IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.3.7. [$(H_2t(2\text{-}Me)pp)ZrCl_4$]

0.5 mmol of $H_2t(2\text{-}Me)pp$ and 0.6 mmol $ZrCl_4$ in 2–3 ml hot chloroform were ground together in a mortar for 30 min at room temperature affording the green SAT complex. The grinding was continued until the complexation was complete, which was determined by the disappearance of the Soret band of the porphyrin in the UV–Vis spectrum. The solvent was evaporated, and the excess $ZrCl_4$ was removed by washing the residue with dry diethylether. The produced SAT complex was dried in a vacuum oven for 12 h

at 50 °C, and was consistent with *Anal.* Calc. for $C_{48}H_{38}N_4ZrCl_4$: C, 63.8; H, 4.2; N, 6.2; Cl, 15.7; Zr, 10.1. Found: C, 63.1; H, 4.2; N, 6.1; Cl, 15.4; Zr, 9.9%. ^{1}H NMR ($CDCl_3$): δ 0.20 (s, 1H, NH), δ 0.23 (s, 1H, NH), δ 2.12 (s, 3H, CH_3), δ 2.14 (s, 3H, CH_3), δ 2.23 (s, 3H, CH_3), δ 2.26 (s, 3H, CH_3), δ 8.25–8.27 (d, 1H, 2), δ 8.30–8.32 (d, 1H, 2), δ 8.36–8.38 (d, 1H, 2), δ 8.39–8.41 (d, 1H, 2), δ 7.69–7.75 (br, 8H, 3, 3′), δ 7.80–7.82 (t, 4H, 4), δ 8.45 (s, 4H, β), δ 8.47 (s, 4H, β). IR (KBr): υ_{NH} (~3320 cm^{-1}).

2.3.8. [(H_2t(2-OMe)pp)$ZrCl_4$]

This complex was synthesized by the method used for [(H_2t(2-Me)pp)$ZrCl_4$]. *Anal.* Calc. for $C_{48}H_{38}N_4O_4ZrCl_4$: C, 59.6; H, 4.0; N, 5.8; Cl, 14.6; Zr, 9.4. Found: C, 58.8; H, 3.8; N, 5.7; Cl, 14.3; Zr, 9.0%. ^{1}H NMR ($CDCl_3$): δ 0.26 (s, 1H, NH), δ 0.29 (s, 1H, NH), δ 3.72 (6H, OCH_3), δ 3.79 (6H, OCH_3), δ 8.21–8.22 (d, 2H, 2), δ 8.29–8.31 (d, 2H, 2), δ 7.85–7.88 (t, 4H, 3), δ 7.45–7.48 (t, 4H, 3′), δ 7.40–7.43 (t, 4H, 4), δ 8.43 (s, 4H, β), δ 8.45 (s, 4H, β). IR (KBr): υ_{NH} (~3320 cm^{-1}).

2.3.9. [H_4tpp]Cl_2

To a H_2tpp solution (in chloroform) was added excess hydrochloric acid. Evaporation of the solvent produced the diprotonated porphyrin species as a green solid. ^{1}H NMR ($CDCl_3$): δ 0.31 (s, 2H, NH), δ 8.62–8.64 (d, 8H, 2, 2′), δ 7.96–8.05 (t, 8H, 3, 3′), δ 7.96–7.97 (d, 4H, 4), δ 8.60 (s, 8H, β).

3. Results and discussion

The ^{1}H NMR spectrum of the [(H_2tpp)$ZrCl_4$] SAT complex showed four signals for NH (one signal), β-pyrrole (one signal) and phenyl ring protons (two signals). This spectrum was similar to the ^{1}H NMR spectrum of H_4tpp^{2+} (Fig. 2), but was completely different from the related metalloporphyrin spectrum. The ^{1}H NMR spectrum of the [$ZrCl_2$(tpp)] metalloporphyrin shows four signals at δ 9.11 (s, pyrrole H), 8.42 (s, 4 o-H), 8.08 (t, 4 p-H) and 7.84 (s, 12H) [19]. Further, for this compound there is no signal related to NH protons, Table 1. SAT complexation of the *meso*-tetraarylporphyrins with $ZrCl_4$, similar to the molecular complexation of *meso*-tetraarylporphyrins by $SbCl_3$ [15], $BiCl_3$ [16], SO_2 [20], DDQ [21], TCNE [22] and SiR_3Cl [23], caused downfield shifts for N–H and aryl ring proton signals, and an upfield shift of the β-hydrogens (Fig. 2 and Table 1). The shifts of the internal N–H and β-protons are related to the ring current in both *meso*-teraarylporphyrins and the SAT complexes. The effect of the ring current is lost in the SAT complexed porphyrins with $ZrCl_4$. This is because of the geometric distortion of the porphyrin macrocycle which produces a positive electric charge in the porphyrin core. The downfield shifts of the aryl ring hydrogens can be related to a direct increase in the ring current of aryl groups produced by an extension of the aryl π-system [21,22]. The *ortho*-substituent porphyrins have four atropisomers. The ^{1}H NMR spectral data indicates that the four atropisomers of the *ortho*-substituent porphyrins are bonded differently to $ZrCl_4$. The ^{1}H NMR titration of H_2tpp with $ZrCl_4$ (1:0.5, 1:0.75, 1:1, 1:2 and 1:excess) in $CDCl_3$ showed that the molar ratio of the reactants in the SAT complexes is 1:1. An amount of $ZrCl_4$ less than that of H_2tpp leads to a superimposition of the spectra for the porphyrin and the related SAT complex. Addition of an excess amount of $ZrCl_4$ beyond a 1:1 mole ratio caused no changes in the spectra of [(H_2t(X)pp)$ZrCl_4$].

The ^{13}C NMR spectrum of H_2tpp gives rise to six sharp signals (120.5 (C_{meso}), 127.1 ($C_{3'}$), 128.1 ($C_{4'}$), 131.5 (C_β), 135.0 ($C_{2'}$) and 142.6 ($C_{1'}$) ppm) and a very broad signal (145 ppm) for the α-carbons, whereas the ^{13}C NMR spectrum of [(H_2tpp)$ZrCl_4$] showed seven signals (123.8 (C_{meso}), 129.3 ($C_{3'}$), 129.5($C_{4'}$), 131.1 (C_β), 140.2 ($C_{2'}$), 141.1 ($C_{1'}$) and 147.2 (C_α) ppm). The formation of the SAT

$\Delta\delta_1$: Chemical shifts of the proton signals for the porphyrins upon SAT complexation.
$\Delta\delta_2$: Chemical shifts of the proton signals for the H_2tpp upon diprotonation with HCl.
$\Delta\delta_3$: Chemical shifts of the proton signals for the H_2tpp upon metallation ([$ZrCl_2$(tpp)]).

complexes sharpens the α-signals in the ^{13}C NMR spectra of the porphyrins and leads to small shifts in the other lines. These changes are quite similar to those in the molecular complexation of *meso*-tetraarylporphyrin with the acceptors $SbCl_3$, $BiCl_3$, DDQ, TCNE and SO_2 or upon diprotonation [15,16,20–23], though in the diacid species the signals due to C_α, C_β and $C_{2,2'}$ are sharper (Fig. 3). These differences are because of lower symmetry for the SAT complexes relative to the diprotonated porphyrins.

The UV–Vis spectra of the various substituted *meso*-tetraarylporphyrins contain five absorption bands in the 415–655 nm region, that upon SAT complexation with $ZrCl_4$ are shifted to the red and appear as two new bands in the 445–690 nm region (Fig. 4a, b and Table 2). The Soret band is observed in the 442–455 nm region and one weaker band appears in the 645–689 nm region. For an example, the UV–Vis spectrum of $[(H_2tpp)ZrCl_4]$ is shown in Fig. 4b. This spectrum is similar to H_4tpp^{2+} (Fig. 4c), whereas it is completely different from the $[ZrCl_2(tpp)]$ metalloporphyrin, Table 2. $[(H_2tpp)ZrCl_4]$ has two absorption bands at 446.2 and 662.4 nm, but $[ZrCl_2(tpp)]$ has five absorption bands at 398, 418, 502, 540 and 574 nm [19]. These red shifts indicate that there is an out-of-plane distortion of the porphyrin core and a strong interaction between the aryl rings and the porphyrin π-system [15,16,20–23]. ^1H NMR and UV–Vis spectral shifts upon SAT complexation of different *meso*-tetraarylporphyrins with $ZrCl_4$ indicate that the π-resonance is more important than the σ-induction effects and so, the trend in electron donating ability for the substituted *meso*-tetraarylporphyrins is *para* > *meta* > *ortho* (Tables 1 and 2). This trend is corresponded to lower steric hindrance from the ortho compared to para substituents.

^1H and ^{13}C NMR, and UV–Vis correspondences between the spectral data of the molecular complexes of *meso*-tetraarylporphyrins with $SbCl_3$ and $BiCl_3$ acceptors and the $[(H_2t(X)pp)ZrCl_4]$ SAT complexes proposed a similar structure for the porphyrin core in all of the species, with non-coplanar pyrrole rings tilted alternately up and down. In this conformation the lone pairs of two pyrrolenine nitrogens act as the electron donors to one zirconium atom of $ZrCl_4$, above or below the mean plane of the porphyrin (Fig. 5).

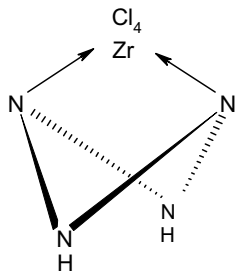

Fig. 5. Only the tetrahedrally tilted pyrrolenine nitrogens of the porphyrin core are shown. Two pyrrolenine nitrogen atoms of the porphyrin act as electron donors to a zirconium atom and the molecule of $ZrCl_4$ is located on one side of the porphyrin plane.

The position of the pyrrolic NHs (trans) in the proposed structure is similar to those in free base *meso*-tetraarylporphyrins. Zirconium(IV) chloride has one chlorine atom more than antimony(III) chloride and bismuth(III) chloride and also the formal positive charge of the central atom in zirconium(IV) chloride is more than that of antimony(III) chloride and bismuth(III) chloride. These two factors increase respectively the steric hindrance and electron accepting capability for zirconium(IV) chloride compared to $SbCl_3$ and $BiCl_3$. The steric hindrance of the four chlorine atoms in $ZrCl_4$ causes more stability of the monomer form than the dimer form in the synthesized SAT complexes.

The IR (400–4000 cm^{-1}) spectra of the free base *meso*-tetraarylporphyrins show the N–H stretching band at 3320 cm^{-1} [24], which upon SAT complexation with $ZrCl_4$ is not considerable changed. The existence of the NH band shows that the metallation of the porphyrins does not occur in our reaction system. Furthermore, this subject is proved by the presence of two NH protons in the ^1H NMR spectra of the SAT complexes.

The ^1H and ^{13}C NMR, and UV–Vis spectra of the SAT complexes of *meso*-tetraarylporphyrins with $ZrCl_4$ were similar to those of the related diprotonated species [25], but the signals of the ^1H and ^{13}C NMR (the signals of C_α, C_β and $C_{2'}$) spectra for the SAT complexes were broader than those of the diprotonated species (Fig. 2b and c, Fig. 3b and c). The broadening can be related to a lower symmetry for the SAT complexes than the diprotonated porphyrins (Fig. 5). On the other hand, the molar conductivity data for the SAT complexes and the related diprotonated species were completely different. For example, the molar conductances of the $[(H_2tpp)ZrCl_4]$ SAT complex (in nitromethane) and $[H_4tpp]Cl_2$ (in methanol) are 10.7 and 213.3 $\Omega^{-1}\,cm^2\,mol^{-1}$, respectively [26]. These results show that the SAT complexes are not electrolytes whereas the diprotonated porphyrins are 1:2 electrolytes. Consequently, the remarkable spectral correspondence between the SAT complexes and the diprotonated species suggest only an analogous tilted porphyrin core structure in these species.

The metalloporphyrin of $[ZrCl_2(tpp)]$ was synthesized by the reaction of $ZrCl_4(THF)_2$ and the dilithium salt of *meso*-tetraphenylporphyrin at reflux conditions (in toluene solvent) under an inert atmosphere [19], whereas the SAT complexes in this study are synthesized in chloroform under mild conditions. There are some other evidences that they are differed two species. The ^1H NMR spectrum of the metalloporphyrin ($[ZrCl_2(tpp)]$) shows four protons signals and its UV–Vis spectrum shows four absorption bands [19]. The corresponding spectral data for $[ZrCl_2(tpp)]$ are completely different from the related SAT complex ($[(H_2tpp)ZrCl_4]$), Tables 1 and 2. On the other hand, the chloroform solutions of the SAT complexes ($[H_2t(X)ppZrCl_4]$) rapidly decomposes to the related porphyrins by addition of natural alumina, whilst $[ZrCl_2(tpp)]$ is purified by an alumina column [19]. It is interesting that the SAT complexes decompose to the related porphyrins in the presence of donor solvents such as DMSO, but the metalloporphyrins are completely stable in these solvents. Further, in Eq. (1), the mole ratio of metal:porphyrin is 1:2 whereas it was 1:1 for our reaction system. Consequently, the synthesized complexes in this work are completely different from the known compounds of diprotonated porphyrins or related metalloporphyrins.

4. Conclusion

The *meso*-tetraarylporphyrins $H_2t(X)pp$ react with zirconium(IV) chloride to form highly stable SAT complexes (for example, $[H_2t(4\text{-}OCH_3)ppZrCl_4]$ is completely stable up to 170 °C). Selection of suitable conditions for the reaction system enabled the successful preparation of the SAT complexes as solids. NMR and UV–Vis spectral data show that the distorted porphyrin core of the SAT complexes is similar to porphyrin diacids [25] and molecular complexes of *meso*-tetraarylporphyrins with various acceptors [15,16,20–23]. In these SAT complexes, two nitrogen atoms of pyrrolenine on one side of the porphyrin plane act as electron donors to a zirconium atom of $ZrCl_4$ and two protons still remain on the pyrrole nitrogens.

Cyrhetrenylamines
X-ray characterization

ABSTRACT

Cyrhetrenyl Schiff base derivatives of the form (η^5-C_5H_4CH=NAr)$Re(CO)_3$, [Ar = Ph (**1a**) C_6H_4OMe-*p* (**1b**) and $C_6H_4NO_2$-*p* (**1c**)] have been prepared from cyrhetrenylcarbaldehyde and the corresponding aromatic amines. ^1H and ^{13}C NMR indicates that these compounds have the *anti*-(*E*) conformation in solution and the X-ray crystal structure of **1b** confirms that it also adopts the *anti*-(*E*) form in the solid state. Further reaction of cyrhetrenylaldimines **1** with sodium borohydride in methanol produces quantitatively, the corresponding amine derivatives (η^5-$C_5H_4CH_2$–NHAr)$Re(CO)_3$ [Ar = Ph (**2a**) C_6H_4OMe-*p* (**2b**) and $C_6H_4NO_2$-*p* (**2c**)]. All these cyrhetrenylamines were characterized by IR, ^1H and ^{13}C NMR, MS. Additionally, **2b** has been characterized structurally.

1. Introduction

Ferrocenylimines (η^5-C_5H_5)Fe(η^5–C_5H_4CR=NAr) and ferrocenylamines (η^5-C_5H_5)Fe(η^5-$C_5H_4CHRNHAr$), R = H, Me, Ph; and Ar = a variety of substituted phenyl, have attracted a great deal of attention in the past two decade due to their wide application in molecular materials [1], bioorganometallic chemistry [2] and as ligands capable of coordinating transition metal ions giving complexes with potential applications in catalysis [3]. The above situation contrasts with the smaller number of analogous compounds bearing the cyrhetrenyl group (η^5-C_5H_4)$Re(CO)_3$, described in the literature. To our best knowledge the only known cyrhetrenylimine (η^5-C_5H_4CH=NPh)$Re(CO)_3$, was briefly described by Kolobova et al. [4,5]. More recently, complexes of these type have been used *in situ*, as intermediates for the preparation of some biological compounds containing the (η^5-C_5H_4)$Re(CO)_3$ group (see below) but details of their isolation and characterization remain unknown [6]. On the other hand, reduction of ferrocenylimines with sodium borohydride or lithium aluminium hydride has been shown to be an efficient procedure for the preparation of (*N*-aryl)-amino methylferrocenes. A similar approach have been used by Jaouen to prepare poly(amidoamine) dendrimers tethered with cyclopentadienyl rhenium tricarbonyl [6]. As part of our interest in comparing the properties of the cyrhetrenyl substituted systems with the well known analogous ferrocenyl [7], in this paper we would like to report the synthesis and characterization of the cyrhetrenylimine (Schiff base) complexes (η^5-C_5H_4CH=NAr)$Re(CO)_3$, and the cyrhetrenyl-amine derivatives (η^5-$C_5H_4CH_2$–NHAr)$Re(CO)_3$. The imine and amine complexes derived from *p*-anisidine were also studied X-ray crystallography.

2. Results and discussion

2.1. Cyrhetrenylimine complexes (η^5-C_5H_4CH=NAr)$Re(CO)_3$ (**1**)

The Schiff bases (η^5-C_5H_4CH=NAr)$Re(CO)_3$, Ar = Ph (**1a**) C_6H_4OMe-*p* (**1b**) and $C_6H_4NO_2$-*p* (**1c**) were synthesized following the same procedure to that described for analogous ferrocenylimines derivatives [8], that is by condensation of the corresponding aniline with formylcyrhetrene (η^5-C_5H_4COH)$Re(CO)_3$ [9] (Scheme 1).

The procedure consists of the reaction of equimolar amounts of formylcyrhetrene and the aromatic amine in refluxing toluene. A Dean–Stark apparatus was used to remove the toluene–water azeotrope formed during the reaction formation of **1c**. In all cases the products were isolated as white crystalline solids after crystallization from CH_2Cl_2-hexane mixture (1:5).

The IR spectra of these compounds showed the expected value of the $\nu_{C=N}$ stretch in the range 1625–1643 cm^{-1}, in CH_2Cl_2 solution. This absorption bands as well as the ν_{CO} of the carbonyls bound to rhenium are shifted to lower wavenumber when compared to the precursor formylcyrhetrene [9]. Similar $\nu_{C=N}$ frequency shifts have been reported for Schiff bases derived from

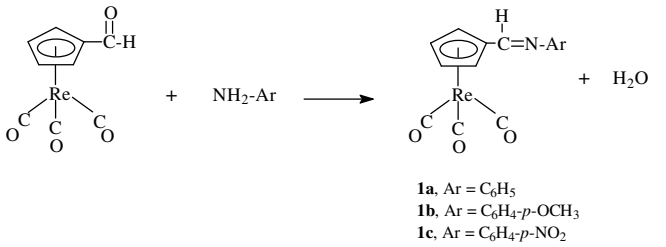

Scheme 1.

formylferrocene [8]. Each of **1a–c** showed a strong molecular ion and fragments corresponding to the successive lost of three CO, in their mass spectra.

The ^{1}H NMR spectra showed a singlet at about δ 8.0 due to the iminic proton and two apparent triplets between 5.42 and 6.07 ppm. The latter are ascribed to the monosubstituted cyclopentadienyl ring. In addition, resonances for the hydrogen atoms of the aryl ring and the methoxy substituent were also observed. ^{13}C NMR data were also in accordance with the existence of a single compound. Despite the fact that these type of compounds could adopt two different forms (*E*- or *Z*-) [1b,3c,10] their ^{1}H and ^{13}C NMR spectra, which agreed with those reported for related ferrocenyl Schiff bases [1b,3c,10], revealed that only one isomer (*E*-form) was present in solution. Further proof was provided by an X-ray crystal structure determination of **1b** (see below). The most important feature of these spectra is the presence of a low field resonance (δ 152–158) assigned to the iminyl carbon. This resonance occurs at almost the same δ as those reported for the ferrocene analogues [1,3c,10] and is indicative of some degree of conjugation of the C_5H_4 ring and the –HC=N entity.

With the aim to compare structural parameters of these compounds with the crystallographic data reported for several ferrocenylimines [1a,8c,10,11], we undertook a crystallographic study of complex **1b**. The structure of **1b** is shown in Fig. 1. Table 1 reports the crystal structure and refinement data and Table 2 shows selected bond lengths and angles. The structure confirms the *E* configuration assigned tentatively by NMR. Taking into account the internal and exocyclic C–C distances of the cyclopentadienyl ring and the classification done for substituted ferrocene derivatives [1a,10], a fulvenoid type of structure can be considered for **1b**, since it possesses alternated two short and three long C–C distances (C(2)–C(3) 1.403 Å; C(4)–C(5) 1.402 Å; C(1)–C(2) 1.446 Å; C(1)–C(5) 1.412 Å and C(3)–C(4) 1.433 Å), and the exocyclic C(1)–C(9) of 1.456 Å. Additional support for this assignment is to be found in the C=N bond length (1.265 Å), which is within the range to those measured in several ferrocenyl Schiff bases [1a,8c,10,11], and the C_5H_4CH=N part of the molecule are practically flat, the maxima deviation from the least-squares plane formed by the atoms of the C_5 ring and C(9), N(1) and C(10) atoms is only 0.1 Å. This is in agreement with the suggestion that some delocalization of electron density is found over the C_5H_4CH=N moiety. On the other hand, within the cyrhetrenyl group, the average Re–C(O) distance and the Re–C–O angle are concordant with related tricarbonyl cyclopentadienyl rhenium(I) complexes [7].

2.2. Cyrhetrenylamine complexes (η^5-$C_5H_4CH_2NHAr$)$Re(CO)_3$ (**2**)

These compounds were prepared according to the general procedure described for most ferrocenylamines [3f,11] that is, by direct reduction of the corresponding cyrhetrenyl imine complex **1** with $NaBH_4$ in anhydrous methanol, at room temperature (Scheme 2).

Table 2
Select bond lengths (Å), bond angles and dihedral angles (°) for **1b** and **2b**

Compound	**1b**	**2b**

2a, Ar = C_6H_5
2b, Ar = C_6H_4-*p*-OCH_3
2c, Ar = C_6H_4-*p*-NO_2

Scheme 2.

The products were purified by column chromatography and isolated in quantitative yields as white solids. The IR spectra, in CH_2Cl_2 solution, showed as expected, the presence of two ν_{CO} bands, which are slightly shifted to lower wavenumber compared to their parent complexes **1**. In addition to the resonances of the cyclopentadienyl and aryl groups, in all cases the ^{1}H NMR spectra, in C_6D_6 solution, clearly showed at $\delta \sim 3.4$, a doublet and a broad singlet for the CH_2 and NH groups, respectively. These assignments were confirmed by ^{1}H–^{1}H NMR COSY.

The main feature of the ^{13}C NMR spectrum of each compound, in $CDCl_3$ solution, is a resonance at about 41 ppm which has been assigned to the CH_2 group on the basis of the reported chemical shifts for the methylene group in analogous ferrocenylamines [12,13]. The resonances of CO groups (Re–CO) occurred to similar chemical shift to others tricarbonyl cyclopententadienyl functionalized complexes [7,9].

The mass spectra of **2a–c** exhibited the molecular ion, and the successive loss of three CO ligands. In all cases, the most intense peak corresponds to the elimination of the amine fragment (NHAr) to give cyrhetrenylmetylene cation (*m*/*z* 349, 100%). This fragmentation is similar to that observed for the complex (η^5-$C_5H_4CH_2NHC_6H_5$)Fe(η^5-C_5H_5) [12,13].

The elementals analyses are in a good agreement with the proposed structures.

The molecular structure of amine **2b** (Fig. 2) shows no significant differences in bond lengths and angles (Table 1) when compared to the structure of the ferrocene related compounds [12–14]. The torsion angle C(10)–N–C(9)–C(1) of 59.0° indicates a Syn-Clinal arrangement of the substituents at the N–C(9) bond. The angle 81.6° between the planes of the Cp ring with the aromatic ring is almost orthogonal. On the other hand, the rhenium-ring centroid distance 1.949 (5) Å, the average Re–C(O) distance and the Re–C–O angles are concordant with the corresponding values reported for substituted-cyclopentadienyl tricarbonyl rhenium(I) complexes [7,15].

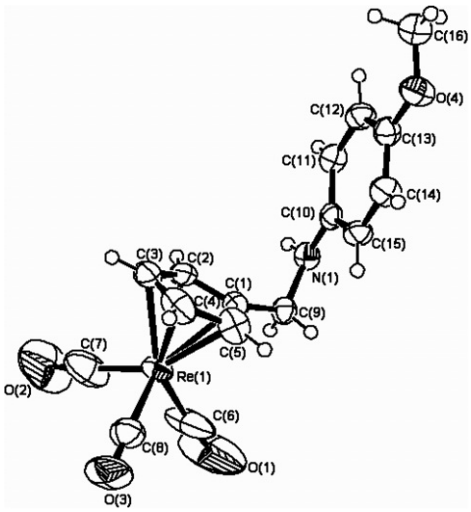

Fig. 2. Molecular structure of cyrhetrenylamine **2b**.

3. Experimental

(η^5-C_5H_4CHO)$Re(CO)_3$ was prepared according to the literature method [9]. Anilines and $NaBH_4$ were obtained commercially (Aldrich). All the solvents were purified according standard methods prior to use. Infrared spectra were recorded in solution (NaCl cell) on a Perkin–Elmer FT-1605 spectrophotometer, and the ^{1}H and ^{13}C NMR spectra were measured on a Bruker AVANCE 400 spectrometer. ^{1}H NMR chemical shifts were referenced using the chemicals shifts of residual solvent resonances, and ^{13}C chemical shifts to solvent peaks. Mass spectra were obtained on a Thermo-Finnigan MAT 900XP, at the Facultad de Ciencias Químicas y Farmacéuticas, Universidad de Chile.

3.1. (η^5-C_5H_4CH=NC_6H_5)$Re(CO)_3$ (**1a**)

To a solution of (η^5-C_5H_4CHO)$Re(CO)_3$ (50.0 mg, 0.138 mmol) in toluene (15 mL) was added 1.25 mL (0.138 mmol) of a 0.110 M aniline solution in toluene. The mixture was refluxed for 15 h. After this time, an IR spectrum of the solution showed the complete disappearance of the cyrhetrenylcarboxaldehyde complex (2033s; 1940s and 1694 cm^{-1}) and the presence of the new CO absorptions due to **1a**. The solvent was pumped off and the solid crystallized from CH_2Cl_2/hexane at −18 °C to give white crystals of **1a** (yield: 58.0 mg, 0.132 mmol, 95.7%). IR (CH_2Cl_2, cm^{-1}) 2026s, (νCO); 1934s, (νCO); 1630w, (νC=N). ^{1}H NMR ($CDCl_3$) δ: 5.44 (t, *J* = 2.4 Hz, 2H,C_5H_4); 6.00 (t, *J* = 2.4 Hz, 2H, C_5H_5); 7.09 (m, 2H, C_6H_5); 7.23 (t, *J* = 7.4, 1H, C_6H_5); 7.37 (t, *J* = 7.8, 2H, C_6H_5); 8.07 (s, 1H, C*H*=N). ^{13}C NMR ($CDCl_3$) δ: 84.9 (C_5H_4); 86.0 (C_5H_4); 99.5 (s, C_{ipso}, C_5H_4); 120.6 (s, C_6H_4); 126.3 (s, C_6H_4); 129.2 (s, C_6H_4); 151.0 (s, C_6H_4); 152.1 (*C*H=N); 192.7 (*C*O). Mass spectrum (based on ^{187}Re) *m*/*z* 439 [M$^+$], 411 [M$^+$−CO], 383 [M$^+$−2CO], 355 [M$^+$−3CO]. *Anal.* Calc. for $C_{15}H_{10}O_3NRe$: C, 41.09; H, 2.28. Found: C, 42.02; H, 2.31%.

3.2. (η^5-C_5H_4CH=$NC_6H_4OCH_3$-*p*)$Re(CO)_3$ (**1b**)

To a solution of (η^5-C_5H_4CHO)$Re(CO)_3$ 50.0 mg (0.138 mmol) in toluene (10 mL) was added *p*-anisidine 17.0 mg (0.138 mmol). The mixture was refluxed under nitrogen atmosphere for 5 h. After this time, the solution changed color from yellow to brown. The IR spectrum showed the complete disappearance of the starting complex and three new absorption bands. The solvent was removed under vacuum and a gray oil was obtained. Crystallization from CH_2Cl_2/hexane (1:5) at −18 °C to give off-white microcrystals of **1b** (Yield: 61 mg, 0.130 mmol, 94.4%). IR (CH_2Cl_2, cm^{-1}): 2026s, (νCO), 1932s, (νCO), 1627w, (νC=N). ^{1}H NMR ($CDCl_3$): δ: 3.81 (s, 3H, O*CH*$_3$); 5.42 (t, *J* = 2.4 Hz, 2H, C_5H_4); 5.96 (t, *J* = 2.4 Hz, 2H, C_5H_4); 6.90 (pseudo-dt, 2H, C_6H_4); 7.11 (pseudo-dt, 2H, C_6H_4); 8.08 (s,1H, C*H*=N). ^{13}C NMR ($CDCl_3$): δ: 55.5 (s, OCH_3); 84.8 (C_5H_4); 85.7 (C_5H_4); 100.2 (s, C_5H_4); 114.4 (s, C_6H_4); 122.0 (s, C_6H_4); 143.8 (s, C_6H_4); 150.0 (s, C_6H_4); 158.54 (*C*H=N), 192.86 (*C*O). Mass spectrum (based on ^{187}Re) *m*/*z*: 469 [M$^+$], 441 [M$^+$−CO], 413 [M$^+$−2CO], 385 [M$^+$−3CO]. *Anal.* Calc. for $C_{16}H_{12}O_4NRe$: C, 41.02; H, 2.58. Found: C, 42.13; H, 2.64%.

3.3. (η^5-C_5H_4CH=$NC_6H_4NO_2$-*p*)$Re(CO)_3$ (**1c**)

The synthesis of the complex **1c** was carried out in a similar manner to that described for complex **1b** using (η^5-C_5H_4CHO)$Re(CO)_3$ (50.0 mg, 0.138 mmol) and *p*-nitroaniline (19.0 mg, 0.138 mmol) but refluxing for 48 h using a Dean–Stark apparatus. **1c** was

obtained as white-yellow crystals (Yield: 61, 0.126 mmol, mg, 91.3%). IR (CH_2Cl_2, cm^{-1}) 2028s (νCO), 1936s (νCO), 1625w (νC=N). ^1H NMR ($CDCl_3$) δ: 5.49 (t, J = 2.0 Hz, 2H,C_5H_4), 6.03 (t, J = 2.0 Hz, 2H, C_5H_4), 7.13 (pseudo-dt, 2H, C_6H_4); 8.08 (s, 1H, CH=N); 8.24 (pseudo-dt, 2H, C_6H_4); ^{13}C NMR ($CDCl_3$): δ 85.4 (C_5H_4); 86.8 (C_5H_4); 97.5 (s, C_5H_4); 111.3 (s, C_6H_4); 121.1 (s, C_6H_4); 125.0 (s, C_6H_4); 126.3 (s, C_6H_4); 156.7 (CH=N), 192.86 (CO). Mass spectrum (based on ^{187}Re) m/z: 484 [M^+], 456 [M^+−CO], 428 [M^+−2CO], 400 [M^+−3CO]. *Anal.* Calc. for $C_{15}H_9O_5N_2Re$: C, 37.19; H, 1.86. Found: C, 37.79; H, 1.97%.

3.4. (η^5-$C_5H_4CH_2NHC_6H_5$)Re(CO)$_3$ (**2a**)

Complex **1a** (50.0 mg, 0.114 mmol) was dissolved in anhydrous methanol (10 ml) followed by addition an excess of solid $NaBH_4$ (16.0 mg, 0.423 mmol). The mixture was stirred under nitrogen atmosphere for 2 h. After this time, the IR spectrum showed the complete disappearance of the imine complex **1a**, and the presence of two new absorption bands shifted to low energy (2020, 1924 cm^{-1}). The white solid obtained after evaporation of methanol was chromatographed on a silica gel column; elution with CH_2Cl_2 moved the amine complex. The complex **2a** was isolated quantitatively as white solid, after crystallization from CH_2Cl_2/hexane (1:5) at −18 °C. (Yield: 50.0 mg, 0.114, 100%). IR (CH_2Cl_2, νCO, cm^{-1}): 2024s, 1929s. ^1H NMR ($CDCl_3$) δ: 4.14 (s, 2H, CH_2); 5.28 (t, J = 2.4 Hz, 2H, C_5H_4); 5.43 (t, J = 2.4 Hz, 2H, C_5H_4); 6.66 (d, J = 7.8 Hz, 2H, C_6H_5); 6.78 (d, J = 7.3 Hz, 1H, C_6H_5); 7.22 (pseudo-dt, 2H, C_6H_5). ^1H NMR (C_6D_6) δ: 3.19 (s, broad, 1H, NH); 3.48 (d, J = 6.6 Hz, 2H, CH_2); 4.38 (pseudo- t, 2H, C_5H_4); 4.58 (pseudo-t, 2H, C_5H_4); 6.37 (d, J = 7.7 Hz, 2H, C_6H_5); 6.79 (d, J = 7.3 Hz, 1H, C_6H_5); 7.15 (t, J = 7.7 Hz, 2H, C_6H_5). ^{13}C NMR ($CDCl_3$) δ: 41.4 (s, CH_2); 83.5 (s, C_5H_4); 83.7 (s, C_5H_4); 108.7 (s, C_5H_4); 113.1 (s, C_6H_5); 118.5 (s, C_6H_5); 129.5 (s, C_6H_5); 147.3 (s, C_6H_5); 193.9 (CO). Mass spectrum (based on ^{187}Re) m/z: 441 [M^+]; 413 [M^+−CO]; 385 [M^+−2CO]; 357 [M^+−3CO]; 349 [M^+−NHC_6H_5]. *Anal.* Calc. for $C_{15}H_{12}O_3NRe$: C, 40.81; H, 2.72. Found: C, 40.94; H, 2.86%.

3.5. (η^5-$C_5H_4CH_2NHC_6H_4OCH_3$-p)Re(CO)$_3$ (**2b**)

Complex **2b** was obtained following the same procedure described for **2a**. It was isolated as white crystals. (Yield: 50.0 mg, 0.106 mmol, 100%). IR (CH_2Cl_2, νCO, cm^{-1}): 2022 s, 1926 s. ^1H NMR ($CDCl_3$): δ 3.76 (s, 3H, OCH_3); 4.08 (s, 2H, CH_2); 5.27 (t, J = 2.4 Hz, 2H, C_5H_4); 5.41 (t, J = 2.4 Hz, 2H, C_5H_4); 6.63 (pseudo-dt, 2H, C_6H_4); 6.80 (pseudo-dt, 2H, C_6H_4). ^1H NMR (C_6D_6): δ 2.98 (s, broad, 1H, NH); 3.44 (s, 3H, OCH_3); 3.50 (d, J = 6.6 Hz, 2H, CH_2); 4.35 (t, J = 2.0 Hz, 2H, C_5H_4); 4.66 (t, J = 2.0 Hz, 2H, C_5H_4); 6.36 (pseudo-dt, 2H, C_6H_4); 6.81 (pseudo-dt, 2H, C_6H_4). ^{13}C NMR ($CDCl_3$) δ: 42.5(CH_2); 55.6 (s, OCH_3); 83.5 (s, C_5H_4); 83.6 (s, C_5H_4); 108.8 (s, C_5H_4); 114.7 (s, C_6H_4); 115.5 (s, C_6H_4); 141.3 (s, C_6H_4); 152.9 (s, C_6H_4); 193.94(CO). Mass spectrum (based on ^{187}Re) m/z: 471 [M^+]; 443 [M^+−CO]; 415 [M^+−2CO]; 387 [M^+−3CO]; 349 [M^+−NHC_6H_4-p-OCH_3]. *Anal.* Calc. for $C_{16}H_{14}O_4NRe$: C, 40.85; H, 3.00. Found: C, 40.98; H, 3.05%.

Complex **2b** was obtained following the same procedure described for **2a**. It was isolated as white crystals. (Yield: 50.0 mg, 0.103 mmol, 100%). IR (CH_2Cl_2, νCO, cm^{-1}): 2024 s, 1929 s. ^1H NMR ($CDCl_3$) δ: 4.24 (d, J = 5.9 Hz, 2H, CH_2); 4.54 (pseudo-t, 1H, NH); 5.33 (t, J = 2.4 Hz, 2H, C_5H_4); 5.43 (t, J = 2.4 Hz, 2H, C_5H_4); 6.63 (pseudo-dt, 2H, C_6H_4); 8.13 (pseudo-dt, 2H, C_6H_4). ^1H NMR (C_6D_6) δ: 3.21 (d, J = 6.1 Hz, 2H, CH_2); 3.48 (pseudo-t, 1H, NH); 4.37 (pseudo-t, 2H, C_5H_4); 4.48 (pseudo-t, 2H, C_5H_4); 5.80 (d, J = 9.0 Hz, 2H, C_6H_4); 8.04 (d,J = 9.0 Hz, 2H, C_6H_4). ^{13}C NMR ($CDCl_3$): δ 40.7 (s, CH_2); 83.7 (s, C_5H_4); 84.1 (s, C_5H_4); 106.2 (s, C_5H_4); 111.4 (s, C_6H_4); 126.4 (s, C_6H_4); 139.1 (s, C_6H_4); 152.2 (s, C_6H_4); 193.4 (s, CO). Mass spectrum (based on ^{187}Re) m/z: 486 [M^+]; 458 [M^+−CO]; 430 [M^+−2CO]; 402 [M^+−3CO]; 349 [M^+−NHC_6H_4-p-NO_2]. *Anal.* Calc. for $C_{15}H_{11}O_5N_2Re$: C, 37.04; H, 2.26. Found: C, 37.61; H, 2.37%.

4. Crystal structure determination

A summary of the fundamental crystal and refinement data for **1a** and **1b** are given in Table 1. Crystals of **1b** and **2b** were mounted on a Brucker-Siemens Smart CCD diffractometer equipped with a normal focus, 2.4 kW sealed tube X-ray source (Molybdenum radiation, λ = 0.71073 Å) operating at 50 kV and 20 mA. Data were collected over a hemisphere of the reciprocal space by a combination of three frame sets. The cell parameters were determined and refined by least-squares fit of all reflection collected. Each frame exposure time was of 20 s. covering 0.3° in ω. The crystal to detector distance was 5.08 cm. The first 100 frames were recollected at the end of the data collection to monitor crystal decay. Empirical absorption corrections were made using SADABS program [16]. The structure solution by direct methods, Fourier methods, and full matrix least-square refinement was carried out using SHELXTL [17] minimizing $w(F_o^2 - F_c^2)^2$. Hydrogen atoms have been located y refined isotropically except the hydrogen atoms of the methyl group of the compound **1b**. Weighted R factors (Rw) and all goodness of fit$S$ are based on F^2, conventional R factors (R) are based on F.

Acknowledgements

ABSTRACT

A novel supramolecular assembly $[\{Cu(enac)\}_2Cr(NCS)_4(NH_3)_2][Cr(NCS)_4(NH_3)_2]_3 \cdot 4(CH_3)_2CO$ (enac = 4,6,6-trimethyl-3,7-diazanon-3-ene-1,9-diamine), the first example of a Cu/Cr heterometallic compound containing a Schiff-base ligand such as enac, and an anion of Reineckes salt, $Cr(NCS)_4(NH_3)_2^-$, as a building block, was obtained by the self-assembly reaction of copper powder and Reineckes salt in an acetone/methanol (1:4) solution of ethylenediamine in the open air. An X-ray study shows that the complex includes a trinuclear Cu_2Cr cation, constructed from two $Cu(enac)^{2+}$ moieties and a *trans*-$[Cr(NCS)_4(NH_3)_2]^-$ block as a two-linking bridging ligand. The metal–metal separations within the cation are Cu···Cr = 6.393(31) Å and Cu···Cu = 12.786(63) Å. The supramolecular architecture of the complex involves two types of H-bonded chains, the first chain is generated by trinuclear cations $[\{Cu(enac)\}_2Cr(NCS)_4(NH_3)_2]^{2+}$, $[Cr(NCS)_4(NH_3)_2]^-$ anions and $(CH_3)_2CO$ molecules, while the second by crystallographically different anions of Reineckes salt and $(CH_3)_2CO$. Variable-temperature (1.8–300 K) magnetic susceptibilities show a slight change of the μ_B value at low temperature, indicative of weak antiferromagnetic interactions ($J_{CuCr} = -0.9\ cm^{-1}$) between the paramagnetic centers.

1. Introduction

The design of heterometallic complexes with macrocyclic and open-chain ligands, as well as the elaboration of synthetic procedures is of current importance owing to the role which such systems play in biochemical processes, material science, catalysis, etc. [1]. One of the appealing approaches for the synthesis of coordination compounds with Schiff-base ligands is the method discovered by N.F. Curtis, which is based on the reaction of the metal complexes containing a primary amine group with aliphatic carbonyl compounds [2]. As a result, a large number of homometallic complexes with such Schiff-base ligands have been described [3–6], but the number of examples of heterometallic compounds with such ligands is still limited [7–12]. It is obvious that the simultaneous presence of two dissimilar metal centers could lead to fascinating architectures and intriguing properties, such as magnetic, catalytic, electrochemical or optical [13–16]. A popular and successful two-step approach for the preparation of heterometallic systems is the metalloligand strategy, based on the interaction between the preformed complex with free chelating sites, used as the ligand, and a complex with labile ligands playing the role of the metal [17].

It was proved that an efficient route to the preparation of novel heterometallic complexes, which eliminates the separate step of building block construction, is the direct synthesis of coordination compounds. The method is based on the self-assembly of building blocks generated *in situ* from a zerovalent metal ($M^0_{(A)}$) and an oxide or salt of the second metal ($M_{(B)}O$ or $M_{(B)}X_2$) in the same reaction vessel (L = amine or amino alcohol; Solv = non-aqueous solvent) [18–23]:

$$M^0_{(A)} - M_{(B)}O/M_{(B)}X_2 - L - NH_4X - Solv \qquad \text{(Strategy 1)}$$

Previously, it has been reported that the combination of the Curtis template reaction with the direct synthesis approach opens up new possibilities in generating heterometallic complexes with open-chain Schiff-base ligands [7–9]:

$$M^0_{(A)} - M^0_{(B)}/M_{(B)}O - L/L \cdot 2HX - NH_4X - (CH_3)_2CO - Solv \qquad \text{(Strategy 2)}$$

In the present article, we propose to combine the second strategy with the metalloligand approach and to use Reineckes salt as the source of the second metal:

$$Cu^0 - NH_4[Cr(NCS)_4(NH_3)_2]\text{-en-}(CH_3)_2CO - Solv$$

doi:10.1016/j.poly.2008.04.032

The ability of the Cu(II) ion to exhibit different preferences in geometry and coordination number, as well as the ability of the $[Cr(NCS)_4(NH_3)_2]^-$ anion to reveal a bridging function and participate in hydrogen-bonding could lead to structural diversity and more complicated physico-chemical properties of the formed heterometallic complexes. According to the Cambridge Structural Database [24,25], examples of thiocyanato-bridged Cu(II)/Cr(III) compounds are quite limited and only one Cu(II)/Cr(III) complex based on the anion of Reineckes salt has been crystallographically characterized to date [26].

Herein, we report the synthesis, crystal structure, spectroscopic and magnetic properties of the novel complex $[\{Cu(enac)\}_2Cr(NCS)_4(NH_3)_2][Cr(NCS)_4(NH_3)_2]_3 \cdot 4(CH_3)_2CO$, which, to the best of our knowledge, represents the first example of a Cu/Cr heterometallic compound based on the anion of Reineckes salt, $Cr(NCS)_4(NH_3)_2^-$, and contains the Schiff-base ligand enac (4,6,6-trimethyl-1,9-diamino-3,7-diazanon-3-ene), in the $Cu(enac)^{2+}$ moiety.

2. Experimental

2.1. General

All chemicals were of reagent grade and were used as received. All experiments were carried out in air. Elemental analyses were performed by atomic absorption spectroscopy for copper and spectrophotometrically for chromium (as the chromate at $\lambda = 370$ nm) in the Department of Chemistry, National Taras Shevchenko University of Kyiv and with a vario EL III Universal CHNOS Elemental Analyzer (for C, H, N, S) in the Faculty of Chemistry, University of Wroclaw.

2.2. Synthesis of $[\{Cu(enac)\}_2Cr(NCS)_4(NH_3)_2][Cr(NCS)_4(NH_3)_2]_3 \cdot 4(CH_3)_2CO$

Copper powder (0.08 g, 1.26 mmol), $NH_4[Cr(NCS)_4(NH_3)_2] \cdot H_2O$ (0.89 g, 2.51 mmol), CH_3OH (20 ml), acetone (5 ml) and ethylenediamine (0.17 ml, 2.54 mmol) were heated to 50–60 °C and magnetically stirred until total dissolution of the copper was observed (10 min). The resulting solution was slowly evaporated at room temperature until dark-violet crystals suitable for crystallographic study were formed. The crystals were filtered off and dried in vacuo at room temperature. Yield: 0.90 g, 70%. *Anal.* Calc. for $C_{48}H_{96}N_{32}S_{16}O_4Cr_4Cu_2$ ($M_r = 2033.79$): C, 28.35; H, 4.76; N, 22.04; S, 25.23; Cr, 10.23; Cu, 6.25. Found: C, 28.0; H, 4.5; N, 22.3; S, 25.0; Cr, 10.6; Cu, 6.3%. IR (KBr, cm^{-1}): 3315(w), 3240(w), 3170(w), 2970(w), 2100(vs), 1685(s), 1655(s), 1610(s), 1460(m), 1420(m), 1360(m), 1310(w), 1260(s), 1230(m), 1200(w), 1110(m), 1060(m), 1040(w), 985(w), 830(w). The compound is soluble in CH_3CN, dmso and dmf.

2.3. Physical measurements

Infrared spectra were recorded as KBr discs on a UR-10 spectrophotometer in the 4000–400 cm^{-1} region using conventional techniques. UV/Vis spectra were recorded on a Perkin–Elmer Lambda 900 spectrophotometer using the diffuse-reflectance technique. The EPR spectra were recorded on a Bruker ESP 300E (Bruker, Germany) spectrometer operating at X-band and equipped with a Bruker NMR gaussmeter ER 035M and a Hewlett–Packard microwave frequency counter HP 5350B. Magnetic susceptibility data of a powdered sample were measured with a SQUID magnetometer (Quantum Design MPMSXL-5) over the temperature range 1.8–300 K at the magnetic induction of 0.5 T. The corrections for diamagnetism of the constituent atoms were calculated from Pascal's constants [27].

2.4. X-ray structure determination

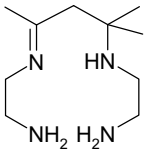
$C_{48}H_{96}N_{32}S_{16}O_4Cr_4Cu_2$ (formula weight = 2033.79), 200 K, triclinic, $P\bar{1}$, $a = 11.7882(6)$, $b = 12.3534(5)$, $c = 16.4188(8)$ Å, $\alpha = 77.791(9)°$, $\beta = 83.418(9)°$, $\gamma = 80.610(9)°$, $V = 2297.6(2)$ Å^3, $Z = 1$, $D_{calc} = 1.470$ g/cm^3, 10557 reflections measured ($\Theta_{max} = 29.40$), 9269 unique ($R_{int} = 0.0252$) and of these 3871 had $F > 4\sigma(F)$ and were considered to be observed.

Data were collected on a Rigaku AFC7 diffractometer equipped with a Mercury CCD area detector using graphite monochromated Mo Kα radiation at 200 K. The data were corrected for Lorentz and polarization effects. A multi-scan absorption correction was applied to all data sets. The structure was solved by direct methods using the SIR-92 [28] program implemented in the program package TEXSAN [29] and refined with SHELX-97 [30] software (program packages TEXSAN and WINGX) [31]. Positions of the hydrogen atoms were located from the difference map of electron density and refined by the "riding" model with $U_{iso} = nU_{eq}$ of the non-hydrogen atom bonded to the H atom ($n = 1.5$ for methyl and 1.2 for other H atoms). Full-matrix least-squared refinement against F^2 in anisotropic approximation for non-hydrogen atoms (total 484 parameters) was converged to $R_1 = 0.0868$ ($wR_2 = 0.2383$, $S = 1.071$).

3. Results and discussion

3.1. Synthesis and spectroscopic characterization

The reaction of copper powder and Reineckes salt in an acetone/CH_3OH (1:4) solution of ethylenediamine, using a molar ratio of $Cu:NH_4[Cr(NCS)_4(NH_3)_2]:en$ of 1:2:2, gave a heterometallic compound with an open-chain aliphatic Schiff-base ligand (enac).



enac

The interaction proceeds in the following way:

$$2Cu^0 + 4NH_4[Cr(NCS)_4(NH_3)_2] + 4en + 8(CH_3)_2CO + O_2 \rightarrow [\{Cu(enac)\}_2Cr(NCS)_4(NH_3)_2][Cr(NCS)_4(NH_3)_2]_3 \cdot 4(CH_3)_2CO + 4NH_3 + 6H_2O$$

Noticeably, the compound could be also obtained using a molar ratio of $Cu:NH_4[Cr(NCS)_4(NH_3)_2]:en$ of 4:1:8 in the presence of ammonium thiocyanate, but in this case the homometallic complex $Cu(enac)(NCS)_2$ was formed as a byproduct.

The IR spectrum of the compound confirmed that the enac ligand is present. Its characteristic peaks at 3315 and 3240, 3170, 2970, 1685, 1610, 1060 and 985 cm^{-1}, can be easily identified as $\nu(NH_2)$, $\nu(N–H)$, $\nu(C–H)$, $\nu(C{=}N)$, $\delta(NH_2)$, $\nu(C–N)$ and $\nu(C–C)$, respectively. The presence of acetone molecules is supported by a strong $\nu(C{=}O)$ absorption peak at 1655 cm^{-1}, corresponding to the carbonyl groups involved in hydrogen bonding [32]. The intense absorption bands in the spectrum attributed to $\nu(C{\equiv}N)$ suggest the presence of bridging (2150 cm^{-1}) and terminal N-bonded thiocyanate groups (2090 cm^{-1}); the latter groups can be also recognized by the weak band at 840 cm^{-1} corresponding to the $\nu(CS)$ vibration.

The solid-state diffuse reflectance spectrum shows a broad band with a maximum at 515 nm, which probably results from overlap-

ping of d–d transitions for the octahedrally distorted Cu(II) and Cr(III) complexes [33]. Moreover, the spectrum displays a ligand-to-metal charge transfer transition at ca. 300 nm.

3.2. Description of the structure

The structure of the compound consists of a trinuclear cation $[\{Cu(enac)\}_2Cr(NCS)_4(NH_3)_2]^{3+}$, uncoordinated $[Cr(NCS)_4(NH_3)_2]^-$ anions of the Reineckes salt and acetone molecules. The Cu_2Cr cation (Fig. 1) is composed of two $Cu(enac)^{2+}$ moieties linked by a *trans*-$[Cr(NCS)_4(NH_3)_2]^-$ anion. The copper(II) center is included in a distorted square pyramidal CuN_4S chromophore. The equatorial Cu(II) positions are occupied by four nitrogen atoms of the enac ligand, with Cu–N distances in the range 1.978(11)–2.019(10) Å, with slightly shorter bond lengths to the imine nitrogen than to the secondary amine nitrogen (Table 1), which is usually observed for complexes with similar ligands [34,6]. The axial Cu–S distance has a value of 2.808(13) Å, which is close to those found in other copper(II) complexes with the sulfur atom at the apical position [35–40], indicating a *semi*-coordination character of this bond. The compound contains four crystallographically independent chromium(III) atoms. All of them are located in a distorted octahedral environment with a N_6 donor set, formed by two NH_3 molecules at the axial positions and four NCS groups in the equatorial plane. The Cr–N_{NCS} bond lengths lie within a short range [1.981(11)–2.006(11) Å], with no difference between the terminal and bridging character of the NCS groups. The terminal thiocyanate groups are almost linear [with N–C–S angles ranging from 176.7(8)° to 179.7(8)°], but the bridging NCS group shows a slight distortion from linearity, with a N–C–S angle of 175.9(8)°. The last one connects the Cu(1) and Cr(2) atoms into a trinuclear cation with a Cu(1)···Cr(2) separation of 6.39(3) Å, Cu(1)–S(4)–C(13) angle of 110.6(3)° and Cr(2)–N(6)–C(13) angle of 170.8(7)°. The Cu and Cr atom arrangement in the cation is almost linear with a Cu(1)–Cr(2)–Cu(1) angle of 179.99(1)°.

The structure is assisted by N–H···O hydrogen bonds between hydrogen atoms of the NH_3 molecules of the anions of Reineckes salt and oxygen atoms of acetone molecules (Table 2), which results in the formation of two types of supramolecular chain. The first type is generated by trinuclear $[\{Cu(enac)\}_2Cr(2)(NCS)_4(NH_3)_2]^{3+}$ cations, $[Cr(4)(NCS)_4(NH_3)_2]^-$ anions and acetone molecules (Fig. 2a), and the second one is formed by the crystallographically different anions $[Cr(1)(NCS)_4(NH_3)_2]^-$ and $[Cr(3)(NCS)_4(NH_3)_2]^-$, and acetone molecules. It is noteworthy that the weak S···S interactions of 3.693(14) Å link the second type chains into a supramolecular sheet (Fig. 2b). Finally, the structure of the complex can be best described as supramolecular assembly, where different types of H-bonded chains are arranged alternately (Fig. 3).

3.3. EPR and magnetic properties

The EPR spectra at 295 and 77 K of a polycrystalline sample of the compound exhibit an almost isotropic and very broad line

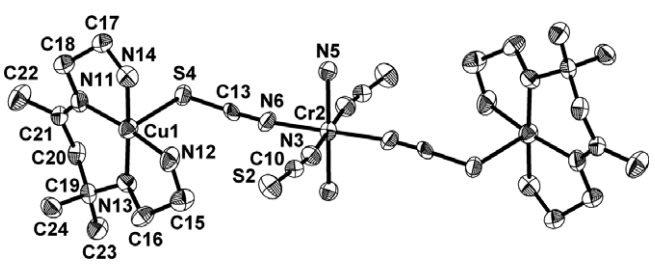


Fig. 1. A view of the trinuclear Cu_2Cr cation with the atom numbering scheme. Atom displacement ellipsoids are shown at the 50% probability level. The hydrogen atoms are omitted for clarity.

N(9)–H(37)···O(26)	0.887(8)	2.303(11)	3.099(15)	149.2(5)

Symmetry codes: (iv) ⟨1 − *x*, 1 − *y*, 1 − *z*⟩; (vii) ⟨*x*, 1 + *y*, −1 + *z*⟩; (x) ⟨1 + *x*, *y*, *z*⟩.

around $g = 2$, which seems to be caused by resonance transitions between the electronic levels split by a small zero-field splitting parameter D (according to the Spin Hamiltonian due to at least $S = 3/2$). It suggests a rather high symmetry of the Cr(III) coordination. The lack of anisotropy and a g value of about 2 indicates that the EPR signal due to the Cu(II) center is overlapped by the spectrum of the Cr(III) center.

The results of magnetic susceptibility measurements are plotted as the effective magnetic moment (μ_{eff}) versus temperature in Fig. 4. The complex shows a room-temperature magnetic moment of 8.02 μ_B, which is very close to the calculated value of 8.01 μ_B for the non-interaction of two Cu(II) and four Cr(III) ions, where the constituent metals have typical μ_{eff} values of 1.8 and 3.8 μ_B, respectively. The good linear dependence of the reciprocal magnetic susceptibility in the whole temperature range gives the Curie–Weiss constants $\Theta = -2.03$ K and $C = 8.10$ $cm^3mol^{-1}K^{-1}$, which point to a weak antiferromagnetic behavior (Fig. 4, inset).

According to the crystal structure investigations, the compound contains a trinuclear CuCrCu cation and three isolated Reineckes anions per molar unit. Thus, the molar magnetic susceptibility can be described as follows:

$$\chi = \chi^c + 3\chi^a,$$

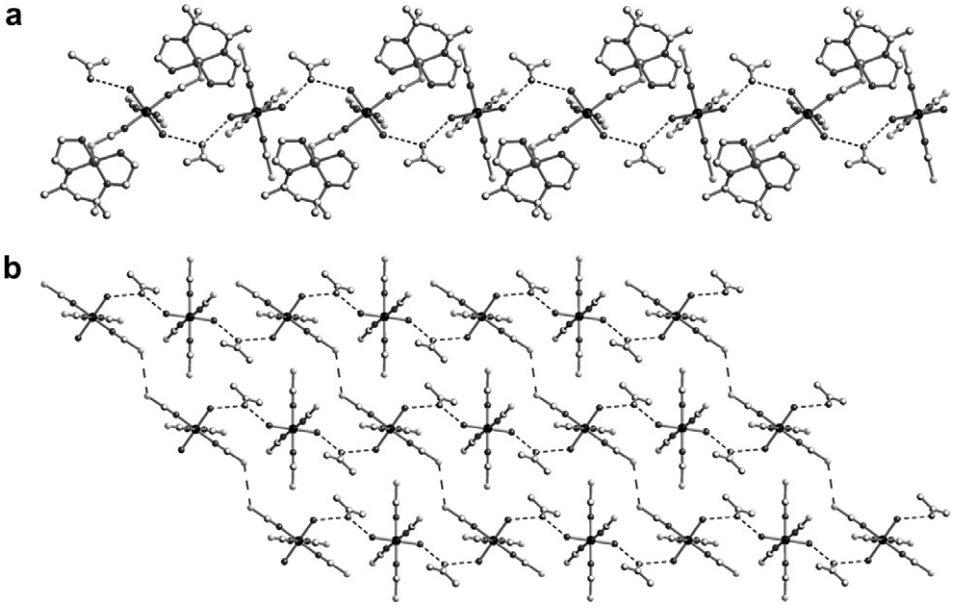

Fig. 2. Fragments of the supramolecular chain (a) and sheet (b) in the structure. The hydrogen atoms are omitted for clarity.

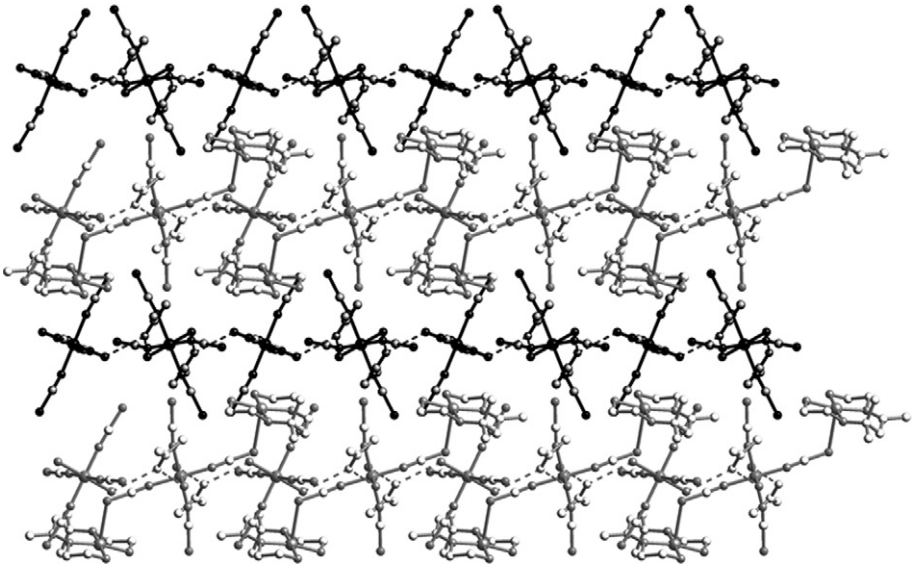

Fig. 3. Packing diagram of the complex projected onto the *ac* plane showing the alternating arrangement of two types of H-bonded chains. The hydrogen atoms are omitted for clarity.

where χ^c is the magnetic susceptibility of the trinuclear cation $[\{Cu(enac)\}_2Cr(NCS)_4(NH_3)_2]^{3+}$ and χ^a is the magnetic susceptibility of the $[Cr(NCS)_4(NH_3)_2]^-$ anion. Considering the exchange interaction between the Cu(II) ions to be very small due to the large Cu···Cu separation of 12.786(63) Å, its contribution may be neglected and the molar magnetic susceptibility of the trinuclear cation can be described by the spin-Hamiltonian $H = -2JS_{Cr}(S_{Cu1} + S_{Cu2})$ [41–43]:

$$\chi^c = \frac{Ng^2_{CuCrCu}\beta^2}{k(T-\Theta)} \times \frac{A}{B},$$
$$A = 35 + 10\exp(-5X) + \exp(-8X) + 10\exp(-3X), \quad (1)$$
$$B = 3 + 2\exp(-5X) + \exp(-8X) + 2\exp(-3X),$$

where $X = J/kT$ and all other symbols have their usual meaning. The χ^a term was evaluated for a Cr(III) ion in a tetragonally distorted octahedral environment with g_{Cr} and D variables [44]. The best fit of the experimental data was obtained with $J = -0.9\ cm^{-1}$, $\Theta = -2.9$ K, $g_{Cr} = 1.94$, $|D| = 4.4\ cm^{-1}$ and $R = 1.6 \times 10^{-4}$, where R is the agreement factor defined as $\sum[(\chi T)_{obs} - (\chi T)_{calcd}]^2 / \sum[(\chi T)_{obs}]^2$. The g_{CuCrCu} value was fixed at the 2.05 level. The zero-field splitting value (D) is somewhat greater than expected for an almost regular octahedral coordination geometry of Cr(III) in a Reineckes anion (less than $1\ cm^{-1}$ [45–47]). The likely reason for this is that the long-range interaction between the copper and chromium cations in the lattice is not completely negligible. However, implementation of the mean field model [44] did not improve the results. Also, if one considers the different ligand field strength of the NCS^- and NH_3 ligands, the environment of the Cr(III) anion could be described as tetragonally distorted. This is partially confirmed by a recent magnetic investigation of $[Cu(en)_2Cr(NCS)_4(NH_3)_2](OAc)$ (with a ligand

field strength and symmetry in the cation close to that reported here), which revealed a $|D|$ value of 1.9 cm^{-1} [48].

4. Conclusion

The presented work describes the synthesis of the first Cu(II)/Cr(III) complex with an open-chain Schiff-base ligand, enac, using a one-step self-assembly process from copper powder and Reinecke's salt in an acetone/methanol solution of ethylenediamine in the open air. The structure of the compound is assisted by N–H···O hydrogen bonds that link together trinuclear Cu_2Cr cations, anions of Reinecke's salt and uncoordinated $(CH_3)_2CO$ molecules forming two types of H-bonded chains. Variable-temperature magnetic susceptibility measurements show a very weak antiferromagnetic interaction between the paramagnetic centers. It is clear that such an approach is an effective and easy pathway for the synthesis of various heterometallic assemblies with open-chain Schiff-base ligands, and further investigations are underway.

ABSTRACT

Magnesium porphyrazinate substituted with eight 4-biphenyl groups on the periphery positions has been synthesized for the first time from cyclotetramerization of 1,2-bis(4-biphenyl)maleonitrile in the presence of magnesium butanolate. Its demetalation by treatment with trifluoroacetic acid, resulted in a partially oxidized product, namely, octakis(4-biphenyl)-2-*seco*-porphyrazine-2,3-dione. Further reaction of this product with copper(II) acetate, zinc(II) acetate and cobalt(II) acetate has led to the metallo derivatives, [octakis(4-biphenyl)-2-*seco*-2,3-dioxoporphyrazinato] M(II) (M = Cu, Zn, Co). These novel compounds have been characterized by elemental analysis, together with FT-IR, ^{1}H NMR, UV–Vis and mass spectral data.

1. Introduction

Peripherally functionalized porphyrazines (tetraazaporphyrins) and related macrocycles, modified by the attachment of peripheral substituents, have found wide applications in many areas such as chemical sensor, optic data collection, catalysis, electron transfer, liquid crystal, electrophotography, laser technology, photodynamic therapy of tumors, pigments as well as and dyes in advanced materials [1–5]. In contrast, the structurally related porphyrazines have been less well studied. However, due to the easy and multi- purpose synthetic route for the preparation of porphyrazines, namely the metal-templated cyclization of the maleonitrile precursors, these macrocyclic compounds are now subject to enhanced interest [6–10]. The porphyrazine macrocycles afford a skilful platform to build up detailed molecular superstructures and this property coupled with a full and well-improved synthetic chemistry has surpassed to the synthesis of different catalytically essential metallo porphyrazines and original model compounds of various functions [11,12].

For many years, aromatic compounds based on biphenyls were overemphasized as the most important core unit for liquid crystals, partly because of their easier synthesis and partly because the link between highly polarizable π-electron systems and mesogenity.

During the last two decades, we have been deeply interested in the preparation of novel porphyrazine and phthalocyanine derivatives. Among these are phthalocyanines which are fused to, or attached through bridges to macrocyclic structures [13] and porphyrazines with peripheral functional groups such as quaternizable amino groups [14], crown ethers [15], ferrocenes [16], triphenylphosphine [17], 4-*tert*-buthylphenylthio [18] and tosylaminoethylthio [19] can be cited.

Recently, we have synthesized porphyrazines with bulky electron rich substituents such as 1-naphthylmethylthio, 9-anthracenylmethylthio units [20,21]. We have also synthesized novel *seco*-porphyrazines substituted with 1-naphthyl, *p*-tolyl, *o*-tolyl groups on the peripheral positions [22,23] as encountered by Barrett, Hoffman and coworkers, with peripheral amino derivatives [24].

In this study, we report novel soluble porphyrazines with eight 4-biphenyl substituents appending to the periphery positions. Magnesium porphyrazinate substituted with eight 4-biphenyl groups on the periphery positions has been synthesized for the first time from the cyclotetramerization of 1,2-bis(4-biphenyl)maleonitrile in the presence of magnesium butanolate. Its demetalation by treatment with trifluoroacetic acid, resulted in a partially oxidized product, namely, octakis(4-biphenyl)-2-*seco*-porphyrazine-2,3-dione. Further reaction of this product with copper(II) acetate, zinc(II) acetate and cobalt(II) acetate has led to the metallo derivatives, [octakis(4-biphenyl)-2-*seco*-2,3-dioxoporphyrazinato] M(II) (M = Cu, Zn, Co). These novel compounds have been characterized by elemental analysis, together with FT-IR, ^{1}H NMR, UV–Vis and mass spectral data.

2. Experimental

IR spectra were recorded on a Perkin–Elmer Spectrum One FT-IR (ATR sampling accessory) spectrophotometer, electronic spectra on a Unicam UV2 spectrophotometer. Elemental analyses were recorded on a Thermo Finnigan Flash EA 1112 instrument at the Instrumental Analysis Laboratory of TUBITAK Marmara Research Center. Proton NMR spectra were recorded on a Varian INOVA 500 MHz spectrometer using TMS and d-chloroform as the reference and solvent, respectively. Mass spectra were recorded on a Bruker Daltonics MicrOTOF LC–MS using the electrospray ionisation (ESI) method. The instrument was operated in positive ion mode. All starting materials were purchased from major suppliers and used without any further purification. The homogeneity of the products was tested in each step by TLC.

(4-Biphenyl)acetonitrile (**1**) was prepared according to the previously reported procedure [25].

2.1. Synthesis of 1,2-bis(4-biphenyl)maleonitrile (*2*)

A slurry of 4-biphenylacetonitrile (1.0 g, 5.2 mmol) and iodine (1.313 g, 5.200 mmol) in 1:1 Et_2O–MeOH (20 ml) was allowed to reflux under nitrogen for 1 h. The solution was cooled to room temperature, and sodium methoxide (2.2 equiv., 2.0 M, 5.7 ml) in methanol was added drop by drop (over a period of 30 min) into the reaction medium under a nitrogen atmosphere. The reaction mixture was stirred for another 3 h. During this time, more and more precipitation was formed in the solution. The solution was filtered at room temperature and the solid product was washed with water. The product was yellow colored and was very soluble in chloroform, dichloromethane and acetone, but insoluble in *n*-hexane. Yield was 0.316 g (32%). FT-IR, $\nu_{max}/(cm^{-1})$: 3070–3030 (CH, aromatic), 2218 (C≡N), 1604 (C=C, aromatic), 1486, 1405, 1209, 1140, 1005, 845, 766, 724, 691. ^{1}H NMR (d-chloroform 500 MHz): δ, ppm 7.99–7.93 (m, 4H, Ar-H), 7.80–7.75 (m, 4H, Ar-H), 7.68–7.26 (m, 10H, Ar-H). MS (ESI): (*m*/*z*): 382.2 $[M]^+$.

2.2. [2,3,7,8,12,13,17,18-Octakis(4-biphenyl)porphyrazinato]Mg(II) (*3a*)

Mg turnings (24.3 mg, 1.00 mmol) and a small I_2 crystal were refluxed in *n*-BuOH (20 ml) for about 8 h to obtain $Mg(BuO)_2$. 1,2-Bis(4-biphenyl)maleonitrile (**2**) (765 mg, 2.00 mmol) was added to this solution and the mixture was refluxed for about 8 h. The dark green product was filtered, washed with ethanol and water and dried in a vacuum. The crude product was dissolved in $CHCl_3$ and filtered. The $CHCl_3$ solution was dried over anhydrous Na_2SO_4. When the solvent was evaporated, a dark green product was obtained. Finally, pure porphyrazine was obtained by chromatography on silica gel using methanol/chloroform (1:50) mixture as eluent. The product was soluble in chloroform, dichloromethane, acetone and toluene, but insoluble in *n*-hexane. Yield: 326 mg (42%). FT-IR, $\nu_{max}/(cm^{-1})$: 3075–3025 (CH, aromatic), 1602 (C=C, aromatic), 1484, 1404, 1208, 1139, 1004, 843, 763, 722, 689. ^{1}H NMR (d-chloroform 500 MHz): δ, ppm 7.97–7.75 (m, 4H, Ar-H), 7.67–7.26 (m, 5H, Ar-H). MS (ESI): (*m*/*z*): 1554.7 $[M]^+$.

2.3. [2,3,7,8,12,13,17,18-Octakis(4-biphenyl)-2-seco-porphyrazine-2,3-dione] (*3b*)

Compound **3a** (155 mg, 0.100 mmol) was dissolved in the minimum amount of trifluoroacetic acid (~4 ml) and stirred for 5 h at room temperature. When the reaction mixture was added to ice drop by drop and neutralized with 25% ammonia solution, precipitation occurred and it was filtered. The precipitate was extracted into the chloroform and the chloroform solution was extracted with water twice. After drying over anhydrous Na_2SO_4, the solvent was evaporated to obtain the green colored metal-free porphyrazine. The crude product was purified by chromatography on silica gel using methanol/chloroform (1:50) mixture as the eluent. Yield: 100 mg (64%). FT-IR, $\nu_{max}/(cm^{-1})$: 3339 (N–H), 3072–3035 (CH, aromatic), 1721 (C=O), 1615 (C=C, aromatic), 1475, 1400, 1212, 1128, 1012, 838, 765, 718, 680. ^{1}H NMR (d-chloroform 500 MHz): 7.91–7.70 (m, 4H, Ar-H), 7.61–7.22 (m, 5H, Ar-H), −0.95 (br s, 2H, NH). MS (ESI): (*m*/*z*): 1563.2 $[M]^+$.

2.4. General procedure for metallo seco-porphyrazines (*3c–3e*)

Compound **3b** (156 mg, 0.100 mmol) in $CHCl_3$(10 ml) was stirred with the metal salt [$Cu(OAc)_2$(182 mg, 1.00 mmol), $Zn(OAc)_2$ (183 mg, 1.00 mmol) or $Co(OAc)_2$ (177 mg, 1.00 mmol)] in ethanol (15 ml) and refluxed under nitrogen for about 4 h. Then, the precipitate composed of the crude product and the excess metal salt were filtered. The precipitate was treated with $CHCl_3$ and the insoluble metal salts were removed by filtration. The filtrate was reduced to the minimum volume under reduced pressure and then added into *n*-hexane (100 ml) drop by drop to realize the precipitation. Finally, pure porphyrazine derivatives were obtained by chromatography on silica gel using methanol/chloroform (1:20) mixture as the eluent.

2.4.1. [2,3,7,8,12,13,17,18-Octakis(4-biphenyl)-2-seco-2,3-dioxoporphyrazinato] Cu(II) (*3c*)

Yield: 72 mg (44%). FT-IR, $\nu_{max}/(cm^{-1})$: 3075–3030 (CH, aromatic), 1718 (C=O), 1622 (C=C, aromatic), 1445, 1410, 1215, 1133, 1018, 868, 753, 715, 688. MS (ESI): (*m*/*z*): 1625.8 $[M]^+$.

2.4.2. [2,3,7,8,12,13,17,18-Octakis(4-biphenyl)-2-seco-2,3-dioxoporphyrazinato] Zn(II) (*3d*)

Yield: 78 mg (48%). FT-IR, $\nu_{max}/(cm^{-1})$: 3055–3025 (CH, aromatic), 1722 (C=O), 1652 (C=C, aromatic), 1440, 1248, 1118, 1023, 848, 752, 724, 685. ^{1}H NMR (d-chloroform 500 MHz): 7.92–7.81 (m, 4H, aromatic H), 7.65–7.24 (m, 5H, Ar-H). MS (ESI): (*m*/*z*): 1627.6 $[M]^+$.

2.4.3. [2,3,7,8,12,13,17,18-Octakis(4-biphenyl)-2-seco-2,3-dioxoporphyrazinato] Co(II) (*3e*)

Yield: 62 mg (38%). FT-IR, $\nu_{max}/(cm^{-1})$: 3065–3020 (CH, aromatic), 1723 (C=O), 1625 (C=C, aromatic), 1476, 1408, 1215, 1146, 1009, 879, 758, 725, 684. MS (ESI): (*m*/*z*): 1620.3 $[M]^+$.

3. Results and discussion

The starting point for these novel porphyrazine structures with eight 4-biphenyl groups bound to the periphery is 1,2-bis(4-biphenyl)maleonitrile (**2**) which was obtained from (4-biphenyl)acetonitrile (**1**) and I_2. The yellow colored product (**2**) was obtained in yield 32%. The conversion of **2** into **3a** was achieved by the template effect of magnesium butanolate (Scheme 1). The cyclotetramerization gave the dark green colored **3a** (Fig. 1) in yield 42%. It

Fig. 2. [2,3,7,8,12,13,17,18-octakis(4-biphenyl)-2-*seco*-porphyrazine-2,3-dione] and metal derivatives {M=2H, Cu(II), Zn(II) or Co(II)}.

was soluble in chloroform, dichloromethane, acetone and toluene, but insoluble in apolar hydrocarbon solvents such as *n*-hexane.

In the conversion of **3a** into **3b** (Fig. 2) by treatment with relatively strong acids (e.g. trifluoroacetic acid), a *seco*-porphyrazine type macrocycle in which one of the four pyrrole rings has been oxidized has been the main product. Sterical tension due to the presence of eight bulky 4-biphenyl units around the core might be the main reason for the cleavage of one of the pyrrol rings. 4-biphenyl units are not comparable with dimethylamino groups [24,26,27], but are comparable with naphthyl groups as electron donors to the 18-π electron system of the inner core [26]. In the present case, the tendency of 4-biphenyl substituted porphyrazine to oxidize to the *seco*-porphyrazine derivative should be higher than dimethylamino substituted ones because the reactions were carried under inert atmospheres during these experiments, but still no product corresponding to the metal-free derivative of **3a** could be isolated. The mass spectral results have clearly indicated the change of the structure from magnesium porphyrazinate (**3a**) to the demetalated *seco*-porphyrazine (**3b**) (Figs. 3 and 4). In addition to the mass spectral results, the intense C=O absorption peak clearly differentiates oxidized products from the symmetrically octakis(4-biphenyl) substituted magnesium porphyrazinate. The metalation reactions of the demetalated *seco*-porpyrazine (**3b**) with metal salts gave the metalated species (**3c**–**e**) (Scheme 1).

All new compounds were identified through several spectroscopic techniques such as ^{1}H NMR, FT-IR, UV–Vis, mass and elemental analysis. The spectroscopic data of desired products were in accordance with the assigned structures.

Elemental analyses correspond closely with the values calculated for (**2**, **3a**–**e**) (Table 1).

In the FT-IR spectrum of **2**, the stretching vibration of C≡N peak is observed at 2218 cm^{-1}, the aromatic C–H peaks are around 3030–3070 cm^{-1} and the aromatic C=C peak is at 1604 cm^{-1}. These values comply with those reported in the literature for similar compounds [20–23]. After the conversion of dinitrile derivative (**2**) to porphyrazine (**3a**), the sharp C≡N vibration around 2218 cm^{-1} disappeared. The N–H stretching absorption of the inner core of the metal-free porphyrazine (**3b**) was observed around 3339 cm^{-1}. Furthermore, during acid-mediated demetalation of the magnesium porphyrazine (**3a**), peripheral oxidation of one pyrrole ring was confirmed with an intense absorption around 1718–1723 cm^{-1} [24,27]. The FT-IR spectra of all porphyrazines derivatives (**3a**–**e**) showed that the aromatic C–H peaks are around 3020–3075 cm^{-1} [18,20–23], indicating the presence of 4-biphenyl substituents as well as the *seco*-porphyrazine derivatives.

The N–H protons of the metal-free porphyrazine (**3b**) were also identified in the ^{1}H NMR spectra with the broad peak at $\delta = -0.95$ ppm, presenting the typical shielding of inner core protons, which is a common feature of the ^{1}H NMR spectra of metal-free porphyrazines [15,16,20,27]. In the ^{1}H NMR spectra of diamagnetic

Table 2
UV–Vis data for the porphyrazines in chloroform

Compound	λ/nm (log ε/dm^3 mol^{-1} cm^{-1})		
3a	380 (4.86)	652 (4.64)	
3b	368 (4.77)	650 (4.41)	712 (4.49)
3c	348 (4.82)	658 (4.58)	
3d	356 (4.80)	654 (4.60)	
3e	352 (4.84)	656 (4.56)	

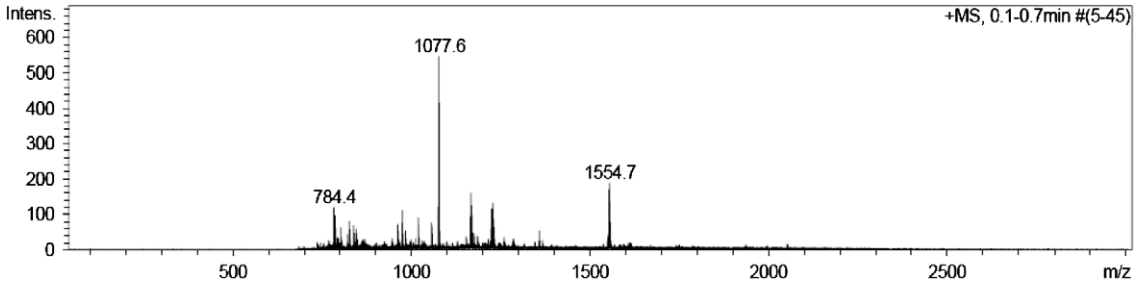

Fig. 3. Mass spectrum of **3a**.

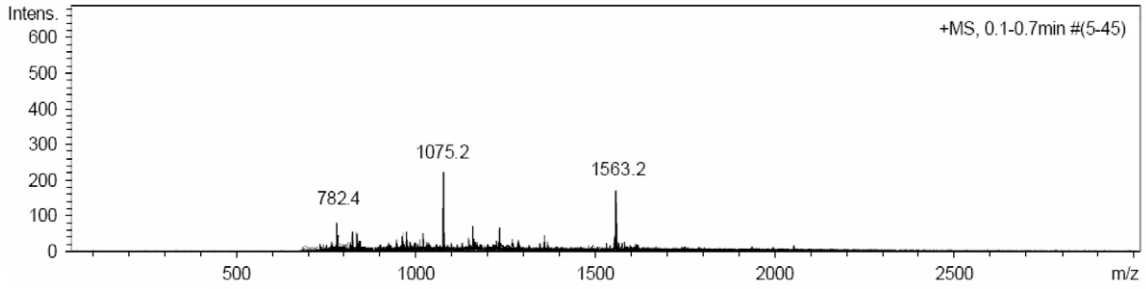

Fig. 4. Mass spectrum of **3b**.

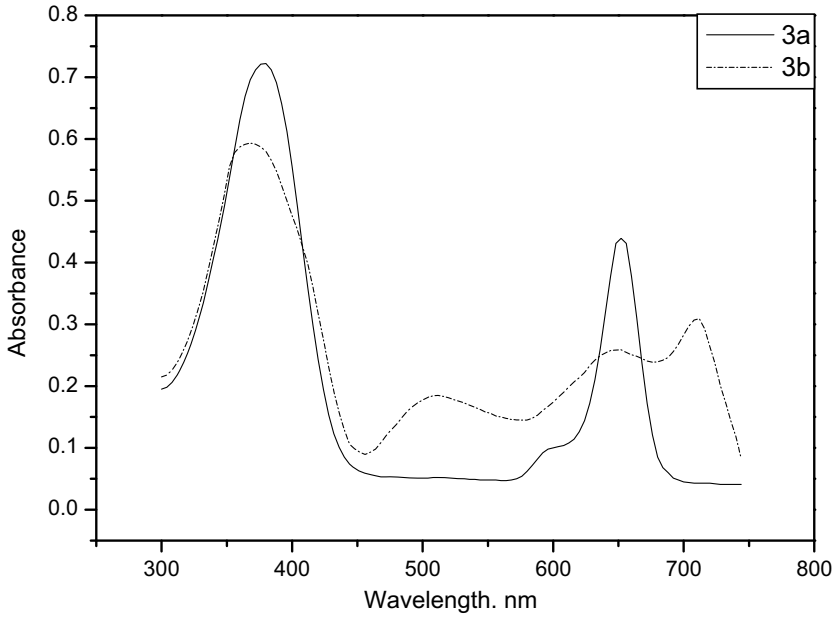

Fig. 5. UV–Vis spectra of **3a** and **3b** in chloroform.

porphyrazines **3a**, **3b** and **3d**, only one chemical shift is clearly seen: a multiplet around 7–8 ppm corresponding to the phenyl protons [20–23].

Electronic spectra are especially useful to identify the structure of the porphyrazines (**3a**–**e**). UV–Vis spectra of porphyrazine core are dominated by two intense bands, the Q band around 652 nm and the B band in the near UV region around 380 nm, both correlated to $\pi \rightarrow \pi^*$ transitions [28,29]. The presence of an electron-donating group on the periphery causes a bathochromic shift on Q bands. The UV–Vis spectra of porphyrazines (**3a**, **3c**–**e** in $CHCl_3$) prepared in the present study exhibited intense single Q band absorption of the $\pi \rightarrow \pi^*$ transitions around 652–658 nm and B bands in the near UV region around 348-380 nm (Table 2). As a consequence of the lowering of the symmetry of porphyrazine core, the electronic absorption spectrum of the *seco*-porphyrazine (**3b**) displays a split in the Q band at 650 and 712 nm. UV–Vis spectra of **3a** and **3b** in chloroform are shown in Fig. 5. An absorbance versus concentration study indicated that due to the bulky 4-biphenyl substituents, no aggregation occurred either for **3a**, **3b**.

4. Conclusion

In conclusion, we have described the synthesis and the spectral characterization of novel *seco*-porphyrazines surrounded with eight 4-biphenyl groups on the periphery. The steric requirements of these groups should be the reasons leading to oxidized *seco*-porphyrazines.

ABSTRACT

Compounds $[HQ]_2[Hg(L)_2]$ and [HQ][PhHg(L)] [where HQ = diisopropylammonium cation; L = pspa, fspa, tspa, where p = 3-(phenyl), f = 3-(2-furyl), t = 3-(2-thienyl), and spa = 2-sulfanylpropenoato] have been prepared by the reaction of mercury(II) acetate or phenylmercury(II) acetate with the corresponding acid in the presence of diisopropylamine in ethanol. The compounds have been characterized by elemental analysis, FAB mass spectrometry and IR and NMR (^1H, ^{13}C) spectroscopy. The crystal structures of the $[HQ]_2[Hg(L)_2]$ compounds show the presence of diisopropylammonium cations and $[Hg(L)_2]^{2-}$ anions. In each anion the Hg atom is in an HgO_2S_2 environment and this can be described as *nido*-tbp. The crystal structures of the [HQ][PhHg(L)] compounds show the presence of diisopropylammonium cations and $[PhHg(L)]^-$ anions in which the Hg atom adopts an HgCOS distorted T-environment. The NMR data suggest that the coordination mode of the ligand L^{2-} determined by X-ray diffractometry in the solid remains in solution.

1. Introduction

The useful properties of mercury and its compounds has as a counterpart in their toxic effects. This metal is widespread today and is emitted as a vapour into the atmosphere from both natural and anthropogenic sources. This vapour is slowly converted to Hg(II) by oxidative process and the mercury returns to the earth in rainwater [1]. Hg(II) has an extremely high affinity for compounds that contain sulfhydryl groups and in the blood and tissues of humans it is bound to these groups of cysteine-containing peptides and proteins. Often very stable forms include linear complexes with two sulfur ligands; however, the Hg–S bonds are labile and for higher coordination numbers the structures are flexible, often with distorted trigonal or tetrahedral coordination geometries [1,2].

The methylmercury(II) cation is formed in the environment in biotic processes by microbial metabolization and in abiotic processes by chemical reactions that do not involve living organisms. In marine sediments or at the bottom of lakes methylmercury(II) is concentrated in plankton and progresses up the food chain as it is readily absorbed and accumulated by living organisms.

The methylmercury and phenylmercury(II) cations also have a high affinity for the S-donor atoms present in proteins, peptides and amino acids. However, the behaviour as a toxic agent is different; methylmercury is neurotoxic, whereas the phenyl derivative shows toxic effects as Hg(II). These facts are consistent with the easier breakdown of the Hg–C bond in the phenyl derivative [1–3].

The breakdown of this bond once the R–Hg fragment is S-bonded is activated by the donating ability of other donor atoms that are able to provide an additional interaction to the Hg–S bond. For the organomercurial lyase enzymes that are able to degrade methylmercury, the influence of additional S-donor atoms from cysteine [4] or O-donor atoms from either a phenolic group [5] or a carboxylate group [6] have been postulated.

As alternatives to the classical chelating agents dimercaptosuccinic acid (DMSA) and dimercaptopropanesulfonic acid (DMPS) [7], the 3-(aryl)-2-sulfanylpropenoic acids (where aryl = phenyl, 2-furyl) were tested [8,9] as chelating agents against mercury intoxication through mobilization of the metal by complex formation. As these complexes have not been studied we selected these two ligands [H_2L, Scheme 1], along with the 2-thienyl derivative for comparative purposes, and reacted them with Hg(II) in order to prepare and structurally characterize the respective complexes.

doi:10.1016/j.poly.2008.04.034

This structural study is relevant because, although there are previous results on S-donor ligands coordinated to Hg(II) and carboxylate "inorganic" complexes, to the best of our knowledge Hg(II) complexes with an S_2O_2 kernel either do not contain or contain only weakly coordinated carboxylates [10]. The contrasting chelating ability of this class of ligand [11,12] should enable the preparation and study of this kernel.

In addition, in the case of phenylmercury(II), an HgCSO kernel with S,O-donor bidentate chelate ligands was not found in the literature [13] or in a search of the CSD database [14] and could contribute to our understanding of Hg–C bond cleavage. As a result, we also prepared and characterized the corresponding phenylmercury(II) complexes with these ligands.

The work described here involves the synthesis and characterization of compounds of the type $[HQ]_2[Hg(L)_2]$, in which the Hg atom has an HgO_2S_2 coordination kernel, and compounds of the type [HQ][PhHg(L)], in which an HgCSO kernel was identified and characterized by X-ray diffraction.

2. Experimental

2.1. Material and methods

The 3-(aryl)-2-sulfanylpropenoic acids H_2pspa, H_2fspa and H_2tspa were prepared by condensation of the appropriate aldehyde with rhodanine, subsequent hydrolysis in an alkaline medium and acidification with HCl [15,16]. Mercury(II) acetate, phenylmercury(II) acetate and diisopropylamine (Merck) were used as supplied. Elemental analyses were performed with a Carlo-Erba 1108 microanalyser. Melting points were determined with a Büchi apparatus and are uncorrected. IR spectra (KBr pellets or Nujol mulls) were recorded on a Bruker IFS66V FT-IR spectrophotometer and are reported in Section 2.2. ^{1}H and ^{13}C NMR spectra were recorded in dmso-d_6 or $CDCl_3$ at room temperature on Bruker AMX 300 and AMX 500 spectrometers operating at 300.14 or 500.14 (^{1}H) and 75.46 or 125.76 MHz (^{13}C), using 5 mm o.d. tubes; chemical shifts are reported relative to TMS using the solvent signal (δ^1H = 2.50 ppm; δ^{13}C = 39.50 ppm) as reference. ^{199}Hg NMR were recorded in dmso-d_6 and, in some cases, $CDCl_3$ (concentration ranging from 10^{-2} to 2.6×10^{-2} M) at room temperature on a Bruker AMX 500 spectrometer operating at 89.47 MHz. Chemical shifts are reported relative to pure dimethylmercury(II) as secondary standard. Mass spectra were recorded on a Kratos MS50TC spectrometer connected to a DS90 system and operating in FAB conditions (Xe, 8 eV) using as liquid matrix 3-nitrobenzyl alcohol.

2.2. Synthesis

2.2.1. Compounds of the type $[HQ]_2[Hg(L)_2]$

These compounds were prepared by reacting diisopropylamine, the appropriate H_2L acid and $Hg(OAc)_2$ in ethanol in a 2:2:1 molar ratio. The solid formed after agitation of the reaction mixture at room temperature was filtered off and vacuum dried.

2.2.2. $[HQ]_2[Hg(pspa)_2]$ (**1**)

H_2pspa (0.90 g, 0.005 mmol), $Hg(OAc)_2$ (0.80 g, 0.0025 mmol), diisopropylamine (0.51 g, 0.005 mmol), ethanol (50 mL), grey solid, yield: 73.6%, M.p.: 163 °C. *Anal.* Calc. for $C_{30}H_{44}N_2O_4S_2Hg$: C, 47.3; H, 5.8; N, 3.7; S, 8.4. Found: C, 47.3; H, 5.9; N, 3.6; S, 8.9%. IR (cm^{-1}): $\nu_a(CO_2^-)$ 1547s; $\nu_s(CO_2^-)$ 1343vs; $\delta(NH_2^+)$ 1618s. ^{1}H NMR (dmso-d_6, ppm): δ C(3)H 7.73 (s, 2), CH_3 1.18, NH_2^+ 8.85. ^{13}C NMR (dmso, ppm): δ C(1) 170.7, C(2) 135.9, C(3) 131.2, CH 46.0, CH_3 18.7. ^{199}Hg NMR (dmso-d_6, ppm): δ −784.7. FAB peaks at m/z (%) = 662.2 (1.20) ([HQ][Hg(pspa)$_2$] + 2H); 102.1 (100) (HQ). Recrystallization from an ethanol–dmso mixture gave crystals suitable for an X-ray study.

2.2.3. $[HQ]_2[Hg(fspa)_2]$ (**2**)

H_2fspa (0.90 g, 0.0053 mmol), $Hg(OAc)_2$ (0.45 g, 0.0026 mmol), diisopropylamine (0.54 g, 0.0053 mmol), ethanol (50 mL), yellow solid, yield: 48.2%, M.p.: 172 °C. *Anal.* Calc. for $C_{26}H_{40}N_2O_6S_2Hg$: C, 42.1; H, 5.4; N, 3.8; S, 8.2. Found: C, 42.2; H, 5.7; N, 3.2; S, 8.6%. IR (cm^{-1}): $\nu_a(CO_2^-)$ 1543s; $\nu_s(CO_2^-)$ 1344vs; $\delta(NH_2^+)$ 1620s. ^{1}H NMR (dmso-d_6, ppm): δ C(3)H 7.61 (s, 2), CH 3.27 (q, 4), CH_3 1.17 (d, 24). ^{13}C NMR (dmso-d_6, ppm): δ C(1) 169.9, C(2) 135.9, C(3) 141.4, CH 45.9, CH_3 18.70. ^{199}Hg NMR (dmso-d_6, ppm): δ −780.7. ^{199}Hg NMR ($CDCl_3$, ppm): δ −853. FAB peaks at m/z (%) = 642.2 (0.96) ([HQ][Hg(fspa)$_2$] + 2H); 102.1 (100.00) (HQ). Crystals suitable for an X-ray study were obtained from the mother liquor.

2.2.4. $[HQ]_2[Hg(tspa)_2]$ (**3**)

H_2tspa (0.90 g, 0.0048 mmol), $Hg(OAc)_2$ (0.77 g, 0.0024 mmol), diisopropylamine (0.49 g, 0.0048 mmol), ethanol (50 mL), white solid, yield: 68.7%, M.p.: 168 °C. *Anal.* Calc. for $C_{26}H_{40}N_2O_4S_4Hg$: C, 40.4; H, 5.2; N, 3.6; S, 16.6. Found: C, 39.8; H, 5.1; N, 3.3; S, 16.1%. IR (cm^{-1}): $\nu_a(CO_2^-)$ 1548s; $\nu_s(CO_2^-)$ 1335vs; $\delta(NH_2^+)$ 1612m. ^{1}H NMR (dmso-d_6, ppm): δ C(3)H 7.97 (s, 2), CH 3.27 (q, 4), CH_3 1.16 (d, 24), NH_2^+ 8.96 (s, br, 4). ^{13}C NMR (dmso-d_6, ppm): δ C(1) 170.2, C(2) 134.5, C(3) 124.6, CH 45.9, CH_3 18.7. ^{199}Hg NMR (dmso-d_6, ppm): δ –810.2. FAB peaks at m/z (%) = 673.1 (0.82) ([HQ][Hg(tspa)$_2$] + H); 102.1 (100) (HQ). Crystals suitable for an X-ray study were obtained by recrystallization from a dmso/dmf mixture.

2.2.5. Compounds of the type [HQ][PhHg(L)]

These compounds were prepared by reacting the appropriate sulfanylpropenoic acid, diisopropylamine and PhHg(OAc) in ethanol in a 1:1:1 molar ratio. The solid formed after agitation of the mixture at room temperature was filtered off and vacuum dried.

2.2.6. [HQ][PhHg(pspa)] (**4**)

H_2pspa (0.90 g, 0.005 mmol), PhHg(OAc) (1.69 g, 0.005 mmol), diisopropylamine (0.51 g, 0.005 mmol), ethanol (50 mL), white solid, yield: 69.7%, M.p.: 183 °C. *Anal.* Calc. for $C_{21}H_{27}NO_2SHg$: C, 45.2; H, 4.9; N, 2.5; S, 5.7. Found: C, 45.0; H, 4.8; N, 2.7; S, 5.8%. IR (cm^{-1}): $\nu_a(CO_2^-)$ 1553s; $\nu_s(CO_2^-)$ 1340vs; $\delta(NH_2^+)$ 1618m. ^{1}H NMR (dmso-d_6, ppm): δ C(3)H 7.66 (s, 1), CH 3.30 (q, 4), CH_3 1.19 (d, 24), NH_2^+ 8.55 (s,br, 1). ^{13}C NMR (dmso-d_6, ppm): δ C(1) 171.5, C(2) 137.9, C(3) 131.0, CH 46.0, CH_3 18.9. ^{199}Hg NMR (dmso-d_6, ppm): δ −755.4. ^{199}Hg NMR ($CDCl_3$, ppm): δ −820.9. FAB peaks at m/z (%) = 558.10 (1.44) ([HQ][PhHg(pspa)] + H); 457.98 (1.68) ([PhHg(pspa)] + H); 102.09 (100.00) (HQ). Crystals suitable for an X-ray study were obtained from the mother liquor.

2.2.7. [HQ][PhHg(fspa)] (**5**)

H_2fspa (0.90 g, 0.0053 mmol), PhHg(OAc) (1.79 g, 0.0053 mmol), diisopropylamine (0.54 g, 0.0053 mmol), ethanol (50 mL), white solid, yield: 76.6%, M.p.: 172 °C. *Anal.* Calc. for $C_{19}H_{25}NO_3SHg$: C, 41.6; H, 4.6; N, 2.6; S, 5.8. IR (cm^{-1}): $\nu_a(CO_2^-)$ 1552s; $\nu_s(CO_2^-)$ 1335vs; $\delta(NH_2^+)$ 1617m. ^1H NMR (dmso-d_6, ppm): δ C(3)H 7.97 (s, 1), CH 3.30 (q, 2), CH_3 1.20 (d, 12), NH_2^+ 8.84 (s, br). ^{13}C NMR (dmso-d_6, ppm): δ C(1) 171.38, C(2) 134.9, C(3) 126.2, CH 45.9, CH_3 18.7. ^{199}Hg NMR (dmso-d_6, ppm): δ −788.8. ^{199}Hg NMR ($CDCl_3$, ppm): δ −839.4. FAB peaks at m/z(%) = 565.06 (1.98) ([HQ][PhHg(tspa)]); 463.93 (3.21) ([PhHg(tspa)] + H); 102.09 (100.00) (HQ). Crystals suitable for an X-ray study were obtained from the mother liquor.

2.3. X-ray studies

Single crystals were mounted on glass fibres in Bruker Smart 1000 CCD (**1**–**3**) or Enraf-Nonius MACH3 (**4**–**6**) automatic diffractometers. Data were collected at 293 K using Mo Kα radiation (λ = 0.71073 Å). The crystal data, experimental details and refinement results are summarized in Table 1.

Corrections for Lorentz effects, polarization [17] and multi-scan (SADABS) [18] for **1**–**3** or semi-empirical (ψ scan) [19,20] for **4**–**6** absorption were carried out. The structures of **1**–**4** were solved using direct methods but by the heavy atom Patterson method in **5** and **6** [21]. In the refinement the non-H atoms were treated anisotropically [21]. The H atoms were localized from difference Fourier maps and refined as riders (N–H 0.90, C–H 0.93–0.98 Å) [21], except in **1** and **3** where the atomic position and isotropic temperature factor were also refined.

The scattering factors were taken from *International Tables for Crystallography* [22]. The main calculations were performed with SHELXL-97 [21] and PLATON [20] and figures were plotted with ZORTEP [23] and MERCURY [24].

3. Results and discussion

3.1. Compounds of the type $[HQ]_2[Hg(L)_2]$

The reaction of diisopropylamine, the corresponding H_2L acid and $Hg(OAc)_2$ in ethanol in a 2:2:1 molar ratio gave rise to solids with this composition. In all the cases the FAB spectra show peaks for the protonated $[HQ][Hg(L)_2]$ species. The compounds are soluble in dmso and dmf but insoluble or sparingly soluble in water, ethanol, acetone, chloroform and acetonitrile.

*3.1.1. Description of the structures of $[HQ]_2[Hg(pspa)_2]$ (**1**), $[HQ]_2[Hg(fspa)_2]$ (**2**) and $[HQ]_2[Hg(tspa)_2]$ (**3**)*

Crystals suitable for X-ray study were obtained for compounds derived from H_2pspa, H_2fspa and H_2tspa. As the structures have significant similarities they are discussed together.

In all cases the crystals contain diisopropylammonium cations and anions of the type $[Hg(L)_2]^{2-}$, where L ($pspa^{2-}$, $fspa^{2-}$ and $tpsa^{2-}$) behaves as a bidentate chelate ligand bonded to Hg through an O atom of the carboxylate group and the S atom of the deprotonated SH group. The numbering scheme for the $[Hg(L)_2]^{2-}$ anions is shown in Fig. 1 and selected values for the bond distances (Å) and angles (°) are given in Tables 2 and 3.

The Hg atom in all the anions is tetracoordinated in an HgO_2S_2 environment, with slightly different parameters in molecules A and B for $[Hg(fspa)_2]^{2-}$ (Table 3). The Hg–S bond distances range from 2.333(2) Å for $[Hg(pspa)_2]^{2-}$ to 2.349(3) Å for $[Hg(tspa)_2]^{2-}$. These values are slightly shorter than those found in Hg(II) compounds with *S,S′*-bidentate ligands [25] to give an HgS_4 environment and are in the range found for linear S–Hg–S bis-thiolato complexes of Hg(II) [26]; the Hg–O bond distances range from 2.499(7) Å in $[Hg(tspa)_2]^{-}$ to 2.553(4) Å in $[Hg(pspa)_2]^{2-}$.

As far as the angles around the metal are concerned, the value for the bite angle of the ligand, which ranges from 77.56(17)° for $[Hg(fspa)_2]^{2-}$ to 80.04(15)° for $[Hg(tspa)_2]^{2-}$, is lower; the largest value is found for the S–Hg–S angle, which ranges from 168.03(9)° in $[Hg(tspa)_2]^{2-}$ to 171.83(8)° in the fspa derivative.

In order to investigate the influence that a possible Hg–S interaction between neighbouring molecules has on the S–Hg–S angle

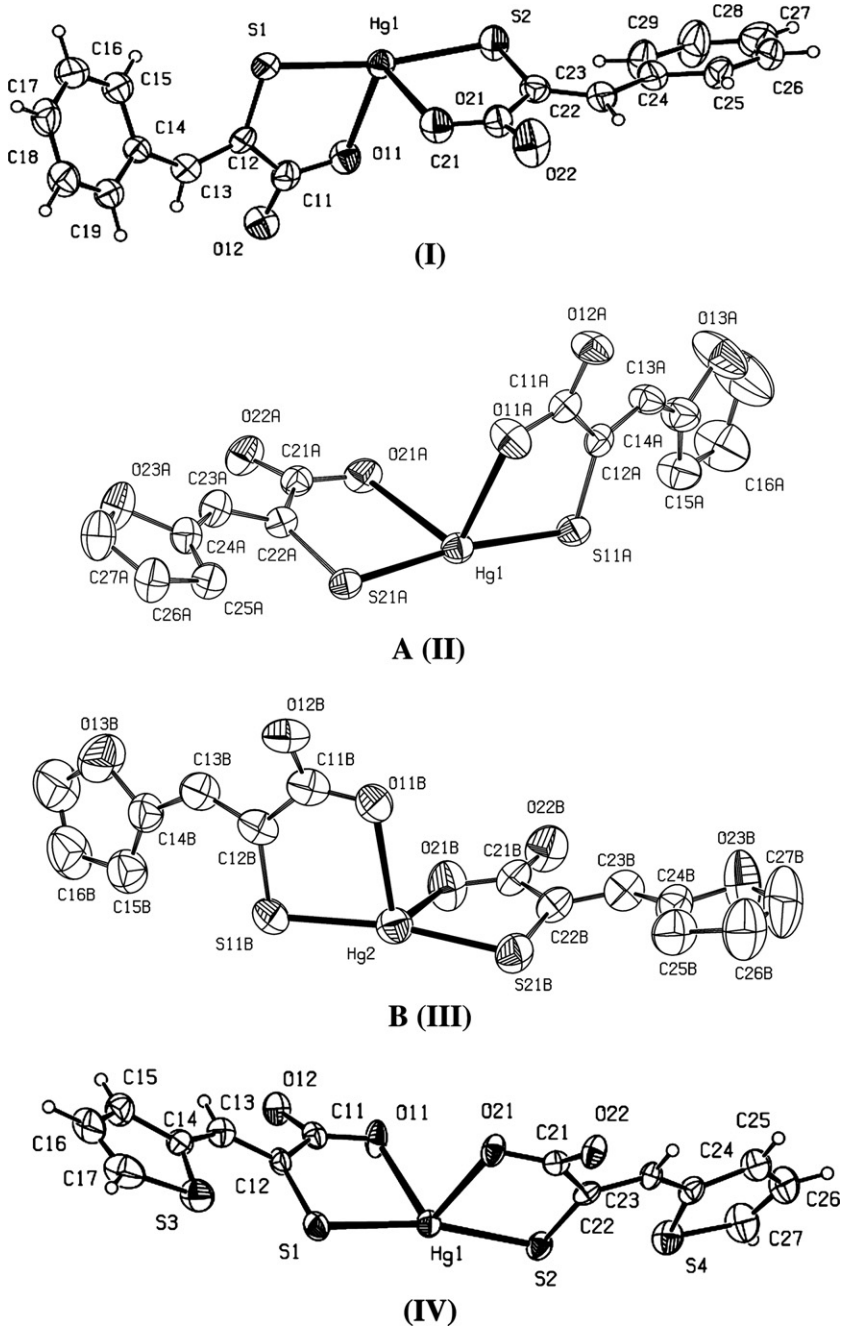

Fig. 1. ORTEP drawing showing the structures of the $[Hg(pspa)_2]^{2-}$ (I), the two molecules A(II) and B(III) of the $[Hg(fspa)_2]^{2-}$ and $[Hg(tspa)_2]^{2-}$ (IV) anions with the numbering scheme. The ellipsoids are drawn at the 30% probability level.

of the Hg kernel, we analysed these distances. Only in the pspa derivative **1** were interactions found that could be considered significant [Hg–S(1)#1 = 3.4272(16) Å]. In the other two cases the intermolecular Hg–S bond distances are greater than 4 Å. At this point we must underline the variability in the sum of the van der Waals radii for Hg and S (on using the value reported by Bondi [27] we obtained a value of 3.3 Å for the sum of the two radii, which was revised to 3.7 Å [13] or to 4.016 Å on using the van der Waals radii reported by Batsanov [28]). However, the influence of this intermolecular interaction on the bond distances and angles of the Hg kernel does not seem to be significant.

The intermolecular interaction is also absent in $[Hg(Htsal)_2]$ [10] and $[Hg(Htsal)_2] \cdot$ 1,4-dioxane [29] (H_2tsal = thiosalicylic acid). The former compound, which cocrystallizes with $[Hg_2(tsal)_2(PPh_3)_2]$, has parameters [Hg–S: 2.3444(12), 2.3392(12) Å; Hg–O: 2.641(3), 2.682(3) Å; S–Hg–S: 170.12(4)°] close to those found in this work, although the Hg–O bond distances are longer and the S–Hg–S angle slightly wider. Other examples in the literature include the 2,2,6, 6-tetramethyl-3,5-heptanedione [30], the 2-dimethylamino-3-4-dioxo-cyclobut-1-en-thiolate [26] and the *N*-(piperidylthiocarbonylcarbonyl)benzamide [31] mercury(II) complexes and these also have, as in the case of the thiosalicylic acid, wider S–Hg–S bond angles than those found in this work.

For the Hg atom in the thiosalicylic acid derivative Henderson and Nicholson [10], taking into account the large tetrahedral distortion in the kernel, proposed a *nido*-trigonal bipyramidal coordination geometry or even an S–Hg–S linear geometry with a weak Hg···O interaction. The compounds described in this work have a shorter Hg–O bond distance than that found in the thiosalicylic acid derivative, making the *nido*-tbp geometry the more appropriate description.

The planarity of the L^{2-} fragment is different in the three structures. In $[Hg(pspa)_2]^{2-}$ the angle between the idealized plane of the chelate ring and that of the C(14)–C(19) phenyl ring is 22.6° and this value is 12.26° for the other L fragment. Equivalent angles are 12.68° and 10.46° in molecule A and 21.68° and 5.58° in molecule B for the fspa derivative and 10.61° and 15.52° in $[HQ]_2[Hg(tspa)_2]$, although there is a lack of planarity in the chelate ring in the latter compound (rms [Hg(1)/S(1)/O(11)/C(11)/C(12)] = 0.0917° and rms [Hg(1)/S(2)/O(21)/C(21)/C(22)] = 0.0970°).

The diisopropylammonium cation in each of the three structures has parameters that are comparable with other previously described examples [32,33].

[a] *Symmetry code*: #1 $x + 1/2, -y + 1/2, z + 1/2$; #2 $-x + 2, -y + 1, -z + 1$; #3 $-x + 2, -y + 2, -z + 1$; #4 $x - 1, y - 1, z$; #5 $x, y - 1, z$; #6 $-x, y + 1/2, -z + 1/2$; #7 $x, -y + 1/2, z + 1/2$.

The $[Hg(L)]^{2-}$ anions and the $[HQ]^{+}$ cations are hydrogen bonded through the NH_2 group of the cation and the O atoms of the carboxylate group. The metric parameters for these bonds are included in Table 4. In the three structures the $[HQ]^{+}$ cation bridges two dianionic $[Hg(L)]^{2-}$ units but the final arrangement is different.

In $[HQ]_2[Hg(pspa)_2]$, two $[HQ]^{+}$ units establish a double-bridge between two $[Hg(pspa)_2]^{2-}$ anions to afford zig-zag chains (Fig. 2a) parallel to the crystallographic direction {1 1 2}. These chains are schematically represented in Fig. 2b using a rod as a symbol for the anion and a left/right arrow as a symbol for the cation. The chains are packed in the crystallographic *c*-axis, as shown in Fig. 2c, in which the hydrogen bond and the weak Hg···S interaction are underlined.

The same interaction in $[HQ]_2[Hg(fspa)_2]$ generates rack-chains running parallel to the crystallographic *b*-axis (Fig. 3) and these are also represented using the same symbols.

In contrast to the above situation, 2D molecular association is observed in the thiophene derivative. The crystal structure may be described in terms of the formation of the unit shown in Fig. 4a by bridge of four $[HQ]^{+}$ units between four $[Hg(tspa)_2]^{2-}$ units. The cyclic unit is associated with another of these units through interactions analogous to those described above (Fig. 4b). The resulting sheet is parallel to the crystallographic *bc*-plane.

3.1.2. Spectroscopy

The IR spectra of the $[HQ]_2[Hg(L)_2]$ complexes do not show a ν(SH) band, which is located near 2550 cm^{-1} in the spectra of the free ligands. Furthermore, the vibrations of the CO_2H group [ν(C=O) = 1670, 1665 and 1673 cm^{-1} for H_2pspa, H_2fspa and H_2tspa are replaced by bands typical of a carboxylate group with [$\nu_{as}(CO_2^-)$] observed between 1548 and 1543 cm^{-1} and [$\nu_{sym}(CO_2^-)$] between 1344 and 1335 cm^{-1}. As in other compounds in which the HQ cation is hydrogen bonded [12,34] to the carboxylate group the $\Delta\nu$ ($=\nu_{as}CO_2^- - \nu_{sym}CO_2^-$) parameter has values smaller than those found for a monodentate carboxylate group [35], which was attributed [34] to the effect of the N–H···O hydrogen bond on the structural parameters of the carboxylate group. A strong band at around 1610 cm^{-1} in all the spectra was assigned [36] to the $\delta(NH_2)$ vibration of the diisopropylammonium cation.

The ^{1}H NMR spectra of the complexes in all cases show the typical signals of the diisopropylammonium cation and the absence of signals attibutable to SH and COOH groups is consistent with bideprotonation of the ligand. These spectra show, in general, a shift of the C(3)–H signal to higher field on complexation, which suggests the persistence of the Hg–S bond in solution.

The persistence of the S-coordination is confirmed [37,38] by the shift of the C(3) signal in the ^{13}C NMR spectra. In these spectra the C(1) signals are in positions close to those found [34,39,40] for compounds with a monodentate coordinated carboxylate group, thus suggesting the persistence in solution of the coordination mode found in the solid state.

The ^{199}Hg NMR spectra show only a signal located between −780.7 and −810.2 ppm, indicating the presence of only one type

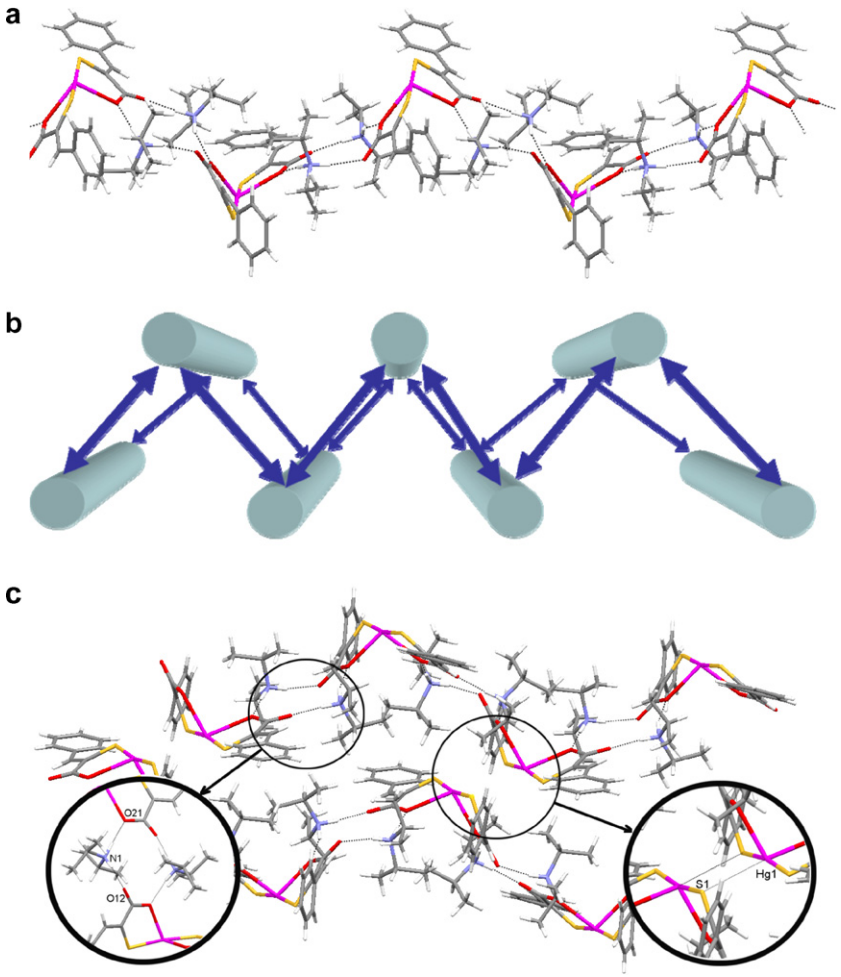

Fig. 2. (a) A view of the polymeric structure of $[HQ]_2[Hg(pspa)_2]$ (**1**) and (b) a schematic view of the structure; and (c) details of the hydrogen bonding and Hg···S intermolecular interactions.

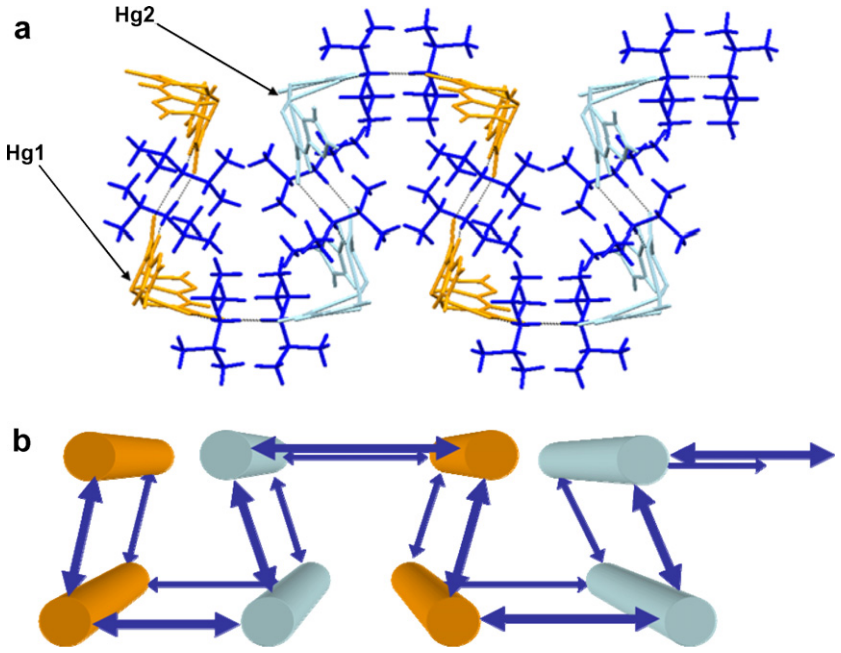

Fig. 3. (a) A view of the polymeric structure of $[HQ]_2[Hg(fspa)_2]$ (**2**) and (b) a schematic view of the structure.

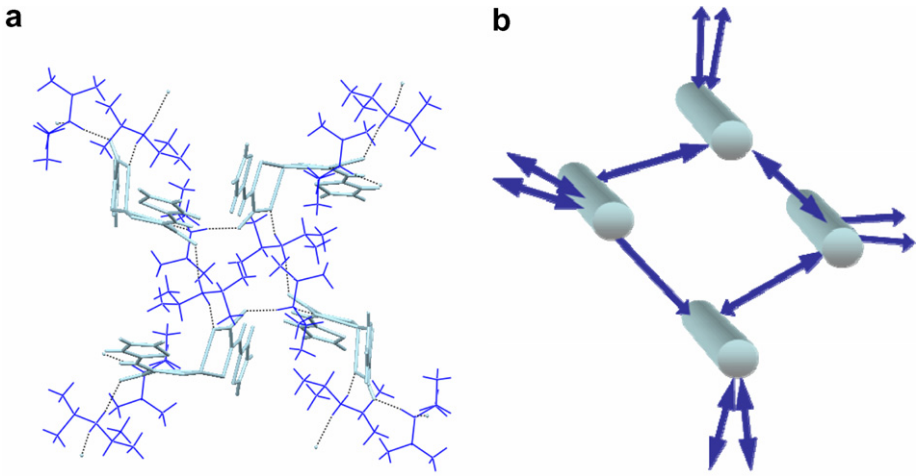

Fig. 4. (a) A partial view of the polymeric structure of $[HQ]_2[Hg(tspa)_2]$ (**3**) and (b) a schematic view of the structure.

of chemical environment for Hg(II). The position of the signal is close to the positions found for other four-coordinated Hg(II) complexes that have the HgS_2N_2 kernel [41]. In the case of **2** the spectrum was recorded in dmso/dmso-d_6 (−780.7 ppm) and in $CDCl_3$ (−853.0 ppm). The difference in the positions of the signal in these spectra is within the accepted range [42] for the influence of the solvent, suggesting the same chemical environment for the metal in both solvents, thus excluding dmso coordination. The additional coordination of these solvent molecules would increase the coordination number and should move the δ (^{199}Hg) signal to higher frequencies [41].

3.2. Compounds of the type [HQ][PhHg(L)]

Reaction of diisopropylamine, the corresponding sulfanylpropenoic acid and PhHg(OAc) in ethanol in a 1:1:1 molar ratio gave solids with this composition. The FAB mass spectra show peaks for the [HQ][HgPh(L)] molecular ion.

3.2.1. Description of the structures of [HQ][PhHg(pspa)] (*4*), [HQ][PhHg(fspa)] (*5*) and [HQ][PhHg(tspa)] (*6*)

Single crystals suitable for X-ray studies were obtained for the three phenyl mercury complexes. The similarity between the structures, indeed the structures of **4** and **6** are isotypic, again means that these compounds will be discussed together. The three crystals contain diisopropylammonium cations and $[HgPh(L)]^-$ anions that interact through hydrogen bonds. The numbering scheme for each compound is shown in Fig. 5 and selected bond distances (Å) and angles (°) are listed in Table 5.

In each anion the ligand is S,O-bidentate chelate to give a HgCOS kernel. It should be noted that such an example in which O and S atoms from the same ligand has not been found previously [13,14] for phenylmercury(II) derivatives. In this kernel the metal adopts a significantly distorted T-environment. In this environment the Hg–C bond distance is about 2.065 Å, which is normal for phenylmercury(II) derivatives [13] and the Hg–O and Hg–S

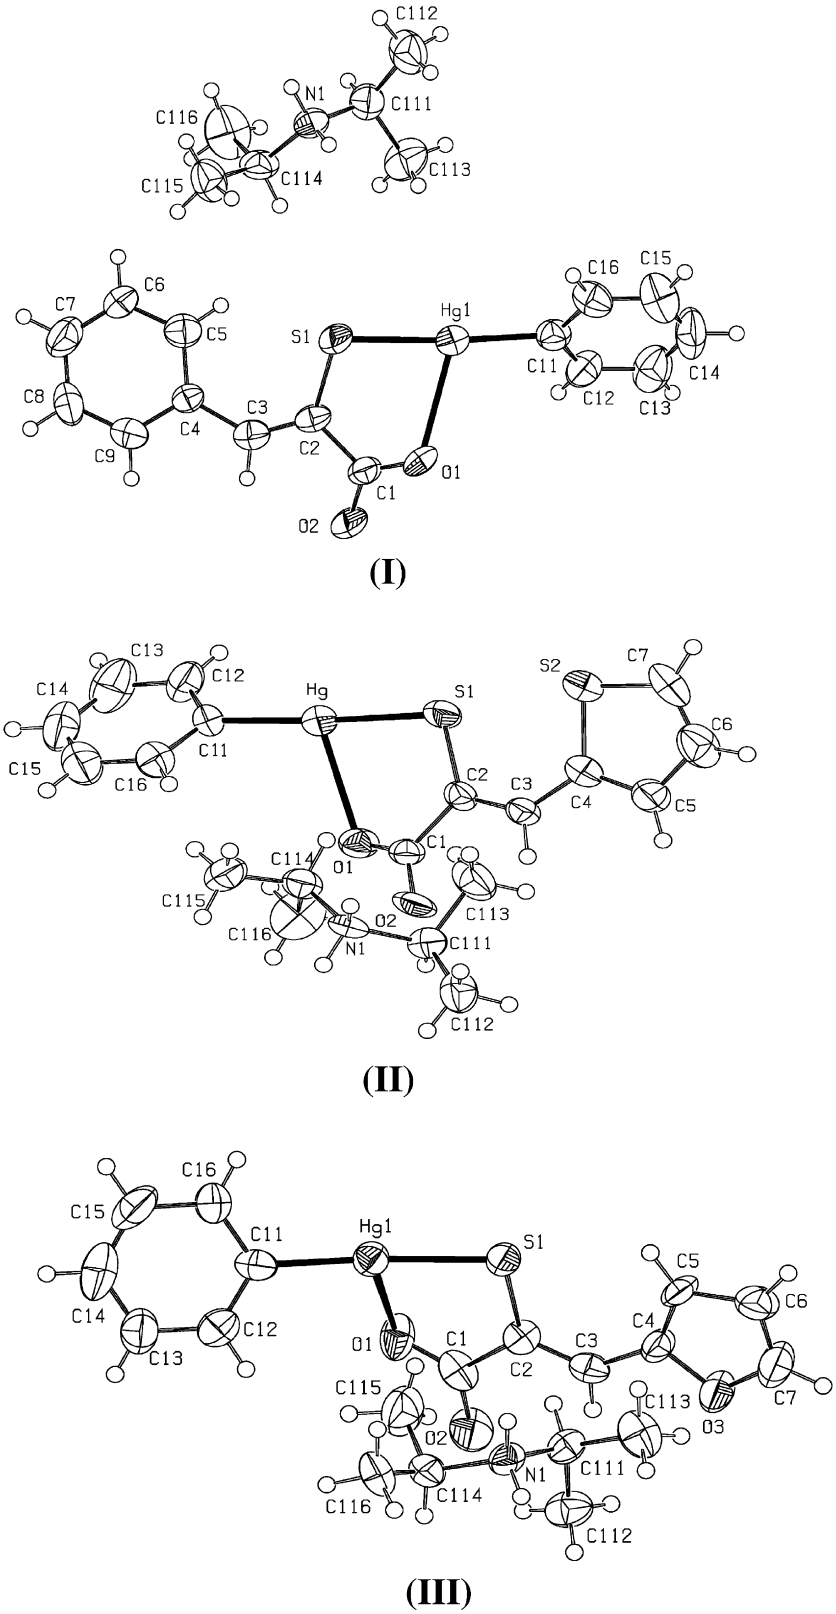

Fig. 5. ORTEP drawing showing the structures of [HQ][PhHg(pspa)] (**4**) (I), [HQ][PhHg(fspa)] (**5**) (II) and [HQ][PhHg(tspa)] (**6**) (III) with the numbering scheme. The ellipsoids are drawn at the 30% probability level.

bond distances are close to 2.565 and 2.355 Å, respectively. The values for the O–Hg–S, C–Hg–O and C–Hg–S angles are about 76.50°, 106.0° and 174.0°, respectively. The sum of these angles is close to 360° in the three anions.

For other kernels values for the Hg–S bond distance between 2.357(3) and 2.405(1) Å were previously described for $PhHg^+$ compounds with thiosemicarbazones [43] and ligands containing P–S bonds [44] and values larger than 2.370 Å have also been described

[b] *Symmetry operation*: #1 $-x+1, -y+1, -\mathbf{z}$.

[45–49]. The values found for the Hg–O bonds can be considered [50] typical of relatively strong bonds.

These structures can be related with that of [HgPh(S_2COEt)] [51], in which an S-donor atom is coordinated to a $PhHg^+$ fragment to give a practically linear C–Hg–S [176.1 (4)°] environment, and with that of [HgPh(pmbp)] (pmbp = 1-phenyl-3-methyl-4-benzoylpyrazol-5-onato] [50] where the pmbp ligand has two O-donor atoms, both coordinated to the Hg atom to give an $HgCO_2$ environment reminiscent of the HgCOS present in this case. The structural parameters for the latter compound [Hg–O(1): 2.585(9) Å; Hg–O(2): 2.087(7) Å; Hg–C: 2.040(11) Å; C–Hg–O(1): 112.1(4)°; C–Hg–O(2): 168.6(3)°; O(1)–Hg–O(2): 78.3(3)°] have some similarities with these structures if the O(2) atom, trans to C but closest to the Hg atom, is replaced by the S atom of the sulfanylpropenoic fragment; the bite of the ligand is also similar.

[a] *Symmetry code*: #1 = $-x+1, -y+1, -z$; #2 = $-x, -y+1, -z$.

The parameters for the diisopropylammonium cation are unremarkable and close to those previously described.

In the three crystals there are weak interactions, which are weaker in the tspa derivative, and these are depicted in the structures of the pspa and fspa derivatives shown in Fig. 6. Similar interactions in methylmercury xanthates of the type MeHgS(S)COR (R = Et, ^{i}Pr, CH_2Ph) [45] lead to supramolecular structures, but in this case such interactions could be hindered by the hydrogen bonds that exist between the diisopropylammonium cations and the corresponding anions. The parameters for these bonds, which involve the NH_2 group and the carboxylate group, are listed in Table 6.

As observed in the complexes $[HQ]_2[Hg(L)_2]$, the $[HQ]^+$ units establish two hydrogen bonds with two molecules of $[HgPh(L)]^-$

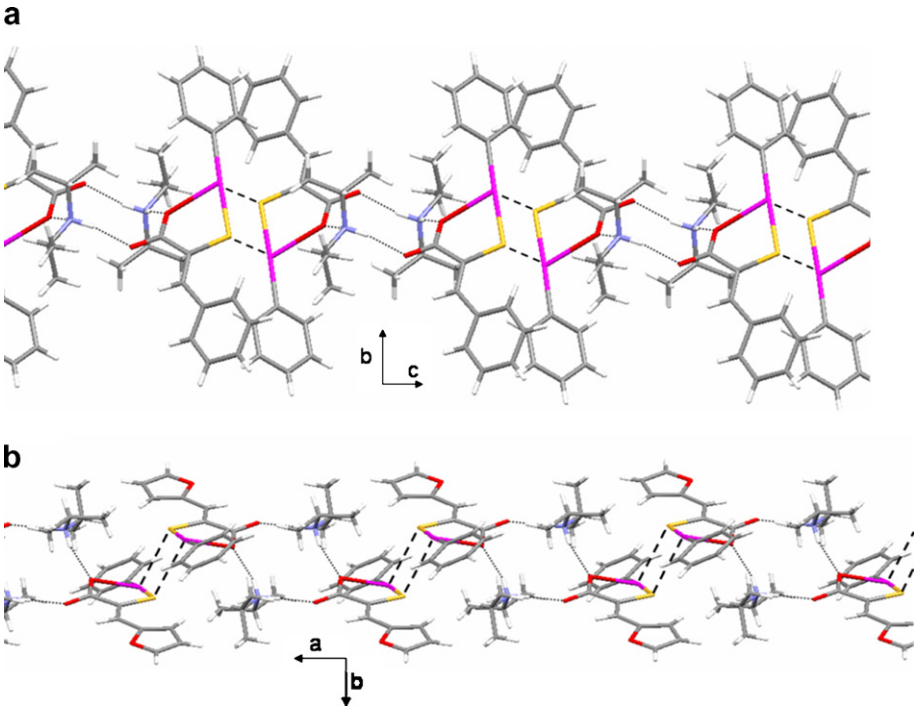

Fig. 6. The polymeric structures of: (a) [HQ][PhHg(pspa)] (**4**) and (b) [HQ][PhHg(fspa)] (**5**).

to afford centrosymmetric dimers. These units are now associated in chains running parallel to crystallographic *c* (compounds **4** and **6**) or *a* (compound **5**) axes (see Fig. 6) through the previously described weak intermolecular Hg–S interaction (Table 5).

3.2.2. Spectroscopy

As for $[HQ]_2[Hg(L)]$, the IR spectra of **4**, **5** and **6** do not show the ν(SH) band and the vibrations of the CO_2H group are replaced by bands typical of the carboxylate group. The $\Delta\nu[\nu_a(CO_2^-)-\nu_s(CO_2^-)]$ values are again typical of a monodentate carboxylate group involved in N–H···O hydrogen bonds.

The ^{1}H NMR spectra show the typical bands of the diisopropylammonium cation, lacking signals attributable to SH and COOH. Furthermore, the spectra show a shift of the C(3)–H signal to higher field on complexation, suggesting the persistence of the Hg–S bond in solution. The position of the C(3) signals in each of the ^{13}C NMR spectra of the complexes again supports S-coordination and the position of the C(1) signal suggests that the carboxylate group remains coordinated in solution. Thus, as in the $[HQ]_2[Hg(L)_2]$ complexes, the ligand remains S,O-coordinated in solution.

The ^{199}Hg NMR spectra of the three complexes show only one signal each. In $CDCl_3$ the signals for **4**, **5** and **6** are at −820.9, −861.5 and −839.4 ppm, respectively, and in dmso the signals range between −755.4 and −788.8 ppm.

The position of the signal in the spectra in chloroform is close to those found for thiosemicarbazonates of phenylmercury(II) in which the metal is tricoordinated [43]. Once again, the difference between the value in $CDCl_3$ and dmso-d_6 suggest that this latter solvent does not increase the coordination number of the metal in comparison to that found in the solid state.

4. Conclusion

In summary, two types of complexes $[HQ]_2[Hg(L)_2]$ and [HQ][PhHg(L)] where HQ is diisopropylammonium and L a bideprotonated 3-(aryl)-2-sulfanylpropenoic acid have been synthesized and characterized.

Among the $[HQ]_2[Hg(L)_2]$ complexes this study has led to the structural characterization of the unusual HgO_2S_2 kernel built on the basis of S,O-bidentate donor ligands. The chelating ability of the corresponding 3-(phenyl)- and 3-(2-furyl)-2-sulfanylpropenoic acids previously used as chelating agents against mercury intoxication is thus confirmed. This S,O-coordination mode was recently described for the widely used chelating agent DMSA, which contains SH and COOH groups, against the diorganotin(IV) fragment [52]. However, X-ray absorption spectroscopy and DFT calculations [7] suggest the presence of metallated species mainly supported by Hg–S bonds in the case of mercury.

The same coordination mode was found for the ligands in the [HQ][PhHg(L)] complexes and this enabled us to determine the structural parameters of the CHgSO kernel, which has been identified previously for S,O-bidentate chelate ligands.

Both types of complex show different supramolecular structures based on N–H···O hydrogen bonds, with weak Hg···S interactions also present in some cases.

ABSTRACT

Two sets of nickel(II) complexes of a series of tetradentate NSNO ligands were synthesized and isolated in their pure form. All these complexes, formulated as $[Ni(L)Cl]_2$ and $[Ni(L)(N_3)]_2$ [HL = pyridylthioazophenols], were characterized using physicochemical and spectroscopic tools. The solid-state structures of two complexes (**1a** and **2a**) were established by X-ray crystallography. The geometry about the nickel ion of the complexes is octahedral and the complexes are dimeric in nature. In **1**, two Ni(II) ions are bridged by two Cl^- anions while in **2** they are bridged by two azide ions in a μ-1,1-bridging fashion.

1. Introduction

Considerable attention has been directed towards the synthesis of nickel(II) complexes in recent years. The potential role played by nickel ions, being present in the active sites of a large number of metalloproteins, has stimulated efforts to design new ligands and characterize of nickel complexes as models for providing better understanding of biological systems and for assisting in the development of new homogeneous catalysts for selective oxidation [1]. The investigation of the magnetic properties of binuclear nickel(II) complexes and correlating them with structures are important in the field of molecular magnetism. A common strategy is to prepare such complexes using a multidentate ligand along with judicial choice of a bridging ligand. The azide ligand in such complexes can act as either end-on [2–5] or end-to-end [6] bridges. The most important aspect of these bridged complexes is the variety of their magnetic exchange interactions. The end-on bridging mode of the azide ligand and the chloride ion exerts ferromagnetic exchange interactions [7–11].

As part of our continuing study on new N,S-donor polydentate ligands [12,13], and also considering the above and the fact that complexes containing N,S-donor sets are of biological relevance due to the discovery of the occurrence of similar donor environments in several bioactive molecules [14], we report here an account on the structural chemistry of two series of nickel(II) complexes having tetradentate pyridylthioazophenolate ligands (HL) (Fig. 1) along with chloride (**1**) and azide (**2**) as bridging ligands. The complexes **1** are hexacoordinated dimer complexes with a chloro-bridge, while the complexes **2** are dimers through end-on azide bridging. The single crystal X-ray structures of **1a** and **2a** are also discussed.

2. Experimental

2.1. Materials and physical measurements

All the reagents were obtained from commercial sources and were used without further purification. The pyridylthioazophenolate ligands were synthesized following the reported procedure [12].

IR spectra were obtained on a JASCO FT-IR model 420 using KBr disks and UV–Vis spectra on a JASCO UV–Vis/NIR model V-570. Microanalyses were performed with the use of a Perkin Elmer 2400 CHN elemental analyzer and nickel analyses were carried out by a gravimetric method [15]. Molar conductances (Λ_M) were measured in a systronics conductivity meter 306 model using $\sim 10^{-3}$ M solutions in MeOH. Magnetic moments (μ, BM) were obtained on a vibrating sample magnetometer PAR 155 model.

2.2. Synthesis of $[Ni(L)Cl]_2$

The preparation follows a common procedure. To a methanolic solution (15 mL) of HL1 (0.335 g, 1.0 mmol), nickel chloride hexahydrate solution (1.0 mmol) was added dropwise and the resulting solution was stirred for a period of 6 h. The solution was dried at

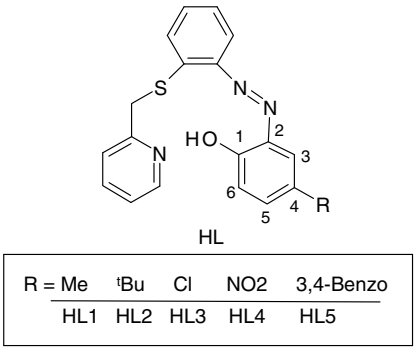

Fig. 1. The pyridylthioazophenols used as chelators.

ambient temperature. The product was collected by washing with cold MeOH–H_2O and dried. The pure crystallized product was obtained from methanol–dichloromethane. Yield 80–85%.

2.3. Synthesis of $[Ni(L)(N_3)]_2$

The preparation follows a common procedure. To a methanolic solution (15 mL) of HL1 (0.335 g, 1.0 mmol), nickel nitrate hexahydrate solution (1.0 mmol) was added dropwise and the resulting solution stirred for a period of 1 h. To this solution an aqueous solution of sodium azide (1.0 mmol) was added and stirring was continued for another 3 h. The volume of the solution was reduced at room temperature by slow evaporation. The product was collected by washing with cold MeOH–H_2O, and dried. The pure crystallized product was obtained from methanol. Yield 80–85%.

2.4. X-ray crystal structure analysis

Single crystals of **1a** suitable for X-ray work were grown by slow evaporation of a solution of complex **1a** in acetonitrile:benzene (1:1), while **2a** was grown by slow evaporation of a solution of complex **2a** in methanol:acetonitrile (2:1) at 298 K. Data of **1a** were measured with Mo Kα radiation using the MARresearch Image Plate System. Data analysis was carried out with the XDS program [16a] to provide 5133 independent reflections. The structure was solved using direct methods with the SHELX 86 program [16b]. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. The structure was refined on F^2 using SHELXL [16c] to $R = 0.0951$, $wR_2 = 0.1945$ for 2736 reflections with $I > 2\sigma(I)$, having goodness of fit value of 1.033.

A suitable single crystal of complex **2a** was mounted on a Bruker SMART CCD diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The intensity data were corrected for Lorentz and polarization effects. A total 14227 (unique data = 6911; $R_{int} = 0.036$) reflections were measured and 5482 reflections were observed applying the condition $I > 2\sigma(I)$. The structure was solved by Patterson syntheses and followed by successive Fourier and difference Fourier syntheses. Full matrix least squares refinements on F^2 were carried out using SHELXL-97 with anisotropic displacement parameters for all non-hydrogen atoms in all cases. The refinement converged to residual indices $R = 0.056$; $wR_2 = 0.1528$ with $I > 2\sigma(I)$. Complex neutral atom scattering factors [17a] were used throughout. All calculations were carried out using SHELXS 93 [17b], SHELXL 97 [17c], PLATON 99 [17d] and ORTEP3 [17e] programs.

3. Results and discussion

3.1. Syntheses

The ligands, having NSNO donor centres, act as tetradentate monobasic chelators in complexation with nickel(II) in both series of complexes. Complexes (**1**) of these ligands were obtained by their reaction with equimolar amounts of nickel(II)chloride salts in methanol. Complexes (**2**) were isolated by adding aqueous sodium azide solution to the reddish coloured reaction mixture of nickel nitrate and the pyridylthioazophenolate at ambient temperature. All the complexes are soluble in common organic solvents except in ether and hexane. The conductivity measurements of the complexes **1** and **2** in methanol suggest that they exist as non-electrolytes. The magnetic moment studies at room temperature show that the complexes of both series (**1** and **2**) are paramagnetic in nature.

The IR spectra of all the complexes (**1** and **2**) show no characteristic IR bands around 3300 cm^{-1} for O–H of the H-bonded phenolic-OH of the ligand systems. This indicates coordination of the oxygen to the metal centre [12]. The $\nu_{N=N}$ mode of the free ligand (1495–1505 cm^{-1}) is shifted to lower wavenumbers ($\Delta \sim 20$–30 cm^{-1}) in the complexes, suggesting coordination of the metal ions to the azo function. The $\nu_{N=N}$ band is observed at 1465–1478 cm^{-1} for all the complexes. In addition to this, ν_{C-S} at 790 cm^{-1} for the ligands shifts to 760 cm^{-1} for the complexes **2**, and they also display a new strong stretching band at 2063 cm^{-1} which suggests the existence of end-on bridging modes in **2** [18].

The solution electronic spectra of the complexes in methanol were obtained at room temperature and the data are tabulated in Table 2. The bands lower than 400 nm are due to intramolecular $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions for the aromatic ring. The absorption band at *ca.* 530 nm is assigned to the phenolate-O → Ni(II) charge transfer (LMCT) [19]. In octahedral nickel(II) complexes, three spin allowed transitions are expected from the energy level diagram for d^8 ions due to $^3A_{2g} \rightarrow {}^3T_{1g}$ (P), $^3A_{2g} \rightarrow {}^3T_{1g}$ (F), $^3A_{2g} \rightarrow {}^3T_{2g}$ transitions, which are observed at low to high wavelengths, respectively [20]. The transitions due to $^3A_{2g} \rightarrow {}^3T_{1g}$ (P) and $^3A_{2g} \rightarrow {}^3T_{1g}$ (F) are probably within the peaks at *ca.* 345 nm and *ca.* 530 nm, respectively. However, the intensity of the peak at around 854 nm observed in **1** due to the $^3A_{2g} \rightarrow {}^3T_{2g}$ transition is very low while in **2** a band in this region is not obtained.

3.2. Crystal structures of the Ni(II) complexes *1a* and *2a*

Perspective drawings of **1a** and **2a** with the atomic-numbering scheme are shown in Figs. 2 and 3, respectively. The crystallographic data and selected bond distances and angles are listed in Tables 3 and 4. Both crystals are of the triclinic system.

In **1a**, the two nickel(II) ions are bridged by two chloride ions in a μ-(1,1) fashion to form a Ni(II)–Ni(II) dinuclear entity in the solid state. Here each Ni(II) is octahedrally coordinated with two chloride, one pyridinic-N and one azo-N in a plane, along with thioether-S and phenolic-O in the axial positions. The molecule has a centre of symmetry and the bridging parallelogram is constructed

Symmetry elements, $1: $1 - x, 2 - y, 1 - z$; $2: $-x, 1 - y, 1 - z$ and $3: $2 - x, -y, -z$.

by $Ni_2N_2Cl_2$ motifs with two unequal bond distances Ni1–Cl2 [2.430(3) Å] and Ni1–Cl2 [2.455(3) Å] and which are longer than that of normal Ni–Cl bond [2.270 Å] [9,10]. The bridging angles are Ni1–Cl–Ni1, 90.85(2)° and Cl2–Ni1–Cl2, 89.15(10)°, with a non-bonding Ni–Ni distance of 3.48 Å. The bridging angle Ni–Cl–Ni is shorter than other reported chloro-bridged Ni(II) complexes [9–11]. The bond Ni1–N25 (azo) [2.000(7) Å] is little bit shorter than Ni1–N11(pyridinic) [2.038(8) Å], though the two nitrogen donors are not the same.

There are two independent centrosymmetric dimers and one water molecule in the solid-state structure of **2a**. The two dimers have similar geometries. In every dimer unit, two nickel(II) ions are octahedrally coordinated with two azide-N, one pyridinic-N and one azo-N in a plane along with thioether-S and phenolic-O in the axial positions. The dimer has a centre of symmetry and the bridging parallelogram is constructed by $Ni_2N_2\{N(azido)\}_2$ motifs. The bridging angles are Ni(1)–N(4)–Ni(1)$2 100.6(1)° and N(4)–Ni(1)–N(4)$2 79.4(1)° in one molecule, with equivalent angles of 97.9(1) and 82.1(1)° in the second molecule, with Ni–Ni distances of 3.16 and 3.24 Å. The azide (N_3) bridges two nickel centres in a μ-(1,1) fashion, as predicted from the IR study. The two Ni(1)–N(4) (azide) bridging bond lengths are 2.096(3) and 2.115(4) Å in one molecule and 2.083(3) and 2.108(4) Å in the other, values which are similar to those found for Ni(1)–N(1) (pyridinic) [2.115(4), 2.077(3) Å] but longer than Ni(1)–N(2) (azo) [2.026(3), 2.017(3) Å].

3.3. Magnetic behaviour

Magnetic susceptibility data (Table 1) for **1** and **2** are in the range 1.96–2.09 BM and 2.06–2.17 BM per Ni(II) ion, respectively. These values are relatively low compared with other Ni(II) (d^8) complexes. This may be due to a ferromagnetic interaction which results from the closeness of the bridging angles to 90° (Ni1–Cl–Ni1, 90.85(2)° and Cl2–Ni1–Cl2, 89.15(10)°) and relies on quasi-orthogonal magnetic orbitals [10,11d,11e]. The bridging angle (Ni1–Cl–Ni1) is very close to 90° which is the prime factor and is a favourable condition for good ferromagnetic coupling due to the interaction between two d^8 ions in an octahedral environment having M–X–M bridging than the otherwise much weaker interactions for such halogen-bridged systems.

4. Supplementary data

CCDC 609504 and 609505 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Mixed halide–dicyanamide polymers
Crystal structures
Luminescence property

ABSTRACT

A series of mixed halide–dicyanamide and halide complexes of cadmium(II) mediated by 2-aminoalkyl-pyridine ligands [2-aminomethylpyridine (ampy) and 2-aminoethylpyridine (aepy)] have been synthesized. Five of them, $[CdCl(dca)(aepy)]_n$ (**1**), $[CdBr(dca)(ampy)]_n$ (**2**), $[CdCl(dca)(ampy)]_n$ (**3**) (dca = dicyanamide); $[CdI_2(aepy)]_n$ (**4**), and $[CdI_2(ampy)]_n$ (**5**), (dca = dicyanamide) have been characterized by X-ray single crystal structure analysis. The structural determination shows that the compounds are 1D coordination polymers, with the exception of **3** that gives origin to a 2D sheet-like network. The ampy and aepy ligands (also with the occurrence of dca anions in **1**–**3**) reveal to be useful ancillary fragments for the construction of unprecedented Cd–halide polymeric species. The crystal packing shows that the dimensionality of all compounds is enlarged to 2D, and 3D in the case of complex **3**, through π–π interactions occurring between the pyridine rings. All the species exhibit interesting luminescence property in solution as well in solid state which is originated from ligand-centered π–π^* transitions. The fluorescence band maxima and fluorescence efficiency (in methanol) are found to be dependent not only on the pyridine ligand but also on the type of halide, and the co-ligand. Solid state luminescent study implies that π–π interactions occurring between pyridine rings are also important in controlling the fluorescence intensity. Amongst the synthesized complexes reported, complex **5** exhibits the highest fluorescence efficiency in methanol.

1. Introduction

Cadmium(II) based metal–organic coordination networks (MOCNs) that extend "infinitely" into one, two or three dimensions (1D, 2D and 3D, respectively), *via* more or less covalent metal–ligand bonding, have been the subject of great interest in recent years owing to their potential application in catalysis, optical properties evolution, clathration, *etc.* [1–5]. The special behavior of cadmium(II) lies on its d^{10} configuration and softness which permit a wide variety of geometries and coordination numbers. Coordination polymers of cadmium(II) have been exploited by using organic ligands as well as coordinating anions (*e.g.*, Cl^-, Br^-, I^-, SCN^-, N^{3-}, $SeCN^-$, $N(CN)_2^-$) [6–20], which are an integral part of the resulting polyhedra. The ligands, as well as the anions, are observed to control the structural diversity and stereochemistry of the cadmium(II) centre and consequently the physical and chemical properties of the species. In presence of pyridine-type ligands coordination polymers of cadmium(II) are observed to exhibit interesting luminescence property and many of such species have been investigated in order to explore the possibility of their application in sensor technology and electroluminescent devices [21–37]. Pyridine and its derivatives are generally non luminescent but their coordination polymers, especially with Cd(II), may exhibit luminescence properties. Moreover, these species possess the ability of affecting the emission wavelength of organic materials upon metal coordination. To the best of our knowledge no investigation has been carried out to rationalize the role of halides and dicyanamide on the structure and luminescence properties of Cd(II)(2-aminoalkyl-pyridine) systems. Thus we report herein the synthesis and characterization of a series of mixed halide–dicyanamide and of halide complexes of cadmium(II) mediated by 2-aminoalkyl-pyridine ligands [2-amino-

doi:10.1016/j.poly.2008.04.047

methylpyridine (ampy) and 2-aminoethylpyridine (aepy)], with the aim to investigate systematically the role of the halide, dicyanamide and organic ligands having different chelating ring. The latter molecules intervene on the structural motif topology of the coordination polymers, as well as on the luminescence property that was investigated in solution as well as in the solid state.

2. Experimental

2.1. Materials

High purity (2-aminomethyl)pyridine (ampy) and 2-(aminoethyl)pyridine (aepy) were purchased from Fluka and Lancaster Chemical Company Inc., respectively. Cadmium(II) chloride, cadmium(II) bromide tetrahydrate and cadmium(II) iodide were purchased from Aldrich Chemical Company Inc. and used as received. Sodium dicyanamide was purchased from Fluka. All other chemicals were of AR grade.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer and cadmium (II) content was estimated gravimetrically. Infrared spectra were recorded on KBr disks (400–4000 cm^{-1}) with a Perkin–Elmer RXI FTIR spectrophotometer. UV–Vis spectra were measured on a Hitachi U-3501 spectrophotometer. Fluorescence spectra of the complexes were recorded in solid powder state with a Perkin–Elmer model LS 55 Luminescence spectrometer. The fluorescence spectra of ligands and the complexes are also recorded in solution using methanol as a solvent.

2.3. Synthesis of the complexes

2.3.1. $[CdCl(dca)(aepy)]_n$ (**1**)

A methanolic solution (5 mL) of aepy (0.122 g, 1 mmol) was slowly poured drop wise into a hot methanolic solution (10 mL) of cadmium(II) chloride (0.183 g, 1 mmol). Sodium dicyanamide (0.178 g, 2 mmol) dissolve in water (1 mL) added dropwise to it. The resultant mixture was stirred for 2 h and filtered. The filtrate was kept in $CaCl_2$ containing desiccator. The colorless single crystals suitable for X-ray analysis were obtained from the filtrate after few weeks. Yield 75%. *Anal. Calc. for $C_9H_{10}CdClN_5$: C, 32.13; H, 2.97; N, 20.83. Found: C, 32.12; H, 2.96; N, 20.82%. IR data:* ν = 3281 (s), 3171 (m), 2938 (m), 2884 (w), 2270 (m), 2209 (w), 2151 (s), 1606 (s), 1483 (w), 1442 (s) cm^{-1}.

2.3.2. $[CdBr(dca)(ampy)]_n$ (**2**)

It was synthesized by adopting the same procedure as in case of **1** using cadmium(II) bromide tetrahydrate and ampy (0.108 g, 1 mmol) replacing aepy. The yellow-colored single crystals suitable for X-ray analysis were obtained from the filtrate after few weeks. Yield 76%. *Anal. Calc. for $C_8H_8CdBrN_5$: C, 26.19; H, 2.18; N, 19.09. Found: C, 26.15; H, 2.16; N, 19.08%. IR data:* ν = 3337 (w), 3274 (m), 2925 (w), 2288 (m), 2231 (w), 2158 (s), 1598 (s), 1482 (w), 1436 (s) cm^{-1}.

2.3.3. $[CdCl(dca)(ampy)]_n$ (**3**)

It was synthesized following the same procedure as in case of **1** using ampy ligand (0.108 g, 1 mmol) instead of aepy. The colorless single crystals suitable for X-ray analysis were obtained from the filtrate after few weeks. Yield 78%. *Anal. Calc. for $C_8H_8CdClN_5$: C, 29.80; H, 2.48; N, 21.73. Found: C, 29.81; H, 2.46; N, 21.74%. IR data:* ν = 3358 (m), 3300 (w), 2932 (w), 2277 (m), 2233 (w), 2160 (s), 1598 (s), 1482 (w), 1433 (m) cm^{-1}.

2.3.4. $[CdI_2(aepy)]_n$ (**4**)

It was synthesised following the same procedure as in case of **1** using cadmium(II) iodide (0.366 g, 1 mmol) instead of cadmium(II) chloride. However dca was not incorporated in the crystal structure. The yellowed-colored single crystals suitable for X-ray analysis were obtained from the filtrate after few days. Yield 97%. *Anal. Calc. for $C_7H_{10}CdI_2N_2$; C, 17.20; H, 2.05; N, 5.73. Found: C, 17.19; H, 2.04; N, 5.73%. IR data:* ν = 3298 (s), 3234 (m), 2923 (m), 2877 (m), 1598 (s), 1566 (s), 1480 (s), 1436 (s) cm^{-1}.

2.3.5. $[CdI_2(ampy)]_n$ (**5**)

It was synthesised following the same procedure as in case of **4** using ampy (0.108 g, 1 mmol) instead of aepy. Here also dca was not incorporated in the crystal. The yellowed-colored single crystals suitable for X-ray analysis were obtained from the filtrate after few days. Yield 95%. *Anal. Calc. for $C_6H_8CdI_2N_2$: C, 15.17; H, 1.68; N, 5.90. Found: C, 15.16; H, 1.67; N, 5.91%. IR data:* ν = 3295 (s), 3242 (m), 2922 (m), 2870 (w), 1600 (s), 1566 (s), 1479 (s), 1434 (s) cm^{-1}.

2.3.6. $[CdBr(dca)(aepy)]_n$ (**6**)

It was synthesised by adopting the same procedure as in case of **1** using cadmium(II) bromide tetrahydrate (0.344 g, 1 mmol), instead of cadmium(II) chloride. The yellow-colored crystalline solid were obtained from the filtrate after few weeks. Yield 86%. *Anal. Calc. for $C_9H_{10}CdBrN_5$: C, 28.39; H, 2.63; N, 18.40. Found: C, 28.37; H, 2.61; N, 18.38%. IR data:* ν = 3335 (w), 3275 (w), 2943 (w), 2885 (w), 2291 (m), 2234 (w), 2159 (s), 1601 (s), 1482 (w), 1443 (s) cm^{-1}.

2.3.7. $[CdCl_2(ampy)]_n$ (**7**)

A methanolic solution (5 mL) of ampy (0.122 g, 1 mmol) was poured slowly dropwise into a hot methanolic solution (10 mL) of cadmium(II) chloride(0.183 g, 1 mmol). The resultant mixture was stirred for 2 h and filtered. The filtrate was kept in $CaCl_2$ containing desiccator. The colorless solid was obtained from the filtrate after few days. Yield 75%. *Anal. Calc. for $C_6H_8CdCl_2N_2$: C, 24.70; H, 2.74; N, 9.60. Found: C, 24.68; H, 2.73; N, 9.59%. IR data:* ν = 3305 (s), 3265 (m), 2925 (m), 2874 (w), 1685 (s), 1600 (s), 1472 (s), 1431 (s) cm^{-1}.

2.3.8. $[CdBr_2(ampy)]_n$ (**8**)

This was synthesised by adopting the same procedure as in case of **7** using cadmium(II) bromide tetrahydrate (0.344 g, 1 mmol), instead of cadmium(II) chloride. The light yellow solid was obtained from the filtrate after few days. Yield 78%. *Anal. Calc. for $C_6H_8CdBr_2N_2$: C, 18.93; H, 2.10; N, 7.36. Found: C, 18.96; H, 2.13; N, 7.38%. IR data:* ν = 3298 (s), 3256 (m), 2921 (m), 2870 (w), 1667 (s), 1596 (s), 1476 (m), 1435 (s) cm^{-1}.

2.4. X-ray data collection and structure determination

Diffraction data for the structures **1**–**5** were carried out on Bruker Smart Apex CCD diffractometer with Mo Kα radiation (λ = 0.71073 Å) by using ω–ϕ scan method. Cell refinement, indexing and scaling of the data sets were carried out using Bruker SMART and Bruker SAINT programs [38]. All the structures were solved by direct methods and Fourier analyses [39] and refined by the full-matrix least-squares method based on F^2 with all observed reflections [39]. All the calculations were performed using the WinGX System, Ver 1.64.05 [40]. Crystallographic data are given in Table 1.

3. Results and discussion

In order to synthesize the desired mixed halide–dicyanamide Cd(II) compounds containing 2-aminomethylpyridine (ampy) or

[b] The high residuals for **5** (close to iodine atoms) is due to the low crystal quality.

2-aminoethylpyridine (aepy) ligands, the Cd(II)X_2, Na(dca) and 2-aminoalkyl-pyridine ratio was maintained 1:2:1 in all cases. On the other hand, for cadmium–halide-2-aminoalkyl-pyridine compounds, the Cd(II)X_2 and 2-aminoalkyl-pyridine ligand ratio was kept just 1:1. The solvent used in all cases was methanol. Any attempt to synthesize the $[Cd(aepy)X_2]_n$ (X = Cl and Br) and $[CdI_2(ampy/aepy)(dca)]_n$ complexes failed. Since Cd(II) is a soft centre, having an inherent tendency to bind with soft anion like I^- more preferably than with hard nitrogen donor site of dca, this may represent the reason of our failure in synthesizing the $[CdI_2(ampy/aepy)(dca)]_n$ species. However, we are not convinced why $[Cd(aepy)X_2]_n$ (X = Cl and Br) did not form under the indicated reaction conditions and our efforts to synthesize these species are still underway.

3.1. Crystal structure description of complexes *1* and *2*

The crystallographic investigation of compounds **1** and **2** reveals topologically similar 1D polymers with a stair like fashion, built up by -Cd(aepy)-dca- (**1**) and -Cd(ampy)-dca- (**2**) chains, having collinear metal ions, connected by pairs of bridging halides that model the rungs (Figs. 1 and 2). The metal exhibits a distorted octahedral coordination geometry (Table 2), being chelated by the aminopyridine ligand, and in *cis* position the nitrogen donors from two different dca and two halides. The distortions of bond angles from the ideal geometry are greater in the case of **2** for the strained conformation held on chelation by the ampy ligand (chelating N(1)–Cd–N(2) angles of 85.76(8) and 72.29(12)°, respectively in **1** and **2**). All the coordination Cd–N bond distances, as well as the Cd–Cl ones, in **1** are close comparable. The correspondent figures in **2** manifest peculiar differences, the Cd–N(dca) bond lengths being slightly different, 2.317(3) and 2.356(4) Å, and the two Cd–Br bonds diverge by about 0.22 Å (2.9194(9) versus 2.696(1) Å). The metal–metal separation spanned by the *dca* anion in **1** and **2** is 7.404(2) and 7.522(2) Å, respectively, correspondent to the length of the crystallographic *a*-axis, that through the halide anions is 3.889(1) and 4.074(1) Å, respectively, in accord with the larger ionic radius for the bromide. The ampy and aepy ligands protrude

Symmetry codes: (′) $-x+1, -y, -z+1$, (″) $x-1, y, z$ (**1**); (′) $x-1, y, z$, (″) $-x+1, -y+1, -z$ (**2**); (′) $-x, -y+1, -z$, (″) $x-1/2, -y+1/2, z-1/2$ (**5**).

from the chains and the packing evidences adjacent polymers linked by π–π interactions with a zip arrangement to give origin to 2D layered structure. The centroid-to-centroid distance is 3.834 Å (**1**) and 3.769 and 4.002 Å (**2**).

3.2. Crystal structure description of complex *3*

The substitution of bromide in **2** with chloride led to a complex having the same stoichiometry $[CdCl(dca)(ampy)]_n$ (**3**), but a different dimensionality. The cadmium ion shows a distorted octahedral coordination sphere (ORTEP drawing, Fig. 3) with significantly different Cd–Cl and Cd–N(dca) distances, being 2.559(1), 2.740(1) Å, and 2.272(4), 2.403(4) Å, respectively. Moreover, the Cd coordination sphere has a different configuration with respect to that observed in the bromide derivative **2**, being the ampy amine nitrogen N(2) located *trans* to a chloride, the pyridine N(1) *trans* to a dca nitrile group (Fig. 3). It is worth of note the almost comparable coordination C≡N–Cd bond angles, of 145.4(4)° and 156.2(4)° (Δ = 11°), with respect to the two values measured in the 1D polymers of **1** and **2**, that differ by 30–40° (Table 1). The polymer results a tessellated 2D undulated layered arrangement of 4,4-net topology with centro-symmetric $Cd(Cl)_2Cd$ units, defining the nodes (separated by 9.627 Å), bridged by the dca anions (Fig. 4). The pyridine rings, which protrude from the layers (Fig. 4b), interact through π–π interactions (the centroid-to-centroid distance is 3.622 Å) giving origin to a 3D arrangement.

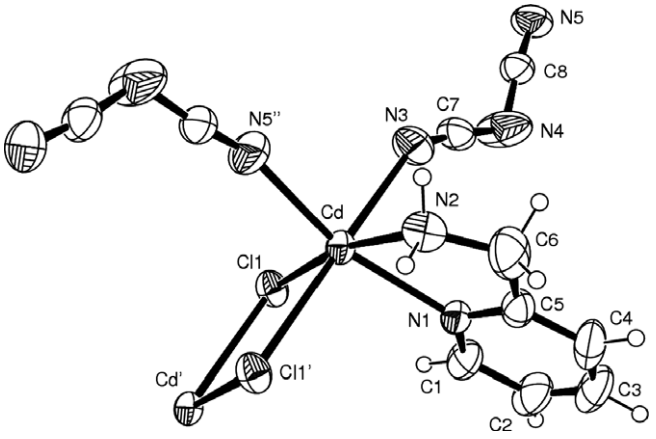

Fig. 3. Coordination sphere of Cd ion in compound **3** (ORTEP drawing, 40% probability ellipsoids).

3.3. Crystal structure description of complexes *4* and *5*

The labeled diagram of the polymeric compounds **4** and **5** are shown in Figs. 5 and 6, respectively, and a selection of bond lengths and angles is reported in Table 3. The structure of **4** consists of neutral zigzag chains, formed of Cd(aepy) units linked by double iodide bridges, which extend along the *a*-direction. The *cis*-octahedral sphere of Cd(II) shows significant distortions from the ideal values. The Cd–N distances are 2.355(4) and 2.261(4) Å, being longer that of the pyridine nitrogen donor, while the Cd–I ones fall in a range from 2.7891(7) to 3.2288(8) Å. The metal–metal distance along the chain is 4.342(1) Å and the Cd–Cd-Cd sequence form an angle of 125.48°. The Cd–I–Cd bridging angles are 87.309(12)° and 93.459(14)°. The following topology is well documented among structurally Cd–halide polymers, similar for example to the derivatives obtaining substituting aepy ligands with ethylene-1,2-diol [14] or by glycine [18,19]. The chains are associated into layers through π–π interactions occurring between py rings with a centroid-to-centroid distance of 4.195 Å. The polymeric chain of complex **5** comprises of Cd square pyramidal units being the metal chelated by the ampy ligand and by two iodide I(1) and I(2), the latter being at the apical position of the preceding metal coordination sphere. The Cd–N distances are 2.361(9) and 2.341(12) Å, the former referring to the pyridine donor, while the Cd–I(1) and the Cd–I(2) ones are 2.8234(15) and 2.9108(15) Å, being the shorter

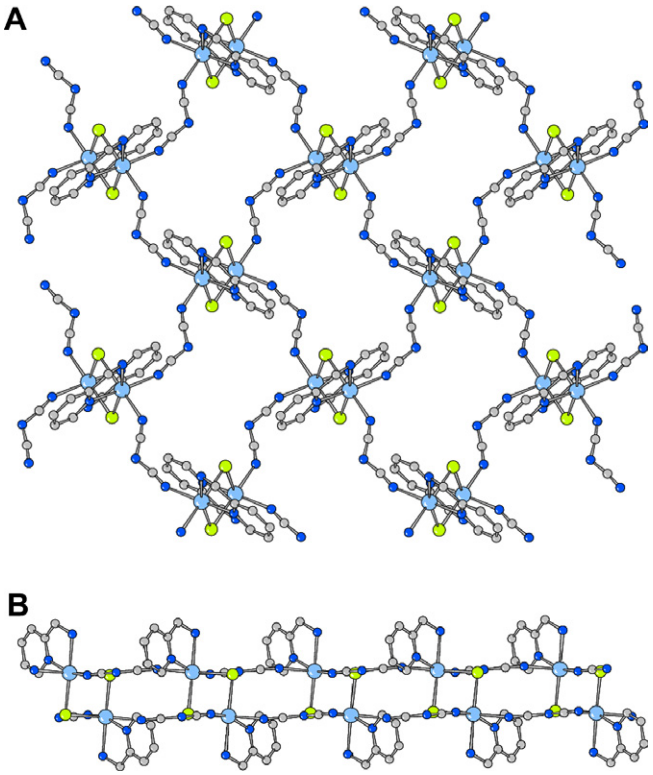

Fig. 4. 2D polymeric network of **3** view down *a*- and *b*-axis respectively.

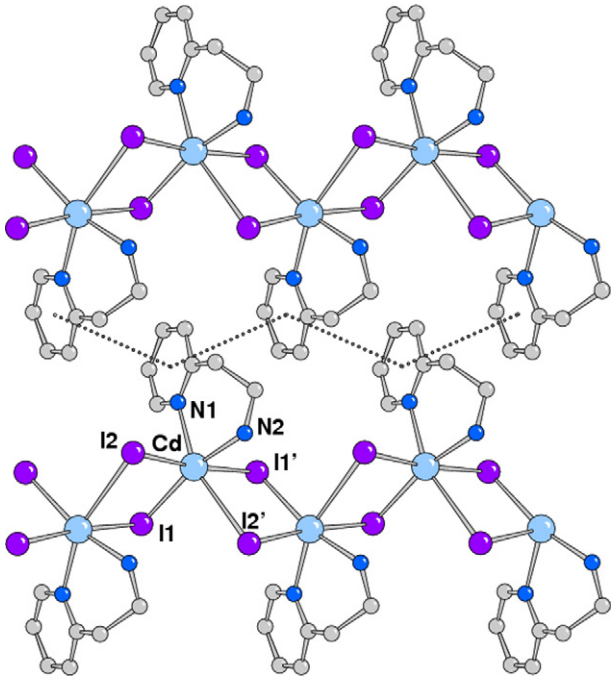

Fig. 5. Polymeric coordination chain of **4** developed along axis *c* zipped by π–π interactions occurring between py rings.

that of the monodentate iodo ligand, and the apical Cd–I(2′) is slightly longer, of 2.9669(18) Å. The small bite angle N(1)–Cd–N(2) of 72.2(4)°, and the N(1)–Cd–I(1), N(2)–Cd–I(2) angles of ca. 159°, are indicative of the severe distortions inside the coordination geometry about Cd(II), which is considerably displaced from the pyramid basal plane towards the apical I(2′) by ca. 0.38 Å. In the ribbon-like polymer the Cd–I(2″) distance (indicated by the dotted line, Fig. 6) is rather long (3.730(2) Å), although shorter than the sum of Van-der Waals atom radii. The separation between Cd ions bridged by I(2) is 4.463(1) Å (slightly longer than that measured in **4**), to which corresponds a Cd–I(2)–Cd angle of 98.81(3)°. The Cd–Cd-Cd angle along the polymer is 96.94(1)°. The dimensionality is augmented through π–π interactions occurring between py rings of adjacent chains. The alternating centroid-to-centroid distances are 3.870 and 4.060 Å. However, as apparent from Fig. 6 (as well as observed for **4,** Fig. 5), the py rings are not located face-to-face and the slippage is likely to induce a weak interaction.

3.4. Absorption and fluorescence properties

In methanol, the ligands ampy and aepy show their absorption band at ~335 and ~350 nm, respectively, simply corresponding to the aromatic pyridine moiety absorption. Usually this absorption is assigned to the n–π* type of transition of pyridine aromatic ring. Excitation of free ligands at 335 and 350 nm does not show any emission band. According to Khasa's rule, n–π* type of transition does not show fluorescence and can afford, at low temperature, phosphorescence instead. Secondly, the free rotation of amino group, single bonded to the pyridine ring, leads to energy dissipation through non-radiative channels. The absorption spectra of complexes either with ampy or aepy ligand show band maxima similarly to that observed for the free ligand (broad band centered at ~350 nm). Although free ligands, dca and CdX_2 (X = Cl^-, Br^- and I^-) are not luminescent, interestingly all the cadmium coordination complexes containing the py-ligands show intense fluorescence band upon excitation at the ligand's absorption band in solution (methanol) as well as in solid state. The appearance of fluorescence upon complex formation could be inferred to MO structure change in the complex compared to that of free ligand, the HOMO–LUMO n–π* type of forbidden transition in free ligand changes to π–π* type of HOMO–LUMO transition in the metal complex. Therefore, upon complexation the non-fluorescent free ligand favors fluorescence characteristic of the simple coordinated aromatic chromophore. In addition, the freely rotating amino group is constrained by the cyclic ring formation and the non-radiative channel through free rotation path results inhibited. Hence, all complexes show characteristics fluorescence. Figs. 7A and 7B represent the lumines-

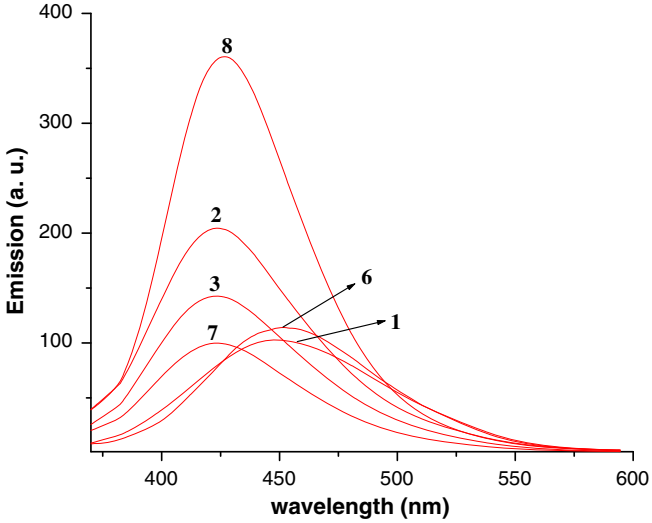

Fig. 7A. Emission spectra of **1–3** and **6–8** in methanol at room temperature.

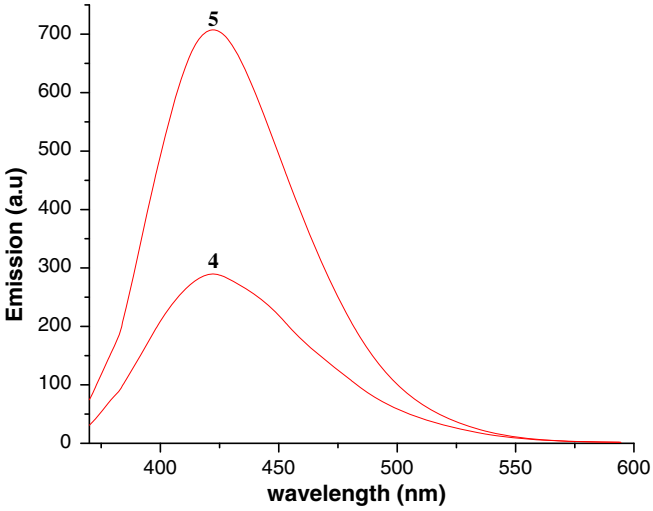

Fig. 7B. Emission spectra of **4** and **5** in methanol at room temperature.

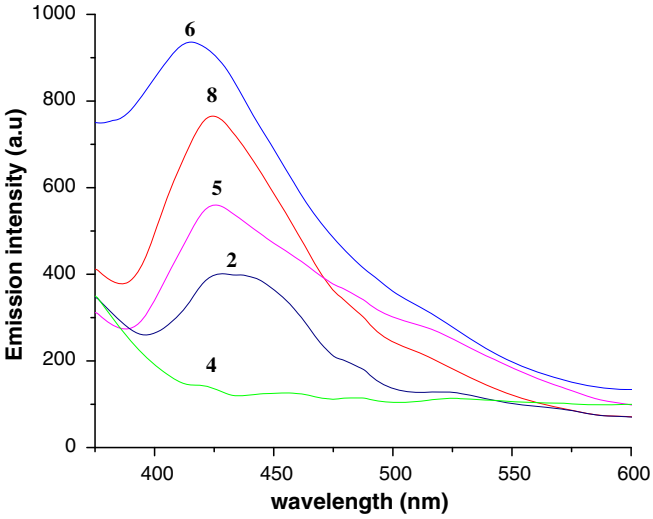

Fig. 8A. Emission spectra of **2, 4–6** and **8** in solid state at room temperature.

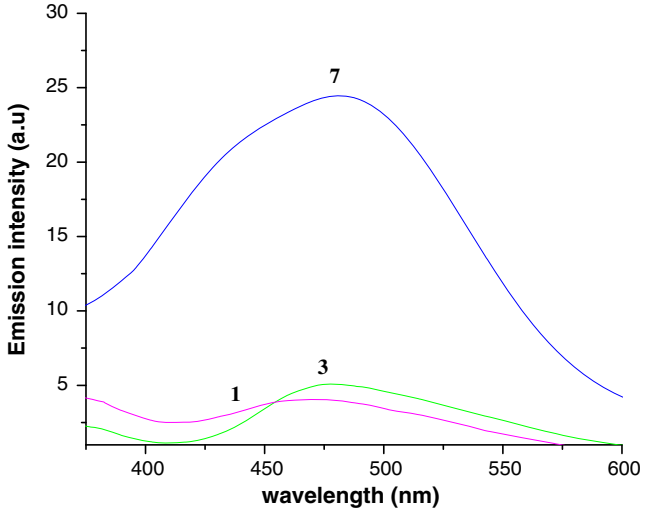

Fig. 8B. Emission spectra of **1**, **3** and **7** in solid state at room temperature.

cence spectra of complexes **1**–**8** in methanol and Figs. 8A and 8B depicted the same in the solid state. Structural investigation indicates the presence of effective π–π stacking amongst the pyridine ligands and the shortest π–π interaction is observed in complex **3** (3.622 Å) and the largest in **4** (4.195 Å). Usually π–π stacking can form H-aggregate (parallel type) or J-aggregate (ladder type) structures in the complexes, where the former generally gives rise to characteristic fluorescence. The π–π type H-aggregates, observed in our complexes; favor the intense fluorescence in them.

3.4.1. Effect of halides

One of the most significant observations in the present fluorescence study is the extraordinary high fluorescence efficiency exhibited by "iodo" ampy complex **5** in methanol (Fig. 7A; Table 4). The role of halides on the fluorescence efficiency of Cd–pyridine system under identical condition (entry complex **5**, **7** and **8**) is observed to follow the trend $I^- \gg Br^- \gg Cl^-$.

3.4.2. Effect of pyridine ligands and co-ligand, dca

The fluorescence band maxima as well as fluorescence efficiency are found to be dependent on the nature of the pyridine ligands. The present study shows that in the solid state complex with "ampy" (a ligand that forms a five-membered chelate) exhibits a red shift of the emission band in comparison with the correspondent "aepy" (a ligand that forms a six-membered chelate) complex (complex **1** & **3** and **2** & **6**). This indicates a stabilization of the energy level in the "ampy" complex more significant than in "aepy" complex. However, just opposite effect is noticed in methanol medium, i.e., complexes with "aepy" show red shifting. The effect of the co-ligand, dca is not very straight forward on

Table 4
Emission data for complexes **1–8** at room temperature in methanol and in the solid state

Complex	Emission λ_{max} (nm)		Quantum yield (φ_f) in methanol
	Solid	Methanol	
$[CdCl(dca)(aepy)]_n$ (**1**)	470	449	0.092
$[CdBr(dca)(ampy)]_n$ (**2**)	434	425	0.113
$[CdCl(dca)(ampy)]_n$ (**3**)	476	421	0.091
$[CdI_2(aepy)]_n$ (**4**)	Broad spectrum	422	0.161
$[CdI_2(ampy)]_n$ (**5**)	424	424	0.445
$[CdBr(dca)(aepy)]_n$ (**6**)	416	456	0.086
$[CdCl_2(ampy)]_n$ (**7**)	482	422	0.049
$[CdBr_2(ampy)]_n$ (**8**)	425	419	0.228

the fluorescence properties of the complexes. In absence of dca red shifting in solid state is observed when we compare complexes **3** and **7**, whereas, if we compare **2** and **8**, in presence of dca red shifting is noticed. Thus it is very difficult to rationalize the role of bridging co-ligand, dca on the fluorescence properties of Cd–pyridine system.

4. Conclusion

Cadmium (II) coordination polymers built up by halide have been widely reported, and the majority with bridging chloride [15]. However, the present compounds **1** and **2** are examples of an unprecedented topology. Conversely, Cd coordination polymers with Br [16–19] and I [20] are less common and only a few examples have been structurally characterized. As a comparison, the polymer reported by Wilkins et al. [20] is similar to compound **4** with cadmium centers bridged by pair of iodide atoms, but the metals are alternatively four- and six-coordinated (two dmso, O molecules are axially bound in the latter case). Thus the aminopyridine chelating molecule represents an ancillary ligand playing a key role in the construction of the present polymers. From our study it may be inferred that the luminescent property of coordination polymers of Cd(II)-pyridine system is largely controlled not only by pyridine ligand but also by the nature of the halide, and even by the co-ligand, dicyanamide. Further study is required to assess the luminescence phenomena in these types of complexes.

Supplementary data

CCDC 668324, 668325, 668326, 668327 and 668328 contain the supplementary crystallographic data for this paper. ABSTRACT

Reaction of manganese acetate and lanthanide nitrates in the presence of excess of PhCOOH affords highly asymmetric dodecanuclear mixed-metal $[Mn_{10}Ln_2(OH)(O)_8(PhCOOH)(PhCOO)_{19}]$ (Ln = Pr^{III} (**1**), Nd^{III} (**2**)) clusters. The similar reaction, but with only 2 equiv. of PhCOOH resulted in the compounds with higher nuclearity $[Mn_{11}Eu_4(O)_8(OH)_8(PhCOO)_{18}(NO_3)_2(H_2O)_6]NO_3 \cdot 4CH_3CN$ (**3**). Variable-temperature solid-state magnetic susceptibility of **1** and **2** in the temperature range 1.8–300 K were carried out, and for both complexes antiferromagnetic exchange interactions between the metal centers were observed, giving an estimated $S = 17/2$ ground state. AC magnetic susceptibility data have revealed out-of-phase signals, which suggest that these complexes exhibit a slow relaxation of magnetization as observed in single-molecule magnets.

1. Introduction

The efforts to produce large clusters with high-spin ground states and unusual magnetic properties have become of primary importance since the discovery of single-molecule magnets (SMMs) [1]. Currently, researchers are interested in synthesizing clusters with characteristic features that may increase the temperature at which the magnetization becomes blocked and the molecules exhibit magnetic hysteresis. Previously, the search for SMMs was based primarily on the use of 3d metals ions [2–5]. However, increasingly, other metal ions that exhibit high spin and single-ion anisotropy are being employed. Along these lines, lanthanide-containing molecules with strong spin-orbit interactions are very good candidates for SMM behaviour. Recently, the first SMMs containing mixed Mn^{III} (or Fe^{III}) and f-metals with different cores: Mn_6Dy_6 [6], $Mn_{11}Dy_4$ [7a], $Mn_{11}Gd_2$ [7b], Mn_5Ln_4 [7c], Mn_2Dy_2 [8], Fe_2Dy_2[9] and Fe_2Ho_2[9] were synthesized. All of them displayed frequency-dependent out-of-phase ac signals and for some of them magnetization hysteresis loops were reported [7–9]. As an extension of our previous work on Fe^{III} and Ln^{III} chemistry [10] we have now included Mn ions, in the quest to synthesize large Mn–Ln clusters examples of which are still limited in the literature.

In this paper we propose a simple and efficient procedure towards the isolation of high-nuclearity heterometallic complexes using simple manganese salts as a source of Mn^{III} ions: $[Mn_{10}Pr_2(OH)(O)_8(PhCOOH)(PhCOO)_{19}] \cdot 11CH_3CN$ (**1** · $11CH_3CN$), and $[Mn_{10}Nd_2(OH)(O)_8(PhCOOH)(PhCOO)_{19}]$ (**2**). Compounds **1** and **2** were obtained from the reaction of $Mn(CH_3COO)_2 \cdot 4H_2O$, with $Ln(NO_3)_3 \cdot 6H_2O$ (Ln = Pr^{III}, Nd^{III}) in the presence of excess of PhCOOH in yields of 64% and 60%, respectively. The similar reaction, but with only 2 equiv. of PhCOOH resulted in the compound $[Mn_{11}Eu_4(O)_8(OH)_8(PhCOO)_{18}(NO_3)_2(H_2O)_6]NO_3 \cdot 4CH_3CN$ (**3** · $4CH_3CN$) with the structure similar to $Mn_{11}Dy_4$ [7a].

2. Experimental

2.1. General considerations

All the reactions were carried out under aerobic conditions. Starting materials were obtained from commercial sources and used without further purification. Elemental analyses for C, H and N were carried out at the Institute for Inorganic Chemistry at the University of Karlsruhe.

2.2. Preparations

2.2.1. $[Mn_{10}Pr_2(OH)(O)_8(PhCOOH)(PhCOO)_{19}]$ (**1**) and $Mn_{10}Nd_2(OH)(O)_8(PhCOOH)(PhCOO)_{19}]$ (**2**)

Heating $Mn(CH_3COO)_2 \cdot 4H_2O$ (0.11 g, 0.45 mmol) with $Pr(NO_3)_3 \cdot 6H_2O$ or $Nd(NO_3)_3 \cdot 6H_2O$ (0.20 g, 0.45 mmol), with excess of PhCOOH (1.00 g, 8.20 mmol) in toluene (10 ml) under reflux for 20 min followed by cooling, evaporation at room temperature until dryness and recrystallizing from 10 ml of acetonitrile affords after 1 day a dark brown crystalline product, **1**, in 64% yield (**2**, in 60%). Elemental *Anal.* Calc. for $C_{140}H_{102}Mn_{10}O_{49}Pr_2$, **1** (dried): C, 49.46; H, 3.02. Found: C, 49.33; H, 2.87%. Elemental *Anal.* Calc. for $C_{140}H_{102}Mn_{10}O_{49}Nd_2$, **2** (dried): C, 49.36; H, 3.01. Found: C, 49.53; H, 2.81%.

2.2.2. $[Mn_{11}Eu_4(O)_8(OH)_8(PhCOO)_{18}(NO_3)_2(H_2O)_6]NO_3 \cdot 4CH_3CN$ (**3**)

This compound was synthesized using similar reaction, but with only 2 equiv. of PhCOOH. Yield: 60%. Elemental *Anal.* Calc. for $C_{126}H_{110}Mn_{11}N_3O_{67}Eu_4$, **3** (dried): C, 38.31; H, 2.80; N, 1.06. Found: C, 38.82; H, 2.56; N, 1.32%.

2.3. Physical measurements

The magnetic susceptibility measurements were obtained with the use of a Quantum Design SQUID magnetometer MPMS-XL. This magnetometer works between 1.8 and 400 K for dc applied fields ranging from −7 to 7 T. Measurements were performed on finely ground polycrystalline samples. *M* versus *H* measurements has been performed at 100 K to check for the presence of ferromagnetic impurities that has been found systematically absent. ac susceptibility measurements have been measured with an oscillating ac field of 3 Oe and ac frequencies ranging from 200 to 1500 Hz. The magnetic data were corrected for the sample holder and the diamagnetic contributions.

2.4. Crystal structure determination

X-ray data were collected for dry crystals of complexes **1** and **2**. In order to ensure that the space group and unit cell of compounds **1** and **2** were correct and to have better diffraction, new crystals were grown for **1** and a further unit cell was collected for crystals separated directly from mother-liquor, which gave slightly inflated cell dimensions to the first collection [a = 42.0114(7), b = 42.0114(7), c = 17.8066(6) Å, V = 31427.9(13) Å^3]. Diffraction intensity data for the new complex **1** were collected at 100 K on a Bruker SMART Apex CCD diffractometer using graphite-monochromated Mo Kα radiation. Complex **1** co-crystallizes with 11 acetonitrile solvate molecules.

X-ray data for complex **2** were collected with a Nonius Kappa CCD diffractometer using graphite-monochromated Mo radiation at 100 K. Some of phenyl rings show pronounced, partial disordering. Three of them were split into two orientations each and refined as rigid rings of idealized geometry. The resulting site occupation factors are between 40% and 60%. The temperature factors of the ring carbon atoms were kept constant at the arbitrarily set value U(iso) = 0.04. In final refinement cycles a maximum of about 2 e/Å^3 has been found and interpreted as a hydration water molecule of partial occupancy. The corresponding s.o.f. value refined to about 20% in the final cycles. All hydrogen atoms were put in calculated positions and included in final refinement as 'riding' on corresponding carbon atoms, with temperature factors set as 1.2 times U(iso) of the corresponding carbons.

X-ray crystallographic measurements for **3** were performed at 100 K using the same diffractometer as for **2**. Crystallographic data and refinement details are summarized in Table 1.

The unit cell determination confirmed that isomorphous with **1** and **2** compounds could be synthesized using salts of Sm^{III} and Eu^{III}. Attempts, to obtain crystals using salts of lanthanides from Gd^{III} to Lu^{III}, were unsuccessful.

3. Results and discussion

3.1. Structural analysis

The molecular structure of **1** and **2** were confirmed by single-crystal X-ray diffraction [11,12]. The compound **1** (Fig. 1) consists of two Pr^{III} ions, one coordinated by two O^{2-}, one OH^- ions and six benzoate O's (ninefold coordinate), the other by eight O^{2-}, one OH^- ions and one benzoate oxygen (tenfold coordinate); the mean Pr^{III}–O bond lengths are 2.54 and 2.58 Å, respectively. (Adopting $d[Pr^{III}–O] < 2.7$ Å as criterion for coordination). The 10 Mn^{III} coordination spheres are tetragonally elongated octahedral.

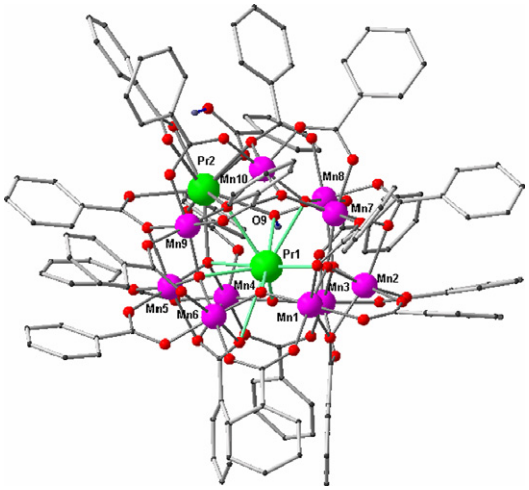

Fig. 1. Structure of the complex $[Mn_{10}Pr_2(OH)(O)_8(PhCOOH)(PhCOO)_{19}]$ (**1**); Pr (green), Mn (pink), C (black), and O (red). H atoms and solvent molecules have been omitted for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The Jahn–Teller radii, $R_{JT} = [\sum(R_i - \langle R\rangle)^2]^{1/2}$, vary between 0.29 and 0.66 Å, indicating differing degrees of distortion of the MnO_6 coordination spheres. Complex **2** is isomorphous with **1**. Hence, the structure of **1** is described in detail as representative for both compounds.

The central core of the complex **1** can best be described as a combination of distorted hexagonal pyramid (Mn_6Pr (Mn1, Mn2, Mn3, Mn4, Mn5, Mn6, Pr1)) (Fig. 2) and distorted tetragonal pyramid (Mn_4Pr (Mn7, Mn8, Mn9, Mn10, Pr2)) (Fig. 3) connected through six μ_4-O^{2-}, one μ_3-OH^- and six benzoates with different types of coordination of carboxylic groups. The six manganese atoms of the hexagon are not in a plane. The hexagon has a twist-boat conformation (Fig. 2, bottom) similar to cyclohexane. The Pr1 atom coordinates with ten Mn^{III} atoms through six μ_4-O^{2-}, two μ_3-O^{2-}, one μ_3-OH^- bridges and one μ-O of one carboxylate group. Thus, the coordination polyhedron may be best described as a distorted hexagonal bipyramid (capped from one side by one atom and from another part by a triangular cupola) (Fig. 2, top). The second Pr^{III} atom (Pr2) is nine-coordinated and situated in one corner of distorted tetragonal pyramid (Fig. 3) and interacts with one Pr^{III} and five Mn^{III} atoms through two μ_4-O^2, one μ_3-OH^-, two μ^3:η^2:η^1 and one μ:η^1:η^1(COO^-) bridges, with its geometry completed by one chelating $PhCOO^-$ anion and one monocoordinated PhCOOH molecule. The coordination polyhedron may be represented as a distorted, tricapped trigonal prism. The various bridging modes (μ^3:η^2:η^1, μ^4:η^2:η^2, μ^3:η^3:η^1, etc.) of the carboxylic groups give rise to the low symmetry of the structure.

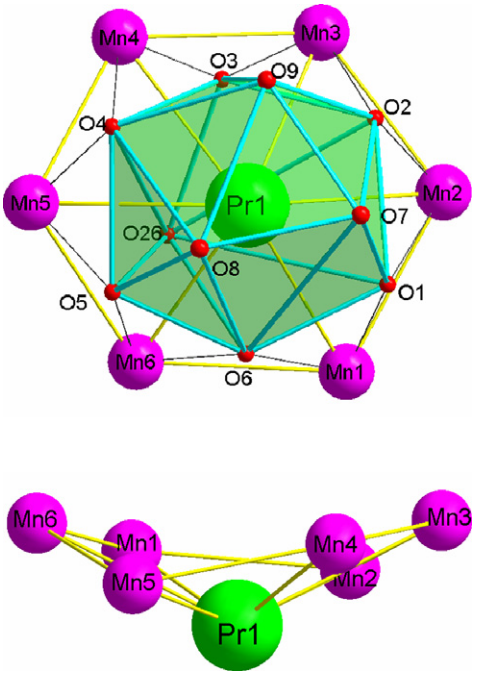

Fig. 2. The symmetry of environment (top) and twist-boat conformation (bottom) of Pr1 ion in compound **1**.

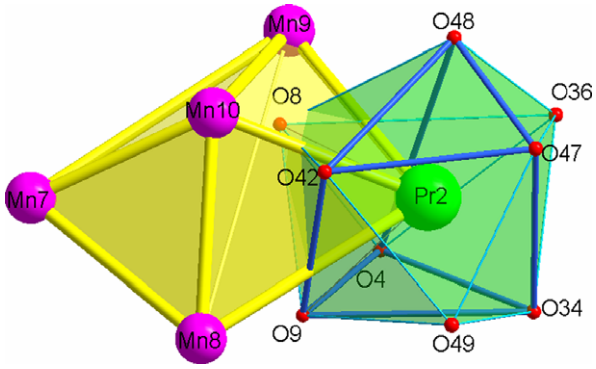

Fig. 3. Structure of pentanuclear unit (tetragonal pyramid $\{Mn_4Pr\}$) in **1** showing also the coordination environment of the Pr2 center.

The similar reaction as for **1** and **2**, but with 0.45 mmol of $Eu(NO_3)_3 \cdot 6H_2O$ and 0.90 mmol of benzoic acid resulted in the similar with $[Mn_{11}Dy_4(O)_8(OH)_6(PhCOO)_{16}(NO_3)_5(H_2O)_3] \cdot 15CH_3CN$ structure [7a] compound, the difference being only in number of nitrate groups and missing of methoxy groups: $[Mn_{11}Eu_4(O)_8(OH)_8(PhCOO)_{18}(NO_3)_2(H_2O)_6]NO_3 \cdot 4CH_3CN$ (**3**) (Fig. 4). In case of published $\{Mn_{11}Dy_4\}$ structure the O10w and O11w atoms correspond to one chelating NO_3^- group and O12 – to μ-OMe^- ion. In the structure of compound (**3**) the O10w and O11w atoms correspond to two water molecules and O12 – to OH^- anion. The charge of the whole molecule is balanced by two monodentate $C_6H_5COO^-$ anions coordinated to Eu2 and Eu2a, and one free NO_3^- anion.

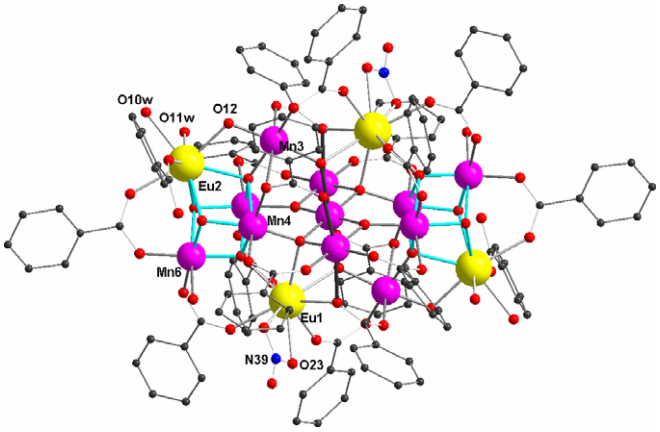

Fig. 4. Molecular structure of complex $[Mn_{11}Eu_4(O)_8(OH)_8(PhCOO)_{18}(NO_3)_2(H_2O)_6]NO_3 \cdot 4CH_3CN$ (**3**); Eu atoms are shown in yellow, Mn atoms in pink, C atoms in black and O atoms in red. H atoms are not shown. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

3.2. Magnetic properties of **1** and **2**

Solid-state dc magnetic susceptibility (χ_M) data for compound **1** were collected in the 1.8–300 K temperature range in a 0.01 T field. The room temperature $\chi_M T$ value (Fig. 5) of 33.37 $cm^3\ mol^{-1}$ K is close to that expected for 10 Mn^{III} ($S = 2$, $g = 2$) and two Pr^{III} ($S = 1$, $L = 5$, $^3H_4$) non-interacting ions (33.20 $cm^3\ mol^{-1}$ K). Upon decreasing the temperature it remains almost constant until at about 75.50 K, when it decreases to a small plateau near 26.50 $cm^3\ mol^{-1}$ K in the approximate range 10–20 K, followed by a sharp drop down to a value 22.06 $cm^3\ mol^{-1}$ K at 1.8 K. This behaviour indicates the presence of predominantly antiferromagnetic interactions within the cluster, reaching a non-diamagnetic ground state with a relatively high spin number.

Solid-state dc magnetic susceptibility (χ_M) data for compound **2**show a similar behaviour, although the room temperature $\chi_M T$ value, 32.92 $cm^3\ mol^{-1}$ K, is less than the value expected for 10 Mn^{III} ($S = 2$, $g = 2$) and two Nd^{III} ($S = 3/2$, $L = 6$, $^4I_{9/2}$) non-interacting ions of 33.27 $cm^3\ mol^{-1}$ K and remains almost constant until around 51.50 K when it decreases sharply down to a value of 22.61 $cm^3\ mol^{-1}$ K at 1.8 K (Fig. 5).

As compounds **1** and **2** have such high $\chi_M T$ values at low temperatures and contain a large number of anisotropic paramagnetic metal ions, we can view these two compounds as potential materials with unusual magnetic properties. In order to assess whether these molecules exhibit a slow relaxation of magnetization ac magnetic susceptibility measurements were performed. The measurements were carried out in the 1.8–10 K range under 3.5 G ac field oscillating at 200–1500 Hz. In the absence of external magnetic field complex **2** showed a weak signal with a low ratio χ'/χ'' frequency- dependent out-of-phase signal (Fig. 6), which could be the tail of a peak lying at a temperature below 1.8 K. It is however difficult to conclude if **2** is a SMM based on measurements down to 1.8 K, the limit of our instrument. Very low temperature studies would therefore be necessary. Studies along these lines and on other Ln-derivatives are the objective of future work.

We have tried to estimate the appreciative spin state using of the following Hamiltonian which allows fitting of the magnetization data for compound **2** with the ANISOFIT 2.0 program [13] implemented on the MATLAB platform and Brillion function [14]:

$$H = DS_z^2 + E(S_x^2 + S_y^2) + g_{iso}\beta SB,$$

where the β is the Bohr magneton and g, D, E, S, and B represent the Lande' g factor, the axial and rhombic zero-field splitting parameters, and the spin and magnetic field vectors, respectively. A comparison between experimental data, fitting data and simulation data by Brillion function is given in Fig. 7. The results show that the spin state can by estimated at 8.5 ± 1. The exact evaluation of

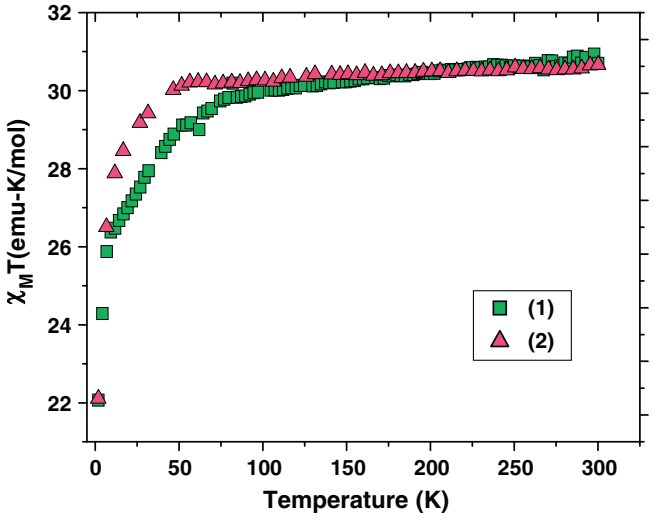

Fig. 5. $\chi_M T$ vs. T plot for complex **1** and **2** in a 100 G (0.01 T) applied dc field.

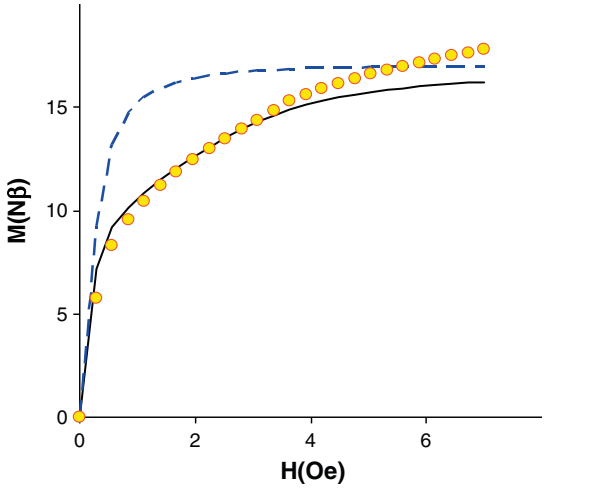

Fig. 7. Plot of magnetization at 1.8 K for compound **2** fitted by ANISOFIT 2.0 [13] program ($S = 8.5$, $g = 1.96$, $D = -0.23$ cm^{-1} $E = 0.002$) (solid line); and simulation by Brillion function ($S = 8.5$, $g = 2.0$) (dotted line).

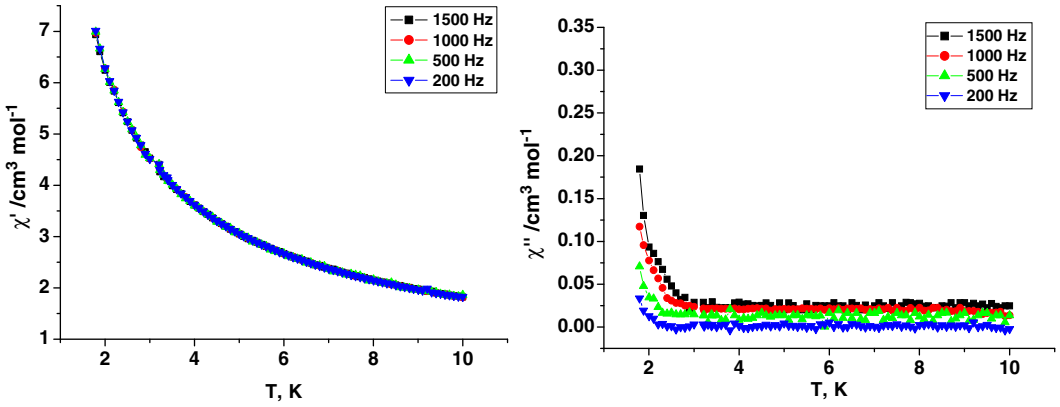

Fig. 6. Plots of the in-phase (χ') and the out-of-phase (χ''_M) ac susceptibility data for **2** under a zero static magnetic field and with different oscillating frequencies.

spin state is not possible due to spin orbital contribution from two Nd ions. The spin orbital contribution of two Nd ions was included in the approximate range of spin state ±1.

The magnetic data presented above suggest that predominantly antiferromagnetic exchange interactions are present within both types of clusters. The high nuclearity and presence of strong spin–orbit coupling effects in the **1** and **2** derivatives makes the fitting of the data to obtain Mn^{III}–Mn^{III}, Mn^{III}–Ln^{III} and Ln^{III}–Ln^{III} exchange parameters a largely unachieved task.

4. Conclusions

A convenient one step route for the synthesis of Mn–Ln polynuclear complexes is demonstrated. It is based on simple reaction between manganese acetate, lanthanide nitrates and benzoic acid. Other remarkable features of this method are successful isolation of target compounds by specific choice of benzoic acid concentration and appreciable yields and significant short reactions times. This opens a wide possibility for molecular construction of transition metal–lanthanide complexes with different nuclearity. Further experiments are underway to design such systems with other lanthanides and other carboxylate ligands, in view of enhancing SMM property.

5. Supplementary data

CCDC 666378, 666379 and 682544 contain the supplementary crystallographic data for **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Zero-field splitting

ABSTRACT

Two Re(IV)–Cu(II) heterometallic complexes $\{(CuL_\alpha)[ReCl_4(ox)]\}_n$ (where L_α = *N-meso*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$), **1**, and $(CuL_\beta)[ReCl_4(ox)]$ (L_β = *N-rac*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$*N-rac*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$), **2**, were synthesized. The $[CuL^{2+}]$ macrocyclic cation is coordinated from above and below by $[ReCl_4(ox)]^{2-}$ units through the chloro-ligands and creates a chloro-bridged heterometallic Re^{IV}–Cu^{II} one-dimensional zig-zag chain. Compound **2** can be viewed as a heterobimetallic dinuclear unit, in which the Re(IV)-Cu(II) centers are linked by an oxalato bridge.The magnetic behavior of **1** and **2** has been investigated over the temperature range 1.8–300 K. Compound **1** behaves like a ferrimagnetic {Re(IV)–Cu(II)} bimetallic, one-dimensional chain with intrachain antiferromagnetic coupling.Compound **2** shows a weak antiferromagnetic interaction within the [Re(IV)–Cu(II)] unit along with a strong single-ion anisotropy,D(Re) = −63 cm^{-1}.

1. Introduction

The search for new synthetic routes leading to polymetallic complexes is of current interest in modern inorganic chemistry [1]. One of the strategies to design polynuclear species is based on metals and organic building blocks. The building block approach was particularly developed in order to obtain heterometallic complexes with interesting magnetic, optical or electronic properties. It consists of the use of anionic complexes with potentially bridging ligands, which may interact with wide variety of assembling cations [2].

We are currently developing a synthetic approach aimed at obtaining polymetallic complexes by using the $[ReCl_4ox]^{2-}$ ion as a building block and macrocyclic-copper(II) ions as a cationic species.

Square-planar macrocyclic complexes of Cu(II) and Ni(II) with two free coordination sites at the metal atom are very attractive species in designing heterometallic complexes. Access to the metal ion is very easy when there are no substituents on the macrocyclic ring (like in the case of $[Cu(cyclam)]^{2+}$) presenting steric hindrance [3]. This situation changes with the size and character of the substituents. The position of the substituents around the equatorial nitrogen atoms of the ligands and the *N*-configuration of the macrocyclic ring influences the coordination mode of the polymetallic complexes, for instance, a simple dimeric form $(CuL)[Co(NCS)_4]$ [4], a trimeric unit $[NiL]_2[Mn(NCS)_4](ClO_4)_2 \cdot H_2O$ [5] or a chain structure $[CuL_\beta][ReCl_4(ox)]$ DMF [6].

Rhenium(IV), as a $5d^3$ ion, usually forms octahedral compounds; numerous types of hexachloro-, hexabromo- and hexaiodorhenate complexes have been throughly studied previously [7–9]. The substitution of two chloro-ligands for an oxalate group in the rhenium(IV) coordination sphere allows the synthesis of new heterodinuclear {Re(IV)–Cu(II)} complexes. The oxalate dianion is a common ligand which usually adopts a bidentate coordination mode when acting as a bridge between two metals. In fact, the coordination mode of the rhenium(IV) precursor, $[ReCl_4ox]^{2-}$ changes with the nature of the co-ligands in the coordination sphere of Cu(II), being monodentate in $[Cu(bpy)_2ReCl_4(ox)]$ and very asymmetric-bidentate in $[Cu(terpy)_2ReCl_4(ox)(H_2O)]$ [10]. The coupling between Re(IV) and Cu(II) can be of ferro- or antiferromagnetic nature; however, it is very weak in all cases because of the long Cu–O bonds and the bite angle of the oxalate ligand. Stronger coupling can be obtained when the ligand is coordinated in a symmetric-bidentate mode with two short Cu–O bonds.

In this paper, we present the synthesis, crystal structure and magnetic data over the temperature range 1.8–300 K for a coordination-unsaturated complex of copper(II) (Scheme 1) as well as of simple $[ReCl_4ox]^{2-}$ ions. It was also interesting to verify whether the geometry around the metallic centers and the electron spin

density exert an influence on the crystalline structure as well as on the magnetic properties.

2. Experimental

2.1. Materials

All materials used in this work were of reagent grade purity and were used as commercially obtained. The $[CuL](ClO_4)_2$ was prepared as previously reported [11].

2.2. Synthesis of the complexes

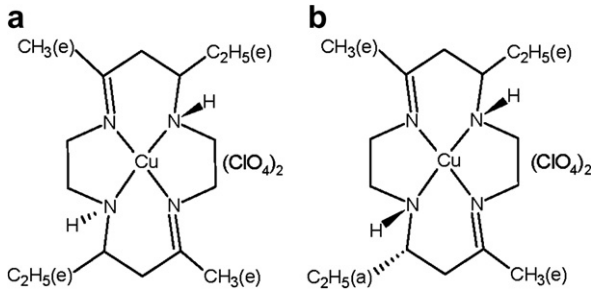
Both complexes were prepared by similar methods. A solution of $[CuL](ClO_4)_2$ (81.44 mg, 0.15 mmol) in CH_3CN (10 cm^3) was added dropwise to a solution containing $[Bu_4N]_2[ReCl_4(ox)]$ (135.14 mg, 0.15 mmol) in the same solvent. The mixture was subsequently stirred. After a few days, a dark-pink crystalline solid was formed by slow evaporation from the violet solution. It was filtered and washed using diethyl ether (10 cm^3, twice). Yield: 108.30 mg (95%). Red, rectangular prism-shaped crystals of $\{(CuL_\alpha)[ReCl_4(ox)]\}_n$ (**1**), suitable for X-ray diffraction studies, were obtained by slow evaporation of a solution of all the reagents in CH_3CN–DMF (1:1) at room temperature. *Anal.* Calc. for $C_{18}H_{32}Cl_4CuN_4O_4Re$ (760.02): C, 28.41; H, 4.49; N, 7.35; Cl, 18.61. Found for isomer α: C, 28.50; H, 3.76; N, 7.09; Cl, 18.78%; found for isomer β: C, 28.43; H, 4.56; N, 7.20; Cl, 18.70%. The copper and rhenium contents were determined by the ICP method: calc. Re, 24.40, Cu, 8.34; found for isomer α: Re, 23.84, Cu, 7.98%; found for isomer β: Re, 24.83, Cu, 8.10%.

The purity of the compounds was confirmed by IR spectra. The infrared spectrum for each complex exhibits bands at 1725vs, 1700vs, 1666m, 1319s and 800s cm^{-1} for **1** and 1718m, 1663s, 1375m and 800m for **2**, which are associated with the oxalato ligand. Complex **1** has a single medium intensity absorption band at approximately 970 cm^{-1}, whereas in complex **2** this band is split into a doublet at 980 and 1010 cm^{-1}.

UV–Vis [λ in nm (ε)]: complex **1**: 1261, 1088, 1069, 712, 660, 493, 370, 262; complex **2**: 1268, 1089, 1071, 718, 670, 497, 258.

2.3. Magnetic measurements

Magnetic measurements were performed using a Quantum Design SQUID-based MPMSXL-5-type magnetometer in the temperature range T = 1.8–300 K. The SQUID magnetometer was calibrated with a palladium rod sample (Materials Research Corporation, measured purity 99.9985%). Measurements were made at a magnetic field of B = 0.5 T. Corrections based on subtracting the sample-holder signal were made and a contribution to the underlying diamagnetism was estimated from Pascal constants [12].



Scheme 1. Schematic view of the macrocyclic-copper(II) complexes: (a) $[CuL_\alpha](ClO_4)_2$, (b) $[CuL_\beta](ClO_4)_2$.

2.4. X-ray crystallographic study

A red rectangular prism-shaped crystal was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and was used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at a temperature of 291.0(3) K, with the ω scan mode. The exposure time was 31 s and reflections inside the Ewald sphere were collected up to $2\theta = 50°$. The unit cell parameters were determined from 9999 strongest reflections. Examination of reflections on six reference frames monitored after each 10 frames measured showed 0.3% loss of the intensity. During the data reduction above, a decay correction coefficient was taken into account. Lorentz, polarization, and numerical absorption [13] corrections were applied. The structure was solved by the partial structure expansion procedure. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique on F^2. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent atom with geometric idealization after each cycle of refinement and individual isotropic displacement factors equal to 1.2 times the value of the equivalent displacement factor of the parent non-methyl atom and 1.5 times of parent methyl group carbon atom. The methyl groups were allowed to rotate about their local threefold axis. The SHELXS97 [14], SHELXL97 [15] and SHELXTL [16] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Results and discussion

3.1. Structural description

Details concerning the crystal data and refinement are given in Table 1. A perspective view of the structure of compound **1** occupying the asymmetric unit of the unit cell, together with the atom numbering scheme, is shown in Fig. 1. The methyl group indicated by the C(7) atom is disordered over two positions with 54:46 participation of the domains. The asymmetric unit includes a half of two macrocycles and a $ReO_4C_2Cl_2$ molecule. The copper atoms lie on inversion centers (special positions *b* and *e* of $P\bar{1}$ space group at 0, 0, 0.5 and 0.5, 0.5, 0, respectively [17]) and remaining atoms lie in general positions. The copper atoms are six coordinated by four macrocyclic nitrogen atoms and two rhenium bonded chlorine atoms.

The coordination polyhedra of the copper atoms can be described as almost ideal tetragonal bipyramid (the CuN_4moiety is planar by symmetry) with chlorine atoms in axial positions. Adopting a slightly disordered tetragonal bipyramid coordination, the rhenium atom is six coordinated by four chlorine atoms and two oxygen atoms of two carboxylic groups of oxalate substituents. The bridging chlorine atoms are located on opposite sides of the rhenium atom. The Cu–Cl distances (Table 2) are distinctly larger than the most common value of 2.293 Å, but lie in the typical range, 2.1–3.1 Å, observed for copper coordination compounds. The macrocycles conformations can be described as sc^-, sc^+, ap^-, ac^-, sc^-, ap^+, ap^+, sc^+, sc^-, ap^+, ac^+, sc^+, ap^-, ap^- and sc^+, sp^-, ap^+, ac^+, ac^+, ap^-, ac^+, sc^-, sp^+, ap^-, ac^-, ac^-, ap^+, ac^-, respectively, for the ligands bonded to the Cu(1) and Cu(2) atoms. The inversion center on the copper atoms expands the molecules to a one-dimensional zig-zag coordination polymer along the [11-1] crystallographic axis (Fig. 2).

In the structure medium strength N–H···Cl hydrogen bonds can be found (Table 3) [18], providing additional stabilization to the polymer chain. Additionally, a couple of weak C–H···O and C–H···Cl hydrogen bonds can be found in the structure (Fig. 3,

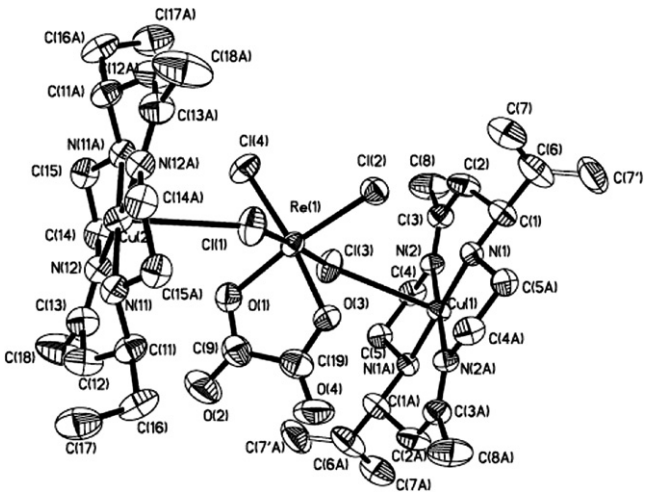

Fig. 1. The molecular conformation of the compound {[CuL][$ReCl_4$(ox)]} with the atom numbering, plotted with 50% probability displacement ellipsoids. The hydrogen atoms are omitted for clarity. The symmetry generated atoms are indicated by the "A" letter added after the atom number. The disordered methyl group is indicated by hollow connections.

Table 2) [19]. The shortest Cu(1)···Re(1) distances are 4.7177(3) Å and they exists in the polymer chain, a longer distance of 7.3517(5) Å occurs between polymer chains. These distances for the Cu(2)···Re(1) atoms are 4.6840(3) and 7.2964(6) Å, respectively.

3.2. Magnetic properties

In this section, the magnetic properties of compounds **1** and **2** are presented together with the analysis of the magnetic exchange interaction. Finally, an analysis of exchange pathways in **1** will be enlightened through spin density calculations using the DFT methodology.

Distances in Å, angles in °. [Symmetry transformations used to generate equivalent atoms: #1: $-x+1$, $-y+1$, $-z$; #2: $-x$, $-y$, $-z+1$.]

The magnetic susceptibility of complexes **1** and **2** is presented in terms of the product function $\chi_{mol}T$ in Fig. 4 between 1.8 and 300 K. The data for $[Bu_4N]_2[ReCl_4(ox)]$ is also included for comparison.

Complex **1** shows a typical 1D ferrimagnetic behavior. At room temperature $\chi_{mol}T$ = 2.09 cm^3 mol^{-1} K (μ_{eff} = 4.10 μ_B) and this value is expected for a magnetically non-interacting {Cu(II)–Re(IV)} entity with local spins S(Cu) = 1/2 and S(Re) = 3/2 (2.25 cm^3 mol^{-1} K, g = 2.0). As the temperature is lowered, the value of $\chi_{mol}T$ smoothly decreases and reaches a minimum at T = 25.0 K ($\chi_{mol}T$ = 1.72 cm^3 K mol^{-1}) corresponding to a short-range order state where the two uncoupled spins of the adjacent ions {Cu(II)–Re(IV)} exist. Below

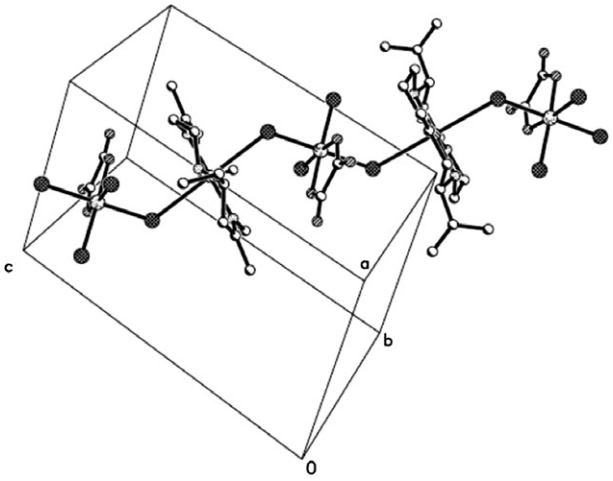

Fig. 2. The coordination polymer.

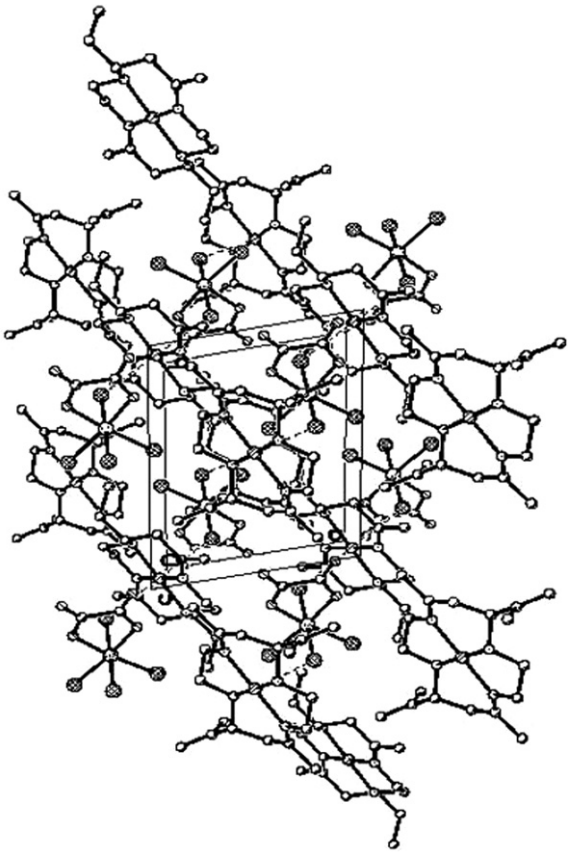

Fig. 3. Unit cell of **1** (H atoms of the macrocycle have been omitted for clarity).

this temperature the $\chi_{mol}T$ value increases and reaches a maximum at 7.0 K ($\chi_{mol}T$ = 1.87 cm^3 K mol^{-1}). Finally, it decreases abruptly between 7.0 and 1.72 K (see inset in Fig. 4). For $\chi_{mol}T$ values below the minimum, a ferrimagnetic ordering [20] in the chain exists. At very low temperatures an additional exchange interaction between the spins of the nearest neighboring chains causes the transition to a three-dimensional magnetic system.

The molar magnetic susceptibility of **1** shows an increase on cooling down to T = 5 K, where it passes through a maximum (Fig. 4, inset). The values of C and Θ determined from the relation $1/\chi_{mol} = f(T)$ over the 50–300 K range of temperatures are equal to C = 2.22 cm^3 mol^{-1} and Θ = −19.4 K, respectively. The negative value of the Weiss constant indicates an antiferromagnetic coupling.

In order to interpret the susceptibility data quantitatively, we approached it using a one-dimensional model in which the magnetic susceptibility in the high-temperature region of the examined compound may be described by two terms. The first contribution comes from the $^4A_{2g}$ term of the Re(IV) ions (with zero-field splitting), the second from the $^2T_{2g}$ term of the Cu(II) ions modified by a factor predicted from the Ising model of the magnetic exchange interactions and different local g values (g_{Cu} and g_{Re}) [14,15]. The relevant spin Hamiltonian is defined by the following equation (1) [21,22]:

$$\hat{H} = \sum_i \{ -J\hat{S}^z_{2i-1}\hat{S}^z_{2i} - j\hat{S}^z_{2i}\hat{S}^z_{2i+1} + 2D[(\hat{S}^z_{2i})^2 - 5/4] + \mu_B g_{Cu,\parallel} B_z \hat{S}^z_{2i-1} + \mu_B g_{Re,\parallel} B_z \hat{S}^z_{2i} + \mu_B g_{Cu,\perp}(B_x \hat{S}^x_{2i-1} + B_y \hat{S}^y_{2i-1}) + \mu_B g_{Re,\perp}(B_x \hat{S}^x_{2i} + B_y \hat{S}^y_{2i}) \} \quad (1)$$

where the total spins $S_{2i} = S_{Re}$ and $S_{2i-1} = S_{Cu}$; J is the isotropic exchange-coupling parameter between the Re(IV) and Cu(II) magnetic centers mediated by the chloro-donor; j is the exchange-coupling parameter through the oxalate oxygen atom, 2D is the energy gap between the ±3/2 and ±1/2 Kramers doublets of the Re(IV) center.

The least squares fit of the experimental data by this expression was limited to the range 20.0–300 K and leads to the following results: $2D$ = 126 cm^{-1}, g_{av}(Re) = 1.89, g_{av}(Cu) = 2.20 and J = −18.1 cm^{-1}, j = −0.72 cm^{-1}. The discrepancy factor, defined as $\lfloor R = \sum(\chi_{exp}T - \chi_{calc}T)^2 / \sum(\chi_{exp}T)^2 \rfloor$, is 2.05 × 10^{-5}. The calculated curve matches the magnetic data very well. It deserves to be noted that the 2D value is greater than that found for [Bu$_4$N]$_2$ReCl$_4$(ox) (2D = 53 cm^{-1}) [9]. These relatively large values of the D parameter for third-row transition metal ions reflect the large value of the spin–orbit splitting parameter ($\lambda \sim 1100$ cm^{-1} for the isolated Re(IV) ion).

The variation of the molar magnetization M_{mol} versus B at T = 2.0 K (Fig. 4, right), i.e. below the magnetic ordering, clearly supports the occurrence of spontaneous magnetic moments in complex **1**. As the magnetic field increases, the *M versus B* curve is linear up to 0.1 T, and then shows a sinusoidal variation before reaching saturation at a value of M_{sat} = 2.11 μ_B per rhenium–copper pair [20]. In such a case the ground state equals S_{max} = 1/2 + 3/2 = 2 and the magnetization (per {Cu–Re} unit) should saturate to the value of M_{sat} = 4.0 μ_B. The obtained value is substantially smaller and it evidences a sizable zero-field splitting for Re(IV) along with the antiferromagnetic exchange coupling between the Re(IV)···Cu(II) ions. For the compound [Bu$_4$N]$_2$ReCl$_4$(ox) the saturation magnetization adopts a value of M_{sat} = 1.60 μ_B (per Re atom).

At the first sight, the efficiency of the intrachain exchange pathways in complex **1** to mediate magnetic interactions is quite surprising. The literature data [6,10,23] reported a detailed description of the magnetic behaviour of heteropolynuclear complexes containing the [ReCl$_4$(ox)]$^{2-}$ ion as a building block. These compounds exhibit different coordination modes depending on the M(II) 3d metal ion and auxiliary ligand used to complete the coordination sphere: isolated dinuclear units in [ReCl$_4$(μ-ox)Mn(dmphen)$_2$] · CH$_3$CN [23]

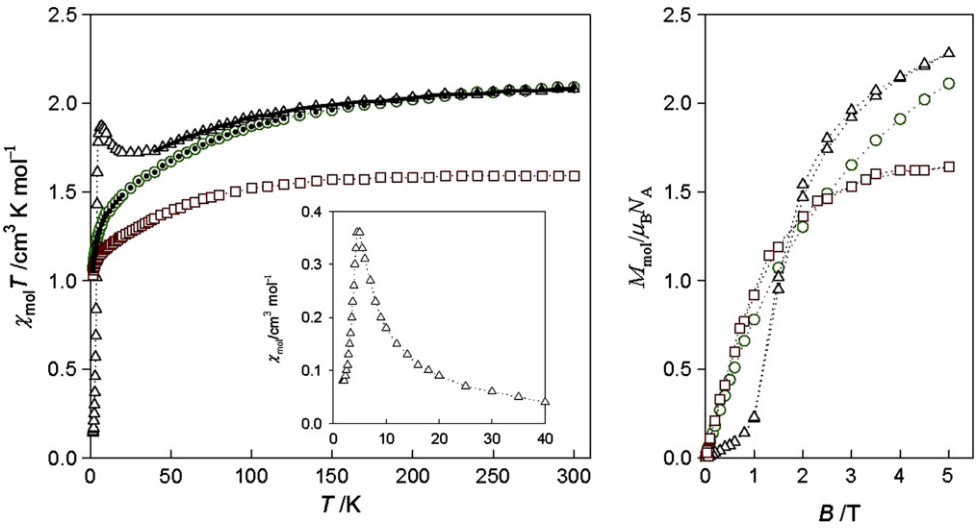

Fig. 4. Magnetic functions: (Δ, **1**) {[CuL_α][$ReCl_4$(ox)]}, (○, **2**) [CuL_β][$ReCl_4$(ox)] and (□) [Bu_4N]$_2$[$ReCl_4$(ox)]. Solid line – calculated curve. Left – temperature dependence of the product function; right – molar magnetization. Inset – the magnetic susceptibility for **1**.

and infinite chains in [CuL_β][$ReCl_4$(ox)] · DMF (L_β = *N-dl*-5,7,7,12, 14,14-hexamethyl-1,4,8,11 tetraazacyclotetradeca-4,11-diene) [6]. However in all of these cases the Re(IV) ion and M(II) metal ion are bridged by the oxalato ligand. Complex **1** is the first example in which a chloro-bridge between Re(IV) and Cu(II) exists. The crystal structure shows that the macrocyclic ligand, with a Cu(II) magnetic center, is linked by a chloro-bridge to the Re(IV) unit and thus generates a chloro-bridged bimetallic zig-zag chain.

A possible mechanism for the one-dimensional ordering in the complex under study can be understood through orbital symmetry considerations. The magnitude of the interaction is due to the overlap of the magnetic orbital on either side of the bridge. Tetrahedral distortion of the copper environment is the apparent cause for the four short equatorial bonds to N(4), N(8), N(11) and N(15), which ensure the delocalization of the unpaired electron of the d_{z^2} magnetic orbital within the equatorial plane and disrupt the orthogonality between this orbital and the d_{xy} orbital of Re(IV) through the chloro ligand. The chloro ligand between the Re(1)–Cu(1) pair causes a poor overlap, resulting in the antiferromagnetic coupling $J = -18.1$ cm^{-1}. Halide bridges have been observed in other copper complexes, but most of these have at least two bridges with angular Cu–halide–Cu bonds. The greater bond lengths of the copper atom to the axial donor will cause a negligible magnetic interaction through this pathway. The Cu–Cl bond distance in the present structure (2.97 Å) is distinctly larger than the most common value of 2.293 Å. On the other hand, there are no relatively efficient interchain exchange pathways possible. As follows from the section of the structure, the shortest Cu(1)···Re(1) distance of 4.7177(3) Å exists inside the polymer chain; the second shortest contact is as long as 7.3517(5) Å and it occurs between chains. Their counterparts for the Cu(2)···Re(1) atoms are 4.6840(3) and 7.2964(6) Å, respectively. This might provide an interchain exchange pathway, for example through the oxalate ion. Three unpaired electrons of Re(IV) are described by π-type orbitals, which have a lower efficiency in mediating exchange coupling than σ orbitals. However, the great diffuse character of the 5d type orbitals of the rhenium atom as well as its high oxidation state lead to significantly greater electronic delocalization.

To confirm this hypothesis DFT calculations were carried out. The computed spin densities are given in Table 4 (the atom numbering of the real structure of **1** has been kept). It deserves to be noted that the net spin density on a particular atomic orbital or atom is the result of two mechanisms: spin delocalization and spin polarization. As we can see in Table 4 there are only positive values of the spin densities in the examined compound, which allows us to suggest that the spin delocalization mechanism predominates and it is responsible for the great spin density on the ligand atoms. This result suggests that in complex **1** there are two magnetic exchange pathways: one (the intrachain magnetic exchange interaction between Re(IV) and Cu(II) paramagnetic centers through the chloro bridges) being much greater that the other (the interchain magnetic exchange interaction through the oxalato ligand).

Table 4
DFT-calculation atomic spin densities for **1**

Atom	Spin density	Atom	Spin density
Re(1)	3.6399	Cl(l)	0.07254
O(1)	0.0185	Cl(2)	0.0426
O(2)	0.0357	Cl(3)	0.0725
O(3)	0.0185	Cl(4)	0.0256
O(4)	0.0357	C(l)	0.0082
Cu(1)	0.3171	C(2)	0.0082

Complex **2** exhibits different magnetic properties. The product function at room temperature adopts the value of $\chi_{mol}T = 2.10$ cm^3 mol^{-1} K, which is expected for uncoupled Re(IV) and Cu(II) units. The product function smoothly decreases over a wide temperature range and then more rapidly drops down at the lowest temperature (Fig. 5). The slight decrease of $\chi_{mol}T$ can be due to the 2zero-field splitting of Re(IV) ions and to intramolecular exchange interactions between Re(IV)···Cu(II) ions.

Discussion of the magnetic properties of complex **2** requires some consideration of its structure, which is unknown because it was not possible to obtain suitable crystals for an X-ray diffraction study. Taking into account the coordination modes of the oxalato bridge, i.e. bidentate as in [CuL_β][$ReCl_4$(ox)] · DMF (L_β = *N-dl*-5,7,7,12,14,14-hexamethyl-1,4,8,11 tetraazacyclotetradeca-4,11-diene) [6] or monodentate as in [Cu(bipy)$_2$$ReCl_4$(ox)] [10], we can imagine the structure of **2** as a dinuclear complex with a single magnetic coupling parameter *J*.

The macrocyclic complex cations $[CuL_\alpha]^{2+}$ and $[CuL_\beta]^{2+}$ used in the synthesis occur in the form of two isomers, differing in the configuration of the donor nitrogen atoms. The differences in the crystalline structure of complex **1** compared to complex **2** have a significant influence on its magnetic properties. Both macrocyclic $[CuL]^{2+}$ ions have the same configuration of the carbon atoms

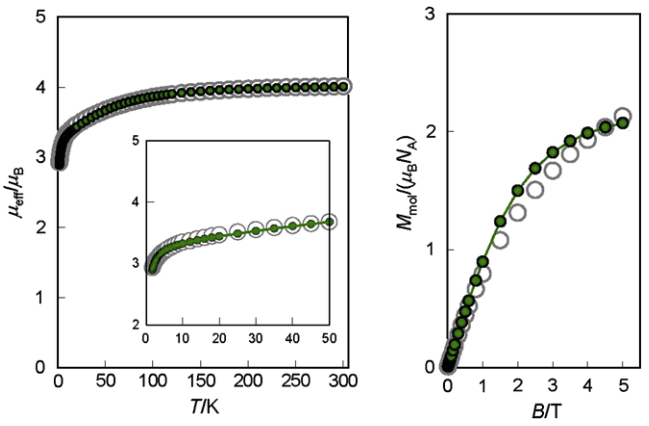

Fig. 5. Experimental (open symbols) and calculated (filled) magnetic data for **2**.

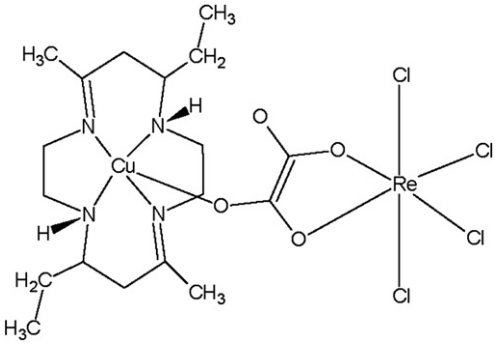
substituted with ethyl groups (*C-meso*). Complex **1** adopts the N–meso-*C-meso* configuration; thus, both ethyl groups take an equatorial position and the central ion is accessible for the bridging ligands from both sides, due to which it forms a linear polymer with the $[ReCl_4ox]^{2-}$ anion.

The inversion of configuration of one asymmetric nitrogen atom causes a partial conversion of the macrocyclic ring conformation, which is accompanied by the inversion of the conformation of the 7-ethyl group from equatorial into axial. The peripheral axial ethyl group blocks one of the axial sites in the isomeric cation (*N-rac–C-meso*). Therefore, the central copper(II) ion is able to coordinate to only one $[ReCl_4ox]^{2-}$ anion and forms the dinuclear complex **2**, bridging by only one oxygen. In fact, the presence of CH_3CN (the solvent used in this synthesis) can be ruled out by the IR spectrum and the elemental analysis. A very similar situation was observed in the previously studied compounds of the general formula (CuL)[$Co(NCS)_4$] with the same macrocyclic isomers (the crystal structures of both isomers were published elsewhere [4]). Based on these considerations, the proposed structure of **2** is shown in Scheme 2.

The magnetic properties of **2** were modelled with the spin Hamiltonian:

$$\hat{H} = -J(\vec{S}_{Re} \cdot \vec{S}_{Cu}) + \mu_B \vec{B} \cdot (g_{Re}\vec{S}_{Re} + g_{Cu}\vec{S}_{Cu}) + D_{Re}(\hat{S}^2_{Re,z} - \vec{S}^2_{Re,z}/3) \quad (2)$$

where the symbols adopt their usual meaning. The magnetic field in the Zeeman term has been applied along the molecular *z*- and *x*-axis and then the corresponding susceptibility and magnetization were averaged. The parameter set to be optimized is *J*, $g_{Re}(z)$, $g_{Re}(x)$ and g_{Cu}(iso). The axial zero-field splitting parameter for the Re(IV) ion has been recovered from the constraint offered by the spin Hamiltonian formalism [24]:



Scheme 2. Proposed dinuclear structure of $[L_\beta Cu(\mu\text{-ox})ReCl_4]$, **2**.

$$D = \lambda(g_z - g_x)/2 \quad (3)$$

with the single-ion spin–orbit splitting parameter $\lambda = 1000\ cm^{-1}$. The matrix elements of the spin Hamiltonian matrix (8×8) have been evaluated in the uncoupled basis set of spin functions, which does not suffer any constraint to magnetic parameters (like the strong-exchange limit) [25]. Indeed, the fitted *J*-value is much lower than the single-ion anisotropy *D*(Re) and the final set of parameters is $J = -0.71\ cm^{-1}$, $g_{Re}(z) = 1.687$, $g_{Re}(x) = 1.813$, g_{Cu}(iso) = 2.470 and $D(Re) = -62.7\ cm^{-1}$. The susceptibility set is recovered perfectly ($R(\chi) = 0.015$) and the magnetization set (with a simple *z*/*x*-average) is satisfactory ($R(M) = 0.078$), as displayed in Fig. 5.

It seems interesting to compare the magnetic behavior of complexes **1** and **2** with that obtained for $[CuL_\beta][ReCl_4(ox)] \cdot DMF$ (L_β = *N-dl*-5,7,7,12,14,14-hexamethyl-1,4,8,11 tetraazacyclotetradeca-4,11-diene) [6]. The partial conversion of the macrocyclic ring conformation in complexes **1** and **2** is caused by an increase of the size of the substituent in the macrocyclic ring (from methyl to ethyl group). As a consequence, the ethyl groups block the possibility of connecting Re(IV) and Cu(II) centers by the oxalato bridge as in the case of the previously reported complexes $[CuL_\beta][ReCl_4(ox)] \cdot DMF$ (L_β = *N-dl*-5,7,7,12,14,14-hexamethyl-1,4,8,11tetraazacyclotetradeca-4,11-diene) and $[(CuL\alpha)_2Cl][ReCl_4(ox)]Cl$ ($L\alpha$ = *N-dl*-5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,14-diene) [6]. Replacement of the methyl group in the macrocycle coordination sphere by a more bulky ethyl group causes steric hindrance, preventing the coordination to the metal ion. However the stronger antiferromagnetic interaction has been registered in the case of the chlorine-bridge complex.

4. Conclusion

Only a few bimetallic {Re(IV)Cu(II)} chain compounds have been reported so far. In these complexes the metal ions were connected by an oxalato bridge [6,10,23]. Our results show that it is possible to synthesize a new chloro-bridged heterometallic {Re(IV)Cu(II)} chain possessing a one-dimensional zig-zag structure by using $[ReCl_4(ox)]^{2-}$ anions as components that bridge macrocyclic $[CuL]^{2+}$ cations. The magnitude of the magnetic coupling between Re(IV) and Cu(II) in this class of compounds can be tuned by changing the coordination geometry around the copper(II) ions. This coordination depends on the position of the ethyl groups around the equatorial nitrogen atoms of the ligands. In the case of **1**, a 1D ferrimagnetic chain compound was obtained. Each $[ReCl_4(ox)]^{2-}$ ion is bound by two Cu–Cl bonds to two macrocyclic fragments. The magnetic measurements indicate antiferromagnetic interactions between the Re(IV) and Cu(II) metal ions within the chains. In the case of **2**, the $[CuL_\beta]^{2+}$ ion brings about the possibility for monodentate coordination of the oxalato ligand. On the basis of literature data [4,8,9], magnetic measurements and elemental analysis, this compound can be viewed as a bimetallic Re(IV)–Cu(II) unit. Replacement of the methyl group in the macrocycle coordination sphere by a larger ethyl group influences the magnitude of the magnetic exchange interaction. The analysis of these results suggest that a stronger magnetic interaction could be obtained if the rhenium(IV) ions were coordinated by other first-row transition metal macrocycles.

5 Supplementary data

CCDC 637068 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

The novel aquabis(ethylenediamine)pyrazine-2,3-dicarboxylatocopper(II) hydrate, $[Cu(pzdca)(H_2O)(en)_2] \cdot H_2O$ (**1**) and aquabis(2,2-dimethylpropane-1,3-diamine)pyrazine-2,3-dicarboxylatocopper(II) complex, $[Cu(pzdca)(H_2O)(dmpen)_2]$ (**2**), (H_2pzdca = pyrazine-2,3-dicarboxylic acid, en = ethylenediamine and dmpen = 2,2-dimethylpropane-1,3-diamine), with a new coordination mode of pyrazine-2,3-dicarboxylic acid, have been prepared and characterized by elemental analyses, IR spectroscopy, thermal analyses and single crystal X-ray diffraction. Both complexes crystallize in the triclinic system, space group $P\bar{1}$ and in which the Cu(II) ions exhibit a distorted octahedral coordination by a monodentate pzdca dianion, two bidentate en or dmpen ligands and one aqua ligand. The thermal decomposition of the complexes has been predicted with the help of thermal analyses (TG, DTG and DTA).

1. Introduction

Pyrazine-2,3-dicarboxylic acid (H_2pzdca) and its anions have been of interest in coordination and supramolecular chemistry and they generally tend to react with metal salts to yield insoluble polynuclear materials. The deprotonated pzdca anions ($Hpzdca^-$ and $pzdca^{2-}$) behave as polyfunctional ligands and they are well known to act as bridging ligands in metal complexes [1–17]. The pzdca anion coordinates to metal ions via its two carboxyl groups and two nitrogen atoms of the pyrazine ring. Various possible coordination modes for the pzdca ligand, such as bidentate [18–22], bis(bidentate) bridge (μ_2) [1–4], tridentate bridge (μ_2) [5–10], tetradentate bridge μ_2 [12], μ_3 [6,11,13–16] and μ_4 [6], and bis(monodentate) bridge (μ_2) [5] have been reported. The pzdca ligand is mainly coordinated via the carboxylate oxygen, nitrogen atom and O atom of a neighboring carboxyl group, acting as a tridentate bridge [5–10]. Furthermore mixed chelating-bridging modes have also been observed [17,23]. In the complex $\{[Ph_3Sn(pzdca)\text{-}SnPh_3]_2(H_2O)\}$ [5], the pzdca ligand acts as a bridge between the tin ions, its coordination sites being the oxygen atoms of the carboxylate groups, as a bis(monodentate) ligand. In the $\{[Mn(pzdca)(H_2O)_2] \cdot 2H_2O\}_n$ [13] and $[Cd(pzdca)(phen)] \cdot H_2O$ [6] polynuclear complexes, the pzdca ligand exhibits the μ_3 coordination mode by means of a bidentate O atom of a carboxyl group, the N atom of pyrazine and as a bis(monodentate) O atom of the neighboring carboxyl group, while in the $[Cd_2(pzdca)_2(4,4'\text{-bipy})(H_2O)_2]$ polynuclear complex, the pzdca ligand is coordinated to three Cd(II) ions through two O atoms and one N atom [6]. The pzdca ligand adopts a bidentate coordination to one Cd(II) ion and one μ_2-bridging oxygen atom coordinates to the other two Cd(II) ions. Up until now, although the literature lists many reports on the coordinating presence of the pzdca ligand, the monodentate coordination mode for a pyrazine-2,3-dicarboxylic acid complex was not known.

Here we report the syntheses, spectral, thermal properties and X-ray structures of the mononuclear $[Cu(pzdca)(H_2O)(en)_2] \cdot H_2O$ (**1**) and $[Cu(pzdca)(H_2O)(dmpen)_2]$ (**2**) complexes, with a new coordination mode of the pyrazine-2,3-dicarboxylate ligand.

2. Experimental

2.1. Preparation of the complexes

A solution of pyrazine-2,3-dicarboxylic acid (0.84 g, 5 mmol) in water (20 mL) was added dropwise with stirring to a solution of $Cu(CH_3COO)_2 \cdot H_2O$ (1 g, 5 mmol) in water (20 mL). The mixture was stirred for 4 h at 50 °C and then en (0.61 g, 10 mmol) or dmpen (1.02 g, 10 mmol) in acetonitrile–water (1:1, 25 ml) was added, and the resulting solution was stirred for 2 h at 50 °C and then cooled to room temperature. The crystals formed were filtered, washed with water and then dried in air. *Anal.* Calc. for $C_{10}H_{22}N_6O_6Cu$: C, 31.13; H, 5.75; N, 21.78. Found: C, 31.63; H,

2.2. Materials and measurements

All chemicals used were of reagent grade and were commercially purchased. IR spectra were obtained with a Bruker Tensor 27 FT-IR spectrometer using KBr pellets in the 4000–400 cm^{-1} range. Elemental analyses for C, H and N were carried out at the TÜBİTAK Marmara Research Centre. Magnetic susceptibility measurements at room temperature were performed using a Sherwood Scientific MXI model Gouy magnetic balance. The UV–Vis spectra were obtained for aqueous solutions of the complexes (10^{-3} M) with a Shimadzu UV-3150 spectrometer in the range 900–190 nm. A Perkin Elmer Diamond TG/DTA thermal analyzer was used to record simultaneous TG, DTG and DTA curves in static air atmosphere at a heating rate of 10 K min^{-1} in the temperature range 30–600 °C using platinum crucibles.

2.3. Crystallographic analyses

Diffraction experiments were carried out at 296 K on a Stoe IPDS diffractometer. The structure was solved by direct methods using the program SHELXS 97 [26]. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares methods [26]. The relevant crystal data and experimental conditions along with the final parameters are summarized in Table 1. Selected bond lengths, bond angles and the hydrogen bonds are listed in Tables 2–4, respectively. Data collection: X-AREA, cell refinement: X-AREA, data reduction on: X-RED [27]; program used to refine structure: SHELXL 97 [26]; molecular graphics: ORTEP-3 for Windows [28]; software used to prepare material for publication: WinGX [29].

3. Results and discussion

3.1. UV–Vis spectra and magnetic susceptibilities

The electronic spectra of the mononuclear complexes **1** and **2** in water exhibit absorption bands centered at 551 (ε = 116 L mol^{-1} cm^{-1}) and 589 nm (ε = 103 L mol^{-1} cm^{-1}), respectively, due to d–d transitions. These values were assigned to $^2B_{1g} \rightarrow {}^2E_g$, $^2B_{1g} \rightarrow {}^2B_{2g}$ and $^2B_{1g} \rightarrow {}^2A_{1g}$, which lie within one broad envelope. The Δ_o values for the complexes were calculated as 18149 and 16978 cm^{-1}, respectively. The Δ_o value of **1** is higher than complex **2** due to en being a stronger field ligand than the dmpen ligand.

Comparing the spectral data of complexes **1** and **2** reveals that while the observed λ_{max} values change in methanol, acetonitrile

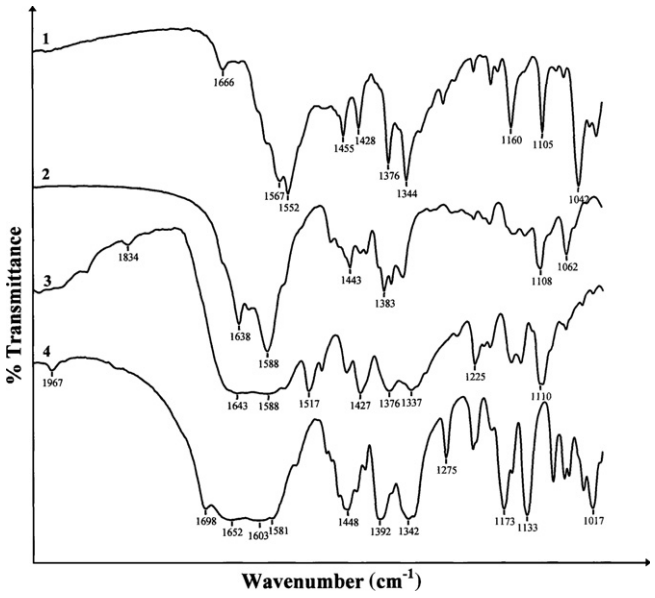

Fig. 1. A comparison of the IR spectra of Cu(II)-pzdca complexes; (**1**) [Cu(pzdca)$(H_2O)(en)_2]\cdot H_2O$, *monodentate*, (**2**) [Cu(pzdca)$(H_2O)(dmpen)_2$], *monodentate,* (**3**) [Cu(pzdca)$(phen)_2]\cdot 5.5H_2O$, *bidentate* and (**4**) [$Cu_2(pzdca)_2(dmen)_2]\cdot 6H_2O$, tridenate bridge [22].

and chloroform solvents, the absorption intensities remain almost unvaried in complexes **1** and **2**. A shoulder peak appears in the methanol spectra at 385 and 387 nm wavelengths, respectively, and is probably due to a charge-transfer.

The magnetic susceptibilities of [Cu(pzdca)$(H_2O)(en)_2]\cdot H_2O$ (**1**) and [Cu(pzdc)$(H_2O)(dmpen)_2$] (**2**) measured at room temperature show that the magnetic moment values μ_{eff} of 1.43 and 1.54 BM, respectively, are slightly smaller than the expected value (1.73 BM).

3.2. IR spectra

The IR spectra of the complexes show a broad band at 3478 cm^{-1} for **1** and 3411 cm^{-1} for **2** due to the ν(OH) vibrations of water molecules. The bands at 3336–3219 cm^{-1} for **1** and 3270–3212 cm^{-1} for **2** are attributed to the $\nu(NH_2)$ vibrations of the en and dmpen ligands, respectively. The weak band range of 3055–2895 cm^{-1} for **1** and 2954–2865 cm^{-1} for **2** can be assigned to ν(CH) vibrations. Strong absorption bands in the ranges 1753–1690 and 1396–1357 cm^{-1} correspond to the asymmetric and symmetric ν(COO) vibrations of the free H_2pzdca ligand. After coordination to the Cu(II) ions, these bands shift to lower wavenumbers and are observed in the ranges 1650–1583 and 1387–1333 cm^{-1} for **1** and 1638–1588 and 1383–1350 cm^{-1} for **2**. The differences between the asymmetric and symmetric stretches of the carboxylate groups of the two complexes, $\Delta\nu = 256$ and 247 cm^{-1}, respectively, suggest a monodentate binding of the carboxylate group to the copper(II) ions [30]. The weak bands between 450 and 613 cm^{-1} are due to Cu–N and Cu–O stretching vibrations.

The carboxyl groups of the ring appear as three main peaks at 1753, 1715 and 1690 cm^{-1} in the free 2,3-pyrazinedicarboxylic acid. Band splitting and shifts of the stretching vibrations of the carboxyl group were observed in the IR spectra of the Cu(II)-pzdca complexes, in which pzdca exhibits a different coordination mode. Therefore, the IR spectra of 2,3-pyrazinedicarboxylic acid and the Cu(II)-pzdca complexes provide important evidence for the coordination of the pzdca ligand to the copper(II) ions. The IR spectra of Cu(II)-pzdca complexes are given in Fig. 1, in which the ligand shows monodentate, bidentate and tridentate bridge coordination modes for comparison.

3.3. Thermal analyses

3.3.1. $[Cu(pzdca)(H_2O)(en)_2]\cdot H_2O$

This complex exhibits five decomposition stages (Fig. 2). In the first stage, endothermic removal of the crystal water molecule occurs in the 73–93 °C range (DTA_{max} = 91 °C, found 4.90%, calc. 4.66%). The second stage, 94–121 °C range, is related to the loss of aqua and 0.5 mol of en ligands (DTA_{max} = 114 °C, found 12.09%, calc. 12.45%). In the temperature range 122–207 °C, the third and fourth stages of the complex are related to the successive decomposition of 1 mol of en ligands, by giving an endothermic contribution (DTA_{max} = 155 and 204 °C, found 16.09%, calc. 15.57%). In the

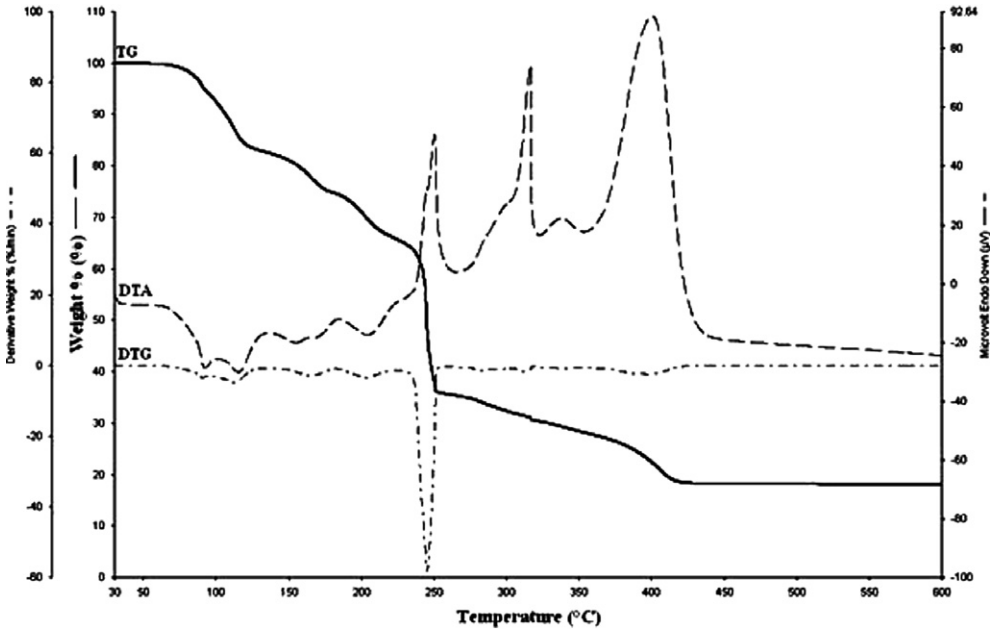

Fig. 2. TG, DTG and DTA curves of **1**.

following stage, the remaining 0.5 mol en ligand and 2 mol CO_2 are released, giving an exothermic effect (DTA_{max} = 251 °C, found 30.98%, calc. 30.59%). The Cu(II) complex shows an exothermic effect at about 317 °C that can be assigned to a phase transition. In the last stage, the remaining organic part is abruptly burnt (DTA_{max} = 400 °C), leading finally to CuO (found 81.78%, calc. 79.39%).

3.3.2. $[Cu(pzdca)(H_2O)(dmpen)_2]$

The thermal decomposition behavior of this complex was followed up to 600 °C in static air atmosphere (Fig. 3). The first stage related to the endothermic removal of the aqua ligand in the 100–154 °C temperature range (DTG_{max} = 150 °C, found 4.07%, calc. 3.98%). The second stage corresponds to the loss of dmpen and pzdca in the 193–307 °C temperature range, giving both an exothermic and endothermic effect (DTA_{max} = 221 and 225 °C), simultaneously. In the last strong exothermic stage, the remaining organic part is abruptly burnt (DTA_{max} = 456 °C). The final decomposition product, CuO, was identified by IR spectroscopy (found 82.58%, calc. 82.40%).

3.4. Crystal structures of the complexes

3.4.1. $[Cu(pzdca)(H_2O)(en)_2] \cdot H_2O$ (1)

Details of the crystal structures are given in Table 1. The crystal structure of **1**, together with the atom labelling, is shown in Fig. 4. The complex is described as a distorted octahedron and the Cu(II) ion is coordinated by two neutral en, one monodentate pzdca and one aqua ligand. The en ligand acts as a bidentate donor through the terminal nitrogen atoms creating a five membered chelate ring [Cu1–N1 = 1.993 (2), Cu1–N2 = 2.014 (2), Cu1–N3 = 2.004 (2) and Cu1–N4 = 2.021 (2) Å] (Table 2). Pzdca coordinated to the copper (II) ions through the carboxylate oxygen atom as a monodentate ligand [Cu1–O2 = 2.403 (2) Å]. To the best of our knowledge, this coordination mode has never been observed in the previously reported complexes of pyrazine-2,3-dicarboxylic acid. The Cu(1)–$O(2)_{pzdca}$ bond distance is similar to the corresponding values found in $[Cd(pzdca)(phen)] \cdot H_2O$ [2.310(2) Å] [6] and $[Cu_2(pzdca)_2(L)(H_2O)_2] \cdot 12H_2O$ [2.552(4) Å] [9], however it is somewhat shorter than that in $[Cu_2(pzdca)_2(H_2O)_2(dmen)_2] \cdot 6H_2O$ [2.887(2) Å] [22]. The distorted octahedral geometry is completed one aqua ligand [Cu1–O1 = 2.727 (2) Å]. The four nitrogen atoms from the en ligands comprise the equatorial plane and one oxygen atom of the pzdca ligand and one oxygen atom from the aqua ligand occupy axial positions [O1–Cu1–O2 = 169.61°].

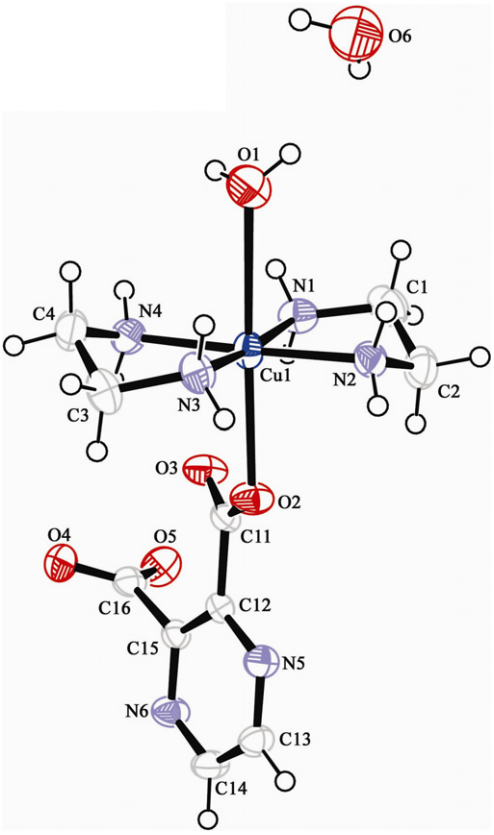

Fig. 4. Ortep III view of **1** with the atom numbering scheme.

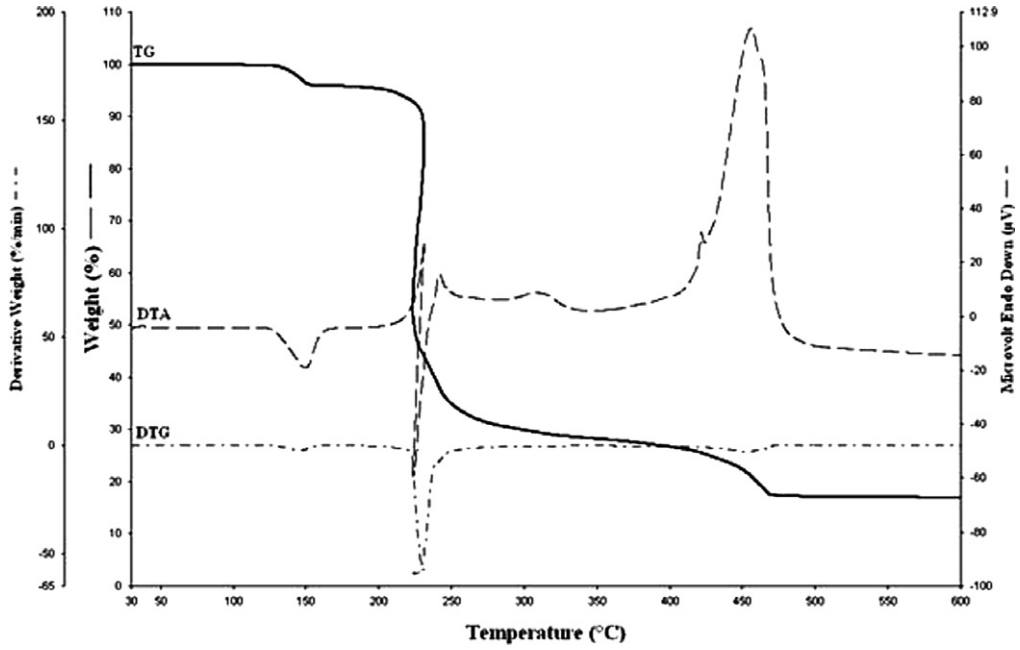

Fig. 3. TG, DTG and DTA curves of **2**.

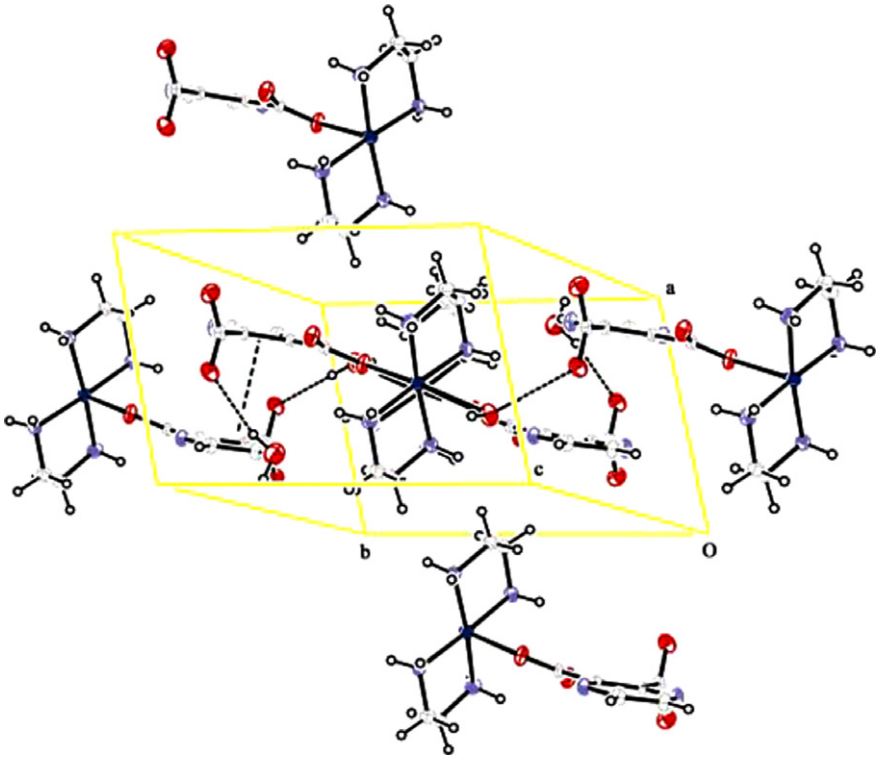

Fig. 5. Packing diagram of **1.**

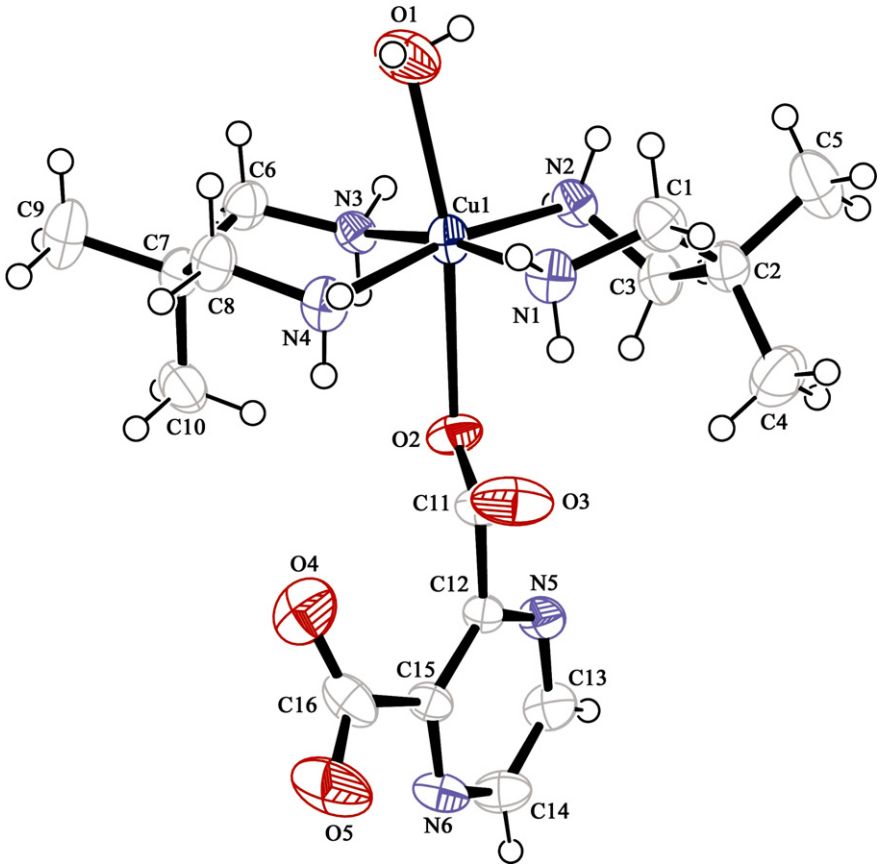

Fig. 6. Ortep III view of **2** with the atom numbering scheme.

The pzdca ligand is almost planar (the r.m.s deviation is 0.0072 Å). The dihedral angles between the pzdca ligand and the carboxyl groups are 16.62° and 81.36° and between the two carboxyl groups, 75.50°.

Details of the hydrogen bonding geometry are given in Table 4. The nitrogen atoms of the pzdca ligands are involved in weak intermolecular hydrogen bonding with the amine group of the en ligand. The oxygen atoms (O1 and O2) of both coordinated water and crystal water molecules are involved in intra- and intermolecular hydrogen bonding with the oxygen atoms of the carboxyl group of the pzdca ligand and the amine group of the en ligands. The intramolecular N1–H6A···O3, N3–H4B···O1 and N4–H3B···O3 bonds have H···O distances of 2.36, 2.63 and 2.54 Å, respectively. The intermolecular O1–H5C···O5^{i}, O1–H5D···O4^{ii}, O6–H6C···O4^{ii} and O6–H6D···O5^{v} bonds have H···O distances of 1.92(2), 2.03(2), 2.16(2) and 2.12(2) Å, respectively ((i): $x+1$, $-y+1$, $-z+2$; (ii): x, $y-1$, z; (v): $x-1$, $y-1$, z). The crystal packing is mainly stabilized by hydrogen bonds. There are also π···π interactions between the Cg3-Cg3^{i} rings (Cg3: N(5)–C(12)–C(15)–N(6)–C(14)–C(13), i: $1-x$, $-y$, $1-z$). Some of these interactions are shown in Fig. 5.

3.4.2. [Cu(pzdca)(H$_2$O)(dmpen)$_2$] (2)

Crystallographic analysis shows that this complex has a mononuclear two-dimensional structure. Moreover, the pyrazine-2,3-dicarboxylate ligand acts as a monodentate ligand through the O atom of the carboxyl group, which has not been reported previously. The asymmetric unit includes [Cu(pzdc)(H$_2$O)(dmpen)$_2$] and the Cu(II) ion is coordinated by one O atom of a carboxyl group from the monodentate pzdca ligand, four N atoms from two dmpen ligands and one O atom from an aqua ligand, forming a distorted octahedral geometry (Fig. 6). The basal coordination plane is formed by the N1, N2, N3 and N4 atoms from the dmpen ligands; [Cu(1)–N(1)$_{dmpen}$ = 2.019(2), Cu(1)–N(2)$_{dmpen}$ = 2.043(2), Cu(1)–N(3)$_{dmpen}$ = 2.012(2) and Cu(1)–N(4)$_{dmpen}$ = 2.046(2) Å] (Table 2). The apical positions are occupied by one oxygen atom of the aqua ligand [Cu(1)–O(1) = 2.379(2) Å] and the one oxygen atom of the pzdca ligand [Cu(1)–O(2) = 2.810(2) Å]. The pzdca ligand is weakly bonded to the copper ion and the Cu(1)–O(2) bond is longer than the equatorial Cu–N bonds due to the Jahn–Teller effect and it is longer than the Cu1–O2 (2.403 (2) Å) bond distance in **1** due to the steric effect of the methyl groups of dmpen ligands.

The Cu(1)–O(2)$_{pzdca}$ bond distances are similar to the corresponding values found in [Cu$_2$(pzdca)$_2$(H$_2$O)$_2$(dmen)$_2$] · 6H$_2$O [2.887(2) Å] [22] and [Cu$_2$(pzdca)$_2$(L)(H$_2$O)$_2$] · 12H$_2$ O [2.552(4) Å] [9], but somewhat longer than that in [Cd(pzdca)(phen)] · H$_2$O [2.310(2) Å] [6], [Ca(Hpzdca)(H$_2$O)$_4$] · NO$_3$ [2.429(2) Å] [24] and {[Eu(pzdca)(NO$_3$)(phen)(H$_2$O)] · H$_2$O}$_n$ [2.344(3) Å] [25].

The pzdca ligand is almost planar (the r.m.s deviation is 0.0111 Å). The dihedral angles between the pzdca ligand and carboxyl groups are 26.76° and 54.92° and between the two carboxyl groups, 52.36°.

The crystal packing of complex is a composite of intermolecular hydrogen bonding, π···π and C–H···π interactions. An intermolecular π···π interaction contact occurs between the two symmetry-related pyrazine rings of the pzdca ligand [Cg3 = N5, N6, C12–C15; Cg3···Cg3^{iv} 3.692(2) Å, (iv): $1-x$, $-y$, $1-z$], while a C–H···π interaction take place between C(9)–H(9A) and the Cg3 ring [C(9)–H(9A)···Cg3^{v} 2.910(2) Å, (v): $1+x$, y, z] (Fig. 7). The crystal is mainly stabilized by strong intermolecular H bonds N(1)–H(1C)···O(4)^{i}, O(1)–H(1E)···O(5)^{iii} and O(1)–H(1F)···O(5)^{i} [(i): $1-x$, $1-y$, $-z$, (iii): x, $1+y$, z]. There are also intramolecular H

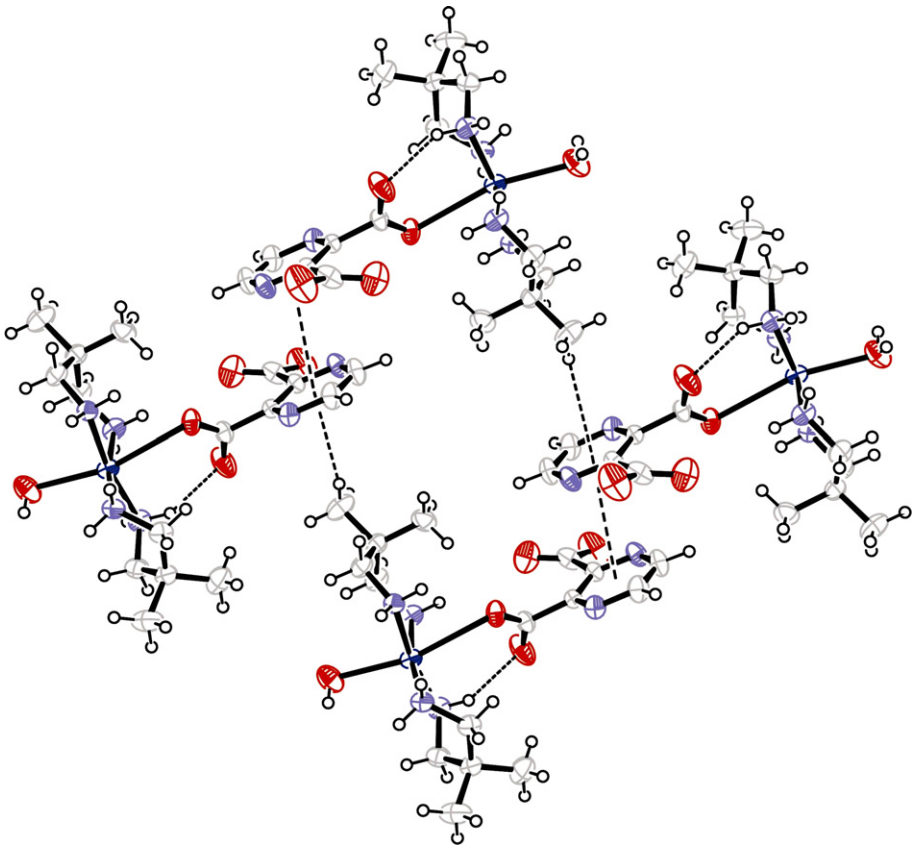

Fig. 7. The π···π and C–H···π interactions of **2**.

bonds between the uncoordinated O3 atom of the carboxyl group and the N1 atom of the dmpen ligand. All of these intermolecular interactions give a two-dimensional network.

4. Conclusion

We have successfully synthesized two novel mononuclear copper(II) complexes with the en ligand, $[Cu(pzdca)(H_2O)(en)_2] \cdot H_2O$ and the dmpen ligand, $[Cu(pzdc)(H_2O)(dmpen)_2]$. In the complexes, the pyrazine-2,3-dicarboxylate ligand exhibits a new coordination mode, though sixteen different other modes have been crystallographically characterized previously. These complexes are the first examples of pzdca ligand exhibiting monodentate coordination mode to the metal ions.

Supplementary data

CCDC 676220 and 675628 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Through-bond interactions

ABSTRACT

Fine structures of 1-(arylethynylselanyl)naphthalenes [1-(*p*-$YC_6H_4C{\equiv}CSe)C_{10}H_7$: **1**, Y = H (**a**), OMe (**b**), Me (**c**), Cl (**e**), CN (**h**), NO_2 (**i**)] have been determined by X-ray crystallographic analysis. The structures are **A** for **1a–c**, bearing Y that is a non-acceptor, **B** for **1e**, **1h** and **1i**, having Y that is a strong acceptor, where the Se–C_{sp} bond is perpendicular to the naphthyl plane in **A**, but is in the plane in **B**; and **C** is intermediate between **A** and **B** (see Scheme 1). The Y-dependence observed in **1** is just the opposite to the case of 1-(arylselanyl)naphthalenes [1-(*p*-$YC_6H_4Se)C_{10}H_7$]. We call the factor the "*ethynyl effect*", which controls the fine structures of **1**. The structures of **1h** and **1i** are planar or almost planar. The energy lowering effect by the parallel direction between n_p(Se) and n_p(Y) must be responsible for the observations if Y is a strong acceptor. The origin of the ethynyl effect is explained by how effectively n_p(Se) and n_p(Y) interact through the C≡C bond. Crystal packing effects, such as the formation of dimmers, also play an important role in determining the fine structures of **1**. The dimer formation in **1a–c** substantially stabilizes the structures. The π-stacking of naphthyl groups may also contribute to the dimer formation. The structures in solutions are also clarified. Compound **1** exist in the **A** form in solutions, with some equilibration with **B**. The ethynyl effect as the factor that controls the fine structures of **1** is also confirmed in solution. The results are well supported by quantum chemical calculations on the structures, energy profiles and the evaluation of electron affinity. The NMR chemical shifts explain the behavior of **1** in solution.

1. Introduction

Weak interactions are of current interest [1–16], since they determine the fine structures of molecules and create the high functionalities of materials. Investigations successfully utilizing weak interactions are increasing, such as in biological and enzymatic activities [17–24], stabilization of folded protein structures [25,26] and supramolecular chemistry [27,28], together with donor–acceptor complexes for electronic materials [29–32]. They are also utilized in the crystal engineering for material development [33–35]. Much attention has also been paid to the ethynyl group in modern physics, chemistry and engineering [36–47]. This group and its derivatives are very important as building blocks when molecules of high functionality are designed [48,49]. It will be of great interest if the ethynyl group is joined to extended hypervalent bonds [10b,10e,10f,10j,10k,10l,10m,10n,16] constructed by group 16 elements.

We intend to construct supramolecular compounds such as **I** [50] and derivatives mainly built by the ethynyl group coordinated to the extended hypervalent 4c–6e bonds of Z_4 (Z = S [10j,16] and Se [10b,10e,16]). It is also of high interest how ethynylchalcogenyl groups operate to control the fine structures. The results will be useful for the design of a system, such as **I**, with high functionality. The effects of ethynylchalcogenyl groups as factors that control fine structures are elucidated by 1-(arylethynylselanyl)naphthalenes [1-(*p*-$YC_6H_4C{\equiv}CSe)C_{10}H_7$ (1-ArC≡CSe-Nap): **1**, Y = H (**a**), OMe (**b**), Me (**c**), F (**d**), Cl (**e**), CN (**h**) and NO_2 (**i**)]. Compounds **1a–e**, **1h** and **1i** have been prepared and the structures determined by X-ray crystallographic analysis.

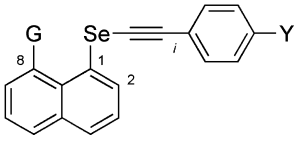
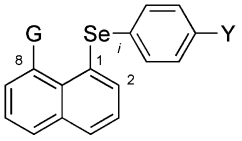
I (Z = S and Se; *n* = 0 and 1)



1 (G = H), **2** (G = Cl and Br)

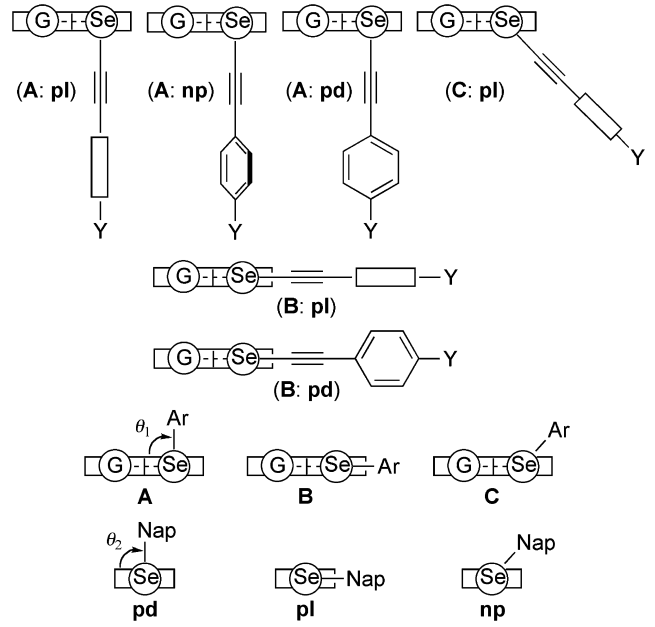


3 (G = H), **4** (G = F, Cl and Br)

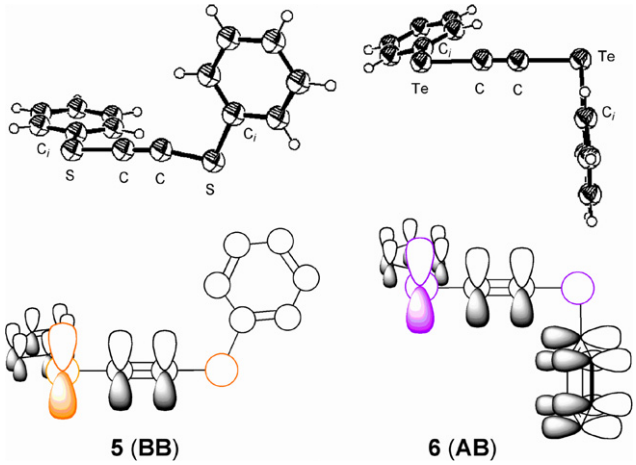
	a	b	c	d	e	f	g	h	i
Y =	H	OMe	Me	F	Cl	Br	COOR	CN	NO_2

Naphthalene 1,8-positions supply a good system to investigate weak interactions [10a,10b,10d,10e,10f,10g,10h,10i,10j,16,51–55], since the distance between the non-bonded atoms of the main group elements at those positions are shorter than the sum of van der Waals radii by about 1 Å. The structures of **1** where G is a halogen (**2**) must also be of great interest. Factors to control the fine structures of 1-(arylselanyl)naphthalenes [1-(*p*-YC_6H_4-Se)$C_{10}H_7$: **3**] [11b] and 8-G-1-(*p*-$YC_6H_4Se)C_{10}H_6$ (**4**) [10h] have been clarified based on those determined by X-ray crystallographic analysis. The factors are explained by means of p(Se)–π(Ar/Nap) conjugation for **3** and a non-bonded n_p(G)–σ^*(Se–C) 3c–4e type interaction for **4**.

Structures of the naphthalene system are well explained by the three types, **A**, **B** and **C**, in our definition, where the Se–C_{sp} bond is perpendicular to the naphthyl plane in **A**, is placed on the plane in **B**, and **C** is an intermediate between **A** and **B** [10c,10d,10f,10g,10h,10i,11b]. The **A**, **B** and **C** notations are employed for the structures around the Se–C_{Nap} bonds in **1**. The planar (**pl**), perpendicular (**pd**) and non-planar and non-perpendicular (**np**) notations are also used to specify the structures of **1** around the Se–C≡C–C_{Ar} (abbreviated Se–C_{Ar}) bonds. Scheme 1 illustrates the plausible structures of **1**. Combined notations such as (**A**: **pl**) and (**B**: **pd**) are employed for the structures. The structures of **3** are **B** when Y is a donating group, such as OMe, whereas they are **A** when Y is an acceptor group, such as NO_2 [10h]. We call the results Y-dependence. The magnitude of the p(Se)–π(Ar/Nap) conjugation must be the origin of the Y-dependence in **3**.



Scheme 1. Plausible structures of **1**, together with the **A**, **B** and **C** and **pd**, **pl** and **np** notations.



Scheme 2. Structures of **5** (**BB**) and **6**(**AB**), together with the orbital interactions.

The structures of **1** correspond to those of **3**, whereas the structures of **2** correspond to those of **4**. Does Y really control the fine structures of **1**? One may wonder that Y would not have an affect on the conformations of **1**, since the arylethynyl group is essentially unhindered around the C≡C bond. However, **BB** and **AB** structures are reported for the 1,2-di(phenylchalcogenyl)ethynes PhSC≡CSPh (**5**) [56] and PhTeC≡CTePh (**6**) [57], respectively, as shown in Scheme 2 [58]. Each n_p(Z) orbital on both sides of the Z–C≡C–Z framework directs parallel to each of the two π(C≡C) orbitals in **5** and **6**, where the torsion angles of ϕ(C_iZZC_i) are close to 90°. The π(Ph)–n_p(Z)–π(C≡C) conjugations may operate to control the structures of **5** (**BB**) and **6** (**AB**). Similar conjugation must also operate to determine the fine structure of PhSeC≡CSePh (**7**).[1]

Here, we report the fine structures of **1** in crystals, as the first step to clarify the ethynyl effect as a factor that controls fine structures. We call the factor the "*ethynyl effect*" in **1**. The behavior of **1** in solution is also discussed by means of NMR spectroscopy.

2. Experimental

2.1. General experimental considerations

Manipulations were performed under an argon atmosphere with standard vacuum-line techniques. Glassware was dried at 130 °C overnight. Solvents and reagents were purified by standard procedures as necessary. Melting points were measured with a Yanaco MP-S3 apparatus and were uncorrected. NMR spectra were recorded at room temperature on a JEOL AL-300 spectrometer (^{1}H, 300 MHz; ^{13}C, 75 MHz: ^{77}Se, 57 MHz). The ^{1}H, ^{13}C and ^{77}Se chem-

[1] The **AA**, **BB** and **AB** conformers are shown to be stable for **7** and the energies are predicted to be almost equal values of −5342.6801 a.u. with the B3LYP/6-311+G(2d, p) method.

ical shifts are given in parts per million relative to those of Me_4Si, internal $CDCl_3$ of the solvent and external MeSeMe, respectively. Column chromatography was performed on silica gel (Fujishilysia PSQ-100B), acidic and basic alumina (E. Merck).

2.2. Preparation of 1-(arylethynylselanyl)naphthalenes

2.2.1. 1-(Phenylethynylselanyl)naphthalene (**1a**)

Under an argon atmosphere, ethynylbenzene (0.50 g, 4.85 mmol) was dissolved in anhydrous THF (15 mL), and LDA (diisopropylamine (0.52 g, 5.09 mmol) and *n*-BuLi (3.2 mL, 5.09 mmol, 1.62 M)) was added to the solution at 0 °C. After the mixture was stirred for 1 h at 0 °C, 1-naphthylselanyl bromide in anhydrous THF (10 mL) was added to the above solution at 0 °C. The reaction mixture was stirred for 2 h at 0 °C, and allowed to warm up to room temperature. Then, acetone (5 mL) was added, evaporated and dried in vacuo. The crude product was purified by column chromatography (flash column, SiO_2, acidic alumina, hexane). Compound **1a** was isolated in 65% yield as colorless prisms, mp 62.0–63.0 °C. *Anal.* Calc. for $C_{18}H_{12}Se$: C, 70.36; H, 3.94. Found: C, 70.04; H, 3.83%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.29–7.36 (m, 3H), 7.41–7.63 (m, 5H), 7.81 (d, *J* 8.2 Hz, 1H), 7.87 (dd, *J* 1.6, 7.6 Hz, 1H), 8.04 (m, 2H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 69.1, 102.9, 123.2, 125.4, 126.3, 126.4, 126.8, 127.3, 128.3, 128.3, 128.6, 128.8, 129.0, 131.8, 132.1, 134.0; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 241.4.

2.2.2. 1-(p-Anisylethynylselanyl)naphthalene (**1b**)

A similar method to that described for the preparation of **1a** was used. Compound **1b** was isolated in 61% yield as colorless prisms, mp 99.0–100.0 °C. *Anal.* Calc. for $C_{19}H_{14}OSe$: C, 67.66; H, 4.18. Found: C, 67.91; H, 4.17%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 3.81 (s, 3H), 6.85 (d, *J* 9.0 Hz, 2H), 7.44 (t, *J* 8.0 Hz, 1H), 7.46 (d, *J* 9.0 Hz, 2H), 7.50–7.61 (m, 2H), 7.79 (d, *J* 8.4 Hz, 1H), 7.86 (dd, *J* 1.7, 7.8 Hz, 1H), 7.99–8.06 (m, 2H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 55.3, 67.0, 103.0, 114.0, 115.3, 125.3, 126.3, 126.4, 126.7, 127.7, 128.1, 128.6, 128.7, 132.0, 133.6, 134.0, 160.0; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 240.9.

2.2.3. 1-(p-Tolylethynylselanyl)naphthalene (**1c**)

A similar method to that described for the preparation of **1a** was used. Compound **1c** was isolated in 70% yield as light yellow prisms, mp 87.0–88.0 °C. *Anal.* Calc. for $C_{19}H_{14}Se$: C, 71.03; H, 4.39. Found: C, 70.79; H, 4.31%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 2.36 (s, 3H), 7.13 (d, *J* 7.9 Hz, 2H), 7.40 (d, *J* 8.2 Hz, 2H), 7.45 (t, *J* 7.8 Hz, 1H), 7.50–7.62 (m, 2H), 7.80 (d, *J* 8.3, 1H), 7.87 (dd, *J* 1.7, 7.8 Hz, 1H), 8.03 (dd, *J* 1.0, 7.9 Hz, 1H), 8.04 (dd, *J* 1.1, 7.3 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 21.5, 68.0, 103.1, 120.1, 125.3, 126.3, 126.4, 126.7, 127.5, 128.1, 128.7, 128.8, 129.1, 131.8, 132.1, 134.0, 138.9; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 241.4.

2.2.4. 1-(p-Fluorophenylethynylselanyl)naphthalene (**1d**)

A similar method to that described for the preparation of **1a** was used. Compound **1d** was isolated in 67% yield as colorless prisms, mp 87.0–88.0 °C. *Anal.* Calc. for $C_{18}H_{11}FSe$: C, 71.03; H, 4.39. Found: C, 70.79; H, 4.31%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.01 (t, *J* 8.8 Hz, 2H), 7.41–7.51 (m, 3H), 7.51–7.63 (m, 2H), 7.81 (d, *J* 8.2 Hz, 1H), 7.87 (dd, *J* 1.6, 7.8 Hz, 1H), 8.02 (dd, *J* 1.1, 7.2 Hz, 1H), 8.05 (dd, *J* 1.1, 8.3 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 68.9 ($^5J_{C,F}$ 1.7 Hz), 101.6, 115.6 ($^2J_{C,F}$ 22.4 Hz), 119.3 ($^4J_{C,F}$ 3.7 Hz), 125.5, 126.3, 126.5, 126.8, 127.2, 128.4, 128.8, 129.1, 132.2, 133.8 ($^3J_{C,F}$ 7.8 Hz), 134.1, 162.7 ($^1J_{C,F}$ 250.4 Hz); δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 240.5.

2.2.5. 1-(p-Chlorophenylethynylselanyl)naphthalene (**1e**)

Under an argon atmosphere, 1-chloro-3-ethynylbenzene (0.66 g, 4.83 mmol) was dissolved in anhydrous THF (15 mL), and LDA (diisopropylamine (0.52 g, 5.09 mmol) and *n*-BuLi (3.2 mL, 5.09 mmol, 1.62 M)) was added to the solution at −78 °C. After the mixture was stirred for 1 h at 0 °C, 1-naphthyl-selanylbromide in anhydrous THF (10 mL) was added to the above solution at −78 °C. The reaction mixture was stirred for 2 h at −78 °C, and allowed to warm up to 0 °C. Then, acetone (5 mL) was added, evaporated and dried in vacuo. The crude product was purified by column chromatography (flash column, SiO_2, acidic alumina, hexane). Compound **1e** was isolated in 27% yield as colorless prisms, mp 71.0–72.0 °C. *Anal.* Calc. for $C_{18}H_{11}ClSe$: C, 63.27; H, 3.24. Found: C, 63.26; H, 3.34%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.29 (d, *J* 8.8 Hz, 2H), 7.40 (d, *J* 8.9 Hz, 2H), 7.46 (t, *J* 7.8 Hz, 1H), 7.51–7.63 (m, 2H), 7.82 (d, *J* 8.4 Hz, 1H), 7.87 (dd, *J* 1.6, 7.8 Hz, 1H), 8.01 (dd, *J* 1.1 and 7.3 Hz, 1H), 8.06 (dd, *J* 1.0, 8.2 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 70.6, 101.5, 121.7, 125.5, 126.2, 126.5, 126.9, 127.0, 128.5, 128.7, 128.8, 129.3, 132.2, 132.9, 134.1, 134.6; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 241.5.

2.2.6. 1-(p-Cyanophenylethynylselanyl)naphthalene (**1h**) [59]

α-(*p*-Cyanophenylcarbonyl)-α-(naphthylselanyl)phosphorane (**8**) (0.68 g, 1.11 mmol) was heated under vacuum (0.1 mmHg) at 230 °C for 5 min. The crude product was purified by column chromatography (flash column, SiO_2, hexane:benzene = 9:1). Compound **1h** was isolated in 16% yield as yellow prisms, mp 96.0–97.0 °C. *Anal.* Calc. for $C_{19}H_{11}NSe$: C, 68.68; H, 3.34; N, 4.22. Found: C, 68.56; H, 3.49; N, 4.22%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.46 (t, *J* 7.8 Hz, 1H), 7.50 (d, *J* 8.7 Hz, 2H), 7.53–7.65 (m, 2H), 7.58 (d, *J* 8.8 Hz, 2H), 7.86 (d, *J* 8.4 Hz, 1H), 7.89 (dd, *J* 1.0, 7.7 Hz, 1H), 8.00 (dd, *J* 1.1, 7.2 Hz, 1H), 8.10 (dd, *J* 1.6, 7.9 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 75.9, 100.8, 111.4, 118.5, 125.7, 126.2, 126.4, 126.6, 127.1, 127.9, 127.9, 128.8, 129.1, 130.0, 131.8, 132.0, 134.1; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 243.9.

2.2.7. α-(p-Cyanophenylcarbonyl)-α-(naphthylselanyl)phosphorane (**8**) [59]

Under an argon atmosphere, (*p*-cyanophenylcarbonylmethylidene)triphenylphosphorane [60] (3.00 g, 7.40 mmol) was dissolved in benzene (30 mL), added to a benzene solution (40 mL) of 1-naphthylselanylbromide at room temperature and stirred for 2 h at room temperature. A white suspension was formed, and the solid was filtered out from the reaction mixture. The filtrate was evaporated and dried in vacuo. The crude product was purified by column chromatography (flash column, SiO_2, CH_2Cl_2). Compound **8** was isolated in 17% yield as yellow prisms, mp 118.0–120.0 °C. *Anal.* Calc. for $C_{19}H_{11}NSe$: C, 72.79; H, 4.29; N, 2.29. Found: C, 73.00; H, 4.63; N, 2.34%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.25–7.39 (m, 9H), 7.40–7.51 (m, 5H), 7.54–7.63 (m, 8H), 7.72–7.83 (m, 4H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 52.4 ($^1J_{C,P}$ 92.8 Hz), 53.4, 112.0, 119.0, 125.0, 125.0 ($^3J_{C,P}$ 11.2 Hz), 125.1, 125.6 ($^4J_{C,P}$ 2.5 Hz), 125.9, 126.1 ($^1J_{C,P}$ 90.9 Hz), 128.2, 128.5, 128.5 ($^3J_{C,P}$ 12.3 Hz), 131.2, 131.8, 132.1 ($^4J_{C,P}$ 2.5 Hz), 133.5, 133.7 ($^2J_{C,P}$ 9.3 Hz), 136.8 ($^4J_{C,P}$ 1.9 Hz), 146.5 ($^3J_{C,P}$ 11.2 Hz), 190.9 ($^2J_{C,P}$ 10.6 Hz); δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 315.4 ($J_{Se,P}$ 8.0 Hz).

2.2.8. 1-(p-Nitrophenylethynylselanyl)naphthalene (**1i**) [59]

α-(*p*-Nitrophenylcarbonyl)-α-(naphthylselanyl)phosphorane (**9**) (0.30 g, 0.79 mmol) was heated under vacuum (0.1 mmHg) at 250 °C for 5 min. The crude product was purified by column chromatography (flash column, SiO_2, hexane:benzene = 4:1). Compound **1i** was isolated in 7% yield as yellow prisms, mp 136.5–137.5 °C. *Anal.* Calc. for $C_{18}H_{11}NO_2Se$: C, 61.38; H, 3.15; N, 3.98. Found: C, 61.23; H, 3.36; N, 3.88%. δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.48 (t, *J* 7.8 Hz, 1H), 7.52–7.62 (m, 2H), 7.55 (d, *J* 9.0 Hz, 2H), 7.87 (d, *J* 7.5 Hz, 1H), 7.90 (d, *J* 7.7 Hz, 1H), 8.02 (dd, *J* 1.1, 7.3 Hz, 1H), 8.12 (dd, *J* 1.3, 8.2 Hz, 1H), 8.17 (d, *J* 9.0 Hz, 2H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 77.4, 100.6, 123.6, 125.8, 126.2,

126.2, 127.1, 128.9, 129.2, 129.9, 130.3, 131.9, 132.4, 134.2, 146.9; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 244.9.

2.2.9. α-(p-Nitrophenylcarbonyl)-α-(naphthylselanyl)phosphorane (9) [59]

A similar method to that described for the preparation of **8** was used. Compound **9** was isolated in 33% yield as yellow prisms, mp 135.0–137.0 °C. *Anal.* Calc. for $C_{19}H_{11}NSe \cdot H_2O$: C, 66.67; H, 4.32; N, 2.16. 2.3. X-ray structure determination

Single crystals of **1a–c** and **1e** were obtained by slow evaporation of dichloromethane–hexane at room temperature, and **1h** and **1i** were obtained from an ethyl acetate solution. X-ray diffraction data were collected on a Rigaku/MSC Mercury CCD diffractometer equipped with a graphite-monochromated MoKα radiation source (λ = 0.71070 Å) at 103(2) K. The structures were solved by direct methods (SIR97) and refined by the full-matrix least squares method on F^2 for all reflections (SHELXL-97) [61]. All of the non-hydrogen atoms were refined anisotropically.

2.4. Quantum chemical calculations

Quantum chemical (QC) calculations were performed by employing the 6-311+G(d) basis set of the GAUSSIAN 03 program [62] at the density functional theory (DFT) level of the Becke three-parameter hybrid functionals combined with the Lee–Yang–Parr correlation functional (B3LYP) [63]. QC calculations were also performed by employing the 6-31+G(d) basis set for Se and the 4-31G(d) basis set for other nuclei of the GAUSSIAN 03 program [62] at the Møller–Plesset second order energy correlation (MP2) level [64–66].

3. Results and discussion

3.1. Structures of 1 in crystals

Single crystals were obtained for **1a–c**, **1e**, **1h** and **1i** via slow evaporation of dichloromethane–hexane or ethyl acetate solutions. The X-ray crystallographic analyses were carried out for a suitable crystal of each compound. One type of structure corresponds to **1b**, **1c**, **1e**, **1h** and **1i**, and two-types to **1a** in the crystals. The crystallographic data are collected in Table 1. Figs. 1–4 show the structures of $\mathbf{1a}_A$, **1b**, **1e** and **1i**, respectively. The structures of $\mathbf{1a}_B$, **1c** and **1h** are shown in the Supplementary data. Selected interatomic distances, angles and torsion angles, necessary for the discussion, are collected in Table 2. Scheme 3 summarizes the structures of **1**, together with those of **3**.

As shown in Figs. 1–4 and Table 2, the structure of **1** is **A** (**1** (**A**)) for non-acceptor Y groups, such as H (**a**), OMe (**b**), and Me (**c**), whereas it is **B** for acceptors Y groups (**1** (**B**)), such as Cl (**e**), CN (**h**) and NO_2 (**i**) (Scheme 3). The results are quite a contrast to the case of **3**, where the structure of **3** is **B** when Y is OMe and **A** when Y is Cl and NO_2. The ethynyl group interrupting between *p*-YC_6H_4 and Se changes the structures dramatically: (**B**: **pd**) of **3b** to (**A**: **pd**) of **1b**, (**A**: **pl**) of **3e** to (**B**: **pd**) of **1e**, and (**A**: **pl**) of **3** (Y = CO_2Et) to (**B**: **pl**) of **1i**, where Y = CO_2Et is employed in place of Y = NO_2 for **3**.[2] The direction of Y-dependence in **1** is just the inverse to the case of **3**. We call the factor to determine the fine structure of **1** the "*ethynyl effect*".

The structures of **1a–c** are observed as dimers. Fig. 5 shows the dimer formed from **1a**, which contains $\mathbf{1a}_A$ and $\mathbf{1a}_B$. Dimers of **1b** and **1c** are essentially the same as that of **1a**, and are shown in the Supplementary data. The Se atoms in the **1a** dimer are in short contact with C at the 6′ position of the partner molecule and the Se1—C6′ distance is 3.392 Å. The overlap between the two naphthyl planes must be large in this case.[3] The driving force of the dimer formation must be the energy lowering effect by the π-stacking of the naphthyl groups. The π(C)–σ*(Se–C_{sp}) 3c–4e interaction must also contribute to stabilize the dimers.

How do the electrons in n_p(Se) extend over the orbitals of **1**? The structures of $\mathbf{1a}_A$ (Y = H), **1b** (Y = OMe) and **1c** (Y = Me) are observed as (**A**: **pd**), that of $\mathbf{1a}_B$ (Y = H) as (**A**: **np**), that of **1d** (Y = Cl) as (**B**: **pd**), and those of **1h** (Y = CN) and **1i** (Y = NO_2) as (**B**: **pl**) (see Figs. 1–4 and Scheme 3). Scheme 4 illustrates the orbital interactions in **1** (**A**: **pd**), **1** (**A**: **pl**), **1** (**B**: **pd**) and **1** (**B**: **pl**). How the electrons in n_p(Se) extend over the π-frameworks are explained as: π(C≡C)–n_p(Se) in (**A**: **pd**), n_p(Y)–π(C_6H_4)–π(C≡C)–n_p(Se) in (**A**: **pl**), π(C≡C)–n_p(Se)–π(Nap) in (**B**: **pd**) and n_p(Y)–π(C_6H_4)–π(C≡C)–n_p(Se)–π(Nap) in (**B**: **pl**). **1** (**A**: **pd**) and/or **1** (**B**: **pd**) would be more stable than **1** (**A**: **pl**) and **1** (**B**: **pl**) for Y donating groups, since n_p(Se) is also a good donor. On the contrary, **1** (**A**: **pl**) and/or **1** (**B**: **pl**) must be more stable than **1** (**A**: **pd**) and **1** (**B**: **pd**) for Y acceptor groups. **1** (**A**: **pd**) is detected in crystals when Y = H, OMe and Me, which is in accordance with the observations, although the dimer formation also contributes to stabilize (**A**: **pd**) in **1a–c**. In the case of Y acceptor groups, **1** (**B**: **pd**) is observed in crystals for Y = Cl and **1** (**B**: **pl**) for Y = CN and NO_2. **1** (**B**: **pl**) must be more stable than **1** (**B**: **pd**) for stronger acceptor Y groups due to the wider extension of π-electrons.[4]

3.2. QC calculations

3.2.1. Evaluation of electron affinity (EA) for ArC≡CH and the structures of 1

The structures of **3** are well understood based on the relative magnitudes of the p(Se)–π(Ar) and p(Se)–π(Nap) conjugations [67]. The magnitudes of the conjugations can be estimated by the electron affinity (EA) of PhY and NapH, which are the components of **3**. The structure of **3** is reported to be **A** if π(Ar) stabilizes the electrons in n_p(Se) more effectively than π(Nap) [67]. The efficiency to stabilize the electrons in n_p(Se) can be estimated by the EA of PhY and NapH, the components of **3**. Namely, the structure of **3** is **A**, if EA(PhY) > EA(NapH).

$$EA = -0.900 \times \varepsilon(LUMO) - 1.484 \quad (1)$$

The EA of the molecules can be predicted based on the energy of the LUMO [67]. ε(LUMO) values are calculated with the B3LYP/6-311+G(d,p) method of the GAUSSIAN 03 program [62,63] for *p*-$YC_6H_4C{\equiv}CH$ (**10**), one of the components of **1**, and NapH. The EA of **10** are obtained based on ε(LUMO) by applying Eq. (1) [67]. Table 3

[2] The structure of **3i** is essentially the same as that of **3g**, although that of the former has not been determined by X-ray analysis due to the very thin nature of the crystals.

[3] An Se atom in the **1b** dimer is in short contact with C at the 4′ position of the partner molecule. The overlap between the two naphthyl planes is rather small in this case.

[4] **3** (**B**: **pl**) is not observed as a stable conformer, the steric repulsion between H_2 and H_o must be very large.

shows the evaluated EA values for **10** (Y = OMe, Me, H, Cl, CN and NO_2), together with ε(LUMO). As mentioned above, the structure of **1** is expected to be **A** if EA (**10**) > EA (PhCl) = −0.75 eV. (The structure of **3** (Y = Cl) is **A**.) The EA of **10** are larger than the EA (PhCl) for all Y examined, containing OMe, Me and H. Therefore, it is demonstrated that the structures of **1** can be **A** for all Y examined without the aid of the dimer formation, if the structures of **1** are determined only by the p(Se)–π(Ar) and p(Se)–π(Nap) conjugations.

3.2.2. Dimer formation

QC calculations were also performed on the dimer of **1a** by employing the 6-31+G(d) basis set for Se and the 4-31G(d) basis set for other nuclei of the GAUSSIAN 03 program [62] at the MP2 level [64–66].

Fig. 6 shows the optimized structure for the dimer of **1a**, the Se1–C6′ distance is 3.500 Å. The dimer formed from **1a** is predicted to be more stable than the corresponding monomers by 60.7 kJ mol^{-1} ($\Delta E = 2E$ (monomer) − E (dimer)). The driving force

for the dimer formation must be the energy lowering effect of the π-stacking of the naphthyl groups. The 3c–4e interaction of the π(C)–σ*(Se–C_{sp}) type would also contribute to stabilize the dimer structure.

3.3. Behavior of *1* in solution based on NMR spectroscopy

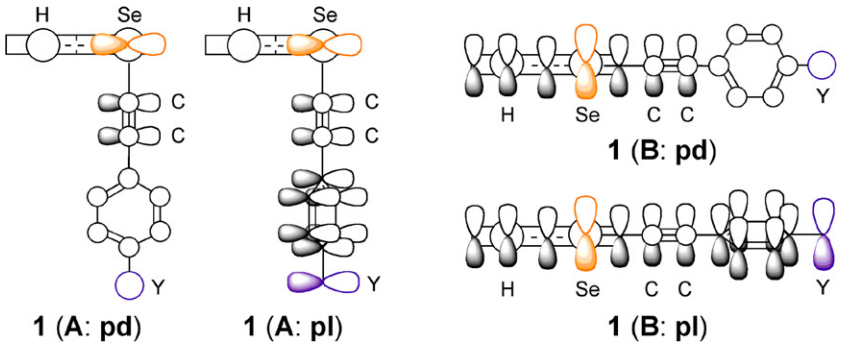
How do **1a**–**e**, **1h** and **1i** behave in solution? ^{1}H, ^{13}C and ^{77}Se NMR chemical shifts were measured in chloroform-*d*. Table 4 collects the $\delta(H_2)$, $\delta(H_8)$ and δ(Se) values. The shift ranges are 0.078, 0.092 and 4.4 ppm, respectively, which are small relative to the usual trends in substituent dependence [68,69]. This must be a reflection of the ethynyl group. It must be the result of the probe site in the NMR spectroscopy being separated far from the *p*-YC_6H_4 group by the ethynyl group.

The structures of **1** in chloroform-*d* solutions are analyzed based on the NMR chemical shifts, which are given in Table 4. The structure of 1-(arylselanly)anthracene [**11**: 1-(*p*-YC_6H_4-Se)$C_{14}H_9$] is established to be the standard of (**A**: **pl**) for all Y in Table 4 [68,69]. Therefore the $\delta(H_1)_{SCS}$ and $\delta(Se)_{SCS}$ values of **11** are employed as the standards for the analysis. Fig. 7 shows the plot of $\delta(H_8$: **1**) versus $\delta(H_1$: **11**). The correlation is shown in Eq. (2) and that for the plot of δ(Se: **1**) versus δ(Se: **11**) is given in Eq. (3).

$$\delta(H_8 : \mathbf{1})_{SCS} = -0.338 \times \delta(H_1 : \mathbf{11})_{SCS} - 0.007 \quad r = 0.991 \qquad (2)$$

$$\delta(Se : \mathbf{1})_{SCS} = 0.096 \times \delta(Se : \mathbf{11})_{SCS} + 0.18 \quad r = 0.960 \qquad (3)$$

The correlation for $\delta(H_8$: **1**) versus $\delta(H_1$: **11**) is good ($r = 0.991$) with a correlation constant (a) of −0.34 ($y = ax + b$: r). The negative value must be the reflection of the inverse direction of the anisotropic effect between the phenyl and the ethynyl groups. Therefore, the structures of **1** are mainly (**A**: **pl**) in solution, which is



Scheme 4. Orbital interactions in (**A**: **pd**), (**A**: **pl**), (**B**: **pd**) and (**B**: **pl**) in **1**.

substantially in accordance with the conclusion obtained from the EA analysis. The inverse effect by the ethynyl group on the structures of **1** is confirmed for non-acceptors Y groups, such as Y = OMe and Me, also in solution. However, the correlation coefficient of 0.991 might be the result of the equilibrium with other conformers such as (**B**: **pd**). The structures of **1** having Y acceptors such as NO_2 and CN seem to equilibrate with (**B**: **pd**), which should also be the reflection of the inverse effect by the ethynyl group.

4. Conclusions

The behavior of ethynylchalcogenyl groups is examined as the factor to control fine structures. Fine structures of

1-(p-$YC_6H_4C{\equiv}CSe$)$C_{10}H_7$ (**1**: Y = H (**a**), OMe (**b**), Me (**c**), Cl (**e**), CN (**h**) and NO_2 (**i**)) are determined by X-ray crystallographic analysis. The structures are (**A**: **pd**) or (**A**: **np**) for **1a–c** bearing non-acceptors Y groups, it is (**B**: **pd**) for **1e** with Y = Cl, and (**B**: **pl**) for **1h** and **1i** with Y being the strong acceptors CN and NO_2. The Y-dependence observed in **1** is just the opposite to the case of 1-(p-YC_6H_4-Se)$C_{10}H_7$ (**3**). The factor to control the fine structures of **1** is called the "*ethynyl effect*". The parallel direction between n_p(Se) and n_p(Y) operates to lower the energy if Y is an acceptor but it destabilize the system for donor Y groups. Therefore, the origin of the ethynyl effect is explained based on the idea how widely the electron in n_p(Se) extends over the π-framework under the conditions for n_p(Se) and n_p(Y). Crystal packing effects giving the formation of dimers also plays an important role in controlling the structures. The structures of **1** in solution are also examined based on NMR chemical shifts, employing the data for (**A**: **pl**) of 1-(arylselanly)anthracene (**11**). The results show that the structures of **1** are mainly (**A**: **pl**) with some equilibria with other conformers such as (**B**: **pd**). The inverse effect of the ethynyl group as the factor to control the structure of **1** in solution is confirmed. The results exhibit that fine structures of arylethynylchalcogenyl compounds can be widely controlled by modulating the electronic conditions around the chalcogen atoms.

Conformational analysis
Cambridge Structural Database
Pseudorotation

ABSTRACT

The conformational preferences in the $\{M(\mu\text{-}OPO)\}_2$ core of transition metal complexes double bridged by phosphate and related ligands have been determined using data retrieved from the Cambridge Structural Database by a probabilistic method. The preferred conformations lie on a pseudorotation pathway (*chair* and *twist-chair* conformations). The influence of intra-ring bridges, metal atom, coordination number or ligand in the conformational preferences has been investigated.

1. Introduction

Conformational features of organic molecules [1] and metallic complexes [2] have been extensively studied, and the CSD has proved to be a useful tool in both fields [3,4]. It is in particular worth mentioning the contribution of Álvarez and co-workers studying several conformational aspects of transition metal complexes [5,6]. The CSD has been widely applied to life-science research too [7], where it has turned out to be a very useful resource for the rational design of biologically active molecules.

Regarding the system analyzed in this paper, it is significant in the study of metalloenzymes that catalyze the hydrolysis of phosphate ester bonds in biological molecules. A systematic variation of ligands and coordination environments in these biological analogues has provided information about the structure and function of enzymes. Although zinc is the most common metal found in these enzymes, copper(II) complexes have also contributed to the general understanding of these processes [8,9].

Other important research areas involving transition metal complexes double bridged by phosphates and related ligands are the preparation of molecular sieves because of their potential application in ion-exchange, catalysis and separations [10], proton conductivity or non-linear optics.

In spite of the importance of the title compounds, we are not aware of a systematic study about the conformational preferences in the solid state of such complexes. This paper tries to cover this lack.

2. Experimental

The Cambridge Structural Database [1] (CSD) V. 5.28 (November 2006 + an update) was searched for all the structures containing the fragment shown in Fig. 1. The query was filtered so that only the structures without disorder in the ring were retrieved. A total of 881 *refcodes* matched the search, the total number of fragments being 2377. Torsion angles were measured by the CONQUEST 1.9 program [1] and transferred to an ASCII text file for statistical and graphical analysis. Out of these 2377 fragments, 1320 were found to incorporate various types of phosphate moieties (hereafter referred to as phosphates), 916 bis(phosphonate) or bis(phosphonate ester) complexes (hereafter referred to as phosphonates), and 141 bis(phosphinate) complexes (hereafter referred to as phosphinates).

The most probable conformation for each fragment was established by the Classification method using the RingConf software with $\sigma = 10°$ [11]. *Refcodes*, torsion angles and the most probable conformations can be found in the Supplementary data.

A total of 21 possible conformations appear when the core shown in Fig. 1 (that shows topological symmetry D_{2h}) is studied, referring to the 10 canonical conformations of cyclooctane [12]. Fig. 2 shows these 21 conformations with their corresponding point group symmetry; bond distances and angles were not considered in the derivation of these *type* conformations.

The Classification method allows an individual classification of the given structure to be assigned. Based on the values of the torsion angles for a structure, we are able, through the Bayes rule, to

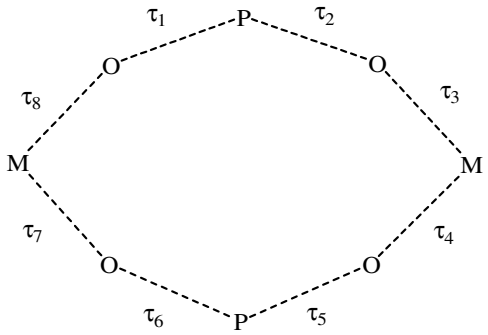

Fig. 1. Substructure used in the conformational study, M = transition metal.

compute the posterior probability that the structure comes from one of the 21 *type* conformations shown in Fig. 2.

3. Results and discussion

The appearance of internal links in the fragment defined in Fig. 1 imposes the most severe conditions to the conformation in the eight-membered ring. Because of this reason we have studied separately three sets of data.

(a) Structures having direct links or one atom bridges in the $\{M(\mu\text{-}OPO)\}_2$ moiety

This set includes the most rigid structures, direct links (or one atom bridges) restrict the conformational freedom. A total of 929 fragments were retrieved from the CSD for this set of data. Most of them correspond to molybdenum complexes. Each of the other metals has less than 10% of the data. Fig. 3 shows the distribution of data by metals.

Only a few conformations from the 21 possible in Fig. 2 are significant for this set of structures. The conformation adopted depends strongly on the kind of bridge. The most abundant types of bridges are:

- M–X–M, X being mostly O and to a minor extent F. 278 fragments contain this bridge, the most frequent conformations in this case are B_1 (36% of fragments), BC_2 (18%) and TCC_1 (17%).
- O–X–O (oxygen atoms in relative positions 1,5), X usually being the metal in the ring (Fig. 1). 235 fragments contain this bridge, conformations are nearly restricted to two kinds: BC_3 (60% of fragments) and TB_1 (38%).

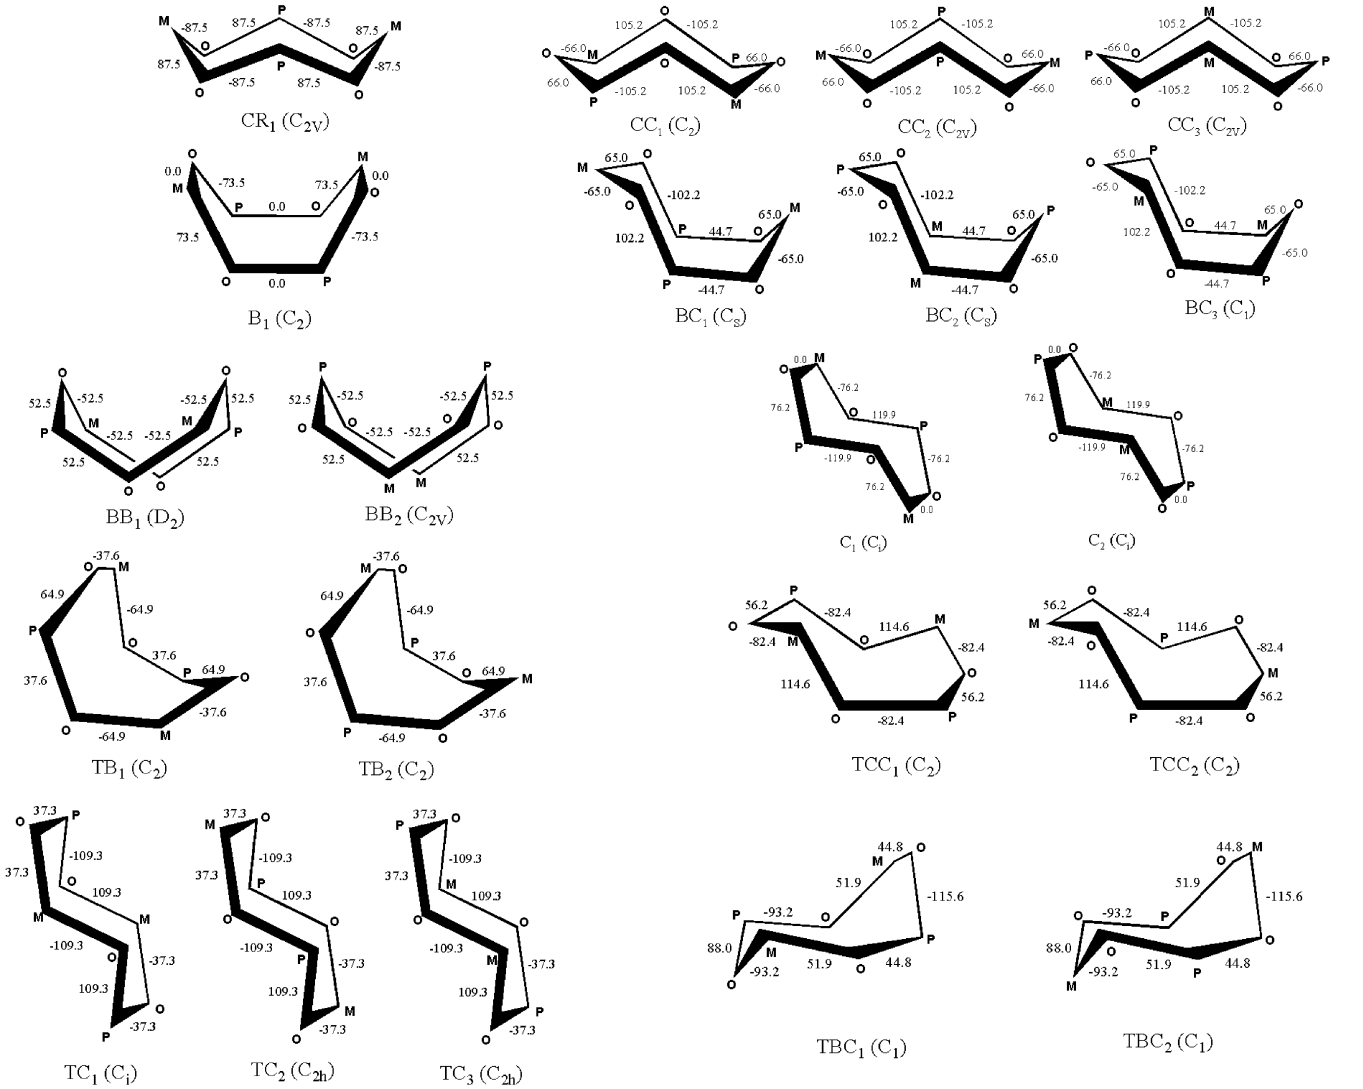

Fig. 2. Conformation type for $\{M(\mu\text{-}OPO)\}_2$. Torsion angles were taken from Ref. [12].

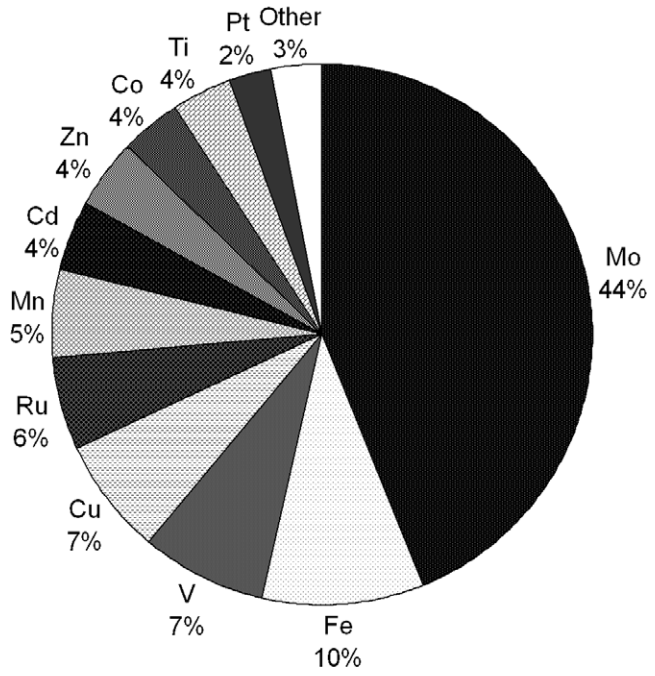

Fig. 3. Relative abundance by metal in set *a*.

- P–X–P, X usually being C. 111 fragments contain this bridge, the most frequent conformations in this case are CC_2 (47%) and BC_1 (30%).
- M···M. 88 fragments contain this bridge, the most frequent conformations in this case are CC_3 (27% of fragments), B_1 (26%) and BC_2 (15%).

There are a significant number of data having at the same time two of the above types of bridge. Forty three data contain both M–X–M and P–X–P bridges and 21 data show P–X–P and M···M links with several metal atoms being represented in these structures. All of them exhibit the BB_2 conformation, which is not the most frequent when there is only one bridge but seems to be the only one compatible with the presence of two bridges simultaneously (Fig. 4).

(b) Structures not included in set *a*

Excluding this way the structures with high constraints in their conformation, the data analysis should allow us to establish the accessible conformations and the influence (if any) of the kind of metal or bridge. Among others, belonging to this set are the polycyclic structures and structures bridged by two or more atoms. In both cases there is still some constraint in the conformation but also some degree of freedom.

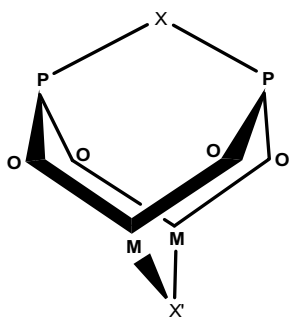

Fig. 4. BB_2 conformation including P–X–P and M–X′–M bridges.

A total of 1448 fragments were retrieved from the CSD for this set. Most of them correspond to zinc complexes (32% of the total); next metals in abundance comprise vanadium (14%), molybdenum (11%) and copper (9%), Fig. 5 shows the distribution of data by metals.

The conformation of these fragments was also assessed using the eight torsion angles in the ring by the Classification method implemented by the authors [11]. A histogram of the conformation assigned to this dataset by this method is shown in Fig. 6. As can be seen the most frequent conformation is C_1 (21% of data), only two more conformations show a frequency higher than 10%: BC_3 and B_1.

Influence of the kind of bridge. In order to determine the influence of the kind of bridge on the conformation, the phosphate, phosphonate and phosphinate bridges were analyzed separately. A total of 888, 457 and 103 fragments of phosphate, phosphonate and phosphinate, respectively, were studied using the Classification method. Histograms showing the frequency for each conformation are shown in Fig. 7.

The histograms for phosphate and phosphonate are very similar. C_1 is the most frequent conformation, it appears in 20% of data approximately, and also in both cases BC_3 and B_1 are the second and third most usual conformations.

Results of the phosphinate structures show similarities and differences with those of the phosphates and phosphonates. Firstly, it is necessary to note that there are far fewer phosphinate bridges than the other kind of bridges. In a similar way C_1 and B_1 are very frequent conformations: 18% and 11% of data, respectively. The principal difference in phosphinate complexes is the high frequency found for TB_1 and BC_2 conformations. This difference can be explained in terms of a statistical distortion of data, as exemplified by the TB_1 conformation. In this case from a total of 19 fragments 15 of them belong to 3 different compounds, furthermore the structure HUWHUC [13] provides 10 fragments. It can be then concluded that there are no significant differences in conformational preferences among phosphates, phosphonates and phosphinates.

Influence of the kind of transition metal atom. In order to investigate the influence of the metal atom in the conformation of the

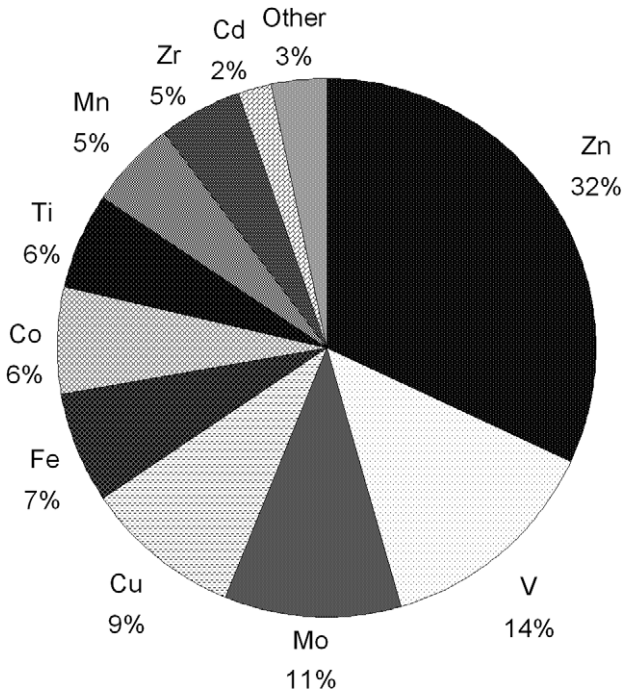

Fig. 5. Relative abundance by metal in set *b*.

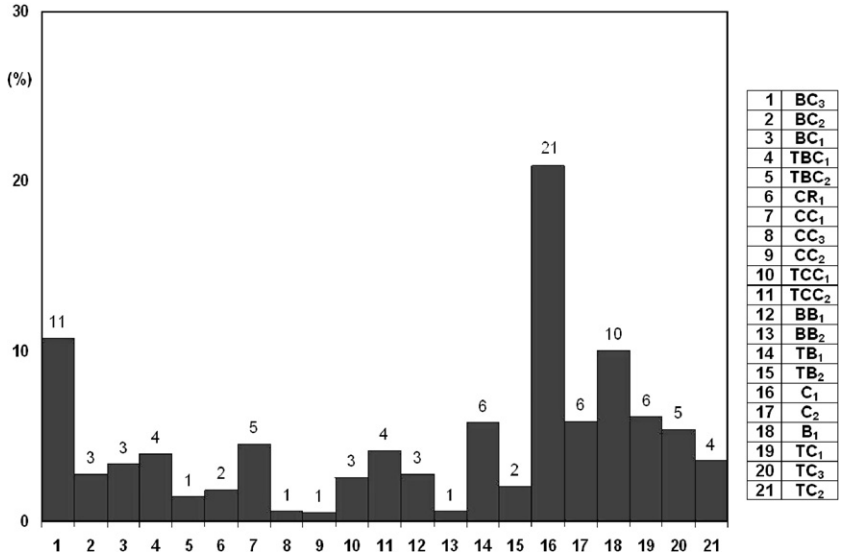

Fig. 6. Frequencies of the most likely conformations for structures included in set *b*.

{M(μ-OPO)}$_2$ core, we performed separated studies by various metals, and the results are summarized in Table 1. As can be seen, conformation C_1 appears in all the metals with a high percentage, indeed even in cobalt (the only case in which C_1 does not appears in Table 1) C_1 appears in 8% of data. Moreover, C_1 is the most frequent conformation in 5 of the 10 metals in Table 1. B_1 and BC_3 conformations also are widely represented through Table 1.

As can be seen in Table 1 there is no correlation between the metal atom or coordination number and the conformation of the {M(μ-OPO)}$_2$ core. Molybdenum and copper complexes show the most defined conformational preferences. In the case of zinc a detailed survey of data reveals the high percentage of the BC_3 conformation is a consequence of a statistical distortion because some *refcodes* supply several fragments. As an example BESJIT [14] and IBOSIB [15] contain 7 and 5 fragments, respectively. This effect is frequent through Table 1 and some significant examples are the following: in the vanadium complexes 21 fragments show a TC_1 conformation, 9 of them belong to the same complex, RARZOZ [16]. In the cobalt complexes 15 fragments show a B_1 conformation, 6 of them belong to the same structure, MEKTUS [17]. In the manganese complexes 16 fragments show a TB_1 conformation, 10 of them belong to the same compound, HUWHUC [13].

In order to elucidate the real influence of the kind of metal and the coordination number, avoiding the statistical distortion induced by *refcodes* with several fragments, we have studied the next set of data.

(c) Structures having only one fragment without internal bridges

Finally, structures having only one fragment without internal bridges were used to establish the conformational preferences when connectivity does not impose any conformational constraint. This set allows the study of conformations avoiding the constraints imposed by internal bridges or polycyclic systems, thus structures in this set have the highest conformational freedom. A total of 285 data fulfilled these conditions, and complexes of Zn (29%), V (18%), Mo (1%), Cu (17%), Fe (8%), Co (6%), Ti (3%), Mn (4%), Zr (3%) and Cd (2%) are included. At the same time all the coordination numbers are significantly represented: 4,4 (35%) 5,5 (25%) and 6,6 (36%).

The most probable conformation was established by the Classification method, and the results are shown in Fig. 8. As can be seen the most frequent conformation is C_1 (21% of data), this result is similar to that obtained in set *b*, but the histogram in Fig. 8 shows significant new features: TC_1 and C_2 are now the second and third most frequent conformations, at the same time B_1 and BC_3 exhibit a much lesser abundance than in set *b* (compare Figs. 8 and 6).

When the data are analyzed separately for each metal the results are more homogeneous than in set *b*. In this case the C_1 conformation is always the most frequent, so it can be concluded that when the influence of having polycyclic systems is removed, the metal atom does not exert a significant influence on the conformation of the ring.

Regarding the coordination number, data were analyzed separately for each possible set (4,4; 5,5 and 6,6) and the results are shown in Table 2. As can be seen, the coordination number cannot be related to the conformation in the {M(μ-OPO)}$_2$ moiety.

The information in Table 2 is completed by other coordination numbers that are also scarcely represented. 4,5 appear in two fragments (CR_1 and B_1); 4,6 appear in one fragment (TC_2); 5,6 appear in six fragments (two BC_3, two BC_2, one BC_1 and one TC_1).

The results shown in Fig. 8 can be rationalized in the next manner: in structures analyzed in set *c* the {M(μ-OPO)}$_2$ core has a high degree of freedom (structures that are not polycyclic and without internal bridges) so the results can be related to the interconversion of conformers.

Conformers of cyclooctane have been grouped in four families: *boat–chair* (conformers BC and TBC), *crown* (TCC, CR, CC), *boat* (BB, TB, B) and *chair* (C, TC). Conformers inside each family can interconvert by a pseudorotational mechanism [18]. In a similar way, the *type* conformations shown in Fig. 2 for the {M(μ-OPO)}$_2$ moiety can be grouped in families whose conformers are able to interconvert by a pseudorotational mechanism. Two more accessible paths for the interconversion of conformations are possible in an analogous mode to that found in cyclooctane [19]. Fig. 9 summarizes the interconversion paths for {M(μ-OPO)}$_2$.

As can be seen in Fig. 9, *chair* and *twist-chair* conformations are situated on a pseudorotation interconversion pathway and it can explain that TC_2, C_1, TC_1, C_2 and TC_3 conformations correspond to 64% of the data in Fig. 8. In a similar way, in the boat family BB_2, TB_2, B_1, TB_1 and BB_1 can interconvert by pseudorotation, and they comprise 18% of the data in Fig. 8. There is also a pseudorotation

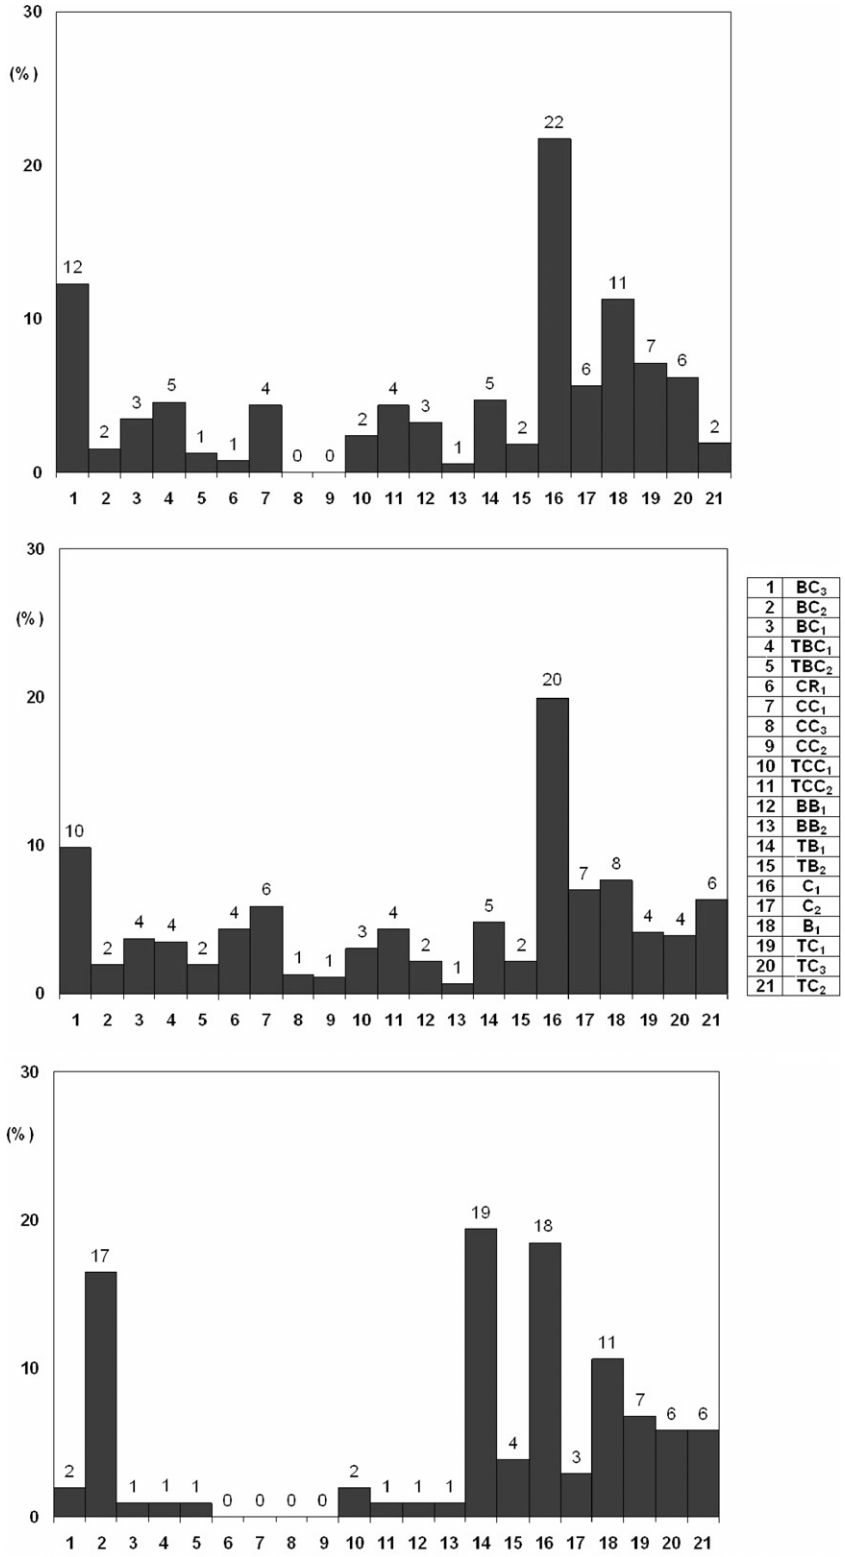

Fig. 7. Frequencies of the most likely conformations in phosphates (top), phosphonates (middle) and phosphinates (bottom) in set *b*.

path for the *boat–chair* family, BC_1, TBC_2, BC_3, TBC_1 and BC_2 group, 12% of the data in Fig. 8.

In order to complete the study of factors that could influence the conformation in the $\{M(\mu\text{-}OPO)\}_2$ core we have tested the role of the terminal ligands coordinated to the metal. Thirteen structures containing the tris(pyrazolyl)borate ligand were found, a high variety of conformations was observed: C_1, C_2, BC_1, BC_2, BC_3, CC_1, TC_1, TC_2, etc. Twelve structures containing the oxalate ligand were retrieved (metal atoms V, Co, Fe and Mn), and again a high variety in the conformation was observed (C_1, C_2, BC_2, BC_3 or TC_1).

Table 1
Conformations for $\{M(\mu\text{-OPO})\}_2$ in transition metal complexes

Metal	Number of fragments	Coordination number[a]	Most frequent conformations
Zn	463	4,4 (86%) 5,5 (10%) 6,6 (3%)	BC_3 (21%) B_1 (11%) C_1 (10%) C_2 (10%)
V	197	4,4 (2%) 5,5 (41%) 6,6 (40%)	TC_3 (13%) TC_1 (11%) BC_3 (10%) C_1 (8%)
Mo	153	6,6 (100%)	C_1 (73%) TBC_1 (14%)

Other	48	4,4 (12%) 5,5 (15%) 6,6 (73%)	C_1 (15%) B_1 (15%) TB_1 (13%) TC_1 (13%) TC_3 (13%)

[a] 6,6 include coordination number 6 or higher.

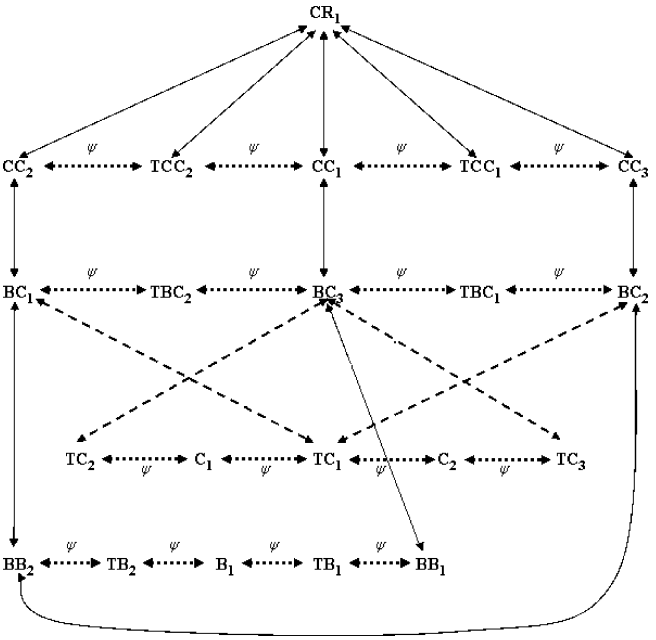

Fig. 9. Interconversions of the $\{M(\mu\text{-OPO})\}_2$ core.

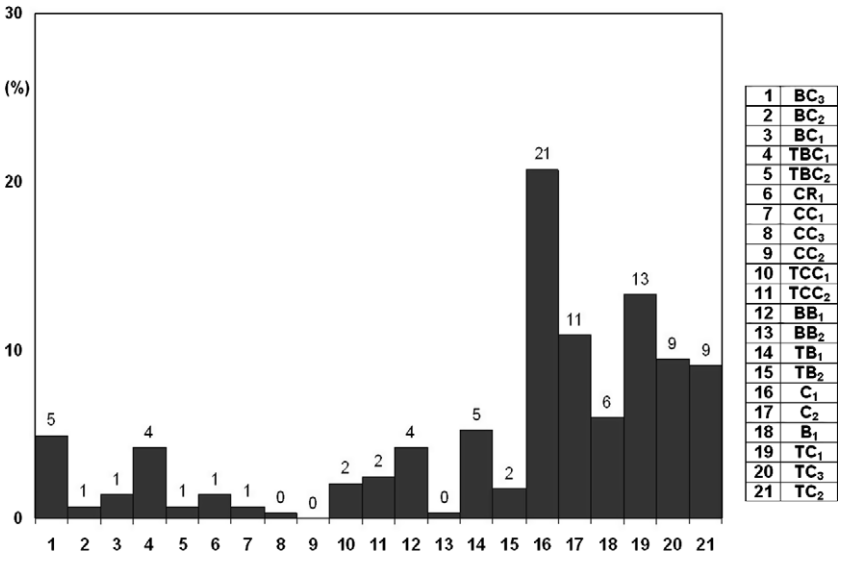

Fig. 8. Frequencies of the most likely conformations in structures included in set *c*.

Table 2
Conformations for $\{M(\mu\text{-OPO})\}_2$ in structures studied in set *c*

Coordination number	Number of data	Most frequent conformations
4,4	100	C_1 (15%) TC_1 (10%) B_1 (10%) BB_1 (10%)
5,5	72	C_1 (32%) TC_1 (14%) C_2 (13%)
6,6	104	C_1 (20%) TC_1 (16%) TC_3 (14%) C_2 (13%)

4. Conclusions

1. The presence of intra-ring bridges in the $\{M(\mu\text{-OPO})\}_2$ moiety is the most determinant factor in the conformation of the eight-membered ring.
   - Structures having two simultaneous links between phosphorus atoms and metal atoms show BB_2 conformations.
   - Structures having O–X–O bridges show BC_3 or TB_1 conformations.
   - Structures having P–X–P bridges show preferably CC_2 or BC_1 conformations.
2. The kind of bridge (phosphate, phosphonate or phosphinate) does not introduce any conformational preference in the $\{M(\mu\text{-OPO})\}_2$ moiety of transition metal complexes.
3. The most frequent conformation in transition metal complexes double bridged by phosphate and related ligands is a *chair* conformation, C_1.
4. When structures without constraints imposed by polycyclic systems or internal bridges are analyzed, the conformations observed can be rationalized in terms of conformation families in pseudorotation pathways:
   - 64% of data show a conformation belonging to the *chair* family (*chair* and *twist-chair* conformations)

- 18% of data show a conformation belonging to the *boat* family (*boat*, *boat–boat* or *twist-boat* conformations)
- 12% of data show a conformation belonging to the *boat–chair* family (*boat–chair* or *twist-boat–chair* conformations)

5. The transition metal or the coordination number in the $\{M(\mu\text{-}OPO)\}_2$ core do not exert a significant influence in the conformation of that ring.

ABSTRACT

Four d^{10}-metal coordination polymers based on the 2,4,5-tri(4-pyridyl)-imidazole ligand (Htpim), $\{[Zn_2(Htpim)_4Cl_4]\cdot 8H_2O\}_n$ (**1**), $\{[Cd(tpim)_2(H_2O)_2]\cdot 4CH_3OH\}_n$ (**2**), $\{[Cu_2(Htpim)(PPh_3)_2I_2]\cdot CH_3CN\}_n$ (**3**) and $\{[Ag(Htpim)](NO_3)\cdot CH_2Cl_2\}_n$ (**4**), have been synthesized and characterized by elemental analyses, IR, thermogravimetric and X-ray structural analyses. Both complexes **1** and **2** show one dimensional ribbon-like structures. Via intermolecular hydrogen bonds, a 2D supramolecular network and 3D framework are formed for **1** and **2**, respectively. Complex **3** shows a 1D zigzag chain with a CuI_2Cu rhomboid dimer. Complex **4** shows a 1D ladder-like polymer with two different metallacycles. The luminescent properties of all the complexes have been studied in the solid state.

1. Introduction

In the past few decades, considerable attention has been devoted to the design and syntheses of coordination polymers not only due to their aesthetic architectures and new topologies [1–3], but also because of their potential applications [4–6], such as gas storage [7–9], catalysis [10,11], ion exchange [12,13], photoluminescence [14–19], non-linear optics [20,21] and magnetism [22–26]. Recently, increasing investigations carried out on coordination polymers were focused on the use of the rigid multi-pyridyl ligands, such as 4,4′-bipyridine [27], 2,4,6-tri(4-pyridyl)-1,3,5-triazine [28,29], 5,10,15,20-tetra-4-pyridy-21H,23H-porphine [30] and 2,5-bis(4-pyridyl)-1,3,4-oxadiazole [31,32] as building blocks, because they can afford structural diversities, robustness and stability of metal–organic coordination polymers.

Among the rigid multi-pyridyl ligands, the 2,4,5-tri(4-pyridyl)-imidazole (Htpim) ligand has three pyridine N atoms and two imidazole N atoms (Scheme 1), and is suitable to be a good spacer in the construction of new metal–organic coordination polymers. To our best knowledge, coordination polymers of the Htpim ligand have not been documented so far. Herein, we report the syntheses, crystal structures and luminescent properties of four 1D coordination polymers of d^{10}-metal ions: $\{[Zn_2(Htpim)_4Cl_4]\cdot 8H_2O\}_n$ (**1**), $\{[Cd(tpim)_2(H_2O)_2]\cdot 4CH_3OH\}_n$ (**2**), $\{[Cu_2(Htpim)(PPh_3)_2I_2]\cdot CH_3CN\}_n$ (**3**) and $\{[Ag(Htpim)](NO_3)\cdot CH_2Cl_2\}_n$ (**4**).

2. Experimental

2.1. General procedures

The rigid ligand 2,4,5-tri(4-pyridyl)-imidazole (Htpim) was synthesized according to the literature method [33]. All other reagents and solvents were commercially available and were used without further purification. Elemental analyses for C, H and N were performed on a CHN-O-Rapid analyzer and an Elementar Vario MICRO analyzer. The IR spectra were recorded on a Bruker Vector 22 FT-IR spectrometer using KBr discs in the 4000–400 cm^{-1} range. Thermogravimetric analyses were carried out on a Perkin–Elmer Pyris 1 TGA analyzer from room temperature to 750 °C with a heating rate of 20 °C/min under nitrogen. Photoluminescence analyses for the solid samples were taken on an AMINCO Bowman Series2 luminescence spectrometer.

2.2. Preparation of the complexes

2.2.1. Preparation of $\{[Zn_2(Htpim)_4Cl_4]\cdot 8H_2O\}_n$ (**1**)

A methanolic solution (4 ml) of Htpim (15 mg, 0.05 mmol) was added to an aqueous solution (6 ml) of $ZnCl_2$ (7 mg, 0.05 mmol) with stirring. Orange diamond-like single crystals of **1** were obtained after the mixture was allowed to stand at room temperature for a week. Yield: 44%. *Anal.* Calc. for $C_{72}H_{68}Cl_4N_{20}O_8Zn_2$: C, 53.58; H, 4.25; N, 17.36. Found: C, 53.70; H, 4.65; N, 16.90%. IR (KBr, cm^{-1}): 3445(br), 1614(vs), 1430(s), 1261(m), 1128(s), 1062(m), 1285(m), 1015(w), 839(s), 747(m), 690(s), 614(m), 511(m).

Htpim

Scheme 1. Molecular structure of the ligand.

*2.2.2. Preparation of {[Cd(tpim)$_2$(H$_2$O)$_2$] · 4CH$_3$OH}$_n$ (**2**)*

$Cd(ClO_4)_2 \cdot 6H_2O$ (21 mg, 0.05 mmol) in 10 ml of CH_3OH was layered onto a solution of Htpim (15 mg, 0.05 mmol) in 10 ml of DMF. The resultant solution was allowed to slowly diffuse for several weeks to give yellow plate-like crystals. The crystals were collected, washed with methanol and dried in vacuum. Yield: 32%. *Anal.* Calc. for $C_{40}H_{44}N_{10}O_6Cd$: C, 55.01; H, 5.08; N, 16.04. Found: C, 54.71; H, 5.35; N, 16.74%. IR (KBr, cm^{-1}): 3448(br), 3205(s), 1600(vs), 1504(m), 1429(m), 1341(w), 1245(w), 1213(m), 1149(w), 1061(w), 983(m), 872(w), 839(m), 751(m), 719(m), 689(m), 522(m).

*2.2.3. Preparation of {[Cu$_2$(Htpim)(PPh$_3$)$_2$ I$_2$] · CH$_3$CN}$_n$ (**3**)*

A mixture of CuI (19 mg, 0.10 mmol), Htpim (15 mg, 0.05 mmol), PPh_3 (22.6 mg, 0.10 mmol) in CH_3CN (8 ml) and MeOH (0.2 ml) was sealed in a Teflon-lined stainless steel vessel, heated at 180 °C for 3 days and cooled to room temperature. The reaction mixture was filtered and left to stand at room temperature. Red-dark rod-like crystals suitable for X-ray analysis were obtained by slow evaporation of the solvent over two days. Yield: 20%. *Anal.* Calc. for $C_{56}H_{46}Cu_2I_2N_6P_2$: C, 54.00; H, 3.72; N, 6.74. Found: C, 54.47; H, 3.70; N, 7.10%. IR (KBr, cm^{-1}): 3447(br), 3261(s),

2.2.4. Preparation of $\{[Ag(Htpim)](NO_3)\cdot CH_2Cl_2\}_n$ (**4**)

A buffer layer prepared by mixing MeCN and CH_2Cl_2 (1:1, v/v) was carefully covered on solution of Htpim (15 mg, 0.05 mmol) in CH_2Cl_2/DMF (5 ml, 4:1). Then, a solution containing $AgNO_3$ (8.5 mg, 0.05 mmol) in MeCN (5 ml) was slowly added above the buffer layer. After four weeks, light yellow rod-like crystals formed at the buffer layer. Yield: 35%. *Anal.* Calc. for $C_{19}H_{15}AgCl_2N_6O_3$: C, 41.25; H, 2.55; N, 15.20. Found: C, 41.12; H, 2.83; N, 15.28%. IR (KBr, cm^{-1}): 3446(br), 1606(vs), 1582(s), 1559(w), 1508(w), 1490(w), 1384(s), 1281(m), 1131(w), 1066(w), 1004(w), 833(s), 745(m), 703(w), 688(m), 617(m), 516(w).

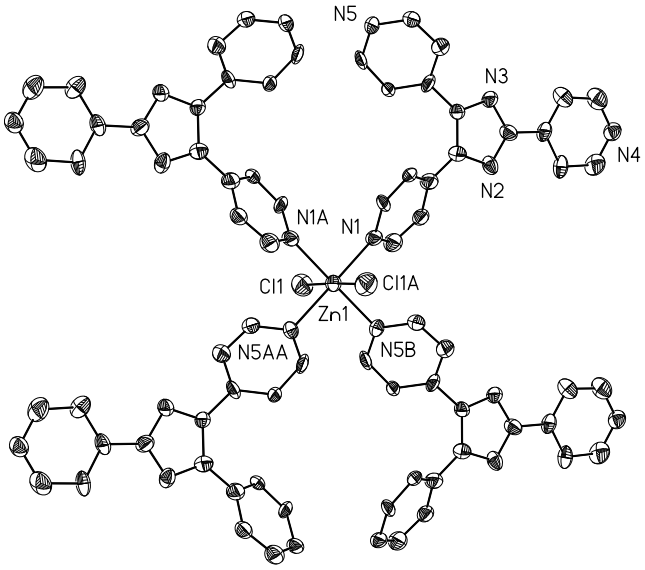

Fig. 1. View of the coordination environment of Zn(II) in complex **1**, thermal ellipsoids are drawn at the 50% probability level. Lattice water molecules and hydrogen atoms have been omitted for clarity.

2.3. X-ray crystallography

Suitable single crystals of **1–4** were selected and mounted on glass fibers in air. X-ray intensity data were collected on a Bruker SMART APEX CCD diffractometer [34] using graphite monochromatized Mo Kα radiation (λ = 0.71073 Å) at 291(2) K. The raw data were reduced and corrected for Lorentz and polarization effects using the SAINT program and for absorption using the SADABS program. The structures were solved by direct methods and refined with the full-matrix least-squares technique using SHELXTL version5.1 [35]. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. The hydrogen atoms were found in a difference Fourier map and the N–H hydrogen atoms were refined with an N–H distance restraint [0.86(7) Å] and $U_{iso}(H) = 1.2U_{eq}(N)$. The remaining hydrogens were added at calculated positions and refined riding on their parent atoms. The crystallographic data are given in Table 1. Selected bond lengths and bond angles are listed in Table 2. The corresponding H-bond data are listed in Table 3.

3. Results and discussion

3.1. Syntheses and IR

The reaction of Htpim with $ZnCl_2$ in MeOH/H_2O afforded compound **1**. Compound **2** was prepared by layering a solution of $Cd(ClO_4)_2\cdot 6H_2O$ in CH_3OH with a Htpim solution in DMF. The hydrothermal reaction of CuI, Htpim and PPh_3 in CH_3CN gave compound **3**. Complex **4** was obtained by the slow diffusion of Htpim in CH_2Cl_2/DMF into $AgNO_3$ in MeCN.

In the IR studies, there is a broad band centered at 3445 cm^{-1} for **1** and it can be assigned to the O–H stretching of the crystalline water molecules. For **2**, the broad band around 3448 cm^{-1} results from the O–H stretching of the crystalline methanol molecules and the coordinated water molecules. For **3** and **4**, the very strong absorptions at 3446 and 3447 cm^{-1} are attributed to the N–H stretching of the ligand. The characteristic absorption band of the crystalline CH_3CN molecules ($\nu_{C\equiv N}$) for **3** appears at 2253 cm^{-1}. For **4**, the characteristic absorption of the NO_3^- anion is at 1384 cm^{-1}. In addition, the absorption bands resulting from the

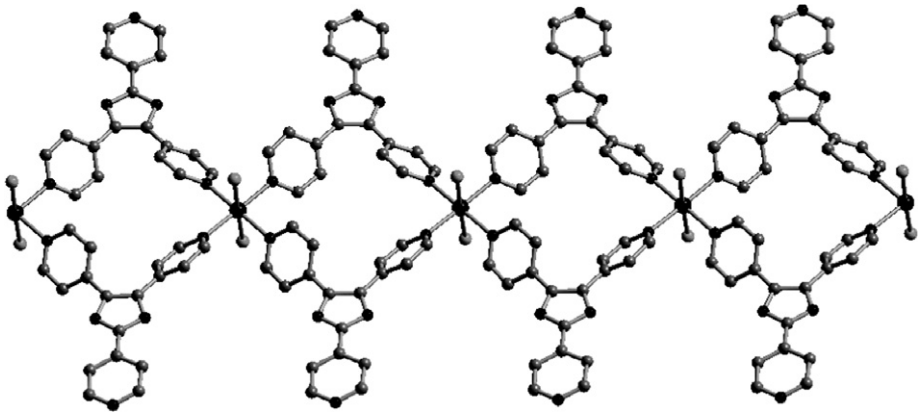

Fig. 2. A ribbon-like chain structure for complex **1**.

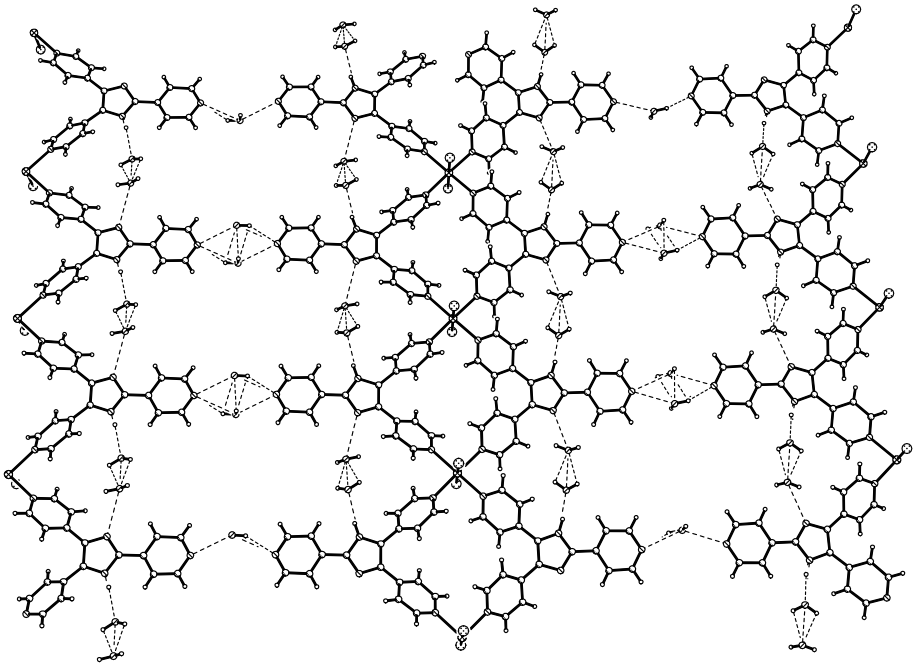

Fig. 3. The 2D layered structure of **1** via intermolecular hydrogen bonds (viewed down the *c* axis).

skeletal vibrations of the aromatic rings of the ligand for all the four complexes appear in the 1400–1600 cm^{-1} region.

3.2. Description of the crystal structures

The X-ray crystallographic analysis reveals that the asymmetric unit of complex **1** contains one ligand molecule, half of one Zn^{2+} ion, one Cl^- ion and two solvated water molecules. As shown in Fig. 1, the Zn(II) center has a slightly distorted octahedral geometry and is six-coordinated with four N atoms of equivalent pyridines from four different ligands in the equatorial plane and two Cl^- ions in the axial sites. The Zn–N distances are 2.162(3) and 2.145(3) Å. The Cl–Zn–Cl bond angle is 177.91(6)°, which is close to a linear geometry. As depicted in Fig. 2, two Zn(II) atoms and two ligands form a 22-membered macrocylic ring and the rings are further connected by the Zn–N coordination bonds to generate a 1D ribbon-like polymer. In the macrometallacycle, the neighboring Zn···Zn diagonal distance is 10.032 Å. Moreover, the hydrogen bond occurring at O3–H3Y···N4(#5) (2.861(4) Å, symmetry code: $x + 1, y, z$) from the uncoordinated N4 atom of the pyridine of the ligand and one solvated water molecule gives rise to a two dimensional network (Fig. 3). In addition, the other solvated water molecule forms an intermolecular hydrogen bond with the N3 atom of imidazole and the N3–H3A···O2 distance is 2.936(5) Å. All the above hydrogen-bonding interactions may stabilize the solid-state structure of **1**.

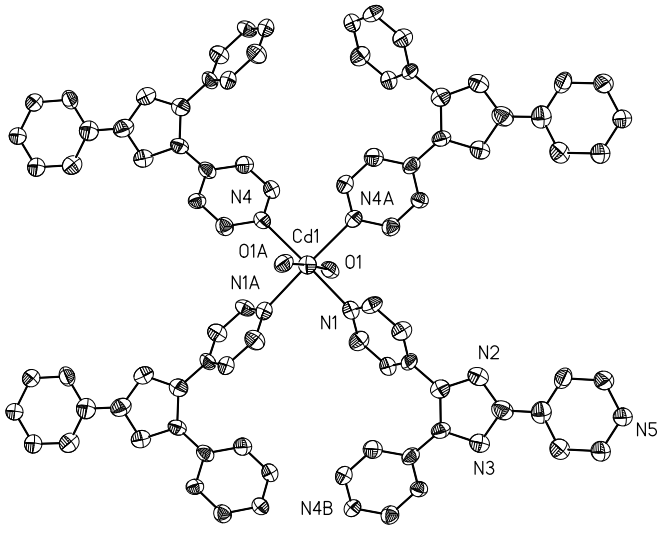

Fig. 4. View of the coordination environment of Cd(II) in complex **2**, thermal ellipsoids are drawn at the 50% probability level. Lattice methanolic, coordinated water molecules and hydrogen atoms have been omitted for clarity.

For **2**, the asymmetric unit consists of one deprotonated ligand, half of one Cd^{2+} ion, one-coordinated aqua molecule and two solvated methanol molecules. As shown in Fig. 4, each Cd(II) center is in an octahedral coordination geometry with four N atoms of equivalent pyridines from four different ligands and two O atoms of two H_2O molecules. It has the same 1D motif as that of complex **1**, as described above. It is noteworthy that the supramolecular architecture of **2** is different from **1**. In complex **2**, the O–H···O and O–H···N hydrogen bonds from coordinated aqua molecules, solvated MeOH molecules and the uncoordinated N atom of the pyridine connect the 1D chain to give a 3D network (Fig. 5). The O1–H1Y···O2 and O2–H2A···O1 distances are 2.630(4) and 2.630(4) Å, and angles are found to be 164.7° and 150.3°, respectively. The O3–H3A···N5(#4) distance is 2.722(5) Å with an angle of 173.0° (symmetry code: $x - 1/2, y + 1/2, z - 1$).

There is one molecule of the Htpim ligand, two molecules of PPh_3, two Cu^+ ions, two I^- ions and one solvated MeCN molecule in the asymmetric unit in the structure of complex **3**. As illustrated in Fig. 6, two Cu(I) centers have the same coordination mode. Each Cu(I) center lies in a distorted tetrahedral coordination sphere which contains of one N atom from pyridine, one P atom from triphenylphosphine and two μ_2-I^- ions. The bond lengths and angles relating to Cu(I) are listed in Table 2. Two μ_2-I^- ions bind to two adjacent Cu(I) centers to give a CuI_2Cu rhomboid dimer, which is further connected to N atoms of the ligands, leading to the formation of a zig-zag chain (Fig. 7). The triphenylphosphine and Htpim

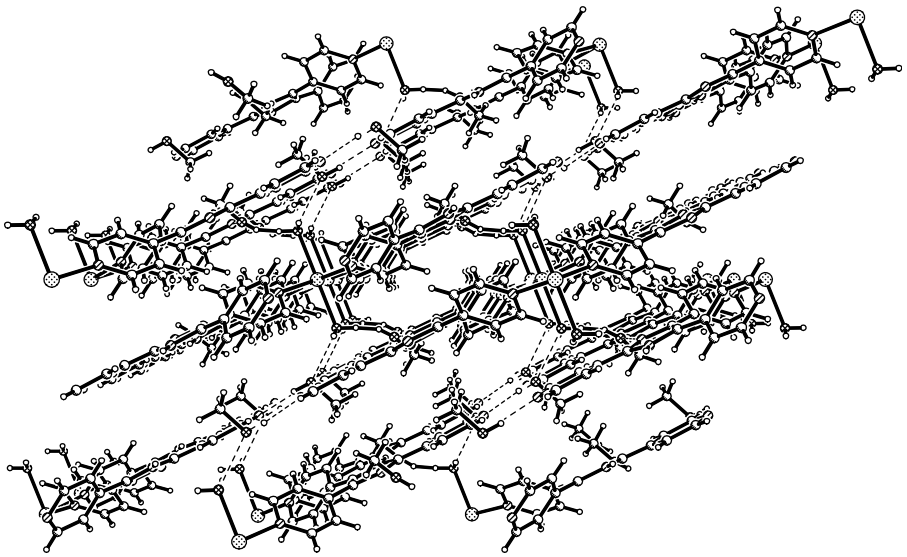

Fig. 5. Crystal packing along the *b*-axis showing the formation of a 3D supramolecular architecture by intermolecular hydrogen bonds.

ligands linking the CuI_2Cu rhomboid dimer are located in *trans* positions.

The asymmetric unit of complex **4** consists of one ligand molecule, one Ag^+ ion, one NO_3^- ion and one solvated CH_2Cl_2 molecule. The Ag(I) center is located in a distorted trigonal arrangement consisting of three N atoms from two equivalent pyridines and one imidazole, as shown in Fig. 8. The Ag–N bond lengths are somewhat different, with relatively longer bond lengths for Ag–N_{py}. As illustrated in Fig. 9, along the symmetry center, the repeating unit is further extended into a 1D ladder-like polymer with two different metallacycles. In the larger one, two Ag (I) atoms and N atoms of equivalent pyridines from two ligands form a 22-membered macrocylic ring with an Ag···Ag diagonal distance of 9.825 Å. In the smaller one, two Ag(I) atoms and N atoms from the pyridine

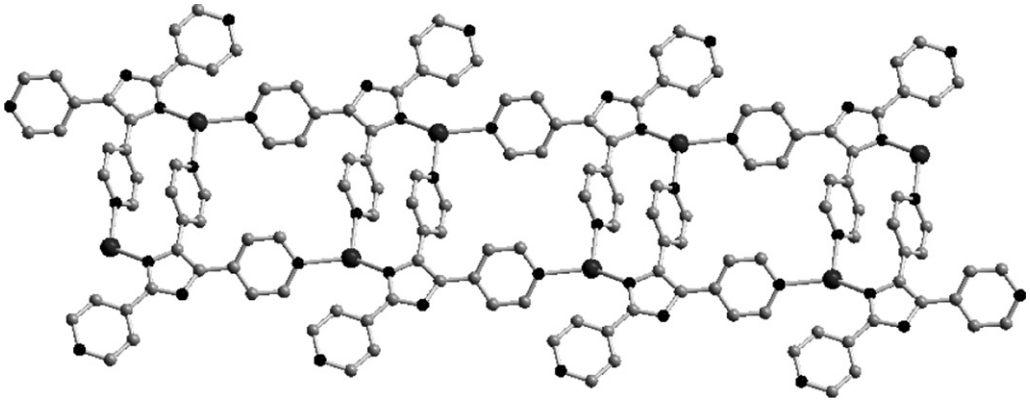

Fig. 9. The ladder-like chain structure for complex **4**.

and imidazole of two ligands form a 14-membered macrocylic ring with an Ag···Ag diagonal distance of 6.948 Å. Additionally, an intermolecular hydrogen bond formed by the N3 atom of imidazole and O2 atom of the NO_3^- ion (N3–H3···O2(#4), symmetry code: $-x+2$, $-y+1$, $-z+2$) makes for the stabilization of the architecture.

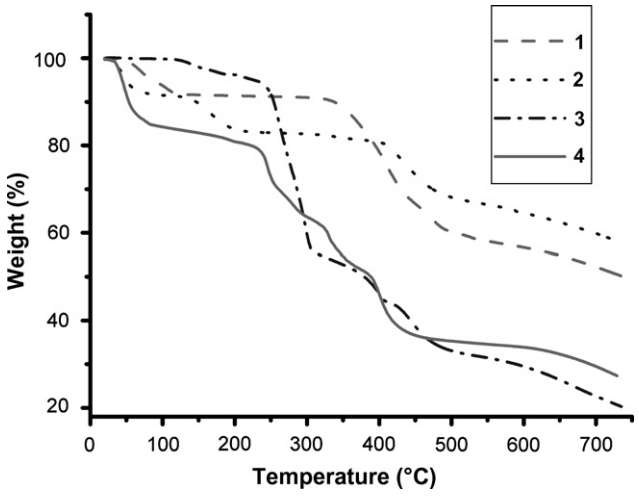

Fig. 10. TGA curves for complexes **1–4**.

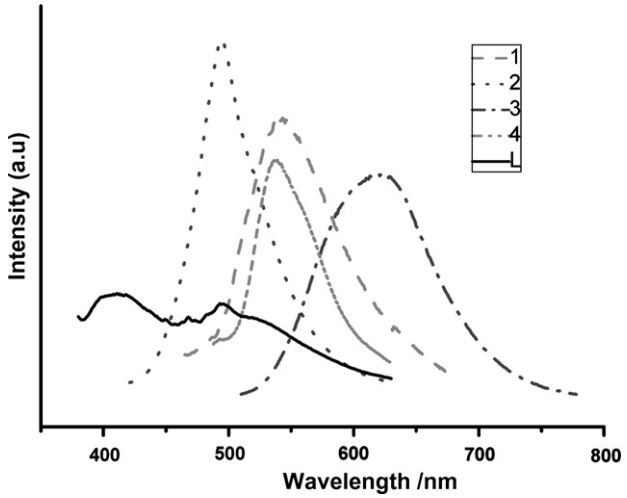

Fig. 11. Emission spectra of **1–4** and the ligand.

3.3. Thermogravimetric analyses

Thermogravimetric analyses (TGA) have been taken on complexes **1–4** by heating to 750 °C under flowing N_2. As shown in Fig. 10, the TGA curve for **1** showed a weight loss between 36 and 157 °C, corresponding to the loss of eight water molecules (8.43% weight loss observed; 8.92% calculated), and the decomposition of the product is observed at ca. 340 °C. Complex **2** displayed two main steps of weight losses: the first step completed the loss of the crystalline methanol molecules at 70 °C (7.43% weight loss observed; 7.34% calculated). The second step occurred between 130 and 230 °C with the loss of two-coordinated water molecules (8.50% weight loss observed; 8.79% calculated). The TGA curve of **3** indicated a weight loss of 3.50% corresponding to the loss of MeCN (calcd. 3.29%) occurring between 120 and 220 °C. Complex **4** lost a guest CH_2Cl_2 molecule in the temperature range of 34–83 °C with a weight loss of 14.76% (calcd. 15.32%).

3.4. Photoluminescent properties

The photoluminescent properties of the free Htpim ligand and compounds **1–4** have been investigated in the solid state at room temperature. As shown in Fig. 11, the free ligand exhibits two emission maxima at 411 and 496 nm upon excitation at 376 nm. The maximum emission peaks of complexes **1** and **4** are located at 540 and 539 nm upon excitation at 362 and 348 nm, respectively. Complex **2** has a very strong emission band centered at 495 nm upon excitation at 375 nm. It is noteworthy that complex **3** displays an emission band in the red region at 623 nm when excited at 346 nm. The emissions could be assigned to a ligand-to-metal charge-transfer (LMCT) transition. Furthermore, the fluorescent intensity of **2** is stronger than compounds **1**, **3** and **4**, which may be attributed to deprotonation of the Htpim ligand in compound **2** [36].

4. Conclusions

In this paper, four new coordination polymers based on a novel rigid multi-pyridyl ligand have been successfully synthesized and characterized. Complexes **1** and **2** have the same one-dimensional motif. Complexes **3** and **4** consist of 1D zigzag and 1D ladder-like chains, respectively. All the complexes reported here, together with the free ligand, display photoluminescence at room temperature.

ABSTRACT

Six organophosphine/phosphite stabilized silver(I) methanesulfonates of type $[L_nAgO_3SCH_3]$ (L = Ph_3P, n = 1, **2a**; n = 2, **2b**; n = 3, **2c**; L = $(EtO)_3P$; n = 1, **2d**; n = 2, **2e**; n = 3, **2f**) were synthesized by the reaction of silver methanesulfonates with triphenylphosphine or triethylphosphite in dichloromethane under nitrogen atmosphere. These complexes were obtained in high yields and characterized by elemental analysis, ^{1}H-, ^{13}C{H} NMR, IR spectroscopy and thermogravimetric analysis (TGA), respectively. X-ray single crystal analysis reveals that complex **2a** is a tetramer $[Ph_3PAgO_3SCH_3]_4$ and complex **2b** is a monomer. The thermal stability of **2a** has been studied by applying thermogravimetric analysis. It starts to decompose between 50 and 440 °C in a three-step process. The final residue (Ag) is about 20.50%.

1. Introduction

Silver(I) complexes have been widely studied because they have shown a great tendency to form rich structure characteristics [1–6], potential application in catalysis [7] and material science [8,9]. Lewis-base stabilized silver(I) complexes have recently attracted renewed interests, mostly because of their application as precursors in the growth of silver thin films via chemical vapor deposition (CVD) techniques, which could be used as new interconnect material for the future generations of deep submicro integrated circuits because of the lower resistivity and superior electromigration resistance [10–15].

The key to achieve success for CVD, however, is the selection of suitable precursors. As the precursor for CVD, the complexes should have: (i) suitable vapor pressure for transporting it from bubbler to CVD reactor; (ii) suitable thermal decomposition mechanism, (iii) suitable thermal stability which means that it could not decompose during the transportation but decompose easily in the reactor [16,17]. Several organic molecules have been often used as ligands to synthesize the silver complexes, such as β-diketonate and its analogous as the main ligands [18,19], and phosphines as ancillary ligands [20,21]. For example, $[(CH_3)_3CCOCHCOC_3F_7AgPEt_3]$ [22], $[(fod)_3Ag(PPh_3)_5]$ [23] were reported to be successfully used as precursors for the silver film deposition. Lewis-base stabilized silver carboxylates such as $[Ph_3PAgO_2CR]$ [24], $[(Ph_3P)_2AgO_2CC_3F_7]$ [25] are another kind of precursors for silver deposition due to the higher utility of silver (100%) according to the radical decomposition mechanism. But to the best of our knowledge, Lewis-base stabilized silver methanesulfonates have not been reported until now. In order to search for the new kind of silver precursor used in CVD technique, a series of organophosphine stabilized silver(I) sulfonates, $[L_nAgO_3SCH_3]$ (L = Ph_3P, n = 1, **2a**; n = 2, **2b**; n = 3, **2c**; L = $(EtO)_3P$; n = 1, **2d**; n = 2, **2e**; n = 3, **2f**), were synthesized and characterized. The single crystal structures of **2a** and **2b** were determined and discussed. The thermal stability of **2a** has been studied by applying thermogravimetric analysis (TGA) has been studied as well.

2. Experimental

2.1. General procedure

All operations were carried out under an atmosphere of purified nitrogen with standard Schlenk techniques. The solvent dichloromethane (CH_2Cl_2) was purified by distillation from P_2O_5 under N_2. The AgO_3SCH_3 was synthesized by reacting CH_3SO_3H with excessive Ag_2CO_3 in water. ^{1}H NMR were recorded on a Bruker Avance 300 spectrometer operating at 300.130 MHz in the Fourier transform mode; ^{13}C{H} NMR spectra were recorded at 75.467 MHz. Chemical shifts are reported in δ units (parts per million) downfield from tetramethylsilane (δ = 0.0 ppm) with the solvent as the reference signal (^{1}H NMR, $CDCl_3$ δ = 7.26; ^{13}C{H} NMR, $CDCl_3$ δ = 77.55). Infrared spectra were collected on Bruker Vector 22 at room temperature. Elemental analyses were performed on a Perkin–Elmer 240C elemental analyzer. Melting points were observed in sealed capillaries and were uncorrected. Thermogravimetric analysis were performed on a American TA2000/2960

analyzer with a heating rate of 10 °C min^{-1} under nitrogen atmosphere.

2.2. Synthesis

2.2.1. Synthesis of CH_3SO_3Ag (**1**)

Methane sulfonic acid (5 g, 0.052 mol) dissolved in 50 mL of H_2O was added dropwise into a stirred suspended solution of $[Ag_2CO_3]$ (8.7 g, 0.031 mol) in 20 mL of H_2O at 20 °C. The clear solution was obtained by filtration through a pad of celite after stirring the reaction mixture for 1 h at 20 °C. A white solid product was obtained after removing water in Rotary Evaporator and Vacuum Drying Oven at 50 °C. The product was stored under nitrogen and keep in dark place. Yield: 8.8 g (83%, based on Ag_2CO_3).

2.2.2. Synthesis of $Ph_3PAgO_3SCH_3$ (**2a**)

Triphenylphosphine (0.1318 g, 0.5 mmol) dissolved in 20 mL of CH_2Cl_2 was added dropwise into a stirred suspended solution of $[CH_3SO_3Ag]$ (0.1020 g, 0.5 mmol) in 20 mL of CH_2Cl_2 at 0 °C. The clear solution was obtained by filtration through a pad of celite after stirring the reaction mixture for 6 h at 0 °C. A white solid product was obtained after removing all the volatiles in oil-pump vacuo, yield: 0.21 g (91%, based on CH_3SO_3Ag). M.p.: 187 °C dec. *Anal.* Calc. for $C_{19}H_{18}O_3AgPS$: C, 49.05; H, 3.90. 2.2.3. Synthesis of $(Ph_3P)_2AgO_3SCH_3$ (**2b**)

Complex **2b** as a white solid was obtained following the above procedure, only using $[CH_3SO_3Ag]$ (0.1401 g, 0.69 mmol) and triphenylphosphine (0.3621 g, 1.38 mmol) instead. Yield: 0.477 g (95%, based on AgO_3SCH_3). M.p.: 195 °C dec. *Anal.* Calc. for $C_{37}H_{33}O_3AgP_2S$: C, 61.08; H, 4.57. 2.2.4. Synthesis of $(Ph_3P)_3AgO_3SCH_3$ (**2c**)

Complex **2c** was synthesized following the synthesis of **2a** (Section 2.2.1). In this respect, triphenylphosphine (0.4388 g, 1.67 mmol) was reacted with $[AgO_3SCH_3]$ (0.1132, 0.558 mmol). After appropriate work-up (see Section 2.2.1), complex **2c** was obtained as a white solid. Yield: 0.51 g (93%, based on AgO_3SCH_3]). M.p.: 215.2 °C dec. *Anal.* Calc. for $C_{55}H_{48}AgO_3P_3S$: C, 66.74; H, 4.89. Found: C, 66.47; H, 4.62%. ^1H NMR ($CDCl_3$): δ 2.5 (s, 3H, CH_3), 7.2–7.4 (m, 45H, Ph). $^{13}C\{H\}$ NMR ($CDCl_3$): δ 39.4 (CH_3), 134.2 (J_{PC} = 16.06 Hz, C_6H_5), 132.3 (J_{PC} = 23.29 Hz, C_6H_5), 130.7 (C_6H_5), 129.3 (J_{PC} = 9.24 Hz, C_6H_5). 2.2.5. Synthesis of $(EtO)_3PAgO_3SCH_3$ (**2d**)

Complex **2d** was synthesized following the synthesis of **2a** (Section 2.2.1). In this respect, $[(EtO)_3P]$ (1.88 g, 11.32 mmol) was reacted with $[AgO_3SCH_3]$ (2.29 g, 11.32 mmol). After appropriate work-up, complex **2d** can be isolated as a colourless liquid. Yield: 3.77 g (90%, based on AgO_3SCH_3). *Anal.* Calc. for $C_7H_{18}O_6AgPS$: C, 22.78; H, 4.92. Found: C, 22.67; H, 4.78%. ^1H NMR ($CDCl_3$): δ 1.2 (t, 9 H, CH_3/CH_3CH_2–, J_{HH} = 7.0), 2.8 (s, 3 H), 4.0 (m, 6H, CH_2/CH_3CH_2–). $^{13}C\{H\}$ NMR ($CDCl_3$): δ 39.2 (CH_3), 16.6 (J_{PC} = 6.5 Hz, CH_3/CH_3CH_2–), 61.4 (J_{PC} = 3.1 Hz, CH_2/CH_3CH_2–). 2.2.6. Synthesis of $[(EtO)_3P]_2AgO_3SCH_3$ (**2e**)

Complex **2e** was synthesized following the synthesis of **2a** (Section 2.2.1). In this respect, $[(EtO)_3P]$ (1.4231 g, 8.57 mmol) was reacted with $[AgO_3SCH_3]$ (0.8700 g, 4.285 mmol). After appropriate work-up (see Section 2.2.1), complex **2e** was obtained as a colourless liquid. Yield: 2.09 g (91%, based on AgO_3SCH_3). *Anal.* Calc. for $C_{13}H_{33}O_9AgP_2S$: C, 29.17; H, 6.21. 2.2.7. Synthesis of $[(EtO)_3P]_3AgO_3SCH_3$ (**2f**)

Complex **2f** was synthesized following the synthesis of **2a** (Section 2.2.1). In this respect, $[(EtO)_3P]$ (1.5644 g, 9.4 mmol) was reacted with $[AgO_3SCH_3]$ (0.6337 g, 3.1 mmol). After appropriate work-up, complex **2f** can be isolated as a colourless liquid. Yield: 2.06 g (93%, based on AgO_3SCH_3). *Anal.* Calc. for $C_{19}H_{48}O_{12}AgP_3S$: C, 32.53; H, 6.90. Found: C, 32.33; H, 6.72%. ^1H NMR ($CDCl_3$): δ 1.2 (t, 27H, CH_3/CH_3CH_2–, J_{HH} = 7.0), 2.6 (s, 3H), 4.0 (m, 18H, CH_2/CH_3CH_2–). $^{13}C\{H\}$ NMR ($CDCl_3$): δ 39.2 (CH_3), 16.6 (J_{PC} = 5.8 Hz, CH_3/CH_3CH_2–), 60.8 (J_{PC} = 3.4 Hz, CH_2/CH_3CH_2–). IR (KBr) data (cm^{-1}): 2982 (vs), 2934 (s), 2902 (m), 1477 (m), 1444 (m), 1391(s), 1241 (s), 1209 (s), 1161 (s), 1098 (m), 1022 (vs), 941 (vs), 764 (vs), 531 (s).

2.3. Single crystal structures of $Ph_3PAgO_3SCH_3$ (**2a**) and $(Ph_3P)_2AgO_3SCH_3$ (**2b**)

Single crystals of **2a** and **2b** could be obtained by cooling a saturated dichloromethane solution to −30 °C. Suitable crystals for X-ray determination were placed in glue under N_2 for they are sensitive to moisture and oxygen. The crystal structure data collection was done on a BRUKER SMART APEX CCD diffractometer using graphite monochromatic Mo Kα radiation (λ = 0.71073 Å) at room temperature. The program SMART [26] was used for determination of the unit cell. Data reduction and integration was carried out with SAINT [26] and absorption corrections were applied using the program SADABS [27]. The structure was solved using direct methods and refined by full-matrix least-squares procedures on F^2 (SHELX-97 [28]). All of the non-hydrogen atoms were refined with anisotropic displacement parameters. Crystallographic data and details on refinement are presented in Table 1. The crystal structures of **2a** and **2b** are drawn using ORTEP [29].

3. Results and discussion

3.1. Synthesis

The phosphine/phosphite stabilized silver(I) methanesulfonates (L = Ph_3P, n = 1, **2a**; n = 2, **2b**; n = 3, **2c**; L = $(EtO)_3P$; n = 1, **2d**; n = 2, **2e**; n = 3, **2f**) were prepared by using $Ph_3P/(EtO)_3P$ reacting with solver(I) methanesulfonate in dichloromethane in stoichiometry at 0 °C under nitrogen atmosphere in high yield (Scheme 1). The complexes were isolated as white solids (**2a**–**2c**) or colourless liquids (**2d**–**2f**). They are very sensitive to temperature, moisture, oxygen as well as light. The complexes are insoluble in cold

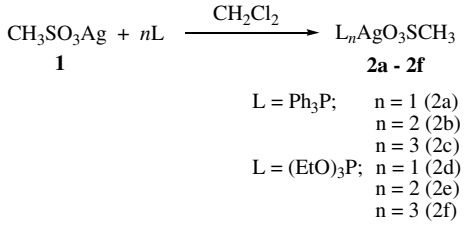
[a] $R_1 = \sum(||F_o| - |F_c||)/\sum|F_o|$; $wR_2 = [\sum(w(F_o^2 - F_c^2)^2)/\sum(wF_o^4)]^{1/2}$.
[b] $w_{2a} = 1/[\sigma^2(F_o^2) + (0.0038P)^2 + 166.3623P]$, $P = (F_o^2 + 2F_c^2)/3$. $w_{2b} = 1/[\sigma^2(F_o^2) + (0.0485P)^2 + 3.1225P]$, $P = (F_o^2 + 2F_c^2)/3$.
[c] $S = [\sum w(F_o^2 - F_c^2)^2]/(n - p)^{1/2}$, n = number of reflections, p = parameters used.



Scheme 1. Synthesis of complexes **2a**–**2f**.

non-polar solvent like petroleum, whereas they are highly soluble in polar or unsaturated hydrocarbons such as methylenechloride, benzene. All the obtained products gave satisfactory elemental analysis results, which were characterized by elemental analysis, IR, ^{1}H NMR, ^{13}C{H} NMR, respectively.

As we know, the typical group vibration of sulfonates shows in the range of 1350–1050 cm^{-1} [30,31]. When the R—SO_3^- anion is "free", that is to say, non-coordinated, it shows local C_{3v}-symmetry with two ν_{so} bands for the symmetrical. Upon coordination to a metal, the C_{3v}-symmetry is broken and for a C_s-symmetrical R–SO_2–O–M moiety and three ν_{SO} bands are observed ($\nu^{as}(SO_2)$; $\nu^{s}(SO_2)$; ν(S–O)). In the case of lithium and sodium salt of the methanesulfonate anion ($CH_3SO_3^-$), the $\nu^{as}(SO_2)$; $\nu^{s}(SO_2)$ are observed at 1233 and 1060 cm^{-1}, respectively (for the NaO_3SCH_3) and $\nu^{as}_{(SO2)}$ (1244 cm^{-1}); $\nu^{s}_{(SO2)}$ (1185 cm^{-1}); $\nu_{(S-O)}$ (1050 cm^{-1}) for LiO_3SCH_3 [32]. In the IR spectra of **2a**–**2f** it shows prominent absorptions in ν_{SO3} region. The absorptions in the range of 1238–1268 cm^{-1} and 1180–1200 cm^{-1} can be interpreted as the asymmetric and symmetric vibration of SO_2, which is the similar as previous reported [33–37]. The absorptions around 1030 cm^{-1} can be assigned as vibration of S–O; which is similar to the reported value [33–37].

The NMR spectra (^{1}H and ^{13}C{H}) were recorded for all six complexes (see Section 2) at room temperature, In ^{1}H NMR, the proton spectra were consistent with the stoichiometries of the complexes. The protons of complexes **2a**–**2c** in the aryl proton region of the ^{1}H NMR spectra were in the range of 7.2–7.6 ppm. The complexes (**2d**–**2f**) are easily distinguished because the resonances of the protons show only two groups. The proton of CH_3 – in CH_3SO_3 – appeared at 2.6–2.8 ppm, which agrees with previous reported [23]. In the ^{13}C{H} NMR spectra of **2a**–**2c** the triphenylphosphine carbon resonances are easily distinguished (in the range of 129.6–134.2 ppm). The carbon resonance of CH_3 – on CH_3SO_3 – shows in the lower field (39.1–39.4 ppm) comparing to that of [$(EtO)_3$P] (ca. 16.7 ppm).

3.2. Single crystal structure of *2a* and *2b*

The X-ray single crystal analysis results indicate that the molecular formula of complex **2a** is $[(Ph_3PAgO_3SCH_3)_4 \cdot 4CH_2Cl_2]$ and complex **2b** is $[(Ph_3P)_2AgO_3SCH_3 \cdot CH_2Cl_2]$. Because of different molar ratio of triphenylphosphine with silver methylsulofonate, complex **2b** is a monomer with each silver atom coordinated by two PPh_3 groups. Complex **2a**, however, is a tetramer with the silver atom coordinated by one PPh_3 group. The molecular structure of **2a** and **2b** are depicted in Fig. 1 and Fig. 2, and selected bond distances (Å) and bond angles (°) are given in Table 2.

Complex **2a** crystallizes in the tetragonal with space group $I4_1/a$, which is composed of a tetramer $[Ph_3PAgO_3SCH_3]_4$ and four molecules of dichloromethane, as shown in Fig. 1. This is different from the reported complex $[Ph_3PAgO_3SCF_3]$ which exists as a trimer [38]. In the tetramer complex, the Ag_4O_4 core of the molecule is regarded as a "cubane-like" framework, with the alternate corners of the cube occupied by the silver atoms and the methanesulfonic oxygen atoms. The phosphorous atoms are approximately apical,

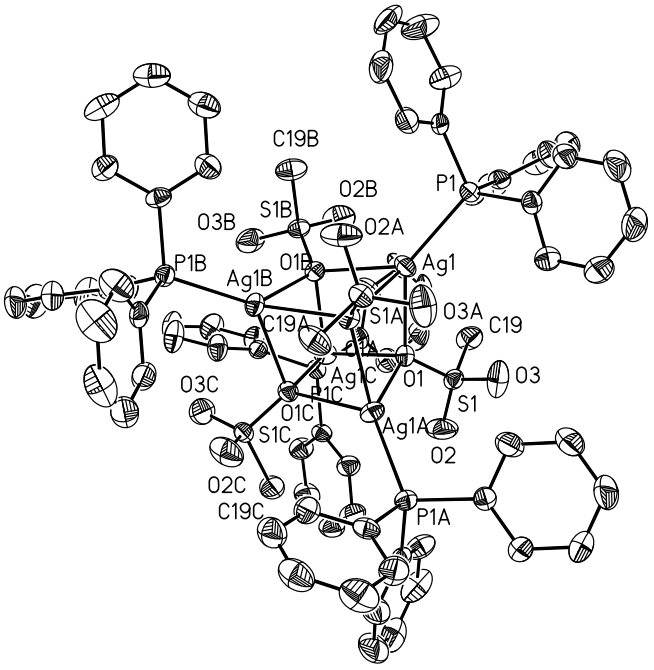


Fig. 1. ORTEP drawing of **2a**, showing 30% probability displacement ellipsoids. The hydrogen atoms and solvent molecules are omitted for clarity.

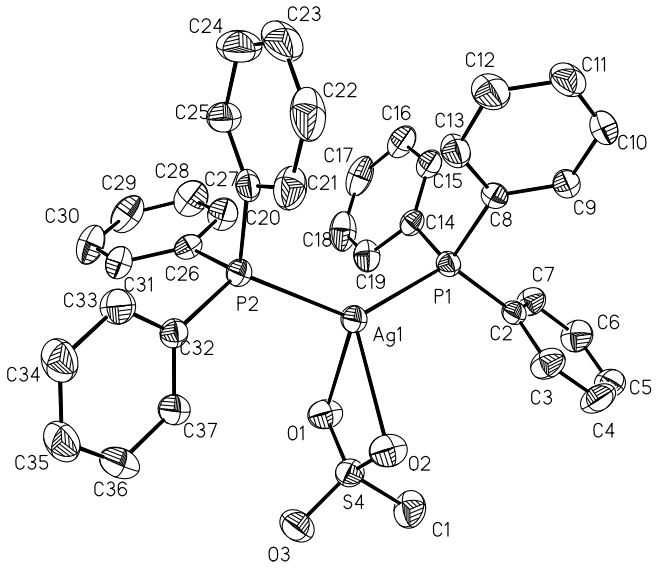

Fig. 2. ORTEP drawing of **2b**, showing 30% probability displacement ellipsoids. The hydrogen atoms and solvent molecules are omitted for clarity.

Table 2
Selected bond distances (Å) and angles (°) for **2a** and **2b**

*Complex **2a***			
Ag(1)–P(1)	2.348(2)	Ag(1)–O(1)	2.389(5)
Ag(1)–O(1)^{b}	2.465(5)	Ag(1)–O(1)^{c}	2.449(5)
P(1)–Ag(1)–O(1)	135.5(1)	P(1)–Ag(1)–O(1)^{b}	133.0(1)
P(1)–Ag(1)–O(1)^{c}	130.8(1)	O(1)–Ag(1)–O(1)^{b}	79.5(2)
O(1)–Ag(1)–O(1)^{c}	78.5(2)	O(1)^{b}–Ag(1)–O(1)^{c}	77.1(2)
Ag(1)–O(1)–Ag(1)^{a}	102.5(2)	Ag(1)^{a}–O(1)–Ag(1)^{b}	100.3(2)
Ag(1)–O(1)–Ag(1)^{b}	98.7(2)		
Complex 2b			
Ag(1)–P(1)	2.434(1)	Ag(1)–P(2)	2.422(1)
Ag(1)–O(1)	2.501(3)	Ag(1)–O(2)	2.552(3)
P(1)–Ag(1)–P(2)	132.4(4)	P(1)–Ag(1)–O(1)	104.0(8)
P(1)–Ag(1)–O(2)	108.9(8)	P(2)–Ag(1)–O(1)	106.6(8)
P(2)–Ag(1)–O(2)	118.3(8)	O(1)–Ag(1)–O(2)	56.5(1)

Symmetry code: a = 5/4 − *y*, 1/4 + *x*, 9/4 − *z*; b = 1 − *x*, 3/2 − *y*, *z*; c = −1/4 + *y*, 5/4 − *x*, 9/4 − *z*.

coordinating to the silver atom, thereby completing a distorted tetrahedral coordination arrangement of the silver atom. The angles of O–Ag–O [79.5(2)°, 77.1(2)°, 78.5(2)°] and Ag–O–Ag [100.7(2)°, 102.5(2)°, 98.7(2)°] are close to 90°, but the former are smaller than the latter, which confirms the deformation of the "cubane" just like other "cubane-like" complexes [39,40]. The P–Ag distance (2.348(2) Å) is close to the sum of covalent radio of P and Ag atoms (2.44 Å) [39] and slightly shorter than other complexes [$(Ph_3P)_2Ag(O_2CC_3F_7)$] 2.406(1) Å [24], [$(Ph_3P)_3Ag(OPhMe_2)$], 2.539(2) Å [41].

Complex **2b** crystallizes in the tetragonal with space group P 2_1/c and exists as a monomer with a molecule of dichloromethane in crystal structure (show in Fig. 2). The silver atom is coordinated by two phosphorus atoms of triphenylphosphine and two methanesulfonic oxygen atoms at the same time. This coordination mode is similar to the reported complex [$(MePh_2P)_2AgO_3SCF_3$] [42] and several silver(I) carboxylates such as [$(Ph_3P)_2Ag(O_2CCH{=}CHCH_2CH_2CH_3)$] [24] and [$(Ph_3P)_2Ag(CO_2CF_3)$], but different from the reported complex [$(Ph_3P)_2AgO_3SCF_3$] [42] which exists as a dimmer. The distances of Ag–P [2.422(1), 2.434(1) Å] are longer than that of [$(R_3P)_2AgO_3SCF_3$] [2.385(8), 2.389(8) Å] and complex **2a** [2.348(2) Å]. The Ag–O distances [2.501(3), 2.552(3) Å] are much shorter than those [2.775(2), 2.854(2) Å] of [$(MePh_2P)_2AgO_3SCF_3$] [42] and much longer than those in complex **2a** [2.389(5), 2.449(5), 2.465(5) Å]. The P–Ag–P angle [132.4(4)°] is much smaller than that [156.2(3)°] of [$(MePh_2P)_2AgO_3SCF_3$] [42], respectively.

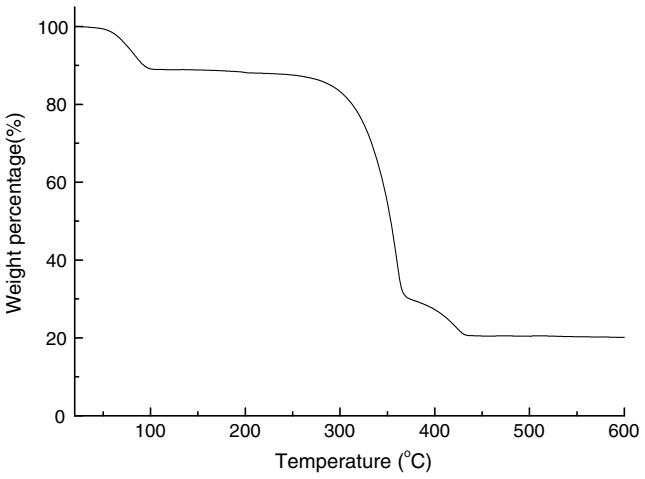

Fig. 3. TG trace of **2a** (heating rate of 10 °C min^{-1}, nitrogen atmosphere).

3.3. Thermogravimetric analysis (TGA)

Thermogravimetric analysis (Fig. 3) was carried-out to determine the relative volatility and evaluate the suitability of complex as possible CVD precursors. These studies are also required to optimize the temperature at which the respective single silver precursor should be maintained during the CVD experiments. Complex **2a**, for example, decomposes between 50 and 440 °C in a three-step process. The first step takes place between 50 and 105 °C with the 10.97% weight loss, the second step is observed in the range of 105–370 °C with the 58.43% weight loss, and the third step is between 370–440 °C with the 10.10% weight loss. The total weight loss is 79.50%. These data show that the percentage of the residue is 20.50% (Ag), which is close to the theoretical value of silver (23.18%) in complex **2a**. The real thermal decomposition mechanism of complex **2a** and other complexes would be studied in the further research.

4. Supplementary data

CCDC 656251 and 666194 contain the supplementary crystallographic data for **2a** and **2b**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Bis(thiosemicarbazone) ligands
Dephenylation process
X-ray diffraction

ABSTRACT

The differences in the reactivity of diphenyllead and diphenyltin dichloride with benzil bis(thiosemicarbazone) LH_6 are explored. The reaction of $PbPh_2Cl_2$ afforded the complex $[Pb(LH_4)]$ **1**, containing the ligand doubly deprotonated and without the phenyl groups bonded to the metal. The reaction with $SnPh_2Cl_2$ in the absence of solvent yielded the complex $[Sn(LH_4)Cl_2]$ **2**. The lead(II) complex, also obtained by the reaction with lead(II) nitrate, was formed by a redistribution of the organolead derivative followed by a reductive elimination reaction, while the tin one was formed by a dephenylation process. Reactions in solution of the organotin derivative are complicated and depending on the working conditions different compounds could be isolated: the organostannoxane $[Sn_2Ph_4ClO(OH)]_2$, which was confirmed by X-ray crystallography, or a complex containing a triazine-3-thione ligand, formed by the loss of one of the thiosemicarbazone arms with subsequent cyclisation. The compounds were characterized by IR, mass spectrometry, ^1H, ^{13}C and ^{119}Sn NMR spectroscopy in solution and in the solid state. The structure of $[Pb(LH_4)]$ has been studied by X-ray diffraction and the ligand acts as a N_2S_2 planar bideprotonated ligand, with the lead(II) ion localized 1.3858 Å over this plane.

1. Introduction

Thiosemicarbazones (TSCs) and their metal complexes present a wide range of pharmacological applications, for example as antiviral, antibacterial and anticancer agents [1–6]. These biological activities are often attributed to their chelating ability with metal ions and are normally increased in bis(thiosemicarbazones). Tin complexes are potential anti-tumour and antiviral agents and a number of them have shown to posses activity, the diorganotin(IV) derivatives being the most active [7,8]. On the other hand, the chelating capacity of TSCs can be used to detect and/or remove toxic metals as such lead, copper or mercury [9,10]. The Pb–C bonds are rather weak, and consequently organolead(IV) halides decompose at room temperature, especially when expose to light, although the aryl derivatives are somewhat more stable than the alkyl derivatives [11,12]. The decomposition of dialkyllead dihalides involves a redistribution reaction

$$2PbR_2X_2 \rightarrow PbR_3X + PbRX_3$$

followed by reductive elimination of RX from the unstable monoorganolead derivative

$$PbRX_3 \rightarrow PbX_2 + RX$$

These reactions hinder the synthesis of diorganolead(IV) complexes with anionic ligands and reactions with soft anionic ligands lead very often to Pb(II) and $R_3Pb(IV)$ complexes instead of to the diorganolead(IV) derivative [13,14]. The Sn–C bonds could also be broken in the presence of strong polydentate ligands. In particular, $SnPh_2Cl_2$ and $SnPh_3Cl$ can lose one or more phenyl groups by the reaction with tri or tetradentate ligands [15,16].

Although organolead compounds have been well studied, the main social concern has been focused on lead(II). Recent studies connect lead(II) toxicity with its coordination preferences, because their significant differences from those of important biometals, such as zinc(II), are probably responsible for lead interfering in the normal functions of certain proteins [17]. Due to its environmental relevance, a renaissance of the interest in the coordination chemistry of lead has been observed in recent years [18–22]. The coordination chemistry is mainly determined by two factors: its large size, which permits coordination numbers that range from quasi-one [23] to twelve and its 6s electron pair, which may or may not play a role in the stereochemistry of lead(II) complexes

doi:10.1016/j.poly.2008.04.055

[24]. When the 6s electrons constitute a stereochemically active lone pair (SALP), they occupy a significant proportion of the coordination sphere of the metal, with the result that bonds with ligand donor atoms tend either to be placed only in the opposite hemisphere or to be shorter in that direction than around the SALP [25].

Following our interest in the coordination chemistry of bis(thiosemicarbazone) ligands with toxic metal ions, in this paper we explore the reactivity of diphenyltin and lead(II) nitrate with the tetradentate ligand LH_6 (Scheme). We also compared it with the reactivity of diphenyllead dichloride, which was previously reported.

2. Experimental

2.1. Physical measurements

Microanalyses were carried out using a Perkin–Elmer 2400 II CHNS/O Elemental Analyser. IR spectra in the 4000–400 cm^{-1} range were recorded in KBr pellets on a Jasco FT/IR-410 spectrophotometer. Fast atom bombardment mass spectra were recorded on a VG Auto Spec instrument using Cs as the fast atom and *m*-nitrobenzylalcohol (*m*NBA) as the matrix. Matrix assisted laser desorption ionisation-time of flight (MALDI-TOF) mass spectra were recorded using a Bruker Reflex III mass spectrometer equipped with a nitrogen laser emitting at 337 nm, using ditranol as the matrix. ^1H spectra were recorded on a Bruker AMX-300 spectrometer using DMSO-d_6 as the solvent; chemical shifts are expressed on the δ scale relative to TMS as an internal reference. ^{119}Sn NMR spectra were recorded in the same spectrometer using $CDCl_3$ as solvent and $SnMe_4$ as a reference. ^{13}C CP/MAS NMR spectra were recorded at 298 K in a Bruker AV400WB spectrometer equipped with a 4 mm MAS NMR probe (magic-angle spinning) and obtained using a cross-polarization pulse sequence. The external magnetic field was 9.4 T and the sample was spun at 10–14 kHz, spectrometer frequencies were set to 100.61 MHz. Chemical shifts are reported relative to TMS, using the CH group of adamantano as a secondary reference (29.5 ppm). ^{119}Sn CP/MAS NMR spectra were recorded at 149.1 MHz, on the same spectrometer using spinning rates of 10 KHz, pulse delays of 30 s, contact times of 8 ms and TPPM high power proton decoupling. Chemical shifts are reported relative to tetramethyltin, using tin(IV) oxide as a secondary reference (−604.3 ppm).

All reagents were obtained from standard commercial sources and were used as received. Methanol, dried Scharlau (max. 0.005% H_2O).

2.2. Synthesis of benzil bis(thiosemicarbazone), LH_6

This was prepared following the procedure previously reported [26]. Selected spectroscopic data: FAB^+ (*m*/*z*): 357 ($[M+1]^+$, 100%), 714 ($[2M+1]^+$, 25%). ^1H NMR (DMSO-d_6, 300 MHz): δ/ppm 9.8 (2H, NH, s), 8.6 (2H, NH_2, s), 8.3 (2H, NH_2, s), 7.7 (4H, Ph, m), 7.4 (6H, Ph, m). ^{13}C CP/MAS NMR (300 MHz): δ/ppm 181.1 (CS); 142.9 (CN); 133.3, 132.4, 130.1 (Ph). IR (KBr, cm^{-1}): 3420, 3386, 3342, 3330, 3210, 3151(s) [ν(NH)], 1608 (w) [ν(CN)], 1581 (s) [$\delta(NH_2)$] and 848 (w) [ν(CS)].

2.3. Synthesis of the complexes

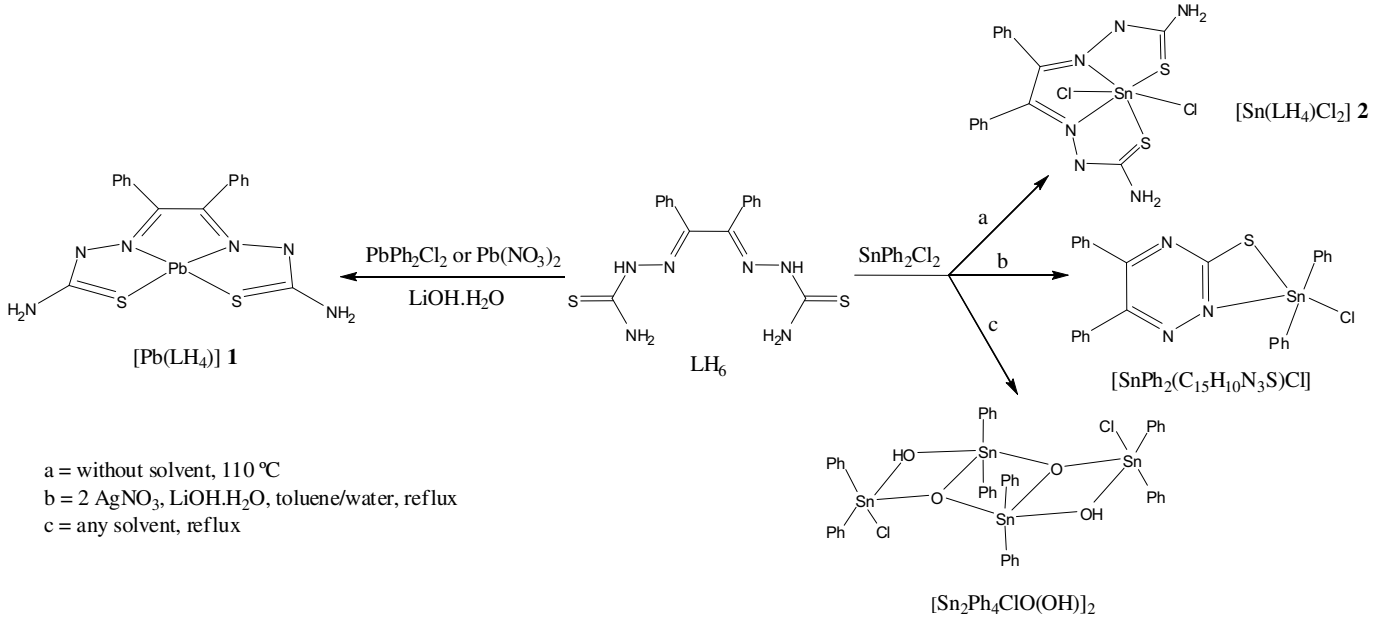
2.3.1. $[Pb(LH_4)]$ (**1**)

A solution of $Pb(NO_3)_2$ (750 mg, 2.30 mmol) in water (5 mL) was mixed with a suspension of LH_6 (540 mg, 1.50 mmol) and $LiOH \cdot H_2O$ (120 mg, 3.00 mmol) in methanol (50 mL). The mixture was stirred for 4 h under reflux. The orange-brown solid that formed was filtered off, washed with hot methanol and dried in vacuo. Yield 59%. M.p.: Decomposes at 199 °C. *Anal.* Calc. for $C_{16}H_{14}N_6S_2Pb$: C, 34.21; H, 2.49; N, 14.97; S, 11.40. Found: C, 34.45; H, 2.69; N, 14.64; S, 11.20%. MS (MALDI-TOF): (*m*/*z*) 563 ($[Pb(LH_4)+1]^+$), 769 ($[Pb_2(LH_4)]^+$), 1330 ($[Pb_3(LH_4)_2]^+$). ^{13}C CP/MAS NMR (300 MHz): δ/ppm 175.9 (CS); 154.7, 150.6 (CN); 138.2, 130.0, 129.5, 127.8, 122.7 (Ph). IR (KBr, cm^{-1}): 3443, 3313 (s) [ν(N–H)], 1565, 1468, 1437 (s) [thioamide II], 768 (w) [ν(CS)]. Crystals suitable for X-ray analysis were obtained from the mother liquor.

This complex was also obtained by reaction of LH_6 and diphenyllead dichloride in methanol in the presence of two moles of $LiOH \cdot H_2O$ [22].

2.3.2. $[Sn(LH_4)Cl_2]$ (**2**)

Diphenyltin dichloride (97 mg, 0.28 mmol) and LH_6 (100 mg, 0.28 mmol) were ground together and transferred to a crucible. The mixture was heated at 110 °C for 12 hours. The orange-brown solid that formed was washed with dichloromethane and dried in vacuo. Yield 83%, M.p.: 260 °C. *Anal.* Calc. for $C_{16}H_{14}N_6S_2Cl_2Sn$: C,



35.32; H, 2.57; N, 15.45; S, 11.73. Found: C, 35.48; H, 2.55; N, 15.64; S, 11.66%. MS (FAB$^+$): (m/z) 509 ([Sn(LH$_4$)Cl]$^+$, 30%). ^{1}H NMR (DMSO-d_6, 300 MHz): δ/ppm 7.9 (4H, NH, s), 7.2–7.0 (10H, Ph, m). ^{13}C CP/MAS NMR (300 MHz): δ/ppm 172.4 (CS); 147.3, 146.3 (CN); 135.2, 133.0, 131.4, 129.5, 127.7 (Ph). ^{119}Sn NMR ($CDCl_3$, 300 MHz,): δ/ppm −550.7. ^{119}Sn CP/MAS NMR (300 MHz): δ/ppm −534. IR (KBr, cm^{-1}) 3450, 3405, 3336, 3297 (s) [ν(N–H)], 1604 (w) [ν(CN)], 1579, 1423 (s) [thioamide II], 823 (w) [ν(CS)].

When the reaction of diphenyltin dichloride was carried out under the same conditions described for the lead(IV) derivative, the starting materials were recovered.

A solution of diphenyltin dichloride (480 mg, 1.40 mmol) in toluene (12 mL) was added over a suspension of LH$_6$ (500 mg, 1.40 mmol) in the same solvent (35 mL). The mixture was heated under reflux for two days. A yellow solid was filtered and identified as LH$_6$. From the orange filtrate, crystals suitable for X-ray study that turned out to be $[Sn_2Ph_4ClO(OH)]_2$ were isolated (Mp 160 °C). The reaction was also carried out under the same conditions but using ethanol, methanol, acetonitrile or DMF, both commercial reagents and dried. In all cases the ligand and the organostannoxane were isolated.

A solution of $AgNO_3$ (290 mg, 1.68 mmol) in distilled water (3 mL) was added to a suspension of $SnPh_2Cl_2$ (290 mg, 0.84 mmol) in the same solvent (3 mL). The mixture was stirred for 30 minutes and filtered off. The filtrate was added slowly, with stirring, to a suspension of LH$_6$ (300 mg, 0.84 mmol) in toluene (40 mL). The mixture was heated under reflux for 24 h. The yellow solid that was separated by filtration was unreacted ligand and $SnPh_2(NO_3)_2$ was isolated from the filtrate. When the same reaction was carried out in the presence of LiOH · H$_2$O, the complex [$SnPh_2(C_{15}H_{10}N_3S)Cl$], containing a triazine-3-thione ligand, was obtained. This complex was previously isolated from the triazine-3-thione ligand and $SnPh_2Cl_2$ in dichloromethane [27].

Table 1
Crystal data and structure refinement for [PbLH$_4$] **1**

Empirical formula	$C_{16}H_{14}N_6PbS_2$

Crystal size (mm^3)	0.20 × 0.10 × 0.05
Theta range for data collection (°)	4.20–71.29
Index ranges	$-10 \leqslant h \leqslant 10$, $-23 \leqslant k \leqslant 23$, $-25 \leqslant l \leqslant 13$
Reflections collected	18 486
Independent reflections (R_{int})	3190 (0.0838)
Completeness to theta = 71.29° (%)	96.9
Absorption correction	semi-empirical from equivalents
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	3190/0/226
Goodness-of-fit on F^2	0.998
Final R indices [I > 2sigma(I)]	R_1 = 0.0358, wR_2 = 0.0799
R indices (all data)	R_1 = 0.0522, wR_2 = 0.0882
Largest difference in peak and hole (e Å^{-3})	1.776 and −1.724

2.4. X-ray crystallography

The crystal data and refinement results are listed in Table 1. Data were collected on a Bruker SMART 6K CCD area-detector three-circle diffractometer with a MAC Science Co., Ltd. Rotating Anode (Cu Kα radiation, λ = 1.54178 Å). The substantial redundancy in data allows empirical absorption corrections (SADABS) [28] to be applied using multiple measurements of symmetry-equivalent reflections. The unit cell parameters were obtained by full-matrix least-squares refinements of 8025 reflections for the complex. The raw intensity data frames were integrated with the SAINT program, which also applied corrections for Lorentz and polarization effects [29].

The software package SHELXTL version 6.10 was used for the space group determination, structure solution and refinement. The structures were solved by direct methods (SHELXS-97) [30], completed with difference Fourier syntheses and refined with full-matrix least-squares using SHELXL-97 minimizing $w(F_o^2 - F_c^2)$. Weighted R factors (R_w) and all goodness-of-fit S are based on F^2; conventional R factors (R) are based on F [31]. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were located in a difference Fourier map, although they were positioned geometrically after each cycle of refinement. All scattering factors and anomalous dispersions factors are contained in the SHELXTL 6.10 program library.

3. Results and discussion

3.1. Synthesis

The reaction of LH$_6$ with lead(II) nitrate yielded complex **1**, with a 1:1 lead:ligand ratio and an absence of nitrate groups, in which the ligand has lost two hydrogen atoms. The MALDI-TOF spectrum in the solid state showed a peak at 563 amu, confirming this ratio. There were also weak peaks at 769 and 1330 amu, corresponding to [Pb$_2$(LH$_4$)]$^+$ and [Pb$_3$(LH$_4$)$_2$]$^+$, respectively, due to the strong interactions existing between the molecules. The same complex was obtained by the reaction with diphenyllead dichloride in methanol and in the presence of two moles of lithium hydroxide [22].

The diphenyltin reactions are complicated, giving different compounds depending on the working conditions (solvent, pH, etc.). With $SnPh_2Cl_2$ in the absence of solvent, the complex [Sn(LH$_4$)Cl$_2$] **2** was obtained. Its analytical data suggest the loss of the two phenyl groups and the presence of the two chlorido ligands, which is confirmed by the mass spectrum, with a peak at 509.1 corresponding to [Sn(LH$_4$)Cl]$^+$ (Fig. 1). This complex is obtained by a dephenylation process, as has been described in the literature for other ligands [15,16]. In the presence of solvent, as was indicated in the experimental part, the ligand is recovered and an organostannoxane containing four tin centers bonded by bridging oxygen atoms and hydroxo groups is isolated. Two Sn centers are bonded to two phenyl groups, one chlorido and one hydroxo group and the other two are bonded to two phenyls and the oxygen atoms (Fig. 2). This compound was previously obtained by the partial hydrolysis of diphenyltin dichloride and it was crystallographically characterized [32]. The crystal obtained in this work is triclinic with a space group $P\bar{1}$, which is different to the crystal previously published, which contains two molecules of acetone. In contrast, $SnPh_2(NO_3)_2$ without base does not react and in the presence of lithium hydroxide yields the complex [$SnPh_2(C_{15}H_{10}N_3S)Cl$], containing a triazine ligand formed by the elimination of one TSC arm of LH$_6$ with a subsequent cyclisation, and that has been reported previously [27].

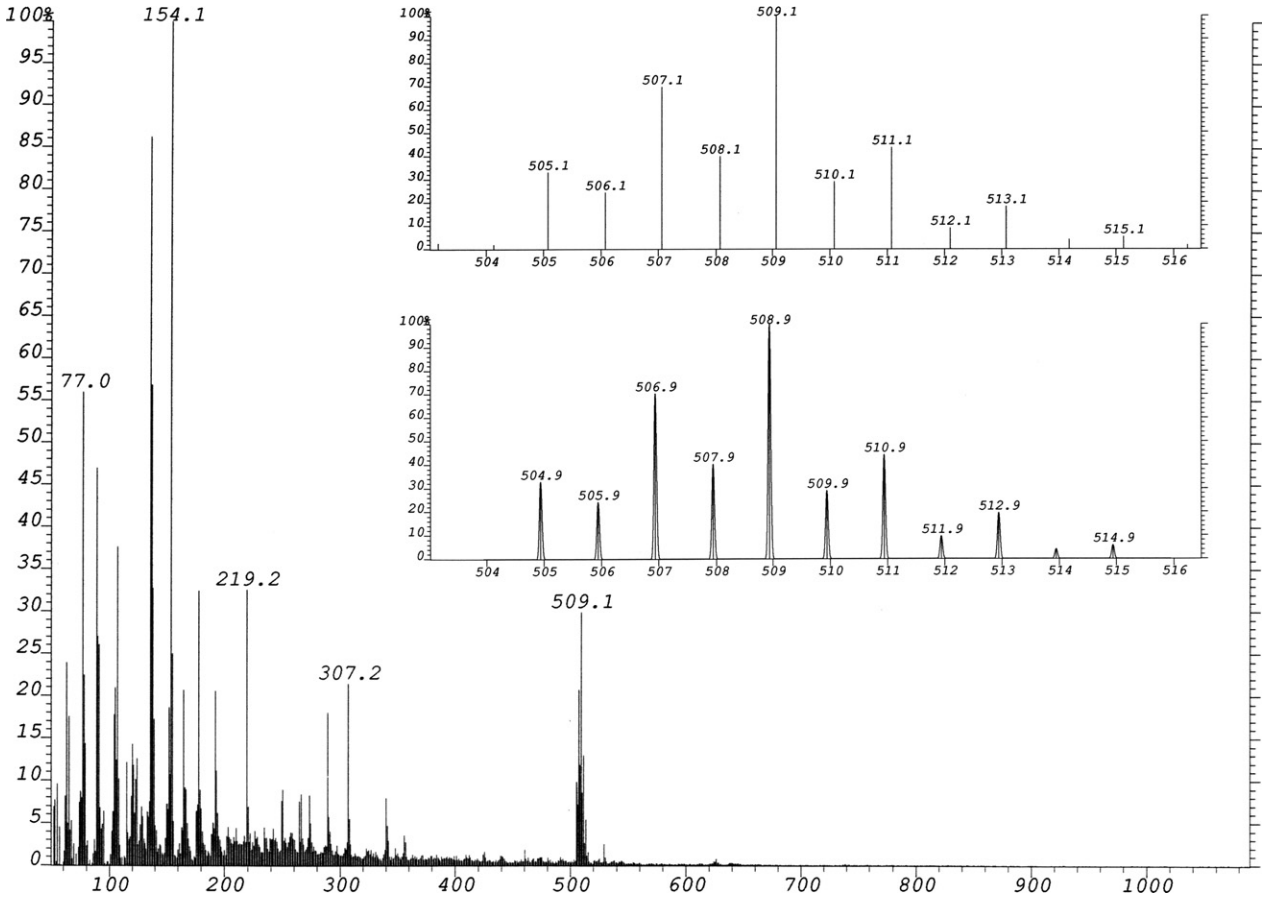

Fig. 1. Mass spectrum of $[Sn(LH_4)Cl_2]$ **2** (theoretical and the experimental isotope distribution in the inset).

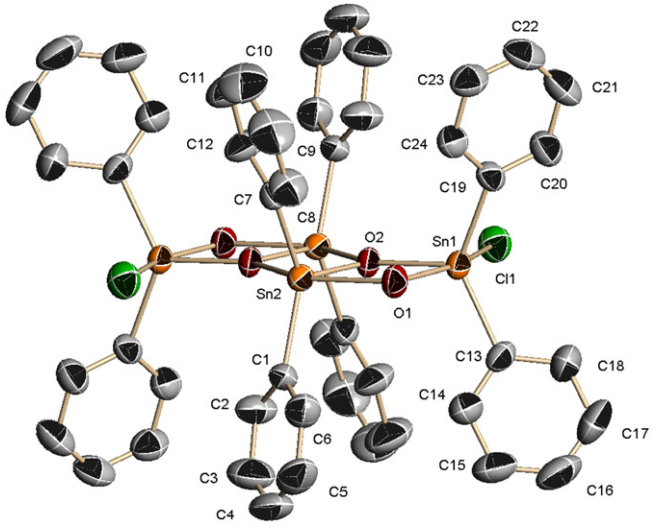

Fig. 2. Crystal structure of $[Sn_2Ph_2ClO(OH)]_2$. Crystal data: $a = 10.3438(2)$ Å, $b = 10.7925(2)$ Å, $c = 11.8431(2)$ Å, $\alpha = 77.6460(10)°$, $\beta = 66.3050(10)°$, $\gamma = 75.5580(19)°$, $R_1 = 0.0253$, $wR_2 = 0.0656$.

These reactions point out the different reactivity of both organoderivatives, since it is not possible to get from $SnPh_2Cl_2$ any complex with the organic groups bonded to the metal, unlike with $PbPh_2Cl_2$ where the complex $[PbPh_2(LH_5)Cl]$ can be synthesised in methanol with one mole of lithium hydroxide [22].

3.2. Spectroscopic studies

In the IR spectra of $[Pb(LH_4)]$ **1** and $[Sn(LH_4)Cl_2]$ **2**, the number of bands corresponding to ν(N–H) decreases, owing to deprotonation, and the remaining bands are displaced with respect to the ligand, probably due to the presence of different networks of hydrogen bonds with respect to the free ligand. The shifts observed in the bands assigned to ν(CN) and ν(CS) are consistent with both groups bonded to the lead or tin atom.

Due to its low solubility or decomposition, a ^{1}H NMR spectrum of complex **1** could not be registered. In the spectrum of $[Sn(LH_4)Cl_2]$ **2** the signal corresponding to the NH protons disappeared, due to the formation of the thiosemicarbazonate anion present in the complex, and the signals of the NH_2 groups were shifted to higher field and merged to form just one signal. The ^{13}C CP/MAS NMR spectra of both complexes were recorded. They show thioamide and imine carbon atoms upfield shifted with respect to the free ligand. The shielding of the thioamide by 4 and 8 ppm for $[Pb(LH_4)]$ and $[Sn(LH_4)Cl_2]$, respectively, is in agreement with the evolution of the thione group to the thiol tautomer when the sulfur atom coordinates to the metal.

It is well known that the ^{119}Sn chemical shift is very sensitive to changes in both the coordination number and the nature of the atoms bonded to tin, so it is a useful tool to determine the environment of this metal in the absence of X-ray data. The ^{119}Sn spectra in solution and in the solid state only showed one signal and the slight difference between the two values indicates that the structure is retained in solution. The chemical shifts are within the range expected for hexa-coordinate complexes [33–36] and agree

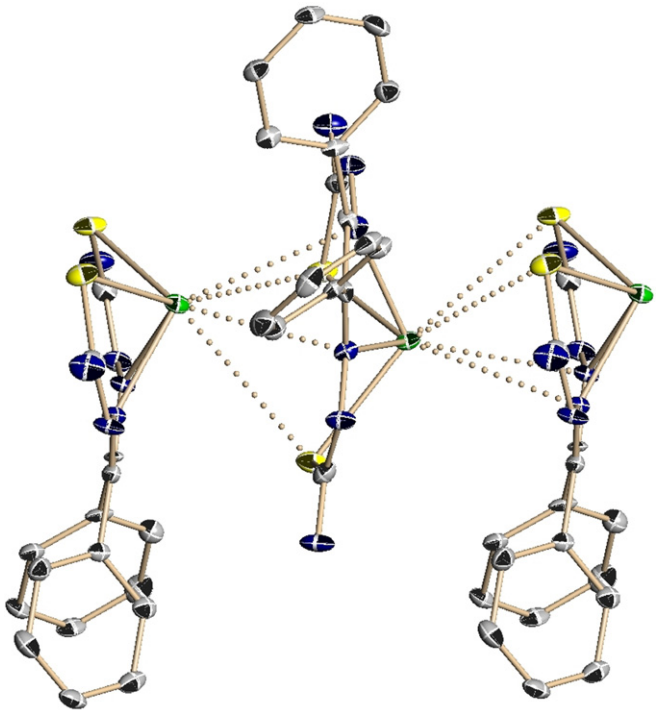

Fig. 4. Secondary interactions Pb-ligand in [Pb(LH$_4$)] along the *a*-axis (symmetry transformations used to generate equivalent atoms: $x + 1/2, y, -z + 1/2 + 1$).

with a $N_2S_2Cl_2$ environment for the tin atom, as the mass data and the ^{13}C NMR spectra have indicated.

3.3. X-ray structure of [Pb(LH$_4$)] *1*

The crystal is made up of discrete [Pb(LH$_4$)] units. This structure rules out the dimeric structure we have previously proposed in view of the mass spectrometry data [22]. The molecular structure is shown together with the numbering scheme in Fig. 3. Selected

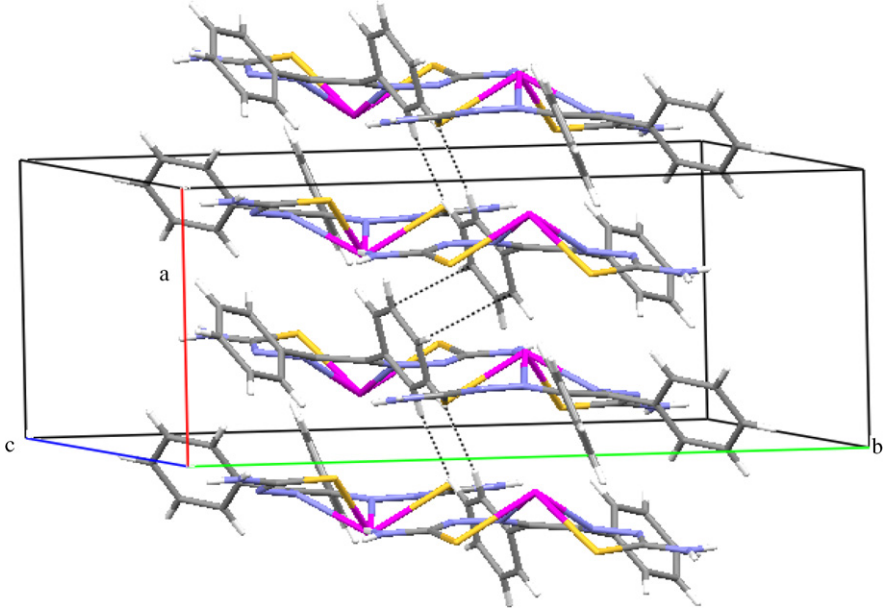

Fig. 5. The unit cell of [Pb(LH$_4$)] showing the stacking within the chains and aromatic interactions linking chains along the *b* and *c*-axes (the hydrogen bonds are omitted for clarity).

bond lengths and angles are summarized in Table 2. The coordination sphere of the lead atom is formed by two sulfurs and two imine nitrogen atoms from the benzil (bisthiosemicarbazonate) ligand. For lead, a coordination number of four is not normally found and only a few cases have been described earlier [21,37,38]. The geometry found in this complex, with all the metal–ligand interactions on the same side of the metal center together with the disposition of the phenyl groups, suggests that the lone pair on the lead center is stereochemically active. This results in a non-spherical charge distribution around the metal and it induces a clear gap in the disposition of the ligand around lead [39]. The four donor atoms of the ligand define the base of a square pyramid, and the Pb(II) cation is 1.3858 Å above this plane. This distortion of the lead atom is greater than that found in other complexes, showing the lone-pair effect that has been previously reported [40,41]. The Pb–N and Pb–S distances in one of the arms are sensitively shorter than in the other, although they are within the normal range. In the lattice (symmetry transformations used to generate equivalent atoms: $x + 1/2$, y, $-z + 1/2 + 1$), the molecules stack along the a-axis, with each Pb center increasing its coordination number to eight by means of two weak Pb···S# bonds [Pb(1)–S(1)# = 3.705 Å, Pb(1)–S(2)# = 3.774 Å] and two weak Pb···N# bonds [Pb(1)–N(3)# = 3.482 Å, Pb(1)–N(4)# 3.497 Å], with distances slightly shorter than the sum of the van der Waals radii (3.55 Å for Pb···N and 3.80 Å for Pb···S). This packing gives rise to polymeric chains with a large Pb···Pb distance of 4.260 Å and in parallel chains, the square-base pyramids are located up and down alternatively (Fig. 4). This induces additional intermolecular interactions based on π–π stacking between the phenyl rings (3.613 Å) linking chains along the b-axis, and CH–CH interactions (3.025 Å) running along the a-axis (Fig. 5). In addition, there is a N(6)–H(6B)–N(2)#1 ($-x + 1/y + 1/z$) hydrogen bond running along the b-axis (d(D–H) 0.88 Å, d(H···A) 2.48 Å, d(D···A) 3.190(8) Å, ∠(DHA) 138.6°). The pseudomacrocyclic coordination mode of the ligand affords three five-member chelate rings, with the C(2)–C(3) bond around 0.35 Å down the N_2S_2 plane. The variation of the distances in the organic backbone with respect to the free benzil bis(thiosemicarbazone) ligand are in the range observed for other complexes in which the ligand is N_2S_2 and is doubly deprotonated [22,42].

ABSTRACT

The reaction of copper dichloride dihydrate and bis(3,5-dimethylpyrazol-1-yl)methane affords $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$. The compound has been studied by IR, UV–Vis spectroscopy and X-ray crystallography. The electronic structure of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation has been calculated with the density functional theory (DFT) method. The spin-allowed doublet–doublet electronic transitions of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ have been calculated with the time-dependent DFT method, and the UV–Vis spectrum of the title compound has been discussed on this basis.

1. Introduction

Bis(pyrazol-1-yl)alkanes and their derivatives constitute a family of stable and flexible bidentate ligands, isoelectronic and isosteric with the well-known bis(pyrazolyl)borates. The coordination properties of bis(pyrazol-1-yl)alkanes may be varied in a rather wide range by introducing substituents into the pyrazole rings. Hence, the donor ability of the ligands is determined by the presence of electron-withdrawing or electron-donating functional groups, and steric factors altered by the introduction of bulky alkyl groups into the rings and the alkane bridge between them [1]. These molecules form a variety of coordination compounds with main group and transition metals [1–3].

Bis(pyrazol-1-yl)methane-copper(II)–complexes have attracted the attention of several research groups during the past three decades. Some bis(3,5-dimethylpyrazol-1-yl)methane-copper(II) complexes of different composition and spectral properties were prepared and characterized so far. In 1979 Jan Reedijk and co-workers reported the preparation of bis(3,5-dimethylpyrazol-1-yl)methane complexes with copper(II) halides and nitrate. These authors isolated compounds of formulas $Cu\{H_2C(3,5\text{-}Me_2pz)_2\}X_2$ ($X = Cl^-$ or Br^-), $Cu\{H_2C(3,5\text{-}Me_2pz)_2\}2X_2$ ($X = Cl^-$, Br^- or NO_3^- and $Cu_3\{H_2C(3,5\text{-}Me_2pz)_2\}_4Cl_6 \cdot EtOH$ trimer [4]. In 1985 the complexes of bis(3,5-dimethylpyrazol-1-yl)methane with copper(II) chloride and nitrate of 1:1 composition were also prepared by Mesubi and Anumba [5]. In 2006 the $Cu\{H_2C(3,5\text{-}Me_2pz)_2\}X_2$ ($X = Cl^-$ or NO_3^- and $Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl_2 \cdot 2H_2O$ compounds were isolated once again by Potapov and co-workers [6]. For copper(II) nitrate, these authors found formation of only complexes of 1:1 composition independent of the metal to ligand ratio used (1:1 or 1:2). In all the cases, structural conclusions concerning bis(3,5-dimethylpyrazol-1-yl)methane-copper(II) complexes were drawn from spectroscopic and magnetic measurements. X-ray studies for the $Cu\{H_2C(3,5\text{-}Me_2pz)_2\}Cl_2$ were performed in 2007 and revealed distorted tetrahedral geometry about the cooper center [7]. From the structural point of view, the $Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2$ unit of $Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2X_2$ compounds may occur either in octahedral geometry leaving two *cis*-positions for X ligands, or in a tetrahedral geometry without space in inner sphere for X ligands, and also in a five-coordinate geometry with one X ligand in inner sphere. The last one geometry has been confirmed very recently by X-ray crystallography in $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2(NO_3)](NO_3)$, $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2(MeOH)](ClO_4)_2 \cdot MeOH$, $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]_2(CuCl_4) \cdot 2Me_2CO$ and $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]_2(Cu_2Cl_6) \cdot 3CH_2Cl_2 \cdot H_2O$. The $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]_2(CuCl_4) \cdot 2Me_2CO$ and $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]_2(Cu_2Cl_6) \cdot 3CH_2Cl_2 \cdot H_2O$ compounds were prepared by the reaction of bis(3,5-dim-

ethylpyrazol-1-yl)methane with copper(II) dichloride dihydrate in molar ratio 4:3 and 1:1, respectively [8].

Here, we present the synthesis, spectroscopic data, crystal, molecular and electronic structure of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$ complex. The electronic structure of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation has been determined with the density functional theory (DFT) method, and time-dependent DFT (TD-DFT) calculations have been employed for discussion of the spectroscopic properties in more detail. Currently density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [9].

2. Experimental

2.1. General procedure

Bis(3,5-dimethylpyrazol-1-yl)methane was synthesised according to the literature method [10,11]. The other reagents used to the synthesis were commercially available and were used without further purification. IR spectrum was recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectrum was measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–180 nm in dichloromethane solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$

A solution of bis(3,5-dimethylpyrazol-1-yl)methane (1.2 mmol, 025 g) in methanol (15 ml) was added to 0.1 g (0.59 mmol) of $CuCl_2 \cdot 2H_2O$ in 10 ml of water and stirred for 2 h. The resulting solution was kept for evaporation at room temperature, and after a few days green prismatic crystals of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$ were obtained, filtered off and dried. Yield 75%. The crystals suitable for X-ray investigation were obtained by recrystallization from methanol. IR (KBr; ν/cm^{-1}): 3504 and 3311 (ν_{O-H}, H_2O); 1651(m) and 1630 (m) (δ_{O-H}, H_2O), 1558 and 1468 (ν_{ring}); 1284(β CH) and 1043 (pyrazole ring breathing).

Anal. Calc. for $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$: C, 44.26; H, 6.42; N, 18.77. Found: C, 44.52; H, 6.30; N, 18.29%.

2.3. X-ray diffraction studies

A green crystal of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$ was mounted on a KM-4-CCD automatic diffractometer equipped with a CCD detector, and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 295(1) K. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption correction [12] were applied. The structure was solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement, and refined as "riding" on the adjacent carbon atom with individual isotropic temperature factor equal 1.2 times the value of equivalent temperature factor of the aromatic parent atom and equal 1.5 times the value of equivalent temperature factor of the methyl parent carbon atom. SHELXS 97 [13], SHELXL 97 [14] and SHELXTL [15] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

Largest difference peak and hole (e Å^{-3})	0.694 and −0.725

2.4. Computational details

The gas phase geometry of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation was optimized without any symmetry restrictions in the doublet state with the DFT method using the hybrid B3LYP functional of GAUSSIAN 03 [16–18]. The calculations were performed by using the LANL2DZ effective core potential (ECP) set of Hay and Wadt [19] for Cu atom and the standard 6-31+G** basis for chloride and nitrogen, 6 − 31G* for carbon and 6 − 31G for hydrogen atoms.

The electronic spectrum of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation was calculated with the TDDFT method starting from the ground-state geometry optimized in the gas phase. The solvent (methanol) effect was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM) [20].

3. Results and discussion

The $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$ complex was prepared in good yield by the reaction of bis(3,5-dimethylpyrazol-1-yl)methane with copper(II) dichloride dihydrate in molar ratio 2:1. The elemental analysis of the complex is in good agreement with its formulation. Bands due to bis(3,5-dimethylpyrazol-1-yl)methane ligand vibrations are observed in the range 1580–1000 cm^{-1} in the IR spectrum of $[Cu\{H2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$. The characteristic bands corresponding to the pyrazole ring stretching vibrations appear at 1558 and 1468 cm^{-1}. The peaks at 3504, 3311, 1651 and 1630 cm^{-1} may indicate the existence of molecular lattice water [21].

3.1. Crystal structure

The crystallographic data of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$ are summarized in Table 1. The asymmetric unit of the title complex consists of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation, chloride ion and three water molecules. A summary of inter- and intramo-

lecular hydrogen bonding contacts detected in the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$ structure is given in Table 2 [22,23]. The molecules of compound are connected *via* medium strength O–H···O and O–H···Cl intermolecular hydrogen bonds to semiinfinite net extended into two dimensions along crystallography *a0b* plane. The intermolecular C–H···O and C–H···Cl weak hydrogen bonds provide additional stabilization to the hydrogen bonded net. Additionally in the complex molecule can be found weak C–H···N intramolecular hydrogen bond.

The molecular structure of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation is presented in Fig. 1, and the selected bond distances and angles of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ are collected in Table 3. The Cu(II) centre is five-coordinated by four N donors from two $H_2C(3,5\text{-}Me_2pz)_2$ ligands and chloride anion. Upon coordination of two molecules of bis(3,5-dimethylpyrazol-1-yl)methane to the copper, two six-membered cycles (made by the four nitrogen atoms, the copper atom and the carbon atom) are formed, and the formed rings show a *boat* conformation with the copper and the carbon atoms off the plane defined by the four nitrogen atoms (deviations of Cu from N_4 least-squares planes are 0.653(7) and 0.604(8) Å, respectively, for planes N(1)/N(2)/N(3)/N(4) and N(5)/N(6)/N(7)/N(8)). The bite angles of 89.07° and 89.78(17)° show no variation from the values reported for $[Cu_2\{H_2C(3,5\text{-}Me_2pz)\}_4(ta)](ClO_4)_2 \cdot 2H_2O$ [24]. The dihedral angle between the above mentioned N(1)–N(4) and N(5)–N(8) least-squares planes is equal to 63.95(14)°.

The angular structural index parameter τ [25] expressed here as the difference between the bond angles N(7)–Cu(1)–N(1) and N(3)–Cu(1)–Cl(1) divided by 60 has a value of 0.47. Compared with the ideal values of 1 for an equilateral bipyramid and 0 for a square pyramid, the τ descriptor of the examined structure suggests a stereochemistry intermediate between equilateral-bipyramidal and square pyramidal, but on the basis of coordination geometry considerations in terms of scalene bipyramid it can be stated that coordination polyhedron is slightly distorted trigonal bipyramid. The same can be deduced from the bond lengths and angles. Despite the almost linear N(1)–Cu(1)–N(7) angle of 176.17(18)°, the equatorial angles Cl(1)–Cu(1)–N(5), Cl(1)–Cu(1)–N(3) and N(3)–Cu(1)–N(5) are grossly distorted from a regular 120° of an equilateral bipyramid. On the other hand the sum of the N(3)–Cu(1)–Cl(1), N(5)–Cu(1)–Cl(1), N(3)–Cu(1)–N(5) angles is equal to 360.0°, a value typical for scalene bipyramid. Furthermore, the Cu(1)–Cl(1) distance of 2.3099(16) Å is much shorter than found for an apically coordinated Cl atom in a five-coordinate tetragonal-pyramidal copper complexes such as $[Cu(cip)(bipy)Cl_{0.7}(NO_3)_{0.3}](NO_3) \cdot 2H_2O$ (cip = ciprofloxacine) and $[Cu(en)(bipy)Cl](OH) \cdot 3H_2O$ with the Cu–Cl bond distances are 2.549(2) Å and 2.733(2) Å [26,27], but is very similar to that found a five-coordinate trigonal-bipyramidal copper complexes such as $[Cu(phen)_2Cl](OH) \cdot 2MeOH \cdot 6H_2O$ and $[Cu(TBZH)2Cl]Cl \cdot 6H_2O \cdot 6EtOH$ (TBZH = thiabendazole) [28]. Summarizing, in terms of regular polyhedra the coordination geometry is intermediate between trigonal bipyramid and square pyramid, and in terms of irregular polyhedra the coordination geometry is almost ideal scalene bipyramid (Scheme 1).

3.2. Geometry optimisation

The geometry of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation was optimized in doublet state using the DFT method with the B3LYP functional. The optimized geometric parameters are gathered in Table 3. In general, the predicted bond lengths are somewhat longer in comparison with the values based upon the X-ray crystal structure data, but the general trends observed in the experimental data are well reproduced in the calculations.

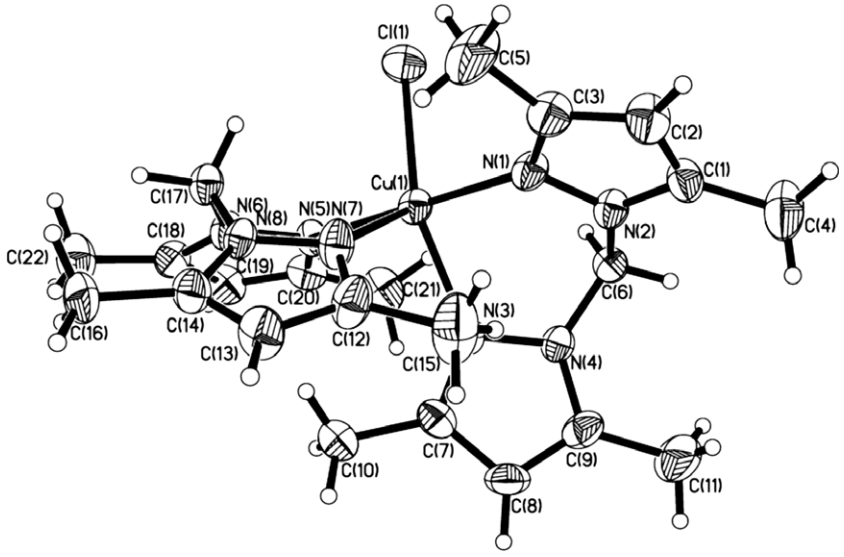

Fig. 1. The molecular structure of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation. Displacement ellipsoids are drawn at 50% probability.

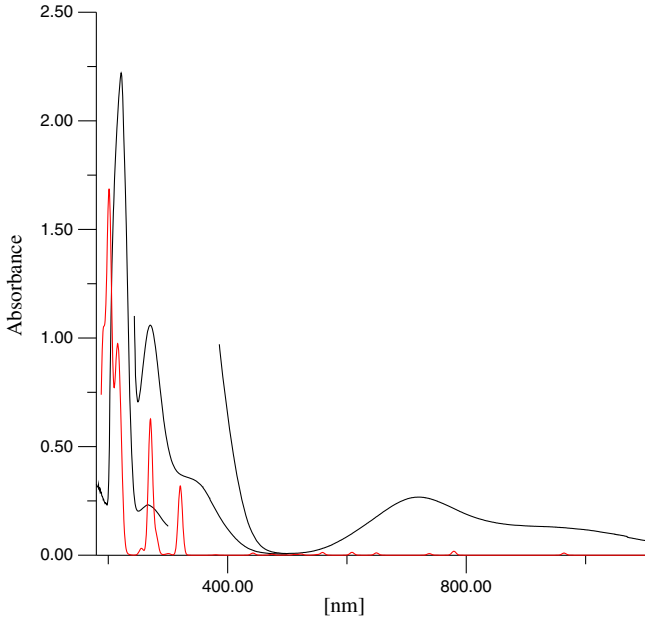

Fig. 2. The experimental (black) and calculated (red) electronic absorption spectra. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

3.3. Electronic spectrum

The nature of the transitions observed in the UV–Vis spectrum of the title complex has been studied by the time-dependent density functional (TDDFT) method. The calculated electronic spectrum of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ in comparison with the experimental one is presented in Fig. 2. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

Table 4
The spin-allowed triplet–triplet electronic transitions calculated with the TDDFT method and the assignments of the calculated transitions to the experimental absorption bands

The most important orbital excitations	Character	λ (nm)	E (eV)	f	Experimental Λ (nm) (E (eV)) ε

H-8(β) → L + 3(β)	π(Cl)/d → π*(L)	189.6	6.54	0.0451	

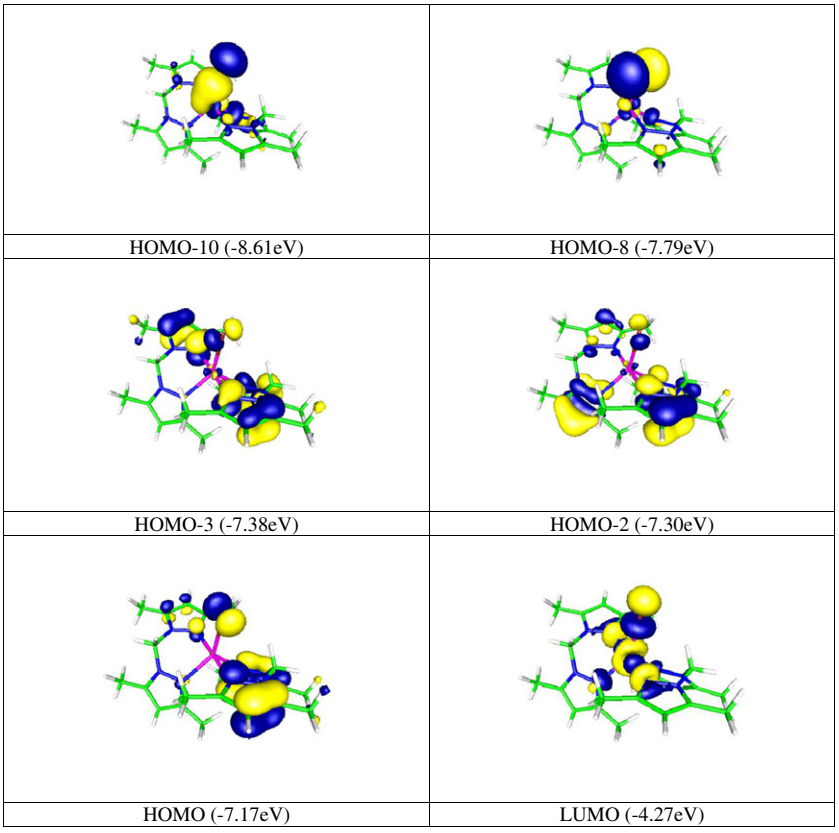

Fig. 3. Contour plots and energy of the selected β-spin HOMO and β-spin LUMO orbitals active in the electronic transitions. The orbitals were plotted with contour values −0.04 (yellow) and 0.04 au (blue). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Table 4 presents the most important electronic transitions calculated with the TDDFT method for $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ and their assignments to the observed absorption bands of the complex. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.0400 are listed in Table 4. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy of occupied and unoccupied molecular orbitals involved in the electronic transitions (Fig. 3).

The TDDFT/PCM calculations show that the two longest wavelength experimental bands at 1011.0 and 738.5 nm originate in the transitions between some lowest β-spin HOMO orbitals and β-spin LUMO orbital. As can be seen from the Fig. 3, the LUMO orbital with β spin is mainly Cu d_z^2 orbital in character, the β-spin HOMO, HOMO-1 and HOMO-2 orbitals are composed of the π-bonding orbitals of bis(3,5-dimethylpyrazol-1-yl)methane and chlorine, the HOMO-3, HOMO-5, HOMO-8 and HOMO-9 are ligand (Cl and bis(3,5-dimethylpyrazol-1-yl)methane) π-bonding orbitals with some contribution of d_{Cu} orbitals, and the HOMO-15 and HOMO-17 are mainly localized on the central ion. Accordingly, the transitions assigned to the two longest wavelength experimental bands can be seen as mixed Cl/bis(3,5-dimethylpyrazol-1-yl)methane → Cu (Ligand–Metal Charge Transfer; LMCT) and d → d (Ligand Field; LF) transitions.

The experimental band at 350.0 nm originates predominately in the transition between β-spin HOMO-10 and β-spin LUMO. As the β-spin HOMO-10 is mainly localized on the chlorine, the absorption band at 350 nm is LMCT transition in nature.

The absorption band at 266.0 nm is also of LMCT character. It can be predominately attributed to the transition from the β-spin HOMO-12 to the β-spin LUMO, and the HOMO-12 is localized on bis(3,5-dimethylpyrazol-1-yl)methane ligand.

The experimental band at 221.5 nm results from the intraligand (IL) and ligand–ligand charge transfer (LLCT) transitions.

4. Conclusion

X-ray studies for the complex of bis(3,5-dimethylpyrazol-1-yl)methane with copper(II) chloride of 2:1 composition revealed five-coordinate geometry about the copper center with one Cl ligand in inner sphere. In terms of regular polyhedra the coordination geometry is intermediate between trigonal bipyramid and square pyramid, and in terms of irregular polyhedra the coordination geometry is almost ideal scalene bipyramid. According to the TDDFT calculations the transitions assigned to the two longest wavelength experimental bands can be seen as mixed Ligand–Metal Charge Transfer and Ligand Field transitions. The reason for this is probably due to the fact that the ligand provide high-lying occupied π bonding orbitals, and as a result the high-lying occupied orbitals are mainly ligand π bonding orbitals in nature.

Supplementary material

CCDC 682987 contains the supplementary crystallographic data for $C_{22}H_{38}N_8O_3Cl_2Cu$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Three binuclear Cu(II) complexes of two pyrimidine derived Schiff base ligands, 2-*S*-methyl-6-methyl-4-formyl pyrimidine-*N*(4)-ethyl thiosemicarbazone (HL_1) and salicyl hydrazone of 2-hydrazino-4,6-dimethylpyrimidine (HL_2), have been prepared. HL_1 produces a bis(μ-thiolato) Cu(II) complex co-crystallizing with its mononuclear analog, $[Cu_2(L_1)_2(NO_3)_2][Cu(L_1)(NO_3)]$ (**1**). On the other hand HL_2 shows versatility by producing two different classes of binuclear Cu(II) complexes, a bis(μ-phenoxo) complex $[Cu_2(L_2)_2(NO_3)_2]$ (**2**) and another a (μ-4,4′-bipyridyl) complex, $[Cu_2(L_2)_2(\mu\text{-}4,4'\text{-bipyridyl})(NO_3)_2]$ (**3**) under suitable conditions. All the three complexes show distorted square pyramidal geometry around each Cu atom but to a varied extent. Magnetic behavior of complex **1** shows that it is strongly ferromagnetic in nature whereas compounds **2** and **3** are weakly antiferromagnetic in nature. A magnetostructural correlation study combined with molecular modelling on complexes **1** and **2** has thrown light on the difference on magnetic interaction between the Cu atoms in these two complexes. Various factors that may be responsible for such differences are also explored. A novel and potentially useful pH dependant conversion of **3** to **2** has also been noticed.

1. Introduction

The chemistry of dinuclear copper complexes with ligands of biological relevance and with metal centers at close proximity is one of the central themes of current research [1–3] due to their interesting structural, electrochemical and magnetic properties [4] and also because of their relevance to the active sites of several metalloenzymes [5] as synthetic models [6,7]. Apart from the binuclear or polynuclear copper(II) complexes of multidentate donor ligands containing in-built bridging units, synthesis and characterization of di, tri and polynuclear copper complexes using bridging molecules like 4,4′-bipyridyl [8], pyrazine [9] and 1,2 bis(4-pyridyl) ethane [10], etc. are also well documented. These bridging molecules may act singularly or in cooperation with other ligands in the complexes and play a crucial role towards developing diverse innovative structural networks, such as chains, sheets and matrices [11]. Such compounds have found potential applications in catalysis [12], absorption chemistry [13] and molecular magnetism [14].

In the present work we report the synthesis and structural characterization of three dinuclear copper (II) complexes using two pyrimidine based Schiff base ligands, HL_1 and HL_2(Fig. 1). The former one, 2-*S*-methyl-6-methyl-4-formylpyrimidine-*N*(4)-ethyl thiosemicarbazone forms a binuclear bis(μ-thiolato) copper(II) complex (**1**). This complex being pyrimidine derived is a refreshing addition among many other pyridine derived similar complexes [15]. The second chosen ligand HL_2, has restricted electron donating capacity because it produces a five membered and a six membered ring at the metal centers (chelation asymmetry) [16,17]. Hence the metal ion's urge for electrons may be supplemented intrinsically by forming a transaxial bis(μ-phenoxo) dimer or by bridging separate monomeric units through an externally added bridging ligand such as 4,4′-bipyridyl. In this work both the possibilities have been duly exploited in synthesizing complexes **2** and **3** respectively. Further, careful selection of the ligands ensures that the synthesized bis(μ-phenoxo) and the bis(μ-thiolato) complexes **1** and **2** are similar in structure with subtle variations in co-ordination atmosphere for which they are suitable for attempting a magnetostructural correlation study on them. Temperature dependant magnetic

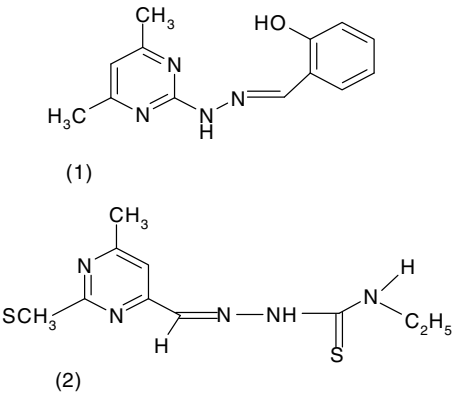

Fig. 1. Representative diagram of ligand HL_2 (**1**) and ligand HL_1 (**2**).

moment studies and molecular modelling have also led to a comparative account of the variation of their magnetic behavior. The 4,4′-bipyridyl bridged complex **3** has been found to have the weakest metal–metal interaction as the metal centers here are far apart.

2. Experimental

2.1. Materials

Ethyl diethoxy acetate and *N*(4)-ethyl-3-thiosemicarbazide, Phosphorus oxychloride, acetyl acetone, urea and hydrazine hydrate were obtained from Aldrich Chemicals, USA and used without further purification. Solvents were also used as received from commercial sources.

2.2. Syntheses

2.2.1. Preparation of ligand HL_1

The ligand HL_1 was synthesized and characterized using the same procedure as reported earlier [18,19].

2.2.2. Preparation of ligand HL_2

The ligand HL_2 was prepared by using 2-hydrazino 4,6-dimethyl pyrimidine and salicylaldehyde in a method similar to that reported by Chiswell and Lions [20]. When a methanolic solution of 1.39 g (10 mmol) of 2-hydrazino 4,6-dimethyl pyrimidine refluxed with a methanolic solution of 1.21 g (10 mmol) of salicylaldehyde for 2 h and the resulting solution kept for slow evaporation, ligand HL_2 separated as crystals from the mother liquor. Filtered and dried in vacuo over fused $CaCl_2$. Yield: 2.20 g (90%). The compound melted with decomposition at 280 °C. IR (ν, cm^{-1}): 3247 (νN–H), 1620 (νC=C), 1566 (νC=NH), 885 (νC_{pym}-H), 1255 (νC–O); ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C, TMS) δ/ppm: (6.68) (s, 1H, C_5–H pyrimidine), (6.8–7.3) (m, 4H, $-C_6H_4$), (8.2) (s,1H, –CH=N–), (12.8) (s, 1H, aromatic-OH), (2.28) (s, 1H, N–H of hydrazone), (2.46–2.53) (m, 6H, CH_3)

2-Hydrazino 4,6-dimethyl pyrimidine was prepared using another literature method [21,22].

2.2.3. Preparation of the complex $[Cu_2(L_1)_2(NO_3)_2][Cu(L_1)(NO_3)]$ (**1**)

The complex **1** was prepared by simply adding an ethanolic solution of hydrated cupric nitrate (1 mmol, 295.5 mg) drop wise to a hot stirred ethanolic solution of ligand HL_1 (0.269 g, 1 mmol). The resulting greenish-yellow solution was refluxed at water bath temperature for 1 h. The solution was filtered and kept for slow evaporation. The dark green compound that separated was filtered off, washed with ice-cold ethanol and dried over fused $CaCl_2$. Yield

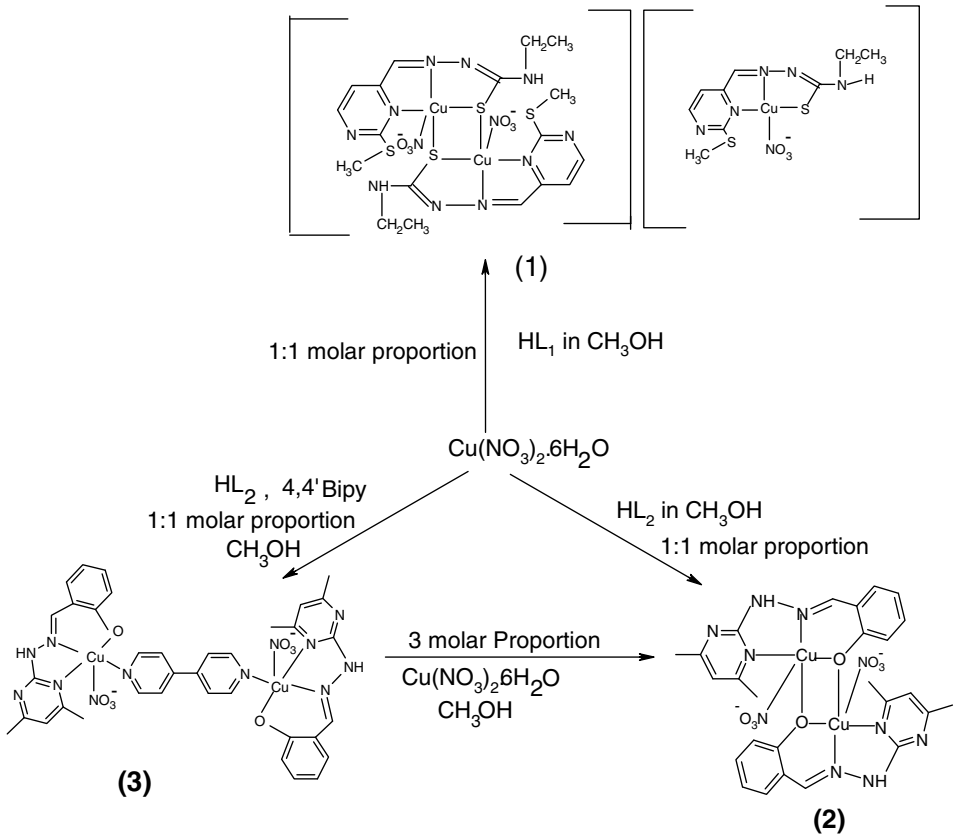

Fig. 2. A scheme showing the method of preparation for the complexes **1**, **2** and **3**.

55%. *Anal.* Calc. for $C_{30}S_6N_{18}O_9H_{42}Cu_3$: C, 30.49; H, 3.18; N, 17.98. Found: C, 30.12; H, 3.56; N, 17.81%. IR (ν, cm^{-1}): 1582 ν(C=N), 1601 ν(C=C), 750 ν(C=S), 800.6 (ν2 of NO_3), 1483, 1292 (ν3 of NO_3). UV–Vis (λ/nm) (ε/L^{-1} mol cm^{-1}): 332.5 (30130)(n → π^* pyrimidine), 434 (10000) (CT, pyrimidine → Cu), 628(440) (d → d). CV E_{pc}/(V): −0.23, −0.92 [$Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{I}$, $Cu^{II}Cu^{I} \rightarrow Cu^{I}Cu^{I}$], Epa/(V): +0.40 [$Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{III}$].

X-ray quality crystals were grown by slow evaporation of ethanolic solution of the complex at room temperature.

2.2.4. Preparation of the complex $[Cu_2(L_2)_2(4,4'\text{-bipy})(NO_3)_2]$ (**3**)

To a mixture of 4,4′-bipyridyl (1 mmol, 150 mg) and HL_2 (1 mmol, 241 mg) in a methanolic solution (20 ml), of $Cu(NO_3)_2 \cdot 6H_2O$ (1 mmol, 295.5 mg) in the same solvent was added with constant stirring. Immediately, a dirty green precipitate appeared. Stirring was continued for 15 min. The precipitate was filtered off, washed with methanol and dried over fused $CaCl_2$ (Yield 80%). *Anal.* Calc. for $C_{46}N_{14}O_8H_{40}Cu_2$: C, 51.92; H, 3.76; N, 18.43. Found: C, 51.43; H, 3.62; N, 18.59%. IR ν/(cm^{-1}): 1561 ν(C=N) 1611 ν(C=C) 814(ν2 of NO_3) 1304, 1418 (ν3 for NO_3). UV–Vis (λ/nm) (ε/L^{-1} mol cm^{-1}): 332.5 (30130) (n → π^* pyrimidine), 434 (10000) (CT, pyrimidine → Cu), 628 (440) (d → d). CV E_{pc}/(V): −0.42, −0.72 [$Cu^{II}Cu^{II} \rightarrow Cu^{II}$ Cu^{I}, $Cu^{II}Cu^{I} \rightarrow Cu^{I}$ Cu^{I}], Epa/(V): +0.479 [$Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{III}$].

The compound was found to be sparingly soluble in common organic solvents; hence X-ray quality crystals were obtained from a mixed solvent of DMF and CH_3OH by slow evaporation.

2.2.5. Preparation of the complex $[Cu_2(L_2)_2(NO_3)_2]$ (**2**)

Method a: The complex **2** was prepared by adding an methanolic solution (10 ml) of $Cu(NO_3)_2 \cdot 6H_2O$ (1 mmol, 295.5 mg) to a methanolic solution (15 ml) of ligand HL_2, (1 mmol, 242 mg) under constant stirring condition. Stirring was continued for half an hour, When dark brown micro crystalline compound separated. It was filtered off, washed with methanol and dried over fused $CaCl_2$. Yield (62%). *Anal.* Calc. for $C_{26}N_{10}O_8H_{24}Cu_2$: C, 41.54 H, 3.19; N, 18.64. Found. C, 41.12; H; 3.52; N,18.69%. IR ν/(cm^{-1}): 1546 ν(C=N), 1607 ν(C=C), 807 (ν2 of NO_3), 1470, 1293 (ν3 of NO_3). UV–Vis (λ/nm) (ε/L^{-1} mol cm^{-1}): 332.5 (32400) (n → π^* pyrimidine), 383 (16000) (Phenoxide → Cu), 429 (19200) (CT, pyrimidine → Cu), 675 (300) (d → d). CV E_{pc}/(V): −0.44, − 0.62 [$Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{I}$, $Cu^{II}Cu^{I} \rightarrow Cu^{I}Cu^{I}$], Epa/(V): +0.515 [$Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{III}$].

X-ray quality crystals were grown by slow evaporation of a methanolic solution of the complex at room temperature.

Method b: To an ethanolic suspension of complex **3** (223 mg, 0.5 mmol), $Cu(NO3)_2 \cdot 6H_2O$ (1.5 mmol, 443.2 mg) was added and the mixture was refluxed for ca. 2 h at water bath temperature. A brown colored solution resulted during this time along with a blue violet insoluble residue which could not be characterized. It was filtered and kept for slow evaporation. Dark blue crystals of complex **2** was found to deposit from the solution within few days.

2.3. Physical measurements

Elemental analyses (C, H and N), IR spectra (KBr discs, 4000–200 cm^{-1}), ^1H NMR spectra (DMSO-d_6) and UV–Vis spectra (MeCN), were done with a Perkin–Elmer Model 240 C CHN analyzer, a Jasco FTIR model 420 spectrophotometer, and a Hitachi U-3501 spectrophotometer, respectively. Cyclic voltammetry (CV) experiments were carried out using Sycopel Model 77 AEW2 1820F/S instrument. The measurements were performed at 300 K in a DMF solution containing 0.2 M TEAP and 10^{-3}–10^{-4} M Cu(II)–Cu(II) complexes **1**, **2**, **3**, deoxygenated by bubbling with nitrogen. A platinum wire, a platinum coil and a SCE were used as a working, a counter and reference electrodes, respectively. Magnetic susceptibility measurements for compounds **1**, **2** and **3** were carried out on polycrystalline samples, at the Servei de Magnetoquímica of the Universitat de Barcelona, with a Quantum Design SQUID MPMS-XL susceptometer apparatus working in the range 2–300 K under magnetic field of approximately 500 G (2–30 K) and 1000 G (35–300 K). Diamagnetic corrections were estimated from Pascal Tables. The EPR spectra have been recorded on X-band Bruker Spectrometer (ESR 300E), working with an oxford helium liquid cryostat for variable temperature.

2.4. Crystallographic measurements

Relevant crystallographic data are listed in Table 1. Intensity data for **1** and **2** were measured on a Bruker SMART APEX CCD diffractometer and the same for **3** were measured on a NONIUS Kappa-CCD diffractometer, using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) in the ω–2θ scan mode. These were corrected for Lorentz-polarization effects. The structures were solved by using SHELXS-97 package of program and refined by full matrix least-squares technique based on F^2 (SHELXL-97). Hydrogen atoms were added in the calculated positions. Selected bond angles and bond distances are supplied in Table S1 (Supplementary data). Perspective view of the complexes **1**, **2** and **3** along with the atom numbering schemes are shown in Figs. 3–5.

3. Results and discussion

3.1. Synthesis

The ligand HL_1, used in this work, is prepared using standard literature procedures [18,19]. Ligand HL_1 has been employed to synthesize the bis(μ-thiolato) complex, **1**, while the ligand HL_2 is synthesized for the first time for preparation of the bis(μ-phenoxo) complex, **2**.

With the examples of several other closely related ligand systems to both HL_1 and HL_2 reported earlier as binucleating ligands towards Cu^{2+} ion [23], it seemed worth while to try them out for this purpose and establish a comparative relation between the resulting thiolato and phenoxide bridged complexes with respect to their structures and magnetic behavior. Our pursuit turned fruitful when binuclear copper complexes resulted from both the ligands using $Cu(NO_3)_2$, $6H_2O$ as the precursor. Both ligands act as tridentate mono negative type donors towards Cu^{2+} ion and the complexes obtained were notably similar from the structural point of view barring the bridging donor atoms. Further we extended the purview of this work by attempting the synthesis of 4.4′-bipyridyl and pyrazine bridged dinuclear Cu^{2+} complexes with ligand HL_2. While the 4,4′-bipyridyl bridged complex was easily formed, the attempt with pyrazine was unsuccessful. This is because formation of such a complex would require a close approach of the monomeric bulky units and would exert a severe steric congestion around the bridging pyrazine ring making the species highly unstable. Thus at such a close approach of the monomeric units formation of the phenoxide bridge was favored to a pyrazine bridged binuclear complex.

A most intriguing observation was that the bipyridyl bridged complex, **3**, which is stable in heat (refluxing MeOH temperature), gets transformed to complex **2** when a suspension of **3** in MeOH is refluxed with 3 equiv. of $Cu(NO_3)_2 \cdot 6H_2O$. Within a span of 2 h, complex **3** which was originally insoluble in MeOH became completely soluble to give a brown solution. Slow evaporation of this solution resulted in X-ray quality crystals of **2**. This conversion of **3** to **2** may be attributed to the slight decrease of pH in the resulting solution on addition of excess $Cu(NO_3)_2 \cdot 6H_2O$ to the suspension of **3** in MeOH. Solvolysis of the metal salt causes lowering of pH (4.5–5.0) which is just enough to free the co-ordinated

4,4′-bipyridyl with a view to protonate it. This slight decrease of pH is however insufficient to protonate other donor atom/ion in the deprotonated prime ligand and thus no change is brought about in the main ligand's binding property. Complex **3** can thus easily get transformed to **2** using the bridging capability of phenoxide ion. The reaction scheme for the preparation of the complexes is shown in Fig. 2.

3.2. Spectroscopic characterization

The ligand HL_1 shows characteristic IR bands for ν(C=N) at 1608 cm^{-1}. This is shifted ca. 26 cm^{-1} towards lower energy in the complex **1** indicating co-ordination via azomethine nitrogen [24]. The ligand HL_1 shows a band at 800 cm^{-1} assigned to ν(C=S), this is also shifted towards the lower frequency to ca. 750 cm^{-1} confirming co-ordination via thiolate sulphur atom in the complex **1**. A band at 272 cm^{-1} may be assigned to $\nu(Cu{-}O_{NO_3})$ consistent with bands at 253–280 cm^{-1} for other nitrato complexes [25]. Moreover two strong bands at 1420 cm^{-1} and 1306 cm^{-1} at a separation of 114 cm^{-1} indicate that the nitrate is bound in monodentate fashion [26].

In the ligand HL_2 the significant bands are observed at 1566 cm^{-1} for ν(C=N), 1620 cm^{-1} for ν(C=C), 2924 cm^{-1} for ν(O–H) and ν(N–H) at 3247 cm^{-1}. Among these the broad band at 2924 cm^{-1} is absent in the complexes **2** and **3** showing that the phenolic –OH is deprotonated in the complexes.

Interestingly, the ν(C=N) band undergoes more deviation towards the lower energy in complex **2** (1546 cm^{-1}) compared to **3** (1561 cm^{-1}). This may be explained as an indirect effect of the difference in co-ordination mode of the phenoxide oxygen of the in **2** and **3**. In **2**, phenoxide ion serves as a bridging ligand. Consequently, the electronic requirement of the copper ions has to be fulfilled more by the other donor atoms (pyrimidine and azomethine nitrogen). Hence the azomethine nitrogen binds more strongly to the copper ions making the C=N bond comparatively weaker. On the other hand in **3** phenoxide ion shares greater responsibility of donation being non-bridging in nature, leaving the azomethine nitrogen rather weakly bound. Similar effects are observed in case of ν(C=C) for complexes **2** and **3**.

In complex **2** the nitrate bands are observed at 807 cm^{-1} (ν2) 1293 cm^{-1} and 1470 cm^{-1}(ν3) indicating that the nitrate bonding mode is bidentate. On the other hand complex **3** the ν3 nitrate vibrations are observed at 1304 cm^{-1} and 1418 cm^{-1} and the ν1 vibration at 841 cm^{-1}. These results signify a monodentate mode of nitrate binding [26].

The ν(C=C) and ν(C=N) peaks for 4,4′-bipy in the complex **3** generally coincide with those of the ligands. An additional peak at 848 cm^{-1} was obtained for 4,4′-bipy [8].

The electronic solution spectra of the complexes were recorded in DMF solution. Complex **1** shows a n–π^* band of the pyrimidine ring at 332.5 nm [27]. A broad band at 434 nm contains the responses for LMCT charge transfer band for pyrimidine → Cu and S → Cu [28]. The n–π^* transition has the highest molar absorption among these bands (ϵ = 30 130 L^{-1} mol cm^{-1}). The d–d transitions occur at much lower energy region and are weak in nature. The broad band at 628 nm is consistent with the broad structured band for square planar (square pyramidal) complexes of copper [29]. Spectra for complex **2** and **3** are almost similar to that of complex **1**. In complex **2**, n–π^* transition is observed at 332 nm, Two very prominent charge transfer bands occur at 383 nm and 429 nm. The former may be assigned to $N_{(pym)}$ → Cu and the latter to $O_{(phenoside)}$ → Cu charge transfer. Much weaker d–d band appears at 675 nm [30]. The CT band in **3** for phenolate → Cu appears at a little higher energy (426 nm) compared to **2** because of the difference of binding mode of the phenolate group in the two compounds. In compound **3** one additional CT band corresponding to $N_{(4,4'bipyridine)}$ → Cu LMCT appears at 344 nm. The d–d transition bands occur at a lower energy in **3** compared to **2** in keeping with the higher distortion of geometry of the copper ion environment. The ϵ value is also considerably higher in the former. In all three complexes intense π–π^* transition bands for ligands are observed at high energy zones.

3.3. Redox behavior

All the complexes show two irreversible cathodic responses at a platinum electrode in DMF solution, with E_{pc} values (versus SCE) at −0.42 V and −0.72 V for complex **3**, 0.44 V and −0.62 V volt for complex **2**, where as the two reductive responses for complex **1** occurs at −0.23 V and −0.92 V. The two reductive responses may be assigned to $Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{I}$. and $Cu^{II}Cu^{I} \rightarrow Cu^{I}Cu^{I}$ [4e] reductions. Both reductions are one electron process compared to Fe/Fe^{+} process. The difference of the peak positions for the two reductive responses is indicative of the stability of the electro generated $Cu^{II}Cu^{I}$ mixed valence state [30]. In complex **1** if is found to be maximum. The thiolate bridging donor may have also played a role. However the irreversible nature of the reductions point to the non-supportive nature of the ligand systems towards the structural reorientations required for different preferred co-ordination polyhedra for Cu(II) and Cu(I).

On an anodic scan between 0 and 1.0 V the complexes show one oxidative response for $Cu^{II} \rightarrow Cu^{III}$ between 0.40 and 0.53 V. The peak to peak separation values range between 0.129 and 0.302 V indicating the irreversible nature of the oxidation. Here again the thiolate-bridged complex undergoes oxidation at the least positive potential. Interestingly, despite the presence of a mononuclear asymmetric unit along with thiolate-bridged dimer, complex **1** shows no additional peak in cathodic as well as anodic scan.

3.4. Description of the structure

3.4.1. Structure of $[Cu_2(L_1)_2(NO_3)_2][Cu(L_1)(NO_3)]$ (**1**)

The crystal structure of **1** consists of two crystallographically independent molecules in the asymmetric unit of the complex. One is a binuclear thiolate-bridged pentacoordinated copper(II) complex while the other is its tetracoordinated mononuclear counter part. In the mononuclear unit the ligand acts as a tridentate mono negative NNS donor, using a pyrimidine nitrogen (N10), the azomethine nitrogen (N9) and the thiolato sulphur (S3) atoms. The fourth co-ordination position in the approximately square planar environment of Cu is occupied by the nitrato oxygen atom. The ligand forms two five membered chelate rings at the copper center. The thiol form of the co-ordinated ligand in the complex is evident from the increased C13–S3 bond length (1.736 Å) and decreased C13–N8 bond length (1.334 Å) compared to standard bond lengths observed in thione form of other thiosemicarbazone ligands [31]. The deviation of the copper atom from the mean square plane containing S3N904N10 is negligible. The two chelate rings formed by the ligand are strikingly co-planar with a dihedral angle of less than 1° between the mean planes of Cu2S3C13N8N9 and Cu2N10C15C14N9. This co-planarity of the chelate rings facilitates electron delocalization in the co-ordination sphere rendering enhanced stability to the complex. The thiosemicarbazone bite angles S3Cu2N9 and N10Cu2N9 are observed to be 84.16° and 81.09° respectively while the angular measurements of the trans donor ligands, O4Cu2N9 and S3Cu2N10 are 176.29° and 165.25°, respectively, showing considerable distortion from ideal square planer angles (90° and 180°). However the results are in agreement with those reported for similar mononuclear thiosemicarbazone complexes of copper[32]. The deviation of the copper atom from the basal plane is found to be negligible.

The binuclear unit may simply be regarded as a centrosymmetric dimer of the mononuclear unit, where the two monomeric units are linked by a four membered ring that includes both symmetry related copper atoms and co-ordinated sulphur donors. The local co-ordination environment of each copper comprises of a square pyramidal N_2OS_2 chromophore. The geometry around the copper atoms may be described as distorted square pyramidal. Where the basal plane is occupied by a pyrimidine nitrogen (N4), azomethine nitrogen N(3), a bridging thiolato sulphur (S1) from a mononegative ligand and an oxygen (O1) from a nitrate anion. The apical position is occupied by a bridging thiolate (S1) from another ligand. The bonds formed by the basal ligand atoms with each copper i.e. Cu(1)–S(1), Cu(1)–N(3) and Cu(1)–N(4) are comparable to those observed in the monomeric unit as well as other structurally characterized binuclear thiolato bridged copper complexes [33]. Despite the fact that the co-ordination angles subtended at each copper center is considerably deviated from ideal square planer angles [180° and 90°] (Table S1, Supplementary data), an approximate square pyramidal geometry is established by the calculation of Addison parameter τ, $\tau = (\beta - \alpha)/60°$. In this case α and β are O1Cu1N3 and N4Cu1S1 angles respectively giving a τ value 0.198 [34]. The apical bridging Cu–S bonds are comparatively longer than the basal Cu–S bonds (2.82 Å versus 2.29 Å). The dominant Jahn–Teller distortion characteristics to square pyramidal copper complexes seem to be the reason behind it. The opposite interior angles of the Cu_2S_2 tetragonal core are 86.54° and 93.46°. Thus from the non-equivalence of bond lengths and bond angles it is clear that this is an asymmetric binuclear thiolate double bridged structure. The distance between the two copper atoms is 3.52 Å, comparable to other similar complexes. The Cu_2S_2 core is essentially planer, with all the four atoms sitting in the mean plane. This facilitates the magnetic exchange interaction between the Copper atoms. The mean basal planes at each copper atom through Sl01N3N4 show that there is very little deviation (<0.1 Å) of the atoms from the mean plane. The copper atom is deviated only ca. 0.06 Å towards the apical bridging Sulphur atom. The basal planes of the square pyramid are almost orthogonal with the mean plane of Cu_2S_2 bridge bearing a dihedral angle of 85.9° in each case.

The binding mode of the NO_3^- as the fifth coordinating ligand is worth discussing as nitrate ions are reported to bind metals in monodentate, bidentate and anisobidentate fashion [35]. Based on the available parameters for assigning the nitrate-binding mode [36], it was determined that in both the asymmetric units monodentate fashion of nitrate binding is present. It is found that the nitrate ion is almost planer in the crystal.

A closer look at the crystal lattice shows that the two asymmetric units are networked by profound H-bonding interaction. Each binuclear unit is H-bonded to four mononuclear units. In this case the interaction is between a nitrate oxygen and the Hydrogen of the secondary amine group of the N(4)-substituted thiosemicarbazone.

3.4.2. Structure of the $[Cu_2(L_2)_2(NO_3)_2]$ (**2**)

This dimeric molecule sits on a crystallographically imposed center of inversion forming a bridged dinuclear structure with each copper being five-coordinate. The geometry around each copper may again be described as an approximate square pyramidal arrangement. Three positions in the basal plane being occupied by the tridentate ligand, acting as a monoanionic NNO donor and the fourth position being occupied by a co-ordinated nitrate. A bridging O from the second ligand unit occupies the apical position. The basal mean plane of the square pyramid through the pyrimidine nitrogen (N1), the azomethine nitrogen (N4), the phenoxide (O1) and the nitrate oxygen (O2) does not contain any of these atoms (The deviations range between 0.167 and 0.201 Å). The copper atom is deviated by 0.125 Å towards the apical bridging oxygen. The chelate rings (one five and another six membered) formed by the ligands at each copper center are at a dihedral angle of 9.2°. The angles produced at the axial phenoxide bridge by the basal donors (~374°) shows considerable pyramidal distortion. Overall it may be inferred that complex **2** suffers less distortion ($\tau = 0.157$) from square pyramidal geometry towards TBP geometry than complex **1** in spite of the fact that angular deviations from ideal square planar angles are more pronounced in **2** than **1**. The Cu–O(1) (bridging) bond distance is 2.33 Å whereas the Cu–O(1) (basal) is 1.921 Å are unexceptional [37], as are the other bond lengths in the co-ordination sphere of each copper atom (Table S1, Supplementary data). The distance between the two copper atoms is 3.18 Å which is more to the higher end of the range (2.9–3.34) Å reported for Cu–Cu distances in macrocyclic and non-macrocyclic bis(μ-phenoxo) bridged dicopper complexes [38]. In this complex the Cu_2O_2 core bears dihedral angle of 88.69° with the mean basal plane of each square pyramid. The internal angles produced at the Cu_2O_2 core (96.57° and 83.43°) are comparable to those observed in the Cu_2S_2core of complex **1**.

Unlike complex **1** the nitrate ion is bound to the copper in an anisobidentate fashion. (See Table S2, Supplementary data) however the large nitrate bite angle (118°) supports the view that the second oxygen (04) of the nitrate should be regarded as a sixth co-ordinating ligand approaching vacant the axial end, rather than both oxygens (O2,O4) of nitrate occupying a single co-ordination position in the basal plane. The Cu–O(4) distance of 2.55 Å suggests an weak axial interaction. No appreciable H-bonding interaction is observed of either intra or intermolecular nature. From the Cg–Cg distances it is observed that there is notable π–π interaction between the benzene and pyrimidine ring systems between two separate dimeric molecules. However such interaction if present between aromatic rings belonging to same molecule may be weak in nature.

3.4.3. Structure of $[Cu_2(\mu\text{-}4,4'bipy)(L_2)_2(NO_3)_2]$ (**3**)

The molecular structure of **3** shows two pentacoordinated copper ions bridged by a 4,4′-bipyridyl molecule. The co-ordination environment around each copper may be described as irregular, distorted to an extent of ~50% ($\tau = 0.496$) along the path way from square pyramidal towards trigonal bipyramid. Similar to complex **2**, the ligand (HL_2) acts as tridentate mono negative donor. The only difference is that the phenoxide group (O1) does not operate as a bridging group, i.e. each phenoxide group donates to a single copper ion. The fourth co-ordination position in the basal plane is occupied by the nitrogen (N5) of the bipyridyl bridging ligand. The axial position is occupied by a nitrate donor. In this complex the nitrate acts as a monodentate donor through (O2), the other oxygen (O3) is too far away from the copper ion (3.25 Å) for any appreciable bonding interaction. The Cu–O(2) bonds being the axial one, are found to be the longest (2.247 Å) among all five bond lengths in the co-ordination sphere of each copper (Other bond lengths are in the range 1.89–2.03 Å). The chelate rings formed by the ligand at each copper center are co-planar, bearing a dihedral angle of only 2.09°. This observation is in contrast to complex **2** where a puckering of the chelate rings was observed to accommodate the rigid bis(μ-phenoxo) bridged structure. The two rings of the 4,4′-bipyridyl bridging donor are co-planar to one another in conformation. Hence the compound bears two fold axis of symmetry perpendicular to the plane containing the bipyridyl rings and also a center of symmetry. The distance between the two copper atoms in 11.14 Å which is similar to other bipyridyl bridged binuclear complexes [8–10].

There are two intermolecular H-bonding interactions between the hydrogen of azomethine nitrogen atoms (N3) of a unit with the bonded nitrate oxygen (O2) of another unit. The binuclear complexes thus forms a mixed one dimensional co-ordination polymer

held by both co-ordinate and H-bonds (Fig. S1 in Supplementary data).

3.5. Magnetic studies

3.5.1. Magnetic study on complexes **1** and **2**

The magnetic behavior of the compound **1** is shown in Fig. 7, as a $\chi_M T$ *versus* T plot. At room temperature the $\chi_M T$ value is 0.860 $cm^3\ K\ mol^{-1}$ which is close to the expected value for two uncoupled copper (II) ions with $g = 2.14$. $\chi_M T$ increases slightly with lowering of temperature and reaches a maximum of 0.962 $cm^3\ K\ mol^{-1}$ *ca.* 7.3 K. Below this temperature $\chi_M T$ decreases to a value of 0.833 $cm^3\ K\ mol^{-1}$ at 2 K. The shape of this curve indicates dominant ferromagnetic coupling which result from the interaction of the copper(II) ions through sulphur atoms (thioalkoxo-bridges). The $\chi_M T$ decreasing observed at low-temperature is may be due to the intermolecular antiferromagnetic exchange and/or the presence of the ZFS of the ground state (S = 1).

To determine the exchange parameters *via* sulphur atoms we have used the Bleaney–Bowers expression for an isotropically coupled pair of $S = 1/2$ ions [39], (Eq. (1)) and a Curie–Weiss correction. The best fit parameters for the reproducing satisfactorily the experimental data, as shown in Fig. 6, are $J = +7.6\ cm^{-1}$, $\theta = -0.78$ K and $g = 2.14$ with $R = 1 \times 10^{-5}$ ($R = \sum_i(\chi T_{icalc} - \chi T_{iexp})^2/(\chi T_{iexp})^2$):

$$\chi_M = \frac{Ng^2\mu_B^2}{k_B(T-\theta)}\frac{2\exp(J/k_B)}{1+3\exp(J/k_B)} \quad (1)$$

For compound **2** the global feature of the $\chi_M T$ versus T curve is characteristic of very weak antiferromagnetic interaction in a dinuclear copper(II) complex and/or intermolecular interaction (Fig. 7). The value of $\chi_M T$ at 300 K is 0.951 $cm^3\ mol^{-1}$ K which is as expected for two uncoupled copper(II) ions (0.475 $cm^3\ mol^{-1}$ K per one Cu^{II} with $g = 2.25$). The $\chi_M T$ values are more or less constant at high temperature and then decreases suddenly in the low-temperature region reaching a value of 0.332 $cm^3\ mol^{-1}$ K at 2 K.

The interaction through oxygen atoms was determined by the use of the above equation Eq. (1) The best fit parameters from 300 down to 2 K are found as $J = -1.8\ cm^{-1}$, $\theta = -1.5$ K and $g = 2.25$ with an error $R = 9.8 \times 10^{-6}$ ($R = 1 \times 10^{-5}$) ($R = \sum_i(\chi T_{icalc} - \chi T_{iexp})^2/(\chi T_{iexp})^2$).

The field dependence of magnetization (0–5.0 T) measured at 2 K for compound **1** is shown in Fig. 6b, in the form of M/Nβ (per Cu_2 unit) versus H. The magnetization reaches a value of 2.11 Nβ at 5.0 T which is close to the expected S = 1 value of 2 Nβ for the Cu_2 system, indicating the presence of ferromagnetic interaction between the nearest copper(II) ions. For compound **2** the field dependence of magnetization (0–5.0 T) measured at 2 K is shown in Fig. 7b, reaches a value of 1.7 Nβ near of two electrons but with a particular shape that we cannot fit satisfactory with Brillouin expression for two isolated ion with $S = 1/2$. The curves indicate very slow magnetization which is consistent with a net weak antiferromagnetic interaction.

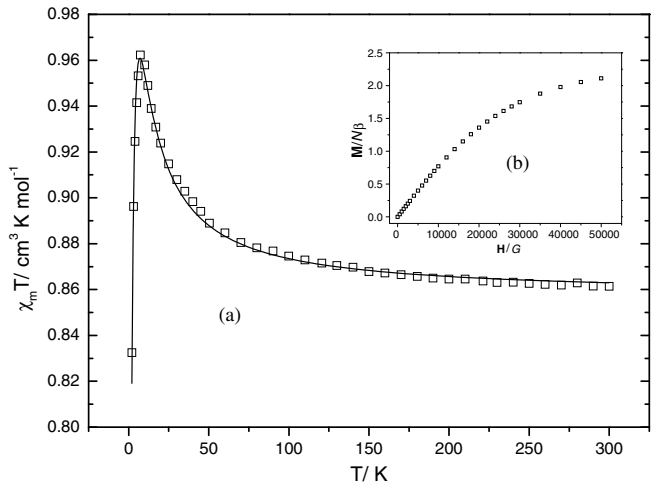

Fig. 6. (a) Plot of the χ_MT vs. T for compound **1**. The squares and solid line are the experimental values and the best fit respectively. (b) The field dependence of magnetization at 2 K for compound **1** (per Cu_2).

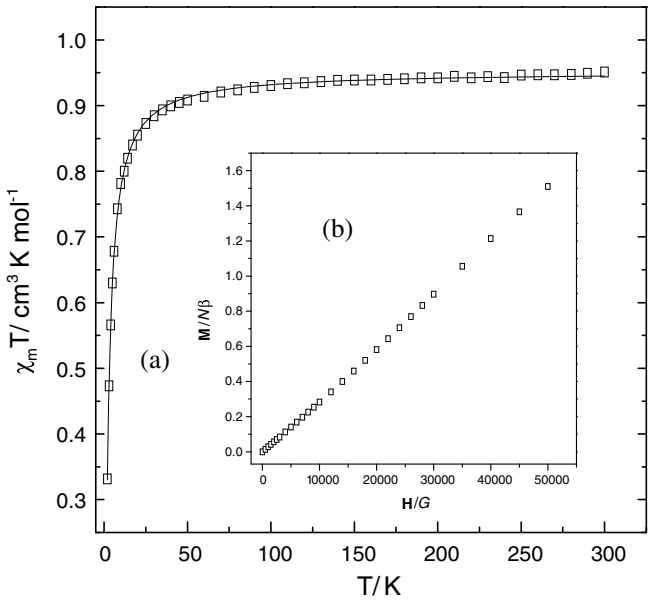

Fig. 7. (a) Plot of the $\chi_M T$ *vs.* T for compound **2**. The squares and solid line are the experimental values and the best fit respectively. (b) The field dependence of magnetization at 2 K for compound **2**.

The EPR spectrum of **1** recorded in X band at 4 K is shown in Fig. S2 (Supplementary data). One band is observed at $g = 2.09$ (3228.66 G for $\nu = 9.460$ GHz), corresponding to the transition $\Delta M_S = \pm 1$. For the compound **2** (Fig. S3, Supplementary data), two bands are located at $g_{\|} = 2.28$ and $g_{\perp} = 2.09$ (2962.77 and 3224.75 G for $\nu = 9.458$ GHz).

In order to evaluate the nature of the interaction with similar topology, via sulphur (thioalkoxo-bridges) and oxygen atoms (alkoxo-bridges) in **1** and **2**, respectively, the experimental atomic co-ordinates were performed to obtain the J values. The calculated $J = +9.9\ cm^{-1}$ for compound **1** are reasonably close to the fit value $+7.6\ cm^{-1}$ but for **2** the calculated J value is $+1.2\ cm^{-1}$ which contradicts the experimental one ($-1.8\ cm^{-1}$).

To clarify this discrepancy, we have modelled the structure of both compounds attempting to understand the influence of the distance, d(Cu–X), in the exchange coupling parameter J between nearest copper(II) (Fig. 8). Therefore, in the model 1 we have varied the Cu–S distance in the range 2.5–2.9 Å in compound **1**. In the model 2, we have varied the Cu–O distance in the range 2.1–2.5 Å in compound **2**. The results of these calculations are reported in Fig. 9 as a J versus d(Cu–X) plots. In the two cases the calculated interactions are ferromagnetic: (i) In the model 1, the calculated J values are varying between +8.0 and $+27.6\ cm^{-1}$ showing a clear parabolic dependence with the Cu–X distance. (ii) A similar trend was observed in the model 2, but with small J values which are varying in the range [+0.3 to $+4.3\ cm^{-1}$].

In previous paper, one of us has analyzed the magnetic properties of alkoxo-bridged dinuclear Cu(II) complexes showing a similar topology of compound **2**. The calculated interactions were also weak and ferromagnetic [40]. In the same way, the calculations of model 2 seem to confirm the weak nature of the interaction. The

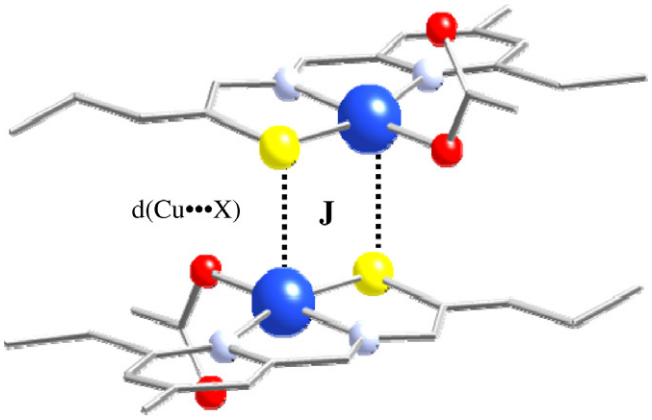

Fig. 8. Molecular structure representation and exchange coupling constant view of compound **1**. The hydrogen atoms are omitted and the non-environment atoms of copper are represented as sticks for clarity. The dotted line represents the apical distance Cu–X that we have varied in mode l for compound **1** and model for compound **2**.

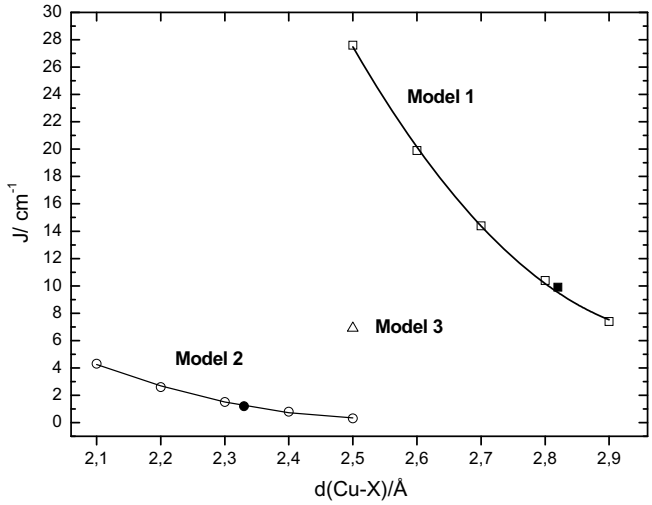

Fig. 9. Variation of the calculated coupling constant as a function of longer distance Cu–X, for **1** (mode1, □) and **2** (model 2, ○). Solids squares and circles represent compound **1** and **2**, respectively. For model 3 (△) see text.

magnetic behavior can easily be rationalized using the Hay–Thibeault–Hoffmann model [41]. If the coupling constant is given by,

$$J = 2K_{ab} - \frac{(\varepsilon_1 - \varepsilon_2)^2}{J_{aa} - J_{ab}}$$

the second term will probably be much smaller, result of the poor overlap between the parallel orbitals on the bridge (Fig. S4, Supplementary data). In such situation, the first term, $2K_{ab}$, is dominating, and leads an overall positive value for the coupling exchange as it shown in compound **1**. In compound **2** this two terms seem to have similar and small values giving a very weak net interaction ferro or antiferromagnetic.

Finally we have substituted in model 1 the sulphur atoms in the bridge by oxygen atoms (with Cu–O distance = 2.5 Å), obtaining a model with a similar bridge of **2** (model 3) but topologically is close to compound **1**. The calculated J value is +6.9 cm^{-1}, which is large than the calculated for compound **2** by the model 2 (Fig. 9). This agrees with the great ferromagnetic J value calculated for compound **1** by model 1, indicating the domain of the $2K_{ab}$ term.

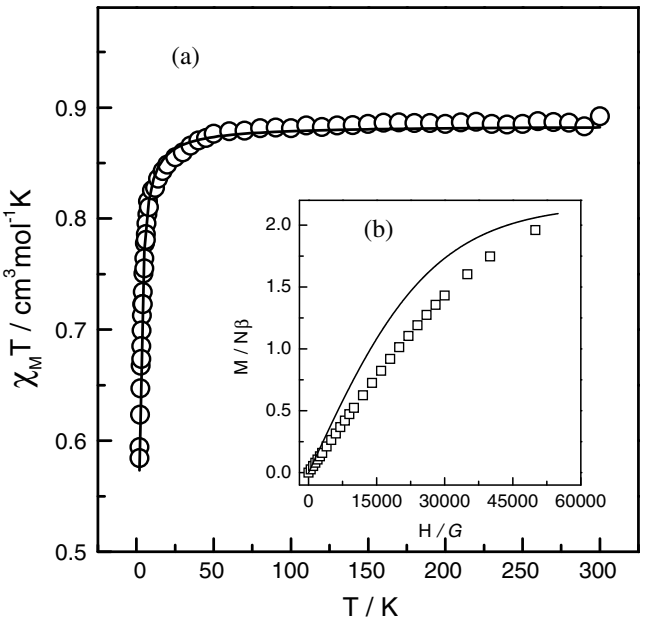

Fig. 10. (a) Plot of the $\chi_M T$ *vs.* T for compound **3**. The squares and solid line are the experimental values and the best fit respectively. (b) The field dependence of magnetization at 2 K for compound **3** (per Cu_2).

*3.5.2. Magnetic study on complex **3***

The magnetic properties of a powder sample of complex **3** are represented as $\chi_M T$ versus T in Fig. 10a. At room temperature, the $\chi_M T$ value of the presented complex is 0.883 $cm^3\ mol^{-1}$ K. This value correspond to two isolated copper(II) ions with one unpaired electron with $g = 2.17$. With decreasing temperature, the $\chi_M T$ value remains almost constant until ca. 25 K and then it decreases sharply, giving the minimum value of 0.594 cm^3 K mol^{-1} at 2 K. The drop in $\chi_M T$ at low-temperatures indicates the presence of a very weak antiferromagnetic coupling between the copper(II) ions.

Analysis of the experimental magnetic data was performed by using the Bleaney–Bowers expression, based on the following isotropic Hamiltonian: $H = -J(S_1 \cdot S_2)$:

$$\chi_M = \frac{Ng^2\mu_B^2}{kT}\frac{2\exp(J/kT)}{1+3\exp(J/kT)} \quad (2)$$

The parameters N, μ_B and k in Eq. (2) have their usual meanings, J = Singlet–triplet splitting. Least-square fitting of experimental data leads to the following parameter $J = -1.6\ cm^{-1}$ and $g = 2.17$.indicating a very weak coupling, as may be expected from the 4,4′-bipyridyl bridge. This weak magnetic exchange can be understood considering the large Cu···Cu distance (11.15 Å).

The very weak antiferromagnetic interaction was confirmed by magnetization measurements at 2 K up to an external field of 5.5 T. At higher field, the magnetization in M/Nβ units indicates a two isolated quasi-saturated $S = 1/2$ system for the compound (Fig. 10b). Comparison of the overall shape of the plot with the Brillouin plot for a fully two isolated ion with $S = 1/2$ system indicates very slower magnetization which consistent with a weak antiferromagnetic interaction.

The EPR of spectra complex **3** at low-temperatures maintain the same shapes and g values as the EPR spectrum at room temperature. The EPR spectrum of the studied compound shows three signals that are quite close and partially overlapped, (see Fig. S5, Supplementary data). The spectrum is a typical rhombic one with three g values at $g_1 = 2.24$, $g_2 = 2.09$ and $g_3 = 2.027$ for the compound. It is necessary to highlight that the foregone signal of $DMs = \pm 2$ for a triplet which should appear in the range 1500–1600 G have not been observed for the complexes **1**, **2** and **3**.

The weak exchange pathways parameter, J; observed in **3** was confirmed by the density functional calculations where the experimental atomic co-ordinates of the compound were performed to obtain the J value, giving -0.3 cm^{-1}. In this compound the spin distribution is mainly localized in d($x^2 - y^2$) orbital as we can observe in the Fig. S6 (Supplementary data) due to the large separation between the Cu(II) paramagnetic centers.

3.6. Computational details

The followed computational strategy to calculate the exchange coupling constants in transition metal complexes was described in previous papers [42–44]. The exchange coupling constants are introduced by a phenomenological Heisenberg Hamiltonian $H = -\sum JS_i \cdot S_j$ (where i and j make reference to the different paramagnetic centers) to describe the interactions between the two paramagnetic transition metals present in the dinuclear complex.

The hybrid B3LYP functional [45] has been used in all calculations as implemented in GAUSSIAN-03 [46] mixing the exact Hartree–Fock-type exchange with Becke's expression for the exchange functional [47] and that proposed by Lee–Yang–Parr for the correlation contribution [48]. Such functional provides calculated J values in excellent agreement with the experimental values [42,49,50]. Basis sets proposed by Schaefer et al. have been employed throughout, triple-ζ quality for the copper atoms [51] and double-ζ for main group elements [52].

4. Conclusion

On a final note, a study on the difference in magnetic behavior of the complexes **1** and **2** has revealed that the major factor in controlling the magnetic interaction between the Cu atoms is the overlap between the parallel orbitals on the bridge. Both the bridging donor atom and the ligand topology are contributory factors for an effective overlap. Further, molecular modelling studies between these two complexes have led to a conclusion that the ligand topology factor dominates the bridging donor atom factor. From a synthetic point of view, ligand HL_2 demonstrates two possible binding modes in complex **2** and **3**. Such versatility in its binding modes has been instrumental in the pH dependant conversion of **3** into **2**. Both the complexes are weakly antiferromagnetic but have slightly different magnetic properties. This phenomenon opens the door towards the potential use of similar ligand systems of multi-utility for the design of metal complexes with magnetic properties tuneable with change of pH of the medium.

Transition state energies

ABSTRACT

Novel Rh(I) diphosphinite catalysts [Rh((*R*,*R*)-3,4-(bis(*O*-diphenylphosphino)-1,2,5,6-tetra-*O*-methyl-*chiro*-inositol)]+ ([Rh-CANDYPHOS]+) and [Rh((*R*,*R*)-3,4-(bis(*O*-diphenylphosphino)-1,2,5,6-tetra-*O*-ethyl-*chiro*-inositol)]+ ([Rh-EtCP]+) have been prepared utilizing naturally-occurring resources. Potential energy surfaces for the catalyzed asymmetric hydrogenation of the prochiral enamides methyl-(*Z*)-α-acetamido cinnamate, methyl-(*Z*)-α-acetamido cinnamic acid and dimethyl itaconate have been surveyed using density function theory (DFT) methods. Key transition states were identified from previous [Rh((*R*,*R*)-DUPHOS)]+ studies for the two diastereoisomeric manifolds [1,2]. Transition state energies were found starting from models based on (1) the X-ray structure of the active complex (CANDYPHOS)(η^4-(*Z*,*Z*)-cyclo-octa-1,5-diene)-rhodium(I) tetrafluoroborate $CHCl_3$ solvate [3] and (2) models in which the complex (without substrate) started with C2 molecular symmetry. The difficulties encountered in calculations of the transition state energies of large cations are outlined and limitations noted. Transition state enthalpy values are compared with the observed experimental free energy differences results and previous studies [1,2]. The predictive aspects of the calculations appear to be limited with the starting models playing an important part in the absolute value of the final energies.

1. Introduction

Interest in highly selective asymmetric catalysis continues at a significant level [4] both from synthetic [3] and computational modelling perspectives [2,5–7,20]. In particular we observe that research into asymmetric hydrogenation involving new metal diphosphine/diphosphinite-based compounds [8–13], mono-phosphine/phosphite metal catalysts [9,14–22], including mixtures of chiral and achiral species [23,24], and more recently self-assembled cyclic monophosphanes [25] as well as improved methods for testing their efficiency [26,27] is intense. This is undoubtedly spurred on by the need to produce high value chiral products economically as noted by Knowles [28] and reviewed recently [4]. In passing we note also the considerable interest in "heterogenized"-homogeneous catalysts, where the active catalyst is attached to a heterogeneous framework [4,27,29], reactions involving biphasic [30,31] and continuous hydrogenation membrane systems [32]. An alternative to the quadrant rule [33] used in prediction has also been recently proposed [7] and we note the multiple model calculations of BINOL-based monophosphite Rh catalysts [20]. Finally, for completeness, we record a recent publication which noted that even for the well-studied [Rh(I)-binap]+ catalyzed reactions the mechanism "is still controversial" [34] as to whether it goes via the dihydride pathway (initial formation of dihydride) [35] or the "alkene" or "unsaturated" route [36,37] via an initial Rh-substrate complex (as shown in Scheme 1).

Along with the synthesis of novel homogeneous chiral bis- and mono-phosphinite catalysts, for which both enantiomeric sources were readily available, we were interested to ascertain whether the density functional calculations (DFT) could provide timely and accurate predictions of the enantiomeric excess (ee) for a general reaction with a specific, and with an homologous catalyst. The difficulty of this task was known: DFT energies are usually accurate to a few kcal/mol while ee's require accuracy of 1 kcal/mol. We began with the advantage of previous mechanistic studies providing knowledge of the mechanism of the reaction and of the enantio-determining steps (see full Refs. 2 and 3 in [2]). Although previous papers noted some energy resolution concerns [6], we anticipated that these would be ameliorated through the subtraction of systematic errors in the difference energy calculations for the (two) energy states.

In order to expedite the process, and take advantage of the previous modelling and kinetically-derived mechanisms [2,38], we chose our initial models from those reported for [Rh((*R*,*R*)-DUPHOS)]+ by Feldgus and Landis [1], (hereafter DUPHOS, see Fig. 1) noting that their more comprehensive report [39] suggested different enantiomeric results could result when the substituent at the alpha-carbon site of the enamide was changed.

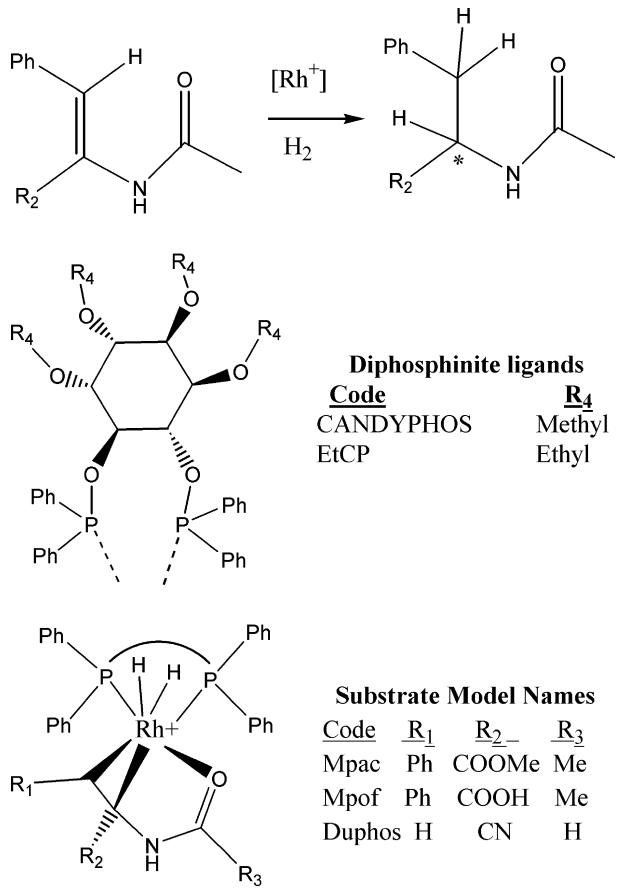

Scheme 1. Overall reaction and model names. *Scheme Key*: Dihydride transition states for the substrate models; for DUPHOS see Ref. [1]. In data tables below, the EtCP-based catalysts are distinguished from the CANDYPHOS ones by the prefix Et (e.g. Mpac and EtMpac).

Our initial calculations with the electron withdrawing cyano group [as in [1]] gave us confidence that we were reproducing both similar energies and geometries (Table 1).

Reference to the compositions shown in Scheme 1 and Fig. 1 show that this work incorporates a new level of detail particularly for the substrate molecule compared with the earlier DUPHOS[1] simplifications. The evaluation involved using a standard Kohn–Sham density functional theory programme suite [40,41] in full DFT mode on two homologous catalysts: [Rh-CANDYPHOS]+ and [Rh-EtCP]+ and three substrates: methyl(*Z*)-α-acetamido cinnamate, methyl(*Z*)-α-acetamido cinnamic acid and dimethyl itaconate (Fig. 1a–c).

2. Results and discussion

We begin this report with an examination of the critical elements of the methodology.

2.1. A. Finding the transition states

The refinement of any model to a transition state (for which the Hessian matrix has a negative eigenvalue) [42] for these molecules is a difficult exercise. A potential energy surface of this dimension will include numerous saddle points and probably several of them in the neighborhood of the saddle point of interest. Ensuring that a transition state search finds the correct saddle point can be a challenge, especially if one or more of the nearby saddle points are lower in energy. In the DUPHOS models [1], there are 4 transition states of significance as recently confirmed in the study by Donoghue et al. [2]. We use the same labels here for the minor and major manifolds (min/MAJ: the major manifolds are labelled in capitals): these are sqpl(SQPL) {the square planar starting complex plus hydrogen molecule}, iid-a‡ (IIDA‡), molh(MOLH), molh‡(MOLH‡) and dihy(DIHY) for the A (approach) series. The highest, and rate determining transition state is the third (MOLH‡) with a typical dihydride H–H distance ~1.28 Å, Rh–H distances ~ 1.6 Å, and H–Rh–H angle ~45° (Table 2; for full description see text and Fig. 6 in Ref. [1]).

For our DUPHOS "proofing" calculations (Table 2), convergence from the provided coordinates was straightforward to the expected values, although the energy differences were rather smaller than previous studies (see Fig. 3 drawn in the Donoghue style [2]). We elected to concentrate on the central transition state (MOLH‡) and the two adjacent states.

2.2. B. Establishing the transition state energies

2.2.1. Reproducibility

In the process of building models from a combination of the X-ray structural parameters for 1L-Rh(CANDYPHOS)+ [3] and the published transition states in DUPHOS, we came to the first decision point: was the reproducibility of electronic energy (and geometry) in the gas-phase calculations for these larger molecules (>100 atoms including Rh) sufficient? Our overall conclusion from a variety of model compounds (the variants of the substrate as we built intermediate models from the CN-bound simplified DUPHOS substrate model to the full methyl(*Z*)-α-acetamido cinnamate (see Fig. 1)) was that the reproducibility was only just adequate (±~0.3 kcal/mol). Our worst agreement of 0.45 kcal/mol occurred when we started from significantly different starting models, using the default integration accuracy parameter of 4.0. In ADF this parameter approximately corresponds to the number of significant figures in the calculated numbers. For all our final calculations therefore we used the more accurate integration accuracy parameter of 5.0.

2.2.2. Convergence parameters

The next decision point concerned the need to establish termination limits for the converging parameters; for any non-linear problem, both the significance level of the calculations and the criteria for three differently determined factors in the ADF package (energy gradient slope, energy differences and distance movement

for the atoms) must be set to obtain accurate results within a practical refinement time (assuming of course that the refinement does not involve untoward oscillation in energies). The recommended minimum integration limit (of 5 significant figures) in the ADF [40] package was used for final calculations, although a limit of 4 (4.0) was frequently applied for QM/MM runs. A series of trials were run with variations of the limiting ratio for energy, gradient and Cartesian coordinates. Reducing the default parameters to one-tenth of the standard values (i.e. to 0.0001, 0.001 and 0.001) prolonged stable refinements unnecessarily with no significant change in total energy (<0.05 kcal/mol). At the same time, less stable refinements (see saddle point location below) frequently bypassed the requested (using a dihydride H–H distance restraint) or expected saddle points. Using empirical trials we came up with a compromise set of 0.0002 (tolE), 0.01 (tolG) and 0.012 (tolCART) for ADF [40]. It was sometimes necessary to reduce the maximum step size to values as low as 0.005 Å to ensure that the search converged on the saddle point of interest. In a few cases which were consistent with the rather flattened saddle point profiles (see below) these convergence parameters gave final cycles with oscillating enthalpy values, within a range of 0.2 kcal/mol.

2.2.3. Saddle point location: strategy

Our initial success in locating saddle points based on the DUPHOS models was not always repeated for the various models built on the same frameworks in which the DUPHOS ligand was replaced with CANDYPHOS or EtCP and/or the simplified substrates were progressively converted to the actual (experimental) substrates. It is our contention that this reflects different shaped energy surfaces as determined by examining (and plotting) these using the internal reaction coordinate (IRC) feature of the ADF package. An example plot, the XMpof2 MOLH‡ transition state, is given in Fig. 4 to illustrate the commonly observed flat gradients, width and asymmetry.

2.2.4. Starting models

The X-ray structural study result for the CANDYPHOS ligand both bound to Rhodium(I) [3] and free [10] represent ground (and solid) state results. We became concerned that this might not be close enough to the real solution (*in situ)* situation when the CANDYPHOS ligand would (at least initially on release of the

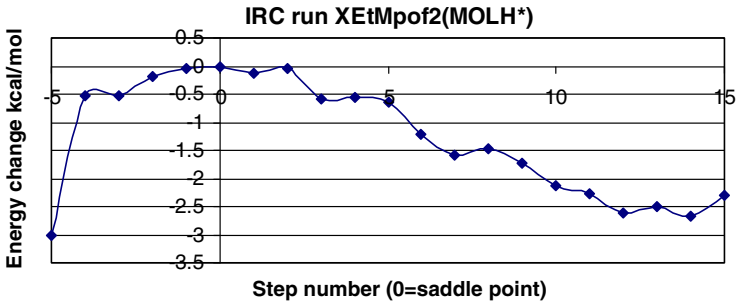

Fig. 4. Enthalpy energy change over the XEtMpof2 saddle point from internal reaction coordinate calculation.

Rh-bound cyclo-octadiene ligand) start from a state with approximate C2-symmetry. Consequently we transformed the X-ray structure-based starting models to a C2-symmetrical state and began a new series of transition state searches. As summarized (Table 3), the transition state attained from this new C2-symmetric start did not convert to the (X) ground-state "non-symmetrical state" found in the crystal structure (Fig. 5) and energies were significantly different: in this case the difference was 6.8 kcal/mol (entries Xmpac2 and C2Mpac2, Table 4). This dramatically emphasizes the requirement that both enantiomers in the two manifolds must be as similar in conformation for a comparative energy to have any meaning. To ensure this point is clear, we have included results for both sets in Tables 3–5 (complex names are prefixed by X or C2 accordingly).

P11–Rh–P10–C37	172.8	161.0

Having recognized that conversion from different conformations of the phenyl rings in the Mpac series was unlikely, we noted that (at least) two different conformations were obvious for the dimethyl itaconate models as shown in Fig. 6. We labelled these Cdmit and CdMeS, respectively (Table 5).

2.2.5. Electronic energies and Gibbs free energies

Our initial trials using DUPHOS suggested that entropy contributions to the transition state energies were small and that zero point energies were not significantly different for the same transition states: room temperature difference of the TS term was 0.7 kcal/mol (Table 1). Although this difference approaches a significant energy, it was anticipated that a cancellation effect would prevail, meaning that electronic energies alone could be used for comparative purposes. The calculation time for the entropy energies is essentially six times the number of atoms longer: so a typical calculation in this 112 atom structure is 672 times one equivalent electronic energy calculation. At present with our 4-cpu cluster, the latter takes around 75 cpu minutes ... the entropy calculation ~36 days! In a recent check calculation using our most studied molecule (Fig. 1a), we found that the difference in vibrational entropy contribution was around 9.4 cal/mol K (cf. 2.4 for DUPHOS) corresponding to a different number of contributing vibrational frequencies leading to an "apparent" entropy difference between the two transition states of 2.5 kcal/mol at room temperature (in this case the total difference between MAJOR and minor energies widened from 4.2 to 6.7 kcal/mol). Moreover, the zero point energies of these two transition states were different by ~0.5 kcal/mol (again increasing the overall difference). We therefore note that the difference in total energy, including the entropy contribution and the

zero point correction terms might well be significant at the ~1 kcal/mol level: a reduction in the computation time, and removal of extra vibrating atoms which contribute to the entropy sum, are two features that would be useful in future studies.

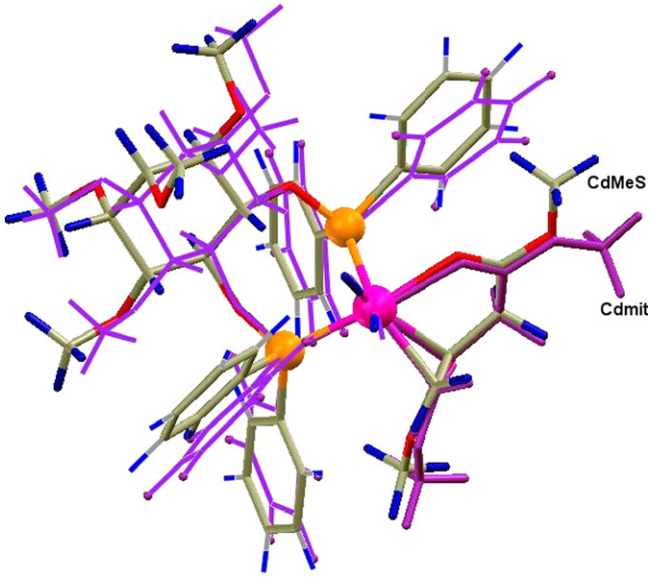

Fig. 6. Superposition of final methyl itaconate transition state models XCdmit1 (in purple) and XCdMes1 (thick bonds with atom colors: O, red; Rh, pink; C, gray; H, blue). Labels indicate the different methyl substrate conformations. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

2.2.6. Comparing like models (the predictive quandary)

We have confirmed that the stereochemistry of the minor and major manifold transition states must be closely aligned also with respect to the dihydride hydrogen geometries. In one case (XMpof2) it was possible to locate transition states with differing H–H distances (1.19 and 1.39 Å) which gave electronic energies differing by 2.5 kcal/mol. On further refinement of both with lower convergence parameters, the energies came closer (within 1 kcal/mol) but with one model not converging in a realistic timeframe: final H–H distances of 1.22 (converged) [quoted in Table 4] and 1.16 Å (oscillating). The models are essentially superimposable (Fig. 7) and serve to warn that care must be taken in comparing similar transition states from the two manifolds. We present a simplified view of this issue in Fig. 8, which maps (using a linear step)

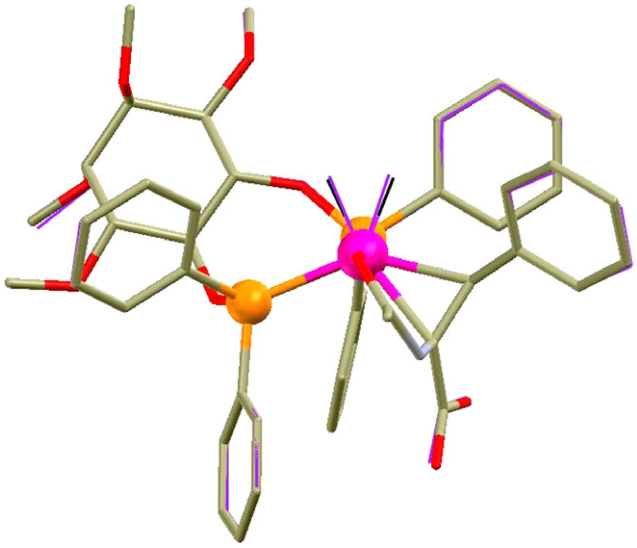

Fig. 7. Overlap of XMof2 transition state models (see text): only the dihydride hydrogen atoms are shown. Converged model with atom colors: O, red; Rh, pink; N, blue; C, gray; H, black. Other model: purple. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

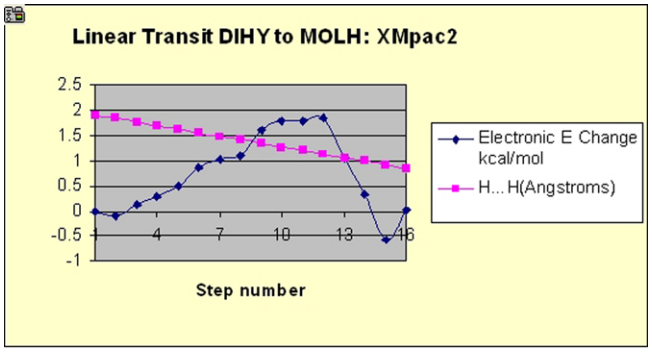

Fig. 8. Energy change vs. H–H dihydride distance (XMpac2 model) (see text).

the energy changes between the DIHY and MOLH models for XMpac2: the energy change compared with the H–H distance is small around the MOLH‡ model region (steps 9–12, Fig. 8).

3. Overall results

We present difference enthalpy results in Tables 4 and 5 and emphasize that the magnitude of the difference between the minor and major manifold transition states is of the order of 0.02% of the total energies by listing the numerical values for the SQPL/sqpl models. Given the notes above about the need to compare similar dihydride geometries, these tables also include the relevant (MOLH‡) dihydride geometric parameters. For comparative purposes, Figs. 9–11 follow the summary format suggested by Donoghue et al. [2] and align with Table 6 which contains the comparative experimental data.

Overall the results indicate that the predicted ee% values are cinnamate > cinnamic acid > itaconate, as observed experimentally. In general, the overall difference magnitudes are much lower than those recently calculated using DFT/ONIOM calculations [2] for the X-ray based starting set, but somewhat similar for the C2-symmetry starting models. Given a choice of model, we would normally take the lowest energy models as being correct but note that the parallel reaction curves suggest the same conclusions. The prediction for the homologous EtCP versus CANDYPHOS based catalysts is mixed with the itaconate and cinnamic acid giving the correct trend, while the cinnamate results are in reverse to the measured value (averaged values 4.1 and 6.4 kcal/mol, respectively). The latter result may well be influenced by other factors, including solvent choice, possibly significant entropy affects and the significance of the DIHY‡ transition state [2].

Another noteworthy aspect of the computations is the relative energy of the square planar starting-complex (the calculations include a non-bound molecule of hydrogen) relative to the transition state energies. This aspect is best shown in the following Figs. 9–11 where the plotted difference values given are relative to the lowest square planar complex in either major or minor manifold (i.e. either sqpl or SQPL models).

3.1. Hydrogenation of methyl-(Z)-α-acetamido-cinnamic acid (Mpof series)

Relative MOLH‡ transition state energies (Fig. 9) are not consistent for the 3 models (see molh‡ & MOLH‡ points), but the relative energies of the square planar starting complexes are quite similar for both manifolds as might be expected. The notable difference is the reversal of chirality predicted from the C2 symmetry-based starting model. Unfortunately no experimental value is available for the EtCP experiment to confirm the lower predicted ee%, though this would be consistent with the Mpac series.

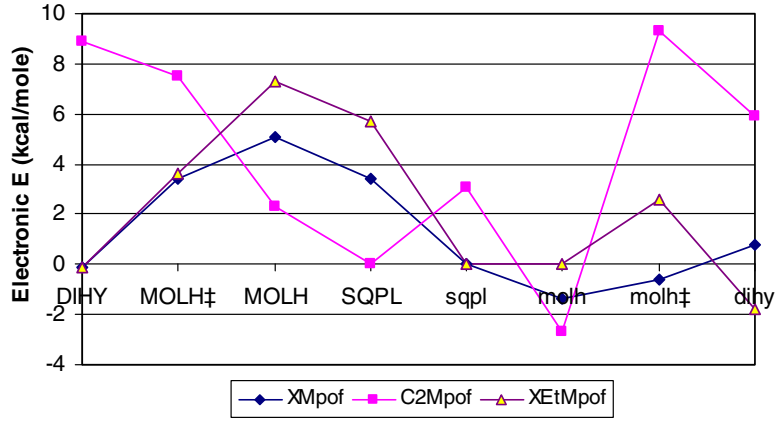

Fig. 9. Calculated enthalpies for substrate methyl(*Z*)-α-acetamido cinnamic acid over pathway A [2] relative to sqpl model.

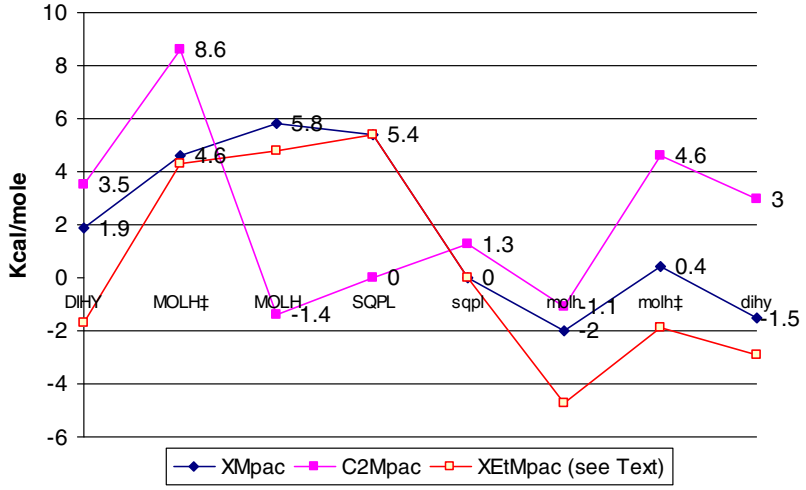

Fig. 10. Calculated enthalpies for substrate methyl(*Z*)-α-acetamido cinnamate over pathway A [2] relative to sqpl model.

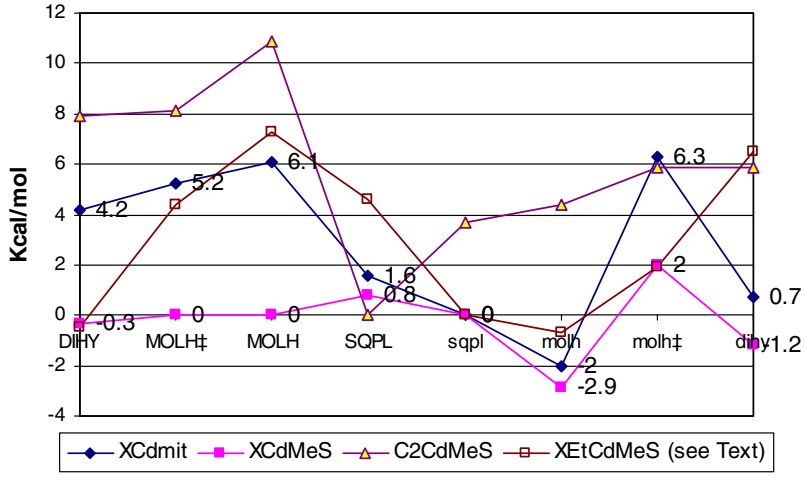

Fig. 11. Calculated enthalpies for substrate dimethyl itaconate over pathway A [2] relative to the sqpl/SQPL model.

3.2. Methyl-(Z)-α-acetamido-cinnamate (Mpac)

For this larger substrate, there is a consistent ee% prediction over the three models (see Fig. 10), with the minor manifold square planar model (sqpl) less stable for both X-ray starting models but not for the C2 model. The relative energies of the molh‡ and molh minor manifold transition states are lower than the starting square-planar complexes, but this comparison is not considered significant given that the starting catalyst is a cyclo-octadiene 6-coordinate complex.

Table 6
Enantiomeric excess: experimental[a] and calculation[b] results

Target	Codename	Experimental (CANDYPHOS)	Calc(X)	Calc (C2)	Exptal (EtCP)	Calc(X)

CdMeS	−7.6	4.4	0.35	−2.5	–	0.65

3.3. Hydrogenation of dimethyl itaconate (Cdmit, CdMes)

The low ee% values observed for this substrate (Table 5) would suggest potential resolution difficulties in the calculation, for the reasons noted above (Fig. 11). The results are surprisingly good in relation to the Mpac and Mpof series. Nevertheless, the transition state geometries were difficult to locate, and show wide variation particularly with respect to the H_a–H_b geometries (Table 5).

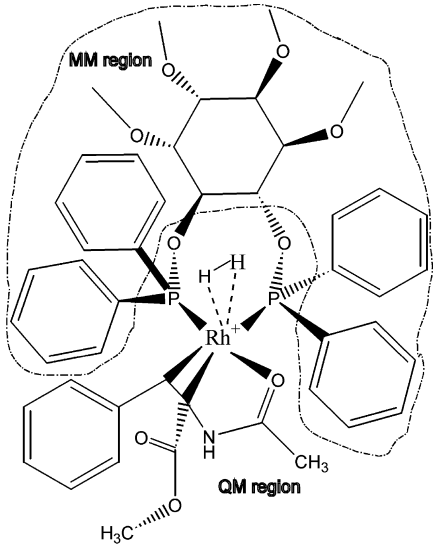

Fig. 12. The division of QM and MM regions in the molecules (Mpac example).

3.4. The QM/MM results

Limitations of QM/MM methods have been identified previously [43]. The QM/MM approach does allow the full system to be treated and "breakout" from starting symmetric geometries to occur, as well as having the bonus of substantial gains in computation time. We present here (Table 7) a summary of our QM/MM trials. Partly as expected from the approximate force constants covering a large part of the molecule (using SYBYL Force Field parameters, 2-layer; see Fig. 12 below), the final energy differences were a poor guide to the ee% values reflecting that the errors involved in this approach are too large.

4. Experimental

4.1. Computational details

DFT calculations were carried out using ADF 2006.01 [40,41] on a cluster of four 3.2 GHz Intel Pentium 4 CPUs with hyperthreading. Each node ran under Redhat 9 Linux configured with OSCAR software from the Open Cluster Group, http://www.openclustergroup.org/. That included the PVM and MPI parallel libraries and PBS (Portable Batch System) used for the queuing and scheduling of batch jobs.

The calculations were carried out within the framework of the generalized gradient approximation (GGA) by using the local den-

sity functional of Voska et al. [44], the exchange correction of Becke [45] and the correlation correction of Perdew [46,47]. Frozen core orbitals were used for all atoms, with the core orbitals for rhodium defined as 1s, 2s, 2p, 3s, 3p and 3d shells. All calculations were spin restricted and relativistic effects were included using the ZORA method [48–50]. Model structures were built from [Rh(CandyPhos)(COD)]+ [3] and the DUPHOS transition state models [1] or locally-programmed C2-symmetric conversions. Substituents were added when required using standard structural data in VEGAZZ[51] and locally written software [52]. The structures were then optimized with respect to their energies using the transition state search algorithm [42] by using double-zeta polarized STO basis sets on all non Rh atoms, and triple-zeta polarized sets for Rh. The division of the atomic coordinates between the QM and MM regions is shown in Fig. 12: the P–C and O–C α link parameters [41] used were 1.28 and 1.44, respectively. A typical sequence involved using a distance restraint on the hydride hydrogens (e.g. H. . .H 1.28 Å) and, in QM/MM runs, the molecular dynamics search using conjugate gradient optimization with a 100 ps for 101 sampled structures heated to a temperature 100–700 K. This final model was then refined under full QM (DFT) calculations with our compromise set of convergent values of 0.0002 (tolE), 0.01 (tolG) and 0.012 (tolCART) with integration limits of 5.0.

4.2. Preparative details

4.2.1. General methods

Manipulations of air sensitive materials were conducted in an argon atmosphere by using either Schlenk techniques or an Innovative Technology dry box. Tetrahydrofuran, ether and toluene were distilled from sodium benzophenone ketal under nitrogen and stored over activated 4 Å molecular sieves. NMR spectra were recorded on an AC300 Bruker spectrometer. Flash column chromatography [53] was carried out on 230–400 silica (Scharlau). Gas chromatographic analysis was performed on a Hewlett–Packard Model 6890. Chiral gas chromatographic separations were accomplished using a Chirasil L-Val (50 m × 0.25 mm, 0.12 μm film thickness) capillary column (Chrompack). Elemental analyses were performed by the Campbell Analytical Laboratory, University of Otago, Dunedin, New Zealand. L-Quebrachitol was obtained from the Rubber Research Institute of Malaysia, Kuala Lumpur, Malaysia. D-Pinitol was obtained from New Zealand Pharmaceuticals Ltd., Palmerston North, New Zealand. Acetamidoacrylate derivatives were synthesized according to literature procedures [54]. (CODRhCl)$_2$ was purchased from Aldrich. All NMR spectra were recorded in $CDCl_3$ unless noted otherwise.

The synthetic pathway that was employed to obtain the diphosphinite ligand was described previously (see ligand D-10 [10]).

4.3. 1,2,5,6-Tetraethyl-chiro-inositol

3,4-Dibenzyl-chiro-inositol [10] (5.0 g, 13.9 mmol) dissolved in dry DMF (150 mL) was treated at 0 °C with NaH (1.5 g, 62.5 mmol) and ethyl bromide (8.76 g, 80.4 mmol). Reaction mixture was allowed to warm to room temperature and stirred overnight. The reaction mixture was quenched with water and extracted with toluene. Removal of the toluene and purification by flash-chromatography (Si-60, hexanes:ethylacetate 4:1) yielded 3,4-dibenzyl-1,2,5,6-tetraethyl-chiro-inositol as a clear oil (4.52 g, yield 69%). This oil was dissolved in ethanol (90 mL), TFA (10 μL) and Pd/C (100 mg) were added, and hydrogenated at 1 atm hydrogen pressure for 4 h. Purification by flash-chromatography (Si-60, hexanes:ethylacetate 3:2) yielded 1,2,5,6-tetraethyl-chiro-inositol (2.97, yield ~100%) as a light orange oil and was committed to the next step without further purification.

^{1}H ($CDCl_3$) 1.22 ppm (m, 12H), 3.2–3.8 (m, 14H).
^{13}C ($CDCl_3$) 15.8 (CH_3), 16.0 (CH_3), 66.1 (CH_3), 67.4 (CH_2), 72.2 (CH), 75.1 (CH), 79.8 (CH).

4.4. 1D-3,4-Bis(O-diphenylphosphino)-1,2,5,6-tetra-O-ethyl-chiro-inositol

The 1,2,5,6-tetra-*O*-ethyl-chiro-inositol (2.28 g, 7.8 mmol), which had been pre-dried azeotropically with dry toluene (2 × 5 mL) and dry pyridine (excess, 4 mL), was added to dry THF (20 mL). The resulting solution was transferred by cannula into a Schlenk tube containing freshly distilled chlorodiphenyl phosphine (3.49, 15.6 mmol) in dry THF (10 mL) under argon. The resulting suspension was stirred at room temperature overnight. The solution was filtered under argon and the solvent removed from the filtrate under vacuum. The remaining solid was washed with dry toluene and filtered. The filtrate was collected and the solvent removed under vacuum to give the diphosphinite as a white solid (5.02 g, 97%). *Anal.* Calc. for $C_{38}H_{46}O_6P$: C, 68.86; H, 6.88. Found: C, 69.08; H, 7.02%.

4.5. 1D-3,4-Bis(O-diphenylphosphino)-1,2,5,6-tetra-O-ethyl-chiro-inositol rhodium cyclooctadiene BF_4

[RhCODCl]$_2$ (123 mg, 0.25 mmol) was dissolved in dichloromethane (4 mL). The ligand (330 mg, 0.5 mmol) dissolved in dichloromethane (5 mL) was added dropwise. The reaction mixture was stirred at room temperature overnight. $AgBF_4$ (97 mg, 0.5 mmol) was added and the reaction mixture stirred for 2 h. The mixture was filtered through Celite® and the solvent removed in vacuo to yield the title compound (480 mg, 100%) as a bright yellow solid. *Anal.* Calc. for $C_{46}H_{59}BF_4O_6P_2Rh$: C, 57.63; H, 6.10. Found: C, 57.40.; H, 6.14%. ^{31}P NMR: 137.6 ppm, J_{Rh-P} −180.7 Hz.

4.6. 1D-3,4-Bis(O-diphenylphosphino)-1,2,5,6-tetra-O-methyl-chiro-inositol rhodium cyclooctadiene BF_4

A solution of 1L-3,4-bis(*O*-diphenylphosphino)-1,2,5,6-tetra-*O*-methyl-chiro-inositol (122 mg, O.20 mmol) in THF (5 mL) was added dropwise to a solution of (RhCODCl)$_2$ (49 mg, 0.10 mmol) in THF (5 mL). The reaction mixture was stirred at room temperature for 17 h. $AgBF_4$ (0.039 g, 0.2 mmol) was added and the reaction mixture stirred for 2 h. Filtration and removal of the solvent yielded an orange solid. Crystallization from $CHCl_3$/ pentane yielded pure title compound as a $CHCl_3$ solvate (0.078 g, 76%). ^{31}P NMR 134.8, J_{Rh-P} = 178 Hz. *Anal.* Calc. for $C_{43}H_{51}BCl_3F_4O_6P_2Rh$: C, 50.54; H, 5.03. Found: C, 50.44; H, 5.00%.

4.7. Hydrogenations

Hydrogenations were carried in 12 mL glass vials equipped with magnetic stirrer bars. The vials were charged with catalyst (0.005 mmol), substrate (1.0 mmol) and solvent (3 mL) inside an inert atmosphere glove box (Innovative Technologies) and placed inside a 300 mL Parr autoclave made from Hastelloy C. In this way several hydrogenation experiments could be carried out at the same time. The autoclave was sealed, taken outside the glovebox and heated to the required temperature using a thermostatic heating mantel. The autoclave was flushed with hydrogen three times before being filled to the required pressure. After the required reaction time the autoclave pressure was reduced to atmospheric pressure and samples of the crude reaction mixture were analyzed by GC.

The GC analysis to obtain conversion and enantiomeric excess were performed on a HP 6890 Series gas chromatography apparatus

using a capillary Supelco GAMMA-DEX 225 (30 m × 0.25 mm × 0.25 μm) column or a SGE CYDEX-B (2 m × 0.32 mm × 0.25 μm) column.

5. Conclusions

Overall, our gas phase calculations (without counterions) supported the observed enantiomeric excess for the catalytic hydrogenation of the prochiral enamides (methyl-(*Z*)-α-acetamido cinnamate, methyl-(*Z*)-α-acetamido cinnamic acid and dimethyl itaconate) using the two homologous Rh(I) bisphosphinite catalysts. The calculations for dimethyl itaconate were not consistent, but the ee% values experimentally observed corresponded to energy differences of <1 kcal/mol. We found that starting models can determine which transition state energies are determined: this raises issues of confidence in predictions as the comparable (other pathway) transition states must represent both the same conformations and comparable "internal" geometries. The observed enthalpy differences are rather smaller than those reported by Feldgus and Landis[1] and Donoghue et al. [2] for the Rh(I)DUPHOS systems.

We have established straightforward chemical routes to two new Rh(I) hydrogenation catalysts based on readily available starting materials.

Our experience in searching for transition state saddle points suggests that a "more intimate" QM/MM relationship would enhance this process, given the difficulty of moving across the energy surface using QM methods alone observed here. Obstacles to the use of DFT calculations for the prediction of enantiomeric excess on larger molecular systems have been identified. Our original intent was to consider other factors, such as solvent effects, but our results suggest that, at the state of current knowledge (mechanism and modeling) such an extension was not justified.

Acknowledgments

This study would not have been possible without the close support of Professor Tom Ziegler (University of Calgary, Calgary, Alberta, Canada). Contributions to the synthetic programme were made by Chris Enright and Joanne Hart. We thank the NZ Foundation for Research Science and Technology for funding (Contract No. CO8X0411).

Appendix A. Supplementary data

The Cartesian coordinates (in XYZ format) for the calculated models in Tables 4 and 5. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.05.011.

ABSTRACT

The betain-like compound $S_2CC(PPh_3)_2$ (**1**), which is obtained from CS_2 and the double ylide $C(PPh_3)_2$, reacts with $[X_2Pt(COD)]$ (X = Cl, I) in THF to afford the complexes $[X_2Pt\{S_2CC(PPh_3)_2\}]$ (**2**, X = Cl; **3**, X = I) in quantitative yields. Both compounds are insoluble in all usual solvents, and **3** could be characterized by an X-ray analysis. For comparison, the structures of $[Pt(Me)_2FI\{S_2CC(PPh_3)_2\}] \cdot 2CH_2Cl_2$ (**4** · $2CH_2Cl_2$) with Pt^{IV} and $[Pt\{S_2CC(PPh_3)_2\}_2][SiF_5]_2 \cdot 2CH_2Cl_2$ (**5** · $2CH_2Cl_2$) with Pt^{II} are also presented. The compounds are further characterized by ^{31}P NMR and IR spectroscopy.

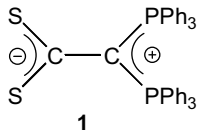
1. Introduction

The Lewis acid CS_2 and the carbodiphosphorane $C(PPh_3)_2$ quantitatively form the yellow addition compound $S_2CC(PPh_3)_2$ (**1**), which has been known for many years [1]. In addition to **1**, further adducts with Lewis acids containing main group [2] or transition metal elements [3] were also described. Recently, we have studied the crystal structure of **1** and its ability as a possible complex ligand.



1

Thus, in $[M(CO)_6]$ (M = Cr, Mo, W) two carbonyl groups can be replaced to produce the corresponding $[(CO)_4M\{S_2CC(PPh_3)_2\}]$ complexes, in which **1** acts as a chelating ligand via the two sulfur atoms [4]. The same is true for cationic manganese and cobalt complexes [5]. An alternative coordination mode of **1** was found upon reaction with silver salts containing weakly coordinating anions; Ag_6^{6+} or Ag_4^{4+} clusters are held together by six or four molecules of **1**, respectively, and each S atom contacts up to two Ag atoms [6]. The S_2C–CP_2 bond length in **1** is shorter than a single bond and further shortening occurs upon complex formation, indicating an increase of bond strength. Calculations have shown that in **1** some π interaction exists between the occupied p orbital of the P_2C sp^2 carbon atom and the empty p orbital of the S_2C sp^2 carbon atom [4]. In this publication, we present the results of the reaction of **1** with some platinum complexes.

2. Results and discussion

Reactions of **1** turned out to be highly problematic because **1** is only slightly soluble in THF and insoluble in the usual non-polar solvents, and it decomposes at elevated temperatures or upon prolonged reaction time to give $SPPh_3$ and the heterocummulene S=C=C=PPh_3 [7]. Compound **1** is soluble in CH_2Cl_2 (^{31}P NMR in CH_2Cl_2: 17.11 ppm), but decomposition proceeds more rapidly in this solvent. However, in some cases the reaction products are soluble in THF, which allows sufficient characterization [4].

If a suspension of **1** in THF is treated with the platinum complexes $[X_2Pt(cod)]$ (X = Cl, I) reaction immediately occurs to produce red-brown precipitates of **2** and **3**, respectively, with release of COD. Both products are obtained in about quantitative yields according to the following equation:

$$[X_2Pt(COD)] + S_2CC(PPh_3)_2 \rightarrow [X_2Pt\{S_2CC(PPh_3)_2\}] + COD \qquad (1)$$

2 (X = Cl), **3** (X = I)

The new platinum complexes **2** and **3** are found to be insoluble in all common solvents including THF and CH_2Cl_2, but are slightly soluble in DMSO. If amorphous **3** from THF is kept in contact with CH_2Cl_2 a kind of mineralization proceeds and the precipitate takes up dichloromethane and is converted into small red crystals. However, the overstanding solution shows no signal in the ^{31}P NMR spectrum confirming the insolubility in this solvent. Unfortunately, no crystals of **2** could be obtained via this way. In the ^{31}P NMR spectra in DMSO singlets at 14.6 ppm (for **2**) and 14.0 ppm (for **3**) were recorded. The solid state IR spectra of **2** and **3** are very similar and contain the same number of bands, which indicate analogous structural properties. Strong absorptions at about 1049 and 1095 cm^{-1} were recorded, which can be assigned to the ν_{as} and ν_s CS_2 vibrations [8]. The related bands in **1** were found at 1067 and 1099 cm^{-1}. A strong band at 1250 cm^{-1} in both compounds can probably be attributed to the vibration of the S_2C–CP_2 bond of the ligand. According to the occupied p orbital at the P_2C carbon atom and the vacant p orbital at the S_2C carbon atom, additional to the σ donor bond a weak and polarized π-interaction is operative [4]. The related band in **1** is found at 1146 cm^{-1} and the shift to higher frequencies upon complex formation can be explained with an increase of the C–C double bond character, which is also expressed in a shorter C–C bond length in **3**.

Additionally, we present the crystal structures of two further compounds with the ligand **1** for comparison. Crystals of the complexes $[(Me)_2PtFI\{S_2CC(PPh_3)_2\}] \cdot 2CH_2Cl_2$ (**4** · $2CH_2Cl_2$) and $[Pt\{S_2CC(PPh_3)_2\}_2][SiF_5]_2 \cdot 2CH_2Cl_2$ (**5** · $2CH_2Cl_2$) were obtained by reacting **1** with a sample of an impure platinum compound which was formed as a result from attempts to fluorinate $[Me_2Pt(cod)]$ (still containing some [Me(I)Pt(cod)]) with XeF_2; the complex $[(CF_3)_2Pt(cod)]$ was expected [9]. The anion $[SiF_5]^-$ may originate from fluorination of some glass or grease by XeF_2.

3. Crystal structures

To get more insight into the nature of the complexes and the bonding situation an X-ray analysis of **3** was performed. Small dark red crystals of **3** · CH_2Cl_2 suitable for an X-ray analysis formed in a suspension of the powder in CH_2Cl_2 at room temperature. To our knowledge, no other platinum(II) compounds with an I_2PtS_2 arrangement are known in which the sulfur atoms come from a CS_2 adduct of the type S_2CR; only two Pt^{IV} complexes with a dithiocarbaminato ligand have been characterized by X-ray analyses [10]. Pt^{II} compounds with this core are described with thiourea derivatives [11], with dimethylsulfoxide [12] or with thioethers [13]. Pt^{II} complexes with other zwitterionic compounds are described with the ligand S_2CPR_3 [14]. For comparison we include the structures of **4** · $2CH_2Cl_2$ and **5** · $2CH_2Cl_2$, which we have obtained as described above. The molecular structures of **3** · CH_2Cl_2, **4** · $2CH_2Cl_2$, and of the cation of **5** · $2CH_2Cl_2$ are depicted in Figs. 1–3. Crystallographic data are listed in Table 1, and distances and angles are summarized in Tables 2–4.

3.1. Crystal structure of **3** · CH_2Cl_2

The environment of the platinum atom is planar as shown by the sum of the bond angles at the Pt atom of 360°; the crystal structure is shown in Fig. 1; the solvent molecule is omitted. On complex formation the ligand **1** undergoes some remarkable changes. The S_2C–CP_2 bond length decreases from 149.4(2) to 141(2) pm indicating an increased double bond character, and together with the S_2C–CP_2 bond lengths of **5** it is the shortest one found in complexes of **1**. The P–C distances to the ylidic carbon atom are slightly longer (mean 178 pm) than those in **1**; only the mean P–C_{Ph} distances are the same as in the free ligand. A slight elongation of the C–S bond length is also observed. These changes in bond lengths upon complex formation can be interpreted in terms of a release of π electron density away from the ylidic carbon atom; the same trends were found in the $(CO)_4M$ adducts [4]. The S–Pt–S angle amounts to 74° and is larger than the corresponding S–M–S angle in the group 6 metal carbonyl derivatives, whereas the S–C–S bite angle is smaller (106°); in going from **1** to **3** a decrease of the bite angle of about 18° occurs, indicating the great

flexibility of this angle according to the nature of the central metal atom. The dihedral angle between the S_2C and the P_2C planes amounts to 26° and is larger than that in the free ligand **1** (20°). The increased deviation from planarity may be due to interactions of the sulfur atoms with phenyl rings in such that one ring at P(1) is pushing up the sulfur atom S(1) and another one at P(2) is pushing down the S(2) atom, and the shorter S_2C–CP_2 bond in **3** relative to the free ligand brings the phenyl groups closer to the sulfur atoms which causes a further increase of the repulsion. The Pt–I distances (mean 262.5(1) pm) and the Pt–S distances (mean 229.2(4) pm) are typical for compounds of Pt^{II} with a PtS_2I_2 core and a *cis* arrangement of the I atoms; the same is true for the I–Pt–I angle [13a,13b,13c,13d,13e,13f,13g].

3.2. Crystal structure of **4** · $2CH_2Cl_2$

The neutral complex **4** contains Pt^{IV} in a distorted octahedral environment; the crystal structure is depicted in Fig. 2. Other Pt^{IV} compounds with the PtS_2 core are equipped either with dithiocarbaminato ligands [10] or pincer ligands with S donor atoms [15]. In **4** the dihedral angle between the S_2C and the P_2C planes amounts to 35° and is larger than that in **3**. The S_2C–CP_2 bond length is in

between that of **1** and **3** amounting to 145(1) pm. The Pt–S bond lengths are up to 20 pm longer than in the Pt^{II} compounds **3** and **5**, while the C–S distances are only slightly shorter and close to that of the free ligand **1**. The higher charge at the central atom causes the S–C–S bite angle to increase and the S–Pt–S angle to decrease by about 7° and 3°, respectively, relative to the Pt(II) compounds. The F atom is disordered with a 0.5–0.5 distribution, and F(12) occupies more exactly the axial octahedron position while F(11) is slightly bent away from the S atoms. The distance between F(11) and F(12) is about 67 pm. According to our X-ray data there is no possibility to introduce a disorder between the positions of the methyl groups and the fluorine atoms because of the displacement parameters which fit only to the arrangement shown in

Fig. 2. The Pt–I distance amounts to 278.2(1) pm and is longer than in other Pt^{IV} compounds with a related ligand arrangement [15]. It is about 16 pm longer than that in **3** to Pt^{II} but 5 pm shorter than the related distance in the tetrameric $[Me_3PtI]$ with a bridging I atom [16]. If we compare terminal and bridging F atoms as in **4** and $[Me_3PtF]_4$, respectively, the terminal one is about 20 pm shorter [17]. The methyl groups are in *trans* position to the sulfur atoms and the Pt–C distances are in the upper range of those in $[Me_3PtX]_4$ complexes [16,17].

3.3. Crystal structure of **5** · $2CH_2Cl_2$

The crystal structure of the dication **5** is shown in Fig. 3. One of the solvent molecules is disordered. The complex contains two molecules of **1** at Pt^{II} as chelating ligands. The dihedral angles between the S_2C and the P_2C planes amount to 19° and 9°, respectively; the environment at the central Pt atom is planar as shown by the sum of the angles of 360.1°, and the deviations of the five atoms from the best plane are very small (Pt(1), S(1), S(2), S(3), S(4) = −1, 0, 1, 0, 1 pm). The S_2C–CP_2 bond lengths are identical with those of **3**; similarly, the S–C–S bite angles and the S–Pt–S angles correspond to those of **3**. The mean Pt–S distance is only slightly longer than that in **3**, but the individual distances differ by about 3 pm, probably due to packing effects. Although compounds with a PtS_4 core are very common in platinum chemistry, cationic compounds with a spiro bicyclic CS_2PtS_2C arrangement have not yet been described. No nearer contacts exist between the cation and the anions. The Si–F distances in the $[SiF_5]^-$ anions range between 153(1) and 160(1) pm at Si(1) and 152(1) and 162(1) pm at Si(2).

4. Conclusion

In contrast to the carbodiphosphorane adducts of CO_2 and COS, which adopt η^1 or η^2 coordination, the CS_2 adduct **1** is found to act only as a chelating ligand towards transition metals as yet. If **1** is connected to Ag^+, aggregates of Ag_4^{4+} or Ag_6^{6+} cluster units are held together by the sulfur atom bonded each to one or two silver atoms [6]. For comparison, the most relevant bond lengths in the compounds **1** and **3**–**5** are summarized in Table 5. Whereas in the starting adduct **1** the S_2C–CP_2 distance is already shorter than a single bond, a further shortening is observed upon complex formation, indicating an increase in double bond character. In the Pt^{II} complexes the related S_2C–CP_2 distances are the shortest ones found as yet with 141(2) pm; they are close to those in aromatic ring systems. This electron release diminishes the P–C (p–σ^*) interaction leading to longer distances. This trend was also observed in the related carbonyl complexes $[(CO)_4MS_2CC(PPh_3)_2]$ where S_2C–CP_2 distances of about 145 pm were found [4]; similar values are also recorded in the silver clusters [6].

Thus, the occupied p orbital of the sp^2 CP_2 carbon atom in **1** and the vacant p orbital at the sp^2 CS_2 carbon atom form a partial double bond which, depending on the nature and charge of the metal, is increased upon coordination of the sulfur atoms at a metal atom. For the first time, we can compare compounds in which **1** is bonded to a metal in different oxidation states. There is a great difference in the coordination of **1** to a Pt^{II} or Pt^{IV} atom with a planar or and octahedral ligand arrangement, respectively. In spite of the higher charge of the central atom in **4** with Pt^{IV} a minor electron release is found, expressed by a longer S_2C–CP_2 bond accompanied by about 16 pm longer (mean) Pt–S distances. The differences in the bonding parameters indicate a weaker bond of the chelating ligand **1** in the complex **4**. Thus, the S_2C–CP_2 double bond character increases in the series **1** < **4** < **3**–**5** corresponding to a decrease of the P–C double bond character in this row. Because **5** is the result of Pt^{II} with weakly coordinating anions, further studies in this field are in progress. Furthermore, the coordination of **1** at Pt^{IV} compounds will also be of interest and the formation of cations with more than one neutral ligand **1**, such as compounds with $[PtS_4X_2]^{2+}$ or $[PtS_6]^{4+}$ cores, will be a challenge for the future.

5. Experimental

All operations were carried out under an argon atmosphere in dried and degassed solvents using Schlenk techniques. The solvents were thoroughly dried and freshly distilled prior to use. The IR spectra were run on a Nicolet 510 spectrometer. For the ^{31}P NMR spectra we used the instrument Bruker AC 200. Elemental analyses were performed by the analytical service of the Fachbereich Chemie der Universität Marburg (Germany). Compound **1** was prepared according to a modified literature procedure [1] by addition of CS_2 to a solution of $C(PPh_3)_2$ in toluene at room temperature. $[Cl_2Pt(cod)]$ and $[I_2Pt(cod)]$ were obtained according to literature procedures [18]. Information concerning the X-ray structure determination is given in Table 1. The residual electron density in **4** · $2CH_2Cl_2$ is near the Pt atom.

Table 5
Comparison of important bond lengths in **1**, **3**, **4** and **5**

	1 [4]	**3**	**4**	**5**

5.1. Preparation of $[Cl_2Pt\{S_2CC(PPh_3)_2\}]$ (**2**)

To a suspension of 520 mg (0.85 mmol) of $S_2CC(PPh_3)_2$ (**1**) in about 40 ml THF was added 320 mg (0.85 mmol) $[Cl_2Pt(cod)]$. The yellow suspension immediately turned red-brown. The mixture was stirred magnetically for about 1 h. Then the precipitate was filtered, washed with 1 ml THF and dried in vacuum. Yield 710 mg (95%). ^{31}P NMR (DMSO): 14.56 ppm. IR (Nujol): 1585 vw, 1497 m, 1438 s, 1253 vs, 1197 w, 1163 w, 1098 s, 1069 w, 1043 m, 1027 w, 998 m, 811 m, 749 m, 736 w, 721 m, 714 w, 690 s, 564 w, 556 w, 524 s, 506 s, 492 m (cm^{-1}). *Anal.* Calc. for $[Cl_2Pt\{S_2CC(PPh_3)_2\}]$ (**2**): C, 51.94; H, 3.44. Found: C, 50.38; H 3.65%.

5.2. Preparation of $[I_2Pt\{S_2CC(PPh_3)_2\}]$ (**3**)

In a similar procedure as outlined for the preparation of **2**, the red-brown complex **3** was obtained from 0.66 g (1.08 mmol) $[I_2Pt(cod)]$ and 0.60 g (1.08 mmol) of $S_2CC(PPh_3)_2$ (**1**). The dry red-brown powder was treated with CH_2Cl_2 which produced small dark red crystals of **3** · CH_2Cl_2 during several hours; yield 1.05 g (92%). ^{31}P NMR (DMSO): 13.96 ppm. IR (Nujol): 1586 vw, 1481 m, 1439 s, 1246 vs, 1192 w, 1163 w, 1096 s, 1073 w, 1049 s, 1024 w, 997 m, 806 m, 740 m, 723 m, 711 w, 693 s, 685 s, 570 w, 553 w, 522 s, 509 s, 494 m (cm^{-1}). *Anal.* Calc. for $[I_2Pt\{S_2CC(PPh_3)_2\}]$ (**3**): C, 42.99; H, 2.85. Found: C, 41.64; H, 2.91%.

5.3. Formation of $[Me_2FIPt(S_2CC(PPh_3)_2)]$ (**4**) and $[Pt(S_2CC(PPh_3)_2)_2][SiF_5]_2$ (**5**)

An impure sample obtained from fluorination of $[Me_2Pt(cod)]$/$I_2Pt(cod)]$ with XeF_2 was used [9] for the reaction with **1** in CH_2Cl_2; the anion $[SiF_5]^-$ may originate from fluorination of glass or grease. Few crystals of **4** (small red blocks) and **5** (orange plates) were obtained from CH_2Cl_2 solutions upon layering with *n*-pentane; no further crystalline product was formed. Compound **4**, ^{31}P NMR (CH_2Cl_2): s, 14.8 ppm. Compound **5**, ^{31}P NMR (CH_2Cl_2): s, 13.3 ppm.

Supplementary material

CCDC 667634, 667635 and 667636 contain the supplementary crystallographic data for **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Reaction of divalent metal chlorides with succinic acid (H_2suc) and the hydrogen-bonding capable tethering organodiimine bis(4-pyridylmethyl)piperazine (bpmp) in a mixed solvent system has afforded three isostructural coordination polymers: $[M(suc)(bpmp)(H_2O)_2]_n$ (M = Co, **1**; M = Ni, **2**; M = Cu, **3**) Single-crystal X-ray diffraction showed that **1**–**3** possess $[M(suc)(bpmp)(H_2O)_2]_n$ 2D layer motifs. Parallel sets of layer motifs in **1**–**3** aggregate into 2d + 2d → 3D mutually inclined interpenetrated systems, fostered by hydrogen bonding interactions between layers. Spectral and thermal properties of these materials are also discussed.

1. Introduction

Over the past decade many researchers have undertaken significant effort towards the synthesis and characterization of metal dicarboxylate and tricarboxylate coordination polymers because of the capability of these materials in diverse applications such as gas storage [1], small molecule shape-selectivity [2], ion-exchange [3], catalysis [4], and optical devices [5]. In these phases, dianionic dicarboxylate ligands not only serve to link metal cations into higher dimensionalities but also provide necessary charge balance, thereby permitting formation of a large number of neutral coordination polymer frameworks that exclude porosity-curtailing smaller anions. A wide range of structural patterns occurs in these systems, based on the disposition of the donor groups within the dicarboxylate moieties, coordination geometry preferences, and an array of available binding carboxylate modes.

While the predominant focus has rested on aromatic dicarboxylates because of their tendency to enforce rigid porous structures, aliphatic -dicarboxylate α,ω-dicarboxylate ligands have also shown their utility in the construction of novel coordination polymers due to their ability to undergo facile conformational interconversions [6–11]. For instance, the succinate dianion (suc, 1,4-butanedioate) has been shown to adopt *anti*, *gauche*, and intermediate conformations when incorporated into coordination polymer systems, thus provoking structurally intriguing frameworks of varying dimensionalities either alone [12–14] or in conjunction with organodiimine co-ligands such as 4,4′-bipyridine (4,4′-bpy) [15,16] or 4,4′-dipyridylamine (dpa) [17].

Recently, we reported the first aromatic dicarboxylate coordination polymers constructed with the aid of bis(4-pyridylmethyl)-piperazine (bpmp, Scheme 1), which exhibited interpenetrated and non-interpenetrated 2D and 3D structural motifs [18]. However, there are currently no reports of aliphatic α,ω-dicarboxylate coordination polymers incorporating this flexible, long, and hydrogen-bonding capable organodiimine tethering ligand to the best of our knowledge. Herein we discuss the synthesis and crystal structures of three isomorphous bpmp-containing succinate coordination polymers exhibiting mutually inclined interpenetration, $[M(suc)(bpmp)(H_2O)_2]_n$ (M = Co, **1**; M = Ni, **2**; M = Cu, **3**). Spectral and thermal properties of these new materials are also reported.

2. Experimental

2.1. General considerations

Metal chlorides and succinic acid (Fisher) were obtained commercially. The organodiimine bis(4-pyridylmethyl)piperazine (bpmp) was prepared via a published procedure [19]. Water was deionized above 3 MΩ in-house. Thermogravimetric analysis was performed on a TA Instruments TGA 2050 Thermogravimetric Analyzer with a heating rate of 10 °C/min up to 900 °C. Elemental analysis was carried out using a Perkin–Elmer 2400 Series II CHNS/O Analyzer. IR spectra were recorded on powdered samples on a Perkin–Elmer Spectrum One instrument.

bpmp

Scheme 1.

2.2. Preparation of [Co(suc)(bpmp)(H$_2$O)$_2$]$_n$ (**1**)

$Co(NO_3)_2 \cdot 6H_2O$ (0.054 g, 0.19 mmol), succinic acid (0.022 g, 0.19 mmol) and bpmp (0.100 g, 0.38 mmol) were placed into 10 g (555 mmol) distilled H_2O in a 23 mL Teflon-lined Parr acid digestion bomb (1:1:2:2900 mol ratio). The bomb was sealed and heated at 120 °C for 48 h, whereupon it was cooled slowly in air to 25 °C. Pink blocks of **1** (0.016 mg, 17% yield based on Co) were isolated after washing with distilled water and acetone. Crystals of **1** were stable indefinitely in air. *Anal.* Calc. for $C_{20}H_{28}CoN_4O_6$ (**1**): C, 50.11; H, 5.89; N, 11.69. Found: C, 49.93; H, 5.75; N, 11.83%. IR (cm^{-1}): 3068 w br, 2811 w, 2773 w, 1616 m, 1540 s, 1459 m, 1425 m, 1406 s, 1351 m, 1323 w, 1293 m, 1222 w, 1154 w, 1135 m, 1066 w, 1013 m, 935 w, 878 w, 835 s, 797 s, 724 m, 662 s.

2.3. Preparation of [Ni(suc)(bpmp)(H$_2$O)$_2$]$_n$ (**2**)

$NiCl_2 \cdot 6H_2O$ (0.044 g, 0.19 mmol) and succinic acid (0.022 g, 0.19 mmol) were added to 4 mL of distilled H_2O in a borosilicate glass tube that had been sealed at one end. A solution of bpmp (0.050 g, 0.19 mmol) in 3 mL methanol was then carefully layered on top of the aqueous solution. Blue blocks of **2**(0.016 g, 17% yield based on Ni) were deposited after ~2 weeks on standing. These were filtered, washed with distilled water and acetone, and dried in air. Crystals of **2** were stable indefinitely in air. *Anal.* Calc. for $C_{20}H_{28}NiN_4O_6$ (**2**): C, 50.13; H, 5.89; N, 11.69. Found: C, 49.96; H, 5.63; N, 11.61%. IR (cm^{-1}): 3070 w br, 2905 w, 2810 w, 1618 m, 1538 s, 1441 w, 1425 m, 1406 s, 1389 m, 1351 m, 1324 m, 1293 m, 1221 m, 1154 w, 1135 m, 1013 m, 934 w, 865 w, 837 s, 800 s, 754 m, 726 m, 672 s.

2.4. Preparation of [Cu(suc)(bpmp)(H$_2$O)$_2$]$_n$ (**3**)

The procedure for the synthesis of **2** was followed except for the use of $CuCl_2 \cdot 2H_2O$ (0.044 g, 0.19 mmol) as the metal source. Blue blocks of **3** (0.058 g, 63% yield based on Cu) were obtained. *Anal.* Calc. for $C_{20}H_{28}CuN_4O_6$ (**3**): C, 49.63; H, 5.83; N, 11.58. Found: C, 49.40; H, 5.71; N, 11.46%. IR (cm^{-1}): 3387 w br, 2958 w, 2914 w, 2807 w, 1619 m, 1550 s, 1505 w, 1456 w, 1428 m, 1385 s, 1353 m, 1322 m, 1296 m, 1241 w, 1227 w, 1197 w, 1162 m, 1134 m, 1065 m, 1036 w, 1012 s, 929 w, 883 w, 838 s, 802 s, 673 s, 662 s.

3. X-ray crystallography

Single crystals of all materials were subjected to single crystal X-ray diffraction using a Bruker-AXS APEX II CCD instrument. Reflection data were acquired using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The data were integrated via SAINT [20]. Lorentz and polarization effect and empirical absorption corrections were applied with SADABS [21]. The structures were solved using direct methods and refined on F^2 using SHELXTL [22]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms bound to carbon atoms were placed in calculated positions and refined isotropically with a riding model. The hydrogen atoms bound to all water molecules were found via Fourier difference maps and then refined isotropically with thermal parameters 1.2 times the average U_{ij} values of the atoms to which they are bound. Relevant crystallographic data are listed in Table 1.

4. Results and discussion

4.1. Synthesis and spectral characterization

The coordination polymers **1–3** were prepared cleanly either by hydrothermal techniques or via slow diffusion of aqueous solutions of the appropriate metal chloride and succinic acid, with ethanolic solutions of bpmp. The infrared spectra of **1–3** were consistent with their formulations. Sharp bands in the vicinity of ~1600–1200 cm^{-1} mark the stretching modes of the pyridyl rings of the bpmp ligands [23]. Features corresponding to pyridyl ring puckering modes were evident in the region between 820 and 600 cm^{-1}. Asymmetric and symmetric C–O stretching modes of the carboxylate moieties gave rise to very strong, slightly broadened bands at ~1530 and ~1380 cm^{-1}. Broad bands in the region of ~3400–3200 cm^{-1} in all cases represent O–H stretching modes within the ligated water molecules. The broadness of these latter spectral features is caused by the hydrogen bonding mechanisms within **1–3**.

4.2. Structural description of [Co(suc)(bpmp)(H$_2$O)$_2$]$_n$ (**1**)

As revealed by single crystal X-ray diffraction, the asymmetric unit of compound **1** consists of a divalent cobalt ion on a crystallographic inversion center, one bound water molecule, and one-half of a bpmp ligand (Fig. 1). Operation of the inversion center at the cobalt ion produces a $[CoO_4N_2]$ octahedral coordination geometry, with *trans* -disposed pyridyl nitrogen donor atoms from two

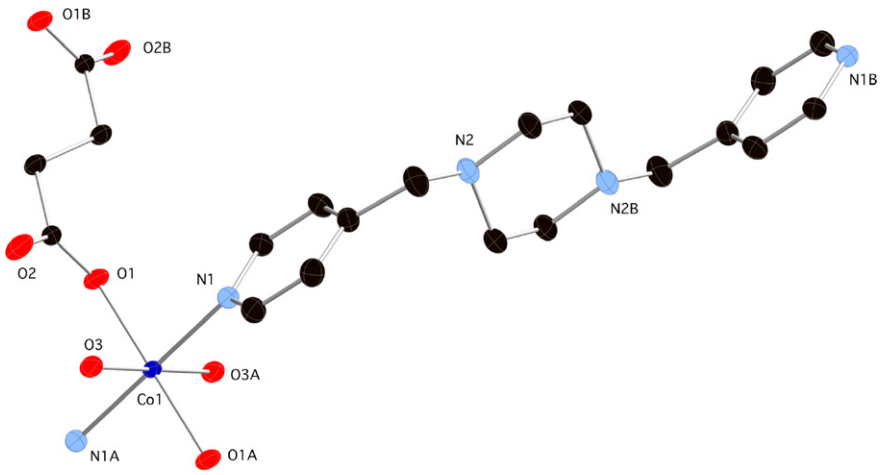

Fig. 1. Coordination environment of **1** with thermal ellipsoids drawn at 50% probability and partial atom numbering scheme. Hydrogen atoms are omitted.

different bpmp ligands situated in axial positions. The equatorial sites are occupied by two *trans* aqua ligands and two oxygen atoms from two different suc ligands. Bond lengths and angles about cobalt are fully consistent with octahedral coordination geometry (Table 2).

Extension of the structure through the *anti*-conformation (four C-atom torsion angle = 180°) bisbridging bismonodentate suc dianions forms one-dimensional (1D) $[Co(suc)(H_2O)_2]_n$ chain motifs parallel to the *c* crystal direction, with a Co···Co distance of 8.964 Å. The covalent connectivity within the chain units is augmented by hydrogen bonding donation from the aquo ligands to the unligated suc carboxylate oxygen atoms. These chains are then connected into a two-dimensional (2D) (4,4) rhomboid grid $[Co(suc)(bpmp)(H_2O)_2]_n$ coordination polymer layer motif, with a through-bpmp Co···Co distance of 15.824 Å (Fig. 2). The incipient void areas within the coordination polymer grid measure 17.652 × 18.706 Å, as determined by through-space Co···Co distances; these grid spaces are nearly rectangular in shape, with Co···Co···Co angles of 86.1° and 93.9°. The $[Co(suc)(bpmp)(H_2O)_2]_n$ 2D dual-ligand layered motifs in **1** contrast with the 1D $[Co(4,4'\text{-bpy})(H_2O)_4]_n$ linear chains observed in the structure of $\{[Co(4,4'\text{-bpy})(H_2O)_4](suc)\}_n$ [15], in which the succinate anions serve asunligated charge-compensating dianions. Within the structure of $[Co(suc)(dpa)_2]_n$, 1D threefold helical $[Co(suc)]_n$ chains are decorated by pendant monodentate dpa ligands [17]. Thus, **1** appears to be a rare example of a cobalt coordination polymer in which both the succinate and organodiimine ligands act as covalent linking agents.

The void spaces within the $[Co(suc)(bpmp)(H_2O)_2]_n$ coordination polymer layers permit mutual inclined 2d + 2d → 3D interpenetration of two parallel sets of layers, coincident with the (−1 1 0) and (−1 −1 0) crystal planes (Fig. 3). Between parallel layers, the nearest Co···Co contact distance is 9.892 Å, corresponding to the *a* lattice parameter. The angle of interpenetration between two members of different parallel layer sets is 77.0°. While there is no direct covalent interaction between interpenetrated layers, structural stability is provided by hydrogen bonding between the aqua ligands in one layer and unligated carboxylate oxygen atoms belonging to suc ligands in another layer. These hydrogen bonding patterns construct supramolecular $[Co(suc)(H_2O)_2]_n$ 1D chain patterns that course along the *b* crystal direction, as seen in Fig. 3. Metrical parameters for the intra- and inter-layer hydrogen bonding interactions in **1** are given in Table 3.

4.3. Structural description of $[Ni(suc)(bpmp)(H_2O)_2]_n$ (**2**)

The asymmetric unit of **2** (Fig. 4) is virtually identical to that of **1**, with the exception of the slightly shorter bond lengths (Table 2) imparted by the smaller ionic radius of Ni^{2+}relative to Co^{2+} [24]. As a result, the through-ligand Ni···Ni distances are slightly shorter than the corresponding contact distances in **1**, measuring 8.953 Å and 15.737 Å through the suc and bpmp ligands, respectively. $[Ni(suc)(bpmp)(H_2O)_2]_n$ (4,4) rectangular grid coordination polymer motifs are present in **2**, again with only slight metrical differences with respect to **1**. The through-space Ni···Ni contact distances within the grid measure 17.481 and 18.366 Å, with Ni···Ni···Ni angles of 88.1° and 91.9°. Therefore, the grid apertures more closely approach an idealized rectangular geometry than those in **1**. Parallel sets of layers, coincident with the (−1 1 0) and (−1 −1 0) crystal planes, engage in mutual inclined interpenetration at an angle of 77.7°, very slightly more obtuse than the corresponding angle in **1**. This subtle shift likely arises from the slight contraction of M–O/M–N bond lengths andhydrogen bonding interactions (Table 3) relative to those in **1**.

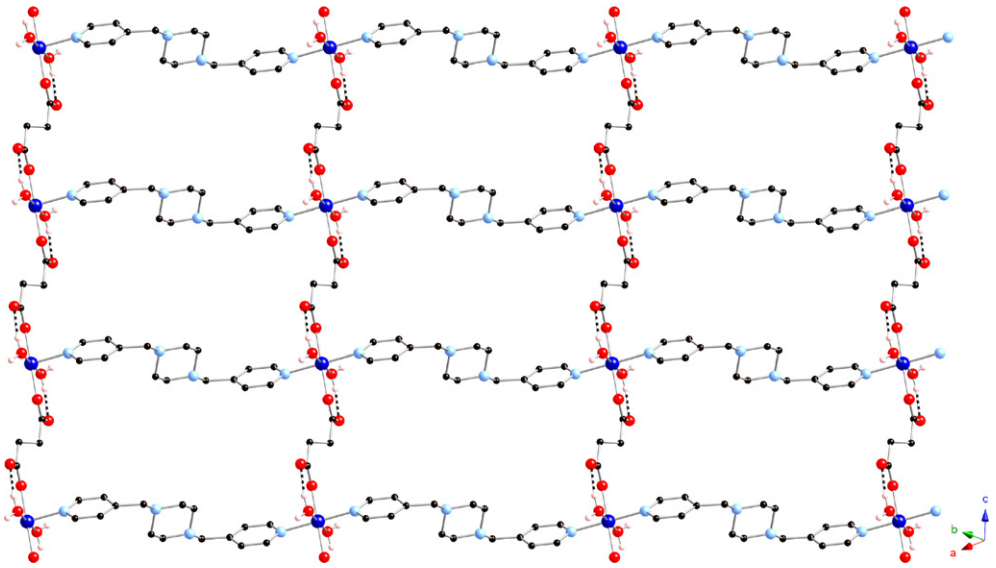

Fig. 2. A single $[Co(suc)(bpmp)(H_2O)_2]_n$ layer in **1**. Hydrogen bonding is indicated as dashed lines.

While some frameworks with three-dimensional nickel succinate connectivity have been prepared [13a,14], reports of dual-ligand nickel succinate/organodiimine extended complexes are less common. $\{[Ni(dpa)_2(suc)]Cl\}_n$ displays a unique self-penetrated structure with 6^{10} topology built from the linkage of fourfold interpenetrated $[Ni(dpa)_2]_n$ cationic framework through

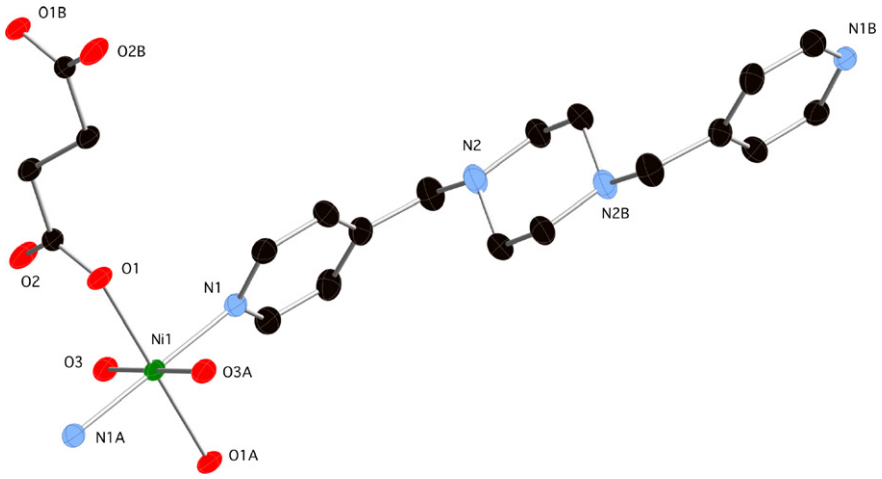

Fig. 4. Coordination environment of **2** with thermal ellipsoids drawn at 50% probability and partial atom numbering scheme. Hydrogen atoms are omitted.

suc ligands [17]. However, the suc ligands in this material only link neighboring nickel atoms between two separate frameworks; no "infinite" nickel succinate building units exist in this structure. Thus, **2** represents an uncommon example of a nickel coordination polymer manifesting extended covalent connectivity through both succinate and organodiimine ligands.

4.4. Structural description of $[Cu(suc)(bpmp)(H_2O)_2]_n$ (**3**)

The asymmetric unit of **3** (Fig. 5) is again very similar to that of **1**, with the exception of the distorted octahedral coordination at copper, imparted by the Jahn–Teller effect of the d^9 Cu^{2+} ion. The oxygen atoms of the two water molecules are positioned 2.554 Å away from each copper atom. Pertinent bond lengths and angles are given in Table 2. $[Cu(suc)(bpmp)(H_2O)_2]_n$ (4,4) rectangular grid coordination polymer motifs are present in **3**, similar to those seen in **1** and **2**. The through-ligand Cu ··· Cu distances are 8.773 Å and 16.060 Å through the suc and bpmp ligands, respectively; these values represent the shortest through-suc and through-bpmp distances within the series **1**–**3**. The through-space Cu ··· Cu contact distances within the grid are 17.873 and 18.717 Å, with Cu ··· Cu ··· Cu angles of 86.9° and 93.1°. The grid apertures in **3** thus deviate more from an idealized rectangular geometry than those in **1** and **2**. Parallel sets of layers, coincident with the (−1 1 0) and (−1 −1 0) crystal planes, engage in mutual inclined interpenetration at an angle of 75.4°. This angle of interpenetration is tighter than the corresponding angles in **1** and **2**, perhaps due to differences in hydrogen bonding provoked by the longer interactions between copper and the ligated water molecules (Table 3).

The structure of **3** can be contrasted with that of its previously reported 4,4′-bipyridine congener $\{[Cu(suc)(4,4'\text{-bpy})(H_2O)_2]2H_2O\}_n$, which possesses a 3D 7^59 (quartz dual) topology formed from 1D $[Cu(suc)(H_2O)_2]_n$ sixfold helices linked through the rigid-rod organodiimine tethers [18]. Fourfold $[Cu(suc)]_n$ helices are observed within the structure of $\{[Cu(suc)(dpa)]0.5H_2O\}_n$, which adopts a doubly interpenetrated 3D 6^58 $CdSO_4$ topology [15,16]. It is thus likely that the specific supramolecular and covalent environment fostered by the longer and more flexible bpmp ligand allows formation of a straight as opposed to a curled $[Cu(suc)(H_2O)_2]_n$ chain motif, resulting in an overall reduction in coordination polymer dimensionality in the case of **3**.

4.5. Thermal analyses

Compound **1** underwent no mass loss until ~125 °C, whereupon ejection of the ligated water molecules occurred obs'd, 7.7% calc'd). (7.5% observed, 7.7% calculated). Between ~150 and ~400 °C a series of mass loss steps totaling 75.3% was observed, consistent with the elimination of the suc and bpmp ligands calc'd). (80.0% calculated). The mass remnant of 17.3% of the original at 500 °C indicated the likely deposition of Co_3O_4 (16.7% predicted). In contrast, the dehydration of compound **3** commenced at ~80 °C, reflective of

the relative weakness of the Cu–O_{water} bonds. A mass loss of 7.5% was completed by 120 °C calc'd (7.4% calculated for two molar equivalents of water). Decomposition of **3** was marked by a mass loss steps totaling 74.0% between ~140 °C and ~500 °C calc'd (79.2% calculated for equivalent 1 equiv. each of suc and bpmp ligands). The 18.5% mass remnant is roughly consistent with the deposition of CuO calc'd). (16.4% calculated). TGA traces for **1** and **3** are shown in Figures S1 and S2, respectively.

5. Conclusions

Three isomorphous divalent metal succinate/bpmp coordination polymers exhibiting mutually inclined interpenetrated layer motifs have been synthesized and structurally characterized, widening the scope of metal-organic extended solids incorporating conformationally flexible ligands. The results hint at an especially rich coordination polymer system in which the aliphatic dicarboxylates components are uniquely suited to adjust to the covalent and supramolecular environments imposed by the presence of organodiimine co-ligands. By extending the aliphatic chain length or including sterically bulky substituents within the dicarboxylate component, or altering nitrogen donor disposition or hydrogen-bonding facility within the flexible organodiimine component, coordination polymers with novel structures and intriguing physicochemical properties are sure to be obtained. Further efforts in this direction are underway in our laboratory and will be reported in due course [25].

Complex stabilization
Ligands derived from vitamin B6

ABSTRACT

The new Schiff bases ligands **1** and **2** were obtained through reaction of vitamin B6 and *o*-phenylenediamine in methanol, and characterized structurally by X-ray diffractometry. The reaction of **1** with $UO_2(NO_3)_2 \cdot 6H_2O$ leads to the stabilization of *N*,*N*′-bis-(pyridoxylideneimine)-*o*-phenylene, giving $[UO_2(H_2pyr_2phen)Cl]NO_3$ (**3**) and $[UO_2(Hpyr_2phen)Cl]$ (**4**). In the new chelate compounds **3** and **4** the uranium ions are the centers of distorted pentagonal bipyramides, characteristic for the coordination number 7. The positive charge of **3** is counter balanced by NO_3^- ions in the lattice. Deprotonation of an *endo* hydroxyl group of the ligand yields a neutral complex, in the case of **4**. In both complexes a Cl^- ion accomplishes the seventh coordination space around the uranium atom.

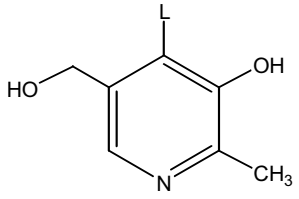
1. Introduction

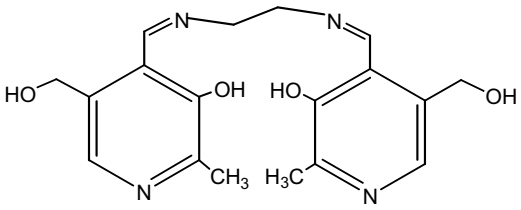
It is known that the compounds derived from the vitamin B6 complex (**A**), pyridoxal (PL), pyridoxamine (PM) and pyridoxine (PN) present a reasonable variety of coordination sites with different charges and hard/soft character [1], allowing the statement of a rich coordination chemistry.



PL: L = CHO; PM: L = CH_2NH_2; PN: L = CH_2OH

The interest for the coordination chemistry of vitamin B6 constituents has increased since Metzler et al. [2] have shown that many different reactions of amino acids are catalyzed by pyridoxal phosphate-containing enzymes [3]. These include, among other important biological reactions, transamination [4], racemization [5], decarboxylation [6] and serine and threonine dehydration [7,8]. Most of these enzymatic reactions have been reproduced by non-enzymatic model reactions in which pyridoxal [9–16] or other appropriate aldehydes [16,17] and a suitable metal salt act as catalysts. For Metzler there is little doubt, therefore, that the catalytic potentialities of pyridoxal phosphate enzymes are basically those of their prosthetic group (the pyridoxal metal complex), and that the non-enzymatic and enzymatic reactions proceed by similar mechanisms.

The Schiff base H_2pyr_2en, *N*,*N*′-bis(pyridoxylideneiminato)ethylene (**B**), derived from the condensation of pyridoxal (PL, **A**) with ethylenediamine (en), is an interesting ligand and a close relative of the vitamin B6 complex.



B was developed by Costa Pessoa and co-workers [18] to investigate its possible substitution in compounds of vanadium and the (Schiff base) ligand sal_2en {*N*,*N*′-ethylenediaminebis(salicylideneiminato)}. Given our previous interests in the metallation of

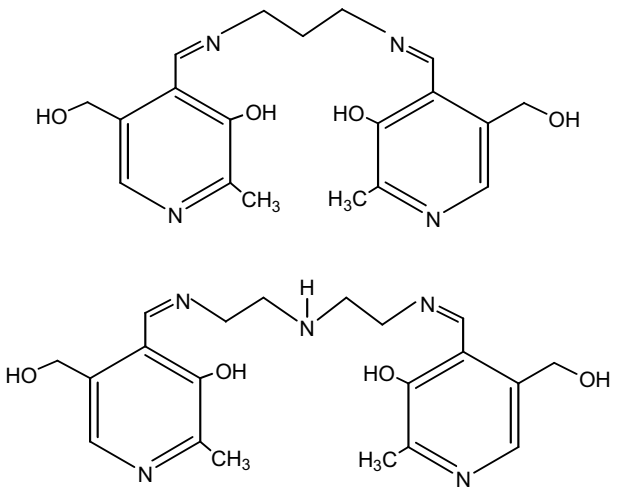
doi:10.1016/j.poly.2008.05.006

biological ligands [19,20] and the synthesis of chelate salts of uranium with compounds derived from the vitamin B6 complex – like for example $[UO_2(PN)_2(H_2O)]Cl_2$ [21] – we have reported [22] the synthesis and the X-ray structural characterization of the new uranium chelates of 4-pyridoxic acid and *N*,*N*′-bis-(pyridoxylideneiminato)ethylene (**B**), $[UO_2(\beta\text{-pyracinide})_2(H_2O)]$ [23,24] and $[UO_2(H_2pyr_2en^*)DMSO]Cl_2$ ($H_2pyr_2en^*$ = the *diammonium* zwitterionic form of **B**; DMSO = dimethyl sulfoxide). To demonstrate the ability of *N*,*N*′-bis(pyridoxylideneiminato)ethylene to react with further heavy metals, hence stabilizing them as chelate systems, we have synthesized also the chelate complexes $[Th(pyr_2en)_2(H_2O)]$ {pyr_2en = *N*,*N*′-ethylenebis(pyridoxylideneiminato)$^{2-}$}, $[Nd(pyr_2en)(Hpyr_2en)] \cdot 12H_2O$ and [Eu (pyr_2en)($Hpyr_2en$)] [25].

The chemical insertion of larger amino groups (than *en*) between the pyridoxal moieties should lead to Schiff bases with remarkable better chelate ability than **B**, like for example, **C** and **D**



The hydroxyl deprotonation of **C** and **D** gives the dianionic Schiff bases (pyr_2pen)$^{2-}$ *N*,*N*′-bis-(pyridoxylideneiminato)$^{2-}$propylenediamine}, and (pyr_2dien)$^{2-}$ {*N*,*N*′-bis-(pyridoxylideneiminato)$^{2-}$diethylentriamine}, respectively. We have recently reported the synthesis of **C** and **D** and their reactions with $UO_2(NO_3)_2$, as well as the reaction of $Th(NO_3)_4 \cdot 5H_2O$ with **C**, and the synthesis and the X-ray characterization of the new chelate complexes $[Th(pyr_2pen)_2]$, $[UO_2(pyr_2pen)(CH_3OH)]$ and $[UO_2(pyr_2dien)] \cdot 2H_2O$, together with their possible radiological significance [26].

The addition of pyridoxal and *o*-phenylenediamine for the achievement of strategic Schiff base ligands do not proceeds according theoretical predictions (see Section 2). We report now the synthesis and the X-ray characterization of two new addition products of pyridoxal and *o*-phenylenediamine (**1** and **2**), as well the zwitterionic chelate salt $[UO_2(H_2pyr_2phen)Cl]NO_3$ (**3**) and the neutral chelate complex $[UO_2(Hpyr_2phen)Cl]$ (**4**) {pyr_2phen = *N*,*N*′-bis-(pyridoxylideneiminato)$^{2-}$phenylene}. Complexes **3** and **4** are typical examples of stabilization by complexation of unstable assembles – the ligand, in this case –, a very important and worldwide approach adopted in the modern inorganic chemistry to realize many virtually inexistent chemical species.

2. Results and discussion

2.1. Structural features of *1*, *2*, *3* and *4*

The X-ray crystal data and the experimental conditions for the analyses of the addition products of pyridoxal/*o*-phenylenediamine **1** and **2**, and of the complexes $[UO_2(H_2pyr_2phen)Cl]NO_3$ (**3**) and $[UO_2(Hpyr_2phen)Cl]$ (**4**) {pyr_2phen = *N*,*N*′-bis-(pyridoxylideneiminato)$^{2-}$phenylene}, are given in Table 1. Selected bond distances and angles of the title compounds are listed in Tables 2 and 3. Half asymmetric unit of ligand **1** is presented in Fig. 1; the molecular structure (asymmetric unit) of the ligand **2** is shown in Fig. 2. Figs. 3 and 4 display the asymmetric units of complexes **3** and **4**, with atom-labeling scheme. For clarity the H_2O solvate molecules – two in complex **3** and one in complex **4** – are not displayed in Figs. 3 and 4.

In the uranyl complexes **3** and **4** the uranium atoms are the centers of distorted pentagonal bipyramides, characteristic for the coordination number 7. The Schiff base nature of **2** and of the complex ligands are evident in the shorter (double) N–C bond distances: N(2)–C(8) = 1.365(6) Å in **2** (in contrast with the longer N(2)–C(9) bond with 1.402(6) Å), N(3)–C(15) = 1.294(5)/N(2)–C(8) = 1.282(5) Å in **3**, and N(2)–C(8) = 1.294(6)/N(3)–C(15) = 1.280(6) Å in **4** (see Figs. 2–4 and Tables 2 and 3). In **3** and **4** a Cl^- ion accomplishes the seventh coordination space around the uranium(VI) ion; the positive charge of complex **3** – which contains a zwitterionic, neutral ligand – is balanced in the crystal lattice by NO_3^- counter ions. The deprotonation of one *endo* OH group in compound **4** yields a neutral complex. In complexes **3** and **4** becomes evident the (concave) spatial adjustment developed by the ligands to literally grip the uranyl cation, thus stabilizing the compounds (Figs. 3 and 4). The new U complexes described in this work are examples of bimolecular chelate systems not yet reported for this Schiff base ligand. The formation of **3** and **4**, hence the stabilization of the ligand, corroborates the remarkable ability of Schiff bases derived from pyridoxal, to afford the stereochemical and electrical requisites for the achievement of heavy metal chelates with uncommon coordination polyhedra.

2.2. Remarks on stoichiometric and stability

As we have already pointed out, predictions on the chemical behavior of reactions between pyridoxal and *o*-phenylenediamine are not so meaningful.

For example, the reaction of 1 equiv. of pyridoxal with 1 equiv. of *o*-phenylenediamine arises according to the Scheme 1, with mayor reaction of only one NH_2 group of *o*-phenylenediamine, yielding **1** as main component (60%), but also forming compound **2** (40%), in this case, occurring simultaneous reaction of both amino groups and cyclization, under lost of water and hydrogen.

If the reaction is carried out in the relation 1:2 – as shown in Scheme 2 – and in the absence of UO_2^{2+} ions, the obtained product is that one expected alone in the first reaction (**1**), instead of the desired, addition product of single pyridoxal molecules to both amino groups of *o*-phenylenediamine.

The aimed Schiff base not obtained in the preceding reaction is achieved only in the presence of UO_2^{2+} ions, since the desired product is now stabilized as a chelate, according to the Scheme 3. In this chelate salt the Schiff base exhibits a zwitterionic equilibrium, without deprotonation.

The stabilization of the condensed Schiff base ligand can also take place under deprotonation of one *endo* hydroxyl group, giving rise to the neutral chelate **4** (see Figs. 3 and 4). On the contrary of the Schiff base ligands **A**, **B** and **C** (see Section 1), the 1:2 condensation of *o*-phenylenediamine and pyridoxal does not occur in the free state, if this process is attained as demonstrated in the Scheme 2. By direct reaction between pyridoxal and *o*-phenylenediamine the adduct only exists in the chelated form, thus, requiring a template (the uranyl ion) for the assemble (Scheme 3). This should be attributed to the proximity of the two Schiff base centers (separated only by three bonds) in the unachieved adduct of the Scheme

2. Worthy of note is the description of a dimeric Cu(II) complex of this ligand, earlier attained by Nepveu et al. [27].

Finally, it has to be enlightened that the syntheses of new Schiff base ligands derived from pyridoxal, as well as their reactions with uranium, thorium and other heavy metals, make part of our researches on modelings for heavy metals damage inhibition in living beings. Nevertheless, only chemical aspects related to the

synthesis of the title compounds, as well their characterization, will be handled in this communication.

3. Experimental

3.1. Synthesis of the pyridoxal/**o**-phenylenediamine adduct ***1***

Pyridoxal chloridrate (0.208 g, 1 mmol), dissolved in 10 ml of anhydrous methanol, was mixed with 0.040 g (1 mmol) of KOH for the pH adjustment (≈7). The yellow solution was stirred by 15 min. Thereafter, 0.108 g (1 mmol) of 1,2-phenylenediamine was added and the mixture was cooled at 0 °C and stirred under Ar atmosphere by 1 h. The orange precipitate was removed by filtration. The slow evaporation of the remained solution yields yellow crystals, suitable for X-ray analysis. Yield, 84%.

Properties: yellow, wedge-like crystals. $C_{28}H_{30}N_6O_4$ (514.58). Melting point: 182–184 °C. IR (KBr): 3441 [shoulder, ν(O–H)]; 1531 (1412) [strong, (medium), ν(C=C, C=N)$_{py.}$]; 1445 [medium, ν(C–O)$_{ar}$]; 1426 [medium, ν(C–N)$_{aliphatic}$]; 1041 [strong, ν(C–O)$_{alkoh.}$]; 727–627 (broad) [weak, δ(N–H)]. C, H, N – *Anal.* Calc.: C, 65.36; H, 5.83; N, 16.34. Found: C, 65.02; H, 5.39; N, 16.46%.

3.2. Synthesis of the pyridoxal/o-phenylenediamine adduct ***2***

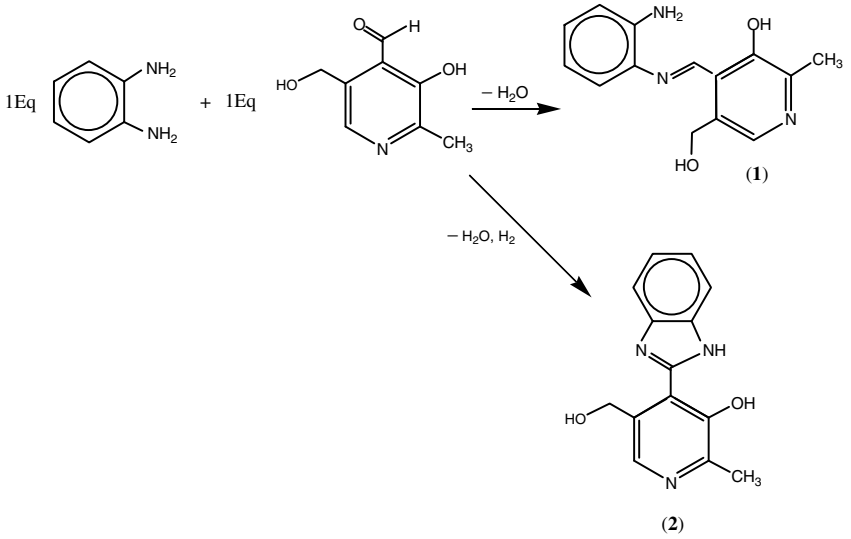
Pyridoxal chloridrate (0.208 g, 1 mmol) and 1,2-phenylenediamine (0.108 g, 1 mmol) were dissolved in 10 ml of anhydrous methanol. The mixture was stirred and kept 15 min in an ultrasound bath at 37 KHz, under precipitation of a red carmine powder. This precipitate was isolated, redissolved in 50 ml of anhydrous ethanol and heated at 70 °C during 2 h. Evaporation of the limpid yellow solution yields after three days yellow crystals, suitable for X-ray analysis. Yield, 87%.

Properties: yellow, tabular crystals. $C_{14}H_{13}N_3O_2$ (255.27). Melting point: 112–115 °C. IR (KBr): 3278–2653 [sh., ν(O–H)]; 1462 (1384) [s, (m), ν(C=C, C=N)$_{py.}$]; 1445 [m, ν(C–O)$_{ar}$]; 1426 [m, ν(C–N)$_{aliphatic}$]; 1025 [s,ν(C–O)$_{alkoh.}$]; 755 [m, δ(N–H)]; 665 [w, δ(N–H)]. C, H, N – *Anal.* Calc.: C, 65.88; H, 5.09; N, 16.47. Found: C, 65.5; H, 5.21; N, 16.02%.

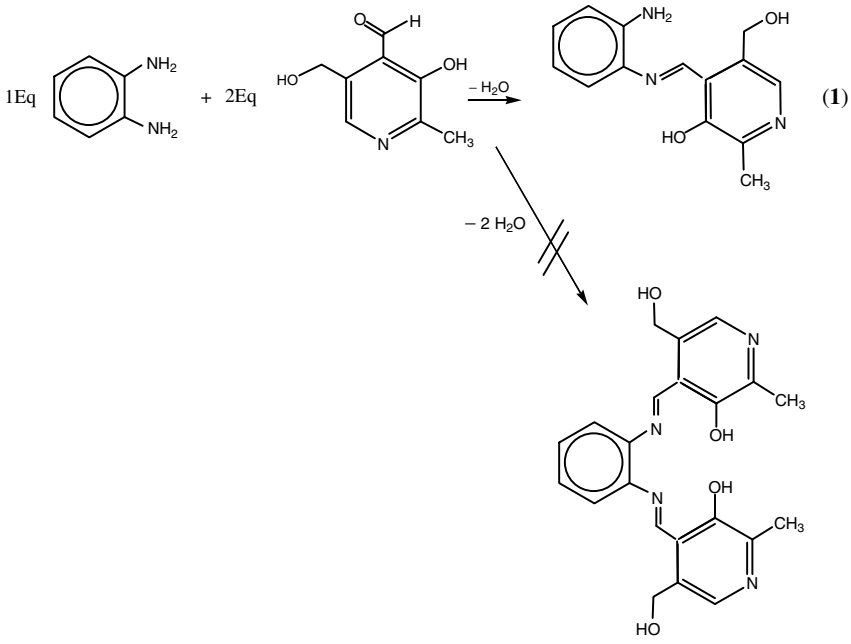
3.3. Synthesis of $[UO_2(H_2pyr_2phen)Cl]NO_3$ (***3***)

Pyridoxal chloridrate (0.101 g, 0.5 mmol) and Na_2CO_3 (0.042 g, 0.5 mmol) were dissolved in 10 ml of methanol. After 15 min stirring the pH of the solution is nearby 7; 0.128 g (0.5 mmol) of the pyridoxal/*o*-phenylenediamine adduct **1** together with $UO_2(NO_3)_2 \cdot 6H_2O$ (0.502 g, 0.5 mmol) were added and the mixture was stirred and refluxed by 1 h. Unstable, but diffractometric measurable crystals were obtained after 24 h. Yield, 30%.

Properties: yellow, air unstable crystals. $C_{22}H_{26}ClN_5O_{11}U$ (809.96). Melting point (decomposition): 205 °C. IR (KBr): 3416 [sh., ν(O–H)]; 1610 [s, ν(C=N)]; 1517, 1430 [m, ν(C=C, C=N)$_{py.}$]; 1438 [m, ν(C–O)$_{ar}$]; 1383 [s, ν(NO$_3$)]; 1039 [s, ν(C–O)$_{alkoh.}$]; 894



Scheme 1.



Scheme 2.

[s, δ (O–U–O)]; 768 [w, $\nu(NO_3)$]. C, H, N – *Anal.* Calc.: C, 32.61; H, 3.21; N, 8.64. Found: C, 32.33; H, 3.19; N, 8.36%.

3.4. Synthesis of $[UO_2(Hpyr_2phen)Cl]$ (4)

Pyridoxal chloridrate (0.101 g, 0.5 mmol) and KOH (0.020 g, 0.5 mmol) were dissolved in 10 ml of methanol. After 15 min stirring the pH of the solution is around 7; 0.128 g (0.5 mmol) of the pyridoxal/*o*-phenylenediamine adduct **1** together with $UO_2(NO_3)_2 \cdot 6H_2O$ (0.502 g, 0.5 mmol) were added and the mixture was stirred and refluxed by 1 h. Red crystals suitable for X-ray analysis were obtained after two days. Yield, 45.4%. Unstable yellow crystals, with melting point of 205 °C and 22.4% yield – probably **3** –, can also be isolated from the mother (solution after a few days).

Properties: red, stable crystals. $C_{22}H_{23}ClN_4O_7U$ (728.92). Melting point (decomposition): 262 °C. IR (KBr): 3440 [sh., ν(O–H)]; 1640 [s, ν(C=N)]; 1500, 1420 [m, ν(C=C, C=N)$_{py.}$]; 1438 [m, $\nu(C–O)_{ar}$]; 1040 [s, $\nu(C–O)_{alkoh.}$]; 894 [s, δ (O–U–O)]. C, H, N – *Anal.* Calc.: C, 36.23; H, 3.15; N, 7.68. Found: C, 36.53; H, 3.27; N, 7.76%.

3.5. X-ray structural determination

Data were collected with a Bruker APEX II CCD area-detector diffractometer and graphite-monochromatized Mo Kα radiation. The structures were solved by direct methods using SHELXS [28]. Subsequent Fourier-difference map analyses yielded the positions of the non-hydrogen atoms. Refinements were carried out with the SHELXL package [28]. All refinements were made by full-matrix least-squares on F^2 with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were included in the refinement in calculated positions. Crystal data and more details of the data collections and refinements are contained in Table 1.

ABSTRACT

The coordination chemistry of *iso*-butyramide based ligands such as: $^iC_3H_7CON(^iC_3H_7)_2$, $^iC_3H_7CON(C_4H_9)_2$ and $^iC_3H_7CON(^iC_4H_9)_2$ with $[UO_2(NO_3)_2 \cdot 6H_2O]$, $[UO_2(OO)_2 \cdot 2H_2O]$ {where OO = $C_4H_3SCOCHCOCF_3$ (TTA), $C_6H_5COCHCOCF_3$ (BTA) and $C_6H_5COCHCOC_6H_5$ (DBM)}, $[Th(NO_3)_4 \cdot 6H_2O]$ and $[La(NO_3)_3 \cdot 6H_2O]$ has been evaluated. Structures for the compounds $[UO_2(NO_3)_2(^iC_3H_7CON\{^iC_4H_9\}_2)_2]$ and $[UO_2(C_6H_5COCHCOC_6H_5)_2(^iC_3H_7CON\{^iC_3H_7\}_2)]$ have been determined by single crystal X-ray diffraction methods. Preliminary separation studies from nitric acid medium using the amide $^iC_3H_7CON(^iC_4H_9)_2$ with U(VI), Th(IV) and La(III) ions showed the selective precipitation of uranyl ion from the mixture. Thermal study of the compound $[UO_2(NO_3)_2(^iC_3H_7CON(^iC_4H_9)_2)_2]$ in air revealed that the ligands can be destroyed completely on incineration.

1. Introduction

Actinide coordination chemistry is very important for the development of new technology concerning the safe processing and storage of irradiated nuclear fuel materials [1–3]. The selective separation of uranium-233 from the mixture of thorium and other fission products is an important step [4a] in the advanced heavy water reactor (AHWR) technology [4b] of the Indian atomic energy program, where upon the thorium oxide is used as a fuel material. In recent years, incinerable organic amide based extractants have proved to be of particular interest in the process chemistry of lanthanides and actinides from the nitric acid medium [5]. It is reported that the *N*,*N*′-2,ethylhexyl *iso*-butyramide shows selective extraction property for the uranium(VI) ion from a mixture containing thorium(IV) or plutonium(IV) ion [6]. The solvent extraction method needs many steps such as: extraction, stripping, precipitation and purification during the reprocessing of fuel materials. The neutral *N*-cyclohexyl,2-pyrrolidone ligand shows selective precipitation of uranium(VI) ion (up to 68%) from the mixture containing various other ions [7] and with this ligand only two steps are required namely precipitation and purification. The selectivity of *N*-cyclohexyl,2-pyrrolidone ligand was explained on the basis of a strong complexing nature of this ligand towards the uranyl nitrate compared to those of other metal nitrate ions. We have reported recently that *iso*-butyramide based amide ligands show an excellent coordination property towards the uranyl group and form air and moisture stable halide and thiolato complexes [8,9]. The stability of these complexes was explained on the basis of very strong bonding between the amide and uranyl group. The observed bond distances in these complexes are much shorter in length compared to those of any of the uranyl-amide [10–12], uranyl-phosphine oxide [13–17] and uranyl-pyrrolidone [18,19] complexes reported. The strong complexing ability of the *iso*-butyramide based ligand promoted us to study their complexing behavior towards uranyl nitrate, thorium nitrate, lanthanum nitrate and uranyl bis(β-diketonate) to investigate whether it was feasible to use these ligands for separation purposes and the results of these studies are reported herein.

2. Experimental

2.1. General considerations

All the starting materials and other chemicals were reagent grade and were used as received. All the amides [8] and uranyl

bis(β-diketonates) [20] were prepared according to the reported methods. FTIR spectra were obtained on a JASCO-610 FTIR spectrometer and the samples were mounted as a Nujol mull. The ^{1}H NMR spectra in $CDCl_3$, on a Brucker 500 MHz spectrometer and the peak positions are calibrated with respect to the internal residual solvent peaks. Elemental analyses were performed by the Analytical Chemistry Division of Bhabha Atomic Research Centre, Mumbai. The TG/DTA for the compound $[UO_2(NO_3)_2(^iC_3H_7CON^iBu_2)_2]$ was recorded on a Mettler TGA-851E instrument under the flow of an air. Elemental compositions in the precipitated $[UO_2(NO_3)_2(^iC_3H_7CON^iBu_2)_2]$ and the supernatant solution were analyzed via an ITAL-TXRF instrument.

2.2. Synthesis of $[UO_2(NO_3)_2\{^iC_3H_7CON(^iC_3H_7)_2\}_2]$ (**1**)

To a solution of $^iC_3H_7CON(^iC_3H_7)_2$ (450 mg, 2.6 mmol) in $CHCl_3$, solid $[UO_2(NO_3)_2 \cdot 6H_2O]$ (502 mg, 1.0 mmol) was added and stirred for few minutes until all $[UO_2(NO_3)_2 \cdot 6H_2O]$ dissolves to give a clear solution. This solution was filtered and layered with *iso*-octane. The solution on slow evaporation deposited a yellow crystalline solid, which was filtered, washed with hexane and dried. Yield: 700 mg (95%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2(^iC_3H_7CON\{^iC_3H_7\}_2)_2]$, $C_{20}H_{42}N_4O_{10}U$: C, 32.6; H, 5.7; N, 7.6. Found: C, 32.3; H, 5.5; N, 7.5%. IR (KBr, Nujol): ν/cm^{-1} 1570 (CO), 930 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 1.40 (d, 7 Hz, 12H, CH_3, $N^iC_3H_7$), 1.57 (d, 7 Hz, 6H, CH_3, $^iC_3H_7$), 3.29 (br, 1H, CH, $^iC_3H_7$), 4.26 (br, 2H, CH, $N^iC_3H_7$).

2.3. Synthesis of $[UO_2(NO_3)_2\{^iC_3H_7CON(C_4H_9)_2\}_2]$ (**2**)

Compound **2** was prepared similarly to **1** by taking $^iC_3H_7CON(C_4H_9)_2$ (460 mg, 2.31 mmol) and $[UO_2(NO_3)_2 \cdot 6H_2O]$ (450 mg, 0.89 mmol). Yield: 730 mg (92%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2\{^iC_3H_7CON(C_4H_9)_2\}_2]$, $C_{24}H_{50}N_4O_{10}U$: C, 36.4; H, 6.3; N, 7.1. Found: C, 36.1; H, 6.1; N, 7.0%. IR (KBr, Nujol mull): ν/cm^{-1} 1571 (CO), 932 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 0.67 (t, 7 Hz, 3H, CH_3, NC_4H_9), 0.97 (m, 2H, CH_2, NC_4H_9), 1.07 (t, 7 Hz, 3H, CH_3, NC_4H_9), 1.43 (d, 6H, CH_3, $^iC_3H_7$), 1.53 (m, 2H, CH_2, NC_4H_9), 1.67 (m, 2H, CH_2, NC_4H_9), 1.86 (m, 2H, CH_2, NC_4H_9), 3.25 (br, 1H, CH, $^iC_3H_7$), 3.63 (m, 4H, NCH_2, NC_4H_9).

2.4. Synthesis of $[UO_2(NO_3)_2\{^iC_3H_7CON(^iC_4H_9)_2\}_2]$ (**3**)

Compound **3** prepared similarly to **1** by taking $^iC_3H_7CON(^iC_4H_9)_2$ (454 mg, 2.28 mmol) and $[UO_2(NO_3)_2 \cdot 6H_2O]$ (502 mg, 1.0 mmol). Yield: 725 mg (91.5%). Elemental *Anal.* Calc. for $[UO_2(NO_3)_2\{^iC_3H_7CON(^iC_4H_9)_2\}_2]$, $C_{24}H_{50}N_4O_{10}$ U: C, 36.4; H, 6.3; N, 7.1. Found: C, 36.3; H, 6.2; N, 7.0%. IR (KBr, Nujol mull): ν/cm^{-1} 1571 (CO), 931 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 0.73 (d, 7 Hz, 6H, CH_3, $N^iC_4H_9$), 1.29 (d, 7 Hz, 6H, CH_3, $N^iC_4H_9$), 1.43 (d, 7 Hz, 6H, CH_3, $^iC_3H_7$), 2.23 (m, 2H, CH, $N^iC_4H_9$), 3.34 (br, 1H, CH, $^iC_3H_7$), 3.5 (m, 4H, CH_2, $N^iC_4H_9$).

2.5. Synthesis of $[UO_2(C_4H_3SCOCHCOCF_3)_2\{^iC_3H_7CON(^iC_3H_7)_2\}]$ (**4**)

To a chloroform solution of $[UO_2(C_4H_3SCOCHCOCF_3)_2 \cdot 2H_2O]$ (500 mg, 0.66 mmol), $^iC_3H_7CON(^iC_3H_7)_2$ (120 mg, 0.70 mmol) was added and refluxed for 30 min. The resultant solution was filtered and layered with *iso*-octane. The solution on slow evaporation yielded an orange colored product. This was filtered, washed with hexane and dried. Yield: 550 mg (93%). Elemental *Anal.* Calc. for $[UO_2(C_4H_3SCOCHCOCF_3)_2\{^iC_3H_7CON(^iC_3H_7)_2\}]$, $C_{26}H_{29}NO_7S_2F_6U$: C, 35.3; H, 3.3; N, 1.6. Found: C, 35.0; H, 3.5; N, 1.2%. IR (KBr, Nujol): ν/cm^{-1} 1565 (CO, $^iC_3H_7CON(^iC_3H_7)_2$), 1600–1630 (CO, $C_4H_3SCOCHCOCF_3$), 919 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 1.43 (br, CH_3, $N^iC_3H_7$), 1.56 (br, CH_3, $^iC_3H_7$), 3.32 (br, CH, $^iC_3H_7$), 4.36 (br, NCH, $N^iC_3H_7$), 6.77, 6.81 (s, CH, $C_4H_3SCOCHCOCF_3$), 7.17–7.33, 7.77–7.85, 8.25–8.30 (m, C_4H_3S, $C_4H_3SCOCHCOCF_3$).

2.6. Synthesis of $[UO_2(C_4H_3SCOCHCOCF_3)_2\{^iC_3H_7CON(^iC_4H_9)_2\}]$ (**5**)

Compound **5** was prepared similarly to **4** by taking $[UO_2(C_4H_3SCOCHCOCF_3)_2 \cdot 2H_2O]$ (500 mg, 0.66 mmol) and $^iC_3H_7CON(^iC_4H_9)_2$ (140 mg, 0.70 mmol). Yield: 580 mg (95%). Elemental *Anal.* Calc. for $[UO_2(C_4H_3SCOCHCOCF_3)_2\{^iC_3H_7CON(^iC_4H_9)_2\}]$, $C_{28}H_{33}NO_7S_2F_6U$: C, 36.9; H, 3.6; N, 1.5. Found: C, 36.7; H, 3.4; N, 1.1%. IR (KBr, Nujol): ν/cm^{-1} 1571 (CO, $^iC_3H_7CON(^iC_4H_9)_2$), 1600–1630 (CO, $C_4H_3SCOCHCOCF_3$), 916 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 0. 72 (d, CH_3, $N^iC_4H_9$), 1.17 (d, CH_3, $N^iC_4H_9$), 1.47 (d, CH_3, $^iC_3H_7$), 2.24 (m, CH, $N^iC_4H_9$), 3.34 (br, CH, $^iC_3H_7$), 3.5–3.6 (m, NCH_2, $N^iC_4H_9$), 6.77, 6.82 (s, CH, $C_4H_3SCOCHCOCF_3$), 7.33, 7.50–7.85, 8.25–8.29 (m, C_4H_3S, $C_4H_3SCOCHCOCF_3$).

2.7. Synthesis of $[UO_2(C_6H_5COCHCOCF_3)_2\{^iC_3H_7CON(^iC_3H_7)_2\}]$ (**6**)

Compound **6** was prepared similarly to **4** by taking $[UO_2(C_6H_5COCHCOCF_3)_2 \cdot 2H_2O]$ (450 mg, 0.611 mmol) and $^iC_3H_7CON(^iC_3H_7)_2$ (110 mg, 0.64 mmol).Yield: 490 mg (92%). Elemental Anal. Calc. for $[UO_2(C_6H_5COCHCOCF_3)_2\{^iC_3H_7CON(^iC_3H_7)_2\}]$, $C_{30}H_{33}$- NO_7F_6U: C, 41.3; H, 3.8; N, 1.6. Found: C, 41.0; H, 3.5; N, 1.2%. IR (KBr, Nujol): ν/cm^{-1} 1565 (CO, $^iC_3H_7CON(^iC_3H_7)_2$), 1604–1630 (CO, $C_6H_5COCHCOCF_3$), 918 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 1.34 (br, CH_3, $N^iC_3H_7$), 1.64 (br, CH_3, $^iC_3H_7$), 3.32 (br, CH, $^iC_3H_7$), 4.36 (br, NCH, $N^iC_3H_7$), 6.98, 7.01 (s, CH, $C_6H_5COCHCOCF_3$), 7.60–7.72, 8.57–8.37 (m, C_6H_5, $C_6H_5COCHCOCF_3$).

2.8. Synthesis of $[UO_2(C_6H_5COCHCOCF_3)_2\{^iC_3H_7CON(^iC_4H_9)_2\}]$ (**7**)

Compound **7** was prepared similarly to **4** by taking $[UO_2(C_6H_5COCHCOCF_3)_2 \cdot 2H_2O]$ (450 mg, 0.61 mmol) and $^iC_3H_7CON(^iC_4H_9)_2$ (125 mg, 0.63 mmol). Yield: 505 mg (92%). Elemental *Anal.* Calc. for $[UO_2(C_6H_5COCHCOCF_3)_2\{^iC_3H_7CON(^iC_4H_9)_2\}]$, $C_{32}H_{37}NO_7F_6U$: C, 42.7; H, 4.1; N, 1.6. Found: C, 42.5; H, 4.4; N, 1.4%. IR (KBr, Nujol): ν/cm^{-1} 1570 (CO, $^iC_3H_7CON(^iC_4H_9)_2$), 1603–1630 (CO, $C_6H_5COCHCOCF_3$), 915 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 0.74 (d, CH_3, $N^iC_4H_9$), 1.18 (d, CH_3, $N^iC_4H_9$), 1.50 (d, CH_3, $^iC_3H_7$), 2.25 (m, CH, $N^iC_4H_9$), 3.38 (br, CH, $^iC_3H_7$), 3.5–3.7 (m, NCH_2, $N^iC_4H_9$), 6.99 (s, CH, $C_6H_5COCHCOCF_3$), 7.59–7.77, 8.57–8.60 (m, C_6H_5, $C_6H_5COCHCOCF_3$).

2.9. Synthesis of $[UO_2(C_6H_5COCHCOC_6H_5)_2\{^iC_3H_7CON(^iC_3H_7)_2\}]$ (**8**)

Compound **8** was prepared similarly to **4** by taking $[UO_2(C_6H_5COCHCOC_6H_5)_2 \cdot 2H_2O]$ (400 mg, 0.532 mmol) and $^iC_3H_7CON(^iC_3H_7)_2$ (95 mg, 0.55 mmol). Yield: 440 mg (93%). Elemental *Anal.* Calc. for $[UO_2(C_6H_5COCHCOC_6H_5)_2\{^iC_3H_7CON(^iC_3H_7)_2\}]$, $C_{40}H_{43}NO_7U$: C, 54.1; H, 4.8; N, 1.6. Found: C, 54.0; H, 4.6; N, 1.4%. IR (KBr, Nujol): ν/cm^{-1} 1591 (CO, $C_6H_5COCHCOC_6H_5$), 1572 (CO, $^iC_3H_7CON(^iC_3H_7)_2$), 921 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ 1.38 (br, CH_3, $N^iC_3H_7$), 1.56 (br, CH_3, $^iC_3H_7$), 3.27 (br, CH, $^iC_3H_7$), 4.35 (br, NCH, $N^iC_3H_7$), 7.40 (s, CH, $C_6H_5COCHCOC_6H_5$), 7.50–7.7, 8.42–8.60 (m, C_6H_5, $C_6H_5COCHCOC_6H_5$).

2.10. Synthesis of $[UO_2(C_6H_5COCHCOC_6H_5)_2\{^iC_3H_7CON(^iC_4H_9)_2\}]$ (**9**)

Compound **9** was prepared similarly to **4** by taking $[UO_2(C_6H_5COCHCOC_6H_5)_2 \cdot 2H_2O]$ (400 mg, 0.532 mmol) and $^iC_3H_7CON(^iC_3H_7)_2$ (110 mg, 0.55 mmol). Yield: 420 mg (86%). Elemental *Anal.* Calc. for $[UO_2(C_6H_5COCHCOC_6F_5)_2\{^iC_3H_7CON(^iC_3H_7)_2\}]$, $C_{40}H_{43}NO_7U$: C, 54.1; H, 4.8; N, 1.6. Found: C, 54.0; H, 4.6; N, 1.4%. IR (KBr, Nujol): ν/cm^{-1} 1580 (CO, $^iC_3H_7CON(^iC_3H_7)_2$), 1591 (CO, $C_6H_5COCHCOC_6H_5$), 922 (O=U=O). ^{1}H NMR (25 °C, $CDCl_3$): δ

0. 72 (d, CH_3, $N^iC_4H_9$), 1.32 (d, CH_3, $N^iC_4H_9$), 1.45 (d, CH_3, $^iC_3H_7$), 2.22 (m, CH, $N^iC_4H_9$), 3.32 (br, CH, $^iC_3H_7$), 3.4–3.6 (m, NCH_2, $N^iC_4H_9$), 7.41 (s, CH, $C_6H_5COCHCOC_6H_5$), 7.52–7.7, 8.40–8.60 (m, C_6H_5, $C_6H_5COCHCOC_6H_5$).

2.11. Reaction of $^iC_3H_7CON(^iC_4H_9)_2$ with $Th(NO_3)_4 \cdot 6H_2O$

To a solution of $^iC_3H_7CON(^iC_4H_9)_2$ (500 mg, 2.5 mmol) in $CHCl_3$, solid [$Th(NO_3)_4 \cdot 6H_2O$] (600 mg, 1.02 mmol) was added and stirred for 12 h. No reaction between the amide and $Th(NO_3)_4 \cdot 6H_2O$ was observed due to the presence of an insoluble starting material. Ten millilitres of methanol was added to the solution and stirred for another 6 h. The clear solution was evaporated to dryness and the hygroscopic material was subjected to IR spectral analysis. IR (KBr, Nujol): ν/cm^{-1} 1640 (CO), 3600–3200 (br, H_2O).

2.12. Reaction of $^iC_3H_7CON(^iC_4H_9)_2$ with $La(NO_3)_3 \cdot 6H_2O$

This reaction was performed similarly to that of $Th(NO_3)_4 \cdot 6H_2O$ by taking the amide (650 mg, 3.27 mmol) and $La(NO_3)_3 \cdot 6H_2O$ (450 mg, 1.03 mmol). The resultant hygroscopic material was subjected to the IR spectral studies. IR (KBr, Nujol): ν/cm^{-1} 1639 (CO), 3600–3200 (br, H_2O).

2.13. Solvent extraction studies

Distribution studies were performed by using a solution of $^iC_3H_7CON(^iC_4H_9)_2$ in toluene (0.2 F) with the required aqueous phase spiked with ^{233}U or ^{239}Pu tracers in a thermostated water bath for 1 h at 25 ± 0.1 °C. Assay of organic and aqueous phases were done in duplicate by alpha counting using a dioxane based liquid scintillator for ^{233}U and ^{239}Pu. The distribution ratio (D) is defined as the ratio of the concentration of uranium in the organic phase to that of the aqueous phase.

2.14. Separation studies

Stock solutions containing 5 g of $Th(NO_3)_4 \cdot 6H_2O$, 300 mg of $La(NO_3)_3 \cdot 6H_2O$ and 500 mg of $UO_2(NO_3)_2 \cdot 6H_2O$ were prepared in 10 ml of 1, 2, 3 and 6 M HNO_3. This solution was layered with 1 g of $^iC_3H_7CON(^iC_4H_9)_2$ amide and allowed to stand for over night. This process deposited yellow crystalline solid material, which was filtered, washed with water, hexane and dried. The supernatants and the solutions of yellow solid in ethanol were used for the elemental analysis using the total reflection X-ray fluorescence (TXRF) method.

2.15. X-ray diffraction studies of **3** and **8**

Data for **3** and **8** were measured with the Mo Kα radiation (λ = 0.71073 Å) at 150 K using the Oxford Instruments X-Calibur CCD System. The crystals were positioned at 50 mm from the Image Plate. Three hundred and twenty-one frames were measured with a counting time of 10 s. Data analysis was carried out with the CRYSALIS program [21a]. The structures were solved using direct methods with the SHELXS97 program [21b]. All non-hydrogen atoms in these structures were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon atoms were included in the geometric positions and given thermal parameters equivalent to 1.2 times those of the atoms to which they attached. Empirical absorption corrections were carried out using the ABSPACK program [21c]. The structures were refined to convergence on F^2 using SHELXL97 [21d]. Selected crystallographic data for **3** and **8** are summarized in Table 1.

3. Results and discussion

3.1. Complexation study of ***iso*-butyramide ligands with the uranyl nitrate**

The complexing ability of $^iC_3H_7CON(^iC_3H_7)_2$, $^iC_3H_7CON(C_4H_9)_2$ and $^iC_3H_7CON(^iC_4H_9)_2$ with uranyl nitrate was studied by using elemental analysis, IR and NMR spectroscopic techniques. The reaction of [$UO_2(NO_3)_2 \cdot 6H_2O$] with the *iso*-butyramide ligands yielded the compounds **1**–**3**. The C, H and N analysis revealed that the ratio of ligand to uranyl nitrate is 1:2 in all these compounds. The IR spectra of **1**–**3** show that the water molecules from the starting compound [$UO_2(NO_3)_2 \cdot 6H_2O$] are completely replaced by the ligand and that the ligand is bonded through the carbamoyl oxygen atom to the uranyl group.

The observed frequency differences for a carbamoyl ($\Delta\nu_{CO}$ = 68–70 cm^{-1}, where $\Delta\nu_{CO} = \nu_{CO(\text{free ligand})} - \nu_{CO(\text{coordinated})}$) group are consistent with the supposition that the carbamoyl group is bonded to the uranyl group directly in the reported compounds. These differences are comparable in magnitude with those of the $[UO_2Cl_2(^iC_3H_7CON\{^iC_3H_7\}_2)_2]$, $[UO_2Br_2(^iC_3H_7CON\{^{sec}C_4H_9\}_2)_2]$ [8], $[UO_2(C_6H_3Cl_2S)_2(^iC_3H_7CON\{^iC_4H_9\}_2)_2]$ [9], $[UO_2(NO_3)_2(N\text{-cyclohexyl,2-pyrrolidone})_2]$ [18] and $[UO_2(NO_3)_2(1,3\text{-dimethyl,2-imidazolidone})_2]$ [19] complexes and much higher in magnitude compared to those observed in other amides or malonamides uranyl complexes [5,22]. The ^1H NMR spectra of **1**–**3** show that the CH proton of the *iso*-propyl group is deshielded by ca. 0.5–0.6 ppm with respect to the free ligand, indicating that the ligand is coordinated to the uranyl group in solution also. It is apparent from the elemental analysis and IR spectral results that ligands are acting as monodentate ligand in compounds **1**–**3** in the solid state to give similar structures to those observed in the compounds of pyrrolidone [18,19] or other monodentate amides [10–12] with the uranyl nitrate. Interestingly, all these complexes are air and moisture stable crystalline solids, having good solubility in $CHCl_3$ and CH_2Cl_2, and can be used as a starting compound for further reactions. The structure of **3** has been determined by single crystal X-ray diffraction methods, which confirms the IR and elemental analysis results.

3.2. Molecular structure of **3**

The molecular structure of **3** is shown in Fig. 1 and the selected interatomic bond distances and angles for are given in Table 2. The

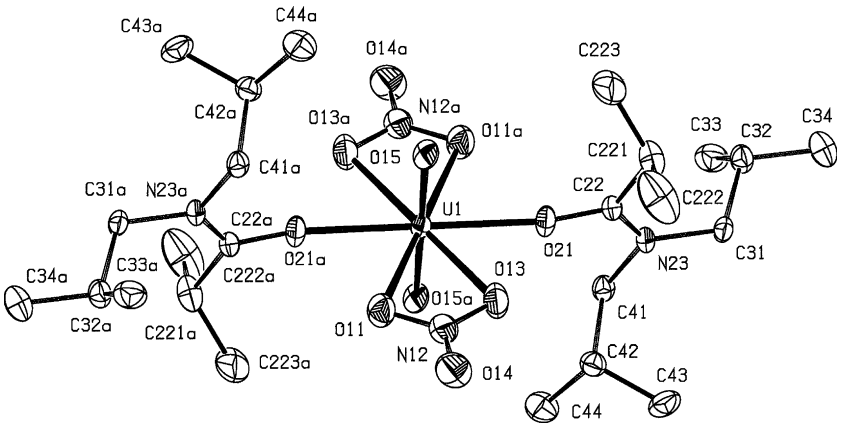

Fig. 1. Molecular structure of **3** (hydrogen atoms omitted for the clarity).

structure contains a crystallographic center of symmetry with the uranium atom surrounded by eight oxygen atoms in a hexagonal bi-pyramidal geometry. Two uranyl oxygen atoms occupy the axial positions. There are two bidentate nitrate ligands in the hexagonal equatorial plane together with two carbamoyl oxygen atoms from the two monodentate *iso*-butyramide ligands. These six oxygen atoms are approximately coplanar to within an r.m.s. of 0.042 Å.

This type of co-ordination is similar to that observed in the compounds of the mono-functional ligands, phosphine oxide, phosphates and amides or pyrrolidones with uranyl nitrate such as: $[UO_2(NO_3)_2(OPPh_3)_2]$ [13], $[UO_2(NO_3)_2(OP\{OEt\}_3)_2]$ [14], $[UO_2(NO_3)_2(OPBu_3)_2]$ [15], $[UO_2(NO_3)_2(TPPPO)_2]$ [16], $[UO_2(NO_3)_2(OP\{OCH_3\}_3)_2]$ [17], $[UO_2(NO_3)_2(DMF)_2]$ [10], $[UO_2(NO_3)_2(N$-cyclohexyl,2-pyrrolidone$)_2]$ [18] and $[UO_2(NO_3)_2(1,3$,dimethyl, 2-imidazolidone$)_2]$ [19]. The U–O(amide) distance (2.349(1) Å) in **3** is much shorter in length compared to those of earlier reported uranyl nitrate–amide compounds such as: $[UO_2(NO_3)(DMF)_2]$ (2.397(6) Å) [10], $[UO_2(NO_3)_2($tetrabutylglutaramide$)_2]$ (2.378(6) Å) [11], $[UO_2(NO_3)_2($dibutyldecanamide$)_2]$ (2.37(2) Å) [12] and $[UO_2(NO_3)_2(^iC_3H_7)_2NCOCH_2CON(^iC_3H_7)_2]$ (2.41(2) Å) [22] and comparable in magnitude with those of $[UO_2(NO_3)_2(N$-cyclohexyl,2-pyrrolidone$)_2]$ (2.347(4) Å) [18] and $[UO_2(NO_3)_2(OPBu_3)_2]$ (2.347(6) Å) [15]. The observed average U–O(NO_3) bond distance 2.531(1) Å is normal [10–19]. The angles subtended at the metal atom show that the uranium atom has a slightly distorted hexagonal bi-pyramidal geometry.

Table 2
Important bond distances (Å) and angles (°) for **3** and **8**

Compound **3**

O1–U1–O25	86.7(2)	O1–U1–O31	89.3(2)
U1–O31–C32	159.8(5)		

The shorter bond lengths observed in this compound can be explained on the basis of a strong π bonding interaction between the filled p orbitals of oxygen atom with those of the vacant d/f orbitals of the uranyl group, which lead to the opening of the U–O–C bond angle from 130° to 140° (normally observed in number of metal–amide compounds [23]) to 171.2(6)°. The observed bond lengths and the U–O–C bond angles are compatible with the earlier reported correlation diagram for the uranyl nitrate–amide compounds [19]. In particular, the characteristic of shorter bond distances and wider bond angles are reported for the *iso*-butyramide based ligands in the compounds of $[Th(NCS)_4(^iC_3H_7CON\{^iC_3H_7\}_2)_3]$ [24], $[UO_2Cl_2(^iC_3H_7CON\{^iC_3H_7\}_2)_2]$, $[UO_2Br_2(^iC_3H_7CON\{^{sec}C_4H_9\}_2)_2]$ [8] and $[UO_2(C_6H_3Cl_2S)_2(^iC_3H_7CON\{^iC_4H_9\}_2)_2]$ [9].

3.3. Complexation study of iso-butyramide with the uranyl bis(β-diketonates)

The reaction of $^iC_3H_7CON(^iC_3H_7)_2$ and $^iC_3H_7CON(^iC_4H_9)_2$ with $[UO_2(OO)_2 \cdot 2H_2O]$ (OO = TTA, BTA or DBM) yielded the compounds **4–9**. The C, H, N analyses revealed that the ratio of ligand to metal is 1:1 in all these compounds. The IR spectra of all these compounds show that the water molecules from the starting compounds $[UO_2(OO)_2 \cdot 2H_2O]$ are replaced completely by the ligands. The spectra show further that the ligands are bonded through the carbamoyl oxygen atoms to the metal ion. ($\Delta\nu_{CO}$ = 70–75 cm^{-1}, where $\Delta\nu_{CO} = \nu_{CO(free\ ligand)} - \nu_{CO(coordinated)}$). The ^1H NMR of the compounds show that CH protons of the *iso*-propyl group is deshielded (ca. 0.5–0.6 ppm) with respect to the free ligand, indicating that the ligand is bonded to the uranyl bis(β-diketonte) in solution also. The structure of compound **8** has been determined by single crystal X-ray diffraction methods, which confirms the spectral and analyses results.

3.4. Molecular structure of *8*

The molecular structure of **8** is shown in Fig. 2 together with the numbering scheme and selected interatomic bond distances and angles are given in Table 2. There is a disordered toluene molecule refined with 50% occupancy in the asymmetric unit which is not shown. The structure shows that the uranyl group is bonded to two $C_6H_5COCHCOC_6H_5$ groups and an amide group to give a coordination number of seven. The amide ligand acts as a monodentate ligand and is bonded through the carbamoyl oxygen atoms to the uranyl bis(β-diketonates). Four oxygen atoms from two $C_6H_5COCHCOC_6H_5$ groups, one oxygen atom from the amide ligand and two oxygen atoms of uranyl group form a pentagonal bi-pyramidal geometry around the uranium(VI) ion. The five contributing

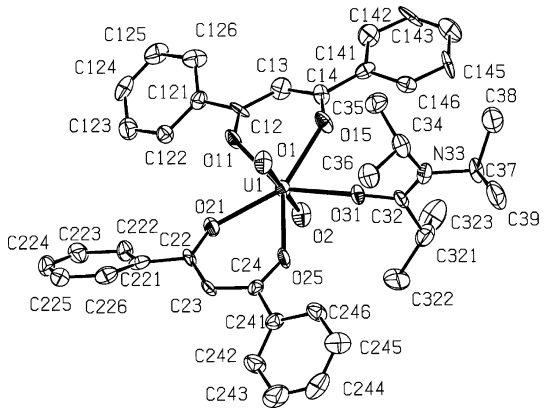

Fig. 2. The structure of **8** (hydrogen atoms omitted for the clarity).

oxygen atoms in the equatorial plane show an r.m.s. deviation of 0.062 Å. Similar structures are also observed in the compounds of phosphine oxide, sulfoxide, N-oxide, ketones and amides with the uranyl bis(β-diketonates) viz; $[UO_2(DBM)_2(OPPh_3)]$ [25a], $[UO_2(DBM)_2(C_6H_5SOCH_3)]$ [25b], $[UO_2(TTA)_2(C_5H_5NO)]$ [25c], $[UO_2(DBM)_2$ (camphor) [25d] and $[UO_2(DBM)_2\{C_4H_9CON(C_5H_{11})(C_4H_9)\}]$ [25e]. The observed metal to amide oxygen distance in **8** (2.379(5) Å) is shorter in length compared to those value reported in $[UO_2(DBM)_2\{C_4H_9CON(C_5H_{11})(C_4H_9)\}]$ (2.42 Å) [25e]. The shortest bond distance observed in compound **8** compared to those observed in $[UO_2(DBM)_2\{C_4H_9CON(C_5H_{11})(C_4H_9)\}]$ can be explained once again on the basis of strong interaction between the amide oxygen and uranyl group, which results in opening of U–O–C bond angle to 159.8(5)°. The longer bond distances in **8** compared to those in **3** can be explained on the basis of a bulkier phenyl group of the β-diketonate units, which may not allow the donor group to come closer to uranyl group compared to those of the less bulkier nitrate groups.

3.5. Complexation study of $^iC_3H_7CON(^iC_4H_9)_2$ with $Th(NO_3)_4 \cdot 6H_2O$ and $La(NO_3)_3 \cdot 6H_2O$

The IR spectra of the product obtained from the reaction between $^iC_3H_7CON(^iC_4H_9)_2$ and $Th(NO_3)_4 \cdot 6H_2O$ or $La(NO_3)_3 \cdot 6H_2O$ show the presence of an uncoordinated carbonyl group (1639 cm^{-1}) and water molecules (3600–3200 cm^{-1}). This shows clearly that there is no reaction between the amide ligand and metal nitrates. However, the uranyl nitrate forms a strong complex with the same amide under identical conditions.

3.6. Thermal studies of the compound **3**

Thermogravimetric (TG) and differential thermal analyses (DTA) of **3** (see the supporting information) were carried out to see whether the bonded ligands can be destroyed completely on heating. These compounds decompose in two steps to give U_3O_8 as a final product without any other impurities as revealed by the powder X-ray diffraction methods.

3.7. Extraction studies of U(VI) and Pu(IV) with $^iC_3H_7CON(^iC_4H_9)_2$ from nitric acid medium

The extraction studies were carried out by using the ligand $^iC_3H_7CON(^iC_4H_9)_2$ in toluene with the U(VI) and Pu(IV) ions in tracer level (using the ^{233}U and ^{239}Pu) from nitric acid medium to assess the feasibility of using this ligand (0.2 F for both the U(VI) and Pu(IV)) for the extraction purpose. Distribution ratios (D) for U(VI) and Pu(IV) as a function of nitric acid concentrations (Fig. 3) shows

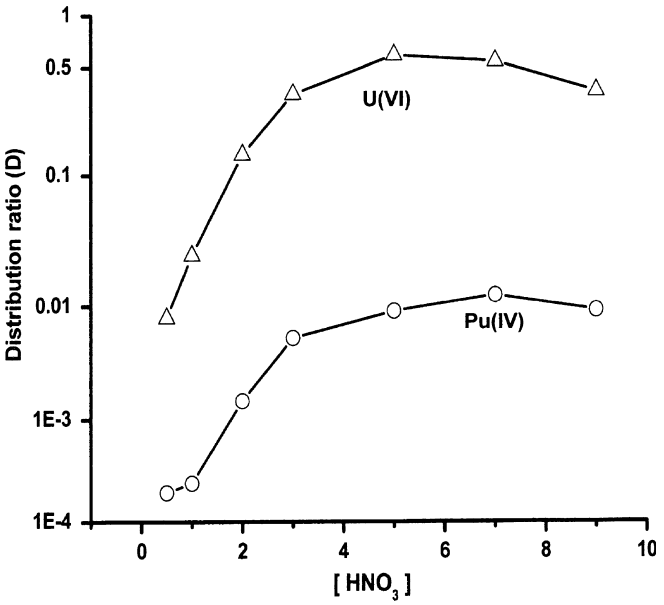

Fig. 3. Variation of distribution ratio for U(VI) and Pu(IV) with HNO_3.

clearly that observed distribution values are very low for both the U(VI) and Pu(IV) under the acid concentrations of 1–10 M. However, under any acid concentration, the D for Pu(IV) is much smaller than those of U(VI). This observation is completely contradictory to the data reported for any of the extractants (either mono-functional or bi-functional) with that of Pu(IV) ($D_{Pu(IV)} \gg D_{U(IV)}$ always) [5a,5b,5c,5d] and agrees well with the result reported for the *iso*-butyramide based extractant [6]. This shows clearly that the uranium can be selectively separated from plutonium or vice versa.

3.8. Selective separation of uranium from thorium by using $^iC_3H_7CON(^iC_4H_9)_2$ ligand

The total reflection X-ray fluorescence (TXRF) spectrum of the supernatant (see the supporting information) clearly shows that more than 98% of the uranium is precipitated from a mixture of thorium, lanthanum and uranium. The TXRF spectrum of the ethanolic solution of the precipitated product shows (see the supporting information) clearly that the precipitate contains more than 98% of uranium and less than 0.2% of thorium and 0% La. It confirms that the uranium is selectively precipitated as its nitrate complex from the solution leaving the thorium and lanthanum ions. This study clearly demonstrates that the uranium can be selectively separated from the mixture of thorium and lanthanum in an equivalent manner to that of the *N*-cyclohexyl,2-pyrrolidone type of ligands. Further work is in progress to investigate the separation of uranium in presences of other lanthanide ions and fission products.

4. Conclusions

Studies on the coordination ability of the *iso*-butyramide based ligands with the uranyl(VI) nitrate show that the ligands act as monodentate ligand and form 1:2 complexes. The studies further show that the ligands are un-reactive towards the thorium(IV) and lanthanum(III) nitrates. Preliminary precipitation studies show that the U(VI) can be selectively separated as an uranyl nitrate amide complex from the solution containing the mixture of U(VI), Th(IV) and La(III) ions. TG/DTA experiments show that the

uranyl nitrate–amide compound can be completely converted in to U_3O_8 without any other impurities.

Supplementary material

X-ray crystallographic files in CIF format for **3** and **8**, IR, ^{1}H NMR spectra and TG/DTA of **3** and TXRF spectra of the Th, U and La mixture, uranyl nitrate precipitate and the supernatant are deposited to the editor as supporting information. Crystallographic data may be obtained from the Cambridge Crystallographic Data Center, by quoting the reference number CCDC: 680831 and 680832. ABSTRACT

Ruthenium monoterpyridine complexes, $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$, with 2,6-bis(benzoxazol-2-yl)pyridine as an ancillary ligand, L, have been synthesized and characterized by UV–Vis, FT-IR and ^{1}H NMR spectroscopic techniques. The formulations of the complexes were confirmed by the single crystal structure of their perchlorate salts. In both complexes, the Ru^{II} center is hexa-coordinated in a distorted geometry. In complex $[\mathbf{1}]^+$, the ancillary ligand L behaves as a bidentate ligand; in $[\mathbf{2}]^{2+}$, however, it binds the metal center as a tridentate ligand. The central pyridine nitrogen of terpyridine ($N_{p,trpy}$) is in a *cis* position with respect to the central pyridine nitrogen of the ancillary ligand ($N_{p,benz}$) in complex $[\mathbf{1}]^+$ and in a *trans*-position in complex $[\mathbf{2}]^{2+}$. The *cis* orientation of $N_{p,trpy}$ and $N_{p,benz}$ in complex $[\mathbf{1}]^+$ forces L to behave as bidentate. The quasi-reversible Ru^{II}/Ru^{III} couple appears at 0.90 and 1.44 V versus SCE in the case of complex $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$, respectively. $[\mathbf{1}]^+$, in the presence of aqueous $AgNO_3$, affords $[\mathbf{2}]^{2+}$ through an intramolecular dissociative interchange pathway.

1. Introduction

Strong metal to ligand charge-transfer transitions, facile electron-transfer properties and long lived ^{3}MLCT excited states of ruthenium–polypyridine complexes make them effective for designing photochemical and electrochemical devices [1–7]. In this direction, a variety of ruthenium–terpyridine complexes incorporating different kinds of bidentate and tridentate ancillary ligands have been synthesized in recent years [8–17]. However, ruthenium–monoterpyridine chemistry with the tridentate 2,6-bis(benoxazol-2-yl)pyridine ligand, structurally analogous to the triimine 2,2′:6′,2″-terpyridine, has not yet been explored, though its chemistry with some transition metals like copper, iron and zinc has been studied well [18,19]. Due to extensive π-delocalization, the rigid planar tridentate ligand will afford a well defined structure for its complexes [18,19] and by virtue, like terpyridine, can bind a metal center in a meridional fashion with a bite angle of about 79°.

In the present study, we have synthesized a ruthenium monoterpyridine complex $[\mathbf{1}]^+$ with the tridentate ancillary ligand, 2,6-bis(benzoxazol-2-yl)pyridine (L). The complex $[\mathbf{1}]^+$, in presence of aqueous silver nitrate solution, undergoes an intramolecular dissociative interchange type reaction to afford complex $[\mathbf{2}]^{2+}$.

2. Experimental

2.1. Materials

The starting complex Ru(trpy)Cl_3 [trpy: 2,2′:6′,2″-terpyridine] was prepared according to the reported procedure [20]. 2,2′:6′,2″-terpyridine and 2,6-pyridinedicarboxylic acid were obtained from Aldrich, USA. 2-Aminophenol was purchased from Loba Chemie, India. Other chemicals and solvents were reagent grade and were used as received. For spectroscopic and electrochemical studies HPLC grade solvents were used. Commercial tetraethyl ammonium bromide was converted into pure tetraethyl ammonium perchlorate by following the available procedure [21].

2.2. Physical measurements

UV–Vis spectra were recorded with a Perkin Elmer Lambda-25 spectrophotometer. FT-IR spectra were taken on a Perkin Elmer spectrophotometer with samples prepared as KBr pellets. Solution electrical conductivity was checked using a Systronic 305 conductivity bridge. ^{1}H NMR spectra were obtained with a 400 MHz Varian FT spectrometer. Cyclic voltammetric, differential pulse voltammetric and coulometric measurements were carried out using a PAR model 273A electrochemistry system. A glassy carbon working electrode, platinum auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in a three electrode configuration. The supporting electrolyte was $[NBu_4]ClO_4$ and the solute concentration was $\sim 10^{-3}$ M. The half-wave poten-

doi:10.1016/j.poly.2008.05.022

tial E^0_{298} was set equal to $0.5(E_{pa} + E_{pc})$, where E_{pa} and E_{pc} are the anodic and cathodic cyclic voltammetric peak potentials, respectively. All experiments were carried out under a dinitrogen atmosphere and were uncorrected for junction potentials. The elemental analyses were carried out with a Perkin Elmer elemental analyser.

2.3. Crystallography

X-ray diffraction data for the complexes were collected on Bruker 3-circle SMART Apex diffractometer with CCD area detectors, using graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation, with increasing ω (width of 0.3° per frame) at a scan speed of 3 s/frame. The structures were solved by direct methods and refined by full-matrix least squares against F^2 for all data, using SHELXTL software [22]. Multi-scan empirical absorption corrections were applied to the data using the program SADABS [23]. All the non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located from the difference Fourier maps and refined. Structural illustrations have been drawn with ORTEP-3 for Windows [24].

2.4. Synthesis of the ligand L

A mixture of pyridine 2,6-dicarboxylic acid (835 mg, 5 mmol) and 2-aminophenol (1.09 g, 10 mmol) in 10 ml *ortho*-phosphoric acid was refluxed for 8 h. It was then cooled down to room temperature and poured into 200 ml pre-cooled water with constant stirring, which resulted in a dark brown precipitate. The precipitate, on washing with 20% sodium carbonate solution, afforded the dark colored ligand, L. It was then recrystallized from hot methanolic solution (yield = 40%).

Elemental *Anal.* Calc.: C, 72.84; H, 3.54; N, 13.41. Found: C, 72.87; H, 3.53; N, 13.39%. ^{1}H NMR data (400 MHz, in $CDCl_3$) δ_{ppm}: 8.52 (d, 2H), 8.10 (t, 1H), 7.85 (d, 2H), 7.73 (d, 2H), 7.46–7.39 (m, 4H).

2.4.1. Synthesis of the complex [*1*](ClO$_4$)

$Ru^{III}(trpy)Cl_3$(200 mg; 0.44 mmol) and the ligand, L (144 mg; 0.46 mmol) were dissolved in 20 ml ethanol, and NEt_3 (0.7 mmol) was added dropwise to the mixture. It was then heated to reflux with constant stirring for 4 h. Then the volume of the mixture was reduced to 5 ml under reduced pressure and a pre-cooled saturated aqueous $NaClO_4$ solution was added. The mixture was kept in a refrigerator overnight. The dark precipitate that formed was filtered off and washed with ice cold distilled water. The product was dried in vacuo over P_4O_{10}. It was then passed through a silica gel column with a CH_2Cl_2/CH_3CN solvent mixture. The reddish brown color complex, [**1**](ClO$_4$) was separated with 4:1 CH_2Cl_2:CH_3CN. Yield: ~45%, 165 mg. Elemental *Anal.* Calc. for complex [**1**]ClO$_4$: C, 52.19; H, 2.81; N, 10.74. Found: C, 52.18; H, 2.83; N, 10.76%. ^{1}H NMR data (400 MHz, in DMSO-d_6) δ_{ppm}: 8.80 (d, 1H), 8.73 (d, 1H), 8.54 (d, 2H) 8.3 (d, 1H), 8.14 (d, 2H), 8.03 (t, 2H), 7.96 (d, 1H), 7.84 (t, 2H), 7.64–7.60 (m, 3H), 7.54 (d, 1H), 7.45 (t, 2H), 7.36 (t, 2H), 7.10 (t, 2H).

2.4.2. Synthesis of the complex [*2*](ClO$_4$)$_2$

The complex [**1**]ClO$_4$ (100 mg, 0.12 mmol) was dissolved in a minimum volume of acetonitrile. To this, an aqueous $AgNO_3$ solution (0.15 M, 10 ml) was added and then heated to reflux for 1 h with constant stirring. The reaction mixture was then cool down to room temperature and filtered through a sintered glass crucible to get rid off the precipitated AgCl. After reducing the volume of the clear filtrate to ~2 ml, a pre-cooled saturated $NaClO_4$ solution (~2 ml) was added, and the resulting solution was kept in a refrigerator overnight. The precipitated complex [**2**](ClO$_4$)$_2$ was filtered off as a brown microcrystalline material. It was then dried under vacuum over P_4O_{10}. Yield: ~68%, 70 mg. Elemental *Anal.* Calc. for complex [**2**](ClO$_4$)$_2 \cdot H_2O$: C, 46.89; H, 3.45; N, 9.66. Found: C, 46.21; H, 3.33; N, 9.72%. ^{1}H NMR data (400 MHz, in DMSO-d_6) δ_{ppm}: 9.15 (d, 2H), 8.92 (d, 2H), 8.70 (d, 2H) 8.60 (t, 2H), 7.93 (d, 2H), 7.60 (t, 4H), 7.41 (d, 2H), 7.25 (t, 4H), 6.20 (d, 2H).

2.5. Crystallographic data

2.5.1. Complex [*1*](ClO$_4$)

CCDC No. 652460, $C_{34}H_{22}Cl_2N_6O_6Ru$, $M = 782.55$, orthorhombic, $a = 19.7242(3)$, $b = 15.7100(2)$, $c = 19.9264(3)$ Å, $V = 6174.54(15)$ Å^3, space group *Pbca*, $Z = 8$, $T = 298(2)$ K, μ(Mo Kα) = 0.740 mm^{-1}, $F(000) = 3152$, Goodness-of-fit = 1.033; final R indices: $R_1 = 0.0344$ [$I > 2\sigma(I)$], $wR_2 = 0.0801$; R indices (all data): $R_1 = 0.0536$, $wR_2 = 0.0898$.

2.5.2. Complex [*2*](ClO$_4$)$_2$H$_2$O

CCDC No. 652461, $C_{34}H_{22}C_{l2}N_6O_{11}Ru$, $M = 862.55$, monoclinic, $a = 8.6420(2)$, $b = 21.3292(6)$, $c = 19.0073(5)$ Å, $\beta = 91.274(2)$, $V = 3502.69(16)$ Å^3, space group $P2(1)/c$, $Z = 4$, $T = 298(2)$ K, μ (Mo Kα) = 0.671 mm^{-1}, $F(000) = 1736$, Goodness-of-fit = 0.971; final R indices: $R_1 = 0.0547$ [$I > 2\sigma(I)$], $wR_2 = 0.1362$; R indices (all data): $R_1 = 0.0823$, $wR_2 = 0.1570$.

3. Results and discussion

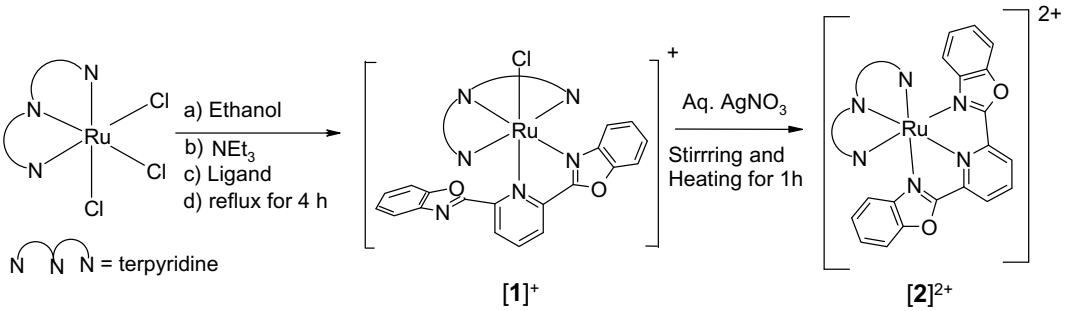
The tridentate ligand L has been synthesized by a modified reported route [25]. The reaction of L with the ruthenium–terpyridine precursor $Ru(trpy)Cl_3$ in ethanol initially afforded a dark solution, from which a dark colored solid mass has been isolated on addition of excess saturated aqueous $NaClO_4$ solution (Scheme 1). Chromatographic purification of the crude product on a silica gel column using a CH_3CN–CH_2Cl_2 mixture (1:4) as the eluent results in a reddish complex [**1**]$^+$ as its perchlorate salt (yield, 45%), followed by other products.

Complex [**1**]$^+$ exhibits satisfactory elemental analyses. The formulation of the complex has been further supported by FT-IR and ^{1}H NMR spectroscopy (Supplementary data, Figs. S1 and S2). The formation of [**1**]ClO$_4$ has also been authenticated by its single crystal X-ray structure.

Complex [**1**]$^+$, when heated for 1 h with constant stirring in the presence of aqueous $AgNO_3$ solution, affords complex [**2**]$^{2+}$ (Scheme 1). The formation of [**2**]$^{2+}$ was authenticated by elemental analysis, FT-IR and ^{1}H NMR spectroscopy, and by its single crystal X-ray structure.

3.1. Crystal structure analyses

X-ray quality single crystals were grown by slow diffusion of an acetonitrile solution of the complexes into benzene followed by the slow evaporation technique. The ORTEP plot of [RuL(terpy)Cl](ClO$_4$), [**1**]ClO$_4$, is shown in Fig. 1. In the monomeric complex, The Ru center is in a distorted octahedral arrangement with a RuN_5Cl coordination environment (Table 1). The largest distortion of the octahedral geometry is due to the geometrical constraints of the terpy ligand, which is shown by small N–Ru–N angles (Table 1) [26–29]. The ligand L is bonded to the metal center in a bidentate fashion. Both the central pyridine nitrogen atoms are in a *cis* orientation and the pyridine nitrogen atom of L is *trans* to the Cl^- ion. The nitrogen from one benzoxazole ring is in a *trans* position with respect to the central pyridine nitrogen of terpyridine. As a result, the second benzoxazole ring becomes distant from the ruthenium center and hence is not coordinated to the metal. The Ru–N distances are in the range 1.962(2)–2.122(19) Å. The average bite angles involving terpyridine/L in [**1**]ClO$_4$ are 79.50(4) and 78.59(13)°.



Scheme 1.

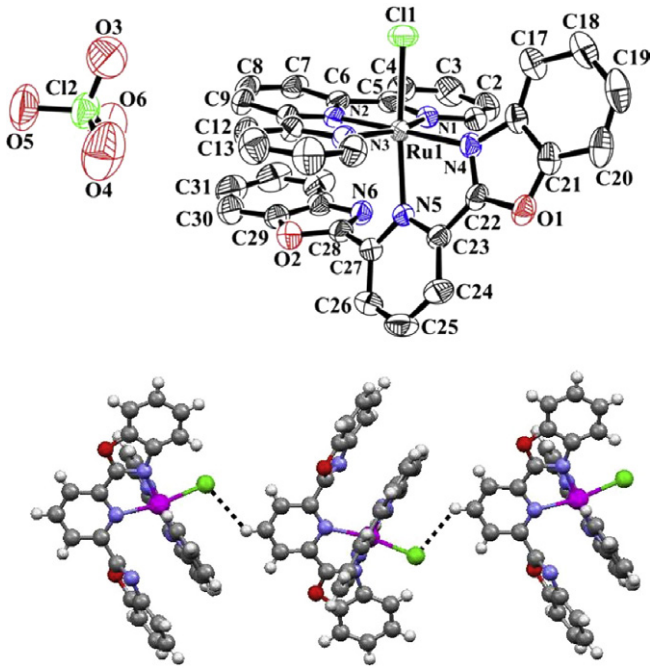


Fig. 1. ORTEP plot with 50% thermal ellipsoids (top) and an infinite chain formed by C–H···Cl interactions in complex [**1**]ClO_4.

Table 1
Selected bond lengths (Å) and bond angles (°)

N(2)–Ru(1)–N(5)	102.62(8)	177.41(16)
N(2)–Ru(1)–N(6)		99.94(16)
N(3)–Ru(1)–N(4)	97.33(8)	95.66(16)
N(3)–Ru(1)–N(5)	86.33(8)	102.53(17)
N(4)–Ru(1)–N(5)	77.66(8)	77.58(17)
N(5)–Ru(1)–Cl(1)	170.20(6)	
N(5)–Ru(1)–N(6)		77.83(16)

The bond distances and angles match well with the reported analogous ruthenium–terpy complexes [26–29]. The Ru^{II}–Cl distance, 2.3815(7) Å, in [**1**]ClO_4 is comparable to that observed in [Ru(trpy)(biq)Cl]PF_6 (biq = 2,2′-bisquinoline), 2.378(2) Å [30], but is smaller than that in other Ru^{II} complexes with a N_5Cl coordination core [31–33]. The metal bonded Cl atom forms a weak intermolecular C–H···Cl type hydrogen bond with the adjacent ligand in the solid-state, which leads to the formation of an infinite chain along the crystallographic *a* axis (Fig. 1b). One of the benzoxazole rings of L is in the plane with its central pyridine ring, while the other is in an almost perpendicular orientation. In the crystal structure both the aromatic rings form π-stacking interactions, which remain in the same plane in the solid-state. It is interesting to note that the ruthenium center is separated from the outside environment and is in buried inside the hydrophobic environment. The counter anions are lined up in a zig-zag fashion along the crystallographic *a* axis. The structure contains alternate hydrophobic and hydrophilic layers (Supplementary data, Fig. S3).

The ORTEP plot of [RuL(terpy)]$(ClO_4)_2 \cdot H_2O$, [**2**]$(ClO_4)_2 \cdot H_2O$, is shown in Fig. 2. In this complex, the RuN_6 chromophore binds the ruthenium center in a distorted octahedral geometry (Table 1). The hydrogen atoms for the solvent water molecule were not located in the electron density map. The Cl^- ion in the complex [**1**]ClO_4 has been replaced by the nitrogen atom (N6) of one of the benzoxazole moieties, which was on the opposite side of the axial Cl atom in [**1**]ClO_4. Unlike in [**1**]ClO_4, here the pyridine nitrogen of the ligand is in a *trans* orientation with respect to the central pyridine nitrogen of terpyridine. Moreover, the ligand is bonded to Ru in a tridentate fashion with both benzoxazole nitrogens in axial positions. The Ru–N distances in the complex [**2**]$(ClO_4)_2 \cdot H_2O$ are in the range 1.986(4)–2.098(4) Å. The average bite angles involving terpyridine/L are 79.80(18) and 78.32(18)°. In the solid-state there are no π-stacking interactions in this complex. Similar to the complex [**1**]ClO_4, several weak C–H···O type hydrogen bonding interactions are present in the solid-state. The metal ion is also buried inside the hydrophobic core of the molecule. Perchlorate anions and water molecules form a hydrogen bonded network in complex [**2**]$(ClO_4)_2 \cdot H_2O$. The oxygen atoms of the benzoxazole unit are in the periphery of the hydrophobic sphere. In [**2**]$(ClO_4)_2 \cdot H_2O$, counter anions along with water of crystallization formed the hydrophilic hemisphere, which is in a face-to-face arrangement in alternate layers. Complex [**2**]$(ClO_4)_2 \cdot H_2O$ formed alternate rows of square boxes in the solid-state along the crystallographic *a* axis (see Supplementary data, Fig. S4).

3.2. UV–Vis spectroscopic studies

Both the complexes, $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$, exhibit strong MLCT transitions in the visible region in acetonitrile solvent (Fig. 3). For complex $[\mathbf{1}]^+$, a band appears at 521 nm ($\varepsilon = 5960\ M^{-1}\ cm^{-1}$) and in the case of complex $[\mathbf{2}]^{2+}$, at 452 nm ($\varepsilon = 4880\ M^{-1}\ cm^{-1}$). The

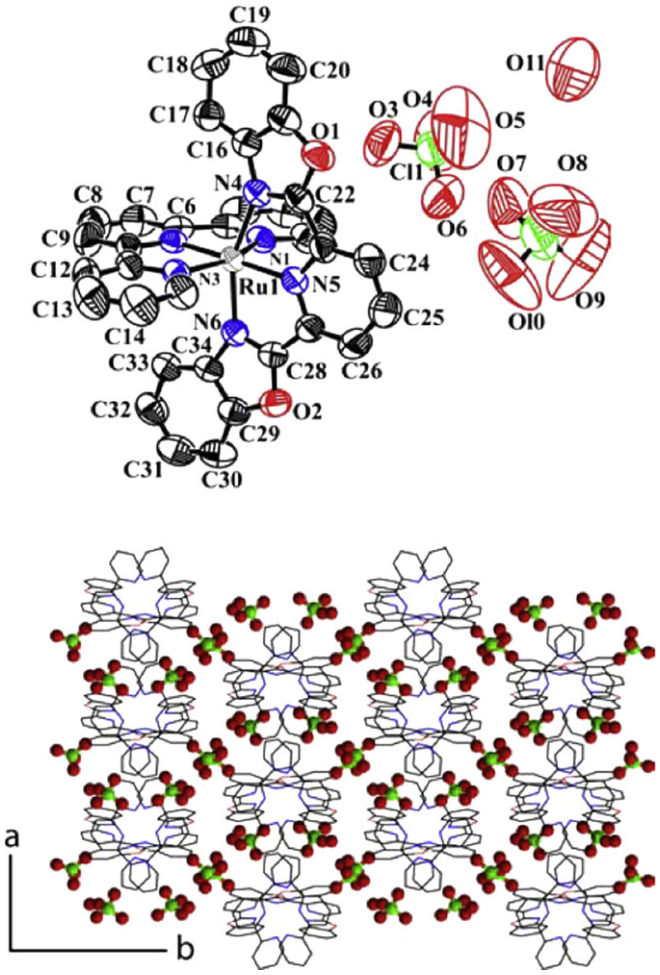

Fig. 2. ORTEP Plot with 50% thermal ellipsoids (top) and packing diagram (below) of complex $[\mathbf{2}](ClO_4)_2 \cdot H_2O$.

intra-ligand $\pi \rightarrow \pi^*$ transitions appear at 318, 272 nm ($\varepsilon = 26600$ and 17050 $M^{-1}\,cm^{-1}$) and 304, 270 nm ($\varepsilon = 23650$ and 15060 $M^{-1}\,cm^{-1}$) for complexes $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$, respectively. It is interesting to note that the MLCT band in $[Ru^{II}(trpy)(bbp)]^{2+}$ appears at 475 nm [trpy = 2,2′:6′,2″-terpyridine; bbp = 2,6-bis(benzimidazoly-2yl)pyridine] [34]. This may be attributed to the weaker π-acceptor properties of the ligand L compared to trpy or bbp [34].

The broad band at 1080–1100 cm^{-1} followed by a band at ~625 cm^{-1} in the FT-IR spectra of the complexes confirms the presence of the perchlorate anion (Supplementary data, Fig. S1). The molar conductivities (Λ_M) of complexes $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$, in acetonitrile solvent are 124 and 216 $\Omega^{-1}\,cm^2\,mol^{-1}$, respectively; which are consistent with the 1:1 and 1:2 electrolytic natures of $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$, respectively. The diamagnetic nature of the complexes is indicative of the presence of Ru(II) with a low-spin d^6 configuration.

3.3. ^1H NMR spectra

The ^1H NMR spectra of complexes $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$ were recorded in DMSO-d_6 solvent [Supplementary data, Figs. S2 and S3]. Both the complexes exhibit the calculated number of aromatic signals, overlapping between 6 and 10 ppm. In both the complexes, the symmetrical terpyridine moiety shows only six signals as expected. In $[\mathbf{1}]^+$, the ancillary ligand, L, due to its bidentate coordination mode, exhibits all eleven signals; whereas, in $[\mathbf{2}]^{2+}$, as L binds the ruthenium center in a symmetrical tridentate fashion, it shows only six signals. Attempts were not made to assign the individual signals because of the overlapping nature of the spectra.

3.4. Electrochemistry

The electron-transfer properties of the complexes $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$ have been studied in acetonitrile solvent versus SCE. The one electron reversible Ru^{II}/Ru^{III} couple appears at 0.90 and 1.44 V in the case of complex $[\mathbf{1}]^+$ and $[\mathbf{2}]^{2+}$, respectively. A representative voltammogram of complex $[\mathbf{1}]^+$ is shown in Fig. 4. The replacement of the strong donor chloride in $[\mathbf{1}]^+$ by the 'N'-donor from the benzoxazole derivative in $[\mathbf{2}]^{2+}$ results in the positive shift of the oxidation potential by ~0.54 V.

The same Ru^{II}/Ru^{III} couple appears at 1.30 and 1.11 V in the case of the complexes $[Ru^{II}(trpy)_2]^{2+}$ and $[Ru^{II}(trpy)(bbp)]^{2+}$, respectively [34,35]. The stronger ligand field strength of trpy compared to bbp or L results in the greater stabilization of the Ru(II) d_π orbitals. On the other hand, poly-imidazole or -oxazole derivatives are known as better σ-donors and weaker π-acceptors than polypyridine derivatives. The effect of these factors is reflected in the shift of the oxidation potential of the Ru^{II}/Ru^{III} couple.

The formation of $[\mathbf{2}](ClO_4)_2$ from $[\mathbf{1}]ClO_4$ can take place either *via* a five coordinated intermediate species [intermediate I] (dissociative mechanism) or through a dissociative interchange type reaction pathway [intermediate II] (Scheme 2).

However, when the same reaction was carried out in the presence of azide, pyridine or thiocyanate, no incorporation of the

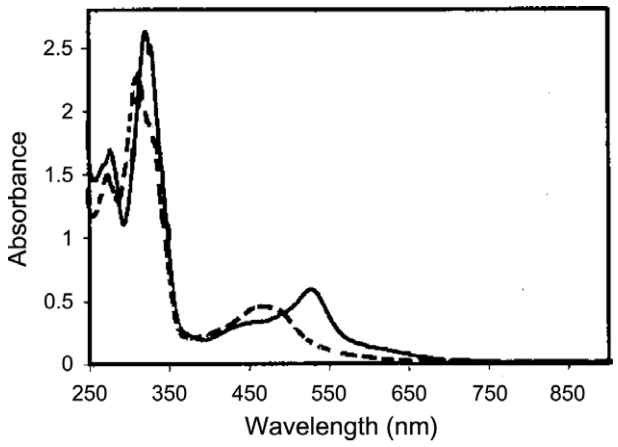

Fig. 3. UV–Vis spectra of $[\mathbf{1}]^+$ (solid line) and $[\mathbf{2}]^{2+}$ (dashed line) in acetonitrile solvent.

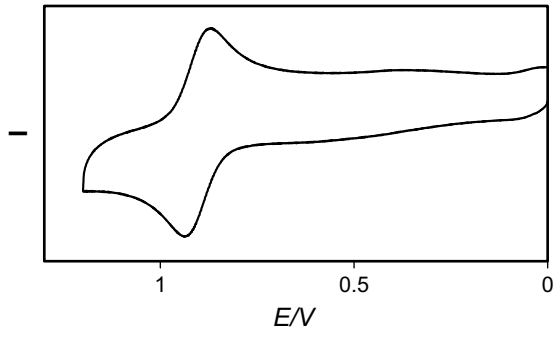

Fig. 4. Cyclic voltammogram of complex $[\mathbf{1}]^+$ in acetonitrile, SCE, TBAP supporting electrolyte, glassy carbon working electrode.

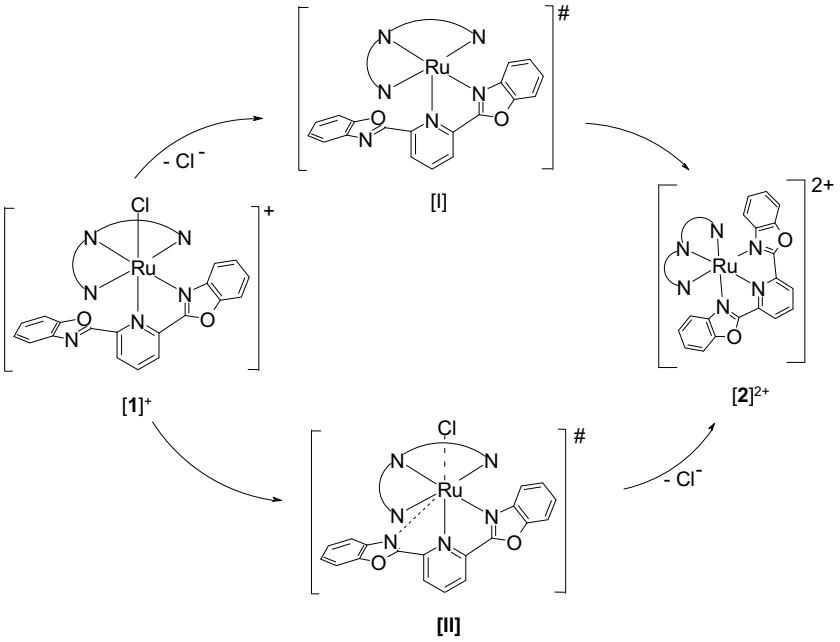

Scheme 2.

azide, pyridine or thiocyanate was found; which, in turn, indicates that the formation of $[\mathbf{2}](ClO_4)_2$ takes place through the dissociative interchange type reaction pathway rather than a dissociative mechanism which involves a pentacoordinated intermediate.

4. Conclusions

In conclusion, the present study demonstrates the synthesis, characterization, electron-transfer properties and structural aspects of a set of ruthenium monoterpyridine complexes with 2,6-bis(benzoxazol-2-yl)pyridine as an ancillary ligand. Complex $[\mathbf{1}]^+$ undergoes an intramolecular dissociative interchange type substitution in the presence of aqueous $AgNO_3$ solution to afford complex $[\mathbf{2}]^{2+}$. Complex $[\mathbf{2}]^{2+}$ represents an unique example where the ruthenium center is encapsulated by a hydrophobic and a hydrophilic hemisphere, which are in planes perpendicular to each other.

ABSTRACT

Treatment of $Fe(NCE)_2$ (E = S or Se) with 1 equiv. of tris-(3,5-dimethylpyrazol-1-yl)methane (tpm′) yields dimeric $[\{Fe(NCE)(\mu\text{-}NCE)(tpm')\}_2]$. These dimers are cleaved in MeCN solution, yielding isolable $[Fe(NCE)_2(tpm')(NCMe)]$, whose solvent ligands can be substituted by moderately basic heterocycle donors to give $[Fe(NCE)_2(tpm')(py)]$, $[Fe(NCS)_2(tpm')(im)]$ or $[\{Fe(NCE)_2(tpm')\}_2(\mu\text{-}4,4'\text{-bipy})]$. The monodentate heterocycles in the latter compounds are readily lost in most solvents, regenerating the dimeric starting materials. $[Fe(NCS)_2(tpm')(py)]$ was also prepared by reacting $[Fe(NCS)_2(py)_4]$ with tpm′. The mononuclear compounds are all high-spin between 5 and 300 K, despite mostly having regular coordination geometries and tpm′ ligand conformations that should in principal favour spin-crossover. Analogous products containing unsubstituted tris-(pyrazol-1-yl)methane (tpm) could not be isolated, but the crystal structure of the double salt $[Fe(tpm)_2][Fe(NCS)_5(py)]$, containing a new iron(III) anion, is described.

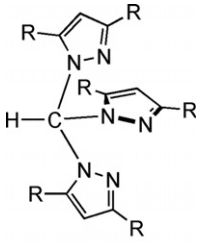
1. Introduction

There is strong continued interest in the synthesis and structural and physical chemistry of spin-crossover materials, whose magnetic moment, dielectric constant and colour can all be switched reversibly upon application of temperature, light or other physical stimuli [1]. By far the majority of spin-crossover research is performed using six-coordinate iron(II) complexes of N-donor ligands, since that is the metal–ligand combination that most reliably exhibits the phenomenon, and is most likely to show novel physical behaviour when it does. Most known spin-crossover compounds of this type can be grouped into two classes, of formula $[FeL_6]^{2+}$ (where L is an amine or imine ligand, or an N-donor group in a larger polydentate ligand framework) or $[Fe(NCE)_2L_4]$ (where $NCE^- = NCS^-$, $NCSe^-$ or another N-donor pseudohalide) [2]. With this in mind, as part of our own continuing research in this area [3] we decided to pursue complexes of formula $[Fe(NCE)_2(tpm)L]$. We were particularly interested in polynuclear compounds containing multiple $[Fe(NCE)_2(tpm)]$ centres linked by bridging heterocyclic ligands, whose iron centres could undergo spin-crossover independently of each other. The interplay between covalently linked spin centres in spin-crossover compounds can lead to unusual cooperative switching behaviour that is not found in mononuclear complexes [4].



Several iron complexes of tris-pyrazolylmethane ligands are known. Salts of $[Fe(tpm)_2]^{2+}$ are low-spin at room temperature but can undergo thermal spin-transitions on heating [5–9]. Several homoleptic complexes of analogous ligands substituted at the pyrazole rings also undergo spin-crossover, at reduced temperatures that are more tractable for detailed study [9–11]. Heteroleptic half-sandwich complexes of tris-pyrazolylmethane coligands are less common, although mononuclear $[Fe(tpm)(solv)_3]^{2+}$ (solv = H_2O or CH_3CN) [12], $[Fe(tpm)(NCS)_2]$ [5,6] and a small number of dinuclear and polynuclear complexes containing $[Fe(tpm)]^{2+}$ centres [13,14] have been reported. All of the latter are high-spin at room temperature and below, where that has been measured.

2. Experimental

All manipulations were carried out in air, using undried reagent-grade solvents. Tris(3,5-dimethylpyrazol-1-yl)methane (tpm′) [15], $[Fe(NCS)_2(py)_4]$ [16] and $[Fe(NCS)_2(pyz)_2]$ [17] were prepared by the reported methods, while all other organic and inorganic reagents were purchased commercially and used as supplied.

2.1. Synthesis of [{Fe(NCS)(μ-NCS)(tpm′)}$_2$] (**1**)

A methanolic solution (40 cm^3) of $Fe[ClO_4]_2 \cdot 6H_2O$ (1.45 g, 4.0 mmol) and a pinch of ascorbic acid was added gradually to a solution of NaNCS (0.64 g, 8.0 mmol) in MeOH (80 cm^3). Tpm′ (1.19 g, 4.0 mmol) in MeOH (40 cm^3) was added to the solution, yielding a white precipitate. This was collected by filtration, washed with MeOH and dried under reduced pressure. Yield 1.10 g, 58%. Calc. for $C_{36}H_{44}Fe_2N_{16}S_4$: C, 46.0; H, 4.71; N, 23.8; S, 13.6. Found: C, 45.6; H, 4.65; N, 23.5; S, 13.4%. ESMS: *m*/*z* 882 $[^{56}Fe_2(tpm')_2(NCS)_3]^+$, 412 $[^{56}Fe(tpm')(NCS)]^+$. IR (Nujol): 2115, 2076 (ν{N=CS}) cm^{-1}.

2.2. Synthesis of [{Fe(NCSe)(μ-NCSe)(tpm′)}$_2$] (**2**)

Method as for (**1**), using KNCSe (1.15 g, 8.0 mmol). The product precipitated from MeOH as an off-white powder. Yield 1.48 g, 65%. Calc. for $C_{36}H_{44}Fe_2N_{16}Se_4$: C, 38.3; H, 3.93; N, 19.9. Found: C, 38.1; H, 3.90; N, 19.6%. ESMS: *m*/*z* 1024 $[^{56}Fe_2(tpm')_2(NCSe)_3]^+$. IR (Nujol): 2115, 2081 (ν{N=CSe}) cm^{-1}.

2.3. Synthesis of [Fe(NCS)$_2$(tpm′)(CH$_3$CN)] · H$_2$O (**3** · H$_2$O)

A solution of **1** (0.24 g, 0.25 mmol) in acetonitrile (30 cm^3) was refluxed for 90 min. The solution was cooled to room temperature and concentrated to *ca.* 5 cm^3 volume. Slow diffusion of diethyl ether vapour through the filtered solution gave pale brown crystals of the product, contaminated by unreacted **1** as a white powder that was removed by decantation. Yield 0.11 g, 49%. Calc. for $C_{20}H_{25}FeN_9S_2 \cdot H_2O$: C, 45.4, H, 5.14; N, 23.8; S, 12.1. Found: C, 45.7; H, 5.15; N, 24.2; S, 12.3%. ESMS: *m*/*z* 882 $[^{56}Fe_2(tpm')_2(NCS)_3]^+$, 412 $[^{56}Fe(tpm')(NCS)]^+$. IR (Nujol): 2304, 2271 (ν{N≡CCH$_3$}), 2083 (ν{N=CS}) cm^{-1}.

2.4. Synthesis of [Fe(NCSe)$_2$(tpm′)(CH$_3$CN)] (**4**)

Method as for **3**, starting from **2** (0.28 g, 0.25 mmol). The product formed pale yellow crystals from MeCN/Et$_2$O. Yield 0.11 g, 45%. Calc. for $C_{20}H_{25}FeN_9Se_2$: C, 39.7; H, 4.16; N, 20.8. Found: C, 39.9; H, 4.30; N, 21.0%. ESMS: *m*/*z* 458 $[^{56}Fe(tpm')(NCSe)]^+$. IR (Nujol): 2302, 2270 (ν{N≡CCH$_3$}), 2083 (ν{N=CSe}) cm^{-1}.

2.5. Synthesis of [Fe(NCS)$_2$(tpm′)(py)] (**5**)

2.5.1. Method A

Solutions of tpm′ (0.30 g, 1.0 mmol) and $[Fe(NCS)_2(py)_4]$ (0.49 g, 1.0 mmol) in dichloromethane (both 25 cm^3) were slowly mixed at room temperature, and the resultant solution heated to reflux for 40 min. The cooled, violet solution was concentrated to *ca.* 10 cm^3, and filtered. Slow diffusion of excess diethyl ether vapour into the solution gave dark red crystals of the product. Yield 0.42 g, 85%. Calc. for $C_{23}H_{27}FeN_9S_2$: C, 50.3; H, 4.95; N, 22.9; S, 11.7%. Found: C, 50.0; H, 4.90; N, 23.0; S, 11.5%. ESMS: *m*/*z* 412 $[^{56}Fe(tpm')(NCS)]^+$. IR (Nujol): 2071 (ν{N=CS}) cm^{-1}.

2.5.2. Method B

Solutions of pyridine (0.12 g, 1.5 mmol) in acetonitrile (10 cm^3), and of **1** (0.24 g, 0.25 mmol) in acetonitrile (20 cm^3), were slowly mixed, and the resultant solution was refluxed for 30 min. The cooled solution was concentrated to *ca.* 5 cm^3 volume and filtered. Slow diffusion of diethyl ether vapour into the solution afforded yellow microcrystals. Yield 0.14 g, 51%. Calc. for $C_{23}H_{27}FeN_9S_2$: C, 50.3; H, 4.95; N, 22.9; S, 11.7. Found: C, 50.3; H, 4.95; N, 23.1; S, 11.6%. ESMS: *m*/*z* 412 $[^{56}Fe(tpm')(NCS)]^+$. IR (Nujol): 2070, 2093 (ν{N=CS}) cm^{-1}.

2.6. Synthesis of [Fe(NCSe)$_2$(tpm′)(py)] (**6**)

Method B for **5** was followed, using **2** (0.28 g, 0.25 mmol). Slow diffusion of diethyl ether vapour into the filtered reaction mixture gave yellow crystals of the product. Yield 0.16 g, 58%. Calc. for $C_{23}H_{27}FeN_9Se_2$: C, 42.9; H, 4.23; N, 19.6. Found: C, 43.1; H, 4.20; N, 19.7%. ESMS: *m*/*z* 458 [^{56}Fe(tpm′)(NCSe)]$^+$. IR (Nujol): 2076 (ν{N=CSe}) cm^{-1}.

2.7. Synthesis of [Fe(NCS)$_2$(tpm′)(im)] (**7**)

A solution of imidazole (0.10 g, 1.5 mmol) in acetonitrile (10 cm^3) was gradually added to a solution of **1** (0.24 g, 0.25 mmol) in acetonitrile (20 cm^3). The resultant solution was refluxed for 30 min, then cooled and concentrated to *ca.* 5 cm^3 volume. Slow diffusion of diethyl ether vapour into the filtered solution afforded red crystals. Yield 0.09 g, 37%. Calc. for $C_{21}H_{26}FeN_{10}S_2$: C, 46.8; H, 4.87; N, 26.0; S, 11.9. Found: C, 47.0; H, 4.90; N, 26.1; S, 11.8%. ESMS: *m*/*z* 412 [^{56}Fe(tpm′)(NCS)]$^+$. IR (Nujol): 2070 (ν{N=CS}) cm^{-1}.

2.8. Synthesis of [{Fe(NCS)$_2$(tpm′)}$_2$(μ-4,4′-bipy)] · H$_2$O (**8** · H$_2$O)

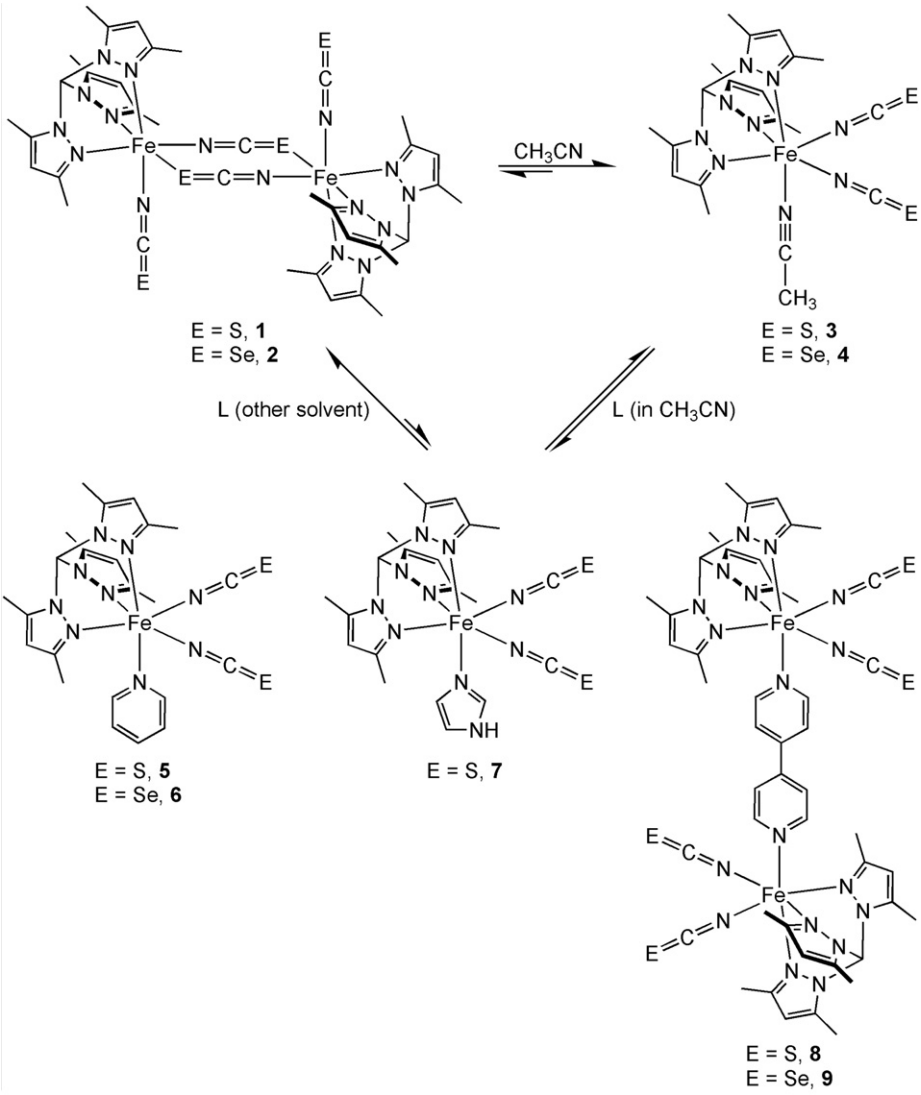
Method as for **7**, using, 4′-bipy (0.16 g, 1.0 mmol). Slow diffusion of diethyl ether vapour into the filtered reaction mixture gave dark red crystals. Yield 0.11 g, 45%. Calc. for $C_{46}H_{52}Fe_2N_{18}S_4 \cdot H_2O$: C, 49.6; H, 4.88; N, 22.6; S, 11.5. Found: C, 49.6; H, 4.75; N, 22.2; S, 11.5%. ESMS: *m*/*z* 882 [^{56}Fe$_2$(L)$_2$(NCS)$_3$]$^+$. IR (Nujol): 2079, 2058 (ν{N=CS}) cm^{-1}.

2.8.1. Synthesis of [{Fe(NCSe)$_2$(tpm′)}$_2$(μ-4,4′-bipy)] (**9**)

Method as for **7**, using **2** (0.28 g, 0.25 mmol) and 4,4′-bipy (0.16 g, 1.0 mmol). The product formed orange crystals from acetonitrile/diethyl ether. Yield 0.19 g, 60%. Calc. for $C_{46}H_{52}Fe_2N_{18}Se_4$: C, 43.0; H, 4.08; N 19.6. Found: C, 43.0; H, 4.35; N, 19.9%. ESMS: *m*/*z* 1024 [^{56}Fe$_2$(tpm′)$_2$(NCSe)$_3$]$^+$. IR (Nujol): 2061 (ν{N=CSe}) cm^{-1}.

2.9. Single crystal X-ray structure determinations

Single crystals of [Fe(tpm)$_2$][Fe(NCS)$_5$(py)] · 2CH$_3$CN (**10** · 2CH$_3$CN) were obtained from a reaction of [Fe(NCS)$_2$(py)$_4$] and 1 equiv. tpm in acetonitrile, following method A described above for **5**. Slow diffusion of diethyl ether vapour into the concentrated reaction mixture yielded a small number of dark red crystals, contaminated by a sticky white impurity. All other single crystals in this work were grown by slow diffusion of diethyl ether vapour into acetonitrile solutions of the preformed products. Experimental details for the structure determinations are given in Table 1. Diffraction data for **3** · 2CH$_3$CN and **9** · 4CH$_3$CN were



Scheme 1. Solution stabilities of the [Fe(NCE)$_2$(tpm′)L] complexes in this work.

measured on a Nonius KappaCCD area detector diffractometer, using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) from a sealed tube source. The other four datasets were obtained using a Bruker X8 Apex diffractometer using graphite-monochromated Mo Kα radiation generated by a rotating anode. The structures were all solved by direct methods [18], then developed by least squares refinement on F^2 [19].

The asymmetric units of **5** and **7** contain two unique molecules, labelled 'A' and 'B', while that of **9** · $4CH_3CN$ contains half a formula unit with the 4,4′-bipy ligand spanning the crystallographic inversion centre at 1/2, 1/2, 1/2. There are two half-cations in the asymmetric unit of **10** · $2CH_3CN$, also labeled 'A' and 'B', whose iron atoms lie on the inversion centres 0, 1/2, 0 and 1/2, 1/2, 1/2, and a complete anion lying on a general position. One of the two unique solvent molecules in **9** · $4CH_3CN$ is disordered over two equally occupied sites, which were refined using the fixed restraints C–C = 1.45(2), C≡N = 1.14(2) and 1,3-C···N = 2.59(2) Å. No disorder was detected in any of the other structures. All non-H atoms in all six structures were refined anisotropically, and all H atoms were placed in calculated positions and refined using a riding model, with methyl group torsions allowed to refine freely.

3. Other measurements

Electrospray mass spectra were obtained using a Waters Micromass LCT TOF spectrometer, from MeCN solution. C, H, N and S microanalyses were performed by the University of Leeds Department of Chemistry microanalytical service. NMR spectra were obtained using a Bruker DPX300 spectrometer, operating at 300.1 MHz (^{1}H) or 75.5 MHz (^{13}C). Infra-red spectra were obtained as KBr disks, between 400 and 4000 cm^{-1} using a Nicolet Avatar 360 spectrophotometer. Variable temperature magnetic susceptibility measurements were obtained in the solid state using a Quantum Design SQUID magnetometer in an applied field of 1000 G. Diamagnetic corrections for the sample (from Pascal's constants [20]) and the sample holder were applied to the data.

4. Results and discussion

Our first approach towards this work was to react tpm or tpm′ with preformed iron(II) thiocyanato precursors. Treatment of $[Fe(NCS)_2(py)_4]$ (py = pyridine) [16] with 1 equiv. of tpm′ in refluxing CH_2Cl_2 yielded dark red crystalline $[Fe(NCS)_2(tpm')(py)]$ (compound **5**, see below) in 85% yield. A similar reaction using tpm did not afford a clean product, however. Some insight into this result was provided when recrystallisation of the crude product from MeCN/Et_2O gave a small number of crystals, of formula $[Fe^{II}(tpm)_2][Fe^{III}(NCS)_5(py)] \cdot 2CH_3CN$ (see below). Although we were unable to isolate a bulk sample of that compound in pure form, it is clearly the product of a ligand disproportionation reaction, with concomitant aerobic oxidation of a fraction of the iron content of the sample. Since the desired product in this initial study (**5**) was obtained using tpm′ but not tpm, the subsequent work described below employed exclusively tpm′ as tridentate ligand. No reaction was observed between $[Fe(NCS)_2(pyz)_2]$ (pyz = pyrazine) [17] and either tpm or tpm′, in CH_2Cl_2 or MeCN. This presumably reflects the insolubility of that 3D coordination polymer iron(II) starting material [21].

In order to find a more general route to $[Fe(NCE)_2(tpm')L]$ (E = S, Se) compounds, the base-free starting materials "$[Fe(NCE)_2(tpm')]$" were synthesised by reacting tpm′ in MeOH with 1 equiv. of $Fe(NCE)_2$ (formed *in situ* from $[Fe[ClO_4]_2 \cdot 6H_2O$ and 2 equiv. NaNCS or KNCSe, in the presence of ascorbic acid to inhibit aerial oxidation of the iron). The white solid products precipitated from the reaction mixtures in *ca.* 60% yield. We assign dinuclear structures to these products, $[\{Fe(NCE)(\mu\text{-}NCE)(tpm')\}_2]$ (E = S, **1**; E = Se, **2**) for two reasons. First, is the observation of a very strong molecular ion corresponding to $[Fe_2(NCE)_3(tpm')_2]^+$ by electrospray mass spectrometry, at m/z = 992 for **1** (E = S) and 1024 for **2** (E = Se). Second, is the presence of two strong peaks in the triple bond region of their IR spectra, one at 2076–2081 cm^{-1} and the other at 2115 cm^{-1}. These can be assigned to the ν{CN} stretches from terminal and bridging thiocyanato or selenocyanato groups, respectively [22]. In that regard, the IR spectra resemble that of the only comparable dinuclear iron(II) compound to have been crystallographically characterised, $[\{Fe(NCS)(\mu\text{-}NCS)(Me_3tacn)\}_2]$ (Me_3tacn = 1,4,7-trimethyl-1,4,7-triazacyclononane), which exhibits ν{CN} = 2020 and 2070 cm^{-1} [23]. While crystalline $[\{Fe(NCNCN)(\mu\text{-}NCNCN)(tpm)\}_2]$ has a similar dinuclear structure to that proposed for **1** and **2** [13], syntheses of apparently distinct forms of $[Fe(NCS)_2(tpm)]$ with mononuclear (ν{CN} = 2058 cm^{-1}) [6] and "polymeric" (2060, 2095 and 2105 cm^{-1}) structures [5] have been

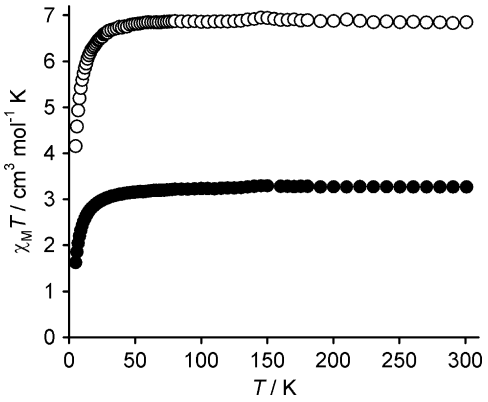


Fig. 1. Variable temperature magnetic data for **5** (red form, ●) and **8** · H_2O (○). Data from **6** and **7** are essentially identical to those of **5**, while the behaviour of **9** closely resembles that of **8** · H_2O.

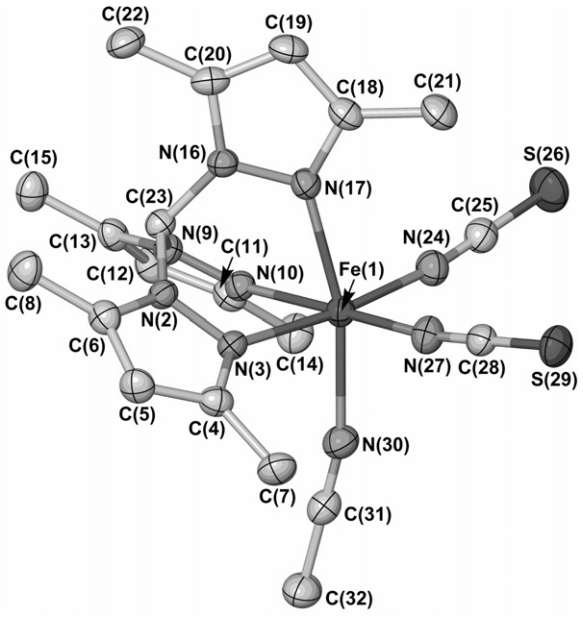

Fig. 2. View of the $[Fe(NCS)_2(tpm')(NCCH_3)]$ molecule in the crystal structure of **3** · $2CH_3CN$. All H atoms have been removed, and thermal ellipsoids are at the 50% probability level. The $[Fe(NCSe)_2(tpm')(NCCH_3)]$ molecule in **4** · $2CH_3CN$ is visually indistinguishable from the one shown, and uses the same atom numbering scheme with 'S' replaced by 'Se'.

reported before. Notably, the IR spectra of both the latter materials are quite distinct from those of **1** and **2**.

Recrystallisation of **1** or **2** from MeCN/Et_2O affords isostructural, solvated crystals of [Fe(NCE)$_2$(tpm′)(NCCH$_3$)] (E = S, **3**; E = Se, **4**), showing that the $[Fe_2(\mu\text{-NCE})_2]^{2+}$ bridges in **1** and **2** can be cleaved by Lewis bases. Compound **4** is obtained in pure form by this method but **3** is always contaminated by unreacted **1**, that can be removed from the freshly prepared crystals by decantation. Treatment of **1** or **2** with a 3-fold excess of pyridine, imidazole or 4,4′-bipyridine in refluxing MeCN affords polycrystalline [Fe(NCE)$_2$(tpm′)(py)] (E = S, **5**; E = Se, **6**), [Fe(NCS)$_2$(tpm′)(im)] (**7**; im = imidazole) and [{Fe(NCE)$_2$(tpm′)}$_2$(μ-bipy)] (E = S, **8**; E = Se, **9**) after the usual work-up. Reaction of **2** with imidazole gave an impure product, for reasons that are unclear, while reactions using pyrazine (pyz) as base afforded **3** and **4** instead of the desired [Fe(NCE)$_2$(tpm′)(pyz)] or [{Fe(NCE)$_2$(tpm′)}$_2$(μ-pyz)]. The choice of solvent is important in these reaction, since analogous procedures carried out in CH_2Cl_2, $CHCl_3$ or $MeNO_2$ led to unchanged **1** and **2** as the only isolable products. Recrystallisation of preformed **3**-**9** from a chlorinated solvent also caused their decomposition to **1** or **2**.

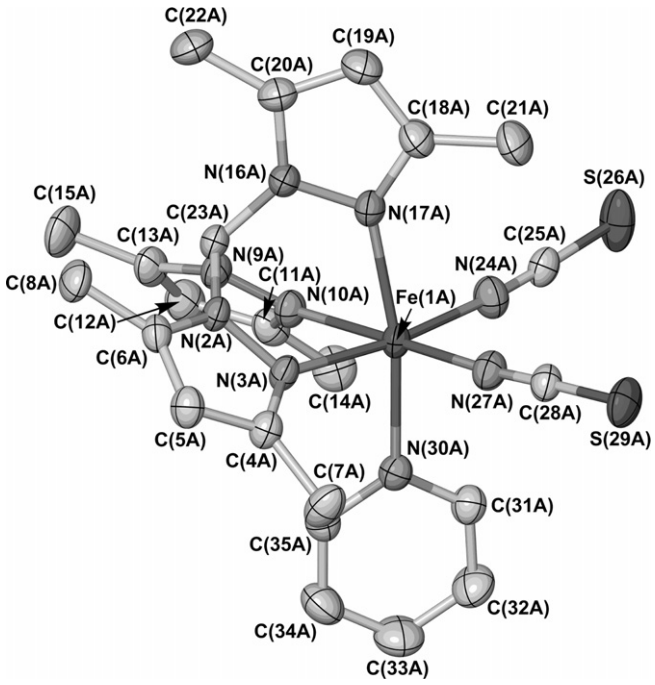

Fig. 3. View of the [Fe(NCS)$_2$(tpm′)(py)] molecule A in the crystal structure of **5**. All H atoms have been removed, and thermal ellipsoids are at the 50% probability level. Molecule B shows only small visual differences from molecule A, and uses the same atom numbering scheme.

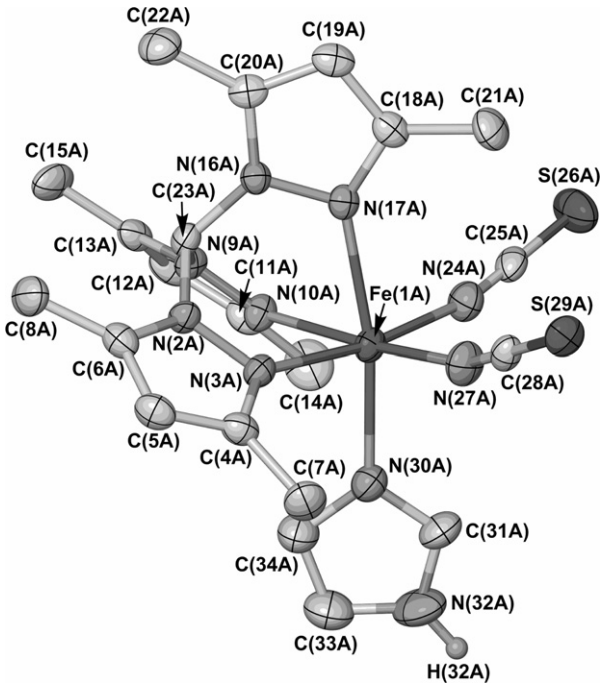

Fig. 4. View of the [Fe(NCS)$_2$(tpm′)(im)] molecule A in the crystal structure of **7**. All C-bound H atoms have been removed, and thermal ellipsoids are at the 50% probability level. Molecule B shows only small visual differences from molecule A, and uses the same atom numbering scheme.

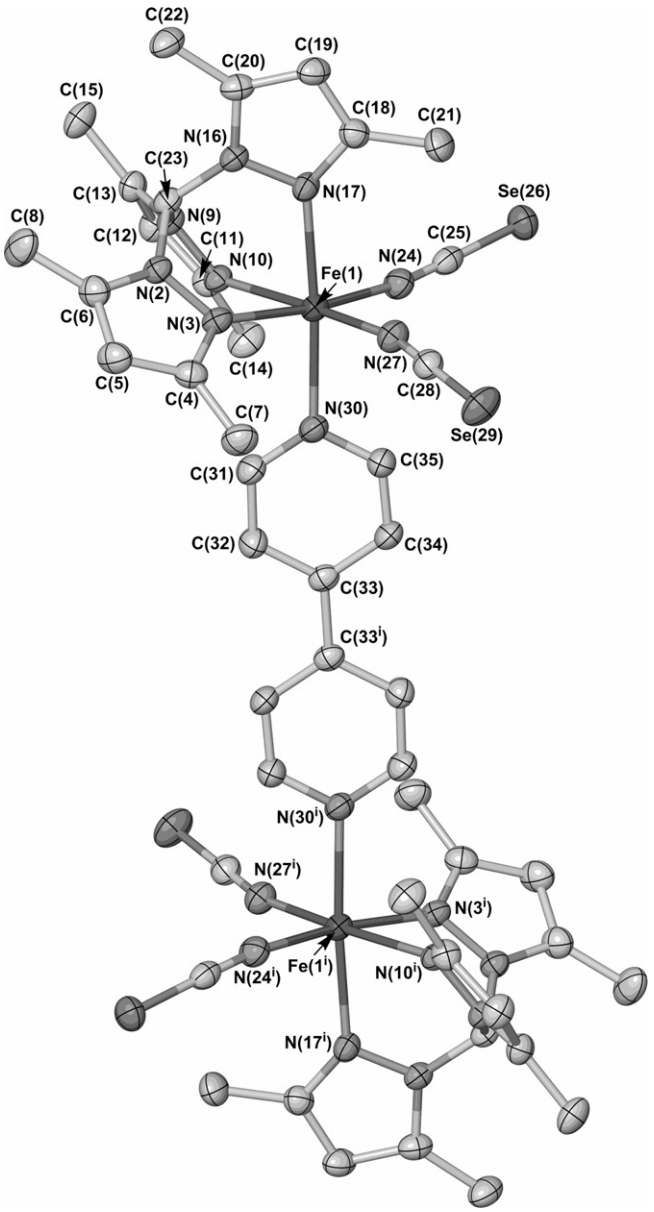

Fig. 5. View of the [{Fe(NCSe)$_2$(tpm′)}$_2$(μ-4,4′-bipy)] molecule in the crystal structure of **9** · 4CH$_3$CN. All H atoms have been removed, and thermal ellipsoids are at the 50% probability level. Symmetry code: (i) $1-x$, $1-y$, $1-z$.

These results imply that the monodentate 'L' ligand in [Fe(NCE)$_2$(tpm′)L] is only weakly coordinated and is readily lost in solution, leading to precipitation of sparingly soluble **1** and **2** from most solvents (Scheme 1). In acetonitrile solution the weakly binding solvent is present in large excess, and the more soluble **3** and **4** are the dominant species in that solvent. The CH_3CN ligand in **3** and **4** is itself substituted by stronger bases, so that **5**–**9** can be crystallised from acetonitrile but not from other solvents (Scheme 1). Presumably, pyrazine is not basic enough to displace CH_3CN from **3** and **4** under these conditions.

Interestingly, **5** was isolated in two crystal forms from different solvents, with red and yellow colouration (the crystal structure described below is of the red crystals). Both forms are solvent-free by microanalysis, but show slightly different IR spectra (see below). In the absence of a crystal structure of the yellow polymorph, the cause of their different colouration is unclear.

The dried solids **3**–**9** all analyse cleanly as the solvent-free compounds, except for **3** and **8** whose microanalyses are more consistent with monohydrate formulations, **3** · H_2O and **8** · H_2O. The water content in **3** · H_2O presumably arises from partial replacement of the lattice solvent in freshly prepared crystals (see below) by atmospheric moisture upon exposure to air. Their Nujol mull IR spectra all contain one strong ν{CN} vibration at between 2058 and 2093 cm^{-1}, except for the yellow form of **5** and **8** · H_2O where two peaks were seen in this range. These values are typical for high-spin iron(II) isothiocyanato and isoselenocyanato complexes [21,24]. The weak doublet in the triple bond region expected from a coordinated acetonitrile molecule was also present in the IR spectra of **3** · H_2O and **4**, around 2270 and 2303 cm^{-1} [25]. Electrospray mass spectra of **3** · H_2O–**9** all show the molecular ions $[Fe_2(NCE)_3(tpm')_2]^+$ and/or $[Fe(NCE)(tpm')]^+$ only, with no peaks attributable to the parent octahedral adducts being observed. Their paramagnetic ^{1}H NMR spectra in $CDCl_3$ are also unusually broadened for high-spin iron(II) species, and could not be unambiguously analysed. Both these latter observations are consistent with our conclusion, that the monodentate ligands in these compounds are very labile in solution.

Variable temperature magnetic measurements were performed on powder samples of **5**–**9**. All the compounds show an effectively constant $\chi_M T$ between 50 and 300 K, at 3.3–3.4 cm^3 mol^{-1} K for **5**–**7** and 6.7–6.8 cm^3 mol^{-1} K for **8** · **H_2O** and **9** (Fig. 1). These are typical values for high-spin mononuclear and dinuclear iron(II) centres, and their invariability over this temperature range shows the compounds all remain high-spin on cooling [20]. In all cases, $\chi_M T$ decreases increasingly rapidly on further cooling below 50 K, which is not caused by a spin-transition but reflects zero-field splitting of the $S = 2$ iron spin manifold [20]. Notably there is no unambiguous evidence for superexchange between the iron centres in **8** · H_2O and **9**, which must therefore be very weak. That is reasonable, given that the only intramolecular pathway for superexchange between the metal atoms is nine covalent bonds long.

Single crystal *X*-ray structures were obtained from crystals of **3** · 2CH_3CN, **4** · 2CH_3CN, the red crystal form of **5**, **7** and **9** · 4CH_3CN (Figs. 2–5). Single crystals of **8** grown from acetonitrile/diethyl ether are apparently isostructural with **9** · 4CH_3CN but suffered from twinning [unit cell data: monoclinic, 2/*m*, $a = 10.6434(14)$, $b = 18.755(2)$, $c = 16.245(2)$ Å, $\beta = 99.523(8)°$, $V = 3198.1(7)$ Å^3 at 150 K]. All the compounds for which a full refinement was obtained contain the expected six-coordinate iron(II) centres, with Fe–N bond lengths in the usual range for high-spin compounds (Table 2) [26]. The crystals of **5** and **7** both contain two unique molecules in their asymmetric units, whose metric parameters show only small differences. The dinuclear molecule of **9** spans a crystallographic inversion centre, giving a single unique iron centre; the intramolecular Fe...Fe distance in that compound is

11.5617(7) Å. Intermolecular N–H···S hydrogen bonding between imidazole and NCS^- ligands occurs in **7**, leading to a 2D hydrogen bond array with a strongly puckered 6^3 honeycomb topology. There are no noteworthy intermolecular interactions in the other crystals.

Several structural indices have been used to quantify different types of angular structural distortion in six-coordinate metal complexes [27]. This can have a bearing on whether a high-spin complex undergoes spin-crossover on cooling, because a compound may be trapped in its high-spin state if its metal coordination sphere or ligand conformation exhibits a large angular structural distortion compared to the expected low-spin structure [11,28–30]. The angular motion of the ligands that would accompany spin-crossover would then be inhibited by intermolecular contacts. The most general ways of quantifying any angular distortion of a six-coordinate complex from an ideal octahedral geometry are *via* two indices. First is $\sum$, which measures local angular distortions of the octahedral donor set (Eq. (1)):

$$\sum = \sum_{i=1}^{12} |90 - \alpha_i| \quad (1)$$

where α_i are the twelve *cis*-N–Fe–N angles in the coordination sphere [27]. Second is Θ, which defines the degree of trigonal distortion of the N donor atoms from an octahedral geometry towards a trigonal prism (Eq. (2)):

$$\Theta = \sum_{j=1}^{24} |60 - \theta_j| \quad (2)$$

where θ_j are the 24 unique N–Fe–N angles measured on the projection of two triangular faces of the octahedron along their common pseudo-threefold axis [31]. An ideal octahedron would give $\sum$ and $\Theta = 0$. Compounds **3**–**9** exhibit a narrow range of values for $\sum$ and Θ that are unusually low for high-spin iron(II) complexes (Table 3) [27,31], showing they have near-regular octahedral coordination geometries.

Also listed in Table 3 is τ, the average of the three Fe(1)–N–N–C(23) torsions to the tpm′ pyrazolyl groups. This has a strong bearing on the ability of homoleptic complexes of tris-pyrazolylborate or tris-pyrazolylmethane derivatives to undergo spin-crossover, which is inhibited when τ is large [11,29,30]. The τ values exhibited by **3**–**9** span the previously observed range, encompassing values that should be both consistent (**3**–**5**) and inconsistent (**9**) with a thermal spin-transition [29]. Hence, there are no consistent angular distortions in these molecules that could explain why none of them undergoes spin-crossover.

The asymmetric unit of $[Fe(tpm)_2][Fe(NCS)_5(py)] \cdot 2CH_3CN$ (**10** · $2CH_3CN$) contains two unique, centrosymmetric $[Fe(tpm)_2]^{2+}$ half-cations, and a whole $[Fe(NCS)_5(py)]^{2-}$ anion lying on a general position (Fig. 6, Table 4). The cations are clearly low-spin at the temperature of measurement (150 K), consistent with other salts

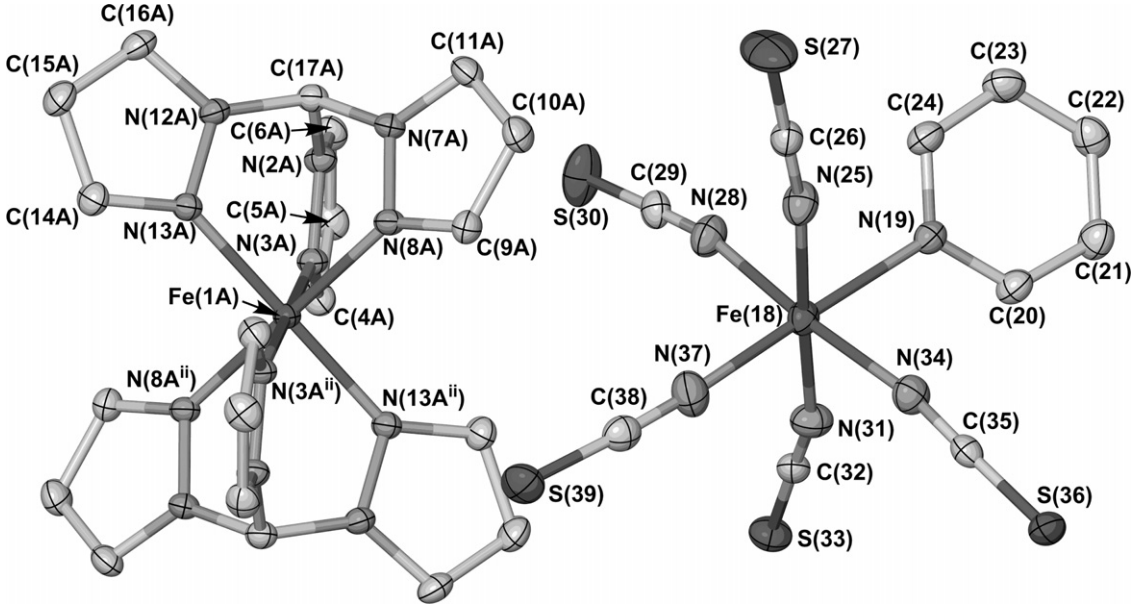

Fig. 6. View of the $[Fe(tpm)_2]^{2+}$ cation A, and the $[Fe(NCS)_5(py)]^{2-}$ anion, in the crystal structure of **10** · $2CH_3CN$. All H atoms have been removed, and thermal ellipsoids are at the 50% probability level. Cation B is visually indistinguishable from cation A, and uses the same atom numbering scheme. Symmetry code: (ii) $-x, 1-y, -z$.

of $[Fe(tpm)_2]^{2+}$ which are all low-spin at room temperature [5–9]. The $[Fe(NCS)_5(py)]^{2-}$ anion is new, and shows Fe–N distances that are consistent with a high-spin iron(III) centre [26]. The Fe–N(pyridine) bond is substantially longer than the five Fe–NCS bonds, reflecting its lower π-donor character. While the Fe–NCS distances vary between 2.0198(14) and 2.0826(14) Å, there is no obvious correlation between these parameters and the position of the NCS^- ligands relative to the pyridine donor. Unfortunately, no magnetochemical or spectroscopic characterisation of **10** was possible, owing to the very small amounts of pure material available.

5. Conclusion

The $[Fe_2(\mu\text{-}NCE)_2]^{2+}$ (E = S or Se) bridge in **1** and **2** is cleaved in acetonitrile solution, yielding the mononuclear adducts $[Fe(NCE)_2(tpm')(NCMe)]$ (**3** and **4**) whose solvent ligands can be substituted by moderately basic heterocycle donors to give $[Fe(NCE)_2(tpm')L]$ (L = pyridine, imidazole or 1/2[4,4′-bipy]; **5**-**9**). The monodentate 'L' ligands in **5**–**9** are only weakly coordinated, being readily lost in solvents other than acetonitrile to reform **1** and **2**. Analogous complexes of the unsubstituted tpm ligand could not be isolated, apparently owing to competing ligand disproportionation reactions. Crystals of $[Fe(tpm)_2][Fe(NCS)_5(py)] \cdot 2CH_3CN$ (**10** · $2CH_3CN$), containing the new $[Fe^{III}(NCS)_5(py)]^{2-}$ anion, were isolated from one such reaction. Compounds **5**-**9** are all high-spin between 5 and 300 K, despite mostly having regular coordination geometries and tpm′ ligand conformations that should favour spin-crossover. Presumably, the ligand field exerted by the $[Fe(NCE)_2(tpm')L]$ donor set is too weak to make the low-spin forms of the compounds accessible.

Acknowledgements

The authors thank Dr. H. J. Blythe (University of Sheffield) for the susceptibility measurements, and the EPSRC for funding.

Appendix A. Supplementary data

CCDC 672295, 672296, 672297, 672298, 672299 and 672300 contain supplementary crystallographic data for **10** · $2CH_3CN$, **5**, **7**, **3** · $2CH_3CN$, **9** · $4CH_3CN$ and **4** · $2CH_3CN$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.05.013.

ABSTRACT

Three new copper(II) complexes of formulae [Cu(bpcam)(tcm)(H_2O)] · 2H_2O (**1**), [Cu(bpcam)(tcm)(H_2O)] (**2**) and [Cu(bpcam)(tcm)]$_n$ (**3**) [bpcam = bis(2-pyrimidylcarbonyl)amidate and tcm = tricyanomethanide] have been prepared and their structures determined by single crystal X-ray diffraction. Complexes **1** and **2** are mononuclear species where each copper atom is five-coordinated in a somewhat distorted square pyramidal environment with a tridentate bpcam ligand and a terminally bound tcm group building the basal plane and a water molecule in the apical position. Compound **3** is a uniform copper(II) chain where the [Cu(bpcam)]$^+$ units are connected through single μ-1,5-tcm bridges which link one equatorial position at one copper atom with the apical position of the adjacent copper. The intrachain meal–metal separation in **3** is 7.678(2) Å. Magnetic susceptibility measurements of **3** in the temperature range 1.9–295 K show the occurrence of a weak intrachain antiferromagnetic interaction [$J = -0.39$ cm^{-1} with the Hamiltonian being defined as $\hat{H} = -J\sum_i \hat{S}_i \cdot \hat{S}_{i+1}$]. This value of the magnetic coupling is analyzed through simple orbital symmetry considerations and compared with those observed through this bridge in other magneto-structurally characterized copper(II) complexes.

1. Introduction

Coordination polymers containing dicyanamide [$N(CN)_2^-$, dca] and tricyanomethanide [$N(CN)_3^-$, tcm] as bridging ligands have been the subject of a recent review which focused on their structures and magnetic properties [1]. These two ligands have several points in common such as their Lewis base character, negative charge, planar stereochemistry (C_{2v} and D_{3h} points groups for dca and tcm, respectively) and potentially coordinating nitrile-nitrogen atoms which provide a five-atom superexchange pathway (a three-atom pathway being also accessible only for dca). The discovery of long range magnetic ordering in the binary d-block series of complexes α-M(dca)$_2$ [2–5] and the wide range of *nD* (*n* = 0–3) structural motifs for [M(dca)$_x$L$_y$] ternary species (*L* is a terminal or bridging coligand, *x* = 1 or 2 and *y* = 1 or 2) [1,6–10], largely account for the great interest in the coordination chemistry of dca in the last decade.

The large number of magneto-structural studies on dca-containing metal complexes contrasts with the small number of reports with the related tcm ligand [1,11]. These reports have shown that tcm can adopt four coordination modes in its metal complexes, one being terminal (μ_1) and the other three bridging ($\mu_{1,5}$, $\mu_{1,5,7}$ and $\mu_{1,1,5,7}$) (see Scheme 1). One appealing feature of tcm is the possibility to design triangular magnetically frustrated systems in the μ-1,5,7 bridging mode [12]. To date, only weak magnetic interactions between the paramagnetic metal ions across bridging tcm have been observed [1,11a–e,11g–i,12]. However, this lack of information on its behaviour as a ligand and also the possibility of generating new structural *nD* metal–organic frameworks motivated us to pursue a further investigation into the coordination chemistry of tcm.

In the framework of our previous magneto-structural studies on polynuclear copper(II) complexes and heterometallic species obtained by reacting the stable [Cu(bpca)]$^+$ and [Cu(bpcam)]$^+$ [bpca = bis-(2-pyridylcarbonyl)amidate and bpcam = 2-bis(2-pyrimidylcarbonyl)amidate] building blocks with potentially bridging ligands or preformed complexes which can act as ligands [6b,13,14], we obtained three tcm-containing complexes of formula [Cu(bpcam)(tcm)(H_2O)] · 2H_2O (**1**), [Cu(bpcam)(tcm)(H_2O)]

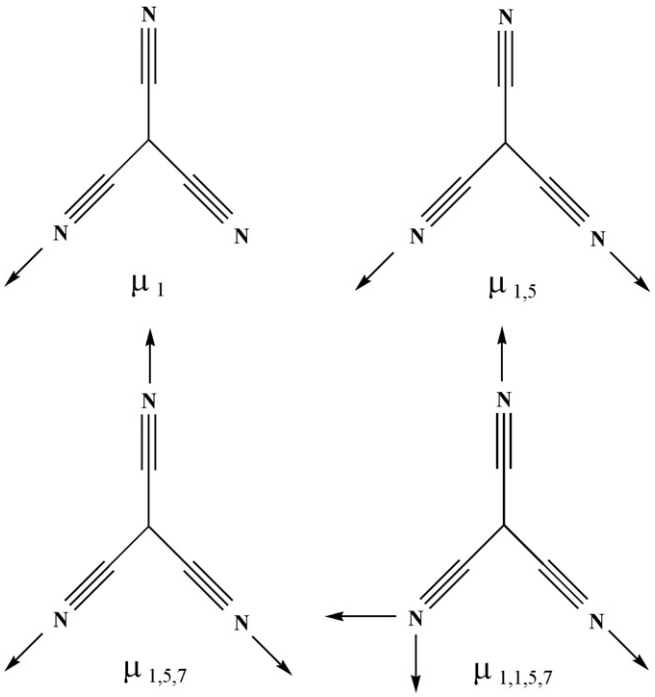

Scheme 1. Coordination modes of the tricyanomethanide.

(**2**) and [Cu(bpcam)(tcm)]$_n$ (**3**). Complexes **1** and **2** are discrete mononuclear species whereas **3** is a chain compound. The preparation and structural characterization of **1**–**3** are presented here together with the variable-temperature magnetic study of **3**.

2. Experimental

2.1. Materials

[Cu(bpcam)(H_2O)$_3$]$NO_3 \cdot 2H_2O$ was prepared by the copper(II)-assisted hydrolysis of the tpymt ligand, as previously reported [15]. Potassium tricyanomethanide was purchased from commercial sources and used and received. Elemental analysis (C, H, N) were conducted by the Microanalytical Service of the Universitat de València.

2.2. Synthesis

2.2.1. [Cu(bpcam)(tcm)(H_2O)] · 2H_2O (**1**)

Compound **1** was obtained as dark green octagonal plates from an aqueous solution (50 cm^3) containing [Cu(bpcam)(H_2O)$_3$]-(NO_3)(H_2O)$_2$ (0.05 mmol) and Ktcm (0.05 mmol) by slow evaporation at room temperature. They were collected by filtration on filter paper, washed with a small amount of cold water and kept in a desiccator over calcium(II) chloride. The yield is practically quantitative. *Anal.* Calc. for $C_{14}H_{12}CuN_8O_5$ (**1**): C, 38.59; H, 2.75; N, 25.71. Found: C, 38.31; H, 2.68; N, 25.54%.

2.2.2. [Cu(bpcam)(tcm)(H_2O)] (**2**) and [Cu(bpcam)(tcm)]$_n$ (**3**)

X-ray quality crystals of **2** and **3** were grown by slow diffusion in an H-shaped tube of aqueous solutions [Cu(bpcam)(H_2O)$_3$]-$NO_3 \cdot 2H_2O$ (0.1 mmol) in one arm and Ktcm (0.1 mmol) in the other one. Both arms were filled with water and cover with parafilm to avoid evaporation. The diffusion was complete after one month at room temperature. Two types of crystals were obtained: dark green parallelepipeds (**2**) and pale green plates (**3**), the former being the main product. They were separated manually, washed with a small amount of cold water and dried on filter paper. The yield is practically quantitative. *Anal.* Calc. for $C_{14}H_8CuN_8O_3$ (**2**): C, 42.07; H, 2.00; N, 28.02. Found: C, 41.92; H, 1.94; N, 27.90%. *Anal.* Calc. for $C_{14}H_6CuN_8O_2$ (**3**): C, 44.05; H, 1.57; N, 29.34. Found: C, 43.90; H, 1.51; N, 29.21%.

2.3. Physical techniques

Infrared spectra of **1**–**3** were recorded with a Bruker IF S55 spectrophotometer as KBr pellets in the 4000–400 cm^{-1} region. The magnetic susceptibility measurements on a polycrystalline sample of **3** were performed in the temperature range 1.9–295 K with a Quantum Design SQUID susceptometer, using an applied magnetic field of 1000 G. Diamagnetic corrections of the constituent atoms of **3** were estimated from Pascal's constants [16] as -163×10^{-6} cm^3 mol^{-1}. A value of 60×10^{-6} cm^3 mol^{-1} was used for the temperature-independent paramagnetism (tip) of the copper(II) ion.

2.4. X-ray data collection and structure refinement

Diffraction data for complexes **1**–**3** were collected at 150(2) K with a Bruker Smart CCD area detector diffractometer equipped with Oxford Cryosystems low temperature system. Crystal parameters and refinement results are listed in Table 1. The reflections of **1**–**3** were measured from a hemisphere of data collected of frames each covering 0.3° in ω. They were corrected for Lorentz and polarization effects and for absorption by semipirical methods based on symmetry-equivalent and repeated reflections through SADABS [17a]. The values of the minimum and maximum transmission coefficients are 0.7679 and 0.8359 (**1**), 0.6141 and 0.6533 (**2**) and 0.6344 and 0.9401 (**3**). The three structures were solved by direct methods and refined by full-matrix least-squares methods on F^2. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms for **1**–**3** were placed geometrically and refined with a riding model and with U_{iso} constrained to be 1.2 times U_{eq} of the carrier atom. The refinements for all reflections converged at final R/wR values which are listed in Table 1. The values of the minimum

and maximum final electron density peaks are −0.640 and 0.418 (**1**), −0.410 and 0.545 (**2**), and −0.410 and 1.029 e Å^{-3} (**3**). A weighting scheme $w = 1/[\sigma(F_o)^2 + (mP)^2 + nP]$ where $P = (F_o + 2F_c^2)/3$ with $m = 0.0330$ (**1**), 0.0484 (**2**) and 0.0573 (**3**) and $n = 0.7152$ (**1**), 0.0000 (**2**), and 1.8442 (**3**) was used in the latter stages of refinement. Complex scattering factors were taken from the program package SHELXTL [17b] as implemented on the Viglen Pentium computer. The graphical manipulations were performed with the XP utility of the SHELXTL system [17c] and the DIAMOND program [17d]. Selected bond lengths and angles are given in Tables 2 (**1** and **2**) and 3 (**3**).

3. Results and discussion

3.1. Synthesis and infrared spectra of *1*–*3*

The coordination of the bpca and bpcam to the coper(II) ion as tridentate ligands through the imido and two pyridyl (bpca) or two pyrimidyl (bpcam) nitrogen atoms affords the very robust [Cu(bpca)]$^+$ and [Cu(bpcam)]$^+$ entities which are shown in Scheme 2. The complex formation of these units with the polynitrile ligands tcm and dca afford the dinuclear complexes [Cu(bpca)(dca)(H_2O)]$_2$ [6b] and [Cu(bpcam)(dca)(H_2O)]$_2$ [13i] and the chain compounds [Cu(bpca)(tcm)]$_n$ [13i] and [Cu(bpcam)(tcm)]$_n$ (**3**) where double $\mu_{1,3}$-dca (dinuclear) and single $\mu_{1,5}$-tcm bridges (chain) link the adjacent copper atoms. However, analogues of the mononuclear species [Cu(bpcam)(tcm)(H_2O)] · 2H_2O (**1**) and [Cu(bpcam)(tcm)-(H_2O)] (**2**) were not observed for the parent bpca-containing system.

The infrared spectra of **1**–**3** show a sharp and strong peak in the range 1730–1720 cm^{-1} [ν_{as}(CO) vibration of the imide group] which is indicative of the presence of coordinated bpcam ligand [13g–i,14b,15]. The high-frequency region of the ir spectra of **1** and **2** is dominated by a strong and broad absorption in the range

3500–3350 cm^{-1} [ν(OH) stretching vibration] which is due to the presence of coordinated (**1** and **2**) and crystallization (**1**) water molecules that are involved in hydrogen bonds [18]. The peaks corresponding to the ν(C≡N) stretches of the tcm ligand in **1**–**3** occur in the range 2260–2170 cm^{-1}: two sharp and strong absorptions at 2237 and 2175 cm^{-1} for **1** and **2** and three peaks at 2260w, 2203s and 2187vs for **3** (comparable to the single absorption at 2178s cm^{-1} in the IR spectrum of Ktcm). A comparison of these absorption patterns with those previously reported for structurally characterized tcm-containing copper(II) complexes [11a,i,j,13i] suggests the presence of monodentate (**1** and **2**) and $\mu_{1,5}$-bridging modes [**3**] for the tcm ligand, which is confirmed by the structures of **1**–**3** (see below).

3.2. Description of the structures

3.2.1. [Cu(bpcam)(tcm)(H_2O)] · 2H_2O (**1**) and [Cu(bpcam)(tcm)(H_2O)] (**2**)

The crystal structures of **1** and **2** contain the same neutral unit of formula [Cu(bpcam)(tcm)(H_2O)], the difference between the structures being the presence of molecules of water of crystallization in the former compound [Figs. 1 (**1**) and 2 (**2**)]. The neutral mononuclear units are interlinked through hydrogen bonds involving the coordinated (**1** and **2**) and non-coordinated water molecules (**1**) as well as the carbonyl-oxygen (**1** and **2**) and one of the free pyrimidyl-nitrogen (**1**) atoms of the bpcam ligand (see end of Table 2) affording the sheet (**1**) and ladder (**2**) supramolecular motifs shown in Figs. 3 (**1**) and 4 (**2**).

The copper atom [Cu(1)] in **1** and **2** is five-coordinated in a somewhat distorted square pyramidal CuN_4O geometry, the values of the trigonality parameter τ being 0.19 (**1**) and 0.16 (**2**) [τ = 0 and 1 for ideal square pyramid and trigonal bipyramid, respectively] [19]. The basal plane is formed by three nitrogen atoms of the tridentate bpcam ligand [Cu–N bonds varying in the range 1.937(2)–2.027(2) (**1**) and 1.935(2)–2.036(2) Å (**2**)] and a nitrile-nitrogen from a terminally bound tcm ligand [Cu(1)–N(6) = 1.958(2) (**1**) and 1.953(2) Å (**2**)], whereas the apical position is occupied by a water molecule [Cu(1)–O(1W) = 2.275(2) (**1**) and 2.280(2) Å (**2**)]. The values of the Cu–N(bpcam) bond lengths agree with those observed in other bpcam-containing copper(II) complexes [13g–i,14b,15]. The angles in the basal plane are distorted from that of an ideal square planar geometry [values varying in the range 81.20(9)–81.60(7)°] mainly due to the steric constraints geometry of the tridentate bpcam ligand subtending two five-membered chelate rings at the copper atom. The atoms defining the basal plane are practically coplanar with maximum deviations of 0.007(1) (**1**) and 0.041(1) Å (**2**) at N(3). The copper atom is displaced by 0.121(1) (**1**) and 0.100(1) Å (**2**) from the basal plane towards O(1w).

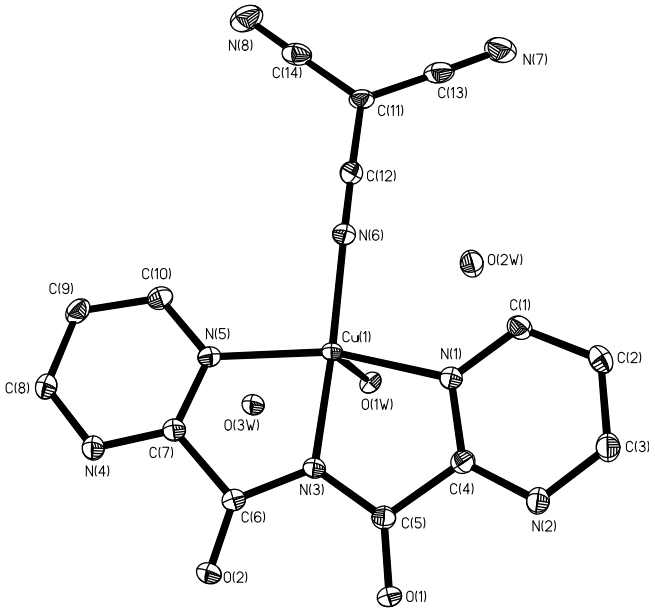

Fig. 1. A perspective view of the molecular structure of **1** showing atom numbering adopted. Hydrogen atoms are omitted for clarity.

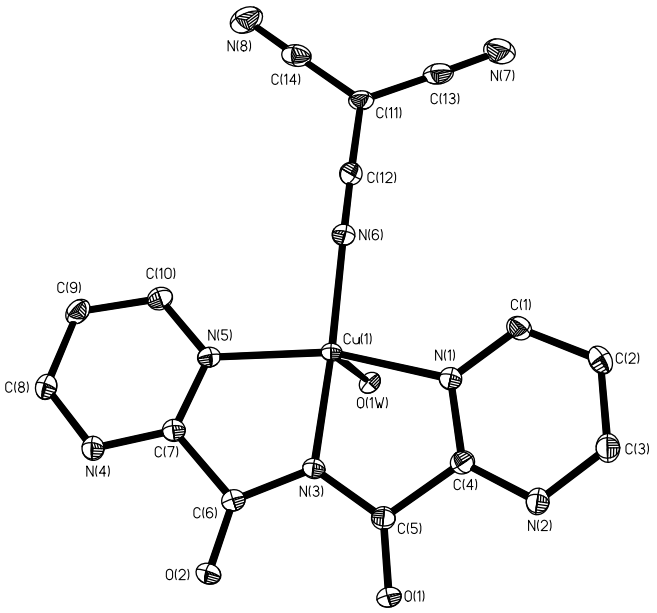

Fig. 2. A perspective view of the molecular structure of **2** showing atom numbering adopted. Hydrogen atoms are omitted for clarity.

The pyrimidyl rings of the bpcam ligand are planar and the values of the dihedral angle between them are 13.24(2) (**1**) and 5.52(1)° (**2**). Bond lengths and angles within the bpcam ligand are in agreement with those reported previously [13g–i,14b,15]. The tcm ligand is planar and the value of the dihedral angle between this group and the equatorial plane at the copper atom is 13.9(1)° for **1** and 14.6(1)° for **2**. The structural parameters of the tcm group indicate localized single C–C and triple C≡N bonds with values for the angles at the central carbon atom [C(11)] and C–C–N fragments varying in the ranges 119.1(2)–121.4(2) (**1**)/119.4(4)–121.1(3)° (**2**) and 177.5(3)–178.6(3) (**1**)/178.4(3)–179.2(3)° (**2**), as expected for sp^2 and sp hybridizations of the appropriate carbon atoms.

The values of the shorter intermolecular copper–copper distance are 6.348(3) [Cu(1)···Cu(1a); (a) = $-x$, $-y$, $1-z$] and 6.607(4) Å [Cu(1)···Cu(1b); (b) = $1-x$, $2-y$, $1-z$] for (**1**) and (**2**), respectively.

3.2.2. [Cu(bpcam)(tcm)]$_n$ (**3**)

This compound has a uniform chain structure with the tcm group adopting a $\mu_{1,5}$-bridging mode between the [Cu(bpcam)] units (Fig. 5). The neutral chains extend along the c axis in a zigzag fashion and they are stacked in a zipper arrangement in the *bc* plane (Fig. 6).

The copper atom is five-coordinated in a distorted square pyramidal surrounding, with τ = 0.17. The equatorial positions are occupied by three bpcam-nitrogen atoms [N(1), N(3) and N(5)] and a nitrile-nitrogen [N(6)] from a tcm group whereas the apical position is occupied by a nitrile-nitrogen [N(7b)] from another tcm ligand. The larger deviation from the mean equatorial plane is

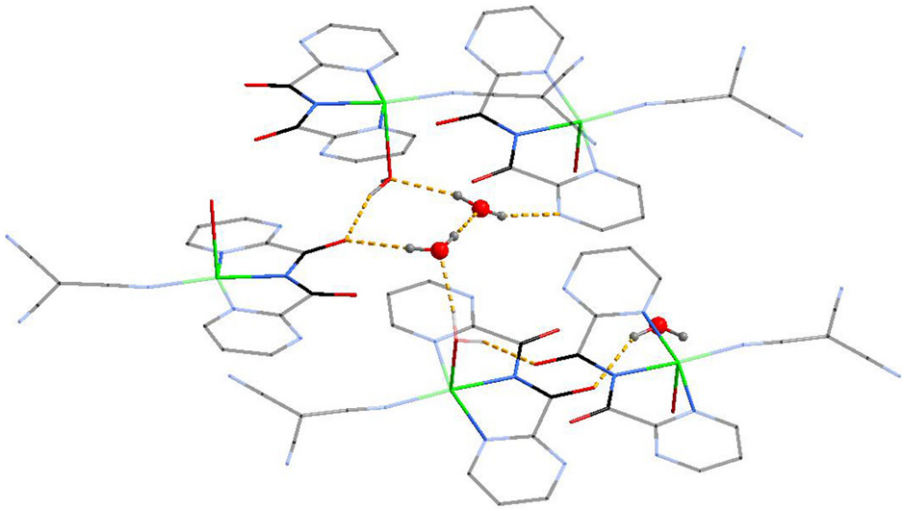

Fig. 3. View of a fragment of the layered structure of **1** in the *ab* plane through hydrogen bonds (yellow broken lines). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

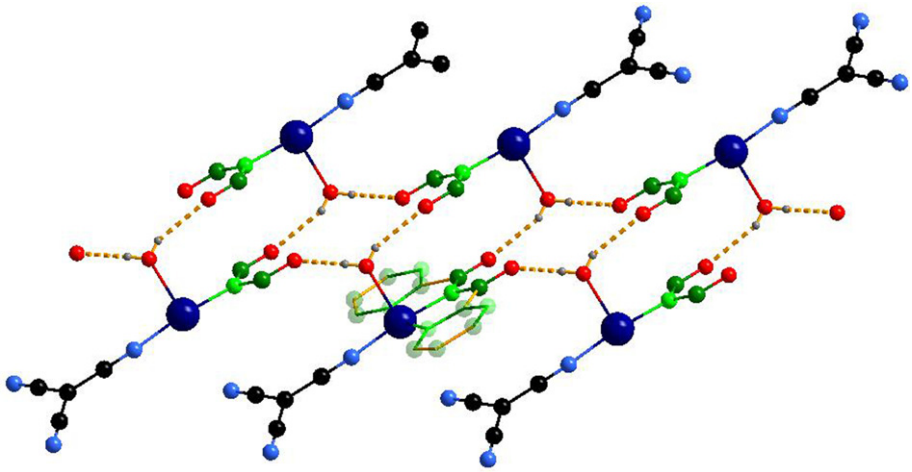

Fig. 4. View of the hydrogen bonding pattern in **2** (yellow broken lines) which leads to a ladder-like motif running parallel to the *a* axis. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

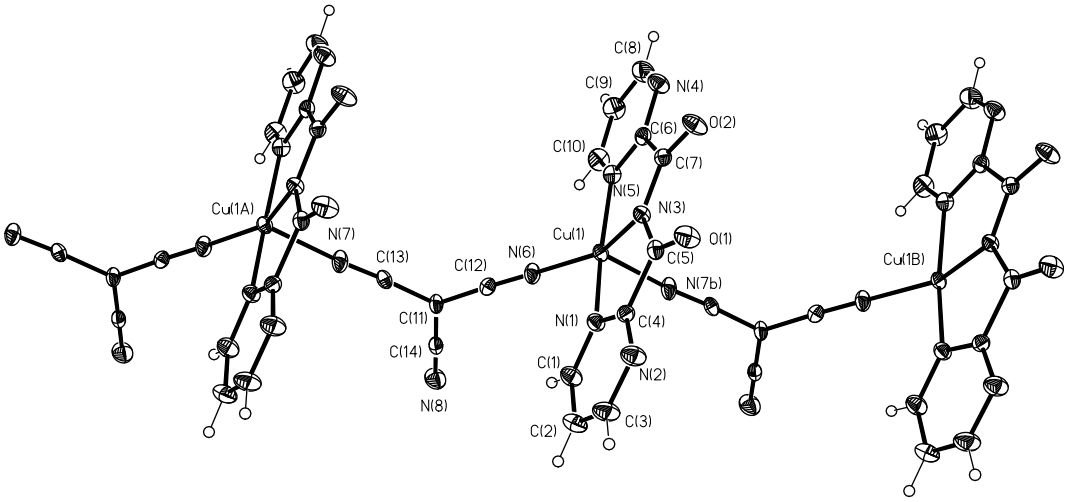

Fig. 5. View of a fragment of the chain structure of **3** with atom numbering.

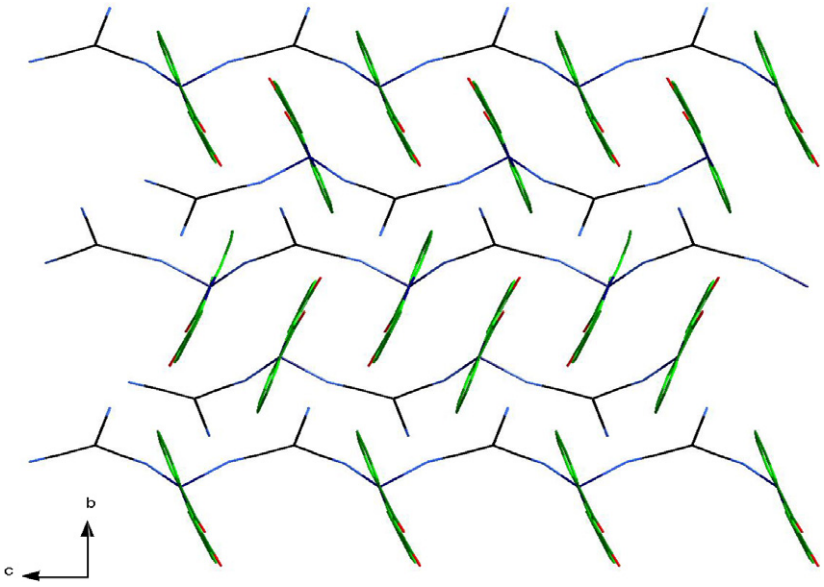

Fig. 6. A view of the stacking of the chains of **3** in the *bc* plane.

0.176(3) Å for N(3) and the copper atom is displaced by 0.284(4) Å from this mean plane toward the apical nitrile-nitrogen. The values of the dihedral angle between the mean basal plane and those of the bpcam and tcm ligands are 10.28(6) and 82.25(8)°, respectively.

As in **1** and **2**, the bpcam ligand adopts a tridentate coordination mode with the inner copper to amido-nitrogen bond being shorter than the outer copper to pyrimidine-nitrogen bonds. The pyrimidyl rings of the bpcam ligand are planar and the dihedral angle between them is 4.94(2)°. The values of the C–C and C–N bond lengths and the C–C–C bond angles of the tcm ligand in **3** remain in rather narrow ranges 1.390(5)–1.410(6) Å, 1.142(5)–1.149(5) Å and 119.1(3)–121.2(3)°, respectively. This is in agreement with almost ideal sp^2 hybridization for the central carbon atom. This single and asymmetric μ-1,5-bridging mode for the tcm ligand has been previously observed in related uniform copper(II) chains $\{[Cu(terpy)(tcm)]\cdot tcm\}_n$ (terpy = 2,2′:6′,2″-terpyridine) [11j] and $[Cu(bpca)(tcm)]_n$ [13i] with values of the intrachain metal–metal separation of 7.469(19) and 7.688(3) Å, respectively [to be compared to 7.678(2) Å for Cu(1)···Cu(1a) in **3**]. The shortest interchain copper–copper distance in **3** is 4.409(9) Å [Cu(1)···Cu(1c); (c) = 2 − *x*, −*y*, 2 − *z*], a value which is much shorter than the analogous intrachain separation.

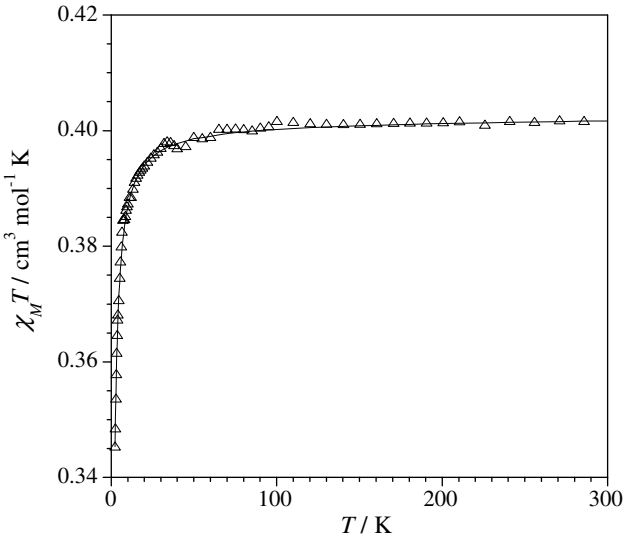

Fig. 7. Thermal dependence of the $\chi_M T$ product for **3**: (Δ) experimental data; (−) best-fit curve through Eq. (1) (see text).

*3.2.3. Magnetic properties of **3***

The magnetic properties of **3** in the form of $\chi_M T$ versus T plot [χ_M is the magnetic susceptibility per copper(II) ion] are shown in Fig. 7. Curie law behaviour for a magnetically isolated copper(II) ion is observed in the temperature range 290–100 K ($\chi_M T$ being practically constant and equal to ca. 0.40 cm^3 mol^{-1} K). The smooth decrease of $\chi_M T$ at $T < 100$ K to reach a minimum value of 0.345 cm^{-1} at 1.9 K is indicative of weak antiferromagnetic coupling in this compound.

Given the one-dimensional structure of **3**, the magnetic data were analyzed through the numerical expression [20] for a uniform chain of local spin doublets [Eq. (1)] which is derived from the isotropic Hamiltonian in Eq. (2)

$$\chi_M = (N\beta^2 g^2/kT)[(0.25 + 0.074975x + 0.075235x^2) / [1.0 + 0.9931x + 0.172135x^2 + 0.757825x^3] \quad (1)$$

$$\hat{H} = -J\sum_i \hat{S}_i \cdot \hat{S}_{i+1} \quad (2)$$

where $x = |J|/kT$ and J is the exchange coupling constant describing the magnetic interaction between the two nearest-neighbour spin doublets. Best-fit parameters through Eq. (1) leads to the following parameters: $J = -0.30$ cm^{-1}, $g = 2.07$ and $R = 1.6 \times 10^{-5}$ (R is the agreement factor defined as $\sum_i[(\chi_M T)_{obs(i)} - (\chi_M T)_{calc(i)}]^2 / \sum_i[(\chi_M T)_{obs(i)}]^2$).

The magnetic coupling in **3** is very weak and antiferromagnetic. Its value is within those observed in other copper(II) complexes through asymmetric single- and double $\mu_{1,5}$-tcm bridges, as shown in Table 4. The out-of-plane exchange pathway involved in **3** and in the other complexes of this table is the origin of the small overlap between the magnetic orbitals of the adjacent copper(II) ions, the unpaired electron of each copper(II) ion being essentially located in the equatorial plane with a weak spin density on the axial position. Under these conditions, a weak magnetic interaction between the copper(II) ions is predicted. Thus, the tcm bridge appears to be a poor mediator of magnetic interactions when adopting the $\mu_{1,5}$-bridging mode in the equatorial axial exchange pathway.

4. Conclusions

Complex formation between the $[Cu(bpcam)]^+$ unit and the polynitrile ligand tcm affords two mononuclear complexes (**1** and **2**) and a uniform copper(II) chain where the tcm ligand adopts the monodentate and $\mu_{1,5}$-bridging coordination modes. A weak intrachain antiferromagnetic coupling occurs in **3** illustrating once more the poor ability of this bridge to transmit magnetic interactions between the magnetic centres separated by more than 7.0 Å. Finally, this work and previous reports show that the high stability of the preformed complex $[Cu(bpcam)]^+$ in aqueous solution facilitates the preparation of mono- and homo- and heterometallic polynuclear complexes using bridging linkers as coligands. The extension of bpcam-based coordination chemistry to other spin carriers will allow a wide variety magnetic compounds with an increased number of exchange pathways to be prepared.

ABSTRACT

A template 2:2:4 condensation of 2,6-diformyl-4-methyl-phenol, triethylenetetramine and zinc acetate gave rise to the crystallisation of $[\{Zn_4(H_4L^1)(OAc)_4\}\{Zn(OAc)_3(H_2O)\}(OAc)] \cdot 7H_2O$ (**1** · $7H_2O$), being H_6L^1 a macrocyclic diphenolate Schiff base ligand. Changing some operation conditions, other template reactions yielded dinuclear complexes of the type $Zn_2(L^n)(OAc) \cdot xH_2O$, where H_3L^n (n = 2, 3) are podant triphenolate Schiff base ligands derived from a 3:1 condensation of the corresponding 2,6-diformyl-4-alkyl-phenol (alkyl = Me or Bu^t, respectively) and triethylenetetramine. After recrystallisation, these two latter complexes could be X-ray characterised as $Zn_2(L^2)(OAc) \cdot 1.25H_2O \cdot 0.5MeCN$ (**2** · $1.25H_2O$ · 0.5MeCN), and $Zn_2(L^3)(OAc)$ (**3**). Furthermore, after addition of a 3:1 molar ratio of 2-amino-4-methyl-phenol to **3**, this underwent imidazolidine hydrolysis and a double imine condensation, yielding $Zn_2(L^4)(OAc)(HOAc) \cdot 2H_2O$ (**4** · $2H_2O$), where H_3L^4 is an acyclic pentadentate Schiff base derived from the 1:2 condensation of 2,6-diformyl-4-*tert*-butyl-phenol and 2-amino-4-methyl-phenol.

1. Introduction

The cyclic Schiff base H_6L^1 (Scheme 1), derived from the 2:2 condensation of 2,6-diformyl-4-methyl-phenol and triethylenetetramine, was first obtained by Kahwa et al. in dinuclear lanthanide complexes [1]. The partial hydrolysis of these macrocyclic dinuclear complexes in mildly acid alcohol solutions resulted in mononuclear complexes of a podant Schiff base (H_3L^2, Scheme 1) [2]. Since then, several tetra- or dinuclear complexes of the mentioned macrocycle [3,4], and its *N*-alkylated derivatives [5,6] have been prepared by template reactions using a 1:1:2 (phenol:amine:metal salt) molar ratio.

During last years we have been working on the coordination chemistry of three-armed triphenolate Schiff bases derived from substituted salicylaldehydes and triethylenetetramine [7–10]. Now, we are presenting our studies on the influence of some reaction conditions when we attempted to obtain polynuclear complexes of some ligands derived from 2,6-diformyl-4-alkyl-phenols (alkyl = methyl or *tert*-butyl, Scheme 1). We have focused our attention on the susceptibility to hydrolysis of their N–C–N and C=N groups. Template reactions have been assayed employing 3:1:2, 1.5:1:2 and 1:1:2 phenol:amine:zinc acetate molar ratios. The use of a diamagnetic ion as zinc(II) has facilitated the identification of the reaction products through NMR techniques.

2. Results and discussion

It was reported that the success in the obtaining of macrocyclic complexes of *N*-alkylated derivatives of H_6L^1 (Scheme 1) arrives when the metal salt and the corresponding phenol are firstly mixed under aerobic conditions, and then, the tetraamine is added to this mixture. In contrast, no macrocyclic complexes were obtained when amine and metal salt were mixed in methanol, and the corresponding phenol subsequently added to the resulting solution, both in aerobic or anaerobic conditions [5].

The essence of the synthetic mechanism reported for these macrocyclic complexes [5] is the formation of two intermediates in methanol solution under aerobic conditions: $[M_2(phenol)(OAc)_2]^+$, which is air-stable, and $[M_2(1{:}1\ SB)(OAc)_2]^+$ (Scheme 2). Dimerisation by a double imine condensation of this second type of intermediate would afford the tetranuclear complexes desired.

In our case study (Scheme 2), the coordination of two zinc(II) ions to 2,6-diformyl-4-methyl-phenol to form $[Zn_2(phenol)(OAc)_2]^+$ seems to be a key factor in the activation of the C=O sites, favouring their reactivity, as it increases their electrophile character, and allowing the formation of the diphenolate macrocyclic Schiff base ligand H_6L^1. This could be confirmed by solving the crystal structure of $[\{Zn_4(H_4L^1)(OAc)_4\}\{Zn(OAc)_3(H_2O)\}(AcO)] \cdot 7H_2O$, **1** · $7H_2O$, which crystallised from the corresponding reaction mixture.

Although high temperatures and a moisture-laden atmosphere are not crucial factors, their concurrence does not favour the obtaining of this type of macrocyclic complexes, since hydrolysis could occur. In fact, the heating and vacuum concentration of the

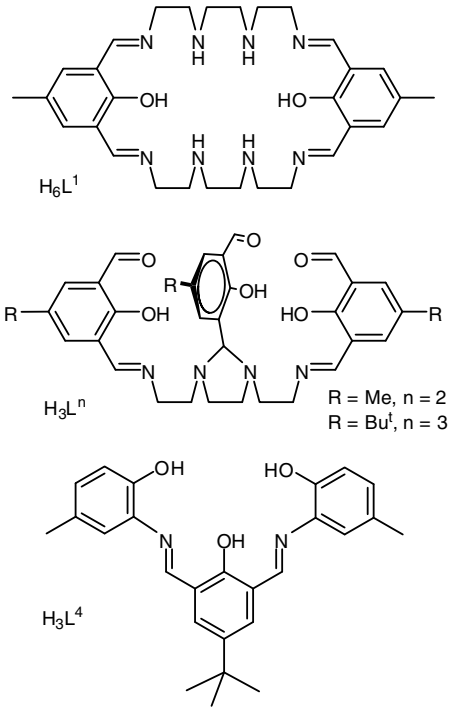


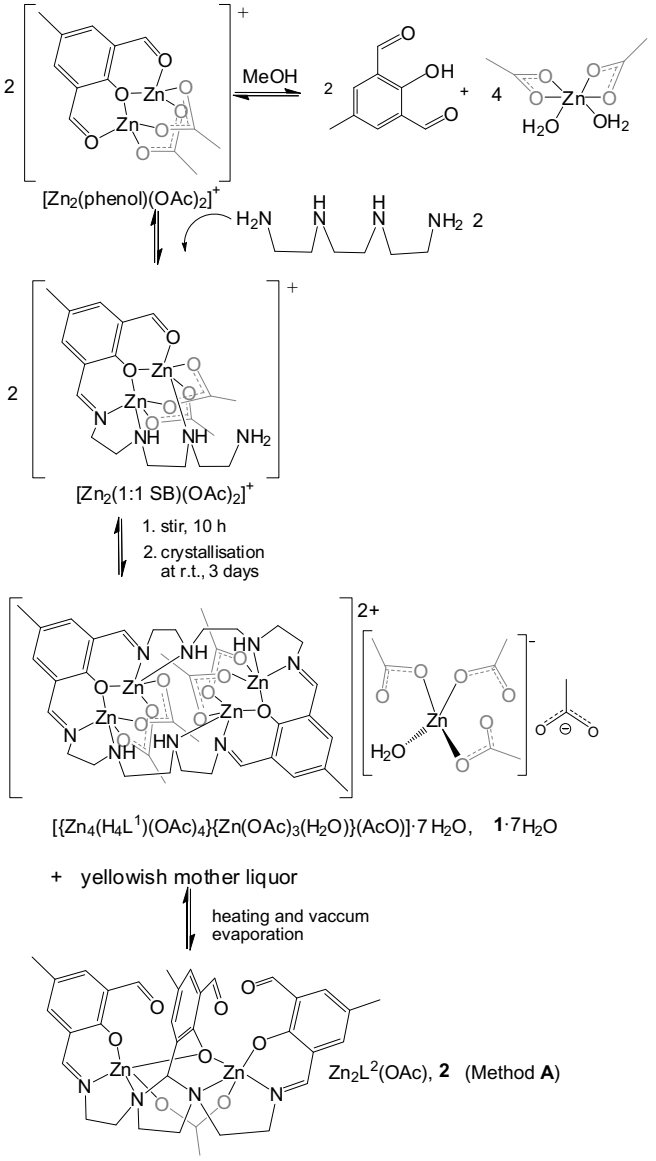
Scheme 1. Ligands used in this work.

yellowish mother liquor obtained after crystallisation of **1** · $7H_2O$, gave rise to the more stable dinuclear neutral complex $[Zn_2(L^2)(OAc)]$, **2** (Scheme 2), which contains a three-armed triphenolate Schiff base ligand $(L^2)^{3-}$, and whose presence was undoubtedly confirmed by NMR. This complex seems to result from an acid hydrolysis of two of the C=N groups of H_6L^1 to yield C=O ones, what joint to the losing of two of the metal ions and three of the acetate ligands, appears to lead to an imidazolidine condensation between adjacent secondary amine sites of the tetraamine, and one of the formyl groups of the 2,6-diformyl-4-methylphenol originated by the hydrolysis of the macrocycle. The characterisation of **1** · $7H_2O$ provides evidence of the presence in the reaction medium of limited amounts of water, being its presence essential for the hydrolysis process that these macrocyclic complexes can undergo [2].

Neutral dinuclear acyclic complexes of the type $[Zn_2(L^n)(OAc)] \cdot xH_2O$ (n = 2–3) have been also obtained by template methods employing 3:1:2, and even 1.5:1:2, (phenol:amine:zinc acetate) molar ratios. Thus, reaction stoichiometry does not seem to be a crucial factor in the success of these template syntheses. However, the order in which the reagents are added to the reaction medium could influence the final product by means of a change in the mechanism of the reaction (Scheme 3, top).

The isolation of H_3L^3, by stirring a methanol solution containing 2,6-diformyl-4-*tert*-butyl-phenol and triethylenetetramine in 3:1 molar ratio, supports the formation of the free ligand prior to the obtaining of $[Zn_2(L^n)(OAc)] \cdot H_2O$ (n = 2–3) complexes, when phenol and amine are firstly mixed, and the metal salt subsequently added to the resulting solution. The stability of the acyclic triphenolate Schiff base ligand sharply contrasts with the marked instability of the macrocyclic diphenolate Schiff base ligand [2].

Finally, the obtaining of $Zn_2(L^4)(OAc)(HOAc) \cdot 2H_2O$, **4** · $2H_2O$ (Scheme 3, bottom) evidences that **3** · $2H_2O$ undergoes an imidazolidine hydrolysis process in the presence of 2-amino-4-methylphenol at room temperature, showing the vulnerability of N–C–N bonds. Thus, it seems reasonable to suppose that **3** · $2H_2O$ undergoes hydrolysis to afford the air-stable $[Zn_2(phenol)(OAc)_2]^+$

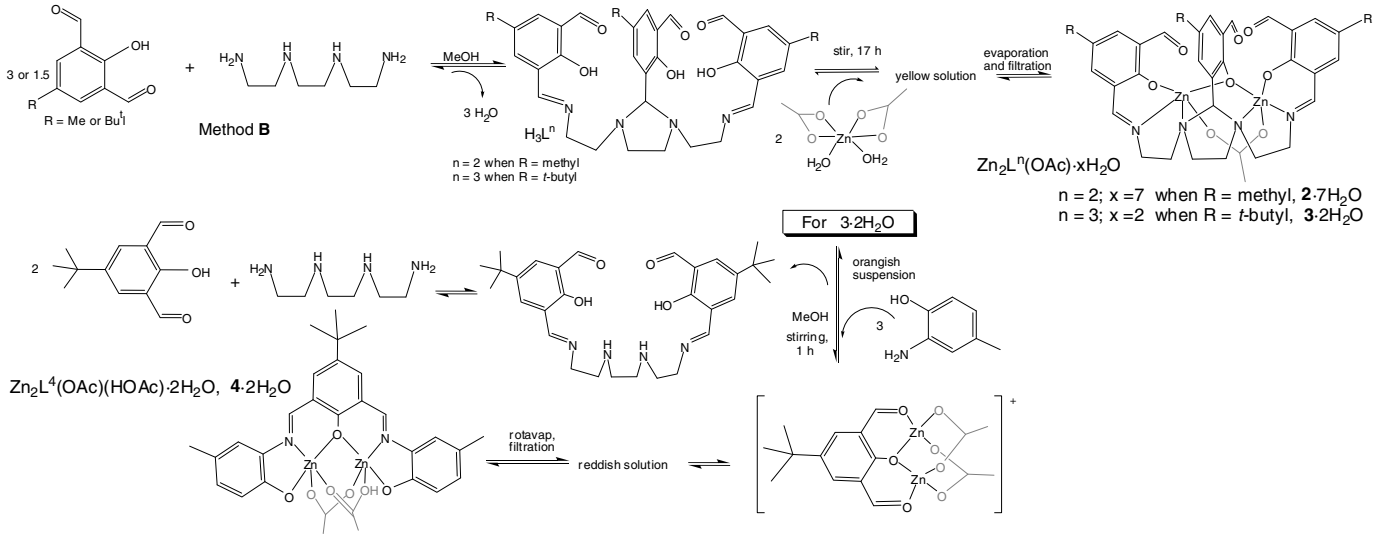


Scheme 2. Synthetic route used to obtain **1** · $7H_2O$ and **2** (Method **A**). The formation of $[Zn_2(phenol)(OAc)_2]^+$ and $[Zn_2(1:1\ SB)(OAc)_2]^+$ species as intermediates had been proposed by Sakiyama et al. [5].

(Schemes 2 and 3). Finally, the 1:2 condensation of this latter compound with 2-amino-4-methyl-phenol would yield **4** · $2H_2O$.

2.1. Crystal structure of 1 · $7H_2O$

X-ray diffraction analyses have revealed that single crystals directly obtained from the reaction mixture described in Scheme 2 contain in its unit cell co-crystallised $[Zn_4(H_4L^1)(OAc)_4]^{2+}$, $[Zn(OAc)_3(H_2O)]^-$, and acetate anions in a 2:2:2 ratio, with disordered water molecules captured in the crystal lattice. Its asymmetric unit only contains half molecule of each one of the two cations, one mononuclear anion, as well as an acetate anion. The macrocyclic ligand involved in $[Zn_4(H_4L^1)(OAc)_4]^{2+}$ is the result of the 2:2 condensation of 2,6-diformyl-4-methyl-phenol with triethylenetetramine. Selected bond distances and angles for all these species are listed in Table 1. An ORTEP view of one of the two $[Zn_4(H_4L^1)(OAc)_4]^{2+}$ cations is shown in Fig. 1, while $[Zn(OAc)_3(H_2O)]^-$ is shown in Fig. 2, together with the atom-numbering schemes for both complexes.



Scheme 3. Synthetic route used to obtain dinuclear acyclic complexes **2** · 7H_2O and **3** · 2H_2O (Method **B**, top); and proposed mechanism for the imidazolidine hydrolysis of **3** · 2H_2O (bottom) leading to obtain **4** · 2H_2O.

Hydrogen atoms potentially bonded to their N or O atoms were studied with particular care, in order to determine the neutral or ionic nature of each one of the species. Thus, in the case of $[Zn_4(H_4L^1)(OAc)_4]^{2+}$ (Fig. 1), ΔF maps showed electron densities at chemically reasonable positions near to the amine N atoms of the macrocyclic ligand, and which could be assumed with full occupancies. This does not occur for any acetate group, neither coordinated nor free, what joint to their geometric parameters have leaded to be considered as anions in all the cases. Hence, the mononuclear complex $[Zn(OAc)_3(H_2O)]^-$ is acting as one of the two monoanionic counterions that each $[Zn_4(H_4L^1)(OAc)_4]^{2+}$ complex needs to achieve electric neutrality.

Each one of the zinc ions corresponding to the macrocyclic complex is bonded to one imine and one amine N atoms, one

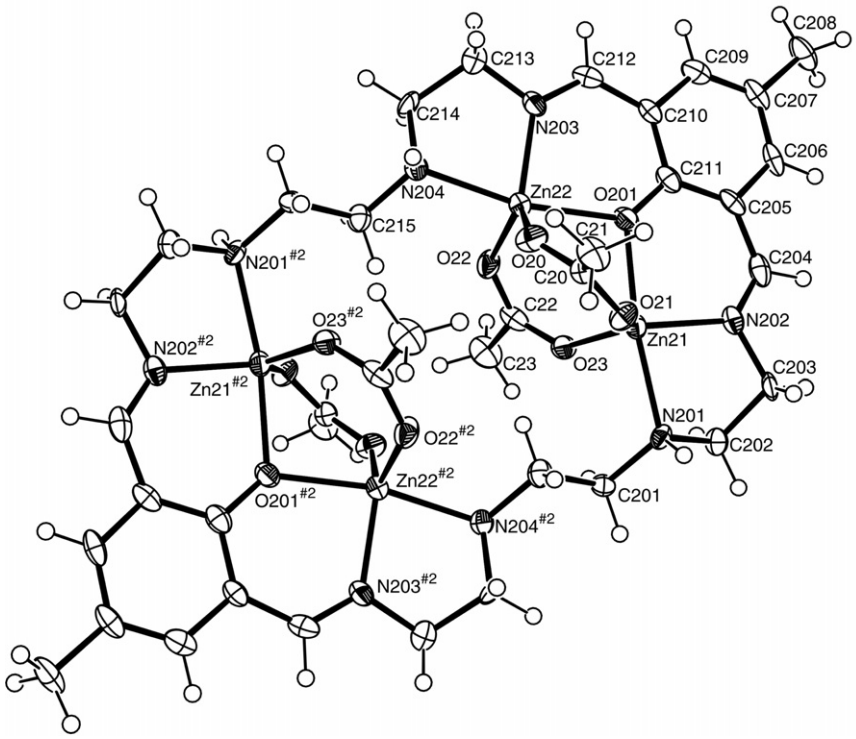

Fig. 1. An ORTEP view of the molecular structure of one of the $[Zn_4(H_4L^1)(OAc)_4]^{2+}$, complexes. The other molecule of this cationic complex present in the unit cell is totally equivalent, being its numbering scheme comparable, but with 1 as first figure. Ellipsoids are drawn at 50% probability.

μ_2-bridging phenolate O atom, and two O atoms corresponding to two μ_2-η^1:η^1 bridging acetate groups, what affords ZnO_3N_2 coordination polyhedra. Their geometries are markedly distorted from regular trigonal-bipyramids, with the phenolate O atom and the amine N atom at their apexes. The $Zn–O_{(phen)}$ and $Zn–O_{(OAc)}$ distances of the macrocyclic complex fall in the range commonly found for zinc(II) complexes with these donor atoms [7,8,11]. The $Zn–N_{(imine)}$ and $Zn–N_{(amine)}$ distances are similar to those found for complexes containing related three-armed ligands [7,8].

The geometry around the metal ion in $[Zn(OAc)_3(H_2O)]^-$ can be depicted as an irregular tetrahedron formed by four O atoms, one of the coordinated water molecule, and the other from monodentate acetate anions (Fig. 2). It must be noted that O4 and O6, can be considered as secondarily bonded to the zinc ion. These interactions are responsible for the distortion of the coordination polyhedron. Selected bond distances and angles are also given in Table 1. The $Zn–O_{(AcO)}$ lengths found in $[Zn(OAc)_3(H_2O)]^-$ can be considered in the range expected in four-coordinated carboxylate zinc complexes [12], being $Zn–O_{(water)}$ also consistent with similar bond lengths [13].

Finally, an intricate H bonding scheme involving the water molecules solvated and the different acetate groups significantly contributes to the crystal packing.

2.2. Crystal structures of $2 \cdot 1.25H_2O \cdot 0.5MeCN$ and 3

Single crystals of $\mathbf{2} \cdot 1.25H_2O \cdot 0.5MeCN$ (Fig. 3) and **3** (Fig. 4) were obtained from recrystallisation of $\mathbf{2} \cdot 7H_2O$ and $\mathbf{3} \cdot 2H_2O$ (Scheme 3), respectively, and as indicated in Section 4. Their X-ray diffraction analyses showed that both compounds consisted of neutral dinuclear complexes with three-armed Schiff base ligands, and some water and solvent molecules as solvates.

The spatial array of the podant triphenolate Schiff base ligands $(L^2)^{3-}$ and $(L^3)^{3-}$ are similar in their respective complexes. These ligands use each one of their N_2O compartments to allocate a zinc atom. Both zinc centres are doubly bridged by a phenolate O atom of the central arm, and by an acetate group acting as a μ_2-η^1:η^1 bridge, what gives rise to ZnN_2O_3 coordination chromophores. These adopt distorted square pyramidal dispositions around the metal centres, with the acetate oxygen atoms at the apexes of their respective distorted pyramids.

Main distances and angles for $\mathbf{2} \cdot 1.25H_2O \cdot 0.5MeCN$ and **3** are listed in Tables 2 and 3, respectively. All the distances and angles are in the range of those expected for this type of complexes [7,8,11], and reflect the symmetry of their phenolate bridges. However, it should be noted that the apical $Zn–O_{(AcO)}$ distances are the shortest ones, as occurred in the macrocyclic complexes, what leads to some distortion of the coordination polyhedra.

A curious feature of $\mathbf{2} \cdot 1.25H_2O \cdot 0.5MeCN$ arises from the conformation adopted by one of O atoms (O18a) of its carbonyl groups, which is disordered on two different occupation sites (0.52 and 0.48, for O18a and O18b, respectively). This leads to the chirality of part of the molecules of this complex (52%) in the solid state,

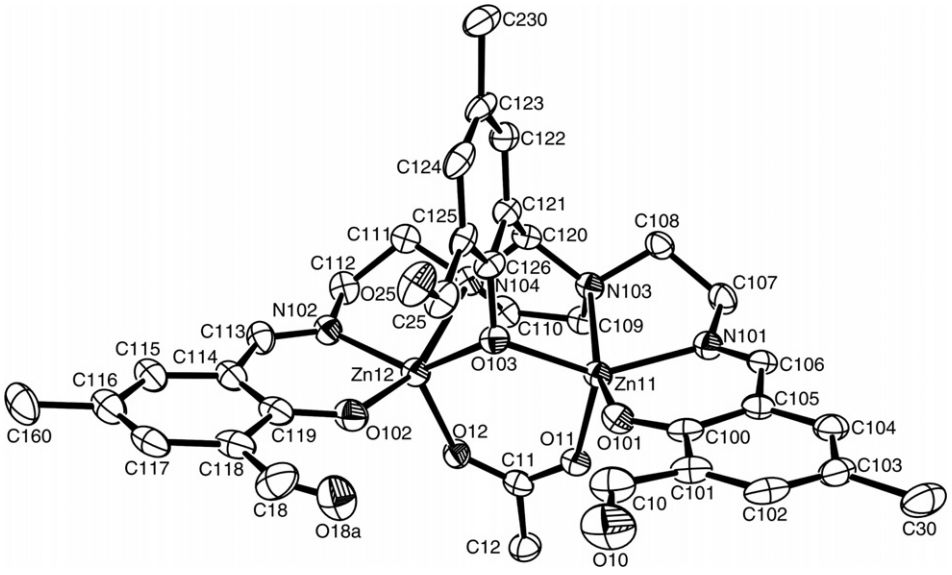

Fig. 3. An ORTEP view of the molecular structure of **2**. Only one of the disordered sites (O18a, 52% occupation) is shown in the figure, and being this the only one involved in the H bonding scheme. Ellipsoids are drawn at 40% probability.

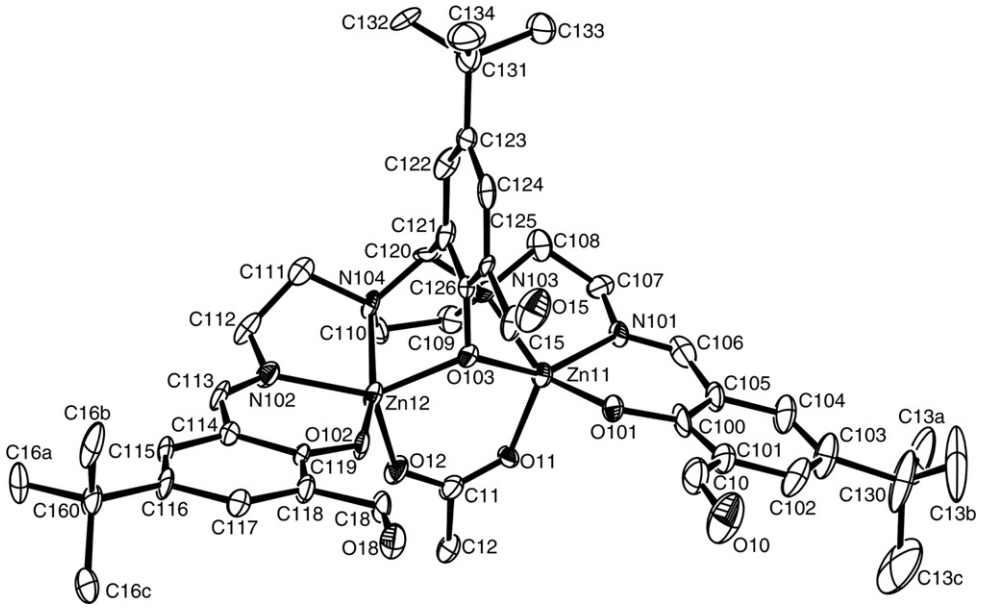

Fig. 4. An ORTEP view of the molecular structure of one of the complex molecules included in the asymmetric unit of **3**. Ellipsoids are drawn at 40% probability.

as this disparity avoids the C_s symmetry that the other 48% of the achiral molecules present, and being only the most occupied site involved in the H bond scheme. In fact, this crystal corresponds to a non-centrosymmetric polar group as *R*3*c*. The correction of the absolute structure was confirmed by the low value observed for the Flack's parameter [14].

2.3. Physicochemical characterisation of the dinuclear complexes

The formation of the complexes **1**, **2, 3** and **4** was evidenced in solid state by microanalytical data and IR spectroscopy, whereas ^{1}H NMR spectroscopy and ESI-MS data show the preservation of the acetate complexes in solution, at least during the time employed in these experiments.

From the current NMR results (Fig. 5), and considering the ligand symmetry of $(L^2)^{3-}$ and $(L^2)^{3-}$, the observation of two separate signals for each methylene group (*e.g.* 3.83 and 2.61 ppm for H_2C–N=C) in the spectra of **2** · 7H_2O and **3** · 2H_2O must be consequence of a diastereotopic nature of these geminal protons, on the NMR timescale at room temperature. This is indicative of a non-planar arrangement for the triethylenetetramine residue in **2** · 7H_2O and **3** · 2H_2O, and reveals a certain kinetic stability of these complexes in DMSO solution. Moreover, the chemical non-equivalence between the free formyl, as well as alkyl, substituents in $(L^n)^{3-}$ is clearly observed through their corresponding chemical shifts.

All the complexes present a signal near to 2 ppm in their ^{1}H NMR spectra that is in agreement with the coordination of the acetate ligand to the metal centres, while a peak near to 4 ppm indicates the permanence of the imidazolidine ring in solution of complexes **2** and **3**. This signal corresponding to the HCN_2 proton disappears in the case of **1** · 7H_2O and **4** · 2H_2O, what is indicative

of the hydrolysis of this ring. The observation of imine, aromatic, methylene and methyl signals in the spectrum of **1** · 7H_2O supports the preservation of the diphenolate Schiff $(H_4L^1)^{2-}$.

The limited number of signals observable in the NMR spectrum of **4** · 2H_2O (Fig. 6) allows an unequivocal full assignment of the signals corresponding to $(L^4)^{3-}$. Thus, the presence of the imine and *tert*-butyl signals, which had been already observed in the spectrum of **3** · 2H_2O, are two clear evidences to support the formation of the triphenolate Schiff. An additional peak at 2.20 ppm reveals the presence of the methyl groups from the 2-amino-4-methyl-phenol residues of $(L^4)^{3-}$. Moreover, the integration value observed for the signal assigned to the methyl group of the acetate ligand in the spectrum of **4** · 2H_2O is coherent with a 6:2 ratio for methyl:imine protons and supports the $Zn_2(L^4)(OAc)(HOAc) \cdot 2H_2O$ formula deduced from elemental analysis and mass spectroscopy. The remaining four signals, two singlets and two "doublets" (in appearance) show the expected chemical shifts.

The observation of a very strong IR band at about 1675 cm^{-1}, which is assignable to $\nu(C{=}O)_{(formyl)}$, is coherent with the presence of free formyl groups in **2** · 7H_2O and **3** · 2H_2O. On the contrary, no bands at the mentioned value can be observed in the **4** · 2H_2O spectrum (Fig. 7), supporting the formation of a new Schiff base ligand derived from a 1:2 condensation of 2,6-diformyl-4-*tert*-butyl-phenol and 2-amino-4-methyl-phenol, this is $(L^4)^{3-}$.

The IR spectra of all these complexes exhibit two intense bands assignable to ν_a(COO) and ν_s(COO) modes that support the presence of coordinated acetate groups. Fig. 7 shows these and other significant bands for **4** · 2H_2O. The Δ value [$\Delta = \nu_a(COO) - \nu_s(COO)$] of about 135 cm^{-1}, which is close to those reported for other acetate bridged complexes [15,16], points to a bidentate bridging behaviour.

3. Conclusions

The reaction stoichiometry does not seem to be a key factor in the obtaining of dinuclear complexes of three-armed triphenolate Schiff base ligands, derived from a 3:1 condensation of 2,6-diformyl-4-alkyl-phenol and triethylenetetramine, whereas the order in which the reagents are added to the reaction medium seems to be more important, although not deciding in the final product (macrocyclic tetranuclear or acyclic dinuclear complexes), if water and acid species are present in enough amounts to hydrolyse the tetranuclear cyclic complexes.

The instability in methanol solution of the tetra- and dinuclear complexes of H_6L^1 and H_3L^3, respectively, lies in the vulnerability of their respective C=N and N–C–N groups to hydrolysis. This occurs in mildly acid methanol solutions with limited amounts of water.

4. Experimental

4.1. Materials and methods

Chemicals of the highest commercial grade available (Aldrich) were used as received, without further purification. Elemental analyses were performed on a Carlo Erba EA 1108 analyser. Positive electrospray ionisation mass spectra were recorded on a LC/MSD Hewlett Packard 1100 spectrometer, using methanol as solvent. NMR spectra were recorded on Bruker spectrometers, using DMSO-d_6 or $CDCl_3$ as solvents. FTIR spectra were recorded as KBr pellets on a Bio-Rad FTS 135 spectrophotometer in the range 4000–600 cm^{-1}. These characterisation analyses were performed at the in-house services (CACTUS).

4.2. Single crystal X-ray diffraction analyses

Crystallographic data at 100 K were collected on a Smart CCD-1000 diffractometer for **1** · 7H_2O, while those corresponding to **2** · 1.25H_2O · 0.5MeCN and **3** were collected on an APEX-II CCD Bruker diffractometer. Graphite monochromated Mo Kα radiation (λ = 0.71073 Å) from a fine focus sealed tube source has been used in the three cases. The computing data reduction, with correction for Lorentz and polarisation factors, was done using XPREP software [17]. Crystal and refinement data for these compounds are summarised in Table 4.

Despite attempts made to select a single crystal, finally a twinned one was selected for data collection corresponding to **1** · 7H_2O. Its structure was identified as a non-merohedral twin using RLATT. The collected reflections were processed with the program CELLNOW, which found two twin components. The absorption

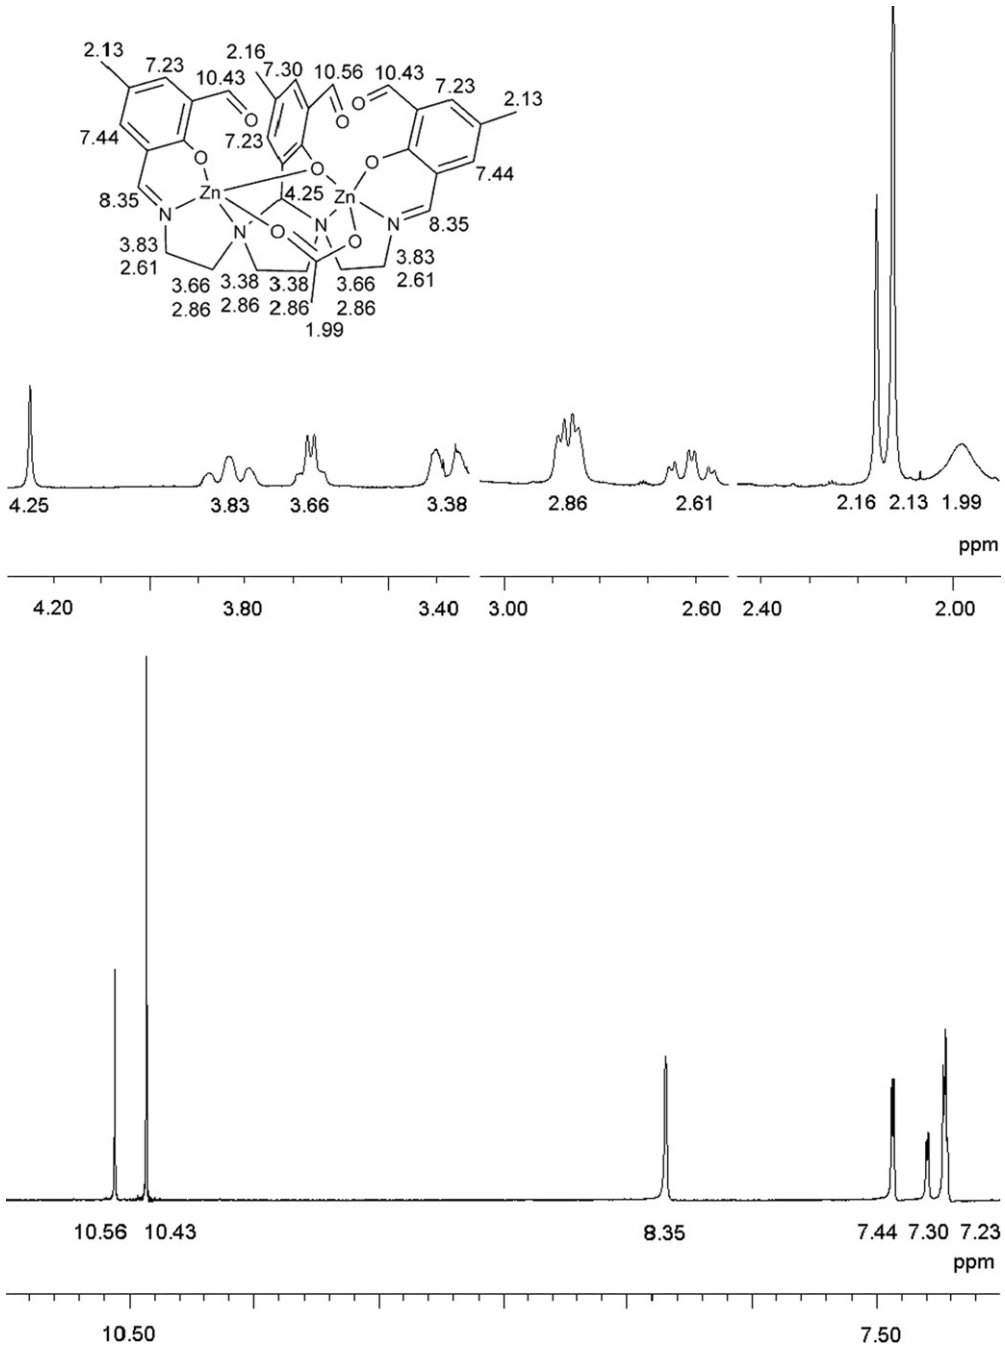

Fig. 5. ^{1}H NMR spectrum of **2** · 7H_2O in DMSO-d_6. Chemical shifts are below their corresponding signals.

correction was applied using TWINABS [18]. The final refinements were performed with all unique reflections using the HKLF 5 format in SHELXL-97 [19]. The ratio of the two twin components were approximately 0.73:027.

Multi-scan absorption corrections were performed with the help of the SADABS routine [20] for **2** · 1.25H_2O · 0.5MeCN and **3**. Although some twinned crystals had been previously selected for **3**, this feature was not detected for the data set whose results are shown herein. However, the quality of these data was not completely satisfactory. In fact, the contribution of the electron density of disordered solvated molecules (methanol, acetonitrile and/or water) had to be subtracted from the measured structure factors using SQUEEZE [21]. After this, subsequent refinement then converged with *R* factors and parameter errors significantly better than those obtained for all attempts made to model the solvent disorder, and being the largest residual peaks adjacent to zinc ions. Up to eleven voids (2594.5 Å^3, 25.3% of the volume) were found in the unit cell of **3**, but only two of them, around two special positions, were actually significant. These two voids, of about 1207 Å^3, meant 90 e each one, so it was difficult to determine the actual nature of the solvated molecules, especially for this type of complexes, which usually favour intricate H bonding schemes and considerable solvatation [7–10]. Despite these inconveniences, the quality of the refinement appear to be reasonable, since these data allowed determining the molecular structure of this complex, which is clearly defined and totally similar for both complex molecules found in the asymmetric unit (Table 3).

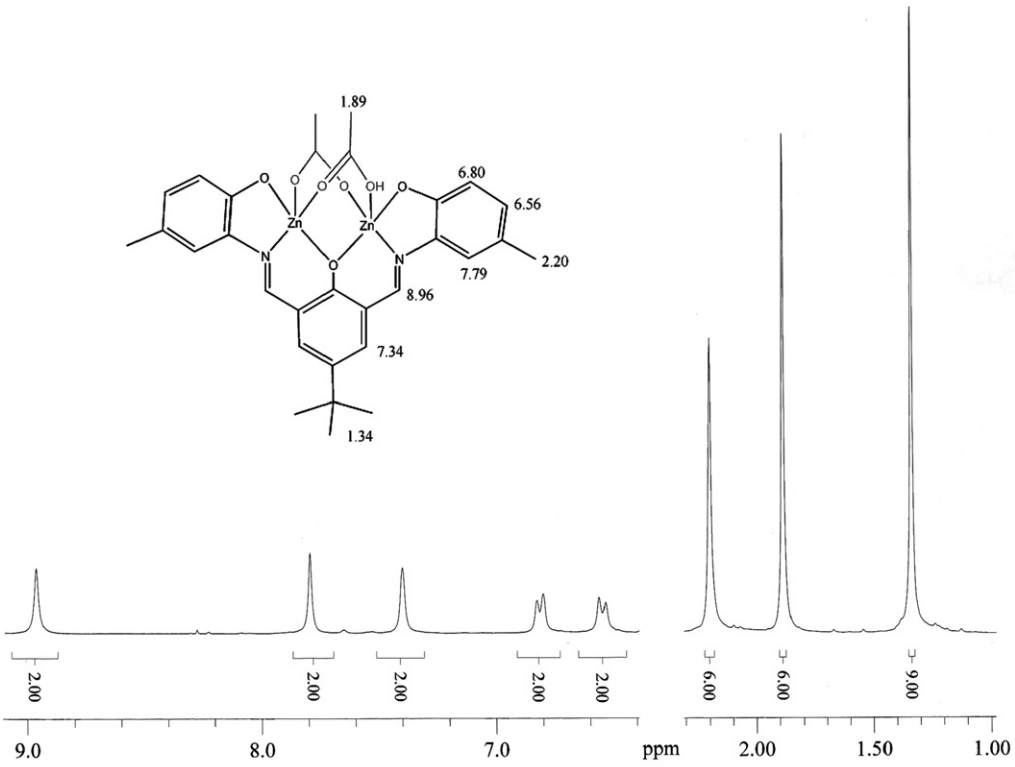

Fig. 6. ^{1}H NMR spectrum of **4** · 2H_2O in DMSO-d_6. Integration values are indicated below their corresponding signals.

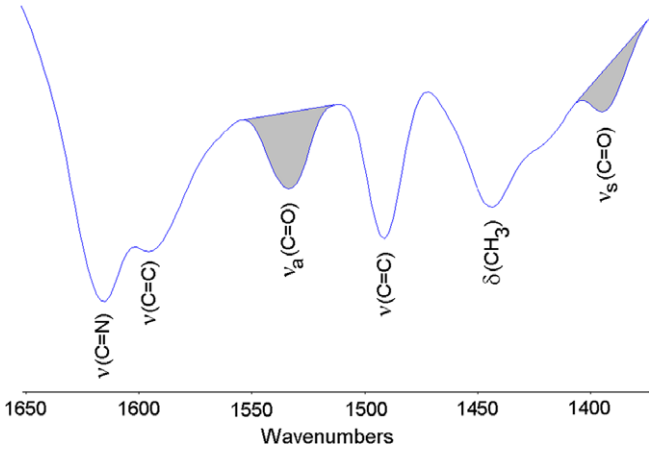

Fig. 7. Partial view of the IR spectrum of **4** · 2H_2O. Bands attributed to ν_a(COO) and ν_s(COO) have been shaded.

The structures were solved by a combination of the direct methods, using SHELXS-97 [19] or DIRDIF99 [22], and difference Fourier syntheses, and refined against F^2 by the full-matrix least-squares technique, using the SHELXL-97 program [19], via WINGX [23]. Non-hydrogen atoms were anisotropically refined for all complex molecules, but some atoms corresponding to disordered sites or solvated molecules with partial occupancies were isotropically treated.

In all cases, H atoms attached to C atoms were included in the model at geometrically calculated positions, and refined in a riding mode using SHELXL [19] default parameters, whereas those bonded to O or N atoms were objectively found on Fourier difference maps. These positions were studied with particular care for **1** · 7H_2O, in order to determine the neutral or ionic nature of each one of the species, as indicated above. The coordinates of hydrogen atoms bonded to N or O atoms were freely refined, but their isotropic thermal parameters were set at 1.2 times the isotropic equivalent of the attached atom. This was not always possible for disordered and/or low-occupancy atoms corresponding to solvated water molecules, so several H atoms could not be found.

*R*3*c* symmetry deduced from a statistical analysis of data collected for **2** · 1.25H_2O · 0.5MeCN was confirmed by successful refinement in this non-centrosymmetric space group. The absolute structure was determined from the Flack parameter [14], $x = -0.008(9)$.

4.3. Ligand synthesis

H_3L^3 could be obtained by stirring a methanol solution containing 2,6-diformyl-4-*tert*-butyl-phenol and triethylenetetramine in 3:1 molar ratio (Scheme 2) for 6 h. Vacuum concentration of the resulting solution, and then, addition of diethyl ether yielded a yellow solid that was filtered, washed with diethyl ether, and dried in vacuum. ^{1}H NMR spectrum showed that the solid was H_3L^3 with their starting compounds as insignificant impurities.

H_3L^3. Yellow powder. ^{1}H NMR (300 MHz, $CDCl_3$, ppm) 14.00 (s, 2H, *H*O), 11.10 (s, 1H, *H*O), 10.24 (s, 2H, *H*CO), 10.11(s, 1H, *H*CO), 8.28 (s, 2H, *H*CN), 7.88 (s, 2H, H_{arom}), 7.66 (s, 1H, H_{arom}), 7.51 (s, 1H, H_{arom}), 7.43 (s, 2H, H_{arom}), 4.10 (s, 1H, *H*CN_2), 3.62–2.76 (12H, H_{aliph}), 1.29 (s, 18H, H_3C).

4.4. Complexes syntheses

4.4.1. 1 · 7H_2O

This compound was obtained when 2,6-diformyl-4-methyl-phenol (0.110 g, 0.67 mmol) and zinc(II) acetate dihydrate (0.295 g, 1.34 mmol) were firstly mixed in methanol (60 mL), and then the tetraamine (0.098 g, 0.67 mmol) added to this mixture (Scheme 2). The resulting solution was stirred for 10 h, and then

was allowed to stand at ambient temperature in an open flask. Yellow single crystals suitable for X-ray diffraction studies were deposited within 3 days. After this time, concentration of the mother liquor on a rotavap yielded a yellow powdery solid, latter NMR characterised as **2**, which was filtered, washed with diethyl ether, and dried in vacuum.

1 · 7H_2O: Yellow powder (0.14 g); *Anal.* Calc. for $C_{46}H_{82}N_8O_{26}Zn_5$ (M, 1489 g mol^{-1}): C, 37.07; H, 5.51; N, 7.52. Found: C, 38.28; H, 5.22; N, 6.91%. FTIR (KBr, cm^{-1}): ν(O–H) 3419(b,m), ν(C=N) 1647(vs), $\nu_a(COO_{ionic})$ 1598(vs,br), $\nu_a(COO_{bridge})$ 1547(vs), $\nu_s(COO_{ionic})$ 1437(vs,br), $\nu_s(COO_{bridge})$ 1399(vs), ν(C–N) 1333(m); ^{1}H NMR (300 MHz, DMSO-d_6, ppm) 8.49 (s, *H*CN), 7.36 (s, H_{arom}), 3.69 (m, H_2C–N=C), 2.88 (m, H_2C–H_2C–N=C), 2.22 (s, H_3C), 1.76 (s, $H_3C_{(OAc)}$).

4.4.2. Compounds 2 and 3

As commented above, **2** can be obtained by concentration of the mentioned mother liquor of **1** (Method **A**). Likewise, **2** · 7H_2O and **3** · 2H_2O were obtained by stirring a methanol solution containing the corresponding 2,6-diformyl-4-alkyl-phenol (alkyl = Me or Bu^t), triethylenetetramine and zinc(II) acetate dihydrate in 3:1:2 molar ratio for 17 h (Scheme 2) (Method **B**). Thus, when 2,6-diformyl-4-alkyl-phenols (1.20 mmol), and triethylenetetramine (0.058 g, 0.40 mmol) were firstly mixed in methanol (20 mL), and about 15 min later, $Zn(OAc)_2(H_2O)_2$ (0.176 g, 0.80 mmol) was added to the resulting suspensions, yellow solutions were obtained. Vacuum concentration of these solutions and the subsequent addition of diethyl ether yielded yellow solids that were filtered, washed with diethyl ether, and dried in vacuum. Recrystallisation at room temperature of these solids in a acetonitrile:ethanol 1:1 mixture gave rise to crystal suitable for X-ray diffraction studies of **2** · 1.25H_2O · 0.5MeCN and **3**.

Similar template reactions, employing the same reaction conditions mentioned above, but with 1.5:1:2 (phenol:amine:metal salt) molar ratios led to the formation of **2** · 6H_2O and **3** · 6H_2O (Method **C**), although these yields were not so good as those obtained for **2** · 7H_2O and **3** · 2H_2O (Method **B**).

2 · *7H$_2$O* (*Method **B***): Yellow powder (0.20 g, 56%); *Anal.* Calc. for $C_{35}H_{36}N_4O_8Zn_2$ · 7H_2O (M, 896.80 g mol^{-1}): C, 46.83; H, 5.57; N, 6.24. Found: C, 46.72; H, 4.85; N, 6.19%. m/z (ESI$^+$-MS, methanol, 150 V): 793.4 (100%) [Zn_2L^2(OAc)+Na]$^+$; FTIR (KBr, cm^{-1}): ν(O–H) 3450(b,m), ν(C=O)$_{(formyl)}$ 1673(vs), ν(C=N) 1635(vs), ν_a(COO) 1535(vs), ν_s(COO) 1399(s), ν(C–N) 1339(m); ^{1}H NMR (300 MHz, DMSO-d_6, ppm) 10.56(s, 1H, *H*CO), 10.43 (s, 2H, *H*CO), 8.35 (s, 2H, *H*CN), 7.44 (s, 2H, H_{arom}), 7.30 (s, 1H, H_{arom}), 7.23 (s, 3H, H_{arom}), 4.25 (s, 1H, *H*CN_2), 3.83 (m, 2H, J = 12.4 Hz, H_2C), 3.66 (m, 2H, J = 4.1 Hz, H_2C), 3.38 (m, 2H, J = 9.4 Hz, H_2C), 2.86 (m, 4H, J = 9.4, 4.1 Hz, H_2C), 2.61 (m, 2H, J = 12.4, 3.6 Hz, H_2C), 2.16 (s, 3H, H_3C), 2.13 (s, 6H, H_3C), 1.99 (s, 3H, $H_3C_{(OAc)}$).

2 · *6H$_2$O (Method **C***): Yellow powder (0.13 g, 18%); *Anal.* Calc. for $C_{35}H_{36}N_4O_8Zn_2$ · 6H_2O (M, 878.80 g mol^{-1}): C, 47.79; H, 5.46; N, 6.37. Found: C, 47.22; H, 5.02; N, 6.41%. The remaining characterisation data are totally similar to those corresponding to **2** · 7H_2O.

3 · *2H$_2$O* (*Method **B***): Yellow powder (0.24 g, 64%); *Anal.* Calc. for $C_{44}H_{54}N_4O_8Zn_2$ · 2H_2O (M, 932.76 g mol^{-1}): C, 56.61; H, 6.22; N, 6.00. Found: C, 56.01; H, 6.20; N, 5.65%. m/z (ESI$^+$-MS, methanol, 150 V): 921.2 (100%) [Zn_2L^3(OAc)+Na]$^+$, FTIR (KBr, cm^{-1}): ν(O–H) 3440(b,m), ν(C=O) 1676(vs), ν(C=N) 1635(vs), ν_a(COO) 1530(vs), ν_s(COO) 1399(s), ν(C–N) 1339(m); ^{1}H NMR (300 MHz, DMSO-d_6, ppm) 10.62(s, 1H, *H*CO), 10.46 (s, 2H, *H*CO), 8.46 (s, 2H, *H*CN), 7.65 (s, 2H, H_{arom}), 7.55 (s, 1H, H_{arom}), 7.50 (s, 2H, H_{arom}), 7.42 (s, 1H, H_{arom}), 4.35 (s, 1H, *H*CN_2), 3.85 (m, 2H, J = 12.4 Hz, H_2C), 3.69 (m, 2H, J = 4.4 Hz, H_2C), 3.42 (m, 2H, J = 12.7 Hz, H_2C), 2.88 (m, 4H, J = 8.9, 4.3 Hz, H_2C), 2.56 (m, 2H, J = 12.6, 3.2 Hz, H_2C), 2.04 (s, 3H, $H_3C_{(OAc)}$), 1.20 (s, 18H, H_3C), 1.19 (s, 9H, H_3C).

3 · *6H$_2$O* (*Method **C***): Yellow powder (0.13 g, 30%); *Anal.* Calc. for $C_{44}H_{54}N_4O_8Zn_2$ · 6H_2O (M, 1004.82 g mol^{-1}): C, 52.55; H, 6.57; N, 5.57. Found: C, 52.43; H, 5.77; N, 5.57%. The remaining characterisation data are absolutely analogous to those corresponding to **3** · 2H_2O.

4.4.3. ***4*** · *2H$_2$O*

4 · 2H_2O was obtained by stirring an orangish methanolic suspension (20 mL) containing **3** · 2H_2O (0.58 g, 0.622 mmol) and 2-

amino-4-methyl-phenol (0.23 g, 1.865 mmol) in 1:3 molar ratio for 1 h (Scheme 3). Vacuum concentration of the resulting reddish solution, and afterwards, addition of diethyl ether yielded a red solid that was filtered, washed with diethyl ether, and dried in vacuum.

4 · $2H_2O$: Red powder (0.31 g, 71%); *Anal.* Calc. for $C_{30}H_{32}N_2O_7Zn_2 \cdot 2H_2O$ (M, 698.8 g mol^{-1}): C, 51.52; H, 5.15; N, 4.01. Found: C, 51.85; H, 5.64; N, 4.08%. m/z (ESI$^+$-MS, methanol, 100 V): 663.0 (100%) $[Zn_2L^4(OAc)(HOAc)]^+$, FTIR (KBr, cm^{-1}): ν(O–H) 3430(b,m), ν(C=N) 1615(vs), ν_a(C=C) 1595(vs), ν_a(COO) 1533(s), ν_s(C=C) 1491(vs), δ (CH_3) 1443(s), ν_s(COO) 1395(s), ν(C–N) 1323(m); ^{1}H NMR (300 MHz, DMSO-d_6, ppm) 8.94 (s, 2H, *H*CN), 7.77 (s, 2H, H_{arom}), 7.38 (s, 2H, H_{arom}), 6.80 (d, 2H, H_{arom}), 6.52 (d, 2H, H_{arom}), 2.20 (s, 6H, H_3C), 1.88 (s, 6H, $H_3C_{(OAc)}$), 1.33 (s, 9H, H_3C).

ABSTRACT

Two neutral ligands, $L^1 \cdot 2H_2O$ and $L^2 \cdot H_2O$, and seven complexes, $[Cu(pmb)_2(L^1)]$ (**1**), $[Cu(pmb)_2(L^2)]$ (**2**), $[Cu(Ac)_2(L^2)] \cdot 4H_2O$ (**3**), $[Cu(4\text{-aba})_2(L^2)]$ (**4**), $[Ag(4\text{-ts})(L^1)(H_2O)]$ (**5**), $[Ag_2(epes)_2(L^1)] \cdot 2H_2O$ (**6**), $[Ag(1,5\text{-nds})_{0.5}(L^2)] \cdot 0.5C_2H_5OH \cdot H_2O$ (**7**) [where L^1 = 1,1′-(1,4-butanediyl)bis(2-methylbenzimidazole); L^2 = 1,1′-(1,4-butanediyl)bis(2-ethylbenzimidazole), pmb = *p*-methoxybenzoate anion; Ac = acetate anion; 4-aba = 4-aminobenzoate anion; 4-ts = *p*-toluenesulfonate anion; epes = *N*-(2-hydroxyethyl)piperazine-*N*′-(2-ethanesulfonate) anion; 1,5-nds = 1,5-naphthalenedisulfonate anion], have been synthesized and characterized by elemental analysis, IR, and single-crystal X-ray diffraction. The L^1 and L^2 ligands in compounds **1**–**7** act as bridging ligands, linking metal ions into chain structures. The chains in compounds **3**, **4** and **6** interlace with each other by hydrogen bonds to generate 3D supramolecular structures. In compound **5**, π–π interactions between adjacent L^1 ligands hold the chains to a supramolecular layer. In compound **7**, the sulfonate anions act as counterions in the framework. The thermal stabilities of **3**, **6** and **7**, and the luminescent properties for **5**–**7** in the solid states are also discussed.

1. Introduction

The crystal engineering of supramolecular architecture based on metal and organic building blocks has been rapidly expanding in recent years owing to their novel and diverse topologies and potential applications in host-guest chemistry, catalysis, electrical conductivity, and magnetism [1–12]. Generally, extended high-dimensional networks can be obtained by the assembly of lower dimensional coordination polymers via noncovalent intermolecular forces such as hydrogen-bonding and π–π stacking interactions [13–17]. According to previous reports, bis(imidazole) ligands are excellent candidates for the construction of extended architectures and supramolecular architectures [18–24]. Carboxylate and sulfonate anions have also been proven to be good candidates for the formation of supramolecular structures because they can be regarded not only as hydrogen-bonding acceptor but also as hydrogen-bonding donors. In this study, copper and silver ions, bis(benzimidazole) ligands (Scheme 1), and carboxylate and sulfonate anions (Scheme 2) are selected as the reactants. We describe the successful syntheses of seven novel compounds: $[Cu(pmb)_2(L^1)]$ (**1**), $[Cu(pmb)_2(L^2)]$ **(2)**, $[Cu(Ac)_2(L^2)] \cdot 4H_2O$ (**3**), $[Cu(4\text{-aba})_2(L^2)]$ (**4**), $[Ag(4\text{-ts})(L^1)(H_2O)]$ (**5**), $[Ag_2(epes)_2(L^1)] \cdot 2H_2O$ (**6**), and $[Ag(1,5\text{-nds})_{0.5}(L^2)] \cdot 0.5C_2H_5OH \cdot H_2O$ (**7**). All crystal structures have been determined by single-crystal X-ray diffraction, and the compounds are also characterized by IR and elemental analyses.

2. Experimental

2.1. Materials and methods

All reagents and solvents for syntheses were purchased from commercial sources and used without further purification. The C, H, and N elemental analysis was conducted on a Perkin–Elmer 240C elemental analyzer. ^1H NMR spectra were recorded at 500 MHz with TMS as internal standard. The FT-IR spectra were recorded from KBr pellets in the range 4000–400 cm^{-1} on a Mattson Alpha-Centauri spectrometer. TGA was performed on a Perkin–Elmer TG-7 analyzer heated from room temperature to 600 °C under nitrogen. The luminescent properties of compounds **5**–**7** were measured on a Perkin–Elmer LS55 spectrometer.

2.2. Syntheses of the ligands and metal complexes

2.2.1. Synthesis of $L^1 \cdot 2H_2O$

A mixture of NaOH (1.18 g, 30 mmol) and 2-methylbenzimidazole (3.96 g, 30 mmol) in acetone (50 mL) was stirred at room temperature to give a clear solution, then 1,4-dibromobutane (3.24 g, 15 mmol) and NaI (0.1 g) were added. The mixture was stirred at 50 °C for 10 h. After removing the acetone, 50 mL water was poured and a brown solid formed. The solid was recrystallized from a mixture of water and ethanol (v:v = 4:1) to give L^1 as a light brown crystalline solid. Yield: 85% based on 2-methylbenzimidazole. *Anal.* Calc. for $C_{20}H_{22}N_4 \cdot 2H_2O$: C, 67.77; H, 7.39; N, 15.81. Found: C, 67.56; H, 7.58; N, 15.80%. IR (KBr) ν/cm^{-1}: 1665 (vw), 1615 (w), 1515 (s), 1474 (m), 1461 (s), 1439 (m), 1406 (vs), 1359

2.2.2. Synthesis of $L^2 \cdot H_2O$

The same synthetic method as for L^1 was used except that 2-methylbenzimidazole was replaced by 2-ethylbenzimidazole (4.38 g, 30 mmol). Yield: 80% based on 2-ethylbenzimidazole. *Anal.* Calc. for $C_{22}H_{26}N_4 \cdot H_2O$: C, 72.50; H, 7.74; N, 15.37. Found: C, 72.26; H, 7.68; N, 15.57%. *2.2.3. Synthesis of [Cu(pmb)$_2$(L^1)] (**1**)*

A mixture of $CuCl_2 \cdot 2H_2O$ (0.171 g, 1 mmol), NaOH (0.08 g, 2 mmol) and Hpmb (0.304 g, 2 mmol) in ethanol was stirring for 10 min at room temperature. Then L^1 (0.318 g, 1 mmol) was added to the solution with stirring for 30 min and a purple precipitate was obtained. The precipitate was dissolved by dropwise addition of ammonia (5 M). Suitable purple single crystals were obtained by slow evaporation of the solution at room temperature. The crystals were collected, washed with water, and dried in air. Yield: 75% based on $CuCl_2 \cdot 2H_2O$. *Anal.* Calc. for $C_{36}H_{36}CuN_4O_6$ (M_r = 684.23): C, 63.19; H, 5.30; N, 8.19. Found: C, 63.21; H, 5.19; N, 8.06%. *2.2.5. Synthesis of [Cu(Ac)$_2$(L^2)] $\cdot$ 4H$_2$O (**3**)*

A mixture of $CuCl_2 \cdot 2H_2O$ (0.171 g, 1 mmol), NaOH (0.080 g, 2 mmol) and HAc (0.120 g, 2 mmol) in ethanol was stirring for 10 min at room temperature. Then L^2 (0.348 g, 1 mmol) was added to the solution with stirring for 30 min and a purple precipitate was obtained. The precipitate was dissolved by dropwise addition of ammonia (5 M). Suitable purple single crystals were obtained by slow evaporation of the solution at room temperature. The crystals were collected, washed with water, and dried in air. Yield: 75% based on $CuCl_2 \cdot 2H_2O$. *Anal.* Calc. for $C_{36}H_{36}CuN_4O_6$ (684.23): C, 63.19; H, 5.30; N, 8.19. Found: C, 63.21; H, 5.19; N, 8.06%. IR (cm^{-1}): 3899 (w), 3859 (m), 3801 (w), 3742 (s), 3673 (m), 3624 (m), 1679 (w), 1646 (s), 1630 (s), 1541 (m), 1515 (s), 1456 (m), 1425 (s), 675 (s).

*2.2.6. Synthesis of [Cu(4-aba)$_2$(L^2)] (**4**)*

The same synthetic method as for **2** was used except that HAc was replaced by 4-abaH (0.274 g, 2 mmol). Yield: 73% based on $CuCl_2 \cdot 2H_2O$. *Anal.* Calc. for $C_{36}H_{38}CuN_6O_4$ (682.26): C, 63.38; H, 5.61; N, 12.32. Found: C, 63.76; H, 5.53; N, 12.56%. IR (cm^{-1}): 3311 (m), 3209 (w), 2937 (w), 1632 (s), 1599 (s), 1558 (m), 1466 (m), 1413 (m), 1354 (s), 1306 (s), 1218 (w), 1166 (m), 1068 (w), 850 (m), 785 (s).

*2.2.7. Synthesis of [Ag(4-ts)(L^1)(H$_2$O)] (**5**)*

A mixture of Ag_2CO_3 (0.028 g, 0.1 mmol), 4-tsH (0.034 g, 0.2 mmol) and L^1 (0.0318 g, 0.1 mmol) in ethanol (10 mL) was stirring for 30 min at room temperature. The mixture was dissolved by dropwise addition of ammonia (5 M). Suitable colorless single crystals were obtained by slow evaporation of the solution at room temperature. Yield: 66% based on Ag_2CO_3. *Anal.* Calc. for $C_{27}H_{31}AgN_4O_4S$ (615.49): C, 52.69; H, 5.08; N, 9.10. Found: C, 52.72; H, 5.04; N, 9.09%. IR (cm^{-1}): 3726 (m), 3047 (w), 2939 (w), 1605 (w), 1512 (m), 1454 (m), 1409 (s), 1359 (m), 1227 (s), 1187 (s), 1008 (s), 817 (m), 746 (s), 675 (s), 561 (w).

*2.2.8. Synthesis of [Ag$_2$(epes)$_2$(L^1)] $\cdot$ 2H$_2$O (**6**)*

The same synthetic method as for **5** was used except that 4-tsH was replaced by Hepes (0.048 g, 0.2 mmol). Yield: 68% based on Ag_2CO_3. *Anal.* Calc. for $C_{36}H_{60}Ag_2N_8O_{10}S_2$ (1044.78): C, 41.39; H, 5.79; N, 10.73. Found: C, 41.58; H, 5.64; N, 10.78%. IR (cm^{-1}): 3794 (w), 3726 (m), 3664 (w), 3282 (m), 2942 (m), 2850 (m), 1453 (s), 1414 (s), 1377 (s), 1174 (s), 1032 (s), 935 (m), 767 (s), 674 (w), 589 (w).

*2.2.9. Synthesis of [Ag(1,5-nds)$_{0.5}$(L^2)] $\cdot$ 0.5C$_2$H$_5$OH $\cdot$ H$_2$O (**7**)*

The same synthetic method as for **5** was used except that 4-tsH was replaced by 1,5-ndsH$_2$ (0.029 g, 0.1 mmol) and L^1 was replaced by L^2 (0.348 g, 1 mmol). Yield: 68% based on Ag_2CO_3. *Anal. Calc. for $C_{27}H_{35}AgN_4O_{5.5}S$ (638.53): C, 50.79; H, 5.52; N, 8.77. Found: C, 51.58; H, 5.64; N, 8.78%. IR (cm^{-1}): 3729 (m), 3661 (m), 3046 (m), 2938 (m), 1598 (m), 1507 (w), 1455 (s), 1414 (s), 1300 (w), 1227 (s), 1185 (s), 1117 (s), 1009 (s), 745 (s), 675 (s), 553 (w), 404 (w).*

2.3. X-ray crystallography

Single-crystal X-ray diffraction data for compounds **1** and **7** were recorded on a Bruker Apex CCD diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at 293 K. Crystallographic data for compounds **$L^1 \cdot 2H_2O$**, **$L^2 \cdot H_2O$**, and **2–6** were collected on a Rigaku RAXIS-RAPID single-crystal

diffractometer with Mo Kα radiation (λ = 0.71073 Å) at 293 K. Absorption corrections were applied using multi-scan technique. All the structures were solved by Direct Method of SHELXS-97 [25] and refined by full-matrix least-squares techniques using the SHELXL-97 program [26]. Non-hydrogen atoms were refined with anisotropic temperature parameters. The disordered ligands in compounds **6** was refined using isotropic C atoms split over two sites, with a total occupancy of 1. The hydrogen atoms of the organic ligands were refined as rigid groups. Some water and ethanol H atoms in compound $\mathbf{L^2 \cdot H_2O}$ and **7** could not be positioned reliably. Other H atoms of water molecules were located from difference Fourier maps.

3. Results and discussion

3.1. Syntheses of the compounds

As well known, the reactions of transition metals with carboxylates or sulfonates and neutral ligands in aqueous solution often result in the formation of insoluble materials, presumably because of the fast coordination of them to form polymeric structures. In this paper, the crystals of compounds **1**–**7** were obtained by using crystallization process through evaporating an ammoniacal solution of them. These compounds were synthesized by allowing a solution of transition metals with carboxylates or sulfonates and

L (L = L^1 or L^2) ligands in a mixed solution of ethanol and ammonia (5 M) to evaporate slowly. All the compounds are insoluble in water and common organic solvents, but they can be dissolved in a concentrated solution of ammonia by segregating the L^1 or L^2 ligands from metal cations. With a 1:2:1 molar ratio of M^{II}: HX: L, **1**–**4** were isolated. The reaction mixtures produce crystals with Ag_2CO_3:HX:L^1 = 1:2:1 for **5** and **6**, and Ag_2CO_3:H_2X:L = 1:1:1 for **7**. Crystallographic data are summarized in Table 1. Selected bond distances and angles for $L^1 \cdot 2H_2O$, $L^2 \cdot H_2O$ and compounds **1**–**7** are listed in Table S1 (Supplementary data).

3.2. Descriptions of crystal structures

3.2.1. Structure of $L^1 \cdot 2H_2O$ and $L^2 \cdot H_2O$

The structure of $L^1 \cdot 2H_2O$ contains discrete L^1 molecules and lattice waters (see Fig. S1 in the Supplementary data). For the L^1 molecule, the dihedral angle between two benzimidazole rings is 47.4°. The guest water molecules are hydrogen-bonded to the N atoms of the L^1 ligands, and the L^1 ligands act as anchors for holding the water clusters. In the case of $L^1 \cdot 2H_2O$, the water clusters which are associated by strong O–H···O hydrogen bonds arrange themselves to form a chain structure (Fig. S2). This supramolecular water chain is associated with the host by O–H···N hydrogen bonds. In $L^1 \cdot 2H_2O$, O1W shows a 4-coordinate mode, and the O2W shows a 2-coordinate mode (Table S2). The discrete L^1 molecules are bridged through the hydrogen-bonding interactions between the water molecules and the N atoms to form an overall two-dimensional supramolecular structure (Fig. S3). The presence of water molecules in the structure can play an important role in stabilizing the supramolecular structure because of the formation of hydrogen bonds. It is similar to $L^1 \cdot 2H_2O$, the structure of $L^2 \cdot H_2O$ contains discrete L^2 molecules and lattice water (Fig. S4).

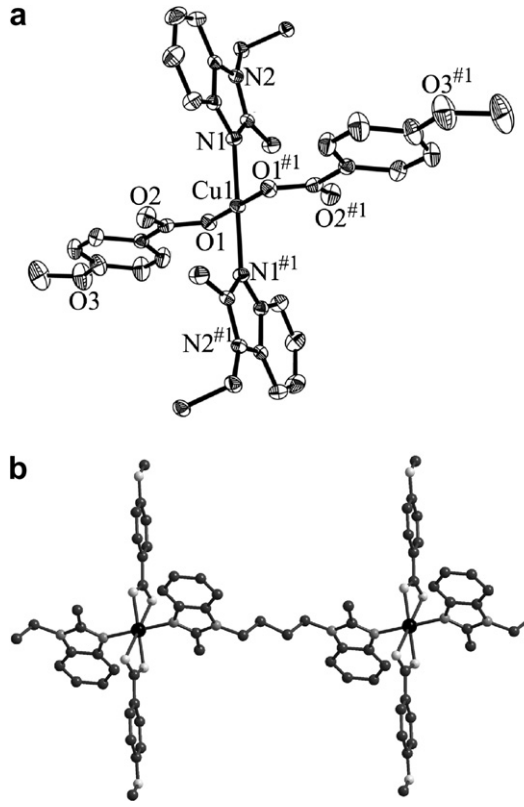

Fig. 1. (a) ORTEP diagram showing the coordination environment for Cu atom in **1**. (b) The infinite zigzag chain of **1**.

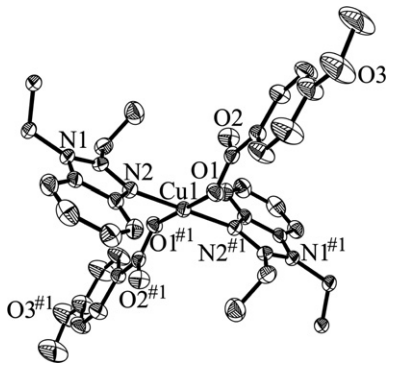

Fig. 2. ORTEP diagram showing the coordination environment for Cu atom in **2**.

3.2.2. Structure of $[Cu(pmb)_2(L^1)]$ (**1**)

Compound **1** shows chains formed by L^1 ligands connecting Cu^{II} atoms. As shown in Fig. 1a, Cu^{II} lies on a crystallographic inversion centre and each Cu^{II} is four-coordinated, forming square planar coordination geometry. The Cu^{II} is coordinated by two nitrogen atoms from two L^1 and two oxygen atoms from two pmb anions. The Cu(1)–N distance of 1.991(3) Å and the Cu(1)-O distance of 1.956(2) Å fall in the range of normal Cu–O [27–29] and Cu–N [29,30] distances. The pmb ligands exhibit monodentate coordination mode to link Cu^{II} centers. The Cu atoms are bridged by L^1 ligands to form an infinite chain (Fig. 1b), with two benzimidazolyl rings of L^1 ligand being parallel to each other.

3.2.3. Structure Description of $[Cu(pmb)_2(L^2)]$ (**2**)

The structure of **2** is similar to compound **1** except L^1 was replaced by L^2 ligands. The structure of **2** is shown in Fig. 2. Cu^{II} cations are bridged by L^2 ligands to form a chain just as that observed in compound **1**. (Fig. S5)

3.2.4. Structure of $[Cu(Ac)_2(L^2)] \cdot 4H_2O$ (**3**)

Part of the structure of compound **3** is shown in Fig. 3a. Cu^{II} cation lies at an inversion center and is six-coordinated by four oxygen atoms from two Ac anions and two nitrogen atoms from two L^2 ligands. The Cu–N distances are 2.029(1) Å, which are similar to the reported distances [31,32], while the Cu–O distances of 2.543 Å in axial positions are much longer than the average values, owing to the Jahn–Teller effect. Each Ac anion in **3** exhibits bidentate chelating coordination mode. Cu^{II} centers are connected by L^2 ligands to form an infinite wavelike chain (Fig. 3b). Compound **3** contains a unique supramolecular organization of these polymeric chains. These polymeric chains are arranged on parallel levels in different propagating directions, rotated by 81.5° on passing from one level to the successive one, thus resulting in an ABAB sequence (Fig. 3c) [33–35].

There exists a $(H_2O)_4$ cluster linked by O1W and O2W atoms (Fig. 3d). Hydrogen-bonding data indicate that the coordinated water molecule (O1W) acts as a donor and is hydrogen-bonded to the carboxylate oxygen atoms O1 and water molecule O2W; and O2W donates to $O2^{\#3}$ and $O1W^{\#4}$ [36,37]. As well-known, water molecule has two hydrogen atoms and two lone-electron pairs which enable it to participate in four hydrogen bonds in a tetrahedral configuration, but it also frequently shows a 3-coordinate configuration [38]. In compound **3**, both of the O1W and O2W show 3-coordinate modes. As shown in Fig. 4d, if we neglect L^2 ligands, the $(H_2O)_4$ clusters link Cu^{II} ions and Ac anions to form a supramolecular layer. The polymeric infinite chains in **3** are bridged through the hydrogen-bonding interactions to form a 3D supramolecular structure (Fig. 3e).

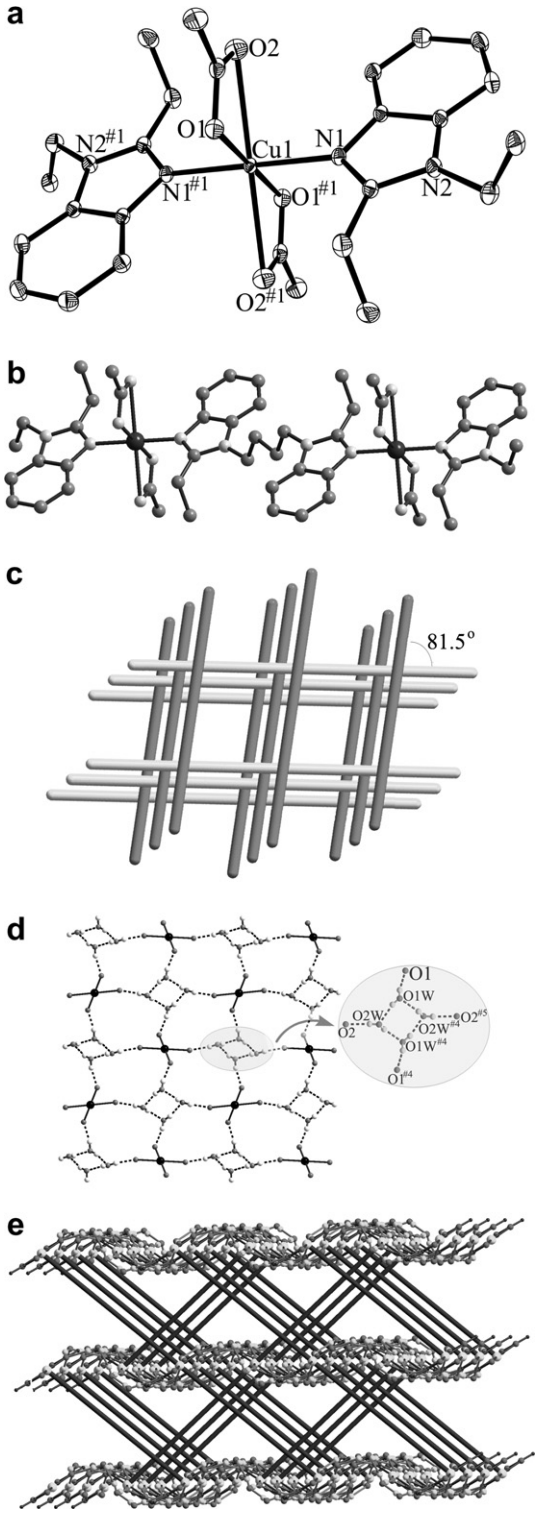

Fig. 3. (a) ORTEP diagram showing the coordination environment for Cu atom in **3**. Hydrogen atoms have been omitted for clarity. (b) The infinite zigzag chain. (c) Rod-packing picture of the chains spanning two different directions (light gray and medium gray) in **3**. (d) The supramolecular layer formed by hydrogen bonds without L^2 (H-bonds: dashed lines). (e) The 3D supramolecular structure linked by hydrogen bonds (black lines: L^2 ligands).

3.2.5. Structure of $[Cu(4\text{-}aba)_2(L^2)]$ (**4**)

As shown in Fig. 4a, Cu^{II} ion lies on a crystallographic inversion center and each Cu^{II} ion is four-coordinated, forming a square planar coordination geometry. The Cu^{II} is coordinated by two nitrogen atoms from two L^2 and two oxygen atoms from two 4-aba anions.

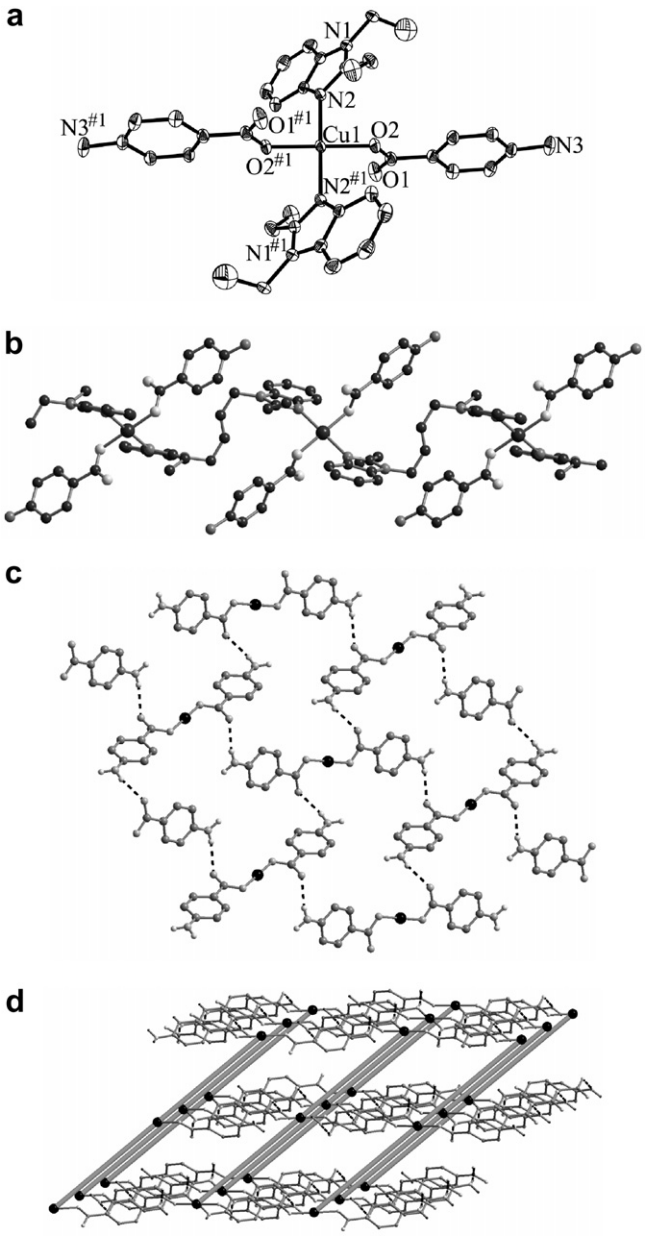

Fig. 4. (a) ORTEP diagram showing the coordination environment for Cu atom in **4**. Hydrogen atoms have been omitted for clarity. (b) The infinite zigzag chain. (c) The supramolecular layer formed by hydrogen bonds without L^2. (H-bonds: dashed lines) (d) The 3D supramolecular structure linked by hydrogen bonds. (Gray lines: L^2 ligands).

The 4-aba anions exhibit monodentate coordination mode to link Cu^{II} centers. The Cu atoms are bridged by L^2 ligands to form an infinite chain (Fig. 4b).

In the compound **4**, hydrogen bonds are present between the hydrogen atoms of the amino group and the carboxylate group of adjacent 4-aba anions. The N···O distances are 2.976(6) Å, which are similar to the reported distances [39–41]. As shown in Fig. 4c, if we neglect L^2 ligands, the hydrogen bonds link Cu^{II} ions and 4-aba anions to form a supramolecular layer. The polymeric infinite chains in **4** are bridged through the hydrogen-bonding interactions to form a 3D supramolecular structure (Fig. 4d).

3.2.6. Structure of $[Ag(4\text{-}ts)(L^1)(H_2O)]$ (**5**)

As shown in Fig. 5a, the silver ion shows a distorted tetrahedral coordination geometry, and is coordinated by two nitrogen atoms from two L^1 ligands (Ag–N = 2.270(2) Å), one sulfonate oxygen

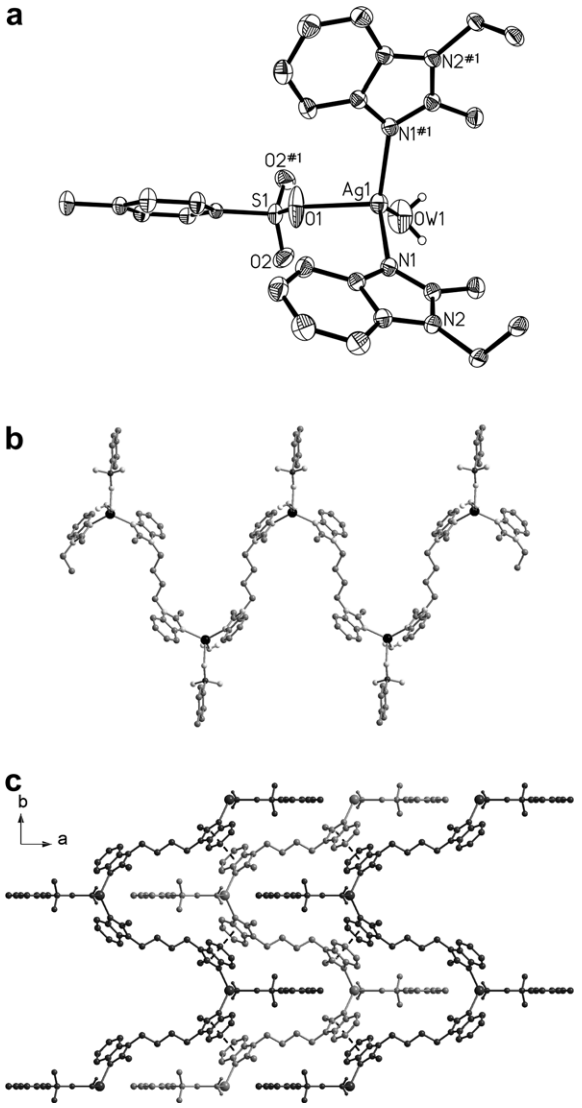

Fig. 5. (a) ORTEP diagram showing the coordination environment for Ag atom in **5**. Hydrogen atoms have been omitted for clarity. (b) The infinite wavelike chain of **5**. (c) View of the π–π interactions.

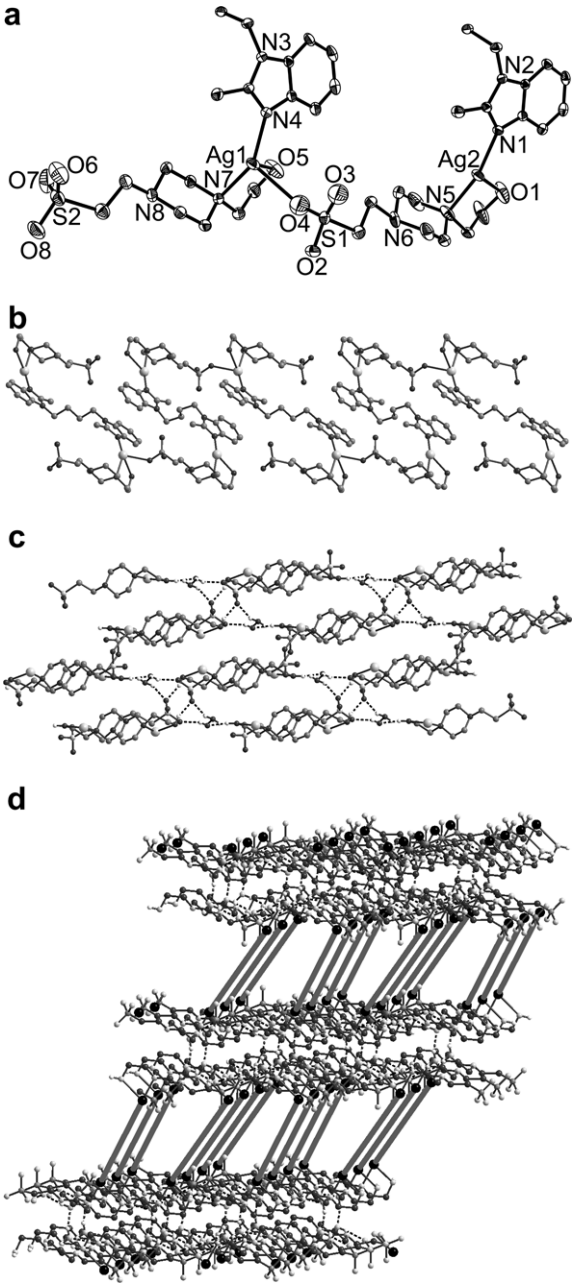

Fig. 6. (a) ORTEP diagram showing the coordination environment for Ag atom in **6**. Hydrogen atoms have been omitted for clarity. (b) The infinite zigzag chain of **6**. (c) The supramolecular layer formed by hydrogen bonds without L^1 of **6** (H-bonds: dashed lines). (d) The 3D supramolecular structure linked by hydrogen bonds. (H-bonds: dashed lines; gray lines: L^2 ligands).

atom (Ag–O = 2.434(3) Å), and one aqua ligand (Ag–O1W = 2.277(4) Å). The Ag–O bond lengths are similar to the normal distances in the related compound (AgOTs) [42]. The Ag cations are bridged by L^1 ligands to form a wavelike chain (Fig. 5b).

Aromatic–aromatic or π–π interactions engendered by aromatic–aromatic stacking are important non-covalent intermolecular forces similar to hydrogen bonding. They can contribute to self-assembly or molecular recognition when extended structures are formed from building blocks with aromatic moieties [43–46]. In compound **5**, there exist π–π stacking interactions between benzimidazole rings of the L^1 ligands, which link the wavelike chains to a supramolecular layer. The centroid-to-centroid distance is 3.61 Å (Fig. 5c).

3.2.7. Structure of $[Ag_2(epes)_2(L^1)] \cdot 2H_2O$ (**6**)

As shown in Fig. 6a, there are two crystallographically unique silver ions in the structure of **6**. Ag1 ion has a distorted tetrahedral geometry consisting of four bonds from one sulfonate oxygen atom, one oxygen atom from hydroxyl group, two nitrogen atoms from one epes anion and one L^1 ligand. Ag2 ion is three-coordinate with a distorted T-shape geometry composed of one hydroxyl oxygen atom from epes anion and two nitrogen atoms from one epes anion and one L^1 ligand. There are two kinds of crystallographically unique epes anions in the structure. One epes anion exhibits bidentate coordination mode to link Ag^I center with its hydroxyl group and nitrogen atom, and the other tridentate epes anion coordinates to two different silver ions with sulfonate oxygen atom, hydroxyl group and nitrogen atom. In the crystal structure of **6**, silver ions are bridged by L^1 ligands to form a polymeric 'S' chain (Fig. 6b).

If we neglect L^2 ligands, sulfonate anions, hydroxyl groups and water molecules are connected by hydrogen bonds to form a double layer (Fig. 6c and Fig. S6). The polymeric infinite chains in **6** are bridged through the hydrogen-bonding interactions to form a 3D supramolecular structure (Fig. 6d).

*3.2.8. Structure of [Ag(1,5-nds)$_{0.5}$(L^2)] · 0.5C_2H_5OH · H_2O (**7**)*

In compounds **5** and **6**, the anions are monosulfonate, in compound **7**, the 1,5-nds was selected as a disulfonate anion. Single X-ray analysis reveals compound **7** possesses chain structure. As shown in Fig. 7a, the Ag^I cation is coordinated by two N atoms from two L^2 ligands. Metal ions are bridged by L^2 molecules to form an infinite zigzag chain. In compound **7**, 1,5-nds anions act as counterions in the framework. This phenomenon may be due to the weak coordination ability of the sulfonate anions. The polymeric chains are arranged in a parallel mode (Fig. 7b).

3.3. Discussion

3.3.1. The effect of the neutral ligands on the structure of the complexes

L^1 and L^2 ligands display similar bidentate bridging coordination mode with two aromatic N atoms coordinating to two metal ions in compounds **1**–**7**. The similar frameworks may be expected when the L^1–L^2 are used. Indeed, compounds **1** and **2** have the similar structures.

In fact, the fine tunability is realized by changing the conformation of the neutral ligands (Scheme 3). In $L^1 \cdot 2H_2O$, the L^1 ligands adopt the zigzag conformation, the two benzimidazole rings of the L^1 ligands has a dihedral angle of 47.3° (Scheme 3a). In compounds **1** and **5**, L^1 ligands also adopt zigzag conformations, but with the benzimidazole rings of L^1 ligands being parallel to each other (Scheme 3b). In compound **6**, L^1 ligands adopt zigzag and 'S' conformations (Scheme 3b and 3c). Similar conformation changes occur for L^2 ligands. In $L^2 \cdot H_2O$, the L^2 ligands adopt zigzag conformations (Scheme 3a′). In compounds **2**, **3**, and **7**, L^2 ligands also adopt zigzag conformations (Scheme 3b′). In compound **4**, L^2 ligands adopt 'S' conformations (Scheme 3c′).

3.3.2. The effect of the anions on the structure of the complexes

From the structures of **1**–**7**, it can be seen that the anions play a very important role in the construction of the frameworks. Each of pmb, Ac and 4-aba anions contain one carboxylate group, and coordinates to only one metal ion, acting as a terminal ligand. And the related complexes (**2**–**4**) contain only one kind of connector (L^1 or L^2), and show chain structures. The 4-ts anion contains one sulfonate group, and coordinates to only one metal ion, acting as a terminal ligand. And the related complex (**5**) contains only one kind of connector (L^1), and shows a chain structure. In compound **6**, epes anion adopts two kinds of coordination modes. One kind of epes anion exhibits bidentate chelating coordination mode to link Ag^I centers with their hydroxyl groups and N atom, and the other kind of epes anion acts as an interesting tridentate ligand, coordinating to two different silver ions by their sulfonate oxygen atom, hydroxyl group and nitrogen atom. The 4-aba and epes anions containing –OH and $–NH_2$ groups have a potential for hydrogen-bonding interactions to construct supramolecular architectures. Compounds **4** and **6** show 3D supramolecular structures containing hydrogen-bonding interactions.

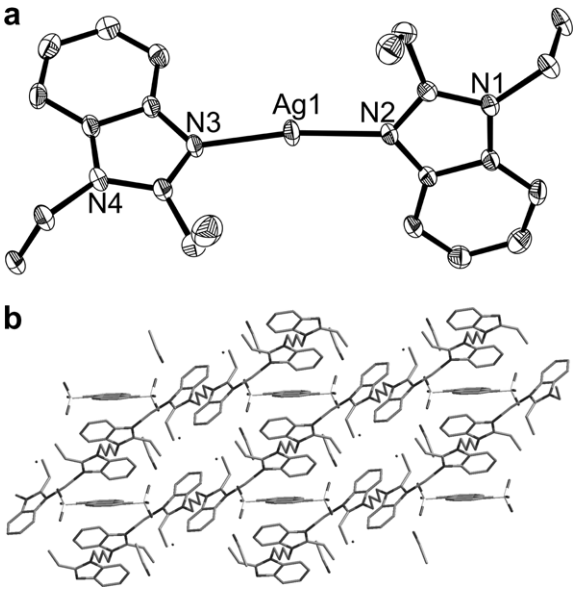

Fig. 7. (a) ORTEP diagram showing the coordination environment for Ag atom in **7**. Hydrogen atoms have been omitted for clarity. (b) Packing diagram of compound **7**.

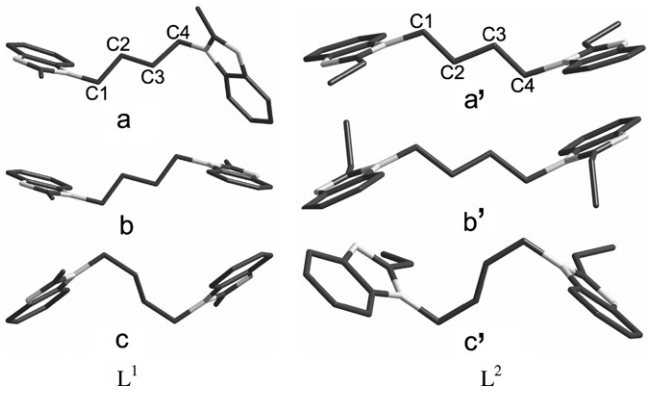

Scheme 3. Conformation of the L^1 and L^2.

3.4. Thermal analysis

In order to characterize the compounds more fully in terms of thermal stability, their thermal behaviors were studied by TGA. The experiments were performed on samples consisting of numerous single crystals of **3**, **6** and **7** under N_2 atmosphere with a heating rate of 10 °C/min (Figs. S7–S9 in the Supplementary data).

For compound **3**, the weight loss in the range of room temperature to 45 °C corresponds to the departure of water molecules (a weight loss of 1.67% is smaller than the calculated value, 10.5%, probably resulting from a very slow liberation of the water molecules from **3** at room temperature) [47]. For compound **6**, the weight loss in the range from room temperature to 156 °C corresponds to the departure of water molecules (obsd 3.9%, calcd 3.6%). The anhydrous compound begins to decompose at 230 °C. For compound **7**, the weight loss in the range from room temperature to 280 °C corresponds to the departure of water and ethanol. The decomposition of the anhydrous compound occurs at 325 °C.

3.5. Luminescent properties

Luminescent compounds are of great current interest because of their various applications in chemical sensors, photochemistry and electroluminescent (EL) display [48–50]. The photoluminescent properties of compounds **5–7** were studied at room temperature. The solid-state photoluminescent spectra of **5–7**, and the neutral

Table 2
The wavelengths of the emission maximums and excitation (nm)

Compound	5	6	7
λ_{em}	435	388, 483	358
λ_{ex}	309	315	310

ligands L^1 and L^2 are depicted in Fig. S10. The wavelengths of the emission maximums and excitation are listed in Table 2.

The free ligands display luminescence with emission maximums at 371 and 515 nm for L^1 and 365 nm for L^2, respectively (λ_{ex} = 295 nm), which are attributed to the $\pi \rightarrow \pi^*$ transitions. Compound **5** exhibits a peak at 435 nm which is probably due to ligand-to-metal charge transfer (LMCT) transition. Similar LMCT has been reported in many metal–organic coordination polymers [51–53]. Compound **6** exhibits two main peaks at 388 and 483 nm upon excitation at 315 nm. The peak at 388 nm would be assigned to $\pi \rightarrow \pi^*$ transition of neutral ligand, while the peaks at 483 nm would be attributed to the emission of LMCT. The main peak of compound **7** exhibits at 358 nm (λ_{ex} = 310 nm), which is probably due to the $\pi \rightarrow \pi^*$ transition of neutral ligand because similar peak also appears for the free bis(benzimidazole) ligand [54–56].

4. Conclusion

In summary, seven metal coordination polymers based on L^1–L^2 ligands and six kinds of different anions have been synthesized and characterized. The results of this study not only illustrate that the neutral ligands play an important role in the construction of coordination polymers, but also illustrate that the coordination modes of anions and the coordination behavior of metal ions can also have an influence on the final frameworks. It is anticipated that more metal complexes containing neutral ligands and carboxylate or sulfonate anions with interesting structures as well as physical properties will be synthesized.

ABSTRACT

Coordination compounds with a *trans*-stereochemistry were prepared for ligands (4-ClC_6H_4)CH=NCH_2(4′-ClC_6H_4) (**L_a**), (2,4,6-$Me_3C_6H_2$)CH=NCH_2(4′-ClC_6H_4) (**L_b**) and (2,6-$Cl_2C_6H_3$)CH=NCH_2(4′-ClC_6H_4) (**L_c**) and were shown to be precursors of the corresponding cyclometallated compounds. The reactions between *cis*-[$PtCl_2$(dmso)$_2$] and ligands ArCH=NCH_2(4′-ClC_6H_4) (Ar = 2-BrC_6H_4 (**L_d**); 2-ClC_6H_4 (**L_e**); C_6F_5 (**L_f**); 2,6-$F_2C_6H_3$ (**L_g**)) under previously described conditions for cycloplatination of *N*-benzylidenebenzylamines gave a cyclometallated compound only for imine **L_f**; the other imines produced coordination compounds with a *cis* arrangement from which cyclometallation could not be achieved. Formation of either *cis* or *trans* coordination compounds [$PtCl_2$(**L**)dmso] (**L** = *N*-benzylidenebenzylamine) can be related to steric effects and to the *E*/*Z* configuration of the C=N bond. All compounds were fully characterized including structure determinations for *trans*-[$PtCl_2${(4-ClC_6H_4)CH=NCH_2(4′-ClC_6H_4)}$SOMe_2$] (**2a**), *trans*-[$PtCl_2${(2,6-$Cl_2C_6H_3$)CH=NCH_2(4′-ClC_6H_4)}$SOMe_2$] (**2c**) and the amine derivative *trans*-[$PtCl_2$(4-$ClC_6H_4CH_2NH_2$)$SOMe_2$] (**2**) obtained as a by-product.

1. Introduction

Cyclometallation of N-donor ligands by platinum and palladium has remained as one of the major topics in organometallic chemistry [1]. Recently *cis*-[$PtCl_2$(dmso)$_2$] has become an useful substrate for direct cycloplatination, and numerous examples have been reported including tridentate [C,N,X] (X = N [2], S [3] and O[4]) as well as bidentate [C,N] systems derived from imines [5], oximes [6], pyridines[7] or even tertiary amines leading to either mono [8] or dinuclear [9] compounds.

Coordination compounds [$PtCl_2$(**L**)dmso] (**L** = nitrogen donor ligand) with a *trans* geometry have been postulated as precursors to the cyclometallated derivatives [5c,10] and crystal structures of these compounds confirm the proposed *trans* arrangement [5c,8c,10,11]. However, these results do not address specifically whether only *trans* isomer of the precursor or also *cis* isomer may lead to successful cyclometallation.

In view of these facts, the synthesis of novel coordination compounds [$PtCl_2$(**L**)dmso] (**L** = nitrogen donor ligand) was envisaged in this work in order to ascertain whether their *cis* or *trans* arrangement is decisive for a successful cyclometallation process. We have recently reported the reactions of *cis*-[$PtCl_2$(dmso)$_2$] with bifunctional *N*-benzylidenebenzylamines of general formula ArCH-NCH_2(4′-ClC_6H_4) leading to either *endo* (containing the imine functionality) or *exo* cyclometallated platinum compounds [12]. These ligands along with similar ones with *ortho* substituents of different bulk were selected for this study.

2. Results and discussion

2.1. Coordination compounds as precursors to cycloplatinated derivatives

Initial work was carried out for imines (4-ClC_6H_4)CH=NCH_2(4′-ClC_6H_4) (**L_a**), (2,4,6-$Me_3C_6H_2$)CH=NCH_2(4′-ClC_6H_4) (**L_b**) and (2,6-$Cl_2C_6H_3$)CH=NCH_2(4′-ClC_6H_4) (**L_c**) for which cyclometallated derivatives **3a**, **3b** and **3c** (see Chart 1) have been previously prepared in a "one-pot" synthesis using *cis*-[$PtCl_2$(dmso)$_2$] as metallating agent [12]. The aim of isolating the corresponding coordination compounds is (i) to determine the *cis* or *trans* arrangement and (ii) to confirm that these compounds are intermediates in the cycloplatination process.

The reaction of the imine 4-ClC_6H_4CH=NCH_2(4′-ClC_6H_4) with *cis*-[$PtCl_2$(dmso)$_2$] in refluxing methanol for 4 h produced the corresponding aldehyde and the amine derivative *trans*-[$PtCl_2$(4-$ClC_6H_4CH_2NH_2$)$SOMe_2$] (**2**) which was characterized crystallographically. This result suggests hydrolysis of the imine with adventitious water in the solvent, a process that has been reported for palladium or platinum compounds under metallation

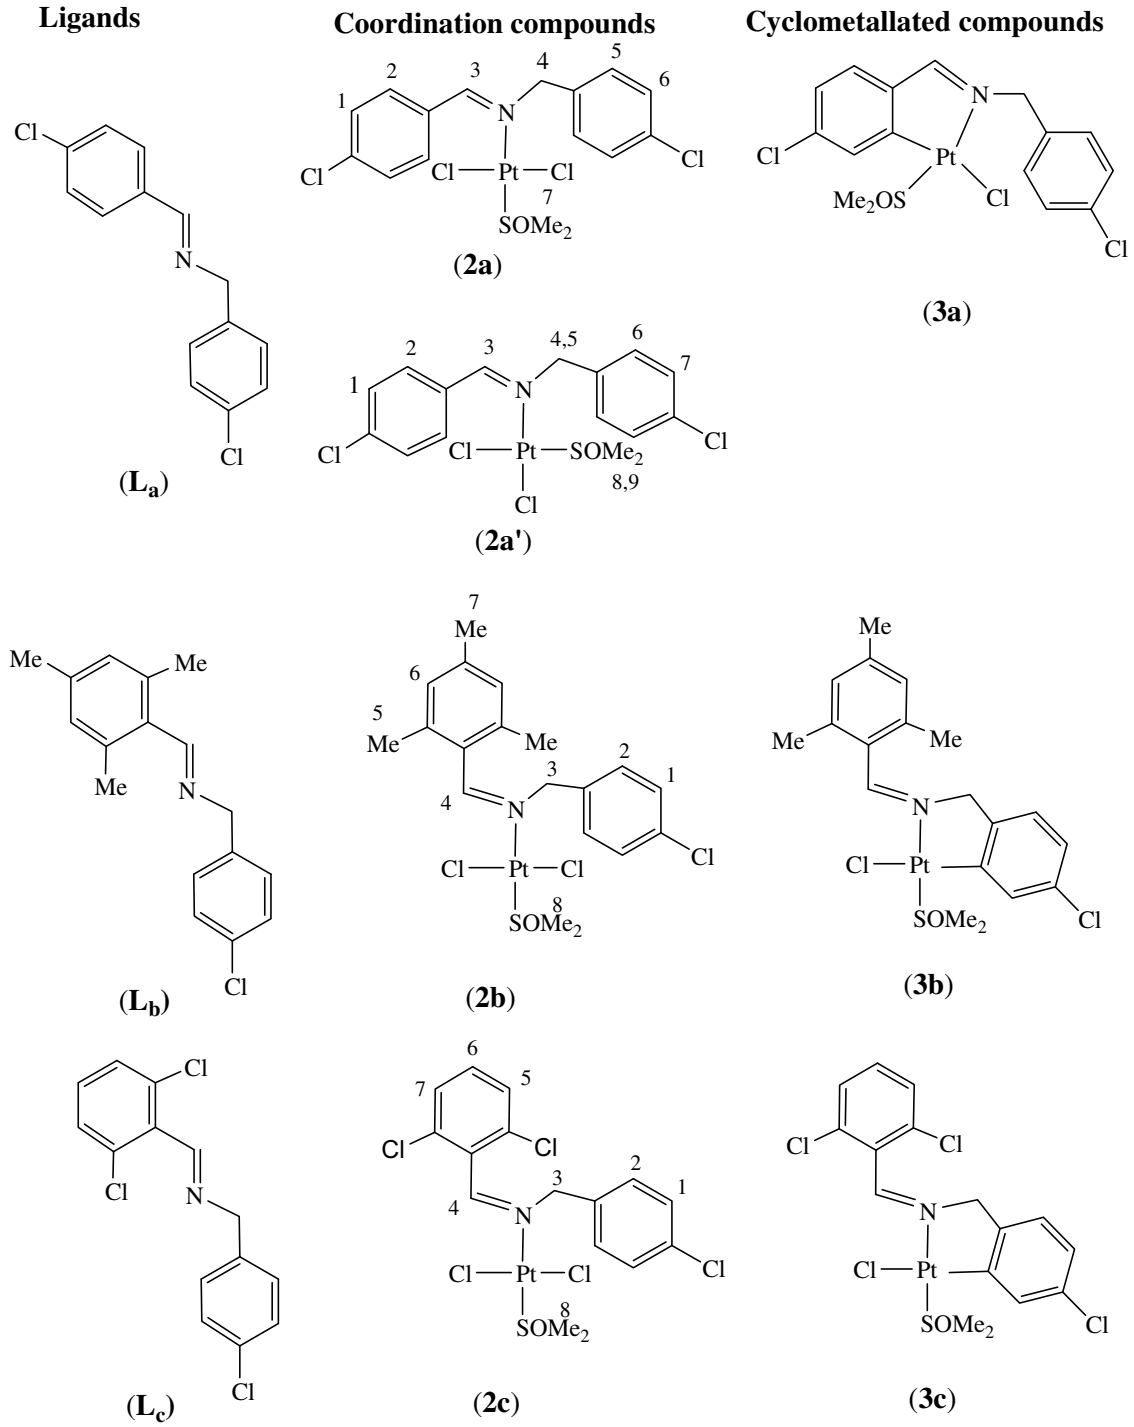

Chart 1.

conditions [2a]. When the reaction was carried out in refluxing dry toluene, hydrolysis was avoided and a mixture of *trans* and *cis*-$[PtCl_2\{(4\text{-}ClC_6H_4)CH{=}NCH_2(4'\text{-}ClC_6H_4)\}SOMe_2]$ (**2a** and **2a**′ shown in Chart 1) was produced. Suitable crystals for structure resolution of the *trans* isomer were obtained. The ^{1}H NMR spectra of the *cis* and *trans* isomers display distinct features. For the *cis* isomer, both the methylene hydrogen atoms and the methyl groups of the dimethylsulfoxide ligand appear as non-equivalent which suggest a low symmetry, and the imine hydrogen displays a large *J*(H–Pt) value (117.4 Hz) which is consistent with the presence of a chloro ligand in a *trans* position and with an *E* conformation[1] of the imine as confirmed by a 2D-NOESY experiment. Conversely, for the *trans* isomer both the methylene hydrogen atoms and the methyl groups of the dimethylsulfoxide ligand appear as equivalent and the *J*(H–Pt) for the imine hydrogen is reduced (84.5 Hz) compared to the *cis* isomer which is consistent with the presence of a dimethylsulfoxide li-

[1] *Z*/*E* conformation has been assigned as for the free imine (not taking into account the platinum coordination to the nitrogen).

gand in a *trans* position to the nitrogen atom. The presence of a cross-peak signal between the imine and the methylene protons in a 2D-NOESY NMR spectrum supports an *E* conformation across the C=N bond.

The reactions of imines $\mathbf{L}_b$ and $\mathbf{L}_c$ with *cis*-[$PtCl_2(dmso)_2$] were also studied in refluxing toluene and produced the corresponding compounds *trans*-[$PtCl_2\{(2,4,6\text{-}Me_3C_6H_2)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2$] (**2b**) and *trans*-[$PtCl_2\{(2,6\text{-}Cl_2C_6H_3)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2$] (**2c**). For these compounds, both the methylene hydrogen atoms and the methyl groups of the dimethylsulfoxide ligand appear as equivalent as expected for a *trans* stereochemistry. The *J*(H–Pt) values for the imine hydrogen of **2b** and **2c** are consistent with a *Z* conformation across the C=N bond [13] since it is reduced (37.2 and 42.6 Hz, respectively) compared to that of **2a** (84.5 Hz).

In order to confirm that *trans*-[$PtCl_2(4\text{-}ClC_6H_4CH{=}NCH_2(4'\text{-}ClC_6H_4))SOMe_2$] (**2a**) is a precursor to the cyclometallated compound **3a**, the coordination compound was dissolved in toluene and treated with an equimolar amount of sodium acetate dissolved in methanol. Refluxing the mixture for 48 h produced quantitative formation of the cyclometallated compound **3a**, thus confirming that the coordination compound is an intermediate in the cyclometallation process which requires the presence of added base. Analogous reactions carried out for *trans*-[$PtCl_2\{(2,4,6\text{-}Me_3C_6H_2)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2$] (**2b**) in refluxing toluene and for *trans*-[$PtCl_2\{(2,6\text{-}Cl_2C_6H_3)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2$] (**2c**) in refluxing methanol lead to the corresponding *exo*-metallacycles **3b** and **3c**.

However, an analogous experiment carried out with a mixture of *trans* and *cis*-[$PtCl_2(4\text{-}ClC_6H_4CH{=}NCH_2(4'\text{-}ClC_6H_4))SOMe_2$] (**2a**/**2a**′) gave a mixture of the cyclometallated compound **3a** and the *cis* coordination compound **2a**′ which was recovered unchanged. This result suggests that only the *trans* isomer may lead to cyclometallation.

2.2. Crystal structures of *trans*-[$PtCl_2(4\text{-}ClC_6H_4CH_2NH_2)SOMe_2$] (**2**), *trans*-[$PtCl_2\{(4\text{-}ClC_6H_4)CH{=}NCH_2(4'\text{-}ClC_6H_4)\}SOMe_2$] (**2a**) and *trans*-[$PtCl_2\{(2,6\text{-}Cl_2\ C_6H_3)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2$] (**2c**)

Crystals of compounds **2**, **2a** and **2c** were grown from dichloromethane–methanol. The crystal structures are composed of discrete molecules separated by van der Waals interactions. The structures of **2** and **2c** consist of the packing in the asymmetric unit of four and two independent molecules, respectively, in both cases with bond parameters equal within experimental error [3σ]. The structures are shown in Figs. 1–3 and selected molecular dimensions are listed in Table 1. The molecular structures confirm the geometries predicted from spectroscopic data. The coordination sphere of platinum is square-planar with two mutually *trans* chloro ligands, a S-bound dimethylsulfoxide and the N-donor ligand completing the coordination sphere. The angles between adjacent atoms in the coordination sphere of platinum lie in the range 85.9–95.36° (**2**), 88.40–93.77° (**2a**) and 87.67–94.16° (**2c**). Pt–Cl, Pt–N and Pt–S bond lengths are well within the range of values obtained for similar complexes of platinum [8c,10,11].

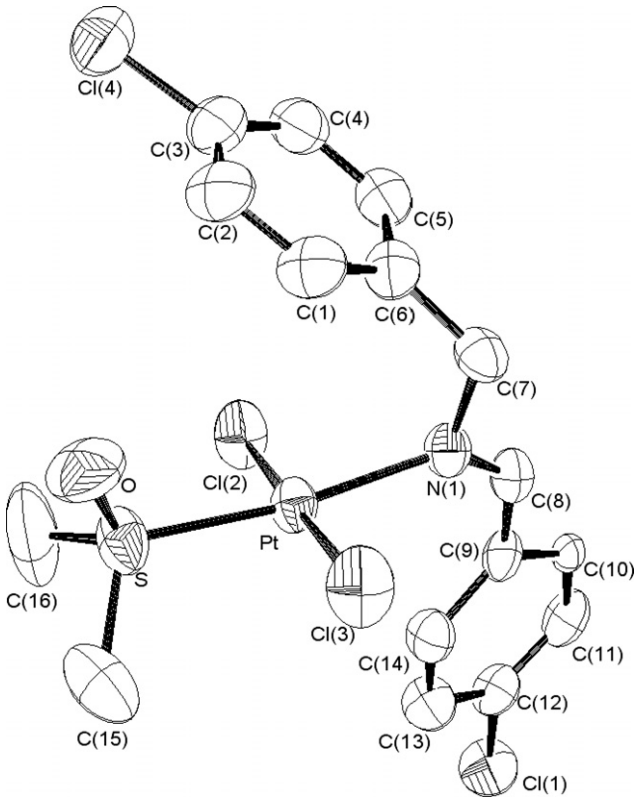

Fig. 2. Molecular structure of **2a**.

For **2a**, the configuration at the C=N moiety is *E* which is the adequate arrangement for formation of an *endo*-metallacycle through activation of a C–H bond at the benzal ring. The Pt···H(14)–C(14) distance is only 2.651 Å, a smaller value than the one observed for the *ortho* hydrogen atoms of the benzylamine (3.161 Å) which suggest that formation of an *endo*-cycle from **2a** is more favoured than that of an *exo* derivative, as experimentally observed [12]. For **2c**, the configuration at the C=N moiety is *Z*, a form that allows formation of an *exo*-cycle [12] and the shortest distance between platinum and the *ortho* hydrogen atoms is 3.289 Å for Pt···H(110)–C(110). For **2a** and **2c**, the distances between platinum

and *ortho* C–H bonds are in the range reported for an analogous compound with a coordinated aryl oxime (3.153 Å), described as an intermediate in the cyclometallation process [10]. The distances between platinum and *ortho* hydrogen atoms observed for the 4-chlorobenzylamine derivative **2** are considerably greater (4.668 Å is the shortest distance for molecule 1) and, consistently, the cyclometallation of 4-chlorobenzylamine did not occurred so readily as for the benzylidenebenzylamine $\mathbf{L}_a$ [12].

2.3. Reactions of *cis*-[$PtCl_2(dmso)_2$] with ligands $ArCH{=}NCH_2(4'\text{-}ClC_6H_4)$ ($Ar = 2\text{-}BrC_6H_4$ ($\mathbf{L}_d$); $2\text{-}ClC_6H_4$ ($\mathbf{L}_e$); C_6F_5 ($\mathbf{L}_f$); $2,6\text{-}F_2C_6H_3$ ($\mathbf{L}_g$))

In order to complete this study, the reactions of *cis*-[$PtCl_2$-$(dmso)_2$] with ligands $\mathbf{L}_d$–$\mathbf{L}_g$ which had not been tested so far towards cycloplatination, were also studied. The *N*-benzylidenebenzylamine ligands $\mathbf{L}_d$–$\mathbf{L}_g$ were prepared by a condensation reaction of 4-chlorobenzylamine with the corresponding aldehyde. They were formed as single isomers and the expected *E* configuration of the C=N bond was confirmed by a cross-peak between the imine and the methylene protons in the 2D-NOESY NMR spectra taken for $\mathbf{L}_d$ and $\mathbf{L}_f$ (see Chart 2).

Ligands $\mathbf{L}_d$ and $\mathbf{L}_e$ might in principle lead to either *endo* (containing the imine functionality) or *exo* five-membered metallacycles. Ligands $\mathbf{L}_f$ and $\mathbf{L}_g$ contain fluoro substituents in the *ortho* positions of the benzal ring and, although intramolecular C–F bond activation for analogous ligands has been reported at electron rich platinum(II) substrates [14], this process is not expected in principle for an electrophilic substrate such as *cis*-[$PtCl_2(dmso)_2$]; therefore, formation of an *exo*-metallacycle through C–H activation in the benzylamine ring is more likely. As shown in Chart 3, both *endo*- and *exo*-cycles can be formed from the *E* form, while only *exo*-cycles are possible for the *Z* form.

Initially, the reactions of imines $\mathbf{L}_d$-$\mathbf{L}_g$ were carried out using *cis*-[$PtCl_2(dmso)_2$], the imine and CH_3CO_2Na in a 1:1:2 ratio and heat-

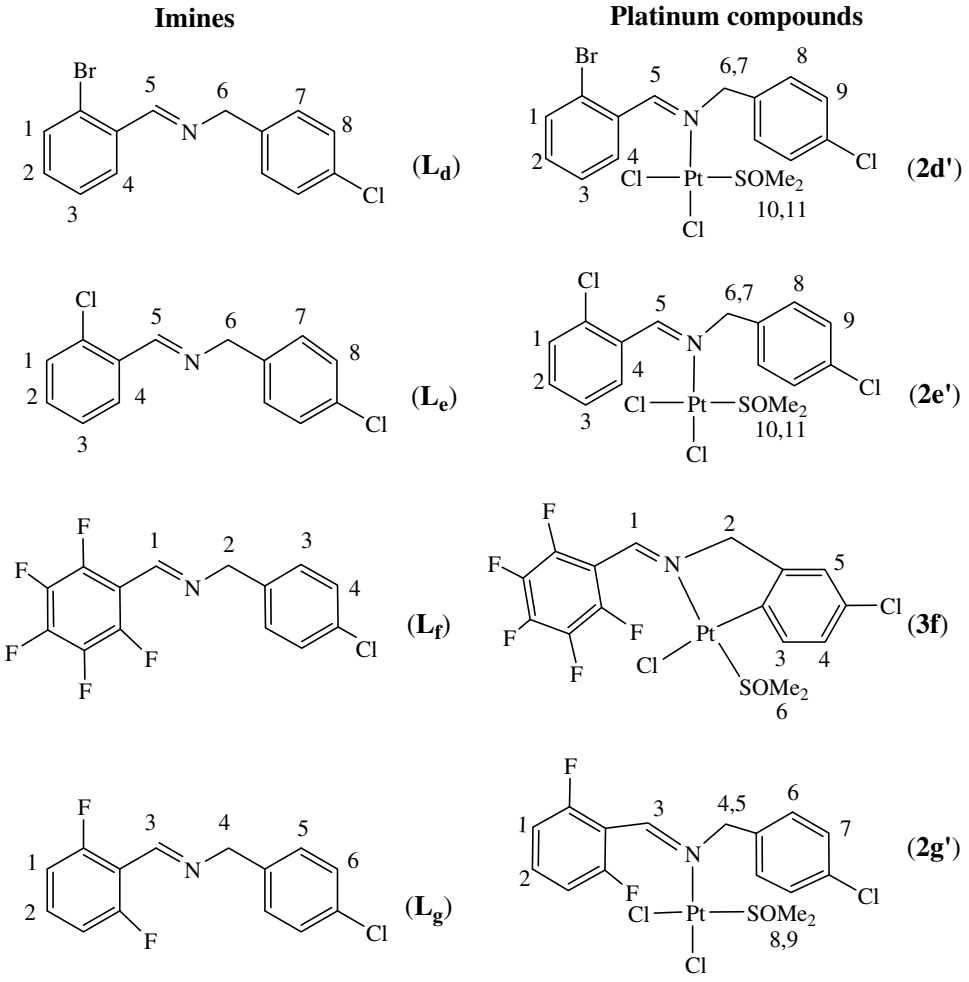

Chart 2.

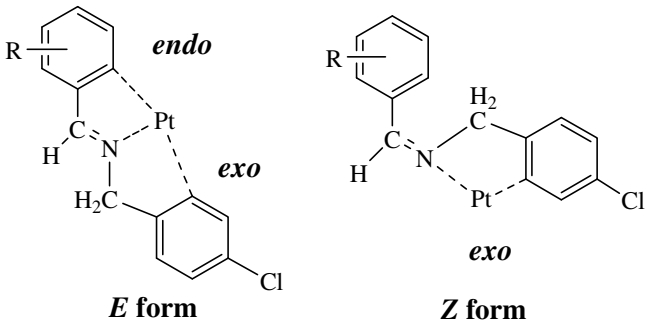

Chart 3.

ing the obtained mixture in refluxing methanol during 48 h. According to the NMR spectra of the crude products, only one platinum compound was detected in each reaction, along with formation of metallic platinum and the corresponding aldehyde. Due to decomposition processes of the platinum compounds as well as to hydrolysis of the imines, low yields were obtained. After work-up of the reaction mixtures, a cyclometallated compound was obtained in extremely low yield for imine $C_6F_5CHNCH_2(4\text{-}C_6H_4Cl)$ ($\mathbf{L}_f$) while the other imines produced coordination compounds with a *cis* arrangement. The proposed structures are shown in Chart 2. For imine $\mathbf{L}_e$, the reaction time was increased up to six days, however the *cis* coordination compound was again the only product and no evidence of formation of the corresponding cyclometallated compound was observed.

With the aim of achieving the syntheses of cyclometallated derivatives, the reactions of imines $\mathbf{L}_d$ and $\mathbf{L}_e$ were tested under more drastic conditions. A molar ratio [Pt]:[**L**]:[acetate] = 1:1:1 was used; sodium acetate was dissolved in a small amount of methanol and added to a solution of imine and *cis*-$[PtCl_2(dmso)_2]$ in toluene and the mixture was refluxed for 48 h under nitrogen. Since a higher concentration of the base could favour the cyclometallation process, a molar ratio [Pt]:[**L**]:[acetate] = 1:1:2 was also tested for both reactions. In all cases, the coordination compounds described above were obtained with similar yields to those obtained when methanol was used as a solvent.

Attempts to obtain the corresponding cyclometallated compound were also carried out using the coordination compound **2e**′ as starting material. In one experiment, compound **2e**′ was dissolved in toluene, sodium acetate dissolved in methanol was added and the mixture was heated under reflux for 48 h; in another experiment, coordination compound **2e**′ in the solid state was heated at 145 °C in an oven for three days following a literature procedure for cycloplatination of a benzophenone imine [11]. In both cases, the coordination compound was recovered and longer reaction times lead only to partial decomposition with no evidence of cyclometallation.

The obtained compounds were characterized by ^1H, ^{13}C (**2e**′), ^{19}F (**3f** and **2g**′), COSY ^1H–^1H (**2d**′), NOESY ^1H–^1H (**2e**′, **3f** and **2g**′) and gHSQC ^1H–^{13}C (**2e**′, **3f** and **2g**′) NMR spectra, mass spectrometry

and elemental analyses (except for **3f** due to its low stability). For compound **3f**, the presence of only three crossing peaks in the aromatic region of the {^{1}H–^{13}C}-heterocorrelation spectra can be taken as evidence of cyclometallation leading to an *exo*-metallacycle and the presence of a cross-peak signal between the imine and the methylene protons in a 2D-NOESY NMR spectrum supports an *E* conformation across the C=N bond [1]. Coordination compounds **2d′**, **2e′** and **2g′** display analogous NMR spectral features to those described in the previous section for compound **2a′**. In addition, the presence of 6 (**2e′**) or 4 (**2g′**) crossing peaks in the aromatic region of the {^{1}H–^{13}C}-heterocorrelation spectra confirms that intramolecular C–H activation did not occur in these reactions. A *cis* arrangement of these coordination compounds is consistent with all the spectral data. In addition, the NOESY NMR spectrum of **2e′** indicates that each methyl of the dimethylsulfoxide ligand is close to one of the aromatic rings of the imine.

The very low yield obtained for cyclometallated compound **3f** was not totally unexpected taking into account the low stability of *exo*-metallacycles as previously observed for ligand 2,4,6-$Me_3C_6H_2CHNCH_2(4'\text{-}ClC_6H_4)$ [12]. More striking is the failure to obtain cyclometallated derivatives for ligands $\mathbf{L}_d$, $\mathbf{L}_e$ and $\mathbf{L}_g$ which are analogous to the *N*-benzylidenebenzylamines previously studied ($\mathbf{L}_a$–$\mathbf{L}_c$) for which cyclometallation was successful. This result could be related to the *cis* arrangement of the coordination compounds derived from $\mathbf{L}_d$, $\mathbf{L}_e$ and $\mathbf{L}_g$ versus the *trans* geometry of $\mathbf{L}_a$, $\mathbf{L}_b$ and $\mathbf{L}_c$ derivatives.

In an attempt to obtain the corresponding *trans* isomer, the reaction of imine $\mathbf{L}_e$ with *cis*-[$PtCl_2(dmso)_2$] was studied under the conditions used for imines $\mathbf{L}_a$, $\mathbf{L}_b$ and $\mathbf{L}_c$, which consist in refluxing the mixture in toluene for 4 h. In contrast to the results obtained for the latter imines, the reaction of $\mathbf{L}_e$ produced exclusively the *cis* isomer of the coordination compound **2e′** without traces of the *trans* isomer. In an analogous procedure for imine $\mathbf{L}_f$, no reaction was observed and the starting materials were recovered; this suggests that the low basicity of the imine bearing an electron-withdrawing group such as C_6F_5 inhibits the coordination to platinum.

3. Conclusions

In agreement with previously suggested mechanism for the cyclometallation process [5c,8c,10], the results here obtained show that cycloplatination is successful for those ligands leading to a *trans* isomer of the coordination compound ($\mathbf{L}_a$, $\mathbf{L}_b$ and $\mathbf{L}_c$), while the cyclometallation process is inhibited for those ligands leading to a *cis* isomer of the coordination compound ($\mathbf{L}_d$, $\mathbf{L}_e$ and $\mathbf{L}_g$). Crystal structures for *trans* complexes **2a** and **2c** indicate a suitable arrangement of these compounds as precursors of *endo* (**3a**) and *exo* (**3c**) metallacycles, respectively. Unfortunately, suitable crystals for structure determination of the *cis* coordination compounds could not be obtained. It is expected, however, that steric effects are important due to the mutual proximity of dimethylsulfoxide and imine ligands in an *E* conformation. In order to minimize the steric effects, it is likely that both aryl rings of the imine ligand would be tilted away from the coordination plane in an arrangement which is not suitable for cyclometallation. In addition, for the *cis* isomer there is only one Pt–Cl *cis* to the N-donor ligand and available for cyclometallation.

It has been reported in the literature that the reaction between *cis*-[$PtCl_2(dmso)_2$] and nitrogen donor ligands lead to formation of *trans*-[$PtCl_2$(**L**)dmso] [15] in a substitution process that takes place with stereo-chemical change as shown in Eq. (1).

$$cis\text{-}[PtCl_2(dmso)_2] + L \rightarrow trans\text{-}[PtCl_2(\mathbf{L})dmso] + dmso \quad (1)$$

In addition, slow *trans* to *cis* isomerization might be observed since complexes having the *cis* configuration are usually more stable than the *trans* compounds [16]. Further studies indicated that if there is a high steric hindrance due to *ortho* substituents in the ligand, direct formation of the *cis* isomer takes place [15]. These results are related to the position of the entering ligand in the five-coordinate intermediate or transition state: axial for non-bulky ligands and equatorial for bulky ligands.

The results here reported can be rationalized on steric grounds taking into account that upon coordination to metal centres, *N*-benzylidenebenzylamines of considerable size might reduce the steric hindrance through *E* to *Z* isomerization around the imine bond [13,17]. Therefore, three distinct types of coordination compounds [$PtCl_2$(**L**)dmso] have been obtained: (i) The less bulky ligand $\mathbf{L}_a$ produced a *trans* isomer with an *E* conformation of the imine which in the absence of added base isomerizes partially to the *cis* isomer **2a′**, but in the presence of CH_3CO_2Na gives the corresponding cyclometallated compound **3a**; (ii) Ligands $\mathbf{L}_d$, $\mathbf{L}_e$ and $\mathbf{L}_g$ containing, respectively, one bromo, one chloro or two fluoro substituents in the *ortho* positions of the benzal ring are sterically more demanding than ligand $\mathbf{L}_a$ and direct formation of the *cis* isomers **2d′**, **2e′** and **2g′** takes place; therefore, cyclometallation is inhibited; (iii) The bulkier ligands $\mathbf{L}_b$ and $\mathbf{L}_c$ adopt a *Z* conformation of the imine to reduce the steric hindrance upon coordination and this allows formation of *trans* isomers **2b** and **2c** which are precursors of cyclometallated compounds **3b** and **3c**. In conclusion, the combined effect of steric hindrance due to *ortho* substituents and of the *E* or *Z* configuration of the C=N bond seems decisive on the formation of either *cis* or *trans* coordination compounds of *N*-benzylidenebenzylamines and, consequently, on the success of the cyclometallation process.

4. Experimental

4.1. General

Toluene (ACS) and methanol (ACS; max. 0.005 H_2O) were used as received from commercial sources.

Microanalyses were performed at Serveis Cientifico-tècnics (Universitat de Barcelona) and at Servei de Recursos Científics i Tècnics (Universitat Rovira i Virgili, Tarragona).

Mass spectra were performed at Servei d'Espectrometria de Masses (Universitat de Barcelona). Electrospray mass spectra were carried out in a LC/MSD-TOF spectrometer using H_2O–CH_3CN 1:1 to introduce the sample. CI mass spectra were carried out in a HP-5988A spectrometer using NH_3. NMR spectra were performed at Unitat de RMN d'Alt Camp (Universitat de Barcelona). ^{1}H, ^{13}C and ^{19}F spectra were recorded by using Varian Unity 300 (^{1}H, 300 MHz; ^{19}F, 282.2 MHz), Mercury-400 (^{1}H, 400 MHz; ^{13}C, 100.6 MHz; ^{19}F, 376.5 MHz) and Varian Inova DMX-500 (^{1}H, 500 MHz; ^{1}H–^{1}H-COSY; ^{1}H–^{1}H-NOESY, ^{1}H–^{13}C-gHSQC) spectrometers, and referenced to $SiMe_4$ (^{1}H, ^{13}C), and $CFCl_3$ (^{19}F). δ values are given in ppm and *J* values in Hz. Abbreviations used: s = singlet; d = doublet; t = triplet; m = multiplet; br = broad; NMR labelling as shown in Charts 1 and 3.

4.2. Preparation of the compounds

4-Chlorobenzylamine was used as received from commercial sources. *cis*-[$PtCl_2(dmso)_2$] [18] and ligands $\mathbf{L}_a$, $\mathbf{L}_b$ and $\mathbf{L}_c$ [12] were prepared using reported procedures.

4.2.1. Preparation of the ligands

Compounds $\mathbf{L}_d$–$\mathbf{L}_g$ were prepared from the reaction of 0.507 g (2.7 mmol) of 2-bromobenzaldehyde ($\mathbf{L}_d$), 0.509 g (3.6 mmol) of 2-chlorobenzaldehyde ($\mathbf{L}_e$), 0.503 g (2.6 mmol) of pentafluorobenzaldehyde ($\mathbf{L}_f$) or 0.506 g (3.6 mmol) of 2,6-difluorobenzaldehyde

($\mathbf{L_g}$) with an equimolar amount (0.396 g ($\mathbf{L_d}$), 0.511 g ($\mathbf{L_e}$), 0.371 g ($\mathbf{L_f}$), 0.511 g ($\mathbf{L_g}$)) of 4-chlorobenzylamine in dichloromethane (20 mL) with an excess of Na_2SO_4. The mixture was stirred under reflux for 2 h and filtered. The solvent was removed in a rotary evaporator to yield white ($\mathbf{L_d}$, $\mathbf{L_e}$) or yellow ($\mathbf{L_f}$, $\mathbf{L_g}$) solids. (2-BrC_6H_4)$CHNCH_2$(4′-ClC_6H_4) ($\mathbf{L_d}$): Yield 708 mg (85%). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.77 [s, 1H, H^5], 8.06 [dd, ^3J(H–H) = 7.8, ^4J(H–H) = 1.8, 1H, H^4], 7.58 [dd, ^3J(H–H) = 8.0, ^4J(H–H) = 1.2, 1H, H^1], 7.36–7.24 [m, 6H, $H^{2,3,7,8}$], 4.82 [s, 2H, H^6]. CI-MS (NH_3) *m*/*z*: 308.2 $[M]^+$. (2-ClC_6H_4)$CHNCH_2$(4′-ClC_6H_4) ($\mathbf{L_e}$): Yield 818 mg (86%). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.84 [s, 1H, H^5], 8.08 [dd, ^3J(H–H) = 7.8, ^4J(H–H)=1.8, 1H, H^4], 7.38–7.26 [m, 6H, $H^{1,2,3,7,8}$], 4.82 [s, 2H, H^6]. (C_6F_5)$CHNCH_2$(4-ClC_6H_4) ($\mathbf{L_f}$): Yield 648 mg (78%). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.50 [s, 1H, H^1], 7.36–7.25 [m, 4H, $H^{3,4}$], 4.86 [s, 2H, H^2]. ^{19}F NMR (376.5 MHz, $CDCl_3$): δ = −138.67 [dd, 2F, *J*(F–F) = 24.4; 8.0, F^{ortho}], −146.68 [t, 1F, *J*(F–F) = 21.8, F^{para}], −157.83 [td, 2F, *J*(F–F) = 21.8; 8.0, F^{meta}]. CI-MS (NH_3) *m*/*z*: 320.3 $[M+H]^+$. (2,6-$F_2C_6H_3$)$CHNCH_2$(4′-ClC_6H_4) ($\mathbf{L_g}$): Yield 746 mg (78%). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.60 [s, 1H, H^3], 7.39–7.23 [m, 5H], 7.00–6.92 [m, 2H], 4.85 [s, 2H, H^4]. ^{19}F NMR (282.2 MHz, $CDCl_3$): δ = -113.67 [t, ^3J(F–H) = 7.0, 2F]. CI-MS (NH_3) *m*/*z*: 266.7 $[M+H]^+$.

4.2.2. Preparation of platinum compounds

$[PtCl_2\{(4\text{-}ClC_6H_4)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2]$ (**2a**/**2a′**) was obtained from 0.322 g (0.76 mmol) of *cis*-$[PtCl_2(dmso)_2]$ and 0.200 g (0.76 mmol) of the imine $\mathbf{L_a}$ which were allowed to react in dry toluene (50 mL) at 100 °C for 4 h. Unreacted *cis*-$[PtCl_2(dmso)_2]$ was removed by filtration of the reaction mixture, the solvent was removed in a rotary evaporator and the residue was re-crystallized in dichloromethane–methanol, yielding a first crop of orange-yellow crystals of **2a** (yield 66 mg; 14.3%) followed by pale-yellow solid which was a mixture of **2a** and **2a′** (yield 115 mg; 24.7%) and a final crop of **2a′** (yield 45 mg; 9.8%). Total yield 226 mg (48.8%). **2a**: ^{1}H NMR (500 MHz, $CDCl_3$): δ = 8.62 [d, $^3J(H^1–H^2)$ = 8.6, 2H, H^1], 8.28 [t, $^3J(^{195}Pt–H^3)$ = 84.5, $^4J(H^4–H^3)$ = 1.5, 1H, H^3], 7.51 [d, $^3J(H^1–H^2)$ = 8.6, 2H, H^2], 7.45–7.40 [m, 4H, $H^{5,6}$], 5.21 [d, $^4J(H^4–H^3)$ = 1.5, 2H, H^4], 3.34 [s, 6H, H^7]. gHSQC (500 MHz): δ = 168.2 [C^3], 132.1 [C^1], 132.0 [C^5], 129.1 [C^6], 128.9 [C^2], 66.6 [C^4], 43.4 [C^7]. Compound **2a′**: ^{1}H NMR (300 MHz, $CDCl_3$): 8.65 [s, ^3J(Pt–H^3) = 117.4, 1H, H^3], 8.65 [d, $^3J(H^1–H^2)$ = 8.4, 2H, H^1], 7.68 [d, $^3J(H^6–H^7)$ = 8.5, 2H, H^6], 7.58 [d, $^3J(H^1–H^2)$ = 8.4, 2H, H^2], 7.46 [d, $^3J(H^6–H^7)$ = 8.5, 2H, H^7], 5.52 [dd, $^2J(H^4–H^5)$ = 13.5, $^4J(H^3–H^4)$ = 1.9, 1H, H^4], 4.94 [d, $^2J(H^4–H^5)$ = 13.6, ^3J(Pt–H^5) = 54.4, 1H, H^5], 2.67 [s, br, 3H, H^8], 2.65 [s, br, 3H, H^9]. *Anal.* Calc. for $C_{16}H_{17}Cl_4NOPtS$: C, 31.59; H, 2.82; N, 2.30; S, 5.27. Found: C, 31.9; H, 3.0; N, 2.4; S, 5.2%.

$[PtCl_2(4\text{-}ClC_6H_4CH_2NH_2)SOMe_2]$ (**2**) was obtained as a by-product in the reaction of equimolar amounts of *cis*-$[PtCl_2(dmso)_2]$ and imine $\mathbf{L_a}$ (see above) carried out in refluxing methanol. The solvent was removed in a rotary evaporator and the residue was re-crystallized in dichloromethane–methanol at low temperature. Orange-yellow crystals of **4** were obtained. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 7.34 [d, $^3J(H^1–H^2)$ = 8.6, 2H, H^2], 7.28 [d, $^3J(H^1–H^2)$ = 8.7, 2H, H^1], 4.61 [s, 2H, H^4], 4.02 [m, 2H, H^3], 3.41 [s, $^3J(^{195}Pt–H^5)$ = 23.7, 6H, H^5]. ESI-MS, *m*/*z*: 502.99 $[M+NH_4]^+$; 485.96 $[M]^+$; 449.98 $[M-Cl]^+$; 414.01$[M-2Cl]^+$. *Anal.* Calc. for $C_9H_{14}Cl_3NOPtS$: C, 22.25; H, 2.90; N, 2.89; S, 6.60. Found: C, 22.5; H, 3.0; N, 2.9; S, 6.6%.

$[PtCl_2\{(2,4,6\text{-}Me_3C_6H_2)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2]$ (**2b**) was obtained from 0.079 g (0.187 mmol) of *cis*-$[PtCl_2(dmso)_2]$ and 0.051 g (0.184 mmol) of the imine $\mathbf{L_b}$ which were allowed to react in toluene under reflux for 4 h. The solvent was removed in a rotary evaporator and the residue was dried in vacuo. Upon addition of diethylether a yellow solid was obtained, filtered and dried in vacuo (yield 73.5 mg; 64.9%). ^{1}H NMR (400 MHz, $CDCl_3$): 9.05 [s, ^3J(Pt–H^4) = 37.2, 1H, H^4], {7.33 [d, $^3J(H^1\text{-}H^2)$ = 8.8, 2H], 7.29 [d, $^3J(H^1–H^2)$ = 8.8, 2H], $H^{1,2}$}, 6.94 [s, 2H, H^6], 4.78 [d, $^3J(H^3–H^4)$ = 1.6, 2H, H^3], 3.30 [s, 6H, H^8], 2.32 [s, 3H, H^7]; 2.27 [s, 6H, H^5]. gHSQC (400 MHz): δ = 169.7 [C^4], 131.9 [C^2], 129.3 [C^6], 129.0 [C^1], 57.9 [C^3], 43.8 [C^8], 21.1 [C^7], 19.2 [C^5]. ESI-MS, *m*/*z*: 580.06 $[M-Cl]^+$; 616.04 $[M+H]^+$; 633.06 $[M+NH_4]^+$. *Anal.* Calc. for $C_{19}H_{24}Cl_3NOPtS \cdot H_2O$: C, 36.0; H, 4.1; N, 2.2; S: 5.1. $[PtCl_2\{(2,6\text{-}Cl_2C_6H_3)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2]$ (**2c**) was obtained from 142 mg (0.34 mmol) of *cis*-$[PtCl_2(dmso)_2]$ and 100 mg (0.34 mmol) of the imine $\mathbf{L_c}$ which were allowed to react in refluxing toluene (50 mL) at 100 °C for 4 h. The solvent was removed in a rotary evaporator and the residue was re-crystallized in dichloromethane–methanol, yielding **2c** (yield 140 mg; 64%). ^{1}H NMR (400 MHz, $CDCl_3$): 8.92 [t, $^3J(H^3–H^4)$ = 1.5, ^3J(Pt–H^4) = 42.6, 1H, H^4], 7.43 [s, 3H, $H^{5,6,7}$], {7.36 [d, $^3J(H^1–H^2)$ = 8.0, 2H], 7.33 [d, $^3J(H^1–H^2)$ = 8.0, 2H], $H^{1,2}$}, 4.92 [d, $^3J(H^3–H^4)$ = 1.5, ^3J(Pt–H^3) = 27.6, 2H, H^3], 3.30 [s, ^3J(Pt–H^8) = 16.8, 6H, H^8]. ESI-MS, *m*/*z*: 640.91 $[M+H]^+$, 604.93 [M−Cl], 568.96 [M−2Cl]. *Anal.* Calc. for $C_{16}H_{16}Cl_3NOPtS$: C, 29.90; H, 2.51; N, 2.18; S, 4.99. Found: C, 29.8; H, 2.6; N, 2.3; S, 4.9%.

$[PtCl_2\{(2\text{-}BrC_6H_4)CHNCH_2(4'\text{-}ClC_6H_4)\}SOMe_2]$ (**2d′**) was obtained from 0.207 g (0.49 mmol) of *cis*-$[PtCl_2(dmso)_2]$, 0.151 g (0.489 mmol) of imine $\mathbf{L_d}$ and 80 mg (0.975 mmol) which were allowed to react in refluxing methanol (30 mL) for 48 h. The reaction mixture was filtered, the solvent was removed in a rotary evaporator and the residue was re-crystallized in dichloromethane–methanol, yielding a light yellow solid which was filtered in vacuo. Yield 81.2 mg (25.4%). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 9.35 [dd, $^3J(H^3–H^4)$ = 7.7, $^4J(H^2–H^4)$ = 1.6, 1H, H^4], 8.87 [s, ^3J(Pt–H^5) = 115.0, $^4J(H^5–H^6)$ = 1.9, 1H, H^5], 7.69–7.63 [m, 2H, $H^{1,3}$], 7.67 [d, $^3J(H^8–H^9)$ = 8.3, 2H, H^8], 7.51 [td, $^3J(H^2–H^{1,3})$ = 7.7, $^4J(H^2–H^4)$ = 1.7, 1H, H^2], 7.47 [d, $^3J(H^8–H^9)$ = 8.4, 2H, H^9], 5.6 [dd, $^2J(H^6–H^7)$ = 13.4, $^4J(H^5–H^6)$ = 1.9, 1H, H^6], 4.94 [d, $^2J(H^6–H^7)$ = 13.4, 1H, H^7], 2.63 [s, br, 3H, H^{10}], 2.48 [s, br, 3H, H^{11}]. *Anal.* Calc. for $C_{16}H_{17}BrCl_3NOPtS$: C, 29.44; H, 2.63; N, 2.15; S, 4.91. Found: C, 31.9; H, 2.9; N, 2.4; S, 5.3%.

4.3. X-ray structure analysis for 2, 2a and 2c

Prismatic crystals were selected and mounted on a MAR 345 diffractometer. Unit cell parameters were determined from 6776 (**2**), 309 (**2a**) and 7029 (**2c**) reflections ($3° < \theta < 31°$) and refined by least-squares methods. Intensities were collected with graphite mono-chromatized Mo Kα radiation. 28622 (**2**), 9983 (**2a**) and 9836 (**2c**) reflections were measured in the range $2.60° < \theta < 30.00°$ (**2**), $3.06° < \theta < 30.00°$ (**2a**) or $2.73° < \theta < 32.34°$ (**2c**). 12272 (**2**), 5345 (**2a**) and 7929 (**2c**) reflections were assumed as observed applying the condition $I > 2\sigma(I)$. Lorentz polarization and absorption corrections were made for **2** and **2c**.

The structures were solved by direct methods using SHELXS program [19], and refined by full-matrix least-squares method with SHELXL97 computer program using 28622 (**2**), 9983 (**2a**) and 9836 (**2c**) reflections. The function minimized was $\sum w||F_o|^2 - |F_c|^2|^2$, where $w = [\sigma^2(I) + (0.0501P)^2 + 11.8165P]^{-1}$ (**2**), $[\sigma^2(I) + (0.0986P)^2 + 3.6436P]^{-1}$ (**2a**) or $[\sigma^2(I) + (0.0734P)^2 + 4.1280P]^{-1}$ (**2c**) and $P = (|F_o|^2 + 2|F_c|^2)/3$. *f*, *f′* and *f″* were taken from International Tables of X-ray Crystallography [20]. All hydrogen atoms were computed and refined using a riding model with an isotropic temperature factor equal to 1.2 times the equivalent temperature factor of the atom to which they are linked. Further details are given in Table 2.

ABSTRACT

A wide variety of primary and secondary alcohols were efficiently converted to their corresponding methoxymethyl (MOM) and ethoxymethyl (EOM) ethers in the presence of catalytic amounts of supported $H_3PW_{12}O_{40}$ on silica gel and zirconia at room temperature and under microwave irradiation at solvent-free conditions, whereas, phenols and tertiary alcohols remained intact under the same reaction conditions. Deprotection of these ethers to their parent alcohols was also achieved using these heterogeneous catalysts in ethanol, as a green solvent, under reflux conditions and microwave irradiation. Selective deprotection of primary and secondary MOM- and EOM-ethers in the presence of phenolic and tertiary ones, methyl and benzyl ethers, esters and trimethylsilyl ethers was achieved by these reagent systems. The present methodology offers several advantages such as short reaction times, high yields, simple procedure, heterogeneous reaction conditions, selectivity, non-toxicity and reusability of the catalysts.

1. Introduction

The use of Keggin-type heteropoly acids (HPAs) as homogeneous or heterogeneous catalysts for organic synthetic processes has been developed for important industries related to fine chemicals, pharmaceutical and food industries [1]. HPAs have several advantages such environmentally benign, reusability, non-corrosive and fewer disposal problems as catalysts which make them economically and environmentally attractive. Heteropoly acids, especially $H_3PW_{12}O_{40}$, have received great attention among the acid catalysts, because of their high acid strength and selectivity properties [2]. A major disadvantage of bulk HPAs, when used as catalysts, lies in their low specific surface area, less than 10 $m^2\ g^{-1}$, which can be improved by immobilization on the solid supports [3]. Procedures for supporting HPAs on different carriers and also their characterization are covered in the literature [3,4]. Several organic transformations using supported HPAs such as Diels–Alder reaction [5], oxidative dehydrogenation of alcohols and amines [6], olefin hydration [7], synthesis of dihydropyrimidinones [8], esterification reactions [9], preparation of oximes [10] and synthesis of oxazolines, imidazolines and thiazolines [11] has been reported in the literature.

The selective protection and deprotection of hydroxyl groups have occupied a unique position in organic synthesis because of the fundamental importance of hydroxyl groups in multi-step synthesis of complex natural products [12]. Alkoxymethyl groups have been induced as suitable protecting groups for alcohols in organic synthesis. These protecting groups provide a number of significant advantages such as ease of introduction and stability toward a wide variety of conditions including many organometallic reagents, reducing and oxidizing agents [13]. Alkoxymethyl ethers are frequently prepared by the reactions of alcohols with formaldehyde dimethyl acetal (FDMA) or formaldehyde diethyl acetal (FDEA) [14]. Deprotection of these ethers to their corresponding alcohols under mild conditions is of practical importance and several methods and catalysts have been reported for these transformations [14h,15]. However, some of the reported methods suffer from one or more disadvantages such as harsh reaction conditions, high reaction temperature, long reaction times, high cost or toxicity of the reagents and tedious work-up. Consequently, introduction of efficient and selective methods for the preparation of alkoxymethyl ethers and their deprotection using inexpensive, relatively non-toxic, easy handling and environmentally friendly catalysts is of practical importance and is still in demand.

The utility of microwave irradiation to carry out organic reactions has now become a regular feature. The main benefits of performing the reaction under microwave conditions are the significant rate enhancements and the higher product yields that

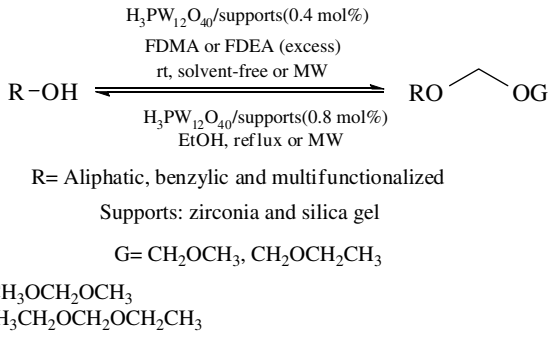

Scheme 1.

can be observed. A key advantage of modern scientific microwave apparatus is the ability to control reaction conditions very specifically, monitoring temperature, pressure and reaction times [16].

In continuation of our research on protection and deprotection reactions [17], we now report the use of $H_3PW_{12}O_{40}$ (TPA) supported on inorganic oxides such as silica gel and zirconia as heterogeneous, relatively non-toxic and reusable catalysts for conversion of primary and secondary benzylic and aliphatic alcohols with FDMA and FDEA to their corresponding methoxymethyl (MOM) and ethoxymethyl (EOM) ethers at room temperature under solvent-free conditions and also deprotection of these ethers in a green solvent, ethanol, under reflux conditions. These reactions were also performed under microwave irradiation (Scheme 1).

2. Experimental

All materials were purchased from Merck chemical company. All products were identified by comparison of their physical and spectral data with those of authentic samples. ^{1}H NMR spectra were recorded in a $CDCl_3$ solution on a Bruker-AC 500 MHz spectrometer. IR spectra were recorded on a Shimadzu IR-435 spectrophotometer. Melting points were determined using Stuart Scientific SMP2 apparatus. The microwave system used for these experiments includes the following items: Micro-SYNTH labstation, complete with glass door, dual magnetron system with pyramid-shaped diffuser, 1000 Watt delivered power, exhaust system, magnetic stirrer, "quality pressure" sensor for flammable organic solvents, ATCFO fiber optic system for automatic temperature control.

2.1. General procedure for the preparation of EOM- and MOM-ethers at room temperature

To a solution of alcohol (3 mmol) and FDEA (15 mmol) or FDMA (21 mmol), supported TPA (0.03 g, 0.4 mol%) was added and the mixture was stirred at room temperature for the appropriate time according to Tables 2 and 3. The progress of the reaction was monitored by TLC (eluent: cyclohexane/ethyl acetate, 4:1). After completion of the reaction, the catalyst was separated by filtration and washed with cold EtOH (10 mL). The filtrate was evaporated and the crude product was purified by column chromatography on silica gel (eluent: cyclohexane/ethyl acetate, 4:1) to afford the pure product.

2.2. General procedure for the preparation of EOM- and MOM-ethers under microwave irradiation

All reactions were carried out at 53–56 °C, with 150 W applied power in a 100 mL round-bottom flask provided with two openings equipped with a glass condenser.

To a mixture of alcohol (3 mmol) and FDEA (15 mmol) or FDMA (21 mmol), supported TPA (0.03 g, 0.4 mol%) was added and the mixture was irradiated with MW for appropriate time as mentioned in Tables 2 and 3. After completion of the reaction (monitored by TLC, eluent: cyclohexane/ethyl acetate, 4:1), the catalyst was filtered and washed with cold EtOH (10 mL). Evaporation of the solvent under reduced pressure and purification by a silica gel column gave the pure product.

2.3. General procedure for the cleavage of EOM- and MOM-ethers under reflux conditions

A mixture of alkoxymethyl ether (1 mmol) and supported TPA (0.06 g, 0.8 mol%) in EtOH (8–10 mL) was stirred under reflux conditions for the appropriate time according to Tables 5 and 6. After completion of the reaction (TLC analysis), the mixture was cooled to room temperature and the catalyst was separated by filtration and washed with cold EtOH (10 mL). Evaporation of the filtrate and purification of the crude product by a silica gel column (eluent: cyclohexane/ethyl acetate, 4:1) afforded the pure product.

2.4. General procedure for the cleavage of EOM- and MOM-ethers under microwave irradiation

All reactions were carried out at 72–75 °C, with 250 W applied power in a 100 mL round-bottom flask provided with two openings equipped with a glass condenser.

A mixture of alkoxymethyl ether (1 mmol) and supported TPA (0.06 g, 0.8 mol%) in EtOH (8–10 mL) was irradiated with MW for the appropriate time according to Tables 5 and 6. After completion of the reaction (TLC analysis), the mixture was cooled to room temperature and the catalyst was separated by filtration and washed with cold EtOH (10 mL). The filtrate was evaporated and the crude product was purified by a silica gel column (eluent: cyclohexane/ethyl acetate, 4:1) to afford the pure alcohol.

3. Results and discussion

3.1. Preparation of the supported 12-tungstophosphoric acid

The supported TPAs (TPA–SiO_2 and TPA–ZrO_2) catalysts were prepared by the method of incipient wetness. In a typical procedure, a 400 mg portion of TPA was dissolved in deionized water (50 mL) and impregnated drop-wise onto 1600 mg high surface area SiO_2 (Cabosil 20) and ZrO_2 (purchased from Merck) supports under constant agitation. The resulting pastes were dried at 110 °C for 4 h and then calcined at 250 °C for 4 h [18].

FT-IR spectra can be used as a powerful technique for the investigation of surface interaction between TPA and inorganic supports. Pure TPA compounds display infrared bands at 1080 cm^{-1} (P–O), 985 (W=O), 887 (W–O_c–W) and 807 cm^{-1} (W–O_b–W) [2,19]. The FT-IR spectrum of TPA–SiO_2 shows bands at 982 (W=O), 899 and 819 cm^{-1} (W–O–W) and the band assigned to P–O vibrations is masked by SiO_2 broad vibrations. The FT-IR spectrum of TPA–ZrO_2 shows bands at 1072 (P–O), 966 (W=O), 870 and 817 cm^{-1} (W–O–W) [20].

The TPA loading on the supports, which were calculated from W content in supported-TPA catalysts, was determined by neutron activation analysis. The amounts of W loading on the supported catalysts were 29.75 ± 0.9 (0.13 mmol/g) and 24.10 ± 0.8 (0.11 mmol/g) for TPA–SiO_2 and TPA–ZrO_2, respectively.

3.2. Protection reactions

First, we studied the reaction of benzyl alcohol with FDMA in the presence of supported TPAs in order to find the best reaction conditions. The reaction was performed in the presence of different molar ratios of FDMA and catalysts. The optimum condition used for the protection of benzyl alcohol with these heterogenized catalysts, was alcohol, FDMA and catalyst, in a molar ratio of 1:7:0.004, at room temperature under solvent-free conditions (Table 1, entries 1 and 2).

In order to show the role of the catalysts, the protection of benzyl alcohol was carried out with silica gel and zirconia alone in the absence of TPA. The experimental results showed that the alcohol remained intact under this condition (Table 1, entries 3 and 4). Comparison of TPA in supported and pure forms in the protection of benzyl alcohol showed that the activity of supported catalysts is higher than the bulk form (Table 1, entry 5).

The protection of benzyl alcohol with FDMA was also investigated in the presence of these catalysts under microwave irradiation. The highest yield of the product was obtained at the power

of 150 W. At this power, the temperature of the reaction vessel was measure to be 53–56 °C.

Under the optimized reaction conditions, various primary and secondary benzylic and saturated alcohols reacted with FDMA and FDEA in the presence of these catalysts at room temperature and under microwave irradiation to afford the corresponding MOM- and EOM-ethers in high yields (Tables 2 and 3). While phenols and tertiary alcohols remained intact in the reaction mixture under the same conditions. The results show that the reaction times are considerably shorter under microwave irradiation. The acceleration of reactions by microwave mainly results from two effects: thermal effect and specific microwave effect [16c,16d]. Thermal effect (dielectric heating) resulting from material-microwave interaction which allows fast and uniform distribution and conversion of microwave energy into heat. Specific microwave effect can be expected for the polar mechanism, when the polarity is increased during the reaction from the ground state (GS) toward the transition state (TS). For the protection reactions under investigation, it seems that stabilization of the transition state is more effective than that of the ground state, and therefore, the reactivity is enhanced as a result of decreased activation energy.

It is noteworthy that in multifunctional compounds containing both benzylic and phenolic hydroxyl groups, only benzylic hydroxyl groups were transformed to their corresponding ethers with excellent chemoselectivity (Tables 2 and 3, entries 6 and 9). Also competitive protection of primary and secondary alcohols in the presence of phenols and tertiary alcohols were investigated. In this manner, a mixture of primary alcohol (1 mmol) and phenol (1 mmol) was reacted with FDMA (7 mmol) or FDEA (5 mmol) in the presence of supported TPA (0.03 g, 0.4 mol%) and it was found

[b] 1.6 mol% of the catalyst was used.

that only primary alcohol was converted to the corresponding ether and the phenol remained intact in the reaction mixture (Table 4, entry 1). Under the same reaction conditions, secondary alcohol was selectively converted to the corresponding ether in the presence of phenol (Table 4, entry 2). Treatment of a mixture of primary alcohol (1 mmol) and tertiary alcohol (1 mmol) with FDMA (7 mmol) or FDEA (5 mmol) in the presence of supported TPA (0.03 g, 0.4 mol%), resulted exclusively in the protection of primary alcohol (Table 4, entry 3). Under these conditions in a mixture of secondary and tertiary alcohols, only secondary alcohol was selectively transformed to the corresponding ether (Table 4, entry 4). Therefore, the results indicate that the present method is potentially applicable for the chemoselective protection of primary and secondary alcohols in the presence of phenols and tertiary alcohols (Table 4).

3.3. Deprotection reactions

Deprotection of these ethers was also investigated under thermal and microwave irradiation. At first, deprotection reaction of EOM-ether of benzyl alcohol was conducted with different amounts of supported catalysts in order to find the optimized reaction conditions. The maximum yields were obtained with 0.8 mol% of supported catalysts in refluxing EtOH. Under microwave irradiation, the best results were obtained at the power of 250 W. At this power, the temperature of the reaction vessel was measure to be 72–75 °C.

Under the above-mentioned conditions, a wide variety of primary and secondary EOM- and MOM-ethers were deprotected in the presence of supported catalysts in EtOH under reflux conditions and microwave irradiation to afford the corresponding alco-

[b] Isolated yields.

hols in high yields (Tables 5 and 6). The results showed that the reaction times were considerably shorter under microwave irradiation. As mentioned in the protection reactions, in the deprotection reactions under microwave irradiation, the thermal and specific microwave effects increases the reaction rates.

In order to explore the general applicability of this method, several competitive deprotection reactions were also investigated using these catalysts. As can be seen, interesting selectivities were observed. When an equimolar mixture of primary or secondary MOM- and EOM-ethers and phenolic MOM- and EOM-ethers was reacted with supported TPA (0.06 g, 0.8 mol%), primary and secondary ethers were deprotected to their parent alcohols with high selectivity (Table 7, entries 1, 3 and 6). Selective deprotection of primary and secondary MOM- and EOM-ethers was also achieved in the presence of tertiary MOM- and EOM-ethers (Table 7, entries 2, 4 and 5). Also, this method can be selectively applied for the chemoselective deprotection of these ethers in the presence of other hydroxyl protecting groups such as benzyl, methyl ethers (Tables 5 and 6, entries 6–9), acetates and trimethylsilyl ethers (Table 8) using these catalytic systems. These selectivities can be considered as useful practical achievements in deprotection reactions.

3.4. Recyclability and reusability of the catalyst

The reusability and recycling of the supported catalysts were tested in the reaction of benzyl alcohol with FDEA. After completion of the reaction, supported catalysts were separated by filtration and washed with cold EtOH. The recovered catalysts were reused six consecutive runs. The filtrates were used for determination of catalyst leaching. Addition of fresh benzyl alcohol and FDEA to the filtrates and only 2–3% of product was detected by GC. The amount of tungsten loading after each consecutive runs was determined by NAA. These results showed that only trace amounts of catalyst are leached from supports (Table 9).

4. Conclusion

In conclusion, we have successfully developed a convenient and efficient protocol for the protection of alcohols as MOM- and EOM-ethers at room temperature and under microwave irradiation at solvent-free conditions and deprotection of these ethers to their parent alcohols in ethanol, as a green solvent, under reflux conditions and microwave irradiation using 12-tungstophosphoric acid supported on silica gel and zirconia as heterogeneous catalysts.

ABSTRACT

Two tridentate N,N,O donor Schiff bases, HL^1 (4-(2-ethylamino-ethylimino)-pentan-2-one) and HL^2 (3-(2-amino-propylimino)-1-phenyl-butan-1-one) on reaction with Cu^{II} acetate in presence of triethyl amine yielded two basal-apical, mono-atomic acetate oxygen-bridging dimeric copper(II) complexes, $[Cu_2L^1_2(OAc)_2]$ (**1**), $[Cu_2L^2_2(OAc)_2]$ (**2**). Whereas two other similar tridentate ligands HL^3 (4-(2-amino-propylimino)-pentane-2-one) and HL^4 (3-(2-amino-ethylimino)-1-phenyl-butan-1-one) under the same conditions produced a mixture of the corresponding dimers and a one-dimensional alternating chain of the dimer and copper acetate moiety, $[Cu_4L^3_2(OAc)_6]_n$ (**3**) and $[Cu_4L^4_2(OAc)_6]_n$ (**4**), formed by a very rare μ_3 bridging mode of the acetate ion. All four complexes (**1**–**4**) have been characterized by X-ray crystallography. The isotropic Hamiltonian, $H = -JS_1S_2$ has been used to interpret the magnetic data. Magnetic measurements of **1** and **2** in the temperature range 2–300 K reveal a very weak antiferromagnetic coupling for both complexes ($J = -0.56$ and -1.19 cm^{-1} for **1** and **2**, respectively).

1. Introduction

The Schiff bases derived from the mono-condensation of diamines e.g. 1,2-diaminothane, 1,3-diaminopropane, etc. and β-diketone e.g. acetyl- or 1-benzoylacetone are a group of mono-negative N,N,O donor ligands that react readily with Cu^{II} to form mono-, di-, or trinuclear complexes depending upon the coligand present. For examples, a neutral monodentate coligand like pyridine or imidazole results in the formation of mono-nuclear square planar complexes [1] whereas an azide or chloride ion yields dinuclear species [2]. Dinuclear complexes can also be obtained by bridging the mono-nuclear units by 4,4′-bipyridine [3]. On the other hand, a μ_3-OH bridged trinuclear copper(II) complex is formed in a slightly alkaline solution with such ligands [4]. With acetate coligands, two complexes have so far been structurally characterized [5] and both of them are mono-atomic acetate oxygen bridged dimers. Variable temperature magnetic measurements of one of the compounds have also been carried out and showed very weak antiferromagnetic coupling [5a].

The carboxylate group is one of the most widely used bridging ligands for designing polynuclear metal complexes with interesting magnetic properties. Normally, each of the two oxygen atoms of a carboxylate group are bonded to a different metal atom to form M–O–C–O–M bridging in one of the *syn–syn*, *syn–anti*, and *anti–anti* modes [6]. The occurrence of M–O–M bridges via one oxygen atom of the carboxylate ligand is relatively scarce. There are some examples of unsymmetrical mono-atomic acetate oxygen bridged copper(II) complexes in the literature [5,7,8]. Variable temperature magnetic measurements of those complexes reveal that they can be either ferromagnetic [8b] or antiferromagnetic [5a,8a,8c,8d]. Till now, there is no clear magneto-structural correlation for such magnetic pathways. Therefore, we have tried to synthesize similar complexes using four different N,N,O donor Schiff base ligands, 4-(2-ethylamino-ethylimino)-pentan-2-one (HL^1), 3-(2-amino-propylimino)-1-phenyl-butan-1-one (HL^2), 4-(2-amino-propylimino)-pentan-2-one (HL^3) and 3-(2-amino-ethylimino)-1-phenyl-butan-1-one (HL^4) (Scheme 1) and the results are presented in this paper. With ligands L^1 and L^2, we have obtained pure mono-atomic acetate oxygen bridged dinuclear complexes and have characterized them both structurally and magnetically. But for the other two ligands (L^3 and L^4), the products were not pure dinuclear species and we failed to grow any single crystals suitable for X-ray analysis. Instead, we have succeeded in obtaining single crystals of the minor products, which are present in the product and characterized them by single crystal X-ray analysis. The crystal structures reveal that in both cases the structures of these minor products are one-dimensional novel chains of alternating dimer and copper acetate moieties.

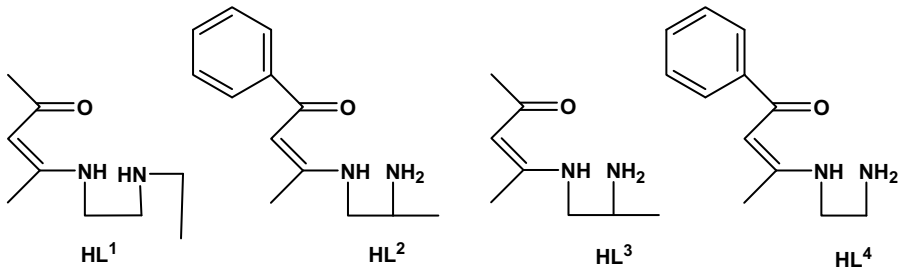

Scheme 1.

2. Experimental

The diamines, 1-benzoylacetone and acetylacetone were purchased from Lancaster Chemical Co. They were of reagent grade and used without further purification.

2.1. Synthesis of the ligands, HL^1 (4-(2-ethylamino-ethylimino)-pentan-2-one), HL^2 (3-(2-amino-propylimino)-1-phenyl-butan-1-one), HL^3 (4-(2-amino-propylimino)-pentane-2-one) and HL^4 (3-(2-amino-ethylimino)-1-phenyl-butan-1-one)

The four mono-condensed tridentate Schiff base ligands HL^1–HL^4 were prepared by half-condensation of the respective diamine with the corresponding β-diketone (acetylacetone or 1-benzoylacetone) under the condition of high dilution in chloroform as reported earlier [4,9].

*2.2. Synthesis of complexes $[Cu_2L^1_2(OAc)_2]$ (**1**), $[Cu_2L^2_2(OAc)_2]$ (**2**), $[Cu_4L^3_2(OAc)_6]_n$ (**3**) and $[Cu_4L^4_2(OAc)_6]_n$ (**4**)*

The clear methanol solution (20 cm^3) of the Schiff bases (2 mmol), were added to the suspension of copper(II) acetate monohydrate (2 mmol, 0.199 g) in methanol (10 cm^3) and the mixed solutions were stirred well. Triethylamine (1.5 mmol, 0.2 cm^3) was added dropwise with constant stirring. For all four complexes, a small amount of green hydrolyzed product which separated immediately during the addition of triethylamine was filtered off. The filtrates were kept several days in a refrigerator to yield bluish green crystalline products. Dark green hexagonal single crystal of **1** was obtained on dissolving the bluish green precipitate in methanol and keeping the resulting solution several days at room temperature. Greenish mass of **2** was obtained next day. Single crystals of **2**, **3** and **4**, suitable for X-ray diffraction analysis were obtained by slow diffusion of *n*-hexane into a dichloromethane solution of the respective compounds.

Complex **1**: Yield: 0.11 g (49%). Calc. for $C_{22}H_{44}Cu_2N_4O_8$ (619.70): C, 42.64; H, 7.16; N, 9.04. Found: C, 42.73; H, 7.19; N, 9.01%. λ_{max}/nm (ε_{max}/$dm^3\,mol^{-1}\,cm^{-1}$) (acetonitrile), 613 (89.3) and 320 (18 700). IR: $\tilde{\nu} = 3178$ [ν(N–H)]; 1589 [$\nu(COO^-)$] cm^{-1}.

Complex **2**: Yield: 0.13 g (56%). Calc. for $C_{31}H_{42}Cl_2Cu_2N_4O_6$ (764.67): C, 48.69; H, 5.54; N, 7.33. Found: C, 48.57; H, 5.59; N, 7.31%. λ_{max}/nm (ε_{max}/$dm^3\,mol^{-1}\,cm^{-1}$) (acetonitrile), 609 (95.2) and 323 (18 400). IR: $\tilde{\nu} = 3152$, 3257 [ν(N–H)]; 1591 [$\nu(COO^-)$] cm^{-1}.

The analytical data of the crystalline solids of **3** and **4** which were obtained from the mother liquor correspond neither to the dimeric species nor to the one-dimensional chain compounds as characterized by X-ray analysis. Instead, the data suggest that they are probably a mixture of these two types of complexes. Moreover, the proportions of the two species in the mixture differ when the syntheses are repeated. Therefore, the analytical data are not presented here.

2.3. Physical measurements

Elemental analyses (C, H, N) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra in KBr (4500–500 cm^{-1}) were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer.

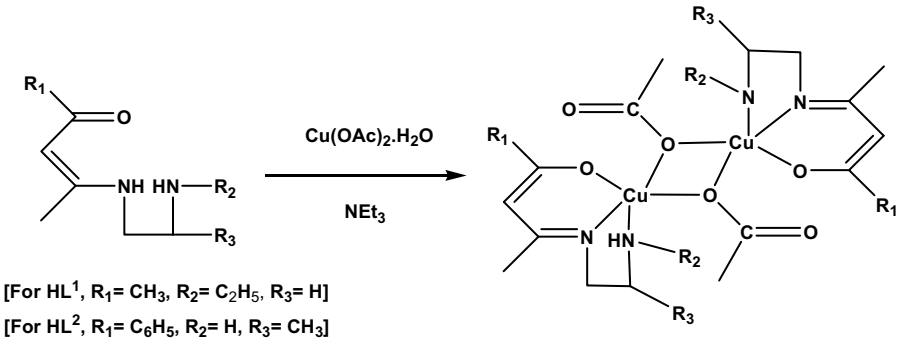
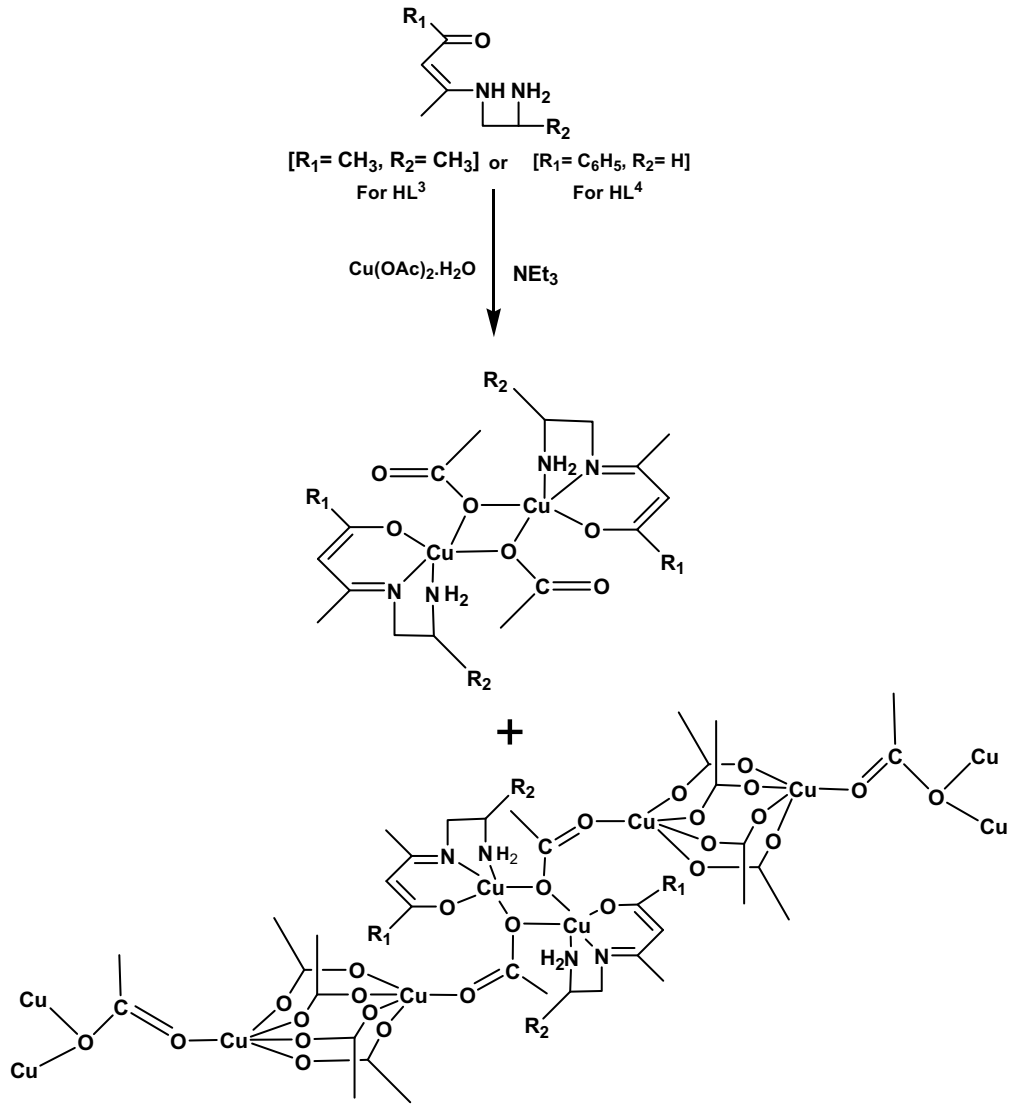
Electronic spectra in methanol (1200–350 nm) were recorded in a Hitachi U-3501spectrophotometer.

2.4. Crystallographic studies

The independent reflections for complexes **1** and **4** were measured with Mo Kα radiation using the MARresearch Image Plate System. The crystals were positioned at 70 mm from the Image Plate. One Hundred frames were measured at 2° intervals at 298 K with a counting time of 2 min. Data analysis was carried out with the XDS program [10]. Data for **2** and **3** were measured on an Oxford Diffraction X-Calibur with a CCD at 150 K. 321 frames were measured for 10 s. Mo Kα radiation was used. Data analysis was carried out with the CRYSALIS program [11]. All four structures



Scheme 2a.



Scheme 2b.

were solved using direct methods with the SHELXS97 program [12]. The hydrogen atoms bonded to carbon were included in geometric positions and given anisotropic displacement parameters proportional to those of the atom to which they were attached and refined on F^2. Non-hydrogen atoms were refined with anisotropic displacement parameters. Empirical absorption corrections were carried out using DIFABS [13] for **1** and **4** and ABSPACK [14] for **2** and **3**. Structures were refined using the SHELXL97 program [12]. Significant crystallographic data are summarized in Table 1.

2.5. Magnetic studies

The magnetic measurements were carried out in the "Servei de Magnetoquimica (Universitat de Barcelona)" on polycrystalline samples (20 mg) with a Quantum Design SQUID MPMSXL magnetometer in the temperature range of 2–300 K and the magnetic field was 0.1 T. The diamagnetic corrections were evaluated from Pascal's constants. EPR spectra were recorded on powder samples at X-band frequency with a Bruker 300E automatic spectrometer, varying the temperature between 4 and 300 K.

3. Results and discussion

The two tridentate ligands HL^1 and HL^2 (Scheme 1) on treatment with the methanol solution of copper acetate monohydrate and triethylamine yield the dinuclear complexes **1** and **2**, respectively, in pure form (Scheme 2a). However, under the same conditions, the other two ligands, HL^3 and HL^4 (Scheme 1), yield a mixture of products as is evident from analytical, spectral and variable temperature magnetic susceptibility data. The products consist of mostly the dimers (similar to **1** and **2**) along with some other minor products. The proportions of the dimers and the minor products change with the variations in metal: ligand ratios and even for different batches of preparation keeping the same metal:ligand ratio. Unfortunately, in spite of several attempts, we failed either to isolate pure dimers with these two ligands (HL^3 and HL^4) or to get diffraction quality single crystals of them. However, during our attempt of crystallization we obtained a few single crystals of the minor products. X-ray analysis reveals that an unreacted copper acetate moiety joins the dimers to form a one-dimensional alternating chain of the dimers and copper acetate (Scheme 2b).

3.1. IR and electronic spectra

Compound **1** contains a non-coordinating water molecule, which is clear from the well-defined band at 3423 cm^{-1} in its IR spectra. It displays a single sharp band at 3178 cm^{-1} due to the N–H stretching vibration, whereas complex **2** displays two bands at 3152 and 3257 cm^{-1} characteristic of the asymmetric and symmetric stretching vibrations of NH_2 group. The attributions of the IR spectra in the 1300–1600 cm^{-1} region are difficult due to the appearance of several absorption bands from both Schiff base ligands and acetate. The strong bands at 1589 cm^{-1} with a shoulder at 1610 cm^{-1} for complex **1** and 1591 cm^{-1} with a shoulder at 1615 cm^{-1} for complex **2** are likely to be due to the overlapping of bands from Schiff bases with the antisymmetric stretching mode of the carboxylate group. The shoulders at 1610 and 1615 cm^{-1} for complexes **1** and **2**, respectively, may be attributed to the ν_{as}(CO) of the CH_3COO^- group [5a]. The symmetric stretching modes for the carboxylate are observed at 1390 and 1401 cm^{-1}. The separations between the two peaks (Δ) are 220 and 214 cm^{-1} for complexes **1** and **2**, respectively. For monodentate carboxylate, the Δ value is usually higher and for bidentate symmetrical chelate the Δ is much lower. For classical carboxylate bridges (Cu–O–C–O–Cu), the value of Δ is usually of ca. 180 cm^{-1} [15]. The Δ values of complexes **1** and **2** are higher than the classical bridges but lower than the monodentate one substantiating the non-symmetric bridging mode of the carboxylate in the complexes. The strong absorption bands at 1518 and 1517 cm^{-1} for complexes **1** and **2**, respectively, are attributed to ν(CN) of the corresponding ligands.

The electronic spectra of these complexes were recorded in acetonitrile solution. Both the complexes show single absorption band (613 and 609 for complexes **1** and **2**, respectively). The positions of these bands are consistent with the observed square-based geometry around the copper centre [16]. The charge-transfer bands are observed at 320 and 323 nm for complexes **1** and **2**, respectively.

3.2. Description of structures of complexes *1*, *2*, *3* and *4*

3.2.1. Complexes *1* and *2*

The structures of **1** and **2** consist of dinuclear units, $[Cu_2L_2(OAc)_2]$ and a solvent molecule which is water in **1** and dichloromethane in **2**. Bond distances and angles are listed in Table 2 and S1. The dimeric unit of **1** contains a crystallographic centre of symmetry. Although there is no crystallographically imposed symmetry in **2**, the structure has an approximate centre of symmetry and in essential details is equivalent to that of **1**. The molecular structures of **1** and **2**, together with the atom-numbering scheme are shown in Figs. 1 and 2, respectively. In these structures, the coordination geometry around the copper atom can be considered to consist of a five-coordinate (4 + 1) distorted square-base pyramid. The basal plane consists of one oxygen and two nitrogen atoms from the respective deprotonated Schiff base ligands and a carboxylate oxygen while the apical site is occupied by one oxygen atom of another acetate anion that is basal to the second copper atom in the dimer of the complexes.

In **1** the four donor atoms, O(11), N(15), N(18) and O(31) that constitute the equatorial plane are approximately coplanar with distances −0.078(1), 0.080(1), −0.076(1) and 0.074(1) Å from the least squares plane through them. The copper atom is 0.040(1) Å from this plane towards the bridging oxygen. The Cu–N bond length is as expected shorter at 1.954(3) Å to the trigonal N(15) than to the tetrahedral N(18) at 2.059(3) Å while the Cu–O bond lengths to the ligand oxygen Cu(1)–O(11) 1.948(3) Å is similar to that of the acetate oxygen, Cu(1)–O(31) 1.978(3) Å. The Cu–O(31′) (1 − *x*, 1 − *y*, −*z*) axial bond (2.508(3) Å) is much longer than the equatorial distances as is expected for Jahn–Teller distorted system. The Addison parameter (τ) [17] which is an index of distortion from the square-pyramidal to the trigonal-bipyramidal geometry is calculated to be 0.09.

Table 2
Bond distances (Å) for the complexes

Compounds	1	2	3	4
Cu(1)–O(11)	1.948(3)	1.920(4)	1.915(2)	1.942(8)
Cu(1)–O(31)	1.978(3)	1.972(3)	1.979(2)	1.998(8)
Cu(1)–N(15)	1.954(3)	1.939(4)	1.933(3)	1.936(9)
Cu(1)–N(18)	2.059(3)	2.017(4)	2.001(2)	2.028(9)
Cu(1)–O(31′)	2.508(3)		2.433(2)	2.500(8)
Cu(1)–O(41)		2.501(3)		
Cu(2)–O(21)		1.942(3)		
Cu(2)–N(25)		1.951(4)		
Cu(2)–N(28)		2.011(4)		
Cu(2)–O(31)		2.429(3)		
Cu(2)–O(41)		1.962(3)	1.969(2)	1.971(9)
Cu(2)–O(33)			2.124(2)	2.134(6)
Cu(2)–O(51)			1.983(3)	1.966(8)
Cu(2)–O(43″)			1.962(2)	1.961(8)
Cu(2)–O(53″)			1.964(2)	1.923(8)

Symmetry code: ′ = 1 − *x*, 1 − *y*, −*z* (complex **1**), ′ = 1 − *x*, 1 − *y*, 1 − *z*, ″ = 1 − *x*, 1 − *y*, −*z* (complex **3**) and ′ = −*x*, 2 − *y*, −*z*; ″ = −*x* + 1/2, −*y* + 3/2, −*z* (complex **4**).

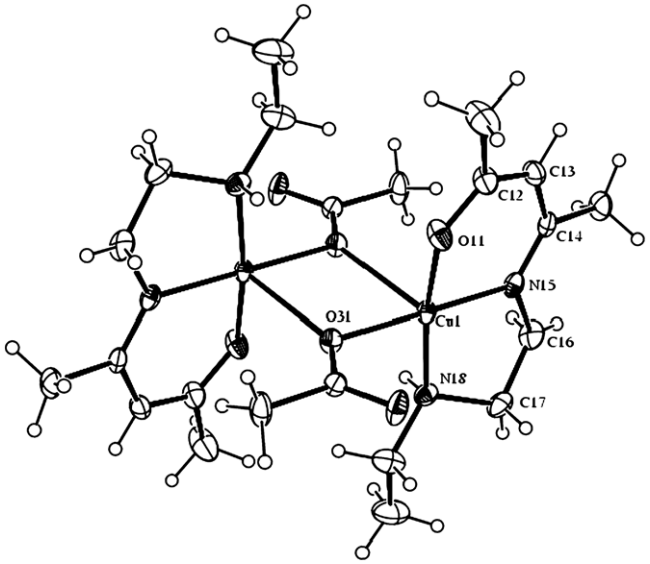


Fig. 1. ORTEP view of complex **1** with ellipsoids at 25% probability.

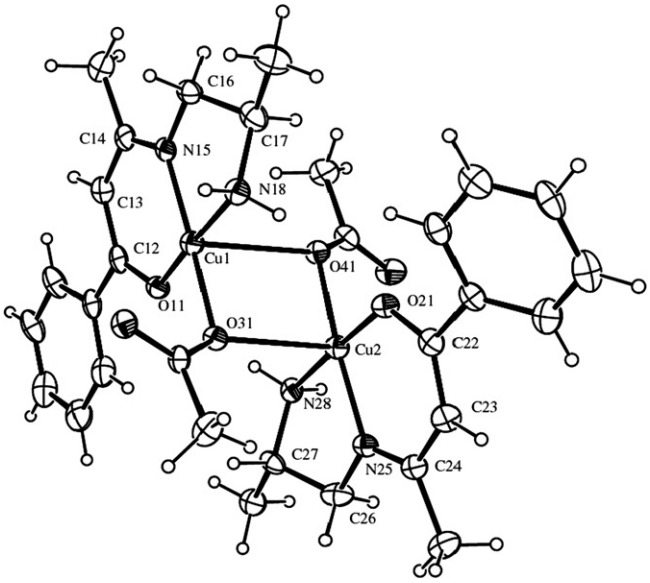

Fig. 2. ORTEP view of complex **2** with ellipsoids at 25% probability.

In **2**, the four coordinating atoms [O(11), N(15), N(18) and O(31)] in the equatorial plane around Cu(1) deviate from the mean plane through them by −0.072(2), 0.074(2), −0.074(2) and 0.072(2) Å, respectively. The Cu^{II} ion is almost coplanar; the deviation is only 0.004(2) Å from the plane towards the apical atom O(41). Whereas, the four atoms [O(21), N(25), N(28) and O(41)] in the equatorial plane of Cu(2) deviate from the mean plane through them by 0.058(2), −0.060(2), 0.059(2) and −0.057(2) Å, respectively. The Cu^{II} ion is displaced by 0.065(2) Å from the plane towards the apical atom O(31). The bond lengths to terminal NH_2 (Cu(1)–N(18) 2.017(4), Cu(2)–N(28) 2.011(4) Å), unsaturated N (Cu(1)–N(15) 1.939(4), Cu(2)–N(25) 1.951(4) Å) and terminal oxygen (Cu(1)–O(11) 1.920(4), Cu(2)–O(21) 1.942(3) Å) are similar to those of **1**. The two axial bonds (Cu(1)–O(41) 2.501(3), Cu(2)–O(31) 2.429(3) Å) by which the two monomeric units are joined to form the dimer are as expected much longer. The Addison parameters (τ) which is 0 for an ideal square planar geometry and 1 for ideal trigonal bipyramid [17], are 0.10 and 0.03 for Cu(1) and Cu(2), respectively, indicating a slight distortion from square planar geometry. The dihedral angle between the bridging Cu(1)–O(31)-Cu(1) plane and mean basal plane of the copper "square bipyramid" in complex **1** is 88.6°; the corresponding average value for complex **2** is 85.4°.

The six membered chelate ring formed by the acetylacetone or benzoylacetone moiety (for complexes **1** and **2**, respectively) is essentially planar and the interatomic distances and angles of the ring are similar. The five-membered chelate ring incorporating the dimethylene fragments from the starting diamines show different conformations in complexes **1** and **2**. In complex **1** this ring is an envelope on C(17) [q = 0.447(3) Å and ϕ = 296.3(3)°] whereas in **2** the ring is an envelope on C27 and half-chair conformation twisted on C(17)–C(18) [q = 0.412(6) Å and ϕ = 117.8(6)°] [18].

In complex **1**, the crystallized water molecule forms strong H-bonds with the amine hydrogen, uncoordinated oxygen atom of the acetate group and the oxygen atom of the ligand to form a one-dimensional supramolecular structure. The oxygen atom (O1) acts as an acceptor for an H-bond involving the H18 from the amine group and it forms two donor hydrogen bonds to O11 and O33′ (−x, 1 − y, −z) (Fig. 3, Table 3). In complex **2** (Fig. S1, Table 3) all the amine hydrogen are involved in hydrogen bonding. H18b and H28a form intra-dimer H-bonds with the oxygen atom of the chelated Schiff base ligand whereas H18a and H28b links the neighboring dimers through H-bonds with O43′ (1/2 + x, 1/2 − y, 1/2 + z) and O33″ (−1/2 + x, 1/2 − y, −1/2 + z), respectively, to form a one-dimensional network.

In both complexes there is no considerable π-stacking interaction between the aromatic rings. However, the C16–H16a bond of each molecule of **2** interacts with the phenyl group of the neighboring molecules (1 − x, 1 − y, 1 − z) by means of weak C_{sp^3}–H···π (phenyl) supramolecular contact to generate a two-dimensional network (the distance H16a···centroid A is 2.65(3) Å), angle between C16–H16a···C_g (ring A) is 169(4)° and the distance C16···C_g (ring A) is 3.612(6) Å (Fig. S2). The C_{sp^3}–H···π contact distance is typical for this type of interaction [19].

3.2.2. Complexes *3* and *4*

The structures of **3** and **4** (Figs. 4 and 5, respectively) are composed of one-dimensional polymeric chains that contain alternating $[Cu_2L_2(OAc)_2]$ and $Cu_2(OAc)_4$ units, each lying on a crystallographic centre of symmetry and are connected by acetate groups in the very rare μ_3-*syn–anti–anti* bridging mode. The structures of the dinuclear units, $[Cu_2L^3_2(OAc)_2]$ and $[Cu_2L^4_2(OAc)_2]$ of complexes **3** and **4**, respectively, are very similar to those of the $[Cu_2L^1_2(OAc)_2]$ and $[Cu_2L^2_2(OAc)_2]$ units of complex **1** and **2**, respectively. Like complexes **1** and **2**, the coordination geometry around copper atom of these dinuclear units can also be considered to consist of a five-coordinate (4+1) distorted square-base pyramid. The basal plane consists of one oxygen and two nitrogen atoms from the respective Schiff base ligand and a carboxylate oxygen while the apical site is occupied by one oxygen atom of another acetate anion that is basal to the second copper atom in the dimer of the complexes. All the bond distances and bond angles of these dinuclear units (Table 2 and Table S1) are comparable to those of complexes **1** and **2** and also to similar other reported complexes [5,8a].

In the dinuclear, $[Cu_2L^3_2(OAc)_2]$ unit of complex **3**, the four donor atoms [O(11), N(15), N(18) and O(31)] in the equatorial plane deviate from the mean plane through them by 0.117(1), −0.120(1), 0.120(1) and −0.116(1) Å, respectively. Cu^{II} ion is displaced 0.014(1) Å from the plane towards the apical atom O31′ (1 − x, 1 − y, 1 − z). In the $[Cu_2L^4_2(OAc)_2]$ unit of complex **4**, the deviations of O11, N15, N18 and O31 from the mean plane through them are −0.104(4), −0.107(4), 0.105(4) and −0.102(4) Å, respectively. The Cu^{II} ion is also displaced 0.016(1) Å from this plane towards the apical atom O31′ (−x, 2 − y, −z). The τ values [17] for these

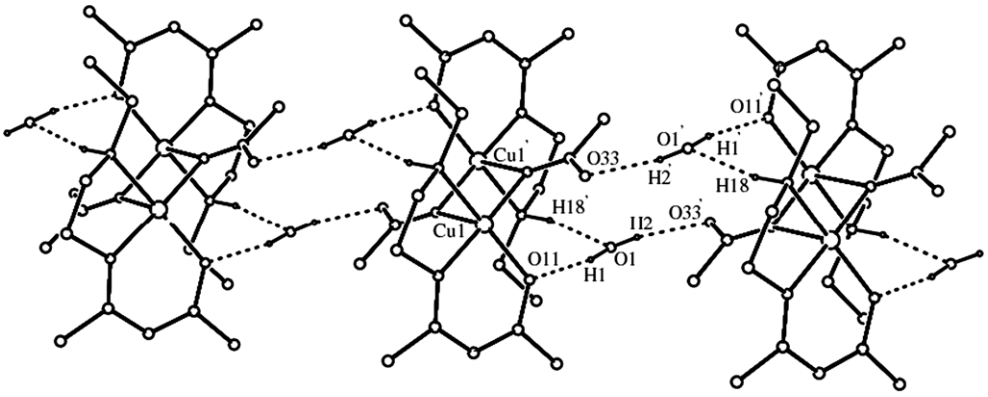

Fig. 3. H-bonding network in complex **1**.

Table 3
Hydrogen bonding distances (Å) and angles (°) for the complexes

Compound	D–H···A	D–H	D···A	A···H	∠D–H···A
1	O1–H1···O11	0.78(3)	2.864(5)	2.08(3)	168(4)

	N18–H18b···O51	0.90	3.307(4)	2.41	173
4	N18–H18b···O41	0.90	3.097(11)	2.20	175
	N18–H18a···O11′	0.90	3.187(12)	2.35	154

Symmetry codes: ′ = $-x$, $1-y$, $-z$ (complex **1**), ′ = $1/2+x$, $1/2-y$, $1/2+z$; ″ = $-1/2+x$, $1/2-y$, $-1/2+z$ (complex **2**), ′ = $1-x$, $1-y$, $1-z$ (complex **3**), ′ = $-x$, $2-y$, $-z$ (complex **4**).

dinuclear units are 0.044 and 0.039 Å for complexes **3** and **4**, respectively. The five-membered chelate ring containing the diamine fragment assumes an envelope conformation on C17 for both the complexes [18].

Unlike complexes **1** and **2**, the other oxygen atom (O33) of the bridging acetate of the dinuclear, $[Cu_2L_2(OAc)_2]$ unit of complexes **3** and **4** is coordinated however not to Cu(1) but rather to the copper(II) atom Cu(2) of the $[Cu_2(OAc)_4]$ unit to form the one-dimensional chains. The $[Cu_2(OAc)_4]$ units contain four bridging acetate ligands in the familiar $\eta^1:\eta^1:\mu$ coordination mode [20]. The overall geometry of the $[Cu_2(OAc)_4]$ units of **3** and **4** is as expected with a Cu···Cu distances of 2.615(1) and 2.635(1) Å for **3** and **4**, respectively. The distances are slightly larger than the 2.614(2) Å in $[Cu_2(OAc)_4(H_2O)_2]$ [21]. The axial bridging O(33)–Cu(2) distances at 2.124(2) and 2.135(6) Å for complexes **3** and **4**, respectively, are slightly shorter than the Cu–O (water) distance at 2.161(2) in $[Cu_2(OAc)_4(H_2O)_2]$ [21]. Other bond distances and angles for these units are fairly similar to those found for $[Cu_2(OAc)_4(H_2O)_2]$ [21].

There are several structurally characterized compounds in which the axial water of the copper acetate dimer is replaced by a coordinating atom from another complex moiety to form high-nuclearity complexes [20,22]. However, the one-dimensional structures of complexes **3** and **4** are rather unusual as they exhibit a very rare μ_3-*syn–anti–anti* bridging mode of the acetate group. In most of the complexes of this type, a carboxylate ion usually bridges the copper acetate dimer with the other complex moiety by the familiar μ_2-mode [20,22]. In the only previously reported example with a μ_3 acetate bridge, the acetate ion bridges two copper(II) acetate dimer and a copper(I) ion from a bis(triethylphosphite)-copper(I) moiety in *syn–syn–anti* mode [23]. Therefore, to our knowledge, complexes **3** and **4** are the first examples of structures which show a μ_3-*syn–anti–anti* bridging mode of the acetate to join copper(II) acetate dimer with another Cu(II) complex moiety.

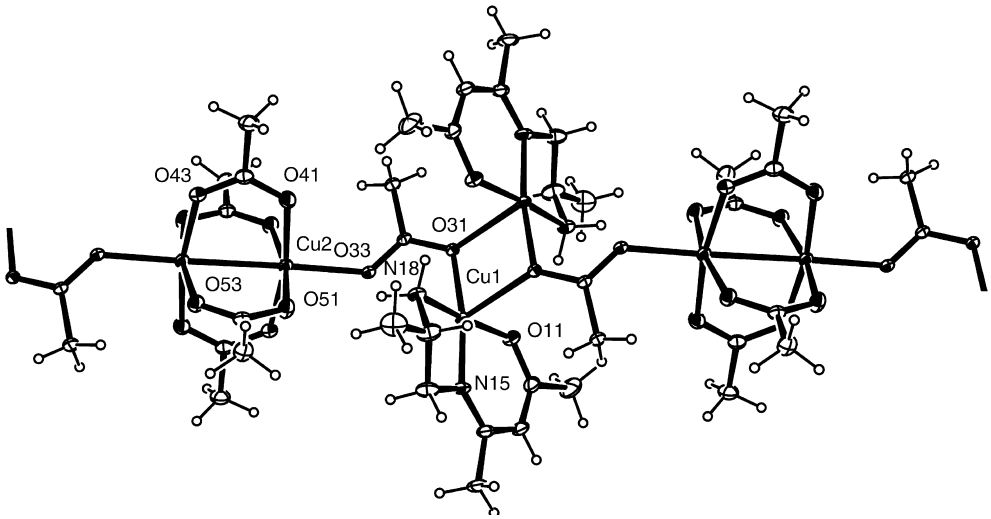

Fig. 4. ORTEP view of complex **3** with ellipsoids at 25% probability.

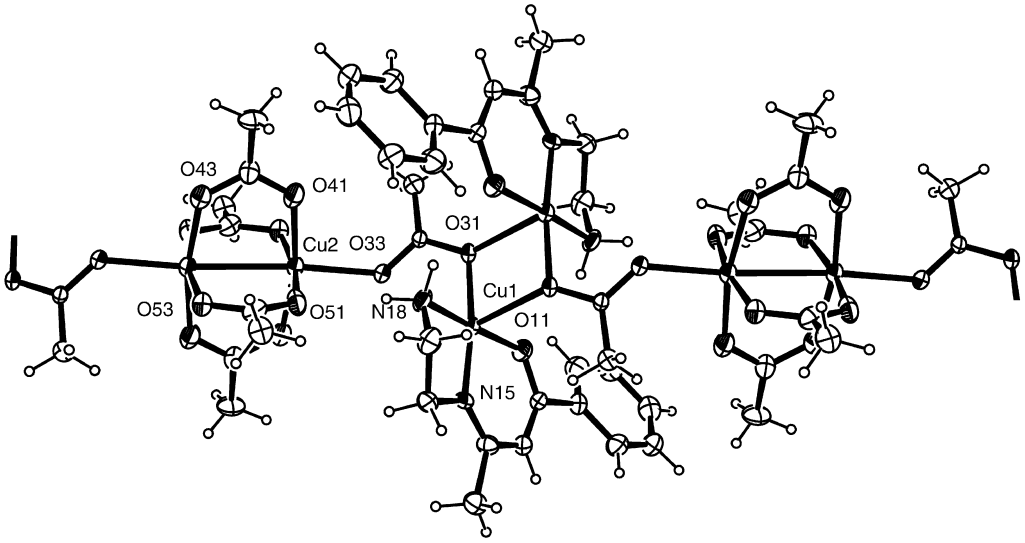

Fig. 5. ORTEP view of complex **4** with ellipsoids at 25% probability.

One of the amine hydrogen atoms, H18a of both **3** and **4** forms strong hydrogen bond with the corresponding Schiff base oxygen atom O11′ within the dimeric unit, whereas the other amine hydrogen, H18b forms a hydrogen bond with O51 for complex **3** and with O41 for complex **4** of an acetate group of the attached $[Cu_2(OAc)_4]$ core (Figs. S3 and S4).

3.3. Magnetic properties of the complexes *1* and *2*

The temperature dependence of the magnetic susceptibility data in the form of $\chi_M T$ versus T and χ_M versus T plots, for complexes **1** and **2**, are shown in Figs. 6a and 7a, respectively (χ_M being the magnetic susceptibility per $[Cu]_2$ unit). The $\chi_M T$ values at 300 K for **1** and **2** are 0.81 and 0.88 $cm^3\ mol^{-1}$ K, respectively which is as expected for two magnetically quasi-isolated spin doublets ($g > 2.00$). When the systems are cooled down, the $\chi_M T$ value remains constant to approximately 20 K for **1** and 50 K for **2** and below these temperatures decreases reaching the values of 0.72 and 0.66 $cm^3\ mol^{-1}$ K, respectively. The profile of the curves indicates the presence of weak antiferromagnetic exchange interactions between the Cu^{II} ions. The isotropic Heisenberg Dirac van Vleck (HDvV) Hamiltonian (Eq. (1)) is the main term used to interpret the magnetic data.

$$H = -JS_1S_2 \tag{1}$$

The Bleaney–Bowers equation (Eq. (2)) was used to fit the experimental data for the two complexes [24].

$$\chi_M = \frac{Ng^2\beta^2}{kT}\cdot\frac{2\exp(J/k_T)}{1+3\exp(J/kT)} \tag{2}$$

The best fit parameters are: $J = -0.56\ cm^{-1}$, $g = 2.09$ and $R = 5 \times 10^{-5}$ for **1** and $J = -1.19\ cm^{-1}$, $g = 2.17$ and $R = 3 \times 10^{-5}$ for **2** ($R = \sum_i(\chi_M T_{icalc} - \chi_M T_{iexp})^2/\sum_i(\chi_M T_{iexp})^2$). Complexes **1** and **2** show a slightly distorted square-pyramidal geometry, so the unpaired electron of the Cu^{II} ion lies in a mainly $d_{x^2-y^2}$ orbital, and there is very small unpaired electron density on the apical, out-of plane ligand. Since in all the present compounds the super exchange pathways involve out-of plane unpaired electron density, a weak exchange interaction may be anticipated. The small values of J parameters, for complexes **1** and **2**, have also been manifested by the curves of the reduced magnetization ($M/N\beta$) versus H compared with the hypothetical Brillouin law for two isolated copper(II) ions. As shown in Figs. 6b and 7b the experimental curves lie slightly bellow the theoretical Brillouin curve, indicating very small antiferromagnetic coupling.

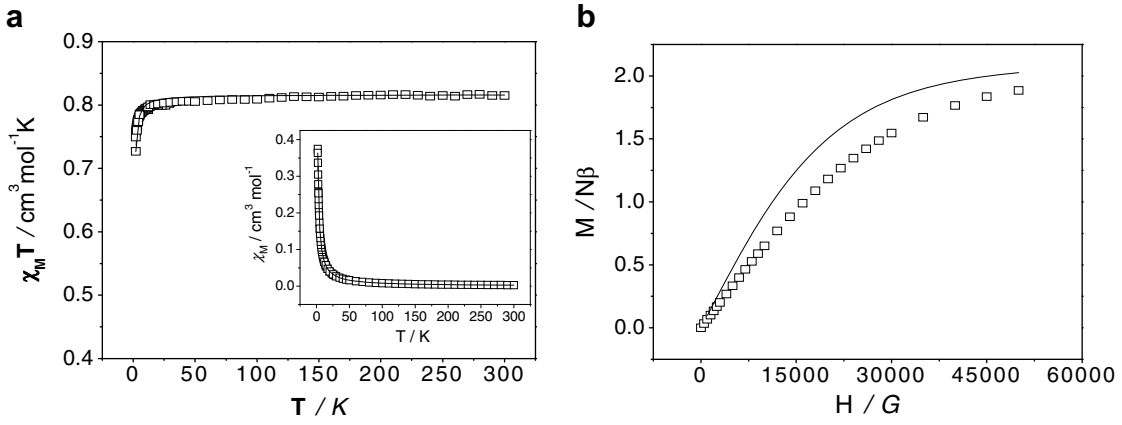

Fig. 6. (a) Plot of the $\chi_M T$ vs. T in the range 2–300 K for **1**. Inset: plot of χ_M vs. T. Solid lines show the best fit obtained. (b) Plot of the reduced magnetization ($M/N\beta$) vs. H for **1** (solid lines represent the Brillouin law for two isolated copper(II) ions).

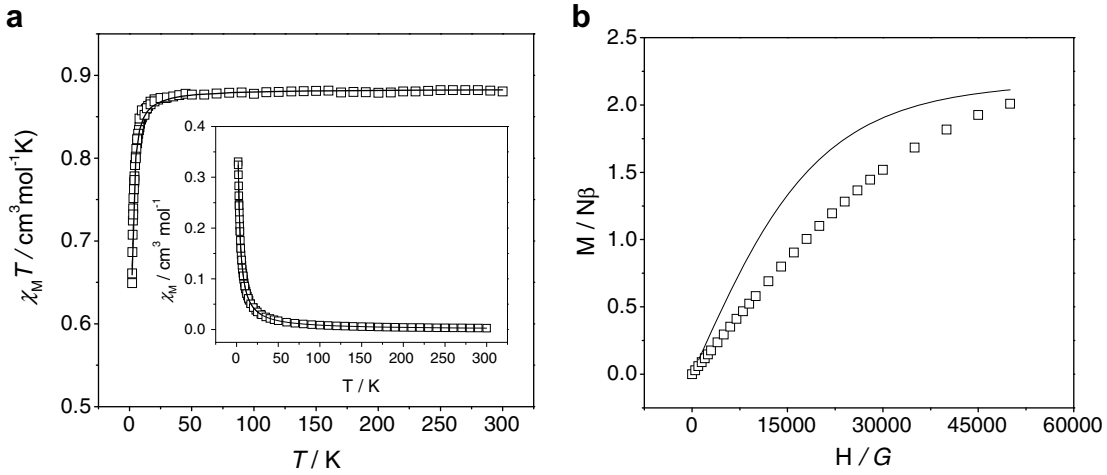

Fig. 7. (a) Plot of the $\chi_M T$ vs. T in the range 2–300 K for **2**. Inset: plot of χ_M vs. T. Solid lines show the best fit obtained. (b) Plot of the reduced magnetization ($M/N\beta$) vs. H for **2** (solid lines represent the Brillouin law for two isolated copper(II) ions).

3.3.1. EPR spectra

The X-band EPR spectra of powdered samples of complexes **1** and **2** were recorded on powder samples varying the temperature between 4 and 298 K. There is no appreciable change in the spectrum in changing the temperature of the sample from room temperature to 4 K. The pattern (Fig. 8) is typical for a square-pyramidal Cu^{II} [25]. The simulated parameters are the following: $g_{\|} = 2.25$ and $g_{\perp} = 2.05$ for **1**, and $g_{\|} = 2.23$ and $g_{\perp} = 2.05$ for **2**.

3.3.2. Discussion

From the structural point of view, in each dimer of complex **1** the ligand environment of the copper atoms is identical owing to crystallographic inversion symmetry and exhibits a 1D structure built of well separated chains in which the dimer units are connected by weakly hydrogen bonded water molecules. In complex **2** the dimer is not centrosymmetric, and therefore the two Cu–O–Cu bridges are dissimilar. The dimer units are linked by van der Waals interactions to form a 2D structure (Fig. S2). Taking into account the structural features the calculated J value for complex **2** is approximately the average of the two J intra values along the two Cu–O–Cu sides.

The magnetic pathway in the complexes is the Cu_2O_2 core. The magnetic properties of this core have been exhaustively studied from an experimental and theoretical point of view but only when the two O atoms occupy equatorial–equatorial positions with respect to copper(II) ions [26]. In contrast, the number of similar complexes containing this Cu_2O_2 core with the two O atoms in equatorial–axial positions is less abundant [5a,8,27] and no general trends have been reported relating the sign of the coupling constant and Cu–O–Cu angles. For such a bridging mode, the relative orientation of the magnetic orbitals centred on the metal ions is highly unfavorable for a strong magnetic coupling. The magnetic orbital for copper(II) ions in a square pyramidal environment is of the $d_{x^2-y^2}$-type; the x and y axes are roughly defined by the equatorial bonds. Some admixture of the d_{z^2} orbital is present as a result of trigonal distortion. The magnetic coupling is very weak because it is the result of the interaction of a $d_{x^2-y^2}$-type orbital with a d_{z^2}-type orbital having a very small spin density. The small J values can be positive (F) or negative (AF) depending upon subtle structural changes which is yet to be defined clearly. The literature shows that the absolute J value mainly depends on the axial Cu–O distances: if this length is ca. 2.3–2.5 Å (the most frequent cases), J lies between 8 and 0.5 cm^{-1} (ferromagnetically coupled systems) [8b,27] and -0.5 to -1 cm^{-1} (antiferromagnetically coupled systems) [5a,8a,8c,8d]. In complexes **1** and **2**, the central Cu_2O_2 core is equatorial–axial coordinated with the axial Cu–O lengths (2.508(4) Å in **1**, 2.501(3) and 2.433(2) Å in complex **2**). Thus, the antiferromagnetic coupling in both complexes is comparable to the values reported in the literature for similar systems. Furthermore, the Addison parameters for both the complexes indicate that the spin density on the apical position should be small, corroborating the small magnitude of the J values.

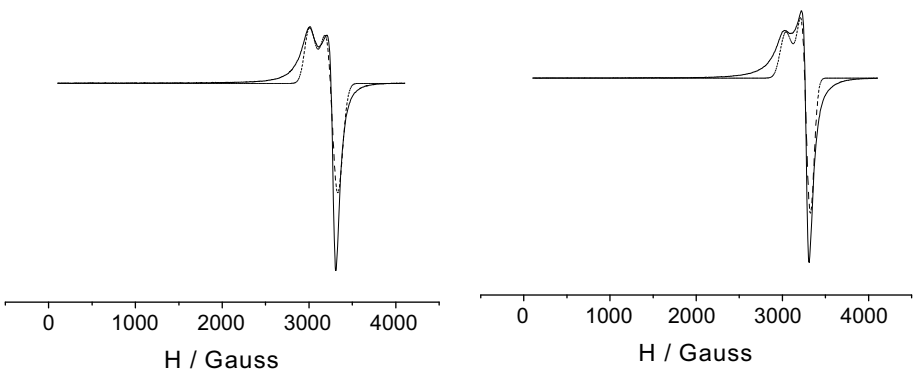

Fig. 8. The X-band EPR spectra of powdered samples and simulated EPR spectra (dotted lines) of complexes **1** and **2** at 4 K.

4. Conclusions

The N,N,O donor Schiff bases obtained by the reaction of acetyl-/benzoylacetone with diamines react with Cu^{II} acetate to yield dinuclear complexes containing mono-atomic acetate oxygen bridge – a relatively rare bridging mode of the carboxylate group. Synthesis of such complexes may also be accompanied by the formation of a one-dimensional alternating chain of the dimer and unreacted copper acetate in which a very rare μ_3-*syn–anti–anti* bridging mode of the acetate ion is observed. The variable temperature magnetic study of the two dimers shows very weak antiferromagnetic coupling caused by the basal-apical, mono-atomic acetate oxygen-bridge. The results corroborate the fact that for such bridging mode, the magnetic coupling is always very small but it can be either ferromagnetic or antiferromagnetic depending upon the subtle structural features that are yet to be understood.

ABSTRACT

A versatile neutral metalloligand [Cu(PySal)$_2$] (**1**) (PySal = 3-pyridylmethylsalicylidene-imino) was exploited as a building unit to construct five complexes {Cu[Cu(PySal)$_2$]$_2$}(ClO$_4$)$_2$ (**2**), {Cd[Cu(PySal)$_2$]$_2$(H$_2$O)$_2$]} (NO$_3$)$_2$ · 2H$_2$O · 4CH$_3$OH (**3**), {Zn[μ_2-Cu(PySal)$_2$]Cl$_2$}$_n$ · nCH$_3$OH (**4**), {Hg[μ_2-Cu(PySal)$_2$]I$_2$}$_n$ (**5**) and {Cd[μ_2-Cu(PySal)$_2$]Cl$_2$}$_n$ · nCH$_2$Cl$_2$ (**6**). [Cu(PySal)$_2$] acts as a chelating ligand in discrete complexes **2** and **3** with unbound anions, but as a bis-monodentate bridging ligand in polymers **4**, **5** and **6** when halogen anions coordinated cooperatively to metal cations. The coordination geometry of Cu^{2+} is well-defined square planar in bridging [Cu(PySal)$_2$], analogous to that in free metalloligand (**1**), but it is distorted square planar in chelating [Cu(PySal)$_2$].

1. Introduction

The design and construction of metal-organic architectures has been received considerable attention not only because of their intrinsic aesthetic appeal in structures but also because of their potential application in catalysis, molecular adsorption, magnetism, non-linear optics and molecular sensing [1–8]. A variety of molecular architectures, such as multiple helicates, cages, grids, two-dimensional sheets, diamondoid networks and porous framework [9–12], have been prepared by the self-assembly of metal ions and organic ligands. The diversity of the structures and new topology are attributed to the selection of metal centers as well as the organic building blocks. The rigid ligands, allowing for a certain control of steric consequence in the assembly process, are usually used to develop metal-organic framework. The use of non-rigid (semi-rigid or flexible) ligands to construct well-shaped molecular architectures is far less common, partly due to the less predictable assembly process [13]. However, the lability and adaptability of flexible ligand can increase the structural diversity and functionality of metal-organic framework [14,15]. In addition, compounds that are capable of rotational motion in response to outside driving forces such as light, heat, or electric fields are intriguing for the development of molecular devices [16].

Metalloligand, the aggregate of metal ion and pure organic ligand, has been taken much interest recently due to its extra oriented donor atoms and well-defined geometry. Exploitation of metalloligand with *exo*-oriented donor atoms for bonding can give more easy access to target structure accommodated by the preconstructed geometry of metalloligand. Many examples have been shown that the use of metalloligands as building blocks is effective not only in the construction of the desired structures but also to design the spatial arrangement of metal ions and to tune the metal–metal interactions [17–28].

In this paper, we report a metalloligand [Cu(PySal)$_2$] **1**, which is prepared by reaction of organic ligand 3-pyridylmethylsalicylideneimine (HPySal) with Cu(Ac)$_2$. This copper-containing ligand not only contains two "free" pyridyl N donors which can coordinate to the external metal ions, but also possesses the nature of flexibility owing to the presence of a –CH$_2$– spacer between pyridyl ring and salicylideneimine moiety. The flexible rotation of pyridyl moiety can meet the requirement of coordination environment of external metal ion to exhibit different spatial conformation. In addition, the flexible coordination geometry of copper(II) ion between square planar and tetrahedral endows [Cu(PySal)$_2$] with adaptability. Based on the building block [Cu(PySal)$_2$], five compounds {Cu[Cu(PySal)$_2$]$_2$}(ClO$_4$)$_2$ (**2**), {Cd[Cu(PySal)$_2$]$_2$(H$_2$O)$_2$]} (NO$_3$)$_2$ · 2H$_2$O · 4CH$_3$OH (**3**), {Zn[μ_2-Cu(PySal)$_2$]Cl$_2$}$_n$ · nCH$_3$OH (**4**), {Hg[μ_2-Cu(PySal)$_2$]I$_2$}$_n$ (**5**) and {Cd[μ_2-Cu(PySal)$_2$]Cl$_2$}$_n$ · nCH$_2$Cl$_2$ (**6**) (Scheme 1) are isolated. The building unit of [Cu(PySal)$_2$], as a bis(pyridyl) ligand, can adopt chelating coordination mode or bis-monodentate bridging mode to construct architectures (Chart 1).

2. Experimental

2.1. Synthesis

All chemicals were of reagent grade and were used as received without further purification. The IR spectrum was recorded as KBr

pellets on a Perkin Elmer FT-IR spectrometer in the 4000–450 cm^{-1}. Elemental analyses for C, H, and N were performed on a Carlo ERBA 1106 analyzer. 3-Pyridylmethylsalicylideneimine (HPySal) was synthesized according to Ref. [29].

*2.1.1. Preparation of $[Cu(PySal)_2]$ (**1**)*

$Cu(Ac)_2 \cdot 2H_2O$ (0.0410 g, 0.20 mmol) was added to a stirring solution of HPySal (0.0852 g, 0.40 mmol) in CH_2Cl_2/CH_3OH (20 mL with 1:1 ratio), and the resulting deep green solution was allowed to stir for another 4 h. By diffusion of diethyl ether into the filtrate, the block deep green crystals were formed for X-ray diffraction analysis. Yield: 0.0830 g, 85%. *Anal.* Calc. for $C_{26}H_{22}N_4O_2Cu$: C, 64.20; H, 4.53; N, 11.52. Found: C, 64.17; H, 4.59; N, 11.48%. IR(cm^{-1}): 1615(s), 1601(m), 1543(m), 1470(m), 1437(s), 1330(m), 1201(m), 1044(m), 754(m), 705(m), 679(m).

*2.1.2. Preparation of $\{Cu[Cu(PySal)_2]_2\}(ClO_4)_2$ (**2**)*

A solution of **1** (0.0972 g, 0.2 mmol) in CH_2Cl_2 (10 mL) was added into a stirring solution of $Cu(ClO_4)_2$ (0.0262 g, 0.1 mmol) in CH_3OH (10 mL), and immediate precipitation of a deep green solid was observed. The mixture was allowed to stir for an additional 1 h to complete precipitate, then the precipitation collected by filtration was washed using CH_3OH and CH_2Cl_2 for two times, respectively, and dried under a vacuum. Yield: 0.1190 g, 85%. *Anal.* Calc. for $C_{52}H_{44}N_8O_{12}Cl_2Cu_3$: C, 50.55; H, 3.56; N, 9.07. Found: C, 50.02; H, 3.23; N, 9.44%. IR(cm^{-1}): 1624(s), 1609(m), 1535(m), 1466(m), 1450(m), 1430(m), 1321(m), 1121(s), 1094(s), 765(m), 706(m), 625(m). Suitable block deep green crystals were grown from the diffusion of diethyl ether into a THF solution of complex **2**.

*2.1.3. Preparation of $\{Cd[Cu(PySal)_2]_2(H_2O)_2]\}(NO_3)_2 \cdot 2H_2O \cdot 4CH_3OH$ (**3**)*

A solution of **1** (0.0972 g, 0.2 mmol) in CH_2Cl_2 (10 mL) was added into a stirring solution of $Cd(NO_3)_2 \cdot 2H_2O$ (0.0272 g, 0.1 mmol) in CH_3OH (10 mL). After allowed to stir for an additional 4 h, diethyl ether was diffused into the mixture solution. Two weeks later, the block red crystals were grown up suitable for X-ray diffraction. Yield: 0.0563 g, 40%. *Anal.* Calc. for $C_{56}H_{68}N_{10}O_{18}Cu_2Cd$: C, 47.73; H, 4.84; N, 9.94. Found: C, 47.45; H, 4.97; N, 9.53%. IR(cm^{-1}): 1620, 1601, 1537, 1469, 1452, 1437, 1428, 1384, 1324, 1150, 1128, 761, 707, 614.

*2.1.4. Preparation of $\{Zn[\mu_2\text{-}Cu(PySal)_2]Cl_2\}_n \cdot nCH_3OH$ (**4**)*

A solution of $ZnCl_2$ (0.0136 g, 0.1 mmol) in CH_3OH (10 mL) was layered onto a solution of **1** (0.0486 g, 0.1 mmol) in CH_2Cl_2 (10 mL). Two weeks later, block green crystals were collected for X-ray diffraction measure. Yield: 0.0348 g, 56%. *Anal.* Calc. for $C_{27}H_{26}N_4O_3CuZnCl_2$: C, 49.54; H, 3.98; N, 8.56. Found: C, 49.95; H, 3.62; N, 8.32%. IR(cm^{-1}): 1616(s), 1586(m), 1540(s), 1471(m), 1452(s), 1433(m), 1399(m), 1328(s), 765(s), 705(m).

*2.1.5. Preparation of {Hg[μ_2-Cu(PySal)$_2$]I$_2$}$_n$ (**5**)*

To a solution of **1** (0.0486 g, 0.1 mmol) in CH_2Cl_2 (10 mL) was dropped a solution of HgI_2 (0.0454 g, 0.10 mmol) in methanol (10 mL), and immediate precipitation of red solid was observed. After stirring for an additional 1 h, 5 ml DMF was added into the mixture to dissolve the precipitation. The resulting solution was layered by diethyl ether for 1 week to give block deep green crystals. Yield: 0.0378 g, 40%. *Anal.* Calc. for $C_{26}H_{22}N_4O_2CuHgI_2$: C, 33.17; H, 2.34; N, 5.95. *2.1.6. Preparation of {Cd[μ_2-Cu(PySal)$_2$]Cl$_2$}$_n \cdot n$CH$_2$Cl$_2$ (**6**)*

A solution of $CdCl_2 \cdot 2.5H_2O$ (0.0219 g, 0.1 mmol) in CH_3OH (10 mL) was layered onto a solution of **1** (0.0486 g, 0.1 mmol) in CH_2Cl_2 (10 mL). Three weeks later, block green crystals were collected for X-ray diffraction measure. Yield: 0.0250 g, 35%. *Anal.* Calc. for $C_{26.5}H_{23}N_4O_2Cl_3CuCd$: C, 44.68; H, 32.31; N, 7.87. Found: C, 44.35; H, 3.23; N, 7.87%. IR(cm^{-1}): 1614(s), 1538(s), 1472(m), 1448(s), 1431(m), 1338(s), 752(s), 708(s), 577(m).

2.2. Crystal structure determination

Crystals were mounted on glass fibers. Data were collected on a Bruker SMART CCD diffractometer using graphic-monochromated Mo Kα radiation (λ = 0.71073) at 293 K and the ω scan mode. The structures were solved with direct method on F^2 with full matrix least-squares methods using SHELXS-97 [30] and SHELXL-97 [31] programs, respectively. Except as mentioned, all non-hydrogen atoms were refined anisotropically. The hydrogen atoms were constrained to idealized geometries and assigned isotropic displacement parameters equal to 1.2- or 1.5-times the U_{iso} values of their respective parent atoms. Thermal ellipsoid diagrams were shown at 30% probability. In **2**, two perchloride anions were disordered over special position with two chlorine atoms at 25% occupancy. Both O6 and O7 were set to 50% occupancy. The anions were left isotropic and the largest residual electron density peaks (2.78–1.10 e/Å^3) were associated with them. In **3**, the solvent molecules of water and methanol were just suggested by elemental microanalysis of crystals from the same batch, and crystallographically modeled due to severely disordered. Geometric restraints were applied to the nitrate anions, and the largest residual electron density peaks (1.29 e/Å^3) were still associated with them. All solvent molecules and nitrate anions were left with isotropic thermal parameters. No hydrogen atoms were assigned on coordination water, crystalline water and methanol molecules. In **5**, the largest residual electron density peaks (2.78–1.10 e/Å^3) were associated with I^- and Hg^{2+} ions. In **6**, solvent CH_2Cl_2molecule, which laid on a symmetry element, was modeled at 50% occupancy with isotropic thermal parameters. Because of symmetry, only one-half molecule was located on the different Fourier map. Crystallographic data for these complexes are showed in Table 1, while the selected bond distances and angles are showed in Table 2.

3. Result and discussion

*3.1. Crystal structure description of **1***

When 3-pyridylmethylsalicylideneimine (HPySal) reacted with $Cu(Ac)_2 \cdot 2H_2O$ in dichloro- methane at room temperature (1:2 metal-to-ligand ratio), neutral complex **1** was obtained in quantitative yield with a formula of Cu(PySal)$_2$. This compound is air-stable and only soluble in organic solvents such as CH_2Cl_2, $CHCl_3$, THF, 1,2-dichloroethane, 1,1,2,2,-tetrachloromethane, not soluble in more polar solvents such as H_2O, DMF, CH_3CN, CH_3OH, CH_3COCH_3, and non-polar solvents. X-ray diffraction analysis shows that complex **1** is centro-symmetric with Cu^{2+} at the inversion center (Fig. 1). The asymmetric unit contains half a metal atom and one PySal entity. The copper center is well-suited for square planar coordination consisted of two phenolate-O and two imine-N atoms from two PySal ligands in a trans arrangement. The pyridyl nitrogen atoms in PySal do not take part in coordination. The bond distances and angles around Cu are similar as expected in other copper complexes of salicylideneimine ligands [32,33]. The chelating rings are in the same plane as the benzene rings forming a large common plane. Two pyridyl rings locate on the opposite sides of the coordination plane pointing in opposite directions, presumably to minimize the steric hindrance. The torsion angle of C7–N1–C8–C9 is −103.5° and the dihedral angle between pyridyl ring and the coordination plane is 86.1°. The separation of two pyridyl nitrogen atoms is 10.828(4) Å, significantly longer than that in 4,4′-bipyridine (7.12(3) Å), but comparable to those of 1,2-bis(4-pyridy)ethane (9.385(5) Å) and 1,2-bis(4-pyridyl)-ethyne (9.685(4) Å) [24].

The important structure feature of **1** is the presence of two uncoordinated nitrogen atoms of pyridyl rings which can endow complex **1** with a potential metalloligand to assemble the external transition metals to produce new coordination complexes, as well as the flexibility from the versatile co-ordination geometry of cop-

per(II) ion and the freely rotating pyridyl moieties which make [Cu(PySal)$_2$] labile to meet the coordination requirement of the external metal ions. By the rotation of pyridyl moieties, [Cu(PySal)$_2$] can take on a variety of conformations.

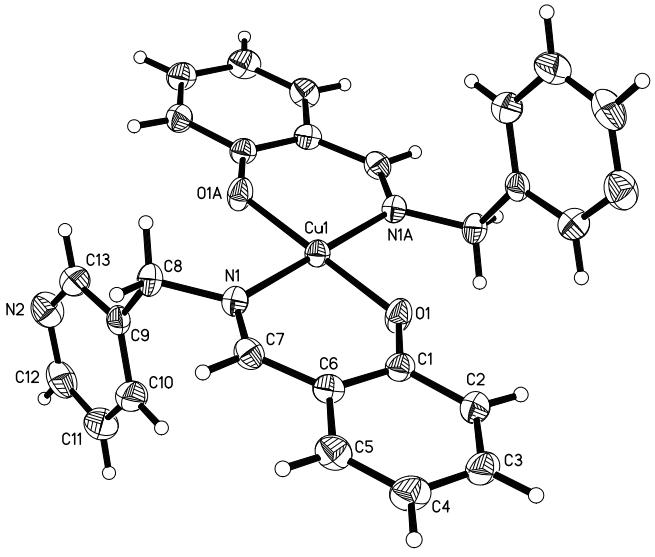

Fig. 1. ORTEP of complex **1** showing the numbering scheme.

3.2. Crystal structure description of *2* and *3*

When **1** was associated with Cu(ClO$_4$)$_2$ and Cd(NO$_3$)$_2$, respectively, trinuclear complexes **2** and **3** were isolated. X-ray diffraction analysis reveals that the building block of [Cu(PySal)$_2$], whose spatial configuration is totally different from that of free metalloligand **1**, takes chelating coordination mode to connect external metal ion through pyridyl nitrogen atoms. The geometry of Cu^{2+} ion in the building block is distorted square planar, significantly deviated from ideal square planar in the process of [Cu(PySal)$_2$] chelating to the external metal ions. Both of pyridyl moieties locate at the same side of distorted square plane. The long arms of methylenepyridine, like pincers, are agile to clamp metals. Complex **2** is composed of two building units of [Cu(PySal)$_2$] and one [Cu(ClO$_4$)$_2$] molecule (Fig. 2). The asymmetric unit contains half a building block. A crystallographically imposed twofold axis that passes through Cu1 bisects the building unit. The O1–Cu1–O1A and N1–Cu1–N1A angles exhibit that the geometry of Cu1 is largely deviated from ideal square plane. However, the bond distances of Cu1–O and Cu1–N are comparable to the corresponding values in **1**. Cu2 has a square planar geometry composed of four crystallographically identical pyridyl nitrogen atoms from two [Cu(PySal)$_2$] units, with the mean deviation of the CuN$_4$ plane of 0.094 Å. The

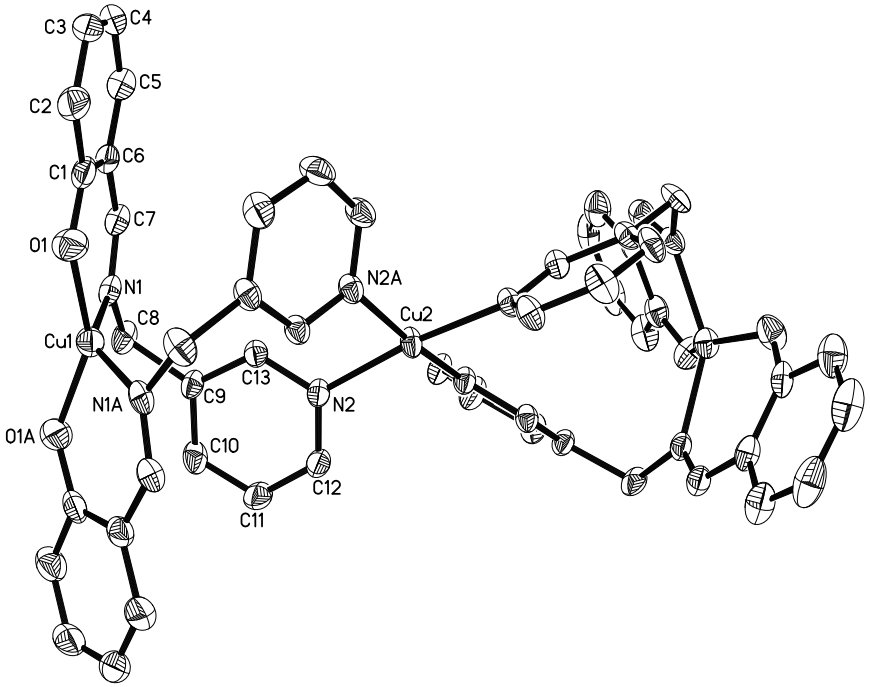

Fig. 2. The cation ORTEP of **2** showing the numbering scheme.

Cu2–N2 distance of 2.023(5) Å is within the normal range observed in bipyridyl Cu^{2+} complexes [34–36]. Counterions anions ClO_4^- are unbound and located between cations. Due to an active electron delocalization, the Cu–N-heterocyclic chelate rings exhibit some degree of "metalloaromaticity" [37]. So intermolecular $\pi\cdots\pi$ interactions between chelate and phenyl rings are observed (the ring-centroid distance of 4.37 Å and dihedral angle of 4°) in the packing structure of **2**[38]. It is surprising that complex **2** was also prepared by reaction of **1** with $[Cu(en)_2](ClO_4)_2$ or $[Cu(phen)_2](ClO_4)_2$ (en = 1,2-ethylenediamine, phen = 1,10-phenanthroline). The chelating ligand of en or phen being replaced by $[Cu(PySal)_2]$ demonstrates that the building block of $[Cu(PySal)_2]$ with long flexible arms is of very strong chelating ability. Complex **3** is composed of two $[Cu(PySal)_2]$, one $Cd(NO_3)_2$, two coordinated water molecules, four CH_3OH and two crystalline water molecules. The crystalline solvents of CH_3OH and H_2O are disordered. The asymmetric unit contains one building block. Two building blocks, whose geometric configuration similar to that in **2**, chelate to Cd^{2+} ion (Fig. 3), but the angles of O–Cu–O and N–Cu–N show that the deviation from ideal square plane in **3** is slightly smaller than that in **2**. The geometry of Cd^{2+} can be described as slightly distorted octahedron with the basal plane occupied by four pyridyl nitrogen atoms from two equivalent $[Cu(PySal)_2]$, and two apical sites associated with two aqua donors. The Cd–O distances are comparable to those in other known Cd complexes containing coordinated water molecules, but the Cd–N distances are shorter than those found in dipyridyl Cd complexes [39,40]. No intermolecular $\pi\cdots\pi$ interactions are observed. The solvents and unbound counterions anions are located between cations. Due to disorder, the weak interactions between solvents, anions and cations are not discussed.

Both **2** and **3** are discrete trinuclear complexes in which the anions are unbound, only as counterions. The geometric flexibility of Cu ion and the free rotating methylpyridine make $[Cu(PySal)_2]$ can adopt chelating coordination mode. It can be predicted that multi-dimensional complexes would be constructed if the building block

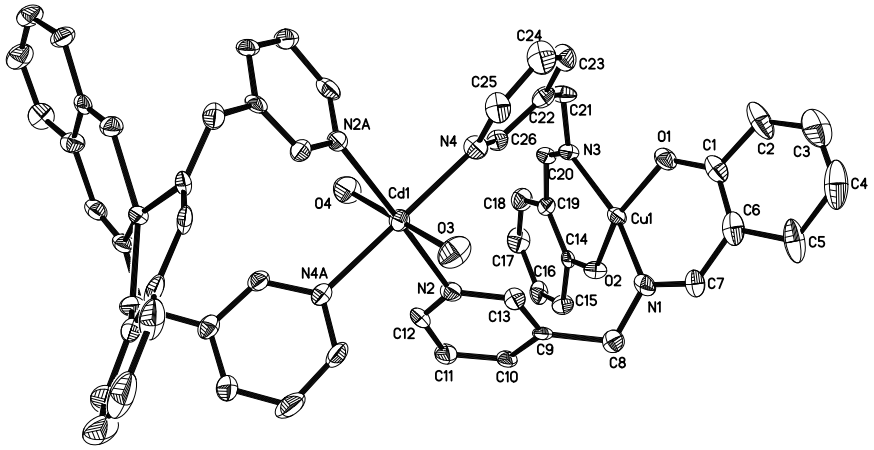

Fig. 3. The cation ORTEP of **3** showing the numbering scheme.

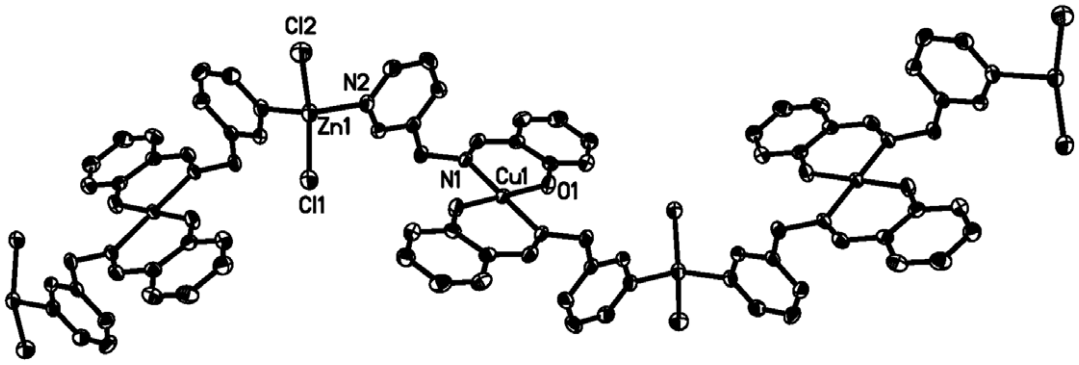

Fig. 4. 1D $[Cu(PySal)_2]/[ZnCl_2]$ polymer of **4**.

of $[Cu(PySal)_2]$ adopts bridging coordination mode in the assembly process. Thus neutral bulky PPh_3 was internationally introduced into molecular architecture to increase steric hindrance and expected to induce the building block taking bridging mode, but it was found that $[Cu(PySal)_2]$ was still inclined to perform as chelating mode in complex $\{Cu(PPh_3)(CH_3CN)[Cu(PySal)_2]\}(BF_4)$.[1]

3.3. Crystal structure description of *4*, *5* and *6*

In order to avoid the presence of unbound anions and to investigate further the coordination behavior of metalloligand $[Cu(PySal)_2]$, the neutral metal halides MX_2(M = Zn, Cd, Hg; X = Cl or I) were associated with experiments. The mixed-metal coordination polymers $\{Zn[\mu_2\text{-}Cu(PySal)_2]Cl_2\}_n \cdot nCH_3OH$ (**4**), $\{Hg[\mu_2\text{-}Cu(PySal)_2]I_2\}_n$ (**5**) and $\{Cd[\mu_2\text{-}Cu(PySal)_2]Cl_2\}_n \cdot nCH_2Cl_2$ (**6**) were obtained. They are air-stable and exhibit low solubility in all common solvents. The single-crystal structural determination reveals that the structures of these three compounds are distinctly different from discrete complexes **2** and **3**. The building unit $[Cu(PySal)_2]$ acts as bridging coordination mode in these three polymers.

Polymer **4** is composed of the building block, $ZnCl_2$ and CH_3OH molecules. Each $[Cu(PySal)_2]$ links two incorporated Zn^{2+} ions and each Zn^{2+} ion is coordinated by two $[Cu(PySal)_2]$ units to generate one-dimensional zigzag $[Cu(PySal)_2]/[ZnCl_2]$ chain along the *b*-axis (Fig. 4). The Zn^{2+} cation adopts a distorted geometry (N–Zn–N and Cl–Zn–Cl angles of *ca.* 105.76° and 118.03°, respectively) and its coordination geometry is composed of two Cl^- anions and two pyridyl nitrogen atoms from two neighboring units of $[Cu(PySal)_2]$. The bond distances of Zn–N and Zn–Cl are comparable to those in similar compounds [41,42]. The shortest separations of Zn···Zn, Cu···Cu and Zn···Cu within the chain are 14.515 Å, 11.171 Å and 7.257 Å, respectively. CH_3OH molecules are located between chains. No special interactions such as π–π interactions are observed between adjacent chains. The conformation of free metalloligand is virtually retained in complex **4**: the building block is

[1] Structural analysis of $[Cu(PPh_3)(CH_3CN)[Cu(PySal)_2](BF_4)$ by X-ray diffraction shows that the building unit of $[Cu(PySal)_2]$ chelates to $[Cu(PPh_3)(CH_3CN)]$ moiety. Triclinic, space group, $P\bar{1}$, a = 12.352(2), b = 14.003(3), c = 14.595(3) Å, α = 87.606(3), β = 82.639(3), γ = 65.819(3)°, V = 2283.8(7) Å^3.

centro-symmetric with Cu^{2+} at the inversion centre; the coordination geometry of Cu^{2+} is square planar and the pyridyl rings locate on the opposite sides of the coordination plane pointing in opposite directions. The torsion angle of C7–N1–C8–C9 (−106.6°), the dihedral angle between pyridyl ring and the coordination plane (87.5°) and the bond distances around Cu^{2+} are also comparable to the corresponding values in **1**. But the separation between pyridyl nitrogen atoms in the building unit $[Cu(PySal)_2]$ is 11.142 Å, a little longer than that in **1** (10.828(4) Å).

For complex **5** obtained when the building unit of $[Cu(PySal)_2]$ was associated with HgI_2, a rather similar structure as **4** was observed. Each $[Cu(PySal)_2]$ bridges two Hg^{2+} ions and each Hg^{2+} ion is coordinated by two $[Cu(PySal)_2]$ units to generate one-dimensional zigzag $[Cu(PySal)_2]/[HgI_2]$ chains along the *b*-axis (Fig. 5). The geometry of Hg^{2+} can be described as significantly distorted tetrahedral and its coordination geometry is composed of two I^- anions and two pyridyl nitrogen atoms from two neighboring units of $[Cu(PySal)_2]$. The shortest separations of Hg···Hg, Cu···Cu and Hg···Cu within the chain are 15.147 Å, 12.653 Å and 7.573 Å, respectively. Interchain π···π weak interactions are observed between the chelating rings around Cu^{2+} cations and phenyl rings (ring-centroid distance of 3.60 Å), which lead to the stack of chains along the crystallographic *a*-axis. These π-stacking interactions between metallo-aromaticity-chelate and aryl rings are usually observed in crystal structures [37,38]. Taking into account of the ionic radius of I^- to be 2.06 Å [43], the I···I distance of 3.977(2) Å between adjacent polymers indicates the formation of I···I weak interactions which lead to the chains array along the crystallographic *c*-axis. Both of interchain π···π interactions and I···I weak interactions lead to chains packing into three-dimen-

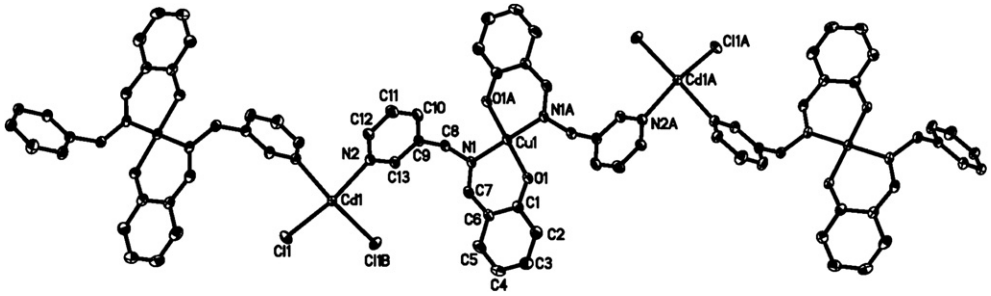

Fig. 6. 1D $[Cu(PySal)_2]/[CdCl_2]$ chain in **6**.

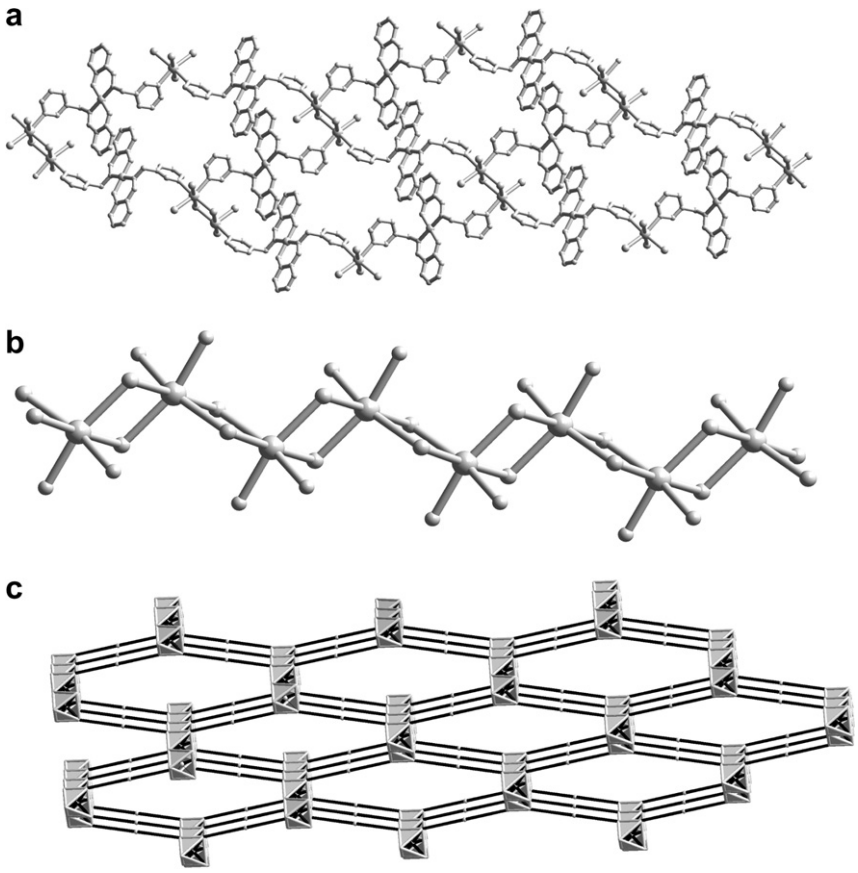

Fig. 7. (a) 2D sheet formed by double μ_2-Cl bridges linking adjacent chains in **6**; (b) 1D inorganic $[Cd(\mu_2\text{-}Cl)_2N_2]_n$ chain in **6**; (c) Schematic representation of 3D structure of **6** constructed by $[Cu(PySal)_2]$ units connecting inorganic chains $[Cd(\mu_2\text{-}Cl)_2]_n$ (polyhedral chains, inorganic chains $[Cd(\mu_2\text{-}Cl)_2]_n$; sticks, $[Cu(PySal)_2]$ units).

sional supramolecular structure (Fig. 5). The building unit [Cu(PySal)$_2$] in **5**, also retains the basic conformation of **1**. The bond parameters around Cu^{2+} and the torsion angle of C7–N1–C8–C9 (−102.3°) are close to the corresponding values in **1**, but the dihedral angle between pyridyl ring and the coordination plane is 95.1°, larger than that in **1**.

The establishment of complex **6** is based on [Cu(PySal)$_2$] and $CdCl_2$ building blocks. X-ray diffraction analysis shows **6** is composed of [Cu(PySal)$_2$], $CdCl_2$ and CH_2Cl_2. The synthetic precursor of [Cu(PySal)$_2$] adopts bridging mode *cis*-coordinating to cadmium cation (Fig. 6). Each [Cu(PySal)$_2$] links two neighboring $CdCl_2$ and each $CdCl_2$ links two [Cu(PySal)$_2$] units to generate a 1D zigzag metal-organic [Cu(PySal)$_2$]/[$CdCl_2$] chain along the crystallographic *a*-axis, as observed in above-mentioned complexes **4** and **5**. The significant difference is that these chains in **6** are further interconnected by double μ_2-Cl bridges between Cd centers into 3D noninterpenetrating network which contains one-dimensional zigzag inorganic chains of [Cd(μ_2-Cl)$_2$]$_n$ along the crystallographic *c*-axis (Fig. 7). In other words, if the inorganic [Cd(μ_2-Cl)$_2$]$_n$ chains can be treated as secondary building units (SUBs), the construction of 3D network in **6** can be also described as adjacent 1D SUBs of [Cd(μ_2-Cl)$_2$]$_n$ connected by [Cu(PySal)$_2$] units (Fig. 7c). The four adjacent SUBs are connected by [Cu(PySal)$_2$] units to form a 1D open channel. Each SUB is shared by four adjacent channels. The channels are filled by CH_2Cl_2 molecules and the phenyl rings of [Cu(PySal)$_2$] units, resulting in the total potential solvent-accessible volume is only 17.6% (501.4 $Å^{-3}$ per 2845.9 $Å^{-3}$) [44].

Within the 1D metal-organic [Cu(PySal)$_2$]/[$CdCl_2$] chain, the neighboring Cd···Cd, Cu···Cu and Cd···Cu separations are 15.795 Å, 14.803 Å and 7.897 Å, respectively. The separation between the two pyridyl nitrogen atoms in the [Cu(PySal)$_2$] unit is 11.820 Å, 1.0 Å longer than that in **1**. π···π weak interactions are observed between phenyl rings (the centroid distance of 3.788 Å) from adjacent 1D [Cu(PySal)$_2$]/[$CdCl_2$] chains, which could make, to some extent, contribution to the formation of 3D network [45].

The cadmium centers are crystallographically identical and lie in distorted octahedral *cis*-{Cd(μ_2-Cl)$_4$N$_2$} coordination spheres. The nitrogen donors are provided by pyridyl rings of [Cu(PySal)$_2$] units. Cadmium-centered octahedrons in inorganic chains are edge-shared. The bond length of Cd-μ_2-Cl (2.589 Å, 2.685 Å) and the angle of Cd-μ_2-Cl–Cd (98.6°) are similar to those observed in other analogous [Cd(μ_2-Cl)$_2$]$_n$ inorganic chains [46,47]. The bond length of Cd–N (2.376 Å) is longer than that in complex **3**. In [Cu(PySal)$_2$], the torsion angle of C7–N1–C8–C9 (85.5°) and the dihedral angle between pyridyl ring and the coordination plane (72.1°) are distinctly different from those in complex **1**, exhibiting the large-angle rotation of pyridyl groups. However, the basic conformation in free metalloligand of **1** is retained in complex **6**.

In the three compounds containing [Cu(PySal)$_2$]/[MX_2] chains, the building units of [Cu(PySal)$_2$] acts as a bridging ligand, and their spatial conformation and geometric parameters are analogous, even close to those in free metalloligand of **1**. The conformational changes of [Cu(PySal)$_2$] in these polymers are completed through the rotation of labile pyridine groups to meet the need of overall structures.

4. Conclusion

Metalloligand **1**, of which the functionality originates from mobile components, can adopt not only bidentate chelating mode, but also bridging mode in the process of metal-organic construction. The flexibility in [Cu(PySal)$_2$] (the geometric variation of Cu ion and the free rotation of methylpyridine moiety) is intrinsic for the metalloligand to meet the coordination requirement of different molecular architectures such as discrete and multi-dimensional structures. [Cu(PySal)$_2$] is inclined to perform as chelating mode with unbond anions. Nevertheless, the bridging coordination mode is preferred for [Cu(PySal)$_2$] in the presence of halogen anion ligand.

ABSTRACT

The pH-control of a reaction between tetracyanooxomolybdate(IV) and 2-pyrazinecarbonitrile (pcn), in aqueous-ethanolic solution under ambient conditions, affords the Mo(IV) mixed-ligand complex anions $[Mo(CN)_4O(pcn)]^{2-}$ (**1**) or $[Mo(CN)_4O(Hpca)]^{2-}$ (**2**) with a monodentately bound 2-pyrazinecarboxylic acid (Hpca), resulting from metal-assisted organonitrile hydrolysis. The acid undergoes slow rearrangement to a bidentate mode in $[Mo(CN)_3O(pca)]^{2-}$ (**3**), which is confirmed by means of UV–Vis spectroscopy. The nitrile hydrolysis, favored by the basic conditions, has been ascertained by elemental analyses as well as IR, ^1H and ^{13}C NMR spectroscopy. The use of Hpca instead of pcn in the synthetic procedure results in the direct formation of $[Mo(CN)_3O(pca)]^{2-}$ (**3**) with the bidentate 2-pyrazinecarboxylate. The coordination versatility of 2-pyrazinecarboxylate toward cyanooxomolybdenum(IV) complexes is demonstrated by the IR and UV–Vis spectroscopy of solids with $[Mo(CN)_4O(Hpca)]^{2-}$ and $[Mo(CN)_3O(pca)]^{2-}$ ions, and the definitive evidence for the structure of $[Mo(CN)_3O(pca)]^{2-}$ is provided by single-crystal X-ray crystallography. The chemical formulations of all the complexes, isolable as $[PPh_4]^+$ salts, have been verified with microanalyses, spectroscopic measurements and X-ray crystal structures of **1** and **3**.

1. Introduction

Mixed-ligand cyanooxocomplexes of molybdenum(IV) and tungsten(IV) are of considerable interest in coordination chemistry in part because of their biological relevance as well as interesting properties and reactivity. Such complexes are also of structural interest, given the versatility of the incorporated hetero-donor ligands in terms of coordination numbers, ligand denticity and structural isomerism.

Tetracyanooxometallates in aqueous solution are labile for substitution which makes them attractive starting materials and allows for the introduction of various other monodentate or polydentate ligands such as, for instance, biologically relevant Schiff bases [1–6]. Recently, it has been shown that some products of these reactions, $[M^{IV}(CN)_4O(L)]^{n-}$ ions (M = Mo, W; L = monodentate ligand), are reactive toward small molecules such as O_2 and NO [7–12]. The binding of molecular oxygen by transition metal complexes is of tremendous importance in that the products act as reagents, catalysts or key intermediates in selective oxidation reactions. Moreover, complexes that bind atmospheric oxygen at the metal centre can be treated as models for oxygen transport systems in living organisms [13,14]. The interest in nitrosyl metal complexes, on the other hand, results to a large degree from the revealed role for nitric oxide as a key physiological regulator [15,16].

In this work, we report on the synthesis and physicochemical properties of $[Mo(CN)_4O(Hpca)]^{2-}$ (Hpca = 2-pyrazinecarboxylic acid), $[Mo(CN)_4O(pcn)]^{2-}$ (pcn = 2-pyrazinecarbonitrile) and $[Mo(CN)_3O(pca)]^{2-}$complexes, as well as the crystal structures of the latter two ions. The complexes were obtained in the pursuit of relevant molybdenum precursors for small molecule activation and the 2-pyrazinecarbonitrile ligand seemed interesting for us also in terms of the versatile reactivity of the coordinated nitriles [17–20]. In the case of the tetracyanocomplexes, the synthetic route involves the reaction of 2-pyrazinecarbonitrile with the $[Mo(CN)_4O(H_2O)]^{2-}$ and $[Mo(CN)_4O(OH)]^{3-}$ ions that remain in a pH-dependent equilibrium. Interestingly, two different products are isolated as $[PPh_4]^+$ salts, depending on the synthetic conditions. The differences between these products are elucidated spectroscopically and crystallographically. The complexes are compared in particular with a tricyanooxo complex, $[Mo(CN)_3O(pca)]^{2-}$, obtained directly from Hpca and the tetracyanooxomolybdate(IV) starting material. Such a coordination versatility of 2-pyrazinecarboxylate has not been observed for any organic ligands in the mixed-ligand cyanooxo complexes of molybdenum(IV) reported to date.

2. Experimental

2.1. Materials and methods

Potassium sodium tetracyanooxomolybdate(IV) hexahydrate, $K_3Na[Mo(CN)_4O_2]\cdot 6H_2O$, was synthesized according to a literature method [21]. All other chemicals were of analytical grade (Aldrich) and were used as supplied. Carbon, hydrogen and nitrogen were determined using an Euro EA 3000 elemental analyzer. Solid samples for IR spectroscopy were compressed as KBr pellets and the IR spectra were recorded on a Bruker EQUINOX 55 FT-IR spectrophotometer. Electronic absorption spectra were measured with a Shimadzu UV-2101PC scanning spectrophotometer. Diffuse reflectance spectra were measured in $BaSO_4$ pellets with $BaSO_4$ as a reference using a Shimadzu 2101 PC equipped with an ISR-260 attachment. The magnetic susceptibility measurements were carried out by the Gouy method on an analytical balance, Radwag WPA120, at room temperature with $VOSO_4\cdot 5H_2O$ as a standard. ^1H and ^{13}C NMR spectra were recorded on a Bruker AVANCE II 300 MHz instrument; the spectra were measured in CD_3OD or CD_3CN at 293 K.

2.2. Synthesis of $[PPh_4]_2[Mo(CN)_4O(pcn)]\cdot 2H_2O$ (**1**)

$K_3Na[Mo(CN)_4O_2]\cdot 6H_2O$ (0.20 g, 0.42 mmol) was dissolved in water (10 ml). To the stirring solution (pH ≈ 11) hydrochloric acid (3.0 M) was added dropwise until a pH value of 8.5 was reached, followed by addition of 2-pyrazinecarbonitrile (0.100 ml, 1.12 mmol) in ethanol (3 ml). The resultant purple solution was treated with an aqueous solution (3 ml) of $[PPh_4]Cl$ (0.32 g, 0.85 mmol). Green crystals of **1** (yield: 0.24 g, 55%), which deposited within a few hours, were filtered off, washed with water and dried in air at room temperature. *Anal.* Calc. for $C_{57}H_{47}MoN_7O_3P_2$: C, 66.09; H, 4.57; N, 9.46. Found: C, 66.07; H, 4.27; N, 9.29%. IR (KBr, cm^{-1}): ν_{MoO} 979s, ν_{CN} 2091s. ^1H NMR (300 MHz, CD_3OD, 293 K): δ (ppm) 8.89 (d, 1H of pcn, J = 3 Hz), 8.47 (d, 1H of pcn, J = 2 Hz), 8.41 (m, 1H of pcn), 7.74–8.01 (40H of $[PPh_4]^+$). ^{13}C NMR (300 MHz, CD_3OD, 293 K): δ (ppm) 117.45, 118.64, 130.19, 130.37, 134.44, 134.58, 135.29, 135.32 (C of $[PPh_4]^+$), 138.72, 142.20, 142.67, 152.02, 158.10 (C of pcn, CN^-). UV–Vis (solid state) λ, nm: 645, 488, 376, 318, 274, 232, 210. Visible [EtOH solution: λ, nm (ε, $dm^3\ mol^{-1}\ cm^{-1}$)]: 625 (120), 487 (270), 404 (200).

2.3. Synthesis of $[PPh_4]_2[Mo(CN)_4O(Hpca)]\cdot 2H_2O$ (**2**)

$K_3Na[Mo(CN)_4O_2]\cdot 6H_2O$ (0.30 g, 0.62 mmol) was dissolved in water (12 ml). To the stirring solution 2-pyrazinecarbonitrile (0.100 ml, 1.12 mmol) was added followed by ethanol (2 ml). The resultant solution at pH ≈ 11 was stirred for *ca.* 15 min and then treated with $[PPh_4]Cl$ (0.48 g, 1.3 mmol) and hydrochloric acid (3.0 M) which was added dropwise until a pH value of 8.5 was reached. Purple crystals of **2** (yield: 0.40 g, 69%), which deposited within a few hours, were filtered off, washed with water and dried in air at room temperature. *Anal.* Calc. for $C_{57}H_{48}MoN_6O_5P_2$: C, 64.90; H, 4.59; N, 7.97. Found: C, 65.22; H, 4.75; N, 8.39%. IR (KBr, cm^{-1}): ν_{MoO} 973m, ν_{CN} 2091s, ν_{CO} 1670s, 1692s. ^1H NMR (300 MHz, CD_3OD, 293 K): δ (ppm) 9.26 (d, 1H of Hpca, J = 2 Hz), 8.81 (d, 1H of Hpca, J = 3 Hz), 8.72 (m, 1H of Hpca), 7.74–8.01 (40H of $[PPh_4]^+$). ^{13}C NMR (300 MHz, CD_3OD, 293 K): δ (ppm) 117.46, 118.65, 130.18, 130.34, 134.44, 134.58, 135.28, 135.32 (C of $[PPh_4]^+$), 143.45, 143.51, 147.18 (C of Hpca, CN^-). UV–Vis (solid state) λ, nm: 590sh, 540, 386, 325, 274, 232, 211. Hydrogen atoms labelling scheme for **2** is the same as that for **1**.

2.4. Synthesis of $[PPh_4]_2[Mo(CN)_3O(pca)]\cdot 3H_2O$ (**3**)

$K_3Na[Mo(CN)_4O_2]\cdot 6H_2O$ (1.86 g, 3.87 mmol) was dissolved in water (30 ml). To the stirring solution 2-pyrazinecarboxylic acid (0.48 g, 3.87 mmol) was added followed by ethanol (8 ml). The resultant solution was treated with $[PPh_4]Cl$ (2.90 g, 7.74 mmol) and hydrochloric acid (3.0 M) was added dropwise until a pH value of 8.5 was reached. Purple crystals of **3** (yield: 1.50 g, 38%), which deposited within one day, were filtered off, washed with water and dried in air at room temperature. The product is also obtainable from $[Mo(CN)_4O(Hpca)]^{2-}$ as a result of slow rearrangement of the Hpca ligand to a bidentate mode, what have been observed by means of UV–Vis spectroscopy. *Anal.* Calc. for $C_{56}H_{49}MoN_5O_6P_2$: C, 64.31; H, 4.72; N, 6.70. Found: C, 64.56; H, 4.52; N, 6.48%. IR (KBr, cm^{-1}): ν_{MoO} 953s, ν_{CN} 2104s, ν_{CO} 1641s. ^1H NMR (300 MHz, CD_3CN, 293 K): δ (ppm) 9.10 (d, 1H of pca^-, J = 3 Hz), 8.62 (s, 1H of pca^-), 8.22 (d, 1H of pca^-, J = 3 Hz), 7.60–7.91 (40H of $[PPh_4]^+$). ^{13}C NMR (300 MHz, CD_3CN, 293 K): δ (ppm) 117.93, 117.98, 130.91, 131.07, 135.27, 135.41, 136.02, 136.07 (C of $[PPh_4]^+$), 140.63, 144.34, 144.68 (C of pca, CN^-). UV–Vis (solid state) λ, nm: 590sh, 541, 410sh, 318, 274, 231, 212. Visible [EtOH solution: λ, nm (ε, $dm^3\ mol^{-1}\ cm^{-1}$)]: 585sh, 516 (9300).

2.5. Crystallographic data collection and structure refinement

The crystals of **1** and **3** suitable for X-ray analysis were selected from the materials prepared as described in Section 2. Intensity data were collected on a Nonius Kappa CCD diffractometer using graphite monochromated Mo Kα radiation, λ = 0.7107 Å. The crystal data and details of data collection and structure refinement parameters are summarized in Table 1. The positions of most atoms were determined by direct methods, other non-hydrogen atoms were located in difference Fourier maps. The hydrogen atoms of water molecules O2 and O3 in **1** and O21 in **3** were located in difference Fourier maps and were refined with restraints on bond lengths and angles. The water molecules O22 and O24 and disordered water O23A and O23B in **3** were refined with an occupancy factor equal to 0.5. No hydrogen atoms of these water molecules could be reliably located and refined. The hydrogen atoms of aromatic rings (phenyl rings and 2-pyrazinecarbonitrile) were refined in idealized positions using a riding model with isotropic displacement parameters. The structures were solved using SIR92 [22] and refined by the SHELXL program [23].

3. Results and discussion

3.1. General remarks for the syntheses

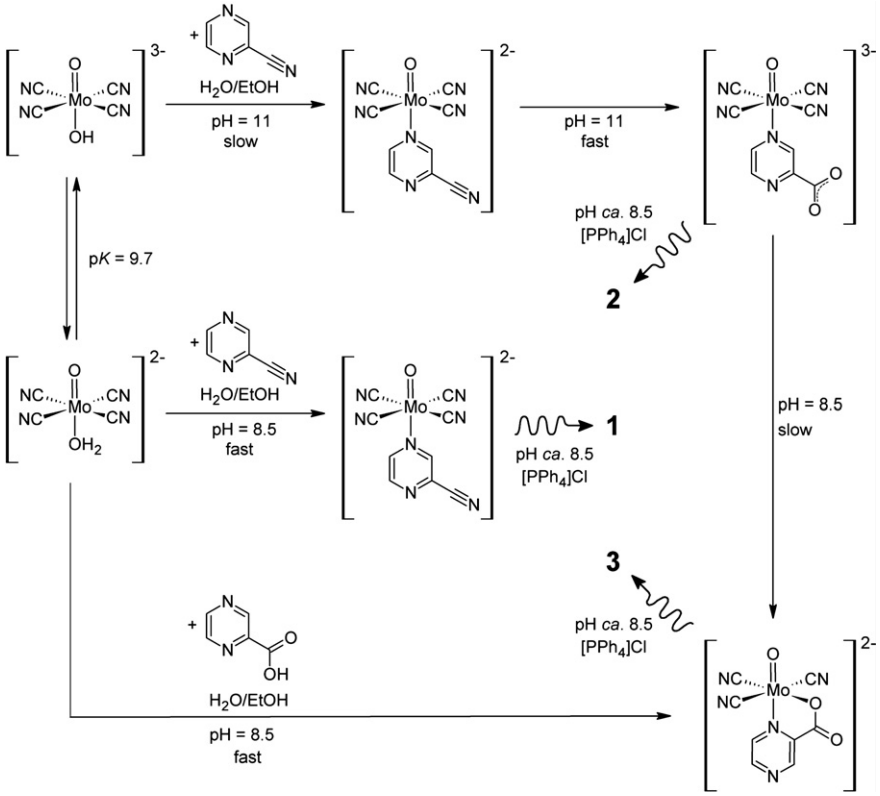
It was found earlier that there are two complexes susceptible to ligand substitution in aqueous solutions of $K_3Na[Mo(CN)_4O_2] \cdot 6H_2O$. One of them is the $[Mo(CN)_4O(OH)]^{3-}$ ion, prevailing in alkaline media (pH > 9.7), whose OH^- ligand can be slowly replaced by cyanide or a monodentate organic ligand L forming $[Mo(CN)_4OL]^{n-}$ complexes [24]. Under less alkaline conditions (pH < 9.7) the $[Mo(CN)_4O(H_2O)]^{2-}$ ion predominates and substitution reactions become considerably faster. Similarly as for the hydroxo complex, the reaction of the aqua complex with monodentate ligands L leads to $[Mo(CN)_4OL]^{n-}$ complexes, whereas the introduction of bidentate ligands, not observed for the hydroxo complex, results in the formation of $[Mo(CN)_3O(LL)]^{n-}$ ions.

Since our first synthetic goal in this work was to introduce 2-pyrazinecarbonitrile (pcn) to the coordination sphere of cyanooxomolybdates(IV), we decided to decrease the initial pH of the solution with the tetracyanooxomolybdate(IV) substrate from *ca.* 11 to 8.5, taking into account both faster substitution reactions for labile $[Mo(CN)_4O(H_2O)]^{2-}$ ions as well as the fact that free nitriles are known to undergo hydrolysis to carboxylates in alkaline and acidic media. The addition of pcn followed by $[PPh_4]^+$ cations under these conditions has resulted in the isolation of compound **1** with a preserved pendant nitrile group in the pcn ligand. On the other hand, when the 2-pyrazinecarbonitrile ligand was introduced to a tetracyanooxomolybdate(IV) solution already at pH = 11, with the resulting mixture being left for some time at this pH, salt **2** containing a monodentate carboxylate ligand was isolated from the solution after $[PPh_4]^+$ addition combined with a pH decrease. This observation confirms that the nitrile has undergone hydrolysis. The main question arises whether it is a free nitrile that hydrolyses at pH = 11 and then is coordinated to a metal centre, or it is a process involving a nitrile already bound to a Mo centre. In order to answer that question we carried out additional experiments with 2-pyrazinecarboxylic acid (Hpca). We have observed that the reaction of the $[Mo(CN)_4O(H_2O)]^{2-}$ ion with 2-pyrazinecarboxylic acid (pH = 8.5) results in the exclusive formation of the $[Mo(CN)_3O(pca)]^{2-}$ ion, isolated as compound **3**. In more alkaline solutions (pH = 11) this reaction did not proceed. One could therefore expect that the hydrolysis of the free nitrile should result in a free carboxylate and as a consequence should lead to compound **3**. Thus, the formation of product **2** could not have been accounted for, as observed in alkaline tetracyanooxomolybdate(IV) solutions. This suggests that the process of 2-pyrazinecarbonitrile hydrolysis follows binding of the nitrile to a molybdenum centre and is metal-assisted. This explanation is additionally supported by the fact that hydrolysis of free nitriles is generally slow [13,19] whereas the formation of **2** in high yield is relatively fast.

The obtained product **2** with coordinated 2-pyrazinecarboxylic acid indicates that the hydrolysis reaction is a two-stage process, which involves two consecutive attacks of hydroxide/water nucleophiles. The initial one produces 2-pyrazinehydroxyimine that may tautomerize to 2-pyrazinecarboxamide, which in turn generates 2-pyrazinecarboxylic acid upon further hydrolysis. Interestingly, the resulting acid undergoes slow rearrangement to a bidentate mode, which has been observed by means of UV–Vis spectroscopy. The reactions involved in the syntheses of **1**, **2** and **3** are summarized in Scheme 1.

3.2. Crystal structures

The crystal structure of **1** contains the $[Mo(CN)_4O(pcn)]^{2-}$ anion, two $[PPh_4]^+$ cations and two water molecules in the asymmetric part of the unit cell (Fig. 1). The packing of molecules in **1** is similar to that found in the crystal structure of $[PPh_4]_2[M(CN)_4O(pz)] \cdot 3H_2O$ [11]. The tetraphenylphosphonium



Scheme 1. Synthetic routes to Mo(IV) complexes with 2-pyrazinecarbonitrile and 2-pyrazinecarboxylate.

cations form infinite chains in the [100] direction, stabilized by alternating face-to-face and face-to-edge π stacking. Chains of $[PPh_4]^+$ cations, related by a translation along the *c* axis, separate layers of anions parallel to the *ac* plane. Water molecules O2 and O3 are located between the tetraphenylphosphonium chains and form a four-membered ring around the centre of symmetry. These water molecules make a network of hydrogen bonds that through bonds to cyano ligands connect pairs of tetracyanides from two separate layers. The observed hydrogen bond distances for **1** are: N1–O2 2.973 Å, N2–O3 2.904 Å, O2–O3 2.866 Å, O2–O3′ 2.808 Å. The cyano ligands are also involved in weak interactions to aromatic C–H groups. The $[Mo(CN)_4O(pcn)]^{2-}$ anions in **1**, related by a centre of symmetry, make pairs connected by weak hydrogen bonds, C6–H6···N3. The anion is also an acceptor in a weak hydrogen bond, C76–H76···N4, to the phenyl ring of a tetraphenylphosphonium cation.

The asymmetric unit cell in the crystal structure of **3** contains the $[Mo(CN)_3O(pca)]^{2-}$ anion, two $[PPh_4]^+$ cations and water molecules (Fig. 1). Only is water O21 well ordered with full occupancy, the other water molecules have occupancy factors equal to 0.5 and occupy four alternative positions. Similarly, as in the structure of **1**, the tetraphenylphosphonium cations form infinite chains in the [010] direction stabilized by alternating face-to-face and face-to-edge π stacking. Chains of $[PPh_4]^+$ cations related by a translation along the *c* axis separate layers of $[Mo(CN)_4O(pca)]^{2-}$ anions parallel to the *bc* plane. Water molecules O21, O22, O23 and O24 are located between tetraphenylphosphonium chains and make strong hydrogen bonds with one of the cyano ligands (C3–N3) and non-coordinated carboxylate oxygen O12. The observed hydrogen bond distances for **3** are: N3–O21 2.841 Å, O11–O24 2.772 Å, O12–O22 2.745 Å.

The structures of complex anions in **1** and **3** are presented in Figs. 2 and 3, and selected bond lengths and angles are listed in Table 2. The complex ions $[Mo(CN)_4O(pcn)]^{2-}$ and $[Mo(CN)_4O(Hpca)]^{2-}$ exhibit distorted octahedral geometries with four equatorial cyano ligands as well as oxo and cyanopyrazine ligands that occupy axial positions. The cyano ligands are displaced from the equatorial plane toward the nitrile ligand and the average O1–Mo–C angle is 100.68° for **1**. The average Mo–C and C–N bond distances in **1** were found to be 2.154 and 1.150 Å. In the case of salt **3**, the 2-pyrazinecarboxylate ligand coordinates in a bidentate mode to the molybdenum(IV) centre to afford a distorted octahedral geometry with a *trans*(*O*,*O*)-$[MoO_2C_3N]$ core (Fig. 3). The cyano ligands in **3** are more displaced from the equatorial plane away from the oxo ligand than in **1** and the average O1–Mo–C angle is 101.85°, whereas the N atom, occupying the fourth equatorial site, lies on the plane (the O1–Mo–N4 angle is 89.91°). The O11 atom is located *trans* to the Mo-oxo group. This indicates that O11 is coordinated first during the complex formation (replacing a labile aqua ligand) and this step is followed by the replacement of the cyano ligand by the N4 nitrogen atom. The average Mo–C and C–N bond distances were found to be the same as in tetracyano complexes and their averages are 2.159 and 1.156 Å, respectively. All observed distances within the anion are very similar to those found in other complexes of this type, $[Mo(CN)_3O(pic)]^{2-}$ [24] and $[Mo(CN)_3O(ensal)]^{2-}$ [3] (where Hpic = picolinic acid and Hensal = *N*-salicylideneethylenediamine).

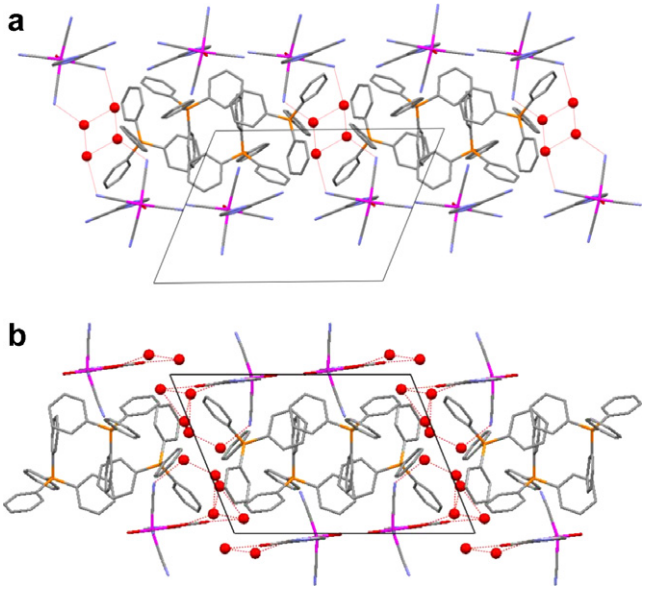


Fig. 1. Partial view of the structure of (a) $[PPh_4]_2[Mo(CN)_4O(pcn)] \cdot 2H_2O$ (**1**) along the *a* direction and (b) $[PPh_4]_2[Mo(CN)_3O(pca)] \cdot 3H_2O$ (**3**) along the *b* direction. H atoms are omitted for clarity. Hydrogen bonds with oxygen atoms as proton acceptors are represented by dotted lines.

3.3. Spectroscopic properties

The IR spectra of compounds **1**, **2** and **3** exhibit the same absorption bands characteristic for $[PPh_4]^+$ cations as well as those assignable to the vibrations within the complex ions. These spectra within the 800–2200 cm^{-1} range are presented in Fig. 4. The absorption of ν(Mo–O) in **1** (979 cm^{-1}) is slightly higher in energy than that observed in **2** (973 cm^{-1}) and it is the highest of all ν(Mo–O) values reported to date for analogous $[Mo(CN)_4O(L)]^{n-}$ complexes with monodentate ligands L having a nitrogen atom in the *trans* position to the Mo–O bond (Table 3).

These high ν(Mo–O) absorptions in **1** and **2** suggest weak bonding of 2-pyrazinecarbonitrile and 2-pyrazinecarboxylic acid and are consistent with short Mo–O1 and long Mo–N8 bond distances, as determined in the X-ray crystal structures of **1** (Table 2). The position of ν(Mo–O) in **3** is 953 cm^{-1} which is in agreement with values reported for analogous tricyanooxo complexes with κ^2-*N*,*O* ligands [24,30,31]. In the C–N stretching region one strong band is observed for each salt, at 2091 cm^{-1} (**1**, **2**) and at 2104 cm^{-1} (**3**) (Fig. 4). In compound **1** this band is broader and it can be assigned to the stretching vibrations of four cyano ligands and the nitrile substituent in the aromatic ring. It is consistent with their similar C–N bond lengths (1.170 Å for the nitrile and 1.15 Å on average for the four cyano ligands). The observed energy of the stretching vibration of the nitrile substituent in **1** is lower than that of free 2-cyanopyrazine (2241 cm^{-1}), which indicates a weakening of the nitrile bond upon coordination [32]. The carbonyl groups in **2** and **3** are conspicuous by their characteristic absorptions at 1670, 1692 (**2**) and 1641 cm^{-1} (**3**) (Fig. 4).

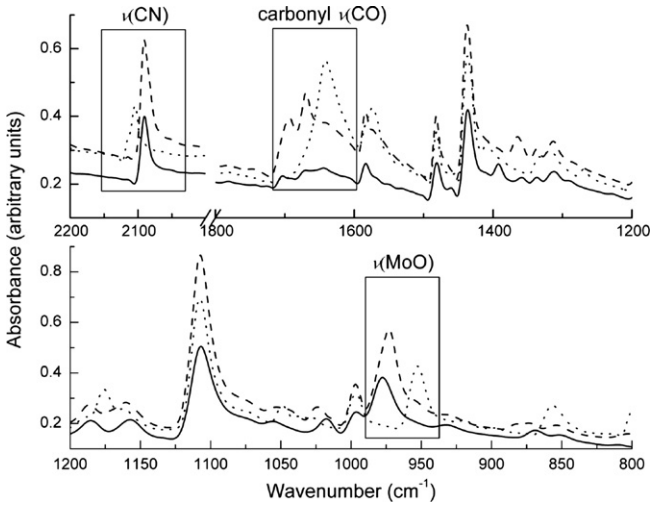

Fig. 4. The IR spectra of **1**(solid line), **2** (dashed line) and **3** (dotted line) in the 800–2200 cm^{-1} region.

[viii] This work.

Magnetic susceptibility measurements carried out by Gouy method at room temperature for salts **1**, **2** and **3** confirm that all the solids are diamagnetic.

The ^1H NMR spectra for solutions of **1** and **2** exhibit signals for the protons of the organic ligands and aromatic rings of the $[PPh_4]^+$ cations. The position of the phenyl resonances in the 7.74–8.01 ppm range is the same for both complexes. The considerable

difference between the complexes is observed for the signals of the substitued pyrazine ligands. The resonances of 2-pyrazinecarbonitrile protons in **1** are observed at 8.41, 8.47 and 8.89 ppm which are in agreement with various pyrazine nitrile derivatives [32,33]. The presence of the COOH substituent in the pyrazine ligand of **2** is manifested by the downfield shifts of positions of the heteroaromatic protons (8.72, 8.81 and 9.26 ppm) compared to **1**. These protons are less shielded in **2** as the electron density is more shifted towards the electron-withdrawing carboxylic group.

The reflectance and solution UV–Vis spectra of **1** and **2** contain bands for the tetraphenylphosphonium cations and the organic ligand (2-pyrazinecarbonitrile or 2-pyrazinecarboxylic acid) within the UV region (<350 nm) as well as bands of lower energy ascribed to d–d transitions. The visible part of these spectra closely resembles those of other $[Mo(CN)_4O(L)]^{n-}$ ions [9,11,30]. The intensities of all these bands are relatively low ($\varepsilon < 300\ dm^3\ mol^{-1}\ cm^{-1}$). However, in the case of **2** it is difficult to determine the molar absorptivities of the d–d bands in solution since the weakly bonded monodentate Hpca is slowly released and rebound in a bidentate mode as pca^-, forming complex **3**. Thus, minute impurities of **3** with very intense bands always affect the spectrum of **2**.

As is usually the case with molybdenum(IV) tricyanoxo complexes with organic ligands, the electronic spectrum of **3** is dominated by a high-intensity absorption attributable to a metal-to-ligand charge transfer (MLCT) transition between the molybdenum and carboxylate ligand [5,24,30]. Additionally, a band corresponding to a d–d transition, obscured by the intense MLCT transition, is observed as a shoulder (Fig. 5). The MLCT band is strongly solvatochromic whereas the position of the lower-energy d–d absorption only slightly depends on the solvent used for measurement, as a result of borrowing intensity from the adjacent MLCT band. The band positions with their corresponding intensities of **3** in various solvents are presented in Table 4. The shifts in the MLCT band energies (E_{abs}) correlate well with the Gutmann "acceptor number" (AN) of the solvent (Fig. 6) [34]. The explanation of the acceptor number dependence can be based on interactions between the coordinated organic ligand and solvent molecules. The greater the hydrophobic nature of solvent used, the stronger its interaction with the carboxylate, which results in the ligand's stabilization and lowering of its energy levels. Among all the solvents used the stabilization of the ligand is the highest for acetone and the lowest for water, which is in agreement with the observed E_{abs}(MLCT) values in these solvents.

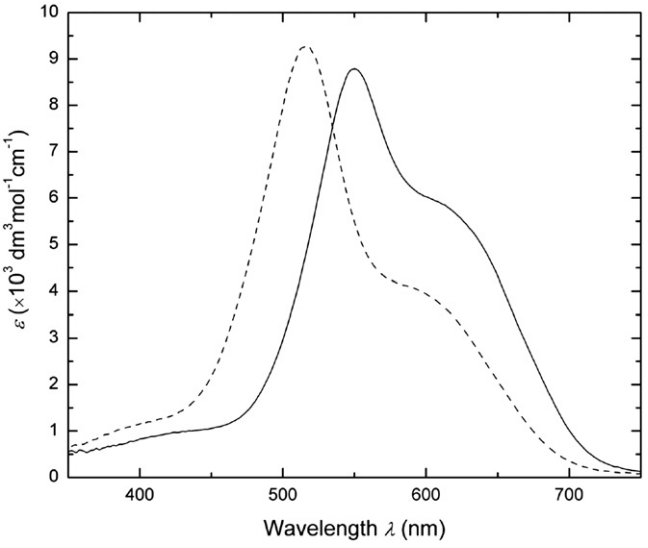

Fig. 5. Electronic spectrum of **3** in acetone (solid line) and EtOH (dashed line).

Table 4
Band positions and intensities of **3** in various solvents

Solvent	Acceptor number (AN)	λ, nm (ε, $\times 10^3\ dm^3\ mol^{-1}\ cm^{-1}$)

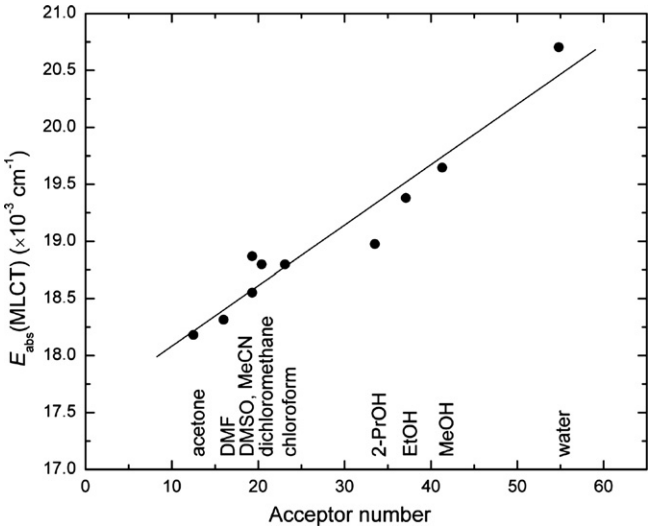

Fig. 6. Shifts in E_{abs}(MLCT) of **3** with acceptor number (AN). The correlation is $E_{abs}(\text{MLCT}, \times 10^{-3}\ cm^{-1}) = (0.053 \pm 0.0051)\text{AN} + (17.55 \pm 0.16) \times 10^{-3}$ with $R^2 = 0.97$.

4. Conclusion

This report has focused attention on the pH-dependent behavior of the molybdate(IV) system $[Mo(CN)_4O(OH)]^{3-}/[Mo(CN)_4O(H_2O)]^{2-}$ in the presence of 2-pyrazinecarbonitrile. Crystallographic and spectroscopic data have revealed that two complexes, $[Mo(CN)_4O(pcn)]^{2-}$ and $[Mo(CN)_4O(Hpca)]^{2-}$, are obtainable in this system; the former via a pure substitutional synthetic route and the latter as a result of metal-assisted nitrile hydrolysis. Interestingly, the resulting acid (Hpca) undergoes slow rearrangement to a bidentate mode yielding $[Mo(CN)_3O(pca)]^{2-}$. The coordination versatility of the 2-pyrazinecarboxylate ion has been demonstrated in the isolated $[Mo(CN)_3O(pca\text{-}\kappa^2\text{-}N,O)]^{2-}$ and $[Mo(CN)_4O(Hpca)]^{2-}$ products.

Appendix A. Supplementary data

CCDC 675046 and 675047 contain the supplementary crystallographic data for **1** and **3**. These data can be obtained free of charge

ABSTRACT

$Cu(OTf)_2(2\text{-mepyz})_2(H_2O)_2$ (2-mepyz = 2-methylpyrazine; $OTf^- = CF_3SO_3^-$ = triflate), **1**, and $Cu(OTf)_2(H_2O)_2(pyz)$ (pyz = pyrazine), **2**, consist of monomeric and polymeric structures, respectively. Both compounds contain octahedral Cu(II) metal centers surrounded by *trans*-coordinated OTf^-, H_2O, and diazines, either 2-mepyz in the case of **1** or pyz in **2**. In **1**, O–H···O(triflate) hydrogen bonds link CuO_4N_2 monomers into quasi-1D chains which are joined via O–H···N interactions to afford a three-dimensional (3D) network. Pyz ligands in **2** link CuO_4N_2 octahedra into linear chains similar to $Cu(NO_3)_2(pyz)$. Magnetically, neither **1** or **2** show indications for long-range magnetic ordering (LRO) above 2 K. Least-squares fits of the magnetic susceptibility data, $\chi(T)$, to a Bonner–Fisher uniform chain model gave $2J/k_B = -0.005(1)$ and $-6.0(1)$ K for compounds **1** and **2**, respectively, indicative of negligible and moderate antiferromagnetic coupling between spin-1/2 Cu(II) ions. Inter-chain magnetic interactions seem to be negligible for both systems.

1. Introduction

Low-dimensional molecule-based magnets comprised of spin-1/2 ions represent an area of intense research interest [1–8]. Spin-1/2 ions such as Cu(II) have been used extensively owing to the lack of single-ion anisotropy leading to more easily interpretable magnetic behaviors. The single spin involved is also more amenable to theoretical investigations.

From a crystal engineering perspective, there are many ways in which the paramagnetic spin-bearing units can be arranged in the solid state which ultimately depends on the choice of organic synthons. The coordinative properties of the synthons dictate the number of ligands to be used, geometrical constraints, and the number of synthons that will attach to the metal ion. Owing to its good Lewis basicity, pyrazine (pyz) is arguably one of the most successfully utilized synthons in crystal design. As hydrogen atoms in the parent pyz molecule are replaced by alkyl groups (Scheme 1), the basicity decreases due to increased steric hindrance, however, there are numerous compounds known to possess mono- or bidentate diazine derivatives that are coordinated to Cu(II) ions. Examples that possess either bridging or mono-coordinate dimethyl-substituted pyrazine ligands include $Cu(NCO)_2(2\text{-mepyz})_2$ [9], $Cu(NO_3)_2(2\text{-mepyz})$ [10], $CuBr_2(2,3\text{-me}_2\text{pyz})$ [11], $Cu_2(HCO_2)_4(2,3\text{-me}_2\text{pyz})$ [12], $CuCl_2(2,5\text{-me}_2\text{pyz})$ [13], $CuCl_2(2,5\text{-me}_2\text{pyz})(CH_3CN)$ [14], $CuCl_2(2,6\text{-me}_2\text{pyz})$ [13], and $[Cu(2,6\text{-me}_2\text{pyz})_4]SiF_6$ [15].

Structural modification can also be achieved by varying the size, molecular shape and charge of the counter-anion. Excluding halides, numerous anions (including coordinating and weakly-coordinating types) such as ClO_4^- [2,16], BF_4^- [4], NO_3^- [10], PF_6^- [16], SO_4^{2-} [17], $CH_3CO_2^-$ [18], and many others are frequently employed in the design of functional molecule-based solids. In our quest to self-assemble novel magnetic materials comprised of molecular building blocks we have combined triflate anions with pyrazine and 2-mepyz. These efforts lead to new molecular and polymeric structures, namely $Cu(OTf)_2(2\text{-mepyz})_2(H_2O)_2$ (**1**) and $Cu(OTf)_2(H_2O)_2(pyz)$ (**2**), respectively, where mono-coordinate 2-mepyz or bridging pyz ligands are involved. Our continued use of pyz and its various substituted variants is driven by our desire to understand and ultimately control the magnetic behavior of complex magnetic solids.

2. Experimental

2.1. Synthesis

Compound **1** was prepared by slow dropwise addition of 2-methylpyrazine (1.52 mmol, 0.1435 g) to a 5-mL CH_3CN solution of $Cu(OTf)_2$ (0.762 mmol, 0.2758 g) to afford a deep blue solution. Crystalline plates suitable for X-ray structure determination were obtained by slow evaporation of the solvent over a 5-week period. The material was collected by vacuum filtration and gently dried (0.3215 g, 72% yield). Compound **2** was synthesized by dissolving each reactant, $Cu(OTf)_2$ (0.781 mmol, 0.2846 g) and pyrazine (1.56 mmol, 0.1260 g), in 5 mL of a 50:50 v:v mixture containing

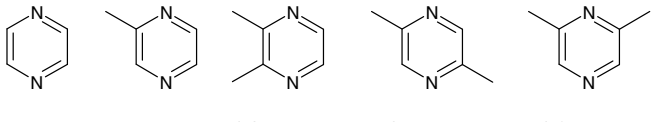

Scheme 1. Parent pyrazine molecule and its dimethyl-substituted variants.

H_2O/CH_3CN. The two solutions were gently mixed to give a dark blue solution from which large pale blue crystals of **2** were obtained upon slow evaporation of the solvent over a period of 2 months. The crystals were collected by vacuum filtration and carefully dried to produce 0.3222 g of solid in 86% yield.

2.2. X-ray crystallography

Crystals of compound **1** and **2** were removed from the flask, a suitable crystal was selected of each, attached to a glass fiber and data were collected at 297(2) K using a Bruker/Siemens SMART APEX X-ray diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å). Data were measured using omega scans of 0.3° per frame for 5 s, and a partial and full sphere of data was collected. A total of 1324 and 2400 frames were collected with a final resolution of 0.83 and 0.77 Å for **1** and **2**, respectively. Cell parameters were retrieved using SMART [19] software and refined using SAINTPLUS [20] on all observed reflections. Data reduction and correction for Lp and decay were performed using the SAINTPLUS software. Absorption corrections were applied using SADABS [21]. Structures were solved by direct methods and refined by least-squares method on F^2 using the SHELXTL [22] program package. Analysis of systematic absences led to the solution and refinement of the structures of **1** and **2** in the space groups $P2_1/n$ (#14) and $C2/c$ (#15), respectively. The triflate anion in **1** was found to be disordered in two positions (70:30%) and only the non-carbon and oxygen atoms were refined anisotropically. All non-hydrogen atoms were refined anisotropically in **2**. No decomposition was observed during data collection. Details of the data collection and refinement are given in Table 1 and selected bond lengths and angles can be found in Table 2. Further details are provided in the Supplementary data.

2.3. Magnetic properties

A Quantum Design MPMS-5XL ac/dc SQUID magnetometer equipped with an RSO transport was used to measure the temperature-dependence of the magnetization. Appropriate amounts of polycrystalline samples of **1** and **2** were loaded into pharmaceutical gelatin capsules, placed inside a plastic drinking straw and affixed to the end of a carbon fiber rod. Samples were mounted in the magnetometer at 295 K and zero-field cooled to 2 K. The magnetic field was charged to 1-kOe and data collected upon warming to room temperature. All magnetic data were corrected for core diamagnetism using Pascal's constants.

3. Results and discussion

The crystal structures of **1** and **2** were determined by conventional X-ray crystallographic techniques and both Cu(II) coordination spheres are shown in Fig. 1. Both compounds feature identical coordination environments with donor atoms of the same type positioned *trans* to one another. The Cu(II) ions in both compounds exhibit the usual Jahn-Teller (4+2) distortion with the Cu–O(triflate) bond distances the longest at 2.420(4) and 2.423(6) Å for **1** and 2.402(2) Å for **2**. The Cu(II) ion in **1** lies on an inversion center while the metal and ligand atoms N(1) and N(4) occupy the two-fold rotation axis in **2**. The CuO_4N_2 octahedron is significantly more distorted in **1** than in **2** with the bond angles O(3)–Cu(1)–O(4A) = 84.7(2)° and O(1)–Cu(1)–O(2) = 88.21(7)°, respectively, exhibiting the greatest deviation from the ideal 90° angle. All observed geometric parameters found for the 2-mepyz and parent pyz ligands in **1** and **2** are in agreement with previously reported structures [2,4,9–15].

The methyl substituents in **1** are distal to the Cu–N coordinate bond which prevents ligation of the second nitrogen atom, thus limiting the lattice dimensionality to molecular. Each molecule is linked to nearest-neighbors through O(1A)···H(3A)–O(3) hydrogen

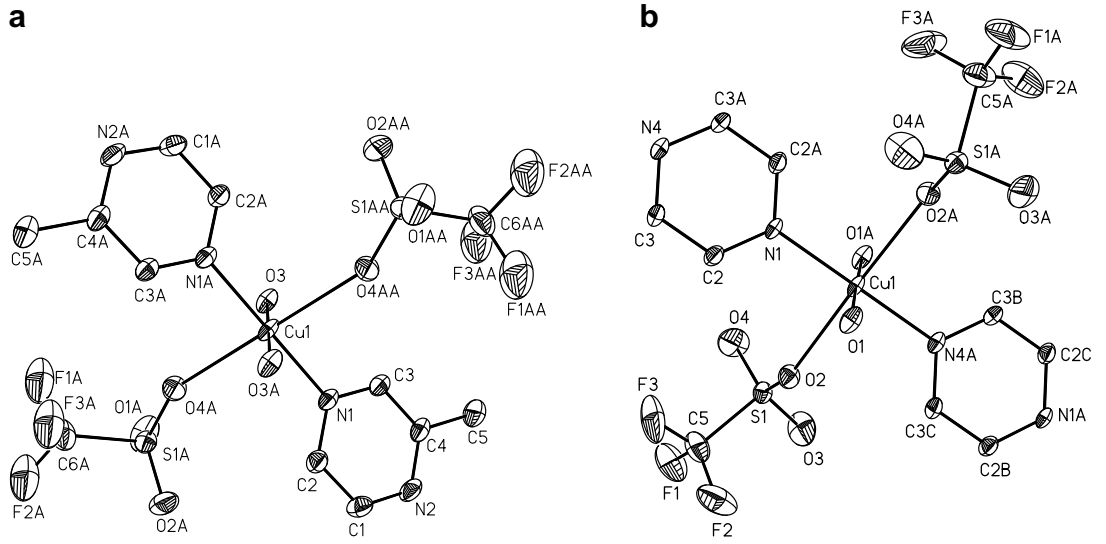

Fig. 1. Thermal displacement diagrams (30%) and atom labeling schemes for (a) $Cu(OTf)_2(2\text{-mepyz})_2(H_2O)_2$ (**1**) and $Cu(OTf)_2(H_2O)_2(pyz)$ (**2**). Only the highest occupied triflate molecule (70%) is shown in (a). Hydrogen atoms have been omitted for clarity.

bonds as shown in Fig. 2a to form a chain that runs along the *b*-axis. These pseudo-chains are linked further by additional N(2)···H(3B)–O(3) hydrogen bonds to form sheets (Fig. 2b) that lie in the *bc*-plane. This particular packing motif is interesting as it produces a distorted triangular lattice where two edges are comprised of N(2)···H(3B)–O(3) hydrogen bonds with a Cu···Cu distance of ca. 8.6 Å. The remaining edge is the O(1A)···(3A)–O(3) bond and is ~1 Å shorter with a Cu···Cu distance of ca. 7.6 Å. The vertices of each triangle are occupied by Cu(II) ions.

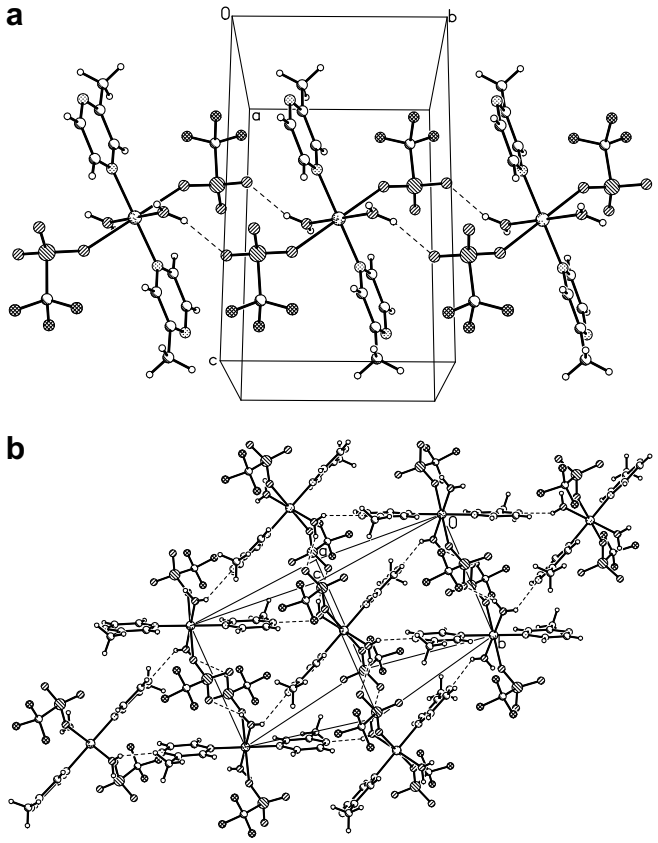

Fig. 2. (a) Portion of a hydrogen bonded chain found in **1**. Only the OTf^- anion with the highest occupancy is shown for clarity. (b) Molecular packing arrangement of **1** viewed approximately perpendicular to the (101) plane. Dashed lines indicate intermolecular hydrogen bonds.

For compound **2**, pyrazine ligands join CuO_4N_2 octahedra into a linear chain as shown in Fig. 3a, giving intrachain Cu···Cu separations of 6.8016(2) Å (*i.e.*, the length of the *b*-axis). The chains are linked via O(3)···H(1B)–O(1) and O(4)···H(1A)–O(1) hydrogen bonds to afford sheets in the *ab*-plane (Fig. 3b) which stack along the *c*-direction. All pyrazine rings are co-planar and align exactly parallel with the *c*-axis, corresponding to a O(1)–Cu(1)–N(1)–C(2) torsion angle of 62.4(1)°. From Fig. 3b it can be seen that hexagonal channels exist in **2** owing to H-bond formation between both protons of the H_2O molecule and triflate oxygen atoms with pyz ligands passing through the center.

In addition to **1** and **2**, several other Cu(II) coordination complexes also exist that contain either coordinated or non-coordinated triflate anions. For example, a search of the Cambridge Crystal Database [23] yielded one molecular complex, namely $[Cu(2,2'\text{-bipy})(H_2O)_2(OTf)_2]$ (bipy = bipyridine) [24], that has a similar CuO_4N_2 core. This complex is composed of coordinated 2,2′-bipy, two triflate anions and two H_2O ligands where the latter aqua ligands are *cis* to one another and occupy the same plane as the chelated 2,2'-bipy ligand. Other related complexes that contain Cu(II) ions and 2-mepyz ligands include $[Cu(2\text{-mepyz})_4(H_2O)X]X$ ($X = NO_3^-$ or ClO_4^-) [25,26], $[Cu(2\text{-mepyz})_4(ClO_4)_2]$[27] and $[Cu(2\text{-mepyz})_2(H_2O)_2(ClO_4)_2]$ [28].

The bulk magnetic properties of **1** and **2** were determined by conventional SQUID magnetometry and the data plotted as χ versus T are shown in Fig. 4. While data was obtained between 2 and 300 K only the region below 80 K are shown to highlight the differing magnetic behavior. Compound **1** is essentially paramagnetic and does not show a maximum in χ versus T down to 2 K suggesting the presence of very weak magnetic interactions. In order to determine the extent of interaction between Cu(II) sites the data were fitted to a Curie–Weiss law, $\chi = g^2S(S+1)/8(T-\theta)$, where g is the Landé value and θ is the Weiss constant. The resulting least-squares fit between 2 and 300 K yielded $g = 2.127(1)$ and $\theta = +0.27(7)$ K with the slightly positive θ-value indicating a very weak ferromagnetic coupling. In order to verify whether the interaction along either the N(2)···H(3B)–O(3) or O(1A)···H(3A)–O(3) pathway is plausible, we fitted the same χ versus T data to a Bon-

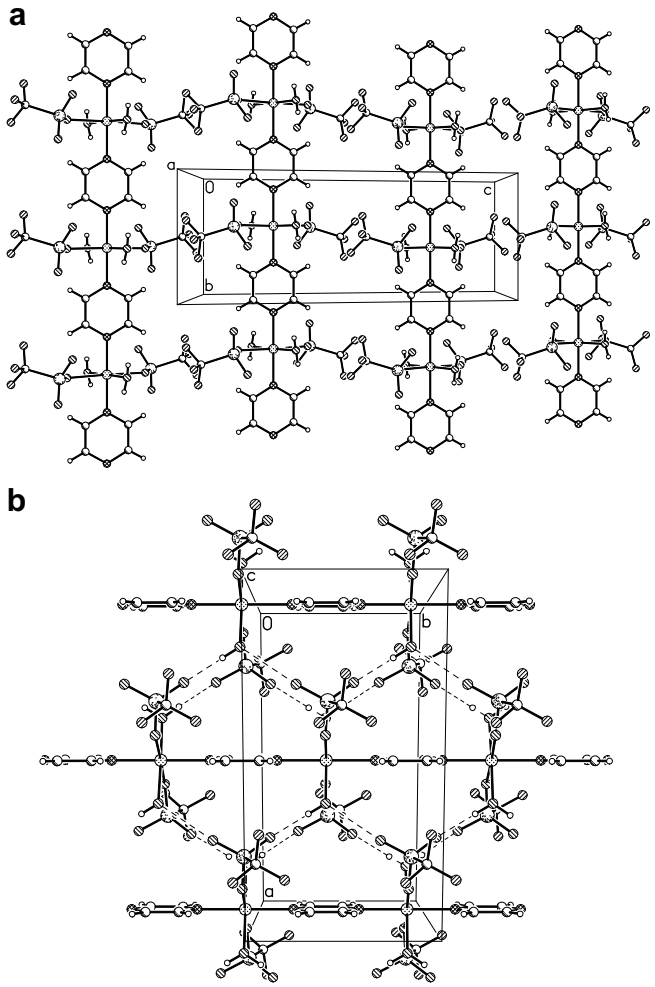

Fig. 3. (a) Crystal packing of linear chains in compound **2** viewed down the *a*-axis. (b) Packing of chains in **2** viewed parallel to the *c*-axis.

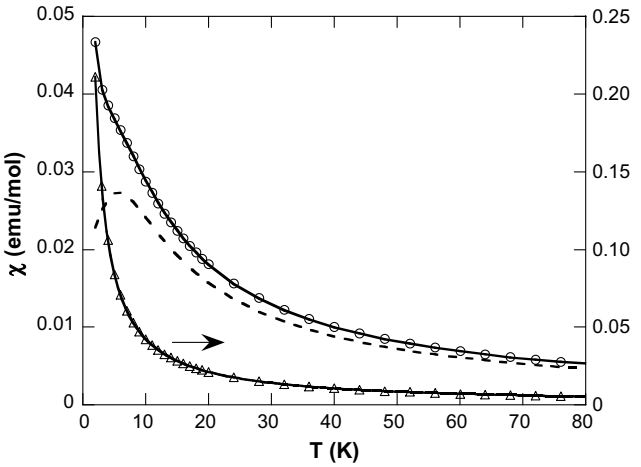

Fig. 4. Temperature-dependence of the magnetic susceptibility for **1** (△) and **2** (○) measured in a 1-kOe external field. The solid lines represent least-squares fits of the data as described in the text. The dashed line is the calculated Bonner–Fisher magnetic susceptibility for compound **2** using the same parameters as previously described however for $\rho = 0$.

ner–Fisher [24] chain model which gave good agreement for $g = 2.128(1)$ and $2J/k_B = -0.005(1)$ K. The Curie–Weiss and Bonner–Fisher results reflect ambiguity in the sign of the very weak, and possibly negligible, interaction. A plot of χT versus T is essentially invariant as the temperature changes, consistent with the apparently negligible exchange interaction.

In contrast to **1**, the temperature-dependence of χ for **2** does show indication for more significant magnetic coupling. As the data are plotted on a per mole basis, the susceptibility of **2** is reduced by a factor of ~5 owing to the presence of stronger antiferromagnetic interactions. While a maximum in χ versus T is not detectable there is clearly anomalous behavior below 10 K. From Fig. 4 it can also be seen that χ versus T rises much more slowly for **2** than it does for **1**, again suggestive of a stronger magnetic interaction. A similar fit of these data to a Curie–Weiss law ($T \geqslant 20$ K) afforded $g = 2.152(1)$ and $\theta = -2.5(1)$ K which suggests antiferromagnetic coupling between Cu(II) spins. Because the structure of **2** consists of polymeric Cu-pyz-Cu chains, we also fitted χ versus T over the entire temperature range to a Bonner–Fisher [28] chain model compensating for any possible spin-1/2 paramagnetic impurity, ρ, in the sample. This fit yielded excellent agreement for $g = 2.133(1)$, $2J/k_B = -6.0(1)$ K, temperature-independent paramagnetism (TIP) = 60×10^{-6} emu/mol and $\rho = 0.0296(1)$. Omission of ρ from the fit would lead to a broad maximum at ~5.6 K (dashed line in Fig. 4) using the same g, $2J$ and TIP values. Close inspection of χ versus T between 2 and 5 K reveals a discontinuous feature that, had an impurity not been present, would have likely displayed a broad maximum associated with short-range spin correlations. We believe the chain model to be the most appropriate because the $d_{x^2-y^2}$ magnetic orbital occupies the CuN_2O_2 (oxygen from H_2O ligands) plane; the lobe directed along the N–Cu–N axis subsequently overlaps with the $2p_z$ orbital of the pyz bridge. An additional inter-chain interaction as mediated by $H_2O\cdots OTf^-$ hydrogen bonds [Cu···Cu = 7.337 Å] does not appear plausible due to overlap between the other lobe of the $d_{x^2-y^2}$ magnetic orbital and the non-magnetic d_{z^2} orbital of next-nearest-neighbor Cu(II) sites. This claim is substantiated by the fact that inclusion of a mean-field correction term, zJ' [29], does not improve the quality of the fit.

To conclude, we have synthesized and structurally and magnetically characterized two new Cu(II) coordination compounds. Both systems contain triflate ions that participate extensively in hydrogen bond interactions. While triflate is generally considered to be a weakly-coordinating anion, it does occupy two sites of the Cu(II) coordination sphere which reduces the lattice (and spin) dimensionality in both cases. Likewise, H_2O ligands take up two additional sites. Future synthetic efforts will be to employ non-aqueous media in an effort to eliminate the possibility of H_2O coordination and subsequently increase the lattice and spin dimensionality.

ABSTRACT

The synthesis of two riboside-containing arsenic compounds, methyl-2,3-*O*-isopropylidene-5-dimethylarsinoyl-β-D-ribofuranoside and methyl-2,3-*O*-isopropylidene-5-deoxy-5-dimethyl-thioarsinoyl-β-D- ribofuranoside is presented in this paper. Intermediates and final products of the synthesis were examined by gas chromatography and thin layer chromatography. The purity of the products was assessed by NMR spectroscopy. Trimethylsilylation was used to volatilise sugar compounds and thus use of the costly HPLC–MS technique was avoided. The results affirmed the presence of tautomers in case of arsenosugars.

1. Introduction

There are an increasing number of papers dealing with arsenic containing ribosides (called arsenosugars) present in sea and freshwater organisms. In marine algae arsenic occurs predominantly as arsenosugar [1], further sources of dietary arsenosugar exposure include herbivorous marine molluscs such as oysters, mussels and clams [2]. Several arsenosugar compounds have already been identified in marine organisms [3,4] and only few studies have been published on the potential health hazard of these compounds [5]. The lack of arsenic toxicity reported in humans after consumption of large amounts of seafood and seaweed suggests that these arsenic compounds are not acutely toxic [6]. However, chronic toxicity of these arsenic compounds should be considered.

Several papers have been published on the synthetic preparation of such arsenosugar compounds [7–9]. The most convenient way to determine the identity and the purity of intermediates and final products is the use of HPLC–MS techniques. Since sugars are easily volatilised by the use of adequate derivatives, the less expensive TLC and GC techniques may replace the costly HPLC–MS technique as far as purity assessment is concerned, while NMR spectroscopy can give information on the structure of molecules.

This article describes the synthetic preparation of two arsenosugars and their characterisation by TLC, GC and NMR spectroscopy. Known methods [7,8] were used for the synthesis of arsenosugars, with some modifications compared to the referred procedures.

The preparation of different arsenosugar compounds is useful for the assessment of potential health risks of a certain kind of food and for improving our understanding of arsenic biochemistry.

2. Experimental

2.1. Chemicals and reagents

D-Ribose (98%) was purchased from Sigma–Aldrich Co. (St. Louis, MO, USA), the sephadex G-25 (50–150 μm) was supplied by Pharmacia Fine Chemicals AB (Uppsala, Sweden). Sulfuric acid (96%), potassium hydrogen carbonate, propanone (Ph. Eur.), hydrochloric acid (37%), chloroform, anhydrous sodium sulfate, ethyl acetate (EtOAc), ethanol (EtOH, 99 %), *N*,*N*-dimethylmethanamide (DMF, puriss), sodium bromide (puriss), hexane, sulfur and hydrogen peroxide (30%) were purchased from Reanal Finomvegyszergyár ZRt. (Budapest, Hungary). *N*,*O*-bis(trimethylsilyl) trifluoroacetic amide (BSTFA, >99%) was obtained from Fluka. Methanol (MeOH, HPLC

grade) was purchased from Carlo-Elba, kiesel gel 40(70–230 mesh), pyridine (Py, dried, pro anal.) and methanesulfonyl chloride (MsCl for synthesis) from Merck (Whitehouse Station, NJ, USA). Tetrahydrofuran (THF) and diethyl ether (Et_2O) were HPLC grade solvents from Romil (Cambridge, UK). Sodium dimethyl arsine (Me_2AsNa) was prepared at the Department of Inorganic Chemistry, Budapest University of Technology and Economics (Budapest, Hungary) following the procedures published by Burrows and Turner [10] and Feltham et al. [11]. Reagents were all of analytical reagent grade except those specified. The purity of argon gas used for the reactions was 99.95%. Distilled water was used except for the water extraction processes where ultra-pure water (Millipore, Guyancourt, France) was used.

2.2. Apparatus

Investigation of the synthesised compounds was carried out on a Chrompack CP-9000 gas chromatograph and kieselgel 60 F254 (aluminium sheet) TLC plates (Merck). The gas chromatographic parameters used are shown in Table 1. Mass spectrometric detection and NMR spectroscopy was used for identification and confirmation of the synthesised products. An API 3200 LC–MS–MS (Applied Biosystems, Foster City, CA, USA) system was used in the electrospray ionisation (ESI) mode applying 30 eV collision energy. A Bruker Avance 500 MHz NMR spectrometer was used for the NMR studies. Spectra were taken at ^{1}H: 500 MHz and ^{13}C: 125 MHz in deuterochloroform.

2.3. Trimethylsilylation

For the GC analyses of the sugar-derivatives a silylation method was used, as the compounds to be analysed have low volatility and are quite heat sensitive. BSTFA was applied as a silylating agent. This method results in highly volatile trimethylsilyl derivatives where active hydrogen atoms of the substrate are substituted for trimethylsilyl groups. The resulting sugar-derivatives have lower

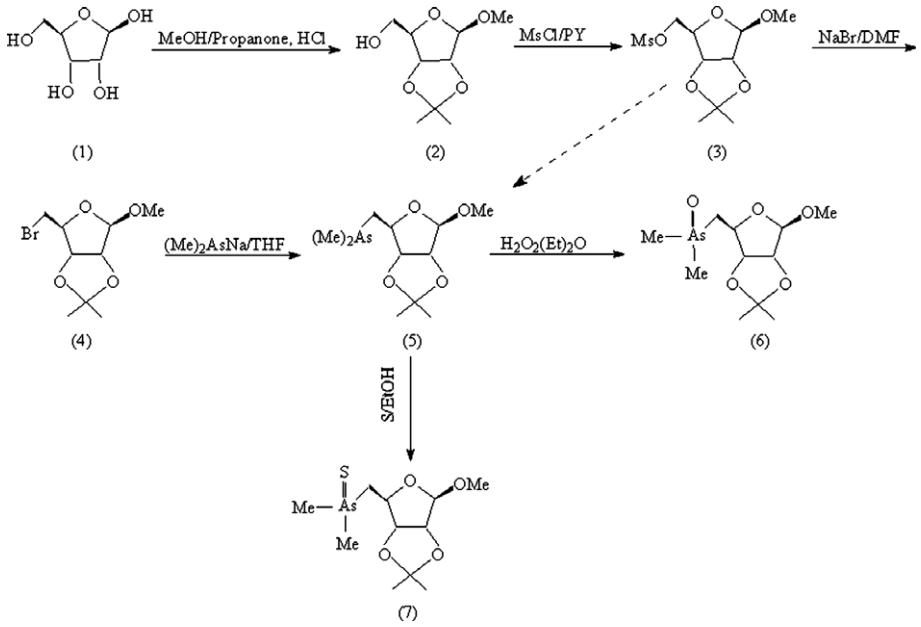

Fig. 1. Structure of ribose, intermediates and the final products formed by means of the synthesis process. (**1**) D-Ribose, (**2**) methyl-2,3-*O*-isopropylidene-β-D-ribofuranoside, (**3**) methyl 2,3-*O*-isopropylidene-5-*O*-mesyl-β-D-ribofuranoside, (**4**) methyl 2,3-*O*-isopropylidene-5-deoxy-5-bromo-β-D-ribofuranoside, (**5**) dimethyl (methyl-2,3-*O*-isopropylidene-5-deoxy-β-D-ribofuranose-5-yl) arsine, (**6**) methyl-2,3-*O*-isopropylidene-5-dimethyl-arsinoyl-β-D-ribofuranoside, (**7**) methyl-2,3-*O*-isopropylidene-5-deoxy-5-dimethyl-thioarsinoyl-β-D-ribofuranoside.

Table 2
Characterisation results of the intermediates and final products

Synthesised intermediates and products	Product weight (g)	Purity (%)	Yield (%)	$R_{f(TLC)}$	Purity according to NMR analysis
2	11	98.5 (GC)	62.2	0.64 [*EtOAc:nC$_6$1:1*]	Pure
3	2.75	99.5 (GC)	95	0.73 [*EtOAc:nC$_6$1:1*]	Pure
4	4	>95 (TLC)	90	*0.95* [*EtOAc:nC$_6$1:1*]	Pure
5	5.65	≈50 (GC)	57.4		Acceptable purity
6	1.15	>86.5 (GC)	57.5	0.34 [*EtOAc:MeOH 1:1*]	Pure
7	0.422	>*98*(GC)	80	0.85 [*EtOAc:MeOH 1:1*]	Pure

polarity and are less heat sensitive, thus this quantitative silylation method makes these derivatives suitable for GC and GC–MS studies.

3. Syntheses

3.1. Methyl 2,3-*O*-isopropylidene-β-D-ribofuranoside (*2*)

Compound **2** was obtained from D-ribose (**1**) by following Lerner's procedure [12]. D-Ribose (13 g), propanone (50 ml), MeOH (50 ml) and cc. HCl (1.4 ml) were heated under reflux for 2 h. The solution was cooled to room temperature and neutralised with saturated $KHCO_3$ (50 ml). After concentration under vacuum, water and $CHCl_3$ were added to the concentrate. The organic phase was washed with water, dried over Na_2SO_4 and evaporated. The product **2** was obtained in a yield of 11 g as a yellowish oil.

3.2. Methyl 2,3-O-isopropylidene-5-O-mesyl-β-D-ribofuranoside (*3*)

A mixture of 2 g of **2**, dry Py (70 ml) and MsCl (4.5 ml) was stirred for 2 h. The solution was poured into a mixture of icy water and H_2SO_4 then extracted with $CHCl_3$ (5 × 10 ml). The Py free extract

was washed with $KHCO_3$ solution and water. Drying of the extract and evaporation afforded 2.75 g of **3** as yellowish crystals.

3.3. Methyl 2,3-O-isopropylidene-5-deoxy-5-bromo-β-D-ribofuranoside (*4*)

A mixture containing 4.57 g of **3**, DMF (70 ml) and NaBr (1.8 g) was heated under reflux for 1.5 h. TLC was used to check the reaction endpoint. The reaction mixture was poured into icy water (300 ml). After extraction with $CHCl_3$ (4×10 ml), the organic phase was washed with water, dried over Na_2SO_4 and evaporated. Four grams of **4** was obtained as an orange oil.

3.4. Dimethyl (methyl-2,3-O-isopropylidene-5-deoxy-β-D-ribofuranose-5-yl) arsine (*5*)

A round-bottomed flask was charged with a solution of THF (120 ml) and Me_2AsNa (~5 g) under an argon atmosphere. While continuously flushing and stirring, a solution of **4** in THF (8.6 g) was added to the flask in drops (over 30 min). The reaction mixture was chilled and extracted with $CHCl_3$ (5×30 ml). The organic phase was dried over Na_2SO_4 and evaporated. The oily residue was dissolved in Et_2O (50 ml), filtered on a silica gel column and distilled. The product **5** was obtained in a yield of 5.65 g as a yellow oil.

3.5. Methyl-2,3-O-isopropylidene-5-dimethyl-arsinoyl-β-D-ribofuranoside (*6*)

1.9 g of **5** were dissolved in Et_2O (40 ml) and H_2O_2 (2.5 ml) was added to the solution dropwise under constant stirring (over 10 min, 20 °C). After 1.5 h the reaction mixture was extracted several times with ultra-pure water (50 ml and 5×10 ml). The water extracts were combined and washed with Et_2O (2×10 ml), then distilled to obtain 1.15 g of a white syrup **6**.

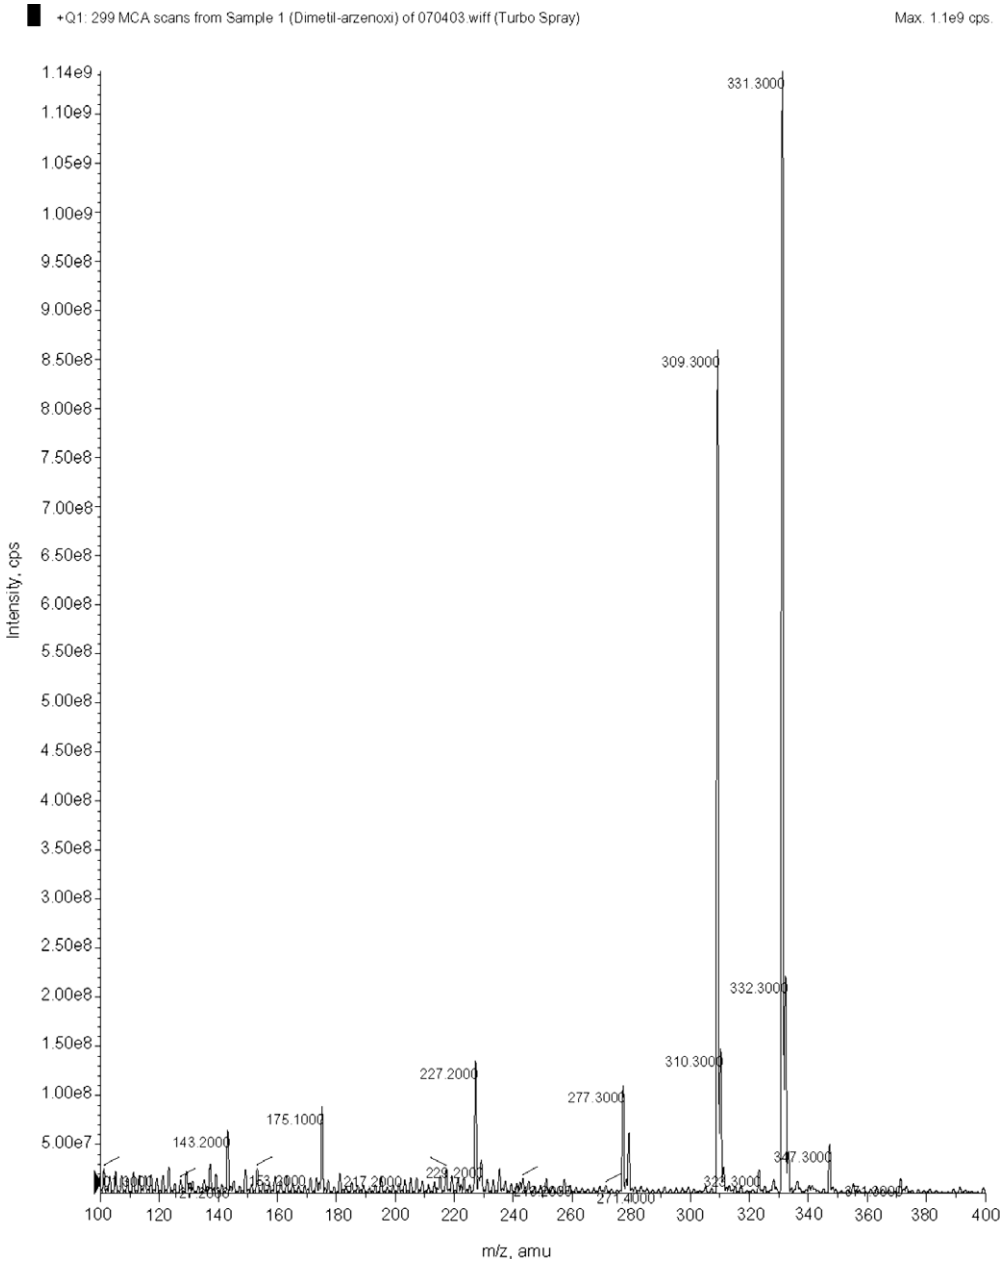

Fig. 5. ESI–MS–MS spectrum of methyl-2,3-O-isopropylidene-5-dimethyl-arsinoyl-β-D-ribofuranoside (**6**) in MeOH (+Q1mode.)

3.6. Methyl-2,3-O-isopropylidene-5-deoxy-5-dimethyl-thioarsinoyl-β-D-ribofuranoside (7)

To a solution of 1.1 g of **5** and EtOH (25 ml), finely powdered sulfur (1.4 g) was added. The mixture was refluxed and heated for 5 h under an argon atmosphere. The solution was cooled down, filtered and evaporated. The residue was dissolved in MeOH (10 ml) and filtered on a Sephadex G-25 column (4 × 10 cm). Finally, the concentrate was dissolved in hot MeOH (5 ml) and was put in a refrigerator to crystallize. The yellowish crystals that formed were separated and washed with cold MeOH and Et_2O. Drying resulted in 0.422 g of **7**.

4. Results and discussion

The known naturally occurring arsenosugars are exclusively organic arsinoyl and thioarsinoyl compounds built on the ribofuranose ring. Our primary goal was the synthesis and characterisation of such compounds using D-ribose as a starting material. First, several ribose derivatives were prepared, offering a good possibility to be followed up as intermediates of subsequent synthesis steps. Such derivates were 2,3-*O*-isopropylidene-riboside and methyl-ribofuranoside. These compounds, with a knowledge of chromatographic theory, could predict the retention behaviour of the synthesised intermediates without the use of standard solutions.

The first product was the methyl 2,3-*O*-isopropylidene-β-D-ribofuranoside (**2**), resulting from the reaction of D-ribose with MeOH and propanone (1:1) in the presence of HCl (Fig. 1). The hydroxyl group located at C5 position of **2** can easily be converted to the corresponding mesylate or tosylate. The use of methanesulfonyl chloride might be more advantageous than that of tosyl chloride, as the former yields a shorter reaction time. The resulting product is easily cleaned after pyridine and acid residues have been eliminated. The methyl 2,3-*O*-isopropylidene-5-*O*-mesil-β-D-ribofuranoside (**3**) was obtained as yellowish crystals. The synthesis

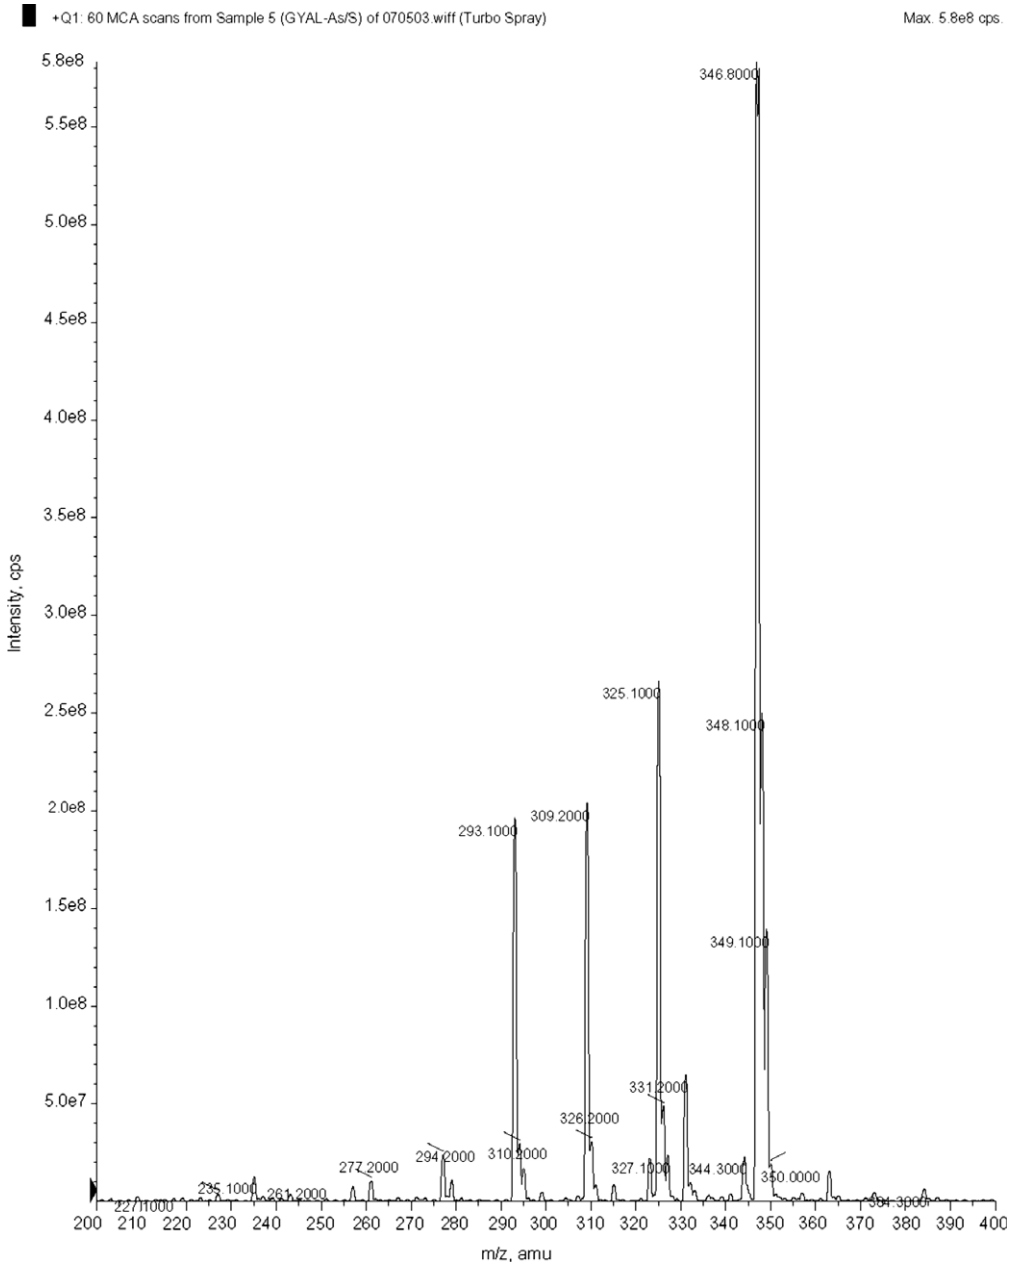

Fig. 6. ESI–MS–MS spectrum of methyl-2,3-*O*-isopropylidene-5-deoxy-5dimethyl-thioarsinoyl-β-D-ribofuranoside (**7**) in MeOH (+Q1mode).

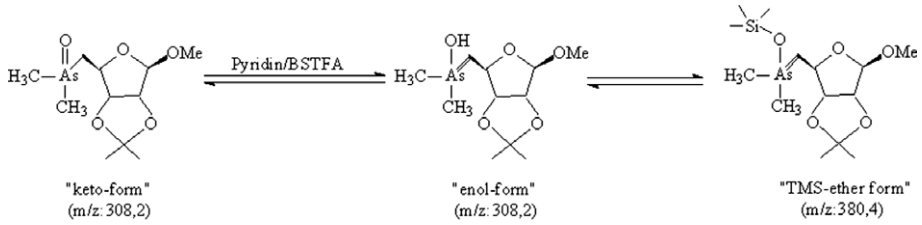

Fig. 7. Equilibrium processes among the keto-, enol- and trimethylsilycated forms (TMS) of methyl-2,3-*O*-isopropylidene-5-dimethyl-arsinoyl-β-D-ribofuranoside.

of methyl 2,3-*O*-isopropylidene-5-deoxy-5-bromo-β-D-ribofuranoside (**4**) was carried out in the presence of DMF solvent and NaBr at a reflux temperature for 1.5 h. A sodium dimethyl arsine reagent was used for the dimethyl arsine side chain construction in dry THF solution, along with continuous stirring and argon flushing. We should emphasize that this substitution reaction works directly from the mesylate intermediate **3** as well, as our NMR spectroscopy studies have proven. The resulting dimethyl (methyl-2,3-*O*-isopropylidene-5-deoxy-β-D-ribofuranose-5-yl) arsine (**5**) was isolated as a yellow oil. The oxidation reaction of the arsinoyl compound takes place easily in the presence of H_2O_2 and Et_2O. The reaction completed in 1.5 h and the resulting final product **6** was isolated as a colourless syrup. The thioarsinoyl analogue **7** was prepared in EtOH from **5** by adding sulfur to the solution. The mixture was held under an argon atmosphere, heated to the reflux temperature of EtOH and refluxed, thus avoiding the presence of oxidized side products. After cleaning steps were carried out, the final product **7** was crystallised from MeOH. Results of TLC, GC and NMR spectroscopy measurements for the characterisation and identification of the synthesis intermediates and products are seen in Tables 2 and 3.

In the case of the arsinoyl final product **6**, it was noticed that the oxygen atom (oxo-group), bonded to the arsenic by a $\sigma + \pi$ bond, was silylised in the presence of a strong trimethylsilycating agent (BSTFA), presumably after tautomerisation. Comparing the chromatograms of Figs. 2 and 3 it can be seen that the peak of the *O*-trimethylsilyl-ether of **6** is sharper and more symmetrical than the tailing peak of the "silyl-free" arsenosugar **6**, due to a more effective volatilisation in the GC. LC–MS–MS studies have supported that the silylation was successful. Fig. 4 shows the MS spectrum of the trimethylsilyl derivative of **6** where the trimethylsilyl-ether parent ion *m*/*z*: 381.2 dominates. Fig. 5 shows the mass spectrum of the arsinoyl compound **6**, here two parent ions, the protonated arsenosugar (*m*/*z*: 309.3) and its sodium-adduct (*m*/*z*: 331.3) are the most intense peaks. As in the case of the thio-analogue, compound **7** silylation was unsuccessful. Its mass spectrum (Fig. 6) is dominated by its sodium-adduct (*m*/*z*: 346.8).

In the case of **6** the mass of the trimethylsilyl-ether parent ion (*m*/*z*: 381.2) proves the deprotonation of the terminal methylene-group. This finding seems to support the assumption of Pergantis et al. [13] on the proposed fragmentation routes of an oxo-arsenosugar.

Keto–Enol tautomerism is characteristic for adequately substituted compounds containing an oxo-group, and the conversion of the enol to the keto form in a base catalysed environment proceeds easily. For these reactions one of the most convenient solvents is pyridine as a base, using it along with BSTFA as a trimethylsilycating agent. The LC–MS–MS results obtained seem to support the assumption of Pergantis and his co-workers [13] that tautomerism also takes place in the case of arsenosugars. Fig. 7 shows the interconversion among the keto-, enol- and trimethylsilycated forms of the arsinoyl compound **6**.

Acknowledgements

We thank János Kuszmann his kind help in the synthesis of the sugars. Special thanks to Ferenc Szederkényi for his advice on the interpretation of chromatographic results.

ABSTRACT

The synthesis and characterization of pyridine alcoholate ligand coordinated Co(II/III) metal complexes are reported. The characterization includes elemental analysis, spectral, magnetism, and X-ray crystallographic studies. Water readily shows nucleophilic addition to the C=O group upon coordination of the 2-pyridyl ring of the ligands, forming a *gem*-diol form of $(2\text{-py})_2CO$. By coordinating through the two pyridine nitrogen atoms and one oxygen atom from the newly formed *gem*-diol, the ligand becomes tridentate rather than bidentate, as might be expected. Two spin allowed ($^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$) d ← d transitions are observed in the electronic spectra of the strong field octahedral Co(III) complex and the $^1A_{1g} \rightarrow {}^1T_{2g}$ transition is obscured by intense MLCT bands. In $[Co\{OC(OH)(2\text{-pyridyl})_2\}_2][OAc] \cdot 4H_2O$ (**1**) the cationic part shows a N_4O_2 coordinated octahedral geometry for the Co(III) species with two di-(pyridyl)-ketone hydrate (DPKH) moieties coordinated in a tridentate fashion. The tetranuclear cluster molecule of $[Co_4\{OC(OH)(2\text{-pyridyl})_2\}_4[OAc]_4] \cdot 7H_2O$ (**2**) has a cubane core with alternate vertices occupied by Co(II) and oxygen atoms, consisting of two interpenetrating tetrahedra. In complex **2** the $1/\chi'_M$ *versus* T plot fitted with the simple Curie–Weiss law $1/\chi'_M = C/(T-\theta)$, and shows an antiferromagnetic behavior with $C = 8.14$ and $\theta = -69.26 \pm 0.06$ K.

1. Introduction

One domain of coordination chemistry which has flourished in recent years is the synthesis of complex polynuclear architectures via self-assembly processes involving suitably designed ligands and transition metal ions. The development of routes and strategies for the synthesis of polynuclear complexes (clusters) of 3d metals in moderate oxidation states is of great importance because these species provide substantial impetus for development in several fields, including bioinorganic chemistry, magnetochemistry, materials chemistry and solid-state physics [1]. The ligand di-2-pyridyl ketone has recently been proved to be a central player in 3d-metal cluster chemistry. There continues to be great interest in the synthesis and study of polynuclear metal complexes (clusters) containing paramagnetic 3d metals in intermediate oxidation states [2]. There are various reasons for this, not least of which is the aesthetically pleasing nature of some of these species [3]. From an applications point of view, however, efforts in this area are part of the continuing search for new examples of molecular species which can function as nanoscale magnetic particles or the so-called single-molecule magnets (SMMs) [4]. Research on single-molecule magnets (SMMs) has been one of the most active fields in the past decade, and is still rapidly expanding. SMMs not only show dramatic architectures, but also provide almost ideal systems for investigating the coexistence of classic and quantum effects, and are hopeful for applications in information storage and quantum computing in the future [5]. The cubane-like structure of tetranuclear metal complexes is a characteristic motif in coordination chemistry of different metal ions and this structural motif, with a close spatial alignment of metal centres, is important also in the chemistry of transition metals where it may have an essential impact on considering possible magnetic and catalytical properties of the compounds [6]. Oxo-bridged cluster complexes of transition metals have recently been the subjects of study because these complexes could provide a fundamental basis for the study of redox and ligand substitution reactions vital to metal catalyzed autoxidation processes [7]. "*Binary* ligand blend" reactions involving (i) the monoanion $(2\text{-py})_2C(OH)O^-$ or the dianion $(2\text{-py})_2CO_2^{2-}$ of the *gem*-diol form of di-2-pyridyl ketone $(2\text{-py})_2CO$ and carboxylates and (ii) the monoanion $(2\text{-py})_2C(OR)O^-$ of the hemiacetal form of $(2\text{-py})_2CO$ and carboxylates have been explored with the belief that they might foster formation of discrete polynuclear metal systems [8]. The reactions of $(2\text{-py})_2CO$ with metal ions have been well studied over the years [9,10]. Water readily shows nucleophilic addition to the C=O group upon coordination of the

doi:10.1016/j.poly.2008.05.024

2-pyridyl ring of the ligands, forming the *gem*-diol form of (2-py)$_2$CO. The hydration reaction is unusual since ketones are not normally hydrated to any appreciable extent in aqueous media, unless flanked by very strong electron withdrawing groups such as Cl or F. By coordinating through the two pyridine nitrogen atoms and one oxygen atom from the newly formed *gem*-diol, the ligand becomes tridentate rather than bidentate, as might be expected.

2. Experimental

2.1. Materials

Chemicals like dipyridyl ketone were purchased from Aldrich, USA. $Co(OAc)_2 \cdot 4H_2O$ was purchased from Merck India Limited. All chemicals and solvents were of reagent grade and used as received without further purification.

2.2. Instrumentation and methods

FT-IR spectra in the range 4000–400 cm^{-1} were recorded using a Perkin–Elmer Spectrum One in KBr disc.

2.3. X-ray crystallography

Single crystal X-ray crystallographic data were collected using a Bruker SMART APEX-CCD diffractometer with Mo Kα radiation (λ = 0.71073 Å). The intensity data were corrected for Lorentz and polarization effects and empirical absorption corrections were applied using the SAINT program [11]. The structure was solved by direct methods using SHELXS-97 and non-hydrogen atoms located from the difference Fourier maps were refined anisotropically by full-matrix least-squares on F^2 using SHELXL-97 [11]. The hydrogen atoms were included in calculated positions and refined isotropically using a riding model.

2.4. Magnetic properties

The AC susceptibility was measured as a function of temperature at an AC field amplitude of 22 A/m by employing the mutual inductance bridge method and using a Perkin–Elmer (model 7265) dual phase lock-in-amplifier. The solid-state AC magnetic susceptibility of the tetranuclear cluster molecule **2** was recorded at an oscillator frequency of 333 Hz at 6 Oe; the magnetic field was generated using a Walker electromagnet. The temperature variation was achieved using a commercial closed cycle helium refrigerator cryostat equipped with a LakeShore Temperature Controller (model-331). The temperature was measured using a LakeShore calibrated GaAlAs sensor with an accuracy of better than ±50 mK.

2.5. Syntheses

2.5.1. $[Co\{OC(OH)(2\text{-pyridyl})_2\}_2][OAc] \cdot 4H_2O$ (**1**)

To 25 mL of a methanolic solution of 500 mg (2.71 mmol) of dipyridyl ketone (DPK), 1.35 g (5.42 mmol) 2 × 10 mL of a methanolic solution of $Co(OAc)_2 \cdot 4H_2O$ were added. The reaction mixture was stirred for 1.5 h, after which a pink colored solution was obtained. The reaction mixture was left for crystallization. After a week block-like crystals were obtained and washed with ice-cold methanol. Yield: 1.75 g (55%). IR (KBr), cm^{-1}: 1613 (C=N$_{py}$), 1476. *Anal.* Calc. for $C_{24}H_{29}N_4O_{10}Co$: C, 48.69; H, 4.90; N, 9.47. Found: C, 48.72; H, 4.95; N, 9.55%.

2.5.2. $[Co_4\{OC(OH)(2\text{-pyridyl})_2\}_4[OAc]_4] \cdot 7H_2O$ (**2**)

Synthetically the procedure for **2** was similar to that of **1**, but a dark pink colored solution was obtained after refluxing for 2.5 h. The reaction mixture was left for crystallization. After a week block-like crystals were obtained and washed with ice-cold methanol. Yield: 40%. IR (KBr), cm^{-1}: 1614 (C=N$_{py}$), 1474. *Anal.* Calc. for $C_{52}H_{64}N_8O_{24}Co_4$: C, 43.91; H, 4.50; N, 7.88. Found: C, 44.08; H, 4.61; N, 7.72%.

3. Results and discussion

3.1. Optical properties

The excitation spectra for the complexes (Fig. 1) were recorded in the region 200–1100 nm. In all of these complexes, four dominant bands were observed. Of these, the first two bands are at higher energies with high ε values and were attributed to intraligand $\pi^* \leftarrow \pi$ or $\pi^* \leftarrow$ n excitations. The remaining two bands (Bands III and IV) present MLCT character and d $\leftarrow$ d transitions of Co(III), respectively. Table 1 presents the excitation and ε values for the Gaussian fitted UV–Vis spectra of complexes **1** and **2**. The shape of the electronic spectra and the low extinction coefficients are suggestive of an octahedral configuration around the Co(III) ion. In general two spin allowed ($^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$) d $\leftarrow$ d transitions are observed in the electronic spectra of strong field octahedral Co(III) complexes. In many nitrogen donor Co(III) complexes the $^1A_{1g} \rightarrow {}^1T_{2g}$ transition is obscured by the intense MLCT bands. The intensities of the $^1A_1 \rightarrow {}^1T_1$ transitions are high due to "intensity stealing". In case of tetranuclear Co(II) cluster **2** two d–d transitions appear at 517 and 455 nm, and two MLCT bands are observed at 295 and 256 nm [12].

3.2. Molecular structure

The molecular structures of $[Co\{OC(OH)(2\text{-pyridyl})_2\}_2][OAc] \cdot 4H_2O$ (**1**) and $[Co_4\{OC(OH)(2\text{-pyridyl})_2\}_4[OAc]_4] \cdot 7H_2O$ (**2**) were determined by X-ray crystallography. The crystallographic data and refinement parameters are summarized in Table 2.

3.2.1. $[Co\{OC(OH)(2\text{-pyridyl})_2\}_2][OAc] \cdot 4H_2O$ (**1**)

The cationic part shows a N_4O_2 coordinated octahedral geometry for the Co(III) species with the two di-(pyridyl)-ketone hydrate (dpkH) moieties coordinated in a tridentate fashion. A perspective view of **1** is shown in Fig. 2. In this case, the hydrated dpkH stabilizes the high oxidation state of the metal centre, owing to the presence of a σ-donor oxygen atom where Co(III) gets neutralized by two deprotonated hydroxyl groups and a counter anionic acetate. The coordinated pendant generates two puckered five membered rings. The dihedral angle ∠Co1–N2–C7–C6 of 4.52(0.73)° is higher than that of ∠Co1–N1–C5–C6, −0.03(0.75)°, and similarly in the another moiety ∠Co1–N4–C18–C17, 6.84(0.80)°, is less than that of ∠Co1–N3–C16–C17, −2.99(0.76)°. The *trans* coordinated pyridyl rings are almost linear, ∠N1–Co1–N4 and ∠N2–Co1–N3 being 178.8(4)° and 179.0(3)°, respectively, but ∠O1–Co1–O2 deviates from linearity by 2.3°. The equatorially coordinated Co–N (N1, N2) bonds are longer than the axially coordinated Co–O1, whereas in the next moiety the equatorially coordinated Co–N (N3, N4) bonds are shorter than the axially coordinated Co–O2 bond. The molecular packing of **1** generates 3D-bilayers through hydrogen bonding (Fig. 3), where a layer of hydrogen bonded acetate and water molecules links to another cationic complex layer through hydrogen bonding.

3.2.2. $[Co_4\{OC(OH)(2\text{-pyridyl})_2\}_4[OAc]_4] \cdot 7H_2O$ (**2**)

The tetranuclear cluster molecule of **2** has a cubane core with the alternate vertices occupied by Co(II) and oxygen atoms. It consists of two interpenetrating tetrahedra, one of four Co(II) atoms and another of four μ_3-oxygen atoms originating from (2-

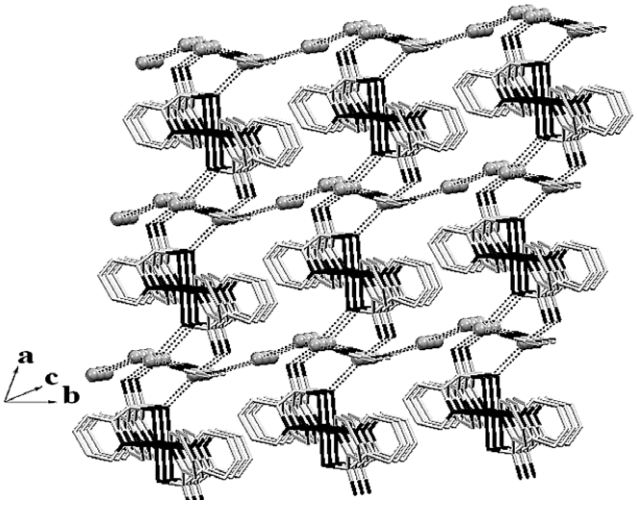

Fig. 3. Molecular packing of **1**, 3D-bilayers generated through hydrogen bonding.

py)$_2$C(OH)O$^-$ ligands. In addition to three μ_3-oxygen atoms, each Co(II) atom is coordinated to two N atoms belonging to two different (2-py)$_2$C(OH)O$^-$ ligands and to a monodentate acetate anion, satisfying an octahedral environment. A perspective view of **2** is shown in Fig. 4. Here each Co(II) atom is coordinated by one N_2O_4 chromophore system with a distorted octahedral geometry. One oxygen atom of each (2-py)$_2$C(OH)O$^-$ ligands remains protonated, without binding to any metal centre. The resultant mono anion functions as a $\eta^1{:}\eta^3{:}\eta^1{:}\mu_3$ ligand forming two five membered CoNCCO chelating rings with two Co(II) metal centres which share a common C–O bridge. There are two types of Co–O(μ_3) bond for each metal ion, where one bond is elongated compared to the adjacent one. The average ∠Co(1)–O–Co(2) angle of 97.16° is lower as compared to the average ∠Co(3)–O–Co(4) angle, 98.07°. A large number of intracubane hydrogen bonds are present in **2**, which reinforce the framework of the cubes. Each hydroxyl group of (2-py)$_2$C(OH)O$^-$ is intramolecularly hydrogen bonded strongly to an O atom from a monodentate acetate anion. One notable feature is that the non-coordinating oxygen atoms in the hydroxyl group

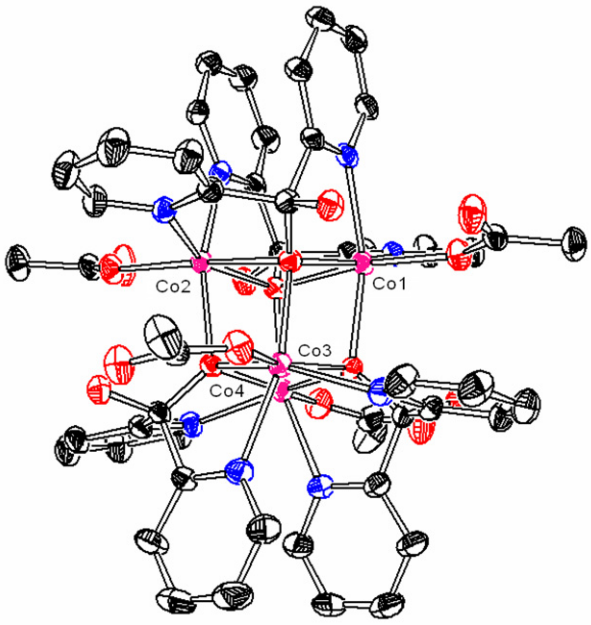

Fig. 4. ORTEP (30% probability) of **2** (hydrogens are omitted for clarity).

in $(2\text{-py})_2C(OH)O^-$ and the terminal acetate participate in intracubane hydrogen bonding. One chair type hydrogen bonding is noticed between the solvated water molecules and the non-coordinating oxygen atoms in the hydroxyl group in $(2\text{-py})_2C(OH)O^-$ and the terminal acetate. The chair consists of two five membered and a central rectangular hydrogen bonding. The water molecules are in a chain in the chair hydrogen bonding where each side is occupied by three water molecules. Besides those interactions, there are π–π stacked interactions, C1···C2 along $-x+1, -y, -z+1$ and C1···C1 along $-x+1, -y, -z+1$, of 3.159(4) and 3.355(3) Å, respectively.

3.3. Magnetic studies

The tetranuclear cluster molecule **2** exhibits a $\chi'_M T$ value of 6.53 $cm^3\ mol^{-1}\ K$ at 293 K, where a spin-only value of 7.3 $cm^3\ mol^{-1}\ K$ is expected for four uncoupled Co(II) centres with a ground state $^4T_1(S = 3/2)$ with $g = 2$, where χ'_M is the molar AC susceptibility for the real component. The important reason for this difference is that the orbital contribution to the magnetic moment is significant as the orbital degeneracy of this state is not quenched. The $\chi'_M T$ value continuously decreases upon cooling from a value of 6.53 $cm^3\ mol^{-1}\ K$ at 293 K to a value of 3.02 $cm^3\ mol^{-1}\ K$ at 25 K. The $\chi'_M T$ value deceases steadily from 293 to 100 K, but below 100 K it decreases suddenly. The χ'_M value increases continuously from a value of 0.0232 $cm^3\ mol^{-1}$ at 293 K to 0.0751 $cm^3\ mol^{-1}$ at 25 K. The overall behavior is a clear indication of an antiferromagnetic nature present in **2** below 100 K. Analysis of the coupling constants of the cobalt(II) tetramer is difficult by means of an effective Hamiltonian based on four $S = 3/2$ spins due to the large anisotropy of this ion [13]. The experimental data were fitted with the help of ORIGIN 6.0 software, using the expression derived from the isotropic Heisenberg Hamiltonian $H = -J_1(S_1S_4 + S_2S_3) - J_2(S_1S_2 + S_3S_4) - J_3(S_1S_3 + S_2S_4)$. The best fit parameters were $J_1 = -21.86\ cm^{-1}$, $J_2 = -14.81\ cm^{-1}$, $J_3 = -10.55\ cm^{-1}$ and $g = 2.03$. The $1/\chi'_M$ *versus* T plot shown in Fig. 5 was fitted with the simple Curie–Weiss law $\chi'_M = C/(T-\theta)$, which shows an antiferromagnetic behavior with $C = 8.14$ and $\theta = -69.26 \pm 0.06$ K. The effective magnetic moment (μ_{eff}) was calculated from the least square fitting and is 3.63 BM per cobalt atom.

4. Conclusion and perspectives

Water readily shows nucleophilic addition to the C=O group upon coordination of the 2-pyridyl ring of the ligands, forming the *gem*-diol form of $(2\text{-py})_2CO$. By coordinating through the two pyridine nitrogen atoms and one oxygen atom from the newly formed *gem*-diol, the ligand becomes tridentate rather than bidentate, as might be expected. The tetranuclear cluster molecule of $[Co_4\{OC(OH)(2\text{-pyridyl})_2\}_4[OAc]_4] \cdot 7H_2O$ (**2**) has a cubane core with alternate vertices occupied by Co(II) and oxygen atoms, consisting of two interpenetrating tetrahedra. The $1/\chi'_M$ *versus* T plot fitted with the simple Curie–Weiss law $\chi'_M = C/(T-\theta)$, and shows an antiferromagnetic behavior with $C = 8.14$ and $\theta = -69.25 \pm 0.06$ K.

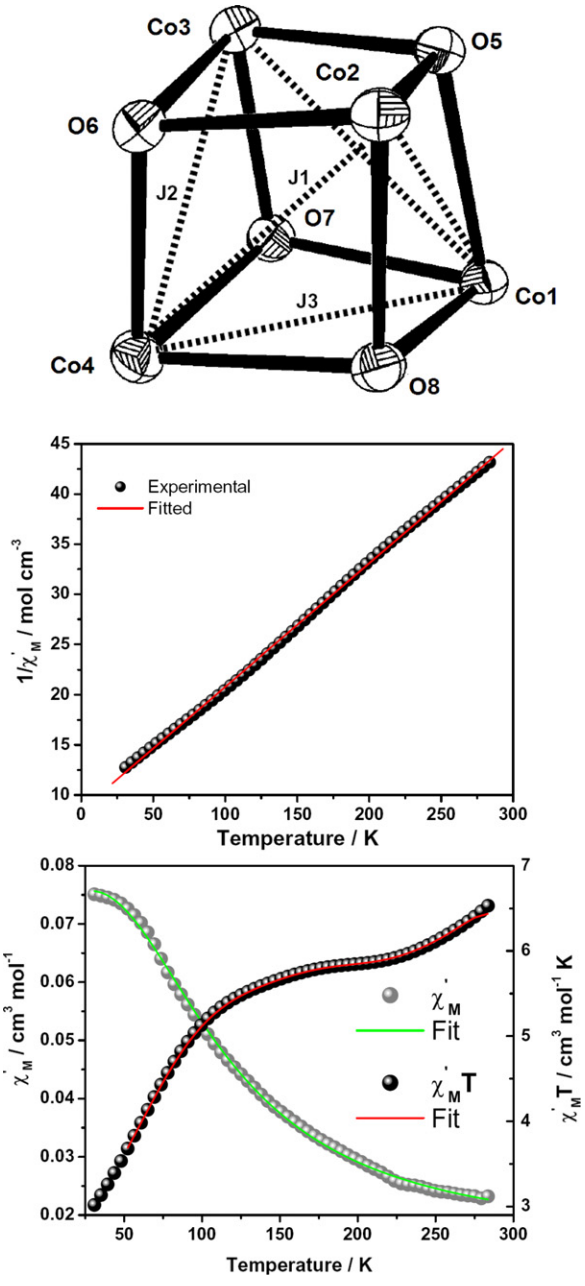

Fig. 5. Assignments of J values and AC susceptibility plot in **2**.

Supplementary data

CCDC 627293 and 645238 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

Dr. V. Manivannan is acknowledged in affording the proper accomplishment and giving us the opportunity to communicate this paper. We are grateful to the Department of Science and Technology (DST) New Delhi for establishing the single crystal X-ray diffractometer facility under FIST scheme. The authors are thankful to Babulal Das for X-ray data and CIF IIT Guwahati for VSM facilities, and Dr. S. Ravi for AC susceptibility measurements.

ABSTRACT

The synthesis, spectroscopic and chromatographic characterization, and X-ray crystal structure of the complex tris(2-methoxyisobutylisocyano) copper(I) tetrafluoroborate, $[Cu(MIBI)_3][BF_4]$, is reported. The Cu atom lies on threefold axis and is bonded to three 2-methoxyisobutylisocyano ligands in a perfect trigonal-planar coordination. The calculated and experimental powder-diffraction spectra of this complex are also reported.

1. Introduction

Mononuclear copper(I) complexes with isocyanide derived ligands is a well-established class of organometallic compounds [1]. Usually, these complexes display a tetrahedral geometry with four isocyanide ligands bound to the same Cu^+ ion through the carbon atom of the carbon–nitrogen triple bond. However, an interesting feature of this category of complexes comes from the fact that they may also exist in a trigonal-planar arrangement, in which only three isocyanide ligands are coordinated to the same metal center. Commonly, this behavior is interpreted by considering the strength of the π-acceptor interaction between the electron-rich Cu(I) atom and the isocyanide ligand [2].

The ligand 2-methoxyisobutylisocyanide (MIBI) occupies a relevant position in nuclear cardiology since it is employed for the preparation of the heart perfusion imaging agent ^{99m}Tc-MIBI (commercial name, Cardiolite®) [3]. This monocationic organometallic radiopharmaceutical is formed by a Tc(I) atom coordinated to six MIBI ligands in an octahedral geometry. Interestingly, the routine preparation of this imaging agent in hospital radiopharmacies is carried out through a ligand exchange reaction between the four-coordinated Cu(I) complex $[Cu(MIBI)_4]^+$ and the *in situ* formed Tc^+ ion.

The synthesis of $[Cu(MIBI)_4]^+$ was reported previously along with X-ray crystal structure determination of the corresponding tetrafluoroborate salt [4]. As expected, X-ray diffraction data showed that this complex has a tetrahedral coordination geometry with four MIBI ligands bound to the same Cu(I) center. In another publication, the synthesis of the three-coordinated complex $[Cu(MIBI)_3]^+$ was also described [5]. However, no structural characterization of this complex has been reported so far.

This study reports the synthesis, characterization and X-ray crystal structure of the tetrafluoroborate salt of the complex $[Cu(MIBI)_3]^+$. Based on structural data, the powder-diffraction spectrum of this complex was calculated and compared with the same spectrum as experimentally determined. Comparison between the powder-diffraction spectra of the four-coordinated and three-coordinated Cu(I) complexes with MIBI ligand is also reported.

2. Experimental

2.1. Materials

The ligand 2-methoxyisobutylisocyanide (IUPAC name: 2-methoxy-2-methylpropan isocyanide) was obtained from ABX, Radeberg, Germany. The compounds $[Cu(CH_3CN)_4][BF_4]$ [6] and $[Cu(MIBI)_4][BF_4]$ [4] were prepared as reported elsewhere. All laboratory chemicals and solvents (Fluka) were reagent grade and used without further purification.

2.2. Instrumentation

Elemental analyses (C, H, N) were performed on a Carlo Erba 1106 elemental analyzer. FT-IR spectra were recorded on a Nicolet 510P Fourier-transform spectrometer in the range 4000–200 cm^{-1} in KBr mixtures using a Spectra-Tech diffuse-reflectance collector

accessory. Proton NMR spectra were collected on a Bruker AC-300 instrument using $SiMe_4$ as internal reference. Positive ion fast atom bombardment mass spectra (FAB^+ MS) of selected complexes in an NBA matrix were recorded on a VG 30-250 spectrometer (VG Instrument) at the probe temperature. Xe was used as the primary beam gas, and the ion gun was operated at 8 keV (ca. 1.28×10–15 J) and 100 μA.

2.3. Synthesis

The complex $[Cu(MIBI)_3][BF_4]$ was prepared as reported previously [5] with only minor modification as briefly described below.

$[Cu(CH_3CN)_4][BF_4]$ (1.07 g, 3.38 mmol) and chloroform (40 mL) were placed in a round-bottom flask equipped with a magnetic bar. The mixture was stirred for 5 min, at room temperature and under a nitrogen atmosphere. $[Cu(MIBI)_4][BF_4]$ (6.13 g, 10.2 mmol) was then added and the reaction mixture was further stirred to form a clear solution. Stirring was continued for additional 30 min and, then, the solvent was evaporated under reduced pressure to obtain a semi-solid residue, which was dried with a high-vacuum pump to give a white solid. This solid was dissolved in a chloroform (50 mL)/ethyl acetate (50 mL) mixture followed by addition of diethyl ether (≈150 mL) to form a cloudy suspension. This suspension was kept at low temperature (4 °C) overnight to yield a microcrystalline solid, which was filtered and dried under vacuum. Yield, 5.2 g (78%).

Crystals suitable for X-ray diffraction were obtained by dissolving part of the solid product (1.2 g) in a mixture of acetone (60 mL) and *n*-propanol (20 mL), and by allowing the resulting solution to slowly evaporate, at room temperature, under air atmosphere. Crystals were collected when some residual solvent was still present (≈10 mL) and, then, washed with *n*-propanol and diethyl ether.

Elemental *Anal.* Calc. for $C_{15}H_{33}N_3O_3CuBF_4$: C, 44.14; H, 6.79; N, 8.58. Found: C, 44.17; H, 6.82; N, 8.51%.

FT-IR (KBr, cm^{-1}): 2982–2839 ν(C–H), 2215 ν(N≡C), 1080 ν(B–F) and ν(C–O–C).

(c) Superimposed experimental spectra of $[Cu(MIBI)_3][BF_4]$ (upper) and $[Cu(MIBI)_4][BF_4]$ (space group: $P2_12_12_1$, cell parameters: $a = 15.198(2)$, $b = 21.478(4)$, $c = 10.095(3)$).

^{1}H NMR ($CDCl_3$, ppm): 1.25 (s, CH_3), 3.23 (s, OCH_3), 3.67 (s, CH_2).

^{13}C NMR ($CDCl_3$, ppm): 22.58 (s, CH_3), 50.13 (s, OCH_3), 52.03 (s, CH_2), 73.40 (s, CH_2C), 137.60 (broad, N≡C).

FAB$^+$ MS (*m/z*): 404, 402 [M^+], 291, 289 [M^+−MIBI].

2.4. Chromatography

High performance liquid chromatography (HPLC) was performed on a System Gold Instrument equipped with a programmable solvent Module 126, a scanning detector Module 166, and a radioisotope detector Module 170 (Beckman Instruments, Fullerton, CA, USA). Chromatographic analyses were carried out on a Restek Allure Basic column (150 × 4.6 mm, ∅ = 5 μm) using the following conditions. Mobile phase: A = ammonium acetate, B = CH_3CN; gradient: 0–10 min, B = 50%, 10–15 min, B = 100%.

2.5. X-ray crystallography and powder diffraction

Data collection was performed on a Nonius Kappa CCD area detector diffractometer using graphite-monochromatized Mo Kα radiation (λ = 0.71073 Å). All intensities were corrected for Lorentz polarization and absorption effects [7]. The structure was solved by direct methods with the SIR97 program [8] and refined on F^2 by full-matrix least-squares methods with anisotropic non-H atoms using SHELXL-97 [9]. Hydrogen atoms were included on calculated positions, riding on their carried atoms. All other calculations were performed using the program PARST [10]. Molecular drawing was obtained using ORTEPIII [11].

Crystal data for tris(2-methoxyisobutylisocyano) copper(I) tetrafluoroborate: crystal dimensions, 0.41 × 0.23 × 0.20 mm, F_w = 489.83 g/mol, hexagonal, space group, $P6_3$, a = 11.7517(3) Å, c = 10.8845(3) Å, V = 1301.79(6) Å^3, Z = 2, D_{Calc} = 1.250 g cm^{-3}, $F(000)$=512, μ(Mo Kα) = 0.887 mm^{-1}, T = 295 K. Measured, independent and observed reflections: 17895, 2091, 1630 [$I > 2\sigma(I)$], R(int) 0.0361, 127 parameters; R [on $F^2 > 2\sigma(F^2)$], wR (on F^2), S: 0.051, 0.157, 1.04.

Powder-diffraction spectra were recorded, at room temperature, on a Bruker D-8 Advance diffractometer with graphite-monochromatized Cu Kα radiation (λ = 1.5406 Å). The data were recorded at 2θ steps of 0.02° with 1 s/step.

3. Results and discussion

The complex $[Cu(MIBI)_3]^+$ was prepared by ligand exchange between the four-coordinated complexes $[Cu(MIBI)_4]^+$ and $[Cu(CH_3CN)_4]^+$. Formally the reaction can be thought to proceed through the transfer of one-coordinated MIBI ligand from each of three $[Cu(MIBI)_4]^+$ complexes to a single $[Cu(CH_3CN)_4]^+$, with the concomitant release of four CH_3CN ligands. This hypothetical exchange yields four molecules of the three-substituted $[Cu(MIBI)_3]^+$ complex as illustrated in the reaction diagram below:

$$3[Cu(MIBI)_4]^+ + [Cu(CH_3CN)_4]^+ \rightarrow 4[Cu(MIBI)_3]^+ + 4\ CH_3CN.$$

Characterization of this compound was carried out by elemental analysis, and by spectroscopic and chromatographic methods. Solid-state and structural determinations were conducted by X-ray powder and single-crystal diffraction studies.

HPLC chromatography showed only a single peak at 8.1 min, thus suggesting the presence of a definite compound.

In the FAB mass spectrum of $[Cu(MIBI)_3]^+$, collected in the positive ion mode, a peak doublet was found at 404, 402 corresponding to the parent ion with the expected isotopic ratio (isotopic abundance, ^{63}Cu = 69.1% and ^{65}Cu = 30.9%). An additional peak was observed at 291, 289 and was associated with the fragment $[Cu(MIBI)_2]^+$ generated through the loss of one MIBI ligand.

The FT-IR spectrum of $[Cu(MIBI)_3]^+$ was consistent with the presence of MIBI ligands coordinated to the metal center. Similarly, ^{1}H and ^{13}C NMR spectra showed characteristic resonance peaks corresponding to functional groups of coordinated MIBI ligands. Interestingly, both FT-IR and NMR spectra of $[Cu(MIBI)_3]^+$ do not substantially differ from those recorded for the four-coordinated complex $[Cu(MIBI)_4]^+$. This result can be easily interpreted by considering that key factors in determining the positions of both vibrational bands and resonance peaks are much dependent on the nature of functional groups of the coordinated ligands and on their reciprocal position within the structure of the metal complex. When the symmetry of the complex leads all the coordinated ligands to become geometrically equivalent, and there is no change in the electronic density on the metal, no significant spectroscopic differences are expected between two closely related complexes differing only in the number of identical ligands bound to the same metal ion.

This observation clearly indicates that the complex $[Cu(MIBI)_3]^+$ should possess a geometry in which the three-coordinated MIBI ligands are all equivalent, and that differences between the four- and three-coordinated complexes should arise mainly at the solid-state. This prediction was nicely confirmed by results of X-ray studies carried out on these two complexes. In particular, the structure of single crystals of $[Cu(MIBI)_3][BF_4]$, obtained from acetone/*n*-propanol, provided unambiguous assignment of the identity of the three-coordinated complex.

Fig. 1 reports the X-ray crystal structure of the compound $[Cu(MIBI)_3][BF_4]$. The Cu atom lies on special position (threefold axis) and is bonded to three 2-methoxyisobutylisocyano ligands in a perfect trigonal-planar coordination with the two terminal methyl groups disordered over two almost equivalent positions (occupancies: 0.4 and 0.6). The cations are isolated and there are no interactions between adjacent copper atoms (Cu···Cu distance: 8.698 Å). The Cu–C1 bond length of 1.917(3) Å is in good agreement with those found in other similar Cu trigonal complexes, which are in the range 1.88–1.95 Å (16 compounds retrieved from the Cambridge Structural Database [12]). The other relevant bond distances involving the bound CN group, C1–N1 = 1.142(4) Å and N1–C2 = 1.435(4) Å, do not show any significant discrepancy from structural parameters of similar groups. The tetrafluoroborate anion is positioned as well on a threefold axis with the fluorine atoms disordered over two non-equivalent positions. In the crystal the different units interact with each other through weak C–H···O and C–H···F intermolecular interactions, mean H···F and H···O interaction distances being 2.42 and 2.45 Å, respectively, for C–H···X angles >140°. The packing diagram is shown in Fig. 2. Comparable weak interactions are found in the crystal structure of $[Cu(MIBI)_4][BF_4]$ [4], showing mean H···F and H···O distances of 2.40 and 2.70 Å, respectively.

Structural data allowed to calculate the theoretical X-ray powder spectrum of $[Cu(MIBI)_3][BF_4]$ as illustrated in Fig. 3a. This appears almost superimposable with the same spectrum determined experimentally (Fig. 3b). Comparison between powder spectra of $[Cu(MIBI)_3][BF_4]$ and $[Cu(MIBI)_4][BF_4]$ is reported in Fig. 3c. These spectra clearly show that physico-chemical differences between the two Cu(I) complexes mainly occur at the solid-state as a result of the different chemical composition and structural geometry.

4. Conclusion

The three-coordinated trigonal-planar Cu(I) complex $[Cu(MIBI)_3]^+$ has been structurally characterized and its spectroscopic properties compared with those of the four-coordinated analogue $[Cu(MIBI)_4]^+$. Experimental findings showed that there exist no significant differences in stretching frequencies and magnetic reso-

nance signals between four- and three-coordinated MIBI ligands, thus indicating that the electronic density and metal–ligand bond strengths are almost the same in the two complexes. Moreover, both tetrahedral and trigonal-planar geometries determine a perfect equivalence of coordinated MIBI ligands that contributes to further averaging of the properties of the two copper complexes.

ABSTRACT

Four copper(II) complexes were synthesized by reactions of new imidazole-containing polyamine ligand N^1-(2-aminoethyl)-N^1-(1*H*-imidazol-4-ylmethyl)-ethane-1,2-diamine (HL) with $Cu(ClO_4)_2 \cdot 6H_2O$ under different pH and their structures were characterized by X-ray crystallography. Interestingly, the complexes have diverse structures from protonated ligand $[H_3(HL)][CuCl_4] \cdot Cl$ (**1**), dinuclear $[Cu_2(HL)_2Cl](ClO_4)_3 \cdot H_2O$ (**2**), one-dimensional chain polynuclear $\{[Cu(L)](ClO_4)\}_n$ (**3**) to cyclic-tetranuclear $[Cu_4(L)_4](ClO_4)_4 \cdot 3CH_3CN$ (**4**) coordination compounds by varying reaction pH from acidic to basic. The results indicate that the reaction pH has great impact on the formation and structure of the complexes. The magnetic measurements show that there are antiferromagnetic interactions between the Cu(II) centers with $g = 2.09$, $J = -39.0\ cm^{-1}$ and $g = 2.17$, $J = -36.8\ cm^{-1}$ for **3** and **4**, respectively.

1. Introduction

In the past few years, imidazole-containing ligands have been extensively investigated due to their versatile use as building blocks in supramolecular and biomimic chemistry [1,2], as well as in new functional materials [3]. Among the reported studies, the switching function of metal complexes controlled by pH is particularly interested since the imidazole group can be deprotonated at high pH to give oligomeric or polymeric frameworks with imidazolate bridging. For instance, the Cu(II) complexes can be converted from monomer to certain oligomer or polymer, which are determined by the nature of the ligand such as linkage position of imidazole (1-, 2- or 4-imidazole), steric effect, etc. [3d,3e,3f,3g,3h,3i]. However, in the most reported cases, the ligands are Schiff-base or reduced Schiff-base, and the interconversions occurred between monomer and certain oligomer or polymer [3c,3d,3e,3f,3g,3h,3i], and only very recently, tripodal imidazole-containing ligands were reported to form tetranuclear and hexanuclear complexes [4].

We focus our attention on construction and property of metal complexes with imidazole-containing organic ligands [5]. For example, we have reported copper(II) and zinc(II) complexes that can fix atmosphere carbon dioxide (CO_2), which are the first examples of polymeric carbonate complexes with supramolecular use of polyamine ligand with imidazole pendant, namely N^1-(2-aminoethyl)-N^1-(2-imidazolethyl)-ethane-1,2-diamine (L1, Scheme 1) [5e]. As an extension of our previous work, we designed and synthesized a new imidazole-containing polyamine ligand N^1-(2-aminoethyl)-N^1-(1*H*-imidazol-4-ylmethyl)-ethane-1,2-diamine (HL, Scheme 1), by varying the spacer from $-CH_2CH_2-$ in L1 to $-CH_2-$ in HL between the polyamine and imidazole groups, and the linkage position of 1-imidazole in L1 to 4-imidazole in HL. Reactions of HL with $Cu(ClO_4)_2 \cdot 6H_2O$ were carried out under different pH and complexes with diverse structures from protonated ligand $[H_3(HL)][CuCl_4] \cdot Cl$ (**1**), dinuclear $[Cu_2(HL)_2Cl](ClO_4)_3 \cdot H_2O$ (**2**), one-dimensional chain polynuclear $\{[Cu(L)](ClO_4)\}_n$ (**3**) to cyclic-tetranuclear $[Cu_4(L)_4](ClO_4)_4 \cdot 3CH_3CN$ (**4**) coordination compounds were isolated (Scheme 2). Herein, the synthesis, structure of the four compounds, and the magnetic property of **3** and **4** are reported.

2. Experimental

2.1. Synthesis of the ligand HL · 4HCl

The NH_2 groups of diethylenetriamine were protected by phthalic anhydride as described previously [5e]. The protected product (1.8 g, 5.0 mmol) was allowed to react with imidazole-4-aldehyde (0.48 g, 5.0 mmol) in mixture of methanol (50 ml) and chloroform

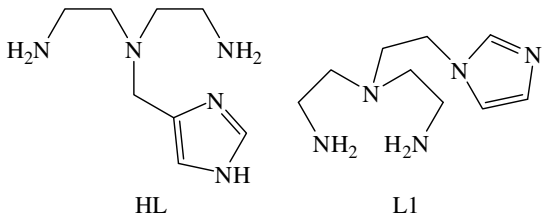


Scheme 1. The imidazole-containing polyamine ligands HL and L1.

(50 ml) for 2 h, then sodium cyanoborohydride (0.32 g, 5.0 mmol) was added in small portions in 3 h. After the resulting solution was stirred for one day at room temperature, the solution was evaporated under reduced pressure. The residual was extracted by CH_2Cl_2 from aqueous phase, and the organic phase was dried over Na_2SO_4 and evaporated to give pale oil. Then concentrated hydrochloric acid (30 ml) was added, and the mixture was boiled for 8 h, and filtered. The filtrate was evaporated to dryness, after recrystallization from ethanol, HL · 4HCl was obtained as white powder (0.95 g, 63%). ^{1}H NMR: (D_2O, 500 MHz): δ = 8.63 (s, 1H), 7.41 (s, 1H), 3.82 (s, 2H), 3.08 (t, 4H), 2.76 (t, 4H) ppm.

2.2. Synthesis of the complexes

2.2.1. Synthesis of $[H_3(HL)][CuCl_4] \cdot Cl$ (**1**)

A methanol solution (3 ml) of HL · 4HCl (16.5 mg, 0.0500 mmol) was added to a methanol solution (3 ml) of $Cu(ClO_4)_2 \cdot 6H_2O$ (18.6 mg, 0.0500 mmol), and the solution was stirred for 10 min, then filtered. The filtrate was diffused by diethyl ether for two days, during which time yellow crystals appeared. The crystal is very deliquescent in air. Yield: (72%). IR: (KBr, cm^{-1}): 3444 (br), 3182 (s), 3129 (s), 2964 (m), 2902 (m), 1625 (m), 1601 (m), 1574 (m), 1504 (m), 1445 (m), 1369 (m), 1319 (w), 1171 (w), 1078 (w), 1029 (w), 987 (w), 948 (w), 833 (w), 769 (w), 685 (m), 624 (m).

2.2.2. Synthesis of $[Cu_2(HL)_2Cl](ClO_4)_3 \cdot H_2O$ (**2**)

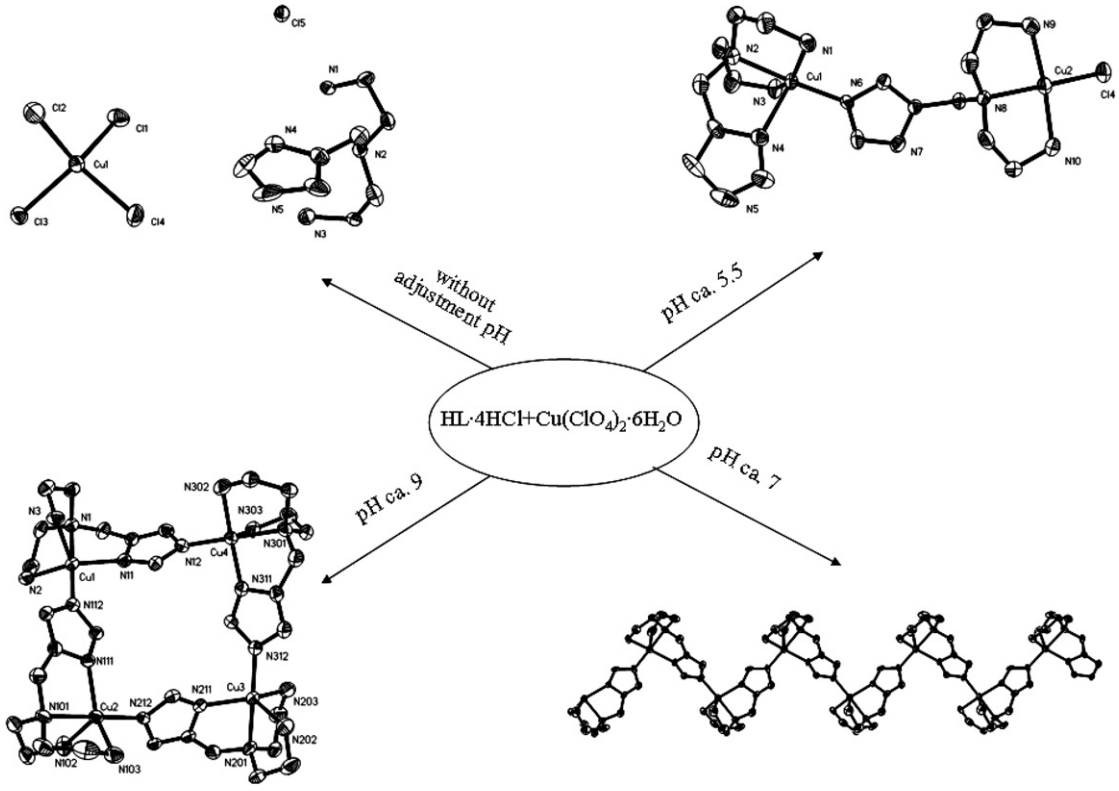
An aqueous solution (3 ml) of HL · 4HCl (16.5 mg, 0.0500 mmol) was added to an aqueous solution (3 ml) of $Cu(ClO_4)_2 \cdot 6H_2O$ (18.6 mg, 0.0500 mmol), and the solution was stirred, then 0.5 M NaOH was added dropwise to pH ca. 5.5. Blue crystals were obtained by slow evaporation of the solution in air for several days. Yield: (65%). *Anal.* Calc. for $C_{16}H_{36}Cl_4Cu_2N_{10}O_{13}$: C, 22.70; H, 4.26; N, 16.56. Found: C, 22.57; H, 4.35; N, 16.44%. IR: (KBr, cm^{-1}): 3337 (s), 3285 (s), 2973 (w), 2921 (w), 1625 (m), 1595 (m), 1469 (m), 1451 (m), 1378 (w), 1319 (w), 1276 (w), 1103 (vs), 1082 (vs), 994 (m), 940 (m), 895 (m), 848 (m), 658 (m), 624 (m).

2.2.3. Synthesis of $\{[Cu(L)](ClO_4)\}_n$ (**3**)

An aqueous solution (3 ml) of HL · 4HCl (16.5 mg, 0.0500 mmol) was added to an aqueous solution (3 ml) of $Cu(ClO_4)_2 \cdot 6H_2O$ (18.6 mg, 0.0500 mmol), and the resulted solution was adjusted to pH ca. 7 with 0.5 M NaOH while stirring. About 10 min later, it was filtered, and the filtrate was allowed to stand for several days, green block crystals were obtained. Yield: (55%). *Anal.* Calc. for $C_{16}H_{32}Cl_2Cu_2N_{10}O_8$: C, 27.81; H, 4.63; N, 20.28. Found: C, 27.77; H, 4.71; N, 20.39%. IR: (KBr, cm^{-1}): 3366 (s), 3336 (s), 3284 (s), 2921 (w), 2880 (w), 1601 (m), 1470 (m), 1358 (w), 1312 (w), 1244 (w), 1220 (w), 1114 (vs), 980 (m), 951 (w), 885 (w), 825 (w), 655 (w), 624 (m).

2.2.4. Synthesis of $[Cu_4(L)_4](ClO_4)_4 \cdot 3CH_3CN$ (**4**)

An aqueous solution (3 ml) of HL · 4HCl (16.5 mg, 0.0500 mmol) was added to an aqueous solution (3 ml) of $Cu(ClO_4)_2 \cdot 6H_2O$ (18.6 mg, 0.0500 mmol), and the resulted solution was adjusted to pH ca. 9 with 0.5 M NaOH while stirring, the solution becomes cloudy immediately. Then 2 ml of CH_3CN was added to give a clear



Scheme 2. Schematic drawing for formation of **1**–**4** under different solution pH.

solution, after stirred for another 10 min, it was filtered, and the filtrate was allowed to stand for several days, and blue crystals were isolated. Yield: (85%). *Anal.* Calc. for $C_{32}H_{64}Cl_4Cu_4N_{20}O_{16}$ (noncoordinated CH_3CN molecules were lost upon drying): C, 27.53; H, 4.58; N, 20.07. Found: C, 27.98; H, 4.55; N, 20.36%. IR: (KBr, cm^{-1}): 3340 (s), 3242 (s), 2925 (w), 2877 (w), 1602 (m), 1469 (s), 1356 (w), 1312 (w), 1236 (w), 1209 (m), 1113(vs), 981 (m), 954 (m), 884 (w), 823 (w), 779 (w), 654 (w), 625 (m).

Caution! Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of materials should be prepared, and the samples should be handled with caution.

2.3. Physical measurements

All commercially available chemicals are of reagent grade and used as received without further purification. Elemental analyses for C, H and N were made on a Perkin–Elmer 240C elemental analyzer. Infrared (IR) spectra were recorded on a Bruker Vector22 FT-IR spectrophotometer by using KBr pellets. Magnetic measurements were performed in a MPMS-SQUID magnetometer at a field of 2000 G on powder samples in a Teflon capsule in the range of 1.8–300 K.

2.4. X-ray crystallography

The unit cell parameters were determined and the data collected at 293 K with a Bruker SMART CCD system equipped with monochromated Mo Kα radiation (λ = 0.71073 Å) for **1–3**. Empirical absorption corrections were applied to the data using the SADABS program [6]. Structures of **1**–**3** were solved by the direct methods and refined by full-matrix least-squares on F^2 using the SHELXL-97 programs [7]. Crystallographic data of **4** was collected at 200 K on a Rigaku RAXIS-RAPID Imaging Plate diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71075 Å). The structure of **4** was solved by direct methods using SIR92, expanded using Fourier techniques DIRDIF94 and refined using SHELXL-97 programs [7,8]. All the non-hydrogen atoms were refined anisotropically on F^2 by full-matrix least-squares techniques. The hydrogen atoms were generated geometrically. All calculations were performed using the TEXSAN crystallographic software package of Molecular Structure Corporation [9]. Crystallographic data for **1–4** are listed in Table 1. Selected bond lengths and angles for complexes **1–4** are listed in Table 2. C4 atom of **1** is disordered in two positions with an occupation of 0.5, for clarity, only one of these sites is shown.

3. Results and discussion

3.1. Description of the crystal structures of complexes *1–4*

3.1.1. $[H_3(HL)][CuCl_4] \cdot Cl$ (*1*)

When the hydrochloride salt of the ligand HL · 4HCl was used to react with $Cu(ClO_4)_2 \cdot 6H_2O$ directly without adjustment of reaction pH, yellow crystals were obtained. The crystallographic analysis revealed that the structure of **1** consists of protonated $[H_3(HL)]^{3+}$ cation, $[CuCl_4]^{2-}$ anion, and one chloride ion as shown in Fig. 1a. It is reasonable that the ligand did not coordinate with Cu(II) atoms under the experiment conditions since the amino and imidazole groups in the ligand are protonated and thus loss coordination ability with the metal atom. On the other hand, the Cu(II) atom is coordinated by four chloride ions to form a $[CuCl_4]^{2-}$ unit with distorted tetrahedral geometry. The Cu–Cl bond distances are from 2.231(2) Å to 2.252(2) Å, and the Cl–Cu–Cl angles fall in the range of 97.77(8)° and 134.38 (8)° (Table 2), which are similar to the reported ones [1a,10].

The protonated $[H_3(HL)]^{3+}$ cations are joined together through N–H···Cl5 hydrogen bonds to form an infinite one-dimensional (1D) chain structure (Fig. 1b). The adjacent 1D chains are further connected together by C–H···Cl and N–H···Cl ($[CuCl_4]^{2-}$ anion) hydrogen bonds to form a three-dimensional (3D) structure (Fig. 1c). The hydrogen-bonding data are summarized in Table S1.

3.1.2. $[Cu_2(HL)_2Cl](ClO_4)_3 \cdot H_2O$ (*2*)

When the reaction solution of HL · 4HCl and $Cu(ClO_4)_2 \cdot 6H_2O$ was adjusted to pH ca. 5.5, a new complex **2** was isolated as blue crystals. There are one dinuclear $[Cu_2(HL)_2Cl]^{3+}$ cation, three perchlorate anions and one lattice water molecule in the asymmetric unit of **2**. As shown in Fig. 2a, the dinuclear $[Cu_2(HL)_2Cl]^{3+}$ unit contains two independent Cu(II) centers with different coordination

Symmetry transformation used to generate equivalent atoms: #1 *x*, *y*, −1 + *z*.

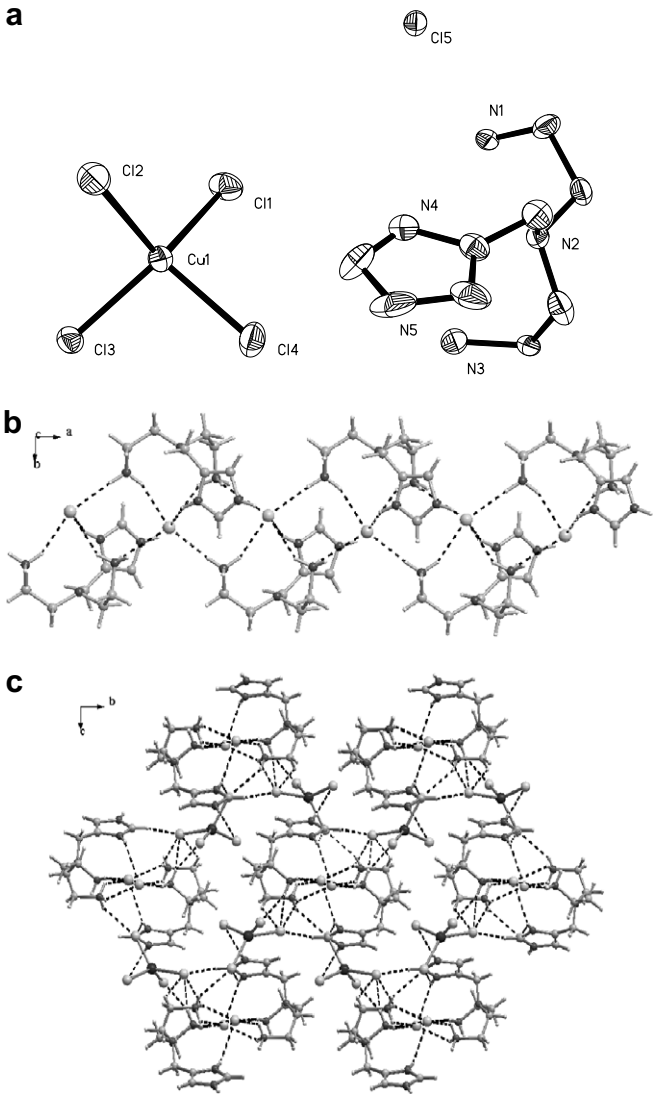

Fig. 1. (a) ORTEP drawing of **1** with thermal ellipsoids set to 30% probability level, the hydrogen atoms were omitted for clarity. (b) View of 1D chain structure of **1** with hydrogen bonds indicated by dashed lines. (c) The 3D structure of **1** with hydrogen bonds indicated by dashed lines.

geometry, namely the Cu1 atom is five-coordinated by three amino nitrogen atoms from one HL and two imidazole nitrogen atoms from two different HL ligands with an average Cu–N bond distance of 2.047(6) Å. The bond angles around Cu1 are in the range of 82.7(2)–176.4(2)° (Table 2). The coordination geometry around Cu1 atom is a distorted square pyramid as indicated by an index τ value of 0.43 as defined by Addison et al.: $\tau = 0$ for an ideal square pyramid and $\tau = 1$ for a perfect trigonal-bipyramid [11]. On the other hand, the Cu2 atom is four-coordinated by three amino nitrogen atoms from one HL ligand and one chloride atom with distorted square planar geometry. The average Cu–N distance around Cu2 is 2.008(6) Å, and the Cu–Cl distance is 2.247(2) Å, the bond angles around Cu2 are ranging from 84.6(2) to 167.17(2)° (Table 2). It should be noticed that the deprotonation of the two imidazole groups at N5 and N7 positions did not occur, and thus they did not participate in the coordination under pH at ca. 5.5.

The dinuclear $[Cu_2(HL)_2Cl]^{3+}$ cations are linked into an infinite 1D zigzag chain by perchlorate anions through C–H···O1 and

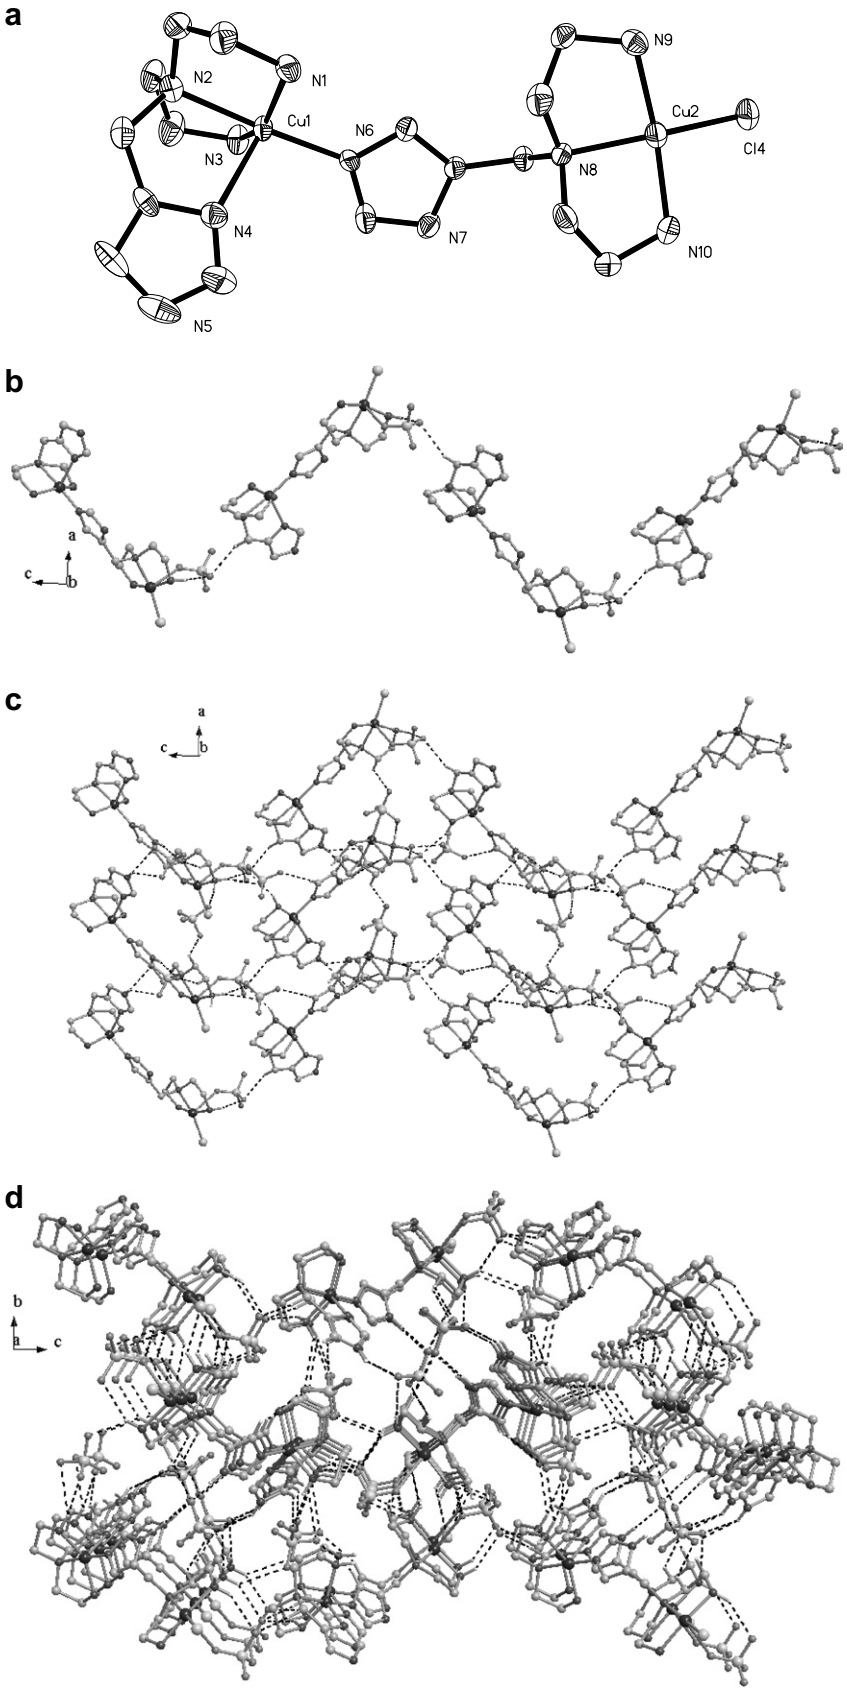

Fig. 2. (a) View of the dinuclear complex of **2** with thermal ellipsoids set to 30% probability level, the hydrogen atoms, perchlorate anions, and uncoordinated water molecules were omitted for clarity. (b) View of 1D zigzag chain structure of **2** with hydrogen bonds indicated by dashed lines. (c) The 2D network of **2** with hydrogen bonds indicated by dashed lines. (d) The 3D framework of **2** with hydrogen bonds indicated by dashed lines.

N–H···O1 hydrogen bonds (Fig. 2b). The 1D chains are further joined together to form two-dimensional (2D) network by C–H···O and N–H···O (perchlorate anion) hydrogen bonds (Fig. 2c), which produce a 3D framework through C–H···O, N–H···O (perchlorate anion), and C–H···Cl4, N–H···Cl4 hydrogen bonds as listed in Table S1 (Fig. 2d).

3.1.3. $\{[Cu(L)](ClO_4)\}_n$ (**3**)

When the pH of the reaction solution was further raised to ca. 7, complex **3** was obtained as green crystals and the result of crystallographic analysis confirmed that the imidazole group of the HL ligand deprotonated to give L^- and as a result each imidazole group acts as imidazolate bridging to coordinate with two metal atoms. As illustrated in Fig. 3a, there are two different Cu(II) centers and two independent L^- ligands in the repeat unit of **3**. The Cu1 atom is five-coordinated by four nitrogen atoms from one L^- ligand and one imidazolate nitrogen atom from another L^- ligand, with an average Cu1–N separation of 2.04(1) Å. There is no structural preference for the coordination geometry of Cu1, since the τ value is calculated to be 0.49 [11]. The Cu2 atom is also five-coordinated which is similar to that in Cu1, but the coordination geometry around Cu2 is a distorted trigonal-bipyramid since the τ value is 0.71 [11]. The average Cu2–N distance is 2.05(1) Å. On the other hand, each L^- ligand, using its two imidazolate nitrogen atoms, acts as a bridge to link two Cu(II) atoms to generate a zigzag chain structure (Fig. 3b). Then, the 1D chains are further connected through C–H···O and N–H···O (perchlorate anion) hydrogen bonds to form 3D structure (Fig. 3c).

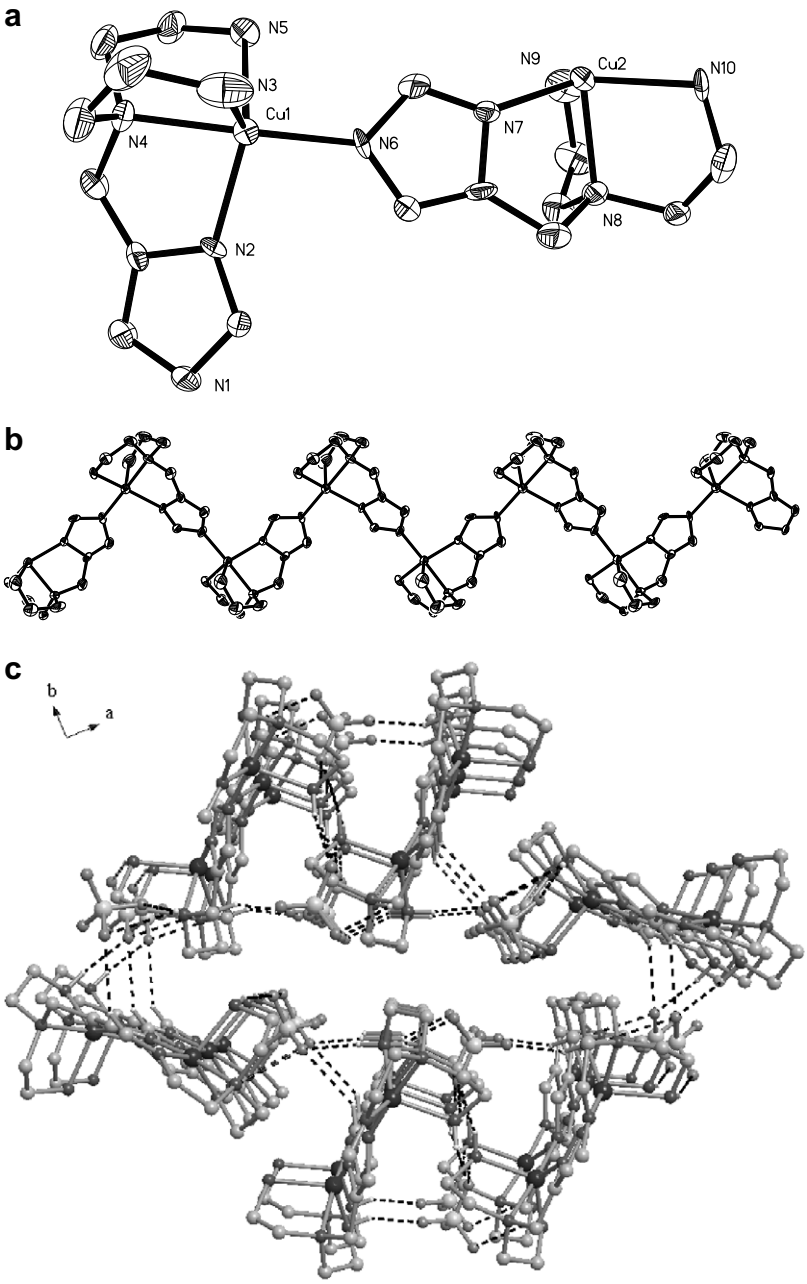

Fig. 3. (a) ORTEP drawing of **3** showing the coordination environment with thermal ellipsoids set to 30% probability level, the hydrogen atoms, and perchlorate anions were omitted for clarity. (b) View of the infinite 1D zigzag chain structure of **3**, the hydrogen atoms and perchlorate anions were omitted for clarity. (c) The 3D structure of **3** with hydrogen bonds indicated by dashed lines.

*3.1.4. $[Cu_4(L)_4](ClO_4)_4 \cdot 3CH_3CN$ (**4**)*

In order to further investigate the influence of pH on the formation and structure of the complex, the pH of the reaction solution was adjusted to ca. 9 and complex **4** was generated. It is interesting to find that the imidazole group of the HL ligand in **4** also deprotonated as observed in **3**, however, the structures of **3** and **4** are totally different. As shown in Fig. 4a, the structure of **4** consists of one cyclic-tetranuclear $[Cu_4(L)_4]^{4+}$ cation, four perchlorate anions, and three non-coordinated acetonitrile molecules. All the Cu(II) atoms have the same coordination environment with

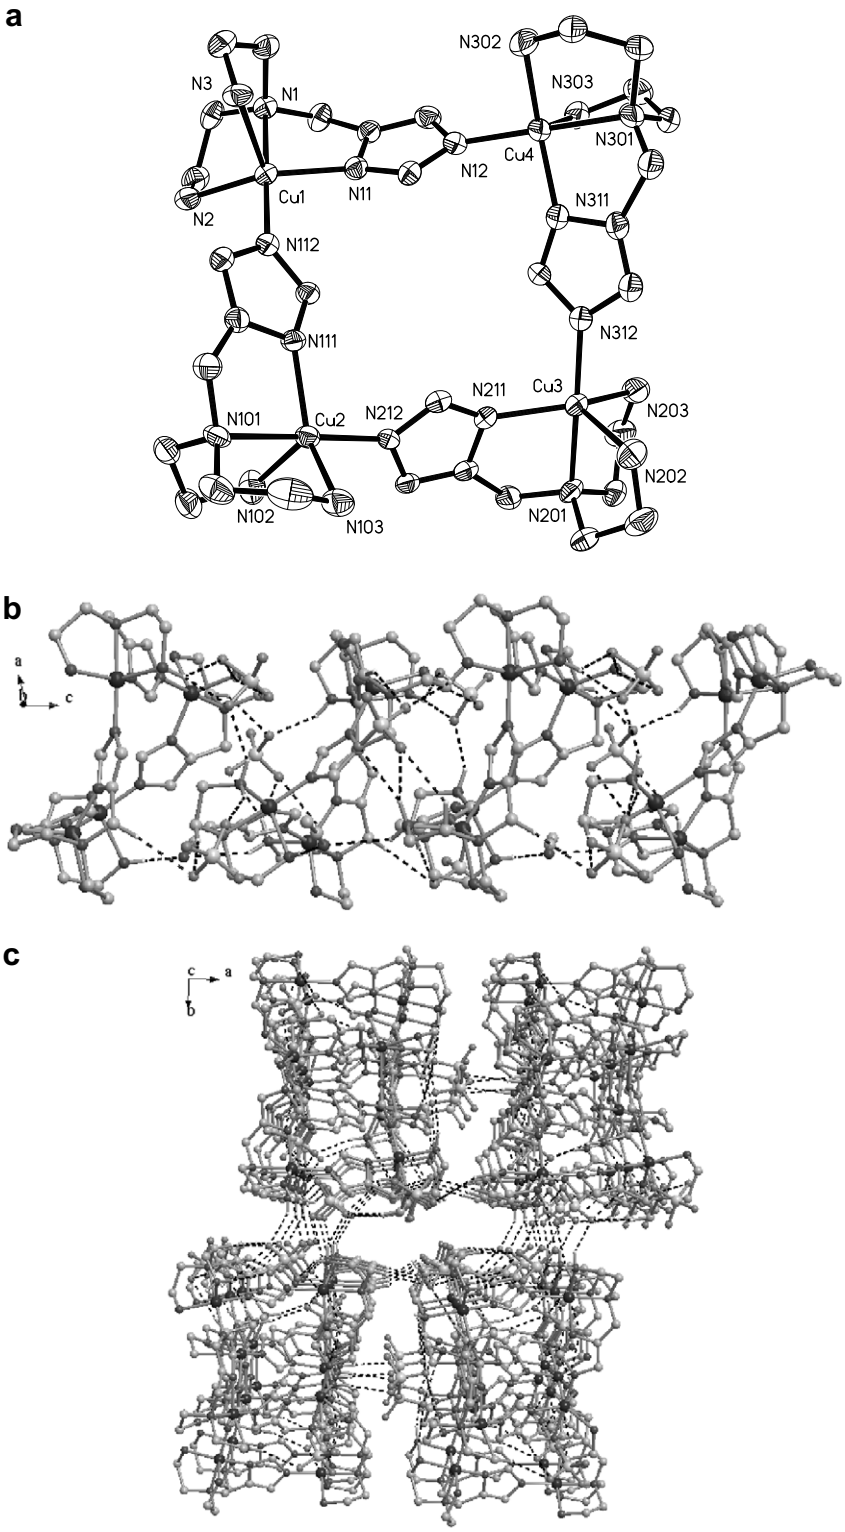

Fig. 4. (a) View of the cyclic-tetranuclear complex of **4** with thermal ellipsoids set to 30% probability level. The perchlorate anions, acetonitrile molecules and hydrogen atoms were omitted for clarity. (b) The 1D chain structure of **4** with hydrogen bonds indicated by dashed lines. (c) The 3D framework of **4** with hydrogen bonds indicated by dashed lines. The acetonitrile molecules are omitted for clarity.

trigonal-bipyramid coordination geometry, but different bond lengths and angles as listed in Table 2. Each Cu(II) atom is five-coordinated by four nitrogen atoms from one ligand, and one imidazolate nitrogen atom from another ligand with the Cu–N bond distances in the range of 1.941(7)–2.183(7) Å.

The $[Cu_4(L)_4]^{4+}$ cations are linked through C–H···O and N–H···O (perchlorate anion) hydrogen bonds to form 1D chain structure (Fig. 4b), and the 1D chains are further connected to form 3D framework by C–H···O and N–H···O (perchlorate anion) hydrogen bonds, with acetonitrile molecules filled in the vacancy (Fig. 4c).

3.2. Magnetic property of **3** and **4**

As observed in the crystal structure, the adjacent copper(II) atoms in complexes **3** and **4** are bridged by imidazolate groups and thus their magnetic property is interested. Variable-temperature magnetic susceptibility measurements were performed on crystalline sample of **3** and **4** in the temperature range of 1.8–300 K, and the results in plots of $\chi_M T$ versus T and χ_M versus T are shown in Fig. 5. For **3**, the value of $\chi_M T$ at 300 K is estimated at 0.35 emu K mol^{-1}, which is smaller than that of spin-only value 0.375 emu K mol^{-1} for S = 1/2. When the temperature is lowered, the $\chi_M T$ decreases gradually to 0.0028 emu K mol^{-1} at 1.8 K. The χ_M versus T curve shows a maximum at about 70 K. The facts clearly indicate the antiferromagnetic interactions between the Cu(II) atoms in **3**. The magnetic susceptibility data were interpreted by the Bonner and Fisher model for a 1D infinite-chain structure for $J < 0$, where the Hamiltonian is $\widehat{H} = -2J\sum S_i\, S_{i+1} J$ is the intra-chain exchange coupling constant [3c,3f,3i]. The least-squares fitting was carried above 10 K including paramagnetic impurity ρ, and the best-fit parameters are $g = 2.09$, $J = -39.0$ cm^{-1}, $\rho = 0.002$ and the linear agreement factor is $R = 0.9992$. The $J = -39.0$ cm^{-1} is compatible with those of the imidazolate-bridged 1D chain complexes reported previously [3c,3f,3i]. The magnetic behavior of **4** is shown in Fig. 5b, the value of $\chi_M T$ at 300 K is estimated at 1.20 emu K mol^{-1}, which is smaller than the spin-only value of 1.50 emu K mol^{-1} for the Cu_4 unit. The $\chi_M T$ decreases gradually from room temperature to 1.8 K and the χ_M versus T curve shows a maximum at about 80 K, which means the operation of antiferromagnetic interactions between the copper(II) atoms. The magnetic susceptibility data were analyzed by a cyclic-tetranuclear structure model [3c,3e,3i,4], where the Hamiltonian is $\widehat{H} = -2J(S_1S_2 + S_2S_3 + S_3S_4 + S_4S_1)$. The least-squares fitting was carried above 10 K including paramagnetic impurity ρ, and the best-fit parameters are $g = 2.17$, $J = -36.8$ cm^{-1}, $\rho = 0.007$ and the linear agreement factor is $R = 0.9999$. Similar results have been reported previously for the cyclic-tetranuclear complexes [3c,3e,3i,4].

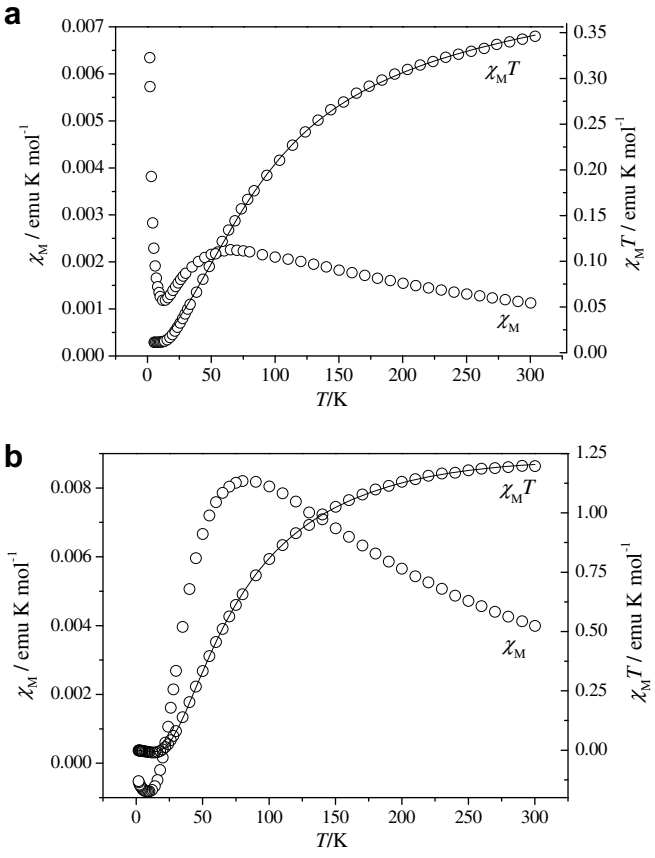

Fig. 5. Temperature dependences of magnetic susceptibility χ_M and χ_MT for **3** and **4**. The solid lines represent the fitted curve: (a) **3**; (b) **4**.

4. Conclusions

In summary, we have designed and synthesized a new tripodal polyamine ligand HL, and investigated its reactions with $Cu(ClO_4)_2 \cdot 6H_2O$ under different pH. Interestingly, it can realize the self-assembly from protonated ligand $[H_3(HL)][CuCl_4] \cdot Cl$ (**1**), dinuclear $[Cu_2(HL)_2Cl](ClO_4)_3 \cdot H_2O$ (**2**), one-dimensional chain polynuclear $\{[Cu(L)](ClO_4)\}_n$ (**3**) to cyclic-tetranuclear $[Cu_4(L)_4](ClO_4)_4 \cdot 3CH_3CN$ (**4**) coordination compounds from acidic to basic conditions. The results indicate that the reaction solution pH has great impact on the assembly process of the complexes and their structures. The magnetic investigation revealed that the imidazolate bridging between the adjacent Cu(II) atoms mediates the antiferromagnetic interactions.

ABSTRACT

The extended structures of Ag-complexes of the azine based ligands phenyl-2-pyridyl ketone azine ($\mathbf{L_1}$) and di-2-pyridyl ketone azine ($\mathbf{L_2}$) are reported, and focus is made on the investigation of the influence of the anion and supramolecular interactions on the self-assembly. Using $AgNO_3$, $AgClO_4$ and CF_3COOAg salts as starting materials for both ligands in acetonitrile, we observed the formation of the dinuclear complexes $[Ag_2(\mathbf{L_1})_2](NO_3)_2$ (**1a**), $[Ag_2(\mathbf{L_1})_2](ClO_4)_2$ (**1b**), from $\mathbf{L_1}$, the tetranuclear complexes $[Ag_4(\mathbf{L_2})_2(NO_3)(CH_3CN)_2](NO_3)_3$ (**2a**), $[Ag_4(\mathbf{L_2})_2(CF_3COO)_3CH_3CN](CF_3COO)$ (**2b**) and the linear chain polynuclear complex $\{[Ag_3(\mathbf{L_2})_2](ClO_4)_3\}_n$ (**3**) from $\mathbf{L_2}$. The X-ray structures show that the molecular geometry depends on the choice of anion. The silver centers have distorted tetrahedral coordination geometry in all the complexes. Weak hydrogen bonding and other interactions result in 2-D and 3-D networks in these complexes.

1. Introduction

Azine and its derivatives are well known and are a useful class of organic compounds [1]. These compounds display important biological properties, are of importance for drug development [2], and are also used to develop supramolecular chemistry [1,3]. Supramolecular materials are found in a variety of applications including separation and host–guest interactions [4], catalytic properties [5], gas storage [6], non-linear optics [7] and magnetism [8]. So the design of metal–organic coordination polymers of supramolecular architecture, using non-covalent interactions such as electrostatic, hydrogen bonding and π-stacking, is an important area for supramolecular chemists and crystal engineers [9]. The formation of supramolecules is largely affected by the organic ligands, the nature of the metal ions, counter anions and other factors [10]. The role of anions in supramolecular chemistry is of enormous interest because of its application in ion pair recognition and anion exchange [11]. Recently, metallosupramolecular systems have been described for various types of ligands in which the anion and solvent play an important role in the design of the molecular architecture [9,11a,12]. As a soft acid the Ag(I) ion plays a central role in the formulation of such supramolecular assemblies, it favors stable coordination to soft bases like unsaturated nitrogen and sulfur [13]. There has only been a limited structural study of azine ligand based Ag-complexes [1b,3a,14]. Here we report the anion dependent formation of new Ag(I) complexes with pyridyl ketone azines.

2. Experimental

2.1. General

The solvents and reagents were purchased from general sources and were used without further purification. $\mathbf{L_1}$ and $\mathbf{L_2}$ were prepared according to the literature [1b,14a]. NMR spectra were recorded on a Bruker DX-300 NMR spectrometer (^{1}H, 300 MHz). Chemical shifts were referenced to TMS and deuterated acetonitrile (Acros) was used as the solvent. IR spectra were recorded using a Jasco FTIR 410 instrument. Mass spectra were measured on a Micromass Platform II spectrometer. Elemental analyses were carried out using a Perkin–Elmer 2400, 2400II elemental analyzer.

2.2. Synthesis of the complexes$[(\mathbf{L_1})_2Ag_2](NO_3)_2$ (**1a**) and $[(\mathbf{L_1})_2Ag_2](ClO_4)_2$ (**1b**)

$\mathbf{L_1}$ (0.362 g, 1 mmol) was dissolved in 10 ml acetonitrile. To this solution $AgNO_3$/$AgClO_4$ salt (1 mmol) was added with stirring. After 6 h a light yellow precipitate was collected by filtration. After washing with ether and drying under vacuum **1a** (81% yield)/**1b** (88% yield) was obtained.

Complex **1a**: ^{1}H NMR (CD_3CN) δ (ppm): 7.11 (d, 2H, J = 7.2 Hz), 7.25 (t, 2H, J = 8.1 Hz), 7.33 (d, 1H, J = 8.1 Hz), 7.52 (tt, 1H, J = 7.5 Hz), 7.67 (ddd, 1H, J = 7.8 Hz), 7.97 (td, 1H, J = 7.8 Hz), 8.38 (dt, 1H, J = 4.8 Hz); IR (KBr film, cm^{-1}) $\nu_{C=N}$: 1578, 1559,

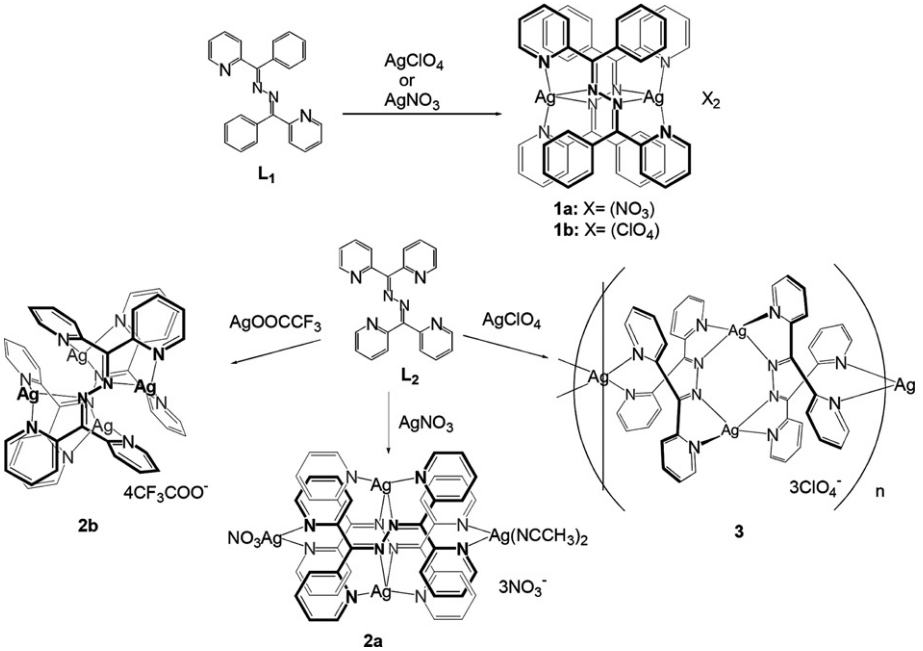
Complex **3**: ^{1}H NMR (CD_3CN) δ (ppm): 7.27 (d, 1H, J = 8.1 Hz), 7.52 (ddd, 1H, J = 7.8 Hz), 7.59 (m, 2H), 7.88 (m, 2H), 8.34 (d, 1H, J = 4.5 Hz), 8.40 (d, 1H, J = 5.1 Hz); IR (KBr film, cm^{-1}): $\nu_{C=N}$: 1591, 1564, $\nu_{ClO_4^-}$: 1090; MS (FAB): m/z 1467, 1453 [M +Ag]$^+$; 1358, 1349, 1346 [M]$^+$. *Anal.* Calc. for $C_{44}H_{34}Ag_3Cl_3N_{12}O_{13}$ (**3** · H_2O): C, 38.57; H, 2.48; N, 12.27. Found: C, 38.46; H, 2.54; N, 12.18%.

2.4. Synthesis of complex $[(\mathbf{L_2})_2Ag_4(CF_3COO)_3](CF_3COO)$ (**2b**)

Ligand $\mathbf{L_2}$ (0.364 g, 1 mmol) was dissolved in 10 ml of acetonitrile. To this solution $AgOOCCF_3$ salt (2 mmol) was added with



Scheme 1.

stirring. After 4 h the yellow solution was concentrated and stirred with a large volume of ether. The precipitate that formed was collected by filtration and dried under vacuum to give complex **2b** (76% yield). ^{1}H NMR (CD_3CN) δ (ppm): 7.25 (dt, 1H, J = 7.8 Hz), 7.61 (m, 2H), 7.71 (d, 1H, J = 7.8 Hz), 7.93 (ddd, 2H, J = 9.3 Hz), 8.38 (dt, 1H, J = 7.8 Hz), 8.43 (d, 1H, J = 5.1 Hz); IR (KBr film, cm^{-1}) $\nu_{C=N}$: 1581, 1562; $\nu_{CF_3COO^-}$: 1684. MS (FAB): m/z 1502, 1494 $[M-(CF_3COO)]^+$. *Anal.* Calc. for $C_{52}H_{38}Ag_4F_{12}N_{12}O_{11}$ (**2b** · $3H_2O$): C, 37.45; H, 2.28; N, 10.08. Found: C, 37.44; H, 2.24; N, 9.98%.

2.5. X-ray diffraction studies

X-ray quality crystals of all the complexes were grown by the slow diffusion of ether into an acetonitrile solution of the complexes. Single crystals were mounted on a glass fiber and the X-ray diffraction intensity data were measured on a Bruker Smart APEXII CCD XRD. The intensity data were collected at 273 K. All data were collected with the ω scan technique using graphite monochromatic Mo Kα radiation (λ = 0.71073 Å). All non-hydrogen atoms were refined with anisotropic displacement parameters and hydrogen atoms were included at calculated positions. The structures were solved by direct methods using the SHELXS-97 computer program and refined by full-matrix least-squares methods on F^2 using SHELXL-97 [15]. The crystal data and structure refinement parameters for complexes **1a**, **1b**, **2b**, and **3** are tabulated in Table 1. Although the main complex cation of the structure of **1a** is correct, there exists an unknown high electron density which could not be resolved with proper chemical meaning. In the structure of complex **2b**, there are some unreasonable displacement parameters for some C atoms and short C–C distances on the F_3CCOO^- anion groups due to the unsolved disorder problem.

3. Result and discussion

To investigate Ag(I) chemistry in the presence of different anions, complexes **1a**, **1b**, **2a**, **2b** and **3** were prepared. The formation of complexes is given in Scheme 1. X-ray quality crystals of **1a**, **1b**, **2a**, **2b**, and **3** were grown by diffusing ether into an acetonitrile solution of the complexes. In all the complexes, $\mathbf{L_1}$ acts as a tetradentate ligand and $\mathbf{L_2}$ acts as a hexadentate one, using their all possible N-donor sites. A similar structure of nitrate complex **2a** had been reported [14a] where it crystallized in the space group $P2_1/c$.

Except for the coordination of anions or solvents, the coordination environments of the Ag(I) centers of the complexes of ligand $\mathbf{L_1}$ are almost same, in the presence of different anions, but the packing of the crystals are different for different anions. For the complexes of $\mathbf{L_2}$, both the coordination environment and the packing of the crystals are different with different anions. Nitrate and trifluoroacetate complexes are tetranuclear with different coordination environments of the Ag(I) centers whereas the perchlorate complex has a polynuclear chain structure. It is important to note that the main chromophore contains $Ag_2(N_{az})_4(N_{py})_4$ units for the perchlorate and nitrate complexes of both ligands. The structural motif of the main chromophore is given in Fig. 1. In this chromophore two Ag centers and two azine (N–N) bridges form a six member distorted ring.

3.1. Crystal structures of complexes

3.1.1. Molecular structures of *1a* and *1b*

X-ray crystal structure determination of **1a** and **1b** lead to the formulation $[Ag_2(\mathbf{L_1})_2](NO_3)_2$ and $[Ag_2(\mathbf{L_1})_2](ClO_4)_2$, respectively. The structures indicated that both complexes are dimeric (Figs. 2 and 3a), with each Ag(I) center coordinated by two pyridine N-atoms from each of the two ligands. Two Ag(I) ions are also doubly bridged by azine (N–N) groups. In this way each Ag(I) center is tetra-coordinated, but their geometry is far from tetrahedral (π-type geometry) due to twisting of the ligands. The Ag–Naz distances are much longer than the Ag–Npy distances in both complexes (Table 2). The Ag–Npy distances are comparable with those reported for similar complexes [14,16] whereas the Ag–Naz distances are longer than similar bonds reported in other Ag–azine bridge complexes [14b]. This is due to the steric crowding of the substituted phenyl rings. The two ligands lie above and below the line made between the two Ag(I) centers. The ligands undergo a twist due to the coordination to the metal centers and form a double helical structure [17]. The twist conformation of the ligands as well as the rings also prevents the formation of an intramolecular π–π interaction. The Ag–Ag separation in both complexes (average 4.829 Å) indicates that there is no argentophilic interaction.

In the perchlorate complex **1b**, C–H···π interactions also generate a two-dimensional network (Fig. 3b, H···π distance range 2.74–2.83 Å, H···centroid distance 3.50 Å). Moreover, the perchlorate

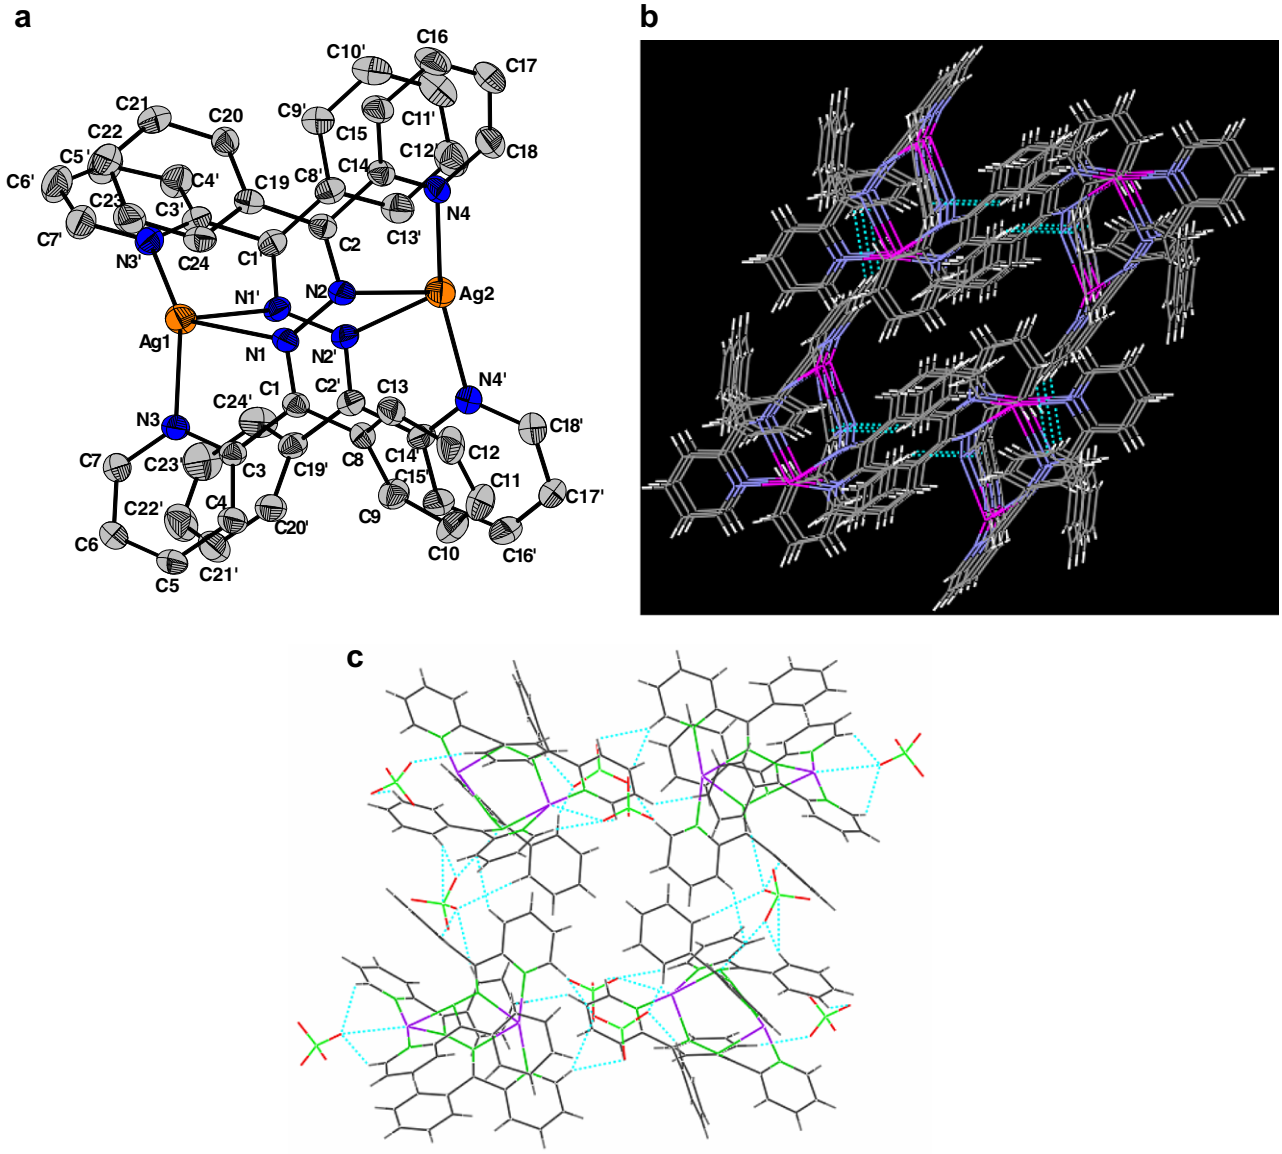

Fig. 3. (a) ORTEP view of **1b** showing 30% probability ellipsoids. Anions and hydrogen atoms are omitted for clarity. (b) C–H···π interactions between molecules to form the 2-D network in complex **1b**. (c) View of the 3-D network of C–H···O and C–H···π interactions in complex **1b**.

groups also make a number of short O···H–C interactions [9a] in the range 2.38–2.66 Å (Fig. 3c). The perchlorate ions contact the pyridine ring protons and benzene ring protons, which may be involved in the stabilization of the solid state structure. Weak C–H···π interactions also help to make a three-dimensional (3-D) network structure.

*3.1.2. Molecular structure of **2b***

The X-ray analysis of **2b** reveals that the asymmetric unit of the complex contains a discrete polynuclear $Ag_4(\mathbf{L_2})_2$ moiety formed by the assembly of four Ag atoms and two ligand molecules. The unit cell contains two of the above complete units with six coordinated trifluoroacetate (F_3CCOO^-), two coordinated acetonitrile (CH_3CN), two free F_3CCOO^- ions and six water molecules. Unlike the nitrate complex, the complex crystallizes in the triclinic system with space group $P\bar{1}$. An ORTEP plot of the discrete unit is shown in Fig. 4.

The coordination environment of each Ag(I) center is completely different from the nitrate complex **2a** [14a]. Among the four Ag(I) centers in the nitrate complex, two Ag(I) ions are coordinated by two azine N-atoms from two ligands and two pyridine N-atoms also from two ligands. Each of the other two Ag(I) ions is coordinated by two pyridine N-atoms from two ligands and a nitrate ion or acetonitrile solvent molecule. Whereas, in the trifluoroacetate complex each of the three Ag(I) centers Ag1, Ag2 and Ag4 completes its three coordination position with the same donor atoms – one azine N-atom and two pyridine N-atoms, and the fourth coordination position is satisfied by either F_3CCOO^- or CH_3CN. One azine N-donor and one pyridine N-donor of a ligand form a five member chelate ring with each Ag center. The remaining Ag3 center is coordinated by two pyridine nitrogen atoms and a F_3CCOO^- ion. The Ag–N_{py} distances around all the Ag centers are in the range 2.250–2.323 Å (Table 2), similar to those found in other pyridine N-donor Ag(I) complexes [12a,14b,16,18] and longer than other reported complexes [3,13b]. The Ag–N_{az} distances are quite a lot longer than the Ag–Npy distances, but are similar to those found in the reported azine bridged Ag complex **2a** [14a] and also longer than another reported Ag complex [14b]. The N–Ag–N angles around the Ag centers are quite dissimilar from one Ag center to

the next (Table 2). The Ag2 and Ag4 centers are bridged by two azine N-atoms of one ligand, but the Ag1 and Ag3 centers are not bridged by the two azine N-atoms of another ligand. Only the Ag1 center is coordinated to one azine nitrogen whereas the large Ag3–N_{az}3 distance (2.778 Å) indicates that there is no bonding due to the strained conformation of the ligand. The large Ag–Ag distances also indicate that there is no argentophilic interaction.

3.1.3. Molecular structure of ***3***

The structure of the cation of **3** is a polymer of stoichiometry $[Ag_3(\mathbf{L_2})_2]^{3+}$, in which each tetrapyridyl azine ligand coordinates three Ag(I) centers (Fig. 5a). All the Ag centers are tetra-coordinated but they are also far from a tetrahedral geometry. Each ligand is bidentate to each Ag center. Each of the Ag1 and Ag2 centers in $[Ag_3(\mathbf{L_2})_2]^{3+}$ has a four coordinate pseudo-tetrahedral or π-type geometry with a coordination sphere consisting of two pyridine N-donors from two ligands and two azine N-donors from two ligands. The Ag3 center in $[Ag_3(\mathbf{L_2})_2]^{3+}$ also has a four coordinate distorted tetrahedral geometry with a coordination sphere consisting of two pyridine N-donors from the same ligand and two other pyridine N-donors from another ligand of another $[Ag_3(\mathbf{L_2})_2]^{3+}$ unit.

The two pyridine rings of the same or different ligands are not co-planar. The dihedral angle (79.63°) of the two pyridine rings which coordinate to Ag1 and Ag2 means that they are almost perpendicular to each other. The dihedral angle of the other two pyridine rings which coordinate to Ag3 is 54.87°. The repetition of the $[Ag_3(\mathbf{L_2})_2]^{3+}$ unit form the linear polynuclear chain. In a closer look, the Ag3 centers helped to form the extended linear chain in the molecule and the linear chains are linked into a two-dimensional (2-D) (Fig. 5b and c) and three-dimensional (3-D) (Fig. 5d) network through C–H···O hydrogen bonding interactions involving pyridine ring protons with perchlorate ions (H···O distance range 2.5–2.68 Å).

4. Conclusions

Four coordination complexes constructed by self assembly of azine based ligands and Ag ions have been structurally characterized. This structural analysis revealed a great difference in the crystal packing due to the influence of the anion symmetry. Such variation in the environment of a complex molecule is termed as 'Chemical Frustration' [9a]. In these complexes, various weak interactions and hydrogen bonding generate 2-D or 3-D networks.

ABSTRACT

A new Eu(II) complex, bis(perchlorato)(bis-pyridino-18-crown)europium(II), has been obtained in the crystalline form by electrolytic reduction. The metal ion is 10-coordinated and its surrounding consists of four macrocycle O atoms, two N ones and four O atoms from perchlorate anions. The compound shows a very broad absorption band, starting gently from 600 nm towards the UV region, and two weak luminescence bands with maxima at 430 and 500 nm. The performed density functional theory (DFT) calculations have shown that the absorption results from mixed f–d, f–s and charge transfer transitions. The possible mechanism of luminescence is also discussed.

1. Introduction

Macrocycles are an important class of ligands in the chemistry of divalent lanthanides because they stabilize to some extent this oxidation state. The Ln(II) complexes that have been investigated extensively feature complexes of crown ethers (with O donors) and cryptands [1,2]. These compounds generally show efficient blue luminescence in solutions and in the solid state. The derivatives of crown ethers with both O and N donors have been devoted less attention and to the best of the authors' knowledge no complexes of Ln(II) with crown ethers containing pyridine rings have been reported. Such a compound could be helpful in gaining insight into some questions relating to the blue emission of divalent europium, namely: (a) the presence of pyridine fragments coordinated to the Eu^{2+} cation would allow the assessment of the impact of the antenna effect on the luminescent properties of the metal centre (such an effect plays an important role in enhancing the luminescent efficiency of trivalent lanthanide complexes [3]), (b) it would be interesting to know the impact of the aromatic π electrons located directly near the Eu^{2+} cation on the spectroscopic properties of the latter. Apart from that, the donor pyridine N atoms are less basic than in azacrown ethers which may result in easier complexation of the ligand under mild (non-anhydrous) conditions (the competition from the hydrogen cations being less severe). Therefore for the present study a ligand of this type, bis-pyridino-18-crown-6 or 3,6,10,13-tetraoxa-1(2,6),8(2,6)-dipyridinacyclotetradecaphan, has been chosen. Generally, only a few examples of metal complexes with this macrocycle or its substituted derivatives have been reported so far; these include a cadmium compound [4], an yttrium and a few lanthanide(III) complexes [5]. According to what has been said above, the purpose of the present work is to investigate the coordination ability of bis-pyridino-18-crown-6 towards Eu(II) and to determine the structure and spectroscopic properties of the obtained compound.

2. Experimental

2.1. Synthesis

2.1.1. 3,6,10,13-Tetraoxa-1(2,6),8(2,6)-dipyridinacyclotetradecaphan

The ligand was obtained according to the method previously described [6]. NaH (0.671 g, 16.8 mmol, 60% in mineral oil) was added at room temperature to a solution of ethylene glycol (0.440 g, 7.11 mmol) in abs. THF (100 ml). The reaction mixture was stirred for 30 min at 23 °C then a solution of 2,6-bis(bromomethyl)pyridine (1.88 g, 7.11 mmol) in abs. THF (100 ml) was added dropwise. After 6 days stirring at 23 °C, H_2O (30 ml) was added to the mixture, the layers were separated and the aqueous layer was extracted with DCM (3 × 30 ml). The combined organic layers were dried over anhydrous $MgSO_4$ and the solvent was removed under reduced pressure. After column chromatography with Al_2O_3 (DCM with a gradient to MeOH) and sublimation (0.14 mbar, 135°C), bis-pyridino-18-crown-6 (126 mg, 0.381 mmol, 11%) was obtained as a colourless crystalline solid. M.p.: 133 °C, Lit.: 147–148 °C; R_f (SiO_2, DCM:MeOH = 1:1) = 0.15–0.44; ^1H NMR (300 MHz, $CDCl_3$): δ = 3.76 (s, 8H), 4.56 (s, 8H), 7.23 (d, J = 7.7 Hz, 4H), 7.61 (t, J = 7.7 Hz, 2H) ppm; $^{13}C\{^1H\}$ NMR

(75 MHz, $CDCl_3$): δ = 69.84 ($4CH_2$), 73.53 ($4CH_2$), 120.40 (4CH), 136.68 (2CH), 157.91 (4C) ppm; IR (ATR): λ^{-1} = 3064 (w), 2956 (m), 2921 (m), 2889 (m), 2852 (m), 2005 (w), 1592 (s), 1579 (m), 1458 (m), 1442 (s), 1369 (m), 1355 (m), 1301 (m), 1258 (m), 1242 (m), 1134 (vs), 1156 (s), 1089 (s), 1027 (s), 986 (m), 881 (m), 838 (m), 802 (s) cm^{-1}.

2.1.2. Bis(perchlorato)(bis-pyridino-18-crown)europium(II)

One hundred milligrams (0.28 mmol) of Eu_2O_3 was dissolved in a small excess of 60% $HClO_4$, evaporated until white fumes appeared, cooled down, and the resulting slurry was dissolved in a few ml of methanol (*caution*!). The resulting solution was placed in the cathode compartment of an electrolyzer provided with a pool Hg cathode and the anode compartment separated from the cathode space with a frit. Then 100 mg (0.30 mmol) of the bis-pyridino-18-crown-6 ligand was added to the solution (in this way the initial solution contained an excess of Eu, which served merely to increase the conductivity). A few drops of perchloric acid diluted with a few ml of methanol was the anolyte. Yellow crystals of the complex formed after approximately 6 h of electrolytic reduction performed at a controlled potential (−1.3 V with respect to the saturated calomel electrode). It was observed that further electrolysis led to redissolution of the complex, probably due to reduction of the pyridine rings.

2.2. X-ray analysis

The appropriate crystal was cut from a larger one, mounted on a Kuma KM4 diffractometer equipped with a CCD counter and measured at 160 K. The structure was solved using Patterson and subsequent difference Fourier maps. The hydrogen atoms were placed in positions calculated from the geometry. The final refinement was anisotropic for all non-H atoms. The computations were performed with SHELXS97 and SHELXL97 programs [7], and the molecular graphic was prepared with DIAMOND [8]. Pertinent details are given in Table 1.

Table 1
Crystal data and structure refinement details

Empirical formula	$C_{18}H_{22}Cl_2EuN_2O_{12}$
Formula weight	681.24
Temperature (K)	160(2)
Wavelength (Å)	0.71073

Data/restraints/parameters	5625/0/316
Goodness-of-fit on F^2	0.953
Final R indices [$I > 2\sigma(I)$]	$R(F)$ = 0.0312, $R_w(F^2)$ = 0.0654
R indices (all data)	$R(F)$ = 0.0505, $R_w(F^2)$ = 0.0765
Largest difference in peak and hole (e Å^{-3})	1.411 and −0.461

2.3. Spectroscopy

The absorption spectrum of the complex was taken on a Cary 500 Scan spectrophotometer at room temperature. The sample was prepared by grinding a small amount of the compound with paraffin oil between two quartz glass plates. The emission spectra of both the complex and the free ligand were recorded at 77 K using a Spectra Pro 750 monochromator, equipped with a Hamamatsu R928 photomultiplier and 1200 l/mm grating blazed at 500 nm. The samples were excited with 320 nm light. The ligand, under these conditions, did not show any emission.

2.4. Theoretical calculations

The electronic structure of the complex molecule was calculated using the density functional approach with the ADF suite of programs [9]. In the first step the geometrical structure was optimized to get acceptable positions of the H atoms, keeping the coordinates of the non-H atoms frozen. The electron density functional used was Perdew–Wang exchange and the correlation functional (PW91 [10]) and the basis was TZ2P+ with the core frozen up to 4d for Eu [denoted hereinafter as TZ2P + (4d), etc.] and TZ2P for the remaining atoms with the core frozen up to 2p for Cl and 1s functions frozen for C, N and O. The scalar relativity was included using the ZORA [11] method, and basis functions scaled to ZORA, supplied with the ADF packet, were used. The second step included freezing of all the coordinates, computing the electronic structure of the molecule with various electron density functionals and simulating the spectra with the supplied time-dependent DFT [12]. The functionals tested were: PW91 [10] and SAOP [13]. The tested combinations of functionals and bases were the following: (**I**) – PW91, TZ2P + (4d) for Eu, TZ2P(2p) for Cl, TZ2P(1s) for C, N, O and TZ2P for H; (**II**) – PW91, TZ2P+ for Eu and TZ2P for the rest; (**III**) – SAOP and the bases like in the preceding variant; (**IV**) – PW91 and QZ4P for all atoms. The relativity treatment was as previously described.

3. Results and discussion

3.1. Structure

The coordination of the Eu^{2+} cation in the present compound follows that found in the bis(perchlorato-*O*,*O*′) (18-crown-6)europium(II) complex [2c], namely two bidentate perchlorate anions occupy the axial positions, and the six equatorial coordination sites are occupied by the donor atoms (4 O and 2 N) of the macrocycle ligand, see Fig. 1. In this way the metal ion is deca-coordinate. The Eu–O_{crown} distances (presented inTable 2) are similar to those

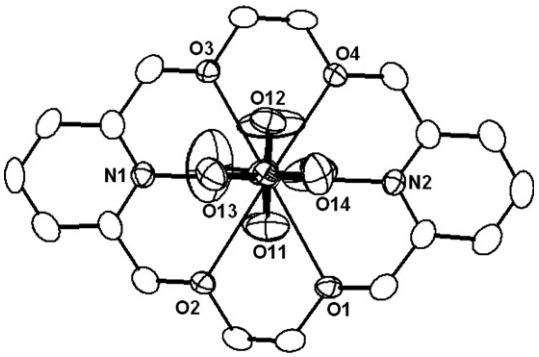

Fig. 1. A view of the complex molecule together with the atom labelling. The Eu and Cl2 atoms are eclipsed by Cl1, and likewise: O21 by O11, O22 by O12, O23 by O14 and O24 by O13.

Table 2

Eu–O22	2.744(4)
Average Eu–$O_{perchlorate}$	2.748(41)

in other complexes of Eu(II) with crown ethers (15-crown-5, benzo-15-crown-5, 18-crown-6, benzo-18-crown-6, 12-crown-4) [2], the latter distances being in the range 2.640(3)–2.760(11) Å. The Eu–$O_{perchlorate}$ bond lengths are generally slightly longer than those observed in the 18-crown-6 complex, which were between 2.628(7) and 2.727(8) Å, average 2.680(50) Å. As Eu–N distances, to the best of the authors' knowledge, have not been reported for Eu(II)–crown ether complexes, it is necessary to invoke other Eu(II) compounds where such bonds are present. Inspection of some carboxylate complexes (ethylenediaminetetraacetates [14], nitrilotriacetates [15] and diethylenetriaminepentaacetate [16]) and bis(triethanolamine)europium diperchlorate [17] reveals that these distances are rather short in the present compound in comparison to those in the former ones, which were in the range 2.725(5)–2.888(6) Å, and this is the most probably brought about by steric reasons. The mutual twisting of the pyridine planes is 36.5° and is similar to that observed in the related light lanthanide(III) complexes [5], 36.9° for Ce and 38.3° for Pr. This suggests that the metal ion utilizes almost the maximum capacity of the macrocycle cavity; for metals with a smaller ionic radius this angle grows to 50.2° in the case of Gd, and 52.4° for Y. The structure is composed only of neutral complex molecules, which means that the crystal network is held together by weak intermolecular forces.

3.2. Spectroscopy

The absorption spectrum is essentially featureless (Fig. 2). The absorption starts to rise gently at approximately 600 nm; as a consequence the spectrum is somewhat different from those recorded for other yellow Eu(II) compounds, diaqua(μ_3-acetato)(acetato-*O*)(acetic acid-*O*)europium(II) [18] and bis(guanidinium) (ethylenediaminetetraacetato)europate(II) [14b], where the growth of the absorption started at 450 and 490 nm, respectively, and was sharper. The peak at 270 nm is due to $\pi \rightarrow \pi^*$ transitions within the pyridine rings.

Introduction of pyridine fragments changes profoundly the luminescent properties of the present complex in comparison with its analogue, bis(perchlorato-*O*,*O*′)(18-crown-6)europium(II) [2c]. First, the emission intensity is practically quenched at room temperature and is weak at 77 K. Second, the spectrum is composed of two rather weak bands (Fig. 3), with maxima at approximately 430 (23 300 cm^{-1}) and 500 nm (20 000 cm^{-1}). The first band lies in the range typical for Eu(II)–crown ether complexes [1,2], whereas the latter is unexpected and distinguishes the present compound from the other Eu(II)–crown ether complexes, where usually one luminescence band (or two closely overlapping bands) is (are) observed.

3.3. Electronic structure

In order to find a plausible explanation of such spectroscopic behaviour, density functional calculations have been undertaken. The following discussion will be based mostly on model **II** (see Section 2.4), unless otherwise stated, and for spin α electrons. The approach with SAOP (model **III**) gave all the virtual orbitals shifted significantly towards higher energies, and in the case of **IV** the interpretation is obscured by large correlations among the basis functions. The outcome from model **I** was practically identical with that of **II**.

The seven 4f orbitals of Eu^{2+} constitute the highest occupied ones and they lie well above the other occupied levels – the difference between the energy of the lowest 4f orbital and the next lower occupied one, which represents non-bonding electrons of oxygen atoms from the perchlorate anions, is 26 100 cm^{-1}. The difference between the lowest and the highest energy of the 4f electrons is 2000 cm^{-1}. The LUMO (located 630 cm^{-1} above the HOMO) and three following states are the empty π^* orbitals of

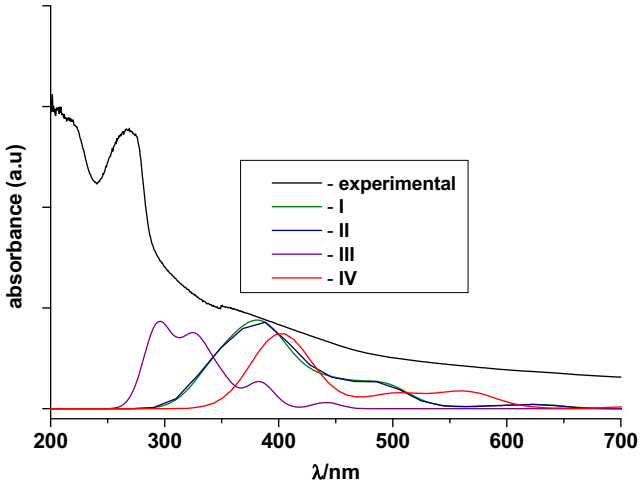

Fig. 2. The experimental and simulated absorption spectra of (bis-pyridino-18-crown)-bis(perchlorato)europium(II). The Roman numerals of the simulated curves refer to the models described in Section 2 (theoretical calculations). Fig. 3. The luminescence spectrum of (bis-pyridino-18-crown)-bis(perchlorato)europium(II); the peaks at the right side come from a Eu(III) impurity.

the pyridine fragments. The next virtual orbital, hereinafter labelled as **A**, 15600 cm^{-1} above the HOMO (22500 cm^{-1} in model **III** and 13100 cm^{-1} in model **IV**), is composed mostly of 1s and 2s functions of hydrogen atoms from the CH_2–O–CH_2CH_2–O–CH_2 fragments. In all the models this orbital had a non-negligible contribution from the 6s and 7s functions of europium. It is perhaps worth noting that analogous functions also appeared in a calculated orbital, 13600 cm^{-1} above the HOMO, in an ytterbium(II) complex with dimethyl oxydiacetate, $[Yb(CH_3OOCCH_2OCH_2COOCH_3)_3]^{2+}$ [19]. The four next levels, labelled as **B**, up to ca. 20500 cm^{-1}, are of a similar type, i.e. they are built up basically from the 1s and 2s functions of H atoms (mostly of the CH_2–O–CH_2CH_2–O–CH_2 fragments). The two upper of these orbitals also have small admixtures of 5,6d functions of Eu and 3s of Cl. The subsequent orbital, at approximately 22100 cm^{-1}, has a remarkable contribution from the 6s function of Eu and from the 3s functions of Cl. In the range of interest (up to 35000 cm^{-1}) there are no pure 5d europium levels; the largest share of this function in a virtual orbital was 57% (24700 cm^{-1} above the HOMO). The energy diagram, where orbitals with significant participation of the metal functions have been singled out, is shown in Fig. 4.

The simulated spectra (computed for the first 150 excitations), shown in Fig. 2, render rather well the gentle rise of absorption. They are basically composed of three groups of excitations, all starting from the 4f orbitals of Eu^{2+}. The first one, ranging from 650 to 550 nm (15400–18200 cm^{-1}), is composed of very weak transitions to the orbital **A**. The second set, from 550 to 450 nm (18200–22200 cm^{-1}), is formed by transitions to the **B** levels. The third group, the most intense, in the range 450–350 nm (22200–28600 cm^{-1}), includes transitions to the ten virtual orbitals above the **B** ones. These transitions are of various natures, including charge transfer excitations to both the ether and the pyridine fragments of the macrocyle, perchlorate anions and those with partial f–d and/or f–s character. Near the shorter wavelength limit of this area excitations from the occupied orbitals in the perchlorate groups to the empty π^* orbitals of the pyridine fragments also begin to appear.

The diagram presented in Fig. 4 allows a possible rationalization of the emission spectrum. It may be noticed that the difference between the energies of the luminescence band maxima, 3200 cm^{-1}, matches rather well the gap between the two higher and the two lower π^* orbitals of the pyridine fragments (3070 cm^{-1} for **I** and **II**, 3720 cm^{-1} for **III** and 3280 for **IV**). Adding 23300 cm^{-1} (the 430 nm emission band) to the energies of the lower π^* orbitals, or 20000 cm^{-1} (the 500 nm emission) to the energies of the higher π^* orbitals, a value of approximately 24000 cm^{-1} will be obtained which is close to the energies of the two orbitals with significant participation of 5d and/or 6,7s functions of europium. It may therefore be presumed that the observed 500 nm emission consists of transitions from one or both of these levels to the two upper π^* orbitals of the pyridine. To illustrate this point the quasi-5d orbital at 24700 cm^{-1} and the highest pyridine π^* one are shown together in Fig. 5. Analogously, two lower π^* levels would be the final states for the emission at 430 nm. It should be noticed, however, that because of the small difference between the LUMO and HOMO and after taking into account possible involvement of the vibrational components of the final state(s) and the limitations of the calculation accuracy, it is also possible that the 430 nm band is the result of the transitions to the 4f levels of Eu. The present data do not unequivocally show whether the former or the latter pathway (or both) are active in this case.

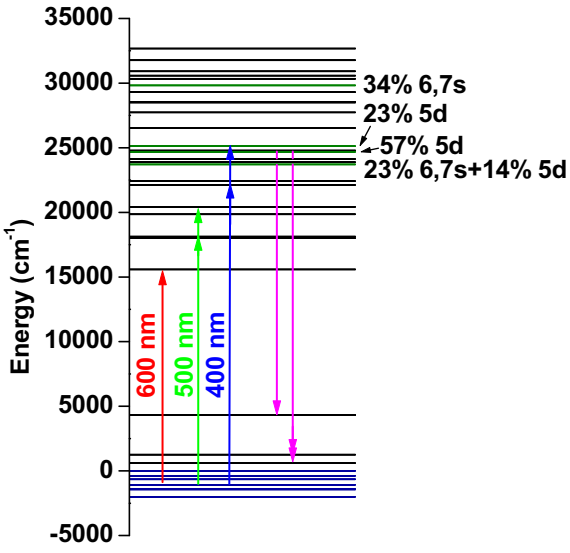

Fig. 4. A scheme of calculated energy levels. The occupied 4f orbitals of Eu are marked in blue and the virtual orbitals with considerable participation of Eu functions – in green. The possible ways of light absorption and emission are shown by red, green, blue and magenta arrows. The energies are given with respect to the HOMO. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

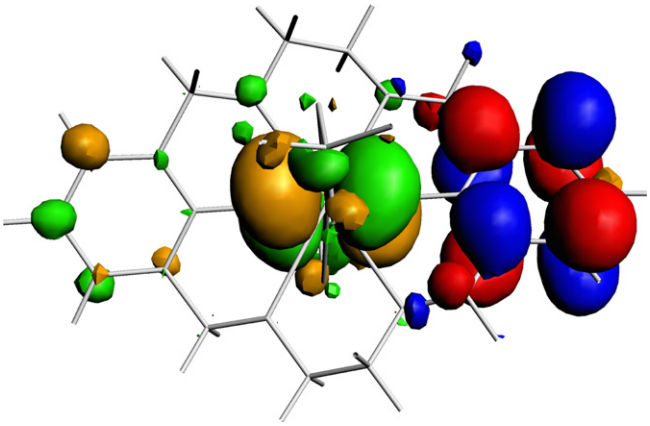

Fig. 5. The highest pyridine-part π^* orbital (blue–red) together with the *quasi*-5d orbital of Eu (green–yellow). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The luminescence mechanisms described above may shed some light on the reasons of the low observed emission intensity. Discharge of the excited state to the π^* levels of the pyridine fragments reduces the intensity of the 5d–4f transition, and radiationless energy transfer deteriorates the efficiency of the 5d → π^* radiative path, which results in an overall decrease of the luminescence intensity.

The Mulliken charges were 1.75 for Eu, 1.78–1.79 for Cl, −0.90 to −0.91 for the ether oxygen atoms, −0.61 to −0.71 for the oxygen atoms in the perchlorate anions, −0.70 in the case of N atoms, 0.76–0.81 for the aliphatic carbon atoms, 0.08–0.28 for the carbon atoms in the pyridine rings, −0.13 to −0.19 for the H atoms in the aliphatic part of the macrocycle and −0.09 to −0.10 for the H atoms that are part of the pyridine fragments.

4. Conclusions

During the electrolytic reduction of a methanolic solution of europium tris(perchlorate) and bis-pyridino-18-crown-6, a decacoordinate complex of Eu(II) with perchlorate anions directly bonded to the metal cation was formed. The absorption spectrum is apparently structureless; this is a consequence of a plethora of various transitions of diverse characters: metal-to ligand charge transfers, f–d and f–s transitions, and also perchlorate–pyridine

excitations, accumulating from 600 nm towards shorter wavelengths. The weak luminescence of the complex is presumably due to the transitions from the *quasi*-5d levels of europium to π^* orbitals in the pyridine rings, as well as to europium 4f orbitals. The presence of the pyridine conjugated π electron system in the vicinity of Eu^{2+} exerts a deleterious impact on the luminescence efficiency of the complex.

Acknowledgements

The authors would like to thank Michael Rössle for the synthesis of the macrocycle, Ing. Halina Trelińska-Nowak for recording the absorption spectra, and Dr. Paula Gawryszewska and Dr. Jerzy Sokolnicki for the luminescence spectra. The ADF calculations have been carried out at the Wrocław Centre for Networking and Supercomputing (http://www.wcss.wroc.pl), grant No. 58.

Appendix A. Supplementary data

CCDC 676612 contains the supplementary crystallographic data for bis(perchlorato)(bis-pyridino-18-crown)europium(II). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Synthesis, crystal engineering, and magnetic properties of an anionic 4-terpyridone (L) based three-dimensional supramolecule, $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]\cdot 2[Cu^{II}(L)(N_3)(H_2O)]\cdot 6H_2O$ (**1**), have been described in the present investigation. The title compound crystallizes in the monoclinic space group *C2/c* with the following unit cell parameters: $a = 27.803(7)$ Å, $b = 14.361(4)$ Å, $c = 16.071(4)$ Å, $\beta = 99.09(2)°$, and $Z = 4$. In this compound, one dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit is cocrystallized with two mononuclear $[Cu^{II}(L)(N_3)(H_2O)]$ units. In both the dinuclear and mononuclear species, 4-terpyridone chelates to the metal centers in its anionic form. The coordination environment of the metal ions is distorted square pyramidal. Eight O–H···O type strong hydrogen bonds involving the oxygen of anionic 4-terpyridone ligand and water molecules link the components of **1** into a three-dimensional framework. Excluding the atoms except the water molecules and ligand oxygens, the topology is a two-dimensional network. The mononuclear $[Cu^{II}(L)(N_3)(H_2O)]$ moiety is appended from this sheet, while the neighboring sheets are interlinked by the dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit to add the third dimension of the overall three-dimensional structure of the title compound.

1. Introduction

The successful development of crystal engineering strategies relies first on developing, understanding, and rationalizating intermolecular interactions in the context of crystal packing, followed by the subsequent utilization and exploitation of this understanding in the design of new solids with predictable structural properties [1]. Several types of intermolecular interactions and topologies resulted therein have been explored in recent years.

4-Terpyridone is known to coordinate to the metal ions in its enolic form (LH) [2]. With an expectation that H–O–pyridine–M–pyridine–O–H fragment in $[M(LH)_2]^{n+}$ species may act as hydrogen bond donor/acceptor and thus may be a potential supramolecular synthon, an enolic 4-terpyridone based nickel(II) dicyanamide supramolecule, $[Ni^{II}(LH)_2](dicyanamide)_2\cdot 2H_2O$ has been previously reported [2b] and therefore it is expected that new compounds derived from 4-terpyridone will generate interesting hydrogen-bonded topologies. If the metal-4-terpyridone fragments are bridged by azide ligands, the derived compound will also be interesting for its magnetic properties. It may be mentioned that azide bridged coordination compounds of paramagnetic metal ions have been one of the most widely studied systems in molecular magnetism [3–8]. Several magnetostructural correlations, both experimental [3–6] and theoretical [6,7], in azide-bridged systems have been developed and the derived ideas have been successfully utilized for the construction of multidimensional systems to exhibit long-range magnetic ordering [3a,8].

To explore further the possibility of 4-terpyridone containing metal complexes to develop extended architecture and to enlighten the magnetic properties of azide-bridged system, we describe here the synthesis, crystal engineering, and magnetic properties of an anionic 4-terpyridone (L) based three-dimensional supramolecule $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]\cdot 2[Cu^{II}(L)(N_3)(H_2O)]\cdot 6H_2O$ (**1**) which contains cocrystallized dinuclear and mononuclear complex units.

2. Experimental

2.1. Materials and methods

All the reagents and solvents were purchased from commercial sources and used as received. Elemental (C, H, and N) analyses were performed on a Perkin–Elmer 2400 II analyzer. IR spectra were recorded in the region 400–4000 cm^{-1} on a Perkin–Elmer

RXIFT spectrophotometer with samples as KBr disks. Variable-temperature (2–300 K) magnetic susceptibility measurements were carried out with a Quantum Design MPMS SQUID magnetometer. Diamagnetic corrections were estimated from the Pascal constants.

2.2. Synthesis

An aqueous solution (10 mL) containing copper(II) nitrate trihydrate (0.24 g, 1 mmol) and sodium azide (0.26 g, 4 mmol) was dropwise added with stirring to an ethanol solution (30 mL) containing 4-terpyridone (0.25 g, 1 mmol). After a few minutes a green precipitate started to deposit. The stirring was continued for an additional period of 2 h. Then the green compound was collected by filtration and washed with ethanol. Recrystallization on diffusing ethanol to dimethylformamide solution of the green compound yielded green crystalline compound containing diffractable single crystals. Yield: 0.137 g (35%). *Anal.* Calc. for $C_{60}H_{56}N_{24}O_{12}Cu_4$: C, 46.21; H, 3.62; N, 21.56. Found: C, 46.30; H, 3.53; N, 21.45%. IR (KBr/cm^{-1}): water 3380 br; azide 2102 sh, 2071 sh, 2051 s.

2.3. Determination of crystal structure

The crystal data are summarized in Table 1. Diffraction data were collected on a Siemens P4 diffractometer in the ω–2ϑ scan mode using graphite-monochromated Mo Kα radiation having $\lambda = 0.71073$ Å. Three standard reflections were periodically monitored and showed no significant variation over data collection. The accurate unit cells were obtained by means of least-squares fittings of 25 centered reflections. The intensity data were corrected for Lorentz and polarization effects, and multi-scan absorption correction was made. A total of 5719 reflections were collected in the range $2\theta = 3.96$–$50.04°$ with $0 \leqslant h \leqslant 33$, $0 \leqslant k \leqslant 17$, and $-19 \leqslant l \leqslant 18$, of which 5597 independent reflections ($R_{int} = 0.0329$) were used for structure determinations. The structures were solved by direct and Fourier methods and refined by full-matrix least-squares methods based on F^2 with the programs SHELXS-97 and SHELXL-97 [9]. The final least-squares refinements (R_1) based on $I > 2\sigma(I)$ converged to 0.0470.

3. Results and discussion

3.1. Description of structure

The asymmetric unit of the structure of $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2] \cdot 2[Cu^{II}(L)(N_3)(H_2O)] \cdot 6H_2O$ (**1**) contains one and a half of a dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit, one mononuclear $[Cu^{II}(L)(N_3)(\text{-}H_2O)]$ moiety and three water molecules ($H_2O(4)$, $H_2O(5)$, and $H_2O(6)$) as solvent of crystallization. As one and a half of the whole molecule are symmetry related to the other half, the composition of the title compound is $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2] \cdot 2[Cu^{II}(L)(N_3)(H_2O)] \cdot 6H_2O$ (**1**) consisting of a dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit in which two metal centers are bridged by two end-on azide ligand, two mononuclear $[Cu^{II}(L)(N_3)(H_2O)]$ moieties in which azide is a monodentate terminal ligand, and six water molecules as solvent of crystallization. The dinuclear and mononuclear units are shown in Fig. 1, while selected bond lengths and angles of the coordination environment of the metal centers are listed in Table 2. The copper(II) center in the bis(azide)-bridged unit is pentacoordinated; the remaining three coordination positions are occupied by three nitrogens of 4-terpyridone. The metal center in the mononuclear $[Cu^{II}(L)(N_3)(H_2O)]$ unit is also pentacoordinated with a terminal azide ligand, three nitrogens of 4-terpyridone and a water molecule. The composition of both the dinuclear and mononuclear moieties indicate that 4-terpyridone is present in the title compound as monoanionic form resulted due to the deprotonation of the secondary amine group in the reaction mixture.

The stereochemistry of the metal ions in both the dinuclear and mononuclear units are distorted square pyramidal. The τ ($(\beta - \alpha)/60$, where β and α are the largest and second largest bond angles, respectively) values in the pentacoordinated environment of Cu(1) and Cu(2) are 0.27 and 0.09, respectively, indicating that the geometry around both the metal centers are distorted square pyramidal and the extent of distortion is much greater for Cu(1) [10]. In the case of the copper(II) ion (Cu(1)) in the dinuclear unit, three nitrogens (N(1), N(2), N(3)) of anionic 4-terpyridone and one nitrogen (N(4)) of a bridging azide ligand define the basal plane, while the apical position is occupied by a nitrogen (N(4A)) of the second bridging azide. For the metal center (Cu(2)) in the mononuclear unit, the basal plane is defined by three nitrogens (N(7), N(8), and N(9)) of anionic 4-terpyridone and a nitrogen (N(10)) of the terminal azide group, while the water oxygen O(3) occupies the apical position. The Cu–N distances involving anionic 4-terpyridone fall into two distinct ranges; those (Cu(1)–N(2) = 1.910(3) Å and Cu(2)–N(8) = 1.919(3) Å) involving the central rings are shorter than the bond lengths (Cu(1)–N(1) = 2.027(4) Å, Cu(1)–N(3) = 2.016(4) Å, Cu(2)–N(7) = 2.048(4) Å, and Cu(2)–N(9) = 2.057(4) Å) involving the terminal rings. The fourth bond length (Cu(1)–N(4) = 1.935(3) Å and Cu(2)–N(10) = 1.955(4) Å) in the basal plane with the bridging azide (for Cu(1)) or terminal azide (for Cu(2)) lies in the range of the short and long bond distances involving anionic 4-terpyridone. In contrast, as expected due to Jahn–Teller distortion, the bond distance (Cu(1)–N(4A) = 2.552(4) Å and Cu(2)–O(3) = 2.242(4) Å) involving the apical ligand is much longer. In addition to the differences in the metal–ligand bond distances, the distortion of the coordination environment can also be evidenced from the *transoid* angles (158.92(13)° and 174.97(16)° for Cu(1); 157.91(14)° and 163.28(18)° for Cu(2)) in the basal plane as well as from the wide range of the *cisoid* angles (79.68(14)–103.64(15)° for Cu(1); 79.38(15)–103.36(19)° for Cu(2)). The metal centers in the dinuclear unit are separated by 3.2679(13) Å with Cu–N–Cu bridge angles of 92.44(15)°.

Eight O–H···O type hydrogen bonds involving oxygens (O(1) and O(2)) of anionic 4-terpyridone ligand and water molecules ($H_2O(3)$, $H_2O(4)$, $H_2O(5)$, and $H_2O(6)$) link the components of **1** into a three-dimensional framework (*vide infra*). As summarized in Table 3, the donor···acceptor contacts of the hydrogen bonds lie in the range 2.68–2.86 Å indicating that the hydrogen bonds can be considered as strong. The understanding of the hydrogen bonding interactions and analyses of the topology resulted therein can be better understood as fragments. As shown down the crystallographic *a* axis in Fig. 2, the topology excluding the atoms except

Symmetry codes: see Fig. 2.

the water molecules and ligand oxygens is a two-dimensional network. It is clear from this figure that the coordinated water molecule ($H_2O(3)$) acts as a double donor, while three solvated water molecules ($H_2O(4)$, $H_2O(5)$, and $H_2O(6)$) behaves as double donor and single acceptor. Regarding the ligand oxygens O(1) and O(2), while the former behaves as a triple acceptor, the later acts as a double acceptor. The two-dimensional sheet can be considered (Fig. 2) as the repetition of fused one 4-member and two 5-member rings of hydrogen-bonded oxygen centers.

Six oxygen centers are the members of the above-mentioned two-dimensional sheet. Two of them, O(3) and O(2), are parts of the mononuclear complex unit $[Cu^{II}(L)(N_3)(H_2O)]$. Clearly, the mononuclear $[Cu^{II}(L)(N_3)(H_2O)]$ unit is appended from the sheet

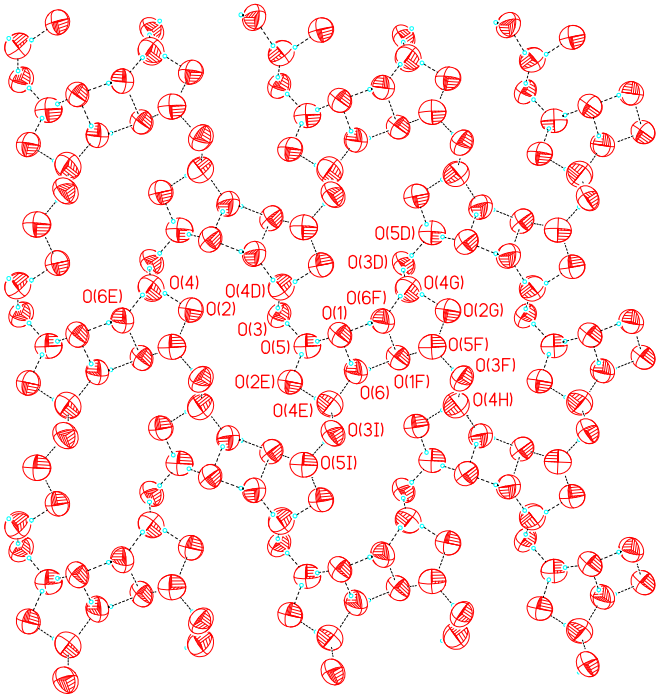

Fig. 2. Perspective view down the crystallographic *a* axis to demonstrate the two-dimensional sheet formed due to the hydrogen bonds involving ligand oxygens (O(1) and O(2)) and water molecules ($H_2O(3)$, $H_2O(4)$, $H_2O(5)$, and $H_2O(6)$). All other atoms are omitted for clarity. Symmetry codes: (D) $x, 1 - y, 0.5 + z$; (E) $0.5 - x, 1.5 - y, -z$; (F) $0.5 - x, 1.5 - y, 1 - z$; (G) $x, y, 1 + z$; (H) $0.5 - x, 1.5 - y, 0.5 - z$; (I) $0.5 - x, 0.5 + y, 0.5 - z$.

(Fig. 3). Another member, O(1), is part of the bis(azide)-bridged dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit. While ligand oxygen O(1) is one end of the dinuclear unit, the symmetry related ligand oxygen O(1A) is the other end of the dinuclear unit (Fig. 1). Therefore, two sheets in which O(1) and O(1A) are members, respectively, may be considered as interlinked by the dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit to result in the third dimension of the structure (Fig. 3). An extended view down the crystallographic *c* axis of the three-dimensional framework containing two-dimensional sheets interlinked by the dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit is shown in Fig. 3.

3.2. Magnetic properties

Variable-temperature (2–300 K) magnetic behavior of the title compound is shown in Fig. 4 in the form of $\chi_M T$ versus T plots. The $\chi_M T$ value at 300 K is 1.65 $cm^3\ mol^{-1}$ K, which is slightly greater than the spin-only $\chi_M T$ value of four Cu^{II} ions with $g = 2$. On lowering of temperatures, $\chi_M T$ increases to 1.85 $cm^3\ mol^{-1}$ K at 15 K. On further lowering of temperatures, $\chi_M T$ diminishes very rapidly to 1.65 $cm^3\ mol^{-1}$ K at 2 K. The profile indicates that there exists ferromagnetic interaction in this molecule. The interaction between dinuclear and mononuclear units in this molecule should be small because the metal centers in two types of units are separated as Cu(dinuclear)–terpyridone···water–Cu(mononuclear) (O(1)···O(5)···O(3) part in Fig. 2) or Cu(dinuclear)–terpyridone···terpyridone–Cu(mononuclear) (O(1)···O(5)···O(2E) part in Fig. 2). Therefore, the two mononuclear copper(II) moieties should only influence the $\chi_M T$ values as a known amount of paramagnetic impurity. Considering molecular field approximation (zJ') for the possible weak dinuclear···mononuclear interaction and the same value for the magnetic moment (μ_{Cu}) of the copper(II) centers in the mononuclear fragments, the theoretical expression for the molar magnetic susceptibility (χ_M) of a system having one exchange-coupled dicopper(II) and two mononuclear copper(II) moieties can be derived as [11].

$$\chi_M = \frac{\chi^1_M}{1 - 2zJ'\chi^1_M/N\beta^2g^2} \tag{1}$$

where

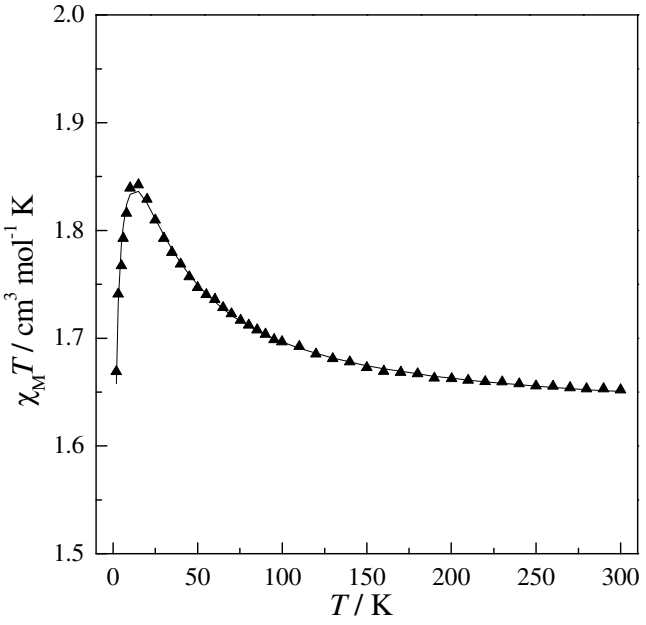

Fig. 4. $\chi_M T$ versus T plots for **1**. The solid lines represent the simulated curves.

$$\chi^1_M = \frac{7.997\chi_D T + 2\mu^2_{Cu}}{7.997T}$$

with

$$\chi_D = \frac{N\beta^2g^2}{kT}\frac{2e^{2J/kT}}{1 + 3e^{2J/kT}}$$

Least-squares fitting of the experimental data with Eq. (1) leads to $J = 15.0\ cm^{-1}$, $zJ' = -0.082\ cm^{-1}$, $g = 2.06$, and $\mu_{Cu} = 1.82$ BM; the agreement factor (R) defined as $[\sum\{(\chi_M T')_{obs} - (\chi_M T')_{calc}\}^2 / \sum(\chi_M T')^2_{obs}]$ is 2.85×10^{-3}. It may be mentioned that on fixing $\mu_{Cu} = 1.73$ BM simulation converges with $J = 15.0\ cm^{-1}$, $zJ' = -0.10\ cm^{-1}$, $g = 2.15$, and $R = 2.85 \times 10^{-3}$. However, in this case little deviation occurs in the temperature range 300–150 K (Fig. S1).

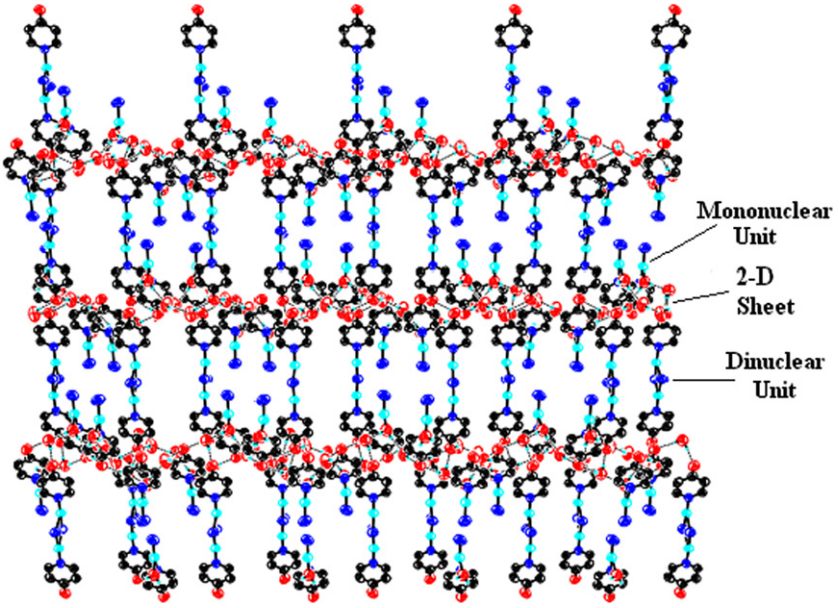

Fig. 3. Perspective view down the crystallographic *c* axis to demonstrate the interlinking of the two-dimensional oxygen sheets in Fig. 2 by the dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit to result in the creation of overall three-dimensional architecture in **1**. Terminal rings of anionic 4-terpyridone, N(5), N(6), N(11), and N(12) are omitted for clarity.

Magnetic properties of azide-bridged dicopper(II) systems have been extensively studied, both experimentally and theoretically [3a–5,7a,7c]. It has been realized that end-to-end (EE)-bridged and end-on (EO)-bridged compounds exhibit antiferromagnetic and ferromagnetic interaction, respectively, [3a–5]. According to established magneto-structural correlations for the EO-bridged dicopper(II) systems having both the bridging azide nitrogens in equatorial positions, the extent of ferromagnetic interaction depends on Cu–N–Cu bridge angle and Cu–N distance [7a,7c]. As the angle decreases below ca. 105°, the interaction becomes more and more ferromagnetic. To be mentioned that as the magnetic orbitals for copper(II) is $d_{x^2-y^2}$, there arises significant extent of spin density in the equatorial sites when the two coordinated azide nitrogens occupy equatorial positions resulting strong ferromagnetic interaction; $J = 85\ cm^{-1}$ and $52\ cm^{-1}$ have been reported for two such dicopper(II) compounds [4a,4b]. In contrast, as the two bridging azide ligands occupy axial and equatorial positions in the title compound, the magnetic orbitals are directed along only one azide moiety. Again, the axial bond length (2.552(4) Å) becomes much longer than the equatorial bond distance (1.935(3) Å). These result in high spin density in the equatorial position and low spin density in the axial position. Therefore, although the title compound displays low value of Cu–N–Cu bridge angle (92.44(15)°), it exhibits weak ferromagnetic interaction ($J = 15\ cm^{-1}$). It may be mentioned that similar weak ferromagnetic interaction have been observed previously in related compounds [5].

4. Conclusions

The synthesis, crystal engineering, and magnetic properties of an anionic 4-terpyridone (L) based three-dimensional supramolecule, $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]\cdot 2[Cu^{II}(L)(N_3)(H_2O)]\cdot 6H_2O$ (**1**), have been described in the present investigation. An important aspect of the title compound is that it contains cocrystallized and self-assembled dinuclear and mononuclear metal complexes. It is an important addition in the family containing a few examples of cocrystals of metal complexes [11,12]. In contrast to the previously reported supramolecule $[Ni^{II}(LH)_2](dicyanamide)_2\cdot 2H_2O$ [2b] which contains neutral and enolic 4-terpyridone, the presence of anionic 4-terpyrodone is another interesting aspect of the present investigation. Again, O–pyridine–M–$(\mu\text{-}N_3)_2$–pyridine–O and O–pyridine–M moieties in the title compound have been found as potential supramolecular synthon. Regarding the ability to create a multidimensional assembly, the O–pyridine–M–$(\mu\text{-}N_3)_2$–pyridine–O moiety (as in **1**) can be considered as similar to H–O–pyridine–M–pyridine–O–H moiety (as in $[M(LH)_2]^{2+}$) and 4,4′-bipyridine or 4,4′-bipyridine-*N*,*N*′-dioxide [1e,2b,13]; Finally, two-dimensional hydrogen bonded sheet created due to the interactions involving oxygen centers of anionic 4-terpyridone and water molecules in the title compound may be considered as an important example in the area of supramolecular chemistry and crystal engineering. Moreover, the title compound is an addition in the family of end-on azide-bridged compounds which exhibit weak ferromagnetic interaction due to the axial–equatorial occupation.

ABSTRACT

A novel family of the general type *cis*-[Ru^{II}(dppe)LCl_2] {L = $C_6H_5N{=}NC(COCH_3){=}NAr$, Ar = 2,4,6-trimethylphenyl (L_1), 2,5-dimethylphenyl (L_2), 4-tolyl (L_3), phenyl (L_4), 4-methoxyphenyl (L_5), 4-chlorophenyl (L_6), 4-nitrophenyl (L_7), 2,5-dichlorophenyl (L_8); dppe = $Ph_2P(CH_2)_2PPh_2$} has been synthesized. These complexes have been characterized through analytical, spectroscopic (IR, UV–Vis, and NMR) and electrochemical (cyclic voltammetry) techniques. In addition, complex **4** (where L = L_4) has been further characterized by X-ray diffraction analysis. Crystallographic, electrochemical and electronic spectral data are all consistent with the azomethine ligands possessing strong π-acceptor properties. These π-acceptor properties can be "tuned" by a judicious choice of substituent on the azomethine ligand.

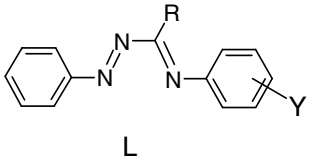
1. Introduction

Ruthenium(II) complexes with heterocyclic N-donor bidentate ligands such as 2,2′-bipyridine (bpy) and its dervatives are of interest because of their fascinating electron-transfer, photochemical and catalytic properties [1,2]. The metal-to-ligand charge-transfer properties of these complexes have been extensively studied by UV–Vis absorption and electrochemical investigations [3]. Correlations have been found between charge transfer (CT) energies and the difference between ligand and ruthenium couples [4]. An arylazoheterocyclic ligand which contains an imine group in a heterocyclic backbone with a pendant azo group such as 2-(arylazo)pyridine (aap) coordinates to a metal ion as an azoimine (–N=N–C=N–) bidentate ligand [5,6]. This type of ligand is a strong π-acceptor, stronger than 2,2′-bipyridine and other N-donor heterocyclic ligands, and stabilizes the lower oxidation states of ruthenium [7,8]. Because of this interesting property, we have developed several arylamidrazone ligands (L) [9,10].



L

Ru(II) complexes containing tertiary phosphines have been extensively studied from a synthetic viewpoint, and their performance as catalysts are well-known [11]. More recently, there has been an increased interest in mixed-ligand ruthenium(II) complexes containing both soft P donor atoms and hard N-containing ligands. This interest is a result of the unique electronic properties that this combination of ligands is able to transmit to the metal center [12–14].

With the aim of contributing to the understanding of how geometric and electronic factors, imposed by a combination of mixed ligands (N and P types), influence the electronic properties of the metal center, we have prepared a family of *cis*-[Ru(L)(dppe)Cl_2] complexes bearing the azoimine ligands L and the P-bidentate bis(1,2-diphenylphosphino)ethane (dppe) ligand. Changing the substituents (Y) on the ligand L is expected to vary the π-acceptor properties on these bidentate ligands. Consequently, this will also "tune" the electronic properties of the ruthenium and

doi:10.1016/j.poly.2008.05.026

consequently the energy of the MLCT bands. The spectral studies, redox properties and single crystal X-ray structure (for complex **4**) of the newly synthesized family will be described in this work.

2. Experimental

2.1. Materials

The reagents: aniline derivatives, ruthenium trichloride hydrate, bis(diphenylphosphino)ethane, lithium chloride and solvents (reagent grade) were purchased from Aldrich and were used as received. Tetrabutylammonium hexafluorophosphate (TBAH), purchased from Aldrich, was recrystallized twice from 1:1 ethanol/water solution and then vacuum dried at 110 °C. Hydrazonyl chlorides were prepared according to the reported procedures [14]. The synthesis and the physical characterization of the ligands L_3, L_4, L_5,L_6 and L_7 have been described previously [9].

2.2. Arylamidrazones (L): general procedure

The arylamidrazones (L) were synthesized by refluxing 20 mmol of arylamine, triethylamine (2.4 g, 24 mmol) and (3.9 g, 20 mmol) of hydrazonyl chloride in 5.0 mL ethanol for 2 h. Condensing the solution followed by cooling produced a yellow solid which was recrystallized from ethanol.

2.2.1. 1-(2,4,6-Trimethylphenylimino)-1-(phenylhydrazono)-propan-2-one (L_1)

Yield (3.2 g, 54%). *Anal. Calc. for* $C_{18}H_{19}N_3O$: C, 73.70; H, 6.53; N, 14.32. Found: C,73.42; H, 6.50; N, 14.11%. *UV–Vis in acetonitrile:* λ_{max} (ε_{max}/M^{-1} cm^{-1}): 368 (8.09×10^4), 276 (4.69×10^4), 254 (6.24×10^4). IR (cm^{-1}): ν(N=N) 1479, ν(C=N) 1599, ν(C=O) 1674. ^{1}H NMR ($CDCl_3$, δ ppm): 6.62 (s, 1H, H3), 6.67 (d, 2H, H11, H7), 6.8 (t, 1H, H9), 7.05 (s, 1H, H5), 7.15 (t, 2H, H10, H8), 2.57 (3H, s, $COCH_3$), 2.30 (s, 3H, CH_3 position 4), 2.15 (s, 6H, CH_3 positions 2 and 6). M.p.: 144–146 °C.

2.2.2. 1-(2,5-Dimethylphenylimino)-1-(phenylhydrazono)-propan-2-one (L_2)

Yield (3.2 g, 58%). *Anal. Calc. for* $C_{17}H_{17}N_3O$: C, 73.10; H, 6.13; N, 15.04. Found. C, 73.41; H, 6.03; N, 15.19%. *UV–Vis in acetonitrile:* λ_{max} (ε_{max}/M^{-1} cm^{-1}): 380 (8.83×10^4), 284 (5.24×10^4), 214 (6.90×10^4). IR (cm^{-1}): ν(N=N) 1507, ν(C=N) 1578, ν(C=O) 1665. ^{1}H NMR ($CDCl_3$, δ ppm): 7.26 (d, 2H, H11, H7), 7.06 (t, 2H, H10, H8), 6.96 (t, 1H, H9), 6.95 (d, 1H, H4), 6.76 (d, 1H, H3), 6.50 (s, 1H, H6), 2.62 (s, 3H, $COCH_3$), 2.28 (s, 3H, CH_3 position 5), 2.19 (s, 3H, CH_3 position 2). M.p.: 114–116 °C.

2.2.3. 1-(2,5-Dichlorophenylimino)-1-(phenylhydrazono)-propan-2-one (L_8)

Yield (3.9 g, 61%). *Anal.* Calc. for $C_{15}H_{11}N_3OCl_2$: C, 56.27; H, 3.46; N, 13.12. Found: C, 56.40; H, 3.48; N, 13.24%. UV–Vis in acetonitrile: λ_{max} (ε_{max}/M^{-1} cm^{-1}): 380 (9.01×10^4), 297 (5.38×10^4), 245 (7.02×10^4). IR (cm^{-1}): ν(N=N) 1493, ν(C=N) 1590, ν(C=O) 1652. ^{1}H NMR (in $CDCl_3$, δ ppm): 7.26 (d, 2H, H11, H7), 7.06 (t, 2H, H10, H8), 6.95 (d, 1H, H4), 6.90 (t, 1H, H9), 6.76 (d, 1H, H3), 6.50 (s, 1H, H6), 2.62 (s, 3H, $COCH_3$). M.p.: 153–155 °C.

2.3. General procedure for the syntheses of the cis-[Ru(dppe)(L)Cl_2] complexes

Ruthenium trichloride. trihydrate (0.26 g, 1.0 mmol) and (1.0 mmol) of (L) were dissolved in 100 mL of absolute ethanol under argon. After refluxing for 1 h, 1.0 mmol of bis(diphenylphosphino)ethane (dppe) was added to the solution. The reaction was heated for an additional 2 h, followed by the addition of excess LiCl (0.50 g, 11.8 mmol). After allowing the reaction mixture to reflux for an additional 1 h, the solvent was then removed by rotary evaporator. The crude product was dissolved in dichloromethane, filtered and washed with water to remove the unreacted ruthenium trichloride and lithium chloride. The filtrate was reduced to 20 mL and purified by chromatography (50×3 cm) on alumina grade (III). The first pale yellow band, thought to be the azomethine ligand (L) was eluted with hexane. Acetone was used to elute the second dark-red band of the product. The complex was recrystallized easily as dark red platelets from a slowly evaporating solution of dichloromethane.

2.3.1. cis-[Ru(dppe)(L_1)Cl_2] CH_2Cl_2 (**1**)

Yield (0.40 g, 47%). *Anal. Calc. for* $C_{25}H_{22}N_6O_3Cl_2Ru \cdot CH_2Cl_2$: C, 58.98; H, 4.89; N, 4.64%. Found: C, 58.78; H, 4.78; N, 4.75%. *UV–Vis in acetonitrile:* λ_{max} (ε_{max}/M^{-1} cm^{-1}): 378 (4.562×10^3), 516 (5.642×10^3), 802 (1.83×10^3). IR (cm^{-1}): ν(N=N) 1434, ν(C=N) 1536, ν(C=O) 1711.^{1}H NMR ($CDCl_3$, δ ppm): 2.2 (s, 6H, CH_3 position 2 and 6), 2.47 (s, 3H, CH_3 position 4), 2.53 (m, 2H, PCH_2), 2.76 (s, 3H, $COCH_3$), 3.02 (m, 2H, PCH_2), 6.11 (s, 2H, H3), 6.21 (s, 2H, H5), 7.68 (t, 2H, H8, H10), 6.81 (t, 1H, H9), 6.88 (m, 6H, PPh_2), 7.15 (m, 8H, PPh_2), 7.33 (m, 6H, PPh_2), 7.56 (d, 2H, H11, H7). ^{31}P NMR ($CDCl_3$, δ ppm): 41.36 (d), 35.60 (d).

2.3.2. cis-[Ru(dppe)(L_2)Cl_2] · H_2O (**2**)

Yield (0.34 g, 40%). *Anal. Calc. for* $C_{43}H_{41}Cl_2N_3OP_2Ru \cdot H_2O$: C, 59.52; H, 4.99; N, 4.84. Found: C, 59.77; H, 4.77; N, 4.47%. *UV–Vis in acetonitrile:* λ_{max} (ε_{max}/M^{-1} cm^{-1}): 362 (6.688×10^3), 512 (5.146×10^3), 800 (2.50×10^2). IR (cm^{-1}): ν(N=N) 1429, ν(C=N) 1536, ν(C=O) 1711. ^{1}H NMR ($CDCl_3$, δ ppm): 2.20 (s, 3H, CH_3 position 2), 2.47 (s, 3H, CH_3 position 5), 2.53 (m, 2H, PCH_2), 2.76 (s, 3H, $COCH_3$). 3.02 (m, 2H, PCH_2), 6.11 (s, 1H, H6), 6.44 (d, 2H, H3), 6.50 (s, 1H, H4), 6.82 (t, 1H, H9), 6.88 (m, 6H, PPh_2), 7.15 (m, 8H, PPh_2), 7.33 (m, 6H, PPh_2), 7.56 (d, 2H, H10, H8), 7.68 (t, 2H, H11, H7). ^{31}P NMR ($CDCl_3$, δ ppm): 42.03 (d), 36.08 (d).

2.3.3. cis-[Ru(dppe)(L_3)Cl_2] · H_2O (**3**)

Yield (0.35 g, 42%). *Anal. Calc. for* $C_{42}H_{39}Cl_2N_3OP_2Ru \cdot H_2O$: C, 59.09; H, 4.84; N, 4.92. Found: C, 59.41; H, 5.18; N, 4.51%. *UV–Vis in acetonitrile:* λ_{max} (ε_{max}/ M^{-1} cm^{-1}): 374 (7.449×10^3), 506 (6.55×10^3), 804 (3.12×10^2). IR (cm^{-1}): ν(N=N) 1434, ν(C=N) 1552., ν(C=O) 1715. ^{1}H NMR (in $CDCl_3$, δ ppm): 2.26 (s, 3H,CH_3, $COCH_3$), 2.53 (m, 2H, PCH_2), 2.95 (m, 2H, PCH_2), 6.42 (d, 2H, H3, H5), 6.49 (d, 2H, H2, H6), 6.70 (t, 1H, H9), 6.73 (m, 2H, PPh_2), 6.93 (m, 6H, PPh_2), 7.17 (m, 6H, PPh_2), 7.34 (m, 6H, PPh_2), 7.58 (t, 2H, H11, H7), 7.67 (t, 2H, H10, H8), ^{31}P NMR ($CDCl_3$, δ ppm): 41.33 (d), 35.61 (d).

2.3.4. cis-[Ru(dppe)(L_4)Cl_2] (**4**)

Yield (0.44 g, 53%). *Anal. Calc. for* $C_{41}H_{37}Cl_2N_3OP_2Ru$: C, 59.93; H, 4.54; N, 5.11. 2.4. Instrumentation

Cyclic voltammetry studies were performed in 99.8% anhydrous acetonitrile (Aldrich, HPLC grade) using a BAS CV-27W voltammetric analyzer and plotted on a BAS XY recorder. Three electrodes were utilized in this system, two platinum-disk working and counter (auxiliary) electrodes (BAS, 1.6-mm diameter), and a silver wire pseudo-reference electrode with ferrocene (0.665 V versus NHE) as an internal reference [15]. To control the temperature, a Haake D8-G refrigerated bath and circulator was used to maintain the cell temperature at 25.0 ± 0.1 °C. Tetrabutylammonium hexafluorophosphate (0.1 M) was twice recrystallized and vacuum dried at 120 °C, and used as the supporting electrolyte. Spectroscopic data were obtained using Cary 5 spectrophotometer. Spectroelectrochemistry for complex **4** was performed using an OTTLE (Optically Transparent Thin Layer Electrochemistry) cell [16]. The cell had interior dimensions of roughly 1 × 2 cm with a path length of 0.2 cm and was fitted with an Ag/AgCl reference electrode. ITO (indium–tin oxide) coated glass served as working and counters electrodes and was purchased from Delta-Technologies. Spectra were obtained on Cary 5 spectrophotometer versus appropriate background of solvent and electrolyte at a scan rate of 1800 nm/min. The potential was controlled by the same BAS CV-27 which was used for cyclic voltammetry. At any given potential, the system was allowed to come to equilibrium ($i \approx 0$ μA) before the spectrum was taken. IR spectra were measured using a FT-IR JASCO model 420. Nuclear magnetic resonances (^{1}H and ^{31}P NMR) spectra were measured on a Bruker-Avance 400 MHz spectrometer at 400 MHz and 161.3 MHz, respectively. All chemical shifts are reported in ppm downfield of TMS (^{1}H) or 85% phosphoric acid (^{31}P) and referenced using the chemical shifts of residual solvent resonances. Elemental analyses were carried out on a Eurovector E.A.3000 instrument using copper sample tubes.

2.5. Crystallography

Dark red crystals of *cis*-[Ru(dppe)(L_4)Cl_2] (**4**) suitable for structural determination were obtained by recrystallization from a dichloromethane solution. X-ray data were collected by a Nonius Kappa CCD diffractometer with a graphite monochromator λ(Mo Kα) = 0.71073 Å. Selected crystal data of **4** are presented in Table 1. The structure was solved by direct methods using SHELXS-97 [17] and refined by full-matrix least-square procedures on $|F|^2$, using SHELX-97 [18]. All non-hydrogen atoms were refined anisotropically and the hydrogen atom positions were refined using the atom corresponded riding model [19]. The structure was determined by the refinement of the Flack x parameter.

3. Results and discussion

3.1. Synthesis

The azomethine ligands (L_1–L_8) used in this study were prepared by the reaction of hydrazonyl chloride **1** with the appropriate aniline derivative **2** according to Scheme 1. The structure of these ligands was confirmed by ^{1}H NMR Spectroscopy and elemental analyses. The synthesis of *cis*-[Ru(dppe)LCl_2] was achieved by the stepwise addition of the azoimine ligands, dppe and then an excess of lithium chloride.

Complex	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**

The neutral complexes **1–8** are air stable and diamagnetic, and their structures were confirmed by ^{1}H and ^{31}P NMR spectra and X-ray diffraction for complex **4**. The aromatic region in the ^{1}H NMR spectra of complexes **1–8** consists of several coupled multiplets due to the aromatic protons of the phenyl rings of the dppe ligand and the phenyl rings of the azoimine ligands. The ^{31}P{^{1}H} NMR spectra of complexes **1–8** showed two doublets in the range 35–42 ppm. It is proposed that the more shielded phosphorus atom is the one trans to the nitrogen while the deshielded P is trans to Cl [20]. In their IR-spectra, all the complexes show bands in the range 1660–1712 cm^{-1} assignable to the C=O stretching frequency of the acetyl group. The intense bands in the ranges 1560–1590 and 1430–1500 cm^{-1} were assigned to the C=N and N=N stretching bands of the azoimine ligands, respectively.

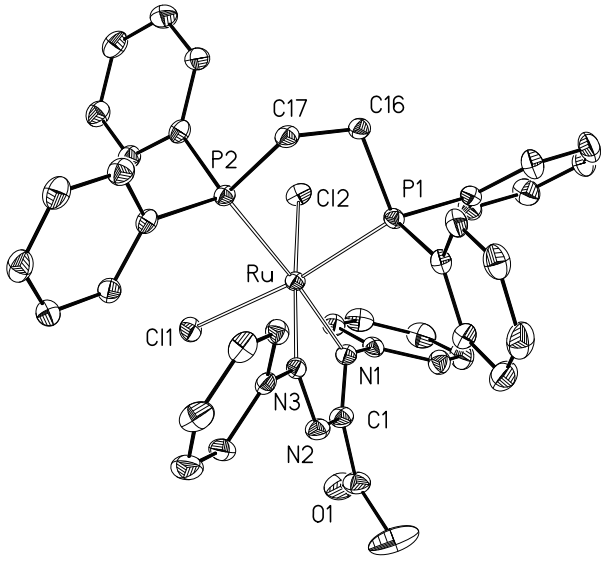

Fig. 1. Thermal ellipsoid plot (30%) of complex **4**. Hydrogen atoms are omitted for clarity.

3.2. Crystal structure

The crystal structure of complex **4** has been solved by X-ray diffraction analysis and its ORTEP plot is depicted in Fig. 1. The main crystallographic data are reported in Table 1. Selected bond distances and angles are found in Table 2. Compound **4** crystallizes in the centrosymmetrical space group *P*2(1)/*n*. The geometry around Ru is distorted octahedral with Ru–N, Ru–P and Ru–Cl bond lengths of 2.027, 2.348 and 2.416 Å, respectively. These data are within the range of bond lengths found for Ru(II) complexes containing these atoms [21]. In this structure, there are two salient features that are worth mentioning: one is the trans influence exerted by the phosphine ligand, which resulted in an elongation of the Ru–Cl distances of **4** (average 2.416 Å) compared to the reported values for *trans*-[Ru(bpy)LCl_2] [22]. The Ru–Cl2 bond length (2.4021(10) Å) trans to the azoimine N atom is shorter than the Ru–Cl1 bond distance of 2.4308(10) Å trans to the P atom of the dppe ligand. This may due to a stronger trans influence of the P versus N donor atom. This trans influence can also be observed in the Ru–N azoimine bonds [Ru–N3], trans to Cl: 1.969(3) Å, Ru–N1, trans to P: 2.084(3) Å. The Ru–P bond lengths of **4** (2.3645(10), 2.332(9) Å) are comparable to Ru–P bond lengths in other reported systems [23].

The second interesting character is that the Ru–N3 [N (azo)] bond distance (1.969(3) Å) is shorter than the Ru–N1 [N (methine)] bond distance (2.084(3) Å), and is also shorter than Ru–N (azo) bond distances for other reported azo-pyridines complexes [24]. This shortening is due to greater π-back donation from the Ru–d orbital to the empty π* orbital of the azoimine ligand and may indicate that the M–L π interaction is localized in the M–azo fragment [24].

3.3. Electrochemistry

The electron-transfer behavior of the complexes in acetonitrile solution was examined by cyclic voltammetry and the corresponding results are summarized in Table 3. As a representative example, the cyclic voltammogram for complex **4** is shown in Fig. 2. Two one-electron reduction steps are observed in the range −0.29 to −0.71 V versus NHE and are localized at the azo group, analogous to the azopyridine systems [23]. Our concern here is the quasi-reversible single oxidation wave which lies between 1.40 and 1.55 V. This wave is assigned to Ru(III/II) and occurs at more positive potentials compared to

the analogous dihalo ruthenium(II) complexes [24]. The Ru(III/II) couples of these complexes are among the highest in ruthenium(II) chemistry. The large positive shift (300 mV) for this family (compared to Ru(L)(bpy)Cl_2 complexes [9,10]) results from the strong π-acceptor properties of the dppe ligand (t2(Ru) → d(P)-backbonding [25]) compared to bpy. This couple is slightly affected by changing the substituent on the azo-imine auxiliary ligand and is shifted to more positive potentials upon replacing the donating methyl group with the more withdrawing nitro group.

3.4. Spectroelectrochemistry

The electronic spectral data for the *cis*-[Ru(dppe)LCl_2] complexes were collected in acetonitrile. The transitions below 400 nm are of the intra-ligand charge transfer ($\pi \rightarrow \pi^*$) type and are not considered further. The complexes exhibit multiple transitions in the visible region. A high intensity ($\varepsilon \sim 10^4$) transition at 500–550 nm is assigned to the MLCT transition [26]. Spectroelectrochemistry of **4** in DMF solution (Fig. 3) was performed in order to obtain the visible electronic absorption spectra of the

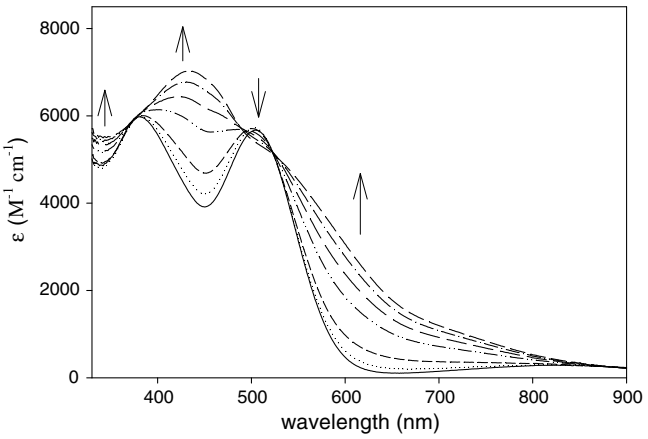

Fig. 3. Spectroelectrochemical oxidation of complex **4** in DMF, 0.1 M TBAH, 25 °C.

Ru(III) oxidation state. As seen in Fig. 3, oxidation of this complex results in a decrease in the band centered at 504 nm that we have assigned to a MLCT transition. The concomitant growth of a broad absorbance at $\lambda > 550$ nm is assigned to Cl-to-Ru(III) ($p\pi \rightarrow d\pi^*$) ligand-to-metal charge transfer transitions and the band centered at 435 nm is assigned to an azoimine-to-Ru(III) LMCT.

The MLCT band of the Ru(II) mononuclear complex and its electrochemistry provide information about the relative energies of the complex's metal and ligand-based orbitals. The change in $d\pi$-orbital energy can be measured experimentally using cyclic voltammetry to obtain the potential of the Ru(III/II) couple, which shifts to more positive potentials as the metal orbitals are stabilized. This has been demonstrated, for example, by the replacement of σ-donating amine ligands with pyridine-type ligands by Crutchley et al. [27]. For Ru(L)(dppe)Cl_2 complexes, electron withdrawing groups shift the Ru(III/II) couple approximately 100 mV positive relative to their donating analogues. This stabilization, however, does not result in a large shift in the MLCT band energy of the Ru(II) complexes, due to the equivalent stabilization of the orbitals involved in the MLCT events (the HOMO and the LUMO azoimine ligand).

The difference in the two successive redox responses at positive and negative values relative to NHE [$\Delta E^0 = E^{0M}_{1/2} - E^0_L(0/-)$] may be correlated with the MLCT transitions. The electronic excitation may be considered as an intramolecular redox process [27,28] and the spin-allowed MLCT transition is expected to correlate linearly with ΔE^0. The least squares plot of E_{MLCT}(kcal mol^{-1}) against

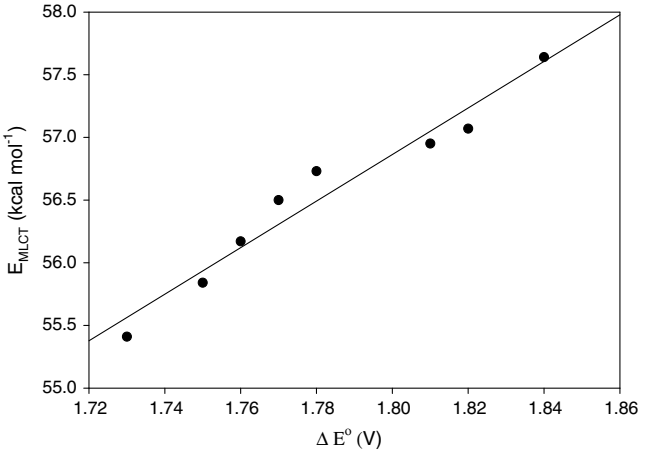

Fig. 4. Linear correlation between MLCT band energies and ΔE^0 (V).

ΔE^0 ($\Delta E^0 = E^{0M}_{1/2} - \mathrm{Azo}(0/-)$) among the entire group of complexes (Fig. 4) corresponds to Eq. (1), with a correlation coefficient of 0.956. A similar correlation has been observed for bpy, arylazopyridine and arylazoimidazole complexes [6–8b].

$$E_{MLCT} = 18.6\Delta E^0 + 23.4 \quad (1)$$

Comparative electrochemistry of [Ru(L)(bpy)Cl_2] [9,10] and [Ru(L)(dppe)Cl_2] complexes showed a positive shift of ~0.3 V in the Ru(III,II) and ~0.2 V in the L(0/−1) couples of the latter complexes. A more convincing explanation is that the much weaker σ-donor strength of bis(diphenylphosphino)ethane causes the metal ion to have a significantly higher effective nuclear charge relative to that of the bipyridyl analogues, and may cause the stabilization of the metal d orbitals. For the ruthenium complexes, the difference between metal oxidation and ligand reduction ($\Delta E^0 = E^{0M}_{1/2} - \mathrm{Azo}(0/-)$) is the same for both families. Thus, the essential identity in the charge-transfer transitions is consistent.

The spectroscopic and electrochemical results may be compared with the literature reported data of 2-(arylazo)pyridine (aap) and its phosphine derivatives $[Ru(aap)_2(dppe)]^{+2}$ [29]. The data reveal that t_2(Ru) is better stabilized in the present series of complexes than in the aap complexes. This may be due to the better π-acidity of the arylamidrazone ligand system (L) than that of 2-(arylazo)pyridine (aap) derivatives.

4. Conclusions

Eight ruthenium (II) complexes, *cis*-[Ru(dppe)LCl_2], where dppe is bis(diphenylphosphino)ethane and L is an azomethine ligand, were synthesized and characterized by crystallography, spectroscopic and electrochemical methods. Cyclic voltammetry studies of the *cis*-[Ru(dppe)LCl_2] complexes showed reversible ruthenium-based oxidation–reduction processes and irreversible ligand-based reductions. The electronic effect of the substituents on the azomethine ligand was shown in the ruthenium couple. This couple is shifted to more positive potentials when stronger electron-withdrawing substituents were introduced. The electronic absorption spectra of these complexes showed a strong band in the visible region which was assigned to a (Ru(II)-to-azomethine) MLCT transition.

5. Supplementary data

CCDC 680294 contains the supplementary crystallographic data for **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

An enantiomeric pair of [1+2] dimeric copper(II) metallomacrocyclic complexes, (*S*,*S*)-**1** and (*R*,*R*)-**2**, prepared from the cleavage of Schiff base C=N double bonds and ring-degradation of their respective chiral [3+3] macrocyclic ligands, are studied in this paper. X-ray single-crystal diffraction determination for (*S*,*S*)-**1** and (*R*,*R*)-**2** reveals that novel dimeric structures are formed where two complementary weak Cu–O coordinative bonds between the formaldehydo O atoms and the copper(II) centers are present and the separations between the dimeric copper(II) centers are 5.546(4) Å in (*S*,*S*)-**1** and 5.555(3) Å in (*R*,*R*)-**2**. The intrinsic chiral differences of these two copper(II) complexes are demonstrated by their circular dichroism (CD) spectra.

1. Introduction

Macrocyclic Schiff bases and related polyamine derivatives have been extensively studied since the first syntheses of homodinuclear macrocyclic complexes via template condensation in the beginning of the 1970s [1]. Depending on the shape of the formyl and amino precursors and/or the metal ion template used, different ring sizes can be attained during the cyclization reaction. The cleavage of Schiff base C=N double bonds and the ring-degradation of macrocycles often take place due to the size matching effect of the macrocycles, the restriction of the coordination geometry of the central metals and the counterions used. A newly published review paper on recent developments of compartmental macrocyclic Schiff bases [2] related polyamine derivatives and some other previous reviews can be found in the literature [3–10].

In our systematic work, a variety of chiral and achiral metallomacrocyclic complexes have been synthesized by sodium(I) template condensation [11–18]. We have newly acquired [2+2], [2+1] and [1+2] kinds of ring-contraction metal complexes from chiral or racemic [3+3] macrocyclic ligands [19], including [2+2] dinuclear macrocyclic copper(II) and [2+1] compartmental dinuclear copper(II) complexes produced by using $Cu(NO_3)_2 \cdot 3H_2O$ as the metal source. In this paper, we report a novel enantiomeric pair of dimeric [1+2] copper(II) metallomacrocyclic complexes (*S*,*S*)-**1** and (*R*,*R*)-**2**, obtained using $Cu(OAc)_2 \cdot 3H_2O$ as the metal source.

2. Experimental

2.1. Materials and measurements

The enantiopure (1*R*,2*R*) and (1*S*,2*S*) cyclohexane-1,2-diamines were purchased directly from Aldrich. 4-Chloro-2,6-diformylphenol was prepared by an improved oxidation method using active manganese(IV) dioxide [20]. The [3+3] macrocyclic compounds were synthesized *via* the sodium(I) template Schiff base condensation of 4-chloro-2,6-diformylphenol and the corresponding chiral cyclohexane-1,2-diamines, as reported previously [19]. The other reagents were of analytical grade from commercial sources and were used without any further purification.

Elemental analyses were measured with a Perkin–Elmer 1400C analyzer. Infrared spectra (4000–400 cm^{-1}) were collected on a Nicolet FT-IR 170X spectrophotometer at 25 °C using KBr plates. Electrospray ionization mass spectra (ESI-MS) were recorded on a Finnigan MAT SSQ 710 mass spectrometer in the scan range 100–1200 amu. UV–Vis spectra were recorded on a Shimadzu UV-3100 double-beam spectrometer using a Pyrex cell with a path length of 10 mm at room temperature. The circular dichroism (CD) spectra were measured with a JASCO J-810 spectropolarimeter using the same solutions as those for the UV–Vis determination. TGA–DTA data were recorded by a CA Instruments DTA–TGA 2960 type simultaneous analyzer heating from 20.00 °C to 700.00 °C at 10 °C/min. The optical rotation values were determined via a WZZ-115 digital auto-polarimeter.

2.2. Preparation for complexes (*S*,*S*)-**1** and (*R*,*R*)-**2**

As illustrated in Scheme 1, the (*S*,*S*) and (*R*,*R*) [3+3] macrocyclic ligands (0.0788 g, 0.1 mmol) were dissolved in 20 mL ethanol,

respectively, and then an ethanol solution (10 mL) of $Cu(OAc)_2 \cdot 3H_2O$ (0.0707 g, 0.3 mmol) was added dropwise. After 2 h of reflux, the mixture was cooled to room temperature and condensed to nearly 5 mL with a rotatory evaporator. The resultant solids, (*S*,*S*)-**1** and (*R*,*R*)-**2**, were collected in yields of 73% and 75%. (*S*,*S*)-**1**: *Anal.* Calc. for $Cu_2C_{44}H_{36}N_4O_8Cl_4$: C, 51.93; H, 3.57; N, 5.51. ESI-MS in methanol: *m*/*z*: $[(S,S)\text{-}\mathbf{1} \cdot CH_3OH]^+$, 1048.8 (100%); $[(S,S)\text{-}\mathbf{1} \cdot 3H_2O]^{2+}/2$, 536.2 (40%). UV–Vis (in ethanol, nm): λ_{max} = 242, 364. $[\alpha]^{20}_D$ = +319 (*c* = 0.1 g/100 mL in ethanol). (*R*,*R*)-**2**: *Anal.* Calc. for $Cu_2C_{44}H_{36}N_4O_8Cl_4$: C, 51.93; H, 3.57; N, 5.51. Found: C, 51.87; H, 3.54; N, 5.49%. Main FT-IR absorptions (KBr pellets, cm^{-1}): 3452 (m), 2924 (m), 1636 (s), 1543 (s), 1434 (s), 1390 (m), 1316 (m), 1206 (m), 1179 (m), 1035 (m), 968 (w). ESI-MS in methanol: *m*/*z*: $[(R,R)\text{-}\mathbf{2} \cdot CH_3OH]^+$ 1048.8, (100%); $[(R,R)\text{-}\mathbf{2} \cdot 3H_2O]^{2+}/2$, 536.2 (37%). UV–Vis (in ethanol, nm): λ_{max} = 242, 364. $[\alpha]^{20}_D$ = −313 (*c* = 0.1 g/100 mL in ethanol). Single-crystal samples of (*S*,*S*)-**1** and (*R*,*R*)-**2** suitable for X-ray diffraction measurement were grown from an acetonitrile/ethanol (v/v = 2:1) mixture by slow evaporation in air at room temperature.

2.3. X-ray crystallographic analysis

Single crystals of (*S*,*S*)-**1** and (*R*,*R*)-**2** were glue-covered and mounted on glass fibers and used for data collection on a Rigaku Mercury CCD area-detector at 291 K using graphite mono-chromated Mo Kα radiation (λ = 0.71073 Å). The collected data were reduced by using the program CRYSTALCLEAR [21] and empirical absorption corrections were done. The original data files generated by CRYSTALCLEAR were transformed to SHELXTL97 format by the TEXSAN program [22]. The crystal systems were determined by laue symmetry and the space groups were assigned on the basis of systematic absences using XPREP. The structures were solved by direct methods and refined by the least-squares method on F^2_{obs} using the SHELXTL-PC software package [23]. All non-hydrogen atoms were refined on F^2 by the full-matrix least-squares procedure using anisotropic displacement parameters and all hydrogen atoms were geometrically located with a riding model and isotropic thermal parameters fixed to 1.2 times the equivalent isotropic *U* of their respective parent atoms (1.5 times for the oxygen atoms). All calculations were carried out with the SHELXTL-PC program package. A summary of crystal data, experimental details and refinement results for (*S*,*S*)-**1** and (*R*,*R*)-**2** is listed in Table 1. Selected bond distances and bond angles involving the copper(II) ions are given in Table 2, while versatile hydrogen bonding interactions are tabulated in Table 3.

3. Results and discussion

3.1. Syntheses and spectral characterization

In the process of metal ion complexation, the size matching effect of macrocycles, the restriction of the central metal coordination geometry and the nature of different counterions are believed to play significant roles in the macrocyclic Schiff base

ring-contraction and formation of the final products. In this work, when $Cu(OAc)_2 \cdot 3H_2O$ was used as the metal source to react with the chiral [3+3] macrocyclic ligands, a new type of dimeric [1+2] copper(II) metallomacrocyclic complex was isolated in relatively high yields. Here the presence of different counterions (OAc^- or NO_3^-) is supposed to be responsible for the formation of the resultant products. The formaldehydo O atoms derived from the cleavage of Schiff base C=N double bonds, which have relatively weak coordination ability, can further coordinate with the copper(II) centers, thus forming novel dimeric macrocyclic structures. In contrast, the nitrate anions occupy some of the coordination sites of central copper(II) ions in the case of the previously reported [2+2] chiral dinuclear macrocyclic copper(II) and [2+1] compartmental dinuclear copper(II) complexes (Scheme 1) [19].

Spectral characterization of (*S*,*S*)-**1** and (*R*,*R*)-**2** reveals that they exhibit very similar behavior except for their CD spectra and optical rotation values. Positive ESI-MS spectra in methanol solutions of (*S*,*S*)-**1** and (*R*,*R*)-**2** show predominant peaks centered at m/z = 1048.8 (see Supplementary data), which are in agreement with the presence of $[(S,S)\text{-}\mathbf{1} \cdot CH_3OH]^+$ or $[(R,R)\text{-}\mathbf{2} \cdot CH_3OH]^+$ species. In addition, doubly charged peaks of medium intensity corresponding to $[(S,S)\text{-}\mathbf{1} \cdot 3H_2O]^{2+}/2$ or $[(R,R)\text{-}\mathbf{2} \cdot 3H_2O]^{2+}/2$ species, at m/z = 536.2, are also observed. All the ESI-MS peaks have been calculated and verified by using the numbers and natural isotopic abundances of the atoms [24].

In their UV–Vis spectra (inset in Fig. 1), the intense adsorption peak at 242 nm is assigned to the π–π* transition of the phenolic rings and the band at 364 nm is assigned to the π–π* transition of the azomethine chromophore. The sign patterns of the CD spectra suggest an intrinsic chiral difference of the enantiomeric pair. It is found that (*S*,*S*)-**1** gives cotton effects that are the mirror image of (*R*,*R*)-**2** (Fig. 1). The first cotton effect of (*S*,*S*)-**1** is positive, but for (*R*,*R*)-**2**, it is negative. In contrast to the corresponding electronic absorption band at 364 nm, their CD bands split into 356 (+) nm and 423 (−) nm with opposite cotton effects, which can be attributed to the split π–π* azomethine transition. On the other hand, one CD peak appears at 273 nm, corresponding to the UV–Vis absorption at 242 nm. In addition, there is a weak d–d transition

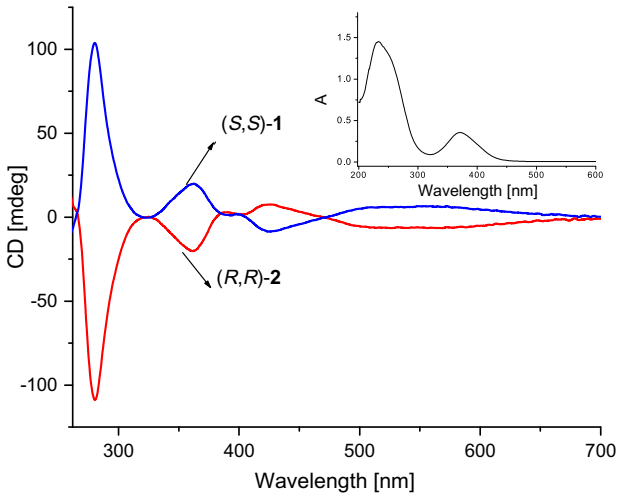

Fig. 1. CD and UV–Vis (inset) spectra of (*S*,*S*)-**1** and (*R*,*R*)-**2** in ethanol.

absorption observed in the long wavelength range at 500–700 nm. The sign patterns of the CD spectra suggest that conformers of negative chirality predominate in the solutions of the [3+3] (*R*,*R*)-macrocycle, whereas conformers of positive chirality predominate in those of the [3+3] (*S*,*S*)-macrocycle.

Both complexes show similar thermal stability because of the same molecular formulae. They are stable in the temperature range 293–571 K, and then a continuous weight loss is found, indicative of the decomposition of the copper(II) complexes.

3.2. Crystal structures of (*S*,*S*)-**1** and (*R*,*R*)-**2**

The molecular structures of (*S*,*S*)-**1** and (*R*,*R*)-**2**, with the atom-numbering scheme, are shown in Fig. 2. The X-ray crystal structural studies indicate that they have the same chiral space group $P2_1$ and their unit cell parameters are identical within experimental error. However, the carbon atoms of the cyclohexane-1,2-diamine moieties in (*S*,*S*)-**1** and (*R*,*R*)-**2** present different configurations, in which all four chiral carbon atoms are in the *S* configuration in (*S*,*S*)-**1** and in the *R* configuration for (*R*,*R*)-**2**, which are in agreement with those of the starting materials. Reasonable Flack parameters

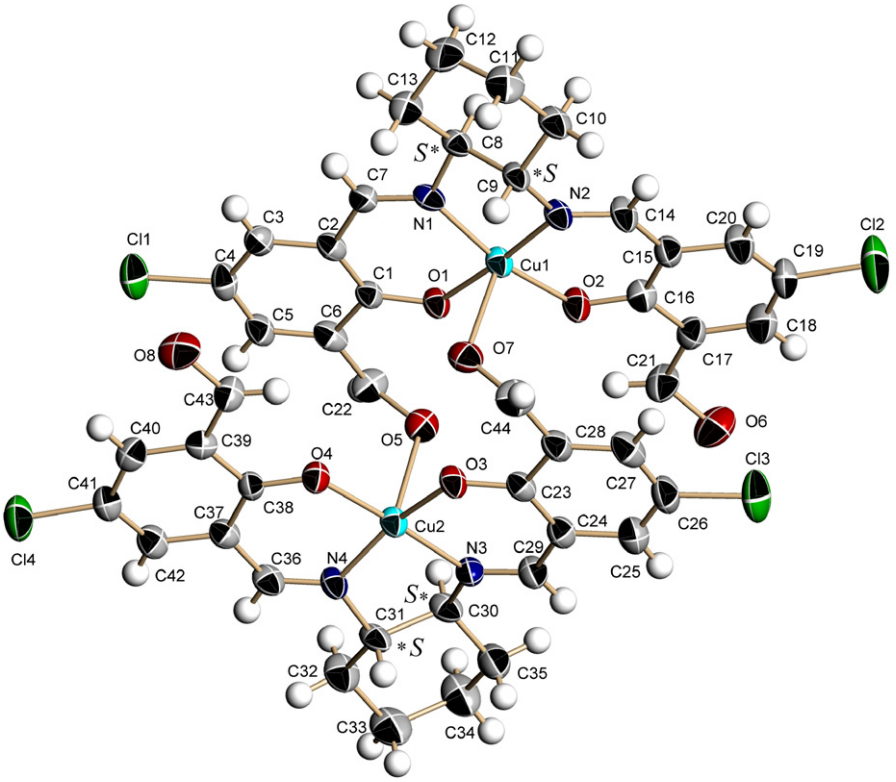

Fig. 2. ORTEP diagram (50% thermal probability) of the molecular structure of (*S*,*S*)-**1** with the atom-numbering scheme, where the chiral carbon atoms are marked.

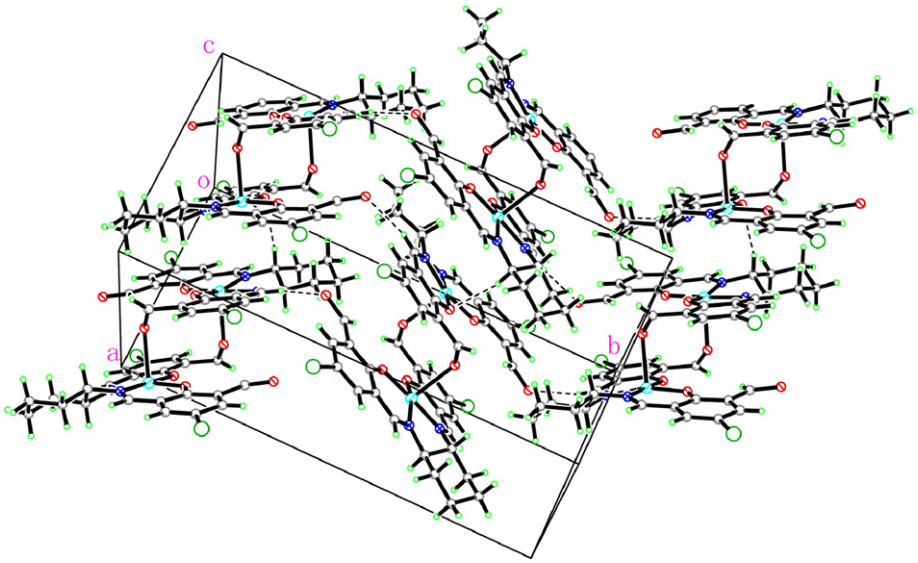

Fig. 3. A crystal packing view of (*S*,*S*)-**1**, together with the unit cell.

0.022(17) in (*S*,*S*)-**1** and 0.018(13) in (*R*,*R*)-**2** demonstrate the right specification of chirality [25].

Each molecular structure consists of a dimer of mononuclear copper(II) units, including the [1+2] compartmental Schiff base. The monomers are linked by two complementary weak Cu–O coordinative bonds where the formaldehydo O atoms act as donors. Each copper(II) center in (*S*,*S*)-**1** and (*R*,*R*)-**2** shows a five-coordinate pyramidal coordination geometry, where two imino N atoms and two phenolato O atoms constitute the basal plane, with Cu–N bond lengths in the range 1.953(5)–1.963(4) Å and Cu–O bond lengths in the range 1.912(3)–1.950(4) Å. The geometry of the coordination basal planes of the (*S*,*S*)-**1** and (*R*,*R*)-**2** monomers is comparable with a previously reported six-coordinate mononuclear Mn(II) complex [26]. However, each apical position of coordination of (*S*,*S*)-**1** and (*R*,*R*)-**2** is occupied by one formaldehydo O atom from another moiety, with a relatively weak coordination ability: longer Cu–O apical bond lengths of 2.401(4) and 2.400(3) Å are observed for (*S*,*S*)-**1** and (*R*,*R*)-**2**, respectively. Each macrocycle in (*S*,*S*)-**1** and (*R*,*R*)-**2** is essentially coplanar and the separations between the dimeric copper(II) centers are 5.546(4) Å in (*S*,*S*)-**1** and 5.555(3) Å in (*R*,*R*)-**2**. The dihedral angles between the intramolecular phenolic planes are 8.3° and 5.8° in (*S*,*S*)-**1** and 8.1° and 5.4° in (*R*,*R*)-**2**. The dihedral angles between the phenolic planes from each compartmental half-macrocycle are 2.4–6.4° in (*S*,*S*)-**1** and 2.6–6.2° in (*R*,*R*)-**2**.

Additionally, the hydrogen-bonding patterns in (*S*,*S*)-**1** and (*R*,*R*)-**2** are identical, in which C–H···O hydrogen bonds play an important role in the crystal packing of the complexes (Fig. 3). Atoms O(6) and O(8) form intermolecular C–H···O hydrogen bonds with the imino hydrogen atoms. In addition, the phenolato oxygen atom O(1) forms a C–H···O hydrogen bond with the hydrogen atom bonded to atom C(31) of the chiral cyclohexane-1,2-diamine.

4. Conclusion

By using $Cu(OAc)_2 \cdot 3H_2O$ as the metal source, an enantiomeric pair of [1+2] dimeric copper(II) metallomacrocyclic complexes, (*S*,*S*)-**1** and (*R*,*R*)-**2**, were obtained by means of the cleavage of Schiff base C=N double bonds and the degradation of their respective chiral [3+3] macrocyclic ligands, where novel dimeric structures are formed by two complementary weak Cu–O coordinative bonds between the formaldehydo O atoms and the copper(II) centers. These two copper(II) products are different from our previously reported [2+2] dinuclear macrocyclic copper(II) and [2+1] compartmental dinuclear copper(II) complexes yielded by using $Cu(NO_3)_2 \cdot 3H_2O$ as the metal source, although similar experimental conditions were used. The size matching effect of the macrocycles, the restriction of the coordination geometry of the copper(II) ion and the nature of counterions used (CH_3COO^- versus NO_3^-) in this comparative study are believed to determine the configuration of the resulting complexes.

ABSTRACT

Mononuclear, square-planar platinum(II) complexes involving derivatives of aromatic cytokinins as the ligands, and having the general formula *cis*-$[Pt(L_n)_2Cl_2]$ (**1–3**) and *trans*-$[Pt(L_n)_2Cl_2]$ (**4–6**), where $n = 1–3$, L_1 = 2-chloro-6-(benzylamino)-9-isopropylpurine, L_2 = 2-chloro-6-[(4-methoxybenzyl)amino]-9-isopropylpurine and L_3 = 2-chloro-6-[(2-methoxybenzyl)-amino]-9-isopropylpurine, have been synthesized and characterized by elemental analysis, MALDI-TOF mass, FT IR, ^1H, ^{13}C, ^{15}N and ^{195}Pt NMR spectral measurements. Dynamic *cis*-to-*trans* isomerization process of complex **1** in *N*,*N*′-dimethylformamide (DMF) has been investigated by means of multinuclear NMR spectroscopy. The solid-state structures of **1, 4** · $(DMF)_2$, and **5** have been determined by single crystal X-ray analysis. X-ray structures revealed that the heterocyclic ligands are coordinated to platinum *via* nitrogen atom N(7) in all the complexes studied. *In vitro* cytotoxicity of the prepared complexes against MCF7, G361, K562, and HOS has been evaluated. Owing to low solubility of the complexes in water, the cytotoxicity has been only tested up to 5 μM concentration. Unfortunately, all complexes have been found to be non-cytotoxic in the accessible concentration range.

1. Introduction

Nowadays, there is indisputable fact that a platinum drug called *Cisplatin*, i.e. *cis*-diamminedichloridoplatinum(II), of which the cytotoxic effects were discovered by Rosenberg et al. in the 1960s [1], and some its derivatives, represent a unique class of antineoplastic drugs used in current chemotherapy [2,3]. A high number of recently prepared *cis* and/or *trans*-$[Pt(L)_2Cl_2]$ (L = amine) complexes showed the possibility to inhibit cell division and growth of cancer cells [4]. This attribute initiated a great interest in the potential application of these inorganic substances in the treatment of tumors [4]. At present, novel potential platinum-based anticancer agents are still intensively studied with the intention to improve their therapeutic profiles to overcome their side effects and acquired resistance to the drugs [5,6]. Thus, an identification of *cis*/*trans* isomers was found to play a crucial role in the characterization of the above mentioned types of Pt(II) complexes because *cis* and *trans* isomers were found to possess substantially different cytotoxic effects when tested against various cancer cell lines [7]. This fact gave rise the reason to study the stereochemistry and geometric isomerism of square-planar complexes of the type $[Pt(L)_2X_2]$ (where L = a monodentate *N*-donor ligand, X = halide) in solid state as well as in solution. Above all, *cis*-to-*trans* isomerization of square–planar Pt(II) complexes in solution is still a subject of great interest. The formation of the *trans* isomer in a process which was supposed to give the *cis* isomer gave impulse to focus on this phenomenon, especially if this effect was already observed and determined, e.g. for $[Pt(L)_2Cl_2]$ complexes with L = aniline, 2,5-dimethyl-aniline or *p*-toluidine [8], cyclobutylamine [9], cyclohexylamine [10], and cycloheptylamine [11], Moreover, *cis*-to-*trans* isomerization reactions of $[Pt(L)_2X_2]$ complexes, where X = Cl, Br or NO_3^-, and L = pyridine or pyrimidine [12,13], ketoxime [14], and pyridine [15], were also previously reported. Generally, it may be concluded that the situation regarding the isomerization process may be a bit complicated in a solution mainly because of the fact that *trans*-isomers may be formed unexpectedly during the synthetic pathway or re-crystallization of *cis*-isomers from some solvents [9,10]. For that reason, the monitoring of *cis*-isomer behavior in solution was showed to be very contributing. For instance, *cis* and *trans*-$[Pt(amine)_2I_2]$ complexes were studied using ^{195}Pt NMR spectrometry in DMF and their *cis*-to-*trans* isomerization was observed [16]. Similarly, the geometric isomers distribution in case of platinum(II) complexes of the type $[M(L)_2X_2]$, where M = Pt or Pd, L = *N*-benzoyl-*N*′-propylthiourea, X = Cl, Br or I, in chloroform was studied by ^{195}Pt and ^1H NMR

doi:10.1016/j.poly.2008.05.021

spectrometry and their *cis*-to-*trans* isomerization process was also investigated [17].

Besides the above-mentioned publications regarding the *Cisplatin*-like complexes, there exists a great number of scientific papers concerning with the preparation, characterization and biological activity testing of *cis* and *trans* Pt-complexes as well as the papers describing the conditions and rules for their DNA binding. Among them, the following may be highlighted as examples, e.g. [18–21].

Based on these facts, we focused our attention on the preparation and characterization of isomerically pure Pt(II) complexes bearing derivatives of plant growth hormones called cytokinins as N-donor ligands and on their *cis*-to-*trans* isomerization processes in solutions. One group of cytokinins, i.e. a class of natural or artificial plant growth regulators discovered in the 1950s [22–24], is represented by compounds bearing a 6-benzylaminopurine moiety. Cytokinins play a very important role in plant growth and development, including the promotion of cell division, senescence and apical dominance regulation, and nutritional signals transmission [25–27]. Since the 1990s, some cytokinin derivatives based on 2,6,9-trisubstituted purine moiety have been extensively studied due to their activity in the regulation of the eukaryotic cell cycle, more specifically, due to their significant inhibition of cyclin-dependent kinases (CDKs) [28,29]. The CDKs are protein kinase enzymes playing a considerable role in regulation of the cell cycle [30]. Some of these CDK inhibitors, e.g. 2-[2-(hydroxyl-ethyl)amino]-6-benzylamino-9-methylpurine (*Olomoucine*), 2-[3-(hydroxypropyl)amino]-6-benzylamino-9-isopropylpurine (*Bohemine*), and 2-{[1-(hydroxylmethyl)-propyl]-amino}-6-benzylamino-9-isopropylpurine (*Roscovitine*, also named as seliciclib or CYC202) were also found effective against the proliferation of some human cancer cell lines both *in vitro* and *in vivo* [31,32]. The reason why we use derivatives of aromatic cytokinins and/or cyclin-dependent kinase inhibitors derived from 6-benzylaminopurine as the ligands for the preparation of transition metal complexes is that the cytotoxicity may be improved after the coordination of these organic molecules to a suitable transition metal ion, *e.g.* to Pt(II) and Pd(II) [33,34], Cu(II) [35], Zn(II) [36] or Co(II) [37], as we have found in the case of complexes prepared previously in our laboratory. Up to now, the dynamic *cis*-to-*trans* isomerization process of Pt(II) complexes involving the above-discussed organic molecules has not been investigated using NMR spectrometry yet. However, the *cis*-to-*trans* isomerization process was previously investigated in the case of Pd(II) complexes of the type $[Pd(L)_2Cl_2]$, where L = cytokinins derived from 6-benzyalminopurine [34].

In this paper, we describe the preparation of a series of isomerically pure *cis* and *trans*-Pt(II) complexes of the general formula *cis*-$[Pt(L_n)_2Cl_2]$ and *trans*-$[Pt(L_n)_2Cl_2]$, where $n = 1–3$, L_1 = 2-chloro-6-(benzylamino)-9-isopropylpurine (**1, 4**), L_2 = 2-chloro-6-[(4-methoxybenzyl)-amino]-9-isopropylpurine (**2, 5**), L_3 = 2-chloro-6-[(2-methoxybenzyl)amino]-9-isopropylpurine (**3, 6**). The complexes have been fully characterized by means of elemental analysis, MALDI-TOF, FT IR and multinuclear NMR spectra, and complexes **1**, **4** and **5** also by single crystal X-ray analysis. The complexes were also investigated for their cytotoxic effects *in vitro* against four human cancer cell lines: MCF7, K 562, G 361 and HOS. The *cis*-to-*trans* isomerization process of the complexes in DMFA solutions was studied by means of ^{1}H, ^{13}C, ^{15}N and ^{195}Pt NMR spectroscopy.

2. Experimental

2.1. Materials

$PtCl_2$ was used as received from Sigma–Aldrich Co. The organic ligands 2-chloro-6-benzylamino-9-isopropylpurine (L_1), 2-chloro-6-[(4-methoxybenzyl)amino]-9-isopropylpurine (L_2) and 2-chloro-6-[(2-methoxybenzyl)amino]-9-isopropylpurine (L_3) were prepared by methods described in the literature [34]. Schematic representations of all the ligands used in this study including atom numbering are depicted in Fig. 1. Organic solvents used for the syntheses were purchased from Lachema Co., while *N*,*N*′-dimethylformamide-d_7 (99.5%) used for NMR spectroscopy was purchased from Sigma–Aldrich Co.

2.2. Synthesis of the complexes

2.2.1. General procedure for the preparation of cis-$[Pt(L_n)_2Cl_2]$ (**1–3**), $L_n = L_1–L_3$

An appropriate ligand (1 mmol) was dissolved in chloroform (15 mL) and added to a mixture of $PtCl_2$ (0.09 g, 0.5 mmol) in the same solvent (10 mL). The reaction mixture was stirred at −18 °C for 15 days. Obtained yellow or light orange solutions were filtered and the filtrate let to stand at room temperature. Yellowish or dark

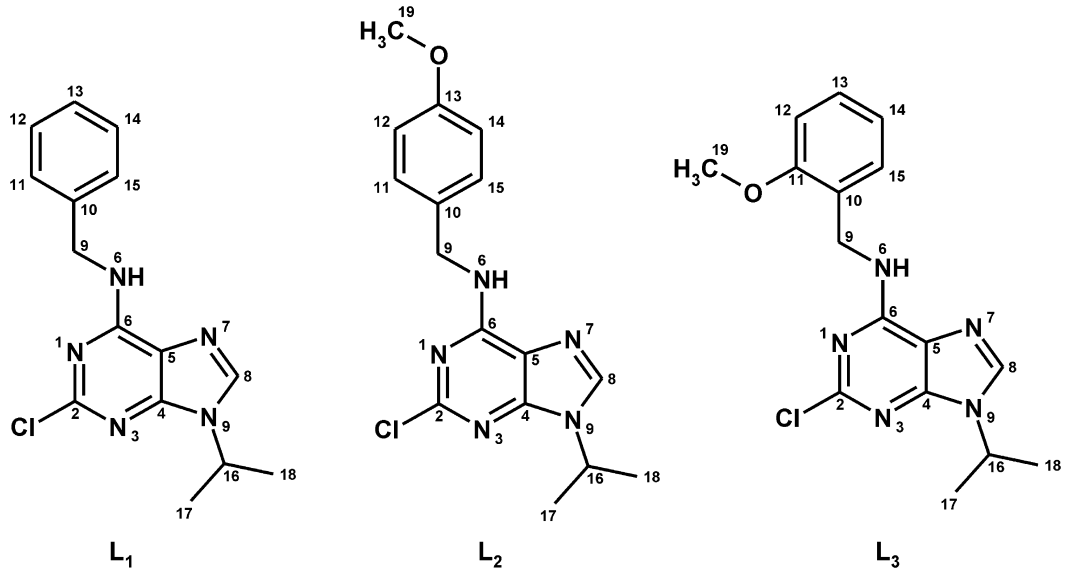

Fig. 1. A representation of organic molecules, including atom numbering scheme, used as ligands L_1–L_3.

yellow precipitates appeared after several days, which were filtered off, and dried in a vacuum desiccator over KOH.

*2.2.1.1. cis-[Pt(L$_1$)$_2$Cl$_2$] (**1**).* The complex was re-crystallized from chloroform and yellowish crystals suitable for X-ray crystallography were obtained by free evaporation of the solvent used. Yield: 76%. λ_M = 0.5 Ω cm^2 mol^{-1} in acetone, 0.8 Ω cm^2 mol^{-1} in DMF. FT-IR (KBr, cm^{-1}): 3342 (s, ν_{N-H}); 3092 (w, $\nu_{(C-H)ar}$); 1617 (vs, $\nu_{(C=N)ar}$), 1168 (m, $\nu_{(C-Cl)ar}$). Found: C, 41.2; H, 4.0; N, 15.0%.

2.3. Physical measurements

Elemental analysis (C,H,N) was performed on the EA1112 Flash analyzer (ThermoFinnigan). Thin layer chromatography (TLC) of the prepared organic molecules was performed using a $CHCl_3$/CH_3OH/NH_4OH (8:2:0.1) mobile phase and carried out using Silica Gel 60 WF_{254} plates (Merck Co.). Positive ion MALDI-TOF mass spectra were measured in the reflection mode on a Microflex MALDI-TOF LRF20 mass spectrometer equipped with a nitrogen laser operating at 337 nm (Bruker Daltonik). MALDI-TOF-MS data of the studied complexes were measured acetone solutions (0.5 mM final concentration). Saturated solution of α-cyano-4-hydroxycinnamic acid in a 50%/0.2% acetonitrile/trifluoroacetic acid solution was used as a MALDI matrix. An aliquot of the sample solution in acetone (5 μL) and 5 μL of the matrix solution were premixed in a test tube. Then, 0.5 μL of the mixture was pipetted onto the target plate and allowed to dry at ambient temperature. Spectra were accumulated from 20 to 50 laser shots at a laser repetition rate of 10 Hz. The instrument was calibrated externally using a mixture of peptide standards. Acquired spectra were processed by FLEXANALYSIS 2.4 software (Bruker Daltonik). Post-source decay (PSD) spectra were recorded in 15 segments with each succeeding segment representing a 10% reduction in reflectron voltage. About 100 shots were averaged per segment. Segment spectra were pasted, calibrated and smoothed using the program FLEXANALYSIS 2.4. Conductivity measurements were performed on a Cond340i/SET conductometer (WTW, Germany) in DMF solution (10^{-3} M) at 25 °C. Far FT-IR spectra were measured using the Nujol technique in the range of 150–600 cm^{-1}, whilst mid FT-IR spectra were obtained by the KBr pellets technique between 400 and 4000 cm^{-1}, both using a NEXUS 670 FT-IR spectrometer (Thermo Nicolet). ^{1}H and ^{13}C NMR spectra were recorded on a Bruker Avance 300 spectrometer at 300 K. The samples were prepared by dissolving the ligands $\mathbf{L}_1$–$\mathbf{L}_3$ and complexes **1–6** in deuterated *N*,*N*′-dimethylformamide (DMF-d_7). The internal reference standard used for ^{1}H and ^{13}C NMR measurements was tetramethylsilane (TMS). ^{15}N NMR chemical shifts were measured relatively to the DMF-d_7 solvent (adjusted to 104.7 ppm). The individual ^{1}H and ^{13}C signals were assigned and refined by means of 2D correlation experiments of ^{1}H–^{1}H *gs*-COSY, ^{1}H–^{13}C *gs*-HMQC and ^{1}H–^{13}C *gs*-HMBC experiments. ^{15}N chemical shifts for the ligands $\mathbf{L}_1$–$\mathbf{L}_3$ and complexes **1–6** were obtained at natural abundance by ^{1}H–^{15}N *gs*-HMQC and ^{1}H–^{15}N *gs*-HMBC experiments and the spectra were recorded at 340 K.

2.4. X-ray crystallography

Diffraction data for single crystals of *cis*-Pt(II) complex of **1** and *trans*-Pt(II) complexes of **4** · $(DMF)_2$ and **5** were collected on an Xcalibur diffractometer (Oxford Diffraction) with Mo Kα (monochromator Enhance, Oxford Diffraction) radiation and ω-scan rotation techniques. The data were collected to maximum θ value of 25° and processed using the CRYSALIS software package (Oxford Diffraction, Ltd.) [38]. A multi-scan absorption correction integrated in the CRYSALIS software was applied on the data of all three complexes. All three structures were determined by direct methods using SHELXS-97 and refined anisotropically on F^2 using full-matrix least-squares procedure by SHELXL-97 [39]. H-atoms were positioned geometrically, with C–H distances of 0.95–1.00 Å and N–H distances of 0.88 Å, and with U_{iso}(H) values of 1.2U_{eq}(C,N). Most of atoms of the L_1 ligand in **1**, methyl groups of the isopropyl moiety in **4** · $(DMF)_2$, and all atoms of the isopropyl moiety as well as chlorine atom of the L_2 ligand in **5** were refined as disordered over two positions. Moreover, because of the disordered nature of the part of the structure in the case of **1**, isotropic restraints were placed on the anisotropic thermal parameters of some atoms of the L_1 ligand. All structural figures were made with DIAMOND [40].

2.5. Cytotoxicity testing

Cytotoxicity values of IC_{50} for complexes **1–6** and for the ligands L_1–L_3 were determined by a calcein AM assay. Human cancer cell lines *in vitro* were used as follows: malignant melanoma (G361), chronic myelogenous leukaemia (K562), osteogenic sarcoma (HOS), and breast adenocarcinoma (MCF7). The technique of the biological activity testing has been previously described in greater detail [33]. All the experiments were repeated in triplicate. The presented IC_{50} values are represented by arithmetic mean values, with a maximal deviation of 15%. All the ligands and complexes were first dissolved in DMF and then immediately diluted in water to a final DMF concentration of 0.6%.

3. Results and discussion

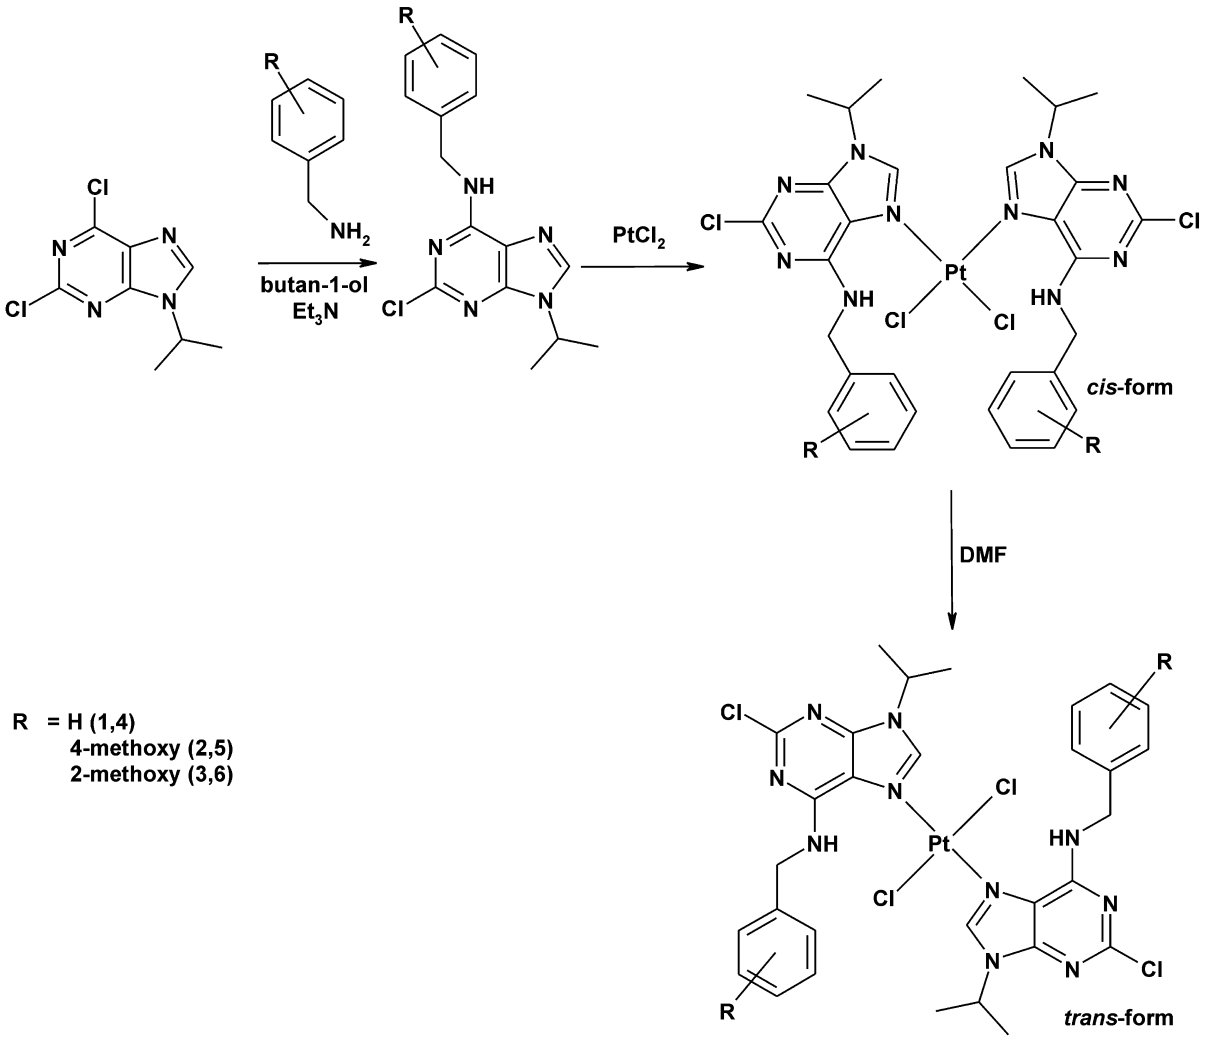
3.1. Synthetic aspects and conductivity measurement results

Scheme 1 illustrates the synthetic pathway that led to the preparation both L_n organic molecules, used as ligands, and *cis*-$[Pt(L_n)_2Cl_2]$ (**1–3**) and *trans*-$[Pt(L_n)_2Cl_2]$ (**4–6**) complexes. As the first step of the complex syntheses, *cis* isomers were prepared. Yellow to light orange solutions appeared after mixing the reactants at the temperature of −18 °C. Then, the reaction mixtures were filtered off in order to remove visible residues originating from initial $PtCl_2$ and let to stand at the temperature of −18 °C for next few days. Yellow precipitates, which appeared after this time period, were collected by filtration and re-crystallized from chloroform (**1–3**). *Trans* isomers were obtained after dissolving of the powdery samples of the appropriate *cis* isomers in DMF. The whole procedure was supported by heating up to 50 °C. Based on our next experiences, *trans* isomers could be also obtained by elongation of the reaction time by several weeks supported by heating (60–70 °C). Generally, it is known that a *cis-to-trans* isomerization process of square-planar Pt(II) complexes can be caused both by recrystallization of *cis* isomers from various solvents (e.g. acetone [9–11], DMF [41], $CHCl_3$ [17]) or solid state thermal heating [14].

All the complexes behave as non-electrolytes both in acetone and DMF solutions with the conductivity values found within the interval of 0.5–2.5 and 1.2–3.2 Ω cm^2 mol^{-1} in acetone, and DMF, respectively. The obtained conductivity values are consistent with the literature data obtained for other complex non-electrolytes [42].

3.2. Mass and FT IR spectral studies

The positive ion MALDI-TOF mass spectra were carried out for all complexes **1–6**. They showed molecular ion $[M+H]^+$ peaks in the spectra of complexes **1–3**, and moreover, the $[M+K]^+$ molecular adduct ions also appeared. Fig. 2 depicts the isotopic distribution of the molecular peak obtained for complex **1** compared to the calculated one obtained using the MASSLYNXTM software taking into



Scheme 1. Schematic representation of the synthesis of ligands and *cis* (**1**–**3**) and *trans* (**4**–**6**) Pt(II) complexes.

account the isotopic representation of all the atoms within the molecule [43]. For complexes **1–4**, there were also found $[M+Na]^+$ molecular adduct ions. Generally, the formation of adducts with Na^+ and K^+ is typical for this type of complexes [44]. All the complexes, except for **3**, showed at least two fragments, *i.e.* $[\{M-Cl\}+H]^+$ and $[\{M-2Cl\}+H]^+$. Moreover, the molecular peak of the appropriate ligand, $[L+H]^+$, appeared in all spectra of the complexes.

FT-IR spectra of both the ligands L_1–L_3 and complexes **1–6** were measured in the region of 150–4000 cm^{-1}. Characteristic bands confirming the presence of organic ligands in complexes **1–6** were observed in the region of 600–4000 cm^{-1} [45]. The bands were found and assigned as follows: strong bands between 3300 and 3342 cm^{-1} are assignable to $\nu_{(N-H)}$, weak to medium bands between 3092 and 3120 cm^{-1} are assignable to $\nu_{(C-H)ar}$, very strong bands between 1614 and 1623 cm^{-1} may be attributed to $\nu_{(C=N)ar}$ and medium bands between 1163 and 1177 cm^{-1} are assignable to $\nu_{(C-Cl)ar}$. The majority of the bands found between 660 and 900 cm^{-1} can be assigned to skeletal vibrations of a purine moiety of the organic ligands which is present in the complexes studied. Medium to strong bands between 1218 and 1244 cm^{-1} and 1027 and 1033 cm^{-1} attributable to $\nu_{(Car-O)}$, and $\nu_{(C-O)aliph}$, respectively, were found in FT IR spectra of complexes **2**, **3**, **5** and **6**, containing ligands L_2 and L_3. Some new bands appeared in the spectra of the complexes in comparison with free organic ligands in the region between 150 and 600 cm^{-1}. Strong or very strong bands between 340 and 362 cm^{-1} assignable to ν(Pt–Cl) and between 521 and 549 cm^{-1} attributable to $\nu_{(Pt-N)}$ were found [46]. For *cis*-complexes, these bands were splitted into two peaks as compared to *trans*-isomers which clearly supports the *cis*-to-*trans* transformation process in case of the Pt(II) complexes studied.

3.3. Multinuclear NMR studies

Multinuclear NMR study of complexes **1–6** and the ligands L_1–L_3 was performed by means of ^1H, ^{13}C, ^{15}N and ^{195}Pt NMR spectroscopy. Chemical shifts of the selected atoms of the free ligands L_1–L_3 and complexes **1–6**, as found in ^1H and ^{13}C NMR spectra, are given in Table 1, while the ^{15}N NMR and ^{195}Pt NMR spectral data are given in Table 2. Observed signals were assigned and refined by means of ^1H–^1H COSY, ^1H–^{13}C HMQC and ^1H–^{13}C HMBC experiments. The signals found in ^1H and ^{13}C NMR spectra confirmed the presence of organic ligands L_1–L_3 in complexes **1–6** and also proved the coordination of these organic molecules to the central Pt(II) ion. The manner of the ligand L_1–L_3 coordinations to Pt(II) can be deduced from the coordination shifts $\Delta\delta$ ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) as found in both ^1H and ^{13}C NMR spectra of the free ligands and complexes. It is evident from ^1H and ^{13}C spectral data given in Table 1 that the greatest coordination shifts in ^1H NMR spectra were found for the N6H ($\Delta\delta$ = 0.35–0.94 ppm, downfield) and

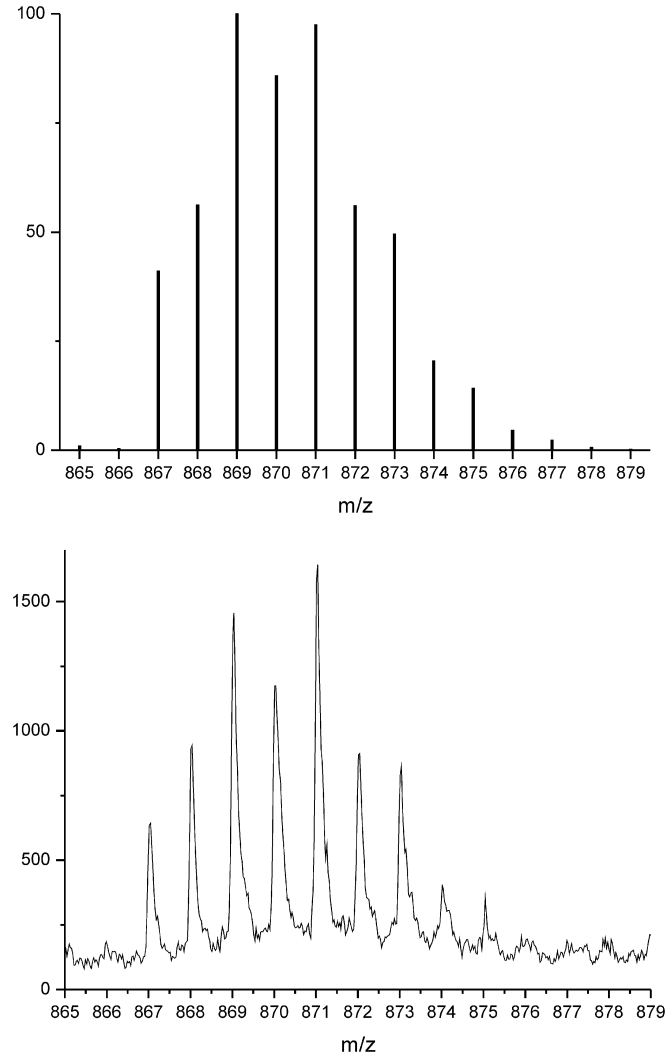


Fig. 2. A representation of the isotopic distribution of the molecular ion of **1** compared to the calculated one obtained using the MASSLYNX software taking into account isotope representation of all the atoms within the molecule.

C8H ($\Delta\delta$ = 0.65–0.97 ppm, downfield) atoms which are situated close to the N7 atom, i.e. to a position where the coordination to platinum(II) [33,34] or palladium(II) [34] can be expected on the basis of our previous findings. These results could be also supported by ^{13}C NMR spectral data, where the greatest chemical shifts were observed for the C5 ($\Delta\delta$ = 3.28–3.69 ppm, upfield) and C8 ($\Delta\delta$ = 2.13–3.33 ppm, downfield) atoms which are adjacent to a coordination site represented by the N7 atom. The signals found in ^{15}N NMR spectra were obtained at natural abundance by long-lasting two dimensional heteronuclear correlation ^{1}H–^{15}N *gs*-HMQC and ^{1}H–^{15}N *gs*-HMBC experiments. Presumable coordination *via* the N7 atom can be also supported by ^{15}N NMR spectral data given in Table 2, from which it is obvious that the greatest coordination shift as compared to the free ligands occurred at the N7 atom ($\Delta\delta$ = 97.67–106.55 ppm, upfield). The chemical shifts of N1, N3, N6 and N9 remained without significant changes, i.e. $\Delta\delta$ were found to be within the interval of 0.80–10.07 ppm that means they are non-significantly influenced by the organic ligand coordinations to platinum. The N7 atom chemical shifts observable in the spectra of the ligands and complexes demonstrably revealed that the coordination of the 6-benzylaminopurine derived ligands to the central platinum(II) ion proceeds *via* the N7 position of the purine moiety.

Generally, it is known, that very important conclusions about the oxidation state of the central Pt ion, stereochemistry, chromophore and isomer types can be obtained from ^{195}Pt NMR experiments, where the significant differences between $\delta(^{195}\text{Pt})$ chemical shifts assignable to *cis* and *trans* complexes are supposed to be observed. It can be evident from the $\delta(^{195}\text{Pt})$ chemical shifts listed in Table 2 that those ones assignable to *cis* isomers **1–3** appeared within the interval of −2017.36 and −2023.06 ppm, while the signals observed for *trans* isomers **4–6** were found between −2061.63 and −2066.07 ppm. The values obtained for complexes **1–3** are in a good agreement with those found for similar complexes of the type *cis*-[Pt(L)$_2$Cl$_2$] (L = methyl derivatives of pyridine), where the $\delta(^{195}\text{Pt})$ values were observed within the interval between −1998 and −2021 ppm [16]. With regard to the fact that we have already studied square-planar platinum(II) complexes bearing 6-benzylaminopurine moiety recently, we can state that the $\delta(^{195}\text{Pt})$ chemical shift values found for *cis*-complexes **1–3** are in good agreement with those determined for Pt(II) complexes of similar structural type and composition published previously [33]. As for *trans*-complexes **4–6**, it is interesting that the observed $\delta(^{195}\text{Pt})$ values between −2061.63 and −2066.07 ppm are shifted to higher fields in comparison with literature data given for similar type of complexes like *trans*-[Pt(L)$_2$Cl$_2$] (L = methyl derivatives of pyridine) being −1948 and −1973 ppm [15]. On the other hand, the achieved values are very close to those published elsewhere, e.g. −2101 ppm for *trans*-[Pt(NH$_3$)$_2$Cl$_2$] [47].

3.3.1. Cis-to-trans isomerization NMR study

It has been known for a long time that square-planar Pt(II) complexes with *cis* arrangement of the type *cis*-[Pt(L)$_2$X$_2$] (where L = NH$_3$ or its derivatives, X = halide) can be transformed into *trans* isomers by re-crystallization from various solvents or by their heating [8–11]. That is why, we decided to prove this ability in the case of the Pt(II) complexes **1–3** involving 6-benzylaminopurine derivatives. A series of 1D (^{1}H, ^{13}C, ^{195}Pt) and 2D (^{15}N *gs*-HMQC and ^{1}H–^{15}N *gs*-HMBC) NMR experiments were per-

Table 1
Selected ^{1}H and ^{13}C NMR spectral data (δ, ppm) for L$_1$–L$_3$ and **1–6**

Coordination chemical shifts ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) are given in parentheses.

formed during six months to obtain necessary data for the study of the *cis*-to-*trans* isomerization process in DMF. Although these measurements were performed for all complexes **1–3**, we decided to describe and interpret NMR data regarding the process for complex **1** only because the obtained results were fully comparable for all the studied complexes. Regarding the proper experiment, the sample was measured 20 min after dissolving complex **1** in DMF, and subsequently after one, three and six months. An example of the ^{1}H–^{15}N *gs*-HMBC experiment performed for complex **1** taken one month after the sample dissolution together with its comparison to the spectra of the corresponding free ligand L_1 is presented in Fig. 1A (see Supplementary data). The presence of both *cis* and *trans* isomers (i.e. complexes **1** and **3**) can be clearly seen from the last-mentioned figure. The same conclusion may be drawn from the ^{1}H NMR experiments of complex **1**. The ^{1}H NMR spectra of complex **1**, showing the integral intensities of hydrogen atoms belonging to N6 and C8 atoms measured after 20 min, and 1, 3, and 6 months, as well as proving the presence of both isomers are depicted in Fig. 3. While a trace signal (3%) belonging to the *trans*-isomer can be seen in the spectrum of complex **1** taken 20 min after dissolving of the sample in DMF, after one month, the *cis*-to-*trans* ratio changed approximately to 6:3. Subsequently, the content of *trans* isomer increased gradually and pure *trans* isomer occurred six months after the beginning of the experiment. On the basis of the above described experiments we can state that the *trans* arrangement of the studied complexes is much more stable than the *cis* one in the DMF solutions. Moreover, the performed experiments gave us clear conclusions regarding the time-dependent stability of *cis* complexes **1–3** in DMF and showed us another possibility how to prepare *trans* isomers in a pure form.

In the quest to better describe the solution behavior of *cis*-complexes **1–3**, we were also trying to determine what is occurring with the complexes in a DMF/water mixture. For that reason, complex **1** was dissolved in DMF-d_7:D_2O mixture in 9:1 (v/v) ratio, and we tried to obtain the signals of some hydroxo or aqua species {i.e *cis*-$[Pt(L_n)_2(OH)_2]$ or *cis*-$[Pt(L_n)_2(H_2O)_2]^{2+}$} that were expected to be formed after dissolving the sample in the mentioned solvent mixture. We could not use higher content of water in the mixture due to low solubility of the prepared complexes in water. The sample was measured in time intervals after 20 min, one week, and 1, 3, and 6 months. We used nearly the same experiment formerly in the case of analogous Pd(II) complexes bearing similar types of ligands, where the signals proving the presence of $[Pd(L)_2(OH)_2]$ species were detected [34]. Unfortunately, we were not successful to observe any obvious NMR signals of $(OH)^-$ group in the case of Pt(II)-complexes **1–3**. This might be caused by the fact that the studied Pt(II) complexes are even less soluble than analogous Pd(II) ones in the same solvent mixture used and the complex concentrations were under the detectable limit of the device used. However, the formation of *cis*-$[Pt(L_n)_2(OH)_2]$ or *cis*-$[Pt(L_n)_2(H_2O)_2]^{2+}$ species in the mixture used may be supported by a simple, but very sensitive, analytical experiment. $AgNO_3$ was added to the solution of complex **1** in the DMF/water (9:1) mixture after one week of standing in room temperature. After this time period, a white precipitate originating from AgCl formed and it showed that chlorine anions had to leave the complex in the solvent. To support assumption that organic ligands remain coordinated to platinum, we simultaneously performed additional NMR experiments. It has been found that complex **1** is sufficiently kinetically inert to hold the organic ligands within the inner coordination sphere of platinum, because signals belonging to the uncoordinated ligands were not detected by means of ^{1}H and ^{13}C NMR measurements. It clearly supports conclusion that *cis*-$[Pt(L_n)_2(OH)_2]$ or *cis*-$[Pt(L_n)_2(H_2O)_2]^{2+}$ species are forming in the mixture of solvents used.

3.4. X-ray molecular structures

Crystallographic data and refinement details for complexes **1**, **4** · $(DMF)_2$ and **5** are summarized in Table 3, while the selected bond lengths and angles are given in Table 4. All important hydrogen-bonding interactions were generated by PARST95 [48].

3.4.1. Molecular and crystal structures of cis-$[Pt(L_1)_2Cl_2]$ (**1**)

The molecular structure of **1** is shown in Fig. 4 (DIAMOND) [40]. The central Pt(II) ion is coordinated by two chlorido and two L_1 ligands through the N7 atoms of the adenine units forming a *cis*-square-planar coordination around the central atom. The Pt–N and Pt–Cl bond distances are comparable with the average bond lengths of 2.027(4) and 2.291(1) Å, respectively, found in related $PtCl_2N_2$ complexes deposited in the Cambridge Structural Database [49]. Most of atoms of one of two L_1 ligands are disordered over two positions. A degree of the disorder can be seen from different positions of adenine moieties and phenyl rings (see Fig. 4). The adenine moieties are turned in the plane of adenine to each other around the center of rotation lying in the N7A atom about 10.3–13.7°. If Cg1 and Cg2 are defined as the centroids of the first and second disordered phenyl rings, then the Cg1···Cg2 distance is 1.9948(2) Å and the dihedral angle between the rings is 41.8(3)°. Two adenine moieties originating from two L_1 ligands (or three, if we consider the disorder in the case of one L_1 ligand) are almost perpendicular to each other [dihedral angles are 93.6(1)° and 93.4(2)°], and the angle between the platinum coordination plane (i.e. a $PtCl_2N_2$ chromophore) and the purine moiety is 65.13(7)°, 72.80(13)° and 71.99(14)°, respectively. The platinum atom deviates significantly from the planarity of the imidazole ring of the first L_1 ligand [the out-of-plane deviation is 0.2807(3) Å] probably as the result of an intramolecular hydrogen-bonding interactions (N6–H···Cl1: N6···Cl1 = 3.275(5) Å; ∠DHA = 141°; where D = a donor atom, H = the corresponding hydrogen atom, A = an acceptor atom), while the deviations of platinum from the other two disordered imidazole rings are notably lower [0.0636(3) and 0.0745(3) Å].

In the crystal packing, the individual molecules of **1** are connected through strong intermolecular C–H···Cl hydrogen-bonding interactions (C8–H···Cl1: H···Cl1 = 2.65 Å, ∠DHA 171°; 2.54 Å,

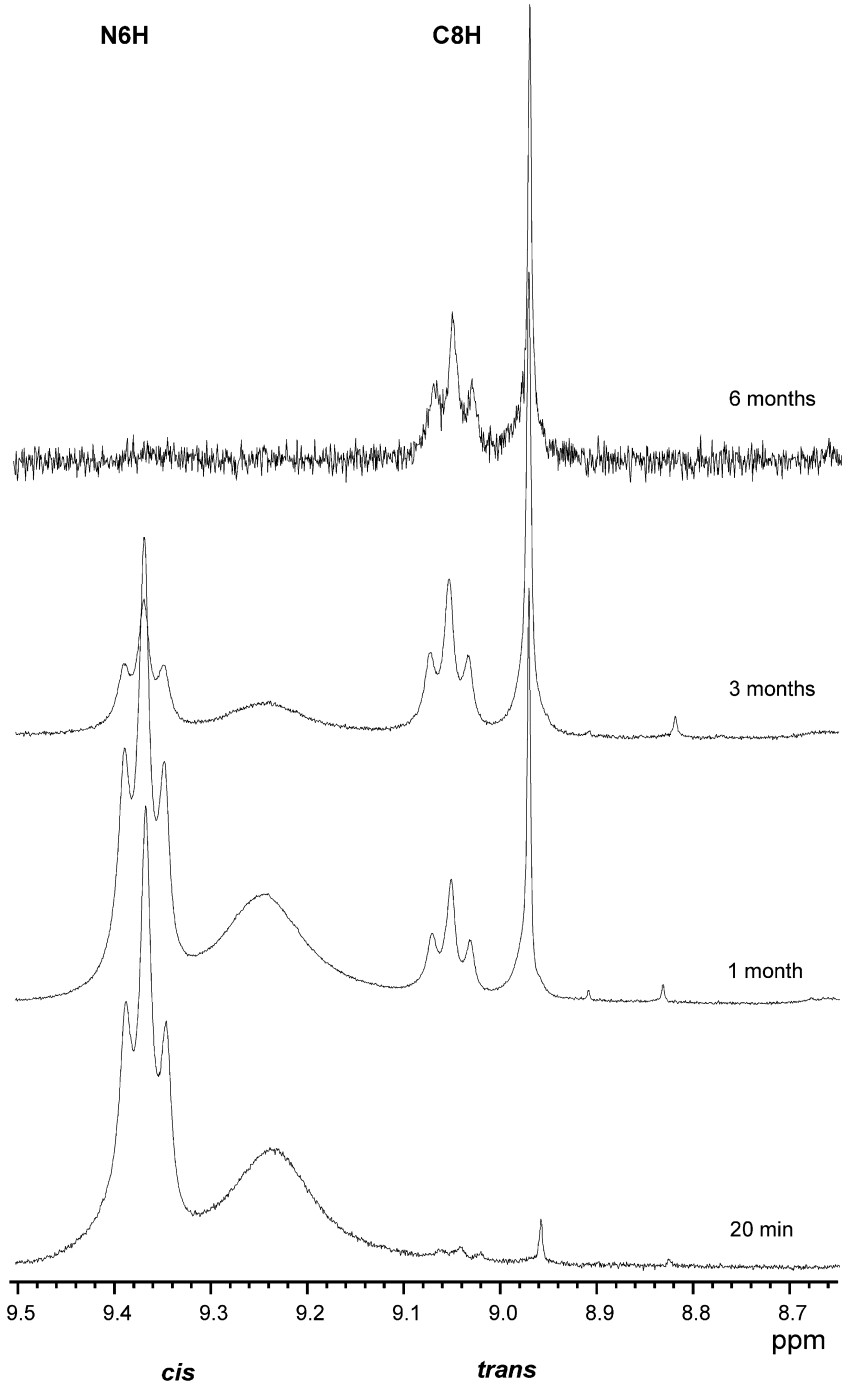

Fig. 3. Selected part of ^{1}H NMR spectra of **1** showing the transformation of *cis* into *trans* isomer of the complex based on the changes of the N6H and C8H signals in dependence on time.

178°; and 2.77 Å; 146°; respectively). The non-bonding intermolecular interactions may be considered to be the main reason of the ligand disorder. Whilst the first position of the disordered L_1 is stabilized by a π interaction [Cl3A···C5: 3.247(8) Å], the second position is stabilized by a π–π stacking interaction [the distance between adjacent parallel imidazole planes is 3.3858 Å].

3.4.2. Molecular and crystal structures of trans-[Pt(L$_1$)$_2$Cl$_2$] (4 · (DMF)$_2$)

The molecular structure of **4** · $(DMF)_2$ (see Fig. 5) revealed a centrosymmetric *trans*-square-planar complex in which the Pt(II) ion is coordinated by two chlorido and two L_1 ligands through the N7 atoms of the adenine moieties [Pt–N: 2.009(2) Å; Pt–Cl: 2.2846(7) Å; N–Pt–Cl: 91.87(7)°]. The Pt(II) ion lies slightly out of the plane of the imidazole ring [the out-of-plane deviation is 0.1332(4) Å]. Similarly to complex **1**, the L_1 ligand is also partially disordered in methyl groups of the isopropyl moiety in the crystal structure of **4** · $(DMF)_2$, i.e. each of the two terminal methyl groups is disordered over two positions. The corresponding methyl groups are turned towards each other about 28° around the axis of rotation lying on the N9–C16 bond. The purine moiety is slightly bent [the dihedral angle between the imidazole and pyrimidine rings is 3.06(13)°] and almost perpendicular to the plane of phenyl group [the dihedral angle is 88.4(1)°].

Symmetry transformations used to generate equivalent atoms labelled A for **4** · $(DMF)_2$: $-x+1, -y+1, -z+1$; for **5**: $-x+1, -y+1, -z+1$.

The crystal packing of **4** · $(DMF)_2$ is stabilized by hydrogen-bonding interactions involving chlorine and some atoms of DMF (e.g. C8–H···O1: H···O1 = 2.16 Å; ∠DHA = 176°; C20–H20C···Cl1: H···Cl1 = 2.78 Å; ∠DHA = 155°; C20–H20A···Cl1: H···Cl1 = 2.81 Å; ∠DHA 148°) forming infinite linear complex–$(DMF)_2$–complex chains.

3.4.3. Molecular and crystal structures of trans-$[Pt(L_2)_2Cl_2]$ (**5**)

The central part of the molecular structure of **5** (see Fig. 6) is very similar to that of **4** · $(DMF)_2$. The complex is centrosymmetric

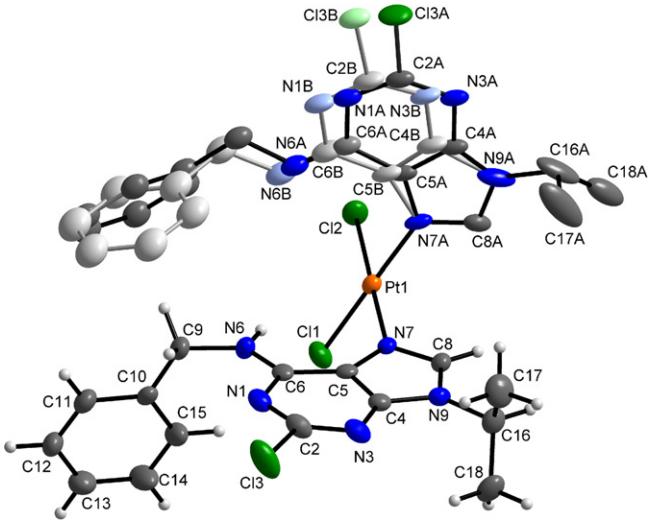

Fig. 4. Molecular structure of complex **1**, showing the atom numbering scheme. Thermal ellipsoids are drawn at the 40% probability level. Some of atoms are disordered over two positions. Some of H-atoms were omitted for clarity.

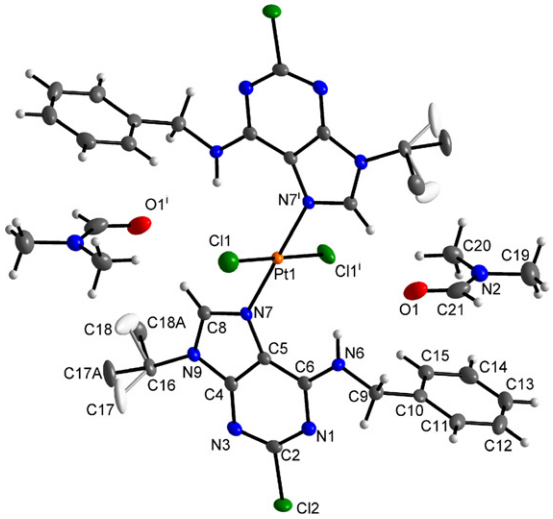

Fig. 5. Molecular structure of the centrosymmetric complex **4** · $(DMF)_2$, showing the atom numbering scheme [symmetry code: (i) $1-x, 1-y, 1-z$]. Some of atoms are disordered over two positions. H-atoms belonging to the disordered part of the molecule were omitted for clarity.

with a *trans*-square-planar coordination around the central Pt(II) ion which is coordinated by two chlorido and two L_2 ligands via the N7 atoms [Pt–N: 2.008(4) Å; Pt–Cl: 2.2954(11) Å; N–Pt–Cl: 91.02(11)°]. The platinum(II) ion lies significantly out of the plane of the imidazole ring [the deviation is 0.1956(1) Å]. The isopropyl group and chlorine atom of the L_2 ligand is disordered over two positions. Atoms of the isopropyl group are turned towards each other around the N9–C16 rotation axis about 31.891(2)°. The purine moiety is also slightly bent [the dihedral angle between the imidazole and pyrimidine rings is 5.23(2)°]. The main structural differences between **4** · $(DMF)_2$ and **5** are in intra- and intermolecular interactions. While the interactions in the crystal structure of **4** · $(DMF)_2$ are affected by the presence of DMF molecules, their absence in **5** result in a more compact molecular packing. The phenyl group of one L_2 ligand in **5** is stabilized by π-interactions with the purine of the other L_2 ligand [if Cg1 is the centroid of the phenyl ring of the first L_2, H8···Cg1 distance is 3.07 Å, H8 distance from

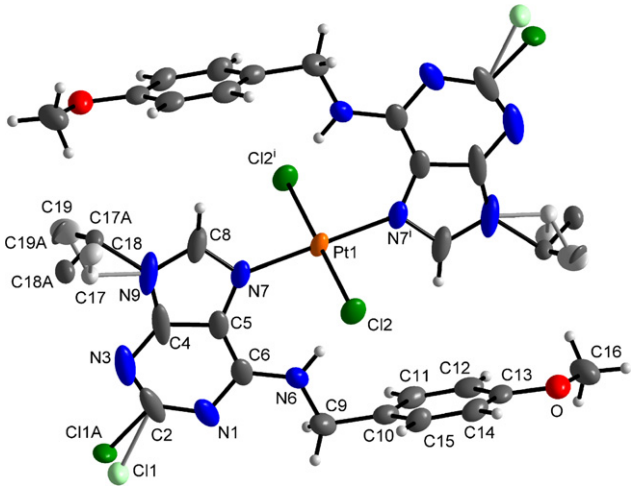

Fig. 6. Molecular structure of the centrosymmetric complex **5**, showing the atom numbering scheme [symmetry code: (i) $1-x, 1-y, 1-z$]. Thermal ellipsoids are drawn at the 50% probability level. Some of atoms are disordered over two positions. H-atoms belonging to the disordered part of the molecule were omitted for clarity.

the plane of the phenyl ring is 3.04 Å, and the dihedral angle between the purine and phenyl moieties is 77.35(13)°]. The crystal packing is further stabilized by intramolecular hydrogen bonds N6–H···Cl2 [N6···Cl2 = 3.281(5) Å; ∠DHA = 139°] and intermolecular Cl···N π–π interactions [Cl2···N1: 3.289(6) Å] arranging molecules of **5** into infinite linear chains.

3.4.4. Crystal structure summary

Generally, the Pt–N and Pt–Cl bond distances in complexes **1**, **4** · $(DMF)_2$ and **5** are in the range of 2.008–2.032 Å, and 2.2834–2.2954 Å, respectively. They are quite comparable to those found for the *trans*-$[PtCl_2(L)_2]$ complex involving two coordinated 2-chloro-6-[(3-hydroxybenzyl)amino]-9-isopropylpurine ligands (L) [50] and also to the average bond lengths found for the Pt–N and Pt–Cl bond lengths (2.02, and 2.29 Å, respectively) in related $PtCl_2N_2$ complexes as reported in the Cambridge Structural Database [49]. In all the discussed complexes, the central platinum atom deviates significantly from the planarity of purine moieties. The degree of deformation of organic ligands within the complexes is markedly influenced by non-bonding intramolecular and intermolecular interactions.

3.5. Biological activity

Complexes **1–6** were screened for their cytotoxic effects *in vitro* against four human cancer cell lines: MCF7, G361, K562 and HOS. Based on the fact that the prepared complexes **1–6** were only slightly soluble in water, and the testing procedure necessarily uses water as a medium, we were limited by the solubility of the complexes in water. That is why we could only prepare water solutions with the complex concentrations being maximally 5 μM. At higher concentrations, the complexes precipitated from the water medium. Unfortunately, the complexes showed to be non-cytotoxic within this low concentration range.

4. Conclusions

We have prepared and fully characterized six new *cis* and *trans* square-planar Pt(II) complexes involving derivatives of plant growth hormones, called cytokinins, derived from 6-benzylaminopurine moiety, and having a general formula of $[Pt(L_n)_2Cl_2]$. X-ray molecular structures of the complexes *cis*-$[Pt(L_1)_2Cl_2]$ (**1**), *trans*-$[Pt(L_1)_2Cl_2]$ (**4** · $(DMF)_2$), and *trans*-$[Pt(L_2)_2Cl_2]$ (**5**) have been determined and supported the composition and stereochemistry following from other physical techniques used for the characterization of the complexes. Moreover, the dynamic *cis*-to-*trans* isomerization process in DMF solutions, as well as the behavior of the complexes in a DMF/water solution has been investigated by the means of multinuclear NMR spectroscopy. The obtained results elucidated and extended our knowledge about time-dependent solution behavior of these complexes. All the complexes were tested *in vitro* against four human cancer cell lines (MCF7, G361, K562 and HOS). The tested compounds could only be tested at low concentrations (up to 5 μM) because of their low solubility in water which is a necessary medium in the testing procedure used. Unfortunately, at this concentration, the complexes, as well as the initial free ligands, showed no cytotoxicity.

ABSTRACT

The novel asymmetric metallo-organic triads *cis*- and *trans*-[B(4-py)BPFPH$_2${Ru$_3$O(Ac)$_6$(py)$_2$}{Ru(bpy)$_2$Cl}](PF$_6$)$_2$ (**5a,b**) for which *cis*- and *trans*-B(4-py)BPFPH$_2$ = 5,10-bis(pentafluorophenyl)-15,20-bis(4-pyridyl)porphyrin and 5,15-bis(pentafluorophenyl)-10,20-bis(4-pyridyl)porphyrin, respectively; Ac = acetate; py = pyridine and bpy = 2,2′-bipyridine, as well as their corresponding monosubstituted dyads *cis*- and *trans*-[B(4-py)BPFPH$_2${Ru$_3$O(Ac)$_6$(py)$_2$}]PF$_6$ (**4a,b**) have been structurally characterized via electrospray ionization mass spectrometry (ESI-MS and ESI-MS/MS). The ESI-MS of dyads **4a,b** display two characteristic Ru-multicomponent clusters of isotopologue ions corresponding to singly charged ions **4a,b**$^+$ of *m/z* 1629 and doubly charged ions [**4a,b**+H]$^{2+}$ of *m/z* 815 and the triads **5a,b** are detected by ESI-MS as the intact doubly charged cluster of isotopologue ions of *m/z* 1039 [**5a,b**]$^{2+}$. The ESI-MS/MS of **4a,b**$^+$, [**4a,b**+H]$^{2+}$ and [**5a,b**]$^{2+}$ reveal characteristic dissociation pathways, which confirm the structural assignments providing additional information on the intrinsic binding strengths of the gaseous ions. Although the gas-phase behavior of each pair of isomers was rather similar, the less symmetric dyads **4a,b** are distinguished via the ^{1}H NMR spectral profile of the pyrrolic signals. Exploratory photophysical assays have shown that both modifying motifs alter the porphyrinic core emission profile, opening the possibility to use these asymmetric systems as photophysical devices.

1. Introduction

Electrospray ionization mass spectrometry (ESI-MS) as well as its tandem version (ESI-MS/MS) have been increasingly used for the structural characterization of organometallic [1], metallo-organic [2], inorganic molecules [3] and supermolecules and their ionic forms [4]. ESI is particularly suited for such species due to its ability to transfer, via an unique and gentle ion evaporation process, pre-formed ions directly from solutions to the gas phase environment of mass spectrometers [5]. ESI-MS is also advantageous for the structural characterization of organometallic and inorganic complexes owing to detailed structural information on both metal cores and ligands, isotope profiles, and high sensitivity, therefore requiring reduced amounts of sample as those required for other conventional techniques, such as NMR and cyclic voltammetry, which are more commonly applied to characterize organometallic and inorganic complexes [6].

Regarding the compounds of interest to this work, porphyrins and metalloporphyrins are molecules of great interest particularly in chemistry, biology and physics, also featuring important industrial applications. They display useful properties such as the ability to mimic biologically-active structures like cytochrome P450 monooxygenases, to act as catalysts and as photosensitizers in photodynamic therapy [7]. Recently, ESI-MS(/MS) has been applied with success to characterize these molecules [8], as well as supramolecular extended structures based on the porphyrinic core [9].

On the other hand, μ-oxo triruthenium acetates complexes constitute a versatile class of molecules that display rich electrochemical behavior, including electrochromism, and interesting spectroscopic and catalytic properties [10]. Relevant work has been done using these triruthenium carboxylates as modifying motifs to porphyrins [11], as building blocks in extended structures which feature electron transfer reactions [12], as well as acceptors for photoinduced transfer reactions in supramolecular assemblies [13]. Their well known chemistry has recently allowed researchers to

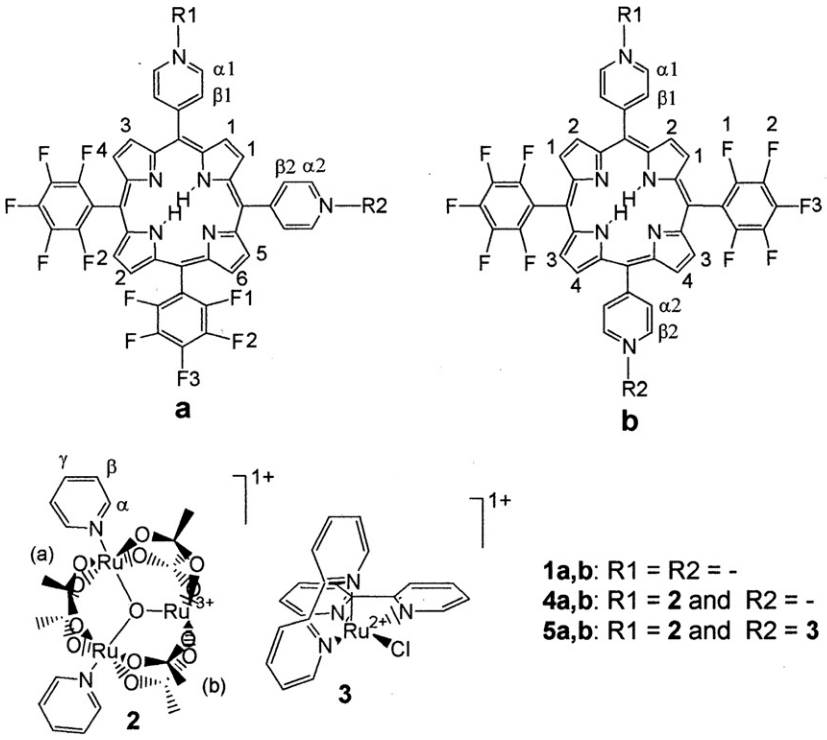

Fig. 1. Structures of the compounds studied herein and labels for NMR assignments.

plan novel clusters with important properties, such as controlled and reversible NO or CO delivery [14]. With respect to the [Ru(bpy)$_3$] moiety, this and related ruthenium polypyridine complexes have been extensively explored and their chemical, electrochemical and spectroscopic (photophysical) behaviors well-described in the literature [15].

This work focuses the structural characterization, via ESI-MS(/MS) and ^{1}H and ^{19}F NMR analysis, of a series of substituted pentafluoropyridylporphyrins synthesised by a suitable approach designed in order to obtain the asymmetric metallo-organic dyads **4a,b** and triads **5a,b** (Fig. 1). It is also presented a brief spectroscopic characterization, as well as preliminary photophysical data. Usually, triads such as **5** are composed by a porphyrin central chromophore and peripheral organic electron donor and acceptor units, which are designed to mimic the active centers of the natural photosynthetic systems. Those triads are able to generate excited states of charge separation and thus convert light into chemical energy [16]. For the novel asymmetric metallo-organic systems **5a,b** that we have prepared, the ruthenium trinuclear complex **2** may act as an electron acceptor owing to its ability to participate in photoinduced electron and energy transfers [13], and the [Ru(bpy)$_2$] moiety **3** would act as a tunable unit able to display either the acceptor or the donating ability, depending on the experiment conditions [17].

2. Experimental

All the reactants were commercially available and used without further purification. The compounds [Ru(bpy)$_2$Cl$_2$] · 2H$_2$O, [Ru$_3$O(Ac)$_6$(py)$_2$(CH$_3$OH)]PF$_6$ and *cis*- and *trans*-B(4-py)BPFPH$_2$(5,10-bis(pentafluorophenyl)-15,20-bis(4-pyridyl)porphyrin and 5,15-bis(pentafluorophenyl)-10,20-bis(4-pyridyl)porphyrin, respectively) were synthesized according to reported procedures [18]. The description of the purification and isolation of the *cis*- and *trans*-pentafluoropyridylporphyrins isomers is detailed elsewhere [19].

2.1. Synthesis of cis- and trans-[B(4-py)BPFPH$_2${Ru$_3$O(Ac)$_6$(py)$_2$}]PF$_6$ (dyads **4a,b**)

About 51.3 mg of [Ru$_3$O(Ac)$_6$(py)$_2$(CH$_3$OH)]PF$_6$ (5.1×10^{-5} mol) was dissolved in 70 mL of dichloromethane and the resulting solution were slowly dropped into a solution of 45 mg (5.6×10^{-5} mol) of *cis*- or *trans*-[B(4-py)BPFPH$_2$], dissolved in 5 mL of dichloromethane. The reaction mixture was magnetically-stirred for 24 h, at room temperature under aerobic conditions. The resulting solution was evaporated to dryness and the purple solid obtained was purified by chromatography in a neutral alumina column of approximately 20 cm high and 2.5 cm of diameter. The solvent used for elution was dichloromethane and the fractions eluted from the column were identified by their UV–Vis absorption spectra. For both dyads **4a,b**, the first fraction eluted was identified as unreacted porphyrin; the following fraction apparently contained mixtures with variable amounts of porphyrin and ruthenium complex. The third fraction contained dyads **4** and the last fraction contained the symmetric, bi-substituted triads *cis*- and *trans*-[B(4-py)BPFPH$_2${Ru$_3$O(Ac)$_6$(py)$_2$}$_2$](PF$_6$)$_2$ (*m/z* 1229 for the cations *cis*- or *trans*-[B(4-py)BPFPH$_2${Ru$_3$O(Ac)$_6$(py)$_2$}$_2$]$^{2+}$; *cis*-[B(4-py)BPFPH$_2$ {Ru$_3$O(Ac)$_6$(py)$_2$}$_2$](PF$_6$)$_2$ $\eta = 6\%$; *trans*-[B(4-py)BPFPH$_2${Ru$_3$O(Ac)$_6$ (py)$_2$}$_2$](PF$_6$)$_2$ $\eta = 9\%$). **4a** ($\eta = 31$); λ_{max}(dichloromethane)/nm ($\log \varepsilon$/dm^3 cm^{-1} mol^{-1} and assignment [18]) 414 (5.5, Soret), 510 (4.4, $Q_{y(1,0)}$), 545 (3.9, $Q_{y(0,0)}$), 587 (4.1, $Q_{x(1,0)}$), 655 (4.0, $Q_{x(0,0)}$) and 691 (4.0, intra-cluster). **4b** ($\eta = 45$); λ_{max}(dichloromethane)/nm ($\log \varepsilon$/dm^3 cm^{-1} mol^{-1} and assignment) 414 (5.4, Soret), 510 (4.4, $Q_{y(1,0)}$), 545 (3.8, $Q_{y(0,0)}$), 587 (4.0, $Q_{x(1,0)}$), 655 (3.9, $Q_{x(0,0)}$) and 691 (3.9, intra-cluster).

2.2. Synthesis of cis- and trans-[B(4-py)BPFPH$_2${Ru$_3$O(Ac)$_6$(py)$_2$}{Ru(bpy)$_2$Cl}](PF$_6$)$_2$ (triads **5a,b**)

About 37.9 mg of dyad **4a,b** (2.1×10^{-5} mol) and 12.2 mg of [Ru(bpy)$_2$Cl$_2$] (2.5×10^{-5} mol) were dissolved in 10 mL of dichlo-

romethane and allowed to react during 48 h, under gentle heat, magnetic stirring and aerobic conditions. The reaction media was then dropped into an alcoholic saturated solution of NH_4PF_6 and, after 2 h, was evaporated to dryness, yielding a black solid. The crude material were purified by chromatography in a neutral alumina column of approximately 20 cm high and 2.5 cm of diameter; the solvent used for elution was a 1% mixture (v/v) of ethanol: dichloromethane and the fractions eluted from the column were identified by their UV–Vis absorption spectra. The products of interest were collected as the third fraction eluted from the column. **5a** (η = 30%); λ_{max}(dichloromethane)/nm ($\log \varepsilon$/dm^3 cm^{-1} mol^{-1} and assignment) 296 (4.4, π–π^*), 417 (5.0, Soret), 511 (4.0, *Qy*(1,0)), 545 (3.7, $Q_{y(0,0)}$), 587 (3.7, $Q_{x(1,0)}$), 650 (3.4, $Q_{x(0,0)}$) and 691 (3.5, intra-cluster). **5b** (η = 6%); λ_{max}(dichloromethane)/nm ($\log \varepsilon$/dm^3 cm^{-1} mol^{-1}and assignment) 295 (4.3, π–π^*), 416 (4.8, Soret), 512 (3.9, *Qy*(1,0)), 548 (3.5, $Q_{y(0,0)}$), 588 (3.6, $Q_{x(1,0)}$), 650 (3.4, $Q_{x(0,0)}$) and 690 (3.4, intra-cluster).

2.3. Physical measurements

The mass spectrometric experiments were performed using a high-resolution hybrid quadrupole (q) and orthogonal time-of-flight (TOF) mass spectrometer (QTOF from Waters Micromass, UK) operating in the positive ion mode at ca. 5000 resolving power. The temperature of the nebulizer was 150 °C and the cone voltage was 30 V. The ESI-MS/MS experiments were performed via Q1 selection of the ion or cluster of ions of interest followed by collision-induced dissociation (CID) with argon in the collision hexapole at energies ranging from 10 to 20 eV and TOF-MS analysis of the ionic fragments. Samples were dissolved in a 1:1 methanol/water solution acidified by the addition of 0.1% formic acid. The ^{1}H, COSY (^{1}H–^{1}H, not shown) and ^{19}F NMR data were collected on a Bruker Advanced DRX 400MHz spectrometer (Bruker Biospin, Bremen, Germany), from 1×10^{-2} mol dm^{-3} $CDCl_3$ solutions. The electronic spectra were recorded on a HP 8453 spectrophotometer, from 1×10^{-5} mol dm^{-3} dichloromethane solutions. Steady-state emission and excitation spectra were recorded on a Spex Fluorolog 2 spectrophotometer (excitation slit = 10 and emission slit = 20), at room temperature in a four faced 1 cm × 1 cm quartz cuvette, from approximately 5×10^{-6} mol dm^{-3} degassed dichloromethane solutions. The quantum yields were calculated from degassed CH_2Cl_2 solutions, using the known value of ϕ_s for $TPPH_2$ (tetraphenyl porphyrin) at room temperature (ϕ_s = 0.099) and the integrated areas under the emission curve corrected by the relative absorbance at the excitation wavelength [17a,20].

3. Results and discussion

3.1. Synthesis

Obtaining the monosubstituted dyads **4a,b** is not a trivial task, since both coordination sites of the precursor isomers **1a,b** (the pyridyl group) are equivalent. Nevertheless, the synthetic approach proposed here is based on the use of sub-stoichiometric amounts of the modifying motif (in this case the trinuclear ruthenium complex **2**), and the addition of a diluted solution of the complex to a more concentrated solution of the porphyrinic core, in order to warranty local excess of porphyrin. Besides that, the reaction was submitted to soft conditions (room temperature and magnetic stirring), and care was taken not to extend the reaction too long, minimizing it to further yield high quantities of the bisubstituted product. This synthetic strategy, along with the adsorption chromatography purification, allowed one to obtain the monosubstituted dyads (η = 31% and η = 45% for **4a** and **4b**, respectively) in higher yield, although the coordination of two trinuclear complexes molecules to the central core has occured to some extent, yielding smaller amounts of the bisubstituted symmetric byproduct, which was collected as the last fraction from the chromatographic column.

In the particular case of compounds **5a,b**, once one of the coordination sites of the porphyrinic center was already compromised with the bond to complex **2**, there was no need to have a rigid control on the synthetic conditions, and the asymmetric triads were obtained by the use of a slight excess of the $[Ru(bpy)_2]$ substituent and a more concentrated reaction medium.

3.2. ESI-MS(/MS)

The porphyrins **1a,b** as well as the dyads **4a,b** and triads **5a,b** show nearly identical gas-phase behaviour, therefore we will comment only on the ESI-MS results for the *cis*-isomers (a). ESI-MS detects the model *cis*-porphyrin **1a** as a cluster of singly-charged mono-protonated molecule [**1a**+H]$^+$ of *m/z* 797 (only the *m/z* of the most intense ion within the isotope cluster will be mentioned). Note that mono-protonation may occur either on a central N atom of the porphyrin ring or on an N hetero-atom of the pyridyl groups. The cluster from the doubly protonated molecule [**1a**+2H]$^{2+}$ of *m/z* 398.5 was not observed at all, indicating that the addition of a second proton to the porphyrin molecule is unfavourable, at least for the gaseous molecule. The gaseous [**1a**+H]$^+$ of *m/z* 797 was then selected and dissociated via 20 eV collisions with argon (spectrum not shown). Interestingly, dissociation occurs to great extent by several successive losses of HF molecules (20 Da). These sequential losses must therefore require substantial molecular rearrangements that are accessed likely due to the lack of alternative less energy-demanding direct bond cleavages.

The ESI-MS of the model compound $[Ru_3O(Ac)_6(py)_2(CH_3OH)]PF_6$, that is **2** · PF_6, display a multicomponent cluster of isotopologue ions of *m/z* 863 mostly characteristic of the Ru_3 composition (ruthenium is a multiple isotope element: ^{104}Ru (18.7%), ^{102}Ru (31.6%), ^{101}Ru (17.0%), ^{100}Ru (12.6%), ^{99}Ru (12.7%), ^{98}Ru (1.88%) and ^{96}Ru (5.52%)). This ion is ascribed to the methanol adduct of **2**$^+$ (Fig. 2) that is, $[Ru_3O(Ac)_6(py)_2(CH_3OH)]^+$. This whole isotopologue cluster of singly charged ions was therefore selected and subjected to 20 eV collision induced dissociation (CID). Extensive CID occurs (Fig. 2) yielding first $[Ru_3O(Ac)_6(py)_2]^+$ of *m/z* 831, that is **2**$^+$. This preferential loss of methanol over pyridine is consistent with the binding strength of both ligands, that is, also in gas phase methanol is more loosely bonded to Ru than py, mimicking the solution behaviour [3]. After methanol loss, successive losses of the two more strongly bonded pyridine ligands (py) occurs thus yielding the fragment ions of *m/z* 751 and *m/z* 672, which are assigned, respectively to $[Ru_3O(Ac)_6py]^+$ and $[Ru_3O(Ac)_6]^+$. The fragment ion of *m/z* 751 dissociates further by an unexpected and interesting process that involves the loss of four acetate (Ac) ligands. We rationalize this dissociation by the release of two neutral dimeric molecules of Ac_2 composition, thus yielding the $[Ru_3O(Ac)_2(py)]^+$ fragment of *m/z* 516. This fragment ion fragments further by pyridine loss to form $[Ru_3O(Ac)_2]^+$ of *m/z* 437.

The ESI-MS of the acidified water:methanol solution of dyad **4a** (spectrum not shown) displays predominantly two prominent clusters of isotopologue ions of similar abundances. In one cluster of *m/z* 1629, the ions are separated by one *m/z* unit indicating that they are singly charged species, ascribed therefore to **4a**$^+$. The other of *m/z* 815 displays ions separated by 1/2 *m/z* unit, and is ascribed to the mono-protonated and therefore doubly charged ion [**4a**+H]$^{2+}$. Fig. 3 shows the ESI-MS/MS of both **4a**$^+$ and [**4a**+H]$^{2+}$.

The gaseous **4a**$^+$ of *m/z* 1629 (Fig. 3a) dissociates promptly upon 20 eV collisions with argon by sequential losses of the peripheral pyridine ligands, yielding the cluster of isotopologues singly-charged ions [**4a**-py]$^+$ and [**4a**-2py]$^+$ of *m/z* 1550 and *m/z* 1471,

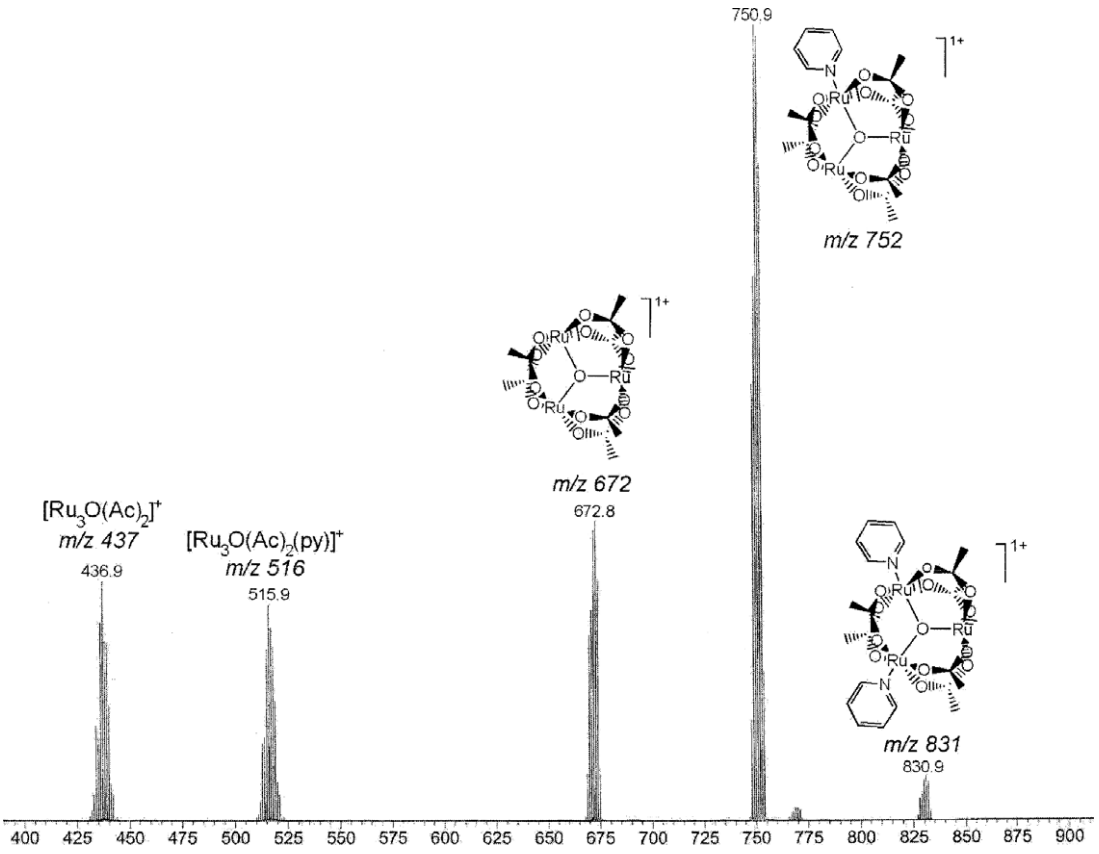

Fig. 2. ESI-MS/MS for 20 eV CID of $[Ru_3O(Ac)_6(py)_2]^+$ of *m/z* 831. Proposed structures and dissociation pathways for the fragment ions are shown as inserts. The parent species $[Ru_3O(Ac)_6(py)_2(CH_3OH)]^+$ of *m/z* 863 dissociates completely and is not detected.

respectively. It dissociates also to form the isotopologue cluster of **2**$^+$ ions of *m/z* 831 due to the loss of the entire porphyrin ligand hence due to the dissassembly of the supramolecular dyad. It was previously reported [9c] that for a similar supramolecular system in which a tetra-pyridyl porphyrin is modified exclusively with the $[Ru(bpy)_2Cl]$ fragment, CID fails to form supramolecular species via the loss of peripheral 2,2′-bipyridine ligand (a fragment that would be analogous to [**4a**-py]$^+$). Instead, only the successive cleavage of the Ru–pyridyl bond was observed thus yielding the two fragments composing the supermolecular assembly. For that assembly, the chelate effect stabilizes the Ru–bpy bond making it stronger than the Ru–pyridyl bond. For **4a**$^+$ however, we observe a different behaviour: the three fragments and their relative abundances, [**4a**-py]$^+$ > [**4a**-2py]$^+$ = [**2**]$^+$ and the absence of any additional effect such as the chelate one lead us to conclude that at least for the unprotonated **4a**$^+$ species, the bond of the $[Ru_3O]$ core to the porphyrin through the pyridyl group (the one that sustain the supramolecular assembly), is as strong as the bond of the $[Ru_3O]$ to the peripheral pyridine ligands.

In Fig. 3a we also observe that **4a**$^+$ of *m/z* 1629 dissociates to form a cluster of singly charged (separated by one *m/z* unit) isotopologue ions of *m/z* 752, which corresponds to [**2**-py]$^+$. Being the most abundant fragment ion, we assume that probably [**2**-py]$^+$ is originated not solely from **2**$^+$ of *m/z* 831, but also from [**4a**-py]$^+$ of *m/z* 1550. Further fragmentation of **4a**$^+$ also occurs to originate less abundant ions such as $[Ru_3O(Ac)_2py]^+$ and $[Ru_3O(Ac)_2]^+$ of *m/z* 516 and *m/z* 437, respectively.

The ESI-MS/MS of the isotopologue cluster of [**4a**+H]$^{2+}$ ions of *m/z* 815 is quite unique and illustrative (Fig. 3b). It shows that the ion loses the peripheral pyridine ligand of 89 Da to form the doubly charged cluster of supramolecular species [**4a**+H-py]$^{2+}$ of *m/z* 775, separated by 1/2 *m/z* units. This loss reinforces the indication that the Ru–porphyrin bond is quite strong. Due to pyridyl–Ru bond cleavage, [**4a**+H]$^{2+}$ of *m/z* 815 also dissociate by "charge partitioning" to form two singly charged species: the singly charged cluster of isotopologue ions [**1a**+H]$^+$ of *m/z* 797 (with a much less diverse isotope pattern) and **2**$^+$ of *m/z* 831 (a diverse Ru_3-isotope pattern) both containing ions separated by one *m/z* unit. Note that **2**$^+$ undergoes further dissociation by the loss of one peripheral pyridine, yielding the cluster of singly charged isotopologue ions [**2**-py]$^+$ of *m/z* 752.

The ESI-MS of the triad **5a** solution shows that ESI is able to gently transfer to the gas phase the doubly charged ion **5a**$^{2+}$ of *m/z* 1039 with spatially separated charge sites, detecting it unambiguously as a characteristic cluster of isotopologue ions separated by 1/2 *m/z* unit. The ESI-MS data shows therefore that the synthetic approach reported herein to obtain the assymmetrical **5a,b** isomeric supermolecules was successful. To obtain structural confirmation for **5a**, and for clarity and illustration, the ESI-MS/MS of the ions of *m/z* 1039 (in fact a mixture of isobaric Ru-isotopologue ions) selected from the multicomponent cluster of isotopologue ions of **5a**$^{2+}$ (see inset) was acquired (Fig. 4). Scheme 1 depicts the "charge partitioning" dissociation pattern proposed for **5a**$^{2+}$.

The doubly charged **5a**$^{+2}$ ions of *m/z* 1039 dissociates mainly by "charge partitioning" to yield two pairs of singly charged cations, that is, (i) **4a**$^+$ of *m/z* 1630 and $[B(4\text{-py})BPFPH_2\{Ru(bpy)_2Cl\}]^+$ of *m/z* 1247 and (ii) **2**$^+$ of *m/z* 833 and **3**$^+$ of *m/z* 449. The fragment **4a**$^+$ undergoes further dissociation by the loss of its peripheral pyridine ligand to yield [**4a**-py]$^+$ of *m/z* 1551.

3.3. NMR spectroscopy

Table 1 summarize the tentative assignment of the observed NMR signals for **1a,b** (^{1}H and ^{19}F) and **4a,b** (^{1}H). ^{19}F-RMN spectra

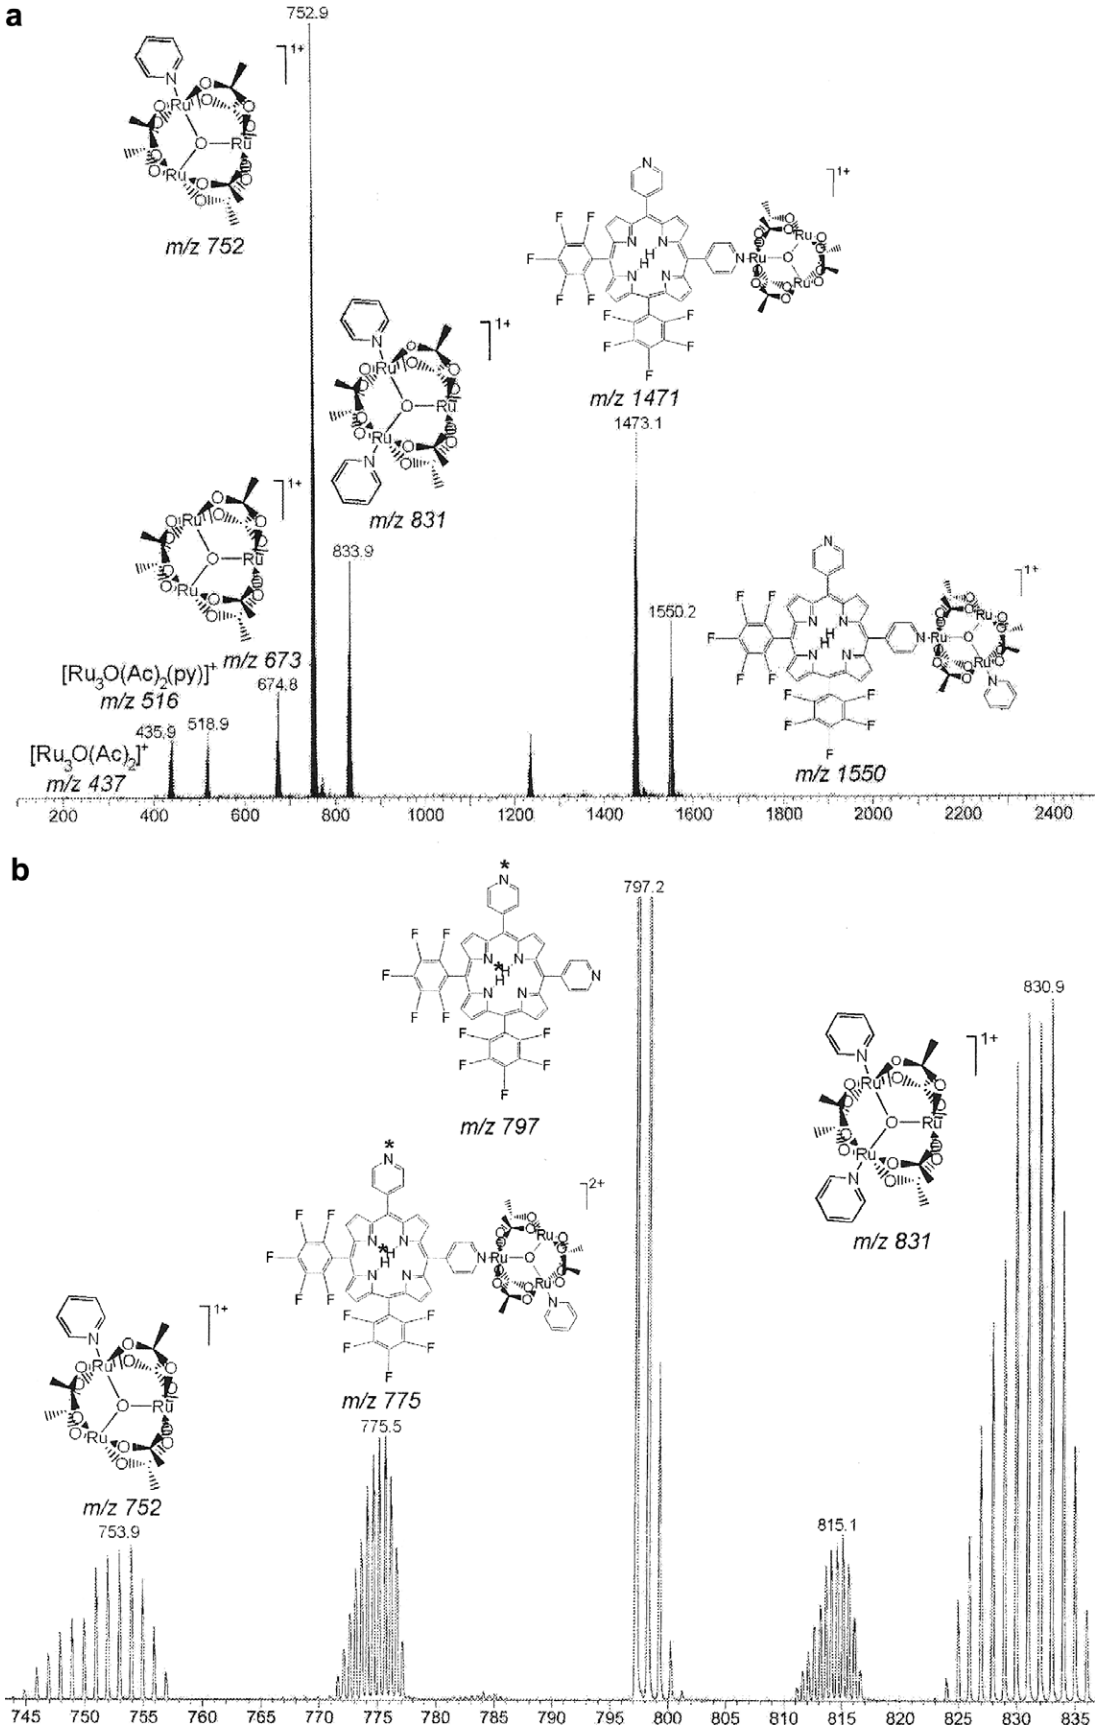

Fig. 3. ESI-MS/MS for 20 eV CID of: (a) $\mathbf{4a}^{+}$ of *m/z* 1629 and (b) $[\mathbf{4a}+H]^{2+}$ of *m/z* 815.

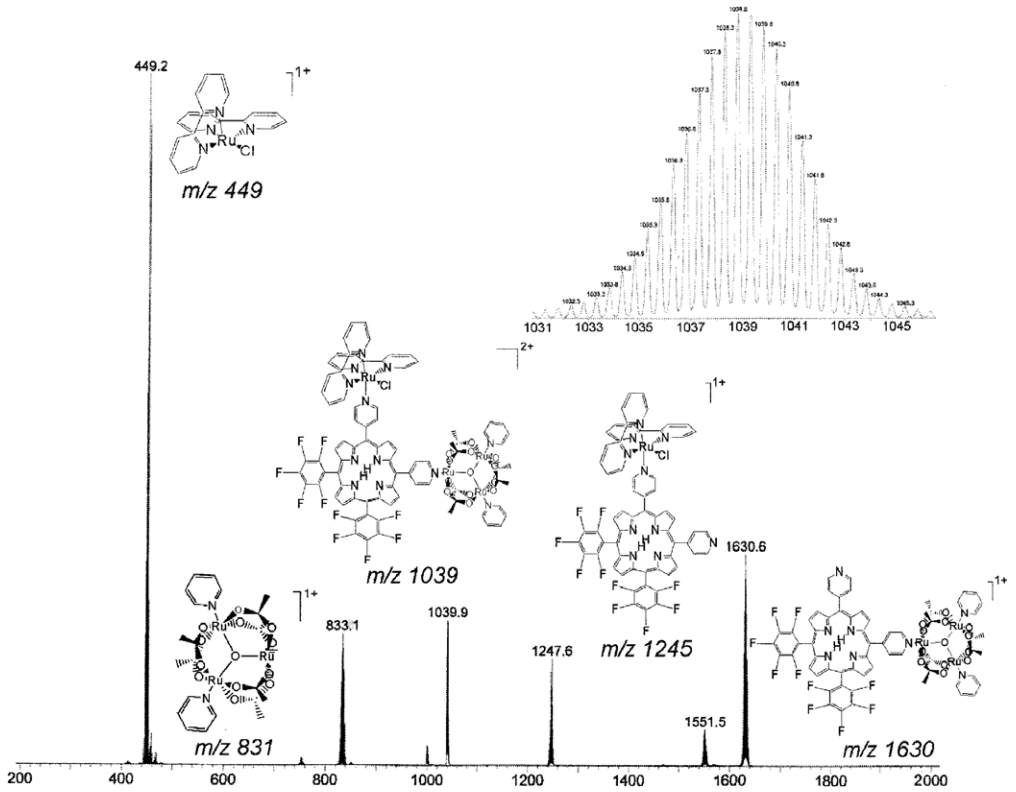

Fig. 4. ESI-MS/MS for 15 eV CID of $\mathbf{5a}^{2+}$ of *m/z* 1039. The inset shows the full cluster of isotopologue ions of $\mathbf{5a}^{2+}$ detected by ESI-MS.

are quite useful to characterize fluorinated porphyrins [21]. As expected for isomers **1a** and **1b**, the ^{19}F-RMN spectra display three sets of signals corresponding to the *ortho*, meta and *para* fluorines. Each signal appears as a doublet and two triplets, respectively, and show no significant variations on the chemical shifts values between the *cis* to the*trans* isomer. The pyrrolic ^{1}H signals of the *cis*-porphyrin isomer 1, however, which were expected to appear as a set of two doublets and two singlets [22], are superimposed into two distorted doublets, each of them integrating to four protons. This spectral profile almost converges to the one observed for the *trans* isomer 1b (two doublets), making it hard to identify the precursors isomers by the ^{1}H NMR spectra. Nevertheless, the coordination of **2** to one pyridyl position of the *cis* and *trans*-dyads **4a,b** lowers the molecular symmetry, leading to different patterns of resonances in the aromatic region of the ^{1}H spectra, making therefore the isomers distinguishable.

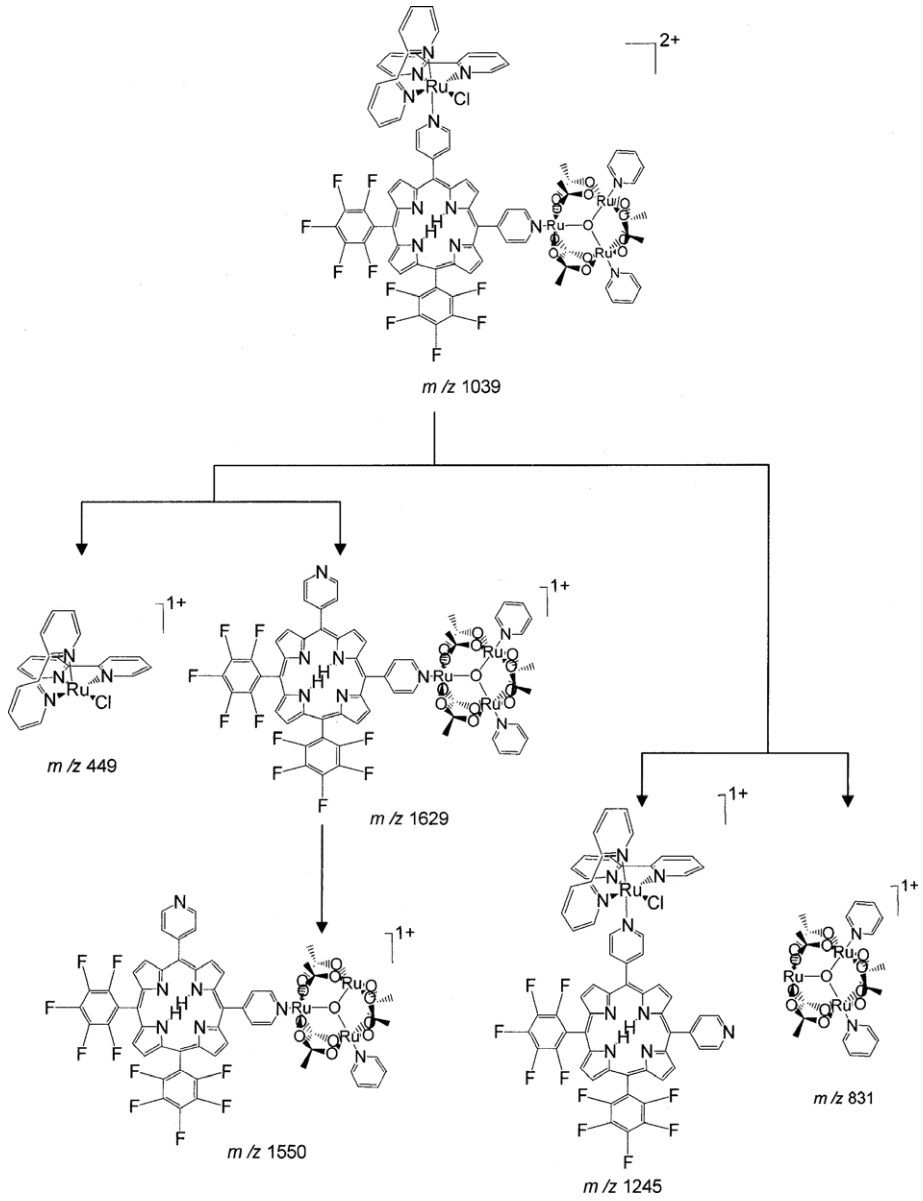
Concerning the $[Ru_3O(Ac)_6(py)_2]$ moiety, the δ values follow the pattern dictated by the paramagnetic anisotropy of the $[Ru_3O]$ core, which contains one unpaired electron [6c,10]. For the ^{1}H spectra, this effect promotes large shifts to higher field on the pyridinic protons α, β, γ, α1 and β1, which tend to vanish with distance, suggesting that the pseudo-contact is the main paramagnetic interaction mechanism operating in these molecules.

3.4. Absorption spectra and exploratory photophysical essays

In terms of the absorption spectra of dyads **4a,b** and triads **5a,b**, the coordination of the ruthenium complexes to the precursors **1a,b** causes very little perturbation on the spectra profiles, resulting in spectra which are a summation of the bands observed in the electronic spectra of each building block that composes the supermolecules (see Section 2 for λ_{max} and assignments).

Exciting isomers **1a,b** in one of their Q band leads to the typical porphyrin emission, centered around 645 and 705 nm, assigned to a fluorescence band with vibrational structure ($Q_{0,0}$ and $Q_{0,1}$ respectively, Table 2) [23]. In spite of the absorption spectra suggest poor electronic coupling among the units composing the supermolecules, going to dyads **4a,b**, one can observe that the coordination of the triruthenium compound **2** to porphyrins **1a,b** leads to a significant decrease in the fluorescence quantum yield (ϕ) and the rise of another emission band, with very low intensity, centered at 770 nm. The coordination of the second substituent (compound **3**), yielding triads **5a,b** leads to a further decrease of ϕ, but do not introduce any modification on the spectra profile.

Although it was not possible to do a selective excitation, due to band overlap in the UV–Vis spectra, triads **5a,b** were excited at 490 nm (approximately the λ_{max} of the $[Ru(bpy)_2]$ MLCT transition) and neither emission from the ruthenium chromophore nor an increase in the ϕ values of the porphyrin emission were observed. In fact, the excitation spectra (not shown) were recorded monitoring all the three observed emission bands and, in all cases the spectra reproduces exclusively the spectral profile of the porphyrin (Soret and four Q bands). This result, and the low emission quantum yield observed for the supermolecules show that there is no contribution from electronic levels of the peripheral units to the porphyrin emission and that these units are quenching that emission. In the particular case of the 770 nm band, it has been assigned to a porphyrin phosphorescence [23], which might appear when there is direct sensitization of the porphyrin triplet state by energy transfer, or when the rate of intersystem crossing (ISC) is high [24]. The absence of any bands of the **2** and **3** units in the excitation spectra of triads **5a,b** excludes the first argument exposed above. Therefore, it seems that the coordination of two ruthenium compounds to the porphyrinic core has simply favored ISC by the heavy atom effect. This explanation also holds for dyads **4a,b**.



Scheme 1. Dissociation pattern of triad **5a**.

On a qualitative basis, the preliminary data presented here allows one to point out some interesting aspects: concerning the triruthenium compound **2**, it could quench the porphyrin fluorescence by a reabsorption interference, since it has an absorption band centered around 690 nm, which matches the emission bands at 650 nm/710 nm. However, there are a few literature examples in which the triruthenium compound is able to quench a $[Ru(bpy)_2]$ chromophore by both photoinduced energy and electron transfers [13a] and quench Zn porphyrins and Zn phtalocyanines by photoinduced electron transfer mechanism [13c,25]. Therefore, in the present case it is possible to propose that the porphyrinic core emission is partially quenched by an electron transfer to the triruthenium moiety.

For triads **5a,b** there is the additional effect of the $[Ru(bpy)_2Cl]$ modifying complex. The porphyrin singlet state might be transfering excitation energy to the $MLCT^3$ (metal to ligand charge transfer) of the metal complex, since the energy of this state [15b] is close to that of the emitting state of the porphyrinic core. If this is so, one would expect to detect the emission of the $[Ru(bpy)_2Cl]$ chromophore. However, in the particular case of ruthenium–bipyridine complexes whose coordination sphere is completed with a chloro ligand, the $MLCT^3$ is normally quenched by a low lying d–d state, which decays by non-radiative (vibrational) pathways [15b,26]. In all cases, the existence of a phosphorescence band, which arises from an ISC process, also contributes to the decrease of the porphyrin ϕ_{fl}.

Finally, although it was demonstrated here that the electronic coupling of the units which composes compound **4a,b** and **5a,b** is rather low, it is worth mentioning that, as far as we consider the present data, it seems that the difference in the position of the coordinating pyridyl groups on the porphyrinic core does not disturb the electronic properties of the molecules under investigation. Consequently, it was not detected significant differences in the spectroscopic behaviour of the isomers studied. Yet, the positional isomerism is manifested in the NMR measurements results for compounds **1a,b** and **4a,b**, since the symmetry of molecules might be directly addressed by this technique.

Table 1
Tentative assignment of the observed ^{1}H and ^{19}F chemical shifts (δ/ppm) for compound **1a,b** and **4a,b** from 1×10^{-2} mol dm^{-3} $CDCl_3$

4. Conclusions

Using ESI-MS and ESI-MS/MS, we have been able to gently transfer to the gas phase the corresponding cationic species **4a,b**$^{+}$ and **5a,b**$^{2+}$ present in solutions of dyads **4a,b** and triads **5a,b**, respectively. Using ESI-MS/MS and by performing CID of isolated gaseous ions, and by following changes in characteristic isotope patters and charge states, we have been able to characterize these gaseous ions via their structurally diagnostic dissociation chemistries. The ESI-MS(/MS) data, besides demonstrating the success of the synthetic approach used to prepare dyads **4a,b** and assymmetric triads **5a,b**, shows that these species constitute another series of gaseous ions with stable, long-lived supramolecular assemblies. The molecular *cis* or *trans* conformation of these species has been found to have no particular effect on their intrinsic dissociation chemistry. Via ESI-MS/MS, it was also possible to access information on the relative bond strengths of these supermolecular ions. For the singly charged dyads **4a,b**$^{+}$, no significant differences were observed for the cleavage of the Ru–pyridine bond or the Ru–pyridyl bond, showing that the supramolecular arrangement is supported by a strong coordinative bond. However, as expected for the doubly charged triad ions **5a,b**$^{2+}$, no preferential cleavage of the Ru–pyridyl bond was observed as opposed to the Ru–bipyridine bond, which is stabilized by the chelate effect, being thus stronger than the interaction that keeps the integrity of the triads.

Regarding the photophysical behaviour of triads **5a,b**, any further comments based on the data presented here would be too speculative. Nevertheless, this work has shown that the coordination of the triruthenium compounds do quench the porphyrin luminescence, thus acting as a final acceptor of excitation energy. Under the conditions investigated here, the $[Ru(bpy)_2Cl]$ unit is also playing the function of excitation energy acceptor. Measurements at low temperature and different solvents are underway in our laboratories in order to evaluate if variations in experimental conditions would lead to a system where the $[Ru(bpy)_2]$ unit would act as a donor of excitation energy and also to get a better understanding on the mechanisms of the porphyrin luminescence quenching by the substituents **2** and **3**.

ABSTRACT

The present paper includes synthesis and spectral characterization of the novel prepared palladium(II) and zinc(II) complexes with 2-formyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone, HFo4Npypipe, **1** and the 2-acetyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone, HAc4Npypipe, **2**. The Pd(II) complexes [PdCl(Fo4Npypipe)], **3**, [PdCl(Ac4Npypipe)], **4** and the Zn(II) complexes [$ZnCl_2$(Fo4Npypipe)], **5** and [$ZnCl_2$(Ac4Npypipe)], **6** have been characterized by elemental analyses and spectroscopic studies. The crystal structure of the complexes [PdCl(Fo4Npippy)], **3** and [PdCl(Ac4Npippy)], **4**, have been solved by single-crystal X-ray diffraction. The electronic, IR, UV/Vis, and NMR spectroscopic data of the complexes are reported. The results of the cytotoxic activity of **1**–**6** have been evaluated *in vitro* against the cells of three human cancer cell lines: MCF-7, T24, A-549 and a mouse L-929 (a fibroblast-like cell line cloned from strain L). For selected compounds **2** and **6** the acute toxicity and antitumor activity were evaluated on leukemia P388-bearing mice. The Zn(II) compounds **5** and **6** are considered as agents with potential antitumor activity, and can therefore be candidates for further stages of screening *in vitro* and/or *in vivo*.

1. Introduction

Tsc's are among the most potent inhibitors of ribonucleotide reductase, RR, activity. RR catalyzes the synthesis of deoxyribonucleotides from their ribonucleotide precursors and as such is responsible for maintaining a balanced supply of the deoxyribonucleotides required for DNA synthesis and repair. Strong positive correlation has been established between RR activity and the rate of replication of cancer cells. The mechanism of action of Tscs is due to their ability to inhibit the biosynthesis of DNA, possibly by blocking the enzyme ribonucleotide diphosphate reductase, binding to the nitrogen bases of DNA, hindering or blocking base replication and creation of lesions in DNA strands by oxidative rupture [1].

The chemistry of transition metal complexes of thiosemicarbazone, Tsc's, has been receiving considerable attention largely because their broad profile of pharmacological activity affords a diverse variety of compounds with different activities [2]. The biological properties of Tsc's are often related to metal ion coordination. Firstly, lipophilicity, which controls the rate of entry into the cell, is modified by coordination and some side effects may decrease upon complexation. In addition, the complex can exhibit bioactivities which are not shown by the free ligand [3–9]. The combination of Tsc's with agents like platinum(II) and palladium(II) that damage DNA produces synergistic inhibition of tumor growth and may lead to improvements in the effectiveness of cancer chemotherapy regimens [3–9]. Zinc is the second most prominent trace metal in the human body after iron. Zinc deficiency may cause growth effects, although unlike copper and iron few noxious effects of excess zinc have been observed. Zinc is essential for growth and developments and plays an important role in various biological systems and is a vital component an essential cofactor, critical for numerous cellular processes and may be a major regulatory ion in the metabolism of cells. Zinc is cytoprotective and suppresses apoptotic pathways. Also, zinc plays a role in brain, where it has a specific function as a neuromodulator in addition to its other typical cellular functions [10].

The present work is an extension of previously studied platinum(II), palladium(II) and zinc(II) complexes of 2-acetylpyridine-thiosemicarbazones and 2-carbaldehyde thiosemicarbazone with potentially interesting biological activities [5–9]. The present paper includes synthesis and spectral characterization of the newly prepared palladium(II) and zinc(II) complexes with 2-formylpyridine

N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone, HFo4Npypipe, **1** and the 2-acetyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone, HAc4Npypipe, **2** and the crystal structure of the complexes [PdCl(Fo4Npippy)], **3** and [PdCl(Ac4Npippy)], **4**. The cytotoxic activities of **1**–**6** have been evaluated *in vitro* against the cells of three human cancer cell lines: MCF-7 (human breast cancer cell line), T24 (bladder cancer cell line), A-549 (non-small cell lung carcinoma) and a mouse L-929 (a fibroblast-like cell line cloned from strain L). For selected compounds **2** and **6** the acute toxicity and antitumor activity were evaluated on leukemia P388-bearing mice.

2. Experimental

2.1. General and instrumental

Solvents were purified and dried according to standard procedures. Infrared and far-infrared spectra were recorded on a Perkin Elmer Spectrum GX Fourier transform spectrophotometer using KBr pellets (4000–400 cm^{-1}) and Nujol mulls dispersed between polyethylene disks (400–40 cm^{-1}). UV–Vis spectra were acquired with a JASCO V-570 UV/Vis/NIR spectrophotometer. The ^1H (250.13 MHz) spectra were obtained on a Bruker AMX-400 spectrometer at room temperature with the signal of the free DMSO or $CHCl_3$ (at 2.49 and 7.24 ppm, respectively) as a reference. Cross-peaking of heteronuclear multiple quantum correlation (HMQC) and heteronuclear multiple bond correlation (HMBC) gradient-assisted spectra **1** and **2** were performed. Elemental analyses, C, H, N and S were performed on a Carlo Erba EA (model 1108).

2.1.1. Preparation of the ligands

*2-Formyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone (HFoPy4PyPiz), **1** and 2-acetyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone (HAcPy4PyPiz), **2***: 4-methyl-4-phenyl-3-thiosemicarbazide was prepared according to the method described by Scovil [11]. The crude product, 4-methyl-4-phenyl-3-thiosemicarbazide, was recrystallized from a mixture of EtOH and distilled water (3:1). To a solution of 4-methyl-4-phenyl-3-thiosemicarbazide (0.905 g, 5 mmol) in CH_3CN (5 ml), 1-(2-pyridyl) piperazine (8 ml, 5 mmol) and 2-formyl pyridine (0.47 ml, 5 mmol) or 2-acetyl pyridine (0.56 ml, 5 mmol) were added. The mixture was refluxed for 25 min and then left standing in a refrigerator for 12 h. The resulting yellow precipitates were filtered off, washed with cold CH_3CN, recrystallized from CH_3CN and dried in vacuo over silica gel, and then at 40 °C in vacuo over P_4O_{10} for 3 h. **1**: Yield: 62%. Mp 159 °C. IR (cm^{-1}): 3141m, ν(NH); 2970, 2835s, $\nu(CH_2)$; 1599s, ν(C=N); 1561s, δ(NH); 1102ms, ν(NN); 922s, ν(C=S); 643ms, δ(py). UV–Vis: ($CHCl_3$)λ/cm^{-1} ($\log\varepsilon$) 31,545 (3.30); (DMF) λ/cm^{-1} ($\log\varepsilon$) 32,400 (4.18). *Anal.* Calc. for $C_{16}H_{18}N_6S$ (M_W: 326.42): C, 58.9; H, 5.6; N, 25.7; S, 9.8. Found: C, 59.0; H, 5.8; N, 25.9; S, 9.7%. Compound **2**: Yield: 43%. Mp 142 °C. IR (cm^{-1}): 3231w, ν(NH); 2995w, 2848 m, $\nu(CH_2)$; 1595s, ν(C=N); 1560m, δ(NH); 1087m, ν(NN); 941ms, ν(C=S); 649m, δ(py). UV–Vis: ($CHCl_3$)λ/cm^{-1} ($\log\varepsilon$) 32 790 (3.17), 25 060 (3.02); (DMF) λ/cm^{-1} ($\log\varepsilon$) 33 420 (3.78). *Anal.* Calc. for $C_{17}H_{20}N_6S$ (M_W: 340.45): C, 59.9; H, 5.9; N, 24.7; S, 9.4. Found: C, 59.7; H, 6.6; N, 25.1; S, 10.2.

2.1.2. Preparation of the complexes

*Chloro(2-formyl pyridine N(4)-1-(2-pyridyl)-piperazinyl-thiosemicarbazonato) palladium(II) [PdCl(FoPy4PyPiz)], **3** and chloro(2-acetyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazonato) palladium(II) ([PdCl(AcPy4PyPiz)], **4***: To lithium tetrachloropalladate, prepared *in situ* from $PdCl_2$ (0.1241 g, 0.7 mmol) and LiCl (0.847 g, 2 mmol), in MeOH (5 ml), was added a soln. of ligand **1** (0.1827 g, 0.56 mmol) or **2** (0.1908 g, 0.56 mmol) in MeOH (5 ml). The mixture was stirred for 24 h at RT and then left in a refrigerator for 24 h. The resulting orange precipitate was filtered off, washed with cold MeOH and Et_2O, recrystallized from MeOH and dried *in vacuo* over silica gel, and then at 70° *in vacuo* over P_4O_{10} for 2 h. Compound **3**: Yield: 83%. Orange powder. Mp 245 °C (dec.) Found: C, 42.9; H, 4.3; N, 17.6; S, 6.7%.

2.2. X-ray crystallography

A summary of the crystal data, experimental details and refinement results are listed in Table 1. All measurements of crystals were performed on a Bruker-P4 diffractometer. Data were collected at 293 K using Mo Kα radiation (λ = 0.71073 Å) and the ω-scan technique, and corrected for Lorentz and polarization effects. A semi-empirical absorption correction (Ψ-scans) was made. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 25 reflections in the range $2.33 < \theta < 24.99$ for **3** and $2.48 < \theta < 26.81$ for **4**. The structure was solved by direct methods (program SHELXS SHELXS-97) and refined by the full-matrix least-squares method on all F^2 data using the WINGX version of SHELXL SHELXL-97 programs [12]. Non-hydrogen atoms were refined with anisotropic displacement parameters; all hydrogen atoms were located in their calculated positions (C–H 0.93–0.97 Å) and refined using a riding model for **3** and **4**. Atomic scattering factors are from "International Tables for X-ray Crystallography" and molecular graphics were performed from PLATON2001 [12].

2.3. In vitro growth inhibition assay

Compounds: Test solutions of the compounds tested (1 mg/ml) were prepared by dissolving the substance in 100 μl of DMSO com-

pleted with 900 μl of tissue culture medium. Afterwards, the tested compounds were diluted in culture medium to reach the final concentrations of 100, 10, 1, and 0.1 ng/μl. The solvent (DMSO) in the highest concentration used in test did not reveal any cytotoxic activity. *Cells*: The cell lines are maintained in the Cell Culture Collection of the University of Ioannina. Twenty-four hours before addition of the tested agents, the cells were plated in 96-well plates at a density of 10^4 cells per well. The MCF-7 cells were cultured in the D-MEM (Modified Eagle's Medium) medium supplemented with 1% antibiotic and 10% fetal calf serum. L-929 cells were grown in Hepes-buffered RPMI 1640 medium supplemented with 10% fetal calf serum, penicillin (50 U/ml) and streptomycin (50 mg/ml). A-549 cells were grown in F-12K Ham's medium supplemented with 1% glutamine, 1% antibiotic/antimycotic, 2% $NaHCO_3$ and 10% fetal calf serum. The cell cultures were maintained at 37 °C in a humid atmosphere saturated with 5% CO_2. Cell number was counted by the Trypan blue dye exclusion method. MCF-7, L-929 and A-549 cells were determined by the sulforhodamine B assay [13], while T24 cells by the MTT assay [14]. The *in vitro* tests were performed as described previously [9a,9c].

2.4. In vivo antitumor experiments [15]

Mice: Male and female DBA/2 and BDF/1 (C57BL x DBA/2) that were 8–10 weeks old and weighed 20–25 g were used for toxicity studies and antitumor evaluation. The mice were obtained from the Experimental Laboratory of Theagenion Anticancer Institute, and kept in sterile cages under conditions of constant temperature and humidity, with water and food. Lymphocytic P388 Leukemia was maintained in ascetic form in DBA/2 mice by injection of 10^6 cells into the peritoneal cavity at 6-day intervals.

Compounds: For intraperitoneal treatment, stock solutions of the compounds used in this study were made immediately before use. They were suspended in corn oil in the desired concentration following initial dissolution in a small amount of 10% dimethylsulfoxide. This concentration by itself produced no observable toxic effect. A drop of Tween 80 was added. The estimation of acute toxicity and the antitumor evaluation were performed as described previously [5b,5c,6b].

3. Results and discussion

3.1. Synthetic aspects

HFo4Npypipe and HAc4Npypipe were synthesized by the condensation of 3-methyl-3-phenyl-thiosemicarbazide synthesized according to Scovil [11], formyl pyridine or 2-acetyl pyridine and 1-(2-pyridyl)-piperazine. The Pd(II) complexes [PdCl(FoPy4PyPiz)], **3** *and* [PdCl(AcPy4PyPiz)], **4** were prepared by reacting lithium tetrachloropalladate (Li_2PdCl_4) – prepared *in situ* from $PdCl_2$ and LiCl – with the **1** or **2** in MeOH solution in a molar ratio of 1:1. It has been found that palladium(II) promotes deprotonation of thiosemicarbazones in the presence of methanolic solutions [6–8]. The Zn(II) complexes [$ZnCl_2$(HFoPy4PyPiz)], **5** and [$ZnCl_2$(HAcPy4-PyPiz)], **6** were prepared by refluxing $ZnCl_2$ with the **1** or **2** in EtOH solution in a molar ratio of 1:1. The formula of these Pd(II) and Zn(II) complexes were confirmed by elemental analysis, spectroscopic studies and for **3** and **4** by X-ray analysis. The stoichiometries of the complexes indicate that Pd(II) is coordinated by the singly charged anion Fo4Npypipe$^-$ and Ac4Npypipe$^-$ in **3** and **4**, while Zn(II) is coordinated by the neutral molecule HFo4Npypipe and HAc4Npypipe in **5** and **6**. For details, (see Section 2).

3.2. Structural characterization

Complexes **3** and **4** were recrystallized from MeCN and dimethylformamide, respectively, to furnish orange prisms suitable for single-crystal X-ray analysis. Selected interatomic distances and bond angles are collected in Table 2. Anionic **1** and **2** act as tridentate ligands coordinating to the Pd^{II} center through the pyridyl N-atom, N(1), the azomethine N-atom, N(2), and the thiolato S-atom, Figs. 1 and 2. The ligand shows a (*Z*, *E*, *Z*)-configuration for these three donor centers, respectively. The S–C bond distance is consistent with an increased single-bond character, and both thioamide C=N distances indicate increased double-bond character. The ligands are planar, as indicated by the dihedral angle between the mean planes of the pyridyl ring and the chelate ring Pd–S–C–N–N, as well as between the mean planes of the pyridyl ring and the Pd–N–C–C–N, with values of only 2.6(2)°, 0.8(2)° and 1.5(3)° and 1.0(3)° for **3** and **4**, respectively. The dihedral angle between the mean planes of the N(4)-1-(2-pyridyl) and the piperazinyl ring is 9.3(2)° and 71.2(4)° for **3** and **4**, respectively. The monomers of **3** form hydrogen-bonded dimers linked by two hydrogen bonds C(2)–H(2)···Cl involving the C(2)H(2) hydrogen atom and the chloro atom and vice versa of centrosymetrically related pairs of

molecules. The observed hydrogen-bonding pattern is of the double DA = AD type. The same chloro atoms of the dimers participates in intermolecular hydrogen bonds of C–H–Cl type. The dimmers are connected by two intermolecular bonds C(4)–H(4)···Cl and C(6)–H(6)···Cl, Fig. 3, Table 3. Also, C–H-π and double weak π → π interactions are observed in **3**. The most significant π → π interactions being that between the pair of rings N(1)–C(1)–C(2))–C(3)–C(4))–C(5) and N(6)–C(13)–C(14))–C(15)–C(16))–C(12) at a center to center separation of 4.165(3) Å. Intermolecular H-bonding, π → π, and CH → π interactions help to stabilize the structure, Fig. 4. The monomers of **4** are connected by strong π–π interactions in dimmers and are arranged in a head to tail fashion.

Cg(3) and Cg(5) refer to the centroids N(1)–C(1)–C(2))–C(3)–C(4))–C(5) and N(6)–C(13)–C(14))–C(15)–C(16) –C(12) resp., Cg(1) and Cg(2) refer to the centroids Pd(1)–S–C(7)–N(3)–N(2) and Pd(1)–N(2)–C(5)–C(4)–N(1). D and A refers to donor and acceptor, respectively.

[a] Symmetry transformations (i), $-x, -y, 2-z$; (ii) $-x, 1/2+y, 3/2-z$; (iii) $x, 1/2-y, -1/2+z$; (iv) $2-x, -y, 1-z$; $1-x, -y, 1-z$.

[b] Cg–Cg is the distance between ring centroids.

[c] Where β is the angle Cg(I) → Cg(J).

[d] CgI-Perp is the perpendicular distance of Cg(I) on ring J.

[e] CgJ-Perp is the perpendicular distance of Cg(J) on ring I.

Double strong π–π interactions connect the pair of rings PdN(2)N(3)C(8)S and N(1)C(1)C(2)C(4)C(5) at a center separation of 3.644(4), Fig. 5, Table 3.

3.3. Spectroscopy

Infrared spectroscopy: The significant IR bands of Pd(II) and zinc(II) complexes are close in energy to those found in other compounds with tridentate coordination [4–9]. The coordination of the azomethine N-atom to the M(II) center was suggested in the IR spectra of complexes **3**–**6**, relative to those of the free ligands, by a shift of the ν(C=N) band to lower frequencies, along with the occurrence of a ν(N–N) band to higher frequency. Furthermore, the presence of a band at *ca.* 450–460 cm^{-1} was assigned to ν(M–N). The thioamide band, which contains considerable ν(CS) character, was less intense in the complexes and found at a lower frequency, suggesting coordination of the metal through sulfur after deprotonation for **3** and **4**. Coordination of the thiolato S-atom was further indicated by a decrease in the energy of the thioamide band, as well as by the presence of a band at *ca.* 360–380 cm^{-1} assignable to ν(M–S). The band at 346 and 348 cm^{-1} is assigned to ν(Pd–Cl) for **3** and **4**, respectively. Bands at 325, 304 cm^{-1} and at 325, 305 cm^{-1} are assigned to ν(Zn–Cl) for **5** and **6**, respectively.

UV/Vis absorption spectra: The electronic absorption spectra of **1** and **2** in (DMF solution) exhibit bands at *ca.* 32400 and 33420 cm^{-1}, respectively, and are due to $n \rightarrow \pi^*$ transitions. This band is associated with the azomethine functions of the thiosemicarbazone moieties [9]. The bands of the Zn(II) complexes **5** and **6**, in the same solvent, are exhibited bands at 23855–24840 and at

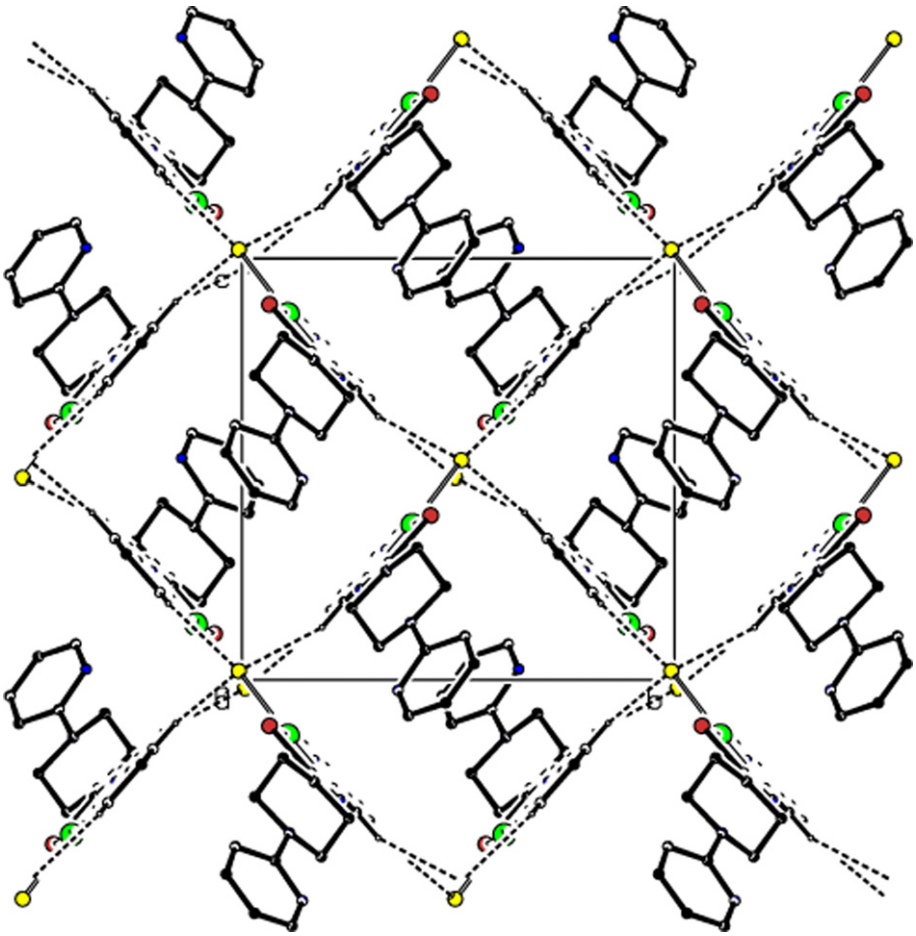

Fig. 4. A view of the extended network of [PdCl(FoPy4PyPiz)], **3**, along the *a* axis.

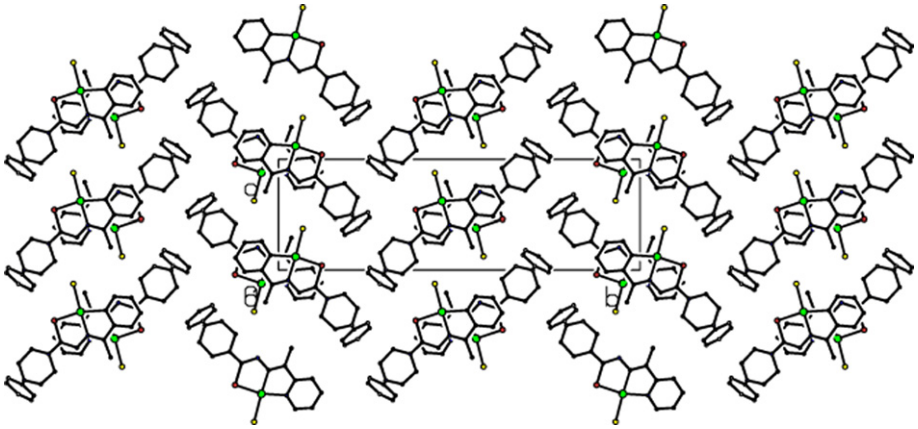

Fig. 5. A view of the extended network of [PdCl(AcPy4PyPiz)], **4**, along the *a* axis.

32 400–32 575 cm^{-1}. The absorptions in the ultraviolet region are assignable to transitions within the ligand orbitals and that in the visible region is probably due to charge transfer transition involving ligand and metal orbitals, transitions from S → Zn and N → Zn [9]. The electronic spectra of complexes **3** and **4** were indicative of square-planar geometries. In the visible region, three spin-allowed S → S (d → d) transitions can be expected. However, strong charge-transfer (CT) transitions interfered preventing the observation of all these predicted bands. The very intense band at about 21 000 cm^{-1} is assignable to a combination of sulfur → Pd(II), nitrogen (pyridyl) → Pt(II) charge transfer (L(p) → MCT) and Pd(II) d–d bands. The strong band at about 26 000 cm^{-1} is assignable to a combination of metal–ligand charge transfer (M → LCT) and d–d bands [5–9].

NMR Spectra: Peak assignments were based on ^{2}D NMR data (^{1}H, ^{1}H-COSY, ^{1}H,^{13}C-HMQC, ^{1}H,^{13}C-HMBC). In the ^{1}H NMR spectra of the ligand **1** and **2** H–N(3) resonated at *ca.* (H) 11.50 and 9.12, respectively, indicating that this H-atom is involved in H-bonding [6]. This resonance was absent in the spectra of the corresponding Pd(II) complexes, which indicated deprotonation of H–**N**(**3**) and, thus, anionic thiosemicarbazone moieties. The absence of peaks corresponding to the imino protons in **3** and **4** indicates that the ligands are present in the deprotonated form. These changes suggest that deprotonation and metallation exists and the structure of the complexes **3** and **4** in the solid state persists in $(CD_3)_2SO$ solution. In the ^{1}H and ^{13}C NMR spectra of the Pd(II) and Zn(II) complexes **3**–**6** the hydrogen and carbon atoms of the pyridyl ring H–C(1) were shifted upon coordination, which indicated variations in the electron density of the pyridyl ring These signals were shifted downfield, in accord with an decreased electron density at these sites in the complexes. The C=S resonance of the thiosemicarbazone moiety in **2** resonated at 180.95 ppm. In the complexes **3** and **5**, downfield shifts were observed, indicating decreased electron density from the thiolato C-atoms [6]. The C=S resonance of the thiosemicarbazone moiety in **2** resonated at 182.71 ppm and in the complexes **4** and **6**, upfield shifts were observed, indicating in-

creased electron density at this site on complexation and due probably to back π-bonding for thiolato sulfur [6] (see Table 4).

3.4. Pharmacology. In vitro growth inhibition assay

Pt(II) complexes of *N*4-ethyl 2-formyl and 2-acetylpyridine thiosemicarbazones showed cytotoxicity and were found to be able to overcome the cisplatin resistance of A2780/Cp8 cells [9]. Pt(II) or Pd(II) complexes with 2-acetyl pyridine N(4)-ethyl-thiosemicarbazone, HAc4Et were tested in a panel of human tumor cell lines of different origins (breast, colon, and ovary cancers), and cisplatin-refractory/resistant cell lines and were found to exhibit very remarkable growth inhibitory activities with mean IC_{50} values of 0.9–0.5 nM and support the hypothesis that both $[Pt(Ac4Et)_2]$ and $[Pd(Ac4Et)_2]$ complexes can be characterized by cellular pharmacological properties distinctly different from those of cisplatin [9b].

The compounds **1**–**6** were tested *in vitro* against the cells of three human cancer cell lines: MCF-7 (human breast cancer cell line), T24 (bladder cancer cell line), A-549 (non-small cell lung carcinoma) and a mouse fibroblast L-929 cell line. The results of cytotoxic activity *in vitro* are expressed as IC_{50} – the concentration of compound (in M) that inhibits a proliferation rate of the tumor cells by 50% as compared to control untreated cells.

The $ZnCl_2$ and K_2PdCl_4 exhibit very poor cytotoxic activity in all these four lines. In the case of L-929 and A-549 cell lines the ligands and the complexes are in the same μM range less cytotoxic compared to *cis-platin*. In this case the observed cytotoxicity is probably due to the cytotoxicity of the ligands **1** and **2** and the metal complexes may be a vehicle for activation of the ligand as the cytotoxic agent. The IC_{50} value for HAc4Npypipe against the A-549 cell line is 16.6 μM and for the Zn(II) complex is 8.08 μM. The two thiosemicarbazones and the metal complexes exhibited cytotoxic activity against the MCF-7 and T-24 cell lines in a μM range better than to *cis-platin.*

Table 5 shows that complex $[ZnCl_2(Ac4Npypipe)]$, **6**, is 43 and four times more active than *cis-platin* in the T24 and MCF-6 cell lines, respectively. Also, complex $[ZnCl_2(Fo4Npypipe)]$, **5**, is four and 33 times more active than *cis-platin* in the T24 and MCF-6 cell lines, respectively. The cytotoxic activity shown by these Zn(II) compounds **5** and **6** against MCF-7 and T24 cell lines indicate that coupling of **1** and **2** to Zn(II) metal center result in metallic complexes with important biological properties and remarkable cytotoxic activity, since they are display IC_{50} values in a μM range better to that of the antitumor drug *cis-platin*. Thus, the Zn(II) compounds **5** and **6** are considered as agents with potential antitumor activity, and can therefore be candidates for further stages of screening *in vitro* and/or *in vivo*.

3.5. In vivo antitumor experiments

Also the acute toxicity and antitumor activity were evaluated on leukemia P388-bearing mice for selected compounds **2** and **6**. The acute toxicity and the antitumor activities of these compounds were correlated with the related complexes of 2-formylpyridine and 2-acetylpyridine thiosemicarbazone, HFoTsc and HAcTsc, respectively, [5,6].

The ligand HAc4Npypipe causes a high acute toxicity and does not display antitumor activity, while the complex $[ZnCl_2(Ac4Npypipe)]$ shows reduction of the toxicity, and very high increase of survival time of the drug treated leukemia bearing mice, Table 6. The ligand is achieving a *T*/*C*% value of 113 and the zinc(II) complex of 285. Also, one of the mice was cured and was considered as long-term survivor. The long-term survivors are defined as mice alive 90 days after tumor inoculation.

Probably the zinc(II) complex, $[ZnCl_2(Ac4Npypipe)]$, may interact better with DNA and/or proteins than the other compounds. In conclusion, these experiments showed that the activity of the metal complex) $[ZnCl_2(Ac4Npypipe)]$ is different compared with the activity of the ligand alone and probably represent independent cytotoxic entities. It was surprising and not predictable that among these compounds the zinc compound, $[ZnCl_2(Ac4Npypipe)]$ was more effective than other related palladium compounds. The re-

ABSTRACT

The reaction of *meso*-tetraarylporphyrins ($H_2T(X)PP$) with $SnCl_4$ affords green intermediate sitting-atop (i-SAT) complexes, [$(H_2T(X)PP)SnCl_4$]. UV–Vis, ^1H NMR and ^{13}C NMR spectral data show that the porphyrin core of the complexes is distorted, thus two nitrogen atoms of the pyrrolenine groups on one side of the porphyrin plane act as electron donors to the tin center of $SnCl_4$. The intermediate sitting-atop (i-SAT) complex is formed each time during the incorporation of the metal center, where in the intermediate state the pyrrolic protons still remain on the porphyrin.

1. Introduction

Understanding the metallation of porphyrins has long been important in biochemistry because of their central role in photosynthesis, biological redox processes, and oxygen transport [1–10]. Depending on their size, charge and spin multiplicity, metal ions can fit into the central hole of the porphyrin ring, forming regular metalloporphyrins, or several of them are located out of the ligand plane, resulting in sitting-atop (SAT) complexes. Most of the natural metalloporphyrins are of the regular type, i.e. their metal centers are located within the plane of the macrocyclic ligand as a consequence of their fitting size. Their ionic radii are in the range 55–80 pm, corresponding to the sphere in the porphyrin core surrounded by the four pyrrolic nitrogens. While the symmetry group of the free base porphyrins is D_{2h} due to the two hydrogen atoms on the diagonally located pyrrolic nitrogens, the coplanar (regular) metalloporphyrins (without these protons) are of higher symmetry (D_{4h}) [11]. Deviating from regular porphyrins, in the sitting-atop complexes, the metal centers are located out of the ligand plane, distorting it and causing lower symmetry (C_{4v} "dome" or S_4 "saddle"). These sitting-atop complexes are called stable sitting-atop (s-SAT) complexes. Another type of sitting-atop complex is the intermediate sitting-atop (i-SAT) complex and it is known as an intermediate in the metallation of porphyrins. In the i-SAT complexes, similar to the molecular complexes of porphyrins, the metal connects to the pyrrolenine nitrogens and the two pyrrolic protons remain on the porphyrin. It is reported that porphyrins are only capable of forming 1:2 molecular complexes with tin(IV) compounds such as $Sn(CH_3)Br_3$, $SnPhCl_3$, $Sn(CH_3)_2Cl_2$, $Sn(Ph)_2Cl_2$ and $Sn(Ph)_2Br_2$ [12–17]. This article presents the synthesis and spectroscopic characterization of the 1:1 molecular complexes or intermediate sitting-atop (i-SAT) complexes of *meso*-tetraarylporphyrins (Fig. 1) with $SnCl_4$. The suitable selection of $SnCl_4$ meant that we could be prepare i-SAT complexes of tin(IV) with *meso*-tetraarylporphyrins.

2. Experimental

2.1. Materials and measurements

Tin(IV) chloride, benzaldehyde and various substituted benzaldehydes (3-CH_3, 4-CH_3, 3-OCH_3, 4-OCH_3, 4-isopropyl) were obtained from Merck and were used without further purification. Pyrrole was purchased from Merck and was distilled before use. Chloroform and acetone (Merck) were dried over anhydrous calcium chloride for 3 days and distilled before use. Other solvents that were employed for the synthesis of the porphyrins and i-SAT complexes were obtained from Merck and Fluka, and were used as received. The substituted *meso*-tetraarylporphyrins were prepared by the literature methods [18].

The NMR spectra (^1H and ^{13}C) were recorded on a Bruker 400 Ultrashield spectrometer in $CDCl_3$. The residual $CHCl_3$ in the conventional 99.8% atom D $CDCl_3$ gives a signal at $\delta = 7.26$ ppm, which was used for calibration of the chemical shift scale. FT-IR spectra were recorded on a Magna 550 Nicolet spectrometer using KBr pellets. The UV–Vis measurements were obtained with a GBC cintra 6

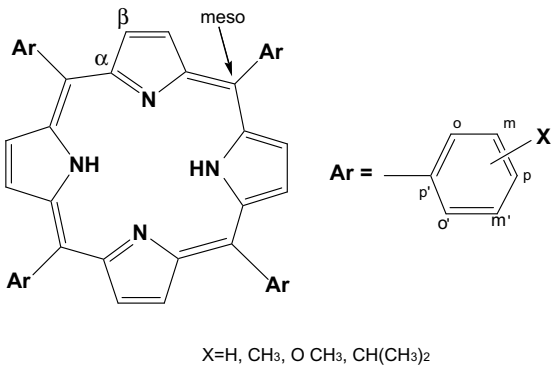

Fig. 1. *meso*-Tetraarylporphyrins, $H_2T(X)PP$.

UV–Vis spectrophotometer. The molar conductance was measured on a METROHM 644 conductometer.

2.2. Preparation of the i-SAT complexes

0.05 mmol $SnCl_4$ was dissolved in 5 ml acetone and added to 0.05 mmol of the *meso*-tetraarylporphyrins in 15 ml chloroform and the mixture was stirred for 15 min. Evaporation of the solvent at room temperature produced the green i-SAT complexes, $[(H_2T(X)PP)SnCl_4]$, without an excess amount of the porphyrins or $SnCl_4$. The progress of the reaction was monitored by UV–Vis spectra. The porphyrins completely changed to the i-SAT complexes and the mixture did not show an absorption band (Soret band) related to the free base *meso*-tetraarylporphyrins. The results of elemental analyses for the i-SAT complexes formed from the porphyrins and $SnCl_4$, which were dried in a vacuum oven for 12 h at 55–60 °C were consistent with $[(H_2T(X)PP)SnCl_4]$.

3. Results and discussion

The UV–Vis spectrum of H_2TPP shows five absorption bands at 416.7 (Soret), 516.8, 551.5, 592.0 and 648.0 nm [19–27], but the $[(H_2TPP)SnCl_4]$ complex shows two new absorption bands at 444.3 (Soret) and 659.1 nm, Fig. 2. Upon the addition of $SnCl_4$ to H_2TPP, the UV–Vis spectrum of the porphyrin is 11–28 nm red shifted. This is an evidence for an increase of the π-resonance interaction in the aryl rings with the porphyrin nucleus in going from H_2TPP to the $[(H_2TPP)SnCl_4]$ complex, which would be produced by the deformation of the porphine core [19–27]. The results of the UV–Vis spectra for the i-SAT complexes are listed in Table 1. The UV–VIS spectra for the titration of tin(IV) chloride into $H_2T(4\text{-}CH_3)PP$ (0.25:1, 0.5:1, 0.75:1, 1:1, 1:1.5 and 1:2) showed the molar ratio of the metal to ligand in the i-SAT complex was 1:1. An excess amount of tin(IV) chloride more than the 1:1 molar ratio had no measurable effect on the UV–Vis spectra of the studied complexes.

^1H NMR spectral data for the mixing of different equivalents of $SnCl_4$ (0.25, 0.5, 0.75, 1.0, 1.5 and 2.0) with H_2TPP showed that the complexation between H_2TPP and $SnCl_4$ had a 1:1 molar ratio. Further, these results indicate that using an amount of $SnCl_4$ less than that of free base H_2TPP leads to a superimposition of the porphyrin and the related i-SAT complex, and an excess of $SnCl_4$ more than the 1:1 molar ratio causes no changes in the spectrum of the i-SAT complex. The reaction of $SnCl_4$ with H_2TPP, similar to the molecular complexation of the porphyrin [19–26] or its diprotonation [28], leads to an upfield shift of the β-protons (0.26 ppm) and

(S): Soret band.
[a] $\Delta\lambda$: Red shifts for the bands of the porphyrins upon SAT complexation.

downfield shifts of the N–H signal (3.06 ppm) and aryl ring protons. The chemical shifts of the NH and β-proton for the *meso*-tetraarylporphyrins and the related i-SAT complexes are listed in Table 2. The chemical shift direction of the NH and β-protons signals of the i-SAT complex, $[(H_2TPP)SnCl_4]$, was similar to the related molecular complexes of the porphyrins. The observed ^1H NMR and UV–Vis spectral shifts upon the SAT complexation of $H_2T(4\text{-}OCH_3)PP$ with $SnCl_4$ was more than the other studied porphyrins (Tables 1 and 2). This result was obtained because of the π-resonance effect and low steric hindrance of the *para*-methoxy group. The spectral shifts of the *para*-substituents were more than the related *meta*-substituents. This is explained by the low steric hindrance of the *para*-groups compared to the *meta*-groups. Further, these results show that the π-resonance effect is more important than σ-induction effect [19,20].

The ^{13}C NMR spectrum of $H_2T(4\text{-}CH_3)PP$ showed seven sharp signals (one signal for the CH_3 group (19.9 ppm) and six signals for the porphine core) and aryl rings ((120.5 (C_{meso}), 127.8 ($C_{m,m'}$), 137.7 (C_p), 131.4 (C_β), 134.9 ($C_{o,o'}$), 139.7 ($C_{p'}$) ppm)) [24,25]. The complexation of $H_2T(4\text{-}CH_3)PP$ with $SnCl_4$ leads to changes in the ^{13}C NMR spectrum of the porphyrin. The new peaks were revealed at 21.7 (CH_3), 122.4 (C_{meso}), 127.8 (C_β), 129.2 ($C_{m,m}$), 137.5(C_p), 139.0 ($C_{o,o'}$), 140.3 ($C_{p'}$) and 146.1 ($C\alpha$) ppm. The observed changes upon the SAT complexation were the same as the diprotonation [28] and molecular complexation of the *meso*-tetraarylporphyrins with π- or σ-acceptors [19,20,24,25].

The UV–Vis, ^1H NMR and ^{13}C NMR spectral correspondences between the molecular complexes produced from various acceptors with *meso*-tetraarylporphyrins [19,20] or H_4TPP^{2+} [28] and $[(H_2TPP)SnCl_4]$ proposed a similar porphyrin core in all of the species, with non-coplanar pyrrole rings tilted alternatively up and down. In the proposed structure, the lone pairs of two pyrrolenine nitrogens act as electron donors to one molecule of $SnCl_4$, and so two hydrogen atoms of pyrroles (N–H) still remain on the macrocycle, Fig. 3. In the FT-IR spectrum of the free base *meso*-tetraarylporphyrin is observed a N–H stretching band at 3320 cm^{-1} [29] that did not show a considerable change upon SAT complexation with $SnCl_4$. Furthermore, as mentioned above, the ^1H NMR spectra of the SAT complexes showed that the two protons on the pyrrole nitrogens still remained on the porphyrins. These data are in complete correspondence with the proposed structure in Fig. 3, but the observation of a singlet for the β-protons in the ^1H NMR spectrum of the $[(H_2TPP)SnCl_4]$ complex is in contrast with the unsymmetrical pyrrole rings in the proposed structure. This

$\Delta\delta$: Chemical shifts of the proton signals for the porphyrins upon SAT complexation.

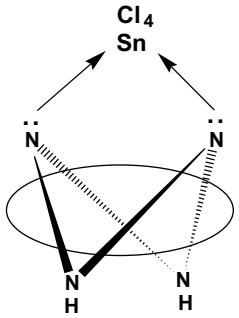

Fig. 3. Two pyrrolenine nitrogen atoms of the porphyrin act as electron donors to a tin center of $SnCl_4$.

can be explained by ring inversion of the saddled core conformation of the porphyrin, which is fast on the NMR timescale [19,20,27].

A comparison of the molar conductivity of the SAT complexes and the related diprotonated species indicates that the synthesized complexes are completely different from the diprotonated porphyrin species, although the spectral data of two species are similar. The measurement of molar conductivity in acetone solution showed the SAT complexes were not electrolytes. This was completely in accordance to the proposed formula of the SAT complexes, Fig. 3. In contrast, the molar conductivities of $[H_4T(X)PP]Cl_2$ in methanol were in accordance with 1:2 electrolytes [30].

The compounds SnR_2Cl_2 and $SnRCl_3$ (R = Me, Ph) reacted with *meso*-tetraarylporphyrins with the formation of 2:1 (acceptor:donor) molecular complexes, whereas $SnCl_4$ has produced 1:1 complexes with the free base porphyrins. The quantity of chlorine atoms in the $SnCl_4$ molecule are more than for SnR_2Cl_2 and $SnRCl_3$ molecules. The chlorine atom has higher electronegativity and lower steric hindrance than methyl and phenyl groups. Consequently, $SnCl_4$ is a better acceptor than SnR_2Cl_2 and $SnRCl_3$ and can accept two lone pairs from the porphyrin molecule for the formation of the complexes with a 1:1 (donor:acceptor) mole ratio.

4. Conclusion

Tin(IV) chloride and *meso*-tetraarylporphyrins ($H_2T(X)PP$) reacted with the formation of i-SAT complexes, $[(H_2T(X)PP)SnCl_4]$. The UV–Vis, ^1H NMR and ^{13}C NMR spectral data showed the porphyrin core of the SAT complexes, similar to the molecular complexes of *meso*-tetraarylporphyrins with various acceptors [19–25] and porphyrin diacids [28], is deformed and two nitrogen atoms of pyrrolenine are situated to one side of the porphyrin plane and act as electron donors to a tin atom of $SnCl_4$.

characterization, electrochemistry, DNA-binding potential and antibacterial activity of the resulting complexes. The general structure of the ligands used in this study is given in Chart 1.

2. Experimental

2.1. Reagents and materials

Analytical or chemically pure grade chemicals were used for the preparation of ligands. $RuCl_3 \cdot 3H_2O$ purchased from Himedia was used as supplied. Protein free herring sperm ds DNA obtained from SRL chemicals was stored at 0–4 °C. All the spectroscopic DNA titrations were carried out in Tris–HCl buffer [0.197 g (5 mmol) of Tris–HCl and 0.73 g (50 mmol) NaCl] are dissolved in double distilled water and the pH was adjusted to 7.1 using 1 mM NaOH solution before making up to 250 ml) at room temperature. A solution of herring sperm DNA (0.1 g) in Tris–HCl buffer (10 ml) gave a ratio of UV absorbance at 260 and 280 nm of ca. 1.8–1.9:1 indicating that the DNA was sufficiently free of protein [25]. The DNA concentration per nucleotide was determined by absorption spectroscopy using the molar absorption coefficient (6600 M^{-1} cm^{-1}) at 260 nm [26]. Distilled dmso was used for the preparation of the starting complex and for the preparation of solutions of complexes for DNA-binding studies. Purified dry methanol was used to record the electronic spectra of the complexes. Commercially available TBAP was properly dried and used as supporting electrolyte for recording cyclic voltammograms of the complexes. The starting complex *cis*-$[RuCl_2(dmso)_4]$ was prepared according to the method reported by Evans et al. [27] and the ligands were prepared by refluxing an ethanolic solution of the aldehyde or ketone with thiosemicarbazide as described in the literature [28].

2.2. Physical measurements

A Nicolet Avatar Model FT-IR spectrophotometer was used to record the IR spectra (4000–400 cm^{-1}) of the free ligands and the complexes. Electronic spectral measurements (800–250 nm) and absorption titrations (DNA binding) were carried out with a Systronics 119 UV–Vis spectrophotometer. ^1H NMR spectra were recorded on Varian-Australia AMX-400 instrument. Micro analyses (C, H, N and S) were performed on a Vario EL III Elementar analyzer. The electrochemical analyzer (CHI 1120A) equipped with a three electrode compartment consisting of Platinum disc working electrode, Platinum wire counter electrode and Ag/AgCl reference electrode was used to record the cyclic voltammograms of the complexes.

2.3. Syntheses

2.3.1. Synthesis of cis-$[RuCl_2(dmso)_4]$

$RuCl_3 \cdot 3H_2O$ (1 g) was refluxed in dmso (5 ml) for 5 min. The solution rapidly turned orange brown and the volume was reduced to half using rotary evaporator. When acetone (20 ml) was added to the solution a yellow precipitate separated out. The precipitate was washed with acetone and ether and dried in vacuum.

2.3.2. Synthesis of ligands

An ethanolic solution of the corresponding aldehyde or ketone (0.01 mol) with thiosemicarbazide (0.01 mol) was heated under reflux for 4–5 h. Then the reaction mixture was cooled to get the respective thiosemicarbazone as precipitate. The precipitate was washed with ethanol and dried.

2.3.3. $[RuCl_2(dmso)_2(petsc)]$ (**1**)

cis-$[RuCl_2(dmso)_4]$ (0.1 g; 0.21 mmol) and the ligand petsc (0.040 g; 0.21 mmol) were heated under reflux in ethanol (30 ml) for 4 h during which a brownish solid separated. The solvent was evaporated on a rotary evaporator and the product was dried under vacuum. Finally, the product was washed with ether several times to get shiny brown crystalline complex. Yield, 73 mg; 67%. Elemental *Anal.* Calc. for $C_{13}H_{23}N_3S_3O_2Cl_2Ru$ (521.53): C, 29.93; H, 4.44; N, 8.06; S, 18.44. Found: C, 29.68; H, 4.12; N, 8.31; S, 18.17%. Chart 1. General structure of the ligands.

*2.3.4. [$RuCl_2(dmso)_2(tetsc)$] (**2**)*

The complex was prepared as described in Section 2.3.3. by the reaction of *cis*-[$RuCl_2(dmso)_4$] (0.1 g; 0.21 mmol) with the ligand tetsc (0.043 g; 0.21 mmol). Yield: 72 mg; 64%. Elemental *Anal.* Calc. for $C_{14}H_{25}N_3S_3O_2Cl_2Ru$ (535.56): C, 31.39; H, 4.70; N, 7.84; S, 17.96. Found: C, 31.48; H, 4.47; N, 7.59; S, 17.77%. IR (KBr, cm^{-1}): $\nu(NH_2$ (asy + sym)), 3434(b,w); ν(NH), 3147(w); ν(C=N), 1625(s); ν(C=S), 740(w) (asy, asymmetric; sym, symmetric; s, strong; w, weak). UV/Vis (dmso) λ, nm (ε, mol^{-1} cm^{-1} L): 272 (9840), 291(7700). ^{1}H NMR ([D_6]-dmso, δ ppm): 1.64 (s, –CH_3, 3H), 2.45 (s, H_3C–C=N, 3H), 3.1–3.4 (group of peaks, dmso, 12H), 3.62 (s, –NH_2, 2H), 6.7–7.3 (multiplet, aromatic protons, 4H), 10.87 (s, –NH, 1H).

*2.3.5. [$RuCl_2(dmso)_2(tctsc)$] (**3**)*

The complex was prepared as described in Section 2.3.3. by the reaction of *cis*-[$RuCl_2(dmso)_4$] (0.1 g; 0.21 mmol) with the ligand tctsc (0.039 g; 0.21 mmol). Yield: 67 mg; 62%. Elemental *Anal.* Calc. for $C_{10}H_{19}N_3S_4O_2Cl_2Ru$ (513.53): C, 23.38; H, 3.72; N, 8.18; S, 24.97. Found: C, 23.29; H, 3.95; N, 8.39; S, 24.76%. IR (KBr, cm^{-1}): $\nu(NH_2$ (asy + sym)), 3380(b,w); ν(NH), 3142(w); ν(C=N), 1629(s); ν(C=S), 720(w) (asy, asymmetric; sym, symmetric; s, strong; w, weak). UV/Vis (dmso) λ, nm (ε, mol^{-1} cm^{-1} L): 295 (15230), 314 (11530). ^{1}H NMR ([D_6]-dmso, δ ppm): 3.2–3.4 (group of peaks, dmso, 12H), 4.22 (s, –NH_2, 2H), 7.05–7.35 (multiplet, aromatic protons, 3H), 8.17 (s, H–C=N, 1H), 11.24 (s, –NH, 1H).

*2.3.6. [$RuCl_2(dmso)_2(fctsc)$] (**4**)*

The complex was prepared as described in Section 2.3.3. by the reaction of *cis*-[$RuCl_2(dmso)_4$] (0.1 g; 0.21 mmol) with the ligand fctsc (0.035 g; 0.21 mmol). Yield: 70 mg; 64%. Elemental *Anal.* Calc. for $C_{10}H_{19}N_3S_3O_3Cl_2Ru$ (497.46): C, 24.14; H, 3.84; N, 8.44; S, 19.33. Found: C, 24.33; H, 3.72; N, 8.69; S, 19.45%. IR (KBr, cm^{-1}): $\nu(NH_2$ (asy + sym)), 3410(b,w); ν(NH), 3138(w); ν(C=N), 1618(s); ν(C=S), 759(w) (asy, asymmetric; sym, symmetric; s, strong; w, weak). UV/Vis (dmso) λ, nm (ε, mol^{-1} cm^{-1} L): 287 (16930), 302 (16510). ^{1}H NMR ([D_6]-dmso, δ ppm): 3.2–3.4 (group of peaks, dmso, 12H), 3.75 (s, –NH_2, 2H), 6.6–7.8 (multiplet, aromatic protons, 3H), 8.09 (s, H–C=N, 1H), 11.00 (s, –NH, 1H).

*2.3.7. [$RuCl_2(dmso)_2(mbtsc)$] (**5**)*

The complex was prepared as described in Section 2.3.3. by the reaction of *cis*-[$RuCl_2(dmso)_4$] (0.1 g; 0.21 mmol) with the ligand mbtsc (0.044 g; 0.21 mmol). Yield: 74 mg; 66%. Elemental *Anal.* Calc. for $C_{13}H_{23}N_3S_3O_3Cl_2Ru$ (537.53): C, 29.04; H, 4.31; N, 7.81; S, 17.89. Found: C, 28.81; H, 4.16; N, 7.59; S, 18.02%. IR (KBr, cm^{-1}): $\nu(NH_2$ (asy)), 3411(w); $\nu(NH_2$ (sym)), 3292(w); ν(NH), 3148(w); ν(C=N), 1602(s); ν(C=S), 680(w) (asy, asymmetric; sym, symmetric; s, strong; w, weak). UV/Vis (dmso) λ, nm (ε, mol^{-1} cm^{-1} L): 287 (18680). ^{1}H NMR ([D_6]-dmso, δ ppm): 3.0–3.4 (group of peaks, dmso, 12H), 3.54 (s, –NH_2, 2H), 3.71 (s, –OCH_3, 3H), 7.1–7.9 (multiplet, aromatic protons, 4H), 8.27 (s, H–C=N, 1H), 11.29 (s, –NH, 1H).

*2.3.8. [$RuCl_2(dmso)_2(mptsc)$] (**6**)*

The complex was prepared as described in Section 2.3.3. by the reaction of *cis*-[$RuCl_2(dmso)_4$] (0.1 g; 0.21 mmol) with the ligand mptsc (0.047 g; 0.21 mmol). Yield: 82 mg; 71%. Elemental *Anal.* Calc. for $C_{14}H_{25}N_3S_3O_3Cl_2Ru$ (551.56): C, 30.48; H, 4.56; N, 7.61; S, 17.44. Found: C, 30.25; H, 4.41; N, 7.39; S, 11.11%. IR (KBr, cm^{-1}): $\nu(NH_2$ (asy)), 3405(w); $\nu(NH_2$ (sym)) 3353(w); ν(NH), 3156(w); ν(C=N), 1598(s); ν(C=S), 696(w) (asy, asymmetric; sym, symmetric; s, strong; w, weak). UV/Vis (dmso) λ, nm (ε, mol^{-1} cm^{-1} L): 277 (7980). ^{1}H NMR ([D_6]-dmso, δ ppm): 2.45 (s, H_3C–C=N, 3H), 3.1–3.6 (group of peaks, dmso, 12H), 3.81 (s, –NH_2, 2H), 3.87 (s, –OCH_3, 3H), 7.0–7.3 (multiplet, aromatic protons, 4H), 11.14 (s, –NH, 1H).

*2.3.9. [$RuCl_2(dmso)_2(cbtsc)$] (**7**)*

The complex was prepared as described in Section 2.3.3. by the reaction of *cis*-[$RuCl_2(dmso)_4$] (0.1 g; 0.21 mmol) with the ligand cbtsc (0.045 g; 0.21 mmol). Yield: 86 mg; 74%. Elemental *Anal.* Calc. for $C_{13}H_{22}N_3S_3O_2Cl_3Ru$ (555.98): C, 28.08; H, 3.98; N, 7.55; S, 17.30. Found: C, 28.24; H, 3.77; N, 7.38; S, 17.54%. IR (KBr, cm^{-1}): $\nu(NH_2$ (asy)), 3360(w); $\nu(NH_2$ (sym)), 3326(w); ν(NH), 3124(w); ν(C=N), 1625(s); ν(C=S), 680(w) (asy, asymmetric; sym, symmetric; s, strong; w, weak). UV/Vis (dmso) λ, nm (ε, mol^{-1} cm^{-1} L): 281 (13780), 312 (8620). ^{1}H NMR ([D_6]-dmso, δ ppm):, 2.48 (s, H_3C–C=N, 3H), 3.1–3.4 (group of peaks, dmso, 12H), 3.74 (s, –NH_2, 2H), 7.4–7.8 (multiplet, aromatic protons, 4H), 10.96 (s, –NH, 1H).

*2.3.10. [$RuCl_2(dmso)_2(bzsc)$] (**8**)*

cis-[$RuCl_2(dmso)_4$] (0.1 g; 0.21 mmol) and the ligand bzsc (0.034 g; 0.21 mmol) were heated under reflux in ethanol (30 ml) for 6 h. Slow evaporation of the solvent after reduction to 50% gave orange crystals suitable for single crystal XRD studies. Yield: 74 mg; 72%. Elemental *Anal.* Calc. for $C_{12}H_{21}N_3S_2O_3Cl_2Ru$ (491.440): C, 29.32; H, 4.29; N, 8.55; S, 13.04. Found: C, 29.54; H, 4.08; N, 8.71; S, 12.88%. IR (KBr, cm^{-1}): $\nu(NH_2$ (asy)), 3325(w); $\nu(NH_2$ (sym)), 3252(w); ν(NH), 3148(w); ν(C=N), 1625(s); ν(C=O), 1665(s) (asy, asymmetric; sym, symmetric; s, strong; w, weak). UV/Vis (dmso) λ, nm (ε, mol^{-1} cm^{-1} L): 276 (10780), 308 (7620). ^{1}H NMR ([D_6]-dmso, δ ppm): 3.1–3.4 (group of peaks, dmso, 12H), 3.82 (s, –NH_2, 2H), 7.5–7.9 (multiplet, aromatic protons, 5H), 8.35 (s, –CH=N, 1H), 11.15 (s, –NH, 1H).

2.4. Crystallographic structure determination

X-ray diffraction measurements were performed on a Nonius Kappa CCD (with Oxford Cryostream) diffractometer with graphite monochromatized Mo Kα radiation. The structure was solved by direct methods and refinements were carried out by full-matrix least-square techniques. The hydrogen atoms were treated by a mixture of independent and constrained refinement. The following computer programs were used: structure solution SIR-97 [29], refinement SHELXL-97 [30], molecular diagrams, ORTEP-3 [31] for windows.

2.5. Antimicrobial screening

The bacterial stains, *Escherichia coli* NCIM 2831, *Staphylococcus aureus* NCIM 2492, *Staphylococcus epidermidis* NCIM 2493, *Klebsiella pneumoniae* NCIM 5082 and *Shigella sonnei* MTCC 2957 were used in the study. Agar-well diffusion method [32] was employed for the determination of antimicrobial activities. Minimum inhibitory concentrations (MICs) of the compounds against test organisms were determined by broth micro dilution method. All the tests were performed in duplicate and repeated twice. Modal values were selected.

2.5.1. Agar-well diffusion method

Compounds were weighed and dissolved in dimethyl sulphoxide (dmso). Compounds were filter sterilized using a 0.45 μm membrane filter. Each microorganism was suspended in sterile saline and diluted at ca.106 colony forming units (cfu/mL). They were flood inoculated onto the surface of Mueller Hinton Agar (MHA). The wells (8 mm in diameter) were cut from the agar and 0.1 mL of solution was delivered into them. After incubation for 24 h at 37 °C, all plates were examined for any zones of growth inhibition, and the diameter of these zones were measured in millimeters.

2.5.2. Determination of minimum inhibitory concentration (MIC)

A microdilution broth susceptibility assay was used as recommended [33] by NCCLS for determination of MIC. All the tests were

performed in Mueller–Hinton Broth (MHB) supplemented with Tween 80 detergent (final concentration of 0.5% (v/v)). Bacterial stains were cultured overnight at 37 °C in MHA. Test strains were suspended in MHB to give a final density of 5 × 105 cfu/ml and these were confirmed by viable counts. Geometric dilutions of the compounds were prepared in a 96-well microtiter plate, including one growth control (MHB + Tween 80) and one sterility control (MHB + Tween 80 + Compound). Plates were incubated under normal atmospheric conditions at 37 °C for 24 h. The MIC of kanamycin and oxytetracycline was individually determined in parallel experiments in order to control the sensitivity of the test organisms. The bacterial growth was indicated by the presence of a white "pellet" on the well bottom.

3. Results and discussion

As the onset of this investigation, the synthesis of thiosemicarbazones was carried out as described in Section 2. On analyzing the ligands for characterization through IR spectroscopy, a sharp peak at 1649 cm^{-1} which is characteristic of ν(C=O) was observed for the ligand (L8) synthesized by condensing benzaldehyde and thiosemicarbazide Based on this observation, the ligand was supposed to be benzaldehyde semicarbazone rather than the expected benzaldehyde thiosemicarbazone. The reactions of the ligands (L1–L7) with the starting complex in 1:1 mole ratio in ethanol yielded complexes of the type $[RuCl_2(dmso)_2(L)]$ (L = thiosemicarbazones) and that of L8 resulted in a complex of the formula $[RuCl_2(dmso)_2(bzsc)]$ (bzsc = benzaldehyde semicarbazone) which is evident from its single crystal XRD data (presented in Section 3.3.). Thus, it becomes manifest that the reaction of benzaldehyde with thiosemicarbazide in ethanol has lead to the formation of benzaldehyde semicarbazone through the conversion of >C=S (of the expected benzaldehyde thiosemicarbazones) to >C=O. Therefore, it is presumed that adventitious water in ethanol should have effected the transformation *in situ* after the formation of thiosemicarbazone as proposed in the tentative mechanism (Scheme 1).

3.1. IR and UV–Vis spectra

The prominent IR regions of interest pertaining to the complexes are furnished in Section 2. The spectra of the free thiosemicarbazone ligands (L1–L7) show peaks of concern around 3400–3250 (two peaks), 3160–3120 and 1615–1585 cm^{-1} attributed to the symmetric and asymmetric stretching of NH_2, ν(NH) and ν(C=N), respectively. The weak to medium intensity band around 782–716 cm^{-1} in the ligands are assigned to ν(C=S). The question of thione-thiol tautometism in the ligands is ruled out because no bands were observed in the region near 2570 cm^{-1}, which is characteristic of ν(C–SH) [34]. This corroborates that the ligands are in thione form in the solid state. In the IR spectra of the ligand L8, besides other characteristic bands, a strong absorption at 1649 cm^{-1} was found and tentatively assigned as due to ν(C=O). In the IR spectra of the complexes, a considerable decrease (5–10 cm^{-1}) for **5** and **6** and increase (5–45 cm^{-1}) for all other complexes in the ν(C=N) frequency shows the coordination of the azomethine nitrogen. The bands due to $\nu(NH_2)$ and ν(NH) almost remain practically unaltered supporting the non-coordination of NH_2 nitrogen and the presence of thione form of the ligand after complex formation. A small negative shift of 10–40 cm^{-1} in ν(C=S) in complexes **1**–**7** shows the neutral coordination of thioamide sulfur. Similarly, the positive shift of ν(C=O) to 1666 cm^{-1} in complex **8**, suggests the neutral coordination of amide oxygen to ruthenium. The peak at 915 cm^{-1}, characteristic of ν(SO)(O-bonded) exhibited by the precursor *cis*-$[RuCl_2(dmso)_4)]$ is absent in the new complexes and thus it is perceived that the ligands act as neutral bidentate donors replacing one O-bonded dmso and one S-bonded dmso from the precursor, which is in accord with a previous study [27].

The electronic spectra of all the complexes were identical showing weak absorptions in the ultraviolet region. The absorption maximum and molar extinction coefficients are given in Section 2. The bands are assignable to transitions within the ligand orbitals (intraligand $\pi \rightarrow \pi^*$ or $n \rightarrow \pi^*$) [35,36].

3.2. ^{1}H NMR spectra

The ^{1}H NMR spectra of the complexes recorded in $[D_6]$-dmso exhibited narrow signals. Comparison of the spectra of the precursor, *cis*-$[RuCl_2(dmso)_4]$ with that of the new complexes seemed inevitable in order to predict the nature of bonding mode of dmso in the new complexes. Out of the six singlets appeared in the ^{1}H NMR spectra of *cis*-$[RuCl_2(dmso)_4]$ at δ 3.50, 3.48, 3.43, 3.32, 2.72 and 2.66 ppm due to six sets of chemically different protons, the peak at δ 2.66 ppm has been assigned to free dmso which resulted from the 10% dissociation of O-bonded dmso. Similarly the peak at δ 2.72 ppm has been attributed to the O-bonded dmso since the methyl resonance is close to that of free dmso (δ 2.50). The other peaks appearing in a group have been assigned to S-bonded dmso and the integration of these peaks had not been possible owing to their proximity and their sharing the same broad base line [27]. Thus it becomes obvious that the group of peaks appearing in the new complexes around $\sim\delta$ 3.0–3.6 ppm should be attributed to S-bonded dmso resonances. The lack of any peak at δ 2.7 ppm for any of the new complexes implied the absence of O-bonded dmso in the complexes and supported the same point inferred from the IR spectra and evidenced by the crystal structure of **8**. The resonance around δ 2.5 ppm in all the complexes is due to the solvent. The Ar-methyl protons in **2** resonated at δ 1.64 ppm. The NH_2 protons in all the complexes gave single resonance peak in the range δ 3.54–4.22. The protons of CH_3–C=N in **1**, **2**, **6** and **7** appeared as a singlet in the range at δ 2.38–2.48. The singlets observed at δ 3.71 (complex **5**) and δ 3.87 (complex **6**) are due to methoxy protons. The protons of the methyl group in **3** and **4** gave resonance at δ 2.2 ppm. The aromatic/heterocyclic ring protons were observed in the range 6.6–7.9 ppm as multiplets. The azomethine (HC=N) proton in **3**, **4**, **5** and **8** resonated in the range δ 8.09–8.35 ppm. The appearance of a singlet in all the complexes around δ 10.87–11.23 ppm is due to NH proton which is matching with the IR observation that the chelating ligand coordinates in its keto form to the metal. From the foregoing discussions, it can be established that the semicarbazone/thiosemicarbazone ligands behave as neutral bidentate donors replacing one O-bonded dmso and one S-bonded dmso from the precursor.

3.3. X-ray crystallography of $[RuCl_2(dmso)_2(bzsc)]$ (**8**)

The structural study of this complex gains importance because the synthesis of this complex attempted previously by Vieites et al. by reacting *trans*-$[RuCl_2(dmso)_4]$ with benzaldehyde semicarbazone in methanol has not afforded any isolable complex and the characterization was limited only to the ^{1}H NMR spectra of the reaction mixture [37]. Unlike their synthesis, in our case, X-ray quality single crystals of the complex could be obtained by following the simple procedure given in Section 2.3.8. The complex crystallizes in the orthorhombic space group $P2_12_12_1$. The compound forms enantiopure crystals, as evidenced by the space group and the value of Flack parameter, −0.01(4) [38] and Hooft parameter, 0.008(11) [39]. However the complex itself does not contain chiral species, and is meso, with potential mirror symmetry. We thus assume that the compound crystallizes as a conglomerate, with individual crystals of each hand in the macroscopic sample.

The details on data collection, refinement and unit cell parameters are collected in Table 1. Fig. 1 shows the ORTEP drawing of **8** and Table 2 presents the selected geometrical parameters that are essential for the discussion. The molecular structure of **8** shows that the coordination sphere around Ru(II) is S_2Cl_2NO. The coordination polyhedron of the ruthenium ion can be described as distorted octahedron. The distortion in the complex from ideal octahedral geometry is due to the small bite angle of the ON chelate of semicarbazone ligand and the bending of chloride ligands towards the chelate which is evident from the angles O1–Ru1–N1 = 77.23(13), Cl1–Ru1–Cl2 = 171.62(4)°.

The average Ru–Cl bond lengths Ru1–Cl1 = 2.4154(12); Ru1–Cl2 = 2.3960(12) Å are slightly longer than found in $[RuCl_2(dmso)_2$(5-nitro-2-furaldehyde semicarbazone)] [Ru1–Cl12 = 2.386(4); Ru1–Cl11 = 2.394(4) Å] [8]. This length is shorter than that found in *cis*-$[RuCl_2(dmso)_4]$ (average Ru–Cl = 2.42 Å) and comparable with that found in the *trans* isomer [Ru–Cl = 2.402(2) Å] which is in agreement with the greater *trans* influence of dmso that weakens the Ru–Cl bond in *cis*-$[RuCl_2(dmso)_4]$ [40]. Similarly, the two Ru–S bond lengths [Ru1–S1 = 2.2054(12); Ru1–S2 = 2.2436(11) Å] are significantly shorter than the four equal Ru–S bonds [2.352(2) Å] in *trans*-$[RuCl_2(dmso)_4]$ and mean Ru–S bond length of 2.25(1) Å in $[Ru(dmso)_6]^{2+}$ [41] which shows the diminished competition between two dmso ligands for π-back donation in **8**. This stronger Ru^{2+}–S bonds in comparison with the Ru^{3+}–S bonds in similar Ru(III) complexes{Ru1–S1 = 1.461(3) Å in $[(dmso)_2H$-[*trans*-$Ru(dmso)_2Cl_4]$; Ru–S2 = 2.330(2), Ru–S3 = 2.351(1) Å in *mer*-$[Ru(dmso)_3Cl_3]$ and Ru1–S1 = 2.295(2) Å in [pyH]*trans*-$[RuCl_4$-(dmso)(py)]} [9,11] is in accordance with the better donation of d-electron density of less positive Ru(II) to sulfur atoms of dmso than by Ru(III) centre.

The complex is stabilized by intermolecular and intramolecular hydrogen bonds. The hydrogen bonding geometries for the complex is given in Table 3. The C–H···O (azomethine carbon, C2 is hydrogen bonded to the oxygen atom of the dmso) type intramolecular hydrogen bonds exhibited by the complex is noteworthy.

Table 4
Cyclic voltammetric data of the complexes in dmso

Complex	Ru(II)/Ru(I)[a] $E_{1/2}/V$ (ΔEp/mV)	(Cl)/(Cl$^-$)[b] $E_{1/2}/V$ (ΔEp/mV)	dmso based reduction[d]
(**1**)	−1.02 (350)	0.90[c]	−0.75
(**2**)	−0.70 (200)	1.06 (300)	−0.20
(**3**)	−0.66 (360)	1.07 (340)	−0.20
(**4**)	−0.72 (240)	0.90[c]	−0.28
(**5**)	−0.73 (300)	1.08 (400)	−0.20
(**6**)	−0.72 (240)	1.08 (360)	−0.24
(**7**)	−0.75 (140)	1.05 (300)	−0.40
(**8**)	−0.76 (160)	1.09 (340)	−0.24

[a] Reduction couple.
[b] Oxidation couple.
[c] Irreversible, Ep_a value.
[d] Irreversible, Ep_c value.

By analogy of the structure of **8**, a similar structure is proposed for other thiosemicarbzone complexes **1**–**7**, whose spectral characterization supports the neutral bidentate coordination of the SN chelate to ruthenium.

3.4. Cyclic voltammetric studies

The electron transfer properties of the new Ru(II) complexes were examined by cyclic voltammetry with dmso solutions ($\sim 1 \times 10^{-3}$ M) using 0.1 M TBAP as supporting electrolyte. The redox potentials measured relative to Ag/AgCl electrode at a scan rate of 0.1 V/s are reported in Table 4. All the complexes were electroactive in the sweep range ±1.5 V and displayed well-defined one-electron quasi-reversible coupled redox wave on either side of the reference electrode besides an irreversible peak at less negative potentials with respect to the coupled redox wave at the negative side of Ag/AgCl electrode. A prototype showing all the voltammetric features is shown Fig. 2. The oxidative couple exhibited by the complexes with formal potentials in the range 1.05–1.09 V (in complexes **1** and **4**, the cathodic counterpart of this couple is ill-defined) is ascribed to the oxidation of a slowly dissociated chloride ion [9,42]. This dissociation in turn accompanies Ru(II)/Ru(I) reduction occurring in the range −0.66 to −1.02 V and this range is concurrent with literature values [43,44]. Further dissociation of chloride has not been evidenced previously [9] for *trans*-$[Ru(dmso)_2Cl_4]^{2-}$ ion and thus the same is expected for the new complexes and also substantiated by the lack of any other reduction wave at more negative potentials than that for Ru(II)/Ru(I) reduction process. Also the dissociation of two chloride ions is unlikely since it will lead to the formation of Ru(0) species which is highly unstable. The other irreversible reduction wave in the range −0.18 to −0.40 V for **2**–**8** and at −0.75 V for **1** could not be thought of semicarbazone/thiosemicarbazones-based reduction for two reasons. Firstly, these ligand-based reductions occur at more negative potentials, almost at the negative-end of the chosen potential window here. The other reason is the observance of a similar peak at −0.15 V in the cyclic voltammogram of the precursor, *cis*-$[RuCl_2(dmso)_4]$ obtained under identical experimental conditions. Thus, this irreversible reduction may be attributed to coordinated dmso. This reduction potential is affected in the complexes due to coordinated semicarbazone/thiosemicarbazones. Nevertheless no correlation could be made out for this with the electronic nature of the ligands.

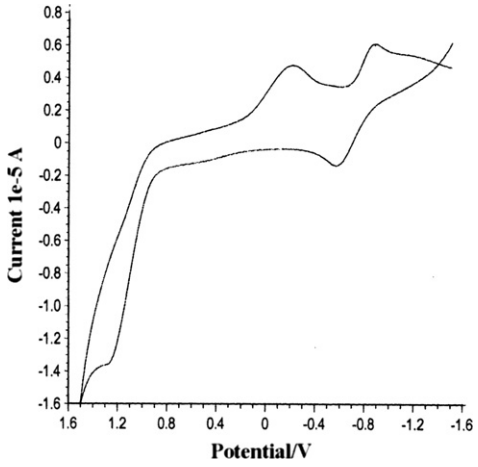

Fig. 2. Cyclic voltammogram of **6**.

3.5. UV–Vis spectra of the complexes in the presence of buffered herring sperm DNA solution

In general, metal complexes can bind to DNA via both covalent and non-covalent interactions [45–47]. These different modes of binding can be monitored by following the changes in the wavelength and intensity of absorption of a particular peak exhibited by the unbound complex. A decrease in absorbance (hypochromism) or an increase in absorbance (hyperchromicity) upon addition of DNA to a compound in solution is indicative of an interaction between these molecules [48].

In a typical experiment, the absorption titration was carried out with a complex of final concentration $\sim 1 \times 10^{-4}$ M and varying the concentration of herring sperm DNA. The concentration of the DNA stock solution was calculated to be 3.7878×10^{-3} M. The addition of DNA to the complex was achieved by adding buffered DNA (in different mixing ratios (r = [DNA]/[Ru-complex]) to the complex (0.3 mL) while maintaining the total volume a constant (3 mL). All the complexes showed single peak in the Tris–HCl buffer in the range 264–329 nm due to intraligand transitions. The change in wavelength and absorbance of this peak in the unbound complex was monitored as increasing amounts of DNA were added

Table 5
Change in UV–Vis spectra of (**1**)–(**8**) upon the gradual addition of herring sperm DNA[a]

4	14	64	13	69	14	55	NA	NT	NA	NT
6	18	58	17	58	NA	NT	NA	NT	NA	NT
7	NA	NT	NA	NT	NA	NT	12	63	12	77
8	15	62	12	74	12	58	14	58	13	63
Oxytetracycline	30	15	37	8	30	8	44	8	32	7
Kanamycin	32	18	48	9	35	10	60	11	40	10

NA – not active; NT – not tested.
[a] WD, disc diffusion method as recommended by NCCLS. Diameter of zone of inhibition (mm) including well diameter 8 mm. One hundred micrograms of both compound and antibiotics were used.
[b] MIC, minimum inhibitory concentration. Values given as μg/ml for both compounds and antibiotics.

and the results are recorded in Table 5. Except **1** and **5**, all the other complexes show small red shift or blue shift with a considerable hypochromism. These changes are indicative of interaction of the complexes with DNA [49].

3.6. Antibacterial activity

The antibacterial activity of the complexes as a measure of inhibition zone as well as minimum inhibitory concentration (MIC) against three Gram negative (*E. coli*, K. pneumoniae, S. sonnei) and two Gram positive (*S. aureus*, S. epidermidis) bacteria have been evaluated and the results are listed in Table 6. Since **1** and **5** showed an inhibition zone of 12 mm only against *S. sonnei* and were inactive against all other species, they were not tested further. The results show that none of the new ruthenium complexes were anywhere near as active as either oxytetracycline or kanamycin.

4. Conclusions

An interesting series of Ru(II)-dmso thiosemicarbazone complexes along with a semicarbazone complex has been synthesized and characterized. The XRD structure of previously ill-characterized [$RuCl_2$(dmso)$_2$(benzaldehyde semicarbazone)] has been reported which also supports the conversion of benzaldehyde thiosemicarbazone to benzaldehyde semicarbazone during ligand preparation. The electrochemistry and preliminary DNA-binding studies of the complexes with herring sperm ds-DNA has also been carried out. The complexes have been screened for their antibacterial activity against five pathogenic bacteria.

Appendix A. Supplementary data

CCDC 608057 contains the supplementary crystallographic data for 8. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

on a Varian E-112 (X band, 9.1 GHz) spectrometer at a microwave power of 1 mW and a modulation amplitude of 0.5 gauss, and the spectra were collected using a quartz dewar. Diphenylpicrylhydrazyl (dpph, $g = 2.0037$) was used to calibrate the spectra. Magnetic measurements were carried out on polycrystalline samples with a Quantum Design MPMS XL SQUID susceptometer operating at a magnetic field of 0.1 T between 2 and 300 K. The diamagnetic corrections were evaluated from Pascal's constants. Elemental analyses (C, H, N) were performed on a Perkin–Elmer 2400 Series II Elemental Analyzer.

2.2. Synthesis of the complexes

$[Fe^{III}(HL)][BPh_4]$ (**1**). H_3L (129 mg, 0.25 mmol) was added to a solution of $FeCl_3 \cdot 6H_2O$ (68 mg, 0.25 mmol) in methanol (10 ml) and the resulting violet solution was stirred at room temperature for 1 h. Addition of Et_3N (0.104 ml, 0.75 mmol) resulted in a deep brown colored solution which yielded a deep brown crystalline product after addition of $NaBPh_4$ (85 mg, 0.25 mmol) on slow evaporation. The product was collected by filtration and washed with cold water. Deep brown crystals were obtained by layering the product with DCM/hexane. Yield: 0.179 g, 80%. *Anal.* Calc. for $C_{55}H_{62}BFeN_4O_3$: C, 73.39; H, 6.92; N, 6.32. Found: C, 73.85; H, 6.99; N, 6.26%. UV–Vis (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$) CH_3CN solution): 500 (5549), 275 (18373). IR (KBr)/cm^{-1}: ν(C–O) 1270; ν(Fe–O) 690. E_{pa} (Fe^{III}/Fe^{II}): −0.191 V (irr.).

$[Fe_2^{III}L(OAC)_2]BPh_4$ (2). A solution containing H_3L (129 mg, 0.25 mmol) and $FeCl_3 \cdot 6H_2O$ (135 mg, 0.5 mmol) in 15 ml methanol was stirred at room temperature. After 15 min sodium acetate (123 mg, 1.5 mmol) was added, followed by $NaBPh_4$ (171 mg, 0.5 mmol) after an additional 30 min. Stirring was continued for 1 h and a deep blue solid started separating; it was evaporated to dryness and the resulting solid was washed thoroughly with water. The deep blue solid was dried in vacuum and recrystallized from methanol. Yield: 0.213 g, 76%. *Anal.* Calc. for $C_{60}H_{73}BFe_2N_4O_9$: C, 64.51; H, 6.52; N, 5.05. Found: C, 64.45; H, 6.59; N, 5.01%. UV–Vis (λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$) CH_3CN solution): 545 (59964), 321 (18295), 275 (36565). IR (KBr)/cm^{-1}: ν(C–O) 1270; ν(Fe–O) 694; ν(O_2CMe) 1564 and 1452. E_{pa} (Fe^{III}/Fe^{II}): −0.131 V.

2.3. Crystallographic studies

Single crystals suitable for X-ray crystallographic analysis of the complex $[Fe^{III}(HL)][BPh_4]$ were obtained by diffusing a dichloromethane solution of the complex into hexane and that of $[Fe_2^{III}L(OAc)_2][BPh_4] \cdot H_2O \cdot CH_3OH$ was obtained from a methanolic solution by slow evaporation. The X-ray intensity data were collected on a Bruker AXS SMART APEX CCD diffractometer (Mo Kα, $\lambda = 0.71073$ Å) at 293 K. The detector was placed at a distance of 6.03 cm from the crystal. A total of 606 frames were collected with a scan width of 0.3° in different settings of φ. The data were reduced in SAINTPLUS [8] and an empirical absorption correction was applied using the SADABS package [8]. The metal atoms were located by the Patterson Method and the rest of the non-hydrogen atoms emerged from successive Fourier synthesis. The structures were refined by a full-matrix least-square procedure on F^2. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were directly located in different Fourier maps. All calculations were performed using the SHELXTL V 6.14 program package [9]. Molecular structure plots were drawn using ORTEP [10]. Relevant crystal data are given in Table 1.

2.4. Computational details

All the calculations were carried out with the Density Functional Theory (DFT) [11] method and the calculations have been performed using the B3LYP exchange correlation function, [12] as implemented in the GAUSSIAN03 (G03) program package [13]. The geometry of complexes **1** and **2** were fully optimized in the gas phase using the 6-31G basis set [14] for the H, C, N, O atoms and the 6-31+g(d) basis set for iron without any symmetry constrain.

Table 1

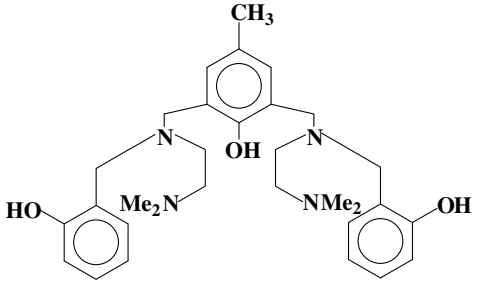
[b] $wR_2 = [\sum w(F_o^2 - F_c^2)^2 / \sum w(F_o^2)^2]^{1/2}$.

3. Results and discussion

The trianionic N_4O_3 coordinating ligand [7] has been used for the present study. The ligand possesses two sets of mono-acidic ONN chelating donor sites along with a central phenolate group. The reaction of $FeCl_3 \cdot 6H_2O$ with H_3L in a ratio 2:1 in the presence of sodium acetate offered a μ-phenoxo μ-acetato bridged diiron(III) complex of the formula $[Fe_2^{III}L(OAc)_2]^+$, (**2**$^+$) in good yields. Interestingly, when the same reaction was carried out with a 1:1 metal-to-ligand ratio in the presence of excess triethylamine instead of sodium acetate it yielded mononuclear $[Fe^{III}(HL)]^+$, **1**$^+$. The Fe(III) complexes are isolated as salts of the BPh_4^- anion.



H_3L

The $\nu_{(C-Ophenolate)}$ vibrations in both cases are observed around 1270 cm^{-1}. Complex **2** displays carboxylate stretches near 1564 and 1452 cm^{-1}. The splitting between the two peaks is 112 cm^{-1}, which indicates that the carboxylate group bridges the two iron ions in a *syn–syn* fashion [15a].

The UV–vis spectra of the complexes were recorded in acetonitrile (CH_3CN) solution and display two well resolved peaks along with a shoulder. The absorption near 500–545 nm is probably due to a phenolate(axial) → Fe(III) or phenolate(equatorial) → Fe(III) LMCT transition [15b,c]. The band near 300 nm is associated with ligand π–π^* transition.

All the complexes are electroactive at a platinum electrode versus SCE in acetonitrile solution. Complexes **1** and **2** exhibit an anodic response at −0.191 and −0.131 V, respectively. The voltammogram response is probably due to Fe(III) → Fe(II) and Fe(III)–Fe(III) → Fe(III)–Fe(II) reduction couples [16], respectively.

4. Crystal structures

The molecular structures of **1** and **2** · H_2O · CH_3OH have been determined by the X-ray diffraction method. The molecular views of the cationic part of the complexes are shown in Figs. 1 and 2, respectively. Selected bond parameters are listed respectively in Tables 2 and 3.

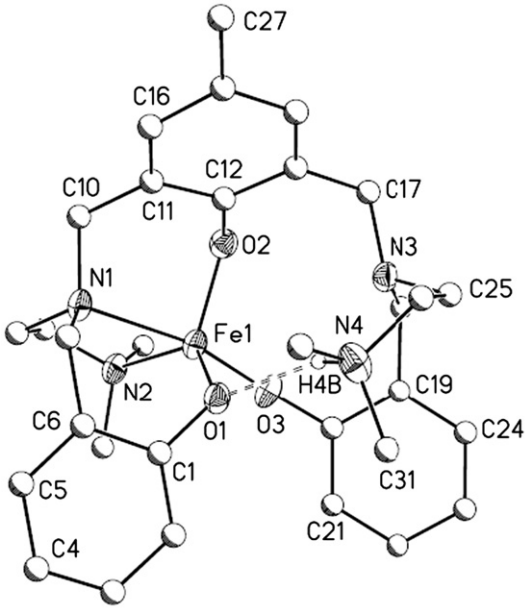


Fig. 1. Perspective view and atom-labelling scheme for [$Fe^{III}LH^+$]. All non-hydrogen atoms are represented by their 30% thermal probability ellipsoids.

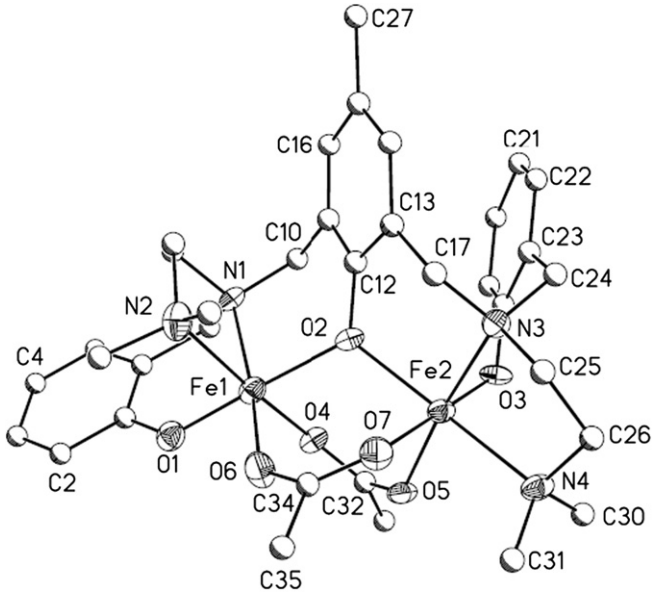

Fig. 2. Perspective view and atom-labelling scheme for [$Fe^{III}_2L(OAC)_2]^+$. All non-hydrogen atoms are represented by their 30% thermal probability ellipsoids.

[Fe^{III}(HL)][BPh_4] (**1**). The coordination environment around the iron atom in [$Fe^{III}LH^+$] is a distorted trigonal bipyramid (τ = 0.84) [17]. The ONN donor atoms along with the central phenolato group occupy four coordinating sites in which the terminal phenolate and tripodal nitrogen occupy equatorial positions whereas the central phenolate and terminal phenolate groups are *trans* to each other in the axial sites. The fifth coordination position is occupied by the terminal phenolato group of another ONN site of H_3L and the other two nitrogen atoms remain uncoordinated. It is interesting to note that the pentadentate nitrogen becomes protonated in the complex. In the lattice, the protonated N–*H* atom is hydrogen bonded with the coordinated O(1), the O(1)···N(4) distance being 2.833(6) Å. The involvement in hydrogen bonding of the O(1) atom explains the large Fe(1)–O(1) bond distance. The Fe–O(phenoxide) bond distances reveal that all three phenol groups are coordinated to iron(III) as phenoxides. The observed Fe–O bond distances (Fe(1)–O(1), 1.900(3), Fe(2)–O(2), 1.849(3) and Fe(1)–O(3), 1.872(3) Å) are shorter than the average octahedral Fe–O(phenoxide) bond distance of 1.92 Å. Fe–N bond distances are usual and span the range 2.15–2.31 Å [4b].

[FeIII2L(OAc)2][BPh4] · H_2O · CH_3OH, 2 · H_2O · CH_3OH. For the cationic part of the complex, two iron centers are bridged by the

central phenolate (O(2)) of the heptadentate ligand and two bidentate *syn–syn* acetato groups, leading to a triply bridged dinuclear species with Fe(1)–Fe(2) = 3.496(9) Å. The remaining coordinating sites of each iron are occupied by the ONN donor atoms of the ligand. The positions of the donor atoms in both iron centers are not identical. The bridging phenolato (O(2)) group in the coordination sphere of Fe(1) is *trans* to a terminal phenoxo group while that in Fe(2) is *trans* to the pentadentate nitrogen atom (N(4)). The Fe(1)–O(2)–Fe(2) bridging angle is 115.81(16)°. The Fe–O(terminal phenolato) span the range 1.864–1.874 Å. The Fe–O(bridging), Fe–N and Fe–O(acetate) distances are normal [5].

5. Optimized geometry

The geometry optimization for the cationic part of complexes **1** and **2** is performed in the gas phase with the complexes in their highest spin state. The geometries are optimized using the crystal coordinates as the initial coordinates. The gas phase optimized structures in both cases are shown in Figs. 3a and b, respectively. The crystal structural parameters of $\mathbf{1}^{+}$ and $\mathbf{2}^{+}$ (Tables 1 and 2) are in excellent agreement with the optimized parameters.

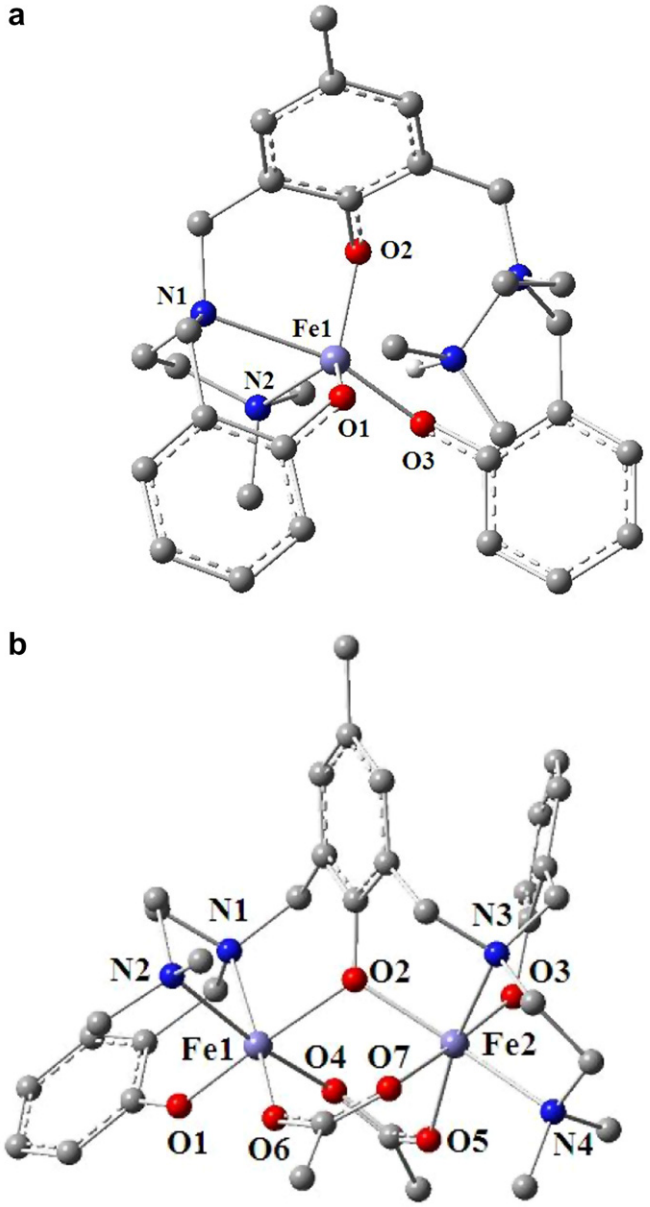

Fig. 3. Optimized molecular structure of (a) $[Fe^{III}LH^{+}]$ and (b) $[Fe^{III}_2L(OAC)_2]^{+}$ (Fe: Cyan, N: Blue, O: Red, C: Grey). Hydrogen atoms are excluded for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

6. EPR spectra

Complex **2** is EPR silent, both in the solid state and in solution. However, in frozen solution complex **1** exhibits an EPR signal near $g = 4.2$ (Fig. 4a). The spectral feature is associated with a rhombically distorted high-spin iron(III) complex [15c,18].

7. Magnetic studies

Variable temperature magnetic susceptibility measurements were performed in the range 2–300 K. The plot of $\chi_M T$ versus T and an inset plot of χ_M versus T are shown in Fig. 4b. The effective magnetic moment at 300 K is 7.49 emu cm^{-1} K and this decreases rapidly to 0.62 emu cm^{-1} K at 2 K, which is a characteristic feature of weak antiferromagnetic interactions. The spin Hamiltonian used to simulate the $\chi_M T$ versus T curve is

$$H = -JS_1S_2$$

where $S_1 = S_2 = 5/2$. The best fit of the $\chi_M T$ versus T curve yielded $J = -14.4(4)$ cm^{-1}, $g = 2.04(2)$ and $\rho = 0.06(1)$.

The weak antiferromagnetic interaction is a characteristic feature of diiron(III) complexes interacting *via* (μ-O) bis(μ-acetato)/(μ-OH) bis(μ-acetato). It has been documented in the literature that the exchange coupling between two iron(III) centers in such a class of complexes take place through Fe(III)–(μ-O)–Fe(III)/Fe(III)–(μ-OH)–Fe(III) bonds and the strength of the exchange primarily depends on the Fe–O(bridge) bond distance; whereas the Fe(III)–O(bridge)–Fe(III) angle has a secondary role [6b]. In the present case, the weak antiferromagnetic coupling is a direct consequence of the large Fe–O(bridging) distance, 2.061 Å, and the exchange coupling is comparable with other reported (μ-$O_{phenoxo}$)bis(μ-acetato) complexes [5].

CASSCF and CASPT2 [19] calculations have been performed for a theoretical investigation of the exchange coupling of complex **2** using 6-31G and ANO-DZP [20] basis sets. The calculated J values are listed in Table 4. For the CASPT2 calculation the model structure **3** has been used, keeping the coordination environment

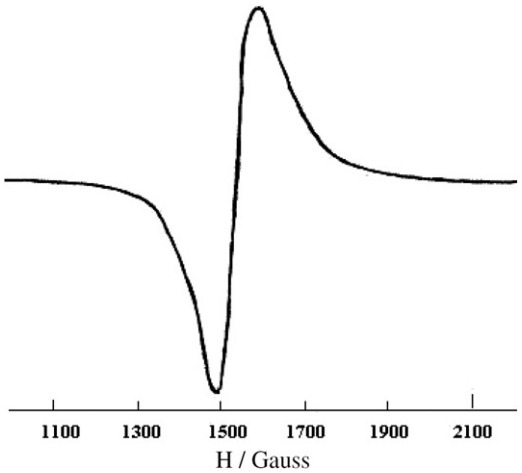

Fig. 4a. X-band EPR spectra for **2** in frozen solution (CH_2Cl_2/Toluene) at 77 K. Instrument settings: microwave frequency, 9.1 GHz; microwave power, 1 mW; modulation frequency,100 kHz; modulation amplitude, 0.5 G; sweep center, 2100 G.

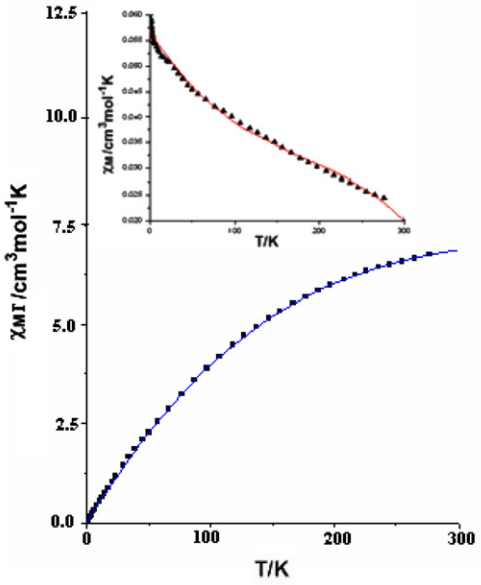

Fig. 4b. $\chi_M T$ vs. T for **2**. Solid line shows the best fit obtained. Inset plot of χ_M vs. T.

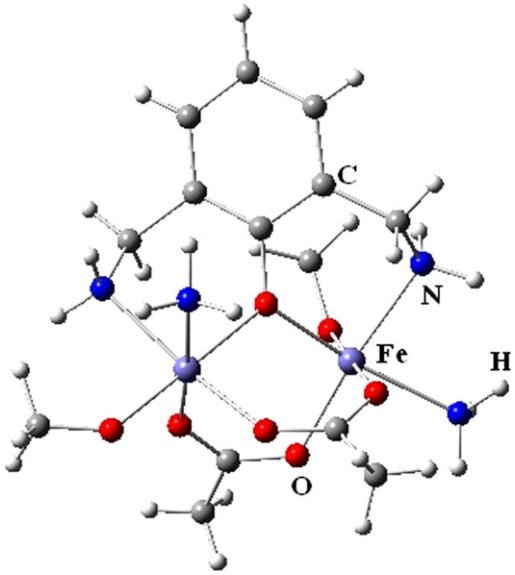
Table 4
Calculated J values (in cm^{-1}) for complex **2** and model **3**

Basis	Molecule	CASSCF	CASPT2
6-31G	**2**	−3.3	
	3	−3.0	−21.7
ANO-DZP	**3**	−2.8	−20.9

around the iron centers unchanged. It has been documented that this has little or no influence on the magnetic coupling as long as the geometry of the core of the molecule and the nature of the atoms directly coordinated to the metal ions remain the same [21]. In the present case the CASSCF results for the real and the model complex confirm the small effect of the modelling and the results are almost identical (Table 4). The calculated J value is in agreement with the experimental result.



8. Conclusion

In summary, we have synthesized and characterized mononuclear and dinuclear iron(III) complexes incorporating a N_4O_3 coordinating heptadentate ligand. Interestingly in the mononuclear complex the ligand binds in the N_2O_3 form. Variable temperature magnetic moment measurements have been performed in the case of the dinuclear species. The optimized geometries, in both cases, are in good agreement with the X-ray structures. The study of different Fe(III) species using various O,N-coordinating ligands, along with theoretical investigations, are in progress.

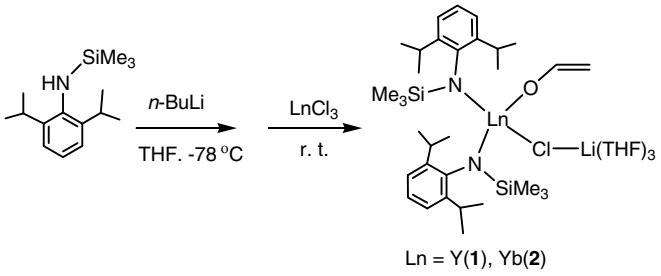
Recently, Steiner et al. reported that the reaction of hexaprotic phosphazene $\{2\text{-}(MeO)(C_6H_4NH)\}_6P_3N_3$ with excess (12 equiv.) *n*BuLi in THF produced a monomeric dodecanuclear complex incorporating six enolate ligands [10]. We report here the synthesis of novel lanthanide complexes incorporating amido and enolate ligands having the general formula $(CH_2{=}CHO)Ln[2,6\text{-}(i\text{Pr})_2C_6H_3NSiMe_3]_2(\mu\text{-}Cl)Li(THF)_3$, by the one-pot reaction of *N*-trimethylsilyl-2,6-diisopropylaniline 2,6-$(i\text{Pr})_2C_6H_3NHSiMe_3$ with excess *n*BuLi in THF, followed by treatment with 1 equiv. of $LnCl_3$. The reactivity of this kind of complexes with aromatic aldehydes is also reported.

2. Results and discussion

The structurally characterized rare earth metal complexes incorporating amido and enolate mixed ligands $(CH_2{=}CHO)Ln[2,6\text{-}(i\text{Pr})_2C_6H_3NSiMe_3]_2(\mu\text{-}Cl)Li(THF)_3$ (Ln = Y(**1**), Yb(**2**)) were synthesized for the first time by the one-pot reaction of *N*-trimethylsilyl-2,6-diisopropylaniline 2,6-$(i\text{Pr})_2C_6H_3NHSiMe_3$ with 1.5 equiv. of *n*BuLi in THF, followed by treatment with $LnCl_3$ in good yields (Scheme 1). The complexes are soluble in toluene, benzene, THF and CH_2Cl_2, but only slightly soluble in *n*-hexane. These complexes were well characterized by spectroscopic methods and elemental analyses. Their structures were additionally determined by X-ray diffraction study (Figs. 1 and 2).

The ^{1}H NMR spectrum of complex **1** exhibited resonances at 6.90, 4.24 and 4.20 ppm, which can be attributed to the corresponding proton resonances of the enolate ligand OCH=CH$_2$ in the complex. The resonances of the enolate ligand exhibited coupling. The proton resonances of the enolate ligand of the complex



Scheme 1.

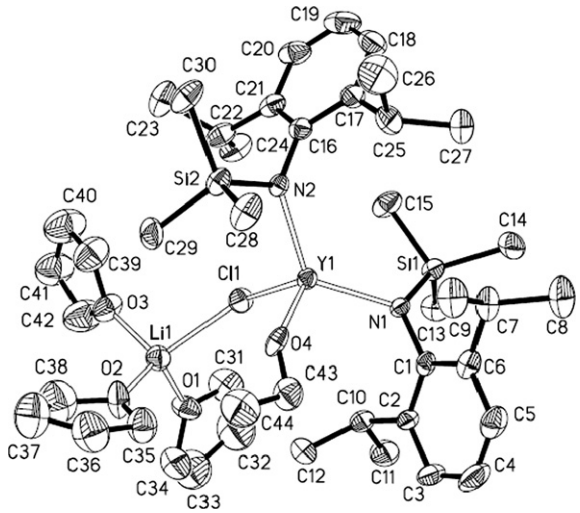


Fig. 1. Molecular structure of complex **1**, hydrogen atoms are omitted for clarity.

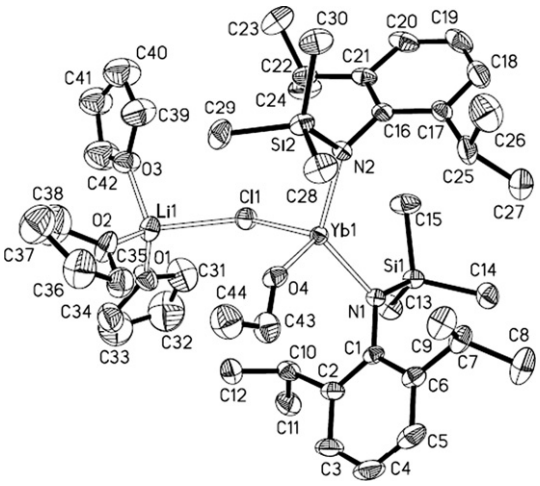

Fig. 2. Molecular structure of complex **2**, hydrogen atoms are omitted for clarity.

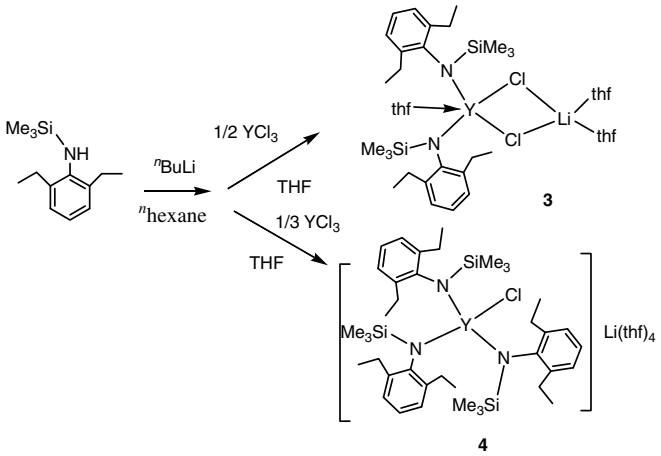
can be compared with those of the enolate ligand in $(Cp'Y)_4(OCH{=}CH_2)(\mu\text{-}O)(\mu\text{-}H)_5(THF)$ [6], $[(C_5H_5)_2Y(\mu\text{-}OCH{=}CH_2)]_2$ or $[(CH_3C_5H_4)_2Y(\mu\text{-}OCH{=}CH_2)]_2$ [7], and LiOCH = CH$_2$ [11]. Each IR spectrum of complex **1** or **2** contains a very broad strong band around 1650 cm^{-1}, which can be attributable to the C=C bond of the enolate and the phenyl ring stretch.

In order to search for the origination of the enolate ligand of the above complexes, 2,6-$(Et)_2C_6H_3NHSiMe_3$ was treated with *n*BuLi in *n*-hexane at first, followed by treatment with 1/2 or 1/3 equiv. of YCl_3 in THF respectively, and complexes with the formula $[2,6\text{-}(Et)_2C_6H_3NSiMe_3]_2Y(THF)(\mu\text{-}Cl)_2Li(THF)_2$ (**3**) and $\{[2,6\text{-}(Et)_2C_6H_3NSiMe_3]_3YCl\}[Li(THF)_4]$ (**4**) were isolated (Scheme 2). The complexes were well characterized by spectroscopic methods and elemental analyses. The elemental analyses data are in agreement with the loss of THF molecules, which is common in lanthanide chemistry. The structures of complexes **3** and **4** were determined by single crystal X-ray analyses. These results suggested that (1) the produced lithium amide Li(2,6-$(i\text{Pr})_2C_6H_3NSiMe_3$) is not responsible for the resulting enolate ligand in complexes **1** and **2**; (2) YCl_3 cannot react with THF leading to the formation of the enolate ligand. Evidence that *n*BuLi can react with THF leading to the cleavage of the THF ring to produce a lithium enolate and ethylene is reported, and this process has been monitored by NMR spectroscopy [11]. Thus, the enolate ligand in complexes **1** and **2** is believed to have come from the cleavage of the THF molecule by *n*BuLi. To further prove the above conclusion, the



Scheme 2.

product of the reaction of *N*-trimethylsilyl-2,6-diethylaniline with 1.5 equiv. of *n*BuLi was analyzed by ^{1}H NMR spectroscopy. The spectra clearly indicated the formation of Li[2,6-$(Et)_2C_6H_3NSiMe_3$)] and LiOCH = CH_2, and the existence of three coordinated THF molecules.

X-ray analyses confirmed that complexes **1** and **2** consisted of two amido ligands, an enolate ligand and a bridged chlorine atom connected with a lithium atom coordinated by three THF molecules. The central rare earth metal of each complex is coordinated by two nitrogen atoms of the amido ligand, an oxygen atom of the enolate ligand and a chlorine atom. The central yttrium atom in complex **3** is coordinated by two nitrogen atoms of the amido ligand, one oxygen atom of a THF molecule and two chlorine atoms (Fig. 3). The central yttrium atom in complex **4** is coordinated by three nitrogen atoms of the amido ligand and one chlorine atom

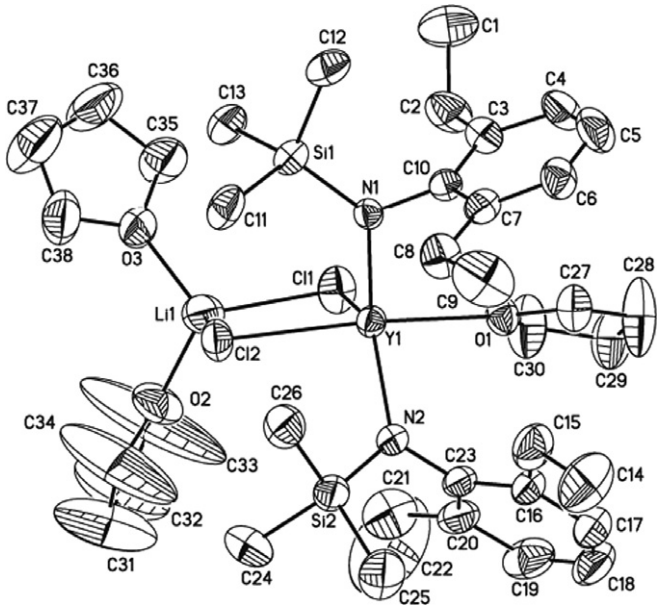


Fig. 3. Molecular structure of complex **3**, hydrogen atoms are omitted for clarity.

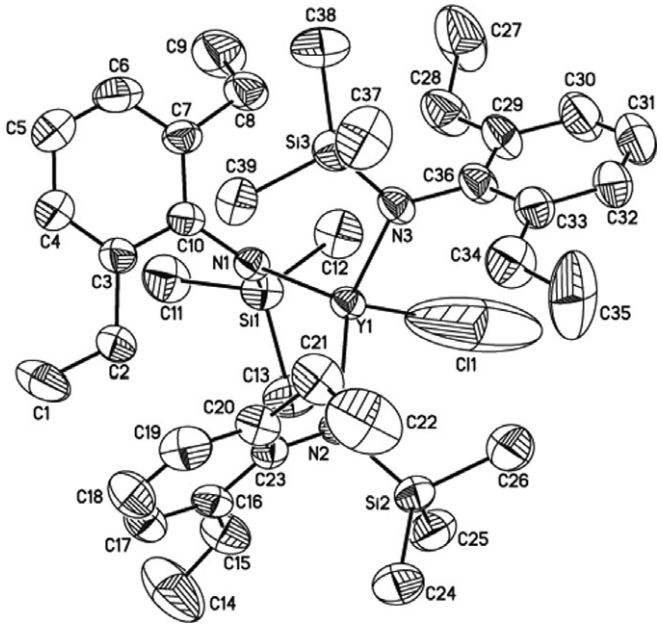

Fig. 4. The structure of the anion in **4**, hydrogen atoms are omitted for clarity.

(Fig. 4). The bond angles of N–Ln–N, Cl–Ln–O, N–Ln–Cl, O–Ln–N (Ln = Y, Yb), in the range 102.7(3)–126.9(2)° (Table 1) for complex **1**, 102.3(3)–127.61(19)° (Table 1) for complex **2**, and 98.5(2)–118.04(18)° for complex **4**, are deviated from the ideal tetrahedral angle. Thus the coordination geometry around the central metal of complexes **1**, **2** and **4** can be described as a distorted tetrahedral. The bond angles of O(1)–Y(1)–Cl(2), N(1)–Y(1)–N(2), N(1)–Y(1)–Cl(1) and N(2)–Y(1)–Cl(1) are 160.16(10), 120.22(14), 111.46(10) and 128.16(11)° (Table 1), respectively in complex **3**, largely deviated from the ideal trigonal bipyramidal bond angles, so the coordination geometry of the central yttrium in complex **3** can be described as pseudo-trigonal bipyramidal with O(1) and Cl(2) at the axial positions.

The Y–N distances are 2.229(5) and 2.254(6) Å, with an average of 2.242(6) Å, in **1**, which is comparable to the average distance of 2.194(5) Å found in **2**, and that of 2.240(4) Å in **3** and 2.294(5) Å in **4**, if the ionic radii difference between the central metal is taken into account. The average Y–N distance of 2.242(6) Å in **1** is similar to that of 2.243(4) Å found in [η^5-$(CH_2)_2(C_9H_6)_2$]YN($SiMe_3$)$_2$ [12]. But the average Yb–N bond distance of 2.194(5) Å found in **2** is slightly longer than that of 2.162(5) Å found in [η^5-$(CH_2)_2(C_9H_6)_2$]YbN($SiMe_3$)$_2$ [13], this difference can be attributable to ionic and steric effects [14]. The Yb–Cl distance of 2.552(2) Å found in **2** is equal to that of 2.552(2) Å found in [$(Me_3Si)_2$-N]$_3$Yb(μ-Cl)Li(THF)$_3$ [13a]. The Y–Cl distance of 2.603(2) Å found in **1** is longer than the Yb–Cl distance of 2.552(2) Å found in **2** due to the ionic radii difference. The Y–Cl distance of 2.603(2) Å found in **1** is shorter than those of 2.648(2) Å in **3** and 2.621(2) Å

in **4**, probably due to steric effects. The Ln–Cl bond distances found in the above complexes are comparable to those found in $Ln\{N[Si(Me)_2CH_2CH_2Si(Me)_2]\}(\mu\text{-}Cl)Li(L)_3$ (L = THF or Et_2O) [15]. The yttrium–oxygen distance of 2.104(10) Å is shorter than those of 2.275(3) and 2.290(3) Å found in $[(CH_3C_5H_4)_2Y(\mu\text{-}OCH{=}CH_2)]_2$ [7] The Li(1)–Cl(1)–Y(1) angle of 136.3(4)° in **1** is comparable to that of 136.1(3)° found in **2**, but these angles are significantly smaller than the corresponding Li–Cl–Ln angles of 175 ± 1° found in $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Sm, Eu) [16], and those of 170 ± 2° found in $Ln\{N[Si(Me)_2CH_2CH_2Si(Me)_2]\}(\mu\text{-}Cl)Li(L)_3$ (L = THF or Et_2O) [15].

The C=C double bond distances of the enolate, 1.351(10) Å in **1** and 1.344(4) Å in **2**, are slightly longer than the standard 1.34 Å expected for the C=C bond in ethylene, they are also longer than that of 1.287(8) Å for the C=C double bond of the enolate found in $[(CH_3C_5H_4)_2Y(\mu\text{-}OCH{=}CH_2)]_2$ [7].

It has been well documented that the Aldol reaction proceeds through an enolate intermediate when the reaction is carried out in an inorganic base medium [8]. We have found that lanthanide amides $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ can initiate the disproportionation reaction of aromatic aldehydes to give the corresponding amides and alcohols [9]. In order to search for the influence of the rare earth metals on the reactivity or selectivity of the amido and enolate ligands with aromatic aldehydes (Scheme 3), the reactivity of the lanthanide complexes **1** and **2** with aromatic aldehydes was explored.

First, a model reaction of 4-bromobenzyl aldehyde with a stoichiometric amount of the yttrium complex **1** was tested (Scheme 4, Table 2). It was found that the reaction can proceed in different solvents such as toluene, CH_2Cl_2 and THF (Table 2, entries 1–3), but the outputs of the reaction products are higher in CH_2Cl_2 than for reactions carried out in other solvents such as THF and toluene. It was found that only the disproportionation products of the corresponding amide and alcohol instead of the Aldol reaction product could be isolated, suggesting that the amido ligand could selectively react with aromatic aldehydes. The outputs of the reaction products were influenced by the reaction temperatures. Low yields of the products could be obtained when the reaction was carried out at moderately higher temperatures. It should be noted that a small amount of imines could be detected when the reaction was carried out at moderately higher temperatures, but the imines is decomposed to aldehydes during workup. Thus, the conditions for doing the following experiments were fixed as room temperature reaction, employing CH_2Cl_2 as the solvent.

Table 2
Conditions and results of the reaction of 4-bromobenzyl aldehyde with a stoichiometric amount of yttrium complex **1**[a]

Entry	Temperature (°C)	Solvent	Time (d)	Yield of amide[b]
1	r. t.	Toluene	2	49
2	r. t.	CH_2Cl_2	2	68
3	r. t.	THF	2	35
4	50	CH_2Cl_2	2	41
5	80	THF	2	23

[a] Aldehyde:yttrium complex = 4:1 (mol ratio).
[b] Isolated yield based on the yttrium complex.

A series of aromatic aldehydes can selectively react with the amido group of the lanthanide complexes **1** and **2** to produce the corresponding disproportionation products of amides and alcohols (Scheme 5, Table 3), and no Aldol reaction products were found to any detectable degree, indicating that the electron-deficient lanthanide metal has a great influence on the reactivity of the enolate group. The substituents on the aromatic aldehydes could be either electron-donating groups such as CH_3^-, CH_3O^- and Me_2N^- or electron-withdrawing ones such as Cl^-, Br^-, O_2N^- and F_3C^-. However, the electronic effects of the substituent groups have an influence on the output of the reactions. When the substituents are electron-donating groups such as CH_3^-, CH_3O^- and Me_2N^- or electron-withdrawing ones such as Cl^- and Br^-, the main products of amides and alcohols (>50% yield based on the lanthanide complexes) could be isolated, and only a trace or a very small amount of the corresponding imines could be detected from the reaction mixture. When the substituents are O_2N^- and F_3C^-, the output of the imines increased as the output of the amides and alcohols decreased. The corresponding imines could be isolated under the workup conditions, and they were well characterized (Fig. 5), however, in all other cases the imine products could not be isolated under the workup conditions. These results are different to our previous work on the reaction of lanthanide amides $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ with aromatic aldehydes, producing the corresponding amides and alcohols as the only products [9a], with no imine products being found to any detectable degree.

Conditions: [a]CH_2Cl_2 as a solvent, room temperature. [b]isolated yield based on lanthanide complex. [c]Data are obtained from the reaction of the aldehydes with yttrium complex **1**. [d]Data in the parenthesis are obtained from the reaction of the aldehydes with ytterbium complex **2**.

We have found that the reaction of lithium amide $(Me_3Si)_2NLi$ with aromatic aldehydes in the presence of $LnCl_3$, or the stoichiometric reaction of $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ with aromatic aldehydes, yielded the corresponding disproportionation products of amides and alcohols. No imine product has been detected in the reaction [9a]. For comparison, the reaction of the lithium amide $\{[2,6\text{-}(i\text{Pr})_2C_6H_3](Me_3Si)N\}Li$ with some selected aromatic aldehydes catalyzed by YCl_3 was investigated (Scheme 6). The reaction goes smoothly producing the disproportionation products of amides and alcohols in the presence of 5 mol% YCl_3 (Table 4) in satisfactory yields. The substituents on the aromatic aldehydes can be either electron-donating groups such as CH_3^- and CH_3O^- or electron-withdrawing ones such as Cl^-, Br^- and O_2N^-. The major differences between the stoichiometric reactions of the lanthanide complexes **1** or **2** with aldehydes and the catalytic reaction of lithium amide with the aldehydes are: (1) no imine products have been detected in all cases (Table 4); and (2) the output of the corresponding amides and alcohols are improved significantly when the substituents on the aromatic aldehydes are electron-withdrawing ones such as O_2N^- and F_3C^- (Table 4, entries 5 and 6) under almost the same reaction conditions. These results are somewhat different to our previous work, which may be due to the coordinated enolate ligand's effect on the reactions. We have proposed that the reaction of lithium amide $(Me_3Si)_2NLi$ with aromatic aldehydes in the presence of $LnCl_3$ goes through lanthanide amides $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ as intermediates. It is reported that the reaction of lithium amides $\{[2,6\text{-}(i\text{Pr})_2C_6H_3](Me_3Si)N\}Li$ with lanthanide chlorides $LnCl_3$ produced the lanthanide amides $\{[2,6\text{-}(i\text{Pr})_2C_6H_3](Me_3Si)N\}_3Ln$ [17]. On the basis of these results, we can conclude that the reaction of lithium amide $\{[2,6\text{-}(i\text{Pr})_2C_6H_3](Me_3Si)N\}Li$ with aldehydes in the presence of YCl_3 may go through a similar mechanism as in our previous work, which has been demonstrated as a Cannizzaro type disproportionation [9a]. The reaction involves the addition of the amido group from the lanthanide metal center to one molecule of aldehyde to give the intermediate $\{ArCH(O)N(SiMe_3)[C_6H_3\text{-}2,6\text{-}(i\text{Pr})_2]\}^-$ (**A**), which leads to the oxidation of the aldehyde by transferring the hydride from the intermediate (**A**) to another molecule of aldehyde to produce the amide precursor, leading to the reduction of the aldehyde, $ArCH_2O^-$. The final products of amide and alcohols could be isolated after workup. The formation of imine products in the stoichiometric reactions of lanthanide complex **1** or **2** with aromatic aldehydes may be due to the influence of the coordinated enolate ligand in the complexes. However, further work on this detail should be carried out.

3. Conclusion

We have for the first time rationally synthesized novel rare earth metal complexes incorporating amido and enolate mixed ligands by a one-pot reaction. The experimental results suggest that this method may be applied to the synthesis of complexes incorporating amido and enolate mixed ligands. Investigation on the reactivity of this kind of lanthanide complex indicates that the amido ligand of the complex can selectively react with aromatic aldehydes to afford the disproportionation products of amides and alcohols, suggesting that the Lewis acid property of the rare earth metals have a great influence on the reactivity of the enolate ligand. When the enolate is coordinated with the rare earth metals; it showed no reactivity with aromatic aldehydes. This kind of complex has compatibility for substituents on the aromatic aldehyde ring such as Cl^-, Br^-, F_3C^-, O_2N^- and other electron-donating groups. The outputs of the reaction were influenced by the substituents on the aromatic aldehydes ring, the solvents and the ligands of the lanthanide complexes. The results of the reaction of the lithium amide {[2,6-(iPr)$_2$C$_6$H$_3$](Me$_3$Si)N}Li with aromatic aldehydes in the presence of a catalytic amount of YCl$_3$ suggested that the method for the preparation of the amides from aldehydes by a one step reaction may be extended to reaction of other lithium amides with aldehydes. Further investigation on the reactivity of other lithium amides with aldehydes in the presence of lanthanide compounds is now in progress in our laboratory.

4. Experimental

4.1. Materials and methods

All syntheses and manipulations of air and moisture-sensitive materials were carried out in flamed dried Schlenk-type glassware on a Schlenk line. All solvents were refluxed and distilled over either finely divided LiAlH$_4$ or sodium benzophenone ketyl under argon prior to use unless otherwise noted. 2,6-(iPr)$_2$C$_6$H$_3$NHSiMe$_3$ 2,6-(Et)$_2$C$_6$H$_3$NHSiMe$_3$ [17] and LnCl$_3$ [18] (Ln = Yb, Y) were prepared according to the literature procedures. CDCl$_3$ was dried over activated 4 Å molecular sieves. Elemental analysis data were obtained on a Perkin–Elmer 2400 Series II elemental analyzer. IR spectra were recorded on a BIO-RAD FTS-40 spectrometer (CsI crystal plate, Nujol and Fluoroble mulls). Melting points were determined in sealed capillaries and are reported without correction. ^{1}H NMR and ^{13}C NMR spectra for analyses of compounds were recorded on a Bruker Avance-300 NMR spectrometer in benzene-d_6 for the lanthanide complexes, and in CDCl$_3$ for organic compounds, and chemical shifts for ^{1}H and ^{13}C NMR spectra were referenced to the internal solvent resonances.

4.2. Preparation of (CH$_2$=CHO)Y[2,6-(iPr)$_2$C$_6$H$_3$NSiMe$_3$]$_2$(μ-Cl)Li(THF)$_3$ (**1**)

To a THF solution of 2,6-(^{i}Pr)$_2$C$_6$H$_3$NHSiMe$_3$ (5.90 g, 23.6 mmol) at −78 °C was slowly added an n-hexane solution of nBuLi (20.6 mL, 35.8 mmol). The temperature of the reaction mixture was then gradually raised to room temperature after the addition. The mixture was stirred at room temperature for another 12 h. The reaction mixture was then transferred to a suspension of YCl$_3$ (2.31 g, 11.8 mmol) in THF. The reaction mixture was stirred at room temperature for 6 h, and then at 60 °C overnight. The solvent was pumped off. The residue was washed with 15 mL of n-hexane. The solid was extracted with a mixture of toluene and n-hexane (2:3, v/v) at 50 °C. Colorless crystals were obtained upon cooling the extracts at −10 °C for several days (6.27 g, 60%). M.p.: 82–84 °C (dec.). ^{1}H NMR (300 MHz, C$_6$D$_6$, δ in ppm): 7.32–7.16 (m, 6H, C$_6H_3$), 6.90 (dd, 1H, J = 12.9 Hz, J = 5.4 Hz, CH=CH$_2$), 4.24 (dd, 1H, J = 12.9 Hz, J = 1.2 Hz, CH=CH_2), 4.20 (dd, 1H, J = 5.4 Hz, J = 1.2 Hz, CH=CH_2), 3.12 (m, 4H, CH(CH$_3$)$_2$), 3.50 (m, 12H, OC$_4H_8$), 1.46 (m, 12H, OC$_4H_8$), 1.25–1.23 (m, 24H, CH(CH_3)$_2$), 0.50 (s, 18H, Si(CH_3)$_3$). IR (Nujol and Fluoroble mulls, cm^{-1}): ν 2961 (w), 2870 (s), 1651 (vs), 1441 (m), 1383 (m), 1327 (w), 1252 (vs), 1196 (w), 1044 (w), 907 (s), 843(s). *Anal.* Calc. for C$_{44}$H$_{79}$ClLiN$_2$O$_4$Si$_2$Y: C, 59.54; H, 8.97; N, 3.16. Found: C, 59.26; H, 9.13; N, 3.00%.

4.3. Preparation of (CH$_2$=CHO)Yb[2,6-(iPr)$_2$C$_6$H$_3$NSiMe$_3$]$_2$(μ-Cl)Li(THF)$_3$ (**2**)

This complex was prepared as yellow crystals in 61% yield from the reaction of 2,6-(iPr)$_2$C$_6$H$_3$NHSiMe$_3$ (4.45 g, 17.8 mmol) with nBuLi (15.5 mL, 26.9 mmol) in THF, followed by treatment with YbCl$_3$ (2.49 g, 8.9 mmol) by applying the procedures similar to those used for the preparation of **1**. M.p.: 86–88 °C (dec.). IR (Nujol and Fluoroble mulls, cm^{-1}): 2960 (s), 2870 (w), 1632 (vs), 1462 (m), 1363 (m), 1263 (w), 1092 (w), 1057 (w), 745 (w). *Anal.* Calc. for C$_{44}$H$_{79}$ClLiN$_2$O$_4$Si$_2$Yb (971.70): C, 54.39; H, 8.19; N, 2.88. Found: C, 54.12; H, 8.03; N, 2.98%.

4.4. Preparation of [2,6-(Et)$_2$C$_6$H$_3$NSiMe$_3$]$_2$Y(THF)(μ-Cl)$_2$Li(THF)$_2$ (**3**)

To a Schlenk flask containing an n-hexane solution of 2,6-(Et)$_2$C$_6$H$_3$NHSiMe$_3$ (2.78 g, 12.6 mmol) was added nBuLi (10.6 mL, 13.0 mmol) at −78 °C. The reaction mixture temperature was slowly raised to room temperature, and it was stirred for another 12 h at room temperature. The excess nBuLi was filtered off and washed with n-hexane, then 30 mL of THF was added. To the THF solution of the resulting lithium amide Li[2,6-(Et)$_2$C$_6$H$_3$NSiMe$_3$], was added YCl$_3$ (1.23 g, 6.3 mmol). The reaction mixture was stirred at room temperature overnight, and then at 60 °C for another 24 h. The solvent was evaporated under reduced pressure. The residue was extracted with toluene and n-hexane mixed solvents (1:1, v/v, 2 × 10 mL), the extraction was combined and concentrated. Colorless crystals were obtained upon standing the concentrated solution at −20 °C for several days (3.54 g, 83%). M.p.: 86–88 °C. ^{1}H NMR (300 MHz, C$_6$D$_6$, δ in ppm): 7.20–6.94 (m, 6H), 3.37–3.26 (m, 4H), 2.97–2.88 (m, 8H), 1.46–1.33 (m, 4H), 1.24–1.19 (m, 12H), 0.46–0.34 (m, 18H). IR (KBr, cm^{-1}): 3406 (w), 2966 (s), 2874 (w), 1624 (s), 1454 (s), 1253 (vs), 1107

(m), 1060 (w), 902 (m), 840 (w), 748 (w). *Anal.* Calc. for $C_{30}H_{52}Cl_2LiN_2OSi_2Y$ (**3**-2THF) (679.67): C, 53.01; H, 7.71; N, 4.12. Found C, 52.81; H, 7.36; N, 3.75%.

4.5. Preparation of {[2,6-(Et)$_2$C$_6$H$_3$NSiMe$_3$]$_3$YCl}[Li(THF)$_4$] (**4**)

This complex was prepared as colorless crystals in 75% yield from the reaction of 2,6-$(Et)_2C_6H_3NHSiMe_3$ (4.59 g, 20.8 mmol) with *n*BuLi (17.4 mL, 21.4 mmol) in *n*-hexane, followed by treatment with YCl_3 (1.35 g, 6.9 mmol) in THF, by employing procedures similar to those used for the preparation of complex **3**. ^{1}H NMR (300 MHz, C_6D_6, δ in ppm): 7.19–6.92 (m, 6H), 3.35–3.25 (m, 4H), 2.95–2.88 (m, 8H), 1.45–1.30 (m, 4H), 1.24–1.19 (m, 12H), 0.46–0.34 (m, 18H). IR (KBr, cm^{-1}): 2962 (s), 2874 (m), 2330 (w), 1631 (s), 1454 (s), 1373 (w), 1253 (vs), 1111 (s), 1057 (m), 906 (s), 840 (m), 748 (w). *Anal.* Calc. for $C_{43}H_{74}ClLiN_3OSi_3Y$ (**4**-3THF) (864.62): C, 59.73; H, 8.63; N, 4.86. Found: C, 59.49; H, 8.63; N 4.97%.

4.6. Reaction of N-trimethylsilyl-2, 6-diethylaniline with nBuLi

To a Schlenk flask containing a tetrahydrofuran (THF) solution of 2,6-$(Et)_2C_6H_3NHSiMe_3$ (0.278 g, 1.26 mmol) was added *n*BuLi (1.60 mL, 2.0 mmol) at −78 °C. The reaction mixture temperature was slowly raised to room temperature after the addition, and it was stirred for another 12 h at room temperature. The excess *n*BuLi was filtered off and washed with *n*-hexane. The solvents were pumped off, and the solid product was dried under vacuum. ^{1}H NMR (300 MHz, C_6D_6, δ in ppm): 7.08–7.06 (m, 6 H), 6.69 (dd, 1H, J = 12.5 Hz, J = 6.9 Hz, C*H*=CH$_2$), 3.99 (dd, 1H, J = 12.5 Hz, J = 1.2 Hz, CH=C*H*$_2$), 3.72 (dd, 1H, J = 6.9 Hz, J = 1.2 Hz, CH=C*H*$_2$), 3.43 (m, 12H, OC$_4$*H*$_8$), 2.94 (t, 8H, J = 7.2 Hz, C*H*$_2$CH$_3$), 1.45 (m, 12H, OC$_4$*H*$_8$), 1.32 (t, J = 7.2 Hz, 12H, CH$_2$C*H*$_3$), 0.24 (s, 18H, Si(C*H*$_3$)$_3$). This clearly shows the formation of Li[2, 6-$(Et)_2C_6H_3NSiMe_3$], LiOCH = CH_2 and the existence of three coordinated THF molecules.

4.7. Reaction of complexes **1** or **2** with aromatic aldehydes

A 30 mL Schlenk tube was charged with the complex (1 mmol) under dried argon. To the flask were added CH_2Cl_2 (3 mL) and the aromatic aldehydes (4 mmol). The reaction mixture was stirred at room temperature for 2–3 days; the mixture was then quenched with diluted HCl (0.1 M, 1. 0 mL). The mixture was extracted with acetyl acetate, and the extracts were dried over $MgSO_4$ and filtered. The solvent was removed by rotary evaporation. The residue was purified with a flash chromatography column (10:1 *n*-hexane:acetyl acetate, v/v) to give the corresponding products. In the case of the reactions of aromatic aldehydes having strong electron-withdrawing groups, such as O_2N^- and F_3C^-, with stoichiometric amounts of complexes **1** or **2**, the imine products could be isolated and characterized under the experimental conditions.

4.8. Reaction of lithium amide {[2,6-(iPr)$_2$C$_6$H$_3$](Me$_3$Si)N}Li with aromatic aldehydes catalyzed by YCl$_3$

A 30 mL Schlenk tube was charged with YCl_3 (5 mol%). To the tube were added solvent (toluene, or CH_2Cl_2, 3 mL), lithium amide [2,6-(iPr)$_2$C$_6$H$_3$NSiMe$_3$]Li (1 mmol) and the aromatic aldehyde (2 mmol). The reaction mixture was stirred at a certain temperature for a fixed interval; the mixture was then quenched with diluted HCl (0.1 M, 1. 0 mL). The mixture was extracted with acetyl acetate, and the extracts were dried over $MgSO_4$ and filtered. The solvent was removed by rotary evaporation. The residue was purified with flash chromatography column (10:1 *n*-hexane:acetyl acetate, v/v) to give the corresponding products.

4.9. X-ray crystallography

A suitable crystal of each of the complexes **1**, **2**, **3**, **4** and **5f′** was mounted in a sealed capillary. Diffraction was performed on a Siemens SMART CCD-area detector diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å); temperature

studied platinum(IV) complexes with different axial ligands where the cytotoxicity increase was observed in the following order: OH < $OOCCH_3$ < Cl < $OOCCF_3$ [9,15,18]. The above compounds suggest a weak correlation between the chemical structure of the platinum(IV) complex and their cytotoxicity. That is why platinum(IV) complexes with other equatorial N-donors, such as 1,2,4-triazolo [1,5-*a*]pyrimidines (tp) have been studied [22]. These heterocycles have a structure similar to purine and adenine (Fig. 1); their fused ring system differing by having the pyrimidine nitrogen atom in a bridge-head position with the disappearance of the proton of the five-membered ring. Due to the similarity of both systems, coordination compounds of 1,2,4-triazolo[1,5-*a*]pyrimidines can be considered as a model system for various naturally occurring metal coordination compounds.

Previously papers demonstrated that dichloride platinum(II) complexes with 1,2,4-triazolo[1,5-*a*]pyrimidine revealed a high antitumor activity [23,24], e.g., *cis*-platinum(II) compounds with HmtpO (5-methyl-1,2,4-triazolo[1,5-*a*]pyrimidin-7(*4H*)-one) [23], dbtp (5,7-ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidine) [24] and dptp (5,7-diphenyl-1,2,4-triazolo[1,5-*a*]pyrimidine) [24] had good *in vitro* cytotoxic activity against the cells of rectal, breast and bladder cancer.

In our continuing efforts to develop new platinum antitumors prodrugs, we have reported the synthesis, molecular characterization and antiproliferative activity *in vitro* of the new Pt(IV) compounds: $PtCl_4(tp)_2$ (**1**), $PtCl_4(dmtp)_2$ (**2**), $PtCl_4(dbtp)_2$ (**3**), $PtCl_4(HmtpO)_2$ (**4**). In addition the crystal structure of $(H_2mtpO)_2PtCl_6$ (**5**) has been determined.

2. Experimental

2.1. Materials

Pt of 99.9% purity was purchased from the Polish State Mint, whereas 3-amino-1,2,4-triazole (98%), 2,4-pentanedione (99%), 5-methyl-*s*-triazolo[1,5-*a*]pyrimidine-7-ol (98%), 5,7-dimethyl-*s*-triazolo[1,5-*a*]pyrimidine (98%) and 2,2,6,6-tetramethyl-3,5-heptanedione (98%) were from Aldrich. A water solution of H_2PtCl_6 was prepared using a standard procedure. 5,7-Ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidine was prepared according to the Bülow and Haas method [25] by the reaction of 3-amino-1,2,4-triazole with 2,2,6,6-tetramethyl-3,5-heptanedione [26].

2.2. Instrumentation

The content of C, H and N was determined by elemental semimicroanalysis. Thermogravimetric analyses were performed with a SDT-2960 TA Instruments (samples – 5 mg, heating range 25–1000 °C, heating rate 3.5 deg/min, N_2 atmosphere). IR spectra were measured with a Perkin–Elmer Spectrum-2000 FT–IR spectrometer, using KBr (400–4000 cm^{-1}) and polyethylene discs (100–400 cm^{-1}). The $^1H\{^{13}C\}$ HSQC, $^1H\{^{13}C\}$ HMBC and $^1H\{^{15}N\}$ HMQC spectra were performed with a Varian INOVA-500 NMR spectrometer equipped with an inverse Nalorac Z-gradient shielded probe. The solvent was DMF-d_7 or DMSO-d_6; the concentrations of the saturated solutions being ca. 0.01–0.05 M, the temperature being 298 K. The reference standard was TMS for ^1H and ^{13}C; CH_3NO_2 (external) for ^{15}N and K_2PtCl_6 (external) for ^{195}Pt.

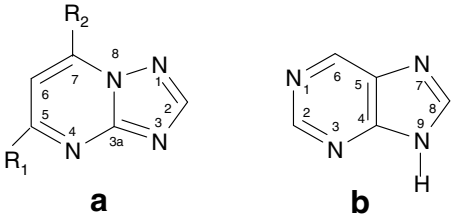

Fig. 1. IUPAC numbering of: (a) 1,2,4-triazolo[1,5-*a*]pyrimidine R_1, R_2 = H (tp); R_1, R_2 = CH_3 (dmtp); R_1, R_2 = $C(CH_3)_3$ (dbtp); R_1 = CH_3, R_2 = O (HmtpO); (b) purine molecule.

2.3. Preparation of the platinum(IV) complexes

*$PtCl_4(tp)_2$ (**1**)* and *$PtCl_4(dmtp)_2$ (**2**)* were obtained by the reaction of H_2PtCl_6 with tp or dmtp in M:L molar ratio of 1:2 [27].

*$PtCl_4(dbtp)_2$ (**3**).* To a solution of 330 μl of H_2PtCl_6 (0.10 mmol) in 10 cm^3 of water, a solution of dbtp (0.0465 g, 0.20 mmol) in 25 cm^3 of ethanol was added. The reaction mixture was stirred at room temperature for 24 h. The solution was slowly evaporated and after a few days a yellow precipitate was obtained. The solid was filtered off and washed with acetone and diethyl ether, and dried in vacuum. Yield: 0.0738 g (92%). *Anal.* Calc. for $C_{26}H_{40}Cl_4N_8Pt$: C, 38.9; N, 14.0; H, 5.0. Found: C, 39.2; N, 14.0; H, 5.3%.

*$PtCl_4(HmtpO)_2 \cdot 3H_2O$ (**4**).* 330 μl of H_2PtCl_6 (0.1 mmol) was added to 10 ml water. Next a solution of HmtpO (0.0366 g, 0.24 mmol) in 5 cm^3 of 1 M HCl was added dropwise. The solution was stirred at room temperature for 24 h. The solution was slowly evaporated and after a few days a yellow precipitate was obtained. The solid was filtered off and washed with water and diethyl ether, and dried in vacuum. Yield: 0.0714 g (92%). *Anal.* Calc. for $C_{12}H_{18}Cl_4N_8O_5Pt$: C, 20.8; N, 16.2; H, 2.6. Found: C, 21.0; N, 16.5; H, 2.3%. The content of water in (**4**) was confirmed by thermogravimetric analyses. The first endothermic step in range 240–270 °C corresponds to a mass loss on the TG curve which can be correlated with detachment of three water molecules and Cl_2 (calcd 18.1%, exp. 18.3%). The next endothermic processes (275–860 °C) can be related to decomposition of (**4**) leaving platinum as the final product.

*$[H_2mtpO]_2[PtCl_6]$ (**5**).* This compound was isolated by slow evaporation of $PtCl_4(HmtpO)_2$ (**4**) from a mixture of water and n-hexane (5:1 v/v) (pH 1) giving crystals suitable for X-ray analysis (*vide infra*).

2.4. X-ray structure determination

$[H_2mtpO]_2[PtCl_6]$ (**5**) crystallized in the monoclinic space group $P2_1/n$. The X-ray data was collected at 293(2) K with an Oxford Sapphire CCD diffractometer, using MoKα radiation (λ = 0.71073 Å) and the ω–2θ method. A shape-based numerical absorption correction was applied with minimum and maximum transmissions of 0.3811 and 0.1971. The structure was solved by Patterson methods and refined with the full-matrix least-squares method on F^2 with the use of the SHELX-97 program package [28]. The data collection and refinement processes are summarized in Table 1.

2.5. Cells

The following established *in vitro* human cancer cell lines were studied: SW707 (rectal adenocarcinoma), HCV29T (bladder cancer) and HL-60 (human acute promyelocytic leukemia).

Cells were patted in 96-well sterile plates (Sarstedt, Costar) at a density of 10^4 cells per well (in 100 μl of culture medium) and incubated for 24 h. The tested complexes **1**–**4** were added to the final concentrations from 0.1 to 100 μg/cm^3 and the incubation was continued for an additional 72 h. The results of the cytotoxic activity *in vitro* were expressed as an IC_{50} – the dose of compound (in μM) that inhibits the proliferation rate of the tumors cells by 50% as compared to the control untreated cells. The details of this technique were described by Skehan [29]. The antiproliferative activity *in vitro* against SW707 and HCV29T cell lines were performed by

using the SRB test [24], whereas against HL-60 tumors cell the MTT test was used [30].

3. Results and discussion

3.1. NMR spectroscopy

The multinuclear NMR spectral data of (**1**) and (**2**) have been reported [27], hence here we present only the ^{1}H, ^{13}C, ^{15}N and ^{195}Pt NMR data for $PtCl_4(dbtp)_2$ in DMF-d_7 and $PtCl_4(HmtpO)_2$ in DMSO-d_6. The chemical shifts of the heterocyclic ligands protons in the platinum(IV) complexes are listed in Table 2. The ^{1}H NMR spectrum of $PtCl_4(dbtp)_2$ exhibits two characteristic signals at 9.34 ppm (t) H(2) and 7.43 ppm (s) H(6). However the ^{1}H NMR spectrum changed with time and after 1 h three different sets of signals (**3**, **3a**, **3b**) appeared (Table 2). In the latter solvent the ^{1}H NMR chemical shift of H(2) and H(6) were 9.45, 7.57 ppm for **3a** and 9.27, 7.58 ppm for **3b**. Probably all the complexes (**3**, **3a**, **3b**) are rotamers (HH (head-to-head) and HT (head-to-tail), formed by the restrained rotation of the dbtp ligand around the Pt–N(3) bond (Fig. 2). This phenomenon is probably affected by the steric hindrance of the bulky *tert*-butyl group.

In the case of the spectrum of (**4**), three hydrogen signals (10.52 ppm (s) N(4)–H, 8.52 ppm (t) H(2) and 6.17 ppm (s) H(6)) are present. In comparison to the free ligand spectrum, the signals

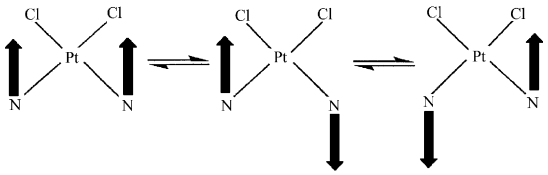

Fig. 2. The possible HH and HT conformers of $PtCl_4(dbtp)_2$. The equatorial ligands are presented only for clarity.

were shifted upon coordination, Δ_{coord} coordination shift ($\Delta_{coord} = \delta_{complex} - \delta_{ligand}$), towards the low field region. The most significant coordination shift was observed for H(2) (0.35–0.81 ppm) (Table 2). However these changes do not confirm unambiguously which of the heterocyclic nitrogen atoms (N(1) or N(3)) is engaged in the formation of a platinum–nitrogen bond. This problem was solved by means of ^{15}N–^{1}H HETCOR spectral analysis (Table 2). In the ^{15}N NMR spectra resonance lines at: −108.9, −247.3, −121.0 and −161.7 ppm for (**3**) and −111.4, −252.4, −255.7 and −157.7 ppm for (**4**) were *detected* (Table 2). In comparison to the free ligand spectra, all the signals in the spectra of the complexes are shielded upon platination. However the highest coordination shift (Δ_{coord} = 87–115 ppm) was observed for the N(3) signals (Table 2), which indicates the monodentate coordination to Pt(IV) in solution. Moreover the ^{15}N resonances of N(3), in (**3**) were observed at much higher fields, than for the platinum(II) analog [24]. Shift towards higher frequencies comes from the higher shielding of the N ligating sites upon coordination. The latter cannot be related only to a σ donation effect from the N atom in the heterocycle to Pt(IV). The second effect which causes an increase of electron density on coordinating nitrogen atom can be correlated with inter- and intramolecular interactions, which influence on the chemical shift of the nitrogen atoms.

The proposed coordination mode of the triazolopyrimidine ligands to the platinum(IV) ion can also be elucidated by ^{13}C NMR spectra, which are more commonly observed and registered. In the ^{13}C NMR spectra of the complexes, the signals of the carbon atoms adjacent to the N(3) coordination site, i.e. C(2) and C(3a) are shielded (Δ_{coord} in the range 2.6–4.1 ppm), whereas the signals of C(5), C(6) and C(7) were deshielded (Δ_{coord} between 2.3–3.8 ppm), except for the signals of (**4**), where the opposite shift was observed. The shielding of carbon atoms adjacent to the coordination site N(3), as well as the deshielding of the other carbons and protons inside the heterocyclic ring, has already been described by us for some Pt(II) chloride complexes with triazolopyrimidine derivatives.

The ^{195}Pt NMR chemical shifts of the studied complexes are listed in Table 3. The ^{195}Pt resonance in the spectra of the platinum(IV) compounds were observed between −113 and 69 ppm, which is characteristic for octahedral platinum(IV) complexes where two adjacent corners are occupied by nitrogen atoms and the other four positions by chlorides [20,31–33]. However, the ^{195}Pt NMR signals for the complexes with triazolopyrimidine (**3**) and (**4**) are observed at a lower field than those reported for Pt(IV) complexes with other N-donor ligands: −145 ppm for $PtCl_4(NH_3)_2$ in H_2O [33]; −150 ppm

for $PtCl_4(HMI)_2$, where HMI = hexamethyleneimine, in acetone [32]; −252 ppm for $PtCl_4$(1,4-dach) in acetone [20]; −358 ppm for $PtCl_4$(Hyp), where Hyp = hypoxantine, in DMSO-d_6 [31].

3.2. IR spectra

The frequencies of the two most characteristic bands of the pyrimidine and imidazole ring skeleton vibrations after coordination appeared at higher frequencies by 18–24 and 15–19 cm^{-1}, respectively. The observed shifts are bigger than for Pt(II) chloride complexes with other 1,2,4-triazolo[1,5-*a*]pyrimidines [27]. This may be caused by the fact that due to the coordination by N(3), the tp ring double bonds (C=N, C=C) reveal a more pronounced double bond character [34].

For the ionic pair (**5**) the discussed bands are significantly shifted towards higher frequencies (21–28 cm^{-1}), which can be the result of either N(3) protonation or formation of hydrogen bonds. In the IR spectrum of (**5**) we also observed an intensive band of rich structure in the 2500–2700 cm^{-1} range, characteristic for the $(N–H)^+$ stretching vibration for salts of tertiary amines [35]. Its presence is in agreement with the X-ray structure where the protonated H_2mtpO^+ species was observed.

The far-IR spectra of the complexes show ligand vibrations as well as new bands originating from Pt–Cl and Pt–N stretchings. The spectra of (**3**) and (**4**) exhibit one new strong broad absorption band in region 328–339 cm^{-1}. The frequencies of these bands are similar to those found in the spectra of Pt(IV) chloride complexes with 1,4-dach in the equatorial position (325–350 cm^{-1}) [36,37] this band and was assigned to a Pt–Cl stretching vibration. The vibrations in the range 227–287 cm^{-1} can be assigned to Pt–N stretching modes.

3.3. Cytotoxic activity

The antitumors activity *in vitro* of the platinum(IV) compounds (**1–4**) have been tested against HL-60, SW707 and HCV29T tumors cells. The results, expressed as the concentration of the compound required to kill the tumor cell by 50% (IC_{50}), are listed in Table 4. Cisplatin was used as a reference substance. We noticed that treatment of tumor cells with the platinum(IV) complexes (**1–4**) display an antiproliferative effect. However, the new platinum complexes (**1**) and (**2**) exhibit negligible cytotoxicity (IC_{50} 170–43.3 μM). Their IC_{50} parameters indicate that $PtCl_4(tp)_2$ and $PtCl_4(dmtp)_2$ have revealed generally lower immunostimulating activity than cisplatinum (Table 4) against the studied tumor cell lines. In contrast, (**3**) and (**4**) were more cytotoxic than **1** and **2** (Table 4). $PtCl_4(HmtpO)_2$ and $PtCl_4(dbtp)_2$ display relatively low IC_{50} values (1.1–57 μM) against the tumor cell lines and they seem to have significant cytotoxic activity. In addition, it should be noted that $PtCl_4(dbtp)_2$ is also expected to be more reactive than (**4**). For example, against HCV29T, $PtCl_4(dbtp)_2$ presents relatively high antitumor activity, (with an IC_{50} value of 1.1 μM) which is a 50 times lower concentration than for the platinum(IV) analog $PtCl_4(HmtpO)_2$ (Table 4).

Table 4
Cytotoxicity of platinum(IV) complexes against HL-60, HCV29T and SW707 tumors cells

Compound	Cell line/IC_{50} (μM) ± SD		
	HL-60	SW707	HCV29T
(**1**) $PtCl_4(tp)_2$	43.3 ± 1.2	>170.0	121.3 ± 1.4
(**2**) $PtCl_4(dmtp)_2$	48.3 ± 3.0	113.0 ± 26.0	94.7 ± 15.0
(**3**) $PtCl_4(dbtp)_2$	1.1 ± 0.7	1.5 ± 1.1	1.1 ± 1.0
(**4**) $PtCl_4(HmtpO)_2$	35.0 ± 3.5	[a]	56.6 ± 5.3
cis-$PtCl_2(NH_3)_2$	11.0 ± 4.6	16.3 ± 1.5	2.3 ± 1.5

[a] Was not recorded.

Against HL-60 and SW707, compounds (**3**) revealed IC_{50} values in the range 1.1–4.7 μM, which indicates moderate antiproliferative activity. In addition, the high cytotoxic values for compound (**3**) were even 10 times higher than the clinically used cisplatin against the human tumors models.

Thus, from the anticancer screening data complex (**3**) demonstrated strong cytotoxic activity *in vitro* and may be recommended for further preclinical studies. The research on lethal toxicity in experimental animals and on antitumors activity *in vivo* in transplantable mouse tumors models will be described in future work.

With regard to structure–activity relationships, it is apparent that the antitumor activity of the platinum(IV) compounds containing 1,2,4-triazolo[1,5-*a*]pyrimidines correlates with the size of the alkyl group in the heterocyclic ligands. The highest antitumor activity was achieved with sterically bulky group, introduced by the two *tert* butyl groups of the heterocycle, which are responsible for the hydrogen-bond properties and this may be reflected in an increase in the lipophilicity and its interaction with cellular components.

A similar relationship between cytotoxicity and the type of heterocycle were noted for platinum(II) complexes with the same triazolopyrimidine ligands [24,38]. Here, the best activity against tumors cell lines has been detected for *cis*-$PtCl_2(dbtp)_2$ and *cis*-$PtCl_2(dptp)_2$, which contain bulky groups (*tert*butyl or phenyl) in the heterocyclic ring [24]. The cytotoxicity data indicate that the antitumor activity of the studied platinum(II) compounds containing 1,2,4-triazolo[1,5-*a*]pyrimidines depends directly on the geometry of platinum(II) and the kinds of ligands and heterocyclic ligands involved.

Careful interpretation of the cytotoxic data for the Pt(II) and Pt(IV) complexes confirm the influence of the geometry and type of heterocyclic ligand on the antitumors activity (Table 4) [38]. Consistently, the octahedral complexes (**1–4**) are also more cytotoxic than their square-planar platinum(II) analogues. For example, against SW707, the value of IC_{50} for $PtCl_4(dbtp)_2$ is five times lower than for *cis*-$PtCl_2(dbtp)_2$ (Fig. 3). Perhaps this observation could serve as a reasonable basis for designing new strategies in finding antitumor drugs based on platinum(IV) complexes.

3.4. Crystal structure of $[H_2mtpO]_2[PtCl_6]$

Fig. 4 shows a perspective view of the crystal along with its atomic labelling. Selected bond lengths and bond angles are given in Table 5.

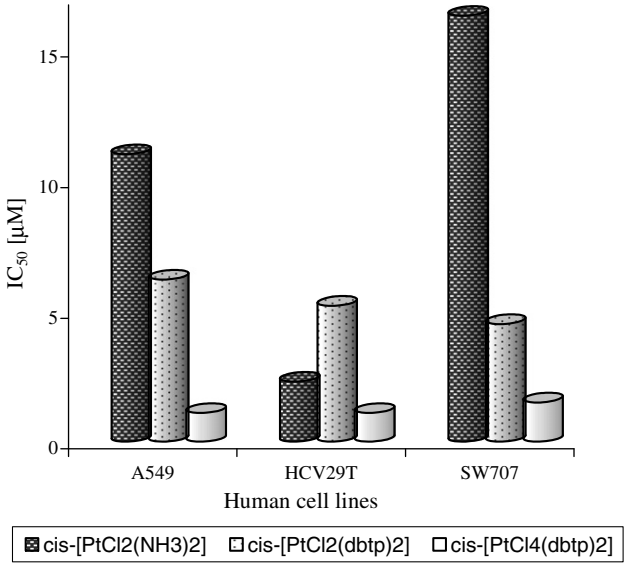

Fig. 3. Comparative chart of the antiproliferative activity in vitro for platinum complexes with 5,7-ditertbutyl-1,2,4-triazolo[1,5-*a*]pyrimidine (dbtp) against tumor cells.

The slight discrepancy between the final R_1 value of 0.0754 and R_{int} = 0.0447 are observed, despite the numerical absorption correction applied. This difference can be explained by the thermal displacement of the H_2mtpO$^+$ cations, as is seen on Fig. 4. The small librations of that moiety, in particular for O(71) and the C(6)–C(7)–N(8)–N(1) fragment of the ring system, cannot be described in a most satisfactory way with the anisotropic displacement parameters during the refinement. Also no discrete positions of the atoms for the cation could be defined to improve the model.

Complex (**5**) is an ionic pair consisting of two N(3)-monoprotonated H_2mtpO$^+$ cations and one octahedral $[PtCl_6]^{2-}$ anion. The Pt(IV) of the hexachloroplatinate ion is located on the center of symmetry. Therefore the asymmetric part of the reported structure contains a half of the $[PtCl_6]^{2-}$ anion. The asymmetric part of the structure is completed by one H_2mtpO$^+$ cation. A small distortion of the octahedral geometry was found for the complex anion, with Cl–Pt–Cl angles in the asymmetric part varying from 88.9(2)° to 90.8(2)°. Due to the centrosymmetric structure of that anion, the chlorides related by the center of symmetry occupy the trans positions with the valence angles being 180°. Such a phenomenon is not unusual and has been described for $[N(CH_3)_4]_2[PtCl_6]$ [39], $[N(C_2H_5)_4]_2[PtCl_6]$ [40], $[NH_2(CH_3)_2]_2[PtCl_6]$ [41], (9-MeGuH)$_2$[PtCl$_6$] [42] (9-MeGuH = 9-methylguaninium cation) and (dmtpH$^+$)$_2$[PtCl$_6$] [27]. The lengths of the Pt–Cl bonds vary from 2.308(4) to 2.313(3) Å.

Table 5
Selected bond lengths (Å) and angles (°) for $[H_2mtpO]_2[PtCl_6]$ (**5**)

Bond		Angle	
Pt(1)–Cl(1)#1	2.308(4)	Cl(1)#1–Pt(1)–Cl(1)	180.0

N(1)–N(8)	1.36(2)	Cl(3)#1–Pt(1)–Cl(2)#1	90.0(1)
C(2)–N(3)	1.36(2)	Cl(3)–Pt(1)–Cl(2)#1	90.03(1)
N(3)–C(3A)	1.309(18)	Cl(1)#1–Pt(1)–Cl(2)	88.9(2)
C(3A)–N(4)	1.286(17)	Cl(1)–Pt(1)–Cl(2)	91.1(2)
C(3A)–N(8)	1.35(2)	Cl(3)#1–Pt(1)–Cl(2)	90.0(1)
N(4)–C(5)	1.40(3)	Cl(3)–Pt(1)–Cl(2)	90.0(1)
C(5)–C(6)	1.26(3)	Cl(2)#1–Pt(1)–Cl(2)	180.0(2)
C(5)–C(51)	1.55(2)	C(2)–N(3)–C(3A)	105.2(13)
C(6)–C(7)	1.53(3)	N(4)–C(3A)–N(3)	136.2(14)
C(7)–O(71)	1.16(2)	O(71)–C(7)–N(8)	127(2)
C(7)–N(8)	1.42(2)	O(71)–C(7)–C(6)	126(2)

Operators for generating equivalent atoms: # $[-x, 1-y, -z]$.

The valence geometry of the H_2mtpO$^+$ cation is similar to that reported for the HmtpO structures. However, few statistically significant differences have been found between the structure of the H_2mtpO$^+$ cation reported here and the HmtpO ligand coordinated to Pt via the N(3) atom in *cis*-$PtCl_2(NH_3)$(HmtpO) and *cis*-$PtCl_2$(HmtpO)$_2$·4H_2O [43]. In the structure reported here the distances N(1)–C(2) and C(3A)–N(4) [1.23(2) and 1.286(17) Å, respectively] are significantly shorter than the corresponding distances reported for the platinum complexes [1.301(7)–1.317(15) and 1.352(6)–1.362(12), respectively]. Also the valence angle N(1)–C(2)–N(3) of 116.1(17)° is larger than the equivalent angle in the HmtpO ligand (average 112.8°), while the N(3)–C(3A)–N(8) angle of 104.8(13)° is smaller than those reported for the complexes (average 108.2°). That seems to reflect the different electron density distribution within the pyrimidine ring moiety between the protonated and coordinated species.

There is a small bend of the H_2mtpO$^+$ ring system, with the dihedral angle between the best planes of the five-membered N(1)–C(2)–N(3)–C(3A)–N(8) and six-membered C(3A)–N(4)–C(5)–C(6)–C(7)–N(8) rings being 1.8(9)°.

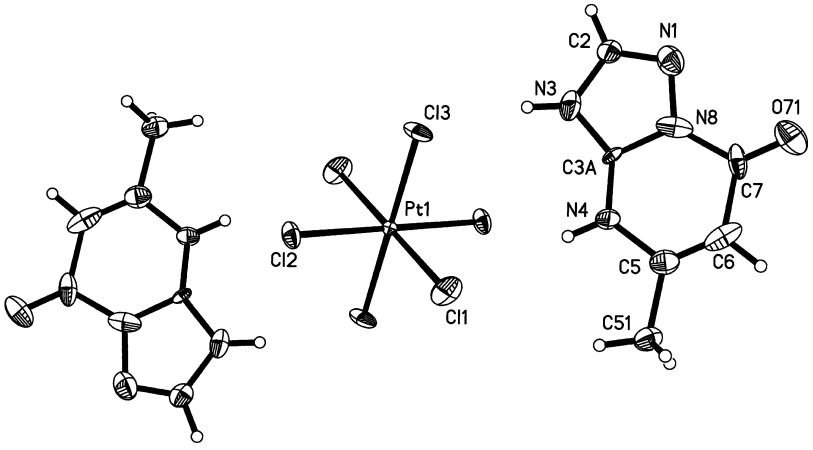

Fig. 4. ORTEP drawing with the atomic labelling scheme for $[H_2mtpO]_2[PtCl_6]$.

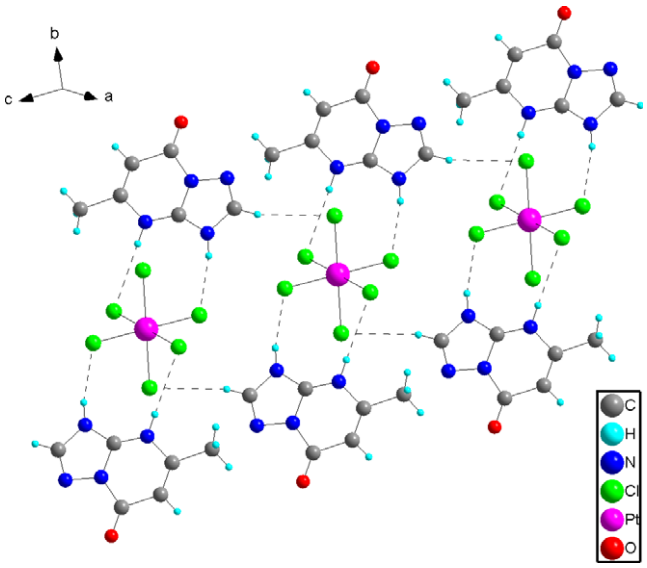

Fig. 5. Intermolecular hydrogen bonding in $[H_2mtpO]_2[PtCl_6]$.

The structure reveals the presence of two H-bonds involving both N–H groups of the ring moiety and chloride ions. The N(3)Cl(3) $[x+1,y,z+1]$ distance is 3.095(15) Å and the N(3)–H(3A)···Cl(3) $[x+1,y,z+1]$ angle is 167.5°. The corresponding values for the N(4)–H(4A)···Cl(1) $[x+1,y,z+1]$ interaction are 3.506(15) Å and 177.5°, respectively. These interactions link the complex anion with the pair of neighboring organic cations (Fig. 5). The C(2)–H group forms an interaction to Cl(2) $[-1+x,y,z]$, with a C(2)···Cl distance of 3.720(17) Å (Fig. 5).

Analysis of the interactions within the ion pair constituting the asymmetric unit of the reported structure reveals the relatively short distances between Cl(1) and the center of gravity of the five-membered ring and between Cl(2) and the center of gravity of the five-membered ring, being 3.520 and 3.769 Å respectively. Also the O(71) atom is positioned near the H_2mtpO^+ $[1/2+x,1/2-y,1/2+z]$ ring system, the distances to the centers of gravity of the five-membered and six-membered rings being 2.915 and 2.844 Å, respectively.

4. Conclusion

The observed monodentate coordination via N(3) may be regarded as representative for triazolopyrimidines and analogous to N(9) complexation in purine. The highest antitumor activities have been observed for platinum(IV) complexes contain a bulky *tert*-butyl group in the heterocycle ring. These results indicate that tetrachloride platinum(IV) complexes with bulky ligands might be a promising source of new metal-based antitumor activity. Perhaps this observation could serve as a reasonable basis for designing new antitumor platinum(IV) prodrugs.

R	Ligand
CH_3	H_2Mebpb
Cl	H_2cbpb

Scheme 1.

of a representative complex, *trans*-[Co(Mebpb)(prldn)$_2$]ClO_4, has been determined. The IR, UV–Vis, and ^{1}H NMR spectra of the complexes are also reported and discussed. The electrochemical behavior of the complexes has also been investigated with the goal of evaluating the effects of axial ligation and equatorial substitution on their redox properties.

2. Experimental

2.1. Materials and general methods

All solvents and chemicals were of commercial reagent grade and used as received from Aldrich and Merck. Elemental analyses were performed by using a Perkin–Elmer 2400II CHNS-O elemental analyzer. UV–Vis spectra were recorded on a Jasco V-570 spectrophotometer. Infrared spectra (KBr pellets) were obtained on a Jasco 680-plus FT-IR spectrophotometer. The ^{1}H NMR spectra of the complexes were obtained on a Bruker AVANCE DR X500 (500 MHz) spectrometer. Proton chemical shifts are reported in parts per million (ppm) relative to an internal standard of Me_4Si. Cyclic voltammograms were recorded by using a Sama Research Analyzer M-500. Three electrodes were utilized in this system, a glassy carbon working electrode, a platinum disk auxiliary electrode, and Ag wire as reference electrode. The glassy carbon working electrode (Metrohm 6.1204.110) with 2.0 ± 0.1 mm diameter was manually cleaned with 1 μm alumina polish prior to each scan. Tetrabutylammonium hexafluorophosphate (TBAH) was used as supporting electrolyte. Acetonitrile was dried over CaH_2. The solutions were deoxygenated by purging with Ar for 5 min. All electrochemical potentials were calibrated versus internal $Fc^{+/0}$ (E^0 = 0.40 V versus SCE) couple under the same conditions [32].

Caution: Perchlorate salts with organic compounds are potentially explosive and should be handled with care.

2.2. Synthesis

2.2.1. H_2Mebpb

4-Methyl-1,2-phenylenediamine was recrystallized from hot ligroin before use. The ligand was prepared according to the method described in the literature with some modification [18]. To a solution of 2-pyridinecarboxylic acid (7.38 g, 60 mmol) in pyridine (25 mL) in a two-necked round-bottom flask equipped with mechanical stirrer was added a solution of 4-methyl-1,2-phenylenediamine (3.66 g, 30 mmol) in 5 mL pyridine, and the mixture stirred at 40 °C for 40 min. Triphenylphosphite (15.6 mL, 60 mmol) was then added dropwise and the reaction mixture was stirred at 90–100 °C for 4 h. Upon cooling to room temperature the product precipitated as a microcrystalline solid. The resulting precipitate was filtered off, washed with ethanol (20 mL), and recrystallized from a mixture of methanol and water (2:1 v/v). Yield (70%). m.p. 168–169 °C. FT-IR (KBr, cm^{-1}) ν_{max}: 3302 (s, N–H), 1689, 1659 (s, C=O), 1589 (m, C=C), 1520 (m, C–N). UV–Vis: λ_{max} (nm) (ε, L M^{-1} cm^{-1}) (CH_3CN): 300 (9427), 267 (15662), 219 (26563).

2.2.2. H_2cbpb

H_2cbpb was synthesized by a procedure similar to that for H_2Mebpb, but 4-chloro-1,2-phenylenediamine was used instead of 4-methyl-1,2-phenylenediamine. The product was recrystallized from ethanol. Yield (70%). m.p. 196–198 °C. *Anal.* Calc. for $C_{18}H_{13}N_4O_2Cl$: C, 61.28; H, 3.71; N, 15.88. Found: C, 61.28; H, 3.61; N, 15.81%. FT-IR (KBr, cm^{-1}) ν_{max}: 3297 (s, N–H), 1697, 1661 (s, C=O), 1588 (m, C=C), 1506 (s, C–N). UV–Vis: λ_{max} (nm) (ε, L M^{-1} cm^{-1}) (CH_3CN): 300 (10735), 267 (18627), 211 (35942). ^{1}H NMR ($CDCl_3$, 300 MHz): δ = 10.32, 10.19 (2H, NH_{amidic}, s), 8.56 (2H_a, dd, J = 9.8, 4.4), 8.31 (2H_d, d, J = 7.8), 8.03 (1H_g, d, J = 7.8), 7.92 (2H_c, dd, J = 7.7, 7.7), 7.81 (1H_e, d, J = 8.6), 7.48 (2H_b, m), 7.26 (1H_f, d, J = 8.0).

2.2.3. Synthesis of trans-[Co(Mebpb)(prldn)$_2$] ClO_4 (**1a**)

To a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (62.3 mg, 0.25 mmol) in methanol (20 mL) was added a boiling solution of H_2Mebpb (83.1 mg, 0.25 mmol) in methanol (30 mL). To this solution was added dropwise 9.07 mmol (0.75 mL) of pyrrolidine and air was bubbled through the reaction mixture for 3 h. The final reaction mixture was filtered, a solution of 0.25 mmol (30.6 mg) of $NaClO_4 \cdot H_2O$ in methanol was slowly added to the filtrate, and the resulting solution was stirred for 5 min. Dark blue crystals were obtained by slow evaporation of methanol. The crystals were isolated by filtration, washed with methanol, and dried in vacuum. Yield: 75%. *Anal.* Calc. for $C_{27}H_{32}N_6O_6ClCo$: C, 51.4; H, 5.11; N, 13.32. Found: C, 50.73; H, 5.29; N, 13.11%. FT-IR (KBr, cm^{-1}) ν_{max}: 3168 (s, N–H), 1626 (s, C=O), 1599 (s, C=C), 1571 (s, C–N), 1109, 1087 (s, Cl–O). UV–Vis: λ_{max} (nm) (ε, L M^{-1} cm^{-1}) (CH_3CN): 625 (180), 418 (6686). ^{1}H NMR (CD_3CN, 500 MHz): δ = 1.29 (8H_i, m), 1.55, 2.12 (8H_h, m), 2.39 (3H, CH_3, s), 3.30 (2H, amine NH, br s), 6.94 (1H_f, d, J = 8.2), 8.00–8.39 (6H $_{b,c,d}$, m), 8.71 (1H_g, s), 8.75 (1H_e, d, J = 8.2), 9.46 (2H_a, dd, 5.2, 5.2).

2.2.4. Synthesis of trans-[Co(cbpb)(prldn)$_2$] PF_6 (**1b**)

To a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (62.3 mg, 0.25 mmol) in methanol–ethanol (2:1 v/v) (20 mL) was added a boiling solution of H_2cbpb (88.2 mg, 0.25 mmol) in methanol–ethanol (2:1 v/v) (30 mL). To this solution was added dropwise 9.07 mmol (0.75 mL) of pyrrolidine and air was bubbled through the reaction mixture for 3 h. The volume of the reaction mixture was increased to 75 mL by adding methanol and the final solution was filtered. A solution of 0.25 mmol (40.6 mg) of ammonium hexafluorophosphate in methanol–ethanol (2:1v/v) (25 mL) was slowly added to the filtrate and the resulting solution stirred for 5 min. Green-blue crystals were obtained by slow evaporation of solvent. The crystals were isolated by filtration, washed with cold methanol, and dried in vacuum. Yield: 75%. *Anal.* Calc. for $C_{29}H_{29}N_6O_2ClPF_6Co$: C, 44.81; H, 4.19; N, 12.05. Found: C, 44.54; H, 4.09; N, 11.91%. FT-IR (KBr, cm^{-1}) ν_{max}: 3171 (s, N–H), 1629 (s, C=O), 1600 (s, C=C), 1563 (s, C–N), 842 (s, PF_6). UV–Vis: λ_{max} (nm) (ε, L M^{-1} cm^{-1}) (CH_3CN): 611 (188), 410 (7354). ^{1}H NMR (CD_3CN, 500 MHz): δ = 1.30 (8H_i, m), 1.52, 2.12 (8H_h, m), 3.28 (2H, NH_{amine}, br s), 7.11 (1H_f, bd, J = 8.6), 7.99–8.41 (6$H_{b,c,d}$, m), 8.82–8.83 (2H, H_e, H_g), 9.42 (2H_a, bd, J = 4.8).

2.2.5. Synthesis of trans-[Co(Mebpb)(pprdn)$_2$]ClO_4 (**2a**)

To a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (62.3 mg, 0.25 mmol) in 20 mL ethanol–methanol (1:2 v/v) was added a boiling solution of H_2Mebpb (83.1 mg, 0.25 mmol) 30 mL ethanol–methanol (1:2

v/v). To this solution was added dropwise 7.58 mmol (0.75 mL) of piperidine and air was bubbled through the reaction mixture for 3 h. The final reaction mixture was filtered and a solution of 0.25 mmol (30.6 mg) of $NaClO_4 \cdot H_2O$ in methanol was added slowly to the filtrate. Dark green-blue crystals were obtained by slow evaporation of solvent. The crystals were isolated by filtration, washed with a mixture of ethanol and methanol (1:2 v/v), and dried in vacuum. Yield: 80%. *Anal.* Calc. for $C_{29}H_{36}N_6O_6ClCo$: C, 52.85; H, 5.51; N, 12.75. Found: C, 52.32; H, 6.1; N, 12.2%. FT-IR (KBr, cm^{-1}) ν_{max}: 3162 (s, N–H), 1626 (s, C=O), 1599 (s, C=C), 1565 (s, C–N), 1111, 1087 (s, Cl–O). UV–Vis: λ_{max} (nm) (ε, $L\,M^{-1}\,cm^{-1}$) (CH_3CN): 682 (193), 417 (6532). ^1H NMR (CD_3CN, 500 MHz): δ = 0.91–1.28 ($12H_{i,j}$, m), 1.40–2.22 ($8H_h$, m), 2.39 (3H, CH_3, s), 2.45 (2H, NH_{amine}, br s), 6.93 ($1H_f$, d, J = 7.9), 8.00–8.41 ($6H_{b,c,d}$, m), 8.71 (H_g, s), 8.75 (H_e, d, 8.2) 9.39 ($2H_a$, br d, J = 5.0).

2.2.6. Synthesis of trans-[Co(cbpb)(pprdn)$_2$]PF_6 (**2b**)

This complex was prepared by the same method as for **1b** except that piperidine was used instead of pyrrolidine. Dark green-blue crystals were obtained after 5 days; they were filtered off, washed with a small amount of cold methanol, and dried in vacuum. Yield: 65%. *Anal.* Calc. for $C_{28}H_{33}N_6O_2ClPF_6Co$: C, 46.39; H, 4.58; N, 11.59. Found: C, 45.52; H, 4.52; N, 11.25%. FT-IR (KBr, cm^{-1}) ν_{max}: 3173 (s, N–H), 1627 (s, C=O), 1600 (s, C=C), 1562 (s, C–N), 841 (s, PF_6). UV–Vis: λ_{max} (nm) (ε, $L\,M^{-1}\,cm^{-1}$) (CH_3CN): 656 (205), 409 (7434). ^1H NMR (CD_3CN, 500 MHz): δ = 0.9–1.29 ($12H_{i,j}$, m), 1.35–2.22 ($8H_h$, m), 2.47 (2H, NH_{amine}, br s), 7.12 ($1H_f$, d, J = 8.6), 7.95–8.45 ($6H_{b,c,d}$, m), 8.83–8.87 (2H, H_e, H_g), 9.36 ($2H_a$, br d, J = 4.8).

2.2.7. Synthesis of trans-[Co(Mebpb)(mrpln)$_2$] ClO_4 (**3a**)

To a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (62.3 mg, 0.25 mmol) in methanol (5 mL) was added a solution of H_2Mebpb (83.1 mg, 0.25 mmol) in acetone (50 mL). To this solution was added dropwise morpholine (8.61 mmol, 0.75 mL) and air was bubbled through the reaction mixture for 3 h. The final reaction mixture was filtered and a solution of 0.25 mmol (30.6 mg) of $NaClO_4 \cdot H_2O$ in acetone was added slowly to the filtrate. Dark green-blue crystals were isolated by filtration, washed with a mixture of acetone and methanol (1:9 v/v), and dried in vacuum. Yield: 70%. *Anal.* Calc. for $C_{27}H_{32}N_6O_8ClCo$: C, 48.92; H, 4.86; N, 12.68. Found: C, 48.01; H, 5.18; N, 12.64%. FT-IR (KBr, cm^{-1}) ν_{max}: 3141 (m, N–H), 1626 (s, C=O), 1599 (s, C=C), 1566 (m, C–N), 1111, 1091 (s, Cl–O). UV–Vis: λ_{max} (nm) (ε, $L\,M^{-1}\,cm^{-1}$) (CH_3CN): 689 (198), 412 (8134). ^1H NMR (CD_3CN, 500 MHz): δ = 1.65–1.95 ($8H_h$, overlaps with solvent signals), 2.39 (3H, CH_3, s), 2.97 (2H, NH_{amine}, br s), 3.20 ($8H_i$, m), 6.95 ($1H_f$, d, J = 7.9), 8.02–8.44 ($6H_{b,c,d}$, m), 8.73 ($1H_g$, s), 8.75 ($1H_e$, d, J = 8.2), 9.42 ($2H_a$, br d, J = 4.9).

2.2.8. Synthesis of trans-[Co(cbpb)(mrpln)$_2$] ClO_4 (**3b**)

To a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (24.9 mg, 0.1 mmol) in methanol–ethanol (2:1 v/v) (20 mL) was added a solution of H_2cbpb (35.3 mg, 0.1 mmol) in methanol–ethanol (2:1 v/v) (30 mL). To this solution was added dropwise morpholine (8.61 mmol, 0.75 mL) and air was bubbled through the reaction mixture for 3 h. The volume of the reaction mixture was increased to 75 mL by adding methanol and the final solution was filtered. A solution of 0.1 mmol (12.2 mg) of $NaClO_4 \cdot H_2O$ in methanol–ethanol (2:1 v/v) (25 mL) was slowly added to the filtrate and the resulting solution stirred for 5 min. Green-blue crystals were obtained by slow evaporation of solvent. The crystals were isolated by filtration, washed with mixture of diethyl ether and methanol (1:9 v/v) and dried in vacuum. Yield: 65%. *Anal.* Calc. for $C_{26}H_{29}N_6O_8Cl_2Co$: C, 45.69; H, 4.28; N, 12.29. Found: C, 45.35; H, 4.29; N, 12.00%. FT-IR (KBr, cm^{-1}) ν_{max}: 3169 (m, N–H), 1626 (s, C=O), 1600 (s, C=C), 1562 (s, C–N), 1119, 1089 (s, ClO_4). UV–Vis: λ_{max} (nm) (ε, $L\,M^{-1}\,cm^{-1}$) (CH_3CN): 663 (232), 405 (7061). ^1H NMR (CD_3CN, 500 MHz): δ = 1.61, 2.98 ($8H_h$, m), 3.55 (2H, NH_{amine}, br s), 3.21 ($8H_i$, m), 7.09 ($1H_f$, m), 7.81–8.48 ($6H_{b,c,d}$, m), 8.82–8.91 ($2H_{e,g}$, m), 9.39 ($2H_a$, br d, J = 4.8).

2.2.9. Synthesis of trans-[Co(Mebpb)(bzlan)$_2$] ClO_4 (**4a**)

To a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (24.9 mg, 0.1 mmol) in methanol (20 mL) was added a boiling solution of H_2 Mebpb (33.2 mg, 0.1 mmol) in methanol (30 mL). To this solution was added dropwise 6.86 mmol (0.75 mL) benzylamine and air was bubbled through the reaction mixture for 3 h. The final reaction mixture was filtered and a solution of 0.1 mmol (12.2 mg) of $NaClO_4 \cdot H_2O$ in methanol was added slowly to the filtrate. Dark green-blue crystals were isolated by filtration, washed with a mixture of ethanol and diethyl ether (9:1 v/v), and dried in vacuum. Yield: 65%. *Anal.* Calc. for $C_{33}H_{32}N_6O_6ClCo$: C, 56.38; H, 4.59; N, 11.95. Found: C, 56.10; H, 4.52; N, 11.84%. FT-IR (KBr, cm^{-1}) ν_{max}: 3251, 3214, 3135 (m, m, s, N–H), 1628 (s, C=O), 1601 (s, C=C), 1566 (s, C–N), 1094, 1081 (s, Cl–O). UV–Vis: λ_{max} (nm) (ε, $L\,M^{-1}\,cm^{-1}$) (CH_3CN): 610 (235), 414 (7013). ^1H NMR (CD_3CN, 500 MHz): δ = 2.42 (3H, CH_3, s), 2.74 ($4H_h$, m), 2.91 (4H, NH_{2amine}, br s), 6.74 ($4H_i$, bd), 7.09–7.15 ($6H_{j,k}$, m), 6.96($1H_f$,d, J = 8.2), 7.94–8.35 ($6H_{b,c,d}$, m), 8.75 ($1H_g$, s), 8.78 ($1H_e$, d, J = 8.2), 9.41 ($2H_a$, dd, J = 4.6, 4.6, 4.6).

2.2.10. Synthesis of trans-[Co(cbpb)(bzlan)$_2$] PF_6 (**4b**)

This complex was prepared by the same method as for **1b** except that benzylamine was used instead of pyrrolidine. Dark green-blue crystals were obtained after one week; they were filtered off, washed with a mixture of ethanol and diethyl ether (9:1 v/v), and dried in vacuum. Yield: 65%. *Anal.* Calc. for $C_{32}H_{29}N_6O_2ClPF_6Co$: C, 49.98; H, 3.80; N, 10.93. Found: C, 49.11; H, 3.80; N, 10.66%. FT-IR (KBr, cm^{-1}) ν_{max}: 3213, 3133 (m, N–H), 1629 (s, C=O), 1601 (s, C=C), 1562 (s, C–N), 843 (s, PF_6). UV–Vis: λ_{max} (nm) (ε, $L\,M^{-1}\,cm^{-1}$) (CH_3CN): 607 (224), 408 (7210). ^1H NMR (CD_3CN, 500 MHz): δ = 2.74 ($4H_h$, m), 3.05 (4H, NH_{2amine}, br s), 6.75 ($4H_i$, bd, 7.6), 7.05–7.16 ($7H_{j,k,f}$, m), 7.96–8.33 ($6H_{b,c,d}$, m), 8.73–8.76 ($2H_{e,g}$, m), 9.41 ($2H_a$, br d).

2.3. X-ray crystallography

Dark blue crystals of **1a** suitable for X-ray crystallography were obtained from methanol. Data were collected at 150 K, on a Nonius KappaCCD diffractometer (Mo Kα radiation, λ = 0.71069 Å) using

the COLLECT [33] program. Cell refinement and data reduction were performed with EVALCCD [34]. Crystal data, together with other relevant information on structure determination, are listed in Table 1. An empirical absorption correction, based on repeated and equivalent reflections, was carried out using SADABS [35]. The structure was solved by SIR97 [36] and refined, against F^2, by SHELXTL [37]. Anisotropic displacement parameters were assigned to all the non-hydrogen atoms. Hydrogen atoms were placed in idealized positions and allowed to ride on their respective parent atoms. The major residual electron density features are close to the anion, which is probably subject to unresolved disorder.

3. Results and discussion

3.1. Synthesis

All complexes were prepared by the following general method. To a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ in an appropriate solvent was added an equimolar amount of ligand in an appropriate solvent. A vigorous stream of air was passed through this solution, to which was gradually added excess amine. The air oxidation was continued for a period of 3 h, during which the color changed from red-brown to green-blue. Dark green-blue crystals of these complexes were obtained in good yield (65–80%).

3.2. Description of structure of trans-[Co(Mebpb)(prldn)$_2$]ClO$_4$ (**1a**)

To the best our knowledge, this is only the second reported structure of a $[Co^{III}(bpb)(amine)_2]^+$ complex containing neutral *N*-donor axial ligands. Fig. 1 shows the molecular structure of **1a** with the atomic numbering scheme. The structure exhibits a distorted octahedral environment around cobalt. Selected bond angles and distances are listed in Table 2. As expected, the ligand ($Mebpb^{2-}$) in **1a** binds to the trivalent metal ion (Co^{III}) via two pyridine N atoms and two amido N atoms in the equatorial plane of the octahedron. There are two pyrrolidine molecules attached to the metal to fill its axial sites. All Co–N bond distances are within the range

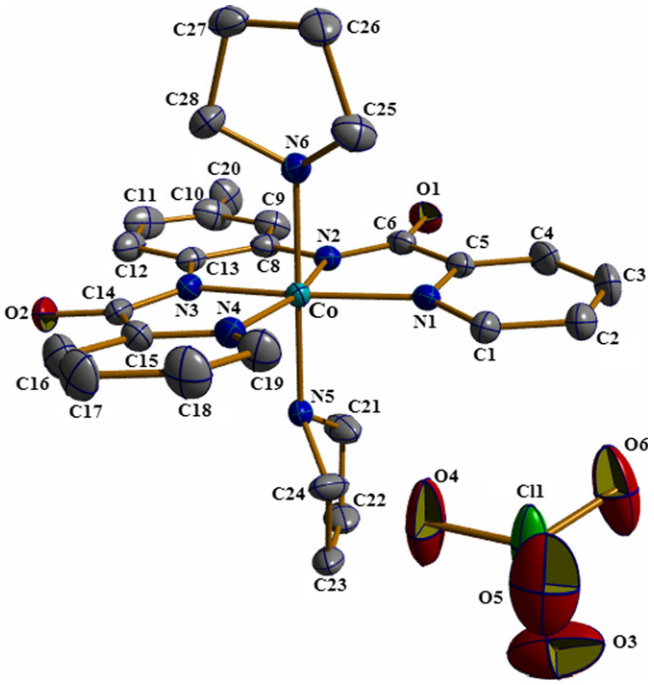

Fig. 1. The asymmetric unit of complex **1a** with the atom labeling scheme. Displacement ellipsoids are drawn at the 50% probability level; H atoms are omitted for clarity.

Table 2
Selected bond lengths (Å) and angles (°) for (**1a**)

Bond lengths

N2–Co–N4	166.28(13)
N2–Co–N5	92.86(13)
N2–Co–N6	88.43(13)
N3–Co–N4	82.46(14)
N3–Co–N5	88.69(13)
N3–Co–N6	92.08(13)
N4–Co–N5	89.59(13)
N4–Co–N6	89.32(13)
N5–Co–N6	178.57(13)

1.892(3)–2.012(3) Å, and are indicative of a low-spin $(t_{2g})^6$ configuration of the central Co^{III} ion [22].

Of the four Co–N bonds in the equatorial plane, the Co–N_{amide} bond distances [Co–N2 = 1.892(3) Å and Co–N3 = 1.892(3) Å], which are comparable to the Co–N_{amide} values [1.885(2) Å and 1.891(1) Å] in *trans*-[Co^{III}(bpb)(prldn)$_2$]NCS, are indicative of strong bonding between the deprotonated amide nitrogens and the cobalt center. This is in agreement with the fact that the deprotonated amide nitrogen is a very strong σ-donor. The deprotonated mode of coordination of the amide nitrogen atoms is also evident from the absence of the amide proton signals in the ^{1}H NMR spectrum of complex **1a** (*vide infra*). The bond distances to the pyridine nitrogen atoms [Co–N1 = 1.997(3) Å and Co–N4 = 1.994(3) Å] are longer than those to N2 and N3, which is in accord with the lower donor ability of the pyridine nitrogen atoms. The N–Co–N bond angles in the equatorial plane consist of one which is larger than 90° [N1–Co–N4 = 110.63(13)°] and three smaller bite angles [N1–Co–N2 = 82.88(13)°, N2–Co–N3 = 84.10(14)°, and N3–Co–N4 = 82.46(14)°]. This indicates that there might be some strain in the coordination due to the rigid geometry of the ligand. The dihedral angle between the two pyridyl rings of the ligand is 15.0°. The dihedral angles between the central benzene plane and the two pyridyl rings are 10.7° and 5.5°. This observation can be attributed to the close intramolecular contact that occurs between the two H atoms in the 6-positions of the pyridyl rings; the H1···H18 distance of 2.05 Å is significantly less than the sum of the van der Waals radii (2.40 Å). The effect would be expected to be more pronounced if the ligand were perfectly planar [38]. The C–O, $C_{pyridyne}$–N, and $C_{carboxy}$–N bond distances agree well with those reported for related complexes [16,20,39–41].

All *cis* N_{eq}–Co–N_{ax} bond angles are within 3° of the ideal right-angle. The *trans*-axial N5–Co–N6 unit with a bond angle of 178.57(13)° is essentially linear. The distances between the cobalt atom and the two axial nitrogen donor atoms differ only slightly [Co–N5 = 1.992(3) Å and Co–N6 = 2.012(3) Å] and compare well with the Co–N distances found in *trans*-[Co^{III}(bpb)(prldn)$_2$]NCS [25].

A further interesting feature of the structure of **1a** is the intermolecular hydrogen bonding (Table 3). The structure consists of chains of cations linked by rather strong N–H···O=C hydrogen bonds zig-zagging along the *c* axis (Fig. 2); the anions are not involved in hydrogen bonding.

Table 3

3.3. Spectroscopic studies

The octahedral geometry of complex **1a** is evident from the X-ray structure analysis (Fig. 1). An octahedral *trans* structure for other complexes (**2a**–**4a**, **1b**–**4b**) can be inferred based on the similarity of the spectroscopic data of these complexes with those of complex **1a**. The FT-IR data of the complexes are listed in Section 2. Meaningful information regarding the bonding sites of the ligand molecules can be obtained by comparing the IR spectra of the cobalt complexes with those of the uncomplexed ligands. In the IR spectra of H_2Mebpb and H_2cbpb a band characteristic of the NH group is observed in the 3295–3305 cm^{-1} region. The disappearance of this band in the IR spectra of the complexes confirms that the ligands coordinate in their deprotonated form [17]. The bands corresponding to the amine N–H stretching vibrations are shifted to lower frequencies by about 98–265 cm^{-1} relative to the uncoordinated amines, which is in accord with expectation. Two sharp C=O stretching vibration bands at 1689 and 1659 cm^{-1} for H_2Mebpb and 1661 and 1697 cm^{-1} for H_2cbpb are shifted to lower frequencies upon coordination of the deprotonated amide, which is in agreement with the data reported for related complexes [31]. The C–N stretching vibration of medium intensity appearing at 1520 cm^{-1} for H_2Mebpb and at 1506 cm^{-1} for H_2cbpb undergoes a significant shift to higher frequencies in the corresponding complexes. This displacement is to be expected because of the resonance enhancement in the deprotonated amide which in turn leads to strengthening of the C–N bond [17]. The stretching vibrations due to the perchlorate and hexafluorophosphate anions appear in the 1080–1120 cm^{-1} and 840–846 cm^{-1} regions, respectively [42].

The UV–Vis data are presented in the Experimental section. The electronic spectra of the *trans*-[Co^{III}(Mebpb)(amine)$_2$]ClO_4 complexes (**1a**–**4a**) consist of ligand field transitions with low intensity ($180 < \varepsilon < 235$) which, depending on the axial amine ligand field strength, appear in the 610–689 nm region, and intense LMCT

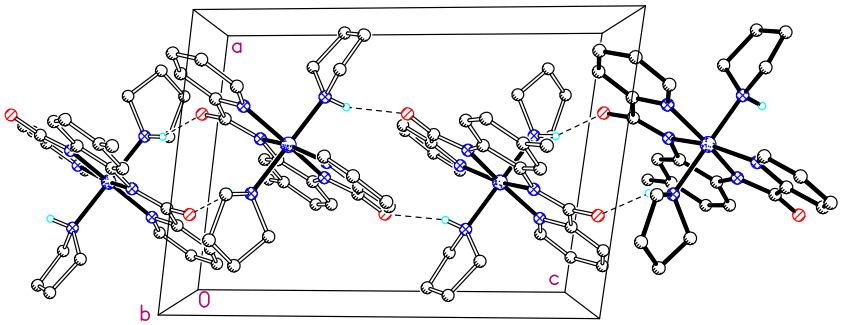

Fig. 2. A view, along the *b* axis, of the packing of **1a**. Hydrogen bonding is shown as dashed lines. Anions have been omitted, together with H atoms not involved in the hydrogen bonding.

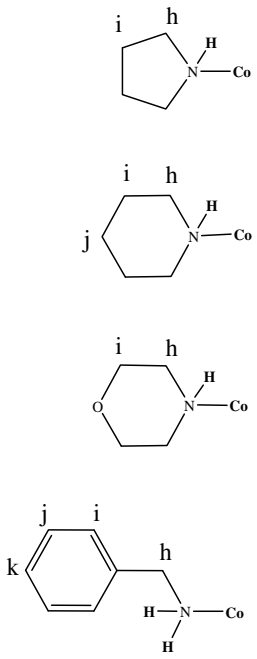
Morpholine	*3a*	*3b*
Benzylamine	*4a*	*4b*



Scheme 2.

transitions appearing in the 412–418 nm region. Similar transitions have been observed in the electronic absorption spectra of *trans*-[Co^{III}(cbpb)(amine)$_2$]X complexes (**1b–4b**) with a blue shift of about 3–25 nm in the position of all the absorption bands relative to those of *trans*-[Co^{III}(Mebpb)(amine)$_2$]ClO_4 complexes (d–d transitions, 607–656 nm and CT transitions, 405–410 nm).

The ^{1}H NMR spectroscopic measurements were performed on samples in CD_3CN and $CDCl_3$ solutions. Scheme 2 displays the labeling system. The assignments are based on comparisons with corresponding rhodium(III), iridium(III), organocobalt(III) and ruthenium(II) complexes and by integrated area ratios [17,18,43–45].

The absence of the amido N–H resonance in the spectra of the complexes indicates that the ligand is coordinated to cobalt in its deprotonated form. The proton signals of the equatorial amide ligand in the complexes are generally shifted downfield relative to the free ligand. As expected, the most significant downfield shifts correspond to the protons *ortho* to the pyridyl nitrogen, H_a, and *ortho* to the nitrogen substituent on the diamido benzene group, $H_{e,g}$ [44]. The broad doublet of doublet at *ca.* δ = 9.39–9.46 is assigned to H_a.

Although the chemical shifts of H_f were found to be virtually unaffected by the axial ligand, chemical shifts of $H_{e,g}$ and H_a of the cobalt complexes varied significantly. In general, δ ($H_{e,g}$) changes in the same direction as δ (H_a) but to a larger extent. The changes in the chemical shift of H_c and H_d are in line with the donor ability of the axial ligands and the UV–Vis spectral data. The trend observed in δ (H_c, H_d) for complexes **1a–4a**, bzlan > prldn > pprdn > mrpln, conforms to the σ-donating strength of the axial ligands, which in turn is evident from the electrochemistry of these complexes.

The appearance of the signals due to the amine protons indicates the coordination of two amine ligands in the axial positions. Aside from the aromatic protons of benzylamine which appear at about 6.74–7.12 ppm, other proton resonances of the axial amines appear between about 0.91 and 3.55 ppm.

The ^{1}H NMR spectra of *trans*-[Co^{III}(cbpb)(amine)$_2$]$^+$ complexes (**1b–4b**) show features similar to those observed for *trans*-[Co^{III}-(Mebpb)(amine)$_2$]$^+$ complexes. As expected, the protons on the benzene ring exhibit slight downfield shifts in the peak positions in the [Co^{III}(cbpb)(amine)$_2$]$^+$ complexes, demonstrating the electron-withdrawing effect of chloro substitution in the equatorial $cbpb^{2-}$ ligand.

3.4. Electrochemistry

Cyclic voltammograms of the ligands and complexes in acetonitrile solutions with 0.1 M [N(*n*-Bu)$_4$]PF_6 as the supporting electrolyte were recorded at a glassy carbon working electrode. The approximate concentrations of the compounds were 1×10^{-3}–10^{-6} M.

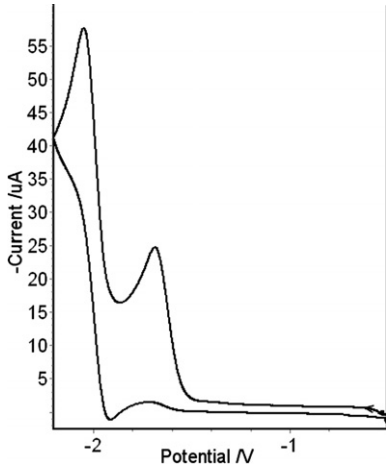


Fig. 3. Cyclic voltammogram of H_2Mebpb ligand in acetonitrile solution at 298 K. Scan rate: 100 mV s^{-1}, $c = 2.8 \times 10^{-3}$ M.

3.4.1. Electrochemistry of the ligands

The cyclic voltammograms of the ligands and their complexes were conducted at 25 °C under an argon atmosphere. It is evident from the cyclic voltammogram of H_2Mebpb, displayed in Fig. 3, that the ligand is electroactive over a range from −0.5 to −2.2 V. Two ligand-centered reductions are observed at −1.89 V and −2.2 V (Fig. 3). These reductions are attributed to the pyridyl rings and are shifted to more positive values in the corresponding complexes (Table 4). The tendency of the ligand towards reduction is apparently increased due to the transfer of electron density to the metal center [46].

The cyclic voltammogram of H_2cbpb shows features similar to those observed for H_2bpb, with an anodic shift in the peak positions resulting from the electron-withdrawing nature of the chloro substitution in the H_2cbpb ligand.

3.4.2. Electrochemistry of the complexes in the absence of amines

The reduction potentials for the cobalt complexes are summarized in Table 4. The cyclic voltammogram of the representative complex, *trans*-[Co^{III}(Mebpb)(pprdn)$_2$]ClO_4 (**2a**), is shown in Fig. 4a. An interesting observation in the cyclic voltammetric measurements of these cobalt(III) complexes is the presence of a nearly reversible oxidative response in the range of $E_{1/2}$ = 0.98–1.01 V (Fig. 4, Table 4) (the first oxidation process, which can be assigned as mainly ligand-centered, occurs at virtually identical potentials).

The next reduction peak observed over the range of −0.31 to −0.53 V in (**1a–4a)** complexes, and −0.22 to −0.49 V in (**1b–4b)** complexes, is metal-centered. This is supported by the relative sensitivity of Co^{III}/Co^{II} reduction potentials to the nature of the axial amine ligand. From the E_{pc1} values (Table 4), it is evident that

Table 4

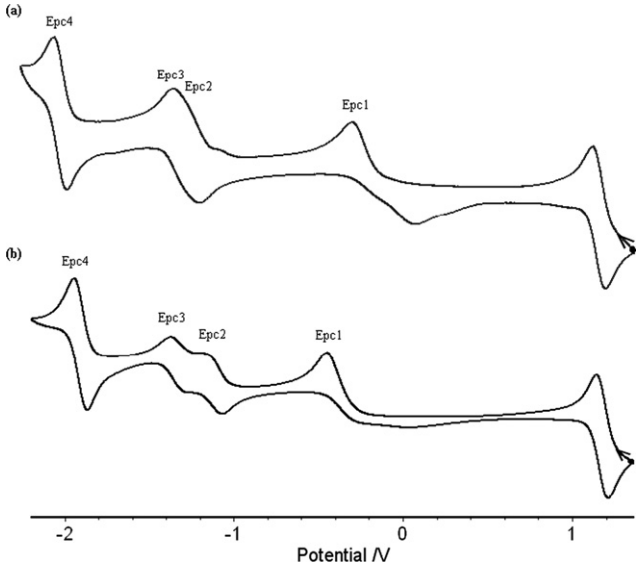

Fig. 4. Cyclic voltammograms of $[Co^{III}(Mebpb)(pprdn)_2]ClO_4$, $c = 1.8 \times 10^{-3}$ M (a), and $[Co^{III}(cbpb)(bzlan)_2]PF_6$, $c = 1.2 \times 10^{-3}$ M (b), in acetonitrile at 298 K. Scan rate, 100 mV s^{-1}.

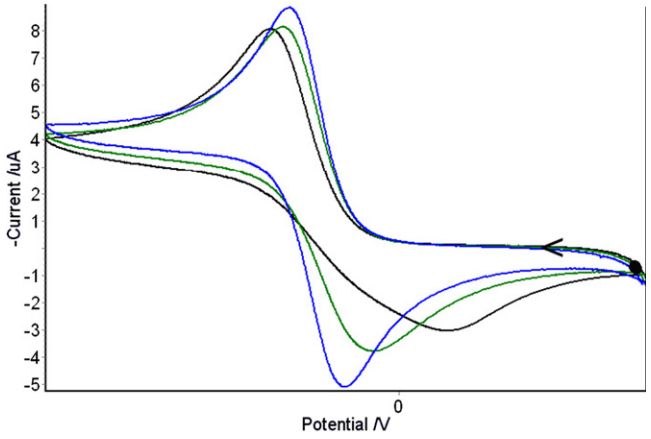

Fig. 5. Cyclic voltammograms of $[Co^{III}(Mebpb)(pprdn)_2]ClO_4$, **2a**, at different piperidine concentrations ratios (0, — black), (50, — green), (100, — blue) in acetonitrile containing 0.1 M TBAH as supporting electrolyte at 298 K. Scan rate 100 mV s^{-1}, $c = 1.5 \times 10^{-3}$ M. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

stronger axial ligands shift the reduction potentials to more negative values. In general the Co^{III}/Co^{II} reductions for all these complexes are electrochemically irreversible in nature [19]. Accordingly, we assume that the lack of reversibility observed (Fig. 4) is most likely due to the loss of axial ligands from the cobalt(II) complex, because the electron is added to the antibonding d_{z^2} orbital [47].

$$[Co^{III}(Mebpb)(amine)_2]^+ + e^- \overset{MeCN}{\rightarrow} [Co^{II}(Mebpb)] + 2\ amine \qquad (1)$$

Owing to the very facile substitution of the axial ligands in the reduced form of these cobalt(III) complexes, electrochemical reversibility for the Co^{III}/Co^{II} couple is not observed. The oxidation of $[Co^{II}(Mebpb)(MeCN)]$ adduct occurs at much higher potentials.

The Co^{III}/Co^{II} cathodic wave in all $[Co^{III}(Mebpb)(amine)_2]^+$ complexes is followed by two overlapping redox waves, resulting from the combination of the Co^{II}/Co^{I} couple [48] and the redox couple corresponding to one of the pyridyl rings (Fig. 4a). In the $[Co^{III}(cbpb)(amine)_2]^+$ complexes, however, these couples are resolved (Fig. 4b). The final electrochemically reversible reduction couple observed in the voltammograms is related to the second pyridyl ring, that appears between $E_{1/2} = -2.01$ and -2.05 V for $[Co^{III}(Mebpb)(amine)_2]^+$ and at $E_{1/2} = -1.96$ V for $[Co^{III}(cbpb)(amine)_2]^+$ complexes. Additional evidence produced in substantiation of this fact are the results obtained from the cyclic voltammetric studies of the Ni(Mebpb) complex, that shows only two reduction waves in the range -1.57 to -2.04 V, attributed to the consecutive reduction of the two pyridyl rings [49]. Similar results have been reported for Ni(bpb) and Ni(bpen) complexes by Fenton et al. [46].

The σ-donor strength of the axial ligands also has a significant influence on the Co^{III}/Co^{II} reduction process, and the tendency of Co^{III} towards reduction increases as the axial ligand becomes a weaker donor. These observations are compatible with the ^{H} NMR and UV–Vis spectroscopic data.

A similar behavior has been found for $[Co^{III}(cbpb)(amine)_2]^+$ complexes. Fig. 4b shows the cyclic voltammogram of $[Co^{III}(cbpb)(bzlan)_2]PF_6$ (**4b**) as an example. In general the redox couples of $[Co^{III}(cbpb)(amine)_2]^+$ complexes are shifted to more positive values relative to those of the corresponding $[Co^{III}(Mebpb)(amine)_2]^+$ complexes, demonstrating the electron-withdrawing effect of chloro substitution on the electron density of the system. Similar results have been reported by Che et al. [16,43] and Ray and Mukherjee [19].

3.4.3. Electrochemistry of the complexes in the presence of amines. It is well established that in many *trans*-$[Co^{III}(N_2O_2)(L)_2]^+$ Schiff base complexes, the first irreversible reduction process (Co^{III}/Co^{II}) can become quasi-reversible under controlled concentration conditions [47,50]. In an attempt to examine the possibility of reversible electrochemical behavior in analogous amido complexes, the electrochemistry of $[Co^{III}(Mebpb)(pprdn)_2]ClO_4$ was carried out in the presence of excess amine. In the absence of additional amine the first reduction processes of (Co^{III}/Co^{II}) is electrochemically irreversible ($\Delta E = 410$ mV). Upon addition of excess amine, the oxidation wave of Co(II) is shifted towards more negative potentials (Fig. 5) ($\Delta E = 107$ mV), indicating the increased formation of six-coordinated adducts; i.e. the electrode process is preceded by a reversible chemical reaction

$$[Co^{II}(Mebpb)] + \text{excess amine} [Co^{III}(Mebpb)(amine)_2]^+ + e^- \qquad (2)$$

The redox potential of the Co(II/I) couple is not significantly changed by the addition of excess amine and can be regarded as approximately independent.

4. Conclusion

The combination of spectroscopic, crystallographic, and electrochemical measurements we have described has illustrated the main features of the coordination and redox chemistry of the *trans*-$[Co^{III}(Mebpb)(amine)_2]ClO_4$ and *trans*-$[Co^{III}(cbpb)(amine)_2]PF_6$ complexes. The coordination geometry around the Co^{III} center in these complexes is distorted octahedral. Electrochemical studies reveal that the first reduction process Co^{III}/Co^{II} is irreversible and strongly influenced by the nature of the axial amines. When the axial ligands are changed from morpholine to pyrrolidine a change in the Co^{III}/Co^{II} cathodic peak of 220 mV for Mebpb complexes and 260 mV for cbpb complexes is observed. This process becomes quasi-reversible upon the addition of excess amine. The two redox waves, resulting from the combination of the Co^{II}/Co^{I} couple and the redox couple corresponding to one of the pyridyl rings, overlap in $[Co(Mebpb)(amine)_2]^+$, but are resolved in $[Co(cbpb)(amine)_2]^+$ complexes. In general, the redox couples of $[Co(cbpb)(amine)_2]^+$ complexes are shifted to more positive values relative to those of the corresponding $[Co(Mebpb)(amine)_2]^+$ com-

plexes due to the electron-withdrawing effect of chloro substitution.

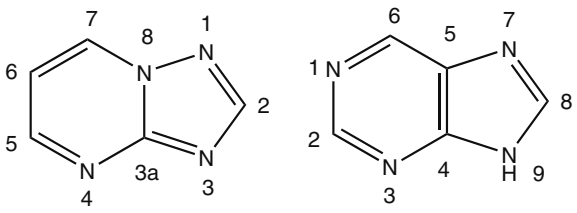

Fig. 1. The basic skeleton of 1,2,4-triazolo[1,5-*a*]pyrimidines and purines.

2. Experimental

2.1. Synthesis of the compounds

1,2,4-Triazolo-[1,5-*a*]pyrimidine (tp), 5,7-dimethyl-1,2,4-triazolo-[1,5-*a*]pyrimidine (dmtp), 1,10-phenanthroline (phen), ethylenediamine (en), $Cu(ClO_4)_2 \cdot 6H_2O$ and $Cu(NO_3)_2 \cdot 3H_2O$ were purchased from Aldrich and used without further purification.

2.1.1. $[Cu(H_2O)(phen)(tp)_2](ClO_4)_2 \cdot H_2O$ (**1**) and $[Cu(H_2O)(phen)(dmtp)_2](ClO_4)_2$ (**2**)

Firstly a green solution was obtained by mixing an aqueous solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (1 mmol, 10 mL) and another one of the appropriate ligand tp (**1**) or dmtp (**2**) (1 mmol, 10 mL). After adding 1,10-phenanthroline dissolved in ethanol (1 mmol, 5 mL) a green precipitate of $Cu(phen)_2(ClO_4)_2 \cdot H_2O$ immediately appeared, which was filtered, washed with water and ethanol. The filtered solution was allowed to evaporate at room temperature and, after several days, blue crystals suitable for X-ray studies were isolated. Elemental analysis data: Compound **1**: *Anal.* Calc. for $C_{22}H_{20}Cl_2CuN_{10}O_{10}$: C, 36.8; H, 2.8; N, 19.5. Found: C, 37.4; H, 2.6; N, 19.8%. Compound **2**: *Anal.* Calc. for $C_{26}H_{26}Cl_2CuN_{10}O_9$: C, 41.3; H, 3.5; N, 18.5. Found: C, 41.3; H, 3.5; N, 18.4%.

2.1.2. $[Cu(NO_3)(H_2O)(phen)(tp)](NO_3)$ (**3**)

The complex was obtained by mixing three solutions, 10 mL each, one containing 1 mmol of $Cu(NO_3)_2 \cdot 3H_2O$, other 1 mmol of tp and the third 1 mmol of 1,10-phenanthroline. The two first solutions are aqueous and the last is ethanolic. After few days blue crystals suitable for X-ray study were obtained. Elemental analysis data: *Anal.* Calc. for $C_{17}H_{14}CuN_8O_7$: C, 40.4; H, 2.8; N, 22.2. Found: C, 40.8; H, 2.7; N, 22.6%.

2.1.3. $[Cu(H_2O)_2(en)(tp)_2](ClO_4)_2$ (**4**) and $[Cu(H_2O)_2(en)(dmtp)_2](ClO_4)_2$ (**5**)

Firstly two aqueous solutions of $Cu(ClO_4)_2 \cdot 6H_2O$ (1 mmol, 10 mL) and the appropriate ligand (tp (**4**) or dmtp (**5**)) (1 mmol, 10 mL) were mixed. After adding 0.5 mmol (34 μL) of ethylenediamine, it was left to stand at room temperature, blue crystals suitable for X-ray studies were isolated. Elemental analysis data: Compound **4**: *Anal.* Calc. for $C_{12}H_{20}Cl_2CuN_{10}O_{10}$: C, 24.1; H, 3.4; N, 23.4. Found: C, 24.3; H, 4.0; N, 23.8%. Compound **5**: *Anal.* Calc. for $C_{16}H_{28}Cl_2CuN_{10}O_{10}$: C, 29.3; H, 4.3; N, 21.4. Found: C, 29.6; H, 4.6; N, 22.0%.

2.1.4. $[Cu_2(OH)(H_2O)_{2.5}(tp)_5](ClO_4)_3(H_2O)_{1.5}$ (**6**)

Two solutions of $Cu(ClO_4)_2 \cdot 6H_2O$ (1 mmol, 10 mL) and tp (1 mmol, 10 mL) in 0.01 M NaOH were mixed. The mixture was allowed to evaporate at room temperature and, after one week, light blue crystals suitable for X-ray studies were obtained. Elemental analysis data: *Anal.* Calc. for $C_{25}H_{29}Cl_3Cu_2N_{20}O_{17}$: C, 26.9; H, 2.6; N, 25.1. Found: C, 27.1; H, 2.9; N, 25.7%.

2.2. Instrumentation

Microanalysis of C, H and N were performed in a Fisons Instruments EA-1008 analyser. Thermal behaviour was studied under an air flow in Shimadzu TGA-50 and Shimadzu DSC-50 equipments, at heating rates of 20 °C min^{-1} and 10 °C min^{-1}, respectively. Reflectance diffuse spectra were made on a VARIAN model CARY-5E spectrophotometer. EPR spectra of powdered samples were recorded at room temperature on a Bruker ESP-300E spectrometer, operating at X-band (9–10 GHz) while the magnetic susceptibility measurements, in the temperature range of 2–300 K, were carried out on powdered samples using a Quantum Design MPMS-XL SQUID (all this equipment is sited at the Centre of Scientific Instrumentation of the University of Granada). IR spectra were recorded on a ThermoNicolet IR 200 spectrometer using KBr pellets.

2.3. Crystallography

Data were collected, at room temperature for **3** and **4** and at 100 K for the rest of the samples, in a Bruker SMART APEX CCD system with Mo Kα radiation (λ = 0.7107 Å). Data were corrected for absorption (multi-scan, transmission ranges, 0.8305–0.7330, 0.7944–0.7122, 0.673–0.545, 0.822–0.614, 0.7013–0.6392 and 0.8659–0.7245 for **1**–**6**, respectively). The structures were solved by the heavy atom method and anisotropically refined in F^2 using SHELXL-97 [17]. There are two non-coordinated nitrate anions in **3** placed in binary axes, one of them disordered between two equally populated positions. Two water molecules in **6** have been refined with half occupancy. Hydrogen atoms of the heterocycles and auxiliary ligands were placed in ideal positions whereas those of water molecules (except the half occupancy ones in **6**) were refined with fixed O–H distance. Isotropic thermal parameters of all H atoms fixed to 1.2 times the equivalent isotropic thermal parameter of their parent atoms. Table 1 summarizes the crystallographic data for the six compounds.

3. Results and discussion

3.1. X-ray structure of the ternary copper complexes

All ternary copper(II) complexes (**1**–**5**) are mononuclear with the triazolopyrimidine ligands monodentately coordinated to the metal via the nitrogen atom at position 3 and the auxiliary ligand (ethylenediamine, en or 1,10-phenanthroline, phen) bidentately attached closing a five-member chelate ring. The geometry around the metal atom is square-pyramidal when the auxiliary ligand is phen (**1**, **2**, **3**) and tetragonally distorted octahedral when the auxiliary ligand is en (**4**, **5**). Figs. 2–4 display the structures of all these complexes. Distances and angles in the coordination sphere are listed in Table 2. These distances agree well with bibliographic data for Cu complexes of both triazolopyrimidine ligands and amine ligands [11]. The trigonality indexes [18] calculated for the five-coordinate compounds are 0.142, 0.187 and 0.022, respectively for **1**, **2** and **3** indicating that the geometries are in fact much closer to tetragonal pyramidal than to trigonal bipyramidal.

Both the triazolopyrimidine moiety and the auxiliary ligands occupy basal or equatorial coordination positions. For compound **3**, in which only one tp molecule is present, the fourth position in the basal plane is occupied by one oxygen atom of the coordinated nitrate anion. The axial positions are filled by one (**1**, **2**, **3**) or two (**4**, **5**) water molecules at a longer distance in typical Cu(II) Jahn–Teller distorted environments. In the two later compounds, distances Cu–water are long enough to let us consider the compounds as quasi-square planar (4+2). A weak interaction of the metal with a second oxygen atom of the coordinated nitrate anion

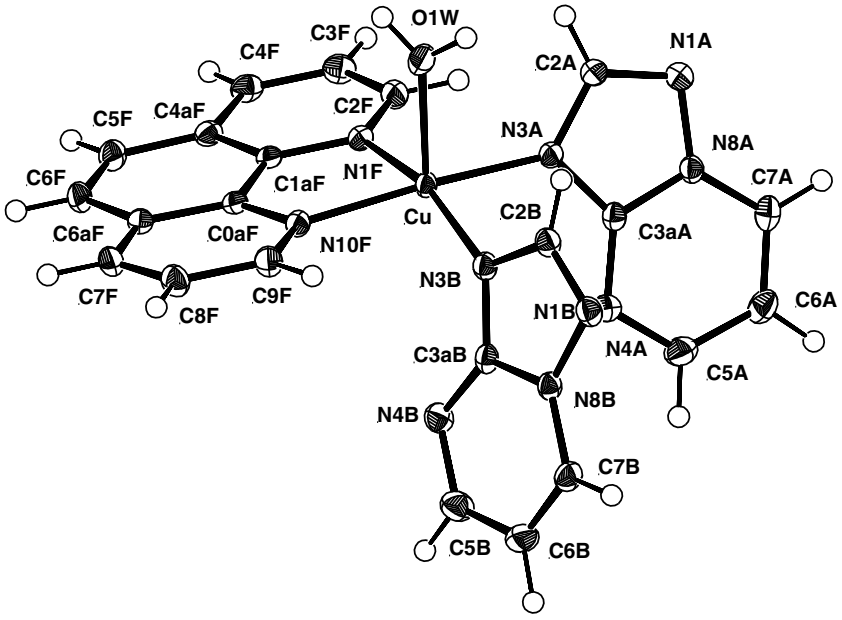

Fig. 2. View of the cationic complex $[Cu(H_2O)(phen)(tp)_2]^{2+}$ in compound **1**. The cation $[Cu(H_2O)(phen)(dmtp)_2]^{2+}$ in compound **2** is analogous to this.

(distance, 2.634(2) Å) is observed in compound **3**. The rotation around the Cu–N3 bonds seems to be quite easy since the dihedral angle between the equatorial coordination plane and the average triazolopyrimidine plane is rather variable (37–83°) and apparently conditioned by the repulsion between the ligands and the interactions with neighbouring species. In compound **3**, the tp ligand has its hexagonal ring pointing to the same side of the coordinated water molecule, this orientation being supported by a intramolecular H-bond (distance O1W···N4, 2.871(3) Å) whereas in compounds **1** and **2**, the orientation of tp or dmtp is just the opposite with relative head–head disposition.

The complex cations in **1** and **2** are associated in couples with the two cations related by an inversion centre and linked by a well-defined stacking interaction between the auxiliary ligands. Stacking interaction between the phen moieties is also observed in compound **3** but, in this case, it leads to the formation of rows of cations along the *b* axis. The formation of these couples of cations in **1** and **2** may explain why the coordination number in these complexes is five, the sixth coordination position being hindered by the other component of the couple. Water molecules form H-bonds towards oxygen atoms of the anions and non-coordinated N atoms of tp and dmtp (N1,N4) of neighbouring complexes.

The charge of the cationic complexes is balanced by two interstitial perchlorate anions placed in general positions in compounds **1**, **2**, **4**, **5** whereas for compound **3** there are two crystallographically independent non-coordinated nitrate moieties both placed in binary axes. An additional interstitial water molecule is present in the asymmetric unit of **1**.

It is clear that the nature of both the auxiliary ligand and the counteranion influences the geometry around the metal atom. The entrance of one nitrate anion (with higher coordination ability than perchlorate) in the coordination sphere of **3** leaves only one free equatorial coordination position available for the triazolopyrimidine ligands, which may explain why the relation Cu:tp is 1:2 for **1**, **2**, **4** and **5** and 1:1 for **3**, despite the fact that all reaction mixtures were initially 1:1. The stacking of phen ligands may explain why the coordination number is clearly five (it may be regarded as 5+1 for **3**) when the auxiliary ligand is phen and 4+2 when

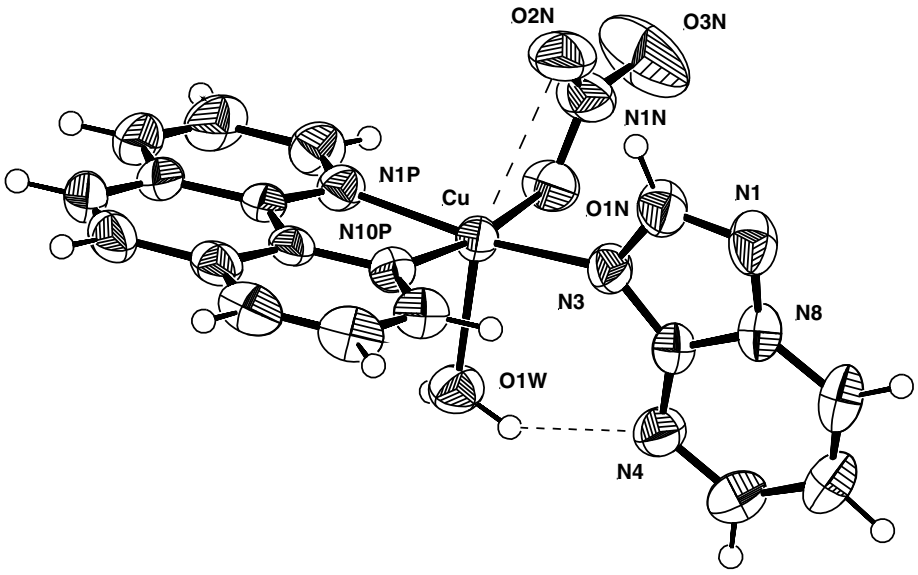

Fig. 3. View of the cationic complex $[Cu(NO_3)(H_2O)(phen)(tp)]^+$ in compound **3**.

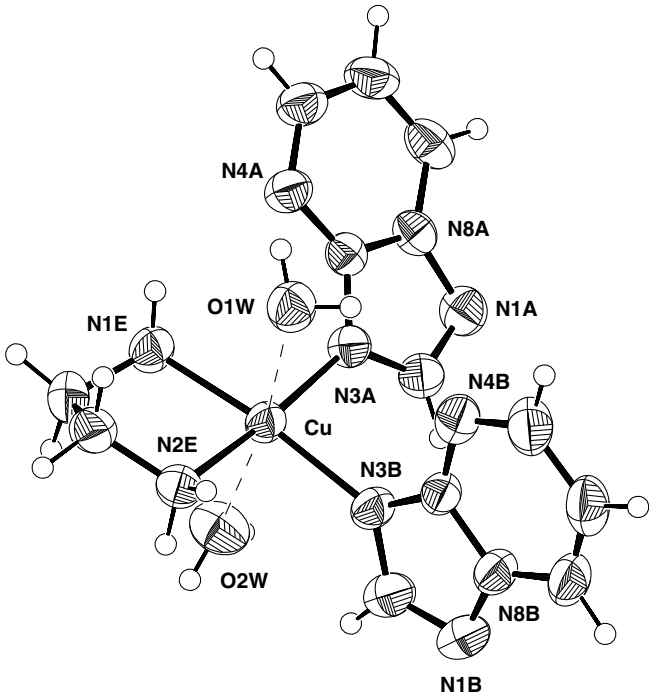

Fig. 4. View of the cationic complex $[Cu(H_2O)_2(en)(tp)_2]^{2+}$ in compound **4**. The cation $[Cu(H_2O)_2(en)(dmtp)_2]^{2+}$ in compound **5** is analogous to this.

Na = nitrogen atom of phen of en, On = oxygen atom of nitrate, Ow = oxygen atom of water.

the auxiliary ligand is en, for which stacking interactions are absent. The presence of the methyl groups at positions 5 and 7 does not seem to influence appreciably the geometry of the cations.

3.2. X-ray structure of the dinuclear compound

Dinuclear complexes of 1,2,4-triazolo-[1,5-*a*]-pyrimidine derivatives with the heterocycle bridging two metal atoms through their nitrogen atoms in positions 3 and 4 have been described for several metals including Cu(I) [19], Ag(I) [20,21], Pd(II) [22] and Pt(II) [23,24]. This coordination mode mimics the behaviour of purine bases like adenine or hypoxanthine bridging metal atoms through N3 and N9 [25–27]. For Cu(II), such compounds have only been described for triazolopyrimidines bearing an ionizable H-atom which is removed raising the pH thus increasing the coordination capability of the ligand [15]. If such strategy is attempted with ligands like tp or dmtp without ionizable protons, the result is usually just the precipitation of $Cu(OH)_2$. Nevertheless, we have succeeded in obtaining a dinuclear compound with the ligand tp by raising only slightly the pH using 0.01 M NaOH as reaction medium. The compound, isolated as X-ray suitable crystals, exhibits the formula $[Cu_2(OH)(H_2O)_{2.5}(tp)_5](ClO_4)_3 \cdot 1.5H_2O$ (**6**). A view of the dinuclear cation of this compound is displayed in Fig. 5.

The asymmetric unit of this compound contains two non-equivalent copper atoms. Two equatorial positions of each of them are occupied by N3-monodentate tp moieties, whereas the other two are occupied by two different species bridging the metal atoms, one hydroxydo group and one tp molecule linked through N3 to one of the metal atoms (Cu1) and through N4 to the other (Cu2). Cu–N3 distances for the terminal tp ligands range from 2.007(3) to 2.028(3) Å, this range being similar to that found in the above

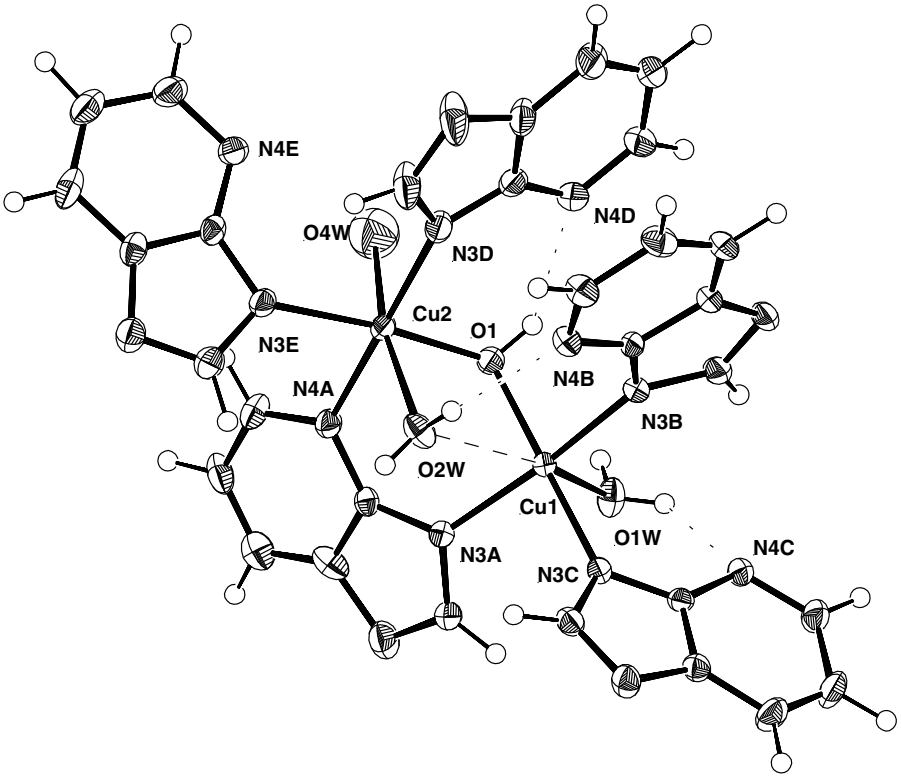

Fig. 5. View of the dinuclear complex $[Cu_2(OH)(H_2O)_{2.5}(tp)_5]^{3+}$ in compound **6**. The water molecule O4W has half occupancy and therefore should be present only in half of the complexes in the crystal.

described mononuclear complexes. Distances for the bridging tp moiety are, as expected, slightly longer (Cu1–N3 = 2.045(3) and Cu2–N4 = 2.063(3) Å) whereas the hydroxydo group is strongly attached to both copper atoms as usual for this species (Cu1–OH = 1.928(3) and Cu2–OH = 1.913(3) Å) but with a rather wide Cu–O–Cu angle (114.61(13)°) probably forced by the simultaneous presence of the bridging tp ligand. Both equatorial planes are not coplanar (dihedral angle 63.79(9)°) and the bridging tp ligand forms a dihedral angle of 28.54(9)° with the equatorial plane of Cu1 and an angle of 43.92(8)° with the equatorial plane of Cu2.

The axial positions of both metal atoms are occupied by water molecules with different structural roles. One of them (O1W) is attached to Cu1 with a distance of 2.300(3) Å whereas a second one (O2W) is linked to Cu2 at 2.412(3) Å, the latter also weakly interacting with Cu1 (distance, 2.697(4) Å) so it might be considered as a third asymmetric bridging ligand between the metal atoms. According to this, the coordination mode of Cu1 may be regarded as "4+1+1". Another water molecule (O4W) does not refine acceptably if considered with full occupancy and, after some trial and error, has finally been introduced in the refinement process with half occupancy, its distance to Cu2 being 2.441(9) Å. Therefore the coordination polyhedra of Cu2 is a square pyramid (4+1) for half of the Cu2 atoms present in the sample and a distorted octahedron (4+2) for the other half.

The hydroxydo group and the coordinated water molecules form intramolecular hydrogen bonds towards the N4 atom of terminal tp ligands thus contributing to stabilize the complex, the corresponding distances are OH···N4D = 2.866(4), O1W···N4C = 2.856(4) and O2W···N4B = 2.858(4) Å.

The charge of the cationic dinuclear complex is balanced by three perchlorate anions. A full-occupancy and another half-occupancy non-coordinated water molecules complete the asymmetric unit.

As told above, the N3,N4 bridging coordination mode for triazolopyrimidine ligands has been reported in previous papers. Nevertheless, this dinuclear complex is novel because it is the first time that this coordination mode is displayed in Cu(II) complexes with triazolopyrimidine derivatives without exocyclic oxygen atoms and also because of the presence of two different bridging ligands (tp and OH). The simultaneous presence of N3-monodentate and N3,N4-bridging modes in the same complex had been only previously observed for a Pt compound containing the anionic form of 4,7-dihydro-5-methyl-7-oxo-1,2,4-triazolo[1,5-*a*]pyrimidine ($mtpO^-$) in $[(mtpO)(NH_3)_2Pt(\mu\text{-}mtpO)Pt(bpy)(OH)](NO_3)\cdot 6H_2O$ [24] (where bpy = 2,2′-bipyridine).

3.3. Spectral and thermal studies

The 1500–1700 cm^{-1} region of the infrared spectra of the free heterocycles displays three bands for tp (1621, 1534 and 1515 cm^{-1}) and two for dmtp (1638 and 1548 cm^{-1}). Szłyk et al. [28] have assigned these bands by comparison with the previously assigned spectra of purine and adenine [29] suggesting that the higher wavenumber band is due to a vibration mode of the whole triazolopyrimidine moiety (ν_{tp}) whereas the other are due to pyrimidine ring modes (ν_{py} for dmtp, split into ν_{py1} and ν_{py2} for tp). These bands are only slightly affected by the coordination, with a displacement of the three bands of tp and the ν_{py} band of dmtp to higher wavenumber and a displacement of ν_{tp} band of dmtp to lower wavenumbers.

The presence of the anions is indicated by the typical stretching vibrations of perchlorate (1146, 1112 and 1087 cm^{-1} (**1**), 1144, 1119 and 1085 cm^{-1} (**2**), 1093 cm^{-1} (**4**), 1147, 1114 and 1087 cm^{-1} (**5**) and 1093 cm^{-1} (**6**)) or nitrate (1385 cm^{-1} (**3**)). The spectra also show broad bands around 3500–3400 cm^{-1}, easily assignable to ν(O–H) of water.

The first step of the thermal decomposition of the isolated complexes is the dehydration process. Complexes **1**, **2**, **3** and **5** display well-defined weight losses in the range 47–152 °C which agree well with the number of water molecules indicated by their elemental analysis. For **4** and **6** the experimental values for weight losses are lower than theoretical values and dehydration enthalpies cannot be reliably obtained from the integration of the peaks in the DSC diagrams since the dehydration partially occurs at room temperature. Dehydration takes place in a single step (endothermic peaks in the range 57–133 °C) except for **5** and **6** for which two well-defined stages are observed (peaks at 87 and 134 °C (**5**) and 58 and 141 °C (**6**)). After this, the decomposition of anions takes place followed of the pyrolysis of organic moiety that normally occurs in several steps (200–900 °C).

The diffuse reflectance spectra for all compounds present a only broad and asymmetric band with a maximum in the range 15 600–16 800 cm^{-1} that can be assigned for a d–d transition in a d^9 configuration with distorted octahedral or square-pyramidal geometries [30].

3.4. Magnetic and EPR studies

The X-band EPR spectra have been recorded for the polycrystalline powdered samples at room temperature. Compounds **1**, **2**, **3** and **5** present a spectrum made up by single very broad asymmetric band attributable to an unresolved anisotropic spectrum with an average g value of 2.06–2.07. The spectrum of compound **4** presents better resolution, with a slightly orthorhombic signal (g_1 = 2.16, g_2 = 2.09, g_3 = 2.06). The dinuclear complex **6** is EPR silent at room temperature, probably due to the broadening of the signal caused by the magnetic interaction between the copper atoms inside the complex.

The magnetic susceptibility of the six complexes has been measured in the 2–300 K range, at the magnetic field 10^4 Oe for all samples except **5** where a 5×10^3 Oe magnetic field was used. Experimental data were corrected for diamagnetism using the Pascal constants [31]. The magnetic data of the ternary copper complexes, **1**–**5**, are typical of magnetically diluted compounds and their magnetic behaviour can be described by the Curie law. The calculated μ_{eff} values (1.82–1.91 BM) are in the expected range for mononuclear Cu(II) complexes with similar geometry [11].

On the other hand, compound **6** displays a smooth decrease of $\chi_M T$ (where χ_M is the magnetic susceptibility per pair of copper(II) ions) as the temperature decreases from a value of 0.79 cm^3 K mol^{-1} at room temperature to a value of 0.19 cm^3 K mol^{-1} at 2 K, which is indicative of antiferromagnetic interactions between the metal centres. Nevertheless, no susceptibility maximum is observed and the data cannot be acceptably fit to the Bleany–Bowers equation for copper dimers [32], which do not let us to calculate an accurate $2J$ value. This may be due to the presence of the partial occupancy water molecule attached to one of the metal atoms (see above) which means that we have, in fact, two different dinuclear species present at the compound with possible different magnetic parameters. Alternatively, the data have been fitted to the Curie–Weiss law [33], the antiferromagnetic interaction being thus quantified by the negative value of θ (−9.424 K). From the Curie constant, a value of 1.81 BM for the effective magnetic moment when $T \to \infty$ has been calculated. The observed antiferromagnetic interaction is much weaker than that for $[Cu_2(biim)_2(5tpO)_2(H_2O)](ClO_4)_2 \cdot 5.5H_2O$ [15], compound with two triazolopyrimidine bridges and also much weaker than that expected for a dinuclear compound with two hydroxydo bridges and a Cu–O–Cu angle like that present in compound **6** [34].

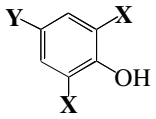
Table 1
Chemical structures and abbreviations of salicyl derivatives examined



Ligand	X	Y
Salicylic acid (**Ac**)	–COOH –H	–H
Salicyl alcohol (**Ol**)	$-CH_2OH$ –H	–H
2,6-Bis(hydroxymethyl)-*p*-cresol (**LMe**)	$-CH_2OH$ $-CH_2OH$	$-CH_3$
3,5-Bis(hydroxymethyl)-4-hydroxybenzoic acid (**LAc**)	$-CH_2OH$ $-CH_2OH$	–COOH

2.2. Preparation of 3,5-bis(hydroxymethyl)-4-hydroxybenzoic acid (*LAc*) and *LAc* loaded resin

The 3,5-bis(hydroxymethyl)-4-hydroxybenzoic acid ethyl ester was prepared according to the literature methods [21–23]. A mixture of 4-hydroxybenzoic acid ethyl ester (50.0 g, 0.301 mol), formaldehyde (63 cm^3 of 37% solution in water, 0.72 mol) and NaOH (13.8 g, 0.331 mol) was heated at 40 °C for 11 days in water (190 cm^3), and then, it was acidified with 7% aqueous HCl. Filtration and recrystallization from a mixed solvent of benzene and ethanol afforded the 3,5-bis(hydroxymethyl)-4-hydroxybenzoic acid ethyl ester as a yellow powder. The powder (30 g, 0.14 mol) and KOH (32 g, 0.48 mol) were dissolved in 150 cm^3 of water and heated at 80 °C for half a day. The reaction mixture was allowed to cool, acidified with 35% aqueous HCl, and filtered off. The product was washed with water and dried in air, yielding 18 g (0.088 mol, 63% yield) of **LAc** as a pale-yellow powder.

LAc (10.0 g, 50.5 mmol) and NaOH (2.36 g, 57.6 mmol) were dissolved in 200 cm^3 of water, and then, the solution was added to 12.0 g of a strong-base type anion-exchange resin, Dowex 1-X8 (100–200 mesh) of the Cl^- form. The mixture was shaken for one day at 25 °C in a thermostatic shaking apparatus. The resulting resin was filtered off, washed thoroughly with water, and dried in air to give 14.7 g of the **LAc** loaded resin. The amounts of the unfixed ligand were estimated from the absorbances of the reaction solution and the washings at 249 nm.

2.3. NMR measurements

The ^1H NMR spectra were recorded by a JEOL JNM-GX270 spectrometer to identify the synthesized ligand **LAc**. TMS was used as the internal reference. The ^{11}B NMR spectra were recorded by a JEOL JNM-GSX500 spectrometer with a 10 mm multinuclear probe at 25 °C located at the Center of Advanced Instrumental Analysis, Kyushu University. The standard NMR parameters were as follows: an observed frequency of 160.0 MHz, a flip angle of *ca.* 90° (36 μs), a pulse repetition time of 1 s and a spectral width of 31 kHz. Sample tubes made of PTFE (poly(tetrafluoroethylene)) were employed for the measurements. Overlapping NMR signals were resolved into individual peaks by a Lorentzian curve-fitting method. A sample solution (I = 0.10 mol dm^{-3}, KCl) containing known amounts of boric acid/borate and ligand was prepared. The pH of the solution was adjusted with 0.04 mol dm^{-3} acetate buffer, phosphate buffer, HEPES (2-[4-(2-hydroxyethyl)-1-piperazinyl]ethanesulfonic acid) buffer or ammonia buffer, and measured by a Horiba pH meter, Model F-22. After being allowed to stand for about 1 day, the solution was used for the ^{11}B NMR measurements. The chemical shifts were reported with respect to BF_3–OEt_2 as the external standard.

2.4. Molecular modeling calculations

Molecular modeling calculations were carried out for the complexes of boric acid with salicyl alcohol (**Ol**) and 2,6-bis(hydroxymethyl)-*p*-cresol (**LMe**). First, the molecular-mechanics (MM) method was applied for all models using MM+ method in HyperChem ver. 6.03 (Hypercube, Inc.) [24]. Semi-empirical molecular-orbital calculations were then done in a vacuum mode for the obtained structures of the complexes using the MOPAC2002 [25] of CAChe 6.1.1 version (Fujitsu Ltd., Japan) [26]. The AM1 method was employed for these calculations and the heat of formation (HOF) was evaluated. Single-point energy and optimization calculations of the complex models were then conducted by Becke's three-parameter hybrid method with LYP correlation (B3LYP) method in the GAUSSIAN98 program package [27]. The 6-31G(d) basis set was employed for all atoms.

2.5. Boric acid adsorption

The adsorption behavior of boric acid onto the **LAc** loaded resin was investigated by the batch technique. The effect of pH on the adsorption was examined as follows: An appropriate amount of the dry adsorbent was added to 20 cm^3 of an aqueous solution containing a known amount of boric acid/borate. The solution pH was adjusted with 0.02 mol dm^{-3} acetate buffer, HEPES buffer, or ammonia buffer, and with the addition of a small amount of KOH or HCl solution, which caused the ionic strength of the solution to range from 0.02 to 0.04 mol dm^{-3}. The mixture was mechanically shaken for 3–5 days at 25 °C in a thermostated water bath. The equilibrated solution was then filtered through a 0.45 μm membrane filter and the pH of the solution measured. The boron concentration in the equilibrated solution was measured by absorption spectrophotometry (SHIMADZU UV-2200) using an Azomethine H [20,28–30] or ICP-MS (Agilent 7500 c).

The column test was performed using a 1.00 cm (i.d.) × 2.86 cm column packed with the **LAc** loaded resin (1.00 g on a dry-weight basis) at 25 °C in a thermostated room. The volume of the swelled resin was 2.21 cm^3. A 10.0 mmol dm^{-3} boric acid/borate solution was continuously fed to the column at the flow rate of 0.52 cm^3 min^{-1}. Every 10 cm^3 of effluent from the column was collected and the concentration of boric acid/borate was spectrophotometrically determined. The quantity of the boron adsorbed onto the resin was calculated by subtracting the boric acid/borate concentration in the equilibrated solution from the initial concentration. The leakage of the ligand from the resin was estimated from the absorbance at 249 nm.

3. Results and discussion

3.1. Boric acid–salicylic acid system

The ^{11}B NMR chemical shifts provide direct information about the boron species formed in solution, and the relative signal intensities of the boron species are proportional to the concentration of the respective species [8–10,12,13,15]. Fig. 1 shows the ^{11}B NMR spectra for boric acid/borate solutions (pH 4) containing salicylic acid (**Ac**). Two signals due to the borate complexes with six-membered ring structures were observed at 2.9 and 3.3 ppm besides the free boric acid signal. The relative signal intensities of the complexes depend on the concentration ratio of the ligand to boric acid/borate. At pHs higher than 5, the peak at 3.3 ppm was not observed even at a high salicylic acid concentration, and the relative intensity of the peak at 2.9 ppm was independent of the solution pH in the pH range from 4 to 8 at a constant ligand to boric acid/borate concentration ratio.

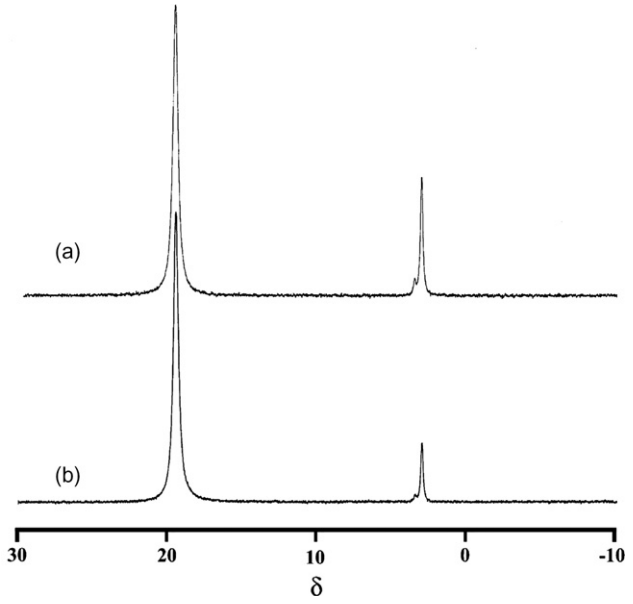


Fig. 1. ^{11}B NMR spectra for solutions containing 10.0 mmol dm^{-3} boric acid/borate and (a): 19.7 mmol dm^{-3} or (b): 9.80 mmol dm^{-3} salicylic acid at pH 4.

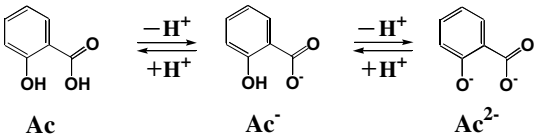
Salicylic acid has two functional groups relating to the acid dissociation reactions expressed as follows:

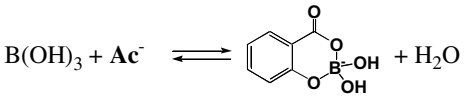


(1)

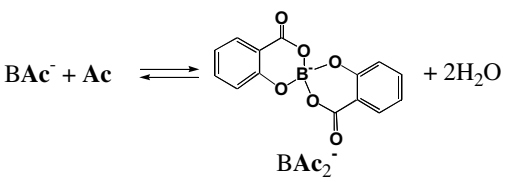
$$K_{a1(\mathbf{Ac})} = [H^+][\mathbf{Ac}^-]/[\mathbf{Ac}] \quad (2)$$

$$K_{a1(\mathbf{Ac})} = [H^+][\mathbf{Ac}^{2-}]/[\mathbf{Ac}^-] \quad (3)$$

The acid dissociation constants of the salicylic acid, $K_{a1(\mathbf{Ac})}$ and $K_{a2(\mathbf{Ac})}$, are $10^{-2.98}$ and $10^{-13.61}$ (I = 0.1 mol dm^{-3}, 25 °C), respectively [31]. The acid dissociation constant of boric acid, $K_{a(B)}$, is reported as $10^{-9.05}$ (I = 0.1 mol dm^{-3}, 25 °C) [3]. Considering the acid dissociation reactions of the respective species, almost all of the salicylic acid is present as $\mathbf{Ac}^-$ in Eq. (1) and the free boron as $B(OH)_3$ under the conditions that only one complex peak was observed at 2.9 ppm in the ^{11}B NMR spectra. On the other hand, another peak at 3.3 ppm appeared at a lower pH where salicylic acid exists as both $\mathbf{Ac}^-$ and **Ac** species. These results can be explained by two complexation reactions. One is the reaction of boric acid with the deprotonated salicylic acid, $\mathbf{Ac}^-$, to form the 1:1 monochelate complex which gives the signal at 2.9 ppm. The other is the condensation reaction between the 1:1 monochelate complex and the fully protonated salicylic acid, **Ac**, to yield the 1:2 bischelate complex which gives the signal at 3.3 ppm.



(4)



(5)

The formation constants are then defined by Eqs. (6) and (7), respectively.

$$K_{f(\mathbf{BAc})} = [\mathbf{BAc}^-]/([B(OH)_3][\mathbf{Ac}^-]) \quad (6)$$

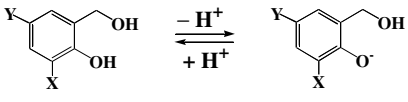
$$K_{f(\mathbf{BAc2})} = [\mathbf{BAc}_2^-]/([\mathbf{BAc}^-][\mathbf{Ac}]) \quad (7)$$

The deprotonated salicylic acid has a carboxy group with a strong nucleophilicity and the trigonal planar boric acid has an empty orbital to accept an electron pair from the ligand. Therefore, boric acid accepts an electron pair through the nucleophilic attack of the deprotonated carboxy group, followed by the condensation reaction with the phenolic hydroxy group of the ligand to form the 1:1 monochelate complex. The monochelate complex then only reacts with the fully protonated salicylic acid through the condensation reaction to give the 1:2 bischelate complex and two water molecules. The formation constants were estimated from the ^{11}B NMR signal intensity data. The calculated values of $K_{f(\mathbf{BAc})}$ and $K_{f(\mathbf{BAc2})}$ were constant at $10^{1.05 \pm 0.01}$ and $10^{2.15 \pm 0.03}$, respectively (Table 2).

When boric acid/borate reacts with polyhydroxy compounds to form borate complexes with six-membered ring structures, the 1:1 monochelate complex gives a signal around 1.1 ppm, and the 1:2 bischelate one gives a new peak around 0.5 ppm [12,13,15]. The chemical shifts in both the monochelate and bischelate complexes with salicylic acid are lower field values compared to the corresponding complexes in the polyol systems. Furthermore, the bischelate complex gave the lower field signal relative to the monochelate one in contrast to the polyol systems. The aromatic ring of the salicylic acid should slightly decrease the electron density of the boron atom in the complex *via* the oxygen atom, which brings about the deshielding effect. Such phenomena were also observed for the complexation of boric acid with salicyl alcohol derivatives as will be shown later.

3.2. Boric acid–salicyl alcohol derivative system

Salicyl alcohol derivatives have two different kinds of hydroxy groups; *i.e.*, alcoholic and phenolic hydroxy groups. The alcoholic hydroxy group is always available for the condensation reaction with the hydroxy group of the boron species. The phenolic hydroxy group is available not only for the condensation reaction, but also for the nucleophilic attack on the empty orbital of boric acid. The acid dissociation constants of the salicyl alcohol derivatives were potentiometrically determined to be $10^{-9.54}$ for the salicyl alcohol (**Ol**), $10^{-9.44}$ for 2,6-bis(hydroxymethyl)-*p*-cresol (**LMe**) and $10^{-8.57}$ for 3,5-bis(hydroxymethyl)-4-hydroxybenzoic acid (**LAc**) as shown in Table 2.



(8)

Table 2
^{11}B NMR chemical shifts and formation constants of boric acid complexes with salicyl derivatives (I = 0.10 mol dm^{-3}, KCl, 25 °C)

Ligand	pK_{a1}	pK_{a2}	Complex	δ	log K_f
Salicylic acid (**Ac**)	2.98*	13.61*	$\mathbf{BAc}^-$	2.9	1.05 ± 0.01
			$\mathbf{BAc}_2^-$	3.3	2.15 ± 0.03
Salicyl alcohol (**Ol**)	9.54		$\mathbf{BOl}^-$	1.6	3.60 ± 0.01
			$\mathbf{BOl}_2^-$	1.8	1.50 ± 0.06
2,6-Bis(hydroxymethyl)-*p*-cresol (**LMe**)	9.44		$\mathbf{BLMe}^-$	1.7	4.23 ± 0.03
			$\mathbf{B(LMe)}_2^-$	1.9	2.45 ± 0.10
3,5-Bis(hydroxymethyl)-4-hydroxybenzoic acid (**LAc**)	4.20	8.57	$\mathbf{BLAc}^{2-}$	1.8	3.74 ± 0.04
			$\mathbf{B(LAc)}_2^{3-}$	2.0	2.42 ± 0.09

* Data from Ref [29].

In addition to the phenolic hydroxy group, **LAc** has a carboxy group for **Y**, and the acid dissociation constant was determined to be $10^{-4.20}$ (Table 2). Considering the acid dissociation reactions of the respective species, it is expected that boric acid forms 1:1 monochelate and 1:2 bischelate complexes with these salicyl alcohol derivatives as follows:

$$B(OH)_3 + \mathbf{L}^- \rightleftharpoons \mathbf{BL}^- + H_2O \quad (9)$$

$$\mathbf{BL}^- + \mathbf{L} \rightleftharpoons \mathbf{BL}_2^- + 2H_2O \quad (10)$$

Boric acid would accept the electron pair through the nucleophilic attack of the deprotonated phenolic hydroxy groups, followed by the condensation reaction with the alcoholic hydroxy group of the ligand to form the 1:1 monochelate complex as expressed by Eq. (9). The monochelate complex should then react with the protonated salicyl alcohol moieties through the condensation reaction to give the 1:2 bischelate complex and two water molecules as expressed by Eq. (10).

The ^{11}B NMR measurements were performed for the boric acid solutions containing **Ol**, **LMe** or **LAc**. As an example, the NMR spectra for the salicyl alcohol are shown in Fig. 2. Two signals due to complexes were observed at 1.8–1.6 ppm and 2.0–1.8 ppm for all the examined salicyl alcohol derivatives. In the same way as that for the salicylic acid system, the higher and lower field signals were assigned to the 1:1 monochelate and 1:2 bischelate complexes, respectively. The formation constants of the 1:1 monochelate and 1:2 bischelate complexes were calculated using the equilibrium concentrations estimated from the ^{11}B NMR signal intensities. The evaluated formation constants are summarized in Table 2 together with the chemical shift values of the chelate complexes. Both bis(hydroxymethyl)phenol derivatives (**LMe** and **LAc**) form highly stable complexes in the salicyl derivatives examined. The overall formation constants of the 1:2 bischelate complexes for **LMe** and **LAc** are comparable to those of the most stable bischelate complexes reported so far (approximately 10^6) [20,32].

Even if the fact that the bis(hydroxymethyl)phenol derivatives have two hydroxymethyl groups available for the chelate complex formation at the ortho position is considered, the stabilities of the complexes are too high compared to the salicyl alcohol; the statistical contribution to the $\log K_f$ value is only 0.30, however, the difference between the values estimated by the NMR method is 1.58, as shown in Table 2. In order to obtain structural and thermodynamic information, we carried out molecular modeling calculations for the 1:2 complexes of boric acid with the salicyl alcohol derivatives, **Ol** and **LMe**. The optimized structures of the 1:2 complexes are shown in Fig. 3. The bond lengths of B–O in the optimized complexes were 1.52–1.42 Å, which agreed well with the values in the Cambridge Structural Database (CSD) [33]. No appreciable difference in the bond length among the salicyl alcohol derivatives was observed. The standard enthalpy change (ΔH°) for the overall complexation (Eq. (11)) was evaluated from the estimated heat of formation as follows: $\Delta H^\circ = -178.694$ kJ/mol for $B\mathbf{Ol}_2^-$ and -194.408 kJ/mol for $B(\mathbf{LMe})_2^-$.

$$B(OH)_3 + \mathbf{L}^- + \mathbf{L} \rightleftharpoons B\mathbf{L}_2^- + 3H_2O \quad (11)$$

Molecular modeling calculations have clarified that the complexation with the bis(hydroxymethyl)phenol derivatives is highly favorable in enthalpy.

Fig. 4 shows the pH dependence of the equilibrium concentrations of the boron species in a large excess of the ligand **LAc**. In the pH range of 6–9, the −3 charged 1:2 bischelate complex prevails in the solution. This calculation provides useful information to optimize the conditions for the boron-selective adsorption utilizing the complexation between the boric acid and the ligand **LAc**.

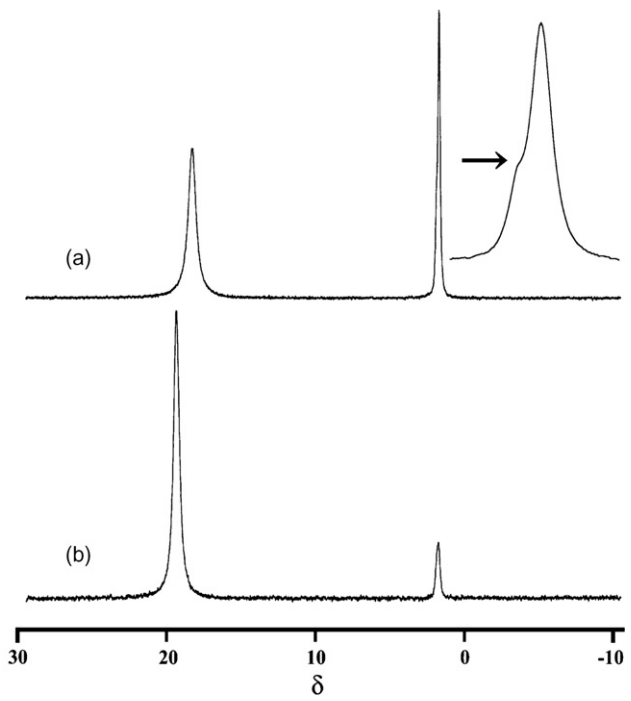


Fig. 2. ^{11}B NMR spectra for solutions containing 9.99 mmol dm^{-3} boric acid/borate and 10.0 mmol dm^{-3} salicyl alcohol at different pH ((a): pH 8.1, (b): pH 7.1).

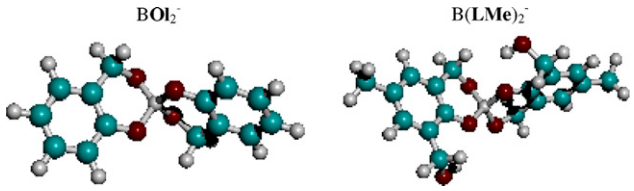

Fig. 3. Optimized structures of the 1:2 complexes of boric acid with $\mathbf{Ol}^-$ and $\mathbf{LMe}^-$.

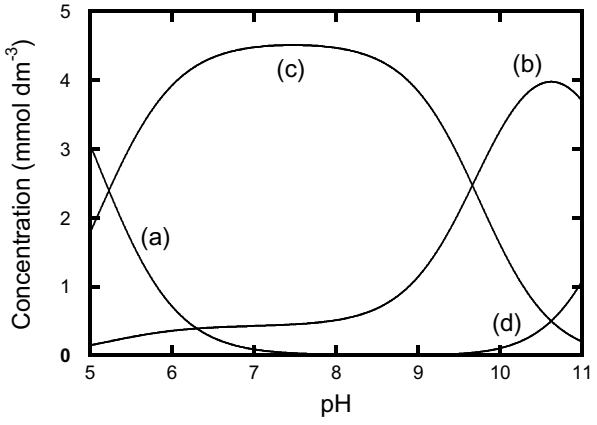

Fig. 4. pH dependent equilibrium concentrations of boron species for a solution containing 5 mmol dm^{-3} boric acid/borate and 50 mmol dm^{-3} **LAc**. (a): $B(OH)_3$; (b): $B(\mathbf{LAc})^{2-}$; (c): $B(\mathbf{LAc}_2)^{3-}$; (d): $B(OH)_4^-$.

3.3. Boron adsorption onto the **LAc** loaded anion-exchange resin

The adsorption of boric acid onto an anion-exchange resin using the ligand **LAc**–boric acid complexation was examined. The **LAc**–boric acid complexes have the negative charges of −2 for the 1:1 monochelate and −3 for the 1:2 bischelate complexes. Therefore, boric acid will be selectively adsorbed onto the strong-base type anion-exchange resin loaded with **LAc**. The boron-selective adsorbent was prepared by mixing the resin beads with the ligand solution. The amount of the ligand fixed into the resin was estimated to be 1.40 mmol g^{-1} by subtracting the amount of the ligand remaining in the solution from the initial amount.

Fig. 5 shows the pH dependence of the boron adsorption onto the **LAc** loaded resin. Boron was adsorbed all over the pH range under the experimental conditions. In particular, almost all of the boron was removed from the neutral solutions. Boron exists as the borate anion in an alkaline solution, however, the selectivity of the borate anion toward the Dowex 1-X8 resin was too low to contribute to the adsorption. The boron uptake is definitely a consequence of the formation of the chelate complexes. Fig. 6 shows the pH dependent adsorption capacities of boron and the ligand **LAc** toward an anion-exchange resin (Dowex 1-X8). The concentration ratios of boron to the ligand in the resin were almost constant, and slightly greater than 50% in the pH range of 4–10. This indicates that the boron species adsorbed onto the resin is predominantly present as the −3 charged 1:2 bischelate complex, and that the formation of the 1:1 monochelate complex makes a relatively low contribution to the overall boron adsorption. The decrease in the amounts of adsorbed boron in the weakly acidic or basic solution is due to the decrease in the conditional formation constants. In order to estimate the formation constants of the chelate complexes of boric acid with the ligand **LAc** in the adsorbent, we have carried out a Langmuir analysis for the adsorption of boron onto the **LAc** loaded resin at the optimum pH of 7. Leakage of the ligand from the resin was less than 1.6% under the experimental conditions. The quotient, $\overline{C}_B/([\overline{B(OH)_3}]\overline{C}_L)$, is given by the following equation:

$$\frac{\overline{C}_B}{[\overline{B(OH)_3}]\overline{C}_L} = \frac{[\overline{B(OH)_3}] + [\overline{B(OH)_4^-}] + [\overline{B\mathbf{LAc}^{2-}}] + [\overline{B(\mathbf{LAc})_2^{3-}}]}{[\overline{B(OH)_3}]([\overline{\mathbf{LAc}^-}] + [\overline{\mathbf{LAc}^{2-}}] + [\overline{B\mathbf{LAc}^{2-}}] + 2[\overline{B(\mathbf{LAc})_2^{3-}}])} \quad (12)$$

where the upper bar refers to the resin phase, and $\overline{C}_L$ (mmol g^{-1}) and $\overline{C}_B$ (mmol g^{-1}) are the total amounts of **LAc** and boron adsorbed onto the resin on a dry-weight basis, respectively. Judging from the strong adsorbability, $[\overline{B(\mathbf{LAc})_2^{3-}}]$ is much higher than $[\overline{B(OH)_3}] + [\overline{B(OH)_4^-}] + [\overline{B\mathbf{LAc}^{2-}}]$, and therefore we can get the following equation for a low boron loading condition:

$$\frac{[\overline{B(OH)_3}]}{\overline{C}_B} = \frac{1}{\overline{\beta}_{f(\mathbf{BLAc2})}} \frac{(\overline{K}_{a2(\mathbf{LAc})} + [\overline{H^+}])^2}{\overline{K}_{a2(\mathbf{LAc})}\overline{C}_L^2[\overline{H^+}]} + 2\frac{[\overline{B(OH)_3}]}{\overline{C}_L} \quad (13)$$

where $\overline{\beta}_{f(\mathbf{BLAc2})}$ (mol^{-2} dm^6) is the overall formation constant of the 1:2 bischelate complex (the main boron species adsorbed) in the resin phase.

$$\overline{\beta}_{f(\mathbf{BLAc2})} = [\overline{B(\mathbf{LAc})_2^{3-}}]/([\overline{B(OH)_3}][\overline{\mathbf{LAc}^{2-}}][\overline{\mathbf{LAc}^-}]) \quad (14)$$

Since $B(OH)_3$ has no charge, $[\overline{B(OH)_3}]$ can be replaced with the concentration of boric acid in the equilibrated solution. According to Eq. (13), the value on the left was plotted versus $[\overline{B(OH)_3}]$. A good linear relationship was obtained as shown in Fig. 7. From the slope, we estimated the total amount of **LAc** adsorbed to be $\overline{C}_L = 1.5$ mmol g^{-1}, which agrees well with the estimated amount of 1.40 mmol g^{-1} from the absorbance change at 249 nm.

In our previous studies [34,35], the hydrogen ion concentration in an anion-exchange resin had been estimated from the ^{31}P NMR chemical shift of phosphorus oxoanions adsorbed onto the resin. A linear relationship was obtained between the pH values in the resin phase and in the equilibrated solution:

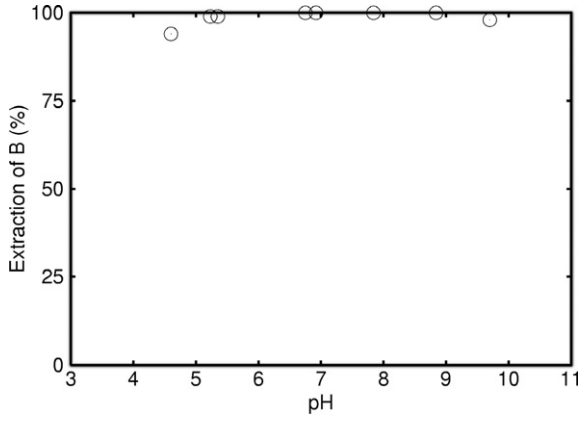

Fig. 5. Extraction percentage of boron by the anion-exchange resin presorbed with **LAc**. Solution (3.0 mmol dm^{-3} boric acid/borate): 20 cm^3; Resin: 0.20 g; Shaking time 3 d at 25 °C.

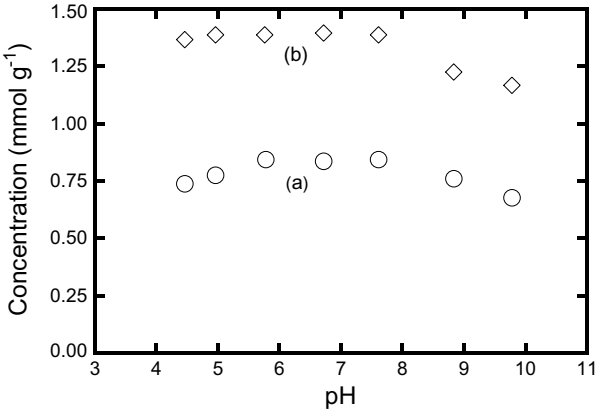

Fig. 6. Adsorption capacity of boron and the ligand **LAc** toward the anion-exchange resin as a function of pH (amounts of (a) boron and (b) ligand adsorbed onto 1 g of dried resin). Solution (30 mmol dm^{-3} boric acid/borate): 20 cm^3; Resin: 0.20 g; shaking time 3 d at 25 °C.

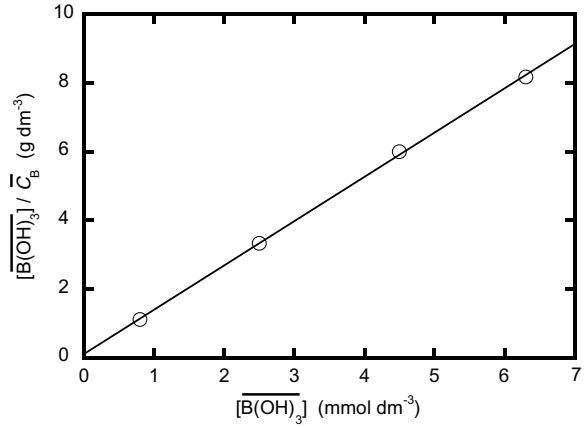

Fig. 7. Langmuir plot for the adsorption of boron onto the anion-exchange resin presorbed with **LAc** at pH 7. Solution (0.02 mol dm^{-3} HEPES): 20 cm^3; Resin: 0.20 g; Shaking time 3 d at 25 °C.

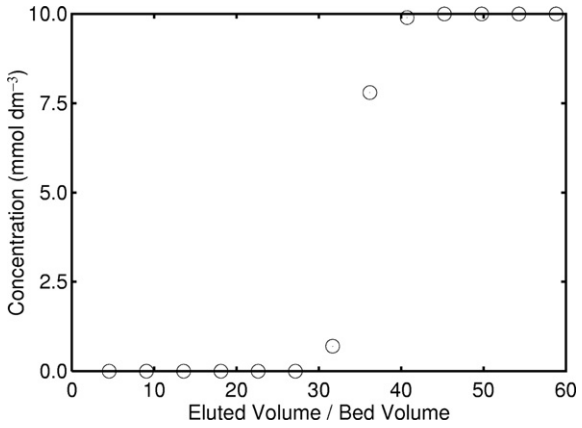

Fig. 8. Column breakthrough profile of boron for the anion-exchange resin presorbed with **LAc** at 25 °C. Flow rate: 0.5 $cm^3\ min^{-1}$; solution: 10 mmol dm^{-3} boric acid/borate; resin: 1.00 g (bed volume: 2.21 cm^3).

$$-\log[\overline{H^+}] = -a\log[H^+] + b \quad (15)$$

where $a \approx 1$ and $b = 0.52$–0.61 for the strong-base type anion-exchange resin of the Cl^- form at $I = 0.1$ mol dm^{-3} (NaCl). This relationship was interpreted as proof of the Donnan relation. We then made a rough estimate of the hydrogen ion concentration in the **LAc** loaded resin by Eq. (15) with $a = 1$ and $b = 0.5$. By assuming $\overline{K}_{a2(\mathbf{LAc})} = K_{a2(\mathbf{LAc})}$, we evaluated the overall formation constant of the 1:2 bischelate complex in the resin phase, $\overline{\beta}_{f(\mathbf{BLAc2})}$, to be $10^{5.0}$ at 25 °C from the intercept of the plot in Fig. 7. The constant in the resin phase roughly agrees with those of the salicyl alcohol derivatives in aqueous solutions (Table 2).

Fig. 8 shows a column breakthrough profile for the **LAc** loaded resin. A flow rate of 0.52 $cm^3\ min^{-1}$ is equal to a space velocity of 14 beds h^{-1}. About 0.72 mmol of boric acid, which is almost half the amount of **LAc** loaded, was removed. Therefore, the prepared resin efficiently removes boric acid/borate from aqueous solutions up to the total boron adsorption capacity at a relatively high flow rate.

4. Conclusion

The interaction of boric acid with salicylic acid, salicyl alcohol and bis(hydroxymethyl)phenol derivatives has been examined in order to develop boron-selective adsorbents having these derivatives as anchor groups. Boric acid accepts the electron pair through the nucleophilic attack of the ligand, followed by the condensation reaction, to form the 1:1 monochelate complex. The monochelate complex then reacts with the ligand through the condensation reaction to give the 1:2 bischelate complex. Bis(hydroxymethyl)phenol derivatives form highly stable chelate complexes among the examined salicyl derivatives. The anion-exchange resin presorbed with 3,5-bis(hydroxymethyl)-4-hydroxybenzoate had a strong adsorbability of boron over a wide pH range. The adsorbent quantitatively removes boron up to approximately half the amount of the ligand loaded onto the resin. The boron species adsorbed onto the resin is predominantly present as the −3 charged 1:2 bischelate complex. The formation constant of the 1:2 bischelate complex with 3,5-bis(hydroxymethyl)-4-hydroxybenzoate in the resin phase was estimated to be $\overline{\beta}_{f(\mathbf{BLAc2})} = 5.0$, which almost agreed with those of the salicyl alcohol derivatives in aqueous solutions. Polyalcohol compounds interact with borate, therefore, functional groups, such as *N*-methyl-glucamine, contribute to the boron uptake from a slightly alkaline solution with the highest degree of efficiency [1–4]. On the contrary, in the bis(hydroxymethyl)phenol derivative system, the optimum pH for the boron adsorption was in the neutral range, so that the presorbed resin will be suitable for the adsorption and/or removal of boron from natural water without any troublesome pretreatment.

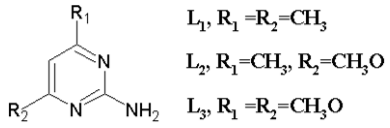

Chart 1. Structural drawings of ligands L_1–L_3.

and $[Ag(L_3)(ClO_4)]_n$ [L_1 = 2-amino-4,6-dimethylpyrimidine; L_2 = 2-amino-4-methoxy-6-methylprimidine; L_3 = 2-amino-4,6-dimethoxyprimidine]. The research results indicate that the nature of counter anions and the ligands have great influence on the formation and structure of metal–organic frameworks.

2. Experimental

2.1. Caution!

Perchlorate salts in the presence of organic ligands are potentially explosive and heating has to be avoided. Only small amounts of the materials should be prepared, and handled with care.

2.2. Materials and instruments

All starting materials were of reagent quality and were obtained from commercial sources without further purification. Infrared spectra were recorded on a Nicolet AVATAT FT-IR360 spectrometer as KBr pellets in the frequency range 4000–400 cm^{-1}. The elemental analyses (C, H, N contents) were determined on a CE instruments EA 1110 analyzer. Photoluminescence measurements were performed on a Hitachi F-4500 fluorescence spectrophotometer with solid powder on a 1 cm quartz round plate at room temperature.

2.3. Synthesis of complexes

2.3.1. Synthesis of complex $[Ag(L_1)(CF_3SO_3)(H_2O)]_n$ (**1**)

A methanol solution (5 ml) of L_1 (47 mg, 0.5 mmol) was slowly diffused into an aqueous solution (5 ml) of silver trifluoromethylsulfonate $AgCF_3SO_3$ (130 mg, 0.5 mmol) in a test tube. Colorless rod-like crystals of **1** were formed at the interface of the solvent in three weeks and were obtained in 55% yield. *Anal.* Calc. for $AgC_7H_{11}N_3O_4F_3S$: C, 21.12; H, 2.78; N, 10.55. Found: C, 21.19; H, 2.70; N, 10.62%. IR (cm^{-1}): 3421 (s), 3331 (m), 3171 (br), 1656 (m), 1589 (m), 1467 (m), 1384 (m), 1285 (s), 1254 (s), 1164 (m), 1040 (s), 950 (m), 825 (m), 794 (m), 638 (m), 554 (m), 520 (m).

2.3.2. Synthesis of complex $[Ag_4(L_1)_4(CF_3CO_2)_4]_n$ (**2**)

The synthesis of **2** was similar to that of **1**, but with silver trifluoroacetate $AgCF_3CO_2$ (0.5 mmol) instead of $AgCF_3SO_3$. Colorless crystals of **2** were obtained in 67% yield. *Anal.* Calc. for $Ag_4C_{32}H_{32}N_{12}O_8F_{12}$: C, 33.04; H, 2.77; N, 14.45. Found: C, 33.07; H, 2.71; N, 14.50%. IR (cm^{-1}): 3396 (s), 3301 (m), 1685 (s), 1654 (m), 1595 (m), 1569 (m), 1467 (m), 1431 (m), 1391 (m), 1366 (w), 1207 (s), 1134 (m), 1039 (m), 985 (w), 927 (w), 838 (m), 804 (m), 723 (m), 567 (m), 547 (m), 467 (w).

2.3.3. Synthesis of complex $[Ag_2(L_1)_4(ClO_4)_2]$ (**3**)

To a solution of silver perchlorate $AgClO_4$ (208 mg, 1 mmol) in water (3 ml) was added a solution of L_1 (123 mg, 1 mmol) in a water–methanol (5:5 v/v, 10 mL) at 60 °C. A small amount of white precipitate was removed from the resulting solution. X-ray-quality crystals of **3** as colorless block-like were obtained by slow evaporation at room temperature after one week. They were washed with a small volume of cold methanol and diethyl ether. Yield: ca. 65% yield. *Anal.* Calc. for $Ag_2C_{24}H_{36}N_{12}O_8Cl_2$: C, 31.77; H, 4.00; N, 18.53. Found: C, 31.84; H, 3.94; N, 18.63%. IR (cm^{-1}): 3396 (s), 3313 (m), 3138 (br), 1654 (s), 1594 (m), 1568 (m), 1475 (m), 1453 (m), 1384 (s), 1233 (m), 1026 (m), 961(m), 834 (m), 825 (m), 788 (m), 729 (m), 567 (m), 547 (m), 474 (m).

2.3.4. Synthesis of complex $[Ag(L_2)(ClO_4)]_n$ (**4**)

The synthesis of **4** was similar to that of **3**, but with ligand L_2 (1 mmol) instead of ligand L_1. Colorless crystals were obtained in 50% yield. *Anal.* Calc. for $AgC_6H_9N_3O_5Cl$: C, 20.80; H, 2.62; N, 12.13. Found: C, 20.85; H, 2.55; N, 12.08%. IR (cm^{-1}): 3367 (s), 3314 (w), 3183 (m), 3023 (m), 1637 (s), 1585 (s), 1458 (m), 1384 (s), 1346 (m), 1204 (m), 1152 (m), 1023 (m), 938 (m), 839 (w), 798 (m), 782 (m), 646 (m), 585 (w), 546 (w).

2.3.5. Synthesis of complex $[Ag(L_3)(ClO_4)]_n$ (**5**)

The synthesis of **5** was similar to that of **3**, but with ligand L_3 (1 mmol) instead of ligand L_1. Colorless crystals were obtained in 60% yield. *Anal.* Calc. for $AgC_6H_9N_3O_6Cl$: C, 22.04; H, 2.77; N, 12.85. Found: C, 21.85; H, 2.90; N, 12.92%. IR (cm^{-1}): 3413 (m), 3312 (m), 3192 (m), 3025 (m), 1637 (s), 1581 (s), 1452 (m), 1384 (s), 1215 (m), 1151 (m), 1102 (m), 1047 (m), 928 (m), 794 (m), 786 (m), 671 (m), 564 (w), 512 (w).

2.4. X-ray crystallography

Single crystals of these complexes with appropriate dimensions were mounted on a glass fiber and used for data collection. Data was collected on a Bruker-AXS CCD diffractometer equipped with a graphite-monochromated Mo Kα radiation source (λ = 0.71073 Å) at 298 K for **1** and **2** and at 173 K for **3**–**5**. All absorption corrections were performed with the SADABS program [24a]. All the structures were solved by direct methods using SHELXS-97 [24b] and refined by full-matrix least-squares techniques using SHELXL-97 [24c]. All the non-hydrogen atoms were treated anisotropically. The positions of hydrogen atoms were generated geometrically. The crystallographic details of **1**–**5** are summarized in Table 1. Selected bond lengths and bond angles of **1**–**5** are displayed in Table 2.

3. Results and discussion

3.1. Construction

The syntheses of complexes **1**–**5** are summarized in Scheme 1 in the Supplementary data. The formation of the products is not significantly affected by changes of the reaction mole ratio of ligands to metal ions, and the resultant crystals are insoluble in water and common organic solvents. The reactions of L_1 with $AgCF_3SO_3$ and $AgCF_3CO_2$ yield 1D zigzag chain structure (**1**), 1D ladder network (**2**), respectively. The different structure of complexes **1**–**2** is caused by the difference in coordination ability and geometry of the counter anions. In contrast to the bridge coordination of $CF_3CO_2^-$ anions in **2**, weak mono-coordination of $CF_3SO_3^-$ anions occurred in **1**. The trifluoromethylsulfonate anions locate to the one side of the 1D chain and link the adjacent 1D chains to form a 1D ladder structure *via* O(w)–H···O($CF_3SO_3^-$) hydrogen bonds. On the other hand, the structures of complexes **3–5** are directed by the different ligands adopted in the reaction system: the reaction of $AgClO_4$ with L_1 yields a dimer (**3**). The reaction of $AgClO_4$ with L_2 leads to a 2D grid network (**4**). When L_3 is used, a 1D zigzag chain (**5**) (if the Ag···Ag interactions are excluded) different from that of **1** is obtained, which further connected into 3D framework through N–H···O intermolecular hydrogen bonds and Ag···O weak interaction. In complexes **3**–**5**,

Symmetry transformations used to generate equivalent atoms: (i), $-x+2$, $-y+1$, $-z+1$, for **3**. (i), x, $-y+1/2$, $z+1/2$; (ii), $-x+1/2$, $-y+1/2$, z, for **5**.

2-aminopyrimidyl derivatives adopt similar coordination modes, a bidentate N,N′-donor ligands binding with silver atoms, while the different substitutions of 2-aminopyrimidyl ligands in the same substitutional positions in the three complexes result in distinct structural motifs. Thus, we have reason to believe that subtle structural changes of ligands might create a tuning effect on the formation of crystal structures. Additionally, as far as certain ligand such as L_1 concerned, the structure of complexes (**1**–**3**) can be controlled by different counter anions. Furthermore, the overall architecture in complexes **1**–**5** may partly be ascribed to the N–H···O interactions between the amino groups of pyrimidyl ligands and the counter anions.

3.2. Description of crystal structures

3.2.1. Crystal structures of $[Ag(L_1)(CF_3SO_3)(H_2O)]_n$ (**1**), $[Ag_4(L_1)_4(CF_3CO_2)_4]_n$ (**2**) and $[Ag_2(L_1)_4(ClO_4)_2]$ (**3**)

To investigate the effect of counter anions on the structure of silver(I) complexes, the reactions of L_1 with $AgCF_3SO_3$, $AgCF_3CO_2$ and $AgClO_4$ were carried out, respectively, and complexes **1**–**3** were isolated. The X-ray crystallographic analysis shows that **1** crystallizes in the orthorhombic space group *Pbca* and has an infinite 1D zigzag chain structure. As depicted in Fig. 1a, the basic repeat is a distorted tetragonal four-coordinate AgO_2N_2 unit, which comprises a unidentate association to one O-atom donor from one anion $CF_3SO_3^-$, one O-atom donor from one coordinated water, and two independent pyrimidine hetero-nitrogens [Ag(1)–N(1) = 2.226(3) Å; Ag(1)–N(2) = 2.235(3) Å] in a distinctly nonlinear geometry [N(1)–Ag(1)–N(2) = 150.1(1)°] forming zigzag chains. The deviation from linear geometry is due to the weak interaction between Ag atom and O atom on the water molecule [Ag(1)–O(1w) = 2.521(3) Å]. The average Ag–N distance in **1** is agreement with those reported in literature, such as $[\{Ag(pts)\}_2(L_1)_3]_n$ [22b] and $[Ag(L_1)(NO_3)]_n$ [22h] (pts = *p*-toluenesulfonate). The anions $CF_3SO_3^-$ are weakly bonded to Ag(I) ions with Ag–O distances of 2.691(3) Å. All anions are oriented to the one side of the 1D chain. In the 1D chain, intramolecular hydrogen bonds are observed involving the amino group of the L_1 with the oxygen atoms on the coordinated $CF_3SO_3^-$ anion, and on the coordinated water molecule, respectively [2.914(4) and 2.950(4) Å for N(3)···O(1w) and N(3)···O(1A), respectively, symmetry for A: $-x + 1/2, y + 1/2, z$]. The chains in **1** are interlinked by means of intermolecular hydrogen bonds in which two coordinated water molecules of adjacent chains and one trifluoromethylsulfonate anion are involved [O(1w)···O(2) = 2.823(5), O(1w)···O(3B) = 2.764(4); symmetry code: B = $x - 1/2, y, -z + 1/2$] to generate 1D ladder structure (Fig. 1b).

Complex **2** crystallizes in the space group $P\bar{1}$ and has a 1D ladder structure. The structure of **2** with the atom labeling is displayed in Fig. 2a. Each four-coordinate Ag which adopts a slightly distorted tetrahedral geometry is coordinated by a μ_1-O of one $CF_3CO_2^-$ [2.382(5) and 2.485(5) Å for Ag(1)–O(1) and Ag(2)–O(2)], a μ_2-O of the other $CF_3CO_2^-$ [2.332(5) and 2.674(5) Å for Ag(1)–O(3) and Ag(2)–O(3)], and two bridging L_1 pyrimidine nitrogen donors, and the angle of O–Ag–O [91.4(2)° for O(3)–Ag(1)–O(1)] is responsible for the slightly distorted tetrahedral geometry of Ag^+ ions. Due to the coordination ability of the $CF_3CO_2^-$ is stronger than the $CF_3SO_3^-$, the Ag–O bond lengths in **2** are shorter than the corresponding ones in **1**, indicative of strong interactions between oxygen and silver. The most remarked feature is that the $[Ag_4(L_1)_4(CF_3CO_2)_4]$ cores in **2** are interlinked together *via* the bridging L_1 groups to generate a 1D ladder motif (Fig. 2b). In the motif, every ring of the ligands is nearly parallel to the adjacent corresponding ring and the intrachain and interchain Ag···Ag separation is 3.843 and 6.463 Å, respectively. In addition, hydrogen bonds

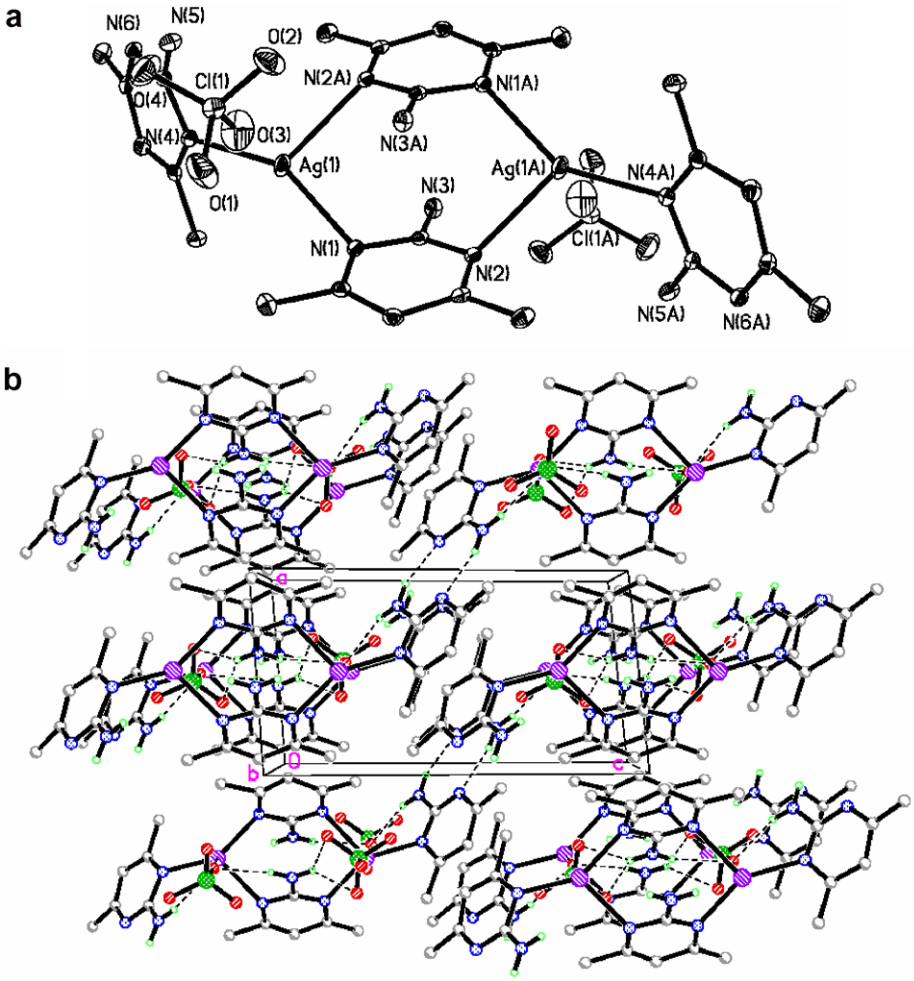

Fig. 3. (a) ORTEP drawing of **3** with 40% probability displacement ellipsoids. (b) A view of the 3D packing diagram in **3**. Hydrogen atoms in methyl and phenyl groups are omitted for clarity.

between the free amino groups on the L_1 ligands and $CF_3CO_2^-$ anions [H···N, 1.97–2.10 Å, N···O, 2.824–2.947 Å, N–H···O, 152.3–177.6°] contribute to the stabilization of the structure of **2** (Fig. S1).

Complex **3** also crystallizes in triclinic space group $P\bar{1}$. Unlike polymer **1** and **2**, **3** is a binuclear Ag^I complex. The asymmetric unit of **3** consists of one Ag^I, two L_1 ligands. Each silver(I) atom in **3** is coordinated by one nitrogen atom from η^1-L_1 and two nitrogen atoms from two different μ_2-L_1 ligands with distorted triangular coordination geometry as shown in Fig. 3a. The bond distances and bond angles around Ag1 range from 2.235(2) to 2.448(2) Å and 92.27(8)° to 147.36(9)°. These bonds distances are slightly longer than the corresponding values for **1**. It is noteworthy that two μ_2-L_1 ligands connect two Ag atoms to form an eight-membered M_2L_2 binuclear ring, rather than to form a 1D chain as observed in **1**. The Ag_2N_4 eight-member ring reveals a chair-like conformation. Each dimeric $[Ag_2(L_1)_4]$ unit is hydrogen bonded to two other units to form a 1D chain resulting from N–H···N hydrogen bonds (Fig. S2). The 1D chains further interact in the form of π–π attractions between pyrimidyl whose rings are arranged in offset face-to face mode to produce an infinite 2D layer framework structure (Fig. S3). The centroid–centroid distance of pyrimidyl in **3** is about 3.37 Å, which indicates a strong π–π stacking. An extended 3D supramolecular structure arises from further hydrogen bonds between oxygen atoms of perchlorate anions and the uncoordinated amino groups on the L_1 ligands (Fig. 3b).

3.2.2. Crystal structure of $[Ag(L_2)(ClO_4)]_n$ (**4**)

To investigate the influence of ligands on the structure of self-assembly product further, we carried out the reaction of $AgClO_4$ with ligand L_2 instead of L_1 under the same reaction conditions as **3**. A new coordination polymer **4** with a different structure was obtained. The crystallographic studies reveal that complex **4** which conforms to the space group $P2_1/n$, exists in the solid state as a 2D grid network structure and the L_2 ligand adopts the coordination mode as we predicted. Fig. 4a depicts a view with atom numbering the molecule. Each central Ag(I) cation has distorted tetragonal geometry, which is confined by two nitrogen atoms [2.257(2) and 2.213(2) Å for Ag(1)–N(1) and Ag(1)–N(2)] from two pyrimidine rings, and weakly coordinated by two oxygen atoms [Ag(1)–O(1), 2.627(3) Å; Ag(1)–O(3A), 2.639(4) Å] from two different perchlorate groups. The average Ag–N distances in **4** are comparable to those found in **1**. As shown in Fig. 4b, each

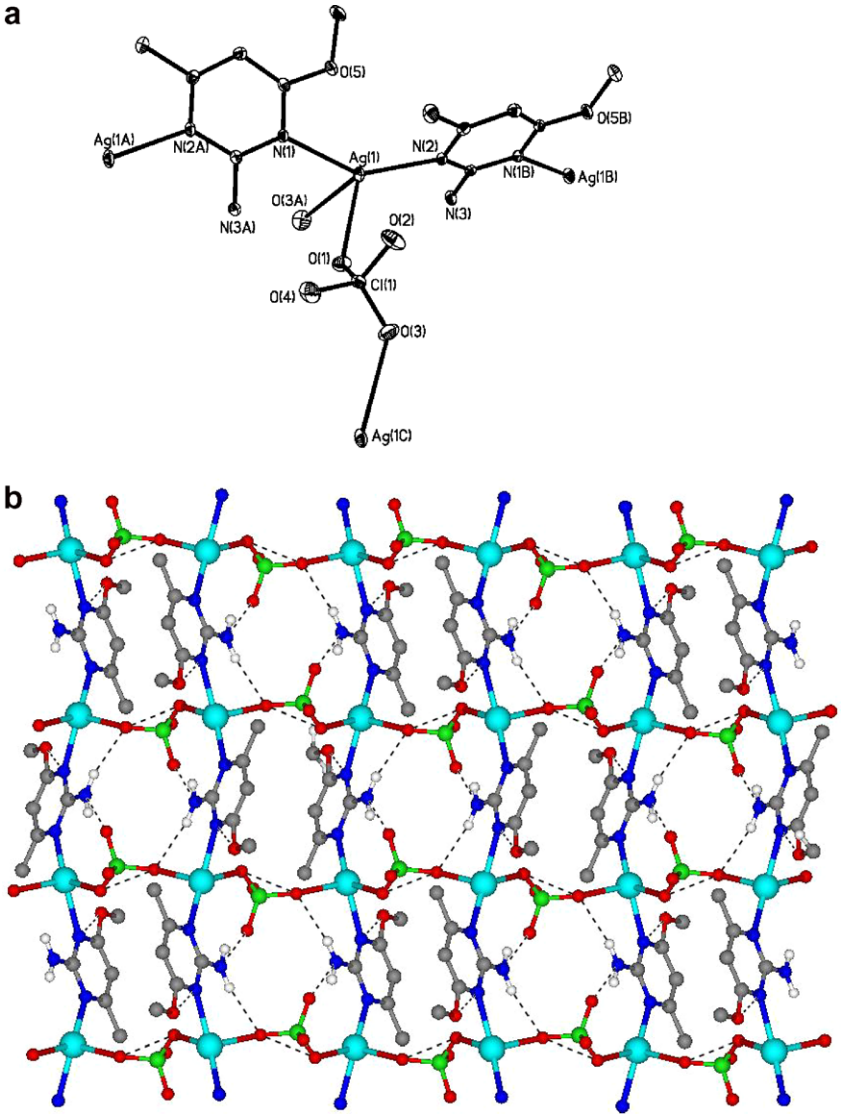

Fig. 4. (a) Crystal structure of **4** with the coordination environment around the silver(I) center (ellipsoids at 40% probability). (b) A view along the *a* axis of the 2D grid network in **4**. Hydrogen atoms in methyl, methoxy and phenyl groups are omitted for clarity. Ag stressed in bigger ball ( ).

L_2 ligand links two Ag atoms to form a zigzag chain which is different from that is described for **1** or **2** (Fig. S4). The adjacent chains are further connected by ClO_4^- groups to generate microporous metal–organic framework which exhibits intriguing tetragonal channels (Fig. 4b). The framework is further stabilized by intermolecular N–H···O hydrogen bonds where oxygen atoms of perchlorate anions serve as acceptors while hydrogen atoms of the free amino group of the L_2 ligand act as donors [2.955(3) and 3.046(3) Å for N(3)···O(4) and N(3)···O(1), respectively] (Fig. 4b). Obvious changes were observed from the structures of **3** and **4**, and the dimension of the complexes increase from 0D(**3**) to 2D(**4**). It is noteworthy that striking structural difference between **3** and **4** simply caused by a subtle difference in the ligand structure, *i.e.*, the replacement of 4-position of methyl group by methoxy group. On the basis of the above results, it may be concluded that structural major transformation between **3** and **4** may partially be attributed to steric effect of substituted groups of ligands.

3.2.3. Crystal structure of $[Ag(L_3)(ClO_4)]_n$ (**5**)

Since L_1 and L_2 ligands give distinct structures (**1**–**4**), it is of interest to examine the effect of other 2-aminopyrimidyl ligands that could possibly coordinate with silver ions. Thus when the L_3 ligand is chosen to react with $AgClO_4$ under the otherwise same conditions as **3** or **4**, a new complex **5** is obtained. The crystal of **5** conforms to the space group *Pccn* and its structure with the atom labeling is displayed in Fig. 5a. The connectivity of the ligands with metals of **5** is similar to that seen in the previous structures **1–4**. The central Ag(I) ion, which is coordinated by two N atoms [2.172(2) and 2.183(2) Å for Ag(1)–N(1) and Ag(1)–N(3B)] from two pyrimidine rings, has a distinctly nonlinear geometry [N(1)–Ag(1)–N(3B) = 167.11(6)°]. The average Ag–N distance in **5** is slightly shorter than the corresponding values for **1**. Each L_3 ligand links two Ag atoms to form a zigzag chain which is similar to that described for **4** and the adjacent chains are further connected by Ag···Ag weak metal–metal interactions to generate one-dimensional ladder structure along *a* axis (Fig. S6). The Ag···Ag separation in the proximal zigzag chains is 3.376 Å, which is slightly shorter than the summed van der Waals radius of two silver atoms (3.44 Å) [25], indicating there are weak interactions between two Ag(I) ions in different zigzag chains. The neighbored 1D ladder structures further interlinked into 3D framework through N–H···O intermolecular hydrogen bonds in the form of chair-like conformations (Fig. S7) where oxygen atoms of perchlorate anions serve as acceptors while hydrogen atoms of NH_2 groups of the pyrimidine rings act as donors: N(2)···O(4A) = 2.978(3) and N(2)···O(3B) = 2.973(3) Å [symmetry codes: (A) = *x*, $-y + 1/2$, $z-1/2$; (B) = $-x + 1$, $y + 1/2$, $-z + 3/2$] and Ag···O weak interactions (Ag···O = 2.731 Å for anion) [26] (Fig. 5b).

3.3. Photoluminescence properties

The mixed inorganic–organic hybrid coordination polymers have been investigated for fluorescence properties and for potential applications. However, owing to the intense spin–orbital cou-

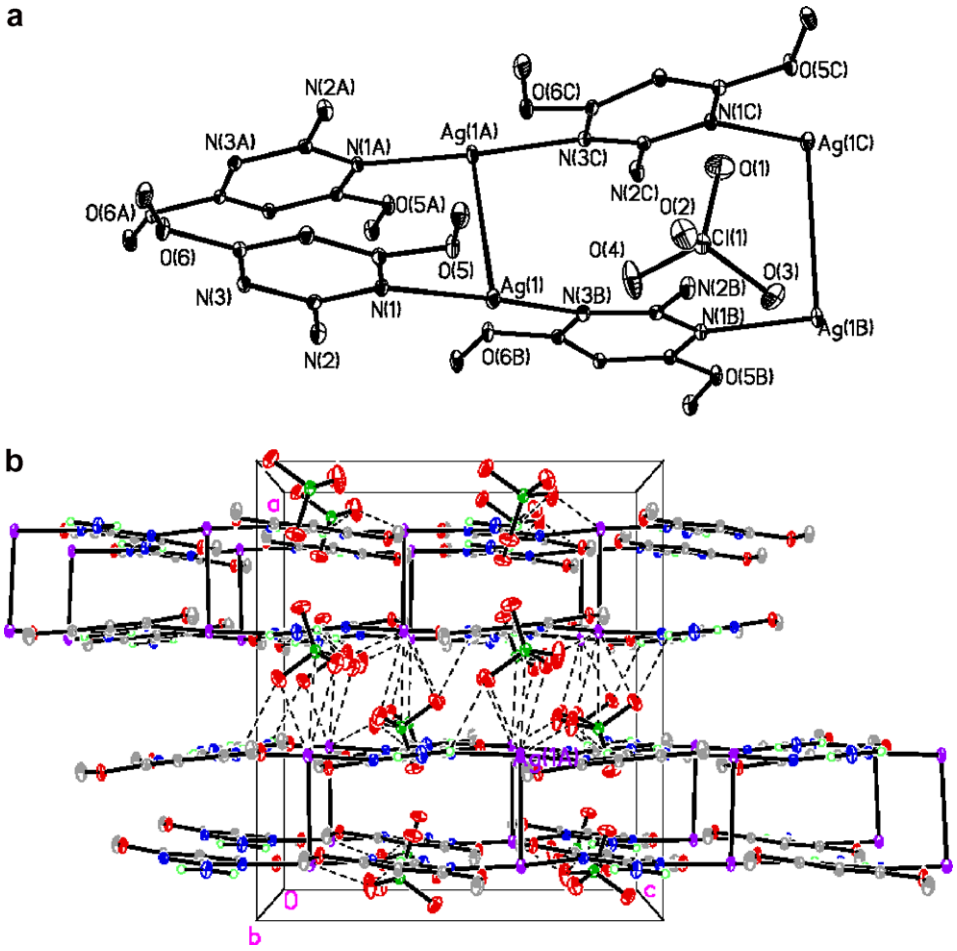

Fig. 5. (a) Local coordination around the silver atoms in **5** with the ellipsoids drawn at the 40% probability level. (b) A view of the 3D framework in **5** constructed by N–H···O hydrogen bonds, Ag···O weak interactions. Hydrogen atoms in methoxy and phenyl groups are omitted for clarity.

pling of Ag(I), most of luminescent Ag(I) complexes exhibit luminescence at low temperature [27] and Ag(I) complexes which exhibit luminescence at room temperature are few [28]. The complexes **1**–**5** reported herein represent room-temperature luminescent Ag-containing polymeric complexes [29].

The solid-state fluorescence data for both free ligands and the complexes **1–5** at room temperature are shown in Table S2. When excited at room temperature at 280 nm, complexes **1**–**5** exhibit some low-energy emission bands, which have shapes and positions similar to the free ligands L_1–L_3. The emissions are neither metal-to-ligand charge (MLCT) nor ligand-to-metal charge transfer (LMCT) in nature and probably can be assigned to the intraligand π_L—π_L^* transitions fluorescent emission (LLCT) because very similar emissions are also observed for the free ligands.

4. Conclusions

In this study, five new complexes with interesting structural motifs have been successfully synthesized from the various rigid ligands L_1, L_2, and L_3 and varied silver salts. The analysis of the crystallographic data of **1–5** clearly shows that the overall architecture of the crystals is not only controlled by the nature of the rigid ligands present in the moiety, but by different counter anions. To the best of our knowledge, the ligands L_2 and L_3 are for the first time employed in coordination chemistry of metal silver. Table S3 shows the cation–anion interaction, metal geometry and structure in complexes **1–5**. Moreover, the photoluminescent properties of free ligands L_1–L_3, and complexes **1**–**5** have been examined.

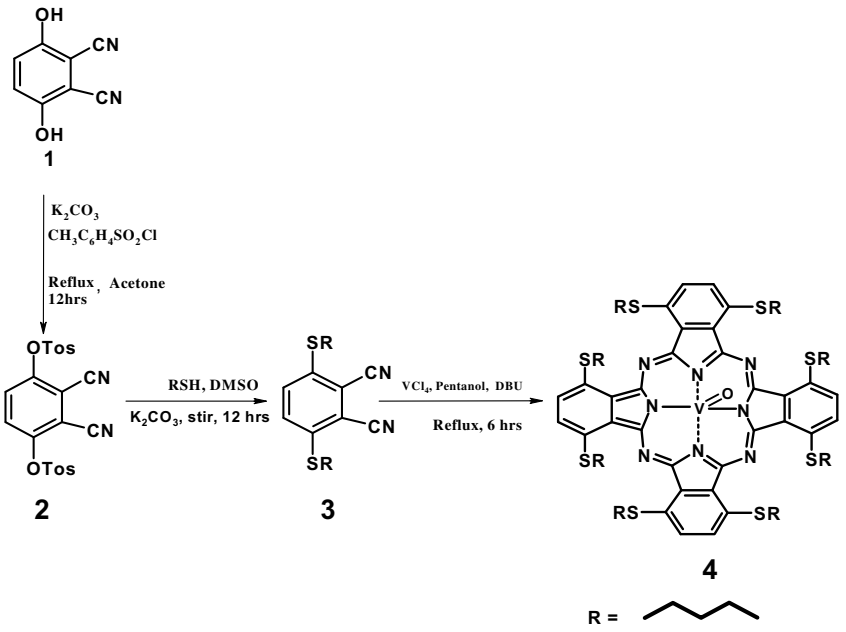

Scheme 1. Synthesis of OVPc derivative **4**.

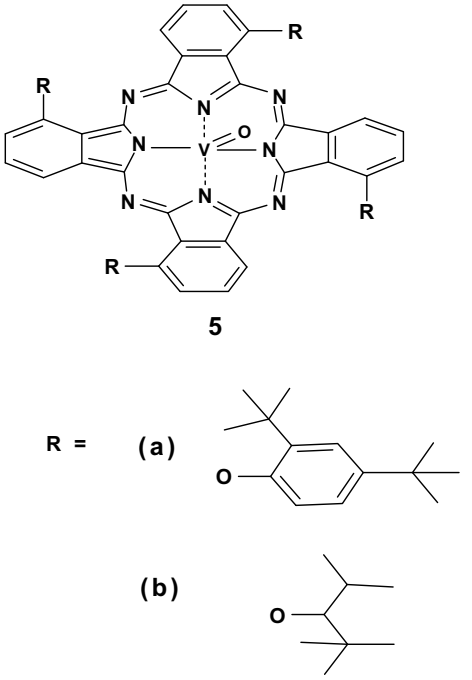

Fig. 1. Molecular structure of reported OVPc [21].

2. Experimental

2.1. Materials

Vanadium tetrachloride, dimethylsulfoxide (DMSO), 1-pentanethiol, 1,8-diazabicyclo{5.4.0}-undec-7-ene(DBU), tetrabutylammonium tetrafluoroborate ($TBABF_4$) and 1-pentanol were purchased from Sigma Aldrich. Potassium carbonate, deuterated chloroform ($CDCl_3$), 2,3-dicyanohydroquinone, *p*-toluenesulfonyl chloride, chloroform ($CHCl_3$) and dichloromethane (DCM), tetrahydrofuran (THF), toluene were procured from Merck. Solvents were dried and/or distilled before use. Column chromatography was performed on Silica Gel 60 (0.04–0.063 mm). Thin layer chromatography was performed on Silica Gel 60P F_{254}.

2.2. Electrochemical methods

Cyclic (CV) and square wave (SWV) voltammetry data were obtained with Autolab potentiostat PGSTAT 30 (Eco Chemie, Utretch, The Netherlands) driven by the General Purpose Electrochemical Systems data processing software (GPES, software version 4.9, Eco Chemie), using a three-electrode set-up with glassy carbon electrode (GCE, 3 mm diameter) as a working electrode, platinum wire as counter electrode and Ag|AgCl wire as pseudo-reference electrode. The potential response of Ag|AgCl pseudo-reference in aqueous conditions was less than the Ag|AgCl (3 M KCl) by 0.015 ± 0.003. Electrochemical experiments were performed in dry DCM containing tetrabutylammonium tetrafluoroborate ($TBABF_4$) as a supporting electrolyte. Prior to scans, the working electrode was polished with alumina paste on a Buehler felt pad, followed by washing with deionised water and rinsing with DCM. Square wave parameters were: step potential 5 mV; amplitude 20 mV at a frequency of 25 Hz. Spectroelectrochemical data were obtained using a home made optically transparent thin-layer electrochemical (OTTLE) cell which was connected to a Bioanalytic Systems (BAS) CV 27 voltammograph.

2.3. Equipment

UV/Vis spectra were recorded on a Cary 50 UV/Vis/NIR spectrophotometer. IR (KBr) was recorded on a Perkin–Elmer spectrum 2000 FTIR spectrometer. Elemental analyses were also performed at University of Cape Town. Low resolution mass spectra electron impact (EIMS) were recorded on a Finnigan MAT GCQ mass spectrometer at 70 eV for complexes **2** and **3**. For complex **4** low resolution atmospheric pressure chemical ionisation (APCI) mass spectra were recorded on a Finnigan MAT LCQ ion trap mass spectrometer equipped with XCALIBUR software.

2.4. Synthesis

For the synthesis of phthalonitriles (**2** and **3**), a procedure similar to that reported in literature [25,26] was employed with slight modification as follows:

2.4.1. 3,6-Bis(4′-methylphenylsulfonyloxy) phthalonitrile (**2**)

p-Toluenesulfonyl chloride (5.16 g, 27 mmol) was added to a mixture of 2,3-dicyanohydroquinone (**1**, 2 g, 12.5 mmol) and potassium carbonate (6.9 g, 50 mmol) in acetone (15 ml). The mixture was heated to reflux for 2 h. Thin layer chromatography (TLC) was performed to determine the consumption of compound **1**. The mixture was cooled to room temperature and poured into water (40 ml). The mixture was stirred for 1 h in water. The light brown product was filtered and oven dried. Yield: 4.51 (79%) IR [(KBr) ν_{max}/cm^{-1}]: 3432, 3239, 3085, 2243, 2226 (CN), 1504, 1449, 1315, 1279, 1204, 1174, 1142, 1021, 1004, 979, 934, 847, 749, 694, 638, 614. LREI-MS *m*/*z*: Calc. 469; found [M^+] 468.

2.4.2. 3,6-Di(pentathio)-4,5-dicyanobenzene (**3**)

1-Pentathiol (2.39 g, 22.9 mmol) was dissolved in DMSO under a nitrogen atmosphere and 3,6-bis(4′-methylphenylsulfoloxy phthalonitrile) (**2**, 4.30 g, 9.18 mmol) was added. The mixture was stirred for 15 min and finely ground anhydrous potassium carbonate (5.07 g, 36.7 mmol) was added portion-wise for 2 h while stirring. The mixture was stirred under a nitrogen atmosphere for 12 h. Water was added and the aqueous phase extracted using chloroform (3 × 50 ml). The extracts were further treated with 5% sodium carbonate solution (2 × 250 ml). The solution was further treated with water (2 × 250 ml) and the solvent was evaporated off using a rotavapor. The product was recrystallised from ethanol. Yield: 2.19 g (71.7%). IR [(KBr)ν_{max}/cm^{-1}]: 3084, 2951, 2930, 2864, 2378 (S–C), 2225 (C≡N), 1444, 1283, 1202, 1181, 1173, 1145, 877, 847, 827, 725, 547, 447. ^{1}H NMR ($CDCl_3$): δ, ppm 7.49 (2-H, s, Ar-H), 3.02–2.99 (4-H, t, $-CH_2$), 1.71–1.63 (4-H, m, $-CH_2$) 1.46–1.37 (4-H, m, $-CH_2$), 1.36–1.28 (4-H, m, $-CH_2$), 0.91–0.88 (6-H, t, $-CH_3$). LREI-MS *m*/*z*: Calc. 333; found [M^+] 332.

2.4.3. 1,4,8,11,15,18,22,25-Octapentylthiophthalocyaninato vanadium(IV) oxide (**4**)

A solution of 3,6-di(pentathio)-4,5-dicyanobenzene (**3,** 0.4 g, 1.20 mmol) in 1-pentanol (3.5 ml) was refluxed under a nitrogen atmosphere and vanadium(IV) tetrachloride (0.069 g, 0.40 mmol) was added. After the addition of DBU (0.13 ml, 0.857 mmol) heating under reflux was continued for 6 h. The mixture was cooled and column chromatography over silica was done (eluent: chloroform).

Yield: 0.24 g (42%). UV–Vis (DCM): λ_{max} (nm) (log ε) 344 (3.96) 754 (3.46) 850 (4.24). IR [(KBr) ν_{max}/cm^{-1}]: 2955, 2916, 2853, 2363 (S–C), 1555, 1456, 1357, 1306, 1281, 1221, 1208, 1186, 1147, 1112, 1075, 992, 925 (V=O), 810, 794, 775, 759, 741, 584, 533. ^{1}H NMR (600 MHz, $CDCl_3$): δ, ppm 7.42 (8H, s, Ar-H), 2.93 (16H, t, $-CH_2$), 1.75 (16H, m, $-CH_2$), 1.47 (16H, m, $-CH_2$), 1.35 (16H, m, $-CH_2$), 0.90 (24H, t, $-CH_3$). *Anal.* Calc. for $C_{72}H_{96}N_8S_8OV$: C, 61.90; H, 6.92; N, 8.02; S, 18.36. Found: C, 61.53; H, 7.04; N, 7.56; S, 18.25%. LRAPCI-MS *m*/*z*: Calc. for $C_{72}H_{96}N_8S_8OV$: 1396.9; found [M^+] 1396.

3. Results and discussion

3.1. Spectroscopic characterisation

The synthesised complex **4** is soluble in solvents such as DCM, $CHCl_3$, THF and toluene. A good yield (42%) for the synthesised **4** was obtained. The new compound was characterised using IR, NMR, UV/Vis and mass spectra and by elemental analysis. The disappearance of the sharp C≡N vibration at ~2225 cm^{-1} confirmed the cyclotetramerisation of the phthalonitrile **3** and typical V=O stretch appearing as a medium band at 925 cm^{-1}. ^{1}H NMR spectrum of complex **4** is simple since the complex is octa substituted hence has isomeric purity. The ^{1}H NMR spectrum showed a singlet integrating for 8 observed at 7.42 ppm, for the Pc ring, and the methylene and methyl proton shifts belonging to the thio-alkyl side chain were clearly observed in the ^{1}H NMR spectrum and integrated correctly. The mass spectra of complex **4** showed a molecular ion peak at *m*/*z* 1396.

The UV/Vis spectrum of the complex **4** is shown in Fig. 2. It is known that red-shifting of absorption spectra is a function of the solvent's refractive index [27], and Table 1 also shows a shift to the red with increase in the solvents' refractive indexes. The Q band is observed at 850 nm in dichloromethane. A broad band between 500 and 600 is probably due to charge transfer. Bands in this region for neutral MPc complexes have been shown to be of charge transfer in nature [28]. The colour of the synthesised complex is purple. The observed colour is due to the fact that the Q band is moved out of the red region of the visible spectrum, which is the region that normally determines the colour of MPcs. The large red shift of the Q band is due to the large electron-donating ability of the sulfur groups. The Q band of complex **4** is red shifted by 160 nm and 209 nm (Table 1) compared to unsubstituted OVPc and $OVPcF_{16}$, respectively, making it the most highly red-shifted OVPc derivative, absorbing in the near infrared region. The reported complexes **5a** and **5b** contained oxygen rather than sulfur bridges to the alkyl substituent, and as stated above oxo complexes are less red shifted (larger HOMO–LUMO gap) than thiol complexes which are more red shifted (smaller HOMO–LUMO gap).

The red-shifting to near infrared region in MPc complexes is highly dependent on the central metal. Alkyl thio MPc containing

transition metals such as Fe and Co, do not show the NIR absorption and they remain blue or green in colour [29–31]. However alkylthio substituted Mn(III)Pc (α or β substituted) and Ti(IV)Pc complexes show red shifting [32–34]. Mn(III)Pc and Ti(IV)Pc complexes octasubstituted with pentylthio groups gave Q band maxima at 893 and 808 nm, respectively in dichloromethane. Mn(III)Pc complex shows a red shifted Q band (with a brown solution) even in the absence of substituents [34], while Mn(II)Pc does not show red-shifting and is blue or green in colour depending on substituents. On electrochemical reduction of Mn(III)Pc or Ti(IV)Pc derivatives, a blue shift of the Q band is observed [32–34], with a change of colour to green or blue. The observation of NIR absorption for complex **4**, containing V(IV) central metal, suggests that NIR absorption is favoured for MPc complexes containing central metals in a high oxidation state. The red shift is a result of the lowering of the HOMO–LUMO gap, by either destabilising the HOMO or stabilising the LUMO by the central metal.

Complex (**4**) did not show aggregation and Beer's law was obeyed for concentrations lower than 3×10^{-5} M.

3.2. Voltammetric and spectroelectrochemical characterisation

The cyclic (CV) and square wave (SWV) voltammetries of **4** were performed in de-aerated DCM containing $TBABF_4$ as electrolyte, Fig. 3. Two oxidations and three reduction couples are observed. This is one of the few OVPc complexes which show two oxidation peaks [21]. The half-wave potentials ($E_{1/2}$) for complex **4** are summarised in Table 2 together with reported data for some OVPc derivatives. The redox processes for complex **4** are labelled **I** ($E_{1/2}$ = 0.59 V), **II** ($E_{1/2}$ = 0.97 V), **III** ($E_{1/2}$ = −0.58 V), and **IV** ($E_{1/2}$ = −0.93 V), **V** ($E_{1/2}$ = −1.18 V), versus Ag|AgCl in Fig. 2. All the redox

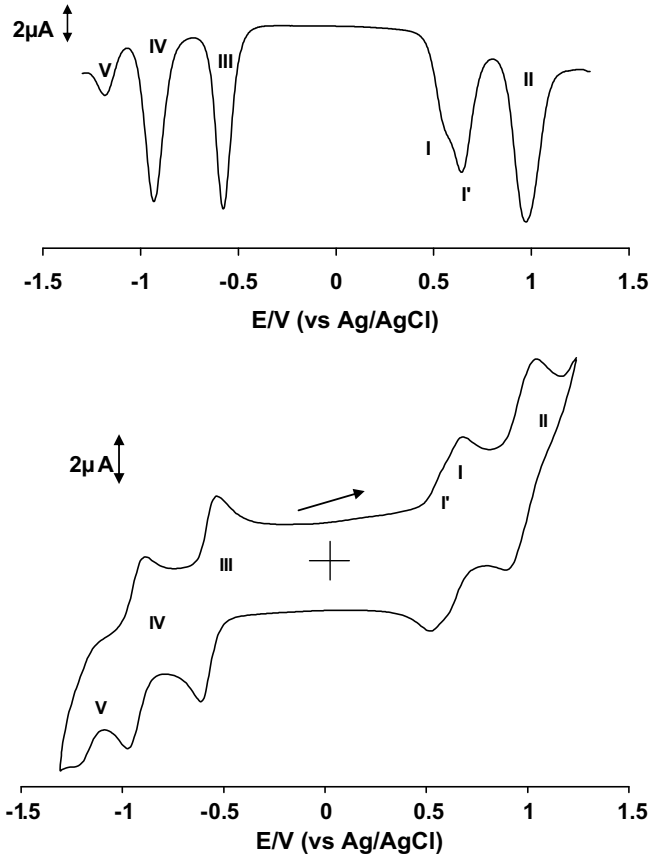

Fig. 3. Cyclic and square wave voltammograms of **4** in DCM containing $TBABF_4$. Scan rate = 100 mV s^{-1}.

processes showed both the cathodic and anodic components. The cathodic to anodic peak separation (ΔE) ranged from 90 to 120 mV, suggesting slow electron transfer. A ΔE value of 90 mV was obtained for ferrocene. The cathodic to anodic peak current ratio (I_{pc}/I_{pa}) were near unity. For all redox couples, plots of peak current (I_p) versus the square root of scan rate ($v^{1/2}$) were linear, thus suggesting diffusion control at the electrode surface. Table 2 also shows that complex **4** containing sulfur groups (due to the electron donating nature of the sulfur group) is more easily oxidised than the complexes containing oxo groups though different substituents are attached. It would therefore be expected that complex **4** would be more difficult to reduce; this is the case in Table 2 when comparing with fluorinated $OVPcF_{16}$. Also comparing complex **4** with other complexes in Table 2, which exhibited only ring based oxidation and reduction processes, we would expect the former also to show only ring based processes since the peak potentials are comparable except for slight differences due to the different substituents. Also the redox processes are in the range for ring-based processes in MPc complexes [22].

The first oxidation process showed an overlap of two peaks labelled **I′** and **I**. The overlap is probably due to aggregation at concentrations used for cyclic voltammetry. Such closely spaced cyclic voltammograms are associated with aggregation [22]. On dilution of the solution, there was disappearance process **I′**, only one process remained as **I**. The nature of the couples as well as the number of electrons transferred was confirmed by spectroelectrochemistry below.

Spectroelectrochemical studies using optically transparent thin layer electrode (OTTLE) cell gave more insight into the origin of the redox couples observed during voltammetric studies of the complexes. Fig. 4a shows the spectral changes observed during the reduction of **4** at potentials of process **III**. At the high concentrations used for the OTTLE cell, the original spectrum before reduction is broad due to aggregation. Aggregation in MPc complexes is usually depicted as a coplanar association of rings progressing from monomer to dimer and higher order complexes. It is dependent on the concentration, nature of the solvent, nature of substituents, complexed metal ions and temperature [35]. In the aggregated state the electronic structure of the complexed phthalocyanine rings are perturbed resulting in alternation of the ground and excited state electronic structures [36], thus broadening of the spectra.

Upon reduction, there is a blue shift in the Q band from 853 to 680 nm and at the same time the colour of the complex changed from purple to green, Fig. 4a. These spectral changes occurred with a clear isosbestic point at 731 nm. The number of electrons transferred (n) was calculated to be approximately 1.

Metal-based redox processes can be identified using UV–Vis spectra since a definite shift in the Q band (without much change in intensity) is generally observed [34]. Spectral changes in Fig. 4a are not similar to those observed for ring reduction in OVPc derivatives ($OV[Pc(OC_6H_3(t\text{-}Bu)_2)_4]$ and $OV[Pc(C_8H_{17})_4]$) [21], in that new weak bands were observed at 571, 618 and 646 nm upon reduction of the latter complexes. For complex **4**, the peak 680 is quite intense, but since only ring based processes have been reported [21,34,37] for VPc complexes, the spectral changes observed in Fig. 4a may be associated with ring based reduction (to Pc(-3) species), with differences in absorption band intensity and positions being due to differences in substituents.

The green colour of ring reduced VPc derivative (**4**) observed in this work, is uncommon in phthalocyanine chemistry, where reduction leads to purplish colour. The green colour is due to the fact that the shift of the main absorption band is to 680 nm, while in general for Pcs, the main (weak) absorption bands occur between 500 and 600 nm [28,38]. The peak at 680 nm is intense relative to the original species with a reduction in $\log \varepsilon$ of only 20%

[c] irr = irreversible.

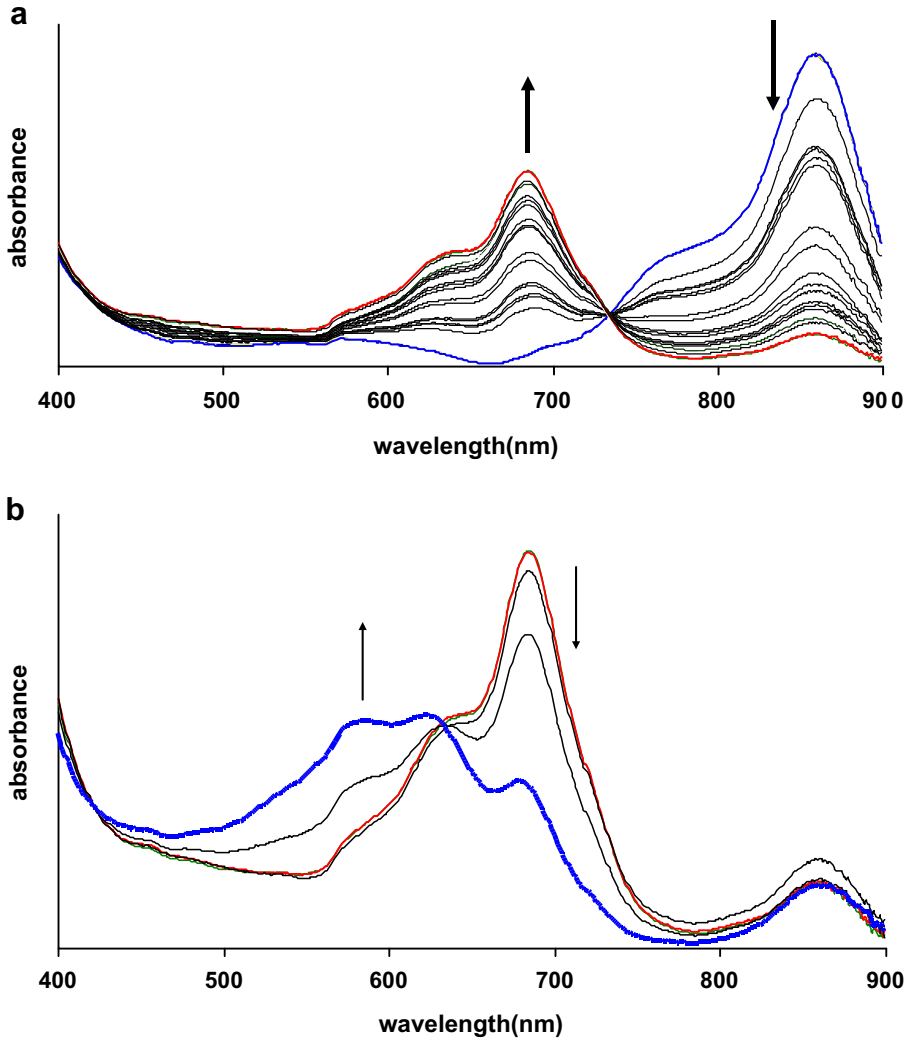

Fig. 4. UV–Vis spectral changes for **4** observed using controlled potential electrolysis at (a) −0.7 V, (b) −1.2. First spectrum in (b) is the same as the last spectrum in (a). Electrolyte = DCM containing 0.1 M $TBABF_4$. Electrolysis time was 30 min for each redox process.

(assuming complete transformation) compared to the more common ring reduction in Pcs with large reduction in intensity upon reduction.

Fig. 4b shows spectral changes observed on further reduction at potentials of couple **IV**. There was emergence of new peaks at 578 and 620 nm. The spectral changes shown in Fig. 4b are similar to those observed for other OVPc derivatives, (OV[Pc(OC_6H_3(*t*-Bu)$_2$)$_4$] and OV[Pc(C_8H_{17})$_4$]) which were assigned to ring based processes [21]. Thus spectral changes shown in Fig. 4b are assigned to the formation of Pc^{4-} species, hence the couple $V^{IV}Pc^{3-}/V^{IV}Pc^{4-}$. Process V may be assigned to further ring reduction and the formation of $V^{IV}Pc^{5-}$.

Spectroelectrochemical characterisation was done to determine the origin of the oxidation couples. Fig. 5 shows the spectroelectro-

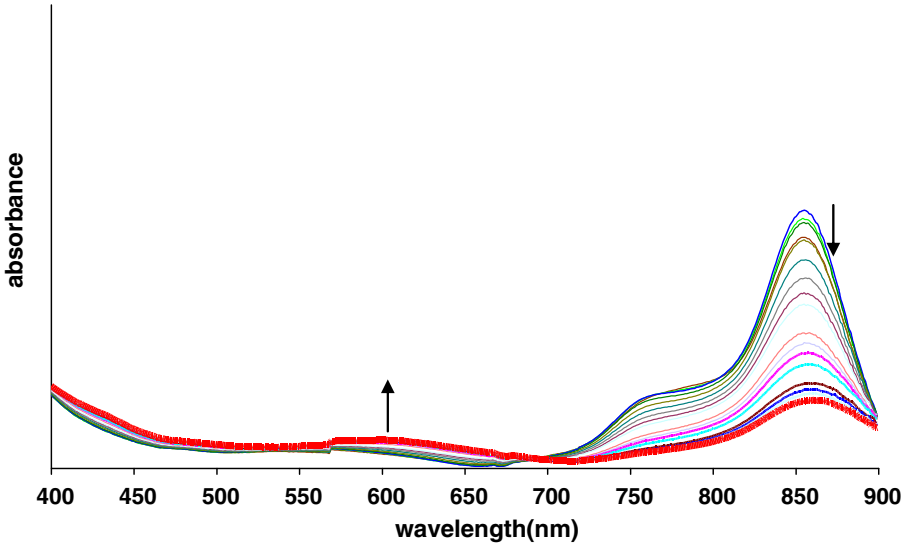

Fig. 5. UV–Vis spectral changes for **4** observed using controlled potential electrolysis at 0.8 V electrolyte = DCM containing 0.1 M $TBABF_4$. Electrolysis time was 30 min.

chemical changes observed upon oxidation at the potential of process **I**. Oxidation at the potential of peak **I** showed the decrease in intensity of the Q band and formation of a weak new peak around the 500–700 nm region, this is indicative of a ring based process and assigned to the oxidation of $V^{IV}Pc^{2-}$ to $V^{IV}Pc^{1-}$, Fig. 5.

Based on the electrochemical data above, we assign processes **I**–**V** as follows:

$$V^{IV}Pc^{2-} \rightarrow V^{IV}Pc^{1-} + e^{-} (\text{process } \mathbf{I}) \quad (1)$$

$$V^{IV}Pc^{1-} \rightarrow V^{IV}Pc^{0} + e^{-} (\text{process } \mathbf{II}) \quad (2)$$

$$V^{IV}Pc^{2-} + e^{-} \rightarrow V^{IV}Pc^{3-} (\text{process } \mathbf{III}) \quad (3)$$

$$V^{IV}Pc^{3-} + e^{-} \rightarrow V^{IV}Pc^{4-} (\text{process } \mathbf{IV}) \quad (4)$$

$$V^{IV}Pc^{4-} + e^{-} \rightarrow V^{IV}Pc^{5-} (\text{process } \mathbf{V}) \quad (5)$$

4. Conclusion

A vanadium phthalocyanine which absorbs in the red region, 850 nm in DCM, has been synthesised. This complex has potential in applications as near-IR absorbers are used in optical recording materials and in IR radiation filters. The electrochemical data reveals five redox processes. The spectroelectrochemical data revealed ring based processes, with spectra of the reduced species being different from the other VPc derivatives in that ring reduction does not result in considerable loss in intensity.

Unicom UV-2 Spectrometer. ^{1}H NMR and ^{13}C NMR spectra were recorded on a Bruker 300 spectrometer instrument. The cyclic voltammetry (CV) and differential pulse voltammetry (DPV) measurements were carried out with a Gamry Reference 600 potentiostat/galvanostat controlled by an external computer and utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt disc with a surface area of 0.071 cm^2. The surface of the working electrode was polished with a diamond suspension before each run. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a double bridge. Ferrocene was used as an internal reference. Electrochemical grade TBAP in extra pure THF was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}. High purity N_2 was used to remove dissolved O_2 for at least 15 min prior to each run and to maintain a nitrogen blanket during the measurements. IR compensation was also applied to the CV scans to further minimize the potential control error. Mass spectra were acquired on a Voyager-DE™ PRO MALDI-TOF mass spectrometer (Applied Biosystems, USA) equipped with a nitrogen UV-Laser operating at 337 nm. Spectra were recorded both in linear and reflectron modes with an average of 50 and 100 shots for the linear and reflectron modes, respectively. A-cyano-4-hydroxycinnamic acid (CHCA) and 3-indole acrylic acid MALDI matrix were used and prepared in chloroform at a concentration of 20 mg/mL for **2**. MALDI samples were prepared by mixing sample solutions (4 mg/mL) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® micro tube. Finally 1 μL of this mixture was deposited on the sample plate, dried at room temperature and then analyzed. 3-Indole acrylic acid (IAA) (20 mg/mL in acetonitrile) matrix for **3** and **4** and α-cyano-4-hydroxycinnamic acid (ACCA) (15 mg/mL 1:1 water–acetonitrile) MALDI matrix for **5** were prepared. MALDI samples were prepared by mixing the complex (2 mg/mL in acetonitrile) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® micro tube. Finally 1 μL of this mixture was deposited on the sample plate, dried at room temperature and then analyzed as described elsewhere [24].

2.1. Synthesis

2.1.1. 4-(3,5-Bis(trifluoromethyl)phenoxy)-phthalonitrile (*1*)

3,5-Bis(trifluoromethyl) phenol (1.62 g, 1.36 mmol) was dissolved in 10.0 cm^3 dry DMF under N_2. Finely ground anhydrous K_2CO_3 (~1.25 g, 1.73 mmol) was added to this solution. After efficient stirring for 0.5 h, 4-nitrophthalonitrile (1.00 g, 5.07 mmol) in DMF (~10 cm^3) was added dropwise at 35 °C over a period of 0.5 h. After the reaction mixture was kept at this temperature under a N_2 atmosphere for 3 days, the solution was cooled to room temperature. Then, the crude compound was poured into ice-water (~200 cm^3). The creamy precipitate that formed was filtered and washed several times with water until the washings became neutral. It was chromatographed over a silica gel column using a mixture of $CHCl_3$:MeOH (100:5 (v:v)) as eluent, giving a powder, 4-(3,5-bis-(trifluoromethyl)phenoxy)-phthalonitrile (**1**). Finally, the pure powder was dried in a vacuum.

Yield: 1.81 g (87.3%); m.p.: 95 °C. *Anal.* Calc. for $C_{16}H_6F_6N_2O$: C, 53.95; H, 1.70; N, 7.86. Found: C, 53.54; H, 1.75; N, 7.73%. 2.1.2. 2(3),9(10),16(17),23(24)-Tetrakis-4′-(3,5-bis(trifluoromethyl)phenoxy)-phthalocyaninatozinc(II) Zn(Pc) (*2*)

A mixture of **1** (0.10 g, 0.28 mmol), anhydrous $Zn(acac)_2$ (0.017 g, 0.10 mmol) and quinoline (~1 cm^3) in a sealed tube was heated with efficient stirring at 170–180 °C for about 8 h under a N_2 atmosphere. After cooling to room temperature, the resulting waxy solid was washed several times successively with hexane and methanol to remove any inorganic and organic impurities until the filtrate was clear. The blue product was isolated by silica gel column chromatography first with $CHCl_3$ and then with THF:$CHCl_3$ (1:1 (v:v)) as the eluent. Pure **2** was obtained as a blue powder following column chromatography over silica gel (eluent: $CHCl_3$:MeOH; 10:1, and then THF) and then dried in vacuum. This product is readily soluble in CH_2Cl_2, $CHCl_3$, THF, pyridine, DMF and DMSO.

Yield: 0.032 g (28.65%). *Anal.* Calc. for $C_{64}H_{246}N_8O4_8Zn$ (1488 g/mol): C, 51.58; H, 1.22; N, 7.52. Found: C, 51.46; H, 1.17; N, 7.28%. 3. Results and discussion

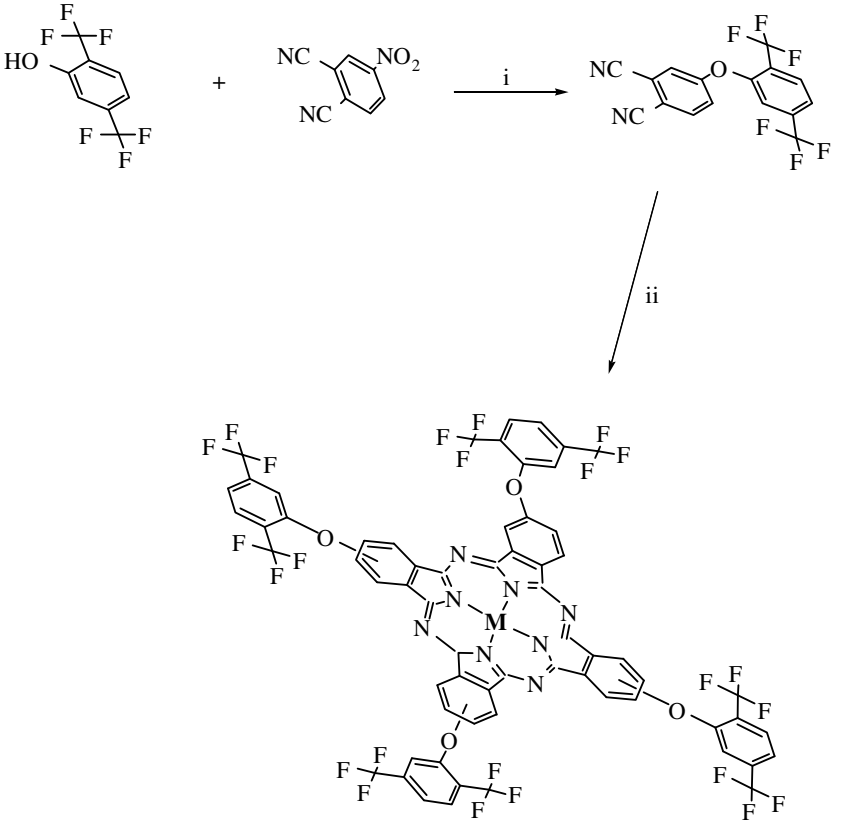
3.1. Synthesis and characterization

Novel phthalocyanines (**2**–**5**) were prepared by the templated cyclization of 4′-(3,5-bis(trifluoromethyl)phenoxy)-phthalonitrile and anhydrous $Zn(OAc)_2$, $CuCl_2$, $CoCl_2$ and $NiCl_2$ in the presence of high boiling quinoline at 170–185 °C under a N_2 atmosphere in the presence of 1,8-diazabicyclo [5.4.0] undec-7-ene (DBU) as a strong base (Scheme 1). The blue cyclotetramerization products, MPc's (M = Zn, Cu, Co and Ni), were purified by column chromatography and were obtained in a moderate yield (28.65% for **2**, 12.31% for **3**, 15.23% for **4** and 14.30% for **5**). Elemental analysis results and the spectral data (^{1}H NMR, FTIR and MALDI-TOF-MS) of the new products are consistent with the assigned formulations. The blue-green phthalocyanine products were isolated as a mixture of isomers, as expected. The presence of isomers could be verified by the slight broadening encountered in the UV–Vis absorption bands and broadening in the ^{1}H NMR spectra as compared with the spectra of octa-substituted phthalocyanines composed of a single isomer [13,14,21,24]. The six peripheral fluoro atoms confer increased solubility of the complexes in both halogenated solvents ($CHCl_2$ and $CHCl_3$) and more polar solvents such as acetone and thf. The solubility of complex **3** and **5** are also affected by the central metal ion; these complexes show slightly lower solubility than **2** and **4** in halogenated solvents.

A strong –*C*–*F* stretching band, with a small shift, and the disappearance of the –*CN* band at 2236 cm^{-1} after phthalocyanine formation were identified in the FTIR spectra. Aliphatic and aromatic –*C*–*H* and ═*C*–*H* peaks at above and below 3000 cm^{-1}, and the remaining spectra are closely similar to that of compound **1** and provide easy diagnosis.

The ^{1}H NMR spectrum of complex **2** was almost identical to that of the starting compound **1**, except for small chemical shifts. The aromatic protons in the lower field region of the ^{1}H NMR spectrum and twelve different aromatic carbon atoms between 110 and 160 ppm in the ^{13}C NMR spectrum are the instinctive indicator signals for **1**. It is likely that the rather broad bands in the case of **2** are probably due to chemical exchange associated with an aggregation–disaggregation equilibria that occurs at the high concentrations used in the NMR measurements. The production of a mixture of four positional isomers are expected to cause broadening of the bands and the chemical shifts [11,14,21].



Scheme 1. Synthetic route of 4-(3,5-bis-(trifluoromethyl)-phenoxy)-phthalonitrile and its metallophthalocyanines (M = Zn(II), Cu(II), Co(II) and Ni(II)): (i) 3,5-bis-(trifluoromethyl)-phenol, 4-nitrophthalonitrile and K_2CO_3 in dmf at 40 °C for 72 h; (ii) anhydrous $Zn(acac)_2$, $CuCl_2$, $CoCl_2$ and $NiCl_2$, DBU, quinoline.

The UV–Vis spectra of the phthalocyanine complexes exhibit characteristic Q and B bands. Two principle π–π^* transitions are seen for phthalocyanines: a Q-band (~550–700 nm, a π–π^* transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the complexes) and a B-band (~300–350 nm, a deeper π–π^* transition from the HOMO's (a_{1u} and a_{2u}) to the LUMO (e_g)) [14,25]. The Q-band absorptions in the UV–Vis absorption spectra of the phthalocyanines (**2**, **3**, **4** and **5**) were observed as a single high intensity band due to a π–π^* transition at 677, 674, 665 and 666 nm, respectively, with shoulders on the slightly higher energy side of the Q-bands, as shown in Fig. 1. The positions of the absorption bands of the complexes are different from each other due to the effect of the ionic radius of the metal center [14,24]. The effect of *O*-substitution on the periphery for all phthalocyanines when compared with those of the *S*-substituted derivatives causes a shift in the Q-bands to shorter wavelengths [13,15,17,18,26–28].

The positive ion MALDI-MS spectrum of **2** is given in Fig. 2. Many different MALDI matrices were tried to find an intense molecular ion peak and low fragmentation under the MALDI-MS conditions for this complex. 3-Indole acrylic acid MALDI matrix yielded the best MALDI-MS spectrum, as seen in Fig. 2. The peak group representing the protonated molecular ion of the **2** was observed starting with a 1488 Da mass and finishing with 1494 Da, following each other by 1 Da mass differences. This type of mass distribution results from the isotopic mass distribution of carbon (mainly ^{13}C) and the isotopes of **2**. In the MALDI-MS spectrum of the complex, only the protonated molecular ion peak was observed, with no fragment ions. It is clear that no leaving group was available for this complex because of the high stability of the complex under the MALDI matrix conditions and also under the laser energy. The protonated molecular ion peak was observed at 1487 Da for **3**, with the other isotopic peaks mainly resulting from the isotopic distribution of the components of **3**, and this distribution exactly overlapped with the mass of the **3** calculated theoretically from its elemental composition (Fig. 3). Beside the protonated molecular ion peak of the complex, no peak was observed between the 500 and 2500 Da mass range, eliminating the presence of any other impurity or fragment ions under the laser shots. Beyond the protonated molecular ion peak of **4**, its MALDI spectrum showed a very clear spectrum and no fragmentations. The protonated molecular ion peak of **4** was observed at 1484 with the other three peaks following each other by a 1 Da mass difference. This peak group is because of the isotopic distribution of cobalt and carbon in the complex structure [14,24]. The best MALDI-MS spectrum of this complex was obtained using α-cyano-4-hydroxycinnamic acid with (ACCA), and it showed only one fragment peak at low intensity around 1380 Da mass. When 3-indole acrylic acid and other conventional matrices (except ACCA) were used, more fragmentations and broad peaks were obtained in each case. The protonated molecular ion peak of **5** was obtained at 1483 Da with a few other low intensity fragment peaks in the positive ion and reflectron mode MALDI-MS spectrum. The molecular ion peak showed an isotopic peak distribution because of the isotopic distribution of both nickel and carbon. In the case of **5**, some fragmentations were observed. This showed that the stability of **5** is lower than complexes **3** and **4**. [14].

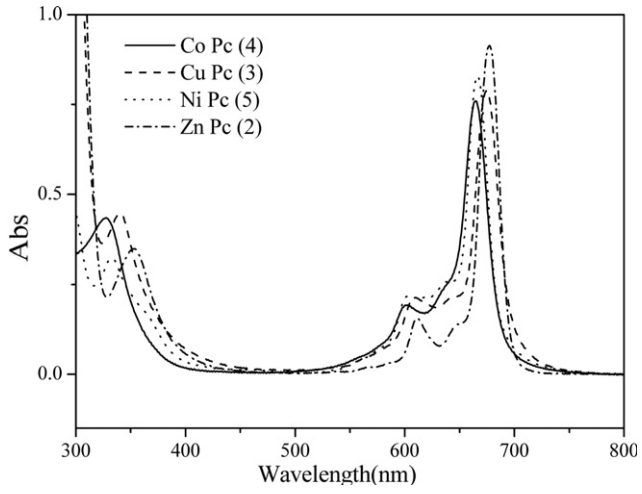


Fig. 1. UV–Vis spectra of the metallophthalocyanines (**2–5**) in THF.

3.2. Electrochemical measurements

The electrochemical behaviors of the phthalocyanines (**2**–**5**) were investigated by cyclic voltammetry (CV) and differential pulse voltammetry (DPV) on a platinum working electrode in THF. The half-wave potential values ($E_{1/2}$) vs SCE are summarized in Table 1.

As shown in the CVs in Fig. 4, complex **4** undergoes a one-electron oxidation and three one-electron reduction reactions within the electrochemical window of TBAP/THF. The DPV of the complex confirms the recorded redox processes clearly (Fig. 4C) [29,30]. The CV and DPV show the aggregation of the complex in solution. As shown in Fig. 4A, the first reduction couple (III) is very broad and irreversible. When the solution is diluted, this couple is split into two waves (Fig. 4B). This behavior shows the existence of an aggregation–disaggregation equilibrium of the species. Thus, first

one of the split peaks results from the monomeric form and the second one from the aggregated form of the complex. To indicate the effect of the switching potential to the peak character, the CVs were recorded with different switching potentials. However there was no significant effect to the reversibility and peak current of the redox waves. The first oxidation and first reduction processes occur on the metal center only for the Mn, Fe and Co phthalocyanine derivatives in polar solvents. For the Ni, Cu and Zn phthalocyanines, the redox processes take place on the Pc ring [31]. According to these studies, the first reduction process of **4** could be assigned easily to the Co^{II}/Co^{I} transformation, and the remaining processes to the phthalocyanine ring. All the predicted redox processes are given in Eq. (1). As shown in Table 1, all the redox processes are shifted toward positive potentials as a result of the increased electron-withdrawing ability of the trifluorophenyl substituents with respect to tetra-(propanediolsulfanyl) tetrachloro CoPc [32], tetrakis(6-hydroxyhexylsulfanyl) CoPc [14], tetrakis 2-aminophenylsulfanyl CoPc [19] and tetrakis-6-(-thiophene-2-carboxylate)-hexylthio CoPc [33], characterized in our previous studies.

tials (Fig. 5C), however there is no significant difference for the redox reaction reversibility and peak currents due to the different

$$[Co^{III}Pc^{-1}]^{2+} \underset{1.13\ V}{\overset{-e^-}{\Leftrightarrow}} [Co^{II}Pc^{-1}]^{1+} \underset{0.75\ V}{\overset{-e^-}{\Leftrightarrow}} [Co^{II}Pc^{-2}] \underset{-0.21\ V}{\overset{+e^-}{\Leftrightarrow}} [Co^{I}Pc^{-2}]^{1-} \left\{ \begin{array}{l} \text{agg.} \Updownarrow \text{disagg.} \\ [Co^{II}Pc^{-2}]_{agg.} \underset{-0.56\ V}{\overset{+e^-}{\Leftrightarrow}} [Co^{I}Pc^{-2}]^{1-} \end{array} \right\} \underset{-1.29\ V}{\overset{+e^-}{\Leftrightarrow}} [Co^{I}Pc^{-3}]^{2-} \quad (1)$$

As shown in Fig. 5, **2**, **3** and **5** represent very similar well-resolved CVs. They undergo a one-electron oxidation and two one-electron reductions within the electrochemical window of TBAP/THF. The main difference is the aggregation tendency of **2**. As shown in Fig. 5A, the first reduction wave is split into two peaks. Diluting the solution decreases the peak current of the wave assigned to the aggregated species more than those of the monomeric species reduction wave. These observations support the aggregation behavior of the complex. The CV of **5** was recorded with different switching potentials. Because of the electro-inactive metal center of the complexes, all of these processes are attributed to the successive removal of electrons from, or addition of electrons to, the macrocycle orbitals. The HOMO–LUMO gaps of the complexes are comparable with those of common metallophthalocyanines (~1.300–1.700 V). A positive potential shift of the redox processes due to the electron-withdrawing nature of the triflorophenyl substituents with respect to the metallophthalocyanines characterized in our previous study [14,19,32,33] was also observed.

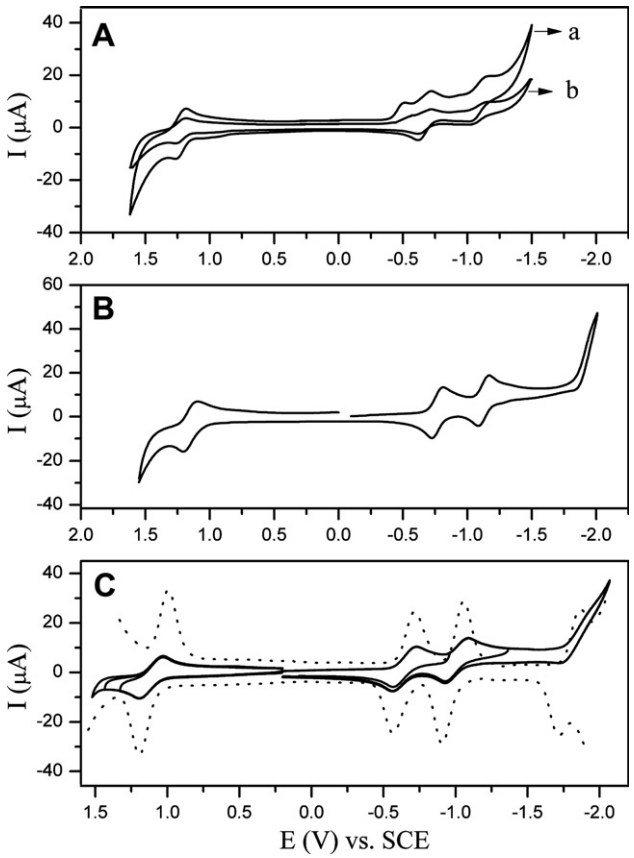

Fig. 5. (A) CVs of **2** ($a = 5.0 \times 10^{-4}$ mol dm^{-3} and $b = 2.5 \times 10^{-4}$ mol dm^{-3}). (B) CVs of **3** (5.0×10^{-4} mol dm^{-3}). (C) Solid lines: CVs of 5 recorded with different switching potentials. Dot lines: DPVs of **5** (5.0×10^{-4} mol dm^{-3}) at 0.100 V s^{-1} scan rate on Pt in THF/TBAP.

temperature range 100–200 °C at low pressure, and exhibit rather good stability during storage and use [8,10], which is rather rare for barium and strontium volatile compounds. Nevertheless, [Ba(hfa)$_2$(tetraglyme)] demonstrates a relatively high melting point of 150 °C, so it must be sublimed into the reactor feed stream. Meanwhile, MOCVD techniques with precursor liquid delivery are well-known and applied for deposition of AEE-containing thin films [10]. Therefore, the development of low-melting AEE precursors, which should be liquid and provide constant surface areas for evaporation and transport during deposition experiments is of interest, especially for barium.

Marks and co-workers [11] have proposed to reduce the melting points of [Ba(hfa)$_2$($CH_3O(CH_2CH_2O)_nCH_3$)] by increasing the number of ether fragments ($n > 4$) and by the introduction of bulky R^1 and R^2 substituents in the polyglyme ligands. In this way, the complexes [Ba(hfa)$_2$($R^1O(CH_2CH_2O)_nR^2$)] with melting points down to 50 °C were obtained, but decomposition and low volatility of some such complexes were observed under heating. This is caused by impossibility of coordination of all the polyglyme oxygen atoms to the barium ion, which leads to additional intermolecular interactions and complicates evaporation.

In contrast to Marks and co-workers [11], Fragala and co-workers [12] suggested the use of glyme ligands with short chains ($n = 1$ or 2, corresponding to monoglyme or diglyme) for the synthesis of low-melting precursors, and such volatile, low-melting mixed ligand complexes with diglyme were obtained for hexafluoroacetylacetonates of lanthanides [12], lead(II) [13] and cobalt(II) [14].

However, the complexes of AEE hexafluoroacetylacetonates with diglyme have not been described yet. Here we report the synthesis, X-ray structures, thermal behavior and mass spectrometric study of [Ca(hfa)$_2$(diglyme)(H_2O)] (**I**), [Sr(hfa)$_2$(diglyme)(H_2O)] (**II**) and [Ba(hfa)$_2$(diglyme)$_2$] (**III**).

2. Experimental

Analytically pure hexane, metallic Ba, $CaCO_3$, $SrCO_3$ and $BaCO_3$ from Reakhim (Russia) were used without further purification. Hhfa (P&M Invest, Russia, 98%) and diglyme (Fluka, 99%) were preliminary distilled under reduced pressure.

The C, H and N contents were determined by conventional elemental analysis. The calcium and strontium contents were determined titrimetrically. IR spectra were recorded on a Perkin–Elmer 1600 FTIR spectrometer as Nujol and hexachlorobutadiene mulls between KBr plates in the region 4000–400 cm^{-1}. ^{1}H and ^{13}C NMR spectra were obtained using a Bruker Avance-400 (400 MHz, $CDCl_3$/TMS). TG curves at low pressure (0.01 torr) were recorded on a ULVAC SINKU-RIKO TA-7000 analyzer with a 10 °C min^{-1} heating rate.

2.1. Synthesis of [Ca(hfa)$_2$(diglyme)(H_2O)] (**I**), [Sr(hfa)$_2$(diglyme)(H_2O)] (**II**), [Ba(hfa)$_2$(diglyme)$_2$] (**III**)

MCO_3 (4 mmol, M = Ca, Sr, Ba) was added to a Hhfa and diglyme mixture (molar ratio 1:2:1 or 1:2:2) in hexane (40 ml) followed by continuous stirring for 2 h at 50 °C, until full dissolution of MCO_3. White crystalline precipitates were obtained after slow solvent evaporation in air. Yield: ~90–95%.

M.p. 83 °C.

The same complex **III** was synthesized by the interaction of metallic Ba (4.23 mmol) with a mixture of Hhfa and diglyme (molar ratio 1:2:2) in hexane (40 ml) under continuous stirring for 8 h at 50 °C, followed by the separation of unreacted Ba pieces and slow solvent evaporation in air. Yield ~70%.

2.2. X-ray crystal structure determination

X-ray quality single-crystals were grown by recrystallization from hexane solution. The single-crystal X-ray diffraction data were collected on Bruker APEX II, Bruker SMART 1000 (with CCD area detectors) and Enraf-Nonius CAD-4 diffractometers (Mo Kα, λ = 0.71073 Å, graphite monochromator). The structures were solved by direct methods and refined with the full-matrix F^2 least-squares technique (SHELXTL PLUS) [15]. The hydrogen atoms of the water molecules were found on difference Fourier synthesis. Other H atoms were placed in idealized positions and refined using a riding model with fixed isotropic thermal parameters. Pertinent details are given in Table 1.

2.3. Mass spectrometry

The mass spectra of **I**–**III** were recorded on a MS 1301 spectrometer having a 50–1500 amu mass range using 65 eV ionizing electrons. The complexes were vaporized from a Knudsen effusion cell. The ratio of evaporation surface to surface of the effusion hole was about 600. The cell temperature was measured with a Pt/Pt(Rh) thermocouple (±2°). The main ion peaks in the mass spectra of **I**–**III** are presented in Tables 5 and 6.

3. Results and discussion

3.1. Synthesis

Two main methods for the synthesis of mixed ligand AEE β-diketonates $[M(dik)_2Q_n]$ are known and used in MOCVD precursor preparation: (i) the interaction between oligomeric homoleptic $[M(dik)_2]_x$ or heteroleptic $[M(dik)_2(Solv)]_x$ (Solv = H_2O, Et_2O or EtOH, $x \leqslant 3$) complexes with neutral donor ligands Q; (ii) the *in situ* reaction of the ethoxides with Hdik and Q [1,19]. A rich variety of monomeric mixed ligand AEE β-diketonates have been prepared, including the complexes of AEE hexafluoroacetylacetonates with polyglymes $CH_3O(CH_2CH_2O)_nCH_3$ ($n \geqslant 3$) [1]. However, for such precursors to be useful MOCVD sources, these methods are too expensive and have several inherent limitations: in method (i), the necessity of the synthesis and purification of the starting homoleptic β-diketonates; in method (ii), the use of air/moisture-sensitive metal ethoxides. An effective simple strategy of synthesis based on the high acidity of Hhfa ($pK_a \sim 4.5$ [20]) was developed for $[M(hfa)_2(CH_3O(CH_2CH_2O)_nCH_3)]$ ($n \geqslant 3$) – the *in situ* interaction of AEE oxide, hydroxide or carbonate with Hhfa and $CH_3O(CH_2CH_2O)_nCH_3$ ($n \geqslant 3$) in EtOH or hydrocarbons in a stoichiometric ratio (method (iii)). In this method, the interaction of MCO_3 ($M(OH)_2$ or MO) with Hhfa results in the formation of hydrated $[M(hfa)_2(H_2O)_x]$, followed by replacement of the water molecules and saturation of the AEE ion coordination sphere by donor oxygen atoms of polyglyme ligands, forming 5-membered chelate rings with the central AEE ions. In the case of polyglymes with $n \geqslant 3$, the number of oxygen atoms is large enough ($\geqslant 4$) for saturation of the AEE coordination sphere, together with four oxygen atoms from two hfa^- ligands, and formation of mixed ligand complexes containing no water molecules. In complexes $[M(hfa)_2(CH_3O(CH_2CH_2O)_nCH_3)]$ ($n \geqslant 3$) the typical coordination number (CN) for Ca and Sr is equal to 8, and for the larger Ba, CN $\geqslant$ 9 (up to 10 in the complexes with polyglymes) [11].

In this work for the synthesis of mixed ligand complexes with diglyme we used method (iii) with starting MCO_3. Diglyme contains only three oxygen atoms, which can form two chelate rings with central metal ions. In the syntheses with a molar ratio $[MCO_3]$:[diglyme] = 1:1, one would expect the formation of hydrated complexes $[M(hfa)_2(diglyme)(H_2O)_m]$, where $m = 1$ for Ca and $\geqslant 1$ for the larger Sr and Ba. In fact the complexes $[M(hfa)_2(diglyme)(H_2O)]$ (M = Ca, Sr) were obtained, but the barium complex contained two diglyme molecules – $[Ba(hfa)_2(diglyme)_2]$ in spite of the starting molar ratio of 1:1. The composition of the complexes formed did not change when the starting molar ratio $[MCO_3]$:[diglyme] was equal to 1:2. The data of elemental analysis, IR spectroscopy and NMR confirm the formation of **I–III**. Notice that **III** was prepared from metallic Ba as a starting reagent too, but the yield of product was about 20% lower than in the synthesis from $BaCO_3$ because the surface of metallic Ba is less than that of crystalline barium carbonate. Additionally metallic Ba does not react totally, as with time its surface is covered by thin layer of product and the reaction stops.

The difference in the composition of the calcium, strontium and barium complexes is attributable to the ionic radii of these elements. The ionic radii of Ca and even Sr are not so large for the coordination of a second diglyme molecule in the chelate mode, and coordination in the bridging mode does not occur owing to the presence of water molecules in the reaction mixture. However when the same method (iii) was used for the synthesis of lead(II) complexes, the anhydrous dimers $[Pb(hfa)_2(\mu\text{-}\eta^3{:}\eta^1\text{-diglyme})]_2$ formed in spite of water presence in the reaction mixture in toluene [13]. It means that the composition and structure of hexafluoroacetylacetonate complexes with diglyme depend not only on the synthesis method and ionic radii, but also on the electronic configuration of the central ion: for CN = 8 the ionic radii of Sr^{2+} (1.40 Å) and Pb^{2+} (1.46 Å) are close to each other. The bridging mode of the diglyme coordination was described in the complex $[Ba(thd)_2(diglyme)]_2$ (Hthd = 2,2,6,6,-tetramethylheptane-3,5-dione), prepared via the reaction of $[Ba_4(thd)_8]$ and diglyme in absolute *n*-hexane and under a dry atmosphere [21].

Only in the case of the largest barium ion is the coordination of a second diglyme molecule possible in the chelating mode. The formation of four diglyme chelate rings stabilizes the mixed ligand complex so strongly that $[Ba(hfa)_2(diglyme)_2]$ forms even in the presence of water and at a $[MCO_3]$:[diglyme] molar ratio of 1:1. A similar situation was described in the synthesis of mixed ligand complexes of lanthanide hexafluoroacetylacetonates with the bidentate ligands Dipy and Phen [22,23].

Finally, a significant reduction in the melting point of AEE diglyme complexes, compared to the tetraglyme complexes, has been observed only for the barium compound (from 125 °C [8] to 83 °C). This is caused by its structural features disordering of the CF_3 groups and the presence of only weak van der Waals intermolecular interactions.

3.2. Structures of the complexes

3.2.1. The structure of $[Ca(hfa)_2(diglyme)(H_2O)]$ (*I*) and $[Sr(hfa)_2(diglyme)(H_2O)]$ (*II*)

Complexes **I** and **II** are isostructural and their crystal structures are built by the packing of two crystallographically non-equivalent molecules $[M(hfa)_2(diglyme)(H_2O)]$ (I^* and I′, II^* and II′) which differ only slightly in the mutual orientation of the hfa^- anions and diglyme ligands in the coordination polyhedron of the central ions.

The independent molecules are combined into dimers by means of four hydrogen bonds between the oxygen atoms of the hfa^- anions and the hydrogen atoms of H_2O molecules (Figs. 1 and 2, Table 2).

In both independent $[M(hfa)_2(diglyme)(H_2O)]$ molecules, the M^{2+} cations have a distorted anti-prismatical coordination (CN = 8) formed by four O atoms (O1–O4 or O1′–O4′) of two chelating hfa^- anions, three O atoms (O5–O7 or O5′–O7′) of the diglyme ligand and one O atom (O1w or O2w) from a water molecule. The oxygen atoms of the diglyme and water ligands lie in an equatorial plane with the hfa^- ligands situating respectively above and below the plane in an approximately orthogonal relationship (dihedral angles 84.3°/89.7° for I*/I′ and 88.8°/84.8° for II*/II′, respectively). The Ca^{2+} ion is displaced from the mean planes of the hfa^- anions by 0.14–0.33 Å for I* and 0.55–0.64 Å for I′. In the structure of **II**, a similar displacement of Sr^{2+} occurs only in II* (0.57–0.68 Å).

In the structures of both **I** and **II**, the $M–O_{hfa}$ bond distances are slightly shorter than the $M–O_{diglyme}$ distances (Table 2). The average $M–O_{hfa}$ and $M–O_{diglyme}$ bond distances increase by 0.11 and 0.07 Å, respectively, from **I** to **II**, which agrees with the difference in ionic radii of Ca^{2+} and Sr^{2+} with CN = 8 (0.14 Å). The M–O bonds inside the same chelate rings forming by hfa^-, as well as by the diglyme ligands, vary in lengths (Table 2), which is rather typical for alkaline and rare earth element β-diketonates and their mixed ligand complexes with predominantly ionic bond nature [24,25]. The $M–O_{water}$ bond distances are the shortest among M–O bonds in coordination polyhedrons of both Ca^{2+} and Sr^{2+} (2.37 and 2.52 Å, respectively).

The literature data about the structures of calcium and strontium β-diketonate complexes with polyglymes are few in number [1]. As for hexafluoroacetylacetonate complexes, only two structures of calcium compounds have been published – $[Ca(hfa)_2$-(tetraglyme)] (**IV**) [19] and $[Ca_2(hfa)_4$(heptaglyme)] (**V**) [20], and to our knowledge, no structures of strontium hexafluroacetylacetonates with glyme ligands have been published as yet. In spite of the difference in the numbers of donor oxygen atoms in diglyme (three), tetraglyme (five) and heptagyme (eight), the gross molecular structures of **I**, **IV** and **V** are similar: a distorted anti-prismatic coordination of the calcium ions with CN = 8, equatorial positions of glyme oxygen atoms and nearly orthogonal arrangements of chelating hfa^- ligands. These general structural features lead one to compare the average Ca–O bond distances in structures of **I**, **IV** and **V** (Table 3). In all these structures a regular correlation in $Ca–O_{hfa}$ and $Ca–O_{glyme}$ bond distances occurs, however, in **I** these distances are the longest. For the $Ca–O_{glyme}$ bonds, this can be explained from the viewpoint of structure stabilization due to the macrochelate effect: in **IV** and **V** the glyme ligands form three chelate rings, in **I** there are only two.

In the case of non-fluorinated AEE β-diketonates, the dimeric complex $[Sr_2(thd)_4(diglyme)_2(\mu\text{-}H_2O)]$ with CN = 8 and a bridging water molecule has been described [26]. In this complex the average $Sr–O_{dik}$ distance is about 0.06 Å shorter and the $Sr–O_{diglyme}$ is about 0.06 Å longer than the corresponding values in **II**, which is caused by the difference between the Lewis acidity of $Sr(thd)_2$ and $Sr(hfa)_2$. The $Sr–OH_2$ distance is 0.45 Å longer than that in **II** due to the bridging function of the water molecule.

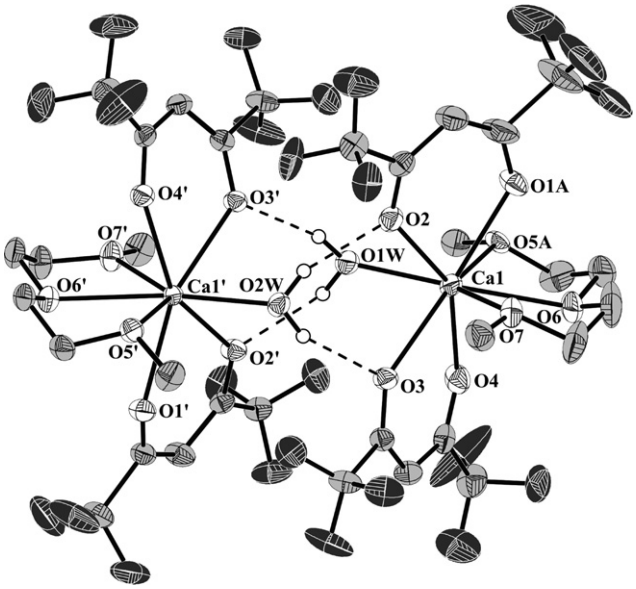

Fig. 1. Molecular structure of $[Ca(hfa)_2(diglyme)(H_2O)]$. H-atoms are partially omitted for clarity. Dash lines show intermolecular hydrogen bonds. For disordered atoms only one position is shown.

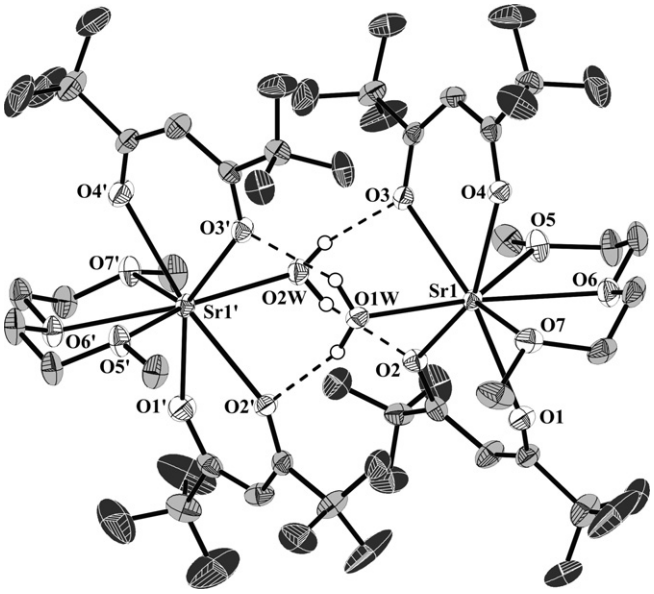

Fig. 2. Molecular structure of $[Sr(hfa)_2(diglyme)(H_2O)]$. H-atoms are partially omitted for clarity. Dash lines show intermolecular hydrogen bonds.

3.2.2. Structure of $[Ba(hfa)_2(diglyme)_2]$ (*III*)

The crystal structure of **III** consists of monomeric molecules with CN = 10 (Fig. 3). The coordination polyhedron of the Ba^{2+} central ion is formed by four oxygen atoms (O1–O4) of two chelating hfa^- anions and six O atoms (O5–O10) of two diglyme ligands (Table 4), and it is rather difficult to describe its geometry exactly.

The diglyme ligands are coordinated on one side of the Ba^{2+} cation (the dihedral angle between the O5–O6–O7 and O8–O9–O10 planes is 79°) while the hfa^- anions are on the other side. In **III**, the Ba^{2+} cation is displaced from the planes of the hfa^- anions by 0.22 Å (O1–C1–C2–C3–O2) and 0.07 Å (O3–C6–C7–C8–O4).

Such a "*cis*"-arrangement of ancillary ligands is typical for mixed ligand complexes with the general formula $[M(hfa)_2(Q)_2]$ and with the CN of the alkaline earth cations equal to 8, for example $[Ba(hfa)_2(Phen)_2]$ [27] and $[Sr(hfa)_2(Dipy)_2]$ [28]. This is in contrast to the non-fluorinated or asymmetrical incompletely fluorinated β-diketones analogues, in which the ancillary ligands are in the "*trans*"-position: $[M(thd)_2(Phen)_2]$ (M = Ca, Sr, Ba) [29], $[Ba(pta)_2(Phen)_2]$ (Hpta = 1,1,1-trifluoro-5,5-dimethyl-hexahe-2,4-dione) [30]. In our opinion, this difference in the mutual arrangement of ligands in the $[M(hfa)_2(Q)_2]$ molecules is caused by the increasing role of the crystal structure packing effects in complexes with fluorinated β-diketones [27].

Among the barium β-diketonate mixed ligand complexes there is only one with diglyme as the ancillary ligand – $[Ba(thd)_2(diglyme)]_2$ [21], which has a dimeric structure with a 7 + 1 coordination number of Ba^{2+} and in which the association into dimers is caused by weak bridging functions of O atoms from diglyme. The high coordination number, equal to 10, occurs in the complex $[Ba(hfa)_2(pentaglyme')]$ (**VI**) [pentaglyme′ = $CH_3O(CH_2CH_2O)_5C_2H_5$], where all six oxygen atoms of pentaglyme are coordinated by barium and are situated in nearly a meridional plane [11].

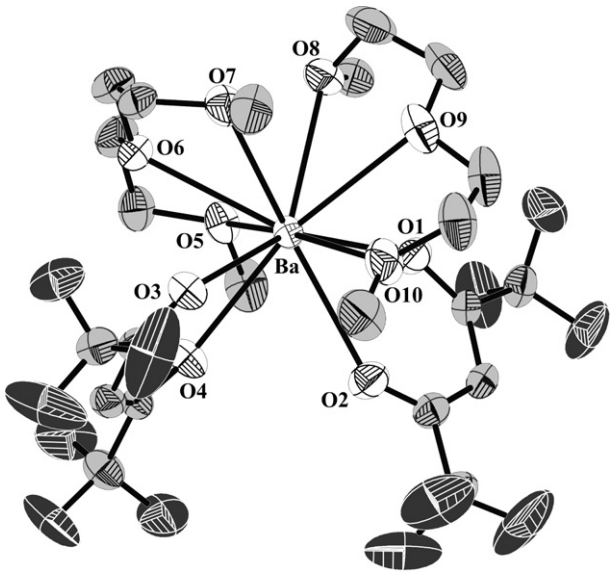

Fig. 3. Molecular structure of $[Ba(hfa)_2(diglyme)_2]$. H-atoms are omitted for clarity.

Table 4
Bond distances (Å) for $[Ba(hfa)_2(diglyme)_2]$ (**III**) and $[Ba(hfa)_2(pentaglyme')]$ (**VI**) [11]

Bond length (Å)	III	III*	VI
$Ba–O_{hfa}$			
Ba–O1	2.720(2)	2.725(3)	2.806(3)
Ba–O2	2.778(2)	2.757(3)	2.775(3)
Ba–O3	2.715(2)	2.725(3)	2.763(3)
Ba–O4	2.753(2)	2.757(3)	2.819(3)
$Ba–O_{glyme}$			
Ba–O5	2.881(2)	2.933(4)	2.842(3)
Ba–O6	2.892(2)	2.941(5)	2.887(3)
Ba–O7	2.910(2)	2.908(4)	2.813(3)
Ba–O8	2.940(3)	2.908(4)	2.827(3)
Ba–O9	2.914(3)	2.941(5)	2.865(3)
Ba–O10	2.909(3)	2.933(4)	2.845(3)

In structure **III** the average $Ba–O_{hfa}$ distance (2.74 Å) is shorter then the same one in **VI** (2.79 Å), but the average $Ba–O_{glyme}$ distances of both diglyme ligands (2.89 and 2.92 Å) are longer than the average $Ba–O_{glyme}$ distance (2.84 Å) in **VI**, which originates from the macrochelate effect in pentaglyme.

The temperature of 143 K for data collection of **III** was chosen due to the fact that further cooling leads to a significant increase of mosaicity and the appearance of additional satellite reflections. It must be mentioned that consequent heating of a single crystal makes it possible to obtain an initial diffraction pattern. Such behavior of a single crystal can be caused by a phase transition or by the anisotropic contraction of the crystal. Surprisingly, in addition to the above possible phase transition below 143 K, we have found that in the temperature range 193–213 K the crystal system changes from triclinic (space group $P\bar{1}$) to monoclinic. The corresponding phase transition was detected in the DSC-curve in this temperature region.

The crystal structure of $[Ba(hfa)_2(diglyme)_2]$ was also determined at 293 K (**III*** in Tables 1 and 4). With the temperature increase, the flexibility of the $[Ba(hfa)_2(diglyme)_2]$ molecule grows, its framework does not vary significantly but the adequacy of the structure determination diminishes (Table 4). The analysis of XRD data array gives no way to determine the space group definitely. The description of the crystal structure in both groups *Cc* and *C*2/*c* gives practically the same results (R_1 values are 3.9% and 4.6%, respectively). In this paper, the results obtained in the more symmetrical *C*2/*c* group are given. In **III*** the average $Ba–O_{hfa}$ distance is still retained (2.74 Å) while the average $Ba–O_{diglyme}$ distances of both diglyme ligands (2.93 Å) are longer than the same ones in **III** (2.89 and 2.92 Å, Table 4).

3.3. Thermal analysis

The thermal behavior of **I–III** has been studied by thermal gravimetric anaysis (TG) at low pressure (Fig. 4). For **I** the TG curve shows two main stages of weight loss (Fig. 4). The weight loss (3%) occurring in the temperature range 50–70 °C corresponds to removal of one water molecule (calc. 3%). The main weight loss (95%) takes place in the temperature range 125–160 °C and the evaporation of the mixed ligand complex $Ca(hfa)_2(diglyme)$ is mainly responsible for the weight loss at this stage. For **I**, the total weight loss is equal to 100% at 200 °C.

Complex **II** undergoes three major stages of weight loss upon heating (Fig. 4). The weight loss for first stage (80–150 °C) is equal to 16% and corresponds to dehydration (calc. 2.7%) and partial elimination of diglyme (total elimination of diglyme – 19%). However, these two processes could not be completely separated from each other. The main weight loss (70%, 150–250 °C) could be caused by three simultaneous processes: elimination of the diglyme residuary part, evaporation of $Sr(hfa)_2(diglyme)$ and evapora-

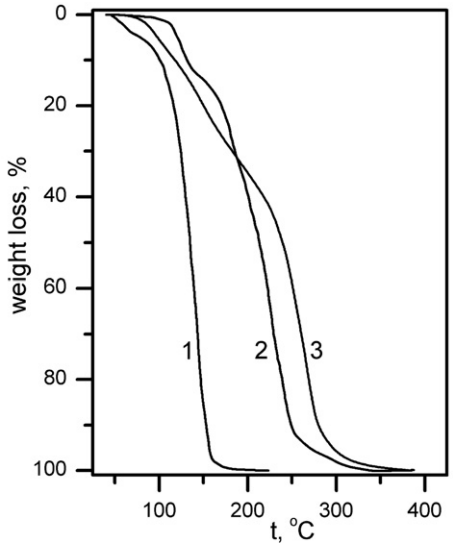

Fig. 4. TG curves for $[Ca(hfa)_2(diglyme)(H_2O)]$ (**1**), $[Sr(hfa)_2(diglyme)(H_2O)]$ (**2**) and $[Ba(hfa)_2(diglyme)_2]$ (**3**).

tion of $Sr(hfa)_2$. In the third stage (250–400 °C) the weight loss could be attributed to $Sr(hfa)_2$ evaporation. In this temperature range the TG-curves of **II** and $Sr(hfa)_2$ are very similar.

In the case of **III**, the TG-curve has two main stages. The first one, in the temperature range 120–250 °C, corresponds to elimination of two diglyme molecules (calc. 31.4%, found 32%). In the second stage (250–400 °C) the evaporation of $Ba(hfa)_2$ takes place. The total weight loss is equal to 100%.

A mass spectrometry study was performed to confirm the processes taking place on the heating of **I**–**III** complexes.

3.4. Mass spectrometry

Under the mass spectrometry experiments (10^{-5} torr), complexes **I** and **II** lose water molecules forming $[Ca(hfa)_2(diglyme)]$ and $[Sr(hfa)_2(diglyme)]$, respectively, under sample degasifying treatment at room temperature (298 K). This is consistent with the data of the TG analysis for **I** and **II**.

3.4.1. [Ca(hfa)$_2$(diglyme)]

The mass spectra of $[Ca(hfa)_2(diglyme)]$ were recorded in the temperature range 298–340 K (Table 5). The analysis of the curves of ionization efficiency, obtained for the main species, shows that the vapor phase over $[Ca(hfa)_2(diglyme)]$ consists of the mixed ligand complex molecules. From the results of full isothermal evaporation experiments it was found that the intensities of the all ion currents were constant during evaporation and the mixed ligand complex $[Ca(hfa)_2(diglyme)]$ sublimed quantitatively (without formation of a non-volatile residue in the Knudsen cell). On the basis of these data, there are grounds for believing that the mixed ligand complex $[Ca(hfa)_2(diglyme)]$ sublimes in the selected temperature range:

$$[Ca(hfa)_2(diglyme)]\ (s) = [Ca(hfa)_2(diglyme)]\ (g) \quad (1)$$

The saturated vapor pressure values of $[Ca(hfa)_2(diglyme)]$ were calculated according to the Hertz–Knudsen equation. At 325 K the vapor pressure of $[Ca(hfa)_2(diglyme)]$ is equal to 2.45×10^{-1} Pa. Based on the temperature dependence of the ion current intensities for the three ions $[Ca(hfa)_2(diglyme)]^+$, $[Ca(hfa)(diglyme)]^+$ and $[Ca(hfa)]^+$, the standard enthalpy of $[Ca(hfa)_2(diglyme)]$ sublimation was calculated:

$$\Delta_s H^0([Ca(hfa)_2(diglyme)],\ s.,\ T) = 99.8 \pm 8.3\ \text{kJ/mol}$$

Table 5
Intensities of the main ion currents (relative units) in the mass spectra of **I** (T = 325 K) and **III** (T = 450 K)

$[Ca(hfa)_2(diglyme)]$		$Ba(hfa)_2(diglyme)_2$	
Ion	I (%)	Ion	I (%)
$[Ca(hfa)-F]^+$	1	$[Ba(hfa)-CH]^+$	80
$[Ca(hfa)]^+$	17	$Ba(hfa)^+$	100
$[Ca(hfa)(diglyme)^-OC(CF_3)CH]^+$	3	$[Ba_2(hfa)+CO]^+$	20
$[Ca(hfa)+OCH_3(CH_2)_2O]^+$	1	$[Ba_2(hfa)+OCC]^+$	80
$[Ca(hfa)(diglyme)]^+$	100	$[Ba_2(hfa)+OCCF_3]^+$	17
$[Ca(hfa)_2(diglyme)-2CF_3]^+$	1	$[Ba_2(hfa)_2+CO]^+$	15
$[Ca(hfa)_2(diglyme)]^+$	6	$[Ba_2(hfa)_2+OCC]^+$	79
$[CH_3O(CH_2)_2]^+$	6	$Ba_2(hfa)_3^+$	60
		$[Ba_3(hfa)_4-OCCF_3CH]^+$	4
		$Ba_3(hfa)_4^+$	10
		$Ba_3(hfa)_5^+$	6

and the temperature dependence of the saturated vapor pressure can be approximated by the equation:

$$\ln P_{[Ca(hfa)_2(diglyme))]}\ (\text{Pa}) = -(12\,004 \pm 1000)/T + (34.6 \pm 2.0)298\text{–}340\ K.$$

3.4.2. [Sr(hfa)$_2$(diglyme)]

For $[Sr(hfa)_2(diglyme)]$ the sublimation is a more complicated process and its dependence on temperature has been found and studied. The mass spectra $[Sr(hfa)_2(diglyme)]$ were recorded in the temperature range 310–457 K (Table 6). At a temperature below 340 K the ions formed from the mixed ligand complex $[Sr(hfa)_2(diglyme)]$ were present in the spectra. Below 320–325 K the ions $[CH_3O(CH_2)_2]^+$ and $[CH_3OCH_2]^+$, corresponding to the ionization of diglyme molecules, were not detected. In the temperature range 330–400 K these ions were detected but their ion current intensities decreased down to the point of disappearance at 410 K.

Really, the mass spectra at 410 K (Table 6) and at higher temperatures were practically identical to the spectra of $[Sr(hfa)_2]$, and the vapor phase contained mainly the dimeric molecules $[Sr(hfa)_2]_2$.

The full isothermal evaporation experiments performed at all the temperatures studied confirm that the thermal behavior of $[Sr(hfa)_2(diglyme)]$ can be described by three partially overlapping processes:

$$[Sr(hfa)_2(diglyme)]\ (s) = [Sr(hfa)_2(diglyme)]\ (g) \quad 310\text{–}340\ K \quad (5)$$

$$[Sr(hfa)_2(diglyme)]\ (s) = Sr(hfa)_2\ (s) + n\ \text{diglyme}\ (g)\ (n < 1) \quad 330\text{–}410\ K \quad (6)$$

$$2\,Sr(hfa)_2\ (s) = [Sr(hfa)_2]_2\ (g) \quad 380\text{–}457\ K \quad (7)$$

The complex $[Sr(hfa)_2(diglyme)]$ sublimes (5) only in the narrow temperature range of 310-340 K. Based on the temperature dependence of the ion current intensities for $[Sr(hfa)_2(diglyme)]^+$, the standard enthalpy of $[Sr(hfa)_2(diglyme)]$ sublimation was estimated:

Table 6
Intensities of the main ion currents (relative units) in the mass spectra of **II** at 330 K and 410 K

T = 330 K		T = 410 K			
Ion	I (%)	Ion	I (%)	Ion	I (%)
$Sr(hfa)^+$	26	$[Sr_2(hfa)-CH(CF_3)_2]^+$	110	$[Sr_2(hfa)_3-OC(CF_3)_2]^+$	82
$[Sr(hfa)(diglyme)]^+$	100	$Sr(hfa)^+$	35	$[Sr_2(hfa)_3-OCCF_3]^+$	2
$[Sr(diglyme)OH]^+$	48	$[Sr_2(hfa)+OCC]^+$	100	$[Sr_2(hfa)_3-2F]^+$	12
$[Sr(hfa)_2(diglyme)]^+$	3	$[Sr(hfa)_2-2CF_3]^+$	40	$Sr_3(hfa)_3^+$	18
$[CH_3O(CH_2)_2]^+$	150	$[Sr(hfa)_2-CF_3]^+$	30	$[Sr_2(hfa)_3+OCCF_2]^+$	1
$[CH_3OCH_2]^+$	50			$[Sr_2(hfa)_4-OCCF_3]^+$	8

$\Delta_s H^0([Sr(hfa)_2(diglyme)],\ s.,\ T) \geqslant 82$ kJ/mol 310—340 K.

On increasing the temperature, the removal of diglyme (6) and evaporation of $[Sr(hfa)_2]$ (7) occurrs. The estimation of the standard enthalpy of $[Sr(hfa)_2]_2$ evaporation was made according to the second thermodynamic law, based on the data of six independent experiments in the temperature range 380–410 K:

$\Delta_s H^0([Sr(hfa)_2]_2,\ T) \leqslant 177 \pm 10$ kJ/mol 380—410 K

3.4.3. [Ba(hfa)$_2$(diglyme)$_2$]

For $[Ba(hfa)_2(diglyme)_2]$ the mass spectra were measured in the temperature range 330–485 K. The results of the full isothermal experiments show that in the temperature range 330–380 K the vapor phase contains only diglyme molecules and the spectra are very similar to that for pure diglyme in the same temperature range. With increasing temperature the current intensities of the $[CH_3O(CH_2)_2]^+$ and $[CH_3OCH_2]^+$ ions decreased and disappeared from the spectra at $T > 430$ K. The peaks of barium-containing ions appeared in the spectra above 380 K, however the mixed ligand ions were not found. Above 430 K the spectra had invariable character (Table 5), which is very similar to that for pure $[Ba(hfa)_2]$, consisting in the trimeric form in the vapor phase [31]. Thus, the sublimation of $[Ba(hfa)_2(diglyme)_2]$ proceeds with the removal of both diglyme molecules and can be described by two consecutive processes:

$$[Ba(hfa)_2(diglyme)_2]\ (s) = Ba(hfa)_2\ (s) + 2\,diglyme\ (g), \quad (8)$$

$$3\,Ba(hfa)_2\ (s) = [Ba(hfa)_2]_3\ (g). \quad (9)$$

The standard enthalpy value of $[Ba(hfa)_2]_3$ sublimation, which was made according the second thermodynamic law, based on the data of six independent experiments:

$\Delta_s H^0([Ba(hfa)_2]_3,\ T) = 183.2 \pm 4.5$ kJ/mol 430—480 K,

is in good agreement with that obtained in [31]:

$\Delta_s H^0([Ba(hfa)_2]_3) = 181.3 \pm 1.5$ kJ/mol 420—470 K.

Thus, the data of thermal analysis at low pressure and mass spectrometry showed that the stability of the mixed ligand complexes $[M(hfa)_2(diglyme)_n]$ to the removal of diglyme molecules under heating decreases in the row **I** > **II** ≈ **II**. Only **I** evaporates as the mixed ligand complex after water removal and it is in line with the decrease of Lewis acidity in the row $Ca(hfa)_2$–$Sr(hfa)_2$–$Ba(hfa)_2$. However, such low thermal stability of the diglyme mixed ligand complexes with both $Sr(hfa)_2$ and $Ba(hfa)_2$ is slightly unexpected. In the literature the thermal behaviors of the similar mixed ligand complexes $[Sr(hfa)_2(Dipy)_2]$ [28] and $[Ba(hfa)_2(Phen)_2]$ [27] have been described and it has been found that $[Sr(hfa)_2(Dipy)_2]$ sublimes intact but the sublimation of $[Ba(hfa)_2(Phen)_2]$ is carried out in two stages: the removal of one Phen ligand and then the sublimation of $[Ba(hfa)_2(Phen)]$. Even for non-fluorinated complexes $[M(thd)_2(Phen)_2]$ (M = Ca, Sr), where $M(thd)_2$ is a weaker Lewis acid than $M(hfa)_2$, the same two-stage scheme with the removal of only one ancillary ligand and the sublimation of $[M(thd)_2(Phen)]$ was found [29]. Diglyme as the ancillary ligand, containing three donor oxygen atoms and forming two chelate rings with the central ion, should be stronger bound together with barium or strontium hexafluoroacetylacetonates than the Dipy or Phen ancillary ligands. In our opinion, the thermal behavior feature of **II** and **III** can be explained with the respect to the rather high volatility of diglyme in comparison with Dipy and Phen. The intensive diglyme evaporation at rather low temperature results in the undesirable thermal dissociation: $[M(hfa)_2Q_n]\ (s) \rightarrow M(hfa)_2\ (s) + nQ\ (g)$ in contrast to the mixed ligand complexes with the low volatile Dipy and Phen. The results obtained give evidence on the important role of $M(dik)_2$ and Q volatility correlation in the thermal stability features of AEE mixed ligand β-diketonates $[M(dik)_2Q_n]$ used as MOCVD precursors.

4. Conclusions

By way of an example of mixed ligand complexes of AEE hexafluoroacetylacetonates with diglyme, this work demonstrated once again a wide variety of compositions, structures and properties typical for the coordination chemistry of AEE β-diketonates. Although the same synthetic procedure was applied for Ca, Sr and Ba compounds, their compositions differed. The complex $[Ba(hfa)_2(diglyme)_2]$ demonstrated an unexpected high stability in solution that originated probably from a macrochelate effect, because the large Ba ions allow the arrangement of two diglyme ligands instead of water in their coordination sphere (CN = 10). Smaller in size, Ca and Sr ions coordinate only one diglyme ligand together with a water molecule, reaching CN = 8. According to the X-ray structural analysis, all the mixed ligand complexes obtained are molecular crystals. In the crystal structures of $[M(hfa)_2(diglyme)(H_2O)]$ (M = Ca, Sr) water molecules take part in intermolecular hydrogen bonds. In spite of this, the water molecules are weakly kept in the crystal lattice and are removed in vacuum (room temperature at 10^{-5} torr or 50–70 °C at 10^{-2} torr) producing unhydrous $[M(hfa)_2(diglyme)]$. The stability of the mixed ligand complexes $[M(hfa)_2(diglyme)_n]$ to removal of diglyme molecules under heating decreases by changing M in the order Ca > Sr ≈ Ba. According to the mass spectrometry data, both diglyme ligands are fully removed by heating $[Ba(hfa)_2(diglyme)_2]$ up to 330 K and the vapor phase consists of trimeric $[Ba(hfa)_2]_3$ molecules at $T > 430$ K. $[Ca(hfa)_2(diglyme)]$ sublimes in the 298–330 K temperature range. The thermal behavior of $[Sr(hfa)_2(diglyme)]$ combines the features of both neighbouring complexes: it sublimes in the very narrow temperature range of 310–330 K, then removes diglyme at higher temperatures (340–410 K) and finally evaporates as dimeric molecules of $[Sr(hfa)_2]_2$ at $T > 410$ K.

The mentioned variety of compositions, structures, properties of the complexes synthesized and studied is caused by the specific features of AEE coordination chemistry, namely by the interplay of three factors – the increase of ionic radii in the row Ca–Sr–Ba, the predominantly ionic bond nature that allows significant variability in the geometry of the coordination sphere, as well as the ability of AEE ions to saturate their coordination sphere by any donor molecules available in the reaction mixture during synthesis.

section into the bridge, which breaks the conjugation, as *e.g.* in Q = 1,2-bi(4-pyridyl)ethane (105 mV, $K_c = 60$) [6], considerably decreases ΔE_f, but does not exclude electronic and magnetic through-bridge interactions. However, few examples of complexes containing completely saturated bridges have been described in the literature, *e.g.* cyclic piperazine-1,4-diyl, Q = NC_4H_8N (560 mV, $K_c = 3 \times 10^9$) [10].

We have shown [11,12] that bimetallic complexes with $\{Mo(NO)(Tp^{Me2})X\}^+$ (X denotes Cl or Br) core incorporating saturated *n*-alkanediolate bridges exhibit two chemically reversible one-electron reduction processes. The separations between these processes, being the largest for the complex with a C_2 bridge (310 mV, $K_c = 1.7 \times 10^5$; Mo···Mo distance >6 Å) decrease by *ca.* 100 mV per CH_2 group for C_2 to C_4 bridges. Starting with C_5 bridge the electrochemical interactions could not be detected. The reappearance of a measurable separation between the redox potentials in fluorinated C_5 analogue $[\{Mo(NO)(Tp^{Me2})Cl\}_2\{OCH_2(CF_2)_3CH_2O\}]$ ($\Delta E_f = 70$ mV), in spite of both bridges imposing the same Mo···Mo distance, is significant and can be explained partly by through-bond interactions enabled by inductive effect of fluorine atoms transmitted through the σ-bond framework. This effect also manifested itself in an anodic shift of *ca.* 300 mV of the first reduction potential, which reflects LUMO stabilization in comparison with a non-fluorinated bimetallic complex. A different solvent reorganization effects cannot be excluded in these two cases.

These findings posed a challenge to prospective theoretical research on the nature of electrochemical interactions in bimetallic complexes with saturated bridging ligands. On the other hand, quick development of quantum chemistry methods (especially DFT) in the last few years prompted us to undertake DFT studies on weakly coupled metallic centers in complexes constructed from $\{M(NO)(Tp^{Me2})\}^{2+}$ core, one or two saturated bridges and/or Cl^- ligands. Such modeling has already been used more and more widely to examine mixed-valence compounds [13,14], recently also for nitrosyl complexes containing tris(3,5-dimethylpyrazol-1-yl)hydroborate ligand [15], what encouraged us to undertake the research presented in this paper.

In this work we focus on the stabilization of reduced mixed-valence species incorporating single and double ethane-1,2-diolate bridges: $[\{Mo(NO)(Tp^{Me2})Cl\}_2\{O(CH_2)_2O\}]$ (**A**) and $[Mo(NO)(Tp^{Me2})\{O(CH_2)_2O\}]_2$ (**B**). Monometallic analogue (**M**) $[Mo(NO)(Tp^{Me2})Cl\{O(CH_2)_2OH\}]$ serves for comparative analysis. Calculated geometries, electron affinities and NO stretching frequencies are correlated with experimental X-ray, CV and IR spectral data, where available, in order to as well validate DFT results as draw conclusions regarding localization of additional electron after electrochemical reduction. Electrochemical data for monometallic and singly bridged complex have already been published [11]. Stretching frequencies of NO for monometallic and singly bridged species in solution are given in this work. Unfortunately, doubly bridged bimetallic complex was not soluble in any solvent allowing for electrochemical studies.

2. Methodology

2.1. Experimental

The complexes $[\{Mo(NO)(Tp^{Me2})Cl\}_n\{O(CH_2)_2OH_{2-n}\}]$ ($n = 1$ or 2) were prepared according to the literature [11]. The reduced forms of these species were prepared by addition of cobaltocene to solutions of the neutral complexes in dichloromethane freshly distilled from CaH_2 under argon. Infrared spectra for singly bridged complex with its monometallic analogue reported in this work were recorded using a Bio-Rad FTS 175C spectrophotometer in CH_2Cl_2 solutions.

2.2. Models

All calculations in this paper were conducted on mimetic models in which outer methyl groups of tris(3,5-dimethylpyrazol-1-yl)hydroborate ligand were cut off to avoid additional energy inaccuracy due to nearly free rotation of these groups. Secondly it helped to decrease computational problem size. Methyl groups next to nitrosyl ligand were retained since they appeared to be important for keeping proper geometry of NO group and bridging unit. Therefore all compounds presented here contain hydrotris(3-methylpyrazol-1-yl)borato ligand.

Starting geometry of bimetallic doubly bridged complex (**B**) was obtained from crystallographic structure of $[Mo(NO)(Tp^{Me2})\{O(CH_2)_2O\}]_2$ [11]. This structure is highly symmetric having C_{2h} point group symmetry. Both monometallic complex (**M**) and bimetallic singly bridged complex (**A**) starting structures were prepared from computed equilibrium geometry of **B**. Complex **A** has C_i symmetry, which was used to prepare the starting structure of this species. Geometries of neutral complexes, monoanions and dianions were optimized independently. Symmetry constraints were used during geometry optimization of non-reduced **A** and **B** compounds. On the contrary, computations for singly and doubly reduced complexes of **A** and **B** were carried both with and without imposing symmetry.

2.3. DFT calculations

Calculations were performed using GAUSSIAN03 [16] within both unrestricted and restricted DFT with hybrid B3LYP functional, widely used in mixed-valence theoretical studies [13,14], and LanL2DZ [17–19] basis set (denoted as BS1), with effective core potential on heavy atoms (molybdenum and chlorine atoms). Additional polarization and diffuse functions were added for chlorine atoms [20]. For BS1 geometries, additional single-point calculations were performed with the extended basis set labeled as BS2 being of triple zeta quality with polarization functions for all atoms. This basis set was constructed using def2TZVPP [21,22] for molybdenum and def2TZVP [21,23] for other atoms. Additionally, for selected properties the performance of non-hybrid OLYP [24] potential was tested in smaller basis BS1.

Vacuum equilibrium geometries were used to estimate solvent effects by means of the self-consistent reactions field (SCRF) method called polarizable continuum model (PCM) [25]. Dielectric constant of actual dichloromethane solvent ($\varepsilon = 8.93$) and UFF scheme for cavity generation were used for single-point computations. IR spectra were calculated for gas phase models using standard harmonic approximation for equilibrium geometries. Contour plots of spin densities were prepared using GABEDIT [26].

3. Results and discussion

3.1. Experimental results

The electrochemical results reported for $[\{Mo(NO)(Tp^{Me2})Cl\}_2\{O(CH_2)_2O\}]$ (**A**) (first reduction process at $E_f = -1.11$ V *vs.* Fc/Fc^+; separation $\Delta E_f = 310$ mV) [11] indicate that the mixed-valence $\{16e{:}17e\}^-$ form of **A** is accessible by the reduction of the neutral precursor $\{16e{:}16e\}$ using cobaltocene ($E_f = -1.34$ V *vs.* Fc/Fc^+). We chose the chloride complex, since voltammetric studies of the iodo complexes revealed that the reduction is followed by the dissociation of I^-, which may disturb the reduction process. The IR spectrum of $\mathbf{A}^-$ in dichloromethane exhibits two NO stretching vibrations, at 1605 and 1542 cm^{-1} ($\Delta\nu_{NO} = 63$ cm^{-1}) instead of one (1680 cm^{-1}) in the neutral precursor or monometallic analogue (Table 10). This shows that this species is valence-trapped

on the IR timescale (*ca.* 10^{-13} s) and can be classified as Class I in the Robin-Day scheme (double minimum on the potential-energy curve).

3.2. Equilibrium geometries

Optimized geometries of **A** and **B** are shown in Fig. 1 and Tables 1 and 2, respectively. Computed geometrical parameters show good agreement with available X-ray crystal structure (Table 2). Even the distance between two molybdenum atoms, which is crucial for electronic interactions investigation but could be very sensitive to any inaccuracies in computed geometry, is reasonably reproduced. In singly bridged complex **A** this distance is greater by nearly 1.3 Å (25%) than in **B**. As a result of close packing, the crystal unit cell of **B** contains two nonequivalent molecules having slightly different geometries; therefore two experimental structure data are shown in Table 2.

Addition of an extra electron triggers symmetry breaking in examined compounds. In both complexes **A** and **B** molybdenum centers become nonequivalent after first reduction. Values of selected bonds and angles in molybdenum's neighborhood are given in Tables 3 and 4. The most dramatic difference relates to distances between molybdenum and bridging oxygen ($\Delta R \sim 6\%$) or chlorine ($\Delta R \sim 5\%$), also the distances molybdenum–nitrosyl ($\Delta R \sim 0.4\%$) and nitrogen–oxygen ($\Delta R \sim 1.5\%$) differ between nonequivalent centers; molybdenum–molybdenum separation changes after reduction by nearly 2%.

Second reduction leads to triplet dianions with selected geometrical parameters shown in Tables 5 and 6 for **A** and **B**, respectively. The inspection of the tables indicates that differences between both molybdenum centers become insignificant in doubly reduced complexes.

As mentioned above, computations for singly and doubly reduced complexes were performed both with and without symmetry constraints. The comparison between energies of equilibrium structures of symmetric and asymmetric singly reduced compounds indicates the stabilization of the asymmetric ones (Table 7), with larger effect for singly bridged compound **A**. Additional single-point BS2 calculations confirm these results. The stabilization of asymmetric structures for singly and doubly bridged species equals to 0.162 eV and 0.037 eV for BS1 and was increased to 0.201 eV and 0.048 eV for BS2, respectively. The energetic stabilization of asymmetric structures and differences in geometries of molybdenum neighborhood confirm nonequivalence of molybdenum atoms in mixed-valence single reduced complexes and, what follows, substantial localization of additional electron. Stabilization of asymmetric structure with extra electron trapped on one molyb-

denum site may be rather underestimated here due to known tendency of B3LYP to favor delocalized solutions [27].

3.3. Analysis of electron affinities

The investigations of mixed-valence compounds carried out most commonly by electrochemical experiments provide information about the strength of the electronic metal–metal interactions, measured as the splitting between the redox potentials of metal centers (ΔE_f). The splitting may be well approximated by the difference between the first and second electron affinity, denoted as $EA^{(1)}$ and $EA^{(2)}$ (in the case of reduction) or ionization potentials (in the case of oxidation) of a mixed-valence complex.

Electron affinities of **A** and **B** shown in Table 8 were calculated as the differences between total energies of neutral and singly reduced ($EA^{(1)}$) or singly reduced and doubly reduced ($EA^{(2)}$) complexes. Table 8 lists also the differences between computed first and second electron affinities that may be directly compared with experimental ΔE_f listed in the last row of Table 8. Comparison of electron affinities calculated in gas phase and with PCM solvent model indicates that solvent effects play crucial role in stabilization of negatively charged complexes. Calculations with significantly bigger BS2 basis set, in which description of negatively charged species should be of better quality, do not change trends in electron affinities neither in vacuum nor in PCM solvent model. Moreover, even rough solvent model such as PCM provides reasonable agreement with experimental data already at the simplest level. The description of electron affinity differences is improved in extended basis set, the introduction of non-hybrid OLYP functional for solvent model also complies with the experiment. However, one has to be aware that PCM methodology depends on the choice of cavity parameters, which brings additional uncertainty to computed energies thus by no means do we claim quantitative reproduction of the experiment.

Table 8

[b] From Ref. [11].

3.4. Analysis of spin densities

Spin density plots for singly reduced complex **A** and **B** are shown on Fig. 2a and 2b, respectively. Localization of an extra electron on one molybdenum center is clearly visible, however, some delocalization (about 10% – see Table 9) occurs in the case of compound **B** with double bridge, where the distance between molybdenum atoms is nearly 25% smaller than in complex **A**. The plots indicate also that the additional electron is partly delocalized towards NO ligand, with antiferromagnetic coupling. This phenomenon has already been reported in the literature both for mononuclear and binuclear metal-nitrosyl complexes [28–30], however, here it may be overestimated due to the tendency of UDFT to favor delocalized solutions [23] and to suffer from spin contamination [24,25]. Data collected in Table 9 bring additional evidence that the injected electron is trapped on $Mo^{(1)}$.

After second reduction the two molybdenum centers become again equivalent. Spin density on NO ligand may be taken as qualitative fingerprint of metal to ligand π-backdonation enhanced by spurious electron density on Mo center after reduction. Both the increase of the basis set and in particular the use of non-hybrid functional increase delocalization of the extra electron towards the second molybdenum center. Nevertheless, this does not change qualitative picture of an electron predominantly trapped on one molybdenum. In the OLYP case the increase of electron delocalization goes in line with known tendency of non-hybrid potentials, favoring delocalized solutions in comparison to hybrid ones [31]. Smaller values of Mo and NO spin densities in **B** than in **A** may be additionally rationalized by to the lack of chlorine ligand in the former case.

3.5. Analysis of IR spectra

In experimental IR spectra after first reduction, both nitrosyl stretching frequencies are shifted towards red, but the splitting of 63 cm^{-1} is registered. Theoretical computations go in line with the experiment, however, the shift of nitrosyl stretching frequency for non-reduced center in $\mathbf{A}^-$ and $\mathbf{B}^-$ is underestimated. Therefore computed splitting of nitrosyl stretching frequencies in singly reduced compound **A** is bigger by 30 cm^{-1} than the experimental value. Nevertheless, both experiment and theory nicely corroborate the issue of electron trapping on IR time scale. Similar situation occurs in singly reduced complex **B** – calculated nitrosyl vibrational bands are split, but due to partial delocalization of the extra electron the splitting is smaller than in **A**. Unfortunately, experimental IR spectra for **B** are not available thus only

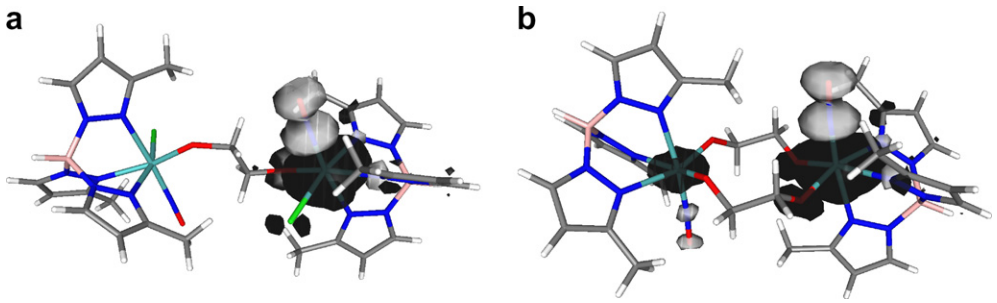

Fig. 2. Spin density plots for singly reduced complexes **A** (a) and **B** (b) (contour value 0.002).

[b] Data from Ref. [11], obtained in KBr disc.
[c] Complex **B** was insoluble in solvents other than $CHCl_3$, which is unsuitable for

theoretical analysis is possible here. On the contrary, the two nitrosyl stretching vibrations calculated for doubly reduced complexes have the same frequency (1545 cm^{-1} in the case of **A** and 1476 cm^{-1} for **B**), slightly lower than the frequency of nitrosyl bound to reduced Mo in singly reduced species, due to additional electrostatic interaction with the second reduced metal center.

Calculated shifts of NO stretching frequencies are consistent with the increase of NO bond distances (Tables 1–6) and metal to ligand π-backdonation ability estimated from spin density transfer towards NO. Nearly linear geometry of NO ligand in neutral complexes would comply with classification of diamagnetic ($S = 0$) and nearly linear MoNO moieties into nitrosonium category [32]. Neither NO bond length nor low IR frequency, however, do correspond to the assumption of NO^+ ligand. Reduction of Mo centers yields more radical character on NO; linearity of Mo–NO fragment is retained what may be attributed to geometrical constraints imposed by surrounding CH_3 groups from hydrotris(3-methylpyrazol-1-yl)borate ligand. In summary, no quantitative agreement of calculated and measured IR spectra could be expected here since theoretical NO frequencies could be calculated only in vacuum whereas experiment was done in solution. Nevertheless, both experiment and theory properly describe qualitative features of IR spectra for neutral and reduced bimetallic complexes; the dependence of NO stretching frequencies on the degree of electron density localization is properly described and helps to understand the nature of mixed-valence compounds.

4. Conclusions

Electronic structure of mixed-valence states of two bimetallic hydrotris(3-methylpyrazol-1-yl)borato molybdenum nitrosyl complexes and their reduced forms has been theoretically investigated. Computed IR spectra, geometrical and energetic parameters show good agreement with experimental results, which allows for the validation of our computational scheme for such large molecules. DFT modeling showed to be capable of describing symmetry-broken structures with the electron trapped on one reduced Mo center in mixed-valence complexes; however, some electron delocalization through the saturated bridge may be also directly evidenced here.

DFT calculations have shown that the nonequivalence of molybdenum centers in mixed-valence compound is energetically favorable and in both investigated bimetallic complexes an extra electron is localized on one of the molybdenum centers. Therefore both compounds should be considered as Class I complexes according to Robin-Day classification. However, in the doubly bridged complex (**B**) partial electron delocalization occurs, which may suggest that saturated bridging ligands could play a role in the strengthening of electronic interactions and, what follows, shifting the complex into Class II category.

In addition, calculating and experimental infrared spectra confirm the assumption of electron localization yielding Class I labeling, stemming from geometry, energetic and spin density discussions. As could be expected, stretching vibrations of NO bound to two molybdenum centers in singly reduced complexes are diversified. After addition of the second electron this difference vanishes. This reasoning corroborates electron localization in mixed-valence compounds prepared from **A** and **B**. Again, in the case of doubly bridged complex (**B**) partial delocalization occurs, while in singly bridged compound (**A**) it is much less significant.

Present work may be regarded as a first part (concentrating on short bridging ligands) of a bigger project that concerns the study of possible mechanisms of electron transfer trough saturated bridges in $\{Mo(NO)Tp\}^{2+/1+}$ complexes, undertaken in our group.

Acknowledgments

The computations were performed at the Academic Computer Centre CYFRONET AGH (Grant Nos. MNiSW/SGI2800/UJ/133/2006 and MNiSW/SGI3700/UJ/133/2006).

All figures of the molecular models were created using xyz-viewer software by Sven de Marothy (from Stockholm University).

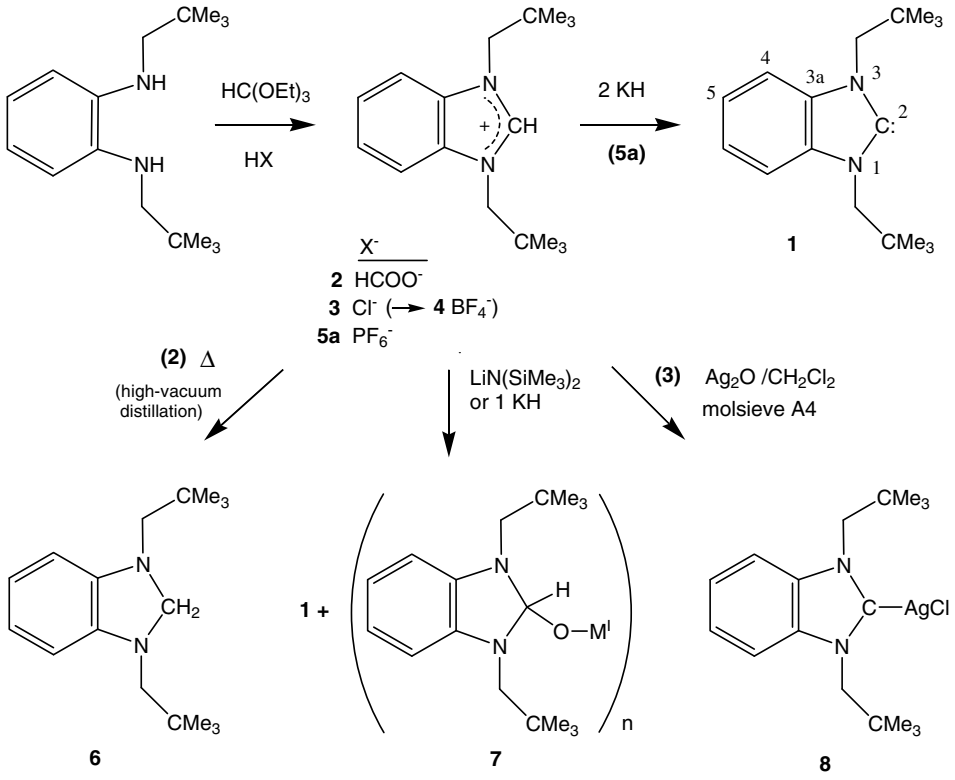
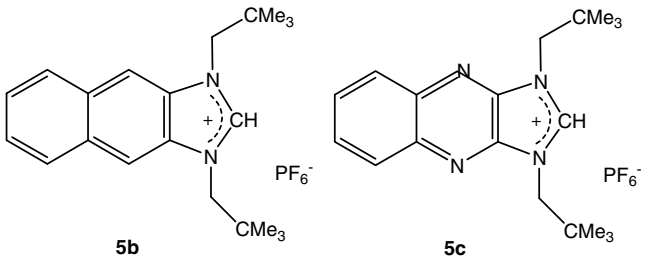


Scheme 1. Formation and deprotonation of anellated *N*,*N*′-dineopentyl-imidazolium salts.

N,*N*′-dimethyl- and dibutylbenzimidazolium formate [14]. The ^{1}H and ^{13}C NMR data are in accordance with those recently reported [6].

Deprotonation of **2** by $LiN(SiMe_3)_2$ in THF furnished mainly the corresponding carbene, but accompanied by a small amount of a lithium salt $\mathbf{7_{Li}}$ that displays similar solution NMR data to a known NHC–KOH adduct, In the solid state the latter is a tetramer anellated imidazolium compound bound at a $(KO^{-})_4$-cluster with distorted cubane structure as the anion, but in solution it disproportionates into the corresponding dihydroimidazole and imidazol-2-one coordinating the potassium oxide [12a]. $\mathbf{7_{Li}}$ is thought to be the corresponding lithium compound, a formal addition product of **1** and LiOH, formed by traces of moisture originating from the aqueous formic acid, that in solution disproportionates into **6** and dineopentyl-benzimidazol-2-one coordinated at Li_2O, and thus displays two sets of signals with equal intensity.

To avoid contamination by water, the benzimidazolium chloride **3** was prepared by cyclocondensation of *N*,*N*′-dineopentyl-1,2-diaminobenzene with triethyl orthoformate in the presence of anhydrous ethereal HCl. Carbon analyses of **3** were not satisfactory, but conversion to the well-defined tetrafluoroborate **4** by treatment with $AgBF_4$ confirmed its composition. As starting material for the synthesis of **1** the hexafluorophosphate **5a**, formed directly by orthoformate condensation in the presence of stoichiometric amounts of NH_4PF_6, proved to be superior. As expected, the protons in position 2 of the anellated imidazolium salts **2–5** are quite acidic and appear in the ^{1}H NMR spectra at low field. The proton chemical shifts depend somewhat on the solvent and the anion. In CD_3CN they are more strongly shifted for the polarizing anion chloride than the weakly coordinating PF_6^{-} anion (**3** $\delta = 9.77$, **5a** $\delta = 8.87$), while in the highly polar O-donor solvent DMSO-d_6 the stronger downfield shift is observed also in the case of weakly coordinating anions (**4** $\delta = 9.70$, **5a** $\delta = 9.71$). The CH-acidity leads to more or less strong H–D exchange, visible by low-intensity H-2 proton and superimposed $\{^{1}H\}^{13}CH$-2 singlet and ^{13}CD-2 triplet signals, but rates or amounts of this exchange were not systematically studied. Attempts to deprotonate the benzimidazolium salts **3** or **5a** on the NMR scale with an equimolar amount of $LiN(SiMe_3)_2$ in toluene or THF did not display the signals of **1** but again the two sets assigned to the disproportion products of $\mathbf{7_{Li}}$. The use of two equivalents of the base provided the carbene in high yield, but accompanied by the second equivalent of $LiN(SiMe_3)_2$ and $HN(SiMe_3)_2$. A convenient synthesis of free **1** in high yield and on a preparative scale proved to be the deprotonation of **5a** by potassium hydride in THF in 1:1, or better in 1:2 molar ratio. The excess KH did not cause reduction but improved the yield. The deprotonation of **3** by KH (1:1) in THF was found to be less suitable and gave only 50 mol% of **1** along with some $\mathbf{7_K}$ and unidentified contamination. The formation of dimers, which might be favored by the presence of the imidazolium salts (proton catalysis) [15], was not observed, probably because of steric hindrance by the neopentyl substituents.



Compounds 5b and 5c

The two closely related hexafluorophosphates **5b** and **5c** were obtained by reaction of the respective aromatic diamines with triethyl orthoformate in the presence of stoichiometric amounts of NH_4PF_6

Table 1

CH_2	58.4	60.0	56.8	57.0	56.4	62.0
C_{bridge}	133.4	134.48	132.0	130.8; 131.2	138.2; 140.4	136.4
C_{aryl1}	115.0; 127.6	116.3; 129.1	114.2; 126.4	111.9		114.41 125.3
C_{aryl2}				126.6; 128.2	128.9; 131.2	
C_{But}	34.14	35.16	33.12	33.2	33.0	35.8
C_{But}	27.57	29.04	27.00	27.1	27.1	30.5

[a] ^{1}H NMR data in parentheses measured in CD_3CN.

in moderate yields. The NMR spectra of **5a**, **5b** and **5c** in DMSO-d_6 show the expected trends of $\delta = 9.71$ (**5a**), 9.92 (**5b**) and 10.50 ppm (**5c**) in the proton NMR spectrum and $\delta = 143.57$ (**5a**), 147.57 (**5b**) and 153.16 ppm (**5c**) in the ^{13}C {^{1}H} NMR spectrum (Table 1). The downfield shift of either the H-2-proton or the C-2-carbon atom is seemingly dependent upon the electron-withdrawing effect of the anellated aromatic ring system in the order quinoxaline > naphthalene > benzene, as predicted by the anellation effect [16].

Reaction of **3** with Ag_2O in methylene chloride affords the AgCl adduct of **1** in nearly quantitative yield (98% isolated). The silver complex is soluble in CH_2Cl_2 and in THF and somewhat light-sensitive.

3. Crystal and molecular structures

Structures of *N*,*N*′-disubstituted imidazolium salts with very short C–H···O hydrogen bonds to oxoanions such as NO_3^-, SO_4^{2-}, $S_2O_7^{2-}$ $CF_3SO_3^-$ or ClO_4^- [2f], HCO_3^- [17] or phenolates [4] have already been reported, but structure reports of anellated species of this type [18] or with carboxylate anions [19] are rare.

A single-crystal X-ray study of **2** · 2HCOOH, taken from the original mother liquor, indicated hydrogen bonding between the formic acid molecules and also between the oxygen atoms of the formate anion and the acidic hydrogen atom at C-2 (Fig. 1). However, disorder of one of the formic acid molecules prevented acceptable refinement, and we therefore present no details of this structure beyond the structural motif.

The formate anion and the formic acid molecules form an unbranched linear chain held together by hydrogen bonding. It is reasonable to assume that the benzimidazolium cation uses its acidic H-2 proton to hydrogen bond to an oxygen atom of the formate anion. This seems to be the case, but we cannot unambiguously distinguish between the formate and the formic acid entities.

Compound **3**·CH_2Cl_2 (Fig. 2) crystallises in the monoclinic space group $P2_1/c$ with four formula units in the unit cell. The bond lengths and angles lie in the expected ranges (Table 2).

The packing (Fig. 3) involves six C–H···Cl interactions, five of them involving the chloride anion (three within the asymmetric unit), the H-1 atom (in ring position 2) prominently amongst them (C1–H1 95(2), H1···Cl1 262(2) pm). Five of these combine to produce layers parallel to the *ab* plane; H13B···Cl1 and the short contact Cl3···Cl1 354.0(2) pm connect the layers.

Compound **5a** (Fig. 4) crystallises in the monoclinic, non-centrosymmetric space group *Pc* with two molecules in the unit cell. The bond lengths and angles lie in the expected ranges with the N1–C2–N3 angle at 111.06(12)° (Table 2). The similarity of the shortest H···F distance from the hydrogen atom at the carbene carbon (H1···F(6) 244(2) pm; C···F 301.83(16) pm) to other F···H contacts in **5a** (242–264 pm; C···F 339.24(17)–352.42(18) pm) and the small variation of the P–F bond lengths (159.36(9)–

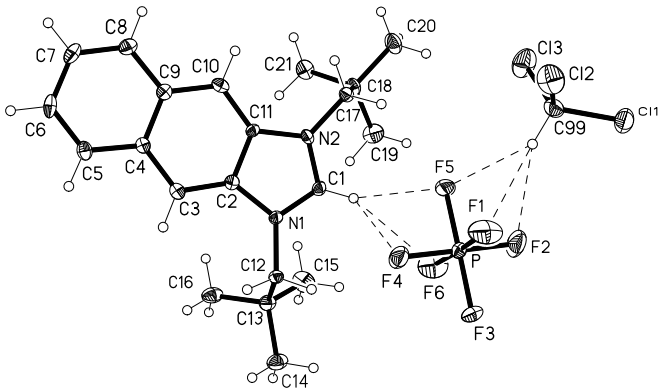

Fig. 6. Structure of **5b** in the crystal (ellipsoids with 30% probability).

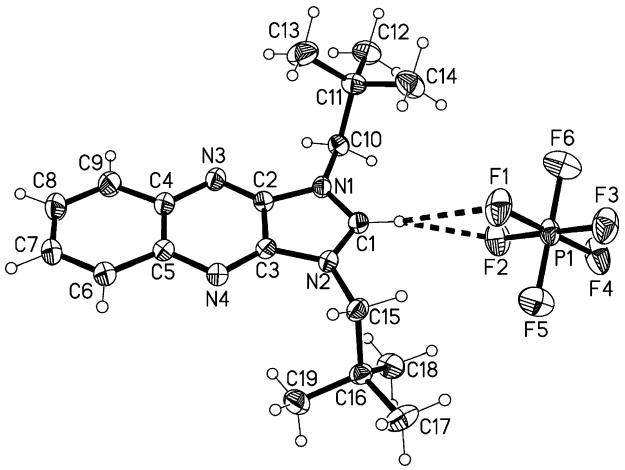

Fig. 7. Molecular structure of **5c** (ellipsoids with 50% probability).

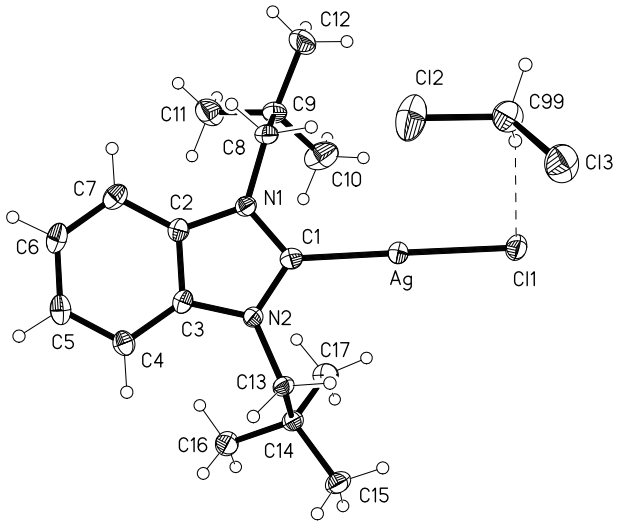

Fig. 8. Molecular structure of **8** · CD_2Cl_2 (ellipsoids with 50% probability).

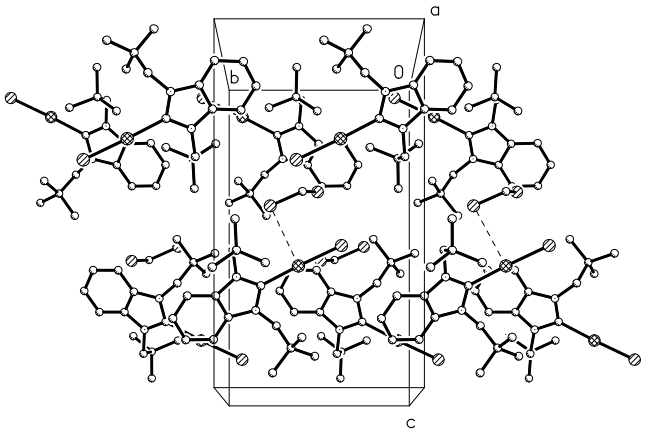
weaker packing effect rather than a directed interaction. The packing of **5a**, with columns of cations and anions parallel to the *a* axis, is depicted in Fig. 5.

For comparison, the structures of related, but differently anellated naphtho- and quinoxalino[2,3-d]imidazolium hexafluorophosphates **5b** and **5c** were also studied. Compound **5b** (Fig. 6) crystallises in the monoclinic space group $P2_1/c$ with four molecules in the unit cell, compound **5c** (Fig. 7) in the triclinic space group $P\bar{1}$ with two molecules in the unit cell. The bond lengths and angles of both compounds lie in the expected ranges and are very similar to those of **5a** and **3** (Table 2).



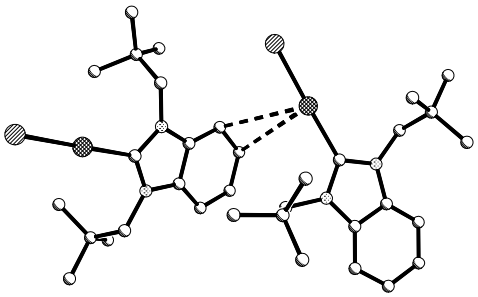


Fig. 9. General packing showing Ag···Cl contacts (a) and intermolecular silver–carbon contacts (b) in the crystal of **8** · CD_2Cl_2.

The packing in both the naphtho- and quinoxalino-anellated imidazolium hexafluoro-phosphates involves some short C–H···F contacts (several involving H1 at the carbenic carbon, Figs. 6,7). However, the overall packing patterns display no clearly recognisable motifs such as ribbons or layers.

Compound **8** is isolobal with the carbene-H···X adducts by virtue of its $4d^{10}5s^1$ electron configuration and preference for twofold coordination, and represents the carbene complex structure with similar molecular architecture (Fig. 8). However, the metal is much larger than hydrogen and possesses d-electrons for back bonding, which limits this comparison. Compound **8** crystallises in the monoclinic space group $P2_1/n$ with four molecules in the unit cell.

The silver atom shows the well-known linear coordination sphere for Ag(I,) with a chloro and a carbene ligand. The C–Ag–Cl angle is 175.88° and thus deviates slightly from linearity. This deviation may be caused by a close contact of the silver atom to the C4–C5 bond of a second carbene moiety in the packing (Ag···C4 340 pm, Ag···C5 367 pm; operator $0.5 - x$, $0.5 + y$, $0.5 - z$) (Fig. 9). Such silver aryl interactions are known, but have been observed in only one silver NHC complex, the naphtho-anellated analogue of **8** [12a], which forms dimers (Ag···C5 343 pm, Ag···C6 311 pm, Ag···C7 358 pm). There is also a contact of 358.39(6) pm from the silver atom to Cl(2) of the solvent, and one of 269 pm from a solvent deuterium to the chloro ligand, both within the asymmetric unit. There are no Ag···Ag interactions in the crystal. The C^{II}–Ag and C^{II}–N bond lengths in **8** are similar to those reported for other NHC–Ag complexes [9a,21–24] and do not indicate any systematic effect of anellation on the bond lengths. As compared to the ligand **1** [6] the NCN angle is markedly larger (by ca. 3°), but the C^{II}–N bonds are not significantly shorter in **8** (difference ca. 1 pm and thus within 3σ). Other bond lengths of **8** (Table 2) are similar to those in related compounds. The resemblance of the structural

motif in **8** to that frequently encountered [9a] in [Ag(NHC)][$AgBr_2$] complexes is noticeable, whereby the aryl formally takes the place of the $AgBr_2$ unit.

4. Conclusions

1,3-Dineopentyl-benzimidazol-2-ylidene (**1**) is available easily and in high yield by ring closure of 1,2-di(neopentylamino)benzene with orthoformate in the presence of NH_4PF_6 and deprotonation with excess KH in THF. Stoichiometric amounts of KH and other bases such as $LiN(SiMe_3)_2$ or KH/KO*t*Bu proved less suitable. Crystal structure analyses of various anellated imidazolium salts, for comparison each *N*,*N*′-dineopentyl substituted, displayed neither significant changes nor systematic trends of bond lengths and angles within the five-membered ring. The ^1H and ^{13}C NMR chemical shifts of the CH(2) nuclei, which are particularly sensitive to the π-electron density, indicate however the electronic influence of the anellated ring and are downfield shifted as a result of electron-withdrawing anellation.

5. Experimental

General remarks: All reactions were carried out in carefully dried, freshly distilled solvents. Reactions with air- or moisture-sensitive compounds were conducted under an argon atmosphere using Schlenk techniques. The synthesis of hexafluorophosphate **5b** was reported earlier [12a], other chemicals were purchased. NMR spectra were recorded on a multinuclear FT NMR spectrometer ARX300 (Bruker) at 300.1 (^1H), 75.5 (^{13}C), and 121.5 (^{31}P) MHz. Shift references are tetramethylsilane for ^1H and ^{13}C and H_3PO_4 (85%) for ^{31}P. Assignment numbers are given in Scheme 1. Coupling constants refer to J_{HH} unless stated otherwise. Assignments are based on CH–COSY NMR experiments, proton-decoupled and DEPT ^{13}C NMR spectra for selected compounds. Melting points (uncorrected) were determined with a Sanyo Gallenkamp melting point apparatus, elemental analysis with a CHNS-932 analyzer from LECO using standard conditions.

5.1. 1,3-Dineopentyl-benzimidazolium formate · formic acid solvates (2 · HCOOH and 2 · 2HCOOH) (2)

Formic acid (0.4 mL, 85% in water, 8.86 mmol) was added to a solution of *N*,*N*′-dineopentyl 1,2-diaminobenzene (1.42 g, 5.71 mmol) in triethyl orthoformate (15 mL), and the resulting solution was heated at 70 °C for 15 h. Hexane (10 mL) was layered slowly over the solution at room temperature, and the product was allowed to crystallize. After some days the off-white crystals were separated, washed with hexane and dried in vacuum to give 1.71 g (85%) of **2** · HCOOH, mp 124 °C. (Before drying, the crystals contain two molecules of formic acid, as discussed above.) ^1H NMR (CH–COSY, D_2O): δ = 0.90 (s, 18H, CMe_3), 4.23 (s, 4H, NCH_2), 7.64 (m, 2H, 5-H), 7.81 (m, 2H, 4-H), 8.33 (s, 2H, $HCOO^-$), 9.29(s, 1H, 2-H); $^{13}C\{^1H\}$ NMR (CH–COSY, D_2O): δ = 29.0 (*C*Me_3), 35.2 (*C*Me_3), 60.0 (NCH_2), 116.3 (C-4), 129.1 (C-5), 134.5 (C-3a), 144.6 (C-2), 170.7 ($HCOO^-$); MS (EI, 70 eV, 345 °C): *m*/*z* (%) = 261 (13), 260 (76), 259 (100) [M^+−2HCOOH], 258 (33), 257 (10), 203 (52), 202 (72) [$M-C_4H_8^+$], 133 (51), 132 (35), 131 (43); Elemental Anal. Calc. (%) for $C_{19}H_{30}N_2O_4$ (350.46): C, 65.12; H, 8.63; N, 7.99. Found: C, 64.84; H, 8.47; N, 8.37%.

5.2. High vacuum thermolysis of 2 · HCOOH to 1,3-dineopentyl-benzimidazoline (6)

Thermolytic distillation of **2** · HCOOH (300 mg, 0.86 mmol) at 170 °C (bath)/10^{-5} bar afforded 215 mg (96%) of *N*,*N*′-dineopentyl-benzimidazoline **6**. The ^1H and ^{13}C NMR data are in accordance with those recently reported [6].

5.3. 1,3-Dineopentyl-benzimidazolium chloride (3)

Ethereal HCl (3.62 mL, 0.5 M, 1.81 mmol) was added to a solution of *N*,*N*′-dineopentyl 1,2-diaminobenzene (450 mg, 1.81 mmol) in triethyl orthoformate (15 mL), and the resulting mixture was stirred for 16 h at ambient temperature. The precipitate was filtered off, repeatedly washed with hexane and recrystallized from CH_3CN to give 523 mg (98%) colorless crystals of **3**, mp >300 °C. Alternatively, NH_4Cl (509 mg, 9.51 mmol), *N*,*N*′-dineopentyl 1,2-diaminobenzene (2.36 g, 9.51 mmol) and triethyl orthoformate (15 mL) were heated at 100 °C overnight in a rectification apparatus and the mixture worked up as above affording 2.53 g (90%) of **3**. Single crystals of **3** · CH_2Cl_2 were grown from CH_2Cl_2 solution by overlayering with *n*-hexane; selected bond lengths and angle bond see Table 2, crystal data see Table 3. ^1H NMR (CD_3CN): δ = 1.05 (s, 18H, CMe_3), 4.35 (s, 4H, NCH_2), 7.66 (m, 2H, 5-H), 7.91 (m, 2H, 4-H), 9.77 (s, 1H, 2-H); $^{13}C\{^1H\}$ NMR (CD_3CN): δ = 27.6 (*C*Me_3), 34.1 (*C*Me_3), 58.4 (NCH_2), 115.0 (C-4), 127.6 (C-5), 133.4 (C-3a), 144.1 (C-2); MS (EI, 70 eV, 345 °C): *m*/*z* (%) = 259 (2) [M^+−Cl], 258 (3), 257 (3), 202 (11) [$M-C_4H_8^+$], 132 (6), 131 (7); Elemental Anal. Calc. (%) for $C_{17}H_{27}N_2Cl$ (294.87): H, 9.23; N, 9.50. Found: H, 9.19; N, 9.43%.

5.4. 1,3-Dineopentyl-benzimidazolium tetrafluoroborate (4)

$AgBF_4$ (764 mg, 3.92 mmol) was added to a solution of **3** (1.15 g, 3.90 mmol) in 15 mL CH_3CN. The suspension was stirred for 1 day at room temperature (light protected) and filtered. The solvent was removed in vacuum to give 1.25 g (92%) crystals of **5**, mp 247–249 °C. ^1H NMR (DMSO-d_6): δ = 1.00 (s, 18H, CMe_3), 4.41 (s, 4H, NCH_2), 7.69 (m, 2H, 5-H), 8.16 (m, 2H, 4-H), 9.70 (s, 1H, 2-H); ^{13}C NMR (DMSO-d_6): δ = 27.0 (*C*Me_3), 33.1 (*C*Me_3), 56.8 (NCH_2), 114.2 (C-4), 126.4 (C-5), 132.0 (C-3a), 143.7 (C-2); Elemental Anal. Calc. (%) for $C_{17}H_{27}N_2BF_4$ (346.22): H, 7.86; N, 8.09. Found: H, 7.83; N, 7.94%.

5.5. 1,3-Dineopentyl-benzimidazolium hexafluorophosphate (5a)

N,*N*′-Dineopentyl 1,2-diaminobenzene (1.01 g, 4.06 mmol), NH_4PF_6 (663 mg, 4.06 mmol), and triethyl orthoformate (15 mL) were heated to 130 °C for 6 h in a rectification apparatus to separate ethanol from the reaction mixture. The solution was then allowed to cool to room temperature, the product was precipitated and washed with hexane (3× each 10 mL). The solid was dissolved in CH_3CN and the solution filtered, and the volatiles were removed in vacuum to give 1.55 g (94%) of **5a**, mp 221 °C. Single crystals grew from saturated solution in acetonitrile (selected bond lengths and angles Table 2, crystal data in Table 3). ^1H NMR (CD_3CN): δ = 1.04 (s, 18H, CMe_3), 4.29 (s, 4H, NCH_2), 7.68 (m, 2H, 5-H), 7.91 (m, 2H, 4-H), 8.87 (s, 0.4H, 2-H); ^1H NMR (DMSO-d_6): δ = 1.01 (s, 18H, CMe_3), 4.40 (s, 4H, NCH_2), 7.69 (m, 2H, 5-H), 8.16 (m, 2H, 4-H), 9.71 (s, 1H, 2-H); ^{13}C NMR (DMSO-d_6): δ = 27.0 (*C*Me_3), 33.1 (*C*Me_3), 56.8 (NCH_2), 114.2 (C-4), 126.4 (C-5), 132.0 (C-3a), 143.6 (C-2); ^{31}P NMR (DMSO-d_6): δ = −143.1 (sept, $^1J_{PF}$ = 711.3 Hz); Elemental Anal. Calc. (%) for $C_{21}H_{29}N_2PF_6$ (404.37): C, 50.49; H, 6.73; N, 6.93. Found: C, 50.62; H, 6.89; N, 7.00%.

5.6. Deprotonation experiments

Deprotonation by LiN(SiMe$_3$)$_2$. A solution of $LiN(SiMe_3)_2$ prepared from *n*BuLi in *n*-hexane and $(Me_3Si)_2NH$ (HMDS) in the given solvent was added at the given temperature to a suspension of the anellated imidazolium salt in the given solvent.

Table 4
Generation of **1** or **7**[a] by deprotonation with $LiN(SiMe_3)_2$ or KH

Exp.	NHC−H+X$^-$ (mg, mmol)	Base[b] (mL/mg, mmol)	Solvent (mL) Temperature (°C)	Products **1**, (**6** + **7**′) (mol%)
1	**2** (500, 1.43)	*n*BuLi (1.91, 2.87), HMDS (0.61, 2.87)	THF (5+10) −78 to 20	92, 8
2	**3** (500, 1.70)	*n*BuLi (1.06, 1.70), HMDS (0.36, 1.70)	Toluene (5+10) −78 to 20	–, >95 (234 mg solid)
3	**3** (300, 1.01)	*n*BuLi (0.67, 1.01), HMDS (0.21, 1.01)	THF (5+10) −78 to 20	–, >95 (176 mg solid)
4	**3** (207, 0.70)	*n*BuLi (0.87, 1.39), HMDS (0.29, 1.40)	Toluene (5+10) −78 to 20	>95, – and $(Me_3Si)N$-species
5	**3** (445, 1.51)	KH (30%) (202, 1.51)	THF (20) 20	50, 25 (and unknown; 160 mg solid)
6	**5a** (1730, 4.28)	KH (30%) (570, 4.27)	THF (20) 20	90, 10[c]
7	**5a** (274, 0.68)	KH (30%) (181, 1.35)	THF (10) −78 to 20	>95, –

[a] Product analysis is based on solution NMR spectra. The solid compound **7** disproportionates in solution and displays two equal intense NMR signal sets of **6** and 1,3-dineopentyl-benzimidazol-2-one, coordinated at M^I (**7**′).
[b] *n*BuLi and HMDS (mL, mmol), KH, KO*t*Bu (mg).
[c] After distillation 860 mg (78%) **1**, bp 10^{-5} Torr/110 °C (bath), contamination by **6** + **7**′ ⩽ 3%.

Deprotonation by KH or KH in the presence of catalytic amounts (5 mol%) of KOtBu. A suspension of the anellated imidazolium salt in THF was added at the given temperature to a suspension of 30% KH in mineral oil, washed beforehand with THF.

Work up and characterization. The mixture was allowed to warm to room temperature (if prepared at low temperature) and stirred overnight. After filtration the solvent was removed in vacuum. If THF was used, the residue was extracted with diethyl ether and the ether evaporated (separation from salts soluble in THF). The oily or solid residue was dissolved in C_6D_6, and ^{1}H and ^{13}C NMR spectra were measured. The ratios of **1** and **7**, which in solution disproportionates into **6** + **7**′, are given in Table 4 and refer to the integration of the characteristic NCH_2 proton signals and/or to the intensity ratio of the ^{13}C-signals of CH-4 and CH-5. The NMR data for **1** and **6** correspond to known values [6,7]. **7**′: ^{1}H NMR (C_6D_6): δ = 0.93 (s, 18H, CH_3), 3.47 (s, 4H, NCH_2), 6.73 (m, 2H, 4-H), 6.94 (m, 2H, 5-H); ^{13}C NMR (C_6D_6): δ = 29.1 (CMe_3), 35.3 (CMe_3), 53.3 (NCH_2), 109.2 (CH-4), 121.3 (CH-5), 132.2 (C_q-3a), 156.8 (C=O).

5.7. 1,3-Dineopentyl-quinoxalino[2,3-d]imidazolium hexafluorophosphate (**5c**)

2,3-Dineopentylamino-quinoxaline (1.50 g, 5.00 mmol), NH_4PF_6 (815 mg, 5.00 mmol) and triethyl orthoformate (15 mL) were heated to 120 °C for 5h in a rectification apparatus to separate ethanol from the reaction mixture. After cooling to room temperature a solid precipitated and was washed with hexane (3 × 10 mL). Then the product was extracted with CH_3CN to give 1.19 g (52%) colourless crystals of **5c**, mp >300 °C. Single crystals grew from saturated solution in acetonitrile (selected bond lengths and angles

Table 2, crystal data in Table 3). ^{1}H (CH–COSY) NMR (DMSO-d_6): δ = 1.11 (s, 18H, CH_3); 4.49 (s, 4H, NCH_2), 8.09 (m, 2H, 6-H), 8.38 (m, 2H, 5-H), 10.50 [in CD_2Cl_2 9.66] (s, 1H, 2-H). ^{13}C (FIDRES 0.332; CH–COSY) NMR (DMSO-d_6): δ = 27.1 (quart, ^1J = 126 Hz, CMe_3), 33.0 (s, $CqMe_3$), 56.4 (t br, ^1J = 144 Hz, NCH_2), 128.9 ($^1J \approx 167$ Hz, CH-5), 131.2 ($^1J \approx 170$ Hz, CH-6), 138.2 (dd, $^3J_{C-H2}$ = 6.6, $^3J_{C-H(neop)}$ = 3.7 Hz, C_q-3a), 140.4 (m, C_q-4a), 153.2 (dpent, ^1J = 221, ^3J = 5 Hz, {^{1}H}: s and t, $^1J_{CD}$ = 84.7 Hz, C_q-2; t). Elemental Anal. Calc. for $C_{19}H_{27}F_6N_4P$ (456.41): C, 50.00; H, 5.96; N, 12.28. Found: C, 49.86; H, 6.00; N, 12.15%.

5.8. (1,3-Dineopentyl-benzimidazol-2-ylidene)silver chloride (**8**)

Ag_2O (117 mg, 0.51 mmol) was added to a solution of **3** (300 mg, 1.02 mmol) in 10 mL of CH_2Cl_2. The suspension was stirred for 24 h at ambient temperature, filtered and washed with CH_2Cl_2. The solvent of the filtrate was partly removed in vacuum (residual solution ca. 2 mL), hexane (4 mL) was added, and the resulting white precipitate was separated and recrystallized. Drying in vacuum led to 202 mg (98%) colorless **8**, mp 220 °C. ^{1}H NMR (CD_2Cl_2): δ = 1.10 (s, 18H, CMe_3), 4.27 (s, 4H, NCH_2), 7.38 (m, 2H, 5-H), 7.54 (m, 2H, 4-H); ^{13}C{^{1}H} NMR (CD_2Cl_2): δ = 30.5 (CMe_3), 35.8 (CMe_3), 62.0 (NCH_2), 114.4 (C-4), 125.3 (C-5), 136.4 (d, $^3J(^{13}C–^{107/109}Ag) \approx 7.6$ Hz, C-3a), 193.2 (2d, $^1J(^{13}C–^{107/109}Ag)$ = 234.9, 271.0 Hz, C-2); MS (EI, 70 eV, 345 °C): *m*/*z* (%) = 367 (11), 365 (13), 366 (18), 364 (17) [M^+–Cl], 258 (38) [M^+–AgCl], 257 (74), 202 (100), 145 (25), 132 (32), 131 (34); Elemental Anal. Calc. (%) for $C_{17}H_{26}N_2AgCl$ (401.73): C, 50.83; H, 6.52. Found: C, 51.02; H, 6.76%; single crystals of **8** · CD_2Cl_2 formed in the NMR tube; selected bond lengths and angles see Table 2, crystal data see Table 3.

5.9. Crystal structure analyses

X-ray diffraction data for **3**, **5a**, **5b** and **8** were recorded at 133 K; on a Bruker SMART 1000-CCD diffractometer, and for **5c** at 173 K on a Bruker/Nonius Apex X8-CCD diffractometer. All measurements were performed using monochromated Mo Kα-radiation. The data of **3**, **5c** and **8** were corrected for absorption effects using the SADABS procedure [25]. The structures were solved by Direct Methods (SHELXS-97) [26] and refined by full-matrix least-squares methods on F^2 for all unique reflections (SHELXL-97) [26]. All non-hydrogen atoms were refined anisotropically. H-atoms were calculated assuming idealized geometries and refined using riding models or rigid methyl groups. Exceptions are the acidic H-atoms of **3**, **5a** and **5b** attached to C1, which were refined freely. *Special features*: For compound **5a** the Flack parameter refined to –0.02(5). Compound **5b** was a pseudo-merohedral twin by 180° rotation about **a**, and the twinning ratio was 68:32%.

Crystallographic data are given in Table 3 and selected bond lengths and angles in Table 2.

6. Supplementary data

CCDC 686030, 271543, 686031, 685607 and 271545 contain the supplementary crystallographic data for **3**, **5a–c** and **8**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Structures of cations in salts **1**–**5**.

absorption in the 750–1000 nm region, while **1** exhibits intense absorption from the UV/Visible to near-IR regions (200–1100 nm).

2. Experimental

2.1. Chemicals and reagents

All reagents and chemicals were purchased from commercial sources and used without further purification.

2.2. Physical measurements

Elemental analyses were performed with an Elementar Vario EL III analytic instrument. IR spectra were recorded on a Bruker Vector 22 Fourier Transform Infrared Spectrometer (170SX) (KBr disc). ^{1}H NMR spectra were carried out with an AVANCE AV-300 NMR spectrometer and the chemical shifts were measured relative to the TMS signal. UV–Vis absorption spectra in the solid state and solution were taken using a Cary 5000 UV–Vis–NIR and a Lambda 35 UV/Vis spectrophotometer, respectively.

2.3. Preparations for ***1–5***

2.3.1. Materials

Disodium maleonitriledithiolate (Na_2mnt)[14] and 1-aminopyridinium iodide ([1-APy]I) [15] were synthesized following the respective published procedures. The Schiff base derivatives, [RBz-1-Apy]I, were prepared employing a similar procedure described in the literature [16].

2.3.2. [p-NO_2Bz-1-Apy]$_2$[Ni(mnt)$_2$] (***1***)

Na_2mnt (456 mg, 2.5 mmol) and $NiCl_2 \cdot 6H_2O$ (297 mg, 1.25 mmol) were mixed under stirring in MeOH (30 mL) at room temperature. Subsequently, a solution of [*p*-NO_2Bz-1-Apy]I (887 mg, 2.5 mmol) in MeOH (15 mL) was added to the mixture, and the brown precipitate that was immediately formed was filtered off, and washed with MeOH. The crude product was recrystallized in acetone (20 mL) to give dark-brown crystals. Yield: 76%. *Anal.* Calc. for $C_{32}H_{20}N_{10}O_4S_4Ni$: C, 48.31; H, 2.54; N, 17.61. Found: C, 48.76; H, 2.66; N, 17.93%. IR spectrum (KBr, cm^{-1}): 2192.6 (s) for $\nu_{C\equiv N}$ and 1480.7 (s) for $\nu_{C=C}$ of mnt^{2-}, 1628. 7 (m) for $\nu_{C=N}$ of Schiff base, and 1343.3 (s) for ν_{-NO_2}. 1H NMR (300 MHz and acetone-d_6): δ 9.77 (s, 1H, –N=CH–), 9.56–9.53 (d, 2H, pyridyl), 8.86–8.80 (t, 1H, pyridyl), 8.54–8.40 (m, 6H, phenyl and pyridyl).

The similar procedures were used to prepare the complexes **2–5**.

2.3.3. [p-BrBz-1-Apy]$_2$[Ni(mnt)$_2$] (***2***)

Dark-brown color and yield: 73%. *Anal.* Calc. for $C_{32}H_{20}N_8Br_2S_4Ni$: C, 44.52; H, 2.34; N, 12.98. Found: C, 44.58; H, 2.21; N, 13.26%. IR spectrum (KBr, cm^{-1}): 2194.5 (s), 2213.7 (sh) for $\nu_{C\equiv N}$ and 1472.9 (s) for $\nu_{C=C}$ of mnt^{2-}, 1624.4 (s) for $\nu_{C=N}$ of Schiff base. ^{1}H NMR (300 MHz and acetone-d_6): δ 9.50 (s, 1H, –N=CH–), 9.48–9.45 (d, 2H, pyridyl), 8.86–8.80 (t, 1H, pyridyl), 8.47–8.42 (t, 2H, pyridyl), 8.09–8.06 (d, 2H, phenyl), 7.89–7.85 (d, 2H, phenyl).

2.3.4. [p-ClBz-1-Apy]$_2$[Ni(mnt)$_2$] (***3***)

Dark-brown color and yield: 75%. *Anal.* Calc. for $C_{32}H_{20}Cl_2N_8S_4Ni$: C, 49.63; H, 2.60; N, 14.47. Found: C, 49.96; H, 2.54; N, 14.76%. IR spectrum (KBr, cm^{-1}): 2195.2 (s) and 2213.2 (sh) for $\nu_{C\equiv N}$ and 1475.9 (s) for $\nu_{C=C}$ of mnt^{2-}, 1626.4 (m) for $\nu_{C=N}$ of Schiff base. ^{1}H NMR (300 MHz and acetone-d_6): δ 9.52 (s, 1H, –N=CH–), 9.50–9.45 (d, 2H, pyridyl), 8.85–8.78 (t, 1H, pyridyl), 8.46–8.40 (t, 2H, pyridyl), 8.18–8.10 (d, 2H, phenyl), 7.72–7.67 (d, 2H, phenyl).

2.3.5. [p-MeBz-1-Apy]$_2$[Ni(mnt)$_2$] (***4***)

Dark-brown color and yield: 79%. *Anal.* Calc. for $C_{34}H_{26}N_8S_4Ni$: C, 55.66; H, 3.58; N, 15.28. Found: C, 55.83; H, 3.51; N, 15.49%. IR spectrum (KBr, cm^{-1}): 2195.1 (s), 2212.2 (sh) for $\nu_{C\equiv N}$ and 1475.5 (s), 1486.4 (m) for $\nu_{C=C}$ of mnt^{2-}, 1620.2 (m) for $\nu_{C=N}$ of Schiff base. ^{1}H NMR (300 MHz and acetone-d_6): δ 9.39 (s, 1H, –N=CH–), 9.43–9.41 (d, 2H, pyridyl), 8.83–8.77 (t, 1H, pyridyl), 8.45–8.40 (t, 2H, pyridyl), 8.02–7.969 (d, 2H, phenyl), 7.49–7.46 (d, 2H, phenyl), 2.48 (s, 3H, –CH_3).

2.3.6. [m-NO_2Bz-1-Apy]$_2$[Ni(mnt)$_2$] (5)

Dark-brown color and yield: 69%. *Anal.* Calc. for $C_{32}H_{20}N_{10}O_4S_4Ni$: C, 48.31; H, 2.54; N, 17.61. Found: C, 48.23; H, 2.30; N, 18.00%. IR spectrum (KBr, cm^{-1}): 2191.9 (s), 2210.8 (sh) for $\nu_{C\equiv N}$ and 1475.2 (s) for $\nu_{C=C}$ of mnt^{2-}, 1625.8 (m) for $\nu_{C=N}$ of Schiff base and 1355.3 (s) for ν_{-NO_2}. 1H NMR (300 MHz and acetone-d_6): δ 9.76 (s, 1H, –N=CH–), 9.56–9.54 (d, 2H, pyridyl), 8.92 (s, 1H, phenyl), 8.88–8.82 (t, 1H, pyridyl), 8.62–8.58 (t, 2H, pyridyl), 8.50–8.45 (m, 2H, phenyl), 8.01–7.96 (t, 1H, phenyl).

The single crystals of **1**–**5** suitable for X-ray analysis were obtained by diffusing diethyl ether into the solution of the corresponding [RBz-1-Apy]$_2$[Ni(mnt)$_2$] compound in acetone for 7–10 days.

2.4. X-ray crystallography

The diffraction data for **1**–**5** were collected at 296K with graphite-monochromated Mo Kα (λ = 0.71073 Å) on a CCD area detector (Bruker-SMART). Data reductions and absorption corrections were performed with the SAINT and SADABS software packages, respectively [17]. Structures were solved by the direct method and refined by the full-matrix least-squares procedure on F^2 using SHELXL-97 program [18]. All non-hydrogen atoms were refined anisotropically, and the hydrogen atoms were introduced at calculated positions. The crystallographic details about data collection and structure refinement are summarized in Table 1.

2.5. DFT calculation details

All calculations were carried out with the GAUSSIAN98 program [19] by density functional theory (DFT) and time-dependent DFT (TDDFT). Becke's three-parameter functional [20] combined with Lee-Yang-Parr's correlation functional [21,22] (B3LYP) and 6-31+G(d,p) [23] basis set were employed for the molecular geometric optimizations for the five [RBz-1-Apy]$^+$ cations as well as

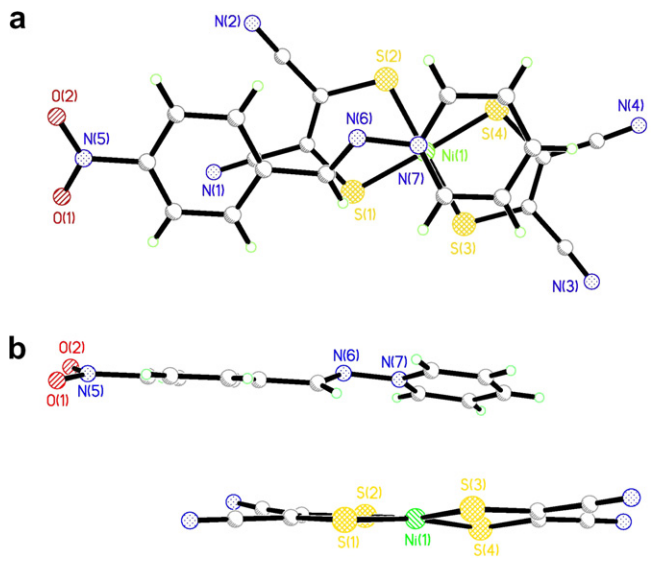

Fig. 2. The arrangement between adjacent anion and cation (a) top view and (b) side view in the crystal of **1**.

TDDFT calculations for the [*p*-NO_2Bz-1-Apy]$^+$ cation; the geometric optimization for the $[Ni(mnt)_2]^{2-}$ anion was performed at B3LYP level, and 6-31+G(d,p) basis set were employed for C, N and S atoms, while LANL2DZ [24] basis set for Ni atom. The TDDFT calculations for the $[Ni(mnt)_2]^{2-}$ anion were carried out at BPW91/LANL2DZ level. The lowest 20 singlet-singlet transitions were computed by TDDFT calculations for both the $[Ni(mnt)_2]^{2-}$ anion and the [*p*-NO_2Bz-1-Apy]$^+$ cation.

3. Results and discussion

3.1. Description of crystal structures

[*p*-NO_2Bz-1-Apy]$_2$[Ni(mnt)$_2$] (1): Complex **1** crystallizes in monoclinic system with $P2_1/n$ space group, as shown in Fig. 1a, an asymmetric unit consists of one $[Ni(mnt)_2]^{2-}$ anion and two [*p*-NO_2Bz-1-Apy]$^+$ cations. The bond lengths and angles in two crystallographically nonequivalent cations are comparable to each other, whereas the interplanar angles are very different between the pyridine and benzene rings (14.99(10)° and 72.24(6)°, respectively). For the $[Ni(mnt)_2]^{2-}$ anion, the Ni-S lengths range from 2.1666(6) to 2.1758(6) Å, and two S–Ni–S bite angles have the same magnitude of 92.52(2)°, these bonding parameters are comparable to the reported values [25]; of particular note is the large deviation from the square-planar environment around the Ni atom, as demonstrated in Fig. 1b, with the dihedral angle between the S1–Ni–S2 and S3–Ni–S4 mean planes being 10.99(6)°. In most

cases, the transition metal ion in a bis(1,2-dithiolato)metal complex favors a planar coordination environment. However, the distorted square planar coordination geometry around a metal centre has also been observed [26,27]. For example, in the cases of the metal centre being Mn^{2+}, Fe^{3+} or Co^{2+} ions in the complexes $[RBzPy]_2[Fe_2(mnt)_4]$ [28], $[Bu_4N]_2[Fe_2(mnt)_4]$ [29], $[Bu_4N]_2[Fe_2(edt)_4]$ [30], $[Et_4N]_2[Mn_2(edt)_4]$ [31], $Co_2[S_2C_2(CF_3)_2]$ [32] and $[Bu_4N]_2[Co_2(S_2C_6Cl_4)_4]$ [33], the deviation from planarity is mainly caused by dimerization via M···S interactions. For bis(1,2-dithiolato)cuprate(II) complexes, notably, there are a few cases of a significantly non-planar environment around a tetra-coordinate Cu^{2+} centre resulting from the weakly intermolecular interactions between the cation and anion [13a,34]. Theoretical investigation for the $[Cu(mnt)_2]^{2-}$ complex further disclosed that the energy gap between distorted and perfect square-planar coordination geometry is not much higher than the values of the crystal packing forces. As a result, the configuration preference for the $[Cu(mnt)_2]^{2-}$ complexes will be controlled by the combination of a variety of intermolecular interactions [35]. For the bis(1,2-dithiolato)nickelate(II) species, reports of significant non-planar environment

around a tetra-coordinate Ni^{2+} ion are very rare, only eight complexes having dihedral angle more than 10° between the mean planes of two S–Ni–S chelate rings have been reported to the best of our knowledge [36] (the corresponding analyses of crystal structures retrieved from the Cambridge Structural Database (CCDC, conquest version 1.3, August, 2007)) [37]. To better understand why there are distortions in the Ni^{2+} coordination environment, we performed the geometry optimization for the $[Ni(mnt)_2]^{2-}$ ion in DFT theoretical framework, and the results revealed that square-planar geometry is the more stable configuration (optimization geometry see Fig. S1). Meanwhile, we inspected the molecular packing and found two notable points: (1) as demonstrated in Fig. 2, there exist close packing interactions between the anion and the cation containing O1 atom, the pyridine ring is almost parallel to the mean plane of the anionic moiety Ni1/S3/S4/C5/C6/C7/C8/N3/N4 with a dihedral angle of 0.54(7)°, the benzene ring makes a dihedral angle of 7.92(8)° with the anionic moiety of Ni1/S1/S2/C1/C2/C3/C4/N1/N2, and the shortest interatomic distance is only 3.394(3) Å for C2···C15; (2) there exist some shorter interatomic separations between the adjacent cations (see Fig. 3), such as N8···C14($1 + x$, $1 + y$, z) = 3.187(3) Å, O2···C28 ($0.5 - x$, $-0.5 + y$, $1.5 - z$) = 3.159(3) Å, O3···H23 ($1.5 - x$, $0.5 + y$, $1.5 - z$) = 2.6354 Å, O4···C31 ($2 - x$, $2 - y$, $2 - z$) = 3.193(3) Å and O4···H31 ($2 - x$, $2 - y$, $2 - z$) = 2.4841 Å, respectively. Therefore, we might conclude that the deviation from planarity for the $[Ni(mnt)_2]^{2-}$ anion in **1** is mainly arisen from intermolecular packing interactions.

Crystal of **2** belongs to monoclinic system with space group $P2_1/n$, and an asymmetric unit contains an anion and two crystallographically independent cations (Fig. 4a), which is similar to **1**. The Ni–S bond lengths and S–Ni–S bite angles are comparable to those in **1**. The crystal structure distinctions from **1** concern three aspects: (1) the $[Ni(mnt)_2]^{2-}$ anion exhibits perfect square-planar geometry; (2) two crystallographically independent [*p*-BrBz-1-Apy]$^+$ cations show almost planar molecular conformations with very similar dihedral angles between the pyridine and benzene rings (2.91(24)° and 4.65(22)°, respectively); (3) as shown in Fig. 4b, the anions and the cations show the slippage arrangement, therefore there is no close packing interactions between the anions and the cations.

Crystal of **3** belongs to triclinic system with space group $P\bar{1}$, and both complexes **4** and **5** crystallize in monoclinic system with space group $P2_1/n$. The molecular structures for **3–5** are displayed in Fig. 5, respectively, and the common structural feature for these three complexes is that an asymmetric unit is composed of one cation and one half of anion, and the Ni^{2+} ion locates at an inversion center. This leads to the Ni^{2+} ion possessing the perfect square-planar coordination environment; additionally, the cation shows a non-planar conformation in each complex. The bond lengths and angles in the $[Ni(mnt)_2]^{2-}$ anions are normal, and the selected bonding parameters for **3–5** are summarized in Table 2. The anions and cations arrange in a slippage fashion, as a consequence, no significant π···π stacking interactions between the anions and cations are observed in the crystals of **3–5** (see Fig. 6 as well as Figs. S3 and S4), which are analogous to **2** but distinct from **1**. It is noteworthy that the structural difference of the cation between **1** and **5** just concerns the position of NO_2 group in the benzene ring, whereas the fashions of the cations and anions are big difference, the slippage arrangement between anion and cation in **5** leads to the overlap of NO_2 group of benzene ring with mnt^{2-} moiety of $[Ni(mnt)_2]^{2-}$ anion, which gives rise to the shorter intermolecular contacts, 3.387(3) Å of C3···O1 ($1 + x$, y, z), 3.453(3) Å of C2···N3 ($1 + x$, y, z) and 3.444(3) Å of N1···C6 ($0.5 - x$, $0.5 + y$, $0.5 - z$).

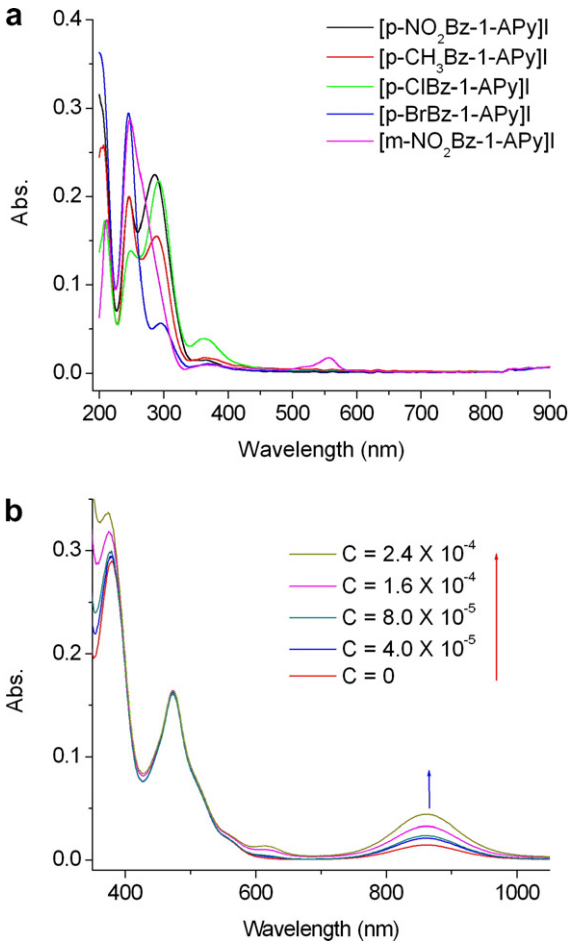

Fig. 8. Electronic absorption spectra in acetonitrile for (a) the compounds [RBz-1-Apy]I (b) $[Bu_4N]_2[Ni(mnt)_2]$ ($c = 5.0 \times 10^{-5}$ mol L^{-1}) with different concentration of [*p*-NO_2Bz-1-Apy]I (c = 0, 4.0×10^{-5}, 8.0×10^{-5}, 1.6×10^{-4} and 2.4×10^{-4} mol L^{-1}).

3.2. UV–Vis–NIR spectra

The UV–Vis–NIR spectra of **1–5** complexes for solids are shown in Fig. 7a. In the solid state, complexes **2–5** show the intense absorption in the UV/visible region (200–700 nm) with a moderately intense absorption band (centered at around 870 nm and the low energy absorption tail extend up to ca. 1000 nm) in the near-IR region. The spectral shape of **1** is strikingly different from the other four, in which a very strong absorption is observed from the UV/Visible to near-IR region and its low energy absorption tail extends up to ca. 1200 nm. Such different spectroscopic features between **1** and the other four complexes will be further discussed in the theoretic analysis section. The UV–Vis–NIR spectra of **1–5** in acetonitrile ($c = 5.0 \times 10^{-6}$ mol L^{-1}) are shown in Fig. 7b, and the absorption spectral properties are listed in Table 3. From these we can summarize: (1) the investigated complexes exhibit different spectral shape in the range of 200–400 nm, and a series of bands have high molar absorptions ($\varepsilon > 10^4$); (2) both the maxima position and the intensity are independent of the cation for the band centered at 473 nm; (3) the maxima position is almost independent of cation, whereas the intensity depends on the cation for the band centered at around 862 nm. A series of bands with high molar extinction coefficients in 200–400 nm region originate from the $\pi \rightarrow \pi^*$ transitions within the cation and anion. For a better understanding of the nature of two bands in the visible and near IR regions (473 and ~862 nm), the UV–Vis–NIR spectra for the corresponding iodide compounds ([RBz-1-Apy]I) of the cations in acetonitrile are presented in Fig. 8a, and the spectroscopic data are listed in Table 4. From Fig. 8a, it can be found that no absorption band appears in more than the 420 nm spectral region for [*p*-NO_2Bz-1-Apy]I, [*p*-BrBz-1-Apy]I, [*p*-ClBz-1-Apy]I and [*p*-CH_3Bz-1-Apy]I; while the compound, [*m*-NO_2Bz-1-Apy]I, possesses a weak
