 5) of the fully deprotonated complex **2** is found to diminish with a gradual growth of a new redox wave at a higher anodic potential (II in Fig. 5, pH ~ 5) corresponding to $[\mathbf{1}]^{2+}$ with doubly-protonated LH_2 and no more significant change is observed with further decrease in pH. Thus Ru^{II}/Ru^{III} couple remains pH independent in the range of <5 and >8.5. The major Ru(II) species in these limits of pH are $[Ru(trpy)(LH_2)]^{2+}$ $[\mathbf{1}]^{2+}$ and $[Ru(trpy)(L^{2-})]$ **2**, respectively, and the electrode processes can be defined as

$$[Ru^{II}(trpy)(LH_2)]^{2+} \rightleftharpoons [Ru^{III}(trpy)(LH_2) + e^- \quad (pH < 5) \qquad (i)$$

$$[Ru^{II}(trpy)(L^{2-})] \rightleftharpoons [Ru^{III}(trpy)(L^{2-})]^{+} + e^- \quad (pH < 8.5) \qquad (ii)$$

Although pH dependent UV–Vis spectral changes clearly indicate the formation of singly-protonated intermediate $[\mathbf{1a}]^+$ (Fig. 4, Scheme 2), the voltammogram involving the singly-protonated species $[\mathbf{1a}]^+$ is not apparently (Fig. 5) involved. Bond and Haga have also reported same observation with $[Ru(bpy)(BiBzImH_2)]^{2+}$ [7]. Significantly, the shift in redox potential of the Ru^{II}/Ru^{III} couple with the change in pH is reversible in nature.

The plot of Ru^{II}/Ru^{III} potential as a function of pH is shown in Fig. 6. The redox process at 0.99 V going from region A to D involves only the protonated species, $[\mathbf{1}]^{2+}$ and the process at 0.45 V going from region C to F involves only the deprotonated species, **2** (Eqs. (i) and (ii)).

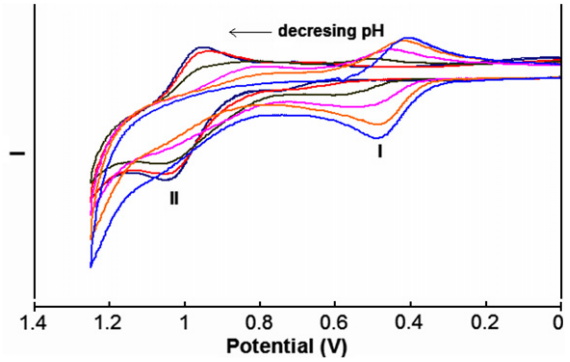

Fig. 5. pH (1.02–12.5) dependent cyclic voltammograms in acetonitrile:water (1:4 v/v).

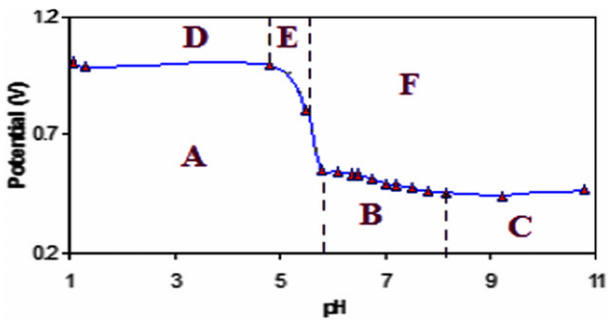

Fig. 6. The half-wave potential, $E_{1/2}$ vs. pH diagram for $[\mathbf{1}]^{2+}$ in acetonitrile:water (1:4 v/v).

The slope of the lines indicate the pH dependent processes in which proton transfer process is coupled with electron transfer (PCET). According to Nernst equation for a reversible electrode process, the slope of $\Delta E_{1/2}/\Delta pH = (m/n)59$ mV/pH-unit where m and n represent the number of protons and electrons involved in the process. From the plot (Fig. 6), it is evident that three distinct PCET processes are involved in the present case. The slope of 53 mV/pH in the region A–E implies one-electron/one-proton transfer process as follows (Eq. iii):

$$[Ru^{II}(trpy)(LH_2)]^{2+} \rightleftharpoons [Ru^{III}(trpy)(LH)]^{2+} + H^+ + e^- \quad \text{(iii)}$$

The change in slope to 114 mV/pH in the region A–F correlates with the expected two-proton/one-electron transfer process (Eq. iv):

$$[Ru^{II}(trpy)(LH_2)]^{2+} \rightleftharpoons [Ru^{III}(trpy)(L)]^{+} + 2H^+ + e^- \quad \text{(iv)}$$

Finally, the electrode reaction in the region B–F comes back to a one-proton/one-electron process with a slope 51 mV/pH (Eq. v):

$$[Ru^{II}(trpy)(LH)]^{+} \rightleftharpoons [Ru^{III}(trpy)(L)]^{+} + H^+ + e^- \quad \text{(v)}$$

Similar observations were reported by Ayers et al. [33] and Bond and Haga [7] with $[Ru(bpy\text{-}bzimH)_2]^{2+}$ and $[(bpy)_2Ru(bibzimH_2)]^{2+}$ (where bpy-bzimH = 6-(2-benzimidazole)-2,2′-bipyridyl; bpy = 2,2′-bipyridine and bibzimH = 2,2′-bibenzimidazole).

4. Conclusion

In conclusion, the present work demonstrates a unique example of a set of ruthenium monoterpyridine complexes, $[\mathbf{1}]^{2+}$ and **2**, with both the fully-protonated and deprotonated ancillary ligand. Both the complexes have been isolated as solid crystals. The complexes were characterized completely using various spectroscopic techniques and single crystal structures. The complex $[\mathbf{1}]^{2+}$, in solution, behaves as a dibasic acid. It, on successive addition of two equivalent of OH^-, results into complex **2**. The conversion of $[\mathbf{1}]^{2+}$ to **2** is found to be completely reversible in nature. The proton (or pH) dependency of the spectral and redox properties of the complexes have been studied in detail.

constant ionic strength (1 mol dm^{-3}), adjusted with lithium perchlorate. The disappearance of $[Co(III)W]^{5-}$ was followed at 390 nm using a Spectrochem MK II colorimeter as described [14]. At least three runs were studied for any given set of experimental conditions. The plots of $\log(A_t - A_\infty)$, where A_t and A_∞ are the absorbance at any time 't' and at infinite time (overnight), against time are linear for more than three half-lives of the reaction and some of the representative plots are shown in Fig. 1. These plots and the others were drawn using the EXCEL program, which also provided the least square values of the intercepts and slopes of the plots. The pseudo first-order rate constants, k_{obs}, were calculated from the slopes of these plots. The reproducibility of k_{obs} from the replicate runs was within ±3%. The mean of the pseudo first-order rate constant k_{obs} is reported in the tables.

2.4. Stoichiometry

A number of reaction mixtures having different concentration ratios of $[Co(III)W]^{5-}$ and $(NHNH_2)_2CO$ were prepared at different $[H^+]$ in a manner so that $[Co(III)W^{5-}]$ was always in excess over $[(NHNH_2)_2CO]$. These reaction mixtures were allowed to react at room temperature. The progress of the reaction was followed by measuring the absorbance from time to time, generally at 390 nm for the remaining $[Co(III)W]^{5-}$ but in few cases the absorbance was also measured at 625 nm, for the formation of $[Co(II)W]^{6-}$. The measurements were continued until a constant absorbance value was obtained. The computation of the results indicated that $\Delta[Co(III)W]^{5-}/\Delta[(NHNH_2)_2CO] = 3.96 \pm 0.08$. The results are reported in Table 1. Hence, the stoichiometry of the reaction is given by Eq. 1:

$$4[Co(III)W]^{5-} + (NHNH_2)_2CO \rightarrow 4[Co(II)W]^{6-} + HCHO + 4H^+ + 2N_2 \quad (1)$$

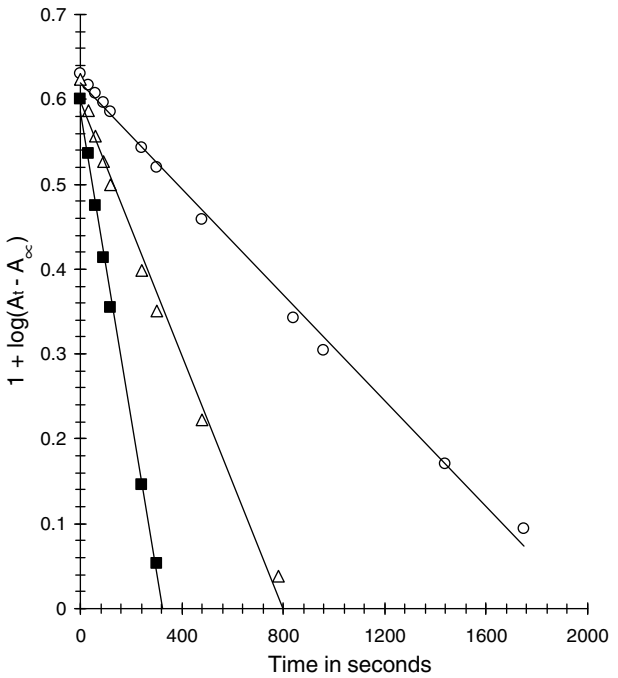

Fig. 1. The plots of $\log(A_t - A_\infty)$, where A_t and A_∞ are the absorbance at any time 't' and at infinite time, against time are linear for more than three half-lives of the reaction for the conditions: (■) $[H^+] = 0.35$, $[CO(NHNH_2)_2] = 0.03$ mol dm^{-3}, 40 °C; (△) $[H^+] = 0.35$, $[CO(NHNH_2)_2] = 0.005$ mol dm^{-3}, 40 °C and (○) $[H^+] = 0.1$, $[CO(NHNH_2)_2] = 0.01$ mol dm^{-3}, 30 °C. The ionic strength is held constant at 0.5 and $10^4[Co(III)W^{5-}] = 4$ mol dm^{-3}.

2.5. Spectral measurements

A HP 8452 UV–Vis spectrophotometer with a 2 nm band width and an integration time of 1 s was used to measure the spectra of the solutions at room temperature.[1] The spectra of the solutions were recorded at room temperature.

The method adopted for recording the spectra of the reaction mixtures is described below. The solutions of $NH_2NHCONHNH_2$ and $[Co(III)W]^{5-}$ ions of desired concentrations at appropriate $[H^+]$ were taken in test tubes. These test tubes were immersed in melting ice taken in a beaker and allowed to stand for sufficient time to attain thermal equilibrium. The melted water was drained out from time to time. The idea was to slow down the rate of the reaction to an extent that would permit the recording of meaningful spectra. These solutions were quickly mixed to give reaction mixtures which were immediately transferred to a silica cell which was placed in its compartment and the spectra were recorded immediately. These spectra are considered to be good enough for qualitative analysis only because the temperature and the time taken in mixing and recording the spectra are not precisely and uniformly maintained.

2.6. Characterisation of formaldehyde

According to the stoichiometric Eq. (1) formaldehyde is one of the products. The same product was characterised by a spot test with chromotropic acid, prepared in 12 N sulfuric acid, [15]. Its quantitative estimation was carried out by repeated extraction (×8) with 5 ml aliquots of ether. The ethereal solution was air evaporated. The liquid product was made up to 50 ml. Further dilution of 1 ml of this solution with 9 ml of chromotropic acid solution resulted in a purple solution which had λ_{max} at 507 nm with an optical density equal to 0.00677. The concentration of formaldehyde was calculated using $\varepsilon = 0.57$ cm^3 (μg)$^{-1}$ [16,17]. Computation of the results indicated that the amount of formaldehyde recovered from the reaction mixtures was 95 ± 4% of the theoretical value expected in terms of Eq. (1).

2.7. Characterisation of $[Co(II)W]^{6-}$

The other product in Eq. (1) is the $[Co(II)W]^{6-}$ ion. It was characterised by its spectra. In Fig. 2 spectra of authentic solutions of $10^5[Co(III)W^{5-}] = 9.85$ mol dm^{-3}, having λ_{max} at 390 nm, and $10^4[Co(II)W^{6-}] = 0.1$ mol dm^{-3}, which has λ_{max} at 625 nm, are given. The later spectra is superimposed by the spectrum of the spent reaction mixture ($10^5[Co(III)W^{5-}] = 1.0$, $[H^+] = 0.1$ and $10^3[H_2NNHCONHNH_2] = 5.0$ mol dm^{-3}). This indicates that the $[Co(II)W]^{6-}$ ion is the reduced product of $[Co(III)W]^{5-}$ ion and is produced quantitatively and that $[Co(III)W]^{5-}$ behaves as a one electron equivalent oxidant.

2.8. Characterisation of N_2

N_2 is another product in Eq. (1), and was qualitatively confirmed, with no attempt being made to quantify it. The qualitative method involved carrying out the reaction at room temperature in a conical flask fitted with standard joints with tubes for incoming and outgoing gases. The reaction was started and pure argon was passed through the reaction mixture. The outgoing gas was passed through a solution of $[Ru(NH_3)_5(H_2O)]^{2+}$, from which a red complex, $[(NH_3)_5Ru(N_2)Ru(NH_3)_5]^{4+}$, was isolated [18]. The Raman

[1] The instrument could not be used for the kinetics study since it had no facility for thermostating the solutions at the desired temperature.

Table 1

[a] Concentrations are in mol dm^{-3}; average $\Delta[Co(III)W]^{5-}/\Delta[(NHNH_2)_2CO] = 3.96 \pm 0.08$.

spectra of the complex showed a strong band of $\nu(N{\equiv}N)$ around 3100 cm^{-1} [18] which is due to the coordinated N_2.

2.9. Spectral changes effected by $[H_2NNHCONHNH_2]$ in the reaction mixture

The optical density measurements of a solution of the $[Co(III)W]^{5-}$ ion (**A**) and those of the reaction mixtures, soon after these were prepared, $10^4[Co(III)W]^{5-} = 1.0$, $[H^+] = 0.10$ and $10^4[H_2NHNCONHNH_2] = 1.25$ (**B**), 2.50 (**C**), 5.0 (**D**), 15.0 (**E**) and 25.0 mol dm^{-3} (**F**) are shown in Fig. 3. It is noted that the optical density of the reaction mixtures increased with the increase in $[H_2NHNCONHNH_2]$, indicating that a new species, probably a complex between the $[Co(III)W]^{5-}$ ion and $H_2NHNCONHNH_2$, is formed.

3. Spectral changes with $[H^+]$

In another series of experiments, several reaction mixtures having $10^5[Co(IIIW)^{5-}] = 9.4$ and $10^3[H_2NHNCONHNH_2] = 1.0$ mol dm^{-3} were prepared at different $[H^+]$ (between 0.001 and 0.07 mol dm^{-3}) in a manner analogous to that described above. The optical densities of these reaction mixtures are shown in Fig. 4 wherein it is noted that the optical density increases with increasing H^+ concentration, indicating that the species $^+H_3NHNCONHNH_2$ forms the complex, which is consistent with the protonation constant of $H_2NHNCONHNH_2$ because the $[Co(IIIW)]^{5-}$ ion is not affected by the presence of the H^+ ion [19]. It is seen later in the mechanism section that the complex so formed deprotonates in the subsequent step and that the decomposition of the deprotonated complex is rate controlling.

3.1. Results

The first-order dependence of the reaction on $[Co(III)W]^{5-}$ is confirmed by measuring the k_{obs} values over $1 \times 10^{-4} \leqslant [Co(III)W^{5-}] \leqslant 1 \times 10^{-3}$ mol dm^{-3} at $[H^+] = 0.35$, $[Co(NHNH_2)_2] = 0.025$ and $[\mu] = 0.50$ mol dm^{-3} at 40 °C. A mean value of 10^3 $k_{obs} = 3.45 \pm 0.04$ (s^{-1}) is obtained from several runs, indicating that the k_{obs} value is independent of the initial $[Co(III)W^{5-}]$.

The k_{obs} values were measured at different initial $[H_2NHNCONHNH_2]$ and at different temperatures, keeping the ionic strength and $[H^+]$ constant. The results, shown in Table 2, provided linear plots of k_{obs} against $[H_2NHNCONHNH_2]$, Fig. 5, that pass through the origin for all temperatures. This indicates that the reaction is first order with respect to $[H_2NHNCONHNH_2]$.

The dependence of k_{obs} was investigated over $0.02 \leqslant [H^+] \leqslant 0.40$ mol dm^{-3} at different temperatures. The results, shown in Table 3, indicate that k_{obs} decreases with an increase in $[H^+]$. The plots between k_{obs} and $[H^+]^{-1}$, Fig. 6, are linear and almost pass through the origin within the limits of the experiment.

The rate of catalysis by alkali metal ions (M^+) is considered characteristic of the redox reactions of 12-tungstocobaltate(III), both with inorganic and organic substrates [20]. Similar catalysis by M^+ has been reported in the oxidation of 12-tungstocobaltate(II) by the permanganate ion [10], oxidations of arsenous acid [21] and S(IV) [22] by 12-tungstocobaltate(III), from our laboratory too. Therefore, the effect of alkali metal ions ($M^+ = Li^+$, Na^+ and K^+) on k_{obs} was investigated at constant $[H^+]$ and $[CO(NHNH_2)_2]$ at 40 °C by adding the chloride salt of the respective ions. The higher concentrations of K^+ ions could not be used because of the insolubility of potassium perchlorate. The Cs^+ ion was also tried, but being

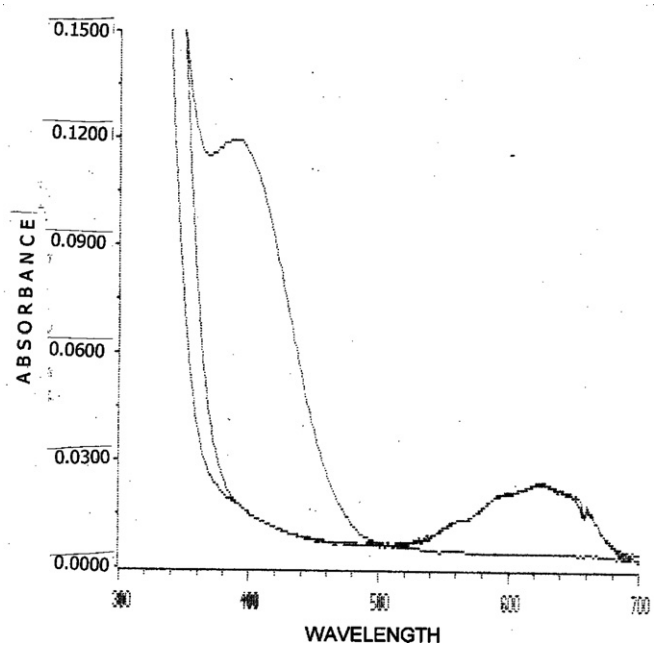

Fig. 2. Spectra of authentic solutions of $10^5[Co(III)W^{5-}] = 9.85$ mol dm^{-3} having λ_{max} at 390 nm and that of $10^4[Co(II)W^{6-}] = 0.1$ mol dm^{-3} and the spent reaction mixture ($10^5[Co(III)W^{5-}] = 1.0$, $[H^+] = 0.1$ and $10^3[H_2NHNCONHNH_2] = 5.0$ mol dm^{-3}). The spectra of $[Co(II)W]^{6-}$ and the spent reaction mixtures are seen to overlap indicating that $[Co(III)W^{5-}]$ is reduced to the $[Co(II)W]^{6-}$ ion.

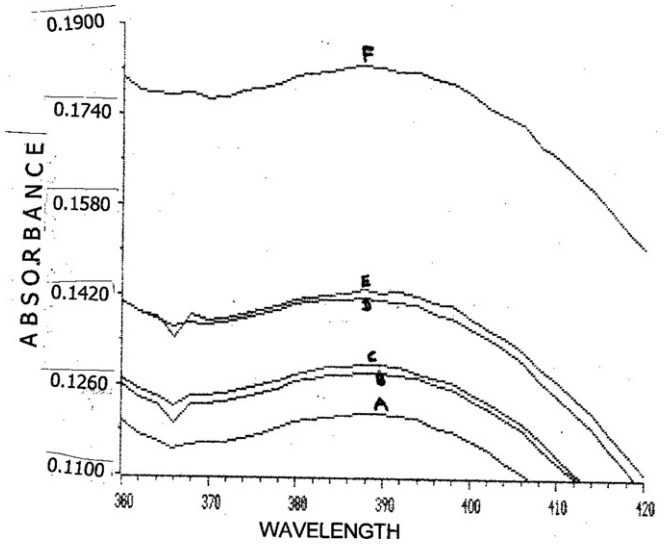

Fig. 3. The optical density changes in the spectra of the reaction mixtures with an increase in the concentration of $H_2NNHCONHNH_2$ at $[H^+] = 0.1$ and $10^4[Co(III)W^{5-}] = 1.0$ mol dm^{-3}. $10^4[H_2NNHCONHNH_2] = 0.0$ (A); =1.25 (B); =2.5 (C); =5.0 (D); =15.0 (E); =25.0 (F).

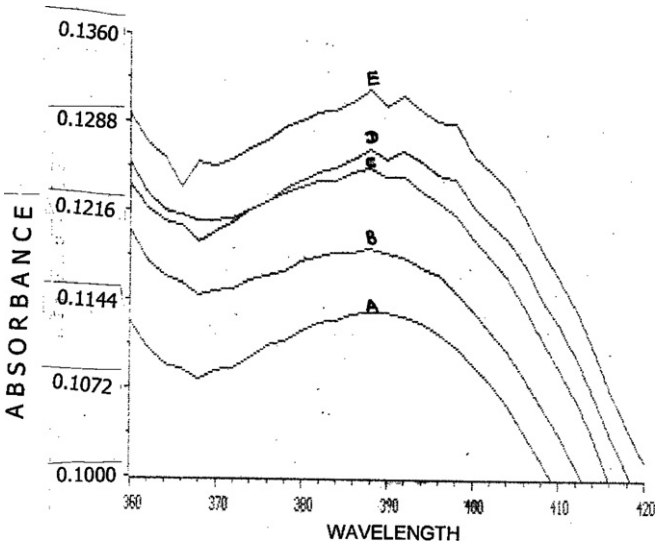

Fig. 4. The optical density changes in the spectra of the reaction mixtures with an increase in the H^+ ion concentration with initial $[H_2NNHCONHNH_2] = 0.001$ and $10^5[Co(III)W^{5-}] = 9.4$ mol dm^{-3}. $[H^+] = 0.0$ (A); =0.001 (B); =0.005 (C); =0.030 (D); =0.070 (E).

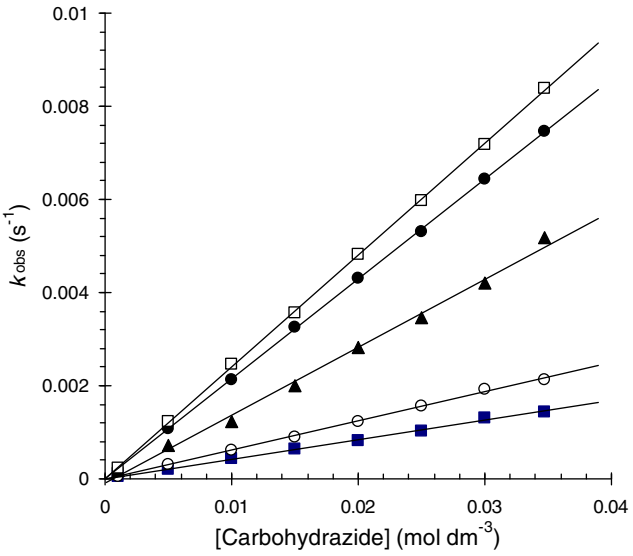

Fig. 5. The plots of k_{obs} against $[CO(NHNH_2)_2]$ pass through the origin or have negligible intercepts at the temperatures 30° (■), 35° (○), 40° (▲), 46° (●) and 49° (□).

more insoluble than $KClO_4$ the rate data could not be collected even for low concentrations. The results, Table 4, show that k_{obs} is retarded with an increase in $[M^+]$. The non-linear plot between k_{obs} and $[M^+]$ is shown in Fig. 7.

The Brønsted's treatment of the effect of the concentration of the alkali cation as ionic strength predicts that the reaction is occurring between oppositely charged ions. The data in Table 4 has been analysed in terms of Eq. (2), proposed by Davies [23].

$$\log k_{obs} = \log k_o + z_a z_b \left(\frac{\sqrt{\mu}}{1+\sqrt{\mu}} - B\mu \right) \quad (2)$$

where z_a and z_b are the charges on the reacting species and B is a constant. The plots, Fig. 8, in terms of Eq. (2) for $B = 0.1$ are linear with slope values −3.85, −3.97 and −2.84 corresponding to Li^+, Na^+ and K^+ ions, respectively, whereas for $B = 0.15$ the plot corresponding to K^+ is linear with slope = −3.82 (plot not shown). Thus the slope valve in each case is ≈ -4.0, indicating that the reaction is taking place between two oppositely charged ions carrying charges of 4 and 1.

3.2. Mechanism and discussion

The reaction is first order with respect to carbohydrazide, as is the oxidation of hydrazine by the 12-tungstocobaltate(III) ion [24]. A comparison of the rate constants of the two oxidations indicates that the oxidation of carbohydrazide is relatively faster than that of hydrazine. The two oxidations are also similar with respect to the dependence of the rate on H^+ concentration; the rate increased with the decrease in $[H^+]$. However, unlike the oxidation of hydrazine, the plots between k_{obs} against $[H^+]^{-1}$ pass through the origin. This indicates a different mechanism.

The first-order dependence in $[H_2NHNCONHNH_2]$ indicates that the complex formed from $[Co(III)W]^{5-}$ and $H_2NHNCONHNH_2$, suggested by the changes in the optical density of the reaction mixtures, is either weak in nature or the formation constant is small so that the complex is not formed in a sufficient quantity for its detection by the kinetics. Further, the participation of the protonated specie(s) in the formation of the complex is indicated by the increasing optical densities of the reaction mixtures with increasing $[H^+]$ at constant $[H_2NHNCONHNH_2]$ and $[Co(III)W]^{5-}$ ion. In an earlier study it was shown that the rapid scans of solutions of constant $[Co(III)W^{5-}]$ recorded in buffer solutions of different pH superimposed themselves, indicating that $[Co(III)W]^{5-}$ is not protonated [19]. The protonation of $H_2NHNCONHNH_2$ is well known, a value of $K_H = 1.38 \times 10^4$ is reported ($\mu = 0.1$ mol dm^{-3}) at 20 °C [25]. Therefore the equilibrium (3) is shifted far to the right[2] so that the analytical concentration of carbohydrazide mainly exists as $^+NH_3HNCONHNH_2$ in the acidic solution.

The alkali metal ions M^+ (Li^+, Na^+, K^+) either enhance or inhibit the rate of reactions [26–29]. The rate enhancement has been reported in several $[Co(III)W]^{5-}$ oxidations [30–32]. The effect of the alkali metal ions in the present reaction is interesting because k_{obs} decreased with the increasing concentration of the individual alkali cation and this is similar to the effect observed in the oxidation of $[Co(II)W]^{6-}$ by $S_2O_8^{2-}$ and IO_4^- ions [33]. However, the comparison of k_{obs} within the alkali metal ions indicated that k_{obs} increased in the order $K^+ > Na^+ > Li^+$.

The inhibition in k_{obs}, $Li^+ > Na^+ > K^+$, parallels with the ionic size of the strongly hydrated M^+_{aq} ions [34], which is in the order $Li^+ > Na^+ > K^+ > Rb^+ > Cs^+$ ion [35]. The M^+ ion, which plays the role of an effective bridge between the two reacting anions, is unlikely to have a similar role in the present case because the reactive species present in solution are $^+NH_3HNCONHNH_2$ and $[Co(III)W]^{5-}$ ions. The formation of an ion pair between M^+ and $[Co(III)W]^{5-}$ is

Table 2
The dependence of k_{obs} on $[CO(NHNH_2)_2]$ at different temperatures $10^4[Co(III)W^{5-}] = 4.0$, $[H^+] = 0.35$ and $[\mu] = 0.50$ mol dm^{-3}

supported by the increase in the optical density of the $[Co(III)W]^{5-}$ solution with increasing $[M^+]$, similar to that reported with $[Co(III)W]^{6-}$ [10].

In view of the above, the following sequence of reactions is considered to constitute the most likely mechanism of the reaction:

$$^{+}H_3NHNCONHNH_2 \overset{K_a}{\rightleftharpoons} H_2NHNCONHNH_2 + H^+ \quad (3)$$

$$[Co(III)W]^{5-} + M^+ \overset{K_m}{\rightleftharpoons} [Co(III)W \cdot M]^{4-} \quad (4)$$

$$[Co(III)W \cdot M]^{4-} + {}^{+}NH_3HNCONHNH_2 \overset{K}{\rightleftharpoons} [Co(III)W \cdot M \cdot NH_3HNCONHNH_2]^{3-} \quad (5)$$

$$[Co(III)W \cdot M \cdot NH_3HNCONHNH_2]^{3-} \overset{K_d}{\rightleftharpoons} [Co(III)W \cdot M \cdot NH_2HNCONHNH_2]^{4-} + H^+ \quad (6)$$

$$[Co(III)W \cdot M]^{4-} + H_2NHNCONHNH_2 \overset{K'}{\rightleftharpoons} [Co(III)W \cdot M \cdot NH_2HNCONHNH_2]^{4-} \quad (7)$$

$$[Co(III)W \cdot M \cdot NH_2HNCONHNH_2]^{4-} \overset{k}{\rightarrow} [Co(II)W \cdot M]^{5-} + H_2NHN\overset{+}{C}ONHNH_2 \quad (8)$$

$$3[Co(III)W \cdot M]^{4-} + H_2NHN\overset{+}{C}ONHNH_2 \overset{\text{fast}}{\rightarrow} 3[Co(II)W \cdot M]^{5-} + 2N_2 + 4H^+ + HCHO \quad (9)$$

Table 4
The dependence of k_{obs} on Li^+, Na^+ and K^+ ions at 40 °C 10^4 $[Co(III)W]^{5-}$ = 4.0, $[CO(NHNH_2)_2]$ = 0.020 and $[H^+]$ = 0.35 mol dm^{-3}

$[M^+]$ (mol dm^{-3})	0.03	0.04	0.05	0.06	0.08	0.10	0.14	0.18	0.26	0.42

10^3 k_{obs}, (K^+)	3.07	3.03	2.99	2.96	2.88	2.82	2.71			

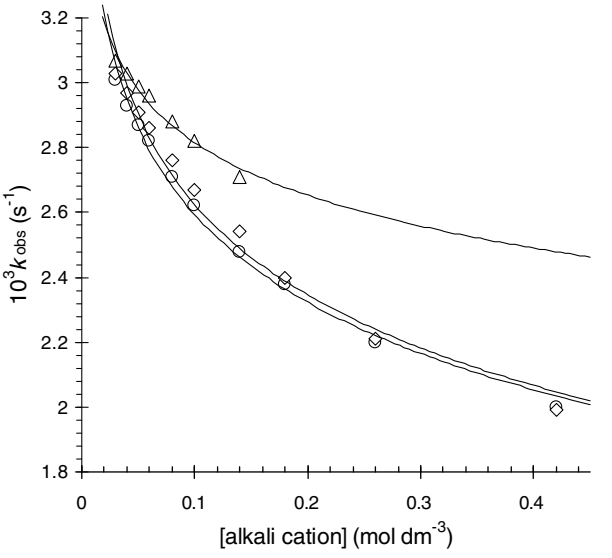

Fig. 7. The non-linear plot between k_{obs} and $[M^+]$ with M^+ = Li^+ (○), Na^+ (◇) and K^+ (△). $10^4[Co(III)W]^{5-}$ = 4.0, $[CO(NHNH_2)_2]$ = 0.020 and $[H^+]$ = 0.35 mol dm^{-3} and 40 °C.

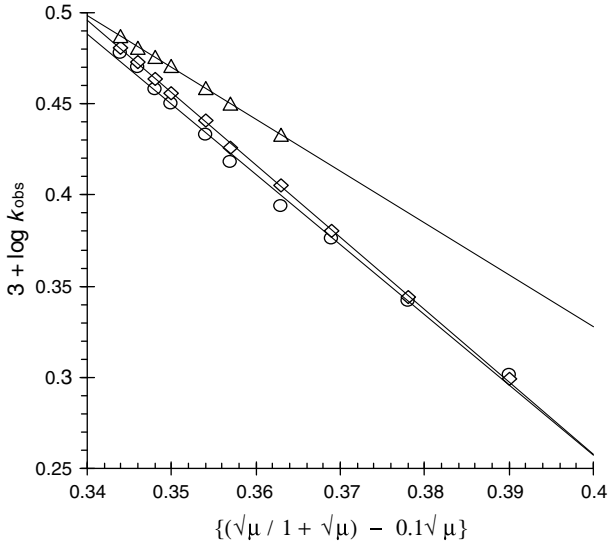

Fig. 8. The plots of log k_{obs} against $\{(\sqrt{\mu}/1+\sqrt{\mu}) - 0.1\sqrt{\mu}\}$ for Li^+ (○), slope = −3.85; Na^+ (◇), slope = −3.97 and K^+ (△), slope = −2.84. However, the slope of the plot between log k_{obs} against $\{(\sqrt{\mu}/1+\sqrt{\mu}) - 0.15\sqrt{\mu}\}$ is −3.82. $10^4[Co(III)W]^{5-}$ = 4.0, $[CO(NHNH_2)_2]$ = 0.020 and $[H^+]$ = 0.35 mol dm^{-3} and 40 °C.

Table 5
The dependence of k_o ($dm^3\ mol^{-1}\ s^{-1}$) at different temperatures

Temperature (°C)	30	35	40	46	49
k_o	0.015	0.022	0.051	0.075	0.084

The two alternate routes for the formation of the complex, $[Co(III)W \cdot M \cdot NH_2HNCONHNH_2]^{4-}$, equilibria (5) and (6), and equilibrium (7), are not kinetically distinguishable because it can be shown that $K_dK = K'K_a$.[3] The rate law deduced from reactions (3)–(9) is expressed by Eq. (10):

$$\frac{-d[Co(III)W]^{5-}}{dt} = kK'K_m[Co(III)W^{5-}][H_2NHNCONHNH_2][M^+] \quad (10)$$

The mass balance for $[Co(III)W]^{5-}$ from Eqs. (4) and (7) is given by Eq. (11), which is approximated to Eq. (12) because $1 \gg K'[H_2NHNCONHNH_2]$ due to the negligibly small concentration of $H_2NHNCONHNH_2$.

$$[Co(III)W^{5-}] = \frac{[Co(III)W^{5-}]_o}{1 + K_m[M^+](1 + K'[H_2NHNHCONHNH_2])} \quad (11)$$

$$[Co(III)W^{5-}] = \frac{[Co(III)W^{5-}]_o}{1 + K_m[M^+]} \quad (12)$$

In a similar manner Eq. (13) is obtained from the mass balance of carbohydrazide species from Eq. (3), remembering that $[H^+] \gg K_a$.

$$[NH_2HNCONHNH_2] = \frac{K_a[NH_2HNCONHNH_2]_o}{[H^+]} \quad (13)$$

The substitution of the respective values of $[Co(III)W^{5-}]$ and $[H_2NHNCONH_2]$ from Eqs. (12) and (13) into Eq. (10) gives the rate law in Eq. (14).

$$k_{obs} = \frac{-d[Co(III)W]^{5-}}{dt[Co(III)W^{5-}]_o} = \frac{kK'K_aK_m[NH_2HNCONHNH_2]_o[M^+]}{[H^+](1 + K_m[M^+])} \quad (14)$$

Eq. (14) is consistent with the plots of k_{obs} against $[H_2NHNCONHNH_2]_o$, Fig. 5, k_{obs} against $[H^+]^{-1}$, Fig. 6, and the non-linear plots of k_{obs} against $[M^+]$ shown in Fig. 7. Eq. (14), at constant concentrations of H^+ and M^+, is expressed by Eq. (15) where $k_o = kK'K_aK_m[M^+]/(1 + K_m)$. The values of k_o (=slope × $[H^+]$), calculated from the slopes of the plots in Fig. 5, are given in Table 5. Because k_o is a composite factor consisting of unknown equilibrium constants K_d and K, activation parameters were not calculated.

$$k_{obs} = \frac{k_o[NH_2HNCONHNH_2]_o}{[H^+]}m \quad (15)$$

It may be mentioned here that the reaction in buffered solutions pH ($\geqslant 2$) is good enough for study with the stopped-flow method. The attempts to control the rate at low concentrations and temperatures did not prove fruitful for the method employed. It was felt that the rate law of the reaction in buffer solutions might turn out to be similar to that obtained for the oxidation of hydrazine in the buffer solution [24].

Yield: 0.199 g (55%). M.p. 157–158 °C. ^1H NMR ($CDCl_3$): δ 1.33 (d, $^3J_{H,H}$ = 6.1 Hz, 12H, CH_3), 1.34 (d, $^3J_{H,H}$ = 6.1 Hz, 12H, CH_3), 3.62–3.97 (m, 16H, CH_2), 4.68 (d sept, $^3J_{P,H}$ = 7.6 Hz, $^3J_{H,H}$ = 6.1 Hz, 4H, OCH). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 9.9. IR: ν 1005 (POC), 1144 (COC), 1154 (P═O), 1547 (SCN) cm^{-1}. *Anal.* Calc. for $C_{22}H_{44}N_4O_8P_2PdS_2$ (724.11): C, 36.44; H, 6.12; N, 7.73. Found: C, 36.49; H, 6.07; N, 7.68%.

2.3. Physical measurements

Infrared spectra (Nujol) were recorded with a Specord M-80 spectrometer in the range 400–3600 cm^{-1}. NMR spectra were obtained on a Varian Unity-300 NMR spectrometer at 25 °C. ^1H and $^{31}P\{^1H\}$ spectra were recorded at 299.948 and 75.429 MHz, respectively. Chemical shifts are reported with reference to $SiMe_4$ (^1H) and H_3PO_4 ($^{31}P\{^1H\}$). Elemental analyses were performed on a Perkin–Elmer 2400 CHN microanalyser.

2.4. Crystal structure determination and refinement

The X-ray data for **1** were collected at −173 °C using a KM4CCD diffractometer and graphite-monochromated Mo Kα radiation generated from Diffraction X-ray tube operated at 50 kV and 35 mA. The images were indexed, integrated and scaled using the KUMA data reduction package [10]. The structure was solved by direct method using SHELXS97 and refined by the full-matrix least-squares method on all F^2 data [11]. Non-hydrogen atoms were included in the refinement, with anisotropic displacement parameters. The hydrogen atoms were positioned geometrically and refined isotropically. The hydrogen atoms of NH groups were included from $\Delta\rho$ maps and fixed at a distance 0.92 and refined isotropically. Calculations were preformed using WINGX program [12].

*trans-[Pd(HL^{I}_2–S)$_2$Cl$_2$] (**1**).* $C_{22}H_{50}Cl_2N_4O_6P_2PdS_2$, M_r = 770.02 g mol^{-1}, yellow prisms, monoclinic, space group $P2_1/c$, a = 10.517(4), b = 17.316(5), c = 9.774(4) Å, β = 99.22(4)°, V = 1757.0(11) $Å^3$, Z = 2, D_c = 1.456 g cm^{-3}, μ(Mo Kα) = 0.929 mm^{-1}, reflections: 12196 collected, 4171 unique, R_{int} = 0.032, R_1(all) = 0.0285, wR_2(all) = 0.0605.

3. Results and discussion

3.1. Synthesis

N-Phosphorylated thioureas were prepared as previously described [9] and purified by recrystallization from dichloromethane–*n*-hexane mixtures.

Complexes **1–5** were prepared by the following procedure: $Pd(PhCN)_2Cl_2$ was dissolved in acetonitrile and added to a solution containing the corresponding ligand in the same solvent (Scheme 1). The compounds obtained are crystalline solids that are soluble in most polar solvents.

The molecular structures of complexes **1–5** were investigated by IR, ^1H, $^{31}P\{^1H\}$ NMR spectroscopy and elemental analysis. The crystal structure of **1** was established by single crystal X-ray diffraction analysis.

3.2. IR and NMR spectroscopy

The IR spectra of complexes **1–3** in Nujol are similar. The absorption bands of the P═O group of the neutral forms $HL^{I–III}$

are shifted by approximately 10–15 cm^{-1} to high frequencies relative to the band of the parent ligands. This confirms their nonparticipation in chelate complex formation. There are two signals for the NH proton in the IR spectra of complexes in the areas 3082–3094 and 3203–3217 cm^{-1} which are the characteristic range for amide protons participating in hydrogen bonds [4,7]. In the spectra of **1–3** there is an intense absorption band at 1515–1549 cm^{-1} corresponding to the S=C–N fragment. Besides very strong absorption bands for the POC group at 1008 cm^{-1}, there is a band of the COC group at 1140 cm^{-1} in the IR spectrum of **3**, containing crown-ether fragments. Presence of a wide absorption band of the POC fragment in the spectra of **1** and **2** in the area 998–1002 cm^{-1} also unequivocally confirms the substituted phosphoric fragment.

Application of the same procedure using the thioureas $\mathbf{HL}^{IV}$ and $\mathbf{HL}^{V}$ did not result in isolation of products with neutral forms of the corresponding ligand (Scheme 2). Complexes **4** and **5** obtained contain the central cation coordinated in a square-planar fashion by the C=S sulfur atoms and the P=O oxygen atoms of two anionic ligands. According to the IR, ^{1}H, $^{31}P\{^{1}H\}$ NMR spectroscopy, elemental analyses and melting point data complexes **4** and **5** are found to be the same as it was synthesized using the potassium salts of the thioureas $\mathbf{HL}^{IV}$ and $\mathbf{HL}^{V}$ in the aqueous ethanol medium [7].

The $^{31}P\{^{1}H\}$ NMR spectra of complexes **1–3** contain two singlet signals at −6.8 to −5.6 ppm, and a down-field shift, relative to that of the free ligands $\mathbf{HL}^{I–III}$, is observed. This confirms the preservation of neutral forms of ligands [4]. Two different signals correspond to the phosphorus atoms with *cis*- and *trans*-configuration of ligands in the structure of complexes in the solution.

The ^{1}H NMR spectra of **1–3** contain a double set of signals. This also confirms the presence of *cis*- and *trans*-complexes in the solution. The signals for the methyl protons are observed at 1.38–1.53 ppm. The signals at 4.58–4.90 ppm correspond to the OCH protons. The aromatic proton signals in complex **2** are at 7.23–7.68 ppm and shifted down-field relative to that in complex **3**. In the ^{1}H NMR spectrum of **3** signals for the CH_2 protons, corresponding to the crown-ether fragment, are in the area 3.65–4.21 ppm.

There is a double set of signals for the NH protons in the ^{1}H NMR spectra of complexes **1–3** in the areas 9.61–10.16 and 10.37–10.83 ppm. The high-field shifted signals for the P(O)NH group are shown as a doublet with a characteristic constant $^{2}J_{PNH}$ = 5.5–5.8 Hz. The low-field signals correspond to the RNH protons. Both set of signals are low-field shifted relative to that in parent ligands [9] because of the intramolecular hydrogen bonds formation of the RNH···O=P and PNH···Cl–Pd types.

The unrecrystallized, pure complexes **1–5** are presumed to be single isomers, in view of the sharp melting points, respectively. However, from the $^{31}P\{^{1}H\}$ NMR spectra of fresh $CDCl_3$ solutions of unrecrystallized complexes **1–3**, it appears that *trans*-isomers predominate. The $^{31}P\{^{1}H\}$ NMR spectra of **1–3** remain invariant for 72 h, suggesting that the isomer distribution rapidly reaches equilibrium on dissolution of the compound. By contrast to complexes **1–3**, the $^{31}P\{^{1}H\}$ NMR spectra of **4** and **5** contain the unique singlet signals in the region characteristic to the deprotonated *N*-phosphorylated thioureas and thioamides [4]. The signals observed correspond to the *cis*-isomer [7]. Moreover, the $^{31}P\{^{1}H\}$ NMR spectra of **4** and **5** remain invariant for 72 h, suggesting that the *trans*-isomer is not observed in the solution of $CDCl_3$.

3.3. Crystal structure of *1*

Crystals of **1** were obtained by slow evaporation of the solvent from dichloromethane–*n*-hexane solution of the complex.

The crystal structure of the *trans*-$[Pd(HL^{I}\text{-}S)_2Cl_2]$ complex **1** is shown in Fig. 1, while the geometrical data such as bond distances, angles, torsion angles and hydrogen bonds are given in Tables 1 and 2.

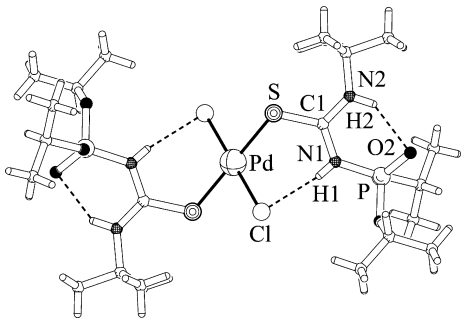

Fig. 1. Molecular structure of complex **1**.

Table 1
Selected bond lengths (Å), and bond angles (°) in complex **1**

Bond lengths			
Pd–Cl	2.3152(11)	P–N(1)	1.674(2)
Pd–S	2.3305(11)	N(1)–C(1)	1.370(3)
S–C(1)	1.708(2)	N(2)–C(1)	1.328(3)
P–O(2)	1.469(2)		
Bond angles			
Cl–Pd–S	85.31(4)	O(2)–P–N(1)	112.07(9)
Cl–Pd–Cl(A)	180.00	P–N(1)–C(1)	126.75(14)
Cl–Pd–S(A)	94.69(4)	S–C(1)–N(1)	120.82(15)
S–Pd–S(A)	180.00	S–C(1)–N(2)	121.71(15)
Pd–S–C(1)	113.86(8)	N(1)–C(1)–N(2)	117.5(2)
Torsion angles			
C(1)–S–Pd–Cl	128.09(9)	S–C(1)–N(1)–P	−170.94(11)
C(1)–S–Pd–Cl(A)	−51.91(9)	N(2)–C(1)–N(1)–P	10.5(3)
N(1)–C(1)–S–Pd	19.4(2)	C(1)–N(1)–P–O(2)	−38.1(2)
N(2)–C(1)–S–Pd	−162.02(14)		

Table 2
Parameters of hydrogen bonds for complex **1** [bond lengths (Å), and bond angles (°)]

N–H···A	*d*(N–H)	*d*(H···A)	D(N···A)	∠(NHA)
N(1)–H(1)···Cl	0.87(2)	2.26(2)	3.113(2)	167(2)
N(2)–H(2)···O(2)	0.90(2)	2.04(2)	2.832(3)	146(2)

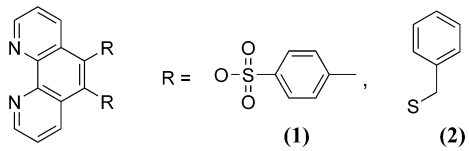
Inspection of the structure shows the expected square-planar coordination with two ligands $\mathbf{HL}^{I}$ bonded through the sulfur atoms with Pd–S 2.316(1) Å. The bond lengths Pd–Cl are 2.442(1) Å, while the bond angles S(A)–Pd–Cl 95.54(3)° and S–Pd–Cl 85.46(3)° deviate significantly from 90°. The distortion being induced by the two hydrogen bonds between N1(H1)···Cl(A) and N1A(H1A)···Cl at 3.924 Å. Similar N(H)···Cl and N(H)···Br hydrogen bonds, and the resultant distortion of bond angles from 90°, have previously been observed for the *cis*-bis(*N*-benzoyl-*N*′-propylthioureato)dichloroplatinum(II) (**6**) and *trans*-bis(*N*-benzoyl-*N*′-propylthioureato)dibromopalladium(II) (**7**) complexes [3]. An additional hydrogen bond between the N2(H2) and the phosphoryl oxygen atom O2 of the coordinated ligand at 2.601(4) Å effectively locks the ring C1–N1–P–O2–H2–N2 into a planar structure. The structure, bond lengths and angles of the coordinated $\mathbf{HL}^{I}$ in *trans*-$[Pd(HL^{I}\text{-}S)_2Cl_2]$ complex **1** are similar to that of the unbound $RNHC(S)NHP(O)(OiPr)_2$ (R = alkyl, aryl) [4], as well as that of the coordinated ligand corresponding *cis*-platinum **6** and *trans*-palladium **7** complexes [3]. This mode of coordination of *N*-phosphorylated thiourea once again highlights the importance and relative stability of the intramolecular hydrogen bond between the thiourea NH group and the phosphoryl oxygen atom of this ligands in determining the preferred mode of S atom coordination.

4. Conclusions

The data presented allow to confirm that in the case of the investigated *N*-phosphorylthiourea ligands **HL**$^{I–III}$, containing secondary nitrogen at the *N*-thioacylamidophosphate moiety C(S)NHP(O)(O*i*Pr)$_2$ (Scheme 1), the pure *trans*-Pd(HL$^{I–III}$–*S*)$_2$Cl$_2$ complexes were obtained by reaction with palladium(II). These complexes undergoes partial isomerization in solution to yield *cis*/*trans* distribution. In contrast the palladium(II) complexes with thioureas **HL**^{IV,V}, containing tertiary nitrogen at the *N*-thioacylamidophosphate moiety, under the same synthesis conditions forms *cis*-Pd(L^{IV,V}–*O*,*S*)$_2$ chelate complexes with deprotonated forms of the ligands both in solution and solid state.

Thus, the formation of the intramolecular hydrogen bonds P═O···HNR is a necessary condition for the monodentate *S*-isomer stabilization in a square-planar complexes of Pd(II). When H-bonding in the coordinated ligands is not possible the deprotonation of them and a change of the coordination mode in the Pd(II) complexes occurs.

5. Supplementary data



CCDC 669887 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail:deposit@ccdc.cam.ac.uk.

Scheme 1. 5,6-Substituted-1,10-phenanthrolines.

poured into ice (1 dm^3). A white solid formed immediately. The suspension was stirred to room temperature. After filtration the obtained solid was washed with MeOH and recrystallized from EtOH. The product is recovered as a crystalline white precipitate. Yield: 3.9 g, 7.5 mmol (80%); m.p. 227–230 °C. *Anal.* Calc. for $C_{26}H_{20}N_2O_6S_2$: C, 59.99; H, 3.87; N, 5.38; S, 12.32. Found: C, 58.65; H, 3.87; N, 5.36; S, 12.13%. ^{1}H NMR (300 MHz, $CDCl_3$): δ/ppm: 9.23 (dd, J = 1.5, 4, 2H, 2H), 8.44 (dd, J = 1.5, 8.1, 2H, H3), 7.66 (t, J = 4.2, 2H, H4), 7.62 (dd, J = 7.2, 4H, phenyl); 7.29 (dd, J = 9.3, 4H, phenyl), 2.48 (s, 6H, CH_3). ^{13}C NMR, (75.373 MHz, $CDCl_3$): δ 21.819, 123.430, 124.329, 128.744, 129.807, 132.035, 132.205, 135.819, 145.208, 146.143, 151.263.

2.2.2. 5,6-Dibenzylthiol-1,10-phenanthroline (*2*)

5,6-Dibromo-1,10-phenanthroline [5] (5.92 mmol; 2 g), $Pd_2(dba)_3$ (3 mol%; 0.184 g), bis-[2-(diphenylphosphino)phenyl]ether (PDEphos) (6 mol%; 0.191 g), *t*-BuOK (2.2 equiv., 13.01 mmol, 1.46 g), and 80 ml of dry and degassed toluene were mixed in a Schlenk tube under inert atmosphere. The solution was stirred for 1 h at room temperature. The benzylthiol (2.2 equiv., 13.01 mmol, 1.42 ml) was added by syringe. A condenser was adapted to the Schlenk tube and under argon atmosphere the reaction mixture was heated to 120 °C. After 48 h, the reaction mixture was allowed to reach room temperature, then filtered and concentrated under vacuum leading to an orange oil. This oil was chromatographed (Silica gel; AcOEt:MeOH:NH_3; (20:1:0.5)) and the product was recovered as a crystalline yellow precipitate. Yield: 1.78 g, 4.2 mmol (71%); m.p. 170–171 °C. *Anal.* Calc. for $C_{26}H_{20}N_2S_2$: C, 73.55; H, 4.75; N, 6.60; S, 15.10. Found: C, 73.53; H, 4.85; N, 5.76; S, 12.46%. ^{1}H NMR (300 MHz, $CDCl_3$): δ/ppm: 9.15 (dd, J = 1.8, 4.2, 2H, H2), 8.97 (dd, J = 1.8, 8.4, 2H, H4), 7.57 (dd, J = 4.2, 8.4, 2H, H3), 7.06 (m, 10H, phenyl), 4.06 (s, 4H, CH_2). ^{13}H NMR (75.373 MHz, $CDCl_3$): δ 42.172, 123.287, 130.293, 136.334, 137.116, 139.626, 146.202, 150.681.

2.2.3. [Fe(phdtos)$_3$](PF$_6$)$_2$ (*5*)

To a suspension of 5,6-bistosyl-1,10-phenanthroline (**1**) (3 equiv., 24.5 mg; 0.471 mmol) in 20 ml of a MeOH/H_2O (60/40) solution was added a MeOH/H_2O (50/50) solution of $FeCl_3 \cdot 6H_2O$ (1 equiv., 42.4 mg; 0.157 mmol). The reaction mixture was allowed to reflux with stir overnight, gradually turning to red. The hot mixture was filtered and a MeOH/H_2O (50/50) solution of $NaPF_6$ (3 equiv., 79.1 mg; 0.471 mmol) was added. The above reaction mixture was left in the refrigerated for several hours. A red precipitated was collected by vacuum filtration, washed with cold water and dried under vacuum. Yield: 101.8 mg, 0.0534 mmol (34%); m.p. 234–236 °C. *Anal.* Calc. for $C_{78}H_{60}F_{12}FeN_6O_{18}P_2S_6$: C, 49.11; H, 3.17; N, 4.41; S, 10.09. Found: C, 48.58; H, 3.26; N, 4.36; S, 9.22%.

2.2.4. [Fe(phdbt)$_3$](PF$_6$)$_2$ (*6*)

Following the previous procedure and using the 5,6-dibenzylthiol-1,10-phenanthroline (**2**) (3 equiv., 0.2 g; 0.471 mmol) instead of **1** a red precipitate was obtained. Yield: 104.7 mg, 0.0646 mmol (41%); m.p. 167–170 °C. *Anal.* Calc. for $C_{78}H_{60}F_{12}FeN_6P_2S_6$: C, 57.85; H, 3.73; N, 5.19; S, 11.88. Found: C, 57.76; H, 4.09; N, 5.18; S, 11.85%.

2.3. X-ray crystallographic study

Single crystals of **1** and **2** suitable for X-ray crystallographic analysis were obtained by slow evaporation in MeOH/CH_2Cl_2 solution and by slow diffusion of hexane into a CH_2Cl_2 saturated solution, respectively. Single crystals of the iron complexes (**5** and **6**) suitable for an X-ray structure determination were obtained by slow diffusion in an H shape cell. A saturated $NaPF_6$ solution in MeOH/H_2O (50:50) was placed in one compartment of a H cell and Fe(L)$_3$ (L = **5** and **6**) in a MeOH/H_2O (60:40) solution in the other compartment. Both solutions were layered with EtOH. Red crystals were obtained after a week.

The data collections of the single crystals suitable for single X-ray were obtained using graphite monochromated Mo Kα radiation

(λ = 0.71073 Å). Crystallographic data of **1** were collected at 294 K on Enraf-Nonius CAD4 diffractometer in the $\omega - 2\theta$ scan mode. Empirical absorption correction (ψ-scans) and data reduction were performed with WINGX suite of programs [6].

Crystallographic data for compounds **2**, **5**, **6** were collected on a Bruker AXS APEX CCD area detector diffractometer equipped with an Oxford Cryosystems low-temperature device at 130 K (**2**) and 150 K (**5** and **6**) in the ω and ϕ scans mode. A semi empirical absorption correction was carried out using SADABS [7]. Data collection, cell refinement and data reduction were done with the SMART and SAINT programs [8].

The structures were solved by direct methods using SIR 97 [9] and refined by full matrix least-squares methods with the SHELXL 97 [10] program using the WINGX software package.

For **6** the crystals obtained were of poor diffraction quality, which results in a low percentage (35%) of observed data [$I > 2\sigma(I)$], even those, the number of reflections was enough for a satisfying structure refinement and unambiguously determination of the geometry of the complex, which is of interest for the present discussion.

In **5** one of the phenyl groups is disordered and in **6** one of the PF_6 anion is also disordered, we tried without success to applied disorder models but it was not possible to achieve a good structure solution refinement. Non-hydrogen atoms were refined with anisotropic thermal parameters, whereas H-atoms were placed in idealized positions and allowed to refine riding on the parent C atom. Molecular graphics were prepared using ORTEP3 [11] and MERCURY 1.4.2 [12]. A summary of the crystal data, structure solution and refinement are given in Table 1.

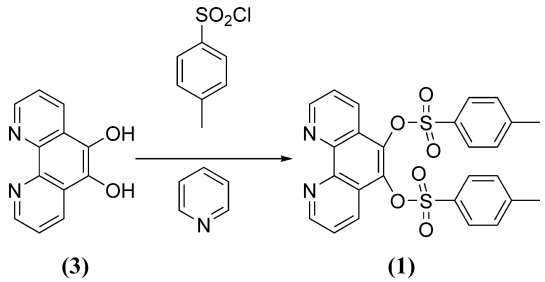
3. Results and discussion

3.1. Synthesis

Different synthetic strategies can be envisaged for the preparation of 5,6-dithiosubstituted-1,10-phenanthroline dithio-diazo ligands. As possible starting materials for these preparations both 5,6-dione-1,10-phenanthroline [4] and 5,6-dibromo-1,10-phenanthroline [5] (**4**) were considered as candidates.

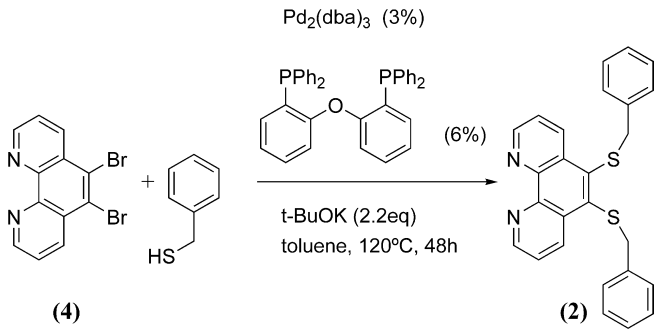
However several of these approaches proved ineffective in our hands:

(1) Starting with the 5,6-dione-1,10-phenanthroline the thionation with P_4S_{10} or Lawesson's reagent [13,14] in the appropriated refluxing solvent proved to be ineffective, even after addition of a nickel chloride solution possibly leading directly to the bisdithiolene complex.



(2) As an alternative, also starting from the 5,6-dione-1,10-phenanthroline, it was envisaged the preparation of the 1,10-phenanthroline-5,6-bistosyl (**1**) via the corresponding dihydroxide [3] (**3**) compound treated with toluenesulfonyl chloride (Scheme 2). The preparation of (**1**) was achieved in good yield as demonstrated by single crystal X-ray structure analyses as well as by ^{1}H and ^{13}H NMR and elemental analyses.The tosyl groups on **1** could be good leaving groups for future nucleophilic aromatic substitution reactions. In spite of the successful preparation of **1** this compound proved to be ineffective for subsequent nucleophilic substitution reactions either with dithiooxamide for the obtention of the corresponding dithiol, or with potassium trithiocarbonate or sodium trithiocarbonate for the obtention of the corresponding 1,3-dithiole-2-thione. We also tried with **1**, without success, two further nucleophilic substitutions with either isopropyl mercaptan, or with benzyl mercaptan aiming at the obtention of the corresponding 5,6-dithiosubstituted 1,10 phenanthrolines.

(3) Starting from 5,6-dibromo-1,10-phenanthroline [5] (**4**) procedures based on the creation of the aryl-sulfur bond including nucleophilic aromatic substitutions, either with isopropyl mercaptan, or with benzyl mercaptan and also treatment of aryl lithium with sulfurated electrophiles, were first tried however all proved unsuccessful. The 5 and 6, 1,10-phenanthroline positions seem to be inactivated for the direct nucleophilic substitution as well as for the treatment of aryllithium with sulfurated electrophiles.



A successful synthesis to obtain the 5,6-dithiosubstituted phenanthroline was the synthesis of 5,6-dibenzylthiol-1,10-phenanthroline (**2**), achieved in good yield starting from **4** by a palladium cross-coupling catalyzed reaction with benzylthiol in the presence of a base and using as catalyst the $Pd_2(dba)_3$/DPEphos system (PDE = bis-[2-(diphenylphosphino)phenyl]ether) (Scheme 3). The compound **2** was unambiguously identified and characterized by single crystal X-ray diffraction, ^{1}H and ^{13}H NMR and elemental analysis.

This Pd-catalyzed cross coupling reaction is related to the one introduced by Migita in 1980 between aryl bromides and thiols [15] for which since then various efficient catalytic systems using bidentate phosphines have been described [16]. Our protocol for preparing **2** involves the deprotonation of the benzylthiol with *t*-BuOK, followed by heating, in refluxing toluene, the resulting potassium benzylthiolate with **4** in the presence of $Pd_2(dba)_3$/DPEphos. Compound **2** can be used as precursor to prepare the corresponding thio-azo ligand. Preliminary experiments aimed at deprotecting the thiolate function have shown that the Pyridine/Na treatment[17] is efficient to generate the 1,2-dithiolate function and the thereof transition metal complexes can be obtain. However, this requires an effective control of the coordination ability to different poles, as it will be published subsequently.

In this work, the diimine function coordination ability of these substituted phenanthroline ligands was explored by the synthesis of the iron(II) complexes **5** and **6** using standard conditions for the

Scheme 2. Synthesis of 5,6-bistosyl-1,10-phenanthroline (**1**).

Scheme 3. Synthesis of 5,6-dibenzylthiol-1,10-phenanthroline (**2**).

preparation of Fe(II) phenanthroline complexes. The elemental analyses of the two complexes are consistent with a 1:2 anion:cation stoichiometry, as confirmed by the X-ray crystal structure determination, indicating Fe(II) in spite of starting from $FeCl_3$.

3.2. Crystal structure

Compounds **1**, **2**, **5** and **6** have been characterized by single crystal X-ray diffraction technique. The ORTEP views of these compounds are shown in Figs. 1–4. Crystallographic data, selected bond angles and distances are given in Tables 1–3.

The compound **1** crystallizes in the orthorhombic system, $P2_12_12_1$ space group. Its asymmetric unit consists of one molecule shown in Fig. 1. The 1,10-phenanthroline core of the molecule and the two oxygen in the 5,6-substituted positions are almost planar (Rms deviation of fitted atoms = 0.0341 Å). The two tosyl groups are tilted 45.76(7)° and 26.30(8)° in opposite directions with respect to the 1,10-phenanthroline core plane, and the other bond distances and angles assume standard values (see Table 2).

The compound **2** crystallizes in the monoclinic system, $P2_1/c$ space group and the asymmetric unit contains one molecule (Fig. 2). Also in this compound the 1,10-phenanthroline core of the molecule and the two sulfur atoms in the 5,6 positions are almost planar (Rms deviation of fitted atoms = 0.1027 Å). The two benzyl groups are tilted 14.56(9)° and 17.98(10)° with respect to the 1,10-phenanthroline core plane. Bond lengths and angles assume standard values (see Table 2).

The compound **5** crystallizes in the orthorhombic system, *Pbcn* space group, with the iron atom lying on a twofold axis. The asymmetric unit has one half of the $[Fe^{II}(phdtos)_3]^{2+}$ cation and two PF_6^- anions (see ORTEP view Fig. 3). One of the 1,10-phenanthroline

S(1)–C(12)		1.763(2)			
S(2)–C(11)		1.800(2)			
Bond angles			Bond angles		
C1–N1–C5	116.47(29)	118.82(20)	C6–N2–C7	117.62(32)	115.83(20)
N1–C5–C6	117.98(29)	119.48(20)	N2–C6–C5	118.71(32)	116.49(20)

core units is almost planar (Rms deviation of fitted atoms = 0.0167 Å), the two other phenanthroline cores present a slight deviation from planarity (Rms deviation of fitted atoms = 0.0561 Å). As the uncoordinated ligand, the two tosyl groups are tilted, in opposite directions, with respect to the phenanthroline core plane 28.59(24)° in the ligand containing N3 and 28.16(16)° and 53.77(14)° on the two other ligands containing N1 and N2. The dihedral angles between the phenanthroline cores are 85.32(5)° and 88.07(5)°. The bond distances and angles of the coordinated ligands in complex **5** do not assume relevant deviation from the compound **1** values, except in the fact that the tosyl groups have different tilted directions and the associated torsion angles are necessarily different.

The compound **6** crystallizes in the monoclinic system, in the $P2_1/n$ space group. The asymmetric unit contains two independent cations $[Fe(phdbt)_3]^{2+}$ and four anions PF_6^- (see ORTEP view Fig. 4). In the Fe1 cation, one of the coordinated phenanthroline cores is almost planar (Rms deviation of fitted atoms 0.023 Å, for the ligand containing N1 and N2) and the two others present small deviation from planarity (Rms deviation of fitted atoms 0.104 and 0.061 Å, for the ligands containing N3–4 and N5–6, respectively). The Fe2 cation presents a similar planarity (Rms deviation of fitted atoms 0.121, 0.090 and 0.023 Å, for the ligands containing N7–8, N9–10, N11–12).

In each cation of **6** only one of the coordinating ligands has the 5,6-disubstituted groups tilted towards opposite sides of the core mean plane. In the Fe1 cation, two of the ligands have the benzyl groups tilted towards the same side of the core mean plane 61.3(2)°, 22.8(2)° and 30.7(2)°, 35.8(2)°. The other ligand has the two benzyl groups tilted towards opposite sides of the core mean plane, with angles of 36.8(2)° and 43.0(3)°. In Fe2 cation, the correspondent angles are 54.5(2)°, 35.8(2)° and 34.2(2)°, 63.3(2)° for the groups tilted towards the same side and 40.0(2)°, 31.6(2)° for the groups tilted towards opposite sides. Similarly to complex **5**, for **6** bond distances and angles of the ligands do not assume relevant deviations from the corresponding values in compound **2**. Also the benzyl groups have different tilted directions and the associated torsion angles are necessarily different.

A common characteristic of the crystal structures of **5** and **6** is the occurrence of parallel cation chains. However they have different packing patterns of anionic and cationic units (Figs. 5 and 6). Whereas in **6**, sheets of cationic layers alternate with anionic ones, in **5** there is not a so clear segregation of cations and anions. In all cases, due to the bulky substituted ligands the iron–iron distances are very large and the shortest Fe–Fe distance in both compounds is 10.5 Å.

The infinite chains of $[Fe(L)_3]^{2+}$ (L = **1** and **2**) complexes in **5** and **6** are shown in Figs. 7 and 8. These chains in **6** are composed of two crystallographic distinct complexes while those of **5** are made of only one complex. The shortest Fe–Fe distance within a chain is 12.2 Å for compound **5** and 10.5 Å for compound **6**.

Within the chains is possible to observe several short contacts but none of them correspond to π–π interactions. In compound **5**, hydrogen bonds between oxygen atoms of the tosyl groups and hydrogen atoms in the phenanthroline rings, O3···H30#*f* 2.327(4) Å, hydrogen bonds between oxygen atoms of the tosyl groups and hydrogen atoms of other tosyl group, O5···H25#*f* 2.601(3) Å, O8···H18#*f* 2.649(5) Å, and also a O···C short contact between a oxygen atom of a tosyl group and a phenanthroline carbon O3···C30#*f* 3.080(7)Å, #*f* = 2 − *x*, −*y*, 1 − *z* (see supplementary material SM1).

The short intrachain contacts in **6** are between sulfur and phenanthroline carbon atoms S3···C130#*b* 3.492(8) Å, #*b* = −1 + *x*, *y*, *z*; S5···C82#*a*, 3.487(22) Å, S5···C139#*a* 3.487(21) Å, S7···C1#*a* 3.483(18) Å, S8···C1#*a* 3.404(20) Å, S7···C58#*a* 3.434(16) Å, *a* = *x*, *y*, *z*. Between phenanthroline carbon atoms and benzyl carbon atoms C49···C132#*b* 3.393(11) Å. Hydrogen bonds between sulfur and phenanthroline rings S3···H130#*b* 2.7391(21) Å, S6···H139#*a* 2.836(19) Å, S8···H1#*a* 2.697(24) Å, S10··· H10#*c* 2.7785(22) Å, *c*# = 1 + *x*, *y*, *z*. Hydrogen mediated short contacts between benzyl groups C50···H151#*b* 2.897(13) Å and C51···H151#*b* 3.822(16) Å (see supplementary material SM2).

Although the mean Fe–N distances and the N–Fe–N angles are in the range usually found in other iron-phenanthroline derivatives [18] there are deviations from a regular octahedron more clearly denoted by other structural parameters. Shortest and longest Fe–N distances are 1.967(4) and 1.989(3) Å in compound **5** and 1.953(5) and 1.983(5) Å in compound **6**. This distortion is not merely an elongation and compression along an axis, as the angles between the phenanthroline moieties differ also from orthogonality, attaining values as low as 82.1(2)° both in **5** and **6**.

The comparison of the N–C bonds lengths in the free ligands and in these coordinating the Fe atom does not reveal any significant change within experimental uncertainty.

Magnetic susceptibility measurements[1] of the **5** and **6** compounds in the 4–300 K range indicate a diamagnetic behavior, indicative of the low spin *S* = 0 state as expected for Fe(II) complexes in an octahedral coordinating geometry.

These results show that the coordination distortion observed is not significant in order to allow an intermediate *S* = 1 spin state, as

[1] Magnetic susceptibility measurements were performed using a longitudinal Faraday system (Oxford Instruments) with a magnetic field of 5 T and gradient field of 1 T/m in a polycrystalline sample (~20 mg) placed inside a previous calibrated thin wall Teflon bucket. The force was measured with a microbalance (Sartorius S3D-V). Magnetization data were corrected for contributions due to the sample holder and core diamagnetism, estimated from tabulated Pascal constants as -11.8×10^{-4} and -9.5×10^{-4} emu/mol for **5** and **6**, respectively.

it has been shown to occur in cases of more severely distorted hexacoordinated complexes. Several examples of iron (II) complexes with substituted phenanthrolines are known with this intermediate spin state [19], usually in square planar or heavily distorted hexacoordinated complexes. Examples of iron(II) complexes, where the metal atom is coordinated to six nitrogen atoms of bipyridine ligands, exhibiting magnetic moments varying with temperature and whose interpretation was based in a two-step transition involving also a $S = 1$ state, are also known [18c]. However the present complexes apparently are not so significantly, distorted from the ideal octahedral geometry to allow such intermediate spin state.

4. Conclusion

In summary, we achieved the synthesis of two new 5,6-substituted-1,10-phenanthrolines. Particularly, we have developed a convenient method for preparing sample quantities of the 5,6-dibenzylthiol-1,10-phenanthroline in two steps from commercially available phenanthroline. This is the first example of a cross-coupling reaction with a 5,6-dihalo-1,10-phenanthroline, achieving a new thio-azo ligand precursor, which can be explored in subsequent work for the preparation of thio-azo ligands. Preliminary

experiments have shown that is possible to generate the 1,2 dithiolate function and the thereof transition metal complexes can be obtained. However, this requires an effective control of the coordination ability to different poles. In this report, we have used the diimine function coordination ability of the 5,6-disubstituted-1,10-phenanthroline ligands, and these two new phenanthroline ligands allowed for the preparation of $[Fe(phdtos)_3](PF_6)_2$ and $[Fe(phdbt)_3](PF_6)_2$ complexes.

Acknowledgements

This work was partially supported by FCT through Contract (PTDC/QUI/64967/2006) and post-doctoral grant to S.R., and by GRICES-Ministère des Affaires Etrangères (France) Pessoa no. 07981RL bilateral agreement and it also benefited from the ESF COST action D35. We also thank Narcis Avarvari (Angers) for useful discussions concerning ligand synthesis.

Appendix A. Supplementary data

CCDC 601085, 601086, 656658 and 656659 contain the supplementary crystallographic data for **1**, **2**, **5** and **6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.03.016.
